We use the Schwarz inequality twice again to (5.17) and substitute the result into (5.16) to conclude that

$$\| D_1(\xi(n) - \xi) \|^2 \leq \frac{1}{2} m^2 (1 - e^{-\beta})^{-1} \sum_{p=1}^{m} \sum_{q=1}^{m} \| \Psi(p, q; n) \|^2 .$$

One notes that each $\Psi(p,q;n)$ contains either $(\Phi_p(n)-\Phi_p)$ or else $(W((1/n)z_p)-\mathbf{1})$, which implies that

$$\|\Psi(p,q;n)\|^2\to 0 \quad \text{as} \quad n\to\infty$$

for any p, q, and so

$$\|D_1(\xi(n)-\xi)\|^2\to 0 \quad \text{as} \quad n\to\infty.$$

The method similar to that used in the above implies that

$$\|D_2(\xi(n)-\xi)\|^2\to 0 \quad \text{as} \quad n\to\infty.$$

By (5.7), (5.8) and (3.11), this proved part (a) of this proposition.

(b) This follows from Theorem 5.1, (3.11) and (5.9).

(c) This follows from (5.4) and part (b) of the proposition. □

Theorem 5.2: (*a*) *The operators* $\tilde{H}$ *and* H_i, $i=1,2$, *are essential self-adjoint and the self-adjoint extension of* $\tilde{H}$ *equals to the Dirichlet operator H given in Theorem 3.1.*

(*b*) *For each* m, $n=0,1,2,\ldots$, $\mathcal{H}_{(m,n)}$ *is an eigenspace of the Dirichlet operator H corresponding to eigenvalue* $\tau_1 m+\tau_2 n$.

Proof: (a) Clearly $\tilde{H}$ and H_i, $i=1,2$, are symmetric on $\mathcal{H}_{fin}$. It follows from (5.5) that the following relations holds: for $\xi=(A_1^*)^m(A_2^*)^n\xi_0$, $m,n=0,1,2,\ldots$,

$$H_1\xi=m\xi, \quad H_2\xi=n\xi. \tag{5.18}$$

By (5.18) any $\xi\in\mathcal{H}_{fin}$ is an analytic vector for $\tilde{H}$ and H_i, $i=1,2$, and $\tilde{H}\mathcal{H}_{fin}\subset\mathcal{H}_{fin}$, $H_i\mathcal{H}_{fin}\subset\mathcal{H}_{fin}$, $i=1,2$. It follows from Corollary 2 of Theorem X.39 in Ref. 21 that $\tilde{H}$ and H_i, $i=1,2$, are essentially self-adjoint on $\mathcal{H}_{fin}$. By Proposition 5.3 (c), $H=\tilde{H}$ on $\mathcal{H}_{fin}$, which implies $H=\tilde{H}$.

(b) By Proposition 5.2 and (5.18), we have that

$$UHU^{-1}=\tau_1 N\otimes\mathbf{1}+\mathbf{1}\otimes\tau_2 N,$$

where N is the number operator on l^2. Thus this completes the proof of (b). □

Finally we are able to produce the proof of Theorem 3.2.

Proof of Theorem 3.2: (a) and (b) follow from Theorem 5.2.

(c) By (b), zero is a simple eigenvalue of H with eigenvector ξ_0. Since ξ_0 is a strictly positive vector, $\{T_t\}_{t\geq 0}$ is ergodic. The proof of Theorem 3.2 is completed. □

(Received 20 October 2003; accepted 29 October 2003)

We consider one flavor lattice quantum chromodynamics in the imaginary time functional integral formulation for space dimensions $d=2,3$ with 4×4 Dirac spin matrices, small hopping parameter κ, $0<\kappa\ll1$, and zero plaquette coupling. We determine the energy-momentum spectrum associated with four-component gauge invariant local meson fields which are composites of a quark and an antiquark field. For the associated correlation functions, we establish a Feynman–Kac formula and a spectral representation. Using this representation, we show that the mass spectrum consists of two distinct masses m_a and m_b, given by $m_c=-2\ln\kappa+r_c(\kappa)$, $c=a,b$, where r_c is real analytic. For $d=2$, m_a and m_b have multiplicity two and the mass splitting is $\kappa^4+\mathcal{O}(\kappa^6)$; for $d=3$, one mass has multiplicity one and the other three, with mass splitting $2\kappa^4+\mathcal{O}(\kappa^6)$. In the subspace of the Hilbert space generated by an even number of fermion fields the dispersion curves are isolated (upper gap property) up to near the two-meson threshold of asymptotic mass $-4\ln\kappa$. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1636000]

I. INTRODUCTION

It is fundamental to determine the existence of particles and their spectral properties of quantum field theory. In quantum chromodynamics (QCD), one needs to establish on a rigorous basis the energy-momentum (EM) spectrum of particles and their bound states, in particular, to prove the existence of mesons and baryons and their bound states. These types of spectral properties involve low energies and one way to study them is by using a lattice regularization of the continuum, and to consider the strong coupling regime. Strong coupling lattice QCD models give a good insight into the low-energy behavior of QCD. Indeed, our partial understanding of confinement up to now comes in this way, and in fact was one reason for the introduction of lattice QCD (see Refs. 1–3 for a reference book and Refs. 4 and 5 for recent reviews).

Basically, there have been two routes used in the rigorous studies of the particle spectrum in lattice theories. One is based on methods which are reminiscent of continuum field theories (e.g., decoupling of hyperplanes, Euclidean subtraction)[6–11] and the others are based on statistical mechanical methods (e.g., random surfaces).[12,13] Here, we take the former approach.

As our main result, we prove the existence of meson particles by showing that mesons arise as tightly bound, bound states of a gauge invariant state composed of one quark and one antiquark. The occurrence of mesons is manifested by an isolated dispersion curve in the EM spectrum. The same kind of spectral problems that we consider here were also treated in previous works, for other types of particles. For the pure gauge case, with small coupling g_0^{-2}, the low-lying glueball spectrum is found in Ref. 8. The corresponding glueball mass is $\approx 8\ln g_0$. The determination of the masses in the baryonic sector was considered in Refs. 14 and 15. Recently, a rigorous treat-

[a]Electronic mail: veiga@icmc.usp.br

ment allowed to prove the existence of baryons and their multiplicities for a one-flavor lattice QCD model in the infinitely strong coupling regime and for small enough hopping parameter $\kappa > 0$, $0 < g_0^{-2} \ll \kappa \ll 1$. In Ref. 16, this was done for space dimension $d = 2$, using 2×2 Pauli spin matrices, and in Ref. 17 for $d = 2,3$ employing 4×4 Dirac spin matrices. The two-baryon bound state spectrum within the context of Ref. 16 was analyzed more recently in Ref. 18.

Here, we work with the same lattice QCD model as in Ref. 17, but our analysis is restricted to the meson sector of the underlying physical Hilbert space $\mathcal{H}$. The method used in Ref. 17 for baryons is largely applied here, with some adaptations. No approximations are made so our results are exact within this context. We will assume the results of Ref. 17 regarding positivity and the construction of $\mathcal{H}$. We begin directly by introducing a local four-component meson field. For the associated correlation functions (CF's), we establish a Feynman–Kac formula and a spectral representation analogous to the Källen–Lehman representation in quantum field theory. We emphasize that it is this representation that allows us to identify complex momentum space singularities of the two-point function with points in the EM spectrum. To our knowledge, such a representation as given here is not found in the literature. We also point out that determining exponential decay rates of CF's, as in Ref. 13, is *not sufficient* to identify these rates with the mass spectrum, since a connection with the energy-momentum spectrum is not established. This is especially true in the case where there are multiplicities involved and mass splitting, as here.

Let $\mathcal{H}_e \subset \mathcal{H}$ denote the subspace generated by an even number of fermions. We show that there are meson particles, with asymptotic masses $-2 \ln \kappa$, manifested by isolated dispersions curves in the EM spectrum (upper mass gap property) and it is the *only* spectrum in the subspace $\mathcal{H}_e \subset \mathcal{H}$, up to near the two-meson threshold which is asymptotically of order $-4 \ln \kappa$.

Besides its intrinsic importance, the determination and control of the meson spectrum is an essential step towards the understanding of, e.g., meson–meson and meson–baryon bound states from first principles. Indeed, a two-meson bound state analysis is in progress,[25] using, e.g., our techniques from previous works (see Refs. 10, 11, and 18). Also, our results open the way to study the EM spectrum for the more realistic case when the glueball mass is large, but is such that $g_0^{-2} \ll 1$ cannot be neglected in comparison with the small hopping parameter $\kappa \ll 1$.

II. THE RESULTS

We first give a very brief definition of one flavor SU(3) gauge-matter QCD model of Ref. 17 and present our results. We use the same notation as in Ref. 17, and the reader is referred there for all details concerning notation, the definition of the model, the introduction of energy, and momentum operators, the derivation of a Feynman–Kac-type formula for general correlation functions, the construction of the underlying physical Hilbert space $\mathcal{H}$, the computation of gauge and Fermi (Grassmann) integrals, and the analysis of symmetries other than gauge that is the main result of its Theorem 4, namely, the symmetries of charge conjugation, parity, lattice coordinate reflections, and lattice spatial rotations. We omit these and other details here, for the sake of brevity.

We consider the case where the space dimension is $d = 2,3$ and the gauge group is SU(3). The partition function of the model is given formally by

$$Z = \int e^{-S(\psi, \overline{\psi}, g)} \, \mathrm{d}\psi \, \mathrm{d}\overline{\psi} \, \mathrm{d}\mu(g), \tag{2.1}$$

and for a function $F(\overline{\psi}, \psi, g)$, of the single flavor (anti)quark Grassmann fields ψ and $\overline{\psi}$, and the gauge field g, the normalized expectations, in the thermodynamic limit, are denoted by

$$\langle F(\overline{\psi}, \psi, g) \rangle \equiv \frac{1}{Z} \int F(\overline{\psi}, \psi, g) e^{-S(\psi, \overline{\psi}, g)} \, \mathrm{d}\psi \, \mathrm{d}\overline{\psi} \, \mathrm{d}\mu(g).$$

The gauge invariant action $S(\psi, \overline{\psi}, g)$ is given by

$$S(\psi,\overline{\psi},g)=\frac{\kappa}{2}\sum\ \overline{\psi}_{a\alpha}(u)\,\Gamma^{\epsilon e^{\rho}}_{\alpha\beta}(g_{u,u+\epsilon e^{\rho}})_{ab}\,\psi_{b\beta}(u+\epsilon e^{\rho})$$

$$+\sum_{u\in\mathbb{Z}_o^{d+1}}\overline{\psi}_{a\alpha}(u)M_{\alpha\beta}\psi_{a\beta}(u)-\frac{1}{g_0^2}\sum_p\ \chi(g_p), \tag{2.2}$$

where the first sum runs over $u=(u^0,\vec{u})=(u^0,u^1,\ldots,u^d)\in\mathbb{Z}_o^{d+1}\equiv\mathbb{Z}_{1/2}\times\mathbb{Z}^d$, where $\mathbb{Z}_{1/2}=\{\pm 1/2, \pm 3/2,\ldots\}$, $\epsilon=\pm 1$, $\rho=0,1,\ldots,d$, and over repeated indices. For notational simplicity, we sometimes drop U from the gauge matrix $U(g)$ associated with each oriented lattice bond. Concerning the parameters, we take $m>0$, $0<g_0^{-2}\ll\kappa\ll 1$ and $M\equiv M(m,\kappa)=(m+2\kappa)I_4$, I_4 being the 4×4 identity matrix. Also, within the family of actions of Ref. 2, we have $\Gamma^{\pm e^{\rho}}=-1\pm\gamma^{\rho}$. For $d=3$, γ^{ρ} are the 4×4 Hermitian traceless anticommuting Dirac matrices. For $d=2$, all but the γ^3 matrix appear in the action. The measure $\mathrm{d}\mu(g)$ is the product measure over non-oriented bonds of normalized SU(3) Haar measures (see Ref. 19) and the integrals over Grassmann fields are defined according to Ref. 20. In Eq. (2.1), $\mathrm{d}\psi\,\mathrm{d}\overline{\psi}$ means $\Pi_{u,a,\alpha}\,\mathrm{d}\psi_{a\alpha}(u)\,\mathrm{d}\overline{\psi}_{a\alpha}(u)$ such that, with a normalization $\mathcal{N}=\langle 1\rangle$, we have

$$\langle\psi_{a\alpha}(x)\,\overline{\psi}_{b\beta}(y)\rangle=(1/\mathcal{N})\ \int\ \psi_{a\alpha}(x)\,\overline{\psi}_{b\beta}(y)\,e^{-\Sigma_u\overline{\psi}_{a'\alpha'}(u)M_{\alpha'\beta'}\psi_{a'\beta'}(u)}\,\mathrm{d}\psi\,\mathrm{d}\overline{\psi}$$

$$=M^{-1}_{\alpha\beta}\delta_{ab}\delta(x,y),$$

with a Kronecker delta for space–time coordinates. With our restrictions on the parameters, there is a quantum mechanical Hilbert space $\mathcal{H}$ of physical states, for $\kappa>0$; and the condition $m>0$ guarantees that the one-particle free Fermion dispersion curve increases in each positive momentum component. Last, without loss of generality, we set $M=I_4$ in (2.2).

We note that by polymer expansion methods (see Refs. 2, 9, 21), CF's exist and are lattice translational invariant in the thermodynamic limit and truncated correlations have exponential tree decay. Furthermore, the CF's extend to analytic functions in the coupling parameters κ and g_0^{-2}.

To state our results on the existence of meson particles, their masses and dispersion curves, we consider the subspace $\mathcal{H}_m\subset\mathcal{H}$ generated by vectors associated with the gauge invariant meson fields composed of a fermion (quark) and an antifermion (antiquark) given by

$$\mu_{\alpha}(u)=\begin{cases}\dfrac{1}{\sqrt{6}}(\psi_{a3}(u)\overline{\psi}_{a1}(u)+\psi_{a4}(u)\overline{\psi}_{a2}(u)), & \alpha=1,\\[2ex] \dfrac{1}{\sqrt{3}}\psi_{a4}(u)\overline{\psi}_{a1}(u), & \alpha=2,\\[2ex] \dfrac{1}{\sqrt{3}}\psi_{a3}(u)\overline{\psi}_{a2}(u), & \alpha=3,\\[2ex] \dfrac{1}{\sqrt{6}}(\psi_{a3}(u)\overline{\psi}_{a1}(u)-\psi_{a4}(u)\overline{\psi}_{a2}(u)), & \alpha=4\,;\end{cases} \tag{2.3}$$

$$\pi_\beta(v)=\begin{cases}\dfrac{1}{\sqrt{6}}(\overline{\psi}_{a3}(v)\psi_{a1}(v)+\overline{\psi}_{a4}(v)\psi_{a2}(v)), & \beta=1,\\ \dfrac{1}{\sqrt{3}}\overline{\psi}_{a4}(v)\psi_{a1}(v), & \beta=2,\\ \dfrac{1}{\sqrt{3}}\overline{\psi}_{a3}(v)\psi_{a2}(v), & \beta=3,\\ \dfrac{1}{\sqrt{6}}(\overline{\psi}_{a3}(v)\psi_{a1}(v)-\overline{\psi}_{a4}(v)\psi_{a2}(v)), & \beta=4\,.\end{cases} \tag{2.4}$$

The normalization is chosen so that the associated matrix-valued two-point CF (see below), at coincident points and zero hopping parameter κ, equals I_4.

To see the connection with the EM spectrum, we define a two-point CF, establish a Feynman–Kac (FK) formula, and a spectral representation. The normalized two-point CF is defined by (χ here denotes the characteristic function)

$$\begin{aligned}G_{\alpha\beta}(u,v)&=\langle\mu_\alpha(u)\pi_\beta(v)\rangle_T\,\chi_{u^0\leqslant v^0}+\langle\pi_\alpha(u)\mu_\beta(v)\rangle_T^*\,\chi_{u^0>v^0}\\&=\langle\mu_\alpha(u)\pi_\beta(v)\rangle\,\chi_{u^0\leqslant v^0}+\langle\pi_\alpha(u)\mu_\beta(v)\rangle^*\,\chi_{u^0>v^0}\\&=G_{\alpha\beta}(u-v),\end{aligned}$$

where the truncation $\langle\ \rangle_T$ is given by

$$\langle F(u)H(v)\rangle_T=\langle F(u)H(v)\rangle-\langle F(u)\rangle\langle H(v)\rangle\,, \tag{2.5}$$

and we used that the truncation for $G_{\alpha\beta}$ is zero, by parity symmetry.

This seemingly awkward definition has three desirable features. First, the extension to equal times of the $u^0>v^0$ definition agrees with the one for $u^0\leqslant v^0$, by translational invariance and time reversal. Second, its Fourier transform admits a simple spectral representation. Third, it permits us to show the existence of particles, such as the upper mass gap property.

We set $\mathcal{E}(\lambda^0,\vec{\lambda})=\mathcal{E}_0(\lambda^0)\mathcal{E}(\vec{\lambda})$, where $\mathcal{E}_0(\lambda^0)$ is the spectral family for the time translation operator T_0, and $\mathcal{E}(\vec{\lambda})=\Pi_{i=1}^d\mathcal{E}_i(\lambda^i)$ is the product of the spectral families for the ith component self-adjoint momentum operator P^i which generates lattice space translations along the ith direction e^i, $i=1,\ldots,d$. The spectral representation of the next proposition is an important tool. Its proof is omitted here since it follows closely the one for baryons given in Ref. 17.

Proposition 2.1: For $u^0\neq v^0$, $\pi_\alpha\equiv\pi_\alpha(1/2,\vec{0})$, the following FK formula holds for the two-point meson CF [and the right-hand-side is an even function of $\vec{v}-\vec{u}$]:

$$G_{\alpha\beta}(u,v)=\int_{-1}^{1}\int_{\mathbf{T}^d}(\lambda^0)^{|v^0-u^0|-1}e^{i\vec{\lambda}.(\vec{v}-\vec{u})}\mathrm{d}(\pi_\alpha,\mathcal{E}(\lambda^0,\vec{\lambda})\pi_\beta)_{\mathcal{H}}\,. \tag{2.6}$$

We now obtain a spectral representation for the Fourier transform of the two-point function $G_{\alpha\beta}(u,v)$. For $x\in\mathbb{Z}^{d+1}$, with an abuse of notation, we define $G_{\alpha\beta}(x=u-v)\equiv G_{\alpha\beta}(u,v)$. Then, the Fourier transform $\tilde{G}_{\alpha\beta}(p)=\Sigma_{x\in\mathbb{Z}^{d+1}}G_{\alpha\beta}(x)e^{-ipx}$, $p\in\mathbf{T}^{d+1}$, admits the spectral representation

$$\widetilde{G}_{\alpha\beta}(p) = \widetilde{G}_{\alpha\beta}(\vec{p}) + (2\pi)^d \int_{-1}^{1} \int_{\mathbf{T}^d} \delta(\vec{p}-\vec{\lambda}) \frac{2(\cos p^0 - \lambda^0)}{1+(\lambda^0)^2 - 2\lambda^0 \cos p^0} \times \mathrm{d}_{\lambda^0}\mathrm{d}_{\vec{\lambda}}(\pi_\alpha(1/2,\vec{0}), \mathcal{E}_0(\lambda^0)\mathcal{E}(\vec{\lambda})\pi_\beta(1/2,\vec{0}))_{\mathcal{H}}, \tag{2.7}$$

where $\widetilde{G}(\vec{p}) = \Sigma_{\vec{x}\in\mathbb{Z}^d} e^{-i\vec{p}.\vec{x}} G(x^0=0,\vec{x})$. From the above spectral representation, we see that points of nonanalyticity in p^0, on the imaginary axis, are points in the EM spectrum. It is possible that points of nonanalyticity of the form $p^0 = \pm\pi + iq^0$ can occur but this is shown not to be the case in our analysis. We determine the spectrum and show the existence of isolated dispersion curves, up to near the threshold $-4\ln\kappa$, by showing that $\Gamma_{\alpha\beta}(u,v)$, the convolution inverse of the two-point function $G_{\alpha\beta}(u,v)$, decays faster than $G_{\alpha\beta}(u,v)$, and hence the Fourier transform $\widetilde{\Gamma}_{\alpha\beta}(p)$ of $\Gamma_{\alpha\beta}(x=u-v)=\Gamma_{\underline{\alpha}\beta}(u,v)$ has a larger region of analyticity in p^0. Thus, as $\widetilde{G}(p)\widetilde{\Gamma}(p)=I_4$, $\widetilde{\Gamma}^{-1}_{\alpha\beta}(p)=[\mathrm{cof}\,\widetilde{\Gamma}]_{\beta\alpha}(p)/\det[\widetilde{\Gamma}(p)]$ provides a meromorphic extension of $\widetilde{G}_{\alpha\beta}(p)$, and the EM spectrum occurs, for each $\vec{p}$, as points given by the p^0 imaginary axis zeroes of $\det[\widetilde{\Gamma}(p)]$.

The reader may wonder, e.g., for space dimension $d=3$, why composite fields of the form $\overline{\psi}(u)\gamma^5\psi(u)$ and, for $k=1,2,3$, $\overline{\psi}(u)\gamma^k\psi(u)$, $\gamma^5=\gamma^0\gamma^1\gamma^2\gamma^3$, are not employed to form the two-point CF matrix rather than those of Eqs. (2.3) and (2.4). Intuitively, these are the vector and the pseudoscalar meson fields. The reason is that, with our choices, it turns out that the zero spatial momentum matrix $\widetilde{G}_{\alpha\beta}(p^0,\vec{p}=\vec{0})$ is already diagonal (see Sec. IV, Lemma 4.1), so that the masses m_α are determined as the solutions of $\widetilde{\Gamma}_{\alpha\alpha}(p^0=im_\alpha,\vec{p}=\vec{0})=0$, $\alpha=1,2,3,4$.

The zero space momentum improper states we obtain can be classified using the irreducible discrete Z_4 rotation group generated by $\pi/2$ rotations in the x^1x^2 plane and the group Z_2 generated by x^3-coordinate reflections. Using the results of Theorem 4 of Ref. 17, about symmetries, we find that, for $\pi_i' \equiv \Sigma_{\vec{x}\in\mathbb{Z}^{d-1}} \pi_i(1/2,\vec{x})$, the improper zero momentum states π_i', $i=1,2,3,4$, satisfy the following: π_1' and π_4' form a basis for the trivial representation of Z_4, while π_2' (π_3') is a basis for the representation of Z_4 generated by i ($-i$) times the identity; $\pi_1'+\pi_4'$ ($\pi_1'-\pi_4'$) forms a basis for the trivial (nontrivial) representation of Z_2; and π_2' and π_3' form a basis for the trivial representation of Z_2. The commuting groups Z_4 and Z_2 are of course subgroups of the full lattice rotation and reflection group. We note that all the states have parity (-1), so that parity does not distinguish among them.

To analyze $\det\widetilde{\Gamma}(p)$, it suffices to obtain a long range bound for $\Gamma(x)$, but we need its precise short distance behavior, for $|x|\leqslant 2$ to determine the masses and the mass splitting up to and including the order κ^4. However, to control the error, bounds on $\Gamma(x)$ (which improve those obtained by the hyperplane decoupling method) are needed for some x's, with $|x^0|\leqslant 3$. These bounds are obtained by exhibiting cancellations in the Neumann series.

The two-point function convolution inverse $\Gamma(x)$ is defined by the Neumann series $\Gamma = \Sigma_{i=0}^{\infty}(-1)^i[G_d^{-1}G_n]^i G_d^{-1}$, where G_d is the diagonal part of G,

$$G_{d,\alpha\beta}(u,v) = G_{\alpha\alpha}(u,u)\delta_{\alpha\beta}\delta(u,v) \tag{2.8}$$

and G_n is the remainder $G_{n,\alpha\beta}(u,v)=G_{\alpha\beta}(u,v)-G_{d,\alpha\beta}(u,v)$. By the bounds in Theorems 2.1 and 2.2 below, G, G_d, G_n, and Γ are bounded as matrix operators on $\ell_2(\mathbb{C}^4\times\mathbb{Z}_o^{d+1})$.

Moreover, $\Gamma_{\alpha\beta}(x)$ is analytic in κ as $G_{\alpha\beta}(x)$ is, and its short distance behavior is determined by expanding in κ. Long-range bounds on the decay of $G_{\alpha\beta}(x)$ and $\Gamma_{\alpha\beta}(x)$ are obtained by the decoupling of the hyperplane method (see Refs. 6, 7, 9, and 11). Our results hold for all sufficiently small hopping parameter $\kappa>0$, $0<g_0^{-2}\ll\kappa\ll 1$. The short-distance behavior and bounds on G and Γ are given in the next two theorems.

Theorem 2.1: *Let* $0<g_0^{-2}\ll\kappa\ll 1$, c *be a positive constant,* $\rho,\sigma=0,1,\ldots,d$ *and* e^0 *denote the time unit vector,* e^i, e^j $(i,j=1,\ldots,d)$, *denote space unit vectors,* $|\vec{x}|\equiv\Sigma_{i=1}^{d}|x^i|$ *and* $\epsilon,\epsilon'=\pm 1$. *The following properties hold for G:*

(1)

$$G_{\alpha\beta}(x)=\begin{cases}\delta_{\alpha\beta}+\mathcal{O}(\kappa^8), & x=0,\\ \delta_{\alpha\beta}\kappa^2+\mathcal{O}(\kappa^6), & x=\epsilon e^0,\\ c_2\delta_{\alpha\beta}\kappa^2+\mathcal{O}(\kappa^6), & x=\epsilon e^j,\\ \delta_{\alpha\beta}\kappa^4+\mathcal{O}(\kappa^8), & x=2\epsilon e^0,\\ c_2\delta_{\alpha\beta}\kappa^4+\mathcal{O}(\kappa^8), & x=2\epsilon e^j,\\ c_{\alpha\beta}(x)\kappa^4+\mathcal{O}(\kappa^8), & x=\epsilon e^\rho+\epsilon' e^\sigma,\quad \rho<\sigma,\end{cases}\tag{2.9}$$

where the κ *independent constants are given by* $c_2=1/4$, *and*

$$c_{\alpha\beta}(x)=\begin{cases}\delta_{\alpha\beta}/2, & x=\epsilon e^0+\epsilon' e^\rho,\\ c_{\alpha\beta}^{ij}, & x=\epsilon e^i+\epsilon' e^j,\quad i<j,\end{cases}\tag{2.10}$$

where $c_{\alpha\beta}^{ij}$ *is given by* $c_{\alpha\beta}^{12}$, *diagonal with* $4c_{11}^{12}=4c_{44}^{12}=1$ *and* $c_{22}^{12}=c_{33}^{12}=0$, $4c_{11}^{13}=8c_{22}^{13}=8c_{33}^{13}=-8c_{23}^{13}=-8c_{32}^{13}=1$, $4c_{11}^{23}=8c_{22}^{23}=8c_{33}^{23}=8c_{23}^{23}=8c_{32}^{23}=1$, *and the remaining elements are zero.*

(2)

$$|G_{\alpha\beta}(x)|\leqslant c|\kappa|^{2|x^0|+2|\vec{x}|}.\tag{2.11}$$

(3) $G_{\alpha\beta}(x)=d_\alpha G_{\alpha\beta}(x')d_\beta^*$, *where*

$$\begin{aligned}&(a)\ \text{for } x'=(x^0,-x^2,x^1,x^3),\quad d_1=1,\quad d_2=-i,\quad d_3=i,\quad d_4=1;\\ &(b)\ \text{for } x'=(x^0,-x^1,-x^2,x^3),\quad d_1=1,\quad d_2=-1,\quad d_3=-1,\quad d_4=1;\\ &(c)\ \text{for } x'=(x^0,-x^1,-x^2,-x^3),\quad d_\alpha=-1,\quad \text{for } \alpha=1,2,3,4.\end{aligned}$$

Also,

$$G(e^1+e^2)=SG(e^1+e^3)S^\dagger,$$

where $S=S^t$ *and* $S^{-1}=S^\dagger$ (*superscript t means transpose and* † *Hermitian conjugate*). S *has the matrix elements* $S_{11}=1$, $S_{12}=S_{13}=S_{14}=S_{44}=0$, $S_{22}=S_{33}=S_{23}=1/2$, *and* $S_{24}=S_{34}^*=i\sqrt{2}/2$.

Remark 2.1: The equality of the diagonal elements of $c_{\alpha\beta}^{13}$ *and* $c_{\alpha\beta}^{23}$ *follows from the symmetry results of Theorem 4 in Ref. 17, namely rotations by* $\pi/2$ *about the* e^3 *axis.*

Remark 2.2: The third result above follows by using the symmetry results of Theorem 4 in Ref. 17 below and holds to all orders in κ.

The short distance and decay behaviors of $\Gamma(x)$ are given by the following.

Theorem 2.2: *Under the same hypotheses of Theorem 2.1, with* c_2 *and* $c_{\alpha\beta}(x)$ *as given there, we have the following:*

(1)

$$\Gamma_{\alpha\beta}(x)=\begin{cases}\delta_{\alpha\beta}+(2+2dc_2^2)\delta_{\alpha\beta}\kappa^4+\mathcal{O}(\kappa^8), & x=0,\\ -\delta_{\alpha\beta}\kappa^2+\mathcal{O}(\kappa^8), & x=\epsilon e^0,\\ -c_2\delta_{\alpha\beta}\kappa^2+\mathcal{O}(\kappa^6), & x=\epsilon e^j,\\ \mathcal{O}(\kappa^{10}), & x=2\epsilon e^0,\\ (-c_2+c_2^2)\,\delta_{\alpha\beta}\kappa^4+\mathcal{O}(\kappa^8), & x=2\epsilon e^j,\\ [-c_{\alpha\beta}(x)+2c_2^2\delta_{\alpha\beta}](1-\delta_{0\rho})(1-\delta_{0\sigma})\kappa^4+\mathcal{O}(\kappa^8), & x=\epsilon e^\rho+\epsilon' e^\sigma,\quad \rho<\sigma,\\ \mathcal{O}(\kappa^8), & |x^0|=1,\quad |\vec{x}|=2,\\ \mathcal{O}(\kappa^{10}), & |x^0|=2,\quad |\vec{x}|=1,\\ \mathcal{O}(\kappa^{12}), & |x^0|=3,\quad |\vec{x}|=0.\end{cases} \tag{2.12}$$

(2)

$$|\Gamma_{\alpha\beta}(x)|\leqslant\begin{cases}c|\kappa|^{2+4(|x^0|-1)+2|\vec{x}|}, & |x^0|>1,\\ c|\kappa|^{2|x^0|+2|\vec{x}|}, & |x^0|\leqslant 1.\end{cases} \tag{2.13}$$

Remark 2.3: The absence of lower order terms in $\Gamma_{\alpha\beta}$, *as compared to* $G_{\alpha\beta}$, *for* $|x^0|=1,2,3$, *is due to explicit cancellations in the Neumann series and improves the hyperplane method bounds obtained in Theorem 2.2, item (2).*

Concerning the mass spectrum, i.e., the EM spectrum at zero-space momentum, it turns out that the mass is determined up to $\mathcal{O}(\kappa^4)$ by the values of $\Gamma_{\alpha\beta}(x)$ up to distance $|x|\leqslant 2$, and $\alpha=\beta$. The κ^4 contribution to $\Gamma(x)$, for these values of x, comes from the first and second order terms in G_n in the Neumann series. The second order terms are independent of α since they are products of two κ^2 terms of $G_{n,\alpha\beta}(x)$, for points x of distance one, which are diagonal and independent of α. For the first order term in $G_n(x)$, $|x|=2$, the κ^4 contributions come from *straight* contributions and *angle* contributions. Straight contributions have two subsequent sets of two bonds, with opposite orientation, connecting, e.g., the point 0 to ϵe^ρ and then to $2\epsilon e^\rho$; and the property of the Γ matrices given above guarantees that these contributions behave like the κ^2, diagonal and α-independent contributions $G_{n,\alpha\beta}(x)$, $|x|=1$, and do not give rise to mass splitting as well. Angles are contributions to $G_{n,\alpha\beta}$ for points of the form $x=\epsilon e^i+\epsilon' e^j$, $i,j=1,2,\ldots,d$, $i<j$, $\epsilon,\epsilon'=\pm 1$. These are L-type contributions associated with two sets of two lattice bonds, with opposite orientation; one set connecting the points $0\to\epsilon e^i$ and the other connecting $\epsilon e^i\to\epsilon e^i+\epsilon' e^j$, or one set connecting the points $0\to\epsilon' e^j$ and the other connecting $\epsilon' e^j\to\epsilon e^i+\epsilon' e^j$. They contribute to mass splitting in $\mathcal{O}(\kappa^4)$ for $d=2,3$. (See Theorem 2.3.)

Before stating our results on the mass spectrum and dispersion curves, we give an intuitive picture for the *asymptotic* behavior of the mass. Retaining only the diagonal part of $\Gamma_{\alpha\beta}(x)$, $x=0$ and $x=(1,\vec{0})$, the equation for the mass m is

$$\det\tilde{\Gamma}(p^0=im,\vec{p}=\vec{0})\cong(1-\kappa^2 e^m)^4=0,\quad m\in\mathbb{R},$$

so we have a mass m of order $-2\ln\kappa$, with a fourfold degeneracy.

To rigorously determine the EM spectrum, we exploit symmetries for $\vec{p}=\vec{0}$. $\tilde{\Gamma}(p^0=im,\vec{p}=\vec{0})$ is shown to be diagonal. The determination of the nonsingular part can be cast into an analytic implicit function problem. For $\vec{p}\neq\vec{0}$, we have not shown that $\tilde{\Gamma}(p^0=im,\vec{p})$ is diagonal, but the asymptotic form of the dispersion curve can be obtained by a Rouché's theorem argument for the zeroes of $\det\tilde{\Gamma}(p^0=iw(\vec{p}),\vec{p})$. Also, our results in $\mathcal{H}_m$ are extended to the whole Hilbert space $\mathcal{H}_e$ by adapting the subtraction method of Ref. 8.

The results for the EM spectrum are given in the theorem below.

Theorem 2.3: *Under the hypotheses of Theorem 2.1, the following mesonic spectral results hold in the even subspace $\mathcal{H}_e$ of the physical Hilbert space $\mathcal{H}$.*

(1) To any order in κ and for $d=2,3$, the mass spectrum in $\mathcal{H}_e$ and in the energy interval $(0, -(4-\epsilon)\ln\kappa)$, $\epsilon>0$, consists of three masses given by $diag[a+c,b,b,a-c]$, $a+c$ for $\alpha=1$, b for $\alpha=2,3$ and $a-c$ for $\alpha=4$. Up to and including order κ^4, $a-c=b$, for $d=3$, and $c=0$, for $d=2$, and there are only two distinct masses m_a and m_b given by

$$m_j=-2\ln\kappa+r_j(\kappa), \quad j=a \text{ or } j=b,$$

where $r_j(\kappa)\equiv\Sigma_{n=2}^{\infty}b_{j,n}\kappa^n$ is real analytic in κ at 0, for each $d=2,3$. We obtain, with the constants given in Theorem 2.1,

$$r_j(\kappa)=-2\,\mathrm{d}c_2\kappa^2+[-4(c_{\alpha\alpha}^{12}+c_{\alpha\alpha}^{13;23})+(1-2\,\mathrm{d}c_2-24c_2^2+20\,\mathrm{d}c_2^2)-2\,\mathrm{d}^2c_2^2]\kappa^4+\mathcal{O}(\kappa^6),$$

where $c_{\alpha\alpha}^{13;23}\equiv c_{\alpha\alpha}^{13}+c_{\alpha\alpha}^{23}$ is to be omitted for $d=2$. Again, up to and including order κ^4, for $d=3$, the mass m_b is associated with $\alpha=1$ and has multiplicity one; m_a is associated with $\alpha=2,3,4$, and has multiplicity three. The mass splitting is $m_a-m_b=2\kappa^4+\mathcal{O}(\kappa^6)$. For $d=2$, m_b (m_a) is associated with $\alpha=1,4$ $(\alpha=2,3)$, and both have multiplicity two. The mass splitting is $m_a-m_b=\kappa^4+\mathcal{O}(\kappa^6)$.

(2) The EM spectrum in $\mathcal{H}_e$ and in the energy interval $(0,-(4-\epsilon)\ln\kappa)$, $\epsilon>0$, consists of four dispersion curves (not necessarily distinct), each of which has the form

$$w(\vec{p})=-2\ln\kappa-2\,dc_2\kappa^2+c_2\kappa^2\sum_{j=1}^{d}2(1-\cos p^j)+\mathcal{O}(\kappa^4). \tag{2.14}$$

The curves $w(\vec{p})$ are increasing functions of each component p^j of $\vec{p}$, and are convex for small $|\vec{p}|$.

Remark 2.4: The action of the charge conjugation transformation defined below leaves the space $\mathcal{H}_m$ stable, and hence we have the same spectral representation for particles and antiparticles, as given by Eq. (2.7). At the level of CF, the two-point function for the meson antiparticle (which we call G'), is related to G by $G'=TGT^{-1}$, with $T=diag[1,-1,-1,-1]$, for $d=3$. For $d=2$, replace T by U, where $U=diag[-1,-1,-1,1]$. As the mass and dispersion curves are determined by the implicit equation $\det\tilde{\Gamma}(p_0,\vec{p})=0$, the meson particle and antiparticle mass spectrum and dispersion curves are identical.

The organization of the rest of the paper is also patterned by that in Ref. 17. Section III is devoted to the proof of Theorems 2.1 and 2.2. In Sec. IV we prove Theorem 2.3.

III. DECAY BOUNDS AND SHORT-DISTANCE BEHAVIOR OF *G* AND Γ

We now use the decoupling of the hyperplane method to obtain bounds on G and Γ, as given in Theorem 2.1. We assume that the reader has some familiarity with this method and refer to Refs. 6, 9, and 11 for more details.

We will encounter gauge group integrals of monomials in the group matrix elements g_{ij} $(i,j=1,2,3)$, denote SU(3) matrix elements, and we suppress the lattice points from the notation and the inverses g_{ij}^{-1}. These are evaluated following techniques developed in Chap. 8 of Ref. 22 and in Refs. 23 and 24, for the general SU(N) case. In particular, to prove Theorem 2.1, we will need $\int g_{a_1b_1}g^{-1}_{a_2b_2}\,\mathrm{d}\mu(g)=\frac{1}{3}\delta_{a_1b_2}\delta_{a_2b_1}$ and $\int g_{a_1b_1}g^{-1}_{a_2b_2}g_{a_3b_3}g^{-1}_{a_4b_4}\,\mathrm{d}\mu(g)=\frac{1}{8}(\delta_{a_1b_2}\delta_{a_3b_4}\delta_{b_1a_2}\delta_{b_3a_4}+\delta_{a_1b_4}\delta_{a_3b_2}\delta_{b_1a_4}\delta_{b_3a_2})-\frac{1}{24}(\delta_{a_1b_2}\delta_{a_3b_4}\delta_{b_1a_4}\delta_{b_3a_2}+\delta_{a_1b_4}\delta_{a_3b_2}\,\delta_{b_1a_2}\delta_{b_3a_4})$. Also, we use the following properties involving Γ matrices $(\rho,\sigma=0,1,\ldots,d,$ and $\epsilon,\ \epsilon'=\pm1)$ $\Gamma^{\epsilon e^\rho}\Gamma^{-\epsilon e^\rho}=0$, $\Gamma^{\epsilon e^\rho}\Gamma^{\epsilon e^\rho}=-2\Gamma^{\epsilon e^\rho}$, and $\Gamma^{\epsilon e^\rho}\Gamma^{\epsilon' e^\sigma}=2I_4-\Gamma^{-\epsilon' e^\sigma}\Gamma^{-\epsilon e^\rho}$.

We will obtain decay properties for the gauge invariant truncated CF's,

$$\langle F(u)H(v)\rangle_T=\langle[T_0^{u^0-1/2}\vec{T}^{\vec{u}}F(1/2,\vec{0})][T_0^{v^0-1/2}\vec{T}^{\vec{v}}H(1/2,\vec{0})]\rangle_T, \tag{3.1}$$

where $F,H\in\mathcal{H}_e$, T_0 is time translation by e^0 and $\vec{T}^{\vec{u}}=T_1^{u^1}\cdots T_d^{u^d}$ is space translation by $\vec{u}=(u^1,\ldots,u^d)\in\mathbb{Z}^d$.

We discuss explicitly the decoupling procedure for the time (vertical) direction. The space directions are treated similarly, and together with the time direction. The arguments are carried out for CF's in a finite volume $\Lambda\in\mathbb{Z}_o^{d+1}$, with bounds uniform in the volume $|\Lambda|$, and extend to the infinite volume using standard consequences of the polymer expansion (see, e.g., Refs. 9 and 21).

For $u^0<v^0$, $p\in\mathbb{Z}$, $u^0+1/2\leqslant p\leqslant v^0-1/2$ (or, if $u^0>v^0$, $v^0+1/2\leqslant p\leqslant u^0-1/2$), replace the hopping parameter $\kappa>0$ multiplying the nonlocal fermionic part of the action (2.2) (*not* the κ in M) by $\kappa_p\in\mathbb{C}$ and denoting $\partial^r/\partial\kappa_p^r$ by ∂^r and by ∂_0^r its $\kappa_p=0$ value, the following properties hold.

Lemma 3.1: Concerning the derivatives of G, we have the following.

(1) If $u^0\neq v^0$, $\partial_0^r\langle F(u)H(v)\rangle_T=0$, $r=0,1,3$.

(2) If $u^0<v^0$, and $r=2$,

$$\partial_0^2\langle F(u)H(v)\rangle_T=2\sum_{w|w^0=-1/2+p}\langle F(u)\pi_\alpha(w)\rangle_T\langle\mu_\alpha(w+e^0)H(v)\rangle_T|_{\kappa_p=0}.$$

(3) If $u^0>v^0$, and $r=2$,

$$\partial_0^2\langle F(u)H(v)\rangle_T=2\sum_{w|w^0=-1/2+p}\langle F(u)\mu_\alpha(w+e^0)\rangle_T\langle\pi_\alpha(w)H(v)\rangle_T|_{\kappa_p=0}.$$

Proof: Consider $u^0<v^0$; the argument for $v^0<u^0$ is similar. For the truncated two-point function of Eq. (2.5), we introduce a duplicate variable representation (see Ref. 8) depending on the hyperplane decoupling parameters $\{\kappa_p\}$,

$$\begin{aligned}\langle F(u)H(v)\rangle_T=\frac{1}{2Z^2}\int\,&[F(u)-F'(u)][H(v)-H'(v)]\\&\times\exp\Bigg[-\sum_{w|w_0=-1/2+p}\kappa_p(A(\psi,\overline{\psi},g,w)+A(\psi',\overline{\psi}',g',w))\Bigg]\\&\times\exp[-S(\psi,\overline{\psi},g)-S(\psi',\overline{\psi}',g')]\,\mathrm{d}\psi\,\mathrm{d}\overline{\psi}\,\mathrm{d}\mu(g)\,\mathrm{d}\psi'\,\mathrm{d}\overline{\psi}'\,\mathrm{d}\mu(g'),\end{aligned}\tag{3.2}$$

where $A(\psi,\overline{\psi},g,w)=\frac{1}{2}[\overline{\psi}_{a\alpha}(w)\,\Gamma^{\epsilon e^0}_{\alpha\beta}(g_{w,w+e^0})_{ab}\,\psi_{b\beta}(w+\epsilon^0)+\overline{\psi}_{\alpha\alpha}(w+e^0)\Gamma^{-e^0}_{\alpha\beta}(g_{w+e^0,w})\,ab\,\psi_{b\beta}(w)]$ and Z^2 is the normalization factor. The primes in F' and H' mean functions of the duplicate variables ψ', $\overline{\psi}'$, and g'. $S(\psi,\overline{\psi},g)$ is the action for the remaining bonds. We now expand the numerator and denominator of (3.2) in powers of κ_p. For the denominator the κ_p coefficient is a sum of bond terms and each term is a product of expectations containing a single ψ or $\overline{\psi}$ which Fermi integrates to zero. The coefficient of κ_p^2 is a sum of terms with two bounds which must be coincident and of opposite orientation to give a nonzero contribution. For the numerator, we consider the coefficients of κ_p. For the first statement, the κ_p^0 is trivially zero. For κ_p^1 and κ_p^3 the expectation factorizes and each factor has an odd number of fermions and gives zero. The integral over interhyperplane gauge field could also be used to show zero contribution for κ_p^1. For the second statement, the κ_p^2 coefficient has terms with two bonds. For a nonzero contribution performing the gauge integral and the matrix structure of $\Gamma^{\pm e^0}$ gives the result. The proof of the third statement is similar to the second one. □

To calculate the κ_p derivatives of Γ, it is convenient to consider instead $\Gamma'\equiv-\Gamma$, minus the convolution inverse of G, and use the formula

$$\partial^r\Gamma'=\sum_{s=0}^{r-1}\binom{r}{s}\Gamma'\,\partial^{r-s}G\,\partial^s\Gamma'.\tag{3.3}$$

The first three $\kappa=0$ derivatives of Γ are given in the next lemma.

Lemma 3.2: For the derivatives of Γ, we have the following.

(1) If $u^0 \neq v^0$, $\partial_0^r \Gamma(u,v) = 0$, $r = 0,1$.
(2) If $u^0 < v^0$, $\partial_0^2 \Gamma(u,v) = -2\Sigma_{w|w^0=-1/2+p}\ \delta(u,w)\delta(w+e^0,v)$.
(3) If $u^0 > v^0$, $\partial_0^2 \Gamma(u,v) = -2\Sigma_{w|w^0=-1/2+p}\ \delta(u,w+e^0)\delta(w,v)$.
(4) If $|u^0 - v^0| > 1$, $\partial_0^3 \Gamma(u,v) = 0$.

Proof: For the first statement, consider first $u^0 < v^0$. Using Eq. (3.3) and Lemma 3.1, the result follows directly; and similarly for $u^0 > v^0$. For the second statement, using the first one and the second statement of Lemma 3.1, we have

$$\partial_0^2 \Gamma(u,v) = -\sum_{w,z|w^0+1/2\leq p\leq z^0-1/2} \Gamma(u,w)\partial^2 G(w,z)\Gamma(z,v)\Big|_{\kappa_p=0}$$

$$= -2\sum_{w,z|w^0+1/2\leq p\leq z^0-1/2} \Gamma(u,w)\sum_{r|r^0+1/2=p} G(w,r)G(r+e^0,z)\,\Gamma(z,v)\Big|_{\kappa_p=0}. \tag{3.4}$$

Using Lemma 3.1 (first item) for $r=0$ the w and z sums can be taken over all values to give the result. The third statement follows from a similar argument. The fourth statement follows from the first three statements and uses Eq. (3.3) again. □

We are now ready to prove Theorem 2.1.

Proof of Theorem 2.1 (first item): Consider the expansion of the denominator of $G_{\alpha\beta}$ in powers of κ. For a point where the bonds arrive and leave in opposite directions the Fermi integration gives products of Γ's, in which case the above property is used to give zero. The first nonvanishing contribution occurs at κ^8, corresponding to two sets of four bonds going around an elementary square in opposite directions. For the numerator we explicitly carry out two typical calculations: one for the κ^2 contribution to $G_{11}(x)$, associated with $x=\epsilon e^\rho$ ($|x|=1$), and another for the case of an angle contribution to $G_{11}(x)$, when $x=\epsilon e^\rho+\epsilon' e^\sigma$. The case $\epsilon=\epsilon'$ and $\rho=\sigma$ is simpler as the property $\Gamma^{\epsilon e^\rho}\Gamma^{\epsilon e^\rho}=-2\Gamma^{\epsilon e^\rho}$ can be used.

The κ^2 contribution to the case $|x=u-v|=1$, involves two bonds, with opposite orientation connecting u and v. After performing the gauge group integral, we obtain for $G_{11}(u,v)$ with $\langle\ \rangle_0$ denoting the expectation with the hopping parameter set equal to zero in the action of (2.2),

$$\frac{\kappa^2}{12}\langle \mu_1(u)\overline{\psi}_{a_1\alpha_1}(u)\psi_{a_1\beta_2}(u)\rangle_0 \Gamma^{\epsilon e^\rho}_{\alpha_1\beta_1}\Gamma^{-\epsilon e^\rho}_{\alpha_2\beta_2}\langle \psi_{a_2\beta_1}(v)\overline{\psi}_{a_2\alpha_2}(v)\pi_1(v)\rangle_0.$$

Using the definitions (2.3), (2.4) and applying again Wick's theorem for the factors $\langle\ \rangle_0$ we get

$$\frac{\kappa^2}{8}(\Gamma^{-\epsilon e^\rho}_{11}\Gamma^{\epsilon e^\rho}_{33}+\Gamma^{-\epsilon e^\rho}_{12}\Gamma^{\epsilon e^\rho}_{43}+\Gamma^{-\epsilon e^\rho}_{21}\Gamma^{\epsilon e^\rho}_{34}+\Gamma^{-\epsilon e^\rho}_{22}\Gamma^{\epsilon e^\rho}_{44}).$$

By the explicit structure of the matrices Γ the second and third terms above are zero (for all ρ) and the sum of the first and fourth is equal to $8\delta_{\rho 0}+2\delta_{\rho j}$ (remember that $j=1,2,3$) and the result follows.

The κ^4 contribution to $G_{11}(u,v)=G_{11}(x=u-v)$ of the angle $0\to\epsilon e^\rho\to\epsilon e^\rho+\epsilon' e^\sigma\equiv x$ is denoted by $A_{11}^{\epsilon e^\rho,x}\kappa^4$ and has $g_{0,\epsilon e^\rho}$ ($g^{-1}_{0,\epsilon e^\rho}$) emanating from 0 ($\epsilon e^\rho$) in the e^ρ direction and $g_{\epsilon e^\rho,x}(g^{-1}_{\epsilon e^\rho,x})$ arriving at $x(\epsilon e^\rho)$ in the e^σ direction. After gauge integration of $g_{0,\epsilon e^\rho}g_{\epsilon e^\rho,0}$ and $g_{\epsilon e^\rho,x}g_{x,\epsilon e^\rho}$, and Fermi integration of the fields at ϵe^ρ using Wick's theorem, we have

$$A_{11}^{\epsilon e^\rho,x}=\tfrac{1}{48}\langle \mu_1(u)\overline{\psi}_{a_1\alpha_1}(u)\psi_{a_1\beta_2}(u)\rangle_0\,(\Gamma^{\epsilon e^\rho}_{\alpha_1\beta_1}\Gamma^{-\epsilon e^\rho}_{\alpha_2\beta_2}\Gamma^{\epsilon' e^\sigma}_{\beta_1\beta_3}\Gamma^{-\epsilon' e^\sigma}_{\alpha_4\alpha_2}$$
$$-3\Gamma^{\epsilon e^\rho}_{\alpha_1\beta_1}\Gamma^{-\epsilon e^\rho}_{\beta_1\beta_2}\Gamma^{\epsilon' e^\sigma}_{\alpha_3\beta_3}\Gamma^{-\epsilon' e^\sigma}_{\alpha_4\alpha_3})\,\langle \psi_{a_4\beta_3}(v)\overline{\psi}_{a_4\alpha_4}(v)\pi_1(v)\rangle_0.$$

The second product of Γ's above is zero by $\Gamma^{\epsilon e^\rho}\Gamma^{-\epsilon e^\rho}=0$. Using the definitions (2.3), (2.4) and applying again Wick's theorem for the factors $\langle\ \rangle_0$ we get

$$A_{11}^{\epsilon e^\rho,x}=\tfrac{1}{32}[\Lambda_{11}^{-\epsilon' e^\sigma,-\epsilon e^\rho}\Lambda_{33}^{\epsilon e^\rho,\epsilon' e^\sigma}+\Lambda_{12}^{-\epsilon' e^\sigma,-\epsilon e^\rho}\Lambda_{43}^{\epsilon e^\rho,\epsilon' e^\sigma}+\Lambda_{21}^{-\epsilon' e^\sigma,-\epsilon e^\rho}\Lambda_{34}^{\epsilon e^\rho,\epsilon' e^\sigma}$$
$$+\Lambda_{22}^{-\epsilon' e^\sigma,-\epsilon e^\rho}\Lambda_{44}^{\epsilon e^\rho,\epsilon' e^\sigma}],$$

where $\Lambda_{uu'}^{-\epsilon' e^\sigma,-\epsilon e^\rho}\equiv\Gamma_{u\alpha}^{-\epsilon' e^\sigma}\Gamma_{\alpha u'}^{-\epsilon e^\rho}$ and $\Lambda_{\ell\ell'}^{\epsilon e^\rho,\epsilon' e^\sigma}\equiv\Gamma_{\ell\beta}^{\epsilon e^\rho}\Gamma_{\beta\ell'}^{\epsilon' e^\sigma}$. Similarly, we can calculate the contribution of $A_{11}^{\epsilon' e^\sigma,x}$. The expression for $c_{11}(x)$ is

$$c_{11}(x)=A_{11}^{\epsilon e^\rho,x}+A_{11}^{\epsilon' e^\sigma,x},$$

with $x=\epsilon e^\rho+\epsilon' e^\sigma$, and similarly for the other $c_{\alpha\beta}(x)$'s. When $\rho=i$ and $\sigma=j$ $(i,j=1,2,3)$ by the symmetry properties of Theorem 4 in Ref. 17 (namely, rotations by π about e^3 and parity), we can show that $c_{\alpha\beta}(x=\epsilon e^i+\epsilon' e^j)$ is independent of ϵ, ϵ' so, we can write $c_{\alpha\beta}(x)=c_{\alpha\beta}(e^i+e^j)\equiv c_{\alpha\beta}^{ij}$ and we get Eq. (2.10). □

Proof of Theorem 2.1 (second item): Using a Cauchy integral representation for each κ_p and for analogous spatial complex hyperplane decoupling parameters, taking into account the number of vanishing derivatives as given in Lemma 3.1, and using Cauchy estimates on the multiple integral gives the result. An argument based on the maximum modulus theorem could also be used (see Ref. 9 for details). □

Let us now turn to the proof of Theorem 2.2. The corrections to the asymptotic mass value of $-2\ln\kappa$ which we need for the determination of mass splitting require precise values of $\Gamma_{\alpha\beta}(x)$, for small $|x|$. The results go beyond those obtained by the hyperplane method, and rely on explicit cancellations in the Neumann series for Γ. The results below are obtained expanding in powers of κ and controlling the remainders using the analyticity of G and Γ, and the decay of G as given by Theorem 2.1.

Proof of Theorem 2.2 (first item): $\Gamma_{\alpha\beta}$ is obtained from the Neumann series and Theorem 2.1 (first item). We show how the cancellations occur, which improves the hyperplane method bound. We explicitly consider the case $x=\epsilon e^0+\epsilon' e^j$; the other cases where there are one, two or three times units are treated similarly. Recall that [see Eq. (2.8)] $G_{d,\alpha\beta}(u,v)=G_{\alpha\alpha}(u,u)\delta_{\alpha\beta}\delta(u,v)$. From Theorem 2.1, we obtain $G_{\alpha\alpha}(0)=1+\mathcal{O}(\kappa^8)$. Using $\Gamma=\Sigma_{i=0}^{\infty}(-1)^i[G_d^{-1}G_n]^iG_d^{-1}$, for $x=u-v\neq 0$, we write

$$\Gamma_{\alpha\beta}(u,v)=-G_{\alpha\alpha}^{-1}(0)G_{n,\alpha\beta}(u,v)G_{\beta\beta}^{-1}(0)+\sum_w\ G_{\alpha\alpha}^{-1}(0)G_{n,\alpha\gamma}(u,w)$$
$$\times\ G_{\gamma\gamma}^{-1}(0)G_{n,\gamma\beta}(w,v)G_{\beta\beta}^{-1}(0)+\mathcal{O}(G_n^3). \tag{3.5}$$

For $\alpha=\beta$, there are two κ^4 angle contributions to $G_{n,\alpha\beta}(u,v)$ in the first term of Eq. (3.5), and these are cancelled by the product of κ^2 contributions for $w-v=\epsilon e^0$ and $w-v=\epsilon e^j$ in the second term of Eq. (3.5). □

Proof of Theorem 2.2 (second item): Similar to Theorem 2.1 (second item). □

IV. SPECTRAL RESULTS

We now prove Theorem 2.3. To determine the meson masses and dispersion curves, we find the p^0 imaginary axis solutions of $\det\tilde{\Gamma}(p^0,\vec{p})=0$. For the mass spectrum, we find, by the use of symmetries, that $\tilde{\Gamma}_{\alpha\beta}(p^0,\vec{p}=\vec{0})$ is diagonal. Furthermore, we show that $m_c+2\ln\kappa$ is real analytic in κ. For $\vec{p}\neq\vec{0}$, as we have *not* found symmetries which simplify the matrix structure, we determine the dispersion curves $w(\vec{p})$, where $\det\tilde{\Gamma}(p^0=iw(\vec{p}),\vec{p})=0$, by an application of Rouché's theorem.

We state some symmetry properties in the next lemma.

Lemma 4.1: The following symmetry properties are satisfied by the matrices G and Γ.

(1) $G_{\alpha\beta}(x) = [G_{\beta\alpha}(x)]^*$ *and* $\Gamma_{\alpha\beta}(x) = [\Gamma_{\beta\alpha}(x)]^*$,
(2) For $\chi \in \mathbb{R}$, *let* $p^0 = i\chi$. *We have* $\tilde{G}_{\alpha\beta}(i\chi,\vec{p}) = [\tilde{G}_{\beta\alpha}(i\chi,\vec{p})]^*$ *and* $\tilde{\Gamma}_{\alpha\beta}(i\chi,\vec{p}) = [\tilde{\Gamma}_{\beta\alpha}(i\chi,\vec{p})]^*$,
(3) At $\vec{p}=\vec{0}$, $\tilde{G}_{\alpha\beta}(p^0,\vec{p}=\vec{0}) = \mathrm{diag}[a+c, b, b, a-c]$, *with* $a, b, c \in \mathbb{C}$.

Proof: Here we use several symmetries given in Theorem 4 in Ref. 17. By the spectral representation of Proposition 2.1, for $x^0 \neq 0$, item (1) follows. For $x^0 = 0$, the result follows from time reversal and parity. Thus, item (1) holds for all x. The proof of item (2) follows from parity invariance $G_{\alpha\beta}(x^0,\vec{x}) = G_{\alpha\beta}(x^0,-\vec{x})$. To prove item (3), we use reflection symmetry in the coordinate x^1. Here $\vec{x}=(x^1,\ldots,x^d) \mapsto \vec{x}\,' = (-x^1,\ldots,x^d)$, and $\tilde{\psi}_{a1}(x) \mapsto -\tilde{\psi}_{a2}(x')$, $\tilde{\psi}_{a2}(x) \mapsto -\tilde{\psi}_{a1}(x')$, $\tilde{\psi}_{a3}(x) \mapsto \tilde{\psi}_{a4}(x')$, $\tilde{\psi}_{a4}(x) \mapsto \tilde{\psi}_{a3}(x')$. Also rotations of $\pi/2$ and π about e^3 will be used. Considering $\pi/2$ and $d=3$ we have, $x=(x^0,x^1,x^2,x^3) \mapsto x' = (x^0,-x^2,x^1,x^3)$ [$x = (x^0,x^1,x^2) \mapsto x' = (x^0,-x^2,x^1)$, for $d=2$] and $\tilde{\psi}_{a\underline{1}}(x) \mapsto \tilde{\psi}_{a\underline{1}}(x')$, $\psi_{a\underline{2}}(x) \mapsto -i\psi_{a\underline{2}}(x')$, $\tilde{\psi}_{a3}(x) \mapsto \tilde{\psi}_{a3}(x')$, $\psi_{a4}(x) \mapsto -i\psi_{a4}(x')$ and $\overline{\psi}_{a\underline{2}}(x) \mapsto i\overline{\psi}_{a\underline{2}}(x')$, $\psi_{a4}(x) \mapsto i\overline{\psi}_{a4}(x')$. For π and $d=3$ we have, $x=(x^0,x^1,x^2,x^3) \mapsto x' = (x^0,-x^1,-x^2,x^3)$ [$x=(x^0,x^1,x^2) \mapsto x' = (x^0,-x^1,-x^2)$, for $d=2$] and $\tilde{\psi}_{a1}(x) \mapsto \tilde{\psi}_{a1}(x')$, $\tilde{\psi}_{a2}(x) \mapsto -\tilde{\psi}_{a2}(x')$, $\tilde{\psi}_{a3}(x) \mapsto \tilde{\psi}_{a3}(x')$, $\tilde{\psi}_{a4}(x) \mapsto -\tilde{\psi}_{a4}(x')$.

These transformations, taken together with the symmetry results given in Theorem 4 in Ref. 17, are used to obtain the matrix structure stated in the third item, for $d=2,3$. □

After using Theorem 2.2 and taking the Fourier transform, we have

$$\tilde{\Gamma}_{\alpha\beta}(p^0,\vec{0}) = [1-2\,dc_2\kappa^2 + 2(1-dc_2-12c_2^2+10\,dc_2^2)\kappa^4]\delta_{\alpha\beta} - 4(c_{\alpha\beta}^{12}+c_{\alpha\beta}^{13}+c_{\alpha\beta}^{23})\kappa^4 + \mathcal{O}(\kappa^6) - [\delta_{\alpha\beta}\kappa^2 + \mathcal{O}(\kappa^8)](e^{ip^0}+e^{-ip^0}) + \cdots . \tag{4.1}$$

We now introduce an auxiliary function $H_\alpha(w,\kappa)$, jointly analytic in w and κ, for small $|\kappa|$ and $|w|$, such that $H_\alpha(w=1-\kappa^2 e^{-ip^0},\kappa) = \tilde{\Gamma}_{\alpha\alpha}(p^0,\vec{p}=\vec{0})$. $H_\alpha(w,\kappa)$ is defined by

$$H_\alpha(w,\kappa), = w - 2\,dc_2\kappa^2 + 2(1-dc_2-12c_2^2+10\,dc_2^2)\kappa^4 - 4(c_{\alpha\alpha}^{12}+c_{\alpha\alpha}^{13;23})\kappa^4 - \frac{\kappa^4}{1-w} + \sum_{\vec{x}} \Gamma'_{\alpha\alpha}(0,\vec{x}) - \sum_{\vec{x}} \Gamma'_{\alpha\alpha}(1,\vec{x})\left[\frac{\kappa^2}{1-w}+\frac{1-w}{\kappa^2}\right] + \sum_{n\geq 1,\vec{x}|(n,\vec{x})\neq(1,\vec{0})} \Gamma_{\alpha\alpha}(n,\vec{x})\left[\left(\frac{\kappa^2}{1-w}\right)^n + \left(\frac{1-w}{\kappa^2}\right)^n\right], \tag{4.2}$$

where $\Gamma'_{\alpha\alpha}(0,\vec{x})$ [respectively, $\Gamma'_{\alpha\alpha}(1,\vec{x})$] contains the contributions of $\mathcal{O}(\kappa^6)$ [respectively, $\mathcal{O}(\kappa^8)$] or higher and $c_{\alpha\alpha}^{13;23}$ is the sum of angle contributions $0 \to e^i \to e^{13}$ $(i=1,3)$ and $0 \to e^j \to e^{23}$ $(j=2,3)$ which is diagonal. $H_\alpha(0,0)=0$ and $(\partial H_\alpha/\partial w)(0,0)=1$, and hence the analytic implicit function theorem applies and gives us an analytic function $w(\kappa) \equiv w_\alpha(\kappa)$ such that $H_\alpha(w(\kappa),\kappa)=0$. Thus, for κ real positive, the mass is given by

$$m_\alpha = -\ln\kappa^2 + \ln(1-w)\,.$$

By an analysis of the formulas for the implicit function derivatives, with $\mathrm{d}w = -(\partial_w H)^{-1}\partial_k H \equiv -(H_w)^{-1}H_k$, we find $\mathrm{d}_0^r w = 0$, $r=0,1,3,5$ and

$$\mathrm{d}_0^2 w = -\partial_\kappa^2 H(0,0) = 4c_2 d$$

$$\mathrm{d}_0^4 w = -\partial_\kappa^4 H(0,0) = -4![1-2\,dc_2-24c_2^2+20\,dc_2^2-4(c_{\alpha\alpha}^{12}+c_{\alpha\alpha}^{13;23})]\,.$$

Hence, for $d=3$,

$$m_\alpha = -2\ln\kappa - 2\,dc_2\kappa^2 + [-4(c^{12}_{\alpha\alpha}+c^{13;23}_{\alpha\alpha}) + (1-2\,dc_2-24c_2^2+20\,dc_2^2) - 2\,d^2c_2^2]\kappa^4 + \mathcal{O}(\kappa^6)\,,$$

and similarly, for $d=2$, with $c^{13;23}_{\alpha\alpha}=0$.

Thus, up to and including $\mathcal{O}(\kappa^4)$, we have, for $d=3$, $m_a\equiv m_\alpha$ and $m_b\equiv m_1$, $m_a-m_b=2\kappa^4$ and $\alpha=2,3,4$; for $d=2$, $m_a\equiv m_\alpha$ and $m_b\equiv m_\beta$, $m_a-m_b=\kappa^4$, $\alpha=2,3$ and $\beta=1,4$.

Let us now turn to the dispersion curves. They satisfy $\det\tilde{\Gamma}(ip^0=iw(\vec{p}),\vec{p})=0$. To determine them, with $c_2(\vec{p})\equiv c_2\sum_{j=1}^d 2\cos p^j$, we write the Fourier transform of $\Gamma_{\alpha\beta}(x)$ as

$$\tilde{\Gamma}_{\alpha\beta}(p^0,\vec{p}) = [1-c_2(\vec{p})\kappa^2-\kappa^2(e^{-ip^0}+e^{ip^0})]\delta_{\alpha\beta} + \sum_{n,\vec{x}}{}' \;\Gamma_{\alpha\beta}(n,\vec{x})\,e^{-i\vec{p}.\vec{x}}(e^{-ip^0n}+e^{ip^0n})\,, \tag{4.3}$$

where $\Sigma'_{n,\vec{x}}$ means that all terms of order κ^4 or higher in $\Gamma_{\alpha\beta}(x)$ are included. Introduce the auxiliary matrix function $H_{\alpha\beta}(w,\kappa)\equiv H_{\alpha\beta}(w,\kappa,\vec{p})$ such that $H_{\alpha\beta}(w=1-c_2(\vec{p})\kappa^2-\kappa^2e^{-ip^0},\kappa) = \tilde{\Gamma}_{\alpha\beta}(p^0,\vec{p})$. $H_{\alpha\beta}(w,\kappa)$ is defined by

$$H_{\alpha\beta}(w,\kappa) = w\,\delta_{\alpha\beta} + \sum_{n,\vec{x}}{}'' \;\Gamma_{\alpha\beta}(n,\vec{x})\,e^{-i\vec{p}.\vec{x}}\left[\left(\frac{1-w-c_2(\vec{p})\kappa^2}{\kappa^2}\right)^n + \left(\frac{\kappa^2}{1-w-c_2(\vec{p})\kappa^2}\right)^n\right],$$

where $\Sigma''_{n,\vec{x}}$ means that only $\mathcal{O}(\kappa^4)$ terms or higher order terms are to be included. $H(w,\kappa)$ is jointly analytic in κ and w at $(w,\kappa)=(0,0)$.

Letting

$$f(w)\equiv\det H(w,\kappa) = \det wI_4 + [\det H(w,\kappa)-\det wI_4] \equiv g(w)+h(w)\,,$$

we can apply Rouché's theorem to $f(w)$ on the circle $|w|=c|\kappa|^4$, $c\gg>1$, $|g(w)|=c^4|\kappa|^{16}$ and $|h(w)|\leqslant c'|\kappa|^{16}<c^4|\kappa|^{16}=|g(w)|$, so that $f(w)$ has four zeroes inside $|w|=c|\kappa|^4$, as $g(w)=w^4$ has a fourth order zero. Notice that the upper bound for $|h(w)|$ comes from an upper bound on the remaining 23 terms in the difference between the two determinants. Now, for $p^0=iw(\vec{p})$, and κ real positive, each of the four zeroes satisfying $\det\tilde{\Gamma}(p^0=iw(\vec{p}),\vec{p})=0$ has the form

$$w(\vec{p}) = -2\ln\kappa - 2\,dc_2\kappa^2 + 2c_2\kappa^2\sum_{j=1}^d(1-\cos p^j) + \mathcal{O}(\kappa^4)\,.$$

We now extend the spectral results from $\mathcal{H}_m$ to the space $\mathcal{H}_e$, using the Euclidean subtraction method established in Ref. 8. We consider the generalized subtracted two-point CF,

$$\mathcal{F}(u,v) = \mathcal{G}_{LL}(u,v) - \sum_{w,w'\in\mathbb{Z}_0^{d+1}} \mathcal{G}_{L,\Phi}(u,w)\Gamma(w,w')\mathcal{G}_{\Phi,L}(w',v)\,,$$

where $\Phi(u)=(\pi_1(u),\ldots,\pi_4(u))$ has four components; $\Gamma(w,w')$ is given by the convolution inverse of the two-point function G. Finally,

$$\mathcal{G}_{FH}(u,v) = \begin{cases} S_{\Theta T_0^{-1}F,H}(u,v), & u^0\leqslant v^0,\\ S^*_{F,\Theta T_0^{-1}H}(u,v), & u^0>v^0,\end{cases}$$

with $S_{F,H}(u,v)=\langle[T_0^{u^0-1/2}\vec{T}^{\vec{u}}F(1/2,\vec{0})][T_0^{v^0-1/2}\vec{T}^{\vec{v}}H(1/2,\vec{0})]\rangle_T$.

The lemma below guarantees that our results hold in the full space $\mathcal{H}_e$.

Lemma 4.2: For $u^0<v^0$, $p\in\mathbb{Z}$, $u^0+1/2\leqslant p\leqslant v^0-1/2$ (or, if $u^0>v^0$, $v^0+1/2\leqslant p\leqslant u^0-1/2$), and again denoting by ∂_0 the κ_p derivative at $\kappa_p=0$, we have $\partial_0^r\mathcal{F}(u,v)=0$, for $r=0,1,2,3$.

Proof: The proof follows Ref. 8 closely. For $u^0<v^0$ (the case $u^0>v^0$ is similar) and from Lemmas 3.1 and 3.2 the power series expansions in κ_p of the functions appearing in the definition of $\mathcal{F}(u,v)$ are of the form

$$\mathcal{G}_{LL}(u,v)=a_2(u,v)\kappa_p^2+\mathcal{O}(\kappa_p^4),$$

$$\mathcal{G}_{L,\Phi}(u,w)=b_0(u,w)\chi_{w^0\leqslant -1/2+p}+b_2(u,w)\kappa_p^2+\mathcal{O}(\kappa_p^4),$$

$$\Gamma(w,w')=c_0(w,w')(\chi_{w^0\leqslant -1/2+p}\chi_{w'^0\leqslant -1/2+p}+\chi_{w^0>-1/2+p}\chi_{w'^0>-1/2+p})+c_2(w,w')\kappa_p^2+\mathcal{O}(\kappa_p^4),$$

$$\mathcal{G}_{\Phi,L}(w',v)=d_0(w',v)\chi_{w'^0>-1/2+p}+d_2(w',v)\kappa_p^2+\mathcal{O}(\kappa_p^4).$$

Substituting these expressions, it is easy to show that $\partial_0^r\mathcal{F}(u,v)=0$ $(r=0,1,3)$. For $r=2$, proceeding exactly as in Theorem 3.7 of Ref. 8, we have four terms which sum up to zero and the result follows. □

This ends the proof of Theorem 2.3. □

(Received 30 September 2003; accepted 4 November 2003)

In the framework of Lorentzian warped products, we study the Friedmann–Robertson–Walker cosmological model to investigate nonsmooth curvatures associated with multiple discontinuities involved in the evolution of the universe. In particular we analyze nonsmooth features of the spatially flat Friedmann–Robertson–Walker universe by introducing double discontinuities occurred at the radiation-matter and matter-lambda phase transitions in astrophysical phenomenology. © *2004 American Institute of Physics.*

I. INTRODUCTION

Since the cosmic microwave background was discovered, there have been many ideas and proposals to figure out how the universe has evolved. The standard big bang cosmological model based on the Friedmann–Robertson–Walker (FRW) space–times has led to the inflationary cosmology[1] and nowadays to the M-theory cosmology with bouncing universes.[2] These space–times are foliated by a special set of spacelike hypersurfaces such that each hypersurface corresponds to an instant of time. From a physical point of view, these warped product space–times are interesting since they include classical examples of space–time such as the FRW manifold and the intermediate zone of Reissner–Nordström (RN) manifold.[3,4]

The Lorentzian manifolds with non-smooth metric tensors have been extensively discussed from various view points.[5–9] In a space–time where the metric tensor is continuous but has a jump in its first and second derivatives across a submanifold in an admissible coordinate system, one can have a curvature tensor containing a Dirac delta function.[10] The support of this distribution may be of three, two, or one dimensional or may even consist of a single event. Moreover, Lichnerowicz's formalism[7] for dealing with such tensors is modified so that one can obtain the Riemannian curvature tensor and Ricci curvature tensor defined in the sense of distributions.

A general theory for matching two solutions of the Einstein field equations has been proposed[8,9] at arbitrary shock-wave interface across which the metric tensor is C^0-Lorentzian, namely at smooth surface across which the first derivatives of the metric suffer at worst a jump discontinuity, so that the simplest solution of Einstein equations can incorporate a shock-wave into a standard FRW metric whose equation of state accounts for the Hubble constant and the microwave background radiation temperature. There have been later presented the evolution of the one point probability distribution function of the cosmological density field based on an exact statistical treatment.[11]

On the other hand, the concept of a warped product manifold was introduced by Bishop and O'Neill long ago,[12] and it was later connected to general relativity[13] and semi-Riemannian geometry[14] by elevating warped products to a central role. Warped product spaces has been also

a)E-mail address: jdong@afa.ac.kr
b)E-mail address: soonhong@ewha.ac.kr

extended to a richer class of spaces involving multiple product spaces.[5,6] One of the authors has investigated the curvature of a multiply warped product possessing C^0-warping functions with a discontinuity at a single point,[5] and in this paper we will generalize this result to a warped product space–time with multiple discontinuities associated with cosmological phenomenology. Of particular interest are space–times with metric tensors which fail to be C^1 across multiple points on the hypersurface, and is C^∞ off the hypersurface. We will also study the Lorentzian metric which fails to be C^0 across multiple points on the hypersurfaces and is C^∞ off the hypersurfaces.

In this paper, as a cosmological model we will exploit the FRW space–times $M_0\times_f H$, which can be treated as a warped product manifold possessing warping function (or scale factor) f with time dependence, to investigate the nonsmooth curvature associated with the multiple discontinuities involved in the evolution of the universe. We will also analyze nonsmooth features of the spatially flat FRW universe by introducing double discontinuities occurred at the radiation-matter and matter-lambda phase transitions in the astrophysical phenomenology.

In Sec. II we will introduce the warped product space–time with multiple warping functions and extend the warped product scheme to the case with multiple discontinuities in the FRW cosmological model in Sec. III. We will study the realistic cosmological phenomenology in the spatially flat FRW universe associated with the radiation-matter and matter-lambda phase transitions in Sec. IV.

II. WARPED PRODUCT SPACE–TIME WITH MULTIPLE WARPING FUNCTIONS

In this section we briefly recapitulate the curvature of the warped product approach to space–time with multiple C^0-warping functions at a single point.

Definition 2.1 (Ref. 5): A multiply warped products space–time with base $(M_0,-\mathrm{d}t^2)$, fibers (F_i,g_i) $i=1,\ldots,n$ and warping functions $f_i>0$ is the product manifold $(M_0\times F_1\times\cdots\times F_n,g)$ endowed with the Lorentzian metric:

$$g=-\pi_{M_0}^{*}\,\mathrm{d}t^2+\sum_{i=1}^{n}\,(f_i\circ\pi_{M_0})^2\pi_i^{*}g_i,$$

where π_{M_0}, π_i $(i=1,\ldots,n)$ are the natural projections of $M_0\times F_1\times\cdots\times F_n$ onto M_0 and $F_1,\ldots,F_n$, respectively. For a specific case of $M_0=R$ and $g_{M_0}=-\mathrm{d}t^2$, the Lorentzian metric is given by

$$g=-\mathrm{d}t^2+\sum_{i=1}^{n}\,f_i^2g_i\,.$$

Proposition 2.2 (Ref. 5): Let $M=M_0\times_{f_1}F_1\times\cdots\times_{f_n}F_n$ be a multiply warped product with Riemannian curvature tensor R. If $X,\ Y\in\mathfrak{L}(M_0),\ U_i,\ V_i,\ W_i\in\mathfrak{L}(F_i)$ $(n=1,2,\ldots,n)$, $f_i\in C^0(S)$ at a single point $p\in M_0$, and $S=\{p\}\times_{f_1}F_1\times\cdots\times_{f_n}F_n$, then

(i)

$$R_{XU_i}U_j=R_{U_iU_j}X=R_{U_jX}U_i=0\quad\text{for } i\neq j,$$

(ii)

$$R_{U_iX}Y=U_iX^1Y^1\frac{f_i''(t)+\delta(t-p)(f_i'^{+}-f_i'^{-})}{f_i},$$

(iii)

$$R_{XU_i}U_j=R_{U_iU_j}X=R_{U_jX}U_i=0,\quad\text{for } i\neq j,$$

(iv)

$$R_{XY}U_i=0, \quad \text{for } i=1,\ldots,n,$$

(v)

$$R_{U_iV_i}U_j=0, \quad \text{for } i\neq j,$$

(vi)

$$R_{U_iU_j}V_j=U_i\langle U_j,V_j\rangle\frac{(f_i'^{+}+f_i'^{-})(f_j'^{+}+f_j'^{-})}{f_if_j}, \quad \text{for } i\neq j,$$

(vii)

$$R_{U_iV_i}W_i={}^{F_i}R_{U_iV_i}W_i+(\langle U_i,W_i\rangle V_i-\langle V_i,W_i\rangle U_i)\frac{f_i'^{+}\mu(t-p)+f_i'^{-}\mu(p-t)}{f_i^2},$$

where $X=X^1\partial/\partial_t$ and $Y=Y^1\partial/\partial_t$, and $\mu(t-p)$ and $\delta(t-p)$ are the unit step function and the delta function, respectively.

Proposition 2.3 (Ref. 5): Let $M=M_0\times_{f_1}F_1\times\cdots\times_{f_n}F_n$ be a multiply warped products with Riemannian curvature tensor R. If $X,\ Y\in\mathfrak{L}(M_0),\ U_i,\ V_i\in\mathfrak{L}(F_i)\ (n=1,2,\ldots,n),\ d_i=\dim F_i$, $f_i\in C^0(S)$ at a single point $p\in M_0$, and $S=\{p\}\times_{f_1}F_1\times\cdots\times_{f_n}F_n$, then

(i)

$$\mathrm{Ric}(X,Y)=-\sum_{i=1}^{n}d_iX^1Y^1\frac{f_i''(t)+\delta(t-p)(f_i'^{+}-f_i'^{-})}{f_i},$$

(ii)

$$\mathrm{Ric}(X,U_i)=0,$$

(iii)

$$\mathrm{Ric}(U_i,V_i)={}^{F_i}\mathrm{Ric}(U_i,V_i)+\langle U_i,V_i\rangle\frac{f_i''(t)+\delta(t-p)(f_i'^{+}-f_i'^{-})}{f_i}+\langle U_i,V_i\rangle\left[(d_i-1)\frac{f_i'^{+}-f_i'^{-}}{f_i^2}+\sum_{j\neq i}d_j\frac{\langle f_i'^{+}-f_i'^{-},f_j'^{+}-f_j'^{-}\rangle}{f_if_j}\right],$$

(iv)

$$\mathrm{Ric}(U_i,U_j)=0, \quad \text{for } i\neq j,$$

where $X=X^1\partial/\partial_t$ and $Y=Y^1\partial/\partial_t$, and $\delta(t-p)$ is the delta function.

III. FRW METRIC WITH MULTIPLE DISCONTINUITIES

The FRW space–time is one of the *warped product* manifold where the base is an open interval M_0 of R with usual metric reversed $(M_0,-\mathrm{d}t^2)$, the fiber is a three-dimensional Riemannian manifold (F,g_F) and the warping function f is any positive function f on M_0. The Robertson–Walker space–time is then the product manifold $M=M_0\times_f H$ endowed with the Lorentzian metric $g=-\mathrm{d}t^2+f^2(t)g_H$ with f being the scale factor of the FRW universe associated with universal expansion. This warping function f is a function of time alone and it measures how

physical separations change with time. The dynamics of the expanding universe only appears implicitly in the time dependence of the warping function (or scalar factor) f.

Consider the space–time (M, g) with metric $g=-\mathrm{d}t^2+f^2\mathrm{d}\sigma^2$ in the form of warped products. Let $M=M_0\times_f H$ be a warped product with $g_{M_0}=-\mathrm{d}t^2$. Let $f>0$ be smooth functions on $M_0=(t_0, t_\infty)$. Assume $f\in C^\infty$ for $t\neq t_i$ and $f\in C^1$ at $t=t_i$ $(i=1,2,\ldots,n)$. When $f\in C^1$ at points $t_i\in(t_0,t_\infty)$ and $S=\{t_i\}\times_f H$, we define $f\in C^1(S)$ as a collection of functions $\{f^{(i)}\}$ with $f^{(i)}$ piecewisely defined on the intervals $t_i\leqslant t\leqslant t_{i+1}$ $(i=0,1,2,\ldots,n)$ with $t_{n+1}=t_\infty$. Since $f\in C^1(S)$, we have $f^{(i-1)}(t_i)=f^{(i)}(t_i)$, $f^{(i-1)'}(t_i)=f^{(i)'}(t_i)$ but $f^{(i-1)''}(t_i)\neq f^{(i)''}(t_i)$. We shall use the unit step function μ for discontinuity of $f^{(i)''}$ at $t=t_i$.

Consider the FRW metric of the form

$$g=-\mathrm{d}t^2+f^2(t)\left(\frac{\mathrm{d}r^2}{1-kr^2}+r^2(\mathrm{d}\theta^2+\sin^2\theta\,\mathrm{d}\phi^2)\right),$$

where k is a parameter denoting the spatially flat $(k=0)$, 3-sphere $(k=1)$ and hyperboloid $(k=-1)$ universes.

Proposition 3.1: Let $M=M_0\times_f H$ be the FRW space–time with Riemannian curvature R and flow vector field $U=\partial_t$. If $f\in C^1(S)$, vector fields $X, Y, Z\in\mathfrak{L}(H)$ satisfy

(i)

$$R_{XY}Z=\frac{f'^2+k}{f^2}(\langle X,Z\rangle Y-\langle Y,Z\rangle X),$$

(ii)

$$R_{XU}U=\frac{f''}{f}X,$$

(iii)

$$R_{XY}U=0,$$

(iv)

$$R_{XU}Y=\frac{f''}{f}\langle X,Y\rangle U,$$

where f'' is given by

$$\begin{aligned}f''=&\left(f^{(n)''}-f^{(n-1)''}+\frac{1}{n}\sum_{k=0}^{n-1}f^{(k)''}\right)\mu(t-t_n)+\sum_{l=1}^{n-1}\left(-f^{(l-1)''}+\frac{1}{n}\sum_{k=0}^{n-1}f^{(k)''}\right)\mu(t-t_l)\\&+\frac{1}{n}\sum_{k=0}^{n-1}f^{(k)''}\mu(t_n-t)+\sum_{l=1}^{n-1}\left(-f^{(l)''}+\frac{1}{n}\sum_{k=0}^{n-1}f^{(k)''}\right)\mu(t_l-t),\end{aligned}\tag{1}$$

with $\mu(t-t_i)$ being the unit step function which becomes unity for $t>t_i$ and vanishes otherwise.

Proof: We derive f'' in terms of the collection of functions $\{f^{(i)}\}$ with $f^{(i)}$ piecewisely defined on the intervals $t_i\leqslant t\leqslant t_{i+1}$ $(i=0,1,2,\ldots,n)$ with $t_{n+1}=t_\infty$. For a single discontinuity $n=1$ case, f is trivially given by

$$f''=f^{(1)''}\mu(t-t_1)+f^{(0)''}\mu(t_1-t)$$

which fulfills (1). For double discontinuities $n=2$ case, f is similarly given by

$$f''=(f^{(2)\prime\prime}-\tfrac{1}{2}f^{(1)\prime\prime}+\tfrac{1}{2}f^{(0)\prime\prime})\mu(t-t_2)+(\tfrac{1}{2}f^{(1)\prime\prime}-\tfrac{1}{2}f^{(0)\prime\prime})\mu(t-t_1)+(\tfrac{1}{2}f^{(1)\prime\prime}+\tfrac{1}{2}f^{(0)\prime\prime})\mu(t_2-t)$$
$$+(-\tfrac{1}{2}f^{(1)\prime\prime}+\tfrac{1}{2}f^{(0)\prime\prime})\mu(t_1-t), \tag{2}$$

which also fulfills (1). By using iteration method, one can obtain (1) for an arbitrary n case. □

For the case of $f\in C^0(S)$ we use the derivative of the unit step function $\mu(t_i)$. For all $t\neq t_i$ this is well-defined, $\mu'(t)=0$. However, at $t=t_i$ there exists a jump discontinuity so that we cannot define classical derivative and thus we use the δ-function, $\mu'(t-t_i)=\delta(t-t_i)$ to obtain the follow results.

Proposition 3.2: Let $M=M_0\times_f H$ be the FRW space–time with Riemannian curvature R and flow vector field $U=\partial_t$. If $f\in C^0(S)$, vector fields X, Y, $Z\in\mathfrak{L}(H)$ then satisfy
(i)

$$R_{XY}Z=\frac{f'^2+k}{f^2}(\langle X,Z\rangle Y-\langle Y,Z\rangle X),$$

(ii)

$$R_{XU}U=\frac{f''}{f}X,$$

(iii)

$$R_{XY}U=0,$$

(iv)

$$R_{XU}Y=\frac{f''}{f}\langle X,Y\rangle U,$$

where f' and f'' are given by

$$f'=\left(f^{(n)\prime}-f^{(n-1)\prime}+\frac{1}{n}\sum_{k=0}^{n-1}f^{(k)\prime}\right)\mu(t-t_n)+\sum_{l=1}^{n-1}\left(-f^{(l-1)\prime}+\frac{1}{n}\sum_{k=0}^{n-1}f^{(k)\prime}\right)\mu(t-t_l)$$
$$+\frac{1}{n}\sum_{k=0}^{n-1}f^{(k)\prime}\mu(t_n-t)+\sum_{l=1}^{n-1}\left(-f^{(l)\prime}+\frac{1}{n}\sum_{k=0}^{n-1}f^{(k)\prime}\right)\mu(t_l-t), \tag{3}$$

$$f''=\left(f^{(n)\prime\prime}-f^{(n-1)\prime\prime}+\frac{1}{n}\sum_{k=0}^{n-1}f^{(k)\prime\prime}\right)\mu(t-t_n)+\sum_{l=1}^{n-1}\left(-f^{(l-1)\prime\prime}+\frac{1}{n}\sum_{k=0}^{n-1}f^{(k)\prime\prime}\right)\mu(t-t_l)$$
$$+\frac{1}{n}\sum_{k=0}^{n-1}f^{(k)\prime\prime}\mu(t_n-t)+\sum_{l=1}^{n-1}\left(-f^{(l)\prime\prime}+\frac{1}{n}\sum_{k=0}^{n-1}f^{(k)\prime\prime}\right)\mu(t_l-t)+(f^{(n)\prime}-f^{(n-1)\prime})\delta(t-t_n)$$
$$+\sum_{l=1}^{n-1}(f^{(l)\prime}-f^{(l-1)\prime})\delta(t-t_l), \tag{4}$$

with $\mu(t-t_i)$ and $\delta(t-t_i)$ being the unit step function and the delta function, respectively.

Proof: Similar to (1) in Proposition 3.1, one can readily obtain f'. Differentiating f' with respect to t and using the definition of the delta function $\mu'(t-t_i)=\delta(t-t_i)$ at $t=t_i$, one can also obtain f''. □

Proposition 3.3: Let $M=M_0\times_f H$ be the FRW space–time with Riemannian curvature R and flow vector field $U=\partial_t$. If $f\in C^0(S)$ and X, $Y\in\mathfrak{L}(H)$, then Ricci curvature is given by

(i)

$$\mathrm{Ric}(U,U) = -\frac{3f''}{f},$$

(ii)

$$\mathrm{Ric}(U,X) = 0,$$

(iii)

$$\mathrm{Ric}(X,Y) = \left(\frac{2(f'^2+k)}{f^2} + \frac{f''}{f}\right)\langle X,Y\rangle, \quad \text{if } X,Y \perp U,$$

where f' and f'' are given by (3) and (4).

Proposition 3.4: Let $M = M_0 \times_f H$ be the FRW space–time with Riemannian curvature R and flow vector field $U = \partial_t$. If $f \in C^0(S)$, the Einstein scalar curvature is given by

$$R = 6\left(\frac{f'^2}{f^2} + \frac{f''}{f} + \frac{k}{f^2}\right),$$

where f' and f'' are given by (3) and (4).

Proposition 3.5: For every plane containing a vector field of $U = \partial_t$, if $f \in C^0(S)$ and X, $Y \in \mathfrak{L}(H)$, we have a sectional curvature K on the space–time (M, g) for an arbitrary plane containing a vector field of $U = \partial_t$ and $W = \alpha U + \beta Y$,

$$K(W,X) = \frac{-\alpha^2 f'' + \beta^2(f'+k)}{(-\alpha^2+\beta^2)f^2},$$

where f' and f'' are given by (3) and (4).

Proof: The result follows $K(W,X) = g(R_{WX}W,X)/g(W,W)g(X,X) - [g(W,X)]^2$ of the non-degenerate 2-plane with basis (W,X). □

IV. COSMOLOGY OF SPATIALLY FLAT FRW METRIC WITH DOUBLE DISCONTINUITIES

In the spatially flat FRW cosmology with $k = 0$, the early universe was radiation dominated, the adolescent universe was matter dominated, and the present universe is now entering into lambda-dominate phase in the absence of vacuum energy. If the universe underwent inflation, there was a very early period when the stress-energy was dominated by vacuum energy. The Friedmann equation may be integrated to give the age of the universe in terms of present cosmological parameters. We have the scale factor f as a function of time t which scales as $f(t) \propto t^{1/2}$ for a radiation-dominated (RD) universe, and scales as $f(t) \propto t^{2/3}$ for a matter-dominated (MD) universe, and scales as $f(t) \propto e^{Kt}$ for a lambda-dominated (LD) universe. Note that the transition from the radiation-dominated phase to the matter-dominated is not an abrupt one; neither is the latter transition from the matter-dominated phase to the exponentially growing lambda-dominated phase.

With the above astrophysical phenomenology in mind, consider the spatially flat FRW space–time (M, g) with metric $g = -\mathrm{d}t^2 + f^2(t)\mathrm{d}\sigma^2$ in the form of warped products. Let $M = M_0 \times_f H$ be a warped product with $g_{M_0} = -\mathrm{d}t^2$.

Definition 4.1: A C^0-Lorentzian metric on M is a nondegenerate (0,2) tensor of Lorentzian signature such that

(i) $g \in C^0$ on S
(ii) $g \in C^\infty$ on $M \cap S^c$

(iii) for all $p \in S$, and $U(p)$ partitioned by S, $g|_{U_p^+}$ and $g|_{U_p^-}$ have smooth extensions to U. We call S a C^0-singular hypersurface of (M,g).

Consider M_0 as a C^0-singular hypersurface of (M,g). In the spatially flat FRW space–time, $f>0$ is smooth functions on $M_0=(t_0, t_\infty)$ except at $t\neq t_i$ $(i=1,2)$, that is $f\in C^\infty(S)$ (where $S=\{t_i\}\times_f H$) for $t\neq t_i$ and $f\in C^0(S)$ at $t=t_i\in M_0$ to yield

$$f=\begin{pmatrix} f^{(0)}=c_0t^{1/2}, & \text{for } t<t_1 \\ f^{(1)}=c_1t^{2/3}, & \text{for } t_1\leqslant t\leqslant t_2 \\ f^{(2)}=c_2e^{Kt}, & \text{for } t>t_2 \end{pmatrix} \tag{5}$$

with the boundary conditions

$$c_0t_1^{1/2}=c_1t_1^{2/3}, \quad c_1t_2^{2/3}=c_2e^{Kt_2}. \tag{6}$$

Experimental values for t_1 and t_2 are given by $t_1=4.7\times10^4$ yr and $t_2=9.8$ Gyr.[15] Moreover c_1 and c_2 are given in terms of c_0, t_1 and t_2 as follows:

$$c_1=c_0t_1^{-1/6}, \quad c_2=c_0t_1^{-1/6}t_2^{2/3}e^{-Kt_2}.$$

Note that in the spatially flat FRW model, $f\in C^0(S)$ since if we assume $f\in C^1(S)$ one could have the boundary conditions $\frac{1}{2}c_0t_1^{-1/2}=\frac{2}{3}c_1t_1^{-1/3}$ and $\frac{2}{3}c_1t_2^{-1/3}=Kc_2e^{Kt_2}$, which cannot satisfy the above boundary conditions (6) simultaneously.

Proposition 4.2: Let $M=M_0\times H$ be the spatially flat FRW space–time with Riemannian curvature R, flow vector field $U=\partial_t$ and warping function $f\in C^0(S)$. For vector fields X, Y, $Z\in\mathfrak{L}(H)$ we have

(i)

$$R_{XY}Z=\frac{f'^2}{f^2}(\langle X,Z\rangle Y-\langle Y,Z\rangle X),$$

(ii)

$$R_{XU}U=\frac{f''}{f}X,$$

(iii)

$$R_{XY}U=0,$$

(iv)

$$R_{XU}Y=\frac{f''}{f}\langle X,Y\rangle U,$$

where f is given by (5) and f' and f'' are given by

$$\begin{aligned} f'=&(\tfrac{1}{4}c_0t^{-1/2}-\tfrac{1}{3}c_1t^{-1/3}+Kc_2e^{Kt})\mu(t-t_2)+(-\tfrac{1}{4}c_0t^{-1/2}+\tfrac{1}{3}c_1t^{-1/3})\mu(t-t_1)\\ &+(\tfrac{1}{4}c_0t^{-1/2}+\tfrac{1}{3}c_1t^{-1/3})\mu(t_2-t)+(\tfrac{1}{4}c_0t^{-1/2}-\tfrac{1}{3}c_1t^{-1/3})\mu(t_1-t), \end{aligned} \tag{7}$$

$$f''=(-\tfrac{1}{8}c_0t^{-3/2}+\tfrac{1}{9}c_1t^{-4/3}+K^2c_2e^{Kt})\mu(t-t_2)+(\tfrac{1}{8}c_0t^{-3/2}-\tfrac{1}{9}c_1t^{-4/3})\mu(t-t_1)+(-\tfrac{1}{8}c_0t^{-3/2}-\tfrac{1}{9}c_1t^{-4/3})\mu(t_2-t)+(-\tfrac{1}{8}c_0t^{-3/2}+\tfrac{1}{9}c_1t^{-4/3})\mu(t_1-t)+(-\tfrac{2}{3}c_1t^{-1/3}+Kc_2e^{Kt})\delta(t-t_2)+(-\tfrac{1}{2}c_0t^{-1/2}+\tfrac{2}{3}c_1t^{-1/3})\delta(t-t_1), \tag{8}$$

with $\mu(t-t_i)$ and $\delta(t-t_i)$ being the unit step function and the delta function, respectively.

Proof: Substituting f in (5) into (3) and (4) in Proposition 3.2, one can readily obtain (7) and (8). □

Proposition 4.3: Let $M=M_0\times H$ be the spatially flat FRW space–time with Riemannian curvature R, flow vector field $U=\partial_t$ and warping function $f\in C^0(S)$. For vector fields X, Y, $Z\in\mathfrak{L}(H)$, the Ricci curvature is given by

(i)

$$\mathrm{Ric}(U,U)=-\frac{3f''}{f},$$

(ii)

$$\mathrm{Ric}(U,X)=0,$$

(iii)

$$\mathrm{Ric}(X,Y)=\left(\frac{2f'^2}{f^2}+\frac{f''}{f}\right)\langle X,Y\rangle, \quad \text{if } X,Y\perp U,$$

where f, f', and f'' are given by (5), (7), and (8), respectively.

Proposition 4.4: Let $M=M_0\times H$ be the spatially flat FRW space–time with Riemannian curvature R, flow vector field $U=\partial_t$ and warping function $f\in C^0(S)$. The Einstein scalar curvature is then given by

$$R=6\left(\frac{f'^2}{f^2}+\frac{f''}{f}\right),$$

where f, f', and f'' are given by (5), (7), and (8), respectively.

Proposition 4.5: For every plane containing a vector field of $U=\partial_t$ and $f\in C^0(S)$, if X, $Y\in\mathfrak{L}(H)$ we have a sectional curvature K on the FRW space–time (M, g) for an arbitrary plane containing a vector field of $U=\partial_t$ and $W=\alpha U+\beta Y$,

$$K(W,X)=\frac{-\alpha^2f''+\beta^2f'}{(-\alpha^2+\beta^2)f^2},$$

where f, f', and f'' are given by (5), (7), and (8), respectively.

Proposition 4.6: Let $M=M_0\times H$ be the spatially flat FRW space–time with Riemannian curvature R, flow vector field $U=\partial_t$ and warping function $f\in C^0(S)$. The evolution equations are then given by

(i)

$$\frac{3f'^2}{f^2}=8\pi\rho+\Lambda,$$

(ii)

$$\frac{3f''}{f} = -4\pi(\rho + 3P) + \Lambda,$$

where f, f', and f'' are given by (5), (7), and (8), respectively. Here ρ, P, and Λ are the mass density and pressure of matter and the cosmological constant.

Proof: Consider the Einstein equation,

$$G_{\mu\nu} + \Lambda g_{\mu\nu} = R_{\mu\nu} - \tfrac{1}{2} R g_{\mu\nu} + \Lambda g_{\mu\nu} = 8\pi T_{\mu\nu}, \tag{9}$$

where $G_{\mu\nu}$ is the Einstein tensor, and $T_{\mu\nu}$ is the stress-energy tensor for all the field present-matter, radiation and so on. To be consistent with the symmetries of the metric, the total stress-energy tensor $T_{\mu\nu}$ must be diagonal, and by isotropy the spatial components must be equal. The simplest realization of such a stress-energy tensor is that of a perfect fluid characterized by a time-dependent energy density $\rho(t)$ and pressure $p(t)$,

$$T^{\mu}_{\nu} = \mathrm{diag}(\rho, -p, -p, -p). \tag{10}$$

Substituting (10) into (9), together with the Ricci and Einstein curvatures given in Proposition 4.3 and Proposition 4.4, one can readily obtain the above evolution equations. □

Remarks 4.7: The $\mu = 0$ component of the conservation of stress-energy tensor, $T^{\mu\nu}_{;\nu} = 0$, gives the first law of thermodynamics of the familiar form $d(\rho f^3) = -p\,d(f^3)$ or equivalently, $d[f^3(\rho + p)] = f^3\,dp$. The change in energy in a co-moving volume element, $d(\rho f^3)$, is equal to minus the pressure times the change in volume element, $-p\,d(f^3)$. For the simple equation of state $p = \omega\rho$, where ω is independent of time, the energy density evolves as $\rho \propto f^{-3(1+\omega)}$. Examples of interest include: radiation ($p = \frac{1}{3}\rho$, $\rho \propto f^{-4}$), matter ($p = 0$, $\rho \propto f^{-3}$), and vacuum energy ($p = -\rho$, $\rho \propto$ const) phases.

V. CONCLUSIONS

We have considered the FRW cosmological model in the warped product scheme to investigate the nonsmooth curvature associated with the multiple discontinuities involved in the evolution of the universe. In particular we have analyzed the nonsmooth features of the spatially flat FRW universe by introducing double discontinuities occurred at the radiation-matter and matter-lambda phase transitions in the astrophysical phenomenology.

(Received 5 November 2002; accepted 12 November 2003)

We give a classification of the type D space–times based on the invariant differential properties of the Weyl principal structure. Our classification is established using tensorial invariants of the Weyl tensor and, consequently, besides its intrinsic nature, it is valid for the whole set of the type D metrics and it applies on both, vacuum and nonvacuum solutions. We consider the Cotton-zero type D metrics and we study the classes that are compatible with this condition. The subfamily of space–times with constant argument of the Weyl eigenvalue is analyzed in more detail by offering a canonical expression for the metric tensor and by giving a generalization of some results about the nonexistence of purely magnetic solutions. The usefulness of these results is illustrated in characterizing and classifying a family of Einstein–Maxwell solutions. Our approach permits us to give intrinsic and explicit conditions that label every metric, obtaining in this way an operational algorithm to detect them. In particular a characterization of the Reissner–Nordström metric is accomplished. © *2004 American Institute of Physics.*
[DOI: 10.1063/1.1640795]

I. INTRODUCTION

Type D space–times have been widely considered in literature and we can point out not only the large number of known families of exact solutions but also the interest of these solutions from the physical point of view. Let us quote, for example, the Schwarszchild or the Kerr metrics which model the exterior gravitational field produced, respectively, by a nonrotating or a rotating spherically symmetric bounded object. Or also the related metrics in the case of a charged object, the Reissner–Nordström or the Kerr–Newman solutions. However, although some classes of type D metrics have been considered taking into account algebraic properties of the Weyl eigenvalue or differential conditions on the null Weyl principal directions, a classification of the type D solutions involving all the first-order differential properties of the Weyl tensor geometry is a task which has not been totally accomplished yet. In this work we present this classification of the type D metrics and we show the role that it can play in studying geometric properties of known space–times, in looking for new solutions of Einstein equations or in offering new elements which allow us to give intrinsic and explicit characterizations of all these space–times.

At an algebraic level, a type D Weyl tensor determines a complex scalar invariant, the eigenvalue, and a $2+2$ almost-product structure defined by its principal 2–planes. Some classes of type D metrics can be considered by imposing the real or imaginary nature of the Weyl eigenvalue. In this way we find the so-called purely electric or purely magnetic space–times. The purely electric character often appears as a consequence of usual geometric or physical restrictions.[1] This is the case of the static type D vacuum spacetimes found by Ehlers and Kundt,[2] or the Barnes degenerate perfect fluid solutions with shear-free normal flow.[3] On the other hand, some restrictions are

[a)]Electronic mail: joan.ferrando@uv.es
[b)]Electronic mail: juan.a.saez@uv.es

known on the existence of purely magnetic solutions.[4,5] A wide bibliography about Weyl-electric and Weyl-magnetic space–times can be found in a recent work[6] where these concepts have been generalized.

The most usual approaches to look for exact solutions of the Einstein equations work in frames or local coordinates adapted to some outlined direction of the curvature tensor. For example, in the case of perfect fluid solutions or static metrics the $3+1$ formalism adapted, respectively, to the fluid flow or to the normal timelike Killing vector can be useful. Sometimes one considers that some of the kinematic coefficients associated with the unitary vector are zero. This means that one is searching for new solutions belonging to a class of metrics that are defined by first-order differential conditions imposed on the curvature tensor. A similar situation appears when local coordinates adapted to the multiple Debever direction are considered when looking for algebraically special solutions. Indeed, if the hypotheses of the generalized Goldberg–Sachs theorem hold, the multiple Debever direction defines a shear-free geodesic null congruence. In this case, or when considering nondiverging or nontwisting restrictions on a Debever direction, we are imposing differential conditions on the Weyl tensor.

It is worth pointing out that the kinematic coefficients associated with a unitary vector completely determine the first-order differential properties of the $1+3$ almost-product structure that it defines. Nevertheless, the conditions usually imposed on the two double Debever directions of a type D space–time do not cover all the differential properties of the principal $2+2$ almost-product structure of the Weyl tensor exhaustively. The first goal of this work is to offer a classification of the type D metrics based on all the first-order differential properties of the principal structure, and to reinterpret under this view the usual conditions that can be found in the literature. This classification is not based on the scalar invariants, but on tensorial invariants of the Weyl tensor. These invariants are well adapted to the generic type D metrics, where a Weyl canonical frame is not univocally determined, and where the eigenvalues and the $2+2$ principal structure are the only invariants associated with the Weyl tensor.

The (proper) Riemannian almost-product structures have been classified according the invariant decomposition of their structure tensor,[7] and the classes have been interpreted in terms of the foliation, minimal and umbilical properties.[8] This classification can be generalized to the space–time structures by also considering the causal character of the planes.[9] Almost-product structures have shown their usefulness in studying the underlying geometry of some physical fields. The $1+3$ structures are frequently used in relativity and sometimes the properties of a physical field can be expressed in terms of the kinematic properties of a unitary vector.[10,11] On the other hand, the $2+2$ structure associated with a regular solution of Maxwell equations[12] is a basic concept in building the ''already unified theory'' for the electromagnetic field.[13] It has also allowed a geometric interpretation[14] of the Teukolsky–Press relations[15] used in analyzing incident electromagnetic waves on a Kerr black hole.

In General Relativity we can also find almost-product structures attached to the geometric or physical properties of the spacetime. Indeed, some energy contents (for example, in the Einstein–Maxwell or perfect fluid solutions) define underlying structures that restrict, via Einstein equations, the Ricci tensor. On the other hand, the Weyl tensor also defines almost-product structures associated with its principal bivectors depending on the different Petrov types.[16] These structures determine the Weyl canonical frames.[17] In the type D case, only the *principal structure* is outlined.

Until now we have mentioned two different ways of classifying the type D space–times: The first one is strictly algebraic and takes into account the real or imaginary character of the Weyl eigenvalues; the second one, which we will present here, involves differential conditions of the $2+2$ principal structure, that is, on the Weyl eigenvectors. Nevertheless, there is a third natural manner to impose restrictions on the type D metrics: To take into account the relative position between the principal 2–planes and the gradient of the Weyl scalar invariants. This is a mixed classification, differential in the eigenvalues and algebraic in the principal structure, which affords 16 different classes of type D metrics. In this work we will show the marked relation that exists between this classification and the two previous ones.

A classification of type D space–times taking into account the properties of the $2+2$ principal

structure shows quite interesting advantages. Indeed, the integration of the static type D vacuum equations using an alternative approach based on the Weyl principal structure has allowed us to complete the results by Ehlers and Kundt[2] in order to accomplish an algorithmic and intrinsic identification of the solutions and, in particular, to obtain the equations that define the Schwarzschild space–time explicitly.[18] Moreover, our classification affords a geometric interpretation of the other families of vacuum type D solutions. Starting from this approach two Killing vectors can be determined in terms of Weyl concomitants,[19] a result which shows that a commutative bidimensional group of isometries exists. Although all the type D vacuum solutions were found by Kinnersley[20] a integration method based on our classification permits their intrinsic label, as well as a geometric interpretation of the NUT and acceleration parameters.[21]

In this work we apply our classification to the study of space–times with zero Cotton tensor. For them, the Bianchi identities impose the same restrictions on the Weyl tensor as the vacuum condition. We interpret these restrictions in terms of geometric properties of the principal structure and we show that the compatible classes can be characterized in terms of the relative position between the gradient of some invariant scalars and the principal 2–planes. From a physical point of view these metrics have two interesting properties. Firstly, the two double Debever directions define shear-free geodesic null congruences and, secondly, the principal structure is Maxwellian. This result can be of interest in order to generalize the Teukolsky–Press relations[14,15] and their applications to type D nonvacuum solutions.

In order to show the usefulness of this approach in analyzing properties of known metrics, in integrating Einstein equations and in labeling the solutions, here we study the space–times with the two properties quoted above for the particular classes with integrable structure. In this case, the space–time metric turns out to be conformal to a product metric. Then, as a first consequence, we extend the result by Hall[4] (see also McIntosh *et al.*[5]) concerning the nonexistence of purely magnetic type D vacuum solutions in a double sense: The family of solutions where the new result applies is wider than the vacuum metrics, and the purely magnetic restriction is weakened to an arbitrary constant argument. Elsewhere[22] we have acquired a similar extension for some results concerning the purely magnetic type I solutions. Moreover, starting from a canonical form we begin on the integration of the Einstein–Maxwell equations for the compatible classes, and we recover the charged counterpart of the A, B, C vacuum metrics by Ehlers and Kundt. The integration method at once provides an algorithm to detect the solutions with intrinsic and explicit conditions and, in particular, it offers a characterization of the Reissner–Nordström space–time. The classification of the Kinnersley rotating type D vacuum solutions will be considered elsewhere.[21]

The paper is organized as follows. In Sec. II we introduce some definitions and notations and we give some results about $2+2$ almost-product structures. In Sec. III we present the classification of the type D metrics based on the first-order differential properties of the Weyl principal structure, as well as the mixed classification involving the eigenvalues gradient and the principal structure. The Cotton-zero type D metrics are analyzed in Sec. IV, and we show that the principal 2–planes define an umbilical structure and, consequently, we only have 16 compatible classes which coincide precisely with those defined by the mixed classification. The four classes with integrable structure are studied in detail in Sec. V: We present a canonical form for them and generalize a result about the nonexistence of purely magnetic solutions. Finally, in Sec. VI, we apply our results to recover a family of Einstein–Maxwell solutions, to give an operational algorithm to detect them and to explicitly and intrinsically characterize the Reissner–Nordström space–time. Some of the results in this paper were communicated without proof at the Spanish Relativity Meeting–96.[19]

II. SPACE–TIME ALMOST-PRODUCT STRUCTURES

On a Riemannian manifold (M,g) an almost-product structure is defined by a p-plane field V and its orthogonal complement H. Let v and $h=g-v$ the respective projectors, and let Q_v be the (2,1)-tensor:

$$Q_v(x,y)=h(\nabla_{vx}vy)\,,\quad \forall\ x,y. \tag{1}$$

Let us consider the invariant decomposition of Q_v into its antisymmetric part A_v and its symmetric part $S_v\equiv S_v^T+(1/p)\,v\otimes \mathrm{Tr}S_v$, where S_v^T is a traceless tensor:

$$Q_v=A_v+\frac{1}{p}v\otimes \mathrm{Tr}\ S_v+S_v^T. \tag{2}$$

The plane V is foliation if, and only if, $A_v=0$. In this case $Q_v=S_v$ and it coincides with the second fundamental form of the integral manifolds of the foliation V.[23] Moreover V is minimal, umbilical or geodesic if, and only if, Tr $S_v=0$, $S_v^T=0$ or $S_v=0$, respectively. Then one can generalize these geometric concepts for plane fields which are not necessarily foliation:

Definition 1: *A plane field V is said to be geodesic, umbilical or minimal if the symmetric part* S_v *of its (generalized) second fundamental form* Q_v *satisfies, respectively,* $S_v=0$, $S_v^T=0$ *or* Tr $S_v=0$.

The (proper) Riemannian almost-product structures (V,H) have been classified taking into account the invariant decomposition (2) of the tensors Q_v and Q_h or, equivalently, according with the foliation, minimal, umbilical, or geodesic character of each plane.[7,8] Some of these properties have also been interpreted in terms of invariance along vector fields.[24] A generalization for the spacetime structures follows taking into account the causal character of the planes. We will say that a structure is integrable when both planes are foliation and we will say that it is minimal, umbilical or geodesic if both of the planes are so.

This way, on an oriented space–time (V_4,g) of signature $(-+++)$ we have generically $2^6=64$ different classes of (almost-product) structures depending on the first-order geometric properties. Nevertheless, when $p=1$, V is always an umbilical foliation and, consequently, only 16 possible classes exist. In this case Q_v and Q_h depend on the kinematic coefficients associated with a unitary vector u, and the classes are defined by the vanishing or nonvanishing of the acceleration, rotation, shear, and expansion. Elsewhere this kinematical interpretation has been extended to the $2+2$ space–time structures and, as a consequence, the Maxwell–Rainich equations have been expressed in terms of kinematical variables.[9]

In order to be used in next sections, we now analyze the space–time $2+2$ almost-product structures in detail by giving the characterization of their properties in terms of their canonical 2–form U, and by showing their relation with other usual approaches, the Newmann–Penrose and the self-dual formalisms. We also study the change of these properties for a conformal transformation and we summarize some results about Maxwellian structures.

A. 2+2 structures

In the case of a $2+2$ space–time structure it is useful to work with the *canonical* unitary 2-form U, volume element of the time-like plane V. Then, the respective projectors are $v=U^2$ and $h=-(*U)^2$, where $U^2=U\times U=\mathrm{Tr}_{23}\ U\otimes U$ and $*$ is the Hodge dual operator.

The tensors Q_v and Q_h determine the derivatives of the volume elements U and $*U$ by means of

$$\nabla_\alpha U_{\beta\lambda}=(Q_v)_{\alpha\mu,[\beta}U^{\mu}{}_{\lambda]}+(Q_h)_{\alpha[\beta,}{}^{\mu}\ U_{\lambda]\mu}\,,$$

$$\nabla_\alpha *U_{\beta\lambda}=(Q_h)_{\alpha\mu,[\beta}*U^{\mu}{}_{\lambda]}+(Q_v)_{\alpha[\beta,}{}^{\mu}*U_{\lambda]\mu}\,. \tag{3}$$

Then, if we denote $\delta=-\mathrm{Tr}\ \nabla$, a straightforward calculation leads to

$$\delta U=i(\mathrm{Tr}\ S_h)U-2(U,A_v)\qquad \delta *U=i(\mathrm{Tr}\ S_v)*U-2(*U,A_h), \tag{4}$$

where $2(U,A_v)^\mu=U^{\alpha\beta}(A_v)_{\alpha\beta}{}^{\mu}$. So, the minimal and the foliation character of the planes can be stated in terms of the projections of δU and $\delta *U$ onto V and H. On the other hand, let us consider

$$G_\perp = U\otimes U - *U\otimes *U + G; \quad \eta_\perp = U\tilde{\otimes} *U + \eta, \tag{5}$$

where η is the metric volume element of the space–time, $G=\frac{1}{2}g\owedge g$ is the metric on the 2–forms space, and $\owedge$ denotes the double-forms exterior product, $(A\owedge B)_{\alpha\beta\mu\nu}=A_{\alpha\mu}B_{\beta\nu}+A_{\beta\nu}B_{\alpha\mu}-A_{\alpha\nu}B_{\beta\mu}-A_{\beta\mu}B_{\alpha\nu}$. The tensors (5) satisfy $G_\perp(U)=G_\perp(*U)=0$, $\eta_\perp(U)=\eta_\perp(*U)=0$ and they can be calculated as

$$G_\perp = v\owedge h, \quad \eta_\perp = U\owedge *U. \tag{6}$$

Then, from expressions (3) and (4) we get

$$(2\nabla U - K)_{\lambda\alpha\beta} = (S_v^T)_{\lambda\mu,[\alpha}\ U^\mu{}_{\beta]} + (S_h^T)_{\lambda\mu,[\alpha}\ *U^\mu{}_{\beta]}, \tag{7}$$

$$K \equiv i(\delta U)G_\perp - i(\delta *U)\eta_\perp, \tag{8}$$

and so, the umbilicity of each plane is equivalent to the vanishing of the respective projections of the first member of (7). We summarize these results in the following lemma:

Lemma 1: *Let* (V,H) *be a* $2+2$ *almost-product structure and let* U *be its canonical 2-form. Then, the following conditions hold*:

(1) V $(resp.\ H)$ *is foliation* $\Leftrightarrow i(\delta U)*U=0$ $(resp.\ i(\delta *U)U=0)$;
(2) V $(resp.\ H)$ *is minimal* $\Leftrightarrow i(\delta *U)*U=0$ $(resp.\ i(\delta U)U=0)$;
(3) V *is umbilical* $\Leftrightarrow U\times\{2\nabla U-[i(\delta U)G_\perp - i(\delta *U)\eta_\perp]\}=0$
H *is umbilical* $\Leftrightarrow *U\times\{2\nabla U-[i(\delta U)G_\perp - i(\delta *U)\eta_\perp]\}=0$.

A $2+2$ structure is also determined by the two null directions $l_\pm$ on the plane V. A family of complex null bases $\{l_+, l_-, m, \overline{m}\}$ exists such that $U=l_-\wedge l_+$. This family is fixed up to change $l_\pm \hookrightarrow e^{\pm\phi}l_\pm$, $m\hookrightarrow e^{i\theta}m$. Then, conditions of lemma 1 can be interpreted in terms of the Newman–Penrose coefficients[25] as

Lemma 2: *Let* $U=l_-\wedge l_+$ *be the canonical 2–form of a* $2+2$ *structure. It holds*:

(1) The plane V is umbilical iff $\kappa=0=\nu$;
(2) the plane H is umbilical iff $\lambda=0=\sigma$;
(3) the plane V is minimal iff $\overline{\pi}=\tau$;
(4) the plane H is minimal iff $\rho+\overline{\rho}=0=\mu+\overline{\mu}$;
(5) the plane V is a foliation iff $\overline{\pi}=-\tau$;
(6) the plane H is a foliation iff $\rho-\overline{\rho}=0=\mu-\overline{\mu}$.

Taking into account the significance of the NP coefficients[25] this lemma implies that the umbilical nature of a $2+2$ structure means that its principal directions $l_\pm$ define shear-free geodesic null congruences. The minimal or foliation character of the spacelike 2-plane have also a kinematical interpretation and state, respectively, that both principal directions are expansion-free or vorticity-free. Elsewhere[9] all the geometric properties have been interpreted in terms of kinematic coefficients associated with every direction in a 2–plane (not only the null ones) with respect to the other 2–plane.

When both planes have a specific differential property, it is more convenient to introduce the self-dual unitary 2–form $\mathcal{U}\equiv(1/\sqrt{2})\,(U-i*U)$ associated with U. We have

$$2\ \mathrm{Re}[i(\delta\mathcal{U})\mathcal{U}] = i(\delta U)U - i(\delta *U)*U \equiv \Phi(U),$$

$$2\ \mathrm{Im}[i(\delta\mathcal{U})\mathcal{U}] = -i(\delta U)*U - i(\delta *U)U \equiv \Psi(U). \tag{9}$$

So, the complex 1–form $\delta\mathcal{U}$ collects the information about the minimal and foliation character of the structure. On the other hand, if $\mathcal{G}=\frac{1}{2}(G-\mathrm{i}\eta)$ is the metric on the self-dual 2–forms space, and $\mathcal{K}\equiv(1/\sqrt{2})(K-\mathrm{i}*K)$ is the self-dual 2-form associated to the vector valued 2–form K given in (8), we have

$$\mathcal{K}=i(\delta\mathcal{U})[\mathcal{U}\otimes\mathcal{U}+\mathcal{G}]. \tag{10}$$

Consequently, from lemma 1 and Eqs. (9) and (10), we have

Lemma 3: *Let us consider the* $2+2$ *structure defined by* $\mathcal{U}=(1/\sqrt{2})(U-\mathrm{i}*U)$. *It holds*:

(1) The structure is minimal if, and only if, $\mathrm{Re}[i(\delta\mathcal{U})\mathcal{U}]=0$;
(2) the structure is integrable if, and only if, $\mathrm{Im}[i(\delta\mathcal{U})\mathcal{U}]=0$;
(3) the structure is umbilical, if, and only if, $\nabla\mathcal{U}=i(\delta\mathcal{U})[\mathcal{U}\otimes\mathcal{U}+\mathcal{G}]$.

B. Almost-product structures and conformal transformations

If (V,H) is a $p+q$ almost-product structure for a metric g, then (V,H) is also an almost-product structure for every conformal metric $\hat{g}=e^{2\lambda}g$, and the projectors are related by the conformal factor: If $g=v+h$, then $\hat{g}=\hat{v}+\hat{h}$, where $\hat{v}=e^{2\lambda}v$, $\hat{h}=e^{2\lambda}h$. The generalized second fundamental form change as

$$Q_{\hat{v}}=e^{2\lambda}\,(Q_v-v\otimes h(\mathrm{d}\lambda)). \tag{11}$$

So, the foliation and the umbilical character are conformal invariants, but the minimal character is not. Indeed, taking the trace of the expression above, we have

$$\mathrm{Tr}\;Q_{\hat{v}}=\mathrm{Tr}\;Q_v-ph(\mathrm{d}\lambda). \tag{12}$$

These expressions immediately lead to the following result.

Lemma 4: *Let* (V,H) *be a* $p+q$ *almost-product structure for a metric* $g=v+h$. *The structure* (V,H) *is minimal for a conformal metric* $\hat{g}=e^{2\lambda}g$ *if, and only if,*

$$\frac{1}{p}\mathrm{Tr}\;Q_v+\frac{1}{q}\mathrm{Tr}\;Q_h=\mathrm{d}\lambda. \tag{13}$$

If $p=q$ (as happens for the space–time $2+2$ structures), we conclude that the necessary and sufficient condition for a structure to be minimal for a conformal metric is the sum of the traces of the second fundamental forms to be a closed 1-form, $\mathrm{d}(\mathrm{Tr}\;Q_v+\mathrm{Tr}\;Q_h)=0$. Thus, taking into account (4) and the expression (9) for $\Phi(U)$, lemma 4 can be stated for the $2+2$ case as

Lemma 5: *Let* U *be the canonical 2–form of a* $2+2$ *structure for the space–time metric* g. *The structure is minimal for a conformal metric if, and only if,* $\mathrm{d}\Phi(U)=0$. *More precisely, when this condition hold, let* λ *be such that* $2\mathrm{d}\lambda=\Phi(U)$. *Then, the structure is minimal for the conformal metric* $\hat{g}=e^{2\lambda}g$.

The most degenerated class of almost-product structures are the product ones, which means, those that satisfy $Q_v=0=Q_h$. A metric that admits a product structure is called a product metric. Then, and only then, local coordinates (x^A,x^i), $A=0,1$, $i=2,3$, exist such that $\tilde{g}=\sigma^-+\sigma^+$, being $\sigma^-=\sigma^-_{AB}(x^C)\mathrm{d}x^A\mathrm{d}x^B$ and $\sigma^+=\sigma^+_{ij}(x^k)\mathrm{d}x^i\mathrm{d}x^j$ bidimensional metrics, hyperbolic and elliptic, respectively. Then, if $\tilde{g}$ is a *2+2* product metric and $g=e^{-2\lambda}\tilde{g}$, lemma 5 and expression (11) lead to the following result.

Lemma 6: *The necessary and sufficient condition for a metric* g *to be conformal to a product metric* $\tilde{g}$, *is that an integrable and umbilical almost-product structure* U *exists such that* $\mathrm{d}\Phi(U)=0$. *More precisely, if* $2\mathrm{d}\lambda=\Phi(U)$, *then* $\tilde{g}=e^{2\lambda}g$ *is a product metric*.

C. Maxwellian structures

A regular 2-form F takes the canonical expression $F=e^{\phi}[\cos\psi U+\sin\psi *U]$, where U defines the $2+2$ associated structure, ϕ is the *energetic index* and ψ is the *Rainich index*. When F is solution of the source-free Maxwell equations, $\delta F=0$, $\delta *F=0$, one says that U defines a *Maxwellian structure*. In terms of the canonical elements (U,ϕ,ψ), Maxwell equations become:[12,14]

$$\mathrm{d}\phi=\Phi(U)\equiv i(\delta U)U-i(\delta *U)*U, \tag{14}$$

$$\mathrm{d}\psi=\Psi(U)\equiv -i(\delta U)*U-i(\delta *U)U. \tag{15}$$

Then, from (14) and (15) the Rainich theorem[12] follows:

Lemma 7: *A unitary 2-form U defines a Maxwellian structure if, and only if, it satisfies*:

$$\mathrm{d}\Phi(U)=0; \qquad \mathrm{d}\Psi(U)=0. \tag{16}$$

The Maxwell–Rainich equations (14) and (15) have a simple expression in the self-dual formalism. Indeed, the self-dual 2–form $\mathcal{F}=(1/\sqrt{2})(F-\mathrm{i}*F)$ may be written as $\mathcal{F}=e^{\phi+\mathrm{i}\psi}\mathcal{U}$. Then, from Maxwell equations, $\delta\mathcal{F}=0$, and taking into account that $2\mathcal{U}^2=g$,

$$\mathrm{d}(\phi+\mathrm{i}\psi)=2i(\delta\mathcal{U})\mathcal{U}. \tag{17}$$

This last equation is equivalent to (14) and (15) if we take into account (9). Moreover, from here we recover the complex version of (16) easily

$$\mathrm{d}i(\delta\mathcal{U})\mathcal{U}=0. \tag{18}$$

III. CLASSIFYING TYPE D SPACE–TIMES

The self–dual Weyl tensor $\mathcal{W}=\frac{1}{2}(W-\mathrm{i}*W)$ of a type D space–time takes the canonical expression[17]

$$\mathcal{W}=3\alpha\mathcal{U}\otimes\mathcal{U}+\alpha\mathcal{G}, \tag{19}$$

where $\alpha=-\operatorname{Tr}\mathcal{W}^3/\operatorname{Tr}\mathcal{W}^2$ is the double eigenvalue and $\mathcal{U}$ is the self-dual principal 2–form. This principal 2–form defines a $2+2$ almost-product structure which is called the *principal structure* of a type D space–time. In terms of the canonical 2–form U of the principal structure the self-dual 2–form $\mathcal{U}$ becomes $\mathcal{U}=(1/\sqrt{2})(U-\mathrm{i}*U)$. So, at the algebraic level, a type D Weyl tensor only determines the complex scalar α and the principal structure U. Consequently, any generic classification of the type D metrics must depend on these invariants associated with the Weyl tensor.

The families of purely electric or purely magnetic type D spacetimes are defined, at first glance, by means of alternative conditions, namely, the nullity of the magnetic or the electric Weyl fields associated with an observer u. But, actually, they admit a simple intrinsic characterization in terms of the Weyl scalar invariant: The eigenvalue is real or imaginary.[5] In spite of these strong conditions, the family of Weyl-electric type D space–times contains quite interesting solutions. We can quote, for example, the static vacuum metrics[2] or the degenerate perfect fluids with shear-free normal flow.[3] All the type D silent universes are also known[26,27] as well as other families of purely electric type D perfect fluid solutions.[28,30] Nevertheless, few Weyl-magnetic type D solutions have been found,[29] and some restrictions about their existence are known. Indeed, there are not vacuum metrics with purely magnetic type D Weyl tensor.[4,5] The classification that we present below allows us to give an extension of this result in Sec. 5. On the other hand, the generalization of the purely electric or magnetic concepts to the spacelike or null directions does not afford new classes in the type D case.[6]

But the purely electric or magnetic properties define very narrow subsets of the generic type D metrics because they impose one of the two real scalar invariants to be zero. The large family of known solutions of the Einstein equation recommends us to consider other classifications, based

on less restrictive properties, which afford new intrinsic elements that increase the knowledge of the metrics and permit their explicit characterization. Besides the *intrinsic* nature, the classification must be *generic*, that is, valid for the whole set of the type D metrics. Consequently, it will be independent of the energy content and it will have to be built on the intrinsic geometry associated with a type D Weyl tensor.

The first classification that we propose is based on the geometric properties of the principal 2–planes, that is, it is induced by the geometric classification of the principal structure. Every principal 2–plane can be submitted or not to three properties, so $2^6=64$ classes can be considered.

Definition 2: *Taking into account the foliation, minimal, or umbilical character of each principal 2–plane we distinguish* 64 *different classes of type D space–times*.

We denote the classes as D^{pqr}_{lmn}, *where the superscripts* p,q,r *take the value 0 if the time-like principal plane is, respectively, a foliation, a minimal or an umbilical distribution, and they take the value 1 otherwise. In the same way, the subscripts* l,m,n *collect the foliation, minimal or umbilical nature of the space-like plane.*

The most degenerated class that we can consider is D^{000}_{000} which corresponds to a type D product metric, and the most regular one is D^{111}_{111} which means that neither V nor H are foliation, minimal or umbilical distributions. We will put a dot in place of a fixed script (1 or 0) to indicate the set of metrics that cover both possibilities. So, for example, the metrics of type $\mathrm{D}^{111}_{11\cdot}$ are the union of the classes D^{111}_{111} and D^{111}_{110}; or a metric is of type $\mathrm{D}^{0\,\cdot\,\cdot}_{\cdot\,\cdot\,\cdot}$ if the timelike 2–plane is a foliation.

Taking into account lemma 1, every class is defined by means of first-order differential equations imposed on the canonical 2–form U. On the other hand, U can be written explicitly in terms of the Weyl tensor[17] and, consequently, every class admits an intrinsic and explicit characterization.

The above classification depends on the derivatives of the principal 2–form U. An alternative classification at first order in the Weyl eigenvalues can also be considered by taking into account the four 1-forms defined by the principal 2–planes and the gradient of the modulus and the argument of the eigenvalue. So, we will have $2^4=16$ classes.

Definition 3: *Let* $\alpha=e^{\frac{3}{2}(\rho+\mathrm{i}\theta)}$ *be the Weyl eigenvalue. Taking into account the relative position between the gradients* $d\theta,d\rho$ *and each principal 2–plane we distinguish* 16 *different classes of type D* space–times.

We denote the classes $D[pq,rs]$ *where* p,q,r,s *take the values* 0 *or* 1 *to indicate, respectively, that one of the 1-forms* $U(d\theta),U(d\rho),{*}U(d\theta),{*}U(d\rho)$ *is zero or nonzero*.

The most degenerated class D[00;00] is occupied by the type D metrics with constant eigenvalues, and the most general one D[11;11] by those type D space–times for which both, the modulus and the argument of the Weyl eigenvalue, have nonzero projection onto the principal planes. As above, a dot means that a condition is not fixed. So, for example, we write $\mathrm{D}[0\cdot;\cdot\cdot]$ to indicate the type D metrics for which the argument of the eigenvalues have zero projection onto the timelike principal 2–plane.

The type D metrics with constant modulus, $d\rho=0$, correspond to the classes $D[\,\cdot 0;\cdot 0]$, and those with constant argument, $d\theta=0$, are the metrics of type $D[0\cdot;0\cdot]$. This last family contains the Weyl-electric and the Weyl-magnetic space–times because a real or imaginary eigenvalue means that the argument takes the constant value 0, π or $\pi/2$, $3\pi/2$, respectively.

In the next section we will show the marked relation between the two classifications given in definitions 2 and 3 when some usual restrictions are imposed on the Ricci tensor.

IV. TYPE D METRICS WITH ZERO COTTON TENSOR

The space–time Cotton tensor P is a vector valued 2–form which depends on the Ricci tensor as

$$P_{\mu\nu,\beta}\equiv\nabla_{[\mu}Q_{\nu]\beta},\qquad 2Q\equiv Ric-\tfrac{1}{6}(\mathrm{Tr}\,Ric)g. \tag{20}$$

The Bianchi identities equal the Cotton tensor with the divergence of the Weyl tensor. Indeed, if $\mathcal{W}$ is the self-dual Weyl tensor and $\mathcal{P}=\frac{1}{2}(P-\mathrm{i}*P)$ is the self-dual 2–form associated with the Cotton tensor, Bianchi identities become

$$\mathcal{P}=-\delta\mathcal{W}. \tag{21}$$

So, the vanishing of the Cotton tensor is equivalent to the Weyl tensor to be divergence free, $\delta\mathcal{W}=0$. Taking into account the canonical expression of a type D Weyl tensor (19), a straightforward calculation leads to the following:

Proposition 1: *Let $\mathcal{U}$ and $\alpha=-\operatorname{Tr}\mathcal{W}^3/\operatorname{Tr}\mathcal{W}^2$ be the principal 2–form and the double eigenvalue of a type D Weyl tensor. Then, the space–time Cotton tensor is zero if, and only if,*

$$\nabla\mathcal{U}=i(\delta\mathcal{U})[\mathcal{U}\otimes\mathcal{U}+\mathcal{G}] \quad ; \quad i(\delta\mathcal{U})\mathcal{U}=\tfrac{1}{3}\mathrm{d}\ln\alpha. \tag{22}$$

From the results of the previous section, we know that the first condition means that the principal structure is umbilical, that is, the principal directions are shear free null geodesics accordingly to the Goldberg–Sachs theorem. Consequently, every type D space–time with zero Cotton tensor is of type $\mathrm{D}^{\cdot\cdot 0}_{\cdot\cdot 0}$. The second equation in (22) shows that the principal structure is Maxwellian and the electromagnetic invariant scalars depend on the Weyl eigenvalue. If we take the real and the imaginary parts of this equation and write $\rho+\mathrm{i}\theta=\frac{2}{3}\ln\alpha$, we get

$$\Phi(U)=\mathrm{d}\rho \; ; \qquad \Psi(U)=\mathrm{d}\theta. \tag{23}$$

So the modulus and the argument of the Weyl eigenvalue govern, respectively, the minimal and the foliation character of the principal planes. This relation establishes a bijection between the classes of the two classifications that we have presented. More precisely, we have:

Theorem 1: *Every type D spacetime with zero Cotton tensor is of type $D^{\cdot\cdot 0}_{\cdot\cdot 0}$. Moreover, it is of class D^{pq0}_{lm0} if, and only if, it is of class $D[lm,pq]$.*

So we have just 16 classes of type D space–times with zero Cotton tensor and each one is characterized by the vanishing or not of the projections of the gradient of the Weyl eigenvalue onto the principal planes. The second condition in (22) implies that a solution of the Maxwell equations exists that has $\mathcal{U}$ as its associated structure. Then, taking into account the results of Sec. II C, it holds:

Proposition 2: *The principal structure of a type D space–time with zero Cotton tensor is Maxwellian. More precisely, if $\mathcal{U}$ and $\alpha=-\operatorname{Tr}\mathcal{W}^3/\operatorname{Tr}\mathcal{W}^2$ are the principal 2–form and the double eigenvalue of the Weyl tensor, the self–dual 2–form*

$$\mathcal{F}_M=\alpha^{2/3}\mathcal{U}, \tag{24}$$

is a solution of the source-free Maxwell equations, $\delta\mathcal{F}_M=0$.

In the following D(M) denotes the type D space–times with Maxwellian principal structure, and $\mathrm{D(M)}^{pqr}_{lmn}$ expresses the type D(M) space–times of class D^{pqr}_{lmn}. With this notation, from theorem 1 and proposition 2 it follows: *Every type D space–time with zero Cotton tensor is of type $D(M)^{\cdot\cdot 0}_{\cdot\cdot 0}$.*

It is worth pointing out that the family of type D metrics admitting a conformal Killing–Yano tensor attached to its principal structure are those of type $\mathrm{D(M)}^{\cdot\cdot 0}_{\cdot\cdot 0}$,[31] and this family includes the Cotton-zero type D metrics.

The results of this section have been used elsewhere[21] in offering a new approach to the Kinnersley type D vacuum solutions. An integration of the Einstein vacuum equations based on the classification given above permits the explicit and intrinsic labeling of the solutions as well as to put over interesting geometric properties of these space–times.

V. SOME RESULTS ABOUT TYPE $D(M)^{0\cdot 0}_{0\cdot 0}$ SPACE–TIMES

Now, in this section, we restrict our study to the type D metrics with Maxwellian, integrable and umbilical structure, that is, those of type $D(M)^{0\cdot 0}_{0\cdot 0}$. We can easily obtain a canonical form for these metrics. Indeed, lemma 6 states that the metric is conformal to a product one with a conformal factor determined by the potential of the closed 1–form $\Phi(U)$. More precisely, the metric can be written as

$$g=\frac{1}{\Omega^2}[\sigma^-_{AB}(x^C)\ dx^A dx^B+\sigma^+_{ij}(x^k)\ dx^i dx^j], \tag{25}$$

where Ω satisfies

$$2\ \mathrm{d}\ln\Omega=\Phi(U)\equiv i(\delta U)U-i(\delta *U)*U. \tag{26}$$

Conversely, we can analyze the Petrov type of the metric (25) by studying a product metric $\tilde{g}=\sigma^-+\sigma^+$. Let X_- and X_+ be the Gaussian curvatures of the arbitrary bidimensional metrics, σ^- and σ^+, hyperbolic and elliptic, respectively. The Gauss–Codazzi equations show that the Riemann and the Ricci tensors of $\tilde{g}$ are

$$Riem(\tilde{g})=\tfrac{1}{2}X_-\sigma^-\owedge\sigma^-+\tfrac{1}{2}X_+\sigma^+\owedge\sigma^+;\quad Ric(\tilde{g})=X_-\sigma^-+X_+\sigma^+. \tag{27}$$

So, the Weyl tensor of a product metric is Petrov-type O precisely when $X_-+X_+=0$, and then both curvatures are constant. On the other hand, when $X_-+X_+\neq 0$, the space–time is type D. Moreover U determines the principal structure and the double eigenvalue is given by

$$\tilde{\alpha}=-\tfrac{1}{6}(X_-+X_+). \tag{28}$$

So, we have

Lemma 8: *Every* $2+2$ *product metric* $\sigma^-+\sigma^+$ *is of type D* (*or O*) *with real eigenvalues, and the double eigenvalue is given by (28), where* X_- *and* X_+ *are the Gaussian curvatures of* σ^- *and* σ^+, *respectively. Moreover, it is of type O if, and only if,* $X_-=-X_+=constant$.

A conformal transformation $\tilde{g}=\Omega^2 g$ preserves the Petrov type and the Weyl eigenvalues change as $\tilde{\alpha}=\Omega^{-2}\ \alpha$. Consequently, from Eq. (26) and taking into account lemmas 1 and 8, we can conclude:

Proposition 3: *A space–time is of type* $D(M)^{0\cdot 0}_{0\cdot 0}$ *if, and only if, there exist local coordinates such that the metric g takes the expression (25) with* $X_-+X_+\neq 0$, *where* X_- *and* X_+ *are the Gaussian curvatures of* σ^- *and* σ^+, *respectively. Moreover, it is of class* D^{010}_{010}, D^{000}_{010}, D^{010}_{000}, *or* D^{000}_{000} *if, and only if,* $\sigma^-(d\Omega)\neq 0\neq\sigma^+(d\Omega)$, $\sigma^+(d\Omega)=0\neq\sigma^-(d\Omega)$, $\sigma^+(d\Omega)\neq 0=\sigma^-(d\Omega)$, *or* $d\Omega=0$, *respectively*.

Furthermore, taking into account the expressions (27) for the Ricci and (28) for the eigenvalue of a product metric, and considering the change of these metric concomitants for a conformal transformation, we can state:

Proposition 4: *The Weyl eigenvalue of the metric (25) is real and it is given by*

$$\alpha=-\tfrac{1}{6}\Omega^2(X_-+X_+). \tag{29}$$

The Ricci tensor of this metric is

$$Ric(g)=\frac{2}{\Omega}\nabla d\Omega+X_-\sigma^-+X_+\sigma^+-\left[\frac{1}{\Omega}\Delta\Omega-\frac{3}{\Omega^2}\tilde{g}(d\Omega,d\Omega)\right]\tilde{g}, \tag{30}$$

where $\nabla=\nabla_{\sigma^-}+\nabla_{\sigma^+}$ *is the connection of the product metric* $\tilde{g}=\sigma^-+\sigma^+$.

Let us consider metrics with zero Cotton tensor again. If they have a constant argument, theorem 1 implies that the principal structure is integrable and so, the space–times are of type $\mathrm{D}(\mathrm{M})^{0\cdot 0}_{0\cdot 0}$. Consequently, from proposition 4 the Weyl tensor has real eigenvalues. So we can state:

Theorem 2: *The Weyl eigenvalues of a type D space–time with zero Cotton tensor have constant argument if, and only if, they are real*.

This result generalizes a previous one by Hall[4] (see also McIntosh *et al.*[5]). He showed that there are no purely magnetic Type D vacuum metrics. But the purely magnetic case occurs when the eigenvalue argument is $\frac{3}{2}\theta=\pm\pi/2$, that is to say, a particular value of constant argument. So, from theorem 2 it follows:

Corollary 1: *There is no purely magnetic Type D metric with zero Cotton tensor*.

This corollary shows that not only the purely magnetic vacuum solutions are forbidden, but also the Weyl-magnetic space–times with zero Cotton tensor. On the other hand the Hall result is also generalized in the sense that theorem 2 excludes all the constant arguments that differ from 0 or π. Although this approach could be of interest in studying the existence of purely magnetic type I solutions, the recent results on this subject have been obtained by using the $1+3$ formalism.[22,32,33]

From the results above it is easy to recover the canonical form for the metrics with zero Cotton tensor and real Weyl eigenvalues. Indeed, expressions (23) and (26) show that the conformal factor and the Weyl eigenvalue are related by $\Omega^2=c^2e^{\rho}=c^2\alpha^{2/3}$, c being an arbitrary constant. On the other hand they also satisfy expression (29) and, consequently, Ω coincides, up to a constant factor, with X_-+X_+. So we have

Proposition 5: *Every type D metric with real eigenvalues and zero Cotton tensor may be written*

$$g=\frac{1}{(X_-+X_+)^2}(\sigma^-+\sigma^+),$$

where $\sigma^-=\sigma^-_{AB}(x^C)dx^Adx^B$, $\sigma^+=\sigma^+_{ij}(x^k)dx^idx^j$, *are two arbitrary bidimensional metrics,* σ^- *hyperbolic and* σ^+ *elliptic, with Gaussian curvatures* X_- *and* X_+, *respectively*.

This canonical expression was obtained in a previous work[18] where it was used to integrate the Einstein vacuum equations, in this way getting an intrinsic algorithm to identify every A, B, and C-metric of Ehlers and Kundt.[2] In the following section, starting from the propositions 3 and 4 we present a similar study for the charged counterpart of these vacuum solutions.

VI. ALIGNED EINSTEIN–MAXWELL SOLUTIONS OF TYPE $\mathrm{D}^{0\cdot 0}_{0\cdot 0}$

If (v,h) is the principal structure of the Weyl tensor, the aligned Einstein–Maxwell solutions satisfy

$$Ric(g)=\chi(v-h)=\kappa\ (\sigma^--\sigma^+), \tag{31}$$

where the second equality is satisfied for the type $\mathrm{D}^{0\cdot 0}_{0\cdot 0}$ metrics as a consequence of proposition 3: $\chi=\kappa\Omega^2$, $\sigma^-=\Omega^2v$, $\sigma^+=\Omega^2h$. Moreover, as the principal structure is integrable, it is Maxwellian and the associated Rainich index is a constant. So, (31) is a necessary and sufficient condition for the metric (25) to be an aligned solution of the Einstein–Maxwell equations. Taking into account the expression (30) for the Ricci tensor, condition (31) becomes

$$\Omega=\lambda_-(x^A)+\lambda_+(x^i), \tag{32}$$

$$\nabla d\lambda_\epsilon=\beta_\epsilon\sigma^\epsilon, \tag{33}$$

$$\frac{\Omega^2}{6}(X_-+X_+)+\Omega\ (\beta_-+\beta_+)=\sigma^-(d\lambda_-,d\lambda_-)+\sigma^+(d\lambda_+,d\lambda_+), \tag{34}$$

$$d\beta_\epsilon+X_\epsilon d\lambda_\epsilon=0. \tag{35}$$

Equations (35) are the integrability conditions of (33). Moreover, if we differentiate (34), project on σ_-, differentiate again and take into account (35), we have

$$2(X_- + X_+)\mathrm{d}\lambda_- \wedge \mathrm{d}\lambda_+ + \Omega[\mathrm{d}X_+ \wedge \mathrm{d}\lambda_- - \mathrm{d}X_- \wedge \mathrm{d}\lambda_+] = 0. \tag{36}$$

Then a simple analysis of the expressions (32)–(36) leads to

Lemma 9: *The following conditions are equivalent*: (i) $dX_\epsilon = 0$, (ii) $\beta_\epsilon = 0$, (iii) $d\lambda_\epsilon = 0$, (iv) $\sigma^\epsilon(d\Omega) = 0$. *Moreover, these conditions hold if* $\sigma^\epsilon(d\lambda_\epsilon, d\lambda_\epsilon) = 0$ *everywhere.*

A. The solutions: A, B, and C charged metrics

Proposition 3 states that the classes D^{0q0}_{0m0} can be discriminated using the vectors $\sigma^\epsilon(\mathrm{d}\Omega)$. Then, lemma 9 implies that, as happens in the vacuum case,[18] the four classes can be characterized by σ^- or σ^+ to be bidimensional metrics that have constant curvature or not.

If g is in class D^{010}_{010}, lemma 9 implies that λ_ϵ can be taken as coordinate in the plane σ^ϵ. Then, Eqs. (34)–(36) say that β_ϵ, X_ϵ, and $\sigma^\epsilon(d\lambda_\epsilon, d\lambda_\epsilon)$ depend just on λ_ϵ, and that $X_\epsilon = -\beta'_\epsilon$. Then, from (34) we have $\beta'''_-(\lambda_-) + \beta'''_+(\lambda_+) = 0$ and, consequently, β_ϵ is a polynomial in λ_ϵ of degree less than or equal to three. But lemma 9 also states that $d\lambda_\epsilon$ is not a null vector everywhere. Then, Einstein–Maxwell equations (32)–(36) finally lead to

$$\sigma^\epsilon = \frac{1}{\epsilon f(\epsilon\lambda_\epsilon)}\mathrm{d}\lambda_\epsilon^2 + f(\epsilon\lambda_\epsilon)dZ^2, \tag{37}$$

with $f(\lambda)$ a fourth degree polynomial. Then, putting (37) and (32) into (25) we recover the known expression of the charged C-metrics.[25]

If g is in class D^{000}_{010}, lemma 9 implies that λ_- can be taken as a coordinate in the plane σ^- and, moreover, σ^+ must be of constant curvature. Thus, a redefinition of Ω and σ^- allows us to consider $X_+ \in \{-1,0,1\}$ and $\Omega = \lambda_-$. Then, if we introduce the coordinate transformation $r = -1/\lambda_-$, a similar procedure that leads in the general case to the charged counterpart of the A_i-metrics:

$$g = -a(r)\mathrm{d}t^2 + \frac{1}{a(r)}\mathrm{d}r^2 + r^2\mathrm{d}\sigma^2, \qquad a(r) \equiv X - \frac{C}{r} + \frac{D}{r^2}, \tag{38}$$

$\mathrm{d}\sigma^2$ being the bidimensional elliptic metric of constant curvature X, with $X = 1,-1,0$ depending on the A_1, A_2, or A_3 case.

If g is in the class D^{010}_{000}, in a similar way λ_+ can be taken as a coordinate in the plane σ^+, and σ^- must be of constant curvature $X_- \in \{-1,0,1\}$. Then, the coordinate transformation $r = -1/\lambda_+$, leads to the charged counterpart of the B_i-metrics:

$$g = r^2\mathrm{d}\sigma^2 + a(r)\mathrm{d}z^2 + \frac{1}{a(r)}\mathrm{d}r^2, \qquad a(r) \equiv X - \frac{C}{r} + \frac{D}{r^2}, \tag{39}$$

$\mathrm{d}\sigma^2$ being the bidimensional hyperbolic metric of constant curvature X, with $X = 1,-1,0$ depending on the B_1, B_2, or B_3 case.

Finally, in class D^{000}_{000} both bidimensional metrics have a constant curvature and Eq. (34) implies that $X_- + X_+ = 0$. This means that the space–times is conformally flat and the metric becomes $g = \sigma^- + \sigma^+$, where σ^ϵ are bidimensional metrics, hyperbolic, and elliptic, respectively, with a constant curvature ϵX. The metrics of this more degenerated class are the only ones that have zero Cotton tensor.

B. The intrinsic characterization

The metrics of type $\mathrm{D(M)}^{0\cdot 0}_{0\cdot 0}$, which take the canonical form (25), admit an intrinsic identification by means of conditions involving the principal 2–form $\mathcal{U}$. These characterization equa-

tions that we have given in previous sections could be written explicitly in terms of metric concomitants because $\mathcal{U}$ can be determined from the Weyl tensor.[17] Nevertheless, as a consequence of the Bianchi identities some of the above conditions can be satisfied identically taking into account the properties of the Ricci tensor. This is the case of vacuum metrics: As $Ric=0$ implies the nullity of the Cotton tensor, the principal planes always define an umbilical and Maxwellian structure as a consequence of the results in Sec. IV. Actually we want to characterize aligned Einstein–Maxwell solutions that are conformal to a product metric. So, the Weyl tensor must have real eigenvalues and the principal planes are the eigenspaces of the Ricci tensor, that is,

$$W=3\alpha(U\otimes U-*U\otimes *U)+\alpha G, \quad Ric=\chi(v-h), \tag{40}$$

where $v=U^2$, $h=-*U^2$. Then, taking into account the expressions in Sec. II about $2+2$ almost-product structures, a straightforward calculation shows that the Bianchi identities (21) can be written

$$(3\alpha+2\chi)\ Q_v=v\otimes h(d\alpha); \quad (3\alpha-2\chi)\ Q_h=h\otimes v(d\alpha), \tag{41}$$

$$v(d\chi)-2\chi i(\delta U)U=0; \quad h(d\chi)+2\chi i(\delta *U)*U=0. \tag{42}$$

From these expressions we find that, under the scalar restriction $(3\alpha)^2\neq(2\chi)^2$, the properties of the structure follow just by imposing that the Weyl and the Ricci tensor take expressions (40). On the other hand, the case $(3\alpha)^2=(2\chi)^2$ leads to the *exceptional* metrics considered by Plebański and Hacyan.[34] Nevertheless, it can easily be shown that $(3\alpha)^2\neq(2\chi)^2$ for the solutions recovered in the subsection above. So we get the following characterization:

Lemma 10: *The charged counterpart of the A, B, and C-metrics are the only aligned Einstein–Maxwell solutions of type D with real eigenvalues that satisfy* $(3\alpha)^2\neq(2\chi)^2$, α *and* χ *being, respectively, the Weyl and the Ricci eigenvalues*.

Elsewhere,[18] conditions for g to be of type D with real eigenvalues have been given in terms of Weyl concomitants. In order to impose the Ricci tensor to take the form (40) we can use the algebraic Rainich conditions.[12] But if the Weyl tensor is of type D with real eigenvalues, a part of these Rainich conditions hold identically when we impose the aligned restriction. From these considerations and lemma 10 we have:

Theorem 3: *The A, B, and C Einstein–Maxwell solutions can be characterized by conditions*

$$\alpha\neq 0; \quad S^2+S=0; \quad Ric(x,x)\geqslant 0,$$

$$\mathrm{Tr}\ Ric=0, \quad S[Ric]+Ric=0; \quad (3\alpha)^2-(2\chi)^2\neq 0.$$

$W\equiv W(g)$ *and* $Ric\equiv Ric(g)$ *being the Weyl and Ricci tensors of the metric* g, *and where* $\alpha=\alpha(g)\equiv-(\frac{1}{12}\,\mathrm{Tr}W^3)^{1/3}$, $\chi=\chi(g)\equiv-\frac{1}{2}(\mathrm{Tr}Ric^2)^{1/2}$, $S=S(g)\equiv\frac{1}{3}(\alpha^{-1}W-\frac{1}{2}g\owedge g)$, $S[Ric]_{\alpha\beta}=S_{\alpha\mu\beta\nu}R^{\mu\nu}$ *and* x *is an arbitrary time-like vector*.

This theorem offers an intrinsic and explicit description of the aligned Einstein–Maxwell solutions of type $\mathrm{D}^{0\cdot 0}_{0\cdot 0}$. Now we look for an intrinsic and explicit way to identify every metric of this family, that is, to distinguish the A_i, B_i, and C charged metrics. In a first step we must discriminate between the classes D^{0p0}_{0m0} and, as a consequence of proposition 3, this depends on the nullity of the vectors $v(d\Omega)$ and $h(d\Omega)$. But the expression (29) for the Weyl eigenvalue and lemma 9 imply that, equivalently, the vectors $v(d\alpha)$ and $h(d\alpha)$ determine these properties. So, the same scheme as in the vacuum case[18] can be used to distinguish between the classes.

The last step to obtain the intrinsic and explicit characterization of the solutions is to get an invariant that provides the sign of the bidimensional curvature when this is constant. A straightforward calculation shows that if X_ϵ is constant, then

$$X_\epsilon\Omega^2=\omega_\epsilon\equiv\tfrac{1}{9}(\mathrm{d}\ln(\alpha+\chi))^2-2\alpha-\epsilon\chi. \tag{43}$$

So, we have a characterization of the Einstein–Maxwell A, B, and C-metrics, and we recover the type D static vacuum solutions making $\chi=0$.

Theorem 4: *Let g be an aligned Einstein–Maxwell solution of type $D^{0\cdot 0}_{0\cdot 0}$ (characterized in theorem 3). Let us take the metric concomitants*

$$M\equiv *W(d\alpha,\cdot,d\alpha,\cdot) \quad N\equiv S(d\alpha,\cdot,d\alpha,\cdot),$$

and let x be an arbitrary unitary timelike vector. Then,

(i) *g is a charged C-metric if, and only if, $M\neq 0$;*
(ii) *g is a charged A-metric if, and only if, $M=0$ and $2N(x,x)+trN>0$. Furthermore, it is of type A_1, A_2 or A_3 if $\omega_+>0$, $\omega_+<0$ or $\omega_+=0$, respectively, where $\omega_+\equiv\frac{1}{9}(\mathrm{d}\ln(\alpha+\chi))^2-2\alpha-\chi$;*
(iii) *g is a charged B-metric if, and only if, $M=0$ and $2N(x,x)+trN<0$. Furthermore, it is of type B_1, B_2 or B_3 if $\omega_->0$, $\omega_-<0$ or $\omega_-=0$, respectively, where $\omega_-\equiv\frac{1}{9}(\mathrm{d}\ln(\alpha+\chi))^2-2\alpha+\chi$.*

This theorem provides an algorithm to identify, in the set of all metrics, the charged counterpart of the Ehlers and Kundt[2] vacuum solutions. The particular case of the A_1 metrics corresponds to a charged spherically symmetric spacetime, that is, to the Reissner–Nordström solution. In this case the metric takes the form (38) with $X=1$, and the mass and the charge are related with the constants C and D, respectively. Moreover, these constants can be given in terms of Weyl and Ricci invariants. Then, from the last theorem and previous subsection it follows:

Theorem 5: *Let $Ric\equiv Ric(g)$ and $W\equiv W(g)$ be the Ricci and the Weyl tensors of a spacetime metric g, and let us take the metric concomitants*:

$$\alpha\equiv-(\tfrac{1}{12}\mathrm{Tr}\ W^3)^{1/3},\quad \chi\equiv-\tfrac{1}{2}(\mathrm{Tr}\ Ric^2)^{1/2},\quad \omega\equiv\tfrac{1}{9}g(d\ln\alpha,d\ln\alpha)-2\alpha-\chi, \tag{44}$$

$$S\equiv\frac{1}{3\alpha}(W-\tfrac{1}{2}\alpha g\owedge g),\quad M\equiv *W(d\alpha,\cdot,d\alpha,\cdot),\quad N\equiv S(d\alpha,\cdot,d\alpha,\cdot). \tag{45}$$

The necessary and sufficient conditions for g to be the Reissner–Nordström metric are

$$\alpha\neq 0,\quad S^2+S=0,\quad Ric(x,x)\geqslant 0,$$

$$\mathrm{Tr}\ Ric=0,\quad S[Ric]+Ric=0,\quad (3\alpha)^2-(2\chi)^2\neq 0,$$

$$M=0,\quad 2N(x,x)+trN>0,\quad \omega>0,$$

where x is an arbitrary unitary time-like vector. Moreover, the mass m and the electric charge e are given, respectively, by $m=(\alpha+\chi)/\omega^{3/2}$ and $e^2=-\chi/\omega^2$, and the timelike Killing vector by $\xi=[\sqrt{\omega}(3\alpha+2\chi)]^{-1}[N(x)/\sqrt{N(x,x)}]$.

C. A summary in algorithmic form

Finally, in order to emphasize the algorithmic nature of our results, we present them as a flow diagram that identifies, among all metrics, every A, B, or C Einstein–Maxwell solution (in the following flow chart we denote them A^*, B^*, and C^*-metrics). The exceptional metrics studied by Plebański are also identified and they are denoted Exc-metrics. This operational algorithm involves an arbitrary unitary timelike vector, x, and some metric concomitants that may be obtained from the components of the metric tensor g in arbitrary local coordinates: The invariants α,

χ, ω_ϵ, S, M, and N are given in (43)–(45) in terms of the Ricci and Weyl tensors. Making $\chi = 0$, we recover the vacuum solutions[18]

Using ODE techniques we prove the existence of large classes of initial data satisfying the constraints for the spherically symmetric Einstein–Vlasov–Maxwell system. These include data for which the ratio of total charge to total mass is arbitrarily large. © *2004 American Institute of Physics.*

I. INTRODUCTION

The global dynamical behavior of self-gravitating matter is a subject of central importance in general relativity. A form of matter which has particularly nice mathematical properties is collisionless matter, described by the Vlasov equation. It has the advantage that it lacks the tendency observed in certain other models, such as perfect fluids, that solutions of the equations of motion of the matter lose differentiability after a finite time. These singularities of the mathematical model form an obstacle to further analysis and prevent the study of the global dynamical properties of the solutions. Collisionless matter is free from these difficulties and there is a growing literature on global properties of solutions of the Einstein–Vlasov system.[1,9]

In Ref. 8, the authors prove the global existence of asymptotically flat solutions of the spherically symmetric Einstein–Vlasov system, with small initial data. That study concerns uncharged particles. We consider, under the same assumption of spherical symmetry, the case where the particles are charged. To describe the full physical situation, we must then couple the previous system to the Maxwell equations that determine the electromagnetic field created by the fast moving charged particles. As will be seen below, that reduces, in the spherically symmetric case, to its electric part.

It is appropriate at this point to examine the motivation for considering this particular problem. We are not aware that it has any direct astrophysical applications. There are, however, two reasons why the problem is interesting. The first is that it extends the knowledge of the Cauchy problem for systems involving the Vlasov equation and it will be seen that it gives rise to new mathematical features compared to those cases studied up to now. The second is connected with the fact that it would be desirable to extend the work of Ref. 8 beyond spherical symmetry. In particular, it would be desirable from a physical point of view to include the phenomenon of rotation. Unfortunately, presently available techniques do not suffice to get away from spherical symmetry. In this situation it is possible to attempt to obtain further intuition by using the analogy between angular momentum and charge, summed up in John Wheeler's statement, ''Charge is a poor man's angular momentum.'' Thus we study spherical systems with charge in the hope that this will give us insight into nonspherical systems without charge. This strategy has recently been

[a]Electronic mail: noundjeu@uycdc.uninet.cm
[b]Electronic mail: nnoutch@uycdc.uninet.cm
[c]Electronic mail: rendall@aei.mpg.de

pursued in the case of a scalar field as matter model, with interesting results.[3,4]

Concerning the Cauchy problem in general relativity, it is well known that in addition to the Einstein evolution equations there are constraint equations which have to be solved. (See, e.g., Ref. 5.) It is only of interest to consider the problem of evolution, if the problem of constraints on the initial data can be solved. In our specific case, we are led to a difficulty in solving the constraints on the initial data, that has not previously been considered in the literature. Let us first recall the situation in Ref. 8 before seeing how it changes in the case of charged particles. In Ref. 8, using the assumption of spherical symmetry, the authors look for two metric functions λ and μ, that depend only on the time coordinate t and on the radial coordinate r, and for the distribution function f of the uncharged particles that depends on t, r and on the 3-velocity v of the particles; the metric functions λ, μ are subject to the Einstein equations with sources generated by the distribution function f of the collisionless uncharged particles which is itself subject to the Vlasov equation. They show that the Einstein equations to determine the unknown metric functions λ and μ, turn out to be two first order ordinary differential equations (ODE) in the radial variable r, coupled to the Vlasov equation in f. Setting $t=0$ in the Einstein equations yields two constraint equations that link the three initial data that are the two initial data for $\lambda(t,r)$ and $\mu(t,r)$ denoted $\mathring{\lambda}(r)$ and $\mathring{\mu}(r)$, respectively, and the initial datum for $f(t,r,v)$ denoted by $\mathring{f}(r,v)$. The equations to be solved are two first order ODE for $\mathring{\lambda}$, $\mathring{\mu}$. The mass function $m(t,r)$ is defined as an integral of f over the hypersurfaces of constant t. The exact definition is given in the next section. Provided the initial mass function $\mathring{m}(r)=m(0,r)$ is everywhere less than $r/2$ the function $\mathring{\lambda}$ can be determined from the relation $1-2m/r=e^{-2\lambda}$. Once this has been done μ can be determined by integration. In this way functions $\mathring{\lambda}$ and $\mathring{\mu}$ can be determined in a straightforward way when $\mathring{f}$ is given, provided the inequality $2m/r<1$ is satisfied on the initial hypersurface. Thus a simple parametrization of the set of initial data satisfying the constraints is obtained. They can be constructed from a non-negative function $\mathring{f}$ which is required to satisfy one inequality.

In the case of charged particles, the problem of constraints on the initial data is not so easy. We consider the case of a spherically symmetric electric field $\vec{E}$ of the form $\vec{E}(t,r)=e(t,r)\,(\vec{r}/r)$, where $e(t,r)$ is an unknown scalar function and $\vec{r}$ the position vector in $\mathbb{R}^3$. We denote by $\mathring{e}$ the initial data for $e(t,r)$. The Maxwell equations imply a constraint equation on the initial data, that is a first order ODE in the radial variable r. We now have to face the problem of constraints between the four initial data $\mathring{\lambda}$, $\mathring{\mu}$, $\mathring{f}$, $\mathring{e}$. If the equations for $\mathring{\lambda}$, $\mathring{f}$, and $\mathring{e}$ can be solved then $\mathring{\mu}$ can be determined by a simple integration as in the case of uncharged particles. On the other hand, the problem of determining the first three quantities is more difficult in the charged case due to the coupling of the gravitational and electromagnetic constraints. Any solution of the constraints must satisfy the condition $2m/r<1$ on the initial hypersurface. However, in the charged case m includes a contribution due to the energy density of the electric field and this depends on e and λ. As a consequence, in contrast to the uncharged case, this condition cannot be expressed as an inequality on f alone. Moreover, the equation for e also contains λ and so it is not possible to solve the electromagnetic constraint separately from the gravitational one. There is no alternative but to solve the two constraints together. When $\mathring{f}$ is prescribed the constraints define a system of two coupled nonlinear ordinary differential equations for $\mathring{\lambda}$ and $\mathring{e}$. These equations are singular at $r=0$.

Solving the ordinary differential equations arising from the constraints is a task which must necessarily be mastered before undertaking the study of the problem of evolution for the Einstein–Vlasov–Maxwell system. Since the equations are singular they cannot be handled by standard results of ODE theory alone. In this paper, we prove, using statements developed in Ref. 10 on singular ODE, that, under smallness assumptions on the prescribed initial data function $\mathring{f}$, a corresponding global solution of the constraints exists. This provides a way of showing the existence of initial data $\mathring{\lambda}$, $\mathring{\mu}$, $\mathring{e}$, in the case of an asymptotically flat space–time with a regular center. In other words, we prove that the results obtained for the constraint equations in Ref. 8 that focuses on the case of uncharged particles, extend to the case of charged particles, in the sense that

the initial datum $\mathring{f}$ can still be considered as the only arbitrary initial datum.

Given the complicated nature of the constraint equations it seems impractible to describe the most general class of functions $\mathring{f}$ for which the constraints can be solved. What we have been able to do is to describe two large classes of functions $\mathring{f}$ for which it is possible. The first case treated is a rather obvious one to try. The charge q of a particle is a free parameter in the equations. In the case $q=0$ the equations reduce to the uncharged situation analyzed in Ref. 8. A perturbation argument then allows the case with fixed $\mathring{f}$ and small q to be treated. A more exotic class of initial data is obtained by a rigorous perturbation argument in a regime where the density of particles tends to zero and the charge per particle tends to infinity. This allows the construction of initial data which coincide outside a compact set with data for the Reissner–Nordström solution with arbitrarily large charge to mass ratio. The restriction of these data to the region outside a large radius does not allow an electrovacuum interior which has a regular center or corresponds to a black hole but, as this construction shows, does allow a regular (dynamical) interior with charged matter.

Note that there is a local in time existence theorem available for the Einstein–Vlasov–Maxwell system without symmetry. This can be obtained as the special case of the results of Ref. 2 on the Einstein–Maxwell–Boltzmann system by setting the collision term to zero. There is no discussion of the existence of solutions of the constraints in that paper.

The paper is organized as follows. In Sec. II, we recall the spherically symmetric Einstein–Vlasov–Maxwell system, from which we deduce the constraint equations. In Sec. III, we recall the main result of Ref. 10 which we use and we prove the existence of large classes of solutions of the constraint equations for the Einstein–Vlasov–Maxwell system. The derivation of some facts required in Sec. III concerning regions where there are no particles is contained in the Appendix.

II. FORMULATION OF THE PROBLEM

We consider fast moving collisionless particles with unit mass and charge q. The basic space–time is $(\mathbb{R}^4,g)$, with g a Lorentzian metric with signature $(-,+,+,+)$. In what follows, we assume that greek indices run from 0 to 3 and italic indices run from 1 to 3, unless otherwise specified. We also adopt the Einstein summation convention. The metric g reads locally, in Cartesian coordinates $(x^\alpha)=(x^0,x^i)\equiv(t,\tilde{x})$,

$$ds^2=g_{\alpha\beta}\,dx^\alpha\otimes dx^\beta. \tag{2.1}$$

The assumption of spherical symmetry means that we can take g of the following form (Schwarzschild coordinates):

$$ds^2=-e^{2\mu}\,dt^2+e^{2\lambda}\,dr^2+r^2(d\theta^2+\sin^2\theta d\varphi^2), \tag{2.2}$$

where $\mu=\mu(t,r)$; $\lambda=\lambda(t,r)$; $t\in\mathbb{R}$; $r\in[0,+\infty[$; $\theta\in[0,\pi]$; $\varphi\in[0,2\pi]$. The Einstein–Vlasov–Maxwell system reads

$$R_{\alpha\beta}-\tfrac{1}{2}g_{\alpha\beta}R=8\pi(T_{\alpha\beta}(f)+\tau_{\alpha\beta}(F)), \tag{2.3}$$

$$\mathcal{L}_{X(F)}f=0, \tag{2.4}$$

$$\nabla_\alpha F^{\alpha\beta}=J^\beta,\quad \nabla_\alpha F_{\beta\gamma}+\nabla_\beta F_{\gamma\alpha}+\nabla_\gamma F_{\alpha\beta}=0 \tag{2.5}$$

with

$$T_{\alpha\beta}(f)=-\int_{\mathbb{R}^3}p_\alpha p_\beta f\omega_p,\quad \tau_{\alpha\beta}(F)=-\frac{g_{\alpha\beta}}{4}F_{\gamma\nu}F^{\gamma\nu}+F_{\beta\gamma}F_\alpha{}^\gamma,$$

$$J^{\beta}(f)(x)=q\int_{\mathbb{R}^3}p^{\beta}f(x,p)\omega_p,\quad \omega_p=|g|^{1/2}\frac{\mathrm{d}p^1\,\mathrm{d}p^2\,\mathrm{d}p^3}{p_0},\quad p_0=g_{00}p^0,$$

$$X^{\alpha}(F)=(p^{\alpha},-\Gamma^{\alpha}_{\beta\gamma}p^{\beta}p^{\gamma}-qp^{\beta}F_{\beta}{}^{\alpha}),$$

where $\Gamma^{\alpha}_{\beta\gamma}$ denote the Christoffel symbols. Here, $x=(x^{\alpha})$ is the position and $p=(p^{\alpha})$ is the 4-momentum of particles. In the expressions above, f stands for the distribution function of the charged particles, F stands for the electromagnetic field created by the charged particles. Here (2.3) are the Einstein equations for the metric tensor $g=(g_{\alpha\beta})$ with sources generated by both f and F, that appear in the stress-energy tensor $T_{\alpha\beta}+\tau_{\alpha\beta}$. Equation (2.4) is the Vlasov equation for the distribution function f of the collisionless particles, with $\mathcal{L}_{X(F)}$ the Lie derivative, and (2.5) are the Maxwell equations for the electromagnetic field F, with source (current) generated by f through $J=J(f)$. One verifies that the conservation laws $\nabla_{\alpha}(T^{\alpha\beta}+\tau^{\alpha\beta})=0$ hold if f satisfies the Vlasov equation.

By the assumption of spherical symmetry, we can take g in the form (2.2). One shows, using the Maxwell equation that F reduces to its electric part. We take it in the form $E=(E^{\alpha})$ with $E^0=0$, $E^i=e(t,r)\,(x^i/r)$ and then, a straightforward calculation shows that

$$\tau_{00}=\tfrac{1}{2}e^{2(\lambda+\mu)}e^2(t,r),\quad \tau_{0i}=0,$$

$$\tau_{ij}=\tfrac{1}{2}e^{2\lambda}e^2(t,r)\left\{\left(\delta_{ij}-\frac{x_ix_j}{r^2}\right)-e^{2\lambda}\frac{x_ix_j}{r^2}\right\},$$

where δ_{ij} is the Kronecker symbol.

These relations and results of Ref. 8 show that the spherically symmetric Einstein–Vlasov–Maxwell system implies the following first order ODE system in λ, μ, f, e:

$$e^{-2\lambda}(2r\lambda'-1)+1=8\pi r^2\rho, \tag{2.6}$$

$$e^{-2\lambda}(2r\mu'+1)-1=8\pi r^2p, \tag{2.7}$$

$$\frac{\partial f}{\partial t}+e^{\mu-\lambda}\frac{v}{\sqrt{1+v^2}}\cdot\frac{\partial f}{\partial\tilde{x}}-\left(e^{\mu-\lambda}\mu'\sqrt{1+v^2}+\dot{\lambda}\frac{\tilde{x}\cdot v}{r}-qe^{\lambda+\mu}e(t,r)\right)\frac{\tilde{x}}{r}\cdot\frac{\partial f}{\partial v}=0, \tag{2.8}$$

$$\frac{\mathrm{d}}{\mathrm{d}r}(r^2e^{\lambda}e(t,r))=qr^2e^{\lambda}\int_{\mathbb{R}^3}f(t,\tilde{x},v)\mathrm{d}v, \tag{2.9}$$

where $\lambda'=\partial\lambda/\partial r$, $\dot{\lambda}=\partial\lambda/\partial t$, and

$$\rho(t,\tilde{x})=\int_{\mathbb{R}^3}f(t,\tilde{x},v)\sqrt{1+v^2}\,\mathrm{d}v+\frac{1}{2}e^{2\lambda(t,\tilde{x})}e^2(t,\tilde{x}), \tag{2.10}$$

$$p(t,\tilde{x})=\int_{\mathbb{R}^3}\left(\frac{\tilde{x}\cdot v}{r}\right)^2f(t,\tilde{x},v)\frac{\mathrm{d}v}{\sqrt{1+v^2}}-\frac{1}{2}e^{2\lambda(t,\tilde{x})}e^2(t,\tilde{x}). \tag{2.11}$$

Here (2.6) and (2.7) are the Einstein equations for λ and μ, (2.8) is the Vlasov equation for f and (2.9) is the Maxwell equation for e. Here $\tilde{x}$ and v belong to $\mathbb{R}^3$, $r:=|\tilde{x}|$, $\tilde{x}\cdot v$ denotes the usual scalar product of vectors in $\mathbb{R}^3$, and $v^2:=v\cdot v$. The distribution function f is assumed to be invariant under simultaneous rotations of $\tilde{x}$ and v, hence ρ and p can be regarded as functions of t and r. It is assumed that $f(t)$ has compact support for each fixed t. We are interested in asymptotically flat space–times which leads to imposing the boundary condition that

$$\lim_{r\to\infty}\mu(t,r)=0. \tag{2.12}$$

They should also have a regular center which means that in addition to λ, μ, and e being smooth functions of t and r, including at $r=0$, the boundary condition $\lambda(t,0)=0$ should be satisfied for all t. Note that the condition that $\lambda(t,r)$ tends to zero as $r\to\infty$, which is part of asymptotic flatness, follows from the field equations and the fact that $f(t)$ has compact support. This is because in the region where f vanishes the general solution of (2.6) satisfies the condition $\lambda(r)=O(1/r)$ as $r\to\infty$.

Let $m(r)=4\pi\int_0^r s^2\rho(s)\mathrm{d}s$. This is the mass function referred to in the introduction. Its limit M as $r\to\infty$ is the total or ADM (Arnowitt–Deser–Misner) mass of the system. The function $n=\int_{\mathbb{R}^3} f\,\mathrm{d}v$ is the number density of particles and nq the charge density. The total charge of the system is given by $Q=4\pi q\int_0^\infty s^2 e^{\lambda(s)}n(s)\mathrm{d}s$.

Now, define the initial data by

$$f(0,\tilde{x},v)=\mathring{f}(\tilde{x},v);\ \lambda(0,\tilde{x})=\mathring{\lambda}(\tilde{x})=\mathring{\lambda}(r);\ \ \mathring{e}(0,\tilde{x})=\mathring{e}(\tilde{x})=\mathring{e}(r) \tag{2.13}$$

with $\mathring{f}\in C_0^\infty$ being a C^∞ function with compact support, which is non-negative and spherically symmetric, i.e.,

$$\forall A\in \mathrm{SO}(3),\ \ \forall(\tilde{x},v)\in\mathbb{R}^6,\ \ \mathring{f}(A\tilde{x},Av)=\mathring{f}(\tilde{x},v).$$

We obtain the constraint equations on the initial data by taking (2.6), (2.7), and (2.9) for $t=0$, that give

$$e^{-2\mathring{\lambda}}(2r\mathring{\lambda}'-1)+1=8\pi r^2\int_{\mathbb{R}^3}\sqrt{1+v^2}\,\mathring{f}(r,v)\mathrm{d}v+4\pi r^2 e^{2\mathring{\lambda}}\mathring{e}^2, \tag{2.14}$$

$$\frac{\mathrm{d}}{\mathrm{d}r}(r^2e^{\mathring{\lambda}}\mathring{e})=qr^2e^{\mathring{\lambda}}\int_{\mathbb{R}^3}\mathring{f}(r,v)\mathrm{d}v=J(\mathring{f}), \tag{2.15}$$

$$e^{-2\mathring{\lambda}}(2r\mathring{\mu}'+1)-1=8\pi r^2\int_{\mathbb{R}^3}\left(\frac{\tilde{x}\cdot v}{r}\right)^2\mathring{f}(r,v)\frac{\mathrm{d}v}{\sqrt{1+v^2}}-4\pi r^2 e^{2\mathring{\lambda}}\mathring{e}^2. \tag{2.16}$$

We observe that, if $\mathring{f}$ is given and if we can solve (2.14) and (2.15) for $\mathring{\lambda}$ and $\mathring{e}$ then (2.16) determines at once $\mathring{\mu}'$. Using the boundary condition (2.12) then determines $\mathring{\mu}$. So we can concentrate on (2.14) and (2.15). In what follows, we fix $\mathring{f}$ in (2.14) and (2.15) and we look for a unique global asymptotically flat solution $(\mathring{\lambda},\mathring{e})$ of the system (2.14) and (2.15) above with regular center. Note that, using the compact support of $\mathring{f}$ and the equations (2.14) and (2.15), it follows that $\mathring{\lambda}$ and $\mathring{e}$ tend to zero as $r\to\infty$. It also follows from (2.14) and (2.15) and the regularity of the solution that $\mathring{\lambda}'(0)=0$ and $\mathring{e}(0)=0$.

III. EXISTENCE OF GLOBAL SOLUTIONS OF THE CONSTRAINTS

In this section the existence of global solutions of the equations (2.14) and (2.15) will be proved. Let us state first of all the following result of Ref. 10 on which our global existence theorem relies.

Theorem 3.1: *Let V be a finite-dimensional real vector space, $N:V\to V$ a linear mapping, $G:I\times V\to V$ a smooth (i.e., C^∞) mapping and $g:I\to V$ a smooth mapping, where I is an open interval in $\mathbb{R}$ containing zero. Consider the equation*

$$s\frac{\mathrm{d}f}{\mathrm{d}s}+Nf=sG(s,f(s))+g(s) \tag{3.1}$$

for a function f defined on a neighborhood of 0 in I and taking values in V. Suppose that each eigenvalue of N has a positive real part. Then there exists an open interval J with $0 \in J \subset I$ and a unique bounded C^1 function f on $J\backslash\{0\}$ satisfying (3.1). Moreover f extends to a C^∞ solution of (3.1) on J. If N, G, and g depend smoothly on a parameter z and if the eigenvalues of N are distinct then the solution also depends smoothly on z.

Proof: See Theorem 1 in Ref. 10, p.989.

Remark 1: The assumption that N has distinct eigenvalues is to ensure that N can be reduced to diagonal form by a similarity transformation depending smoothly on z. In particular, Theorem 3.1 applies if N is already a diagonal matrix.

Theorem 3.2: *(local existence) Let $\mathring{f} \in C^\infty(\mathbb{R}^6)$ be non-negative, compactly supported and spherically symmetric. Then, the equations (2.14) and (2.15) have a unique local and regular solution $(\mathring{\lambda}, \mathring{e})$ defined on some interval $[0,R]$, $R>0$. The solution depends smoothly on the parameter q.*

Proof: Let $\mathring{f} \in C^\infty(\mathbb{R}^6)$ be non-negative, compactly supported and spherically symmetric. By a regular solution we mean one which is smooth and for which $\mathring{\lambda} = 0$ at $r = 0$. It follows that for any regular solution $\mathring{\lambda}$ can be written in the form:

$$\mathring{\lambda}(r) = rL(r) \tag{3.2}$$

for a smooth function $L(r)$. Equation (3.2) implies $\mathring{\lambda}' = L + rL'$ and (2.14)–(2.15) can be written

$$rL' + L = \frac{1}{2r}(1 - e^{2rL}) + 4\pi r e^{2rL}\left(\int_{\mathbb{R}^3} \sqrt{1+v^2}\,\mathring{f}(r,v)\,\mathrm{d}v + \frac{1}{2}e^{2rL}\mathring{e}^2 \right), \tag{3.3}$$

$$r\mathring{e}' + 2\mathring{e} = -r\mathring{e}(L + rL') + rq\int_{\mathbb{R}^3} \mathring{f}(r,v)\,\mathrm{d}v. \tag{3.4}$$

The function $e^{2x} - 1 - 2x$ vanishes to first order at the origin and hence $e^{2x} - 1 - 2x = x^2 F_0(x)$ for a smooth function F_0. Hence the equation for L can be rewritten in the form

$$rL' + L = -L + \frac{r}{2}L^2 F_0(rL) + 4\pi r e^{2rL}\left(\int_{\mathbb{R}^3} \sqrt{1+v^2}\,\mathring{f}\,\mathrm{d}v + \frac{1}{2}e^{2rL}\mathring{e}^2 \right).$$

Thus

$$rL' + 2L = rG_1(r, L, \mathring{e}, \mathring{f}), \tag{3.5}$$

where

$$G_1(r, L, \mathring{e}, \mathring{f}) = \frac{1}{2}L^2 F_0(rL) + 4\pi e^{2rL}\int_{\mathbb{R}^3} \sqrt{1+v^2}\,\mathring{f}(r,v)\,\mathrm{d}v + 2\pi e^{4rL}\mathring{e}^2$$

and (3.4) reads, given (3.5),

$$r\mathring{e}' + 2\mathring{e} = -r\mathring{e}(-L + rG_1(r, L, \mathring{e}, \mathring{f})) + rq\int_{\mathbb{R}^3} \mathring{f}(r,v)\,\mathrm{d}v.$$

Hence,

$$r\mathring{e}' + 2\mathring{e} = rG_2(r, L, \mathring{e}, \mathring{f}), \tag{3.6}$$

where

$$G_2(r,L,\mathring{e},\mathring{f})=L\mathring{e}-r\mathring{e}G_1(r,L,\mathring{e},\mathring{f})+q\int_{\mathbb{R}^3}\mathring{f}(r,v)\mathrm{d}v.$$

Setting $G=\binom{G_1}{G_2}$ and $\Phi=\binom{L}{\mathring{e}}$ and using (3.5) and (3.6), the equations (2.14) and (2.15) can be written:

$$r\frac{\mathrm{d}\Phi}{\mathrm{d}r}+2\Phi=rG(r,\Phi(r)). \tag{3.7}$$

We apply Theorem 3.1 with $V=\mathbb{R}^2$, $N\Phi=2\Phi$ to (3.7) and, since G clearly depends smoothly on q, obtain the desired result. Thus Theorem 3.2 is proved.

Theorem 3.3 (Global existence, low charge): *Let $\mathring{f}\in C^\infty(\mathbb{R}^6)$ be non-negative, compactly supported and spherically symmetric with*

$$8\pi\int_0^r s^2\left(\int_{\mathbb{R}^3}\sqrt{1+v^2}\mathring{f}(s,v)\mathrm{d}v\right)\mathrm{d}s<r. \tag{3.8}$$

Then, for q small enough, the equations (2.14) and (2.15) have a unique global and regular solution $(\mathring{\lambda},\mathring{e})$ defined on $[0,+\infty[$ that satisfies the boundary condition $\mathring{\lambda}(0)=0$.

Proof: Let $\mathring{f}\in C^\infty(\mathbb{R}^6)$ be non-negative, compactly supported and spherically symmetric. We assume that $\mathring{f}$ is fixed and satisfies (3.8). By Theorem 3.2, the equations (2.14) and (2.15) have a unique local regular solution on some interval $[0,R]$, $R>0$. Again, Theorem 3.1 shows that, for fixed $\mathring{f}$, there exists $E>0$, such that for $q\in[-E,E]$, R can be chosen uniformly and the solution on $[0,R]$ depends continuously on the parameter q. Now, for fixed $\mathring{f}$ and q, the solution has a right maximal interval of existence $[0,R_*[$, $R_*=R_*(\mathring{f},q)$. We have to show that $R_*=+\infty$. In fact, the second term on the right-hand side of (2.14) vanishes for $q=0$, as one can see by integrating (2.15) over $[0,r]$, $r>0$. It follows that for $q=0$, (2.14) and (2.15) have a global solution under the sole assumption (3.8) on $\mathring{f}$. Then by the stability theorem for ODE, for every $R>0$, there exists a number $E>0$, such that, for every $q\in[-E,E]$, the system (3.7) has a solution Φ_E that exists on $[0,R]$ (see Theorem 4, p. 92 in Ref. 7). Thus $R_*>R$. Now, we can choose R large so that $\operatorname{supp}\mathring{f}\subset[0,R]\times\mathbb{R}^3$, i.e., $\mathring{f}(r,v)=0$ for $r\geqslant R$. If R_0 is the radius of the support of the distribution function then R may be chosen to be bigger than $m(R_0)+Q^2/(8\pi R_0)$ for all q in the interval $[E,E]$. Hence by the lemma of the appendix the solution extends to one which is global and regular. This completes the proof of the theorem.

Theorem 3.4 (Global existence, high charge): *Let $\overline{f}\in C^\infty(\mathbb{R}^6)$ be non-negative, compactly supported and spherically symmetric. Then, for q large enough, the equations (2.14) and (2.15) have a global and regular solution $(\mathring{\lambda},\mathring{e})$ defined on $[0,+\infty[$ that satisfies the boundary condition $\mathring{\lambda}(0)=0$ for which $\mathring{f}$ is a constant multiple of $\overline{f}$. Moreover the charge to mass ratio Q/M of the solution can be made as large as desired.*

Proof: We assume that $\overline{f}$ is fixed as in the assumptions of the theorem. We set

$$\alpha=q^{-1},\quad \overline{f}=\alpha^{-k}\mathring{f},\quad \overline{e}=\alpha^{-(k-1)}\mathring{e}$$

for some integer $k\geqslant 2$. Then (2.14) and (2.15) can be written as

$$e^{-2\mathring{\lambda}}(2r\mathring{\lambda}'-1)+1=8\pi r^2\left(\alpha^k\int_{\mathbb{R}^3}\overline{f}(r,v)\mathrm{d}v+\frac{1}{2}e^{2\mathring{\lambda}}\alpha^{2(k-1)}\overline{e}^2\right), \tag{3.9}$$

$$2\overline{e}+r\overline{e}\mathring{\lambda}'+r\overline{e}'=-r\int_{\mathbb{R}^3}\overline{f}(r,v)\mathrm{d}v. \tag{3.10}$$

Introducing a variable L as defined in (3.2) puts these equations into a form closely analogous to that obtained in the proof of the last theorem. In fact the left-hand side has the same form as in that case. All that is changed is the form of the nonlinear terms on the right-hand side. The equations depend on α as a parameter in a way which is smooth in a neighborhood of $\alpha=0$. For $\alpha=0$ the function $\mathring{\lambda}$ vanishes identically while the equation for $\overline{e}$ becomes linear and has a global regular solution. From this point on we can argue just as in the proof of Theorem 3.3 to conclude that for α sufficiently small there is a unique global regular solution of these equations. Here we must use the fact that $m(R_0)+Q^2/(8\pi R_0)$ is bounded independently of α for α small. The assumption that α is small corresponds to q being large. The distribution function belonging to the solution is obtained from $\mathring{f}$ by a constant rescaling. The charge to mass ratio of the solution is proportional to α^{-k} and thus tends to infinity as α tends to zero. This completes the proof.

Remark 2: The solution in the exterior region is part of the Reissner–Nordström solution.[6]

Remark 3: Our motivation in proving these theorems was to construct initial data for the Einstein–Vlasov–Maxwell system. The same arguments apply with other kinds of charged matter such as a charged fluid as sources for the Einstein equations.

APPENDIX

This appendix contains an analysis of exterior regions free of particles in initial data sets for the Einstein–Vlasov–Maxwell system. Let $\mathring{f}$ be an initial distribution function of compact support. Let R_0 be the radius of its support in space so that $\mathring{f}$ vanishes for all $r\geqslant R_0$. In this appendix we are only concerned with quantities on the initial hypersurface and so we will drop the label zero indicating the restriction of space–time quantities to the initial hypersurface.

Lemma 1: Consider a solution of the constraint equations for the spherically symmetric Einstein–Vlasov–Maxwell system defined for $0\leqslant r\leqslant R_1$ *and having a regular center. Suppose that radius* R_0 *of the support of the distribution function* f *is less than* R_1. *Let* $\tilde{M}=m(R_0)+Q^2/(8\pi R_0)$. *Then if* $R_1>2\tilde{M}$ *the given solution extends to a unique solution of the constraints defined for all* $r\in[0,\infty[$ *which is asymptotically flat and has* $f=0$ *for* $R\geqslant R_0$.

Proof: Integrating the constraint equation (2.15) gives

$$r^2e^{\lambda(r)}e(r)=q\int_0^r s^2e^{\lambda(s)}\int_{\mathbb{R}^3}f(s,v)\,\mathrm{d}v. \tag{A1}$$

For $r\geqslant R_0$ the upper limit r in the integral can be replaced by R_0 or infinity without changing the value of the expression. It is equal to $Q/4\pi$ where Q is the total charge of the system defined in Sec. II. For $r\geqslant R_0$ the function f vanishes and the mass function m defined in Sec. II satisfies

$$m'=\frac{2\pi}{r^2}(Q/4\pi)^2. \tag{A2}$$

It follows that $\tilde{M}(r)=m(r)+Q^2/(8\pi r)$ is independent of r. If the solution exists globally in r and is asymptotically flat then taking the limit $r\to\infty$ shows that $\tilde{M}$ is equal to the ADM mass M. In any case $\tilde{M}$ is positive and it follows that in the exterior region $m=\tilde{M}-Q^2/(8\pi r)$. In order to determine whether a solution can be extended to larger values of the radius it is enough to ensure that $1-2\tilde{M}/r+Q^2/(4\pi r^2)$ remains positive. For in that case we can define λ by means of the relation

$$e^{-2\lambda}=1-2\tilde{M}/r+Q^2/(4\pi r^2). \tag{A3}$$

Note that $\lim_{r\to\infty}\lambda(r)=0$. Once this has been done we can define μ to be equal to $-\lambda$ and $e(r)=r^{-2}e^{-\lambda}(Q/4\pi)$ in the external region and this gives the unique solution satisfying the correct boundary conditions. If $r>2\tilde{M}$ then $1-2\tilde{M}/r+Q^2/(8\pi r^2)$ is automatically positive and the desired result is obtained.

Relativistic stars in differential rotation: bounds on the dragging rate and on the rotational energy

M. J. Pareja
Departamento de Física Teórica II, Facultad de Ciencias Físicas, Universidad Complutense de Madrid, E-28040 Madrid, Spain

(Received 27 July 2003; accepted 23 October 2003)

For general relativistic equilibrium stellar models (stationary axisymmetric asymptotically flat and convection-free) with differential rotation, it is shown that for a wide class of rotation laws the distribution of angular velocity of the fluid has a sign, say ''positive,'' and then both the dragging rate and the angular momentum density are positive. In addition, the ''mean value'' (with respect to an intrinsic density) of the dragging rate is shown to be less than the mean value of the fluid angular velocity (in full general, without having to restrict the rotation law, nor the uniformity in sign of the fluid angular velocity); this inequality yields the positivity and an upper bound of the total rotational energy. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1636515]

I. INTRODUCTION

One of the most interesting of the relativistic effects produced by the rotation of a star is the dragging of inertial frames (also called Lense-Thirring effect).[1] This has been classically described in terms of its *local* effects on gyroscopes and particles. However, its cumulative effects on the motion of particles give a much simpler description: a locally non-rotating test particle, that is dragged along in the gravitational field of the star, has an angular velocity, as seen from a non-rotating observer at spatial infinity, which is named *angular velocity of cumulative dragging, or rate of rotational dragging*, shortly called *dragging rate*.[2,3] It is physically expected that, for isolated rotating stars in thermodynamic equilibrium, this dragging rate A has the same sign (rotation sense) as the fluid angular velocity Ω, if this one has a ''uniform'' sign throughout the fluid (in the general differentially rotating case). Indeed, Lindblom[4] and, independently, Hansen and Winicour (1977)[5] seem to establish this result, however, without explicitly fulfilling the corresponding requirements when applying the Hopf theorem (a maximum principle) to an elliptic operator in a certain domain, concerning the boundedness of its coefficients on the boundary of the domain, specifically on the axis of rotation, and the C^1 (and not C^2) regularity of the metric functions across the surface of the star.

Also, (assuming in the description above that the test particle does not collide with the star's matter if it goes through the star) one is tempted to conjecture, in principle in the rigidly rotating case with $\Omega=\text{const}=\Omega_*>0$, that the dragging rate is bounded above by the fluid angular velocity, $A\leqslant\Omega_*$. And Hansen and Winicour (1975)[5] offer some proof of this (although with the same objection as above).

In the general differentially rotating case, however, an analogous relation should not be expected to be so simple; first, because different portions of the star's interior could have opposite rotational motion about the same axis (assuming a convection-free fluid), and, second (even if the fluid angular velocity has a sign), because, due to the integrability condition of the equation of motion, the distribution of fluid angular velocity, Ω-profile, cannot be freely prescribed; instead, it is derived (together with the potential functions, integrating the field equations) once an appropriate *rotation law* is given. Most of the literature concerning numerical works on differentially rotating neutron stars make generally the ansatz for a certain rotation law which yields $A\leqslant\Omega$. Nevertheless, for a more general law such a relation is not so obvious. Hansen and Winicour

(1977)[5] have made some attempts to give a result, however they needed the unphysical assumption that the star's matter occupies the whole space.

One of the aims of this work is precisely to find general and physically reasonable assumptions on the rotation law of a differentially rotating stellar model, so that the dragging rate is (at each interior point) less than the fluid angular velocity, and, hence, the *angular momentum density* is positive (vanishing on the axis) provided the weak energy condition is satisfied. For that matter we consider the time-angle field equation's component, which is elliptic and linear in the dragging potential A in coordinates adapted to the symmetries. The approach with the metric in these coordinates is attractive because the field equations become semilinear elliptic. Specially, they reduce to four (coupled) elliptic equations for the four metric functions. One has however to control the coordinate singularities of the equations on the axis of rotation, but these can be treated mathematically using the axial symmetry of the physical problem.[6] So handled, the elliptic equation in A writes in a ''regular'' form and has bounded coefficients; this allows us to apply a maximum principle to several differential inequalities, which, using the C^1-matching on the star's surface and the asymptotic flatness of the metric, will lead to the mentioned and other interesting inequalities.

More generally, as was conjectured by Thorne[2] (p. 245), the *mean value* of A is expected to be less than the *mean value* of Ω. However, to my knowledge, there is in the literature no explicit and so general result in this direction. The other purpose of the present work is then to derive a ''general'' inequality on ''mean values'' with respect to a density function. In addition, related to this question is the concept of *total rotational energy* of the star. Hartle[7] has given bounds for this rotational energy in the slow rotation limit, which we aim here to generalize.

The paper is organized as follows. After reviewing in Sec. II the model for a relativistic star which is rotating differentially, Sec. III is devoted to handle the concerned field equation, elliptic and linear in the dragging potential, with special attention to the regularity and boundedness properties of the involved functions, as a preparation allowing us to apply the maximum principles (reviewed in the Appendixes) in Sec. IV, where inequalities concerning mainly the positivity of the dragging rate and of the angular momentum density are derived. In Sec. V a general ''mean values inequality'' is derived in full general; and the positivity and upper bound of the total rotational energy is established in the general differentially rotating case. Finally, in Sec. VI the relevant results are briefly summarized.

II. MODEL FOR A DIFFERENTIALLY ROTATING RELATIVISTIC STAR

The space–time of an isolated rotating star in thermodynamic equilibrium within general relativity theory is generally represented by an asymptotically flat stationary axisymmetric four-dimensional Lorentzian manifold $(\mathcal{M},\mathbf{g})$, with metric $\mathbf{g}=g_{\alpha\beta}\,\mathrm{d}x^\alpha\,\mathrm{d}x^\beta$ satisfying Einstein's equations,

$$G_{\alpha\beta}:=R_{\alpha\beta}-\tfrac{1}{2}R\,g_{\alpha\beta}=8\pi\,T_{\alpha\beta}\,, \tag{1}$$

for the energy-momentum tensor of a perfect fluid, $T_{\alpha\beta}=(\varepsilon+p)\,u_\alpha u_\beta+p\,g_{\alpha\beta}$, with 4-velocity u^α, energy density ε, and pressure p. Signature of $\mathbf{g}$ is here considered to be $(-+++)$. Since the star is isolated, the matter (perfect fluid) is confined in a compact region in the space (interior), with vacuum, $T_{\alpha\beta}=0$, on the outside.

We denote the two (commuting) global time and axial Killing vector fields[8] by $\boldsymbol{\xi}=\partial_t$ and $\boldsymbol{\eta}=\partial_\phi$, respectively, where $x^0\equiv t$ labels the spacelike hypersurfaces which are invariant under time translations, and $x^1\equiv\phi$ is the axial-angle coordinate around the axis of rotation, given by $\boldsymbol{\eta}\equiv 0$; $(t,\phi)\in\mathbb{R}\times[0,2\pi[$. The metric components will then only depend on the two remaining spatial coordinates, $g_{\alpha\beta}=g_{\alpha\beta}(x^2,x^3)$.

We shall assume that the fluid motion is purely azimuthal (nonconvective), i.e., the fluid 4-velocity is contained in the 2-surface spanned by the two Killing fields, (as one-forms)

$$\mathbf{u}\wedge\boldsymbol{\xi}\wedge\boldsymbol{\eta}=0 \quad \text{(circularity condition)}\,. \tag{2}$$

In that case it can be seen[9] that the 2-surface elements orthogonal to the two-dimensional group orbits of the Killing fields are surface forming (the same holds in the vacuum region); and, consequently, the metric may be written in a form which is explicitly symmetric under the change $(t,\phi)\to(-t,-\phi)$. In the 2-surfaces orthogonal to the orbits we can always introduce *isotropic coordinates* $(x^2,x^3)=(\rho,z)$ without loss of generality, so that the metric can always be reduced to the standard form[3,10]

$$\mathbf{g}=g_{\alpha\beta}\,\mathrm{d}x^{\alpha}\,\mathrm{d}x^{\beta}=-e^{2U}\,\mathrm{d}t^2+e^{-2U}[\rho^2e^{2B}(\mathrm{d}\phi-A\,\mathrm{d}t)^2+e^{2K}(\mathrm{d}\rho^2+\mathrm{d}z^2)]\,, \tag{3}$$

where the metric functions $K,U,B,$ and A depend only on the (ρ,z)- coordinates of the ''meridian plane.'' Here ρ and z are cylindrical coordinates at the asymptotically flat infinity, and, using the remaining freedom of conformal transformations in the meridian plane, we choose these coordinates such that $\rho=0$ represents the axis of rotation and $(\rho,z)\in\mathbb{R}_0^+\times\mathbb{R}$ (denoting $\mathbb{R}_0^+:=\{x\in\mathbb{R}\,|\,x\geqslant 0\}$). The metric functions $\rho\,e^B$, U, and A can be written as invariant combinations of the Killing fields in the form

$$\rho^2e^{2B}=-\det((g_{\mu\nu})_{\mu,\nu=t,\phi})=-\mathbf{g}(\boldsymbol{\xi},\boldsymbol{\xi})\,\mathbf{g}(\boldsymbol{\eta},\boldsymbol{\eta})+\mathbf{g}(\boldsymbol{\xi},\boldsymbol{\eta})^2\,,$$

$$e^{2U}=\frac{\rho^2e^{2B}}{\mathbf{g}(\boldsymbol{\eta},\boldsymbol{\eta})}, \tag{4}$$

$$A=-\frac{\mathbf{g}(\boldsymbol{\xi},\boldsymbol{\eta})}{\mathbf{g}(\boldsymbol{\eta},\boldsymbol{\eta})}\quad,$$

and they can be interpreted physically as follows: $\rho\,e^B$ represents a sort of distance from the rotation axis (and, hence, B is, to some extent, a measure how far is ρ from being that distance); U is a generalization of the gravitational potential; and A is the *angular velocity of cumulative dragging, or dragging rate*. The remaining metric function is K, the conformal factor in the meridian plane.

Throughout the following we shall denote the closure and the boundary of a set X by $\overline{X}$ and ∂X, respectively. We fix the notions

$$I\equiv\text{interior of the star}:=\{(\rho,z)\in\mathbb{R}_0^+\times\mathbb{R}\;\mid\;p(\rho,z)>0\}\subset\mathbb{R}_0^+\times\mathbb{R}\,,$$

$$E\equiv\text{exterior of the star}:=(\mathbb{R}_0^+\times\mathbb{R})\backslash\overline{I}\subset\mathbb{R}_0^+\times\mathbb{R}\,, \tag{5}$$

$$S\equiv\text{star's surface}:=\overline{I}\cap\overline{E}=\partial I\subset\mathbb{R}_0^+\times\mathbb{R}\,,$$

I and E open in the *induced topology in* $\mathbb{R}_0^+\times\mathbb{R}\subset\mathbb{R}^2$; that means, although part of the axis ($\rho=0$) is in I (and part in E), the only points of the axis which are in $\partial I=S$ (and in $\partial E=S\cup\{\infty\}$) are the poles, if they exist. The set $I\subset\mathbb{R}_0^+\times\mathbb{R}$ is supposed to be bounded and connected. Concerning the regularity of $S=\partial I$, we assume it satisfies an exterior sphere condition everywhere (cf. Definition in Appendix A).

Within our star model, the *matching* conditions (from the interior and the exterior solutions) require that the pressure vanishes identically on the star's surface, $p=0$ on S. In the exterior ($T_{\alpha\beta}=0$) we have $\varepsilon=p=0$. Furthermore, ε and p satisfy a barotropic equation of state in the interior,

$$\varepsilon=\varepsilon(p)\quad\text{ in }\ \overline{I}\,. \tag{6}$$

We assume the pressure p to be continuous with respect to the coordinates, and also $p\mapsto\varepsilon(p)$ a continuous function,

$$p \in C^0(\mathbb{R}_0^+ \times \mathbb{R}), \quad p \mapsto \varepsilon(p) \in C^0(\mathbb{R}_0^+), \tag{7}$$

satisfying the *weak energy condition*,[11]

$$\varepsilon + p \geqslant 0 \quad (\text{in} \quad \mathbb{R}_0^+ \times \mathbb{R}). \tag{8}$$

[Notice, by the definition of the interior, (5), if $\varepsilon \geqslant 0$ in $\overline{I}$, as it is generally assumed, we shall have even $\varepsilon + p > 0$ in I, and, hence, condition (8) follows. In addition, since the equation of state is defined only in the interior, (6), requirement (7) does not guarantee the continuity of ε across the star's surface (where $p = 0$), namely, if $\varepsilon(p = 0) > 0$, then a jump discontinuity of ε across the star's surface occurs.]

From the circularity condition (2) on the fluid 4-velocity (in $\overline{I}$), this is of the form

$$\mathbf{u} = u^t(\boldsymbol{\xi} + \Omega\, \boldsymbol{\eta}), \quad \text{where} \quad \Omega \equiv \frac{u^\phi}{u^t} = \frac{\mathrm{d}\phi}{\mathrm{d}t}$$

is the angular velocity of the fluid measured by a distant observer in an asymptotically flat space–time, and the fact that the 4-velocity $\mathbf{u}$ is a unit timelike vector field determines the normalization factor u^t, such that $\mathbf{g}(\mathbf{u},\mathbf{u}) = -1$, i.e.,

$$(u^t)^{-2} = e^{2U} - \rho^2 e^{2(B-U)}(\Omega - A)^2 =: N, \tag{9}$$

from where $N = (u^t)^{-2} > 0$ in $\overline{I}$. Indeed, we do not allow that the velocity of light is approached somewhere, and, hence, even

$$N \geqslant \text{const} > 0 \quad \text{in} \quad \overline{I}. \tag{10}$$

We consider a star rotating differentially with a distribution of angular velocity (*rotation profile*) $\Omega = \Omega(\rho, z)$, a continuously differentiable function,

$$\Omega \in C^1(\overline{I}). \tag{11}$$

However, the Ω-profile of the fluid cannot be freely chosen, this shows up in the following. The integrability conditions of the field equations (1), that is, the equation of hydrostatic equilibrium $T^{\alpha\beta}{}_{;\beta} = 0$ (from $G^{\alpha\beta}{}_{;\beta} = 0$) (where ";" denotes covariant derivative), particularly, its part orthogonal to the fluid 4-velocity $\mathbf{u}$, reduces to the Euler equation,

$$\mathrm{d}p = -(\varepsilon + p)\, \mathbf{a}, \tag{12}$$

where $\mathbf{a}$ is the 4-acceleration of the fluid, $\mathbf{a} = \nabla_{\mathbf{u}}\mathbf{u}$. Specifically,

$$\mathbf{a} = \mathrm{d}V + u^t u_\phi\, \mathrm{d}\Omega, \quad V \equiv \tfrac{1}{2} \ln N, \tag{13}$$

$u^t u_\phi = \rho^2 e^{2(B-U)}(\Omega - A) N^{-1}$. But the integrability condition of Eq. (12) taking into account (6) is $\mathrm{d}\mathbf{a} = 0$; following then, from (13), $d(u^t u_\phi) \wedge \mathrm{d}\Omega = 0$. The special case where $\Omega = \text{const}$ is called *rigid rotation* (or *uniform rotation*). In general we shall have $\Omega \neq \text{const}$, following then,

$$u^t u_\phi = \mathcal{F}(\Omega), \tag{14}$$

for some function $\mathcal{F}$, *rotation law*. By specifying the function $\mathcal{F}(\Omega)$ a specific model of *differential rotation* is obtained. [Note, since in the Newtonian limit $u^t u_\phi \to \rho^2 \Omega$, Eq. (14) expresses the general relativistic generalization of the Newtonian "rotation on cylinders" theorem, $\Omega = \mathcal{G}(\rho^2)$.]

Further requirements on our stellar model are

(a) the metric functions are (at least) two times continuously differentiable in the interior and in the exterior of the star, and continuously differentiable everywhere (cf. note in Sec. III B),

$$K,U,B,A \in C^2(I)\cap C^2(E)\cap C^1(\mathbb{R}_0^+\times\mathbb{R})\,; \tag{15}$$

(b) in order that the metric functions are symmetric with respect to the z-axis ($\rho=0$) (''axisymmetric solutions''), and, hence, the metric (3), defined on $\mathcal{M}$ excluding the axis, can be extended to an at least C^1 axisymmetric tensor field in the whole space–time $\mathcal{M}$, we assume that

$$\text{as } \rho\to 0,\quad \partial_\rho K,\ \partial_\rho U,\ \partial_\rho B,\ \partial_\rho A\to 0\,, \tag{16}$$

and, for completeness, also $\partial_\rho\varepsilon$, $\partial_\rho p\to 0$;

(c) finally, by the asymptotic flatness requirement, denoting $\mathcal{D}:=(\partial_\rho,\partial_z)$,

$$\text{as } R:=(\rho^2+z^2)^{1/2}\to\infty,\quad K,U,B,A\to 0 \text{ and } \mathcal{D}K,\mathcal{D}U,\mathcal{D}B,\mathcal{D}A\to\mathbf{0}\,. \tag{17}$$

Notice, from C^1 regularity, in (15), and asymptotic flatness, (17), it follows, in particular, that the metric functions and their derivatives are bounded,[12]

$$|K|,|U|,|B|,|A|<\infty \quad \text{and} \quad \|\mathcal{D}K\|,\|\mathcal{D}U\|,\|\mathcal{D}B\|,\|\mathcal{D}A\| <\infty \quad \text{in } \mathbb{R}_0^+\times\mathbb{R}\,. \tag{18}$$

III. THE ELLIPTIC EQUATION FOR THE DRAGGING RATE *A*

A. The time-angle field equation component

The $(t\phi)$ component of Einstein's equation (1) in these coordinates takes the form[6]

$$\partial_{\rho\rho}A+\partial_{zz}A+\frac{3}{\rho}\partial_\rho A+\langle 3\mathcal{D}B-4\mathcal{D}U\,,\,\mathcal{D}A\rangle=-\psi^2\cdot(\Omega-A)\,, \tag{19}$$

$$\text{with}\quad \psi^2:=16\pi\frac{e^{2K}}{N}(\varepsilon+p)\quad [\geqslant 0,\ \text{by (8) and (10)}]\,, \tag{20}$$

where $\langle .,.\rangle$ denotes the Euclidean scalar product. Since, from condition (16), $v(\rho,z)=v(-\rho,z)$ for $v=K,U,B,A$, i.e., we are considering only axisymmetric solutions of the field equations, and since only ''axisymmetric operations'' appear in these equations, we consider the following transformation (in the spirit of Ref. 6) in order to avoid the coordinate singularity [of Eq. (19)] on the axis of symmetry (z-axis, i.e., $\rho=0$). To this end we use the 5-*lift* of each function $v\equiv v(\rho,z)$ (on $\mathbb{R}^5$), for the metric functions $v=K,U,B,A$ and also for $v=\Omega,\varepsilon,p$, where the *n-lift* of $v:\mathbb{R}_0^+\times\mathbb{R}\to\mathbb{R}$ on flat $\mathbb{R}^n$, axisymmetric around the x_n-axis, is defined as follows:

$$v\mapsto\tilde{v}\quad \text{such that } \tilde{v}(x)\equiv\tilde{v}(x_1,\ldots,x_n):=v(\rho=({x_1}^2+\cdots+{x_{n-1}}^2)^{1/2},\ z=x_n)\,, \tag{21}$$

and, for every function $\tilde{v}:\mathbb{R}^n\to\mathbb{R}$, the *meridional cut* (*in direction* x_1) *of* $\tilde{v}$,

$$\tilde{v}\mapsto v\quad \text{such that } v(\rho,z):=\tilde{v}(\rho,0,\ldots,0,z)\,. \tag{22}$$

For axisymmetric functions, both operations are isomorphisms and inverse to each other; but the relevant properties of n-lift and meridional cut are that (a) they leave the regularity conditions and the norms invariant, (b) they commute with ''axisymmetric operations,'' in particular, with all operations in Eq. (19), like multiplication and scalar product, yielding especially (for $n=5$)

$$\langle\mathcal{D}v,\mathcal{D}w\rangle=\langle\nabla\tilde{v},\nabla\tilde{w}\rangle\,,\ \text{denoting } \nabla:=(\partial_1,\ldots,\partial_5)\quad (\partial_i\equiv\partial_{x_i},\quad \partial_{ij}\equiv\partial_{x_i}\partial_{x_j})\,,$$

and, remarkably, (c) they transform the operator $\partial_{\rho\rho}+\partial_{zz}+[(n-2)/\rho]\,\partial_\rho$ $(n\geqslant 2)$ into the flat n-dimensional Laplacian, and vice versa; having for $n=5$,

$$\partial_{\rho\rho}v+\partial_{zz}v+\frac{3}{\rho}\partial_{\rho}v=\sum_{i=1}^{5}\partial_{ii}\tilde{v}=:\Delta\tilde{v}\,.$$

Hence, with the 5-lift, Eq. (19) writes in the form

$$\Delta\tilde{A}+\langle 3\nabla\tilde{B}-4\nabla\tilde{U}\,,\nabla\tilde{A}\rangle=-\tilde{\psi}^2\cdot(\tilde{\Omega}-\tilde{A})\,, \tag{23}$$

$\tilde{\psi}^2$ defined like ψ^2, (20), but with 5-*lifted* functions (on $\mathbb{R}^5$).

B. Regularity and boundedness of the metric functions

Let us see how conditions (15)–(18) transmit through the 5-lift. First, from conditions (15) and (16) it follows

$$\tilde{K},\tilde{U},\tilde{B},\tilde{A}\in C^1(\mathbb{R}^5)\,, \tag{24}$$

because (for $v=K,U,B,A$) $v\in C^1(\mathbb{R}_0^+\times\mathbb{R})$ and $\partial_\rho v\to 0$ as $\rho\to 0$ imply $\tilde{v}\in C^1(\mathbb{R}^5)$.

Note: In fact, as seen in Ref. 6, with the use of these mathematical tools (n-lift and meridional cut, for different numbers n), the elliptic system of field equations (1) may be regarded as a set of *Poisson-like equations*, where the nonlinearities (quadratic terms in the first derivatives of the metric functions) are contained in the inhomogeneous terms on the right-hand side. Making the weak requirement that the metric functions and their derivatives are essentially bounded, $\tilde{v},\nabla\tilde{v}\in L^\infty$, since also $\tilde{\varepsilon},\tilde{p}\in L^\infty$ [by condition (7) and $\tilde{\varepsilon}=\tilde{p}=0$ in the exterior], and $\tilde{\Omega}\in L^\infty$ [by (11)], we have that the right-hand side is essentially bounded. Then, by the regularity of Poisson's integral,[13] (at least) $\tilde{v}\in C^{1,\alpha}$ for some $\alpha<1$; in particular, $\tilde{v}\in C^1$, i.e., (24). This justifies requirements (15) and (16) in Sec. II.

Combining (15) and (16) we obtain also that the 5-lifted metric functions are class C^2 in the interior and in the exterior of the star (in $\mathbb{R}^5$). That is, denoting

$$\mathcal{I}:=\{(x_1,\ldots,x_5)\in\mathbb{R}^5\ \ |\ ((x_1{}^2+\cdots+x_4{}^2)^{1/2},x_5)\in I\}\subset\mathbb{R}^5 \tag{25}$$

and, analogously, $\mathcal{E}$ and $\mathcal{S}$, from E and S [cf. (5)], respectively, we have for $\tilde{v}=\tilde{K},\tilde{U},\tilde{B},\tilde{A}$,

$$\tilde{v}\in C^2(\mathcal{I})\cap C^2(\mathcal{E})\cap C^1(\mathbb{R}^5)\,. \tag{26}$$

The asymptotic flatness condition (17) implies, through the 5-lift, that

$$\text{as}\quad R=\|x\|=(x_1{}^2+\cdots+x_5{}^2)^{1/2}\to\infty,\quad \tilde{v}\to 0\ \text{ and }\ \nabla\tilde{v}\to\mathbf{0}\,; \tag{27}$$

but $\tilde{v}\in C^1(\mathbb{R}^5)$, that is, $\tilde{v}\in C^0(\mathbb{R}^5)$ and $\nabla\tilde{v}\in[C^0(\mathbb{R}^5)]^5$, yielding, together with conditions (27), their respective boundedness,

$$|\tilde{v}|<\infty\quad\text{and}\quad\|\nabla\tilde{v}\|<\infty\ \text{ in }\ \mathbb{R}^5\,. \tag{28}$$

C. Notation convention and roundup

We have seen in Sec. III A that Eq. (23) is equivalent to Eq. (19) through the 5-lift and the meridional cut, (21) and (22) for $n=5$. Furthermore, the 5-lift leaves regularity and boundedness properties invariant; see Sec. III B.

Convention: For simplicity in the notation, we omit throughout the following the symbols "$\sim$" for all 5-lifted functions we use. [Once it has been seen how regularity and boundedness properties transmit from the functions defined on $\mathbb{R}_0^+\times\mathbb{R}$ to the lifted ones (on $\mathbb{R}^5$), and since they are equivalent in terms of positivity, and no explicit reference to the first ones will appear throughout the following section, this notation convention seems appropriate.]

Accordingly, we write Eq. (23) in the form

$$L_0 A = -\psi^2 \cdot (\Omega - A)\,, \tag{29}$$

$$\text{with} \quad L_0 A := \Delta A + \langle 3\nabla B - 4\nabla U\,,\, \nabla A\rangle\,, \tag{30}$$

$$\begin{gathered}\psi^2 := 16\pi \frac{e^{2K}}{N}(\varepsilon + p) \;\geqslant 0 \quad (=0 \quad \text{in} \quad \mathcal{E})\,, \\ \text{and} \quad N := e^{2U} - \rho^2 e^{2(B-U)}(\Omega - A)^2 \;\geqslant\; \text{const} > 0 \quad \text{in} \quad \overline{\mathcal{I}},\end{gathered} \tag{31}$$

where $K, U, B, A : \mathbb{R}^5 \to \mathbb{R}$, axisymmetric around the x_5-axis. [Notice, Eq. (29) is so defined in the whole space–time, interior (fluid) and exterior (vacuum), $\overline{\mathcal{I}} \cup \mathcal{E} = \mathbb{R}^5$, but in the exterior $\psi^2 \equiv 0$ ($\varepsilon = p = 0$) and the vacuum field equation is recovered, $L_0 A = 0$ in $\mathcal{E}$.] Also, we have (26)–(28), i.e. (with the notation convention),

$$K, U, B, A \in C^2(\mathcal{I}) \cap C^2(\mathcal{E}) \cap C^1(\mathbb{R}^5)\,, \tag{32}$$

$$\text{as} \quad R = \|x\| = (x_1{}^2 + \cdots + x_5{}^2)^{1/2} \to \infty, \quad K, U, B, A \to 0\,, \tag{33}$$

$$\nabla K, \;\; \nabla U, \;\; \nabla B, \;\; \nabla A \to \mathbf{0}\,; \tag{34}$$

$$|K|, \;\; |U|, \;\; |B|, \;\; |A| \;\; < \infty\,, \tag{35}$$

$$\text{and} \quad \|\nabla K\|, \;\; \|\nabla U\|, \;\; \|\nabla B\|, \;\; \|\nabla A\| \;\; < \infty \;\; \text{in} \;\; \mathbb{R}^5\,. \tag{36}$$

Equation (29), i.e.,

$$L A := L_0 A - \psi^2 \cdot A = -\psi^2 \cdot \Omega\,, \tag{37}$$

writes then

$$L A \equiv a_{ij}(x)\, \partial_{ij} A + b_i(x)\, \partial_i A + c(x)\, A = g(x)$$

with

$$\begin{gathered}a_{ij} \equiv \text{const} = \delta_{ij} \quad (=1 \;\; \text{if} \;\; i=j, \;\; \text{and} \;\; =0 \;\; \text{otherwise})\,, \\ b_i = 3\,\partial_i B - 4\,\partial_i U \quad (\forall\, i,j \in \{1,\ldots,5\}), \quad \text{and} \\ c = -\psi^2 (\leqslant 0)\,, \\ g = c\,\Omega\end{gathered} \tag{38}$$

(where repeated indices indicate summation from 1 to 5). The flat five-dimensional Laplacian Δ, in (30), ($a_{ij} \equiv \delta_{ij}$), and hence L, is obviously strictly and uniformly elliptic everywhere. The coefficients b_i are measurable and bounded functions everywhere, because B and U are C^1, (32), and have bounded derivatives, (36). On the other hand, for the coefficient c [cf. (31)], since (i) the metric functions are continuous, (32), and bounded, (35); (ii) p is continuous everywhere, (7), and has compact support; (iii) ε is continuous in the (closed) interior $\overline{\mathcal{I}}$, from (7); (iv) Ω is in particular continuous (in $\overline{\mathcal{I}}$), (11), and, hence, measurable; and (v) $N \geqslant \text{const} > 0$ (also in $\overline{\mathcal{I}}$), (10); it follows that $c \equiv -\psi^2$ is measurable and bounded in the interior $\mathcal{I}$, and, since $\psi^2 \equiv 0$ ($\varepsilon = p = 0$) in the exterior $\mathcal{E}$, and the boundary (the star's surface) $\partial\mathcal{I} = \mathcal{S}$ is a set of measure zero, we have that the coefficient c is measurable and bounded everywhere. This will allow us in the following section to apply maximum principles in the classical and in the generalized sense to the operator L (and L_0); see Appendixes A and B.

IV. BOUNDS ON THE DRAGGING RATE

A. Positivity of the dragging rate

Proposition 1: If the distribution of angular velocity of the fluid is non-negative (and non-trivial), then the dragging rate is positive everywhere,

$$\Omega \geqslant 0, \quad \Omega \not\equiv 0 \Rightarrow \; A > 0 \, .$$

Proof: Consider the domain G defined by a ball in $\mathbb{R}^5$ centered at the origin $x = \mathbf{0}$ and of arbitrarily large radius σ,

$$G := \mathcal{B}_\sigma(\mathbf{0}) \subset \mathbb{R}^5 \, . \tag{39}$$

Since A is continuously differentiable in $\mathbb{R}^5$, cf. (32), so is in particular in G; but A and ∇A continuous in $\mathbb{R}^5$ implies that they are 2-integrable (are in L^2) in G; consequently,

$$A \in W^{1,2}(G) \cap C^1(G) \, . \tag{40}$$

Hence, the strictly elliptic linear partial differential equation (in A) with measurable and bounded coefficients, (37), is satisfied in a generalized sense in G; see Appendix B. Remarkably, whenever $\Omega \geqslant 0$, Eq. (37) yields the differential inequality

$$L\,A \leqslant 0 \quad \text{in } \; G \, , \tag{41}$$

i.e., A is a generalized supersolution relative to the operator L and the domain G. We pay now special attention to the behavior of A on the boundary: since the radius of the ball G, σ, is arbitrary, we can make it sufficiently large ($\sigma \to \infty$) such that, by the asymptotic flatness condition on A [cf. (33)], A is arbitrarily small on ∂G,

$$\lim_{\sigma \to \infty} A\big|_{\partial G} = 0 \, . \tag{42}$$

We first observe that $A \not\equiv \text{const}$ [because, by (42) and $A \in C^0(\mathbb{R}^5)$, would be $A \equiv \text{const} = 0$, which yields, by Eq. (37), $\Omega \equiv 0$, and we are assuming $\Omega \not\equiv 0$]. Hence, by the strong minimum principle, Theorem 4 in Appendix B, applied to the differential inequality (41), A cannot attain a nonpositive minimum at an interior point of G; using (42), we conclude then $A > 0$ in G, i.e., everywhere.□

Remark 1: A result analogous to Proposition 1 holds with the opposite sense of the rotation; that is, if $\Omega \leqslant 0$ $(\Omega \not\equiv 0)$, then $A < 0$. This follows because Eq. (29) is invariant with respect to the simultaneous change of sign $(\Omega, A) \to (-\Omega, -A)$.

B. Upper bound Ω. Positivity of the angular momentum density

Hereafter we discuss the sign of the difference $\Omega - A$. Remarkably, this determines the sign of $u^t u_\phi$, which, with assumption (8), is the sign of the *angular momentum density*, integrand of the total angular momentum, given by the "volume" integral[14] $J = \int_{\mathcal{I}} 2\pi\, T^t_\phi\, (-g)^{1/2}\, \mathrm{d}x$, where $g \equiv \det(\mathbf{g})$ and $T^t_\phi = (\varepsilon + p)\, u^t u_\phi$.

1. In the rigidly rotating case

Proposition 2: In the particular case of rigid rotation, with $\Omega \equiv \text{const} =: \Omega_* > 0$,

$$0 < A < \Omega_*$$

holds everywhere. As a consequence, in this case, $u^t u_\phi$, *and, hence, the angular momentum density, is non-negative.*

Proof: We consider Eq. (29) for $\Omega \not\equiv \text{const} = \Omega_* > 0$, i.e., $L_0\, A = -\psi^2 \cdot (\Omega_* - A)$, which, since the differential operator L_0, (30), is free from linear term, can be rewritten in the form

$$L_0(A-\Omega_*)=-\psi^2\cdot(\Omega_*-A)\,,$$

or, denoting again the differential operator $L:=L_0-\psi^2$ and defining

$$w(x):=A(x)-\Omega_* \tag{43}$$

in the whole space–time, $x\in\overline{\mathcal{I}}\cup\mathcal{E}=\mathbb{R}^5$ (as already 5-lifted function; cf. Sec. III A),

$$Lw=L(A-\Omega_*)=L_0(A-\Omega_*)-\psi^2\cdot(A-\Omega_*)=0 \quad \text{in } \mathbb{R}^5\,.$$

We have then the strictly elliptic linear (in w) equation

$$Lw=0 \quad (\text{in particular}) \text{ in } G\equiv\mathcal{B}_\sigma(\mathbf{0})\subset\mathbb{R}^5\,, \tag{44}$$

where the radius σ is arbitrary, with $w\in W^{1,2}(G)\cap C^1(G)$, by (40) and (43). On the other hand, by the condition of asymptotic flatness on A [in (33)], A is arbitrarily small on ∂G, provided that σ is sufficiently large, i.e., (42); consequently,

$$\lim_{\sigma\to\infty} w|_{\partial G}=-\Omega_*<0\,. \tag{45}$$

Since $w\not\equiv$const [because, by (45) and continuity, would be $w\equiv$const$=-\Omega_*$ in G, that is, $A\equiv$const$=0$ in G, which is not allowed, by Eq. (37), since here $\Omega\equiv\Omega_*>0$], applying the strong maximum principle, Theorem 4 in Appendix B, to Eq. (44), we get that w cannot attain a nonnegative maximum at an interior point of G; hence, using (45), $w<0$ in G (everywhere), i.e., $A<\Omega_*$ everywhere. Moreover, $A>0$ everywhere, by Proposition 1. This establishes the conclusion of the proposition. □

Observe, in the static case, $\Omega_*=0$, we would have $Lw=0$ and $\lim_{\sigma\to\infty}w|_{\partial G}=0$, following, by the strong maximum and minimum principles, $w\equiv0$, i.e., $A\equiv\Omega_*=0$; as expected, $A\equiv0$.

Remark 2: Likewise, if $\Omega\equiv$const$\equiv\Omega_*<0$, then $0>A>\Omega_*$ everywhere, and, hence, the angular momentum density is nonpositive. We obtain this by applying Proposition 2 to the function $\hat{A}:=-A$, solution of Eq. (29) for $\hat{\Omega}_*:=-\Omega_*>0$ (cf. Remark 1). More explicitly, the angular momentum density of a rigidly rotating stellar model has the same sign as the angular velocity of the fluid. Also, as a result, we have for a fluid rotating rigidly with $\Omega\equiv$const$\equiv\Omega_*\neq0$,

$$0<|A|<|\Omega_*|\,.$$

2. In the general (differentially rotating) case

In the following we shall assume that a function $\mathcal{F}$ (to be specified) has been given, and we have a solution of the problem, that is, (four) metric functions, K, U, B, and A, and a fluid angular velocity distribution, Ω, satisfying the (four) field equations (1) [in particular, the elliptic equation for A, Eq. (29)] and Eq. (14), $u^t u_\phi=\mathcal{F}(\Omega)$. [Notice, in the interior, where the matter terms do not vanish ($p>0,\varepsilon\geqslant0$), substituting into the equation of motion (12) [with (13)] its integrability condition, i.e., Eq. (14), and the equation of state, Eq. (6), we obtain the pressure, p, and the energy density, ε, as functions of ρ, U, B, A, and Ω.]

Remarkably, $u^t u_\phi$ may be written

$$u^t u_\phi\equiv\frac{\rho^2 e^{2(B-U)}(\Omega-A)}{e^{2U}-\rho^2 e^{2(B-U)}(\Omega-A)^2}=\frac{\varrho^2(\Omega-A)}{1-\varrho^2(\Omega-A)^2}=:\Phi(\varrho\,,\Omega-A)\quad\text{with}\quad\varrho:=\rho\,e^{B-2U}\,, \tag{46}$$

where, from (10), $1-\varrho^2(\Omega-A)^2=Ne^{-2U}\geqslant$const$>0$ in $\overline{\mathcal{I}}$. With the defined function (46), Eq. (14) writes

$$\Phi(\varrho\,,\Omega-A)=\mathcal{F}(\Omega)\,. \tag{47}$$

Lemma: Assume

(i) *the function* $\mathcal{F}:\mathbb{R}\to\mathbb{R}$ *is strictly decreasing, and*
(ii) $\exists$ *a constant* Ω_c $(|\Omega_c|<\infty)$ *such that* $\mathcal{F}(\Omega_c)=0$,

then, at each interior point (in $\overline{\mathcal{I}}$*), where Eq.* (47), $\Phi=\mathcal{F}$, *is satisfied, the following holds:*

$$\begin{aligned} &A<\Omega \Leftrightarrow A<\Omega\leqslant\Omega_c \quad (A<\Omega_c),\\ &A>\Omega \Leftrightarrow A>\Omega\geqslant\Omega_c \quad (A>\Omega_c),\\ &A=\Omega \Leftrightarrow A=\Omega=\Omega_c \quad (A=\Omega_c)\,. \end{aligned} \tag{48}$$

Note 1: Due to (i), Ω_c [defined in (ii)] is unique. Also, observe, Ω_c exists and coincides with the (constant) value of Ω on the rotation axis, provided that part of the axis, $\varrho=0$, is in the interior, $\mathcal{I}$, (i.e., if the rotating fluid does not have toroidal topology). This is because at points in $\{\varrho=0\}\cap\mathcal{I}\neq\varnothing$, since $\Phi|_{\varrho=0}=0$ and $\Phi=\mathcal{F}$ in $\mathcal{I}$, we have $\mathcal{F}(\Omega)|_{\varrho=0}=0$; and $\mathcal{F}$ is, by requirement (i), invertible; yielding $\Omega|_{\varrho=0}=\text{const}=\Omega_c$.

Note 2: Observe, if $\mathcal{F}\in C^1$ and $\mathcal{F}'<0$, then, since $\partial_\Omega\Phi\geqslant 0$, Eq. (47) can be solved for Ω, by virtue of the implicit function theorem, yielding $\Omega=\Omega(\rho,U,B,A)$; and, by the regularity of the metric functions, (32), it follows in particular $\Omega\in C^1(\overline{\mathcal{I}})$, requirement (11).

Note 3: It should be stressed that, since Φ is an *increasing* function in Ω, choosing the function $\mathcal{F}$ strictly *decreasing* [requirement (i)], Eq. (47) has a unique solution in Ω (''curve'' solution with ϱ variable). Specially, this makes likely the existence of functions Ω, K, U, B, and A, solutions of the field equations and Eq. (14). Indeed, in numerical works concerning differential rotation the ansatz for the $\mathcal{F}$-law $\mathcal{F}(\Omega)=R_0^2(\Omega_c-\Omega)$, where R_0 is a free parameter describing the length of scale over which Ω changes, is generally used, and they claim they have a solution. (See, e.g., Refs. 15–17.)

Proof: We consider a point $x\in\overline{\mathcal{I}}$ where the metric functions and the fluid angular velocity are solution, in particular, with reference to Eq. (47), the functions Φ and $\mathcal{F}$ valued at this point ''intersect'' each other, i.e.,

$$\Phi(\varrho(x)\,,\,\Omega(x)-A(x))=\mathcal{F}(\Omega(x))\quad(\forall x\in\overline{\mathcal{I}})\,.$$

From requirements (i) and (ii), it follows (at each interior point) $\text{sign}(\mathcal{F})=\text{sign}(\Omega_c-\Omega)$. As regards Φ (at the interior point), on the axis $(\varrho=0)$ it obviously vanishes, cf. (46); following, from the relation $\Phi=\mathcal{F}$ (in $\overline{\mathcal{I}}$), $\Phi=\mathcal{F}=0$ and, thus, $\Omega=\Omega_c$ on the axis. Outside the axis $(\varrho\neq 0)$ we have $\text{sign}(\Phi)=\text{sign}(\Omega-A)$; and, hence (outside the axis)

$$\begin{aligned} &\Phi=\mathcal{F}>0\Leftrightarrow A<\Omega<\Omega_c\,,\\ &\Phi=\mathcal{F}<0\Leftrightarrow A>\Omega>\Omega_c\,,\\ &\Phi=\mathcal{F}=0\Leftrightarrow A=\Omega=\Omega_c\,. \end{aligned}$$

But also,

$$\forall x\in\overline{\mathcal{I}}\ \ /\ \ A(x)<\Omega(x),\quad \begin{cases} A(x)<\Omega(x)<\Omega_c & \text{if } \varrho(x)\neq 0,\\ A(x)<\Omega(x)=\Omega_c & \text{if } \varrho(x)=0, \end{cases}$$

$$\forall x\in\overline{\mathcal{I}}\ \ /\ \ A(x)>\Omega(x),\quad \begin{cases} A(x)>\Omega(x)>\Omega_c & \text{if } \varrho(x)\neq 0,\\ A(x)>\Omega(x)=\Omega_c & \text{if } \varrho(x)=0, \end{cases}$$

$$\text{and}\ \ \forall x\in\overline{\mathcal{I}}\ \ /\ \ A(x)=\Omega(x),\quad A(x)=\Omega(x)=\Omega_c\,.$$

This yields (48). □

We are now in a position to get one of the main results of this work in the general differentially rotating case, namely, the following proposition.

Proposition 3: If the $\mathcal{F}$-law [in Eq. (14)] specifying the model of differential rotation is chosen such that

(i) $\mathcal{F}:\mathbb{R}\to\mathbb{R}$ *strictly decreasing,*
(ii) $\exists$ *a constant* Ω_c $(|\Omega_c|<\infty)$ *such that* $\mathcal{F}(\Omega_c)=0$, *and*
(iii) $\Omega_c>0$,

then

$$0<A<\Omega\leqslant\Omega_c \quad in\ \ \overline{\mathcal{I}}; \tag{49}$$

in particular, $u^t u_\phi\geqslant 0$, *and, hence, the angular momentum density is non-negative. Moreover,*

$$0<A<\max_{\mathcal{S}}\Omega\leqslant\Omega_c \quad in\ \ \mathcal{E}. \tag{50}$$

Note: As remarked above, if the interior (fluid) contains points of the axis, then condition (ii) is already guaranteed, and Ω_c is the constant value of Ω on the axis; cf. Note 1 in the previous lemma. See also Notes 2 and 3. And observe, requirement (iii) is in principle much weaker than $\Omega>0$, but, as seen in the conclusion of this proposition, $\Omega>0$ already follows. Furthermore, the fact that $\Omega\leqslant\Omega_c$ in $\overline{\mathcal{I}}$ shows that in differentially rotating stars the core may rotate faster than the envelope, so that the core can be supported by rapid rotation before mass shedding is reached at the equator.[18]

Proof: We divide the proof in four steps.

First step: Let us see first $A\leqslant\Omega$ in $\overline{\mathcal{I}}$. Suppose (to get a contradiction) $A(x_0)>\Omega(x_0)$ for some $x_0\in\overline{\mathcal{I}}$. We have seen, in the previous lemma, cf. (48), that this is equivalent to $A(x_0)>\Omega(x_0)\geqslant\Omega_c$; and, hence, using hypothesis (iii), $A(x_0)>\Omega_c>0$. Therefore, by the continuity of A [indeed $A\in C^1$, cf. (32)] and the asymptotic flatness [$\lim_{\|x\|\to\infty}A=0$, cf. (33)], we infer that there exists an open and connected neighborhood of x_0, $\mathcal{N}_{x_0}\subset\mathbb{R}^5$, such that

$$\begin{aligned} &A>\Omega_c \quad \text{in}\ \ \mathcal{N}_{x_0},\\ &\text{and}\ \ A=\Omega_c \quad \text{on}\ \ \partial\mathcal{N}_{x_0}. \end{aligned} \tag{51}$$

We distinguish two cases.

Case 1: $\mathcal{N}_{x_0}\cap\mathcal{E}=\varnothing$, that is, the neighborhood is contained in the interior, $\mathcal{N}_{x_0}\subseteq\mathcal{I}$. Thus we have, again using the previous lemma, $A>\Omega\geqslant\Omega_c>0$ in $\mathcal{N}_{x_0}$; particularly, $\Omega-A<0$ in $\mathcal{N}_{x_0}$, and, therefore, by Eq. (29),

$$L_0 A>0 \quad \text{in}\ \ \mathcal{N}_{x_0}\subseteq\mathcal{I}.$$

From (32), in particular, $A\in C^2(\mathcal{I})\cap C^0(\overline{\mathcal{I}})$, and, hence, $A\in C^2(\mathcal{N}_{x_0})\cap C^0(\overline{\mathcal{N}}_{x_0})$. And applying the weak maximum principle, Theorem 1 in Appendix A, to the operator L_0 (on A) in $\mathcal{N}_{x_0}$, we obtain that the maximum of A is reached on the boundary, i.e.,

$$\max_{\overline{\mathcal{N}}_{x_0}} A=\max_{\partial\mathcal{N}_{x_0}} A,$$

contradicting (51).

Case 2: $\mathcal{N}_{x_0}\cap\mathcal{E}\neq\varnothing$. (Notice, here is included the case where $x_0\in\partial\mathcal{I}=\mathcal{S}$.) We denote

$$\mathcal{I}_{x_0} \equiv \mathcal{N}_{x_0} \cap \mathcal{I} \quad \subseteq \mathcal{I},$$

$$\mathcal{E}_{x_0} \equiv \mathcal{N}_{x_0} \cap \mathcal{E} \quad \subset \mathcal{E},$$

and

$$\Gamma \equiv \mathcal{N}_{x_0} \cap \mathcal{S}.$$

Observe, $\Gamma \neq \varnothing$, because $\mathcal{N}_{x_0}$ is connected, $x_0 \in \mathcal{N}_{x_0} \cap \overline{\mathcal{I}} \neq \varnothing$, and, by assumption in this case, $\mathcal{N}_{x_0} \cap \mathcal{E} \neq \varnothing$. Moreover, $\Gamma = \overline{\mathcal{I}}_{x_0} \cap \overline{\mathcal{E}}_{x_0} = \partial\mathcal{I}_{x_0} \cap \partial\mathcal{E}_{x_0}$. Thus, we have in the interior, from (51),

$$A > \Omega_c \quad \text{in} \quad \mathcal{I}_{x_0} \cup \Gamma \quad \subset \mathcal{N}_{x_0} \quad (\Gamma \subset \partial\mathcal{I}_{x_0}),$$

$$A = \Omega_c \quad \text{on} \quad \partial\mathcal{I}_{x_0} \backslash \Gamma \quad \subset \partial\mathcal{N}_{x_0};$$

and, applying the weak maximum principle (Theorem 1 in Appendix A) to the differential inequality [cf. (29)]

$$L_0 A > 0 \quad \text{in} \quad \mathcal{I}_{x_0} \subset \mathcal{I}$$

[again using (48), $A > \Omega \geqslant \Omega_c$ in $\mathcal{I}_{x_0}$], with $A \in C^2(\mathcal{I}_{x_0}) \cap C^0(\overline{\mathcal{I}}_{x_0})$, it follows

$$\max_{\overline{\mathcal{I}}_{x_0}} A = \max_{\partial\mathcal{I}_{x_0}} A = \max_{\Gamma} A;$$

in the exterior, we have analogously, from (51),

$$A > \Omega_c \quad \text{in} \quad \mathcal{E}_{x_0} \cup \Gamma \quad \subset \mathcal{N}_{x_0} \quad (\Gamma \subset \partial\mathcal{E}_{x_0}),$$

$$A = \Omega_c \quad \text{on} \quad \partial\mathcal{E}_{x_0} \backslash \Gamma \quad \subset \partial\mathcal{N}_{x_0}.$$

(Note, the point ∞ is not included in $\partial\mathcal{E}_{x_0}$, because $\Omega_c > 0$ and A is asymptotically flat, $A|_\infty = 0$.) But, in the exterior, $\mathcal{E}$, $\psi^2 \equiv 0$, and we have the elliptic equation for A

$$L_0 A = 0 \quad \text{in} \quad \mathcal{E}_{x_0} \subset \mathcal{E};$$

as a consequence, again by virtue of the maximum principle (Theorem 1 in Appendix A) now in $\mathcal{E}_{x_0}$

$$\max_{\overline{\mathcal{E}}_{x_0}} A = \max_{\partial\mathcal{E}_{x_0}} A = \max_{\Gamma} A.$$

We therefore have

$$\max_{\overline{\mathcal{I}}_{x_0}} A = \max_{\overline{\mathcal{E}}_{x_0}} A = \max_{\Gamma} A =: A(x_1), \quad \text{for some} \quad x_1 \in \Gamma.$$

Thus ($\overline{\mathcal{N}}_{x_0} = \overline{\mathcal{I}}_{x_0} \cup \overline{\mathcal{E}}_{x_0}$)

$$\max_{\overline{\mathcal{N}}_{x_0}} A = A(x_1), \quad \text{for some} \quad x_1 \in \Gamma \subset \mathcal{N}_{x_0} \quad (x_1 \text{ interior point});$$

and, since $A \in C^1(\mathbb{R}^5)$, in particular, $A \in C^1(\mathcal{N}_{x_0})$, it follows

$$\nabla A|_{x_1} = \mathbf{0}. \tag{52}$$

However, this is not possible, because, on the other hand, x_1 is a point of the star's surface $x_1 \in \Gamma \subset \mathcal{S}$, and, from the assumptions on the stellar model, $\partial\mathcal{I} = \mathcal{S}$ satisfies an exterior sphere condition everywhere, i.e., $\partial\mathcal{E} = \mathcal{S} \cup \{\infty\}$ satisfies at each point of $\mathcal{S}$ (in particular, at x_1) an interior sphere condition (cf. Definition in Appendix A). This allows us to apply the called boundary-point lemma, Theorem 2 in Appendix A, for the operator L_0 in the exterior domain $\mathcal{E}_{x_0}$, with respect to the point $x_1 \in \Gamma \subset \partial\mathcal{E}_{x_0}$, being $A(x_1) = \max A$ in $\overline{\mathcal{E}_{x_0}}$. And, since $A \not\equiv \text{const}$ [because $A > \Omega_c > 0$ in $\mathcal{E}_{x_0} \cup \Gamma, A = \Omega_c$ or $2\mathcal{E}_{x_0} \setminus \Gamma$, and A is continuous], this yields

$$\langle \boldsymbol{\nu}, \nabla A \rangle|_{x_1} = \partial_{\boldsymbol{\nu}} A|_{x_1} \neq 0, \quad \boldsymbol{\nu} \equiv \text{ outward pointing unit normal to } \mathcal{S} \text{ at } x_1;$$

contradicting (52). Consequently,

$$A \leqslant \Omega \quad \text{in } \overline{\mathcal{I}}. \tag{53}$$

Second step: $A < \Omega \leqslant \Omega_c$ in $\overline{\mathcal{I}}$. This can be seen as follows. From inequality (53) and using (48) we also have

$$\Omega \leqslant \Omega_c \quad \text{in } \overline{\mathcal{I}}, \tag{54}$$

and, combining (53) and (54),

$$A \leqslant \Omega_c \quad \text{in } \overline{\mathcal{I}}. \tag{55}$$

On the other hand, we have Eq. (29), i.e., $L_0 A = -\psi^2 \cdot (\Omega - A)$, satisfied everywhere, in particular, in the interior (in a classical sense). Let

$$u(x) := A(x) - \Omega_c \quad \forall x \in \overline{\mathcal{I}}.$$

Since Ω_c is constant, we can rewrite Eq. (29),

$$Lu := L_0 u - \psi^2 \cdot u = +\psi^2 \cdot (\Omega_c - \Omega) \geqslant 0 \quad [\text{by } (54)].$$

Hence, we have

$$Lu \geqslant 0 \quad \text{in } \mathcal{I}, \tag{56}$$

where, like A, $u \in C^2(\mathcal{I}) \cap C^0(\overline{\mathcal{I}})$, and

$$u \leqslant 0 \quad \text{in } \overline{\mathcal{I}}, \tag{57}$$

by inequality (55). We want to see $u < 0$. Suppose (to get a contradiction) that $u(\hat{x}) = 0$ for some $\hat{x} \in \mathcal{I}$; then, by (57), $0 = u(\hat{x}) = \max_{\overline{\mathcal{I}}} u$, $\hat{x} \in \mathcal{I}$ (interior point). However, by the strong maximum principle, Theorem 3 in Appendix A, for (56), u cannot reach a non-negative maximum at an interior point of $\mathcal{I}$, unless u is a constant in $\mathcal{I}$. That means, in our case, u cannot vanish somewhere in $\mathcal{I}$ unless it vanishes identically in $\mathcal{I}$. But $u \equiv \text{const} = u(\hat{x}) = 0$ in $\mathcal{I}$, i.e.,

$$A \equiv \text{const} = \Omega_c > 0 \quad \text{in } \mathcal{I}, \quad A \in C^1 \text{ everywhere}, \tag{58}$$

yields, in particular,

$$\nabla A = \mathbf{0} \quad \text{on } \partial\mathcal{I} = \mathcal{S}. \tag{59}$$

On the other hand, in the exterior, $\mathcal{E}$, we have $L_0 A=0$, with $A\in C^2(\mathcal{E})\cap C^0(\overline{\mathcal{E}})$, and, by the weak maximum principle (Theorem 1 in Appendix A)

$$\max_{\overline{\mathcal{E}}} A = \max_{\partial\mathcal{E}=\mathcal{S}\cup\{\infty\}} A\,,$$

but, using asymptotic flatness ($A|_\infty=0$) and (58), actually,

$$\max_{\overline{\mathcal{E}}} A = \max_{\mathcal{S}} A =: A(x_1) \quad \text{for some } x_1\in\mathcal{S}\subset\partial\mathcal{E}\,.$$

In particular, since $A\not\equiv$const, the boundary-point lemma, Theorem 2 in Appendix A, applied to the operator L_0 in the exterior domain $\mathcal{E}$ (where, by assumption, an interior sphere condition is satisfied in particular at $x_1\in\mathcal{S}\subset\partial\mathcal{E}$) yields a nonvanishing outward normal derivative

$$\langle \boldsymbol{\nu}, \nabla A\rangle|_{x_1} = \partial_{\boldsymbol{\nu}} A|_{x_1} \neq 0\,,$$

in contradiction to (59). Therefore, $u<0$ everywhere in $\mathcal{I}$, i.e., $A<\Omega_c$ in $\mathcal{I}$; and, hence, also on $\partial\mathcal{I}$, because, by the weak minimum principle, Theorem 1 in Appendix A, applied to $L_0 A=-\psi^2\cdot(\Omega-A)\leqslant 0$ in $\mathcal{I}$ [by (53)], we get $\min_{\overline{\mathcal{I}}} A=\min_{\partial\mathcal{I}} A$. Therefore, $A<\Omega_c$ in $\overline{\mathcal{I}}$, or, equivalently [cf. (48)],

$$A<\Omega\leqslant\Omega_c \quad \text{in } \overline{\mathcal{I}}\,.$$

Third step: $A>0$ everywhere (i.e., the same conclusion of Proposition 1, but now using different hypotheses). We have seen in the first step $A\leqslant\Omega$ in $\overline{\mathcal{I}}$; which yields, $L_0 A\leqslant 0$ in $\overline{\mathcal{I}}$. On the other hand, $L_0 A=0$ in $\mathcal{E}$. Accordingly,

$$L_0 A\leqslant 0 \quad \text{everywhere in } \overline{\mathcal{I}}\cup\mathcal{E}=\mathbb{R}^5\,.$$

Applying now the strong minimum principle for generalized supersolutions, Theorem 4 in Appendix B, and using asymptotic flatness, as was argued in the proof of Proposition 1, it follows $A>0$ everywhere. [Notice, here $A\not\equiv$const, because, by asymptotic flatness and continuity, $A\equiv$const is equivalent to $A\equiv 0$; by Eq. (37), also $\Omega\equiv 0$, and, hence, from $\Omega-A\equiv 0$, we would have [cf. (46)] $0\equiv\Phi=\mathcal{F}(0)$; but this is not possible, since requirements (i) and (ii) imply $\mathcal{F}(0)>\mathcal{F}(\Omega_c)=0$.] Thus, $A>0$ everywhere, in particular, in the interior; using now the result of the second step, we finally get (49), $0<A<\Omega\leqslant\Omega_c$ in $\overline{\mathcal{I}}$. Notice, hence, $\Omega>0$ (in $\overline{\mathcal{I}}$).

Fourth step: $A<\max_{\mathcal{S}}\Omega\leqslant\Omega_c$ in $\mathcal{E}$. The elliptic equation holding in the exterior,

$$L_0 A=0 \quad \text{in } \mathcal{E}\,,$$

yields, by virtue of the weak maximum principle (Theorem 1 in Appendix A),

$$\max_{\overline{\mathcal{E}}} A = \max_{\partial\mathcal{E}=\mathcal{S}\cup\{\infty\}} A\,;$$

but, using asymptotic flatness ($A|_\infty=0$), we actually have $\max_{\mathcal{S}\cup\{\infty\}} A=\max_{\mathcal{S}} A$. On the other hand, we have seen $A<\Omega\leqslant\Omega_c$ in particular in $\partial\mathcal{I}=\mathcal{S}$, and $\mathcal{S}$ is compact. Hence,

$$\text{in } \mathcal{E}, \quad 0<A\leqslant\max_{\overline{\mathcal{E}}} A = \max_{\mathcal{S}=\partial\mathcal{I}} A < \max_{\mathcal{S}}\Omega\leqslant\Omega_c\,,$$

establishing also (50). □

Remark 3: Analogously as argued in Remarks 1 and 2, it is possible to ''reflect'' Proposition 3. As a consequence, in particular, in a model for a star which is rotating differentially with the

function $\mathcal{F}$ either strictly decreasing with $\Omega_c>0$ or strictly increasing with $\Omega_c<0$, $\mathcal{F}(\Omega_c)=0$, the angular momentum density has the same sign as Ω_c, and, hence, as the angular velocity of the fluid. Also, accordingly, the following holds:

$$0<|A|<|\Omega|\leqslant|\Omega_c| \quad \text{in } \overline{\mathcal{I}},$$

$$0<|A|<|\max_{\mathcal{S}}\Omega|\leqslant|\Omega_c| \quad \text{in } \mathcal{E}.$$

V. GENERAL BOUNDS. ROTATIONAL ENERGY

A. Preliminary observation

Let $u:\mathbb{R}^n\to\mathbb{R}$ be a differentiable function, $V:\mathbb{R}^n\to\mathbb{R}^n$ be a vector field, and $G\subset\mathbb{R}^n$ a domain where Gauss' theorem can be applied. Then, due to

$$\operatorname{div}(uV)=\sum_i \partial_i(uV_i)=\langle \mathcal{D}u,V\rangle+u\operatorname{div}V$$

[where $\langle .,.\rangle$ is the Euclidean scalar product, $\mathcal{D}$ is the gradient operator, and $\operatorname{div}V:=\Sigma_i\partial_i(V_i)$, the divergence], we get, integrating over G and applying the Gauss theorem,

$$\int_G u\operatorname{div}V=-\int_G\langle \mathcal{D}u,V\rangle+\int_{\partial G}u\,\langle V,\boldsymbol{\nu}\rangle\,, \tag{60}$$

where $\boldsymbol{\nu}$ is the outer unit normal of ∂G (and, for simplicity in the notation, volume- and surface elements have been dropped).

B. Appropriate form of the field equation

The general (elliptic) field equation for A, Eq. (19), may be rewritten as follows:

$$\operatorname{div}(\rho^3e^{3B}e^{-4U}\mathcal{D}A)=-f^2\cdot(\Omega-A)\,, \tag{61}$$

where $\mathcal{D}:=(\partial_\rho,\partial_z)$ and div are the flat expressions in $\mathbb{R}^2$, and

$$f^2(\rho,z)\equiv f^2:=\rho^3e^{3B-4U}\psi^2=16\pi\,(\varepsilon+p)\,\frac{\rho^3e^{3B}e^{2(K-2U)}}{e^{2U}-\rho^2e^{2(B-U)}(\Omega-A)^2}\geqslant 0\,.$$

Especially we have $f^2\equiv 0$ in the exterior E of the star [cf. (5)].

Note, in this section (independent of Sec. IV) we go back to the field equation in the meridian plane coordinates, $(\rho,z)\in\mathbb{R}_0^+\times\mathbb{R}$, instead of the 5-*lifted* one (on $\mathbb{R}^5$) (cf. Sec. III A).

C. Main observation

Multiplying Eq. (61) by A, and using Eq. (60), by setting $u=A$, $V=\rho^3e^{3B}e^{-4U}\mathcal{D}A$, and $G=\mathbb{R}_0^+\times\mathbb{R}\subset\mathbb{R}^2$ [actually, we consider a ball in $\mathbb{R}^2$ centered at the origin of the coordinate system with arbitrarily large radius, $\mathcal{B}_\sigma(\mathbf{0})\subset\mathbb{R}^2$, and take $G=\mathcal{B}_\sigma(\mathbf{0})\cap(\mathbb{R}_0^+\times\mathbb{R})\subset\mathbb{R}^2$, $\sigma\to\infty$], we obtain

$$-\int_I f^2A(\Omega-A)=-\int_{\mathbb{R}_0^+\times\mathbb{R}}\rho^3e^{3B}e^{-4U}\|\mathcal{D}A\|^2+\int_{\partial(\mathbb{R}_0^+\times\mathbb{R})}A\,\rho^3e^{3B}e^{-4U}\langle\mathcal{D}A,\nu\rangle\,,$$

where $I\subset\mathbb{R}_0^+\times\mathbb{R}\subset\mathbb{R}^2$ represents the (ρ,z)-coordinates of the interior of the star (note, f^2 vanishes in the exterior E). The first term on the right-hand side (which converges, since $\|\mathcal{D}A\|$ falls off rapidly enough at the spacelike "infinity" [19]) is obviously nonpositive. And the second term

vanishes, because of the asymptotic behavior of A at spatial infinity,[19] and because the integrand, due to the factor ρ^3, vanishes on the axis of rotation $\rho=0$, which is the other part of $\partial(\mathbb{R}_0^+\times\mathbb{R})=\{R=(\rho^2+z^2)^{1/2}\to\infty\}\cup\{\rho=0\}$. Hence, we have found

$$\int_I f^2 A\,(\Omega-A)\geqslant 0\,. \tag{62}$$

D. Consequences

In order to see more the linear algebra behind, we introduce now the bilinear form

$$\langle u,v\rangle_f := \int_I f^2(\rho,z)\,u(\rho,z)\,v(\rho,z)\,\mathrm{d}\rho\,\mathrm{d}z\,,\quad u,v:I\to\mathbb{R}\quad \text{in } L^2(I)\,,$$

and the induced seminorm $\|.\|_f := (\langle .\,,.\rangle_f)^{1/2}$. With this definition we can write inequality (62) as

$$\langle A,\Omega\rangle_f \geqslant \|A\|_f^2\,,$$

and immediately see that especially

$$\langle \Omega,A\rangle_f = \langle A,\Omega\rangle_f \geqslant 0\,. \tag{63}$$

Furthermore, using the Cauchy–Schwarz inequality, we have $\|A\|_f\|\Omega\|_f\geqslant\langle A,\Omega\rangle_f\geqslant\|A\|_f^2$, and hence (since $A\equiv 0\Leftrightarrow\ \Omega\equiv 0$) we get (in full general) the main result of these sections, namely,

$$0\leqslant\|A\|_f\leqslant\|\Omega\|_f\,. \tag{64}$$

Proposition 4:

$$0\leqslant\int_I f^2 A^2\leqslant\int_I f^2\ \ \Omega^2 \tag{65}$$

[without any restriction concerning the rotation law, $\Omega\mapsto\mathcal{F}(\Omega)$ in (14), in the differentially rotating case, nor the regularity and sign uniformity of Ω]. These integrals can be regarded as some kind of "mean value" with respect to the "density" f^2, thus, (65) fulfilling the physical expectations.[2]

In addition, multiplying inequality (64) by $\|\Omega\|_f$, we find (again using the Cauchy–Schwarz inequality) $\|\Omega\|_f^2\geqslant\|\Omega\|_f\|A\|_f\geqslant\langle\Omega,A\rangle_f$, i.e.,

$$\langle\Omega,\Omega-A\rangle_f\geqslant 0\,. \tag{66}$$

Remarkably, the integral given in (66) has an important physical meaning; it is, up to a constant factor, the so-called *total rotational energy* (see, e.g., Refs. 15, 16, 18, and 20),

$$T\equiv\frac{1}{2}\int_I\Omega\,\mathrm{d}J\ \ =\ \ \frac{1}{2}\int_I 2\pi\,\Omega\,T_\phi{}^t\,(-g)^{1/2}\,\mathrm{d}\rho\,\mathrm{d}z\ \ =\ \ \frac{1}{16}\langle\Omega,\Omega-A\rangle_f$$

(also denoted E_{rot} or M_{rot}). Thus, (66) shows $T\geqslant 0$. Furthermore,

$$16\ \ T=\langle\Omega,\Omega-A\rangle_f=\|\Omega\|_f^2-\langle\Omega,A\rangle_f\leqslant\|\Omega\|_f^2\,,$$

by (63). Hence, we have the following proposition.

Proposition 5:

$$0 \leqslant T \equiv \frac{1}{16}\int_I f^2 \ \Omega\,(\Omega - A) \leqslant \frac{1}{16}\int_I f^2 \ \Omega^2\,. \tag{67}$$

This generalizes the result given by Hartle (cf. Ref. 7, Sec. IV) in the limit of slow (differential) rotation to the general differentially rotating case.

VI. CONCLUSIONS

Aiming to derive general properties of equilibrium nonsingular stellar models with differential rotation, we have established that for a wide class of rotation laws the distribution of angular velocity of the fluid has a sign, and then both the dragging rate (angular velocity of locally nonrotating observers) and the angular momentum density have the sign of the fluid angular velocity (Sec. IV). In addition, the mean value (with respect to a density function) of the dragging rate is shown to be less than the mean value of the fluid angular velocity; and this is proved in full general, without having to restrict the rotation law, nor the uniformity in sign of the fluid angular velocity. A further simple calculation of linear algebra on this inequality yields a generalization of the result given by Hartle[7] concerning positivity and upper bound of the total rotational energy in the limit of slow (differential) rotation to the general differentially rotating case (Sec. V).

APPENDIX A: MAXIMUM (MINIMUM) PRINCIPLES FOR CLASSICAL SUB-(SUPER-) SOLUTIONS

By G we denote an open and connected set, i.e., a domain, in $\mathbb{R}^n$, $n \geqslant 2$. The boundary is denoted by $\partial G \equiv \overline{G} \cap (\mathbb{R}^n \backslash G)$. We define the differential operators

$$L_0 u := a_{ij}(x) \ \partial_{ij} u + b_i(x)\, \partial_i u\,, \quad a_{ij} = a_{ji}\,,$$

and

$$L u := L_0 u + c(x) \cdot u$$

(where the summation convention that repeated indices indicate summation from 1 to n is followed), such that[21]

(1) L (and, hence, L_0) is uniformly elliptic in G in the special form

$$0 < \lambda\,|y|^2 \leqslant a_{ij}(x)\, y_i y_j \leqslant \Lambda\,|y|^2, \quad \forall y \in \mathbb{R}^n \backslash \{0\}, \quad \forall x \in G \quad \left(|y|^2 := \sum_i \ y_i{}^2 \right), \tag{A1}$$

where λ and Λ are constants such that $0 < \lambda \leqslant \Lambda < \infty$;

(2) all coefficients in L (and in L_0), a_{ij}, b_i (for all i and j), and c, are measurable and bounded functions in G,

$$|a_{ij}| < \infty, \quad |b_i| < \infty, \quad |c| < \infty \ \text{ in } \ G \quad (i,j \in \{1,\ldots,n\})\,. \tag{A2}$$

Theorem 1: [the weak maximum (minimum) principle for L_0 $(c = 0)$] *Suppose that* $L_0 u \geqslant 0$ $(\leqslant 0)$ *in a bounded domain* G, *with* $u \in C^2(G) \cap C^0(\overline{G})$. *Then the maximum (minimum) of* u *is attained on the boundary, that is,*

$$\max_{\overline{G}} u = \max_{\partial G} u \quad \left(\min_{\overline{G}} u = \min_{\partial G} u \right).$$

(A proof of that theorem can be found, e.g., in Ref. 22, Theorem 3.1.)

Definition: For a set $G \subset \mathbb{R}^n$, the boundary ∂G is said to satisfy an interior (exterior) sphere condition *at a point $x_1 \in \partial G$ iff there exists a ball $B \subset G$ ($B \subset \mathbb{R}^n \backslash \overline{G}$) with $x_1 \in \partial B$.*

Theorem 2 (the boundary-point lemma): *Suppose that $L_0 u \geqslant 0$ ($c = 0$) in a domain G not necessarily bounded. Let $x_1 \in \partial G$ be such that*

(i) *u is continuous at x_1,*
(ii) *$u(x_1) \geqslant u(x)$ for all $x \in G$, and*
(iii) *∂G satisfies an interior sphere condition at x_1.*

Then the outer normal derivative of u at x_1, if it exists, satisfies the strict inequality

$$\partial_{\boldsymbol{\nu}} u(x_1) > 0,$$

unless $u \equiv \text{const} = u(x_1)$. (A proof of that result can be found, e.g., in Ref. 23, Theorem 7, Chap. 2.) *If $c \leqslant 0$ (in $Lu \geqslant 0$), the same conclusion holds provided $u(x_1) \geqslant 0$.* (See Ref. 23, Theorem 8, Chap. 2. Also Ref. 22, Lemma 3.4.)

Theorem 3 [the strong maximum (minimum) principle for *L*]: *Let $Lu \geqslant 0$ ($\leqslant 0$) in a domain G not necessarily bounded, with $u \in C^2(G) \cap C^0(\overline{G})$, and the operator L satisfying*

$$c \leqslant 0 \quad \text{in } G \tag{A3}$$

apart from conditions (A1) and (A2) above. Then u cannot attain a non-negative maximum (non-positive minimum) at an interior point of G, unless $u \equiv \text{const}$ in G. For $c = 0$, i.e., $L = L_0$, the same conclusion holds without the requirement non-negative (nonpositive). (For the proof we refer again to Ref. 22, Theorem 3.5; or Ref. 23, Theorems 5 and 6, Chap. 2.)

APPENDIX B: MAXIMUM (MINIMUM) PRINCIPLE FOR GENERALIZED SUB-(SUPER-) SOLUTIONS

Consider in a domain (open and connected set) $G \subset \mathbb{R}^n$ ($n \geqslant 2$) the differential operator with principal part of divergence form, defined by

$$Lu = \partial_i [a_{ij}(x) \partial_j u + a_i(x)\, u] + b_i(x)\, \partial_i u + c(x)\, u\,,$$

with $a_{ij} = a_{ji}$. Notice, an operator L of the general form $Lu = \tilde{a}_{ij}(x) \partial_{ij} u + \tilde{b}_i(x) \partial_i u + \tilde{c}(x) u$ may be written in divergence form provided its principal coefficients $\tilde{a}_{ij}$ are differentiable. If furthermore the $\tilde{a}_{ij}$ are constants, then even with coinciding coefficients ($a_{ij} = \tilde{a}_{ij}$, $b_i = \tilde{b}_i$, $c = \tilde{c}$) and $a_i \equiv 0$. Let us assume that

(1) L is strictly elliptic in G, i.e., $\exists$ a constant $\lambda > 0$ such that $\lambda \leqslant$ the minimum eigenvalue of the principal coefficient matrix $[a_{ij}(x)]$,

$$\lambda |y|^2 \leqslant a_{ij}(x)\, y_i y_j \quad \forall y \in \mathbb{R}^n, \quad \forall x \in G\,; \tag{B1}$$

(2) a_{ij}, a_i, b_i, and c are measurable and bounded functions in G,

$$|a_{ij}| < \infty, \quad |a_i| < \infty, \quad |b_i| < \infty, \quad |c| < \infty \text{ in } G \quad (i,j \in \{1,\ldots,n\})\,. \tag{B2}$$

By definition, for a function u which is only assumed to be *weakly differentiable* and such that the functions $a_{ij} \partial_j u + a_i u$ and $b_i \partial_i u + cu$, $i = 1,\ldots,n$ are locally integrable [in particular, for u belonging to the Sobolev space $W^{1,2}(G)$], u is said to satisfy $Lu = g$ in G *in a generalized (or weak) sense* (g also a locally integrable function in G) if it satisfies

$$\mathcal{L}(u,\varphi;G) := \int_G \{(a_{ij}\partial_j u + a_i u)\partial_i\varphi - (b_i\partial_i u + cu)\varphi\}\mathrm{d}x = -\int_G g\,\varphi\,\mathrm{d}x, \quad \forall\varphi \geqslant 0 \quad \varphi \in C_c^1(G)$$

[where $C_c^1(G)$ is the set of functions in $C^1(G)$ with compact support in G].

Notice, u is *generalized sub-(super-)solution* relative to a differential operator L and the domain G [i.e., satisfies $Lu \geqslant 0$ ($\leqslant 0$) in G in a generalized sense] if it satisfies $\mathcal{L}(u,\varphi;G) \leqslant 0$ ($\geqslant 0$), $\forall\varphi \geqslant 0$ $\varphi \in C_c^1(G)$.

Theorem 4 [strong maximum (minimum) principle]: *Let $u \in W^{1,2}(G) \cap C^0(G)$ satisfy $Lu \geqslant 0$ ($\leqslant 0$) in G in a generalized sense, with*

$$\int_G (c\varphi - a_i\partial_i\varphi)\,\mathrm{d}x \leqslant 0, \quad \forall\varphi \geqslant 0\ \varphi \in C_c^1(G) \tag{B3}$$

[equivalent to requirement (A3) in the classical case] and conditions (B1) and (B2) above. Then u cannot achieve a non-negative maximum (nonpositive minimum) in the interior of G, unless u $\equiv$const. (A proof of this theorem can be found in Ref. 22, Theorem 8.19.)

[12] One could think in principle that on the rotation axis ($\boldsymbol{\eta} \to 0$) $A = -\mathbf{g}(\boldsymbol{\xi},\boldsymbol{\eta})/\mathbf{g}(\boldsymbol{\eta},\boldsymbol{\eta})$ might diverge, however the example of the Minkowski metric in cylindrical coordinates (ρ,z), rotating with angular velocity Ω_0 (and *locally* every metric can be represented in that way), where $\mathbf{g}(\boldsymbol{\xi},\boldsymbol{\eta}) = -\rho^2\Omega_0$, $\mathbf{g}(\boldsymbol{\eta},\boldsymbol{\eta}) = \rho^2$, and, hence, $A = \Omega_0$, shows that the dragging potential A is indeed bounded for any singularity-free space–time.
[13] Consider $\Delta u = f$, if f is an essentially bounded function, $f \in L^\infty(G)$, with compact support, then $u \in C^{1,\alpha}(G)$ for some $\alpha < 1$. See, e.g., O.D. Kellogg, *Foundations of Potential Theory* (Dover, New York, 1953), pp. 151 and 139.

Elliptic solitons and Gröbner bases

Yurii V. Brezhnev[a)]
Theoretical Physics Department, Kaliningrad State University, A. Nevsky st. 14, Kaliningrad 236041, Russia

(Received 18 August 2003; accepted 17 October 2003)

We consider the solution of spectral problems with elliptic coefficients in the framework of the Hermite *Ansatz*. We show that the search for exactly solvable potentials and their spectral characteristics is reduced to a system of polynomial equations solvable by the Gröbner bases method and others. New integrable potentials and corresponding solutions of the Sawada-Kotera, Kaup-Kupershmidt, Boussinesq equations and others are found. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1633353]

I. INTRODUCTION

The article is devoted to the algorithmic problems associated with integrating the spectral problems

$$\hat{L}\Psi \equiv \frac{d^n}{dx^n}\Psi(x;\lambda)+u_1(x,\lambda)\frac{d^{n-1}}{dx^{n-1}}\Psi(x;\lambda)+\cdots+u_n(x,\lambda)\,\Psi(x;\lambda)=0, \tag{1}$$

where u_j are elliptic functions of x and arbitrary (rational or transcendental) functions of λ. We shall restrict our consideration to the Schrödinger equation

$$\Psi''-u(x)\,\Psi=\lambda\,\Psi, \tag{2}$$

the equation

$$\Psi'''-u(x)\,\Psi'=\lambda\,\Psi, \tag{3}$$

and the generalization of the Halphen equation

$$\Psi'''-u(x)\,\Psi'-v(x)\,\Psi=\lambda\,\Psi. \tag{4}$$

We use the term *potential* for the $u(x), v(x)$-functions. Until the 1970/80s, few exactly solvable potentials were known. Earlier, in 1872, Hermite[28] developed an approach for the integration of the Lamé equation

$$\Psi''-n(n+1)\,\wp(x)\,\Psi=\lambda\,\Psi, \tag{5}$$

and, later, Halphen extended it to the third order equation

$$\Psi'''-(n^2-1)\,\wp(x)\,\Psi'-\tfrac{1}{2}(n^2-1)\,\wp'(x)\,\Psi=\lambda\,\Psi. \tag{6}$$

Here and below $\sigma, \zeta, \wp, \wp'$ denote the standard Weierstrassian functions. See Refs. 25, 19, and 29 for an extensive discussion of these classical examples. According to modern terminology, the set of exactly solvable elliptic potentials is a particular case of finite-gap potentials in elliptic func-

a)Current address: Department of Mathematics and Statistics, Boston University, 111 Cummington St, Boston, Ma 02215. Electronic mail: brezhnev@math.bu.edu

tions. An intense investigation of elliptic potentials was initiated by Ref. 30, and in 1987 Verdier and Treibich[41,38] unexpectedly found new potentials for the equation (2) in elliptic functions

$$u(x)=6\,\wp(x)+2\,\wp(x-\omega_j) \tag{7}$$

and gave the term *elliptic solitons* to them. Recently V. Matveev drew attention to the fact that such potentials, in Jacobian form, were already considered by Darboux in a short note[12] in 1882. The following year, two comprehensive mémoires by Sparre[36] appeared on this topic.

The development of a theory led to the current result that elliptic solitons are the widest class of finite-gap *explicit* solutions. See, for example, Refs. 34 and 17, recent results in Refs. 35 and 37 and references therein. Reference 1 reviews work in finite-gap theory up to the beginning of the 1990s and Refs. 22 and 24 contain a wide bibliography on that score.

One feature of elliptic solitons is the potential, and the Ψ-function can be found by the Hermite *Ansatz* method.[28] In the case of the potentials with the only pole in a parallelogram of periods, the derivation of the algebraic curve and other characteristics is not difficult. For this purpose it is enough to take a few resultants,[15,1] but in the general case the elimination technique is insufficient. Section II contains a pure algebraic interpretation of Hermite's method. In Sec. III, we show that the general scheme for solving the problem under consideration (1) is reduced to the computation of the Gröbner basis for some polynomial system. After Buchberger's discovery in the 1960s of an algorithm for finding the polynomial ideal bases, this area of algorithmic mathematics has rapidly developed. See Ref. 32 with regard to the modern achievements in this area. Section IV contains a relation between the method and traditional objects in finite-gap integration theory: the canonical form of an algebraic curve $\tilde{F}(\mu,\lambda)=0$ and reduction of one of the holomorphic differentials to the elliptic. Some new examples of elliptic solitons and their applications to the integrable partial differential equations (PDEs) are presented in Secs. V and VI and development of the theory is discussed in Sec. VII.

II. ALGEBRAIC CHARACTERIZATION OF THE HERMITE METHOD

Based on the Φ-function

$$\Phi(x;\alpha)=\frac{\sigma(\alpha-x)}{\sigma(\alpha)\,\sigma(x)}e^{\zeta(\alpha)\,x}, \tag{8}$$

or more precisely *l'élément simple*

$$\mathbf{\Phi}(x;\alpha,k)=\frac{\sigma(\alpha-x)}{\sigma(\alpha)\,\sigma(x)}e^{(\zeta(\alpha)+k)\,x}$$

by Halphen,[26,27] Hermite and Halphen[28,25] considered the following *Ansatz* for the Ψ-function:

$$\Psi=\mathbf{\Phi}(x;\alpha,k)+a_1\mathbf{\Phi}'(x;\alpha,k)+\cdots+a_n\mathbf{\Phi}^{(n)}(x;\alpha,k). \tag{9}$$

The function $\mathbf{\Phi}(x;\alpha,k)$ as well its x-derivatives $\mathbf{\Phi}'(x;\alpha,k)$, …, $\mathbf{\Phi}^{(n)}(x;\alpha,k)$ are doubly-periodic functions of x of the second kind. According to (1), (8) and (9), the expression $\hat{L}\Psi/\mathbf{\Phi}(x-x_0;\alpha,k)$ is a two-periodic meromorphic function with only one simple pole at the point x_0. It must be a constant function. Setting it to be equal to zero, we have $\hat{L}\Psi=0$ under the corresponding choice of additional parameters k, α and a_j. As the $\mathbf{\Phi}(x;\alpha,k)$-function has the first order pole at $x=0$ (Ref. 26, p. 231),

$$\mathbf{\Phi}(x;\alpha,k)=\frac{1}{x}+k+\frac{k^2-\wp(\alpha)}{2}x+\frac{k^3-3\,\wp(\alpha)\,k+\wp'(\alpha)}{6}x^2+\cdots,$$

to solve the problem, it is sufficient to equate to zero only the principal part(s) of the Laurent's expansion(s) of the expression $\hat{L}\Psi$, where Ψ is the *Ansatz* (9) or its multi-pole generalizations (see Examples 1–3 and 7 in Sec. V).

As a nontrivial example we shall consider the five-gap Lamé potential with $n=5$ in (5). It has been studied in Ref. 15, but we give a more simple solution. Note that the cases $n=2, 3, 4$ and partially 5 were considered already in Ref. 27, pp. 527–531. In the same place one can find mention of eliminations.

By Frobenius theory, Ψ must have a fifth order pole at $x=0$ and therefore the *Ansatz* for the Ψ-function should be the following:

$$\Psi=\mathbf{\Phi}+a_1\mathbf{\Phi}'+\cdots+a_4\mathbf{\Phi}^{(\mathrm{IV})}. \tag{10}$$

Substituting (10) in (5) and expanding the result at $x=0$, we obtain a system of equations in the variables k, α, a_j. This system is linear with respect to a_j. We do not write expressions for the a_j [Ref. 15, formula (3.7)]. The remaining equations have the form

$$\begin{aligned} w_1 &\equiv -6k^5+\tfrac{20}{3}(9\wp+\lambda)k^3-60\wp' k^2+(90\wp^2-20\lambda\wp-\tfrac{10}{7}\lambda^2+\tfrac{144}{7}g_2)k-\tfrac{4}{3}(9\wp-5\lambda)\wp', \\ w_2 &\equiv -5k^6+(75\wp+5\lambda)k^4-100\wp' k^3+(225\wp^2-30\lambda\wp-\tfrac{5}{7}\lambda^2+\tfrac{180}{7}g_2)k^2 \\ &\quad -20(3\wp-\lambda)\wp' k+25\wp^3-15\lambda\wp^2+\tfrac{5}{7}(\lambda^2-20g_2)\wp-40g_3-\tfrac{1}{21}\lambda^3+\tfrac{44}{7}g_2\lambda, \end{aligned} \tag{11}$$

which are understood to be equal to zero. The argument α in the $\wp, \wp'$-functions is omitted for brevity. The system (11) has to be considered as algebraic with respect to k and *transcendental* in α. We emphasize that everywhere in the article λ is a parameter, but not variable in polynomial bases. Insomuch as functions $\wp(\alpha)$ and $\wp'(\alpha)$ are related by the Weierstrass equation (torus)

$$w_3\equiv\wp'(\alpha)^2-4\wp(\alpha)^3+g_2\wp(\alpha)+g_3, \tag{12}$$

we supplement (11) by (12) and consider (11) and (12) as a *polynomial* system with respect to independent variables $(k, \wp, \wp')$. The simplest method of solution consists of the elimination of the variable $\wp$ followed by $\wp'$. As a result, we find that k must be a root of the polynomial

$$k^4(5103k^4-945\lambda k^2+40\lambda^2+54g_2)^4(225(27g_2-\lambda^2)P_6^2(\lambda)k^2+P_9(\lambda)P_3^2(\lambda)),$$

where $P_{6,9,3}(\lambda)$ are some polynomials in λ with degrees 6, 9, 3, respectively. It is not difficult to guess that the correct result requires that k and λ are related by the following equation,

$$F(k,\lambda): 225(27g_2-\lambda^2)P_6^2(\lambda)k^2+P_9(\lambda)P_3^2(\lambda)=0, \tag{13}$$

since the differential equation (5) is of second order and we must have not more than two solutions for k with fixed λ. Curve (13) can be brought into the canonical hyperelliptic form

$$\tilde{F}(\mu,\lambda): \mu^2=(27g_2-\lambda^2)P_9(\lambda)$$

by an obvious birational transformation [note a misprint $27g_2^2$ in this formula in Ref. 15, formula (3.8)]. The variables $\wp, \wp'$ as functions of k can be found in the same way: by the sequential reduction of exponents of $\wp, \wp'$ in (11) and (12).

Obviously, the resultant technique is almost impossible if the potential has several poles,[17,34] as the number of variables increases. Another approach consists of finding an equivalent system with the following criterion. It is advisable for the new system to contain linear equations in $\wp, \wp'$. These equations define α as a function of (k, λ):

$$\wp(\alpha)=R_1(k;\lambda), \quad \wp'(\alpha)=R_2(k;\lambda), \tag{14}$$

and we call (14) a cover of torus (12) in *algebraic* form. Suppose one of the new equations does not contain $\wp, \wp'$ (i.e., be a univariate polynomial in k) if the nontrivial solution for k exists. We interpret such a polynomial as *the algebraic curve* $F(k,\lambda)=0$ corresponding to given an elliptic potential. If $F(k,\lambda)$ has a factorized form, then each of the factors is investigated separately. The curve is one of them. It is clear that its degree in k has to be equal to the order n of the equation (1). The canonical form $\tilde{F}(\mu,\lambda)=0$ of the curve is obtained with the help of a birational transformation between variables $(k,\lambda)\leftrightarrow(\mu,\lambda)$ (see an explanation in Sec. IV). Note, there are specialized algorithms for the computation of the univariate polynomial in an ideal without solving the system as a whole.

III. GRÖBNER BASES, CURVES AND COVERS

We clarify the main idea using the previous example. Let us consider three polynomials $w_{1,2,3}(\wp',\wp,k)$ as a system generating an ideal in a polynomial ring $\mathbb{Q}(\lambda,g_2,g_3)[\wp',\wp,k]$,

$$\langle I\rangle = h_1 w_1 + h_2 w_2 + h_3 w_3,$$

where $h_j=h_j(\wp',\wp,k)$ are arbitrary elements of the ring. As is well known, the structure of the solution of the polynomial systems depends on the monomial ordering in a ring.[32] The arguments at the end of Sec. II (see also the elimination theorem in Ref. 11) lead to the choice of pure lexicographic ordering $\wp'\succ\wp\succ k$. Reference 11 contains a good exposition of details of this subject. The main property of the Gröbner base is expressed in the following.

Definition:[11] *Let* $\{w_1, w_2, \ldots\}$ *be a basis of ideal* $I=\langle w_1, w_2, \ldots\rangle$. *Let* $\succ$ *be a monomial ordering on the ring* $\mathbb{Q}[\ldots]$ *and* $\mathrm{LT}(f)$ *denote the leading term (monomial) of a polynomial* $f \in \mathbb{Q}[\ldots]$. *The set* $G=\{f_1, f_2, \ldots, f_N\}$ *is said to be a standard basis (Gröbner basis) if the monomial ideal generated by*

$$\langle \mathrm{LT}(f_1), \mathrm{LT}(f_2), \ldots, \mathrm{LT}(f_N)\rangle$$

is coincident with an ideal $\langle \mathrm{LT}(I)\rangle$ *generated by all the leading terms of* I.

In other words, the leading term of any polynomial in I is divisible by one of the $\mathrm{LT}(f_j)$. According to the definition at the end of Sec. II, the polynomial $F(k;\lambda)$, determining the algebraic curve

$$F(k;\lambda)=0, \tag{15}$$

is a generator of the intersection of the ideal I and the ring of all polynomials in k:

$$\langle F(k;\lambda)\rangle = I \cap \mathbb{Q}(\lambda)[k].$$

Thus we arrive at a general recipe for the solution of the spectral problem (1).

Proposition: Let $\{w_1, w_2, \ldots\}$ *be polynomials in* $\wp'(\alpha), \wp(\alpha), k, \ldots$ *appearing in the Hermite method and determining the solution of the spectral problem (1): the cover of torus (14) and the curve (15). Then we have the following.*

(1) Algorithmically, the method of solution is reduced to the computation of a standard basis for the ideal $I=\langle w_1, w_2, \ldots\rangle$ *with respect to pure lexicographic ordering* $\wp'(\alpha)\succ\wp(\alpha)\succ k \succ\cdots$. (*For example, by Buchberger's syzygy polynomials algorithm.*[7])

(2) Let $G=\{f_1, f_2, \ldots, f_N\}$ *be this basis. The algebraic curve (15) and its projection on the torus (12) in algebraic form (14) are contained in G if the univariate polynomial in k and polynomials (14) exist.*

(3) If G contains a polynomial free from variables $k, \wp'(\alpha), \wp(\alpha)$, *then the spectral problem (1) is* **not integrable** *in the framework of Hermite's Ansatz.*

Proof:

(1) The standard basis always exists and Buchberger's algorithm terminates.[11]

(2) Taking the resultants of $w_1, w_2, \ldots$ we eliminate variables $\wp, \wp'$ and get polynomial(s) $R(k)$. It is obvious that $R(k) \in I$. Using the divisibility

$$\langle \mathrm{LT}(f_1), \mathrm{LT}(f_2), \ldots, \mathrm{LT}(f_N)\rangle = \langle \mathrm{LT}(I)\rangle$$

and lexicographic ordering, the equality $R(k) = h(k)\,\hat{f}$ has to occur for some $\hat{f} \in G$ and $h(k) \in \mathbb{Q}(\lambda)[k]$ (possibly equal to 1). Therefore there exists a polynomial $\hat{f}$ depending only on k. Designating $\hat{f}(k) \equiv F(k;\lambda)$, we obtain the curve (15). If $F(k;\lambda)$ has a factorized form, then the algebraic curve is one of its factors. Analogously, if the polynomials (14) exist, then they necessarily belong to G. In the same way, an important formula, the curve as a cover of the torus (12) in a *transcendental* form (an equation in α)

$$R(\wp'(\alpha), \wp(\alpha); \lambda) = 0, \tag{16}$$

necessarily must be contained in G computed with the ordering $k \succ (\wp'(\alpha) \succ \wp(\alpha) \succ \cdots)$, where permutations inside the brackets are allowed. Note the order of elliptic function (16) in α is equal to the order n of the equation (1).

(3) An existence of such a polynomial implies a restriction on the spectral parameter λ (see an illustrative Example 5). ■

Note a direct link of the point (3) to a treatment of finite-gap potentials as Picard's potentials.[21]

There are numerous algorithmic methods to solve this problem. Among them are the Gröbner basis method,[7,10] the method of characteristic sets, and an effective method of elimination based on the Seidenberg theory.[43] We do not discuss all the modern achievements in this area. See Ref. 32 and references therein for details. Note that the reduction of the holomorphic differential $d\alpha$ to the elliptic one is derived from (14) by the formula

$$d\alpha = \frac{d\wp(\alpha)}{\wp'(\alpha)} = \frac{F_k R_{1\lambda} - F_\lambda R_{1k}}{R_2 F_k} d\lambda, \tag{17}$$

where subscripts k, λ denote the derivatives with respect to k and λ.

IV. CANONICAL FORM OF CURVES AND HOLOMORPHIC DIFFERENTIAL

Formulas (15)–(17) give a noncanonical form of the curve and holomorphic differential, i.e., expressions in the variables (k, λ). The canonical variables (μ, λ) in the algebraic curve $\tilde{F}(\mu, \lambda) = 0$ we call variables λ in (1) and eigenvalue μ of a commuting operator pencil

$$\hat{P}(\lambda)\,\Psi = \mu\,\Psi. \tag{18}$$

Supplementing the polar expansion of the equation (1) by the polar expansion of (18), we get the algebraic equations in variables $(\wp, \wp', k, \mu, \ldots)$. Again, based on the above properties of the Gröbner base, a canonical representation of the solution and all the spectral characteristics are extracted by computing the base with the ordering $(\wp \succ \wp' \succ \cdots) \succ k \succ \mu$. Such a base contains a birational transformation between the (k, μ)-variables in one direction:

$$\mu \to k: \quad k = R_3(\mu; \lambda). \tag{19}$$

An inverse transformation

$$k \to \mu: \quad \mu = R_4(k; \lambda), \tag{20}$$

where $R_{3,4}$ are rational functions of its arguments, is computed by the ordering $(\wp \succ \wp' \succ \cdots) \succ \mu \succ k$.

We add a few words about the efficiency of computations. The solution of a spectral problem itself does not require the inclusion of a commuting operator (18). So, among of its polar expansions one may take (and supplement) those containing only the μ-variable. Evidently, it will enter into the polar expansion with first degree:

$$\mu = w(k, \wp, \wp'; \lambda). \tag{21}$$

After the computation of the base [not including (18)], we will have the curve (15) and cover in algebraic form (14). Substituting it into the equation (21), the pair of equations for the determination of the above transformation (19) and (20) becomes

$$\mu = w(k, R_1(k;\lambda), R_2(k;\lambda); \lambda), \quad F(k;\lambda) = 0. \tag{22}$$

Formulas (19) and (20) are obtained by computation of the bases for (22) with ordering $(k \succ \mu)$ and $(\mu \succ k)$, respectively. See Example 6 for details.

V. EXAMPLES

In this section we demonstrate the ideology of Secs. III and IV on examples. The generality of the technique allows us to make further proofs. Let us prove that the well known potential of Treibich and Verdier (7)[41] for the equation (2) is the only possible integrable two-pole potential in the class

$$u(x) = 6\,\wp(x) + 2\,\wp(x-\Omega), \quad \Omega \neq 0. \tag{23}$$

Example 1. The Treibich–Verdier potential: Parameters λ, g_2, g_3 are fixed and Ω is an unknown constant. The *Ansatz* for the Ψ-function must be the following:

$$\Psi = a_0 \mathbf{\Phi}(x;\alpha,k) + a_1 \mathbf{\Phi}'(x;\alpha,k) + a_2 \mathbf{\Phi}(x-\Omega;\alpha,k). \tag{24}$$

Substituting (23) and (24) into (2) and equating the poles to zero, we obtain Ψ-function

$$\Psi = 6\,\mathbf{\Phi}(-\Omega;\alpha,k)\,\mathbf{\Phi}'(x;\alpha,k) - (3\,k^2 - 3\,\wp_\alpha - 2\,\wp_\Omega - \lambda)\,\mathbf{\Phi}(x-\Omega;\alpha,k)$$

and a system of five polynomials:

$$\begin{aligned}
w_1 &= 2\,(\wp_\alpha - \wp_\Omega)\,k^3 + 3\,(\wp'_\Omega - \wp'_\alpha)\,k^2 + 2\,(\wp_\alpha - \wp_\Omega)(3\,\wp_\alpha - \lambda - 2\,\wp_\Omega)\,k \\
&\quad + (6\,\wp_\Omega - \wp_\alpha)\,\wp'_\alpha - (\wp'_\Omega - \wp'_\alpha)\,\lambda - (7\,\wp_\alpha - 2\,\wp_\Omega)\,\wp'_\Omega, \\
w_2 &= 3\,k^3 - (9\,\wp_\alpha - 4\,\wp_\Omega + \lambda)\,k + 3\,\wp'_\alpha + 3\,\wp'_\Omega, \\
w_3 &= 3\,k^4 - 2\,(9\,\wp_\alpha - 14\,\wp_\Omega - \lambda)\,k^2 + 12\,(\wp'_\Omega + \wp'_\alpha)\,k - 9\,\wp_\alpha^2 \\
&\quad - 2\,(14\,\wp_\Omega + \lambda)\,\wp_\alpha + 12\,\wp_\Omega^2 - 8\,\lambda\,\wp_\Omega - \lambda^2, \\
w_4 &= \wp'^2_\alpha - 4\,\wp^3_\alpha + g_2\,\wp_\alpha + g_3, \\
w_5 &= \wp'^2_\Omega - 4\,\wp^3_\Omega + g_2\,\wp_\Omega + g_3,
\end{aligned} \tag{25}$$

where we used the addition theorems for elliptic functions, the important equality

$$\mathbf{\Phi}(\Omega;\alpha,k)\,\mathbf{\Phi}(-\Omega;\alpha,k) = \wp_\alpha - \wp_\Omega,$$

and designated $\wp_\alpha \equiv \wp(\alpha)$, $\wp_\Omega \equiv \wp(\Omega)$, etc. A common factor $\wp_\alpha - \wp_\Omega$ was removed in polynomial w_3 because it leads to the contradiction: $\alpha = \Omega$ $(a_2 = \infty)$. The system (25) generates the ideal

$$\langle w_1, w_2, w_3, w_4, w_5 \rangle \in \mathbb{Q}(\lambda, g_2, g_3)[k, \wp'_\alpha, \wp_\alpha, \wp'_\Omega, \wp_\Omega]. \tag{26}$$

Note, the same ideal $\langle w_1, \ldots, w_5 \rangle$ in the ring $\mathbb{Q}(\lambda, g_2, g_3, \wp_\Omega)[k, \wp'_\alpha, \wp_\alpha, \wp'_\Omega]$ leads to the just mentioned condition $\wp_\alpha - \wp_\Omega = 0$. Therefore Ω is not arbitrary. Computing the minimal reduced Gröbner basis for (26) with pure lexicographic ordering $\wp'_\alpha \succ \wp_\alpha \succ k \succ \wp'_\Omega \succ \wp_\Omega$, we obtain eight polynomials, some of them having a factorized form. If some of the factors do not depend on λ, we obtain restrictions on $\wp'_\Omega$ and $\wp_\Omega$ equating these factors to zero. There are four such polynomials:

$$G_1 = \wp'_\Omega((\lambda^3 - 4\, g_2 \lambda - 16\, g_3)\, k + (3\, \lambda^2 - 4\, g_2)\, \wp'_\Omega) M,$$

$$G_2 = \wp'_\Omega(16\, \wp'_\Omega\, k + 3\, \lambda^2 - 4\, g_2) M,$$

$$G_3 = (4\, \wp_\Omega^3 - g_2\, \wp_\Omega - g_3)\, (4\, \wp_\Omega - \lambda)\, M,$$

$$G_4 = \wp'_\Omega\, (4\, \wp_\Omega - \lambda)\, M,$$

where the multiplier M denotes $3\, k^2 - \lambda - 5\, \wp_\Omega$. The equation $M = 0$ yields the trivial result $\wp(\alpha) = \wp(\Omega)$. It is checked by recomputing the base (25) with an additional polynomial M. Further, Ω must not depend on λ (!). Therefore, the only solution for Ω is defined by the equation

$$\wp'(\Omega) = 0 \Rightarrow \Omega = \omega_1, \omega_2, \omega_3,$$

where ω_j are the half-periods of elliptic functions. Substituting $\wp'_\Omega = 0, \wp_\Omega = e_1$, $g_2 = 4\,(e_1^2 + e_1 e_2 + e_2^2)$, $g_3 = -4\, e_1 e_2 (e_1 + e_2)$ into (25) and recomputing the basis with respect to the ordering $\wp'_\alpha \succ \wp_\alpha \succ k$, we obtain the well known algebraic curve of genus 2 and all algebraic-geometric objects.[2,34]. For classification results of the Treibich–Verdier potentials and other elliptic ones, see Ref. 34, the appendix in Ref. 16 and the most recent results in Ref. 37.

Example 2: As a preliminary, we shall consider Eq. (3) with potential

$$u(x) = 6\, \wp(x) + 6\, \wp(x - \Omega) \tag{27}$$

and the restriction $g_2 = 0$. As before, we have the *Ansatz* for the Ψ-function

$$\Psi = \mathbf{\Phi}(x; \alpha, k) + a_1 \mathbf{\Phi}(x - \Omega; \alpha, k)$$

and the original basis of the ideal is generated by five polynomials. Computing the Gröbner basis G, we obtain a system of eight polynomials. Only two of them have a factorized form:

$$G_1 = (64\, \lambda^3 k^3 - 27\, (\lambda^2 + 16\, g_3)^2)(\wp'_\Omega\, k - 3\, \wp_\Omega^2),$$

$$G_2 = (64\, \lambda^3 k^3 - 27\, (\lambda^2 + 16\, g_3)^2)((4\, \wp_\Omega^3 - g_3) k - 3\, \wp'_\Omega \wp_\Omega^2).$$

The nontrivial solution will take place if and only if (k, λ) are coordinates of the algebraic curve which is the first factor in G_1, G_2. In the next example we rule out the condition $g_2 = 0$.

Example 3: If g_2 is free, the straightforward computing of the basis is unsuccessful. Indeed, the Gröbner base method is universal and therefore it can be ineffective in some special cases. But our interest is only with the *zero structure* of the polynomial system. Thus, the characteristic sets method[42] is the best approach in this case. Under the ordering $\wp_\Omega \prec \wp'_\Omega \prec k \prec \wp_\alpha \prec \wp'_\alpha$, the characteristic set has the form

$$f_1 = (64\, (k\, \lambda + g_2)(k\, \lambda - 2\, g_2)^2 - 27\, (\lambda^2 + 16\, g_3)^2)\, k\, M,$$

$$
\begin{aligned}
f_2 &= (8\,(k\lambda - 2\,g_2)\,\wp_\alpha - 8\,k^3\lambda + 16\,g_2\,k^2 + 3\,\lambda^2 + 48\,g_3)\cdot(4\,\wp'_\Omega k + g_2 - 12\,\wp_\Omega^2)\,k,\\
f_3 &= (32\,(k\lambda - 2\,g_2)\,\lambda^3\,\wp'_\alpha - 192\,g_2^2\,k^2\,\lambda^2 + (\lambda^4 - 288\,g_3\,\lambda^2 - 6912\,g_3^2 + 2^8\,g_2^3)\,k\,\lambda\\
&\quad - g_2\,(11\,\lambda^4 + 864\,g_3\,\lambda^2 + 6912\,g_3^2 - 2^8\,g_2^3))\,k\,M,\\
f_4 &= \wp'^2_\Omega - 4\,\wp^3_\Omega + g_2\,\wp_\Omega + g_3,
\end{aligned}
\tag{28}
$$

where

$$
M \equiv 64\,\wp'_\Omega\,\wp_\Omega\,k^2 - 4\,(3\,\wp'_\Omega\,\lambda - 16\,g_2\,\wp_\Omega - 12\,g_3 + 96\,\wp^3_\Omega)\,k + 3\,(12\,\wp^2_\Omega - g_2)(\lambda + 4\,\wp'_\Omega).
$$

Factorization shows that the variable Ω is separated in polynomials $f_{1,2,3}$. Therefore f_1 gives an algebraic curve independent of Ω:

$$
64\,(k\,\lambda + g_2)(k\,\lambda - 2\,g_2)^2 = 27\,(\lambda^2 + 16\,g_3)^2. \tag{29}
$$

The polynomials $\{f_2, f_3\}$ are an algebraic form of the cover (14). However, the genus of the curve (29) is unity and we have a cover of a torus by a torus. Hence, if moduli of both tori are equal, then there is a one-to-one correspondence between the global parameter α of the torus (12) and the global parameter τ of the torus (29). The next step is to find it. After the birational change of variables $(k,\lambda)\leftrightarrow(y,x)$,

$$
k = \frac{3\,y^2 + 2\,g_2\,x + 3\,g_3}{4\,y\,x}, \quad \lambda = 4\,y,
$$

we obtain the canonical form of the curve (29) as $y^2 = 4\,x^3 - g_2\,x - g_3$ with an obvious uniformization and the equality $\alpha = 2\,\tau$. The final solution of the problem (3) and (27) is as follows:

$$
\begin{aligned}
\Psi(x;\lambda) &= a\,\mathbf{\Phi}(x;2\,\tau,k) + \mathbf{\Phi}(\Omega;2\,\tau,k)\,\mathbf{\Phi}(x-\Omega;2\,\tau,k), \quad \lambda = -4\,\wp'(\tau),\\
a &= \zeta(2\,\tau + \Omega) - 2\,\zeta(\tau) - \zeta(\Omega), \quad k = 2\,\zeta(\tau) - \zeta(2\,\tau).
\end{aligned}
\tag{30}
$$

The passage to the limit $\tau \to \omega_j$ in (30) leads to the solution under the condition $\lambda = 0$:

$$
\Psi(x;\lambda = 0) = C_1\,(\zeta(x) - \zeta(x-\Omega)) + C_2.
$$

An attempt to integrate the more general potential

$$
u(x) = 6\,\wp(x - \Omega_1) + 6\,\wp(x - \Omega_2) + A
$$

with a nonzero constant A failed. However, this point has an explanation in the theory of nonlinear partial differential equations. Indeed, the spectral problem (3) is associated with the Sawada–Kotera (SK) equation[33]

$$
u_t = u_{xxxxx} - 5\,u\,u_{xxx} - 5\,u_x\,u_{xx} + 5\,u^2\,u_x. \tag{31}
$$

By assuming that the poles $\Omega_{1,2}$ depend on time t, one obtains an isospectral deformation of this potential. This simple calculation yields the stationary solution of (31)

$$
u(x,t) = 6\,\wp(x - c\,t) + 6\,\wp(x - c\,t - \Omega) + A
$$

with the conditions

$$
c + 12\,g_2 + 5\,A^2 + 60\,A\,\wp(\Omega) = 0, \quad A\,\wp'(\Omega) = 0.
$$

Therefore ($\Omega=\omega_j$ and A is free) or ($A=0$ and Ω is free). In the both cases we obtain a restriction on a velocity c of two canoidal waves. See an example in Ref. 40 for the case $A=0$. Recently, Conte and Musette obtained a similar result [Ref. 31 formula (84)] and revealed a remarkable more general solution in an old paper by Chazy[8] in the context of the Painlevé analysis:

$$u(x,t)=6\,\wp(x-c\,t-\Omega;\,g_2,g_3)+6\,\wp(x-\tilde{c}\,t-\tilde{\Omega};\,\tilde{g}_2,\tilde{g}_3),$$
$$c=3\,g_2-15\,\tilde{g}_2,\quad \tilde{c}=3\,\tilde{g}_2-15\,g_2. \tag{32}$$

Strictly speaking, Chazy's solution (Ref. 8 p. 380) corresponds to the stationary equation (31) and therefore to the case $\tilde{g}_2=g_2$ ($\tilde{c}=c$) in (32). One can show that the potential (32) is the stationary solution of a linear combination of the equation (31) and higher SK–equation of the seventh order

$$u_t=u_{7x}-\ -7(u\,u_{5x}+2\,u_x\,u_{4x}+3\,u_{xx}u_{xxx}-2\,u^2\,u_{xxx}-6\,u\,u_x\,u_{xx}-u_x^3+\tfrac{4}{3}u^3\,u_x). \tag{33}$$

Section VII contains additional information for this potential. We do not enumerate other one-pole elliptic potentials $u(x)=A\,\wp(x)+B$ for the equation (3). For example, one of them is $u=30\,\wp(x)\pm 3\,\sqrt{3\,g_2}$ (see also Ref. 5).

Example 4: Let us consider a general one-pole elliptic potential for the equation (4),

$$\Psi'''-(a\,\wp(x)+d)\,\Psi'-(b\,\wp'(x)+c\,\wp(x))\,\Psi=\lambda\,\Psi, \tag{34}$$

in the framework of the *Ansatz*

$$\Psi=\mathbf{\Phi}(x;\alpha,k).$$

Using the above techniques in the ring $\mathbb{Q}(a,b,c,d)[\wp_\alpha,\wp'_\alpha,k]$ we do not get the solution: $I=\langle 1\rangle$. Therefore (a,b,c,d) have to depend on each other. After calculations in the ring $\mathbb{Q}(a,b,c)[\wp_\alpha,\wp'_\alpha,k,d]$ we determine step by step the constants $(a,\,b,\,c,\,d)$ and get the following. The first polynomial in a base is

$$-8\,b^3\,(2\,b-3)^3\,\lambda^2-4\,c\,(2\,b-3)^2\,(4\,d\,b^3-12\,b^2\,d-b\,c^2+6\,c^2)\,\lambda+\cdots=0.$$

Equating to zero the coefficients in front of $\lambda^2,\,\lambda$ we obtain

$$b=\tfrac{3}{2}\quad\text{or}\quad b=0.$$

In these cases we will have, respectively,

$$3\,d-c^2=0,\quad (216\,\lambda+c^3-36\,c\,d)\,c^3=0.$$

Therefore $(b=\frac{3}{2}, d=c^2/3)$ or $b=c=0$. In the first case, we have

$$\Psi'''-3\,(\wp(x)+c^2)\,\Psi'-(\tfrac{3}{2}\wp'(x)+3\,c\,\wp(x))\Psi=\lambda\,\Psi,\qquad \Psi(x;\lambda)=\mathbf{\Phi}(x;\alpha,c).$$

The nonramified cover of the torus (16) of genus $g=1$ is

$$\wp'(\alpha)-6\,c\,\wp(\alpha)+2\,\lambda+4\,c^3=0.$$

c is an arbitrary constant and the condition $g_2=0$ (Ref. 29, example 3.10) does not appear. Note, there is no such restriction in the Halphen equation (6) with $n=5$ as in Ref. 15. It appears only for $n=4$.[17] The second case is known:[29]

$$\Psi'''-(6\,\wp(x)+d)\,\Psi'=\lambda\,\Psi,$$
$$108\,\lambda\,\wp'(\alpha)+36\,(d^2-3\,g_2)\,\wp(\alpha)+27\,\lambda^2-108\,g_3-4\,d^3=0 \quad (\text{genus } g=2). \tag{35}$$

See Ref. 3 for an application of this potential.

Note that both cases can be found in Ref. 28 t. III, pp. 372, 522, in Jacobian functions and Ref. 19, III/IV, pp. 460, 462, in Weierstrassian functions. No other possibilities exist. The same technique is applicable to other *Ansätze*. The next one is a nontrivial example along these lines.

Example 5: The equation (34) in the framework of the *Ansatz*

$$\Psi=a_0\mathbf{\Phi}(x;\alpha,k)+\mathbf{\Phi}'(x;\alpha,k). \tag{36}$$

As a consequence of corresponding indicial equation (38) with $\nu=2$, without loss of generality we set $b=12-a$ in (34). Solutions for a,c,d must not depend on λ and k. One solution suggests itself. Indeed, the first polynomial in the original base has the form

$$(a-12)\,((a-18)\,(k^2-\wp_\alpha)+2\,c\,k)+2\,(a-18)\,d+c^2=0.$$

With $a=12$, this polynomial does not depend on k,α and we get (after the replacement $c\to 12\,c$)

$$a=12,\quad b=0,\quad d=12\,c^2,\quad a_0=k-2\,c.$$

Moreover, the ideal in the ring $\mathbb{Q}(\lambda,c,g_2,g_3)[\wp_\alpha,\wp'_\alpha,k]$ is not equal to $\langle 1\rangle$ and, therefore, c is an arbitrary constant. Thus, the equation (34) and its solution take the form

$$\Psi'''-12\,(\wp(x)+c^2)\,\Psi'-12\,c\,\wp(x)\,\Psi=\lambda\,\Psi,$$
$$\Psi(x;\lambda)=\mathbf{\Phi}'(x;\alpha,k)-2\,c\,\mathbf{\Phi}(x;\alpha,k). \tag{37}$$

We do not give here the large formulas for the cover (14), or the four-sheet cover in the form (16) and write only a skeleton of the nonhyperelliptic trigonal algebraic curve (15) of genus $g=3$,

$$64\,(\lambda^2+32\,c^3\,\lambda+2^8\,c^6-108\,g_2\,c^2)(\lambda-11\,c^3)\,k^3+(\cdots)\,k^2+(\cdots)\,k+(\cdots)=0,$$

where $(\cdots)$ designate some polynomials in λ,c,g_2,g_3 with integer coefficients.[5] Under $c=0$ we arrive at the case (27) with $\Omega=0$.

The higher *Ansätze* (9) are investigated in a similar manner. Indeed, by Fuchs–Frobenius theory, if Ψ has the expansion $\Psi=x^{-\nu}+\cdots$, then a,b satisfy the determining equation

$$-\nu(\nu+1)(\nu+2)+a\,\nu+2\,b=0. \tag{38}$$

A natural question appears: under what parameters (a,b) does the equation (38) have integral solutions for ν? One of solutions is Halphen's equation (6). It corresponds to $2\,b=a$ and (38) reduces to

$$a=n^2-1 \quad (n\equiv\nu+1).$$

As in the previous example we can list all the possible cases for the *Ansatz* (36). Indeed, assuming $b=12-a$ and (a,d,c) to be arbitrary, the origin base contains three polynomials.[5] The first and second of them are linear in $\wp$, $\wp'$. Solving them and substituting into the base again, we obtain the remaining polynomial in (λ,k):

$$-4\,(a-12)^2\,(a-18)^2\,((a-6)\,(a-18)\,k+c\,(a-9))\,\lambda+(\cdots)\,k+(\cdots)=0,$$

where dots denote a polynomial in (a,c,d,g_2,g_3). It must be zero for all values of λ. Splitting it in λ we get two linear polynomials in k. Their compatibility condition is the polynomial

$$(a-6)(a-8)(108\,c^4-72\,(a-18)^2\,d\,c^2+(a-18)^4\,(12\,d^2-(a-12)^2\,g_2))=0$$

and solution for k

$$k=-\frac{(a-9)\,c}{(a-6)\,(a-18)}.$$

The verifying of Weierstrass's relation (12) yields a polynomial in λ:

$$(a-6)^3(a-12)^3(a-18)^6\,\lambda^2+(\cdots)\,\lambda+(\cdots)=0.$$

Under $a\neq 6,12,18$ we arrive at the point (3) of the Proposition. Therefore, only three possibilities exist: $a=6,12,18$. The corresponding final solutions for the variables $(\wp',\wp,k)$ are obtained separately: by recomputing the base. Thus, besides (37), we have the following integrable potentials [note a misprint $\wp(x)$ instead of $\wp'(x)$ in one of the formulas in Ref. 5]:

$$\Psi'''-(18\,\wp(x)+d)\,\Psi'+6\,\wp'(x)\,\Psi=\lambda\,\Psi,\quad \Psi'''-(6\,\wp(x)+d)\,\Psi'-6\,\wp'(x)\,\Psi=\lambda\,\Psi.$$

See Ref. 39 for solutions of the generalized Halphen equation (6) and Ref. 5 for details of Example 5.

It should perhaps be noted here that the example (37) is the generalization $c\neq 0$ of the first nontrivial case $n=-3$ in a series of other Halphen's equations (Ref. 27, p. 554),

$$w'''-\frac{4}{3}n^2\,w'\,\wp(z)-\frac{2}{27}n\,(n+3)\,(4\,n-3)\,w\,\wp'(z)=0 \tag{39}$$

without a spectral parameter. [The example (39) was revealed by E. Previato.] Notation as in Ref. 19 III/IV: Ex. 15, p. 464. Indicial equation (38) for the example (39) becomes

$$(3\,\nu+2\,n)(3\,\nu+2\,n+6)(3\,\nu-4\,n+3)=0$$

and $(n+3)(n+6)(4\,n-9)=0$ for the *Ansatz* (36) $(\nu=2)$.

Example 6: Halphen's equation (6) with $n=5$. Here we display only the final formulas in the context of Sec. IV:

(i) the commuting operator pencil (18):

$$\lambda\,\Psi''-14\,(4\,\wp(x)^2-g_2)\,\Psi'+16\,(7\,\wp'(x)-\lambda)\,\wp(x)\,\Psi=\mu\,\Psi;$$

(ii) the polynomial (21):

$$6\,\mu-56\,k^5+560\,\wp_\alpha\,k^3-20\,(28\,\wp'_\alpha-\lambda)\,k^2+168\,(5\,\wp_\alpha^2-g_2)\,k-4\,(28\,\wp'_\alpha+5\,\lambda)\,\wp_\alpha=0;$$

(iii) the birational transformation (19, 20), which is quadratic in (k,μ):

$$\mu=\frac{32}{49}\,\frac{(2\,(\lambda^2-392\,g_3)\,k\,\lambda+7\,(5\,\lambda^2-784\,g_3)\,g_2)\,((\lambda^2-392\,g_3)\,k-21\,g_2\,\lambda)}{\lambda^4-208\,g_3\lambda^2+3136\,(g_2^3+4\,g_3^2)},$$

$$k=\frac{7}{8}\,\frac{\mu^2-4\,g_2\,(5\,\lambda^2-784\,g_3)}{(\lambda^2-392\,g_3)\,\lambda};$$

(iv) the canonical form of the algebraic curve of genus 4 (see also Ref. 39):

$$\tilde{F}(\mu,\lambda):\mu^3-4\,g_2\,(11\,\lambda^2-784\,g_3)\,\mu-\lambda^5+208\,g_3\,\lambda^3-3136\,(g_2^3+4\,g_3^2)\,\lambda=0;$$

(v) the eight-sheet cover in the form (16):

$$2^8\,(\lambda^2-392\,g_3)^3\,\lambda\,\wp'(\alpha)-2^8 49\,g_2\,(\lambda^2+112\,g_3)\,(\lambda^2-392\,g_3)^2\,\wp(\alpha)+\lambda^8-\cdots=0.$$

Note that both this cover and its algebraic form (14) are the expansive expressions, whereas the reduced holomorphic differential (17) in the variables (k,λ) and (μ,λ) is given by the simple formulas:

$$\frac{d\wp(\alpha)}{\wp'(\alpha)}=\frac{-8\,(\lambda^2-56\,g_3)}{3\,\mu^2-4\,g_2\,(11\,\lambda^2-784\,g_3)}\,d\lambda=\frac{-7\,(\lambda^2-56\,g_3)}{(\lambda^2-392\,g_3)\,(3\,\lambda\,k+14\,g_2)}\,d\lambda.$$

Analogs of the above formulas are derived for all other examples in the article.

Example 7: The two-pole potential for the equation (4) with *Ansatz*

$$\Psi=\mathbf{\Phi}(x;\alpha,k)+a_1\,\mathbf{\Phi}(x-\Omega;\alpha,k).$$

The general two-pole elliptic potentials contain many parameters—multipliers before the $\wp'$, $\wp$, ζ-functions. We do not give their exhaustive classification and consider only the most interesting case

$$\Psi'''-3\,(\wp(x)+\wp(x-\Omega)-\wp(A))\,\Psi'-\tfrac{3}{2}(\wp'(x)+\wp'(x-\Omega)+B\,\wp(x)-B\,\wp(x-\Omega))\Psi=\lambda\,\Psi. \tag{40}$$

By virtue of the Proposition, the Gröbner base contains all the information about the solution, i.e., all the following formulas. As before we obtain that Ω, A are arbitrary constants and

$$B=2\,\sqrt{\wp(\Omega)-\wp(A)}.$$

The parameters k and λ as meromorphic functions are connected by an algebraic equation of the genus 2 independent of Ω (compare with Ref. 35):

$$2\,\lambda\,k^3+(3\,\wp_A^2-g_2)\,k^2-3\,\wp_A\,\lambda\,k-\tfrac{1}{4}\lambda^2+\wp_A'^2=0. \tag{41}$$

The equation (41) can be realized as a two-sheet cover of a torus in the form (16),

$$\lambda\,\wp'(\alpha)+(3\,\wp_A^2-g_2)\,\wp(\alpha)+\tfrac{1}{4}\lambda^2+\wp_A^3-g_3=0.$$

The algebraic form of cover (14) has the form

$$\wp(\alpha)=k^2+\wp_A,\quad \wp'(\alpha)=(g_2-3\,\wp_A^2)\,\frac{k^2}{\lambda}-\frac{\wp_A'^2}{\lambda}-\frac{\lambda}{4}.$$

VI. SOLUTIONS OF INTEGRABLE PDEs

The spectral problem (4) and (40) corresponds to the Boussinesq equation

$$3\,u_{tt}=(2\,u^2-u_{xx})_{xx}, \tag{42}$$

and the arbitrariness of Ω means the existence of an isospectral deformation of the potential

$$u(x,t)=3\,\wp(x-\Omega_1(t))+3\,\wp(x-\Omega_2(t))-3\,\wp_A. \tag{43}$$

Substituting the two-gap *Ansatz* (43) in (42), we get the well known system of pairwise-interacting particles $\Omega_{1,2}(t)$ of the Calogero–Moser system type[30] with a repulsion potential and immovable center of mass. Integration leads to an equation for $\Omega_1(t)$:

$$\dot{\Omega}_1^2 = 4\,\wp(2\,\Omega_1 - c) - 4\,\wp_A, \quad \Omega_2 = c - \Omega_1.$$

Using the uniformization of the corresponding elliptic curve, we obtain the explicit solution

$$\Omega_1(t) = \frac{1}{2}\wp^{-1}\left(\widetilde{\zeta}(\tau+\nu) - \widetilde{\zeta}(\tau-\nu) - \widetilde{\zeta}(2\,\nu) + \frac{1}{4}\wp_A\right) + \frac{c}{2},$$
$$\nu = \pm\frac{1}{2}\widetilde{\wp}^{-1}\left(\frac{\wp_A^2}{16} + \frac{g_2}{24}\right), \quad \widetilde{\wp}'(2\,\nu) = -\frac{1}{32}(\wp_A^3 - g_2\,\wp_A + 2\,g_3), \tag{44}$$

where $\tau = 8\,(t - t_0)$ and c, t_0 are arbitrary constants. An implicit form of this solution with $c = 0$ in terms of Jacobi's sn, cn, dn-functions is given in Ref. 20 and in the earlier citation[9] in the context of solutions of the Kadomtsev–Petviashvili equation. In (44), the elliptic integral $\wp^{-1}$ is calculated with invariants g_2, g_3, and the $\widetilde{\zeta}$, $\widetilde{\wp}^{-1}$-functions with invariants

$$\widetilde{g}_2 = \frac{1}{16}\left(g_2\,\wp_A^2 + 3\,g_3\,\wp_A + \frac{g_2^2}{12}\right), \quad \widetilde{g}_3 = -\frac{g_3}{2^8}(\wp'^2_A + 2g_3) + \frac{g_2^3}{2^7 3^3} - \frac{g_2\,\widetilde{g}_2}{24}.$$

The reduction case $B = 0$ in (40) corresponds to the Kaup–Kupershmidt (KK) equation

$$u_t = u_{xxxxx} - 5\,u\,u_{xxx} - \tfrac{25}{2}u_x\,u_{xx} + 5\,u^2\,u_x \tag{45}$$

and its stationary solution

$$u(x,t) = 3\,\wp(x - c\,t) + 3\,\wp(x - c\,t - \Omega) - 3\,\wp(\Omega), \tag{46}$$

but the velocity c depends on the distance between poles:

$$c = 3g_2 - 45\,\wp^2(\Omega).$$

The generalization of (46) in a similar way as the solution (32) is

$$u(x,t) = -12\,(\wp_1 + \wp_2) + 3\left(\frac{\wp_1' - \wp_2'}{\wp_1 - \wp_2}\right)^2, \tag{47}$$

where

$$\wp_1 \equiv \wp(x - c\,t - \Omega; g_2, g_3), \quad \wp_2 \equiv \wp(x - c\,t - \hat{\Omega}; g_2, \hat{g}_3), \quad c = -12\,g_2.$$

Here Ω, $\hat{\Omega}$, g_2, g_3, $\hat{g}_3$ are five arbitrary constants. Using a connection between the SK(u)- and KK(w)-equations and the Tzitzeica equation

$$\phi_{xt} = e^{\phi} - e^{-2\,\phi} \tag{48}$$

with the Fordy–Gibbons equation[18]

$$v_t = v_{xxxxx} - 5\,(v_x\,v_{xxx} + v^2\,v_{xxx} + v_{xx}^2 + v_x^3 + 4\,v\,v_x\,v_{xx} - v^4\,v_x)$$

via the Miura transformations

$$u=v^2-v_x, \quad w=v^2+2\,v_x, \quad u=\phi_{xx}+\phi_x^2,$$

we obtain stationary solutions for the v-function

$$v(x,t)=\frac{\wp_1'-\wp_2'}{\wp_1-\wp_2}.$$

Nonstationary solution of the equation (48) has the form

$$\phi(x,t)=\ln 2\,c+\ln(\wp(x+c\,t-\Omega;g_2,g_3)-\wp(x-c\,t-\hat{\Omega};g_2,\hat{g}_3))$$

with the restriction: $4\,(\hat{g}_3-g_3)\,c^3=1$. The details of calculations (44) are expounded in Ref. 5 and the formula (47), and the Ψ-function for the potentials (32) and (47) in Refs. 5, 4, and 40.

VII. CONCLUDING REMARKS AND DISCUSSION

The investigation of elliptic solitons can be automated by polynomial techniques. The Gröbner base method provides a unified approach to the solution of related problems. The technique suggested with minor modifications is extended to matrix spectral problems.

As the Examples 2, 3 and 5 show, the algebraic curves can be degenerate (multiply roots of discriminant).

The general case in Example 7 for the equation (4),

$$\begin{gathered}u(x)=a\,\wp(x)+b\,\wp(x-\Omega)+c\,\zeta(x)-c\,\zeta(x-\Omega),\\ v(x)=d\,\wp'(x)+e\,\wp'(x-\Omega)+f\,\wp(x)+g\,\wp(x-\Omega)+h\,\zeta(x)-h\,\zeta(x-\Omega),\end{gathered} \tag{49}$$

requires additional research.

To all appearances, the example (37) has to fit into the hierarchy of higher Boussinesq equations, studied in full in Refs. 13 and 14. Multi-pole potentials are investigated by involving the addition theorem for the $\mathbf{\Phi}$-function:

$$\mathbf{\Phi}(x+z;\alpha,k)=\frac{1}{2}\,\frac{\mathbf{\Phi}(x;\alpha,k)\,\mathbf{\Phi}(z;\alpha,k)}{\wp_x-\wp_z}\left(\frac{\wp_\alpha'+\wp'_x}{\wp_\alpha-\wp_x}-\frac{\wp_\alpha'+\wp'_z}{\wp_\alpha-\wp_z}\right).$$

A natural assumption suggests itself: *all the potentials, obtained by the above method, are finite-gap ones*. At least, by construction, all such potentials belong to the set of exact integrable (explicit Ψ[40]) and the Ψ-function is a single-value function on a Riemann surface of the algebraic curve $F(k,\lambda)=0$ and meromorphic function (in x) for all values of λ (Picard's theorem[21,23]). Since our Ψ is expressible in terms of Weierstrassian σ, all the corresponding spectral problems become quadrature integrable. See Ref. 6 for further explanations of this concept of integrability in the example of the Schrödinger equation and see Ref. 40 and the example below for other spectral problems. Note that all linear independent solutions for the Ψ-function are obtained by choosing the k-branch of algebraic equation (15).

If the assumption is valid, then the potentials for the spectral problems (2)–(4) are free of residues (a consequence of Θ-formulas), and therefore *Ansätze* for the multi-pole potentials [say (49)] do not have to involve the ζ-functions. This strongly decreases the number of parameters and the computational task.

The potential (32)

$$u=6\,\wp(x-\Omega;g_2,g_3)+6\,\wp(x-\tilde{\Omega};\tilde{g}_2,\tilde{g}_3) \tag{50}$$

with arbitrary invariants $g_2, g_3, \tilde{g}_2, \tilde{g}_3$ is a finite-gap one for the equation (3), but its spectral characteristics can not be obtained in the framework of elliptic soliton theory. The corresponding commuting operator pencil is derived with the help of the equation (33) and takes the form

$$(9\,(u-c_1)\,\lambda-3\,u'''+6\,u\,u'+c_1\,u')\,\Psi''-(27\,\lambda^2+9\,u'\,\lambda-u^{(\mathrm{IV})}-3\,u'^2+\tfrac{4}{3}u^3-c_1\,u''-c_1\,u^2$$
$$+27\,c_2)\,\Psi'+6\,\lambda\,(u''-u^2+c_1\,u)\,\Psi=\mu\,\Psi.$$

Hence, the canonical form $\widetilde{F}(\mu,\lambda)=0$ of the associated trigonal curve of genus $g=4$ is obtained by elimination of Ψ:

$$a^3\,\mu^3+3^5(36\,a^2\,b\,\lambda^4-(a^5-16\,g_2\,a^4+16\,g_2^2\,a^3+192\,(b-3\,g_3)\,a^2\,b+192\,g_2\,a\,b^2)\,\lambda^2$$
$$+48\,(g_3\,a^5-g_2\,a^4\,b+4\,a^2\,b^3))\,\mu+3^6\,(27\,a^3\,\lambda^7-216\,(a^3b-4\,g_3\,a^3+2\,g_2\,a^2\,b+8\,b^3)\,\lambda^5$$
$$-2\,(a^6+30\,g_2\,a^5-96\,g_2^2\,a^4-8\,(45\,b^2-216\,g_3\,b-8\,g_2^3+432\,g_3^2)\,a^3+576\,(b$$
$$+6\,g_3)\,g_2\,a^2\,b-2^8 9\,g_2^2\,a\,b^2-2^8 3^3\,(b^4-2\,g_3\,b^3)\,\lambda^3-288\,(a^3-2\,g_2\,a^2+24\,b^2)(g_3\,a^3$$
$$-g_2\,a^2\,b+4\,b^3)\,\lambda=0,\quad a\equiv g_2-\tilde{g}_2,\quad b\equiv g_3-\tilde{g}_3,$$

and the corresponding Ψ-function is given by the expression

$$\Psi(x;\lambda)=\exp\int\frac{\lambda\,F^2-G\,H+F\,H'-F'\,H}{G^2-u\,F^2-F\,H+F'\,G-F\,G'}\,dx,$$

where prime denotes a derivation in x and

$$F\equiv-3\,u'''+6\,u\,u'-3\,c_1\,u'+9\,(u-c_1)\,\lambda,\quad H\equiv6\,(u''-u^2+c_1\,u)\,\lambda-\mu,$$

$$G\equiv u^{(\mathrm{IV})}+c_1\,(u''+u^2)-3\,u'^2-9\,u'\,\lambda-\frac{4}{3}u^3-27\,(\lambda^2+c_2),$$

$$c_1\equiv-12\,\frac{g_3-\tilde{g}_3}{g_2-\tilde{g}_2},\quad c_2\equiv\frac{8\,(3\,\tilde{g}_3+g_3)\,g_2-(3\,g_3+\tilde{g}_3)\,\tilde{g}_2}{3\,g_2-\tilde{g}_2}.$$

One particular case of the potential (50) and the more general property of finite-gap potentials are discussed in Ref. 40.

The natural generalization of Hermite's method is to consider nonlinear homogeneous *Ansätze* for the Ψ-function. For instance, the quadratic *Ansatz*

$$\Psi=e^{kx}\sum_{j,\,n}A_{jn}\,\Phi(x-\Omega_j;\,\alpha)\,\Phi(x-\Omega_n;\,\alpha).$$

However, this does not fit into the framework of finite-gap integration theory, because the poles of the potential can depend on the spectral parameter. The following example with the transcendental dependence on spectral parameter elucidates this:

$$\Psi''=(6\,\wp(x)+2\,\wp(x-\lambda)+4\,\wp(\lambda))\,\Psi,\quad \Psi(x;\lambda)=\Phi^2(x;\,\lambda).$$

Actually, the quadratic (and higher) *Ansätze* will not give an advantage due to the relation

$$\Phi(x;\alpha)^2=-\boldsymbol{\Phi}'(x;2\,\alpha,\zeta(2\,\alpha)-2\,\zeta(\alpha))$$

and we again arrive at the framework of Hermite's method.

Note that the nonintegrability of equation (1) in context of the point (3) of the Proposition, nevertheless, can be useful for its integrability with special values of λ or for more complex operator pencils with a dependence of the potential (say parameters a,b,c,d in Examples 4 and 5) on λ. The availability of additional constants in the potentials may be considered as a family of spectral pencils, and under fixed values of λ, as new spectral problems. For instance, the two-gap

Lamé potential $u=6\,\wp(x)$ for Eq. (5) is obtained from example (35) with $\lambda=0$ and $d\to\lambda$, $\Psi'\to\Psi$. A less simple example is to swap the parameters $\lambda\leftrightarrow c$ in Eq. (37), whereupon one finds the finite-gap operator λ-pencil

$$\Psi'''-12\,(\wp(x)+\lambda^2)\,\Psi'-(c+12\,\lambda\,\wp(x))\,\Psi=0$$

with the algebraic curve $F(k,\lambda)=0$ of genus $g=8$ [Ref. 5, formula (15)].

ACKNOWLEDGMENTS

The author is grateful to Dr. A. Smirnov for helpful discussions. The equation (40) was considered in collaboration with him. My special thanks are due to Professor E. Previato, Professor R. Conte, and Professor V. Enol'skii for much attention to the work and discussions, and Mark van Hoeij for discussions of the computer algorithms. Dr. N. Ustinov made some important observations.

The author also is grateful to Professor J. C. Eilbeck for numerous discussions, remarks and hospitality at Heriot–Watt University where the article was improved.

The author was supported by Royal Society/NATO Fellowship and RFBR (00–01–00782) and partially by NSF/NATO Grant No. DGE–0209549.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 45, NUMBER 2 FEBRUARY 2004

A class of nonautonomous coupled KdV systems

Refik Turhan[a)]
Department of Physics, Faculty of Art and Sciences, Middle East Technical University, 06531 Ankara, Turkey

(Received 24 January 2003; accepted 25 September 2003)

A class of nonautonomous coupled Korteweg–de Vries (KdV) systems in $(1+1)$ dimensions are considered for integrability classification. Integrability of the systems is associated with the existence of a certain recursion operator. Some new integrable nonautonomous two-component KdV systems are found. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1628838]

I. INTRODUCTION

There has been a constant interest in finding new scalar and multicomponent integrable nonlinear equations because of both the rich mathematical structures they possess and the wide variety of physical systems having interesting properties that are described by such equations. For this purpose, many classes of scalar and multicomponent KdV type equations are classified based on different aspects of integrability such as existence of infinitely many symmetries and/or conservation laws, bi-Hamiltonian structure, master symmetries, recursion operator, formal symmetry of infinite rank, Lax representation, Painlevé property, etc.[1–13]

Despite their frequent appearance in applications where inhomogeneous properties of physical media are taken into account, nonautonomous versions of KdV type equations are only investigated for scalar equations. These investigations gave negative results for existence of original nonautonomous scalar KdV type equations.[5,14,15] All the known equations that are apparently nonautonomous were also found to be transformable to the usual KdV or to its well-known modifications. On the other hand, due to their importance in applications, systematic derivation of nonautonomous versions of KdV and other integrable equations are considered in Ref. 16.

Most of the systematic integrability classifications of multicomponent equations are performed only for nondegenerate systems,[1–4,9,12,13] usually having the identity matrix as the coefficient of highest order (derivative) terms. Degenerate systems are relatively less interested. Systems of this latter type are usually introduced on their own.[17,18] There are also systematic works to obtain such systems.[6,8,10] However, the most generic degenerate systems known so far are obtained in a physical problem,[7] where a class of degenerate KdV type extended two-component equations are introduced with their bi-Hamiltonian structure in the context of asymptotic integrability of water waves.

Recently, we have started classification of nonautonomous multicomponent KdV systems based on the existence of a certain recursion operator.[13] We obtained the nonautonomous versions of autonomous Svinolupov Jordan KdV systems[4] therein. In the present work, we proceed with the recursion operator based integrability classification of nonautonomous KdV type multicomponent equations. Motivated by the results of the above-mentioned earlier works and the form of cylindrical KdV equation, here we aim to classify both degenerate and nondegenerate classes of the following N-component nonautonomous KdV type extended equations

$$q_t^i = b_j^i q_{xxx}^j + s_{jk}^i(t) q^j q_x^k + y_j^i(t) q^j, \quad i,j,k = 1,2,\ldots,N, \tag{1}$$

a)Electronic mail: refik@metu.edu.tr

where $q^i=q^i(x,t)$ are the dependent variables. We associate integrability of system (1) with the existence of a recursion operator whose form we assume to be

$$\mathcal{R}^i_j=z^i_j(t)D^2+a^i_{jk}(t)q^k+h^i_j(x,t)+[c^i_{jk}(t)q^k_x+w^i_j(t)]D^{-1}, \tag{2}$$

where $D=d/dx$ and D^{-1} is the formal inverse operator ($DD^{-1}=D^{-1}D=1$).

Systems admitting a recursion operator are integrable in existence of infinitely many symmetries sense because by definition a recursion operator maps symmetries of a system to other symmetries of it endlessly.[19]

Here, in (1) and (2) except for b^i_j which are assumed to be constants, all the coefficient terms are introduced with their presumed dependence on the independent variables x and t. Sufficient differentiability of these coefficients with respect to their independent variables is also assumed.

System (1) admits recursion operator (2) if they satisfy the integrability criterion[19]

$$\mathcal{R}^i_{j,t}=\mathcal{K}'^i_r\mathcal{R}^r_j-\mathcal{R}^i_r\mathcal{K}'^r_j, \tag{3}$$

where

$$\mathcal{K}'^i_j=b^i_jD^3+s^i_{kj}(t)q^kD+s^i_{jk}(t)q^k_x+y^i_j(t)$$

is the Fréchet derivative of the system (1).

In Sec. II we give the conditions for (1) and (2) to satisfy the integrability criterion (3) for an arbitrary number N of components. In Sec. III we briefly explain our classification algorithm which is based on the Jordan canonical forms of matrices and finally in Sec. IV we give the two-component ($N=2$) systems we found as solutions of the integrability conditions.

II. INTEGRABILITY CONDITIONS

The integrability criterion (3) leads to some algebraic and differential conditions among the coefficient terms of the system (1) and the recursion operator (2). In the following proposition we give these conditions.

Proposition 1: Let $q^i(x,t)$ be functions of x and t satisfying system of equations (1) which admits a recursion operator $\mathcal{R}^i_j$ given in (2). Then the coefficient terms $b^i_j,s^i_{jk}(t),y^i_j(t),z^i_j(t),a^i_{jk}(t),h^i_j(x,t),c^i_{jk}(t),w^i_j(t)$ satisfy the following relations:

$$\begin{gathered}
3b^i_ka^k_{jl}+b^i_kc^k_{jl}+s^i_{kl}z^k_j-2z^i_ks^k_{lj}-z^i_ks^k_{jl}-c^i_{kl}b^k_j=0,s^i_{mk}a^k_{jl}-a^i_{km}s^k_{lj}=0,\\
3b^i_ka^k_{jl}+3b^i_kc^k_{jl}-z^i_ks^k_{lj}-2z^i_ks^k_{jl}=0,a^i_{jk}b^k_l-b^i_ka^k_{jl}-3b^i_kc^k_{jl}+z^i_ks^k_{jl}=0,\\
b^i_kz^k_j-z^i_kb^k_j=0,b^i_kh^k_j-h^i_kb^k_j=0,b^i_kc^k_{jl}-c^i_{jk}b^k_l=0,w^i_k(s^k_{lj}-s^k_{jl})=0,\\
c^i_{km}(s^k_{jl}-s^k_{lj})=0,c^i_{jk}s^k_{ml}-s^i_{km}c^k_{jl}=0,c^i_{jk}s^k_{ml}-s^i_{mk}c^k_{jl}=0,\\
a^i_{jk}s^k_{ml}+a^i_{km}s^k_{jl}+c^i_{kl}s^k_{jm}-s^i_{mk}a^k_{jl}-s^i_{mk}c^k_{jl}-s^i_{kl}a^k_{jm}=0,\\
b^i_ka^k_{jl}+s^i_{lk}z^k_j-z^i_ks^k_{lj}-a^i_{kl}b^k_j=0,s^i_{lk}h^k_j-h^i_ks^k_{lj}=0,s^i_{kl}h^k_j-h^i_ks^k_{jl}=0,\\
z^i_{j,t}-3b^i_kh^k_{j,x}-b^i_kw^k_j-y^i_kz^k_j+z^i_ky^k_j+w^i_kb^k_j=0,w^i_{j,t}-y^i_kw^k_j+w^i_ky^k_j=0,\\
a^i_{jl,t}+a^i_{jk}y^k_l-s^i_{lk}h^k_{j,x}-s^i_{lk}w^k_j-y^i_ka^k_{jl}+a^i_{kl}y^k_j+w^i_ks^k_{jl}=0,b^i_kh^k_{j,xx}=0,\\
c^i_{jl,t}+c^i_{jk}y^k_l-s^i_{kl}w^k_j-y^i_kc^k_{jl}+c^i_{kl}y^k_j=0,h^i_{j,t}-b^i_kh^k_{j,xxx}-y^i_kh^k_j+h^i_ky^k_j=0.
\end{gathered} \tag{4}$$

This proposition is the straightforward result of calculating operator equality (3) together with (1) and (2).

Although we obtained the integrability conditions for systems with any arbitrary number N of components, our focus in the rest of this work is to systematically obtain the solutions of these conditions in the two-component ($N=2$) case.

III. CLASSIFICATION ALGORITHM

Having obtained the integrability conditions and specified the number N, our basic aim is to determine the integrable systems (or classes of systems) with their associated recursion operators by solving the whole set of conditions (4). For this purpose we base our classification on b^i_j and solve conditions (4) for each of the specially chosen different forms of b^i_j matrix. Having chosen a certain b^i_j matrix, we first solve the algebraic part of the equations in (4). Although the number of algebraic equations is quite large even for $N=2$, since the constituent equations are polynomials of order at most two in the unknowns, they can be solved by computer algebra systems conveniently. We used REDUCE[20] and MUPAD[21] software for computations. Each nontrivial solution to the algebraic part is then subjected to the remaining differential conditions.

In general, for a certain b^i_j matrix there exist many solutions to the integrability conditions (4). However, some of these solutions give rise to systems which are not interesting: Decoupled systems, trivially coupled systems like $u_t=F[u,t]$, $v_t=G[u,t]$ or completely linear systems. Besides these, some solutions require the recursion operator to be identity, in case of which (3) is obviously inconclusive for the integrability of the system at hand. We call solutions giving rise to these kind of systems or recursion operators as *trivial solutions*. We discard all such trivial solutions.

For the choice of the form of b^i_j matrix we make use of the Jordan canonical form theorem of matrices which says that under similarity transformations any 2×2 constant matrix, say A, is equivalent to one of the following matrices which are the Jordan canonical forms:

$$J(1)=\begin{pmatrix}1&0\\0&1\end{pmatrix},\quad J(2)=\begin{pmatrix}\lambda_1&0\\0&\lambda_2\end{pmatrix},\quad J(3)=\begin{pmatrix}\lambda&1\\0&\lambda\end{pmatrix}, \tag{5}$$

where λ_i are the eigenvalues of original matrix A. Nonautonomous systems associated with the identity matrix $J(1)$ are extensively investigated in Ref. 13. Our present classification concerns the classes associated with the latter two matrices $J(2)$ and $J(3)$. Starting from these matrices and taking equivalence of systems under scale transformations of evolution parameter t into account we conclude that (excluding the null matrix) without loss of generality, it is sufficient to consider

$$b(1)=\begin{pmatrix}1&0\\0&\lambda\end{pmatrix},\quad b(2)=\begin{pmatrix}1&\lambda\\0&1\end{pmatrix},\quad b(3)=\begin{pmatrix}1&0\\0&0\end{pmatrix},\quad b(4)=\begin{pmatrix}0&1\\0&0\end{pmatrix} \tag{6}$$

as 2×2 matrices for b^i_j in our classification. Here, in $b(1)$ $\lambda\neq1$ and $\lambda\neq0$, in $b(2)$ $\lambda\neq0$. Any two-component quasilinear evolution equation, such as (1), whose coefficient matrix b^i_j of leading order terms other than the identity can be put in a form such that its transformed coefficient matrix, say $\tilde{b}^i_j$, is either of $b(1)$, $b(2)$, $b(3)$ or $b(4)$. Therefore, it is natural to say a system is in Jordan canonical form if so is its coefficient matrix b^i_j.

In literature, except for a few systems, most of the integrable systems are given in Jordan canonical form. One of these exceptions is the systems with five arbitrary constants introduced by Fokas and Liu in the context of asymptotic integrability of water waves.[7] As an illustrative example of the above proposal about the Jordan canonical forms of systems, we reconsider the Fokas–Liu systems and give their Jordan canonical forms together with the transformations bringing them to these forms here. These systems are originally given as

$$
\begin{aligned}
&u_t+v_x+\epsilon[(3\beta_1+2\beta_4)\beta_3 uu_x+(2+\beta_1\beta_4)\beta_3(uv)_x+\beta_1\beta_3 vv_x\\
&\quad+(\beta_1+\beta_4)\beta_2 u_{xxx}+(1+\beta_1\beta_4)\beta_2 v_{xxx}]=0,\\
&v_t+u_x+\epsilon[(2+3\beta_1\beta_4)\beta_3 vv_x+(\beta_1+2\beta_4)\beta_3(uv)_x+\beta_1\beta_3\beta_4 uu_x\\
&\quad+(1+\beta_1\beta_4)\beta_2\beta_4 v_{xxx}+(\beta_1+\beta_4)\beta_2\beta_4 u_{xxx}]=0,
\end{aligned}
\tag{7}
$$

where ϵ, β_1, β_2, β_3, β_4 are arbitrary constants and $\beta_1^2\neq 1$. Systems (7) reduce to linear systems for $\epsilon=0$ or $\beta_3=0$ and to first order (hydrodynamic type) systems for $\beta_2=0$. Here, we consider only the third order nonlinear systems by taking $\epsilon\neq 0$, $\beta_2\neq 0$, $\beta_3\neq 0$. Furthermore, we make the following distinction:

(i) $\beta_1\neq -2\beta_4/\beta_4^2+1$, $\beta_1^2\neq 1$,
(ii) $\beta_1=-2\beta_4/\beta_4^2+1$, $\beta_4\neq 0$, $\beta_4^2\neq\pm 1$,
(iii) $\beta_1=-2\beta_4/\beta_4^2+1$, $\beta_4=0$,

in the space of arbitrary parameters.

In case (i), applying the following change of dependent variables

$$
\begin{pmatrix}\tilde{u}\\ \tilde{v}\end{pmatrix}=\frac{\beta_3}{2\beta_2(\beta_1\beta_4^2+\beta_1+2\beta_4)}\begin{pmatrix}\beta_1+\beta_4 & \beta_1\beta_4+1\\ \pm\beta_4\sqrt{\beta_1^2-1} & \mp\sqrt{\beta_1^2-1}\end{pmatrix}\begin{pmatrix}u-A_1\\ v-B_1\end{pmatrix},
\tag{8}
$$

and rescaling of evolution parameter t,

$$
\tau=-\epsilon\beta_2(\beta_1\beta_4^2+\beta_1+2\beta_4)t,
\tag{9}
$$

we arrive at a Jordan canonical form of systems (7) irrespective of the values of constant shifting parameters A_1 and B_1.[10] But let us for the sake of simplicity of final expression take

$$
A_1=\frac{-\beta_1\beta_4^3+3\beta_1\beta_4+2}{\epsilon\beta_3[\beta_1\beta_4^2+\beta_1+2\beta_4]^2},\quad B_1=\frac{3\beta_1\beta_4^2-\beta_1+2\beta_4^3}{\epsilon\beta_3[\beta_1\beta_4^2+\beta_1+2\beta_4]^2}.
$$

After all, we get

$$
\begin{aligned}
\tilde{u}_\tau&=\tilde{u}_{xxx}+3\tilde{u}\tilde{u}_x+2\tilde{v}\tilde{v}_x+\frac{4(\beta_4^2+2\beta_1\beta_4+1)}{\epsilon\beta_2[\beta_1\beta_4^2+\beta_1+2\beta_4]^2}\tilde{u}_x,\\
\tilde{v}_\tau&=2(\tilde{u}\tilde{v})_x,
\end{aligned}
\tag{10}
$$

as a Jordan canonical form of systems (7) in the new variables in the mentioned case of arbitrary parameters ϵ and β_i, $i=1,2,3,4$.

In case (ii), the following transformation:

$$
\begin{pmatrix}\tilde{u}\\ \tilde{v}\end{pmatrix}=\begin{pmatrix}0 & \dfrac{\beta_3}{\beta_2\beta_4}\\ \dfrac{\epsilon\beta_3\beta_4(1-\beta_4^2)}{\beta_4^2+1} & -\dfrac{\epsilon\beta_3(1-\beta_4^2)}{\beta_4^2+1}\end{pmatrix}\begin{pmatrix}u-A_2\\ v-B_2\end{pmatrix},
\tag{11}
$$

where

$$
A_2=\frac{-2\beta_4^4-\beta_4^2+1}{2\epsilon\beta_3\beta_4^2(\beta_4^2-1)^2},\quad B_2=\frac{-\beta_4(\beta_4^2+1)}{2\epsilon\beta_3(\beta_4^2-1)^2},
$$

gives the following Jordan canonical form of systems (7):

$$\begin{aligned}\tilde{u}_t&=\tilde{v}_{xxx}+2(\tilde{u}\tilde{v})_x+\frac{2(\beta_4^2+1)}{\epsilon\beta_2\beta_4(\beta_4^2-1)^2}\tilde{v}\tilde{v}_x,\\ \tilde{v}_t&=2\tilde{v}\tilde{v}_x+\frac{2}{\beta_4}\tilde{v}_x+\frac{\epsilon\beta_2(\beta_4^2-1)^2}{\beta_4^2+1}\tilde{u}_x.\end{aligned}\tag{12}$$

In case (iii), i.e., for $\epsilon\neq 0$, $\beta_2\neq 0$, $\beta_3\neq 0$, $\beta_1=0$, $\beta_4=0$, systems (7) reduce to a system which is already in Jordan canonical form. A simple scaling of t brings it to the form which has $b(4)$ as its b_j^i matrix.

It is apparent and in accordance with the above proposal regarding the Jordan canonical forms that the coefficient matrix b_j^i of systems (10) and (12) are $b(3)$ and $b(4)$, respectively. By including the Jordan matrices into the classification algorithm at the beginning, we restrict ourselves to a convenient base for obtaining the results without any loss of generality. In our classification algorithm each of the matrices $b(i)$, $i=1,2,3,4$ in (6) cause a different set of solutions to the integrability conditions (4). We call a collection of systems obtained under a certain $b(i)$ matrix as a class and naturally identify each class with its $b(i)$ matrix.

IV. CLASSES

In the rest of our work, we present the found two-component nontrivial integrable systems and their associated recursion operators with a slight change $q^1=u$ and $q^2=v$ in notation.

A. Class $b(1)$

Although our main concern is the nonautonomous systems, solutions of integrability conditions (4) give rise to autonomous systems as well. In each class we first give the autonomous systems with their respective recursion operators. In the present class, there is only the following autonomous integrable system:

$$\begin{aligned}u_t&=u_{xxx}+c_1(2vu_x+uv_x),\\ v_t&=\tfrac{1}{4}v_{xxx}+2c_1vv_x,\end{aligned}\tag{13}$$

where c_1 is an arbitrary constant.[10] The recursion operator admitted by (13) is

$$\mathcal{R}=\begin{pmatrix} D^2+\frac{4}{3}c_1v & c_1u+\frac{2}{3}c_1u_xD^{-1}\\ 0 & \frac{1}{4}D^2+\frac{4}{3}c_1v+\frac{2}{3}c_1v_xD^{-1}\end{pmatrix}.$$

The only nonautonomous system in the present class is

$$\begin{aligned}u_t&=u_{xxx}+\frac{c_1}{\sqrt{t}}(2vu_x+uv_x),\\ v_t&=\frac{1}{4}v_{xxx}+\frac{2c_1}{\sqrt{t}}vv_x,\end{aligned}\tag{14}$$

where c_1 is an arbitrary constant. This system admits the following recursion operator:

$$\mathcal{R}=\begin{pmatrix} tD^2+\frac{1}{3}x+\frac{4}{3}c_1\sqrt{t}v & c_1\sqrt{t}u+\frac{2}{3}c_1\sqrt{t}u_xD^{-1} \\ 0 & \frac{1}{4}tD^2+\frac{1}{3}x+\frac{4}{3}c_1\sqrt{t}v+\frac{1}{3}(2c_1\sqrt{t}v_x+\frac{1}{2})D^{-1} \end{pmatrix}.$$

The above-mentioned systems (13) and (14) are the only nontrivial systems in $b(1)$ class. All other solutions of integrability conditions (4) with $b^i_j=b(1)$ are trivial.

Systems related by invertible transformations are considered equivalent.[13–16] Therefore, we analyzed all the found nonautonomous systems in regard to their transformability to autonomous systems through a certain class of transformations. In the next proposition we present the result relevant to the system (14).

Proposition 2: Nonautonomous system (14) is not transformable to any autonomous system by the invertible change of variables:

$$\begin{aligned} x&=\alpha(\tilde{t})\tilde{x}+\beta(\tilde{t}),\ t=\gamma(\tilde{t}),\\ u(x,t)&=\delta(\tilde{t})\tilde{u}(\tilde{x},\tilde{t})+\phi(\tilde{x},\tilde{t}),\\ v(x,t)&=\rho(\tilde{t})\tilde{v}(\tilde{x},\tilde{t})+\psi(\tilde{x},\tilde{t}). \end{aligned} \tag{15}$$

This proposition can be verified by explicitly transforming system (14) by transformations (15). After the transformation, requirement of the coefficients of new dependent variables to be constants leads to contradiction.

B. Class $b(2)$

In this class there is only the following nontrivial system as solution of integrability conditions (4):

$$\begin{aligned} u_t&=u_{xxx}+\lambda v_{xxx}+\frac{c_1}{\sqrt{t}}(uv)_x+\frac{\lambda c_1}{2\sqrt{t}}vv_x,\\ v_t&=v_{xxx}+\frac{c_1}{\sqrt{t}}vv_x, \end{aligned} \tag{16}$$

which is integrable for arbitrary constants c_1 and $\lambda\neq 0$ introduced in $b(2)$ of (6). This system admits the recursion operator $\mathcal{R}=\left(\begin{smallmatrix}\mathcal{R}^0_0 & \mathcal{R}^0_1\\ \mathcal{R}^1_0 & \mathcal{R}^1_1\end{smallmatrix}\right)$ with

$$\mathcal{R}^0_0=tD^2+\frac{1}{3}x+\frac{2}{3}c_1\sqrt{t}v+\frac{1}{3}(c_1\sqrt{t}v_x+\frac{1}{2})D^{-1},$$

$$\mathcal{R}^0_1=\lambda tD^2+\frac{2}{3}c_1\sqrt{t}u+\frac{1}{3}\lambda c_1\sqrt{t}v+\frac{1}{3}c_1\sqrt{t}\left(u_x+\frac{\lambda}{2}v_x\right)D^{-1},$$

$$\mathcal{R}^1_0=0,$$

$$\mathcal{R}^1_1=tD^2+\frac{1}{3}x+\frac{2}{3}c_1\sqrt{t}v+\frac{1}{3}(c_1\sqrt{t}v_x+\frac{1}{2})D^{-1}.$$

A straightforward calculation proves the following statement about system (16).

Proposition 3: System (16) is not transformable to any autonomous system by transformations (15).

C. Class $b(3)$

For $b_j^i = b(3)$ in (6), solutions of integrability conditions (4) give rise to the following list of autonomous systems and their associated recursion operators:

(i)

$$\begin{matrix} u_t = u_{xxx} + 3c_1 u u_x, \\ v_t = c_1 u v_x + c_2 v u_x, \end{matrix} \quad \mathcal{R} = \begin{pmatrix} D^2 + 2c_1 u + c_1 u_x D^{-1} & 0 \\ c_2 v + c_1 v_x D^{-1} & 0 \end{pmatrix}, \tag{17}$$

where c_1 and c_2 are arbitrary constants.[6,17]

(ii)

$$\begin{matrix} u_t = u_{xxx} + 3c_1 u u_x + c_2 v v_x, \\ v_t = c_1 (uv)_x, \end{matrix} \quad \mathcal{R} = \begin{pmatrix} D^2 + 2c_1 u + c_1 u_x D^{-1} & c_2 v \\ c_1 v + c_1 v_x D^{-1} & 0 \end{pmatrix}, \tag{18}$$

where c_1 and c_2 are arbitrary constants. For $c_1 \neq 0$ and $c_2 \neq 0$ this system is equivalent to the Ito system[18] through $u \to (2/c_1)\, u$, $v \to (2/\sqrt{c_1 c_2})\, v$. It is also possible to obtain the Ito system as $\beta_1 = -(\beta_4^2 + 1)/2\beta_4$ $(\beta_4 \neq 0)$, reduction of system (10). Therefore, Fokas–Liu system[7] includes the Ito system as a special case.

(iii)

$$\begin{matrix} u_t = u_{xxx} + 3c_1 u u_x, \\ v_t = (c_1 u + c_2 v) v_x, \end{matrix} \quad \mathcal{R} = \begin{pmatrix} D^2 + 2c_1 u + c_1 u_x D^{-1} & 0 \\ c_1 v_x D^{-1} & c_2 v \end{pmatrix}, \tag{19}$$

where c_1 and c_2 are arbitrary constants.[8]

The followings are the nonautonomous systems with their respective recursion operators in the $b(3)$ class.

(iv)

$$\begin{gathered} u_t = u_{xxx} + c_1 t^{-(\alpha + 2/3)} v v_x + c_2 t^{-(\alpha+1)} v, \\ v_t = t^{-2/3} v v_x, \end{gathered} \tag{20}$$

where c_1, c_2, and α are arbitrary constants. This system admits the recursion operator

$$\mathcal{R} = \begin{pmatrix} tD^2 + \dfrac{x}{3} + \alpha D^{-1} & t^{-\alpha}(c_1 t^{1/3} v + c_2 D^{-1}) \\ 0 & t^{1/3} v + \dfrac{x}{3} \end{pmatrix}. \tag{21}$$

(v)

$$\begin{gathered} u_t = u_{xxx} + e^{-\alpha t}(c_1 v v_x + c_2 v), \\ v_t = v v_x, \end{gathered} \tag{22}$$

where c_1, c_2, and α are arbitrary constants. The recursion operator is

$$\mathcal{R} = \begin{pmatrix} D^2 + \alpha D^{-1} & e^{-\alpha t}(c_1 v + c_2 D^{-1}) \\ 0 & v \end{pmatrix}. \tag{23}$$

(vi)

$$u_t = u_{xxx} + c_1 c_2 t^{-1/2} u u_x,$$
$$v_t = \tfrac{1}{3}(c_1 c_2 t^{-1/2} u v_x + c_1 t^{-2/3} v v_x + c_2 t^{-5/6} u), \tag{24}$$

where c_1 and c_2 are arbitrary constants. This system admits the recursion operator

$$\mathcal{R}_0^0 = tD^2 + \frac{x}{3} + \frac{2}{3} c_1 c_2 t^{1/2} u + \frac{1}{3}\left(c_1 c_2 t^{1/2} u_x + \frac{1}{2} \right) D^{-1},$$
$$\mathcal{R}_1^0 = 0,$$
$$\mathcal{R}_0^1 = \tfrac{1}{3} c_2 (c_1 t^{1/2} v_x + t^{1/6}) D^{-1}, \tag{25}$$
$$\mathcal{R}_1^1 = \tfrac{1}{3}(c_1 t^{1/3} v + x).$$

Solutions of integrability conditions (4) other than those giving the above list of systems are trivial. Therefore, the above list of systems is the complete list of nontrivial systems in the $b(1)$ class.

The following proposition is about the transformability of nonautonomous systems found in the present class.

Proposition 4: None of the nonautonomous systems (20), (22), and (24) is transformable to any autonomous system by transformations (15).

The $\alpha = 0$ special case of system (22) is the only exception. In this case system (22) is apparently autonomous. This proposition can be verified by direct calculation for each of the mentioned systems.

D. Class $b(4)$

Solutions of integrability conditions (4) with $b_j^i = b(4)$ in (6) give rise to the following list of nontrivial, integrable subclasses of systems:

(i)

$$u_t = v_{xxx} + v u_x + c_1 u v_x + s v v_x + y v,$$
$$v_t = v v_x, \tag{26}$$

where c_1 is an arbitrary constant, is integrable if the undetermined functions $s = s(t)$ and $y = y(t)$ satisfy the differential constraint

$$\frac{ds}{dt} + c_1 y = 0. \tag{27}$$

These systems admit the recursion operator

$$\mathcal{R} = \begin{pmatrix} \left(1 - \dfrac{c_1}{2}\right) v & D^2 + c_1 u + s v + \dfrac{c_1}{2} u_x D^{-1} \\ 0 & \left(1 - \dfrac{c_1}{2}\right) v + \dfrac{c_1}{2} v_x D^{-1} \end{pmatrix}. \tag{28}$$

(ii)

$$u_t = v_{xxx} + c_1(vu_x + 2uv_x) + svv_x + yv,$$
$$v_t = vv_x, \tag{29}$$

where c_1 is an arbitrary constant, is integrable if the undetermined functions $s=s(t)$ and $y=y(t)$ satisfy the differential constraint

$$\frac{ds}{dt} + (3c_1 - 1)y = 0. \tag{30}$$

The recursion operator is

$$\mathcal{R} = \begin{pmatrix} 0 & D^2 + 2c_1u + sv + c_1u_xD^{-1} \\ 0 & (1-c_1)v + c_1v_xD^{-1} \end{pmatrix}. \tag{31}$$

In this subclass we observed that the $c_1=1$ particular case of system (29) with (30) admits two recursion operators $\mathcal{R}(1)$ and $\mathcal{R}(2)$. The first one is (31) with $c_1=1$. The second recursion operator is

$$\mathcal{R}(2) = \begin{pmatrix} 0 & tD^2 + 2tu + tsv + (tu_x - \frac{1}{2}s)D^{-1} \\ 0 & (tv_x + 1)D^{-1} \end{pmatrix}. \tag{32}$$

(iii)

$$u_t = v_{xxx} + t^{-2/3}(vu_x + c_1vv_x) + yv,$$
$$v_t = t^{-2/3}vv_x, \tag{33}$$

where c_1 is an arbitrary constant, is integrable for any arbitrary function $y=y(t)$. The recursion operators of this system are

$$\mathcal{R}(1) = \begin{pmatrix} \frac{x}{3} + t^{1/3}v & tD^2 + c_1t^{1/3}v \\ 0 & \frac{x}{3} + t^{1/3}v \end{pmatrix}, \quad \mathcal{R}(2) = \begin{pmatrix} 0 & D^{-1} \\ 0 & 0 \end{pmatrix}. \tag{34}$$

The second operator $\mathcal{R}(2)$ is not a proper recursion operator because of its nilpotent character. Even though $\mathcal{R}(2)$ solely is not sufficient for integrability, any linear combination of it with $\mathcal{R}(1)$ is a recursion operator for system (33).

(iv)

$$u_t = v_{xxx} + t^{\alpha}\left(uv_x + \frac{\alpha+1}{3\alpha+2}vu_x + svv_x\right) + yv,$$
$$v_t = \frac{\alpha+1}{3\alpha+2}t^{\alpha}vv_x, \tag{35}$$

where $\alpha \neq -2/3$ is an arbitrary constant, is integrable if the undetermined functions $s=s(t)$ and $y=y(t)$ satisfy the differential constraint

$$\frac{ds}{dt} + y = 0. \tag{36}$$

These systems admit the recursion operator

$$\mathcal{R}_0^0=-\frac{\alpha}{2}\left(x+\frac{t^{\alpha+1}}{3\alpha+2}v\right),$$

$$\mathcal{R}_1^0=tD^2+t^{\alpha+1}u+t^{\alpha+1}sv+\tfrac{1}{2}[t^{\alpha+1}u_x-(3\alpha+2)s]D^{-1},$$

$$\mathcal{R}_0^1=0, \tag{37}$$

$$\mathcal{R}_1^1=-\frac{\alpha}{2}\left(x+\frac{t^{\alpha+1}}{3\alpha+2}v\right)+\frac{1}{2}[t^{\alpha+1}v_x+3\alpha+2]D^{-1}.$$

(v)

$$u_t=v_{xxx}+e^{t/\alpha}(vu_x+3uv_x+svv_x)+yv,$$

$$v_t=e^{t/\alpha}vv_x, \tag{38}$$

where $\alpha\neq 0$ is an arbitrary constant, is integrable if the undetermined functions $s=s(t)$ and $y=y(t)$ satisfy the differential constraint

$$\frac{\mathrm{d}s}{\mathrm{d}t}+3y=0. \tag{39}$$

The recursion operator is

$$\mathcal{R}_0^0=-\tfrac{1}{2}(x+\alpha e^{t/\alpha}v),$$

$$\mathcal{R}_1^0=\alpha\left[D^2+3e^{t/\alpha}u+e^{t/\alpha}sv+\frac{1}{2}\left(3e^{t/\alpha}u_x-\frac{1}{\alpha}s\right)D^{-1}\right],$$

$$\mathcal{R}_0^1=0, \tag{40}$$

$$\mathcal{R}_1^1=-\tfrac{1}{2}(x+\alpha e^{t/\alpha}v)+\tfrac{3}{2}(\alpha e^{t/\alpha}v_x+1)D^{-1}.$$

(vi)

$$u_t=v_{xxx}+(uv)_x+svv_x+yv,$$

$$v_t=vv_x, \tag{41}$$

is integrable for any arbitrary functions $s=s(t)$ and $y=y(t)$. These systems admit the recursion operators $\mathcal{R}(1)$, $\mathcal{R}(2)$, and $\mathcal{R}(3)$, where

$$\mathcal{R}(1)_0^0=-v_xD^{-1},$$

$$\mathcal{R}(1)_1^0=D^2+2u-2\left(\int y\,\mathrm{d}t\right)v+\left[u_x+\left(\int y\,\mathrm{d}t\right)v_x\right]D^{-1},$$

$$\mathcal{R}(1)_0^1=0, \tag{42}$$

$$\mathcal{R}(1)_1^1=v_xD^{-1},$$

$$\mathcal{R}(2)_0^0=-x-tv-2(tv_x+1)D^{-1},$$

$$\mathcal{R}(2)_1^0=2tu+2\left(\int (s-ty)\mathrm{d}t\right)v+\left[tu_x+\left(\int\left(s+2ty+3\int y\,\mathrm{d}t\right)\mathrm{d}t\right)v_x+3\int y\,\mathrm{d}t\right]D^{-1},$$

$$\mathcal{R}(2)_0^1=0,$$

$$\mathcal{R}(2)_1^1=-x-tv+(tv_x+1)D^{-1},$$

$$\mathcal{R}(3)=\begin{pmatrix}0 & x+tv\\ 0 & 0\end{pmatrix}. \tag{43}$$

(vii)

$$u_t=v_{xxx}+\frac{1}{\sqrt{t}}(uv)_x+svv_x+yv,$$

$$v_t=\frac{1}{\sqrt{t}}vv_x, \tag{44}$$

is integrable for any arbitrary functions $s=s(t)$ and $y=y(t)$. These systems admit the recursion operators $\mathcal{R}(1)$, $\mathcal{R}(2)$, and $\mathcal{R}(3)$ where

$$\mathcal{R}(1)_0^0=x+2\sqrt{t}v+(2\sqrt{t}v_x+1)D^{-1},$$

$$\mathcal{R}(1)_1^0=2tD^2-\left[\left(\int\left(2\sqrt{t}y+\frac{1}{\sqrt{t}}\int y\,\mathrm{d}t\right)\mathrm{d}t\right)v_x+\int y\,\mathrm{d}t\right]D^{-1},$$

$$\mathcal{R}(1)_0^1=0,$$

$$\mathcal{R}(1)_1^1=x+2\sqrt{t}v, \tag{45}$$

$$\mathcal{R}(2)_0^0=x+2\sqrt{t}v,$$

$$\mathcal{R}(2)_1^0=4tD^2+4\sqrt{t}u+2\left(\int(s-2\sqrt{t}y)\mathrm{d}t\right)v+\left[2\sqrt{t}u_x+\left(\int\left(s+\frac{1}{\sqrt{t}}\int y\,\mathrm{d}t\right)\mathrm{d}t\right)v_x+\int y\,\mathrm{d}t\right]D^{-1},$$

$$\mathcal{R}(2)_0^1=0,$$

$$\mathcal{R}(2)_1^1=x+2\sqrt{t}v+(2\sqrt{t}v_x+1)D^{-1},$$

$$\mathcal{R}(3)=\begin{pmatrix}0 & x+2\sqrt{t}v\\ 0 & 0\end{pmatrix}. \tag{46}$$

Solutions of integrability conditions (4) with $b_j^i=b(4)$ other than those giving the above list of systems are trivial.

We have the following proposition on the transformability of nonautonomous systems of the above subclasses found in the present class.

Proposition 5: None of the nonautonomous systems in each of the subclasses (26), (29), (33), (35), (38), (41) and (45) of class $b(4)$ *is transformable to any autonomous system by transformations (15).*

In the above subclasses, some choice of undetermined functions or arbitrary constants, like, for example, $y(t)=0$ in (30), can lead to autonomous systems. Such autonomous systems are out of the scope of Proposition 5.

It has been recently observed that some recursion operators, which are called weak, do not always generate symmetry hierarchies correctly.[22] Some of the operators we found in this work are of this type. The source of this weakness and possible solutions which relies on the found weak recursion operators are extensively investigated in Ref. 23.

We would like to remark that our classification is a partial classification which gives only systems (1) admitting recursion operator of form (2). As it is shown in a recent work,[24] even an autonomous coupled KdV system may admit a strange recursion operator which is not of form (2).

Systems whose recursion operators are bi-Hamilton factorizable, are of special interest from a physical point of view. Our knowledge on whether the recursion operators we obtained in this work are factorizable in this way is very limited at the moment. We have only some negative results about the bi-Hamilton factorizability of some of the found recursion operators up to the Hamilton operators, which are a multicomponent generalization of the Hamilton operators of the usual KdV equation.

(Received 19 October 2003; accepted 6 November 2003)

By using two different procedures we show that on the space of solutions of a certain class of second-order ordinary differential equations, $u''=\Lambda(s,u,u')$, a two-dimensional definite or indefinite metric, g_{ab}, can be constructed such that the two-dimensional Hamilton–Jacobi equation, $g^{ab}u_{,a}u_{,b}=1$ holds. Furthermore, we show that this structure is invariant under a certain subset of contact transformations (canonical transformations). Two examples are given. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1639957]

I. INTRODUCTION

In the early years of the 20th century, while studying the structure and transformation properties of second- and third-order ordinary differential equations (ODEs), Lie, Tresse, Wünschmann,[1–4] among others, discovered that there was a rich differential geometry induced on the solution spaces of the differential equations. This work was greatly developed and generalized by Cartan and Chern[5–9] in the 1930s–1940s. Bryant,[10] in more recent years, studied the geometry associated with fourth-order ODEs. Tod[11] showed how third-order ODEs could generate three-dimensional Einstein–Weyl metrics.

With a totally different motivation and from a different point of view originating with general relativity, Frittelli, Kozameh and Newman, in a series of papers,[12–17] came to the same set of issues and problems. Rather than starting with given differential equations, the point of view of these authors began with three- and four-dimensional conformal Lorentzian manifolds, already containing a metric. They then studied families of complete solutions to the eikonal equation on these manifolds. From these solutions, by the elimination of the space–time coordinates, the differential equations of Cartan and Chern were reobtained. However, from this point of view, unwittingly, the Cartan/Chern work was generalized from ODEs to pairs of second-order partial differential equations (PDEs) whose solution spaces could be identified with any four-dimensional manifold with a conformal Lorentzian metric. In particular, they showed that the Einstein equations could be reformulated in terms of pairs of second-order PDEs.

Later, with Kamran and Nurowski,[18–22] this work was connected with the Cartan/Chern work for both the equivalence problem for differential equations under a variety of transformations and with the theory of Cartan normal conformal connections. With this consideration one saw how the differential equations (both the third-order equation and the pair of second-order equations) had to lie in a restricted class defined by the vanishing of the so-called Wünschmann (or generalized Wünschmann) equation.

An underlying unifying theme in many of the discussions was the existence of the eikonal

a)Electronic mail: newman@pitt.edu

equation and families of complete solutions. These solutions could be obtained either via the given third-order ODE or pair of second-order PDEs or alternatively from the solutions to the eikonal equation on the given conformal background space.

In the present work, we return to the geometry associated with a new class of second-order ODEs. The connecting link with the earlier work is that now we use the time-independent Hamilton–Jacobi equation rather than the eikonal equation to obtain this new class. We show (via two different procedures) that, in the solution spaces of the ODEs, either a two-dimensional Riemannian or Lorentzian metric can be constructed in a natural way. Furthermore all 2-metrics can be found by this procedure. The metric structure associated with each differential equation is preserved when the equation is transformed by a subset of contact transformations (namely canonical transformations).

In Sec. II we begin with a two-dimensional manifold, $\mathcal{M}$, with no further structure and then investigate arbitrary families of curves on $\mathcal{M}$ given by $u=\text{constant}=Z(x^a,s)$. (The x^a are local coordinates on $\mathcal{M}$ and s parametrizes the families and takes values on $\mathcal{S}^1$ or on $\mathcal{R}$.) More specifically, we ask when do such families of curves define a two-dimensional metric, $g_{ab}(x^a)$, such that

$$g^{ab}\nabla_a Z(x^a,s)\nabla_b Z(x^a,s)=1. \tag{1}$$

We will show that the $u=Z(x^a,s)$ must also satisfy a second-order ODE,

$$u''=\Lambda(u,u',s), \tag{2}$$

that lies in a special class of equations that we will refer to as ''Wünschmann-like,'' defined by the restriction of Λ to solutions of

$$\Lambda_{us}+\Lambda_{uu}u'+\Lambda_{uu'}\Lambda-2\Lambda_u\Lambda_{u'}=0. \tag{3}$$

The prime denotes ''s'' derivatives. Note that in the solutions $u=Z(x^a,s)$, the x^a are a pair of integration constants for Eq. (2) while the ''s'' is an integration constant for Eq. (1).

Before proceeding we make the following important remark:

Remark 1: The time independent Hamilton–Jacobi equation for a particle, with mass m and energy E, in a two-dimensional Riemannian space under the influence of a potential and the eikonal equation describing the evolution of the light rays in a two-dimensional isotropic optical medium characterized by its index of refraction, i.e., either of

$$g^{*ab}\nabla_a S(x^a,s)\nabla_b S(x^a,s)=E-V(x^a),$$

$$g^{*ab}\nabla_a S(x^a,s)\nabla_b S(x^a,s)=n(x^a),$$

can be rewritten in the form of Eq. (1) by dividing the equations by either $E-V(x^a)$ or by $n(x^a)$ and simultaneously rescaling the metric by the same factors.

This action has the effect of changing certain properties of solutions to the Hamilton–Jacobi (HJ) equation. Normally for the two-dimensional (HJ) equation a complete solution contains two constants of integration, where one of them is E. In our case, after the conformal rescaling, the E is hidden as a *fixed* constant in the metric g^{ab} and the solution will depend now on only one parameter, ''s.'' With an abuse of language, we will refer to $u=Z(x^a,s)$ as a ''restricted complete'' solution to the (HJ) equation. This change, in turn, leads to modifications in certain transformation properties of the solutions; contact transformations become canonical transformations. This issue is discussed in Sec. III.

In Sec. III we begin with a general second-order ODE (prime denotes s derivatives)

$$u''=\Lambda(s,u,u'), \tag{4}$$

whose solution space is parametrized by two independent constants of integration $x^a=(x^1,x^2)$. Then by studying the two-parameter family of curves in the (u,s) space defined as solutions to Eq. (2), namely,

$$u=Z(x^a,s), \tag{5}$$

and their generalized Jacobi fields, $(\delta u,\ \delta u')$ obtained by the independent variation of the two constants of integration x^a and one s derivative of Eq. (5) we show how a simple condition leads to the Wünschmann-like condition and the associated two-dimensional metric. In this section it is also remarked that this structure is invariant under a certain subclass of contact transformations. Finally, two particular examples are presented.

II. TWO-DIMENSIONAL METRICS AND THE WÜNSCHMANN-LIKE CONDITION

We begin with a two-dimensional manifold $\mathcal{M}$ (with local coordinates $x^a=(x^1,x^2)$) and assume we are given a one-parameter set of functions $u=Z(x^a,s)$, the parameter s can take values on $\mathcal{S}^1$ or on $\mathcal{R}$. We also assume that for a fixed value of the parameter s, the level curves

$$u=\text{const}=Z(x^a,s), \tag{6}$$

locally foliate the manifold $\mathcal{M}$ and that $u=Z(x^a,s)$ satisfies the (HJ) equation, Eq. (1),

$$g^{ab}\nabla_a Z(x^a,s)\nabla_b Z(x^a,s)=1, \tag{7}$$

for some unknown metric $g_{ab}(x^a)$.

Remark 2: The statement that for any fixed value of s, $u=Z(x^a,s)$ is a solution of Eq. (1), in the case of the eikonal equation, means that the level curves of u are wave fronts. That is, in this case we are looking for the conditions on the one-parameter family of functions u such that its associated level curves are the wave fronts associated with an optical metric (see Torres del Castillo[23] for a definition of the optical metric). In this case, it can be shown that in order to construct an arbitrary wave front in the two-dimensional isotropic optical medium, via the envelope construction, we require that $-\pi\leqslant s\leqslant\pi$.

The basic idea now is to solve Eq. (1) for the three components of the metric in terms of $\nabla_a Z(x^a,s)$. To do so, we will consider a number of parameter derivatives of the condition (1), and then by manipulation of these derivatives, obtain both the two-dimensional metric and the equation defining the curves and the conditions it must satisfy, which we will refer to as the Wünschmann-like condition.

Remark 3: The notation is as follows: there will be two types of differentiation, one is with respect to the local coordinates, x^a, of the manifold $\mathcal{M}$, denoted by ∇_a or "comma a," the other is with respect to the parameter s, denoted by a prime.

We first note that the one-parameter family of ''level'' curves, Eq. (6), can be obtained as solutions to the second-order ODE

$$u''=\Lambda(u,u',s). \tag{8}$$

It can be found by first calculating

$$u''(x^a,s)\equiv\Lambda^*(x^a,s). \tag{9}$$

Then by inverting the pair

$$u=Z(x^a,s),$$

$$u'=Z'(x^a,s)$$

obtaining

$$x^a = x^a(u,u',s) \tag{10}$$

the two x^a can be eliminated in Λ^* yielding Eq. (8).

Remark 4: Equation (10) can be thought of as an "s" dependent coordinate transformation between x^a and (u,u').

We define two parametrized scalars,

$$\theta^i = \{\theta^0, \theta^1\} \equiv \{u,u'\} = \{Z(x^a,s), Z'(x^a,s)\}, \tag{11}$$

which for each value of s forms a coordinate system intrinsically adapted to the curves.

From the two scalars, θ^i, we have their associated gradient basis $\theta^i{}_a$ given by

$$\theta^i{}_a = \nabla_a \theta^i = \{Z_{,a}, \partial Z_{,a}\}, \tag{12}$$

and its dual vector basis $\theta_i{}^a$, so that

$$\theta_i{}^a \theta^j{}_{,a} = \delta_i^j, \quad \theta_i{}^a \theta^i{}_{,b} = \delta_b{}^a. \tag{13}$$

Remark 5: The total s derivative of a function $F = F(s,u,u')$ is defined by

$$DF \equiv F_s + F_u u' + F_{u'} \Lambda. \tag{14}$$

It is easier to search for the components of the two-dimensional metric in the gradient basis rather than in the original coordinate basis. Furthermore, it is preferable to use the contravariant components rather than the covariant components of the metric; that is, we are interested in

$$g^{ij}(x^a,s) = g^{ab}(x^a)\, \theta^i{}_{,a}\, \theta^j{}_{,b}. \tag{15}$$

The metric components and the Wünschmann-like condition, for this case, are obtained by repeatedly operating with ∂_s on Eq. (7), that is on

$$g^{00} = g^{ab} Z_{,a} Z_{,b} = 1. \tag{16}$$

Applying ∂_s on Eq. (16) yields

$$\partial_s (g^{ab} Z_{,a} Z_{,b}) = 2 g^{ab} Z'_{,a} Z_{,b} = 2 g^{10} = 0, \tag{17}$$

where we have used that $\partial_s g^{ab} = 0$. Applying ∂_s on Eq. (17) we obtain, using Eq. (8),

$$g^{ab} (\Lambda_{,a} Z_{,b} + Z'_{,a} Z'_{,b}) = 0. \tag{18}$$

Since

$$\Lambda_{,a} = \Lambda_u Z_{,a} + \Lambda_{u'} Z'_{,a}, \tag{19}$$

then Eq. (18) is equivalent to

$$g^{11} = g^{ab} Z'_{,a} Z'_{,b} = -\Lambda_u.$$

Therefore, the final result is

$$(g^{ij}) = \begin{pmatrix} 1 & 0 \\ 0 & -\Lambda_u \end{pmatrix}. \tag{20}$$

Remark 6: Since $\det(g^{ij}) \neq 0$ *then* Λ_u *cannot be zero.*

Finally taking the ∂_s of Eq. (18), we obtain the Wünschmann-like condition, for $\Lambda(u,u',s)$; namely,

$$D\Lambda_u = 2\Lambda_u \Lambda_{u'}. \tag{21}$$

Since

$$D\Lambda_u = \Lambda_{us} + \Lambda_{uu} u' + \Lambda_{uu'} \Lambda, \tag{22}$$

then Eq. (21) is equivalent to

$$\Lambda_{us} + \Lambda_{uu} u' + \Lambda_{uu'} \Lambda - 2\Lambda_u \Lambda_{u'} = 0. \tag{23}$$

Summarizing: We have the result that given a second-order ODE, $u'' = \Lambda(u, u', s)$, where Λ satisfies Eq. (23), then in its space of solutions there exists a natural two-dimensional metric given by

$$g = g_{ab} \mathrm{d}x^a \, \mathrm{d}x^b = \left[Z_{,a} Z_{,b} - \left(\frac{1}{\Lambda_u} \right) \partial Z_{,a} \partial Z_{,b} \right] \mathrm{d}x^a \, \mathrm{d}x^b. \tag{24}$$

Furthermore, the solutions $u = Z(x^a, s)$ satisfy the (HJ) equation

$$g^{ab} \nabla_a Z(x^a, s) \nabla_b Z(x^a, s) = 1$$

with the just determined metric, Eq. (24). (See the examples to follow.)

III. AN ALTERNATIVE DERIVATION OF THE METRICS AND THE WÜNSCHMANN-LIKE CONDITION

We begin with the general second-order ODE

$$u'' = \Lambda(u, u', s) \tag{25}$$

and its two-parameter family of solution

$$u = Z(x^a, s). \tag{26}$$

We define the varied solution by

$$\delta u = Z_{,a}(x^a, s) \mathrm{d}x^a, \tag{27}$$

$$\delta u' = Z'_{,a}(x^a, s) \mathrm{d}x^a \tag{28}$$

which, in turn, satisfies the deviation equation [or linearized Eq. (25)]

$$\delta u'' = \delta\Lambda(u, u', s) \equiv \Lambda_u \delta u + \Lambda_{u'} \delta u'. \tag{29}$$

In the two-dimensional (u, s) space, for fixed x^a, Eqs. (27) and (28) define, via the two $\mathrm{d}x^a$, a two-parameter family of neighboring curves. Rather than treating the variation to be associated with the independent $\mathrm{d}x^a$, we will treat the two $(\delta u, \delta u')$ as independent variations (the s behavior is subjected to the deviation equation). On this two-dimensional space of independent curves we define an infinitesimal quadratic distance; that is a metric distance between nearby curves. At the beginning of the discussion this distance will depend on the value of s; that is, will depend on a point on the first curve for the comparison with the neighboring one. As conditions are imposed this distance is completely determined.

To begin with, we define a metric distance (the g_{AB} to be determined) between nearby curves, at the point s, by

$$g(x^a, s) = g_{AB} \delta u^A \delta u^B = g_{00} \delta u \, \delta u + 2 g_{01} \delta u \, \delta u' + g_{11} \delta u' \, \delta u'. \tag{30}$$

The following conditions are imposed on the metric:

(1) The first condition is that $g_{00}=1$.

Remark 7: Actually g_{00} can be taken as an arbitrary function of x^a, e.g., $E-V(x^a)$ or $n(x^a)$ which can then be used to conformally rescale the metric. (See Remark 1.)

(2) The second condition is that

$$Dg=0, \tag{31}$$

where D, the total "s" derivative, is defined by Eq. (14).

Remark 8: This is simply the condition that the metric distance between the two curves is independent of the point on the curves.

Theorem 1: *Given a second-order ODE [Eq. (25)] and its deviation equation, Eq. (29), if the metric defined by Eq. (30) with $g_{00}=1$ satisfies Eq. (31), then the metric is uniquely determined as a function of $\Lambda(u,u',s)$ when $\Lambda(u,u',s)$ satisfies the differential equation (the Wünschmann-like condition) given by Eq. (23).*

Proof: By directly applying the two conditions to Eq. (30), we obtain

$$g_{00}=1, \tag{32}$$

$$g_{01}=0,$$

$$g_{11}=-\left(\frac{1}{\Lambda_u}\right), \tag{33}$$

and

$$Dg_{11}=-2\Lambda_{u'}g_{11}. \tag{34}$$

From Eqs. (33) and (34), the Wünschmann-like condition, Eq. (23) immediately follows. Since $\delta u(x^a,s)=Z_{,a}\mathrm{d}x^a$ and $\delta u'(x^a,s)=Z'_{,a}\mathrm{d}x^a$, then by using Eqs. (32)–(34), we find that the metric Eq. (30) can be written as

$$g(x^a,s)=\left[Z_{,a}Z_{,b}-\frac{1}{\Lambda_u}Z'_{,a}Z'_{,b}\right]\mathrm{d}x^a\,\mathrm{d}x^b. \tag{35}$$

That is, we have obtained Eq. (24) by another procedure. Observe that the condition $g_{00}=1$ is equivalent to Eq. (1).

In some of the earlier mentioned work on the eikonal equation in three- and four-dimensional Lorentzian spaces, it was proved that the conformal Lorentzian metrics associated with third-order ODEs and pairs of second-order PDEs satisfying the Wünschmann condition and generalized Wünschmann condition is preserved when the differential equation is transformed by a contact transformation. For our case, there is an analogous result given by the following:

Theorem 2: *Let Eq. (25) be a second-order ODE, with Λ satisfying condition (23) and let*

$$\overline{u''}=\overline{\Lambda}(\overline{u},\overline{u'},\overline{s}) \tag{36}$$

be a second-order ODE locally equivalent to Eq. (25) under the subset of contact transformations generated by the generating function

$$H(s,u,\overline{s},\overline{u})=\overline{u}-u-G(s,\overline{s}). \tag{37}$$

Then under this subset of contact transformations the metric (30) is preserved.

The proof is exactly as that presented in Ref. 18 for the third-order ODE case. Here we only justify the form of the generating function (37). To this end, we review the definition of a general contact transformation.

Theorem 3: *Every contact transformation which is not a prolonged point transformation is determined in terms of a generating function* $H(s,u,\overline{s},\overline{u})$ *by solving the following three implicit equations for* $\overline{s}$, $\overline{u}$, $\overline{u}'$:

$$H(s,u,\overline{s},\overline{u})=0, \quad H_s+u'H_u=0, \quad H_{\overline{s}}+\overline{u}'H_{\overline{u}}=0. \tag{38}$$

The generating function $H(s,u,\overline{s},\overline{u})$ *is an arbitrary smooth function, subject only to the solubility of Eq. (38) for* $\overline{s}$, $\overline{u}$, $\overline{u}'$.

For a proof of this theorem see, for example, Olver.[24]

Without loss of generality one can take

$$H=\overline{u}-\overline{V}(u,s,\overline{s}), \tag{39}$$

so that the contact transformation has the form

$$\begin{aligned}\overline{u}&=\overline{V}(u,s,I(s,u,u')),\\ \overline{s}&=I(s,u,u'),\\ \overline{u}'&=\overline{V}_{\overline{s}}(u,s,I(s,u,u')),\end{aligned} \tag{40}$$

where $I(s,u,u')$ is obtained by solving

$$\overline{V}_s+u'\overline{V}_u=0, \tag{41}$$

for $\overline{s}$ in terms of s, u and u'.

As we pointed out earlier, for each value of s, the two-parameter family of solutions

$$u=Z(x^a,s) \tag{42}$$

of (25) is also a one-parameter family of solutions of Eq. (1), i.e., are ''restricted complete'' integrals of Eq. (1). We now invoke the envelope construction (slightly changed by our modification of the complete integral) to take one ''restricted complete'' integral of Eq. (1) into another such solution.

Consider the function $\overline{u}=\overline{Z}(x^a,\overline{s})$ defined by

$$\overline{u}=\overline{V}(u,s,\overline{s}), \tag{43}$$

where u is defined by Eq. (42) and s is defined implicitly as a function of x^a and $\overline{s}$ by the envelope condition[18,25]

$$\overline{V}_u u'+\overline{V}_s=0. \tag{44}$$

Note that although (44) has the same form as (41), it involves the variables x^a and s. Using both Eqs. (43) and (44), we have that

$$\overline{u}_{,a}=\overline{V}_u u_{,a}\,. \tag{45}$$

By direct substitution of $\overline{u}_{,a}$ into the (HJ) equation, Eq. (1), we see that it is a new ''restricted complete'' integral if and only if $\overline{V}_u^2=1$. That is, $\overline{u}=\overline{V}(u,s,\overline{s})$ has the form $\overline{u}=\pm u+G(s,\overline{s})$. For simplicity, taking the positive sign, we have that if $u(x^a,s)$ is a ''restricted complete'' integral of Eq. (1) then

$$\overline{u}=u+G(s,\overline{s}), \tag{46}$$

where s is defined implicitly as a function of x^a and $\bar{s}$ by the envelope condition

$$u' + G_s = 0, \tag{47}$$

which is a new "restricted complete" integral of Eq. (1). Equations (46) and (47) define a particular subset of the contact transformations given by contact transformations

$$\bar{u} = u + G(s, \bar{s}), \tag{48}$$

$$u' = -G_s, \tag{49}$$

$$\bar{u}' = G_{\bar{s}}. \tag{50}$$

The generating function for this set of contact transformation is given by

$$H(s, u, \bar{s}, \bar{u}) = \bar{u} - u - G(s, \bar{s}) = 0. \tag{51}$$

Remark 9: The transformations Eqs. (48), (49), and (50) have a rather strange or perhaps unconventional interpretation as a canonical transformation. If we have a two-dimensional phase space (q,p) *and a canonical transformation to* (P,Q) *given by*

$$p = \partial_q G,$$

$$P = -\partial_Q G,$$

with generating function $G(q,Q)$*, we see that this is identical to Eqs. (49) and (50) if we identify* $(q,Q) \Leftrightarrow (s,\bar{s})$ and $(p,P) \Leftrightarrow (u', \bar{u}')$ *and ignore the* $u \Leftrightarrow \bar{u}$ *transformation.*

IV. TWO EXAMPLES

Observe that the trivial solutions to Eq. (23) under the condition that $\Lambda_u \neq 0$ are: $\Lambda = \pm u$. Here we discuss these two cases.

(a) *The case* $\Lambda = -u$. From Eq. (25) we obtain that u is such that

$$u'' + u = 0. \tag{52}$$

That is, $u(x^a, s)$, satisfies the harmonic oscillator equation with unit frequency. The general solution to Eq. (52) is given by

$$u = Z(x^a, s) = x^a l_a \equiv x \cos s + y \sin s, \tag{53}$$

where $-\pi \leqslant s \leqslant \pi$, $l_a = (\cos s, \sin s)$ and $x^a = (x,y)$ are two constants of integration, which define locally the space of solutions of Eq. (52). From Eq. (53), we have

$$u' = Z'(x^a, s) = x^a m_a \equiv -x \sin s + y \cos s. \tag{54}$$

That is, $m_a = (-\sin s, \cos s)$. We thus obtain that for this case

$$\begin{aligned} \theta^0{}_{,a} &= Z_{,a} = l_a, \\ \theta^1{}_{,a} &= Z'_{,a} = m_a. \end{aligned} \tag{55}$$

From Eq. (24) and the definitions of l_a and m_b, we find that the two-dimensional metric living on the space of solutions of Eq. (52) is given by

$$g = g_{ab} \mathrm{d}x^a \, \mathrm{d}x^b = (l_a l_b + m_a m_b) \mathrm{d}x^a \, \mathrm{d}x^b = \mathrm{d}x^2 + \mathrm{d}y^2, \tag{56}$$

i.e., the two-dimensional Euclidean metric. In this case the eikonal equation reduces to

$$Z_{,x}^{2}+Z_{,y}^{2}=1. \tag{57}$$

From theorem 2, we know that there is a large family of second-order ODEs such that their solutions also yield two-dimensional Euclidean metrics on the solution space. The entire family is connected by a contact transformation given by the generating function (51), with u given by Eq. (53). We give a particular example, obtained with

$$G(s,\overline{s})=\overline{s}(\cos s+\sin s).$$

After a straightforward calculation one obtains the new solution

$$\overline{u}^{2}=(x+\overline{s})^{2}+(y+\overline{s})^{2} \tag{58}$$

and the new second-order ODE

$$\overline{u}''=\overline{\Lambda}(\overline{s},\overline{u},\overline{u}')=\left(\frac{2-(\overline{u}')^{2}}{\overline{u}}\right). \tag{59}$$

A direct computation shows that, $\overline{u}$, given by Eq. (58), is a new family of solutions of the (HJ) equation (57). The explicit contact transformations yielding these results are

$$\overline{u}=u+u'\left(\frac{\cos s+\sin s}{\sin s-\cos s}\right),\quad \overline{s}=\left(\frac{u'}{\sin s-\cos s}\right),\quad \overline{u}'=\cos s+\sin s. \tag{60}$$

(b) The case $\Lambda=u$. In this case, our ODE, Eq. (25) is

$$u''-u=0, \tag{61}$$

with general solution

$$u=Z(x^{a},s)=x^{a}\tilde{l}_{a}\equiv x\cosh s+y\sinh s, \tag{62}$$

where $s\in\mathcal{R}$, $\tilde{l}_{a}=(\cosh s,\sinh s)$ and $x^{a}=(x,y)$ are two constants of integration defining the space of solutions. By differentiating, we have

$$u'=Z'(x^{a},s)=x^{a}\tilde{m}_{a}\equiv x\sinh s+y\cosh s, \tag{63}$$

with $\tilde{m}_{a}=(\sinh s,\cosh s)$. From Eq. (12) we see that

$$\begin{aligned}\theta^{0}{}_{,a}&=Z_{,a}=\tilde{l}_{a},\\ \theta^{1}{}_{,a}&=Z'_{,a}=\tilde{m}_{a},\end{aligned} \tag{64}$$

and the two-dimensional metric living on the solution space is given by

$$g=g_{ab}\mathrm{d}x^{a}\,\mathrm{d}x^{b}=(\tilde{l}_{a}\tilde{l}_{b}-\tilde{m}_{a}\tilde{m}_{b})\mathrm{d}x^{a}\,\mathrm{d}x^{b}=\mathrm{d}x^{2}-\mathrm{d}y^{2}, \tag{65}$$

i.e., the two-dimensional Minkowski metric. Equation (1) reduces to

$$u_{,x}^{2}-u_{,y}^{2}=1. \tag{66}$$

As in the previous example, there is a further family of second-order ODEs producing two-dimensional Lorentzian metrics on their solution spaces obtained by the special contact transformations. A particular example, obtained when

$$G(s,\overline{s})=\overline{s}(\cosh s+\sinh s),$$

is

$$\overline{u}^2=(x+\overline{s})^2-(y+\overline{s})^2, \tag{67}$$

which satisfies the ODE

$$\overline{u}''=\overline{\Lambda}(\overline{s},\overline{u},\overline{u}')=-\left(\frac{(\overline{u}')^2}{\overline{u}}\right). \tag{68}$$

The contact transformation is explicitly given by

$$\overline{u}=u-u',\quad \overline{s}=-\left(\frac{u'}{\sinh s+\cosh s}\right),\quad \overline{u}'=\sinh s+\cosh s. \tag{69}$$

V. CONCLUSIONS

In this work, we have shown that the ideas and procedures developed earlier that related certain ODEs and PDEs to the eikonal equation and conformal metrics on their solution spaces can be generalized to the Hamilton–Jacobi equation. In the earlier treatment of the eikonal equation we had complete solutions of the equation which led to ODEs and sets of PDEs. These, in turn, led to the transformation groups, connecting the ODEs and PDEs, being the contact group. Here the ''restricted complete'' solutions yielded a special class (Wünschmann-like) of ODEs and, in addition, limited the allowed transformations to a restricted set of contact transformations.

We point out that, though we have used, in the present work, only the two-dimensional, time independent HJ equation, this can be generalized. In a future paper we will present the results for the three-dimensional HJ equation.

(Received 28 April 2003; accepted 20 October 2003)

We point out some interesting analogies between colored Lévy noise and the random channel approach to disordered kinetics. These analogies are due to the fact that the probability density of the Lévy noise source plays a similar role as the probability density of rate coefficients in disordered kinetics. Although the equations for the two approaches are not identical, the analogies can be used for deriving new, useful results for both problems. The random channel approach makes it possible to generalize the fractional Uhlenbeck–Ornstein processes (FUO) for space- and time-dependent colored noise. We describe the properties of colored noise in terms of characteristic functionals, which are evaluated by using a generalization of Huber's approach to complex relaxation [Phys. Rev. B **31**, 6070 (1985)]. We start out by investigating the properties of symmetrical white noise and then define the Lévy colored noise in terms of a Langevin equation with a Lévy white noise source. We derive exact analytical expressions for the various characteristic functionals, which characterize the noise, and a functional fractional Fokker–Planck equation for the probability density functional of the noise at a given moment in time. Second, by making an analogy between the theory of colored noise and the random channel approach to disordered kinetics, we derive fractional equations for the evolution of the probability densities of the random rate coefficients in disordered kinetics. These equations serve as a basis for developing methods for the evaluation of the statistical properties of the random rate coefficients from experimental data. Special attention is paid to the analysis of systems for which the observed kinetic curves can be described by linear or nonlinear stretched exponential kinetics.
[DOI: 10.1063/1.1634350]

I. INTRODUCTION

In this article we show that there are some useful analogies between the theory of colored Lévy noise and the random channel approach for rate processes in disordered systems. Even though the evolution equations for the two problems are different, they share some common features, which may be used for deriving new results in both fields. We show that the theory of colored Lévy noise can be formulated in a simple way by applying the random channel approach from disordered kinetics; moreover, it is possible to introduce a more complex type of Lévy noise, which is both space and time dependent. Conversely, by analogy with the theory of colored Lévy

a)Electronic mail: marceluc@stanford.edu

noise, it is possible to derive equations for the probability density of rate coefficients in disordered kinetics. These equations serve as a basis for proposing methods for extracting statistical informations about the fluctuations of the rate coefficients from experimental data.

The study of Lévy stochastic processes is a major subject of topical interest in statistical physics; its development is of importance in connection with a broad class of phenomena from physics, chemistry and biology and even economics. Examples include the dispersive transport in solid-state physics,[1] the study of vortex motion in high-temperature superconductors, moving interfaces in porous media, random field magnets, spin glasses, the propagation of electromagnetic or acoustic waves in random media,[2–4] random phase modulation in spectroscopy,[5] reaction kinetics in disordered systems,[6,7] the structure of biological organs,[8] the growth of a population in a random environment,[9] and the fluctuation of prices in the stock market.[10]

For the study of these types of processes most classical approaches cannot be used, due to the presence of the diverging moments of the Lévy distribution; new theoretical methods are needed, such as the development of path integrals for Lévy-type stochastic processes.[11] The study of Lévy stochastic processes is an active area of research. In this context the fractional Uhlenbeck–Ornstein processes (FUO), with a long history, play an important role. A first stochastic process of this type was introduced in 1942 by Doob[12] by starting out from the classical Uhlenbeck–Ornstein (CUO) process[13] and by replacing the standard Wiener noise by a (symmetric) Lévy stable noise. In 1982 West and Shesadri studied a harmonic oscillator with a fluctuating Lévy noise source.[14] In 2000 Garbaczewski and Olkiewicz[15] introduced an Ornstein–Uhlenbeck–Cauchy process, where the noise source obeys a probability law of the Cauchy (Lorentz) type.

A second type of fractal generalization of the Uhlenbeck–Ornstein process is based on the use of fractional evolution equations. Metzler, Barkai, and Klafter introduced a fractional Fokker–Planck equation describing the stochastic evolution of a particle under the combined influence of an external, nonlinear force and a thermal heat bath.[16] It seems plausible that there is a connection between their Fokker–Planck equation and a fractional generalization of the Uhlenbeck–Ornstein process. This type of connection is apparent in other studies of Lévy diffusion in external force fields, which make use both of Langevin equations with Lévy noise sources and fractional evolution equations.[17,18]

A third type of FUO was introduced by Koyama and Hara[19] in connection with earthquake dynamics. They started out from an overdamped harmonic oscillatior with a random noise source and applied a succession of renormalization processes of the type introduced by Shlesinger, Hughes, Montroll, and West[8,20,21] in stochastic dynamics. The result is a FUO process characterized by temporal correlation functions with long tails, which seems to have different properties from the first two types mentioned above.

The relaxation and reaction processes occurring in disordered systems have been studied both from the experimental and theoretical points of view.[6,7,22–28] In this field most papers focus on the experimental and theoretical study of processes with linear kinetics described by stretched exponential survival functions. There are also some attempts of extending this research to the case of nonlinear processes.[24] Many theoretical developments are based on the idea that the rate coefficients are random variables, which are the result of the additive contribution of a random number of reaction channels which obey certain probability laws. This idea was introduced in 1948 in a seminal paper by Foerster[25] dealing with the extinction of fluorescence in spectroscopical experiments. The description of the fluctuations of rate coefficients in terms of the contribution of a random number of reaction channels is referred to the as random channel approach (RCA). Various developments of the RCA for linear kinetics have been reported.[6,22–24,26] In this paper we are especially interested in the RCA approach suggested by Huber[22] in 1985 and in an alternative approach for systems with dynamic disorder developed by Allinger and Blumen.[26] Recently it has been shown that Huber's theory is exact for a Poissonian distribution of independent channels.[23] Moreover, this equation also holds beyond the range of validity of the Poissonian distribution: it emerges as a universal scaling law for a uniform random distribution of reaction channels characterized by nonintermittent fluctuations.[23] These universal scaling laws have been extended to systems with dynamical disorder.[23] A major problem in disordered kinetics is the evaluation of the

statistical properties of rate coefficients from experimental data. The field of chemical kinetics dealing with this problem is referred to as "spectral kinetic analysis."[29] Though this field is in an early stage of development, a few methods of spectral kinetic analysis are available.

In this article we aim to bridge the gap between these two area of research. The structure of the article is the following. In Secs. II–IV we show that with suitable changes Huber's approach to RCA in disordered kinetics can be used for describing white and colored Lévy noise. We study space- and time-dependent colored Lévy noise and introduce a space-dependent generalization of the fractional Uhlenbeck–Ornstein processes. In Sec. V we use the analogies between the random-channel approach to disordered kinetics and the theory of Lévy colored noise, by deriving equations for the probability densities of the random rate coefficients. In Sec. VI we use these equations for deriving methods of evaluation of the statistical properties of rate coefficients from experimental data.

II. HUBER STOCHASTIC PROCESSES AND LÉVY NOISE

In this section we make a connection between Huber stochastic processes and Lévy noise and extend the theory of Gaussian colored noise to the more complicated case of Lévy fluctuations. The Gaussian colored noise is assumed to be generated by the exponential damping of a random variable subject to the action of Gaussian white noise.[30] Consider a scalar noise source $F(\mathbf{r},t)$ at position $\mathbf{r}$ and time t: the properties of colored noise can be described by the Langevin equation

$$\frac{\partial F(\mathbf{r},t)}{\partial t}=\mathbb{L}F(\mathbf{r},t)+\omega F_0(\mathbf{r},t), \tag{1}$$

where $\mathbb{L}$ is a time-independent, but generally space-dependent, linear transport operator, ω is a characteristic frequency, and $F_0(\mathbf{r},t)$ is a Gaussian noise source with an average value equal to zero and with delta correlated cumulants of the second order:

$$\langle F_0(\mathbf{r},t)\rangle=0, \quad \langle\langle F_0(\mathbf{r}_1,t_1)F_0(\mathbf{r}_2,t_2)\rangle\rangle=A\,\delta(t_1-t_2)\,\delta(\mathbf{r}_1-\mathbf{r}_2). \tag{2}$$

A suitable choice for the transport operator is

$$\mathbb{L}\ldots=-\omega+\cdots+\omega\lambda^2\nabla_r^2+\cdots, \tag{3}$$

where λ is a characteristic diffusion length.

The classical analysis of the colored Gaussian noise characterized by Eqs. (1)–(3) is usually done by performing a Fourier analysis of the moments and the cumulants of the noise source $F(\mathbf{r},t)$. This method cannot be extended to the Lévy noise, because in this case the moments and cumulants of $F(\mathbf{r},t)$ diverge. To overcome this difficulty we generalize a method recently used by us[18] for the analysis of one-dimensional Lévy diffusion in a force field. We focus our efforts on the evaluation of characteristic functionals of the noise which can be evaluated even if the moments and cumulants are divergent. Such an approach is useful because many experimental observables can be evaluated if the characteristic functional is known. Our analysis proceeds in two steps. We first consider the noise source $F_0(\mathbf{r},t)$ to establish a suitable physical model for Lévy white noise and evaluate the characteristic functionals, which describe its stochastic properties. The next step is to study the colored Lévy noise as characterized by the Langevin equation (1) where the fluctuation of the random force $F_0(\mathbf{r},t)$ is described by Lévy white noise.

The fluctuations of the random force $F_0(\mathbf{r},t)$ are described by using a generalized Huber approach.[22,23] The random force $F_0(\mathbf{r},t)$ is made up of the additive contribution of a large number N of individual components $g_m(\mathbf{r},t)$, each of which is a random function corresponding to a given relaxation channel

$$F_0(\mathbf{r},t)=\sum_{m=1}^{N} g_m(\mathbf{r},t). \tag{4}$$

This physical model of white Lévy noise is essentially a model of Brownian motion for which the contribution of an individual event (a collision) to the random force is a stochastic function, which obeys fractal statistics. The statistics of individual events can be conveniently expressed in terms of Huber's theory of complex relaxation.[22] In this context we formally attach a channel to each individual (collision) event. Both the number N of channels and the contributions $g_1(\mathbf{r},t),\ldots,g_N(\mathbf{r},t)$ of the different channels are random; their stochastic properties can be described by a Poissonian random point process characterized by a density of channels which obeys a scaling law of the negative power law type. The space–time characteristic functional of white noise can be expressed as a dynamic average

$$\mathfrak{G}^0_{\mathbf{r},t}[\mathcal{K}(\mathbf{r}',t')]=\left\langle \exp\left\{ i\int_{-\infty}^{+\infty}\cdots\int_{-\infty}^{+\infty}\mathcal{K}(\mathbf{r}',t')\sum_{m=1}^{N} g_m(\mathbf{r}',t')d\mathbf{r}'\,dt'\right\}\right\rangle. \tag{5}$$

where $\mathcal{K}(\mathbf{r}',t')$ is a suitable test function attached to the random force $F_0(\mathbf{r},t)$ and the dynamic average $\langle\cdots\rangle$ is taken over all possible values of the number N of channels and over all possible values of the random functions $g_1(\mathbf{r}',t'),\ldots,g_N(\mathbf{r}',t')$. The detailed computation of the average in Eq. (5) is presented in Sec. III.

The second step of our analysis consists in expressing the random force $F(\mathbf{r},t)$ of the colored noise as a functional of the noise source of the white noise $F_0(\mathbf{r},t)$ and in evaluating the characteristic functional of the colored noise

$$\mathfrak{G}_{\mathbf{r},t}[\mathcal{K}(\mathbf{r}',t')]=\left\langle \exp\left\{ i\int_{-\infty}^{+\infty}\cdots\int_{-\infty}^{+\infty}\mathcal{K}(\mathbf{r}',t')F(\mathbf{r}',t')d\mathbf{r}'\,dt'\right\}\right\rangle, \tag{6}$$

in terms of the characteristic functional $\mathfrak{G}^0_{\mathbf{r},t}[\mathcal{K}(\mathbf{r}',t')]$ of the white noise. The computations are presented in Sec. IV.

III. TIME- AND SPACE-DEPENDENT LÉVY WHITE NOISE

The dynamic average in Eq. (5) can be expressed by using two different sets of probability density functionals, either in terms of the probability density functional attached to the components $g_1(\mathbf{r}',t'),\ldots,g_N(\mathbf{r}',t')$ or of the probability density functional of the random force $F_0(\mathbf{r},t)$, respectively. The stochastic properties of the number N of channels and of the components $g_1(\mathbf{r}',t'),\ldots,g_N(\mathbf{r}',t')$ attached to the different channels can be expressed in terms of a set of grand canonical probability density functionals

$$Q_0,Q_N[g_1(\mathbf{r};t),\ldots,g_N(\mathbf{r};t)]\mathcal{D}[g_1(\mathbf{r};t)]\cdots\mathcal{D}[g_N(\mathbf{r};t)],\quad N=1,2,..., \tag{7}$$

which obey a normalization condition which includes an $1/N!$ Gibbs factor

$$Q_0+\sum_{N=1}^{\infty}\frac{1}{N!}\overline{\int\int}\cdots\overline{\int\int}\,Q_N[g_1(\mathbf{r};t),\ldots,g_N(\mathbf{r};t)]\mathcal{D}[g_1(\mathbf{r};t)]\cdots\mathcal{D}[g_N(\mathbf{r};t)]=1. \tag{8}$$

Here $\mathcal{D}[g_1(\mathbf{r};t)],\ldots,\mathcal{D}[g_M(\mathbf{r};t)]$ are suitable integration measures over the space of functions $g_1(\mathbf{r};t),\ldots,g_N(\mathbf{r};t)$ and $\overline{\int\int}$ stands for the operation of path integration. Similarly, the stochastic properties of the total random force $F_0(\mathbf{r},t)$ attached to the Lévy white noise can be expressed in terms of the probability density functional:

$$\mathcal{P}^0_{\mathbf{r},t}[F_0(\mathbf{r}',t')]\mathcal{D}^0_{\mathbf{r},t}[F_0(\mathbf{r}',t')]\ \text{ with }\ \overline{\int\int}_{\mathbf{r},t}\mathcal{P}^0_{\mathbf{r},t}[F_0(\mathbf{r}',t')]\mathcal{D}^0_{\mathbf{r},t}[F_0(\mathbf{r}',t')]=1. \tag{9}$$

In this article we assume that the different channels are independent and thus the grand canonical probability density functionals (6) obey Poissonian statistics:

$$Q_0=\exp\left\{-\overline{\int\int}\rho_g[g(\mathbf{r}';t')]\mathcal{D}[g(\mathbf{r}';t')]\right\}, \tag{10}$$

$$Q_N[g_1(\mathbf{r};t),\ldots,g_N(\mathbf{r};t)]\mathcal{D}[g_1(\mathbf{r};t)]\cdots\mathcal{D}[g_N(\mathbf{r};t)]$$
$$=\exp\left\{-\overline{\int\int}\rho_g[g(\mathbf{r}';t')]\mathcal{D}[g(\mathbf{r}';t')]\right\}\rho_g[g_1(\mathbf{r};t)]\mathcal{D}[g_1(\mathbf{r};t)]\cdots\rho_g[g_N(\mathbf{r};t)]\mathcal{D}[g_N(\mathbf{r};t)]. \tag{11}$$

For Lévy white noise the functional average density of states $\rho_g[g(\mathbf{r};t)]\mathcal{D}[g(\mathbf{r};t)]$ obeys a scaling condition of the negative power law type. By generalizing the approach from Ref. 23 for space-dependent systems we can give the following discrete representation for $\rho_g[g(\mathbf{r};t)]\mathcal{D}[g(\mathbf{r};t)]$:

$$\rho_g(g;\Delta\mathbf{r},\Delta t)dg=\kappa_0(\alpha)(\Delta t\Delta\mathbf{r})^{(1-\alpha)}|g|^{-(1+\alpha)}dg,\quad \Delta\mathbf{r}=\prod_{=1}^{m}\Delta r,\ \ \kappa_0(\alpha)>0,\ \ 2>\alpha>0, \tag{12}$$

and

$$g_n^{(u,\mathbf{v})}=g_n(t_0+u\Delta t,r_1+v_1\Delta r_1,\ldots,r_m+v_m\Delta r_m),\quad n=1,...,N, \tag{13}$$

where m is the space dimension, $\kappa_0>0$ is a positive proportionality factor, u,v are current labels, and $2>\alpha>0$ is a dimensionless fractal exponent. By using this discrete representation we can formally express the Poissonian grand canonical probability density functionals $Q_0,\ldots,Q_N[g_t(\mathbf{r};t),\ldots,g_N(\mathbf{r};t)]\mathcal{D}[g_t(\mathbf{r};t)]\cdots\mathcal{D}[g_N(\mathbf{r};t)],\ldots,$ (10) and (11) with the following limits:

$$Q_0=\lim_{\Delta\mathbf{r}\to\mathbf{0},\Delta t\to 0}\prod_{u,\mathbf{v}}\left[\exp\left(-\int_{-\infty}^{+\infty}\rho_g(g^{(u,\mathbf{v})};\Delta\mathbf{r},\Delta t)dg^{(u,\mathbf{v})}\right)\right], \tag{14}$$

$$Q_N[g_1(\mathbf{r};t),\ldots,g_N(\mathbf{r};t)]\mathcal{D}[g_1(\mathbf{r};t)]\cdots\mathcal{D}[g_N(\mathbf{r};t)]$$
$$=\lim_{\Delta\mathbf{r}\to\mathbf{0},\Delta t\to 0}\left\{\prod_{u,\mathbf{v}}\left[\exp\left(-\int_{-\infty}^{+\infty}\rho_g(g^{(u,\mathbf{v})};\Delta\mathbf{r},\Delta t)dg^{(u,\mathbf{v})}\right)\prod_{w=1}^{N}\rho_g(g_w^{(u,\mathbf{v})})dg_w^{(u,\mathbf{v})}\right]\right\}. \tag{15}$$

By using the discrete representation (14) and (15) the ensemble average in Eq. (5) can be easily evaluated. After some calculations we come to a closed expression for the characteristic functional $\mathfrak{G}^0_{\mathbf{r},t}[\mathcal{K}(\mathbf{r}',t')]$ of Lévy white noise

$$\mathfrak{G}^0_{\mathbf{r},t}[\mathcal{K}(\mathbf{r}',t')]=\lim_{\Delta\mathbf{r}\to\mathbf{0},\Delta t\to 0}\left\langle\prod_{w=1}^{N}\prod_{u,\mathbf{v}}\exp\{i\mathcal{K}^{(u,\mathbf{v})}g_w^{(u,\mathbf{v})}\Delta\mathbf{r}\Delta t\}\right\rangle$$
$$=\lim_{\Delta\mathbf{r}\to\mathbf{0},\Delta t\to 0}\prod_{u,\mathbf{v}}\exp\left(-\int_{-\infty}^{+\infty}\rho_g(g^{(u,\mathbf{v})};\Delta\mathbf{r},\Delta t)dg^{(u,\mathbf{v})}\right)$$
$$\times\sum_{N}\frac{1}{N!}\left[\prod_{w=1}^{N}\int_{-\infty}^{+\infty}\exp\{i,\mathcal{K}^{(u,\mathbf{v})}g_w^{(u,\mathbf{v})}\Delta\mathbf{r}\Delta t\}\rho_g(g_w^{(u,\mathbf{v})})dg_w^{(u,\mathbf{v})}\right]$$
$$=\lim_{\Delta\mathbf{r}\to\mathbf{0},\Delta t\to 0}\prod_{u,\mathbf{v}}\exp\left(-\kappa_0(\Delta t\Delta\mathbf{r})^{-(1-\alpha)}2\int_0^{+\infty}|g|^{-(1+\alpha)}\right.$$

$$\times(1-\cos\{\mathcal{K}^{(u,\mathbf{v})}g\Delta t\Delta\mathbf{r}\})dg\Bigg)$$

$$=\lim_{\Delta\mathbf{r}\to\mathbf{0},\Delta t\to 0}\prod_{u,\mathbf{v}}\exp\left(-\kappa_0(\Delta t\Delta\mathbf{r})^{1-\alpha}2\frac{\Gamma(1-\alpha)}{\alpha}|\mathcal{K}^{(u,\mathbf{v})}\Delta t\Delta\mathbf{r}|^{\alpha}\cos\left(\frac{\pi\alpha}{2}\right)\right). \tag{16}$$

By passing to the continuous limit in Eq. (16) we have

$$\mathfrak{G}^0_{\mathbf{r},t}[\mathcal{K}(\mathbf{r}',t')]=\exp\left(-c\int_{-\infty}^{+\infty}\cdots\int\int_{-\infty}^{+\infty}|\mathcal{K}(\mathbf{r}',t')|^{\alpha}\,d\mathbf{r}'\,dt'\right), \tag{17}$$

where

$$c=2\kappa_0(\alpha)\frac{\Gamma(1-\alpha)}{\alpha}\cos\left(\frac{\pi\alpha}{2}\right), \tag{18}$$

and $\Gamma(x)$ is the complete gamma function. Equation (17) is the main result of this section. The characteristic functional $\mathfrak{G}^0_{\mathbf{r},t}[\mathcal{K}(\mathbf{r}',t')]$ expresses all stochastic properties of Lévy white noise. By evaluating the functional derivatives of $\mathfrak{G}^0_{\mathbf{r},t}[\mathcal{K}(\mathbf{r}',t')]$ and $\ln\mathfrak{G}^0_{\mathbf{r},t}[\mathcal{K}(\mathbf{r}',t')]$ with respect to the test function $\mathcal{K}(\mathbf{r}',t')$ we can check that for $2>\alpha>0$ all positive moments as well as all cumulants attached to the Lévy white noise are divergent. The probability density functional of white Lévy noise, $\mathcal{P}^0_{\mathbf{r},t}[F_0(\mathbf{r}',t')]\mathcal{D}^0_{\mathbf{r},t}[F_0(\mathbf{r}',t')]$, can be formally expressed as an inverse Fourier transform of the characteristic functional $\mathfrak{G}^0_{\mathbf{r},t}[\mathcal{K}(\mathbf{r}',t')]$. We rewrite the definition (5) of the characteristic functional $\mathfrak{G}^0_{\mathbf{r},t}[\mathcal{K}(\mathbf{r}',t')]$ of the Lévy white noise in terms of the probability functional $\mathcal{P}^0_{\mathbf{r},t}[F_0(\mathbf{r}',t')]\mathcal{D}^0_{\mathbf{r},t}[F_0(\mathbf{r}',t')]$

$$\mathfrak{G}^0_{\mathbf{r},t}[\mathcal{K}(\mathbf{r}',t')]=\overline{\int\int_{\mathbf{r},t}}\exp\left\{i\int_{-\infty}^{+\infty}\cdots\int\int_{-\infty}^{+\infty}\mathcal{K}(\mathbf{r}',t')F_0(\mathbf{r}',t')d\mathbf{r}'\,dt'\right\}$$
$$\times\mathcal{P}^0_{\mathbf{r},t}[F_0(\mathbf{r}',t')]\mathcal{D}^0_{\mathbf{r},t}[F_0(\mathbf{r}',t')]. \tag{19}$$

Now we use a discrete representation for Eq. (19):

$$G^0_{\mathbf{r},t}[\mathcal{K}^{(u,\mathbf{v})}]=\int\cdots\int\exp\left\{i\sum_{u,\mathbf{v}}\mathcal{K}^{(u,\mathbf{v})}F_0^{(u,\mathbf{v})}\Delta t\Delta\mathbf{r}\right\}P^0_{\mathbf{r},t}[\|F_0^{(u,\mathbf{v})}\|]\prod_{u,\mathbf{v}}dF_0^{(u,\mathbf{v})}, \tag{20}$$

where $P^0_{\mathbf{r},t}[\|F_0^{(u,\mathbf{v})}\|]\Pi_{u,\mathbf{v}}dF_0^{(u,\mathbf{v})}$ is a joint probability which is a discrete representation of the probability functional $\mathcal{P}^0_{\mathbf{r},t}[F_0(\mathbf{r}',t')]\mathcal{D}^0_{\mathbf{r},t}[F_0(\mathbf{r}',t')]$ and $G^0_{\mathbf{r},t}[\mathcal{K}^{(u,\mathbf{v})}]$ is the Fourier transform of $P^0_{\mathbf{r},t}[\|F_0^{(u,\mathbf{v})}\|]$. We have

$$\mathcal{P}^0_{\mathbf{r},t}[F_0(\mathbf{r}',t')]\mathcal{D}^0_{\mathbf{r},t}[F_0(\mathbf{r}',t')]=\lim_{\Delta\mathbf{r}\to\mathbf{0},\Delta t\to 0}P^0_{\mathbf{r},t}[\|F_0^{(u,\mathbf{v})}\|]\prod_{u,\mathbf{v}}dF_0^{(u,\mathbf{v})}, \tag{21}$$

$$\mathfrak{G}^0_{\mathbf{r},t}[\mathcal{K}(\mathbf{r}',t')]=\lim_{\Delta\mathbf{r}\to\mathbf{0},\Delta t\to 0}G^0_{\mathbf{r},t}[\mathcal{K}^{(u,\mathbf{v})}]. \tag{22}$$

By applying an inverse Fourier transformation to Eq. (20) we come to

$$P^0_{\mathbf{r},t}[\|F_0^{(u,\mathbf{v})}\|]\prod_{u,\mathbf{v}} dF_0^{(u,\mathbf{v})}=\prod_{u,\mathbf{v}} dF_0^{(u,\mathbf{v})}\int\cdots\int \exp\left\{-i\sum_{u,\mathbf{v}} \mathcal{K}^{(u,\mathbf{v})}F_0^{(u,\mathbf{v})}\Delta t\Delta\mathbf{r}\right\}$$
$$\times G^0_{\mathbf{r},t}[\mathcal{K}^{(u,\mathbf{v})}]\prod_{u,\mathbf{v}}\left(\frac{d\mathcal{K}^{(u,\mathbf{v})}}{2\pi}\right). \tag{23}$$

In the continuous limit Eq. (23) becomes

$$\mathcal{P}^0_{\mathbf{r},t}[F_0(\mathbf{r}',t')]\mathcal{D}^0_{\mathbf{r},t}[F_0(\mathbf{r}',t')]$$
$$=\left\{\overline{\int\int}_{\mathbf{r},t}\exp\left[-\int_{-\infty}^{+\infty}\cdots\int\int_{-\infty}^{+\infty}[i\mathcal{K}(\mathbf{r}',t')F_0(\mathbf{r}',t')\right.\right.$$
$$\left.\left.+c|\mathcal{K}(\mathbf{r}',t')|^{\alpha}]d\mathbf{r}'\,dt'\right]\right\}\mathcal{D}^{\mathrm{inv}}_{\mathbf{r},t}[\mathcal{K}(\mathbf{r}',t')]\,\mathcal{D}^0_{\mathbf{r},t}[F_0(\mathbf{r}',t')], \tag{24}$$

where

$$\mathcal{D}^{\mathrm{inv}}_{\mathbf{r},t}[\mathcal{K}(\mathbf{r}',t')]=\lim_{\Delta\mathbf{r}\to\mathbf{0},\Delta t\to 0}\prod_{u,\mathbf{v}}\left(\frac{d\mathcal{K}^{(u,\mathbf{v})}}{2\pi}\right) \tag{25}$$

is an integration measure over the space of functions $\mathcal{K}(\mathbf{r}',t')$.

From Eqs. (21)–(25) we notice that the Lévy white noise is described by an independent stochastic process, that is, the fluctuations of the noise source at a given time and position are independent of the fluctuations of the noise source at other times and positions. For this reason, the expressions for the characteristic functional and for the probability density functional are separable, that is, they can be expressed as products of factors corresponding to different points in the space–time continuum. This can be easily seen from the discrete representations $G^0_{\mathbf{r},t}[\mathcal{K}^{(u,\mathbf{v})}]$ and $P^0_{\mathbf{r},t}[\|F_0^{(u,\mathbf{v})}\|]$. We have

$$G^0_{\mathbf{r},t}[\mathcal{K}^{(u,\mathbf{v})}]=\prod_{u,\mathbf{v}}\exp\{-c(\Delta t\Delta\mathbf{r})|\mathcal{K}^{(u,\mathbf{v})}|^{\alpha}\}, \tag{26}$$

$$P^0_{\mathbf{r},t}[\|F_0^{(u,\mathbf{v})}\|]=\prod_{u,\mathbf{v}}\left\{\frac{1}{[c(\Delta t\Delta\mathbf{r})]^{1/\alpha}}\Psi_{\alpha}\left\{\frac{F_0^{(u,\mathbf{v})}}{[c(\Delta t\Delta\mathbf{r})]^{1/\alpha}}\right\}\right\}, \tag{27}$$

where

$$\Psi_{\alpha}(x)=(2\pi)^{-1}\int_{-\infty}^{+\infty}\exp(-ikx-|k|^{\alpha})dk \tag{28}$$

is the one-variable symmetrical Lévy probability density.[8]

In various physical, chemical, and biological problems the observables of physical interest are linked averages of the type

$$\Phi(t)=\left\langle\exp\left[-\int_{-\infty}^{+\infty}\cdots\int\int_{t_0}^{t}\zeta(\mathbf{r}',t')F_0(\mathbf{r}',t')d\mathbf{r}'\,dt'\right]\right\rangle. \tag{29}$$

By using Eq. (17) such linked averages can be easily evaluated with our approach. We have

$$\Phi(t)=\mathfrak{G}^0_{\mathbf{r},t}[\mathcal{K}(\mathbf{r}',t')=\zeta(\mathbf{r}',t')[h(t'-t_0)-h(t'-t)]]$$
$$=\exp\left(-c\int_{-\infty}^{+\infty}\cdots\int\int_{t_0}^{t}|\zeta(\mathbf{r}',t')|^{\alpha}\,d\mathbf{r}'\,dt'\right), \tag{30}$$

where $h(x)$ is the Heaviside step function.

It is easy to check that in the limit $\alpha\to 2$ the white Lévy noise studied in this section reduces to the usual Gaussian white noise. The characteristic functional and the probability density functional of the noise become Gaussian. We pass in Eq. (17) to the limit $\alpha\to 2$ and assume that the limit

$$\lim_{\alpha\to 2}\left[2k_0(\alpha)\frac{\Gamma(1-\alpha)}{\alpha}\cos\left(\frac{\pi\alpha}{2}\right)\right]=c_2 \tag{31}$$

exists and is finite. We come to

$$\mathfrak{G}^0_{\mathbf{r},t}[\mathcal{K}(\mathbf{r}',t')]=\exp\left(-c_2\int_{-\infty}^{+\infty}\cdots\int\int_{-\infty}^{+\infty}|\mathcal{K}(\mathbf{r}',t')|^2\,d\mathbf{r}'\,dt'\right), \tag{32}$$

which corresponds to an independent, space- and time-dependent Gaussian stochastic process with finite cumulants:

$$\langle\langle F_0(\mathbf{r},t)\rangle\rangle=0, \tag{33}$$

$$\langle\langle F_0(\mathbf{r}_1,t_1)F_0(\mathbf{r}_2,t_2)\rangle\rangle=2c_2\delta(t_1-t_2)\,\delta(\mathbf{r}_1-\mathbf{r}_2), \tag{34}$$

$$\langle\langle F_0(\mathbf{r}_1,t_1)\cdots F_0(\mathbf{r}_m,t_m)\rangle\rangle=0,\quad m>2. \tag{35}$$

In conclusion, in this section we have used the Huber approach for studying the stochastic properties of the space- and time-dependent Lévy white noise. The type of Lévy white noise introduced by using the Huber approach is a space-dependent generalization of the Lévy noises introduced by Doob,[12] West and Shesadri,[14] and Garbaczewski and Olkiewicz.[15] We have derived expressions for the characteristic functional and the probability functional of the noise source and have indicated that the positive moments and the cumulants of the noise source are infinite. We have shown that the Gaussian white noise can be recovered as a limit case of Lévy white noise, which corresponds to a fractal exponent α equal to two.

IV. TIME- AND SPACE-DEPENDENT LÉVY COLORED NOISE

In the case of the white Lévy noise studied in the preceding section the values of the noise source at different positions in the space–time continuum are independent random variables selected from the same probability density, which is of the Lévy type. For this reason the stochastic process which describes the white Lévy noise is stationary. In the case of colored noise, however, it makes sense to consider the broader case where the noise is generally nonstationary. In this section we study Lévy colored noise which obeys a Langevin equation of the type (1), where $F_0(\mathbf{r},t)$ is a Lévy white noise described by Eq. (17); however the white noise does not act from any time value between $-\infty$ and $+\infty$, but rather in a time window, limited by a lower value $t=t_0$. Under these circumstances we should introduce a lower time cutoff in Eq. (17), resulting in

$$\mathfrak{G}^0_{\mathbf{r},t}[\mathcal{K}(\mathbf{r}',t')]=\exp\left(-c\int_{-\infty}^{+\infty}\cdots\int\int_{t_0}^{+\infty}|\mathcal{K}(\mathbf{r}',t')|^{\alpha}\,d\mathbf{r}'\,dt'\right). \tag{36}$$

Then the colored noise is generally nonstationsary and the stationary colored noise corresponds to the limit $t_0\to-\infty$.

The next step is to express the properties of colored noise in terms of the properties of white noise. We express the general solution of the evolution equation (1) in terms of a Green function, which is the solution of

$$\frac{\partial \mathcal{G}(\mathbf{r};\mathbf{r}'',t-t'')}{\partial t}=\mathbb{L}\mathcal{G}(\mathbf{r};\mathbf{r}'',t-t''), \tag{37}$$

with the initial condition

$$\mathcal{G}(\mathbf{r};\mathbf{r}'',0)=\delta(\mathbf{r}-\mathbf{r}''); \tag{38}$$

in particular, if the linear transport operator $\mathbb{L}...$ is translationally invariant, so is the Green function, that is, $\mathcal{G}(\mathbf{r};\mathbf{r}'',t-t'')=\mathcal{G}(\mathbf{r}-\mathbf{r}'',t-t'')$. The solution of Eq. (1), corresponding to the initial condition $F(\mathbf{r},t=t_0)=F(\mathbf{r},t_0)$, is

$$F(\mathbf{r},t)=\int_{-\infty}^{+\infty}\cdots\int \mathcal{G}(\mathbf{r};\mathbf{r}_0,t-t_0)F(\mathbf{r}_0,t_0)d\mathbf{r}_0+\omega\int_{-\infty}^{+\infty}\cdots\int\int_{t_0}^{t}\mathcal{G}(\mathbf{r};\mathbf{r}'',t-t'')F_0(\mathbf{r}'',t'')d\mathbf{r}''\,dt''. \tag{39}$$

The characteristic functional of the noise source $F(\mathbf{r},t)$ can be easily evaluated. By assuming that the distribution of the initial value $F(\mathbf{r},t=t_0)=F(\mathbf{r},t_0)$ is independent of the noise source $F_0(\mathbf{r},t)$ from Eq. (6) we come to

$$\begin{aligned}\mathfrak{G}_{\mathbf{r},t}[\mathcal{K}(\mathbf{r}',t')]&=\left\langle \exp\left\{ i\int_{-\infty}^{+\infty}\cdots\int\int_{t_0}^{+\infty}\mathcal{K}(\mathbf{r}',t')\int_{-\infty}^{+\infty}\cdots\int\mathcal{G}(\mathbf{r}';\mathbf{r}_0,t'-t_0)F(\mathbf{r}_0,t_0)d\mathbf{r}_0\,d\mathbf{r}'\,dt'\right\}\right\rangle\\&\times\left\langle \exp\left\{ i\omega\int_{-\infty}^{+\infty}\cdots\int\int_{t_0}^{+\infty}\mathcal{K}(\mathbf{r}',t')\int_{-\infty}^{+\infty}\cdots\int\int_{t_0}^{t}\mathcal{G}(\mathbf{r}';\mathbf{r}'',t'-t'')F_0(\mathbf{r}'',t'')d\mathbf{r}''\,dt''\,d\mathbf{r}'\,dt'\right\}\right\rangle.\end{aligned} \tag{40}$$

Now we introduce the probability functional of the random force field $F(\mathbf{r},t_0)$ at the initial time $t=t_0$,

$$\mathcal{P}_{\mathbf{r}}[F(\mathbf{r}');t_0]\mathcal{D}_{\mathbf{r}}[F(\mathbf{r}');t_0]\ \text{ with }\ =\overline{\int\int_{\mathbf{r}}}\mathcal{P}_{\mathbf{r}}[F(\mathbf{r}');t_0]\mathcal{D}_{\mathbf{r}}[F(\mathbf{r}');t_0]=1, \tag{41}$$

and the corresponding characteristic functional

$$\begin{aligned}\mathfrak{G}_{\mathbf{r}}[K(\mathbf{r}');t_0]&=\left\langle \exp\left\{ i\int_{-\infty}^{+\infty}\cdots\int F(\mathbf{r}')K(\mathbf{r}')d\mathbf{r}'\right\}\right\rangle\\&=\overline{\int\int_{\mathbf{r}}}\exp\left[i\int K(\mathbf{r}')F(\mathbf{r}')d\mathbf{r}'\right]\mathcal{P}_{\mathbf{r}}[F(\mathbf{r}');t_0]\mathcal{D}_{\mathbf{r}}[F(\mathbf{r}');t_0].\end{aligned} \tag{42}$$

By combining Eqs. (40) and (42) we obtain

$$\mathfrak{G}_{\mathbf{r},t}[\mathcal{K}(\mathbf{r}',t')]=\mathfrak{G}_{\mathbf{r},t}^{\text{transient}(t_0)}[\mathcal{K}(\mathbf{r}',t')]\mathfrak{G}_{\mathbf{r},t}^{\text{normal}(t_0)}[\mathcal{K}(\mathbf{r}',t')], \tag{43}$$

where

$$\mathfrak{G}_{\mathbf{r},t}^{\text{transient}(t_0)}[\mathcal{K}(\mathbf{r}',t')]=\mathfrak{G}_{\mathbf{r}}\left[K(\mathbf{r}')=\int_{t_0}^{\infty}\mathcal{K}(\mathbf{r}'',t'')\int_{-\infty}^{+\infty}\cdots\int\mathcal{G}(\mathbf{r}'';\mathbf{r}',t''-t_0)d\mathbf{r}''\,dt''\right] \tag{44}$$

is a transient component and

$$\mathfrak{G}_{\mathbf{r},t}^{\text{normal}(t_0)}[\mathcal{K}(\mathbf{r}',t')] = \exp\left(-D_{\text{fract.}} \int_{-\infty}^{+\infty} \cdots \int \int_{t'=t_0}^{+\infty} \left| \int_{-\infty}^{+\infty} \cdots \int \int_{t''-t'}^{\infty} \mathcal{G}(\mathbf{r}''-\mathbf{r}',t''-t')\mathcal{K}(\mathbf{r}'',t'')d\mathbf{r}''\,dt'' \right|^{\alpha} d\mathbf{r}'\,dt' \right) \tag{45}$$

is a normal component;

$$D_{\text{fract.}} = \frac{2\kappa_0(\alpha)\omega^{\alpha}}{\alpha}\Gamma(1-\alpha)\cos\left(\frac{\pi\alpha}{2}\right) = c\,\omega^{\alpha} \tag{46}$$

is a fractional diffusion coefficient.

Equations (43)–(45) are the main results of this section. The characteristic functional $\mathfrak{G}_{\mathbf{r},t}[\mathcal{K}(\mathbf{r}',t')]$ expresses all stochastic properties of the Lévy colored noise. In particular, by computing the functional derivatives of $\mathfrak{G}_{\mathbf{r},t}[\mathcal{K}(\mathbf{r}',t')]$ and $\ln \mathfrak{G}_{\mathbf{r},t}[\mathcal{K}(\mathbf{r}',t')]$ we can show that for $2>\alpha>0$ all positive moments and cumulants of the noise source are infinite. The probability functional of the colored noise

$$\mathcal{P}_{\mathbf{r},t}[F(\mathbf{r}',t')]\mathcal{D}_{\mathbf{r},t}[F(\mathbf{r}',t')] \quad \text{with} \quad \overline{\int\int}_{\mathbf{r},t} \mathcal{P}_{\mathbf{r},t}[F(\mathbf{r}',t')]\mathcal{D}_{\mathbf{r},t}[F(\mathbf{r}',t')] = 1 \tag{47}$$

can be formally expressed as an inverse Fourier transform of $\mathfrak{G}_{\mathbf{r},t}[\mathcal{K}(\mathbf{r}',t')]$. By using a discrete representation for $\mathcal{P}_{\mathbf{r},t}[F(\mathbf{r}',t')]\mathcal{D}_{\mathbf{r},t}[F(\mathbf{r}',t')]$ similar to the one used in the preceding section we can show that

$$\begin{aligned}\mathcal{P}_{\mathbf{r},t}[F(\mathbf{r}',t')]&\mathcal{D}_{\mathbf{r},t}[F(\mathbf{r}',t')] \\ &= \left\{ \overline{\int\int}_{\mathbf{r},t} \exp\left[-i \int_{-\infty}^{+\infty} \cdots \int \int_{-\infty}^{+\infty} \mathcal{K}(\mathbf{r}',t')F_0(\mathbf{r}',t')d\mathbf{r}'\,dt' \right] \right. \\ &\quad \left. \times \mathfrak{G}_{\mathbf{r},t}[\mathcal{K}(\mathbf{r}',t')]\mathcal{D}_{\mathbf{r},t}^{\text{inv}}[\mathcal{K}(\mathbf{r}',t')] \right\} \mathcal{D}_{\mathbf{r},t}[F_0(\mathbf{r}',t')].\end{aligned} \tag{48}$$

For the study of many problems it is enough if we know the stochastic properties of the noise source at a given moment in time, $t'=t$. In this case we can use the marginal probability density functional

$$\begin{aligned}\mathcal{P}_{\mathbf{r}}[F(\mathbf{r}');t]&\mathcal{D}_{\mathbf{r}}[F(\mathbf{r}');t] \\ &= \overline{\int\int}_{\mathbf{r},t} \{\delta[F(\mathbf{r}',t')-F(\mathbf{r}',t)]\mathcal{D}_{\mathbf{r}}[F(\mathbf{r}'),t]\}\mathcal{P}_{\mathbf{r},t}[F(\mathbf{r}',t')]\mathcal{D}_{\mathbf{r},t}[F(\mathbf{r}',t')]\end{aligned} \tag{49}$$

and the corresponding characteristic functional

$$\mathfrak{G}_{\mathbf{r}}[K(\mathbf{r}');t] = \overline{\int\int}_{\mathbf{r}} \exp\left\{ i \int_{-\infty}^{+\infty} \cdots \int K(\mathbf{r}')F(\mathbf{r}')d\mathbf{r}' \right\} \mathcal{P}_{\mathbf{r}}[F(\mathbf{r}');t]\mathcal{D}_{\mathbf{r}}[F(\mathbf{r}');t]. \tag{50}$$

This characteristic functional can be easily evaluated from Eqs. (43)–(45). We have

$$\mathfrak{G}_{\mathbf{r}}[K(\mathbf{r}');t]=\mathfrak{G}_{\mathbf{r},t}[\mathcal{K}(\mathbf{r}',t')=K(\mathbf{r}')\,\delta(t-t')]$$
$$=\mathfrak{G}_{\mathbf{r}}\left[\int_{-\infty}^{+\infty}\cdots\int K(\mathbf{r}'')\mathcal{G}(\mathbf{r}'';\mathbf{r}',t-t_0)d\mathbf{r}'';t_0\right]$$
$$\times\exp\left(-D_{\text{fract.}}\int_{-\infty}^{+\infty}\cdots\int\int_{t_0}^{t}\left|\int_{-\infty}^{+\infty}\cdots\int\mathcal{G}(\mathbf{r}'';\mathbf{r}',t-t')K(\mathbf{r}'')d\mathbf{r}''\right|^{\alpha}d\mathbf{r}'\,dt'\right). \tag{51}$$

We notice that the $\mathfrak{G}_{\mathbf{r}}$ term can be viewed as an integration constant and thus Eq. (51) has the structure of a solution of a linear evolution equation. Such an evolution equation can be easily built by evaluating the time derivative $\partial\mathfrak{G}_{\mathbf{r}}[K(\mathbf{r}');t]/\partial t$ and the functional derivative $\delta\mathfrak{G}_{\mathbf{r}}[K(\mathbf{r}');t]/\delta K(\mathbf{r}'')$ and by eliminating the initial condition $\mathfrak{G}_{\mathbf{r}}[K(\mathbf{r}');t_0]$ from the resulting equations. After some computations we come to

$$\frac{\partial}{\partial t}\mathfrak{G}_{\mathbf{r}}[K(\mathbf{r}');t]=\int\left\{iK(\mathbf{r}'')\mathbb{L}\left[\mathbf{r}'',-i\frac{\delta}{\delta K(\mathbf{r}')}\right]\right\}\mathfrak{G}_{\mathbf{r}}[K(\mathbf{r}');t]\,d\mathbf{r}''$$
$$-D_{\text{fract.}}\mathfrak{G}_{\mathbf{r}}[K(\mathbf{r}');t]\int|K(\mathbf{r}'')|^{\alpha}\,d\mathbf{r}''. \tag{52}$$

We recall that the symmetric fractional derivative of order α of a function $\varphi(\lambda)$ can be defined as an inverse Fourier transform:[17,31]

$$\frac{\partial^{\alpha}}{\partial\lambda^{\alpha}}\varphi(\lambda)=-\mathcal{F}^{-1}[\overline{\varphi}(q)|q|^{\alpha}]=\frac{-1}{2\pi}\int_{-\infty}^{+\infty}\overline{\varphi}(q)|q|^{\alpha}\exp(-iq\lambda)dq, \tag{53}$$

where

$$\overline{\varphi}(q)=\int_{-\infty}^{+\infty}\varphi(\lambda)\exp(iq\lambda)d\lambda \tag{54}$$

is the Fourier transform of $\varphi(\lambda)$. By using Eqs. (53) and (54) we can introduce the following heuristic definition for the fractional functional derivative of order α, evaluated at a single position $\mathbf{r}=\mathbf{r}''$,

$$\frac{\delta^{\alpha}}{\delta[F(\mathbf{r}'',t)]^{\alpha}}\mathcal{P}_{\mathbf{r}}[F(\mathbf{r}',t)]=\frac{\partial^{\alpha}}{\partial\lambda^{\alpha}}\mathcal{P}_{\mathbf{r}}[F(\mathbf{r}',t)+\lambda\,\delta(\mathbf{r}'-\mathbf{r}'')]|_{\lambda=0}. \tag{55}$$

In Appendix A we show that, by means of an inverse Fourier transformation, Eq. (52) leads to a fractional functional Fokker–Planck equation for the probability density functional $\mathcal{P}_{\mathbf{r}}[F(\mathbf{r}',t)]$, which contains the fractional derivative (55). We obtain

$$\frac{\partial}{\partial t}\mathcal{P}_{\mathbf{r}}[F(\mathbf{r}',t)]=\int\frac{\delta}{\delta F(\mathbf{r}'',t)}\{[\mathbb{L}F(\mathbf{r}',t)]\mathcal{P}_{\mathbf{r}}[F(\mathbf{r}',t)]\}d\mathbf{r}''$$
$$+D_{\text{fract.}}\int\frac{\delta^{\alpha}}{\delta[F(\mathbf{r}'',t)]^{\alpha}}\mathcal{P}_{\mathbf{r}}[F(\mathbf{r}',t)]d\mathbf{r}''. \tag{56}$$

Equation (56) has an important consequence: it can be used for deriving evolution equations for joint probability density functionals of dynamical systems subject to colored noise by means of Van Kampen's method of compound master equations. A simple example is a nonlinear reaction-diffusion system subject to environmental fluctuations, described in terms of a one-variable multiplicative noise, such as fluctuations of the temperature.

An important type of colored noise corresponds to the case where the linear Langevin equation (1) is an equation of the reaction-diffusion type in unlimited space and the evolution operator $\mathbb{L}...$ has the standard form (3). In this case the Green function is translationally invariant. We have

$$\mathcal{G}(\mathbf{r}-\mathbf{r}'',t-t'')=[4\pi\omega\lambda^2(t-t'')]^{-m/2}\exp\left[-\omega(t-t'')-\frac{(\mathbf{r}-\mathbf{r}'')^2}{4\omega\lambda^2(t-t'')}\right], \tag{57}$$

with

$$\int_{-\infty}^{+\infty}\cdots\int\int_{t=t''}^{+\infty}\omega\mathcal{G}(\mathbf{r}-\mathbf{r}'',t-t'')d\mathbf{r}\,dt=1, \tag{58}$$

where m is the space dimension. It is easy to check that in the limit $\mathfrak{G}_t[\mathcal{K}(t')]$ with the constraint (31) the colored noise corresponding to Eq. (57) reduces to the standard Gaussian colored noise introduced by Lam and Bagayoko[30] and studied by Vlad, Ross, and Mackey.[32]

In conclusion, in this section we have derived analytic expressions for the characteristic functional and probability density functional of space- and time-dependent colored Lévy noise [Eqs. (48)–(51)]. In Appendix B we show that our general expression describes as a particular case the main properties of space-independent colored Lévy noise studied in the literature. By using a heuristic definition of the fractional functional derivative introduced in Appendix A, we have derived a fractional functional Fokker–Planck equation, which describes the properties of Lévy colored noise at a given moment in time, Eq. (58). This fractional functional Fokker–Planck equation can be used as a basis for deriving evolution equations for dynamical systems subjected to Lévy colored noise.

V. RATE PROCESSES IN DISORDERED SYSTEMS. EQUATIONS FOR THE RATE COEFFICIENTS

In this section we make an analogy between the theory of Lévy noise developed in this paper and the theory of rate processes in disordered systems. Our purpose is to use this analogy for deriving equations for the stochastic properties of the rate coefficients of a rate process in disordered systems. The results derived in this section are used in Sec. VI for suggesting methods for extracting kinetic information from experimental data.

For simplicity, in this section we limit ourselves to the study of rate processes with static disorder. We assume the validity of the random channel model in its simplest form. We consider a rate process described by a system of deterministic kinetic evolutions with random parameters of the type

$$d\mathbf{x}/dt=\mathcal{R}(\mathbf{x},\mathbf{W}), \tag{59}$$

where $\mathbf{x}=(x_1,x_2,\ldots)$ is the composition vector of the system, $\mathbf{W}=(W_1,W_2,\ldots)$ is the vector of the total rate coefficients and $\mathcal{R}=(\mathcal{R}_1,\mathcal{R}_2,\ldots)$ is the vector of the reaction rates. In Eq. (59) the intrinsic chemical fluctuations of the composition vector $\mathbf{x}$ are neglected and the only source of randomness are the random values of the vector of rate coefficients $\mathbf{W}$. We assume that the random variations of the different total rate coefficients $W_1,W_2,\ldots$ are independent of each other and that each total rate W_v can be represented by a linear superposition of various contributions of different reaction channels

$$W_v=\sum_u k_{vu}, \quad v=1,...,m, \tag{60}$$

where v is the channel label and m is the number of total rate coefficients.

We assume that the number N_v and the magnitudes $k_{v1},\ldots,k_{vN_v}$ obey Poissonian statistics. For processes with static disorder we can introduce the grand canonical probability densities

$$Q_{vN_v}(k_{v1},\ldots,k_{vN_v})dk_{v1}\cdots dk_{vN_v},\ \ Q_{1v}(k_{1v})dk_{1v},\ldots, \tag{61}$$

which obey the normalization conditions

$$Q_{v0}+\sum_{N_v=1}^{\infty}\frac{1}{N_v!}\int\cdots\int Q_{vN_v}(k_{v1},\ldots,k_{vN_v})dk_{v1}\cdots dk_{vN_v}=1. \tag{62}$$

For Poissonian statistics we have

$$Q_{v0}=\exp\left[-\int\rho_v(k_v)dk_v\right], \tag{63}$$

$$Q_{vN_v}(k_{v1},\ldots,k_{vN_v})dk_{v1}\cdots dk_{vN_v}=\exp\left[-\int\rho_v(k_v)dk_v\right]\rho_v(k_{v1})dk_{v1}\cdots\rho_v(k_{vN_v})dk_{vN_v}, \tag{64}$$

where $\rho_v(k_v)dk_v$, $v=1,2,...$, are average numbers of channels with contributions to the total rates between k_v and k_v+dk_v.

Now we introduce the probability density $\mathcal{P}(\mathbf{W})$ of the total rate coefficients, which obeys the normalization condition $\int\mathcal{P}(\mathbf{W})d\mathbf{W}=1$, and the corresponding characteristic function:

$$\mathcal{G}(\boldsymbol{\theta})=\int_0^{\infty}\cdots\int_0^{\infty}\exp\left(-\sum_v\theta_vW_v\right)\mathcal{P}(\mathbf{W})d\mathbf{W}, \tag{65}$$

where θ_v are the Laplace variables conjugated to the total rate coefficients W_v. We notice that, since the total rate coefficients are non-negative, the generating function $\mathcal{G}(\boldsymbol{\theta})$ of the probability density $\mathcal{P}(\mathbf{W})$ of the total rate coefficients can be defined as a multiple Laplace transform of $\mathcal{P}(\mathbf{W})$ with respect to the random variables W_v.

The probability density $\mathcal{P}(\mathbf{W})$ of the total rate coefficients W_v can be expressed as a multiple grand canonical average of a product of delta functions:

$$\begin{aligned}\mathcal{P}(\mathbf{W})&=\left\langle\prod_v\delta\left(W_v-\sum_u k_{vu}\right)\right\rangle\\&=\sum_{N_1}^{\infty}\cdots\sum_{N_m}^{\infty}\int\cdots\int\prod_{v=1}^{m}\left[\frac{1}{N_v!}\delta\left(W_v-\sum_u k_{vu}\right)Q_{vN_v}(k_{v1},\ldots,k_{vN_v})dk_{v1},\ldots,dk_{vN_v}\right].\end{aligned} \tag{66}$$

In general the grand canonical averages in Eq. (66) are hard to evaluate directly. However, if we take the multiple Laplace transform of Eq. (66) the generating function $\mathcal{G}(\boldsymbol{\theta})$ can be easily computed. By using the Poissonian laws (63) and (64) we come to

$$\begin{aligned}\mathcal{G}(\boldsymbol{\theta})&=\int_0^{\infty}\cdots\int_0^{\infty}\exp\left(-\sum_v\theta_vW_v\right)\sum_{N_1}^{\infty}\cdots\sum_{N_m}^{\infty}\int_0^{\infty}\cdots\int_0^{\infty}\prod_{v=1}^{m}\left[\frac{1}{N_v!}\delta\left(W_v-\sum_u k_{vu}\right)\right.\\&\quad\left.\times Q_{vN_v}(k_{v1},\ldots,k_{vN_v})dk_{v1},\ldots,dk_{vN_v}\right]d\mathbf{W}\\&=\prod_{v=1}^{m}\left\{\sum_{N_v=0}^{\infty}\frac{1}{N_v!}\left[\int\rho_v(k_v)\exp(-\theta_vk_v)dk_v\right]^{N_v}\exp\left[-\int\rho_v(k_v)dk_v\right]\right\},\end{aligned} \tag{67}$$

from which, by evaluating the sum over N_v, we come to

$$\mathcal{G}(\boldsymbol{\theta})=\exp\left[-\sum_{v=1}^{m}\int_0^{\infty}(1-\exp(\theta_v k_v))\rho_v(k_v)dk_v\right]=\prod_{v=1}^{m}\mathcal{G}_v(\theta_v) \tag{68}$$

with

$$\mathcal{G}_v(\theta_v)=\exp\left[-\int_0^{\infty}(1-\exp(-\theta_v k_v))\rho_v(k_v)dk_v\right]. \tag{69}$$

By taking the inverse Laplace transform of Eq. (68) we come to

$$\mathcal{P}(\mathbf{W})d\mathbf{W}=\prod_{v=1}^{m}[\mathcal{P}_v(W_v)dW_v], \tag{70}$$

where

$$\mathcal{P}_v(W_v)dW_v=\mathcal{L}^{-1}[\mathcal{G}_v(\theta_v)]dW_v \tag{71}$$

is the probability that the vth total rate has a value between W_v and W_v+dW_v; the functions $\mathcal{G}_v(\theta_v)$ are the characteristic functions of the probability densities $\mathcal{P}_v(W_v)$ and $\mathcal{L}^{-1}$ denotes the inverse Laplace transformation. As expected for independent random variables the probability density of the vector of the total rate coefficients, $\mathbf{W}$, is the product of the probability densities of different rate coefficients.

An important particular case is that for which the average densities of channels $\rho_v(k_v)$, $v=1,...,m$, attached to the different rate coefficients W_v, $v=1,...,m$, obey self-similar power scaling laws, similar to Eq. (12) introduced in Sec. III for Lévy noise

$$\rho_v(k_v)=\kappa_v\alpha_v(k_v)^{-(1+\alpha_v)},\quad 1>\alpha_v>0;\quad v=1,...,m, \tag{72}$$

where κ_v and α_v are scaling factors and fractal exponents attached to the different total rate coefficients, respectively. By using the scaling laws (72) the integrals in Eqs. (69) and (70) can be easily evaluated, resulting in

$$\mathcal{G}_v(\theta_v)=\exp[-(\Omega_v\theta_v)^{\alpha_v}], \tag{73}$$

where

$$\Omega_v=[(\alpha_v)^{-1}\kappa_v(\alpha_v)\Gamma(1-\alpha_v)]^{1/\alpha_v}. \tag{74}$$

The probability densities $\mathcal{P}_v(W_v)$ can be easily evaluated, resulting in

$$\mathcal{P}_v(W_v)=(\Omega_v)^{-1}\varphi_{\alpha_v}(W_v/\Omega_v), \tag{75}$$

where

$$\varphi_\alpha(x)=\mathcal{L}^{-1}[\exp(-s^\alpha)],\quad 1>\alpha>0, \tag{76}$$

is a Lévy probability density of a non-negative variable x, s is the Laplace variable conjugated to x, and α is a dimensionless fractal exponent.

Since the probability densities $\mathcal{P}_v(W_v)$ of the total rate are of the Lévy type we expect that they obey fractional evolution equations similar to Eqs. (56) and (B18) from Sec. IV and Appendix B. By differentiating Eqs. (73) with respect to Ω_v we come to

$$\Omega_v\frac{\partial}{\partial\Omega_v}\mathcal{G}_v+\alpha_v(\Omega_v\theta_v)^{\alpha_v}\mathcal{G}_v=0,\quad v=1,...,m. \tag{77}$$

Now we recall the definition of the asymmetric fractional derivative of order $\alpha, 1>\alpha>0$ of a function $f(x)$ of a non-negative variable[31] x,

$$\frac{d^{\alpha}}{dx^{\alpha}} f(x) = \frac{1}{\Gamma(1-\alpha)} \frac{d}{dx} \int_0^x \frac{f(y)dy}{(x-y)^{\alpha}}, \quad 1>\alpha>0, \tag{78}$$

and apply the inverse Laplace transformation to Eqs. (77), resulting in

$$\frac{\partial}{\partial \Omega_v} \mathcal{P}_v + \alpha_v (\Omega_v)^{\alpha_v - 1} \frac{\partial^{\alpha_v}}{\partial (W_v)^{\alpha_v}} \mathcal{P}_v = 0. \tag{79}$$

The fractional Fokker–Planck equation (79) can be easily extended to the more general case where the state densities $\rho_v(k_v)$, $v=1,...,m$, are arbitrary. Since $\rho_v(k_v)dk_v$, $v=1,...,m$, are pure numbers, it follows that the state densities $\rho_v(k_v)$, $v=1,...,m$, have the physical dimension $[k_v]^{-1}$. Dimensional analysis requires that $\rho_v(k_v)$, $v=1,...,m$, must depend on m constants Ω_v, $v=1,...,m$ with physical dimension $[k_v]$. We have

$$\rho_v(k_v) = (\Omega_v)^{-1} \chi_v(k_v/\Omega_v), \quad v=1,...,m, \tag{80}$$

where $\chi_v(x_v)$, $v=1,...,m$, are dimensionless densities of channels and $x_v = k_v/\Omega_v$. By using Eqs. (80) we can express Eqs. (69) in the following form,

$$\mathcal{G}_v(\theta_v) = \exp[-\eta_v(\theta_v \Omega_v)], \tag{81}$$

where

$$\eta_v(y) = \int_0^{\infty} (1-\exp(-xy)) \chi_v(x) dx. \tag{82}$$

By differentiating Eq. (81) with respect to Ω_v we come to

$$\frac{\partial}{\partial \Omega_v} \mathcal{G}_v + \theta_v \xi_v(\Omega_v \theta_v) \mathcal{G}_v = 0, \tag{83}$$

with

$$\xi_v(y) = \frac{\partial}{\partial y} \eta_v(y) = \int_0^{\infty} \exp(-xy) x \chi_v(x) dx = \mathcal{L}[x \chi_v(x)], \tag{84}$$

where $\mathcal{L}$ denotes the direct Laplace transformation. Now we apply the inverse Laplace transformation to Eqs. (83), resulting in a set of integrodifferential equations which are generalizations of the Fokker Planck equations (79)

$$\frac{\partial}{\partial \Omega_v} \mathcal{P}_v + (\Omega_v)^{-2} \frac{\partial}{\partial (W_v)} \int_0^{W_v} (W_v - W') \chi_v \left(\frac{W_v - W'}{\Omega_v} \right) \mathcal{P}_v(W') dW' = 0. \tag{85}$$

If the self-similar scaling laws (72) hold, then

$$\chi_v(x) = \frac{\alpha_v}{\Gamma(1-\alpha_v)} x^{-(1+\alpha_v)}, \tag{86}$$

and Eqs. (85) reduces to the fractional equations (79).

In conclusion in this section we have studied the statistical properties of the total rate coefficients for a nonlinear disordered system obeying independent random channel statistics. We have

derived relations for the probability densities of the total rate coefficients and their characteristic functions, and have shown that if the average densities of channels obey self-similar power scaling laws, then the probability densities of the total rate coefficients are of the Lévy type. In this particular case we have derived stationary fractional Fokker–Planck equations for the probability densities of the total rate coefficients. In the general case where the average densities of channels are arbitrary we have derived integrodifferential equations for the probability densities of the total rate coefficients; as expected, for self-similar distributions of channels these integrodifferential equations reduce to fractional Fokker–Planck equations. In the next section we use these results for suggesting methods for the extraction of kinetic information from experimental data.

VI. RATE PROCESSES IN DISORDERED SYSTEMS. EXTRACTION OF INFORMATION FROM EXPERIMENTAL DATA

In disordered kinetics the experimental observables are usually average concentrations. We denote by

$$\mathbf{x}(t)=\mathbf{\Theta}(\mathbf{x}_0,\mathbf{W};t) \tag{87}$$

the solution of the evolution equations (59) with the initial condition. We need to evaluate the average concentration vector

$$\langle \mathbf{x}(t)\rangle=\int_0^\infty\cdots\int_0^\infty \mathbf{\Theta}(\mathbf{x}_0,\mathbf{W};t)\mathcal{P}(\mathbf{W})d\mathbf{W}. \tag{88}$$

We express $\mathbf{\Theta}(\mathbf{x}_o,\mathbf{W};t)$ as an inverse Fourier transform,

$$\mathbf{\Theta}(\mathbf{x}_o,\mathbf{W};t)=\frac{1}{(2\pi)^m}\int_{-\infty}^{+\infty}\cdots\int_{-\infty}^{+\infty}\overline{\mathbf{\Theta}}(\mathbf{x}_o,\mathbf{q};t)\exp(-i\mathbf{q}\cdot\mathbf{W})d\mathbf{q}, \tag{89}$$

where

$$\overline{\mathbf{\Theta}}(\mathbf{x}_o,\mathbf{q};t)=\int_0^\infty\cdots\int_0^\infty \mathbf{\Theta}(\mathbf{x}_o,\mathbf{W};t)\exp(i\mathbf{q}\cdot\mathbf{W})d\mathbf{W}, \tag{90}$$

and where $\mathbf{q}$ is the vector of Fourier variables attached to the vector of total rate coefficients $\mathbf{W}$. In Eq. (90) we have taken into account that the total rate coefficients cannot be negative. By inserting Eqs. (89) and (90) into Eq. (88) and making use of Eq. (65) we come to

$$\begin{aligned}\langle \mathbf{x}(t)\rangle&=\frac{1}{(2\pi)^m}\int_0^\infty\cdots\int_0^\infty\int_{-\infty}^{+\infty}\cdots\int_{-\infty}^{+\infty}\mathbf{\Theta}(\mathbf{x}_o,\mathbf{W}';t)\exp(i\mathbf{q}\cdot\mathbf{W}')\\&\quad\times d\mathbf{W}'d\mathbf{q}\int_0^\infty\cdots\int_0^\infty\exp(-i\mathbf{q}\cdot\mathbf{W})\mathcal{P}(\mathbf{W})d\mathbf{W}\\&=\frac{1}{(2\pi)^m}\int_0^\infty\cdots\int_0^\infty\int_{-\infty}^{+\infty}\cdots\int_{-\infty}^{+\infty}\mathcal{G}(i\mathbf{q})\mathbf{\Theta}(\mathbf{x}_o,\mathbf{W}';t)\exp(i\mathbf{q}\cdot\mathbf{W}')d\mathbf{W}'\,d\mathbf{q}.\end{aligned} \tag{91}$$

Now we insert Eq. (68) into Eq. (91) resulting in

$$\langle \mathbf{x}(t)\rangle = \frac{1}{(2\pi)^m}\int_0^\infty\cdots\int_0^\infty\int_{-\infty}^{+\infty}\cdots\int_{-\infty}^{+\infty}\exp\left(i\mathbf{q}\cdot\mathbf{W}' - \sum_{v=1}^{m}\int_0^\infty (1-\exp(-iq_vk_v))\rho_v(k_v)dk_v\right)$$
$$\times\Theta(\mathbf{x}_o,\mathbf{W}';t)d\mathbf{W}'\,d\mathbf{q}$$
$$= \pi^{-m}\int_0^\infty\cdots\int_0^\infty\int_{-\infty}^{+\infty}\cdots\int_{-\infty}^{+\infty}\Theta(\mathbf{x}_o,\mathbf{W}';t)\exp\left(-\sum_{v=1}^{m}\int_0^\infty (1-\cos(q_vk_v))\rho_v(k_v)dk_v\right)$$
$$\times\prod_{v=1}^{m}\left\{\cos\left[q_vW_v' + \int_0^\infty \sin(q_vk_v)\rho_v(k_v)dk_v\right]\right\}d\mathbf{W}'\,d\mathbf{q}. \tag{92}$$

In particular, if the average densities of channels obey the self-similar scaling laws (72), we have

$$\langle \mathbf{x}(t)\rangle = \pi^{-m}\int_0^\infty\cdots\int_0^\infty\int_0^\infty\cdots\int_0^\infty\Theta(\mathbf{x}_o,\mathbf{W}';t)\exp\left(-\sum_{v=1}^{m}(q_v\Omega_v)^{\alpha_v}\cos\left(\frac{\pi\alpha_v}{2}\right)\right)$$
$$\times\prod_{v=1}^{m}\left\{\cos\left[q_vW_v' + (q_v\Omega_v)^{\alpha_v}\sin\left(\frac{\pi\alpha_v}{2}\right)\right]\right\}d\mathbf{W}'\,d\mathbf{q}. \tag{93}$$

Equation (92) expresses the experimental observables, the average concentrations, in terms of the average densities of channels for a general nonlinear kinetic system with static disorder described by the independent random channel model. In particular, Eq. (93) gives the average concentration vector for scale-independent, self-similar distributions of reaction channels. From this point of view Eq. (93) can be considered as a nonlinear generalization of the stretched exponential kinetic law, for multi-species nonlinear chemical processes.

The experimental evaluation of kinetic parameters for the rate processes in disordered systems usually proceeds in two steps. The analysis starts with the extraction from experimental data of the statistical properties of the rate coefficients, that is, with the evaluation of the probability densities $\mathcal{P}_v(W_v)$ or of the moments or cumulants of the total rate coefficients, followed by the evaluation of the average densities of channels $\rho_v(k_v)$ from the probability densities $\mathcal{P}_v(W_v)$ of the total rate coefficients. We think that there are at least two different methods for evaluating the functions $\rho_v(k_v)$ in terms of the probability densities $\mathcal{P}_v(W_v)$. One first method is based on the use of the generalized fractional equations (85). By taking the inverse Laplace transform of Eqs. (81) we notice that the total probability densities of the total rates can be expressed as $\mathcal{P}_v(W_v) = (\Omega_v)^{-1}\mathfrak{G}_N(W_v/\Omega_v)$ where $\mathfrak{G}_v(w_v)$ are the probability densities of the dimensionless total rates $w_v = W_v/\Omega_v$. By expressing Eqs. (85) in terms of $\mathfrak{G}_v(w_v)$, after lengthy manipulations we get a set of integral equations for the average densities of channels $\rho_v(k_v)$. A second method is based on the derivation, from Eqs. (69), of a set of differential equations for the generating functions $\mathcal{G}_v(\theta_v)$. Since both methods lead to the same integral equations, in the following we present only the second method, which is shorter.

We differentiate Eqs. (69) with respect to θ_v, resulting in

$$-\frac{\partial}{\partial\theta_v}\mathcal{G}_v(\theta_v) = \mathcal{G}_v(\theta_v)\frac{\partial}{\partial\theta_v}\int_0^\infty (1-\exp(-\theta_vk_v))\rho_v(k_v)dk_v = \mathcal{G}_v(\theta_v)\mathcal{L}\{k_v\rho_v(k_v)\}, \tag{94}$$

from which we come to

$$\mathcal{L}\{W_v\mathcal{P}_v(W_v)\} = \mathcal{L}\{\mathcal{P}_v(W_v)\}\mathcal{L}\{k_v\rho_v(k_v)\}. \tag{95}$$

By applying the inverse Laplace transformation to Eqs. (95) we obtain a set of convolution equations for the densities of channels, which can be solved numerically:

$$W_v \mathcal{P}_v(W_v) = \int_0^{W_v} \mathcal{P}_v(W_v - k_v) k_v \rho_v(k_v) dk_v . \tag{96}$$

Equations (92), (93), (95), and (96) are general theoretical results. In order to apply them for the analysis of experimental data more detailed kinetic information is necessary. In this section we consider three single and two species chemical systems for which a detailed analysis is possible.

The first example is the first order, irreversible reaction

$$\mathrm{X} \rightarrow \text{Products}. \tag{97}$$

In this case the solution of the evolution equation (59) is

$$x(t) = x_0 \exp(-Wt), \tag{98}$$

and the average concentration is described by Huber's equation[22]

$$\langle x(t) \rangle / x_0 = \mathcal{G}(t) = \exp\left\{ -\int_0^{\infty} [1 - \exp(-kt)] \rho(k) dk \right\}, \tag{99}$$

where $\mathcal{G}(t)$ is the characteristic function of the probability density of the total rate coefficient. In this case the ratio between the average concentration at time t and the initial concentration is simply the Laplace transform of the probability density $\mathcal{P}(W)$ of the total rate coefficient:

$$\langle x(t) \rangle / x_0 = \int_0^{\infty} \exp(-Wt) \mathcal{P}(W) dW. \tag{100}$$

It follows that for first order kinetics the probability density $\mathcal{P}(W)$ of the total rate coefficient can be obtained from Eq. (100) by means of inverse numerical Laplace transformation. If $\mathcal{P}(W)$ is known, then the average density of channels $\rho(k)$ can be evaluated from Eqs. (95) and (96). We note that for stretched exponential kinetics the moments and the cumulants of the total rate coefficient are divergent. However, if the average density of channels $\rho(k)$ does not obey a self-similar scaling law the moments and cumulants of the total rate coefficients may be finite. If numerical data are not precise, inverse numerical Laplace transformation is not possible. However, the first few moments and cumulants can be evaluated from the time derivatives of the average concentration. We have

$$\langle W^m \rangle = (-1)^m \frac{d^m}{dt^m} \left[\frac{\langle x(t) \rangle}{x_0} \right] \Bigg|_{t=0} \tag{101}$$

for the moments and

$$\langle\langle W^m \rangle\rangle = (-1)^m \frac{d^m}{dt^m} \ln \left[\frac{\langle x(t) \rangle}{x_0} \right] \Bigg|_{t=0} \tag{102}$$

for the cumulants.

The second example is a first order, irreversible reaction, with a single equilibrium state:

$$\mathrm{X} \rightleftarrows \mathrm{Y}. \tag{103}$$

The solution of the kinetic equations (59) for a closed system is given by

$$\frac{x(t)}{x_0 + y_0} = \frac{1}{K_{\mathrm{eq}} + 1} + \left[\frac{x_0}{x_0 + y_0} - \frac{1}{K_{\mathrm{eq}} + 1} \right] \exp(-W_{\Sigma} t), \tag{104}$$

and a similar equation for the concentration $y(t)$ of the species Y. Here x_0 and y_0 are the initial concentrations of the species X and Y, respectively, $W_\Sigma = W_+ + W_-$ is the total rate coefficient of the process; W_+ and W_- are rate coefficients of the forward and backward processes (103), respectively, and $K_{\rm eq} = W_-/W_-$ is the equilibrium constant of the process. For a process with a single equilibrium state, although the rate coefficients W_+ and W_- are random, their ratio $K_{\rm eq} = W_+/W_-$ is constant and equal to the equilibrium constant of the process. Under these circumstances it can be shown[24] that the random channel model can be expressed in terms of a single density of channels, $\rho_\Sigma(k_\Sigma)$ corresponding to the total rate coefficient $W_\Sigma = W_+ + W_-$. We have

$$\frac{\langle x(t)\rangle}{x_0+y_0} = \frac{1}{K_{\rm eq}+1} + \left[\frac{x_0}{x_0+y_0} - \frac{1}{K_{\rm eq}+1}\right]\int_0^\infty \mathcal{P}_\Sigma(W_\Sigma)\exp(-W_\Sigma t)\,dW_\Sigma$$
$$= \frac{1}{K_{\rm eq}+1} + \left[\frac{x_0}{x_0+y_0} - \frac{1}{K_{\rm eq}+1}\right]\exp\left\{-\int_0^\infty \rho_\Sigma(k_\Sigma)[1-\exp(-k_\Sigma t)]\,dk_\Sigma\right\}. \quad (105)$$

and a similar equation for the average concentration $\langle y(t)\rangle$ of the Y species. It follows that the probability density of the rate coefficients can be expressed as

$$\mathcal{P}_\Sigma(W_\Sigma) = \mathcal{L}^{-1}\left\{\frac{\langle x(t)\rangle(K_{\rm eq}+1)-(x_0+y_0)}{x_0(K_{\rm eq}+1)-(x_0+y_0)}\right\} \quad (106)$$

and the moments and cumulants of the total rate coefficient can be computed from

$$\langle W^m\rangle = (-1)^m \frac{d^m}{dt^m}\left[\frac{\langle x(t)\rangle(K_{\rm eq}+1)-(x_0+y_0)}{x_0(K_{\rm eq}+1)-(x_0+y_0)}\right]\Bigg|_{t=0}, \quad (107)$$

$$\langle\langle W^m\rangle\rangle = (-1)^m \frac{d^m}{dt^m}\ln\left[\frac{\langle x(t)\rangle(K_{\rm eq}+1)-(x_0+y_0)}{x_0(K_{\rm eq}+1)-(x_0+y_0)}\right]\Bigg|_{t=0}. \quad (108)$$

The average density of channels can be determined from Eqs. (95) and (96).

The third example is a nonlinear, irreversible reaction,

$$\nu \mathrm{X} \rightarrow \text{Products}, \quad (109)$$

where ν is a stoichiometric coefficient bigger than one. The solution of the kinetic equation for a given realization of the total rate coefficient W is given by

$$x(t)/x_0 = \{1+(\nu-1)(x_0)^{\nu-1}Wt\}^{-1/(\nu-1)}, \quad (110)$$

where W is the total rate coefficient of the process. The application of Eq. (92) leads to the following expression for the average concentration $\langle x(t)\rangle$ of species X:

$$\frac{\langle x(t)\rangle}{x_0} = \frac{1}{\Gamma((\nu-1)^{-1})}\int_0^\infty \lambda^{1/(\nu-1)}\exp\left\{-z-\int_0^\infty \rho(k)[1-\exp(-\lambda(\nu-1)(x_0)^{\nu-1}kt)]\,dk\right\}d\lambda$$
$$= \int_0^\infty \frac{\mathcal{P}(W)\,dW}{\{1+(\nu-1)(x_0)^{\nu-1}Wt\}^{1/(\nu-1)}}. \quad (111)$$

Equation (111) is a linear integral equation for the probability density $\mathcal{P}(W)$ of the total rate coefficient. This integral equation can be transformed, through discretization, into a linear matrix equation which can be solved numerically. If the probability density $\mathcal{P}(W)$ is known, then the average density $\rho(k)$ of channels can be evaluated from Eqs. (95) and (96).

The positive moments of the total rate coefficient can be evaluated from a relation similar to Eqs. (101) and (107):

$$\langle W^m\rangle=[-(\nu-1)(x_0)^{\nu-1}]^{-m}\frac{\Gamma(m+(\nu-1)^{-1})}{\Gamma((\nu-1)^{-1})}\frac{d^m}{dt^m}\left[\frac{\langle x(t)\rangle}{x_0}\right]\Bigg|_{t=0}. \tag{112}$$

We do not have direct expressions for the cumulants of the total rate coefficient; they can, however, be computed step by step from the moments.

In conclusion, in this section we have made, a connection between the probability densities of the total rate coefficients, the average densities of channels, and the average concentrations, which are experimental observables in disordered chemical kinetics. We have developed methods for extracting statistical information about the fluctuations of the rate coefficients from experimental data. We have illustrated our approach by considering three simple chemical reactions.

VII. CONCLUSIONS

In this article we have pointed out some useful analogies between colored Lévy noise and the random channel approach in disordered kinetics. The exploitation of these analogies produces interesting results in both areas of research. By using Huber's stochastic approach for disordered kinetics we have managed to come up with a space- and time-dependent generalization of Lévy colored noise. In disordered kinetics, by using the analogies with Lévy colored noise, we have managed to develop a general theory of nonlinear chemical kinetics with static disorder. We have studied the statistical properties of the rate coefficients and developed methods for extracting information about rate statistics from experimental data.

APPENDIX A: FRACTIONAL, FUNCTIONAL FOKKER–PLANCK EQUATION FOR COLORED LÉVY NOISE

We consider a discrete representation $P_{\mathbf{r}}[\|F_0^{(u,\mathbf{v})}\|;t]\Pi_{\mathbf{v}}dF^{(\mathbf{v})}$ of the probability $\mathcal{P}_{\mathbf{r}}[F(\mathbf{r}');t]\mathcal{D}_{\mathbf{r}}[F(\mathbf{r}');t]$. We have

$$\mathcal{P}_{\mathbf{r}}[F(\mathbf{r}');t]\mathcal{D}_{\mathbf{r}}[F(\mathbf{r}');t]=\lim_{\Delta\mathbf{r}\to 0}P_{\mathbf{r}}[\|F_0^{(\mathbf{v})}\|;t]\prod_{\mathbf{v}}dF^{(\mathbf{v})}, \tag{A1}$$

$$\mathfrak{G}_{\mathbf{r}}[K(\mathbf{r}');t]=\lim_{\Delta\mathbf{r}\to\mathbf{0}}G_{\mathbf{r}}[K^{(\mathbf{v})};t], \tag{A2}$$

where

$$G_{\mathbf{r}}[K^{(\mathbf{v})};t]=\int_{-\infty}^{+\infty}\cdots\int\exp\left\{i\sum_{\mathbf{v}}K^{(\mathbf{v})}F^{(\mathbf{v})}\Delta\mathbf{r}\right\}P_{\mathbf{r}}[\|F^{(\mathbf{v})}\|;t]\prod_{\mathbf{v}}dF_0^{(\mathbf{v})} \tag{A3}$$

is the Fourier transform of the discrete probability $P_{\mathbf{r}}[\|F_0^{(u,\mathbf{v})}\|;t]\Pi_{\mathbf{v}}dF^{(\mathbf{v})}$. We use a discrete representation of Eq. (52), in terms of $G_{\mathbf{r}}[K^{(\mathbf{v})};t]$, and evaluate the inverse Fourier transform with respect to $K^{(\mathbf{v})}$. The evaluation of the inverse Fourier transform of the first two terms is trivial. In order to evaluate the inverse Fourier transform of the third term,

$$\mathcal{J}_3=D_{\text{fract.}}\int_{-\infty}^{+\infty}\cdots\int\exp\left\{-i\sum_{\mathbf{v}}K^{(\mathbf{v})}F^{(\mathbf{v})}\Delta\mathbf{r}\right\}\left[\sum_{\mathbf{v}}\Delta\mathbf{r}|K^{(\mathbf{v})}|^{\alpha}\right]G_{\mathbf{r}}[K^{(\mathbf{v})};t]\prod_{\mathbf{v}}\left(\frac{dK^{(\mathbf{v})}\Delta\mathbf{r}}{2\pi}\right), \tag{A4}$$

we use the definition (57) of the symmetric fractional derivative of order α, resulting in

$$\mathcal{J}_3 = D_{\text{fract.}} \sum_{\mathbf{v}} (\Delta \mathbf{r})^{1-\alpha} \frac{\partial^\alpha}{\partial [F^{(\mathbf{v})}]^\alpha} P_{\mathbf{r}}[\|F_0^{(u,\mathbf{v})}\|;t]. \tag{A5}$$

By passing to the continuous notations and using the heuristic definition (55) of the fractional functional derivative of order α we come to Eq. (56).

APPENDIX B: SPACE-INDEPENDENT COLORED LÉVY NOISE

In this appendix we apply our approach for studying the particular case of space-independent Lévy colored noise. The space independent white noise can be characterized by the probability functional

$$\mathcal{P}_t^0[F_0(t')]\mathcal{D}_t^0[F_0(t')] \quad \text{with} \quad \overline{\int\int_t} \mathcal{P}_t^0[F_0(t')]\mathcal{D}_t^0[F_0(t')] = 1 \tag{B1}$$

or by the characteristic functional

$$\mathfrak{G}_t^0[\mathcal{K}(t')] = \overline{\int\int_t} \exp\left\{ i \int_{-\infty}^{+\infty} \mathcal{K}(t') F_0(t') dt' \right\} \mathcal{P}_t^0[F_0(t')]\mathcal{D}_t^0[F_0(t')]. \tag{B2}$$

The random force $F_0(t')$ can be expressed as the sum of the contributions of different individual events (channels):

$$F_0(t') = \sum_{m=1}^{N} g_m(t'). \tag{B3}$$

We assume that the fluctuations of the components $g_m(t')$ can be described by a Poissonian point process characterized by an average functional density of states $\rho_g[g(t)]\mathcal{D}[g(t)]$ which obeys a scaling condition of the negative power law type similar to Eq. (12). By considering a discrete representation of the average functional density of states $\rho_g[g(t)]\mathcal{D}[g(t)]$ we have

$$\rho_g(g;\Delta t)dg = \chi_0(\alpha)(\Delta t)^{(1-\alpha)}|g|^{-(1+\alpha)}dg, \quad \chi_0(\alpha) > 0, \quad 2 > \alpha > 0. \tag{B4}$$

The scaling law (B4) leads to the following expression for the characteristic functional of the white noise:

$$\mathfrak{G}_t^0[\mathcal{K}(t')] = \exp\left(-c \int_{-\infty}^{+\infty} |\mathcal{K}(t')|^\alpha dt' \right), \quad \text{where} \quad c = 2\chi_0(\alpha) \frac{\Gamma(1-\alpha)}{\alpha} \cos\left(\frac{\pi\alpha}{2}\right). \tag{B5}$$

The probability functional corresponding to the characteristic functional (B5) can be expressed as the continuous limit of a product of symmetric Lévy probability densities:

$$\mathcal{P}_{\mathbf{r},t}^0[F_0(\mathbf{r}',t')]\mathcal{D}_{\mathbf{r},t}^0[F_0(\mathbf{r}',t')] = \lim_{\Delta t \to 0} \prod_u \left\{ \frac{dF_0^{(u)}}{[c(\Delta t)]^{1/\alpha}} \Psi_\alpha \left\{ \frac{F_0^{(u,\mathbf{v})}}{[c(\Delta t)]^{1/\alpha}} \right\} \right\}, \tag{B6}$$

where $\Psi_\alpha(x)$ is the one-variable symmetrical Lévy probability density given by Eq. (28).

A given realization $F(t)$ of space-independent colored noise obeys the Langevin equation

$$\partial F(t)/\partial t = \omega[-F(t) + F_0(t)]. \tag{B7}$$

We start out by considering the case of nonstationary colored noise and for this reason we introduce a cutoff value t_0 in the expression (B5) for the characteristic functional $\mathfrak{G}_t^0[\mathcal{K}(t')]$ of the white noise, resulting in

$$\mathfrak{G}_t^0[\mathcal{K}(t')]=\exp\left(-c\int_{t_0}^{+\infty}|\mathcal{K}(t')|^{\alpha}\,dt'\right). \tag{B8}$$

From Eqs. (B7) and (B8) we get the following expression for the characteristic functional of colored noise:

$$\mathfrak{G}_t[\mathcal{K}(t')]=\mathfrak{G}_t^{\text{transient}(t_0)}[\mathcal{K}(t')]\mathfrak{G}_t^{\text{normal}(t_0)}[\mathcal{K}(t')], \tag{B9}$$

where the transient component $\mathfrak{G}_t^{\text{transient}(t_0)}[\mathcal{K}(t')]$ and the normal component $\mathfrak{G}_t^{\text{normal}(t_0)}[\mathcal{K}(t')]$ are given by

$$\mathfrak{G}_t^{\text{transient}(t_0)}[\mathcal{K}(t')]=\mathfrak{G}_r\left[K=\int_{t_0}^{\infty}\mathcal{K}(t'')\exp[-\omega(t''-t_0)dt'';t_0\right], \tag{B10}$$

$$\mathfrak{G}_t^{\text{normal}(t_0)}[\mathcal{K}(t')]=\exp\left(-c\int_{t_0}^{+\infty}\left|\int_{t''=t'}^{\infty}\mathcal{K}(t'')\,\omega\exp[-\omega(t''-t')]dt''\right|^{\alpha}dt'\right) \tag{B11}$$

and where

$$\mathfrak{G}[K;t_0]=\int_{-\infty}^{+\infty}P(F;t_0)\exp(iKF)dF \tag{B12}$$

is the Fourier transform of the probability density $P(F;t_0)$ of the colored noise at time t_0.

In particular, the characteristic function

$$\mathfrak{G}[K;t]=\int_{-\infty}^{+\infty}P(F;t)\exp(iKF)dF \tag{B13}$$

of the colored noise at time t is given by

$$\mathfrak{G}[K;t]=\mathfrak{G}[K\exp[-\omega(t-t_0)];t_0]\exp\left\{-\frac{D_{\text{fract.}}}{\alpha\omega}|K|^{\alpha}[1-\exp[-\alpha\omega(t-t_0)]]\right\}, \tag{B14}$$

where

$$D_{\text{fract.}}=c\,\omega^{\alpha}=2\,\omega^{\alpha}\chi_0(\alpha)\frac{\Gamma(1-\alpha)}{\alpha}\cos\left(\frac{\pi\alpha}{2}\right) \tag{B15}$$

is a space-independent fractional diffusion coefficient similar to the one defined in the space-dependent case by Eq. (46).

The probability density $P(F;t)$ of the colored noise at time t can be easily evaluated by taking the inverse Fourier transform of Eq. (B14). We have

$$P(F;t)=\left(\frac{\alpha\omega}{D_{\text{fract.}}}\right)^{1/\alpha}\frac{\exp[\omega(t-t_0)]}{[\exp[\alpha\omega(t-t_0)]-1]^{1/\alpha}}\int_{-\infty}^{+\infty}P(F_0;t_0)$$
$$\times\Psi_{\alpha}\left\{\left(\frac{\alpha\omega}{D_{\text{fract.}}}\right)^{1/\alpha}\frac{F\exp[\omega(t-t_0)]-F_0}{[\exp[\alpha\omega(t-t_0)]-1]^{1/\alpha}}\right\}dF_0. \tag{B16}$$

From Eq. (B16) we notice that as $t\to\infty$ the probability density $P(F;t)$ of the colored noise tends towards a Lévy stable form which is independent of the initial condition $P(F_0;t_0)$:

$$P(F;t)\to P_{st}(F)=(\alpha\omega/D_{\text{fract.}})^{1/\alpha}\Psi_\alpha[F(\alpha\omega/D_{\text{fract.}})^{1/\alpha}],\ \text{independent of}\ P(F_0;t_0),\ \text{as}\ t\to\infty. \tag{B17}$$

It is easy to check that the probability density $P(F;t)$ of the colored noise given by Eq. (B16) is the solution of a fractional Fokker–Planck equation:

$$\frac{\partial}{\partial t}P(F;t)=\frac{\partial}{\partial F}[\omega FP(F;t)]+D_{\text{fract.}}\frac{\partial^\alpha}{\partial F^\alpha}P(F;t). \tag{B18}$$

We notice that the fractional Fokker–Planck equation (B18) is the same as the fractional Fokker–Planck equation introduced by Metzler, Barkai, and Klafter for describing the stochastic evolution of a particle under the combined influence of an external, nonlinear force and a thermal heat bath.[16] It follows that the fractional Lévy noise introduced by using the Huber approach is equivalent to the fractional Lévy noise described by the fractional Fokker–Planck equation of Metzler, Barkai, and Klafter.[16] We also point out that our fractional functional Fokker–Planck equation (56) is a generalization of the Metzler, Barkai, and Klafter equation (B18) to the case of space and time dependent Lévy colored noise.

In particular, if $t_0\to-\infty$ or if the initial probability density $P(F_0;t_0)$ is the same as the stationary probability density $P_{st}(F)$, then the colored noise is stationary and the characteristic functional (B14) becomes

$$\mathfrak{G}_t[\mathcal{K}(t')]=\exp\left(-D_{\text{fract.}}\int_{-\infty}^{+\infty}\left|\int_{t''=t'}^{\infty}\mathcal{K}(t'')\exp[-\omega(t''-t')]dt''\right|^\alpha dt'\right). \tag{B19}$$

The stochastic process described by the characteristic functional (B19) is a statistical fractal generalization of the Uhlenbeck–Ornstein process. In the particular case where the fractal exponent α tends towards 2, $\alpha\to2$, and the limit

$$\lim_{\alpha\to2}D_{\text{fract.}}=\lim_{\alpha\to2}\left[2\omega^\alpha\chi_0(\alpha)\frac{\Gamma(1-\alpha)}{\alpha}\cos\left(\frac{\pi\alpha}{2}\right)\right]=D \tag{B20}$$

exists and is finite, we recover the classical Uhlenbeck–Ornstein process.

A linked average depending on the colored noise,

$$\Phi(t)=\left\langle\exp\left[-\int_{t_0}^{t}\zeta(t')F(t')dt'\right]\right\rangle, \tag{B21}$$

can be easily evaluated from the expression (B19) for the characteristic functional $\mathfrak{G}_t[\mathcal{K}(t')]$. We have

$$\Phi(t)=\mathfrak{G}_t^0[\mathcal{K}(t')=\zeta(t')[h(t'-t_0)-h(t'-t)]]. \tag{B22}$$

The fractional Fokker–Planck equation (B18) can be used for deriving evolution equations for joint probability density functions of dynamical systems subject to colored noise by means of Van Kampen's method of compound master equations. For example, we consider a nonlinear system subjected to environmental fluctuations, described in terms of a one-variable multiplicative noise. We express the evolution equations of the system in the following form:

$$\frac{\partial}{\partial t}\mathbf{x}(t)=\mathfrak{F}[\mathbf{x}(t);F(t);t], \tag{B23}$$

where $\mathbf{x}(t)$ is a state vector, and $\mathfrak{F}[\mathbf{x}(t);F(t);t]$ is a nonlinear vectorial function which depends on the state vector $\mathbf{x}(t)$, the noise $F(t)$ and the time t. By using the method of compound master equations we can derive a fractional stochastic Liouville equation for the joint probability density $P(\mathbf{x},F;t)$:

$$\frac{\partial}{\partial t}P(\mathbf{x},F;t)=-\nabla_{\mathbf{x}}\cdot[\mathfrak{F}[\mathbf{x};F;t]P(\mathbf{x},F;t)]+\frac{\partial}{\partial F}[\omega F P(\mathbf{x},F;t)]+D_{\text{fract.}}\frac{\partial^{\alpha}}{\partial F^{\alpha}}P(\mathbf{x},F;t). \tag{B24}$$

The probability density $P(\mathbf{x};t)$ of the state vector $\mathbf{x}$ at time t can be evaluated by solving Eq. (B24) with suitable initial and boundary conditions and by integrating the solution over all possible values of the random noise source F:

$$P(\mathbf{x},t)=\int_{-\infty}^{\infty}P(\mathbf{x},F;t)dF. \tag{B25}$$

In summary, in this appendix we studied the particular case of space-independent colored Lévy noise. We have derived expressions for the characteristic functional and probability density functional of space-independent colored Lévy noise. We have shown that the probability density of Lévy noise at a given time obeys a fractional Fokker–Planck equation. The colored Lévy noise derived by using the Huber approach is equivalent to the colored Lévy noise described by the fractional Fokker–Planck equation (B18), which is the same as the fractional Fokker–Planck equation derived by Metzler, Barkai and Klafter[16] by using a different approach.

(Received 23 May 2003; accepted 22 October 2003)

Several new formulas are developed that enable the evaluation of a family of definite integrals containing the product of two Whittaker $W_{\kappa,\mu}(x)$-functions. The integration is performed with respect to the second index μ, and the first index κ is permitted to have any complex value, within certain restrictions required for convergence. The method utilizes complex contour integration along with various symmetry relations satisfied by the Whittaker functions. The new results derived in this article are complementary to the previously known integrals of products of Whittaker functions, which generally treat integration with respect to either the first index κ or the primary argument x. A physical application involving radiative transport is discussed. © *2004 American Institute of Physics.*

I. INTRODUCTION

Many problems in mathematical physics involve differential equations with solutions that can be expressed in terms of Whittaker's functions $W_{\kappa,\mu}(x)$ and $M_{\kappa,\mu}(x)$. Examples of the diverse applications include studies of the spectral evolution resulting from the Compton scattering of radiation by hot electrons,[1–3] modeling of the structure of the hydrogen atom,[4] analysis of the Schrödinger equation,[5] studies of the Coulomb Green's function,[6] and analysis of fluctuations in financial markets.[7]

In a number of applications, it is necessary to evaluate integrals of Whittaker functions. This need may arise out of the requirement to satisfy normalization or orthogonality conditions. In particular, in the analysis of time-dependent Compton scattering, it is necessary to evaluate integrals containing the product of two Whittaker $W_{\kappa,\mu}(x)$-functions, where the variable of integration is the second index μ. This is an unusual situation that is not covered by any of the previously known formulas for integrals of products of Whittaker functions. The required integrals in the Compton scattering application are members of the general family

$$I(s)\equiv\int_0^\infty \frac{u\sinh(2\pi u)\Gamma(\frac{1}{2}-\kappa-iu)\Gamma(\frac{1}{2}-\kappa+iu)}{s+u^2}W_{\kappa,iu}(x)W_{\kappa,iu}(x_0)\,du, \tag{1}$$

where x and x_0 are real and positive, and s and κ are complex. This integral converges for all values of s in the complex plane, with the exclusion of the negative real semiaxis, provided that $\mathcal{R}e\,\kappa\neq 1/2,3/2,5/2,...$, if $\mathcal{I}m\,\kappa\neq 0$. It also converges in the special case $s=0$, provided $\mathcal{R}e\,\kappa\neq 1/2,3/2,5/2,...$. In this article we derive several exact formulas for the evaluation of the integral $I(s)$ that fully describe all of the convergent cases.

II. FUNDAMENTAL EQUATIONS

We shall begin by briefly reviewing some of the basic properties of the Whittaker functions that will be useful in our later work. The Whittaker functions $W_{\kappa,\mu}(z)$ and $M_{\kappa,\mu}(z)$ are confluent hypergeometric functions that are related to the Kummer functions $\Phi(a,b,z)$ and $\Psi(a,b,z)$ by[8,9]

$$\begin{aligned} M_{\kappa,\mu}(z) &= z^{\mu+1/2}e^{-z/2}\Phi(\tfrac{1}{2}+\mu-\kappa,1+2\mu;z), \\ W_{\kappa,\mu}(z) &= z^{\mu+1/2}e^{-z/2}\Psi(\tfrac{1}{2}+\mu-\kappa,1+2\mu;z). \end{aligned} \tag{2}$$

For small values of $|z|$, the function $M_{\kappa,\mu}(z)$ is given by the power series

$$M_{\kappa,\mu}(z) = e^{-z/2}z^{\mu+1/2}\sum_{n=0}^{\infty}\frac{(\frac{1}{2}-\kappa+\mu)_n}{(1+2\mu)_n}\frac{z^n}{n!}, \tag{3}$$

where $(a)_n$ denotes the Pochhammer symbol, defined by[9]

$$(a)_n \equiv \frac{\Gamma(a+n)}{\Gamma(a)}. \tag{4}$$

The function $W_{\kappa,\mu}(z)$ can be expressed in terms of $M_{\kappa,\mu}(z)$ using[8]

$$W_{\kappa,\mu}(z) = \frac{\Gamma(-2\mu)}{\Gamma(\frac{1}{2}-\mu-\kappa)}M_{\kappa,\mu}(z) + \frac{\Gamma(2\mu)}{\Gamma(\frac{1}{2}+\mu-\kappa)}M_{\kappa,-\mu}(z). \tag{5}$$

The integrand in Eq. (1) for $I(s)$ is an even function of u, and therefore we can write

$$I(s) = \frac{1}{2}\int_{-\infty}^{\infty}\frac{u\sinh(2\pi u)\Gamma(\frac{1}{2}-\kappa-iu)\Gamma(\frac{1}{2}-\kappa+iu)}{s+u^2}W_{\kappa,iu}(x)W_{\kappa,iu}(x_0)du. \tag{6}$$

Next we utilize (5) to express $W_{\kappa,iu}(x_0)$ as

$$W_{\kappa,iu}(x_0) = \frac{\Gamma(-2iu)}{\Gamma(\frac{1}{2}-\kappa-iu)}M_{\kappa,iu}(x_0) + \frac{\Gamma(2iu)}{\Gamma(\frac{1}{2}-\kappa+iu)}M_{\kappa,-iu}(x_0), \tag{7}$$

which can be rewritten as

$$W_{\kappa,iu}(x_0) = \frac{\Gamma(-2iu)\Gamma(2iu)}{\Gamma(\frac{1}{2}-\kappa-iu)\Gamma(\frac{1}{2}-\kappa+iu)}\left[\frac{\Gamma(\frac{1}{2}-\kappa+iu)}{\Gamma(2iu)}M_{\kappa,iu}(x_0) + \frac{\Gamma(\frac{1}{2}-\kappa-iu)}{\Gamma(-2iu)}M_{\kappa,-iu}(x_0)\right]. \tag{8}$$

By employing the recurrence formula for the gamma function, $z\Gamma(z)=\Gamma(z+1)$, we can obtain the alternative form

$$W_{\kappa,iu}(x_0) = \frac{\Gamma(-2iu)\Gamma(1+2iu)}{\Gamma(\frac{1}{2}-\kappa-iu)\Gamma(\frac{1}{2}-\kappa+iu)}\left[\frac{\Gamma(\frac{1}{2}-\kappa+iu)}{\Gamma(1+2iu)}M_{\kappa,iu}(x_0) - \frac{\Gamma(\frac{1}{2}-\kappa-iu)}{\Gamma(1-2iu)}M_{\kappa,-iu}(x_0)\right]. \tag{9}$$

Using this result to substitute for $W_{\kappa,iu}(x_0)$ in (6) now yields

$$I(s)=\frac{1}{2}\int_{-\infty}^{\infty}\frac{u\sinh(2\pi u)}{s+u^2}\Gamma(-2iu)\Gamma(1+2iu)W_{\kappa,iu}(x)$$
$$\times\left[\frac{\Gamma(\frac{1}{2}-\kappa+iu)}{\Gamma(1+2iu)}M_{\kappa,iu}(x_0)-\frac{\Gamma(\frac{1}{2}-\kappa-iu)}{\Gamma(1-2iu)}M_{\kappa,-iu}(x_0)\right]du. \tag{10}$$

By utilizing the reflection formula for the gamma function,

$$\Gamma(1+2iu)\Gamma(-2iu)=\frac{\pi i}{\sinh(2\pi u)}, \tag{11}$$

along with the symmetry relation [see Eq. (5)]

$$W_{\kappa,iu}(x)=W_{\kappa,-iu}(x), \tag{12}$$

we can rewrite (10) as

$$I(s)=\frac{\pi i}{2}\int_{-\infty}^{\infty}\frac{u}{s+u^2}\left[\frac{\Gamma(\frac{1}{2}-\kappa+iu)}{\Gamma(1+2iu)}W_{\kappa,iu}(x)M_{\kappa,iu}(x_0)\right.$$
$$\left.-\frac{\Gamma(\frac{1}{2}-\kappa-iu)}{\Gamma(1-2iu)}W_{\kappa,-iu}(x)M_{\kappa,-iu}(x_0)\right]du. \tag{13}$$

This relation can be split into two identical integrals, and consequently our expression for $I(s)$ can be reduced to

$$I(s)=-\pi i\int_{-\infty}^{\infty}\frac{u}{s+u^2}\frac{\Gamma(\frac{1}{2}-\kappa-iu)}{\Gamma(1-2iu)}W_{\kappa,-iu}(x)M_{\kappa,-iu}(x_0)du. \tag{14}$$

III. CONTOUR INTEGRATION

The fundamental expression for the integral $I(s)$ given by (1) is clearly symmetrical with respect to the interchange of x and x_0. We can use this flexibility to select the arguments of the W and M functions in such a way that the integration along the curved portion of the closed contour C in Fig. 1 vanishes in the limit $r\to\infty$. By employing asymptotic analysis, we find that this occurs if $x_{\max}$ is the argument of the W function and $x_{\min}$ is the argument of the M function, where

$$x_{\min}\equiv\min(x,x_0),\quad x_{\max}\equiv\max(x,x_0). \tag{15}$$

Equation (14) for $I(s)$ can therefore be recast as the complex contour integral

$$I(s)=\oint_C L(u)du, \tag{16}$$

where

$$L(u)\equiv-\pi i\frac{u}{s+u^2}\frac{\Gamma(\frac{1}{2}-\kappa-iu)}{\Gamma(1-2iu)}W_{\kappa,-iu}(x_{\max})M_{\kappa,-iu}(x_{\min}). \tag{17}$$

We shall proceed to obtain an exact, closed form expression for $I(s)$ by utilizing the residue theorem to evaluate the integral in (16).

The integrand $L(u)$ has a simple pole located at $u=i\sqrt{s}$, where $\sqrt{s}$ denotes the principle branch of the square root function. This pole is located in quadrant II of the complex u plane if

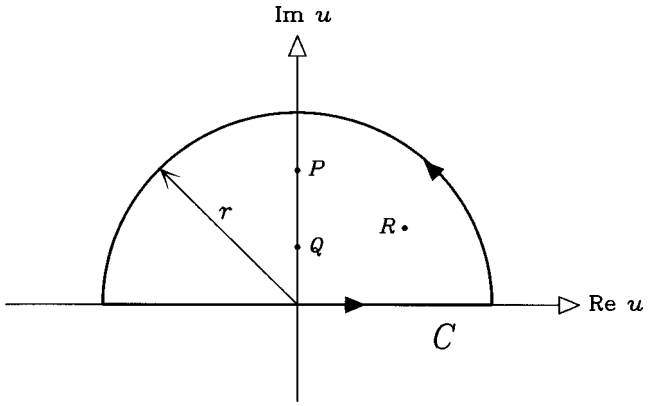

FIG. 1. Integration around the closed contour C yields $I(s)$ in the limit $r\to\infty$ [see Eq. (16)]. In this example, κ is a real number in the range $\frac{3}{2}<\kappa<\frac{5}{2}$, and consequently there are two simple poles (P and Q) located inside the contour on the imaginary axis [see Eq. (18)]. The imaginary part of s is less than zero in this instance, and consequently there is also a simple pole, R, located at $u=i\sqrt{s}$ in quadrant I.

$\mathcal{I}ms\geqslant 0$, and otherwise it is located in quadrant I. In either case, the pole is contained within the closed integration contour C. Additional simple poles are located at the singularities of the function $\Gamma(\frac{1}{2}-\kappa-iu)$, which occur where the quantity $\frac{1}{2}-\kappa-iu$ is equal to zero or a negative integer. At least one of the poles falls in the upper half-plane if $\mathcal{R}e\kappa>\frac{1}{2}$. The poles are located at $u=u_n$, where

$$u_n\equiv i(\kappa-\tfrac{1}{2}-n),\quad n=0,1,...,[\mathcal{R}e\kappa-\tfrac{1}{2}], \tag{18}$$

and $[a]$ indicates the integer part of a. Note that if $\mathcal{R}e\kappa<\frac{1}{2}$, then only the pole at $u=i\sqrt{s}$ is contained within the contour C.

We can now use the residue theorem to write

$$I(s)=2\pi i\sum_{n=0}^{[\mathcal{R}e\kappa-1/2]}\mathrm{Res}(u_n)+2\pi i\,\mathrm{Res}(i\sqrt{s}), \tag{19}$$

where $\mathrm{Res}(u_*)$ denotes the residue associated with the simple pole located at $u=u_*$.

IV. EVALUATION OF THE RESIDUES

The residue corresponding to the simple pole at $u=i\sqrt{s}$ is easily computed using the formula

$$\mathrm{Res}(i\sqrt{s})=\lim_{u\to i\sqrt{s}}(u-i\sqrt{s})L(u), \tag{20}$$

which can be immediately evaluated to obtain

$$\mathrm{Res}(i\sqrt{s})=-\frac{\pi i}{2}\frac{\Gamma(\frac{1}{2}-\kappa+\sqrt{s})}{\Gamma(1+2\sqrt{s})}W_{\kappa,\sqrt{s}}(x_{\max})M_{\kappa,\sqrt{s}}(x_{\min}). \tag{21}$$

Similarly, the residues associated with the simple poles located at $u=u_n$ are evaluated using

$$\mathrm{Res}(u_n)=\lim_{u\to u_n}(u-u_n)L(u). \tag{22}$$

Because the poles in this case correspond to the singularities of the function $\Gamma(\frac{1}{2}-\kappa-iu)$, we will require evaluation of the quantity

$$\lim_{u\to u_n}(u-u_n)\Gamma(\tfrac{1}{2}-\kappa-iu). \tag{23}$$

By combining (4) and (18) with the recurrence relation $z\Gamma(z)=\Gamma(z+1)$, we obtain

$$\Gamma\left(\frac{1}{2}-\kappa-iu\right)=\frac{\Gamma(\frac{1}{2}-\kappa-iu+n)}{(\frac{1}{2}-\kappa-iu)_n}=\frac{i\Gamma(1+iu_n-iu)}{(iu_n-iu-n)_n(u-u_n)}, \tag{24}$$

and therefore

$$\lim_{u\to u_n}(u-u_n)\Gamma\left(\frac{1}{2}-\kappa-iu\right)=\frac{i(-1)^n}{n!}, \tag{25}$$

where we have used the fact that $(-n)_n=(-1)^n n!$ Next we need to evaluate the Whittaker functions appearing on the right-hand side of (17) in the limit $u\to u_n$. Using (2) and (18), we find that

$$\begin{aligned} M_{\kappa,-iu_n}(z)&=e^{-z/2}z^{\kappa-n}\Phi(-n,2\kappa-2n;z),\\ W_{\kappa,-iu_n}(z)&=e^{-z/2}z^{\kappa-n}\Psi(-n,2\kappa-2n;z). \end{aligned} \tag{26}$$

By employing Eqs. (13.6.9) and (13.6.27) from Abramowitz and Stegun,[9] we can rewrite these expressions as

$$\begin{aligned} M_{\kappa,-iu_n}(z)&=\frac{n!}{(\alpha+1)_n}e^{-z/2}z^{(\alpha+1)/2}P_n^{(\alpha)}(z),\\ W_{\kappa,-iu_n}(z)&=(-1)^n n!e^{-z/2}z^{(\alpha+1)/2}P_n^{(\alpha)}(z), \end{aligned} \tag{27}$$

where $P_n^{(\alpha)}(z)$ denotes the Laguerre polynomial, and

$$\alpha\equiv 2\kappa-2n-1=-2iu_n. \tag{28}$$

Combining (17), (22), (25), and (27), we obtain for the residue

$$\mathrm{Res}(u_n)=\frac{2\pi i\alpha}{4s-\alpha^2}\frac{n!}{\Gamma(\alpha+n+1)}e^{-(x+x_0)/2}(xx_0)^{(\alpha+1)/2}P_n^{(\alpha)}(x)P_n^{(\alpha)}(x_0). \tag{29}$$

Utilizing this result along with (19) and (21), we conclude that

$$\begin{aligned} I(s)&=\int_0^\infty \frac{u\sinh(2\pi u)\Gamma(\frac{1}{2}-\kappa-iu)\Gamma(\frac{1}{2}-\kappa+iu)}{s+u^2}W_{\kappa,iu}(x)W_{\kappa,iu}(x_0)du\\ &=\pi^2\frac{\Gamma(\frac{1}{2}-\kappa+\sqrt{s})}{\Gamma(1+2\sqrt{s})}W_{\kappa,\sqrt{s}}(x_{\max})M_{\kappa,\sqrt{s}}(x_{\min})\\ &\quad-4\pi^2e^{-(x+x_0)/2}\sum_{n=0}^{[\mathcal{R}e\,\kappa-1/2]}\frac{\alpha n!}{\Gamma(\alpha+n+1)}\frac{(xx_0)^{(\alpha+1)/2}}{4s-\alpha^2}P_n^{(\alpha)}(x)P_n^{(\alpha)}(x_0), \end{aligned} \tag{30}$$

where $\alpha=2\kappa-2n-1$. This previously unknown integral formula is one of the main results of the article. Note that the summation is carried out only if $\mathcal{R}e\,\kappa\geqslant\frac{1}{2}$. The integral on the left-hand side

of (30) converges for all complex values of s with the exception of the negative real semiaxis, provided that $\mathcal{R}e\,\kappa \neq 1/2,3/2,5/2,...$, if $\mathcal{I}m\,\kappa \neq 0$. When $s=0$, the integral converges provided $\mathcal{R}e\,\kappa$ is not a positive half-integer.

A case of special interest can be generated by setting $x_0 = x$ in (30). The result obtained is the *quadratic normalization integral*,

$$\int_0^\infty \frac{u \sinh(2\pi u)\Gamma(\frac{1}{2}-\kappa-iu)\Gamma(\frac{1}{2}-\kappa+iu)}{s+u^2} W^2_{\kappa,iu}(x)\,du$$
$$= \pi^2 \frac{\Gamma(\frac{1}{2}-\kappa+\sqrt{s})}{\Gamma(1+2\sqrt{s})} W_{\kappa,\sqrt{s}}(x) M_{\kappa,\sqrt{s}}(x) - 4\pi^2 e^{-x} \sum_{n=0}^{[\mathcal{R}e\,\kappa - 1/2]} \frac{\alpha n!}{\Gamma(\alpha+n+1)} \frac{x^{\alpha+1}}{4s-\alpha^2} [P_n^{(\alpha)}(x)]^2, \tag{31}$$

which is useful in situations involving the development of a series expansion in terms of a set of normalized basis functions. In the following sections, we shall proceed to discuss the limiting behavior of (30) observed when two of the poles coincide, as well as its relation to formulas appearing in the previous literature.

V. LIMITING BEHAVIOR

An interesting situation arises if the quantity $\frac{1}{2}-\kappa+\sqrt{s}$ is equal to zero or a negative integer, because in this case the integral $I(s)$ converges, although the first term on the right-hand side of (30) formally *diverges* due to the appearance of the factor $\Gamma(\frac{1}{2}-\kappa+\sqrt{s})$. This occurs when

$$\sqrt{s} = \sqrt{s_m} \equiv \kappa - \tfrac{1}{2} - m, \tag{32}$$

where m is a positive integer or zero. Since $\sqrt{s}$ denotes the principle branch of the square root function, it follows that $\sqrt{s}$ is located in either quadrants I or IV of the complex s plane, depending on whether $\mathcal{I}m\,s$ is positive or negative. Hence $\mathcal{R}e\,\sqrt{s} \geqslant 0$ in general, and therefore the function $\Gamma(1/2-\kappa+\sqrt{s})$ has no singularities unless $\mathcal{R}e\,\kappa \geqslant \frac{1}{2}$. The values of m yielding singularities for a given value of κ are

$$m = 0,1,...,[\mathcal{R}e\,\kappa - \tfrac{1}{2}]. \tag{33}$$

When $s = s_m$, the divergence of the first term on the right-hand side of (30), containing the factor $\Gamma(\frac{1}{2}-\kappa+\sqrt{s})$, is exactly balanced by the divergence of the $n=m$ term in the sum, leaving a finite residual quantity. This situation corresponds to a coincidence of the pole located at $u = i\sqrt{s}$ with the pole located at $u = u_m = i(\kappa - \frac{1}{2} - m)$ [see Eq. (18)]. In this case the resulting pole has order two. The associated residue can be computed by using the standard formula for a second-order pole, but it is more efficient to approach the calculation by evaluating Eq. (30) for $I(s)$ in the limit $s \to s_m$. The limiting value of the sum of the two divergent terms is given by

$$K \equiv \lim_{s \to s_m} \pi^2 \frac{\Gamma(\frac{1}{2}-\kappa+\sqrt{s})}{\Gamma(1+2\sqrt{s})} W_{\kappa,\sqrt{s}}(x_{\max}) M_{\kappa,\sqrt{s}}(x_{\min})$$
$$- 4\pi^2 e^{-(x+x_0)/2} \frac{\lambda m!}{\Gamma(\lambda+m+1)} \frac{(x x_0)^{(\lambda+1)/2}}{4s-\lambda^2} P_m^{(\lambda)}(x) P_m^{(\lambda)}(x_0), \tag{34}$$

where

$$\lambda \equiv 2\kappa - 2m - 1 = 2\sqrt{s_m}. \tag{35}$$

Equation (34) can be rewritten as

$$K=\lim_{s\to s_m}\frac{N}{D}, \tag{36}$$

where

$$N\equiv\pi^2(s-s_m)\frac{\Gamma(\frac{1}{2}-\kappa+\sqrt{s})}{\Gamma(1+2\sqrt{s})}W_{\kappa,\sqrt{s}}(x_{\max})M_{\kappa,\sqrt{s}}(x_{\min})$$
$$-\pi^2e^{-(x+x_0)/2}\frac{\lambda m!}{\Gamma(\lambda+m+1)}(xx_0)^{(\lambda+1)/2}P_m^{(\lambda)}(x)P_m^{(\lambda)}(x_0), \tag{37}$$

and

$$D\equiv s-s_m. \tag{38}$$

We can demonstrate that the numerator N vanishes in the limit $s\to s_m$ as follows. First we use (4) and (32) along with the recurrence relation for the gamma function to write

$$\Gamma\left(\frac{1}{2}-\kappa+\sqrt{s}\right)=\frac{\Gamma(\frac{1}{2}-\kappa+\sqrt{s}+m)}{(\frac{1}{2}-\kappa+\sqrt{s})_m}=\frac{(\sqrt{s}+\sqrt{s_m})\Gamma(1+\sqrt{s}-\sqrt{s_m})}{(s-s_m)(\sqrt{s}-\sqrt{s_m}-m)_m}, \tag{39}$$

and therefore [cf. Eq. (25)]

$$\lim_{s\to s_m}(s-s_m)\Gamma\left(\frac{1}{2}-\kappa+\sqrt{s}\right)=\frac{(-1)^m}{m!}2\sqrt{s_m}. \tag{40}$$

Furthermore, based on (27), (28), and (35), we note that

$$M_{\kappa,\sqrt{s_m}}(z)=\frac{m!}{(\lambda+1)_m}e^{-z/2}z^{(\lambda+1)/2}P_m^{(\lambda)}(z),$$
$$W_{\kappa,\sqrt{s_m}}(z)=m!(-1)^me^{-z/2}z^{(\lambda+1)/2}P_m^{(\lambda)}(z). \tag{41}$$

Taken together, (37), (40), and (41) indicate that the numerator N vanishes in the limit $s\to s_m$. The denominator D also vanishes in this limit, and therefore we can employ L'Hôpital's rule to evaluate K by writing

$$K=\lim_{s\to s_m}\frac{\partial N}{\partial s}\Big/\lim_{s\to s_m}\frac{\partial D}{\partial s}. \tag{42}$$

Since $\partial D/\partial s=1$ and the second term on the right-hand side of (37) is independent of s, we obtain

$$K=\lim_{s\to s_m}\frac{\partial}{\partial s}\pi^2(s-s_m)\frac{\Gamma(\frac{1}{2}-\kappa+\sqrt{s})}{\Gamma(1+2\sqrt{s})}W_{\kappa,\sqrt{s}}(x_{\max})M_{\kappa,\sqrt{s}}(x_{\min}). \tag{43}$$

Upon differentiation, we obtain after a fairly lengthy calculation

$$K=\frac{\pi^2e^{-(x+x_0)/2}(xx_0)^{(\lambda+1)/2}m!P_m^{(\lambda)}(x)P_m^{(\lambda)}(x_0)}{\Gamma(\lambda+m+1)}\left[-\gamma_E+\frac{1}{\lambda}+H-2\psi(\lambda+1)-\frac{1}{m+1}+\sum_{n=1}^{m+1}\frac{1}{n}\right], \tag{44}$$

where $\gamma_E\approx-0.577$ is Euler's constant, $\lambda=2\kappa-2m-1$,

$$H \equiv \frac{\partial}{\partial \beta} \ln[\, W_{\kappa,\beta}(x_{\max}) M_{\kappa,\beta}(x_{\min})\,] \Big|_{\beta=\sqrt{s_m}}, \tag{45}$$

and

$$\psi(z) \equiv \frac{d}{dz} \ln \Gamma(z). \tag{46}$$

Combining results, we find that in the special case $s = s_m = (\kappa - m - \frac{1}{2})^2$ the integral $I(s)$ is given by

$$\begin{aligned} I(s) &= \int_0^\infty \frac{u \sinh(2\pi u)\Gamma(\frac{1}{2}-\kappa-iu)\Gamma(\frac{1}{2}-\kappa+iu)}{(\kappa-m-1/2)^2+u^2} W_{\kappa,iu}(x) W_{\kappa,iu}(x_0)\, du \\ &= K - 4\pi^2 e^{-(x+x_0)/2} \sum_{\substack{n=0 \\ n\neq m}}^{[\mathcal{R}e\,\kappa - 1/2]} \frac{\alpha n!}{\Gamma(\alpha+n+1)} \frac{(x x_0)^{(\alpha+1)/2}}{4s-\alpha^2} P_n^{(\alpha)}(x) P_n^{(\alpha)}(x_0), \end{aligned} \tag{47}$$

where $\alpha = 2\kappa - 2n - 1$. The allowed range of values for m is given by (33), which indicates that we must have $\mathcal{R}e\,\kappa \geqslant \frac{1}{2}$ in order for any of these special cases to occur. Note that the singular term with $n = m$ is not included in the sum, since that term is contained within K. Equations (30) and (47) cover all of the convergent cases of the fundamental integral $I(s)$. In Sec. VI we present simplified results obtained for certain values of the parameters.

VI. SPECIAL CASES

The general nature of the expression for $I(s)$ given by (30) encompasses many interesting special cases involving particular values for the parameters κ, s, x, and x_0. In this section, we shall briefly discuss a few illustrative examples obtained when the first index κ is equal to an integer, in which case the general solution for $I(s)$ simplifies considerably. For brevity, we shall focus here on situations with $s \neq s_m$. However, we emphasize that formulas similar to those discussed below that are applicable to the case $s = s_m$ can also be obtained in a straightforward manner by starting with (47) rather than (30).

A. $\kappa = 0$

When $\kappa = 0$, the summation in (30) is not performed at all. Making use of the identities[9]

$$\Gamma\left(\frac{1}{2} - iu\right)\Gamma\left(\frac{1}{2} + iu\right) = \frac{\pi}{\cosh(\pi u)} \tag{48}$$

and

$$\sinh(2\pi u) = 2 \sinh(\pi u)\cosh(\pi u), \tag{49}$$

we find that (30) reduces to

$$\int_0^\infty \frac{u \sinh(\pi u)}{s+u^2} W_{0,iu}(x) W_{0,iu}(x_0)\, du = \frac{\pi}{2} \frac{\Gamma(1/2+\sqrt{s})}{\Gamma(1+2\sqrt{s})} W_{0,\sqrt{s}}(x_{\max}) M_{0,\sqrt{s}}(x_{\min}). \tag{50}$$

This result is convergent for all complex values of s, excluding the negative real semiaxis. Hence the point $s = 0$ is convergent in this case.

B. $\kappa=1$

When $\kappa=1$, there is one simple pole located at $s_0=\frac{1}{4}$, and we can make use of the identity

$$\Gamma\left(-\frac{1}{2}-iu\right)\Gamma\left(-\frac{1}{2}+iu\right)=\frac{4\pi}{\cosh(\pi u)(1+4u^2)}, \tag{51}$$

along with (49) to reduce (30) to the form

$$\int_0^\infty \frac{u\sinh(\pi u)}{(1+4u^2)(s+u^2)}W_{1,iu}(x)W_{1,iu}(x_0)du=\frac{\pi}{8}\frac{\Gamma(\sqrt{s}-\frac{1}{2})}{\Gamma(1+2\sqrt{s})}W_{1,\sqrt{s}}(x_{\max})M_{1,\sqrt{s}}(x_{\min}) - \frac{\pi}{2}\frac{xx_0e^{-(x+x_0)/2}}{4s-1}. \tag{52}$$

The right-hand side converges for all complex values of s with the exception of the point $s=\frac{1}{4}$ [which must be treated using (47)] and the negative real semiaxis. The point $s=0$ is convergent.

C. $\kappa=2$

In this case there are two simple poles, located at $s_0=\frac{9}{4}$ and $s_1=\frac{1}{4}$. Utilizing the identity

$$\Gamma\left(-\frac{3}{2}-iu\right)\Gamma\left(-\frac{3}{2}+iu\right)=\frac{16\pi}{\cosh(\pi u)(9+4u^2)(1+4u^2)}, \tag{53}$$

along with (49), we can simplify (30) to obtain

$$\int_0^\infty \frac{u\sinh(\pi u)}{(9+4u^2)(1+4u^2)(s+u^2)}W_{2,iu}(x)W_{2,iu}(x_0)du = \frac{\pi}{32}\frac{\Gamma(\sqrt{s}-\frac{3}{2})}{\Gamma(1+2\sqrt{s})}W_{2,\sqrt{s}}(x_{\max})M_{2,\sqrt{s}}(x_{\min})-\frac{\pi}{8}e^{-(x+x_0)/2} \times\sum_{n=0}^{1}\frac{(3-2n)n!}{\Gamma(4-n)}\frac{(xx_0)^{2-n}}{4s-(3-2n)^2}P_n^{(3-2n)}(x)P_n^{(3-2n)}(x_0). \tag{54}$$

Evaluation of the Laguerre polynomials yields

$$\int_0^\infty \frac{u\sinh(\pi u)}{(9+4u^2)(1+4u^2)(s+u^2)}W_{2,iu}(x)W_{2,iu}(x_0)du = \frac{\pi}{32}\frac{\Gamma(\sqrt{s}-\frac{3}{2})}{\Gamma(1+2\sqrt{s})}W_{2,\sqrt{s}}(x_{\max})M_{2,\sqrt{s}}(x_{\min})-\frac{\pi}{16}xx_0e^{-(x+x_0)/2}\left[\frac{xx_0}{4s-9}+\frac{(2-x)(2-x_0)}{4s-1}\right], \tag{55}$$

which is convergent for all complex values of s, excluding the negative real semiaxis and the points $s=\frac{1}{4}$, $s=\frac{9}{4}$. These two points must be treated using (47). Note that the point $s=0$ is convergent in this case. Similar results can be obtained for any positive or negative integer value of κ. The integral formula given by (55) is of particular significance in treating the scattering of radiation in an ionized plasma with a constant temperature, as discussed in Sec. VII.

VII. APPLICATION TO THERMAL COMPTONIZATION

One of the most important physical applications of the results developed in this article involves the repeated Compton scattering of photons by a hot Maxwellian distribution of electrons with temperature T_e and number density n_e in an ionized plasma. This process, referred to as "thermal Comptonization," is the primary mechanism responsible for the production of the radiation spectra observed from celestial x-ray sources such as active galaxies, black holes, and neutron

stars.[2] When the electron temperature T_e is constant, the Green's function, $f_{\rm G}$, describing the temporal evolution of an initially monoenergetic radiation distribution satisfies the Kompaneets partial differential equation[1]

$$\frac{\partial f_{\rm G}}{\partial y}=\frac{1}{x^2}\frac{\partial}{\partial x}\left[x^4\left(f_{\rm G}+\frac{\partial f_{\rm G}}{\partial x}\right)\right], \tag{56}$$

where the dimensionless photon energy and the dimensionless time are denoted by

$$x(\epsilon)\equiv\frac{\epsilon}{kT_e},\quad y(t)\equiv n_e\sigma_{\rm T}c\,\frac{kT_e}{m_ec^2}(t-t_0), \tag{57}$$

respectively, and the quantities ϵ, t_0, t, $\sigma_{\rm T}$, m_e, c, and k represent the photon energy, the initial time, the current time, the Thomson cross section, the electron mass, the speed of light, and Boltzmann's constant, respectively. The terms proportional to $f_{\rm G}$ and $\partial f_{\rm G}/\partial x$ inside the parentheses on the right-hand side of (56) express in turn the effects of electron recoil and stochastic (second-order Fermi) photon energization. At the initial time $t=t_0$, the radiation distribution is monoenergetic, and the Green's function satisfies the initial condition

$$f_{\rm G}(x,x_0,y)\big|_{y=0}=x_0^{-2}\delta(x-x_0), \tag{58}$$

where the dimensionless initial energy is given by

$$x_0\equiv\frac{\epsilon_0}{kT_e}. \tag{59}$$

By operating on (56) with $\int_0^\infty x^2\,dx$, we can establish that $f_{\rm G}$ has the convenient normalization

$$\int_0^\infty x^2 f_{\rm G}(x,x_0,y)\,dx=\text{const}=1, \tag{60}$$

where the final result follows from the initial condition [Eq. (58)]. Note that this normalization is maintained for all values of y, which reflects the fact that Compton scattering conserves photons. It can be shown based on (56) that the Laplace transform of the Green's function,

$$F(x,x_0,s)\equiv\int_0^\infty e^{-sy}f_{\rm G}(x,x_0,y)\,dy, \tag{61}$$

is given by[3]

$$F(x,x_0,s)=x_0^{-2}x^{-2}e^{(x_0-x)/2}\frac{\Gamma(\mu-\frac{3}{2})}{\Gamma(1+2\mu)}M_{2,\mu}(x_{\rm min})W_{2,\mu}(x_{\rm max}), \tag{62}$$

where the quantity μ is a function of the transform variable s, defined by

$$\mu(s)\equiv(s+\tfrac{9}{4})^{1/2} \tag{63}$$

and

$$x_{\rm min}\equiv\min(x,x_0),\quad x_{\rm max}\equiv\max(x,x_0). \tag{64}$$

The solution for the Green's function is obtained by performing the inverse Laplace transformation using the Mellin integral,

$$f_G(x,x_0,y)=\frac{1}{2\pi i}\int_{\gamma-i\infty}^{\gamma+i\infty}e^{sy}F(x,x_0,s)ds, \tag{65}$$

where the real constant γ is chosen so that the line $\mathcal{R}es=\gamma$ lies to the right of the singularities in the integrand. By transforming the variable of integration from s to

$$s'\equiv s+\tfrac{9}{4}, \tag{66}$$

we can obtain the equivalent expression

$$f_G(x,x_0,y)=\frac{e^{-9y/4}}{2\pi i}\int_{\gamma-i\infty}^{\gamma+i\infty}e^{s'y}\tilde{F}(x,x_0,s')ds', \tag{67}$$

where

$$\tilde{F}(x,x_0,s')\equiv x_0^{-2}x^{-2}e^{(x_0-x)/2}\frac{\Gamma(\sqrt{s'}-\frac{3}{2})}{\Gamma(1+2\sqrt{s'})}M_{2,\sqrt{s'}}(x_{\min})W_{2,\sqrt{s'}}(x_{\max}). \tag{68}$$

The exact solution for the Green's function $f_G(x,x_0,y)$ can be obtained by taking the inverse Laplace transformation of (55), which yields

$$\begin{aligned}&\frac{1}{2\pi i}\int_{\gamma-i\infty}^{\gamma+i\infty}e^{sy}\frac{\Gamma(\sqrt{s}-\frac{3}{2})}{\Gamma(1+2\sqrt{s})}W_{2,\sqrt{s}}(x_{\max})M_{2,\sqrt{s}}(x_{\min})ds\\&\quad=\frac{32}{\pi}\int_0^\infty\frac{u\sinh(\pi u)}{(9+4u^2)(1+4u^2)}W_{2,iu}(x)W_{2,iu}(x_0)\frac{1}{2\pi i}\int_{\gamma-i\infty}^{\gamma+i\infty}\frac{e^{sy}}{s+u^2}ds\,du\\&\qquad+\frac{xx_0}{2}e^{-(x+x_0)/2}\frac{1}{2\pi i}\int_{\gamma-i\infty}^{\gamma+i\infty}e^{sy}\left[\frac{xx_0}{s-9/4}+\frac{(2-x)(2-x_0)}{s-1/4}\right]ds,\end{aligned} \tag{69}$$

where we have interchanged the order of integration in the double integral. The inverse Laplace transformations on the right-hand side of (69) are elementary in nature and can be evaluated using the formula

$$\frac{1}{2\pi i}\int_{\gamma-i\infty}^{\gamma+i\infty}\frac{e^{sy}}{s+k}ds=e^{-ky}. \tag{70}$$

By utilizing this result in (69), we obtain

$$\begin{aligned}&\frac{1}{2\pi i}\int_{\gamma-i\infty}^{\gamma+i\infty}e^{sy}\frac{\Gamma(\sqrt{s}-\frac{3}{2})}{\Gamma(1+2\sqrt{s})}W_{2,\sqrt{s}}(x_{\max})M_{2,\sqrt{s}}(x_{\min})ds\\&\quad=\frac{32}{\pi}\int_0^\infty e^{-u^2y}\frac{u\sinh(\pi u)}{(9+4u^2)(1+4u^2)}W_{2,iu}(x)W_{2,iu}(x_0)du\\&\qquad+\frac{xx_0}{2}e^{-(x+x_0)/2}[xx_0e^{9y/4}+(2-x)(2-x_0)e^{y/4}].\end{aligned} \tag{71}$$

We can now combine (67), (68), and (71) to show that the exact solution for the time-dependent Green's function is given by[3]

$$f_G(x,x_0,y)=\frac{32}{\pi}e^{-9y/4}x_0^{-2}x^{-2}e^{(x_0-x)/2}\int_0^\infty e^{-u^2y}\frac{u\sinh(\pi u)}{(1+4u^2)(9+4u^2)}W_{2,iu}(x_0)W_{2,iu}(x)du+\frac{e^{-x}}{2}$$
$$+\frac{e^{-x-2y}}{2}\frac{(2-x)(2-x_0)}{x_0x}. \tag{72}$$

Since the fundamental partial differential equation (56) is linear, the particular solution for the radiation distribution corresponding to an *arbitrary* initial spectrum can be found via convolution using the Green's function. The result given by (72) is therefore of central importance in the field of theoretical x-ray astronomy.

VIII. CONCLUSION

In this article, we have developed several new formulas for the evaluation of a family of integrals containing the product of two Whittaker $W_{\kappa,\mu}(x)$-functions, when the integration occurs with respect to the second index μ, and that index is imaginary. The fundamental integral we have focused on is

$$I(s)\equiv\int_0^\infty\frac{u\sinh(2\pi u)\Gamma(\frac{1}{2}-\kappa-iu)\Gamma(\frac{1}{2}-\kappa+iu)}{s+u^2}W_{\kappa,iu}(x)W_{\kappa,iu}(x_0)du. \tag{73}$$

This is related to the Whittaker function index transformation discussed in Refs. 10 and 11. An expression of particular interest is the quadratic normalization integral given by (31). The results presented in (30) and (47) for $I(s)$ allow the exact evaluation of all of the convergent cases of this integral without the need to resort to numerical integration. We also point out that by utilizing Eqs. (2), one can easily obtain a set of analogous integration formulas applicable to the Kummer functions $\Phi(a,b,z)$ and $\Psi(a,b,z)$. While integrals of this precise type have not been considered before, it is worth noting that $I(s)$ is a member of a wider group of integrals containing the product of two Whittaker *W*-functions. In general, the other integrals in this group involve integration with respect to one of the other parameters, rather than the second index as we have considered here. We briefly review a few of these related integrals below.

Several formulas are available in the previous literature for evaluating the integral of the product of two Whittaker $W_{\kappa,\mu}(x)$-functions with respect to the primary argument *x*. For example, based upon Eq. (9.12) from Buchholz[12] or Eq. (20.3.40) from Erdélyi *et al.*[13] or Eq. (7.611.3) from Gradshteyn and Ryzhik,[8] we have

$$\int_0^\infty W_{\kappa,\mu}(x)W_{\sigma,\mu}(x)\frac{dx}{x}=\frac{1}{\kappa-\sigma}\frac{\pi}{\sin(2\pi\mu)}\left[\frac{1}{\Gamma(\frac{1}{2}-\kappa+\mu)\Gamma(\frac{1}{2}-\sigma-\mu)}\right.$$
$$\left.-\frac{1}{\Gamma(\frac{1}{2}-\kappa-\mu)\Gamma(\frac{1}{2}-\sigma+\mu)}\right], \tag{74}$$

which is valid provided $|\mathcal{R}e\,\mu|<\frac{1}{2}$. We note that the formulas in Refs. 8 and 13 are missing a factor of π, and the formula in Ref. 12 contains two incorrect signs. Another closely related example is given by Eq. (7.611.6) from Gradshteyn and Ryzhik[8] or Eq. (20.3.41) from Ref. 13,

$$\int_0^\infty x^{\sigma-1}W_{\kappa,\mu}(x)W_{-\kappa,\mu}(x)dx=\frac{\Gamma(\sigma+1)\Gamma(\sigma/2+\frac{1}{2}+\mu)\Gamma(\sigma/2+\frac{1}{2}-\mu)}{2\Gamma(\sigma/2+1+\kappa)\Gamma(\sigma/2+1-\kappa)}, \tag{75}$$

which is valid provided $\mathcal{R}e\,\sigma>2|\mathcal{R}e\,\mu|-1$.

A few formulas that treat the integration of a product of two Whittaker $W_{\kappa,\mu}(x)$-functions with respect to the first index κ have also been known for some time. The most general expression is Eq. (15.10b) from Buchholz,[12] which can be written as

$$\int_0^\infty \Gamma(k-iu)\Gamma(k+iu)W_{iu,k-1/2}(x)W_{-iu,k-1/2}(x_0)du$$

$$=\sqrt{\pi}\Gamma(2k)(xx_0)^k(x+x_0)^{-2k+1/2}K_{2k-1/2}\left(\frac{x+x_0}{2}\right), \tag{76}$$

where $K_{2k-1/2}(z)$ denotes the modified Bessel function. When $k=\frac{1}{2}$, this formula reduces to Eq. (7.691) from Ref. 8, which states that

$$\int_0^\infty \mathrm{sech}(\pi u)W_{iu,0}(x)W_{-iu,0}(x_0)du=\frac{\sqrt{xx_0}}{x+x_0}e^{-(x+x_0)/2}. \tag{77}$$

The new results for $I(s)$ obtained in this article [Eqs. (30) and (47)] are in some sense complementary to these previously known formulas. We emphasize that the expressions developed here are of significance in a variety of applications, including the problem of the Comptonization of radiation in an isothermal plasma, discussed in Sec. VII. Our general approach may also allow the determination of the Green's function solution for the one-dimensional Schrödinger equation with the Morse potential.[14] We plan to pursue this question in future work.

The author would like to gratefully acknowledge the insightful comments provided by the anonymous referee, which led to simplifications in the main derivation and also helped to broaden the applicability of the results.

(Received 10 February 2003; accepted 30 October 2003)

Given a complete noncompact surface Σ embedded in $\mathbb{R}^3$, we consider the Dirichlet Laplacian in the layer Ω that is defined as a tubular neighborhood of constant width about Σ. Using an intrinsic approach to the geometry of Ω, we generalize the spectral results of the original paper by Duclos *et al.* [Commun. Math. Phys. **223**, 13 (2001)] to the situation when Σ does not possess poles. This enables us to consider topologically more complicated layers and state new spectral results. In particular, we are interested in layers built over surfaces with handles or several cylindrically symmetric ends. We also discuss more general regions obtained by compact deformations of certain Ω. © *2004 American Institute of Physics.*

I. INTRODUCTION

The spectral properties of the Dirichlet Laplacian in infinitely stretched regions have attracted a lot of attention since the existence of geometrically induced discrete spectrum for certain strips in the plane was proved in Ref. 1. The study was motivated by mesoscopic physics where a reasonable model for the dynamics of a particle in quantum waveguides is given by the Laplacian in hard-wall tubular neighborhoods of infinite curves in $\mathbb{R}^d$, $d=2,3$ (quantum strips, tubes), or surfaces in $\mathbb{R}^3$ (quantum layers); see Refs. 2 and 3 for the physical background and references. Nowadays, it is well known that any nontrivial curvature of the reference curve, that is asymptotically straight, produces bound states below the essential spectrum in the strips and tubes.[2,4,5]

The analogous problem in curved layers is much more complicated and it was investigated quite recently in Refs. 6–8. Let Σ be a complete noncompact surface embedded in $\mathbb{R}^3$, Ω be a tube of radius $a>0$ about Σ, i.e. (see Fig. 1),

$$\Omega := \{z \in \mathbb{R}^3 \mid \text{distance}\,(z,\Sigma) < a\}, \tag{1}$$

and $-\Delta_D^{\Omega}$ denote the Dirichlet Laplacian in $L^2(\Omega)$. If the surface is a locally deformed plane, the existence of bound states below the essential spectrum of the Laplacian was demonstrated in Ref. 7. A more general situation was treated in Ref. 6; assuming that Σ is nontrivially curved, it has asymptotically vanishing curvatures and possesses a pole, several sufficient conditions are found

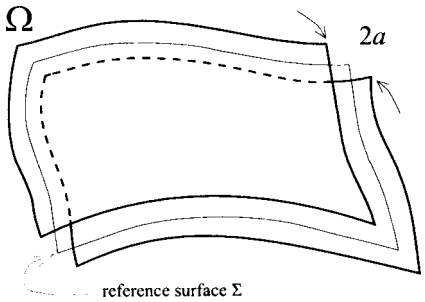

FIG. 1. The configuration space Ω defined by (1) as the space delimited by two parallel surfaces at the distance a from Σ.

which guarantee the existence of discrete spectrum. Finally, let us mention that an asymptotic expansion of the ground-state eigenvalue in layers built over mildly curved planes was found in Ref. 8.

While Ref. 6 covers a wide class of layers, the technical requirement about the existence of a pole on Σ (i.e., the exponential map is a diffeomorphism) restricted substantially the topological structure of the reference surface. In particular, Σ was necessarily diffeomorphic to $\mathbb{R}^2$ and as such it was simply connected. The main goal of this paper is to extend the sufficient conditions established in Ref. 6 without assuming the existence of poles on Σ and without making any other (unnatural) topological and geometrical assumptions. In addition to this substantial generalization, we will derive particularly interesting spectral results for quantum layers built over surfaces with handles or several cylindrically symmetric ends (see Figs. 2–4).

Let us recall the reason why the existence of a pole on Σ was required in Ref. 6. According to the usual strategy used in the spectral theory of quantum waveguides, one expresses the Laplacian $-\Delta_D^\Omega$ in the pair of coordinates (x,u), where x parametrizes the reference surface Σ and $u \in (-a,a)$ its normal bundle. Assuming the existence of a pole, Σ could be parametrized globally by means of geodesic polar coordinates, which were well suited for the construction of explicit mollifiers on Σ needed to regularize generalized trial functions establishing the existence of bound states below the essential spectrum.

There are several possibilities how to treat surfaces without poles. Since the above-mentioned regularization is needed out of a compact part of Σ only, one way is to replace the polar coordinates by geodesic coordinates based on a curve enclosing the interior part. This approach is well suited for surfaces of one end (see the definition below), however, it has to be modified in more general situations. In this paper, we introduce a different strategy which does not require any special choice of coordinates on Σ. We employ substantially a consequence of Ref. 9 that if the Gauss curvature is integrable then there always exists a sequence of functions on Σ having the properties of the mollifiers mentioned earlier.

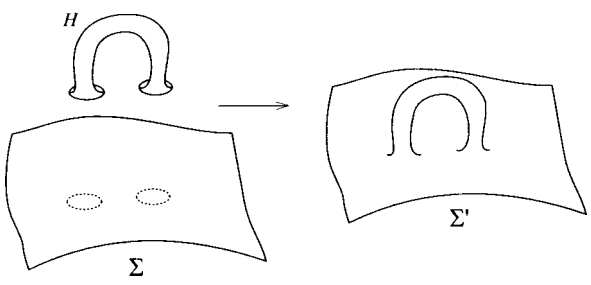

FIG. 2. Surface with a handle Σ' is constructed from Σ by attaching smoothly to it a curved cylindrical surface H. By virtue of Corollary 1, one handle is sufficient to achieve the condition (a) of Theorem 1.

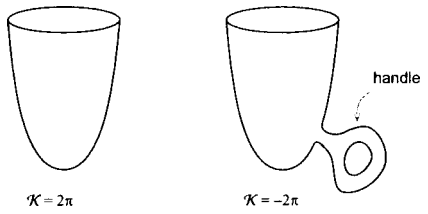

FIG. 3. Elliptic paraboloid (without or with one handle attached, respectively) of Example 1.

II. STATEMENT OF RESULTS

To state here the main results we need to introduce some notation and basic assumptions. Let κ_1^2 denote the spectral threshold of the planar layer of width $2a$, i.e., $\kappa_1 := \pi/(2a)$. The induced metric on Σ and the corresponding covariant derivative will be denoted by g and ∇_g, respectively. Let K, M, and $k_\pm$ denote, respectively, the Gauss curvature, the mean curvature, and the principal curvatures of Σ. Denoting by $\mathrm{d}\Sigma$ the surface area-element, we may define the total Gauss curvature $\mathcal{K}$ and the total mean curvature $\mathcal{M}$, respectively, by the integrals

$$\mathcal{K} := \int_\Sigma K \, \mathrm{d}\Sigma, \quad \mathcal{M}^2 := \int_\Sigma M^2 \, \mathrm{d}\Sigma. \tag{2}$$

The latter always exists (it may be $+\infty$), while the former is well defined provided

$$\langle \mathrm{H1} \rangle \quad K \in L^1(\Sigma),$$

which will be a characteristic assumption of this work. Henceforth, we shall also assume that $k_\pm$ are bounded and

$$\langle \mathrm{H2} \rangle \quad a < \rho_m := (\max\{\|k_+\|_\infty, \|k_-\|_\infty\})^{-1} \quad \text{and } \Omega \text{ does not overlap,}$$

which we need in order to ensure that the layer Ω is a submanifold of $\mathbb{R}^3$. An open set $E \subseteq \Sigma$ is called an *end* of Σ if it is connected, unbounded and if its boundary ∂E is compact (see Fig. 4); its total curvatures are defined by means of (2) with the domain of integration being the subset E only. We say that a manifold embedded in $\mathbb{R}^3$ is cylindrically symmetric if it is invariant under rotations about a fixed axis in $\mathbb{R}^3$. Our main result reads as follows.

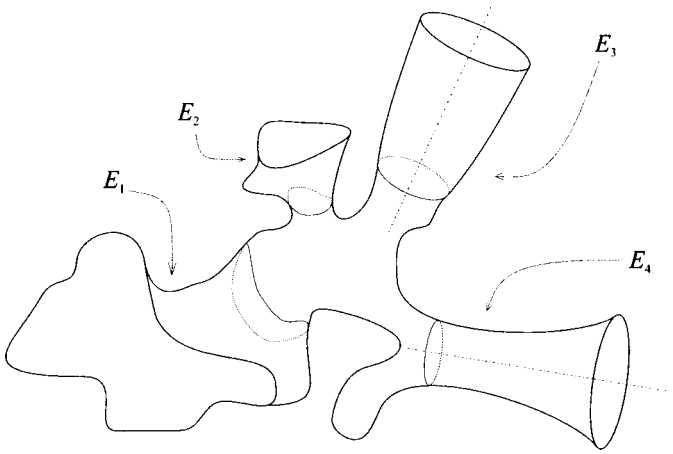

FIG. 4. Surface with four ends $(E_1, \ldots, E_4)$. By virtue of Theorem 2, each cylindrically symmetric end (E_3, E_4) with a positive total Gauss curvature and curvatures vanishing at infinity produces at least one discrete eigenvalue.

Theorem 1: *Let Σ be a complete noncompact connected surface of class C^2 embedded in $\mathbb{R}^3$ and satisfying $\langle$H1$\rangle$. Let the layer Ω defined by (1) as the tube of radius $a>0$ about Σ satisfy $\langle$H2$\rangle$.*

(i) If the curvatures K and M vanish at infinity of Σ, then

$$\inf \sigma_{\mathrm{ess}}(-\Delta_D^{\Omega}) = \kappa_1^2 .$$

(ii) If the surface Σ is not a plane, then any of the conditions

(a) $\mathcal{K} \leqslant 0$,
(b) *a is small enough and* $\nabla_g M \in L^2_{\mathrm{loc}}(\Sigma)$,
(c) $\mathcal{M} = +\infty$ *and* $\nabla_g M \in L^2(\Sigma)$,
(d) *Σ contains a cylindrically symmetric end with a positive total Gauss curvature*

is sufficient to guarantee that

$$\inf \sigma(-\Delta_D^{\Omega}) < \kappa_1^2 .$$

Consequently, if the surface Σ is not a plane but its curvatures vanish at infinity, then any of the conditions (a)–(d) is sufficient to guarantee that $-\Delta_D^{\Omega}$ has at least one eigenvalue of finite multiplicity below the threshold of its essential spectrum, i.e., $\sigma_{\mathrm{disc}}(-\Delta_D^{\Omega}) \neq \varnothing$.

Let us compare this theorem with the results obtained in Ref. 6. An improvement concerns the essential spectrum. While only a lower bound on the threshold was found in Ref. 6, here we shall use known results about the spectral threshold of complete surfaces in order to show that the essential spectrum starts just at κ_1^2. Conditions (a)–(d) are adopted from Ref. 6, however, we do not assume that Σ is of class C^3 in (b) and (c) of Theorem 1, which was required in Ref. 6 in order to give a meaning to $\nabla_g M$. Indeed, only the integrability conditions on the gradient are needed.

The most significant generalization concerning all the results is that we have gotten rid of the strong assumption about the existence of a pole on Σ. Actually, Theorem 1 involves quantum layers built over general surfaces without any additional hypotheses about the existence of a special global parametrization, the number of ends, and other topological and geometrical restrictions.

An interesting new spectral result then follows from the observation that making the topology of Σ more complicated than that of the plane, one always achieves that the basic condition (a) is satisfied.

Corollary 1: Under the assumptions of Theorem 1, one has $\inf \sigma(-\Delta_D^{\Omega}) < \kappa_1^2$ *whenever Σ is not conformally equivalent to the plane.*

Indeed, the Cohn–Vossen inequality[10] yields

$$\mathcal{K} \leqslant 2\pi\,(2-2h-e), \tag{3}$$

where h is the genus of Σ, i.e., the number of handles, and e is the number of ends. In particular, the condition (a) of Theorem 1 is always fulfilled whenever the surface is not simply connected.

Example 1: Let Σ be the elliptic paraboloid. It is easy to check that it has curvatures vanishing at infinity and that the condition (c) of Theorem 1 is always fulfilled. On the other hand, it violates the condition (d) whenever it is not a paraboloid of revolution, and the condition (a) does not hold because the total Gauss curvature is always equal to 2π. Attaching a handle to Σ, the total curvature becomes equal to -2π (see Fig. 3).

It was proven in Ref. 6 that any layer built over a cylindrically symmetric surface diffeomorphic to $\mathbb{R}^2$ has a spectrum below the energy κ_1^2. Since this class of reference surfaces may only have a non-negative total Gauss curvature, it gave an important alternative condition to (a) in the case $\mathcal{K}>0$. In Theorem 1, an interesting generalization to Ref. 6 is introduced by virtue of the condition (d), where it is supposed now that only an unbounded subset of Σ admits a cylindrical symmetry at infinity (see Fig. 4). This extension is possible due to the fact that the sequence of trial functions establishing the existence of spectrum below κ_1^2 for surfaces of revolution with $\mathcal{K}>0$ is ''localized at infinity'' (i.e., for any compact set of Ω, there is an element from the

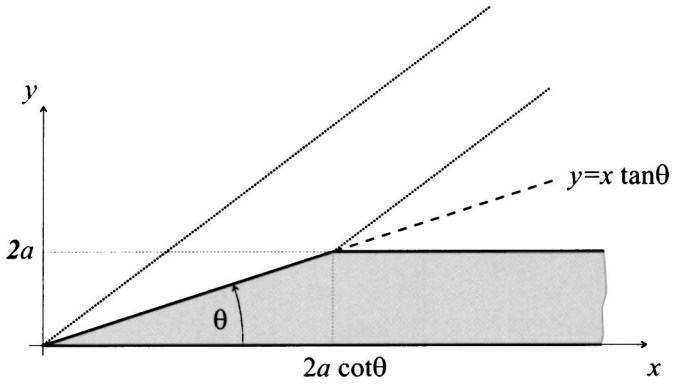

FIG. 5. The planar region of Example 2.

sequence supported out of the compact). Consequently, it may be localized just at the end satisfying condition (d) of Theorem 1. Since any deformation of a bounded part of Ω does not affect this spectral result, we may consider more general regions than tubes (1). What is important is that such local deformations do not include only bends and protrusions which are traditionally a source of binding, but constrictions as well. Moreover, since such trial functions localized at different ends will be orthogonal as elements of $L^2(\Omega)$, we may produce an arbitrary number of bound states by attaching to Ω a sufficient number of suitable outlets. Finally, since the essential spectrum is stable under compact deformation of Ω, we arrive at the following result.

Theorem 2: *Let Ω be a layer (1) satisfying $\langle$H1$\rangle$, $\langle$H2$\rangle$ and the condition (i) of Theorem 1. Assume that the reference surface Σ contains $N\geqslant 1$ cylindrically symmetric ends, each of them having a positive total Gauss curvature. Let Ω' be an unbounded region without boundary in $\mathbb{R}^3$ obtained by any compact deformation of Ω. Then*

(i) $\inf\sigma_{\mathrm{ess}}(-\Delta_D^{\Omega'})=\kappa_1^2$,
(ii) there will be at least N eigenvalues in $(0,\kappa_1^2)$, with the multiplicity taken into account.

Example 2: Fix $\theta\in(0,\pi/2)$ and consider the conical region Ω' in $\mathbb{R}^3$ given by rotating the planar region (see Fig. 5):

$$\{(x,y)\in\mathbb{R}^2\,|\;\;(x,y)\in((0,2a\cot\theta)\times(0,x\tan\theta])\cup([2a\cot\theta,\infty)\times(0,2a))\}$$

along the axis $y=x\tan\theta$ in $\mathbb{R}^3$. Note that Ω' is not a layer (1) because of the singularity of the conical surface. Nevertheless, it may be considered as a compact deformation of the layer built over a smoothed cone whose total Gauss curvature is equal to $2\pi(1-\sin\theta)\in(0,2\pi)$. Consequently, we know that $-\Delta_D^{\Omega'}$ possesses at least one discrete eigenvalue below κ_1^2 due to Theorem 2. This is a nontrivial result for flat enough conical layers only, since using a trick analogous to that of Ref. 11 one can check that the cardinality of $\sigma_{\mathrm{disc}}(-\Delta_D^{\Omega'})$ can exceed any fixed integer for θ small enough.

III. PRELIMINARIES

Let Σ be a connected orientable surface of class C^2 embedded in $\mathbb{R}^3$. The orientation can be specified by the choice of a globally defined unit normal vector field, $n:\Sigma\to S^2$, which is a function of class C^1. For any $x\in\Sigma$, the Weingarten map

$$L_x:\; T_x\Sigma\to T_x\Sigma:\{\xi\mapsto-\mathrm{d}n_x(\xi)\} \tag{4}$$

defines the principal curvatures $k_\pm$ of Σ as its eigenvalues with respect to the induced metric g. The Gauss curvature and the mean curvature are defined by $K:=k_+k_-$ and $M:=\frac{1}{2}(k_++k_-)$, respectively, and are continuous functions on Σ.

Put $a>0$. We define a layer Ω of width $2a$ as the image of the mapping

$$\mathcal{L}:\ \Sigma\times(-a,a)\to\mathbb{R}^3:\{(x,u)\mapsto x+u\,n(x)\}. \tag{5}$$

Henceforth, we shall always assume ⟨H2⟩. Then $\mathcal{L}$ induces a diffeomorphism and Ω is a submanifold of $\mathbb{R}^3$ corresponding to the set of points squeezed between two parallel surfaces at the distance a from Σ (see Fig. 1), i.e., if Σ does not have a boundary then the definition of Ω via (5) and (1) are equivalent. We shall identify it with the Riemannian manifold $\Sigma\times(-a,a)$ endowed with the metric G induced by the immersion (5). One has

$$G=g\circ(I_x-u\,L_x)^2+\mathrm{d}u^2,\quad \mathrm{d}\Omega=(1-2Mu+Ku^2)\mathrm{d}\Sigma\,\mathrm{d}u, \tag{6}$$

where I_x denotes the identity map on $T_x\Sigma$ and $\mathrm{d}\Omega$ stands for the volume element of Ω. It is worth noticing that (6) together with ⟨H2⟩ yields that G can be estimated by the surface metric,

$$C_-g+\mathrm{d}u^2\leqslant G\leqslant C_+g+\mathrm{d}u^2,\quad \text{where}\quad C_\pm:=(1\pm a\rho_m^{-1})^2. \tag{7}$$

Remark 1: Formally, it is possible to consider $(\Sigma\times(-a,a),G)$ as an abstract Riemannian manifold where only the surface Σ is embedded in $\mathbb{R}^3$. Then we do not need to assume the second part of ⟨H2⟩, i.e., "Ω does not overlap."

We denote by $-\Delta_D^\Omega$, or simply $-\Delta$, the Dirichlet Laplacian on $L^2(\Omega)$. We shall consider it in a generalized sense as the operator associated with the Dirichlet form

$$Q(\psi,\phi):=\int_\Omega\langle\nabla\psi,\nabla\phi\rangle\,\mathrm{d}\Omega\quad\text{with}\quad \mathrm{Dom}\,Q:=W_0^{1,2}(\Omega). \tag{8}$$

Here ∇ is the gradient corresponding to the metric G and $\langle\cdot,\cdot\rangle$ denotes the inner product in the manifold Ω induced by G; the associated norm will be denoted by $|\cdot|$. Similarly, the inner product and the norm in the Hilbert space $L^2(\Omega)$ will be denoted by $(\cdot,\cdot)$ and $\|\cdot\|$, respectively. We shall sometimes abuse the notation slightly by writing $(\cdot,\cdot)\equiv\int_\Omega\langle\cdot,\cdot\rangle\mathrm{d}\Omega$ and $\|\cdot\|\equiv\int_\Omega|\cdot|\mathrm{d}\Omega$ for vector fields. The subscript "g" will be used in order to distinguish similar objects associated to the surface Σ.

Since the quadratic form Q is densely defined, symmetric, positive, and closed on its domain, the corresponding Laplacian $-\Delta$ is a positive self-adjoint operator. Denoting by $(x^\mu)\equiv(x^1,x^2)$ local coordinates for Σ and by G^{ij} the coefficients of the inverse of G in the coordinates $(x^i)\equiv(x^\mu,u)$ for Ω, we can write

$$-\Delta\ =\ -|G|^{-1/2}\partial_i|G|^{1/2}G^{ij}\partial_j\ =\ -|G|^{-1/2}\partial_\mu|G|^{1/2}G^{\mu\nu}\partial_\nu-\partial_u^2+2M_u\,\partial_u \tag{9}$$

in the form sense, where $|G|:=\det G$ and

$$M_u:=\frac{M-Ku}{1-2Mu+Ku^2}, \tag{10}$$

which is the mean curvature of the parallel surface $\mathcal{L}(\Sigma\times\{u\})$.

The above definitions of Ω and the corresponding Dirichlet Laplacian are valid for any orientable surface Σ of class C^2 provided ⟨H2⟩ (or its first part only in view of Remark 1) holds true. Nevertheless, since we are interested in the existence of discrete spectrum of $-\Delta_D^\Omega$, and it always exists whenever Ω is bounded, in the sequel we shall assume that Σ is *complete* and *noncompact*.

It is easy to see that the spectrum of the planar layer $\Omega_0 := \mathbb{R}^2 \times (-a,a)$ is purely continuous and coincides with the interval $[\kappa_1^2, \infty)$, where the threshold is the first eigenvalue of the Dirichlet Laplacian on the transverse section, i.e., $\kappa_1 := \pi/(2a)$. In what follows we shall use the corresponding normalized eigenfunction given explicitly by

$$\chi_1(u) := \sqrt{\frac{1}{a}} \cos \kappa_1 u. \tag{11}$$

Using the identities $|\nabla u| = 1$ and $-\Delta u = 2M_u$, we get

$$-\Delta \chi_1(u) = 2M_u \chi_1'(u) + \kappa_1^2 \chi_1(u)\,. \tag{12}$$

IV. ESSENTIAL SPECTRUM

We shall localize the essential spectrum of $-\Delta_D^\Omega$ for *asymptotically planar* layers, i.e., the curvatures of Σ vanish at infinity which we abbreviate by

$$K, M \overset{\infty}{\to} 0. \tag{13}$$

Recall that a function f, defined on a noncompact manifold Σ, is said to vanish at infinity if

$$\forall \epsilon > 0 \quad \exists R_\epsilon > 0, x_\epsilon \in \Sigma \quad \forall x \in \Sigma \setminus \overline{B(x_\epsilon, R_\epsilon)} : \quad |f(x)| < \epsilon\,,$$

where $B(x_\epsilon, R_\epsilon)$ denotes the open ball of center x_ϵ and radius R_ϵ. The property (13) is equivalent to the vanishing of the principal curvatures, i.e., $k_\pm \overset{\infty}{\to} 0$.

The proof of statement (i) of Theorem 1 is achieved in two steps. If the layer is asymptotically planar, then it was shown in Ref. 6 that the essential spectrum of $-\Delta_D^\Omega$ is bounded from below by κ_1^2 provided the surface possesses a pole. Here we adapt this proof (based on a Neumann bracketing argument) to the case of any complete surface with asymptotically vanishing curvatures. In the second part of this section, we establish the opposite bound on the threshold by means of a different method.

A. Lower bound, $\inf \sigma_{\mathrm{ess}}(-\Delta_D^\Omega) \geqslant \kappa_1^2$

Fix an $\epsilon > 0$ and consider an open precompact region $\mathcal{B} \supseteq B(x_\epsilon, R_\epsilon)$ with C^1-smooth boundary such that

$$\forall (x,u) \in \Omega_{\mathrm{ext}} : (1 - a\epsilon)^2 \leqslant 1 - 2M(x)\, u + K(x)\, u^2 \leqslant (1 + a\epsilon)^2, \tag{14}$$

where $\Omega_{\mathrm{ext}} := \Omega \setminus \overline{\Omega}_{\mathrm{int}}$ with $\Omega_{\mathrm{int}} := \mathcal{B} \times (-a,a)$. Denote by $-\Delta_N$ the Laplacian $-\Delta_D^\Omega$ with a supplementary Neumann boundary condition on $\partial\mathcal{B} \times (-a,a)$, that is, the operator associated with the form $Q_N := Q_N^{\mathrm{int}} \oplus Q_N^{\mathrm{ext}}$, where

$$Q_N^\omega(\psi, \phi) := \int_{\Omega_\omega} \langle \nabla \psi, \nabla \phi \rangle \, \mathrm{d}\Omega, \quad \mathrm{Dom}\, Q_N^\omega := \{ \psi \in W^{1,2}(\Omega_\omega) \,|\, \psi(\cdot, \pm a) = 0 \}$$

for $\omega \in \{\mathrm{int}, \mathrm{ext}\}$. Since $-\Delta_D^\Omega \geqslant -\Delta_N$ and the spectrum of the operator associated to Q_N^{int} is purely discrete, cf. Ref. 12, Chap. 7, the minimax principle gives the estimate

$$\inf \sigma_{\mathrm{ess}}(-\Delta_D^\Omega) \geqslant \inf \sigma_{\mathrm{ess}}(-\Delta_N^{\mathrm{ext}}) \geqslant \inf \ \sigma(-\Delta_N^{\mathrm{ext}}),$$

where $-\Delta_N^{\mathrm{ext}}$ denotes the operator associated to Q_N^{ext}. Neglecting the non-negative "longitudinal" part of the Laplacian [i.e., the first term at the right-hand side of (9)] and using the estimates (14), we arrive easily at the following lower bound:

$$-\Delta_N^{\mathrm{ext}} \geqslant \left(\frac{1-a\epsilon}{1+a\epsilon}\right)^2 \kappa_1^2 \quad \text{in} \quad L^2(\Omega_{\mathrm{ext}}),$$

which holds in the form sense (see also proof of Theorem 4.1 in Ref. 6). The claim then follows by the fact that ϵ can be chosen arbitrarily small.

B. Upper bound, $\inf \sigma_{\mathrm{ess}}(-\Delta_D^{\Omega}) \leqslant \kappa_1^2$

It follows from Ref. 13 that if $K \overset{\infty}{\to} 0$ then the threshold of the (essential) spectrum of the Laplacian on Σ, $-\Delta_g$, equals 0. This is equivalent to the statement that for any $\varepsilon > 0$ there exists an infinite-dimensional subspace $\mathcal{D}_g \subseteq C_0^\infty(\Sigma)$ such that

$$\forall \varphi \in \mathcal{D}_g: \quad \|\nabla_g \varphi\|_g \leqslant \varepsilon \|\varphi\|_g . \tag{15}$$

It is easy to see that the following identity holds true:

$$\forall \varphi \in C_0^\infty(\Sigma): \quad \|\nabla \varphi \chi_1\|^2 = \||\nabla \varphi|\, \chi_1\|^2 - (\varphi \chi_1, \varphi \Delta \chi_1). \tag{16}$$

Using the estimates (7) and (15), we have

$$\||\nabla \varphi|\, \chi_1\|^2 \leqslant (C_+ / C_-^2)\, \varepsilon^2 \|\varphi\, \chi_1\|^2,$$

while the second term at the right-hand side of (16) can be rewritten by means of (12) as follows:

$$-(\varphi \Delta \chi_1, \varphi \chi_1) = \kappa_1^2 \|\varphi\, \chi_1\|^2 + (\varphi \chi_1', 2M_u \varphi \chi_1).$$

Integrating by parts with respect to u in the second term at the right-hand side of the last equality, we conclude from (16) that for any $\varepsilon > 0$ there exists $\mathcal{D} := \mathcal{D}_g \otimes \{\chi_1\} \subset C_0^\infty(\Omega)$ such that

$$\forall \psi \in \mathcal{D}: \quad \|\nabla \psi\|^2 - (\psi, K_u \psi) \leqslant (\kappa_1^2 + (C_+ / C_-^2)\, \varepsilon^2) \|\psi\|^2,$$

where

$$K_u := \frac{K}{1 - 2Mu + Ku^2}$$

is the Gauss curvature of the parallel surface $\mathcal{L}(\Sigma \times \{u\})$. This proves that $\inf \sigma_{\mathrm{ess}}(-\Delta - K_u) \leqslant \kappa_1^2$. Since K_u vanishes at infinity by the assumption (13), i.e., the operator $K_u(-\Delta + 1)^{-1}$ is compact in $L^2(\Omega)$, the same spectral result holds for the operator $-\Delta$.

Remark 2: Notice that only $K \overset{\infty}{\to} 0$ is needed in order to establish the upper bound.

V. GEOMETRICALLY INDUCED SPECTRUM

It was shown in Sec. IV that the threshold of the essential spectrum is stable under any deformation of the planar layer such that the deformed layer is still planar asymptotically in the sense of (13). The aim of this section is to prove the sufficient conditions (a)–(d) of the second part of Theorem 1, which guarantee the existence of spectrum below the energy κ_1^2. Since the spectral threshold of the planar layer is just κ_1^2, the spectrum below this value is induced by the curved geometry and it consists of discrete eigenvalues if the layer is asymptotically planar.

All the proofs here are based on the variational idea of finding a trial function Ψ from the form domain of $-\Delta_D^{\Omega}$ such that

$$Q_1[\Psi] := Q[\Psi] - \kappa_1^2 \|\Psi\|^2 < 0. \tag{17}$$

The important technical tool needed to establish conditions (a)–(c) is the existence of appropriate mollifiers on Σ which is ensured by the following lemma.

Lemma 1: Assume $\langle$H1$\rangle$. *Then there exists a sequence* $\{\varphi_n\}_{n\in\mathbb{N}}$ *of smooth functions with compact supports in* Σ *such that*

(1) $\forall n\in\mathbb{N}$: $0\leqslant\varphi_n\leqslant 1$,
(2) $\|\nabla_g\varphi_n\|_g \underset{n\to\infty}{\to} 0$,
(3) $\varphi_n \underset{n\to\infty}{\to} 1$ *uniformly on compacts of* Σ.

Proof: If $\langle$H1$\rangle$ holds true then it follows from Ref. 9 that (Σ,g) is conformally equivalent to a closed surface from which a finite number of points have been removed. However, the integral $\|\nabla_g\varphi_n\|_g$ is a conformal invariant and it is easy to find a sequence having the required properties on the ''pierced'' closed surface. □

This sequence enables us to regularize a generalized trial function which would give formally a negative value of the functional (17), however, it is not integrable in $L^2(\Sigma)$. Since the trial functions used below are adopted from Ref. 6 and the proofs using different mollifiers of Lemma 1 require just slight modifications, we will not go into great details in the proofs of conditions (a)–(c). The sufficient condition (d) does not use the mollifiers of Lemma 1. This condition is established by means of the fact that the sequence of trial functions employed in Ref. 6 for cylindrically symmetric layers was localized only at infinity of the layer.

A. Condition (a)

Using the first transverse mode (11) as the generalized trial function, one gets

$$Q_1[\varphi_n\chi_1]=\||\nabla\varphi_n|\,\chi_1\|^2+(\varphi_n,K\varphi_n)_g\,.$$

Since $|\nabla\varphi_n|$ can be estimated by $|\nabla_g\varphi_n|_g$ by means of (7), the first term at the right-hand side tends to zero as $n\to\infty$ due to Lemma 1. The second one tends to the total Gauss curvature $\mathcal{K}$ because of Lemma 1 and the dominated convergence theorem. Hence, if $\mathcal{K}<0$, we can find a finite n_0 such that $Q_1[\varphi_{n_0}\chi_1]<0$.

In the critical case, i.e., $\mathcal{K}=0$, one adds to $\varphi_n\chi_1$ a small deformation term. Let ε be a real number, which will be specified later, and let j be an infinitely smooth positive function on Σ with a compact support in a region where the mean curvature M is nonzero and does not change sign. Defining $\theta(x,u):=j(x)u\chi_1(u)$, one can write

$$Q_1[\varphi_n\chi_1+\varepsilon\theta]=Q_1[\varphi_n\chi_1]+2\varepsilon\,Q_1(\theta,\varphi_n\chi_1)+\varepsilon^2Q_1[\theta].$$

Since $\mathcal{K}=0$, the first term at the right-hand side of this identity tends to zero as $n\to\infty$. The shifted quadratic form in the second term can be written as a sum of three terms:

$$Q_1(\theta,\varphi_n\chi_1)=(\theta,2M_u\,\varphi_n\chi_1')+(\nabla\theta\chi_1,\nabla\varphi_n)-2(\theta\nabla\chi_1,\nabla\varphi_n),$$

where the last two terms tend to zero as $n\to\infty$ by means of the Schwarz inequality, the estimates (7) and Lemma 1, while an explicit calculation gives that the first integral is equal to $-(j,M\varphi_n)_g$ which tends to a *nonzero* number $-(j,M)_g$. Since θ does not depend on n, one gets

$$Q_1[\varphi_n\chi_1+\varepsilon\theta]\underset{n\to\infty}{\to}-2\varepsilon\,(j,M)_g+\varepsilon^2Q_1[\theta],$$

which may be made negative by choosing ε sufficiently small and of an appropriate sign. □

B. Conditions (b) and (c)

Here we use the trial function $\psi_n(x,u):=(1+M(x)u)\,\varphi_n(x)\chi_1(u)$. Since

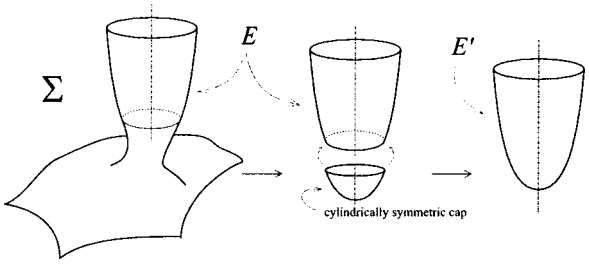

FIG. 6. Construction of a simply connected surface of revolution E' from a cylindrically symmetric end $E\subset\Sigma$.

$$\nabla\psi_n(\cdot,u)=(1+Mu)(\nabla\varphi_n)\chi_1(u)+(\nabla M)u\,\varphi_n\chi_1(u)$$
$$+\,((1+Mu)\kappa_1\,\varphi_n\chi_1'(u)+M\varphi_n\chi_1(u))\nabla u, \tag{18}$$

it is easy to see that $\psi_n\in\mathrm{Dom}\,Q$ provided $\nabla_g M\in L^2_{\mathrm{loc}}(\Sigma)$. In this context and for further considerations, we recall that the curvatures K and M are uniformly bounded, cf. ⟨H2⟩. One has

$$Q_1[\psi_n]\leqslant 2((1+a\|M\|_\infty)^2\||\nabla\varphi_n|\,\chi_1\|^2+a^2\||\nabla M|\,\varphi_n\chi_1\|^2)$$
$$+(\varphi_n,(K-M^2)\varphi_n)_g+\frac{\pi^2-6}{12\kappa_1^2}(\varphi_n,KM^2\varphi_n)_g\,. \tag{19}$$

The inequality giving the factor 2 comes from the first line at the right-hand side of (18) and is established by means of Minkovski's inequality and evident estimates. The second line of (19) is the result of a direct calculation and concerns the terms of the second line of (18).

We start by checking the sufficient condition (c) of Theorem 1. If $\nabla_g M$ is L^2-integrable and ⟨H1⟩ holds true, then all the terms at the right-hand side of (19) tend to finite values as $n\to\infty$, except for the first integral at the second line which tends to $-\infty$ due to the assumption $\mathcal{M}=+\infty$. Hence we can find a finite n_0 such that $Q_1[\psi_{n_0}]<0$.

There are two observations which lead to the condition (b). First, the integral containing $K-M^2$ in (19) is always negative for any nonplanar and noncompact surface, which can be seen by rewriting the difference of curvatures by means of the principal curvatures, i.e., $K-M^2=-\frac{1}{4}(k_+-k_-)^2$. Second, the first term at the right-hand side of (19) tends to zero as $n\to\infty$ because of (7) and Lemma 1, and the remaining ones vanish for n fixed as $a\to 0$. (For the latter we recall that κ_1^{-2} is proportional to a^2.) Hence we can find a sufficiently large n_0 such that the sum of the first term at the right-hand side of (19) and the first integral at the second line of (19) is negative, and then choose the layer half-width a so small that $Q_1[\psi_{n_0}]<0$. □

C. Condition (d)

Let Σ contain a cylindrically symmetric end E with a positive total Gauss curvature, $\mathcal{K}_E>0$.

Let us recall first the strategy employed in Ref. 6 to prove the existence of bound states in layers built over surfaces of revolution diffeomorphic to $\mathbb{R}^2$ with a positive total Gauss curvature, i.e., $E=\Sigma$. The essential ingredient is supplied by an information about the behavior of the mean curvature M at infinity. In particular, if $\mathcal{K}>0$, then $|M|(\det g)^{1/2}$ is bounded but does not vanish at infinity of Σ and neither M nor M^2 are integrable in $L^1(\Sigma)$. On the other hand, the Gauss curvature is supposed to be integrable, cf. ⟨H1⟩. Constructing an appropriate family of trial functions $\{\Psi_n\}_{n\in\mathbb{N}}$ that is localized at infinity (i.e., $\forall$ compact $\Omega_c\subset\Omega\,\exists n\in\mathbb{N}$: supp $\Psi_n\cap\Omega_c=\varnothing$) one succeeds to eliminate the contribution of the Gauss curvature and, at the same time, to ensure that $Q_1[\Psi_n]$ remains negative as $n\to\infty$. We refer to the proof of Theorem 6.1 in Ref. 6 for more details and an explicit form of $\{\Psi_n\}_{n\in\mathbb{N}}$.

The fact that the family of trial functions was localized at infinity makes it possible to extend the proof to our more general situation. If $E \neq \Sigma$, we construct from E a new cylindrically symmetric surface E' diffeomorphic to $\mathbb{R}^2$ by attaching smoothly to it a cylindrically symmetric *cap*, i.e., a simply connected surface with a compact boundary (see Fig. 6). Since the attached surface is cylindrically symmetric and simply connected, its total Gauss curvature cannot be negative, which can be seen by the Gauss–Bonnet theorem and a natural parametrization, cf. Ref. 6, Sec. 6. Consequently, the total Gauss curvature of E' will not be less than the value $\mathcal{K}_E$. Since the latter is positive by assumption, the mean curvature of E' behaves at infinity like required for the use of $\{\Psi_n\}_{n\in\mathbb{N}}$, which proves the existence of spectrum below κ_1^2 for the layer about E'. However, the identical asymptotic behavior holds for the mean curvature of E as well. Hence, in order to establish the desired spectral result for the initial Ω, it is sufficient to construct the sequence $\{\Psi_n\}_{n\in\mathbb{N}}$ only at the infinity of the cylindrically symmetric layer built over the end E.

VI. CONCLUDING REMARKS

The main interest of this paper was the Dirichlet Laplacian, $-\Delta_D^\Omega$, in the layer region Ω defined as a tubular neighborhood of a complete noncompact surface embedded in $\mathbb{R}^3$. Using an intrinsic approach to the geometry of Ω, the conditions of the original paper,[6] sufficient to guarantee the existence of bound states below the essential spectrum of $-\Delta_D^\Omega$, were significantly extended to layers built over general surfaces without any strong topological restrictions; see Theorem 1 for the summary of the main results.

An important open problem is to decide whether the discrete spectrum exists also for layers over surfaces with $\mathcal{K}>0$ such that none of the conditions (b)–(d) of Theorem 1 is satisfied. (We remind that, due to Corollary 1, it concerns surfaces diffeomorphic to $\mathbb{R}^2$ only.) In view of the condition (c), it would be very desirable to prove the following conjecture:

$$\mathcal{K}>0 \;\Rightarrow\; \mathcal{M}=+\infty. \tag{20}$$

Taking into account the definition of K and M by means of the principal curvatures, it may seem that there is no reason to expect this property. However, the principal curvatures cannot be regarded as arbitrary functions because the first and second fundamental forms of Σ have to satisfy some integrability conditions (the Gauss and Codazzi–Mainardi equations). Note that we have proved the conjecture (20) for cylindrically symmetric surfaces in Ref. 6.

Finally, interesting spectral results are expected if the ambient space $\mathbb{R}^3$ is replaced by an Euclidean space of higher dimension (more complicated normal bundle of Σ) or even by a general Riemannian manifold (nontrivial structure of the ambient curvature tensor).

(Received 25 June 2003; accepted 20 October 2003)

We compute for any ordering the star exponentials of all polynomials of degree not greater than two on the 2ℓ-dimensional phase space of a quantum system with ℓ degrees of freedom, and we show in the particular case of the Moyal star product that the Weyl transform of the Moyal star exponential of the one-dimensional harmonic oscillator Hamiltonian is the evolution operator of this quantum system.
 [DOI: 10.1063/1.1634352]

I. INTRODUCTION

A general method of quantization, known under the name of star products method, was proposed in Ref. 1 for an arbitrary symplectic manifold, by Bayen *et al.* In the case of the symplectic phase space $\mathbb{R}^{2\ell}$ of a nonrelativistic quantum system with ℓ degrees of freedom, the Weyl transform[2,3] of the Moyal star product of two admissible symbols (which are functions or distributions on this space) is the product of the corresponding operators on the Hilbert space $L^2(\mathbb{R}^\ell)$. The Moyal star exponentials were introduced and computed in Refs. 1 and 2 for specific homogeneous polynomials, in order to determine the spectrum of the corresponding observables. Later, the Moyal star exponentials of all polynomials of degree not greater than two on $\mathbb{R}^{2\ell}$ were obtained in Ref. 4 and were used to show the existence of classical trajectories for quantum systems whose Hamiltonian belongs to the space of these polynomials.

However, it was noticed in Ref. 5 that the Moyal star product, which corresponds to the completely symmetric ordering, is not appropriate in field theory for the quantization of the free scalar field Hamiltonian. So, a new star product, called the normal star product, which corresponds to the normal ordering, was introduced in this paper and the normal star exponential of this Hamiltonian was computed in this paper, in order to determine (in the context of the star product method) the spectrum of this Hamiltonian. More recently, the normal star exponentials of all quadratic forms on the space $\mathbb{R}^2$ were obtained in Ref. 6.

The purpose of this article is to compute for any ordering, including the normal ordering, the star exponentials of all polynomials of degree not greater than two on the symplectic space $\mathbb{R}^{2\ell}$, $\ell \geqslant 1$. Furthermore, it was proved in Ref. 3 that the Weyl transforms of the Moyal star exponentials of the real homogeneous polynomials of degree two on $\mathbb{R}^{2\ell}$ are one-parameter groups of unitary operators. In the last section of this article, we prove in the particular case of the (real) Hamiltonian H of the one-dimensional harmonic oscillator that the one-parameter group $\mathrm{op}(\mathrm{Exp}_*^{M} tH)$, $t \in \mathbb{R}$, is generated by the essentially skew self-adjoint operator $\mathrm{op}(H/i\hbar)$, and then that this one-parameter group is the evolution operator of this quantum system.

II. GENERAL RESULTS AND NOTATIONS

Let $\mathbb{R}^{2\ell}$ be the phase space of a nonrelativistic quantum system with ℓ degrees of freedom, whose points are denoted by $x=\Sigma_{j=1}^{\ell} q^j e_j + \Sigma_{j=1}^{\ell} p^j e_j^-$ or $x=\Sigma_{j=1}^{2\ell} x^j e_j$, where $e_j^- = e_{j+\ell}$ if $1 \leqslant j \leqslant \ell$. Let $\omega = \Sigma_{j=1}^{\ell} dq^j \wedge dp^j$ be the canonical symplectic form on $\mathbb{R}^{2\ell}$. The Poisson bracket of two elements f and g of $\mathcal{C}^\infty(\mathbb{R}^{2\ell})$ is given by the formula

a)Electronic mail: jean-marie.maillard@u-bourgogne.fr

$$P(f,g)=\sum_{j,k=1}^{2\ell}\Lambda^{jk}\frac{\partial f}{\partial x^j}\frac{\partial g}{\partial x^k}$$

with $\Lambda^{j,j+\ell}=-\Lambda^{j+\ell,j}=1$ if $1\leqslant j\leqslant \ell$, the other coefficients being equal to zero.

A general star product of f and g is given by the formal expansion[1]

$$f*g=fg+\sum_{n=1}^{\infty}\frac{1}{n!}\left(\frac{i\hbar}{2}\right)^n C_n(f,g),$$

where the two-cochains C_n are given by the formula

$$C_n(f,g)=\sum_{j_r,k_s=1}^{2\ell}\Gamma^{j_1k_1}\cdots\Gamma^{j_nk_n}D_{j_1\cdots j_n}fD_{k_1\cdots k_n}g,$$

where the coefficients Γ^{jk} are arbitrary constant numbers and where

$$D_{j_1\cdots j_n}\ f=\frac{\partial^n f}{\partial x^{j_1}\cdots\partial x^{j_n}}.$$

Furthermore, we suppose that these two-cochains satisfy the following formulas:[1,7]

$$\sum_{r+s=n}\frac{1}{r!s!}C_r(C_s(f,g),h)=\sum_{r+s=n}\frac{1}{r!s!}C_r(f,C_s(g,h)), \tag{1a}$$

$$C_1(f,g)-C_1(g,f)=2P(f,g). \tag{1b}$$

Formula (1a), which implies the associativity of the star product, is automatically satisfied if the coefficients Γ^{jk} are arbitrary constant numbers (Theorem 3, p. 69 of Ref. 1, and note that the proof of this theorem remains valid for arbitrary constant coefficients). We denote by Λ and Γ, respectively, the matrices (Λ^{jk}) and (Γ^{jk}), $1\leqslant j,\ k\leqslant 2\ell$. Then, formula (1b), which implies the relation $q_j*p_k-p_k*q_j=i\hbar\,\delta_{jk}$, is equivalent to the following formula:

$$\Gamma-{}^T\Gamma=2\Lambda, \tag{2}$$

where ${}^T\Gamma$ denotes the transpose of the matrix Γ. We have on the precedently chosen basis of $\mathbb{R}^{2\ell}$

$$\Lambda=\begin{pmatrix}0 & I_\ell\\ -I_\ell & 0\end{pmatrix}\quad (I_\ell \text{ is the unit } \ell\times\ell \text{ matrix}).$$

We have $\Gamma_M=\Lambda$ for the Moyal star product,

$$\Gamma_N=2\begin{pmatrix}0 & I_\ell\\ 0 & 0\end{pmatrix}$$

for the normal star product, and $\Gamma_{aN}=-{}^T\Gamma_N$ for the antinormal star product. In this article, the symbols M, N, and aN will, respectively, refer to the Moyal, normal, and antinormal star products. Let us note that we have the same (as the last two one) matrices of coefficients for respectively the antistandard and standard orderings.[8]

The star exponential (for a general star product) of $f\in\mathcal{C}^\infty(\mathbb{R}^{2\ell})$ is defined by the formal expansion:[1,2]

$$\mathrm{Exp}_*tf=\sum_{n=0}^{\infty}\frac{1}{n!}\left(\frac{t}{i\hbar}\right)^n f^{*n}$$

with $f^{*n}=f*\cdots*f$ (n factors).

In the following, we consider the star exponentials of functions for a general ordering, that is for star products whose associated matrix Γ with constant entries satisfies formula (2).

III. STAR EXPONENTIALS FOR ANY ORDERING OF THE ELEMENTS OF THE HOMOGENEOUS SYMPLECTIC LIE ALGEBRA

Let us consider the case of the homogeneous polynomials of degree two on $\mathbb{R}^{2\ell}$ of the form $X(x)=\Sigma_{j,k=1}^{2\ell}a_{jk}x^jx^k$, where the matrix $A=(a_{jk})$ is symmetric with complex entries. Let us write $X(x)=(Ax|x)$, where $(-|-)$ denotes the usual inner product on $\mathbb{R}^{2\ell}$ that we extend in a natural way to a symmetric bilinear product on $\mathbb{C}^{2\ell}$. Let us note that if X is a polynomial of degree not greater than 2 and if $f\in C^\infty(\mathbb{R}^{2\ell})$, then $C_n(X,f)=0$ for $n\geqslant 3$.

Let us write $f_n=X^{*n}$ with $X=(Ax|x)$ and denote by $\tilde{A}=(\tilde{a}_{jk})$ the symmetric matrix $\tilde{A}={}^T\Gamma A\Gamma$. We have the following lemma.

Lemma 1: The functions f_n are polynomials of degree $2n$ on $\mathbb{R}^{2\ell}$ which satisfy the following recursion relation:

$$f_{n+1}=Xf_n+i\hbar\sum_{j,k,r=1}^{2\ell}\Gamma^{jk}a_{jr}x^rD_kf_n-\frac{\hbar^2}{4}\sum_{j,k=1}^{2\ell}\tilde{a}_{jk}D_{jk}f_n \tag{3}$$

with $f_0(x)=1$.

Remark: The analogs of Lemma 1 of Ref. 4 and of its corollary are not true for a general ordering.

To obtain the expression of Exp_*tX, we first look for a solution of the partial differential equation:

$$i\hbar\frac{\partial F}{\partial t}(t,x)=XF+i\hbar\sum_{j,k,r=1}^{2\ell}\Gamma^{jk}a_{jr}x^rD_kF-\frac{\hbar^2}{4}\sum_{j,k=1}^{2\ell}\tilde{a}_{jk}D_{jk}F \tag{4}$$

with $F(0,x)=1$, in the form

$$F(t,x)=f(t)^{-1}\exp i(g(t)x|x), \tag{5}$$

where $f(t)$ and $g(t)$ are holomorphic functions with values, respectively, in the complex field and in the space of the symmetric $2\ell\times 2\ell$ matrices with complex entries. We are led to the following differential system:

$$g'(t)=-\frac{1}{\hbar}A+A\Gamma g(t)+g(t)^T\Gamma A-\hbar g(t)\tilde{A}g(t), \tag{6}$$

$$\frac{f'(t)}{f(t)}=\frac{\hbar}{2}\mathrm{tr}(\tilde{A}g(t)), \tag{7}$$

with $g(0)=0$, $f(0)=1$, and where $\mathrm{tr}\,A$ denotes the trace of the matrix A. [Let us note that we have used the formula $(A\Gamma g(t)x|x)=(g(t)^T\Gamma Ax|x)$ in this computation, in order to obtain a symmetric matrix $g(t)$.]

Let us note that Eq. (6) is a Riccati matrix differential equation. So, following Ref. 9, p. 11, we look for a solution of this differential equation in the form $g(t)=V(t)U(t)^{-1}$, where $U(t)$ is a nonsingular matrix. We then obtain the following linear matrix differential system:

$$U'(t)=-{}^T\Gamma AU(t)+\hbar\tilde{A}V(t), \tag{8a}$$

$$V'(t)=-\frac{1}{\hbar}AU(t)+A\Gamma V(t), \tag{8b}$$

with $U(0)=I_{2\ell}$ and $V(0)=0$. The solution of this system can be written in the form

$$\begin{pmatrix} U(t) \\ V(t) \end{pmatrix} = (\exp t\Phi)\begin{pmatrix} I_{2\ell} \\ 0_{2\ell} \end{pmatrix},$$

and if we consider the $4\ell\times 4\ell$ matrices Φ^n, $n\geqslant 1$, as 2×2 block matrices (Φ^n_{jk}), $1\leqslant j,\ k\leqslant 2$, we obtain with the aid of formula (2): $\Phi^n_{11}=-2^{n-1}\,{}^T\Gamma A(\Lambda A)^{n-1}$ and $\Phi^n_{21}=-(2^{n-1}/\hbar)\times A(\Lambda A)^{n-1}$. We deduce from these formulas that

$$U(t)=I-(1/2)\sum_{n=1}^{\infty}((2t)^n/n!)^T\Gamma A(\Lambda A)^{n-1}, \tag{9a}$$

$$V(t)=-(1/2\hbar)\sum_{n=1}^{\infty}((2t)^n/n!)A(\Lambda A)^{n-1}. \tag{9b}$$

If we introduce the relation $\Lambda^2=-I$ in the preceding formulas and if we set $\Pi_1=-(\frac{1}{2})\Gamma\Lambda$, $\Pi_2=(\frac{1}{2})\,{}^T\Gamma\Lambda$, $\Pi=\Pi_1-\Pi_2$, and if we note [with the aid of formula (2)] that $\Pi_1+\Pi_2=I$, we obtain

$$U(t)=(\cosh t\Lambda A-\Pi\sinh t\Lambda A)\exp t\Lambda A, \tag{9a$'$}$$

$$V(t)=(1/\hbar)\Lambda(\sinh t\Lambda A)\exp t\Lambda A. \tag{9b$'$}$$

We thus obtain

$$g(t)=(1/\hbar)\Lambda\sinh t\Lambda A(\cosh t\Lambda A-\Pi\sinh t\Lambda A)^{-1}. \tag{10}$$

To solve Eq. (7), let us first note that if $u_{jk}(t)$ are the entries of the nonsingular matrix $U(t)$, and if $U_{jk}(t)$ are the corresponding cofactors, we have

$$\mathrm{tr}(U'(t)U(t)^{-1})=(\det U(t))^{-1}\sum_{j,k=1}^{2\ell}u'_{jk}(t)U_{jk}(t).$$

We then obtain, with the aid of the derivative property of determinants, the following lemma:

Lemma 2: If $U(t)$ is a nonsingular matrix with differentiable or holomorphic entries, we have

$$\mathrm{tr}(U'(t)U(t)^{-1})=(\det U(t))^{-1}(\det U(t))'.$$

With the aid of this lemma and of formulas (7) and (8a), we obtain

$$\frac{f'(t)}{f(t)}=\frac{1}{2}(\det U(t))^{-1}(\det U(t))'+\frac{1}{2}\mathrm{tr}({}^T\Gamma A),$$

and if we use the relation $\det(\exp t\Lambda A)=1$ (due to $\mathrm{tr}\,\Lambda A=0$, since ${}^T\Lambda=-\Lambda$) in formula (9a$'$), we obtain

$$f(t)=\exp\left(\frac{t}{2}\mathrm{tr}\,A\Gamma\right)(\det(\cosh t\Lambda A-\Pi\sinh t\Lambda A))^{1/2}. \tag{11}$$

If we consider now the power series expansion in t of the holomorphic function $F(t,x)$ [of formula (5)] around the origin,

$$F(t,x)=\sum_{n=0}^{\infty}\frac{1}{n!}\left(\frac{t}{i\hbar}\right)^n C_n(x)$$

with $C_n(x)=(i\hbar)^n\partial^n F(t,x)/\partial t^n|_{t=0}$, and if we keep in mind that the function $F(t,x)$ is a solution of the partial differential equation (4), it is easy to show that the functions $C_n(x)$ satisfy the recursion relation (3) with $C_0(x)=1$. We thus have $C_n(x)=f_n(x)$ for all $n\in\mathbb{N}$.

Finally, let us note that formula (10) can be written in the form

$$g(t)=(1/\hbar)\Lambda\tanh t\Lambda A(I-\Pi\tanh t\Lambda A)^{-1},$$

and let us note that if we denote by $\|A\|$ the operator norm of the matrix A in the 2ℓ-dimensional Hilbert space $\mathbb{C}^{2\ell}$, the function $F(t,x)$ is analytic if $\|tA\|<\pi/2$ and $\|\Pi\tanh t\Lambda A\|\leqslant\|\Pi\|\tan\|tA\|<1$. We can now formulate the main result of this paper.

Theorem 1: *Let $X=(Ax|x)$ for $x\in\mathbb{R}^{2\ell}$, where A is a symmetric matrix with complex entries. Then the power series in t,*

$$\mathrm{Exp}_*tX=\sum_{n=0}^{\infty}\frac{1}{n!}\left(\frac{t}{i\hbar}\right)^n X^{*n},\tag{12}$$

has a radius of convergence $\rho\geqslant(1/\|A\|)\mathrm{Arc}\tan(1/\|\Pi\|)$ [we set Arc tan $(1/0)=\pi/2$*], and we have for any $t\in\mathbb{C}$, $|t|<\rho$ and any $x\in\mathbb{R}^{2\ell}$,*

$$\mathrm{Exp}_*tX=f(t)^{-1}\exp i(g(t)x|x)$$

with

$$f(t)=\exp\left(\frac{t}{2}\mathrm{tr}\,A\Gamma\right)(\det(\cosh t\Lambda A-\Pi\sinh t\Lambda A))^{1/2},$$

$$g(t)=\frac{1}{\hbar}\Lambda(\tanh t\Lambda A)(I-\Pi\tanh t\Lambda A)^{-1},$$

$$\Pi=-\tfrac{1}{2}(\Gamma+{}^T\Gamma)\Lambda.$$

We choose for $(\det(\cosh t\Lambda A-\Pi\sinh t\Lambda A))^{1/2}$ *the principal value.*

Remark: We have $\|A\|=\sup|\mu_i|$ where μ_i are the eigenvalues of the matrix A if A is a real (and symmetric) matrix or if A is a normal (complex) matrix.

Since the function $F(t,x)$ is analytic for $|t|<\rho$ and $x\in\mathbb{R}^{2\ell}$, then for each $t\in\mathbb{C}$, $|t|<\rho$, the series (12) converges uniformly on compact sets of $\mathbb{R}^{2\ell}$. We have the following theorem.

Theorem 2: *For any $t\in\mathbb{C}$, $|t|<\rho$, the series (12) converges weakly in $\mathcal{D}'(\mathbb{R}^{2\ell})$.*

Remarks:

(1) The symmetry of the matrix $g(t)$ follows from the formula ${}^T\Pi=\Lambda\Pi\Lambda$ and is easily checked by using the power series expansion of the function $(1-x)^{-1}$. We have

$$g(t)={}^Tg(t)=(1/\hbar)\Lambda(I-(\tanh t\Lambda A)\Pi)^{-1}\tanh t\Lambda A.$$

(2) We have $\Pi_M=0$, and we can note that, in this particular case of the Moyal star product, Theorem 1 was previously obtained in Ref. 4. We have

$$\Pi_N=\begin{pmatrix}I_\ell & 0\\ 0 & -I_\ell\end{pmatrix}$$

(Π_N is the projection operator on the q-space minus the projection operator on the p-space), and we have $\Pi_{aN}=-\Pi_N$.

(3) In the case of the space $\mathbb{R}^2$, it is easy to show by using the Hamilton–Cayley theorem that $(\Lambda A)^2=dI_2$ [since $\mathrm{tr}(\Lambda A)=0$] with $d=-\det A$. We then have $\cosh t\Lambda A=(\cosh t\sqrt{d})I_2$ and

$\sinh t\Lambda A=((\sinh t\sqrt{d})/\sqrt{d})\Lambda A$ where $\sqrt{d}$ is one of the square roots of d and an easy calculation using the preceding formulas shows that we have, for $X(q,p)=aq^2+2bqp+cp^2$ and $\varepsilon=+1$ for the normal star product and $\varepsilon=-1$ for the antinormal star product,

$$\mathrm{Exp}_*^{\varepsilon} tX=(f_\varepsilon(t))^{-1}\exp i(\alpha_\varepsilon(t)X(q,p)+\beta_\varepsilon(t)qp)$$

with

$$f_\varepsilon(t)=e^{\varepsilon tb}(\varphi_\varepsilon(t))^{1/2}$$

[we choose for $(\varphi_\varepsilon(t))^{1/2}$ the principal value],

$$\varphi_\varepsilon(t)=\cosh 2t\sqrt{d}-\varepsilon b(\sinh 2t\sqrt{d})/\sqrt{d},$$

$$\alpha_\varepsilon(t)=-(2\hbar\varphi_\varepsilon(t))^{-1}(\sinh 2t\sqrt{d})/\sqrt{d},$$

$$\beta_\varepsilon(t)=\varepsilon(\hbar\varphi_\varepsilon(t))^{-1}(\cosh 2t\sqrt{d}-1),$$

$d=b^2-ac$, where $\sqrt{d}$ is one of the square root of d. Let us note that this result does not depend on the choice of the square root of d. This result was previously obtained in Ref. 6 for the case $\varepsilon=+1$ with a minor difference due to a minor difference of the definition of star exponentials.

(4) In the case of a homogeneous polynomial of degree two on $\mathbb{R}^{2\ell}$, $\ell>1$, of the form $X(q,p)=\Sigma_{j=1}^{\ell}X_j(q,p)$ with $X_j(q,p)=a_jq_j^2+2b_jq_jp_j+c_jp_j^2$ and if we choose the basis e_1, $e_{\overline{1}},\ldots,e_\ell$, $e_{\overline{\ell}}$ of $\mathbb{R}^{2\ell}$, the matrices A, Λ, Γ, and Π are block diagonal matrices with 2×2 blocks, we then have for most orderings, including the completely symmetric (Moyal), normal and antinormal orderings

$$\mathrm{Exp}_* tX=\prod_{j=1}^{\ell}\mathrm{Exp}_* tX_j.$$

($\Pi_{j=1}^{\ell}$ denotes the ordinary product of the preceding functions.) We have for the Moyal star product

$$\mathrm{Exp}_*^M tX=\prod_{j=1}^{\ell}(\cosh t\sqrt{d_j})^{-1}\exp\left(-\frac{i}{\hbar}\frac{\tanh t\sqrt{d_j}}{\sqrt{d_j}}X_j\right),$$

which is a generalization of formula (6–11) of Ref. 2.

(5) If we consider the matrix A as a 2×2 block matrix (A_{jk}), $1\leqslant j,k\leqslant2$, we have $\tilde{A}_N=0$ if $A_{11}=0$ and $\tilde{A}_{aN}=0$ if $A_{22}=0$. We have $f(t)=1$ in both cases. We have in particular

$$\mathrm{Exp}_*^{\varepsilon}\left(t\sum_{j=1}^{\ell}\omega_jq_jp_j\right)=\exp\frac{\varepsilon i}{\hbar}\left(\sum_{j=1}^{\ell}(1-e^{\varepsilon t\omega_j})q_jp_j\right).$$

Let us note that to connect this result in the case $\varepsilon=+1$ with formula 3.5 of Ref. 5, and since the deformation parameter in Ref. 5 is $\hbar$ instead of $i\hbar$, we must replace Λ and Γ_N by $(1/i)\Lambda$ and $(1/i)\Gamma_N$, respectively. Formulas (2), (9a), (9b), and (11) remain valid when expressed with these new matrices, but we must introduce the relation $(-i\Lambda)^2=I$ in (9a), (9b) and set $\Pi=(\frac{1}{2})(-i\Gamma_N-i^T\Gamma_N)(-i\Lambda)=\Pi_N$. The right-hand side of (10) is then multiplied by -1. Hence we have

$$f(t)=f_N(-it)\quad\text{and}\quad g(t)=ig_N(-it).$$

IV. STAR EXPONENTIALS FOR ANY ORDERING OF THE ELEMENTS OF THE INHOMOGENEOUS SYMPLECTIC LIE ALGEBRA

Let us now consider the case of the inhomogeneous polynomials of degree not greater than 2 on $\mathbb{R}^{2\ell}$. We obtain in the same way as in the homogeneous case the following theorem.

Theorem 3: *Let $X=(Ax|x)+(b|x)+c$ where $A=(a_{jk})$ is a symmetric matrix with complex entries, $b=(b_j)\in\mathbb{C}^{2\ell}$ and $c\in\mathbb{C}$. Then the power series*

$$\mathrm{Exp}_*tX=\sum_{n=0}^{\infty}\frac{1}{n!}\left(\frac{t}{i\hbar}\right)^n X^{*n}$$

has a radius of convergence $\rho\geqslant(1/\|A\|)\,\mathrm{Arc\,tan}(1/\|\Pi\|)$ and we have for $t\in\mathbb{C}$, $|t|<\rho$ and $x\in\mathbb{R}^{2\ell}$

$$\mathrm{Exp}_*tX=f(t)^{-1}\exp i[(g(t)x|x)+(k(t)|x)-ct/\hbar]$$

with

$$g(t)=\frac{1}{\hbar}\Lambda(I-(\tanh t\Lambda A)\Pi)^{-1}\tanh t\Lambda A,$$

$$k(t)=\frac{1}{\hbar}\Lambda(I-(\tanh t\Lambda A)\Pi)^{-1}\frac{\tanh t\Lambda A}{\Lambda A}\Lambda b,$$

$$f(t)=\exp\left(\frac{t}{2}\mathrm{tr}\,A\Gamma\right)\exp\left(\frac{i}{4}(\varphi(t)|b)\right)(\det(\cosh t\Lambda A-\Pi\sinh t\Lambda A))^{1/2},$$

$$\varphi(t)=\frac{1}{\hbar}\,\frac{\tanh t\Lambda A-t\Lambda A}{(\Lambda A)^2}\Lambda b-\frac{\tanh t\Lambda A}{\Lambda A}\Pi\Lambda k(t).$$

For the proof of this theorem, we first look for a solution of the partial differential equation:

$$i\hbar\,\frac{\partial F(t,x)}{\partial t}=XF+i\hbar\sum_{j,k=1}^{2\ell}\Gamma^{jk}\left(\frac{bj}{2}+\sum_{r=1}^{2\ell}a_{jr}x^r\right)D_kF-\frac{\hbar^2}{4}\sum_{j,k=1}^{2\ell}\tilde{a}_{jk}D_{jk}F$$

such that $F(0,x)=1$, in the form

$$F(t,x)=f(t)^{-1}\exp i((g(t)x|x)+(k(t)|x)+\ell(t)),$$

where $g(t)$, $k(t)$, $\ell(t)$, and $f(t)$ are holomorphic functions with values in the space of the symmetric $2\ell\times2\ell$ matrices with complex entries, in $\mathbb{C}^{2\ell}$ and in $\mathbb{C}$ for the last two functions, respectively. We are led to the differential system

$$g'(t)=-\frac{1}{\hbar}A+A\Gamma g(t)+g(t)^{T}\Gamma A-\hbar g(t)\tilde{A}g(t), \tag{13}$$

$$k'(t)=-\frac{b}{\hbar}+A\Gamma k(t)+g(t)^{T}\Gamma b-\hbar g(t)\tilde{A}k(t), \tag{14}$$

$$\frac{f'(t)}{f(t)}=\frac{\hbar}{2}\mathrm{tr}(\tilde{A}g(t))+i\left(\frac{c}{\hbar}+\ell'(t)\right)-\frac{i}{2}(b|\Gamma k(t))+i\frac{\hbar}{4}(\tilde{A}k(t)|k(t)), \tag{15}$$

with $g(0)=0$, $k(0)=0$ and $f(0)=1$.

Let us note that Eq. (13) was already solved in Sec. III (see Remark 1 following Theorem 2). To solve Eq. (14), let us consider the analytic function

$$g_1(t)=\frac{1}{\hbar}\Lambda(I-(\tanh t\Lambda A)\Pi)^{-1}\frac{\tanh t\Lambda A}{\Lambda A},$$

which satisfies the relation $g_1'(t)=g'(t)/\Lambda A$.

We deduce from Eq. (13) that the function $g_1(t)$ satisfies the following equation:

$$g_1'(t)=-\frac{1}{\hbar}\Lambda^{-1}+A\Gamma g_1(t)+g(t)^{T}\Gamma\Lambda^{-1}-\hbar g(t)\tilde{A}g_1(t). \tag{16}$$

It is then obvious that the function $k(t)=g_1(t)\Lambda b$ is the solution of Eq. (14). To solve Eq. (15), let us set $\ell(t)=-ct/\hbar$ and let us note that the first part of the right-hand side of this equation was already integrated in Sec. III. The last part of this right-hand side is equal to $(i/4)(h(t)\Lambda b|b)$ with

$$h(t)=-\Gamma g_1(t)-\Lambda^{T}g_1(t)^{T}\Gamma\Lambda-\hbar\Lambda^{T}g_1(t)\tilde{A}g_1(t).$$

Let us note that the matrix $g_1(t)$ is not symmetric. Introducing the relation $g(t)=-A\Lambda^{T}g_1(t)$ in formula (16), we deduce that $(\Lambda g_1(t)+t/\hbar I)'=-\Lambda Ah(t)$. Now, if we set

$$g_2(t)=\frac{1}{\hbar}\frac{\tanh t\Lambda A-t\Lambda A}{(\Lambda A)^2}-\frac{\tanh t\Lambda A}{\Lambda A}\Pi\Lambda g_1(t),$$

and if we use the power series expansion of the function $(1-x)^{-1}$, we obtain

$$\Lambda g_1(t)+\frac{t}{\hbar}I=-\Lambda Ag_2(t).$$

We then deduce from the analytic properties of these functions that $h(t)=g_2'(t)$ and it suffices to set $\varphi(t)=g_2(t)\Lambda b$ to obtain the solution of Eq. (15).

V. MOYAL STAR EXPONENTIAL OF THE HAMILTONIAN OF THE ONE-DIMENSIONAL HARMONIC OSCILLATOR AND EVOLUTION OPERATOR OF THIS QUANTUM SYSTEM

Let us consider the homogeneous polynomials of degree 2 on $\mathbb{R}^{2\ell}$ written in the form $X=(Ax|x)$ where A is a real and symmetric matrix. Then the Weyl transforms $\mathrm{op}(\mathrm{Exp}_*^M tX)$ of the Moyal star exponentials of these polynomials form groups of unitary operators of the Hilbert space $L^2(\mathbb{R}^\ell)$ (propositions 13 and 14 of Ref. 3). In this section, we prove in the particular case of the Hamiltonian $H=\frac{1}{2}(p^2+q^2)$ of the one-dimensional harmonic oscillator that the group of unitary operators $\mathrm{op}\,(\mathrm{Exp}_*^M tH)$ is the evolution operator of this quantum system. We have the following proposition:

Proposition 1: Let $H=\frac{1}{2}(q^2+p^2)$ be the Hamiltonian of the one-dimensional harmonic oscillator. Then the Weyl transform $\mathrm{op}(H)$ of the function H is an essentially self-adjoint operator on $L^2(\mathbb{R})$ and we have for t real and sufficiently small

$$\mathrm{op}(\mathrm{Exp}_*^M tH)=\exp\frac{t}{i\hbar}\overline{\mathrm{op}(H)},$$

where $\overline{\mathrm{op}(H)}$ is the closure of the operator $\mathrm{op}(H)$.

Proof: We have for $u,\ v\in\mathscr{S}(\mathbb{R})$: $(\mathrm{op}(H)u|v)=\langle\hat{H}(\alpha),\chi_{u,v}(\alpha)\rangle=\langle H(x),\hat{\chi}_{u,v}(x)\rangle$ where $(u|v)=\int u(q)\overline{v(q)}\,dq$ is the scalar product on $L^2(\mathbb{R})$, $\hat{f}(\alpha)=\int e^{-i\langle\alpha,x\rangle}f(x)\,d\mu(x)$ with $f\in\mathscr{S}(\mathbb{R}^2)$, $x=(q,p)$, $\alpha=(a,b)$, $\langle\alpha,x\rangle=aq+bp$, $d\mu(x)=dqdp/2\pi$ and

$$\chi_{u,v}(a,b)=\exp\left(i\frac{\hbar}{2}ab\right)\int e^{iaq'}u(q'+\hbar b)\overline{v(q')}\,dq'.$$

(Let us note that an apparently different but equivalent definition is given in Ref. 3 with the use of the symplectic Fourier transformation.) We must prove for t real and sufficiently small that

$$\langle \mathrm{Exp}_*^M tH,\quad \hat{\chi}_{u,v}\rangle=\sum_{n=0}^{\infty}\frac{1}{n!}\left(\frac{t}{i\hbar}\right)^n\langle H^{*n},\ \hat{\chi}_{u,v}\rangle \tag{17}$$

with

$$\hat{\chi}_{u,v}(q,p)=\frac{2}{|\hbar|}\int \exp\left(2\frac{i}{\hbar}pb\right)u(q-b)\overline{v(q+b)}\,db. \tag{18}$$

The convergence of the expansion (17) does not hold automatically, since the series (12) (with $X=H$) converges in $\mathcal{D}'(\mathbb{R}^2)$ but $\hat{\chi}_{u,v}$ belongs to $\mathcal{S}(\mathbb{R}^2)$.

We shall estimate the functions $\hat{X}_{u,v}$ in order to apply Lebesgue's dominated convergence theorem. For this purpose, we consider the complete system of eigenvectors (then of analytic vectors) of the operator $\mathrm{op}(H)$:

$$u_n(q)=(2^n n!\sqrt{\pi|\hbar|})^{-1/2}e^{-q^2/2|h|}H_n(q/\sqrt{|\hbar|}),\quad n\in\mathbb{N},$$

where H_n denotes the Hermite polynomial of degree n (cf. Ref. 10). The operator $\mathrm{op}(H)$ is then essentially self-adjoint and we obtain by using formula (18)

$$\hat{\chi}_{u_r,u_s}(q,p)=e^{-(q^2+p^2)/|\hbar|}P_{r,s}(q,p),\quad r,\quad s\in\mathbb{N},$$

where $P_{r,s}$ is a polynomial of degree not greater than $r+s$ in p and q. On the other hand, we know that we have $H^{*n}=K_n(H)$ for the Moyal star product on the phase space $\mathbb{R}^2$, where the functions $K_n(x)$ are polynomials of degree n which satisfy the recursion relation [formula (6.2) of Ref. 2, or remark 2 at the end of this section]

$$K_{n+1}(x)=xK_n(x)-\frac{\hbar^2}{4}K_n'(x)-\frac{\hbar^2}{4}xK_n''(x),\quad K_0(x)=1.$$

Let us now consider the polynomials $C_n(x)$ with non-negative coefficients, defined by the recursion relation

$$C_{n+1}(x)=xC_n(x)+\frac{|\hbar|^2}{4}C_n'(x)+\frac{|\hbar|^2}{4}xC_n''(x),\quad C_0(x)=1. \tag{19}$$

It is then obvious that we have

$$|H^{*n}|=|K_n(H)|\leqslant C_n(|H|),$$

hence

$$\sum_{n=0}^{\infty}\frac{1}{n!}\left|\frac{t}{i\hbar}\right|^n|H^{*n}(q,p)|\leqslant\sum_{n=0}^{\infty}\frac{1}{n!}\left|\frac{t}{\hbar}\right|^n C_n\left(\frac{q^2+p^2}{2}\right). \tag{20}$$

Let us now consider the Moyal star product with the deformation parameter $-i|\hbar|$ instead of $\hbar$ (let us note that this parameter does not need to be real in the definition of star products and in the computation of star exponentials), and let us note that the recursion relation (19) is the relation

giving $H^{*n}=C_n(H)$ for this new deformation parameter. Then by using (for this new parameter) Theorem 1 and Remark 4 following Theorem 2 for $|t|$ instead of t, it is easy to show that the right-hand side of inequality (20) is equal to

$$\left(\cos\frac{|t|}{2}\right)^{-1}\exp\left(\frac{p^2+q^2}{|\hbar|}\tan\frac{|t|}{2}\right),$$

and the convergence of the series (17) is then established with $u=u_r$ and $v=u_s$ for $|t|$ sufficiently small.

Remarks:

(1) The property that X^{*n}, for the Moyal star product, is a function $K_n(X)$ of X if X is a homogeneous polynomial of degree two on $\mathbb{R}^2$ does not remain valid on $\mathbb{R}^{2\ell}$ with $\ell>1$. This property does not remain valid for a general ordering, even for $\ell=1$.

(2) If $X=(Ax|x)$ is a homogeneous polynomial of degree two on $\mathbb{R}^2$, where A is a symmetric 2×2 matrix with complex entries, and if we set $X^{*n}=K_n(X)$ for the Moyal star product, then it is easy to show by using Remark 3 following Theorem 2 that the recursion relation (3) can be written in the form

$$K_{n+1}(X)=XK_n(X)+d\hbar^2K_n'(X)+d\hbar^2XK_n''(X)$$

with $d=-\det A$.

ACKNOWLEDGMENTS

I would like to dedicate this work to the memory of Moshé Flato who initiated me to the theory of star products. I am indebted to Daniel Sternheimer for numerous suggestions and helpful advice and I thank Giuseppe Dito for interesting discussions and for a careful reading of the manuscript.

A system of nonlinear algebraic equations connected with the multisoliton solution of the Benjamin–Ono equation

Yoshimasa Matsuno[a)]
Department of Applied Science, Faculty of Engineering, Yamaguchi University, Ube 755-8611, Japan

(Received 29 August 2003; accepted 11 November 2003)

The multisoliton solution of the Benjamin–Ono equation is derived from the system of nonlinear algebraic equations. This finding is unexpected from the scheme of the inverse scattering transform method, which constructs the multisoliton solution through the system of linear algebraic equations. The anlaysis developed here is also applied to the rational multisoliton solution of the Kadomtsev–Petviashvili equation. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1641153]

I. INTRODUCTION

The Benjamin–Ono (BO) equation describes the unidirectional prepagation of weakly nonlinear internal waves in a stratified fluid of great depth.[1–3] It can be written in an appropriate dimensionless form as

$$u_t+2uu_x+Hu_{xx}=0, \tag{1.1a}$$

where $u=u(x,t)$ is a real function representing the amplitude of the wave, the operator H is the Hilbert transform defined by

$$Hu(x,t)=\frac{1}{\pi}P\int_{-\infty}^{\infty}\frac{u(y,t)}{y-x}dy, \tag{1.1b}$$

and the subscripts t and x appended to u denote partial differentiation.

A large number of studies have been done for the mathematical structure of the BO equation.[4] In particular, the initial value problem under vanishing boundary conditions has been solved by means of the inverse scattering transform (IST) method.[5,6] The IST provides a procedure to construct solutions explicitly for a certain class of initial data. A typical example is the reflectionless potential (or multisoliton potential) for which the solution is obtained simply by solving the system of *linear* algebraic equations. This remarkable feature is common to the completely integrable nonlinear evolution equations solvable by the IST.

The purpose of this paper is to show that the multisoliton solution of the BO equation can also be derived from a system of *nonlinear* algebraic equations. Since the IST reduces the nonlinear problem to the linear one characterized by a system of linear integral equations, the novel result presented here will not be predicted from the scheme of the IST. An alternative derivation of the multisoliton solution described here will give a new insight into the structure of the solution.

In Sec. II, we first describe the N-soliton (N: positive integer) solution of the BO equation constructed by the IST. Then, we introduce a system of nonlinear algebraic equations and show that it leads to the N-soliton solution as well. This fact is verified based only on an elementary theory of determinants. Section III is devoted to concluding remarks where the analysis, similar to

a)Electronic mail: matsuno@yamaguchi-u.ac.jp

that developed here, is aplied to the rational N-soliton solution of the Kadomtsev–Petviashvili (KP) equation. In the Appendix, we summarize the Lagrange interpolation formula and related formulas which will be used in Sec. II.

II. SYSTEM OF NONLINEAR ALGEBRAIC EQUATIONS

A. Notation

Before entering into the detailed analysis, we introduce the notation which will be used throughout this paper.

1. Matrices

The $N\times N$ matrices $M,V,\tilde{V},W,Z,F,$ and $\tilde{F}$ are defined by the relations

$$M=(m_{jk})=(\zeta_j\delta_{jk}-2i(1-\delta_{jk})(a_j-a_k)^{-1}),\quad \zeta_j=x-a_jt-x_{j0}+\frac{i}{a_j}, \tag{2.1a}$$

$$V=(v_{jk})=(\alpha_j^{k-1}), \tag{2.1b}$$

$$\tilde{V}=(\tilde{v}_{jk})=\left(\frac{\partial|V|}{\partial v_{jk}}\right),\quad |V|=\det V, \tag{2.1c}$$

$$W=(w_{jk})=((k-1)\alpha_j^{k-2}), \tag{2.1d}$$

$$Z=(z_{jk})=(z_j\delta_{jk}),\quad z_j=\zeta_j+\sum_{\substack{k=1\\(k\neq j)}}^{N}\frac{1}{\alpha_j-\alpha_k}, \tag{2.1e}$$

$$F=Z-WV^{-1}=(f_{jk}), \tag{2.1f}$$

$$\tilde{F}=(\tilde{f}_{jk})=\left(\frac{\partial|F|}{\partial f_{jk}}\right),\quad |F|=\det F, \tag{2.1g}$$

where δ_{jk} is Kronecker's delta, a_j and x_{j0} are real constants satisfying the conditions $a_j>0$,$a_j\neq a_k$ for $j\neq k$ $(j,k=1,2,\ldots,N)$ and $\alpha_j=ia_j/2$ $(j=1,2,\ldots,N)$. Note that V is the Vandermonde matrix and $\tilde{v}_{jk}$ is the cofactor of v_{jk}. We use the convention that a term like $(1-\delta_{jk})(a_j-a_k)^{-1}$ is taken to be zero if $j=k$.

2. Vectors

The column vectors $\mathbf{x}$ and $\mathbf{b}$ with N elements are defined as follows:

$$\mathbf{x}={}^t(x_j)={}^t(s_{N-j+1}), \tag{2.2a}$$

$$\mathbf{b}={}^t(b_j)={}^t(-z_j\alpha_j^N+N\alpha_j^{N-1}), \tag{2.2b}$$

where the superscript t denotes the transpose and the elements s_{N-j+1} will be defined later.

3. Polynomials

The polynomials $g(x)$ and $g_k(x)$ are defined by the relations

$$g(x)=\prod_{j=1}^{N}(x-\alpha_j)=\sum_{s=0}^{N}(-1)^s\sigma_s x^{N-s},\quad (\sigma_0=1), \tag{2.3a}$$

$$g_k(x)=\prod_{\substack{j=1\\(j\neq k)}}^{N}(x-\alpha_j)=\sum_{s=0}^{N-1}(-1)^s\sigma_{s,k}x^{N-1-s},\ \ (k=1,2,\ldots,N), \tag{2.3b}$$

where σ_s are fundamental symmetric polynomials constructed from α_j according to the relations

$$\sigma_1=\sum_{j=1}^{N}\alpha_j,\ \ \sigma_2=\sum_{\substack{j,k=1\\(j<k)}}^{N}\alpha_j\alpha_k,\ldots,\ \ \sigma_N=\prod_{j=1}^{N}\sigma_j, \tag{2.3c}$$

and $\sigma_{k,s}$ in (2.3b) is expressed in terms of σ_p and α_k as[7]

$$\sigma_{k,s}=\sum_{p=0}^{s}\sigma_p(-\alpha_k)^{s-p}. \tag{2.3d}$$

It follows from the definition (2.3) that $g'(\alpha_j)=g_j(\alpha_j)$ where $g'(x)=dg(x)/dx$.

B. *N*-soliton solution of the BO equation

Let ϕ_j be the solution of the following system of *linear* algebraic equations

$$\zeta_j\phi_j-2i\sum_{\substack{k=1\\(k\neq j)}}^{N}\frac{\phi_k}{a_j-a_k}=1,\ \ (j=1,2,\ldots,N). \tag{2.4}$$

Then, the N-soliton solution of the BO equation is given by[5,6,8]

$$u=i\sum_{j=1}^{N}(\phi_j-\phi_j^*)=i\frac{\partial}{\partial x}\ln\frac{f}{f^*}, \tag{2.5}$$

where $f=|M|$ and ϕ_j^* denotes the complex conjugate of ϕ_j. We note that a direct proof of the N-soliton solution, without recourse to the IST, has been performed on the basis of Eq. (2.4).[8] The last expression in (2.5) is very important in the present analysis. It stems from the relation[8]

$$\sum_{j=1}^{N}\phi_j=\frac{f_x}{f}. \tag{2.6}$$

To show (2.6), we note the relation

$$f_x=\begin{vmatrix} m_{11} & \cdots & m_{1N} & 1\\ \vdots & \ddots & \vdots & \vdots\\ m_{N1} & \cdots & m_{NN} & 1\\ -1 & \cdots & -1 & 0\end{vmatrix}, \tag{2.7}$$

which is derived with use of the formula

$$\begin{vmatrix} m_{11} & \cdots & m_{1N} & x_1\\ \vdots & \ddots & \vdots & \vdots\\ m_{N1} & \cdots & m_{NN} & x_N\\ y_1 & \cdots & y_N & z\end{vmatrix}=|M|z-\sum_{j,k=1}^{N}\tilde{m}_{jk}x_jy_k, \tag{2.8}$$

combined with the relation $\sum_{\substack{j,k=1\\(j\neq k)}}^{N}\tilde{m}_{jk}=0$ ($\tilde{m}_{jk}$: cofactor of m_{jk}).

C. System of nonlinear algebraic equations

Let ψ_k be the solution of the following system of *nonlinear* algebraic equations:

$$\sum_{k=1}^{N} \frac{1}{\alpha_j-\alpha_k+\psi_k}=\zeta_j+\sum_{\substack{k=1\\(k\neq j)}}^{N} \frac{1}{\alpha_j-\alpha_k}\equiv z_j \quad (j=1,2,\ldots,N). \tag{2.9}$$

Now, we show that the above system of equations yields the N-soliton solution (2.5) of the BO equation. The basic idea in performing the analysis is to transform the nonlinear system (2.9) into the linear system by introducing the nonlinear transformation

$$s_1=\sum_{j=1}^{N}(\psi_j-\alpha_j),\quad s_2=\sum_{\substack{j,k=1\\(j<k)}}^{N}(\psi_j-\alpha_j)(\psi_k-\alpha_k),\ldots,s_N=\prod_{j=1}^{N}(\psi_j-\alpha_j). \tag{2.10}$$

It then follows that the system (2.9) can be transformed into the system of linear algebraic equations for the new variables s_j

$$\sum_{k=1}^{N}\{z_j\alpha_j^{k-1}-(k-1)\alpha_j^{k-2}\}s_{N-k+1}=-z_j\alpha_j^N+N\alpha_j^{N-1} \quad (j=1,2,\ldots,N). \tag{2.11}$$

If we use the notations (2.1) and (2.2), we can write (2.11) compactly in the matrix form

$$(ZV-W)\mathbf{x}=FV\mathbf{x}=\mathbf{b}. \tag{2.12}$$

D. Solution

To solve Eq. (2.12), we first observe that $|F|\neq 0$ and $|V|\neq 0$. The former relation follows from $|F|=|M|$ [see (2.25) later] together with a fact $|M|\neq 0$ for real x and t which is derived from (2.4). The latter relation is obvious since $|V|=\Pi_{\substack{j,k=1\\(j>k)}}^{N}(\alpha_j-\alpha_k)$ (:Vandermonde determinant) and $\alpha_j\neq\alpha_k$ for $j\neq k$. With these facts in mind, the solution of Eq. (2.12) is readily obtained by using Cramer's rule as

$$\mathbf{x}=\frac{{}^t(\tilde{F}\tilde{V})\mathbf{b}}{|F||V|}. \tag{2.13}$$

Hence, the jth element of $\mathbf{x}$ is given by

$$x_j=\frac{1}{|F||V|}\sum_{m,n=1}^{N} b_m\tilde{f}_{mn}\tilde{v}_{nj} \quad (j=1,2,\ldots,N), \tag{2.14}$$

where $\tilde{v}_{nj}$ is the cofactor of v_{nj}. In terms of (2.3b) and (2.3d), the explicit expression of $\tilde{v}_{nj}$ reads as[7]

$$\tilde{v}_{nj}=\frac{(-1)^{N-j}\sigma_{n,N-j}}{g_n(\alpha_n)}|V|. \tag{2.15}$$

Using the formula (2.8), we can put (2.14) into the form of the bordered determinant

$$x_j=-\frac{1}{|F||V|}\begin{vmatrix} f_{11} & \cdots & f_{1N} & b_1\\ \vdots & \ddots & \vdots & \vdots\\ f_{N1} & \cdots & f_{NN} & b_N\\ \tilde{v}_{1j} & \cdots & \tilde{v}_{Nj} & 0\end{vmatrix}. \tag{2.16}$$

The next step is to modify (2.16) by employing the properties of the determinant. Since $V^{-1}={}^t\tilde{V}/|V|$, one sees that $F=Z-WV^{-1}=Z-W{}^t\tilde{V}/|V|$. In view of (2.1d), (2.1e), and (2.3b), the (j,k) element of F takes the form

$$f_{jk}=z_j\delta_{jk}-\frac{1}{|V|}\sum_{l=1}^{N} w_{jl}\tilde{v}_{kl}=z_j\delta_{jk}-\frac{g_k'(\alpha_j)}{g_k(\alpha_k)}, \tag{2.17}$$

where $g_k'(\alpha_j)=dg_k(x)/dx|_{x=\alpha_j}$. The relations

$$\frac{g_j'(\alpha_j)}{g_j(\alpha_j)}=\sum_{\substack{k=1\\(k\neq j)}}^{N}\frac{1}{\alpha_j-\alpha_k},\quad g_k'(\alpha_j)=\frac{g_j(\alpha_j)}{\alpha_j-\alpha_k}\quad (j\neq k), \tag{2.18}$$

follow immediately from the definition (2.3b) of $g_k(x)$. Substituting (2.18) into (2.17), we arrive at the expression

$$f_{jk}=\zeta_j\delta_{jk}-(1-\delta_{jk})\frac{1}{\alpha_j-\alpha_k}\frac{g_j(\alpha_j)}{g_k(\alpha_k)}. \tag{2.19}$$

Let $|B|$ be the $(N+1)\times(N+1)$ bordered determinant which appears on the right-hand side of (2.16). We modify $|B|$ in a sequence of steps. First, we add the kth column multiplied by α_k^N to the $(N+1)$th column $(k=1,2,\ldots,N)$. Then, after some calculations, the $(n,N+1)$ element of $|B|$ which is referred to as $b_{n,N+1}$ is found to be as

$$\begin{aligned} b_{n,N+1}&=-\sum_{\substack{k=1\\(k\neq n)}}^{N}\frac{\alpha_k^n}{\alpha_n-\alpha_k}\frac{g_n(\alpha_n)}{g_k(\alpha_k)}-\sum_{\substack{k=1\\(k\neq n)}}^{N}\frac{\alpha_n^N}{\alpha_n-\alpha_k}+N\alpha_n^{N-1}\\ &=g_n(\alpha_n)\sum_{s=1}^{N}\alpha_n^{s-1}\sum_{k=1}^{N}\frac{\alpha_k^{N-s}}{g_k(\alpha_k)}-\alpha_n^N\sum_{\substack{k=1\\(k\neq n)}}^{N}\frac{1}{\alpha_n-\alpha_k}\left(\frac{g_n(\alpha_n)}{g_k(\alpha_k)}+1\right). \end{aligned} \tag{2.20}$$

If we use the formulas (A2) and (A3), this expression simplifies to

$$b_{n,N+1}=g_n(\alpha_n)\quad (n=1,2,\ldots,N). \tag{2.21}$$

On the other hand, the $(N+1,N+1)$ element of $|B|$ which is referred to as $b_{N+1,N+1}$ is given by

$$b_{N+1,N+1}=(-1)^{N-j}|V|\sum_{k=1}^{N}\frac{\sigma_{k,N-j}\alpha_k^N}{g_k(\alpha_k)}=(-1)^{N-j}|V|\sigma_{N-j+1}, \tag{2.22}$$

where the formula (A7) has been used in deriving the last expression of (2.22). Thus, $|B|$ is modified into the form

$$|B|=\begin{vmatrix} f_{11} & \cdots & f_{1N} & g_1(\alpha_1)\\ \vdots & \ddots & \vdots & \vdots\\ f_{N1} & \cdots & f_{NN} & g_N(\alpha_N)\\ \tilde{v}_{1j} & \cdots & \tilde{v}_{Nj} & b_{N+1,N+1}\end{vmatrix}. \tag{2.23}$$

Next, we extract the factor $g_j(\alpha_j)$ from the jth row of $|B|$ $(j=1,2,\ldots,N)$ and the factor $g_j^{-1}(\alpha_j)$ from the jth column of $|B|$ $(j=1,2,\ldots,N)$, respectively, and see that these factors cancel out completely. If we combine this result with (2.15), (2.19), and (2.22) and note the relations $\alpha_j=ia_j/2(j=1,2,\ldots,N)$, $|B|$ is transformed into the form

$$|B|=(-1)^{N-j}|V|\begin{vmatrix} m_{11} & \cdots & m_{N1} & 1 \\ \vdots & \ddots & \vdots & \vdots \\ m_{1N} & \cdots & m_{NN} & 1 \\ \sigma_{1,N-j} & \cdots & \sigma_{N,N-j} & \sigma_{N-j+1} \end{vmatrix}. \tag{2.24}$$

The relation

$$|F|=|M| \tag{2.25}$$

follows from (2.1a) and (2.19) by a similar calculation. Substititing (2.24) and (2.25) into (2.16) and using the formula $|{}^tM|=|M|$, we finally obtain

$$x_j=-\frac{(-1)^{N-j}}{|M|}\begin{vmatrix} m_{11} & \cdots & m_{1N} & \sigma_{1,N-j} \\ \vdots & \ddots & \vdots & \vdots \\ m_{N1} & \cdots & m_{NN} & \sigma_{N,N-j} \\ 1 & \cdots & 1 & \sigma_{N-j+1} \end{vmatrix} \quad (j=1,2,\ldots,N). \tag{2.26}$$

In the above solution, the case $j=N$ yields the particularly interesting result since $\sigma_{k,0}=1$ ($k=1,2,\ldots,N$) by virtue of (2.3d). Applying the formula (2.8) into (2.26) with $j=N$, we find that

$$s_1=x_N=-\sigma_1+\frac{1}{|M|}\begin{vmatrix} m_{11} & \cdots & m_{1N} & 1 \\ \vdots & \ddots & \vdots & \vdots \\ m_{N1} & \cdots & m_{NN} & 1 \\ -1 & \cdots & -1 & 0 \end{vmatrix}. \tag{2.27}$$

It then turns out from (2.3c), (2.6), (2.7), (2.10), and (2.27) that

$$\sum_{j=1}^{N}\psi_j=s_1+\sigma_1=\frac{f_x}{f}=\sum_{j=1}^{N}\phi_j. \tag{2.28}$$

If we combine (2.5) with (2.28), we obtain the expression of the BO N-soliton solution in terms of the solution of the nonlinear system (2.9) as

$$u=i\sum_{j=1}^{N}(\psi_j-\psi_j^*). \tag{2.29}$$

III. CONCLUDING REMARK

The analysis developed in this paper can be applied to soliton solutions with the structure similar to that of the N-soliton solution of the BO equation. An example is the rational N-soliton solution of the following KP equation:[9]

$$(u_t+6uu_x+u_{xxx})_x+3\alpha^2u_{yy}=0,\ \ u=u(x,y,t), \tag{3.1}$$

where α is a complex parameter. Consider the system of linear algebraic equations for Φ_j

$$\xi_j\Phi_j+2\sum_{\substack{k=1\\(k\neq j)}}^{N}\frac{\Phi_k}{\nu_j-\nu_k}=1 \quad (j=1,2,\ldots,N), \tag{3.2a}$$

with

$$\xi_j = x + \alpha^{-1}\nu_j y - 3\nu_j^2 t - \xi_{j0}, \tag{3.2b}$$

where ν_j and ξ_{j0} are complex constants satisfying the conditions $\nu_j \neq \nu_k$ for $j \neq k$ $(j,k = 1,2,\ldots,N)$. Then, the N-soliton solution of Eq. (3.1) can be expressed in terms of Φ_j as[10,11]

$$u = 2\frac{\partial}{\partial x}\left[\sum_{j=1}^{N} \Phi_j\right]. \tag{3.3}$$

Suppose that Ψ_j satisfy the following system of nonlinear algebraic equations:

$$\sum_{k=1}^{N} \frac{2}{\nu_j - \nu_k + 2\Psi_k} = \xi_j + \sum_{\substack{k=1 \\ (k\neq j)}}^{N} \frac{2}{\nu_j - \nu_k} \quad (j = 1,2,\ldots,N). \tag{3.4}$$

Then, one finds that

$$\sum_{j=1}^{N} \Phi_j = \sum_{j=1}^{N} \Psi_j. \tag{3.5}$$

In conclusion, it will be worthwhile to comment on an application of the result presented in this paper. We first point out that the analog of the nonlinear system (2.9) has been proposed for providing an alternative way to construct the N-soliton solution of the Korteweg–de Vries (KdV) equation.[12] It has played a central role in the study of the initial value problem of the KdV equation with small dispersion.[12] While the corresponding initial value problem is still unsolved for the BO equation, the nonlinear system (2.9) may be employed to elucidate asymptotic solution of the BO equation in the limit of small dispersion.

APPENDIX: LAGRANGE INTERPOLATION AND RELATED FORMULAS

In this appendix, we summarize the Lagrange interpolation formula and related formulas which are used in Sec. II.

The Lagrange interpolation formula is given by the relation

$$\frac{f(z)}{g(z)} = \sum_{j=1}^{N} \frac{f(\alpha_j)}{g'(\alpha_j)} \frac{1}{z - \alpha_j}, \tag{A1}$$

where $g(z)$ is defined by (2.3a), $f(z)$ is a polynomial of order $N-1$ at most and $g'(\alpha_j) = dg(x)/dx|_{x=\alpha_j} = g_j(\alpha_j)$.

If we put $f(z) = z^m$ $(m = 1,2,\ldots,N-1)$ and integrate (A1) with respect to z along the large circle $|z| = R$ within which all the α_j locate, we obtain $\int_{|z|=R} f(z)/g(z)dz = 2\pi i \delta_{m,N-1}$ in the limit of $R \to \infty$. On the other hand, we can use the Cauchy residue theorem to evaluate the integral of the right-hand side of (A1). This gives the result $2\pi i \Sigma_{j=1}^{N} \alpha_j^N / g'(\alpha_j)$. Equating the two expressions, one obtains

$$\sum_{j=1}^{N} \frac{\alpha_j^m}{g'(\alpha_j)} = \delta_{m,N-1} \quad (m = 1,2,\ldots,N-1). \tag{A2}$$

Applying the same procedure to the integral $\int_{|z|=R} [(z-\alpha_n)g(z)]^{-1} dz$ yields the formula

$$\sum_{\substack{k=1\\(k\neq n)}}^{N} \frac{1}{\alpha_k-\alpha_n}\left(\frac{g_n(\alpha_n)}{g_k(\alpha_k)}+1\right)=0 \quad (n=1,2,\ldots,N). \tag{A3}$$

If we put $f(z)=z^{N-1}, z=x^{-1}$ in (A1), expand it in powers of x and note (2.3a), (A1) can be written in the form

$$1=\left\{\sum_{m=0}^{N}(-1)^m\sigma_m x^m\right\}\sum_{n=0}^{\infty}J_n x^n, \quad J_n\equiv\sum_{j=1}^{N}\frac{\alpha_j^{N-1+n}}{g'(\alpha_j)}. \tag{A4}$$

Comparing the same power of x on both-sides of (A4), one obtains the recurrence relation that determines J_n:

$$J_0=1, \quad \sum_{m=0}^{p}(-1)^m\sigma_m J_{p-m}=0 \quad (p=1,2,\ldots). \tag{A5}$$

The first four of J_n read as

$$J_1=\sigma_1, \quad J_2=-\sigma_2+\sigma_1^2, \quad J_3=\sigma_3-2\sigma_1\sigma_2+\sigma_1^3,$$

$$J_4=-\sigma_4+2\sigma_1\sigma_3+\sigma_2^2-3\sigma_1^2\sigma_2+\sigma_1^4.$$

It follows from (A5) with $p=n+1$ that

$$\sigma_{n+1}=\sum_{m=0}^{n}(-1)^{n-m}\sigma_m J_{n+1-m}. \tag{A6}$$

The following relation is a consequence of (2.3d) and (A6):

$$\sum_{k=1}^{N}\frac{\sigma_{k,j-1}\alpha_k^N}{g'(\alpha_k)}=\sigma_j \quad (j=1,2,\ldots,N). \tag{A7}$$

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 45, NUMBER 2 FEBRUARY 2004

On the reduction and the existence of approximate analytic solutions of some basic nonlinear ODEs in mathematical physics and nonlinear mechanics

Dimitrios E. Panayotounakos[a] and Nikolaos V. Sotiropoulos[a]
Division of Mechanics, Department of Applied Mathematics and Physical Sciences, National Technical University of Athens, GR-15773, Athens, Greece

(Received 10 April 2003; accepted 17 October 2003)

Using series of admissible functional transformations we reduce the one-dimensional axisymmetric nonlinear Schrödinger (NLS) equation, as well as the forced damped nonlinear Duffing (NLD) equation to equivalent nonlinear first-order integrodifferential equations. The forced undamped (NLD) equation results as a special case. The reduced integrodifferential equations are exact. In the limits of small or large values of the parameters characterizing these nonlinear problems, we prove that further reductions lead to first-order nonlinear ordinary differential equations which, except in case of the (NLS) equation, are of the Abel classes. The approximate reduced (NLS) equation admits exact analytic solutions. On the other hand, taking into account the known exact analytic solutions of the equivalent Abel classes of equations we show that there do not exist analytic solutions of the above two nonlinear Duffing oscillators. However, if further asymptotic approximations take place, new approximate analytic solutions concerning the (NLD) equations are constructed. [DOI: 10.1063/1.1635065]

I. INTRODUCTION

Standing and traveling waves in one-dimensional lattices[1–3] and in systems described by nonlinear partial differential equations[4] have been extensively studied in the literature. In Refs. 5 and 6 the existence and properties of standing wave solutions of the nonlinear Schrödinger (NLS) equation were investigated. Also, the study of two-dimensional axisymmetric breathers using Padé approximants was developed in Ref. 7. This problem is governed by a one-dimensional (NLS) equation with cubic nonlinearities. On the other hand, whereas weakly nonlinear oscillators with weak damping can be approximately solved using techniques such as averaging,[8] or multiple-scale,[9] exact solutions of undamped or damped forced oscillators with strong nonlinearities are still leaking. Perturbation problems addressing approximately damped nonlinear free oscillations include Refs. 10–12. Also, the unforced Van der Pol oscillator was studied extensively as the prototypical system possessing a limit cycle and as a model for relaxation oscillation of large values of its parameter. Representative works include Refs. 13 and 14. Additional works focused on the forced response, the resulting bifurcations as parameters change, and on chaotic response of the oscillator (see Refs. 15 and 16).

Recently, it was proved that there are not analytic solutions of the unforced damped Duffing oscillator in terms of known (tabulated) functions.[17] It followed that in order to solve this free damped problem a set of new analytic functions must be defined. The same holds true also for the Van der Pol free oscillator.[18] However, in this last case and for large values of the characteristic parameter (relaxation oscillations) it was proved that there exists an approximate analytic solution.

In this work we deal with the possibility of constructing exact analytic solutions for the one-dimensional axisymmetric (NLS) equation, as well as for the forced damped and undamped (NLD) equations. Using series of admissible functional transformations we succeed in reducing

[a]Electronic mail: tsakstel@central.ntua.gr

the examined nonlinear ODEs to equivalent first-order nonlinear integrodifferential equations, constituting the corresponding intermediate integrals in the phase plane. The reduced equations are exact. In the limits of small or large values of the parameters characterizing these nonlinear problems, we prove that the reduced equations assume approximate asymptotic forms that are amenable to perturbation analysis. These approximations also change the NLS to a solvable nonlinear first-order ODE, and the NLD equations to nonlinear ODEs of the Abel classes. Taking into account the existing known exact analytic solutions of these classes of equations, we show that there do not exist exact analytic solutions of the above two (NLD) problems in terms of known (tabulated) analytic functions. However, if further asymptotic approximations take place, new approximate analytic solutions concerning the two nonlinear Duffing oscillators are constructed.

The solution methodology introduced in the paper is general and can be applied to some of the most interesting second- and third-order nonlinear ODEs of mathematical physics and nonlinear mechanics, including the forced Van der Pol nonlinear oscillator; the Thomas–Fermi equation; the simplified Blasius equation; the Langmuir equation; the Kidder equation,[19] as well the plastic spin equations in simple shear.[20]

II. THE REDUCTION PROCEDURE

We shall investigate three kinds of strongly nonlinear ODEs appearing in the fields of nonlinear mechanics and mathematical physics. The first is the one-dimensional axisymmetric NLS equation, deriving in the ''continuum approximation'' of the equations of motion governing the antiphase vibrations of a two-dimensional array of weakly coupled nonlinear oscillators. The other two are the forced damped and undamped Duffing equations with no linear stiffness terms [(NLD) equations], produced in 1918 by Duffing and describing strongly nonlinear oscillations.

Before we address the issue of the reduction of the above-mentioned equations, we will provide an admissible functional transformation that can reduce a class of nonlinear ODEs to a different class. Consider the nonlinear ODE of the second order of the type

$$\left[f\left(\frac{1}{y'_x} \right) + g(y) \right]'_x - H(x) y'_x = 0, \tag{2.1}$$

where y, f, g, and H are known smooth and continuously differentiable functions. Here the notation $y'_x = dy/dx$, $y''_{xx} = d^2y/dx^2, \ldots$ is used for the derivatives.

The functional transformation

$$w'_\xi = F(x)y(x), \quad \xi = \pm |G(x)| \tag{2.2}$$

in which w and ξ are also smooth and continuously differentiable functions, while F and G are to be determined, furnishes the expressions

$$y'_x = \left(\frac{w'_\xi}{F} \right)'_x = \frac{\pm |G'_x|}{F} w''_{\xi\xi} - \frac{F'_x}{F^2} w'_\xi, \quad \xi'_x = \pm |G'_x|. \tag{2.3}$$

Introducing these results into (2.1) we obtain

$$\left[f\left(\frac{1}{\dfrac{\pm |G'_x|}{F} w''_{\xi\xi} - \dfrac{F'_x}{F^2} w'_\xi} \right) + g\left(\frac{w'_\xi}{F} \right) \right]'_\xi (\pm |G'_x|) - H(x) \left(\frac{\pm |G'_x|}{F} w''_{\xi\xi} - \frac{F'_x}{F^2} w'_\xi \right) = 0. \tag{2.4}$$

We define functions F and G such that

$$\frac{\pm|G_x'|}{F}=\frac{F_x'}{F^2},\quad \pm|G_x'|=H\frac{\pm|G_x'|}{F}, \tag{2.5}$$

that is to say such that

$$F(x)=H(x),\quad (\ln|F|)_x'=\pm|G_x'|=\xi_x'.$$

Thus, the above-mentioned functional transformation takes the following concrete form:

$$w_\xi'=e^\xi y(x),\quad F(x)=H(x)=e^\xi\quad (\ln F=\pm G), \tag{2.6}$$

and the ODE (2.1) is transformed to the equivalent one

$$\left[f\left(\frac{e^{2\xi}}{H_x'}\frac{1}{w_{\xi\xi}''-w_\xi'}\right)+g(e^{-\xi}w_\xi')\right]_\xi'=w_{\xi\xi}''-w_\xi'. \tag{2.7}$$

Note that H_x' can be expressed in terms of the function $\exp(\xi)$ by way of the second of (2.6). Integration of the last equation results in

$$f\left(\frac{e^{2\xi}}{H_x'}\frac{1}{w_{\xi\xi}''-w_\xi'}\right)+g(e^{-\xi}w_\xi')=w_\xi'-w, \tag{2.8}$$

where the constant of integration is missing since both second-order equations (2.1) and (2.8) are equivalent between them.

Let us now analyze the three kinds of prescribed equations.

A. The one-dimensional axisymmetric Schrödinger equation

The type of the equation is

$$\begin{gathered}y_{xx}''+\frac{1}{x}y_x'-\lambda_1 y+\lambda_2 y^k=0,\quad k=\text{integer},\\ \lambda_1>0,\quad \lambda_2>0,\quad -\infty<x<+\infty\quad (x\neq 0).\end{gathered} \tag{2.9}$$

By the first transformation,

$$y(x)=\eta(\xi),\quad \xi=\xi(x)\Rightarrow y_x'=\eta_\xi'\xi_x',\quad y_{xx}''=\eta_{\xi\xi}''\xi_x'^2+\eta_\xi'\xi_{xx}'', \tag{2.10}$$

we reduce (2.9) in the form

$$\xi_x'^2\eta_{\xi\xi}''+\xi_{xx}''\eta_\xi'+\frac{1}{x}\xi_x'\eta_\xi'-\lambda_1\eta+\lambda_2\eta^k=0$$

and we define $\xi(x)$ such that $\xi_{xx}''=-(1/x)\xi_x'$. Thus, the transformation (2.10) becomes

$$y(x)=\eta(\xi),\quad \xi=\pm\ln|x|,\quad -\infty<\xi<+\infty \tag{2.11}$$

and (2.9) is transformed to the following second-order ODE:

$$\begin{gathered}\eta_{\xi\xi}''-(\lambda_1\eta-\lambda_2\eta^k)e^{\pm 2\xi}=0,\\ -\infty<\xi<+\infty,\quad -\infty<\eta<+\infty.\end{gathered} \tag{2.12}$$

The additional substitution

$$\eta(\xi)=\omega(t), \quad t=e^{\pm 2\xi} \tag{2.13}$$

converts (2.12) in

$$\begin{gathered}(t\omega_t')_t'-\tfrac{1}{4}(\lambda_1\omega-\lambda_2\omega^k)=0,\\ 0<t<+\infty, \quad -\infty<\omega<+\infty,\end{gathered} \tag{2.14}$$

while, changing the variables in the last equation, we extract a second-order nonlinear ODE of the type (2.1), that is

$$\left(\frac{t}{t_\omega'}\right)_\omega'-\frac{1}{4}(\lambda_1\omega-\lambda_2\omega^k)t_\omega'=0. \tag{2.15}$$

Thus, referring to the transformation (2.3), that is to say setting

$$w_{\bar\xi}'=g(\omega)t(\omega), \quad \bar\xi=\pm|f(\omega)| \tag{2.16a}$$

with concrete form

$$g(\omega)=\tfrac{1}{4}(\lambda_1\omega-\lambda_2\omega^k), \quad \bar\xi=\pm|f(\omega)|=\pm\ln|g(\omega)|\Rightarrow g(\omega)=e^{\bar\xi}, \tag{2.16b}$$

we succeed in reducing (2.15) in

$$\left[\frac{w_{\bar\xi}'}{\bar\xi_\omega'(w_{\bar\xi\bar\xi}''-w_{\bar\xi}')}\right]_{\bar\xi}'=w_{\bar\xi\bar\xi}''-w_{\bar\xi}', \tag{2.17a}$$

where

$$\begin{gathered}w_{\bar\xi}'=e^{\bar\xi}t(\omega), \quad \lambda_1\omega-\lambda_2\omega^k=4e^{\bar\xi},\\ -\infty<\bar\xi<+\infty, \quad -\infty<\omega<+\infty, \quad 0<t<+\infty.\end{gathered} \tag{2.17b}$$

Integrating (2.17a) we extract the following second-order nonlinear ODE:

$$\frac{w_{\bar\xi}'}{\bar\xi_\omega'}=(w_{\bar\xi}'-w)(w_{\bar\xi}'-w)_{\bar\xi}', \tag{2.18}$$

similar to Eq. (2.8).

By way of the second of (2.17b) we have $\bar\xi=\ln|\frac{1}{4}(\lambda_1\omega-\lambda_2\omega^k)|$ and thus one evaluates

$$\bar\xi_\omega'=\frac{(\lambda_1-k\lambda_2\omega^{k-1})}{(\lambda_1\omega-\lambda_2\omega^k)}.$$

Therefore, (2.18) can be rewritten as

$$\begin{gathered}(w_{\bar\xi}'-w)(w_{\bar\xi}'-w)_{\bar\xi}'=\tfrac{1}{4}e^{-\bar\xi}h(e^{\bar\xi}),\\ h(e^{\bar\xi})=\lambda_1-k\lambda_2\omega^{k-1}.\end{gathered} \tag{2.19}$$

Integration of (2.19) results in

$$\frac{1}{2}(w'_{\bar{\xi}}-w)^2-4\int \frac{e^{\bar{\xi}}}{h(e^{\bar{\xi}})}w'_{\bar{\xi}}d\bar{\xi}=C_1, \tag{2.20a}$$

or, equivalently, in

$$\frac{1}{2}(w'_{\bar{\xi}}-w)^2-4\frac{e^{\bar{\xi}}}{h(e^{\bar{\xi}})}w+4\int \frac{h(e^{\bar{\xi}})e^{\bar{\xi}}-h'_{e^{\bar{\xi}}}(e^{\bar{\xi}})e^{2\bar{\xi}}}{h^2(e^{\bar{\xi}})}wd\bar{\xi}=C_1,$$
$$0<w<+\infty, \quad -\infty<\bar{\xi}<+\infty, \tag{2.20b}$$

where C_1 is a constant of integration.

The nonlinear integrodifferential equation of the first-order (2.20a) constitutes the intermediate integral in the phase plane of the one-dimensional axisymmetric (NLS) equation (2.9).

B. The forced damped nonlinear Duffing equation

The equation under consideration is of the type

$$y''_{xx}+\lambda_3 y'_x-\lambda_1 y+\lambda_2 y^3=A\sin(\Omega x),$$
$$\lambda_1>0, \quad \lambda_2>0, \quad \lambda_3>0, \quad A>0, \tag{2.21}$$
$$-\infty<x<+\infty.$$

By a transformation similar to (2.10), that is to say by the transformation

$$y(x)=z(s), \quad s=\sqrt{\lambda_1}x \tag{2.22}$$

we reduce (2.21) in the form

$$z''_{ss}+\mu z'_s-z+\lambda z^3=\Lambda\sin(\overset{*}{\Omega}s),$$
$$\mu=\frac{\lambda_3}{\sqrt{\lambda_1}}>0, \quad \lambda=\frac{\lambda_2}{\lambda_1}>0, \quad \Lambda=\frac{A}{\lambda_1}>0, \quad \overset{*}{\Omega}=\frac{\Omega}{\sqrt{\lambda_1}}, \tag{2.23}$$
$$-\infty<s<+\infty.$$

Changing the variables and setting simultaneously

$$\omega(z)=\overset{*}{\Omega}s(z), \tag{2.24}$$

we transform (2.24) to the following null nonlinear ODE of the second order:

$$\omega''_{zz}-\overset{*}{\mu}\omega'^2_z+(az-bz^3)\omega'^3_z+c\sin\omega\omega'^3_z=0, \tag{2.25a}$$

$$\overset{*}{\mu}=\frac{\mu}{\overset{*}{\Omega}}=\frac{\lambda_3}{\overset{*}{\Omega}\sqrt{\lambda_1}}>0, \quad a=\frac{1}{\overset{*}{\Omega}^2}>0, \quad b=\frac{\lambda}{\overset{*}{\Omega}^2}>, \quad c=\frac{\Lambda}{\overset{*}{\Omega}^2}=\frac{A}{\overset{*}{\Omega}^2\lambda_1}>0, \quad \overset{*}{\Omega}=\frac{\Omega}{\sqrt{\lambda_1}}>0,$$
$$-\infty<\omega<+\infty, \quad -\infty<z<+\infty. \tag{2.25b}$$

For $\omega_z' \neq 0$ the last equation can be rewritten as follows:

$$\left(\frac{1}{\omega_z'} + c\cos\omega + \overset{*}{\mu} z\right)_z' - (\mathrm{a}z - bz^3)\omega_z' = 0, \tag{2.26}$$

which is of the type (2.1). Introducing transformation (2.2) with concrete form

$$\begin{gathered} w_\xi' = e^\xi \omega(z), \quad az - bz^3 = e^\xi, \\ -\infty < \xi < +\infty, \end{gathered} \tag{2.27}$$

(2.26) becomes

$$\left[\frac{e^{2\xi}}{h(e^\xi)}\frac{1}{w_{\xi\xi}'' - w_\xi'} + c\cos(e^{-\xi}w_\xi') + \overset{*}{\mu} f(e^\xi)\right]_\xi' = w_{\xi\xi}'' - w_\xi', \tag{2.28a}$$

$$h(e^\xi) = \mathrm{a} - 3bz^2, \quad f(e^\xi) = z, \quad \mathrm{a}z - bz^3 = e^\xi,$$

$$\mathrm{a},\ b,\ c,\ \text{and}\ \overset{*}{\mu}\ \text{as in Eq. (2.25b)}, \tag{2.28b}$$

$$-\infty < \xi < +\infty, \quad -\infty < w < +\infty.$$

Setting again

$$e^{-\xi}w(\xi) = p(\xi) \Rightarrow e^{-\xi}(w_\xi' - w) = p_\xi', \quad e^{-\xi}(w_{\xi\xi}'' - w_\xi') = p_{\xi\xi}'' + p_\xi' \tag{2.29}$$

and integrating (2.28a), we extract the following second-order nonlinear ODE:

$$\frac{e^\xi}{h(e^\xi)} + c\cos(p + p_\xi')(p + p_\xi')_\xi' + \overset{*}{\mu} f(e^\xi)(p + p_\xi')_\xi' - e^\xi p_\xi'(p + p_\xi')_\xi' = 0, \tag{2.30}$$

which is similar to Eq. (2.8).

Noting that

$$\int e^\xi p_\xi' p_{\xi\xi}'' \mathrm{d}\xi = \frac{1}{2}e^\xi p_\xi'^2 - \frac{1}{2}\int e^\xi p_\xi'^2 \mathrm{d}\xi,$$

$$\int f(e^\xi)(p + p_\xi')_\xi' \mathrm{d}\xi = f(e^\xi)(p + p_\xi') - \int (p + p_\xi') f_{e^\xi}' e^\xi \mathrm{d}\xi = f(p + p_\xi') - p f_{e^\xi}' e^\xi + \int p f_{e^\xi e^\xi}'' e^{2\xi} \mathrm{d}\xi,$$

the integration of (2.30) results in

$$\begin{aligned} &\frac{1}{2}e^\xi p_\xi'^2 + \frac{1}{2}\int e^\xi p_\xi'^2 d\xi - c\sin(p + p_\xi') - \overset{*}{\mu} f(e^\xi)(p + p_\xi') + \overset{*}{\mu} p f_{e^\xi}' e^\xi - \overset{*}{\mu}\int p f_{e^\xi e^\xi}'' e^{2\xi} \mathrm{d}\xi \\ &\quad - \int \frac{e^\xi}{h(e^\xi)} \mathrm{d}\xi = C_1, \end{aligned} \tag{2.31}$$

where C_1 is an integration constant.

The nonlinear integrodifferential equation of the first-order (2.31) constitutes the intermediate integral in the phase plane of the forced damped (NLD) oscillator (2.21).

C. The forced undamped nonlinear Duffing equation

This equation has the following restricted form in comparison with (2.21):

$$y''_{xx}-\lambda_1 y+\lambda_2 y^3=A\sin(\Omega x),$$
$$\lambda_1>0,\quad \lambda_2>0,\quad A>0, \tag{2.32}$$
$$-\infty<x<+\infty.$$

In other words it is a special case of (2.21). Thus, according to the same procedure as previously developed, the intermediate integral corresponding to (2.31) in the case of the forced undamped (NLD) oscillator becomes through (2.31) by setting $\overset{*}{\mu}=0$ $(\lambda_3=0)$, that is

$$\frac{1}{2}e^{\xi}p'^{2}_{\xi}+\frac{1}{2}\int e^{\xi}p'^{2}_{\xi}\mathrm{d}\xi-c\sin(p+p'_{\xi})-\int\frac{e^{\xi}}{h(e^{\xi})}\mathrm{d}\xi=C_1. \tag{2.33}$$

Here, C_1 is an integration constant, while $p(\xi)$ and $h(e^{\xi})$ are as in Eqs. (2.29) and (2.28b), respectively.

The three nonlinear integrodifferential equations (2.20a), (2.31), and (2.33), constitute the intermediate integrals in the phase plane of the corresponding one-dimensional axisymmetric (NLS) equation, and the forced damped and undamped (NLD) oscillators. They are exact since no approximations were made in the already introduced admissible functional transformations. As these equations do not admit exact analytic solutions, as a result one must resort to asymptotic approximations by considering specific ranges of the parameters being introduced. In Sec. III we focus on the limits of small or large values of the parameter $\lambda=\lambda_2/\lambda_1$, $(1/\lambda=\lambda_1/\lambda_2)$, and derive simplified approximations for the reduced three equations.

III. APPROXIMATIONS: EXISTENCE AND NONEXISTENCE OF EXACT ANALYTIC SOLUTIONS

We now consider the three types of equations examined in Sec. II and investigate their reductions to equivalent nonlinear differential equations of the first order. Our study of the reduced equations indicates the absence of exact analytic solutions of the original (NLS) equation and the (NLD) oscillators, e.g., the absence of exact solutions in terms of known (tabulated) functions.

A. The one-dimensional axisymmetric (NLS) equation with cubic nonlinearities

In Ref. 7 it was proved that the study of two-dimensional axisymmetric breathers using Padé approximants leads to the solution of a one-dimensional (NLS) equation with cubic nonlinearities. Thus, according to the results of this reference and in order to have the same order of nonlinearities for the three types of equations being examined, we prefer to investigate the NLS equation with cubic nonlinearities.

In this case the function $h(e^{\bar{\xi}})$ of the intermediate integral (2.20a) becomes

$$h(e^{\bar{\xi}})=\lambda_1-3\lambda_2\omega^2,\quad \lambda_1\omega-\lambda_2\omega^3=4e^{\bar{\xi}}. \tag{3.1}$$

We express the cubic (Cardan) equation $\lambda_1\omega-\lambda_2\omega^3=4e^{\bar{\xi}}$ in the form

$$\omega^3+\overset{*}{p}\omega+\overset{*}{q}=0, \tag{3.2a}$$

with

$$\overset{*}{p}=-\lambda,\quad \overset{*}{q}=\frac{4}{\lambda_2}e^{\bar{\xi}},\quad \lambda=\frac{\lambda_1}{\lambda_2} \tag{3.2b}$$

and discriminant $\overset{*}{Q}$ given by the well-known formula

$$\overset{*}{Q}=\left(\frac{\overset{*}{p}}{3}\right)^3+\left(\frac{\overset{*}{q}}{2}\right)^2=-\frac{\lambda^3}{27}+\left(\frac{2e^{\overline{\xi}}}{\lambda_2}\right)^2. \tag{3.2c}$$

When $\overset{*}{Q}<0$, Eq. (3.2a) possesses three real, distinct roots, whereas when $\overset{*}{Q}>0$ there exist a single real root and a complex conjugate pair of roots. The case $\overset{*}{Q}=0$ must be rejected since, if $\overset{*}{Q}$ vanishes, the variable $\overline{\xi}$, and therefore the variable y, become constants. Based on these observations we now distinguish the following cases.

Case 1: $\overset{*}{Q}<0$. The distinct real roots of the cubic equation (3.2a) are ($\overset{*}{q}<0$)

$$\omega_1=2\sqrt{-\frac{\overset{*}{p}}{3}}\cos\frac{\alpha}{3}>0,\quad \omega_2=-2\sqrt{-\frac{\overset{*}{p}}{3}}\cos\frac{\alpha-\pi}{3}<0,$$

$$\omega_3=-2\sqrt{-\frac{\overset{*}{p}}{3}}\cos\frac{\alpha+\pi}{3}<0,\quad \cos\alpha=-\frac{\overset{*}{q}}{2\sqrt{-\left(\frac{\overset{*}{p}}{3}\right)^3}},\quad -\frac{\pi}{2}<\alpha<\pi. \tag{3.3}$$

Case 2: $\overset{*}{Q}>0$. The one real root of the cubic equation (3.2a) is given by

$$\omega=A+B,\quad A=\sqrt[3]{-\frac{\overset{*}{q}}{2}+\sqrt{\overset{*}{Q}}},\quad B=\sqrt[3]{-\frac{\overset{*}{q}}{2}-\sqrt{\overset{*}{Q}}}. \tag{3.4}$$

By now, we focus on the limits of small or large values of the parameter $\lambda=\lambda_1/\lambda_2>0$, and derive simplified approximations for the nonlinear integrodifferential equation (2.20a).

The limit $0<\lambda=\lambda_1/\lambda_2\ll 1$. We develop an analytic approximation to the reduced equation (2.20a) in the limit of small values of the parameter $\lambda=\lambda_1/\lambda_2$. Recalling formula (3.2c) giving the discriminant $\overset{*}{Q}$ of the cubic equation (3.2a) we observe that, if $\lambda\ll 1$, then $\overset{*}{Q}$; is positive, e.g., $\overset{*}{Q}=(2e^{\overline{\xi}}/\lambda_2)^2+\mathbf{O}(\lambda^3)>0$, and the real root of Eq. (3.2a) becomes

$$\omega=-\left(\frac{4e^{\overline{\xi}}}{\lambda_2}\right)^{1/3}\Rightarrow e^{\overline{\xi}/3}=-\left(\frac{\lambda_2\omega^3}{4}\right)^{1/3}. \tag{3.5}$$

This approximation permits us to write the following:

(i)

$$\overline{\xi}=\ln\left|\frac{\lambda_2\omega^3}{4}\right|=\ln\left|\frac{\lambda_2}{4}\right|+\ln|\omega|^3=\ln\left|\frac{\lambda_2}{4}\right|+3\ln|\omega|=\ln\left|\frac{\lambda_2}{4}\right|+3\ln\left|\frac{4\lambda_1 e^{\overline{\xi}}}{\lambda_1\lambda_2}\right|=\ln\left|\frac{\lambda_2}{4}\right|+\ln\left|\frac{4}{\lambda_1}\right|+\ln|\lambda e^{\overline{\xi}}|$$

$$=\ln\left|\frac{\lambda_2}{\lambda_1}\right|+n\lambda e^{\overline{\xi}}-1-C_0+\mathbf{O}(\lambda^2),\quad C_0=\sum_{m=2,3,\ldots}^{n}\frac{1}{m}.$$

For simplicity and without loss of generality one neglects the constant C_0 and takes $n=1$. Thus one obtains

$$\lambda e^{\bar{\xi}}=\bar{\xi}+1-\ln\left|\frac{1}{\lambda}\right|\Rightarrow e^{\bar{\xi}}=\frac{\bar{\xi}+1-\ln\left|\frac{1}{\lambda}\right|}{\lambda}. \tag{3.6}$$

(ii)

$$\frac{\bar{\xi}}{3}=\frac{1}{3}\ln\left|\frac{\lambda_2\omega^3}{4}\right|=\frac{1}{3}\ln\left|\frac{\lambda_2}{4}\right|+\ln|\omega|=\frac{1}{3}\ln\left|\frac{\lambda_2}{4}\right|+\ln\left|\frac{4e^{\bar{\xi}}}{\lambda_2}\right|^{1/3}=\frac{1}{3}\ln\left|\frac{\lambda_2}{4}\right|+\frac{1}{3}\ln\left|\frac{4}{\lambda_1}\right|+\ln|\lambda e^{\bar{\xi}}|^{1/3}$$

$$=\frac{1}{3}\ln\left|\frac{1}{\lambda}\right|+[(\lambda e^{\bar{\xi}})^{1/3}-1].$$

Thus, we obtain

$$(\lambda e^{\bar{\xi}})^{1/3}=\frac{\bar{\xi}}{3}+1-\frac{1}{3}\ln\left|\frac{1}{\lambda}\right|\Rightarrow e^{\bar{\xi}/3}=\frac{\bar{\xi}+3-\ln\left|\frac{1}{\lambda}\right|}{3\lambda^{1/3}}. \tag{3.7}$$

Recalling the intermediate integral (2.20a) we evaluate

$$\frac{e^{\bar{\xi}}}{h(e^{\xi})}=\frac{e^{\bar{\xi}}}{\lambda_1-3\lambda_2\omega^2}=\frac{1}{\lambda_1}\frac{e^{\bar{\xi}}}{1-3\frac{1}{\lambda}\omega^2}=\frac{1}{\lambda_1}\frac{e^{\bar{\xi}}}{1-\frac{3}{\lambda}\left(\frac{4e^{\xi}}{\lambda_2}\right)^2},$$

which, since $1/\lambda\gg 1$, and based on the previous results, it can be approximately written as

$$\frac{e^{\bar{\xi}}}{h(e^{\xi})}\cong\sim-\frac{e^{\bar{\xi}}}{3\lambda_2\left(\frac{4e^{\xi}}{\lambda_2}\right)^{2/3}}=-\frac{e^{\bar{\xi}/3}}{6\sqrt[3]{2}\lambda_2^{1/3}}=-\frac{1}{18\sqrt[3]{2}}\frac{\bar{\xi}+3-\ln\left|\frac{1}{\lambda}\right|}{\sqrt[3]{\lambda_1}}.$$

We estimate now the integral appearing in (2.20a) as follows:

$$4\int\frac{e^{\bar{\xi}}}{h(e^{\xi})}w'_{\bar{\xi}}d\bar{\xi}=-\frac{2}{3\sqrt[3]{2}\sqrt[3]{\lambda_2}}\int w'_{\bar{\xi}}e^{\bar{\xi}/3}d\bar{\xi}=-\frac{2}{\sqrt[3]{2}\sqrt[3]{\lambda_2}}\int w'_{\bar{\xi}}d(e^{\bar{\xi}/3})$$

$$=-\frac{\sqrt[3]{4}}{\sqrt[3]{\lambda_2}}\int w'_{\bar{\xi}}d\left(\frac{\bar{\xi}+3-\ln\left|\frac{1}{\lambda}\right|}{3\sqrt[3]{\lambda}}\right)=-\frac{\sqrt[3]{4}}{3\sqrt[3]{\lambda_1}}w.$$

Thus, the integrodifferential equation (2.20a), constituting the exact intermediate integral of the (NLS) equation (2.9) with cubic nonlinearities, can be approximated in case $0<\lambda\ll 1$ by the following first-order nonlinear ODE:

$$\frac{1}{2}(w'_{\bar{\xi}}-w)^2+\frac{\sqrt[3]{4}}{3\sqrt[3]{\lambda_1}}w=C_1. \tag{3.8}$$

The limit $+\infty>\lambda=\lambda_1/\lambda_2\gg 1$. In this case the discriminant $\overset{*}{Q}$ of the cubic equation (3.2c) becomes negative. In fact, since $0<1/\lambda\ll 1$, we have

$$\overset{*}{Q}=\left(\frac{\overset{*}{p}}{3}\right)^3+\left(\frac{\overset{*}{q}}{2}\right)^2=-\frac{\lambda^3}{27}+\left(\frac{2\lambda e^{\bar{\xi}}}{\lambda_1}\right)^2=-\left(\frac{\lambda}{3}\right)^3\left[1-\left(\frac{3}{\lambda}\right)^3\left(\frac{2\lambda e^{\bar{\xi}}}{\lambda_1}\right)^2\right]$$

$$=-\left(\frac{\lambda}{3}\right)^3\left[1-\frac{1}{\lambda}\left(\frac{6\sqrt{3}e^{\bar{\xi}}}{\lambda_1}\right)^2\right]=-\left(\frac{\lambda}{3}\right)^3+\mathbf{O}(\lambda^{-1})<0.$$

Then, the positive real root ω of (3.2a) is given by the first of equations (3.3) and it can be asymptotically approximated by expanding the general form of the variable α in terms of large parameter. Indeed, taking into account the fourth of equations (3.3) we find

$$\alpha=\arccos\left(-\frac{2e^{\bar{\xi}}}{\lambda_2}\frac{1}{\sqrt{\left(\frac{\lambda}{3}\right)^3}}\right)$$

$$=\frac{\pi}{2}-\left[-\frac{2e^{\bar{\xi}}}{\lambda_2}\frac{1}{\sqrt{\left(\frac{\lambda}{3}\right)^3}}-\frac{1}{6}\left(\frac{2e^{\bar{\xi}}}{\lambda_2}\frac{1}{\sqrt{\left(\frac{\lambda}{3}\right)^3}}\right)^3-\cdots\right]$$

$$=\frac{\pi}{2}+\frac{2e^{\bar{\xi}}}{\lambda_2}\frac{1}{\sqrt{\left(\frac{\lambda}{3}\right)^3}}+\mathbf{O}(\lambda^{-9/2}),$$

and thus we evaluate

$$\frac{\alpha}{3}=\frac{\pi}{6}+\frac{2\sqrt{3}e^{\bar{\xi}}}{\lambda_2\lambda^{3/2}}+\mathbf{O}(\lambda^{-9/2}).$$

Therefore we obtain

$$\cos\frac{\alpha}{3}=\cos\left(\frac{\pi}{6}+\frac{2\sqrt{3}e^{\bar{\xi}}}{\lambda_2\lambda^{3/2}}\right)=\frac{\sqrt{3}}{2}(1+\mathbf{O}(\lambda^{-3}))-\frac{1}{2}\left(\frac{2\sqrt{3}e^{\bar{\xi}}}{\lambda_2\lambda^{3/2}}+\mathbf{O}(\lambda^{-9/2})\right)$$

$$=\frac{\sqrt{3}}{2}-\frac{\sqrt{3}e^{\bar{\xi}}}{\lambda_2\lambda^{3/2}}+\mathbf{O}(\lambda^{-3}),$$

and the above-mentioned real root ω is asymptotically approximated in terms of large parameter as

$$\omega=\sqrt{\lambda}-\frac{\sqrt{3}e^{\bar{\xi}}}{\lambda_2\lambda}+\mathbf{O}(\lambda^{-3}). \tag{3.9}$$

The above-given approximations enable us to also write the following approximations:

(i)

$$\bar{\xi}=\ln\left|\frac{\lambda\lambda_2}{2}(\sqrt{\lambda}-\omega)\right|=\ln\left|\frac{\lambda_1}{2}\right|+\ln|\sqrt{\lambda}-\omega|=\ln\left|\frac{\lambda_1}{2}\right|+\ln\left|\sqrt{\lambda}-\sqrt{\lambda}+\frac{2e^{\bar{\xi}}}{\lambda\lambda_2}\right|$$

$$=\ln\left|\frac{\lambda_1}{2}\right|+\ln\left|\frac{2e^{\bar{\xi}}}{\lambda\lambda_2}\right|=\ln\left|\frac{\lambda_1}{2}\right|+n\frac{2e^{\bar{\xi}}}{\lambda\lambda_2}-1-C_0+\mathbf{O}(\lambda^{-2}),\quad C_0=\sum_{m=2,3,\ldots.}^{n}\frac{1}{m}.$$

Neglecting the constant C_0 and taking $n=1$, one obtains

$$\frac{2e^{\bar{\xi}}}{\lambda_2}=\lambda(\bar{\xi}+1-K),\quad K=\ln\left|\frac{\lambda_1}{2}\right|. \tag{3.10}$$

(ii)

$$\begin{aligned}\frac{e^{\bar{\xi}}}{h(e^{\bar{\xi}})}&=\frac{e^{\bar{\xi}}}{\lambda_1-3\lambda_2\left(\sqrt{\lambda}-\dfrac{2e^{\bar{\xi}}}{\lambda\lambda_2}\right)^2}=\frac{e^{\bar{\xi}}}{\lambda_1-3\lambda_2\lambda-3\lambda_2\left(\dfrac{2e^{\bar{\xi}}}{\lambda\lambda_2}\right)^2+6\lambda_2\sqrt{\lambda}\dfrac{2e^{\bar{\xi}}}{\lambda\lambda_2}}\\&=-\frac{1}{2\lambda_1}\frac{e^{\bar{\xi}}}{\dfrac{3}{2\lambda^3}\left(\dfrac{2e^{\bar{\xi}}}{\lambda_2}\right)^2-\dfrac{3}{\lambda^{3/2}}\left(\dfrac{2e^{\bar{\xi}}}{\lambda_2}\right)}=\frac{1}{6\lambda_1}\frac{\lambda^2e^{\bar{\xi}}}{\sqrt{\lambda}\left(\dfrac{2e^{\bar{\xi}}}{\lambda_2}\right)\left[1-\dfrac{1}{2\lambda^{3/2}}\left(\dfrac{2e^{\bar{\xi}}}{\lambda_2}\right)\right]}\\&=\frac{1}{6\lambda_1}\frac{\lambda_2\lambda^{3/2}}{2}\frac{1}{1-\dfrac{1}{2\lambda^{3/2}}\left(\dfrac{2e^{\bar{\xi}}}{\lambda_2}\right)}=\frac{\lambda^{1/2}}{12}\left(1+\frac{1}{2\lambda^{3/2}}\frac{2e^{\bar{\xi}}}{\lambda_2}\right)+\mathbf{O}(\lambda^{-3}).\end{aligned}$$

Thus, we write

$$\frac{e^{\bar{\xi}}}{h(e^{\bar{\xi}})}=\frac{1}{12}\left[\lambda^{1/2}+\frac{1}{2}(\bar{\xi}+1-K)\right]+\mathbf{O}(\lambda^{-3})=\frac{1}{12}\left(\lambda^{1/2}+\frac{e^{\bar{\xi}}}{\lambda\lambda_2}\right)+\mathbf{O}(\lambda^{-3}).$$

After the above abbreviations the integrodifferential equation (2.20a) with cubic nonlinearities can be asymptotically approximated as follows:

$$\frac{1}{2}(w'_{\bar{\xi}}-w)^2-\frac{1}{3}\sqrt{\lambda}w-\frac{1}{3\lambda\lambda_2}\int w'_{\bar{\xi}}de^{\bar{\xi}}=C_1$$

or equivalently

$$\frac{1}{2}(w'_{\bar{\xi}}-w)^2-\frac{1}{3}\left(\sqrt{\lambda}+\frac{1}{2}\right)w=C_1. \tag{3.11}$$

In the next section we will show that both reduced equations (3.8) and (3.11) of the (NLS) equation (2.9) with cubic nonlinearities admit exact analytic solutions.

B. The forced damped (NLD) equation

In the case of the forced damped (NLD) equation the corresponding reduced nonlinear first-order integrodifferential equation is given by (2.31), while the cubic equation (2.27) becomes

$$\begin{gathered}z^3+\overset{*}{p}z+\overset{*}{q}=0,\quad \overset{*}{p}=-\frac{1}{\lambda},\quad \overset{*}{q}=\frac{e^{\xi}}{b}=\frac{\overset{*}{\Omega}{}^2}{\lambda}e^{\xi},\\ b=\frac{\lambda}{\overset{*}{\Omega}{}^2}>0,\quad \lambda=\frac{\lambda_2}{\lambda_1}>0,\quad \overset{*}{\Omega}{}^2=\frac{\Omega^2}{\lambda_1},\end{gathered} \tag{3.12}$$

with the following discriminant $\overset{*}{Q}$:

$$\overset{*}{Q}=\left(\frac{\overset{*}{p}}{3}\right)^3+\left(\frac{\overset{*}{q}}{2}\right)^2=-\frac{1}{27\lambda^3}+\frac{1}{4}\left(\frac{\overset{*}{\Omega}^2}{\lambda}e^{\xi}\right)^2. \tag{3.13}$$

Thus, according to the previously developed in Sec. III A, we distinguish the cases $\overset{*}{Q}<0$ and $\overset{*}{Q}>0$, where the real distinct roots corresponding to the cubic equation (3.12) are given by (3.3) and (3.4), respectively.

The limit $0<\lambda\ll 1$. We approximate $\overset{*}{Q}$ as

$$\overset{*}{Q}=-\frac{1}{27\lambda^3}+\mathbf{O}\left(\frac{1}{\lambda^2}\right)<0, \tag{3.14}$$

and the positive real root of the cubic equation (3.12) becomes

$$z=2\sqrt{\frac{1}{3\lambda}}\cos\frac{\alpha}{3},\quad \alpha=\arccos\left(-\frac{\sqrt{27\lambda}}{2}\,\overset{*}{\Omega}^2e^{\xi}\right). \tag{3.15}$$

This real root can be asymptotically approximated by expanding the general form of α in terms of the small parameter. Indeed, taking into account the expansion

$$\alpha=\arccos\left(-\frac{\sqrt{27\lambda}}{2}\,\overset{*}{\Omega}^2e^{\xi}\right)=\frac{\pi}{2}+\frac{\sqrt{27\lambda}}{2}\,\overset{*}{\Omega}^2e^{\xi}+\mathbf{O}(\lambda^{3/2}),$$

we extract

$$\cos\frac{\alpha}{3}=\cos\left(\frac{\pi}{6}+\frac{\sqrt{27\lambda}}{6}\,\overset{*}{\Omega}^2e^{\xi}\right)=\frac{\sqrt{3}}{2}-\frac{\sqrt{3\lambda}}{4}\,\overset{*}{\Omega}^2e^{\xi}+\mathbf{O}(\lambda).$$

Thus, the real root z becomes

$$z=\frac{1}{\sqrt{\lambda}}-\frac{1}{2}\,\overset{*}{\Omega}^2e^{\xi}+\mathbf{O}(\lambda). \tag{3.16}$$

According to Eq. (2.31), the above-given approximations enable us to also write the following approximations:

(i)

$$\frac{e^{\xi}}{h(e^{\xi})}=\frac{e^{\xi}}{a-3bz^2}=\overset{*}{\Omega}^2e^{\xi}\frac{1}{1-3\lambda\left(\frac{1}{\sqrt{\lambda}}-\frac{\overset{*}{\Omega}^2e^{\xi}}{2}\right)^2}=\overset{*}{\Omega}^2e^{\xi}\frac{1}{1-3+3\sqrt{\lambda}\,\overset{*}{\Omega}^2e^{\xi}-\frac{3\lambda}{4}(\overset{*}{\Omega}^2e^{\xi})^2}$$

$$=-\frac{\overset{*}{\Omega}^2e^{\xi}}{2}e^{\xi}\left[1+\frac{3\sqrt{\lambda}}{2}(\overset{*}{\Omega}^2e^{\xi})\right]+\mathbf{O}(\lambda). \tag{3.17a}$$

(ii)

$$e^{\xi}=(\sqrt{\lambda_1}-\sqrt{\lambda_2}z)\frac{2}{\overset{*}{\Omega}{}^2\sqrt{\lambda}\sqrt{\lambda_1}}\Rightarrow\xi=\ln\left|\frac{2}{\overset{*}{\Omega}{}^2\sqrt{\lambda}\sqrt{\lambda_1}}\right|+\ln|\sqrt{\lambda_1}-\sqrt{\lambda_2}z|$$

$$=\ln\left|\frac{2}{\overset{*}{\Omega}{}^2\sqrt{\lambda}\sqrt{\lambda_1}}\right|+\ln\left|\frac{\sqrt{\lambda}\sqrt{\lambda_1}\,\overset{*}{\Omega}{}^2}{2}e^{\xi}\right|=n\frac{\sqrt{\lambda}\sqrt{\lambda_1}\,\overset{*}{\Omega}{}^2}{2}e^{\xi}-1+\ln\left|\frac{2}{\overset{*}{\Omega}{}^2\sqrt{\lambda}\sqrt{\lambda_1}}\right|-C_0+\mathbf{O}(\lambda),$$

$$C_0=\sum_{m=2,3,\ldots}^{n}\frac{1}{m}.$$

Neglecting the constant C_0 and taking $n=1$ we evaluate

$$e^{\xi}=\frac{2}{\sqrt{\lambda}\sqrt{\lambda_1}\,\overset{*}{\Omega}{}^2}(\xi+1-K),\quad K=\ln\left|\frac{2}{\overset{*}{\Omega}{}^2\sqrt{\lambda}\sqrt{\lambda_1}}\right|. \tag{3.17b}$$

(iii)

$$\sin(p+p'_{\xi})=\sin(e^{-\xi}w'_{\xi})=\sin\left[\frac{\overset{*}{\Omega}{}^2\sqrt{\lambda}\sqrt{\lambda_1}}{2}\frac{1}{1+\xi-K}w'_{\xi}\right]=\frac{\overset{*}{\Omega}{}^2\sqrt{\lambda}\sqrt{\lambda_1}}{2}\frac{1}{1+\xi-K}w'_{\xi}+\mathbf{O}(\lambda^{3/2}). \tag{3.17c}$$

Furthermore, by means of Eq. (2.28b), we evaluate

$$f(e^{\xi})=z=\frac{1}{\sqrt{\lambda}}-\frac{1}{2}\,\overset{*}{\Omega}{}^2e^{\xi},\quad f'_{e^{\xi}}=-\frac{1}{2}\,\overset{*}{\Omega}{}^2,\quad f''_{e^{\xi}e^{\xi}}=0, \tag{3.17d}$$

while using transformation (2.29), as well as Eqs. (3.17a)–(3.17d), the nonlinear integrodifferential equation (2.31) can be approximated in case $0<\lambda\ll 1$ by the following first-order nonlinear ODE:

$$\left(1-\frac{1}{2\xi}\right)(w'_{\xi}-w)^2-cw'_{\xi}-\overset{*}{\mu}\left(\frac{1}{\sqrt{\lambda}}-\frac{1}{\sqrt{\lambda}\sqrt{\lambda_1}}\overline{\xi}\right)w'_{\xi}-\frac{\overset{*}{\mu}}{\sqrt{\lambda}\sqrt{\lambda_1}}\overline{\xi}w+\frac{2}{\overset{*}{\Omega}{}^2\lambda\lambda_1}\overline{\xi^2}+\frac{3}{\overset{*}{\Omega}{}^2\lambda\lambda_1\sqrt{\lambda_1}}\overline{\xi^3}$$

$$-\frac{2C_1}{\overset{*}{\Omega}{}^2\sqrt{\lambda}\sqrt{\lambda_1}}\overline{\xi}=0, \tag{3.18}$$

$$\overline{\xi}=\xi+1-K,\quad K=\ln\left|\frac{2}{\overset{*}{\Omega}{}^2\sqrt{\lambda}\sqrt{\lambda_1}}\right|.$$

Through Eq. (3.17b) we finally evaluate

$$1-\frac{1}{2\bar{\xi}}=1-\frac{1}{2[\ln|\sqrt{\lambda_2}z-\sqrt{\lambda_1}|+K+1-K]}=1-\frac{1}{2[\ln|1-\sqrt{\lambda}z|+\ln|\sqrt{\lambda_1}|+1]}$$

$$=1-\frac{1}{2[1+\ln|\sqrt{\lambda_1}|-\sqrt{\lambda z}]+\mathbf{O}(\lambda)}. \tag{3.19}$$

Setting for simplicity

$$1-\frac{1}{2\bar{\xi}}\cong 1-\frac{1}{2(1+\ln|\sqrt{\lambda_1}|)}=\frac{1+2\ln|\sqrt{\lambda_1}|}{2(1+\ln|\sqrt{\lambda_1}|)},$$

and taking into account that $\overset{*}{\Omega}=\Omega/\sqrt{\lambda_1}$, Eq. (3.18) becomes of the following nonlinear form:

$$(w'_{\bar{\xi}}-w)^2+k\bar{\xi}(w'_{\bar{\xi}}-w)+aw'_{\bar{\xi}}-\beta\bar{\xi}^2+\gamma\bar{\xi}^3-\delta\bar{\xi}=0, \tag{3.20}$$

where

$$k=\frac{\lambda_3}{\Omega\sqrt{\lambda}\sqrt{\lambda_1}}\frac{2(1+\ln|\sqrt{\lambda_1}|)}{1+2\ln|\sqrt{\lambda_1}|},\quad a=-\frac{A\sqrt{\lambda}+\Omega\lambda_3}{\Omega^2\sqrt{\lambda}}\frac{2(1+\ln|\sqrt{\lambda_1}|)}{1+2\ln|\sqrt{\lambda_1}|}, \tag{3.20a}$$

$$\beta=-\frac{4(1+\ln|\sqrt{\lambda_1}|)}{\Omega^2\lambda(1+2\ln|\sqrt{\lambda_1}|)},\quad \gamma=\frac{3(1+\ln|\sqrt{\lambda_1}|)}{\Omega^2\lambda\sqrt{\lambda_1}(1+2\ln|\sqrt{\lambda_1}|)},\quad \delta=\frac{4C_1\sqrt{\lambda_1}(1+\ln|\sqrt{\lambda_1}|)}{\Omega^2\sqrt{\lambda}(1+2\ln|\sqrt{\lambda_1}|)}.$$

We shall prove now that Eq. (3.20) can be further reduced to a first-order Abel nonlinear ODE of the form $yy'_x-y=f(x)$. In fact, we introduce the parameter $\tau=w'_{\bar{\xi}}$ and by differentiation we obtain the well-known equations

$$\frac{d\bar{\xi}}{d\tau}=-\frac{F_{,\tau}}{F_{,\bar{\xi}}+\tau F_{,w}},\quad \frac{dw}{d\tau}=-\frac{\tau F_{,\tau}}{F_{,\bar{\xi}}+\tau F_{,w}} \tag{3.21}$$

in which

$$F\equiv F(\tau,w,\bar{\xi})=(\tau-w)^2+k\bar{\xi}(\tau-w)+a\tau-\beta\bar{\xi}^2+\gamma\bar{\xi}^3-\delta\bar{\xi}=0. \tag{3.22}$$

Here the notation $F_{,x}=\partial F/\partial x$, $F_{,y}=\partial F/\partial y,\ldots$ is used for the partial derivatives.

We compute

$$F_{,\tau}=2(\tau-w)+k\bar{\xi}+a,\quad F_{,w}=-2(\tau-w)-k\bar{\xi},\quad F_{,\bar{\xi}}=k(\tau-w)-2\beta\bar{\xi}+3\gamma\bar{\xi}^2-\delta$$

and the first of (3.21a) becomes

$$\frac{d\bar{\xi}}{d\tau}=-\frac{2(\tau-w)+k\bar{\xi}+a}{-2\beta\bar{\xi}+3\gamma\bar{\xi}^2-\delta+k(\tau-w)-2\tau\left[(\tau-w)+\dfrac{k\bar{\xi}}{2}\right]}. \tag{3.23}$$

Solving also (3.22) for $(\tau-w)$, we evaluate

$$t-w=\frac{-k\bar{\xi}\pm\sqrt{-4a\tau+(4\beta+k^2)\bar{\xi}^2-4\gamma\bar{\xi}^3+4\delta\bar{\xi}}}{2},\quad -4a\tau+(4\beta+k^2)\bar{\xi}^2-4\gamma\bar{\xi}^3+4\delta\bar{\xi}>0, \tag{3.24}$$

while combining the results (3.23) and (3.24) we extract the following:

$$\frac{1}{\tau'_{\bar{\xi}}}=\frac{\pm 2\sqrt{-4a\tau+(4\beta+k^2)\bar{\xi}^2-4\gamma\bar{\xi}^3+4\delta\bar{\xi}}+2a}{-6\gamma\bar{\xi}^2+(4\beta+k^2)\bar{\xi}+2\delta\pm\sqrt{-4a\tau+(4\beta+k^2)\bar{\xi}^2-4\gamma\bar{\xi}^3+4\delta\bar{\xi}}}. \tag{3.25}$$

By the substitution

$$\sqrt{-4a\tau+(4\beta+k^2)\bar{\xi}^2-4\gamma\bar{\xi}^3+4\delta\bar{\xi}}=\sqrt{-4a\tau+\omega(\bar{\xi})}=\sqrt{Q(\bar{\xi})}, \tag{3.26a}$$

$$\begin{aligned}\omega(\bar{\xi})&=(4\beta+k^2)\bar{\xi}^2-4\gamma\bar{\xi}^3+4\delta\bar{\xi},\\ \omega'_{\bar{\xi}}&=2(4\beta+k^2)\bar{\xi}-12\gamma\bar{\xi}^2+4\delta,\end{aligned} \tag{3.26b}$$

which furnishes $1/\tau'_{\bar{\xi}}=4a/(\omega'_{\bar{\xi}}-Q'_{\bar{\xi}})$, Eq. (3.25) results in

$$2\omega\sqrt{Q}-2Q\sqrt{Q}-4ak\sqrt{Q}=2\omega'_{\bar{\xi}}\sqrt{Q}-2\sqrt{Q}Q'_{\bar{\xi}}+2aQ'_{\bar{\xi}}. \tag{3.27}$$

By the new substitution

$$\sqrt{Q}=Z\Rightarrow Q=Z^2\Rightarrow Q'_{\bar{\xi}}=2ZZ'_{\bar{\xi}}, \tag{3.28}$$

we transform (3.27) into the following Abel equation of the second kind:

$$(Z\pm a)Z'_{\bar{\xi}}=\tfrac{1}{2}Z^2+\tfrac{1}{2}(\omega'_{\bar{\xi}}-\omega)+ak, \tag{3.29}$$

while by the well-known transformation (Ref. 21, p. 50)

$$v=(Z\pm a)\exp\left(-\frac{1}{2}\int d\bar{\xi}\right)=(Z\pm a)\exp\left(-\frac{\bar{\xi}}{2}\right), \tag{3.30}$$

we reduce (3.29) in

$$vv'_{\bar{\xi}}\pm ae^{-\bar{\xi}/2}v=\tfrac{1}{2}(\omega'_{\bar{\xi}}-\omega+2ak+a^2)e^{\bar{\xi}}. \tag{3.31}$$

In the sequel, through the general transformation

$$v(\bar{\xi})=q(s),\quad s=s(\bar{\xi})\Rightarrow v'_{\bar{\xi}}=q'_s s'_{\bar{\xi}}$$

with concrete form

$$v(\bar{\xi})=q(s),\quad s=\pm 2ae^{-\bar{\xi}/2}\ (e^{\bar{\xi}/2}=\pm 2a/s), \tag{3.32}$$

(3.31) results in the following Abel equation of the normal form:

$$\begin{aligned}qq'_s-q&=(a+k)\frac{s}{4a^2}-(\omega'_{\bar{\xi}}-\omega)\frac{s}{4a^2},\\ \omega'_{\bar{\xi}}-\omega&=4\gamma\bar{\xi}^3-(12\gamma+4\beta+k^2)\bar{\xi}^2+2(4\beta+k^2-2\delta)\bar{\xi}+4\delta.\end{aligned} \tag{3.33}$$

Also, (3.32) and (3.17b) enable us to write the approximation

$$\left|\frac{2a}{s}\right|=e^{\bar{\xi}/2}\Rightarrow\ln\left|\frac{2a}{s}\right|=\frac{\bar{\xi}}{2}=\frac{\xi+2-K}{2}-\frac{1}{2}=\sqrt{\frac{\sqrt{\lambda}\sqrt{\lambda_1}\overset{*}{\Omega}^2}{2}}e^{(1-K)/2}\left|\frac{2a}{s}\right|-\frac{1}{2},$$

that is to say the approximation

$$\ln\left|\frac{2a}{s}\right|=M\left|\frac{2a}{s}\right|-\frac{1}{2}=Me^{\bar{\xi}/2}-\frac{1}{2},\quad M=\sqrt{\frac{\sqrt{\lambda}\sqrt{\lambda_1}\overset{*}{\Omega}^2}{2}}e^{(1-K)/2}=\frac{1}{\sqrt{e}}. \tag{3.34}$$

Therefore, we evaluate

$$\begin{aligned}\bar{\xi}&=2\ln\left|\frac{2a}{s}\right|=\pm 2M\left(\frac{2a}{s}\right)-1,\\ \bar{\xi}^2&=4M^2\left(\frac{2a}{s}\right)^2+\frac{1}{4}\mp 4M\left(\frac{2a}{s}\right),\\ \bar{\xi}^3&=\pm 8M^3\left(\frac{2a}{s}\right)^3-12M^2\left(\frac{2a}{s}\right)^2\pm 6M\left(\frac{2a}{s}\right)-1,\end{aligned} \tag{3.35}$$

and the Abel equation (3.33) becomes

$$qq_s'-q=p_1s^{-2}+p_2s^{-1}+p_3s+p_4, \tag{3.36a}$$

where

$$\begin{aligned}&p_1=\mp 64a\gamma M^3,\quad p_2=4(24\gamma+4\beta+k^2)M^2,\\ &p_3=\frac{-(-16\gamma-12\beta-3k^2+8\delta+2k+\alpha)}{4\alpha^2},\quad p_4=\pm\frac{4(-9\gamma-4\beta+k^2+\delta)}{a}M,\\ &\alpha,\beta,\gamma,\delta,\quad\text{and } k \text{ as in (3.20a).}\end{aligned} \tag{3.36b}$$

The limit $+\infty>\lambda\gg 1$. We develop new analytic approximations of the reduced integrodifferential equation (2.31) in the limit of large values of the parameter $\lambda=\lambda_2/\lambda_1$, that is to say in case of strongly nonlinear damped oscillations. In terms of the before mentioned analysis, in this case the discriminant $\overset{*}{Q}$ of the cubic equation (3.12) becomes positive, e.g.,

$$\overset{*}{Q}=\frac{1}{4}\left(\frac{\overset{*}{\Omega}^2e^{\xi}}{\lambda}\right)^2+\mathbf{O}(\lambda^{-3})>0 \tag{3.37}$$

and the only one real root z can be asymptotically approximated by expanding the general form (3.4) in terms of the large parameter. This furnishes

$$z=-\left(\frac{\overset{*}{\Omega}^2e^{\xi}}{\lambda}\right)^{1/3}+\mathbf{O}(\lambda^{-1}). \tag{3.38}$$

Thus, according to (2.31), we write the following:

(i)

$$e^{\xi}=-\frac{\lambda}{\overset{*}{\Omega}{}^2}z^3=\frac{\lambda}{\overset{*}{\Omega}{}^2}|z|^3\Rightarrow\xi=\ln\left|\frac{\lambda}{\overset{*}{\Omega}{}^2}\right|+\ln\left|\frac{\overset{*}{\Omega}{}^2e^{\xi}}{\lambda}\right|=\ln\left|\frac{\lambda}{\overset{*}{\Omega}{}^2}\right|+n\frac{\overset{*}{\Omega}{}^2e^{\xi}}{\lambda}-1-C_0+\mathbf{O}(\lambda^{-2}),$$

$$C_0=\sum_{m=2,3,\ldots}^{n}\frac{1}{m}.$$

For simplicity and without loss of generality one neglects C_0 and takes $n=1$. Thus, one obtains

$$e^{\xi}=(\xi+1-K)\frac{\lambda}{\overset{*}{\Omega}{}^2},\quad K=\ln\left|\frac{\lambda}{\overset{*}{\Omega}{}^2}\right|. \tag{3.39a}$$

(ii)

$$\frac{e^{\xi}}{h(e^{\xi})}=\frac{e^{\xi}}{\mathrm{a}-3bz^2}=\frac{\overset{*}{\Omega}{}^2e^{\xi}}{1-3\lambda^{1/3}(\overset{*}{\Omega}{}^2e^{\xi})^{2/3}}. \tag{3.39b}$$

(iii)

$$\sin(p+p'_{\xi})=\sin(e^{-\xi}w'_{\xi})=\sin\left(\frac{\overset{*}{\Omega}{}^2}{\lambda(\xi+1-K)}w'_{\xi}\right)=\frac{\overset{*}{\Omega}{}^2}{\lambda(\xi+1-K)}w'_{\xi}+\mathbf{O}(\lambda^{-3}). \tag{3.39c}$$

(iv)

$$f(e^{\xi})=z=-\left(\frac{\overset{*}{\Omega}{}^2e^{\xi}}{\lambda}\right)^{1/3},\quad f'_{e^{\xi}}=-\frac{1}{3}\left(\frac{\overset{*}{\Omega}{}^2}{\lambda}\right)^{1/3}e^{-2\xi/3},$$

$$f''_{e^{\xi}e^{\xi}}=\frac{2}{9}\left(\frac{\overset{*}{\Omega}{}^2}{\lambda}\right)^{1/3}e^{-5\xi/3}. \tag{3.39d}$$

Using now transformation (2.29), as well as Eqs. (3.39a)–(3.39d), the nonlinear integrodifferential equation (2.31) can be approximated for $+\infty>\lambda\gg1$ by the following first-order nonlinear ODE:

$$\begin{aligned}&\left[1-\frac{1}{2(\xi+1-K)}\right](w'_{\xi}-w)^2-cw'_{\xi}+\overset{*}{\mu}\rho e^{\xi/3}\left(w'_{\xi}-\frac{1}{3}w\right)+\frac{\overset{*}{\mu}\rho}{3}\xi(w'_{\xi}-w)\\&\quad+\frac{\overset{*}{\mu}\rho}{2}e^{-2\xi/3}\left(w'_{\xi}-\frac{5}{3}w\right)-\frac{\overset{*}{\mu}\rho}{2}\left(w'_{\xi}-\frac{1}{3}w\right)+\frac{1}{4}\rho^4e^{7\xi/3}=C_1e^{\xi},\\&\rho=\left(\frac{\overset{*}{\Omega}{}^2}{\lambda}\right)^{1/3}.\end{aligned} \tag{3.40}$$

Setting

$$\bar{\xi}=\xi+1-K \quad \left(\bar{\xi}=\frac{\overset{*}{\Omega}^2}{\lambda}e^{\xi}\right) \tag{3.41a}$$

and writing

$$(\rho e^{\xi})\ll 1\Rightarrow(\rho e^{\xi})^{1/3}\ll(\rho e^{\xi})^{-2/3},\quad \bar{\xi}\ll 1\Rightarrow\xi\ll K=\ln\left|\frac{\lambda}{\overset{*}{\Omega}^2}\right|,$$
$$e^{-2\xi/3}=\rho^2\bar{\xi}^{-2/3}, \tag{3.41b}$$

the above equation can be further simplified as follows:

$$-\frac{1}{2\xi}(w'_{\bar{\xi}}-w)^2-cw'_{\bar{\xi}}+\frac{\overset{*}{\mu}\rho^3}{2}\bar{\xi}^{-2/3}\left(w'_{\bar{\xi}}-\frac{5}{3}w\right)-\frac{\overset{*}{\mu}\rho}{2}\left(w'_{\bar{\xi}}-\frac{1}{3}w\right)+\frac{1}{4}\frac{1}{\rho^3}\bar{\xi}^{7/3}=C_1\frac{1}{\rho^3}\bar{\xi},$$

or equivalently as follows:

$$(w'_{\bar{\xi}}-w)^2+2c\bar{\xi}w'_{\bar{\xi}}-\overset{*}{\mu}\rho^3\bar{\xi}^{1/3}\left(w'_{\bar{\xi}}-\frac{5}{3}w\right)+\overset{*}{\mu}\rho\bar{\xi}\left(w'_{\bar{\xi}}-\frac{1}{3}w\right)-\frac{1}{2}\frac{1}{\rho^3}\bar{\xi}^{10/3}+\frac{2C_1}{\rho^3}\bar{\xi}^2=0. \tag{3.42}$$

We rewrite the third and the fourth terms of (3.42) in the form

$$-\overset{*}{\mu}\rho^3\bar{\xi}^{1/3}(w'_{\bar{\xi}}-w)+\frac{2}{3}\overset{*}{\mu}\rho^3\bar{\xi}^{1/3}w,\quad \frac{\overset{*}{\mu}\rho}{3}\bar{\xi}(w'_{\bar{\xi}}-w)+\frac{2}{3}\overset{*}{\mu}\rho\bar{\xi}w'_{\bar{\xi}}$$

and since it is valid $\rho^3\ll 1$ and $\rho\bar{\xi}\ll\bar{\xi}$, comparison of $2/3\,\overset{*}{\mu}\rho\bar{\xi}w'_{\bar{\xi}}$ with $2c\bar{\xi}w'_{\bar{\xi}}$, as well as of $2/3\,\overset{*}{\mu}\rho^3\bar{\xi}^{1/3}w$ with w^2, results in the following further simplification for the nonlinear ODE (3.42):

$$(w'_{\bar{\xi}}-w)^2+F(\bar{\xi})(w'_{\bar{\xi}}-w)+a\bar{\xi}w'_{\bar{\xi}}+G(\bar{\xi})=0, \tag{3.43a}$$

where

$$a=2c,\quad F(\bar{\xi})=-\overset{*}{\mu}\rho^3\bar{\xi}^{1/3}+\frac{\overset{*}{\mu}\rho}{3}\bar{\xi},\quad G(\bar{\xi})=-\frac{1}{2\rho^3}\bar{\xi}^{10/3}+\frac{2C_1}{\rho^3}\bar{\xi}^2. \tag{3.43b}$$

Both Eqs. (3.20) and (3.43a) are of the same type. Thus, introducing the parameter $\tau=w'_{\bar{\xi}}$ and following the already developed methodology on Eq. (3.43a), we obtain

$$\frac{1}{\tau'_{\bar{\xi}}}=\frac{\pm 2\sqrt{-4a\bar{\xi}\tau+F^2-4G}+2a\bar{\xi}}{F'_{\bar{\xi}}F\mp F'_{\bar{\xi}}\sqrt{-4a\bar{\xi}\tau+F^2-4G}-2G'_{\bar{\xi}}-2a\tau\pm 2\tau\sqrt{-4a\bar{\xi}\tau+F^2-4G}}. \tag{3.44}$$

By the substitution

$$\sqrt{-4a\xi\tau+F^2-4G}=\sqrt{-4a\xi\tau+H(\xi)}=\sqrt{Q(\xi)},$$
$$H(\bar{\xi})=F^2-4G, \tag{3.45}$$

(3.44) becomes

$$\mp 4a\overline{\xi^2}F'_{\overline{\xi}}\sqrt{Q}\pm 2\overline{\xi}F^2\sqrt{Q}\mp 8\overline{\xi}G\sqrt{Q}\mp 2\overline{\xi}Q\sqrt{Q}=\pm 4\overline{\xi}FF'_{\overline{\xi}}\sqrt{Q}\mp 8\overline{\xi}G'_{\overline{\xi}}\sqrt{Q}\mp 2\overline{\xi}\sqrt{Q}Q'_{\overline{\xi}}\mp 2F^2\sqrt{Q}$$
$$\pm 8G\sqrt{Q}\pm 2Q\sqrt{Q}-2a\overline{\xi^2}Q'_{\overline{\xi}},$$

which, further, by the new substitution

$$\sqrt{Q}=Z\Rightarrow Q=Z^2,\quad Q'_{\overline{\xi}}=2ZZ'_{\overline{\xi}} \tag{3.46}$$

results in the following Abel equation of the second kind:

$$(\overline{\xi}Z\pm a\overline{\xi^2})Z'_{\overline{\xi}}=\tfrac{1}{2}(\overline{\xi}+1)Z^2+P(\overline{\xi}),$$
$$P(\overline{\xi})=a\overline{\xi^2}F'_{\overline{\xi}}-\tfrac{1}{2}\overline{\xi}F^2+2\overline{\xi}\gamma+\overline{\xi}FF'_{\overline{\xi}}-2\overline{\xi}G'_{\overline{\xi}}-\tfrac{1}{2}F^2+2G. \tag{3.47}$$

As in the case $0<\lambda\ll 1$, the well-known transformation

$$\omega(\overline{\xi})=(z+a\overline{\xi})\overline{\xi}^{-1/2}\exp\left(-\frac{1}{2}\overline{\xi}\right), \tag{3.48}$$

reduces Eq. (3.47) into the modified Abel form

$$\omega\omega'_{\overline{\xi}}-F_1(\overline{\xi})\omega=F_0(\overline{\xi}),$$
$$F_1(\overline{\xi})=\mp ae^{-\overline{\xi}/2}\overline{\xi}^{1/2},\quad F_0(\overline{\xi})=\left[\frac{P(\overline{\xi})}{\overline{\xi^2}}+\frac{1}{2}(1+\overline{\xi})\right]e^{-\overline{\xi}}. \tag{3.49}$$

In order to reduce Eq. (3.49) to the normal Abel form, we introduce the final general transformation

$$\omega(\overline{\xi})=q(s),\quad s=s(\overline{\xi}) \tag{3.50a}$$

with concrete form

$$\omega(\overline{\xi})=q(s),\quad s=\int F_1(\overline{\xi})\mathrm{d}\overline{\xi}=\mp a\int\overline{\xi}^{1/2}e^{-\overline{\xi}/2}\mathrm{d}\overline{\xi}=-2\overline{\xi}^{1/2}e^{-\overline{\xi}/2}+2\sqrt{\pi}\,\mathrm{erf}\left(\frac{\sqrt{2}}{2}\overline{\xi}^{1/2}\right), \tag{3.50b}$$

where

$$\mathrm{erf}(x)=\frac{2}{\sqrt{\pi}}\int_0^x e^{-t^2}\mathrm{d}t$$

is the probability integral.

Thus, (3.49) becomes

$$qq'_s-q=\frac{F_0(\overline{\xi})}{F_1(\overline{\xi})},$$
$$s=\int F_1(\overline{\xi})d\overline{\xi}=-2\overline{\xi}^{1/2}e^{-\overline{\xi}/2}+2\sqrt{\pi}\,\mathrm{erf}\left(\frac{\sqrt{2}}{2}\overline{\xi}^{1/2}\right). \tag{3.51}$$

This equation corresponds to (3.33) and it is valid in case of the limit $0<\lambda\ll 1$. Further approximations, concerning the second member of (3.51), are beyond the scope of this investigation.

We have already proved that in the limit of weakly ($0<\lambda\ll 1$) or strongly ($+\infty>\lambda\gg 1$) nonlinear oscillations the forced damped (NLD) equation leads to Abel's equations of the second kind of the normal form [types (3.33) and (3.51)]. It was recently proved by Panayotounakos, Panayotounakou, and Vakakis,[17] that these types of nonlinear ODEs do not admit exact analytic solutions in terms of known (tabulated) functions. Thus, the general conclusion from the above-presented discussion of the forced damped (NLD) equation is that in both limits of weakly or strongly nonlinear oscillations the equivalent equations of the Abel normal form do not admit exact analytic solutions in terms of known functions. For major reason this holds true for the original forced damped problem.

C. The forced undamped (NLD) equation

The forced undamped (NLD) equation is a special case of the damped (NLD) equation, since the governing nonlinear ODE (2.32) arises form (2.21) by setting $\lambda_3=0$. Thus, the procedure of reduction in this case is the same as that of the damped problem. The new results are the following.

The limit $0<\lambda\ll 1$. The approximate ODE (3.30) becomes

$$(w'_{\bar{\xi}}-w)^2+aw'_{\bar{\xi}}-\beta\bar{\xi}^2+\gamma\bar{\xi}-\delta\bar{\xi}=0, \tag{3.52a}$$

where

$$a=-\frac{2(1+\ln|\sqrt{\lambda_1}|)}{1+2\ln|\sqrt{\lambda_1}|}\frac{A}{\Omega^2},\quad \beta=-\frac{2(1+\ln|\sqrt{\lambda_1}|)}{1+2\ln|\sqrt{\lambda_1}|}\frac{2}{\lambda\Omega^2},$$

$$\gamma=\frac{2(1+\ln|\sqrt{\lambda_1}|)}{1+2\ln|\sqrt{\lambda_1}|}\frac{3}{\lambda\sqrt{\lambda_1}\Omega^2},\quad \delta=\frac{4C_1(1+\ln|\sqrt{\lambda_1}|)}{1+2\ln|\sqrt{\lambda_1}|}\frac{\sqrt{\lambda_1}}{\sqrt{\lambda}\Omega^2}, \tag{3.52b}$$

$$\bar{\xi}=1+\xi-K,\quad K=\ln\left|\frac{2}{\overset{*}{\Omega}{}^2\sqrt{\lambda}\sqrt{\lambda_1}}\right|,\quad \overset{*}{\Omega}=\frac{\Omega}{\sqrt{\lambda_1}}.$$

Further reduction of (3.52a) follows the corresponding steps of (3.20) and thus, the equivalent to (3.36a) The Abel equation of the normal form becomes

$$qq'_s-q=p_1s^{-2}+p_2s^{-1}+p_3s+p_4, \tag{3.53a}$$

in which

$$p_1=\mp 8a\gamma M^3,\quad p_2=4(\beta+6\gamma)M^2,\quad p_3=-\frac{a^2+4(3\beta+4\gamma-2\delta)}{4a^2},$$

$$p_4=\mp\frac{2(9\gamma+4\beta-\delta)}{a}M. \tag{3.53b}$$

The limit $1\ll\lambda<+\infty$. In this case the corresponding to (3.40) reduced equation becomes by setting in (3.40) $\overset{*}{\mu}=0$, and thus, the approximate nonlinear ODE (3.42) takes the simplified form

$$(w'_{\bar{\xi}}-w)^2+2c\bar{\xi}w'_{\bar{\xi}}-\frac{1}{2\rho^3}\bar{\xi}^{10/3}+\frac{2C_1}{\rho^3}\bar{\xi}^2=0. \tag{3.54}$$

Therefore the final approximate Abel equation of the normal form, in which the nonlinear exact integrodifferential equation (2.33) reduces, becomes

$$qq_s'-q=\frac{F_0(\bar{\xi})}{F_1(\bar{\xi})}, \tag{3.55a}$$

where

$$\frac{F_0(\bar{\xi})}{F_1(\bar{\xi})}=\mp\frac{1}{a}\left\{[\bar{\xi}F_{\bar{\xi}}'-(1+\bar{\xi})F]\bar{\xi}^{-5/2}+\frac{a^2}{4}(1+\bar{\xi})\bar{\xi}^{-1/2}\right\}e^{-\bar{\xi}/2},$$

$$F(\bar{\xi})=-(\beta\bar{\xi}^{10/3}+\gamma\bar{\xi}^2), \tag{3.55b}$$

$$s=\int F_1(\bar{\xi})\mathrm{d}\bar{\xi}=\mp\frac{a}{2}\int\bar{\xi}^{1/2}e^{-\bar{\xi}/2}\mathrm{d}\bar{\xi}=\pm 2\bar{\xi}^{1/2}e^{-\bar{\xi}/2}+2\sqrt{\pi}\,\mathrm{erf}\left(\frac{\sqrt{2}}{2}\bar{\xi}^{1/2}\right),$$

$$\mathrm{erf}(x)=\frac{2}{\sqrt{\pi}}\int_0^x e^{-t^2}\mathrm{d}t=\text{probability integral.}$$

The solvability of both approximated reduced Eqs. (3.53a) and (3.55a) in the present case of the limit $1\ll\lambda<+\infty$ follows the general conclusion of the forced damped (NLD) problem.

In the following we provide approximate analytic solutions of the already examined three nonlinear ODEs. In some cases such solutions are indispensable to making use of further assumptions and approximations. These assumptions and approximations are realistic and usual for deriving exact solutions for these strongly nonlinear problems.

IV. APPROXIMATE ANALYTIC SOLUTIONS

We shall present new approximate analytic solutions of the three kinds of equations being examined.

A. The one-dimensional axisymmetric (NLS) equation with cubic nonlinearities

It is was already proved that for the NLS equation and for the limits $0<\lambda=\lambda_1/\lambda_2\ll 1$, and $1\ll\lambda=\lambda_1/\lambda_2<+\infty$, the equivalent nonlinear first-order integrodifferential equation (2.20a) can be asymptotically approximated by the following two nonlinear first-order ODEs.

(i) For $0<\lambda=\lambda_1/\lambda_2\ll 1$ [Eq. (3.8)],

$$\frac{1}{2}(w_{\bar{\xi}}'-w)^2+w=C_1,\quad A=\frac{1}{3}\sqrt[3]{\frac{4}{\lambda_2\lambda}}. \tag{4.1a}$$

(ii) For $1\ll\lambda=\lambda_1/\lambda_2<+\infty$ [Eq. (3.11)],

$$\tfrac{1}{2}(w_{\bar{\xi}}'-w)^2-Bw=C_1,\quad B=\tfrac{1}{3}(\sqrt{\lambda}+\tfrac{1}{2}). \tag{4.1b}$$

Both these equations are of the same type, that is to say of the type

$$(w_{\bar{\xi}}'-w)^2+2aw-2\beta=0, \tag{4.2a}$$

where

$$a=\frac{2}{3}\sqrt[3]{\frac{4}{\lambda_2\lambda}}\quad\text{or}\quad a=-\frac{2}{3}\left(\sqrt{\lambda}+\frac{1}{2}\right),\quad 2\beta=2C_1, \tag{4.2b}$$

and they can be analytically solved. In fact, solving (4.2a) for $(w'_{\bar{\xi}}-w)$ and setting $\sqrt{2(\beta-aw)}=\omega$, we obtain

$$\frac{\omega d\omega}{\omega^2\mp a\omega-2\beta}=-d\bar{\xi},$$

the integration which furnishes (see Ref. 22, p. 69)

$$-\frac{1}{4\beta}\ln\left|\frac{\omega^2}{\omega^2\mp a\omega-2\beta}\right|\mp\frac{a}{4\beta}\int\frac{d\omega}{\omega^2\mp a\omega-2\beta}=-\bar{\xi}+C_2.$$

This integral depends on the sign of the quantity $\Delta=(8C_1+a^2)$. Thus, we distinguish the following three possible solutions in terms of w:

$$\begin{aligned}
&-\frac{1}{4\beta}\ln\left|\frac{2(\beta-aw)}{2(\beta-aw)\mp a\sqrt{\beta-aw}-2\beta}\right|\mp\frac{a}{4\beta\sqrt{-(8C_1+a^2)}}\\
&\quad-\ln\left|\frac{\mp a+2\sqrt{2(\beta-aw)}-\sqrt{-(8C_1+a^2)}}{\mp a+2\sqrt{2(\beta-aw)}+\sqrt{-(8C_1+a^2)}}\right|\\
&\quad=-\bar{\xi}+C_2 \quad \text{if } (8C_1+a^2)<0,\\
&-\frac{1}{4\beta}\ln\left|\frac{2(\beta-aw)}{2(\beta-aw)\mp a\sqrt{\beta-aw}-2\beta}\right|\pm\frac{2a}{4\beta(\mp a+2\sqrt{\beta-aw})}=-\bar{\xi}+C_2 \quad \text{if } -(8C_1+a^2)=0,\\
&-\frac{1}{4\beta}\ln\left|\frac{2(\beta-aw)}{2(\beta-aw)\mp a\sqrt{\beta-aw}-2\beta}\right|\pm\frac{2}{4\beta\sqrt{8C_1+a^2}}\arctan\left(\frac{\mp a+2\sqrt{\beta-aw}}{\sqrt{8C_1+a^2}}\right)\\
&\quad=-\bar{\xi}+C_2 \quad \text{if } (8C_1+a^2)>0,
\end{aligned} \tag{4.3}$$

where C_2 is a second constant of integration.

B. The forced damped (NLD) equation

We shall try to construct approximate analytic solutions of the reduced equation (3.36a) holding in case of the parameter $(0<\lambda\ll 1)$. First one observes that Eq. (3.36a) does not admit exact solutions in terms of known (tabulated) functions (see Ref. 21, pp. 29–32). Thus, new approximations are indispensable. Now combining Eqs. (3.17b) and (3.34) we extract the following:

$$\begin{aligned}
&e^{-\xi}=\frac{1}{1-\sqrt{\lambda}z}\,\frac{1}{\sqrt{\lambda_1}}e^{-K}, \quad \xi=\bar{\xi}-1+K,\\
&s=\pm 2ae^{-\bar{\xi}/2}=\pm 2ae^{(1+\xi-K)/2}=\pm\frac{2a}{\sqrt{e}}\,\frac{1}{\lambda^{1/4}}\,\frac{1}{\sqrt{1-\sqrt{\lambda_1}z}}=\pm\frac{2a}{\sqrt{e}}\,\frac{1}{\lambda^{1/4}}\left(1+\frac{1}{2}\sqrt{\lambda}z\right)+\mathbf{O}(\lambda).
\end{aligned} \tag{4.4}$$

Rewriting the second of the above equations as

$$s=\pm\frac{a}{\sqrt{e}}\,\frac{1}{\lambda^{1/4}}(3-1+\sqrt{\lambda}z)=\pm\frac{3a}{\sqrt{e}\lambda^{1/4}}\mp\frac{a}{\sqrt{e}\lambda^{1/4}}(1-\sqrt{\lambda}z)$$

and introducing the quantity $(1-\sqrt{\lambda}z)$ by way of the first of (4.4), we find

$$s=\pm\frac{3a}{\sqrt{e}\lambda^{1/4}}\mp\frac{a}{e\lambda^{3/4}}e^{\bar{\xi}}=\pm\frac{3a}{\sqrt{e}\lambda^{1/2}}\mp\frac{4a^3}{e\lambda_1^{3/4}}\frac{1}{s^2}.$$

Thus, since $\lambda_1=\lambda_2/\lambda$, one produces the following approximation:

$$\frac{1}{s^2}=\frac{c_1}{\lambda^{1/2}}\mp\frac{c_2}{\lambda^{3/4}}s+\mathbf{O}(\lambda),\quad c_1=\frac{3a^2(e\lambda_2)^{1/2}}{4},\quad c_2=\frac{e\lambda_2^{3/4}}{4a^3}. \tag{4.5}$$

On the other hand, solving this last equation for s we deduce

$$s=\mp\frac{\frac{1}{s^2}-\frac{c_1}{\lambda^{1/2}}}{\frac{c_2}{\lambda^{3/4}}}=\mp\frac{1-\frac{c_1}{\lambda^{1/2}}s^2}{\frac{c_2}{\lambda^{3/4}}s^2},$$

a fact that permits us to write

$$\frac{1}{s}=\mp\frac{1}{\frac{1}{c_2s^2/\lambda^{3/4}}-\frac{c_1/\lambda^{1/2}}{c_2/\lambda^{3/4}}}=\pm\frac{1}{\frac{c_1\lambda^{1/2}}{c_2}-\frac{\lambda^{3/4}}{c_2s^2}}=\pm\frac{1}{\left(1-\frac{\lambda^{1/4}}{c_1s^2}\right)\frac{c_1\lambda^{1/2}}{c_2}}.$$

We approximate again and we obtain

$$\frac{1}{s}=\pm\frac{c_2}{c_1\lambda^{1/2}}\left(1+\frac{\lambda^{1/4}}{c_1}\frac{1}{s^2}\right)+\mathbf{O}(\lambda^{1/2}). \tag{4.6}$$

Until now we succeeded in expressing $1/s^2$ and $1/s$ in terms of s up to $\mathbf{O}(\lambda)$ and $\mathbf{O}(\lambda^{1/2})$, respectively.

Introducing the above-given results into (3.36a) we extract the following Abel nonlinear ODE of the normal form:

$$qq_s'-q=As+B,$$

$$A=p_3\mp\frac{c_2}{\lambda^{3/4}}p_1-\frac{c_2^2}{c_1\lambda^{1/4}}p_2,\quad B=p_4\pm\frac{c_1}{\lambda^{1/2}}p_1\pm\frac{c_2}{c_1}\left(\frac{1}{\lambda^{1/2}}+\frac{1}{\lambda^{3/4}}\right)p_2, \tag{4.7}$$

$$p_1,\ p_2,\ p_3,\ p_4 \text{ as in Eq. (3.36a)};\quad c_1,\ c_2 \text{ as in Eq. (4.5)}.$$

The Abel equation (3.7) admits an exact parametric solution given by the restored formula (see Ref. 21, p. 29, type 1.3.2)

$$s=C_2\exp\left(-\int\frac{v\mathrm{d}v}{v^2-v-A}\right),$$

$$q=C_2\frac{v-1}{A}\exp\left(-\int\frac{v\,dv}{v^2-v-A}\right)-\frac{B}{A}, \tag{4.8}$$

$$v=q_s'=\text{parameter}.$$

Note that for the forced undamped (NLD) equation a similar approximate analytic solution to (4.8) holds true with different factors p_i (i=1,2,3,4) given by Eq. (3.53b).

V. CONCLUSIONS

By a series of admissible functional transformations we reduced the one-dimensional axisymmetric (NLS) equation, and the forced damped or undamped (NLD) equations to equivalent nonlinear integrodifferential equations of the first order. These equations are exact and constitute the intermediate integrals in the phase plane. In the limits of small or large values of the parameters characterizing these nonlinear problems, we expand the reduced integrodifferential equations asymptotically to nonlinear ODEs of the first order. The (NLS) equation changes to solvable first-order form, while the (NLD) equations change to nonlinear ODEs of the Abel classes. Taking into account the existing known exact analytic solutions of these classes of equations, we show that both (NLD) equations do not admit exact analytic solutions in terms of known (tabulated) functions. For further asymptotic approximations we succeed in constructing exact analytic solutions for (NLD) oscillators. The reduction methodology introduced in the paper is general and can be applied to some of the most interesting ODEs of mathematical physics and nonlinear mechanics, including the forced Van der Pol nonlinear oscillator; the Thomas–Fermi equation; the Blasius equation $y'''_{xxx}+\lambda_1 y y''_{xx}=0$; the Langmuir equation $3yy''_{xx}+y'^2_x+4yy'_x+y^2-1=0$; the Kidder equation $\sqrt{1-ayy''_{xx}}+2xy'_x=0$, $0<a<1$, as well as the plastic spin equations in simple shear.[20]

[DOI: 10.1063/1.1636511]

The Hall conductivity on noncommutative plane is given as in (30) if the current defined in (28) is rescaled with a γ factor:

$$\hat{\vec{J}} = \frac{e\gamma^2\rho}{m}\left(\gamma\hat{\vec{p}} + \frac{e}{c}\vec{A} + \vec{a}\right).$$

However, this is not a very natural definition. If one retains the more natural definition (28), the noncommutative Hall conductivity σ_H^{nc} will be independent of the noncommutativity parameter θ and the comments given in Ref. 1 should be taken into account.

(Received 24 November 2003; accepted 25 November 2003)

In this paper, we present a new entanglement monotone for bipartite quantum states. Its definition is inspired by the so-called intrinsic information of classical cryptography and is given by the halved minimum quantum conditional mutual information over all tripartite state extensions. We derive certain properties of the new measure which we call "squashed entanglement": it is a lower bound on entanglement of formation and an upper bound on distillable entanglement. Furthermore, it is convex, additive on tensor products, and superadditive in general. Continuity in the state is the only property of our entanglement measure which we cannot provide a proof for. We present some evidence, however, that our quantity has this property, the strongest indication being a conjectured Fannes-type inequality for the conditional von Neumann entropy. This inequality is proved in the classical case. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1643788]

I. INTRODUCTION

Ever since Bennett *et al.*[1,2] introduced the entanglement measures of *distillable entanglement* and *entanglement of formation* in order to measure the amount of nonclassical correlation in a bipartite quantum state, there has been an interest in an axiomatic approach to entanglement measures. One natural axiom is LOCC-monotonicity, which means that an entanglement measure should not increase under *Local Operations and Classical Communication*. Furthermore, every entanglement measure should vanish on the set of separable quantum states; it should be convex, additive, and a continuous function in the state. Though several entanglement measures have been proposed, it turns out to be difficult to find measures that satisfy all of the above axioms. One unresolved question is whether or not entanglement of formation is additive. This is an important question and has recently been connected to many other additivity problems in quantum information theory.[24] Other examples are distillable entanglement, which shows evidence of being neither additive nor convex,[25] and *relative entropy of entanglement*,[28] which can be proven to be nonadditive.[30]

In this paper we present a functional called "squashed entanglement" which has many of these desirable properties: it is convex, additive on tensor products and superadditive in general. It is upper bound by entanglement cost, lower bound by distillable entanglement, and we are able to present some evidence of continuity.

The remaining sections are organized as follows: in Sec. II we will define squashed entanglement and prove its most important properties. In Sec. III we will explain its analogy to a quantity called *intrinsic information*, known from classical cryptography. This constitutes the motivation for our definition.

[a)]Electronic mail: matthias.christandl@qubit.org
[b)]Electronic mail: a.j.winter@bris.ac.uk

The only property that we could not find proof for is continuity. A detailed discussion of this problem follows in Sec. IV, where we show that squashed entanglement is continuous on the interior of the set of states and where we provide evidence in favor of continuity in general. This evidence is based on a Fannes-type inequality for the conditional von Neumann entropy. It is conjectured in general and is true in the classical case, which we will prove in the Appendix.

II. SQUASHED ENTANGLEMENT

In this paper all Hilbert spaces are assumed to be finite dimensional, even though some of the following definitions and statements make sense also in infinite dimension.

Definition 1: Let ρ^{AB} be a quantum state on a bipartite Hilbert space $\mathcal{H}=\mathcal{H}_A\otimes\mathcal{H}_B$. We define the *squashed entanglement* of ρ^{AB} by

$$E_{\mathrm{sq}}(\rho^{AB}) := \inf\{\tfrac{1}{2} I(A;B|E) : \rho^{ABE} \text{ extension of } \rho^{AB}\}.$$

The infimum is taken over all extensions of ρ^{AB}, i.e., over all quantum states ρ^{ABE} with $\rho^{AB}=\mathrm{Tr}_E\rho^{ABE}$. $I(A;B|E) := S(AE)+S(BE)-S(ABE)-S(E)$ is the quantum conditional mutual information of ρ^{ABE}.[3] ρ^A stands for the restriction of the state ρ^{ABE} to subsystem A, and $S(A)=S(\rho^A)$ is the von Neumann entropy of the underlying state, if it is clear from the context. If not, we emphasize the state in subscript, $S(A)_\rho$. Note that the dimension of E is *a priori* unbounded.

Tucci[26] has previously defined the same functional (without the factor $\frac{1}{2}$) in connection with his investigations into the relationship between quantum conditional mutual information and entanglement measures, in particular entanglement of formation.

Our name for this functional comes from the idea that the right choice of a conditioning system reduces the quantum mutual information between A and B, thus "squashing out" the nonquantum correlations. See Sec. III for a similar idea in classical cryptography, which motivated the above definition.

Example 2: Let $\rho^{AB}=|\psi\rangle\langle\psi|^{AB}$ be a pure state. All extensions of ρ^{AB} are of the form $\rho^{ABE}=\rho^{AB}\otimes\rho^E$; therefore

$$\tfrac{1}{2} I(A;B|E) = S(\rho^A) = E(|\psi\rangle),$$

which implies $E_{\mathrm{sq}}(|\psi\rangle\langle\psi|)=E(|\psi\rangle)$.

Proposition 3: E_{sq} *is an* entanglement monotone, *i.e., it does not increase under local quantum operations and classical communication (LOCC) and it is convex.*

Proof: According to Ref. 29 it suffices to verify that E_{sq} satisfies the following two criteria:

(1) For any quantum state ρ^{AB} and any unilocal quantum instrument $(\mathcal{E}_k)$—the $\mathcal{E}_k$ are completely positive maps and their sum is trace preserving[6]—performed on either subsystem,

$$E_{\mathrm{sq}}(\rho^{AB}) \geq \sum_k p_k E_{\mathrm{sq}}(\tilde{\rho}_k^{AB}),$$

where

$$p_k = \mathrm{Tr}\,\mathcal{E}_k(\rho^{AB}) \quad \text{and} \quad \tilde{\rho}_k^{AB} = \frac{1}{p_k}\mathcal{E}_k(\rho^{AB}).$$

(2) E_{sq} is convex, i.e., for all $0\leq\lambda\leq 1$,

$$E_{\mathrm{sq}}(\lambda\rho^{AB}+(1-\lambda)\sigma^{AB}) \leq \lambda E_{\mathrm{sq}}(\rho^{AB})+(1-\lambda)E_{\mathrm{sq}}(\sigma^{AB}).$$

In order to prove 1, we modify the proof of theorem 11.15 in Ref. 19 for our purpose. By symmetry we may assume that the instrument $(\mathcal{E}_k)$ acts unilocally on A. Now, attach two ancilla systems A' and A'' in states $|0\rangle^{A'}$ and $|0\rangle^{A''}$ to the system ABE (i). To implement the quantum operation

$$\rho^{ABE} \to \tilde{\rho}^{AA'BE} := \sum_k (\mathcal{E}_k \otimes \mathrm{id}_E)(\rho^{ABE}) \otimes |k\rangle\langle k|^{A'},$$

with $(|k\rangle^{A'})_k$ being an orthonormal basis on A', we perform (ii) a unitary transformation U on $AA'A''$ followed by (iii) tracing out the system A''. Here, $\tilde{i}$ denotes the system $i \in \{A,B,AB\}$ after the unitary evolution U. Then, for any extension of ρ^{AB},

$$\begin{aligned} I(A;B|E) &\overset{\text{(i)}}{=} I(AA'A'';B|E) \\ &\overset{\text{(ii)}}{=} I(\tilde{A}\tilde{A}'\tilde{A}'';\tilde{B}|\tilde{E}) \\ &\overset{\text{(iii)}}{\geq} I(\tilde{A}\tilde{A}';\tilde{B}|\tilde{E}) \\ &\overset{\text{(iv)}}{=} I(\tilde{A}';\tilde{B}|\tilde{E}) + I(\tilde{A};\tilde{B}|\tilde{E}\tilde{A}') \\ &\overset{\text{(v)}}{\geq} \sum_k p_k I(\tilde{A};\tilde{B}|\tilde{E})_{\rho_k} \\ &\overset{\text{(vi)}}{\geq} \sum_k 2 p_k E_{\mathrm{sq}}(\rho_k). \end{aligned}$$

The justification of these steps is as follows: attaching auxiliary pure systems does not change the entropy of a system, step (i). The unitary evolution affects only the systems $AA'A''$ and therefore does not affect the quantum conditional mutual information in step (ii). To show that discarding quantum systems cannot increase the quantum conditional mutual information

$$I(\tilde{A}\tilde{A}';\tilde{B}|\tilde{E}) \leq I(\tilde{A}\tilde{A}'\tilde{A}'';\tilde{B}|\tilde{E})$$

we expand it into

$$S(AA'E) + S(BE) - S(AA'BE) - S(E) \leq S(AA'A''E) + S(BE) - S(AA'A''BE) - S(E),$$

which is equivalent to

$$S(AA'E) - S(AA'BE) \leq S(AA'A''E) - S(AA'A''BE),$$

the strong subadditivity;[17] this shows step (iii), and for step (iv) we use the *chain rule*,

$$I(XY;Z|U) = I(X;Z|U) + I(Y;Z|UX).$$

For step (v), note that the first term, $I(\tilde{A}';\tilde{B}|\tilde{E})$, is non-negative and that the second term, $I(\tilde{A};\tilde{B}|\tilde{E}\tilde{A}')$, is identical to the expression in the next line. Finally, we have (vi) since $\rho_k^{\tilde{A}\tilde{B}\tilde{E}}$ is a valid extension of ρ_k. As the original extension of ρ^{AB} was arbitrary, the claim follows.

To prove convexity, property 2, consider any extensions ρ^{ABE} and σ^{ABE} of the states ρ^{AB} and σ^{AB}, respectively. It is clear that we can assume, without loss of generality, that the extensions are defined on identical systems E. Combined, ρ^{ABE} and σ^{ABE} form an extension

$$\tau^{ABEE'} := \lambda \rho^{ABE} \otimes |0\rangle\langle 0|^{E'} + (1-\lambda)\sigma^{ABE} \otimes |1\rangle\langle 1|^{E'}$$

of the state $\tau^{AB} = \lambda\rho^{AB} + (1-\lambda)\sigma^{AB}$. The convexity of squashed entanglement then follows from the observation

$$\lambda I(A;B|E)_\rho + (1-\lambda) I(A;B|E)_\sigma = I(A;B|EE')_\tau \geq 2E_{\mathrm{sq}}(\tau^{AB}).$$

Proposition 4: E_{sq} is superadditive in general, and additive on tensor products, i.e.,

$$E_{\mathrm{sq}}(\rho^{AA'BB'}) \geq E_{\mathrm{sq}}(\rho^{AB}) + E_{\mathrm{sq}}(\rho^{A'B'})$$

is true for every density operator $\rho^{AA'BB'}$ on $\mathcal{H}_A \otimes \mathcal{H}_{A'} \otimes \mathcal{H}_B \otimes \mathcal{H}_{B'}$, $\rho^{AB} = \mathrm{Tr}_{A'B'}\rho^{AA'BB'}$, and $\rho^{A'B'} = \mathrm{Tr}_{AB}\rho^{AA'BB'}$,

$$E_{\mathrm{sq}}(\rho^{AA'BB'}) = E_{\mathrm{sq}}(\rho^{AB}) + E_{\mathrm{sq}}(\rho^{A'B'})$$

for $\rho^{AA'BB'}=\rho^{AB}\otimes\rho^{A'B'}$.

Proof: We start with superadditivity and assume that $\rho^{AA'BB'E}$ on $\mathcal{H}_A\otimes\mathcal{H}_{A'}\otimes\mathcal{H}_B\otimes\mathcal{H}_{B'}\otimes\mathcal{H}_E$ is an extension of $\rho^{AA'BB'}$, i.e., $\rho^{AA'BB'}=\mathrm{Tr}_E\rho^{AA'BB'E}$. Then,

$$\begin{aligned}I(AA';BB'|E)&=I(A;BB'|E)+I(A';BB'|EA)\\&=I(A;B|E)+I(A;B'|EB)+I(A';B'|EA)+I(A';B|EAB')\\&\geqslant I(A;B|E)+I(A';B'|EA)\geqslant 2E_{\mathrm{sq}}(\rho^{AB})+2E_{\mathrm{sq}}(\rho^{A'B'}).\end{aligned}$$

The first inequality is due to strong subadditivity of the von Neumann entropy. Note that E is an extension for system AB and EA extends system $A'B'$. Hence, the last inequality is true since squashed entanglement is defined via the infimum over all extensions of the respective states. The calculation is independent of the choice of the extension, which proves superadditivity.

A special case of the above is superadditivity on product states $\rho^{AA'BB'}:=\rho^{AB}\otimes\rho^{A'B'}$. To conclude that E_{sq} is indeed additive on tensor products, it therefore suffices to prove subadditivity on tensor products.

Let ρ^{ABE} on $\mathcal{H}_A\otimes\mathcal{H}_B\otimes\mathcal{H}_E$ be an extension of ρ^{AB} and let $\rho^{A'B'E'}$ on $\mathcal{H}_{A'}\otimes\mathcal{H}_{B'}\otimes\mathcal{H}_{E'}$ be an extension for $\rho^{A'B'}$. It is evident that $\rho^{ABE}\otimes\rho^{A'B'E'}$ is a valid extension for $\rho^{AA'BB'}=\rho^{AB}\otimes\rho^{A'B'}$, hence

$$\begin{aligned}2E_{\mathrm{sq}}(\rho^{AA'BB'})&\leqslant I(AA';BB'|EE')\\&=I(A;B|EE')+\underbrace{I(A;B'|EE'B)}_{=0}+I(A';B'|EE'A)+\underbrace{I(A';B|EE'AB')}_{=0}\\&=I(A;B|E)+I(A';B'|EE'A)\\&=I(A;B|E)+I(A';B'|E').\end{aligned}$$

This inequality holds for arbitrary extensions of ρ^{AB} and $\rho^{A'B'}$. We therefore conclude that E_{sq} is subadditive on tensor products. □

Proposition 5: E_{sq} *is upper bounded by* entanglement of formation[1,2]

$$E_{\mathrm{sq}}(\rho^{AB})\leqslant E_F(\rho^{AB}).$$

Proof: Let $\{p_k,|\Psi_k\rangle\}$ be a pure state ensemble for ρ^{AB},

$$\sum_k p_k|\Psi_k\rangle\langle\Psi_k|^{AB}=\rho^{AB}.$$

The purity of the ensemble implies

$$\sum_k p_k S(A)_{\Psi_k}=\tfrac{1}{2}\sum_k p_k I(A;B)_{\Psi_k}.$$

Consider the following extension ρ^{ABE} of ρ^{AB}:

$$\rho^{ABE}:=\sum_k p_k|\Psi_k\rangle\langle\Psi_k|^{AB}\otimes|k\rangle\langle k|^E.$$

It is elementary to compute

$$\sum_k p_k S(A)_{\Psi_k}=\tfrac{1}{2}\sum_k p_k I(A;B)_{\Psi_k}=\tfrac{1}{2}I(A;B|E).$$

Thus, it is clear that entanglement of formation can be regarded as an infimum over a certain class of extensions of ρ^{AB}. Squashed entanglement is an infimum over *all* extensions of ρ^{AB}, evaluated on the same quantity $\frac{1}{2}I(A;B|E)$ and therefore smaller or equal to entanglement of formation. □

Corollary 6: E_{sq} *is upper bounded by* entanglement cost,

$$E_{\mathrm{sq}}(\rho^{AB}) \leqslant E_C(\rho^{AB}).$$

Proof: Entanglement cost is equal to the regularized entanglement of formation,[12]

$$E_C(\rho^{AB}) = \lim_{n\to\infty} \frac{1}{n} E_F((\rho^{AB})^{\otimes n}).$$

This, together with proposition 5, and the additivity of the squashed entanglement (proposition 4) implies

$$E_C(\rho^{AB}) = \lim_{n\to\infty} \frac{1}{n} E_F((\rho^{AB})^{\otimes n}) \geqslant \lim_{n\to\infty} \frac{1}{n} E_{\mathrm{sq}}((\rho^{AB})^{\otimes n}) = E_{\mathrm{sq}}(\rho^{AB}).$$

□

Theorem 7: *Squashed entanglement vanishes for every separable density matrix* ρ^{AB}*, i.e.,*

$$\rho^{AB} \textit{separable} \Rightarrow E_{\mathrm{sq}}(\rho^{AB}) = 0.$$

Conversely, if there exists a finite extension ρ^{ABE} *of* ρ^{AB} *with vanishing quantum conditional mutual information, then* ρ^{AB} *is separable, i.e.,*

$$I(A;B|E) = 0 \quad \textit{and} \quad \dim \mathcal{H}_E < \infty \Rightarrow \rho^{AB} \quad \textit{separable}.$$

Proof: Every separable ρ^{AB} can be written as a convex combination of separable pure states,

$$\rho^{AB} = \sum_i p_i |\psi_i\rangle\langle\psi_i|^A \otimes |\phi_i\rangle\langle\phi_i|^B.$$

The quantum conditional mutual information of the extension

$$\rho^{ABE} := \sum_i p_i |\psi_i\rangle\langle\psi_i|^A \otimes |\phi_i\rangle\langle\phi_i|^B \otimes |i\rangle\langle i|^E,$$

with orthonormal states ($|i\rangle^E$), is zero. Squashed entanglement thus vanishes on the set of separable states.

To prove the second assertion assume that there exists an extension ρ^{ABE} of ρ^{AB} with $I(A;B|E)=0$ and $\dim \mathcal{H}_E < \infty$. Now, a recently obtained result[13] on the structure of such states ρ^{ABE} applies: there it was shown that in this case the system E can be written as a direct sum of tensor products, such that with a suitable basis transformation $E \to EE'E''$ the state can be rewritten

$$\rho^{ABE} = \sum_i p_i \rho_i^{AE'} \otimes \rho_i^{E''B} \otimes |i\rangle\langle i|^E.$$

Then $\rho^{AB} = \Sigma_i p_i (\mathrm{Tr}_{E'} \rho_i^{AE'}) \otimes (\mathrm{Tr}_{E''} \rho_i^{E''B})$ is separable.

Remark 8: The minimization in squashed entanglement ranges over extensions of ρ^{AB} *with a priori unbounded size.* $E_{\mathrm{sq}}(\rho)=0$ *is thus possible, even if any finite extension has strictly positive quantum conditional mutual information. Therefore, without a bound on the dimension of the extending system, the second part of theorem 7 does not suffice to conclude that* $E_{\mathrm{sq}}(\rho^{AB})$ *implies separability of* ρ^{AB}*. A different approach to this question could be provided by a possible approximate version of the main result of Ref. 13: if there is an extension* ρ^{ABE} *with small quantum conditional mutual information, then the* ρ^{AB} *is close to a separable state. For further discussion on this question, see Secs. III and IV.*

Note that the strict positivity of squashed entanglement for entangled states would, via corollary 6, imply strict positivity of entanglement cost for all entangled states. This is not yet proven, but conjectured as a consequence of the additivity conjecture of entanglement of formation.

Example 9: It is worth noting that in general E_{sq} is strictly smaller than E_F and E_C: consider the totally antisymmetric state σ^{AB} in a two-qutrit system

$$\sigma^{AB}=\tfrac{1}{3}(|\mathrm{I}\rangle\langle\mathrm{I}|+|\mathrm{II}\rangle\langle\mathrm{II}|+|\mathrm{III}\rangle\langle\mathrm{III}|),$$

with

$$|\mathrm{I}\rangle=\frac{1}{\sqrt{2}}(|2\rangle^A|3\rangle^B-|3\rangle^A|2\rangle^B),$$

$$|\mathrm{II}\rangle=\frac{1}{\sqrt{2}}(|3\rangle^A|1\rangle^B-|1\rangle^A|3\rangle^B),$$

$$|\mathrm{III}\rangle=\frac{1}{\sqrt{2}}(|1\rangle^A|2\rangle^B-|2\rangle^A|1\rangle^B).$$

On the one hand, it is known from Ref. 31 that $E_F(\sigma^{AB})=E_C(\sigma^{AB})=1$, though, on the other hand, we may consider the trivial extension,

$$E_{\mathrm{sq}}(\sigma^{AB})\leqslant\tfrac{1}{2}I(A;B)=\tfrac{1}{2}\log 3\approx 0.792.$$

The best known upper bound on E_D for this state, the *Rains bound*,[21] gives the only slightly smaller value $\log\frac{5}{3}\approx 0.737$. It remains open if there exist states for which squashed entanglement is smaller than the Rains bound.

Proposition 10: E_{sq} is lower bounded by distillable entanglement[1,2]

$$E_D(\rho^{AB})\leqslant E_{\mathrm{sq}}(\rho^{AB}).$$

Proof: Consider any entanglement distillation protocol by LOCC, taking n copies of the state $(\rho^{AB})^{\otimes n}$ to a state σ^{AB} such that

$$\|\sigma^{AB}-|s\rangle\langle s|^{AB}\|_1\leqslant\delta, \tag{1}$$

with $|s\rangle$ being a maximally entangled state of Schmidt rank s. We may assume without loss of generality that the support of σ^A and σ^B is contained in the s-dimensional support of $\mathrm{Tr}_B|s\rangle\langle s|$ and $\mathrm{Tr}_A|s\rangle\langle s|$, respectively. Using propositions 4 and 3, we have

$$nE_{\mathrm{sq}}(\rho^{AB})=E_{\mathrm{sq}}((\rho^{AB})^{\otimes n})\geqslant E_{\mathrm{sq}}(\sigma^{AB}), \tag{2}$$

so that it is only necessary to estimate $E_{\mathrm{sq}}(\sigma^{AB})$ vs $E_{\mathrm{sq}}(|s\rangle\langle s|^{AB})=\log s$ (see example 2). For this, let σ^{ABE} be an arbitrary extension of σ^{AB} and consider a purification of it, $|\Psi\rangle\in\mathcal{H}_{ABEE'}$. Chain rule and monotonicity of the quantum mutual information allow us to estimate

$$I(A;B|E)=I(AE;B)-I(E;B)\geqslant I(A;B)-I(EE';AB)=I(A;B)-2S(AB).$$

Further applications of Fannes inequality,[9] lemma 13, give $I(A;B)\geqslant 2\log s-f(\delta)\log s$ and $2S(AB)\leqslant f(\delta)\log s$, with a function f of δ vanishing as δ approaches 0. Hence

$$\tfrac{1}{2}I(A;B|E)\geqslant\log s-f(\delta)\log s.$$

Since this is true for all extensions, we can put this together with Eq. (2), and obtain

$$E_{\mathrm{sq}}(\rho^{AB}) \geqslant \frac{1}{n}(1-f(\delta))\log s,$$

which, with $n\to\infty$ and $\delta\to 0$, concludes the proof, because we considered an arbitrary distillation protocol. □

Remark 11: In the proof of proposition 10 we made use of the continuity of E_{sq} in the vicinity of maximally entangled states. Similarly, E_{sq} can be shown to be continuous in the vicinity of any pure state. This, together with proposition 3, the additivity on tensor products (second part of proposition 4), and the normalization on Bell states, suffices to prove corollary 6 and proposition 10.[15]

Corollary 12:

$$\tfrac{1}{2}(I(A;B)-S(AB)) \leqslant E_{\mathrm{sq}}(\rho^{AB}).$$

Proof: The recently established *hashing inequality*[7] provides a lower bound for the *one-way distillable entanglement* $E_{\mathbf{D}}(\rho^{AB})$,

$$S(B)-S(AB) \leqslant E_{\mathbf{D}}(\rho^{AB}).$$

Interchanging the roles of A and B, we have

$$\tfrac{1}{2}(I(A;B)-S(AB)) \leqslant E_{D}(\rho^{AB}),$$

where we use the fact that one-way distillable entanglement is smaller or equal to distillable entanglement. This, together with the bound from proposition 10, implies the assertion. □

III. ANALOGY TO INTRINSIC INFORMATION

Intrinsic information is a quantity that serves as a measure for the correlations between random variables in information-theoretical secret-key agreement.[18] The *intrinsic (conditional mutual) information* between two discrete random variables X and Y, given a third discrete random variable Z, is defined as

$$I(X;Y\downarrow Z) = \inf\{I(X;Y|\overline{Z}):\overline{Z} \text{ with } XY\to Z\to\overline{Z} \text{ a Markov chain}\}.$$

The infimum extends over all discrete channels Z to $\overline{Z}$ that are specified by a conditional probability distribution $P_{\overline{Z}|Z}$.

A first idea to utilize intrinsic information for measuring quantum correlations was mentioned in Ref. 11. This inspired the proposal of a *quantum analog to intrinsic information*[4] in which the Shannon conditional mutual information plays a role similar to the quantum conditional mutual information in squashed entanglement. This proposal possesses certain good properties demanded of an entanglement measure, and it opened the discussion that has resulted in the current work.

Before we state some similarities in the properties that the *intrinsic information* and *squashed entanglement* have in common, we would like to stress their obvious relation in terms of the definitions. Let $|\Psi\rangle^{ABC}$ be a purification of ρ^{AB} and let ρ^{ABE} be an extension of ρ^{AB} with purification $|\Phi\rangle^{ABEE'}$. Remark that all purifications of ρ^{AB} are equivalent in the sense that there is a suitable unitary transformation on the purifying system with

$$\mathbb{1}^{AB}\otimes U:|\Psi\rangle^{ABC}\mapsto|\Phi\rangle^{ABEE'}.$$

Applying a partial trace operation over system E' then results in the completely positive map

$$\Lambda:\mathcal{B}(\mathcal{H}_C)\to\mathcal{B}(\mathcal{H}_E),$$

$$\mathrm{id}\otimes\Lambda:|\Psi\rangle\langle\Psi|^{ABC}\mapsto\rho^{ABE}.$$

Conversely, every state ρ^{ABE} constructed in this manner is an extension of ρ^{AB}.

This shows that the squashed entanglement equals

$$E_{\mathrm{sq}}(\rho^{AB}) = \inf\{\tfrac{1}{2} I(A;B|E) : \rho^{ABE} = (\mathrm{id}\otimes\Lambda)|\Psi\rangle\langle\Psi|^{ABC}\}, \tag{3}$$

where the infimum includes all quantum operations $\Lambda : \mathcal{B}(\mathcal{H}_C) \to \mathcal{B}(\mathcal{H}_E)$.

In Ref. 5 it is shown that the minimization in $I(X;Y\downarrow Z)$ can be restricted to random variables $\overline{Z}$ with a domain equal to that of Z. This shows that the infimum in the definition is in effect a minimum and that the intrinsic information is a continuous function of the distribution P_{XYZ}. It is interesting to note that the technique used there (and, for that matter, also in the proof that entanglement of formation is achieved as a minimum over pure state ensembles $\rho^{AB} = \Sigma_k p_k |\Psi_k\rangle\langle\Psi_k|^{AB}$ of size $(\mathrm{rank}\ \rho^{AB})^2$), does not work for our problem, and so, we do not have an easy proof of the continuity of squashed entanglement. In the following section this issue will be discussed in some more detail.

In the cryptographic context in which it appears, intrinsic information serves as an upper bound for the secret-key rate $S = S(X;Y||Z)$.[18] S is the rate at which two parties, having access to repeated realizations of X and Y, can distill secret correlations about which a third party, holding realizations of Z, is almost ignorant. This distillation procedure includes all protocols in which the two parties communicate via a public authenticated classical channel to which the eavesdropper has access but cannot alter the transmitted messages. Clearly, one can interpret distillable entanglement as the quantum analog to the secret-key rate. On the one hand, *secret quantum correlations*, i.e., maximally entangled states of qubits, are distilled from a number of copies of ρ^{AB}. In the classical cryptographic setting, on the other hand, one aims at distilling *secret classical correlations*, i.e., secret classical bits, from a number of realizations of a triple of random variables X, Y, and Z.

We proved in proposition 10 that squashed entanglement is an upper bound for distillable entanglement. Hence, it provides a bound in entanglement theory which is analogous to the one in information-theoretic secure key agreement, where intrinsic information bounds the secret-key rate from above.

This analogy extends further to the bound on the formation of quantum states (proposition 5 and corollary 6), where we know of a recently proven classical counterpart, namely, that the intrinsic information is a lower bound on the formation cost of correlations of a triple of random variables X, Y, and Z from secret correlations.[22]

IV. THE QUESTION OF CONTINUITY

Intrinsic information, discussed in the previous section, and entanglement of formation are continuous functions of the probability distribution and state, respectively. This is so, because in both cases we are able to restrict the minimization to a compact domain; in the case of intrinsic information to bounded range $\overline{Z}$ and in entanglment of formation to bounded size decompositions, noting that the functions to be minimized are continuous.

Thus, by the same general principle, we could show continuity if we had a universal bound d on the dimension of E in definition 1, in the sense that every value of $I(A;B|E)$ obtainable by general extensions can be reproduced or beaten by an extension with a d-dimensional system E. Note that if this were true, then (just as for intrinsic information and entanglement of formation) the infimum would actually be a minimum: in remark 7 we have explained that then $E_{\mathrm{sq}}(\rho^{AB}) = 0$ would imply, using the result of,[13] that ρ^{AB} is separable.

As it is, we cannot yet decide on this question, but we would like to present a reasonable conjecture, an inequality of the Fannes-type[9] for the conditional von Neumann entropy, which we can show to imply continuity of E_{sq}. Let us first revisit Fannes' inequality in a slightly nonstandard form:

Lemma 13: For density operators ρ, σ on the same d-dimensional Hilbert space, with $\|\rho-\sigma\|_1\leqslant\epsilon$,

$$|S(\rho)-S(\sigma)|\leqslant\eta(\epsilon)+\epsilon\log d,$$

with the universal function

$$\eta(\epsilon)=\begin{cases}-\epsilon\log\epsilon & \epsilon\leqslant\frac{1}{2},\\ \frac{1}{2} & \text{otherwise.}\end{cases}$$

Observe that η is a concave function. □

Now we can state the conjecture, recalling that for a density operator ρ^{AB} on a bipartite system $\mathcal{H}_A\otimes\mathcal{H}_B$, the conditional von Neumann entropy[3] is defined as

$$S(A|B):=S(\rho^{AB})-S(\rho^B).$$

Conjecture 14: For density operators ρ, σ on the bipartite system $\mathcal{H}_A\otimes\mathcal{H}_B$, with $\|\rho-\sigma\|_1\leqslant\epsilon$,

$$|S(A|B)_\rho-S(A|B)_\sigma|\leqslant\eta(2\epsilon)+3\epsilon\log d_A,$$

with $d_A=\dim\mathcal{H}_A$, or some other universal function $f(\epsilon,d_A)$ vanishing at $\epsilon=0$ on the right-hand side.

Note that the essential feature of the conjectured inequality is that it only makes reference to the dimension of system A. If we were to use Fannes inequality directly with the definition of the conditional von Neumann entropy, we would pick up additional terms containing the logarithm of $d_B=\dim\mathcal{H}_B$. In the Appendix we show that this conjecture is true in the classical case, or more precisely, in the more general case where the states are classical on system B.

In order to show that the truth of this conjecture implies continuity of E_{sq}, consider two states ρ^{AB} and σ^{AB} with $\|\rho^{AB}-\sigma^{AB}\|_1\leqslant\epsilon$. By well-known relations between fidelity and trace distance[10] this means that $F(\rho^{AB},\sigma^{AB})\geqslant1-\epsilon$, hence[16,27] we can find purifications $|\Psi\rangle^{ABC}$ and $|\Phi\rangle^{ABC}$ of ρ^{AB} and σ^{AB}, respectively, such that $F(|\Psi\rangle^{ABC},|\Phi\rangle^{ABC})\geqslant1-\epsilon$. Using Ref. 10 once more, we get

$$\||\Psi\rangle\langle\Psi|^{ABC}-|\Phi\rangle\langle\Phi|^{ABC}\|_1\leqslant2\sqrt{\epsilon}.$$

Now, let Λ be any quantum operation as in Eq. (3): it creates extensions of ρ^{AB} and σ^{AB},

$$\rho^{ABE}=(\mathrm{id}\otimes\Lambda)|\Psi\rangle\langle\Psi|^{ABC},$$

$$\sigma^{ABE}=(\mathrm{id}\otimes\Lambda)|\Phi\rangle\langle\Phi|^{ABC},$$

with

$$\|\rho^{ABE}-\sigma^{ABE}\|_1\leqslant2\sqrt{\epsilon}.$$

Hence, using $I(A;B|E)=S(A|E)+S(B|E)-S(AB|E)$, we can estimate

$$\begin{aligned}|I(A;B|E)_\rho-I(A;B|E)_\sigma|\leqslant{}&|S(A|E)_\rho-S(A|E)_\sigma|+|S(B|E)_\rho-S(B|E)_\sigma|+|S(AB|E)_\rho\\&-S(AB|E)_\sigma|\leqslant3\,\eta(2\sqrt{\epsilon})+6\sqrt{\epsilon}\log(d_Ad_B)=:\epsilon'.\end{aligned}$$

Since this applies to any quantum operation Λ and thus to every state extension of ρ^{AB} and σ^{AB}, respectively, we obtain

$$|E_{\mathrm{sq}}(\rho^{AB})-E_{\mathrm{sq}}(\sigma^{AB})|\leqslant\epsilon',$$

with ϵ' universally dependent on ϵ and vanishing with $\epsilon \to 0$. □

Remark 15: Since E_{sq} is convex it is trivially upper semicontinuous. This also follows from the fact that squashed entanglement is an infimum of continuous functions obtained by bounding the size of the dimension of system E.

This observation, together with results from the general theory of convex functions, implies that squashed entanglement is continuous ''almost everywhere.'' Specifically, with theorem 10.1 in Ref. 23, we have:

Proposition 16: E_{sq} is continuous on the interior of the set of states (i.e., on the faithful states), and more generally, it is continuous when restricted to the relative interior of all faces of the state set.

Continuity near pure states (see remark 11) thus implies continuity of E_{sq} on the set of all rank-2 density operators. □

V. CONCLUSION

In this paper we have presented a new measure of entanglement, which by its very definition allows for rather simple proofs of monotonicity under LOCC, convexity, additivity for tensor products and superadditivity in general, all by application of the strong subadditivity property of quantum entropy. We showed the functional, which we call ''squashed entanglement,'' to be lower bounded by the distillable entanglement and upper bounded by the entanglement cost. Thus, it has most of the ''good'' properties demanded by the axiomatic approaches[14,20,29] without suffering from the disadvantages of other superadditive entanglement monotones. The one proposed in Ref. 8, for example, diverges on the set of pure states.

The one desirable property from the wish list of axiomatic entanglement theory that we could not yet prove is continuity. We have shown, however, that squashed entanglement is continuous near pure states and in the relative interior of the faces of state space. Continuity in general would follow from a conjectured Fannes-type inequality for the conditional von Neumann entropy. The proof of this conjecture thus remains the great challenge of the present work. It might well be of wider applicability in quantum information theory and certainly deserves further study.

Another question to be asked is whether or not there exist states that are nonseparable but, nonetheless, have zero squashed entanglement. We expect this not to be the case: if not by means of proving that the infimum in squashed entanglement is achieved, then by means of an approximate version of the result of Ref. 13. The relation to entanglement measures other than entanglement of formation, entanglement cost and distillable entanglment remains open in general. If $E_{sq}=0$ would imply separability, however, it would follow that for the class of PPT states, squashed entanglement is larger than entanglement measures based on the partial transpose operation, like relative entropy of entanglement, the logarithmic negativity and the Rains bound.

Note added in proof. Alicki and Fannes (quant-ph/0312081) have recently proven our Conjecture 14, with the upper bound $4\epsilon \log d_A + 2\eta(\epsilon) + 2\eta(1-\epsilon)$. Thus, squashed entanglement is now known to be continuous.

APPENDIX: THE CLASSICAL CASE OF THE CONDITIONAL FANNES INEQUALITY

In this appendix we prove the conjecture 14 for states

$$\rho^{AB} = \sum_k p_k \rho_k^A \otimes |k\rangle\langle k|^B, \tag{A1}$$

$$\sigma^{AB}=\sum_k q_k \sigma_k^A \otimes |k\rangle\langle k|^B, \tag{A2}$$

with an orthogonal basis $(|k\rangle)_k$ and of $\mathcal{H}_B$, probability distributions (p_k) and (q_k), and states ρ_k^A and σ_k^A on A. Note that this includes the case of a pair of classical random variables. In this case, the states ρ_k^A and σ_k^A are all diagonal in the same basis $(|j\rangle)_j$ of $\mathcal{H}_A$ and thus ρ^{AB} and σ^{AB} describe joint probability distributions on a Cartesian product.

The key to the proof is that for states of the form (A1),

$$S(A|B)_\rho=\sum_k p_k S(\rho_k^A),$$

and similarly for the states given in Eq. (A2).

First of all, the assumption implies that

$$\epsilon \geqslant \|\rho^B-\sigma^B\|_1=\sum_k |p_k-q_k|.$$

Hence, we can successively estimate,

$$|S(A|B)_\rho-S(A|B)_\sigma| \leqslant \sum_k |p_k S(\rho_k^A)-q_k S(\sigma_k^A)| \leqslant \sum_k p_k |S(\rho_k^A)-S(\sigma_k^A)|+\sum_k |p_k-q_k| S(\sigma_k^A)$$

$$\leqslant \sum_k p_k(\eta(\epsilon_k)+\epsilon_k \log d_A)+\epsilon \log d_A \leqslant \eta(2\epsilon)+3\epsilon \log d_A,$$

using the triangle inequality twice in the first line, then using $S(\sigma_k^A)\leqslant \log d_A$, applying the Fannes inequality, lemma 13 (with $\epsilon_k := \|\rho_k^A-\sigma_k^A\|_1$), and finally making use of the concavity of its upper bound. To complete this step, we have to show $\Sigma_k p_k \epsilon_k \leqslant 2\epsilon$, which is done as follows:

$$\epsilon \geqslant \|\rho^{AB}-\sigma^{AB}\|_1=\sum_k \|p_k\rho_k^A-q_k\sigma_k^A\|_1 \geqslant \sum_k (\|p_k\rho_k^A-p_k\sigma_k^A\|_1-\|p_k\sigma_k^A-q_k\sigma_k^A\|_1) \geqslant \sum_k p_k\epsilon_k-\epsilon,$$

where we have used the triangle inequality. □

Note that in the case of pure states the conjecture is directly implied by Fannes inequality, lemma 13, since $S(AB)=0$ and $S(A)=S(B)$. Clearly, a proof of the general case cannot proceed along these lines as they do not have the possibility to present the conditional von Neumann entropy as an average of entropies on A.

Quantum mechanics of damped systems. II. Damping and parabolic potential barrier

Dariusz Chruściński
Institute of Physics, Nicolaus Copernicus University,
ul. Grudziądzka 5/7, 87-100 Toruń, Poland

(Received 25 July 2003; accepted 3 December 2003)

We investigate the resonant states for the parabolic potential barrier known also as inverted or reversed oscillator. They correspond to the poles of meromorphic continuation of the resolvent operator to the complex energy plane. As a by-product we establish an interesting relation between parabolic cylinder functions (representing energy eigenfunctions of our system) and a class of Gel'fand distributions used in our recent paper. © *2004 American Institute of Physics.*

I. INTRODUCTION

In a recent paper[1] we have investigated a quantization of the simple damped system[1]

$$\dot{u} = -\gamma u. \tag{1.1}$$

To quantize this system we double the number of degrees of freedom, i.e., together with (1.1) we consider $\dot{v} = +\gamma v$. We slightly change the notation: the coordinates (x,p) used in Ref. 1 are replaced by (u,v) in the present paper. The enlarged system is a Hamiltonian one and its quantization leads to the following quantum Hamiltonian:

$$\hat{H} = -\frac{\gamma}{2}(\hat{u}\hat{v} + \hat{v}\hat{u}). \tag{1.2}$$

This Hamiltonian, apart from the continuous spectrum $\sigma(\hat{H}) = (-\infty, \infty)$, displays two families of generalized eigenvectors $f_n^{\pm}$ corresponding to purely imaginary eigenvalues $\hat{H} f_n^{\pm} = \pm E_n f_n^{\pm}$. Clearly, these eigenvectors are not elements from the Hilbert space $\mathcal{H} = L^2(\mathbb{R}_u)$. To describe the quantum-mechanical system defined by (1.2) it is convenient to go beyond the standard Hilbert space formulation of quantum mechanics and to consider a rigged Hilbert space (or so-called Gel'fand triplet)[2,3]

$$\Phi \subset L^2(\mathbb{R}_u) \subset \Phi', \tag{1.3}$$

where Φ is a dense nuclear subspace of $L^2(\mathbb{R}_u)$ and Φ' denotes its dual, i.e., the space of continuous functionals on Φ. The rigged Hilbert space version of quantum mechanics was developed by Böhm,[4] Roberts,[5] and Antoine,[6] and further investigated by Brussels/Austin groups, see, e.g., Refs. 7–10 and the recent review.[11] The primary application of the rigged Hilbert space quantum mechanics is the description of resonances in scattering theory. The conventional definition [see, e.g., Refs. 12–14 and the review (Ref. 15)] states that a resonance corresponds to a pair of conjugated poles of the S-matrix analytically continued to the complex energy plane

$$z_R = E_R - i\frac{\Gamma}{2}, \quad \overline{z_R} = E_R + i\frac{\Gamma}{2}, \tag{1.4}$$

where E_R is the resonant energy and Γ is the width of the resonance. The corresponding generalized eigenvectors $|z_R\rangle$ are called resonant states (or Gamow vectors; see Ref. 11). Other definitions locate resonances as poles of generalized energy eigenfunctions when continued to the complex energy plane or as poles of meromorphic continuation of the resolvent operator. It is argued that resonant states are responsible for the irreversible behavior of quantum systems.

It was shown in Ref. 1 that generalized eigenvectors of the Hamiltonian (1.2) may be interpreted as resonant states, i.e., they correspond to the poles of energy eigenfunctions when continued to the complex energy plane. It turns out that resonant states are responsible for the irreversible behavior. Indeed, we showed that there are two dense subspaces $\Phi_\pm \in L^2(\mathbb{R}_u)$ such that restriction of the unitary group $U(t)=e^{-i\hat{H}t}$ to $\Phi_\pm$ no longer defines a group but gives rise to two semigroups: $U_-(t)=U(t)|_{\Phi_-}$ defined for $t\geqslant 0$ and $U_+(t)=U(t)|_{\Phi_+}$ defined for $t\leqslant 0$. In the framework of Gel'fand triplets it means that the quantum version of the damped system (1.1) corresponds to the Gel'fand triplet $\Phi_-\subset L^2(\mathbb{R}_u)\subset\Phi_-'$ together with the Hamiltonian $\hat{H}|_{\Phi_-}$. Another triplet $\Phi_+\subset L^2(\mathbb{R}_v)\subset\Phi_+'$ together with $\hat{H}|_{\Phi_+}$ corresponds to the quantum pumped system $\dot{v}=+\gamma v$. This way, the fashionable ''arrow of time'' is introduced by restricting the time evolution either to Φ_- or to Φ_+.

In the present paper we continue to study this system but in a different representation. Moreover, we are going to relate the resonant states to the poles of the corresponding S-matrix. Let us observe that performing the linear canonical transformation $(u,v)\to(x,p)$

$$u=\frac{\gamma x-p}{\sqrt{2\gamma}}\,,\quad v=\frac{\gamma x+p}{\sqrt{2\gamma}}\,, \tag{1.5}$$

one obtains for the Hamiltonian

$$\hat{H}=\tfrac{1}{2}(\hat{p}^2-\gamma^2\hat{x}^2). \tag{1.6}$$

It represents the parabolic potential barrier $V(x)=-\gamma^2x^2/2$ and it was studied by several authors in various contexts.[16–22] For obvious reasons it is also called an inverted or reversed oscillator. It is well known that this system gives rise to the generalized complex eigenvalues—the physical reason for that is the potential unbounded from below. We find the corresponding energy eigenstates for (1.6). They are given in terms of parabolic cylinder functions $D_\nu(x)$. Using the Gel'fand–Maurin spectral decomposition we find the resolvent operator $R(z,\hat{H})=(\hat{H}-z)^{-1}$ and relate its poles to the resonant states. Finally, we investigate the scattering problem and derive the relation between resonant and scattering states. It is shown that resonant states have the standard Breit–Wigner energy distribution.

As a by-product we established an interesting relation between the Gel'fand distributions $u_\pm^\lambda$ [23,24] (used in Ref. 1) and parabolic cylinder functions $D_\nu(x)$. The details are included in the Appendix.

II. INVERTED OSCILLATOR AND COMPLEX EIGENVALUES

Let us note that $\hat{H}$ defined in (1.6) corresponds to the Hamiltonian of the harmonic oscillator with purely imaginary frequency $\omega=\pm i\gamma$ (in the literature it is also called an inverted or reversed oscillator). The connection with a harmonic oscillator may be established by the following scaling operator:[25]

$$\hat{V}_\lambda:=\exp\left(\frac{\lambda}{2}(\hat{x}\hat{p}+\hat{p}\hat{x})\right), \tag{2.1}$$

with $\lambda\in\mathbb{R}$. Using commutation relation $[\hat{x},\hat{p}]=i$, this operator may be rewritten as follows:

$$\hat{V}_\lambda = e^{-i(\lambda/2)}\, e^{\lambda \hat{x}\hat{p}} = e^{-i(\lambda/2)}\, e^{-i\lambda x \partial_x}, \tag{2.2}$$

and therefore it defines a complex dilation, i.e., the action of $\hat{V}_\lambda$ on a function $\varphi = \varphi(x)$ is given by

$$\hat{V}_\lambda\, \varphi(x) = e^{-i(\lambda/2)}\, \varphi(e^{-i\lambda} x). \tag{2.3}$$

In particular, one easily finds

$$\hat{V}_\lambda\, \hat{x}\, \hat{V}_\lambda^{-1} = e^{-i\lambda}\hat{x} \quad , \quad \hat{V}_\lambda\, \hat{p}\, \hat{V}_\lambda^{-1} = e^{i\lambda}\hat{p}, \tag{2.4}$$

and hence

$$\hat{V}_\lambda\, (\hat{p}^2 - \gamma^2 \hat{x}^2)\, \hat{V}_\lambda^{-1} = e^{2i\lambda}\, (\hat{p}^2 - e^{-4i\lambda}\, \gamma^2 \hat{x}^2). \tag{2.5}$$

Therefore, for $e^{4i\lambda} = -1$, i.e., $\lambda = \pm \pi/4$, one has

$$\hat{V}_{\pm \pi/4}\, \hat{H}\, \hat{V}_{\pm \pi/4}^{-1} = \pm i \hat{H}_{\rm ho}, \tag{2.6}$$

where

$$\hat{H}_{\rm ho} = \tfrac{1}{2}(\hat{p}^2 + \gamma^2 \hat{x}^2), \tag{2.7}$$

stands for the oscillator Hamiltonian. In particular, if $E_n^{\rm ho} = \gamma(n + \frac{1}{2})$ is an oscillator spectrum

$$\hat{H}_{\rm ho} \psi_n^{\rm ho} = E_n^{\rm ho} \psi_n^{\rm ho}, \tag{2.8}$$

then

$$\hat{H} \mathfrak{f}_n^{\pm} = \pm E_n \mathfrak{f}_n^{\pm}, \tag{2.9}$$

with

$$E_n = i E_n^{\rm ho} = i\, \gamma(n + \tfrac{1}{2}), \tag{2.10}$$

and

$$\mathfrak{f}_n^{\pm}(x) = \hat{V}_{\mp \pi/4}\, \psi_n^{\rm ho}(x) = e^{\pm i \pi/8}\, \psi_n^{\rm ho}(e^{\pm i \pi/4} x). \tag{2.11}$$

Now, recalling that (see, e.g., Ref. 26)

$$\psi_n^{\rm ho}(x) = N_n\, e^{-(\gamma/2) x^2} H_n(\sqrt{\gamma} x), \tag{2.12}$$

where H_n stands for the nth Hermite polynomial and the normalization constant

$$N_n = \left(\frac{\sqrt{\gamma}}{2^n n! \sqrt{\pi}} \right)^{1/2}, \tag{2.13}$$

one obtains the following formulas for the generalized eigenvectors of $\hat{H}$:

$$\mathfrak{f}_n^{\pm}(x) = N_n^{\pm}\, e^{\mp i (\gamma/2) x^2} H_n(\sqrt{\pm i \gamma} x), \tag{2.14}$$

with

$$N_n^{\pm}=e^{\pm i\pi/8}N_n=\left(\frac{\sqrt{\pm i\gamma}}{2^n n!\sqrt{\pi}}\right)^{1/2}. \tag{2.15}$$

Clearly, $\mathfrak{f}_n^{\pm}$ are not elements from $L^2(\mathbb{R})$ but they do belong to the dual of the Schwartz space $\mathcal{S}(\mathbb{R}_x)'$, i.e., they are tempered distributions.

Proposition 1: Two families of generalized eigenvectors $\mathfrak{f}_n^{\pm}$ satisfy the following properties:

1. They are conjugated to each other:

$$\overline{\mathfrak{f}_n^{+}(x)}=\mathfrak{f}_n^{-}(x). \tag{2.16}$$

2. They are orthonormal

$$\langle \mathfrak{f}_n^{\pm}|\mathfrak{f}_m^{\mp}\rangle=\delta_{nm}. \tag{2.17}$$

3. They are complete

$$\sum_{n=0}^{\infty}\overline{\mathfrak{f}_n^{\pm}(x)}\,\mathfrak{f}_n^{\mp}(x')=\delta(x-x'). \tag{2.18}$$

The proof follows immediately from orthonormality and completeness of oscillator eigenfunctions ψ_n^{ho}. Formula (2.16) implies that $\mathfrak{f}_n^{+}$ and $\mathfrak{f}_n^{-}$ are related by the time-reversal operator $\mathbf{T}$: $\mathbf{T}\psi:=\overline{\psi}$.

III. CHANGE OF REPRESENTATION

It should be clear that there exists a relation between generalized eigenvectors $\mathfrak{f}_n^{\pm}(x)$ and $f_n^{\pm}(u)$ found in Ref. 1,

$$f_n^{+}(u)\sim u^n,\quad f_n^{-}(u)\sim\delta^{(n)}(u). \tag{3.1}$$

They define the same eigenvectors $|\pm n\rangle$ but in different representations

$$\mathfrak{f}_n^{\pm}(x)=\langle x|\pm n\rangle,\quad f_n^{\pm}(u)=\langle u|\pm n\rangle.$$

To find this relation, let us observe that the canonical transformation (1.5) is generated by the following generating function:

$$S(x,u)=\frac{\gamma}{2}x^2-\sqrt{2\gamma}xu+\frac{1}{2}u^2, \tag{3.2}$$

that is

$$p=\frac{\partial S}{\partial x},\quad v=-\frac{\partial S}{\partial u}. \tag{3.3}$$

Let us define a unitary operator

$$\mathcal{U}:L^2(\mathbb{R}_u)\to L^2(\mathbb{R}_x)$$

by

$$f\quad\to(\mathcal{U}f)(x)=C\int_{-\infty}^{\infty}f(u)e^{iS(x,u)}\,du, \tag{3.4}$$

where the constant "C" is determined by

$$|C|^2 \int_{-\infty}^{\infty} e^{iS(x,u)}\, e^{-iS(x',u)}\, du = \delta(x-x'). \tag{3.5}$$

It implies $C = e^{i\alpha} C_0$, where α is an arbitrary phase and

$$C_0 = \left(\frac{\gamma}{2\pi^2}\right)^{1/4}. \tag{3.6}$$

In the next section it would be clear that a natural choice for the phase is $\alpha = -\pi/8$. Clearly, $\mathcal{U}$ may be extended to act on $\mathcal{S}(\mathbb{R}_u)'$. It is easy to show that

$$\mathcal{U}(\mathcal{S}(\mathbb{R}_u)') \subset \mathcal{S}(\mathbb{R}_x)'. \tag{3.7}$$

Proposition 2: The generalized eigenvectors $\mathfrak{f}_n^{\pm} \in \mathcal{S}(\mathbb{R}_x)'$ and $f_n^{\pm} \in \mathcal{S}(\mathbb{R}_u)'$ are related by:

$$\mathfrak{f}_n^{\pm} = \mathcal{U} f_n^{\pm}. \tag{3.8}$$

Proof. Let us show that $\mathfrak{f}_n^{+} = \mathcal{U} f_n^{+}$, that is

$$\mathfrak{f}_n^{+}(x) \sim \int u^n e^{iS(x,u)} du. \tag{3.9}$$

Using the definition of $S(x,u)$, one has

$$\begin{aligned} \int u^n e^{iS(x,u)} du &= (-i\sqrt{2\pi\gamma})^{-n} e^{i\gamma x^2/2} \frac{d^n}{dx^n} \int e^{iu^2/2 - i\sqrt{2\gamma}xu} du \\ &= \sqrt{-2\pi i}(-i\sqrt{2\pi\gamma})^{-n} e^{-i\gamma x^2/2} \left(e^{i\gamma x^2} \frac{d^n}{dx^n} e^{-i\gamma x^2} \right). \end{aligned} \tag{3.10}$$

Now, due to the well-known formula for the Hermite polynomials

$$e^{iz^2} \frac{d^n}{dz^n} e^{-iz^2} = (-1)^n H_n(z), \tag{3.11}$$

one obtains

$$\int u^n e^{iS(x,u)} du = \sqrt{-2\pi i} \left(\frac{i}{2}\right)^{-n/2} e^{-i\gamma(x^2/2)} H_n(\sqrt{i\gamma}x) \sim \mathfrak{f}_n^{+}(x). \tag{3.12}$$

To prove that $\mathfrak{f}_n^{-} = \mathcal{U} f_n^{-}$, let us note that

$$\mathfrak{f}_n^{-}(x) = \overline{\mathfrak{f}_n^{+}(x)} \sim \int u^n e^{-iS(x,u)} du. \tag{3.13}$$

It turns out that a function

$$\tilde{S}(x,v) = -S(x,v) = -\frac{\gamma}{2}x^2 + \sqrt{2\gamma}xv - \frac{1}{2}v^2,$$

serves as a generating function for the canonical transformation (1.5)

$$p=\frac{\partial\widetilde{S}}{\partial x},\qquad u=-\frac{\partial\widetilde{S}}{\partial v}.$$

Now, taking into account that f_n^+ and f_n^- are related by the Fourier transformation

$$u^n=\sqrt{2\pi}(-i)^n F^{-1}[\delta^{(n)}(k)](u), \tag{3.14}$$

one obtains

$$\int u^n e^{-iS(x,u)}du=\sqrt{2\pi}(-i)^n\int \delta^{(n)}(u)F^{-1}[e^{-iS}](u)\,du. \tag{3.15}$$

Finally,

$$F^{-1}[e^{-iS}](u)=\frac{1}{\sqrt{2\pi}}\int e^{-iku}\,e^{-iS(x,k)}dk=\sqrt{-i}\,e^{iS(x,u)}, \tag{3.16}$$

and hence

$$\mathfrak{f}_n^-(x)\sim\int \delta^{(n)}(u)e^{iS(x,u)}du, \tag{3.17}$$

which ends the proof. □

IV. ENERGY EIGENSTATES

The spectrum of the self-adjoint operator (1.2) reads $\sigma(\hat{H})=(-\infty,\infty)$ and the corresponding energy eigenstates (in u-representation) are given by (cf. Sec. 6 in Ref. 1)

$$\psi_\pm^E(u)=\frac{1}{\sqrt{2\pi\gamma}}u_\pm^{-(iE/\gamma+1/2)}, \tag{4.1}$$

with $E\in\mathbb{R}$. For the basic properties of the tempered distributions $u_\pm^\lambda\in\mathcal{S}(\mathbb{R}_u)'$, we refer the reader to Refs. 23, 24 (see also the Appendix in Ref. 1). Now, using (x,p) coordinates, the corresponding eigenvalue problem $\frac{1}{2}(\hat{p}^2-\gamma^2\hat{x}^2)\chi^E=E\chi^E$ reads

$$\partial_x^2\chi^E(x)+(\gamma^2x^2+2E)\chi^E(x)=0. \tag{4.2}$$

Introducing a new variable

$$z=\sqrt{2i\gamma}\,x, \tag{4.3}$$

the above equation may be rewritten as follows:

$$\partial_z^2\chi^E+\left(\nu+\frac{1}{2}-\frac{z^2}{4}\right)\chi^E=0, \tag{4.4}$$

with

$$\nu=-\left(i\frac{E}{\gamma}+\frac{1}{2}\right), \tag{4.5}$$

which is the defining equation for the parabolic cylinder functions.[27–29] Its solution $\chi^E(z)$ is a linear combination of $D_\nu(z)$, $D_\nu(-z)$, $D_{-\nu-1}(iz)$, and $D_{-\nu-1}(-iz)$. [These four functions are linearly dependent. For the linear relation see, e.g., formula 9.248 in Ref. 27.] On the other hand,

the energy eigenstates in x-representation $\chi^E(x)$ may be obtained by applying the operator $\mathcal{U}$ defined in (3.4) to the corresponding eigenstates in u-representation $\psi^E_\pm(u)$

$$\chi^E_\pm(x)=(\mathcal{U}\psi^E_\pm)(x)=C\int_{-\infty}^{\infty}\psi^E_\pm(u)\,e^{iS(x,u)}\,du. \tag{4.6}$$

Hence

$$\chi^E_+(x)=\frac{C}{\sqrt{2\pi\gamma}}e^{i\gamma/2\,x^2}\int_0^\infty u^\nu\,e^{-i\sqrt{2\gamma}xu+iu^2/2}\,du=\frac{C}{\sqrt{2\pi\gamma}}\sqrt{i}^{\nu+1}\,e^{-y^2/4}\int_0^\infty\xi^\nu\,e^{y\xi-\xi^2/2}\,d\xi, \tag{4.7}$$

with $y=\sqrt{-2i\gamma}\,x$, and using an integral representation for $D_p(y)$ [formula 9.241(2) in Ref. 27]

$$D_p(y)=\frac{e^{-y^2/4}}{\Gamma(-p)}\int_0^\infty\xi^{-p-1}\,e^{-y\xi-\xi^2/2}\,d\xi, \tag{4.8}$$

one finds

$$\chi^E_+(x)=\frac{C_0}{\sqrt{2\pi\gamma}}\sqrt{i}^{\nu+1/2}\,\Gamma(\nu+1)D_{-\nu-1}(-\sqrt{-2i\gamma}x), \tag{4.9}$$

with ν given in (4.5). The validity of this formula is restricted in Ref. 27 for $\mathrm{Re}\,p<0$. However, as we shall show (see the proof of Proposition 4), it is valid for all $p\in\mathbb{C}$. Similarly, using an obvious relation $(-u)^\lambda_+=u^\lambda_-$, one obtains

$$\chi^E_-(x)=\frac{C_0}{\sqrt{2\pi\gamma}}\sqrt{i}^{\,\nu+1/2}\,\Gamma(\nu+1)D_{-\nu-1}(\sqrt{-2i\gamma}x), \tag{4.10}$$

that is, $\chi^E_-(x)=\chi^E_+(-x)$. Actually, instead of $\chi^E_\pm$ one may use energy eigenstates with the definite parity

$$\chi^E_{\mathrm{even}}=\frac{1}{\sqrt{2}}(\chi^E_+ +\chi^E_-), \tag{4.11}$$

$$\chi^E_{\mathrm{odd}}=\frac{1}{\sqrt{2}}(\chi^E_+ -\chi^E_-), \tag{4.12}$$

that is

$$\mathbf{P}\,\chi^E_{\mathrm{even}}=\chi^E_{\mathrm{even}},\quad \mathbf{P}\,\chi^E_{\mathrm{odd}}=-\chi^E_{\mathrm{odd}}, \tag{4.13}$$

where **P** stands for the parity operator.

Proposition 3: Energy eigenstates $\chi^E_\pm$ satisfy

$$\int_{-\infty}^{\infty}\overline{\chi^E_\pm(x)}\chi^{E'}_\pm(x)\,dx=\delta(E-E') \tag{4.14}$$

and

$$\int_{-\infty}^{\infty}\overline{\chi^E_\pm(x)}\chi^E_\pm(x')\,dE=\delta(x-x'). \tag{4.15}$$

The proof follows immediately from the analogous properties satisfied by energy eigenstates $\psi_{\pm}^{E}$ in u-representation.[1]

In Ref. 1 we have also used another generalized basis $F[\psi_{\pm}^{-E}](u)$. Now, we find its $\mathcal{U}$ image in $\mathcal{S}(\mathbb{R}_x)'$. Recalling the Fourier transformation of $x_{\pm}^{\lambda}$ (see Ref. 23 and Appendix in Ref. 1)

$$F[x_{\pm}^{\lambda}](u)=\frac{\pm i}{\sqrt{2\pi}}e^{\pm i\lambda\pi/2}\Gamma(\lambda+1)(u+i0)^{-\lambda-1}, \tag{4.16}$$

one has

$$F[\psi_{+}^{-E}](u)=\frac{1}{\sqrt{2\pi\gamma}}\frac{(-i)^{\nu}}{\sqrt{2\pi}}\Gamma(-\nu)(u+i0)^{\nu}. \tag{4.17}$$

Therefore, the corresponding x-representation

$$\eta_{+}^{E}(x)=(\mathcal{U}F[\psi_{+}^{-E}])(x) \tag{4.18}$$

is given by

$$\begin{aligned}\eta_{+}^{E}(x)&=\frac{C}{\sqrt{2\pi\gamma}}\frac{(-i)^{\nu}}{\sqrt{2\pi}}\Gamma(-\nu)\int_{-\infty}^{\infty}(u+i0)^{\nu}e^{iS(x,u)}du\\&=\frac{C}{\sqrt{2\pi\gamma}}\frac{(-i)^{\nu}}{\sqrt{2\pi}}(2\sqrt{i})^{\nu+1}\Gamma(-\nu)\,e^{y^2/4}\int_{-\infty}^{\infty}(\xi+i0)^{\nu}e^{-2\xi^2-2iy\xi}d\xi,\end{aligned} \tag{4.19}$$

with $y=\sqrt{2i\gamma}x$. Now, using the following integral representation [formula 9.241(1) in Ref. 27]:

$$D_{\nu}(y)=\frac{1}{\sqrt{\pi}}2^{\nu+1/2}(-i)^{\nu}e^{(y^2/4)}\int_{-\infty}^{\infty}(\xi+i0)^{\nu}e^{-2\xi^2+2iy\xi}d\xi, \tag{4.20}$$

one obtains

$$\eta_{+}^{E}(x)=\frac{C_0}{\sqrt{2\pi\gamma}}\sqrt{i}^{\nu+1/2}\Gamma(-\nu)D_{\nu}(-\sqrt{2i\gamma}x). \tag{4.21}$$

Similarly, one shows that

$$\eta_{-}^{E}(x)=(\mathcal{U}F[\psi_{-}^{-E}])(x) \tag{4.22}$$

is given by

$$\eta_{-}^{E}(x)=\frac{C_0}{\sqrt{2\pi\gamma}}\sqrt{i}^{\nu+1/2}\Gamma(-\nu)D_{\nu}(\sqrt{2i\gamma}x). \tag{4.23}$$

Let us note that

$$\overline{\nu+1}=-\nu \tag{4.24}$$

and

$$\overline{\sqrt{i}^{\nu+1/2}}=\sqrt{i}^{\nu+1/2}. \tag{4.25}$$

Clearly, the transition $\nu+1\to-\nu$ is equivalent to $E\to-E$ and it corresponds to the fact that $\hat{H}\eta_+^E=-E\eta_+^E$, while $\hat{H}\chi_+^E=+E\chi_+^E$. The symmetry between $\chi_\pm^E$ and $\eta_\pm^E$ fully justifies the specific choice of the phase factor in the constant C. One has

$$\eta_\pm^E(x)=\overline{\chi_\pm^E(x)}, \tag{4.26}$$

that is, they are related by the time-reversal operator $\mathbf{T}$: $\eta_\pm^E=\mathbf{T}\chi_\pm^E$. Thus energy eigenstates $\eta_\pm^E$ correspond to the time-reversed system. This way, all four solutions of (4.4) were used to construct four families of energy eigenstates: χ_+^E, χ_-^E, η_+^E, and η_-^E.

V. ANALYTIC CONTINUATION, RESOLVENT, AND RESONANCES

Now, let us continue the energy eigenfunctions $\chi_\pm^E$ and $\eta_\pm^E$ into the energy complex plane $E\in\mathbb{C}$ and let us study its analyticity as functions of E.

Proposition 4: The parabolic cylinder function $D_\lambda(z)$ is an analytic function of $\lambda\in\mathbb{C}$.

For the proof see the Appendix. Due to the above proposition the analytic properties of the energy eigenfunctions are entirely governed by the analytic properties of the Γ function which is present in the definition of $\chi_\pm^E$ and $\eta_\pm^E$. Since $\Gamma(\lambda)$ has simple poles at $\lambda=-n$, with $n=0,1,2,\ldots$, functions $\chi_\pm^E$ have poles at $E=-E_n$, whereas functions $\eta_\pm^E$ have poles at $E=E_n$, where E_n is defined in (2.10). Using a well-known formula for a residue of the Γ function

$$\mathrm{Res}(\Gamma(\lambda);\lambda=-n)=\frac{(-1)^n}{n!}, \tag{5.1}$$

one has

$$\mathrm{Res}(\chi_\pm^E(x);-E_n)=\frac{C_0}{\sqrt{2\pi\gamma}}\frac{(-1)^n}{n!}\sqrt{i}^{-n-1/2}D_n(\mp\sqrt{-2i\gamma}x), \tag{5.2}$$

and

$$\mathrm{Res}(\eta_\pm^E(x);+E_n)=\frac{C_0}{\sqrt{2\pi\gamma}}\frac{(-1)^n}{n!}\sqrt{i}^{n+1/2}D_n(\mp\sqrt{2i\gamma}x). \tag{5.3}$$

Hence, using the relation[27–29] (in Ref. 27 the corresponding equation 9.253 has a wrong sign)

$$D_n(z)=2^{-(n/2)}e^{-z^2/4}H_n\left(\frac{z}{\sqrt{2}}\right),\quad n=0,1,2,\ldots, \tag{5.4}$$

together with

$$H_n(-z)=(-1)^nH_n(z), \tag{5.5}$$

one obtains

$$\mathrm{Res}(\chi_\pm^E(x);-E_n)\sim\mathfrak{f}_n^+(x), \tag{5.6}$$

and

$$\mathrm{Res}(\eta_\pm^E(x);+E_n)\sim\mathfrak{f}_n^-(x). \tag{5.7}$$

Now, it is natural to introduce two Hardy classes of functions.[30,31] Recall that a smooth function $f=f(E)$ is in the Hardy class from above $\mathcal{H}_+^2$ (from below $\mathcal{H}_-^2$) if $f(E)$ is a boundary

value of an analytic function in the upper, i.e., $\mathrm{Im}\,E\geqslant 0$ (lower, i.e., $\mathrm{Im}\,E\leqslant 0$) half complex E-plane vanishing faster than any power of E at the upper (lower) semi-circle $|E|\to\infty$. Define

$$\Phi_- := \{\phi\in\mathcal{S}(\mathbb{R}_x)\mid f(E):=\langle\,\chi_\pm^E|\phi\,\rangle\in\mathcal{S}(\mathbb{R}_E)\cap\mathcal{H}_-^2(\mathbb{R}_E)\}, \tag{5.8}$$

and

$$\Phi_+ := \{\phi\in\mathcal{S}(\mathbb{R}_x)\mid f(E):=\langle\,\eta_\pm^E|\phi\,\rangle\in\mathcal{S}(\mathbb{R}_E)\cap\mathcal{H}_+^2(\mathbb{R}_E)\}. \tag{5.9}$$

It is evident from (4.26) that $\Phi_+=\overline{\Phi_-}$, that is

$$\Phi_+=\mathbf{T}(\Phi_-). \tag{5.10}$$

This construction enables one to define two Gel'fand triplets,

$$\Phi_\pm\subset L^2(\mathbb{R}_x)\subset\Phi_\pm'. \tag{5.11}$$

Note, that $\mathcal{H}_\pm^2(\mathbb{R}_E)$ are Hilbert spaces and the Fourier transform define an isometry between $L^2(-\infty,0)$ [respectively, $L^2(0,\infty)$] and $\mathcal{H}_+^2(\mathbb{R}_E)$ [respectively, $\mathcal{H}_-^2(\mathbb{R}_E)$]. Defining $\Psi_\pm := \mathcal{S}(\mathbb{R}_E)\cap\mathcal{H}_\pm^2(\mathbb{R}_E)$ one obtains the following rigged Hilbert spaces of Hardy class functions:

$$\Psi_\pm\subset\mathcal{H}_\pm^2(\mathbb{R}_E)\subset\Psi_\pm',$$

introduced by Gadella.[13]

Due to the Gel'fand–Maurin spectral theorem,[2,3] any function $\phi^-\in\Phi_-$ may be decomposed with respect to $\chi_\pm^E$ family

$$\phi^-(x)=\sum_\pm\int_{-\infty}^{\infty}dE\,\chi_\pm^E(x)\langle\,\chi_\pm^E|\phi^-\,\rangle, \tag{5.12}$$

and any function $\phi^+\in\Phi_+$ may be decomposed with respect to $\eta_\pm^E$ family

$$\phi^+(x)=\sum_\pm\int_{-\infty}^{\infty}dE\,\eta_\pm^E(x)\langle\,\eta_\pm^E|\phi^+\,\rangle. \tag{5.13}$$

Applying the residue theorem, one easily proves the following.

Theorem 1: *For any function $\phi^\pm\in\Phi_\pm$, one has*

$$\phi^-(x)=\sum_{n=0}^{\infty}\mathfrak{f}_n^-(x)\langle\,\mathfrak{f}_n^+|\phi^-\,\rangle, \tag{5.14}$$

and

$$\phi^+(x)=\sum_{n=0}^{\infty}\mathfrak{f}_n^+(x)\langle\,\mathfrak{f}_n^-|\phi^+\,\rangle. \tag{5.15}$$

The proof goes along the same lines as the corresponding proof of Theorem 2 in Ref. 1. The above theorem implies the following spectral resolutions of the Hamiltonian:

$$\hat{H}=\sum_\pm\int_{-\infty}^{\infty}dE\,E|\chi_\pm^E\,\rangle\langle\,\chi_\pm^E|=-\sum_{n=0}^{\infty}E_n|\mathfrak{f}_n^-\,\rangle\langle\,\mathfrak{f}_n^+|, \tag{5.16}$$

on Φ_-, and

$$\hat{H}=\sum_{\pm}\int_{-\infty}^{\infty}dE\,E|\,\eta_{\pm}^{E}\rangle\langle\,\eta_{\pm}^{E}|=\sum_{n=0}^{\infty}E_n|\mathfrak{f}_n^{+}\rangle\langle\,\mathfrak{f}_n^{-}|, \tag{5.17}$$

on Φ_+. The same techniques may be applied for the resolvent operator

$$R(z,\hat{H})=\frac{1}{\hat{H}-z}\ . \tag{5.18}$$

One obtains

$$R(z,\hat{H})=\sum_{\pm}\int_{-\infty}^{\infty}\frac{dE}{E-z}|\chi_{\pm}^{E}\rangle\langle\,\chi_{\pm}^{E}|=\sum_{n=0}^{\infty}\frac{1}{-E_n-z}|\mathfrak{f}_n^{-}\rangle\langle\,\mathfrak{f}_n^{+}|, \tag{5.19}$$

on Φ_-, and

$$R(z,\hat{H})=\sum_{\pm}\int_{-\infty}^{\infty}\frac{dE}{E-z}|\,\eta_{\pm}^{E}\rangle\langle\,\eta_{\pm}^{E}|=\sum_{n=0}^{\infty}\frac{1}{E_n-z}|\mathfrak{f}_n^{+}\rangle\langle\,\mathfrak{f}_n^{-}|, \tag{5.20}$$

on Φ_+. Hence, $R(z,\hat{H})|_{\Phi_-}$ has poles at $z=-E_n$, and $R(z,\hat{H})|_{\Phi_+}$ has poles at $z=E_n$. As usual, eigenvectors $\mathfrak{f}_n^{-}$ and $\mathfrak{f}_n^{+}$ corresponding to poles of the resolvent are interpreted as resonant states. Note that

$$-\frac{1}{2\pi i}\oint_{\gamma_n}R(z,\hat{H})dz=|\mathfrak{f}_n^{+}\rangle\langle\,\mathfrak{f}_n^{-}|:=\hat{P}_n, \tag{5.21}$$

where γ_n is a closed curve that encircles the singularity $z=E_n$. Clearly

$$\hat{P}_n\cdot\hat{P}_m=\delta_{nm}\hat{P}_n, \tag{5.22}$$

and the spectral decomposition of $\hat{H}$ may be written as follows:

$$\hat{H}=\sum_{n=0}^{\infty}E_n\hat{P}_n=-\sum_{n=0}^{\infty}E_n\hat{P}_n^{\dagger}. \tag{5.23}$$

Finally, let us note, that restriction of the unitary group $U(t)=e^{-i\hat{H}t}$ defined on the Hilbert space $L^2(\mathbb{R})$ to $\Phi_\pm$ no longer defines a group. It gives rise to two semigroups

$$U_-(t):\Phi_-\to\Phi_- \qquad \text{for} \qquad t\geqslant 0, \tag{5.24}$$

and

$$U_+(t):\Phi_+\to\Phi_+ \qquad \text{for} \qquad t\leqslant 0. \tag{5.25}$$

These semigroups frequently appear in the literature on the rigged Hilbert space approach to scattering phenomena, see, e.g., an article by Böhm and Harshman in Ref. 11. We stress that the Hardy classes $\Phi_\pm$ used in our paper have slightly different meaning. Böhm's spaces describe the prepared *in* and *out* states. In our case they are not directly related to the scattering experiment and serve as subspaces of initial conditions.

Using (5.16), (5.17), and the formula for $E_n=i\gamma(n+1/2)$, one finds

$$\phi^{-}(t)=U_-(t)\phi^{-}=\sum_{n=0}^{\infty}e^{-\gamma(n+1/2)t}\,\hat{P}_n^{\dagger}\phi^{-}, \tag{5.26}$$

for $t \geqslant 0$, and

$$\phi^+(t) = U_+(t)\phi^+ = \sum_{n=0}^{\infty} e^{\gamma(n+1/2)t} \hat{P}_n \phi^+, \tag{5.27}$$

for $t \leqslant 0$. We stress that ϕ_t^- (ϕ_t^+) does belong to $L^2(\mathbb{R})$ also for $t<0$ ($t>0$). However, $\phi_t^- \in \Phi_-$ ($\phi_t^+ \in \Phi_+$) only for $t \geqslant 0$ ($t \leqslant 0$). This way the irreversibility enters the dynamics of the reversed oscillator by restricting it to the dense subspace $\Phi_\pm$ of $L^2(\mathbb{R})$.

VI. SCATTERING VS RESONANT STATES

To compare the physical properties of energy eigenstates $\chi_\pm^E$ and $\eta_\pm^E$ and resonant states $\mathfrak{f}_n^\pm$, let us investigate its asymptotic behavior at $x \to \pm\infty$. Following Ref. 29 (see also Refs. 19, 20) one finds

$$\chi_-^E(x \to +\infty) \sim \sqrt{\frac{1}{x}} \exp\left[i\left(\frac{\gamma}{2}x^2 + \frac{E}{\gamma}\log(\sqrt{2\gamma}x) + \frac{\pi}{4}\frac{E}{\gamma} + \frac{\pi}{8} \right) \right], \tag{6.1}$$

and

$$\chi_-^E(x \to -\infty) \sim i\sqrt{\frac{1}{x}} \Bigg\{ (1 + e^{-2\pi(E/\gamma)}) \exp\left[-i\left(\frac{\gamma}{2}x^2 + \frac{E}{\gamma}\log(\sqrt{2\gamma}x) - \frac{\pi}{4}\frac{E}{\gamma} + \frac{3\pi}{8} + \phi \right) \right]$$
$$- e^{-\pi(E/\gamma)} \exp\left[i\left(\frac{\gamma}{2}x^2 - \frac{E}{\gamma}\log(\sqrt{2\gamma}x) - \frac{\pi}{4}\frac{E}{\gamma} + \frac{\pi}{8} \right) \right] \Bigg\}, \tag{6.2}$$

where $\phi = \arg\Gamma(-iE/\gamma + 1/2) = \Gamma(\nu+1)$. Putting $a = -E/\gamma$ in Eq. 19.17.9 in Ref. 29 and using relation 19.3.1

$$U(a,x) = D_{-a-1/2}(x),$$

one finds

$$U\left(-i\frac{E}{\gamma}, \sqrt{2\gamma}x e^{-(1/4)i\pi} \right) = D_{-\nu-1}(\sqrt{-2i\gamma}x) \sim \chi_-^E(x).$$

Hence, energy eigenstates χ_-^E represent scattering states (see Ref. 19 for more details). The same is true for χ_+^E and $\eta_\pm^E$. In particular, one finds for the reflection and transmission amplitudes R and T for $\chi_\pm^E$ scattering states:[17,19]

$$R(\chi_\pm^E) = -\frac{i}{\sqrt{2\pi}} e^{-\pi E/2\gamma} \Gamma\left(\frac{1}{2} - i\frac{E}{\gamma} \right), \tag{6.3}$$

$$T(\chi_\pm^E) = \frac{1}{\sqrt{2\pi}} e^{\pi E/2\gamma} \Gamma\left(\frac{1}{2} - i\frac{E}{\gamma} \right). \tag{6.4}$$

Clearly, computing R and T for time-reversed $\eta_\pm^E$ scattering states, one finds

$$R(\eta_\pm^E) = \overline{R(\chi_\pm^E)}, \qquad T(\eta_\pm^E) = \overline{T(\chi_\pm^E)}. \tag{6.5}$$

Note that $R(\chi_\pm^E)$ and $T(\chi_\pm^E)$ have poles at $E = -E_n$, whereas $R(\eta_\pm^E)$ and $T(\eta_\pm^E)$ have poles at $E = +E_n$. Obviously, the corresponding reflection and transition coefficients $|R|^2$ and $|T|^2$ are time-reversal invariant.

On the other hand, the eigenstates $\mathfrak{f}_n^\pm$ behave as follows:

$$\mathfrak{f}_n^+(x\to\pm\infty)\sim(\pm\sqrt{i\gamma}x)^n\,e^{-i(\gamma/2)x^2}, \tag{6.6}$$

and

$$\mathfrak{f}_n^-(x\to\pm\infty)\sim(\pm\sqrt{-i\gamma}x)^n\,e^{i(\gamma/2)x^2}. \tag{6.7}$$

Note that $\mathfrak{f}_n^-$ are purely outgoing states, whereas $\mathfrak{f}_n^+$ are purely ingoing states. Moreover, resonant states have Breit–Wigner energy distribution. Indeed

$$\langle\chi_-^E|\mathfrak{f}_n^+\rangle\sim\Gamma(-\nu)\int_{-\infty}^{\infty}D_\nu(\sqrt{2\gamma i}x)\,\mathfrak{f}_n^+(x)\,dx. \tag{6.8}$$

Now, D_ν is an entire function of ν and $\Gamma(-\nu)$ has poles at $\nu=k\in\mathbb{N}$. In the domain where $n+1>\mathrm{Re}\,\nu\geqslant 1$, one has

$$\Gamma(-\nu)=\text{analytical part}+\sum_{k=0}^{n}\frac{(-1)^k}{k!(k-\nu)^k}. \tag{6.9}$$

Hence

$$\langle\chi_-^E|\mathfrak{f}_n^+\rangle\sim\text{analytical function of } E+\sum_{k=0}^{n}\frac{(-1)^k}{k!\left(k+i\dfrac{E}{\gamma}+\dfrac{1}{2}\right)}\langle\mathfrak{f}_k^-|\mathfrak{f}_n^+\rangle$$

$$\sim\text{analytical function of } E+\frac{\gamma}{E-E_n}, \tag{6.10}$$

which is consistent with the Breit–Wigner formula.

APPENDIX

The integral formula 9.241(2) in Ref. 27

$$D_\lambda(y)=\frac{e^{-y^2/4}}{\Gamma(-\lambda)}\int_{-\infty}^{\infty}\xi_+^{-\lambda-1}\,e^{-y\xi-\xi^2/2}\,d\xi, \tag{A1}$$

contains two objects: $\Gamma(-\lambda)$ and a distribution $\xi^{-\lambda-1}$ which are singular for $\lambda=0,1,2,\ldots$. However, it is easy to see[23] that

$$\left.\frac{\xi_+^{-\lambda-1}}{\Gamma(-\lambda)}\right|_{p=n}=\delta^{(n)}(\xi), \tag{A2}$$

which shows that (A1) defines an entire function of $\lambda\in\mathbb{C}$. The same is true for

$$D_\lambda(y)=\frac{e^{-y^2/4}}{\Gamma(-\lambda)}\int_{-\infty}^{\infty}\xi_-^{-\lambda-1}\,e^{y\xi-\xi^2/2}\,d\xi, \tag{A3}$$

due to

$$\left.\frac{\xi_-^{-\lambda-1}}{\Gamma(-\lambda)}\right|_{\lambda=n}=(-1)^n\delta^{(n)}(\xi). \tag{A4}$$

The second integral representation given by 9.241(1) in Ref. 27

$$D_\lambda(y)=\frac{1}{\sqrt{\pi}}2^{\lambda+1/2}(-i)^\lambda e^{y^2/4}\int_{-\infty}^{\infty}(\xi+i0)^\lambda\, e^{-2\xi^2+2iy\xi}\,d\xi, \tag{A5}$$

where $(\xi+i0)^\lambda=\xi_+^\lambda+e^{i\pi\lambda}\xi_-^\lambda$, seems to have poles at $\lambda=-1,-2,\ldots$. However, the limit $\lim_{\lambda\to -n}(\xi+i0)^\lambda$ is well defined[23]

$$(\xi+i0)^{-n}=\xi^{-n}-\frac{i\pi(-1)^{n-1}}{(n-1)!}\,\delta^{(n-1)}(\xi). \tag{A6}$$

Thus, formula (A5) also defines an entire function of λ.

(Received 1 October 2002; accepted 1 December 2003)

We consider the perturbed Schrödinger equation, which is an elliptic operator with unbounded coefficients. We use wavelets adapted to the Schrödinger operator to deal with problems on the unbounded domain. The wavelets are constructed from Hermite functions, which characterizes the space generated by the Schrödinger operator. We show that the Galerkin matrix can be pre-conditioned by a diagonal matrix so that its condition number is uniformly bounded. Moreover, we introduce a periodic pseudo-differential operator and show that its discrete Galerkin matrix under periodic wavelet system is equal to the Galerkin matrix for the equation with unbounded coefficients under the Hermite system. The convergence is proved in the L^2 topology. © *2004 American Institute of Physics.*
[DOI: 10.1063/1.1643541]

I. INTRODUCTION

Wavelets have been applied to differential and integral operators in recent years.[5] The main advantage of the wavelet numerical scheme compared with the finite element method and the multilevel method is that for the resulting system of algebraic equations its condition number is uniformly bounded after a simple preconditioning (see, e.g., Jaffard[12] and Dahmen[5]). Moreover, its stiffness matrix can be approximated by a sparse matrix.[2,4,5]

With wavelets constructed through the usual multiresolution analysis method,[7] they cannot be readily applied to operators with unbounded coefficients such as the Schrödinger equation appeared in quantum mechanics

$$-u''(x)+x^2u(x)=f(x), \quad -\infty<x<\infty,$$

as well as operators with singular coefficients. This kind of (partial) differential equations appears in mathematics and physics.

Our purpose in this paper is to use a wavelet basis of the space $L^2(\mathbb{R})$ of the square-integrable functions on the real line $\mathbb{R}$ so that we can apply a Galerkin scheme to the numerical analysis of the following perturbed Schrödinger equation,

$$-(a(x)u'(x))'+b(x)u(x)=f(x), \quad -\infty<x<\infty,$$

which can be viewed as a model of second-order elliptic operators with unbounded coefficients.

The wavelets $\{\psi_{j,k}\}_{j,k\in\mathbb{Z}}$ generated from a mother wavelet ψ are the time–frequency localization of the Fourier kernel $\{e^{ix\xi}\}$, which forms a set of eigenfunctions of the second-order differential operator $-d^2/dx^2$. Jaffard[12] successfully adapted wavelets on the finite domain to the analysis of the general second-order elliptic operator $-d/dx(A(x)d/dx)+B(x)$ with regular coefficients.

[a]Electronic mail: bhan@math.ualberta.ca

Frazier and Zhang[8] studied the Bessel operator $-g''(x)+(\nu^2-1/4)/x^2\,g(x)$ with singular coefficients. They used the Bessel function $J_\nu(x)$ and the Hankel transform. Their basis functions were obtained through the Hankel transform of the Meyer wavelets. These basis functions have explicit expressions in the Hankel domain just as the Meyer wavelets do in the Fourier domain.

In this paper we shall use eigenfunctions of the Schrödinger operator, namely the Hermite functions, to construct a wavelet-like basis and then adapt them to the analysis of the perturbed Schrödinger equation with unbounded coefficients.

Our basis is adapted to a Schrödinger operator and can be explicitly expressed using the Hermite functions and a known wavelet function from an MRA. These functions are obtained through a similarity between the Hermite functions and the orthonormal system $\{e^{in2\pi x}\}_{n\in\mathbb{Z}}$ instead of the continuous version $\{e^{ix\xi}\}$. Moreover, this construction can be easily generalized to any operators with a complete eigenfunction system.

Hermite functions have been utilized to approximate solutions of partial differential equations on unbounded domains in the context of the spectral method (Refs. 9, 11, 14). When dealing with problems on unbounded domain with a finite difference method or finite element method numerically, one often restricts calculations to some bounded domains and imposes certain conditions on artificial boundaries, which causes numerical errors. The Hermite functions defined on the whole real line can be used to avoid such difficulty. Meanwhile, with the spectral method, solutions can be approximated with accuracy adapted up to its smoothness. Wavelet bases have been applied to numerical solutions of partial differential equations since for its discrete stiffness matrix, the pre-conditioner can be easily constructed and its entries can be compressed.[5,12] Our method will take advantage from both the eigenfunctions and the wavelet functions. We use the former to deal with the geometry of differential operators and regularities of their coefficients so that we can deal with differential equations defined on unbounded domain with unbounded coefficients, and the latter to obtain a simple diagonal pre-conditioner.

The organization of this paper is as follows. In Sec. II, we shall present the construction of our basis functions. We shall introduce a space H associated with the Schrödinger operator and give a characterization of its functions in terms of their coefficients. We notice that the second-order Schrödinger operator acts like a first-order differential operator according to Theorem 3 which is the main result of Sec. II. In Sec. III, we shall use the Galerkin method to approximate solutions of the perturbed Schrödinger equations. Then, we shall estimate the condition number for the discrete Galerkin matrix and establish the convergence of the Galerkin scheme in the $L^2(\mathbb{R})$ space. Finally, we shall introduce a periodic pseudo-differential operator and show that its discrete Galerkin matrix under a periodic wavelet system is equal to the Galerkin matrix for the equation with unbounded coefficients under the Hermite system.

II. HERMITE WAVELETS

We shall use Hermite functions to construct wavelets, for the background on their applications to numerical solutions of partial differential equations; the reader is referred to Refs. 9–11, 15. The Hermite polynomials are defined by

$$h_n(x)=(-1)^n e^{x^2}\frac{d^n}{dx^n}(e^{-x^2}),\quad n=0,1,\ldots.$$

These polynomials are orthogonal in the weighted sense,

$$\int_{-\infty}^{\infty} h_n(x)h_m(x)e^{-x^2}dx=2^n n!\sqrt{\pi}\,\delta_{m,n},$$

where $\delta_{m,n}$ is the Kronecker symbol such that $\delta_{m,n}=1$ when $m=n$ and $\delta_{m,n}=0$, otherwise. It is possible to start with these polynomials, but since the corresponding approximation results are

measured in a weighted sense, their performance might become poor for large x due to the presence of the negative power of the exponential e^{-x^2}. We therefore use Hermite functions instead.

The normalized Hermite function under the norm of $L^2(\mathbb{R})$ is defined to be

$$e_n(x)=\frac{e^{-x^2/2}h_n(x)}{\sqrt{2^n n!\sqrt{\pi}}},\quad \text{with}\quad \|e_n\|_{L^2(\mathbb{R})}=1,\quad n=0,1,\ldots, \tag{1}$$

which satisfies the Schrödinger equation,

$$-e_n''(x)+x^2e_n(x)=(2n+1)e_n(x),\quad n=0,1,\ldots .$$

For fixed n, the function e_n is well-localized in the spatial domain. Moreover, it has the following asymptotic behavior:[10]

$$e_{2n}(x)=\frac{(-1)^n(2n-1)!!}{\sqrt{(2n)!\sqrt{\pi}}}\left[\cos(\sqrt{4n+1}x)+O\left(\frac{1}{\sqrt[4]{n}}\right)\right],\quad \text{as}\quad n\to\infty,$$

$$e_{2n+1}(x)=\frac{(-1)^n(2n-1)!!}{\sqrt{(2n+1)!\sqrt{\pi}}}\left[\sin(\sqrt{4n+3}x)+O\left(\frac{1}{\sqrt[4]{n}}\right)\right],\quad \text{as}\quad n\to\infty.$$

We consider the Schrödinger operator L defined on $C_0^\infty(\mathbb{R})$ by

$$(Lu)(x)=-u''(x)+x^2u(x),\quad u\in C_0^\infty(\mathbb{R}), \tag{2}$$

where $C_0^\infty(\mathbb{R})$ consists of compactly supported C^∞ functions on $\mathbb{R}$.

For the positive operator L, we introduce a norm by

$$\|u\|_{\mathrm{H}}=\langle Lu,u\rangle^{1/2}.$$

The domain of the operator L can be extended to the Hilbert space H defined by

$$H=\overline{\{u\ :\ u\in C_0^\infty(\mathbb{R})\text{such that}\ \|u\|_{\mathrm{H}}<\infty\}},$$

which is the completion of $C_0^\infty(\mathbb{R})$ under the norm $\|\cdot\|_{\mathrm{H}}$.

Functions in the space H can be characterized by the expansion coefficients under the basis $\{e_n\}_{n\in\mathbb{Z}}$. For a proof, the reader is referred to Ref. 13.

Lemma 1: Let $u\in L^2(\mathbb{R})$ with $u=\Sigma_{n=0}^\infty\langle u,e_n\rangle e_n$. Then $u\in H$ if and only if

$$\sum_{n=0}^{\infty}(2n+1)|\langle u,e_n\rangle|^2<\infty. \tag{3}$$

The Fourier transform $\hat{\varphi}$ of φ is defined to be

$$\hat{\varphi}(\xi)=\int_{-\infty}^{\infty}\varphi(x)e^{-i2\pi x\xi}dx.$$

Let φ be a function in $L^2(\mathbb{R})$ such that the following occurs.

(1) φ is a father wavelet; that is, $\hat{\varphi}(2\xi)=m(\xi)\hat{\varphi}(\xi)$ for some 1-periodic measurable function m.
(2) The shifts of φ are orthonormal; that is,

$$\langle\varphi(\cdot-k),\varphi(\cdot-k')\rangle=\delta_{k,k'},\quad \forall\ k,k'\in\mathbb{Z}.$$

(1) φ is normalized by $\hat{\varphi}(0)=1$ and there exist two positive constants C and $\sigma>1$ such that

$$|\hat{\varphi}(\xi)| \leqslant C(1+|\xi|)^{-\sigma}, \quad \forall \quad \xi \in \mathbb{R}. \tag{4}$$

Throughout the paper, C always denotes a general constant.

For example, the father wavelets in the Meyer wavelets and all of the Daubechies wavelets (except the Haar wavelet) satisfy all the above three conditions in (1), (2) and (3).

Now we define a mother wavelet function ψ (see Ref. 7) by

$$\hat{\psi}(\xi) = e^{-i\xi/2}\overline{m(\xi/2+1/2)}\,\hat{\varphi}(\xi/2).$$

We use $\mathbb{Z}_+$ to denote the set of non-negative integers. Denote $\varphi_{j,k} = 2^{j/2}\varphi(2^j \cdot - k)$ and $\psi_{j,k} = 2^{j/2}\psi(2^j \cdot - k)$. It is well known that for any $j_0 \in \mathbb{Z}_+$,

$$\{\varphi_{j_0,k} \ : \ k \in \mathbb{Z}\} \cup \{\psi_{j,k} \ : \ j \geqslant j_0, k \in \mathbb{Z}\} \tag{5}$$

is an orthonormal basis for $L^2(\mathbb{R})$. It follows from (4) that $|\hat{\psi}(\xi)| \leqslant C(1+|\xi|)^{-\sigma}$ for all $\xi \in \mathbb{R}$ since $|m(\xi)| \leqslant 1$.

Let $\mathbb{T} = \mathbb{R}/\mathbb{Z}$ be the torus. Throughout the paper, we shall use the following notation. For any $u \in L^2(\mathbb{R})$, we define a function $u^{\mathrm{per}} \in L^2(\mathbb{T})$ as follows:

$$u^{\mathrm{per}}(x) := \sum_{l \in \mathbb{Z}} u(x+l), \quad x \in \mathbb{T}. \tag{6}$$

Using the Poisson summation formula, for $u \in L^2(\mathbb{R})$ satisfying $|\hat{u}(\xi)| \leqslant C(1+|\xi|)^{-\sigma}$, $\forall$ $\xi \in \mathbb{R}$ for some C and $\sigma > 1$, we have

$$u^{\mathrm{per}}(x) = \sum_{l \in \mathbb{Z}} u(x+l) = \sum_{n \in \mathbb{Z}} \hat{u}(n) e^{i2\pi nx}. \tag{7}$$

Using the Hermite functions $\{e_n\}_{n=0}^{\infty}$ and the wavelet basis in (5), we can construct a wavelet-like system in $L^2(\mathbb{R})$ as follows.

Theorem 1: Let φ and ψ be given above such that the system in (5) is an orthonormal basis for $L^2(\mathbb{R})$. Let e_n be the Hermite functions defined in (1). For $j \in \mathbb{Z}_+$ and $k = 0,1,\ldots,2^j - 1$, we define

$$\Phi_{j,k} = 2^{-j/2} e_0 + \sum_{n=1}^{\infty} [\widehat{\varphi_{j,k}}(n) e_{2n} + \widehat{\varphi_{j,k}}(-n) e_{2n-1}], \tag{8}$$

$$\Psi_{j,k} = \sum_{n=1}^{\infty} [\widehat{\psi_{j,k}}(n) e_{2n} + \widehat{\psi_{j,k}}(-n) e_{2n-1}]. \tag{9}$$

Then for any $j_0 \in \mathbb{Z}_+$,

$$\{\Phi_{j_0,k} \ : \ k = 0,1,\ldots,2^{j_0} - 1\} \cup \{\Psi_{j,k} \ : \ j \geqslant j_0, k = 0,1,\ldots,2^j - 1\} \tag{10}$$

is an orthonormal basis for $L^2(\mathbb{R})$.

Proof: When the functions φ and ψ are the Meyer wavelets, the assertion was proved in Dai.[6] For completeness, here we present a sketch of the proof.

Note that the system in (5) is an orthonormal basis for $L^2(\mathbb{R})$. By a simple argument, it can be easily shown that

$$\{(\varphi_{j_0,k})^{\mathrm{per}} \ : \ k = 0,1,\ldots,2^{j_0} - 1\} \cup \{(\psi_{j,k})^{\mathrm{per}} \ : \ j \geqslant j_0, k = 0,1,\ldots,2^j - 1\} \tag{11}$$

is an orthonormal basis for $L^2(\mathbb{T})$. Since $\widehat{\varphi_{j,k}}(0) = 2^{-j/2}$ and $\widehat{\psi_{j,k}}(0) = 0$, it follows from (7) that

$$(\varphi_{j_0,k})^{\mathrm{per}}(x)=\sum_{n\in\mathbb{Z}}\widehat{\varphi_{j_0,k}}(n)e^{i2\pi nx}=2^{-j_0/2}+\sum_{n=1}^{\infty}[\widehat{\varphi_{j_0,k}}(n)e^{i2\pi nx}+\widehat{\varphi_{j_0,k}}(-n)e^{-i2\pi nx}],$$
$$(\psi_{j,k})^{\mathrm{per}}(x)=\sum_{n\in\mathbb{Z}}\widehat{\psi_{j,k}}(n)e^{i2\pi nx}=\sum_{n=1}^{\infty}[\widehat{\psi_{j,k}}(n)e^{i2\pi nx}+\widehat{\psi_{j,k}}(-n)e^{-i2\pi nx}]. \tag{12}$$

Replacing 1, $e^{i2\pi n\cdot}$ and $e^{-i2\pi n\cdot}$ by e_0, e_{2n} and e_{2n-1} in (12), we obtain (8) and (9). Note that $\{e_n\}_{n=1}^{\infty}$ is an orthonormal basis for $L^2(\mathbb{R})$ and $\{e^{i2\pi n\cdot}\}_{n=-\infty}^{\infty}$ is an orthonormal basis for $L^2(\mathbb{T})$. Now one can easily show that the system in (10) is an orthonormal basis for $L^2(\mathbb{R})$ since the system (11) is an orthonormal basis for $L^2(\mathbb{T})$.

The advantage of replacing the orthonormal basis $\{e_n\}_{n=0}^{\infty}$ by the wavelet-like orthonormal basis in (10) lies in the fact that the new system preserves many desirable features of a wavelet system.

As a direct consequence of Theorem 1, we have the following result.

Theorem 2: Let $u\in L^2(\mathbb{R})$. Then for any $j_0\in\mathbb{Z}_+$, we have

$$u=\sum_{k=0}^{2^{j_0}-1}\langle u,\Phi_{j_0,k}\rangle\Phi_{j_0,k}+\sum_{j=j_0}^{\infty}\sum_{k=0}^{2^j-1}\langle u,\Psi_{j,k}\rangle\Psi_{j,k},\quad \text{in}\quad L^2(\mathbb{R}).$$

Lemma 2: The functions $\Phi_{j,k}$ and $\Psi_{j,k}$ belong to H for all $j\in\mathbb{Z}_+$ and $k=0,1,\ldots,2^j-1$.

Proof: We only prove $\Phi_{j,k}\in H$. The proof for $\Psi_{j,k}$ is similar. Since $\{e_n\}_{n=0}^{\infty}$ is orthonormal, it follows from the definition of $\Phi_{j,k}$ in (8) that

$$\langle\Phi_{j,k},e_n\rangle=\begin{cases}\widehat{\varphi_{j,k}}(n/2), & n \text{ even},\\ \widehat{\varphi_{j,k}}(-(n+1)/2), & n \text{ odd}.\end{cases}$$

Hence, by (4) and $\sigma>1$, we have

$$\begin{aligned}\sum_{n=0}^{\infty}(2n+1)|\langle\Phi_{j,k},e_n\rangle|^2&=(2^{-j/2})^2+\sum_{n=1}^{\infty}[(4n+1)|\widehat{\varphi_{j,k}}(n)|^2+(4n-1)|\widehat{\varphi_{j,k}}(-n)|^2]\\&=2^{-j}+2^{-j}\sum_{n=1}^{\infty}[(4n+1)|\hat{\varphi}(n/2^j)|^2+(4n-1)|\hat{\varphi}(-n/2^j)|^2]\\&\leqslant 2^{-j}+2^{-j}C\sum_{n=1}^{\infty}[(4n+1)(1+n/2^j)^{-2\sigma}+(4n-1)(1+n/2^j)^{-2\sigma}]\\&<\infty.\end{aligned}$$

By Lemma 1, we conclude that $\Phi_{j,k}\in H$.

Let $V_j=\mathrm{span}\{\Phi_{j,k}\}_{k=0}^{2^j-1}$. The subspace V_j will serve as our Galerkin approximation space. By Lemma 2, we have the following result.

Lemma 3: For each $j\in\mathbb{Z}_+$, V_j is a subspace of the Hilbert space H.

We shall use the Sobolev space $H^s(\mathbb{T})$ which consists of all functions $f\in L^2(\mathbb{T})$ such that

$$\|f\|_s=\left(\sum_{n\in\mathbb{Z}}(1+n^2)^s|\hat{f}(n)|^2\right)^{1/2}<\infty,$$

where the discrete Fourier transform $\hat{f}(n)$ of $f\in L^2(\mathbb{T})$ is defined to be

$$\hat{f}(n)=\int_{\mathbb{T}}f(x)e^{-i2\pi nx}\,dx,\quad n\in\mathbb{Z}.$$

Throughout this paper, we use the notation $A \approx B$, which means that there exist positive constants C_1 and C_2, independent of A, B, such that $C_2 B \leqslant A \leqslant C_1 B$.

A periodic function $u \in H^s(\mathbb{T})$ can be characterized in terms of wavelet coefficients in the periodic wavelet system in (11). For a proof of the following result, the reader is referred to Refs. 3, 7.

Lemma 4: Let $u \in H^s(\mathbb{T})(s>0)$ be decomposed into

$$u(x) = c_{0,0}(\varphi_{0,0})^{\mathrm{per}}(x) + \sum_{j=0}^{\infty} \sum_{k=0}^{2^j-1} d_{j,k}(\psi_{j,k})^{\mathrm{per}}(x), \quad x \in \mathbb{T}.$$

Then we have the following norm equivalence:

$$\|u\|_s \approx \left(|c_{0,0}|^2 + \sum_{j=0}^{\infty} 2^{2js} \sum_{k=0}^{2^j-1} |d_{j,k}|^2 \right)^{1/2}.$$

To prove our main results of this section, it is convenient to use pseudo-differential operators. For a background on pseudo-differential operators, see Taylor.[15,16] Let $p: \mathbb{Z} \to \mathbb{C}$ be a symbol. The pseudo-differential operator $P(D)$ with the symbol p is defined to be

$$[P(D)u](x) = \sum_{n \in \mathbb{Z}} e^{i2\pi nx} p(n) \hat{u}(n), \quad u \in C^{\infty}(\mathbb{T}). \tag{13}$$

Lemma 5: Suppose that the symbol p satisfies

$$p(n) \approx (1+n^2)^{r/2},$$

for some $r>0$. Then for $u \in H^{r/2}(\mathbb{T})$, we have

$$\langle P(D)u, u \rangle \approx \|u\|_{r/2}^2.$$

Proof: For $u \in C^{\infty}(\mathbb{T})$, we have the Fourier expansion

$$u(x) = \sum_{n \in \mathbb{Z}} \hat{u}(n) e^{i2\pi nx}.$$

From the orthogonality of $\{e^{i2\pi n \cdot}\}_{n \in \mathbb{Z}}$ in $L^2(\mathbb{T})$, we have

$$\langle P(D)u, u \rangle = \sum_{n \in \mathbb{Z}} p(n) |\hat{u}(n)|^2.$$

Since $p(n) \approx (1+n^2)^{r/2}$, we have

$$\langle P(D)u, u \rangle \approx \sum_{n \in \mathbb{Z}} (1+n^2)^{r/2} |\hat{u}(n)|^2 = \|u\|_{r/2}^2.$$

This completes the proof.

We now characterize the space H via our wavelet system $\{\Phi_{0,0}\} \cup \{\Psi_{j,k} : j \in \mathbb{Z}_+, k = 0,1,\ldots,2^j-1\}$.

Theorem 3: Suppose that $u \in H$ is decomposed as

$$u = c_{0,0}\Phi_{0,0} + \sum_{j=0}^{\infty} \sum_{k=0}^{2^j-1} d_{j,k}\Psi_{j,k}. \tag{14}$$

Then for the Schrödinger operator L, we have

$$\langle Lu,u\rangle \approx |c_{0,0}|^2 + \sum_{j=0}^{\infty} 2^j \sum_{k=0}^{2^j-1} |d_{j,k}|^2. \tag{15}$$

Proof: From the definition of $\Phi_{j,k}$ and $\Psi_{j,k}$, by Theorem 1, we have

$$u = c_{0,0}e_0 + \sum_{j=0}^{\infty} \sum_{k=0}^{2^j-1} d_{j,k} \sum_{n=1}^{\infty} [\widehat{\psi_{j,k}}(n)e_{2n} + \widehat{\psi_{j,k}}(-n)e_{2n-1}].$$

Hence, by applying the operator L, we have

$$Lu = c_{0,0}e_0 + \sum_{j=0}^{\infty} \sum_{k=0}^{2^j-1} d_{j,k} \sum_{n=1}^{\infty} [\widehat{\psi_{j,k}}(n)(4n+1)e_{2n} + \widehat{\psi_{j,k}}(-n)(4n-1)e_{2n-1}].$$

By the orthogonality of the Hermite system $\{e_n\}_{n=0}^{\infty}$, we get

$$\begin{aligned}\langle Lu,u\rangle = |c_{0,0}|^2 + \sum_{j,j'=0}^{\infty} \sum_{k=0}^{2^j-1} \sum_{k'=0}^{2^{j'}-1} d_{j,k}\overline{d_{j',k'}} \sum_{n=1}^{\infty} [(4n+1)\widehat{\psi_{j,k}}(n)\overline{\widehat{\psi_{j',k'}}(n)} \\ + (4n-1)\widehat{\psi_{j,k}}(-n)\overline{\widehat{\psi_{j',k'}}(-n)}].\end{aligned} \tag{16}$$

Consider the pseudo-differential operator $P(D)$ with the symbol p given by

$$p(n) = \begin{cases} 4n+1, & n \geqslant 0, \\ 4|n|-1, & n < 0. \end{cases} \tag{17}$$

Then we have $p(n) \approx (1+n^2)^{1/2}$.

From (7) we deduce that

$$u^{\mathrm{per}} = c_{0,0} + \sum_{j=0}^{\infty} \sum_{k=0}^{2^j-1} d_{j,k} \sum_{n\in\mathbb{Z}} \widehat{\psi_{j,k}}(n)e^{i2\pi n\cdot}. \tag{18}$$

Hence, the application of the pseudo-differential operator $P(D)$ with symbol p defined in (17) can be written as

$$P(D)u^{\mathrm{per}} = c_{0,0} + \sum_{j=0}^{\infty} \sum_{k=0}^{2^j-1} d_{j,k} \sum_{n\in\mathbb{Z}} p(n)\widehat{\psi_{j,k}}(n)e^{i2\pi n\cdot}. \tag{19}$$

From (18) and (19) we get

$$\begin{aligned}\langle P(D)u^{\mathrm{per}},u^{\mathrm{per}}\rangle = |c_{0,0}|^2 + \sum_{j,j'=0}^{\infty} \sum_{k=0}^{2^j-1} \sum_{k'=0}^{2^{j'}-1} d_{j,k}\overline{d_{j',k'}} \sum_{n=1}^{\infty} [(4n+1)\widehat{\psi_{j,k}}(n) \\ \times \overline{\widehat{\psi_{j',k'}}(n)} + (4n-1)\widehat{\psi_{j,k}}(-n)\overline{\widehat{\psi_{j',k'}}(-n)}].\end{aligned} \tag{20}$$

By (17) and Lemma 5 we conclude that

$$\langle P(D)u^{\mathrm{per}},u^{\mathrm{per}}\rangle \approx \|u^{\mathrm{per}}\|_{1/2}^2. \tag{21}$$

On the other hand, by Lemma 4,

$$\|u^{\mathrm{per}}\|_{1/2}^2 \approx |c_{0,0}|^2 + \sum_{j=0}^{\infty} 2^j \sum_{k=0}^{2^j-1} |d_{j,k}|^2. \tag{22}$$

Combining (16), (20)–(22), we conclude that (15) holds.

We point out that in (15) the exponent of 2^j is 1 instead of 2 for the second-order differential operator L, as compared to Lemma 4.

III. GALERKIN ANALYSIS

In this section, we consider the perturbed Schrödinger operator,

$$(Su)(x) = -\frac{d}{dx}\left(a(x)\frac{du(x)}{dx}\right) + b(x)u(x), \quad x \in \mathbb{R}, \tag{23}$$

where the functions a and b are measurable and satisfy

$$0 < a_1 \leqslant a(x) \leqslant a_2, \quad 0 < b_1 \leqslant b(x)/x^2 \leqslant b_2, \quad \forall \ x \in \mathbb{R}, \tag{24}$$

for some positive constants a_1, a_2, b_1 and b_2. In this section, we are interested in the perturbed Schrödinger equation $Su = f$.

We shall use the wavelet system $\{\Phi_{0,0}\} \cup \{\Psi_{j,k} : j \in \mathbb{Z}_+, k = 0,1,\ldots,2^j - 1\}$ to construct a Galerkin approximation scheme for the Schrödinger equation $Su = f$ with a given function $f \in L^2(\mathbb{R})$. We shall first show that the resulting system of algebraic linear equations can be preconditioned by a diagonal matrix. We then show that the Galerkin solution converges. Next we shall show that the discrete Galerkin scheme for the differential equation with unbounded coefficients is equivalent to a discrete Galerkin scheme of a periodic pseudo-differential operator. The latter equation is naturally related to the spectral Galerkin approximation using Hermite functions to solve the equation (23).

A. Galerkin scheme

We use the subspace $V_J \subset H$, which is defined by

$$V_J = \mathrm{span}\{\Phi_{J,k}\}_{k=0}^{2^J-1}$$

to be the Galerkin space. Since the space $\{V_j\}_{j \in \mathbb{Z}_+}$ forms a multi-resolution analysis,[6] the subspace V_J can be also spanned by

$$V_J = \mathrm{span}\{\Phi_{0,0}, \Psi_{j,k} \ : \ 0 \leqslant j < J, 0 \leqslant k < 2^j\}. \tag{25}$$

For convenience of notation, we denote

$$\Psi^0 = \Phi_{0,0} \quad \text{and} \quad \Psi^m = \Psi_{j,k}, \quad m = 1,2,\ldots, \tag{26}$$

where j,k are the unique non-negative integers such that $m = 2^j + k$ and $0 \leqslant k < 2^j$.

The Galerkin scheme for the Schrödinger equation $Su = f$ with $f \in L^2(\mathbb{R})$ is to find $u_J \in V_J$ such that

$$\langle Su_J, v \rangle = \langle f, v \rangle, \quad \forall \ v \in V_J. \tag{27}$$

In view of (25), (27) is equivalent to

$$\langle Su_J, \Psi^m \rangle = \langle f, \Psi^m \rangle, \quad m = 0,1,\ldots,2^J - 1. \tag{28}$$

Since $u_J \in V_J$, there exist $c_{0,0}$ and $d_{j,k}, j = 0,\ldots,J-1, k = 0,\ldots,2^j - 1$ such that

$$u_J = c_{0,0}\Phi_{0,0} + \sum_{j=0}^{J-1}\sum_{k=0}^{2^j-1} d_{j,k}\Psi_{j,k} = \sum_{m=0}^{2^J-1} d^m\Psi^m,$$

where we denote $d^0 = c_{0,0}, d^m = d_{j,k}$ for $m = 2^j + k$ and $0 \leqslant k < 2^j$.

Using matrix notation, the system of equations (28) takes the following form:

$$M_J d = F_J, \tag{29}$$

where M_J is a $2^J \times 2^J$ matrix with entries $M_{m,m'}$ given by

$$M_{m,m'} = \langle S\Psi^m, \Psi^{m'}\rangle,$$

and $F = (\langle f, \Psi^{m'}\rangle)^T$ is a column vector, and $d = (d^0, d^1, \ldots, d^{2^J-1})^T$ is the unknown vector.

B. Pre-conditioning

We now estimate the condition number of the matrix M_J in terms of the scale J. Let D_J be the $2^J \times 2^J$ diagonal matrix with diagonal elements,

$$d_{0,0} = 1, \quad d_{(2^j+k),(2^j+k)} = 2^{j/2}, \quad j = 0,1,\ldots,J-1,\ k = 0,1,\ldots,2^j - 1.$$

Then the equation $M_J d = F_J$ can be rewritten as

$$D_J^{-1} M_J D_J^{-1} D_J d = D_J^{-1} F_J. \tag{30}$$

Let $A_J = D_J^{-1} M_J D_J^{-1}, x_J = D_J d$ and $b_J = D_J^{-1} F_J$. Then the system of equations (30) becomes

$$A_J x_J = b_J. \tag{31}$$

We show that as a function of J, the condition number of the matrix A_J is uniformly bounded.

Lemma 6: Assume that (24) holds. Let A_J be defined as in (31). Then for any J, we have

$$\langle A_J v, v\rangle \approx \langle v, v\rangle, \quad \forall\ v \in \mathbb{C}^{2^J}, \tag{32}$$

where $\langle \cdot, \cdot \rangle$ is the inner product in $\mathbb{C}^{2^J}$. Hence, the system of equations (31) is uniquely solvable.

Proof: For the vector v, we define $g = v_0\Psi_{0,0} + \Sigma_{j=0}^{J-1}\Sigma_{k=0}^{2^j-1} v_{2^j+k} 2^{-j/2}\Psi_{j,k}$. Then by Lemma 3, $g \in H$. Integrating by parts gives

$$\langle Sg, g\rangle = \langle -(ag')' + bg, g\rangle = \langle ag', g'\rangle + \langle bg, g\rangle \approx \langle Lg, g\rangle,$$

where (24) has been used in the last step. Furthermore, by Theorem 3, we have

$$\langle Lg, g\rangle \approx |v_0|^2 + \sum_{j=0}^{J-1} 2^j \sum_{k=0}^{2^j-1} |v_{2^j+k} 2^{-j/2}|^2 = |v_0|^2 + \sum_{j=0}^{J-1}\sum_{k=0}^{2^j-1} |v_{2^j+k}|^2 = \sum_{m=0}^{2^J-1} |v_m|^2 = \langle v, v\rangle.$$

On the other hand, from (26) we have $g = \Sigma_{m=0}^{2^J-1} v_m 2^{-j/2}\Psi^m$ and

$$\langle Sg, g\rangle = \sum_{m,m'=0}^{2^J-1} v_m \overline{v_{m'}} 2^{-(j+j')/2} \langle S\Psi^m, \Psi^{m'}\rangle = \langle A_J v, v\rangle.$$

Therefore, $\langle A_J v, v\rangle \approx \langle v, v\rangle$, as desired.

By Lemma 6 we now estimate the condition number of the matrix A_J in Eq. (31). We have the following result.

Theorem 4: Under the assumption in (24), the condition numbers of the matrices A_J ($J \in \mathbb{Z}_+$) are uniformly bounded (independent of J).

Proof: By Lemma 6, the ratio of the largest eigenvalue and the smallest eigenvalue of the matrix A_J is uniformly bounded. Since the condition number of a matrix can be estimated as the ratio of its largest eigenvalue and smallest eigenvalue, we conclude that the condition numbers of the matrices A_J are uniformly bounded.

C. Convergence of the Galerkin scheme

In this subsection we show that the approximate solution u_J in (27) converges to the solution u of (23) when $J \to +\infty$. The convergence is not in the weighted norm but directly in the $L^2(\mathbb{R})$ sense. We have the following result.

Theorem 5: For $J>0$, let u and u_J be solutions of (23) and (27), respectively. Then we have the estimate

$$\|u-u_J\|_{\mathrm{H}} \leqslant C \inf_{v_J \in V_J} \|u-v_J\|_{\mathrm{H}}, \tag{33}$$

where C is a constant independent of J. In particular, we have

$$u_J \to u, \quad \text{in} \quad L^2(\mathbb{R}).$$

Proof: For $w \in V_J$, from (23) and (27) we have

$$\langle S(u-u_J), w\rangle = 0.$$

Since S is self-adjoint and positive, as in the proof Lemma 6, we have

$$\|u-u_J\|_{\mathrm{H}}^2 \approx \langle S(u-u_J), u-u_J\rangle = \langle S(u-u_J), u-v_J\rangle \leqslant C\|u-u_J\|_{\mathrm{H}} \cdot \|u-v_J\|_{\mathrm{H}}.$$

Hence, we have

$$\|u-u_J\|_{\mathrm{H}} \leqslant C\|u-v_J\|_{\mathrm{H}}, \qquad \forall \ \ v_J \in V_J,$$

which proves (33). Moreover, by virtue of Theorem 3 we have

$$\|u-u_J\|_{L^2(\mathbb{R})} \leqslant \|u-u_J\|_{\mathrm{H}}.$$

Hence, $u_J \to u$ in $L^2(\mathbb{R})$. The proof of Theorem 5 is complete.

D. Spectral approximation

Hermite functions are eigenfunctions of the Schrödinger operator. We can use them to approximate solutions of the equation (23) in the context of the spectral method.

We introduce the notation

$$\tilde{n} = \begin{cases} 2n, & \text{if } \ n \geqslant 0, \\ 2|n|-1, & \text{if } \ n < 0. \end{cases}$$

For the differential operator S defined in (23), let q be a function from $\mathbb{Z}\times\mathbb{Z}$ to $\mathbb{R}$ defined by

$$q(n,n') = \langle S e_{\tilde{n}}, e_{\tilde{n}'}\rangle, \quad n,n' \in \mathbb{Z}. \tag{34}$$

Then the truncated matrix $(q(n,n'))_{|n|,|n'|\leqslant N} (N \in \mathbb{Z}_+)$ is the Galerkin matrix of the spectral approximation of the operator S by Hermite functions.

When S is the Schrödinger operator L in (2), we have $q(n,n') = (2\tilde{n}+1)\delta_{n,n'}$, which is a diagonal matrix. In general, the matrix q is a full matrix.

E. A pseudo-differential operator

We introduce a periodic pseudo-differential operator connected to the Schrödinger equation $Su=f$. This also suggests the necessity to study numerical solutions for pseudo-differential equations.[3,4]

Lemma 7: Let q be defined as in (23) and assume that (24) holds. Then for every $n\in\mathbb{Z}$, $\{q(n,\cdot)\}$ is square summable, that is, $\Sigma_{n'\in\mathbb{Z}}|q(n,n')|^2<\infty$.

Proof: Let $n\in\mathbb{Z}$. Then we have

$$\begin{aligned}\sum_{n'\in\mathbb{Z}}|q(n,n')|^2&=\sum_{n'\in\mathbb{Z}}|\langle Se_{\tilde{n}},e_{\tilde{n}'}\rangle|^2\\&=|\langle Se_{\tilde{n}},e_0\rangle|^2+\sum_{n=1}^{\infty}\left(|\langle Se_{\tilde{n}},e_{2n'}\rangle|^2+|\langle Se_{\tilde{n}},e_{2n'-1}\rangle|^2\right)\\&=\sum_{n'=0}^{\infty}|\langle Se_{\tilde{n}},e_{n'}\rangle|^2\\&=\|Se_{\tilde{n}}\|^2\\&<\infty,\end{aligned}$$

since $\{e_{n'}\}_{n'\in\mathbb{Z}}$ is an orthonormal basis for $L^2(\mathbb{R})$.

Lemma 8: Suppose that the functions a and b satisfy the condition (24). Then we have

$$\sum_{n,n'\in\mathbb{Z}}c_n\overline{c_{n'}}q(n,n')\approx\sum_{n\in\mathbb{Z}}(2|n|+1)|c_n|^2.$$

Proof: Let $u=\Sigma_{n\in\mathbb{Z}}c_ne_{\tilde{n}}$. Then by Lemma 1 we have

$$\sum_{n,n'\in\mathbb{Z}}c_n\overline{c_{n'}}q(n,n')=\sum_{n,n'\in\mathbb{Z}}\langle Sc_ne_{\tilde{n}},c_{n'}e_{\tilde{n}'}\rangle=\langle Su,u\rangle\approx\langle Lu,u\rangle\approx\sum_{n\in\mathbb{Z}}(2|n|+1)|c_n|^2,$$

which completes the proof.

For $(x,n)\in\mathbb{T}\times\mathbb{Z}$, we use the symbol

$$p(x,n)=\sum_{l\in\mathbb{Z}}q(n,n+l)e^{i2\pi lx}.$$

It follows that

$$q(n,n')=\int_0^1 p(x,n)e^{i2\pi(n-n')x}\,dx.$$

Consider the periodic pseudo-differential operator $P(\cdot,D)$ with symbol $p(x,n)$

$$[P(x,D)u](x)=\sum_{n\in\mathbb{Z}}e^{i2\pi nx}p(x,n)\hat{u}(n),\quad u\in C^{\infty}(\mathbb{T}).\tag{35}$$

Theorem 6: Suppose that the assumption (24) holds. Then the pseudo-differential operator defined in (35) can be extended to $H^1(\mathbb{T})$. Moreover, the operator $P(\cdot,D)$ is positive and there is a positive constant C such that

$$P(\cdot,D):H^1(\mathbb{T})\mapsto L^2(\mathbb{T})\quad\text{and}\quad\langle P(\cdot,D)u,u\rangle\geqslant C\|u\|_{1/2}^2,\quad\forall u\in H^{1/2}(\mathbb{T}).$$

Proof: For $u,v\in C^\infty(\mathbb{T})$, we have

$$\begin{aligned}\langle P(\cdot,D)u,v\rangle &= \int_0^1 [P(x,D)u](x)\overline{v(x)}dx\\ &= \int_0^1 \left(\sum_{n\in\mathbb{Z}} e^{i2\pi nx}p(x,n)\hat{u}(n)\right)\overline{\left(\sum_{n'\in\mathbb{Z}} e^{i2\pi n'x}\hat{v}(n')\right)}dx\\ &= \sum_{n,n'\in\mathbb{Z}} \hat{u}(n)\overline{\hat{v}(n')}\int_0^1 e^{i2\pi(n-n')x}p(x,n)dx = \sum_{n,n'\in\mathbb{Z}} \hat{u}(n)\overline{\hat{v}(n')}q(n,n').\end{aligned}$$

Hence, by Lemma 8, we have

$$\begin{aligned}|\langle P(\cdot,D)u,v\rangle| &\leqslant \left|\sum_{n,n'\in\mathbb{Z}} \hat{u}(n)\overline{\hat{v}(n')}q(n,n')\right|\\ &\leqslant C\left(\sum_{n\in\mathbb{Z}}(1+n^2)|\hat{u}(n)|^2\right)^{1/2}\left(\sum_{n'\in\mathbb{Z}}|\hat{v}(n')|^2\right)^{1/2} = C\|u\|_1\|v\|_0, \quad \forall\ v\in C^\infty(\mathbb{T}).\end{aligned}$$

It follows that $\|P(\cdot,D)u\|\leqslant C\|u\|_1$. Moreover, we have

$$\langle P(\cdot,D)u,u\rangle = \sum_{n,n'\in\mathbb{Z}} \hat{u}(n)\overline{\hat{u}(n')}q(n,n') \approx \sum_{n\in\mathbb{Z}}(1+|n|^2)^{1/2}|\hat{u}(n)|^2 = \|u\|_{1/2}^2.$$

Since $C^\infty(\mathbb{T})$ is dense in $H^{1/2}(\mathbb{T})$ and $H^1(\mathbb{T})$, the proof of Theorem 6 is complete.

F. Galerkin scheme for the pseudo-differential operator $P(\cdot,D)$

For a pseudo-differential operator $P(\cdot,D)$ which is defined in (35) and for any given periodic function $f^{\mathrm{per}}\in L^2(\mathbb{T})$, we consider the periodic problem on $\mathbb{T}$,

$$[P(x,D)u^{\mathrm{per}}](x) = f^{\mathrm{per}}(x), \quad x\in\mathbb{T}. \tag{36}$$

We use two bases on $\mathbb{T}$ to approximate solutions of (36). The first basis is the standard Fourier basis $\{e^{i2\pi nx}\}_{n\in\mathbb{Z}}$ and the second one is the periodic wavelet basis.

The Galerkin scheme for the periodic pseudo-differential equation (36) with a Fourier basis is to find

$$u_N^{\mathrm{per}}(x) = \sum_{|n|\leqslant N} u_n e^{i2\pi nx},$$

so that

$$\langle P(\cdot,D)u_N^{\mathrm{per}},v\rangle = \langle f^{\mathrm{per}},v\rangle \quad \forall\ v\in \mathrm{span}\{e^{i2\pi nx}\ :\ n=-N,-N+1,\ldots,N\}. \tag{37}$$

The system of algebraic equations in (37) can be rewritten as

$$F_N u^N = f_N,$$

where $F_N=\{\langle P(\cdot,D)(e^{i2\pi n\cdot}),e^{i2\pi n'\cdot}\rangle\}$ is a $(2N+1)\times(2N+1)$ matrix, $f_N=\{\langle f^{\mathrm{per}},e^{i2\pi n\cdot}\rangle\}^T$ and $u^N=(u_{-N},u_{-N+1},\ldots,u_N)^T$. It can be easily verified that the discrete Galerkin matrix F_N is equal to the Galerkin matrix (34), that is, we have

$$F_N=(q(n,n'))_{|n|,|n'|\leqslant N}.$$

The Galerkin scheme for the periodic pseudo-differential equation (36) with periodic wavelets is to find

$$u^{\mathrm{per}}=d_0+\sum_{j=0}^{J-1}\sum_{k=0}^{2^j-1} d_{2^j+k}(\psi_{j,k})^{\mathrm{per}}$$

such that

$$\langle P(\cdot,D)u^{\mathrm{per}},v\rangle=\langle f^{\mathrm{per}},v\rangle \quad \forall \quad v\in \mathrm{span}\{(\varphi_{J,k})^{\mathrm{per}}(x):\ k=0,\ldots,2^J-1\}. \tag{38}$$

Rewriting the system of equations (38) in terms of $\{d_m\}_{m=0}^{2^J-1}$, we get the matrix equation

$$P_J d=f_J, \tag{39}$$

where $P_J=\{\langle P(\cdot,D)\Psi_{m'}^{\mathrm{per}},\Psi_m^{\mathrm{per}}\rangle\}$ is a $2^J\times 2^J$ matrix, $f_J=\{\langle f^{\mathrm{per}},\Psi_m^{\mathrm{per}}\rangle\}^T$ is a $2^J\times 1$ vector, and $d=\{(d_0,d_1,\ldots,d_{2^J-1})^T\}$. Here we have used the notation $\Psi_0^{\mathrm{per}}=(\varphi_{0,0})^{\mathrm{per}}=1$ and $\Psi_m^{\mathrm{per}}=(\psi_{j,k})^{\mathrm{per}}$, where j,k are the unique non-negative integers such that $m=2^j+k$ and $0\leqslant k<2^j$.

G. Equivalence of the Galerkin matrix M_J and P_J

In this subsection we show that the Galerkin equation (27) for the operator S can be realized by the pseudo-differential operator $P(\cdot,D)$.

We show that the matrix M_J defined in (29) is equal to the matrix defined in (39). To this end, we introduce an isomorphism between $L^2(\mathbb{R})$ and $L^2(\mathbb{T})$. Suppose that $f\in L^2(\mathbb{R})$ has an expansion,

$$f(x)=\sum_{n=0}^{\infty} f_n e_n(x), \quad x\in\mathbb{R},$$

we define a one-periodic function $\underline{f}(x)$ by

$$\underline{f}(x)=f_0+\sum_{n=1}^{\infty}[f_{2n}e^{i2\pi nx}+f_{2n-1}e^{-i2\pi nx}], \quad x\in\mathbb{T}. \tag{40}$$

It is easy to show that $\underline{f}\in L^2(\mathbb{T})$ and in fact $\|f\|_{L^2(\mathbb{R})}=\|\underline{f}\|_{L^2(\mathbb{T})}$. Moreover, we have the following result connecting the differential operator S with the pseudo-differential operator $P(\cdot,D)$.

Lemma 9: For any $f\in H$ and $g\in L^2(\mathbb{R})$, if $\underline{f}$ and $\underline{g}$ are defined in (40), then we have

$$\langle Sf,g\rangle=\langle P(\cdot,D)\underline{f},\underline{g}\rangle. \tag{41}$$

Proof: By (40), it suffices to prove (41) for $g(x)=e_n(x), n\in\mathbb{Z}_+$. First we consider the case $g=e_{2n}, n\in\mathbb{Z}_+$. For $f(x)=\Sigma_{n=0}^{\infty}f_n e_n(x)$ such that all but finitely many f_n are zeros, by definition the periodic function $\underline{g}(x)=e^{i2\pi nx}$. Hence, we have

$$\langle Sf,e_{2n}\rangle=\sum_{n'=0}^{\infty} f_{n'}\langle Se_{n'},e_{2n}\rangle,$$

and for the pseudo-differential operator,

$$\begin{aligned}\langle P(\cdot,D)\underline{f},\underline{g}\rangle &= f_0\langle P(\cdot,D)(1),e^{i2\pi n\cdot}\rangle+\sum_{n'=1}^{\infty}\left[f_{2n'}\langle P(\cdot,D)(e^{i2\pi n'\cdot}),e^{i2\pi n\cdot}\rangle\right.\\ &\quad\left.+f_{2n'-1}\langle P(\cdot,D)(e^{-i2\pi n'\cdot}),e^{i2\pi n\cdot}\rangle\right]\\ &= f_0\int_0^1 p(x,0)e^{-i2\pi nx}\,dx+\sum_{n'=1}^{\infty}\left[f_{2n'}\int_0^1 p(x,n')e^{i2\pi(n'-n)x}\,dx\right.\\ &\quad\left.+f_{2n'-1}\int_0^1 p(x,n')e^{i2\pi(-n'-n)x}\,dx\right]\\ &= f_0 q(0,n)+\sum_{n'=1}^{\infty}\left[f_{2n'}q(n',n)+f_{2n'-1}q(-n',n)\right]\\ &= f_0\langle Se_0,e_{2n}\rangle+\sum_{n'=1}^{\infty}\left[f_{2n'}\langle Se_{2n'},e_{2n}\rangle+f_{2n'-1}\langle Se_{2n'-1},e_{2n}\rangle\right].\end{aligned}$$

The proof for $g=e_{2n+1}$ is similar. The proof of Lemma 9 is complete by the facts that $\mathrm{span}\{e_n : n\in\mathbb{Z}_+\}$ is dense in H and $\{e_n : n\in\mathbb{Z}_+\}$ is an orthonormal basis for $L^2(\mathbb{R})$.

Lemma 10: For $k=0,1,\ldots,2^j-1$, $j,j'=0,1,\ldots,J-1$ and $k'=0,1,\ldots,2^{j'}-1$, for the differential operator S and the pseudo-differential operator P, we have

$$\langle S\Phi_{j,k},\Psi_{j',k'}\rangle=\langle P(\cdot,D)((\varphi_{j,k})^{\mathrm{per}}),(\psi_{j',k'})^{\mathrm{per}}\rangle,$$

$$\langle S\Psi_{j,k},\Psi_{j',k'}\rangle=\langle P(\cdot,D)((\psi_{j,k})^{\mathrm{per}}),(\psi_{j',k'})^{\mathrm{per}}\rangle,$$

$$\langle S\Phi_{j,k},\Phi_{j',k'}\rangle=\langle P(\cdot,D)((\varphi_{j,k})^{\mathrm{per}}),(\varphi_{j',k'})^{\mathrm{per}}\rangle.$$

Proof: From the definition of the functions $\Phi_{j,k}$ and $\Psi_{j,k}$, according to (40), it is easy to verify that $\Phi_{j,k}=(\varphi_{j,k})^{\mathrm{per}}$ and $\Psi_{j,k}=(\psi_{j,k})^{\mathrm{per}}$. Hence, Lemma 10 follows directly from Lemma 9.

The following result is a direct consequence of Lemma 10:

Theorem 7: Let the matrices M_J and P_J be defined, respectively, in (29) and (39). Then we have $M_J=P_J$.

Numerical solutions of pseudo-differential equations by means of wavelets have been studied in several papers such as Refs. 2–4. By Theorem 7 and some results in the literature, the stiffness matrix P_J could be compressed and be approximated by a sparse matrix.

IV. CONCLUSION

We have presented an approximation method to deal with second order elliptic equations with unbounded coefficients on an unbounded domain. The combination of Hermite functions and wavelet functions have the advantages from both the wavelet approximation method and the spectral method.

Note added in the revised version: After submitting this paper, we became aware that multiresolution norm equivalences in weighted spaces $L^2_w((0,1))$ with a weight function w in (0,1) have been obtained in Ref. 1. The Galerkin scheme proposed in this paper deals with the perturbed Schrödinger equations with unbounded coefficients on the unbounded domain $\mathbb{R}$. Our approximation results are measured directly in the $L^2(\mathbb{R})$ and $H^s(\mathbb{R})$ spaces instead of in a weighted sense as in Ref. 1 which deals with the bounded domain (0,1).

(Received 16 May 2002; accepted 30 November 2003)

We analyze a class of parametrized random matrix models, introduced by Rosenzweig and Porter, which is expected to describe the energy level statistics of quantum systems whose classical dynamics varies from regular to chaotic as a function of a parameter. We compute the generating function for the correlations of energy levels, in the limit of infinite matrix size. The crossover between Poisson and Wigner statistics is measured by a renormalized coupling constant. The model is exactly solved in the sense that, in the limit of infinite matrix size, the energy-level correlation functions and their generating function are given in terms of a finite set of integrals. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1644752]

I. INTRODUCTION

Random Matrix Theory (RMT),[1] originally introduced by Wigner to characterize the statistical behavior of the energy levels of nuclei, has found many successful applications in various fields of physics in recent years. Originally, it was thought that RMT was applicable only to complex systems with many degrees of freedom. Hence, it came as a surprise when it was found that it could equally well describe simple quantum systems, with very few degrees of freedom, as long as their classical dynamics were chaotic. The first evidence of this fact was provided in the seminal paper by Bohigas *et al.*[2] in which the energy level fluctuations of the quantum Sinai billiard were analyzed and shown to be consistent with the predictions of the Gaussian orthogonal ensemble of RMT. Since this pioneering work, it has been checked numerically on a wide variety of systems, that the local statistical properties of the energy levels of a quantum system, whose classical counterpart is chaotic, are well-described by RMT. In particular, the nearest neighbor spacing distribution was found to be in excellent agreement with the spacing distribution between adjacent eigenvalues of random matrices.

In contrast, Berry and Tabor[3] had given strong arguments to justify that, for integrable systems with more than one degree of freedom, the nearest neighbor spacing distribution of the quantum energy levels should have a Poisson distribution, characteristic of uncorrelated levels. This has been confirmed by many numerical studies. There now exist excellent reviews on this topic.[4,5]

However, it is well-known in classical mechanics that purely integrable or purely chaotic systems are rare (at least for systems with a few degrees of freedom). For most systems, the phase space is partitioned into regular and chaotic regions and hence these systems can be referred to as *mixed systems*.

An important physical system illustrating these different behaviors, is the hydrogen atom in a magnetic field. The classical system is essentially integrable (chaotic) at weak (strong) fields but appears to be mixed at intermediate values of the field. This classical behavior has its counterpart in the energy level statistics of the corresponding quantum system, which exhibits a crossover from Poisson to Wigner-type, when the magnetic field is increased.[6] It is, therefore, important to find models of random matrices which could describe the statistics of the energy levels of such mixed systems. Qualitatively, such a model should be governed by a Hamiltonian matrix which is

essentially a sum of two parts, one describing the chaotic part of phase space and hence belonging to the Wigner–Dyson ensemble of the relevant symmetry, and the other corresponding to the regular part of phase space. A number of authors have studied models in which block-diagonal GOE matrices are weakly coupled by matrix elements also belonging to a GOE ensemble.[7,8] In this paper, we consider another class of models, first introduced by Rosenzweig and Porter[9] to describe the observed deviations from the Wigner and Poisson statistics in the spectra of some transition metal atoms.

This class of models is governed by an ensemble of $N\times N$ matrices of the form,

$$H=A+\frac{\lambda}{N^{\alpha}}G, \tag{1}$$

where A and G are either real symmetric matrices (in the orthogonal case) or complex self-adjoint ones (in the unitary case). The matrix elements of G are chosen to be independent random variables with a Gaussian distribution of unit variance. In the context of quantum chaos, G is supposed to correspond to the chaotic region of the classical phase space and hence its eigenvalue distribution should obey the Wigner–Dyson statistics. In contrast, A should correspond to the classically regular region and hence its eigenvalues should exhibit Poisson statistics. It is easily seen that the statistics of the energy levels of H depend only on the eigenvalues of A. Hence, without loss of generality, the matrix A can be chosen to be diagonal. The simplest type of model which can be considered is, therefore, the following one: A is a diagonal matrix, whose elements are independent random variables with a probability distribution $\nu(\cdot)$. Different behaviors can be expected by varying the exponent α in (1). the The case $\alpha=1/2$, corresponds to a perturbed Wigner–Dyson ensemble. It was recently analyzed by Brezin and Hikami.[10] They considered the case in which G belongs to the Gaussian Unitary ensemble (GUE) and A is a *fixed* diagonal matrix. They showed that the energy level statistics for such a matrix ensemble was the same as that of G, i.e., the statistics relevant to the GUE. If $\alpha>1$, the energy level statistics is expected to be Poissonian. The value $\alpha=1$ corresponds to the *crossover regime* and for it one expects new statistics. In fact, by making a numerical study of this model, Rosenzweig and Porter showed that if one chooses the exponent α to be unity, then one obtains energy level statistics which is intermediate between Wigner and Poisson statistics.

Analytical studies of the model for $\alpha=1$, has been done only in the unitary case. These studies made use of certain special features of unitary matrices. However, the case of the GOE, which one encounters more often, and is technically more challenging, had remained virtually unsolved thus far. The only results for this case were perturbative ones in the small λ limit.[11]

In this article, we develop a technique which can be used to study the spectral correlations for the case in which G belongs to the GOE as well as to the one in which it belongs to the GUE. We compute the generating function for the average value of the product of traces of advanced Green's functions, and the mixed product of traces of advanced and retarded Green's functions. All the correlation functions of energy levels can be obtained from it, in the limit where N goes to infinity.

In the case $\alpha=1$, our result for the generating function (in the infinite N limit) is in the form of a finite set of ordinary integrals. Quite generally, we show that the density of states at an energy e is given by $\nu(e)$, and that all the correlation functions are universal functions depending only on the ''renormalized'' coupling constant $\Lambda=\lambda\nu(e)$. This suggests that in order to make a comparison of the results of the model with a given quantum system, it might be plausible to take Λ to be the ratio of $\rho(e)$ and $\rho_{\mathrm{reg}}(e)$, where $\rho(e)$ is the classsical Louiville measure of the energy surface and $\rho_{\mathrm{reg}}(e)$ is the measure corresponding to the regular part of the phase space.

In order to obtain more concrete results, one needs to evaluate the integrals appearing in the expression for the generating functions. This explicit computation, which turns out to be a rather lengthy one, has been done in this paper for the generating function for the two-point correlation function, in the unitary case. From it we can recover the two-point correlation function itself, in

the form of certain integrals over modified Bessel functions. In the orthogonal case, the generating function, even for the two-point correlation function, appears in the form of integrals over elliptic functions and we postpone the study of it to a future paper.

Recently, there has been a certain interest in the computation of the generating function itself.[12–14] In the case of the standard Wigner unitary ensemble this has been motivated by the connection between such a RMT and the statistics of the zeroes of the Riemann zeta function. We think therefore that it is worth reporting the expression we get for the two-point generating function in the unitary case, for the Rosenzweig–Porter ensemble. In the unitary case, in some approaches the formula of Harish-Chandra and Itzykson–Zuber[15,16] proved to be very useful. Recently, Guhr and Kohler[17,18] have extended it to the orthogonal and symplectic cases and, using this approach, have obtained an expression for the two-point correlation function in the orthogonal case for the Rosenzweig–Porter model. However, it is not possible to compare their results with those of this paper due to the difference in the two approaches and the complexity of the formulas.

We would like to make a few remarks about the technique used in this paper. We basically use integrals over auxiliary Grassmannian variables to compute the average over the distribution of the Hamiltonian. However, finally, we evaluate these Grassmannian integrals so as to arrive at a representation in terms of ordinary integrals, in the large N limit. Such an approach for the average Green's function and density of states of a random matrix model was made by Ziegler[20] and Brezin.[21] It is similar, of course in spirit, to the familiar supersymmetric approach, introduced by Efetov[19] in this kind of problem. Note, however, that in the articles using the supersymmetric technique, the supersymmetry plays a crucial role for the computation of the saddlepoint of the action, and of the fluctuations around it. In contrast, in the case considered in this paper, we never have to compute a saddlepoint and Grassmannian variables are only used as an intermediate step in the computation, for purposes of simplification. In this case, no further simplication can be achieved by the use of supersymmetry.

II. GENERATING FUNCTION

We want to calculate the correlation functions $\rho^{(n)}(e_1,\ldots,e_n)$ of the eigenvalues λ_j of an $N \times N$ self-adjoint matrix H. They are defined as

$$\rho^{(n)}(e_1,\ldots,e_n)=\left\langle \prod_{\alpha=1}^{n} \hat{\rho}(e_\alpha) \right\rangle, \tag{2}$$

where

$$\hat{\rho}(e)=\frac{1}{N}\sum_j \delta(e-\lambda_j)$$

is the local density of eigenvalues at the energy e. The angular brackets will henceforth indicate an average over the probability distribution of H.

If $G^s(e)$ denotes the advanced $(s=+1)$ and retarded $(s=-1)$ Green's function

$$G^s(e)=\frac{1}{e-H-is\varepsilon},$$

then

$$\hat{\rho}(e)=\lim_{\varepsilon\uparrow 0^+}\left\{\frac{1}{2\pi i N}\operatorname{tr}[G^+(e)-G^-(e))\right\}.$$

We will use the following identity to compute $[\operatorname{tr} G^s(e)]/N$:

$$\frac{\partial}{\partial\varepsilon_{\pm}}\frac{\det[(\varepsilon_{-}/N)\mathbb{1}_N+is\,(e\mathbb{1}_N-H)]}{\det[(\varepsilon_{+}/N)\mathbb{1}_N+is\,(e\mathbb{1}_N-H)]}\bigg|_{\varepsilon_{-}=\varepsilon_{+}}=\mp\frac{1}{isN}\operatorname{tr}G^{s}(e).$$

The symbol $\mathbb{1}_N$ is used to denote the $N\times N$ identity matrix. Hence, it is evident that the correlation functions of energy levels can be obtained from the *generating function*

$$J_n^S=\left\langle\prod_{\alpha=1}^{n}\frac{\det[\varepsilon_{-}(\alpha)/N+is_{\alpha}(e_{\alpha}-H)]}{\det[\varepsilon_{+}(\alpha)/N+is_{\alpha}(e_{\alpha}-H)]}\right\rangle, \tag{3}$$

where $S=\{s_{\alpha}\}_{\alpha=1}^{n}$, $s_{\alpha}\in\{1,-1\}$, and $\varepsilon_{\pm}(\alpha)>0$, by taking suitable derivatives of it with respect to the variables $\varepsilon_{-}(\alpha)$ or $\varepsilon_{+}(\alpha)$.

In particular, the density of states is given by

$$\rho(e)=\rho^{(1)}(e)=\lim_{\varepsilon_{-}\uparrow 0^{+}}\operatorname{Re}\left\{\frac{1}{\pi}\frac{\partial}{\partial\varepsilon_{-}}J_1^{+}\bigg|_{\varepsilon_{-}=\varepsilon_{+}}\right\}$$

and the two-point correlation function by

$$\rho^{(2)}(e_1,e_2)=\lim_{\varepsilon_{-}\uparrow 0^{+}}\operatorname{Re}\left\{\frac{1}{2\pi^2}\frac{\partial^2[J_2^{+-}+J_2^{++}]}{\partial\varepsilon_{-}(1)\,\partial\varepsilon_{-}(2)}\bigg|_{\varepsilon_{-}=\varepsilon_{+}}\right\}.$$

In this paper, we will consider Hamiltonians H of the form

$$H=A+\frac{\lambda}{N}G, \tag{4}$$

where G is an $N\times N$ matrix whose elements are independent random variables with a Gaussian distribution of unit variance and zero mean. When the matrix elements of G are real (complex), the matrix G belongs to the Gaussian orthogonal (unitary) ensemble of standard RMT. Since the probability distribution of G is independent of the basis, the correlations of the energy levels of H depend only on the eigenvalues $\{a_j\}$ of A. Hence, without loss of generality, we can choose A to be a diagonal matrix whose elements are independent random variables with a probability distribution $\nu(a_j)$.

A. The orthogonal case for finite matrix size

Consider a mixed system governed by a Hamiltonian matrix of the form (4), with the matrix G belonging to the Gaussian orthogonal ensemble (GOE). In this case, it is convenient to express the generating function J^S as the ratio of the *square roots* of the determinants of an antisymmetric matrix and a symmetric one. This is because one can cast such a ratio as a product of integrals over real and Grassmannian variables. In this way the average over the matrix G and a can be easily done. After some standard manipulations, the generating function can be written as follows:

$$J^S=(\det\mathcal{S})^{N/2}\,e^{(1/2\lambda^2)[\operatorname{tr}(\rho_{+}\mathcal{S})^2-\operatorname{tr}\rho_{-}^2]}\int D\nu(A)\int D\varphi_{+}\int D\varphi_{-}\,e^{-(\lambda^2/2N^2)\operatorname{tr}[L_{+}^{t}\mathcal{S})^2+(\rho_{+}\mathcal{S}N/\lambda^2)]^2}$$
$$\times\,e^{(\lambda^2/2N^2)\operatorname{tr}[L_{-}^{t}\Upsilon-(\rho_{-}N/\lambda^2)]^2}\,e^{-(\varphi_{+},(i\mathcal{S}\otimes(e\mathbb{1}_N-A)\varphi_{+})}\,e^{-(\varphi_{-},(i\Upsilon\otimes(\lambda^2/N^2)\,T)\varphi_{-})}. \tag{5}$$

The integration is carried over the vectors φ_{+}, whose components are real, and φ_{-}, whose components are Grassmanian variables, as well as over the variables denoted by a_j. We have used the notation

$$D\nu(A) := \prod_{j=1}^{N} da_j\, \nu(a_j), \tag{6}$$

where the $\nu(a_j)$'s denote the probability distributions of the variables a_js. The $2n\times 2n$ matrices L_σ, with $\sigma = +,-$, and the $N\times N$ matrix T are given by

$$L_\sigma(p\alpha|p'\alpha') = \sum_{i=1}^{n} \varphi_{\sigma i}(p\alpha)\, \varphi_{\sigma i}(p'\alpha')$$

and

$$T_{ij} = \sum_{p=1}^{2} \sum_{\alpha=1}^{n} \varphi_{+i}(p\alpha)\, \varphi_{+j}(p\alpha) s_\alpha. \tag{7}$$

The $2n\times 2n$ matrices $\mathcal{S}$ and Υ are given by

$$\mathcal{S}(p\alpha|p'\alpha') = \delta_{\alpha\alpha'}\, \delta_{pp'} s_\alpha, \tag{8}$$

$$\Upsilon(p\alpha|p'\alpha') = \delta_{\alpha\alpha'}\, \gamma(pp'), \tag{9}$$

where

$$\gamma(pp) = 0, \quad \gamma(12) = -\gamma(21) = 1. \tag{10}$$

Since we consider correlation functions between energy levels around some energy e, on the scale of the mean level spacing, we have decomposed the energies e_α into

$$e_\alpha = e + \frac{r_\alpha}{N}, \tag{11}$$

so that we have introduced the matrices ρ_+ and ρ_- of elements

$$\rho_+(p\alpha|p'\alpha') = \delta_{\alpha\alpha'}\delta_{pp'}[\varepsilon_+(\alpha) + i r_\alpha s_\alpha], \tag{12}$$

$$\rho_-(p\alpha|p'\alpha') = \delta_{\alpha\alpha'}\delta_{pp'}[\varepsilon_-(\alpha) s_\alpha + i r_\alpha]. \tag{13}$$

With the help of Gaussian integrations over auxiliary $n\times n$ matrices Q_+ and Q_-, the exponents in the integrands [on the RHS of (5)] can be reduced to quadratic forms in φ_+ and φ_-. This procedure, which is analogous to the Hubbard Stratonovich transformation, yields the following identities:

$$e^{-(\lambda^2/2N^2)\mathrm{tr}(L_+^t \mathcal{S} + (N/\lambda^2)\mathcal{S}\rho_+)^2} = \frac{1}{d_+} \int DQ_+\, e^{-(1/2)\mathrm{tr}\, Q_+^2}\, e^{-(i\lambda/N)\mathrm{tr}[Q_+(L_+^t \mathcal{S} + N/\lambda^2 \mathcal{S}\rho_+)]},$$

and

$$e^{(\lambda^2/2N^2)\mathrm{tr}(L_-^t \Upsilon - (N/\lambda^2)\rho_-)^2} = \frac{1}{d_-} \int DQ_-\, e^{-(1/2)\mathrm{tr}\, Q_-^2}\, e^{-(\lambda/N)\mathrm{tr}[Q_-(L_-^t \Upsilon - (N/\lambda^2)\rho_-)]}, \tag{14}$$

with

$$d_\pm = \int DQ_\pm\, e^{-(1/2)\mathrm{tr}\, Q_\pm^2}. \tag{15}$$

Following Schäfer and Wegner[22] we choose the matrix Q_+ to be of the form

$$Q_+ = \begin{pmatrix} Q_{11} - i\sqrt{\delta^2 + Q_{12}Q_{21}} & Q_{12} \\ Q_{21} & Q_{22} + i\sqrt{\delta^2 + Q_{21}Q_{12}} \end{pmatrix}. \tag{16}$$

If $s_\alpha = -1$ for $\alpha = 1,\ldots,q$ and $s_\alpha = 1$ for $\alpha = q+1,\ldots,n$, then Q_{11} is a $2(n-q)\times 2(n-q)$ real symmetric matrix, Q_{22} is a $2q\times 2q$ real symmetric matrix, Q_{12} is a $2q\times 2(n-q)$ real matrix, and Q_{21} is a $2(n-q)\times 2q$ real matrix, such that

$$Q_{21}^t = Q_{12}.$$

Here the superscript t denotes the transpose of the matrix.

We consider Q_- to be Hermitian: $Q_-^\dagger = Q_-$, so for $n=1$ it reduces to a real number. In addition, we require Q_- to satisfy the following relation:

$$(Q_- \Upsilon)^t = -(Q_- \Upsilon). \tag{17}$$

The constraint (17) on the matrix Q_- is imposed so as to ensure the validity of the identity (14). Indeed the latter identity, involving such a matrix Q_-, uses the fact that the linear term in Q_-, appearing in the exponential, is of the form $\mathrm{tr}(Q_- E \Upsilon)$, with E being an antisymmetric matrix. We can therefore write the generating function in the form

$$J^S = \frac{(\det \mathcal{S})^{N/2}}{d_+ d_-} \int DQ_+ \int DQ_- \exp\left(-\frac{1}{2}\mathrm{tr}\left[Q_+ + i\frac{\mathcal{S}\rho_+}{\lambda} \right] \right)^2 \times \exp\left(-\frac{1}{2}\mathrm{tr}\left[Q_- - \frac{\rho_-}{\lambda} \right] \right)^2 \hat{K}(Q_+, Q_-) \tag{18}$$

with

$$\hat{K}(Q_+, Q_-) = \int D\nu(a) \int D\varphi_+ \, e^{-(\varphi_+, (i\mathcal{S}\otimes(e\mathbb{1}_N - A)\varphi_+)} \, e^{-(\varphi_+, (i\lambda/N)\mathcal{S}Q_+ \otimes \mathbb{1}_N)\varphi_+)} \times \mathbb{I}_-, \tag{19}$$

where $\mathbb{I}_-$ is the integral over the Grassmannian variables $\{\varphi_{-j}\}$ and is given by

$$\mathbb{I}_- = \int \mathcal{D}\varphi_- \exp[-(\varphi_-, R\varphi_-)], \tag{20}$$

with

$$R := \frac{\lambda}{N}(\Upsilon Q_-) \otimes \mathbb{1}_N + \Upsilon \otimes \left(i(e\mathbb{1}_N - A) + \frac{\lambda^2}{N^2} T \right). \tag{21}$$

The matrix T is defined by (7). In the following section we evaluate the integral $\mathbb{I}_-$ and show that $\hat{K}(Q_+, Q_-)$ depends only on the eigenvalues of the matrices Q_+ and Q_-.

Evaluation of the integral $\mathbb{I}_-$*:* Due to the constraint (17) on the matrix Q_-, the matrix R, defined by (21) is antisymmetric, and we obtain

$$\mathbb{I}_- = \sqrt{\det R}. \tag{22}$$

Moreover, we can show, as follows, that the matrix R depends only on the *eigenvalues* of the matrix Q_-: Defining an $N\times N$ matrix A_1,

$$A_1 := i(e\mathbb{1}_N - A) + \frac{\lambda^2}{N^2} T, \tag{23}$$

we write

$$\det R = \det(\Upsilon \otimes \mathbb{1}_N) \det\left[\frac{\lambda}{N} Q_- \otimes \mathbb{1}_N + \mathbb{1}_{2n} \otimes A_1\right] = \det(\Upsilon \otimes \mathbb{1}_N) \det\left[\frac{\lambda}{N} q_- \otimes \mathbb{1}_N + \mathbb{1}_{2n} \otimes A_1\right] =: \det C, \tag{24}$$

where q_- is the diagonal matrix whose diagonal elements are the eigenvalues of Q_-.

The elements of the matrix C, (24), are given by

$$C(p\alpha, j | p'\alpha', j') = \Upsilon(pp')\left[\frac{\lambda}{N} q_-(\alpha)\delta_{\alpha\alpha'}\,\delta_{jj'} + \delta_{\alpha\alpha'} A_1(jj')\right],$$

where $q_-(\alpha) \equiv q_-(p\alpha)$. This follows from the fact that the eigenvalues of Q_- are doubly degenerate. Hence, the matrix C is *antisymmetric in the label p* and has the form

$$C = \begin{pmatrix} 0 & D \\ -D & 0 \end{pmatrix},$$

where D is an $nN \times nN$ matrix defined as follows:

$$D := \frac{\lambda}{N} \tilde{q}_- \otimes \mathbb{1}_N + \mathbb{1}_n \otimes A_1. \tag{25}$$

In (25), $\tilde{q}_-$ denotes an $n \times n$ diagonal matrix with diagonal elements $\tilde{q}_{-\alpha} = q_{1\alpha}$. This leads to the result

$$\mathbb{I}_- = \det D.$$

From (23) and (25) it follows that

$$\det D = \prod_{\alpha=1}^{n} \det\left(\tilde{q}_{-\alpha} \frac{\lambda}{N} \mathbb{1}_N + i(e\mathbb{1}_N - A) + \frac{\lambda^2}{N^2} T\right).$$

For each $\alpha \in \{1, \ldots, n\}$, let us define an $N \times N$ diagonal matrix

$$b_\alpha := \tilde{q}_{-\alpha} \frac{\lambda}{N} \mathbb{1}_N + i(e\mathbb{1}_N - A). \tag{26}$$

In terms of this matrix, we can write

$$\mathbb{I}_- \equiv \det D = \prod_{\alpha} \det b_\alpha \det\left(\mathbb{1}_N + \frac{\lambda^2}{N^2} b_\alpha^{-1} T\right). \tag{27}$$

For each α, let F_α denote a $2n \times 2n$ matrix whose elements are given by

$$F_\alpha(p\gamma | p'\gamma') := \sum_{j=1}^{N} (b_\alpha^{-1})_j \, \varphi_{+j}(p\gamma)\, \varphi_{+j}(p'\gamma').$$

If $\operatorname{tr} A^j = \operatorname{tr} B^j$ for any arbitrary integer j, then

$$\det(\mathbb{1}_n + A) = \det(\mathbb{1}_m + B). \tag{28}$$

Using (28) we have the identity

$$\det\left(\mathbb{1}_N + \frac{\lambda^2}{N^2} b_\alpha^{-1} T\right) = \det\left(\mathbb{1}_{2n} + \frac{\lambda^2}{N^2} \mathcal{S} F_\alpha\right). \tag{29}$$

Hence from (27), (26), and (29) it follows that

$$\mathbb{I}_- = \prod_{j=1}^{N} \det\left(\frac{\lambda}{N}\tilde{q}_- + i(e-a_j)\mathbb{I}_n\right) \prod_{\alpha=1}^{n} \det\left(\mathbb{I}_{2n} + \frac{\lambda^2}{N^2}\mathcal{S}F_\alpha\right), \tag{30}$$

where a_j denotes a diagonal element of the diagonal matrix A. Using the representation of a determinant in terms of a Grassmannian integral, we can write

$$\prod_{\alpha} \det\left(\mathbb{I}_{2n} + \frac{\lambda^2}{N^2}\mathcal{S}F_\alpha\right) = \int D\overline{\Psi}\, D\Psi\, e^{-(\overline{\Psi},\Psi)}\, e^{-(\overline{\Psi},B\Psi)}, \tag{31}$$

where Ψ $(\overline{\Psi})$ is a column (row) vector of length $2n^2$, and

$$(\overline{\Psi},B\Psi) = \sum_{\alpha=1}^{n} \sum_{\beta,\beta'=1}^{2n} \overline{\Psi}_\alpha(\beta) B_\alpha(\beta\beta') \Psi_\alpha(\beta'),$$

where β now refers to the double index $(p\,\gamma)$ and B_α denotes a $2n\times 2n$ matrix whose elements are given by

$$B_\alpha(\beta\beta') = \frac{\lambda^2}{N^2}\mathcal{S}(\beta)\, F_\alpha(\beta\beta'),$$

with $\mathcal{S}(\beta) = s_\gamma$. The relations (30) and (31) yield the following expression for the integral $\mathbb{I}_-$:

$$\mathbb{I}_- = \int D\overline{\Psi}\, D\Psi\, e^{-(\overline{\Psi},\Psi)} \prod_{j=1}^{N} \det\left(\frac{\lambda}{N}\tilde{q}_- + i(e-a_j)\mathbb{I}_n\right)$$
$$\times \exp\left(-\left[\frac{\lambda^2}{N^2}\sum_{j=1}^{N} \sum_{\beta,\beta'=1}^{2n} \varphi_{+j}(\beta)\, \varphi_{+j}(\beta')\, \mathcal{S}_\beta \sum_{\alpha=1}^{n} [b_\alpha^{-1}]_j\, \overline{\Psi}_a(\beta)\, \Psi_a(\beta')\right]\right). \tag{32}$$

We can now insert the representation of $\mathbb{I}_-$, given by (32), in the expression (19) for $\hat{K}$, and perform the integration over φ_+. This yields

$$\hat{K}(Q_+,Q_-) = \int D\overline{\Psi}\, D\Psi\, e^{-(\overline{\Psi},\Psi)} \int D\nu(a) \left[\prod_{j'=1}^{N} \det\left(\frac{\lambda}{N}\tilde{q}_- + i(e-a_{j'})\mathbb{I}_n\right)\right]$$
$$\times \prod_{j=1}^{N} \det\left[\mathcal{S}\left(i(e-a_j)\mathbb{I}_{2n} + i\frac{\lambda}{N}Q_+ + \frac{\lambda^2}{N^2}\mathcal{R}_j\right)\right]^{-(1/2)}, \tag{33}$$

where each R_j is a $2n\times 2n$ matrix with elements

$$\mathcal{R}_j(\beta\beta') = \sum_{\alpha=1}^{n} (b_\alpha^{-1})_j \overline{\Psi}_\alpha(\beta)\, \Psi_\alpha(\beta') = \sum_{\alpha=1}^{n} \left(\frac{\lambda}{N}\tilde{q}_{-\alpha}\mathbb{I}_N + i(e\mathbb{I}_N - A)\right)^{-1}_j \overline{\Psi}_\alpha(\beta)\, \Psi_\alpha(\beta'). \tag{34}$$

From the definition (6) of the measure $D\nu(a)$, it follows that the expression for $\hat{K}(Q_+,Q_-)$ involves a product of N identical integrals and hence can be written in the form

$$\hat{K} = (\det\mathcal{S})^{-N/2} \int D\overline{\chi} D\chi e^{-(\overline{\chi},\chi)} P^N, \tag{35}$$

where

$$P := \int da\ \nu(a) \det\left(\frac{\lambda}{N}\tilde{q}_- + i(e-a)\mathbb{1}_n\right) \det\left[i(e-a)\mathbb{1}_{2n} + i\frac{\lambda}{N}q_+ + \frac{\lambda^2}{N^2}\mathcal{R}\right]^{-1/2}, \tag{36}$$

with

$$\mathcal{R}(\beta\beta') = \sum_{\alpha=1}^{n}\left(\frac{\lambda}{N}\tilde{q}_{-\alpha} + i(e-a)\right)^{-1} \overline{\chi}_\alpha(\beta)\,\chi_\alpha(\beta'). \tag{37}$$

Using the degeneracy of the eigenvalues of α_- we can rewrite P as

$$P = \int da\ \nu(a)\left[\frac{\det X_-}{\det X_+}\right]^{1/2} \det\left(\mathbb{1}_n + \frac{\lambda^2}{N^2}\frac{M(X_+)}{x_-}\right)^{1/2}, \tag{38}$$

where M is the

$$M_{\alpha_1\alpha_2}(q_+) = \sum_{p=1}^{2}\sum_{\gamma=1}^{n}\frac{\chi_{\alpha_1}(p\gamma)\,\overline{\chi}_{\alpha_2}(p\gamma)}{X_+(p\gamma)},$$

and x_- is a diagonal $n\times n$ matrix of elements $x_-(\gamma)$.

Hence, the generating function in the orthogonal case, for finite matrix size, is given by

$$J^S = \frac{(\det\mathcal{S})^{N/2}}{d_+\,d_-}\int DQ_+ \int DQ_- \exp\left(-\frac{1}{2}\mathrm{tr}\left[Q_+ + i\frac{\mathcal{S}\rho_+}{\lambda}\right]\right)^2 \times \exp\left(-\frac{1}{2}\mathrm{tr}\left[Q_- - \frac{\rho_-}{\lambda}\right]\right)^2 \hat{K}(Q_+, Q_-), \tag{39}$$

where

$$\hat{K} = (\det\mathcal{S})^{-N/2}\int D\overline{\chi}D\chi e^{-(\overline{\chi},\chi)}P^N,$$

and P is given by (38).

B. The unitary case for finite matrix size

When the Hamiltonian matrix (4),

$$H = A + \frac{\lambda}{N}G,$$

is such that G belongs to the Gaussian unitary ensemble (GUE), we arrive at an analogous expression for the generating function. There is now no necessity to double the dimension of the matrices so as to accommodate the real variables as we did in the GOE case. Proceeding exactly as before, we arrive at the following expression of the generating function:

$$J^S = \frac{1}{d_+\,d_-}\int DQ_+ \int DQ_- \exp\left(-\frac{1}{2}\mathrm{tr}\left(Q_+ + \frac{iS\rho_+}{\lambda}\right)^2\right) \quad \exp\left(-\frac{1}{2}\mathrm{tr}\left(Q_- - \frac{\rho_-}{\lambda}\right)^2\right)\tilde{K}(q_+, q_-), \tag{40}$$

where

$$\tilde{K} = \int D\overline{\chi}D\chi e^{-(\overline{\chi},\chi)}P^N.$$

Q_- is now simply an $n\times n$ self-adjoint matrix. The $n\times n$ matrix Q_+ has the same block structure as before, but now Q_{ii} with $i=1,2$ are self-adjoint matrices and $Q_{12}=Q_{21}^{\dagger}$. Here $\overline{\chi},\chi$ are Grassmannian vectors of length n, and P is given by

$$P:=\int da\ \nu(a)\left[\frac{\det X_-}{\det X_+}\right]\det\left(\mathbb{1}_n+\frac{\lambda^2}{N^2}\frac{M(X_+)}{X_-}\right), \tag{41}$$

where

$$M_{\alpha_1\alpha_2}=\sum_{\gamma=1}^{n}\frac{\chi_{\alpha_1}(\gamma)\,\overline{\chi}_{\alpha_2}(\gamma')}{X_+(\gamma)},$$

and $X_\pm$ are diagonal $n\times n$ matrices with diagonal elements

$$x_+(\gamma):=i(e-a)+i\frac{\lambda}{N}q_+(\gamma), \tag{42}$$

$$x_-(\gamma):=i(e-a)+\frac{\lambda}{N}q_-(\gamma), \tag{43}$$

respectively.

The above relations, (40)–(41), for the GUE, are found to be very similar in form to the corresponding relations (18)–(38) for the GOE. The only difference lies in the fact that the expression for P involves *square roots* of determinants for the GOE [see (38)], whereas there is no square root appearing in the corresponding relation (41), in the case of the GUE.

C. The orthogonal and unitary case in the limit of infinite matrix size

We will now evaluate the generating function in the limit $N\to\infty$, from which the correlation functions can be obtained by taking various derivatives with respect to the variables $\varepsilon_-(\alpha)$. It can be easily shown that there is no problem in the interchange of the limit $N\to\infty$, with the derivation with respect to ε_-, and the subsequent limit $\varepsilon_-=\varepsilon_+\to 0$.

The result for the generating function both in the orthogonal ($\beta=1$) and the unitary case ($\beta=2$) can be put in the following form:

$$J^S=\frac{\exp\left(\frac{ip\beta}{2}\mathrm{tr}(\varepsilon_--\varepsilon_+)S\right)}{d_+d_-}\int DQ_+Dq_-D\overline{\chi}D\chi\exp\left(-\frac{1}{2}\mathrm{tr}\left[Q_++\frac{i\rho_+S}{\lambda}-\frac{\beta\lambda p}{2}\right]^2\right)$$
$$\times\exp\left(-\frac{1}{2}\mathrm{tr}\left[Q_--\frac{\rho_-}{\lambda}-\frac{i\beta\lambda p}{2}\right]^2-(\overline{\chi},\chi)\right)\exp\left(\lambda\nu(e)\left[\frac{\beta A_o}{2}+A_1^\beta+A_2^\beta\right]\right). \tag{44}$$

Here $\varepsilon_\pm$ are $n\times n$ matrices with diagonal elements $\varepsilon_\pm(\alpha)$, and

$$p=p(e)=\mathbb{P}\int da\frac{\nu(a)}{a-e},$$

with the symbol $\mathbb{P}$ denoting the principal value of the integral. The matrix A_0 is given by

$$A_0=i\pi\,\mathrm{tr}(q_++iq_-)\sigma(q_+),$$

where $\sigma(q_+)$ is the diagonal matrix whose elements are the signs of the imaginary parts of the eigenvalues $q_+(p\gamma)$ of the matrix Q_+,

$$A_1^\beta = \int_{-\infty}^{+\infty} dt \left\{ \left(\frac{\det(t - iq_-)}{\det(t + q_+)} \right)^{\beta/2} - \left[1 - \frac{\beta}{2} \operatorname{tr} \frac{q_+ + iq_-}{t + q_+} \right] \right\}$$

and

$$A_2^\beta = \int_{-\infty}^{+\infty} dt \left(\frac{\det(t - iq_-)}{\det(t + q_+)} \right)^{\beta/2} [\det(1 - R^\beta)^{\beta/2} - 1], \tag{45}$$

where

$$R^1_{\alpha\alpha'} = \frac{1}{t - iq_-(\alpha)} \sum_{p=1}^{2} \sum_{\gamma=1}^{n} \frac{\overline{\chi}_\alpha(p\gamma)\chi_{\alpha'}(p\gamma)}{t + q_+(p\gamma)}$$

and

$$R^2_{\alpha\alpha'} = \frac{1}{t - iq_-(\alpha)} \sum_{\gamma=1}^{n} \frac{\overline{\chi}_\alpha(\gamma)\chi_{\alpha'}(\gamma)}{t + q_+(\gamma)}.$$

This is the main result of this paper. We have expressed the generating function for the correlation functions in terms of a finite set of integrals. Hence we have reduced the problem of the computation of the generating function, in the limit of infinite matrix size, to that of the evaluation of a finite set of integrals. This was our main purpose, since, starting from this explicit expression, we can proceed to evaluate the physically relevant correlation functions. However, as we shall see, the task of evaluating these integrals is nontrivial. Nevertheless, a general conclusion can be drawn from this expression by noting that the generating function has the following structure:

$$J^S = \exp\left(\frac{ip\beta}{2} \operatorname{tr}[(\varepsilon_- - \varepsilon_+)S] \right) K^S\left(\nu\varepsilon_-, \nu\varepsilon_+, \left\{ \nu r_\alpha + \frac{\lambda^2 \beta \nu p}{2} \right\}, \Lambda \right),$$

where $\Lambda = \lambda\, \nu(e)$, can be called the *renormalized coupling constant*.

Since the correlation functions can be computed from the generating function by using the formula

$$\left(\frac{1}{2\pi} \right)^n \prod_{\alpha=1}^{n} \frac{\partial}{\partial \varepsilon_-(\alpha)} J^{(1_n, -1_n)} \Big|_{\varepsilon_- = \varepsilon_+ = 0} = \rho^{(n)}(r_1, \ldots, r_n),$$

where

$$J^{(1_n, -1_n)} = \left\langle \prod_{\alpha=1}^{n} \frac{\det[\varepsilon_-^2(\alpha) + (e_\alpha - H)^2]}{\det[\varepsilon_+^2(\alpha) + (e_\alpha - H)^2]} \right\rangle,$$

is positive, it follows that

$$J^{(1_n, -1_n)} = |K^{(1_n, -1_n)}|,$$

and therefore $\rho^{(n)}$ has the structure

$$\rho^{(n)}(r_1, \ldots, r_n) = \nu^n f_\beta^{(n)}(r_1\nu + a, r_2\nu + a, \ldots, r_n\nu + a; \Lambda), \tag{46}$$

with $a = \lambda^2\beta/2$. However, since the correlation functions are translation invariant, the RHS of (46) does not depend on a.

We shall prove that the density of states $\rho(e)$ is equal to $\nu(e)$. We can therefore conclude that, *on the scale of energy where the mean level spacing is equal to unity*, the correlation functions are *universal*, i.e., they depend only on β and Λ. More precisely,

$$\left[\frac{1}{\rho(e)}\right]^n \rho^{(n)}\left(\frac{r_1}{\rho(e)},\ldots,\frac{r_n}{\rho(e)}\right)=f_\beta^{(n)}(r_1,r_2,\ldots,r_n;\Lambda).$$

Let us now derive Eq. (44). We start with the expressions for the generating functions J^S for the orthogonal [(39)] and unitary [(40)] cases. The integrals (38) and (41) which occur in these expressions can be written in the form of a single integral:

$$P=\int da\ \nu(a)\left(\frac{\det X_-}{\det X_+}\right)^{\beta/2}\left(\det\left[\mathbb{1}+\frac{\lambda^2 M(X_+)}{N^2 X_-}\right]\right)^{\beta/2}.$$

We decompose this into three terms, i.e., $P=P_0+P_1+P_2$, where

$$P_0:=1+\frac{\beta}{2}\int da\ \nu(a)\ \mathrm{tr}\frac{X_- - X_+}{X_+},$$

$$P_1:=\int da\ \nu(a)\left\{\left(\frac{\det X_-}{\det X_+}\right)^{\beta/2}-\left[1+\frac{\beta}{2}\mathrm{tr}\frac{X_- - X_+}{X_+}\right]\right\}$$

and

$$P_2:=\int da\ \nu(a)\left(\frac{\det X_-}{\det X_+}\right)^{\beta/2}\left\{\left[\det\left(1+\frac{\lambda^2 M(X_+)}{N^2 X_-}\right)\right]^{\beta/2}-1\right\}.$$

Let us first evaluate P_0 in the large-N limit,

$$\int da\ \nu(a)\mathrm{tr}\frac{X_- - X_+}{X_+}=-\frac{\lambda}{N}\int da\ \nu(a)\mathrm{tr}\left[(q_+ + iq_-)\left((e-a)\mathbb{1}_{2n}+\frac{\lambda}{N}q_+\right)^{-1}\right]. \tag{47}$$

Since $\mathrm{Im}\, q_+(\gamma)\neq 0$, the integral on the RHS of (47) tends to the expression

$$-p(e)-i\pi\nu(e)\sigma_+(p\gamma)$$

as $N\to\infty$, where $\sigma_+(p\gamma)$ denotes the sign of the imaginary part of the eigenvalue $q_+(p\gamma)$.

Hence, for large N,

$$P_0=1+\frac{\lambda}{N}\frac{\beta}{2}[p\ \mathrm{tr}(q_+ + iq_-)+i\pi\nu\ \mathrm{tr}(q_+ + iq_-)\sigma(q_+)],$$

where $\sigma(q_+)$ is the diagonal matrix with elements $\sigma_+(p\gamma)$. In the second term, P_1, we make the change of variables $e-a=t\lambda/N$, so that it reads

$$P_1=\frac{\lambda}{N}\int_{-\infty}^{+\infty}dt\ \nu(e-t\lambda/N)\left\{\left(\frac{\det(t-iq_-)}{\det(t+q_+)}\right)^{\beta/2}-\left[1-\frac{\beta}{2}\mathrm{tr}\frac{q_+ + iq_-}{t+q_+}\right]\right\}.$$

The term in parentheses is bounded in t and decays like $1/t^2$ when t is large, since $\mathrm{Im}\, q_+(\gamma)\neq 0$. Hence, we can use the dominated convergence theorem[23] to show that if

$$\sup_t \nu(t)<\infty,$$

and $\nu(t)$ is continuous, then for large N,

$$P_1=\frac{\lambda\nu(e)}{N}A_1^\beta.$$

The term P_2 is treated in exactly the same way as P_1, so that asymptotically,

$$P_2=\frac{\lambda\nu(e)}{N}A_2^\beta.$$

Finally,

$$\lim_{N\to\infty}P^N=\exp\left(\frac{\lambda\beta p}{2}\mathrm{tr}(Q_+ + iQ_-)+\lambda\nu\left[\frac{\beta}{2}A_0+A_1^\beta+A_2^\beta\right]\right). \tag{48}$$

Here and henceforth, we write ν for $\nu(e)$. Expression (44) for the generating function, J^S, in the limit of infinite matrix size, is obtained by substituting (48) in expressions (39) and (40) and completing the squares in Q_+ and Q_-.

III. THE DENSITY OF STATES AND THE AVERAGE OF THE PRODUCT OF TRACES OF ADVANCED GREEN'S FUNCTIONS

The only computation which is easy in the general case, is that of the generating function for traces of advanced Green's functions. This corresponds to the choice $s_\alpha=1$ for all $\alpha\in\{1,...,n\}$.

Let $q_\pm(j)$ denote the eigenvalues of the matrices $Q_\pm$. For the above-mentioned choice of the matrix S, we know that $q_+(j)=q'_+(j)-i\delta$, where $q'_+(j)$ is real and δ is positive. Since $q_-(j)$ is also real (and doubly degenerate in the $\beta=1$ case) we see that the integrands in the expressions for A_1^β and A_2^β are analytic in the variable t in the lower half-plane, and decay like $1/t^2$. We can therefore apply Cauchy's theorem to simply conclude that $A_1^\beta=A_2^\beta=0$. In contrast, if we computed these quantities for the case of a mixed product of advanced and retarded Green's functions ($s_\alpha=1, \alpha=1,...,p, s_\alpha=-1, \alpha=p+1,\ldots,n$), there would be $n-p$ singularities in the lower half-plane, and, therefore, A_1^β and A_2^β would be nonzero.

Hence, it follows easily from (44) that the generating function factorizes as follows:

$$J^{1_n}=\exp\left(i(p+i\pi\nu)\sum_{\alpha=1}^{n}[\varepsilon_-(\alpha)-\varepsilon_+(\alpha)]\right)J_+J_-,$$

where

$$J_+=\frac{1}{d_+}\int DQ_+\exp\left(-\frac{1}{2}\mathrm{tr}\left[Q_+ + \frac{i\rho_+ S}{\lambda}-\frac{\beta\lambda}{2}(p+i\pi\nu)\right]^2\right),$$

and

$$J_-=\frac{1}{d_-}\int DQ_-\exp\left(-\frac{1}{2}\mathrm{tr}\left[Q_- - \frac{\rho_-}{\lambda}-\frac{i\beta\lambda}{2}(p+i\pi\nu)\right]^2\right).$$

Hence, we see from the definitions of $d_\pm$ [(15)] that $J_\pm=1$ and

$$J^{1_n}=\exp\left(i(p+i\pi\nu)\sum_{\alpha=1}^{n}[\varepsilon_-(\alpha)-\varepsilon_+(\alpha)]\right).$$

This implies that

$$\lim_{N\to\infty}\left\langle \prod_{\alpha=1}^{n}\frac{1}{N}\operatorname{tr} G^{+}_{e_\alpha}\right\rangle = [-p-i\pi\nu]^n,$$

which in turn shows that average of a product of the traces of advanced (or retarded) Green's functions factorize. In particular, we see that the density of states, $\rho(e)$, is simply given by

$$\rho(e)=\nu(e).$$

IV. UNITARY CASE: THE TWO-POINT GENERATING FUNCTION

There is one major simplification in the unitary case. The integral defining A_2 [(45)] can be explicitly evaluated and gives a *meromorphic* function of the eigenvalues $\{q_{-j}\}$ and $\{q_{+j}\}$ of the matrices Q_- and Q_+, respectively. We first integrate over the Grassmannian variables $\{\chi_j^\alpha, \overline{\chi}_j^\alpha\}$, then over Q_- and finally over Q_+. After a rather lengthy computation we find that the generating function can be expressed as

$$J^{+-}=\frac{4i}{\pi v t}\exp\left[uy+\frac{1}{2\lambda^2}\operatorname{tr}(\rho_+^2-\rho_-^2)\right]\partial_t R, \tag{49}$$

where R is

$$R=\sum_{j=-1}^{4}\alpha_j B_j, \tag{50}$$

$$u=\frac{1}{2i\lambda}\operatorname{tr}(\rho_- -\rho_+ s), \tag{51}$$

$$y=-2\lambda p-\frac{1}{2i\lambda}[\operatorname{tr}\rho_- +\operatorname{tr}(\rho_+ s)], \tag{52}$$

$$t=\frac{1}{\lambda}\operatorname{tr}(\rho_- s), \tag{53}$$

$$v=\frac{\operatorname{tr}\rho_+}{\lambda}, \tag{54}$$

and

$$B_n=\int_{\operatorname{Im} w=-c} dw\, w^{-n}\exp\left[-w^2-iw(v+\Lambda)-\frac{i\Lambda u^2}{w}\right]\int_{-\infty}^{+\infty}dz\exp\left[-z^2\left(1+\frac{i\Lambda}{w}\right)-tz\right], \tag{55}$$

with c being an arbitrary constant larger than Λ. The coefficients α_j are given by

$$\alpha_{-1}==1,\ \alpha_0=2i\Lambda,\ \alpha_1=-\frac{13}{4}\Lambda^2-\frac{v\Lambda}{2},$$

$$\alpha_2=-\frac{3}{2}i\Lambda^3+\frac{i\Lambda}{2}-\frac{3}{4}v\Lambda^2,\ \alpha_3=\frac{\Lambda^4}{4}-\frac{7}{8}\Lambda^2+\frac{v\Lambda^3}{4}+\frac{v^2}{16}\Lambda^2+u^2\Lambda^2,$$

$$\alpha_4=iu^2\Lambda^3-\frac{3}{8}i\Lambda^3,\ \alpha_5=-\frac{u^2}{4}\Lambda^4. \tag{56}$$

Using the recursion formula

$$\partial_t B_n = \frac{t}{2} B_n - i\Lambda \partial_t B_{n+1} \tag{57}$$

we can express the generating function in terms of the B_n for $n \in \{-1,4\}$ and $\partial_t B_5$. One can also show that the B_n can be represented as an integral over the modified Bessel functions.

Once we have this expression for the generating function, we can also compute the two-point correlation function. One finds that it is given [as in Ref. 24] by a sum of integrals over modified Bessel functions. Details of this computation can be found in Ref. 25.

V. ORTHOGONAL CASE: THE TWO-POINT GENERATING FUNCTION

We start from the equation

$$\rho^{(2)}(r_1,r_2) = \frac{1}{2\pi^2} \mathrm{Re}\left\{ \frac{\partial^2 [J_2^{+-} + J_2^{++}]}{\partial \varepsilon_-(1)\, \partial \varepsilon_-(2)} \bigg|_{\varepsilon_- = \varepsilon_+ = 0} \right\}, \tag{58}$$

in order to compute the correlation function $\rho^{(2)}(e_1,e_2)$. Using the fact (established in Sec. III) that

$$J^{+-}|_{\varepsilon_- = \varepsilon_+} = 1, \tag{59}$$

$$\frac{\partial J^{+-}}{\partial \varepsilon_-(1)} = \pi\nu + ip, \tag{60}$$

$$\frac{\partial J^{+-}}{\partial \varepsilon_-(2)} = \pi\nu - ip, \tag{61}$$

$$\frac{\partial^2 J^{++}}{\partial \varepsilon_-(1)\varepsilon_-(2)} \bigg|_{\varepsilon_- = \varepsilon_+ = 0} = (\pi\nu + ip)^2, \tag{62}$$

we can express $\rho^{(2)}(r_1,r_2)$ as

$$\begin{aligned} \rho^{(2)}(r_1,r_2) = &- \frac{1}{\lambda^2\pi^2} p(r_1+r_2) - \frac{2}{\pi^2\lambda^4} r_1 r_2 + \frac{1}{2}\nu^2 - \frac{p^2}{2\pi^2} \\ &- \frac{1}{2d_+ d_- \lambda^2 \pi^2} \int DQ_+ DQ_- \prod_{\alpha=1}^{2} [Q_-(1\alpha|1\alpha) + Q_-(2\alpha|2\alpha)] \\ &\times \exp\left(-\frac{1}{2} \mathrm{tr} \left[\left(Q_- - \frac{\rho_-}{\lambda} - i\beta p \lambda \right)^2 + \left(Q_+ + \frac{i\rho_+ S}{\lambda} - \frac{\beta p \lambda}{2} \right)^2 \right] \right) \times K(q_+,q_-), \end{aligned} \tag{63}$$

where

$$K(q_+,q_-) = \int D\overline{\chi} D\chi \exp(-(\overline{\chi},\chi)) \exp\left(\lambda \nu(e) \left[\frac{1}{2} A_0 + A_1 + A_2 \right] \right);$$

with

$$A_0 = i\pi \,\mathrm{tr}[(q_+ + iq_-)\sigma(q_+)],$$

$$A_1 = \int_{-\infty}^{+\infty} dt\,[\Delta(t)]^{1/2}\left[1 - \frac{1}{2}\sum_{p=1}^{2}\sum_{\gamma=1}^{2}\frac{q_+(p\gamma)+iq_-(\gamma)}{t+q_+(p\gamma)}\right],$$

$$A_2 = \int_{-\infty}^{+\infty} dt\,[\Delta(t)]^{1/2}[\det(\mathbb{1}_2 - R)^{1/2} - 1],$$

and

$$\Delta(t) = \frac{(t-iq_-(1))^2\,(t-iq_-(2))^2}{\prod_{p=1}^{2}\prod_{\gamma=1}^{2}(t+q_+(p\gamma))}.$$

The 2×2 matrix R is given by

$$R_{\alpha\alpha'} = \frac{1}{t-iq_-(\alpha)}\sum_{p=1}^{2}\sum_{\gamma=1}^{2}\frac{\overline{\chi}_\alpha(p\gamma)\chi_{\alpha'}(p\gamma)}{t+q_+(p\gamma)}.$$

We recall that $q_+(p\gamma)$ and $q_-(\gamma)$ are the eigenvalues of Q_+ and Q_-. Two eigenvalues of Q_+ have a positive imaginary part. The other two have a negative imaginary part.

A_1 can be expressed in terms of elliptic integrals. The same is true for A_2, once we note that

$$\det(\mathbb{1}_2 - R) = 1 - X \quad \text{with} \quad X = \mathrm{tr}\,R - \det R,$$

so that

$$\det(\mathbb{1}_2 - R)^{1/2} - 1 = \sum_{n=1}^{8} X^n c_n,$$

since the X are Grassmannian variables [c_n are constants]. One can then integrate over the Grassmannian variables, to compute K. We will not reproduce this computation here, since we have not analyzed the resulting expression for the correlation function. It can finally be noted that for higher order correlation functions, hyperelliptic integrals appear.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 45, NUMBER 3 MARCH 2004

Time dependent transformations in deformation quantization

Nuno Costa Dias[a] and João Nuno Prata[b]
Departamento de Matemática, Universidade Lusófona de Humanidades e Tecnologias, Av. Campo Grande, 376, 1749-024 Lisboa, Portugal

(Received 20 August 2003; accepted 10 November 2003)

We study the action of time dependent canonical and coordinate transformations in phase space quantum mechanics. We extend the covariant formulation of the theory by providing a formalism that is fully invariant under both standard and time dependent coordinate transformations. This result considerably enlarges the set of possible phase space representations of quantum mechanics and makes it possible to construct a causal representation for the distributional sector of Wigner quantum mechanics. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1641152]

I. INTRODUCTION

The phase space formulation of quantum mechanics was originally introduced by Weyl[1] and Wigner[2] and further developed by Moyal.[3] The theory lives on the classical phase space and its key algebraic structures (the star-product and the Moyal bracket) are both $\hbar$-deformations of the standard algebraic structures of classical mechanics.[4–11] Because of this its mathematical formalism is remarkably similar to that of classical statistical mechanics, a property that has been perceived by many as a conceptual and technical advantage when addressing a wide range of specific problems.[11–17] This relative success, together with the fact that the deformed algebraic structures play a key part in some current developments in M-theory,[18–21] led to an intense research on applications of the deformation quantization approach as well as on the further development of its mathematical structure.

The Wigner theory uses the symmetric ordering prescription (the Weyl order) to find a particular phase space representation of quantum mechanics. Different representations provide different points of view and may suggest new solutions for both technical and conceptual problems. They may even suggest new interpretations for the entire quantum theory, as in the case of the de Broglie Bohm formulation. For its importance, the topic of finding new, more general phase space representations of quantum mechanics has been studied in depth. Cohen[22] introduced a generalization of the Weyl map, providing in an unified fashion all phase space representations that correspond to different ordering prescriptions of operator quantum mechanics. The resulting theory of quasidistributions includes as particular cases the Wigner and the de Broglie Bohm[23,24] formulations. Vey[25] and several others,[8,11,26–30] developed the covariant generalization of Wigner's theory. The new formulation renders phase space quantum mechanics fully invariant under the action of phase space coordinate transformations. By doing so it provides a general formula for the $\hbar$-deformations of the Poisson bracket and makes it possible to apply deformation quantization methods to a larger set of dynamical systems including those displaying the structure of a curved phase space manifold.

The aim of this article is to extend the covariant formulation further by admitting the possibility of time dependent coordinate transformations. We will study the action of these transformations in phase space quantum mechanics and rewrite the covariant Wigner theory in a fully invariant form under their action. We derive the time dependent covariant form of the starproduct,

[a]Electronic mail: ncdias@mail.telepac.pt
[b]Electronic mail: joao.prata@ulusofona.pt

Moyal bracket, Moyal dynamical equation and stargenvalue equation as well as the covariant probabilistic functionals, providing all key ingredients of the time dependent covariant formulation of Wigner quantum mechanics. This result enlarges the set of possible phase space representations of quantum mechanics and provides a more general formula for the $\hbar$-deformations of the Poisson bracket, which may now include an explicit time dependence.

The new set of representations provides new possible formulations for a generic quantum mechanical problem. In some cases this may considerably simplify the technical resolution of the problem. In Sec. VI a simple example illustrates how a suitable time dependent representation leads to a far simpler description of the dynamics of the quasidistribution. More relevant is the fact that the new formalism makes it possible to construct a phase space representation of quantum mechanics where the quasidistribution displays a classical causal structure, i.e., the Wigner function evolves according to the Liouville equation. A formulation displaying this set of properties cannot be (easily) accomplished using the standard methods of quantum mechanics (not even within the standard covariant Wigner formalism) and it proves that the de Broglie Bohm theory is not the unique possible causal formulation of quantum mechanics. In the new causal representation the quantum dynamical behavior is completely removed from the distributional sector of the theory and is exclusively placed on the observables' sector. In particular, if the quasidistribution is positive defined at the initial time, it will remain so for all times. These properties reinforce the formal analogy between phase space quantum mechanics and classical statistical mechanics and make the causal formulation especially suitable to study the semiclassical limit of quantum mechanics.

This article is organized as follows: in Sec. II we review the main topics of the covariant formulation of the Wigner theory. In Sec. III we study the action of time dependent canonical transformations in standard operator quantum mechanics. Particular attention is devoted to the behavior of the density matrix. In Sec. IV we derive the time dependent covariant formulation of Wigner quantum mechanics. In Sec. V a particular set of coordinates is used to obtain the causal phase space representation. In Sec. VI a simple example illustrates some of the former results and in Sec. VII we present the conclusions.

II. COVARIANT WIGNER QUANTUM MECHANICS

Let us consider an N dimensional dynamical system. Its classical formulation lives on the phase space T^*M which, to make it simple, we assume to be flat. A global Darboux chart can then be naturally defined on T^*M, for which the symplectic structure reads $w=dq_i\wedge dp_i$, where $\{q_i,p_i,i=1,...,N\}$ is a set of canonical variables.

Upon quantization the set $\{\hat{q}_i\}$ yields a complete set of commuting observables. Let then $\hat{A}(\hat{\vec{q}},\hat{\vec{p}})$ be a generic operator acting on the physical Hilbert space $\mathcal{H}$. The Weyl map

$$W_{(q,p)}(\hat{A})=\hbar^N\int d^N\vec{y}e^{-i\vec{p}\cdot\vec{y}}\left\langle \vec{q}+\frac{\hbar}{2}\vec{y}\left|\hat{A}\right|\vec{q}-\frac{\hbar}{2}\vec{y}\right\rangle, \tag{1}$$

where we introduced the vector notation $\vec{y}\equiv(y_1,\ldots,y_N)$ and $|\vec{q}\pm\hbar/2\vec{y}\rangle$ are eigenstates of $\hat{\vec{q}}$, provides a Lie algebra isomorphism between the algebra $\hat{\mathcal{A}}(\mathcal{H})$ of linear operators acting on the Hilbert space $\mathcal{H}$ and the algebra of phase space functions $\mathcal{A}(T^*M)$ endowed with a $*$-product and Moyal bracket [let $A,B\in\mathcal{A}(T^*M)$]:

$$A*_{(q,p)}B=Ae^{(i\hbar/2)\overleftarrow{\partial}_k J^{kl}_{(q,p)}\overrightarrow{\partial}_l}B,\quad [A,B]_{M_{(q,p)}}=\frac{2}{\hbar}A\sin\left(\frac{\hbar}{2}\overleftarrow{\partial}_k J^{kl}_{(q,p)}\overrightarrow{\partial}_l\right)B, \tag{2}$$

where the derivatives $\overleftarrow{\partial}$ and $\overrightarrow{\partial}$ act on A and B, respectively, and $J^{kl}_{(q,p)}$ is the klth element of the symplectic matrix in the variables $(\vec{q},\vec{p})$:

$$J_{(q,p)}=\begin{pmatrix} 0_{N\times N} & -1_{N\times N} \\ 1_{N\times N} & 0_{N\times N} \end{pmatrix}. \tag{3}$$

We also introduced the compact notation: $O^k=p_k, k=1,\ldots,N$; $O^k=q_{k-N}, k=N+1,\ldots,2N$; $\partial/\partial O^k=\partial_k$ and sum over repeated indices is understood.

We now consider a second set of fundamental operators $(\hat{\vec{Q}},\hat{\vec{P}})$ unitarily related to $(\hat{\vec{q}},\hat{\vec{p}})$, i.e., $\hat{\vec{q}}=\hat{U}\hat{\vec{Q}}\hat{U}^{-1}$ and $\hat{\vec{p}}=\hat{U}\hat{\vec{P}}\hat{U}^{-1}$ where $\hat{U}$ is some unitary operator. The new operators satisfy the Heisenberg commutation relations, yield a new Weyl map $W_{(Q,P)}$ and induce a phase space transformation $(\vec{q},\vec{p})\rightarrow(\vec{Q},\vec{P})$ acting on a generic observable through the procedure (let $U=W_{(Q,P)}(\hat{U})$):

$$A(\vec{q},\vec{p})=W_{(q,p)}(\hat{A})\rightarrow A'(\vec{Q},\vec{P})=W_{(Q,P)}(\hat{A})=U*_{(Q,P)}A(\vec{Q},\vec{P})*_{(Q,P)}U^{-1}\quad . \tag{4}$$

The phase space implementation of the unitary transformation preserves the starproduct and the Moyal bracket but, as is well known, it does not act as a coordinate transformation (the exceptions are the linear transformations): let $\vec{q}(\vec{Q},\vec{P})=W_{(Q,P)}(\hat{q})$ and $\vec{p}(\vec{Q},\vec{P})=W_{(Q,P)}(\hat{p})$ and we find that in general $A'(\vec{Q},\vec{P})\neq A(\vec{q}(\vec{Q},\vec{P}),\vec{p}(\vec{Q},\vec{P}))$. We conclude that the standard Wigner formulation is non-covariant.

We now introduce the generalized Weyl map.[8] Let the transformation $(\vec{q},\vec{p})\rightarrow(\vec{Q},\vec{P})$ be a phase space diffeomorphism defined, in general terms, by $\vec{q}=\vec{q}(\vec{Q},\vec{P})$ and $\vec{p}=\vec{p}(\vec{Q},\vec{P})$. In particular, the transformation of the canonical variables $(\vec{q},\vec{p})$ might be given by the unitary transformation above, but this is not required. The generalized Weyl map is then defined by[8]

$$W^{(q,p)}_{(Q,P)}(\hat{A})=\hbar^N\int d^N\vec{x}\int d^N\vec{y}\, e^{-i\vec{p}(\vec{Q},\vec{P})\cdot\vec{y}}\delta(\vec{x}-\vec{q}(\vec{Q},\vec{P}))\left\langle \vec{x}+\frac{\hbar}{2}\vec{y}\right|\hat{A}\left|\vec{x}-\frac{\hbar}{2}\vec{y}\right\rangle, \tag{5}$$

where $|\vec{x}\pm\hbar/2\vec{y}\rangle$ are eigenstates of $\hat{\vec{q}}$. The new map implements the transformation $(\vec{q},\vec{p})\rightarrow(\vec{Q},\vec{P})$ as a coordinate transformation in quantum phase space; let $A'(\vec{Q},\vec{P})=W^{(q,p)}_{(Q,P)}(\hat{A})$ and $A(\vec{q},\vec{p})=W_{(q,p)}(\hat{A})$ and we have $A'(\vec{Q},\vec{P})=A(\vec{q}(\vec{Q},\vec{P}),\vec{p}(\vec{Q},\vec{P}))$, though in general it does not preserve the functional form of the star-product and Moyal bracket. Instead it yields the more general covariant star-product and Moyal bracket:[8,11]

$$\begin{aligned} A'(\vec{Q},\vec{P})*'_{(Q,P)}B'(\vec{Q},\vec{P})&=A'(\vec{Q},\vec{P})e^{(i\hbar/2)\vec{\nabla}'_iJ'^{ij}_{(Q,P)}\vec{\nabla}'_j}B'(\vec{Q},\vec{P}),\\ [A'(\vec{Q},\vec{P}),B'(\vec{Q},\vec{P})]_{M'_{(Q,P)}}&=\frac{2}{\hbar}A'(\vec{Q},\vec{P})\sin\left(\frac{\hbar}{2}\vec{\nabla}'_iJ'^{ij}_{(Q,P)}\vec{\nabla}'_j\right)B'(\vec{Q},\vec{P}), \end{aligned} \tag{6}$$

where the covariant derivative is given by (let $O'^i=P_i, i=1,\ldots,N$; $O'^i=Q_{i-N}, i=N+1,\ldots,2N$)

$$\nabla'_iA'=\partial'_iA',\quad \nabla'_i\nabla'_jA'=\partial'_i\partial'_jA'-\Gamma'^k_{ij}\partial'_kA',\quad \partial'_i=\partial/\partial O'^i,\quad i,j,k=1,\ldots,2N, \tag{7}$$

and

$$J'^{ij}_{(Q,P)}(\vec{Q},\vec{P})=\frac{\partial O'^i}{\partial O^k}\frac{\partial O'^j}{\partial O^l}J^{kl}_{(q,p)},\quad \Gamma'^i_{jk}(\vec{Q},\vec{P})=\frac{\partial O'^i}{\partial O^b}\frac{\partial^2O^b}{\partial O'^j\partial O'^k} \tag{8}$$

are the new symplectic structure and Poisson connection associated to the coordinates $(\vec{Q},\vec{P})$. Notice that in Eq. (8) we explicitly took into account the phase space flat structure.

When formulated in terms of these structures Wigner mechanics becomes invariant under the action of general coordinate transformations:

$$A'(\vec{Q},\vec{P})*'_{(Q,P)}B'(\vec{Q},\vec{P})=A(\vec{q}(\vec{Q},\vec{P}),\vec{p}(\vec{Q},\vec{P}))*_{(q,p)}B(\vec{q}(\vec{Q},\vec{P}),\vec{p}(\vec{Q},\vec{P})) \quad \forall_{A,B\in\mathcal{A}(T*M)}, \tag{9}$$

the covariant generalization of the Moyal and stargenvalue equations reading

$$\begin{gathered}\dot{f}'_W=[H',f'_W]_{M'_{(Q,P)}},\\ A'*'_{(Q,P)}g'_a=g'_a*'_{(Q,P)}A'=ag'_a,\end{gathered} \tag{10}$$

where $f'_W(\vec{Q},\vec{P};t)=(1/(2\pi\hbar)^N)\,W^{(q,p)}_{(Q,P)}(|\psi(t)\rangle\langle\psi(t)|)$ is the covariant Wigner function and g'_a is the left- and right-stargenfunction associated to the eigenvalue a.

These equations transform covariantly under arbitrary phase space diffeomorphisms yielding, in any coordinates, identical mathematical solutions and thus identical physical predictions:

$$P(A'(\vec{Q},\vec{P};t)=a)=\int d^N\vec{Q}\int d^N\vec{P}(\det J'^{ij}_{(Q,P)})^{-1/2}\delta_{*'_{(Q,P)}}(A'(\vec{Q},\vec{P})-a)f'_W(\vec{Q},\vec{P};t), \tag{11}$$

where $\delta_{*'_{(Q,P)}}(A'-a)$ is a particular solution of (10), displaying the following explicit form:[9,11]

$$\delta_{*'_{(Q,P)}}(A'(\vec{Q},\vec{P})-a)=\frac{1}{2\pi}\int dk\ \ e^{ik(A'(\vec{Q},\vec{P})-a)}_{*'_{(Q,P)}}, \tag{12}$$

the $*$-exponential being given by $e^{A'}_{*'_{(Q,P)}}=\Sigma_{n=0}^{\infty}(1/n!)\,\Omega_n$ where $\Omega_0=1$ and $\Omega_{n+1}=\Omega_n*'_{(Q,P)}A'$.

This concludes our review of the main topics of the covariant formulation of Wigner quantum mechanics. The reader should refer to Refs. 8 and 11 for more detailed presentations of the theory.

III. TIME DEPENDENT CANONICAL TRANSFORMATIONS

The aim of this section is to succinctly review some aspects of time dependent canonical transformations in standard operator quantum mechanics. Let $\hat{\vec{A}}=\hat{\vec{A}}(\hat{\vec{q}},\hat{\vec{p}},t)$ and $\hat{\vec{B}}=\hat{\vec{B}}(\hat{\vec{q}},\hat{\vec{p}},t)$ be a new set of fundamental operators $[\hat{A}_i,\hat{B}_j]=i\hbar\,\delta_{ij},\forall t$. Let $\hat{T}$ be the generator of the canonical transformation,

$$\frac{\partial}{\partial t}\hat{\vec{A}}=\frac{1}{i\hbar}[\hat{\vec{A}},\hat{T}] \quad \text{and} \quad \frac{\partial}{\partial t}\hat{\vec{B}}=\frac{1}{i\hbar}[\hat{\vec{B}},\hat{T}], \tag{13}$$

and to make it simple let us also impose the initial conditions $\hat{\vec{A}}(0)=\hat{\vec{q}}$ and $\hat{\vec{B}}(0)=\hat{\vec{p}}$. Then, the unitary transformation reads

$$\hat{\vec{A}}=\hat{V}(t)\hat{\vec{q}}\,\hat{V}^{-1}(t)=\hat{\vec{A}}(\hat{\vec{q}},\hat{\vec{p}},t) \quad \text{and} \quad \hat{\vec{B}}=\hat{V}(t)\hat{\vec{p}}\,\hat{V}^{-1}(t)=\hat{\vec{B}}(\hat{\vec{q}},\hat{\vec{p}},t), \tag{14}$$

where $\hat{V}(t)=\exp((i/\hbar)\hat{T}t)$. The former relations can be immediately inverted, $\hat{\vec{q}}=\hat{V}^{-1}(t)\hat{\vec{A}}\hat{V}(t)$ and $\hat{\vec{p}}=\hat{V}^{-1}(t)\hat{\vec{B}}\hat{V}(t)$, and lead straightforwardly to the dynamical equation for a generic observable:

$$\frac{d}{dt}\hat{F}(\hat{\vec{A}},\hat{\vec{B}},t)=\frac{1}{i\hbar}[\hat{F},\hat{H}+\hat{T}]+\frac{\partial}{\partial t}\hat{F}(\hat{\vec{A}},\hat{\vec{B}},t). \tag{15}$$

We now consider the density matrix of the system: $\hat{\rho}(t)=|\psi(t)\rangle\langle\psi(t)|$ where $|\psi(t)\rangle$ is the corresponding quantum state at the time t. In the $\hat{q}$ representation we have[9]

$$\hat{\rho}(t)=\int d^N\vec{q}\,'\,d^N\vec{q}\,''\langle\vec{q}\,''|\psi(t)\rangle\langle\psi(t)|\vec{q}\,'\rangle|\vec{q}\,''\rangle\langle\vec{q}\,'|$$
$$=\int d^N\vec{q}\,'\,d^N\vec{q}\,''\;\;\psi(\vec{q}\,'',t)\psi^*(\vec{q}\,',t)e^{-(i/\hbar)(\vec{q}\,''-\vec{q}\,')\cdot\hat{\vec{p}}}\hat{\Delta}(\hat{\vec{q}}-\vec{q}\,')$$
$$=\int d^N\vec{q}\,'\,d^N\vec{q}\,''\;\;\psi(\vec{q}\,'',0)\psi^*(\vec{q}\,',0)e^{-(i/\hbar)(\vec{q}\,''-\vec{q}\,')\cdot\hat{\vec{p}}(\hat{\vec{q}},\hat{\vec{p}},-t)}\hat{\Delta}(\hat{\vec{q}}(\hat{\vec{q}},\hat{\vec{p}},-t)-\vec{q}\,')=\hat{\rho}(\hat{\vec{q}},\hat{\vec{p}},t), \tag{16}$$

where $\hat{\Delta}(\hat{\vec{q}}-\vec{q}\,')=\hat{\Delta}(\hat{q}_1-q_1')\cdots\hat{\Delta}(\hat{q}_N-q_N')$ and $\hat{\Delta}(\hat{q}_i-q_i')=(1/2\pi)\int dk e^{ik(\hat{q}_i-q_i')}$. Moreover, $\hat{\vec{q}}(\hat{\vec{q}},\hat{\vec{p}},t)$ and $\hat{\vec{p}}(\hat{\vec{q}},\hat{\vec{p}},t)$ are the Heisenberg time evolutions of the fundamental operators $\hat{\vec{q}}$ and $\hat{\vec{p}}$. The action of the time dependent canonical transformation on the density matrix is now easily implemented, $\hat{\rho}(t)=\hat{\rho}(\hat{\vec{q}}(\hat{\vec{A}},\hat{\vec{B}},t),\hat{\vec{p}}(\hat{\vec{A}},\hat{\vec{B}},t),t)=\hat{V}^{-1}(t)\hat{\rho}(\hat{\vec{A}},\hat{\vec{B}},t)\hat{V}(t)=\hat{\rho}'(\hat{\vec{A}},\hat{\vec{B}},t)$, from where it follows that in the $\hat{A}$ representation

$$\frac{\partial}{\partial t}\hat{\rho}'(\hat{\vec{A}},\hat{\vec{B}},t)=\frac{\partial\hat{V}^{-1}(t)}{\partial t}\hat{\rho}\hat{V}(t)+\hat{V}^{-1}(t)\left(\frac{\partial}{\partial t}\hat{\rho}(\hat{\vec{A}},\hat{\vec{B}},t)\right)\hat{V}(t)+\hat{V}^{-1}(t)\hat{\rho}\frac{\partial\hat{V}(t)}{\partial t}$$
$$=\frac{1}{i\hbar}[\hat{T},\hat{\rho}']+\frac{1}{i\hbar}\hat{V}^{-1}[\hat{H},\hat{\rho}]\hat{V}=\frac{1}{i\hbar}[\hat{T}+\hat{H}',\hat{\rho}'], \tag{17}$$

where $\hat{H}'(\hat{\vec{A}},\hat{\vec{B}},t)=\hat{H}(\hat{\vec{q}}(\hat{\vec{A}},\hat{\vec{B}},t),\hat{\vec{p}}(\hat{\vec{A}},\hat{\vec{B}},t))=\hat{V}^{-1}(t)\hat{H}(\hat{\vec{A}},\hat{\vec{B}})\hat{V}(t)$.

IV. TIME DEPENDENT TRANSFORMATIONS IN PHASE SPACE QUANTUM MECHANICS

In this section we study the action of time dependent transformations in phase space quantum mechanics. We consider an arbitrary N dimensional quantum system with Hamiltonian $\hat{H}$ and described by the wave function $\psi(t)$. As we have seen, the original Weyl transform $W_{(q,p)}$ yields the standard Wigner formulation of the system. The time evolution of the Wigner function $f_W(\vec{q},\vec{p},t)=(1/(2\pi\hbar)^N)\,W_{(q,p)}(|\psi(t)\rangle\langle\psi(t)|)$ is dictated by the standard Moyal equation where the Moyal bracket and the starproduct are given by Eq. (2). We then consider two different phase space implementations of a time dependent operator transformation.

(1) *Unitary time dependent transformations and the map* $W_{(A,B)}$. At the quantum operator level we introduce the unitary transformation $(\hat{\vec{q}},\hat{\vec{p}})\rightarrow(\hat{\vec{A}},\hat{\vec{B}})$ defined by Eqs. (13) and (14). The new variables $(\hat{\vec{A}},\hat{\vec{B}})$ satisfy the Heisenberg commutation relations and thus a new Weyl map $W_{(A,B)}$ can be constructed. It displays the standard functional structure given by Eq. (1) and yields a starproduct $*_{(A,B)}$ and Moyal bracket $[,]_{M_{(A,B)}}$ also displaying the non-covariant functional form Eq. (2). The time evolution of the new Wigner function,

$$f_W'(\vec{A},\vec{B},t)=\frac{1}{(2\pi\hbar)^N}W_{(A,B)}(\hat{\rho}'(\hat{\vec{A}},\hat{\vec{B}},t))=V^{-1}(t)*_{(A,B)}f_W(\vec{A},\vec{B},t)*_{(A,B)}V(t), \tag{18}$$

where $V(t)=W_{(A,B)}(\hat{V})$, reads

$$\frac{\partial}{\partial t}f_W'(\vec{A},\vec{B},t)=[H'+T,f_W']_{M_{(A,B)}}, \tag{19}$$

and is just the (A,B)-Weyl transform of Eq. (17). Notice that just like in the time independent case the unitary transformation $(\vec{q},\vec{p})\rightarrow(\vec{A},\vec{B})$ does not, in general, act as a coordinate transformation: $f_W'(\vec{A},\vec{B},t)\neq f_W(\vec{q}(\vec{A},\vec{B},t),\vec{p}(\vec{A},\vec{B},t),t)$.

(2) *Coordinate transformations and the map* $W^{(q,p)}_{(A,B)}$. We follow the steps of the time independent case and introduce a time dependent phase space diffeomorphism $(\vec{q},\vec{p})\to(\vec{A},\vec{B})$ defined in generic terms by $\vec{q}=\vec{q}(\vec{A},\vec{B},t)$; $\vec{p}=\vec{p}(\vec{A},\vec{B},t)$. This coordinate transformation is not required to be a symplectomorphism (i.e., to preserve the Poisson bracket) nor to preserve the Moyal bracket between the fundamental variables (i.e., to satisfy $[q_i(\vec{A},\vec{B},t),p_j(\vec{A},\vec{B},t)]_{M_{(A,B)}}=\delta_{ij}$ and $[q_i(\vec{A},\vec{B},t),q_j(\vec{A},\vec{B},t)]_{M_{(A,B)}}=[p_i(\vec{A},\vec{B},t),p_j(\vec{A},\vec{B},t)]_{M_{(A,B)}}=0$ for all $i,j=1,\ldots,N$).

We then define the time dependent generalized Weyl transform in the variables $(\vec{A},\vec{B})$:

$$W^{(q,p)}_{(A,B)}:\hat{\mathcal{A}}(\mathcal{H})\to\mathcal{A}(T^*M);\quad \hat{F}\to F'(\vec{A},\vec{B},t)=W^{(q,p)}_{(A,B)}(\hat{F})=W_{(q,p)}(\hat{F})\big|_{\vec{q}=\vec{q}(\vec{A},\vec{B},t)\wedge\vec{p}=\vec{p}(\vec{A},\vec{B},t)}. \tag{20}$$

The explicit form of $W^{(q,p)}_{(A,B)}$ is given by the trivial time dependent generalization of Eq. (5):

$$W^{(q,p)}_{(A,B)}(\hat{F})=\hbar^N\int d^N\vec{x}\int d^N\vec{y}\;\; e^{-i\vec{p}(\vec{A},\vec{B},t)\cdot\vec{y}}\,\delta(\vec{x}-\vec{q}(\vec{A},\vec{B},t))\left\langle \vec{x}+\frac{\hbar}{2}\vec{y}\left|\hat{F}\right|\vec{x}-\frac{\hbar}{2}\vec{y}\right\rangle, \tag{21}$$

from which follows the covariant *time dependent* $*$-product and Moyal bracket:

$$W^{(q,p)}_{(A,B)}(\hat{F}\hat{G})=F'(\vec{A},\vec{B},t)*'_{(A,B)}G'(\vec{A},\vec{B},t)=F(\vec{q}(\vec{A},\vec{B},t),\vec{p}(\vec{A},\vec{B},t))*_{(q,p)}G(\vec{q}(\vec{A},\vec{B},t),\vec{p}(\vec{A},\vec{B},t)), \tag{22}$$

and $[F',G']_{M'_{(A,B)}}=(1/i\hbar)\,(F'*'_{(A,B)}G'-G'*'_{(A,B)}F')$ where $F'(\vec{A},\vec{B},t)=W^{(q,p)}_{(A,B)}(\hat{F})$, $F(\vec{q},\vec{p},t)=W_{(q,p)}(\hat{F})$ and likewise for G and G'. The two algebraic structures display the functional form given by Eqs. (6)–(8) with the obvious inclusion of an explicit time dependence.

The dynamical structure of the theory displays more significant corrections. Let $f'_W(\vec{A},\vec{B},t)=(1/(2\pi\hbar)^N)\,W^{(q,p)}_{(A,B)}(|\psi(t)\rangle\langle\psi(t)|)$ be the covariant Wigner function. It satisfies $f'_W(\vec{A},\vec{B},t)=f_W(\vec{q}(\vec{A},\vec{B},t),\vec{p}(\vec{A},\vec{B},t),t)$ and thus

$$\begin{aligned}
\frac{\partial}{\partial t}f'_W(\vec{A},\vec{B},t)&=\left(\frac{\partial}{\partial t_1}+\frac{\partial}{\partial t_2}\right)f_W(\vec{q}(\vec{A},\vec{B},t_1),\vec{p}(\vec{A},\vec{B},t_1),t_2)\Big|_{t_1=t_2=t}\\
&=[H(\vec{q}(\vec{A},\vec{B},t),\vec{p}(\vec{A},\vec{B},t),t),f_W(\vec{q}(\vec{A},\vec{B},t),\vec{p}(\vec{A},\vec{B},t),t)]_{M_{(q,p)}}+\frac{\partial f_W}{\partial\vec{q}}\cdot\frac{\partial\vec{q}}{\partial t_1}+\frac{\partial f_W}{\partial\vec{p}}\\
&\quad\cdot\frac{\partial\vec{p}}{\partial t_1}\Big|_{t_1=t}=[H'(\vec{A},\vec{B},t),f'_W(\vec{A},\vec{B},t)]_{M'_{(A,B)}}+\left(\frac{\partial f'_W}{\partial A_i}\frac{\partial A_i}{\partial q_j}+\frac{\partial f'_W}{\partial B_i}\frac{\partial B_i}{\partial q_j}\right)\frac{\partial q_j}{\partial t}\\
&\quad+\left(\frac{\partial f'_W}{\partial A_i}\frac{\partial A_i}{\partial p_j}+\frac{\partial f'_W}{\partial B_i}\frac{\partial B_i}{\partial p_j}\right)\frac{\partial p_j}{\partial t}=[H'(\vec{A},\vec{B},t),f'_W(\vec{A},\vec{B},t)]_{M'_{(A,B)}}+\frac{\partial f'_W}{\partial A_i}\left(\frac{\partial A_i}{\partial q_j}\frac{\partial q_j}{\partial t}\right.\\
&\quad\left.+\frac{\partial A_i}{\partial p_j}\frac{\partial p_j}{\partial t}\right)+\frac{\partial f'_W}{\partial B_i}\left(\frac{\partial B_i}{\partial q_j}\frac{\partial q_j}{\partial t}+\frac{\partial B_i}{\partial p_j}\frac{\partial p_j}{\partial t}\right)=[H'(\vec{A},\vec{B},t),f'_W(\vec{A},\vec{B},t)]_{M'_{(A,B)}}-\frac{\partial f'_W}{\partial\vec{A}}\\
&\quad\cdot\frac{\partial\vec{A}}{\partial t}-\frac{\partial f'_W}{\partial\vec{B}}\cdot\frac{\partial\vec{B}}{\partial t},
\end{aligned} \tag{23}$$

where in the last step we used the fact that $\vec{A}=\vec{A}(\vec{q}(\vec{A},\vec{B},t),\vec{p}(\vec{A},\vec{B},t),t)$ and likewise for $\vec{B}$. Further, contraction over repeated indices is understood, i.e.,

$$\frac{\partial f_W}{\partial q_i}\frac{\partial q_i}{\partial t_1}=\frac{\partial f_W}{\partial \vec{q}}\cdot\frac{\partial \vec{q}}{\partial t_1}=\sum_{i=1}^{N}\frac{\partial f_W}{\partial q_i}\frac{\partial q_i}{\partial t_1}.$$

Equation (23) constitutes a generalization of the Moyal covariant equation (10) and renders the dynamics of the Wigner function fully invariant under the action of general time dependent phase space diffeomorphisms.

Let us then consider several particular cases in more detail:

(a) If the transformation $(\vec{q},\vec{p})\rightarrow(\vec{A},\vec{B})$ is time independent, then Eq. (23) reduces to the standard covariant Moyal equation (10).

(b) If, on the other hand, it is unitary, i.e., if $\vec{A}(\vec{q},\vec{p},t)=V(t)*_{(q,p)}\vec{q}*_{(q,p)}V^{-1}(t)$ and $\vec{B}(\vec{q},\vec{p},t)=V(t)*_{(q,p)}\vec{p}*_{(q,p)}V^{-1}(t)$ satisfying $\partial\vec{A}/\partial t=[\vec{A},T]_{M_{(q,p)}}$ and $\partial\vec{B}/\partial t=[\vec{B},T]_{M_{(q,p)}}$ with initial conditions $\vec{A}(\vec{q},\vec{p},0)=\vec{q}$ and $\vec{B}(\vec{q},\vec{p},0)=\vec{p}$, then in Eq. (23) we have

$$\begin{aligned}\frac{\partial\vec{A}}{\partial t}=\frac{\partial}{\partial t}\vec{A}(\vec{q},\vec{p},t)\Big|_{\vec{q}=\vec{q}(\vec{A},\vec{B},t)\wedge\vec{p}=\vec{p}(\vec{A},\vec{B},t)}&=[\vec{A}(\vec{q}(\vec{A},\vec{B},t),\vec{p}(\vec{A},\vec{B},t),t),T(\vec{q}(\vec{A},\vec{B},t),\vec{p}(\vec{A},\vec{B},t),t))]_{M_{(q,p)}}\\&=[\vec{A},T'(\vec{A},\vec{B},t)]_{M'_{(A,B)}},\end{aligned}\tag{24}$$

where $T'(\vec{A},\vec{B},t)=W^{(q,p)}_{(A,B)}(\hat{T})$. An equivalent result is valid for $\partial\vec{B}/\partial t$. Substituting these results in Eq. (23) we get

$$\frac{\partial}{\partial t}f'_W(\vec{A},\vec{B},t)=[H'(\vec{A},\vec{B},t),f'_W(\vec{A},\vec{B},t)]_{M'_{(A,B)}}+\frac{\partial f'_W}{\partial\vec{A}}\cdot[T',\vec{A}]_{M'_{(A,B)}}+\frac{\partial f'_W}{\partial\vec{B}}\cdot[T',\vec{B}]_{M'_{(A,B)}}.\tag{25}$$

(c) Finally, we consider the case where the transformation $(\vec{q},\vec{p})\rightarrow(\vec{A},\vec{B})$ is a symplectomorphism. Let T be the generator. Then $\vec{A}(\vec{q},\vec{p},t)$ satisfies $\partial\vec{A}/\partial t=\{\vec{A},T\}_{(q,p)}=\{\vec{A},T\}_{(A,B)}$ and likewise for $\vec{B}$. Hence, Eq. (23) reduces to

$$\begin{aligned}\frac{\partial}{\partial t}f'_W(\vec{A},\vec{B},t)&=[H'(\vec{A},\vec{B},t),f'_W(\vec{A},\vec{B},t)]_{M'_{(A,B)}}-\frac{\partial f'_W}{\partial\vec{A}}\cdot\{\vec{A},T\}_{(A,B)}-\frac{\partial f'_W}{\partial\vec{B}}\cdot\{\vec{B},T\}_{(A,B)}\\&=[H'(\vec{A},\vec{B},t),f'_W(\vec{A},\vec{B},t)]_{M'_{(A,B)}}+\{T,f'_W\}_{(A,B)}.\end{aligned}\tag{26}$$

To finish this section let us study the $^{(q,p)}_{(A,B)}$-representation of a general stargenfunction. Let $\hat{F}$ be a generic operator and $F'(\vec{A},\vec{B},t)=W^{(q,p)}_{(A,B)}(\hat{F})$. The $*$-genvalue equation in the $^{(q,p)}_{(A,B)}$-representation is then written

$$F'(\vec{A},\vec{B},t)*'_{(A,B)}g'_a(\vec{A},\vec{B},t)=g'_a(\vec{A},\vec{B},t)*'_{(A,B)}F'(\vec{A},\vec{B},t)=ag'_a(\vec{A},\vec{B},t)\tag{27}$$

and displays the solution

$$\begin{aligned}g'_a(\vec{A},\vec{B},t)=\delta_{*'_{(A,B)}}[F'(\vec{A},\vec{B},t)-a]&=\frac{1}{2\pi}\int dk e^{ik[F'(\vec{A},\vec{B},t)-a]}_{*'_{(A,B)}}\\&=\frac{1}{2\pi}\int dk e^{ik[F(\vec{q}(\vec{A},\vec{B},t),\vec{p}(\vec{A},\vec{B},t),t)-a]}_{*_{(q,p)}},\end{aligned}\tag{28}$$

where $F(\vec{q},\vec{p},t)=W_{(q,p)}(\hat{F})$. Further, if $g_a(\vec{q},\vec{p},t)$ is such that $F*_{(q,p)}g_a=g_a*_{(q,p)}F=ag_a$ then $g'_a(\vec{A},\vec{B},t)=g_a(\vec{q}(\vec{A},\vec{B},t),\vec{p}(\vec{A},\vec{B},t),t)$, a result that follows immediately from Eqs. (22) and (28). Therefore the stargenvalue equation transforms covariantly under the action of general time dependent coordinate transformations.

As an illustrative example let us consider the one-dimensional simple case $\hat{F}=\hat{q}\Rightarrow W^{(q,p)}_{(A,B)}(\hat{q})=q(A,B,t)$. The solution of the $*$-genvalue equation (27) is then

$$g'_a(A,B,t)=\frac{1}{2\pi}\int dk e^{ik[q(A,B,t)-a]}_{*'_{(A,B)}}=\frac{1}{2\pi}\int dk e^{ik[q(A,B,t)-a]}_{*_{(q,p)}}=\frac{1}{2\pi}\int dk e^{ik[q(A,B,t)-a]}$$
$$=\delta[q(A,B,t)-a], \tag{29}$$

and displays the time evolution

$$\frac{\partial}{\partial t}g'_a(A,B,t)=\frac{\partial\delta}{\partial q}[q(A,B,t)-a]\frac{\partial q}{\partial t}(A,B,t). \tag{30}$$

Furthermore, if the transformation $(q,p)\rightarrow(A,B)$ is symplectic with generator T, then $\partial q/\partial t=\{q,-T\}_{(A,B)}$ and

$$\frac{\partial}{\partial t}g'_a(A,B,t)=-\{g'_a,T\}_{(A,B)}. \tag{31}$$

V. THE CAUSAL REPRESENTATION

As an application of the formalism let us consider a finite dimensional dynamical system described by a generic Hamiltonian $\hat{H}$ and use the generalized time dependent Weyl map to derive in a systematic way (1) the Schrödinger and (2) the Heisenberg phase space pictures and (3) a new phase space representation where the Wigner function displays a fully classical time evolution.

To begin with, we introduce the time dependent unitary transformation generated by $\hat{T}=-\hat{H}$. A new set of fundamental operators is given by $\hat{\vec{A}}=\hat{\vec{A}}(\hat{\vec{q}},\hat{\vec{p}},t)$ and $\hat{\vec{B}}=\hat{\vec{B}}(\hat{\vec{q}},\hat{\vec{p}},t)$, solutions of Eq. (13) and satisfying the initial conditions $\hat{\vec{A}}(0)=\hat{\vec{q}}$ and $\hat{\vec{B}}(0)=\hat{\vec{p}}$. Given the relation between $\hat{H}$ and $\hat{T}$ they also satisfy

$$\hat{\vec{A}}=\hat{\vec{A}}(\hat{\vec{q}},\hat{\vec{p}},t)=\hat{\vec{q}}(\hat{\vec{q}},\hat{\vec{p}},-t)\quad\text{and}\quad\hat{\vec{B}}=\hat{\vec{B}}(\hat{\vec{q}},\hat{\vec{p}},t)=\hat{\vec{p}}(\hat{\vec{q}},\hat{\vec{p}},-t), \tag{32}$$

where $\hat{\vec{q}}(\hat{\vec{q}},\hat{\vec{p}},t)$ and $\hat{\vec{p}}(\hat{\vec{q}},\hat{\vec{p}},t)$ are the Heisenberg time evolution of the fundamental operators $\hat{\vec{q}}$ and $\hat{\vec{p}}$. From (32) we define a new set of phase space coordinates $\vec{A}=\vec{A}_M(\vec{q},\vec{p},t)=W_{(q,p)}(\hat{A})$ and $\vec{B}=\vec{B}_M(\vec{q},\vec{p},t)=W_{(q,p)}(\hat{B})$ satisfying the Moyal equations,

$$\frac{\partial\vec{A}_M}{\partial t}=[\vec{A}_M,T]_{M_{(q,p)}},\quad\frac{\partial\vec{B}_M}{\partial t}=[\vec{B}_M,T]_{M_{(q,p)}},\quad T=W_{(q,p)}(\hat{T}), \tag{33}$$

and the initial conditions $\vec{A}_M(\vec{q},\vec{p},0)=\vec{q}$ and $\vec{B}_M(\vec{q},\vec{p},0)=\vec{p}$. The subscript M indicates that the *functions* A_M and B_M obey the Moyal equations. Intuitively, they can be seen as the quantum phase space histories of the system.

A second set of (purely classical) phase space coordinates will also be required: $\vec{Q},\vec{P}$ are given by $\vec{Q}=\vec{Q}(\vec{A},\vec{B},t)$ and $\vec{P}=\vec{P}(\vec{A},\vec{B},t)$ and satisfy the classical Hamiltonian equations,

$$\frac{\partial\vec{Q}}{\partial t}=\{\vec{Q},-T(\vec{A},\vec{B})\}_{(A,B)},\quad\frac{\partial\vec{P}}{\partial t}=\{\vec{P},-T(\vec{A},\vec{B})\}_{(A,B)},\quad T(\vec{A},\vec{B})=W_{(A,B)}(\hat{T}), \tag{34}$$

and the initial conditions $\vec{Q}(\vec{A},\vec{B},0)=\vec{A}$, $\vec{P}(\vec{A},\vec{B},0)=\vec{B}$. Notice that $T(\vec{A},\vec{B})$ displays the same functional form as $T(\vec{q},\vec{p})=W_{(q,p)}(\hat{T})$. Solving the algebraic equations $\vec{Q}=\vec{Q}(\vec{A},\vec{B},t)$, $\vec{P}=\vec{P}(\vec{A},\vec{B},t)$ with respect to $\vec{A},\vec{B}$ we get $\vec{A}=\vec{A}_C(\vec{Q},\vec{P},t)$ and $\vec{B}=\vec{B}_C(\vec{Q},\vec{P},t)$ where the subscript C indicates that $\vec{A}_C$ and $\vec{B}_C$ are the solutions of the classical Hamilton's equations,

$$\frac{\partial\vec{A}_C}{\partial t}=\{\vec{A}_C,T(\vec{Q},\vec{P})\}_{(Q,P)},\quad \frac{\partial\vec{B}_C}{\partial t}=\{\vec{B}_C,T(\vec{Q},\vec{P})\}_{(Q,P)}, \tag{35}$$

where $T(\vec{Q},\vec{P})=T(\vec{A}_C(\vec{Q},\vec{P},t),\vec{B}_C(\vec{Q},\vec{P},t))$ displays the same functional form as $T(\vec{A},\vec{B})$ (notice that T is the generator of the canonical transformation). Also notice that in general $\vec{q}(\vec{A},\vec{B},t)\neq\vec{Q}(\vec{A},\vec{B},t)$ and $\vec{p}(\vec{A},\vec{B},t)\neq\vec{P}(\vec{A},\vec{B},t)$ (the exceptions happen for T quadratic in the phase space variables). While the variables $(\vec{q},\vec{p})$ describe the *quantum* phase space time evolution, the variables $(\vec{Q},\vec{P})$ describe the *classical* phase space trajectories. The transformation $(\vec{A},\vec{B})\rightarrow(\vec{Q},\vec{P})$ is a phase space symplectomorphism exclusively defined at the classical level, i.e., it is not [and unlike $(\vec{q},\vec{p})\rightarrow(\vec{A},\vec{B})$ it could not be] inherited from a quantum operator transformation.

Finally, from Eqs. (16) and (32) the density matrix $\hat{\rho}(t)=|\psi(t)\rangle\langle\psi(t)|$ admits the expansions

$$\hat{\rho}(t)=\int d^N\vec{q}\,'d^N\vec{q}\,''\psi(\vec{q}\,'',0)\psi^*(\vec{q}\,',0)e^{-(i/\hbar)(\vec{q}\,''-\vec{q}\,')\cdot\hat{\vec{p}}(\hat{\vec{q}},\hat{\vec{p}},-t)}\hat{\Delta}[\hat{\vec{q}}(\hat{\vec{q}},\hat{\vec{p}},-t)-\vec{q}\,']=\hat{\rho}(\hat{\vec{q}},\hat{\vec{p}},t),$$
$$\hat{\rho}(t)=\int d^N\vec{q}\,'d^N\vec{q}\,''\psi(\vec{q}\,'',0)\psi^*(\vec{q}\,',0)e^{-(i/\hbar)(\vec{q}\,''-\vec{q}\,')\cdot\hat{\vec{B}}}\hat{\Delta}(\hat{\vec{A}}-\vec{q}\,')=\hat{\rho}(\hat{\vec{A}},\hat{\vec{B}},0). \tag{36}$$

With these preliminaries settled down we address the derivation of the three phase space pictures:

(1) *Schrödinger picture and the map* $W_{(q,p)}$. From the first expansion for the density matrix (36) we immediately get

$$\begin{aligned}f_W(\vec{q},\vec{p},t)&=\frac{1}{(2\pi\hbar)^N}W_{(q,p)}[\hat{\rho}(t)]\\&=\frac{1}{(2\pi\hbar)^N}\int d^N\vec{q}\,'d^N\vec{q}\,''\psi(\vec{q}\,'',0)\psi^*(\vec{q}\,',0)e_{*(q,p)}^{(-i/\hbar)(\vec{q}\,''-\vec{q}\,')\cdot\vec{p}(\vec{q},\vec{p},-t)}*_{(q,p)}\\&\quad\times\delta_{*(q,p)}[\vec{q}(\vec{q},\vec{p},-t)-\vec{q}\,']\end{aligned} \tag{37}$$

and the time evolution of the Wigner function obeys the standard Moyal equation: $(\partial/\partial t)f_W=[H,f_W]_{M_{(q,p)}}$. We also have $W_{(q,p)}(|\vec{q}_0\rangle\langle\vec{q}_0|)=\delta_*(\vec{q}-\vec{q}_0)=\delta(\vec{q}-\vec{q}_0)$ and so $(\partial/\partial t)\,\delta(\vec{q}-\vec{q}_0)=0$ and likewise for $\vec{p}$, i.e., the dynamics is cast in the Schrödinger picture.

(2) *Heisenberg picture and the map* $W_{(A,B)}$. From the second expansion in (36) we get

$$\begin{aligned}\frac{1}{(2\pi\hbar)^N}W_{(A,B)}[\hat{\rho}(t)]&=\frac{1}{(2\pi\hbar)^N}W_{(A,B)}[\hat{\rho}(\vec{A},\vec{B},0)]\\&=\frac{1}{(2\pi\hbar)^N}\int d^N\vec{q}\,'d^N\vec{q}\,''\psi(\vec{q}\,'',0)\psi^*(\vec{q}\,',0)e_{*(A,B)}^{-(i/\hbar)(\vec{q}\,''-\vec{q}\,')\cdot\vec{B}}*_{(A,B)}\\&\quad\times\delta^N{}_{*(A,B)}(\vec{A}-\vec{q}\,').\end{aligned} \tag{38}$$

Let us check explicit that the previous formula yields the standard (in this case time independent) expression of the Wigner function. The same derivation would also apply to Eq. (37). We start by considering the term evolving starproducts in more detail:

$$
\begin{aligned}
e^{-i/\hbar(\vec{q}\,''-\vec{q}\,')\cdot\vec{B}}_{*(A,B)} *_{(A,B)} \delta^N *_{(A,B)} (\vec{A}-\vec{q}\,') &= e^{-(i/\hbar)(\vec{q}\,''-\vec{q}\,')\cdot\vec{B}} *_{(A,B)} \delta^N(\vec{A}-\vec{q}\,') \\
&= \frac{1}{(2\pi)^N} \sum_{n=0}^{+\infty} \frac{1}{n!} \left(-\frac{i\hbar}{2} \right)^n e^{-(i/\hbar)(\vec{q}\,''-\vec{q}\,')\cdot\vec{B}} \left[-\frac{i}{\hbar}(\vec{q}\,'' \right. \\
&\quad \left. -\vec{q}\,')\cdot\frac{\partial}{\partial\vec{A}} \right]^n \int d^N\vec{k}\, e^{i\vec{k}\cdot(\vec{A}-\vec{q}\,')} \\
&= \frac{1}{(2\pi)^N} e^{-(i/\hbar)(\vec{q}\,''-\vec{q}\,')\cdot\vec{B}} \int d^N\vec{k} \sum_{n=0}^{+\infty} \frac{1}{n!} \left(-\frac{i}{2}\vec{k}\cdot(\vec{q}\,'' \right. \\
&\quad \left. -\vec{q}\,') \right)^n e^{i\vec{k}\cdot(\vec{A}-\vec{q}\,')} \\
&= e^{-(i/\hbar)(\vec{q}\,''-\vec{q}\,')\cdot\vec{B}} \frac{1}{(2\pi)^N} \int d^N\vec{k}\, e^{i\vec{k}\cdot(\vec{A}-\vec{q}\,'+\vec{q}\,'/2-\vec{q}\,''/2)} \\
&= e^{-i/\hbar(\vec{q}\,''-\vec{q}\,')\cdot\vec{B}} \delta^N\left(\vec{A}-\frac{\vec{q}\,'}{2}-\frac{\vec{q}\,''}{2} \right). \qquad (39)
\end{aligned}
$$

Substituting this expression in (38) we get

$$
\begin{aligned}
\frac{1}{(2\pi\hbar)^N} W_{(A,B)}[\hat{\rho}(t)] &= \frac{1}{(2\pi\hbar)^N} \int d^N\vec{q}\,' d^N\vec{q}\,'' \psi(\vec{q}\,'',0)\psi^*(\vec{q}\,',0) 2^N \delta^N(2\vec{A}-\vec{q}\,' \\
&\quad -\vec{q}\,'') e^{-(2i/\hbar)(\vec{A}-\vec{q}\,')\cdot\vec{B}} = \frac{1}{(\pi\hbar)^N} \int d^N\vec{q}\,' \psi(2\vec{A} \\
&\quad -\vec{q}\,',0)\psi^*(\vec{q}\,',0) e^{-(2i/\hbar)(\vec{A}-\vec{q}\,')\cdot\vec{B}} = \frac{1}{(\pi\hbar)^N} \int d^N\vec{y}\, \psi(\vec{A}+\vec{y},0)\psi^*(\vec{A} \\
&\quad -\vec{y},0) e^{-(2i/\hbar)\vec{y}\cdot\vec{B}} = f_W(\vec{A},\vec{B},0), \qquad (40)
\end{aligned}
$$

where in the last step we made $\vec{y}=\vec{A}-\vec{q}\,'$. We indeed recovered the standard definition of the Wigner function. Moreover we see that $(\partial/\partial t) f_W = 0$, as it should and in perfect agreement with Eq. (19) taking into account that $T=-H$. On the other hand, we also have

$$
g_{\vec{q}_0}(\vec{A},\vec{B},t) = W_{(A,B)}(|\vec{q}_0\rangle\langle\vec{q}_0|) = \delta^N_{*(A,B)}[\vec{q}(\vec{A},\vec{B},t)-\vec{q}_0] = \frac{1}{(2\pi)^N} \int d^N\vec{k}\, e^{i\vec{k}\cdot(\vec{q}(\vec{A},\vec{B},t)-\vec{q}_0)}_{*(A,B)}, \qquad (41)
$$

where $\vec{q}=\vec{q}(\vec{A},\vec{B},t)$ is the solution with respect to $\vec{q}$ of the algebraic equations $\vec{A}=\vec{A}_M(\vec{q},\vec{p},t)$, $\vec{B}=\vec{B}_M(\vec{q},\vec{p},t)$ defined in Eq. (33). It also follows from Eq. (33) that $\vec{q}(\vec{A},\vec{B},t)$ satisfies $\partial\vec{q}/\partial t = [\vec{q},-T]_{M_{(A,B)}}$. Therefore,

$$
\frac{\partial}{\partial t} g_{\vec{q}_0}(\vec{A},\vec{B},t) = [g_{\vec{q}_0}(\vec{A},\vec{B},t),H]_{M_{(A,B)}}, \qquad (42)
$$

and we obtained the phase space Heisenberg picture.

(3) *Causal picture and the map* $W^{(A,B)}_{(Q,P)}$. We finally consider the action of the map $W^{(A,B)}_{(Q,P)}$ on the second expansion for the density matrix (36). From Eq. (40) it follows that (notice that $W^{(A,B)}_{(Q,P)} = W_{(A,B)}$)

$$
\begin{aligned}
f'_W(\vec{Q},\vec{P},t) &= \frac{1}{(2\pi\hbar)^N} W^{(A,B)}_{(Q,P)}[\hat{\rho}(t)] \\
&= \frac{1}{(2\pi\hbar)^N} \int d^N\vec{q}\,' d^N\vec{q}\,'' \psi(\vec{q}\,'',0)\psi^*(\vec{q}\,',0) e^{-(i/\hbar)(\vec{q}\,''-\vec{q}\,')\cdot \vec{B}_C(\vec{Q},\vec{P},t)}_{*'(Q,P)} *'_{(Q,P)} \delta^N_{*'(Q,P)} \\
&\quad [\vec{A}_C(\vec{Q},\vec{P},t)-\vec{q}\,'] \\
&= \frac{1}{(2\pi\hbar)^N} \int d^N\vec{q}\,' d^N\vec{q}\,'' \psi(\vec{q}\,'',0)\psi^*(\vec{q}\,',0) e^{-(i/\hbar)(\vec{q}\,''-\vec{q}\,')\cdot \vec{B}_C(\vec{Q},\vec{P},t)}_{*(A,B)} *_{(A,B)} \delta^N_{*(A,B)} \\
&\quad [\vec{A}_C(\vec{Q},\vec{P},t)-\vec{q}\,'] \\
&= f_W(\vec{A}_C(\vec{Q},\vec{P},t),\vec{B}_C(\vec{Q},\vec{P},t),0) = f_W(\vec{Q}(\vec{Q},\vec{P},-t),\vec{P}(\vec{Q},\vec{P},-t),0),
\end{aligned} \tag{43}
$$

where $\vec{Q}(\vec{Q},\vec{P},t)=\vec{A}_C(\vec{Q},\vec{P},-t)$ and $\vec{P}(\vec{Q},\vec{P},t)=\vec{B}_C(\vec{Q},\vec{P},-t)$ are the classical time evolution of the canonical variables $(\vec{Q},\vec{P})$ [cf. (35)]

$$
\dot{\vec{Q}}=\{\vec{Q},-T(\vec{Q},\vec{P})\}_{(Q,P)} \quad \text{and} \quad \dot{\vec{P}}=\{\vec{P},-T(\vec{Q},\vec{P})\}_{(Q,P)} \tag{44}
$$

associated with the Hamiltonian $H(\vec{Q},\vec{P})=-T(\vec{Q},\vec{P})=W_{(A,B)}(\hat{H})|_{\vec{A}=\vec{Q}\wedge\vec{B}=\vec{P}}$. Hence, the time evolution of the Wigner function is given by

$$
\frac{\partial}{\partial t} f'_W(\vec{Q},\vec{P},t)=\{f'_W,T\}_{(Q,P)}=\{H,f'_W\}_{(Q,P)}. \tag{45}
$$

On the other hand, for the $*$-genfunctions $W^{(A,B)}_{(Q,P)}(|\vec{q}_0\rangle\langle\vec{q}_0|)$ we have from Eq. (41)

$$
\begin{aligned}
g'_{\vec{q}_0}(\vec{Q},\vec{P},t) &= \delta^N_{*'_{(Q,P)}}(\vec{q}-\vec{q}_0) = \delta^N_{*_{(A,B)}}(\vec{q}(\vec{A},\vec{B},t)-\vec{q}_0)|_{\vec{A}=\vec{A}_C(\vec{Q},\vec{P},t)\wedge\vec{B}=\vec{B}_C(\vec{Q},\vec{P},t)} \\
&= g_{\vec{q}_0}(\vec{A}_C(\vec{Q},\vec{P},t),\vec{B}_C(\vec{Q},\vec{P},t),t),
\end{aligned} \tag{46}
$$

and so [cf. (35) and (42)]

$$
\begin{aligned}
\frac{\partial}{\partial t} g'_{\vec{q}_0}(\vec{Q},\vec{P},t) &= \left\{ \frac{\partial}{\partial t_1}+\frac{\partial}{\partial t_2} \right\} g_{\vec{q}_0}(\vec{A}_C(\vec{Q},\vec{P},t_2),\vec{B}_C(\vec{Q},\vec{P},t_2),t_1)\Big|_{t_1=t_2=t} \\
&= [g'_{\vec{q}_0},H]_{M'_{(Q,P)}} - \{g'_{\vec{q}_0},H\}_{(Q,P)}.
\end{aligned} \tag{47}
$$

In this representation both the Wigner function and the stargenfunctions evolve in time, the Wigner function displaying a fully classical evolution. In particular, if the Wigner function is positive defined at the initial time, it will remain so for all times. We conclude that the source of the quantum behavior has been completely removed from the distributional sector of the theory and is now exclusively placed on the observables (stargenfunctions) sector.

VI. EXAMPLE

To illustrate our previous results let us consider a two particle system described by the Hamiltonian,

$$
\hat{H}=\frac{\hat{p}_1^2}{2M}+\frac{\hat{p}_2^2}{2m}+k\hat{q}_1\hat{p}_2^2, \tag{48}
$$

where $(\hat{q}_1,\hat{p}_1)$ are the canonical variables of the particle of mass M and $(\hat{q}_2,\hat{p}_2)$ are those of the particle of mass m and k is a coupling constant.

The Weyl map $W_{(q,p)}$ yields the (q,p)-Hamiltonian symbol,

$$H=W_{(q,p)}(\hat{H})=\frac{p_1^2}{2M}+\frac{p_2^2}{2m}+kq_1p_2^2, \tag{49}$$

and the Moyal equations $\dot{z}=[z,H]_{M_{(q,p)}}$ for the fundamental variables $z=q_1,q_2,p_1$ or p_2. These display the solutions

$$\begin{aligned} q_1(t)&=q_1(0)+\frac{p_1(0)}{M}t-\frac{k}{2M}p_2(0)^2t^2,\\ p_1(t)&=p_1(0)-kp_2(0)^2t,\\ q_2(t)&=q_2(0)+\left\{\frac{p_2(0)}{m}+2kq_1(0)p_2(0)\right\}t+\frac{k}{M}p_1(0)p_2(0)t^2-\frac{k^2}{3M}p_2(0)^3t^3,\\ p_2(t)&=p_2(0), \end{aligned} \tag{50}$$

which coincide exactly with the classical time evolution, i.e., with the solutions of the classical Hamiltonian equations for the classical Hamiltonian (49). This property is not shared by the Wigner function, its time evolution satisfying the equation

$$\frac{\partial f_W}{\partial t}=[H,f_W]_{M_{(q,p)}}\Leftrightarrow\frac{\partial f_W}{\partial t}=\{H,f_W\}_{(q,p)}+\frac{\hbar^2}{24}\left[2\left\{2kp_2,\frac{\partial^2 f_W}{\partial q_2\partial p_1}\right\}_{(q,p)}-\left\{2kq_1,\frac{\partial^2 f_W}{\partial q_2^2}\right\}_{(q,p)}\right], \tag{51}$$

which is obviously not of the form of the Liouville equation. Consequently, the Wigner function does not satisfy $f_W(\vec{q},\vec{p},t)=f_W(\vec{q}(-t),\vec{p}(-t),0)$ with $\vec{q}(t),\vec{p}(t)$ given by Eq. (50), and $\vec{q}=(q_1,q_2)$, $\vec{p}=(p_1,p_2)$, i.e., it does not display a classical causal structure.

We now introduce a new set of fundamental operators,

$$\begin{aligned} \hat{A}_1&=\hat{q}_1-\frac{\hat{p}_1}{M}t-\frac{k}{2M}\hat{p}_2^2t^2,\\ \hat{B}_1&=\hat{p}_1+k\hat{p}_2^2t,\\ \hat{A}_2&=\hat{q}_2-\left\{\frac{\hat{p}_2}{m}+2k\hat{q}_1\hat{p}_2\right\}t+\frac{k}{M}\hat{p}_1\hat{p}_2t^2+\frac{k^2}{3M}\hat{p}_2^3t^3,\\ \hat{B}_2&=\hat{p}_2, \end{aligned} \tag{52}$$

satisfying the Heisenberg algebra $[\hat{A}_1,\hat{B}_1]=[\hat{A}_2,\hat{B}_2]=i\hbar$, all other commutators being zero. The transformation (52) is unitary and generated by $\hat{T}=-\hat{H}$. Applying the Weyl map $W_{(q,p)}$ to Eq. (52) and comparing the result with (50) we get

$$\left.\begin{array}{l} A_1(\vec{q},\vec{p},t)=q_1(-t) \\ B_1(\vec{q},\vec{p},t)=p_1(-t) \\ A_2(\vec{q},\vec{p},t)=q_2(-t) \\ B_2(\vec{q},\vec{p},t)=p_2(-t) \end{array}\right. \Leftrightarrow \left\{\begin{array}{c} q_1(\vec{A},\vec{B},t)=A_1+\dfrac{B_1}{M}t-\dfrac{k}{2M}B_2^2t^2 \\ p_1(\vec{A},\vec{B},t)=B_1-kB_2^2t \\ q_2(\vec{A},\vec{B},t)=A_2+\left\{\dfrac{B_2}{m}+2kA_1B_2\right\}t+\dfrac{k}{M}B_1B_2t^2-\dfrac{k^2}{3M}B_2^3t^3 \\ p_2(\vec{A},\vec{B},t)=B_2\,. \end{array}\right. \tag{53}$$

The density matrix satisfies $\hat{\rho}(\hat{\vec{q}},\hat{\vec{p}},t)=\hat{\rho}(\hat{\vec{A}}(\hat{\vec{q}},\hat{\vec{p}},t),\hat{\vec{B}}(\hat{\vec{q}},\hat{\vec{p}},t),0)$ [cf. (36)] and thus the Wigner function $f_W(\vec{A},\vec{B},t)=W_{(A,B)}(\hat{\rho})=f_W(\vec{A},\vec{B},0)$ is static. On the other hand, in this representation, the fundamental stargenfunctions do evolve in time. For instance, (let $|x\rangle$ be the general eigenket of $\hat{q}_1$ with associated eigenvalue x),

$$g_x(\vec{A},\vec{B},t)=W_{(A,B)}(|x\rangle\langle x|)=\delta_{*_{(A,B)}}[q_1(\vec{A},\vec{B},t)-x]=\frac{1}{2\pi}\int dk\, e^{ik(q_1(\vec{A},\vec{B},t)-x)}_{*_{(A,B)}}$$

$$=\frac{1}{2\pi}\int dk\, e^{ik(q_1(\vec{A},\vec{B},t)-x)}=\delta[q_1(\vec{A},\vec{B},t)-x] \tag{54}$$

satisfies

$$\frac{\partial}{\partial t}g_x(\vec{A},\vec{B},t)=[g_x(\vec{A},\vec{B},t),H]_{M_{(A,B)}}=\{g_x(\vec{A},\vec{B},t),H\}_{(A,B)}\,. \tag{55}$$

Hence, the Weyl transform $W_{(A,B)}$ casts the phase space dynamics in the Heisenberg picture. Accordingly, the time dependence is exclusively displayed by the observable (stargenfunction) sector of the theory.

We now consider the action of the generalized Weyl map $W^{(A,B)}_{(q,p)}$. The associated time dependent covariant starproduct $*'_{(q,p)}$ and Moyal bracket $[\ ,\ ]_{M_{(q,p)}}$ are characterized by [using the time dependent version of Eqs. (6)–(8) and making $O'^1=p_1$, $O'^2=p_2$, $O'^3=q_1$, $O'^4=q_2$, $O^1=B_1$, $O^2=B_2$, $O^3=A_1$, $O^4=A_2$ and $i,j=1,...,4$]

$$\begin{gathered} J'^{ij}_{(q,p)}=J^{ij}_{(q,p)}\,, \\ \Gamma'^1_{22}=2kt,\quad \Gamma'^3_{22}=\frac{k}{M}t^2,\quad \Gamma'^4_{12}=\Gamma'^4_{21}=\frac{k}{M}t^2,\quad \Gamma'^4_{22}=\frac{2k^2}{M}p_2t^3,\quad \Gamma'^4_{32}=\Gamma'^4_{23}=-2kt, \end{gathered} \tag{56}$$

all other Christoffel symbols being zero. Notice that the connection is time dependent.

The new Wigner function [cf. (53)]

$$f'_W(\vec{q},\vec{p},t)=W^{(A,B)}_{(q,p)}(\hat{\rho})=f_W(\vec{A}(\vec{q},\vec{p},t),\vec{B}(\vec{q},\vec{p},t),0)=f_W(\vec{q}(\vec{q},\vec{p},-t),\vec{p}(\vec{q},\vec{p},-t),0) \tag{57}$$

satisfies the Liouville equation

$$\frac{\partial f'_W}{\partial t}=\frac{\partial f_W}{\partial\vec{A}}\cdot\frac{\partial\vec{A}}{\partial t}+\frac{\partial f_W}{\partial\vec{B}}\cdot\frac{\partial\vec{B}}{\partial t}=\frac{\partial f_W}{\partial\vec{q}}\cdot\{H,\vec{q}\}_{(q,p)}+\frac{\partial f_W}{\partial\vec{p}}\cdot\{H,\vec{p}\}_{(q,p)}=\{H,f_W\}_{(q,p)}=\{H,f'_W\}_{(q,p)}\,. \tag{58}$$

The quantum behavior is displayed by the stargenfunction sector alone. However, for this system, we also have (let $z=q_1,p_1\vee p_2$ and $|z_0\rangle$ be a generic eigenket of $\hat{z}$ with associated eigenvalue z_0)

$$W^{(A,B)}_{(q,p)}(|z_0\rangle\langle z_0|)=\delta_{*'(q,p)}(z-z_0)=\delta_{*(A,B)}(z(\vec{A},\vec{B},t)-z_0)|_{\vec{A}=\vec{A}(\vec{q},\vec{p},t)\wedge\vec{B}=\vec{B}(\vec{q},\vec{p},t)}$$
$$=\delta(z(\vec{A},\vec{B},t)-z_0)|_{\vec{A}=\vec{A}(\vec{q},\vec{p},t)\wedge\vec{B}=\vec{B}(\vec{q},\vec{p},t)}=\delta(z-z_0), \quad (59)$$

where in the third step we used the fact that $e^{ik(z(\vec{A},\vec{B},t)-z_0)}_{*_{(A,B)}}=e^{ik(z(\vec{A},\vec{B},t)-z_0)}$. Hence, the former three fundamental stargenfunctions display a classical structure and satisfy $\{\delta_{*'(q,p)}(z-z_0),H\}=0$. We conclude that for this system, in this representation, the nontrivial (quantum) behavior is displayed by the stargenfunction $z=q_2$ alone.

A final remark is in order: in this example we were not required to use the most general formalism of Sec. V (3) (causal picture and the map $W^{(A,B)}_{(Q,P)}$) to derive the causal phase space representation of the system. This is so because the dynamical structure of the system is exceptionally simple: the quantum and the classical trajectories [which in the most general case have to be described by two different sets of coordinates, $(\vec{q},\vec{p})$ and $(\vec{Q},\vec{P})$, respectively] are identical. Indeed, Eq. (50) solves both the Moyal and the Hamiltonian equations of motion and thus we were not required to introduce a second set of ''classical'' coordinates $(\vec{Q},\vec{P})$.

VII. CONCLUSIONS

Using a time dependent extension of the generalized Weyl map we enlarged the set of possible phase space representations of quantum mechanics, derived a more general formula for the $\hbar$-deformations of the Poisson bracket and proved that there is a phase space representation where the quantum quasidistribution displays a causal dynamical structure. In this formulation the quantum behavior is displayed by the $*$-genfunctions (observables) sector alone. Such a property may lead to interesting applications in the field of the semiclassical limit of quantum mechanics given the fact that in the causal representation the quantum behavior has become, in fact, independent from the state of the system.

The comparison with the de Broglie Bohm formulation seems inevitable. In the de Broglie Bohm theory the source of quantum behavior is the quantum potential together with a modification of the momentum $*$-genvalue equation. The theory admits an interpretation in terms of causal (but not classical) trajectories. In the Wigner causal formulation the effect of the quantum potential has been replaced by further corrections in the observables ($*$-genfunctions) sector of the theory and the achievement was that the particle trajectories became fully classical. It is quite remarkable that this shift of the source of the quantum behavior (from the distributional to the observables sector) could be fully performed and it may lead to an alternative causal interpretation for quantum mechanics.

Contextual approach to quantum mechanics and the theory of the fundamental prespace

Andrei Khrennikov[a)]
MSI, University of Växjö, S-35195 Växjö, Sweden

(Received 12 June 2003; accepted 10 December 2003)

We constructed a Hilbert space representation of a contextual Kolmogorov model. This representation is based on two fundamental observables—in the standard quantum model these are the position and momentum observables. This representation has all distinguishing features of the quantum model. Our representation is not standard model with hidden variables. In particular, this is not a reduction of the quantum model to the classical one. © *2004 American Institute of Physics.*

I. INTRODUCTION

We construct a representation of a Kolmogorovian contextual model in a Hilbert space. Complexes of physical conditions—contexts—are represented by complex amplitudes (or in the abstract framework by normalized vectors of a Hilbert space).

In the papers of Refs. 1–3 there was shown that by using non-Kolmogorovian probabilistic models (see Accardi[4–8] on the role of non-Kolmogorovian models in foundations of QM) such a representation can be constructed on the basis of a so called *contextual formula of total probability* for observables b and a:

$$p_C^b(x)=\sum_y \quad p_C^a(y) \quad p^{b/a}(x/y)$$

$$+2\sum_{y_1<y_2}\sqrt{p_C^a(y_1) \quad p_C^a(y_2) \quad p^{b/a}(x/y_1) \quad p^{b/a}(x/y_2)} \quad \cos\theta_C^{(y_1y_2)}(x), \tag{1}$$

where $p_C^a(y)=\mathbf{P}(a=y/C), p_C^b(x)=\mathbf{P}(b=x/C)$ are probabilities to observe values $a=y$ and $b=x$ under the complex of physical conditions—*context*—C and $p^{b/a}(x/y)=\mathbf{P}(b=x/a=y)$ are transition probabilities. A complex amplitude $\varphi_C^{b/a}(x)$ corresponding to the representation (1) gives the QM-representation of context C. Recently in the preprints[9] it was shown that we can do the same even in the conventional Kolmogorov framework by using the *contextual interpretation* of his measure-theoretical probabilistic model. This paper contains an extended presentation of ideas from Ref. 9.

We shall show that for a Kolmogorov probability space $\mathcal{K}=(\Omega,\mathcal{F},\mathbf{P})$ and a pair of *incompatible Kolmogorovian random variables* b and a we can construct a natural quantum representation. This representation is rigidly based on a pair of variables b and a—fundamental (for that concrete representation of physical reality) observables. In particular, the standard quantum representation is based on the *position and momentum observables*. There exists a map $J^{b/a}$ which maps contexts (represented by subsets of Ω) into quantum states≡complex b/a-transition amplitudes of probability. In some sense we came back to the original Hilbert's viewpoint to a wave function as a transition amplitude; see Ref. 10; see also Lande,[11] Accardi,[4] Ballentine,[12] and Gudder.[13]

[a)]Also at the International Center for Mathematical Modeling in Physics and Cognitive Sciences. Electronic mail: Andrei.Khrennikov@msi.vxu.se; supported by EU-Network QP and Applications.

Points of Ω are interpreted as *fundamental physical parameters*. If you like HV... But the general HV-approach was so discredited by former investigations (since people wanted too much for such a HV-description) that we would not like even to refer to HV. We call Ω *prespace* and fundamental parameters—prepoints.

The main distinguishing feature of the representation map $J^{b/a}$ is the huge *compression of information*. In particular, every point represented in the conventional mathematical model of physical space by a vector $x \in \mathbf{R}^3$ is the image of a subset

$$B_x = \{\omega \in \Omega : b(\omega) = x\},$$

of Ω which can contain millions of prepoints. In the conventional quantum the representation of the prespace the fundamental variable $b = q$ is the position observable. We have a similar picture for the momentum observable. In the quantum model we consider "classical physical points" $x \in \mathbf{R}^3$ as represented by eigenvectors of the position operator. Thus by going from the "classical physical space" $\mathbf{R}^3$ to the quantum physical (Hilbert) space H and then to the prespace Ω we obtain finer and finer descriptions of reality.

Another distinguishing feature of the $J^{b/a}$-representation of the prespace Ω in the Hilbert space H is the creation of superpositions of "classical states." The origin of the quantum superposition can be very easily explained by our prespace model. For example, let us consider a context $C \subset \Omega$ such that $C \subset B_{x_1} \cup B_{x_2}, x_1, x_2 \in \mathbf{R}^3, x_1 \neq x_2$, but neither $C \subset B_{x_1}$ nor $C \subset B_{x_2}$. The image $\varphi_C = J^{b/a}(C) \in H$ is a quantum state describing a quantum system which is "in a superposition of the positions" x_1 and x_2.

In this model (as it was wanted by Einstein) *the Heisenberg uncertainty relation can be violated* for fundamental observables (e.g., the position and momentum) which are used for our classical and quantum representations of reality. Points ($\omega \in \Omega$) of the prespace are *dispersion free states*.

In our model only the two fundamental observables correspond to random variables on the prespace. Other quantum and classical observables have only some indirect relation to random variables on the prespace. So we could not consider such, e.g., quantum observables as real observables–functions of fundamental parameters. Nevertheless, for a wide class of quantum observables (including QM-Hamiltonians) we have the coincidence of averages with averages of corresponding random variables on Ω. Here we speak about averages with respect to the state $\varphi_C = J^{b/a}(C)$ and context C, respectively. In our model only quantum observables belonging to a special class [class $\mathcal{O}_+(a,b)$] have a realist interpretation.

We underline that our investigations have nothing to do with attempts to find some general probabilistic model which would contain Kolmogorov as well as quantum probabilities as particular cases, cf., e.g., Mackey,[14] Gudder,[13] Ludwig,[15] Devies and Lewis,[16] Ballentine,[12] and Hardy.[17] For us the main distinguishing feature of quantum theory is not a new ("quantum") behavior of probabilities, but a special way of the representation of (ordinary) probability.

By our model dispersion free states (e.g., position and momentum observables) can exist and *the Heisenberg's uncertainty principle can be violated*.

II. CONTEXTUAL FORMULA OF TOTAL PROBABILITY

Let $(\Omega, \mathcal{F}, \mathbf{P})$ be a Kolmogorov probability space.[18]

By the standard Kolmogorov axiomatics sets $A \in \mathcal{F}$ represent *events*. In our simplest model of *contextual probability* (Kolmogorovian contextual model) the same system of sets, $\mathcal{F}$, is used to represent complexes of experimental physical conditions—*contexts*. We can consider a set $C \in \mathcal{F}$ as a collection of physical parameters ω describing a complex of physical conditions. This is a context–interpretation of sets $C \in \mathcal{F}$.

By the event–interpretation of sets $A \in \mathcal{F}$ such a set A is a collection of physical parameters inducing the corresponding event (denoted by the same symbol A).

In principle, in a mathematical model events and contexts can be represented by different families of sets, see, e.g., Renye's model. We will not do this from the beginning. But later we will fix a proper subfamily of contexts $\mathcal{C}\subset\mathcal{F}$.

The conditional probability is mathematically defined by the Bayes' formula:

$$\mathbf{P}(A/C)=\frac{\mathbf{P}(AC)}{\mathbf{P}(C)},\quad \mathbf{P}(C)\neq 0.$$

In our contextual model this probability has the meaning of the probability of occurrence of the event A under the complex of physical conditions C. Thus it is not the probability of occurrence of the event A under the condition that the event C has occurred (as it is assumed in the Kolmogorov theory). (The reader might think that the difference in interpretations is negligible. But I would like to underline that this is the crucial point of all our considerations.)

Thus it would be more natural to call $\mathbf{P}(A/C)$ a *contextual probability* and not *conditional probability*. Roughly speaking, to find $\mathbf{P}(A/C)$ we should find parameters ω^A favoring the occurrence of the event A among parameters ω^C describing the complex of physical conditions C.

Let $\mathcal{A}=\{A_n\}$ be finite or countable complete group of inconsistent contexts:

$$A_iA_j=\varnothing,\quad i\neq j,\qquad \cup_i A_i=\Omega.$$

Let $B\in\mathcal{F}$ be an event and $C\in\mathcal{F}$ be a context and let $\mathbf{P}(C)>0$. We have the standard formula of total probability:

$$\mathbf{P}(B/C)=\frac{\mathbf{P}(BC)}{\mathbf{P}(C)}=\sum_n \frac{\mathbf{P}(BA_nC)\mathbf{P}(A_nC)}{\mathbf{P}(C)\mathbf{P}(A_nC)}$$

[if $\mathbf{P}(A_nC)>0$ for all n], and hence

$$\mathbf{P}(B/C)=\sum_n \mathbf{P}(A_n/C)\mathbf{P}(B/A_nC). \tag{2}$$

Of course, in the conventional Kolmogorov model we operate only with events. Thus, in spite of using the standard Kolmogorov measure-theoretical probabilistic formalism, from the very beginning we use a new interpretation of conditioning in this formalism. Instead of the conventional even-conditioning, we use *context-conditioning*. Thus there is nothing new from the mathematical viewpoint and the reader may be curious: Is it possible to find something new by using the same mathematical apparatus and by changing only the interpretation? Yes, we shall construct a totally new representation of the Kolmogorov model in a Hilbert space. This representation is nontrivial—Kolmogorovian (but contextual) random variables are represented by in general noncommutative operators.

In particular, let a and b be discrete random variables taking values $a_i, i=1,\ldots,k_a$ and $b_j, j=1,\ldots,k_b$, where $k_a, k_b<\infty$. We have

$$\mathbf{P}(b=b_i/C)=\sum_n \mathbf{P}(a=a_n/C)\mathbf{P}(b=b_i/a=a_n,C)\quad .$$

Let a measurement of the variable a disturb essentially physical systems $\omega\in\Omega$. Let us fix some complex of conditions (*context*) C. One cannot measure b and a simultaneously in the context C. Thus the probabilities $\mathbf{P}(b=b_i/a=a_n,C)$ are "hidden" (or ontic) probabilities. (We are not able to select parameters ω^{A_n} favouring to the realization of $a=a_n$ without to disturb context C.) However, we can measure the variable b in the context $A_n=\{\omega: a(\omega)=a_n\}$. Thus we cannot prepare for the context C systems ω such that we know that simultaneously $b(\omega)$

$=b_i, a(\omega)=a_n$, but we can prepare systems ω such that $a(\omega)=a_n$ and in this context we can perform the b-measurement. Hence the probabilities $\mathbf{P}(b=b_i/a=a_n)=\mathbf{P}(B_i/A_n)$ are well defined. Here

$$B_i=\{\omega\in\Omega: b(\omega)=b_i\} \quad \text{and} \quad A_n=\{\omega\in\Omega: a(\omega)=a_n\}.$$

I would like to modify the formula of total probability (2) by eliminating hidden probabilities $\mathbf{P}(b=b_i/a=a_n, C)$ and using only observable probabilities $\mathbf{P}(b=b_i/a=a_n)$.

Definition 1: (Context) *A set C belonging to $\mathcal{F}$ is said to be a context with respect to a complete group of inconsistent contexts $\mathcal{A}=\{A_n\}$ if $\mathbf{P}(A_nC)\neq 0$ for all n.*

We denote the set of all $\mathcal{A}$-contexts by the symbol $\mathcal{C}_{\mathcal{A}}$.

Definition 2: Let $\mathcal{A}=\{A_n\}$ and $\mathcal{B}=\{B_n\}$ be two complete groups of inconsistent contexts. They are said to be incompatible if $\mathbf{P}(B_nA_k)\neq 0$ for all n and k.

Thus $\mathcal{B}$ and $\mathcal{A}$ are incompatible iff every B_n is a context with respect to $\mathcal{A}$ and *vice versa*; see Appendix 1 for details.

Random variables a and b inducing incompatible complete groups $\mathcal{A}=\{A_n\}$ and $\mathcal{B}=\{B_k\}$ of inconsistent contexts are said to be *incompatible random variables*.

Theorem 1 (Interference formula of total probability): *Let $\mathcal{A}$ and $\mathcal{B}$ be incompatible and let C be a context with respect to $\mathcal{A}$. Then the following "interference formula of total probability" holds true for any $B\in\mathcal{B}$:*

$$\mathbf{P}(B/C)=\sum \mathbf{P}(A_n/C)\mathbf{P}(B/A_n)+2\sum_{n<m}\lambda_{nm}(B/\mathcal{A},C)\sqrt{\mathbf{P}(A_n/C)\mathbf{P}(A_m/C)\mathbf{P}(B/A_n)\mathbf{P}(B/A_m)}, \tag{3}$$

where

$$\lambda_{nm}(B/\mathcal{A};C)=\frac{\delta_{nm}(B/\mathcal{A};C)}{2\sqrt{\mathbf{P}(A_n/C)\mathbf{P}(B/A_n)\mathbf{P}(A_m/C)\mathbf{P}(B/A_m)}}$$

and

$$\delta_{nm}(B/\mathcal{A};C)=\frac{[\mathbf{P}(A_n/C)(\mathbf{P}(B/A_nC)-\mathbf{P}(B/A_n))+\mathbf{P}(A_m/C)(\mathbf{P}(B/A_mC)-\mathbf{P}(B/A_m))]}{k_a-1} \tag{4}$$

Proof: We have

$$\mathbf{P}(B/C)=\sum_n \mathbf{P}(A_n/C)(\mathbf{P}(B/A_nC)+\mathbf{P}(B/A_n)-\mathbf{P}(B/A_n))=\sum_n \mathbf{P}(A_n/C)\mathbf{P}(B/A_n)+\delta(B/\mathcal{A},C),$$

where

$$\delta(B/\mathcal{A},C)=\sum_n \mathbf{P}(A_n/C)(\mathbf{P}(B/A_nC)-\mathbf{P}(B/A_n)). \tag{5}$$

Finally, we remark that we can represent the perturbation term as the sum of perturbation terms corresponding to pairs of (A_n, A_m):

$$\delta(B/\mathcal{A},C)=\sum_{n<m}\delta_{nm}(B/\mathcal{A};C),$$

where $\delta_{nm}(B/\mathcal{A};C)$ is given by (4).

The $\lambda_{nm}(B/\mathcal{A},C)$ are called *coefficients of statistical disturbance*. Coefficients $\lambda_{nm}(B/\mathcal{A},C)$ describe disturbances of probabilities induced by filtrations with respect to values $a=a_n$ in the

context C. Depending on magnitudes of these coefficients we can rewrite the nonconventional formula of total probability in various forms that are useful for representing (3) as a transformation in a complex linear space or a Clifford modular; see Ref. 19 for details.

In our further investigations we will use the following result.

Lemma 1: Let conditions of Corollary 1 hold true. Then

$$\sum_k \delta(B_k/\mathcal{A},C)=0. \tag{6}$$

Proof: We have $1=\Sigma_k \mathbf{P}(B_k/C)=\Sigma_k\Sigma_n \mathbf{P}(A_n/C)\mathbf{P}(B_k/A_n)+\Sigma_k\delta(B_k/\mathcal{A},C)$. But $\Sigma_n(\Sigma_k \mathbf{P}(B_k/A_n))\mathbf{P}(A_n/C)=1$.

As a consequence of this lemma we have

$$\sum_k \sum_{l<m} \lambda_{lm}(B_k/\mathcal{A},C)\sqrt{\mathbf{P}(A_l/C)\mathbf{P}(A_m/C)\mathbf{P}(B_k/A_l)\mathbf{P}(B_k/A_m)}=0. \tag{7}$$

(1) Suppose that $a=a_n$ filtrations (in the context C) induce statistical disturbances having relatively small coefficients $\lambda_{nm}(B/\mathcal{A},C)$, namely, for every $B\in\mathcal{B}$,

$$|\lambda_{nm}(B/\mathcal{A},C)|\leqslant 1 \ .$$

[First we prepare a statistical ensemble O_C of physical systems ω under the complex of (e.g., physical) conditions C. Then we perform a measurement of the random variable a for elements of the ensemble O_C. Finally, we select all systems for which we obtained the value $a=a_n$.]

In this case we can introduce new statistical parameters $\theta_{nm}(B/\mathcal{A},C)\in[0,\pi]$ and represent the coefficients of statistical disturbance in the trigonometric form:

$$\lambda_{nm}(B/\mathcal{A},C)=\cos\theta_{nm}(B/\mathcal{A},C).$$

Parameters $\theta_{nm}(B/\mathcal{A},C)$ are said to be *relative phases* of an event B with respect to a complete group of inconsistent events $\mathcal{A}$ (in the context C).

In this case we obtain the following interference formula of total probability:

$$\mathbf{P}(B/C)=\sum_n \mathbf{P}(A_n/C)\mathbf{P}(B/A_n)+2\sum_{n<m}\cos\theta_{nm}(B/\mathcal{A},C)$$
$$\times\sqrt{\mathbf{P}(A_n/C)\mathbf{P}(A_m/C)\mathbf{P}(B/A_n)\mathbf{P}(B/A_m)}. \tag{8}$$

This is nothing other than the famous *formula of interference of probabilities*. [Typically this formula is derived by using the Hilbert space (unitary) transformation corresponding to the transition from one orthonormal basis to another and Born's probability postulate. The orthonormal basis under quantum consideration consist of eigenvectors of operators (noncommutative) corresponding to quantum physical observables a and b.] We demonstrated that in the opposite of the common (especially in quantum physics) opinion nontrivial interference of probabilities need not be related to some non-Kolmogorovian features of a probabilistic model. In our considerations everything is Kolmogorovian. The interference of probabilities is a consequence of the impossibility of using conditioning with respect to $\{a=a_n,C\}$ (to combine two contexts—C and a) for random variables a which measurement disturbs essentially physical systems $\omega\in\Omega$.

Starting from (8) we shall derive (for dichotomous random variables) Born's rule, construct for any context C a complex probability amplitude, introduce a Hilbert space structure on the space of complex amplitudes and represent random variables on the Kolmogorov probability space by (in general noncommutative) operators in the Hilbert space.

(2) Suppose that $a=a_n$ filtrations induce statistical disturbances having relatively large coefficients $\lambda_{nm}(B/\mathcal{A},C)$, namely, for every $B\in\mathcal{B}$,

$$|\lambda_{nm}(B/\mathcal{A},C)|\geqslant 1\ .$$

In this case we can introduce new statistical parameters $\theta_{nm}(B/\mathcal{A},C)\in[0,+\infty]$ and represent the coefficients of statistical disturbance in the trigonometric form

$$\lambda_{nm}(B/\mathcal{A},C)=\pm\cosh\theta_{nm}(B/\mathcal{A},C).$$

Parameters $\theta_{nm}(B/\mathcal{A},C)$ are said to be hyperbolic *relative phases* of an event B with respect to a complete group of inconsistent events $\mathcal{A}$ (in the context C).

In this case we obtain the following interference formula of total probability:

$$\mathbf{P}(B/C)=\sum_n \mathbf{P}(A_n/C)\mathbf{P}(B/A_n)\pm 2\sum_{n<m}\cosh\theta_{nm}(B/\mathcal{A},C)$$
$$\times\sqrt{\mathbf{P}(A_n/C)\mathbf{P}(A_m/C)\mathbf{P}(B/A_n)\mathbf{P}(B/A_m)}. \tag{9}$$

(3) Suppose that $a=a_n$ filtrations induce for some n statistical disturbances having relatively small coefficients $\lambda_{nm}(B/\mathcal{A},C)$ and for other n statistical disturbances having relatively large coefficients $\lambda_{nm}(B/\mathcal{A},C)$. Here we have the interference formula of total probability containing trigonometric as well as hyperbolic interference terms.

III. DICHOTOMOUS RANDOM VARIABLES

We study only models with *trigonometric interference*. We set

$$\mathcal{C}=\{C\in\mathcal{C}_{\mathcal{A}}:|\lambda(B_j/\mathcal{A},C)|\leqslant 1\}.$$

We call elements of $\mathcal{C}$ trigonometric contexts. We shall see that QM can be interpreted as a representation of trigonometric contexts. We can also introduce hyperbolic contexts which can be represented in a hyperbolic Hilbert space; see Ref. 19.

A. Interference and complex probability amplitude, Born's rule

Let us study in more detail the case of incompatible dichotomous random variables $a=a_1,a_2,b=b_1,b_2$. We set $Y=\{a_1,a_2\},X=\{b_1,b_2\}$ ("spectra" of random variables a and b). Let $C\in\mathcal{C}$ be a context for both random variables a and b. We set

$$p_C^a(y)=\mathbf{P}(a=y/C),p_C^b(x)=\mathbf{P}(b=x/C),p(x/y)=\mathbf{P}(b=x/a=y),$$

$x\in X,y\in Y$. The interference formula of total probability (8) can be written in the following form:

$$p_c^b(x)=\sum_{y\in Y}p_C^a(y)p(x/y)+2\cos\theta_C(x)\sqrt{\prod_{y\in Y}p_C^a(y)p(x/y)}\ , \tag{10}$$

where $\theta_C(x)=\theta(b=x/\mathcal{A},C)=\arccos\lambda(b=x/\mathcal{A},C),x\in X,C\in\mathcal{C}$. We remark that in the case of dichotomous random variables:

$$\delta(b=x/\mathcal{A},C)=p_c^b(x)-\sum_{y\in Y}p_C^a(y)p(x/y)$$

and

$$\lambda(b=x/\mathcal{A},C)=\frac{\delta(b=x/\mathcal{A},C)}{2\sqrt{\prod_{y\in Y}p_C^a(y)p(x/y)}}.$$

By using the elementary formula:

$$D=A+B+2\sqrt{AB}\cos\theta=|\sqrt{A}+e^{i\epsilon\theta}\sqrt{B}|^2,$$

for $A,B>0,\epsilon=\pm 1,\theta\in[0,\pi]$. we can represent the probability $p_C^b(x)$ as the square of the complex amplitude:

$$p_C^b(x)=|\varphi_C(x)|^2 \quad . \tag{11}$$

We fix some pair of signs $\epsilon(x),x\in X$ [e.g., $\epsilon(b_1)=-1$ and $\epsilon(b_2)=+1$]. We set

$$\varphi(x)\equiv\varphi_C(x)=\sqrt{p_C^a(a_1)p(x/a_1)}+e^{\epsilon(x)\theta_C(x)}\sqrt{p_C^a(a_2)p(x/a_2)} \quad . \tag{12}$$

We denote the space of functions: $\varphi:X\to\mathbf{C}$ by the symbol $E=\Phi(X,\mathbf{C})$. Since $X=\{b_1,b_2\}$, the E is the two dimensional complex linear space. Dirac's δ-functions $\{\delta(b_1-x),\delta(b_2-x)\}$ form the canonical basis in this space. For each $\varphi\in E$ we have

$$\varphi(x)=\varphi(b_1)\,\delta(b_1-x)+\varphi(b_2)\,\delta(b_2-x).$$

By using the representation (12) we construct the map

$$J^{b/a}:\mathcal{C}\to\Phi(X,\mathbf{C}). \tag{13}$$

The $J^{b/a}$ maps contexts (complexes of, e.g., physical conditions) into complex amplitudes. The representation (11) of probability as the square of the absolute value of the complex (b/a)-amplitude is nothing other than the famous *Born rule*.

Remark 1: We underline that the complex linear space representation (12) of the set of contexts $\mathcal{C}$ is based on a pair (a,b) of incompatible (Kolmogorovian) random variables. Here $\varphi_C=\varphi_C^{b/a}$.

The complex amplitude $\varphi_C(x)$ can be called a *wave function* of the complex of physical conditions, context C; cf. Refs. 1–3, or a *pure state*.

We recall that we obtained complex probability amplitudes in the conventional Kolmogorov framework without appealing to the standard wave or Hilbert space arguments. As we shall see, the map $J^{b/a}$ gives a *quantum-like representation* of the conventional Kolmogorov probability model.

In principle, we can represent each context $C\in\mathcal{C}$ by a family of complex amplitudes:

$$\varphi(x)\equiv\varphi_C(x)=\sum_{y\in Y}\sqrt{p_C^a(y)p(x/y)}e^{i\xi_C(x/y)}, \tag{14}$$

such that

$$\xi_C(x/a_1)-\xi_C(x/a_2)=\theta_C(x).$$

For such complex amplitudes we also have Born's rule (11). However, to simplify considerations we shall consider only the representation (12) and the map (13) induced by this representation.

B. Hilbert space representation of Born's rule

We set

$$e_x^b(\cdot)=\delta(x-\cdot).$$

The representation (11) can be rewritten in the following form:

$$p_C^b(x)=|(\varphi_C,e_x^b)|^2 \quad , \tag{15}$$

where the scalar product in the space $E=\Phi(X,C)$ is defined by the standard formula:

$$(\varphi,\psi)=\sum_{x\in X}\varphi(x)\overline{\psi}(x).$$

The system of functions $\{e_x^b\}_{x\in X}$ is an orthonormal basis in the Hilbert space $H=(E,(\cdot,\cdot))$.

Let $X\subset R$. By using the Hilbert space representation of Born's rule (15) we obtain the Hilbert space representation of the expectation of the (Kolmogorovian) random variable b:

$$E(b/C)=\sum_{x\in X}xp_C^b(x)=\sum_{x\in X}x|\varphi_C(x)|^2=(\hat{b}\varphi_C,\varphi_C)\quad, \tag{16}$$

where $\hat{b}:\Phi(X,\mathbf{C})\to\Phi(X,\mathbf{C})$ is the multiplication operator. This operator can also be determined by its eigenvectors: $\hat{b}e_x^b=xe_x^b, x\in X$.

We set

$$u_j^a=\sqrt{p_C^a(a_j)},u_j^b=\sqrt{p_C^b(b_j)},p_{ij}=p(b_j/a_i),u_{ij}=\sqrt{p_{ij}},\theta_j=\theta_C(b_j),\epsilon_j=\epsilon(b_j)\quad.$$

We remark that the coefficients u_j^a,u_j^b depend on a context C; so $u_j^a=u_j^a(C),u_j^b=u_j^b(C)$. We also consider the *matrix of transition probabilities* $\mathbf{P}^{b/a}=(p_{ij})$. It is always a *stochastic matrix*. (So $p_{i1}+p_{i2}=1,i=1,2.$) We have, see (14), that

$$\varphi_C=v_1^be_1^b+v_2^be_2^b,\quad\text{where}\quad v_j^b=u_1^au_{1j}+u_2^au_{2j}e^{i\epsilon_j\theta_j}\quad.$$

So

$$p_C^b(b_j)=|v_j^b|^2=|u_1^au_{1j}+u_2^au_{2j}e^{i\epsilon_j\theta_j}|^2. \tag{17}$$

This is the *interference representation of probabilities* that is used, e.g., in quantum formalism. [By starting with the general representation (14) we obtain $v_j^b=u_1^au_{1j}e^{i\xi_{1j}}+u_2^au_{2j}e^{i\xi_{2j}}$ and the interference representation $p_C^b(b_j)=|v_j^b|^2=|u_1^au_{1j}e^{i\xi_{1j}}+u_2^au_{2j}e^{i\xi_{2j}}|^2$.] We recall that we obtained (17) starting with the interference formula of total probability (10).

C. Born's rule and Hilbert space representations

We would like to obtain (17) by using the standard quantum procedure, namely, transition from the orthonormal basis $\{e_j^b\}$ corresponding the b-variable to a new basis $\{e_j^a\}$ which corresponds to the a-variable. Thus we would like to have Born's rule not only in the b-representation, but also in the a-representation. As we shall see, we cannot be lucky in the general case. Starting from two arbitrary incompatible (Kolmogorovian) random variables a and b we obtained a complex linear space representation of the probabilistic model which is essentially more general than the standard quantum representation. In our (more general) linear representation the "dual variable" a need not be represented by a symmetric operator (matrix) in the Hilbert space H generated by the b.

For any context C_0, we can represent the $\varphi=\varphi_{C_0}$ in the form

$$\varphi=u_1^ae_1^a+u_2^ae_2^a, \tag{18}$$

where

$$e_1^a=(u_{11},\quad u_{12})\quad e_2^a=(e^{i\epsilon_1\theta_1}u_{21},\quad e^{i\epsilon_2\theta_2}u_{22}). \tag{19}$$

Here $\{e_i^a\}$ is a system of vectors in E corresponding to the a-observable. We suppose that vectors $\{e_i^a\}$ are linearily independent, so $\{e_i^a\}$ is a basis in E. We have

$$e_1^a = v_{11}e_1^b + v_{12}e_2^b, \qquad e_2^a = v_{21}e_1^b + v_{22}e_2^b.$$

Here $V=(v_{ij})$ is the matrix corresponding to the transformation of complex amplitudes: $v_{11}=u_{11}, v_{21}=u_{21}$ and $v_{12}=e^{i\epsilon_1\theta_1}u_{21}, v_{22}=e^{ii\epsilon_2\theta_2}u_{22}$.

We would like to find a class of matrixes V such that Born's rule (in the Hilbert space form), see (15), holds true also in the a-basis:

$$p_C^a(a_j) = |(\varphi, e_j^a)|^2 \quad .$$

By (18) we have Born's rule iff $\{e_i^a\}$ was an *orthonormal basis*, i.e., the V is a *unitary* matrix. Since we study the two-dimensional case (i.e., dichotomous random variables), $V \equiv V^{b/a}$ is unitary iff the matrix of transition probabilities $\mathbf{P}^{b/a}$ is *double stochastic*. (So it is stochastic and, moreover, $p_{1j}+p_{2j}=1, j=1,2$.)

However, there is some difficulty. In fact, we constructed the a-basis starting with one fixed context C_0. The basis e_j^a depends on C_0 [via the phases $\theta_{C_0}(x)$]: $e_j^a = e_j^a(C_0)$. In principle, the validity of Born's rule for the context C_0 in the basis $e_j^a(C_0)$ need not imply this rule for any context C in the same basis $e_j^a(C_0)$. We shall see that for double stochastic matrices of transition probabilities (and only such matrices) we can really construct the a-representation starting with some fixed C_0. However, we should choose signs $\epsilon(x)$ in the representation (12) in a special way. We recall that the map $J^{b/a}$ was constructed for fixed signs ϵ_1 and ϵ_2; so $J^{b/a}=J^{b/a}(\epsilon_1,\epsilon_2)$.

We now investigate this problem. We remind the reader that we constructed the matrix V by using the fixed context C_0, so $V=V(C_0)$. For any $C \in \mathcal{C}$, we would like to represent the wave function as

$$\phi_C = v_1^a(C)e_1^a(C_0) + v_2^a(C)e_2^a(C_0), \quad \text{where} \quad |v_j^a(C)|^2 = p_C^a(a_j). \tag{20}$$

It is clear that, for any $C \in \mathcal{C}$, we can represent the wave function as

$$\phi_C(b_1) = u_1^a(C)v_{11}(C_0) + e^{i\epsilon_1[\theta_C(b_1)-\theta_{C_0}(b_1)]}u_2^a(C)v_{12}(C_0),$$

$$\phi_C(b_2) = u_1^a(C)v_{21}(C_0) + e^{i\epsilon_1[\theta_C(b_2)-\theta_{C_0}(b_2)]}u_2^a(C)v_{22}(C_0).$$

Thus to obtain (20) we should have

$$\epsilon_1[\theta_C(b_1)-\theta_{C_0}(b_1)] = \epsilon_2[\theta_C(b_2)-\theta_{C_0}(b_2] \pmod{2\pi}, \tag{21}$$

for any pair of contexts C_0 and C_1. Thus

$$\Delta(C) = \epsilon_1\theta_C(b_1) - \epsilon_2\theta_C(b_2) = \Delta \tag{22}$$

should be a constant (mod 2π) on $\mathcal{C}$.

D. The role of the condition of double stochasticity

Lemma 2: Let a and b be incompatible random variables and let the matrix of transition probabilities $\mathbf{P}^{b/a}$ *be double stochastic. Then*

$$\cos\theta_C(b_1) = -\cos\theta_C(b_2), \tag{23}$$

for any context $C \in \mathcal{C}$.

Proof: By Lemma 1 we have

$$\sum_{x\in X} \cos\theta_C(x)\sqrt{\prod_{y\in Y} p_c^a(y)p(x/y)} = 0.$$

But for a double stochastic matrix $(p(x/y))$ we have

$$\prod_{y\in Y} p_c^a(a_1)p(b_1/y)=\prod_{y\in Y} p_c^a(a_2)p(b_2/y).$$

Since random variables a and b are incompatible, we have $p(x/y)\neq 0, x\in X, y\in Y$. Since $C\in\mathcal{C}_{\mathcal{A}}$, we have $p_C^a(y)\neq 0, y\in Y$. We obtain (23).

Thus for a double stochastic matrix $\mathbf{P}^{b/a}$ we can choose

$$\theta_C(b_2)=\pi-\theta_C(b_1). \tag{24}$$

Proposition 1: Let the conditions of Lemma 2 hold true. Then the condition (22) holds true for any Kolmogorov model iff $\epsilon_1=-\epsilon_2$.

Proof: By (24) we obtain

$$\Delta(C)=(\epsilon_1+\epsilon_2)\theta_C(b_1)-\epsilon_2\pi.$$

Let us denote the unit sphere in the Hilbert space $E=\Phi(X,\mathbf{C})$ by the symbol S. The map $J^{b/a}:\mathcal{C}\to S$ need not be a surjection (injection); see the examples in Sec. VI. In general the set of pure states corresponding to a Kolmogorovian model,

$$S_{\mathcal{C}}\equiv S_{\mathcal{C}}^{b/a}=J^{b/a}(\mathcal{C}),$$

is just a proper subset of the sphere S. The structure of the set of pure states $S_{\mathcal{C}}$ is determined by the Kolmogorov model.

We remark that for a double stochastic matrix $\mathbf{P}^{b/a}$ (and $\epsilon_1=-\epsilon_2$) the condition (22) does not depend on the set $\mathcal{C}$ (i.e., a Kolmogorov model). Here always $\Delta=\pi$. We also remark that, in fact, only double stochastic matrices $\mathbf{P}^{b/a}$ has such a property. By using calculations which have been done in the proof of Lemma 1 we obtain the following more general result.

Lemma 2a: Let a and b be incompatible random variables. Then for any context $C\in\mathcal{C}$ *the following equality holds true*:

$$\cos\theta_C(b_1)=-k\cos\theta_C(b_2), \tag{25}$$

where

$$k\equiv k^{b/a}=\sqrt{\frac{p_{12}p_{22}}{p_{11}p_{21}}}.$$

Proposition 2: Let $k>0$ *be a real number and let angles* $\theta_1,\theta_2\in[0,\pi]$ *be connected by (22). If for all* $\theta_2\in[0,\pi]$,

$$\cos\theta_1=-k\cos\theta_2,$$

then $k=1$ *and* $\Delta=\pi$.

Proof: By (22) we have $\theta_1=\epsilon_1\Delta+\epsilon_1\epsilon_2\theta_2$. Thus $\cos(\epsilon_1\Delta+\epsilon_1\epsilon_2\theta_2)=-k\cos\theta_2$ for all $\theta_2\in[0,\pi]$. So $\cos(\Delta+\epsilon_2\theta_2)=-k\cos\theta_2$. Let $\theta_2=\epsilon_2(-\Delta+\pi/2)$. So $\cos(-\Delta+\pi/2)=0$. Thus $\Delta=0$ or $\Delta=\pi$. Let $\Delta=0$. Then $\cos\theta=-k\cos\theta$ for any $\theta\in[0,\pi]$. This contradicts the positivity of k. So $\Delta=\pi$ and $k=1$. To get both $\theta_1,\theta_2\in[0,\pi]$ we should choose $\epsilon_1=-\epsilon_2$.

We also remark that $k^{b/a}=1$ iff $\mathbf{P}^{b/a}$ is double stochastic.

E. Extension of the Hilbert space representation map

The sets A_i are not contexts with respect to $\mathcal{A}$, since $\mathbf{P}(A_1A_2)=0$. Thus $J^{b/a}(A_i)$ cannot be defined by (12). It is natural to extend the map $J^{b/a}$ to sets A_i by setting

$$J^{b/a}(A_i)=e_i^a,\quad i=1,2.$$

We set

$$\overline{\mathcal{C}}=\mathcal{C}\cup\mathcal{A}.$$

Thus we have constructed the Hilbert space representation:

$$J^{b/a}:\overline{\mathcal{C}}\to S.$$

We set $S_{\overline{\mathcal{C}}}=J^{b/a}\overline{\mathcal{C}}$.

F. Nonsensitive contexts

Let $\delta(B_i/\mathcal{A},C)=0,i=1,2$. So $\lambda(B_i/\mathcal{A},C)=0$ and, hence, $\theta(B_i/\mathcal{A},C)=\pi/2$. Here (for $x\in X$)

$$\varphi_C(x)=J^{b/a}(C)(x)=\sqrt{p_C^a(a_1)p(x/a_1)}+e^{i\epsilon(x)(\pi/2)}\sqrt{p_C^a(a_2)p(x/a_2)}. \tag{26}$$

Thus

$$\varphi_C(x)=\sqrt{p_C^a(a_1)p(x/a_1)}+\epsilon(x)i\sqrt{p_C^a(a_2)p(x/a_2)}. \tag{27}$$

We set

$$\mathcal{C}_0=\{C\in\mathcal{C}:\delta(B_j/\mathcal{A},C)=0\}.$$

Contexts $C\in\mathcal{C}_0$ are said to be b/a-nonsensitive contexts. These are complexes of physical (or, e.g., social) conditions C such that a measurement of a under C does not disturb the probability distribution of b. We remark that Ω always belong to $\mathcal{C}_0$. However, in general $\mathcal{C}_0\neq\{\Omega\}$; see Sec. VI.

G. Noninjectivity of the Hilbert space representation map

Let $C_1,C_2\in\mathcal{C}$ be contexts such that probability distributions of random variables a and b under C_1 and C_2, respectively, coincide:

$$p_{C_1}^a(y)=p_{C_2}^a(y),y\in Y,\quad p_{C_1}^b(x)=p_{C_2}^b(x),x\in X.$$

In such a case $\delta(b=x/\mathcal{A},C_1)=\delta(b=x/\mathcal{A},C_2)$. Thus corresponding phases also coincide: $\theta(b=x/\mathcal{A},C_1)=\theta(b=x/\mathcal{A},C_2)$. Hence $\phi_{C_1}(x)=\phi_{C_2}(x),x\in X$, and $J^{b/a}(C_1)=J^{b/a}(C_2)$; see Sec. VI for examples.

H. Nonquantum Hilbert space representations of Kolmogorovian models

Of course, for arbitrary random variables a and b the matrix $\mathbf{P}^{b/a}$ need not be double stochastic. Thus a representation of probabilities by vectors in a *single Hilbert space* we can obtain for a very restricted class of random variables. In particular, such random variables are considered in quantum theory (in the formalism of Dirac–von Neumann). In general, for each random variable we should introduce its own scalar product and corresponding Hilbert space:

$H_b=(E,(\cdot,\cdot)_b)$, $H_a=(E,(\cdot,\cdot)_a),\ldots$, where

$$(\varphi,\psi)_b=\sum_j v_j^b\overline{w}_j^b,\quad \text{for}\quad \varphi=\sum_j v_j^b e_j^b,\psi=\sum_j w_j e_j^b$$

and

$$(\varphi,\psi)_a=\sum_j v_j^a\overline{w_j^a},\quad \text{for}\quad \varphi=\sum_j v_j^a e_j^a,\psi=\sum_j w_j^a e_j^a.$$

The Hilbert spaces $H_b,H_a,\ldots,$ give the b-representation, the a-representation, ... Thus $p_C^b(b_j)=|(\varphi,e_j^b)_b|^2$ and $p_C^a(a_j)=|(\varphi,e_j^a)_a|^2$ and so on. In the H_a we have

$$E(a/C)=\sum_{y\in Y} yp_C^a(y)=a_1|(\varphi_C,e_1^a)_a|^2+a_2|(\varphi_C,e_2^a)_a|^2=(\hat{a}\varphi_C,\varphi_C)_a\ ,$$

where the operator $\hat{a}:E\to E$ is determined by its eigenvectors: $\hat{a}e_j^a=a_je_j^a$.

Of course, the representation of random variables by linear operators is just a convenient mathematical tool to represent the average of a random variable by using only the Hilbert space structure. We recall that we started with purely ''classical'' Kolmogorovian random variables.

As in the conventional quantum formalism we can also consider the map

$$\tilde{J}^{b/a}:\overline{\mathcal{C}}\to\tilde{\Phi}(X,\mathbf{C}).\tag{28}$$

Here $\tilde{\Phi}(X,\mathbf{C})$ is the space of equivalent classes of functions under the equivalence relation: φ equivalent ψ iff $\varphi=t\psi$, $t\in\mathbf{C}$, $|t|=1$, and $\tilde{J}^{b/a}(C)=t\phi_C$, $t\in\mathbf{C}$, $|t|=1$, where $C\in\overline{\mathcal{C}}$.

Conclusion: In the contextual probabilistic approach we can construct a natural map from the set of contexts into the unit sphere of the complex Hilbert space. Such a map is determined by a pair a,b of incompatible random variables. Unitarity of the matrix $V^{b/a}$ of transition from the basis $\{e_i^a\}$ to the basic $\{e_i^b\}$ (these basis correspond to random variables a and b, respectively) is equivalent to the possibility of using Born's rule both in the a and b representations. In general (i.e., for an arbitrary set of contexts) such a construction can be realized only for a **double stochastic matrix** *of transition probabilities*.

Everywhere below we restrict our considerations to the case in which the matrix of transition probabilities $\mathbf{P}^{b/a}$ is *double stochastic*.

IV. NONCOMMUTATIVITY OF OPERATORS REPRESENTING KOLMOGOROVIAN RANDOM VARIABLES

We consider in this section the case of real valued random variables. Here the spectra of random variables b and a are subsets of $\mathbf{R}$.

We set $q_1=\sqrt{p_{11}}=\sqrt{p_{22}}$ and $q_2=\sqrt{p_{12}}=\sqrt{p_{21}}$.

Thus the vectors of the a-basis, see (19), have the following form:

$$e_1^a=(q_1,q_2),\quad e_2^a=(e^{i\epsilon_1\theta_1}q_2,e^{i\epsilon_2\theta_2}q_1)\ .$$

Since $\theta_1+\theta_2=\pi$, we get $e_2^a=e^{i\epsilon_2\theta_2}(-q_2,q_1)$. The factor $e^{i\epsilon_2\theta_2}$ does not play any role in probabilistic considerations. Hence we can work in the new basis:

$$e_1^a=(q_1,q_2),\quad e_2^a=(-q_2,q_1).$$

We now find matrices of operators $\hat{a}$ and $\hat{b}$ in the b-representation. The latter one is diagonal. For $\hat{a}$ we have $\hat{a}=V\,\mathrm{diag}(a_1,a_2)V^\star$, where $v_{11}=v_{22}=q_1,v_{21}=-v_{12}=q_2$. Thus

$$a_{11}=a_1q_1^2+a_2q_2^2,\ \ a_{22}=a_1q_2^2+a_2q_1^2,\ \ a_{12}=a_{21}=(a_1-a_2)q_1q_2.$$

Hence

$$[\hat{b},\hat{a}]=\hat{m},$$

where $m_{11}=m_{22}=0$ and $m_{12}=-m_{21}=(a_1-a_2)(b_2-b_1)q_1q_2$. Since $a_1\neq a_2, b_1\neq b_2$ and $q_j\neq 0$, we have $\hat{m}\neq 0$.

V. THE ROLE OF SIMULTANEOUS DOUBLE STOCHASTICITY OF $P^{b/a}$ AND $P^{a/b}$

Starting with the b-representation—complex amplitudes $\phi_C(x)$ defined on the spectrum (range of values) of a random variable b—we constructed the a-representation. This construction is natural (i.e., reproduce Born's probability rule) only in the case in which $\mathbf{P}^{b/a}$ is double stochastic. We would like to have a symmetric model. So by starting with the a-representation—complex amplitudes $\phi_C(y)$ defined on the spectrum (range of values) of a random variable a—we would like to construct the natural b-representation. Thus both matrices of transition probabilities $\mathbf{P}^{b/a}$ and $\mathbf{P}^{a/b}$ should be double stochastic.

Theorem 2: *Let the matrix* $\mathbf{P}^{b/a}$ *be double stochastic. The contexts* B_1, B_2 *belong to* $\mathcal{C}$ *iff the matrix* $\mathbf{P}^{a/b}$ *is double stochastic.*

Proof: We have

$$\lambda(B_2/\mathcal{A},B_1)=-\frac{\mu_1^2+\mu_2^2}{2\mu_1\mu_2},$$

where $\mu_j=\sqrt{p^a_{B_1}(a_j)p(b_2/a_j)}$. So $\lambda(B_2/\mathcal{A},B_1)\geqslant 1$ and we have the trigonometric behavior only in the case $\mu_1=\mu_2$. Thus $p^a_{B_1}(a_1)p(b_2/a_1)=p^a_{B_1}(a_2)p(b_2/a_2)$. In this case $\lambda(B_2/\mathcal{A},B_1)=-1$, so $\theta(B_2/\mathcal{A},B_1)=\pi$, and consequently $\theta(B_1/\mathcal{A},B_1)=0$. We pay attention to the fact that $p^a_{B_i}(a_j)=p^{a/b}(a_j/b_i)\equiv p(a_j/b_i)$. Thus we have

$$p(a_1/b_1)p(b_2/a_1)=p(a_2/b_1)p(b_2/a_2). \tag{29}$$

In the same way by using conditioning with respect to B_2 we obtain

$$p(a_1/b_2)p(b_1/a_1)=p(a_2/b_2)p(b_1/a_2).$$

By using the double stochasticity of $\mathbf{P}^{b/a}$ we can rewrite the last equality as

$$p(a_1/b_2)p(b_2/a_2)=p(a_2/b_2)p(b_2/a_1). \tag{30}$$

Thus by (29) and (30) we have

$$\frac{p(a_1/b_2)}{p(a_2/b_1)}=\frac{p(a_2/b_2)}{p(a_1/b_1)}.$$

Hence $p(a_1/b_2)=tp(a_2/b_1)$ and $p(a_2/b_2)=tp(a_1/b_1), t>0$. But $1=p(a_1/b_2)+p(a_2/b_2)=t[p(a_2/b_1)+p(a_1/b_1)]=t$.

To finish the proof we need the following well known result.

Lemma 3: Both matrices of transition probabilities $\mathbf{P}^{b/a}$ *and* $\mathbf{P}^{a/b}$ *are double stochastic iff the transition probabilities are symmetric, i.e.,*

$$p(b_i/a_j)=p(a_j/b_i), \quad i,j=1,2. \tag{31}$$

This is equivalent that random variables a and b have the uniform probability distribution: $p^a(a_i)=p^b(b_i)=1/2$, $i=1,2$.

This lemma has important physical consequences. A natural (Bornian) Hilbert space representation of contexts can be constructed only on the basis of a pair of (incompatible) uniformly distributed random variables.

Lemma 4: Let both matrices $\mathbf{P}^{b/a}$ *and* $\mathbf{P}^{a/b}$ *be double stochastic. Then*

$$\lambda(B_i/\mathcal{A},B_i)=1. \tag{32}$$

Proof: Here $\delta(B_i/\mathcal{A},B_i)=1-p(b_i/a_1)p(a_1/b_i)-p(b_i/a_2)p(a_2/b_i)=1-p(a_1/b_i)^2-p(a_2/b_i)^2=2p(a_1/b_i)p(a_2/b_i)$. Thus $\lambda(B_i/\mathcal{A},B_i)=1$.

By (32) we have

$$\lambda(B_i/\mathcal{A},B_j)=-1, i\neq j.$$

Thus

$$\theta(B_i/\mathcal{A},B_i)=0 \text{ and } \theta(B_i/\mathcal{A},B_j)=\pi, i\neq j.$$

Proposition 2: Let both matrices of transition probabilities $\mathbf{P}^{b/a}$ *and* $\mathbf{P}^{a/b}$ *be double stochastic. Then*

$$J^{b/a}(B_j)(x)=\delta(b_j-x), x\in X, \quad \text{and} \quad J^{a/b}(A_j)(y)=\delta(a_j-y), y\in Y.$$

Proof: Because $\theta(B_1/\mathcal{A},B_1)=0$ we have

$$J^{b/a}(B_1)(b_1)=\sqrt{p(a_1/b_1)p(b_1/a_1)}+e^{i0}\sqrt{p(a_2/b_1)p(b_1/a_2)}=p(a_1/b_1)+p(a_2/b_1)=1.$$

Because $\theta(B_2/\mathcal{A},B_1)=\pi$ we have

$$\begin{aligned} J^{b/a}(B_1)(b_2)&=\sqrt{p(a_1/b_1)p(b_2/a_1)}+e^{i\pi}\sqrt{p(a_2/b_1)p(b_2/a_2)}\\ &=\sqrt{p(a_1/b_1)}(\sqrt{p(b_2/a_1)}-\sqrt{p(a_2/b_1)})=0. \end{aligned}$$

Thus in this case,

$$J^{b/a}(B_i)=e_i^b, \quad i=1,2.$$

VI. EXAMPLE OF THE HILBERT SPACE REPRESENTATION OF THE CONTEXTUAL KOLMOGOROVIAN MODEL

We consider an example of a Kolmogorov probability space and a pair of dichotomous random variables a,b which are incompatible. In this example the set of contexts with nontrivial disturbance term $\delta, \delta\neq 0$, is nonempty, so $\mathcal{C}_0\neq\mathcal{C}$.

A. Kolmogorov probability space and incompatible random variables

We find the image $S_{\mathcal{C}}$ of the set of contexts $\mathcal{C}$ in the Hilbert sphere $S\subset E=\Phi(X,C)$. In this example $S_{\mathcal{C}}$ is a proper subset of the sphere S. The Hilbert space representation map $J^{b/a}$ is not injective. Random variables a and b are represented by symmetric operators in the Hilbert space E. They do not commute.

Let $\Omega=\{\omega_1,\omega_2,\omega_3,\omega_4\}$ and $\mathbf{P}(\omega_j)=p_j>0, \Sigma_{j=1}^4 p_j=1$. Let

$$A_1=\{\omega_1,\omega_2\}, A_2=\{\omega_3,\omega_4\},$$

$$B_1=\{\omega_1,\omega_4\}, B_2=\{\omega_2,\omega_3\}.$$

Let $p_1=p_3=q<\frac{1}{2}$ and $p_2=p_4=(1-2q)/2$. We denote this Kolmogorov probability space by the symbol $\mathcal{K}(q)$.

Here $\mathbf{P}(A_1)=\mathbf{P}(A_2)=\mathbf{P}(B_1)=\mathbf{P}(B_2)=\frac{1}{2}$. So the random variables a and b are uniformly distributed. Thus both matrices of transition probabilities $\mathbf{P}^{b/a}$ and $\mathbf{P}^{a/b}$ are double stochastic. Here

$$\mathbf{P}^{b/a}=\mathbf{P}^{a/b}=\begin{pmatrix} 2q & 1-2q \\ 1-2q & 2q \end{pmatrix}.$$

We have the symmetry condition $\mathbf{P}(B_i/A_j)=\mathbf{P}(A_j/B_i)$.

B. Hilbert space representation of contexts

We choose $\epsilon_1=-1$ and $\epsilon_2=+1$ to fix the map $J^{b/a}$. We start with two point contexts.

(a) Let $C=C_{24}=\{\omega_2,\omega_4\}$. Here $\mathbf{P}(C)=1-2q$, $\mathbf{P}(B_j/C)=\mathbf{P}(A_j/C)=\frac{1}{2}$. Thus $\delta=0$. By using the representation (27), we obtain

$$\varphi_{C_{24}}(x)=\begin{cases}\sqrt{q}-i\sqrt{\dfrac{1-2q}{2}}, & x=b_1;\\ \sqrt{\dfrac{1-2q}{2}}+i\sqrt{q}, & x=b_2.\end{cases} \tag{33}$$

(b) Let $C=C_{13}=\{\omega_1,\omega_3\}$. Here everything is as in (a). So we have $\varphi_{C_{13}}=\varphi_{C_{24}}$ Thus $J^{b/a}$ is not injective: $J^{b/a}(C_{24})=J^{b/a}(C_{13})$.

(c) Let $C=C_{14}=\{\omega_1,\omega_4\}=B_1$. By general theory we have $\varphi_{C_{14}}(x)=\delta(b_1-x)=e_1^b$. In the same way, $\varphi_{C_{23}}=\delta(b_2-x)=e_2^b$.

To find the Hilbert space representation of sets $C=C_{12}=\{\omega_1,\omega_2\}=A_1$ and $C=C_{34}=\{\omega_3,\omega_4\}=A_2$ we have to construct the basis $\{e_j^a\}$. We can choose

$$e_1^a=\begin{pmatrix}\sqrt{2q}\\ \sqrt{1-2q}\end{pmatrix},\quad e_2^a=\begin{pmatrix}-\sqrt{1-2q}\\ \sqrt{2q}\end{pmatrix}.$$

(d) Let $C=C_{123}=\{\omega_1,\omega_2,\omega_3\}$. Here $\mathbf{P}(C)=(2q+1)/2$, $\mathbf{P}(A_1/C)=\mathbf{P}(B_2/C)=1/(2q+1)$, $\mathbf{P}(A_2/C)=\mathbf{P}(B_1/C)=2q/(2q+1)$. Thus $\delta(B_1/\mathcal{A},C)=2q(2q-1)/(2q+1)$ and, hence, $\lambda(B_1/\mathcal{A},C)=-\sqrt{1-2q}/2$. This context is trigonometric, i.e., the measurement of the random variable a under the complex of physical conditions C induces nontrivial, but a relatively small statistical disturbance of the "b-property;" so $C_{123}\in\mathcal{C}$. We remark that $\lambda(B_2/\mathcal{A},C)=\sqrt{1-2q}/2$ (since $\mathbf{P}^{b/a}$ is double stochastic). [We pay attention on the dependence of $\theta=\arccos\sqrt{1-2q}/2$ on the parameter q: $\theta(q)$ increases from $\pi/3$ to $\pi/2$, when q increases from 0 to 1/2.] We have

$$\varphi_{C_{123}}(x)=\begin{cases}\sqrt{\dfrac{2q}{2q+1}}-e^{i\arccos\sqrt{1-2q}/2}\sqrt{\dfrac{2q(1-2q)}{2q+1}}, & x=b_1,\\ \sqrt{\dfrac{1-2q}{2q+1}}+e^{i\arccos\sqrt{1-2q}/2}\dfrac{2q}{\sqrt{2q+1}}, & x=b_2.\end{cases}$$

Remark: In principle, we could choose, e.g.,

$$e_2^a=\begin{pmatrix}-e^{i\theta}\sqrt{1-2q}\\ e^{i\theta}\sqrt{2q}\end{pmatrix},\quad \theta=\arccos\frac{\sqrt{1-2q}}{2}.$$

Thus

$$\varphi_{C_{123}}=\frac{1}{\sqrt{2q+1}}e_1^a+e^{i\arccos\sqrt{1-2q}/2}\sqrt{\frac{2q}{2q+1}}e_2^a\ .$$

(e) Let $C=C_{124}=\{\omega_1,\omega_2,\omega_4\}$. Here $\mathbf{P}(C)=1-q$, $\mathbf{P}(A_1/C)=\mathbf{P}(B_1/C)=1/2(1-q)$, $\mathbf{P}(A_2/C)=\mathbf{P}(B_2/C)=(1-2q)/2(1-q)$. Thus $\delta(B_1/\mathcal{A},C)=q(1-2q)/(1-q)$ and, hence, $\lambda(B_1/\mathcal{A},C)=\sqrt{q/2}<1$, and the context $C_{124}\in\mathcal{C}$. Thus

$$\varphi_{C_{124}}(x)=\begin{cases}\sqrt{\dfrac{q}{1-q}}+e^{-i\arccos\sqrt{q/2}}\dfrac{1-2q}{\sqrt{2(1-q)}}, & x=b_1,\\ \sqrt{\dfrac{1-2q}{2(1-q)}}-e^{-i\arccos\sqrt{q/2}}\sqrt{\dfrac{q(1-2q)}{1-q}}, & x=b_2;\end{cases}$$

$$\varphi_{C_{124}}(x)=\frac{1}{\sqrt{2(1-q)}}\ e_1^a-e^{-i\arccos\sqrt{q/2}}\sqrt{\frac{1-2q}{2(1-q)}}\ e_2^a.$$

(f) Let $C=C_{234}=\{\omega_2,\omega_3,\omega_4\}$. Here $\mathbf{P}(C)=1-q$, $\mathbf{P}(A_1/C)=\mathbf{P}(B_1/C)=(1-2q)/2(1-q)$, $\mathbf{P}(A_2/C)=\mathbf{P}(B_2/C)=1/2(1-q)$. Thus $\delta(B_1/\mathcal{A},C)=q(2q-1)/(1-q)$ and, hence, $\lambda(B_1/\mathcal{A},C)=-\sqrt{q/2}$, $\lambda(B_2/\mathcal{A},C)=\sqrt{q/2}$. Here

$$\varphi_{C_{234}}(x)=\begin{cases}\sqrt{\dfrac{q(1-2q)}{1-q}}-e^{i\arccos\sqrt{q/2}}\sqrt{\dfrac{1-2q}{2(1-q)}}, & x=b_1,\\ \dfrac{1-2q}{\sqrt{2(1-q)}}+e^{i\arccos\sqrt{q/2}}\sqrt{\dfrac{q}{1-q}}, & x=b_2;\end{cases}$$

$$\varphi_{C_{234}}(x)=\sqrt{\frac{1-2q}{2(1-q)}}\ e_1^a+e^{i\arccos\sqrt{q/2}}\frac{1}{\sqrt{2(1-q)}}\ e_2^a\ .$$

(g) Let $C=C_{134}=\{\omega_1,\omega_3,\omega_4\}$. Here $\mathbf{P}(C)=(2q+1)/2$, $\mathbf{P}(A_1/C)=\mathbf{P}(B_2/C)=2q/(2q+1)$, $\mathbf{P}(A_2/C)=\mathbf{P}(B_1/C)=1/(2q+1)$. Thus $\delta(B_1/\mathcal{A},C)=2q(1-2q)/(2q+1)$ and, hence, $\lambda(B_1/\mathcal{A},C)=\sqrt{1-2q}/2$. Thus

$$\varphi_{C_{134}}(x)=\begin{cases}\dfrac{2q}{\sqrt{2q+1}}+e^{-i\arccos\sqrt{1-2q}/2}\sqrt{\dfrac{1-2q}{2q+1}}, & x=b_1,\\ \sqrt{\dfrac{2q(1-2q)}{2q+1}}-e^{-i\arccos\sqrt{1-2q}/2}\sqrt{\dfrac{2q}{2q+1}}, & x=b_2;\end{cases}$$

$$\varphi_{C_{134}}=\sqrt{\frac{2q}{2q+1}}\ e_1^a-e^{-i\arccos\sqrt{1-q}/2}\frac{1}{\sqrt{2q+1}}\ e_2^a.$$

(h) Let $C=\Omega$. Here we know from the beginning that $\delta(B_j/\mathcal{A},C)=0$. Here $\mathbf{P}(A_i/C)=\mathbf{P}(A_i)=1/2$ and $\mathbf{P}(B_i/C)=\mathbf{P}(B_i)=1/2$. Thus $J^{b/a}(\Omega)=J^{b/a}(C_{24})=J^{b/a}(C_{13})=(33)$.

In this example the set of nonsensitive contexts contains three contexts: $\mathcal{C}_0=\{\Omega,C_{24},C_{13}\}$. We have

$$S_{\mathcal{C}}=\{\varphi_\Omega,\varphi_{C_{14}}=e_1^b,\varphi_{C_{23}}=e_2^b,\varphi_{C_{12}}=e_1^a,\varphi_{C_{23}}=e_2^a,\varphi_{C_{124}},\varphi_{C_{234}},\varphi_{C_{123}},\varphi_{C_{134}}\}.$$

So the set of pure states $S_{\mathcal{C}}$ is a finite, nine-point, subset of the unit sphere in the two-dimensional Hilbert space.

We remark that there is a parameter $q\in(0,1/2)$ determining a Kolmogorov probability model $\mathcal{K}(q)$. For each value of q we have a finite set of pure states. However, a family $\mathcal{K}(q)$, $q\in(0,1/2)$, of Kolmogorov probability spaces generates a "continuous" set $\cup_q S_{\mathcal{C}}(q)$ of pure states.

VII. CONTEXTUAL CORRESPONDENCE BETWEEN KOLMOGOROVIAN RANDOM VARIABLES AND QUANTUM OBSERVABLES

We begin with the following standard definition:

Definition 3: For a self-adjoint operator $\hat{d}$ the quantum mean value in the state φ is defined by

$$\langle\hat{d}\rangle_\varphi=(\hat{d}\varphi,\varphi).$$

Theorem 3: *For any map $f:\mathbf{R}\to\mathbf{R}$ we have*

$$\langle f(\hat{a})\rangle_{\varphi_C}=E(f(a)/C), \qquad \langle f(\hat{b})\rangle_{\varphi_C}=E(f(b)/C),$$

for any context $C\in\overline{\mathcal{C}}$.

Proof: By using Borness of the b-representation we obtain

$$E(f(b/C))=\sum_{x\in X} f(x)p_c^b(x)=\sum_{x\in X} f(x)|(\varphi_C,e_x^b)|^2=\langle f(\hat{b})\rangle_{\varphi_C}.$$

The same result we have for the $f(\hat{a})$ since (as $\mathbf{P}^{b/a}$ is double stochastic) we have Born's probability rule both for b and a.

Theorem 4: *Let $f,g:\mathbf{R}\to\mathbf{R}$ be two arbitrary functions. Then*

$$E(f(a)+g(b)/C)=\langle f(\hat{a})+g(\hat{b})\rangle_{\varphi_C},$$

for any context $C\in\overline{\mathcal{C}}$.

Proof: By using linearity of the Kolmogorov mathematical expectation, Theorem 3, and linearity of the Hilbert space scalar product we obtain

$$\begin{aligned}E(f(a(\omega))+g(b(\omega))/C)&=E(f(a(\omega)/C)+E(g(b(\omega))/C))\\&=\langle f(\hat{a})\rangle_{\varphi_C}+\langle g(\hat{b})\rangle_{\varphi_C}=\langle f(\hat{a})+g(\hat{b})\rangle_{\varphi_C}.\end{aligned}$$

Denote the linear space of all random variables of the form $d(\omega)=f(a(\omega))+g(b(\omega))$ by the symbol $\mathcal{O}_+(a,b)$ and the linear space of operators of the form $\hat{d}=f(\hat{a})+g(\hat{b})$ by $\mathcal{O}_+(\hat{a},\hat{b})$.

Theorem 5: *The map $T=T^{a/b}:\mathcal{O}_+(a,b)\to\mathcal{O}_+(\hat{a},\hat{b}), d=f(a)+g(b)\to\hat{d}=f(\hat{a})+g(\hat{b})$, preserves the conditional expectation*

$$\langle T(d)\rangle_{\varphi_C}=(T(d)J(C),J(C))=E(d/C). \tag{34}$$

The transformation T preserves the conditional expectation for random variables $d\in\mathcal{O}_+(a,b)$. But in general we cannot expect anything more, since in general T does not preserve probability distributions. The important problem is to extend the map T for a larger class (linear space?) of Kolmogorovian random variables with preserving (34). It is natural to define (as we always do in the conventional quantum formalism):

$$T(f)(\hat{a},\hat{b})=f(\hat{a},\hat{b}),$$

where $f(\hat{a},\hat{b})$ is the pseudo differential operator with the Weyl symbol $f(a,b)$. We shall see that already for $f(a,b)=ab$ [so $f(\hat{a},\hat{b})=(\hat{a}\hat{b}+\hat{b}\hat{a})/2$] the equality (34) is violated.

We can consider the b and the a as discrete analogs of the position and momentum observables. The operators $\hat{b}$ and $\hat{a}$ give the Hilbert space (quantum) representation of these observables.

We also introduce an analog of the energy observable:

$$\mathcal{H}(\omega)=\frac{h}{2}[a^2(\omega)+V(b(\omega))],$$

where $h>0$ is a constant and $V:\mathbf{R}\to\mathbf{R}$ is a map. The Hilbert space representation of this observable is given by the operator of energy (Hamiltonian),

$$\hat{\mathcal{H}}=\frac{h}{2}(\hat{a}^2+V(\hat{b})).$$

By Theorem 5 for contexts $C \in \overline{\mathcal{C}}$ the averages of the observables $\mathcal{H}(\omega)$ (Kolmogorovian) and $\hat{\mathcal{H}}$ (quantum) coincide:

$$E(\mathcal{H}(\omega)/C) = \langle \mathcal{H} \rangle_{\varphi_C}.$$

However, as we shall see, probability distributions do not coincide.

Proposition 3: There exists context C such that the probability distribution of the random variable $d(\omega) = a(\omega) + b(\omega)$ with respect to C does not coincide with the probability distribution of the corresponding quantum observable $\hat{d} = \hat{a} + \hat{b}$ with respect to the state φ_C.

Proof: It suffices to present an example of such a context C. Take the context $C = C_{234}$ from Sec. VI. We consider the case: $a(\omega) = \pm\gamma, b(\omega) = \pm\gamma, \gamma > 0$; so $d(\omega) = -2\gamma, 0, 2\gamma$. Corresponding Kolmogorovian probabilities can easily be found:

$$p_C^d(-2\gamma) = q/(1-q), \quad p_C^d(0) = (1-2q)/(1-q), \quad p_C^d(2\gamma) = 0.$$

We now find the probability distribution of $\hat{d}$. To do this, we find eigenvalues and eigenvectors of the self-adjoint operator $\hat{d}$. We find the matrix of the operator $\hat{d}$ in the basis $\{e_j^b\}$: $d_{11} = -d_{22} = 4q\gamma$ and $d_{12} = d_{21} = 2\gamma\sqrt{2q(1-2q)}$. We have $k_{1,2} = \pm 2\sqrt{2q}\,\gamma$. Of course, the range of values of the quantum observable $\hat{d}$ differs from the range of values of the random variable d. However, this difference of ranges of values is not so large a problem in this case. The random variable d takes only two values, $-2\gamma, 0$, with the probability one. Moreover, we can represent values of the quantum observable $\hat{d}$ as just an affine transform of values of the random variable d:

$$d_{\text{quantum}} = 2\sqrt{2q}\ \ d - \gamma.$$

In principle we can interpret such a transformation as representing some special measurement procedure. Thus in this example the problem with the spectrum is not crucial. The crucial problem is that d and $\hat{d}$ have different probability distributions.

The corresponding eigenvectors are

$$e_1^d = \frac{1}{\sqrt{2(1-\sqrt{2q})}}(-\sqrt{1-2q}, \sqrt{2q}-1),$$

$$e_2^d = \frac{1}{\sqrt{2(1+\sqrt{2q})}}(-\sqrt{1-2q}, \sqrt{2q}+1).$$

Finally, we find (by using the expression for $\varphi_{C_{234}}$ which was found in Sec. VI):

$$p_c^{\hat{d}}(k_1) = |(\varphi_C, e_1^d)|^2 = \frac{(1-\sqrt{2q})(2+\sqrt{2q})}{4(1-q)},$$

$$p_c^{\hat{d}}(k_2) = |(\varphi_C, e_2^d)|^2 = \frac{(1+\sqrt{2q})(2-\sqrt{2q})}{4(1-q)}.$$

Thus d and $\hat{d}$ have essentially different probability distributions.

VIII. DISPERSION-FREE STATES

As originally stated by von Neumann,[20] the problem of hidden variables is to find whether *dispersion free states exist* in QM. He answered the question in the negative. The problem of the

existence of dispersion free states as well as von Neumann's solution were the subject of great debates. We do not want to go into detail; see, e.g., Ref. 21. In our contextual approach an analog of this problem can be formulated as follows.

Do dispersion free contexts exist? The answer is the positive. In the example of Sec. VI. We can take any atom of the Kolmogorov probability space $\mathcal{K}_q$, e.g., $C=\{\omega_1\}$. Since, for any random variable ξ on the Kolmogorov space $\mathcal{K}_q$, it has a constant value on such a C the dispersion of ξ under the context C is equal to zero:

$$D(\xi/C)=E[(\xi-E(\xi/C))^2/C]=0.$$

However, dispersion free contexts do not belong to the system $\overline{\mathcal{C}}$ of contexts which can be mapped by $J^{a/b}$ into the Hilbert space H. On the one hand, our contextual approach gives the possibility to have the realist viewpoint to QM. On the other hand, it does not contradict to the von Neumann as well as other ''no-go'' theorems. The mathematical representation of contexts (complexes of physical conditions) given by the quantum formalism it too rough to represent dispersion free contexts.

IX. CLASSICAL AND QUANTUM SPACES AS ROUGH IMAGES OF FUNDAMENTAL PRESPACE

Our contextual probabilistic model induces the following picture of physical reality.

A. Prespace and classical space

There exists a prespace Ω which points corresponds to primary (irreducible) states of physical systems, *prestates or fundamental physical parameters*. Functions $d:\Omega\to\mathbf{R}^m$ are said to be *preobservables*. The set of all preobservables is denoted by the symbol $\mathcal{O}_p\equiv\mathcal{O}_p(\Omega)$. We are not able (at least at the moment) to measure an arbitrary preobservable $d\in\mathcal{O}_p$.

Nevertheless, some preobservables can be measured. Suppose that there exists a preobservable b such that all measurements can be reduced to some measurements of b; cf. De Broglie[10] on the possibility of reducing any measurement to a position measurement. Let $X\subset\mathbf{R}^m$ be the range of values of b. The X is said to be a classical space Set $B_x=\{\omega\in\Omega:b(\omega)=x\}=b^{-1}(x),x\in X$.

In principle a set B_x could contain millions of points. Dynamics in X is classical dynamics. In our model, classical dynamics is a rough image of dynamics in the prespace Ω.

B. Quantum mechanics and the Hilbert space representation of prespace contexts

By our *contextual interpretation* the wave function has a realist prespace interpretation. A complex amplitude is nothing than an image (induced by the contextual formula of total probability) of a set of fundamental parameters—context. Thus the Hilbert state space H is not less real than the classical real space $\mathbf{R}^3$.

Observables which probability distributions can be found by using the representation by self-adjoint operators in the Hilbert space are called quantum observables. The set of quantum observables is denoted by the symbol $\mathcal{O}_q(H)$. Neither classical statistical nor quantum mechanics can provide knowledge about the probability distribution of an arbitrary preobservable. Nevertheless, the quantum theory gives some information about some preobservables, namely fundamental preobservable b and a and preobservables d belonging to the class $\mathcal{O}_+(a,b)$.

Neither classical nor quantum mechanics are fundamental theories. They could not give information about the pointwise structure of the prespace Ω. But the quantum formalism represents some complexes of physical conditions—domains in the prespace—which are not represented in the classical space or phase space. Of course, the quantum formalism also represents classical position states $x\in X$ by wave functions φ_{B_x} (Hilbert states e_x^b). Classical states $x\in X$ are images of prespace contexts B_x. But the quantum formalism represents also some sets $C\subset\Omega$ which have no classical images (namely, images in X or Π).

Example: In the example of Sec. VI we take the set $C=C_{123}=\{\omega_1,\omega_2,\omega_3\}$. Neither $C\subset B_1$ nor $C\subset B_2$. This prespace domain C can be described neither by the position $x=b_1$ nor $x=b_2$.

The quantum state $\varphi_C \in S \subset H$ representing this domain of the prespace describes the superposition of the two classical states $x = b_1$ and $x = b_2$. Hence a physical system prepared under the complex physical conditions $C = C_{123}$ is (from the classical viewpoint) in the superposition of two different positions.

Finally, we remark that we have investigated only the case of dichotomous random variables. The general case is essentially more complicated from the mathematical viewpoint. In particular, not every double stochastic matrix can be represented as the square of a unitary matrix and so on... . But I think that from the phemenological viewpoint the case of dichotomous observables is the most important; cf., e.g., Mackey[14] and the general quantum logic approach.

(Received 17 October 2003; accepted 10 November 2003)

We derive a bound on the total number of negative energy bound states in a potential in two spatial dimensions by using an adaptation of the Schwinger method to derive the Birman–Schwinger bound in three dimensions. Specifically, counting the number of bound states in a potential gV for $g=1$ is replaced by counting the number of g_i's for which zero energy bound states exist, and then the kernel of the integral equation for the zero-energy wave functon is symmetrized. One of the keys of the solution is the replacement of an inhomogeneous integral equation by a homogeneous integral equation. © *2004 American Institute of Physics.*

I. INTRODUCTION

In a previous paper,[1] Chadan, Khuri, and the present authors obtained a bound on the number of bound states in a two-dimensional central potential. This bound has the merit that, for a potential gV, the coupling constant dependence for large g is optimal, i.e., the same as the one of the semiclassical estimate.[2] Previous work on the subject was done by Newton[3] and Seto.[4] We also obtained a bound for the noncentral case, but only by using a rather brutal method which consists of replacing the potential by a central potential which is defined, after choosing a certain origin, by

$$V_c(r)=\mathrm{Inf}\, V(\vec{x}),\qquad |\vec{x}|=r. \tag{1}$$

Because of the monotonicity of the energy levels with respect to the potential, putting V_c in our formulas will give a bound for the potential V. However, for potentials with singularities outside the given origin, this may lead to no bound at all. Our attention has been attracted by the fact that in condensed matter physics problems exist, where counting the bound states on a surface may be useful,[5] but where it is very unlikely that the potential will be central, even approximately.

In the present paper, we obtain a bound on the number of bound states in a noncentral two-dimensional potential, using an adaptation of the Schwinger method to derive the Birman–Schwinger bound[6] in the three-dimensional case. The condition under which we obtain a bound is

$$\int\int \mathrm{d}^2x\,\mathrm{d}^2y\,|V(x)|(\ln|x-y|)^2|V(y)|<\infty. \tag{2}$$

This condition is *nonlinear*, just like that of Birman and Schwinger, but we show in the Appendix that it follows from the linear conditions

a)Electronic mail: andre.martin@cern.ch

$$\int d^2x\,(\ln(2+|x|))^2\,|V(x)|<\infty,$$
$$\int d^2x\,V_R(|\vec{x}|)\,\ln^-|x|<\infty, \tag{3}$$

where V_R is the circular decreasing rearrangement of $|V|$ (for the definition of V_R, see the Appendix).

Condition (2) has already been proposed by Sabatier.[7] Condition (3) appears in a forthcoming work by Khuri *et al.* dealing with the scattering problem. It has the advantage of showing more clearly what kind of behavior the potential is allowed to have at short and large distances.

The strategy of Schwinger consists of counting the number of zero-energy bound states for a potential gV for $0<g<1$ instead of the actual number of negative energy bound states for $g=1$. In three dimensions these two numbers are equal. Indeed, let $0<g_1,g_2,\ldots,g_n<1$ be the coupling constants for which we have zero-energy bound states. Each g_i is the origin of a bound state trajectory in the $E-g$ plane, $E_i(g)$, with $E_i(g_i)=0$. These trajectories are monotonous decreasing:

$$\frac{dE_i}{dg}=\int V\psi^2 d^nx, \tag{4}$$

by the Feynman–Hellmann theorem, but

$$g_i\int V\psi^2 d^nx=E-\int |\nabla\psi|^2\,d^nx<0 \quad \text{for } E<0. \tag{5}$$

This shows that the number of negative-energy bound states is exactly the same as the number of g_i's<1. At the crossing of any pair of trajectories there is no problem because of their monotonicity.

The same result holds in two dimensions with one modification: any attractive potential (i.e., $\int d^2x\,V<0$) has a bound state for arbitrarily small g, with a binding energy going to zero for $g\to 0$ like $-\exp-(C/g)$.[1] At $E=0$ it disappears and is not included in Schwinger's accounting, so we have to add one unit.

Since we only want a *bound* on the number of bound states, we can always replace $V(y)$ by $-V^-(y)$:

$$V^-(y)=0 \quad \text{for } V>0,$$
$$V^-(y)=-V(y) \quad \text{for } V\leqslant 0. \tag{6}$$

Using $-|V(y)|$ instead of $-V^-(y)$ gives a more crude bound.

It can be shown that the general solution of the zero-energy Schrödinger equation

$$-\Delta\psi-V^-\psi=0 \tag{7}$$

in the equivalent integral form

$$\psi(x)=C-\frac{1}{2\pi}\int \ln k_0|x-y|V^-(y)\psi(y)d^2y \tag{8}$$

has a general asymptotic behavior for $|x|\to\infty$,

$$\psi(x)-C\sim-\ln k_0|x|\;\frac{1}{2\pi}\int V^-(y)\psi(y)d^2y+o(1) \tag{9}$$

under the condition

$$\int V^-(y)\,(\ln(2+|y|))^2\,\mathrm{d}^2y<\infty, \tag{10}$$

which follows from condition (1) as shown in the Appendix. In fact, the proof is easier if one assumes that the potential is lower bounded for large x. One can always cut off the potential and use a limiting procedure at the end.

Zero-energy bound states are characterized by the fact that ψ is *bounded*. Hence we get the necessary condition:

$$\int V^-(y)\psi(y)\mathrm{d}^2y=0. \tag{11}$$

Now we have two possibilities:

I. At infinity $\psi(\vec{x})\to 0$ and hence $C=0$ and those bound state wave functions satisfy a *homogeneous* integral equation

$$\psi_i(x)=-\frac{g_i}{2\pi}\int \mathrm{d}^2y\,\ln(k_0|x-y|)\,V^-(y)\psi_i(y) \tag{12}$$

[notice that the scale factor k_0 disappears because of condition (11)].

This is what happens in the case of a central potential for a nonzero azimuthal angular momentum m.

II. At infinity, $\psi(\vec{x})\to C$, with $C\neq 0$. In this case, the bound state wave functions satisfy an inhomogeneous integral equation. This case has been described in Ref. 8, where it is shown that for a central potential in two dimensions, the $m=0$ phase shift has the universal behavior

$$\delta(k)\sim\frac{\pi}{2\ln k}\quad \text{for } k\to 0, \tag{13}$$

except if there is a zero-energy bound state of type II. Then

$$\delta(k)\ln k\to 0. \tag{14}$$

In Ref. 8, a much stronger result is stated. This much stronger result, however, holds only for a very rapidly decreasing potential.

II. COUNTING BOUND STATES IN CASE I

Following Schwinger, we symmetrize the kernel of the integral equation:

$$\phi_i(x)=g_i\int K(x,y)\,\phi_i(y)\mathrm{d}^2y \tag{15}$$

with

$$\begin{aligned}\phi_i(x)&=\sqrt{V^-(x)}\;\;\psi_i(x),\\ K(x,y)&=-\frac{1}{2\pi}\sqrt{V^-(x)}\,\ln k_0|x-y|\;\;\sqrt{V^-(y)}.\end{aligned} \tag{16}$$

If $V^-(x)$ vanishes in some regions, it seems impossible to go back from ϕ_i to ψ_i. However, this can be remedied by defining

$$V_\epsilon^-(x)=V^-(x)+\epsilon\exp-\mu|x|. \tag{17}$$

Since the bounds we shall get are continuous in V, we can take the limit $\epsilon\to 0$ at the end.

K can be written as

$$K=\Sigma\frac{1}{g_i}|\phi_i\rangle\langle\phi_i|+R. \tag{18}$$

R is a sum over states which do not satisfy (11). The ϕ_i's in themselves do not form a complete set. If we define a by

$$a(x)=\frac{\sqrt{V^-(x)}}{\sqrt{\int V^-(y)\mathrm{d}^2y}} \tag{19}$$

we have

$$\langle a|\phi_i\rangle=0 \tag{20}$$

from property (11), and naturally $\langle a|a\rangle=1$.

If we define $\widehat{\mathrm{Tr}}$, a trace restricted to the ϕ_i's, we have

$$\widehat{\mathrm{Tr}}\,K=\Sigma\frac{1}{g_i}>\sum_{g_i\leqslant 1}\frac{1}{g_i}>N_\mathrm{I},$$

N_I being the number of bound states of type I. However, this trace turns out to be divergent because of the logarithmic singularity of the kernel (the same happened in Schwinger's original work!), and we follow Schwinger to iterate the integral equation (15):

$$\phi_i(x)=g_i^2\int K(x,y)K(y,z)\,\phi_i(z)\mathrm{d}^2y\mathrm{d}^2z$$

and then

$$\widehat{\mathrm{Tr}}\,K^2=\Sigma\frac{1}{g_i^2}>N_\mathrm{I}. \tag{21}$$

Forgetting the caret on the trace still gives a bound because K^2 is a positive operator (contrary to K!), but this bound depends on the scale parameter k_0 entering in the logarithm. Among the missing states in $\widehat{\mathrm{Tr}}$ is the state $|a\rangle$, orthogonal to the ϕ_i's, and this one should be removed from the complete trace. In this way, we get

$$N_\mathrm{I}<\mathrm{Tr}\,K^2-\langle a|K^2|a\rangle,$$

or more explicitly

$$N_\mathrm{I}<\frac{1}{(2\pi)^2}\int V^-(x)(\ln k_0|x-y|)^2V^-(y)\mathrm{d}^2x\mathrm{d}^2y-\frac{1}{(2\pi)^2}$$
$$\times\frac{1}{\int V^-(x)\mathrm{d}^2x}\int V^-(x)(\ln k_0|x-z|)\quad V^-(z)(\ln k_0|z-y|)V^-(y)\,\mathrm{d}^2x\mathrm{d}^2y\mathrm{d}^2z. \tag{22}$$

It is visible that the second term is negative as we announced.

Rewriting N_{I} as

$$\frac{1}{(2\pi)^2}\frac{1}{\int V^-(z)\mathrm{d}^2z}\int \mathrm{d}^2x\mathrm{d}^2y\mathrm{d}^2z\, V^-(x)V^-(y)V^-(z)\ \ [(\ln k_0|x-y|)^2-\ln k_0|x-z|\ln k_0|y-z|],$$

we see that (22) is manifestly *independent* of the scale factor k_0.

III. COUNTING BOUND STATES IN CASE II

At first it would seem that Schwinger's technique will not work because, in Eq. (8), the constant is not zero and therefore we deal with an *inhomogeneous* integral equation which can be written, after the same changes of variables as in Sec. II, given by (16) and (19):

$$\phi_i = C_i a + g_i K\phi_i, \tag{23}$$

with, again,

$$\langle a|\phi_i\rangle = 0, \quad \langle a|a\rangle = 1. \tag{24}$$

Equation (24) is precisely the key property which will make it possible to replace (23) by a *homogeneous equation*.

Again, the ϕ_i's corresponding to different g_i's are orthogonal because

$$\langle\phi_i|\phi_j\rangle = C_j\langle\phi_i|a\rangle + g_j\langle\phi_i|K\phi_j\rangle$$

$$= C_i\langle\phi_j|a\rangle + g_i\langle\phi_j|K\phi_i\rangle.$$

Hence, from (24):

$$\left(\frac{1}{g_i}-\frac{1}{g_j}\right)\langle\phi_i|\phi_j\rangle = 0. \tag{25}$$

Let us call $\mathcal{S}$ the Hilbert space associated with the integral equation (23), and construct a new Hilbert space by removing the element a:

$$\mathcal{S} = \mathcal{S}' \oplus \{a\}. \tag{26}$$

We want to define a new operator K' acting in $\mathcal{S}'$. Let

$$b = Ka. \tag{27}$$

Notice that

$$\langle b|\phi_i\rangle = -\frac{C_i}{g_i}\langle a|a\rangle = -\frac{C_i}{g_i}. \tag{28}$$

We try

$$K' = K - |b\rangle\langle a| - |a\rangle\langle b| + C|a\rangle\langle a|$$

where C will be chosen so that

$$K'a = 0. \tag{29}$$

We have

$$K'|a\rangle = |b\rangle - |b\rangle - \langle b|a\rangle|a\rangle + C|a\rangle,$$

and hence we take

$$C = \langle b|a\rangle = \langle a|K|a\rangle. \tag{30}$$

K' is Hermitian like K, and we get

$$g_i K'|\phi_i\rangle = g_i|K|\phi_i\rangle - g_i\langle b|\phi_i\rangle|a\rangle$$

$$= g_i|K|\phi_i\rangle + C_i|a\rangle.$$

Hence

$$g_i K'|\phi_i\rangle = |\phi_i\rangle, \tag{31}$$

which is *homogeneous*.

To get a bound on the number of bound states of type II, we have to get a bound on trace K'^2 (not surprisingly, trace K' is divergent). It is a lengthy but straightforward exercise to calculate that trace, which gives

$$N_{\mathrm{II}} < \mathrm{tr}\, K^2 - 2\langle a|K^2|a\rangle + (\langle a|K|a\rangle)^2. \tag{32}$$

The last two terms give an overall negative contribution. The first term is the same as the one appearing in N_{I}. It is easy to see that the right-hand side of (32) is independent of the scale parameter k_0 entering into the kernel K. Finally, let us notice that the treatment of case II *contains* case I because, in the argument, it has never been said that $C_i \neq 0$. Equation (31) holds irrespective of whether $C_i = 0$ or $C_i \neq 0$. Notice that the bound on N_{I} is larger than the bound on N_{II}. Therefore the bound on N_{I} becomes completely obsolete.

IV. CONCLUDING REMARKS

If we include the bound state with evanescent energy for zero coupling constant, we get the bound

$$N < 1 + \mathrm{tr}\, K^2 - 2\langle a|K^2|a\rangle + (\langle a|K|a\rangle)^2.$$

Dropping the last two terms still gives a scale-dependent bound—which can be minimized with respect to the scale—which precisely appears in condition (2), itself following from the linear condition (3) as shown in the Appendix.

Conditions (2) and (3) both allow a potential behaving like

$$\frac{1}{r^2(\ln r)^{3+\epsilon}}$$

at infinity, with local singularities not worse than

$$-\frac{1}{|r-r_0|^2(|\ln|r-r_0||)^{2+\epsilon}},$$

ϵ positive, arbitrarily small. Both conditions are violated for $\epsilon < 0$. However, we shall see in the Appendix that (2) is definitely weaker than (3).

Our bound has the merit of being valid for the noncentral case, which, as we said in Sec. I, is important for solid-state physics. However, for a potential gV, it behaves like g^2 for large g, while in Ref. 1, in the central case, we get a bound behaving like g. In Ref. 1 we make a conjecture

which is very far from being proved, but clever mathematical physicists might prove it or something similar. The present work should be considered only as a first step which could possibly give reasonable results for not too large g.

Note added in proof. Our attention has been drawn to the related work by Stoiciu.[10] In this work, which uses a different method, the same integral (2) appears to control the number of bound states. However, there are no counterterms like in Eq. (32), and, as a consequence, the result is scale dependent.

ACKNOWLEDGMENTS

T.T.W. was supported in part by the U.S. Department of Energy under Grant No. DE-FG02-84-ER40158. We are grateful to P. Sabatier for suggesting the use of the nonlinear expression defined by (2) for potentials in two dimensions. Our work was stimulated by discussions with our colleagues K. Chadan and N.N. Khuri. T.T.W. would also like to thank the CERN Theoretical Physics Division for hospitality. This paper was put in final form while A.M. was visiting the ''Institut des Hautes Etudes Scientifiques,'' whose hospitality is acknowledged.

APPENDIX: COMPARISON OF CONDITIONS (2) AND (3)

Condition (2) is

$$I=\int \mathrm{d}^2x\mathrm{d}^2y\, V^-(x)(\ln|x-y|)^2\, V^-(y)<\infty. \tag{A1}$$

Condition (3) is a set of two conditions:

$$\int \mathrm{d}^2x\,(\ln(2+|x|))^2\, V^-(x)<\infty, \tag{A2}$$

$$\int \mathrm{d}^2x\, V_R(|x|)\ln^-(|x|)<\infty. \tag{A3}$$

In (A3) we use

$$-\ln^-(|x|)=\begin{cases}0 & \text{if } |x|>1\\ -\ln|x| & \text{if } |x|<1.\end{cases}$$

$-V_R(|x|)$, the circular decreasing rearrangement of $V^-(x)$. Since this notion is not very well known among physicists, let us remind the reader that $V_R(|x|)$ is a decreasing function of $|x|$, such that

$$\mu(V_R(|x|)>A)=\mu(V^-(x)>A),\ \forall A,$$

where μ is the Lebesque measure. In more familiar terms, the rearranged Mont Blanc would be a mountain with axial symmetry, with a single peak, such that the surface between the level lines would be the same as the surface between the level lines of the original Mont Blanc (rather awfully dull!).

We shall prove first that the convergence of I in (A1) follows from the convergence of (A2) and (A3). More exactly, we shall get an explicit bound on (A1) in terms of (A2) and (A3). We write

$$I=I_+ + I_- \tag{A4}$$

with

$$I_+ = \int \mathrm{d}^2x \mathrm{d}^2y\, V^-(x)\, (\ln^+|x-y|)^2\, V^-(y), \tag{A5}$$

$$I_- = \int \mathrm{d}^2x \mathrm{d}^2y\, V^-(x)\, (\ln^-|x-y|)^2\, V^-(y). \tag{A6}$$

$\ln^-$ has already been defined. $\ln^+(a)=\ln a$ for $a\geqslant 1, =0$ for $a<1$. It is elementary to get a bound on I_+ from (A2) only. Indeed,

$$0<\ln^+|x-y|<\ln^+(|x|+|y|)<\ln(2+|x|)+\ln(2+|y|)$$

and thus

$$(\ln^+|x-y|)^2<2[(\ln 2+|x|)^2+(\ln(2+|y|))^2]. \tag{A7}$$

Hence

$$I_+<4\int \mathrm{d}^2x\, V^-(x) \quad \int \mathrm{d}^2y\, V^-(y)\, (\ln(2+|y|))^2. \tag{A8}$$

The convergence of the right-hand side of (A8) follows directly from (A2).

Concerning I_-, we use a rearrangement inequality due to Luttinger and Friedberg,[9] which says

$$\int\int \; A(x)\, B(|x-y|)\, C(y)\mathrm{d}^2x\mathrm{d}^2y \leqslant \int \; A_R(|x|)\, B_R(|x-y|)\, C_R(|y|)\, \mathrm{d}^2x\mathrm{d}^2y, \tag{A9}$$

where A,B,C are non-negative functions and A_R, B_R, C_R are their decreasing rearrangements. Since $\ln^-$ and $(\ln^-)^2$ are decreasing functions of their argument they are their own rearrangement. Hence

$$I_-<\int \; \mathrm{d}^2x\mathrm{d}^2y \quad V_R(|x|)(\ln^-(|x-y|))^2\, V_R(|y|). \tag{A10}$$

In (A10), we can carry out first the angular integration, the angle $(\vec{x},\vec{y})$ appearing only in $\ln^-$. However, to be able to do that easily we have to sacrifice some information, i.e., use $(\ln^-|x-y|)^2\leqslant(\ln(|x-y|))^2$. We have to calculate

$$\int \; \frac{\mathrm{d}\theta}{2\pi}(\ln(|x|^2+|y|^2-2|x||y|\cos\theta))^2.$$

We have

$$\ln(|x|^2+|y|^2-2|x||y|\cos\theta)=\ln(|x|-|y|e^{i\theta})+\ln(|x|-|y|e^{-i\theta}).$$

Assume $|x|>|y|$. Then we get

$$\ln(|x|^2+|y|^2-2|x||y|\cos\theta)=2\left[\ln|x|-\Sigma\left(\frac{|y|}{|x|}\right)^n\frac{\cos n\theta}{n}\right]. \tag{A11}$$

Hence, if $|x|>|y|$, using the orthogonality of the $\cos n\theta$:

$$\int \; \frac{\mathrm{d}\theta}{2\pi}(\ln(|x|^2+|y|^2-2|x||y|\cos\theta))^2=4(\ln|x|)^2+2\sum_{n=1}^{\infty}\left(\frac{|y|}{|x|}\right)^{2n}\frac{1}{n^2}.$$

We see a dilogarithm, or Spence function, appearing on the right-hand side. However, we only need to notice that

$$\sup_{|y|\leqslant|x|} \int \frac{\mathrm{d}\theta}{2\pi}(\ln|x|^2+|y|^2-2|y||x|\cos\theta)^2=4(\ln|x|)^2+2\sum_{n=1}^{\infty}\frac{1}{n^2}=4(\ln|x|)^2+\frac{\pi^2}{3}. \tag{A12}$$

In this way we get

$$I_-<(2\pi)^2\times 2\int_{|x|>|y|}|x|\mathrm{d}|x|\,|y|\mathrm{d}|y|\,V_R(|x|)V_R(|y|)\ \left[4(\ln|x|)^2+\frac{\pi^2}{3}\right].$$

Again, we split the integral into

$$\begin{aligned}&32\pi^2\int_{|x|>|y|}|x|\mathrm{d}|x|\,|y|\mathrm{d}|y|\,V_R(|x|)V_R(|y|)(\ln^-|x|)^2\\&\quad+32\pi^2\int_{|x|>|y|}|x|\mathrm{d}|x|\,|y|\mathrm{d}|y|\,V_R(|x|)V_R(|y|)(\ln^+|x|)^2+\frac{4\pi^4}{3}\left[\int|x|\mathrm{d}|x|\,V_R(|x|)\right]^2.\end{aligned} \tag{A13}$$

In the first term of (A13) we can replace $(\ln^-(|x|))^2$ by $\ln^-|x|\ln^-|y|$, since $|x|>|y|$ and since $\ln^-$ is decreasing.

In the second term, we can drop the restriction $|x|>|y|$ and notice that

$$\int \mathrm{d}^2x V_R(|x|)\,(\ln^+(|x|))^2<\int \mathrm{d}^2x V_-(x)(\ln^+(|x|))^2.$$

Indeed, $\int \mathrm{d}^2x A_R(x)\phi(|x|)$, where $\phi(|x|)$ is *increasing*, is less than $\int \mathrm{d}^2x\,A(x)\,\phi(|x|)$. Suppose that $\phi(|x|)\to L$. Then

$$\int \mathrm{d}^2x A_R(x)\phi(|x|)=\int \mathrm{d}^2x A_R(x)L-\int \mathrm{d}^2x A_R(x)(L-\phi(|x|)).$$

$L-\phi(|x|)$ is its own decreasing rearrangement and following the well-known properties

$$\int A_R B_R \mathrm{d}^2x\geqslant\int A(x)B(x)\mathrm{d}^2x$$

and

$$\int A_R(|x|)\mathrm{d}^2x=\int A(x)\mathrm{d}^2x,$$

we get the desired property. If L is infinite, we can use a limiting procedure. Finally, we get

$$\begin{aligned}I_-<16\pi^2\left[\int \mathrm{d}^2x\,V_R(|x|)\ln^-\left|x\right|\right]^2+32\pi^2\int \mathrm{d}^2x\,V_-(x)\int \mathrm{d}^2y\,V_-(y)(\ln(2+|y|))^2\\+\frac{4\pi^4}{3}\left[\int \mathrm{d}^2x\,V_-(x)\right]^2.\end{aligned} \tag{A14}$$

From (A2) and (A3) we see that I_- is bounded. This concludes the proof.

One question is: can we go in the opposite direction? Assume that we know that (A1) holds. There exists certainly a region $|x-x_0|<R$ where $\mathrm{Inf}\, V^- = m > 0$. If such a region did not exist, V^- would be zero almost everywhere! So

$$I > \pi R^2 m \int_{|x|>|x_0|+R+2} V^-(x) \ln[2+|x|]^2 \mathrm{d}^2x. \tag{A15}$$

Now we choose $y_0 > 4+|x_0|+R+2$ and R such that

$$\mathrm{Inf}_{|y-y_0|<R'}\, V_-(y) = m' > 0,$$

then

$$I > \pi R'^2 m' \int_{|x|<|x_0|+R+2} V^-(x)(\ln(4-R'))^2 \mathrm{d}^2x. \tag{A16}$$

This proves that the convergence of (A1) implies the convergence of (A2).

It is not possible to deduce (A3) from (A1) because (A3) involves V_R and (A1) does not. However, in practice the conditions are very similar. Nevertheless, the following example shows that (A3) is stronger than (A1), even for a potential which does not need rearrangement: take the central potential

$$V(|x|) = \begin{cases} -\dfrac{1}{|x|^2 |\ln x|^2 (\ln|\ln|x||)^\gamma} & \text{for } |x| < \dfrac{1}{2e} \\ 0 \quad \text{for } |x| \geqslant \dfrac{1}{2e}. \end{cases} \tag{A17}$$

For $\gamma \leqslant \frac{1}{2}$ (A1) and (A3) are divergent, for $\frac{1}{2} < \gamma \leqslant 1$ (A1) is convergent and (A3) is divergent, for $\gamma > 1$ (A1) and (A3) are convergent.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 45, NUMBER 3 MARCH 2004

Pseudounitary operators and pseudounitary quantum dynamics

Ali Mostafazadeh[a)]
Department of Mathematics, Koç University, Rumelifeneri Yolu, 34450 Sariyer, Istanbul, Turkey

(Received 15 May 2003; accepted 15 December 2003)

We consider pseudounitary quantum systems and discuss various properties of pseudounitary operators. In particular we prove a characterization theorem for block-diagonalizable pseudounitary operators with finite-dimensional diagonal blocks. Furthermore, we show that every pseudounitary matrix is the exponential of $i=\sqrt{-1}$ times a pseudo-Hermitian matrix, and determine the structure of the Lie groups consisting of pseudounitary matrices. In particular, we present a thorough treatment of 2×2 pseudounitary matrices and discuss an example of a quantum system with a 2×2 pseudounitary dynamical group. As other applications of our general results we give a proof of the spectral theorem for symplectic transformations of classical mechanics, demonstrate the coincidence of the symplectic group $\mathrm{Sp}(2n)$ with the real subgroup of a matrix group that is isomorphic to the pseudounitary group $\mathrm{U}(n,n)$, and elaborate on an approach to second quantization that makes use of the underlying pseudounitary dynamical groups. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1646448]

I. INTRODUCTION

For the past 2 years we have witnessed a growing interest in pseudo-Hermitian Hamiltonians.[1–13] Initially, the concept of a pseudo-Hermitian operator was developed to describe the mathematical structure of (the possibly nonunitary) PT-symmetric quantum systems.[1,2] Then it became clear that any diagonalizable Hamiltonian that admitted a symmetry generated by an invertible antilinear operator was necessarily pseudo-Hermitian.[3,9] The intriguing spectral properties of pseudo-Hermitian Hamiltonians generalize to the class of block-diagonalizable Hamiltonians with finite-dimensional blocks,[6] so does the connection with antilinear symmetries.[10] Among the most important outcomes of the study of pseudo-Hermitian Hamiltonians is the recent solution of the old problem of constructing invariant positive–definite inner products on the solution space of the Klein–Gordon-type equations.[14,15]

A quantum system with a (time-independent) pseudo-Hermitian Hamiltonian has necessarily a pseudounitary evolution. Pseudounitary quantum systems with a two-dimensional Hilbert space provide the simplest nontrivial examples of such systems. As shown in Ref. 14, a classical simple harmonic oscillator is equivalent to a pseudounitary quantum system with a two-dimensional Hilbert space. Recently Ahmed and Jain[11,12] and Ahmed[13] have considered the application of certain 2×2 pseudo-Hermitian matrices in statistical mechanics and elaborated on the fact that they form a Lie algebra.

The purpose of this paper is threefold. First, we use the method of Ref. 6 to obtain a characterization of the block-diagonalizable pseudounitary operators having finite-dimensional diagonal blocks. Next, we confine our attention to pseudounitary matrices and show that they are obtained by exponentiating pseudo-Hermitian matrices. This is a nontrivial result, because, for a fixed η, not every η-pseudounitary matrix is the exponential of $i=\sqrt{-1}$ times an η-pseudo-Hermitian matrix. Finally, we emphasize that unlike the set of η-pseudounitary operators (with a fixed η), the

a)Electronic mail: amostafazadeh@ku.edu.tr

set of all pseudounitary operators does not form a group. If the Hilbert space in which these operators act is finite dimensional, then the group of η-pseudounitary operators is isomorphic to one of the groups $\mathrm{U}(n)$ or $\mathrm{U}(n,m)$ for some $m,n\in\mathbb{Z}^+$. For example, the Lie algebra of the pseudounitary matrices constructed in Ref. 11 is isomorphic to u(1,1). This follows from the fact that the corresponding inner product is indefinite; there is no need to go through the calculation of the structure constants as done in Ref. 11.

The paper is organized as follows. In Sec. II we present a brief discussion of some basic properties of pseudounitary operators and their relevance to symplectic transformations. In Sec. III we explore block-diagonalizable pseudounitary operators with finite-dimensional diagonal blocks. In Sec. IV we use the results of Secs. II and III to study pseudounitary matrices. In Sec. V we offer a thorough discussion of the 2×2 pseudounitary matrices. In Sec. VI we study an application of our general results for a quantum system with a pseudounitary dynamical group and elaborate on the relation between the choice of the dynamical group and the issue of second quantization. Finally, in Sec. VII we provide a survey of our main results and present our concluding remarks.

II. PSEUDO-HERMITIAN AND PSEUDOUNITARY OPERATORS

By definition,[1] a linear operator $H:\mathcal{H}\to\mathcal{H}$ acting in a Hilbert space $\mathcal{H}$ is said to be pseudo-Hermitian if there exists a linear, invertible, Hermitian operator $\eta:\mathcal{H}\to\mathcal{H}$ such that

$$H^\dagger=\eta H\eta^{-1}. \tag{1}$$

For a given pseudo-Hermitian operator H, the operator η satisfying (1) is not unique.[7,14] Each choice of η determines a possibly indefinite inner product (a pseudoinner product) on $\mathcal{H}$, namely,

$$\langle\!\langle\psi,\phi\rangle\!\rangle_\eta:=\langle\psi|\,\eta\phi\rangle, \tag{2}$$

where $\psi,\phi\in\mathcal{H}$, and $\langle\,|\,\rangle$ is the original inner product of $\mathcal{H}$. Conversely, every pseudoinner product on $\mathcal{H}$ has the form (2). As a result, η is sometimes called a metric operator.

If we make a particular choice for η, we say that H is η-pseudo-Hermitian. In this case, it is Hermitian with respect to the inner product $\langle\!\langle\,,\rangle\!\rangle_\eta$. Therefore, the study of η-pseudo-Hermitian operators is equivalent to the study of Hermitian operators in a vector space with an indefinite metric.[16] The application of the latter in quantum physics dates back to the 1940s.[17] See also Refs. 18 and 19. As emphasized in Ref. 19, there is an important distinction between the concept of pseudo-Hermiticity, where one does not fix the inner product and has the freedom of choosing it, and the well-studied notion of η-pseudo-Hermiticity.

We can express the defining condition (1) in the form $H^\#=H$ where $H^\#:=\eta^{-1}H^\dagger\eta$ is the η-pseudoadjoint of H. Using the latter one can also define the notion of an η-pseudounitary operator $U:\mathcal{H}\to\mathcal{H}$ by requiring that U satisfies $U^\#=U^{-1}$.

Definition: A linear invertible operator $U:\mathcal{H}\to\mathcal{H}$ is said to be pseudounitary if there exists a linear, invertible, Hermitian operator $\eta:\mathcal{H}\to\mathcal{H}$ such that U is η-pseudounitary, i.e.,

$$U^\dagger=\eta U^{-1}\eta^{-1}. \tag{3}$$

Similarly to the case of pseudo-Hermitian operators, η is not unique. If we make a choice for η, we say that U is η-pseudounitary. In this case it is not difficult to show that U leaves the pseudoinner product $\langle\!\langle\,,\rangle\!\rangle_\eta$ invariant. This is easily seen by writing (3) in the form

$$U^\dagger\eta U=\eta, \tag{4}$$

and using (2) and (4) to check that

$$\langle\!\langle U\psi,U\phi\rangle\!\rangle_\eta=\langle\!\langle\psi,\phi\rangle\!\rangle_\eta,\quad \forall\,\psi,\phi\in\mathcal{H}. \tag{5}$$

Given an η-pseudo-Hermitian operator H one can construct a one-parameter family of η-pseudounitary operators, namely $U(t)=e^{-itH}$ with $t\in\mathbb{R}$.

Proposition 1: Let $\epsilon\in\mathbb{R}^+$, $t\in(-\epsilon,\epsilon)$, $H:\mathcal{H}\to\mathcal{H}$ be a t-independent linear operator acting in a Hilbert space $\mathcal{H}$, $U(t):=e^{-itH}$, and $\eta:\mathcal{H}\to\mathcal{H}$ be a t-independent Hermitian, invertible, linear operator. Then H is η-pseudo-Hermitian if and only if $U(t)$ is η-pseudounitary for all $t\in(-\epsilon,\epsilon)$.

Proof: Suppose that H is η-pseudo-Hermitian, then a direct application of Eq. (1), $U(t)^\dagger=e^{itH^\dagger}$ and $U(t)^{-1}=e^{itH}$, shows that $U(t)$ satisfies (3), i.e., it is η-pseudounitary. Conversely, let $U(t)$ be η-pseudounitary for all $t\in(-\epsilon,\epsilon)$. Then substituting $U(t)$ for U in Eq. (3), taking the derivative of both sides with respect to t, and setting $t=0$ in the resulting expression, we find that H satisfies (1), i.e., it is η-pseudo-Hermitian. □

Because $U(t)$ may be identified with the evolution operator for a quantum system having H as its Hamiltonian, a quantum system with a time-independent Hamiltonian has a pseudounitary evolution if and only if the Hamiltonian is pseudo-Hermitian.[14]

The one-parameter family $U(t)$ clearly forms an Abelian Lie group under composition. This is indeed a subgroup of the group $\mathcal{U}_\eta(\mathcal{H})$ of all η-pseudounitary operators. The latter forms a group because for any pair U_1, $U_2:\mathcal{H}\to\mathcal{H}$ of η-pseudounitary operators,

$$(U_1^{-1}U_2)^\dagger=U_2^\dagger(U_1^\dagger)^{-1}=\eta U_2^{-1}\eta^{-1}(\eta U_1^{-1}\eta^{-1})^{-1}=\eta U_2^{-1}\eta^{-1}\eta U_1\eta^{-1}=\eta(U_1^{-1}U_2)^{-1}\eta^{-1}.$$

Therefore $\mathcal{U}_\eta(\mathcal{H})$ is a subgroup of the group $\mathrm{GL}(\mathcal{H})$ of all invertible linear transformations acting in $\mathcal{H}$. In Ref. 11, the authors considered this group for the case $\mathcal{H}=\mathbb{C}^n$. They call it the pseudounitary group. This terminology is rather misleading as it does not reflect the important fact that a particular choice for η has been made. In fact, it is not true that the product of any two pseudounitary operators V_1 and V_2 is pseudounitary. This is because they may belong to $\mathcal{U}_\eta(\mathcal{H})$ with different η. This observation calls for a more careful study of the structure of the set $\mathcal{U}(\mathcal{H})$ $:=\cup_\eta\mathcal{U}_\eta(\mathcal{H})$ of all pseudounitary operators acting in $\mathcal{H}$.

In the remainder of this section we discuss two simple properties of pseudounitary operators that will be of future use.

Proposition 2: Let η_1 be a Hermitian, invertible, linear operator acting in a Hilbert space $\mathcal{H}$, $A:\mathcal{H}\to\mathcal{H}$, $U_1:\mathcal{H}\to\mathcal{H}$ be invertible linear operators, $U_2:=A^{-1}U_1A$ and $\eta_2:=A^\dagger\eta_1A$. Then U_1 is η_1-pseudounitary if and only if U_2 is η_2-pseudo-Hermitian.

Proof: First note that the defining condition (3) may be written in the form $U\eta^{-1}U^\dagger\eta=I$, where I is the identity operator. Then a simple calculation shows that

$$U_2\eta_2^{-1}U_2^\dagger\eta_2=A^{-1}U_1AA^{-1}\eta_1^{-1}A^{-1\dagger}A^\dagger U_1A^{-1\dagger}A^\dagger\eta_1A=A^{-1}(U_1\eta_1^{-1}U_1^\dagger\eta_1)A.$$

Therefore, $U_1\eta_1^{-1}U_1^\dagger\eta_1=I$ if and only if $U_2\eta_2^{-1}U_2^\dagger\eta_2=I$. □

Proposition 3: Let $U_1:\mathcal{H}\to\mathcal{H}$ be a pseudounitary operator acting in a Hilbert space $\mathcal{H}$ and u be an eigenvalue of U. Then $1/u^*$ is also an eigenvalue of U. In other words, eigenvalues of U are either unimodular ($|u|=1$) or they come in inverse-complex-conjugate pairs $(u,1/u^*)$.

Proof: Let $|u\rangle$ be an eigenvector of U with eigenvalue u, i.e., $U|u\rangle=u|u\rangle$. Acting out both sides of (4) on $u^{-1}|u\rangle$, we find $U^\dagger\eta|u\rangle=u^{-1}\eta|u\rangle$. Because η is invertible, $\eta|u\rangle\neq0$. This in turn means that u^{-1} is an eigenvalue of $U^\dagger$. But the eigenvalues of $U^\dagger$ are complex conjugates of those of U. Therefore, $u^{-1*}=1/u^*$ is an eigenvalue of U. If $u=1/u^*$, u is unimodular; otherwise $(u,1/u^*)$ is a pair of distinct inverse-complex-conjugate eigenvalues. □

As a straightforward application of Proposition 3, consider the case that $\mathcal{H}=\mathbb{C}^{2m}$, for some $m\in\mathbb{Z}^+$, and endow $\mathbb{C}^{2m}$ with the metric operator

$$\eta_J:=iJ, \tag{6}$$

where $J:\mathbb{C}^{2m}\to\mathbb{C}^{2m}$ has the following matrix representation in the standard orthonormal basis of $\mathbb{C}^{2m}$:

$$J=\begin{pmatrix}0_m & -1_m\\ 1_m & 0_m\end{pmatrix}. \tag{7}$$

Here 0_m and 1_m are, respectively, the $m\times m$ zero and identity matrices, respectively. According to (6) and (7), the operator η_J has a Hermitian matrix representation in an orthonormal basis, and $\eta_J^2=1$. Hence η_J is indeed a Hermitian invertible (metric) operator acting in $\mathbb{C}^{2m}$.

Next, observe that the operator J restricted to $\mathbb{R}^{2m}$ yields the usual symplectic form[20] on $\mathbb{R}^{2m}$. The associated symplectic transformations coincide with real $2m\times 2m$ matrices S satisfying[20]

$$S^tJS=J, \tag{8}$$

where S^t stands for the transpose of S. We can view the symplectic transformations S as linear operators acting in $\mathbb{C}^{2p}$. Then the condition that they admit real matrix representations (in the standard basis) takes the form

$$TST=S, \tag{9}$$

where T is the (time-reversal) operator defined by $\forall\vec{z}\in\mathbb{C}^{2p}$, $T\vec{z}=\vec{z}^*$. Making use of (6) and the fact that $T^{-1}=T$ and $S^\dagger=S^t$, we can, respectively, express the defining relations (8) and (9) of the symplectic transformations S as

$$S^\dagger\eta_JS=\eta_J, \tag{10}$$

$$[S,T]=0. \tag{11}$$

Because T is an antilinear Hermitian invertible operator, according to Theorem 2 of Ref. 3, Eq. (11) implies that S is a pseudo-Hermitian operator. Furthermore, Eq. (10) means that S is in addition a pseudounitary operator.

In view of Proposition 3 and the spectral characterization theorem for pseudo-Hermitian operators (Ref. 1, Theorem 2), the fact that symplectic transformations are both pseudo-Hermitian and pseudounitary leads to the following well-known spectral theorem for symplectic transformations.[20]

Theorem 1: Let λ be an eigenvalue of a symplectic transformation S, then so are λ^*, $1/\lambda$, and $1/\lambda^*$.

Proof: Because S is pseudounitary $1/\lambda^*$ is an eigenvalue. Because it is pseudo-Hermitian λ^* and $(1/\lambda^*)^*=1/\lambda$ are eigenvalues. □

III. BLOCK-DIAGONALIZABLE PSEUDOUNITARY OPERATORS WITH FINITE-DIMENSIONAL DIAGONAL BLOCKS

Consider an operator $U:\mathcal{H}\to\mathcal{H}$ acting in a Hilbert space $\mathcal{H}$ and having a discrete spectrum. Then U is said to be block diagonalizable with finite-dimensional diagonal blocks[6] if it can be expressed in the form

$$U=\sum_n\sum_{a=1}^{d_n}\left(u_n\sum_{i=1}^{p_{n,a}}|\psi_n,a,i\rangle\langle\phi_n,a,i|+\sum_{i=1}^{p_{n,a}-1}|\psi_n,a,i\rangle\langle\phi_n,a,i+1|\right), \tag{12}$$

where n is the spectral label, u_n are the eigenvalues of U, d_n is the geometric multiplicity of u_n, $a\in\{1,2,...,d_n\}$ is a degeneracy label, $p_{n,a}$ is the dimension of the Jordan block associated with the labels n and a (these are called the Jordan dimensions[6]), and $\{|\psi_n,a,i\rangle,|\phi_n,a,i\rangle\}$ is a complete biorthonormal system satisfying

$$\langle\psi_n,a,i|\phi_m,b,j\rangle=\delta_{mn}\delta_{ab}\delta_{ij},\quad \sum_n\sum_{a=1}^{d_n}\sum_{i=1}^{p_{n,a}}|\psi_n,a,i\rangle\langle\phi_m,a,i|=1. \tag{13}$$

In view of (12) and (13),

$$U|\psi_n,a,1\rangle=u_n|\psi_n,a,1\rangle,\quad U^\dagger|\phi_n,a,p_{n,a}\rangle=u_n^*|\phi_n,a,p_{n,a}\rangle, \tag{14}$$

i.e., $|\psi_n,a,1\rangle$ are the eigenvectors of U and $|\phi_n,a,p_{n,a}\rangle$ are the eigenvectors of $U^\dagger$. Clearly, the eigenvalues of $U^\dagger$ are complex conjugates of those of U, and if U is invertible the eigenvalues u_n do not vanish.

Lemma 1: Let $U:\mathcal{H}\to\mathcal{H}$ be an invertible operator acting in a Hilbert space $\mathcal{H}$ and $z\in\mathbb{C}-\{0\}$. Then for all $\ell\in\mathbb{Z}^+$,

$$\text{kernel}[(U^{-1}-z^{-1})^\ell]=\text{kernel}[(U-z)^\ell]. \tag{15}$$

Proof: This identity follows by induction over ℓ. For $\ell=1$, we have

$$\begin{aligned}|\xi\rangle\in\text{kernel}[U^{-1}-z^{-1}]&\Leftrightarrow(U^{-1}-z^{-1})|\xi\rangle=0\\ &\Leftrightarrow zU(U^{-1}-z^{-1})|\xi\rangle=0\Leftrightarrow(z-U)|\xi\rangle=0\Leftrightarrow|\xi\rangle\in\text{kernel}[U-z],\end{aligned} \tag{16}$$

where we have used the fact that zU is an invertible operator. Relations (16) show that (15) holds for $\ell=1$. Now, suppose (15) holds for some $\ell=k\in\mathbb{Z}^+$. Then

$$\begin{aligned}|\xi\rangle\in\text{kernel}[(U^{-1}-z^{-1})^{k+1}]&\Leftrightarrow(U^{-1}-z^{-1})^k(U^{-1}-z^{-1})|\xi\rangle=0\\ &\Leftrightarrow(U^{-1}-z^{-1})|\xi\rangle\in\text{kernel}[(U^{-1}-z^{-1})^k]\\ &\Leftrightarrow(U^{-1}-z^{-1})|\xi\rangle\in\text{kernel}[(U-z)^k]\\ &\Leftrightarrow(U-z)^k(U^{-1}-z^{-1})|\xi\rangle=0\\ &\Leftrightarrow zU(U-z)^k(U^{-1}-z^{-1})|\xi\rangle=0\\ &\Leftrightarrow(U-z)^k(z-U)|\xi\rangle=0\Leftrightarrow|\xi\rangle\in\text{kernel}[(U-z)^{k+1}].\end{aligned}$$

Therefore, (15) holds for $\ell=k+1$; by induction, it holds for all $\ell\in\mathbb{Z}^+$. □

Theorem 2: Let $U:\mathcal{H}\to\mathcal{H}$ be an operator acting in a Hilbert space $\mathcal{H}$ and having a discrete spectrum. Suppose that U is block diagonalizable with finite-dimensional diagonal blocks so that (12) holds. Then U is pseudounitary if and only if the eigenvalues u_n of U are either unimodular (i.e., $|u_n|=1$) or they come in inverse-complex-conjugate pairs $(u_n,1/u_n^*)$ and that the geometric multiplicity and the Jordan dimensions for the inverse-complex-conjugate eigenvalues coincide.

Proof: Suppose that U is pseudounitary. Then, according to Proposition 3 the eigenvalues of U are either unimodular or they come in inverse-complex-conjugate pairs. Suppose that u_n and $1/u_n^*$ form a pair of distinct inverse-complex-conjugate eigenvalues. In order to show that they have the same geometric multiplicity and Jordan dimensions we prove that for all $\ell\in\mathbb{Z}^+$, $\text{kernel}(U-u_n)^\ell$ and $\text{kernel}(U-1/u_n^*)^\ell$ have the same (finite) dimension. To see this, first note that U and $U^\dagger$ have the same Jordan block structure; in view of (12), for all $\ell\in\mathbb{Z}^+$, $\text{kernel}(U-u_n)^\ell$ and $\text{kernel}(U^\dagger-u_n^*)^\ell$ have the same (finite) dimension. Hence they are isomorphic as vector spaces. Next, we use the fact that η is an invertible operator to establish the isomorphism between $\text{kernel}(U^\dagger-u_n^*)^\ell$ and

$$\begin{aligned}\text{kernel}[\eta^{-1}(U^\dagger-u_n^*)^\ell\eta]=\text{kernel}[(\eta^{-1}U^\dagger\eta-u_n^*)^\ell]&=\text{kernel}[(U^{-1}-u_n^*)^\ell]\\ &=\text{kernel}[(U-1/u_n^*)^\ell].\end{aligned}$$

Here we have made use of the defining relation (3) and the identity (15) of Lemma 1. This completes the proof that for all $\ell\in\mathbb{Z}^+$, $\text{kernel}(U-u_n)^\ell$ is isomorphic to $\text{kernel}(U-1/u_n^*)^\ell$. Therefore, they have the same (finite) dimension.

Next, suppose that U has unimodular and/or inverse-complex-conjugate pairs of eigenvalues with identical geometric multiplicity and Jordan dimensions. Then U may be expressed as

$$U=\sum_{\nu_0}\sum_{a=1}^{d_{\nu_0}}\left(u_{\nu_0}\sum_{i=1}^{p_{\nu_0,a}}|\psi_{\nu_0},a,i\rangle\langle\phi_{\nu_0},a,i|+\sum_{i=1}^{p_{\nu_0,a}-1}|\psi_{\nu_0},a,i\rangle\langle\phi_{\nu_0},a,i+1|\right)$$
$$+\sum_{\nu}\sum_{a=1}^{d_\nu}\left[\sum_{i=1}^{p_{\nu,a}}\left(u_\nu|\psi_{\nu+},a,i\rangle\langle\phi_{\nu+},a,i|+\frac{1}{u_\nu^*}|\psi_{\nu-},a,i\rangle\langle\phi_{\nu-},a,i|\right)\right.$$
$$\left.+\sum_{i=1}^{p_{\nu,a}-1}(|\psi_{\nu+},a,i\rangle\langle\phi_{\nu+},a,i+1|+|\psi_{\nu-},a,i\rangle\langle\phi_{\nu-},a,i+1|)\right], \tag{17}$$

where we have set $n=\nu_0$, $\nu+$, or $\nu-$ depending on whether $|u_n|=1$, $|u_n|>1$, or $|u_n|<1$, respectively, and used ν to denote the common value of $\nu+$ and $\nu-$. In order to show that U, as given by (17), is pseudounitary we construct a Hermitian, invertible, linear operator η satisfying (3) or equivalently (4). Consider the ansatz

$$\eta=\sum_{\nu_0}\sum_{a=1}^{d_{\nu_0}}\sum_{i,j=1}^{p_{\nu_0,a}}z_{\nu_0,a,i,j}|\phi_{\nu_0},a,i\rangle\langle\phi_{\nu_0},a,j|+\sum_{\nu}\sum_{a=1}^{d_\nu}\sum_{i,j=1}^{p_{\nu,a}}(\zeta_{\nu,a,i,j}|\phi_{\nu-},a,j\rangle\langle\phi_{\nu+},a,i|$$
$$+\zeta^*_{\nu,a,i,j}|\phi_{\nu+},a,i\rangle\langle\phi_{\nu-},a,j|), \tag{18}$$

where $z_{\nu_0,a,i,j}$ and $\zeta_{\nu,a,i,j}$ are complex coefficients and

$$z^*_{\nu_0,a,i,j}=z_{\nu_0,a,j,i}. \tag{19}$$

The latter relation ensures that η is Hermitian. Now, impose the condition (4). Substituting (17) and (18) in (4) and using the biorthonormality and completeness relations (13), we find after a quite lengthy calculation that $z_{\nu_0,a,i,j}$ and $\zeta_{\nu,a,i,j}$ are solutions of the following equations for $u=u_{\nu_0}$, $p=p_{\nu_0,a}$ and $u=u_\nu$, $p=p_{\nu,a}$, respectively,

$$x_{1,i}=x_{i,1}=0,\quad \forall i\in\{1,2,...,p-1\}, \tag{20}$$

$$ux_{i-1,j}+u^{-1}x_{i,j-1}+x_{i-1,j-1}=0,\quad \forall i,j\in\{2,...,p\}. \tag{21}$$

It turns out that these equations have the following exact solution:

$$x_{i,j}=\begin{cases}0 & \text{for } i+j\leqslant p,\\ \displaystyle\sum_{k=1}^{i+j-p}\binom{i-k-1}{p-j-1}(-1)^{i-k}u^{p+i-j-k}x_{k,p} & \text{for } j<p<i+j,\end{cases} \tag{22}$$

where for all $r,s\in\mathbb{Z}^+$ with $r\leqslant s$

$$\binom{s}{r}:=\frac{s!}{r!(s-r)!},$$

and $x_{k,p}$ with $k\in\{1,2,...,p\}$ are arbitrary complex numbers. We have obtained the solution (22) by a tedious inspection scheme and checked its validity by direct substitution in (21); it clearly satisfies (20). It is important to note that according to (22), $x_{i,j}$ form a $p\times p$ matrix x of the form

$$x=\begin{pmatrix} 0 & 0 & 0 & \cdots & 0 & 0 & x_{1,p} \\ 0 & 0 & 0 & \cdots & 0 & x_{2,p-1} & x_{2,p} \\ 0 & 0 & 0 & \cdots & x_{3,p-2} & x_{3,p-1} & x_{3,p} \\ \vdots & \vdots & \vdots & \vdots\vdots\vdots & \vdots & \vdots & \vdots \\ 0 & 0 & x_{p-2,3} & \cdots & x_{p-2,p-2} & x_{p-2,p-1} & x_{p-2,p} \\ 0 & x_{p-1,2} & x_{p-1,3} & \cdots & x_{p-1,p-2} & x_{p-1,p-1} & x_{p-1,p} \\ x_{p,1} & x_{p,2} & x_{p,3} & \cdots & x_{p,p-2} & x_{p,p-1} & x_{p,p} \end{pmatrix}. \tag{23}$$

In view of (22) all the entries of x are determined in terms of the entries in the last column. For example, we have

$$x_{i,p-i+1}=(-1)^{i-1}u^{2(i-1)}x_{1,p}, \quad \forall i\in\{1,2,...,p\}. \tag{24}$$

Moreover note that the determinant of x is up to a sign the product of the entries (24). Therefore, x is an invertible matrix provided that $x_{1,p}\neq 0$ and $u\neq 0$. Next, consider the case that u is unimodular and seek for the solutions (22) that make x Hermitian, i.e., find solutions for (20) and (21) subject to the condition

$$x^*_{i,j}=x_{j,i}. \tag{25}$$

Imposing this condition on the solution (22) restricts the choice of the initially free entries, namely $x_{i,p}$. For example, setting $i=p$ and $j=1$ in (22) or alternatively setting $i=p$ in (24), we find $x_{p,1}=(-1)^{p-1}u^{2(p-1)}x_{1,p}$. Now, using (25) which implies $x_{p,1}=x^*_{1,p}$, we find

$$x_{1,p}=\pm\sqrt{(-1)^{p-1}}u^{1-p}\rho, \tag{26}$$

where $\rho=|x_{1,p}|$ is an arbitrary non-negative real number. A similar analysis shows that the condition (25) leads to similar restrictions on the choices of $x_{i,p}$ with $i>1$. But these restrictions do not lead to any contradictions, i.e., (25) can always be satisfied. Indeed there are infinitely many solutions of the form (22) that fulfill (25). In particular, if we choose $|u|=1$ and $\rho\neq 0$, the matrix x is an invertible Hermitian matrix. Setting $u=u_{\nu_0}$, we have a set of solutions $z_{\nu_0,a,i,j}$ of (20) and (21) that respect the condition (19) and that the matrices $z_{\nu_0,a}$ formed out of $z_{\nu_0,a,i,j}$ are invertible. Similarly, setting $u=u_\nu$ we have a set of solutions $\zeta_{\nu,a,i,j}$ of (20) and (21) such that the matrices $\zeta_{\nu,a}$ formed out of $\zeta_{\nu,a,i,j}$ are also invertible. The existence of these solutions is equivalent to the existence of a linear operator η of the form (18) that satisfies (4) and is Hermitian and invertible. The inverse of η is given by

$$\eta^{-1}=\sum_{\nu_0}\sum_{a=1}^{d_{\nu_0}}\sum_{i,j=1}^{p_{\nu_0,a}}\widetilde{z}_{\nu_0,a,i,j}|\psi_{\nu_0},a,i\rangle\langle\psi_{\nu_0},a,j|+\sum_{\nu}\sum_{a=1}^{d_\nu}\sum_{i,j=1}^{p_{\nu,a}}(\widetilde{\zeta}_{\nu,a,i,j}|\psi_{\nu-},a,j\rangle\langle\psi_{\nu+},a,i|$$
$$+\widetilde{\zeta}^*_{\nu,a,i,j}|\psi_{\nu+},a,i\rangle\langle\psi_{\nu-},a,j|), \tag{27}$$

where $\widetilde{z}_{\nu_0,a,i,j}$ are the entries of the matrix $z^{-1}_{\nu_0,a}$, and $\widetilde{\zeta}_{\nu,a,i,j}$ are those of $\zeta^{-1\dagger}_{\nu,a}$. One can check by direct calculation that $\eta^{-1}\eta=1$. This completes the proof of the pseudounitarity of U. □

IV. PSEUDOUNITARY MATRICES

According to Theorem 2, a square matrix U is pseudounitary if its eigenvalues are either unimodular or they come in inverse-complex-pairs and that geometric multiplicity and the Jordan dimensions of the latter are identical. A direct consequence of this observation is the following.

Proposition 4: Every pseudounitary matrix U has a unimodular determinant, i.e., $|\det U|=1$.

Proof: This follows from the fact that in the Jordan canonical form of U the nonunimodular entries come is inverse-complex-conjugate pairs $(u_n, 1/u_n^*)$. Hence their product which yields $\det U$ is unimodular. □

According to this proposition the set $\mathcal{U}(\mathbb{C}^n)$ of all $n\times n$ pseudounitary matrices is a subset of the group

$$\Sigma L(n,\mathbb{C}) := \{g \in \mathrm{GL}(n,\mathbb{C}) \mid \ |\det g| = 1\}, \tag{28}$$

of $n\times n$ matrices with unimodular determinant. We shall call $\Sigma L(n,\mathbb{C})$ the *pseudospecial groups*. As a subset of $\mathrm{GL}(n,\mathbb{C})$, $\Sigma L(n,\mathbb{C})$ is the inverse image of the group $\mathrm{U}(1)$ under the homomorphism $\det:\mathrm{GL}(n,\mathbb{C})\to\mathrm{GL}(1,\mathbb{C})$. Therefore, $\Sigma L(n,\mathbb{C})$ is a subgroup of $\mathrm{GL}(n,C)$. In fact, it is not difficult to show that $\Sigma L(n,\mathbb{C})$ is isomorphic to the product group $\mathrm{U}(1)\times\mathrm{SL}(n,\mathbb{C})$. Note however that not every element of the pseudospecial groups is pseudounitary. For example let g be a 2×2 diagonal matrix with diagonal entries $2i$ and $-i/2$. Clearly, $\det g = 1 \in \mathrm{U}(1)$, so $g \in \Sigma L(2,\mathbb{C})$. But, $(2i)^{-1*} = i/2 \neq -i/2$. Hence the eigenvalues $2i$ and $-i/2$ are not inverse-complex-conjugates, and g is not pseudounitary. In general, $\mathcal{U}(\mathbb{C}^n)$ is a proper subset of $\Sigma L(n,\mathbb{C})$.

Next, consider the group $\mathcal{U}_\eta(\mathbb{C}^n)$ for a fixed Hermitian invertible $n\times n$ matrix η. We recall Sylvester's law of inertia according to which η satisfies

$$\eta = A^\dagger \eta_{p,q} A, \tag{29}$$

where A is some invertible $n\times n$ matrix and $\eta_{p,q}$ is a diagonal matrix of the form

$$\eta_{p,q} = \mathrm{diag}(-1,-1,\ldots,-1,1,1,\ldots,1), \tag{30}$$

which has p negative and $q := n-p$ positive entries.

Proposition 5: Let η be an $n\times n$ Hermitian and invertible matrix. Then the group $\mathcal{U}_\eta(\mathbb{C}^n)$ is isomorphic to the pseudounitary group

$$\mathrm{U}(p,q) := \{g \in \mathrm{GL}(n,\mathbb{C}) \mid g^\dagger \eta_{p,q} g = \eta_{p,q}\} = \mathcal{U}_{\eta_{p,q}}(\mathbb{C}^n),$$

for some $p \in \{0,1,\ldots,n\}$ and $q := n-p$. [Note that $\mathrm{U}(0,n) = \mathrm{U}(n)$.]

Proof: Setting $U_2 = U$, $\eta_2 = \eta$, and $\eta_1 = \eta_{p,q}$ in Proposition 2, we see that $U \in \mathcal{U}_\eta(\mathbb{C}^n)$ if and only if $U_1 := AUA^{-1} \in U(p,q)$. Hence, $\mathcal{U}_\eta(\mathbb{C}^n) = A^{-1}U(p,q)A$. Because the conjugation $i_A:\mathrm{GL}(n,\mathbb{C})\to\mathrm{GL}(n,\mathbb{C})$ defined by $i_A(g) := A^{-1}gA$ is an automorphism of the group $\mathrm{GL}(n,\mathbb{C})$ that maps $\mathcal{U}_\eta(\mathbb{C}^n)$ onto $\mathrm{U}(p,q)$, the subgroups $\mathcal{U}_\eta(\mathbb{C}^n)$ and $\mathrm{U}(p,q)$ are isomorphic. □

According to Proposition 5, the pseudounitary groups $\mathcal{U}_\eta(\mathbb{C}^n)$ are isomorphic to and obtained from the classical groups $\mathrm{U}(p,q)$ [or $\mathrm{U}(n)$] by conjugation; $\mathcal{U}_\eta(\mathbb{C}^n) = A^{-1}U(p,q)A$ for some $A \in \mathrm{GL}(n,\mathbb{C})$. Therefore, the set $\mathcal{U}(\mathbb{C}^n)$ may be viewed as the union of the orbits of the subgroups $\mathrm{U}(p,q)$ under conjugation in $\mathrm{GL}(n,\mathbb{C})$. Obviously these orbits, which according to Proposition 4 lie in the pseudospecial group $\Sigma L(n,\mathbb{C})$, are not disjoint. For example, $e^{iH} \in \mathcal{U}(\mathbb{C}^n)$ belongs to both $\mathcal{U}_{\eta_1}(\mathbb{C}^n)$ and $\mathcal{U}_{\eta_2}(\mathbb{C}^n)$, if H is both η_1- and η_2-pseudo-Hermitian. The latter holds if and only if $\eta_2 = A^\dagger \eta_1 A$ for some $A \in \mathrm{GL}(n,\mathbb{C})$ commuting with H.[7]

Another simple consequence of Proposition 5 is the following.

Corollary: Let $m \in \mathbb{Z}^+$. Then the group $\mathrm{Sp}(2m)$ of symplectic transformations of $\mathbb{R}^{2m}$ is isomorphic to the real subgroup of (a matrix group that is isomorphic to) the pseudounitary group $\mathrm{U}(m,m)$.

Proof: According to the argument given above Theorem 1, $\mathrm{Sp}(2m)$ may be identified with the subgroup of $\mathcal{U}_{\eta_J}(\mathbb{C}^{2m})$ consisting of real matrices. It is not difficult to show that the spectrum of η_J consists of -1 and 1 each with multiplicity m. Hence according to Proposition 5, $\mathcal{U}_{\eta_J}(\mathbb{C}^{2m})$ is isomorphic to $\mathrm{U}(m,m)$, and $\mathrm{Sp}(2m)$ is isomorphic to the real subgroup of $\mathcal{U}_{\eta_J}(\mathbb{C}^{2m})$. □

Note also that according to the argument used in the above proof of Theorem 1 and the spectral characterization theorems for pseudo-Hermitian and pseudounitary operators (i.e., Theorem 1 of Ref. 6 and Theorem 2 above), given an eigenvalue λ of a symplectic transformation $S \in \mathrm{Sp}(2m)$, the eigenvalues λ^*, $1/\lambda$, and $1/\lambda^*$ have the same geometric multiplicity and Jordan

dimensions as λ. This in particular proves the well-known fact that S has a unit determinant. In particular, $\mathrm{Sp}(2m)$ may be identified with the real subgroup of (a matrix group that is isomorphic to) $\mathrm{SU}(m,m)$.

Next, we state and prove the following lemma.

Lemma 2: Let $p\in\mathbb{Z}^+$, $E\in\mathbb{C}$, and h be a $p\times p$ matrix of the Jordan form

$$h=E1_p+a_p, \tag{31}$$

where 1_p is the $p\times p$ identity matrix and a_p is the $p\times p$ matrix

$$a_p:=\begin{pmatrix} 0 & 1 & 0 & \cdots & 0 & 0 & 0\\ 0 & 0 & 1 & \cdots & 0 & 0 & 0\\ \vdots & \vdots & \ddots & \ddots & \vdots & \vdots & \vdots\\ 0 & 0 & 0 & \cdots & 0 & 1 & 0\\ 0 & 0 & 0 & \cdots & 0 & 0 & 1\\ 0 & 0 & 0 & \cdots & 0 & 0 & 0 \end{pmatrix} \tag{32}$$

(a_p provides an irreducible representation of the annihilation operator for a para-Fermion of order $p-1$[21]). Then e^{ih} has the following canonical Jordan form:

$$e^{iE}1_p+a_p. \tag{33}$$

Equivalently, e^{iE} is the unique eigenvalue of e^{ih} with geometric multiplicity 1 and algebraic multiplicity p.

Proof: Using the fact that $a_p^p=0$, we can easily compute

$$e^{ih}=e^{iE}\sum_{\ell=0}^{p-1}\frac{i^\ell a^\ell}{\ell!}.$$

This is an upper triangular matrix with a single eigenvalue (namely e^{iE}) and a single (linearly independent) eigenvector. Therefore its geometric multiplicity is 1 and its algebraic multiplicity is p. □

Theorem 3: Every pseudounitary matrix U may be expressed as e^{iH} for some pseudo-Hermitian matrix H.

Proof: Let U be an $n\times n$ pseudounitary matrix. Clearly, $U\in\mathrm{GL}(n,\mathbb{C})$. Now, because the exponential map for the group $\mathrm{GL}(n,\mathbb{C})$ is onto,[22] there is a square matrix H such that $U=e^{iH}$. We can perform a similarity transformation $H\to\tilde{H}:=A^{-1}HA$ that maps H into its Jordan canonical form $\tilde{H}$. We then have

$$U=Ae^{i\tilde{H}}A^{-1}. \tag{34}$$

In view of Proposition 2 and Lemma 2, $e^{i\tilde{H}}$ is pseudounitary, and its eigenvalues are of the form e^{iE_n} where E_n are the eigenvalues of $\tilde{H}$. Moreover, the geometric multiplicity and the Jordan dimensions of (the canonical Jordan form of) $e^{i\tilde{H}}$ coincide with those of $\tilde{H}$. Now, because $e^{i\tilde{H}}$ is pseudounitary, Theorem 2 implies that the eigenvalues e^{iE_n} of $e^{i\tilde{H}}$ are either unimodular or they come in inverse-complex-conjugate pairs with identical geometric multiplicity and Jordan dimensions. First we consider the unimodular eigenvalues which we denote by $e^{iE_{\nu_0}}$. Because $1=|e^{iE_{\nu_0}}|^2=e^{iE_{\nu_0}}e^{-iE^*_{\nu_0}}$, we have $E_{\nu_0}-E^*_{\nu_0}=2\pi k_{\nu_0}$ for some $k_{\nu_0}\in\mathbb{Z}$. But the left-hand side of this equation is imaginary while its right-hand side is real. This implies $k_{\nu_0}=0$. Hence E_{ν_0} is real. Next, consider the eigenvalues e^{iE_ν} that are not unimodular. These are paired with their inverse-

complex-conjugate, namely, $e^{iE_\nu^*}$. e^{iE_ν} and $e^{iE_\nu^*}$ have the same geometric multiplicity d_ν and Jordan dimensions $p_{\nu,a}$. Because $e^{iE_\nu^*}$ is an eigenvalue of $e^{i\tilde{H}}$, according to Lemma 2 there is an eigenvalue E'_ν of $\tilde{H}$ such that

$$e^{iE_\nu^*}=e^{iE'_\nu}, \tag{35}$$

and that E'_ν has the same geometric multiplicity and Jordan dimensions as $e^{iE_\nu^*}$. Hence the geometric multiplicity and Jordan dimensions of E'_ν are, respectively, d_ν and $p_{\nu,a}$. Furthermore, Eq. (35) implies $E'_\nu=E_\nu^*+2\pi k_\nu$ for some $k_\nu\in\mathbb{Z}$. Now, let $E_{\nu+}$ and $E_{\nu-}$, respectively, denote the eigenvalues of $\tilde{H}$ with positive and negative imaginary part. In view of the preceding argument, for each $E_{\nu+}$ there is an eigenvalue $E_{\nu-}=E_{\nu+}^*+2\pi k_{\nu+}$. Furthermore all the eigenvalues with negative imaginary part may be obtained from the eigenvalues with positive imaginary part in this way. Now, let $\tilde{H}'$ be the matrix obtained from $\tilde{H}$ by replacing the eigenvalues $E_{\nu-}$ with $E'_{\nu-}$ $:=E_{\nu-}-2\pi k_{\nu+}=E_{\nu+}^*$. Then, by construction, $\tilde{H}'$ has real and/or complex-conjugate pairs of eigenvalues, the latter having identical geometric multiplicity and Jordan dimensions. In light of Theorem 1 of Ref. 6, this implies that $\tilde{H}'$ is pseudo-Hermitian. One can also check that

$$e^{i\tilde{H}'}=e^{i\tilde{H}}. \tag{36}$$

Next, let

$$H':=A\tilde{H}'A^{-1}. \tag{37}$$

Clearly, $\tilde{H}'$ is the Jordan canonical form of H'. In particular, H' is also pseudo-Hermitian. Combining Eqs. (34), (36), and (37), we finally have

$$U=Ae^{i\tilde{H}}A^{-1}=Ae^{i\tilde{H}'}A^{-1}=e^{iA\tilde{H}'A^{-1}}=e^{iH'}.$$

This completes the proof of the fact that U is the exponential of i times a pseudo-Hermitian matrix. □

Corollary 1: A square matrix U is pseudounitary if and only if $-i\ln U$ is pseudo-Hermitian, i.e., $U=e^{iH}$ for a pseudo-Hermitian matrix H.

Proof: If U is pseudounitary, then according to Theorem 3 it is of the form e^{iH} for some pseudo-Hermitian matrix. If $U=e^{iH}$ for a pseudo-Hermitian matrix H, then setting $\epsilon=2$, $t=-1$ in Proposition 1 we find that $U=\mathrm{U}(-1)$ is pseudounitary. □

Corollary 1 is rather surprising, for it is well known that the exponential map is not onto for pseudounitary groups such as U(1,1).[22] This does not however contradict the statement of Corollary 1, because when one speaks of a pseudounitary group one fixes the operator η. What has been done in the proof of Theorem 3 is to show that for a given pseudounitary operator U there is an η such that U is η-pseudounitary and $H:=-\ln U$ is η-pseudo-Hermitian. This is not equivalent to the erroneous statement that given an η, $-i\ln U$ is η-pseudo-Hermitian for every η-pseudounitary matrix U. The exponential map for the pseudounitary group $\mathcal{U}_\eta(\mathbb{C}^n)$ is generally not onto, but the exponential map for the set of all pseudounitary matrices is onto. This is another demonstration of the importance of the difference between the notions of η-pseudo-Hermiticity (respectively, η-pseudounitarity) and pseudo-Hermiticity (respectively, pseudounitarity).[19]

V. 2×2 PSEUDOUNITARY MATRICES

In this section we shall study the case $n=2$ in more detail. The following corollary of Theorem 3 yields the general form of 2×2 pseudounitary matrices.

Corollary 2: A 2×2 matrix U is pseudo-Hermitian if and only if $U=A^{-1}DA$ where A is an invertible 2×2 matrix and D is a matrix assuming one of the following three forms:

$$D_1=\begin{pmatrix} e^{i\theta} & 0 \\ 0 & e^{i(\varphi-\theta)} \end{pmatrix}, \quad \theta,\varphi\in\mathbb{R}, \tag{38}$$

$$D_2=\begin{pmatrix} re^{i\theta} & 0 \\ 0 & e^{i\theta}/r \end{pmatrix}, \quad r\in\mathbb{R}^+, \quad \theta\in\mathbb{R}, \tag{39}$$

$$D_3=\begin{pmatrix} e^{i\theta} & 1 \\ 0 & e^{i\theta} \end{pmatrix}, \quad \theta\in\mathbb{R}. \tag{40}$$

Proof: Block diagonalizing U we find a matrix D which is either diagonal or has the form

$$D=\begin{pmatrix} u & 1 \\ 0 & u \end{pmatrix}, \tag{41}$$

where $u\in\mathbb{C}$. According to Proposition 2, D is also pseudounitary. This together with Theorem 3 imply that

(i) if D is diagonal, its eigenvalues are either both unimodular, i.e., D is of the form (38), or they are inverse-complex-conjugate, i.e., D is of the form (39);
(ii) if D has the form (41), then it has a single eigenvalue u which is necessarily unimodular. That is D is of the form (40). □

In order to demonstrate the utility of Theorem 3, here we include a direct proof of Corollary 2. This proof involves the calculation of the matrices η whose general form is given in the proof of Theorem 2.

A direct proof of corollary 2: First consider the case that U is diagonalizable, then the canonical Jordan form $D=AUA^{-1}$ of U is diagonal. Clearly $\det D=\det U$ and according to Proposition 4 $\det U\in\mathrm{U}(1)$. Hence $|\det D|=1$. This implies that D must have the form

$$D=\begin{pmatrix} \zeta & 0 \\ 0 & e^{i\varphi}/\zeta \end{pmatrix}, \tag{42}$$

where $\zeta:=re^{i\theta}\in\mathbb{C}-\{0\}$ and $e^{i\varphi}\in U(1)$, i.e., $r\in\mathbb{R}^+$ and $\theta,\varphi\in\mathbb{R}$. Next, note that in view of Proposition 2, U is η-pseudounitary if and only if D is $A^{-1\dagger}\eta A^{-1}$-pseudounitary. This reduces the problem to finding the necessary and sufficient conditions on ζ (alternatively r, θ) and φ that make D pseudounitary. Using the general form

$$\eta=\begin{pmatrix} a & \xi \\ \xi^* & b \end{pmatrix}, \quad a,b\in\mathbb{R}, \quad \xi\in\mathbb{C}, \quad ab\neq|\xi|^2, \tag{43}$$

of the Hermitian matrix η and the fact that D is η-pseudounitary for some η of the form (43), i.e., $D^\dagger=\eta D^{-1}\eta^{-1}$ or $D^\dagger\eta D=\eta$, we find that for $\xi=0$: $r=1$ and $D=D_1$, and for $\xi\neq0$: $e^{i\varphi}=e^{i\theta}$ and $D=D_2$. Next, consider the case that U is not diagonalizable. Then D has the form (41). Again because D is pseudounitary, $\det D\in\mathrm{U}(1)$. This implies $u\in\mathrm{U}(1)$, i.e., $u=e^{i\theta}$ for some $\theta\in\mathbb{R}$. Substituting this expression and the general form (43) of η in $D^\dagger\eta D=\eta$, we find that this equation can always be satisfied without restricting θ. Therefore, in this case $D=D_3$. □

The above analysis also yields the form of η for each of the cases considered.

(1) For $D=D_1$, there are two possibilities.
(1a) $e^{i\varphi}\neq e^{2i\theta}$: In this case, $\xi=0$ and η has the diagonal form

$$\eta=\eta_1:=\begin{pmatrix} a & 0 \\ 0 & b \end{pmatrix}, \quad a,b\in\mathbb{R}-\{0\}. \tag{44}$$

TABLE I. Operators H_D and η for $D=D_1$, D_2, D_3.

i	D_i	H_{D_i}	η_i
1	$\begin{pmatrix} e^{i\theta} & 0 \\ 0 & e^{i(\varphi-\theta)} \end{pmatrix}$	$\begin{pmatrix} \theta & 0 \\ 0 & \varphi-\theta \end{pmatrix}$	$\begin{pmatrix} a & 0 \\ 0 & b \end{pmatrix}$
2	$\begin{pmatrix} re^{i\theta} & 0 \\ 0 & e^{i\theta}/r \end{pmatrix}$	$\begin{pmatrix} \theta-i\ln r & 0 \\ 0 & \theta+i\ln r \end{pmatrix}$	$\begin{pmatrix} 0 & \xi \\ \xi^* & 0 \end{pmatrix}$
3	$\begin{pmatrix} e^{i\theta} & 1 \\ 0 & e^{i\theta} \end{pmatrix}$	$\begin{pmatrix} \theta & \theta(e^{i\theta}-1)^{-1} \\ 0 & \theta \end{pmatrix}$	$\begin{pmatrix} 0 & \pm ire^{-i\theta} \\ \mp ire^{i\theta} & 0 \end{pmatrix}$

Because a and b may have arbitrary sign, the group $\mathcal{U}_{\eta_1}(\mathbb{C}^2)$ is isomorphic to either U(2) or U(1,1).

(1b) $e^{i\varphi}=e^{2i\theta}$: In this case, $D=e^{i\theta}I$ where I is the 2×2 unit matrix. Hence, there is no restriction on η; it has the general form (43), and $\mathcal{U}_\eta(\mathbb{C}^2)$ is isomorphic to either U(2) or U(1,1). (2) If $D=D_2$ with $r=1$ we recover the case (1b). If $D=D_2$ and $r\neq1$, then $a=b=0$ and η has the off-diagonal form

$$\eta=\eta_2:=\begin{pmatrix} 0 & \xi \\ \xi^* & 0 \end{pmatrix}, \quad \xi\in\mathbb{C}-\{0\}. \tag{45}$$

Because η_2 is an indefinite matrix, $\mathcal{U}_{\eta_2}(\mathbb{C}^2)$ is isomorphic to U(1,1). (3)

(3) If $D=D_3$. Then η has the general form

$$\eta=\eta_3:=\begin{pmatrix} 0 & \pm ire^{-i\theta} \\ \mp ire^{i\theta} & 0 \end{pmatrix}, \quad r\in\mathbb{R}^+, \quad \theta\in\mathbb{R}, \tag{46}$$

and $\mathcal{U}_{\eta_3}(\mathbb{C}^2)$ is isomorphic to U(1,1).

We can check that the above expressions for η are consistent with the general form of η as given in the proof of Theorem 2. Furthermore, we can obtain the explicit form of the operator $H:=-i\ln U$. In view of the identity $U=A^{-1}DA$, it is not difficult to see that if we obtain an operator H_D satisfying $D=e^{iH_D}$, then $H=A^{-1}H_DA$ will satisfy $U=e^{iH}$. Table I gives the operators H_D and η for $D=D_1$, D_2, D_3. Note that in this table $\theta,\varphi\in\mathbb{R}$, $r\in\mathbb{R}^+$, $a,b\in\mathbb{R}-\{0\}$, $\xi\in\mathbb{C}-\{0\}$, and that the trivial case where D is proportional to the unit matrix is omitted.

VI. PSEUDOUNITARY DYNAMICAL GROUPS AND THE HARMONIC OSCILLATOR

Suppose that H is a 2×2 pseudo-Hermitian matrix serving as the (time-independent) Hamiltonian for a quantum system, $U(t):=e^{-itH}$ is the corresponding evolution operator, $\mathcal{E}_H$ is the set of all invertible Hermitian 2×2 matrices η satisfying (1), and

$$\mathcal{U}_H:=\bigcup_{\eta\in\mathcal{E}_H}\mathcal{U}_\eta(\mathbb{C}^2), \quad \mathcal{GU}_H:=\bigcup_{\eta\in\mathcal{E}_H}\mathcal{GU}_\eta(\mathbb{C}^2),$$

where $\mathcal{GU}_\eta(\mathbb{C}^2)$ denotes the Lie algebra of $\mathcal{U}_\eta(\mathbb{C}^2)$. Then clearly $iH\in\mathcal{GU}_H$ and for all $t\in\mathbb{R}$ $U(t)\in\mathcal{U}_H$. This in particular means that for each $\eta\in\mathcal{E}_H$, $\mathcal{U}_\eta(\mathbb{C}^2)$ serves as a dynamical group for the quantum system.[23] If H is diagonalizable with a real spectrum then the dynamical group may be taken to be (isomorphic to) either U(2) or U(1,1) (or one of their subgroups). If H has (nonreal) complex eigenvalues or if it is not diagonalizable, then the dynamical group is necessarily (isomorphic to a subgroup of) U(1,1). [The generalization of this statement to arbitrary block-

diagonalizable pseudo-Hermitian Hamiltonians with finite-dimensional blocks is immediate. If the Hamiltonian is not diagonalizable or has complex eigenvalues, then the dynamical groups that the system admits are necessarily (isomorphic to a subgroup of) $\mathrm{U}(p,q)$ with $p\neq 0\neq q$.]

A concrete example is provided by the classical equation of motion for a simple harmonic oscillator of frequency ω,

$$\ddot{x}+\omega^2 x=0. \tag{47}$$

As explained in Refs. 4 and 14, this equation is equivalent to the Schrödinger equation,

$$i\hbar\frac{d}{dt}\Psi=H\Psi, \tag{48}$$

where

$$\Psi=\begin{pmatrix} x+i\lambda\dot{x} \\ x-i\lambda\dot{x}\end{pmatrix},\quad H=\frac{\hbar}{2}\begin{pmatrix} \lambda\omega^2+\lambda^{-1} & \lambda\omega^2-\lambda^{-1} \\ -\lambda\omega^2+\lambda^{-1} & -\lambda\omega^2-\lambda^{-1}\end{pmatrix}, \tag{49}$$

and $\lambda\in\mathbb{R}^+$ is a time scale. Clearly H is a traceless matrix. It is also easy to check that $\det H\in\mathbb{R}$ if and only if $\omega^2\in\mathbb{R}$. Therefore, according to Theorem 3 of Ref. 6, H is a pseudo-Hermitian matrix provided that $\omega^2\in\mathbb{R}$. Furthermore, H is diagonalizable unless $\omega=0$.

In the following we shall only consider the case $\omega^2\in\mathbb{R}$.

For $\omega\neq 0$, we can easily solve the eigenvalue problem and diagonalize H. The corresponding diagonal matrix has the form $H_D=\hbar\omega\sigma_3$ where σ_3 is the diagonal Pauli matrix $\mathrm{diag}(1,-1)$. Comparing the expression for H_D with the results given in the above table, we see that H_D is η-pseudo-Hermitian with respect to a diagonal metric operator η of the form (44) provided that $\omega^2>0$. In this case the system admits both the dynamical groups U(2) and U(1,1). If $\omega^2<0$, H is η-pseudo-Hermitian with respect to an off-diagonal metric operator η of the form (45) and the system only admits the dynamical group U(1,1). Finally for $\omega=0$, H is not diagonalizable; $U=e^{iH}$ has the Jordan canonical form D_3; it is η-pseudounitary for a metric operator η of the form (46) and the system admits the dynamical group U(1,1). [It is interesting to observe that the noncompact dynamical group U(1,1) arises for the case that $\omega^2<0$ where Eq. (47) admits unbounded solutions.]

For the case $\omega^2>0$, the freedom in the choice of the dynamical group is equivalent to the choice of a positive–definite or an indefinite inner product on the space of solutions of Eq. (47).[14] This freedom does not exist if $\omega^2\leqslant 0$.

Now, consider changing the parameter ω^2 from a positive value down to a negative value. If one adopts an indefinite (but possibly ω^2-dependent) inner product, one can keep H Hermitian with respect to this inner product and view the evolution operator as tracing a curve in the dynamical group U(1,1). The best-known example is the Klein–Gordon inner product that corresponds to the choice $\eta=\sigma_3$, and therefore is independent of the value of the parameter ω^2. However, if one initially adopts a (possibly ω^2-dependent) positive–definite inner product, one cannot maintain the Hermiticity of H with respect to this inner product once ω^2 crosses zero. The dynamical group undergoes an abrupt transition from the group U(2) to the group U(1,1). This transition may be identified with the change of the signature of the metric (operator).

For $\omega^2>0$, one may endow the Hilbert space ($\mathbb{C}^2$) with a positive–definite invariant inner product. In this case the system has a U(2) dynamical group and is physically equivalent to the two-level spin system,[23] i.e., a spin-1/2 particle interacting with a fixed magnetic field. The time evolution is clearly unitary. This equivalence is destroyed once ω^2 becomes nonpositive. In this case the dynamical group is U(1,1) and the system does not admit a unitary evolution with respect to any positive–definite inner product on $\mathbb{C}^2$. For the case that $\omega^2>0$ one could as well choose an indefinite invariant inner product (this is precisely what was done historically). But such a choice leads to a nonunitary quantum system with a two-dimensional Hilbert space and a U(1,1) dynamical group. As is well known the corresponding quantum harmonic oscillator also has a U(1,1) [or

rather SU(1,1)] dynamical group.[23] Therefore, as far as the dynamics is concerned the nonunitary system describing the dynamics of the classical oscillator is equivalent to the unitary quantum harmonic oscillator.

For the case $\omega^2>0$ there are therefore two alternatives. One is to choose a positive–definite invariant inner product which corresponds to the dynamical group U(2). The other is to choose an indefinite invariant inner product which leads to the dynamical group U(1,1).

Now, suppose that one wishes to keep the same dynamical group but insists on being able to describe the dynamics using a unitary quantum system. In the first alternative this is already the case. But in the second alternative one needs to use an infinite-dimensional Hilbert space, because being a noncompact Lie group U(1,1) does not admit a finite-dimensional unitary representation. Therefore *it is the demand for unitarity that leads to the quantization of the oscillator*. The latter is however not unique because U(1,1) has inequivalent unitary irreducible representations. This does not lead to any problems, because the dynamics always takes place in the dynamical group.[23] As a result the dynamical aspects of all possible quantum systems associated with the classical harmonic oscillator are equivalent. [Note that here quantization does not mean the canonical quantization which is unique in the sense that the Weyl–Heisenberg algebra has a unique irreducible (projective) representation. It means defining the Hilbert space as the representation space of a unitary irreducible projective representation of the dynamical group, and representing the Hamiltonian as an element of the Lie algebra of the dynamical group.]

The above two alternatives are also available in describing free Klein–Gordon fields (or more generally Klein–Gordon fields interacting with a stationary magnetic field). The second alternative applies more generally even to the cases of interacting fields. It corresponds to Dirac's method of second quantization that forms the foundations of quantum field theories. The first alternative was noticed quite recently.[14,15,24] (See however Ref. 25 that were brought to the author's attention after the completion of this project.) Its advantage is to provide a genuine probability interpretation for first quantized Klein–Gordon fields.[26] Its main application is in quantum cosmology.[15]

VII. CONCLUSION

In this paper, we explored various properties of pseudounitary operators and proved a spectral characterization theorem for the class of block-diagonalizable pseudounitary operators with finite-dimensional blocks. We applied our results to clarify the structure of pseudounitary matrices paying attention to the role of the inner product and the fact that it is not unique. We showed that the relationship between Hermitian and unitary matrices generalize to the pseudo-Hermitian and pseudounitary matrices. Specifically every pseudounitary matrix is the exponential of i times a pseudo-Hermitian matrix.

We showed that the symplectic transformations of classical mechanics are certain pseudounitary and pseudo-Hermitian operators. This led to a proof of the spectral theorem for symplectic matrices and to the identification of the symplectic groups $\mathrm{Sp}(2n)$ with the real subgroups of certain pseudounitary matrix groups that are isomorphic to $\mathrm{U}(n,n)$. The description of the symplectic transformations in terms of pseudounitary and pseudo-Hermitian operators suggests the possibility of the application of the latter in classical mechanics. (For a related discussion see Ref. 27.)

Furthermore, we derived the canonical forms of arbitrary 2×2 pseudounitary matrices, and studied the pseudounitary system describing a classical harmonic oscillator. For real nonzero frequencies, this system admits both the dynamical groups U(2) or U(1,1). If one imposes the condition of the unitarity of the evolution, then the choice U(2) identifies the dynamics of the oscillator with that of a two-level quantum system, and the choice U(1,1) leads to a quantization of the oscillator. This picture provides a rather interesting link between the demand for unitarity and the need for (second) quantization.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 45, NUMBER 3 MARCH 2004

Equal rank embedding and its related construction to superconformal field theories

Teparksorn Pengpan[a)]
Department of Physics, Faculty of Science, Prince of Songkla University, Hatyai, P.O. Box 3 Khohong, 90112, Thailand

(Received 11 February 2000; accepted 12 December 2003)

The lowest lines of Euler multiplets corresponding to massless and massive supersymmetric representations are classified. At the level of representation theory, the Euler multiplets constructed by the GKRS method of equal rank embedding of semisimple complex Lie algebras are found to be the intrinsic ground states of superconformal field theories according to the Kazama–Suzuki construction. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1645975]

I. INTRODUCTION

Although a Dirac operator with a cubic term and its square appeared as supercurrent and energy-momentum tensor, respectively, in studies of the superconformal field theories and the supersymmetric Wess–Zumino–Witten action many years ago,[1–3] there has not been much progress on understanding their spectrum. It still needs to determine the explicit representations of these superconformal models.

Recently, a study of equal rank embedding of semisimple complex Lie algebras[4] led Kostant to determine an Euler multiplet as the kernel of the cubic Dirac operator and its square in general.[5] By accident, it was observed that some of the lowest lines of the Euler multiplets match exactly with the known massless and massive supermultiplets[6] and the higher lines of them possibly involve higher spin massless and massive fields. It was also observed that the Kostant operator and its square are the zero mode of the supercurrent and the energy-momentum tensor.[7] In this paper, we will observe these relations from the representation-theoretic viewpoint of Lie algebras and of affine Lie algebras. Understanding a method to obtain the Euler multiplets may help to obtain what the spectrum of the superconformal models really are level by level.

The contents of this paper are organized as follows. In Sec. II, the Kostant operator is reviewed and an eigenvalue of its square is alternatively derived from the representation-theoretic viewpoint including a condition for getting an Euler multiplet. In Sec. III, Euler multiplets that give the massless and massive supermultiplets are classified. Sections IV and V are devoted to a super-Kac–Moody algebras and the Kazama–Suzuki construction of superconformal models. In the last section, the Euler multiplet is shown to be inherent in a ground state of the Kazama–Suzuki superconformal models.

II. KOSTANT OPERATOR AND EULER MULTIPLET

Let J's be generators of a semisimple complex Lie algebra g such that

$$[J_A, J_B] = i f_{[ABC]} J_C, \tag{1}$$

where indices $A,B,C = 1 \cdots \dim g$. A basis of the generators is chosen so that these generators are orthonormal with respect to an inner product on g that is invariant under the adjoint action. In the case that g is semisimple, the inner product on g is the Killing form. Let Λ be in the positive Weyl chamber of g and let J_A^Λ be the image of J_A under the irreducible representation of g with highest

a)Electronic mail: pteparks@ratree.psu.ac.th

weight Λ. Kostant's cubic Dirac operator of the pair (g,Λ) is the operator on $V_\Lambda \otimes S$, where V_Λ is a vector space of the representation with the highest weight Λ and S is a spinor module of the complexified Clifford algebra which can be decomposed into the direct sum of the positive spinor representation S^+ and the negative spinor representation S^- when the dimension of the complexified Clifford algebra is even, given by

$$\mathcal{K}_g(\Lambda) = \gamma_A J_A^\Lambda - \frac{i}{2} f_{[ABC]} \gamma_{[A} \gamma_B \gamma_{C]}. \tag{2}$$

The Dirac γ-matrices satisfy the Clifford algebra,

$$\{\gamma_A, \gamma_B\} = 2\delta_{AB}. \tag{3}$$

Squaring (2) gives us

$$\mathcal{K}_g^2(\Lambda) = (J_A^\Lambda)^2 + \left(\frac{i}{2} f_{[ABC]} \gamma_{[A} \gamma_B \gamma_{C]}\right)^2 = C_2(\Lambda) + |\rho_g|^2, \tag{4}$$

where $C_2(\Lambda) = (\Lambda, \Lambda + \rho_g)$ is the quadratic Casimir eigenvalue of the irreducible representation Λ and ρ_g is one-half the sum of positive roots of g. Both $C_2(\Lambda)$ and $|\rho_g|^2$ are calculated in the orthornormal basis $\{e_i\}$ where $(e_i, e_j) = \delta_{ij}$. The eigenvalue of (4) is always positive definite. Therefore, $\mathcal{K}_g^2$ is a positive eigenvalue operator.

In the case of the quotient g/h, the generators $J_i, i = 1 \cdots \dim h$, lie in g and the generators $J_a, a = h+1 \cdots \dim g$, are a basis of the orthogonal complement of h with respect to the Killing form on g. Both J_i and J_a satisfy the following commutation relations:

$$[J_i, J_j] = i f_{[ijk]} J_k, \tag{5}$$

$$[J_i, J_a] = i f_{[iab]} J_b, \tag{6}$$

$$[J_a, J_b] = i f_{[abj]} J_j + i f_{[abc]} J_c. \tag{7}$$

The twisted Dirac operator on $h \subset g$ acting on $V_\Lambda \otimes S$ is

$$\mathcal{K}_h(\Lambda) = \gamma_i \left(J_i^\Lambda - \frac{i}{2} f_{[iab]} \gamma_{[a} \gamma_{b]} \right) - \frac{i}{2} f_{[ijk]} \gamma_{[i} \gamma_j \gamma_{k]}, \tag{8}$$

and the Kostant operator of the quotient g/h is

$$\mathcal{K}_{g/h}(\Lambda) = \mathcal{K}_g(\Lambda) - \mathcal{K}_h(\Lambda) = \gamma_a J_a^\Lambda - \frac{i}{2} f_{[abc]} \gamma_{[a} \gamma_b \gamma_{c]}. \tag{9}$$

(This operator first appeared in the Kazama and Suzuki paper.[2]) Decompose $V_\Lambda \otimes S$ into irreducible representations of h and let V_μ be one of these h-representations, where μ is its highest weight. Restricting (9) to V_μ and squaring gives a scalar operator:

$$(\mathcal{K}_{g/h}(\Lambda)|_{V_\mu})^2 = (J_A^\Lambda)^2 - (J_i^\Lambda + S_i)^2 + S_i^2 = C_2(\Lambda) - C_2(\mu) + |\rho_g|^2 - |\rho_h|^2, \tag{10}$$

where $S_i = -(i/2) f_{[iab]} \gamma_{[a} \gamma_{b]}$. In the last line of (10), $C_2(\Lambda)$ is the quadratic Casimir eigenvalue for g and $C_2(\mu)$ for h. The rhs of Eq. (10) gives the eigenvalues of $(\mathcal{K}_{g/h}(\Lambda)|_{V_\mu})^2$ acting on $V_\Lambda \otimes S$. Since the Kostant operator is self-adjoint, all eigenvalues of (10) are non-negative.

From the representation-theoretic viewpoint of Lie algebras, the eigenvalue of (10) can be naively derived by considering the following inequality:

$$\Lambda + \rho_g \geqslant w^{-1}(\mu + \rho_h), \tag{11}$$

where μ is a weight of h appearing in the decomposition of $V_\Lambda \otimes S$ into irreducible representations of h and w is an element in the Weyl group of g such that $w^{-1}(\mu+\rho_h)$ is a dominant weight. Since the Weyl group preserves scalar product, squaring (11) yields

$$|\Lambda+\rho_g|^2 \geqslant |\mu+\rho_h|^2. \tag{12}$$

The equation (12) gives rise to

$$(\Lambda,\Lambda+2\rho_g)+|\rho_g|^2 \geqslant (\mu,\mu+2\rho_h)+|\rho_h|^2, \tag{13}$$

i.e.,

$$C_2(\Lambda)-C_2(\mu)+|\rho_g|^2-|\rho_h|^2 \geqslant 0. \tag{14}$$

Let c be an element in C, the quotient set of the Weyl group $W(g)/W(h)$. When $\mu = c\cdot\Lambda \equiv c(\Lambda+\rho_g)-\rho_h$, (14) is minimum and equal to zero:

$$C_2(\Lambda)-C_2(\mu)+|\rho_g|^2-|\rho_h|^2 = \begin{cases} 0, & \text{if } \mu = c\cdot\Lambda; \\ \text{positive} & \text{otherwise.} \end{cases}$$

A set of all highest weights $c\cdot\Lambda$ is called the Euler multiplet.

III. CLASSIFICATION OF THE LOWEST LINES OF THE EULER MULTIPLETS

Alternatively, the Euler multiplet can be simply obtained by using the GKRS index,[4]

$$V_\Lambda \otimes S^+ - V_\Lambda \otimes S^- = \sum_{c\in C} \operatorname{sgn}(c) V_{c\cdot\Lambda}, \tag{15}$$

when V_Λ is the one-dimensional irreducible representation of g and it is trivially branched into a one-dimensional representation of h. The lowest line of the Euler multiplets of h is equal to a decomposition of the two spinor representations of $SO(\dim g/h)$ into irreducible representations of h. In the case that an Euler number **C**, the number of c elements in $W(g)/W(h)$, is a small integer, one can compute the Euler multiplet from $\lambda \equiv c(\Lambda+\rho_g)-\rho_h$ as shown in Ref. 6. In the case that the Euler number is a high integer, e.g., $\mathbf{C}>10$, the Euler multiplet can be obtained by branching the irreducible representation V_Λ and the spinor representations of SO(dim g/h) into the representations of h, tensoring them together, and taking the difference between positive and negative spin spaces.

It is observed that when dim $g/h = 4$, 8, 16, and 32, the lowest lines of the Euler multiplets have the right degrees of freedom of the massless and massive supersymmetric representations of the supersymmetric gauge field theories.[6] So, it is convenient to classify the lowest lines of the Euler multipets according to SO(dim g/h). (The Euler multiplets in this section are written in terms of dimensions of the irreducible representations of h.)

(1) SO(4):

$$S^+ = 2_s \text{ and } S^- = 2_c.$$

- $\mathrm{Sp}(4) \supset \mathrm{Sp}(2)\times\mathrm{Sp}(2)$,

$$S^+ = (1,2),$$
$$S^- = (2,1).$$

[In this paper, $\mathrm{Sp}(2n) \equiv U(2n)\cap \mathrm{Sp}(2n,C)$ is a unitary symplectic group.] Since the group Sp(2), a simply-connected double covering group of SO(3), is locally isomorphic to the group SO(3), i.e. $\mathrm{Sp}(2)\sim\mathrm{SO}(3)$, this Euler multiplet corresponds to the $N=1$ smallest massive representation in $3+1$ space–time dimensions when one of the Sp(2) is interpreted as the little group of the inhomogenous Lorentz group $ISO(3,1)$ and to the $N=1$ shortest

massless representation in $5+1$ space–time dimensions when one of the $\mathrm{Sp}(2)\sim\mathrm{SU}(2)$ algebras is interpreted as a chirality group in $\mathrm{SO}(4)\sim\mathrm{SU}(2)_L\times\mathrm{SU}(2)_R$, the light-cone little group of $ISO(5,1)$.

- $\mathrm{SU}(3)\supset\mathrm{SU}(2)\times\mathrm{U}(1)$,

$$S^+=2_0,$$
$$S^-=1_{1/2}\oplus 1_{-1/2}.$$

This Euler multiplet corresponds to the $N=2$ massless representation in $3+1$ dimensions when the $\mathrm{U}(1)\sim\mathrm{SO}(2)$ algebra is interpreted as the little group of $ISO(3,1)$ and to the massless representation in $4+1$ when the $\mathrm{SU}(2)\sim\mathrm{SO}(3)$ algebra is interpreted as the little group of $ISO(4,1)$. The $N=2$ supersymmetric multiplet with the highest helicity equal to 1/2 is sometimes called a hypermultiplet.

It is noticed that the $N=2$ massless representation in $3+1$ dimensions which is the lowest line of the Euler multiplets of $\mathrm{SU}(3)\supset\mathrm{SU}(2)\times\mathrm{U}(1)$ can be assembled into an $N=1$ massive representation in $3+1$ dimensions which is the lowest line of the Euler multiplets of $\mathrm{Sp}(4)\supset\mathrm{Sp}(2)\times\mathrm{Sp}(2)$. On the 4-dimensional coset space, the $N=2$ massless representation, considered as a fundamental state of one theory at weak (strong) coupling limit, possibly has a duality with an $N=1$ massive representation, considered as a solitonic state of the other theory at a strong (weak) coupling limit.

(2) $\mathrm{SO}(8)$:

$$S^+=8_s \text{ and } S^-=8_c.$$

- $\mathrm{Sp}(6)\supset\mathrm{Sp}(4)\times\mathrm{Sp}(2)$ and $G_2\supset\mathrm{SU}(2)\times\mathrm{SU}(2)$,

$$S^+=(5,1)\oplus(1,3),$$
$$S^-=(4,2).$$

This Euler multiplet corresponds to the $N=2$ smallest massive representation in $3+1$ dimensions and the $N=2$ shortest massless representation in $5+1$ dimensions.

- $\mathrm{SU}(5)\supset\mathrm{SU}(4)\times\mathrm{U}(1)$,

$$S^+=1_1\oplus 6_0\oplus 1_{-1},$$
$$S^-=4_{1/2}\oplus\overline{4}_{-1/2}.$$

This Euler multiplet corresponds to the $N=4$ Yang–Mills massless representation in $3+1$ dimensions and, since $\mathrm{SU}(4)\sim\mathrm{SO}(6)$, a massless representation in $7+1$ dimensions. However, there are two more possibilities to interpret this Euler multiplet, one as a massless representation on the anti–de Sitter space when the $\mathrm{SU}(4)\times\mathrm{U}(1)\sim\mathrm{SO}(6)\times\mathrm{SO}(2)$ algebra is interpreted as the subgroup of $\mathrm{SO}(6,2)$, the anti-de Sitter group in $6+1$ dimensions, and the other as a massless representation of a conformal theory when interpreted as the conformal group in $5+1$ dimensions.

- $\mathrm{SO}(6)\supset\mathrm{SO}(4)\times\mathrm{SO}(2)$ and $\mathrm{SU}(4)\supset\mathrm{SU}(2)\times\mathrm{SU}(2)\times\mathrm{U}(1)$,

$$S^+=(1,1)_1\oplus(3,1)_0\oplus(1,3)_0\oplus(1,1)_{-1},$$
$$S^-=(2,2)_{1/2}\oplus(2,2)_{-1/2}.$$

There are many possibilities to view this Euler multiplet. It corresponds to the $N=4$ Yang–Mills supermultiplet in $3+1$ dimensions and to a massless multiplet in either $4+1$ or $5+1$ dimensions.

Note that $N=4$ massless representation in $3+1$ dimensions which is the lowest line of the Euler multiplets of $SU(5)\supset SU(4)\times U(1)$, $SO(6)\supset SO(4)\times SO(2)$ and $SU(4)\supset SU(2)\times SU(2)\times U(1)$ can also be assembled into an $N=2$ massive representation in $3+1$ dimensions which is the lowest line of the Euler multiplets of $Sp(6)\supset Sp(4)\times Sp(2)$ and $G_2\supset SU(2)\times SU(2)$. On the 8-dimensional coset space, the $N=2$ massless representations, considered as the fundamental states of one theory at the weak (strong) coupling limit, possibly have a duality with $N=1$ massive representations, considered as the solitonic states of the other theory at the strong (weak) coupling limit.

(3) $SO(16)$:

$$S^+=128_s \text{ and } S^-=128_c.$$

- $F_4\supset SO(9)$,

$$S^+=44\oplus 84,$$
$$S^-=128.$$

This multiplet can be viewed as the $N=1$ massive soliton representation in $9+1$ dimensions and as the $N=1$ massless representation in $10+1$ dimensions. In the later case, it is called the supergravity triplet where the 44-dimensional representation is the degrees of freedom of the spin-2 graviton, the 84-dimensional is the degrees of freedom of the third-rank antisymmetric tensor field and the 128-dimensional is the degrees of freedom of the Rarita–Schwinger spinor-vector called the gravitino.

- $Sp(10)\supset Sp(8)\times Sp(2)$,

$$S^+=(42,1)\oplus(27,3)\oplus(1,5),$$
$$S^-=(48,2)\oplus(8,4).$$

This Euler multiplet corresponds to the $N=4$ smallest massive representation in $3+1$ dimensions and the $N=4$ short massless representation in $5+1$ dimensions.

- $SO(8)\supset SO(4)\times SO(4)\sim SU(2)\times SU(2)\times SU(2)\times SU(2)$,

$$S^+=(5,1,1,1)\oplus(1,5,1,1)\oplus(1,1,5,1)\oplus(1,1,1,5)\oplus(1,3,3,3)\oplus(3,1,3,3)\oplus(3,3,1,3)\oplus(3,3,3,1),$$
$$S^-=(4,2,2,2)\oplus(2,4,2,2)\oplus(2,2,4,2)\oplus(2,2,2,4).$$

This Euler multiplet corresponds to the $N=4$ smallest massive representation in $3+1$ dimensions and $N=2$ massless representaton in $5+1$ dimensions.

- $SU(9)\supset SU(8)\times U(1)$,

$$S^+=1_2\oplus 28_1\oplus 70_0\oplus\overline{28}_{-1}\oplus 1_{-2},$$
$$S^-=8_{3/2}\oplus 56_{1/2}\oplus\overline{56}_{-1/2}\oplus\overline{8}_{-3/2}.$$

Since the highest value of $SO(2)$ is 2, the helicity of graviton in $3+1$ dimensions, this Euler multiplet corresponds to the $N=8$ supergravity representation.

- $SO(10)\supset SO(8)\times SO(2)$,

$$S^+=1_2\oplus 28_1\oplus(35_s)_0\oplus(35_c)_0\oplus 28_{-1}\oplus 1_{-2},$$
$$S^-=8_{3/2}\oplus(56_v)_{1/2}\oplus(56_v)_{-1/2}\oplus 8_{-3/2}.$$

This Euler multiplet corresponds to the $N=8$ supergravity representation in $3+1$ dimensions. After using $SO(8)$ triality, it also corresponds to the chiral $N=4$ supermultiplet of type IIB string theory in $9+1$ dimensions.

- $SU(6)\supset SU(4)\times SU(2)\times U(1)\sim SO(6)\times SO(3)\times SO(2)$,

$$S^+=(1,1)_2\oplus(10,1)_1\oplus(6,3)_1\oplus(20',1)_0\oplus(15,3)_0\oplus(1,5)_0\oplus(\overline{10},1)_{-1}\oplus(6,3)_{-1}\oplus(1,1)_{-2},$$
$$S^-=(4,2)_{3/2}\oplus(20,2)_{1/2}\oplus(\overline{4},4)_{1/2}\oplus(\overline{20},2)_{-1/2}\oplus(4,4)_{-1/2}\oplus(\overline{4},2)_{-3/2}.$$

This Euler multiplet also corresponds to the $N=8$ supergravity representation in $3+1$ dimensions and to a massless representation in $4+1$ and $7+1$ dimensions.

Note that the $N=8$ supergravity multiplet in $3+1$ dimensions which is the lowest line of the Euler multiplets of $SU(9)\supset SU(8)\times U(1)$ and $SO(10)\supset SO(8)\times SO(2)$ can also be assembled into an $N=2$ massive representation in $3+1$ dimensions which is the lowest line of the Euler multiplets of $Sp(10)\supset Sp(8)\times Sp(2)$. On the 16-dimensional coset space, the $N=8$ massless representations, considered the fundamental states of one theory at weak (strong) coupling limit, possibly have a duality with $N=4$ massive representations, considered as the solitonic states of the other theory at the strong (weak) coupling limit.

(4) SO(32):

- $E_6\supset SO(10)\times SO(2)$,

$$S^+=1_4\oplus120_3\oplus770_2\oplus1050_2\oplus3696_1\oplus4312_1\oplus660_0\oplus4125_0\oplus8085_0\oplus4312_{-1}\oplus3696_{-1}$$
$$\oplus1050_{-2}\oplus770_{-2}\oplus120_{-3}\oplus1_{-4},$$
$$S^-=(16_s)_{7/2}\oplus(560_c)_{5/2}\oplus(672_c)_{3/2}\oplus(3696_c)_{3/2}\oplus(2640_s)_{1/2}\oplus(8800_c)_{1/2}\oplus(8800_s)_{-1/2}$$
$$\oplus(2640_c)_{-1/2}\oplus(672_s)_{-3/2}\oplus(3696_s)_{-3/2}\oplus(560_c)_{-5/2}\oplus(16_c)_{-7/2}.$$

This Euler multiplet possibly corresponds to a massive supermultiplet with spin >2 in $10+1$ dimensions.

There also exist the lowest lines of the Euler multiplets that are of SO(6), SO(10), SO(12), etc. and not all of them can be interpreted as the degrees of freedom of the supersymmetric gauge field theories except $Sp(8)\supset Sp(6)\times Sp(2)$ that its lowest line emerges as $N=3$ massive (massless) representation in $3+1$ $(5+1)$ dimensions.

In conclusion, from the facts of group theory, there are different coset spaces. For the 4-, 8-, and 16-dimensional coset spaces, there exist the lowest lines of the Euler multiplets corresponding to the massive and massless supermultiplets.

IV. SUPER-KAC–MOODY ALGEBRAS

By relaxing a positivity condition of determinant of the Cartan matrices, one can get Kac–Moody algebras, of which a subclass constitutes the finite-dimensional (semi)simple Lie algebras. Another subclass of Kac–Moody algebras is affine Lie algebras having the corresponding structure and representation theory in analogy to those of the Lie algebras.[8]

A super-Kac–Moody algebra $\hat{g}$ associated with the Lie algebra g and Lie group G is a Kac–Moody algebra over superspace (z,θ). With the supersymmetrized current decomposition over ordinary space z,

$$J_A(z,\theta)=j_A(z)+\theta J_A(z), \tag{16}$$

the fermions $j_A(z)$ in the adjoint representation of g and $J_A(z)$ are not independent and satisfy the OPEs,

$$j_A(z)j_B(0)\sim\frac{\delta_{AB}}{z}, \tag{17}$$

$$J_A(z)j_B(0)\sim j_A(z)J_B(0)\sim\frac{if_{[ABC]}j_C(0)}{z}, \tag{18}$$

$$J_A(z)J_B(0)\sim\frac{if_{[ABC]}J_C(0)}{z}+\frac{k\delta_{AB}}{z^2}. \tag{19}$$

The level k in (17) is absorbed into the fermion bilinear. To make the fermion and boson current generators independent, Kazama and Suzuki[2] introduced the level $k=\hat{k}+g^\vee$ current decomposition,

$$J_A^k(z)=\hat{J}_A^{\hat{k}}(z)+S_A=\hat{J}_A^{\hat{k}}(z)-\frac{i}{2}f_{[ABC]}j_{[B}j_{C]}(z), \tag{20}$$

so that $\hat{J}_A^{\hat{k}}(z)$ and $S_A(z)$ are mutually independent and, respectively, generate the level $\hat{k}$ and $g^\vee$ ordinary Kac–Moody algebras $\hat{g}$. The level $g^\vee$ Kac–Moody algebra $\hat{g}$ that is constructed by a bilinear form of the fermions in the adjoint representation of g turns out to be isomorphic to the level 1 ordinary Kac–Moody algebra $\widehat{so}(\dim g)$. Therefore, the level k super-Kac–Moody algebra can be regarded as a direct sum of two mutually independent ordinary Kac–Moody algebras,

$$\hat{g}_k=\hat{g}_{\hat{k}}\oplus\widehat{so}(\dim g)_1. \tag{21}$$

In terms of oscillators, (20) is

$$\sum_n (J_n)_A z^{-n-1}=\sum_n (\hat{J}_n)_A z^{-n-1}-\frac{i}{2}f_{[ABC]}\sum_n (b_{-n})_B(b_n)_C z^{-1}. \tag{22}$$

In the representation theory of the ordinary Kac–Moody algebra, (22) corresponds to an affine weight decomposition,

$$(\Lambda+\rho_g;\hat{k}+g^\vee;-n)=(\Lambda;\hat{k};-n)+(\rho_g;g^\vee;0), \tag{23}$$

where n is called a grade. When $n=0$, the affine weight $(\Lambda;\hat{k};0)$ is called the highest weight. From the decomposition (21) of the super-Kac–Moody algebra, there exists the associated $N=1$ superconformal model with the superconformal generators,

$$G(z)=(2/k)^{1/2}\left(j_A(z)\hat{J}_A(z)-\frac{i}{2}f_{[ABC]}j_{[A}j_Bj_{C]}(z)\right), \tag{24}$$

and

$$T(z)=\frac{1}{k}(\hat{J}_A(z)\hat{J}_A(z)-j_A(z)\partial_z j_A(z)). \tag{25}$$

On the rhs of the holomorphic energy-momentum tensor $T(z)$, the first term commutes with the second term. Thus, the central charge of this superconformal model is the sum of the central charges of $\hat{g}_{\hat{k}}$ and $\widehat{so}(\dim g)_1$,

$$c=\frac{\hat{k}\dim \mathrm{G}}{\hat{k}+g^\vee}+\frac{1}{2}\dim \mathrm{G}. \tag{26}$$

The superconformal generators $T(z)$ and $G(z)$ satisfy the OPEs,

$$T(z)T(0)\sim\frac{c}{2z^4}+\frac{2T(0)}{z^2}+\frac{\partial_z T(0)}{z}, \tag{27}$$

$$T(z)G(0)\sim G(z)T(0)\sim \frac{3G(0)/2}{z^2}+\frac{\partial_z G(0)}{z}, \tag{28}$$

$$G(z)G(0)\sim \frac{2c/3}{z^3}+\frac{2T(0)}{z}. \tag{29}$$

The underlying supersymmetric Wess–Zumino–Witten Lagrangian in two dimensions that posseses the super-Kac–Moody algebra $\hat{g}_k$ and the $N=1$ superconformal symmetry was constructed in Ref. 1. The supersymmetric WZW Lagrangian was shown to be equal to the original WZW Lagrangian of $\hat{g}_{\hat{k}}$ plus the Lagrangian of free fermions in the adjoint representation of $\hat{g}_k$. By applying Witten's non-Abelian bosonization rules to the WZW Lagrangian, the supersymmetric WZW theory is equivalent to two free fermion theories.

V. KAZAMA–SUZUKI CONSTRUCTION OF $N=1$ AND $N=2$ SUPERCONFORMAL MODELS

Instead of using Wick's theorem to calculate the OPEs to get the superconformal generators on the coset space, one can simply follow Brink and Ramond's canonical method.[7] The construction of superconformal generators from the coset space method applied to a super-Kac–Moody algebra can be done in analogy to Sec. II.

On the world-sheet, there exists a natural generalization of γ-matrices and generators of a Lie algebra,

$$\gamma_A\rightarrow j_A(z), \tag{30}$$

$$J_A\rightarrow \hat{J}_A(z). \tag{31}$$

The fermions $j_A(z)$ satisfy the anticommutator

$$\{j_A(z),j_B(0)\}=2\delta_{AB}, \tag{32}$$

and the bosonic current generators $\hat{J}_A(z)$ satisfy the level $\hat{k}$ Kac–Moody commutator,

$$[\hat{J}_i(z),\hat{J}_j(0)]=if_{[ijk]}\hat{J}_k(0)+\hat{k}\delta_{ij}\partial_z\delta(z), \tag{33}$$

$$[\hat{J}_i(z),\hat{J}_a(0)]=if_{[iab]}\hat{J}_b(0), \tag{34}$$

$$[\hat{J}_a(z),\hat{J}_b(0)]=if_{[abc]}\hat{J}_c(0)+if_{[abj]}\hat{J}_j(0)+\hat{k}\delta_{ab}\partial_z\delta(z). \tag{35}$$

All indices are the same as in Sec. II.

The supercurrent of $\hat{h}$ that lies in $\hat{g}$ is

$$G_{\hat{h}}(z)=\left(\frac{2}{k}\right)^{1/2}\left(j_i\left(\hat{J}_i-\frac{i}{2}f_{[iab]}j_{[a}j_{b]}\right)-\frac{i}{2}f_{[ijk]}j_{[i}j_jj_{k]}\right)(z), \tag{36}$$

and that of $\hat{g}/\hat{h}$ is

$$G_{\hat{g}/\hat{h}}(z)=G_{\hat{g}}(z)-G_{\hat{h}}(z)=\left(\frac{2}{k}\right)^{1/2}\left(j_a\hat{J}_a-\frac{i}{2}f_{[abc]}j_{[a}j_bj_{c]}\right)(z). \tag{37}$$

By squaring (37) and then using OPEs as in (17)–(19), one yields the energy-momentum tensor,

$$T_{\hat{g}/\hat{h}}(z)=\frac{1}{k}(\hat{J}_a\hat{J}_a-if_{[iab]}\hat{J}_{[i}j_aj_{b]}-\hat{k}j_a\partial_z j_a-f_{[acd]}f_{[acd]}j_{[a}\partial j_{b]}-f_{[abc]}f_{[ade]}j_{[b}j_cj_{[d}j_{e]})(z). \tag{38}$$

In the case that the coset space is symmetric, i.e., the torsion terms $f_{[abc]}$ vanish, (38) reduces to

$$T_{\hat{g}/\hat{h}}(z)=\frac{1}{k}(\hat{J}_A^2-(\hat{J}_i+S_i)^2-\hat{k}j_a\partial_z j_a+S_i^2)(z), \tag{39}$$

where $S_i(z)=-i/2\,f_{[iab]}j_{[a}j_{b]}(z)$. In comparison to (10), the energy-momentum tensor $T_{\hat{g}/\hat{h}}(z)$ is a generalization of Kostant operator $\mathcal{K}^2_{g/h}$. One can also see that OPEs,

$$T_{\hat{g}/\hat{h}}(z)\hat{J}_i(0)\sim T_{\hat{g}/\hat{h}}(z)j_i(0)\sim 0, \tag{40}$$

imply the orthogonal decomposition of the superconformal generators,

$$T_{\hat{g}/\hat{h}}(z)G_{\hat{h}}(0)\sim T_{\hat{g}/\hat{h}}(z)T_{\hat{h}}(0)\sim 0. \tag{41}$$

From (39), one can regard the Kazama–Suzuki construction of the equal rank embedding of super-Kac–Moody algebra as an extension of the GKO construction[9] of ordinary Kac–Moody algebra,

$$(\hat{g}_k/\hat{h}_k)\sim(\hat{g}_{\hat{k}}/\hat{h}_{\hat{k}+g^\vee-h^\vee})\oplus\widehat{so}(\dim\, g/h)_1, \tag{42}$$

with central charge

$$c_{\hat{g}/\hat{h}}=\frac{\hat{k}}{\hat{k}+g^\vee}\dim\, g+\frac{1}{2}\dim\, g/h-\frac{\hat{k}+g^\vee-h^\vee}{\hat{k}+g^\vee}\dim\, h=\frac{3}{2}(\dim\, g/h)-\frac{12}{(\hat{k}+g^\vee)}(|\rho_g|^2-|\rho_h|^2). \tag{43}$$

The equal rank embeddings in Sec. III that can be used to construct the $N=1$ super-conformal models are as follows:

- $\hat{F}_4/\widehat{so}(9)$ with central charge $c_{\hat{g}/\hat{h}}=24\hat{k}/(\hat{k}+9)$;
- $\widehat{Sp}(2n+2)/\widehat{Sp}(2n)\times\widehat{Sp}(2)$ with central charge $c_{\hat{g}/\hat{h}}=6\hat{k}n/(\hat{k}+n+2)$.

In the case that the subalgebra has a $u(1)$ factor, there exists a class of $N=2$ superconformal theories. The $N=2$ superconformal theories have a $u(1)$ current $U(z)$, two supercurrent $G_\pm(z)$ with $u(1)$ charges ±1, and energy-momentum tensor $T(z)$ as their generators. These generators satisfy the OPEs,

$$T(z)T(0)\sim\frac{c/2}{z^4}+\frac{2T(0)}{z^2}+\frac{\partial_z T(0)}{z}, \tag{44}$$

$$T(z)U(0)\sim\frac{\mathrm{U}(0)}{z^2}+\frac{\partial_z \mathrm{U}(0)}{z}, \tag{45}$$

$$T(z)G_\pm(0)\sim\frac{3G_\pm(0)/2}{z^2}+\frac{\partial_z G_\pm(0)}{z}, \tag{46}$$

$$\mathrm{U}(z)\mathrm{U}(0)\sim\frac{c/3}{z^2}, \tag{47}$$

$$\mathrm{U}(z)G_{\pm}(0)\sim\frac{\pm G_{\pm}(0)}{z}, \tag{48}$$

$$G_{+}(z)G_{-}(0)\sim\frac{2c/3}{z^3}+\frac{2\mathrm{U}(0)}{z^2}+\frac{2T(0)+\partial_z\mathrm{U}(0)}{z}, \tag{49}$$

$$G_{+}(z)G_{+}(0)\sim G_{-}(z)G_{-}(0)\sim 0. \tag{50}$$

The simplest representation of the $N=2$ superconformal theories is the $\widehat{su}(2)/\hat{u}(1)$ minimal model with superconformal generators as follows:

$$G_1(z)=\left(\frac{2}{k}\right)^{1/2}(j_1\hat{J}_1+j_2\hat{J}_2)(z), \tag{51}$$

$$G_2(z)=\left(\frac{2}{k}\right)^{1/2}(j_2\hat{J}_1-j_1\hat{J}_2)(z), \tag{52}$$

$$U(z)=\frac{2}{k}\left(\hat{J}_3+\frac{i\hat{k}}{k}\epsilon_{123}j_1j_2\right)(z), \tag{53}$$

$$T(z)=\frac{1}{k}((\hat{J}_1)^2+(\hat{J}_2)^2-ij_1j_2\hat{J}_3-\hat{k}(j_1\partial_z j_1+j_2\partial_z j_2))(z). \tag{54}$$

The superconformal generators (51) and (54) are the generalization of the Kostant operator and its square of the $\mathrm{su}(2)/u(1)$ model. The equal rank embeddings in Sec. III that are extented to construct the $N=2$ superconformal models are as follows:

- $\widehat{\mathrm{su}}(n+1)/\widehat{\mathrm{su}}(n)\times\hat{u}(1)$ with central charge $c_{\hat{g}/\hat{h}}=3\hat{k}n/(\hat{k}+n+1)$;
- $\widehat{\mathrm{so}}(n+2)/\widehat{\mathrm{so}}(n)\times\widehat{\mathrm{so}}(2)$ with central charge $c_{\hat{g}/\hat{h}}=3\hat{k}n/(\hat{k}+n)$, $n\geqslant 2$;
- $\widehat{\mathrm{su}}(m+n)/\widehat{\mathrm{su}}(m)\times\widehat{\mathrm{su}}(n)\times\hat{u}(1)$ with central charge $c_{\hat{g}/\hat{h}}=3\hat{k}mn/(\hat{k}+m+n)$;
- $\hat{E}_6/\widehat{\mathrm{so}}(10)\times\hat{u}(1)$ with central charge $c_{\hat{g}/\hat{h}}=48\hat{k}/(\hat{k}+12)$.

VI. GROUND STATES OF SUPERCONFORMAL THEORIES

As discussed in the previous sections, the decomposition of $\hat{g}$ and $\hat{h}$ at level k are, respectively,

$$\begin{aligned}\hat{g}_k&=\hat{g}_{\hat{k}}\oplus\widehat{\mathrm{so}}(\dim g)_1,\\ \hat{h}_k&=\hat{h}_{\hat{k}+g^\vee-h^\vee}\oplus\widehat{\mathrm{so}}(\dim h)_1,\end{aligned} \tag{55}$$

and in terms of generators are, respectively,

$$\begin{aligned}J^k_A(z)&=\hat{J}^{\hat{k}}_A(z)\underbrace{-\frac{i}{2}f_{[ABC]}j_{[B}j_{C]}(z)}_{g^\vee},\\ J^k_i(z)&=\hat{J}^{\hat{k}}_i(z)\underbrace{-\frac{i}{2}f_{[iab]}j_{[a}j_{b]}(z)}_{g^\vee-h^\vee}\underbrace{-\frac{i}{2}f_{[ijk]}j_{[j}j_{k]}(z)}_{h^\vee}.\end{aligned} \tag{56}$$

From the viewpoint of representation theory, the affine weights of $\hat{g}_k$ and $\hat{h}_k$ corresponding to (55) and (56) are, respectively,

$$\hat{\Lambda}+\hat{\rho}_g=(\Lambda;\hat{k};-m)+(\rho_g;g^\vee;0), \tag{57}$$

$$\hat{\lambda}+\hat{\rho}_h=(\lambda;\hat{k}+g^\vee-h^\vee;-n)+(\rho_h;h^\vee;0). \tag{58}$$

Recall that an affine Weyl group of $\hat{g}$ is a semidirect product of the Weyl group of g by the group of translations by coroots. The affine Weyl group still preserves the affine scalar product.[8] This allows us to define an Euler multiplet of $\hat{g}/\hat{h}$ as a set of the affine weights of $\hat{h}$ in accordance with that of g/h, i.e.,

$$\{c\cdot\hat{\Lambda}\equiv c(\hat{\Lambda}+\hat{\rho}_g)-\hat{\rho}_h\}. \tag{59}$$

Now let us suppose that

$$\hat{\Lambda}+\hat{\rho}_g\geqslant\hat{w}^{-1}(\hat{\mu}+\hat{\rho}_h), \tag{60}$$

where $\hat{\mu}$ is an affine weight of $\hat{h}$ in the decomposition of $V_{\hat{\Lambda}}\otimes\hat{S}$ into irreducible representations of $\hat{h}$ and $\hat{w}$ is an element of the affine Weyl group such that $\hat{w}^{-1}(\hat{\mu}+\hat{\rho}_h)$ is a dominant weight. Squaring (60) yields

$$\frac{1}{2(\hat{k}+g^\vee)}(C_2(\Lambda)-C_2(\mu)+|\rho_g|^2-|\rho_h|^2)-m+n\geqslant 0. \tag{61}$$

From (14), in case of $\mu=c\cdot\Lambda$, one yields a condition $m=n$. This means that in the Kazama–Suzuki construction if $\hat{\mu}=c\cdot\hat{\Lambda}$, the affine weight of $\hat{g}_{\hat{k}}$ at grade m always gives the affine weights of $\hat{h}_{\hat{k}+g^\vee-h^\vee}$ at the same grade m as the Euler multiplet. Adding and subtracting by the eigenvalue of the spinor highest weight of $\widehat{so}(\dim g/h)_1$ to (61), one obtains

$$\underbrace{\frac{1}{2(\hat{k}+g^\vee)}(C_2(\Lambda)-C_2(\mu))+\frac{1}{2}\tilde{\Lambda}^2}_{\Delta\ (=\ \text{conformal dimension})}\underbrace{-\frac{1}{16}(\dim\ g/h)+\frac{1}{2(\hat{k}+g^\vee)}(|\rho_g|^2-|\rho_h|^2)}_{-c_{\hat{g}/\hat{h}}/24}\geqslant 0. \tag{62}$$

The minimum of (62) corresponds to the vanishing of the modular anomaly of the Kazama–Suzuki coset model and is the eigenvalue of zero mode of energy-momentum tensor (39). It also implies that the Euler multiplets are the intrinsic ground states of the superconformal theories.

(Received 27 August 2003; accepted 12 December 2003)

We show that hierarchies of differential Schrödinger operators for identical particles which are separating for the usual (anti-)symmetric tensor product, are necessarily linear, and offer some speculations on the source of quantum linearity. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1646449]

I. INTRODUCTION

One of the properties considered in speculations about possible fundamental nonlinearities in quantum mechanics is *separation*, that is, product functions evolve as product functions. Separation is considered a nonlinear version of the notion of noninteraction, as then uncorrelated states remain uncorrelated under time evolution. We show here that if separation is combined with either Fermi or Bose statistics embodied in the usual (anti-)symmetrized tensor product states, and if all the multiparticle Shrödinger operators are differential, then they are necessarily linear.

The motivation for studying hierarchies of multiparticle nonlinear Schrödinger equations comes from two sources: (1) intellectual speculation about possible nonlinearities in quantum mechanics,[1] and (2) examples arising in representations of current algebras (diffeomorphism groups).[2] We consider the second motivation compelling as current algebra representations were found to include many known linear quantum systems and to predict new ones, anyons in particular.[3]

The nonlinear theories considered still maintain that states are represented by rays in a Hilbert space, that evolution is given by a (nonlinear) Schrödinger-type equation for the wave function, and that the modulus of the (normalized) wave function gives the probability density of detection. Though these assumptions can all be questioned, an important class of theories do satisfy them.

A complete analysis of separating hierarchies of Schrödinger-type equations for nonidentical particles was given in Ref. 4, however as the world is made up of bosons and fermions, the identical particle case has to be addressed. In Ref. 5 we explored the possibility of formulating a nonlinear relativistic theory based on a nonlinear version of the consistent histories approach to quantum mechanics. A toy model led to a set of equation among which there were instances of a weakened form of the separation property for scalar bosons. This showed once more that such a property is fundamental for understanding any nonlinear extension of ordinary quantum mechanics.

In Ref. 6 we showed that separating second-order differential hierarchies for identical particles are necessarily linear under various simplifying assumptions. We here prove linearity under fewer assumptions and in a more transparent fashion.

The present result should not be taken as an argument against nonlinear quantum mechanics. As such, it would be a much weaker physical argument than the causality violation objections already raised by various authors.[7,8] Though a degree of separability is necessary to be able to isolate and observe an independent physical system, it need not be exact. Another possibility is that in nonlinear theories one could conceivably form multiparticle states from states of fewer number of particles in a way other than by the usual (anti-)symmetric tensor product. In fact by

a)Electronic mail: svetlich@mat.puc-rio.br

using the nonlinear gauge transformations of Doebner, Goldin, and Nattermann[9] one can deform a linear separating hierarchy of differential Schrödinger operators to a nonlinear hierarchy of differential Schrödinger separating with respect to a deformed tensor product. Whether differential hierarchies that are not equivalent to linear ones and separating with respect to deformed tensor products exist, is still to be determined. Last, our results are strictly nonrelativistic. Causal relativistic nonlinear theories are seemingly hard to formulate, though they probably do exist.[5,10] What separation implies in such a context is still to be explored. What the present result hints at is the origin of linearity about which we comment in the final section.

II. SEPARATION

At time t an n-particle wave function Ψ depends on the positions $x_1,\ldots,x_n$ of each particle, where each $x_i \in \mathbb{R}^d$, d being the dimension of space, and on $A_1,\ldots,A_n$ where each A_i is an index denoting the internal degrees of freedom of each particle. Initially we assume the n particles to always belong to different species and so no permutation symmetry property is assumed of the wave function. We use the symbol $s=(s_1,\ldots,s_n)$ as labelling the species of the particle. For initial notational ease we shall combine the internal degrees of freedom index A_i with the position x_i into a single symbol $\xi_i=(x_i,A_i)$ and denote the n-tuple of such by ξ. Thus we denote an n-particle wave function at time t by $\Psi(\xi,t)$.

We assume that the evolution from time t_1 to time t_2 of the state corresponding to the ray with representative wave function $\Psi(\xi,t_1)$ can be expressed by a not necessarily linear evolution operator $E_s(t_2,t_1)$ applied to the wave function, that is

$$\Psi(\xi,t_2)=(E_s(t_2,t_1)\Psi)(\xi,t_1).$$

The simple tensor product of an n- and an m-particle wave function is defined as

$$(\phi\otimes\psi)(\xi_1,\ldots,\xi_n,\xi_{n+1},\ldots,\xi_{n+m})=\phi(\xi_1,\ldots,\xi_n)\psi(\xi_{n+1},\ldots,\xi_{n+m}). \tag{1}$$

The separation property for the simple tensor product now reads

$$E_s(t_2,t_1)(\Psi_1\otimes\Psi_2)=E_{s_1}(t_2,t_1)(\Psi_1)\otimes E_{s_2}(t_2,t_1)(\Psi_2), \tag{2}$$

where the species index s of Ψ is the concatenation of the species indices s_i of the Ψ_i. Strictly speaking, since states correspond to rays and not vectors, the right-hand side should be multiplied by a complex number $\gamma(t_2,t_1,s_1,s_2,\Psi_1,\Psi_2)$. To our knowledge, a full analysis of the possibility of such a factor has not been carried out. For the rest of this paper we shall assume that $\gamma=1$, the general assumption in the literature.

Now, the world is made of bosons and fermions and one should reconsider the separation property when one is dealing with a single species of identical particles. The separation property (2) must then be reformulated with respect to the symmetric or antisymmetric tensor product $\phi\,\hat{\otimes}\,\psi$ which is the right-hand side of (1) symmetrized or antisymmetrized according to either Bose or Fermi statistics:

$$(\phi\hat{\otimes}\psi)(\xi_1,\ldots,\xi_n,\xi_{n+1},\ldots,\xi_{n+m})=\frac{n!m!}{(n+m)!}\sum_{\mathcal{I}}(-1)^{fp(\mathcal{I})}\phi(\xi_{i_1},\ldots,\xi_{i_n})\psi(\xi_{j_1},\ldots,\xi_{j_m}), \tag{3}$$

where $\mathcal{I}=(i_1,\ldots,i_n)$ are n numbers from $\{1,\ldots,n+m\}$, in ascending order, $(j_1,\ldots,j_m)$ the complementary numbers, also in ascending order, f is the Fermi number 0 for bosons and 1 for fermions, and $p(\mathcal{I})$ is the parity (0 for even and 1 for odd) of the permutation $(1,\ldots,n+m)\mapsto(i_1,\ldots,i_n,j_1,\ldots,j_m)$. We have taken into account that both ϕ and ψ are either symmetric or antisymmetric with respect to permutations of their arguments. The normalizing factor

makes the product associative and the map $\phi\otimes\psi\mapsto\phi\hat{\otimes}\psi$ into a projection. For the identical particle case, the species symbol s reduces just to the particle number n.

If we pass to the generators of the evolution operators

$$H_s(t)=\frac{1}{i}\frac{\partial}{\partial t_2}E_s(t_2,t_1)\bigg|_{t_2=t_1=t},$$

then the separation property (2) (under the assumption that $\gamma=1$) becomes

$$H_s(\Psi_1\otimes\Psi_2)=H_{s_1}(\Psi_1)\otimes\Psi_2+\Psi_1\otimes H_{s_2}(\Psi_2), \tag{4}$$

where for notational simplicity we have suppressed indicating the t dependence of the H's. This relation (which we called tensor derivation) was fully analyzed in Ref. 4. Canonical decompositions and constructions were also presented.

An (anti-)symmetric tensor derivation would be a hierarchy of operators H_n that satisfies (4) with $\hat{\otimes}$ instead of $\otimes$. One does not have a classification of these as one has for ordinary tensor derivations as given in Ref. 4. It seems that the conditions to be a tensor derivation in the (anti-)symmetric case is rather stringent, and as we shall now see, in the case of differential operators, implies linearity.

It now becomes convenient to disentangle the space-coordinate x and the internal degree of freedom index A. Our one-particle wave function will thus be denoted by $\psi^A(x)$ with the index as a superscript for convenience. Multiparticle wave function will carry multiple indices in the usual way. The possibly nonlinear operators of the tensor derivation will be assumed to depend on the real and imaginary parts of the wave function in an independent fashion, though, to simplify notation, this is not denoted explicitly. Likewise, for notational ease, internal degree of freedom indices will be suppressed when no confusion can arise.

We shall use a multi-index notation for partial derivatives. Given a function $u(x_1,\ldots,x_n)$ and $I=(i_1,\ldots,i_n)$ an n-tuple of non-negative integers, we denote by $|I|$ the sum $i_1+\cdots+i_n$ and by u_I the partial derivative

$$\partial_I u=\frac{\partial^{|I|}u}{\partial x_1^{i_1}\cdots\partial x_n^{i_n}}.$$

For the case of a function $u(x,y)$ of two variables we write $u_{I,J}$ for I differentiations with respect to x, and J with respect to y.

Let us consider possibly nonlinear differential operators of any order (dependence on time can be construed as simply dependence on a parameter). Such a two-particle operator has the form $H(x,y,\phi^{AB}_{I,J}(x,y))$. Introducing variable names for the arguments of H, we write $H(x,y,a^{AB}_{I,J})$. When ϕ is constrained to be an (anti-)symmetrized product

$$\phi^{AB}(x,y)=\tfrac{1}{2}(\alpha^A(x)\beta^B(y)+(-1)^f\beta^A(x)\alpha^B(y)),$$

then the arguments of H are constrained to take on values of the form

$$a^{AB}_{I,J}=\tfrac{1}{2}(\alpha^A_I\tilde{\beta}^B_J+(-1)^f\beta^A_I\tilde{\alpha}^B_J). \tag{5}$$

Here quantities without the tilde are derivatives evaluated at x and those with, at y. The quantities on the right-hand sides: $\alpha^A_I,\beta^A_I,\tilde{\alpha}^B_J,\tilde{\beta}^B_J$, which we shall call the $\alpha\beta$ quantities, can be given, by Borel's lemma, arbitrary complex values by an appropriate choice of the points x and y and functions α and β. Denote the right-hand sides of the above equations by $\hat{a}^{AB}_{I,J}$.

The separability condition for the symmetrized tensor product now reads

$$2H_2^{AB}(x,y,\hat{a}_{I,J}) = H_1^A(x,\alpha_I)\tilde{\beta}_0^B + \alpha_0^A H_1^B(y,\tilde{\beta}_J) + (-1)^f H_1^A(x,\beta_I)\tilde{\alpha}_0^B + (-1)^f \beta_0^A H_1^B(y,\tilde{\alpha}_J). \tag{6}$$

Now we come to the main point: in the space of the $\alpha\beta$ quantities there are flows that leave $\hat{a}_{I,J}$ invariant, and so must leave the right-hand side of (6) invariant. This leads to linearity.

III. PROOF OF LINEARITY

One easily sees that the following transformations leave the $\alpha\beta$-quantities invariant:

$$\alpha_I^A \mapsto s\alpha_I^A, \quad \tilde{\beta}_J^B \mapsto s^{-1}\tilde{\beta}_J^B;$$

$$\alpha_I^A \mapsto \alpha_I^A + s\beta_I^A, \quad \tilde{\alpha}_J^B \mapsto \tilde{\alpha}_J^B - s(-1)^f \tilde{\beta}_J^B; \tag{7}$$

and the same with α and β interchanged. Symmetry (7) is enough to force linearity.

Note that s is a *complex* parameter, which means that the real and imaginary parts of the quantities undergo separate transformations. As a result, the right-hand side of (6) has to be annihilated by the vector field corresponding to (7):

$$\sum_{C,I} \left(\beta_I^C \frac{\partial}{\partial \alpha_I^C} - (-1)^f \tilde{\beta}_I^C \frac{\partial}{\partial \tilde{\alpha}_I^C} \right), \tag{8}$$

where by $\partial/\partial\alpha_I^C$ we mean the usual convention $(1/2)(\partial/\partial \operatorname{Re}\alpha_I^C - i\partial/\partial \operatorname{Im}\alpha_I^C)$ and similarly for the other partial derivative.

Applying now (8) to the right-hand side of (6), we get

$$\left[\sum_{C,I} \beta_I^C \frac{\partial H_1^A}{\partial \alpha_I^C}(x,\alpha) - H_1^A(x,\beta) \right] \tilde{\beta}_0^B - \beta_0^A \left[\sum_{C,I} \tilde{\beta}_I^C \frac{\partial H_1^B}{\partial \tilde{\alpha}_I^C}(y,\tilde{\alpha}) - H_1(y,\tilde{\beta}) \right] = 0.$$

Now the $\alpha\beta$ quantities can be chosen arbitrarily and generically we have $\beta_0^A \neq 0$ and $\tilde{\beta}_0^B \neq 0$ for all A and B and so generically

$$\frac{1}{\beta_0^A} \left[\sum_{C,I} \beta_I^C \frac{\partial H_1^A}{\partial \alpha_I^C}(x,\alpha) - H_1^A(x,\beta) \right] = \frac{1}{\tilde{\beta}_0^B} \left[\sum_{C,I} \tilde{\beta}_I^C \frac{\partial H_1^B}{\partial \tilde{\alpha}_I^C}(y,\tilde{\alpha}) - H_1(y,\tilde{\beta}) \right].$$

Since both sides depend on different sets of variables, each side is a constant k and we now have

$$\sum_{C,I} \beta_I^C \frac{\partial H_1^A}{\partial \alpha_I^C}(x,\alpha) - H_1^A(x,\beta) = k\beta_0^A.$$

Fixing α this equation states that $H_1(x,\beta)$ is a linear function of β with coefficients depending on x. We have thus shown the following.

Lemma: In an (anti-)symmetric tensor derivation in which the one-particle and two-particle operators are differential, the one-particle operator is necessarily linear.

To show the whole hierarchy is linear we proceed as in Ref. 6. An N-particle wave function for particles in $\mathbb{R}^d$ can be viewed as a one-particle wave function for particles (call them *conglomerate* particles) in $\mathbb{R}^{Nd}$. Consider the separating property for a $2N$-particle operator acting on an (anti-)symmetrized tensor product of two N-particle wave functions, reinterpreted now as a separating property for operators acting on the wave functions of two and one conglomerate particles. The only difference in relation to what we have already done, is the permutation symmetry of conglomerate particles. Let $\phi(x_1,\ldots,x_N)$ and $\psi(y_1,\ldots,y_N)$ be two properly (anti-)symmetric N-particle wave functions. One has using the conventions of (3),

$$(\phi\hat{\otimes}\psi)^{\mathcal{A}}(x_1,\ldots,x_{2N})=\frac{N!^2}{(2N)!}\sum_{\mathcal{I}}(-1)^{fp(I)}\phi^{\mathcal{A}_I}(x_{i_1},\ldots,x_{i_N})\psi^{\mathcal{A}_J}(x_{j_1},\ldots,x_{j_N}),\tag{9}$$

where $\mathcal{A}=(A_1,\ldots,A_{2N})$, $\mathcal{A}_I=(A_{i_1},\ldots,A_{i_N})$, and $\mathcal{A}_J=(A_{j_1},\ldots,A_{j_N})$ are internal degree of freedom indices. For (9) the possible values that one can attribute to the wave function and its derivatives at a point is now more complicated than that given by (5), but since by an appropriate choice of coordinates and an appeal to Borel's lemma we can again use (5) as a particular case for two conglomerate particles, the only differences being the change of the combinatorial factor 1/2 to $N!^2/(2N)!$ and the possibility that the factor $(-1)^f$ may be absent even in the Fermi case. These differences are nonessential to the derivation, and repeating the argument presented above for the two-particle case we see that the operator for one conglomerate particle must be linear and so the N-particle operator must be linear. With this the whole hierarchy must be linear. We thus have the following.

Theorem: *An (anti-)symmetric tensor derivation in which all multiparticle operators are differential, is necessarily linear*.

IV. COMMENTS ON THE ORIGIN OF QUANTUM LINEARITY

Our view on quantum-mechanical linearity is that it is an emergent feature of the world that arises along with the manifold structure of space–time from some more fundamental pregeometric reality. Thus questions of (non)linearity should be joined with the general quantum gravity program. Previous clues in this direction are provided by (1) the apparent connections between linearity and the causal structure of space–time[8,11] and by (2) the difficulty of incorporating internal degrees of freedom, such as spin, in separating nonlinear theories, requiring new multiparticle effects at every particle number.[12] We consider the present result as another such clue, linking linearity to the statistics of identical particles and the possibility of independently evolving systems.

The emergent view of linearity is also supported by the present extremely small experimental bounds on possible nonlinear effects, the suppression factor being about 10^{-20}.[13] If linearity is emergent, experimental evidence would be hard to come by. There is however the possibility that ultra-high-energy cosmic rays actually do probe the hypothetically nonlinear pregeometric regime.[14] The possible role of nonlinearities on the Planck scale has also been considered by Singh,[15] and by Mavromatos and Szabo.[16]

(Received 27 October 2003; accepted 13 November 2003)

For a certain class of triangles (with angles proportional to π/N, $N\geqslant 3$) we formulate an image method by making use of the group G_N generated by reflections with respect to the three lines which form the triangle under consideration. We formulate the regularization procedure by classification of subgroups of G_N and corresponding fixed points in the triangle. We then also calculate Casimir energy for a cavity of infinite height with triangular cross section for scalar massless fields. More detailed calculation is given for odd N. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1643196]

I. INTRODUCTION

There is a rather restricted class of geometries, for which we have Casimir energies in explicit forms. On the other hand, to have calculations for larger sets of geometries in hand will certainly help the better understanding of the phenomena and, may also offer new experimental realizations especially in light of the rapid progress in the nanotechnologies.[1] To calculate the energy momentum tensor one has to solve the boundary problem, that is one has to obtain eigenvalues and eigenfunctions for the field which is confined into the given region. The eigenvalues usually correspond to the roots of some special functions. For example for the three-dimensional ball[2] or cylindrical regions[3] to impose the required radial boundary conditions; one has to deal with Bessel functions and with the roots of them.

For some geometries with plane boundaries the Casimir problem is easier, especially if we can employ the method of images. The original parallel plate geometry, and in general rectangular prisms[4] are of that type. For parallel plates the Dirichlet Green function is computed as an infinite sum of the ''free'' propagators to the image points. The images are due to infinite reflections between the planes, a fact that is best visualized in the path integral formulation of the quantum mechanics.[5] Similarly for multiply connected geometries (i.e., for Aharonov–Bohm case) one sums over all homotopically nonequivalent paths. As we see in the next sections the groups generated by the reflections too provide useful guides in the construction of the Green functions. For the parallel plate the group is isomorphic to Z, for the three-dimensional rectangular prism for example, it is Z^3. However if the rectangularity condition is dropped, the groups generated by reflections becomes noncommutative which is the case for the present work.

We calculate the Casimir energy for the massless scalar field for a certain class of triangular regions. We restrict our attention on the triangles whose angles are proportional to π/N, where N is a natural number greater than 2. Namely one of the angles is π/N and another is $\pi/2$ for even N and $\pi[(N-1)/2N]$ for odd N. We also develop a regularization technique by reducing the problem of finding divergences to the classification of points of the region and their stability subgroups.

In Sec. II we investigate the structure of the group G_N generated by the reflections with respect to the three lines which form the triangle. This group will play central role in the con-

[a]Electronic mail: hagi@gursey.gov.tr
[b]Electronic mail: duru@gursey.gov.tr.

struction of the Green function satisfying the Dirichlet boundary condition, and in the regularization procedure.

We show that this group is isomorphic to the semidirect product of the dihedral group D_N and finite dimensional lattices.

Section III is devoted to the construction of the Green function for the massless scalar field which vanishes on the boundary of the triangle.

In Sec. IV we formulate the regularization procedure for the Green function in the triangle by classification of points in the triangle and their stability groups. The trivial group consisting of the identity element is the stability group for any points in the triangle. The corresponding term in the Green function is the free Green function in Minkowski space which makes an infinite contribution to the energy momentum tensor. Stability group of the points on a side of the triangle is generated by the reflection operator with respect to this side. In this way terms with surface divergences is found. Since at the vertices of the triangle the smoothness condition is violated we also have line divergences (vertex of the triangle in the plane corresponds to the line in three dimensions, that is why we call it line divergence). We find stability groups of these points and corresponding singular terms in the Green function.

In Sec. V we give the general expression for the energy momentum tensor in terms of the sum over elementary power functions. We also see that the energy density per unit length in the direction perpendicular to the triangle under consideration can be represented as the integral over the boundary of this triangle and the integrand is the elementary power functions. We presented the calculation for odd N in detail.

II. REFLECTIONS IN A CLASS OF TRIANGLES

For $N=3,4,5,\ldots$ and $k=1,2,\ldots,N-2$ consider the triangles Δ_k^N in x^1x^2-plane formed by the lines

$$L_1=\{\mathbf{x}\in R^2: x^2=0\}, \tag{1}$$

$$L_2=\{\mathbf{x}\in R^2: x^2=x^1\tan\upsilon\}, \tag{2}$$

$$L_3=\{\mathbf{x}\in R^2: x^2=(b-x^1)\tan(k\upsilon)\}, \tag{3}$$

where b is the length of the side laying on the line L_1 and $\upsilon=\pi/N$ is the angle between L_1 and L_2. (Note that in calculating the Casimir energy for the wedge geometry one also starts with angle π/N, then makes analytic continuation.[6])

The actions of the reflections Q_j with respect to the lines L_j, $j=1,2,3$ on the vector

$$\mathbf{x}=\begin{pmatrix} x^1 \\ x^2 \end{pmatrix} \tag{4}$$

are given by

$$Q_1\mathbf{x}=p\mathbf{x},\quad Q_2\mathbf{x}=rp\mathbf{x},\quad Q_3\mathbf{x}=pr^k\mathbf{x}+\mathbf{x}_0, \tag{5}$$

where

$$r=\begin{pmatrix} \cos 2\upsilon & -\sin 2\upsilon \\ \sin 2\upsilon & \cos 2\upsilon \end{pmatrix},\quad p=\begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix},\quad \mathbf{x}_0=(1-pr^k)\begin{pmatrix} b \\ 0 \end{pmatrix}. \tag{6}$$

Denote by G_N the group generated by the these reflections. G_N is one free group with relations. Relations between the elements Q_1, Q_2, and Q_3 can be obtained from the formulas (5), and from the properties of the rotation r and reflection p operators

$$r^N=1,\quad p^2=1,\quad pr=r^{N-1}p,\quad r^k\mathbf{x}_0=-p\mathbf{x}_0. \tag{7}$$

Some of the obvious relations are

$$Q_j^2=1,\ (Q_1Q_2)^N=1, \tag{8}$$

from which we conclude that the reflections Q_1 and Q_2 generate the finite subgroup

$$D_N=\{r^s,pr^s,s=0,1,\ldots,N-1\}, \tag{9}$$

which is the dihedral group of dimension $2N$. Consider the linear space V_N which consists of the vectors

$$\boldsymbol{\xi}=\sum_{s=0}^{N-1} n_s\mathbf{x}_s, \tag{10}$$

where n_s are integers and

$$\mathbf{x}_s=r^s\mathbf{x}_0. \tag{11}$$

The equalities

$$r\mathbf{x}_s=\mathbf{x}_{s+1},\ \ p\mathbf{x}_s=\mathbf{x}_{N-s+k} \tag{12}$$

imply that D_N is the automorphism group of the linear space V_N. The action of D_N is given in the natural way

$$\pi(q)\boldsymbol{\xi}=q\boldsymbol{\xi};\ \ q\in D_N. \tag{13}$$

Since V_N is a vector space over the integer numbers, unlike the spaces over the real numbers, the dimension $|V_N|$ is not necessarily equal to the dimension of the vectors $\mathbf{x}_s$. It may be larger, that is in our case may be greater than two. For example the dimensions of V_5, V_8 are four; while the dimensions of V_3, V_6, and V_4 are two (the vector spaces $V_3\equiv V_6$ and V_4 are known as the hexagonal and square lattices[7]). (For a detailed discussion of this problem, see Appendix A.)

The group G_N is the subgroup of the semidirect product group $D_N\star V_N$. In fact for any element $g\in G_N$ one can find the pair of elements $q\in D_N$ and $\boldsymbol{\xi}\in V_N$ as

$$g\mathbf{x}=q\mathbf{x}+\boldsymbol{\xi}\equiv(q,\boldsymbol{\xi})\mathbf{x};\ \ \mathbf{x}\in R^2. \tag{14}$$

In particular,

$$Q_1=(p,0),\quad Q_2=(rp,0),\ \ Q_3=(pr^k,\mathbf{x}_0). \tag{15}$$

G_N contains two subgroups: D_N and the one generated by Q_3. Since V_N does not contain invariant subspaces with respect to (13) we conclude that there is no subgroup in the semidirect product group which contains D_N and the group generated by Q_3 simultaneously. This fact implies that G_N is isomorphic to $D_N\star V_N$. In the special case of $|V_N|=2$ this group is called the wallpaper group.[7]

III. CONSTRUCTION OF THE GREEN FUNCTION IN THE TRIANGLES WITHOUT OBTUSE ANGLES

Consider the representation of the group G_N in the space of functions on the four-dimensional Minkowski space

$$T(g)f(x)=f(gx). \tag{16}$$

Here the action of the group G_N is given by substitution $\mathbf{x}\to x$, $\boldsymbol{\xi}\to\xi$, $p\to P$, $r\to R$ where

$$R=\begin{pmatrix}1&0&0\\0&r&0\\0&0&1\end{pmatrix},\quad P=\begin{pmatrix}1&0&0\\0&p&0\\0&0&1\end{pmatrix},\tag{17}$$

which are 4×4 matrices and

$$\xi=\begin{pmatrix}0\\ \boldsymbol{\xi}\\0\end{pmatrix},\quad x=\begin{pmatrix}x^0\\ \mathbf{x}\\x^3\end{pmatrix},\tag{18}$$

which are four-dimensional column vectors.

Using (15) one can verify that the operator

$$\mathbf{O}=\sum_{n\in Z}\sum_{s=0}^{N-1}\left(T((R^s,\xi))-T((PR^s,\xi))\right)\tag{19}$$

satisfies the following property:

$$T(Q_j)\mathbf{O}=-\mathbf{O}.\tag{20}$$

In (19), $n=(n_0,n_1,\ldots,n_{|V_N|-1})$ is multi-index and

$$\xi=\sum_{t=0}^{|V_N|-1}n_t x_t,\tag{21}$$

where

$$x_s=\begin{pmatrix}x^0\\ \mathbf{x}_s\\x^3\end{pmatrix}\tag{22}$$

and $\mathbf{x}_s$ are the base vectors described in the previous section.

It is obvious that if we define a function $\mathbf{O}f(x)$, it must vanish on the lines L_j of reflections Q_j; the fact that we make use in the construction of the Green function inside the triangle Δ_k^N, satisfying the Dirichlet boundary conditions. Since the operator $\mathbf{O}$ commutes with the Klein–Gordon operator (which is invariant under translations, rotations and reflections) the function

$$K(x,x')\equiv\mathbf{O}G(x,x')=\sum_{n\in Z}\sum_{s=0}^{N-1}\left(G(R^sx+\xi,x')-G(PR^sx+\xi,x')\right),\tag{23}$$

satisfies the equation

$$\eta^{\mu\nu}\frac{\partial^2}{\partial x^\mu\partial x^\nu}K(x,x')=\mathbf{O}\delta(x-x')\tag{24}$$

for any $x,x'\in M^2\times\Delta_k^N$, $M^2=\{(x_0,x_3)\}$; i.e., the two-dimensional Minkowski space, and the boundary condition

$$K(x,x')\big|_{x\in M^2\times\partial\Delta_k^N}=0,\tag{25}$$

where $\partial\Delta_k^N$ is the boundary of the triangle Δ_k^N. G is is the Green function in the Minkowski space with the metric $\eta=\mathrm{diag}(1,-1,-1,-1)$,

$$G(x,x')=-\frac{1}{4\pi^2}\frac{1}{|x-x'|^2}. \tag{26}$$

The function $K(x,x')$ is the Green function if the right-hand side of (24) is a delta function

$$\mathbf{O}\delta(x-x')=\delta(x-x') \tag{27}$$

for any $x,x'\in M^2\times\Delta_k^N$. The above condition implies that for any $(q,\boldsymbol{\xi})\neq(1,0)$ and for any $\mathbf{x},\mathbf{x}'\in\Delta_k^N$,

$$\delta(q\mathbf{x}+\boldsymbol{\xi}-\mathbf{x}')=0 \tag{28}$$

must be satisfied. In other words any points inside the triangle should be the representative of different orbits of the coset space R^2/G_N. The orbits of the coset space R^2/D_N are

$$[\mathbf{x}]=\{r^s\mathbf{x},pr^s\mathbf{x}:\ s=0,\ldots,N-1\}. \tag{29}$$

It is clear that we can identify this coset space with region X between two lines L_1 and L_2 including the boundaries. For any orbit in R^2/D_N there exists a unique representative in X. Since the group G_N is generated by the elements of D_N and Q_3 the problem of constructing the coset space R^2/G_N reduces to finding the subspaces Y of X such that the reflection Q_3 maps Y into X. Consider the area between three lines L_j, which is the triangle under consideration. The previous condition implies that the two angles $k\upsilon$ and $s\upsilon$ of the triangle between the lines L_1, L_3 and L_2, L_3 must be less than or equal to $\pi/2$. The restrictions

$$k\upsilon\leqslant\frac{\pi}{2},\quad s\upsilon\equiv\pi-(k+1)\upsilon\leqslant\frac{\pi}{2} \tag{30}$$

with solutions

$$k=\begin{cases}\dfrac{N}{2}, & \text{for even } N\\[2ex] \dfrac{N-1}{2}, & \text{for odd } N\end{cases} \tag{31}$$

imply that for triangles without obtuse angle the function $K(x,x')$ in (23) is indeed the Green function. Note that Eqs. (30) have also been solved by $k=(N-2)/2$ for even N. In this case $s=N/2$. For $k=N/2$ we have $s=(N-2)/2$. Therefore this solution is congruent to the previous one; that is $\Delta_{N/2}^N$ goes to $\Delta_{(N-2)/2}^N$ when the length b goes to $b\cos\upsilon$.

Finally we like to remark that, for massive fields, instead of $G(x,x')$ one has to put the Green function for the massive scalar fields in the Minkowski space in (23).

IV. REGULARIZATION OF THE GREEN FUNCTION

In polygonal regions there are three types of singular terms that to be subtracted to obtain the regularized Green function: Free space term, surface, and vertex terms.

Inspecting (23) we observe that the term

$$T(g)G(x,x')=G(gx,x') \tag{32}$$

leads to singularity whenever $gx=x$; that is, the singularities arise at the elements of the group G_N which leave the points fixed. The regularization problem is then reduced to the classification of the points of the region and their stability subgroups:

(i) The identity element (which is the trivial subgroup) leaves all points fixed. The term $T((1,0))G(x,x')$ in (23) therefore gives the volume singularity and is the free Green function.

(ii) The points on the line L_j are left fixed by the reflection Q_j. The group generated by Q_j is then the stability subgroup for the line L_j. Since the identity element of the two-dimensional reflection group is already employed in the volume regularization, the surface singularity terms in (23) are

$$K_S(x,x')=\sum_{j=1}^{3} T(Q_j)G(x,x'). \tag{33}$$

(iii) To discuss the vertex singularities, let us first consider the vertex at the intersection point of the lines L_1 and L_2. The N-dimensional subgroup generated by the element Q_1Q_2 is the stability subgroup of this vertex. The divergence term at the vertex we consider is

$$K_{L_1L_2}(x,x')=\sum_{j=1}^{N-1} T((Q_1Q_2)^j)G(x,x'). \tag{34}$$

The element Q_1Q_3 generates the stability subgroup of the vertex at the intersection point of the lines L_1 and L_3. Due to restriction (31) and $Q_1Q_3=(r^k,-r^k\mathbf{x}_0)$ we conclude that the dimension of this group is 2 for even N and N for odd N. Therefore we have

$$K_{L_1L_3}(x,x')=\sum_{j=1}^{L-1} T((Q_1Q_3)^j)G(x,x'), \tag{35}$$

where L is the dimension of the stability group, that is $L=2$ if N is even and $L=N$ if N is odd.

Finally let us consider the third vertex which is the intersection point of the lines L_2 and L_3. The stability group of this point is generated by the element Q_2Q_3. One can verify that the dimension D of this group is

$$D=\begin{cases} N & \text{for even } \dfrac{N}{2} \\ \dfrac{N}{2} & \text{for odd } \dfrac{N}{2} \\ N & \text{for odd } N, \end{cases} \tag{36}$$

and the corresponding singular line terms are

$$K_{L_2L_3}(x,x')=\sum_{j=1}^{D-1} T((Q_2Q_3)^j)G(x,x'). \tag{37}$$

Collecting all the above terms we arrive at

$$K_L(x,x')=\sum_{j=1}^{N-1} (T((Q_1Q_2)^j)+T((Q_1Q_3)^j)+T((Q_2Q_3)^j))G(x,x') \tag{38}$$

for odd N, and

$$K_L(x,x')=\left(T(Q_1Q_3)+\sum_{j=1}^{N-1} (T((Q_1Q_2)^j)+T((Q_2Q_3)^j))\right)G(x,x') \tag{39}$$

for even $N/2$, and

$$K_L(x,x')=\left(T(Q_1Q_3)+\sum_{j=1}^{N-1}T((Q_1Q_2)^j)+\sum_{j=1}^{(N/2)-1}T((Q_2Q_3)^j)\right)G(x,x') \tag{40}$$

for odd $N/2$. Subtracting all divergences from (23) we obtain the regularized Green function

$$K_r(x,x')=K(x,x')-G(x,x')-K_S(x,x')-K_L(x,x'). \tag{41}$$

Before closing this section we would like to emphasize that if the method of images is applicable to a geometry, the stability group classification is quite a reliable approach to the regularization.

V. ENERGY MOMENTUM TENSOR

The energy momentum tensor for conformally coupled massless scalar field is given by[8]

$$T_{\mu\nu}=\tfrac{2}{3}\partial_\mu\phi\partial_\nu\phi-\tfrac{1}{6}\eta_{\mu\nu}\partial_\rho\phi\partial^\rho\phi-\tfrac{1}{3}\phi\partial_\mu\partial_\nu\phi+\tfrac{1}{12}\eta_{\mu\nu}\phi\partial_\rho\partial^\rho\phi. \tag{42}$$

Since the vacuum expectation value of the product of two scalar fields is the Green function, we can express the energy momentum tensor in the region we study as

$$T_{\mu\nu}=\lim_{x\to x'}\left[\frac{1}{3}(\partial_\mu\partial'_\nu+\partial'_\mu\partial_\nu)-\frac{\eta_{\mu\nu}}{6}\eta^{\sigma\rho}\partial_\sigma\partial'^{\rho}-\frac{1}{6}(\partial_\mu\partial_\nu+\partial'_\mu\partial'_\nu)\right]K_r(x,x'), \tag{43}$$

where $\partial_\mu\equiv\partial/\partial x^\mu$, and $K_r(x,x')$ is given by (41).

The vacuum energy density in particular is given by the following expression (for details, see Appendix B):

$$T_{00}=\frac{1}{6\pi^2}\sum_{(n,s)}\left[\frac{|(pr^s+1)\boldsymbol{\xi}|^2}{|(pr^s-1)\mathbf{x}+\boldsymbol{\xi}|^6}-\frac{2+\cos(2s\upsilon)}{|(r^s-1)\mathbf{x}+\boldsymbol{\xi}|^4}\right]. \tag{44}$$

The summation runs over the indices $n=(n_0,n_1,\ldots,n_{|V_N|-1})\in Z^{|V_N|}$, and $s=0,1,\ldots,N-1$. The terms corresponding to the singularities described in the previous section should be dropped in (44). The term in the second summation in (44) with $(n=0,s=0)$ is the energy of the free vacuum. The terms with $(n=0,s=0)$, $(n=0,s=1)$, and $(n=(1,0,\ldots,0),s=k)$ in the first summation of (44) are surface divergence terms. Note that due to the $|(pr^s+1)\boldsymbol{\xi}|^2$ factor they are automatically zero. This is not surprising since it is known that the energy momentum tensor for comformally coupled scalar field is finite on flat surfaces.[9] Terms $(n=0,s=1,2,\ldots,N-1)$ in the second summation of (44) are line divergent ones in the vertex which is the intersection point of the lines L_1 and L_2. Using the results of the previous section one may also find the vertex divergence terms for other two vertices.

Integrating the above energy density over the triangle Δ_k^N we arrive at the energy density E per unit length in x^3 direction. First we observe the existence of two exact forms

$$\omega_1^s=\frac{2+\cos(2s\upsilon)}{2|(r^s-1)\mathbf{x}+\boldsymbol{\xi}|^4}dx^1\wedge dx^2, \tag{45}$$

$$\omega_2^s=\frac{|(pr^s+1)\boldsymbol{\xi}|^2}{|\mathbf{v}(pr^s)|^6}dx^1\wedge dx^2. \tag{46}$$

They can be rewritten as $\omega_j^s=d\Omega_j^s$, where

$$\Omega_1^s=D_s\frac{((r^s-1)\mathbf{x}+\boldsymbol{\xi})^2dx^1-((r^s-1)\mathbf{x}+\boldsymbol{\xi})^1dx^2}{|(r^s-1)\mathbf{x}+\boldsymbol{\xi}|^4},\quad s\neq 0, \tag{47}$$

$$\Omega_2^s=\frac{|(pr^s+1)\boldsymbol{\xi}|^2}{|(pr^s-1)\mathbf{x}+\boldsymbol{\xi}|^6}(r^{s/2}\mathbf{x})^1 d(r^{s/2}\mathbf{x})^2, \tag{48}$$

where

$$D_s=\frac{2+\cos(2sv)}{6(1-\cos(2sv))}.$$

By making use of the Stokes theorem one can convert the integration over the triangle Δ_k^N into the integral over its boundary $\partial\Delta_k^N$. The energy density per unit length in x^3 direction is then

$$E=-\frac{1}{6\pi^2}\langle J_0+J_1-J_2\rangle, \tag{49}$$

where S_k^N is the area of the triangle Δ_k^N and

$$J_0=\sum_{n\in Z^{|V_N|}}\frac{3S_k^N}{|\boldsymbol{\xi}|^4}, \tag{50}$$

$$J_1=\sum_{n\in Z^{|V_N|}}\sum_{s=1}^{N-1}\int_{\partial\Delta_k^N}\Omega_s^1, \tag{51}$$

$$J_2=\sum_{n\in Z^{|V_N|}}\sum_{s=0}^{N-1}\int_{\partial\Delta_k^N}\Omega_s^2. \tag{52}$$

In J_j we take summation over all values of n and s. The brackets $\langle\ \rangle$ in (49) means that we have to drop the singularity terms. J_j may be divergent if $|V_N|$ is greater than 3. However their difference should be finite. We have to treat each term as formal series. Then collecting them together we obtain the final result.

A. N=odd case as an example

Let us restrict our attention to the case of odd N, for which the vector space V_N appears to be invariant under the half angle rotations $r^{s/2}$. This can be shown from the identity

$$r^{N/2}\boldsymbol{\xi}=-\boldsymbol{\xi}. \tag{53}$$

Using the relations

$$(pr^s\pm 1)=r^{-(s/2)}(p\pm 1)r^{(s/2)},\quad (r^s-1)=-a_s r^{(s/2)+(N/4)} \tag{54}$$

with $a_s=2\sin(sv)$ and making the reparametrization in the multi-index n which is equivalent to the change of variable $r^{s/2}\boldsymbol{\xi}\to\boldsymbol{\xi}$ we arrive at

$$J_1=-\sum_{n\in Z^{|V_N|}}\sum_{s=1}^{(N-1)/2} D_s\int_{\partial\Delta_{N/2}}\frac{(a_s\mathbf{z}-\boldsymbol{\xi})^2dz^1-(a_s\mathbf{z}-\boldsymbol{\xi})^1dz^2}{|a_s\mathbf{z}-\boldsymbol{\xi}|^4}, \tag{55}$$

$$J_2=\sum_{n\in Z^{|V_N|}}\sum_{s=0}^{N-1}\int_{\partial\Delta_s}\frac{|(p+1)\boldsymbol{\xi}|^2}{|(p-1)\mathbf{y}+\boldsymbol{\xi}|^6}y^1dy^2. \tag{56}$$

Here we have used the short notation $\Delta_0\equiv\Delta_k^N$ and $\Delta_s=r^{s/2}\Delta_0$, that is, the triangle Δ_s is Δ_0 rotated by the angle sv. We also used the symmetry $s\to N-s$ in (55) to reduce the summation over s. Denote by a_0, a_1, and c_0 the sides of the triangle Δ_0 laying on the lines L_1, L_2, and L_3.

Then a_s, a_{s+1}, and c_s will be the sides of the triangle Δ_s, that is, $a_{s+1}=r^{s/2}a_s$ and $c_{s+1}=r^{s/2}c_s$. Since the orientation on the side a_{s+1} of the triangle Δ_s is opposite to the one on the side a_{s+1} of Δ_{s+1} we have

$$J_2=\sum_{n\in Z^{|V_N|}}\int_U\frac{|(p+1)\boldsymbol{\xi}|^2}{|(p-1)\mathbf{y}+\boldsymbol{\xi}|^6}y^1dy^2, \tag{57}$$

where the integration contour $U=a_0\cup b_0\cup b_1\cup\cdots\cup b_{N-1}\cup a_N$ oriented anticlockwise. On the sides a_0, a_N, and $c_{(N-1)/2}$ we have $y^2=\text{const}$, that is, these sides do not make contribution in J_2. We also observe that reflection operator $-p$ with respect to the y^2 axis send c_j to c_{N-j-1} with opposite orientation. Since the one form in the integral changes sign under reflection $\mathbf{y}\to-p\mathbf{y}$ one can rewrite the above expression as

$$J_2=2\sum_{n\in Z^{|V_N|}}\sum_{j=0}^{(N-3)/2}\int_{c_j}\frac{|(p+1)\boldsymbol{\xi}|^2}{|(p-1)\mathbf{y}+\boldsymbol{\xi}|^6}y^1dy^2. \tag{58}$$

For given c_j we construct closed contour in the following way. From the end points of c_j draw lines which are parallel to the y^1-axis. They intersect y^2 axis at the points $b\sin j\upsilon$ and $b\sin(j+1)\upsilon$. The interval between these two points, c_j and two intervals between them, which are parallel to the y^1-axes form the desired contour which we denote by C_j. Since at $y^1=0$ and $y^2=\text{const}$ the one form in the above integral is zero. We then have

$$J_2=2\sum_{n\in Z^{|V_N|}}\sum_{j=0}^{(N-3)/2}\int_{C_j}\frac{|(p+1)\boldsymbol{\xi}|^2}{|(p-1)\mathbf{y}+\boldsymbol{\xi}|^6}(y^1-A_jy^2-B_j)dy^2, \tag{59}$$

where we have added the exact forms, which are the second and third terms in the bracket, for an integral of the exact form over the closed form is zero. We choose the coefficients A_j and B_j to satisfy

$$y^1-A_jy^2-B_j=0, \tag{60}$$

for $\mathbf{y}\in c_j$, that is, to make the value of the one form zero on the side c_j. We have

$$A_j=-\frac{\cos\upsilon(k-j)}{\sin\upsilon(k-j)},\quad B_j=b\frac{\sin\upsilon k}{\sin\upsilon(k-j)}, \tag{61}$$

where $k=(N-1)/2$. Nonzero contribution to the integral comes only from the integration over the interval laying on the y^2 axis:

$$J_2=8\sum_{n\in Z^{|V_N|}}\sum_{j=0}^{(N-3)/2}\int_{b\sin j\upsilon}^{b\sin(j+1)\upsilon}\frac{(\xi^1)^2(A_jt+B_j)dt}{((\xi^1)^2+(2t-\xi^2)^2)^3} \tag{62}$$

or

$$J_2=\frac{1}{2b^2\sin^2k\upsilon}\sum_{n\in Z^{|V_N|}}\sum_{j=0}^{(N-3)/2}\frac{\eta_1^2}{\sin(k-j)\upsilon}\int_{f_j}^{f_{j+1}}dx\,\frac{1-x\cos((k-j)\upsilon)}{(\eta_1^2+(x-\eta_2)^2)^3}, \tag{63}$$

where $f_j=\sin j\upsilon/\sin k\upsilon$ and $\boldsymbol{\xi}=2b\sin k\upsilon\boldsymbol{\eta}$ or

$$\boldsymbol{\eta}=\sum_{t=0}^{|V_N|-1}n_t\mathbf{x}_t',\quad \mathbf{x}_t'=r^{t+1/4}\begin{pmatrix}1\\0\end{pmatrix}. \tag{64}$$

(We also used lower indices for the vector $\boldsymbol{\eta}$.)

Now consider expression (55). Rotation $r^{1/2}$ maps interval $a_{N/2}$ on $a_{(N/2)+1}$ which has the opposite orientations. Since the expression under the integral is invariant under transformation $\mathbf{z} \rightarrow r^{1/2}\mathbf{z}$, the contributions from these intervals cancel each other. J_1 is nonzero on the interval $c_{N/2}$. Let us make the change of variable $\mathbf{y}=r^{-(N+1)/4}\mathbf{z}$. Then $c_{N/2}$ goes to $c_{-1/2}$ on which $y^1 = b\cos\upsilon/2$ and $y^2 \in [-b\sin\upsilon/2, b\sin\upsilon/2]$. Therefore,

$$J_1=\sum_{n\in Z^{|V_N|}}\sum_{s=1}^{(N-1)/2} D_s \int_{-b\sin\upsilon/2}^{b\sin\upsilon/2} \frac{\left(ba_s\cos\frac{\upsilon}{2}-\xi^1\right)dy}{\left(\left(ba_s\cos\frac{\upsilon}{2}-\xi^1\right)^2+(a_s y-\xi^2)^2\right)^2} \tag{65}$$

or

$$J_1=\frac{\sin\frac{\upsilon}{2}}{8b^2\sin^3 k\upsilon}\left\langle \sum_{n\in Z^{|V_N|}}\sum_{s=1}^{(N-3)/2}\frac{D_s}{f_s}\int_{-f_s}^{f_s}\frac{\left(f_s\cos\frac{\upsilon}{2}-\eta_1\right)dx}{\left(\left(f_s\cos\frac{\upsilon}{2}-\eta_1\right)^2+\left(x\sin\frac{\upsilon}{2}-\eta_2\right)^2\right)^2}\right\rangle. \tag{66}$$

Note that in the above expression we have dropped the term $s=(N-1)/2$. Since $f_{(N-1)/2}=1$ by the reparametrization $\boldsymbol{\eta}\rightarrow\boldsymbol{\eta}+\mathbf{x}_0'$ we can rewrite it as

$$-\frac{1}{8b^2\sin^3 k\upsilon}D_{(N-1)/2}\sum_{n\in Z^{|V_N|}}\int_{-1}^{1}\frac{\eta_1 dx}{\eta_1^2+\left((x-1)\sin\frac{\upsilon}{2}-\eta_2\right)^2\Big)^2} \tag{67}$$

which is an odd function in the η_1 variable. Therefore it is zero.

B. A special example: $N=3$

Finally let us consider the special case when $N=3$ and $k=1$. We have $\upsilon=\pi/3$ and $\boldsymbol{\xi}=\sqrt{3}b\,\boldsymbol{\eta}$ with

$$\boldsymbol{\eta}=\frac{n_0}{2}\begin{pmatrix}\sqrt{3}\\1\end{pmatrix}+\frac{n_1}{2}\begin{pmatrix}-\sqrt{3}\\1\end{pmatrix}, \tag{68}$$

that is, $|V_3|=2$. We have $S_1^3=(\sqrt{3}/4)\,b^2$, $J_1=0$, and

$$J_0=\frac{\sqrt{3}}{12b^2}\sum_{n\in Z^2}\frac{1}{|\boldsymbol{\eta}|^4}, \tag{69}$$

$$J_2=\frac{2}{3\sqrt{3}b^2}\sum_{n\in Z^2}\eta_1^2\int_0^1 dx\,\frac{2-x}{(\eta_1^2+(x-\eta_2)^2)^3}. \tag{70}$$

The vacuum energy density per unit length in x^3 direction is then

$$E=\frac{\sqrt{3}}{12b^2}\left\langle\sum_{n\in Z^2}\left(\frac{1}{|\boldsymbol{\eta}|^4}+\frac{8}{3}\eta_1^2\int_0^1 dx\,\frac{2-x}{(\eta_1^2+(x-\eta_2)^2)^3}\right)\right\rangle. \tag{71}$$

VI. DISCUSSION

We have calculated the Casimir energy for a class of triangles without an obtuse angle. We applied the method of images. Unlike the case of parallel plate or rectangular prisms, the group generated by reflections is not Abelian; thus, the employment of the image method for triangles is not trivial.

The regularization procedure is observed to be equivalent to the classification of the points in the triangle and their stability subgroups. To renormalize the Green function we subtract the terms corresponding to these stability subgroups. The identity element is the stability subgroup for the all points, reflections, and bi-product of reflections generate the stability subgroups of points on the planes involving the sides, and of the lines passing through the vertices, respectively.

We hope that the technique we used which essentially is based on the employment of the groups generated by reflections from the surfaces, can be employed for other polygonal regions. We also hope that it may even be possible to study some other geometries with smooth boundaries, as the limiting case of the suitable polygonal regions. For example, for an elliptical region such a process may not be as hopeless as dealing with the roots of the Mathieu functions.

ACKNOWLEDGMENT

APPENDIX A

To find the dimension $|V_N|$ of V_N one has to investigate the nonzero independent solutions of the equation

$$\sum_{s=0}^{N-1} n_s \mathbf{x}_s = 0. \tag{A1}$$

Assume that we have found all independent solutions $n^t=(n_0^t, n_1^t, \ldots, n_{N-1}^t)$, $t=1,\ldots,m$, then $|V_N|=N-m$. From (11) we observe that Eq. (A1) can be rewritten in the form

$$\sum_{s=0}^{N-1} n_s r^s = 0. \tag{A2}$$

Let N be a prime number. The periodicity condition $r^N=1$ and the identity

$$\frac{1-x^N}{1-x} = 1 + x + \cdots + x^{N-1} \tag{A3}$$

which is valid for $x \neq 1$ imply the solution $n^0=(1,1,\ldots,1)$ of (A1). Let $N=M^l$, where M is a prime and l is a natural number. Then the operators $R_p = r^{N/M^p}$, $p=1,2,\ldots,l$ satisfy the periodicity condition $R_p^{M^p}=1$. This implies $(N/M) + (N/M^2) + \cdots + (N/M^{l-1}) + 1$ relations of the form

$$r^{s_p}(1 + R_p + \cdots + R_p^{M^p-1}) = 0 \tag{A4}$$

or

$$r^{s_p} + r^{(N/M^p)+s_p} + \cdots + r^{(N/M^p)(M^p-1)+s_p} = 0. \tag{A5}$$

We denote the corresponding solutions by n^{s_p}, where $p=1,2,\ldots,l$ and $s_p=0,1,\ldots,(N/M^p)-1$. The rank of the matrix $(n_s^{s_p})$ appears to be N/M and we choose solutions n^{s_1} as independent set. We demonstrate it for $N=2^3$. We have four relations

$$r^{s_1}+r^{4+s_1}=0, \quad s_1=0,1,2,3, \tag{A6}$$

two relations

$$r^{s_2}+r^{2+s_2}+r^{4+s_2}+r^{6+s_2}=0, \quad s_2=0,1, \tag{A7}$$

and one relation

$$1+r+\cdots+r^7=0. \tag{A8}$$

We see that relations (A7) reduce to

$$r^{s_2}+r^{4+s_2}=0, \quad r^{(2+s_2)}+r^{4+(2+s_2)}=0. \tag{A9}$$

Summation of four relations (A9) leads to relation (A8). Therefore we have four independent solutions. The general case can be proved in a similar fashion. Let now $N=M_1^{l_1}M_2^{l_2}\cdots M_f^{l_f}$, where M_j are prime numbers such that $M_1<M_2<\cdots<M_f$. In this case we have $(N/M_1)+(N/M_2)+\cdots+(N/M_f)$ solutions n^{s^j}:

$$r^{s^j}+r^{(N/M_j)+s^j}+\cdots+r^{(N/M_j)(M_j-1)+s^j}=0, \tag{A10}$$

where $j=1,2,\ldots,f$ and $s^j=0,\ldots,(N/M_j)-1$. The rank of the matrix $A_N=(n_s^{s^j})$ gives the number of independent relations. The matrix A_N which consist of $(N/M_1)+(N/M_2)+\cdots+(N/M_f)$ rows and N columns can be shown to have the following form:

$$A_N=\begin{pmatrix} I_1 & I_1 & \cdots & I_1 \\ I_2 & I_2 & \cdots & I_2 \\ \cdots & \cdots & \cdots & \cdots \\ I_f & I_f & \cdots & I_f \end{pmatrix}, \tag{A11}$$

where I_j is the $(N/M_j)\times(N/M_j)$ unit matrix. Note that the number of I_j matrices in the jth row is M_j. Assume that the relations described above exhaust all relations of the form (A1). Then we have $|V_N|=N-\mathrm{rank}(A_N)$. For example, the vector spaces V_3, V_4, and V_6 has dimension two. We conjecture the following result:

$$|V_N|=N-1, \text{ for a prime } N, \tag{A12}$$

$$|V_N|=N-\frac{N}{M}, \quad \text{for } N=M^l \text{ and a prime } M. \tag{A13}$$

APPENDIX B

Here we give a list of formulas used in the derivation of (44),

$$\frac{\partial}{\partial x^\mu}\frac{1}{|ax-x'+\eta|^2}=-\frac{1}{|ax-x'+\eta|^4}\frac{\partial|ax-x'+\eta|^2}{\partial x^\mu}, \tag{B1}$$

$$\frac{\partial^2}{\partial x^\mu\partial x^\nu}\frac{1}{|ax-x'+\eta|^2}=-\frac{1}{|ax-x'+\eta|^4}\frac{\partial^2|ax-x'+\eta|^2}{\partial x^\mu\partial x^\nu} + \frac{2}{|ax-x'+\eta|^6}\frac{\partial|ax-x'+\eta|^2}{\partial x^\mu}\frac{\partial|ax-x'+\eta|^2}{\partial x^\nu}, \tag{B2}$$

$$\frac{\partial}{|ax-x'+\eta|^2}\partial x^{\mu}=2(a(ax-x'+\eta))_{\mu}, \tag{B3}$$

$$\frac{\partial}{|ax-x'+\eta|^2}\partial x'^{\mu}=-2(ax-x'+\eta)_{\mu}, \tag{B4}$$

$$\frac{\partial^2}{|ax-x'+\eta|^2}\partial x^{\mu}\partial x^{\nu}=2a^2_{\mu\nu}, \tag{B5}$$

$$\frac{\partial^2}{|ax-x'+\eta|^2}\partial x^{\mu}\partial x'^{\nu}=-2a_{\mu\nu}, \tag{B6}$$

$$\frac{\partial^2}{|ax-x'+\eta|^2}\partial x'^{\mu}\partial x'^{\nu}=2\eta_{\mu\nu}. \tag{B7}$$

Here a is the matrix of the form PR^s.

(Received 24 May 2003; accepted 19 November 2003)

In this paper, we explicitly construct a series of projectors on integrable noncommutative orbifold T^2/Z_4 by extended *GHS* construction. They include integration of two arbitary functions with Z_4 symmetry. Our expression possesses manifest Z_4 symmetry. It is proven that the expression includes all projectors with minimal trace and in their standard expansions, the eigenvalue functions of coefficient operators are continuous with respect to the arguments k and q. Based on the integral expression, we alternately show the derivative expression in terms of the similar kernal to the integral one. Since projectors correspond to soliton solutions of the field theory on the noncommutative orbifold, we thus present a series of corresponding solitons. © *2004 American Institute of Physics.*

I. INTRODUCTION

String theory is a very promising candidate for a unified description of the fundamental interactions, including quantum gravity. It may provide a conceptual framework to resolve the clash between two of the greatest achievements of 20th century physics: general relativity and quantum mechanics. Noncommutative geometry is originally an interesting topic in mathematics.[1–3] In the past few years, it has been shown that some noncommutative gauge theories can be embedded in string theories[4–6] and noncommutative geometry can also be applied to condensed matter physics. The currents and density of a system of electrons in a strong magnetic field may be described by a noncommutative quantum field theory.[7–9] The connection between a finite quantum Hall system and a noncommutative Chern–Simon matrix model first proposed in Ref. 8 was further elaborated in subsequent papers.[10,11] Many papers concentrated on the research for the related questions about the quantum Hall effect.[12–18] Since the noncommutative space resembles a quantum phase space, it exhibits an interesting spacetime uncertainty relation, which causes an UV/IR mixing[19,20] and a teleological behavior. Noncommutative field theories can be regarded as highly constrained deformation of local field theory. Thus it may help us to understand nonlocality at short distances in quantum gravity.

Solitons in various noncommutative theories have played a central role in understanding the physics of noncommutative theories and certain situations of string theories. The quantum Hall effect practically provides a good illustration of the combination of the three theories.[13,17,18,21] The existence and form of these classical solutions are fairly independent of the details of the theory, making them useful to probe the string behavior. In fact these solitons are the (lower-dimensional) D-branes of string theory manifested in a field theory limit while still capturing many string features.

Starting from the celebrated paper of Gopakumar, Minwalla, and Strominger,[22] there are many

[a]Electronic mail: hdeng_phy@cn.yahoo.com

works to study soliton solutions of noncommutative field theory and integrable systems in the background of noncommutative spaces.[23–30] Although Derrick's theorem forbids solitons in ordinary $2+1$ dimensional scalar field theory,[31] solitons in noncommutative scalar field theory on the plane were constructed in terms of projection operators in Ref. 22. It was soon realized that noncommutative solitons represent D-branes in string field theory with a background B field, and many of Sen's conjectures[32,33] regarding tachyon condensation in string field theory have been beautifully confirmed using properties of noncommutative solitons. Gopakumar, Minwalla, and Strominger made an important finding that in a noncommutative space, a projector may correspond to a soliton in the field theory,[22] which proves the significance of the study of projection operators in various noncommutative spaces. Reiffel[34] constructed the complete set of projection operators on the noncommutative torus T^2. On the basis Boca studied the projection operators on noncommutative orbifold[35] obtaining many important results and showed the well-known example of the projection operator for T^2/Z_4 in terms of the elliptic function. Soliton solutions in noncommutative gauge theory were introduced by Polychronakos in Ref. 23. Martinec and Moore in their important article deeply studied soliton solutions namely projectors on a wide variety of orbifolds, and the relation between physics and mathematics in this area.[27] Gopakumar, Headrick, and Spradlin have shown a rather apparent method to construct the multisoliton solution on noncommutative integrable torus with generic τ.[24] This approach can be generalized to construct the projection operators on the integrable noncommutative orbifold T^2/Z_N.[30]

In this paper, in the case of integrable noncommutative orbifold T^2/Z_4 generated by u_1 and u_2 with

$$u_1u_2=u_2u_1e^{2\pi i/A}, \qquad A=1,2,3,\ldots . \tag{1}$$

We generalize the GHS construction, presenting the explicit symmetric form of a series of projectors with manifest Z_4 symmetry. It includes all the solutions with minimal trace, and in the standard expansions for the projectors [see Eq. (9)]

$$P=\sum_{s,t} u_1^s u_2^t \Psi_{s,t}(u_1^A,u_2^A), \tag{2}$$

where the eigenvalue function $\Psi_{s,t}(v_1^A,v_2^A)$ is continuous (where v_1^A and v_2^A are eigenvalues of u_1^A and u_2^A). The solutions include two arbitrary complex functions with Z_4 symmetry. The kernels of the integrations are closed analytic functions of u_1 and u_2. In the simplest case, when A is an even number, we reobtain the Boca's classic result[35] and obtain a new result when A is an odd number. Moreover the above construction is also applicable to the integrable $T^2/Z_N(N=3,6)$ cases.

This paper is organized as follows: In Sec. II, we introduce operators on the noncommutative orbifold T^2/Z_N. In Sec. III, we introduce the $|k,q\rangle$ representation and provide the matrix element relation for the projectors and deduce the relation between the eigenvalue functions of coefficients and the matrix elements of operators in the $|k,q\rangle$ representation. In Sec. IV, we study the general projectors with minimal trace when the eigen value functions of coefficients are continuous. In Sec. V, we present two kinds of explicit expressions for the projectors with elliptical functions as kernel.

II. NONCOMMUTATIVE ORBIFOLD T^2/Z_N

In this section, we introduce operators on the noncommutative orbifold T^2/Z_N. First we introduce two Hermitian operators $\hat{y}_1$ and $\hat{y}_2$, which satisfy the following commutation relation:

$$[\hat{y}_1,\hat{y}_2]=i. \tag{3}$$

The operators made up of $\hat{y}_1$ and $\hat{y}_2$

$$\hat{O}=\sum_{m,n} C_{mn}\hat{y}_1^m\hat{y}_2^n \tag{4}$$

form the noncommutative plane R^2. All operators on R^2 which commute with U_1 and U_2

$$U_1=e^{-il\hat{y}_2}, \qquad U_2=e^{il(\tau_2\hat{y}_1-\tau_1\hat{y}_2)}, \tag{5}$$

where l,τ_1,τ_2 are all real numbers and $l,\tau_2>0,\tau=\tau_1+i\tau_2$, constitute the noncommutative torus T^2. We have

$$U_1^{-1}\hat{y}_1U_1=\hat{y}_1+l, \qquad U_2^{-1}\hat{y}_1U_2=\hat{y}_1+l\tau_1,$$
$$U_1^{-1}\hat{y}_2U_1=\hat{y}_2, \qquad U_2^{-1}\hat{y}_2U_2=\hat{y}_2+l\tau_2. \tag{6}$$

The operators U_1 and U_2 are two different wrapping operators around the noncommutative torus and their commutation relation is $U_1U_2=U_2U_1e^{-2\pi i(l^2\tau_2/2\pi)}$. When $A=l^2\tau_2/2\pi$ is an integer, we call the noncommutative torus integrable, and introduce two operators u_1 and u_2:

$$u_1=e^{-il\hat{y}_2/A}, \quad u_2=e^{-il(\tau_2\hat{y}_1-\tau_1\hat{y}_2)/A},$$
$$u_1u_2=u_2u_1e^{2\pi i/A}, \quad u_1^A=U_1, \quad u_2^A=U_2^{-1}. \tag{7}$$

The operators on the noncommutative torus are composed of the Laurant series of u_1 and u_2,

$$\hat{O}_{T^2}=\sum_{m,n} C'_{mn}u_1^mu_2^n, \tag{8}$$

where $m,n\in Z$ and C'_{00} is called the trace of the operators, and Eq. (8) includes all operators on the noncommutative torus T^2, satisfying the relation $U_i^{-1}\hat{O}_{T^2}U_i=\hat{O}_{T^2}$. From (7) we can rewrite Eq. (8) as

$$\hat{O}_{T^2}=\sum_{s,t=0}^{A-1} u_1^su_2^t\Psi_{\mathrm{st}}(u_1^A,u_2^A), \tag{9}$$

where Ψ_{st} is Laurant series of the operators u_1^A and u_2^A. We call this formula the standard expression for the operator on the noncommutative torus T^2. The trace for the operator is the constant term's coefficient of Ψ_{00}. Next we introduce rotation R in noncommutative space R^2

$$R(\theta)=e^{-i\theta[(\hat{y}_1^2+\hat{y}_2^2)/2]+i(\theta/2)} \tag{10}$$

with

$$R^{-1}\hat{y}_1R=\cos\theta\hat{y}_1+\sin\theta\hat{y}_2, \qquad R^{-1}\hat{y}_2R=\cos\theta\hat{y}_2-\sin\theta\hat{y}_1, \tag{11}$$

when $\tau=\tau_1+\tau_2=e^{2\pi i/N}$, setting $\theta=2\pi/N(N\in Z)$. The noncommutative torus T^2 is kept invariant under rotation $R_N\equiv R(2\pi/N)$.[35,27,30] Namely $R_N^{-1}\hat{O}_{T^2}R_N$ is still the operators on the noncommutative torus T^2. Now $U_i'\equiv R_N^{-1}U_iR_N$ can be expressed by the monomial of $\{U_i\}$ and their inverses.[27] In this case, we call the operators invariant under rotation R_N on the noncommutative torus as operators on the noncommutative orbifold T^2/Z_N. We can also realize these operators in Fock space. Introduce

$$a=\frac{\hat{y}_2-i\hat{y}_1}{\sqrt{2}}, \qquad a^+=\frac{\hat{y}_2+i\hat{y}_1}{\sqrt{2}}, \tag{12}$$

then

$$[a,a^+]=1, \tag{13}$$

$$R_N=e^{-i\theta a^+ a}. \tag{14}$$

In this paper, we study the projector P on the orbifold T^2/Z_4:

$$\tau=i, \tag{15}$$

$$P^2=P, \tag{16}$$

$$U_j^{-1}PU_j=P, \quad j=1,2, \tag{17}$$

$$R_4^{-1}PR_4=P. \tag{18}$$

III. THE $|k,q\rangle$ REPRESENTATION, STANDARD FORM, AND EIGENVALUE FUNCTION

From the above discussion, we know that the operators U_1 and U_2 commute with each other on the integrable torus T^2 when A is an integer. So we can introduce a complete set of their common eigenstates, namely $|k,q\rangle$ representation[36,37]

$$|k,q\rangle=\sqrt{\frac{l}{2\pi}}e^{-i\tau_1\hat{y}_2{}^2/2\tau_2}\sum_j e^{ijkl}|q+jl\rangle, \tag{19}$$

where the ket on the right is a $\hat{y}_1$ eigenstate. We have

$$\begin{gathered}U_1|k,q\rangle=e^{-ilk}|k,q\rangle, \qquad U_2|k,q\rangle=e^{il\tau_2 q}|k,q\rangle=e^{2\pi iqA/l}|k,q\rangle,\\ id=\int_0^{2\pi/l}dk\int_0^l dq|k,q\rangle\langle k,q|.\end{gathered} \tag{20}$$

It also satisfies

$$|k,q\rangle=\left|k+\frac{2\pi}{l},q\right\rangle=e^{ilk}|k,q+l\rangle. \tag{21}$$

Consider Eq. (9), namely, the standard expansion of operators on T^2 we have

$$\Psi_{\rm st}(u_1^A,u_2^A)|k,q\rangle=\Psi_{\rm st}(e^{-ilk},e^{-2\pi iqA/l})|k,q\rangle\equiv\psi_{\rm st}(k,q)|k,q\rangle, \tag{22}$$

where $\psi_{\rm st}$ is a function of the independent variables k and q, called the eigenvalue function of $\Psi_{\rm st}(u_1^A,u_2^A)$. From (22), we see that the function $\psi_{\rm st}$ is invariant when $q\to q+l/A$,

$$\psi_{\rm st}\left(k,q+\frac{ln}{A}\right)=\psi_{\rm st}(k,q). \tag{23}$$

As long as the eigenvalue function is obtained, the operator on the noncommutative torus can be completely determined. Introducing the new basis $|k,q_0;n\rangle\equiv|k,q_0+ln/A\rangle, k\in[0,2\pi/l), q_0\in[0,l/A)$, we have from (20)

$$\sum_{n=0}^{A-1}\int_0^{2\pi/l}dk\int_0^{l/A}dq_0\left|k,q_0+\frac{ln}{A}\right\rangle\left\langle k,q_0+\frac{ln}{A}\right|=id, \tag{24}$$

$$u_1|k,q\rangle=\left|k,q+\frac{l}{A}\right\rangle, \tag{25}$$

$$u_2|k,q\rangle=e^{-2\pi i\,(q/l)}|k,q\rangle. \tag{26}$$

From the above equation and (21), we see that when any power of the operators u_1 and u_2 act on the $|k,q_0+ln/A\rangle$, the result can be expanded in the basis $|k,q_0+ln'/A\rangle$ with the same k,q_0. So the operators on the noncommutative torus have the same property, namely do not change k and q_0. Thus, for every k and q_0 we get an $A\times A$ matrix, called reduced matrix for the operator, as well as the projector,

$$P_{T^2}\left|k,q_0+\frac{ln}{A}\right\rangle=\sum_{n'}M(k,q_0)_{n'n}\left|k,q_0+\frac{ln'}{A}\right\rangle. \tag{27}$$

It is easy to find that the sufficient and necessary condition for $P^2=P$ is[30]

$$M(k,q_0)^2=M(k,q_0). \tag{28}$$

When T^2 satisfies Z_N symmetry, since after R_N rotation U_i' can be expressed by the monomial of $\{U_i\}$ and their inverses, the state vector $R_N|k,q_0+ln/A\rangle$ is still the common eigenstate of the operators U_1 and U_2. With the completeness of $\{|k,q+ls/A\rangle\}$ and the A-fold degeneracy eigenvalues of U_i in the kq representation, the state can be expanded in the basis $\{|k',q'+ls'/A\rangle\}$

$$R_N\left|k,q_0+\frac{ln}{A}\right\rangle=\sum_{n'}A(k,q_0)_{n'n}\left|k,q_0+\frac{ln'}{A}\right\rangle \tag{29}$$

(it is necessary to point out that the matrix A defined here is the transposed matrix of A defined in formula (93) in Ref. 30) where $k'\in[0,2\pi/l),q'\in[0,l/A)$ are definite and

$$R_N^{-1}\left|k',q_0'+\frac{ln'}{A}\right\rangle=\sum_{n''}A^{-1}(k,q_0)_{n''n'}\left|k',q_0'+\frac{ln''}{A}\right\rangle. \tag{30}$$

We can get the expression for the relation between k', q_0' and k, q_0, The mapping $W:(k,q_0)\rightarrow(k',q_0'),W^N=id$, is essentially a linear relation, and area-preserving. By this fact and since R_N is unitary, we conclude that the matrix A is a unitary matrix, that is to say

$$A^*(k,q_0)_{nn'}=A^{-1}(k,q_0)_{n'n}. \tag{31}$$

The projector on the noncommutative orbifold T^2/Z_N satisfies $R_N^{-1}PR_N=P$, then from (27), (29), (30) one obtains

$$R_N^{-1}PR_N\left|k,q_0+\frac{ln}{A}\right\rangle=\sum_{n}{}'\,[A^{-1}(k,q_0)M(k',q_0')A(k,q_0)]_{n'n}\left|k,q_0+\frac{ln'}{A}\right\rangle, \tag{32}$$

which should be equal to

$$P\left|k,q_0+\frac{ln}{A}\right\rangle=\sum_{n''}M(k,q_0)_{n''n}\left|k,q_0+\frac{ln''}{A}\right\rangle. \tag{33}$$

So, we have

$$M(k',q_0')=A(k,q_0)M(k,q_0)A^{-1}(k,q_0) \tag{34}$$

and the sufficient and necessary condition for the projector on noncommutative orbifold T^2/Z_N to satisfy is

$$M(k,q_0)^2=M(k,q_0), \tag{35}$$

$$M(k',q_0')=A(k,q_0)M(k,q_0)A^{-1}(k,q_0). \tag{36}$$

Next we will study the relation between coefficient function $\psi_{\mathrm{st}}(k,q)$ and the reduced matrix $M(k,q_0)$. From (23), (25), (26), and (27) we have

$$\begin{aligned} P\left|k,q_0+\frac{ln}{A}\right\rangle &= \sum_{s,t} u_1^s u_2^t \Psi_{\mathrm{st}}(u_1^A,u_2^A)\left|k,q_0+\frac{ln}{A}\right\rangle \\ &= \sum_{s,t} e^{-2\pi i(q_0/l+n/A)t}\psi_{\mathrm{st}}(k,q_0)\left|k,q_0+\frac{l(n+s)}{A}\right\rangle \\ &= \sum_{n'} M(k,q_0)_{n'n}\left|k,q_0+\frac{ln'}{A}\right\rangle. \end{aligned} \tag{37}$$

So for $n+s<A$ case, we have

$$M(k,q_0)_{n+s,n}=\sum_{t=0}^{A-1} e^{-2\pi i(q_0/l+n/A)t}\psi_{\mathrm{st}}(k,q_0) \tag{38}$$

and for $n+s\geqslant A$ case, we have

$$M(k,q_0)_{n+s-A,n}=\sum_{t=0}^{A-1} e^{-2\pi i(q_0/l+n/A)t}\psi_{\mathrm{st}}(k,q_0)e^{-ilk}. \tag{39}$$

Setting

$$M(k,q_0)_{n+s,n}=M(k,q_0)_{n+s-A,n}e^{ilk}, \tag{40}$$

we can uniformly write as

$$M(k,q_0)_{n+s,n}=\sum_{t=0}^{A-1} e^{-2\pi i(q_0/l+n/A)t}\psi_{\mathrm{st}}(k,q_0) \tag{41}$$

and have

$$\psi_{\mathrm{st}}(k,q_0)=\frac{1}{A}\sum_{n=0}^{A-1} M(k,q_0)_{n+s,n}e^{2\pi i(q_0/l+n/A)t}. \tag{42}$$

Equations (41) and (42) are the relation between ψ_{st} and the elements of the reduced matrix M.

IV. CONTINUOUS SOLUTION FOR THE PROJECTOR WITH MINIMAL TRACE

Now one may ask what property the reduced matrix M possesses when the coefficient function ψ_{st} is a continuous function. In this section, we mainly answer this question. First we prove the $A\times A$ matrix satisfying the condition $M^2=M$ is always diagonalizable. For any vector ψ, $M\psi$ is invariant under M, namely,

$$M(M\psi)=M\psi. \tag{43}$$

Assume there are totally B linear independent invariant vectors under transformation M, then

(1) For $A=B$ case, the matrix M is identity of the space expanded by the vectors, namely $A\times A$ unit matrix. Of course it is diagonal.

(2) For $B<A$ case, considering any vector a and setting $b=Ma-a$, we find $Mb=0$. Namely any vector a can be expressed as linear combination of invariant vector $c=Ma$ and null vector b under action of M. So the whole linear space is composed of certain invariant vectors and null vectors under action of M. M can be diagonalized in the representation with these vectors as basis. So we have

$$M(k,q_0)=S^{-1}(k,q_0)\overline{M}(k,q_0)S(k,q_0), \tag{44}$$

where

$$\overline{M}(k,q_0)=\mathrm{diag}(1,1,\ldots,1,0,0,\ldots,0). \tag{45}$$

Due to (41), when $\psi_{\mathrm{st}}(k,q_0)$ is continuous, $M(k,q_0)$ is also continuous. However $\mathrm{tr}\,M(k,q_0)=\mathrm{tr}\,\overline{M}(k,q_0)=0,1,2,\ldots,A$, which is discrete, so when ψ_{st} is continuous, the value of $\mathrm{tr}\,M(k,q_0)=A\psi_{00}(k,q_0)$ is invariant for all k and q_0. The trace of the projector is the zero order term of $\psi_{00}(k,q_0)$ in the Laurant expression of e^{-ilk} and $e^{-2\pi iqA/l}$, so we have

$$\mathrm{tr}\,P=\int_0^{2\pi/l}dk\int_0^{l/A}dq\,\frac{A}{2\pi}\psi_{00}(k,q_0)=\int_0^{2\pi/l}dk\int_0^{l/A}dq\,\frac{1}{2\pi}\mathrm{tr}\,M(k,q_0)=\frac{1}{A}\mathrm{tr}\,M(k,q_0). \tag{46}$$

The projector is trivial for $\mathrm{tr}\,M(k,q_0)=0,A$, indicating $P=0$ and $identity$. The nontrivial $\mathrm{tr}\,P=1/A, 2/A,\ldots,(A-1)/A$. In this paper, we only study the nontrivial projector with minimal trace $(\mathrm{tr}\,M(k,q_0)=1)$. Thus

$$M(k,q_0)=s^{-1}(k,q_0)\begin{pmatrix}1&&&\\&0&&\\&&0&\\&&&\ddots\end{pmatrix}s(k,q_0), \tag{47}$$

$$M(k,q_0)_{nn'}=s^{-1}(k,q_0)_{n0}s(k,q_0)_{0n'}\equiv a(k,q_0)_n b(k,q_0)_{n'}. \tag{48}$$

Explicit calculation about R_N acting on $|k,q;n\rangle$ shows that we can divide the complete area $\Sigma:\{k\in[0,2\pi/l),q_0\in[0,l/A)\}$ into N subarea $\sigma_0,\ldots,\sigma_{N-1}$, making $W:\sigma_i\to\sigma_{i+1},(i=0,1,\ldots,N-2),\sigma_{N-1}\to\sigma_0$. If we construct a reduced matrix $M(k,q_0)$ to satisfy (48) in the area σ_0, then the projector corresponding to continuous ψ_{st} with minimal trace is completely determined. In area σ_0, set

$$a_n=\left\langle k,q_0+\frac{ln}{A}\middle|\,\phi_1\right\rangle,\qquad b_n=\left\langle\phi_2\middle|\,k,q_0+\frac{ln}{A}\right\rangle, \tag{49}$$

where

$$\sum_n a_n b_n=\mathrm{tr}\,M(k,q_0)=1. \tag{50}$$

In the other areas σ_j with $(k,q_0)\to(k_j,q_{0j})$ by mapping W^j, we demand

$$a_n(k_j,q_{0j})=\left\langle k_j,q_{0j}+\frac{ln}{A}\middle|\,\phi_1\right\rangle=A^j(k,q_0)_{nn'}a_{n'}(k,q_0), \tag{51}$$

$$b_n(k_j,q_{0j})=\left\langle\phi_2\middle|\,k_j,q_{0j}+\frac{ln}{A}\right\rangle=b_{n'}(k,q_0)A^{-j}(k,q_0)_{n'n}. \tag{52}$$

We thus have all coefficients of $|\phi_1\rangle,\langle\phi_2|$ in $\sigma_0,\ldots,\sigma_{N-1}$. Owing to the completeness of $|k,q_0+ln/A\rangle$ in the area Σ, $|\phi_1\rangle$ and $\langle\phi_2|$ can be determined by the coefficient (49) of $|\phi_1\rangle$ and $\langle\phi_2|$. Meanwhile, in the area σ_j, we have

$$M(k_j,q_{0j})_{nn'}=a_n(k_j,q_{0j})b_{n'}(k_j,q_{0j})=[A^j(k,q_0)M(k,q_0)A^{-j}(k,q_0)]_{nn'}. \tag{53}$$

The matrix $M(k,q_0)$ really satisfies Eq. (34). Consider the state vector

$$\begin{aligned}|\phi_1\rangle&=\int dkdq_0\sum_n\left|k,q_0+\frac{ln}{A}\right\rangle\left\langle k,q_0+\frac{ln}{A}\right|\phi_1\right\rangle\\&=\sum_{j=0}^{N-1}\int_{\sigma_j}dk_jdq_{0j}\sum_n\left|k_j,q_{0j}+\frac{ln}{A}\right\rangle a_n(k_j,q_{0j})\\&=\sum_{j=0}^{N-1}\int_{\sigma_j}dkdq_0\sum_{nn_1}\left|k,q_0+\frac{ln}{A}\right\rangle A^j_{nn_1(k,q_0)}a_{n_1}(k,q_0)\\&=\sum_{j=0}^{N-1}R_N^j\int_{\sigma_0}dkdq_0\sum_n\left|k,q_0+\frac{ln}{A}\right\rangle a_n(k,q_0).\end{aligned} \tag{54}$$

Thus we have

$$R_N|\phi_1\rangle=|\phi_{1\rangle}. \tag{55}$$

In the same way, we get

$$\langle\phi_2|R_N=\langle\phi_2|. \tag{56}$$

That is to say that the state vectors $|\phi_1\rangle$ and $\langle\phi_2|$ are invariant under the rotation R_N.

More generally, we can take any state vectors $|\phi_1\rangle$ and $\langle\phi_2|$ satisfying

$$R_N|\phi_1\rangle=e^{i\alpha_1}|\phi_1\rangle,\qquad\qquad\langle\phi_2|R_N^{-1}=e^{-i\alpha_2}\langle\phi_2| \tag{57}$$

to construct a projection operator on noncommutative orbifold T^2/Z_N. Let $M(k,q_0)$ be given by (48) with

$$a_n(k,q_0)=\frac{\left\langle k,q_0+\frac{ln}{A}\middle|\phi_1\right\rangle}{\sqrt{\Sigma_{n'}\left\langle k,q_0+\frac{ln'}{A}\middle|\phi_1\right\rangle\left\langle\phi_2\middle|k,q_0+\frac{ln'}{A}\right\rangle}}, \tag{58}$$

$$b_n(k,q_0)=\frac{\left\langle\phi_2\middle|k,q_0+\frac{ln}{A}\right\rangle}{\sqrt{\Sigma_{n'}\left\langle k,q_0+\frac{ln'}{A}\middle|\phi_1\right\rangle\left\langle\phi_2\middle|k,q_0+\frac{ln'}{A}\right\rangle}}. \tag{59}$$

The projector of minimal trace and with continuous coefficient functions is surely of this form. It can be verified that $M^2=M$. And it is also covariant under R_N. From (30) we have

$$\begin{aligned}\left\langle\phi_2\middle|k',q_0'+\frac{n'l}{A}\right\rangle&=\left\langle\phi_2\middle|R_N\sum_{n''}A^{-1}(k,q_0)_{n''n'}\middle|k,q_0+\frac{n''l}{A}\right\rangle\\&=e^{i\alpha_2}\sum_{n''}A^{-1}(k,q_0)_{n''n'}\left\langle\phi_2\middle|k,q_0+\frac{n''l}{A}\right\rangle\end{aligned}$$

and similarly

$$\left\langle k',q_0'+\frac{n'l}{A}\middle|\phi_1\right\rangle = e^{-i\alpha_1}\sum_{n''}\left\langle k,q_0+\frac{n''l}{A}\middle|\phi_1\right\rangle A(k,q_0)_{n'n''},$$

giving

$$\sum_n \left\langle k',q_0'+\frac{ln}{A}\middle|\phi_1\right\rangle\left\langle \phi_2\middle|k',q_0'+\frac{ln}{A}\right\rangle = \sum_n \left\langle k,q_0+\frac{ln}{A}\middle|\phi_1\right\rangle\left\langle \phi_2\middle|k,q_0+\frac{ln}{A}\right\rangle e^{-i(\alpha_1-\alpha_2)}. \tag{60}$$

Thus,

$$M(k',q_0')_{nn'} = a_n(k',q_0')b_{n'}(k',q_0') = [AMA^{-1}](k,q_0)_{nn'}, \tag{61}$$

P is invariant under rotation R_N due to (36) and really gives the projection operator on the noncommutative orbifold T^2/Z_N. The form of (58) is a generalization of GHS construction. (The condition $P^\dagger = P$ is not satisfied by P like this, which might represent the solitons in a "complex" field.) From the above result, we have

$$M(k,q_0)_{nn'} = \frac{\left\langle k,q_0+\frac{ln}{A}\middle|\phi_1\right\rangle\left\langle \phi_2\middle|k,q_0+\frac{ln'}{A}\right\rangle}{\sum_{n''}\left\langle k,q_0+\frac{ln''}{A}\middle|\phi_1\right\rangle\left\langle \phi_2\middle|k,q_0+\frac{ln''}{A}\right\rangle}. \tag{62}$$

Noticing that this equation satisfies (40), we have

$$\begin{aligned}\psi_{\mathrm{st}}(k,q_0) &= \frac{1}{A}\sum_{n=0}^{A-1} M(k,q_0)_{n+s,n}e^{2\pi i(q_0/l+n/A)t} \\ &= \frac{\frac{1}{A}\sum_{n=0}^{A-1}\left\langle k,q_0+\frac{l(n+s)}{A}\middle|\phi_1\right\rangle\left\langle \phi_2\middle|k,q_0+\frac{ln}{A}\right\rangle e^{2\pi i(q_0/l+n/A)t}}{\sum_n \left\langle k,q_0+\frac{ln}{A}\middle|\phi_1\right\rangle\left\langle \phi_2\middle|k,q_0+\frac{ln}{A}\right\rangle} = \frac{F_{\mathrm{st}}(k,q_0)}{AF_{00}(k,q_0)},\end{aligned} \tag{63}$$

where

$$F_{\mathrm{st}}(k,q_0) \equiv \sum_{n=0}^{A-1}\left\langle k,q_0+\frac{l(n+s)}{A}\middle|\phi_1\right\rangle\left\langle \phi_2\middle|k,q_0+\frac{ln}{A}\right\rangle e^{2\pi i(q_0/l+n/A)t}, \tag{64}$$

with

$$F_{\mathrm{st}}(k,q_0) = F_{\mathrm{st}}(k,q_0+l/A) = F_{\mathrm{st}}(k+2\pi/l,q_0), \tag{65}$$

$$F_{\mathrm{st}}(k,q_0) = F_{s+A,t}(k,q_0)e^{-ilk} \tag{66}$$

$$= F_{s,t+A}(k,q_0)e^{-2\pi i q_0 A/l}. \tag{67}$$

So the function F_{st} is the function of independent variables $X = e^{-ilk}$ and $Y = e^{-2\pi i q_0 A/l}$, namely $F_{\mathrm{st}}(k,q_0) = \Phi_{\mathrm{st}}(X,Y)$. Similarly,

$$\psi_{\mathrm{st}}(k,q_0) = \Psi_{\mathrm{st}}(X,Y) = \frac{\Phi_{\mathrm{st}}(X,Y)}{A\Phi_{00}(X,Y)}. \tag{68}$$

If we change the variable X and Y into u_1^A and u_2^A, respectively, the standard form (9) of the projection operator can be easily obtained. So the key question is to find out $F_{\rm st}(k,q_0)$.

V. COHERENT STATE REPRESENTATION

Introduce coherent states

$$|z\rangle = e^{-(1/2)z\bar{z}} e^{a^+ z}|0\rangle,$$

where $z=x+iy, \bar{z}=x-iy$, satisfies

$$\frac{1}{\pi}\int_{-\infty}^{\infty} d^2z|z\rangle\langle z| \equiv \frac{1}{\pi}\int_{-\infty}^{\infty} dxdy|z\rangle\langle z| = \text{identity}, \tag{69}$$

$$R_N|z\rangle = |\omega_N z\rangle. \tag{70}$$

We can show[30]

$$\langle k,q|z\rangle = \frac{1}{\sqrt{l}\,\pi^{1/4}}\theta\left(\frac{q+\frac{\tau}{\tau_2}k - i\sqrt{2}z}{l}, \frac{\tau}{A}\right) e^{-(\tau/2i\tau_2)k^2 + ikq + \sqrt{2}kz - (z^2 + z\bar{z})/2}, \tag{71}$$

where

$$\theta(z,\tau) \equiv \theta\begin{bmatrix}0\\0\end{bmatrix}(z,\tau)$$

and

$$\theta\begin{bmatrix}a\\b\end{bmatrix}(z,\tau) = \sum_m e^{\pi i\tau(m+a)^2} e^{2\pi i(m+a)(z+b)}. \tag{72}$$

Thus we can expand the state vectors $|\phi_1\rangle$ and $\langle\phi_2|$ in terms of the coherent state,

$$|\phi_1\rangle = \frac{1}{\pi}\int_{-\infty}^{\infty} dxdy|z\rangle\langle z|\phi_1\rangle \equiv \frac{1}{\pi}\int_{-\infty}^{\infty} dxdy f_1(z)|z\rangle, \tag{73}$$

$$\langle\phi_2| = \frac{1}{\pi}\int_{-\infty}^{\infty} dxdy\langle\phi_2|z\rangle\langle z| = \frac{1}{\pi}\int_{-\infty}^{\infty} dxdy f_2(z)\langle z|. \tag{74}$$

The condition (57) is satisfied if and only if

$$f_1(\omega_N^{-1}z) = f_1(z)e^{i\alpha_1}, \tag{75}$$

$$f_2(\omega_N^{-1}z) = f_2(z)e^{-i\alpha_2}. \tag{76}$$

Here $\omega_N = e^{-i(2\pi/N)}$. We have

$$F_{\rm st}(k,q_0) = \frac{1}{\pi^2}\sum_{n=0}^{A-1}\int\left\langle k, q_0 + \frac{l(n+s)}{A}\middle| z_1\right\rangle f_1(z_1)dx_1dy_1\int\left\langle z_2\middle| k, q_0 + \frac{ln}{A}\right\rangle f_2(z_2)dx_2dy_2$$

$$\times e^{2\pi i(q_0/l + n/A)t} = \frac{1}{\pi^2}\int dx_1dy_1dx_2dy_2 g_{\rm st}(k,q_0,z_1,z_2)f_1(z_1)f_2(z_2), \tag{77}$$

where

$$g_{\mathrm{st}}(k,q_0,z_1,z_2)=\sum_{n=0}^{A-1}\left\langle k,q_0+\frac{l(n+s)}{A}\middle|z_1\right\rangle\left\langle z_2\middle|k,q_0+\frac{ln}{A}\right\rangle e^{2\pi i(q_0/l+n/A)t}. \tag{78}$$

We call the kernel g as generating function in coherent state representation. Next, we study the expression of g for Z_4 case. Through g we can give the integration expression for all the projection operators on the T^2/Z_4 with minimal trace and continuous eigenvalue function. Consider the equation

$$\theta(z,\tau)^*=\theta(z^*,-\tau^*). \tag{79}$$

For the z_4 case, $\tau=i, A=l^2/2\pi$. From (71), (73), and (74) we get

$$\begin{aligned}\left\langle k,q+\frac{ls}{A}\middle|z_1\right\rangle\left\langle z_2\middle|k,q+\frac{ls'}{A}\right\rangle &= \frac{1}{l\sqrt{\pi}}\theta\left(\frac{q}{l}+\frac{i}{l}k+\frac{s}{A}-\frac{i\sqrt{2}z_1}{l},\frac{i}{A}\right)\theta\left(\frac{q}{l}-\frac{i}{l}k+\frac{s'}{A}+\frac{i\sqrt{2}z_2^*}{l},\frac{i}{A}\right)\\ &\quad\times e^{-k^2+(k/2)(z_1+z_2^*)+ik[l(s-s')/A]}e^{-(1/2)(z_1^2+(z_2^*)^2+z_1z_1^*+z_2z_2^*)}\\ &\equiv K_{ss'}.\end{aligned} \tag{80}$$

Let $u=lk/2\pi, v=q/l, \mu=-i(\sqrt{2}A/l)z_1, \nu=i(\sqrt{2}A/l)z_2^*$, then

$$K_{ss'}=\frac{C_1}{l\sqrt{\pi}}\theta\left(v+\frac{iu}{A}+\frac{s+\mu}{A},\frac{i}{A}\right)\theta\left(v-\frac{iu}{A}+\frac{s'+\nu}{A},\frac{i}{A}\right)e^{\pi i\,2i/A\,u^2+2\pi i((s+\mu-s'-\nu)/A))u}, \tag{81}$$

where

$$C_1=e^{2\pi i[(-i/4A)(\mu^2+\nu^2)+(i/4A)(|\mu|^2+|\nu|^2)]}. \tag{82}$$

It can be proven that for integer A,

$$\begin{aligned}&\sum_{r=0}^{A-1}e^{2\pi irt/A}\theta(x+r/A,\tau/A)\,\theta(y+r/A,\tau/A)\\ &\quad=A\sum_{d=0,1}\theta\left(-\frac{\tau}{A}(Ad-t)+x-y,\frac{2\tau}{A}\right)\theta\left(\frac{\tau}{A}(-At+A^2d)+A(x+y),2\tau A\right)e^{\pi i(\tau/A)(Ad-t)^2}\\ &\quad\times e^{2\pi i(Ad-t)y}\end{aligned} \tag{83}$$

and

$$\theta(z,\tau)=\sqrt{\frac{i}{\tau}}e^{-\pi iz^2/\tau}\theta\left(\pm\frac{z}{\tau},-\frac{1}{\tau}\right). \tag{84}$$

Thus we have

$$
\begin{aligned}
G_{\mathrm{st}}(u,v) &\equiv g_{\mathrm{st}}(k,q,z_1,z_2) \\
&= e^{2\pi i v t}\sum_r e^{2\pi i r t/A} K_{s+r,r}(u,v) \\
&= \frac{AC_1}{l\sqrt{\pi}}\sqrt{\frac{A}{2}}\sum_{d=0,1} e^{-(\pi/2A)(Ad-t)^2+2\pi i(Ad-t)(\nu/A)-(\pi/2A)(s+\mu-\nu)^2} \\
&\quad \times e^{(\pi i/A)(s+\mu-\nu)(Ad-t)+2\pi i v Ad}\theta\left(u-\frac{1}{2}(Ad-t)+\frac{i}{2}(s+\mu-\nu),\frac{Ai}{2}\right) \\
&\quad \times \theta(2Av+s+\mu+\nu-t\tau+iAd,2Ai). \qquad (85)
\end{aligned}
$$

Due to

$$
\sum_{a=0,1}\theta\left(x+\frac{a}{2},\tau\right)=2\theta(2x,4\tau), \qquad (86)
$$

$$
\sum_{a=0,1}(-1)^a\theta\left(x+\frac{a}{2},\tau\right)=2e^{2\pi i(x+\tau/2)}\theta(2x+2\tau,4\tau), \qquad (87)
$$

when d is equal to 0,1,

$$
\theta(2x+2\tau d,4\tau)=\frac{1}{2}\sum_{a=0,1}(-1)^{ad}e^{2\pi i(x+(\tau/2))d}\theta\left(x+\frac{a}{2},\tau\right), \qquad (88)
$$

the function $G_{\mathrm{st}}(u,v)$ can be rewritten as

$$
\begin{aligned}
G_{\mathrm{st}}(u,v) &= \frac{A}{4\pi}e^{2\pi i\phi}\sum_{a,d=0,1}(-1)^{ad}\theta\left(-u+\frac{1}{2}(Ad+t)+\frac{i}{2}(s+\mu-\nu),\frac{Ai}{2}\right) \\
&\quad \times\theta\left(-Av+\frac{1}{2}(s+a-\mu-\nu)+\frac{i}{2}t,\frac{Ai}{2}\right), \qquad (89)
\end{aligned}
$$

where

$$
\phi=\frac{i}{4A}(s^2+t^2)-\frac{\mathrm{st}}{2A}+\frac{i}{2A}s(\mu-\nu)-\frac{t}{2A}(\mu+\nu)+\frac{i}{4A}(|\mu|^2+|\nu|^2-2\mu\nu). \qquad (90)
$$

From the above discussion, we know that when A is an even number, only $a=0$ contributes, so we have

$$
G_{\mathrm{st}}(u,v)=\frac{A}{2\pi}e^{2\pi i\phi}\theta\left(-u+\frac{1}{2}t+\frac{i}{2}(s+\mu-\nu),\frac{Ai}{2}\right)\theta\left(-Av+\frac{1}{2}(s-\mu-\nu)+\frac{i}{2}t,\frac{Ai}{2}\right)
$$

and when A is an odd number,

$$
\begin{aligned}
G_{\mathrm{st}}(u,v) &= \frac{A}{4\pi}e^{2\pi i\phi}\sum_{a,d=0,1}(-1)^{ad}\theta\left(-u+\frac{1}{2}(Ad+t)+\frac{i}{2}(s+\mu-\nu),\frac{Ai}{2}\right) \\
&\quad \times\theta\left(-Av+\frac{1}{2}(Aa+s-\mu-\nu)+\frac{i}{2}t,\frac{Ai}{2}\right). \qquad (91)
\end{aligned}
$$

They can be uniformly written as

$$G_{\mathrm{st}}(u,v)=\frac{A}{4\pi}e^{2\pi i\phi}\sum_{a,d=0,1}(-1)^{ad}\theta\left(-u+\frac{1}{2}(Ad+t)+\frac{i}{2}(s+\mu-\nu),\frac{Ai}{2}\right)$$
$$\times\theta\left(-Av+\frac{1}{2}(Aa+s-\mu-\nu)+\frac{i}{2}t,\frac{Ai}{2}\right),\tag{92}$$

which is Z_4 covariant. So we have from (63), (77), and (85),

$$\psi_{\mathrm{st}}(k,q)=\frac{1}{A}\left\{\frac{\int d^2\mu d^2\nu G_{\mathrm{st}}(u,v)f_1(\mu)f_2(\nu)}{\int d^2\mu d^2\nu G_{00}(u,v)f_1(\mu)f_2(\nu)}\right\},\tag{93}$$

where functions f_i should satisfy

$$f_i(\omega_N\xi)=e^{i\alpha_i}f_i(\xi).\tag{94}$$

Let $\hat{u}=(l/2\pi)\hat{y}_2$ and $A\hat{v}=(l/2\pi)\hat{y}_1$, we may replace u,v by $\hat{u}$ and $\hat{v}$ in (93) and get

$$\Psi_{\mathrm{st}}(u_1^A,u_2^A)=\frac{1}{A}\frac{\int d^2\mu d^2\nu G_{\mathrm{st}}\left(\frac{l}{2\pi}\hat{y}_2,\frac{l}{2A\pi}\hat{y}_1\right)f_1(\mu)f_2(\nu)}{\int d^2\mu d^2\nu G_{00}\left(\frac{l}{2\pi}\hat{y}_2,\frac{l}{2A\pi}\hat{y}_1\right)f_1(\mu)f_2(\nu)}.\tag{95}$$

The operators u_1 and u_2 commute with the operators u_1^A and u_2^A, and from (7)

$$u_1^s=e^{-2\pi i\,s/A\hat{u}},\tag{96}$$

$$u_2^t=e^{-2\pi it\hat{v}}.\tag{97}$$

Further taking u_1^s and u_2^t into account, we can insert them to the corresponding operator form of Eq. (89). This leads to the function of $\hat{u}$ and $\hat{v}$

$$\begin{aligned}h_{ad}&\equiv u_1^s u_2^t G_{\mathrm{st}}(\hat{u},\hat{v})\\&=\frac{A}{4\pi}\sum_{a,d=0}^{1}(-1)^{ad}e^{2\pi i\phi}e^{-2\pi i\,s/A\hat{u}}\theta\left(-\hat{u}+\frac{1}{2}(Ad+t)+\frac{i}{2}(s+\mu-\nu),\frac{Ai}{2}\right)\\&\quad\times e^{-2\pi i\hat{v}t}\theta\left(-A\hat{v}+\frac{1}{2}(Aa+s-\mu-\nu)+\frac{i}{2}t,\frac{Ai}{2}\right)\\&=\frac{A}{4\pi}\sum_{a,d=0}^{1}(-1)^{ad}e^{2\pi i(-(3\mathrm{st}/2A)+(i/4A)(|\mu|^2+|\nu|^2-2\mu\nu))}e^{-2\pi i((sd/2)+(ta/2))}\\&\quad\times\theta\begin{bmatrix}\frac{s}{A}\\ \frac{t}{2}\end{bmatrix}\left(-\hat{u}+\frac{1}{2}Ad+\frac{i}{2}(\mu-\nu),\frac{Ai}{2}\right)\theta\begin{bmatrix}\frac{t}{A}\\ \frac{s}{2}\end{bmatrix}\left(-A\hat{v}+\frac{1}{2}Aa-\frac{1}{2}(\mu+\nu),\frac{Ai}{2}\right).\end{aligned}\tag{98}$$

Due to $|\omega_N\mu|=|\mu|,|\omega_N\nu|=|\nu|$, $e^{2\pi i\,(i/4A)(|\mu|^2+|\nu|^2)}$ in the above formula can be attributed to $f_1(\mu)$ and $f_2(\nu)$. Finally, we have

$$
\begin{aligned}
P=&\sum_{s,t} u_1^s u_2^t \Psi_{\mathrm{st}}(u_1^A,u_2^A)\\
=&\sum_{s,t} e^{2\pi i(-(3\mathrm{st}/2A))}\sum_{a,d=0}^{1}(-1)^{ad}\int d^2\mu d^2\nu f_1(\mu)f_2(\nu)e^{\pi i(\mu\nu/A)}e^{-2\pi i((sd/2)+(ta/2))}\\
&\times\theta\begin{bmatrix}\frac{s}{A}\\ \frac{t}{2}\end{bmatrix}\left(-\frac{l\hat{y}_2}{2\pi}+\frac{1}{2}Ad+\frac{i}{2}(\mu-\nu),\frac{Ai}{2}\right)\theta\begin{bmatrix}\frac{t}{A}\\ \frac{s}{2}\end{bmatrix}\left(-\frac{l\hat{y}_1}{2\pi}+\frac{1}{2}Aa-\frac{1}{2}(\mu+\nu),\frac{Ai}{2}\right)\\
&\times\left\{A\sum_{a,d=0}^{1}(-1)^{ad}\int d^2\mu d^2\nu f_1(\mu)f_2(\nu)e^{\pi i(\mu\nu/A)}\theta\left(-\frac{l\hat{y}_2}{2\pi}+\frac{1}{2}Ad+\frac{i}{2}(\mu-\nu),\frac{Ai}{2}\right)\right.\\
&\left.\times\theta\left(-\frac{l\hat{y}_1}{2\pi}+\frac{1}{2}Aa-\frac{1}{2}(\mu+\nu),\frac{Ai}{2}\right)\right\}^{-1}. \qquad (99)
\end{aligned}
$$

In the above equation, the two θ functions can not exchange orders with each other. It holds for any integer number A. In the following, we present some discussion.

(1) A is an even number, so $Ad/2$ and $Aa/2$ are integers, too. Due to (72) we have

$$
\begin{aligned}
P=&\sum_{s,t} e^{-3\pi i(\mathrm{st}/A)}\int d^2\mu d^2\nu f_1(\mu)f_2(\nu)e^{\pi i(\mu\nu/A)}\\
&\times\theta\begin{bmatrix}\frac{s}{A}\\ \frac{t}{2}\end{bmatrix}\left(-\frac{l\hat{y}_2}{2\pi}+\frac{i}{2}(\mu-\nu),\frac{Ai}{2}\right)\theta\begin{bmatrix}\frac{t}{A}\\ \frac{s}{2}\end{bmatrix}\left(-\frac{l\hat{y}_1}{2\pi}-\frac{1}{2}(\mu+\nu),\frac{Ai}{2}\right)\\
&\times\left\{A\int d^2\mu d^2\nu f_1(\mu)f_2(\nu)e^{\pi i(\mu\nu/A)}\theta\left(-\frac{l\hat{y}_2}{2\pi}+\frac{i}{2}(\mu-\nu),\frac{Ai}{2}\right)\right.\\
&\left.\times\theta\left(-\frac{l\hat{y}_1}{2\pi}-\frac{1}{2}(\mu+\nu),\frac{Ai}{2}\right)\right\}^{-1}. \qquad (100)
\end{aligned}
$$

The above equation is the generalization of the Boca's formula Proposition 3.1(i).[35]

(2) A is an odd number

$$
\begin{aligned}
P=&\sum_{s,t=0}^{A-1} e^{-3\pi i(\mathrm{st}/A)}\int d^2\mu d^2\nu f_1(\mu)f_2(\nu)e^{\pi i(\mu\nu/A)}\sum_{a,d=0}^{1}(-1)^{ad}e^{-2\pi i((sd/2)+(ta/2))}\\
&\times\theta\begin{bmatrix}\frac{s}{A}\\ \frac{t}{2}\end{bmatrix}\left(-\frac{l\hat{y}_2}{2\pi}+\frac{Ad}{2}+\frac{i}{2}(\mu-\nu),\frac{Ai}{2}\right)\theta\begin{bmatrix}\frac{t}{A}\\ \frac{s}{2}\end{bmatrix}\left(-\frac{l\hat{y}_1}{2\pi}+\frac{Aa}{2}-\frac{1}{2}(\mu+\nu),\frac{Ai}{2}\right)\\
&\times\left\{A\int d^2\mu d^2\nu f_1(\mu)f_2(\nu)e^{\pi i(\mu\nu/A)}\sum_{a,d=0}^{1}(-1)^{ad}\theta\left(-\frac{l\hat{y}_2}{2\pi}+\frac{Ad}{2}+\frac{i}{2}(\mu-\nu),\frac{Ai}{2}\right)\right.\\
&\left.\times\theta\left(-\frac{l\hat{y}_1}{2\pi}+\frac{Aa}{2}-\frac{1}{2}(\mu+\nu),\frac{Ai}{2}\right)\right\}^{-1}. \qquad (101)
\end{aligned}
$$

Due to

$$\theta\begin{bmatrix} \frac{s}{A} \\ \frac{t}{2} \end{bmatrix}\left(x+\frac{Ad}{2},\tau\right)=\theta\begin{bmatrix} \frac{s}{2A} \\ 0 \end{bmatrix}(2x,4\tau)(-1)^{sd}e^{2\pi i\,(\mathrm{st}/2A)}$$

$$+\theta\begin{bmatrix} \frac{s+A}{2A} \\ 0 \end{bmatrix}(2x,4\tau)(-1)^{(s+A)d}e^{2\pi i\,[(s+A)t/2A]}, \tag{102}$$

the numerator of P can be written as

$$2\int d^2\mu d^2\nu f_1(\mu)f_2(\nu)e^{\pi i\,(\mu\nu/A)}\sum_{s,t=0}^{A-1}\{\overline{\theta}_0\theta_0++\overline{\theta}_1\theta_0(-1)^s+\overline{\theta}_0\theta_1(-1)^t+\overline{\theta}_1\theta_1(-1)^{s+t-1}\}$$

$$=2\int d^2\mu d^2\nu f_1(\mu)f_2(\nu)e^{\pi i\,(\mu\nu/A)}\sum_{s,t=0}^{2A-1}e^{(\pi i/A)\,\mathrm{st}}\overline{\theta}_0\theta_0, \tag{103}$$

where

$$\overline{\theta}_\delta=\theta\begin{bmatrix} \frac{t+A\delta}{2A} \\ 0 \end{bmatrix}(2y,4\tau),$$

$$\theta_\delta=\theta\begin{bmatrix} \frac{t+A\delta}{2A} \\ 0 \end{bmatrix}(2x,4\tau),\delta=0,1$$

with

$$x=-\frac{l\hat{y}_2}{2\pi}+\frac{i}{2}(\mu-\nu)$$

and

$$y=-\frac{l\hat{y}_1}{2\pi}-\frac{1}{2}(\mu+\nu).$$

The denominator of P is $2A\int d^2\mu d^2\nu f_1(\mu)f_2(\nu)e^{\pi i\,(\mu\nu/A)}\Sigma_{\delta_1,\delta_2=0}^{1}e^{\pi i\delta_1\delta_2}\overline{\theta}'_{\delta_1}\theta'_{\delta_2}$, where

$$\theta'_\delta=\theta\begin{bmatrix} \frac{\delta}{2} \\ 0 \end{bmatrix}(2x,4\tau),$$

$$\overline{\theta}'_\delta=\theta\begin{bmatrix} \frac{\delta}{2} \\ 0 \end{bmatrix}(2y,4\tau).$$

This formula gives another result compared with Boca's when $f_1(z)=f_2(z)=\delta^2(z-0)$.

Finally, we will give another explicit form of P in terms of the derivative of elliptic functions. Note that the basis $\{|n\rangle\}$ of Fock space produces a phase ω^n under action of R_N. It is not difficult

to find that $e^{i\alpha_1}$ and $e^{i\alpha_2}$ in (57) are both integral powers of ω_N because of $(R_N)^N=$identity. Therefore $|\phi_1\rangle$ and $\langle\phi_2|$ can, respectively, be expanded in the basis $\{|n\rangle\}$ and $\{\langle n|\}$, where

$$|n\rangle=\frac{(a^+)^n}{\sqrt{n!}}|0\rangle. \tag{104}$$

We have the relation between coherent state and particle number eigenstate as the following:

$$\langle z|n\rangle=e^{-(1/2)z\bar{z}}\frac{z^n}{\sqrt{n!}}. \tag{105}$$

Obviously, the general forms of $|\phi_1\rangle$ and $\langle\phi_2|$ in the expansion in terms of particle number eigenstates are $\Sigma_{m=0}^{\infty}c_m\,|i+4m\rangle$ and $\Sigma_{n=0}^{\infty}d_n\,\langle j+4n|$, where i and j are non-negative integers and c_m and d_n are arbitrary constant coefficients. So

$$|\phi_1\rangle=\sum_m\ c_m|i+4n\rangle=\frac{1}{\pi}\sum_m\ \int_{-\infty}^{\infty}dxdyc_m|z\rangle\langle z|i+4m\rangle, \tag{106}$$

$$\langle\phi_2|=\sum_{m=0}^{\infty}\ d_m\langle j+4m|=\frac{1}{\pi}\sum_{n=0}^{\infty}\ \int_{-\infty}^{\infty}dxdyd_n\langle j+4n|z\rangle\langle z|. \tag{107}$$

We let R_N act on $|\phi_1\rangle$ and $\langle\phi_2|$ and get

$$R_N|\phi_1\rangle=\omega^i|\phi_1\rangle, \tag{108}$$

$$\langle\phi_2|R_N^{-1}=\langle\phi_2|\omega^{-j}. \tag{109}$$

Subsequently, we substitute (105), (106), (107) into (64) and make use of the formula

$$\langle k,q|n\rangle=\frac{1}{\sqrt{n!}}\frac{d^n}{dz^n}(e^{(1/2)z\bar{z}}\langle k,q|z\rangle)\|_{z=0} \tag{110}$$

to obtain

$$\begin{aligned}F_{\mathrm{st}}(k,q_0)&=\sum_{m,n}\sum_{h=0}^{A-1}c_md_n\left\langle k,q_0+\frac{l(h+s)}{A}\middle|i+4m\right\rangle\times\left\langle j+4n\middle|k,q_0+\frac{lh}{A}\right\rangle\times e^{2\pi i(q_0/l+h/A)t}\\&=\sum_{m,n}\sum_{h=0}^{A-1}c_md_n\frac{1}{\sqrt{(i+4m)!(j+4n)!}}\frac{d^{n+m}}{dz_1^m\bar{z}_2^n}\left(e^{(1/2)(z_1\bar{z}_1+z_2\bar{z}_2)}\sum_{h=0}^{A-1}\left\langle k,q_0+\frac{l(h+s)}{A}\middle|z_1\right\rangle\right.\\&\quad\left.\times\left\langle z_2\middle|k,q_0+\frac{lh}{A}\right\rangle\times e^{2\pi i(q_0/l+h/A)t}\right)\Bigg\|_{z_1=\bar{z}_2=0}\\&=\sum_{m,n}\sum_{h=0}^{A-1}c_md_n\frac{1}{\sqrt{(i+4m)!(j+4n)!}}\frac{d^{n+m}}{dz_1^m\bar{z}_2^n}(e^{1/2(z_1\bar{z}_1+z_2\bar{z}_2)}g_{\mathrm{st}}(k,q_0,z_1,z_2))\|_{z_1=\bar{z}_2=0}.\end{aligned} \tag{111}$$

So, we get the projector in the case of z_4

$$P=\sum_{m,n} c_m d_n \frac{1}{\sqrt{(i+4m)!(j+4n)!}} \frac{d^{n+m}}{dz_1^m \bar{z}_2^n} \Bigg(e^{z_1\bar{z}_1+z_2\bar{z}_2} \times e^{2\pi i(-(3st/2A))} \times e^{4\pi^2 i z_1 \bar{z}_2}$$

$$\times e^{-2\pi i((sd/2)+(ta/2))} \sum_{a,d=0}^{1} (-1)^{ad} \theta \begin{bmatrix} \frac{s}{A} \\ \frac{t}{2} \end{bmatrix} \left(-\frac{l\hat{y}_2}{2\pi} + \frac{1}{2}Ad + \frac{\sqrt{2}A}{2l}(z_1+\bar{z}_2), \frac{Ai}{2} \right)$$

$$\times \theta \begin{bmatrix} \frac{t}{A} \\ \frac{s}{2} \end{bmatrix} \left(-\frac{l\hat{y}_1}{2\pi} + \frac{1}{2}Aa + \frac{i\sqrt{2}A}{2l}(z_1-\bar{z}_2), \frac{Ai}{2} \right) \Bigg) \Bigg\|_{z_1=\bar{z}_2=0}$$

$$\times \Bigg\{ A \sum_{m,n} \sum_{a,d=0}^{1} (-1)^{ad} c_m d_n \frac{d^{n+m}}{dz_1^m \bar{z}_2^n} \Bigg(e^{z_1\bar{z}_1+z_2\bar{z}_2} \times e^{4\pi^2 i z_1 \bar{z}_2}$$

$$\times \theta \left(-\frac{l\hat{y}_2}{2\pi} + \frac{1}{2}Ad + \frac{\sqrt{2}A}{2l}(z_1+\bar{z}_2), \frac{Ai}{2} \right)$$

$$\times \theta \left(-\frac{l\hat{y}_1}{2\pi} + \frac{1}{2}Aa + \frac{i\sqrt{2}A}{2l}(z_1-\bar{z}_2), \frac{Ai}{2} \right) \Bigg) \Bigg\}^{-1} \Bigg\|_{z_1=\bar{z}_2=0}. \tag{112}$$

Thus, we derive two forms of explicit expressions of the projector P in terms of the integration and derivative of the classical theta functions.

VI. DISCUSSION

In this paper, P is represented by a form of a fraction which make sense only when the denominator has an inverse. The formula demands

$$D=A\int d^2\mu d^2\nu f_1(\mu) f_2(\nu) G_{00}(u,v) \tag{113}$$

is unequal to zero for any real variables u and v. It is easy to prove that when f_1 is equal to f_2^*, the related denominator

$$D=A\sum_n \left\langle k,q+\frac{ln}{A}\middle|\phi\right\rangle \left\langle \phi\middle|k,q+\frac{ln}{A}\right\rangle = A\sum_n \left|\left\langle k,q+\frac{ln}{A}\middle|\phi\right\rangle\right|^2. \tag{114}$$

Thus if $D=0$, then

$$\left\langle k,q+\frac{ln}{A}\middle|\phi\right\rangle = 0, \qquad n=0,1,\ldots,A-1. \tag{115}$$

The zero points of the state vector $|\phi\rangle$ in $|k,q\rangle$ representation should be points equally spaced along q with an interval of l/A. The mapping from k and q to $\langle k,q+ln/A|\phi\rangle \in C$ is a mapping from plane to plane. In general, $\langle k,q+ln/A|\phi\rangle=0$ are some discrete points, and thus it is casual that D is equal to zero. So in this sense, for most of $f_1=f_2^*$, this still not happens (in some sense, the measure of $D=0$ event is zero). Specially, when the state $|\phi_1\rangle=|\phi_2\rangle=|0\rangle$, it can be proved[35] that D is not equal to zero everywhere. Thus set

$$|\phi_1\rangle=|0\rangle+\epsilon|\psi_1\rangle, \qquad \langle\phi_2|=\langle 0|+\epsilon\langle\psi_2|. \tag{116}$$

D is also not equal to zero everywhere for small enough ϵ. But we do not know the situation for general $f_1\neq f_2^*$.

The BMS group and generalized gravitational instantons

Evangelos Melas[a)]
Department of Mathematical Sciences, QMW London, United Kingdom

(Received 1 June 2003; accepted 11 December 2003)

The ordinary Bondi–Metzner–Sachs (BMS) group B is the best candidate for the fundamental symmetry group of General Relativity. It has been shown that B admits generalizations to real space–times of any signature, and also to complex space–times. It has been suggested that certain continuous unitary irreducible representations (IRs) of B and of its generalizations correspond to gravitational instantons. Here I make this correspondence more precise and I take this suggestion one step further by arguing that a subclass of IRs of B and of its generalizations correspond to *generalized* gravitational instantons. Some of these *generalized* gravitational instantons involve in their definition certain subgroups of the Cartesian product group $C_n \times C_m$, where C_r is the cyclic group of order r. With this motivation, I give the subgroups of $C_n \times C_m$ explicitly. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1645976]

I. INTRODUCTION

In 1962, an intensive study of asymptotically flat space–times, representing bounded gravitational sources emitting gravitational radiation, was undertaken by Bondi and others[1] and this work was generalized by Sachs.[2] These authors imposed radiation-dictated boundary conditions and found, among other things, that the ''asymptotic symmetries'' of such asymptotically flat space–times formed a group B which was independent of the detailed structure of the particular asymptotically flat space–time in question, hence the universality of B and its importance. This group, the so called Bondi–Metzner–Sachs (BMS) group B, contains the Poincare group P, and, furthermore, is infinite dimensional.

Soon after its discovery, the importance of finding the irreducible representations of B was emphasized.[2–4] The irreducible representations of B were constructed in a series of papers by McCarthy.[5–7] The role of the IRs of B is much less well understood than the role of the IRs of P.[8,9] McCarthy, in order to make this role better understood and in order to make contact with other approaches to quantum gravity, where complexified or Euclidean versions of general relativity are frequently considered, generalized B[9] to real space–times of any signature, and also to complex space–times. A significant input in the attempt to interpret the irreducibles of B and of its generalizations came from Kronheimer's work,[11,12] in which he classified *all* ALE gravitational instantons. McCarthy, using Kronheimer's work, conjectured[9] that there is a correspondence between ALE gravitational instantons and certain IRs of B, of EB, and of CB; the groups EB and CB are correspondingly the Euclidean BMS group and the Complex BMS group and both of them are defined in Ref. 9. The aim of this paper is to state and extend this correspondence, and, furthermore, to give explicitly a class of groups which are expected to be involved in the definition of new solutions to the Einstein equations. First, I make explicit and precise the expected correspondence between ALE spaces and IRs of B, EB, and CB; this correspondence has been stated, at least implicitly, in some cases by McCarthy (Ref. 9). Second, I argue that the representation theory of B and of its variants strongly suggests that in all signatures the aforementioned correspondence is naturally extended to non-self-dual solutions of the Einstein equations. Guided by this extended correspondence I (Ref. 10) put forward the conjecture that there are solutions to the Euclidean,

a)Electronic mail: E.Melas@qmul.ac.uk; evangelosmelas@yahoo.co.uk

Complex and Ultrahyperbolic Einstein equations which are neither self-dual nor anti-self-dual but far more general mixtures of them and which involve in their definition subgroups of the Cartesian product group $C_n \times C_m$, where C_r is the cyclic group of order r. With this motivation, I give the subgroups of $C_n \times C_m$ explicitly.

In Sec. II I make explicit the expected correspondence between BMS IRs and (generalized) gravitational instantons. Finally, in Sec. III I give explicitly the subgroups of $C_n \times C_m$.

II. RELATION OF BMS IRs WITH INSTANTONS AND WITH GENERALIZED INSTANTONS

In 1989 Kronheimer[11,12] gave an implicit description of all ALE gravitational instantons. (For the various types of gravitational instantons and for the role they play in the path integral approach to quantum gravity, see for example Ref. 13 and references therein.) Asymptotically locally Euclidean means that outside some compact region the metric approaches the flat (Euclidean) metric on $(S^3/T)\times R$, where T is a finite group of isometries acting freely on S^3 (S^3 is a 3-sphere and R is the straight line of real numbers). (If T is the identity the instanton is asymptotically Euclidean; in this case, however, according to a theorem of Showen and Yau,[14] the only instanton is the Euclidean four space. Eguchi and Hanson[15] gave an explicit metric in the case which T is a cyclic group Z_2 of order 2. Gibbons and Hawking[16] generalized Eguchi's and Hanson's result and gave explicit metrics in the case where T is a cyclic group C_k of order $k \geqslant 2$. The same result was obtained by Hitchin[17] by the Penrose nonlinear graviton technique, which can be extended to any finite subgroup of $SU(2)$. His approach however gives the solutions only implicitly.) Kronheimer's description of ALE instantons is implicit because he does not give explicit expressions for the metrics of the ALE instantons; the description involves constraints, namely, algebraic equations difficult to solve. He proved that the description of the moduli space of *all* gravitational ALE instantons involves the complex linear irreducible representations of the cyclic, the dihedral groups and the symmetry groups of the tetrahedron, cube and icosahedron. More precisely, the description involves the complex linear irreducible representations of the corresponding binary groups. It is precisely these binary groups which appear in the representation theory of B[6] as little groups. In fact, it is this coincidence which led McCarthy[9] to conjecture that there is a relation between IRs of B induced from finite little groups and ALE instantons. To make contact with other approaches to quantum gravity, where complexified or Euclidean versions of general relativity are considered, McCarthy generalized B to real space–times of any signature and to complex space–times and obtained 42 groups. For the purposes of this paper more relevant among these 42 groups are the Complex BMS group $CB = C^\infty(S^2 \times S^2, R) \circledS_T (SL(2,C) \times SL(2,C))$ and its various real sections: the Euclidean BMS group $EB = C^\infty(S^3, R) \circledS_T (SU(2) \times SU(2))$, the Ultrahyperbolic BMS group $B(2,2) = C^\infty(S^1 \times S^1, R) \circledS_T (SL(2,R) \times SL(2,R))$, and the original BMS group $B = C^\infty(S^2, R) \circledS_T SL(2,C)$ (typically $G = C^\infty(A,R) \circledS_T H$ denotes a semi-direct product, where, $C^\infty(A,R)$ is the normal Abelian subgroup of G. A denotes in all cases a compact space and $C^\infty(A,R)$ consists of the supertranslations; they are real-valued infinitely-differentiable functions defined on A. The space $C^\infty(A,R)$ can be given the structure of a linear vector space (over the field of real numbers) under point-wise addition. The representation "T" of H on the linear vector space $C^\infty(A,R)$ which specifies in each case the semi-direct product is not relevant here).

Now, I will state a number of conjectures which establish the relation of gravitational instantons and BMS IRs. Some of them are contained implicitly in Ref. 9. Here, I make them more explicit. These conjectures provide part of the driving force of the research program expounded here; namely of approaching quantum gravity via the representation theory of the BMS group and of its variants. The conjectures will be stated in order of increasing generality.

Conjecture 1: The Eguchi–Hanson metric[15] corresponds to the irreducible of EB induced from the group $I \times C_2$, where I is the identity and C_2 is the cyclic group of order 2.

It should be noted that there is also[9] a correspondence between the Eguchi–Hanson metric and the irreducible of CB induced from the group $I \times C_2$. It appears though, in a very preliminary consideration of the problem, that this correspondence can be explored and made explicit only in a round-about way by using the results of Hithin[17] and Newman,[18] whereas, it appears that the correspondence between the Eguchi–Hanson metric and the relevant irreducible of EB can be

established in a more straightforward way. This explains the reason I am restricting attention to the Euclidean BMS EB in Conjecture 1. Having said that, it is of paramount importance to try and establish the correspondence between the Eguchi–Hanson metric and the associated irreducible of CB, because this will also offer some clues about the relation of IRs of CB and EB; the interrelationship of the groups in Ref. 9 and of their IRs is an indispensable element of the research program considered here. Now I proceed to give Conjecture 2.

Conjecture 2: The gravitational multi-instantons of Gibbons and Hawking[16] correspond to the irreducibles of EB induced from the groups $I\times C_k$, where I is the identity and C_k is the cyclic group of order k, $k\geqslant 2$.

As in the case of the Eguchi–Hanson metric, there is a correspondence between the gravitational multi-instantons of Gibbons and Hawking and the IRs of CB induced from the groups $I\times C_k$. Making explicit this correspondence, by using the results of Hithin[17] and Newman[18] is an important part of the research program considered here. The following Conjecture proceeds one step further than the previous 2 Conjectures and states that there is a strong link between Kronheimer's work[11,12] and the IRs of EB.

Conjecture 3: The moduli spaces of ALE instantons given by Kronheimer in Refs. 11, 12 are precisely the irreducibles of EB induced from the groups $\Gamma\times I$, where Γ is the binary cyclic, binary dihedral, binary tetrahedral, binary octahedral or binary icosahedral and I is the identity element.

Note that here the IRs of EB are induced from little groups which lie only in the first factor of $SU(2)\times SU(2)$. The moduli spaces associated with instantons arise from only one factor of $SU(2)\times SU(2)$ [$SU(2)\times I$ for anti-instantons and $I\times SU(2)$ for instantons]. In Conjecture 3, the choice $\Gamma\times I$ is made because Kronheimer's work deals with anti-instantons. Kronheimer's description of the ALE moduli spaces is partial since it involves constraints. Kronheimer does not solve the constraint equations but the conjecture is being put forward here that the EB IRs give an unconstrained description of the same moduli spaces. There is also a correspondence between the moduli spaces of ALE instantons described by Kronheimer and the IRs of CB induced from the groups $\Gamma\times I$, where Γ was defined in Conjecture 3. As in the previous cases this correspondence can be explored and made clear by using the results of Hitchin and Newman. Kronheimer's work describes *all* ALE instantons; i.e., self-dual solutions to *Euclidean* Einstein equations. The representation theory of the BMS group and of its variants provide clues about (self-dual) solutions of Einstein equations in all signatures, as well as of Complex Einstein equations. First, I will comment on self-dual solutions. Indeed, the representation theory of the groups CB,[9] $B(2,2)$[19] strongly suggests the following Conjecture.

Conjecture 4: There are self-dual solutions to the complex Einstein equations which involve in their definition the IRs of Γ (where Γ was defined in Conjecture 3). The moduli spaces of these solutions correspond to the IRs of CB which are induced from the groups $I\times\Gamma$. There are also self-dual solutions to the ultrahyperbolic Einstein equations which involve in their definition the IRs of C_n, where C_n is the cyclic group of order n. The moduli spaces of these solutions correspond to the IRs of $B(2,2)$ which are induced from the groups C_n.

More importantly, the representation theory of EB, CB,[9] and $B(2,2)$[19] suggests that there are solutions to Euclidean, complex and ultrahyperbolic Einstein equations which are neither self-dual nor anti-self-dual but far more general mixtures of them. To be more precise, we have the following Conjecture.

Conjecture 5: There are solutions to the Euclidean and Complex Einstein equations which are neither self-dual nor anti-self-dual but more general mixtures of them. The moduli spaces of these solutions involve in their definition IRs of subgroups of the direct product $\Gamma_1\times\Gamma_2$, where Γ_1, Γ_2 are (independently) binary cyclic, binary dihedral, binary tetrahedral, binary octahedral or binary icosahedral. The moduli spaces of these solutions correspond to IRs of the groups EB and CB which are induced from the groups $\Gamma_1\times\Gamma_2$. There are also solutions to the ultrahyperbolic Einstein equations which are neither self-dual nor anti-self-dual but more general mixtures of them. The moduli spaces of these solutions involve in their definition IRs of subgroups of the

direct product $C_n \times C_m$. The moduli spaces of these solutions correspond to the IRs of the group $B(2,2)$ which are induced from the same subgroups of $C_n \times C_m$.

It is to be noted that the IRs of CB, EB, and $B(2,2)$ which correspond to solutions which are neither self-dual nor anti-self-dual but more general mixtures of them are not induced from little groups which lie within only one factor of $SU(2) \times SU(2)$ in the cases of CB and EB, or within only one factor of $SO(2) \times SO(2)$ in the case of $B(2,2)$, but are induced from little groups which "lie across" $SU(2) \times SU(2)$ or across $SO(2) \times SO(2)$. Two remarks are now in order.

(1) The previous conjectures claim that there is a correspondence between certain solutions to complex Einstein equations as well as to Euclidean or ultrahyperbolic Einstein equations and certain IRs of the CB, EB, and $B(2,2)$. In *all cases* the IRs give an *unconstrained* description of the corresponding moduli spaces. In the Euclidean signature, Kronheimer's description of the ALE moduli spaces involves constraints, i.e., algebraic equations which he has not solved. The suggestion is being put forward here that in fact one can attempt to use the relevant IRs of EB in order to solve Kronheimer's constraint equations.
(2) In the correspondence conjectured here the IRs, of the relevant in each case, BMS-group are induced from the, relevant in each case, finite *little groups*.

According to the last conjecture in the ultrahyperbolic case, the little groups of $B(2,2)$ are involved in the description of moduli spaces of solutions of the ultrahyperbolic Einstein equations. These little groups are subgroups of $C_n \times C_m$. The direct product $C_n \times C_m$ also appears in the representation theory of both CB and EB and, according to Conjecture 5, subgroups of them are involved in the description of moduli spaces of solutions to the complex and Euclidean Einstein equations. For this reason I give explicitly the subgroups of $C_n \times C_m$ in the next section.

III. SUBGROUPS OF $C_n \times C_m$

It turns out that the explicit construction of the subgroups of $C_n \times C_m$ is a problem more difficult than it might appear at a first consideration. I constructed the subgroups of $C_n \times C_m$ with two entirely independent methods to assure correctness; full details of the construction will be given elsewhere, here I only give the result of the construction. The result is given in an algorithmic fashion; it can be used to write a program which would construct them automatically. It is an interesting fact that the explicit construction of the subgroups of $C_n \times C_m$ involves the prime decomposition of the numbers n and m. An attempt to find them explicitly without invoking the prime decomposition of n and m failed. A key observation is that the direct product $C_n \times C_m$ is a finite Abelian group, and therefore, its rank, i.e., the number of its independent generators, is greater or equal than the rank of any of its subgroups. Consequently, the subgroups of $C_n \times C_m$ have either one or two generators. First, in the first Theorem, I give the generators of the cyclic subgroups of $C_n \times C_m$, and then, in the second Theorem I give the generators of the noncyclic subgroups of $C_n \times C_m$. It will prove convenient to introduce some notation at this point. $\mathcal{P}$ will denote a permutation of the s pairs of numbers $(p_1^{a_1}, p_1^{\beta_1})$, $(p_2^{a_2}, p_2^{\beta_2}), \ldots, (p_s^{a_s}, p_s^{\beta_s})$. Therefore, if $(p_i^{a_i}, p_i^{\beta_i})$, $i = 1,2,\ldots,s$ is one of these pairs of numbers then, $\mathcal{P}(p_i^{a_i}, p_i^{\beta_i}) = (p_j^{a_j}, p_j^{\beta_j})$, for some $j = 1,2,\ldots,s$. For convenience, we will write

$$\mathcal{P}(p_i^{a_i}, p_i^{\beta_i}) = (p_j^{a_j}, p_j^{\beta_j}) \equiv (p_i^{a_i}, p_i^{b_i}), \quad i = 1,2,\ldots,s.$$

Thus, the integer p_j is written as p_i, the non-negative integer a_j is written as a_i, and the non-negative integer β_j is written as b_i. I proceed now to give the first theorem.

Theorem I: *Let $C_n \times C_m$ be the direct product of the cyclic groups of finite order C_n and C_m. Let $n = p_1^{a_1} \cdot p_2^{a_2} \cdots p_s^{a_s}$ and $m = p_1^{\beta_1} \cdot p_2^{\beta_2} \cdots p_s^{\beta_s}$ be the prime decomposition of the integers n and m, i.e., p_i, $i = 1,2,\ldots,s$, are distinct prime numbers and a_i, β_i are non-negative integers. Then we have the following.*

(1) A group,

$$\mathcal{C}=A_1\times A_2\times A_3\times\cdots\times A_s, \tag{1}$$

where A_i *is a cyclic subgroup, not necessarily different from the identity element, of* $C_{p_i^{a_i}}\times C_{p_i^{\beta_i}}$, $i=1,2,...,s$, *is a cyclic subgroup of* $C_n\times C_m$.

(2) Every cyclic subgroup $\mathcal{C}$ *of* $C_n\times C_m$ *is of the form*

$$\mathcal{C}=A_1\times A_2\times A_3\times\cdots\times A_s,$$

where A_i *is a cyclic subgroup, not necessarily different from the identity element of* $C_{p_i^{a_i}}\times C_{p_i^{\beta_i}}$, $i=1,2,...,s$.

(3) For every cyclic group $\mathcal{C}$ *of* $C_n\times C_m$ *the expression (1) is unique.*

A generator of the cyclic subgroup $\mathcal{C}$ *is given by*

$$(x^{\mathcal{A}},y^{\mathcal{B}}), \tag{2}$$

where, x is a generator of C_n, *y is a generator of* C_m,

$$\mathcal{A}=\sum_{i=1}^{\nu} r_i p_i^{a_i-k_i}(n/p_i^{a_i})+\sum_{i=\nu+1}^{\nu+\chi} p_i^{a_i-k_i}(n/p_i^{a_i})+\sum_{i=\nu+\chi+1}^{\nu+\chi+\tau} j_i(n/p_i^{a_i})+\sum_{i=\nu+\chi+\tau+1}^{\nu+\chi+\tau+\psi} p_i^{a_i-k_i}(n/p_i^{a_i}), \tag{3}$$

and

$$\mathcal{B}=\sum_{i=1}^{\nu} p_i^{b_i-k_i}(m/p_i^{b_i})+\sum_{i=\nu+1}^{\nu+\chi} \rho_i p_i^{b_i-k_i+1}(m/p_i^{b_i})+\sum_{i=\nu+\chi+1}^{\nu+\chi+\tau} p_i^{b_i-k_i}(m/p_i^{b_i}) + \sum_{i=\nu+\chi+\tau+1}^{\nu+\chi+\tau+\psi} j_i(m/p_i^{b_i}). \tag{4}$$

The order $|\mathcal{C}|$ *of the group* $\mathcal{C}$ *is given by*

$$|\mathcal{C}|=\prod_{i=1}^{\nu+\chi+\tau+\psi} p_i^{k_i}. \tag{5}$$

The non-negative integers ν, χ, τ, ψ *are such that* $\nu+\chi+\tau+\psi\leqslant s$. *Moreover,* $(p_i^{a_i},p_i^{b_i})=\mathcal{P}(p_i^{a_i},p_i^{\beta_i})$, $i=1,2,...,s$, *for some permutation* $\mathcal{P}$ *of the s pairs of numbers* $(p_1^{a_1},p_1^{\beta_1})$, $(p_2^{a_2},p_2^{\beta_2}),\ldots,(p_s^{a_s},p_s^{\beta_s})$. *Furthermore, when* $i\in\{1,2,...,\nu\}$, $r_i\in\{0,1,2,...,p_i^{k_i}-1\}$, *and when* $\sigma\in\{\nu+\chi+1,\nu+\chi+2,...,\nu+\chi+\tau\}$, $a_\sigma<k_\sigma\leqslant b_\sigma$ *and* $j_\sigma\in\{0,1,2,...,p_\sigma^{a_\sigma}-1\}$. *Finally, when* $q\in\{\nu+1,\nu+2,...,\nu+\chi\}$, $\rho_q\in\{0,1,2,...,p_q^{k_q-1}-1\}$, *and when* $\theta\in\{\nu+\chi+\tau+1,\nu+\chi+\tau+2,...,\nu+\chi+\tau+\psi\}$, $a_\theta\geqslant k_\theta>b_\theta$ *and* $j_\theta\in\{0,1,2,...,p_\theta^{b_\theta}-1\}$.

I give now the second theorem, where generators of all the noncyclic subgroups of $C_n\times C_m$ are given explicitly.

Theorem II: *Let* $C_n\times C_m$ *be the direct product of the cyclic groups of finite order* C_n *and* C_m. *Let* $n=p_1^{a_1}\cdot p_2^{a_2}\cdots p_s^{a_s}$ *and* $m=p_1^{\beta_1}\cdot p_2^{\beta_2}\cdots p_s^{\beta_s}$ *be the prime decomposition of the integers n and m,* i.e., p_i, $i=1,2,...,s$, *are distinct prime numbers and* a_i, β_i *are non-negative integers. Then we have the following.*

(1) A group,

$$\mathcal{C}=A_1\times A_2\times A_3\times\cdots\times A_s, \tag{6}$$

where A_i is a subgroup, not necessarily different from the identity element, of $C_{p_i^{a_i}} \times C_{p_i^{\beta_i}}$, $i=1,2,...,s$, is a subgroup of $C_n \times C_m$ with two generators if at least one of the A_i, $i=1,2,...,s$, has two generators.

(2) Every subgroup $\mathcal{C}$ of $C_n \times C_m$ with two generators is of the form

$$\mathcal{C}=A_1 \times A_2 \times A_3 \times \cdots \times A_s,$$

where A_i is a subgroup, not necessarily different from the identity element, of $C_{p_i^{a_i}} \times C_{p_i^{\beta_i}}$, $i=1,2,...,s$, and, where at least one of the A_i, $i=1,2,...,s$, has two generators.

(3) For every subgroup $\mathcal{C}$ of $C_n \times C_m$ with two generators the expression (6) is unique.

Two generators of a subgroup $\mathcal{C}$ of $C_n \times C_m$ with two generators are given by the following.
(1)

$$g_1=(x^{\mathcal{A}_1}, y^{\mathcal{B}_1}), \tag{7}$$

where x is a generator of C_n, y is a generator of C_m,

$$\begin{aligned}\mathcal{A}_1=&\sum_{i=1}^{\nu} r_i p_1^{a_i-k_i}(n/p_i^{a_i})+\sum_{i=\nu+1}^{\nu+\chi} p_i^{a_i-k_i}(n/p_i^{a_i})+\sum_{i=\nu+\chi+1}^{\nu+\chi+\tau} j_i(n/p_i^{a_i})+\sum_{i=\nu+\chi+\tau+1}^{\nu+\chi+\tau+\psi} p_i^{a_i-k_i}(n/p_i^{a_i})\\&+\sum_{i=\nu+\chi+\tau+\psi+1}^{\nu+\chi+\tau+\psi+\sigma} r_i p_i^{a_i-k_i}(n/p_i^{a_i})+\sum_{i=\nu+\chi+\tau+\psi+\sigma+1}^{\nu+\chi+\tau+\psi+\sigma+\theta} p_i^{a_i-k_i}(n/p_i^{a_i})\\&+\sum_{i=\nu+\chi+\tau+\psi+\sigma+\theta+1}^{\nu+\chi+\tau+\psi+\sigma+\theta+\phi} t_i(n/p_i^{a_i})+\sum_{i=\nu+\chi+\tau+\psi+\sigma+\theta+\phi+1}^{\nu+\chi+\tau+\psi+\sigma+\theta+\phi+\xi} p_i^{a_i-k_i}(n/p_i^{a_i})\end{aligned} \tag{8}$$

and

$$\begin{aligned}\mathcal{B}_1=&\sum_{i=1}^{\nu} p_i^{b_i-k_i}(m/p_i^{b_i})+\sum_{i=\nu+1}^{\nu+\chi} \rho_i p_i^{b_i-k_i+1}(m/p_i^{b_i})+\sum_{i=\nu+\chi+1}^{\nu+\chi+\tau} p_i^{b_i-k_i}(m/p_i^{b_i})\\&+\sum_{i=\nu+\chi+\tau+1}^{\nu+\chi+\tau+\psi} j_i(m/p_i^{b_i})+\sum_{i=\nu+\chi+\tau+\psi+1}^{\nu+\chi+\tau+\psi+\sigma} p_i^{b_i-k_i}(m/p_i^{b_i})+\sum_{i=\nu+\chi+\tau+\psi+\sigma+1}^{\nu+\chi+\tau+\psi+\sigma+\theta} \rho_i p_i^{b_i-k_i+1}(m/p_i^{k_i})\\&+\sum_{i=\nu+\chi+\tau+\psi+\sigma+\theta+1}^{\nu+\chi+\tau+\psi+\sigma+\theta+\phi} p_i^{b_i-k_i}(m/p_i^{b_i})+\sum_{i=\nu+\chi+\tau+\psi+\sigma+\theta+\phi+1}^{\nu+\chi+\tau+\psi+\sigma+\theta+\phi+\xi} t_i(m/p_i^{b_i})\end{aligned} \tag{9}$$

(2)

$$g_2=(x^{\mathcal{A}_2}, y^{\mathcal{B}_2}), \tag{10}$$

where,

$$\mathcal{A}_2=\sum_{i=\nu+\chi+\tau+\psi+1}^{\nu+\chi+\tau+\psi+\sigma} p_i^{a_i-l_i}(n/p_i^{a_i})+\sum_{i=\nu+\chi+\tau+\psi+\sigma+\theta+1}^{\nu+\chi+\tau+\psi+\sigma+\theta+\phi} p_i^{a_i-l_i}(n/p_i^{a_i}) \tag{11}$$

and

$$\mathcal{B}_2=\sum_{i=\nu+\chi+\tau+\psi+\sigma+1}^{\nu+\chi+\tau+\psi+\sigma+\theta} p_i^{b_i-l_i}(m/p_i^{b_i})+\sum_{i=\nu+\chi+\tau+\psi+\sigma+\theta+\phi+1}^{\nu+\chi+\tau+\psi+\sigma+\theta+\phi+\xi} p_i^{b_i-l_i}(m/p_i^{b_i}). \tag{12}$$

The order $|\mathcal{C}|$ of the group $\mathcal{C}$ is given by

$$|\mathcal{C}| = \prod_{i=1}^{\nu+\chi+\tau+\psi+\sigma+\theta+\phi+\xi} p_i^{k_i} \times \prod_{i=\nu+\chi+\tau+\psi+1}^{\nu+\chi+\tau+\psi+\sigma+\theta+\phi} p_i^{l_i}. \tag{13}$$

The non-negative integers ν, χ, τ, ψ, σ, θ, ϕ, ξ are such that $\nu+\chi+\tau+\psi+\sigma+\theta+\phi+\xi \leqslant s$. Moreover, $(p_i^{a_i}, p_i^{b_i}) = \mathcal{P}(p_i^{a_i}, p_i^{\beta_i})$, $i=1,2,...,s$, for some permutation $\mathcal{P}$ of the s pairs of numbers $(p_1^{a_1}, p_1^{\beta_1})$, $(p_2^{a_2}, p_2^{\beta_2}), \ldots, (p_s^{a_s}, p_s^{\beta_s})$. Furthermore, when $i \in \{1,2,...,\nu\}$, $k_i \leqslant \min(a_i, b_i)$ and $r_i \in \{0,1,2,...,p_i^{k_i}-1\}$, and when $w \in \{\nu+\chi+1, \nu+\chi+2, ..., \nu+\chi+\tau\}$, $a_w < k_w \leqslant b_w$ and $j_w \in \{0,1,2,...,p_w^{a_w}-1\}$. When $q \in \{\nu+1, \nu+2, ..., \nu+\chi\}$, $k_q \leqslant \min(a_q, b_q)$ and $\rho_q \in \{0,1,2,...,p_q^{k_q-1} - 1\}$, and when $y \in \{\nu+\chi+\tau+1, \nu+\chi+\tau+2, ..., \nu+\chi+\tau+\psi\}$, $a_y \geqslant k_y > b_y$ and $j_y \in \{0,1,2,...,p_y^{b_y}-1\}$. When $i_1 \in \{\nu+\chi+\tau+\psi+1, \nu+\chi+\tau+\psi+2, ..., \nu+\chi+\tau+\psi+\sigma\}$, $1 \leqslant l_{i_1} \leqslant k_{i_1} \leqslant \min(a_{i_1}, b_{i_1})$ and $r_{i_1} \in \{0,1,2,...,p_{i_1}^{k_{i_1}-l_{i_1}}-1\}$, and when $q_1 \in \{\nu+\chi+\tau+\psi+\sigma+1, ..., \nu+\chi+\tau+\psi+\sigma+\theta\}$, $1 \leqslant l_{q_1} < k_{q_1} \leqslant \min(a_{q_1}, b_{q_1})$ and $\rho_{q_1} \in \{0,1,2,...,p_{q_1}^{k_{q_1}-l_{q_1}-1}-1\}$. When $w_1 \in \{\nu+\chi+\tau+\psi+\sigma+\theta+1, \nu+\chi+\tau+\psi+\sigma+\theta+2, ..., \nu+\chi+\tau+\psi+\sigma+\theta+\phi\}$, $1 \leqslant l_{w_1} \leqslant a_{w_1} < k_{w_1} \leqslant b_{w_1}$ and $t_{w_1} \in \{0,1,2,...,p_{w_1}^{a_{w_1}-l_{w_1}}-1\}$. Finally, when $y_1 \in \{\nu+\chi+\tau+\psi+\sigma+\theta+\phi+1, \nu+\chi+\tau+\psi+\sigma+\theta+\phi+2, ..., \nu+\chi+\tau+\psi+\sigma+\theta+\phi+\xi\}$, $1 \leqslant l_{y_1} \leqslant b_{y_1} < k_{y_1} \leqslant a_{y_1}$ and $j_{y_1} \in \{0,1,2,...,p_{y_1}^{b_{y_1}-l_{y_1}}-1\}$.

The previous theorems give the subgroups of $C_n \times C_m$. The large number of subgroups indicates that, in the Euclidean, for example, case, the gravitational multi-instantons of Gibbons and Hawking[16] are only a small class of solutions compared to the more general ones which are parametrized with IRs of subgroups of $C_n \times C_m$.

ACKNOWLEDGMENTS

I would like to thank Professor Peter Cameron for all his help while I was working on the problem of finding the subgroups of $C_n \times C_m$. I would like also to express my gratitude to Dr. Patrick McCarthy for introducing me to the research program presented here and for assisting me in clarifying the ideas presented in this paper.

Hamiltonians separable in Cartesian coordinates and third-order integrals of motion

Simon Gravel[a)]
Département de physique et Centre de recherche mathématiques, Université de Montréal, C.P.6128, Succursale Centre-Ville, Montréal, Québec H3C 3J7, Canada

(Received 7 February 2003; accepted 8 October 2003)

We present in this article all Hamiltonian systems in $E(2)$ that are separable in Cartesian coordinates and that admit a third-order integral, both in quantum and in classical mechanics. Many of these superintegrable systems are new, and it is seen that there exists a relation between quantum superintegrable potentials, invariant solutions of the Korteweg–de Vries equation and the Painlevé transcendents. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1633352]

I. INTRODUCTION

In classical mechanics, an n-dimensional Hamiltonian system is called Liouville integrable if it allows n functionally independent integrals of motion in involution (including the Hamiltonian), that is,

$$\{H,X_i\}=0,$$

$$\{X_i,X_j\}=0,\forall i,j.$$

The Hamiltonian $H=H(x_1,\ldots,x_n,p_1,\ldots,p_n)$ and the integrals of motion $X_i=X_i(x_1,\ldots,x_n,p_1,\ldots,p_n)$ must be well defined functions on phase space.[1,11] The system is superintegrable if it allows more than n functionally independent integrals, n of them in involution. It is called maximally superintegrable if it allows $2n-1$ integrals of motion. The best known superintegrable systems in n dimensions are the harmonic oscillator $V=\omega r^2$ and the Coulomb potential $V=\alpha/r$, and they are indeed maximally superintegrable. This may be closely related to Bertrand's theorem[1,2] which states that these are the only rotationally invariant systems for which all finite trajectories are closed.

In quantum mechanics, a Hamiltonian system is said to be integrable if there exists a set $\{X_i\}$ of n well defined, algebraically independent operators (including the Hamiltonian) that commute pairwise. It is superintegrable if it possesses further independent operators, $\{Y_j\}$ that commute with the Hamiltonian. The Y_j do not necessarily commute with each other, nor with the X_i.

The independence of operators in quantum mechanics remains to be defined rigorously.[13,14,17,29] Since we are dealing here only with polynomial differential operators, we can proceed by analogy with the classical case, keeping in mind that a rigorous definition will be needed as soon as we will want to make some more general statements. This choice of a definition will be used only for discussion purposes, since we will find all potentials that admit third-order integrals and all their integrals. The results obtained will therefore hold for any definition of the independence of operators.

Integrable and superintegrable systems, both in quantum and in classical mechanics, attracted considerable interest in the last years. Extensive literature exists about systems with second-order integrals of motion, either in Euclidian space[7–10,22,30] or in spaces with nonzero constant[19,25] or nonconstant curvature.[20] As long as there was no magnetic field in the Hamiltonian, the quantum and classical integrals of motion obeyed the same determining equations, and therefore quantum

a)Electronic mail: sg324@cornell.edu

and classical integrability were very similar. Both properties were related to separation of the Hamilton–Jacobi or Schrödinger equations, and also to exact solvability[27] and generalized symmetries.[26]

Systems with higher-order integrals have been studied and classified as early as 1935 in a well-known paper by Drach.[4] This paper considered classical Hamiltonians in complex Euclidian space.[23,24] Efforts were made recently to understand and classify more completely systems with higher-order integrals in classical[13,28] and quantum mechanics.[13,15,16] In spite of these efforts, still relatively few such systems are known. This article is the logical sequel of a systematic search for superintegrable systems with higher order integrals started in Ref. 13. Here we consider two-dimensional real Euclidian space with a one-particle Hamiltonian:

$$H=\tfrac{1}{2}(p_x^2+p_y^2)+V(x,y).$$

We request the existence of two additional integrals of motion, one of second order in the momenta and the other of third order.

The condition of existence for second-order integral implies, both in classical and quantum mechanics, that the Hamiltonian be separable in Cartesian, polar, parabolic or elliptic coordinates. In this article we consider potentials that are separable in Cartesian coordinates:

$$H=\tfrac{1}{2}(p_x^2+p_y^2)+V_1(x)+V_2(y).$$

We found all such systems which admit third-order integrals. Quantum and classical mechanics will be treated simultaneously, for the conditions of existence of integrals of motion, even though not equivalent, are quite similar in both cases.

II. EXISTENCE OF A THIRD-ORDER INTEGRAL

In quantum and classical mechanics, the general third-order commuting operator

$$X=\sum_{i+j=0}^{3} P_{ij}(x,y)p_x^i p_y^j$$

can be reduced to a much simpler form,

$$X=\sum_{\substack{i,j,k\\ i+j+k=3}} A_{ijk}\{L_3^i,p_x^j p_y^k\}+\{g_1(x,y),p_x\}+\{g_2(x,y),p_y\},$$
$$L_3=xp_y-yp_x, \tag{1}$$

where the A_{ijk} are real constants and the g_i real functions. The bracket is the anticommutator. It is not needed in classical mechanics, but in quantum mechanics it allows us to get rid of terms with even powers of the p_i and to make sure the operator is self-adjoint. Furthermore, its use allows us to see clearly the relations between the quantum and the classical cases. Indeed, it was found in Ref. 13 that the requirement that the operator commutes (or Poisson-commutes) with the Hamiltonian

$$H=\tfrac{1}{2}(p_x^2+p_y^2)+V(x,y)$$

implies equations that behave well in the classical limit. Namely, commutativity implies

$$0=g_1V_x+g_2V_y-\frac{\hbar^2}{4}(f_1V_{xxx}+f_2V_{xxy}+f_3V_{xyy}+f_4V_{yyy}$$
$$+8A_{300}(xV_y-yV_x)+2(A_{210}V_x+A_{201}V_y)), \tag{2}$$

$$(g_1)_x = 3f_1(y)V_x + f_2(x,y)V_y, \tag{3}$$

$$(g_2)_y = f_3(x,y)V_x + 3f_4(x)V_y, \tag{4}$$

$$(g_1)_y + (g_2)_x = 2(f_2(x,y)V_x + f_3(x,y)V_y) \tag{5}$$

in quantum mechanics, where

$$f_1(y) = -A_{300}y^3 + A_{210}y^2 - A_{120}y + A_{030},$$

$$f_2(x,y) = 3A_{300}xy^2 - 2A_{210}xy + A_{201}y^2 + A_{120}x - A_{111}y + A_{021},$$

$$f_3(x,y) = -3A_{300}x^2y + A_{210}x^2 - 2A_{201}xy + A_{111}x - A_{102}y + A_{012},$$

$$f_4(x) = A_{300}x^3 + A_{201}x^2 + A_{102}x + A_{003}.$$

The equations in classical mechanics are obtained by setting $\hbar = 0$. We may notice from the quantum equations, or directly from the condition $[H,X]=0$, that we can express all quantum integrable potentials as $\hbar^2\tilde{V}(x,y)$ where $\tilde{V}$ does not depend on $\hbar$. It is often more natural and interesting though to choose arbitrary parameters contained in $\tilde{V}$ to be depending on $\hbar$, so that the potential V does not vanish in the classical limit. One may always verify, though, that through an appropriate transformation of the arbitrary parameters one can write the potential as being proportional to $\hbar^2$.

The three last equations, identical in the quantum and classical cases, yield a linear compatibility condition for V, which reads

$$\begin{aligned} 0 = &-f_3V_{xxx} + (2f_2 - 3f_4)V_{xxy} + (-3f_1 + 2f_3)V_{xyy} - f_2V_{yyy} + 2(f_{2y} - f_{3x})V_{xx} \\ &+ 2(-3f_{1y} + f_{2x} + f_{3y} - 3f_{4x})V_{xy} + 2(-f_{2y} + f_{3x})V_{yy} + (-3f_{1yy} + 2f_{2xy} - f_{3xx})V_x \\ &+ (-f_{2yy} + 2f_{3xy} - 3f_{4xx})V_y. \end{aligned} \tag{6}$$

Further nonlinear compatibility conditions can be obtained from (2)–(5) for the potential, and these are listed in Ref. 13. They are quite complicated, though, and were not used for the results stated in this article.

III. POTENTIALS SEPARABLE IN CARTESIAN COORDINATES

If we set $V = V_1(x) + V_2(y)$ in Eqs. (2)–(5), we find

$$0 = g_1V_{1x} + g_2V_{2y} - \frac{\hbar^2}{4}(f_1V_{1xxx} + f_4V_{2yyy} + 8A_{300}(xV_{2y} - yV_{1x}) + 2(A_{210}V_{1x} + A_{201}V_{2y})), \tag{7}$$

$$(g_1)_x = 3f_1(y)V_{1x} + f_2(x,y)V_{2y}, \tag{8}$$

$$(g_2)_y = f_3(x,y)V_{1x} + 3f_4(x)V_{2y}, \tag{9}$$

$$(g_1)_y + (g_2)_x = 2(f_2(x,y)V_{1x} + f_3(x,y)V_{2y}), \tag{10}$$

with $\hbar = 0$ in the classical case. Equations (8) and (9) are readily integrated, so in the Cartesian case two equations remain to be solved.

The compatibility condition (6) allows us to find ODEs for V_1 and V_2. If we set alternatively $y=0$ and $x=0$, we find

$$(A_{210}x^2 + A_{111}x + A_{012})V_1^{(3)}(x) + 4(2A_{210}x + A_{111})V_1''(x) + 12A_{210}V_1'(x) = ax + b, \tag{11}$$

$$(A_{201}y^2-A_{111}y+A_{021})V_2^{(3)}(y)+4(2A_{201}y-A_{111})V_2''(y)+12A_{201}V_2'(y)=cy+d. \qquad (12)$$

The solutions to the homogeneous part of these equations are easily found and brought to a simple form by translations in x and y. If we take the first one for definiteness, we have four different types of solution. When $A_{210}\neq 0$, we have two possible solutions,

$$V_{1hom}=\frac{c_1}{(x+\alpha)^2}+\frac{c_2}{(x-\alpha)^2},$$

$$V_{1hom}=\frac{c_1}{x^2}+\frac{c_2}{x^3}.$$

If $A_{210}=0$ and $A_{111}\neq 0$, we get

$$V_{1hom}=\frac{c_1}{x^2}+c_2x.$$

Finally, if only $A_{012}\neq 0$, the solution may be brought to the form

$$V_{1hom}=c_2x^2+c_1x.$$

Special solutions are also simple. If $A_{210}\neq 0$, we have $V_{1part}=\alpha x^2+\beta x$. Otherwise, when $A_{111}\neq 0$, $V_{1part}=\alpha x^3+\beta x^2$, finally, if only $A_{012}\neq 0$, $V_{1part}=\alpha x^4+\beta x^3$. Provided that (11) or (12) does not vanish trivially, we can choose V_1 or V_2, respectively, among the following functions:

$$(\text{A.1})\quad f_1=\frac{c_1}{(x+\alpha)^2}+\frac{c_2}{(x-\alpha)^2}+c_3x^2+c_4x,$$

$$(\text{A.2})\quad f_2=\frac{c_1}{x^2}+\frac{c_2}{x^3}+c_3x^2+c_4x,$$

$$(\text{A.3})\quad f_3=\frac{c_1}{x^2}+c_2x^3+c_3x^2+c_4x,$$

$$(\text{A.4})\quad f_4=c_1x^4+c_2x^2+c_3x,$$

$$(\text{A.5})\quad f_5=c_1x^3+c_2x,$$

$$(\text{A.6})\quad f_6=c_1x^2,$$

$$(\text{A.7})\quad f_7=c_1x,$$

and then solve (7)–(10). These long but rather straightforward calculations yield the 15 superintegrable potentials included in Table I. Some of them are obviously particular cases of others, but we listed them separately to account for their additional integrals. Only the third-order integrals are listed, some of them being trivial consequences of lower-order ones. With the exception of the harmonic oscillator, potentials that have first-order integrals are not listed here for they were already presented in Ref. 13 with all their third-order integrals. The complete integrals of motion can be found in the Appendix.

Many of these potentials were not known. The only classical potentials among these are indicated with a $\star$. These are well-known superintegrable potentials (see, e.g., Ref. 10), and all of them, except V_i, are in fact quadratically superintegrable.

TABLE I. Superintegrable potentials that satisfy linear compatibility conditions for nonzero parameters.

Superintegrable potentials	Leading-order terms of the integrals
$\star V_a = a(x^2+y^2)$	L^3; $\{L,p_xp_y\}$; $\{L,p_y^2\}$; $\{L,p_x^2\}$
$\star V_b = a(x^2+y^2)+\frac{b}{x^2}+\frac{c}{y^2}$	$\{L,p_xp_y\}$
$V_c = a(x^2+y^2)+\frac{\hbar^2}{x^2}+\frac{\hbar^2}{y^2}$	L^3; $\{L,p_xp_y\}$
$V_d = a(x^2+y^2)+\frac{\hbar^2}{y^2}$	L^3; $\{L,p_xp_y\}$; $\{L,p_y^2\}$
$V_e = \frac{\hbar^2}{8\alpha^4}(x^2+y^2)+\frac{\hbar^2}{(x-\alpha)^2}+\frac{\hbar^2}{(x+\alpha)^2}$	$2L^3-3\alpha^2\{L,p_y^2\}$; $\{L,p_x^2\}$
$V_f = \frac{\hbar^2}{8\alpha^4}(x^2+y^2)+\frac{\hbar^2}{y^2}+\frac{\hbar^2}{(x+\alpha)^2}+\frac{\hbar^2}{(x-\alpha)^2}$	$2L^3-3\alpha^2\{L,p_y^2\}$
$V_g = \frac{\hbar^2}{8\alpha^4}(x^2+y^2)+\frac{\hbar^2}{(y-\alpha)^2}+\frac{\hbar^2}{(x-\alpha)^2}+\frac{\hbar^2}{(y+\alpha)^2}+\frac{\hbar^2}{(x+\alpha)^2}$	$2L^3-3\alpha^2(\{L,p_x^2\}+\{L,p_y^2\})$
$\star V_h = a(4x^2+y^2)+\frac{b}{y^2}+cx$	$p_xp_y^2$
$\star\ V_i = a(9x^2+y^2)$	$\{L,p_y^2\}$
$V_j = a(9x^2+y^2)+\frac{\hbar^2}{y^2}$	$\{L,p_y^2\}$
$V_k = \frac{\hbar^2}{8\alpha^4}(9x^2+y^2)+\frac{\hbar^2}{(y+\alpha)^2}+\frac{\hbar^2}{(y-\alpha)^2}$	$\{L,p_y^2\}$
$V_l = \frac{\hbar^2}{x^2}+\frac{a}{y^2}$	$\{L^2,p_x\}$; $\{L,p_xp_y\}$; p_x^3
$V_m = \frac{\hbar^2}{x^2}+\frac{\hbar^2}{y^2}$	L^3; $\{L^2,p_x\}$; $\{L^2,p_y\}$ $\{L,p_xp_y\}$; p_x^3; p_y^3
$V_n = ax+\frac{\hbar^2}{y^2}$	$\{L,p_y^2\}$; p_y^3; $p_xp_y^2$
$V_o = \frac{\hbar^2}{y^2}+V(x)$	p_y^3

All the potentials are superintegrable in the quantum case. We therefore notice that classical nontrivial potentials can have many different quantum equivalents. The classical harmonic oscillator V_a can be seen as a limiting case of the quantum potentials V_a, V_c and V_d, and, also, if we set $\alpha=\sqrt{\hbar}/\omega$, of V_e, V_f and V_g, not to mention the similar potentials that can be obtained by permutations of x and y. The anisotropic harmonic oscillator with ratio 1:3 also admits many quantum deformations, but, interestingly, the anisotropic oscillator with ratio 1:2 does not admit such deformations. Notice also that if we want to deal with real potentials only, α must be either real or purely imaginary in potentials V_e, V_f, V_g and V_k. Therefore, these have as a classical limit harmonic oscillators with $a>0$.

All quantum superintegrable potentials reduce to classical ones when the classical limit is considered, sometimes in more than one way. For example, potentials V_e, V_f and V_g give the free motion potential instead of the harmonic oscillator if α remains constant as $\hbar\to 0$.

These potentials all satisfy the linear equations (11) and (12), and can be expressed as sums of simple superintegrable potentials.

Let us now set $A_{210}=A_{111}=A_{012}=0$ so that (11) vanishes trivially. We may also assume that V_1 does not take one of the forms (A.1)–(A.7), for we have already worked these cases out. This is quite useful, for if we set $y=1$ in (6), we obtain for V_1 an equation of the same form as (11)

with different coefficients. These coefficients must therefore vanish, so $A_{300}=A_{201}=A_{102}=0$. This is a significant simplification that allows us to restrict our attention, when considering Eq. (12), to the following three cases:

(i) $V_2=ay^2$;
(ii) $V_2=ay$;
(iii) $A_{120}=A_{021}=0$.

Before we consider each case separately, it is worth noticing that potentials of the form $V=V_1(x)$ that admit third-order integrals independent of y and p_y should appear as solutions here, for the integral remains if we add a function $V_2(y)$ to these potentials. These potentials were found in Refs. 13 and 17 to satisfy the equation

$$\hbar^2 V_1'^2=4V_1^3-g_2V_1-g_3, \tag{13}$$

and can therefore be written as

$$V_1=\hbar^2\mathcal{P}(x), \tag{14}$$

where $\mathcal{P}(x)$ is the Weierstrass elliptic function. Since the y variable plays no role here and these potentials admit integrals with leading-order terms proportional to p_x^3, these solutions will appear in cases (i)–(iii).

A. Case i: $V=V_1(x)+ay^2$

When $V=V_1(x)+ay^2$ and $a\neq 0$, we find that $A_{300}=0$, and the following two equations must be satisfied:

$$0=A_{030}(\hbar^2V_1^{(3)}-6(V_1^2)')+\gamma_1V_1', \tag{15}$$

$$\begin{aligned}0=&A_{120}(-\hbar^2V_1^{(4)}-24a(xV_1)'+6(V_1^2)''-4ax^2V_1''+8a^2x^2)\\&+8aA_{021}(2ax-(xV_1')'-2V_1')+4\eta(2a-V_1''),\end{aligned} \tag{16}$$

where γ_1 and η are arbitrary constants. When $A_{030}\neq 0$, Eq. (15) is equivalent to (13) (up to a translation of V_1 to get rid of γ_1), hence its solutions are of the form (14). These potentials cannot satisfy simultaneously Eq. (16) for nontrivial parameters. This can be observed by expanding (13) in series around $x=0$ and substituting the result in (16). Therefore solutions given by $A_{030}\neq 0$ are of no special interest here.

Let us now set $A_{030}=\gamma_1=0$. Equation (16) can be greatly simplified. We assume that $A_{120}\neq 0$, for otherwise Eq. (16) can be solved to give potential V_h. Then by an appropriate translation of x and V, we can get rid of the terms involving A_{021} and η and finally divide by A_{120}:

$$0=-\hbar^2V_1^{(4)}-24a(xV_1)'+6(V_1^2)''-4ax^2V_1''+8a^2x^2. \tag{17}$$

This equation admits a first integral, namely,

$$k=\hbar^2(xV_1'''-V_1'')+4x(ax^2-3V_1)V_1'+6V_1^2+12ax^2V_1-2a^2x^4. \tag{18}$$

Both (17) and (18) can be simplified by setting $V_1=W(x)+ax^2/3$. Then

$$\hbar^2W^{(4)}=12WW''+12(W')^2+bxW'+2bW-\tfrac{1}{6}b^2x^2 \tag{19}$$

with $b=-8a\neq 0$ for (17), and

$$k_2=3\hbar^2(xW'''-W'')-18x(W^2)'+2(2ax^2+3W)^2 \tag{20}$$

for the first integral. Equation (19) is well known. It is equivalent to Eqs. (3.16) in Ref. 5 and (2.17) in Ref. 21, which were obtained by nonclassical reduction of the Boussinesq equation. It was also shown in Ref. 3 to be a nonclassical reduction of the Kadomtsev–Petviashvili equation. It has the Painlevé property, and, when $b\neq 0$, its solution, given in Ref. 6 [Eq. (2.88)] may be written in terms of the fourth transcendant function of Painlevé, namely,

$$W=\frac{\hbar}{2}b_1P_4'\left(x,\frac{b}{\hbar^2}\right)-\frac{1}{2}bP_4^2\left(x,\frac{b}{\hbar^2}\right)-\frac{1}{2}bxP_4\left(x,\frac{b}{\hbar^2}\right)-\frac{1}{6}\left(\frac{b}{2}x^2+\hbar^2K_1-\hbar b_1\right), \tag{21}$$

where $b_1\equiv\pm\sqrt{-b}=\pm\sqrt{8a}$ and $P_4(x,b/\hbar^2)=P_4(x,b/\hbar^2,K_1,K_2)$ is the fourth transcendant function of Painlevé, and therefore satisfies the equation

$$P_4''(x,\alpha)=\frac{(P_4'(x,\alpha))^2}{2P_4(x,\alpha)}-\frac{3\alpha}{2}P_4(x,\alpha)^3-2\alpha xP_4(x,\alpha)^2-\left(\frac{\alpha}{2}x^2+K_1\right)P_4(x,\alpha)+\frac{K_2}{P_4(x,\alpha)}. \tag{22}$$

K_1 and K_2 are integration constants. The potential therefore reads

$$\begin{aligned}V(x,y)=a(x^2+y^2)+\frac{\hbar}{2}b_1P_4'\left(x,\frac{-8a}{\hbar^2}\right)+4aP_4^2\left(x,\frac{-8a}{\hbar^2}\right)\\ +4axP_4\left(x,\frac{-8a}{\hbar^2}\right)+\frac{1}{6}(-\hbar^2K_1+\hbar b_1).\end{aligned} \tag{23}$$

This potential admits as special cases two anisotropic harmonic oscillators, $V=a(x^2+y^2)$ when $K_2=0$ (and $P_4=0$), and $V=a(x^2/9+y^2)$ when $K_1=0$ and $K_2=-\frac{1}{18}$ (and $P_4=-x/3$), as well as all their quantum deformations that have the form $V=a(p^2x^2+y^2)+f(x)$, that is, potentials V_d, V_e, V_j and V_k (up to a permutation of x and y).

The constant term in the potential, $(-\hbar^2K_1+\hbar b_1)$, can be set to zero, but we will keep it in order to be able to write the quantum and classical integrals in a unified way.

In classical mechanics, the equation (18) with $\hbar=0$ admits a first integral, which reads

$$c=\frac{(9V_1-ax^2)(V_1-ax^2)^3+k^2/4-k(V_1-ax^2)(3V_1+ax^2)}{x^2}.$$

We may therefore write the solution for V_1 implicitly as

$$cx^2-d^2+2d(V_1-ax^2)(3V_1+ax^2)=(9V_1-ax^2)(V_1-ax^2)^3, \tag{24}$$

where c and d are arbitrary constants. If $c=d=0$, we find either the familiar anisotropic harmonic oscillators, or a potential obtained by joining at $x=0$ two halves of anisotropic harmonic oscillators with different ratios. Even though this potential does not have a continuous second derivative, it can be obtained as a limiting case of the family of smooth superintegrable potentials (26).

In the general case the potential may be expressed as the root of a fourth-order polynomial with three arbitrary parameters (a, c and d), although we can set $a=1$ and one of the other two coefficients to ± 1 by scaling x and V_1.

Since Eq. (24) may describe new two-dimensional potentials with bounded motion, it is worth studying for interesting special cases. Indeed, if we assume $a>0$ and $d\geqslant 0$, we can consider the case $c=128a^4\tilde{d}^3/27^2$ and $d=4a^2\tilde{d}^2/27$. Four solutions exist in that case, two of which are translated harmonic oscillators. The remaining two potentials are

$$V=ay^2+\frac{a}{9}(2\tilde{d}+5x^2\pm 4x\sqrt{(\tilde{d}+x^2)}). \tag{25}$$

Up to an additive constant, potentials (25) are equal to

$$V=ay^2+\frac{a}{9}(x\pm 2\sqrt{\tilde{d}+x^2})^2. \tag{26}$$

Those potentials are smooth interpolations between anisotropic harmonic oscillators with ratio 1:1 and 1:3. When $\tilde{d}=0$ (and therefore $c=d=0$) they are the junctions of the two halves of harmonic oscillators mentioned above.

The integral of motion is similar in quantum and classical mechanics, and reads

$$X=\{L,p_x^2\}+\{ax^2y-3yV_1(x),p_x\}-\frac{1}{2a}\left\{\frac{\hbar^2}{4}V_{1xxx}+(ax^2-3V_1)V_{1x},p_y\right\}, \tag{27}$$

where V_1 is a solution to Eq. (24). Therefore the integral for (26) must be slightly modified to take into account the constant term we removed.

B. Case ii: $V=ay+V_1(x)$

Here we find again two equations:

$$\begin{aligned} 0&=\hbar^2A_{120}V_1^{(3)}-6A_{120}(V_1^2)'+12a^2A_{003}+\gamma_1V_1',\\ 0&=\frac{A_{030}}{4}(-6(V_1^2)'+\hbar^2V_1^{(3)})'-\frac{a}{2}A_{120}(6(xV_1)'+x^2V_1'')-aA_{021}((xV_1')'+2V_1')-\gamma_2V_1''+a\gamma_1. \end{aligned} \tag{28}$$

This time we cannot treat the equations separately, but we can, when $A_{120}\neq 0$, translate V to annihilate γ_1. Then we can substitute the first equation in the second to get rid of A_{030}, and finally translate x to get rid of A_{021}. We can then solve the remaining system, first by solving the second, linear equation, and then by substituting the result in the first one. The only solution remaining is then potential $V_n=ay+\hbar^2/x^2$. Hence we can set $A_{120}=0$, and therefore also $A_{003}=\gamma_1=0$ (as $V_1\neq bx$ and $a\neq 0$). In the second equation we can set $\gamma_2=0$. If then $A_{030}=0$, we find $V_1=a/x^2$ which was already classified. If $A_{030}\neq 0$ and $A_{021}=0$, though, the potential $V_1(x)$ is solution to

$$\hbar^2V_1''=6V_1^2+\lambda x+k. \tag{29}$$

If $\lambda\neq 0$, we can set $k=0$, and we find that V_1 can be expressed in terms of the first Painlevé transcendent:

$$V=ay+\hbar^2\omega^2P_1(\omega x), \tag{30}$$

with $\omega^5=\lambda/\hbar^4$.

The integral of motion is

$$X=2p_x^3+3\{V_2(x),p_x\}+\left\{\frac{\hbar^4\omega^5}{4a},p_y\right\}.$$

Notice that in order to consider the limiting case $a=0$, we can multiply the integral by a, and thus we find a potential that depends only on x with a trivial p_y integral. We can also set $\omega^5=a\omega^{5'}$ first, in which case we find the potentials (14). If we look for the classical limit, we find

$$V=ay+b\sqrt{x} \tag{31}$$

with the integral

$$X=2p_x^3+3b\{\sqrt{x},p_x\}-\left\{\frac{3b^2}{2a},p_y\right\}.$$

Returning to Eq. (29) and assuming $\lambda=0$, we find again that V_1 has the form (14), and the integral depends only on x and p_x.

Finally, if we set $A_{030}A_{021}\neq 0$, we have to solve the equation

$$0=\left(-\frac{3}{2}(V_1^2)'+\frac{\hbar^2}{4}V_1^{(3)}\right)'+b((xV_1')'+2V_1'),\quad b=\frac{-aA_{021}}{A_{030}}\neq 0. \tag{32}$$

It can be integrated once to give

$$C_1=-\frac{3}{2}(V_1^2)'+\frac{\hbar^2}{4}V_1^{(3)}+b((xV_1')+2V_1).$$

We can set $C_1=0$ by translations in x and V. The equation admits a first integral which reads

$$2b\hbar^2(V_1(x)-bx)V_1''(x)+b\hbar^2(2b-V_1'(x))V_1'(x)-8bV_1(x)(V_1(x)-bx)^2=k_1. \tag{33}$$

In the classical case, $\hbar=0$, this is enough to solve. The solution, which can be written implicitly in a more compact form, is given by

$$d=V_1(V_1-bx)^2, \tag{34}$$

where d is an arbitrary constant. When $d=0$ we find the familiar case $V=bx+ay$ which admits a first-order integral. We may notice that the implicit form of the solution is somewhat similar to (24).

In the quantum case, we notice that the transformation $W(x)=V_1(x)-bx$, that preserves the Painlevé property, simplifies Eq. (33) which becomes

$$\hbar^2(2WW''-W'^2)-8(W+bx)W^2=k_2 \tag{35}$$

or

$$W''=\frac{W'^2}{2W}+\frac{4W^2}{\hbar^2}+\frac{4bxW}{\hbar^2}+\frac{k_2}{2\hbar^2W}. \tag{36}$$

We can also substitute $Y(x)=\sqrt{W(x)}$ to find

$$\hbar^2Y''=2(Y^2+bx)Y+\frac{k_2}{4Y^3}.$$

If $k_2=0$, we can set $\hbar=1$ and $b=\frac{1}{2}$ by the change of variables

$$Y=(2\hbar b)^{1/3}Z,\quad x=\left(\frac{\hbar^2}{2b}\right)^{1/3}\xi.$$

The solution for $Z(\xi)$ is then a special case of the second Painlevé transcendant, defined by the equation

$$P_2''(x,\alpha)=2P_2(x,\alpha)^3+xP_2(x,\alpha)+\alpha.$$

The solution for V is

$$V(x,y)=bx+ay+(2\hbar b)^{2/3}P_2^2\left(\left(\frac{2b}{\hbar^2}\right)^{1/3}x,0\right), \tag{37}$$

with the particular case $V=bx+ay$.

Now if $k_2\neq 0$, we use (36), which can be normalized by a change of variables,

$$x=-\left(\frac{\hbar^2}{(4b)}\right)^{1/3}\xi, \quad W=-\frac{\sqrt{-k_2}}{(4\hbar b)^{1/3}}Y.$$

We then find

$$Y''=\frac{Y'^2}{2Y}+4\beta Y^2-\xi Y-\frac{1}{2Y}, \tag{38}$$

where $\beta=-\sqrt{-k_2}/(4\hbar b)\neq 0$ is an arbitrary constant. Equation (38) corresponds to case XXXIV, p. 340, in Ref. 18. The solution for $Y(\xi)$ reads

$$2\beta Y=P_2'\left(\xi,-2\beta-\frac{1}{2}\right)+P_2\left(\xi,-2\beta-\frac{1}{2}\right)^2+\frac{\xi}{2}, \tag{39}$$

where P_2 is once again the second Painlevé transcendant. Since β is an arbitrary constant, we can set $\kappa=-2\beta-\frac{1}{2}$.

Back to the original variables, we get

$$V(x,y)=ay+(2\hbar^2b^2)^{1/3}(P_2'(-(4b/\hbar^2)^{1/3}x,\kappa)+P_2^2(-(4b/\hbar^2)^{1/3}x,\kappa)). \tag{40}$$

This potential admits $V=ay$ and $V=ay+\hbar^2/x^2$ as particular cases.

In all cases with $V=ay+V_1(x)$ and $A_{012}A_{030}\neq 0$ the integral of motion is

$$2ap_x^3-2bp_x^2p_y+a\{3V_1(x)-bx,p_x\}-2b\{V_1(x),p_y\}. \tag{41}$$

Limiting values for a, b and $\hbar$ give either known potentials or trivial integrals.

C. Case iii: $A_{120}=A_{021}=0$

Since we set here $A_{120}=A_{021}=0$, we assume $A_{030}A_{003}\neq 0$ [otherwise we would find potentials of the form (14)]. The conditions for the existence of a third-order operator then read

$$\begin{aligned}\hbar^2V_1''(x)&=6V_1^2(x)+A_{003}\sigma x,\\ \hbar^2V_2''(y)&=6V_2^2(y)-A_{030}\sigma y.\end{aligned} \tag{42}$$

If σ vanishes, we find the potential

$$V=\hbar^2(\mathcal{P}(x)+\mathcal{P}(y)),$$

with two integrals that each depend on only one variable, as could have been predicted from the results of Eq. (13). If σ does not vanish, let us set $b_1=A_{003}\sigma$ and $b_2=-A_{030}\sigma$.

If $\hbar=0$, we find that

$$V=\pm\sqrt{\beta_1x}\pm\sqrt{\beta_2y}$$

is superintegrable, where the $\beta_i=b_i/6$ are arbitrary constants.

This defines similar real potentials on each quadrant of the plane. We can again patchwork the pieces to find real continuous potentials defined everywhere, e.g., $V=c_1\sqrt{|x|}+c_2\sqrt{|y|}$, although in that case neither the Hamiltonian nor the integral are differentiable at the equilibrium point.

Finally, if $\hbar \neq 0$, we find that V_1 and V_2 can be both written using the first Painlevé transcendent,

$$V = \hbar^2 \omega_1^2 P_1(\omega_1 x) + \hbar^2 \omega_2^2 P_1(\omega_2 y), \tag{43}$$

where the $\omega_i = (b_i/\hbar^4)^{1/5}$ are arbitrary constants.

The integral of motion is

$$X = 2b_2 p_x^3 - 2b_1 p_y^3 + 3b_2\{V_1(x,b_1),p_x\} - 3b_1\{V_2(y,b_2),p_y\}, \tag{44}$$

both in quantum and classical mechanics.

IV. CONCLUSION

We have found all systems in two-dimensional Euclidian space that admit separation of variables in Cartesian coordinates and at least one third-order integral, both in quantum and classical mechanics. Many new superintegrable potentials were found, and, interestingly, all the quantum superintegrable potentials are found as solutions of equations having the Painlevé property, and this is probably not accidental. Many of the quantum potentials can in fact be written in terms of different transcendent functions of Painlevé, and many are related to group invariant solutions of the Korteweg–de Vries equation, and to reductions of the Boussinesq and KP equations. All classical integrable potentials were found to be limiting cases of quantum ones. They do not obey equations having the Painlevé property, though, for many classical integrable potentials have movable branch points of the form $\sqrt{x-b}$. Thus, in that respect, quantum integrable potentials behave more regularly than classical ones. A natural question is what does the Painlevé property, in quantum mechanics, tell us about classical integrable potentials. Since this article deals mostly with the classification of superintegrable systems, the consideration of such questions regarding their properties and their solutions will be postponed to a future article.

Our investigation provided interesting new examples of the differences between quantum and classical integrability. A systematic search for systems with higher-order integrals is therefore a useful task since we still know little about such systems, and they are likely to share interesting properties.

Note added: The article mentioned earlier[12] indeed shows that superintegrability of separable systems has important physical implications. Even though the systems considered here can all be separated in two independent one-dimensional systems, two-dimensional superintegrability is useful to understand the one-dimensional properties of those separated systems.

Equations (2)–(5) are the necessary and sufficient conditions for the existence of third-order integrals. The general solution to these equations is highly nontrivial, and it is not likely that a direct approach will lead to such a solution for integrals of order higher than four, without the use of new methods. In order to develop such methods, it would be useful to have a rigorous definition of quantum integrability.

ACKNOWLEDGMENTS

The author thanks gratefully P. Winternitz for his very helpful comments and suggestions, and also J. Bérubé for useful discussions. The author benefits from a NSERC ES-A fellowship.

APPENDIX

Here is the complete list of two-dimensional Hamiltonians separable in Cartesian coordinates that admit at least one third-order integral. We also gave all their third-order integrals. Potentials depending on only one Cartesian coordinate are not listed here, for they were classified in Ref. 13. Many of the potentials listed below were already known to be superintegrable, but we listed them

here for completeness and in some cases to take into account additional third-order integrals. Potentials in boxes are those who do not admit enough first- or second-order integrals to make them superintegrable. Most of them were not known before.

Some potentials (namely, V_p and V_q) are not superintegrable according to the usual definition, for their integrals have simple though nontrivial relations with the Hamiltonian. For definitions of parameters the reader is referred to the body of the article. In order to write the integrals of motion in a compact form we often use the notation $V(x,y)=V_1(x)+V_2(y)=V_1+V_2$.

(Received 30 September 2003; accepted 10 December 2003)

By means of a simple new approach, a general Kadomtsev–Petviashvili (KP) family with an arbitrary function of group invariants of arbitrary order is proposed. It is proved that the general KP family possesses a common infinite dimensional Kac–Moody–Virasoro Lie point symmetry algebra. The known fourth order one can be re-obtained as a special example. The finite transformation group is presented in a clearer form. The Kac–Moody–Virasoro group invariant solutions and the Kac–Moody group invariant solutions of the KP family are determined by the Boussinesq and KdV families, respectively. © *2004 American Institute of Physics.*

I. INTRODUCTION

The symmetry study plays a very important role in the nonlinear science. Especially, in the study of $(2+1)$-dimensional integrable models, it is found that for all the known integrable systems there is an isomorphic centerless Virasoro symmetry algebra (Witt algebra):[1–9]

$$[\sigma(f_1),\ \sigma(f_2)]=\sigma(f_2\dot{f}_1-f_1\dot{f}_2), \tag{1.1}$$

where f_1 and f_2 are arbitrary functions of a single independent variable. The dot over the functions f_1 and f_2 denotes the derivative of the functions with respect to their argument. In Ref. 7, a method was established to obtain the models with centerless Virasoro symmetry algebras. In Ref. 3, Güngör and Winternitz pointed out that the variable coefficient Kadomtsev–Petviashvili (KP) equation,

$$\begin{aligned}&[u_t+p(t)uu_x+q(t)u_{xxx}]_x+\sigma(y,t)u_{yy}+a(y,t)u_y\\&\quad+b(y,t)u_{xy}\ c(y,t)u_{xx}+e(y,t)u_x+f(y,t)u+h(y,t)=0,\end{aligned} \tag{1.2}$$

possesses the Virasoro symmetry algebra (1.1) iff it can be transformed to the usual *integrable* constant coefficient KP equation,

$$(u_t+\tfrac{3}{2}uu_x+u_{xxx})_x+\tfrac{3}{4}\delta u_{yy}=0,\quad \delta=\pm 1. \tag{1.3}$$

By using the standard group approach, David, Levi and Winternitz[4] had proved that

$$(u_t+\tfrac{3}{2}uu_x)_x+\tfrac{3}{4}\delta u_{yy}+u_{xx}^{3/2}H(K_2,\ldots,K_{10})=0, \tag{1.4}$$

a)Electronic mail: sylou@sjtu.edu.cn

with $H(K_2,\ldots,K_{10})$ being an arbitrary function of $K_2,\ldots,K_{10}$ is the only fourth order KP family with the same Kac–Moody–Virasoro symmetry algebra of the usual KP equation. In (1.4), $K_2,\ldots,K_{10}$ are defined by

$$K_2=u_{xxxx}u_{xx}^{-3/2}, \tag{1.5}$$

$$K_3=u_{xxx}u_{xx}^{-5/4}, \tag{1.6}$$

$$K_4=(u_{xx}u_{xxy}-u_{xxx}u_{xy})u_{xx}^{-5/2}, \tag{1.7}$$

$$K_5=(u_{xxx}u_{xyy}-u_{xxy}^2-2\delta u_x u_{xx}u_{xxx})u_{xx}^{-3}, \tag{1.8}$$

$$K_6=[u_{xxx}^2u_{yyy}+2u_{xxy}^3-3u_{xxx}u_{xyy}u_{xxy}+6\delta u_x u_{xxx}(u_{xx}u_{xxy}-u_{xy}u_{xxx})]u_{xx}^{-9/2}, \tag{1.9}$$

$$K_7=(u_{xx}u_{xxxy}-u_{xxxx}u_{xy})u_{xx}^{-11/4}, \tag{1.10}$$

$$K_8=(u_{xxxx}u_{xxyy}-u_{xxxy}^2-2\delta u_x u_{xxx}u_{xxxx})u_{xx}^{-7/2}, \tag{1.11}$$

$$K_9=[u_{xxxx}^2u_{xyyy}+2u_{xxxy}^3-3u_{xxxx}u_{xxyy}u_{xxxy}+6\delta u_x u_{xxxx}(u_{xxx}u_{xxxy}-u_{xxy}u_{xxxx})]u_{xx}^{-21/4}, \tag{1.12}$$

$$\begin{aligned}K_{10}=[&u_{xxxx}u_{yyyy}+2u_{xxyy}^2-4u_{xyyy}u_{xxxy}+12u_x^2(u_{xx}u_{xxxx}+u_{xxx}^2)\\&-12\delta u_x(u_{xyy}u_{xxxx}-2u_{xxy}u_{xxxy}+u_{xxx}u_{xxyy})]u_{xx}^{-4}.\end{aligned} \tag{1.13}$$

In Ref. 5, it is proved that a special type of arbitrary order equation,

$$\left(u_t+\frac{3}{2}uu_x+u_{xxx}\right)_x+\frac{3}{4}\delta u_{yy}+\sum_{n=2}^{M}C_n u_{nx}^{6/(n+2)}=0\quad(M=2,\ 3,\ldots), \tag{1.14}$$

also possesses the symmetry group of the KP equation. In this paper, by using a simple new method, we concentrate on giving some types of autonomous higher order KP family,

$$(u_t+\tfrac{3}{2}uu_x+u_{xxx})_x+\tfrac{3}{4}\delta u_{yy}+F(u)=0, \tag{1.15}$$

which possess a same infinite dimensional Kac–Moody–Virasoro Lie point symmetry algebra, where

$$F(u)\equiv F(u,\ u_x,\ u_{xx},\ldots,u_{x^ny^mt^l},\ \ldots)\equiv F \tag{1.16}$$

is an undetermined function of the field u and its any order derivatives of x, y and t but not explicitly space–time dependent.

II. REVIEW ON THE LIE POINT SYMMETRIES AND FINITE TRANSFORMATIONS OF THE KP EQUATION

The Lie point symmetries and the related Kac–Moody–Virasoro algebra of the usual KP equation (1.3) have been first given by David, Kamran, Levi, and Winternitz[1] by using the standard classical Lie approach.[10,11] The generalized symmetries and the corresponding generalized w_∞ symmetry algebra is obtained by Lou via the formal series symmetry approach.[12,13]

A symmetry σ of the KP equation is a solution of its linearized equation,

$$(\sigma_t+\tfrac{3}{2}\sigma u_x+\tfrac{3}{2}u\sigma_x+\sigma_{xxx})_x+\tfrac{4}{3}\delta\sigma_{yy}=0, \tag{2.1}$$

which means (1.3) is form invariant under the transformation

$$u \to u + \epsilon\sigma,$$

where ϵ is an infinitesimal parameter.

According to the results of Ref. 1, the full Lie point symmetries of the KP equation (1.3) are the linear combinations of the following generators:

$$\sigma_0(h) = hu_x - \tfrac{2}{3}\dot{h}, \tag{2.2}$$

$$\sigma_1(g) = -2gu_y + \tfrac{4}{3}\delta\dot{g}yu_x - \tfrac{8}{9}\delta y\ddot{g}, \tag{2.3}$$

and

$$\sigma_2(f) = fu_t + \tfrac{1}{3}(x\dot{f} - \tfrac{2}{3}\delta y^2\ddot{f})u_x + \tfrac{2}{3}\dot{f}(yu)_y - \tfrac{4}{27}(\tfrac{3}{2}x\ddot{f} - \delta y^2\dddot{f}), \tag{2.4}$$

where f, g, and h are all arbitrary functions of t.

The Kac–Moody–Virasoro type algebra constituted by $\sigma_0(h), \sigma_1(g)$ and $\sigma_2(f)$ reads as

$$[\sigma_0(h_1),\ \sigma_0(h_2)] = [\sigma_0(h),\ \sigma_1(g)] = 0, \tag{2.5}$$

$$[\sigma_1(g_1),\ \sigma_1(g_2)] = \tfrac{2}{3}\sigma_0(\dot{g}_1 g_2 - \dot{g}_2 g_1), \tag{2.6}$$

$$[\sigma_2(f),\ \sigma_0(h)] = \tfrac{1}{3}\sigma_0(\dot{f}h - 3\dot{h}f), \tag{2.7}$$

$$[\sigma_2(f),\ \sigma_1(g)] = \tfrac{1}{3}\sigma_1(2\dot{f}g - 3\dot{g}f), \tag{2.8}$$

$$[\sigma_2(f_1),\ \sigma_2(f_2)] = \sigma_2(\dot{f}_1 f_2 - \dot{f}_2 f_1), \tag{2.9}$$

while the commutator $[G, H]$ of $G \equiv G(u)$ and $H \equiv H(u)$ is defined by

$$[G,\ H] = \lim_{\epsilon \to 0} \frac{\partial}{\partial \epsilon}(G(u + \epsilon H) - H(u + \epsilon G)) \equiv G'H - H'G. \tag{2.10}$$

From (2.9) we know that the subalgebra constituted by $\sigma_2(f)$ is just the Virasoro algebra (1.1).

The general finite transformations related to the symmetries (2.2)–(2.4) had also been given in Ref. 1. Here we rewrite them down in a much simpler and slightly extended form:

Theorem 1: *If $u = u(x,y,t)$ is a solution of the KP equation (1.3) then so also is u' with*

$$u' = \tau_t^{2/3} u(\xi, \eta, \tau) - \frac{2(\ln \tau_t)_t}{9}x - \frac{4\delta\tau_t^{1/3}}{9}\left[(\tau_t^{-1/3})_t y - \frac{\alpha_t}{\tau_t}\right]_t y - \frac{2\beta_t}{3\tau_t^{1/3}} - \frac{2\delta\alpha_t^2}{9\tau_t^{4/3}}, \tag{2.11}$$

where

$$\xi = \tau_t^{1/3}x - \frac{2\delta}{9}\left(\frac{\tau_{tt}}{\tau_t^{2/3}}y^2 + \frac{3\alpha_t}{\tau_t^{1/3}}y\right) + \beta, \tag{2.12}$$

$$\eta = \tau_t^{2/3}y + \alpha, \tag{2.13}$$

and $\{\tau \equiv \tau(t),\ \alpha \equiv \alpha(t),\ \beta \equiv \beta(t)\}$ are arbitrary functions of t.

III. A KP FAMILY WITH A COMMON KAC–MOODY–VIRASORO SYMMETRY ALGEBRA

In this section, we look for the possible equations which possess the totally same symmetries (2.2)–(2.4) and then the Kac–Moody–Virasoro type symmetry algebra (2.5)–(2.9).

A. Models with the Virasoro symmetry (2.4)

The symmetry equation of (1.15) has the form

$$(\sigma_t+\tfrac{3}{2}\sigma u_x+\tfrac{3}{2}u\sigma_x+\sigma_{xxx})_x+\tfrac{3}{4}\delta\sigma_{yy}+F'\sigma=0, \tag{3.1}$$

where F' is the linearized operator of F defined by

$$F'G=\lim_{\epsilon\to 0}\frac{\partial}{\partial\epsilon}F(u+\epsilon G) \tag{3.2}$$

for arbitrary G.

The substitution (2.4) into (3.1) yields

$$\begin{aligned}&\left[f\partial_t+\frac{1}{3}\dot f(x\partial_x+2y\partial_y+6)-\frac{2\delta}{9}y^2\ddot f\partial_x\right]\left(u_{xt}+\frac{3}{2}uu_{xx}+\frac{3}{2}u_x^2+u_{xxxx}+\frac{3}{4}\delta u_{yy}\right)\\&\quad+F'\left[fu_t+\frac{1}{3}\left(x\dot f-\frac{2\delta}{3}y^2\ddot f\right)u_x+\frac{2}{3}\dot f(yu)_y-\frac{4}{27}\left(\frac{3}{2}x\ddot f-\delta y^2\dddot f\right)\right]=0.\end{aligned} \tag{3.3}$$

The use of (1.15) and the elimination of u_{xt} from (3.3) lead to

$$\begin{aligned}&F'\left[fu_t+\frac{1}{3}\left(x\dot f-\frac{2\delta}{3}y^2\ddot f\right)u_x+\frac{2}{3}\dot f(yu)_y-\frac{4}{27}\left(\frac{3}{2}x\ddot f-\delta y^2\dddot f\right)\right]\\&\quad-\left[fF'u_t+\frac{1}{3}\dot f(xF'u_x+2yF'u_y+6F)-\frac{2\delta}{9}y^2\ddot fF'u_x\right]=0.\end{aligned} \tag{3.4}$$

According to the definitions of the function F (1.16) and its linearized operator F' (3.2), we have

$$F'=\sum_{n,m,l}\frac{\partial F}{\partial u_{x^ny^mt^l}}\frac{\partial^{n+m+l}}{\partial x^n\partial y^m\partial t^l},\quad m,n,l\geqslant 0. \tag{3.5}$$

The substitution (3.5) into (3.4) leads to

$$\begin{aligned}&\sum_{n,m,l}\sum_{i=0}^{l-1}C_l^i\frac{\partial F}{\partial u_{x^ny^mt^l}}\left[f^{(l-i)}\partial_t+\frac{f^{(l-i+1)}}{3}(x\partial_x+2y\partial_y)-\frac{2\delta f^{(l-i+2)}}{9}y^2\partial_x\right]u_{x^ny^mt^i}\\&\quad+\sum_{n,m,l}\sum_{i=0}^{l}C_l^i\frac{\partial F}{\partial u_{x^ny^mt^l}}\left[\frac{n}{3}f^{(l-i+1)}\partial_y^2-\frac{2m\delta}{9}f^{(l-i+2)}(2y\partial_y+m-1)\partial_x\right.\\&\quad\left.+\frac{2}{3}(m+1)f^{(l-i+1)}\partial_y^2\right]u_{x^ny^{m-2}t^i}-\sum_l\left[\frac{2}{9}f^{(l+2)}\left(\frac{\partial F}{\partial u_{xt^l}}+x\frac{\partial F}{\partial u_{t^l}}\right)\right.\\&\quad\left.-\frac{4\delta}{27}f^{(l+3)}\left(2\frac{\partial F}{\partial u_{yyt^l}}+2y\frac{\partial F}{\partial u_{yt^l}}+y^2\frac{\partial F}{\partial u_{t^l}}\right)\right]=2\dot fF,\end{aligned} \tag{3.6}$$

where

$$C_{l'}^i\equiv\frac{l'!}{i!(l'-i)!},\quad u_{x^{-n}y^{-m}t^{-l}}=0,\ \forall n\geqslant 1,\ m\geqslant 1,\ l\geqslant 1. \tag{3.7}$$

If we can find an f-independent solution F from (3.6), then we get a model with a Virasoro symmetry (2.4) for arbitrary f. Under the f-independent requirement and the autonomous condition of F, (3.6) is equivalent to the following equation system:

$$\sum_{n,m,l}(n+3l+2m+2)u_{x^n y^m t^l}\frac{\partial F}{\partial u_{x^n y^m t^l}}=6F, \tag{3.8}$$

$$\sum_{n,m,l}(l+1)\frac{\partial F}{\partial u_{x^n y^m t^{l+1}}}u_{x^{n+1}y^m t^l}-\frac{2}{3}\frac{\partial F}{\partial u}=0, \tag{3.9}$$

$$\sum_{n,m,l}\frac{\partial F}{\partial u_{x^n y^m t^l}}\left(\frac{3}{2}\delta l\partial_y^2-m\partial_x\partial_t\right)u_{x^n y^{m-1}t^{l-1}}=0, \tag{3.10}$$

$$\sum_{n,m,l}\frac{\partial F}{\partial u_{x^n y^m t^l}}\left[l(3l+n+2m-4)\partial_y^2-\frac{2m\delta}{3}(m-1)\partial_x\partial_t\right]u_{x^n y^{m-2}t^{l-1}}-\frac{2}{3}\frac{\partial F}{\partial u_x}=0, \tag{3.11}$$

$$\sum_{n,m,l}\frac{\partial F}{\partial u_{x^n y^m t^{l+2}}}u_{x^{n+1}y^m t^{l-k}}-\frac{2}{9}\frac{\partial F}{\partial u_{t^{k+1}}}=0, \tag{3.12}$$

$$\frac{2}{3}\frac{\partial F}{\partial u_{t^k}}-\sum_{n,m,l}\frac{\partial F}{\partial u_{x^n y^m t^{l+1}}}C_l^{l-k}u_{x^{n+1}y^m t^{l-k}}=0, \tag{3.13}$$

$$\frac{2}{3}\frac{\partial F}{\partial u_{yt^k}}+\sum_{n,m,l}\frac{\partial F}{\partial u_{x^n y^m t^{l+2}}}\left[\frac{3}{2}\delta C_l^{l-k}\partial_y^2-mC_l^{l-k+1}\partial_x\partial_t\right]u_{x^n y^{m+1}t^{l-k}}=0, \tag{3.14}$$

$$\begin{aligned}&2\frac{\partial F}{\partial u_{yyt^k}}-\frac{3}{2}\delta\frac{\partial F}{\partial u_{xt^{k+1}}}+\frac{3}{4}\sum_{n,m,l}\frac{\partial F}{\partial u_{x^n y^m t^{l+3}}}\{3\delta[3C_l^{l-k}+C_l^{l-k+1}(n+2m+2)]\partial_y^2\\&-2m(m-1)C_l^{l-k+2}\partial_x\partial_t\}u_{x^n y^{m-2}t^{l-k+1}}=0,\end{aligned} \tag{3.15}$$

where $k=0,\ 1,\ 2,\ldots,$ for (3.12)–(3.15).

To solve the full equation system (3.8)–(3.15) is still quite difficult. However, if we require that the function F is $u_{x^n y^m t^l}$ independent for $l\geqslant 1$, then (3.8)–(3.15) are reduced to

$$\frac{\partial F}{\partial u}=\frac{\partial F}{\partial u_y}=\frac{\partial F}{\partial u_{yy}}=0, \tag{3.16}$$

$$\sum_{n,m}(n+2m+2)u_{x^n y^m}\frac{\partial F}{\partial u_{x^n y^m}}=6F, \tag{3.17}$$

$$\sum_{n,m}mu_{x^{n+1}y^{m-1}}\frac{\partial F}{\partial u_{x^n y^m}}=0, \tag{3.18}$$

$$\sum_{n,m}m(m-1)u_{x^{n+1}y^{m-2}}\frac{\partial F}{\partial u_{x^n y^m}}+\delta\frac{\partial F}{\partial u_x}=0. \tag{3.19}$$

The general solution of (3.16)–(3.17) reads as

$$F=u_{xx}^{3/2}F_1(v_{nm},n,m=0,\ 1,\ 2,\ \ldots,\ \{n,\ m\}\neq\{0,\ 0\},\ \{0,\ 1\},\ \{0,\ 2\})\equiv u_{xx}^{3/2}F_1, \tag{3.20}$$

$$v_{nm}\equiv v_{n,m}\equiv u_{x^n y^m}u_{xx}^{-(n+2m+2)/4}. \tag{3.21}$$

Substituting (3.20) with (3.21) into (3.18) and (3.19), we have

$$\sum_{n,m} m v_{n+1,m-1}\frac{\partial F_1}{\partial v_{nm}}=0, \tag{3.22}$$

$$\sum_{n,m} m(m-1)v_{n+1,m-2}\frac{\partial F_1}{\partial v_{nm}}+\delta\frac{\partial F_1}{\partial v_{10}}=0. \tag{3.23}$$

The general solution of (3.22) has the form of

$$F_1=F_2(y_{nm},n,m=0,\ 1,\ 2,\ \ldots,\ \{n,\ m\}\neq\{0,\ 0\},\ \{0,\ 1\},\ \{0,\ 2\})\equiv F_2, \tag{3.24}$$

$$y_{nm}\equiv y_{n,m}\equiv\sum_{k=0}^{m}(-1)^{m-k}C_m^k v_{n+m-k,k}v_{11}^{m-k}=\sum_{k=0}^{m}(-1)^{m-k}C_m^k u_{x^{n+m-k}y^k}u_{xy}^{m-k}u_{xx}^{(4k-n-6m-2)/4}. \tag{3.25}$$

After finishing some tedious calculations, we know that the substitution of (3.24) into (3.23) yields

$$\sum_{n,m} m(m-1)y_{n+1,m-2}\frac{\partial F_2}{\partial y_{nm}}+\delta\frac{\partial F_2}{\partial y_{10}}=0. \tag{3.26}$$

The general solution of (3.26) reads as

$$F_2=F_0(K_{n,m},m,\ n=0,\ 1,\ 2,\ \ldots)\equiv F_0, \tag{3.27}$$

where F_0 is an arbitrary function of K_{nm} and K_{nm} is given by the following recursion relation

$$K_{nm}=y_{nm}-\sum_{j=1}^{[m/2]}\frac{m!}{j!(m-2j)!}K_{n+j,m-2j}(\delta y_{10})^j, \tag{3.28}$$

with ($\delta_{ii}=1,\ \delta_{ij}=0,\ i\neq j$)

$$K_{n0}=(1-\delta_{n,0}-\delta_{n,1})y_{n0}=(1-\delta_{n,0}-\delta_{n,1})u_{x^n}u_{xx}^{-(n+2)/4}, \tag{3.29}$$

$$K_{n1}=(1-\delta_{n,0})y_{n1}=(1-\delta_{n,0})(u_{x^n y}u_{xx}-u_{xy}u_{x^{n+1}})u_{xx}^{-(n+8)/4}. \tag{3.30}$$

Some further concrete examples of K_{nm} are

$$K_{n2}=(1-\delta_{n,0})(u_{x^n y^2}u_{xx}^2-2u_{x^{n+1}y}u_{xx}u_{xy}+u_{x^{n+2}}u_{xy}^2-2\delta u_{x^{n+1}}u_x u_{xx}^2)u_{xx}^{-(n+14)/4}, \tag{3.31}$$

$$\begin{aligned}K_{n3}=&(u_{x^n y^3}u_{xx}^3-3u_{x^{n+1}y^2}u_{xx}^2u_{xy}+3u_{x^{n+2}y}u_{xx}u_{xy}^2-u_{x^{n+3}}u_{xy}^3)u_{xx}^{-(n+20)/4}\\&-6\delta u_x(u_{x^{n+1}y}u_{xx}-u_{x^{n+2}}u_{xy})u_{xx}^{-(n+12)/4}.\end{aligned} \tag{3.32}$$

$$\begin{aligned}K_{n4}=&(u_{x^n y^4}u_{xx}^4-4u_{x^{n+1}y^3}u_{xx}^3u_{xy}+6u_{x^{n+2}y^2}u_{xx}^2u_{xy}^2-4u_{x^{n+3}y}u_{xy}^3u_{xx}+u_{x^{n+4}}u_{xy}^4)u_{xx}^{-(n+26)/4}\\&-6\delta u_x u_{xx}^{-(n+18)/4}(u_{x^{n+1}y^2}u_{xx}^2-2u_{x^{n+2}y}u_{xx}u_{xy}+u_{x^{n+3}}u_{xy}^2)+12u_{x^{n+2}}u_x^2u_{xx}^{-(n+10)/4}.\end{aligned} \tag{3.33}$$

In summary, it has been proven that the equation

$$(u_t+\tfrac{3}{2}uu_x+u_{xxx})_x+\tfrac{3}{4}\delta u_{yy}+u_{xx}^{3/2}F_0(K_{n,m},m,\ n=0,\ 1,\ 2,\ldots)=0, \tag{3.34}$$

with an arbitrary function of $K_{n,m}$ possesses a common Virasoro symmetry algebra (2.9).

It is straightforward to see that the result (1.4) with (1.5)–(1.13) obtained by David, Levi, and Winternitz is a special case of (3.34) because

$$K_2=K_{4,0},\quad K_3=K_{3,0},\quad K_4=K_{2,1},\quad K_7=K_{3,1},\quad K_5=K_{1,2}K_{3,0}-K_{2,1}^2,$$

$$K_6=K_{3,0}^2K_{0,3}-3K_{2,1}K_{1,2}K_{3,0}+2K_{2,1}^3,\quad K_9=K_{4,0}^2K_{1,3}-3K_{3,1}K_{2,2}K_{4,0}+2K_{3,1}^3, \tag{3.35}$$

$$K_8=K_{2,2}K_{4,0}-K_{3,1}^2,\quad K_{10}=K_{4,0}K_{0,4}-4K_{1,3}K_{3,1}+3K_{2,2}^2.$$

B. Models with the symmetry (2.2)

The substitution (2.2) into (3.1) yields

$$h(u_{xt}+\tfrac{3}{2}uu_{xx}+\tfrac{3}{2}u_x^2+u_{xxxx}+\tfrac{3}{4}\delta u_{yy})_x+F'(hu_x-\tfrac{2}{3}\dot{h})=0. \tag{3.36}$$

Eliminating u_{xt} from (3.36) with help of (1.15), (3.36) becomes

$$F'\left(hu_x-\frac{2}{3}\dot{h}\right)-hF'u_x=0. \tag{3.37}$$

Substituting (3.5) into (3.37), we have

$$\sum_{n,m,l'}\sum_{i=0}^{l'-1}C_{l'}^i h^{(l'-i)}\frac{\partial F}{\partial u_{x^ny^mt^{l'}}}u_{x^{n+1}y^mt^i}-\frac{2}{3}\sum_l h^{(l+1)}\frac{\partial F}{\partial u_{t^l}}=0,\quad l'\geqslant 1. \tag{3.38}$$

If we can find an h-independent solution F from (3.38), then we get a model with a symmetry (2.2) for arbitrary h.

To find all the h-independent solution of (3.38) is equivalent to solve the following infinitely many linear equation system with infinitely many arbitrary independent variables,

$$\sum_{n,m,l}C_l^{l-k-1}\frac{\partial F}{\partial u_{x^ny^mt^l}}u_{x^{n+1}y^mt^{l-k-1}}-\frac{2}{3}\frac{\partial F}{\partial u_{t^k}}=0,\quad k=0,\ 1,\ 2,\ldots,\infty. \tag{3.39}$$

To find general solution of the over-determined equation system of (3.39) is difficult. However, if we require F is not $u_{x^ny^mt^l}$, $(l\geqslant 1)$ dependent, then the general solution of (3.39) reads as

$$F=f_1\equiv f_1(u_{x^ny^m},\ n,m=0,\ 1,\ 2,\ldots,n^2+m^2\neq 0). \tag{3.40}$$

Obviously, $F=u_{xx}^{3/2}F_0(K_{n,m},m,\ n=0,\ 1,\ 2,\ldots)$ shown by (3.34) is only a special case of f_1 of (3.40).

C. Models with the symmetry (2.3)

The substitution (2.3) into (3.1) results in

$$(-2g\partial_y+\tfrac{4}{3}\delta y\dot{g}\partial_x)(u_{xt}+\tfrac{3}{2}uu_{xx}+\tfrac{3}{2}u_x^2+u_{xxxx}+\tfrac{3}{4}\delta u_{yy})$$
$$+F'(-2gu_y+\tfrac{4}{3}\delta\dot{g}yu_x-\tfrac{8}{9}\delta y\ddot{g})=0. \tag{3.41}$$

Eliminating u_{xt} from (3.41) by means of (1.15), we have

$$2gF'u_y-\tfrac{4}{3}\delta y\dot{g}F'u_x+F'(-2gu_y+\tfrac{4}{3}\delta\dot{g}yu_x-\tfrac{8}{9}\delta y\ddot{g})=0. \tag{3.42}$$

The substitution (3.5) into (3.42) leads to

$$\frac{4}{3}\delta\sum_{n,m,l}\sum_{i=0}^{l}C_l^i g^{(l-i+1)}\frac{\partial F}{\partial u_{x^n y^m t^l}}u_{x^{n+1}y^{m-1}t^i}-\frac{8}{9}\delta\sum_l g^{(l+2)}\left(\frac{\partial F}{\partial u_{yt^l}}+y\frac{\partial F}{\partial u_{t^l}}\right)$$
$$+\sum_{n,m,l'}\sum_{i=0}^{l'-1}C_{l'}^i\frac{\partial F}{\partial u_{x^n y^m t^{l'}}}\left(-2g^{(l'-i)}\partial_y+\frac{4}{3}\delta g^{(l'-i+1)}\partial_x\right)u_{x^n y^m t^i}=0. \tag{3.43}$$

If we can find a g-independent solution F from (3.43), then we get a model with a symmetry (2.3) for arbitrary g.

To find out all the g-independent autonomous solutions of (3.43) is equivalent to solve the following equation system:

$$\sum_{n,m,l}mC_l^{l-k-1}\frac{\partial F}{\partial u_{x^n y^m t^l}}u_{x^{n+1}y^{m-1}t^{l-k-1}}-\frac{2}{3}\frac{\partial F}{\partial u_{t^k}}=0, \tag{3.44}$$

$$\sum_{n,m,l}\frac{\partial F}{\partial u_{x^n y^m t^l}}\left[\left(mC_l^{l-k-1}\partial_x\partial_t-\frac{3}{2}\delta C_l^{l-k-2}\partial_y^2\right)u_{x^n y^{m-1}t^{l-k-2}}\right]-\frac{2}{3}\frac{\partial F}{\partial u_{yt^k}}=0. \tag{3.45}$$

To find the general solutions of (3.44)–(3.45) is very difficult. However, if we require that F is $u_{x^n y^m t^l}$ independent for $l\neq 0$, the equation system (3.44)–(3.45) is reduced to

$$\frac{\partial F}{\partial u}=0,\quad \frac{\partial F}{\partial u_y}=0, \tag{3.46}$$

that means

$$F=f_2\equiv f_2(u_{x^n y^m},\ \{n,\ m\}\neq\{0,\ 0\},\{0,\ 1\}), \tag{3.47}$$

where f_2 is an arbitrary function of the indicated variables.

Obviously, (3.47) is a special case of (3.40) and $F=u_{xx}^{3/2}F_0(K_{n,m},m,\ n=0,\ 1,\ 2,\dots)$ is a special case of (3.47). In other words, the general KP family (3.34) possesses not only the Virasoro symmetry algebra (2.9) but also the full Kac–Moody–Virasoro symmetry algebra (2.5)–(2.9). Then the Theorem 1 can be extended as follows.

Theorem 2: *If $u=u(x,\ y,\ t)$ is a solution of the KP family (3.34), then so is u' shown by (2.11)–(2.13).*

IV. GROUP INVARIANT SOLUTIONS OF THE KP FAMILY (3.34)

To find group invariant solutions of a given system means to find the solutions which are solutions of not only the original model but also the symmetry constrained condition, $\sigma=0$. For the KP family (3.34), if the field u satisfies either the model equation or the symmetry constrained condition,

$$\sigma_0(h)+\sigma_1(g)+\sigma_2(f)=0, \tag{4.1}$$

with $\{\sigma_0(h),\ \sigma_1(g),\ \sigma_2(f)\}$ given by (2.2)–(2.4), then the solution is invariant under the Kac–Moody–Virasoro group transformations.

The symmetry constrained equation (4.1) can be easily solved because it is only a first order linear equation.

For the full Kac–Moody–Virasoro symmetries, $f\neq 0$, the general solution of (4.1) read as

$$u=f^{-2/3}U(\xi,\eta)+\frac{2f_t x}{9f}+\frac{4\delta(2f_t^2-3ff_{tt})y^2}{81f^2}+\frac{8\delta(3g_t f-2f_t g)y}{27f^2}+\frac{8\delta g^2}{9f^2}+\frac{2h}{3f}, \tag{4.2}$$

where

$$\xi=\frac{x}{f^{1/3}}+\frac{2\delta(f_t y^2-6gy)}{9f^{4/3}}-\frac{8}{3}\delta\int\frac{g^2}{f^{7/3}}\mathrm{d}t-\int\frac{h}{f^{4/3}}\mathrm{d}t, \tag{4.3}$$

$$\eta=\frac{y}{f^{2/3}}+2\int\frac{g}{f^{5/3}}\mathrm{d}t, \tag{4.4}$$

while the group invariant function, $U(\xi,\ \eta)\equiv U$, should be determined by the so-called similarity reduction equation (a Boussinesq family),

$$\tfrac{3}{4}\delta U_{\eta\eta}+(U_{\xi\xi\xi}+\tfrac{3}{2}UU_\xi)_\xi+U_{\xi\xi}^{3/2}F_0(K_{n,m}(\xi,\eta),m,\ n=0,\ 1,\ 2,\ \ldots)=0, \tag{4.5}$$

which can be obtained by substituting (4.2) into (3.34), where $K_{n,m}(\xi,\ \eta)$ is just $K_{n,m}$ expressed by (3.28) with the transformations $u_{x^n y^m}\to U_{\xi^n\eta^m}$.

For the Kac–Moody symmetries, $f=0$, the general solution of (4.1) possesses the form

$$u=\frac{1}{g}U(\xi,\ \tau)+\frac{g_t x}{3g}+\frac{2\delta(2g_t^2-gg_{tt})y^2}{9g^2}+\frac{(2g_t h-h_t g)y}{6g^2}-\frac{h^2}{6g^2}, \tag{4.6}$$

where

$$\xi=\frac{1}{\sqrt{g}}\left(x+\frac{\delta g_t y^2}{3g}+\frac{hy}{2g}\right), \tag{4.7}$$

$$\tau=\int g^{-3/2}\,\mathrm{d}t \tag{4.8}$$

while the similarity reduction equation of $U(\xi,\ \tau)\equiv U$ is a KdV family,

$$\left(U_\tau+U_{\xi\xi\xi}+\frac{3}{2}UU_\xi\right)_\xi+U_{\xi\xi}^{3/2}F_0(K_{n,m}(\xi,\tau),m,\ \ n=0,\ \ 1,\ \ 2,\ \ \ldots)=0, \tag{4.9}$$

which is a result of the substitution of (4.6) into (3.34) while $K_{n,m}(\xi,\ \tau)$ is just $K_{n,m}$ expressed by (3.28) with the transformations $u_{x^n}\to U_{\xi^n}$ and $u_{x^n y^m}\to 0$ for $m\neq 0$.

V. SUMMARY AND DISCUSSION

In summary, starting from the Kac–Moody–Virasoro symmetry of the usual KP equation and using a quite simple symmetry approach, a general KP family is found such that the family possesses the same Kac–Moody–Virasoro symmetry algebra as the usual KP equation. An arbitrary function of the higher order group invariants is included in the family. The finite Kac–Moody–Virasoro symmetry transformation group is naturally valid for the whole KP family.

The similarity reduction equation for the full Kac–Moody–Virasoro symmetry algebra is expressed by a Boussinesq family while for the Kac–Moody symmetry algebra [constituted by $\sigma_0(h)$ and $\sigma_1(g)$] can be expressed by a KdV family.

For the usual KP equation (1.3),[12] in addition to the Lie point symmetries, there are infinitely many generalized (higher order nonpoint) symmetries which constitute the generalized w_∞ symmetry algebra. If one makes the similar calculations for the general symmetries of the KP equation, one can find that the general nonpoint symmetries of the KP equation are not symmetries of the KP family (3.34).

To obtain (3.34), we have used not only the autonomous condition (i.e., F is not explicitly $\{x, y, t\}$-dependent), but also the condition

$$F_{u_{x^n y^m t^l}}=0, \quad \forall l\neq 0. \tag{5.1}$$

Generally, F may be both $\{x, y, t\}$ and $u_{x^n y^m t^l}$ dependent. We have not yet had a good idea to find all $u_{x^n y^m t^l}$ and $\{x, y, t\}$ dependent solutions of F. However, these kinds of solutions really exist. For instance, by the direct calculations, one can find that

$$J_{n1}\equiv u_{xx}^{-(n+6)/4}\left[\left(u_t+\frac{3}{2}uu_x\right)_x+\frac{3}{4}\delta u_{yy}\right]_{x^n}, \quad n=0, 1, 2,\ldots, \tag{5.2}$$

are also group invariants related to the symmetry algebra (2.5)–(2.9). That means

$$F=u_{xx}^{3/2}f_0(K_{n,m}, J_{n1}, m, n=0, 1, 2, \ldots), \tag{5.3}$$

with f_0 being an arbitrary function of the indicated variables is a special solution of the equation systems (3.8)–(3.15), (3.39) and (3.44)–(3.45).

From (1.15) [or (5.3)] and (3.28), we know that in addition to the KP equation itself and the dispersion-less KP [the Zabolotskaya–Khokhlov (ZK)] equation, one may obtain various models in the family that are rational in the derivatives, say, by selecting F_0 of (1.15) being a linear function of $K_{4k,2l}$, $K_{4k-2,2l+1}$, $k=1, 2,\ldots,l=0, 1, 2, \ldots$, etc.

Though we have found many arbitrary order equations which possess the same Lie point symmetry group of the KP equation, it is still very difficult to say something about the integrability properties of any equations in the family except for the KP and the ZK equation. In particular, we have not yet found higher symmetries or Painlevé properties of any other equations.

Because all the known $(2+1)$-dimensional integrable systems possesses the Virasoro symmetry algebra, the similar properties obtained in this paper for the KP equation may be valid for other $(2+1)$-dimensional systems.

We study hyperelliptic Nambu flows associated with some n dimensional maps and show that discrete integrable systems can be reproduced as flows of this class. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1643195]

I. INTRODUCTION

Let us consider an n dimensional rectangular box with edges of length $X_1, X_2, \ldots, X_n$. The box will be rigid if there are n independent relations among X_j's

$$x_j = f_j(X_1, X_2, \ldots, X_n), \quad j = 1,2,\ldots,n. \tag{1}$$

This set of constraints defines a map

$$\boldsymbol{x} = (x_1, x_2, \ldots, x_n) \to \boldsymbol{X} = (X_1, X_2, \ldots, X_n). \tag{2}$$

If we relax one of the constraints, say $x_n = f_n$, the box changes its form as x_n varies. We are interested in how it changes. To make clear the problem let us see the case of $n=3$ and assume, for example, that relations (1) are given by the elementary symmetric polynomials

$$\begin{aligned} x_1 &= X_1 + X_2 + X_3, \\ x_2 &= X_1X_2 + X_1X_3 + X_2X_3, \\ x_3 &= X_1X_2X_3. \end{aligned} \tag{3}$$

When all x_j's are fixed the map is determined algebraically by solving the equation

$$X^3 - x_1X^2 + x_2X - x_3 = 0, \tag{4}$$

up to permutations. Relations (3) amount to fix the total length of edges, the total area of surfaces, and the volume of the box. If the volume of the box x_3 varies while x_1 and x_2 are fixed, we will obtain a circle as an intersection of the sphere $X_1^2 + X_2^2 + X_3^2 = x_1^2 - 2x_2$ and the plane $X_1 + X_2 + X_3 = x_1$ in $\boldsymbol{R}^3$ along which $\boldsymbol{X}$ moves. If we fix x_1 and x_3 but leave x_2 free, we will find another curve in $\boldsymbol{R}^3$. Our problem is to find such a curve in general.

[b)]Electronic mail: saitoh@lam.osu.sci.ynu.ac.jp
[c)]Electronic mail: yoshida@kiso.phys.metro-u.ac.jp

It will be worthwhile to notice here that relations (1) defines an algebraic manifold in $\boldsymbol{R}^n$ if some of x_j's are fixed and the relations are purely algebraic. To see the properties of the manifold one can leave one of the constraints free and vary the constant to study a response of the variables $X_1, X_2, \ldots, X_n$ to the variation.

In our previous work[1,2] we have shown that there exists a Nambu–Hamiltonian flow[3] corresponding to an arbitrary differentiable map such that one of the initial values of the map plays the role of time of the flow. We can apply this result to see the change of the box when x_n varies.

We will study, in this article, how the problem is transcribed into the problem of solving the Nambu equation and the change of the boxes are described in terms of hyperelliptic curves under certain constraints. We are interested in the appearance of the hyperelliptic functions, since they are known to solve soliton equations in general. The second purpose of this article is to show that the reason of the appearance of the hyperelliptic functions is common in two systems, i.e., the soliton equations and the Nambu equations. In other words the Nambu equations provide a way to describe dynamics of integrable systems. We will show that, once the Nambu equations associated with a soliton equation are solved, solutions to the soliton equation can be given by solving purely algebraic relations.

II. NAMBU–HAMILTONIAN FLOWS

Let us first recall briefly the Nambu equations and review our previous results. For a function $f(\boldsymbol{X})$ of n-dimensional variable $\boldsymbol{X} \in \boldsymbol{R}^n$, the generalized Nambu Hamilton equations[3,4] are given by

$$\frac{df}{dt}(\boldsymbol{X}) = \{H_1, H_2, \ldots, H_{n-1}, f(\boldsymbol{X})\}. \tag{5}$$

We define the Nambu bracket $\{\varphi_1, \varphi_2, \ldots, \varphi_n\}$, in this article, by the Jacobian

$$\{\varphi_1, \varphi_2, \ldots, \varphi_n\} := \frac{\partial(\varphi_1, \varphi_2, \ldots, \varphi_n)}{\partial(X_1, X_2, \ldots, X_n)}.$$

$n-1$ Hamiltonians $H_1, H_2, \ldots, H_{n-1}$ satisfy

$$\frac{dH_j}{dt} = 0, \quad j = 1,2,\ldots,n-1$$

by definition of the equations. The equations of motion for the dynamical variables X_j's are

$$\begin{aligned}\frac{dX_j}{dt} &= \{H_1, H_2, \ldots, H_{n-1}, X_j\}, \quad j = 1,2,\ldots,n \\ &= (-1)^{n-j} \frac{\partial(H_1, H_2, \ldots, H_{n-1})}{\partial(X_1, X_2, \ldots, X_n)_j}.\end{aligned} \tag{6}$$

Here $(X_1, X_2, \ldots, X_n)_j$ means that X_j is missing among $(X_1, X_2, \ldots, X_n)$.

In Refs. 1 and 2, we proved the following:

Proposition 1: For a differentiable and invertible map (2), with its Jacobian $\det J$*, there exists a Nambu–Hamiltonian flow described by the equations*

$$\frac{dX_j}{dx_n} = \{H_1, H_2, \ldots, H_{n-1}, X_j\}, \quad j = 1,2,\ldots,n, \tag{7}$$

such that the Hamiltonians are given by

$$H_j = x_j, \quad j = 1,2,\ldots,n-2,$$

$$H_{n-1} = \int^{x_{n-1}} (\det J)\ dx_{n-1}.$$

Note that the initial value x_n of the map plays the role of the time variable in this flow. In addition to this proposition we would like to supply a new one which is more convenient to study our present problems.

Proposition 2: For a differentiable and invertible map (2), with its Jacobian $\det J$*, there exists a Nambu–Hamiltonian flow described by the equations*

$$\frac{dX_j}{dt} = \{H_1, H_2, \ldots, H_{n-1}, X_j\}, \quad j = 1,2,\ldots,n, \tag{8}$$

such that the Hamiltonians are given by

$$H_j = x_j, \quad j = 1,2,\ldots,n-1,$$

and the variable t *satisfies*

$$\frac{dx_k}{dt} = \frac{\delta_{k,n}}{\det J}. \tag{9}$$

Here the time variable t is not the initial value x_n itself but related to it by (9). This formulation has an advantage since the other initial values $x_1, x_2, \ldots, x_{n-1}$ of the map remain constant along the Nambu flow.

The proof of Proposition 2 is straightforward. From (9) it follows that

$$\frac{dX_j}{dt} = \sum_k \frac{\partial X_j}{\partial x_k}\frac{dx_k}{dt} = \frac{\partial X_j}{\partial x_n}\frac{1}{\det J} = \frac{\partial(x_1, x_2, \ldots, x_{n-1}, X_j)}{\partial(x_1, x_2, \ldots, x_{n-1}, x_n)}\frac{1}{\det J} = \frac{\partial(x_1, x_2, \ldots, x_{n-1}, X_j)}{\partial(X_1, X_2, \ldots, X_{n-1}, X_n)}$$

$$= \frac{\partial(H_1, H_2, \ldots, H_{n-1}, X_j)}{\partial(X_1, X_2, \ldots, X_{n-1}, X_n)}.$$

Q.E.D.

Hence (8) is true. Conversely (8) implies $dH_j/dt = 0$, hence (9) follows. We notice that, when the Nambu equation (8) is solved,

$$t = \int^{x_n} (\det J)\ dx_n \tag{10}$$

holds. If the Jacobian $\det J$ of the map $\boldsymbol{x} \to \boldsymbol{X}$ was one, we simply have $t = x_n$.

Now suppose we have solved the Nambu equations (8). We then obtain a map $(x_1, \ldots, x_{n-1}, t) \to \boldsymbol{X}$. We can show that the Jacobian $\det J'$ of this map is unity.

To see that we calculate the Jacobian of the inverse map $\boldsymbol{X} \to (x_1, \ldots, x_{n-1}, t)$ and expand it along the last row

$$\det J'^{-1} = \frac{\partial(x_1, x_2, \ldots, x_{n-1}, t)}{\partial(X_1, X_2, \ldots, X_n)} = \sum_{j=1}^{n} \frac{\partial t}{\partial X_j}\Delta_{nj},$$

where Δ_{nj} is the minor of the (nj) element of J'^{-1}. We notice that the right-hand side of (8) is exactly Δ_{nj}. Therefore we obtain

$$\det J'^{-1} = \sum_{j=1}^{n} \frac{\partial t}{\partial X_j} \frac{dX_j}{dt} = 1$$

as a result of equations of motion. Therefore the Jacobian $\det J'$ of the map $(x_1,\ldots,x_{n-1},t)\to \boldsymbol{X}$ is also one and the map preserves the hypervolume element.

III. STUDY OF SOLUTIONS

Since x_j, $j=1,2,\ldots,n-1$ are constants of the flow (8), they form $n-1$ dimensional hypersurfaces

$$x_j = H_j(\boldsymbol{X}), \quad j=1,2,\ldots,n-1 \tag{11}$$

in $\boldsymbol{R}^n$, while the point $\boldsymbol{X}$ moves along a curve formed by an intersection of the hypersurfaces as t changes. Suppose we can solve the constraints (11) for $X_1, X_2, \ldots, X_{n-1}$ as functions of $W := X_n$ and the constants x_j, $j=1,2,\ldots,n-1$. Substituting the results into the right-hand side of the equation for W in (8), we obtain a first order ordinary differntial equation for W,

$$\frac{dW}{dt} = F(W), \tag{12}$$

where F is a function of W and the constants of the flow. The orbit is determined by solving (12), i.e.,

$$t = \int^{W} \frac{dW}{F(W)}. \tag{13}$$

Combining this result with (10) we find

$$\frac{dW}{dx_n} = F(W)\det J.$$

Similarly we obtain equations for all other variables X_j's which determine the dependence on x_n.

A. Elementary symmetric polynomials

First we study a Nambu flow when the constraints (1) are given by the elementary symmetric polynomials

$$\begin{aligned}
x_1 &= X_1 + X_2 + X_3 + \cdots + X_n, \\
x_2 &= X_1X_2 + X_1X_3 + X_2X_3 + \cdots + X_{n-1}X_n, \\
&\vdots \\
x_j &= \sum_{k_1<k_2<\cdots<k_j} X_{k_1}X_{k_2}\cdots X_{k_j}, \\
&\vdots \\
x_n &= X_1X_2\cdots X_n.
\end{aligned} \tag{14}$$

When all x_j's are fixed the map is determined by solving the algebraic equation

$$X^n - x_1X^{n-1} + \cdots - (-1)^n x_{n-1}X + (-1)^n x_n = 0, \tag{15}$$

up to permutations. The relations (14) amount to fix the total length of edges, the total area of surfaces, ..., the total hypervolume of the box. If the hypervolume of the box x_n varies while other x_j's are fixed, we will obtain a curve in $\boldsymbol{R}^n$ along which $\boldsymbol{X}$ moves. Our problem is to find the curve.

The Nambu equation whose Hamiltonians are $x_1, x_2, \ldots, x_{n-1}$ in (14) is given for $W = X_n$ (Ref. 4) by

$$\frac{dW}{dt} = \prod_{1 \leqslant k < l \leqslant n-1} (X_k - X_l).$$

Therefore our task is to solve this equation explicitly. For this to be done we have to know the W dependence of the right hand side. We first notice that the square of the right-hand side is the discriminant of the equation $P_{n-1}(X) = 0$, where

$$P_{n-1}(X) := (X - X_1)(X - X_2) \cdots (X - X_{n-1}). \tag{16}$$

If we expand the polynomial $P_{n-1}(X)$ as

$$P_{n-1}(X) = h_0 X^{n-1} - h_1 X^{n-2} + h_2 X^{n-3} - \cdots + (-1)^{n-1} h_{n-1} \quad (h_0 = 1)$$

$h_1, h_2, \ldots, h_{n-1}$ are the elementary symmetric polynomials of $X_1, X_2, \ldots, X_{n-1}$. Since the discriminant

$$D_{n-1} := \prod_{1 \leqslant k < l \leqslant n-1} (X_k - X_l)^2$$

of $P_{n-1}(X) = 0$ is a symmetric polynomial it can be expressed in terms of $h_1, h_2, \ldots, h_{n-1}$. In fact it is a homogeneous polynomial of h_j's of degree $2(n-2)$. For example in the cases of $n = 3,4,5$

$$D_2 = h_1^2 - 4h_0 h_2,$$

$$D_3 = h_1^2 h_2^2 - 4h_0 h_2^3 - 4h_1^3 h_3 + 18 h_0 h_1 h_2 h_3 - 27 h_0^2 h_3^2,$$

$$\begin{aligned} D_4 = {} & h_1^2 h_2^2 h_3^2 - 4h_1^2 h_2^3 h_4 - 4h_1^3 h_3^3 + 18 h_1^3 h_2 h_3 h_4 - 27 h_1^4 h_4^2 - 4h_0 h_2^3 h_3^2 + 18 h_0 h_1 h_2 h_3^3 + 16 h_0 h_2^4 h_4 \\ & - 80 h_0 h_1 h_2^2 h_3 h_4 + 144 h_0 h_1^2 h_2 h_4^2 - 6 h_0 h_1^2 h_3^2 h_4 + 144 h_0^2 h_2 h_3^2 h_4 - 128 h_0^2 h_2^2 h_4^2 - 192 h_0^2 h_1 h_3 h_4^2 \\ & - 27 h_0^2 h_3^4 + 256 h_0^3 h_4^3. \end{aligned}$$

On the other hand h_j's are related with x_j's according to

$$x_k = h_k + W h_{k-1}, \quad k = 1,2,\ldots,n-1$$

or, equivalently,

$$h_k = x_k - x_{k-1} W + \cdots + (-1)^k W^k, \quad k = 1,2,\ldots,n-1.$$

Therefore the discriminant D_{n-1} is a polynomial of W of degree $(n-2)(n-1)$.

If we susbstitute $D_{n-1}(W)$ into F of (13), we find

$$t = \int^W \frac{dW}{\sqrt{D_{n-1}(W)}}.$$

The other variables $X_1, X_2, \ldots, X_{n-1}$ will be obtained similarly. Hence the orbits derived from the Nambu equations, whose Hamiltonians are elememtary symmetric polynomials, are given by hyperelliptic functions.

In the case of $n=3$ the motion of three variables X_1, X_2, X_3 are constrained on a circle fixed by the constants x_1 and x_2. We find

$$\begin{aligned} X_1 &= \tfrac{1}{3}(x_1 + 2\sqrt{x_1^2 - 3x_2}\cos(\sqrt{3}\ t)), \\ X_2 &= \frac{1}{3}\left(x_1 + 2\sqrt{x_1^2 - 3x_2}\cos\left(\sqrt{3}\ t - \frac{2\pi}{3}\right)\right), \\ X_3 &= \frac{1}{3}\left(x_1 + 2\sqrt{x_1^2 - 3x_2}\cos\left(\sqrt{3}\ t + \frac{2\pi}{3}\right)\right). \end{aligned} \tag{17}$$

If all x_j's are fixed besides x_i the Nambu equation for $W = X_i$ becomes

$$\frac{dW}{dt} = (-W)^{n-i} \prod_{\substack{1 \leqslant k \leqslant l \leqslant n \\ k,j \neq i}} (X_k - X_l).$$

Note that the right-hand side of this equation is just the square root of discriminant of the equation $P_{n-1,i}(X) = 0$, where

$$P_{n-1,i}(X) = \frac{\prod_{j=1}^{n} (X - X_j)}{X - X_i}.$$

The discriminant $D_{n-1,i}$ can be expressed in terms of $h'_1, h'_2, \ldots, h'_{n-1}$, where h'_j is an elementary symmetric polynomial without X_i. As before, $D_{n-1,i}$ is also a polynomial of W of degree $(n-1)(n-2)$. We find

$$t = (-1)^{n-i} \int^{W} \frac{dW}{W^n \sqrt{D_{n-1,i}(W)}}.$$

In the case of $n=3$ we could leave x_2 free, instead of x_3. Under the constraints

$$x_1 = X_1 + X_2 + X_3,$$

$$x_3 = X_1 X_2 X_3,$$

being constant, we find an elliptic curve parameterized by

$$X_1 = \frac{\alpha\gamma\,\mathrm{sn}^2(u,k)}{\gamma - \alpha\,\mathrm{cn}^2(u,k)},$$

$$X_{2,3} = x_1 - \frac{\alpha\gamma\,\mathrm{sn}^2(u,k)}{\gamma - \alpha\,\mathrm{cn}^2(u,k)} \pm \frac{(\alpha-\gamma)^{3/2}\sqrt{\beta}\,\mathrm{cn}(u,k)\ \mathrm{dn}(u,k)}{2(\gamma - \alpha\,\mathrm{cn}^2(u,k))\ \mathrm{sn}(u,k)},$$

where

$$u = \tfrac{1}{2}\sqrt{(\alpha-\gamma)\beta}\ \ t, \quad k = \sqrt{\frac{\alpha(\beta-\gamma)}{\beta(\alpha-\gamma)}}$$

and α, β, and γ are the roots of

$$x^3 - 2x_1x^2 + x_1^2 x - 4x_3 = 0.$$

B. *n* dimensional generalization of Euler top and Nahm equation

An n dimensional box has $n(n-1)/2$ rectangles which are orthogonal with each other. Among them we choose n independent rectangles. If we fix a relation between edge lengths of each of the n rectangles, all X_j's are determined, hence the box becomes rigid.

For example we can fix the diagonals of n rectangles as follows:

$$x_j = \tfrac{1}{2}(X_j^2 + X_{j+1}^2), \quad j = 1,2,\ldots,n, \tag{18}$$

with $X_{n+1} = X_1$ to make the box rigid. The Jacobian of this map is, when n is odd,

$$\det J = (2X_1X_2\cdots X_n)^{-1}.$$

If $x_n = (X_n^2 + X_1^2)/2$ is varied, all X_j's will be changed simultaneously and $\boldsymbol{X}$ draws a curve in $\boldsymbol{R}^n$. The corresponding Nambu equations are

$$\frac{dX_j}{dt} = (-1)^{n-j}\frac{X_1X_2\cdots X_n}{X_j}, \quad j = 1,2,\ldots,n. \tag{19}$$

We can solve the constraints (18) for X_j's

$$X_j^2 = \alpha_j + (-1)^{n-j}W^2, \quad j = 1,2,\ldots,n-1,$$

where

$$\alpha_j = 2(x_j - x_{j+1} + \cdots - (-1)^{n-j}x_{n-1}).$$

The right-hand side of

$$\frac{dW}{dt} = X_1X_2\cdots X_{n-1}$$

is given by a function of W. In fact we obtain

$$t = \int^W \frac{dW}{\sqrt{\prod_{j=1}^{n-1}(\alpha_j + (-1)^{n-j}W^2)}}.$$

Thus we conclude that the point $\boldsymbol{X}$ moves along a hyperelliptic curve. When $n = 3$, the solutions are given by the Jacobi elliptic functions as

$$X_1 = \sqrt{2(x_1 - x_2)}\,\mathrm{dn}(u,k),$$

$$X_2 = \sqrt{2x_2}\,\mathrm{cn}(u,k),$$

$$X_3 = \sqrt{2x_2}\,\mathrm{sn}(u,k),$$

where

$$u := \sqrt{2(x_1 - x_2)}\;\; t, \quad k := \sqrt{\frac{x_2}{x_2 - x_1}}.$$

The above example can be readily generalized to the cases whose constraints can be reduced into the form

$$x_j=\frac{1}{2}\sum_{k=1}^{n}\ \alpha_{jk}X_k^2,\quad j=1,2,\ldots,n-1. \tag{20}$$

The Nambu equations are

$$\frac{dX_j}{dt}=(-1)^{n-j}\det A_j\frac{X_1X_2\cdots X_n}{X_j},\quad j=1,2,\ldots,n,$$

where the matrix A_j is given by eliminating the jth column from the $(n-1)\times n$ matrix $\{\alpha_{jk}\}$. By solving (20) for X_k as a function of $W=X_n$ and the constants and substituting them into

$$\frac{dW}{dt}=\det A_n\ \ X_1X_2\cdots X_{n-1}$$

we again obtain a hyperelliptic integral.

A simple case, i.e.,

$$A=\begin{pmatrix}1 & -1 & 0\\ 0 & 1 & -1\end{pmatrix},$$

which is called the Nahm equation, was discussed in Ref. 4. Another example is the famous Euler top corresponding to the matrix

$$\begin{pmatrix}1 & 1 & 0\\ 0 & 1 & 1\end{pmatrix},$$

which was discussed by Nambu.[3] We note that our generalization of this top to n dimension is different from either one of Refs. 5 or 6.

IV. COMPLETELY INTEGRABLE MAPS

The hyperelliptic functions have been known to solve soliton equations.[7,8] They appear through the variation of subspectral parameters of Lax operators. We are going to show, in this section, that the hyperelliptic solutions of soliton equations can be obtained equally by solving the Nambu equations, which we discussed in the previous section.

A. Brief review of 3 point Toda lattice

Before going into details of the discussion we will review briefly how the hyperelliptic solutions are derived from soliton equations. In order to make clear the point of our arguments we consider a simple example, i.e., 3-point Toda lattice. The time evolution of the 6-dynamical variables $(a_1,a_2,a_3,b_1,b_2,b_3)$ are determined by means of the Lax equation

$$\frac{dL}{dt}=[B,L], \tag{21}$$

where

$$L=\begin{pmatrix}b_1 & a_1 & a_3\\ a_1 & b_2 & a_2\\ a_3 & a_2 & b_3\end{pmatrix},\quad B=\begin{pmatrix}0 & -a_1 & a_3\\ a_1 & 0 & -a_2\\ -a_3 & a_2 & 0\end{pmatrix}.$$

In addition to the periodicity condition, which imposes to a_1,a_2,a_3 a constraint

$$a_1a_2a_3=1/8, \tag{22}$$

the eigenvalues $\lambda_1,\lambda_2,\lambda_3$ of L are constants of motion. Therefore only two variables out of six remain independent. It is conventional to choose two eigenvalues μ_1,μ_2 of the matrix $\left(\begin{smallmatrix} b_1 & a_1 \\ a_1 & b_2 \end{smallmatrix}\right)$ as new such variables. They are called subspectral parameters. The relations between the dynamical variables $(a_1,a_2,a_3,b_1,b_2,b_3)$ and $(\lambda_1,\lambda_2,\lambda_3,\mu_1,\mu_2)$ are algebraic. For instance we have

$$\mu_1+\mu_2=\lambda_1+\lambda_2+\lambda_3-b_3,$$

$$\mu_1\mu_2=b_1b_2-a_1^2.$$

Hence the time dependence of the dynamical variables can be found if we know how μ_1 and μ_2 vary in time.

Solving these algebraic relations for $(\lambda_1,\lambda_2,\lambda_3,\mu_1,\mu_2)$, the Lax equation (21) can be converted into equations which determine the time evolution of μ_1,μ_2 as

$$\frac{d\mu_j}{dt}=\frac{1}{4}\frac{\sqrt{\Delta^2(\mu_j)-4}}{\mu_2-\mu_1}, \quad j=1,2.$$

Here $\Delta(\lambda)$ is a third order polynomial of λ. Solutions to these equations are given in terms of elliptic functions.

We can summarize this result as follows. For the five dynamical variables, which are constrained by three constants of motion, we introduce two intermediate variables, which are also related with the dynamical variables algebraically. If we can find the dependence of the new variables on time, the time dependence of the five dynamical variables will be found by solving the five algebraic relations.

B. Generalization to integrable maps

Let us generalize this idea of solving 3-point Toda lattice to study larger class of integrable systems. For this purpose we consider a map $M(t)\to M(t+1)$ of an $m\times m$ matrix given by

$$M(t+1)=U^{-1}M(t)U. \tag{23}$$

A large number of integrable maps have been known being represented in this form.[9] For an illustration we present here the discrete time m point Toda lattice,

$$M(t)=\begin{pmatrix} i_1+v_1 & 1 & 0 & \cdots & 0 & i_1v_m \\ i_2v_1 & i_2+v_2 & 1 & 0 & & 0 \\ 0 & i_3v_2 & i_3+v_3 & 1 & & \\ \vdots & & \cdots & & \vdots & \\ 0 & 0 & \cdots & & & 1 \\ 1 & 0 & \cdots & 0 & i_mv_{m-1} & i_m+v_m \end{pmatrix},$$

$$U(t)=\begin{pmatrix} i_1 & 1 & 0 & \cdots & 0 \\ 0 & i_2 & 1 & & 0 \\ & & \vdots & & \\ 0 & & & i_{m-1} & 1 \\ 1 & 0 & \cdots & 0 & i_m \end{pmatrix}. \tag{24}$$

In the continuum limit of time the variables (v_j,i_j) are related with (a_j,b_j) of the Lax form by

$$(v_j,i_j)=(2a_j,1-b_j), \quad j=1,2,\ldots,m.$$

Suppose elements of the matrix M in (23) are determined in terms of $m+n-1$ dynamical variables with $n<m+1$. Since eigenvalues of the matrix, which we denote $\lambda_1,\ldots,\lambda_m$, are constant under the map, m variables can be eliminated by solving algebraic relations between the elements of M and the eigenvalues. The problem of solving the evolution equation (23) is turned to finding proper intermediate n variables. They must be responsible faithfully to a variation of the system under the constraints that the eigenvalues are conserved. We can use the Nambu equations to describe such a system.

In order to make concrete our argument we adopt the elementary symmetric polynomials as m independent constants of the map:

$$\begin{aligned} x_1&=\lambda_1+\lambda_2+\cdots+\lambda_m,\\ x_2&=\lambda_1\lambda_2+\lambda_1\lambda_3+\cdots+\lambda_{m-1}\lambda_m,\\ &\vdots\\ x_j&=\sum_{1\leqslant k_1<k_2<\cdots<k_j\leqslant m}\lambda_{k_1}\lambda_{k_2}\cdots\lambda_{k_j},\\ &\vdots\\ x_m&=\lambda_1\lambda_2\cdots\lambda_m. \end{aligned} \tag{25}$$

Writing them explicitly in terms of the elements M_{jk} of the matrix M, we have

$$\begin{aligned} x_1&=M_{11}+M_{22}+\cdots+M_{mm},\\ x_2&=\sum_{1\leqslant j<k\leqslant m}(M_{jj}M_{kk}-M_{jk}M_{kj}),\\ &\vdots\\ x_m&=\det M. \end{aligned} \tag{26}$$

Now we let $X_1,X_2,\ldots,X_n$ be the new n intermediate variables and $x_1,x_2,\ldots,x_{n-1}$ be $n-1$ Hamiltonians of the system such that the intermediate variables are constrained by

$$\begin{aligned} X_1+X_2+\cdots+X_n&=x_1,\\ X_1X_2+X_1X_3+\cdots+X_{n-1}X_n&=x_2,\\ &\vdots\\ \sum_{1\leqslant k_1<k_2<\cdots<k_{n-1}\leqslant n}X_{k_1}X_{k_2}\cdots X_{k_{n-1}}&=x_{n-1}. \end{aligned} \tag{27}$$

The Nambu equations for the new variables are nothing but (8) with $H_j=x_j$, $j=1,2,\ldots,n-1$ and solutions have been already discussed in Sec. III A.

In order to find the behavior of the matrix M of (23), we first identify (25) and (26) to express m variables of the matrix in terms of the m constants $\lambda_1,\ldots,\lambda_m$. The rest of the $n-1$ independent variables of the matrix M will be determined by $X_1,X_2,\ldots,X_n$ if we identity $x_1,x_2,\ldots,x_{n-1}$ of (27) with those of (26). We would like to emphasize here that these steps will be done by purely algebraic procedures.

To be specific we consider the map (23) with M given by (24). We further restrict to the case of $m=3$, i.e., the 3-point Toda lattice. Corresponding to the condition (22) we may impose a constraint

$$v_1v_2v_3=\text{const}, \tag{28}$$

so that the number of independent dynamical variables is five. Via explicit calculations we have

$$\begin{aligned} x_1&=i_1+i_2+i_3+v_1+v_2+v_3,\\ x_2&=i_1i_2+i_1i_3+i_2i_3+i_1v_2+i_2v_3+i_3v_1+v_1v_2+v_1v_3+v_2v_3,\\ x_3&=(1+i_1i_2i_3)(1+v_1v_2v_3) \end{aligned} \tag{29}$$

in the place of (26). The correspondence between (25) and (26) enables us to write three variables of M, say i_1,i_2,i_3, in terms of v_1,v_2,v_3 and the constants $\lambda_1,\lambda_2,\lambda_3$.

If we further identify x_1,x_2 in (29) with those of (3), they, together with the condition (28), determine v_1,v_2,v_3 as functions of X_1,X_2,X_3. Since X_1,X_2,X_3 have been known as given in (17), the behavior of the matrix M is determined.

V. REMARKS AND DISCUSSIONS

We have developed a method to derive Nambu equations from a given map (2). There exist some ambiguities how to relate the time variable t of the Nambu equations to the initial variables of the map. It could be one of the initial variables of the map as in the case of Proposition 1, or a function of it as it was the case of Proposition 2. They are not independent but are related with each other through a reparametrization of the variable t.

If the functions $f_1,f_2,\ldots,f_n$ of the map defined by (1) are purely algebraic, the map will determine an algebraic manifold. To study the nature of the manifold we change one of the initial variables of the map and see the response. Our propositions claim that the Nambu equations provide a systematic method to investigate such a response. By means of some examples we have shown that the manifolds described by certain types of map are characterized by hyperelliptic curves.

When there are known some number of invariants under time evolution, the Nambu equations determine the change of the dynamical variables. Since any function of the invariants is again an invariant there are many possible sets of Nambu equations. Suppose we can choose a proper set of invariants such that the functions are algebraic and the Nambu equations can be solved explicitly. Then the problem of solving the equations of motion are replaced to solve the algebraic relations among variables. We have demonstrated that the hyperelliptic solutions of soliton equations can be derived in this way.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 45, NUMBER 3 MARCH 2004

Geometric integrators and nonholonomic mechanics

M. de León,[a] D. Martín de Diego,[b] and A. Santamaría-Merino[c]
Instituto de Matemáticas y Física Fundamental, CSIC, Serrano 123, 28006 Madrid, Spain

(Received 2 July 2003; accepted 3 December 2003)

A geometric derivation of nonholonomic integrators is developed. It is based in the classical technique of generating functions adapted to the special features of nonholonomic systems. The theoretical methodology and the integrators obtained are different from those obtained in Cortés and Martínez ["Nonholonomic integrators," Nonlinearity **14**, 1365–1392 (2001)]. In the case of mechanical systems with linear constraints a family of geometric integrators preserving the nonholonomic constraints is given. © *2004 American Institute of Physics.*

I. INTRODUCTION

A. Introduction to nonholonomic mechanics

The theory of systems with nonholonomic constrains goes back to the XIX century. D'Alembert's or Lagrange–D'Alembert's principle of virtual work and Gauss principle of least constraint can be considered to be the first solutions to the analysis of systems with constraints, holonomic or not. After a period of decay, many authors have recently shown a new interest in that theory and also in its relation to the new developments in control theory, sub-Riemannian geometry, robotics, etc. (see, for instance, Ref. 45). The main characteristic of this period is that Geometry was used in a systematic way (see L.D. Fadeev and A.M. Vershik[49] as an advanced and fundamental reference, and also, Refs. 3, 4, 7, 10, 13, 24, 25, 28, 29, 30, 38).

As is well known, in most problems of particle mechanics, the motion of the particles is constrained in some way; this is the term used to denote the condition that some motions or configurations are not allowed. First, we shall start with a configuration space Q, which is a n-dimensional differentiable manifold, with local coordinates q^i. General two-side or equality constraints are functions of the form $\phi^a(q^i,\dot{q}^i)=0,1\leqslant a\leqslant m$, depending, in general, on configuration coordinates and their velocities. The various kinds of constraints we are concerned with will roughly come in two types: holonomic and nonholonomic, depending whether the constraint is derived from a constraint in the configuration space or not. Therefore, the dimension of the space of configurations is reduced by holonomic constraints but not by nonholonomic constraints. Thus, holonomic constraints permit a reduction in the number of coordinates of the configuration space needed to formulate a given problem (see Ref. 45).

We will restrict ourselves to the case of nonholonomic constraints, since the case of holonomic constraints, and, in particular, the construction of holonomic integrators, is well established in the existing literature. Geometrically, nonholonomic constraints are globally described by a submanifold $\tilde{M}$ of the velocity phase space TQ, the tangent bundle of the configuration space Q. If case $\tilde{M}$ is a vector subbundle of TQ, we are dealing with linear constraints. We will usually refer to $\tilde{M}$ as D and, in such case, the constraints are alternatively defined by a distribution D on the configuration space Q. If this distribution is integrable, we are precisely in the case of holonomic constraints. In case $\tilde{M}$ is an affine subbundle modeled on a vector bundle D, we are in the

[a]Electronic mail: mdeleon@imaff.cfmac.csic.es
[b]Electronic mail: d.martin@imaff.cfmac.csic.es
[c]Electronic mail: aitors@imaff.cfmac.csic.es

case of affine constraints. In what follows, we will denote by D the constraint submanifold on the velocity phase space, no matter if they are determined by linear or nonlinear constraints.

Given the constraints, we need to specify the dynamical evolution of the system. The central concepts permitting the extension of mechanics from the Newtonian point of view to the Lagrangian one are the notions of virtual displacements and virtual work; these concepts were formulated in the developments of mechanics, in their application to statics. In nonholonomic dynamics, the procedure is given by Lagrange–D'Alembert's principle. We usually consider nonholonomic constraints of linear type, which are the constraints that we will regard as natural in a mechanical sense (although the extension for general nonholonomic constraint will be straightforward). We now come to the description of the constraint forces; for constraints of that type, Lagrange–D'Alembert's principle allows us to determine the set of possible values of the constraint forces only from the set of admissible kinematic states, that is, from the constraint manifold D determined by the vanishing of the nonholonomic constraints. Therefore, assuming that the dynamical properties of the system are mathematically described by a configuration space Q, by a Lagrangian function L and by a distribution determining the linear constraints D, the equations of motion, following Lagrange–D'Alembert's principle, are

$$\left[\frac{d}{dt}\left(\frac{\partial L}{\partial \dot{q}^i}\right)-\frac{\partial L}{\partial q^i}\right]\delta q^i=0, \tag{1}$$

where δq^i denotes the virtual displacements verifying

$$\mu_i^a \delta q^i=0 \tag{2}$$

and $D^o=\text{span}\{\mu^a=\mu_i^a dq^i\}$ (for the sake of simplicity, we will assume that the system is not subject to nonconservative forces). By using the Lagrange multiplier rule, we obtain that

$$\frac{d}{dt}\left(\frac{\partial L}{\partial \dot{q}^i}\right)-\frac{\partial L}{\partial q^i}=\overline{\lambda}_a\mu_i^a. \tag{3}$$

The term on the right-hand side represents the constraint force or reaction force induced by the constraints. The functions $\overline{\lambda}_a$ are Lagrange multipliers to be determined in order to obtain a set of second order differential equations. These Lagrangian multipliers are computed using the constraint equations. An interesting remark, that will be used in what follows, is that whenever the Lagrange multipliers $\overline{\lambda}_a=\overline{\lambda}_a(q^i,\dot{q}^i)$ have been determined, then the system of equations (3) can be considered a Lagrangian system subject to external conservative forces given by the right-hand side term, taking, obviously, an initial condition on the constraint submanifold D. The choice of the Lagrange multipliers $\overline{\lambda}_a$ automatically implies that the solution integral curves also verifies the constraint equations.

B. Introduction to geometric integration and discrete mechanics

Standard methods for simulating the motion of a dynamical system, generically called numerical integrators, usually take an initial condition and move it in the direction specified by the equation of motion or an appropriate discretization. But these standard methods ignore all the geometric features of many dynamical systems, as for instance, for Hamiltonian systems we have preservation of the symplectic form, energy (in the autonomous case) and symmetries, if any. However, new methods have been recently developed, called geometric integrators, which are concerned with some of the extra features of geometric nature of the dynamical systems. Usually, these integrators can run, in simulations, for long times with lower spurious effects (for instance, bad energy behavior for conservative systems) than the traditional ones. As is well known, the typical test example is the simulation of the solar system. Therefore, there is presently a great interest in geometric integration of differential equations as, for instance, symplectic integrators of Hamiltonian systems.[17,48]

Discrete variational integrators appear as a special kind of geometric integrators. These integrators have their roots in the optimal control literature in the 1960s and 1970s (Jordan and Polack,[20] Cadzow,[8] Maeda[36,37]) and in the 1980s by Lee,[26,27] Veselov.[44,50] In these papers, there appear the discrete action sum, discrete Euler–Lagrange equations, discrete Noether theorem,.... Although this kind of symplectic integrators have been considered for conservative systems,[18,21,39,43,51,52] it has been recently shown how discrete variational mechanics can include forced or dissipative systems,[22,43] holonomic constraints,[16,43] time-dependent systems,[31,43] frictional contact,[47] and nonholonomic constraints (see Refs. 10, 12). Moreover, it has also been discussed by reduction theory,[5,6,41,42] extension to field theories,[19,40] and quantum mechanics.[46] All these integrators have demonstrated exceptionally good long time behavior and the research of this topic is interesting for numerical and geometric considerations.

At this point, we will describe the discrete variational calculus, following the approach in Ref. 51 (see also Refs. 2, 15). A discrete Lagrangian is a map $L_d: Q\times Q\to\mathbb{R}$ (this discrete Lagrangian may be considered as an approximation of the continuous Lagrangian $L:TQ\to\mathbb{R}$). Define the action sum $S_d: Q^{N+1}\to\mathbb{R}$ corresponding to the Lagrangian L_d by

$$S_d=\sum_{k=1}^{N} L_d(q_{k-1},q_k),$$

where $q_k\in Q$ for $0\leqslant k\leqslant N$. For any covector $\alpha\in T^*_{(x_1,x_2)}(Q\times Q)$, we have a decomposition $\alpha=\alpha_1+\alpha_2$ where $\alpha_i\in T^*_{x_i}Q$. Therefore,

$$dL_d(q_0,q_1)=D_1L_d(q_0,q_1)+D_2L_d(q_0,q_1).$$

The discrete variational principle or Cadzow's principle states that the solutions of the discrete system determined by L_d must extremize the action sum given fixed points q_0 and q_N. Extremizing S_d over q_k, $1\leqslant k\leqslant N-1$, we obtain the following system of difference equations:

$$D_1L_d(q_k,q_{k+1})+D_2L_d(q_{k-1},q_k)=0.$$

These equations are usually called the *discrete Euler–Lagrange equations*. Under some regularity hypothesis (the matrix $(D_{12}L_d(q_k,q_{k+1}))$ is regular), this implicit system of difference equations defines a discrete flow $\Upsilon: Q\times Q\to Q\times Q$, by $\Upsilon(q_{k-1},q_k)=(q_k,q_{k+1})$.

The geometrical properties corresponding to this numerical method are obtained defining the discrete Legendre transformation associated to L_d by

$$FL_d: Q\times Q\to T^*Q,\quad (q_0,q_1)\mapsto(q_0,-D_1L_d(q_0,q_1)),$$

and the 2-form $\omega_d=FL_d^*\omega_Q$, where ω_Q is the canonical symplectic form on T^*Q. The discrete algorithm determined by Υ preserves the symplectic form ω_d, i.e., $\Upsilon^*\omega_d=\omega_d$. Moreover, if the discrete Lagrangian is invariant under the diagonal action of a Lie group G, then the discrete momentum map $J_d: Q\times Q\to\mathfrak{g}^*$ defined by $\langle J_d(q_k,q_{k+1}),\xi\rangle=\langle D_2L_d(q_k,q_{k+1}),\xi_Q(q_{k+1})\rangle$ is preserved by the discrete flow. Therefore, these integrators are symplectic-momentum preserving integrators. Here, ξ_Q is the fundamental vector field determined by $\xi\in\mathfrak{g}$.

Another alternative approach to discrete variational calculus comes from the classical theory of generating functions (see, for instance, Ref. 1). Since (T^*Q,ω_Q) is an exact symplectic manifold, where ω_Q is the canonical symplectic form of T^*Q and $\omega_Q=-d\theta_Q$, the symplectic flow $F_h: T^*Q\to T^*Q$ of a Hamiltonian vector field X_H consists of canonical transormations, and then Graph(F_h), the graph of F_h, is a Lagrangian submanifold of the symplectic manifold $(T^*Q\times T^*Q,\Omega)$ where $\Omega=\pi_2^*\omega_Q-\pi_1^*\omega_Q$. Here, we denote by $\pi_i: T^*Q\times T^*Q\to T^*Q$, $i=1,2$ the canonical projections. Therefore, denoting $\Theta=\pi_2^*\theta_Q-\pi_1^*\theta_Q$ we have that

$$i_{F_h}^*\Omega=-di_{F_h}^*\Theta=0,$$

where $i_{F_h}:\mathrm{Graph}(F_h)\mapsto T^*Q\times T^*Q$ is the canonical inclusion. Then, at least locally, there exists a function $\mathcal{S}^h:\mathrm{Graph}(F_h)\to\mathbb{R}$ such that $i_{F_h}^*\Theta=d\mathcal{S}^h$. Taking (q^i,p_i) as natural coordinates in $\mathrm{Graph}(F_h)$ and $(q^i,p_i,\mathbf{q}^i,\mathbf{p}_i)$ the coordinates in $T^*Q\times T^*Q$, then, $\mathcal{S}^h$ is locally a function of the (q,p) coordinates. Hence, along $\mathrm{Graph}(F_h)$, we have $\mathbf{q}^i=\mathbf{q}^i(q,p)$ and $\mathbf{p}^i=\mathbf{p}^i(q,p)$ and moreover

$$\mathbf{p}_i\,d\mathbf{q}^i-p_i dq^i=d\mathcal{S}^h(q,p).$$

Assume that in a neighborhood of some point $x\in\mathrm{Graph}(F_h)$, we can change this system of coordinates by new independent coordinates $(q^i,\mathbf{q}^i)$ (the local condition is that $\det(\partial\mathbf{q}/\partial p)\neq 0$). In such a case, the function $\mathcal{S}^h$ can be locally expressed as $\mathcal{S}^h=\mathcal{S}^h(q,p)=S^h(q,\mathbf{q})$. The function $S^h(q,\mathbf{q})$ will be called a *generating function of the first kind* of the canonical transformation F_h. Moreover,

$$\begin{cases} p_i=-\dfrac{\partial S^h}{\partial q^i}, \\ \mathbf{p}_i=\dfrac{\partial S^h}{\partial \mathbf{q}^i}. \end{cases}$$

A nice and useful interpretation of the discrete Euler-Lagrange equations is the following theorem.[23,33]

Theorem 1.1: *Let the function S^{Nh} be defined by*

$$S^{Nh}(q_0,q_N)=\sum_{k=0}^{N-1} S^h(q_k,q_{k+1}),$$

where q_k, $1\leqslant k\leqslant N-1$, are stationary points of the right-hand side, that is

$$0=D_2S^h(q_{k-1},q_k)+D_1S^h(q_k,q_{k+1}),\quad 1\leqslant k\leqslant N-1, \tag{4}$$

then S^{Nh} is a generating function of first class for $F_{Nh}:T^*Q\to T^*Q$, for h sufficiently small and where F_{Nh} denotes the flow of X_H over time Nh.

Moreover, if we start with a regular Lagrangian function $L:TQ\to\mathbb{R}$, and $H:T^*Q\to\mathbb{R}$ is the locally associated Hamiltonian, then we also have the following result (for example, see Ref. 33).

Proposition 1.2: *A generating function of the first kind for F_h is given by*

$$S^h(q_0,q_1)=\int_0^h L(q(t),\dot{q}(t))\,dt,$$

where $q(t)$ is a solution of the Euler–Lagrange equations such that $q(0)=q_0$ and $q(h)=q_1$.

The conclusion is that the discrete variational calculus reduces to taking an approximation of the generating function S^h. From this approximation, we obtain a new Lagrangian submanifold of $T^*Q\times T^*Q$ and the relation between subsequent steps is given by (4) for the new generating function, which are precisely the discrete Euler–Lagrange equations. The symplecticity and preservation of momentum are now direct consequences of this description.

C. Introduction to nonholonomic integrators

In a recent paper, Cortés and Martínez[12] have proposed a construction of nonholonomic integrators which is useful for numerical considerations. Their construction is based on the *discrete Lagrange–D'Alembert's principle*. Assuming that the constraints are given by a distribution D, this principle states that

$$(D_1L_d(q_k,q_{k+1})+D_2L_d(q_{k-1},q_k))_i\delta q_k^i=0,\quad 1\leqslant i\leqslant N-1,$$

where $\delta q_k \in D_{q_k}$ and, in addition $(q_k, q_{k+1}) \in D_d$. Here D_d denotes a discrete constraint space $D_d \subset Q \times Q$. This integrator has a good performance and naturally inherits some geometric properties of the continuous problem. Observe that the method is based on the discretization of the Lagrangian and a coherent discretization of the constraints, and both determine the discrete constraint forces.

Alternatively, we propose a nonholonomic integrator based also on the discretization of the Lagrangian function (in a more precise sense, we discretize the action function) but now we take a coherent discretization of the constraint forces and both determine the discrete constraint submanifold. This method gives us, in general, different integrators from those in Ref. 12. The last considerations of the previous section will be our starting point to study nonholonomic integrators, and our equations will be conceptually equivalent to the proposed for systems with external forces (see Ref. 43). In the particular case of mechanical systems with linear constraint in the velocities, we study a subclass of our family of nonholonomic integrators with the property of preservation of the original nonholonomic constraints.

II. GEOMETRICAL FORMULATION OF NONHOLONOMIC SYSTEMS

Let Q be a n-dimensional differentiable manifold, with local coordinates (q^i). The tangent bundle TQ, with induced coordinates $(q^i, \dot{q}^i)$, is equipped with two fundamental geometrical objects:[34] the Liouville vector field Δ and the vertical endomorphism S. In natural bundle coordinates we have

$$\Delta = \dot{q}^i \frac{\partial}{\partial \dot{q}^i}, \quad S = dq^i \otimes \frac{\partial}{\partial \dot{q}^i}.$$

Consider a Lagrangian system, with Lagrangian $L: TQ \to \mathbb{R}$, subject to nonholonomic constraints, defined by a submanifold D of the velocity phase space TQ. We will assume that $\dim D = 2n - m$ and that D is locally described by the vanishing of m independent functions ϕ^a (the "constraint functions").

In geometrical terms, the D'Alembert's principle (or Chetaev's principle for nonlinear constraints) implies that the constraint forces, regarded as 1-forms on TQ along D, take their values in the subbundle $S^*(TD^o)$ of T^*TQ, where TD^o denotes the annihilator of TD in T^*TQ. In an intrinsic way, the equations of motion can be written as (see Refs. 28, 30)

$$(i_X \omega_L - dE_L)_{|D} \in S^*(TD^o),$$

$$X_{|D} \in TD,$$

where ω_L is the Poincaré–Cartan 2-form defined by $\omega_L = -d(S^*(dL))$ and $E_L = \Delta(L) - L$ is the energy function.

In what follows we will also assume that the following *admissibility condition* holds

$$\dim TD^o = \dim S^*(TD^o).$$

This essentially means that the matrix $(\partial \phi^a / \partial \dot{q}^i)$ has rank m everywhere.

We now turn to the Hamiltonian description of the nonholonomic system on the cotangent bundle T^*Q of Q.[3,25,38] The canonical coordinates on T^*Q are denoted by (q^i, p_i), and the cotangent bundle projection will be $\pi_Q: T^*Q \to Q$. Assuming the regularity of the Lagrangian, we have that the Lagrangian and Hamiltonian formulations are locally equivalent. If we suppose, in addition, that the Lagrangian L is hyperregular, then the Legendre transformation $Leg: TQ \to T^*Q, (q^i, \dot{q}^i) \mapsto (q^i, p_i = \partial L / \partial \dot{q}^i)$, is a global diffeomorphism. The constraint functions on T^*Q become $\Psi^a = \phi^a \circ Leg^{-1}$, i.e.,

$$\Psi^a(q^i,p_i)=\phi^a\left(q^i,\frac{\partial H}{\partial p_i}\right),$$

where the Hamiltonian $H:T^*Q\to\mathbb{R}$ is defined by $H=E_L\circ Leg^{-1}$. Since locally $Leg^{-1}(q^i,p_i)=(q^i,\partial H/\partial p_i)$, then

$$H=p_i\dot{q}^i-L(q^i,\dot{q}^i),$$

where $\dot{q}^i$ is expressed in terms of q^i and p_i using Leg^{-1}.

The equations of motion for the nonholonomic system on T^*Q can now be written as follows:

$$\begin{cases}\dot{q}^i=\dfrac{\partial H}{\partial p_i},\\ \dot{p}_i=-\dfrac{\partial H}{\partial q^i}-\lambda_a\dfrac{\partial\Psi^a}{\partial p_j}\mathcal{H}_{ji},\end{cases}\tag{5}$$

together with the constraint equations $\Psi^a(q,p)=0$, where $\mathcal{H}_{ij}$ are the components of the inverse of the matrix $(\mathcal{H}^{ij})=(\partial^2H/\partial p_i\partial p_j)$. Note that

$$\left(\frac{\partial\Psi^a}{\partial p_j}\mathcal{H}_{ji}\right)(q,p)=\left(\frac{\partial\phi^a}{\partial\dot{q}^i}\circ Leg^{-1}\right)(q,p).$$

The symplectic 2-form ω_L is related, via the Legendre map, with the canonical symplectic form ω_Q on T^*Q. Let M denote the image of the constraint submanifold D under the Legendre transformation, and let F be the distribution on T^*Q along M, whose annihilator is given by

$$F^o=Leg_*(S^*(TD^o)).$$

Observe that F^o is locally generated by the m independent 1-forms

$$\mu^a=\frac{\partial\Psi^a}{\partial p_i}\mathcal{H}_{ij}dq^j,\quad 1\leqslant a\leqslant m.$$

Therefore, the ''Hamilton equations'' for the nonholonomic system can be rewritten in intrinsic form as

$$\begin{aligned}&(i_X\omega_Q-dH)_{|M}\in F^o,\\ &X_{|M}\in TM.\end{aligned}\tag{6}$$

Suppose in addition that the following *compatibility condition* $F^\perp\cap TM=\{0\}$ holds, where ''$\perp$'' denotes the symplectic orthogonal with respect to ω_Q. Observe that, locally, this condition means that the matrix

$$(C^{ab})=\left(\frac{\partial\Psi^a}{\partial p_i}\mathcal{H}_{ij}\frac{\partial\Psi^b}{\partial p_j}\right)\tag{7}$$

is regular. On the Lagrangian side, the compatibility condition is locally written as

$$\det(\tilde{C}^{ab})=\det\left(\frac{\partial\phi^a}{\partial\dot{q}^i}W^{ij}\frac{\partial\phi^b}{\partial\dot{q}^j}\right)\neq 0,\tag{8}$$

where W^{ij} are the entries of the Hessian matrix $(\partial^2L/\partial\dot{q}^i\partial\dot{q}^j)_{1\leqslant i,j\leqslant n}$. The compatibility condition is not too restrictive, since, taking into account the admissibility assumption, it is trivially verified by the usual systems of mechanical type (i.e., with a Lagrangian of the form kinetic minus

potential energy), where the $\mathcal{H}_{ij}$ represent the components of a positive definite Riemannian metric. The compatibility condition guarantees in particular the existence of a unique solution of the constrained equations of motion (6) which, henceforth, will be denoted by $X_{H,M}$ on the Hamiltonian side and $\xi_{L,D}$ on the Lagrangian side.

Moreover, if we denote by X_H the Hamiltonian vector field of H, i.e., $i_{X_H}\omega_Q = dH$ then, using the constraint functions, we may explicitely determine the Lagrange multipliers λ_a as

$$\lambda_a = -\mathcal{C}_{ab} X_H(\Psi^b).$$

Next, writing the 1-form

$$\Lambda = -\mathcal{C}_{ab} X_H(\Psi^b) \frac{\partial \Psi^a}{\partial p_j} \mathcal{H}_{ji} dq^i,$$

the nonholonomic equations are equivalently rewritten as

$$\begin{cases} \dot{q}^i = \dfrac{\partial H}{\partial p_i}, \\ \dot{p}_i = -\dfrac{\partial H}{\partial q^i} - \Lambda_i, \end{cases} \tag{9}$$

for initial conditions $(q_0, p_0) \in M$ and $\Lambda = \Lambda_i\, dq^i$. We also denote by $\tilde{\Lambda} = Leg^*(\Lambda)$ the 1-form on TQ wich represents the constraint force once the Lagrange multipliers have been determined. Now, consider the flow $F_t : M \to M$, $t \in I \subseteq \mathbb{R}$ of the vector field $X_{H,M}$, solution of the nonholonomic problem.

Since (9) is geometrically rewritten as

$$i_{X_{H,M}} \omega_Q = dH + \Lambda,$$

($i_{\xi_{L,D}} \omega_L = dE_L + \tilde{\Lambda}$, with $\tilde{\Lambda} = Leg^* \Lambda$, on the Lagrangian side) then

$$L_{X_{H,M}} \theta_Q = d(i_{X_{H,M}} \theta_Q - H) - \Lambda,$$

or, equivalently,

$$L_{X_{H,M}} \theta_Q = d(L \circ Leg^{-1}) - \Lambda.$$

Now, from the dynamical definition of the Lie derivative, we have

$$F_t^*(L_{X_{H,M}} \theta_Q) = \frac{d}{dt}(F_t^* \theta_Q),$$

and integrating, we obtain the following expression, with some abuse of notation,

$$F_h^* \theta_Q - \theta_Q = d\left(\int_0^h L \circ \tilde{F}_t \, dt \right) - \int_0^h F_t^* \Lambda, \tag{10}$$

where $\tilde{F}_t$ is the flow of the vector field $\xi_{L,D}$. In the following sections, we will study geometric integrators which verify a discrete version of Eq. (10).

III. "GENERATING FUNCTIONS" AND NONHOLONOMIC MECHANICS

At this point, we will follow similar arguments for the construction of generating functions for symplectic or canonical maps.[1] However, because of Eq. (10), we have that the nonholonomic flow is not a canonical transformation, i.e.,

$$F_h^*\omega_Q-\omega_Q=d\left(\int_0^h F_t^*\Lambda\right). \tag{11}$$

This description will allow us to construct a new family of nonholonomic integrators for Eq. (3). Denote by $\pi_i:T^*Q\times T^*Q\to T^*Q$, $i=1,2$, the canonical projections. Consider the following forms:

$$\Theta=\pi_2^*\theta_Q-\pi_1^*\theta_Q,$$

$$\Omega=\pi_2^*\omega_Q-\pi_1^*\omega_Q=-d\Theta.$$

Denote by i_{F_h}:Graph$(F_h)\hookrightarrow T^*Q\times T^*Q$ the inclusion map and observe that Graph$(F_h)\subset M\times M$. Then, from (11)

$$i_{F_h}^*\Omega=(\pi_{1_{|\mathrm{Graph}(F_h)}})^*(F_h^*\omega_Q-\omega_Q)=(\pi_{1_{|\mathrm{Graph}(F_h)}})^*\left[d\left(\int_0^h F_t^*\Lambda\right)\right],$$

or, from (10),

$$i_{F_h}^*\Theta=(\pi_{1_{|\mathrm{Graph}(F_h)}})^*\left[d\left(\int_0^h L\circ\tilde{F}_t\,dt\right)-\int_0^h F_t^*\Lambda\right].$$

Let (q_0,p_0,q_1,p_1) be coordinates in $T^*Q\times T^*Q$ in a neighborhood of some point in Graph(F_h). If $(q_0,p_0,q_1,p_1)\in\mathrm{Graph}(F_h)$ then $\Psi^a(q_0,p_0)=0$ and $\Psi^a(q_1,p_1)=0$. Moreover, along Graph(F_h), $q_1=q_1(q_0,p_0)$ and $p_1=p_1(q_0,p_0)$,

$$p_1\,dq_1-p_0dq_0=d\left(\int_0^h L(q(t),\dot{q}(t))\,dt\right)-\int_0^h\tilde{\Lambda}(q(t),\dot{q}(t)), \tag{12}$$

where $(q(t),\dot{q}(t))=\tilde{F}_t(q_0,\dot{q}_0)$ with $Leg(q_0,\dot{q}_0)=(q_0,p_0)$. Here, $\tilde{F}_t$ denotes the flow of $\xi_{L,D}$. Equation (12) is satisfied along Graph(F_h).

Assume that, in a neighborhood of some point $x\in\mathrm{Graph}(F_h)$, we can change this system of coordinates to a new coordinates (q_0,q_1). Denote by

$$S^h(q_0,q_1)=\int_0^h L(q(t),\dot{q}(t))\,dt,$$

where $q(t)$ is a solution curve of the nonholonomic problem with $q(0)=q$ and $q(h)=q_1$. This solution always exists for adequate values of q_0 and q_1. In fact, observe that

$$q_1=q_0+h\frac{\partial H}{\partial p}(q_0,p_0)+o(h^2),$$

hence, since $\det(\partial^2H/\partial p_i\partial p_j)\neq0$, we locally have that $p_0=p_0(q_0,q_1,h)$. But, in addition, $(q_0,p_0)\in M$; therefore $\varphi^a(q_0,q_1,h)=\Psi^a(q_0,p_0(q_0,q_1,h))=0$. Then, the curve

$$(q(t),\dot{q}(t))=Leg^{-1}(F_t(q_0,p_0(q_0,q_1,h))),$$

verifies the required assumptions if $\varphi^a(q_0,q_1,h)=0$.

Thus, we deduce that

$$\begin{cases} p_0 = -\dfrac{\partial S^h}{\partial q_0} + \displaystyle\int_0^h \tilde{\Lambda}(q(t),\dot{q}(t))\,\frac{\partial q}{\partial q_0}, \\ p_1 = \dfrac{\partial S^h}{\partial q_1} - \displaystyle\int_0^h \tilde{\Lambda}(q(t),\dot{q}(t))\,\frac{\partial q}{\partial q_1}, \end{cases} \tag{13}$$

where (q_0,q_1) verifies the constraint functions $\varphi^a(q_0,q_1,h)=0$, now explicitly defined by

$$\varphi^a(q_0,q_1,h) = \Psi^a\left(q_0, -\frac{\partial S^h}{\partial q_0}(q_0,q_1) + \int_0^h \tilde{\Lambda}(q(t),\dot{q}(t))\,\frac{\partial q}{\partial q_0}\right), \quad 1\leqslant a\leqslant m, \tag{14}$$

with $q(t)$ solution of the nonholonomic problem with $q(0)=q_0$ and $q(h)=q_1$.

Next, we will show how the group composite law of the flow F_h

$$F_{Nh} = \underbrace{F_h \circ \ldots \circ F_h}_{N}$$

is expressed in terms of the corresponding ''generating functions'' S^h. Moreover, the following Theorem will result in a new construction of numerical integrators for nonholonomic mechanics when we change the ''generating function'' and the constraint forces by appropriate approximations. As a generalization of Theorem 1.1 we have the following:

Theorem 3.1: *The function S^{Nh}, the "generating function" for F_{Nh}, is given by*

$$S^{Nh}(q_0,q_N) = \sum_{k=0}^{N-1} S^h(q_k,q_{k+1}),$$

where q_k, $1\leqslant k\leqslant N-1$, are points verifying

$$D_2S^h(q_{k-1},q_k) + D_1S^h(q_k,q_{k+1}) = \int_0^h \tilde{\Lambda}(q(t),\dot{q}(t))\,\frac{\partial q}{\partial q_1} + \int_h^{2h} \tilde{\Lambda}(q(t),\dot{q}(t))\,\frac{\partial q}{\partial q_0}, \tag{15}$$

and $q(t)$ is a solution curve of the nonholonomic problem with $q(0)=q_{k-1}$ and $q(h)=q_k$ (respectively, $q(h)=q_k$ and $q(2h)=q_{k+1}$) for the first integral (resp., second integral) of the right-hand side.

Proof: By a recursion argument, it is suffices to prove the result for $N=2$; that is,

$$S^{2h}(q_0,q_2) = S^h(q_0,q_1) + S^h(q_1,q_2),$$

where q_1 verifies condition (15).

Since

$$p_1\,dq_1 - p_0\,dq_0 = dS^h(q_0,q_1) - \int_0^h \tilde{\Lambda}(q(t),\dot{q}(t)),$$

$$p_2\,dq_2 - p_1\,dq_1 = dS^h(q_1,q_2) - \int_h^{2h} \tilde{\Lambda}(q(t),\dot{q}(t)),$$

then

$$p_2\,dq_2 - p_0\,dq_0 = d(S^h(q_0,q_1) + S^h(q_1,q_2)) - \int_0^h \tilde{\Lambda}(q(t),\dot{q}(t)) - \int_h^{2h} \tilde{\Lambda}(q(t),\dot{q}(t)).$$

Since the variables q_1 do not appear on the left-hand side term, it follows that

$$0=D_2S_1^h(q_0,q_1)+D_1S_2^h(q_1,q_2)-\int_0^h\tilde{\Lambda}(q(t),\dot{q}(t))\frac{\partial q}{\partial q_1}-\int_h^{2h}\tilde{\Lambda}(q(t),\dot{q}(t))\frac{\partial q}{\partial q_0}, \quad (16)$$

and for a choice of q_1 verifying (16), then

$$S^{2h}(q_0,q_2)=S^h(q_0,q_1)+S^h(q_1,q_2)$$

is a ''generating function of the first kind'' of F_{2h} because

$$p_2\,dq_2-p_0\,dq_0=dS^{2h}(q_0,q_2)-\int_0^{2h}\tilde{\Lambda}(q(t),\dot{q}(t)).$$

■

Equation (15) determines a implicit system of difference equations which permits us to obtain q_2 from the initial data q_0 and q_1. An interesting consequence of this is that these equations preserve the constraint submanifold determined by the constraints $\varphi^a=0$, $1\leqslant a\leqslant m$. In fact, if $\varphi^a(q_0,q_1,h)=0$ (that is $\Psi^a(q_0,p_0)=0$) then

$$\varphi^a(q_1,q_2,h)=\Psi^a\left(q_1,\frac{\partial S^h}{\partial q_1}(q_0,q_1)-\int_0^h\tilde{\Lambda}(q(t),\dot{q}(t))\frac{\partial q}{\partial q_1}\right),$$

and now, applying (13), we obtain that

$$\varphi^a(q_1,q_2,h)=\Psi^a(q_1,p_1)=0,$$

since $F_h(q_0,p_0)=(q_1,p_1)$ and the flow preserves the constraints.

The next remark will be a key result for the construction of nonholonomic integrators.

Remark 3.2: Replace Eq. (13) by

$$\begin{cases} p_0=-\dfrac{\partial\tilde{S}^h}{\partial q_0}+\alpha_0^h(q_0,q_1), \\ p_1=\dfrac{\partial\tilde{S}^h}{\partial q_1}-\alpha_1^h(q_0,q_1), \end{cases} \quad (17)$$

where $\tilde{S}^h$ is a function of (q_0,q_1) coordinates and $\alpha^h=\alpha_0^h\,dq_0+\alpha_1^h\,dq_1$, and replace the constraints functions by

$$\tilde{\varphi}^a(q_0,q_1,h)=\Psi^a\left(q_0,-\frac{\partial\tilde{S}^h}{\partial q^0}+\alpha_0^h(q_0,q_1)\right), \quad (18)$$

that is,

$$p_1\,dq_1-p_0\,dq_0=d\tilde{S}^h-\alpha^h,$$

along $\tilde{\varphi}^a=0$.

Assume that

$$\det\left(\frac{\partial^2\tilde{S}^h}{\partial q_0\partial q_1}-\frac{\partial\alpha_0^h}{\partial q_1}\right)\neq 0, \quad (19)$$

then, applying the implicit function theorem we have that, locally, $q_1=q_1(q_0,p_0)$, and therefore, the mapping

$$G_h(q_0,p_0)=(q_1,p_1)$$

is well-defined.

Consider the mapping G_{Nh} defined by

$$G_{Nh}=\underbrace{G_h\circ\ldots\circ G_h}_{N}.$$

Following a similar argument to Theorem 3.1, Graph(G_{Nh}) is described by

$$\begin{cases} p_0=-\dfrac{\partial\widetilde{S}^{Nh}}{\partial q_0}(q_0,q_N)+\alpha_0^{Nh}(q_0,q_N), \\ p_N=\dfrac{\partial\widetilde{S}^{Nh}}{\partial q_N}(q_0,q_N)-\alpha_1^{Nh}(q_0,q_N), \end{cases} \tag{20}$$

where $\widetilde{S}^{Nh}(q_0,q_N)=\Sigma_{k=0}^{N-1}\widetilde{S}^h(q_k,q_{k+1})$ and $\alpha^{Nh}(q_0,q_N)=\Sigma_{k=0}^{N-1}\alpha^h(q_k,q_{k+1})$. Here, the q_k's, $1\leqslant k\leqslant N-1$, verify

$$D_2\widetilde{S}^h(q_{k-1},q_k)+D_1\widetilde{S}^h(q_k,q_{k+1})=\alpha_1^h(q_{k-1},q_k)+\alpha_0^h(q_k,q_{k+1}),\quad 1\leqslant k\leqslant N-1. \tag{21}$$

A. Constraint error analysis

As we have seen, if our "generating function" is S^h, then we have exact preservation of the constraints φ^a. We now investigate what happens when the "generating function" is an approximation. We follow similar arguments to those in Sec. III C in Ref. 43.

Assume that Q, and also TQ and T^*Q, are finite-dimensional vector spaces with inner product $\langle .,. \rangle$ and corresponding norm $\|\ \|$.

Consider an "approximated generating function" $\widetilde{S}^h$ and an approximated discrete constraint force $\alpha^h=\alpha_i^h\,dq^i$ for the nonholonomic problem, both of order r (all the functions are assumed to be C^2); hence, there exists an open set $U\subset D$ with compact closure and constants $c,d_i>0$, $1\leqslant i\leqslant n$, and $H>0$ such that

$$\widetilde{S}^h(q_0,q_1)=S^h(q_0,q_1)+C(q_0,q_1,h)h^{r+1}, \tag{22}$$

$$\alpha_i^h=\int_0^h\tilde{\Lambda}_i(q(t),\dot{q}(t))\,dt+D_i(q_0,q_1,h)h^{r+1}, \tag{23}$$

for all solution $q(t)$ of the nonholonomic problem with $q(0)=q_0$, $q(h)=q_1$ and initial condition belonging to U and $h\leqslant H$. Here C and D_i, $1\leqslant i\leqslant n$, are smooth functions such that $\|C(q_0,q_1,h)\|\leqslant c$ and $\|D_i(q_0,q_1,h)\|\leqslant d_i$ on U.

Taking derivatives we have that

$$\frac{\partial\widetilde{S}^h}{\partial q_0}(q_0,q_1)=\frac{\partial S^h}{\partial q_0}(q_0,q_1)+\frac{\partial C}{\partial q_0}(q_0,q_1,h)h^{r+1}$$

and also

$$\alpha_0^h(q_0,q_1)=(\alpha_0)_i^h\frac{\partial q^i}{\partial q_0}=\int_0^h\tilde{\Lambda}_i(q(t),\dot{q}(t))\frac{\partial q^i}{\partial q_0}dt+\sum_{i=1}^n\frac{\partial D_i}{\partial q_0}(q_0,q_1,h)h^{r+1},$$

where now $\alpha^h=\alpha_0^h\,dq_0+\alpha_1^h\,dq_1$.

Therefore, we deduce that

$$\begin{aligned}\tilde{\varphi}^a(q_0,q_1,h)&=\Psi^a\left(q_0,-\frac{\partial\tilde{S}}{\partial q^0}+\alpha_0(q_0,q_1)\right)\\&=\Psi^a\left(q_0,-\frac{\partial S^h}{\partial q_0}+\int_0^h\tilde{\Lambda}(q(t),\dot{q}(t))\frac{\partial q}{\partial q_0}\right)+E^a(q_0,q_1,h)h^{r+1}\\&=\Psi^a(q_0,p_0)+E^a(q_0,q_1,h)h^{r+1}\\&=E^a(q_0,q_1,h)h^{r+1},\end{aligned}$$

where E^a are bounded functions. Thus, the discrete algorithm preserves the constraints up to order r.

B. Local error analysis

Assuming that

$$\det\left(\frac{\partial^2\tilde{S}^h}{\partial q_0\partial q_1}-\frac{\partial\alpha_0^h}{\partial q_1}\right)\neq 0, \tag{24}$$

we obtain a discrete flow $G^h: V\subseteq T^*Q\to T^*Q$. Now, using Eqs. (13), (22), and (23) we deduce that

$$\begin{cases} p_0=-\dfrac{\partial S^h}{\partial q_0}+\displaystyle\int_0^h\tilde{\Lambda}(q(t),\dot{q}(t))\frac{\partial q}{\partial q_0}=\frac{\partial\tilde{S}^h}{\partial q_0}(q_0,q_1)+\alpha_0^h(q_0,q_1)+E_0(q_0,q_1,h)h^{r+1},\\ p_1=\dfrac{\partial S^h}{\partial q_1}-\displaystyle\int_0^h\tilde{\Lambda}(q(t),\dot{q}(t))\frac{\partial q}{\partial q_1}=\frac{\partial\tilde{S}^h}{\partial q_1}(q_0,q_1)-\alpha_1^h(q_0,q_1)+E_1(q_0,q_1,h)h^{r+1},\end{cases} \tag{25}$$

where E_0 and E_1 are smooth and bounded functions.

Applying the implicit function theorem to (25), it is easy to show, from conditions (22) and (23), that G^h is an integrator of $X_{H,M}$ of order r (see for details Theorem 2.3.1 in Ref. 43).

IV. CONSTRUCTION OF NONHOLONOMIC INTEGRATORS

In what follows and for simplicity assume that Q is a vector space. Since $S^h(q_0,q_1)=\int_0^h L(q(t),\dot{q}(t))\,dt$, where $q(t)$ is a nonholonomic solution with $q(0)=q_0$ and $q(h)=q_1$, using Remark 3.2, we can obtain nonholonomic integrators by taking adequate approximations of the "generating function" S^h and the extra-term $\int_0^h\tilde{\Lambda}(q(t),\dot{q}(t))$.

Consider, for instance, the approximation

$$S_\alpha^h(q_0,q_1)=hL\left((1-\alpha)q_0+\alpha q_1,\frac{q_1-q_0}{h}\right), \tag{26}$$

for some parameter $\alpha\in[0,1]$. (In general, we will write $S_\alpha^h(q_0,q_1)\approx S^h(q_0,q_1)$.)

A natural approximation of the constraint forces adapted to our choice of approximation for S^h are

$$\int_0^h\tilde{\Lambda}(q(t),\dot{q}(t))\frac{\partial q}{\partial q_0}\approx(1-\alpha)h\tilde{\Lambda}\left((1-\alpha)q_0+\alpha q_1,\frac{q_1-q_0}{h}\right),$$

$$\int_0^h\tilde{\Lambda}(q(t),\dot{q}(t))\frac{\partial q}{\partial q_1}\approx\alpha h\tilde{\Lambda}\left((1-\alpha)q_0+\alpha q_1,\frac{q_1-q_0}{h}\right).$$

Consequently, Eqs. (21) give us the following numerical method for nonholonomic systems:

$$D_2S^h_\alpha(q_{k-1},q_k)+D_1S^h_\alpha(q_k,q_{k+1})=\alpha h\tilde{\Lambda}\left((1-\alpha)q_{k-1}+\alpha q_k,\frac{q_k-q_{k-1}}{h}\right)$$
$$+(1-\alpha)h\tilde{\Lambda}\left((1-\alpha)q_k+\alpha q_{k+1},\frac{q_{k+1}-q_k}{h}\right),$$
$$1\leqslant k\leqslant N-1,$$

with initial condition satisfying

$$\tilde{\varphi}^a(q_0,q_1,h)=\Psi^a\left(q_0,-\frac{\partial S^h_\alpha}{\partial q_0}(q_0,q_1)+(1-\alpha)h\tilde{\Lambda}\left((1-\alpha)q_0+\alpha q_1,\frac{q_1-q_0}{h}\right)\right)=0.$$

Remark 4.1: Obviously, it is possible to produce a wider variety of discrete methods. For example,

$$S^h_{\mathrm{sym},\alpha}=\tfrac{1}{2}S^h_\alpha+\tfrac{1}{2}S^h_{1-\alpha},$$

gives a second-order method for any $\alpha\in[0,1]$. Also, higher-order approximations of the function S^h may be considered.

Example 4.2: Nonholonomic particle: Consider the Lagrangian $L:T\mathbb{R}^3\to\mathbb{R}$

$$L=\tfrac{1}{2}(\dot{x}^2+\dot{y}^2+\dot{z}^2)-(x^2+y^2),$$

subject to the constraint

$$\phi=\dot{z}-y\dot{x}=0.$$

It is easy to compute the nonholonomic differential equations

$$\ddot{x}=-\frac{2x+y\dot{x}\dot{y}}{1+y^2},$$

$$\ddot{y}=-2y,$$

$$\ddot{z}=\frac{-2xy+\dot{x}\dot{y}}{1+y^2},$$

where now the constraint 1-form is

$$\tilde{\Lambda}=\frac{2xy-\dot{x}\dot{y}}{1+y^2}(dz-ydx).$$

The system being simulated here is purely conservative and so there should be no loss of energy over time.

Taking

$$S^h_{1/2}(x_0,y_0,z_0,x_1,y_1,z_1)=\frac{h}{2}\left[\left(\frac{x_1-x_0}{h}\right)^2+\left(\frac{y_1-y_0}{h}\right)^2+\left(\frac{z_1-z_0}{h}\right)^2\right]-\left(\frac{x_0+x_1}{2}\right)^2-\left(\frac{y_0+y_1}{2}\right)^2,$$

we obtain the nonholonomic integrator

$$\frac{x_1-x_0}{h}-h\frac{x_1+x_0}{2}-\frac{x_2-x_1}{h}-h\frac{x_2+x_1}{2}=-\frac{h}{2}\left[\frac{\frac{(x_1+x_0)(y_1+y_0)}{2}-\frac{(x_1-x_0)(y_1-y_0)}{h^2}}{1+\left(\frac{y_1+y_0}{2}\right)^2}\cdot\frac{y_1+y_0}{2}\right.$$
$$\left.+\frac{\frac{(x_2+x_1)(y_2+y_1)}{2}-\frac{(x_2-x_1)(y_2-y_1)}{h^2}}{1+\left(\frac{y_2+y_1}{2}\right)^2}\cdot\frac{y_2+y_1}{2}\right],$$

$$\frac{y_1-y_0}{h}-h\frac{y_1+y_0}{2}-\frac{y_2-y_1}{h}-h\frac{y_2+y_1}{2}=0,$$

$$\frac{z_1-z_0}{h}-\frac{z_2-z_1}{h}=\frac{h}{2}\left[\frac{\frac{(x_1+x_0)(y_1+y_0)}{2}-\frac{(x_1-x_0)(y_1-y_0)}{h^2}}{1+\left(\frac{y_1+y_0}{2}\right)^2}\right.$$
$$\left.+\frac{\frac{(x_2+x_1)(y_2+y_1)}{2}-\frac{(x_2-x_1)(y_2-y_1)}{h^2}}{1+\left(\frac{y_2+y_1}{2}\right)^2}\right].$$

The constraint function on $\mathbb{R}^3\times\mathbb{R}^3$ is

$$\tilde{\varphi}^a(x_0,y_0,z_0,x_1,y_1,z_1,h)$$
$$=-\frac{z_1-z_0}{h}-\frac{h}{2}\frac{\frac{(x_1+x_0)(y_1+y_0)}{2}-\frac{(x_1-x_0)(y_1-y_0)}{h^2}}{1+\left(\frac{y_1+y_0}{2}\right)^2}$$
$$+y_0\left[\frac{x_1-x_0}{h}+h\frac{x_1+x_0}{2}-\frac{h}{2}\frac{\frac{(x_1+x_0)(y_1+y_0)}{2}-\frac{(x_1-x_0)(y_1-y_0)}{h^2}}{1+\left(\frac{y_1+y_0}{2}\right)^2}\cdot\frac{y_1+y_0}{2}\right].$$

Figures 1 and 2 show the preservation of energy as a key point of comparison of computational implementations of the method exposed above to other methods. In Fig. 3 we show the behavior of the constraint function.

Remark 4.3: Generating function approach and discrete Lagrange–d'Alembert principle: A discussion: As is well known, a remarkable feature of symplectic transformations is that it can be expressed in terms of a single real-valued function S, the generating function of the canonical transformation. Therefore, any symplectic integrator has associated a generating function. Now, taking adequate approximations of the generating function associated to the exact flow of a Hamiltonian system, we generate symplectic integrators (see, for instance, symplectic and symplectic partitioned Runge–Kutta methods in Ref. 17) by using generating functions of the first kind, second kind, and so on. It is also possible to construct symplectic numerical methods of higher order considering better approximations of the generating function in the Hamilton–Jacobi equation (see Ref. 9).

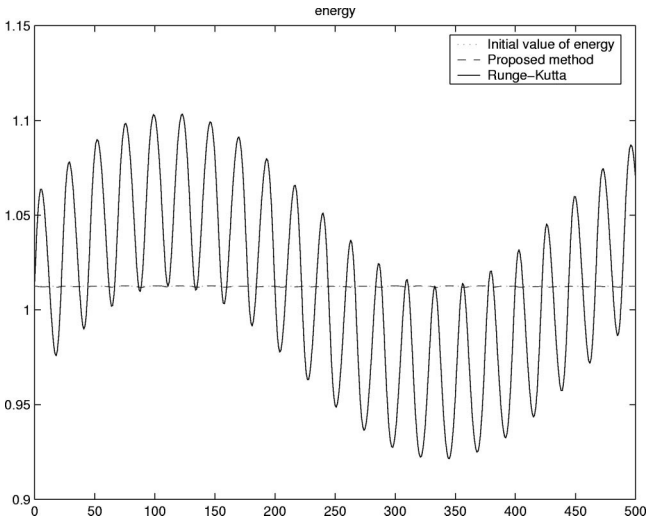

FIG. 1. Comparison of the method introduced here to the traditional Runge–Kutta method of fourth order, showing an improvement in several orders of magnitude. Observe that, in this scale, the value of the energy in each step of our algorithm is practically undistinguishable from the initial value of the energy, therefore our method does not artificially dissipate energy.

As we have said in Sec. I B, the discrete variational approach and the generating function approach are in fact the same on generating function of the first kind. That is, considering the action integral as a function of (q_0,q_1), for the solution $q(t)$ of the Euler–Lagrange equations we have that

$$S^h(q_0,q_1)=\int_0^h L(q(t),\dot{q}(t))\,dt$$

(this is precisely, the exact discrete Lagrangian following the notation in Marsden and West[43]). Therefore, a discrete Lagrangian L_d is a discrete approximation of the above action integral or, in other words, an approximated generating function for S^h.

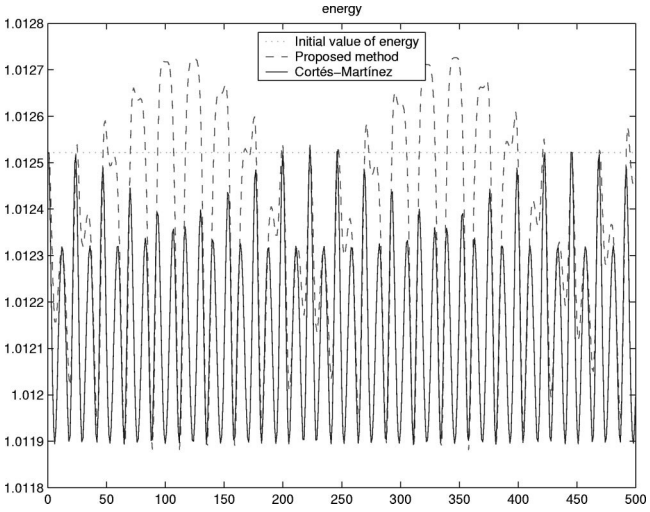

FIG. 2. A comparison between our method and the one that appeared in Refs. 10 and 12. A similar behavior is observed. Nevertheless, a slightly better behavior can also be appreciated, where the proposed algorithm shows on average a better preservation of the original energy.

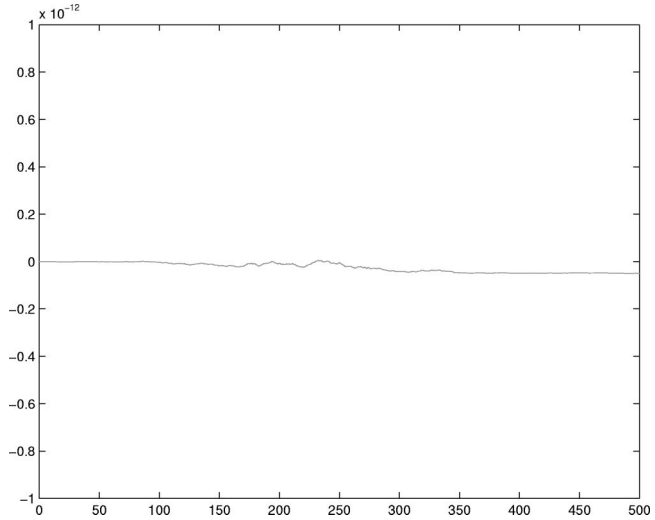

FIG. 3. For the same initial conditions and data, the following graph shows very good behavior of the constraint function evolution with time (notice the small scale).

In Sec. III B of Ref. 43, the authors discuss Discrete variational mechanics with forces and using the so-called *Discrete Lagrange–d'Alembert principle*, they simulate a given forced Lagrangian or Hamiltonian system choosing discrete Lagrangians and discrete forces to approximate the exact quantities.

Formally, the approach followed in Secs. III and IV is equivalent to the approach given in Ref. 43 considering a nonholonomic system as a Lagrangian system with forces determined with the constraint equations. However, a new insight is gained from the generating function approach. First, our theory is ready for the constructions of new numerical integrators for nonholonomic systems using Hamilton–Jacobi theory for nonholonomic systems (see Ref. 14) or even ''generating functions'' for nonholonomic system of different kinds. Observe that, for instance, symplectic Runge–Kutta methods were generated using generating functions of the third kind (see Ref. 48). Second, since symplectic integrators based on generating functions is strongly established in numerical analysis research, we think that our presentation will be clearer than the usual one of discrete Lagrangians frequently used by the geometrical mechanics researchers.

V. MECHANICAL SYSTEMS WITH LINEAR CONSTRAINTS: GEOMETRIC NUMERICAL METHODS PRESERVING CONSTRAINTS

In Secs. III and IV we have constructed a family of numerical integrators for nonholonomic mechanics; these integrators do not preserve the constraint but we show that the violation of the constraint is very small. This answer is not completely satisfactory for a numerical method for a nonholonomic system (as, for instance, rolling constraints in wheeled vehicles), therefore we impose the preservation of the nonholonomic constraints obtaining a subfamily of the above numerical integrators in this section. As we shall show more insight is performed by restricting ourselves to the particular (but general in a mechanical sense) case of Lagrangians of mechanical type ($L=T-V$) and constraints linear on velocities.

Therefore, suppose that the mechanical system, given by the Lagrangian $L:TQ\to\mathbb{R}$

$$L(v_q)=\tfrac{1}{2}g(v_q,v_q)-V(q)$$

is subjected to nonholonomic constraints $\phi^a:TQ\to\mathbb{R}$, $1\leqslant a\leqslant m$. Since the nonholonomic constraints usually found in mechanics are linear in the velocities, we will assume that

$$\phi^a(q,\dot{q}) = \mu_i^a(q)\dot{q}^i, \quad 1 \leqslant a \leqslant m.$$

From a geometric point of view, these linear constraints are determined by prescribing a distribution $\mathcal{D}$ on Q of dimension $n-m$ such that the annihilator of $\mathcal{D}$ is locally given by

$$\mathcal{D}^o = \langle \mu^a = \mu_i^a dq^i; 1 \leqslant a \leqslant m \rangle .$$

In this manner, the solutions of the nonholonomic Lagrangian system satisfy

$$\nabla_{\dot{c}(t)}\dot{c}(t) = -\operatorname{grad} V(c(t)) + \lambda(\dot{c}(t)), \quad \dot{c}(t) \in \mathcal{D}_{c(t)}, \tag{27}$$

where λ is a section of $\mathcal{D}^\perp$ along c, and $\mathcal{D}^\perp$ stands for the orthogonal complement of $\mathcal{D}$ with respect to the metric g.

Since g is a Riemannian metric, the $m \times m$ matrix $(C^{ab}) = (\mu_i^a g^{ij} \mu_j^b)$ is symmetric and regular. Therefore, we can explicitly determine

$$\lambda(q^i(t),\dot{q}^i(t)) = C_{ab}\left(\left(-\Gamma_{jk}^i \dot{q}^j \dot{q}^k - g^{ij}\frac{\partial V}{\partial q^j} \right) \mu_i^a + \dot{q}^i \dot{q}^j \frac{\partial \mu_i^a}{\partial q^j} \right) Z^b, \tag{28}$$

where (C_{ab}) is the inverse matrix of (C^{ab}), Γ_{jk}^i are the Christoffel components and the vector field Z^a is defined by

$$g(Z^a, Y) = \mu^a(Y), \quad \text{for all vector field } Y, \quad 1 \leqslant a \leqslant m,$$

that is, Z^a is the gradient of the 1-form μ^a. Thus, $\mathcal{D}^\perp = \langle Z^a \rangle$, $1 \leqslant a \leqslant m$. In local coordinates, we have

$$Z^a = g^{ij}\mu_i^a \frac{\partial}{\partial q^j}.$$

By using the metric g and the distribution $\mathcal{D}$ we can obtain two complementary projectors

$$\mathcal{P}: TQ \to \mathcal{D},$$

$$\mathcal{Q}: TQ \to \mathcal{D}^\perp,$$

with respect to g. The projector $\mathcal{Q}$ is locally described by

$$\mathcal{Q} = C_{ab} Z^a \otimes \mu^b.$$

Using these projectors we can obtain the equations of motion as follows. A curve $c(t)$ is a motion for the nonholonomic system if it satisfies the constraints, say, $\phi^a(\dot{c}(t)) = 0$, for all a, and, in addition, the "projected equation of motion,"

$$\mathcal{P}(\nabla_{\dot{c}(t)}\ \dot{c}(t)) = -\mathcal{P}(\operatorname{grad} V(c(t))) \tag{29}$$

is fulfilled. But these conditions are equivalent to

$$\dot{c}(t) \in \mathcal{D}_{c(t)}, \quad \overline{\nabla}_{\dot{c}(t)}\dot{c}(t) = -\mathcal{P}(\operatorname{grad} V(c(t))),$$

where $\overline{\nabla}$ is the modified linear connection defined by

$$\overline{\nabla}_X Y = \nabla_X Y + (\nabla_X \mathcal{Q})(Y)$$

for all vector fields X and Y on Q.

Since the constraints are linear then, from (14)

$$-\mu_i^a(q_0)g^{ij}(q_0)\frac{\partial S^h}{\partial q_0^j}(q_0,q_1)+\mu_i^a(q_0)g^{ij}(q_0)\int_0^h\tilde{\Lambda}(q(t),\dot{q}(t))\frac{\partial q}{\partial q_0^j}=0,\quad 1\leqslant a\leqslant m,\quad (30)$$

or, in terms of projectors,

$$\mathcal{Q}_{|q_0}(D_1S^h(q_0,q_1)))=\mathcal{Q}_{|q_0}\left(D_1\int_0^h\tilde{\Lambda}(q(t),\dot{q}(t))\right).\quad (31)$$

Moreover, the dynamics preserves the constraints Ψ^a which implies that

$$\Psi^a\left(q_1,\frac{\partial S^h}{\partial q_1}(q_0,q_1)-\int_0^h\tilde{\Lambda}(q(t),\dot{q}(t))\frac{\partial q}{\partial q_1}\right)=0,$$

or, in other words,

$$\mathcal{Q}_{|q_1}(D_2S^h(q_0,q_1))=\mathcal{Q}_{|q_1}\left(D_2\int_0^h\tilde{\Lambda}(q(t),\dot{q}(t))\right).\quad (32)$$

Therefore, Eqs. (31) and (32) show that the preservation of the exact constraints is equivalent to give a prescription about the relationship between the ''generating function'' and the constraint forces.

Thus, Eq. (15),

$$D_2S^h(q_{k-1},q_k)+D_1S^h(q_k,q_{k+1})=\int_0^h\tilde{\Lambda}(q(t),\dot{q}(t))\frac{\partial q}{\partial q_1}+\int_h^{2h}\tilde{\Lambda}(q(t),\dot{q}(t))\frac{\partial q}{\partial q_0},$$

can be rewritten using expression (32) as follows:

$$\mathcal{P}_{|q_k}(D_2S^h(q_{k-1},q_k))+D_1S^h(q_k,q_{k+1})=\mathcal{P}_{|q_k}\left(\int_0^h\tilde{\Lambda}(q(t),\dot{q}(t))\frac{\partial q}{\partial q_1}\right)+\int_h^{2h}\tilde{\Lambda}(q(t),\dot{q}(t))\frac{\partial q}{\partial q_0}.\quad (33)$$

Now, considering an approximated generating function $\tilde{S}^h$ and an approximate constraint force $\alpha^h=\alpha_0^h(q_0,q_1)\,dq_0+\alpha_1^h(q_0,q_1)\,dq_1$, as in Remark 3.2, from the previous discussion, we now substitute the approximated constraint force by

$$\tilde{\alpha}^h=\alpha_0^h(q_0,q_1)\,dq_0+\mathcal{P}_{|q_1}(\alpha_1^h(q_0,q_1)\,dq_1)+\mathcal{Q}_{|q_1}(D_2\tilde{S}^h(q_0,q_1))).$$

Therefore for $\tilde{S}^h$ and $\tilde{\alpha}^h$, Eqs. (21) are rewritten as

$$\mathcal{P}_{|q_k}(D_2\tilde{S}^h(q_{k-1},q_k))+D_1\tilde{S}^h(q_k,q_{k+1})=\mathcal{P}_{|q_k}(\alpha_1^h(q_{k-1},q_k))+\alpha_0^h(q_k,q_{k+1}),\quad (34)$$

for $1\leqslant k\leqslant N-1$. The importance of Eq. (34) is that they generate an algorithm which automaticaly preserves the exact constraint functions Ψ^a. In fact, if we apply the projector $\mathcal{Q}$ to Eq. (34) we obtain

$$\mathcal{Q}_{|q_k}(D_1S^h(q_k,q_{k+1}))=\mathcal{Q}_{|q_k}(\alpha_0^h(q_k,q_{k+1}))\quad (35)$$

or

$$\tilde{\varphi}^a(q_k,q_{k+1},h)=\Psi^a\left(q_k,-\frac{\partial\tilde{S}^h}{\partial q_0}(q_k,q_{k+1})+\alpha_0^h(q_k,q_{k+1})\right)=0,$$

that is, the constraints are satisfied.

Therefore the geometric algorithm that we have obtained work as follows:

$$\mathcal{P}_{|q_k}(D_2\tilde{S}^h(q_{k-1},q_k))+D_1\tilde{S}^h(q_k,q_{k+1})=\mathcal{P}_{|q_k}(\alpha_1^h(q_{k-1},q_k))+\alpha_0^h(q_k,q_{k+1}),$$

with initial condition satisfying:

$$\tilde{\varphi}^a(q_0,q_1,h)=0.$$

Choosing α_0^h and α_1^h in $\mathcal{D}^0$, we obtain equations for nonholonomic integrators with more geometric flavor:

Geometric nonholonomic integrator:

$$\mathcal{P}_{|q_k}(D_2\tilde{S}^h(q_{k-1},q_k)+D_1\tilde{S}^h(q_k,q_{k+1}))=0 \tag{36}$$

which is interpreted as a discretization of Eq. (29),

$$\overline{\nabla}_{\dot{c}(t)}\dot{c}(t)=-\mathcal{P}(\mathrm{grad}\,(V(c(t)))).$$

In a future work we will study from numerical and geometrical points of view this particular subclass of geometric integrators.

Nonholonomic integrators preserving constraints: For the class of integrators introduced in Sec. IV, we find the following family of nonholonomic integrators preserving constraints:

$$\begin{aligned}\mathcal{P}_{|q_k}(D_2S_\alpha^h(q_{k-1},q_k))+D_1S_\alpha^h(q_k,q_{k+1})=\alpha h\mathcal{P}_{|q_k}&\left(\tilde{\Lambda}\left((1-\alpha)q_{k-1}+\alpha q_k,\frac{q_k-q_{k-1}}{h}\right)\right)\\&+(1-\alpha)h\tilde{\Lambda}\left((1-\alpha)q_k+\alpha q_{k+1},\frac{q_{k+1}-q_k}{h}\right),\\&1\leqslant k\leqslant N-1\ ,\end{aligned}$$

with initial conditions satisfying

$$-\mu_i^a(q_0)g^{ij}(q_0)\frac{\partial S_\alpha^h}{\partial q_0^j}(q_0,q_1)+(1-\alpha)h\mu_i^a(q_0)g^{ij}(q_0)\tilde{\Lambda}_j\left((1-\alpha)q_0+\alpha q_1,\frac{q_1-q_0}{h}\right)=0.$$

Example 5.1 (The nonholonomic particle revisited): Constructing the previous algorithm for the nonholonomic particle, we obtain the following preserving constraint integrator:

$$\frac{1}{1+y_1^2}\left(\frac{x_1-x_0}{h}-h\frac{x_1+x_0}{2}\right)-\frac{x_2-x_1}{h}-h\frac{x_2+x_1}{2}+\frac{y_1}{1+y_1^2}\left(\frac{z_1-z_0}{h}\right)$$

$$=-\frac{h}{2}\left[\frac{\frac{1}{1+y_1^2}\cdot\frac{(x_1+x_0)(y_1+y_0)}{2}-\frac{(x_1-x_0)(y_1-y_0)}{h^2}}{1+\left(\frac{y_1+y_0}{2}\right)^2}\cdot\frac{y_1+y_0}{2}\right.$$

$$+\frac{\frac{(x_2+x_1)(y_2+y_1)}{2}-\frac{(x_2-x_1)(y_2-y_1)}{h^2}}{1+\left(\frac{y_2+y_1}{2}\right)^2}\cdot\frac{y_2+y_1}{2}$$

$$\left.-\frac{y_1}{1+y_1^2}\frac{\frac{(x_1+x_0)(y_1+y_0)}{2}-\frac{(x_1-x_0)(y_1-y_0)}{h^2}}{1+\left(\frac{y_1+y_0}{2}\right)^2}\right]\frac{y_1-y_0}{h}$$

$$-h\frac{y_1+y_0}{2}-\frac{y_2-y_1}{h}-h\frac{y_2+y_1}{2}=0,$$

$$\frac{y_1^2}{1+y_1^2}\left(\frac{z_1-z_0}{h}\right)-\frac{z_2-z_1}{h}+\frac{y_1}{1+y_1^2}\left(\frac{x_1-x_0}{h}-h\frac{x_1+x_0}{2}\right)$$

$$=\frac{h}{2}\left[\frac{y_1^2}{1+y_1^2}\frac{\frac{(x_1+x_0)(y_1+y_0)}{2}-\frac{(x_1-x_0)(y_1-y_0)}{h^2}}{1+\left(\frac{y_1+y_0}{2}\right)^2}+\frac{\frac{(x_2+x_1)(y_2+y_1)}{2}-\frac{(x_2-x_1)(y_2-y_1)}{h^2}}{1+\left(\frac{y_2+y_1}{2}\right)^2}\right.$$

$$\left.-\frac{y_1}{1+y_1^2}\frac{\frac{(x_1+x_0)(y_1+y_0)}{2}-\frac{(x_1-x_0)(y_1-y_0)}{h^2}}{1+\left(\frac{y_1+y_0}{2}\right)^2}\cdot\frac{y_1+y_0}{2}\right]$$

with initial conditions satisfying (see Fig. 4)

$$\tilde{\varphi}^a(x_0,y_0,z_0,x_1,y_1,z_1,h)$$

$$=-\frac{z_1-z_0}{h}-\frac{h}{2}\frac{\frac{(x_1+x_0)(y_1+y_0)}{2}-\frac{(x_1-x_0)(y_1-y_0)}{h^2}}{1+\left(\frac{y_1+y_0}{2}\right)^2}$$

$$+y_0\left[\frac{x_1-x_0}{h}+h\frac{x_1+x_0}{2}-\frac{h}{2}\frac{\frac{(x_1+x_0)(y_1+y_0)}{2}-\frac{(x_1-x_0)(y_1-y_0)}{h^2}}{1+\left(\frac{y_1+y_0}{2}\right)^2}\cdot\frac{y_1+y_0}{2}\right].$$

Remark 5.2: In numerical analysis, an approach to the numerical solution of differential equations is by projecting into a subset of invariants. These projection techniques do not deteriorate the convergence order of the method but they can, in some cases, destroy the good long-time behavior of the solution. However a different behavior arises in the projection techniques that we have constructed in this section.

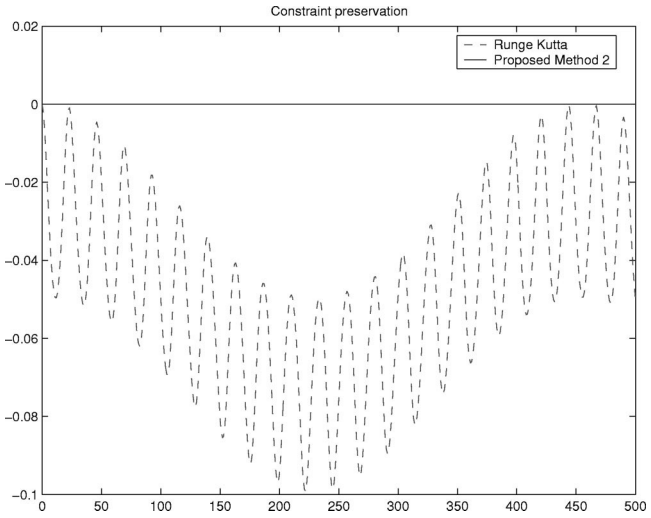

FIG. 4. For the same initial conditions and data, the graph shows the exact preservation of the constraint function evolution with time of our algorithm.

Observe that a remarkable feature of nonholonomic systems is the nonpreservation of the symplectic form, therefore its flow does not act as symplectic transformations; in a geometric way

$$L_{X_{H,M}}\omega_Q = d\Lambda \neq 0.$$

In Sec. III, we have generated integrators verifying a discrete version of the previous equation. The use of projection techniques are adequate in this case, since we *recover* the geometrical properties of the nonholonomic system.

In the continuous setting it is well known, for instance, in Ref. 30, how to obtain the solution of nonholonomic systems from the free dynamics using projection techniques. Also, projection techniques are used in a Riemannian setting, modifying the Levi–Civita connection to obtain an affine connection which gives as the correct dynamics (see Ref. 11 and references therein). This is the main idea of Sec. V, where we show that projection techniques are useful for nonholonomic systems. Observe, for instance, the integrator proposed in (36). We take a variational integrator and then symplectic (a bad property for a nonholonomic integrator), and projecting orthogonally the discrete Euler–Lagrange equations, we obtain a nonholonomic integrator.

VI. CONCLUSION

A new numerical algorithm has been proposed for nonholonomic mechanics. This algorithm is based in the underlying geometry of nonholonomic systems. For mechanical systems with linear constraints, a geometric integrator preserving constraints is proposed.

In future work, we will explore reduction schemes for discrete systems using the approach of generating functions. It is also interesting to use generating functions of different kinds; in a recent work,[32] we have shown that generating functions of second class generate algorithms which are symplectic (in some sense) for discrete optimal control theory (see also Ref. 33). Moreover, we may easily extend the generating function technique in order to consider variable time stepping and also the time-dependent case and it would be possible to use this formalism for classical field theories.

(Received 20 May 2003; accepted 1 December 2003)

In this paper we investigate the Suslov problem in the case when the vector of nonholonomic constraint coincides with the third principal axis of the body, and the fixed point of the body lies in the principal plane defined by the third and the first principal axes but is out of these axes. We called this version of the Suslov problem the generalized Kozlov case, and we prove that in this case a third real meromorphic first integral functionally independent together with the energy and geometrical integrals does not exist. © *2004 American Institute of Physics.*

I. INTRODUCTION

Let us consider the rotational motion of a rigid body around a fixed point O in a constant gravity field. The motion of the body is restricted by one nonholonomic constraint $\langle \mathbf{a},\boldsymbol{\omega}\rangle=0$, where $\boldsymbol{\omega}=(\omega_1,\omega_2,\omega_3)$ is the body angular velocity and $\mathbf{a}$ is a vector fixed in the body. Here and below all vectors are taken with respect to the principal axes reference frame, and $\langle\cdot,\cdot\rangle$ denotes the standard scalar product. This is the formulation of the classical Suslov problem[30] which is one of the most famous problems in nonholonomic mechanics. Equations of motion of the Suslov problem have the following form:

$$\begin{aligned} \mathbb{I}\dot{\boldsymbol{\omega}}&=\mathbb{I}\boldsymbol{\omega}\times\boldsymbol{\omega}+\epsilon\boldsymbol{\gamma}\times\mathbf{b}+\lambda\mathbf{a},\\ \dot{\boldsymbol{\gamma}}&=\boldsymbol{\gamma}\times\boldsymbol{\omega},\quad \langle\mathbf{a},\boldsymbol{\omega}\rangle=0, \end{aligned} \tag{1}$$

where λ is the Lagrange multiplier, $\mathbb{I}=\mathrm{diag}(I_1,I_2,I_3)$ is the matrix of inertia of the body; ϵ is the product of the mass of the body, the gravity constant and the distance between point O and the mass center of the body; vectors $\boldsymbol{\gamma}=(\gamma_1,\gamma_2,\gamma_3)$ and $\mathbf{b}=(b_1,b_2,b_3)$ are the unit vertical vector and the unit vector along the line connecting point O with the center of mass of the body, respectively.

In this paper we assume that vector $\mathbf{a}$ coincides with one of the principal axes, and, without loss of generality, we can choose it as the third axis, i.e., $\mathbf{a}=(0,0,1)$. For such choice equations (1) read

$$\begin{aligned} I_1\dot{\omega}_1&=\epsilon(\gamma_2 b_3-\gamma_3 b_2),\\ I_2\dot{\omega}_2&=\epsilon(\gamma_3 b_1-\gamma_1 b_3),\\ \dot{\gamma}_1&=-\omega_2\gamma_3, \end{aligned} \tag{2}$$

a)Electronic mail: maciejka@astro.ia.uz.zgora.pl
b)Electronic mail: Maria.Przybylska@sophia.inria.fr; Maria.Przybylska@astri.uni.torun.pl

$$\dot{\gamma}_2 = \omega_1 \gamma_3,$$

$$\dot{\gamma}_3 = \omega_2 \gamma_1 - \omega_1 \gamma_2.$$

The above system has two independent first integrals

$$\mathcal{I}_1 = \tfrac{1}{2}(I_1\omega_1^2 + I_2\omega_2^2) + \epsilon\langle \mathbf{b}, \boldsymbol{\gamma}\rangle, \quad \mathcal{I}_2 = \langle \boldsymbol{\gamma}, \boldsymbol{\gamma}\rangle.$$

Additionally, the above mentioned choice of **a** guarantees that the phase flow of system (2) preserves the standard measure in $\mathbb{R}^5 = \mathbb{R}^2\{\omega_1, \omega_2\} \times \mathbb{R}^3\{\boldsymbol{\gamma}\}$, see Refs. 13 and 14. Thus, by the theorem of Jacobi about the last multiplier,[8] if there exists a third independent first integral $\mathcal{I}_3$ which is functionally independent together with $\mathcal{I}_1$ and $\mathcal{I}_2$, then the Suslov problem is integrable by quadratures.

The known integrable cases of system (2) are the following:

(1) the Suslov case,[30] where $\epsilon = 0$, then $\mathcal{I}_3 = \omega_1$;
(2) the Kharlamova–Zabelina case,[11] where $\langle \mathbf{b}, \mathbf{a}\rangle = 0$. The third first integral is $\mathcal{I}_3 = I_1\omega_1 b_1 + I_2\omega_2 b_2$;
(3) the Kozlov case, where **b** is parallel to **a** and $I_1 = I_2$, then $\mathcal{I}_3 = \omega_1\gamma_1 + \omega_2\gamma_2$.

In what follows we study cases when $\epsilon \neq 0$, and, without loss of generality, we can put $\epsilon = 1$.

For the case when **b** is parallel to **a** Kozlov[13,14] reduced equations (2) to a Hamiltonian system with two degrees of freedom. The Hamiltonian function of this system is the following:

$$H = \frac{1}{2}(p_1^2 + p_2^2) + \frac{1}{2}\left[h - \frac{1}{2}\left(\frac{q_1^2}{I_1} + \frac{q_2^2}{I_2}\right)\right]^2, \tag{3}$$

where $q_1 = I_1\omega_1$ and $q_2 = I_2\omega_2$. It depends on parameter h which is the fixed energy value of the original problem. The integrability of the Hamiltonian system generated by (3) was investigated by Ziglin in Ref. 37 where he proved the following two theorems.

Theorem 1: *If $h \neq 0$ and $I_1 \neq I_2$, then the Hamiltonian system given by (3) has no additional complex meromorphic first integral in the complexified phase space.*

Theorem 2: *If $h = 0$ and*

(1) $\eta \neq r$, or

(2) $\sqrt{2}\cos(\pi\eta) \neq \cos(\pi r)$, where $\eta = \sqrt{1 + 8\alpha}/4$, $\alpha = I_1/I_2$, and r is rational,

then the system with Hamiltonian (3) has no additional complex meromorphic first integral in the neighborhood of the origin of coordinates.

Using these results, in Ref. 39 Ziglin showed that

Theorem 3: *If $b_1 = b_2 = 0$, then the Suslov system (2) has an additional complex meromorphic first integral only in the case $I_1 = I_2$.*

In the above theorem it is assumed that the complexified phase space of system (2) is $M^4 = \mathbb{C}^2 \times \mathbb{S}^2_{\mathbb{C}}$, where $\mathbb{S}^2_{\mathbb{C}}$ is the complex Poisson sphere

$$\mathbb{S}^2_{\mathbb{C}} = \{(\gamma_1, \gamma_2, \gamma_3) \in \mathbb{C}^3 \,|\, \gamma_1^2 + \gamma_2^2 + \gamma_3^2 = 1\}.$$

In Ref. 16 we proved that in the cases 1 and 2 excluded in Theorem 2 the system is also nonintegrable. Finally, in Ref. 38, Ziglin proved the following:

Theorem 4: *If $b_1 = b_2 = 0$, then the Suslov system (2) has an additional real meromorphic first integral only in the case $I_1 = I_2$.*

Ziglin obtained results formulated in Theorems 1–3 applying his theory formulated in two fundamental papers.[35,36] The main idea of his approach lies in a study of the monodromy group of variational equations for a particular nonequilibrium solution. In our improvement of the Ziglin result given by Theorem 2 we applied the differential Galois extension of the Ziglin theory developed by Morales-Ruiz and Ramis (see Refs. 20, 23, 24). In this approach the monodromy

group is replaced by the differential Galois group of the variational equations. Both the Ziglin and Morales-Ramis theories are specified for Hamiltonian systems. However, the main ideas of both of them are valid for general systems. In fact, Ziglin proved Theorem 2 using this ''non-Hamiltonian'' part of his theory.

In this paper we consider a case when vector **b** is not parallel or perpendicular to vector **a**. More precisely, we assume that $b_2=0$ but $b_1b_3\neq 0$, in other words, the vector of nonholonomic constraint coincides with the third principal axis of the body, and the fixed point of the body lies in the principal plane defined by the third and the first principal axes and is out of them. We called this version of the Suslov problem the generalized Kozlov case and our aim is to prove its nonintegrability. Our main result is the following:

Theorem 5: *If $b_2=0$ and $b_1b_3\neq 0$, then system (2) does not possess a real meromorphic first integral which is functionally independent together with $\mathcal{I}_1$ and $\mathcal{I}_2$.*

Let us notice that in the above theorem, as in Theorem 4, we talk about the nonexistence of a *real* first integral. Using Ziglin or Morales-Ramis theory we are able to prove the nonexistence of a *complex* meromorphic first integral. To show the nonexistence of a real meromorphic first integral we need to investigate variational equations along one parameter family of particular solutions for which the corresponding Riemann surfaces depend on the parameter values in a prescribed way. The key point is to show that in an *arbitrary* complex neighborhood of the real phase space the system does not admit an additional meromorphic first integral, and for this purpose a family of particular solutions is needed. These ideas were applied by Ziglin[38] in his proof of Theorem 4. In this proof the crucial role plays the fact that, in the Kozlov case, the Suslov problem admits *two* families of particular solutions. In the generalized Kozlov case considered in this paper, the system depends on two parameters, and there exists only one family of particular solutions (see Sec. III). This makes the problem difficult. In our proof of Theorem 5 we combine ideas of Ziglin[38] with the differential Galois approach.

Our interest in the Suslov problem is motivated by the fact that, recently, nonholonomic systems attracted attention of many investigators, see, e.g., Refs. 15, 2, 18, 5, 34. The dynamics of nonholonomic systems differs in many respects from the dynamics of the holonomic ones. Let us mention only that for nonholonomic systems we have no widely accepted notion of integrability as it is the case for Hamiltonian systems, see Refs. 13, 7, 19. Investigations of known integrable cases of the generalized Suslov problem[25,1,26] showed that for generic values of first integrals invariant manifolds defined by their common level have genus higher than one. Thus a global view of an integrable nonholonomic system is different from the familiar image of an integrable Hamiltonian system when the phase space is foliated by invariant tori. We also remark that several generalizations of the Suslov problem to higher dimensions were proposed recently, see Refs. 9, 33.

The plan of this paper is following. In the next section we describe basic facts from the Ziglin and differential Galois theory which are needed to understand the proof of our main result. In Sec. III we derive a family of particular solutions of the system and variational equations around them. Finally, in Sec. IV, we present a proof of Theorem 5.

II. THEORY

Below we describe only basic notions and facts concerning the Ziglin theory following[35] in our exposition. A more detailed and formal presentation can be found in Ref. 3. Let M be a complex n-dimensional manifold. We consider a system of differential equations

$$\frac{\mathrm{d}}{\mathrm{d}t}x=v(x),\quad t\in\mathbb{C},\quad x\in M. \tag{4}$$

If $\varphi(t)$ is a nonequilibrium solution of (4) passing through $p\in M$, i.e., $\varphi(0)=p$, then the maximal analytic continuation of $\varphi(t)$ defines a Riemann surface Γ with t as a local coordinate. More formally it can be described as follows. The map $(t,q)\to\Phi_t(q)$, where $\Phi_t(q)$ is the solution of (4) passing through $q\in M$, is defined in a certain neighborhood $\mathcal{U}\times V$ of $(0,p)\in\mathbb{C}\times M$. Then Γ is the

component of p in the topology on M defined by the basis given by the sets $\{\Phi_t(p)|t\in\mathcal{U}\}$. The natural inclusion $i:\Gamma\to M$ is an immersion but not necessarily a proper map. Thus, using a global language it is necessary to distinguish Γ and $i(\Gamma)\subset M$.

Together with system (4) we also consider variational equations restricted to $T_\Gamma M$, i.e.,

$$\dot{\xi}=T(v)\xi, \quad \xi\in T_\Gamma M. \tag{5}$$

We can reduce the order of this system by one. Let $N:=T_\Gamma M/T\Gamma$ be the normal bundle of Γ, and π: $T_\Gamma M\to N$ be the projection. Then system (5) induces the following system on *N:*

$$\dot{\eta}=\pi_\star(T(v)\pi^{-1}\eta), \quad \eta\in N, \tag{6}$$

which is called the normal variational equations along Γ.

Assume now that f is a holomorphic first integral of Eqs. (4) defined in a neighborhood of Γ. By $[f]_p$ we denote the first nonconstant homogeneous term in the Taylor expansion of f at the point $p\in\Gamma$. We called it the leading part of f. Although to define $[f]_p$ we have to use local coordinates, it is a well defined homogeneous polynomial function on T_pM. Moreover, the degree of $[f]_p$ does not depend on $p\in\Gamma$. Such function $[f]$ defined on $T_\Gamma M$ is a holomorphic first integral of variational equations (5) which is a polynomial with respect to fibers variables. If f is a meromorphic first integral of (4), then we define $[f]_p$ in the following way. As f is meromorphic, we can write $f=a/b$, where a and b are holomorphic, and then we put $[f]_p=[a]_p/[b]_p$. This defines correctly a rational function on T_pM and a rational (with respect to fibers variables) first integral $[f]$ of (5). If $[f]$ is a first integral of (5), then $[f]\circ\pi^{-1}$ is a first integral of (6). For details, see Refs. 36, 20, 3.

If we know that system (4) possesses holomorphic first integrals $H=(H_1,\ldots,H_k)$ in a neighborhood of Γ such that their differentials $\mathrm{d}H_i$, $i=1,...,k$ are linearly independent on Γ, then $\mathrm{d}H_i\circ\pi^{-1}$ for $i=1,...,k$ are independent first integrals of (6). Their common zero level

$$N_0:=\{\eta\in N|\mathrm{d}H_i\circ\pi^{-1}\eta=0,\ i=1,...,k\},$$

defines a m-dimensional linear bundle over Γ, where $m=n-k-1$. Using these integrals we can reduce the order of system (6). Namely, we consider the reduced normal variational equations

$$\dot{\eta}=\pi_\star(T(v)\pi^{-1}\eta), \quad \eta\in N_0. \tag{7}$$

The monodromy group $\mathcal{M}$ of this system is the image of the fundamental group $\pi_1(\Gamma,t_0)$ obtained in the process of continuation of local solutions defined in a neighborhood of t_0 along closed paths with the base point t_0. In our case it is a subgroup of $\mathrm{GL}(m,\mathbb{C})$. If we fix the set of m linearly independent solutions of (7) then group $\mathcal{M}$ is a matrix group acting naturally on m vector space of variables $Z=(z_1,\ldots,z_m)$. Thus, it acts also on the ring of polynomials $\mathbb{C}[Z]$ and on the field of fractions $\mathbb{C}(Z)$. By $L:=\mathbb{C}(Z)^{\mathcal{M}}$ we denote the field of invariants of this action. We can consider $\mathbb{C}\subset L$ as a field extension. For an integer r, $1\leqslant r\leqslant m$, we say that $\mathcal{M}$ is r-Ziglin or exactly r-Ziglin, if the $\mathrm{transdeg}_{\mathbb{C}}L\geqslant r$ or $\mathrm{transdeg}_{\mathbb{C}}L=r$, respectively; here $\mathrm{transdeg}_{\mathbb{C}}L$ denotes the transcendence degree of field extension $\mathbb{C}\subset L$. The following lemma formulated by Ziglin gives the necessary condition for integrability, see Proposition on p. 183 in Ref. 35 and Proposition on p. 4 in Ref. 38.

Lemma 1: If system (4) possesses a meromorphic first integral which is functionally independent together with H and defined in a neighborhood $\mathcal{U}\subset M$ such that the fundamental group of Γ is generated by loops lying in $\mathcal{U}$ then, the monodromy group $\mathcal{M}$ of the reduced normal variational equations (7) is 1-Ziglin.

Thus, under assumptions of the above lemma the monodromy group possesses at least one nonconstant rational invariant function, which in the Ziglin nomenclature is called a first integral of the monodromy group. Here it is important to notice that the existence of the rational invariant mentioned in the above lemma is related to the fact that from the existence of a meromorphic first

integral for system (4) follows the existence of a rational first integral (with respect to fibres variables) of variational equations, and this integral must be constant along an arbitrary continuation of a local solution of variational equations.

Having a linear system (6) we can apply for its study also the differential Galois theory. For a general introduction to this theory, see Refs. 27, 10, 4, 17. Here we only describe basic notions of this theory and we refer the reader to the cited papers for a fully detailed exposition.

Let F be a differential field of characteristic zero, i.e., a field with an additive operation $'$: $F\to F$, called derivation, satisfying the Leibniz rule. For example, $F=\mathbb{C}(z)$ with derivation being the standard differentiating d/dz. The kernel of the derivation is a subfield of F called the subfield of constants and we denote it by F'. We assume that it is algebraically closed. When $F\subset L$ is a field extension, and L is a differential field, then we call it a differential field extension if the derivation on L restricted to F coincides with that of F. An automorphism σ: $L\to L$ is called a differential automorphism if it commutes with the derivation on L. The differential Galois group $\mathcal{G}(L/F)$ of a differential field extension $F\subset L$ is a subgroup of differential automorphisms σ: $L\to L$ for which $\sigma_{|F}=\mathrm{id}_F$.

Let us consider the following system of linear equations

$$x'=Ax, \tag{8}$$

where A is an $n\times n$ matrix with elements in F, and $x=[x_1,\ldots,x_n]^T$ is a vector of length n. If x is a solution of the above system, then usually its components x_i for $i=1,\ldots,n$ are not elements of F and belong to a certain differential extension of F. A differential extension field L of F is called a Picard–Vessiot extension associated with (8) if it is generated by n linearly independent over F' solutions $x^{(i)}\in L^n$, $i=1,\ldots,n$ of (8) and the field of constants of L coincides with F'. It can be shown that a Picard–Vessiot extension exists and it is unique up to the differential isomorphism. The differential Galois group of (8) is the differential Galois group $\mathcal{G}(L/F)$ of the Picard–Vessiot extension $F\subset L$ associated with (8). It can be shown that the differential Galois group of (8) is an algebraic subgroup of $\mathrm{GL}(n,F')$.

Now, we can return to Eq. (7). Let $\mathcal{G}$ denote its differential Galois group. It is an algebraic subgroup of $\mathrm{GL}(n-k-1,\mathbb{C})$. Group $\mathcal{G}$ is "bigger" than the monodromy group and it contains $\mathcal{M}$, see Theorem 2.4 in Ref. 20. For a Fuchsian system the monodromy group is dense in $\mathcal{G}$ (in the Zariski topology), see Theorem 3.16 in Ref. 3.

As we mentioned above, if system (4) possesses a meromorphic first integral, then (7) has a first integral and this fact imposes a restriction on $\mathcal{G}$. In fact, we have a lemma which is analogous to Lemma 1.

Lemma 2: If system (4) possesses a meromorphic first integral which is functionally independent together with H and defined in a neighborhood $\mathcal{U}\subset M$ of Γ, then the differential Galois group $\mathcal{G}$ of the reduced normal variational Eqs. (7) is 1-Ziglin.

The above lemma is a variant of Lemma 4.6 in Ref. 20 adopted for a general situation.

Remark 1: In Refs. 36 and 38 instead of common zero level of first integrals $\mathrm{d}H_i\circ\pi^{-1}$ Ziglin considered an arbitrary level

$$N_p:=\{\eta\in F\,|\,\mathrm{d}H_i\circ\pi^{-1}\eta=p_i,\ \ p_i\in\mathbb{C},\ \ i=1,\ldots,k\}.$$

Then, instead of a linear, we have an affine bundle over Γ, Eqs. (7) are generally not homogeneous ones, and the monodromy group is a subgroup of affine transformations in dimension m. Until now this construction has not been translated to the differential algebra language. In the proof of nonintegrability of the Goryachev–Chaplygin case of the heavy top, it was necessary to consider N_p with $p\neq 0$, see Ref. 38. Thus, it seems that this extension is important in applications.

In our considerations given in the last section we use some facts concerning the differential Galois group of a second order differential equation of the following form:

$$y''=ry,\quad r\in\mathbb{C}(z),\quad '\equiv\frac{\mathrm{d}}{\mathrm{d}z}. \tag{9}$$

For this equation $\mathcal{G}$ is an algebraic subgroup of $\mathrm{SL}(2,\mathbb{C})$. The following lemma describes all possible types of $\mathcal{G}$ and relates these types to forms of solution of (9), see Refs. 12, 20.

Lemma 3: Let $\mathcal{G}$ be the differential Galois group of Eq. (9). Then one of four cases can occur.

(1) $\mathcal{G}$ is triangulizable; in this case Eq. (9) has a solution of the form $y=\exp\int\omega$, where $\omega\in\mathbb{C}(z)$;
(2) $\mathcal{G}$ is conjugated with a subgroup of

$$D^{\dagger}=\left\{\left[\begin{array}{cc} c & 0 \\ 0 & c^{-1}\end{array}\right]\middle| c\in\mathbb{C}^*\right\}\cup\left\{\left[\begin{array}{cc} 0 & c \\ c^{-1} & 0\end{array}\right]\middle| c\in\mathbb{C}^*\right\},$$

in this case Eq. (9) has a solution of the form $y=\exp\int\omega$, where ω is algebraic over $\mathbb{C}(z)$ of degree 2;
(3) $\mathcal{G}$ is primitive and finite; in this case all solutions of Eq. (9) are algebraic;
(4) $\mathcal{G}=\mathrm{SL}(2,\mathbb{C})$ and Eq. (9) has no Liouvillian solution.

For a definition of Liouvillian solution see, e.g., Ref. 12. We need a more precise characterization of case 1 in the above lemma. It is given by the following lemma, see Lemma 4.2 in Ref. 28.

Lemma 4: Let $\mathcal{G}$ be the differential Galois group of Eq. (9) and assume that $\mathcal{G}$ is triangulizable. Then, either

(1) Eq. (9) has a unique solution y such that $y'/y\in\mathbb{C}(z)$, and $\mathcal{G}$ is conjugate to a subgroup of the triangular group

$$\mathcal{T}=\left\{\left[\begin{array}{cc} a & b \\ 0 & a^{-1}\end{array}\right]\middle| a,b\in\mathbb{C},a\neq 0\right\}.$$

Moreover, $\mathcal{G}$ is a proper subgroup of $\mathcal{T}$ if and only if there exists $m\in\mathbb{N}$ such that $y^m\in\mathbb{C}(z)$. In this case $\mathcal{G}$ is conjugate to

$$\mathcal{T}_m=\left\{\left[\begin{array}{cc} a & b \\ 0 & a^{-1}\end{array}\right]\middle| a,b\in\mathbb{C},a^m=1\right\},$$

where m is the smallest positive integer such that $y^m\in\mathbb{C}(z)$, or
(2) Eq. (9) has two linearly independent solutions y_1 and y_2 such that $y_i'/y_i\in\mathbb{C}(z)$, then $\mathcal{G}$ is conjugate to a subgroup of

$$\mathcal{D}=\left\{\left[\begin{array}{cc} a & 0 \\ 0 & a^{-1}\end{array}\right]\middle| a\in\mathbb{C},a\neq 0\right\}.$$

In this case, $y_1y_2\in\mathbb{C}(z)$. Furthermore, $\mathcal{G}$ is conjugate to a proper subgroup of $\mathcal{D}$ if and only if $y_1^m\in\mathbb{C}(z)$ for some $m\in\mathbb{N}$. In this case $\mathcal{G}$ is a cyclic group of order m where m is the smallest positive integer such that $y_1^m\in\mathbb{C}(z)$.

In case 2 of the above lemma we know that $s=y_1y_2\in\mathbb{C}(z)$. Differentiating s three times, and using the fact that y_i satisfies Eq. (9), we obtain

$$s'''=2r's+4rs'. \tag{10}$$

The above equation is called the second symmetric power of Eq. (9). For applications of symmetric powers of differential operators to study the existence of Liouvillian solutions and differential Galois group see, e.g., Refs. 28, 29, 32.

III. PARTICULAR SOLUTIONS AND VARIATIONAL EQUATIONS

We consider now the complexification of system (2), i.e., we assume that $(\omega_1,\omega_2,\gamma_1,\gamma_2,\gamma_3)\in\mathbb{C}^5$ and $t\in\mathbb{C}$. From now on we put $I_2=1$. This can be achieved without loss of generality by a proper choice of units.

First, let us notice that if $b_2=0$, then the following three-dimensional complex hyperplane:

$$\Pi=\{(\omega_1,\omega_2,\gamma_1,\gamma_2,\gamma_3)\in\mathbb{C}^5|\omega_1=\gamma_2=0\},$$

is invariant with respect to the flow generated by (2). System (2) restricted to Π reads

$$\begin{aligned}\dot{\omega}_2&=\gamma_3 b_1-\gamma_1 b_3,\\ \dot{\gamma}_1&=-\omega_2\gamma_3,\\ \dot{\gamma}_3&=\omega_2\gamma_1,\end{aligned}\tag{11}$$

possesses two first integrals

$$\mathcal{I}_1|_\Pi=\tfrac{1}{2}\omega_2^2+b_1\gamma_1+b_3\gamma_3,\quad \mathcal{I}_2|_\Pi=\gamma_1^2+\gamma_3^2,$$

and can be integrated explicitly. Phase curves $i(\Gamma_E)\subset\Pi\subset\mathbb{C}^5$ of system (2) defined by

$$\tfrac{1}{2}\omega_2^2+b_1\gamma_1+b_3\gamma_3=E,\quad \gamma_1^2+\gamma_3^2=1,\quad (\omega_2,\gamma_1,\gamma_2)\in\Pi=\mathbb{C}^3$$

are algebraic and, as an intersection of two quadrics, they are elliptic curves. For further analysis we choose a one parameter family Γ_k which in time parametrization is given by

$$\varphi_k(t)=(0,\omega_2(t),\gamma_1(t),0,\gamma_3(t)),\tag{12}$$

where

$$\begin{aligned}\omega_2(t)&:=-2k\,\mathrm{cn}(t,k),\\ \gamma_1(t)&:=-[1-2k^2\,\mathrm{sn}^2(t,k)]b_1-2k\,\mathrm{sn}(t,k)\mathrm{dn}(t,k)b_3,\\ \gamma_3(t)&:=-[1-2k^2\,\mathrm{sn}^2(t,k)]b_3+2k\,\mathrm{sn}(t,k)\mathrm{dn}(t,k)b_1,\end{aligned}\tag{13}$$

and

$$k=\sqrt{\frac{1+E}{2}},\quad 0<k<1.$$

In the above formulas $\mathrm{sn}(t,k)$, $\mathrm{cn}(t,k)$, and $\mathrm{dn}(t,k)$ denote the Jacobi elliptic functions of argument t and modulus k. Particular solutions defined by (12) and (13) are single-valued, meromorphic, and double periodic with periods

$$T_1(k)=2K(k)+2iK'(k),\quad T_2(k)=2K(k)-2iK'(k),$$

where $K(k)$ is the complete elliptic integral of the first kind with modulus k, $K'(k):=K(k')$, and $k':=\sqrt{1-k^2}$. In each period cell they have two simple poles at

$$s_1(k)=iK'(k),\quad s_2(k)=-iK'(k)\ \mod\ (T_1(k),T_2(k)).$$

Thus, Riemann surfaces Γ_k are tori with two points removed.

The variational equations along a particular solution $\varphi_k(t)$ have the following form:

$$\frac{\mathrm{d}}{\mathrm{d}t}\begin{bmatrix} o_1 \\ o_2 \\ g_1 \\ g_2 \\ g_3 \end{bmatrix} = \begin{bmatrix} 0 & 0 & 0 & b_3/I_1 & 0 \\ 0 & 0 & -b_3 & 0 & b_1 \\ 0 & -\gamma_3(t) & 0 & 0 & -\omega_2(t) \\ \gamma_3(t) & 0 & 0 & 0 & 0 \\ 0 & \gamma_1(t) & \omega_2(t) & 0 & 0 \end{bmatrix} \begin{bmatrix} o_1 \\ o_2 \\ g_1 \\ g_2 \\ g_3 \end{bmatrix},$$

and they have two first integrals

$$\mathcal{J}_1 = \omega_2(t)o_2 + b_1 g_1 + b_3 g_3, \quad \mathcal{J}_2 = \gamma_1(t)g_1 + \gamma_3(t)g_3.$$

Let us notice that these first integrals do not depend on o_1 and g_2, and this is why we can choose them as coordinates in the fibre over $\varphi_k(t)$ of the reduced phase space. Thus the reduced normal variational equations read

$$\dot{o}_1 = \frac{b_3}{I_1} g_2, \quad \dot{g}_2 = \gamma_3(t)o_1,$$

or simply

$$\ddot{o} = \frac{b_3}{I_1}\gamma_3(t)o, \quad o = o_1. \tag{14}$$

From the form of this equation, we can see that its monodromy group, as well as its differential Galois group, are contained in SL(2,$\mathbb{C}$). Now, in order to apply the differential Galois approach effectively, the crucial point is to transform (14) to an equation with rational coefficients. In other words, we want to transform (14) from Γ_k to the Riemann sphere $\mathbb{CP}^1$. If we make the following mapping:

$$t \to z = \frac{1 + b_1\gamma_1(t) + b_3\gamma_3(t)}{b_1\gamma_3(t) - b_3\gamma_1(t)}, \tag{15}$$

then (14) transforms to

$$o'' + p(z)o' + q(z)o = 0, \quad ' = \frac{\mathrm{d}}{\mathrm{d}z}, \tag{16}$$

where

$$p(z) = \frac{z(1 - 2k'^2(1+z^2))}{(1+z^2)(k^2 - k'^2 z^2)},$$
$$q(z) = -\frac{\alpha b_3(2b_1 z + b_3(z^2-1))}{(1+z^2)^2(k^2 - k'^2 z^2)}, \quad \alpha = \frac{1}{I_1}. \tag{17}$$

We note here that transformation (15) does not change the identity component of (14).

Equation (16) is Fuchsian and it possesses four regular singular points over $\mathbb{CP}^1$

$$z_1 = i, \quad z_2 = -i, \quad z_3 = \frac{k}{k'}, \quad z_4 = -\frac{k}{k'}.$$

It is more convenient to work with the reduced form of (16) which we obtain introducing a new dependent variable w by the following formula:

$$w = o \exp\left[\frac{1}{2}\int_{z_0}^{z} p(s)\mathrm{d}s\right]. \tag{18}$$

As the result, we obtain the following equation:

$$w'' = r(z)w, \quad r(z) = \tfrac{1}{2}p'(z) + \tfrac{1}{4}p(z)^2 - q(z). \tag{19}$$

The partial fraction decomposition of rational function $r(z)$ can be written as

$$r(z) = \sum_{i=1}^{4}\left[\frac{\alpha_i}{(z-z_i)^2} + \frac{\beta_i}{z-z_i}\right], \tag{20}$$

where

$$\alpha_1 = \alpha_2^* = -\tfrac{3}{16} + \tfrac{1}{2}\alpha b_3(b_3 - ib_1),$$

$$\alpha_3 = \alpha_4 = -\tfrac{3}{16},$$

and

$$\beta_1 = \beta_2^* = -\frac{i}{16}(1+4k'^2) + \alpha(b_1 + ib_3)b_3k'^2,$$

$$\beta_3 = \frac{1}{16}\sqrt{\frac{k'}{k}}[(6k^2-1) - 8\alpha b_3((2k^2-1)b_3 + 2k'kb_1)],$$

$$\beta_4 = -\frac{1}{16}\sqrt{\frac{k'}{k}}[(6k^2-1) - 8\alpha b_3((2k^2-1)b_3 - 2k'kb_1)].$$

In the above formulas the star denotes the complex conjugation. It is important to notice that transformation (18) with $p(z)$ given by (17) does not change the identity component of differential Galois group of (16), see Proposition 4.25 in Ref. 3.

IV. PROOF OF THEOREM 5

For Eq. (19) exponents $\rho_i^{\pm}$ at singular points z_i, $i = 1,...,4$ are the following:

$$\rho_i^{\pm} = \tfrac{1}{2}(1 \pm \Delta_i), \quad \Delta_i = \sqrt{1+4\alpha_i}, \quad i = 1,...,4.$$

Let M_i be the local monodromy matrix corresponding to a small circle around singular point z_i, see, e.g., Ref. 28. Then eigenvalues $\lambda_i^{\pm}$ of matrix M_i are given by the following formula:

$$\lambda_k^{\pm} = \exp[2\pi i\rho_k^{\pm}], \quad k = 1,...,4.$$

Let us notice here that when $b_1b_3 \neq 0$, then $\rho_k^{\pm} \notin \mathbb{Q}$ for $k = 1, 2$. Thus, $\lambda_k^{\pm}$ for $k = 1, 2$ are not roots of unity.

First, we show the following:

Lemma 5: If $b_1b_3 \neq 0$, then for $0 < k < 1$ the identity component $\mathcal{G}^0$ of differential Galois group of Eq. (19) is not Abelian.

Proof: From Lemma 3 it follows that $\mathcal{G}^0$ can be Abelian only in the first three cases given in this lemma. We consider them successively.

Assume that $\mathcal{G}$ is conjugate to a subgroup of triangular group $\mathcal{T}$ and that $\mathcal{G}^0$ is Abelian. By Lemma 4 $\mathcal{G}^0$ is Abelian in two cases: either $\mathcal{G}$ is conjugate to a proper subgroup of $\mathcal{T}$, or it is conjugate to a subgroup of the diagonal group $\mathcal{D}$. The first possibility cannot occur. In fact, if it is

so, then all elements g of $\mathcal{G}$ have eigenvalues a and a^{-1} such that $a^m=1$ for some $m\in\mathbb{N}$. We know that local monodromy matrices around singular points belong to $\mathcal{G}$. But we also know that eigenvalues of M_1 and M_2 are not mth roots of unity. Thus this case is impossible. Let us consider the second possibility. It follows from Lemma 4 that in this case there exist two solutions y_1 and y_2 of (19) such that $y_i'/y_i\in\mathbb{C}(z)$, $i=1$, 2, and $s=y_1y_2\in\mathbb{C}(z)$. As we remarked just after formulation of Lemma 4, s satisfies a third order linear differential Eq. (10). We show that this equation in the case considered does not have a rational solution. For $r=r(z)$ given by (20) Eq. (10) is Fuchsian and has the same singular points z_i, $i=1,...,4$, as (19). The infinity is also a regular singular point for Eq. (10). Exponents at singular points are the following:

$$R_i=\{1,1\pm\Delta_i\},\quad i=1,...,4,$$

and the exponents at infinity are $R_\infty=\{-2,-1,0\}$.

Now, let $s=P/Q$, $P,Q\in\mathbb{C}[z]$ be a rational solution of (10). Without loss of generality we can assume that

$$Q=\prod_{i=1}^{K}(z-r_i)^{n_i},\quad n_i\in\mathbb{N}.$$

Then, as it is well known, $r_i\in\{z_1,\ldots,z_4\}$ and $-n_i$ are exponents at r_i. However, in our case there is no singular point at $\mathbb{C}$ with an exponent which is a negative integer. Thus $Q=1$ and $s=P$. Let $N=\deg P$. Then $\rho=-N$ is an exponent at infinity. Hence $\deg P\leqslant 2$. Assume that $\deg P=2$, then from (10) it follows that

$$2r'(z)P+4r(z)P'=0,$$

and thus $(r(z)P^2)'=0$. Consequently, $r(z)=cP^{-2}$ for some $c\in\mathbb{C}$. However, direct calculations show that when $b_1b_3\neq 0$, and $0<k<1$, it is impossible. This excludes the second possibility in case 1 of Lemma 3.

Let us assume that $\mathcal{G}$ is conjugate to a subgroup of $D^\dagger$ (i.e., we have case 2 from Lemma 3). In this case $\mathcal{G}^0$ is Abelian. We show that for Eq. (19) this cannot occur. To this end, we apply case II of the Kovacic algorithm, see p. 18 of Ref. 12. First, we determine auxiliary sets E_i for each singular point. These sets are defined as follows:

$$E_i=\{2,2\pm 2\Delta_i\}\cap\mathbb{Z},\quad i=1,...,4.$$

Thus we have

$$E_1=E_2=\{2\},\quad E_3=E_4=\{1,2,3\}.$$

Additionally, we define $E_\infty=\{0,2,4\}$. Then, according to the Kovacic algorithm, we check if there exists an element $e=(e_\infty,e_1,\ldots,e_4)$ in Cartesian product $E=E_\infty\times E_1\times\cdots\times E_4$ such that the following number

$$d(e)=\frac{1}{2}\left(e_\infty-\sum_{i=1}^{4}e_i\right),$$

is a non-negative integer. However, in our case $d(e)<0$ for all $e\in E$. Thus, $\mathcal{G}$ is not conjugate to a subgroup of $D^\dagger$.

Finally, let us assume that $\mathcal{G}$ is conjugate to a finite imprimitive subgroup of $\mathrm{SL}(2,\mathbb{C})$ (this is case 3 in Lemma 3). However, a necessary condition for this case is that at each singular point exponents are distinct and rational, see Theorem 3.6 in Ref. 29. As we have already mentioned, in our case when $b_1b_3\neq 0$ then $\rho_k^{\pm}\notin\mathbb{Q}$ for $k=1$, 2. Thus, $\mathcal{G}$ cannot conjugate to a finite imprimitive subgroup of $\mathrm{SL}(2,\mathbb{C})$.

In this way, we eliminate all possibilities when $\mathcal{G}^0$ can be Abelian and this ends the proof.□

Using the above lemma we are able to prove the following:

Lemma 6: If $b_1 b_3 \neq 0$, then for $0<k<1$, in an arbitrary neighborhood $\mathcal{U}\in\mathbb{C}^5$ of phase curve Γ_k, the complexified Suslov system (2) does not possess a meromorphic first integral which is functionally independent together with $\mathcal{I}_1$ and $\mathcal{I}_2$.

Proof: Assume that there exists a meromorphic first integral of (2) which is defined in a neighborhood $\mathcal{U}\subset\mathbb{C}^5$ of phase curve Γ_k, and is functionally independent together with $\mathcal{I}_1$ and $\mathcal{I}_2$. Then, according to Lemma 2, the differential Galois group $\mathcal{G}$ of Eq. (14) has a rational invariant. But $\mathcal{G}$ is an algebraic subgroup of SL(2,C) and such groups possess a rational invariant only if $\mathcal{G}^0$ is Abelian, see Example 2.11(b) in Ref. 3. As the identity components of differential Galois group of Eqs. (14), (16), and (19) are the same, $\mathcal{G}^0$ of (19) is Abelian. However, in Lemma 5 we proved that $\mathcal{G}^0$ for this equation is not Abelian. The contradiction finishes the proof. □

Point $x_0=(0,0,b_1,0,b_3)\in\Pi$ is a hyperbolic equilibrium of system (2). The phase curve Γ_1 corresponds to solution (13) with $k=1$. It contains two real components which are real phase curves corresponding to real solutions homoclinic to x_0. Their union is $\mathrm{Re}\,\Gamma_1$ and we denote its closure by Ω.

Lemma 7: For an arbitrary complex neighborhood $\mathcal{U}\subset\Pi$ of Ω there exists $\epsilon>0$, such that for $0<|k-1|<\epsilon$ the fundamental group $\pi_1(\Gamma_k)$ of phase curve Γ_k is generated by loops lying in $\mathcal{U}$.

Proof: Periods $T_1(k)$ and $T_2(k)$ of solution (13) are primitive. Minimal real and imaginary periods are $T(k)=4K(k)$ and $T'(k)=4iK'(k)$. As a base point $x(k)\in\Gamma_k$ we choose $x(k)=\varphi_k(t_0(k))$ where $t_0(k)=K(k)$. Let us notice that from (13) it follows that

$$\gamma_1(t_0(k))=(2k^2-1)b_1-2kk'b_3,$$
$$\gamma_3(t_0(k))=(2k^2-1)b_3+2kk'b_1,\quad \omega_2(t_0(k))=0. \tag{21}$$

Now, let

$$\lambda_k,\lambda_k':[0,1]\to\Gamma_k,$$

be the loops with base point $x(k)$ corresponding to periods $T(k)$ and $T'(k)$. These loops cross at point

$$x'(k)=\Phi_k(t_0(k)+T(k)/2)=\Phi_k(t_0(k)+T'(k)/2). \tag{22}$$

As a result, we obtain four semiloops with end points $x(k)$ and $x'(k)$. The fundamental group $\pi_1(\Gamma_k)$ of Γ_k is generated by these semiloops, see Fig. 1. Let us analyze what happens when k tends to 1. From (21) it follows that $x(k)$ tends to x_0 and from (13) we deduce that loop λ_k tends to Ω. To see what happens with loop λ_k' when k tends to 1, let us put $t=t_0(k)+i\tau$ in formulas (13). We obtain

$$\omega_2(t)=2ikk'\frac{\mathrm{sn}(\tau,k')}{\mathrm{dn}(\tau,k')},$$

$$\gamma_1(t)=-\left[1-\frac{2k^2}{\mathrm{dn}^2(\tau,k')}\right]b_1-2kk'\frac{\mathrm{cn}(\tau,k')}{\mathrm{dn}^2(\tau,k')}b_3, \tag{23}$$

$$\gamma_3(t)=-\left[1-\frac{2k^2}{\mathrm{dn}^2(\tau,k')}\right]b_3+2kk'\frac{\mathrm{cn}(\tau,k')}{\mathrm{dn}^2(\tau,k')}b_1.$$

Thus, loop λ_k' tends to point x_0 as k tends to 1. □

Now, we are ready to present our proof of Theorem 5.

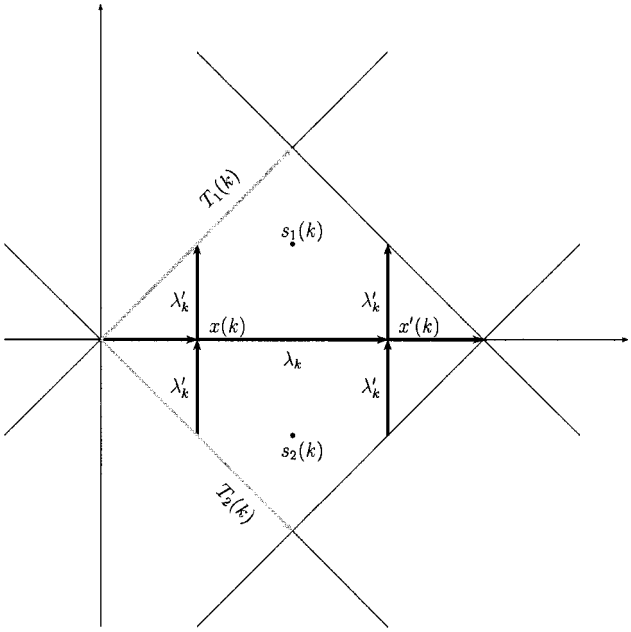

FIG. 1. Parallelogram of period with marked loops.

Proof: Assume that there exists a real meromorphic first integral $\mathcal{I}$ of system (2) which is functionally independent together with $\mathcal{I}_1$ and $\mathcal{I}_2$. We can extend it to a complex meromorphic first integral defined in a complex neighborhood of $\mathbb{R}^5 \subset \mathbb{C}^5$. Thus, there exists a meromorphic first integral defined in a neighborhood $\mathcal{U}$ of Ω. Moreover, by Lemma 7, there exists ϵ such that for $0<|1-k|<\epsilon$ the fundamental group of phase curves Γ_k is generated by loops lying in $\mathcal{U}$. Hence, by Lemma 1, the monodromy group $\mathcal{M}$ of the reduced normal variational equations for the phase curve Γ_k possesses a rational invariant. However, in Lemma 5, we show that the identity component of differential Galois group of (19) is not Abelian. Thus, as (19) is Fuchsian, by Theorem 3.17 of Ref. 3, $\mathcal{M}$ does not possess a rational invariant. Contradiction with Lemma 1 finishes the proof. □

V. REMARKS

Without doubt the Ziglin and Morales-Ramis theories are elegant and, what is more important, powerful tools for proving nonintegrability. However, both of them do not give any information about *dynamical mechanisms* which cause the nonintegrability. For Hamiltonian systems some efforts were done to connect known dynamical phenomena causing the nonintegrability with the properties of the differential Galois group of the variational equations. A nice example is described in Chap. 7 of Ref. 20, see also Ref. 21. It seems that the analysis presented in Ref. 22 gives a new ideas to better understanding of dynamical meaning of the nonintegrability in the sense of the differential Galois theory.

In the generalized Kozlov case the Suslov problem is not a Hamiltonian one, and we can only conjecture what the dynamical mechanism of the nonintegrability is. Restricting system (2) to the level $\mathcal{I}_2=1$ we obtain a four-dimensional system preserving the volume. It possesses a hyperbolic equilibrium of the saddle type. The stable and unstable manifolds of this equilibrium cross transversally along two pendulumlike homoclinic loops. In the case of Hamiltonian systems it is known that a transversal intersection of asymptotic manifolds is not an obstacle for the integrability—an example is the famous C. Neumann system, see Ref. 6. However, as it was shown by Turaev and Shilnikov,[31] if there exists at least three transversal homoclinic orbits that leave and approach the saddle equilibrium tangentially to the leading directions, then the system is not integrable and chaotic. The leading directions correspond to the eigendirections of the minimal positive and

maximal negative characteristic exponents. Four-dimensional systems preserving the volume are ''close'' to the Hamiltonian one. We suspect that for the Suslov system considered in this paper the existence of a large number of orbits homoclinic to the equilibrium causes its nonintegrability.

(Received 23 April 2003; accepted 17 November 2003)

We develop a new approach to the study of Killing tensors defined in pseudo-Riemannian spaces of constant curvature that is ideologically close to the classical theory of invariants. The main idea, which provides the foundation of the new approach, is to treat a Killing tensor as an algebraic object determined by a set of parameters of the corresponding vector space of Killing tensors under the action of the isometry group. The spaces of group invariants and conformal group invariants of valence two Killing tensors defined in the Minkowski plane are described. The group invariants, which are the generators of the space of invariants, are applied to the problem of classification of orthogonally separable Hamiltonian systems defined in the Minkowski plane. Transformation formulas to separable coordinates expressed in terms of the parameters of the corresponding space of Killing tensors are presented. The results are applied to the problem of orthogonal separability of the Drach superintegrable potentials. © *2004 American Institute of Physics.*
[DOI: 10.1063/1.1644902]

I. INTRODUCTION

The classical theory of algebraic invariants has long been recognized as a common branch of commutative algebra, algebraic geometry, representation theory, and algebraic combinatorics. This observation confirms yet again that ''Mathematics is the study of analogies between analogies ....'' [1] With this perspective the main aim of this paper is to establish an apparently new connection between the classical theory of algebraic invariants of vector spaces of homogeneous polynomials and a theory of algebraic invariants of vector spaces of Killing tensors defined in pseudo-Riemannian spaces of constant curvature. A second goal is to apply the results to a classification problem which arises in the theory of separation of variables for the Hamilton–Jacobi equation in classical dynamics. The results obtained provide a framework for the solution of many problems arising in mathematical physics.

Recall that the prime object of study in the classical theory of algebraic invariants[2,3] is the space $V=S^n\mathbb{C}^m$ of homogeneous polynomials of degree n in m variables $x_1,\ldots,x_m$, which has

[a)]Electronic mail: rgmclena@sirius.math.uwaterloo.ca
[b)]Present address: Department of Mathematics and Statistics, Dalhousie University, Halifax, Nova Scotia, Canada, B3H 3J5. Electronic mail: smirnov@mathstat.dal.ca

dimension $d=\binom{n+m-1}{n}$. As a consequence, the main problem is to describe the set of invariants and covariants (i.e., polynomials of the parameters $a_1,\ldots,a_d$ and $a_1,\ldots,a_d,x_1,\ldots,x_m$, respectively) that remain fixed under the action of the group $GL_m(\mathbb{C})$ acting linearly on V.[2] Consider the following illustrating example:[2]

Example 1.1: Let $f\in S^2\mathbb{C}^2$ be a general quadratic form defined over $\mathbb{C}$

$$f(x_1,x_2)=a_1x_1^2+2a_2x_1x_2+a_3x_2^2. \tag{1.1}$$

Under the action of the corresponding group $GL_2(\mathbb{C})$:

$$T=\begin{bmatrix}\alpha_{11} & \alpha_{12}\\ \alpha_{21} & \alpha_{22}\end{bmatrix}\in GL_2(\mathbb{C}),\quad \begin{matrix}x_1=\alpha_{11}x_1'+\alpha_{12}x_2',\\ x_2=\alpha_{21}x_1'+\alpha_{22}x_2'\end{matrix},\quad \det(T)\neq 0$$

the quadratic form given by (1.1) transforms as follows:

$$f'(x_1',x_2')=a_1'x_1'^{\,2}+2a_2'x_1'x_2'+a_3'x_2'^{\,2},$$

where

$$a_1'=a_1\alpha_{11}^2+2a_2\alpha_{11}\alpha_{21}+a_3\alpha_{21}^2,$$

$$a_2'=a_1\alpha_{11}\alpha_{12}+a_2(\alpha_{11}\alpha_{22}+\alpha_{12}\alpha_{21})+a_3\alpha_{21}\alpha_{22},$$

$$a_3'=a_1\alpha_{12}^2+2a_2\alpha_{12}\alpha_{22}+a_3\alpha_{22}^2.$$

It is easily seen that the quantity $\Delta_{qf}=a_1a_3-a_2^2$ is an *invariant* modulo the factor $\det(T)^2$, since it tansforms under the transformation induced by the groups as follows:

$$\Delta_{qf}'=a_1'a_3'-a_2'^{\,2}=(\det T)^2\Delta_{qf}.$$

We observe that the invariant Δ_{qf} can be immediately applied to the *classification of (centrally symmetric) conic sections* in the Euclidean plane $\mathbb{R}^2$ (the above considerations also hold true for $x_1,x_2\in\mathbb{R}^2$). Indeed, for the conic sections defined by

$$f(x_1,x_2)=a_1x_1^2+2a_2x_1x_2+a_3x_2^2=\text{const} \tag{1.2}$$

we can distinguish, for example, the following cases:

(a) if Δ_{qf}, a_1 and $f(x_1,x_2)$ are of the same sign, then (1.2) defines an ellipse in $\mathbb{R}^2$,
(b) if $\Delta_{qf}<0$, then (1.2) defines a hyperbola in $\mathbb{R}^2$,
(c) if $\Delta_{qf}=0$, and $a_1\neq 0$, then (1.2) defines a pair of straight lines $\mathbb{R}^2$.

The example above illustrates that the invariants are very effective in various classification problems.

In modern mathematical language the main problem of the classical theory of algebraic invariants can be formulated as follows:

Problem 1.1: Determine the linear action of a group G on a K-vector space V. Then in the ring of polynomial functions $K[V]$ describe the subring $K[V]^G$ of all polynomial functions on V which are invariant under the action of G.

In order to create a satisfactory realization of these ideas in pseudo-Riemannian geometry, we need to determine counterparts of the group G and K-vector space V, as well as properly define the action of the group in the corresponding vector space defined in a pseudo-Riemannian manifold $(M,\mathbf{g})$. The natural choice for such a group is the isometry group $I(M)$ if it exists, while the vector space where its action can be determined is the vector space of Killing tensors of a fixed valence defined on $(M,\mathbf{g})$.

Killing tensors of valence two play a pivotal role in the theory of orthogonally separable Hamiltonian systems. Therefore the results of such an extension, by which we mean group invariants of the vector spaces of Killing tensors, can be applied to the problem of classification of orthogonally separable Hamiltonian systems (see Sec. IV) which admit first integrals quadratic in the momenta that, in turn, are determined by the Killing tensors of valence two.

The paper is organized as follows: In Sec. II we describe how the basic ideas of the classical theory of algebraic invariants can be incorporated into the study of Killing tensors defined in pseudo-Riemannian manifolds of constant curvature. In Sec. III we solve the problem of finding all isometry group invariants of the space of Killing tensors of valence two defined in the Minkowski plane $\mathbb{R}^2_1$. Section IV links the theory of group invariants of Killing tensors with the Hamilton–Jacobi theory of separation of variables. In Sec. V we characterize Killing tensors defined in $\mathbb{R}^2_1$ with respect to the Liouville–Morera coordinates. Section VI contains an analogous classification in terms of the pseudo-Cartesian coordinates. We describe all admissible rigid motions of $\mathbb{R}^2_1$ in Sec. VII. Section VIII contains a group invariant classification of Killing tensors defined in $\mathbb{R}^2_1$. In Sec. IX we compare the results of Sec. VIII with analogous classifications obtained by other methods. In Sec. X we present transformation formulas in terms of the parameters of the space of Killing tensors of valence two to separable coordinates for Hamiltonian systems defined in $\mathbb{R}^2_1$. The main algorithm based on the results of Secs. VIII and X is the subject of Sec. XI. In Sec. XII we show how the obtained results can be employed in the study of systems of hydrodynamic type. Section XIII is devoted to applications of the results to the problem of orthogonal separability of the Drach superseparable potentials. In Sec. XIV we make concluding remarks.

II. THE EXTENSION

Using the ideas presented in the Introduction as a motivation, we consider a pseudo-Riemannian space $(M,\mathbf{g})$ of constant curvature, where $\dim M=n$ and $\mathbf{g}$ denotes the metric tensor. We shall assume that the manifold M is complete.

Definition 2.1: A Killing tensor $\mathbf{K}^p$ *of valence* p *defined in* $(M,\mathbf{g})$ *is a symmetric* $(p,0)$ *tensor satisfying the Killing tensor equation:*

$$[\mathbf{K}^p,\mathbf{g}]=0, \tag{2.1}$$

where $[,]$ *denotes the Schouten bracket.*[4] *When* $p=1$, $\mathbf{K}^1$ *is said to be a Killing vector (infinitesimal isometry) and Eq. (2.1) reads*

$$\mathcal{L}_{\mathbf{K}^1}\mathbf{g}=0, \tag{2.2}$$

where $\mathcal{L}$ *denotes the Lie derivative operator*.

Remark 2.1: Throughout this paper, unless otherwise specified, $[,]$ denotes the Schouten bracket, which is a generalization of the usual Lie bracket of vector fields.

The set of all Killing vectors of $(M,\mathbf{g})$, denoted by $i(M)$, is a Lie algebra, which is also a Lie subalgebra of the space $\mathcal{X}(M)$ of all vector fields defined on M. As is well-known, $d=\dim i(M)=\frac{1}{2}n(n+1)$ iff the space $(M,\mathbf{g})$ is of constant curvature.[5,6]

It follows immediately from (2.1) that the Killing tensors of the same valence p constitute a vector space $\mathcal{K}^p(M)$. Moreover, the following properties hold true:

$$[\ ,\ ]:\ \mathcal{K}^p(M)\oplus\mathcal{K}^q(M)\to\mathcal{K}^{p+q-1}(M), \tag{2.3}$$

$$[\mathbf{K}^p,\mathbf{K}^q]=-[\mathbf{K}^q,\mathbf{K}^p]\quad(\text{skew-symmetry}), \tag{2.4}$$

$$[[\mathbf{K}^p,\mathbf{K}^q],\mathbf{K}^r]+(\text{cycle})=0\quad(\text{Jacobi identity}). \tag{2.5}$$

Therefore one can consider a graded Lie algebra of Killing tensors defined on $(M,\mathbf{g})$ with respect to the Schouten bracket $[,]$:

TABLE I. Comparison with the classical theory of algebraic invariants.

	Classical theory of algebraic invariants	Group invariants of Killing tensors
Group	Linear group $GL_m(\mathbb{C})$	Isometry group $I(M)$
Space	Vector space $S^n\mathbb{C}^m$	Space $\Sigma \simeq \mathbb{R}^d$ determined by $\mathcal{K}^p(M)$
Objects preserved by the group	Polynomials of $a_1,\ldots,a_d$ (invariants) and $a_1,\ldots,a_d,x_1,\ldots,x_m$ (covariants), where $d=\dim S^n\mathbb{C}^m$	Functions of $a_1,\ldots,a_d$, where $d=\dim \mathcal{K}^p(M)$

$$\mathcal{K}_{\text{alg}}=\mathcal{K}^0(M)\oplus\mathcal{K}^1(M)\oplus\mathcal{K}^2(M)\oplus\cdots\oplus\mathcal{K}^p(M)\oplus\cdots, \tag{2.6}$$

where $\mathcal{K}^0(M)=\mathbb{R}$, $\mathcal{K}^1(M)=i(M)$ and $p=0,1,2,\ldots$, denotes the valence of the Killing tensors belonging to the corresponding space $\mathcal{K}^p(M)$. The following two fundamental *structural properties* of Killing tensors defined on pseudo-Riemannian spaces of constant curvature are crucial in applications:

SPI: A Killing tensor $\mathbf{K}^p$ defined on $(M,\mathbf{g})$ is a *sum of symmetrized tensor products* of Killing vectors, or infinitesimal generators of the Lie algebra of the corresponding isometry group.

SPII: The set of all Killing tensors of valence $p\geqslant 1$ defined on $(M,\mathbf{g})$, where $\dim(M)=n$, is a *vector space of dimension d* determined by the *Delong–Takeuchi–Thompson (DTT) formula:*[7–9]

$$d=\frac{1}{n}\binom{n+p}{p+1}\binom{n+p-1}{p},\quad p\geqslant 1. \tag{2.7}$$

Accordingly, a Killing tensor of valence p is an *algebraic object* determined by its d parameters, or an element of the corresponding vector space of Killing tensors.

Recall that formula (2.7) was derived first for the cases $p=1$ (see above) and $p=2$.[10,11,13] An extensive study of Killing tensors defined in pseudo-Riemannian spaces of constant curvature was undertaken by Delong in his 1982 Ph.D. thesis,[7] where the author discovered, among many other beautiful results, formula (2.7) for arbitrary $p>2$. This result was obtained independently by Takeuchi[8] and Thompson[9] by making use of SPI. In addition, SPI has been routinely employed to solve classification problems in the Hamilton–Jacobi theory of separation of variables (see, for instance, Refs. 14, 15). Our approach to these problems is based on SPII, which we use to extend the basic ideas of the classical theory of algebraic invariants to pseudo-Riemannian geometry. The results are applied to problems arising in the Hamilton–Jacobi theory of separation of variables. Indeed, in view of SPII, a Killing tensor of valence p can be interpreted as an algebraic object, or an element of the corresponding vector space $\mathcal{K}^p(M)$, determined by d parameters $a_1,\ldots,a_d$, where $d=\dim \mathcal{K}^p(M)$, which makes it natural to consider the induced action of the isometry group $I(M)$ in the space Σ with the coordinates $a_1,\ldots,a_d$ (note Σ is isomorphic to $\mathbb{R}^d$:$\Sigma\simeq\mathbb{R}^d$). Therefore in complete analogy with the main problem of the classical theory of algebraic invariants (see above), we formulate the following problem for the vector spaces of Killing tensors defined in pseudo-Riemannian spaces of constant curvature:

Problem 2.1: Determine the action induced by the group of isometries in the space Σ determined by $a_1,\ldots,a_d$. Then in the space of functions defined on Σ describe the subspace of all functions in Σ which are invariant under the action induced by the isometry group.

To make the exposition clearer, we compare the corresponding main components of the two theories in Table I.

It should be mentioned that Delong[7] made a considerable effort to establish a link between the study of Killing tensors defined in spaces of constant curvature and the classical theory of algebraic invariants. However, his approach appears to be different from the one employed in this work. More specifically, by treating the Killing tensors as functions on the cotangent bundle T^*M, he considered the action of the Hamiltonian flow group in $\mathcal{K}_{\text{alg}}$. This set up prompted him to

consider cotangent bundles of the spaces where the group acted linearly (for instance, $T^*\mathbb{R}^n$). In this view, the algebra $\mathcal{K}_{\text{alg}}$ is itself the algebra of invariants of the Hamiltonian flow group.

In our setting, in order to determine the action of $I(M)$ in Σ, we treat each element of the vector space $\mathcal{K}^p(M)$ as a function of its parameters $a_1^0,\ldots,a_d^0$: $\mathbf{K}_0^p=\mathbf{K}_0^p(a_1^0,\ldots,a_d^0)$, where the number d is given by (2.7). Denote by $\mathrm{Diff}\,\mathcal{K}^p(M)$ all Killing tensors in $\mathcal{K}^p(M)$ whose parameters are smooth functions of $a_1,\ldots,a_d$. It is easy to see that $\mathrm{Diff}\,\mathcal{K}^p(M)$ is generated by $\mathrm{Diff}\,(\mathbb{R}^d)$—the group of all diffeomorphisms of $\Sigma\simeq\mathbb{R}^d$. To determine the action of $I(M)$ we introduce a *map* π: $\mathrm{Diff}\,\mathcal{K}^p(M)\to\mathcal{X}(\Sigma)$ defined as follows:

$$\pi:\ \mathbf{K}^p(a_1^0,\ldots,a_d^0)\to\sum_{i=1}^{d} a_i^0\frac{\partial}{\partial a_i}, \tag{2.8}$$

where $a_1,\ldots,a_d$ are the general parameters that span the space Σ and $\mathcal{X}(\Sigma)$ denotes the space of vector fields on Σ. Note, in general a_i^0, are functions of $a_1,\ldots,a_d$: $a_i^0=a_i^0(a_1,\ldots,a_d)$, $i=1,\ldots,d$. Hence, every element of the vector space $\mathcal{K}^p(M)$ is mapped to a vector field in $\mathcal{X}(\Sigma)$. Moreover, it is clear that $\ker\pi=\{\mathbf{0}\}$, therefore π is an *isomorphism* between the two spaces. A simple interpretation of this construction is the following: With a given Killing vector field $\mathbf{X}$ on M we associate a linear mapping $\mathcal{L}_{\mathbf{X}}:\mathcal{K}^p(M)\to\mathcal{K}^p(M)$, hence, a linear mapping $\tilde{\mathcal{L}}_{\mathbf{X}}:\Sigma\to\Sigma$, since $\mathcal{K}^p(M)$ is identified with Σ. This mapping is represented by d equations:

$$a_i^0=a_i^0(a_1,\ldots,a_d),\quad i=1,\ldots,d.$$

Accordingly, we define a vector field $\mathbf{V}_{\mathbf{X}}$ on Σ by setting

$$\mathbf{V}_{\mathbf{X}}=a_i^0(a_1,\ldots,a_d)\frac{\partial}{\partial a_i}.$$

Remark 2.2: To define the map π according to the formula (2.8) properly, we need an explicit representation of the general Killing tensor $\mathbf{K}^p\in\mathcal{K}^p(M)$ under consideration given in terms of a fixed system of coordinates. Such a representation can be obtained on a case by case basis. For example, consider the case $p=2$, $M=\mathbb{R}^2$: Solving the corresponding Killing tensor equation (2.1) in (say) Cartesian coordinates, one obtains the general form of a Killing tensor in $\mathcal{K}^2(\mathbb{R}^2)$:

$$K^{ij}=\begin{pmatrix} A+2\alpha y+\gamma y^2 & C-\alpha x-\beta y-\gamma xy\\ C-\alpha x-\beta y-\gamma xy & B+2\beta x+\gamma x^2\end{pmatrix}, \tag{2.9}$$

where K^{ij} are the components of the general $\mathbf{K}^2\in\mathcal{K}^2(\mathbb{R}^2)$. The six parameters $A,B,C,\alpha,\beta,\gamma$ are the constants of integration. They also represent the dimension of the space $\mathcal{K}^2(\mathbb{R}^2)$, which alternatively can be calculated by making use of the formula (2.7).

Now for a fixed $\mathbf{K}_0^2\in\mathrm{Diff}\,\mathcal{K}^2(\mathbb{R}^2)$ given in terms of the Cartesian coordinates $(x,y)\in\mathbb{R}^2$ the map π: $\mathrm{Diff}\,\mathcal{K}^2(\mathbb{R}^2)\to\mathcal{X}(\Sigma)$ can be defined[20] as follows:

$$\pi\begin{pmatrix} A_0+2\alpha_0 y+\gamma_0 y^2 & C_0-\alpha_0 x-\beta_0 y-\gamma_0 xy\\ C_0-\alpha_0 x-\beta_0 y-\gamma_0 xy & B_0+2\beta_0 x+\gamma_0 x^2\end{pmatrix}$$
$$=A_0\frac{\partial}{\partial A}+B_0\frac{\partial}{\partial B}+C_0\frac{\partial}{\partial C}+\alpha_0\frac{\partial}{\partial\alpha}+\beta_0\frac{\partial}{\partial\beta}+\gamma_0\frac{\partial}{\partial\gamma},$$

where the parameters $A_0,B_0,C_0,\alpha_0,\beta_0,\gamma_0$ determine a given Killing tensor $\mathbf{K}_0^2\in\mathrm{Diff}\,\mathcal{K}^2(\mathbb{R}^2)$ and are smooth functions of parameters $A,B,C,\alpha,\beta,\gamma$ that span the corresponding space Σ.

Let $\mathbf{X}_1,\ldots,\mathbf{X}_r$, $r=\frac{1}{2}n(n+1)$ be the generators (Killing vectors) of the Lie algebra $i(M)=\mathcal{K}^1(M)$. Define the set of vector fields $\mathbf{V}_1,\ldots,\mathbf{V}_r\in\mathcal{X}(\Sigma)$ via a composition $F_*:=\pi\circ\mathcal{L}$ of π and

the Lie derivative deformation of the general Killing tensor $\mathbf{K}^p=\mathbf{K}^p(a_1,\ldots,a_d)\in\mathcal{K}^p(M)$ (i.e., the general solution of the Killing tensor equation $[\mathbf{K}^p,\mathbf{g}]=0$, with $a_1,\ldots,a_d$ as the constants of integration):

$$\mathbf{V}_i:=\pi\mathcal{L}_{\mathbf{X}_i}\mathbf{K}^p, \quad \text{or} \quad \mathbf{V}_i=F_*(\mathbf{X}_i), \quad i=1,\ldots,r. \tag{2.10}$$

Note $\mathcal{L}_{\mathbf{X}_i}\mathbf{K}^p\in\mathrm{Diff}\,\mathcal{K}^p(M)$, hence π is well-defined.

Remark 2.3: Note that in view of the Jacobi identity (2.5) for any $\mathbf{X}\in\mathcal{K}^1(M)$ and $\mathbf{K}^p\in\mathrm{Diff}\,\mathcal{K}^p(M)$ the deformed tensor $\tilde{\mathbf{K}}^p=\mathcal{L}_{\mathbf{X}}\mathbf{K}^p$ is also a Killing tensor: $\tilde{\mathbf{K}}^p\in\mathcal{K}^p(M)$, $p\geqslant 1$, which confirms that the formula (2.10) is well-defined. In general, a Lie algebra deformation $\mathcal{L}_{\mathbf{Y}}\mathbf{K}^p$, where $\mathbf{Y}\in TM$ is an arbitrary vector field, does not yield a Killing tensor: $\mathcal{L}_{\mathbf{Y}}\mathbf{K}^p\notin\mathcal{K}^p(M)$.

This interesting fact about the Lie derivative deformation of symmetric tensorial quantities is reminiscent of a well-known fact in Poisson geometry, where skew-symmetric tensorial quantities are involved in similar settings. More specifically, recall that for a bi-Hamiltonian system defined by a bi-Hamiltonian vector field $\mathbf{X}_{H_1,H_2}$ satisfying

$$\mathbf{X}_{H_1,H_2}=[\mathbf{P}_1,H_1]=[\mathbf{P}_2,H_2],$$

where $\mathbf{P}_1$, $\mathbf{P}_2$ are compatible Poisson bi-vectors (i.e., $[\mathbf{P}_1,\mathbf{P}_2]=0$) Oevel[16] considered a *scaling symmetry*, namely, a vector field $\mathbf{Z}_0$ satisfying the following scaling properties for $\mathbf{X}_{H_1,H_2}$ and the compatible Poisson pair $\mathbf{P}_1$, $\mathbf{P}_2$:

$$\mathcal{L}_{\mathbf{Z}_0}\mathbf{X}_{H_1,H_2}=\alpha\mathbf{X}_{H_1,H_2}, \quad \mathcal{L}_{\mathbf{Z}_0}\mathbf{P}_1=\beta\mathbf{P}_1, \quad \mathcal{L}_{\mathbf{Z}_0}\mathbf{P}_2=\gamma\mathbf{P}_2,$$

where α, β and $\gamma\in\mathbb{R}$. Recall also that in this situation the scaling symmetry $\mathbf{Z}_0$ is a *master symmetry*, a concept introduced by Fuchssteiner[17] (see also Ref. 18 for more details). Indeed, for the vector field $\mathbf{X}_{H_1,H_2}$ we have $[[Z_0,\mathbf{X}_{H_1,H_2}],\mathbf{X}_{H_1,H_2}]=0$. Therefore Z_0 is a master symmetry of $\mathbf{X}_{H_1,H_2}$. Then the hierarchy of the vector fields $\{\mathbf{Z}_i\}_{i=0}^{\infty}$, where $\mathbf{Z}_i=\mathbf{A}^i\mathbf{Z}_0$ ($\mathbf{A}=\mathbf{P}_2\mathbf{P}_1^{-1}$, provided $\det\mathbf{P}_1\neq 0$) constitute a Virasoro type Lie algebra with the commutator relation $[\mathbf{Z}_i,\mathbf{Z}_j]=(\beta+\gamma)(i-j)\mathbf{Z}_{i+j}$, $i,j=0,1,2,\ldots$. Moreover, the Lie derivative deformations $\mathcal{L}_{\mathbf{Z}_i}\mathbf{P}_1=\tilde{\mathbf{P}}_1^i$, $\mathcal{L}_{\mathbf{Z}_i}\mathbf{P}_2=\tilde{\mathbf{P}}_2^i$, $i=0,1,2,\ldots$. yield Poisson bi-vectors $\tilde{\mathbf{P}}_1^i$ and $\tilde{\mathbf{P}}_2^i$. For more details see Ref. 16. Just like in the case of the Lie derivative deformations of Killing tensors described above, this fact also does not hold true in general for arbitrary vector fields. More specifically, for an arbitrary vector field $\mathbf{X}$ defined on the corresponding manifold, the tensorial quantities $\mathcal{L}_{\mathbf{X}}\mathbf{P}_i$, $i=1,2$ are not necessarily Poisson bi-vectors.

We also note that the parameters $\tilde{a}_1,\ldots,\tilde{a}_d$ of $\tilde{\mathbf{K}}^p\in\mathrm{Diff}\,\mathcal{K}^p(M)$ are functions of the general parameters $a_1,\ldots,a_d$ that span the space $\Sigma:\tilde{\mathbf{K}}^p=\tilde{\mathbf{K}}^p(\tilde{a}_1(a_1,\ldots,a_d),\ldots,\tilde{a}_d(a_1,\ldots,a_d))$. Moreover, each vector field $\mathbf{V}_i\in\mathcal{X}(\Sigma)$, $i=1,\ldots,r$ carries the information about both the corresponding Killing vector $\mathbf{X}_i\in i(M)=\mathcal{K}^1(M)$, $i=1,\ldots,r$ and the general Killing tensor $\mathbf{K}^p\in\mathcal{K}^p(M)$. However, *the action of* $\mathbf{V}_i$ *is determined in the space* Σ *of the parameters* $a_1,\ldots,a_d$.

Conjecture 2.1: Suppose the generators $\mathbf{X}_1,\ldots,\mathbf{X}_r$ *of* $i(M)$ *satisfy the following commutator relations:*

$$[\mathbf{X}_i,\mathbf{X}_j]=c_{ij}^k\mathbf{X}_k, \tag{2.11}$$

where c_{ij}^k, $i,j,k=1,\ldots,r$ *are the structural constants. Then the corresponding vector fields* $\mathbf{V}_i\in\mathcal{X}(\Sigma)$, *defined by (2.10) satisfy the same commutator relations:*

$$[\mathbf{V}_i,\mathbf{V}_j]=c_{ij}^k\mathbf{V}_k. \tag{2.12}$$

Therefore the map $F_*:=\pi\circ\mathcal{L}:i(M)\to i_\Sigma(M)$ *is a Lie algebra isomorphism, where* $i_\Sigma(M)$ *is the Lie algebra generated by* $\mathbf{V}_1,\ldots,\mathbf{V}_r$.

The validity of the formula (2.12) can be confirmed directly on a case by case basis, provided that the general form of a Killing tensor $\mathbf{K}^p \in \mathcal{K}^p(M)$ is available (see Sec. III). Thus, the authors, Robin Deeley and Joshua Horwood have verified in this way that the isomorphism described in Conjecture 2.1 holds true for the following spaces of Killing tensors (vectors): $\mathcal{K}^1(\mathbb{R}^2)$, $\mathcal{K}^1(\mathbb{R}^2_1)$, $\mathcal{K}^1(\mathbb{R}^3)$, $\mathcal{K}^2(\mathbb{R}^2)$, $\mathcal{K}^2(\mathbb{R}^2_1)$ (see below), $\mathcal{K}^2(\mathbb{S}^2)$, $\mathcal{K}^3(\mathbb{R}^2)$, and $\mathcal{K}^2(\mathbb{R}^3)$,[19] where $\mathbb{S}^2$ denotes the two-sphere.

Note that the same procedure can be carried out for any invariant subspace of $\mathcal{K}^p(M)$. Therefore one can determine the action of $I(M)$ on any subspace of $\mathcal{K}^p(M)$ invariant under the action of $I(M)$. Once the isomorphism $i(M) \simeq i_\Sigma(M)$ is established, we can define $I(M)$-*invariants* and *conformal* $I(M)$-*invariants* of a vector space of Killing tensors $\mathcal{K}^p(M)$ as well as its invariant subspaces.

Definition 2.2: Let $(M,\mathbf{g})$ *be an n-dimensional pseudo-Riemannian manifold of constant curvature,* $\mathcal{K}^p(M)$*—the corresponding vector space of Killing tensors of valence p defined on* $(M,\mathbf{g})$ *and* $\mathcal{Q}(M) \subseteq \mathcal{K}^p(M)$*—an invariant subspace of* $\mathcal{K}^p(M)$*. A smooth function* $F:\Sigma \to \mathbb{R}$ *is said to be an* $I(M)$*-invariant of* $\mathcal{Q}(M) \subseteq \mathcal{K}^p(M)$ *iff*

$$\mathbf{V}_i(F) = 0, \tag{2.13}$$

where $\mathbf{V}_i$, $i = 1,\ldots,r$ *are the generators of the Lie algebra* $i_\Sigma(M)$ *defined as above for* $\mathcal{Q}(M)$.

A smooth function $G:\Sigma \to \mathbb{R}$ *is said to be a conformal* $I(M)$*-invariant of* $\mathcal{Q}(M) \subseteq \mathcal{K}^p(M)$ *iff*

$$\mathbf{V}_i(G) = \epsilon_i, \tag{2.14}$$

where $\epsilon_i \in \mathbb{R}$ *for* $i = 1,\ldots,r$.

Definition 2.3: An element $\mathbf{K}^2 \in \mathcal{K}^2(M)$ *is said to be nontrivial if and only if it is not a multiple of the metric* $\mathbf{g}$: $\mathbf{K}^2 \neq \ell\mathbf{g}$, $\ell \in \mathbb{R}$.

Let $\mathcal{Q}(\mathbb{R}^2)$ denote the subspace of all nontrivial Killing tensors in $\mathcal{K}^2(\mathbb{R}^2)$. Without loss of generality we can assume that $\mathcal{Q}(\mathbb{R}^2)$ is defined by the general nontrivial Killing tensor whose components are given by

$$Q^{ij} = \begin{pmatrix} A' + 2\alpha y + \gamma y^2 & C - \alpha x - \beta y - \gamma xy \\ C - \alpha x - \beta y - \gamma xy & 2\beta x + \gamma x^2 \end{pmatrix}, \quad i,j = 1,2, \tag{2.15}$$

where $A' = A - B$, and $A, B, C, \alpha, \beta, \gamma$ are the parameters appearing in (2.9). In view of Definition 2.2, one can determine $I(\mathbb{R}^2)$-invariants of $\mathcal{Q}(\mathbb{R}^2)$. Recall that Problem 2.1 for the vector subspace of nontrivial Killing tensors of $\mathcal{K}^2(\mathbb{R}^2)$ has been solved by the authors in Ref. 20. The precise result is given in the following theorem:

Theorem 2.1: *Every smooth* $I(\mathbb{R}^2)$*-invariant of the subspace* $\mathcal{Q}(\mathbb{R}^2) \subset \mathcal{K}^2(\mathbb{R}^2)$ *enjoys the following form:*

$$F(\Delta^1_{\mathbb{R}^2}, \Delta^2_{\mathbb{R}^2}), \tag{2.16}$$

where $F: \mathbb{R}^2 \to \mathbb{R}$ *is a smooth function,*

$$\Delta^1_{\mathbb{R}^2} = \gamma, \quad \Delta^2_{\mathbb{R}^2} = (\alpha^2 - \beta^2 - \gamma A')^2 + 4(\gamma C + \alpha\beta)^2, \tag{2.17}$$

and $A, B, C, \alpha, \beta, \gamma$ *are the parameters defined in (2.9).*

Definition 2.4: The quantities $\Delta^i_{\mathbb{R}^2}$, $i = 1,2$ *are called the fundamental* $I(\mathbb{R}^2)$*-invariants of* $\mathcal{K}^2(\mathbb{R}^2)$.

Note that the fundamental $i(\mathbb{R}^2)$-invariants are homogeneous polynomials in $A, B, C, \alpha, \beta, \gamma$. It is important to note that both the number of fundamental invariants and the form of F in this case are in compliance with the following well-known theorem of the theory of invariants.

Theorem 2.2 (Ref. 12): *Let G act semiregularly on the m-dimensional manifold M with s-dimensional orbits. If $x_0 \in M$, then there exist precisely $m-s$ functionally independent local invariants $\zeta^1(x),\ldots,\zeta^{m-s}(x)$ defined in a neighborhood of x_0. Moreover, any other local invariant of the group action defined near x_0 is of the form*

$$\zeta(x)=F(\zeta^1(x),\ldots,\zeta^{m-s}(x)) \tag{2.18}$$

for some smooth function F. If the action of G is regular, then the invariants can be taken to be globally invariant in a neighborhood of x_0.

Indeed, $\dim \Sigma' = 5$, $\dim i_{\Sigma'}(\mathbb{R}^2)=3$. Therefore, according to Theorem 2.2, the number of fundamental invariants comes down to $5-3=2$.

The quantities $\Delta^i_{\mathbb{R}^2}, i=1,2$ to classify families of confocal conics in $\mathbb{R}^2$ which define orthogonally-separable coordinate webs for the Hamiltonian systems with two degrees of freedom defined in $\mathbb{R}^2$ admitting quadratic first integrals of motion. In this case the confocal conics are the integral curves of the eigenvectors of the corresponding Killing tensors $\mathcal{K}^2(\mathbb{R}^2)$. If the eigenvalues λ_1,λ_2 are not everywhere constant, they define the two families of confocal conics: $\lambda_i = \text{const}, i=1,2$. If one or both of the eigenvalues are everywhere constant one also has to consider the eigenvectors. Once an element of $\mathcal{Q}(\mathbb{R}^2)\subset\mathcal{K}^2(\mathbb{R}^2)$ is available, it is easy to determine the type of the corresponding confocal conics (*coordinate webs*), provided the Killing tensor in question is linearly independent of the metric tensor **g**. Thus, we have the following classification (compare with Example 1.1):

(a) if $\Delta^1_{\mathbb{R}^2}=0$, $\Delta^2_{\mathbb{R}^2}=0$, then (2.9) defines the Cartesian web in $\mathbb{R}^2$;

(b) if $\Delta^1_{\mathbb{R}^2}=0$, $\Delta^2_{\mathbb{R}^2}\neq 0$, then (2.9) defines the parabolic web in $\mathbb{R}^2$;

(c) if $\Delta^1_{\mathbb{R}^2}\neq 0$, $\Delta^2_{\mathbb{R}^2}=0$, then (2.9) defines the polar web in $\mathbb{R}^2$;

(d) if $\Delta^1_{\mathbb{R}^2}\neq 0$, $\Delta^2_{\mathbb{R}^2}\neq 0$, then (2.9) defines the elliptic-hyperbolic web in $\mathbb{R}^2$.

The geometrical significance of the invariants is given by the following formula:

$$k^2=\frac{\sqrt{\Delta^2_{\mathbb{R}^2}}}{(\Delta^1_{\mathbb{R}^2})^2}, \tag{2.19}$$

where k is interpretable as half the distance between the foci of the confocal conics in the elliptic–hyperbolic case.

In the following section we describe the vector space of Killing tensors $\mathcal{K}^2(\mathbb{R}^2_1)$ from this viewpoint and derive the corresponding $I(\mathbb{R}^2_1)$-invariants and conformal $I(\mathbb{R}^2_1)$-invariants to be applied in the sequel to a classification problem in the Hamilton–Jacobi theory of separation of variables that is described in Sec. IV.

III. GROUP INVARIANTS OF THE VECTOR SPACE $\mathcal{K}^2(\mathbb{R}^2_1)$

In this section the discussion proceeds from the general to the particular. We apply the concepts introduced in the previous section to the study of the Killing tensors of valence two defined in the Minkowski plane $\mathbb{R}^2_1$ that constitute the vector space $\mathcal{K}^2(\mathbb{R}^2_1)$.

Remark 3.1: Here and below **K** denotes a Killing tensor of valence two.

The analysis presented in this section is parallel to the corresponding study carried out by the authors in Ref. 20 of the Killing tensors of valence two defined the Euclidean plane $\mathbb{R}^2$, i.e., the elements of the vector space $\mathcal{K}^2(\mathbb{R}^2)$. We observe first that in view of the formula (2.7) $\dim \mathcal{K}^2(\mathbb{R}^2_1)=6$. Alternatively, this fact can be verified by solving the corresponding Killing tensor equation $[\mathbf{K},\mathbf{g}]=0$ in, (say) pseudo-Cartesian coordinates $(t,x)\in\mathbb{R}^2_1$ for the Lorentzian metric $\mathbf{g}=\text{diag}(1,-1)$ of $\mathbb{R}^2_1$. As expected, the general solution given by

$$K^{ij}=\begin{pmatrix} A+2\alpha x+\gamma x^2 & C+\alpha t+\beta x+\gamma tx \\ C+\alpha t+\beta x+\gamma xt & B+2\beta t+\gamma t^2 \end{pmatrix}, \tag{3.1}$$

contains six parameters A, B, C, α, β, and γ (constants of integration) that span the vector space $\mathcal{K}^2(\mathbb{R}^2_1)$. Here K^{ij} are the contravariant components of the general Killing tensor $\mathbf{K}\in\mathcal{K}^2(\mathbb{R}^2_1)$. We also note that the form of the general solution (3.1) is analogous to the general solution of the Killing tensor equation in the Euclidean plane (2.9). Next, in order to compute the $I(\mathbb{R}^2_1)$-invariants and conformal $I(\mathbb{R}^2_1)$-invariants of $\mathcal{K}^2(\mathbb{R}^2_1)$ we have to make use, in accordance with the procedure described in the preceding section, of the Lie algebra isomorphism between $i(\mathbb{R}^2_1)=\mathcal{K}^1(\mathbb{R}^2_1)$ and $i_\Sigma(\mathbb{R}^2_1)$, where $i_\Sigma(\mathbb{R}^2_1)$ is the corresponding subspace of $\mathcal{X}(\Sigma)$ generated by the vector fields defined via the formula (2.10) and $\Sigma\simeq\mathbb{R}^6$ is the space spanned by the six parameters A,B,C, α, β, and γ. In what follows, we establish the isomorphism directly by employing the general representation (3.1).

Lemma 3.1: The vector space $i_\Sigma(\mathbb{R}^2_1)$ is a Lie subalgebra of $\mathcal{X}(\Sigma)$ isomorphic to $i(\mathbb{R}^2_1)=\mathcal{K}^1(\mathbb{R}^2_1)$.

Proof: Consider the Lie algebra $i(\mathbb{R}^2_1)$ of the Lie group $I(\mathbb{R}^2_1)$ generated by the three Killing vectors:

$$\mathbf{T}=\frac{\partial}{\partial t},\quad \mathbf{X}=\frac{\partial}{\partial x},\quad \mathbf{H}=x\frac{\partial}{\partial t}+t\frac{\partial}{\partial x}. \tag{3.2}$$

They correspond, respectively, to the translations along t and x and a hyperbolic rotation and satisfy the following commutator relations:

$$[\mathbf{T},\mathbf{X}]=0,\quad [\mathbf{T},\mathbf{H}]=\mathbf{X},\quad [\mathbf{X},\mathbf{H}]=\mathbf{T}. \tag{3.3}$$

The corresponding flows generated by the vector fields (3.2) are given by

$$\begin{aligned} &\sigma_{\mathbf{T}}(a,(t,x))=t+a,\quad a\in\mathbb{R},\\ &\sigma_{\mathbf{X}}(b,(t,x))=x+b,\quad b\in\mathbb{R},\\ &\sigma_{\mathbf{H}}(\phi,(t,x))=(t\cosh\phi+x\sinh\phi,t\sinh\phi+x\cosh\phi), \end{aligned} \tag{3.4}$$

where $\phi\in\mathbb{R}$ is the (oriented) *Lorentz angle*. To define the map $\pi:\mathrm{Diff}\,\mathcal{K}^2(\mathbb{R}^2_1)\to\mathcal{X}(\Sigma)$ we use the generic formula (3.1) and the definition (2.8):

$$\begin{aligned} &\pi\begin{pmatrix} A_0+2\alpha_0 x+\gamma_0 x^2 & C_0+\alpha_0 t+\beta_0 x+\gamma_0 tx \\ C_0+\alpha_0 t+\beta_0 x+\gamma_0 tx & B_0+2\beta_0 t+\gamma_0 t^2 \end{pmatrix}\\ &\quad=A_0\frac{\partial}{\partial A}+B_0\frac{\partial}{\partial B}+C_0\frac{\partial}{\partial C}+\alpha_0\frac{\partial}{\partial\alpha}+\beta_0\frac{\partial}{\partial\beta}+\gamma_0\frac{\partial}{\partial\gamma}, \end{aligned}$$

for a particular element of $\mathrm{Diff}\,\mathcal{K}^2(\mathbb{R}^2_1)$ defined by $A_0,B_0,C_0,\alpha_0,\beta_0,\gamma_0$:

$$\mathbf{K}^2_0=\mathbf{K}^2_0(A_0,B_0,C_0,\alpha_0,\beta_0,\gamma_0)\in\mathcal{K}^2(\mathbb{R}^2_1).$$

Our next step is to define the vector fields $\mathbf{V}_1$, $\mathbf{V}_2$, and $\mathbf{V}_3$ in $\mathcal{X}(\Sigma)$ that correspond to the Killing vectors $\mathbf{T}$, $\mathbf{X}$, and $\mathbf{H}$ in $\mathcal{X}(\mathbb{R}^2_1)$, respectively, via the composition map $\pi\circ\mathcal{L}$ employing the formula (2.10). They are found to be

$$\mathbf{V}_1=\pi(\mathcal{L}_{\mathbf{T}}(\mathbf{K}))=2\beta\frac{\partial}{\partial B}+\alpha\frac{\partial}{\partial C}+\gamma\frac{\partial}{\partial\beta},$$

$$\mathbf{V}_2=\pi(\mathcal{L}_{\mathbf{X}}(\mathbf{K}))=2\alpha\frac{\partial}{\partial A}+\beta\frac{\partial}{\partial C}+\gamma\frac{\partial}{\partial\alpha},$$

$$\mathbf{V}_3=\pi(\mathcal{L}_{\mathbf{H}}(\mathbf{K}))=-2C\left(\frac{\partial}{\partial A}+\frac{\partial}{\partial B}\right)-(A+B)\frac{\partial}{\partial C}-\beta\frac{\partial}{\partial\alpha}-\alpha\frac{\partial}{\partial\beta}.$$

Note that the vector fields $\mathbf{V}_1$, $\mathbf{V}_2$, and $\mathbf{V}_3$ satisfy the commutator relations

$$[\mathbf{V}_1,\mathbf{V}_2]=0,\quad [\mathbf{V}_1,\mathbf{V}_3]=-\mathbf{V}_2,\quad [\mathbf{V}_2,\mathbf{V}_3]=-\mathbf{V}_1. \tag{3.5}$$

Choosing $-\mathbf{V}_1$, $-\mathbf{V}_2$, and $-\mathbf{V}_3$ as a basis of the Lie algebra $i_\Sigma(\mathbb{R}_1^2)$ immediately confirms that it is isomorphic to $i(\mathbb{R}_1^2)$ [see (3.3)]. □

Now we can *bring the problem of finding $I(\mathbb{R}_1^2)$-invariants and conformal $I(\mathbb{R}_1^2)$-invariants of $\mathcal{K}^2(\mathbb{R}_1^2)$ to the space Σ spanned by the six parameters $A,B,C,\alpha,\beta,\gamma$ or any $I(\mathbb{R}_1^2)$-invariant subspace of $\mathcal{K}^2(\mathbb{R}_1^2)$*. Indeed, the action of $I(\mathbb{R}_1^2)$ in Σ is equivalent to its action in Σ', where Σ' is the parameter space spanned by the five parameters $A'',C,\alpha,\beta,\gamma$, where $A''=A+B$ and $A,B,C,\alpha,\beta,\gamma$ span Σ and Σ' is the five-parameter space of parameters corresponding on the subspace of nontrivial Killing tensors $\mathcal{Q}(\mathbb{R}_1^2)\subset\mathcal{K}^2(\mathbb{R}_1^2)$. Thus, we can assume without loss of generality that contravariant components of the general nontrivial Killing tensor $\mathbf{Q}\in\mathcal{Q}(\mathbb{R}_1^2)$ are given by

$$Q^{ij}=\begin{pmatrix} A''+2\alpha x+\gamma x^2 & C+\alpha t+\beta x+\gamma tx\\ C+\alpha t+\beta x+\gamma xt & 2\beta t+\gamma t^2\end{pmatrix}, \tag{3.6}$$

where $A,B,C,\alpha,\beta,\gamma$ are as in (3.1).

Remark 3.2: We note that the general form (3.6) can be transformed to the form

$$\tilde{Q}^{ij}=\begin{pmatrix} A'''+2\alpha x+\gamma x^2 & C+\alpha t+\beta x+\gamma tx\\ C+\alpha t+\beta x+\gamma xt & A'''+2\beta t+\gamma t^2\end{pmatrix}, \tag{3.7}$$

where $A'''=(A+B)/2$, by adding a multiple of the metric. Obviously, this transformation does not affect the $I(\mathbb{R}_1^2)$-invariants of the subspace of nontrivial Killing tensors.

Next, using the procedure described above we can employ the composition $F_*=\pi\circ\mathcal{L}$ to determine the vector fields $\mathbf{V}_i'\in\mathcal{X}(\Sigma')$, $i=1,2,3$ that correspond to the generators of $i(\mathbb{R}_1^2)$.

Corollary 3.1: Let $\mathcal{Q}(\mathbb{R}_1^2)\subset\mathcal{K}^2(\mathbb{R}_1^2)$ be the invariant subspace of nontrivial Killing tensors of valence two defined in the Minkowski plane. Then the vector space $i_{\Sigma'}(\mathbb{R}_1^2)$ spanned by $\mathbf{V}_i'$, $i=1,2,3$ is a Lie subalgebra of $\mathcal{X}(\Sigma')$ isomorphic to $i(\mathbb{R}_1^2)=\mathcal{K}^1(\mathbb{R}_1^2)$.

Proof: The proof is identical to that of Lemma 3.1. □

Employing Definition 2.2 and the result of Corollary 3.1 we obtain the following theorem:

Theorem 3.1: *(a) Assume in (3.6) $\gamma\neq 0$. Then a smooth function $G:\Sigma\to\mathbb{R}$ is a conformal $I(\mathbb{R}_1^2)$-invariant of $\mathcal{Q}(\mathbb{R}_1^2)\subset\mathcal{K}^2(\mathbb{R}_1^2)$ iff it has the following form:*

$$G=|Z_+|^{\epsilon}\tilde{F}(\Delta^1_{\mathbb{R}_1^2},\Delta^2_{\mathbb{R}_1^2}), \tag{3.8}$$

where $\tilde{F}:\mathbb{R}^2\to\mathbb{R}$ is a smooth function, $\epsilon\in\mathbb{R}$ and $\Delta^1_{\mathbb{R}_1^2},\Delta^2_{\mathbb{R}_1^2}\in\Sigma'$ are homogeneous polynomials of $A'',C,\alpha,\beta,\gamma$ given by

$$\Delta^1_{\mathbb{R}_1^2}=\gamma,\quad \Delta^2_{\mathbb{R}_1^2}=(\alpha^2+\beta^2-\gamma A'')^2-4(\gamma C+\alpha\beta)^2 \tag{3.9}$$

and

$$Z_+=\gamma(A''+2C)-(\alpha-\beta)^2. \tag{3.10}$$

(b) Assume in (3.6) $\gamma\neq 0$. Then a smooth function $F:\Sigma\to\mathbb{R}$ is a $I(\mathbb{R}^2_1)$-invariant of $\mathcal{Q}(\mathbb{R}^2_1)\subset\mathcal{K}^2(\mathbb{R}^2_1)$ iff it assumes the following form:

$$F=F(\Delta^1_{\mathbb{R}^2_1},\Delta^2_{\mathbb{R}^2_1}), \tag{3.11}$$

where $A'',C,\alpha,\beta,\gamma$ are as in (3.6).

Proof: Recall that invariance of an object under the entire Lie group is equivalent to infinitesimal invariance under the infinitesimal generators of the corresponding Lie algebra. In view of Corollary 3.1 the vector fields $\mathbf{V}'_i$, $i=1,2,3$ given by

$$\mathbf{V}'_1=\pi(\mathcal{L}_{\mathbf{T}}(\mathbf{Q}))=\alpha\frac{\partial}{\partial C}+\gamma\frac{\partial}{\partial\beta},$$

$$\mathbf{V}'_2=\pi(\mathcal{L}_{\mathbf{X}}(\mathbf{Q}))=2\alpha\frac{\partial}{\partial A''}+\beta\frac{\partial}{\partial C}+\gamma\frac{\partial}{\partial\alpha},$$

$$\mathbf{V}'_3=\pi(\mathcal{L}_{\mathbf{H}}(\mathbf{Q}))=-2C\frac{\partial}{\partial A''}-A''\frac{\partial}{\partial C}-\beta\frac{\partial}{\partial\alpha}-\alpha\frac{\partial}{\partial\beta}$$

can be chosen as a basis of the Lie algebra $i_{\Sigma'}(\mathbb{R}^2_1)$. Here $\mathbf{Q}$ is given by (3.6).

(a)$\Rightarrow$We solve the system of PDE's

$$\mathbf{V}'_i(G)=\epsilon_i, \tag{3.12}$$

for $i=1,2,3$. We view the system (3.12) as a system of three inhomogeneous linear partial differential equations in five variables that can be conveniently solved by repeated application of the method of characteristics. In the case $\gamma\neq 0$, we obtain solution (3.8). We note that the existence of a solution forces $\epsilon_1=\epsilon_2=0$, while ϵ in (3.8) is ϵ_3.

(a)$\Leftarrow$Straightforward.

(b)$\Rightarrow$The proof is analogous to part (a). This time we solve by the method of characteristics a simpler system of PDE's, namely,

$$\mathbf{V}'_i(F)=0, \tag{3.13}$$

for $i=1,2,3$. The general solution is given by (3.11).

(b)$\Leftarrow$Straightforward. □

Corollary 3.2: $\Delta^i_{\mathbb{R}^2_1}$, $i=1,2$ given by (3.11) are $I(\mathbb{R}^2_1)$-invariants of $\mathcal{K}^2(\mathbb{R}^2_1)$.

Definition 3.1: The quantities $\Delta^i_{\mathbb{R}^2_1}$, $i=1,2$ are called the fundamental $I(\mathbb{R}^2_1)$-invariants of $\mathcal{K}^2(\mathbb{R}^2_1)$.

Remark 3.3: As expected, in view of Theorem 2.2, we have obtained two $I(\mathbb{R}^2_1)$-invariants: $\dim\Sigma'-\dim i(\mathbb{R}^2_1)=5-3=2$.

Remark 3.4: We note that the $I(\mathbb{R}^2_1)$-invariants of the subspace of nontrivial Killing tensors of $\mathcal{K}^2(\mathbb{R}^2_1)$ have a striking resemblance to the $I(\mathbb{R}^2)$-invariants of the subspace of nontrivial Killing tensors of $\mathcal{K}^2(\mathbb{R}^2)$ [see (4.18)]. In spite of such a similarity, however, the polynomial $\Delta^2_{\mathbb{R}^2}\geqslant 0$, while $\Delta^2_{\mathbb{R}^2_1}$ factors over the reals.

Corollary 3.3: Let $Z_\pm=\gamma(A''\pm 2C)-(\alpha\mp\beta)^2$. The functions $I_\pm:\Sigma\to\mathbb{R}$ given by

$$I_\pm:=\operatorname{sgn}(Z_\pm) \tag{3.14}$$

are $I(\mathbb{R}^2_1)$-invariants of $\mathcal{Q}(\mathbb{R}^2_1)\subset\mathcal{K}^2(\mathbb{R}^2_1)$.

Proof: We note first that

$$Z_+ Z_- = \Delta^2_{\mathbb{R}^2_1}.$$

Next, using formulas (3.4) for the flows of the generators of $i(\mathbb{R}^2_1)$, we obtain

$$\overline{Z}_\pm = e^{\mp 2\phi} Z_\pm,$$

which implies the result. □

Various additional conformal $I(\mathbb{R}^2_1)$-invariants arise from the solution of the system of PDE's (3.12) used in the proof of part (a) of Theorem 3.1 when $\gamma = 0$. They will be used in the sequel to solve the problem of classification of separable Hamiltonian systems defined in the Minkowski plane $\mathbb{R}^2_1$.

Theorem 3.2: *Let $\gamma = 0$ in (3.7). Then $G: \Sigma \to \mathbb{R}$ is a conformal $I(\mathbb{R}^2_1)$-invariant of $\mathcal{Q}(\mathbb{R}^2_1) \subset \mathcal{K}^2(\mathbb{R}^2_1)$ iff*

(*a*)

$$G = \exp\left(\epsilon_3 \operatorname{arctanh}\left(\frac{-\beta}{\alpha} \right) \right) \tilde{F}(\alpha^2 - \beta^2), \tag{3.15}$$

when $\alpha^2 \neq \beta^2$. In this case $\epsilon_1 = \epsilon_2 = 0$.

(*b*)

$$G = |\alpha|^{-\epsilon_3/2} \exp\left(\frac{\epsilon_1 (A'' - 2C)}{4\alpha} \right) \tilde{F}((A'' + 2C)\alpha), \tag{3.16}$$

when $\alpha^2 = \beta^2 \neq 0$, $\alpha = \beta$. In this case $\epsilon_1 = \epsilon_2$.

(*c*)

$$G = |\alpha|^{\epsilon_3/2} \exp\left(\frac{-\epsilon_1 (A'' + 2C)}{4\alpha} \right) \tilde{F}((A'' - 2C)\alpha), \tag{3.17}$$

when $\alpha^2 = \beta^2 \neq 0$, $\alpha = -\beta$. In this case $\epsilon_1 = -\epsilon_2$.

In each of the above cases, $\tilde{F}$ represents an arbitrary smooth function.

Using the results of Theorem 3.2 we can derive additional $I(\mathbb{R}^2_1)$-invariants that will be used in the forthcoming sections to classify special separable cases of Hamiltonian systems defined in $\mathbb{R}^2_1$.

Corollary 3.4: Let $\gamma = 0$ in (3.6). Then we have
(i) $F = \operatorname{sgn}(\alpha^2 - \beta^2)$ is an $I(\mathbb{R}^2_1)$-invariant of $\mathcal{Q}(\mathbb{R}^2_1) \subset \mathcal{K}^2(\mathbb{R}^2_1)$,
(ii) let $\alpha^2 = \beta^2 \neq 0$. *Define*

$$\mu_\pm := \frac{A'' \pm 2C}{\alpha}. \tag{3.18}$$

Then we have

- *(a) then for $I_+ = 0, I_- = -1$ (i.e., $\alpha = \beta$), $F = \operatorname{sgn}(\mu_+)$ is an $I(\mathbb{R}^2_1)$-invariant of $\mathcal{Q}(\mathbb{R}^2_1) \subset \mathcal{K}^2(\mathbb{R}^2_1)$,*
- *(b) then for $I_+ = -1, I_- = 0$ (i.e., $\alpha = -\beta$), $F = \operatorname{sgn}(\mu_-)$ is an $I(\mathbb{R}^2_1)$-invariant of $\mathcal{Q}(\mathbb{R}^2_1) \subset \mathcal{K}^2(\mathbb{R}^2_1)$.*

IV. HAMILTON–JACOBI THEORY OF SEPARATION OF VARIABLES AND GROUP INVARIANTS OF KILLING TENSORS

Since the time of its inception in the 19th century the problem of integrability of a general Hamiltonian system defined by a natural Hamiltonian has been extensively studied. Its beauty and richness are largely due to a profound connection with the Hamilton–Jacobi theory of separation

of variables.[21–27] To establish the requisite language of the theory to be used throughout this paper, we recall briefly its basic concepts. Let $(M,\mathbf{g})$ be an n-dimensional pseudo-Riemannian manifold. Recall that a Hamiltonian system defined by a natural Hamiltonian function with a scalar potential V, which can be written as

$$H(\mathbf{q},\mathbf{p})=\tfrac{1}{2}g^{ij}(\mathbf{q})p_ip_j+V(\mathbf{q}), \tag{4.1}$$

can in many cases be integrated by quadratures by considering the corresponding Hamilton–Jacobi equation (HJE). Here g^{ij} are the contravariant components of the corresponding metric tensor $\mathbf{g}$ and $(\mathbf{q},\mathbf{p})\in T^*M$ are the canonical position-momenta coordinates. The procedure consists of a canonical coordinate transformation (CT) $T:(\mathbf{q},\mathbf{p})\rightarrow(\mathbf{u},\mathbf{v})$ to *separable coordinates* (SC) $(\mathbf{u},\mathbf{v})$, with respect to which the Hamilton–Jacobi equation

$$\frac{1}{2}g^{ij}(\mathbf{u})\frac{\partial W}{\partial u^i}\frac{\partial W}{\partial u^j}+V(\mathbf{u})=E,\quad v_j=\frac{\partial W}{\partial u^i}, \tag{4.2}$$

admits a *complete integral* (CI) $W(\mathbf{u},\mathbf{c})$, satisfying the nondegeneracy condition: $\det\|\partial^2W/\partial u^i\partial c_j\|_{n\times n}\neq 0$, where $\mathbf{c}=(c_1,\ldots,c_n)$ is a constant vector. The function W is usually sought in the form

$$W(\mathbf{u},\mathbf{c})=\sum_{i=1}^{n}W_i(u^i,\mathbf{c}),$$

which is the essence of the *additive separation ansatz*. In view of Jacobi's theorem, once W has been found, the integral curves of the flow generated by (4.40) can be determined from the equations

$$v_i=\frac{\partial W}{\partial u^i},\quad b_j=\frac{\partial W}{\partial c_j},\quad t-t_0=\frac{\partial W}{\partial E},$$

where $i=1,\ldots,n$, $j=1,\ldots,n-1$. The inverse canonical transformation $(\mathbf{u},\mathbf{v})\rightarrow(\mathbf{q},\mathbf{p})$ yields the solution in terms of the original position-momenta coordinates $(\mathbf{q},\mathbf{p})$. Geometrically, the Hamilton–Jacobi equation and its solution W can be interpreted as follows (see Benenti[22]): In a neighborhood of a regular point Eq. (4.2) determines a hypersurface $\mathcal{H}\subset T^*M$, while the set of equations $v_i=\partial W/\partial u_i$ determine a Lagrangian submanifold $\Lambda\subset T^*M$, as an image of a closed one-form dW. Therefore W is a solution to (4.2) iff $\mathcal{H}\subset\Lambda$.

The principal special cases of the canonical transformations to separable coordinates are the *point transformation*, in which case the separable coordinates are given by $u^i=u^i(\mathbf{q})$, $i=1,\ldots,n$ and the *generic (nonpoint) transformation*, in which case we have: $u^i=u^i(\mathbf{q},\mathbf{p})$, $v^i=v^i(\mathbf{q},\mathbf{p})$, $i=1,\ldots,n$. Moreover, the point transformation in this context is *(non)orthogonal* iff the metric tensor $\mathbf{g}$ of (4.40) is (non)diagonal with respect to the separable coordinates $u^1,\ldots,u^n$.

The existence of separable coordinates $(\mathbf{u},\mathbf{v})$ is usually guaranteed by the existence of an additional geometrical structure associated with the dynamics of the Hamiltonian system defined by (4.1). Thus, in the case of a point transformation to separable coordinates, they can be determined by the geometric properties of a certain Killing tensor (orthogonal separation of variables), or a Killing tensor in conjunction with an abelian Lie algebra of Killing vectors (nonorthogonal separation of variables).[28] These Killing tensors correspond to first integrals quadratic in the momenta of the Hamiltonian system defined by (4.1). When the canonical transformation to the separable coordinates is not a point transformation, the separable coordinates $(\mathbf{u},\mathbf{v})$ can be determined by the existence of either a (quasi-)bi-Hamiltonian structure or a Lax pair or both. A vast literature on the subject has emerged in recent years. Many papers have been devoted to the study

of integrable systems admitting bi-Hamiltonian and/or Lax representations from the point of view of separation of variables (see, for example, Refs. 29–35, as well as the relevant references therein).

Orthogonally separable Hamiltonian systems defined by natural Hamiltonians of the type (4.1) represent the most studied class of systems whose integrability can be asserted within the framework of the Hamilton–Jacobi theory. Examples of the Hamiltonian system belonging to this class include such well-known physical models as the harmonic oscillator, Coulomb–Kepler potential, the two integrable cases of the Hénon–Heiles potential, Yatsun's integrable potentials, the two particle nonperiodic Toda lattice, Calogero–Moser potential, and others. Global properties of the Hamiltonian systems defined on Riemannian manifolds have also been extensively studies by many authors (see Ref. 36 and the references therein). Since the first paper by Liouville[37] (see also Ref. 38 for historical details) devoted to the study of orthogonally separable Hamiltonians, the theoretical background has been developed by many well-known authors, including Morera,[39] Stäckel,[40] Eisenhart,[5] Kalnins and Miller,[13] Benenti,[28] and others (see also the relevant references therein). The compact and refined criterion of orthogonally separability due to Benenti[28] subsumes most of the previous results on orthogonal separability. It reads:

Theorem 4.1: *The Hamiltonian system defined by (4.1) is orthogonally separable if and only if there exists a valence two Killing tensor* $\mathbf{K}$ *with pointwise simple and real eigenvalues, orthogonally integrable eigenvectors such that* $d(\hat{\mathbf{K}}dV)=0$, *where the linear operator* $\hat{\mathbf{K}}$ *is given by* $\hat{\mathbf{K}}:=\mathbf{Kg}$.

The separable coordinates are defined by the integral curves of the eigenvectors of $\mathbf{K}$.[28] When $n=2$ the separable coordinates are also defined by the eigenvalues and/or the eigenvectors of $\mathbf{K}$. The tensor $\mathbf{K}$ satisfies the Killing tensor Eq. (2.1), which in component form can be written as follows:

$$[\mathbf{g},\mathbf{K}]^{ijk}=g^{(ij}{}_{,\ell}K^{k)\ell}-K^{(ij}{}_{,\ell}g^{k)\ell}=0. \tag{4.3}$$

It should be mentioned, however, that in applications involving the Hamiltonian systems defined in higher dimensions often an auxiliary tensor $\mathbf{L}$ is required in order to construct the separable coordinates. It is given by $\mathbf{L}:=1/(n-1)\mathrm{tr}(\mathbf{K})\mathbf{g}-\mathbf{K}$ and called a *conformal Killing tensor* (CKT).[41] The eigenvalues of $\mathbf{L}$ provide the coordinates of separations. Clearly, the Killing tensors $\mathbf{L}$ and $\mathbf{K}$ share the same *integrable* eigenvectors.

An important new facet to the theory of orthogonally separable Hamiltonian systems was added by Ferapontov and Fordy[42,43] in the form of a connection between the theory of orthogonally separable Hamiltonian systems and the theory of partial differential equations of *hydrodynamic type*. It appears that a system satisfying the conditions of Theorem 4.1 can be naturally associated with such a system of PDE's. Moreover, the process of finding separable coordinates in the original Hamiltonian system can then be related to the process of determining Riemann invariants in the corresponding system of hydrodynamic type. This fruitful idea has been extended to the study of Hamiltonian systems with vector potentials (see the review in Ref. 43, and references therein).

As has been previously mentioned, the study of orthogonally separable natural Hamiltonians in the sense described above was initiated by Liouville.[37] He considered the Hamiltonian system with two degrees of freedom modeling the motion of a particle on a curved surface. More specifically, Liouville showed that if there exists a coordinate system (u,v) in which the Hamiltonian enjoys the form

$$H=(A(u)+B(v))^{-1}[\tfrac{1}{2}(\epsilon_1 p_u^2+\epsilon_2 p_v^2)+C(u)+D(v)], \tag{4.4}$$

then the canonical Hamilton equations can be integrated by quadratures. The form of H also implies that the corresponding HJE can be integrated by separation of variables. In (4.4) $A(u)$,

$B(v)$, $C(u)$, $D(v)$ are smooth functions and $(\epsilon_1)^2=(\epsilon_2)^2=1$. Note that the form (4.4) has been derived without making any assumptions about the curvature of the two-dimensional pseudo-Riemannian space $(M,\mathbf{g})$.

In 1881 Morera[39] solved the converse problem. Thus, he showed that if a Hamiltonian system with two degrees of freedom can be solved by separation of variables, then there exists a system of coordinates in which the Hamiltonian (4.1) assumes the *Liouville form* (4.4). He also showed that in the Euclidean plane *orthogonal* separation of variables occurred only in Cartesian, polar, parabolic, and elliptic–hyperbolic coordinates, provided the Hamiltonian assumed the form (4.4) in the separable coordinates. We note that there can exist other systems of coordinates with respect to which the HJE separates, while the Hamiltonian (4.1) is not in the Liouville form (4.4).

This remarkable equivalence can also be reformulated in the form of the celebrated *Bertrand–Darboux–Whittaker theorem*,[47] which states that separability of the HJE corresponding to the Hamiltonian system with two degrees of freedom defined by (4.1) is equivalent to the existence of a second first integral quadratic in the momenta:

$$F=K^{ij}(\mathbf{q})p_ip_j+U(\mathbf{q}),\quad i,j=1,2, \tag{4.5}$$

where K^{ij} are the components of the corresponding Killing tensor $\mathbf{K}$ with pointwise simple and real eigenvalues and $dU=2\hat{\mathbf{K}}dV$. The theorem appears to be a particular case of Theorem IV, since the eigenvectors of $\mathbf{K}$ in this case are automatically integrable. For a long time a procedure based on the Bertrand–Darboux–Whittaker theorem has provided a working method for integrating the Hamiltonian systems with two degrees of freedom defined by (4.1). More specifically, once a second integral quadratic in the momenta has been found, the method consists of solving the second order PDE resulting from the involutiveness of F and H. The solution is used to transform a given Hamiltonian to the form (4.4). The coordinates (u,v), thus determined, provide separable coordinates for the associated HJE, which entails complete integrability of the Hamiltonian system defined by (4.1). However, even in the simplest case, namely when the Hamiltonian system (4.1) is defined in the Euclidean plane, finding the separable coordinates following this scheme involves quite a few steps.[47] The procedure is illustrated by the following example.

Example 4.1 (Method I. Second Integrable Case of Yatsun): Let a Hamiltonian system be defined by the following Hamiltonian function:

$$H_2(q^1,q^2,p_1,p_2) = \tfrac{1}{2}(p_1^2 + p_2^2) + V_2(q^1,q^2), \tag{4.6}$$

where

$$V_2(q^1,q^2) = -2\left((q^1)^4 + 2(q^1)^2(q^2)^2 + \frac{2\lambda}{g^2}(q^2)^4\right) + 4((q^1)^3 + q^1(q^2)^2) - 2((q^1)^2 + (q^2)^2). \tag{4.7}$$

This system describes the equations of motion of an SU(2) Yang–Mills theory after O(4)-symmetry reduction.[44,45] It has been shown[44,45] that the Hamiltonian system is completely integrable if $g^2=2\lambda$ admitting the following additional first integral independent of (4.6):

$$F_2=((q^2)^2+\tfrac{3}{4})p_1^2-(2q^1-1)q^2p_1p_2+(q^1-1)q^1p_2^2-3(q^1)^4-2(q^1)^2(q^2)^2+(q^2)^4 +6(q^1)^3+2(q^1)(q^2)^2-3(q^1)^2. \tag{4.8}$$

Therefore in view of the previous comments the Hamiltonian system in question can be solved by the Hamilton–Jacobi method of separation of variables. To find the separable coordinates, we employ the procedure based on the Bertrand–Darboux–Whittaker theorem, which involves bringing the Hamiltonian function (4.6) to the form (4.4):

(1) Observe that the components of the Killing tensor are given by

$$K^{(1)}=\begin{pmatrix} \frac{3}{4}+(q^2)^2 & \frac{1}{2}q^2-q^1q^2 \\ \frac{1}{2}q^2-q^1q^2 & -q^1+(q^1)^2 \end{pmatrix}. \tag{4.9}$$

(2) Write down the PDE implied by the compatibility condition $d(\hat{\mathbf{K}}dV)=0$:

$$\left(\frac{\partial^2 V}{\partial(q^2)^2}-\frac{\partial^2 V}{\partial(q^1)^2}\right)(-2q^1q^2+q^2)+2\frac{\partial^2 V}{\partial q^1\partial q^2}\left((q^2)^2-(q^1)^2+\frac{3}{4}+q^1\right)+\frac{\partial V}{\partial q^1}6q^2+\frac{\partial V}{\partial q^2}(-6q^1+3)=0. \tag{4.10}$$

(3) Perform the change of the variable $q^1\to z+\frac{1}{2}$, $q^2\to y$, to obtain

$$\left(\frac{\partial^2 V}{\partial z^2}-\frac{\partial^2 V}{\partial y^2}\right)zy+\frac{\partial^2 V}{\partial z\partial y}(y^2-z^2+1)+\frac{\partial V}{\partial z}3y-\frac{\partial V}{\partial y}3z=0. \tag{4.11}$$

(4) Consider (following Darboux!) the differential equation of the characteristics of (4.11):

$$zy(dy^2-dz^2)+(z^2-y^2-1)dzdy=0. \tag{4.12}$$

(5) Introduce the new variables $u:=z^2$ and $v:=y^2$ to transform (4.12) into the following ODE:

$$\left(\frac{dv}{du}\right)^2(u-v)+\frac{dv}{du}(u-v-1)=0, \tag{4.13}$$

which is a *Clairaut's equation,* which has a general solution of the form

$$(m+1)(mz^2-y^2)-m=0 \tag{4.14}$$

in the original variables z,y.

(6) Rewrite (4.14) in terms of a new parameter α to get

$$\frac{z^2}{\alpha^2}+\frac{y^2}{\alpha^2-1}=1.$$

Observe that the characteristic curves of the PDE are two families of confocal conics. Therefore taking the parameters of the confocal hyperbolas and ellipses as coordinates, we have

$$z=\alpha\beta, \quad y=[(\alpha^2-1)(1-\beta)]^{1/2},$$

or

$$z=\cosh(u)\cos(v), \quad y=\sinh(u)\sin(v).$$

(7) Write the PDE (4.11) in terms of new variables α and β to obtain

$$(\beta^2-\alpha^2)\frac{\partial^2 V}{\partial\alpha\partial\beta}+2\beta\frac{\partial V}{\partial\alpha}-2\alpha\frac{\partial V}{\partial\beta}=0,$$

which has a general solution

$$V=\frac{f(\alpha)-\phi(\beta)}{\alpha^2-\beta^2}$$

in the Liouville form.

(8) Finally, transform back to the original coordinates q^1 and q^2 to find

$$\begin{cases} q^1 = \frac{1}{2} + \cosh(u)\cos(v), \\ q^2 = \sinh(u)\sin(v). \end{cases} \tag{4.15}$$

Therefore the separable coordinates are of the shifted elliptic–hyperbolic type.

(9) Transform the momenta and potential accordingly, to obtain the following Liouville form of the Hamiltonian H_2 in the elliptic–hyperbolic coordinates

$$H_2 = \frac{\frac{1}{2}(p_u^2 + p_v^2) + g(\cos^2(v)) - g(\cosh^2(u))}{\cosh^2(u) - \cos^2(v)}, \tag{4.16}$$

where $p_u = \partial W/\partial u$, $p_v = \partial W/\partial v$, and

$$g(\eta) = 2\eta^3 - 3\eta^2 + \tfrac{9}{8}\eta. \tag{4.17}$$

Hence we conclude that the Hamiltonian H_2 is orthogonally separable in the (u,v) coordinates.

For example, this is essentially the procedure used by Rauch–Wojciechowski[48] to integrate the second integrable case of the Hénon–Heiles potential by the Hamilton–Jacobi method of separation of variables and obtain the transformations to the separable coordinates. Recently the method has been generalized to higher dimensions,[49] in which case one has to deal not with a single PDE, but a system of PDE's of the type (4.10) called the *Bertrand–Darboux system of PDE's*.

The above example illustrates that the problem of integrating a Hamiltonian system by the Hamilton–Jacobi method of separation of variables consists essentially of two parts. *First*, one has to determine the type of the system of separable coordinates involved and recall the known coordinate transformations from (q^1,q^2) to (u,v). At this stage the separable coordinates are defined up to the action of the isometry group $I(\mathbb{R}^2)$. *Second*, one has to locate the separable coordinates (u,v) with respect to the given original coordinates (q^1,q^2), that is to take into account any additional translation and/or rotation determined by the action of $I(\mathbb{R}^2)$. Thus, in Example 4.1 the orthogonal separable coordinates have been determined to be shifted elliptic–hyperbolic coordinates. The corresponding coordinate transformation from (q^1,q^2) to (u,v) is given by (4.15).

It is clear that the whole procedure rests on the properties of the Killing tensor (4.9) as well as the action of the isometry group $I(\mathbb{R}^2)$. This observation enabled the present authors to considerably simplify the procedure by making it completely algebraic.[20] To this end, we determined the action of the isometry group $I(\mathbb{R}^2)$ in the space $\mathcal{K}^2(\mathbb{R}^2)$ defined by the general form (2.9) and derived the $I(\mathbb{R}^2)$-*invariants* $\Delta^1_{\mathbb{R}^2}$ and $\Delta^2_{\mathbb{R}^2}$ of (2.9) as polynomial functions of the parameters $A,B,C,\alpha,\beta,\gamma$:

$$\Delta^1_{\mathbb{R}^2} = \gamma, \quad \Delta^2_{\mathbb{R}^2} = (\alpha^2 - \beta^2 + \gamma(B-A))^2 + 4(\gamma C + \alpha\beta)^2. \tag{4.18}$$

The functions $\Delta^i_{\mathbb{R}^2}$, $i=1,2$ can be used to characterize the type of separable coordinate(s), given the Killing tensor defined by a first integral (4.1) quadratic in the momenta. The six parameters $A,B,C,\alpha,\beta,\gamma$ have also been used to determine any translation and/or rotation of the separable coordinates (u,v) with respect to the original coordinates (q^1,q^2). See Table I in Ref. 20 for more details. In order to illustrate the new method and compare it with Method I used above, we reconsider the Hamiltonian system defined by (4.7) from this new viewpoint.

Example 4.2 [Method II (Ref. 20). Second Integrable Case of Yatsun]: To employ the new method based on the $I(\mathbb{R}^2)$-group invariants of the Killing tensors, we again begin by considering the Killing tensor defined by the first integral (4.8).

(1) The corresponding Killing tensor defined by the first integral quadratic in the momenta is found to be

$$K^{(1)}=\begin{pmatrix} \frac{3}{4}+(q^2)^2 & \frac{1}{2}q^2-q^1q^2 \\ \frac{1}{2}q^2-q^1q^2 & -q^1+(q^1)^2 \end{pmatrix}. \tag{4.19}$$

(2) Comparing (4.19) with (2.9), we determine the parameters: $A=\frac{3}{4}$ $B=C=\alpha=0$ $\beta=-\frac{1}{2}$, and $\gamma=1$. Next, we use Table I in Ref. 20 to find after a simple computation that in addition to $\Delta^1_{\mathbb{R}^2}=\gamma=1\neq 0$, the second $I(\mathbb{R}^2)$-invariant $\Delta^2_{\mathbb{R}^2}=1/4\neq 0$. This indicates that the coordinates of separation are of the elliptic–hyperbolic type. Using the corresponding formulas presented in Table I,[20] we find the constants $a=1/2$, $b=0$ (translations along the q^1 and q^2 axes, respectively), $\theta=0$ (rotation angle), $k=1$ (the distance between the foci). This immediately yields the transformation formulas to the separable coordinates:

$$\begin{cases} q^1=\frac{1}{2}+\cosh(u)\cos(v), \\ q^2=\sinh(u)\sin(v), \end{cases} \tag{4.20}$$

which agrees with the results previously obtained.

Clearly, the new method considerably simplifies the process of integration by replacing an *analytical* procedure with an *algebraic* one (compare with Example 4.1). Due to this fact, *it is now easy to incorporate the algorithm into a computer algebra package*. The corresponding programs have been implemented in the computer algebra system MAPLE.

In the present paper we take the next step in developing the algorithm by extending its applicability to the Hamiltonian systems defined in the Minkowski plane $\mathbb{R}^2_1$. The situation in this case is much more complicated than the case of Hamiltonian systems defined in the Euclidean plane $\mathbb{R}^2$ due to the fact that there exist a larger number of separable coordinate systems. It is well known[25,15] that in this setting there exist ten distinct (in a certain sense) types of separable systems of coordinates determined by the corresponding Killing tensors. Therefore one has to find an appropriate set of invariants of the general Killing tensor that can be used to characterize each of the separable coordinate systems and to determine the corresponding transformations to separable coordinates.

V. SEPARABLE KILLING TENSORS IN THE LIOUVILLE–MORERA COORDINATES (u,v)

In this section we extend our study to the Hamiltonian systems defined in the Minkowski plane $\mathbb{R}^2_1$. We shall follow the general procedure based on $I(\mathbb{R}^2)$-invariants devised in Ref. 20 to classify orthogonally separable Hamiltonian systems defined in the Euclidean plane $\mathbb{R}^2$. In order to be able to employ the (conformal) $I(\mathbb{R}^2_1)$-invariants of $\mathcal{K}^2(\mathbb{R}^2_1)$ to the classification problem, we determine first the orthogonally-separable Hamiltonian systems defined in $\mathbb{R}^2_1$ with respect to a special system of coordinates that is introduced below.

Consider a Hamiltonian system with two degrees of freedom defined by

$$H(\mathbf{q},\mathbf{p})=\tfrac{1}{2}g^{ij}p_ip_j+V(\mathbf{q}), \tag{5.1}$$

where g^{ij}, $i,j=1,2$ are the contravariant components of a Lorentzian metric $\mathbf{g}$, which asserts that the underlying manifold $(M,\mathbf{g})$ is pseudo-Riemannian. According to the approach to the study of integrability of Hamiltonian systems with two degrees of freedom defined in Riemannian spaces introduced by Liouville,[37] we claim that if the metric $\mathbf{g}$ as well as the potential function V in (5.1) take on special *separable* forms in some coordinate system (u,v), the Hamiltonian system defined by (5.1) can be integrated by quadratures with respect to (u,v). It has been shown in Ref. 53 that in the coordinates (u,v) the Hamiltonian function takes on the following form:

$$H=(A(u)+B(v))^{-1}[\tfrac{1}{2}(p_u^2-p_v^2)+C(u)+D(v)], \tag{5.2}$$

where $A(u)$, $B(v)$, $C(u)$, and $D(v)$ are arbitrary smooth functions. This setting also implies additive separation of variables in the corresponding HJE (4.2). Note that the metric entering the formula (5.2) enjoys the *Liouville form:*

$$ds^2=(A(u)+B(v))(du^2-dv^2). \tag{5.3}$$

Conversely, following Morera,[39] we can also conclude that if the Hamiltonian system defined by (5.1) can be integrated via additive separation of variables in the associated HJE (4.2), the Hamiltonian function (5.1) can be transformed to the form (5.2) with respect to the separable coordinates. Hence, in view of this classical equivalence, we call (u,v) the *Liouville–Morera (LM) separable coordinates*.

It is easy to see that the Hamiltonian system defined by (5.1) in the LM coordinates admits an additional first integral of motion of the form:

$$F=\frac{B(v)p_u^2+A(u)p_v^2+2(B(v)C(u)-A(u)D(v))}{A(u)+B(v)}. \tag{5.4}$$

Note, the integral of motion (5.4) is quadratic in the momenta with the corresponding (covariant) Killing tensor $\mathbf{K}^{LM}\in\mathcal{K}^2(\mathbb{R}_1^2)$ given by

$$\mathbf{K}^{LM}=(A(u)+B(v))\,\mathrm{diag}(B(v),A(u)). \tag{5.5}$$

Clearly, the functions $A(u)$ and $B(v)$ are the eigenvalues of the linear operator $\hat{\mathbf{K}}=\mathbf{K}^{LM}\mathbf{g}^{-1}$, where $\mathbf{g}$ is the metric of (5.1). Employing the corresponding eigenvectors of $\mathbf{K}^{LM}$, one can show by solving the Killing tensor equation (2.1) in the moving frame of the normalized eigenvectors,[52] that the most general solution has the following form:

$$\mathbf{K}=\ell\mathbf{g}+m\mathbf{K}^{LM}, \tag{5.6}$$

where $\ell,m\in\mathbb{R}$ are arbitrary constants. In this work we are concerned with the case when the Riemann curvature tensor is zero. Solving the resulting differential equation allows us to determine the ten admissible metrics along with the corresponding Killing tensors [corresponding to (5.3) and (5.6), respectively], which we list below (see Ref. 52 for more details). In essence, solving these differential equations yields the explicit formulas for the functions $A(u),B(v),C(u)$, and $D(v)$ in (5.3) and (5.6). Note that the eigenvalues λ_1,λ_2 of the Killing tensor (5.5) determine the *ten orthogonal separable coordinate webs:* $\lambda_i=\mathrm{const}$, $i=1,2$, provided they are not everywhere constant. If one or both of them are everywhere constant, the corresponding eigenvectors have to be also used. The orthogonal separable webs so defined can be employed to solve the associated HJE via additive separation of variables. In summary, the ten *separable cases* (SC) are determined by their respective metrics and Killing tensors:

$$\mathrm{SC1}:\ \begin{cases}\mathrm{d}s^2_{(1)}=\mathrm{d}u^2-\mathrm{d}v^2,\\ \mathbf{K}^{(1)}=\mathrm{diag}(1,0),\end{cases} \tag{5.7}$$

$$\mathrm{SC2}:\ \begin{cases}\mathrm{d}s^2_{(2)}=\mathrm{d}u^2-u^2\mathrm{d}v^2,\\ \mathbf{K}^{(2)}=\mathrm{diag}(0,u^4),\end{cases} \tag{5.8}$$

$$\mathrm{SC3}:\ \begin{cases}\mathrm{d}s^2_{(3)}=(u+v)(\mathrm{d}u^2-\mathrm{d}v^2),\\ \mathbf{K}^{(3)}=(u+v)\mathrm{diag}(v,u),\end{cases} \tag{5.9}$$

$$\mathrm{SC4}:\ \begin{cases}\mathrm{d}s^2_{(4)}=(u^2-v^2)(\mathrm{d}u^2-\mathrm{d}v^2),\\ \mathbf{K}^{(4)}=(u^2-v^2)\mathrm{diag}(v^2,u^2),\end{cases} \tag{5.10}$$

$$\text{SC5:}\quad \begin{cases} ds^2_{(5)} = k^2(\sin u + \sin v)(du^2 - dv^2), \\ \mathbf{K}^{(5)} = k^2(\sin u + \sin v)\,\mathrm{diag}(\sin v, \sin u), \end{cases} \tag{5.11}$$

$$\text{SC6:}\quad \begin{cases} ds^2_{(6)} = (e^u + e^v)(du^2 - dv^2), \\ \mathbf{K}^{(6)} = (e^u + e^v)\,\mathrm{diag}(e^v, e^u), \end{cases} \tag{5.12}$$

$$\text{SC7}\ :\begin{cases} ds^2_{(7)} = (e^u - e^v)(du^2 - dv^2), \\ \mathbf{K}^{(7)} = (e^u - e^v)\,\mathrm{diag}(-e^v, e^u), \end{cases} \tag{5.13}$$

$$\text{SC8:}\quad \begin{cases} ds^2_{(8)} = k^2(\sinh u + \sinh v)(du^2 - dv^2), \\ \mathbf{K}^{(8)} = k^2(\sinh u + \sinh v)\,\mathrm{diag}(\sinh v, \sinh u), \end{cases} \tag{5.14}$$

$$\text{SC9}\ :\begin{cases} ds^2_{(9)} = k^2(\cosh u + \cosh v)(du^2 - dv^2), \\ \mathbf{K}^{(9)} = k^2(\cosh u + \cosh v)\,\mathrm{diag}(\cosh v, \cosh u), \end{cases} \tag{5.15}$$

$$\text{SC10:}\quad \begin{cases} ds^2_{(10)} = k^2(\cosh u - \cosh v)(du^2 - dv^2), \\ \mathbf{K}^{(10)} = k^2(\cosh u - \cosh v)\,\mathrm{diag}(-\cosh v, \cosh u). \end{cases} \tag{5.16}$$

Thus, once the coordinates of separation (u,v) for the Hamiltonian (5.1) and additional first integral (5.4) are available, it is not difficult to determine the type of separation of variables occurring in the associated HJE (4.2). Indeed, one has to simply compare the metric of the Hamiltonian (5.1) and Killing tensor of the additional first integral of motion (5.4) with the list above and select the right SC. Then, the problem is solved. However, it is often the case that a Hamiltonian function is determined initially with respect to the pseudo-Cartesian coordinates, in which case (5.1) takes the form:

$$H(\mathbf{q},\mathbf{p}) = \tfrac{1}{2}(p_1^2 - p_2^2) + V(q^1, q^2). \tag{5.17}$$

Thus, in order to solve the problem of integrability in this case, one needs to answer the following questions.

(1) Is the Hamilton–Jacobi equation of (5.17) orthogonally separable in one or *more* of the above systems of coordinates?
(2) If yes, how does one determine the coordinate transformation(s) to the system(s) of separable coordinates?

The first question can be solved by employing Theorem 4.1, which generalizes the results concerning the geodesic case obtained by Eisenhart[5] (see also Ref. 13). Next, one can make use of the general solution of the Killing tensor equation (2.1) in the coordinates (5.17):

$$K_{ij} = \begin{pmatrix} A + 2\alpha q^2 + \gamma(q^2)^2 & C - \alpha q^1 - \beta q^2 - \gamma q^1 q^2 \\ C - \alpha q^1 - \beta q^2 - \gamma q^1 q^2 & B + 2\beta q^1 + \gamma(q^1)^2 \end{pmatrix}. \tag{5.18}$$

By applying the compatibility condition $d(\hat{\mathbf{K}}dV) = 0$ (see Theorem 4.1) to (5.18) one then obtains all of the admissible Killing tensors defining the first integrals quadratic in momenta. If there is at least one Killing tensor with real and pointwise distinct eigenvalues, the system defined by (4.1) is *orthogonally separable*. The existence of more Killing tensors with the designated properties indicates that the system is *superseparable*.[20,28,51]

Finding the answer to the second problem is much more complex. It is largely due to the fact that the separable coordinates defined by the ten Killing tensors above are defined only up to the action of the isometry group $I(\mathbb{R}^2_1)$, i.e., up to the corresponding *hyperbolic* rotation and/or translations of the Minkowski plane $\mathbb{R}^2_1$. Geometrically, this means that in general (due to the existence of the potential function V in (5.1)) the two systems of coordinates of $\mathbb{R}^2_1$ featured in this

section, namely, (q^1,q^2) and (u,v) are not aligned in $\mathbb{R}^2_1$. It is our main objective therefore to use the (conformal) $I(\mathbb{R}^2_1)$-invariants of the space $\mathbb{R}^2_1$ to develop an effective *algorithmic method* for determining the transformations to separable coordinates for the Hamiltonian system defined by (5.1).

VI. SEPARABLE KILLING TENSORS IN THE CANONICAL PSEUDO-CARTESIAN COORDINATES (t,x)

Consider the geodesic Hamiltonian function defined in $\mathbb{R}^2_1$, which amounts to setting $V(\mathbf{q})=$constant in (5.17):

$$H(t,x,p_t,p_x)=\tfrac{1}{2}(p_t^2-p_x^2), \tag{6.1}$$

where (t,x) are *canonical pseudo-Cartesian coordinates*. Unlike the general case ($V(\mathbf{q})\neq$const) described in the previous section, the corresponding Hamiltonian system is orthogonally separable in all ten of the coordinate systems SC1-10. Moreover, we can choose pseudo-Cartesian coordinates to have a particularly simple relation with the separable web in each of the separable cases SC1-10. We call the pseudo-Cartesian coordinates thus chosen *canonical pseudo-Cartesian coordinates* (t,x). The transformations $(t,x)\to(u,v)$ between the separable coordinates (u,v) defined by each of the separable webs and the canonical pseudo-Cartesian coordinates (t,x) are listed below, together with their corresponding Killing tensors obtained from (5.7) to (5.16) via the tensor transformation laws.

Coordinate transformations:

SC1

$$\begin{aligned} t&=u,\\ x&=v, \end{aligned} \tag{6.2}$$

SC2

$$\begin{aligned} t&=u\cosh v,\\ x&=u\sinh v, \end{aligned} \tag{6.3}$$

SC3

$$\begin{aligned} t&=\tfrac{1}{4}(u+v)^2+\tfrac{1}{2}(u-v),\\ x&=-\tfrac{1}{4}(u+v)^2+\tfrac{1}{2}(u-v), \end{aligned} \tag{6.4}$$

SC4

$$\begin{aligned} t&=\tfrac{1}{2}(u^2+v^2),\\ x&=uv, \end{aligned} \tag{6.5}$$

SC5

$$\begin{aligned} t&=2\sqrt{2}k\cos\left(\frac{u}{2}+\frac{\pi}{4}\right)\cos\left(\frac{v}{2}+\frac{\pi}{4}\right),\\ x&=2\sqrt{2}k\sin\left(\frac{u}{2}+\frac{\pi}{4}\right)\sin\left(\frac{v}{2}+\frac{\pi}{4}\right), \end{aligned} \tag{6.6}$$

SC6

$$t=\sinh(\tfrac{1}{2}(u-v))+2e^{(1/2)(u+v)},$$
$$x=\sinh(\tfrac{1}{2}(u-v))-2e^{(1/2)(u+v)}, \tag{6.7}$$

SC7

$$t=\cosh(\tfrac{1}{2}(u-v))+2e^{(1/2)(u+v)},$$
$$x=\cosh(\tfrac{1}{2}(u-v))-2e^{(1/2)(u+v)}, \tag{6.8}$$

SC8

$$t=k\sqrt{2}(\cosh(\tfrac{1}{2}(u+v))+\sinh(\tfrac{1}{2}(u-v))),$$
$$x=k\sqrt{2}(\cosh(\tfrac{1}{2}(u+v))-\sinh(\tfrac{1}{2}(u-v))), \tag{6.9}$$

SC9

$$t=2k\sqrt{2}\sinh\frac{u}{2}\cosh\frac{v}{2},$$
$$x=2k\sqrt{2}\cosh\frac{u}{2}\sinh\frac{v}{2}, \tag{6.10}$$

SC10

$$t=2k\sqrt{2}\cosh\frac{u}{2}\cosh\frac{v}{2}$$
$$x=2k\sqrt{2}\sinh\frac{u}{2}\sinh\frac{v}{2}. \tag{6.11}$$

Separable Killing tensors in canonical pseudo-Cartesian coordinates:
SC1

$$\begin{pmatrix}1 & 0\\ 0 & 0\end{pmatrix}, \tag{6.12}$$

SC2

$$\begin{pmatrix}x^2 & -tx\\ -tx & t^2\end{pmatrix}, \tag{6.13}$$

SC3

$$\begin{pmatrix}\frac{1}{4}-x & -\frac{1}{4}+\frac{1}{2}t-\frac{1}{2}x\\ -\frac{1}{4}+\frac{1}{2}t-\frac{1}{2}x & \frac{1}{4}+t\end{pmatrix}, \tag{6.14}$$

SC4

$$\begin{pmatrix} 0 & -x \\ -x & 2t \end{pmatrix}, \tag{6.15}$$

SC5

$$\begin{pmatrix} k^2-\frac{1}{4}x^2 & \frac{1}{4}tx \\ \frac{1}{4}tx & k^2-\frac{1}{4}t^2 \end{pmatrix}, \tag{6.16}$$

SC6

$$\begin{pmatrix} \frac{1}{4}x^2 & -\frac{1}{4}-\frac{1}{4}tx \\ -\frac{1}{4}-\frac{1}{4}tx & \frac{1}{4}+\frac{1}{4}t^2 \end{pmatrix}, \tag{6.17}$$

SC7

$$\begin{pmatrix} -\frac{1}{4}+\frac{1}{4}x^2 & \frac{1}{4}-\frac{1}{4}tx \\ \frac{1}{4}-\frac{1}{4}tx & -\frac{1}{4}+\frac{1}{4}t^2 \end{pmatrix}, \tag{6.18}$$

SC8

$$\begin{pmatrix} \frac{1}{4}x^2 & k^2-\frac{1}{4}tx \\ k^2-\frac{1}{4}tx & \frac{1}{4}t^2 \end{pmatrix}, \tag{6.19}$$

SC9

$$\begin{pmatrix} k^2+\frac{1}{4}x^2 & -\frac{1}{4}tx \\ -\frac{1}{4}tx & k^2+\frac{1}{4}t^2 \end{pmatrix}, \tag{6.20}$$

SC10

$$\begin{pmatrix} -k^2+\frac{1}{4}x^2 & -\frac{1}{4}tx \\ -\frac{1}{4}tx & -k^2+\frac{1}{4}t^2 \end{pmatrix}. \tag{6.21}$$

Remark 6.1: Note that the Killing tensors (6.12)–(6.21) in the coordinates (t,x) are symmetrized sums of (tensor) products of the Killing vectors (3.2). In addition, we observe that the formulas (6.12)–(6.21) are compatible with the general form (5.18).

Figures 1–10 illustrate the ten separable webs defined by the eigenvectors of the respective Killing tensors (6.12)–(6.21) in terms of the corresponding canonical pseudo-Cartesian coordinates (6.2)–(6.11) (see also Refs. 14, 15).

Remark 6.2: We can use the separable Killing tensors in the (t,x) coordinates to solve the problem of classification in terms of the $I(\mathbb{R}^2_1)$-invariants of $\mathcal{K}^2(\mathbb{R}^2_1)$. However, to solve the problem of finding (point) transformations from the noncanonical pseudo-Cartesian coordinates (q^1,q^2) of (5.17) to orthogonally separable coordinates (u,v) a more delicate analysis, which takes into account all the metric-preserving and signature-reversing transformations of $\mathbb{R}^2_1$ including the actions induced by the isometry group $I(\mathbb{R}^2_1)$, has to be undertaken.

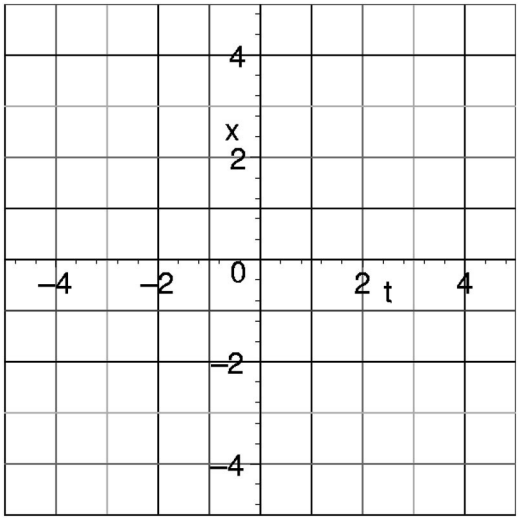

FIG. 1. Separable case 1.

VII. RIGID MOTIONS

As explained in the previous section the canonical pseudo-Cartesian coordinates (t,x) have been chosen to have a simple relation with the separable webs in each of the cases SC1–SC10. These choices are reflected in the coordinate transformations $(t,x)\rightarrow(u,v)$ defined by (6.2)–(6.11). It must be noted that even though the original coordinates (q^1,q^2) are also pseudo-Cartesian, they are equivalent to the coordinates (t,x) only modulo transformations which preserve the Lorentzian metric **g** of the Hamiltonian (4.1) or reverse its signature. The set of such transformations forms a group L (under composition) generated by elements of the discrete group $R=\langle R_1,R_2\rangle$, where

$$R_1:\ \overline{t}=t,\ \overline{x}=-x \quad (\text{spatial reflection } x\leftrightarrow -x),$$

$$R_2:\ \overline{t}=x,\ \overline{x}=t \quad (\text{permutation } t\leftrightarrow x),$$

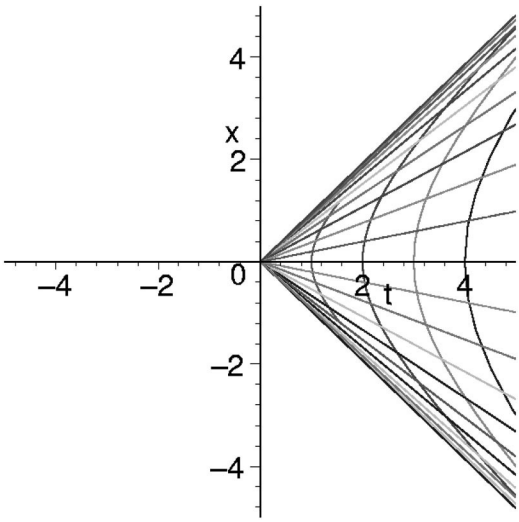

FIG. 2. Separable case 2.

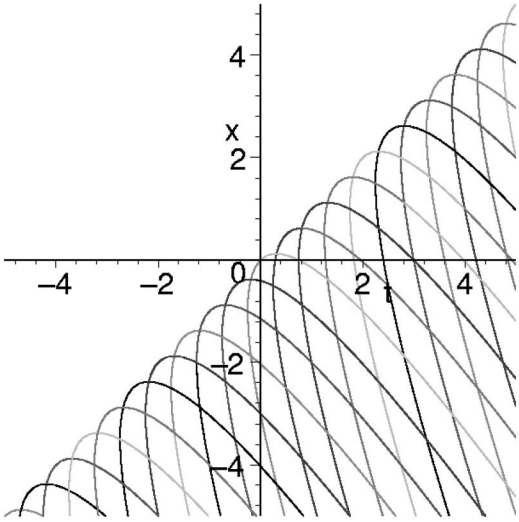

FIG. 3. Separable case 3.

and the continuous group $I(\mathbb{R}_1^2)$. Note that R consists of eight discrete transformations. Recall that the set of isometries $I(\mathbb{R}_1^2)$ constitutes a Lie group that consists of all translations $t_{\mathbf{a}}$ of $\mathbb{R}_1^2$ [which is an abelian subgroup of $I(\mathbb{R}_1^2)$ isomorphic under vector addition to $\mathbb{R}^2$] and the set of linear isometries $\mathrm{O}_1(2)$ [the latter being a closed subgroup of $GL_2(\mathbb{R})$] $I(\mathbb{R}_1^2)$ is commonly known as the *Poincaré group* or *inhomogeneous Lorentz group*. Note that the element of $\mathrm{O}_1(2)$ defined by the semiorthogonal matrix

$$\begin{pmatrix} \cosh\phi & \sinh\phi \\ \sinh\phi & \cosh\phi \end{pmatrix}$$

for the corresponding $\phi \in \mathbb{R}$ is called a *hyperbolic rotation* in $\mathbb{R}_1^2$ through an (oriented) Lorentz angle ϕ. $\mathrm{O}_1(2)$ is not compact [unlike O(2)] and has four components. The canonical pseudo-Cartesian coordinates (t,x) can be related to the given pseudo-Cartesian coordinates (q^1,q^2) through the following parametrization of the group L:

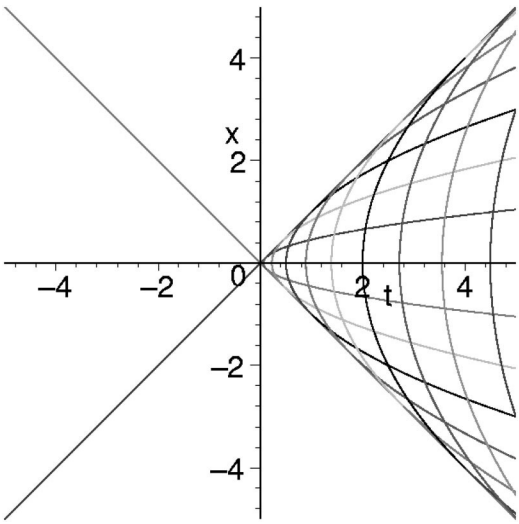

FIG. 4. Separable case 4.

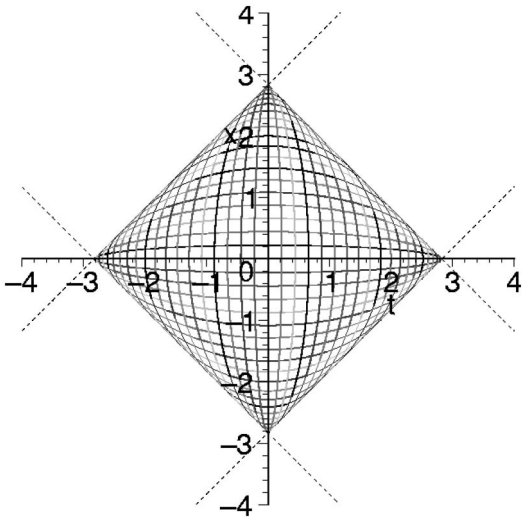

FIG. 5. Separable case 5.

$$\begin{pmatrix} q^1 \\ q^2 \end{pmatrix} = t_{\mathbf{a}} \circ \rho_\phi \circ r \begin{pmatrix} t \\ x \end{pmatrix} = \begin{pmatrix} \cosh\phi & \sinh\phi \\ \sinh\phi & \cosh\phi \end{pmatrix} \left[r \begin{pmatrix} t \\ x \end{pmatrix} \right] + \begin{pmatrix} a \\ b \end{pmatrix}, \tag{7.1}$$

where $r \in R$. Hence, once the problem of classifying the separable cases has been accomplished, we can effect the transformation from the given coordinates (q^1,q^2) to the separable coordinates (u,v) according to

$$(q^1,q^2) = t_{\mathbf{a}} \circ \rho_\phi \circ r \circ T_{(i)}(u,v), \tag{7.2}$$

where $T_{(i)}$ is the appropriate standard coordinate transformation [listed in (6.2)–(6.11)] corresponding to the separable case.

Recall that the components of any Killing tensor in Minkowski space have a similar form (2.9) with respect to any system of pseudo-Cartesian coordinates. Following the approach developed in Ref. 20, we note that transformations (7.1) from the (q^1,q^2) pseudo-Cartesian coordinates

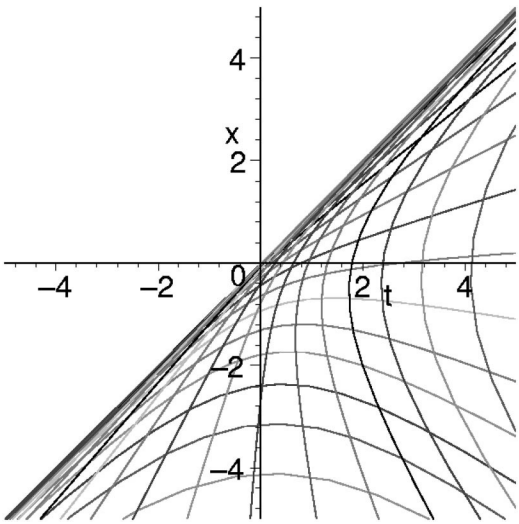

FIG. 6. Separable case 6.

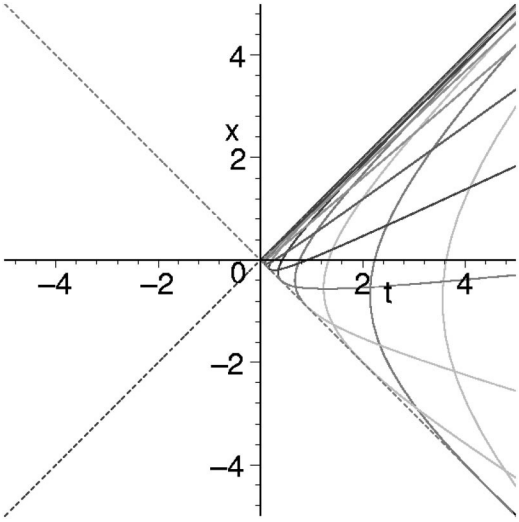

FIG. 7. Separable case 7.

to the (t,x) pseudo-Cartesian coordinates induces (under the tensor transformation laws) a transformation on the parameters A,B,C,α,β and γ of (2.9). In the following, the barred parameters define the components of the Killing tensor of (4.5) in the coordinates (q^1,q^2).

The discrete transformations R_1 and R_2 induce the following transformations:

$$R_1:\ \overline{A}=A,\ \overline{B}=B,\ \overline{C}=-C,\ \overline{\alpha}=-\alpha,\ \overline{\beta}=\beta,\ \overline{\gamma}=\gamma, \tag{7.3}$$

$$R_2:\ \overline{A}=B,\ \overline{B}=A,\ \overline{C}=C,\ \overline{\alpha}=\beta,\ \overline{\beta}=\alpha,\ \overline{\gamma}=\gamma. \tag{7.4}$$

Every continuous transformation of the Lie group $I(\mathbb{R}_1^2)$ can be parametrized according to [see (3.4)]

$$\begin{pmatrix} q^1 \\ q^2 \end{pmatrix} = t_{\mathbf{a}} \circ \rho_\phi \begin{pmatrix} t \\ x \end{pmatrix} = \begin{pmatrix} \cosh\phi & \sinh\phi \\ \sinh\phi & \cosh\phi \end{pmatrix} \begin{pmatrix} t \\ x \end{pmatrix} + \begin{pmatrix} a \\ b \end{pmatrix}, \tag{7.5}$$

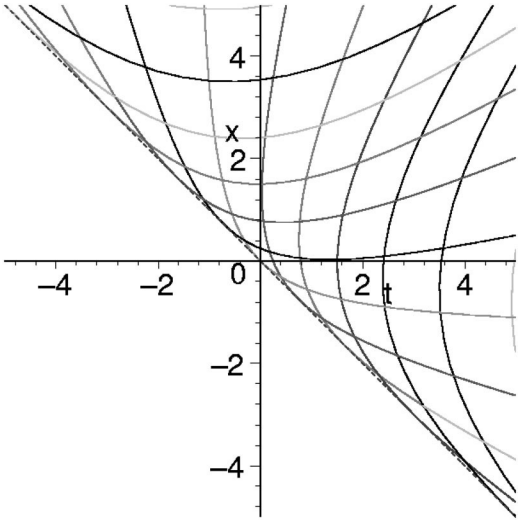

FIG. 8. Separable case 8.

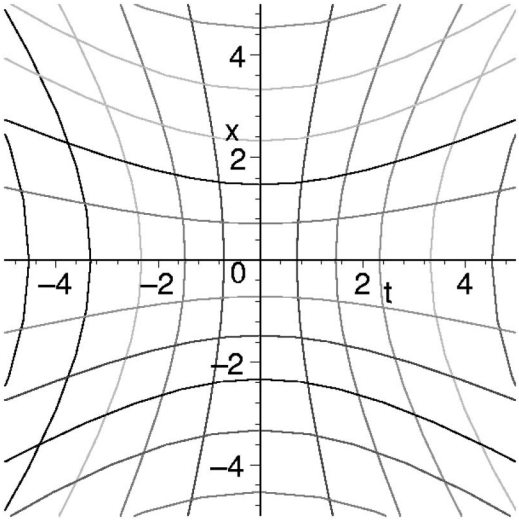

FIG. 9. Separable case 9.

and induces the following transformations on the parameters:

$$\overline{A}=A\cosh^2\phi-2C\cosh\phi\sinh\phi+B\sinh^2\phi+\gamma b^2-2(\alpha\cosh\phi+\beta\sinh\phi)b,$$

$$\overline{B}=A\sinh^2\phi-2C\cosh\phi\sinh\phi+B\cosh^2\phi+\gamma a^2-2(\beta\cosh\phi+\alpha\sinh\phi)a,$$

$$\begin{aligned}\overline{C}=&C(\cosh^2\phi+\sinh^2\phi)-(A+B)\cosh\phi\sinh\phi,\\&+(a\alpha+b\beta)\cosh\phi+(a\beta+b\alpha)\sinh\phi-\gamma ab,\end{aligned}\tag{7.6}$$

$$\overline{\alpha}=\alpha\cosh\phi+\beta\sinh\phi-\gamma b,$$

$$\overline{\beta}=\alpha\sinh\phi+\beta\cosh\phi-\gamma a,$$

$$\overline{\gamma}=\gamma.$$

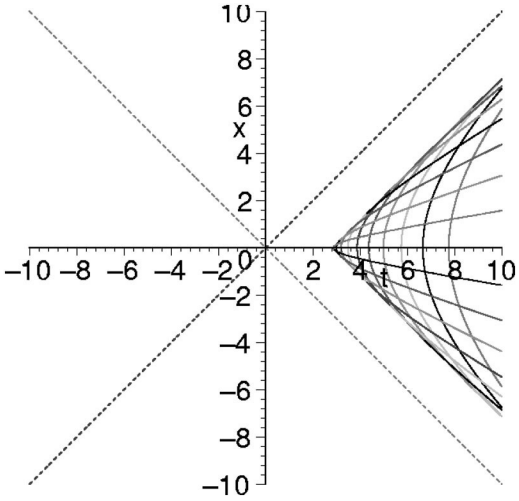

FIG. 10. Separable case 10.

TABLE II. Relevant reflections for the separable cases of Minkowski space.

SC	Type I	Type II	Reflections possibly needed
SC1	R_1, R_2	R_1	none
SC2	R_1	R_1, R_2	none
SC3	none	$(R_1 \circ R_2)^2$	$R_1, R_2, R_1 \circ R_2$
SC4	R_1	R_1	R_2
SC5	R_1	R_1, R_2	none
SC6	none	R_2	R_1
SC7	none	R_2	R_1
SC8	none	R_2	R_1
SC9	R_1, R_2	R_1, R_2	none
SC10	R_1	R_1, R_2	none

Note that for a given separable case, the transformation (7.2) to the separable coordinates need not be unique. In fact, the presence of the discrete group $R = \langle R_1, R_2 \rangle$ of transformations allows for certain redundancies to occur. We formalize these ideas below.

Definition 7.1: $(U,V) = \psi(u,v)$ *is a trivial separable transformation if either:*

(1) $\psi(u,v) = (\psi_1(u), \psi_2(v))$, *or*
(2) $\psi(u,v) = (\psi_1(v), \psi_2(u))$

where $\psi_1, \psi_2 : \mathbb{R} \to \mathbb{R}$ *are invertible maps.*

Remark 7.1: Note that (u,v) are separable coordinates for the Hamilton–Jacobi equation iff (U,V) are.

Definition 7.2: Let $r \in R$ *and* $T_{(n)}$ *be one of the standard coordinate transformations associated with* $SC[n]$ (*i.e.*, $(t,x) = T_{(n)}(u,v)$). *We say that*

(a) r *is a type I trivial reflection if* $r \circ T_{(n)}(u,v) = T_{(n)}(\psi(u,v))$, *where* $\psi(u,v)$ *is a trivial separable transformation.*
(b) r *is a type II trivial reflection if* r *induces a tensor transformation law which leaves invariant the components of the canonical separable Killing tensor associated with* $SC[n]$.

We define r *to be a trivial reflection with respect to* $SC[n]$ *if it is either a type I or type II trivial reflection.*

Type I trivial reflections are redundant in the classification because they can be realized as a composition of the standard coordinate transformation and a trivial separable transformation on (u,v)-space. Trivial reflections of type II are redundant because the components of the separable Killing tensor with respect to given (q^1, q^2) coordinates (i.e., the coordinate system in which we perform the classification) are the same for both (7.1) and (7.5).

To motivate these definitions, we consider the following examples:

Example 7.1: Suppose that we have a Hamiltonian H which admits a separation of variables of SC5 type and the transformation to separable coordinates (u,v) is given by

$$(q^1, q^2) = t_{\mathbf{a}} \circ \rho_\phi (t,x), \tag{7.7}$$

$$(t,x) = T_{(5)}(u,v) \tag{7.8}$$

for some $\mathbf{a}$ and ϕ. Consider the trivial separable transformation $(u,v) = (-U - \pi/2, V)$. Then $R_1 \circ T_{(5)}(U,V) = T_{(5)}(\psi(U,V))$. Thus, R_1 is a type I trivial reflection with respect to SC5.

Example 7.2: Consider SC9. The parameters appearing in the components (6.20) of the corresponding separable Killing tensor with respect to (t,x) coordinates are $A = B = k^2$, $C = \alpha = \beta = 0$, $\gamma = \frac{1}{4}$. These values are invariant under the transformation laws (7.3), (7.4) induced by R_1, R_2. Thus, R_1 and R_2 are type II trivial reflections with respect to SC9.

Examining each separable case, we generate the following list of trivial reflections (see Table II), and hence narrow down the list of discrete transformations which potentially play an role in

TABLE III. Group invariant classification scheme of the ten separable cases of the Minkowski space $\mathbb{R}_1^2$.

Separable case	SC1	SC2	SC3	SC4	SC5
γ	0	$\neq 0$	0	0	$\neq 0$
$\{I_+, I_-\}$	$\{0\}$	$\{0\}$	$\{0,-1\}$	$\{-1\}$	$\{-1\}$
Separable case	SC6	SC7	SC8	SC9	SC10
γ	$\neq 0$	$\neq 0$	$\neq 0$	$\neq 0$	$\neq 0$
$\{I_+, I_-\}$	$\{0,+1\}$	$\{0,-1\}$	$\{-1,+1\}$	$\{+1\}$	$\{-1\}$

the classification to be developed. In effect, we concentrate on developing a classification *up to trivial reflection*.

Note that in SC3, there are no type I trivial reflections, and $(R_1 \circ R_2)^2$ is the only type II trivial reflection. It can be shown that the identity transformation, R_1, R_2, and $(R_1 \circ R_2)^2$ induce different transformations of the components of the separable Killing tensor of SC3. Moreover, every element of R induces a transformation on the components of the SC3 separable Killing tensor which coincides with one of these four transformations.

The strategy for classifying the separable cases in the Minkowski plane is an extension of the ideas presented in Ref. 20. More specifically, we derive invariants under the action of $I(\mathbb{R}_1^2)$ and $R = \langle R_1, R_2 \rangle$ which can be used to distinguish the Killing tensors (6.12)–(6.20). These invariants will lead to an efficient algorithm for constructing the transformation to separable coordinates.

VIII. CLASSIFICATION IN TERMS OF THE ISOMETRY AND REFLECTION GROUPS

Having considered invariants under the action of continuous transformations, we now consider the effect of the discrete transformations on each of the $I(\mathbb{R}_1^2)$-invariants I_+, I_-, γ. Using the transformation laws (7.3) and (7.4), we get

$$R_1: \ \overline{I}_+ = I_-, \ \ \overline{I}_- = I_+, \ \ \overline{\gamma} = \gamma, \tag{8.1}$$

$$R_2: \ \overline{I}_+ = I_+, \ \ \overline{I}_- = I_-, \ \ \overline{\gamma} = \gamma. \tag{8.2}$$

Hence, we can say that the *unordered* list $\{I_+, I_-\}$ is invariant under hyperbolic rotations, translations, and the reflections R_1, R_2.

We now use the three $I(\mathbb{R}_1^2)$-invariants γ, I_+ and I_-, to classify the ten separable cases of the Minkowski space $\mathbb{R}_1^2$. Evaluating these invariants on each of the Killing tensors listed in (6.12)–(6.21) (i.e., representatives of each separable case SC1–SC10), we arrive at the following classification scheme for the separable cases of Minkowski space $\mathbb{R}_1^2$. We summarize these results in Table III.

Remark 8.1: If $\gamma = 0$, $I_\pm = 0$ or -1, whereas if $\gamma \neq 0$, $I_\pm = -1, 0$, or $+1$. Hence, there are nine combinations of γ and $\{I_+, I_-\}$. Note that SC5 and SC10 are characterized by the same values of the group invariants γ, I_-, and I_+. This agrees with the geometrical properties of the corresponding metrics, namely, they give rise to two *distinct* coordinate systems that cover two disjoint areas of the same space (for more details, see Refs. 27, 14, 15).

IX. EQUIVALENT CLASSIFICATIONS

We note that the above *group invariant* scheme allows the classification of the separable cases SC1–SC10 modulo a hyperbolic rotation and translation of the space $\mathbb{R}_1^2$ and as such can be compared with the classification derived by Kalnins[14] for the Laplace equation defined in $\mathbb{R}_1^2$ and

$\mathbb{R}_1^3$. An excellent exposition of these results based on the generators of the Lie symmetry algebra of the Klein–Gordon equation can be found in Ref. 27. Indeed, recall that the product separation of variables in the Helmholtz equation

$$\Delta\psi + K^2\psi = 0 \tag{9.1}$$

is equivalent to orthogonal separation of variables in the corresponding geodesic Hamiltonian.[54,55] In this setting the Laplacian Δ is a Casimir operator of the corresponding group of isometries, which clearly corresponds to the metric of the Hamiltonian (4.1). Thus, the Laplacian acting in the Minkowski space $\mathbb{R}_1^2$ takes the form

$$\Delta = \frac{\partial^2\psi}{\partial t^2} - \frac{\partial^2\psi}{\partial x^2}.$$

In order to classify the separable systems in this case, Kalnins[14] considered the generators of the Lie algebra $i(\mathbb{R}_1^2)$ (in our notations) **T**, **X**, and **H** to construct inequivalent quadratic operators corresponding to the ten separable cases. In our language these operators are the ten separable Killing tensors exhibited in Sec. VI, viewed, according to SPI, as sums of symmetrized products of **T**, **X**, and **H**.

A different approach to this problem for the geodesic equations in $\mathbb{R}_1^2$ has been developed by Rastelli,[15] who considered it from the point of view of singular points of the orthogonal separable coordinates (which are naturally equivalent to the singular points of the eigenvalues of the separable Killing tensors) and both classified the ten separable cases and found the coordinate transformations to the separable coordinates from the given ones.

The method of classification presented in the previous section is equivalent to the classifications described above.

X. TRANSFORMATION FORMULAS TO SEPARABLE COORDINATES

The $I(\mathbb{R}_1^2)$-invariants γ, I_+ and I_- of a Killing tensor $\mathbf{K}\in\mathcal{K}^2(\mathbb{R}_1^2)$ indicate, according to Table III, which SC it corresponds to. Although being exhaustive, this classification does not tell us where the corresponding separable web is located in $\mathbb{R}_1^2$ with respect to the origin or its orientation with respect to the given coordinate axes. Therefore a more delicate analysis is necessary to formalize the procedure. In this section we analyze each separable case and find the corresponding Lorentz angle ϕ along with the parameters of translation a and b [see (7.2)].

Let **K** be a particular solution of the Killing tensor equation (2.1) and the compatibility condition $d(\hat{\mathbf{K}}dV)=0$. We assume that this particular solution is a nonmetric solution, i.e., **K** is linearly independent of **g**. If multiples of the metric are the only Killing tensors compatible with the potential V, then the Hamiltonian is not separable. Recall from (5.6) that **K** satisfies the tensorial equation $\mathbf{K}=\ell\mathbf{g}+m\mathbf{K}^{(\mathbf{L})}$, where $\mathbf{K}^{(\mathbf{L})}$ is one of the separable Killing tensors. In components,

$$K_{ij} = \ell g_{ij} + m\overline{K}_{ij}^{(L)}, \quad \ell, m \in \mathbb{R}. \tag{10.1}$$

Note that if (10.1) is written with respect to the pseudo-Cartesian coordinates (t,x), then the right-hand side of the equation is determined according to the ten cases listed in Sec. VI. (There are in fact only nine cases since $\mathbf{K}^{(5)}$ and $\mathbf{K}^{(10)}$ are linearly dependent.) The difficulty here is that the left-hand side is not determined since the relation between (t,x) coordinates and given (q^1,q^2) is not known *a priori*. It is known that they are related by a proper or improper rigid motion (7.1). To determine the parameters a,b,ϕ,k,r appearing in (7.1) in terms of the known information (i.e., $A,B,C,\alpha,\beta,\gamma$) appearing in the components of **K** written with respect to (q^1,q^2), we adopt the following approach:

(1) Use the group invariant classification (Table III) to determine which separable Killing tensor $\mathbf{K}^{(\mathbf{L})}$ appears in Eq. (10.1).

(2) Starting with the (t,x) components of the appropriate $\mathbf{K}^{(\mathbf{L})}$ [see (6.12)–(6.21)], use the tensor transformation laws associated with (7.1) to write (10.1) with respect to (q^1,q^2). Here, a,b,ϕ,k,r appearing in (7.1) are the parameters to be determined.
(3) Solve (10.1), expressing a,b,ϕ,k in terms of $A,B,C,\alpha,\beta,\gamma$ and determining which $r\in R$ must be used.

In carrying out step (2) of the above approach, we permit only the relevant reflections listed in Table II to complete the classification of each separable case. The components of the separable Killing tensors with respect to (q^1,q^2) coordinates are given below.

SC1: No reflections used,

$$\overline{K}^{(1)}=\begin{pmatrix}\cosh^2\phi & -\cosh\phi\sinh\phi\\ -\cosh\phi\sinh\phi & \sinh^2\phi\end{pmatrix}. \tag{10.2}$$

SC2: No reflections used,

$$\overline{K}^{(2)}=\begin{pmatrix}(q^2-b)^2 & -(q^1-a)(q^2-b)\\ -(q^1-a)(q^2-b) & (q^1-a)^2\end{pmatrix}. \tag{10.3}$$

SC3.11: No reflections used,

$$\overline{K}^{(3)}=\begin{pmatrix}\frac{1}{4}e^{2\phi}-e^{-\phi}(q^2-b) & -\frac{1}{4}e^{2\phi}+\frac{1}{2}e^{-\phi}(b-a+q^1-q^2)\\ -\frac{1}{4}e^{2\phi}+\frac{1}{2}e^{-\phi}(b-a+q^1-q^2) & \frac{1}{4}e^{2\phi}+e^{-\phi}(q^1-a)\end{pmatrix}. \tag{10.4}$$

SC3.12: Reflection R_2 used,

$$\overline{K}^{(3)}=\begin{pmatrix}\frac{1}{4}e^{2\phi}+e^{-\phi}(q^2-b) & -\frac{1}{4}e^{2\phi}-\frac{1}{2}e^{-\phi}(b-a+q^1-q^2)\\ -\frac{1}{4}e^{2\phi}-\frac{1}{2}e^{-\phi}(b-a+q^1-q^2) & \frac{1}{4}e^{2\phi}-e^{-\phi}(q^1-a)\end{pmatrix}. \tag{10.5}$$

SC3.21: Reflection R_1 used,

$$\overline{K}^{(3)}=\begin{pmatrix}\frac{1}{4}e^{-2\phi}+e^{\phi}(q^2-b) & \frac{1}{4}e^{-2\phi}+\frac{1}{2}e^{\phi}(a+b-q^1-q^2)\\ \frac{1}{4}e^{-2\phi}+\frac{1}{2}e^{\phi}(a+b-q^1-q^2) & \frac{1}{4}e^{-2\phi}+e^{\phi}(q^1-a)\end{pmatrix}. \tag{10.6}$$

SC3.22: Reflection $R_1\circ R_2$ used,

$$\overline{K}^{(3)}=\begin{pmatrix}\frac{1}{4}e^{-2\phi}-e^{\phi}(q^2-b) & \frac{1}{4}e^{-2\phi}-\frac{1}{2}e^{\phi}(a+b-q^1-q^2)\\ \frac{1}{4}e^{-2\phi}-\frac{1}{2}e^{\phi}(a+b-q^1-q^2) & \frac{1}{4}e^{-2\phi}-e^{\phi}(q^1-a)\end{pmatrix}. \tag{10.7}$$

SC4.1: No reflections used,

$$\overline{K}^{(4)}=\begin{pmatrix}2\sinh\phi(q^2-b) & (a-q^1)\sinh\phi+(b-q^2)\cosh\phi\\ (a-q^1)\sinh\phi+(b-q^2)\cosh\phi & 2\cosh\phi(q^1-a)\end{pmatrix}. \tag{10.8}$$

SC4.2: Reflection R_2 used,

$$\overline{K}^{(4)}=\begin{pmatrix}2\cosh\phi(q^2-b) & (a-q^1)\cosh\phi+(b-q^2)\sinh\phi\\ (a-q^1)\cosh\phi+(b-q^2)\sinh\phi & 2\sinh\phi(q^1-a)\end{pmatrix}. \tag{10.9}$$

SC5: No reflections used,

$$\overline{K}^{(5)}=\begin{pmatrix} k^2(\cosh^2\phi+\sinh^2\phi)-\frac{1}{4}(q^2-b)^2 & -2k^2\cosh\phi\sinh\phi+\frac{1}{4}(q^1-a)(q^2-b) \\ -2k^2\cosh\phi\sinh\phi+\frac{1}{4}(q^1-a)(q^2-b) & k^2(\cosh^2\phi+\sinh^2\phi)-\frac{1}{4}(q^1-a)^2 \end{pmatrix}. \tag{10.10}$$

SC6.1: No reflections used,

$$\overline{K}^{(6)}=\begin{pmatrix} \frac{1}{4}(e^{2\phi}+(q^2-b)^2) & -\frac{1}{4}(e^{2\phi}+(q^1-a)(q^2-b)) \\ -\frac{1}{4}(e^{2\phi}+(q^1-a)(q^2-b)) & \frac{1}{4}(e^{2\phi}+(q^1-a)^2) \end{pmatrix}. \tag{10.11}$$

SC6.2: Reflection R_1 used,

$$\overline{K}^{(6)}=\begin{pmatrix} \frac{1}{4}(e^{-2\phi}+(q^2-b)^2) & \frac{1}{4}(e^{-2\phi}-(q^1-a)(q^2-b)) \\ \frac{1}{4}(e^{-2\phi}-(q^1-a)(q^2-b)) & \frac{1}{4}(e^{-2\phi}+(q^1-a)^2) \end{pmatrix}. \tag{10.12}$$

SC7.1: No reflections used,

$$\overline{K}^{(7)}=\begin{pmatrix} \frac{1}{4}((q^2-b)^2-e^{2\phi}) & \frac{1}{4}(e^{2\phi}-(q^1-a)(q^2-b)) \\ \frac{1}{4}(e^{2\phi}-(q^1-a)(q^2-b)) & \frac{1}{4}((q^1-a)^2-e^{2\phi}) \end{pmatrix}. \tag{10.13}$$

SC7.2: Reflection R_1 used,

$$\overline{K}^{(7)}=\begin{pmatrix} \frac{1}{4}((q^2-b)^2-e^{-2\phi}) & -\frac{1}{4}(e^{-2\phi}+(q^1-a)(q^2-b)) \\ -\frac{1}{4}(e^{-2\phi}+(q^1-a)(q^2-b)) & \frac{1}{4}((q^1-a)^2-e^{-2\phi}) \end{pmatrix}. \tag{10.14}$$

SC8.1: No reflections used,

$$\overline{K}^{(8)}=\begin{pmatrix} -2k^2\cosh\phi\sinh\phi+\frac{1}{4}(q^2-b)^2 & k^2(\cosh^2\phi+\sinh^2\phi)-\frac{1}{4}(q^1-a)(q^2-b) \\ k^2(\cosh^2\phi+\sinh^2\phi)-\frac{1}{4}(q^1-a)(q^2-b) & -2k^2\cosh\phi\sinh\phi+\frac{1}{4}(q^1-a)^2 \end{pmatrix}. \tag{10.15}$$

SC8.2: Reflection R_1 used,

$$\overline{K}^{(8)}=\begin{pmatrix} 2k^2\cosh\phi\sinh\phi+\frac{1}{4}(q^2-b)^2 & -k^2(\cosh^2\phi+\sinh^2\phi)-\frac{1}{4}(q^1-a)(q^2-b) \\ -k^2(\cosh^2\phi+\sinh^2\phi)-\frac{1}{4}(q^1-a)(q^2-b) & 2k^2\cosh\phi\sinh\phi+\frac{1}{4}(q^1-a)^2 \end{pmatrix}. \tag{10.16}$$

SC9: No reflections used,

$$\overline{K}^{(9)}=\begin{pmatrix} k^2(\cosh^2\phi+\sinh^2\phi)+\frac{1}{4}(q^2-b)^2 & -2k^2\cosh\phi\sinh\phi-\frac{1}{4}(q^1-a)(q^2-b) \\ -2k^2\cosh\phi\sinh\phi-\frac{1}{4}(q^1-a)(q^2-b) & k^2(\cosh^2\phi+\sinh^2\phi)+\frac{1}{4}(q^1-a)^2 \end{pmatrix}. \tag{10.17}$$

SC10: No reflections used,

$$\overline{K}^{(10)}=\begin{pmatrix} -k^2(\cosh^2\phi+\sinh^2\phi)+\frac{1}{4}(q^2-b)^2 & 2k^2\cosh\phi\sinh\phi-\frac{1}{4}(q^1-a)(q^2-b) \\ 2k^2\cosh\phi\sinh\phi-\frac{1}{4}(q^1-a)(q^2-b) & -k^2(\cosh^2\phi+\sinh^2\phi)+\frac{1}{4}(q^1-a)^2 \end{pmatrix}. \tag{10.18}$$

TABLE IV. Invariant classification of subcases.

Separable case	γ	$\{I_+, I_-\}$	Subcase	Invariant classification
SC3	0	$\{0,-1\}$	SC3.11: No reflections.	$\mu_-<0$
			SC3.12: R_2 used.	$\mu_->0$
			SC3.21: R_1 used.	$\mu_+>0$
			SC3.22: $R_1\circ R_2$ used.	$\mu_+<0$
SC4	0	$\{-1\}$	SC4.1: No reflections.	$\alpha^2-\beta^2<0$
			SC4.2: R_2 used.	$\alpha^2-\beta^2>0$
SC6	$\neq 0$	$\{0,+1\}$	SC6.1: No reflections.	$I_+=0$, $I_-=+1$
			SC6.2: R_1 used.	$I_+=+1$, $I_-=0$
SC7	$\neq 0$	$\{0,-1\}$	SC7.1: No reflections.	$I_+=0$, $I_-=-1$
			SC7.2: R_1 used.	$I_+=-1$, $I_-=0$
SC8	$\neq 0$	$\{-1,+1\}$	SC8.1: No reflections.	$I_+=+1$, $I_-=-1$
			SC8.2: R_1 used.	$I_+=-1$, $I_-=+1$

Now take any Killing tensor **K** with pointwise real and simple eigenvalues. With respect to given coordinates (q^1,q^2), it must have components of the form (2.9), and must satisfy Eq. (10.1), where $\overline{K}_{ij}^{(L)}$ has components according to one of the separable cases listed in (10.2)–(10.18). To identify which of these components must be used, we use the invariant classification provided in Table III. However, we refine this classification to distinguish subcases where reflections are required. According to Table II, we have to consider reflections for the separable cases SC3, SC4, SC6, SC7, and SC8. For these cases, we can use derived conformal invariants (which *are* sensitive to certain reflections) to provide a classification of these subcases. We present the invariant classification of subcases in Table IV.

By using the invariant classification of the separable cases listed in Tables III and IV, and Eq. (10.1), we can account for the action of the Lie group $I(\mathbb{R}_1^2)$ and find expressions for the parameters a, b, ϕ and k in terms of the given A, B, C, α, β, and γ. Thus, we have (see also Sec. IV in Ref. 20) the transformation to separable coordinates (u,v):

$$\begin{pmatrix} q^1 \\ q^2 \end{pmatrix} = (t_{\mathbf{a}}\circ\rho_{\phi}\circ r\circ T_{(i)})\begin{pmatrix} u \\ v \end{pmatrix}, \tag{10.19}$$

where r is an element of the discrete group of reflections $R=\langle R1,R2\rangle$. Letting $\tilde{T}_{(i)}=r\circ T_{(i)}$ we get

$$\begin{cases} q^1 = t\cosh\phi + x\sinh\phi + a \\ q^1 = t\sinh\phi + x\cosh\phi + b, \end{cases} \quad \begin{pmatrix} t \\ x \end{pmatrix} = \tilde{T}_{(i)}\begin{pmatrix} u \\ v \end{pmatrix}. \tag{10.20}$$

The values of the parameters a,b,ϕ,k and the transformation $\tilde{T}_{(i)}$ are given below for each separable case.

SC1: $\gamma=0, I_\pm=0$ [Note, in this case, real and distinct eigenvalues occur iff $(A+B)^2-4C^2>0$].

$$a,b \text{ arbitrary}, \quad \sinh(2\phi)=\begin{cases} \dfrac{-2C}{\sqrt{(A+B)^2-4C^2}}, & \text{if } A+B>0, \\ \dfrac{2C}{\sqrt{(A+B)^2-4C^2}}, & \text{if } A+B<0. \end{cases} \tag{10.21}$$

$$\tilde{T}_{(1)}: \begin{cases} t=u, \\ x=v. \end{cases} \tag{10.22}$$

SC2: $\gamma\neq 0, I_\pm=0$

$$a=\frac{-\beta}{\gamma},\quad b=\frac{-\alpha}{\gamma},\quad \phi \text{ arbitrary.} \tag{10.23}$$

$$\tilde{T}_{(2)}:\begin{cases} t=u\cosh(v),\\ x=u\sinh(v). \end{cases} \tag{10.24}$$

SC3: $\gamma=0,\{I_+,I_-\}=\{-1,0\}$

Define $\mu_\pm=(A+B\pm 2C)/\alpha$.

Subcase 3.1: If $I_+=-1, I_-=0$, then

$$a-b=\frac{A+B+2C}{4\alpha}\quad \text{(one parameter family)}, \tag{10.25}$$

$$e^{3\phi}=\left|\frac{A+B-2C}{2\alpha}\right|, \tag{10.26}$$

$\mu_-<0$	$\mu_->0$
$\tilde{T}_{(3.11)}:\begin{cases} t=\frac{1}{4}(u+v)^2+\frac{1}{2}(u-v)\\ x=-\frac{1}{4}(u+v)^2+\frac{1}{2}(u-v)\end{cases}$	$\tilde{T}_{(3.12)}:\begin{cases} t=-\frac{1}{4}(u+v)^2+\frac{1}{2}(u-v).\\ x=\frac{1}{4}(u+v)^2+\frac{1}{2}(u-v)\end{cases}$

Subcase 3.2: If $I_+=0, I_-=-1$, then

$$a+b=\frac{2C-A-B}{4\alpha}\quad \text{(one parameter family)}, \tag{10.27}$$

$$e^{3\phi}=\left|\frac{2\alpha}{A+B+2C}\right|, \tag{10.28}$$

$\mu_+>0$	$\mu_+<0$
$\tilde{T}_{(3.21)}:\begin{cases} t=\frac{1}{4}(u+v)^2+\frac{1}{2}(u-v)\\ x=\frac{1}{4}(u+v)^2-\frac{1}{2}(u-v)\end{cases}$	$\tilde{T}_{(3.22)}:\begin{cases} t=-\frac{1}{4}(u+v)^2-\frac{1}{2}(u-v).\\ x=-\frac{1}{4}(u+v)^2+\frac{1}{2}(u-v)\end{cases}$

SC4: $\gamma=0, I_\pm=-1$

$$a=\frac{\beta(A+B)+2\alpha C}{2(\alpha^2-\beta^2)},\quad b=\frac{\alpha(A+B)+2\beta C}{2(\beta^2-\alpha^2)}. \tag{10.29}$$

If $\alpha^2-\beta^2<0$, then $\tanh\phi=\alpha/\beta$ and

$$\tilde{T}_{(4a)}:\begin{cases} t=\frac{1}{2}(u^2+v^2),\\ x=uv. \end{cases} \tag{10.30}$$

If $\alpha^2-\beta^2>0$, then $\tanh\phi=\beta/\alpha$ and

$$\tilde{T}_{(4b)}:\begin{cases} t=uv,\\ x=\frac{1}{2}(u^2+v^2). \end{cases} \tag{10.31}$$

SC5 and SC10: $\gamma\neq 0, I_{\pm}=-1\ (\Rightarrow \Delta^2_{\mathbb{R}^2_1}>0)$

$$a=-\frac{\beta}{\gamma},\quad b=-\frac{\alpha}{\gamma},\quad \sinh(2\phi)=\frac{2(\gamma C+\alpha\beta)}{\sqrt{\Delta^2_{\mathbb{R}^2_1}}},\quad k^2=\frac{\sqrt{\Delta^2_{\mathbb{R}^2_1}}}{8\gamma^2}. \tag{10.32}$$

$$\tilde{T}_{(5)}:\begin{cases} t=2k\sqrt{2}\cos\left(\frac{u}{2}+\frac{\pi}{4}\right)\cos\left(\frac{v}{2}+\frac{\pi}{4}\right),\\ x=2k\sqrt{2}\sin\left(\frac{u}{2}+\frac{\pi}{4}\right)\sin\left(\frac{v}{2}+\frac{\pi}{4}\right),\end{cases} \tag{10.33}$$

or

$$\tilde{T}_{(10)}:\begin{cases} t=2k\sqrt{2}\cosh\left(\frac{u}{2}\right)\cosh\left(\frac{v}{2}\right),\\ x=2k\sqrt{2}\sinh\left(\frac{u}{2}\right)\sinh\left(\frac{v}{2}\right)\end{cases}. \tag{10.34}$$

SC6: $\gamma\neq 0, \{I_+, I_-\}=\{0,+1\}$

$$a=-\frac{\beta}{\gamma},\quad b=-\frac{\alpha}{\gamma}. \tag{10.35}$$

If $I_+=0, I_-=+1\ (\Rightarrow \gamma C+\alpha\beta<0)$, $e^{2\phi}=-(\gamma C+\alpha\beta)/\gamma^2$ and

$$\tilde{T}_{(6a)}:\begin{cases} t=\sinh\left(\frac{u-v}{2}\right)+2\exp\left(\frac{u+v}{2}\right),\\ x=\sinh\left(\frac{u-v}{2}\right)-2\exp\left(\frac{u+v}{2}\right)\end{cases}. \tag{10.36}$$

If $I_+=+1, I_-=0\ (\Rightarrow \gamma C+\alpha\beta>0)$, $e^{2\phi}=\gamma^2/(\gamma C+\alpha\beta)$ and

$$\tilde{T}_{(6b)}:\begin{cases} t=\sinh\left(\frac{u-v}{2}\right)+2\exp\left(\frac{u+v}{2}\right),\\ x=-\sinh\left(\frac{u-v}{2}\right)+2\exp\left(\frac{u+v}{2}\right)\end{cases}. \tag{10.37}$$

SC7: $\gamma\neq 0, \{I_+, I_-\}=\{0,-1\}$

$$a=-\frac{\beta}{\gamma},\quad b=-\frac{\alpha}{\gamma}. \tag{10.38}$$

If $I_+=0, I_-=-1\ (\Rightarrow \gamma C+\alpha\beta>0)$, $e^{2\phi}=(\gamma C+\alpha\beta)/\gamma^2$ and

$$\tilde{T}_{(7a)}:\begin{cases} t=\cosh\left(\frac{u-v}{2}\right)+2\exp\left(\frac{u+v}{2}\right),\\ x=\cosh\left(\frac{u-v}{2}\right)-2\exp\left(\frac{u+v}{2}\right)\end{cases}. \tag{10.39}$$

If $I_+=-1, I_-=0\ (\Rightarrow \gamma C+\alpha\beta<0)$, $e^{2\phi}=\gamma^2/-(\gamma C+\alpha\beta)$ and

$$\tilde{T}_{(7b)}:\begin{cases} t=\cosh\left(\dfrac{u-v}{2}\right)+2\exp\left(\dfrac{u+v}{2}\right), \\ x=-\cosh\left(\dfrac{u-v}{2}\right)+2\exp\left(\dfrac{u+v}{2}\right). \end{cases} \tag{10.40}$$

SC8: $\gamma\neq 0, \{I_+, I_-\}=\{+1,-1\}$ $(\Rightarrow \Delta^2_{\mathbb{R}^2_1}<0)$,

$$a=-\frac{\beta}{\gamma}, \quad b=-\frac{\alpha}{\gamma}, \quad k^2=\frac{\sqrt{-\Delta^2_{\mathbb{R}^2_1}}}{8\gamma^2}. \tag{10.41}$$

If $I_+=+1, I_-=-1$, then

$$\sinh(2\phi)=\frac{\alpha^2+\beta^2-\gamma(A+B)}{\sqrt{-\Delta^2_{\mathbb{R}^2_1}}},$$

and

$$\tilde{T}_{(8a)}:\begin{cases} t=k\sqrt{2}\left(\cosh\left(\dfrac{u+v}{2}\right)+\sinh\left(\dfrac{u-v}{2}\right)\right), \\ x=k\sqrt{2}\left(\cosh\left(\dfrac{u+v}{2}\right)-\sinh\left(\dfrac{u-v}{2}\right)\right). \end{cases} \tag{10.42}$$

If $I_+=-1, I_-=+1$ then

$$\sinh(2\phi)=\frac{\gamma(A+B)-\alpha^2-\beta^2}{\sqrt{-\Delta^2_{\mathbb{R}^2_1}}},$$

and

$$\tilde{T}_{(8b)}:\begin{cases} t=k\sqrt{2}\left(\cosh\left(\dfrac{u+v}{2}\right)+\sinh\left(\dfrac{u-v}{2}\right)\right), \\ x=-k\sqrt{2}\left(\cosh\left(\dfrac{u+v}{2}\right)-\sinh\left(\dfrac{u-v}{2}\right)\right). \end{cases} \tag{10.43}$$

SC9: $\gamma\neq 0, I_\pm=+1$ $(\Rightarrow \Delta^2_{\mathbb{R}^2_1}>0)$,

$$a=-\frac{\beta}{\gamma}, \quad b=-\frac{\alpha}{\gamma}, \quad \sinh(2\phi)=\frac{-2(\gamma C+\alpha\beta)}{\sqrt{\Delta^2_{\mathbb{R}^2_1}}}, \quad k^2=\frac{\sqrt{\Delta^2_{\mathbb{R}^2_1}}}{8\gamma^2}, \tag{10.44}$$

$$\tilde{T}_{(9)}:\begin{cases} t=2k\sqrt{2}\sinh\left(\dfrac{u}{2}\right)\cosh\left(\dfrac{v}{2}\right), \\ x=2k\sqrt{2}\cosh\left(\dfrac{u}{2}\right)\sinh\left(\dfrac{v}{2}\right). \end{cases} \tag{10.45}$$

Remark 10.1: The formulas above indicate that the parameter k that enters the transformation formulas (6.6), (6.9), (6.10), and (6.11) is determined by $\Delta^1_{\mathbb{R}^2_1}=\gamma$ and $\Delta^2_{\mathbb{R}^2_1}$ according to the following formulas for the corresponding separable cases:

$$\text{SC5, SC9, SC10:}\quad k^2=\frac{\sqrt{\Delta^2_{\mathbb{R}^2_1}}}{8\Delta^1_{\mathbb{R}^2_1}},\quad (\Delta^2_{\mathbb{R}^2_1}>0),$$

$$\text{SC8:}\quad k^2=\frac{\sqrt{-\Delta^2_{\mathbb{R}^2_1}}}{8\Delta^1_{\mathbb{R}^2_1}},\quad (\Delta^2_{\mathbb{R}^2_1}<0). \tag{10.46}$$

Note they bear a striking resemblance to the analogous formula (2.19) derived in the study of Killing tensors of valence two defined in the Euclidean plane.

XI. THE ALGORITHM

The algorithm based on the results above for solving the Hamiltonian systems defined in $\mathbb{R}^2_1$ mimics the corresponding algorithm described in Ref. 20 for the Hamiltonian systems defined in $\mathbb{R}^2$ and consists of the following major steps:

(1) For a given natural Hamiltonian defined in the pseudo-Cartesian coordinates (q^1,q^2) by (5.17), use the generic Killing tensor (2.9) and impose the compatibility condition $d(\hat{\mathbf{K}}dV)=0$, to find the restrictions on the coefficients.
(2) Decompose the solution found in step (1) as follows:

$$\mathbf{K}=\ell_0\mathbf{g}+\sum_{i=1}^{n}\ell_i\mathbf{K^{(i)}}, \tag{11.1}$$

where ℓ_i are arbitrary constants and $\{\mathbf{g},\mathbf{K^{(1)}},\ldots,\mathbf{K^{(n)}}\}$ is a pointwise linearly independent set of Killing tensors. Since $\dim\mathcal{K}^2(\mathbb{R}^2_1)=6$, then $n\leqslant 5$. If $n=0$, then H is not orthogonally separable. If $n\geqslant 2$, then H is superseparable.
(3) Each component $\mathbf{K^{(i)}}$ in the decomposition (11.1) represents one of SC1–SC10. They can be determined by evaluating the invariants γ, I_-, I_+ for each $\mathbf{K^{(i)}}$. Then the results of the previous section can be used to find the parameters a,b,k, and ϕ. Finally, employ (7.5) to perform the coordinate transformation from (q^1,q^2) to separable coordinates.

We stress that this algorithm is purely algebraic in the sense that once the parameters a,b,k, and ϕ are determined in each case, the transformation to separable coordinates amounts to algebraic operations presented in the previous section for SC1–SC10.

XII. DIAGONALIZATION OF CERTAIN SYSTEMS OF THE HYDRODYNAMIC TYPE

Recall that a Hamiltonian function (4.1) along with an additional first integral quadratic in momenta (4.5) gives rise to a quasilinear system of the hydrodynamic type in a natural way. This remarkable observation due to Ferapontov and Fordy[42] (see also Ref. 43 for more details) allows us to use the classification above in terms of the group invariants γ, I_-, and I_+ in order to diagonalize the corresponding system of hydrodynamic type and thus find its Riemann invariants. Indeed, the Hamiltonian flows generated by the commuting H and F induce a two-dimensional surface parametrized by the "times" κ and τ:

$$q^i_\kappa=\frac{\partial H}{\partial p_i},\quad q^i_\tau=\frac{\partial F}{\partial p_i},$$

or, taking into account the formulas (5.17) and (2.9), we may write

$$q^1_\kappa=p_1,$$

$$q^2_\kappa=-p_2, \tag{12.1}$$

$$q^1_\tau = 2[(A+2\alpha q^2+\gamma(q^2)^2)p_1+(C-\alpha q^1-\beta q^2-\gamma q^1 q^2)p_2],$$

$$q^2_\tau = 2[(C-\alpha q^1-\beta q^2-\gamma q^1 q^2)p_1+(B+2\beta q^1+\gamma(q^1)^2)p_2].$$

Eliminating p_1 and p_2, we arrive at the following system of hydrodynamic type:

$$\begin{aligned} q^1_\tau &= 2[(A+2\alpha q^2+\gamma(q^2)^2)q^1_\kappa-(C-\alpha q^1-\beta q^2-\gamma q^1 q^2)q^2_\kappa], \\ q^2_\tau &= 2[(C-\alpha q^1-\beta q^2-\gamma q^1 q^2)q^1_\kappa-(B+2\beta q^1+\gamma(q^1)^2)q^2_\kappa]. \end{aligned} \tag{12.2}$$

At this stage we can use the information provided by the parameters A, B, C, α, β, γ to diagonalize the system (12.2). Indeed, computing the $I(\mathbb{R}^2_1)$-invariants γ, I_- and I_+ and then transforming the given coordinates of the original Hamiltonian system to the separable coordinates (u,v) according to the scheme of Sec. VI brings the original Hamiltonian system (i.e., H and F) to the Liouville form (5.2)–(5.4) and thus, the system of PDE's (12.2) to the following diagonal form:

$$\begin{aligned} u_\tau &= B(v)u_\kappa, \\ v_\tau &= A(u)v_\kappa. \end{aligned} \tag{12.3}$$

After a point transformation the system (12.3) can be brought to the form

$$\begin{aligned} \tilde{u}_\tau &= \tilde{v}\tilde{u}_\kappa, \\ \tilde{v}_\tau &= \tilde{u}\tilde{v}_\kappa, \end{aligned} \tag{12.4}$$

with $\tilde{u}$ and $\tilde{v}$ as the Riemann invariants of the associated system of hydrodynamic type. The methods of solving of such systems of PDE's are presented in Ref. 42.

XIII. APPLICATION: THE DRACH SUPERINTEGRABLE POTENTIALS

The method described in the preceding sections provides a systematic and straightforward means of determining separable coordinates for the Hamiltonian systems defined in the Minkowski plane admitting first integrals of motion quadratic in the momenta. For an application of the method, we turn our attention to the well-known Drach potentials.[56] Indeed, recall that in 1935, Drach listed ten scalar potentials $V(x,y)$ for a general Hamiltonian systems defined by a Hamiltonian of the form

$$H(x,y,p_x,p_y)=p_x p_y+V(x,y), \tag{13.1}$$

each of which admits an additional first integral cubic in the momenta. Note that the metric of (13.1) is Lorentzian.

It has been shown recently by Rañada[57] and independently later by Tsiganov[58] that seven out of the ten integrable cases isolated by Drach are in fact superintegrable admitting, in addition quadratic first integrals of motion. More specifically, it has been shown explicitly in Ref. 58 that the seven integrable systems in question are of the Stäckel-type.

It is easy to see that the signature-preserving point transformation

$$x=\frac{1}{\sqrt{2}}(q^1+q^2), \quad y=\frac{1}{\sqrt{2}}(q^1-q^2), \tag{13.2}$$

brings the Hamiltonian system defined by (13.1) to the form (5.17). After this transformation has been performed we can employ the algorithm presented in Sec. XI to determine the transformations to separable coordinates and thus solve the corresponding Hamiltonian systems by quadra-

tures. Indeed, as illustrative examples consider cases (b) and (c) from the Drach list[56] assuming $\mu=1$ and $a=1$, respectively. The transformation (13.2) yields the following potentials with respect to the pseudo-Cartesian coordinates (q^1,q^2):

$$\tilde{V}_1(q^1,q^2)=\frac{c_1\sqrt{2}}{\sqrt{(q^1)^2-(q^2)^2}}+\frac{2c_2}{(q^2)^2}+\frac{2c_3q^1}{\sqrt{(q^1)^2-(q^2)^2}(q^2)^2}, \tag{13.3}$$

$$\tilde{V}_2(q^1,q^2)=\frac{c_1}{2}((q^1)^2-(q^2)^2)+\frac{2c_2}{(q^2)^2}+\frac{2c_3}{(q^1)^2}, \tag{13.4}$$

where $c_1,c_2,c_3\in\mathbb{R}$ are arbitrary constants. Following the algorithm, we use the generic Killing tensor (5.18) and impose the compatibility conditions $d(\hat{\mathbf{K}}d\tilde{V}_1)=0$ and $d(\hat{\mathbf{K}}d\tilde{V}_2)=0$, respectively. These conditions imply the corresponding Killing tensors have the following forms:

$$\mathbf{K}_{\tilde{V}_1}=\begin{pmatrix} A+\gamma(q^2)^2 & -\beta q_2-\gamma q^1q^2 \\ -\beta q^2-\gamma q^1q^2 & -A+2\beta q^1+\gamma(q^1)^2 \end{pmatrix}, \tag{13.5}$$

and

$$\mathbf{K}_{\tilde{V}_2}=\begin{pmatrix} A+\gamma(q^2)^2 & -\gamma q^1q^2 \\ -\gamma q^1q^2 & B+\gamma(q^1)^2 \end{pmatrix}, \tag{13.6}$$

respectively, where A, B, β, $\gamma\in\mathbb{R}$ are arbitrary constants. The presence of the arbitrary constants indicates that the respective Hamiltonian systems are in fact *superintegrable*. Indeed, according to (11.1) the compatible Killing tensors $\mathbf{K}_{\tilde{V}_1}$ and $\mathbf{K}_{\tilde{V}_2}$ decompose as follows:

$$\mathbf{K}_{\tilde{V}_1}=A\mathbf{g}+\beta\mathbf{K}^{(4)}+\gamma\mathbf{K}^{(2)}, \tag{13.7}$$

$$\mathbf{K}_{\tilde{V}_2}=-B\mathbf{g}+(A+B)\mathbf{K}^{(1)}+\gamma\mathbf{K}^{(2)}, \tag{13.8}$$

where $\mathbf{g}$ denotes the metric tensor and the Killing tensors $\mathbf{K}^{(1)}$, $\mathbf{K}^{(2)}$, and $\mathbf{K}^{(4)}$ correspond to SC1, SC2, and SC4, respectively [see (6.12), (6.13), and (6.15)]. This fact can also be independently confirmed by evaluating the invariants γ, $\{I_-,I_+\}$ and the parameters a, b, k, and ϕ for $\mathbf{K}^{(1)}$, $\mathbf{K}^{(2)}$, and $\mathbf{K}^{(4)}$. Indeed, employing the results of Secs. VIII and X, we have

$$\begin{aligned} &\mathbf{K}^{(1)}:\ \ \gamma=0,\{I_-,I_+\}=\{0\},\quad \phi=0,\\ &\mathbf{K}^{(2)}:\ \ \gamma\neq 0,\{I_-,I_+\}=\{0\},\quad a=b=0,\\ &\mathbf{K}^{(4)}:\ \ \gamma=0,\{I_-,I_+\}=\{-1\},\quad a=b=\phi=0. \end{aligned} \tag{13.9}$$

We conclude therefore that the Hamiltonian systems defined by (13.3) and (13.4) are orthogonally s̄uperseparable. More specifically, the Hamiltonian system defined by (13.3) is separable with respect to SC2 and SC4, while the Hamiltonian system defined by (13.4) with respect to SC1 and SC2. The corresponding transformation formulas to separable coordinates are given by the formulas (6.2) (SC1), (6.3) (SC2), and (6.5) (SC4) [see also (13.9) and (10.20)].

XIV. CONCLUSION

We wish to conclude our paper with another quotation from Gian-Carlo Rota:[1]

''The apex of mathematical achievement occurs when two or more fields which were thought to be entirely unrelated turn out to be closely intertwined. Mathematicians have never decided whether they should feel excited or upset by such events.''

We have demonstrated how the ideas of classical invariant theory developed by many notable mathematicians of the 19th century, including Cayley, Gauss, Gordan, Hermite, Hilbert, and Sylvester,[3] can naturally be incorporated into the study of Killing tensors defined in pseudo-Riemannian spaces of constant curvature. A new set of group invariants has been brought to light and applied to the problem of the classification of separable Hamiltonians in the Minkowski plane. The application has enabled us to recognize their geometrical significance. The new method has been also successfully applied by the authors to the study of Hamiltonian systems with two degrees of freedom defined in $\mathbb{R}^2$ admitting first integrals that are cubic in the momenta.[19] More specifically, the corresponding set of $I(\mathbb{R}^2)$-invariants of $\mathcal{K}^3(\mathbb{R}^2)$ has led to a classification of the first integrals up to their leading cubic terms. Analogous programs have been launched to study the group invariants of the Killing tensors of valence two defined in two-dimensional spaces of nonzero constant curvature[59] and in the Euclidean space $\mathbb{R}^3$ (Ref. 60) (see also Refs. 61 and 62).

ACKNOWLEDGMENTS

The authors wish to thank Sergio Benenti, Claudia Chanu, Benno Fuchssteiner, Ernie Kalnins, Willard Miller, Jr., Giovanni Rastelli, and Pavel Winternitz for useful discussions pertinent to various parts of the paper. We also thank Willard Miller, Jr. for bringing our attention to Ref. 7 and the anonymous referee for her or his useful remarks and suggestions that have helped to improve the quality of the paper. The Potts model with countable set Φ of spin values on $\mathbb{Z}^d$ is considered. It is proved that with respect to Poisson distribution on Φ the set of limiting Gibbs measures is not empty. © *2004 American Institute of Physics.*
[DOI: 10.1063/1.1643194]

I. INTRODUCTION

The Potts model [Potts (1982)] has received an increasing theoretical and experimental interest in recent years, and at present a great many rigorous and approximate results are known. An extended summary of results and bibliography can be found in the review article by Wu (1982) and references therein.

The model can be studied both $\mathbb{Z}^d$ and Cayley tree J^k, i.e., a graph having no cycles, from each vertex of which emanates exactly $(k+1)$ edges. In the Potts model spin variables $\sigma(x)$ which take values on a discrete set $\Phi=\{0,1,2,\ldots,q\}$, $q\geqslant 2$ are associated with each vertex x of the $\mathbb{Z}^d$ or tree J^k. The Potts model on the $\mathbb{Z}^d$ or Cayley tree J^k is defined by the Hamiltonian

$$H(\sigma)=-J\sum_{\langle x,y\rangle}\delta_{\sigma(x)\sigma(y)}-h\sum_{x\in V}\delta_{0\sigma(x)},$$

where V is Z^d or the set of vertices in J^k, the first sum is taken over all nearest neighbors, δ in the first and second sums is the Kroneker's symbol.

In this paper we consider the case when Φ is the set of non-negative integer numbers, i.e., Φ is a countable set. We show that for the Poisson distribution on Φ the set of limiting Gibbs distribution is a nonempty set.

II. THE POISSON GIBBS MEASURES

Let Φ be the set of non-negative integer numbers. In this paper we consider the Potts model on the integer lattice $\mathbb{Z}^d$, $d\geqslant 1$. It is defined by the Hamiltonian

$$H(\sigma)=-J\sum_{\substack{\langle x,y\rangle\\ x,y\in\mathbb{Z}^d}}\delta_{\sigma(x)\sigma(y)}-h\sum_{x\in\mathbb{Z}^d}\delta_{0\sigma(x)},$$

where $\sigma:\mathbb{Z}^d\to\Phi$ is a configuration and the first sum taken over all nearest neighbors, i.e., $\|x-y\|=1$ with $\|x\|=\max|x_i|$.

Let Ω be the set of all configurations and for arbitrary finite subset $\Lambda\subset\mathbb{Z}^d$; $\Omega(\Lambda)$ be a set of all configuration $\sigma(\Lambda)$ *on* Λ. For finite $V_n=\{x\in\mathbb{Z}^d|\ \|x\|=n\}\subset\mathbb{Z}^d$, the full energy of configuration $\sigma(V_n)$ under boundary condition $\overline{\sigma}(\mathbb{Z}^d\backslash V_n)$, i.e., fixed configuration on $\mathbb{Z}^d\backslash V_n$, is defined the following way:

a)Electronic mail: nasirgani@hotmail.com; gnasir@iiu.edu.my

$$H(\sigma(V_n)|\overline{\sigma}(\mathbb{Z}^d\backslash V_n))=-J\sum_{\substack{\langle x,y\rangle,\\ x\in V_n}}\delta_{\sigma(x)\sigma(y)}-J\sum_{\substack{\langle x,y\rangle\\ x\in V_n,\,y\in\mathbb{Z}^d\backslash V_n}}\delta_{\sigma(x)\sigma(y)}-h\sum_{x\in V_n}\delta_{0\sigma(x)}.$$

Let us consider the partition function on V_n with respect to some measure λ on Φ:

$$Z_n(\overline{\sigma}(\partial V_n))=\int_{\Omega(V_n)}\exp(-H(\sigma(V_n)|\overline{\sigma}(\mathbb{Z}^d\backslash V_n)))\prod_{s\in V_n}d\lambda(\sigma(s)),$$

where $\partial V_n=V_{n+1}\backslash V_n$.

As λ is a discrete measure, then this integral is represented in the form of plurigenus,

$$\begin{aligned}Z_n(\overline{\sigma}(\partial V_n))&=\sum_{x\in V_n}\sum_{\sigma(x)=0}^{\infty}\exp(-H(\sigma(V_n)|\overline{\sigma}(\mathbb{Z}^d\backslash V_n)))\prod_{x\in V_n}\lambda(\sigma(x))\\&=\sum_{x\in V_n}\sum_{\sigma(x)=0}^{\infty}\exp\Bigg(J\sum_{\substack{\langle x,y\rangle\\ x,y\in V_n}}\delta_{\sigma(x)\sigma(y)}+J\sum_{\substack{\langle x,y\rangle\\ x\in V_n,\,y\in\mathbb{Z}^d\backslash V_n}}\delta_{\sigma(x)\sigma(y)}\\&\quad+h\sum_{x\in V_n}\delta_{0\sigma(x)}\Bigg)\prod_{x\in V_n}\lambda(\sigma(x)).\end{aligned}$$

If λ is the counting measure, i.e., $\lambda(\{i\})=1$ for any $i\in\Phi$, then the partition function reduces to infinity for arbitrary boundary condition $\overline{\sigma}(Z\backslash V_n)$.

Let λ be a probabilistic measure on Φ. Then the partition function is a finite under arbitrary boundary condition $\overline{\sigma}(\mathbb{Z}^d\backslash V_n)$ and conditional Gibbs measure on volume V_n has the following form:

$$P_n(\sigma(V_n)|\ \overline{\sigma}(\mathbb{Z}^d\backslash V_n))=\frac{\exp(-H(\sigma(V_n)|\ \overline{\sigma}(\mathbb{Z}^d\backslash V_n)))\prod_{x\in V_n}\lambda(\sigma(x))}{Z_n(\overline{\sigma}(\partial V_n))},$$

that is, P_n is the discrete measure on $\Omega(V_n)$.

The main result is the following.

Theorem: For a Poisson distribution ν on Φ, i.e., $\nu(i)=\exp(-\lambda)(\lambda^i/i!)$, where λ is the arbitrary positive number and the set of all limit Gibbs measure is a nonempty set.

Proof: The proof is based on the Dobrushin theorem about the existence of the limit of Gibbs measures if the set of values of variables $\sigma(x)$, $x\in\mathbb{Z}^d$ is the separable complete metric space [Dobrushin (1968, 1970)].

Evidently, the set Φ of all non-negative integer numbers with discrete metric,

$$d(x,y)=\begin{cases}1, & x\neq y;\\ 0, & x=y,\end{cases}\tag{1}$$

is the complete separable metric space.

Definition [Dobrushin (1968)]: Let M be a complete separable metric space. A continuous function h on M is called a *compact*, if for any $t\in(-\infty,\infty)$ the set $\{m\in M\colon h(m)\leqslant t\}$ is the compact set in M.

As the set of all non-negative integer numbers Φ is complete separable metric space with respect to discrete metric (1), then arbitrary function h on Φ is continuous. Evidently, there are a lot of compact non-negative functions on Φ. For example, the identity map $h(i)=i$ for any $i\in\Phi$ is a compact function.

Theorem of Dobrushin [Dobrushin (1968, 1970)]: Assume that there is a Hamiltonian H, for which is possible to find the following: (1) a compact non-negative function h on the set Φ; (2) the system of numbers $\{c(x,y),\ x\in\mathbb{Z}^d, y\in\mathbb{Z}^d\}$, and a constant $c\in(0,1)$ with $\Sigma_y|c(x,y)|\leqslant c$ for any $x\in\mathbb{Z}^d$, and number $K>0$, such that for finite subset $V\subset\mathbb{Z}^d$ and arbitrary boundary condition $\overline{\sigma}(\mathbb{Z}^d\backslash V)$ with $\max_{x\in V}\Sigma_{y\in\mathbb{Z}^d\backslash V}|c(x,y)|h(\overline{\sigma}(y))<\infty$, the conditional Gibbs measure is defined and

$$\int h(\sigma(x))\ p(\sigma(V))|\sigma(\mathbb{Z}^d\backslash V)\prod_{y\in V} d\chi(\sigma(y))\leqslant K+\sum_{y:y\neq x} c(x,y)h(\overline{\sigma}(y)),$$

where χ is a measure on Φ.

(3) For any $x\in\mathbb{Z}^d$ and for any continuous bounded function $g(\sigma)$ on Φ there is the sequence of finite subset $W_n\subset\mathbb{Z}^d, \cup_n W_n=\mathbb{Z}^d\backslash\{x\}$, the system of non-negative numbers $d^{(n)}(x,y)$, $y\neq x$ with $\Sigma_{y\in\mathbb{Z}^d}d^{(n)}(x,y)\leqslant D^{(n)}\to 0$ and the sequence of continuous boundary functions $f_n(\sigma(W_n))$ such that

$$\left|\int g(\sigma(x))p(\sigma(x)\left|\overline{\sigma}(\mathbb{Z}^d\backslash\{x\}))d\chi(\sigma(x))-f_n(\sigma(W_n))\right|\right|\leqslant D^n+\sum_{y\neq x} d^{(n)}(x,y)h(\sigma(y)),$$

for arbitrary boundary condition $\overline{\sigma}(\mathbb{Z}^d\backslash\{x\})$ with $\Sigma_{y\neq x}c(x,y)h(\overline{\sigma}(y))<\infty$.

Then there exists at least one limit Gibbs measure.

Let us take the function $h(i)=i$ as a compact function. Then [see Sinai (1982)], our problem amounts to the finding of constants K, $c(x,y)$, $c\in(0,1)$ with $\Sigma_y|c(x,y)|\leqslant c<1$ such that

$$\frac{\sum_{\sigma(x)=0}^{\infty}\sigma(x)\exp(-H(\sigma(x)|\overline{\sigma}(\partial x))\nu(\sigma(x)))}{\sum_{\sigma(x)=0}^{\infty}\exp(-H(\sigma(x)|\overline{\sigma}(\partial x))\nu(\sigma(x)))}\leqslant K+\sum_{y\neq x} c(x,y)\sigma(y), \tag{2}$$

where $\partial x=\{y\in\mathbb{Z}^d|\ \|x-y\|=1\}=\{y^1,y^2,\ldots,y^{3^d-1}\}$.

Assume

$$A=\frac{\sum_{\sigma(x)=0}^{\infty}\sigma(x)\exp(-H(\sigma(x)|\overline{\sigma}(\partial x))\nu(\sigma(x)))}{\sum_{\sigma(x)=0}^{\infty}\exp(-H(\sigma(x)|\overline{\sigma}(\partial x))\nu(\sigma(x)))}=\frac{\sum_{j=0}^{\infty} j\exp\left(h\delta_{0j}+J\sum_{i=1}^{3^d\text{-}1}\delta_{j\overline{\sigma}(y^i)}\right)\nu(j)}{\sum_{j=0}^{\infty}\exp\left(h\delta_{0j}+J\sum_{i=1}^{3^d\text{-}1}\delta_{j\overline{\sigma}(y^i)}\right)\nu(j)}.$$

As for a Poisson measure ν we have $j\nu(j)=\lambda\nu(j-1)$ *for* $j\geqslant 1$ and for $j=0$ the first term in the numerator is equal to zero; then

$$A=\frac{\lambda\sum_{j=1}^{\infty}\exp\left(h\delta_{0j}+J\sum_{i=1}^{3^d-1}\delta_{j\overline{\sigma}(y^i)}\right)\nu(j-1)}{\sum_{j=0}^{\infty}\exp\left(h\delta_{0j}+J\sum_{i=1}^{3^d-1}\delta_{j\overline{\sigma}(y^i)}\right)\nu(j)}.$$

After the change of variable $j-1$ to j in the numerator, we have

$$A=\frac{\lambda\sum_{j=0}^{\infty}\exp\left(h\delta_{j+1,0}+J\sum_{i=1}^{3^d-1}\delta_{j+1,\overline{\sigma}(y^i)}\right)\nu(j)}{\sum_{j=0}^{\infty}\exp\left(h\delta_{0j}+J\sum_{i=1}^{3^d-1}\delta_{j\overline{\sigma}(y^i)}\right)\nu(j)}$$

$$=\lambda+\lambda\frac{\sum_{j=0}^{\infty}\left[\exp\left(h\delta_{j+1,0}+J\sum_{i=1}^{3^d-1}1\,\delta_{j+1,\overline{\sigma}(y^i)}\right)-\exp\left(h\delta_{0j}+J\sum_{i=1}^{3^d-1}\delta_{j\overline{\sigma}(y^i)}\right)\right]\nu(j)}{\sum_{j=0}^{\infty}\exp\left(h\delta_{0j}+J\sum_{i=1}^{3^d-1}\delta_{j\overline{\sigma}(y^i)}\right)\nu(j)}.$$

Assume

$$c(x,y)=\begin{cases}(4d)^{-1}, & \text{if } \|x-y\|=1;\\ 0 & \text{otherwise.}\end{cases}$$

Then inequality (2) is essentially more simple and it is necessary to find a constant K, such that

$$A\leqslant K+\frac{1}{4d}\sum_{i=1}^{3^d-1}\overline{\sigma}(y^i), \tag{3}$$

for all boundary configurations $\overline{\sigma}(\mathbb{Z}^d\backslash\{x\})$.

In order to avoid numerous indices we are restricted to considering the case $d=1$. Then A has the form

$$\lambda+\lambda\frac{\sum_{j=0}^{\infty}(B(j)-B'(j))\nu(j)}{\sum_{j=0}^{\infty}B'(j)\nu(j)},$$

where

$$B(j)=\exp\left(h\delta_{j+1,0}+J(\delta_{j+1,\overline{\sigma}(x-1)}+\delta_{j+1,\overline{\sigma}(x+1)})\right)$$

and

$$B'(j)=\exp\left(h\delta_{0j}+J(\delta_{j,\overline{\sigma}(x-1)}+\delta_{j,\overline{\sigma}(x+1)})\right).$$

Then it is necessary to find a constant K such that

$$A\leqslant K+\frac{\overline{\sigma}(x-1)+\overline{\sigma}(x+1)}{4}, \tag{4}$$

for all boundary configurations $\overline{\sigma}(Z\backslash\{x\})$.

Let us assume for definiteness, that $J>0$. We shall divide the domain $\{\overline{\sigma}(x-1)\geqslant 0,\ \overline{\sigma}(x+1)\geqslant 0\}$ into 4 subsets (Fig. 1).

Let us divide the proof of the inequality (4) into three steps.

(1) If $(\overline{\sigma}(x-1),\overline{\sigma}(x+1))\in F_1$, then we can find a constant K_1, such that

$$A\leqslant K_1+\frac{\overline{\sigma}(x-1)+\overline{\sigma}(x+1)}{4}.$$

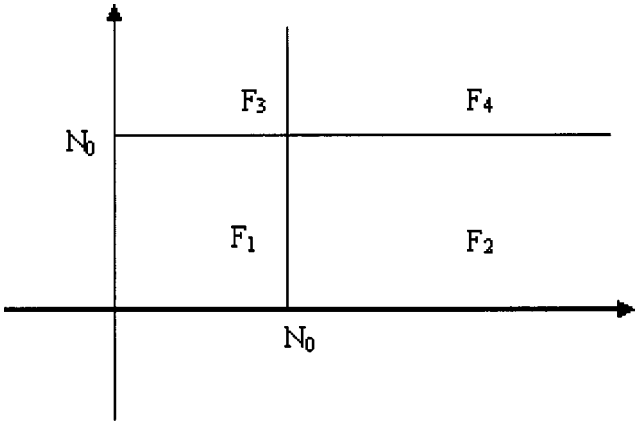

FIG. 1. The partion of the domain into 4 subsets.

It is possible as F_1 is a finite set.

(2) For $(\overline{\sigma}(x-1),\overline{\sigma}(x+1))\in F_4$, we shall consider separately the following cases.

(a) Assume $|\overline{\sigma}(x-1)-\overline{\sigma}(x+1)|\geqslant 2$. Then A has the following form:

$$A=\lambda+\lambda\frac{\alpha\nu(0)+\beta\nu(\overline{\sigma}(x-1)-1)-\beta\nu(\overline{\sigma}(x+1)-1)-\beta\nu(\overline{\sigma}(x+1))}{\exp(h)\nu(0)+\exp(J)(\nu(\overline{\sigma}(x-1))+\nu(\overline{\sigma}(x+1)))+\gamma}$$

$$<\lambda+\lambda\frac{\left(|\alpha|\nu(0)+\beta\left(\frac{\overline{\sigma}(x-1)\nu(\overline{\sigma}(x-1))}{\lambda}-\nu(\overline{\sigma}(x-1))\right)\right.}{\exp(h)\nu(0)}$$

$$+\lambda\frac{\beta\left(\frac{\overline{\sigma}(x+1)\nu(\overline{\sigma}(x+1))}{\lambda}-\nu(\overline{\sigma}(x+1))\right)}{\exp(h)\nu(0)}$$

$$<\lambda+\lambda\frac{|\alpha|}{\exp(h)}+\frac{|\beta|}{\exp(h)\nu(0)}[\overline{\sigma}(x-1)\nu(\overline{\sigma}(x-1))+\overline{\sigma}(x+1)\nu(\overline{\sigma}(x+1))]$$

$$<\lambda\left(1+\frac{|\alpha|}{\exp(h)}\right)+\frac{\beta\nu(N_0)}{\exp(h)\nu(0)}[\overline{\sigma}(x-1)+\overline{\sigma}(x+1)],$$

where $\alpha=1-\exp(h)$, $\beta=\exp(J)-1$ and $\gamma=1-(\nu(0)+\nu(\overline{\sigma}(x-1))+\nu(\overline{\sigma}(x+1)))$.

If we choose N_0^a such that $(\exp(J)-1)\nu(N_0^a)/\exp(h)\nu(0)<1/4$, then

$$K_4^a=\lambda+\lambda\frac{|\exp(h)-1|}{\exp(h)}.$$

(b) Let $|\overline{\sigma}(x-1)+\overline{\sigma}(x+1)|=1$. Then

$$A=\lambda+\lambda\frac{\alpha\nu(0)+(\exp(J)-\exp(h))\nu(\overline{\sigma}(x-1)-1)-\beta\nu(\overline{\sigma}(x+1))}{\exp(h)\nu(0)+\exp(J)(\nu(\overline{\sigma}(x-1))+\nu(\overline{\sigma}(x+1)))+\gamma}$$

$$<\lambda+\lambda\frac{|\alpha|\nu(0)+|\exp(J)-\exp(h)|\cdot\frac{\overline{\sigma}(x-1)\nu(\overline{\sigma}(x-1))}{\lambda}}{\exp(h)\nu(0)}$$

$$=\lambda\left(1+\frac{|\alpha|}{\exp(h)}\right)+\frac{|\exp(J)-\exp(h)|\overline{\sigma}(x-1)\nu(\overline{\sigma}(x-1))}{\exp(h)\nu(0)},$$

where α, β, γ are as above.

If we choose N_0^b such that $(\exp(J)-1)\nu(N_0^b)/\exp(h)\nu(0)<1/2$, then

$$K_4^b=\lambda+\lambda\frac{|\exp(h)-1|}{\exp(h)}=K_4^a.$$

Let $\overline{\sigma}(x-1)=\overline{\sigma}(x+1)$. Then

$$A=\lambda+\lambda\frac{\alpha\nu(0)+\beta'\nu(\overline{\sigma}(x-1)-1)-\beta'\nu(\overline{\sigma}(x-1))}{\exp(h)\nu(0)+\exp(2J)\nu(\overline{\sigma}(x-1))+\gamma'}$$

$$<\lambda\left(1+\frac{|\exp(h)-1|}{\exp(h)}\right)+\frac{\exp(2J)-1}{\exp(h)\nu(0)}\overline{\sigma}(x-1)\nu(\overline{\sigma}(x-1)),$$

where $\alpha=1-\exp(h)$, $\beta'=\exp(2J)-1$ and $\gamma'=1-\nu(0)-\nu(\overline{\sigma}(x-1))$.

If we choose N_0^c such that $(\exp(2J)-1)/\exp(h)\nu(0)\,\nu(N_0^c)<1/2$, then for $N_0=\max(N_0^a,N_0^b,N_0^c)$ will be valid (4) with $K=\lambda(1+|\exp(h)-1|/\exp(h))$ for all $(\overline{\sigma}(x-1),\overline{\sigma}(x-1))\in F_4$.

(3) At last we consider the case $(\overline{\sigma}(x-1),\overline{\sigma}(x+1))\in F_2\cup F_3$.

Let for definiteness $0\leqslant\overline{\sigma}(x-1)\leqslant N_0$ and $\overline{\sigma}(x+1)>N_0$, that is $(\overline{\sigma}(x-1),\overline{\sigma}(x+1))\in F_2$. Here we shall divide the proof of inequality (4) into four steps

(a) Assume $\overline{\sigma}(x-1)=0$. Then

$$A=\lambda+\lambda\frac{(1-\exp(h+J))\nu(0)+\beta\nu(\overline{\sigma}(x+1)-1)-\beta\nu(\overline{\sigma}(x+1))}{\exp(h+J)\nu(0)+\exp(J)\nu(\overline{\sigma}(x+1))+1-\nu(0)-\nu(\overline{\sigma}(x+1))}$$

$$<\lambda\left(1+\frac{|\exp(h+J)-1|}{\exp(h+J)}\right)+\frac{\exp(J)-1}{\exp(h+J)\nu(0)}\nu(\overline{\sigma}(x+1)).$$

As $\exp(J)>1$, then for choosing above N_0 it is evidently

$$\frac{(\exp(J)-1)\nu(N_0)}{\exp(h+J)\nu(0)}<\frac{(\exp(J)-1)\nu(N_0)}{\exp(h)\nu(0)}<\frac{1}{4}.$$

(b) Assume $\overline{\sigma}(x-1)=1$. Then

$$A<\lambda\left(1+\frac{|\exp(h)-\exp(J)|}{\exp(h)}\right)+\frac{\exp(J)-1}{\exp(h)\nu(0)}\nu(\overline{\sigma}(x+1))\overline{\sigma}(x+1),$$

and for choosing N_0, inequality (4) is valid. Here $K=\lambda(1+|\exp(J)-\exp(h)|/\exp(h))$.

(c) Assume $1<\overline{\sigma}(x-1)<N_0$. Then A is defined as case (2)(a) and

$$A<\lambda\left(1+\frac{|\exp(h)-1|}{\exp(h)}\right)+\frac{\exp(J)-1}{\exp(h)\nu(0)}\nu(\overline{\sigma}(x-1))\overline{\sigma}(x-1)+\frac{\exp(J)-1}{\exp(h)\nu(0)}\nu(\overline{\sigma}(x+1))\overline{\sigma}(x+1).$$

As $\overline{\sigma}(x+1)>N_0$, $1<\overline{\sigma}(x-1)<N_0$ and

$$A<\lambda\left(1+\frac{|\exp(h)-1|}{\exp(h)}\right)+\frac{\exp(J)-1}{\exp(h)\nu(0)}\nu(\overline{\sigma}(x-1))\overline{\sigma}(x-1)+\frac{1}{4}\overline{\sigma}(x+1),$$

then at the expense of the extension the constant will be valid (4).

(d) At last let $\overline{\sigma}(x-1)=N_0$. Then it is enough to consider the case $\overline{\sigma}(x+1)=N_0+1$ and again at the expanse of extension of constant will be valid. Thus all conditions of Dobrushin's theorem are valid, so that the set of limiting Gibbs measures is not empty. The same way we can prove inequality (2) for arbitrary positive integer d.

To prove similar theorem for Potts model on Cayley tree, we can use the theory of Markov random fields. This result will be presented in other paper.

(Received 16 August 2003; accepted 1 December 2003)

We consider Novikov problem of the classification of level curves of quasiperiodic functions on the plane and its connection with the conductivity of two-dimensional electron gas in the presence of both orthogonal magnetic field and the superlattice potentials of a special type. We show that the modulation techniques used in the recent papers on the two-dimensional (2-D) heterostructures permit us to obtain the general quasiperiodic potentials for 2-D electron gas and consider the asymptotic limit of conductivity when $\tau\to\infty$. We use the quasiclassical approach introduced by Beenakker for the modulated electron gas and investigate the level curves of quasiperiodic potentials (Novikov problem) to get the asymptotic behavior of conductivity in this limit. Using the theory of quasiperiodic functions we introduce here the topological characteristics of the quasiperiodic potentials observable in the conductivity. The corresponding characteristics are the direct analog of the ''topological numbers'' introduced recently by Novikov and the present author in the conductivity of normal metals. © *2004 American Institute of Physics.*

I. INTRODUCTION

In the present paper we consider the modern experimental techniques of potential modulation for the two-dimensional electron gas and show that they permit us to obtain the quasiperiodic potentials on the plane with different numbers of quasiperiods. Then we use the topological results concerning the geometry of the level curves of such potentials (the Novikov problem) to obtain the asymptotic ($\tau\to\infty$) behavior of the conductivity phenomena in these systems. Namely, we consider the quasiclassical approach, where the quasiclassical cyclotron orbits drift along the level curves of potential in the presence of magnetic field B which makes the geometry of such level curves important for transport phenomena. Our approach is based on the topological methods used previously (by Novikov and the author) in the theory of normal metals (Refs. 19, 25, 30) and the quasiclassical description of the transport phenomena in high-mobility 2-D electron gas introduced by Beenakker[36] for the explanation of new oscillations in B-dependence of conductivity found in the periodically modulated 2-D electron gas (Weiss, Klitzing, Ploog, and Weimann).[33]

We will consider here the cases of potentials with 3 and 4 quasiperiods and use the set of rather deep topological theorems concerning the Novikov problem obtained during the last years. Let us say here that these two cases are actually the only cases which were studied seriously in topology and where the very nice results were obtained. Namely, the full classification of the nonclosed level curves was obtained for the case of potentials with 3 quasiperiods on the plane and it was shown[15,26] that only the so-called ''topologically regular'' level curves appear in the case when the nonclosed level curves exist in the nonzero energy interval $\epsilon_1\leqslant V(\mathbf{r})\leqslant\epsilon_2$. The corresponding curves reveal the nice geometrical properties being bounded by the straight strips of the finite width in the plane and passing through them. Moreover, it can be shown that the mean directions of these strips always correspond to some topological numbers characterizing the potential $V(\mathbf{r})$. Thus for the case of 3 quasiperiods these numbers can be represented as the indivis-

a)Electronic mail: maltsev@itp.ac.ru

ible integer triples (m_1,m_2,m_3) which can be defined experimentally from the mean directions of potential level curves. For the case of 4 quasiperiods the corresponding numbers are the 4-tuples which can again be defined from the mean directions of the topologically regular open level curves in the transport phenomena. However, in the last case the existence of topologically regular open level curves can be stated only for small perturbations of purely periodic potentials in $\mathbb{R}^2$.[27]

In this paper we show that the special modulations of 2-D electron gas give the quasiperiodic potentials on the plane and introduce the corresponding topological numbers and their connection with the modulation pictures. Let us say that the topological numbers of this kind were introduced already in the theory of normal metals,[19,25,30] where the "geometric strong magnetic field limit" in the galvanomagnetic phenomena was considered. For this case only the situation with 3 quasiperiods was important and the topological numbers had the form of the integer triples (m_1,m_2,m_3). Another feature of the situation in the normal metals is that just the Fermi energy level ϵ_F is important for the asymptotic behavior of conductivity in the "geometric limit."

As we already said, we will use here the "drifting orbits" approximation and consider the case $\tau\to\infty$ which corresponds to the "geometric limit" in the situation of 2-D electron gas. We consider in detail the electrical conductivity tensor σ^{ik} in the asymptotic form for $\tau\to\infty$ when the strong anisotropy of σ^{ik} reveals the mean directions of topologically regular trajectories and gives the corresponding topological numbers.

Let us say also that the cases of chaotic behavior of the potential level curves are also possible for the quasiperiodic potentials $V(\mathbf{r})$.[16,22] The asymptotic behavior of σ^{ik} is more complicated in this case and we will not consider it here in detail. For the case of 3 quasiperiods, however, the generic behavior of conductivity should correspond to a topologically regular situation and the chaotic cases are "exclusive," unlike the cases with big numbers of quasiperiods.

II. BASIC DEFINITIONS AND HISTORICAL NOTES

According to the standard definition the quasiperiodic function $f(\mathbf{r})$, $\mathbf{r}\in\mathbb{R}^n$ with N quasiperiods $(N\geqslant n)$ is a restriction of a periodic function $F(\mathbf{R})$, $\mathbf{R}\in\mathbb{R}^N$ with N linearly independent periods $\mathbf{l}_1,\ldots,\mathbf{l}_N$ in the bigger linear space $\mathbb{R}^N$ to some "plane" $\mathbb{R}^n\subset\mathbb{R}^N$. The corresponding subspace $\mathbb{R}^n$ can then be given by a linear system,

$$a_{11}y^1+a_{12}y^2+\cdots+a_{1N}y^N=b_1,$$

$$\cdots$$

$$a_{N-n,1}y^1+a_{N-n,2}y^2+\cdots+a_{N-n,N}y^N=b_{N-n}.$$

We will say that the plane $\mathbb{R}^n$ has the maximal irrationality if it is not parallel to any vector $\mathbf{l}$ belonging to the lattice L generated by vectors $\mathbf{l}_1,\ldots,\mathbf{l}_N$:

$$L=\{p_1\mathbf{l}_1+\cdots+p_N\mathbf{l}_N,\quad p_1,\ldots,p_N\in\mathbb{Z}\}.$$

We will call the plane $\mathbb{R}^n\subset\mathbb{R}^N$ rational if it contains (i.e., parallel to) exactly n linearly independent vectors belonging to L.

Obviously the generic planes $\mathbb{R}^n$ in $\mathbb{R}^N$ have the maximal irrationality. It is easy to see also that any vector $\mathbf{l}\in L$ parallel to the plane $\mathbb{R}^n$ in the nongeneric situation becomes a period of the function $f(\mathbf{r})$ in $\mathbb{R}^n$. The function $f(\mathbf{r})$ corresponding to the rational plane $\mathbb{R}^n\subset\mathbb{R}^N$ is an n-periodic function in the ordinary sense. It is easy to see also that the generic quasiperiodic function $f(\mathbf{r})$ with N quasiperiods has no periods in $\mathbb{R}^n$ for $N>n$.

We are going to consider the case $n=2$ such that the function $f(\mathbf{r})=f(x,y)$ is a quasiperiodic function on the two-dimensional plane $\mathbb{R}^2$. Namely, we will describe here the important features of the global geometry of the level curves $f(\mathbf{r})=\text{const}$ (Novikov problem) which will play the main role for the phenomena discussed in this paper.

Let us say here that the Novikov problem is still unsolved for the case of arbitrary $N>2$ and we are going to deal here with the cases $N=3$ and $N=4$ where the new topological and physical results were obtained during the last years (see Refs. 10–30). According to the definition the corresponding functions $f(\mathbf{r})$ will be the restrictions of the periodic functions in $\mathbb{R}^3$ and $\mathbb{R}^4$ on some two-dimensional planes $\mathbb{R}^2$. Let us say some words here about this situation.

We will start with the very important case $N=3$ where the full classification of the curves $f(\mathbf{r})=\text{const}$ is constructed now. This case plays an extremely important role for the galvanomagnetic phenomena in normal metals (see Refs. 19, 25, 30) where the function $\hat{f}(\mathbf{p})$, $\mathbf{p}=(p_1,p_2,p_3)$ is defined in the space of quasimomenta of the Bloch electron in the crystal. The function $f(\mathbf{p})$ is a restriction of the three-periodic function $\hat{f}(\mathbf{p})$ on the two-dimensional plane (orthogonal to the magnetic field) embedded in $\mathbb{R}^3$. The level curves of $f(\mathbf{p})$ are the intersections of the corresponding plane $\Pi=\mathbb{R}^2$ with the 3-periodic two-dimensional level surfaces of the (smooth) function $\hat{f}(\mathbf{p})$ (dispersion relation). From the physical point of view the level curves of the function f are the quasiclassical electron trajectories in the **p**-space in the presence of magnetic field **B**. We have in this case the one-parametric family of planes Π orthogonal to **B** and the one-parametric set of the quasiperiodic functions defined in the different planes. The form of trajectory in the coordinate space is defined in this case by its form in the **p**-space, keeping all the main features of global geometry. For instance the projection of orbit on xy-plane in **r**-space coincides precisely with the trajectory in **p**-space rotated by $\pi/2$. We do not discuss here the corresponding foundations in detail and just give a reference on the well-known books (Refs. 6–9) where different points of this approach are considered. Let us give also the reference on the recent papers,[31,32] where the mathematically rigorous approach to a derivation of the corresponding system in **p**-space and the history of the question are represented. We also point out that only the trajectories close to the Fermi level are important for the case of normal metals.

The importance of the geometry of these trajectories for the galvanomagnetic phenomena was pointed out in Refs. 1–3 (see also survey articles[4,5]) where also the first examples of concrete two-dimensional periodic Fermi surfaces in $\mathbb{R}^3$ were considered. The problem of full classification of such trajectories was set by Novikov in Ref. 10 and considered later in his school (Zorich, Dynnikov, and Tsarev).

Let us say here that this problem is rather complicated already for $N=3$ and required the nontrivial methods based on topology and dynamical systems theory to be solved completely. The most important breakthroughs in this problem were made in Refs. 11 and 15, where the very important topological theorems about the nonclosed trajectories were proved.

Based on these methods the ''topological quantum characteristics'' observable in the conductivity of normal metals were introduced in Ref. 19. These characteristics arise from the geometry of the Fermi surface and have the form of the triples of the integer numbers connected with the asymptotic behavior of conductivity for $B\to\infty$ (see also the survey articles[25,30]). For these physical phenomena the additional property pointed out in Ref. 19 and called later the ''topological resonance'' played an important role. We will see here how all these properties can be revealed in the two-dimensional electron gas in the quasiperiodic potential $V(\mathbf{r})$.

Recently the full classification of the different trajectories in this situation was finished by Dynnikov,[22,26] which permits us to describe the total picture of the asymptotic behavior of conductivity for $B\to\infty$ in normal metals with arbitrary complicated dispersion relations.[30]

The case $n=2$, $N=4$ was started by Novikov in Ref. 27 where the deep topological theorem analogous to the result of Ref. 11 for this situation was proved. Let us point out here that the case $N=4$ looks very complicated from topological point of view and this theorem is the only deep topological result in this case up to now.

In this paper, however, we work with the coordinate space rather than with the momenta space and consider the quasiperiodic functions $V(\mathbf{r})$ where $\mathbf{r}=(x,y)$ plays the role of the ordinary coordinate vector on the plane. In this situation only one plane $\mathbb{R}^2$ embedded in $\mathbb{R}^3$ or $\mathbb{R}^4$ will be important. However, also the global characteristics of the total family of potentials corresponding

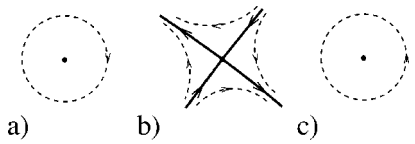

FIG. 1. The level curves of the function $V(\mathbf{r})$ close to the local minimum, the saddle-point and the local maximum of $V(\mathbf{r})$.

to different parallel planes will arise through the action of the ''quasiperiodic group'' as we will see below.

III. THE QUASICLASSICAL TRAJECTORIES AND 2-D ELECTRON GAS

Let us introduce first the notations for the different level curves of potential $V(\mathbf{r})$ according to Refs. 22, 25, 26, 30. We will assume now that the function $V(\mathbf{r})$ is a Morse function on $\mathbb{R}^2$, i.e., all the critical points of $V(\mathbf{r})$ ($\nabla V(\mathbf{r})=0$) are nondegenerate ($\det\|\partial_i\partial_j V\|\neq 0$). All the critical points of $V(\mathbf{r})$ can then be just the nondegenerate local minima, the nondegenerate saddle points or the nondegenerate local maxima. The local geometry of the level curves close to these critical points are shown in Figs. 1(a)–1(c).

Let us call now the level curves of $V(\mathbf{r})$ the quasiclassical drift trajectories according to our further considerations.[62] We will also put formally the arrows on the level curves according to the direction of drift in the magnetic field.

Definition 1: We call the trajectory nonsingular if it is not adjacent to the critical (saddle) point of the function $V(\mathbf{r})$. The trajectories adjacent to the critical points as well as the critical points themselves we call singular trajectories (see Fig. 1).

Definition 2: We call the nonsingular trajectory compact if it is closed on the plane. We call the nonsingular trajectory open if it is unbounded in $\mathbb{R}^2$.

The examples of singular, compact and open nonsingular trajectories are shown in Figs. 2(a)–2(c).

It is easy to see also that the singular trajectories have the measure zero among all the trajectories on the plane.

The geometry of compact trajectories will not be interesting for us here since we are going to consider the ''geometric'' limit corresponding to the long lifetime between the two scattering processes. In this limit we assume that every center of drifting cyclotron orbit belongs to the same trajectory for a rather long time. This means in particular that all compact trajectories will be passed many times before jumping to another trajectory due to the scattering act. This situation corresponds precisely to the ''geometric strong magnetic field limit'' considered in Refs. 1–3, 19, 25, 30 where the conductivity in normal metals was studied. However, in our situation this geometric limit does not correspond to strong magnetic field limit as we will see below.

Definition 3: We call the open trajectory topologically regular (corresponding to ''topologically integrable'' case) if it lies within the straight line of finite width in $\mathbb{R}^2$ and passes through it from $-\infty$ to ∞ [see Fig. 3(a)] All other open trajectories we will call chaotic [Fig. 3(b)].

In the simple case of periodic function $V(\mathbf{r})$ ($N=2$) all open trajectories are periodic and we have only a ''topologically regular'' case according to our classification. However, in the quasiperiodic case the situation is much more complicated and the chaotic trajectories can exist already

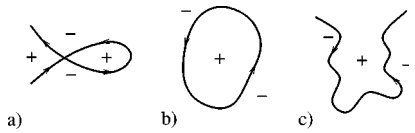

FIG. 2. The singular, compact and open nonsingular quasiclassical trajectories. The signs ''+'' and ''−'' show the regions of larger and smaller values of $V(\mathbf{r})$, respectively.

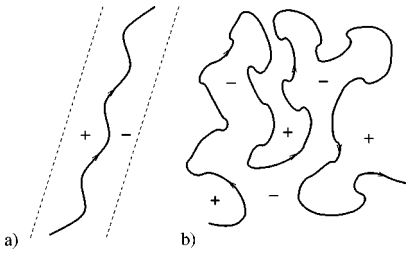

FIG. 3. "Topologically regular" (a) and "chaotic" (b) level curves of the function $V(\mathbf{r})$ in the plane $\mathbb{R}^2$.

for $N=3$.[16,22] These special trajectories can reveal rather complicated stochastic behavior for the general quasiperiodic potentials but fortunately the "generic" open trajectories are still topologically regular for the case $N=3$. Let us point out that this fact was formulated first by Novikov in the form of conjecture and plays now (together with "topological resonance") the crucial role for topological phenomena in normal metals (Refs. 19, 25, 30). Here we are also going to consider mainly the "topologically regular" situation for $N=3$ and $N=4$, and we will show that the same "topological numbers" can be observed also for two-dimensional electron gas in the specific potentials (quasiperiodic superlattices) built by the special experimental techniques in 2-dimensional structures.

Let us describe now the quasiclassical approach for the two-dimensional electron gas that we are going to consider.

The quasiclassical consideration of the 2-D electron gas in the presence of rather strong magnetic field B and a potential $V(\mathbf{r})$ was started in Ref. 36 in connection with the oscillations of conductivity discovered in Ref. 33. The experiment in Ref. 33 (Weiss, Klitzing, Ploog, and Weimann) used the holographic illumination of high mobility AlGaAS–GaAS heterojunctions at the temperatures $T\leqslant 4.2$ K. The expanded laser beam was split into two parts which gave an interference picture with the period a on the two-dimensional sample. The magnetic field $\mathbf{B}$ was directed normally to the sample and the electron behavior was determined by the magnetic field and the additional periodic potential,

$$V(\mathbf{r})=V(x), \quad V(x+a)=V(x),$$

arising after the holographic illumination. The amplitude of $V(x)$ was much smaller than the Fermi energy of the system. Measuring the resistivity in the both directions along and perpendicular to the interference fringes the authors of Ref. 33 found the magnetoresistance oscillations in $1/B$ for magnetic fields smaller than needed for Shubnikov–de Haas oscillations.

This phenomenon was explained by Beenakker in Ref. 36 from the quasiclassical consideration and called the "Commensurability oscillations." According to the quasiclassical approach the potential $V(x)$ should be averaged over the quasiclassical electron cyclotron orbit with radius $r_B=mv_F/eB$ on the Fermi level to get the effective averaged potential $\overline{V}(x,B)=V_B^{\text{eff}}(x)$ depending on the magnetic field B. The condition of weakness of potential $V(x)$ $[eV_{\text{rms}}/\epsilon_F\ll 1$, where V_{rms} is the root mean square of $V(x)]$ should be imposed in this situation. The drift of the center of cyclotron orbit is then given by the equation

$$\frac{d\mathbf{r}_0}{dt}=\frac{e}{B^2}[\nabla V_B^{\text{eff}}(\mathbf{r}_0)\times\mathbf{B}]. \tag{1}$$

According to (1) we have the drift of the centers of cyclotron orbits along the level curves of $V_B^{\text{eff}}(\mathbf{r})=V_B^{\text{eff}}(x)$ with the speed proportional to $\|\nabla V_B^{\text{eff}}(\mathbf{r})\|$ on these curves. As was pointed out in Ref. 36 the drifting motion gives the anisotropic contribution to the conductivity in the plane depending on the potential $V_B^{\text{eff}}(x)$. The crucial role for the magnetoresistance oscillations is then played by the strong dependence of $V_B^{\text{eff}}(\mathbf{r})$ on the value of B connected with the commensurability

of the cyclotron radius r_B (for a given Fermi energy) and the period of potential a. The corresponding contribution to the conductivity was thus the oscillating function of $1/B$ due to the periodic commensurability $2r_B=ka$ with some integer k.

The explicit formulas for the conductivity was obtained in Ref. 36 for the model potential having the form $V(x)=V_x\cos 2\pi x/a$. Obviously the main features of this picture will also be true for many generic periodic potentials $V(x)$. Let us also give here the references on the papers in Refs. 34, 35, 37, 42, 44, 45, 47–52, 54, 57, 60, 61, where different questions connected with this problem were considered (we are sorry for the impossibility to give here the complete list of works in this area).

Let us consider now the works where the situation of potentials $V(\mathbf{r})$ modulated both in the x and y directions was considered. The potential $V(\mathbf{r})=V(x,y)$ was induced in this case by the two independent sets of interference fringes parallel to the x and y axes and the potential $V(x,y)$ was the periodic function in $\mathbb{R}^2$ with two periods given by vectors $(a,0)$ and $(0,a)$.

As was found experimentally,[47,49,50] the additional modulation in the y direction suppresses the commensurability oscillations in this case. The quasiclassical consideration of this situation was made in Ref. 58 where again the drift of electron orbits along the constant energy levels of potential $V(x,y)$ was considered. Two types of the drift trajectories were considered in Ref. 58: (1) the ''pinned orbits'' (corresponding to compact energy level curves); (2) the ''drifting orbits'' (corresponding to unbounded energy level curves in the plane).

As was assumed in Ref. 58 only the contribution of the ''drifting orbits'' was important for the commensurability oscillations in this case and the ''pinned orbits'' were unessential for this phenomenon. According to this assumption the suppression of the commensurability oscillations can be explained by the appearance of the ''pinned orbits'' for the potentials modulated both in the x and y directions. Unlike the case of potentials modulated just in the x direction the new condition that the compact trajectories are passed many times by the centers of cyclotron orbits between two scattering acts appeared in Ref. 58. This requirement is similar to the condition of the ''geometric strong magnetic field limit'' considered in Refs. 1–3 for normal metals. However, the limit $B\to\infty$ does not correspond to the geometric limit in this situation and only $\tau\to\infty$ should be considered as the geometric limit for this case. It is easy to see also that only periodic ''drifting orbits'' can appear for purely periodic potentials $V(x,y)$.

Let us also point out here that the analytic dependence of the resistance on the value of B was also calculated in Ref. 58 in the interesting interval for the model potentials having few harmonics. This dependence is more complicated compared with the case of 1-D modulated potentials but still reveals the effect of commensurability also in this situation. The mean directions of trajectories that appeared in Ref. 58 were parallel to x and y axes and to the diagonal $y=-x$ in the different examples. As was also pointed out in Ref. 58 the ''drifting orbits'' can exist only for potentials with the broken rotational symmetry which explains the maximal suppression of the commensurability oscillations for the case of equal modulation intensity in both the x and y directions.

In this paper we will not consider in detail the B-dependence of conductivity for our more complicated potentials since it should reveal much more complicated behavior in this case. Instead we are going to consider the geometric properties of the conductivity tensor in the limit $\tau\to\infty$ arising from the global geometry of nonsingular open trajectories. Namely, we will show that this type of potential can be considered as the particular case of the quasiperiodic potentials with the fixed number of quasiperiods and use the results obtained for the Novikov problem to get the ''topological characteristics'' of the conductivity in this case. Let us say that this type of ''topological quantities'' arise in the completely different way compared, for example, with the Hall effect and characterize the geometry of the asymptotic of the conductivity tensor (but not its absolute values).

We will not also put any special conditions on potential $V(x,y)$ except the quasiperiodic properties. The formulated results will have the general topological form valid for the generic potentials $V(x,y)$.

Before we start the geometric consideration we want to say also that the holographic illumination is not the unique way to produce the superlattice potentials for the two-dimensional electron

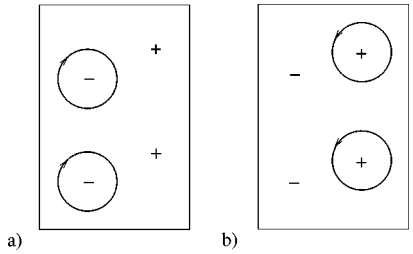

FIG. 4. The level curves of $f(\mathbf{r})$ close to the minimal and maximal values of f.

gas. Let us mention here the works,[38–41,43,46,47,50,53,55,56] where the different techniques using the biasing of the specially made metallic gates and the piezoelectric effect were considered. Both 1-D and 2-D modulated potentials as well as more general periodic potentials with square and hexagonal geometry appeared in this situation. We want to point out that the quasiperiodic potentials can also be made by these techniques in the same way using the superposition of several 1-D modulations. Actually these techniques give even more possibilities to produce the potentials of different types even for the quasiperiodic situation. For example, the superposition of the general periodic potential with the generic 1-D modulation will give the quasiperiodic potentials with 3 quasiperiods which are more general than made just by 3 interference pictures. Also the superpositions of two general periodic potentials on the plane will give the class of the quasiperiodic potentials with 4 quasiperiods more general than those which we will consider in detail here. However, we would like for simplicity to restrict ourselves to the simpler pictures of superpositions of 1-D modulation pictures which give already all the features of general behavior. We will also use everywhere the term ''interference picture'' for the modulation pictures. The general geometrical results will then be true for the other techniques also.

IV. NOVIKOV PROBLEM AND THE GEOMETRIC LIMIT FOR THE CASE OF 3 QUASIPERIODS

Let us come now to the Novikov problem and start the topological consideration of the level curves of quasiperiodic functions.

We will first describe the situation for the arbitrary periodic potential $V(x,y)$ with some periods $\mathbf{l}_1,\mathbf{l}_2 \in \mathbb{R}^2$. This picture is rather simple from the topological point of view but it is convenient to give it here just to introduce the notations and to show the general approach which we are going to use. Let us consider the generic periodic function $f(\mathbf{r})$ on $\mathbb{R}^2$ with the values belonging to some interval $[f_{\min},f_{\max}]$. We are interested in the form of the level curves $f(\mathbf{r})=c$ where $f_{\min}\leqslant c\leqslant f_{\max}$. It is easy to see that for the values of c close to the minimal or maximal value of f all such level curves are just the small closed loops bounding the small regions of lower or higher values of f [see Figs. 4(a) and 4(b)].

It is not difficult to prove also that the extended trajectories (singular or nonsingular) always exist in some closed connected ''energy interval'' $f_1\leqslant c\leqslant f_2$ ($f_{\min}<f_1\leqslant f_2<f_{\max}$). In a generic situation we have $f_1<f_2$, but for special functions $f(\mathbf{r})$ also the case $f_1=f_2$ is possible. This fact is actually true for any quasiperiodic function and does not depend on the number of quasiperiods (the proof in Ref. 22 given for $N=3$, works actually for any N without any change). Every nonsingular open trajectory is periodic for the periodic function $f(\mathbf{r})$ with the mean direction given by some integral vector $\mathbf{l}=m_1\mathbf{l}_1+m_2\mathbf{l}_2$ of lattice generated by periods $\mathbf{l}_1,\mathbf{l}_2$. We can see then that every nonsingular open trajectory for periodic $f(\mathbf{r})$ corresponds to ''topologically regular'' case.

It is easy to see also that there can be only the finite number of energy levels for the periodic Morse function where the singular trajectories can exist. We can claim then that the nonsingular open trajectories always exist in the generic case $f_1<f_2$. The opposite statement is also true since

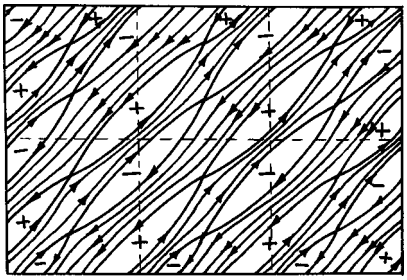

FIG. 5. The layers of open periodic trajectories with the ''nontrivial'' opposite directions [(1,1) and $(-1,-1)$] for the generic periodic function $f(\mathbf{r})$.

the nonsingular open trajectories are stable with respect to the small change of energy level. The typical situation of the generic case with the layers of open trajectories is shown in Fig. 5.

All the open trajectories do not intersect each other and have the common mean direction passing in both the ''direct'' and the ''opposite'' way.

The opposite nongeneric case $f_1=f_2$ corresponds to the absence of the nonsingular open trajectories in the plane. The typical picture for $f_1=f_2$ is a ''singular net'' on the level $f(\mathbf{r})=f_1=f_2$ and the closed trajectories at all the other levels (Fig. 6). Let us pay here special attention to the last fact to compare this situation with the more complicated quasiperiodic case.

It follows also that the case $f_1=f_2$ always takes place for potentials with any kind of rotational symmetry since the nonsingular open trajectories cannot exist in this situation.

Let us give here also the references on the work[59] where the nice quantization picture based on the topology of periodic quasiclassical drift trajectories in the magnetic field was considered.

The generic periodic potentials $V(\mathbf{r})$ arise in the experiments described above when the two independent interference pictures with arbitrary directions of interference fringes are present at the same sample. The potential $V(\mathbf{r})$ is a functional of the total intensity of radiation $I(\mathbf{r})$ and has the same periodicity for any (even nonlocal) translationally invariant dependence of $V(\mathbf{r})$ on the field $I(\mathbf{r}')$. For simplicity we will put the requirement that the functional $V(\mathbf{r})[I]$ has the variational derivative $\delta V(\mathbf{r})/\delta I(\mathbf{r}')$ decreasing for large enough $|\mathbf{r}-\mathbf{r}'|$. We assume also that the functional $V(\mathbf{r})[I]$ is smooth, i.e., gives the smooth function $V(\mathbf{r})$ for any smooth distribution $I(\mathbf{r}')$.

Let us now come to our main purpose and consider the potentials $V(\mathbf{r})$ having the more complicated form. Let us have now three independent interference pictures on the plane with three different generic directions of fringes $\boldsymbol{\eta}_1, \boldsymbol{\eta}_2, \boldsymbol{\eta}_3$ and periods a_1, a_2, a_3 (see Fig. 7).

The total intensity $I(\mathbf{r})$ will be the sum of intensities,

$$I(\mathbf{r})=I_1(\mathbf{r})+I_2(\mathbf{r})+I_3(\mathbf{r}),$$

of the independent interference pictures.

We assume that there are at least two noncoinciding directions (say $\boldsymbol{\eta}_1, \boldsymbol{\eta}_2$) among the set $(\boldsymbol{\eta}_1, \boldsymbol{\eta}_2, \boldsymbol{\eta}_3)$.

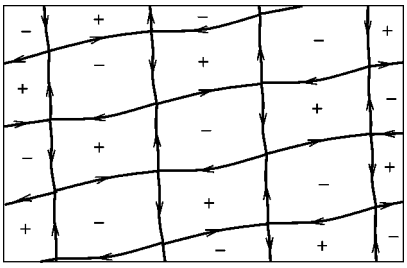

FIG. 6. The singular periodic net on the level $f(\mathbf{r})=f_1=f_2$ for the nongeneric periodic function $f(\mathbf{r})$.

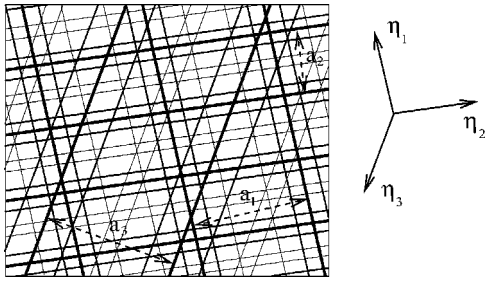

FIG. 7. The schematic sketch of the three independent interference pictures on the plane with different periods and intensities.

Let us draw three straight lines q_1, q_2, q_3 with the directions $\boldsymbol{\eta}_1, \boldsymbol{\eta}_2, \boldsymbol{\eta}_3$ and choose the "positive" and "negative" half-planes for every line q_i on the plane. Let us consider now three linear functions $X(\mathbf{r})$, $Y(\mathbf{r})$, $Z(\mathbf{r})$ on the plane which are the distances from the point $\mathbf{r}$ to the lines q_1, q_2, q_3 with the signs "+" or "−" depending on the half-plane for the corresponding line q_i (Fig. 8).

The coordinates

$$\mathbf{R}(\mathbf{r}) = (X(\mathbf{r}), Y(\mathbf{r}), Z(\mathbf{r}))$$

now give the parametric representation of our plane $\Pi^2 = \mathbb{R}^2$ in the 3-dimensional space $\mathbb{R}^3$. The total intensity $I(\mathbf{r})$ can be considered then as the restriction to Π^2 of the periodic function $\hat{I}(X,Y,Z)$:

$$\hat{I}(X,Y,Z) = I_1(X) + I_2(Y) + I_3(Z),$$

corresponding to the lattice in $\mathbb{R}^3$ generated by vectors $(a_1,0,0)$, $(0,a_2,0)$, $(0,0,a_3)$. The plane Π^2 passes through the origin according to Fig. 8 (although it is not necessary if the lines q_1, q_2, q_3 do not intersect at one point in $\mathbb{R}^2$).

Let us point out here that the standard inner product on the plane Π^2 does not coincide with the product in $\mathbb{R}^3$ in this construction [from the metric point of view the plane $\mathbb{R}^2$ will be linearly deformed in the embedding $\mathbf{R} = \mathbf{R}(x,y)$]. However, the inner product will not be important at all in our further considerations so we do not pay any attention to this fact. Let us just say that it is possible to introduce the special inner product in $\mathbb{R}^3$ such that it's restriction on Π^2 will give the standard metric in $\mathbb{R}^2$. Nevertheless, all the topological statements will be invariant under the group of all nondegenerate linear transformations and we will not need this construction at all.

We can define now the smooth periodic functions $\hat{V}(X,Y,Z)$ and $\hat{V}_B^{\text{eff}}(X,Y,Z)$ in $\mathbb{R}^3$ such that the functions $V(x,y)$ and $V_B^{\text{eff}}(x,y)$ will be the restrictions of $\hat{V}(X,Y,Z)$ and $\hat{V}_B^{\text{eff}}(X,Y,Z)$ on the plane Π^2. Indeed, consider any point $\mathbf{R} = (X,Y,Z) \in \mathbb{R}^3$. Let us draw the two-dimensional plane

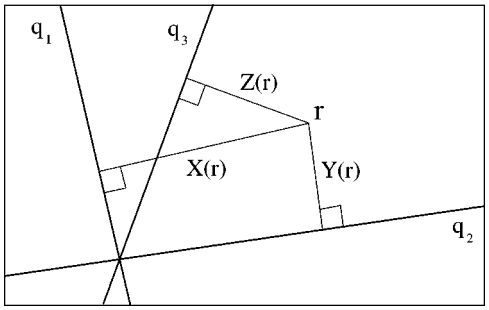

FIG. 8. The coordinates $X(\mathbf{r})$, $Y(\mathbf{r})$ and $Z(\mathbf{r})$ on the plane.

$\Pi^{2\prime}$ through the point $\mathbf{R}$ parallel to the plane Π^2. We have then the total intensity $I'(\mathbf{R})$ in the plane $\Pi^{2\prime}$ defined as the restriction of $\hat{I}(X,Y,Z)$ on $\Pi^{2\prime}$. Let us define now the functions $\hat{V}(X,Y,Z)$ and $\hat{V}_B^{\text{eff}}(X,Y,Z)$ at the point $\mathbf{R}$ as the corresponding functions defined in the plane $\Pi^{2\prime}$ passing through $\mathbf{R}$ using the functional $V(\mathbf{r})[I]$ and the averaging over the cyclotron orbits in $\Pi^{2\prime}$. It is easy to see that the functions $\hat{V}(X,Y,Z)$, $\hat{V}_B^{\text{eff}}(X,Y,Z)$ are the smooth periodic functions in $\mathbb{R}^3$ with periods $(a_1,0,0)$, $(0,a_2,0)$, $(0,0,a_3)$. Obviously the functions $\hat{V}|_{\Pi^2}$ and $\hat{V}_B^{\text{eff}}|_{\Pi^2}$ give the required potential $V(\mathbf{r})$ and the effective potential $V_B^{\text{eff}}(\mathbf{r})$ in the initial two-dimensional plane $\mathbb{R}^2$.

Let us introduce now the important definition of the ''quasiperiodic group'' acting on the potentials described above. As we saw, our construction gives us the embedding Π^2 of the initial plane $\mathbb{R}^2$ in the three-dimensional space $\mathbb{R}^3$. At the same time we get the additional planes $\Pi^{2\prime}$ in $\mathbb{R}^3$ parallel to Π^2 with different $I'(\mathbf{r})$, $V'(\mathbf{r})$, $V_B^{\text{eff}\prime}(\mathbf{r})$ corresponding to the same $\hat{I}(\mathbf{R})$, $\hat{V}(\mathbf{R})$ and $\hat{V}_B^{\text{eff}}(\mathbf{R})$. It is easy to see that the functions $I'(\mathbf{r})$, $V'(\mathbf{r})$, $V_B^{\text{eff}\prime}(\mathbf{r})$ correspond to the case of three interference pictures with the same mean directions of fringes and periods $(\boldsymbol{\eta}_1,a_1)$, $(\boldsymbol{\eta}_2,a_2)$, $(\boldsymbol{\eta}_3,a_3)$ but with shifted positions of maxima and minima for every interference picture.

Definition 4: We will say that all the potentials $V'(\mathbf{r})$ (*as well as* $V_B^{\text{eff}\prime}(\mathbf{r})$ *for every given* B) *are related by a "quasiperiodic group" of transformations.*

According to the Definition 4 we define the action of a ''quasiperiodic group'' in $\mathbb{R}^2$ as the parallel shifts of the plane Π^2 in the space $\mathbb{R}^3$. The ''quasiperiodic group'' is then the 3-parametric Abelian group isomorphic to 3-dimensional torus $\mathbb{T}^3=\mathbb{R}^3/L$,

$$L=m_1(a_1,0,0)+m_2(0,a_2,0)+m_3(0,0,a_3),$$

$$(m_1,m_2,m_3)\in\mathbb{Z}^3,$$

containing the (noncompact) algebraic subgroup of ordinary translations in $\mathbb{R}^2$.

As we will see below, this definition will be very convenient in the consideration of open trajectories for potentials of this type in $\mathbb{R}^2$. Namely, we will see that all the global properties of open trajectories will be the same for all potentials related by the ''quasiperiodic group'' in the case of generic $(\boldsymbol{\eta}_1,a_1)$, $(\boldsymbol{\eta}_2,a_2)$, $(\boldsymbol{\eta}_3,a_3)$. In other words, for the generic $(\boldsymbol{\eta}_1,a_1)$, $(\boldsymbol{\eta}_2,a_2)$, $(\boldsymbol{\eta}_3,a_3)$ the global geometry of open trajectories will not depend on the positions of minima and maxima of the interference pictures and will be defined just by the set $(\boldsymbol{\eta}_1,a_1)$, $(\boldsymbol{\eta}_2,a_2)$, $(\boldsymbol{\eta}_3,a_3)$ and the intensities I_1, I_2, I_3 [although the potentials $V(\mathbf{r})$, $V_B^{\text{eff}}(\mathbf{r})$ will be different in these cases]. Let us say, however, that this property can be broken for the special $(\boldsymbol{\eta}_1,a_1)$, $(\boldsymbol{\eta}_2,a_2)$, $(\boldsymbol{\eta}_3,a_3)$ corresponding to purely rational directions of Π^2 in $\mathbb{R}^3$.

According to the previous definition we will say that the quasiperiodic potential has irrationality 3 or maximal irrationality if it has no periods in $\mathbb{R}^2$. We will say that the potential $V(\mathbf{r})$ has irrationality 2 if it has only one (up to the integer multiplier) period in $\mathbb{R}^2$. We will say that the potential $V(\mathbf{r})$ has irrationality 1 if it has two linearly independent periods in $\mathbb{R}^2$.[63] As can be easily seen the last case corresponds to the purely periodic potentials $V(\mathbf{r})$. It is easy to see also that the potentials $V(\mathbf{r})$ of irrationality 3, 2 and 1 correspond to the cases when the plane Π^2 contains no vectors belonging to L, just one (up to the integer multiplier) vector belonging to L and two linearly independent vectors belonging to L, respectively. Obviously all the potentials related by the ''quasiperiodic group'' have the same irrationality in the plane.

Let us discuss now briefly the connection of irrationality with the directions and periods of interference pictures in our situation.

We assume as previously that there are at least two different directions of the interference fringes in our picture. The picture given by the two corresponding sets of interference fringes is purely periodic in $\mathbb{R}^2$ with the periods $\mathbf{u}_1$, $\mathbf{u}_2$ parallel to $\boldsymbol{\eta}_1$ and $\boldsymbol{\eta}_2$, respectively (see Fig. 9).

We can see then that the total picture has a period in $\mathbb{R}^2$ if some nontrivial integer linear combination,

$$m_1\mathbf{u}_1+m_2\mathbf{u}_2\ ,\quad (m_1,m_2)\in\mathbb{Z}^2/(0,0),$$

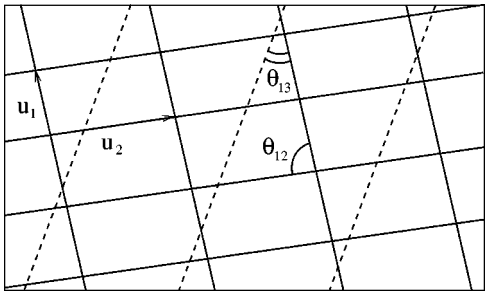

FIG. 9. The periodic picture formed by two sets of parallel interference fringes with common directions $\boldsymbol{\eta}_1$, $\boldsymbol{\eta}_2$ and the added third set with direction $\boldsymbol{\eta}_3$.

of periods $\mathbf{u}_1$, $\mathbf{u}_2$ leaves invariant also the third interference picture corresponding to pair $(\boldsymbol{\eta}_3, a_3)$.

The corresponding condition for $m_1\mathbf{u}_1+m_2\mathbf{u}_2$ can then be written in the form

$$(m_1\mathbf{u}_1+m_2\mathbf{u}_2, \boldsymbol{\xi}_3)=ka_3 \quad , \quad k\in\mathbb{Z}, \tag{2}$$

where $\boldsymbol{\xi}_3$ is a unit vector orthogonal to $\boldsymbol{\eta}_3$ in the plane.

The equation (2) has no nontrivial solutions in the generic situation and can be satisfied only for special $\boldsymbol{\eta}_3$ and a_3. It is not difficult to show that for purely rational potentials $V(\mathbf{r})$ [two linearly independent solutions of (2)] the direction $\boldsymbol{\eta}_3$ should also correspond to the integer vector in the lattice L' generated by vectors $\mathbf{u}_1$, $\mathbf{u}_2$:

$$L'=\{m_1\mathbf{u}_1+m_2\mathbf{u}_2 \quad , \quad (m_1,m_2)\in\mathbb{Z}^2\}.$$

We can put for this case $\boldsymbol{\eta}_3 \sim m_1\mathbf{u}_1+m_2\mathbf{u}_2$ for some integer m_1, m_2. Also the corresponding period a_3 should satisfy the special condition in this situation. If we introduce the angles θ_{12}, θ_{13} between the directions $\boldsymbol{\eta}_1$, $\boldsymbol{\eta}_2$ and $\boldsymbol{\eta}_1$, $\boldsymbol{\eta}_3$, $0<\theta_{12}\leqslant\pi/2$, $0<\theta_{13}\leqslant\pi$ (Fig. 9) we can get the relations for θ_{13} and a_3 which define all the pairs $(\boldsymbol{\eta}_3, a_3)$ corresponding to purely rational potentials $V(\mathbf{r})$:

$$tg\ \theta_{13}=\frac{m_2a_1\sin\theta_{12}}{m_1a_2-m_2a_1\cos\theta_{12}}, \tag{3}$$

$$k_3a_3\sin\theta_{12}=k_1a_1\sin(\theta_{12}+\theta_{13})+k_2a_2\sin\theta_{13}, \tag{4}$$

where $m_1,m_2,k_1,k_2,k_3\in\mathbb{Z}$, $(m_1,m_2)\neq(0,0)$, $(k_1,k_2)\neq(0,0)$, $k_3\neq0$.

For the case of just one period (irrationality 2) we can have either the condition (3) for θ_{13} (''+ rational'' direction of $\boldsymbol{\eta}_3$) but with a_3 not satisfying to (4) or the condition (4) for a_3 but with θ_{13} not satisfying to (3).

It is easy to see that both cases of irrationality 1 and 2 have the measure zero among all potentials constructed by three arbitrary interference pictures.

As we already said above the case of irrationality 1 corresponds to the purely periodic potentials $V(x,y)$. Let us however make here some remark. Namely, for arbitrary periodic potential $V(x,y)$ the corresponding periods $\mathbf{l}_1$, $\mathbf{l}_2$ can be much bigger than the values of a_1, a_2, a_3. We can conclude then that even the ''topologically regular'' periodic open trajectories can have a rather nontrivial structure on the rather long distances since the period of the trajectory is very big. The width of the straight line containing the periodic trajectory can be also compatible with periods of $V(x,y)$ in this case being quite big with respect to the periods of modulations a_1, a_2, a_3. Also the rational mean direction of the periodic trajectories can have a ''rather big denominator'' such that this rationality will not play an essential role in the real picture. Instead, the typical features observable in the generic situation of irrationality 3 will appear on the distances smaller than the

periods $|\mathbf{l}_1|$, $|\mathbf{l}_2|$ of potential $V(x,y)$. According to this remark we can actually try to consider the potentials of irrationality 1 or 2 as the generic potentials of irrationality 3 if the periods of these potentials are rather big. The special features connected with rationality can then be revealed only for very big values of τ such that the free motion length is much larger than $|\mathbf{l}_1|$, $|\mathbf{l}_2|$.

Let us formulate now (in our language) the first theorem about the open trajectories for the quasiperiodic potentials $V(\mathbf{r})$ and $V_B^{\text{eff}}(\mathbf{r})$ with 3 quasiperiods corresponding to the first theorem on the Novikov problem proved in Ref. 11.

Theorem 1: *Consider the purely periodic potential* $V^{(0)}(\mathbf{r})$ *(or* $V_B^{(0)\text{eff}}(\mathbf{r})$*) generated by three independent interference pictures with some parameters* $(\boldsymbol{\eta}_1^{(0)},a_1^{(0)})$, $(\boldsymbol{\eta}_2^{(0)},a_2^{(0)})$, $(\boldsymbol{\eta}_3^{(0)},a_3^{(0)})$ *satisfying to (3), (4). Then for all the potentials* $V(\mathbf{r})$ *(and* $V_B^{\text{eff}}(\mathbf{r})$*) with parameters* $(\boldsymbol{\eta}_1,a_1)$, $(\boldsymbol{\eta}_2,a_2)$, $(\boldsymbol{\eta}_3,a_3)$ *close enough to* $(\boldsymbol{\eta}_1^{(0)},a_1^{(0)})$, $(\boldsymbol{\eta}_2^{(0)},a_2^{(0)})$, $(\boldsymbol{\eta}_3^{(0)},a_3^{(0)})$ *all the open nonsingular electron trajectories will correspond to the topologically regular case only.*

Using the same methods as in Ref. 11 it is possible to prove also that Theorem 1 will be true also for small variations of the intensities $I_1(\mathbf{r})$, $I_2(\mathbf{r})$, $I_3(\mathbf{r})$ of the laser beams and the form of the functional $V(\mathbf{r})[I]$.

Let us say here that Theorem 1 makes a rather strong statement about the generic potentials close to periodic ones. However, the corresponding "stability zones" for parameters $(\boldsymbol{\eta}_1,\boldsymbol{\eta}_2,\boldsymbol{\eta}_3,a_1,a_2,a_3)$ (and I_1, I_2, I_3) depend on the initial values of $(\boldsymbol{\eta}_1^{(0)},a_1^{(0)})$, $(\boldsymbol{\eta}_2^{(0)},a_2^{(0)})$, $(\boldsymbol{\eta}_3^{(0)},a_3^{(0)})$ and become very small for the large values of periods $|\mathbf{l}_1|$, $|\mathbf{l}_2|$ of the initial potential. Due to this reason Theorem 1 cannot say anything about arbitrary potential $V(\mathbf{r})$ (with 3 quasiperiods) since we can have the situation when it does not belong to any stability zone corresponding to any rational potential $V^{(0)}(\mathbf{r})$. Nevertheless, this theorem is very important and we will see also that only the result of this type can be formulated for the more complicated case of potentials with 4 quasiperiods.

Let us discuss now the general situation of arbitrary potentials $V(\mathbf{r})$ with 3 quasiperiods. We will start first with the generic situation of potentials of irrationality 3 and then discuss the additional features which can arise in the cases of irrationality 1 and 2. Let us make here the reference on the survey article,[26] where the final theorems in the most complete form were formulated. The development of this problem and the considerations of physical phenomena can be found in Refs. 10–30. Let us say also that all the results in Ref. 26 and in all previous papers were formulated in another language using the 3-dimensional topology terminology. We will not discuss here the topological questions in detail and just claim that the following statements can be derived from the topological theorems formulated in Ref. 26.

Theorem 2: *Let us fix the value of B and consider the generic quasiperiodic potential* $V_B^{\text{eff}}(\mathbf{r})$ *(of irrationality 3) taking the values in some interval* $\epsilon_{\min}(B)\leqslant V_B^{\text{eff}}(\mathbf{r})\leqslant\epsilon_{\max}(B)$*. Then we have the following.*

(1) Open quasiclassical trajectories $V_B^{\text{eff}}(\mathbf{r})=c$ *always exist either in the connected energy interval,*

$$\epsilon_1(B)\leqslant c\leqslant\epsilon_2(B)$$

$[\epsilon_{\min}(B)<\epsilon_1(B)<\epsilon_2(B)<\epsilon_{\max}(B)]$ *or just at one energy value* $c=\epsilon_0(B)$ *[i.e.* $\epsilon_1(B)=\epsilon_2(B)=\epsilon_0(B)$*].*

(2) For the case of the finite interval $[\epsilon_1(B)<\epsilon_2(B)]$ *all the nonsingular open trajectories correspond to the topologically regular case, i.e., lie in the straight strips of the finite width [Fig. 3(a)] and pass through them. All the strips have the same mean directions for all the energy levels* $c\in[\epsilon_1(B),\epsilon_2(B)]$ *such that all the open trajectories are on average parallel to each other for all values of* c*.*

(3) The values $\epsilon_1(B)$, $\epsilon_2(B)$ *or* $\epsilon_0(B)$ *are the same for all the potentials of irrationality 3 connected by the "quasiperiodic group."*

(4) For the case of the finite energy interval $[\epsilon_1(B)<\epsilon_2(B)]$ *all the nonsingular open trajectories also have the same mean direction for all the potentials (of irrationality 3) connected by the "quasiperiodic group."*

We can see from Theorem 2 that the ''topologically integrable'' situation is typical also for the case of quasiperiodic functions with 3 quasiperiods being connected with the generic case $\epsilon_1(B)<\epsilon_2(B)$. Let us say also that for the case of just one energy level $[\epsilon_1(B)=\epsilon_2(B)=\epsilon_0(B)]$ containing the open trajectories both the topologically regular and ''chaotic'' behavior of open trajectories are possible (see Ref. 22). This situation can be compared with the situation of purely periodic potentials where the nonsingular periodic open trajectories always appear in the case of a finite energy interval $[\epsilon_1(B)>\epsilon_2(B)]$ but only the periodic ''singular nets'' are possible for the case $\epsilon_1(B)=\epsilon_2(B)=\epsilon_0(B)$. As we see here the quasiperiodic potentials give another possibility in the last case.

Let us consider now the asymptotic behavior of conductivity in the case of topologically regular open trajectories when $\tau\to\infty$. According to previous papers[36,51,58] we will divide here the conductivity tensor in two parts $\sigma_0^{ik}(B)$ and $\Delta\sigma^{ik}(B)$ corresponding to the conductivity without any potential $V(\mathbf{r})$ and an additional contribution due to potential $V(\mathbf{r})$. We have then

$$\sigma^{ik}(B)=\sigma_0^{ik}(B)+\Delta\sigma^{ik}(B).$$

In the approximation of the drifting cyclotron orbits the parts $\sigma_0^{ik}(B)$ and $\Delta\sigma^{ik}(B)$ can be interpreted as caused, respectively, by the (infinitesimally small) difference in the electron distribution function on the same cyclotron orbit (weak angular dependence) and the (infinitesimally small) difference in the occupation of different trajectories by the centers of cyclotron orbits at different points of $\mathbb{R}^2$ (on the same energy level) as the linear response to the (infinitesimally) small external field $\mathbf{E}$. The asymptotic $\tau\to\infty$ of both parts $\sigma_0^{ik}(B)$ and $\Delta\sigma^{ik}(B)$ can then be written from the same arguments used in Refs. 1–3 with some additional remarks specific for this situation. We will just say here that the first part $\sigma_0^{ik}(B)$ has the standard asymptotic form:

$$\sigma_0^{ik}(B)\sim\frac{ne^2\tau}{m^{\mathrm{eff}}}\begin{pmatrix}(\omega_B\tau)^{-2} & (\omega_B\tau)^{-1}\\ (\omega_B\tau)^{-1} & (\omega_B\tau)^{-2}\end{pmatrix},$$

for $\omega_B\tau\gg 1$ due to the weak angular dependence ($\sim 1/\omega_B\tau$) of the distribution function in the same cyclotron orbit. We have then that the corresponding longitudinal conductivity decreases for $\tau\to\infty$ in all the directions in $\mathbb{R}^2$ and the corresponding condition is just $\omega_B\tau\gg 1$ in this case.

For the part $\Delta\sigma^{ik}(B)$ the limit $\tau\to\infty$ should, however, be considered as the condition that every trajectory is passed for a rather long time by the drifting cyclotron orbits to reveal its global geometry. Thus another parameter τ/τ_0 where τ_0 is the characteristic time of completion of close trajectories should be used in this case and we should put the condition $\tau/\tau_0\gg 1$ to have the asymptotic regime for $\Delta\sigma^{ik}(B)$. In this situation the difference between the open and closed trajectories plays the main role and the asymptotic behavior of conductivity can be calculated in the form analogous to that used in Refs. 1–3 for the case of normal metals. Namely,

$$\Delta\sigma^{ik}(B)\sim\frac{ne^2\tau}{m^{\mathrm{eff}}}\begin{pmatrix}(\tau_0/\tau)^2 & \tau_0/\tau\\ \tau_0/\tau & (\tau_0/\tau)^2\end{pmatrix},$$

in the case of closed trajectories and

$$\Delta\sigma^{ik}(B)\sim\frac{ne^2\tau}{m^{\mathrm{eff}}}\begin{pmatrix}* & \tau_0/\tau\\ \tau_0/\tau & (\tau_0/\tau)^2\end{pmatrix},$$

$(*\sim 1)$ for the case of open topologically regular trajectories if the x-axis coincides with the mean direction of trajectories.

We can see then that only the contribution of open orbits to $\Delta\sigma^{ik}(B)$ remains in (longitudinal) conductivity for $\tau\to\infty$. Let us say that these formulas give just the asymptotic form of conductivity for $\tau\to\infty$. In the more precise form they should include also the multipliers proportional to

the parts of the phase volume filled by the closed and open trajectories and the appropriate definition of m^{eff} in this situation. We will not, however, consider this part in detail since we will need only the anisotropy of the tensor σ^{ik} in the ''geometric limit.''

The condition $\tau/\tau_0 \gg 1$ is much stronger than $\omega_B \tau \gg 1$ in the situation described above just according to the definition of the slow drift of the cyclotron orbits. We can keep then just this condition in our further considerations and assume that the main part of conductivity is given by $\Delta\sigma^{ik}(B)$ in this limit. It is easy to see also that the magnetic field B should not be ''very strong'' in this case.

According to the remarks above we can write now the main part of the conductivity tensor $\sigma^{ik}(B)$ in the limit $\tau \to \infty$ for the case of topologically regular open orbits. Let us take the x axis along the mean direction of open orbits and take the y axis orthogonal to x. The asymptotic form of σ^{ik}, $i,k=1,2$ can then be written as

$$\sigma^{ik} \sim \frac{ne^2\tau}{m^{\text{eff}}} \begin{pmatrix} * & \tau_0/\tau \\ \tau_0/\tau & (\tau_0/\tau)^2 \end{pmatrix}, \quad \tau_0/\tau \to 0, \tag{5}$$

where $*$ is some value of order of 1 (constant as $\tau_0/\tau \to 0$).

The asymptotic form of σ^{ik} makes possible the experimental observation of the mean direction of topologically regular open trajectories if the value τ/τ_0 is rather big.

Let us introduce here the ''topological numbers'' characterizing the regular open trajectories introduced first in Ref. 19 for the case of normal metals. We will give the topological definition of these numbers using the action of the ''quasiperiodic group'' on the quasiperiodic potentials. Let us assume for simplicity that the potential $V_B^{\text{eff}}(\mathbf{r})$ is generic and has irrationality 3. We assume that we have the ''topologically integrable'' situation where the topologically regular open trajectories exist in some finite energy interval $\epsilon_1(B) \leqslant c \leqslant \epsilon_2(B)$. According to Theorem 2 the values $\epsilon_1(B)$, $\epsilon_2(B)$ and the mean directions of open trajectories are the same for all the potentials constructed from our potential with the aid of the ''quasiperiodic group.'' It follows also from the topological picture that all the topologically regular trajectories are absolutely stable under the action of the ''quasiperiodic group'' (for the case of irrationality 3) and can just ''crawl'' in the plane for the continuous action of such transformations.

Let us make now the following transformation.

We take the first interference picture $((\boldsymbol{\eta}_1, a_1))$ and shift continuously the interference fringes in the direction of $X(\mathbf{r})$ (orthogonal to $\boldsymbol{\eta}_1$) to the distance a_1 keeping two other interference pictures unchanged. It is easy to see that we will have at the end the same potentials $V(x,y)$ and $V_B^{\text{eff}}(x,y)$ due to the periodicity of the first interference picture with period a_1. Let us fix now some energy level $c \in (\epsilon_1(B), \epsilon_2(B))$ and look at the evolution of nonsingular open trajectories [for $V_B^{\text{eff}}(x,y)$] while making our transformation. We know that we should have the parallel open trajectories in the plane at every time and the initial picture should coincide with the final picture according to the construction. The form of trajectories can change during the process but their mean direction will be the same according to Theorem 2.[64]

We can claim then that every open trajectory will be ''shifted'' to another open trajectory of the same picture by our continuous transformation. It is not difficult to prove that all the trajectories will then be shifted by the same number of positions n_1 (positive or negative) which depends on the potential $V_B^{\text{eff}}(x,y)$ (Fig. 10).

The number n_1 is always even since all the trajectories appear by pairs with the opposite drift directions.

Let us now do the same with the second and the third sets of the interference fringes and get an integer triple (n_1, n_2, n_3) which is a topological characteristic of potential $V_B^{\text{eff}}(x,y)$ (the ''positive'' direction of the numeration of trajectories should be the same for all these transformations).

The triple (n_1, n_2, n_3) (defined up to the common sign) can be represented as

$$(n_1, n_2, n_3) = M\,(m_1, m_2, m_3),$$

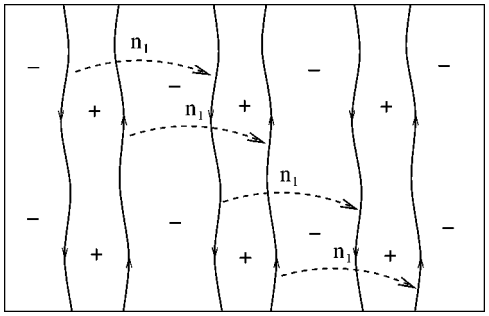

FIG. 10. The shift of "topologically regular" trajectories by a continuous transformation generated by the special path in the "quasiperiodic group."

where $M \in \mathbb{Z}$ and (m_1,m_2,m_3) is the indivisible integer triple. Both M and (m_1,m_2,m_3) have the topological meaning connected with the number of connected components carrying open trajectories in $\mathbb{R}^3$ and the homological class of every component in $\mathbb{T}^3=\mathbb{R}^3/L$ up to the sign.

Let us mention that for periodic potentials $V(x,y)$ made just by two interference pictures with common directions $\boldsymbol{\eta}_1$, $\boldsymbol{\eta}_2$ the corresponding transformations are actually equivalent to the shifts along the periods $\mathbf{u}_2$ and $\mathbf{u}_1$, respectively (Fig. 9). It is not difficult to see that the corresponding numbers (m_1,m_2) are equal then (up to the common sign) to $(-i_1,i_2)$ where (i_1,i_2) is the indivisible integer mean direction of periodic open trajectories in the lattice L' generated by vectors $\{\mathbf{u}_1,\mathbf{u}_2\}$. It is easy to see also that the vectors $\{X(\mathbf{r})/a_1, Y(\mathbf{r})/a_2\}$ give the dual basis to the basis $\{\mathbf{u}_2,\mathbf{u}_1\}$ and the mean direction of open orbits can be defined from the linear equation

$$m_1X(\mathbf{r})/a_1+m_2Y(\mathbf{r})/a_2=0$$

on the plane.

It can be proved that the similar situation also takes place for the topologically regular open trajectories in the case of quasiperiodic potentials $V(\mathbf{r})$. Let us omit here the detailed consideration of the topological picture and just say that the common direction of open trajectories in $\mathbb{R}^2$ is defined completely by the triple (m_1,m_2,m_3). Let us formulate here the corresponding statement:

Theorem 3: *Consider the functions*

$$X'(\mathbf{r})=X(\mathbf{r})/a_1\ ,\ \ Y'(\mathbf{r})=Y(\mathbf{r})/a_2\ ,\ \ Z'(\mathbf{r})=Z(\mathbf{r})/a_3,$$

in $\mathbb{R}^2$. *The mean direction of the regular open trajectories is given by the linear equation:*

$$m_1X'(x,y)+m_2Y'(x,y)+m_3Z'(x,y)=0 \tag{6}$$

where (m_1,m_2,m_3) *is the indivisible integer triple introduced above.*

The triples (m_1,m_2,m_3) coincide precisely with the "Topological Quantum Numbers" introduced in Ref. 19 for the conductivity in normal metals. Let us say that the condition (6) determines completely the numbers (m_1,m_2,m_3) (from the mean direction of open trajectories) for potentials of irrationality 3. This fact permits us to extract the values of (m_1,m_2,m_3) from the direct conductivity observations using the anisotropy of tensor $\sigma^{ik}(B)$. [The formula (6) is also true for the case of so-called "stable" open trajectories for potentials of irrationality 1 and 2 (see below). The triple (m_1,m_2,m_3) generally speaking may not be defined uniquely from the mean directions of open trajectories in these cases and the arguments based on quasiperiodic group play then the main role in the definition of (m_1,m_2,m_3). However, it can be measured from the direct conductivity observations also in these cases due to the stability of these numbers with respect to the small change of parameters $(\boldsymbol{\eta}_1,a_1)$, $(\boldsymbol{\eta}_2,a_2)$, $(\boldsymbol{\eta}_3,a_3)$.]

The very important property of the integer triples (m_1,m_2,m_3) is their stability with respect to the small variations of all the parameters $\boldsymbol{\eta}_1$, $\boldsymbol{\eta}_2$, $\boldsymbol{\eta}_3$, a_1, a_2, a_3, I_1, I_2, I_3 and even of the form of dependence $V(\mathbf{r})[I]$. This means that the space of parameters $(\boldsymbol{\eta}_1,\boldsymbol{\eta}_2,\boldsymbol{\eta}_3,a_1,a_2,a_3,I_1,I_2,I_3)$ where the situation $\epsilon_2(B)>\epsilon_1(B)$ for the energy interval containing the open trajectories takes place can be divided into different ''stability zones'' Γ_α where the relations (6) are valid for generic $V_B^{\mathrm{eff}}(\mathbf{r})$ with the same values of $(m_1^\alpha,m_2^\alpha,m_3^\alpha)$. Let us emphasize here that the mean directions of open trajectories are different for the different values of parameters even within the same stability zone Γ_α and the equation (6) gives the fixed relation of these directions with the directions and periods of the interference fringes for a given stability zone.

The zones Γ_α form an everywhere dense set in the total space of parameters and in general we can have an infinite number of zones parametrized by the numbers $(m_1^\alpha,m_2^\alpha,m_3^\alpha)$. The triples $(m_1^\alpha,m_2^\alpha,m_3^\alpha)$ form some subset of all possible integer triples (m_1,m_2,m_3) (defined up to the common sign) and give an important topological characteristic of the potentials $V_B^{\mathrm{eff}}(\mathbf{r})$ made by 3 interference pictures. The sizes of zones Γ_α decrease for the big numbers $(m_1^\alpha,m_2^\alpha,m_3^\alpha)$ and the total set $\{\cup\Gamma_\alpha\}$ give a rather complicated subset in the space of parameters $(\boldsymbol{\eta}_1,\boldsymbol{\eta}_2,\boldsymbol{\eta}_3,a_1,a_2,a_3,I_1,I_2,I_3)$. Let us say also that the topologically regular open trajectories are also stable with respect to any variation of potential $V_B^{\mathrm{eff}}(\mathbf{r})$ small enough which makes it possible to observe them also for slightly imperfect quasiperiodic potentials $V(\mathbf{r})$.

Before starting with special possibilities for the periodic (irrationality 1) or ''partly periodic'' (irrationality 2) potentials we will say here some words about the ''chaotic'' behavior of open trajectories possible in the case $\epsilon_1(B)=\epsilon_2(B)=\epsilon_0(B)$. Let us say that for $\epsilon_1(B)=\epsilon_2(B)$ both the situations of topologically regular and chaotic behavior of open trajectories are possible in the quasiperiodic case. The first situation always takes place when the corresponding set $(\boldsymbol{\eta}_1,\boldsymbol{\eta}_2,\boldsymbol{\eta}_3,a_1,a_2,a_3,I_1,I_2,I_3)$ belongs to the boundary of some stability zone Γ_α in the space of parameters. In this case all the nonsingular open trajectories are topologically regular and correspond to the same numbers $(m_1^\alpha,m_2^\alpha,m_3^\alpha)$. Another situation arises when the set $(\boldsymbol{\eta}_1,\boldsymbol{\eta}_2,\boldsymbol{\eta}_3,a_1,a_2,a_3,I_1,I_2,I_3)$ is an accumulation point for the zones Γ_α but does not belong to the boundary of any Γ_α. In this situation much more complicated chaotic behavior of open orbits appear at the energy level $V_B^{\mathrm{eff}}(\mathbf{r})=\epsilon_0(B)$. Obviously the ''chaotic'' behavior can be possible only for potentials of irrationality 2 or 3. Let us say also that the cases of irrationality 2 (Tsarev chaotic behavior) and 3 (Dynnikov chaotic behavior) demonstrate completely different types of chaotic behavior in this situation.

The first example of chaotic open trajectory was constructed by Tsarev[16,22] for the case of irrationality 2. The corresponding chaotic trajectory, however, has an asymptotic direction but cannot be bounded by any straight strip of the finite width in $\mathbb{R}^2$. As was later proved by Dynnikov,[22] this situation always takes place for chaotic trajectories in the case of irrationality 2. The asymptotic behavior of the conductivity tensor reveals also the strong anisotropy for large τ in this situation with slightly different from (5) dependence on τ for $\tau\to\infty$.

The more complicated chaotic trajectories were constructed by Dynnikov[22] for the case of irrationality 3 (the approximate form of such kinds of trajectories is shown in Fig. 3(b). The trajectories of this second kind do not have any asymptotic direction in $\mathbb{R}^2$ ''walking everywhere'' in the plane. The form of the conductivity tensor for this type of trajectory was suggested in Ref. 24 and is more complicated, then (5). We will not discuss here all the details and just say that the conductivity decreases in this case in all directions for $\tau\to\infty$ as some noninteger powers of τ.[65] Let us also add here that all the chaotic trajectories are completely unstable with respect to the small variations of parameters $(\boldsymbol{\eta}_1,\boldsymbol{\eta}_2,\boldsymbol{\eta}_3,a_1,a_2,a_3,I_1,I_2,I_3)$ (but remain chaotic with the ''same geometric properties'' under the action of the ''quasiperiodic group'').

Let us discuss also the B-dependence of tensor $\sigma^{ik}(B)$ for the limit $\tau\to\infty$. The value of B belongs here to some interval $B_1\leqslant B\leqslant B_2$ such that both the drifting orbits approximation and the condition $\tau/\tau_0\gg 1$ (as well the absence of quantum oscillations) are true. The effective potential $V_B^{\mathrm{eff}}(\mathbf{r})$ is a function of B in this case and the geometry of trajectories depends on B through the potential $V_B^{\mathrm{eff}}(\mathbf{r})$. Let us just say here that it can also be proved using topological considerations that the topologically regular open orbits are also ''locally stable'' with respect to the small

variations of B. However, for rather big changes of value of B it is possible to have ''jumps'' in this picture and get different mean directions of open trajectories (as well as the chaotic cases) in the different parts of the interval $[B_1,B_2]$. Let us add also that the structure of the B dependence can be rather complicated in this case containing the infinite number of small subintervals with very big numbers (m_1,m_2,m_3) as well as the chaotic cases.

Actually, all the theorems 1–3 can be reformulated in the same form if we add the parameter B to parameters $\boldsymbol{\eta}_1$, $\boldsymbol{\eta}_2$, $\boldsymbol{\eta}_3$, a_1, a_2, a_3, I_1, I_2, I_3 introduced above. The probability of ''jumps'' will then increase for the small stability zones Γ_α corresponding to big numbers (m_1,m_2,m_3) and the B-dependence of $\sigma^{ik}(B)$ will depend strongly on the part of the phase space. The chaotic trajectories will be completely unstable with respect to any small variations of B.

In the same way we can consider the ''stability zones'' $\Gamma_\alpha^{\text{ext}}$ in the extended space of parameters including the value of the magnetic field B. The total set $\{\cup\Gamma_\alpha^{\text{ext}}\}$ will have then the analogous structure containing in general the infinite number of zones $\Gamma_\alpha^{\text{ext}}$ and triples (m_1,m_2,m_3) being everywhere dense in the total set of parameters.

Let us formulate now the general conjecture of Novikov about the chaotic cases for potentials with 3 quasiperiods. In our situation we will assume that potentials are parametrized by parameters,

$$(\boldsymbol{\eta}_1,\boldsymbol{\eta}_2,\boldsymbol{\eta}_3,a_1,a_2,a_3,I_1,I_2,I_3)$$

or

$$(\boldsymbol{\eta}_1,\boldsymbol{\eta}_2,\boldsymbol{\eta}_3,a_1,a_2,a_3,I_1,I_2,I_3,B),$$

and maybe some additional parameters characterizing the functional $V(\mathbf{r})[I]$.

Novikov conjecture: The set of parameters corresponding to the chaotic behavior of open trajectories has measure zero in the total space of parameters.

Let us point out that the Novikov conjecture was strictly proved in the important case when only the quasiclassical trajectories belonging to some fixed energy level are taken into account.[22] This is precisely the situation arising in the conductivity in normal metals where only the trajectories close to the Fermi surface are important. The more general situation was also investigated numerically[29] for the case of the special analytic dispersion relations where the Novikov conjecture was also confirmed. However, the general proof of Novikov conjecture for an arbitrary set of parameters is still unknown.

We will point out now some additional possibilities which can arise in the nongeneric case of potentials of irrationality 1 or 2 (see Ref. 26 for detailed mathematical considerations).

Let us start with the case of irrationality 2 when only one period $\mathbf{l}$ (up to the integer multiplier) exists in $\mathbb{R}^2$. All the parts (1)–(4) of Theorem 2 are also true for potentials of irrationality 2. We need, however, to make one remark about the situation when the mean direction of the ''topologically regular'' open trajectories coincides with the period $\mathbf{l}$ of potential. Easy to see that the open trajectories are actually periodic in $\mathbb{R}^2$ in this case with the same period $\mathbf{l}$. In this situation some ''additional pairs'' of periodic open trajectories can arise and disappear under the action of the ''quasiperiodic group.'' These pairs arise from the periodic sets of closed trajectories under the changing of positions of interference fringes [with the same $(\boldsymbol{\eta}_1,\boldsymbol{\eta}_2,\boldsymbol{\eta}_3,a_1,a_2,a_3)$] and disappear in the same way (Fig. 11).

The trajectories of this kind are unstable with respect to the small variations of parameters $(\boldsymbol{\eta}_1,\boldsymbol{\eta}_2,\boldsymbol{\eta}_3,a_1,a_2,a_3)$ and will be destroyed after any small variation which does not conserve the period $\mathbf{l}$ of potential. These trajectories always present for all the potentials of irrationality 2 connected by the ''quasiperiodic group'' (on the same energy levels) if they exist at least for one of them. However, these trajectories can ''jump'' over the two-dimensional plane $\mathbb{R}^2$ disappearing in one place and arising in the other under the action of group transformations. We can call these trajectories ''partly stable'' (or also ''jumping'') in contrary to the absolutely stable (''crawling'')

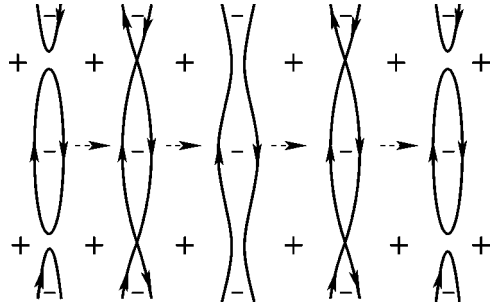

FIG. 11. The arising and the disappearance of the periodic trajectories under the action of the ''quasiperiodic group'' for potentials of irrationality 2 or 1.

trajectories described above. It can be proved also that the phase volume corresponding to both stable and ''jumping'' open trajectories is also the same for potentials connected by the quasiperiodic group in this situation.

The triple of the integer numbers (n_1,n_2,n_3) can be defined here in the same way as in the case of irrationality 3 but these additional pairs of trajectories should be completely ignored when the action of the ''quasiperiodic group'' is considered. The motion of stable open orbits (which always exist in this situation) gives then the same topological numbers M and (m_1,m_2,m_3) as for close generic potentials.

All the trajectories still have the same mean direction in this situation and the asymptotic form (5) for $\tau\to\infty$ is also true in this case. The formula (6) is also valid for the directions of open trajectories with the same (m_1,m_2,m_3). At the end we mention that the situation described above can arise only if the mean directions of stable open orbits coincide with the period $\mathbf{l}$ of potential $V_B^{\text{eff}}(\mathbf{r})$ and is absent if it is not so. As we already mentioned the chaotic behavior is also possible for potentials of irrationality 2 but it is always simpler than for the irrationality 3 potentials.

Let us now say some words about the purely periodic potentials (irrationality 1) which can also appear for special $(\boldsymbol{\eta}_1,\boldsymbol{\eta}_2,\boldsymbol{\eta}_3,a_1,a_2,a_3)$. As we already said all the open trajectories are purely periodic in this case and only a ''topologically integrable'' situation is possible. We also mentioned already that the extended trajectories can exist here either in the continuous energy interval $\epsilon_1(B)\leqslant c\leqslant\epsilon_2(B)$ or just at one energy level $c=\epsilon_0(B)$ (periodic singular nets). All the values $\epsilon_1(B)$, $\epsilon_2(B)$, $\epsilon_0(B)$, however, are not necessarily invariant here with respect to the ''quasiperiodic group'' action and can be different for different potentials connected by the ''quasiperiodic group'' transformations. Also the mean directions of open orbits can be different for two potentials belonging to the same orbit of the ''quasiperiodic group.''

We have then that unlike the cases of irrationality 3 or 2 the positions of interference minima and maxima can be important here for the conductivity behavior and the parameters $(\boldsymbol{\eta}_1,a_1)$, $(\boldsymbol{\eta}_2,a_2)$, $(\boldsymbol{\eta}_3,a_3)$ do not determine the picture completely. It can be proved, however, that the change of the mean directions of open orbits is possible only if the case of a ''periodic singular net'' takes place at least for one (actually at least for two) potential belonging to the same orbit of the ''quasiperiodic group.'' We can assume then that this situation takes place only if the periodic potential is prepared specially to have this property and it does not take place for potentials with rather big periods $\mathbf{l}_1$, $\mathbf{l}_2$ appearing ''by chance'' in the modulation picture. Thus we can assume that the periodic potentials with rather big $\mathbf{l}_1$, $\mathbf{l}_2$ arising ''by chance'' can be considered actually as the generic potentials on the physical level of strictness and do not give any special features.

V. NOVIKOV PROBLEM FOR THE CASE OF POTENTIALS WITH 4 QUASIPERIODS

Let us consider now a more complicated case when $N=4$ and we have the potential made by 4 independent interference pictures (Fig. 12).

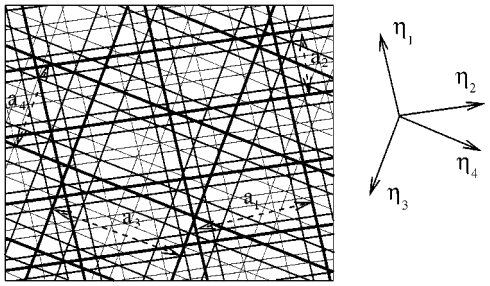

FIG. 12. The potential with 4 quasiperiods made by 4 independent sets of interference fringes with directions $\boldsymbol{\eta}_1$, $\boldsymbol{\eta}_2$, $\boldsymbol{\eta}_3$, $\boldsymbol{\eta}_4$ and periods a_1, a_2, a_3, a_4.

The situation in this case is more complicated than in the case $N=3$ and no general classification of open trajectories exists at the time. We will present here the theorem of Novikov[27] which gives the statement analogous to the Zorich theorem (Theorem 1) in this situation.

Like in the previous case we define here the embedding of the plane $\mathbb{R}^2$ in the four-dimensional space $\mathbb{R}^4$ using the functions $X(\mathbf{r})$, $Y(\mathbf{r})$, $Z(\mathbf{r})$, $W(\mathbf{r})$ defined in the same way for four interference pictures. We will need also the functions $X'(\mathbf{r})$, $Y'(\mathbf{r})$, $Z'(\mathbf{r})$, $W'(\mathbf{r})$ defined as

$$X'(\mathbf{r})=X(\mathbf{r})/a_1\ ,\ Y'(\mathbf{r})=Y(\mathbf{r})/a_2\ ,$$

$$Z'(\mathbf{r})=Z(\mathbf{r})/a_3\ ,\ W'(\mathbf{r})=W(\mathbf{r})/a_4$$

(in the same way as previously for the case $N=3$).

The "total intensity function" $\hat{I}(\mathbf{R})$, $\mathbf{R}\in\mathbb{R}^4$ is defined here as

$$\hat{I}(\mathbf{R})=I_1(X)+I_2(Y)+I_3(Z)+I_4(W),$$

and is a periodic function with periods $(a_1,0,0,0)$, $(0,a_2,0,0)$, $(0,0,a_3,0)$, $(0,0,0,a_4)$ in $\mathbb{R}^4$. The "big potentials" $\hat{V}(\mathbf{R})$ and $\hat{V}_B^{\mathrm{eff}}(\mathbf{R})$ are also defined for every point $\mathbf{R}\in\mathbb{R}^4$ through the functional $V(\mathbf{R})[I]$ and the averaging over the cyclotron orbits in the plane $\Pi^{2\prime}\in\mathbb{R}^4$ passing through the point $\mathbf{R}$ and parallel to the initial plane Π^2. It is easy to see again that the functions $\hat{V}(\mathbf{R})$, $\hat{V}_B^{\mathrm{eff}}(\mathbf{R})$ are the smooth 4-periodic functions in $\mathbb{R}^4$ and the potentials $V(\mathbf{r})$, $V_B^{\mathrm{eff}}(\mathbf{r})$ are the restrictions of $\hat{V}(\mathbf{R})$ and $\hat{V}_B^{\mathrm{eff}}(\mathbf{R})$ on the plane Π^2 embedded in $\mathbb{R}^4$. We can define again the action of the "quasiperiodic group" on the potentials $V(\mathbf{r})$, $V_B^{\mathrm{eff}}(\mathbf{r})$ which is now isomorphic to the four-dimensional torus $\mathbb{T}^4=\mathbb{R}^4/L$, where L is an integer lattice generated by vectors $(a_1,0,0,0)$, $(0,a_2,0,0)$, $(0,0,a_3,0)$, $(0,0,0,a_4)$. Let us mention also that the action of this group can be defined here in the same way as the shifts of positions of minima and maxima of the interference fringes keeping the same the directions $\boldsymbol{\eta}_1$, $\boldsymbol{\eta}_2$, $\boldsymbol{\eta}_3$, $\boldsymbol{\eta}_4$ and periods a_1, a_2, a_3, a_4.

Again the statement that the open trajectories always exist either on the connected energy interval $\epsilon_1(B)\leqslant c\leqslant\epsilon_2(B)$ or just at one energy level $\epsilon_0(B)$ for any $V_B^{\mathrm{eff}}(\mathbf{r})$ is true for the case of 4 quasiperiods. It can be also proved that the values of $\epsilon_1(B)$, $\epsilon_2(B)$ or $\epsilon_0(B)$ are the same for generic potentials belonging to the same orbit of the "quasiperiodic group." Moreover, the global behavior of open trajectories is also the same in this case for all such potentials and the asymptotic behavior of conductivity (which is *a priori* unknown here for the general case) does not depend on the positions of maxima and minima for the fixed generic $(\boldsymbol{\eta}_1,a_1)$, $(\boldsymbol{\eta}_2,a_2)$, $(\boldsymbol{\eta}_3,a_3)$, $(\boldsymbol{\eta}_4,a_4)$. These properties, however, can be destroyed for the specially made periodic potentials $V(\mathbf{r})$ like in the case of 3 quasiperiods.

Let us consider now the purely periodic potential $V(\mathbf{r})$ formed now by four interference pictures. We assume again that at least two (say $\boldsymbol{\eta}_1$, $\boldsymbol{\eta}_2$) directions of interference fringes are not parallel to each other and give a double-periodic picture in the plane like in the case of potentials with 3 quasiperiods. Let us introduce the angles $(\theta_{12},\ \theta_{13},\ \theta_{14})$ between the directions $\boldsymbol{\eta}_1$ and $\boldsymbol{\eta}_2$,

$\boldsymbol{\eta}_3$, $\boldsymbol{\eta}_4$ in the same way as in the case of three interference pictures. From the requirement of periodicity we then will have the same requirements (3)–(4) for the angles θ_{13}, θ_{14} and the periods a_3, a_4 with some integer numbers m_1', m_2', k_1', k_2', k_3' (for θ_{13} and a_3) and m_1'', m_2'', k_1'', k_2'', k_3'' (for θ_{14} and a_4). It is easy to prove that these conditions are also sufficient for the periodicity of the resulting potential $V(\mathbf{r})$.

The theorem of Novikov permits us to formulate here the following property of the potentials $V_B^{\text{eff}}(\mathbf{r})$ close enough to purely periodic potentials:

Theorem 4: *Consider the purely periodic potential* $V_B^{(0)\text{eff}}(\mathbf{r})$ *built by four interference pictures with the directions and periods* $(\boldsymbol{\eta}_1^{(0)}, a_1^{(0)})$, $(\boldsymbol{\eta}_2^{(0)}, a_2^{(0)})$, $(\boldsymbol{\eta}_3^{(0)}, a_3^{(0)})$, $(\boldsymbol{\eta}_4^{(0)}, a_4^{(0)})$. *Then there exists such small region* Γ *of parameters* $\boldsymbol{\eta}_1$, $\boldsymbol{\eta}_2$, $\boldsymbol{\eta}_3$, $\boldsymbol{\eta}_4$, a_1, a_2, a_3, a_4, I_1, I_2, I_3, I_4 *containing the initial potential* $V_B^{(0)\text{eff}}(\mathbf{r})$ *that for all the generic potentials* $V_B^{\text{eff}}(\mathbf{r})$ *corresponding to the point of* Γ *the following statements are true.*

(1) All the nonsingular open trajectories lie in the straight strips of finite width and pass through them.

(2) All the regular trajectories have the mean direction in $\mathbb{R}^2$ *given by the equation*

$$m_1 X'(\mathbf{r}) + m_2 Y'(\mathbf{r}) + m_3 Z'(\mathbf{r}) + m_4 W'(\mathbf{r}) = 0,$$

with some integer (indivisible) 4-tuple (m_1, m_2, m_3, m_4) *which is the same for all the (generic) points of "stability zone"* Γ.

(3) The mean direction of open trajectories are the same for generic potentials belonging to the same orbit of the "quasiperiodic group."

Using Novikov theorem it is possible to prove also that the 4-tuples (m_1, m_2, m_3, m_4) can be also defined through the action of the "quasiperiodic group" in the same way as in the case of 3 quasiperiods.

The asymptotic behavior of conductivity tensor σ^{ik} is also the same in this case by the same reasons and the mean directions of the open trajectories [and the integer 4-tuples (m_1, m_2, m_3, m_4)] can be measured experimentally.

According to Novikov theorem the regions with "topologically regular" behavior can be found in any (arbitrarily small) open region of parameters $\boldsymbol{\eta}_1$, $\boldsymbol{\eta}_2$, $\boldsymbol{\eta}_3$, $\boldsymbol{\eta}_4$, a_1, a_2, a_3, a_4, I_1, I_2, I_3, I_4 and B. However, unlike the case $N=3$ there is no theorem here restricting the existence of "chaotic" trajectories only to the case of just one energy level ($\epsilon_1 = \epsilon_2 = \epsilon_0$) containing open trajectories. As we mentioned already, the case $N=4$ is much more complicated from topological point of view and there is no general classification of open trajectories in this case at the time. It is not clear also if the topologically regular behavior corresponds here to the generic situation or not and the probability to find the chaotic behavior is unknown for this situation.

Let us now make some more general remark about the Novikov problem in connection with 2-D potentials $V(\mathbf{r})$. As can be seen, the potentials $V(\mathbf{r})$ with rather many quasiperiods can be considered also as an interesting model of random potentials on the plane. This model is rather different from the standard models of random potentials but still can have common features with them for big N when the chaotic behavior of the open trajectories appears. However, there is no strict theorems now which could connect Novikov problem with the problems of random potentials on the plane.

VI. CONCLUSION

We considered the special type of superlattices modulations giving the quasiperiodic potentials $V(\mathbf{r})$ and $V_B^{\text{eff}}(\mathbf{r})$ on the plane. For this type of potentials we considered the "geometric limit" ($\tau \to \infty$) of conductivity in the presence of a magnetic field based on the global geometry of the level curves of $V_B^{\text{eff}}(\mathbf{r})$. The main attention was paid to the so-called "topologically regular" behavior of nonsingular open level curves for the cases of potentials with 3 and 4 quasiperiods. It was shown that it is possible to introduce the "topological numbers" characterizing the asymptotic

behavior of σ^{ik} similar to the numbers introduced previously in the theory of normal metals. For the case of 3 quasiperiods it was possible to give also the description of the structure of the space of parameters giving potentials $V_B^{\text{eff}}(\mathbf{r})$ according to the topological type of their nonsingular open level curves. For the case of 4 quasiperiods only the part of the space of parameters corresponding to potentials close to ''purely rational'' was considered. It was shown that the corresponding ''topological numbers'' having the form of the integer of 4-tuples can be also introduced in this case.

ACKNOWLEDGMENTS

The author is grateful to Professor S. P. Novikov for many fruitful discussions on this problem. The author is also grateful to Professor I. A. Larkin, who brought the articles on 2-D electron gas to his attention for the interest to this work and advice. [62] Let us use here the word ''orbit'' for the circular cyclotron electron orbit in the magnetic field **B** and ''trajectory'' for the drift of the center of cyclotron orbit in the presence of $V(\mathbf{r})$. We hope that there should be no misunderstanding because of two similar terms.
[63] We are sorry for a little bit unnatural definitions of irrationality. Here we follow the standard definitions arising from the 3-D topology approach.
[64] The last property was first mentioned in Ref. 19 in the case of normal metals and called later the ''Topological Resonance.'' This property plays the important role for the conductivity of normal metals making possible the experimental observation of ''Topological Numbers'' for this case.
[65] The consideration in Ref. 24 is based on the purely geometrical aspects and does not include the quantum corrections due to the jumps from one part of trajectory to another. It can be shown, however, that for chaotic trajectories of the Dynnikov type these jumps should be also important for rather big values of τ. It is possible to show also that the power dependence on τ should then change to rapid exponential decreasing of σ when $\tau \to \infty$ after some characteristic (rather big) value of τ due to these quantum corrections.

(Received 23 July 2003; accepted 30 October 2003)

Representations of $SU_q(2)$ are labeled by a phase playing the role of a Casimir operator. The coproduct $SU_q(2)$ is used to form direct product representations which can be reduced to irreducible ones. Direct product of two representations with given phases can be reduced to a representation with any given phase. Coefficients necessary for this procedure are calculated. The calculation can also be performed in the Fourier transformed space which replaces the phase by an integer. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1644753]

q-deformations of Lie groups and Lie algebras[1–4] have attracted a lot of attention in recent years and have been intensively studied. These deformations are endowed with a Hopf algebra structure and the coproduct of the Hopf algebra makes the construction of tensor products of representations possible. For the special case of (nondeformed) SU(2) Lie algebra, this procedure is very well known in physics and is called the addition of angular momentum. For q-deformed Lie algebras, this procedure is well investigated and q-Clebsch–Gordan coefficients[5] have been computed. For q-deformed matrix Lie groups, however, this procedure exhibits some new methods and ideas. The irreducible $*$-representations of continuous functions $C(SU_q(2))$ on the quantum group $SU_q(2)$ were classified in the late 1980s and it was found that $C(SU_q(2))$ has two distinct families of irreducible representations, one of which is one dimensional and the other is infinite dimensional.[6,7] The tensor products of the irreducible representation of the algebra of $C(SU_q(2))$ on the quantum group $SU_q(2)$ were studied by Lesniewski and Rinaldi.[8] They proved by using a number of combinatorial identities of q-calculus that the tensor product of two infinite dimensional irreducible representations is equivalent to a direct integral of infinite dimensional irreducible representations. On the other hand, Van der Jeugt[9,10] developed the representation theory for the Jordanian quantum algebra $U_h(sl(2))$ and gave the closed form expressions for the action of the generators of $U_h(sl(2))$ on the basis vectors of finite-dimensional irreducible representations. He also obtained a general formula for the Clebsch–Gordan coefficients.

In this paper, we investigate the decomposition of the tensor product of two irreducible representations of $C(SU_q(2))$ algebra generated by the elements belonging to a 2×2 $SU_q(2)$ quantum matrix group by using the Hopf algebra coproduct and the Fourier transformed space. As has been shown by Vaksman and Soibelman,[7] the representation space has a basis $|n,\alpha\rangle$ when $n \in \mathbb{N}$ is discrete and $\alpha \in [0,2\pi)=S^1$. If the tensor product of representations after reduction is taken, then it is found that

$$|n,\alpha\rangle=\sum_{n_1,n_2} C(n,\alpha|n_1,\alpha_1,n_2,\alpha_2)\ |n_1,\alpha_1\rangle\otimes|n_2,\alpha_2\rangle.$$

Our approach is the same as that of Lesniewski and Rinaldi except that the dependence on α, α_1, and α_2 is handled more carefully. Note that there is no integration over α_1 and/or α_2 in the

formula above since the parameter α denotes the eigenvalue of a central operator and is analogous to the total angular momentum quantum number j of the Lie algebra SU(2) for which the analog formula is given by

$$|j,m\rangle=\sum_{m_1+m_2=m} C(j,m|j_1,m_1,j_2,m_2)|j_1,m_1\rangle\otimes|j_2,m_2\rangle,$$

where m is the magnetic quantum number and

$$j=|j_1-j_2|,|j_1-j_2|+1,\ldots,j_1+j_2.$$

It should be pointed out that for the quantum group $SU_q(2)$ there is no constraint on the summation over n_1 and n_2. It will be shown that all possible values of n_1 and n_2 contribute to a given value of n. A similar remark is also valid for α_1, α_2, and α.

The well-known $SU_q(2)$ quantum matrix group is composed of the matrices[4]

$$U=\begin{pmatrix} a & -qb \\ b^* & a^* \end{pmatrix}.$$

Let A be the Hopf algebra over the complex numbers generated by the elements a, a^*, b, and b^*, satisfying the Hermiticity conditions $(a^*)^*=a$, $(b^*)^*=b$ and the commutation relations

$$aa^*+q^2bb^*=1,$$

$$a^*a+b^*b=1,$$

$$ab=qba,$$

$$ab^*=qb^*a,$$

$$bb^*=b^*b. \tag{1}$$

The coproduct $\Delta:A\mapsto A\otimes A$, the antipode $S:A\mapsto A$ and the co-unit $\varepsilon:A\mapsto\mathbb{C}$ are defined by

$$\Delta(a)=a\otimes a-qb\otimes b^*,\ \ \varepsilon(a)=1,\ \ S(a)=a^*,$$

$$\Delta(b)=a\otimes b+b\otimes a^*,\ \ \varepsilon(b)=0,\ \ S(b)=-q^{-1}b,$$

$$\Delta(a^*)=(\Delta(a))^*,\quad \varepsilon(a^*)=1,\ \ S(a^*)=a,$$

$$\Delta(b^*)=(\Delta(b))^*,\quad \varepsilon(b^*)=0,\ \ S(b^*)=-q(b^*). \tag{2}$$

It can easily be seen that the defining commutation relations in (1) of the algebra A are invariant under $b\leftrightarrow b^*$. Therefore, it turns out to be that under $b\leftrightarrow b^*$ there exists a related second coproduct with

$$\Delta(a)=a\otimes a-qb^*\otimes b,$$

$$\Delta(b^*)=a\otimes b^*+b^*\otimes a^*,$$

$$\Delta(a^*)=(\Delta(a))^*,$$

$$\Delta(b)=(\Delta(b^*))^*. \tag{3}$$

Then one should look for a representation of the Hopf algebra A on a Hilbert space such that b is invertible. If b is not invertible, then its zero eigenvalue subspace is a trivial irreducible

representation where $b=0$ and a is any unitary operator. If b is invertible, then a^*a and the phase of b form a commuting set. It should be noted that a^* and a act as creation and annihilation operators, respectively. In other words, the actions of a, a^*, b, and b^* on $|n,\alpha\rangle$ are

$$a|n,\alpha\rangle=(1-q^{2n})^{1/2}|n-1,\alpha\rangle,$$

$$a^*|n,\alpha\rangle=(1-q^{2n+2})^{1/2}|n+1,\alpha\rangle,$$

$$b|n,\alpha\rangle=q^n e^{i\alpha}|n,\alpha\rangle,$$

$$b^*|n,\alpha\rangle=q^n e^{-i\alpha}|n,\alpha\rangle, \tag{4}$$

where $\alpha,\beta\in[0,2\pi)$ and the normalization is chosen $\langle n,\alpha|m,\beta\rangle=\delta_{nm}\delta(\alpha-\beta)$. For a fixed α, we denote the Hilbert space spanned by $|n,\alpha\rangle$ by H_α. H_α having different values of α are orthogonal.

The coproduct given by (2) is an homomorphism from the Hopf algebra A into $A\otimes A$ and hence it can be used to find a representation of A in $H_{\alpha_1}\otimes H_{\alpha_2}$.

Proposition 1: If $|0,\alpha;\alpha_1,\alpha_2\rangle\in H_{\alpha_1}\otimes H_{\alpha_2}$ is defined such that

$$\Delta(a)|0,\alpha;\alpha_1,\alpha_2\rangle=0,$$

$$\Delta(b)|0,\alpha;\alpha_1,\alpha_2\rangle=e^{i\alpha}\ |0,\alpha;\alpha_1,\alpha_2\rangle, \tag{5}$$

then

$$|0,\alpha;\alpha_1,\alpha_2\rangle=\sum_{n,m=0}^{\infty}\frac{q^{nm}}{\sqrt{f_n(q^2)}\ \sqrt{f_m(q^2)}}e^{i(m\alpha_1-n\alpha_2)}e^{i(n-m)\alpha}|n,\alpha_1\rangle\otimes|m,\alpha_2\rangle, \tag{6}$$

where

$$|n,\alpha\rangle\equiv\frac{(a^*)^n}{\sqrt{f_n(q^2)}}\ |0,\alpha\rangle \tag{7}$$

with

$$f_n(q^2)=(1-q^2)\cdots(1-q^{2n}). \tag{8}$$

Proof 1: Let $|0,\alpha;\alpha_1,\alpha_2\rangle=\Sigma_{n,m=0}^{\infty}C_{n,m}\ |n,\alpha_1\rangle\otimes|m,\alpha_2\rangle$, where $C_{n,m}$ are the coefficients to be determined so that the relations in (5) hold.

If the Hopf algebra coproduct relations given by (2) are taken into consideration together with (5), then one gets the following recursion relations for $C_{n,m}$:

$$C_{n+1,m+1}=\frac{q^{n+m+1}}{\sqrt{1-q^{2(n+1)}}\ \sqrt{1-q^{2(m+1)}}}e^{i(\alpha_1-\alpha_2)}C_{n,m},$$

$$C_{n,m}=q^m\ \sqrt{1-q^{2(n+1)}}\ e^{i(\alpha_2-\alpha)}\ C_{n+1,m}+q^n\ \sqrt{1-q^{2m}}\ e^{i(\alpha_1-\alpha)}C_{n,m-1}. \tag{9}$$

The recursion relations above for $C_{n,m}$ have the unique solution

$$C_{n,m}=\frac{q^{nm}}{\sqrt{f_n(q^2)}\ \sqrt{f_m(q^2)}}e^{i(m\alpha_1-n\alpha_2)}e^{i(n-m)\alpha} \tag{10}$$

for $C_{0,0}=1$. This can easily be verified by putting

$$C_{n,m}=\frac{q^{nm}}{\sqrt{f_n(q^2)}\ \sqrt{f_m(q^2)}}\ e^{in(\alpha-\alpha_2)}\ e^{im(\alpha_1-\alpha)}\ B_{n,m}$$

into (9) which leads to $B_{n,m}$ being independent of n and m.

It should be pointed out that $|n,\alpha;\alpha_1,\alpha_2\rangle$ can be computed as

$$|n,\alpha;\alpha_1,\alpha_2\rangle=\frac{(\Delta(a^*))^n}{\sqrt{f_n(q^2)}}|0,\alpha;\alpha_1,\alpha_2\rangle \tag{11}$$

satisfying

$$\Delta(a)|n,\alpha;\alpha_1,\alpha_2\rangle=\sqrt{1-q^{2n}}|n-1,\alpha;\alpha_1,\alpha_2\rangle,$$

$$\Delta(a^*)|n,\alpha;\alpha_1,\alpha_2\rangle=\sqrt{1-q^{2(n+1)}}|n+1,\alpha;\alpha_1,\alpha_2\rangle,$$

$$\Delta(b)|n,\alpha;\alpha_1,\alpha_2\rangle=q^n e^{i\alpha}|n,\alpha;\alpha_1,\alpha_2\rangle,$$

$$\Delta(b^*)|n,\alpha;\alpha_1,\alpha_2\rangle=q^n e^{-i\alpha}|n,\alpha;\alpha_1,\alpha_2\rangle. \tag{12}$$

It is important to note that the recursion relations in (9) where the coefficients $C_{n,m}$ are given by (10) have the appearance of Fourier series in α_1 and α_2. In the Lesniewski and Rinaldi approach, α_1 and α_2 are taken to be zero. Our approach suggests that the construction being made can also be performed in the Fourier dual space where instead of a phase $0\leqslant\alpha<2\pi$, one can use an integer $k\in\mathbb{Z}$ such that

$$|n,\alpha\rangle=\sum_{k=-\infty}^{\infty} e^{ik\alpha}|n,k\rangle, \tag{13}$$

where the inverse of (13) reads

$$|n,k\rangle=\frac{1}{2\pi}\int_0^{2\pi}|n,\alpha\rangle\ \ e^{-ik\alpha}\ \ d\alpha \tag{14}$$

and $\langle n_1,k_1|n_2,k_2\rangle=\delta_{n_1n_2}\ \delta_{k_1k_2}$.

The actions of a, a^*, b, and b^* on $|n,k\rangle$ are

$$a|n,k\rangle=\sqrt{1-q^{2n}}|n-1,k\rangle,$$

$$a^*|n,k\rangle=\sqrt{1-q^{2n+2}}|n+1,k\rangle,$$

$$b|n,k\rangle=q^n|n,k-1\rangle,$$

$$b^*|n,k\rangle=q^n|n,k+1\rangle, \tag{15}$$

where $n\in\mathbb{N}$ and $k\in\mathbb{Z}$.

Proposition 2: If the analog of (5) in the Fourier dual space H_k of H_α is given by

$$\Delta(a)|0,k;k_1,k_2\rangle=0,$$

$$\Delta(b)|0,k;k_1,k_2\rangle=|0,k-1;k_1,k_2\rangle, \tag{16}$$

then

$$|0,k;k_1,k_2\rangle=\begin{cases}\displaystyle\sum_{n=0}^{\infty}\frac{q^{n(n+k)}}{\sqrt{f_n(q^2)f_{n+k}(q^2)}} & \\ \quad\cdot|n+k,k_1-n\rangle\otimes|n,k_2+k+n\rangle \quad \text{if } k\geqslant 0 & \\ \displaystyle\sum_{n=0}^{\infty}\frac{q^{n(n-k)}}{\sqrt{f_n(q^2)f_{n-k}(q^2)}} & \\ \quad\cdot|n,k_1+k-n\rangle\otimes|n-k,k_2+n\rangle \quad \text{if } k\leqslant 0 & \end{cases} \tag{17}$$

where $|n,k\rangle$ is given by (14) and $f_n(q^2)$ is defined by (8).

Proof 2: Let $|0,k;k_1,k_2\rangle=\Sigma_{n_1,n_2}C^k_{n_1,k_1,n_2,k_2}|n_1,k_1\rangle\otimes|n_2,k_2\rangle$, where $C^k_{n_1,k_1,n_2,k_2}$ are the coefficients to be determined so that the relations in (16) hold. Then, the following recursion relations are found:

$$C^{k-1}_{n_1,k_1,n_2,k_2}=C^k_{n_1+1,k_1,n_2,k_2+1}q^{n_2}\sqrt{1-q^{2(n_1+1)}}+C^k_{n_1,k_1+1,n_2-1,k_2}q^{n_1}\sqrt{1-q^{2n_2}},$$

$$C^k_{n_1,k_1+1,n_2,k_2-1}=\frac{\sqrt{1-q^{2n_1+2}}\ \sqrt{1-q^{2n_2+2}}}{q^{n_1+n_2+1}}C^k_{n_1+1,k_1,n_2+1,k_2}. \tag{18}$$

Even though these recursion relations are rather difficult to handle, their solution can be found by considering the Fourier transform of (6). The analog of (13) for $|0,\alpha;\alpha_1,\alpha_2\rangle$ is

$$|0,\alpha;\alpha_1,\alpha_2\rangle=\sum_{k,k_1,k_2=-\infty}^{\infty}e^{ik\alpha}e^{ik_1\alpha_1}e^{ik_2\alpha_2}|0,k;k_1,k_2\rangle, \tag{19}$$

where $|0,k;k_1,k_2\rangle$ is given by (18).

Inverting (20) and then using (6) together with (13), one obtains

$$|0,k;k_1,k_2\rangle=\frac{1}{(2\pi)^3}\int_0^{2\pi}\int_0^{2\pi}\int_0^{2\pi}\sum_{n,m=0}^{\infty}\sum_{k_1',k_2'=-\infty}^{\infty}\frac{q^{nm}}{\sqrt{f_n(q^2)}\ \sqrt{f_m(q^2)}}$$
$$\cdot e^{i(m-k_1+k_1')\alpha_1}\ e^{-i(n+k_2-k_2')\alpha_2}\ e^{i(n-m-k)\alpha}\cdot|n,k_1'\rangle\otimes|m,k_2'\rangle\ d\alpha\ d\alpha_1\ d\alpha_2.$$

Considering whether $k\geqslant 0$ or $k\leqslant 0$, $n=m+k$ or $m=n-k$ is chosen, respectively, and hence $|0,k;k_1,k_2\rangle$ is calculated to be the required solution given by (17).

Then $|n,k;k_1,k_2\rangle$ can be computed from $|0,k;k_1,k_2\rangle$ given by (17) by applying $\Delta(a^*)$ n-times; that is

$$|n,k;k_1,k_2\rangle=\frac{(\Delta(a^*))^n}{\sqrt{f_n(q^2)}}|0,k;k_1,k_2\rangle. \tag{20}$$

The algebra defined by (1) for invertible b contains a central element $b^{-1}b^*$ which is represented by $e^{-i\alpha}$. Omitting this element from the algebra yields another consistent algebra whose defining relations are again (1) with one additional equation $b=b^*$. However, this truncated algebra is not endowed with a Hopf algebra structure and thus can not be considered to be a quantum group. Although the representation of this truncated algebra is essentially the same and given by (4) with $\alpha=0$, direct products are not amenable to reduction as there is no coproduct. Hence formulas such as (6) and (17) are direct consequences of the quantum group structure.

The methods of this paper can readily be extended to representations of more general quantum groups. One important point in this regard is the correct handling of the central elements of the algebra. Although these central elements are represented by real or complex numbers in the

representation, their nontrivial coproduct gives a highly nontrivial contribution to the decomposition of the tensor product of two irreducible representations of the quantum group.

(Received 8 April 2003; accepted 2 December 2003)

We prove that the extended Poincaré group in $(1+1)$ dimensions $\overline{\mathcal{P}}$ is nonnilpotent solvable exponential, and therefore that it belongs to type I. We determine its first and second cohomology groups in order to work out a classification of the two-dimensional relativistic elementary systems. Moreover, all irreducible unitary representations of $\overline{\mathcal{P}}$ are constructed by the orbit method. The most physically interesting class of irreducible representations corresponds to the anomaly-free relativistic particle in $(1+1)$ dimensions, which cannot be fully quantized. However, we show that the corresponding coadjoint orbit of $\overline{\mathcal{P}}$ determines a covariant maximal polynomial quantization by unbounded operators, which is enough to ensure that the associated quantum dynamical problem can be consistently solved, thus providing a physical interpretation for this particular class of representations. © *2004 American Institute of Physics.*

I. INTRODUCTION

Much of the interest in the extended Poincaré group in $(1+1)$ dimensions $\overline{\mathcal{P}}$ stems from the fact that the Callan–Giddings–Harvey–Strominger (CGHS) model of two-dimensional dilatonic gravity[1] may be formulated as a gauge theory[2] of $\overline{\mathcal{P}}$. The ''string-inspired'' CGHS theory is particularly interesting because it generates an exactly solvable model of quantum gravity, which allows the investigation of several aspects of quantum black hole physics.[3,4] An outstanding problem in this context is the coupling of matter sources in an extended Poincaré gauge-invariant fashion.[5–7]

The main purpose of this paper is to prove that $\overline{\mathcal{P}}$ is solvable exponential, so that the Bernat–Pukanszky theory of exponential groups[8,9] can be strictly applied to work out all its unitary irreducible representations (irrep's). Some of these irrep's were presented in Gadella *et al.*[10] but, although it was mentioned[11] that these irrep's were calculated by the Mackey theory and the orbit method, it was not shown that $\overline{\mathcal{P}}$ has a regular semidirect product structure, nor that $\overline{\mathcal{P}}$ is solvable exponential. These authors adopt the same point of view as that of Cariñena *et al.*,[12] which should be contrasted with ours.

Our approach to the two-dimensional relativistic elementary systems is similar to that which was adopted by Azcárraga and Izquierdo[13] with respect to a nonrelativistic particle of unit charge in a constant magnetic field. Indeed, we show in this paper that the coadjoint orbit corresponding to the anomaly-free relativistic particle in $(1+1)$ dimensions determines a covariant maximal polynomial quantization for it, which provides a physical interpretation for the associated class of irrep's of $\overline{\mathcal{P}}$.

This paper is organized as follows. In Sec. II, we show that $\overline{\mathcal{P}}$ is solvable exponential and calculate its first and second cohomology groups. In Sec. III, we determine the coadjoint orbits of

[a]Electronic mail: ricardo@fma.if.usp.br
[b]Electronic mail: rivelles@fma.if.usp.br

$\bar{\mathcal{P}}$ in order to classify the two-dimensional relativistic elementary systems and to work out explicitly all the irrep's of $\bar{\mathcal{P}}$. In Sec. IV, we provide a physical interpretation for a particular class of irrep's of $\bar{\mathcal{P}}$ through a covariant maximal polynomial quantization of the anomaly-free relativistic particle in $(1+1)$ dimensions. Finally, in Sec. V we draw our conclusions and discuss further possible developments. We sketch the method of orbits in the Appendix, in order to provide some supplementary material for the understanding of Sec. III.

II. THE EXTENDED POINCARÉ GROUP IN (1+1) DIMENSIONS $\bar{\mathcal{P}}$

The extended Poincaré algebra $\bar{\mathfrak{i}}_2^1$ is defined by means of an unconventional contraction of a pseudoextension[13] of the anti–de Sitter algebra so(2,1) as

$$[P_a,J]=\sqrt{-h}\varepsilon_a{}^b P_b, \quad [P_a,P_b]=B\varepsilon_{ab}I, \quad \text{and} \quad [P_a,I]=[J,I]=0, \tag{1}$$

where $a,b\in\{0,1\}$, $\varepsilon^{01}=-\varepsilon_{01}=1$, and the indices a and b are raised and lowered by the metric $h_{ab}=\mathrm{diag}(1,-1)$ with $h:=\det h_{ab}=-1$. Throughout this paper, we shall adopt units where $c=1$. The generators of translations are $P_a:=\bar{T}_a$, and their dimensions are L^{-1}. The generator of Lorentz transformations is $J:=\bar{T}_2$, which is dimensionless. The central generator, the dimension of which is $[\hbar]^{-1}$, is $I:=\bar{T}_3$, and the central charge has dimension $[B]=L^{-2}\times[\hbar]$.

The group law $g''(\theta''^a,\alpha'',\beta'')=g'(\theta'^a,\alpha',\beta')g(\theta^a,\alpha,\beta)$ determined by Eq. (1) is given by

$$\theta''^b=\theta'^b+\Lambda(\alpha')^b{}_a\theta^a, \quad \alpha''=\alpha'+\alpha, \quad \text{and} \quad \beta''=\beta'+\beta+\frac{B}{2}\theta'^c\varepsilon_{cb}\Lambda(\alpha')^b{}_a\theta^a, \tag{2}$$

where $\Lambda(\alpha)^a{}_b=\delta^a{}_b\cosh\alpha+\sqrt{-h}\varepsilon^a{}_b\sinh\alpha$, and it corresponds to the coset decomposition $g(\theta^a,\alpha,\beta)=\exp(\theta^a P_a)\exp(\alpha J)\exp(\beta I)$. The adjoint representation of $\bar{\mathcal{P}}$ is given by

$$(\mathrm{Ad}\,g)^A{}_B=\begin{pmatrix} \Lambda^a{}_b & \theta^c\varepsilon_c{}^a\sqrt{-h} & 0 \\ 0 & 1 & 0 \\ B\theta^c\varepsilon_{cd}\Lambda^d{}_b & -\dfrac{B}{2\sqrt{-h}}\theta^a\theta_a & 1 \end{pmatrix},$$

and the invariant Casimir operator determines the metric h_{AB} such that $\langle V,V\rangle=h^{AB}V_AV_B=V^aV_a-2(B/\sqrt{-h})V_2V_3$, for any vector $V=V^A\bar{T}_A$ in $\bar{\mathfrak{i}}_2^1$, with $A,B\in\{0,1,2,3\}$. The dimensions of the metric components are $[h_{ab}]=L^{-2}$, and $[h_{23}]=[h_{32}]=[\hbar]^{-1}$.

The extended Poincaré algebra has the structure of a semidirect product $\bar{\mathfrak{i}}_2^1=\mathrm{so}(1,1)\times_\rho\mathrm{wh}$, where $\mathrm{so}(1,1)=\mathfrak{R}$ is the Abelian subalgebra generated by J, and wh is the maximal nilpotent ideal spanned by $\{P_0,P_1,I\}$, which is isomorphic to the Lie algebra of the Weyl–Heisenberg group WH. The representation ρ of so(1, 1) on wh is given by the restriction of the adjoint representation of $\bar{\mathfrak{i}}_2^1$ to so(1, 1).

It is well-known that $\bar{\mathfrak{i}}_2^1$ is solvable;[5] however, it is also not nilpotent, since its descending central series, $\bar{\mathfrak{i}}_2^{1\,1}=\bar{\mathfrak{i}}_2^1$, $\bar{\mathfrak{i}}_2^{1\,2}=[\bar{\mathfrak{i}}_2^1,\bar{\mathfrak{i}}_2^{1\,1}]=\mathrm{wh}$, …, $\bar{\mathfrak{i}}_2^{1\,k}=[\bar{\mathfrak{i}}_2^1,\bar{\mathfrak{i}}_2^{1\,k-1}]=\mathrm{wh}$ $\forall k\geqslant 2$, does not vanish for any value of k. It is also not difficult to see that the extended Poincaré group $\bar{\mathcal{P}}$ and its Lie algebra $\bar{\mathfrak{i}}_2^1$ are solvable exponential, since for any $X\in\bar{\mathfrak{i}}_2^1$ the eigenvalues of $ad(X)$ are all real.[14]

As a consequence, $\bar{\mathcal{P}}$ is defined as the connected and simply connected image of $\bar{\mathfrak{i}}_2^1$ by the exponential mapping $\bar{\mathcal{P}}=\exp(\bar{\mathfrak{i}}_2^1)$, and every element $g\in\bar{\mathcal{P}}$ belongs to a one-parameter subgroup, so the group law given by Eq. (2) holds globally. Another consequence is that $\bar{\mathcal{P}}$ is homologically trivial; therefore, the Van Est theorem[13] ensures that the cohomology groups on $\bar{\mathcal{P}}$ are canonically isomorphic to the corresponding cohomology groups on $\bar{\mathfrak{i}}_2^1$.

The first cohomology group of $\overline{\mathfrak{i}_2^1}$ can be readily calculated, $H_0^1(\overline{\mathfrak{i}_2^1},\mathfrak{R})=(\overline{\mathfrak{i}_2^1}/[\overline{\mathfrak{i}_2^1},\overline{\mathfrak{i}_2^1}])^*=\mathfrak{R}$. In order to work out the second cohomology group, it is enough to show that the space of two-cocycles $Z_0^2(\overline{\mathfrak{i}_2^1},\mathfrak{R})\subset\Lambda^2\overline{\mathfrak{i}_2^1}$ has the same dimension of the space of two coboundaries $B_0^2(\overline{\mathfrak{i}_2^1},\mathfrak{R})$. It turns out that $\dim H_0^2(\overline{\mathfrak{i}_2^1},\mathfrak{R})=\dim Z_0^2(\overline{\mathfrak{i}_2^1},\mathfrak{R})-\dim B_0^2(\overline{\mathfrak{i}_2^1},\mathfrak{R})=0$.

III. CONSTRUCTION OF THE IRREP'S OF $\overline{\mathcal{P}}$ BY ITS COADJOINT ORBITS

It will be shown in Sec. IV that the anomaly-free Lagrangian describing a relativistic particle in flat two-dimensional space–time must be invariant under $\overline{\mathcal{P}}$, consistently with $H_0^2(\overline{\mathcal{P}},\mathfrak{R})=0$. It follows that the relevant dynamical group in two dimensions is $\overline{\mathcal{P}}$, so the adequate statement of the principle of relativity in $(1+1)$ dimensions should require that the equations of motion are covariant under the transformations of $\overline{\mathcal{P}}$.

This means that the elementary particles in $(1+1)$ dimensions must belong to irrep's of $\overline{\mathcal{P}}$ at the quantum level, and constitute relativistic elementary systems in this sense. On the other hand, the group-theoretic approach is concerned about a corresponding notion of elementary system at the classical level, i.e., a system that cannot be decomposed into smaller parts without breaking the symmetry.[15] It turns out that the irreducibility condition is translated naturally into a transitivity one at the classical level; therefore, a classical elementary system is defined as a homogeneous symplectic manifold (HSM). We say that an elementary system (S,Ω) is a Hamiltonian G-space,[16] or a strictly homogeneous symplectic manifold, if further the dynamical group G possesses a Poisson action upon S.

We recall that, due to the Kirillov theorem,[17] every HSM associated with some dynamical group G is locally isomorphic to a coadjoint orbit of G or to a coadjoint orbit of the central extension of G by $\mathfrak{R}$. Then, if further all the coadjoint orbits of G are simply connected and $H_0^2(\mathfrak{g},\mathfrak{R})=0$, then the momentum mapping will be a symplectomorphism between every classical elementary system (S,Ω) upon which the action of $\mathfrak{g}$ is globally Hamiltonian and a certain coadjoint orbit.

Applying this theorem, we discover that every classical relativistic elementary system upon which the action of $\overline{\mathfrak{i}_2^1}$ is globally Hamiltonian is simply connected, and symplectomorphic to one of the coadjoint orbits of $\overline{\mathcal{P}}$ that are calculated below, since it is a connected solvable exponential Lie group with $H_0^2(\overline{\mathfrak{i}_2^1},\mathfrak{R})=0$ (see Sec. II). Although this classification does not exhaust all the two-dimensional relativistic elementary systems, since $H_0^1(\overline{\mathcal{P}},\mathfrak{R})=\mathfrak{R}$, it is general enough to include the most physically interesting cases, such as the anomaly-free relativistic particle in $(1+1)$ dimensions.

The coadjoint orbit through $\zeta=\zeta_A\overline{\omega}^A$ in $\overline{\mathfrak{i}_2^1}^*$ is formed by the points $\mu=u_A\overline{\omega}^A$ satisfying $u_A=\zeta_B(Adg^{-1})^B{}_A$, where $\{\overline{\omega}^A\}$ is the basis of $\overline{\mathfrak{i}_2^1}^*$ dual to $\{\overline{T}_A\}$. As a consequence, the following identities hold: $u^Au_A=\zeta^A\zeta_A$ and $u_3=\zeta_3$. The stability group of $\zeta\in\overline{\mathfrak{i}_2^1}^*$ is generated by the subalgebra $\overline{\mathfrak{i}_{2\zeta}^1}\subset\overline{\mathfrak{i}_2^1}$, which is the kernel of the Kirillov two-form $B_\zeta(X,Y)$, formed by the vectors $Y\in\overline{\mathfrak{i}_2^1}$ for which $\langle\zeta,[X,Y]\rangle=0$, $\forall X\in\overline{\mathfrak{i}_2^1}$. The dimension of the coadjoint orbit can be deduced from the dimension of the stability group.

As the space of coadjoint orbits of $\overline{\mathcal{P}}$ parametrizes both the set of relativistic elementary systems in two dimensions and the unitary dual of $\overline{\mathcal{P}}$, we will present the coadjoint orbits of $\overline{\mathcal{P}}$ together with their associated irrep's. The problem splits into three cases, and we will follow the methodology sketched in the Appendix for working out all the irrep's of $\overline{\mathcal{P}}$.

Since $ad(X)$ is traceless for all $X\in\overline{\mathfrak{i}_2^1}$, $\overline{\mathcal{P}}$ is unimodular (i.e., $\Delta_{\overline{\mathcal{P}}}=1$). Also, because the real eigenvalues of $ad(X)$ are not all zero for every $X\in\overline{\mathfrak{i}_2^1}$, $\overline{\mathcal{P}}$ is not quasinilpotent (see the Appendix). Consequently, in order to apply the method of orbits to $\overline{\mathcal{P}}$, we must find for any $\zeta\in\overline{\mathfrak{i}_2^1}^*$ a subalgebra $\mathfrak{h}\subset\overline{\mathfrak{i}_2^1}$ of a maximal dimension in the family of the subalgebras subordinate to ζ, further satisfying Pukanszky's condition.

A. Case $\zeta_3 \neq 0$

The coadjoint orbit is the two-dimensional surface diffeomorphic to $\mathfrak{R}^2$ in the three-dimensional hyperplane $u_3=\zeta_3$, defined by the equations

$$u_2=\frac{u^a u_a\sqrt{-h}}{2Bu_3}-\frac{\zeta^A\zeta_A\sqrt{-h}}{2Bu_3} \quad \text{and} \qquad u_3=\zeta_3, \tag{3}$$

and passing through the point $\zeta=(0,0,-[(\zeta^A\zeta_A\sqrt{-h})/2B\zeta_3],\zeta_3)$. These coadjoint orbits are classified by ζ_3 and $\zeta^A\zeta_A$.

Since we may choose any point on the coadjoint orbit (see the Appendix), we pick ζ. Denoting by (J,P_+,I) the subalgebra of $\overline{1_2^1}$ spanned by these vectors, where $P_+=P_0+P_1$, it is clear that $\mathfrak{h}=(J,P_+,I)$ is subordinate to ζ, since its first derived algebra is $[\mathfrak{h},\mathfrak{h}]=(P_+)$, which is orthogonal to ζ or $\langle\zeta,(P_+)\rangle=0$. The subalgebra $\mathfrak{h}$ subordinate to ζ is also admissible, since its codimension is 1, which is half the dimension of the coadjoint orbit, and it satisfies Pukanszky's condition $\zeta+\mathfrak{h}^\perp\subset\mathrm{orb}(\zeta)$. Since any other admissible subalgebra leads to a unitary equivalent representation (see the Appendix), we choose $\mathfrak{h}$.

The typical element of the subgroup H generated by $\mathfrak{h}$ will be denoted by $h(\theta^+,\alpha,\beta)=\exp(\theta^+P_+)\exp(\alpha J)\exp(\beta I)$, so that we can define (see the Appendix) the one-dimensional representation of H by $\chi(\theta^+,\alpha,\beta)=U(h(\theta^+,\alpha,\beta))=\exp(i(-\alpha[(\zeta^A\zeta_A\sqrt{-h})/2B\zeta_3]+\beta\zeta_3))$. The adjoint representation of the subgroup H can be straightforwardly calculated, so that the modulus of H is given by $\Delta_H(h)=|\det(\mathrm{Ad}\,h)|^{-1}=e^{\alpha}$. The space $L(\overline{\mathcal{P}},H,U)$ invariant under right translations on $\overline{\mathcal{P}}$ is formed by the complex functions satisfying the condition (see the Appendix)

$$\begin{aligned}
&F(h(\theta^{+\prime},\alpha',\beta')\cdot g(\theta^a,\alpha,\beta))=e^{-(\alpha'/2)}\chi(\theta^{+\prime},\alpha',\beta')F(g(\theta^a,\alpha,\beta)),\\
&F\left(g\left(\Lambda^a{}_b(\alpha')\theta^b+\theta^{+\prime},\alpha'+\alpha,\beta'+\beta+\frac{B}{2}\theta^{+\prime}e^{\alpha'}(\theta^0-\theta^1)\right)\right)\\
&\quad=e^{-(\alpha'/2)}\exp\left(i\left(-\alpha'\frac{\zeta^A\zeta_A\sqrt{-h}}{2B\zeta_3}+\beta'\zeta_3\right)\right)F(g(\theta^a,\alpha,\beta)).
\end{aligned} \tag{4}$$

This means that the space $L(\overline{\mathcal{P}},H,U)$ is determined by the value of F at $\theta^0=\alpha=\beta=0$.

It is not difficult to see that every element of $\overline{\mathcal{P}}$ can be uniquely written as $g=h\cdot k$, where $h\in H$, $k\in K$, and K is the one-parameter subgroup of $\overline{\mathcal{P}}$ generated by $P_1\in\overline{1_2^1}$. Choosing the Borel mapping $s(x):=k$, where $x\in X=H\backslash\overline{\mathcal{P}}$ and $x=Hg=Hhk=Hk$, we can identify the right-coset space X with the subgroup $K\subset\overline{\mathcal{P}}$, in the sense that $s(X)=K$. The bi-invariant measure on $\overline{\mathcal{P}}$ splits into $d\mu(g)=\Delta_{H,\overline{\mathcal{P}}}(h)d\nu_s(x)d\nu(h)$, where the measure on X is determined by the right Haar measure on $K=\mathfrak{R}$, $d\nu_s(x)=d\nu(s(x))$, which is only $\overline{\mathcal{P}}$-quasi-invariant, because $\Delta_{\overline{\mathcal{P}}}(h)\neq\Delta_H(h)$, and is recognized to be just the Lebesgue measure $d\mu$ on $\mathfrak{R}$. Then, we can construct the Hilbert space $L^2(X,\nu_s,\mathbf{C})=L^2(\mathfrak{R},d\mu)$, formed by the functions defined by $f(x)=F(s(x))$, for every $F\in L^2(\overline{\mathcal{P}},H,U)$ (see the Appendix), which obviously admits a $\overline{\mathcal{P}}$-invariant scalar product.

Solving the equation $s(x)g=hs(xg)$ for $h=h(\theta^+,\alpha',\beta')$, where $k=k(\theta^1)$ and $g=g(\theta''^a,\alpha'',\beta'')$, we can realize the induced representation $\mathrm{ind}(\overline{\mathcal{P}},H,U)$ on the separable Hilbert space $L^2(\mathfrak{R},d\mu)$ of the square-integrable complex functions having compact support on $\mathfrak{R}$ through

$$\begin{aligned}
[T(g)f](\theta^1)=e^{-(\alpha''/2)}\exp\Bigg[i\Bigg(&-\frac{\zeta^A\zeta_A\sqrt{-h}}{2B\zeta_3}\alpha''+\Bigg(\beta''+\frac{B}{2}\theta''^0\theta^1-\frac{B}{4}((\theta''^0)^2-(\theta^1+\theta''^1)^2)\\
&-\frac{B}{4}e^{-2\alpha''}(\theta''^0-\theta^1-\theta''^1)^2\Bigg)\zeta_3\Bigg)\Bigg]f((\theta^1+\theta''^1-\theta''^0)e^{-\alpha''}).
\end{aligned} \tag{5}$$

The corresponding representation of any $X \in \overline{\mathfrak{i}_2^1}$ can be readily calculated, yielding

$$\rho(I) = i\zeta_3, \quad \rho(J) = -\frac{1}{2} + i\left(-\frac{\zeta^A \zeta_A \sqrt{-h}}{2B\zeta_3} + \frac{B}{2}(\theta^1)^2 \zeta_3 \right) - \theta^1 \frac{\partial}{\partial \theta^1},$$

$$\rho(P_0) = iB\theta^1 \zeta_3 - \frac{\partial}{\partial \theta^1}, \quad \text{and} \quad \rho(P_1) = \frac{\partial}{\partial \theta^1}. \tag{6}$$

This representation is anti-Hermitian, and the operator identity $\rho(J) = \sqrt{-h}(\rho(P^a)\rho(P_a) + \zeta^A \zeta_A)/2B\rho(I)$ holds. So, we can write these irrep's simply as $T^{\zeta^A \zeta_A, \zeta_3}(g(\theta^a, \alpha, \beta)) = \exp(\theta^a \rho(P_a))\exp(\alpha\rho(J))\exp(\beta\rho(I))$.

The irrep's $T^{\zeta^A \zeta_A, \zeta_3}$ are faithful, and it can be shown that, in natural units and for $B = 1$, they are unitary equivalent to the irrep's of $\overline{\mathcal{P}}$ presented in Gadella *et al.*,[10] but they are more general than the latter. Since the quantization of the corresponding elementary systems does not look anomalous (see Sec. IV), the irrep's in the form $T^{\zeta^A \zeta_A, \zeta_3}$ are the most physically interesting ones, although they do not correspond to coadjoint orbits of $\overline{\mathcal{P}}$ which are HSM's for $\mathcal{P}$.

B. Case $\zeta_3 = 0$ and $\zeta_a = 0$

The coadjoint orbit is the point $(0,0,\zeta_2,0)$ in the three-dimensional hyperplane $u_3 = 0$. These coadjoint orbits are classified by ζ_2. It is clear that the subalgebra $\mathfrak{h} = \overline{\mathfrak{i}_2^1}$ is subordinate to ζ, since its first derived algebra is $[\mathfrak{h}, \mathfrak{h}] = \mathfrak{wh}$, which is orthogonal to ζ or $\langle \zeta, \mathfrak{wh} \rangle = 0$. The subalgebra $\mathfrak{h}$ subordinate to ζ is also admissible, since $\operatorname{codim} \mathfrak{h} = 0$, which is half the dimension of the coadjoint orbit, and it satisfies Pukanszky's condition $\zeta + \mathfrak{h}^\perp \subset \operatorname{orb}(\zeta)$. It is not difficult to see that there is no other admissible subalgebra subordinate to ζ.

Denoting by $h(\theta^a, \alpha, \beta) = \exp(\theta^a P_a)\exp(\alpha J)\exp(\beta I)$ the typical element of the subgroup H generated by $\mathfrak{h}$, we can (see the Appendix) define the one-dimensional representation of H by $\chi(\theta^a, \alpha, \beta) = U(h(\theta^a, \alpha, \beta)) = \exp(i\alpha\zeta_2)$. Since $H = \overline{\mathcal{P}}$ is unimodular, the space $L(\overline{\mathcal{P}}, H, U)$ invariant under right translations on $\overline{\mathcal{P}}$ is formed by the complex functions satisfying the condition

$$F(h(\theta'^a, \alpha', \beta') \cdot g(\theta^a, \alpha, \beta)) = \chi(\theta'^a, \alpha', \beta') F(g(\theta^a, \alpha, \beta)),$$

$$F\left(g\left(\Lambda^a{}_b(\alpha')\theta^b + \theta'^a, \alpha' + \alpha, \beta' + \beta + \frac{B}{2}\theta'^a \varepsilon_{ab} \Lambda^b{}_c(\alpha')\theta^c \right) \right) = \exp(i\alpha'\zeta_2) F(g(\theta^a, \alpha, \beta)). \tag{7}$$

This means the space $L(\overline{\mathcal{P}}, H, U) = \mathbf{C}$ is determined by the value of F at $\theta^a = \alpha = \beta = 0$, or $F(g(\theta^a, \alpha, \beta)) = \exp(i\alpha\zeta_2)F(e)$, so it is identified with the set of complex numbers.

It follows that the Hilbert space $L^2(\overline{\mathcal{P}}, H, U)$ is one-dimensional and it is formed by the complex functions $F \in L(\overline{\mathcal{P}}, H, U)$ for which $\|F\|^2 < \infty$, where $\|F\|^2 = (F, F)$ and the $\overline{\mathcal{P}}$-invariant scalar product is given by $(F_1, F_2) = \overline{F_1(e)} F_2(e)$. Consequently (see the Appendix), we can realize the induced representation $\operatorname{ind}(\overline{\mathcal{P}}, H, U)$ on the Hilbert space $L^2(\overline{\mathcal{P}}, H, U)$ through $[T(g)F](g') = \exp(i\alpha\zeta_2)F(g')$, where $g = g(\theta^a, \alpha, \beta)$ and $g' = g(\theta'^a, \alpha', \beta')$. The corresponding representation of any $X \in \overline{\mathfrak{i}_2^1}$ is given by $\rho(I) = 0$, $\rho(J) = i\zeta_2$, and $\rho(P_a) = 0$.

The representation of $\overline{\mathfrak{i}_2^1}$ on the Hilbert space $\mathbf{C}$ given above is clearly anti-Hermitian; therefore, the irrep's of $\overline{\mathcal{P}}$ may be simply written as $T^{\zeta_2}(g(\theta^a, \alpha, \beta)) = \exp(\theta^a \rho(P_a))\exp(\alpha\rho(J))\exp(\beta\rho(I))$, and the operator identity $\rho(P^a)\rho(P_a) - 2B/\sqrt{-h}\,\rho(J)\rho(I) = -\zeta^A \zeta_A$ holds. We note that the irrep's T^{ζ_2} are obviously unfaithful and lack physical interest, although they correspond to coadjoint orbits of $\overline{\mathcal{P}}$ which are HSM's for $\mathcal{P}$.

C. Case $\zeta_3=0$ and $\zeta_a\neq 0$

The coadjoint orbit is the two-dimensional surface diffeomorphic to $\Re^2$, immersed in the three-dimensional hyperplane $u_3=0$ and defined by the equation

$$u^a u_a=\zeta^a\zeta_a, \tag{8}$$

which can be a hyperbolic cylinder or a half-plane translationally invariant in the direction of the u_2 axis. These coadjoint orbits are classified by ζ_a and gather into eight distinct families: two families with $\zeta^a\zeta_a<0$, two with $\zeta^a\zeta_a>0$, and the other four with $\zeta^a\zeta_a=0$ (the u_2 axis does not belong to any family).

As we may choose any point on the coadjoint orbit (see the Appendix), we pick $\zeta=(\zeta_a,\zeta_2,0)$. The subalgebra $\mathfrak{h}=\mathrm{wh}$ is subordinate to ζ, since its first derived algebra is $[\mathfrak{h},\mathfrak{h}]=(I)$, which is orthogonal to ζ or $\langle\zeta,(I)\rangle=0$. The subalgebra $\mathfrak{h}$ subordinate to ζ is also admissible, since $\mathrm{codim}\,\mathfrak{h}=1$, which is half the dimension of the coadjoint orbit, and it satisfies Pukanszky's condition $\zeta+\mathfrak{h}^{\perp}\subset\mathrm{orb}(\zeta)$. Since any other admissible subalgebra leads to a unitary equivalent representation (see the Appendix), we choose $\mathfrak{h}$.

Denoting by $h(\theta^a,\beta)=\exp(\theta^a P_a)\exp(\beta I)$ the typical element of the subgroup H generated by $\mathfrak{h}$, we can (see the Appendix) define the one-dimensional representation of H by $\chi(\theta^a,\beta)=U(h(\theta^a,\beta))=\exp(i\theta^a\zeta_a)$. Due to the fact that $H=\mathrm{WH}$ is unimodular, the space $L(\overline{\mathcal{P}},H,U)$ invariant under right translations on $\overline{\mathcal{P}}$ is formed by the complex functions satisfying the condition

$$F(h(\theta'^a,\beta')\cdot g(\theta^a,\alpha,\beta))=\chi(\theta'^a,\beta')F(g(\theta^a,\alpha,\beta)),$$

$$F\left(g\left(\theta^a+\theta'^a,\alpha,\beta'+\beta+\frac{B}{2}\theta'^a\varepsilon_{ab}\theta^b\right)\right)=\exp(i\theta'^a\zeta_a)F(g(\theta^a,\alpha,\beta)). \tag{9}$$

This means that the space $L(\overline{\mathcal{P}},H,U)$ is determined by the value of F at $\theta^a=\beta=0$.

It is not difficult to see that every element of $\overline{\mathcal{P}}$ can be uniquely written as $g=h\cdot k$, where $h\in H$, $k\in K$, and K is the one-parameter subgroup of $\overline{\mathcal{P}}$ generated by $J\in\overline{1}_2^1$. Choosing the Borel mapping $s(x):=k$, where $x\in X=H\backslash\overline{\mathcal{P}}$ and $x=Hg=Hhk=Hk$, we can identify the right-coset space X with the subgroup $K\subset\overline{\mathcal{P}}$, in the sense that $s(X)=K$. The bi-invariant measure on $\overline{\mathcal{P}}$ splits into $d\mu(g)=\Delta_{H,\overline{\mathcal{P}}}(h)d\nu_s(x)d\nu(h)$, where the measure on X is determined by the right Haar measure on $K=\Re$, $d\nu_s(x)=d\nu(s(x))$, which is $\overline{\mathcal{P}}$-invariant, since $\Delta_{\overline{\mathcal{P}}}(h)=\Delta_H(h)$, and is just the Lebesgue measure $d\mu$ on $\Re$. Then, we can construct the Hilbert space $L^2(X,\nu_s,\mathbf{C})=L^2(\Re,d\mu)$, formed by the functions defined by $f(x)=F(s(x))$ for every $F\in L^2(\overline{\mathcal{P}},H,U)$ (see the Appendix), which obviously admits a $\overline{\mathcal{P}}$-invariant scalar product.

Solving the equation $s(x)g=hs(xg)$ for $h=h(\theta'^a,\beta')$, where $k=k(\alpha)$ and $g=g(\theta''^a,\alpha'',\beta'')$, we can realize the induced representation $\mathrm{ind}(\overline{\mathcal{P}},H,U)$ on the separable Hilbert space $L^2(\Re,d\mu)$ of the square-integrable complex functions having compact support on $\Re$ through $[T(g)f](\alpha)=\exp(i\Lambda(\alpha)^a{}_b\theta''^b\zeta_a)f(\alpha+\alpha'')$. The corresponding representation of any $X\in\overline{1}_2^1$ is given by $\rho(I)=0$, $\rho(J)=\partial/\partial\alpha$, and $\rho(P_a)=i\Lambda(\alpha)^b{}_a\zeta_b$.

The operator identity $\rho(P^a)\rho(P_a)-2(B/\sqrt{-h})\rho(J)\rho(I)=-\zeta^A\zeta_A$ holds and the representation of $\overline{1}_2^1$ on the Hilbert space $L^2(\Re,d\mu)$ is clearly anti-Hermitian, so the irrep's of $\overline{\mathcal{P}}$ may be simply written as $T^{\zeta_a}(g(\theta^a,\alpha,\beta))=\exp(\theta^a\rho(P_a))\exp(\alpha\rho(J))\exp(\beta\rho(I))$. It can be shown that the irrep T^{ζ_a} is equivalent to the Wigner representation of the Poincaré group in $(1+1)$ dimensions $\mathcal{P}$ (see Gadella *et al.*[10] and Ali and Antoine[18]). We note that the irrep's T^{ζ_a} are unfaithful and not too interesting physically, since the quantization of the corresponding classical elementary systems looks anomalous, although they correspond to coadjoint orbits of $\overline{\mathcal{P}}$ which are HSM's for $\mathcal{P}$.

IV. THE ANOMALY-FREE RELATIVISTIC PARTICLE IN (1+1) DIMENSIONS

It is known that the dynamics of the relativistic particle in a flat $(1+1)$ dimensional space–time M is described by the Lagrangian $L_B=L_0+L_{WZ}$, where $L_0=-m\sqrt{\dot{q}^2}$ and $L_{WZ}=-(B/2)\,\varepsilon_{ab}\dot{q}^a q^b$. The central charge B is similar to an applied electrical force driving the particle into an uniformly accelerated relativistic motion[5] and it is an additional free parameter (besides the mass m), fixed at the outset, that the relativistic particle theory must allow for, due to the existence of a nontrivial two cocycle in the second cohomology group of the Poincaré group in $(1+1)$ dimensions $\mathcal{P}$. In fact, it was shown by Bargmann that $H_0^2(\mathcal{P},\mathfrak{R})=\mathfrak{R}$ then, as a consequence of the Lévy–Leblond theorem,[13] all the inequivalent Lagrangians L_B quasi-invariant under $\mathcal{P}$ are classified by the central charge B.

However, it must be emphasized that the Lagrangian L_B is classically anomalous, since it is quasi-invariant under the transformations of $\mathcal{P}$, while the three conserved Noether charges together with the identity $\{\mathcal{N}_a,\mathcal{N}_2,1\}$ constitute a Poisson bracket realization of $\overline{\mathfrak{i}_2^1}$, assuming $B\neq 0$ and $m\neq 0$. Since $H_0^2(\overline{\mathcal{P}},\mathfrak{R})=0$ (see Sec. II), we can eliminate the classical anomaly by adding a third term to L_B, depending on an extra degree of freedom χ with dimension of action and transforming as $\chi'=\chi+\beta+(B/2)\,\theta^a\varepsilon_{ab}\Lambda^b{}_c q^c$ under $\overline{\mathcal{P}}$. This addition neutralizes the Wess–Zumino term L_{WZ}, causing the new Lagrangian $\overline{L}=L_B-\dot{\chi}$ to be invariant under the transformations of $\overline{\mathcal{P}}$. Now, there are four conserved Noether charges $\{\mathcal{N}_a,\mathcal{N}_2,\mathcal{N}_3\}$ associated with the anomaly-free Lagrangian $\overline{L}$, which realize $\overline{\mathfrak{i}_2^1}$ with the identically conserved charge $\mathcal{N}_3=-1$ corresponding to the central generator realized by minus the identity.

Performing the Hamiltonian formulation of the system described by $\overline{L}$, we learn that χ is an internal gauge degree of freedom, corresponding to the phase of the particle's wave function at the quantum level. The reduced phase space Γ_R^+ can be determined by observing that the constraint surface Γ^+ is globally diffeomorphic to $\overline{\mathcal{P}}$, such that the action of the dynamical group upon Γ^+ is simply transitive and free.

It is not difficult to see that the generators of the gauge transformations corresponding to the two primary first-class constraints ϕ_m span a subalgebra of $\mathfrak{X}(\Gamma^+)$ which realizes a two-dimensional Abelian subalgebra of $\overline{\mathfrak{i}_2^1}$; therefore, the reduced phase space $\Gamma_R^+\sim\mathfrak{R}^2$ is diffeomorphic to the homogeneous coset space generated by the translations P_a and can be globally parametrized by the space–time coordinates q^a. The space Γ_R^+ is endowed with the symplectic form $\Omega^{+R}=d\Lambda^{+R}=(B/2)\,\varepsilon_{ab}dq^a\wedge dq^b$, the canonical one form of which is given by the Wess–Zumino form $\Lambda^{+R}=(B/2)\,\varepsilon_{ab}q^a dq^b$.

It turns out that the symplectic manifold (Γ_R^+,Ω^{+R}) is a Hamiltonian G-space and hence a classical relativistic elementary system. Indeed (Γ_R^+,Ω^{+R}) is homogeneous under the action of the dynamical group $\overline{\mathcal{P}}$, which has a Poisson action upon Γ_R^+, such that the globally Hamiltonian vector fields at $s\in\Gamma_R^+$ are given by $\overline{T}_a^{\Gamma_R^+}(s)=(\partial/\partial q^a)$, $\overline{T}_2^{\Gamma_R^+}(s)=\sqrt{-h}\varepsilon^a{}_b q^b(\partial/\partial q^a)$, and $\overline{T}_3^{\Gamma_R^+}(s)=0$. The comoments are given by $u_a^{+R}(s)=Bq^b\varepsilon_{ba}$, $u_2^{+R}(s)=(m^2/2B)+[B/(2\sqrt{-h})]\,q_a q^a$, and $u_3^{+R}(s)=-1$. Note that they are not uniquely determined, since u_2^{+R} is defined up to an additive constant, consistently with $H_0^1(\overline{\mathcal{P}},\mathfrak{R})=\mathfrak{R}$.

The identities $u_A^{+R}u^{+RA}(s)=m^2/\sqrt{-h}$ and $u_3^{+R}(s)=-1$ hold, so $u_2^{+R}(s)$ is functionally dependent on the $u_a^{+R}(s)$, which are regarded as the fundamental dynamical variables, and using the fact that the comoments constitute a Poisson bracket realization of $\overline{\mathfrak{i}_2^1}$, it is not difficult to see that $\{q^a,q^b\}=[\varepsilon^{ab}(\sqrt{-h})^2]/B$. The value of the momentum mapping $\mu_R^+(s)=([u_A^{+R}(s)]/\hbar)\overline{\omega}^A$ at the origin $s_0=(0,0)$ in Γ_R^+ shall be denoted by $\zeta=\mu_R^+(s_0)=(0,0,m^2/(2B\hbar),-1/\hbar)$, which satisfies

$$\zeta^A\zeta_A=\frac{m^2}{\sqrt{-h}\hbar^2}\quad\text{and}\quad\zeta_3=-\frac{1}{\hbar}. \tag{10}$$

The second identity in Eq. (10) follows from the value of $u_3^{+R}(s)$ and the definition of the momentum mapping, so the quantization of (Γ_R^+,Ω^{+R}) satisfies Dirac's quantum condition (this will be shown later).

Moreover, a straightforward calculation shows that[19] the momentum mapping $\mu_R^+:\Gamma_R^+ \to \mathrm{orb}(\zeta)$ is a symplectomorphism between the elementary system (Γ_R^+,Ω^{+R}) and the coadjoint orbit $(\mathrm{orb}(\zeta),b)$ through $\zeta \in \overline{\mathfrak{i}_2^1}^*$, with $\mu_R^+ * b = (\Omega^{+R}/\hbar)$. It follows that Eq. (10) provides a physical interpretation for the parameters labeling the irrep $T^{\zeta^A \zeta_A,\zeta_3}$ of $\overline{\mathcal{P}}$, which corresponds to the relativistic elementary system (Γ_R^+,Ω^{+R}).

A. Quantization of the anomaly-free relativistic particle in (1+1) dimensions

Before we address the quantum dynamics of the relativistic particle, though, let us clear up the quantization of the system at the kinematical level. Let $\varphi(\overline{T_A}) := i\rho(\overline{T_A})$ be the Hermitian representation of $\overline{\mathfrak{i}_2^1}$ on the Hilbert space $L^2(\mathfrak{R},dx)$ defined from Eq. (6), for $\zeta=(0,0,-[(\zeta^A\zeta_A\sqrt{-h})/2B\zeta_3],\zeta_3)$ satisfying Eq. (10), and $\mathfrak{j}\cong\overline{\mathfrak{i}_2^1}$ be the finite-dimensional Lie subalgebra of $C^\infty(\Gamma_R^+)$ spanned by the comoments $\{u_A^{+R}\}$. In addition, let $\lambda:\overline{\mathfrak{i}_2^1}\mapsto C^\infty(\Gamma_R^+)$ be the lift of the mapping $\sigma:\overline{\mathfrak{i}_2^1}\mapsto\mathcal{A}(\Gamma_R^+)$ induced by the left action of $\overline{\mathcal{P}}$ on Γ_R^+, where $\mathcal{A}(\Gamma_R^+)$ denotes the set of all the globally Hamiltonian vector fields on Γ_R^+. The mapping $\lambda(\overline{T_A})=u_A^{+R}$ is a Lie algebra homomorphism and it is well-defined, since Γ_R^+ is simply connected and $H_0^2(\overline{\mathfrak{i}_2^1},\mathfrak{R})=0$.

Then, $\mathrm{orb}(\zeta)$ determines the linear map $\mathcal{Q} := (1/\zeta_3)\,\varphi\circ\lambda^{-1}$ from $\mathfrak{j}$ onto the linear space $\mathrm{Op}(D)=\mathrm{span}\{\mathcal{Q}(u_A^{+R})\}$ of (in general) unbounded Hermitian (or symmetric) operators preserving a fixed dense domain D in $L^2(\mathfrak{R},dx)$, which satisfies $\mathcal{Q}(\{u_A^{+R},u_B^{+R}\}) = -i\zeta_3[\mathcal{Q}(u_A^{+R}),\mathcal{Q}(u_B^{+R})]$ and $\mathcal{Q}(u_3^{+R})=-\mathbf{1}$. For the domain D, we can take the Schwartz space $\boldsymbol{\mathcal{S}}(\mathfrak{R},\mathbf{C})\subset L^2(\mathfrak{R},dx)$ of rapidly decreasing smooth complex-valued functions, for instance.

Recalling that $u_3^{+R}=-1$, we can see that Dirac's quantum condition is satisfied if and only if $\zeta_3=-(1/\hbar)$, consistently with Eq. (10). Furthermore, assuming that D is a domain of essential self-adjointness for $\mathrm{Op}(D)$, we can see that the linear map $\mathcal{Q}$ is actually a prequantization of $\mathfrak{j}$ in the sense of Gotay,[20] since the globally Hamiltonian vector fields $\overline{T}_A^{\Gamma_R^+}$ are complete. It is not difficult to see that $\boldsymbol{\mathcal{S}}(\mathfrak{R},\mathbf{C})$ is a domain of essential self-adjointness for the representation of $\mathfrak{j}$ given by $\mathrm{Op}(D)$.

In order to determine the maximal Lie subalgebra $\mathcal{O}$ of $C^\infty(\Gamma_R^+)$ that can consistently be quantized, we will tie to the approach that aims at providing a quantization of the pair $(\mathcal{O},\mathfrak{b})$, i.e., a prequantization of $\mathcal{O}$ which (among other things) irreducibly represents a suitably chosen basic algebra of observables $\mathfrak{b}\subset C^\infty(\Gamma_R^+)$.[20] It turns out that the suitable basic algebra is $\mathfrak{b}=\mathrm{wh}=\mathrm{span}\{u_0^{+R},u_1^{+R},u_3^{+R}\}$, since the restriction of $\mathcal{Q}$ to $\mathrm{wh}\subset\mathfrak{j}=\mathrm{span}\{u_A^{+R}\}$ provides actually a quantization of the pair $(\mathfrak{b},\mathfrak{b})$, which is equivalent to the usual Schrödinger quantization of a one-dimensional nonrelativistic free particle.

In fact, in the coordinates of Γ_R^+ defined by $q := -(u_0^{+R}+u_1^{+R})/B = -q^1+q^0$ and $p := u_1^{+R} = -Bq^0$, the expression of the associated quantization map $\mathcal{Q}$ is exactly given by the Schrödinger representation of wh in the position representation $\{|x\rangle\}$; $\hat{q} := \mathcal{Q}(q)=x$, $\hat{p} := \mathcal{Q}(p) = -i\hbar\,(\partial/\partial x)$, and $\hat{1} := \mathcal{Q}(1)=\mathbf{1}$ on the domain D, such as $D=\boldsymbol{\mathcal{S}}(\mathfrak{R},\mathbf{C})\subset L^2(\mathfrak{R},dx)$. The standard canonical quantization is well-defined; however, there is no full quantization of $(C^\infty(\Gamma_R^+),\mathfrak{b})$ in which a Von Neumann rule is compatible with the Schrödinger quantization.

Indeed, due to the strong Groenewold–Van Hove no-go theorem,[20] there is no quantization of (P,wh) on $\mathfrak{R}^2\sim\Gamma_R^+$, where P denotes the polynomial subalgebra of $C^\infty(\Gamma_R^+)$ generated by $\mathfrak{b}=\mathrm{wh}$. It turns out that the only two distinct isomorphism classes of maximal Lie subalgebras of P which contain wh are those represented by P^2 and by the set of polynomials $S=\{f(q)p+g(q)\}$, where P^2 denotes the subspace of polynomials of degree at most 2, and f,g are polynomials.[20]

The quantization of the pair (P^2,wh) is provided by the well-known extended metaplectic quantization. On the other hand, the only classical observable in this paper that will require it is

the comoment u_2^{+R}, which is in $P^2 \subset P$ but not in wh. For all the other observables that we will consider, such as position, momentum, potential energy, relativistic energy, or the Hamiltonian, the Schrödinger quantization will be enough. In particular, we will not consider any observable in S.

In addition, a straightforward calculation shows that the extended metaplectic quantization $\mathcal{Q}$ of (P^2,wh) is covariant with respect to $\overline{\mathcal{P}}$ in the sense that, for every $f(q,p)$ in $P^2 \subset P \subset C^\infty(\Gamma_R^+)$ and $g=g(\theta^a,\alpha,\beta) \in \overline{\mathcal{P}}$, we have $\mathcal{Q}(f(q',p'))=T^{\zeta^A\zeta_A,\zeta_3}(g^{-1})\mathcal{Q}(f(q,p))T^{\zeta^A\zeta_A,\zeta_3}(g)$, where $(q',p')=l_g(q,p)$ is the left action on Γ_R^+ generated by the globally Hamiltonian vector fields $\overline{T}_A^{\Gamma_R^+}$, and ζ satisfies Eq. (10).

B. Quantum dynamics of the anomaly-free relativistic particle in (1+1) dimensions

As far as the quantum dynamics of the system is concerned, we remark that the total energy of the particle depends explicitly on time, so it does not provide a suitable Hamiltonian. For this reason, we turn to consider the dynamics from the point of view of the reduced phase space Γ_R^+. The volume two form of space–time determines the symplectic form $\Omega^{+R}=-(B/\sqrt{-h})\,\text{vol}$, which is expressed in the coordinates (q,p) of Γ_R^+ by $\Omega^{+R}=-dp\wedge dq$, with the Wess–Zumino form given by minus the Liouville form $\Lambda^{+R}=-pdq$.

Up to gauge equivalence, the dynamics on Γ_R^+ is specified by $q^0(\tau)=\tau$

$$q^1(\tau)=q^1(\tau_0)-\sqrt{m^2+\tilde{p}(\tau_0)^2}/B+\sqrt{m^2+\tilde{p}(\tau)^2}/B,$$

and $\tilde{p}(\tau)=\tilde{p}(\tau_0)+B(\tau-\tau_0)$, for a given $\tilde{p}(\tau_0)$, with $\tau_0 \in \Re$. It follows that the proper time is given by $t'=m/B\,\text{arsinh}[\tilde{p}(\tau)/m]$, and $\tilde{p}(\tau)$ is the kinematical momentum, since $\tilde{p}(\tau)=\gamma(\tau)m\,(dq^1/dt)\,(\tau)$.

Note that the equations for $q^a(\tau)$ are regarded as Hamilton equations, while that for $\tilde{p}(\tau)$ is an identity. Moreover, retaining the space–time meaning of the reduced phase space, the world-line W of the particle is also a Hamiltonian flow in the symplectic manifold Γ_R^+. Calculating the globally Hamiltonian vector field corresponding to this flow, $X_H(\tau)=\overline{T}_0^{\Gamma_R^+}(\tau)+[\tilde{p}(\tau)/\sqrt{m^2+\tilde{p}(\tau)^2}]\overline{T}_1^{\Gamma_R^+}(\tau)$, and applying the antihomomorphism of Lie algebras $\lambda \circ \sigma^{-1}(\overline{T}_a^{\Gamma_R^+})=u_a^{+R}$, we get the Hamiltonian $H(q,p,\tau)$.

The corresponding Hamiltonian operator splits into two parts $\hat{H}(\hat{q},\hat{p},\tau)=\hat{H}_0(\hat{q},\hat{p})+\hat{V}(\hat{p},\tau)$, where $\hat{H}_0(\hat{q},\hat{p})=-B\hat{q}-\hat{p}$ and $\hat{V}(\hat{p},\tau)=[\tilde{p}(\tau)/\sqrt{m^2+\tilde{p}(\tau)^2}]\,\hat{p}$. Solving the eigenvalue problem $\hat{H}_0|E\rangle=E|E\rangle$, we discover that $\hat{H}_0$ has continuous spectrum with the normalized eigenfunctions given by $\langle x|E\rangle=(1/\sqrt{2\pi\hbar})\exp[-(i/\hbar)(Ex+(B/2)x^2)]$, so $\langle E'|E\rangle=\delta(E'-E)$.

Note that classically $H_0=u_0^{+R}=Bq^1=-2\mathcal{E}_{\text{pot}}(q^1)$, so $\hat{H}_0(\hat{q},\hat{p})=-2\hat{\mathcal{E}}_{\text{pot}}(\hat{q},\hat{p})$ has the meaning of a potential energy operator. Besides this fact, the total energy operator $\hat{\mathcal{H}}(\hat{q},\hat{p},\tau)=\mathcal{E}(\tau)-\frac{1}{2}\hat{H}_0(\hat{q},\hat{p})$, where $\mathcal{E}(\tau):=\sqrt{m^2+\tilde{p}(\tau)^2}$ is the relativistic energy of the particle, satisfies $[\hat{\mathcal{H}},\hat{H}_0]=0$; therefore the eigenvectors of $\hat{H}_0$ are simultaneously total energy eigenstates. Then, the eigenvalues of the total energy operator are related with those of $\hat{H}_0$ through $\hat{\mathcal{H}}(\tau)|E\rangle=E_T(\tau)|E\rangle$, where $E_T(\tau)=\mathcal{E}(\tau)-E/2$.

In terms of the base kets $\{|E\rangle\}$, the state ket of the system is given at $\tau=\tau_0$ by $|\alpha\rangle=\int_{-\infty}^{+\infty}dE\,c_E(\tau_0)|E\rangle$, where $c_E(\tau_0)$ is some known complex function of E satisfying $\int_{-\infty}^{+\infty}dE|c_E(\tau_0)|^2=1$. Then, for $\tau>\tau_0$, the state ket will be $|\alpha,\tau_0;\tau\rangle=\int_{-\infty}^{+\infty}dE c_E(\tau)e^{-(iE/\hbar)(\tau-\tau_0)}|E\rangle$, where the $c_E(\tau)$'s satisfy the coupled differential equations

$$i\hbar\frac{dc_E}{d\tau}(\tau)=\int_{-\infty}^{+\infty}dE'\langle E|\hat{V}|E'\rangle e^{[i(E-E')/\hbar](\tau-\tau_0)}c_{E'}(\tau).$$

Solving the resulting linear homogeneous partial differential equations, we get

$$c_E(\tau)=\frac{1}{\sqrt{2\pi\hbar|B|}}\exp\left(-\frac{iE^2}{2B\hbar}\right)\int_{-\infty}^{+\infty}D_\lambda\exp\left[\frac{i\lambda}{\hbar B}(-E-\sqrt{m^2+\tilde{p}(\tau)^2}+\sqrt{m^2+\tilde{p}(\tau_0)^2})\right]d\lambda,$$

$$\text{where}\quad D_\lambda=\frac{1}{\sqrt{2\pi\hbar|B|}}\int_{-\infty}^{+\infty}c_E(\tau_0)\exp\left[\frac{iE}{B\hbar}\left(\frac{E}{2}+\lambda\right)\right]dE.$$

Suppose now that the system is initially prepared in an energy eigenstate $|\alpha\rangle=|E\rangle$, then at a later time $\tau>\tau_0$ the state will be given by

$$|\alpha,\tau_0;\tau\rangle=\exp\left[\frac{i}{2B\hbar}(-(E-\sqrt{m^2+\tilde{p}(\tau)^2}+\sqrt{m^2+\tilde{p}(\tau_0)^2})^2+E^2)\right]\cdot\exp\left[-\frac{i}{\hbar}(E-\sqrt{m^2+\tilde{p}(\tau)^2}\right.$$
$$\left.+\sqrt{m^2+\tilde{p}(\tau_0)^2})(\tau-\tau_0)\right]\cdot|E-\sqrt{m^2+\tilde{p}(\tau)^2}+\sqrt{m^2+\tilde{p}(\tau_0)^2}\rangle. \tag{11}$$

The probability as a function of time for the particle to be found in the state $|E'\rangle$ is given by $|\langle E'|\alpha,\tau_0;\tau\rangle|^2/\langle\alpha,\tau_0;\tau|\alpha,\tau_0;\tau\rangle\,dE'=\delta(E'-E+\sqrt{m^2+\tilde{p}(\tau)^2}-\sqrt{m^2+\tilde{p}(\tau_0)^2})dE'$, which equals 1 if $E'=E-\sqrt{m^2+\tilde{p}(\tau)^2}+\sqrt{m^2+\tilde{p}(\tau_0)^2}$ or zero otherwise. From Eq. (11), we note that the states $|E\rangle$ are not stationary although they are total energy eigenstates, since the τ-dependent part of the Hamiltonian $\hat{V}(\hat{p},\tau)$ causes transitions to eigenstates $|E-\sqrt{m^2+\tilde{p}(\tau)^2}+\sqrt{m^2+\tilde{p}(\tau_0)^2}\rangle$ of different energy.

In fact, the expectation value of the total energy operator, for instance,

$$\langle\hat{\mathcal{H}}\rangle(\tau)=\frac{\langle\alpha,\tau_0;\tau|\hat{\mathcal{H}}|\alpha,\tau_0;\tau\rangle}{\langle\alpha,\tau_0;\tau|\alpha,\tau_0;\tau\rangle}=\frac{3\mathcal{E}(\tau)}{2}-\frac{\mathcal{E}(\tau_0)}{2}-\frac{E}{2}$$

is τ-dependent. It is not difficult to see that the function $\langle\hat{\mathcal{H}}\rangle(\tau)$ attains to a minimum at $\tau=\tau_0-[\tilde{p}(\tau_0)]/B$, when its value is $\langle\hat{\mathcal{H}}\rangle(\tau_0-[\tilde{p}(\tau_0)/B])=3m/2-[\sqrt{m^2+\tilde{p}(\tau_0)^2}/2]-(E/2)$, which only happens after τ_0 if $\tilde{p}(\tau_0)$ satisfies the condition sign $(B)\tilde{p}(\tau_0)<0$; otherwise, $\langle\hat{\mathcal{H}}\rangle(\tau)$ is a monotonically increasing function of $\tau>\tau_0$. For this reason, the presented quantum states are stable, even though there is no true ground state.

V. DISCUSSION

We showed that the extended Poincaré group in $(1+1)$ dimensions $\overline{\mathcal{P}}$ is a connected solvable exponential Lie group, with $H_0^2(\overline{\mathcal{P}},\Re)=0$ and $H_0^1(\overline{\mathcal{P}},\Re)=\Re$ (see Sec. II). These facts were important to apply the Kirillov theorem to perform a classification of the two-dimensional relativistic elementary systems and to work out explicitly all the irrep's of $\overline{\mathcal{P}}$ by the orbit method (see Sec. III). The particular class of irrep's $T^{\zeta^A\zeta_A,\zeta_3}$ with ζ satisfying Eq. (10) turned out to be connected to a covariant maximal polynomial quantization of the anomaly-free relativistic particle in $(1+1)$ dimensions, which provided a quantum-mechanical interpretation for the construction in this most physically interesting case (see Sec. IV).

We remark that the Bohr–Wilson–Sommerfeld condition[21] is trivially satisfied by the anomaly-free relativistic particle in $(1+1)$ dimensions, and it does not yield the quantization of any observable quantity, which is consistent with the fact that the system is not conservative and the world lines are open. It is worth mentioning that $\overline{\mathcal{P}}$ is related to the one-dimensional oscillator group Os(1) by the Weyl unitary trick. However, the group Os(1) is not solvable exponential, and the orbit method gives all its irrep's only through holomorphic induction.[22]

It is remarkable that the extended metaplectic quantization of the anomaly-free relativistic particle is covariant with respect to $\overline{\mathcal{P}}$, inasmuch as a covariant Stratonovich–Weyl kernel for the corresponding coadjoint orbits has not been found yet.[10] However, this difficulty is not directly

related to the fact that there is an obstruction to fully quantizing the system, since there are symplectic manifolds such as $\mathfrak{R}^2$ or S^2 for which the problem of the generalized Weyl–Wigner–Moyal quantization has successfully been solved,[10] although obstructions have been found.[20]

The group $\overline{\mathcal{P}}$ enjoys several properties in common with the groups WH, E(2), and $\mathrm{Aff}_+(1,\mathfrak{R})$, which found applications in fields such as electronics, signal processing, and quantum optics. As all these groups have square-integrable representations, in a subsequent publication it would be interesting to test whether the irrep's $T^{\zeta^A\zeta_A,\zeta_3}$ of $\overline{\mathcal{P}}$ are square integrable with respect to $\mathrm{orb}(\zeta)$. This fact would allow us to work out the associated generalized coherent states, generalized wavelet transforms, and generalized Wigner functions,[23] which would surely be an invaluable mathematical tool in the context of the phase-space formulation of the quantum anomaly-free relativistic particle in $(1+1)$ dimensions.

APPENDIX: THE METHOD OF ORBITS

Before considering the Bernat–Pukanszky theory of exponential groups,[8,9] let us briefly review the standard procedure to form a unitary induced representation, since the theory of induced representations developed by Mackey[24,25] plays an essential role in the method of orbits.

Let H be a closed subgroup of a locally compact topological group with a countable basis G and U a one-dimensional unitary representation of H on the complex numbers $\mathbf{C}$. We introduce the space $L(G,H,U)$ of complex-valued measurable functions F on G that satisfy the condition $F(hg)=\Delta_{H,G}(h)^{-1/2}U(h)F(g)$, where $\Delta_{H,G}(h)=\Delta_H(h)/\Delta_G(h)$, $h\in H$, $g\in G$, and $g\mapsto\Delta_G(g)$ is the modulus of the group G.

The group G can be identified with $H\times X$, where X is the right G-space $X=H\backslash G$, since every element of $g\in G$ can be written uniquely in the form $g=hs(x)$ with $x\in X$. Under this identification, the right Haar measure on G splits into the product of a quasi-invariant measure ν_s on X, depending upon the choice of a Borel mapping s of X into G having the property that $s(Hg)\in Hg$, by the right Haar measure on H; $d\nu(g)=\Delta_{H,G}(h)d\nu_s(x)d\nu(h)$. The measure ν_s on X is G-invariant if and only if $\Delta_G(h)=\Delta_H(h)$.

The space $L(G,H,U)$ is clearly invariant under right translations on G. Let $L^2(G,H,U)$ denote the Hilbert space generated by the square-integrable functions F in $L(G,H,U)$; then, we call the unitary representation T acting by right translations upon the Hilbert space $L^2(G,H,U)$, according to $[T(g)F](g')=F(g'g)$, the representation induced in the sense of Mackey by the representation U and we will denote it by $\mathrm{ind}(G,H,U)$.

It is not difficult to see that there is an isomorphism $F\mapsto f$ of the Hilbert space $L^2(G,H,U)$ onto the Hilbert space $L^2(X,\nu_s,\mathbf{C})$, generated by the square-integrable complex functions having compact support on X with respect to the measure ν_s, which associates a function $f\in L^2(X,\nu_s,\mathbf{C})$ defined by $f(x)=F(s(x))$ with every $F\in L^2(G,H,U)$. Under this isomorphism, the induced representations in the sense of Mackey can be realized on the Hilbert space $L^2(X,\nu_s,\mathbf{C})$ through $[T(g)f](x)=\Delta_{H,G}(h)^{-1/2}U(h)f(xg)$, where the element $h\in H$ is defined from the relation $s(x)g=hs(xg)$.

Now, we can sketch the orbit method. Let G be an exponential group, $\mathfrak{g}$ its real exponential Lie algebra, and $\mathfrak{g}^*$ its dual. We say that a subalgebra $\mathfrak{h}\subset\mathfrak{g}$ is subordinate to $\zeta\in\mathfrak{g}^*$ if its first derived algebra is orthogonal to ζ, or $\langle\zeta,[\mathfrak{h},\mathfrak{h}]\rangle=0$. Denoting by $H\subset G$ the subgroup corresponding to the subalgebra $\mathfrak{h}$ subordinate to $\zeta\in\mathfrak{g}^*$, we define the unitary one-dimensional representation of H by $U(\exp X)=\exp(i\langle\zeta,X\rangle)$, which is related to the character χ of H simply by $\chi(\exp X)=U(\exp X)$, where $X\in\mathfrak{h}$.

Then a unitary induced representation $\mathrm{ind}(G,H,U)$ of G is irreducible if and only if the subalgebra $\mathfrak{h}$ subordinate to $\zeta \in \mathfrak{g}^*$ is admissible, i.e., if its dimension is maximal in the family of all subalgebras subordinate to ζ and if it satisfies Pukanszky's condition.[9] The maximality condition is equivalent to $\dim \mathfrak{h} = \dim \mathfrak{g} - \frac{1}{2}\dim \mathrm{orb}(\zeta)$, and Pukanszky's condition requires that the linear variety $\zeta + H^{\perp}$ is contained in $\mathrm{orb}(\zeta)$, where $H^{\perp}$ denotes the orthogonal complement of H in $\mathfrak{g}^*$. Bernat[8] showed that the first condition implies the second one if $\mathfrak{g}$ is quasinilpotent (i.e., all the real eigenvalues of $\mathrm{ad}(X)$ are zero, for all $X \in \mathfrak{g}$), otherwise the two conditions are independent. In particular, every nilpotent group is quasi-nilpotent.

It can be shown[26] that, for any given ζ, there is a subordinate subalgebra $\mathfrak{h}$ satisfying the two conditions above. Moreover, if $\mathfrak{h}_1$ and $\mathfrak{h}_2$ are, respectively, maximal dimension subalgebras subordinate to ζ_1 and ζ_2, further obeying Pukanszky's condition, then $\mathrm{ind}(G,H_1,U_1) = \mathrm{ind}(G,H_2,U_2)$ if and only if ζ_1 and ζ_2 belong to the same coadjoint orbit, the equal sign indicating unitary equivalence. Reciprocally, any irrep of G is representable in the form $\mathrm{ind}(G,H,U)$ by specifying $\mathfrak{h}$ and ζ appropriately, thus establishing a canonical bijection between the space $\mathcal{O}(G)$ of coadjoint orbits and the unitary dual $\hat{G}$ of any solvable exponential Lie group. It is worth mentioning that every coadjoint orbit of the connected and simply connected solvable type I Lie groups (and, in particular, of the exponential groups) is integral (i.e., satisfies the integrality condition).

Multiplicative anomaly and zeta factorization

E. Elizalde and M. Tierz

(Received 29 October 2002; accepted 15 December 2003)

Some aspects of the multiplicative anomaly of zeta determinants are investigated. A rather simple approach is adopted and, in particular, the question of zeta function factorization, together with its possible relation with the multiplicative anomaly issue is discussed. We look primordially into the zeta functions instead of the determinants themselves, as was done in previous work. That provides a supplementary view, regarding the appearance of the multiplicative anomaly. Finally, we briefly discuss determinants of zeta functions that are not in the pseudodifferential operator framework. © *2004 American Institute of Physics.*

I. INTRODUCTION

A pseudodifferential operator (ΨDO) A of order m on a manifold M_n is defined through its symbol $a(x,\xi)$, which is a function belonging to the space $S^m(\mathbf{R}^n\times\mathbf{R}^n)$ of $\mathbf{C}^\infty$ functions such that for any α, β there exists a constant $C_{\alpha,\beta}$ so that $|\partial_\xi^\alpha\partial_x^\beta a(x,\xi)|\leqslant C_{\alpha,\beta}(1+|\xi|)^{m-|\alpha|}$. The definition of A is given (in the distribution sense) by

$$Af(x)=(2\pi)^{-n}\int e^{i\langle x,\xi\rangle}a(x,\xi)\hat{f}(\xi)\,\mathrm{d}\xi, \tag{1}$$

where f is a smooth function ($f\in\mathcal{S}$) and $\hat{f}$ its Fourier transform. When $a(x,\xi)$ is a polynomial in ξ one gets a differential operator but, in general, the order m can be even complex. For A a positive–definite elliptic ΨDO of positive order $m\in\mathbf{R}$, acting on the space of smooth sections of an n-dimensional vector bundle E over a closed, n-dimensional manifold M, the zeta function is defined as

$$\zeta_A(s)=\mathrm{tr}\,A^{-s}=\sum_j \lambda_j^{-s},\quad \mathrm{Re}\,s>\frac{n}{m}\equiv s_0. \tag{2}$$

Here s_0 is called the abscissa of convergence of $\zeta_A(s)$, which is proven to have a meromorphic continuation to the whole complex plane $\mathbf{C}$ (regular at s_0), provided that A admits a spectral cut: $L_\theta=\{\lambda\in\mathbf{C};\mathrm{Arg}\,\lambda=\theta,\theta_1<\theta<\theta_2\}$, $\mathrm{Spec}\,A\cap L_\theta=\varnothing$ (the Agmon–Nirenberg condition).

The Wodzicki (or noncommutative) residue[1] is the only extension of the Dixmier trace to ΨDOs which are not in $\mathcal{L}^{(1,\infty)}$. Even more, it is the only trace one can define in the algebra of ΨDOs up to a multiplicative constant, and is given by the integral

$$\mathrm{res}\,A=\int_{S^*M}\mathrm{tr}\,a_n(x,\xi)\,\mathrm{d}\xi, \tag{3}$$

with $S^*M\subset T^*M$ the co-sphere bundle on M (some authors set a coefficient in front of the integral). If $\dim M=n=-\mathrm{ord}\,A$ (M compact Riemann, A elliptic, $n\in\mathbf{N}$) it coincides with the Dixmier trace, and one has[1]

$$\operatorname{Res}_{s=1}\zeta_A(s)=\frac{1}{n}\operatorname{res}A^{-1}. \tag{4}$$

However, the Wodzicki residue continues to make sense for ΨDOs of arbitrary order and, even if the symbols $a_j(x,\xi)$, $j<m$, are not invariant under coordinate choice, the integral in (3) is, and defines a trace. In particular, the residua of the poles of the extended definition of zeta function to operators of complex order are also given by the noncommutative residue.

It is well known that the study of zeta functions is central—at least at a basic level, the one needed in fact in usual applications to physics[2,3]—for the issue of giving a sense to the definition of determinant of a ΨDO (see Ref. 4 for the actual state of the art of this concept). This definition goes back to Ray and Singer:[5] for an operator A with spectrum $\lambda_i, i\in I$ (here I needs not be discrete, it can be a multi-index made up of parts of different nature), formally

$$\det A=\prod_{i\in I}\lambda_i=\exp\left(\sum_{i\in I}\log\lambda_i\right). \tag{5}$$

But from the definition of the zeta function

$$\zeta_A(s)=\sum_{i\in I}\lambda_i^{-s}, \tag{6}$$

it turns out that

$$\zeta_A'(0)=-\sum_{i\in I}\log\lambda_i. \tag{7}$$

It is most natural then to define (as Ray and Singer did) the determinant of A by means of the zeta function as[5]

$$\det_\zeta A\equiv\exp[-\zeta_A'(0)]. \tag{8}$$

Note that this is a *definition*, since the above manipulations are formal as long as the convergence properties of the expressions at hand are not fully specified, in accordance with the theorem at the beginning of this section. This is taken care of by the analytical continuation provided in the definition of the zeta function of A.

The definition of the determinant $\det_\zeta A$ only depends on the homotopy class of the spectral cut for A (see above). And one has the following (very useful) asymptotic expansion for the heat kernel:

$$\operatorname{tr}e^{-tA}=\sum_{\lambda\in\operatorname{Spec}A}{}'\ e^{-t\lambda}\sim\alpha_n(A)+\sum_{n\neq j\geqslant 0}\alpha_j(A)t^{-s_j}+\sum_{k\geqslant 1}\beta_k(A)t^k\ln t,\quad t\downarrow 0, \tag{9}$$

where

$$\alpha_n(A)=\zeta_A(0),\quad \alpha_j(A)=\Gamma(s_j)\operatorname{Res}_{s=s_j}\zeta_A(s),\quad s_j\notin-\mathbf{N},$$

$$\alpha_j(A)=\frac{(-1)^k}{k!}[PP\zeta_A(-k)+\psi(k+1)\operatorname{Res}_{s=-k}\zeta_A(s)],\quad s_j=-k,\ k\in\mathbf{N}, \tag{10}$$

$$\beta_k(A)=\frac{(-1)^{k+1}}{k!}\operatorname{Res}_{s=-k}\zeta_A(s),\quad k\in\mathbf{N}\backslash\{0\}.$$

This paper is organized as follows: in the next section we give a short but rather self-contained introduction to the appearance of the multiplicative anomaly[6–18] of zeta determinants. In Sec. III, we point out certain particularities of this anomaly by presenting two very different cases: On the one hand, a new and rather general condition that guarantees the absence of anomaly and, in sharp contrast, a quite particular and very simple case where the anomaly is already nonzero. Then, in Sec. IV, extending and complementing previous work on this subject,[7,8] we pay attention to the product of zeta functions rather than its associated determinants. This lead to the consideration of $\det(B\otimes C)$ instead of $\det(BC)$, with B and C two arbitrary operators. Thus, from that point of view, we are able to obtain rather simple new expressions for determinants, mainly thanks to the strong property of factorization of the zeta function. In the last section we present, in a somewhat more qualitative way, the relationship between all the previous concepts, multiplicative anomaly and zeta factorization, with the appearance of complex poles in the zeta function and other zeta functions that do not belong to the pseudodifferential operator framework. In the Appendix, due to the implementation in a regularization context, we investigate further the topic of zeta function factorization, presenting results, mainly from Number Theory, with two opposite points of view: the construction of Dirichlet L functions from multiplication of simple zeta functions on one hand, and the decomposition of a zeta function in terms of simpler factors on the other hand. This leads to some physical interpretation for the associated heat kernel that we briefly discuss.

II. APPEARANCE OF THE MULTIPLICATIVE ANOMALY

Now, it would seem clear that, if we have a product of two commuting operators,

$$\det{}_\zeta(AB)=\exp\left[\sum_{i\in I}\ \log(\lambda_i\mu_i)\right]=\exp\left[\sum_{i\in I}\ (\log\lambda_i+\log\mu_i)\right]=\exp\left[\sum_{i\in I}\ \log\lambda_i+\sum_{i\in I}\ \log\mu_i\right]$$
$$=\exp\left[\sum_{i\in I}\ \log\lambda_i\right]\exp\left[\sum_{i\in I}\ \log\mu_i\right]=\det{}_\zeta A\,\det{}_\zeta B. \tag{11}$$

But this is *not* true, and *only one* of these steps fails to be true. Below we provide some specific examples to help the reader understand where the problem is.

Actually, very much related with this is the fact that the zeta function trace

$$\mathrm{tr}_\zeta A=\sum_{i\in I}\ \lambda_i=\zeta_A(s=-1) \tag{12}$$

fails to satisfy the additive property; in general

$$\mathrm{tr}_\zeta(A+B)\neq\mathrm{tr}_\zeta A+\mathrm{tr}_\zeta B, \tag{13}$$

for, again, this is a regularized trace (involves analytical continuation) which is used with non-trace-class operators (see also Ref. 4 for the general definition of the trace).

As an example, consider the following commuting linear operators in an infinite-dimensional space, given in diagonal form by

$$A_1=\mathrm{diag}\ (1,2,3,4,\ldots),\quad A_2=\mathrm{diag}\ (1,1,1,1,\ldots), \tag{14}$$

and their sum

$$A_1+A_2=\mathrm{diag}\ (2,3,4,5,\ldots). \tag{15}$$

The corresponding ζ-traces are easily obtained,

$$\mathrm{tr}_\zeta A_1=\zeta_R(-1)=-\tfrac{1}{12},\quad \mathrm{tr}_\zeta A_2=\zeta_R(0)=-\tfrac{1}{2}, \tag{16}$$

$$\mathrm{tr}_\zeta(A_1+A_2)=\zeta_R(-1)-1=-\tfrac{13}{12},$$

ζ_R being the Riemann zeta function. The last trace has been calculated according to the rules of infinite series summation (see, e.g., Hardy[9]). We observe that

$$\mathrm{tr}_\zeta(A_1+A_2)-\mathrm{tr}_\zeta A_1-\mathrm{tr}_\zeta A_2=-\tfrac{1}{2}\neq 0. \tag{17}$$

Unlike for ordinary, finite dimensional determinants, for which we have the property: $\det(AB)=\det(A)\det(B)$, for zeta determinants one rather has to consider, in general, an additional piece (called *anomaly* or *defect*). It is usually written as

$$a(A,B)=\ln\frac{\det(AB)}{\det(A)\det(B)} \tag{18}$$

or

$$a(A,B)=\zeta_A'(0)+\zeta_B'(0)-\zeta_{AB}'(0). \tag{19}$$

Thus the anomaly $a(A,B)$ will vanish if the derivatives at $s=0$ of the respective zeta function satisfy the additive property. There is an explicit expression, due to Wodzicki, for $a(A,B)$, that simplifies enormously the calculation of the multiplicative anomaly in many cases.[1]

III. UNDERSTANDING ZETA TRACES AND ZETA DETERMINANTS

There exist many examples of simple cases with and without multiplicative anomaly.[7,8] We give now a condition that guarantees its absence. Consider the two following zeta functions:

$$\zeta_A(s)=\sum_i \lambda_i^{-s}, \tag{20}$$

$$\zeta_B(s)=\sum_i (c\lambda_i^\alpha)^{-s}=c^{-s}\zeta_A(\alpha s) \quad \text{with} \quad c,\alpha\in\mathbf{R}. \tag{21}$$

The zeta function associated with the product of the eigenvalues is

$$\zeta_{AB}(s)=\sum_i (c\lambda_i^{\alpha+1})^{-s}=c^{-s}\zeta_A((\alpha+1)s), \tag{22}$$

and thus

$$\zeta_{AB}(s)=c^{-s}\zeta_A((\alpha+1)s)\neq\zeta_A(s)+c^{-s}\zeta_A(\alpha s). \tag{23}$$

Performing the substitution $s=0$, we have that

$$\zeta_{AB}'(0)=(\alpha+1)\zeta_A'(0)=\zeta_A'(0)+\alpha\zeta_A'(0)=\zeta_A'(0)+\zeta_B'(0). \tag{24}$$

Therefore, in spite of the fact that the two zeta functions are different, their respective derivatives at zero are equal. This is enough to guarantee the absence of the multiplicative anomaly, namely $a(A,B)=0$. This is quite a general situation, since we have not fixed the λ_i at all. We have only played with the relative difference between the spectra.

A rather different thing is to consider two spectra which are related by an *additive* constant,

$$\mu_i=\lambda_i+c. \tag{25}$$

For simplicity, let us restrict our analysis to the specific example

$$\lambda_n = n, \quad \mu_n = n+1, \quad n = 1,2,3,\ldots. \tag{26}$$

Thus

$$\zeta_A(s) = \zeta_R(s), \quad \zeta_B(s) = \zeta_R(s) - 1, \tag{27}$$

while the zeta function of the product is of Epstein type:[7]

$$\zeta_A(s) = \sum_{n=1}^{\infty} (n^2+n)^{-s} = \sum_{n=1}^{\infty} \frac{\Gamma(n+s)\, 2^{-2n}}{n!\, \Gamma(s)} \zeta_H(2(n+s),3/2). \tag{28}$$

Thus

$$\zeta_A'(0) + \zeta_B'(0) = 2\zeta_R'(0) = -\ln(2\pi), \tag{29}$$

while

$$\zeta_{AB}'(0) = \sum_{n=1}^{\infty} \frac{2^{-2n}}{n} \zeta_H(2n,3/2), \tag{30}$$

which are not equal. Numerically

$$\zeta_{AB}'(0) = 0.4417, \quad \zeta_A'(0) + \zeta_B'(0) = -1.8379, \tag{31}$$

even the signs are different and the anomaly, in such a simple case, is larger in absolute value than the individual results themselves,

$$a = \zeta_A'(0) + \zeta_B'(0) - \zeta_{AB}'(0) = -2.2796. \tag{32}$$

Up to now, we have addressed and tried to explain the problem by looking carefully in the various zeta functions involved in the process. Nevertheless, we can gain a new insight into the multiplicative anomaly issue through consideration of the factorizability properties of the corresponding zeta functions, an analysis important by itself in, e.g., number theory.

IV. ZETA FUNCTION FACTORIZATIONS AND THE MULTIPLICATIVE ANOMALY

As explained, the main practical consequence about the existence of the multiplicative anomaly is that, if, e.g., we want to compute

$$\det A = \det(BC), \tag{33}$$

from the (in principle simpler) determinants $\det B$ and $\det C$, we have to take also into account $a(A,B)$. This is specially important when different factorizations of A, say $A = BC$ and $A = B'C'$, are alternatively considered.[8] We begin by introducing the associated zeta functions that we would use in the computation of the factor determinants,

$$\zeta_B(s) = \sum_i \lambda_i^{-s}, \tag{34}$$

$$\zeta_C(s) = \sum_j \mu_j^{-s}. \tag{35}$$

But, instead of applying the usual and direct procedure as before, here we shall deal with the product of these two zeta functions,

$$\zeta_D(s)=\zeta_B(s)\zeta_C(s)=\sum_i \lambda_i^{-s}\sum_j \mu_j^{-s}. \tag{36}$$

Note that this is the zeta function of an operator, D, which is different from the previous A. Actually, $D=B\otimes C$, as is immediate to realize. In fact, from

$$\zeta_{B\otimes C}(s)=\sum_{i,j}(\lambda_i\mu_j)^{-s}=\sum_i \lambda_i^{-s}\sum_j \mu_j^{-s}, \quad \mathrm{Re}\, s>\max\{\alpha,\beta\}, \tag{37}$$

being α, β, the abscissas of convergence of the individual series, and owing to the uniqueness of the asymptotic continuation to the rest of the complex plane, it turns out that

$$\zeta_{B\otimes C}(s)=\zeta_B(s)\zeta_C(s). \tag{38}$$

In particular,

$$\zeta_{B\otimes C}(s=-1)=\zeta_B(s=-1)\zeta_C(s=-1), \tag{39}$$

that is

$$\mathrm{tr}_\zeta(B\otimes C)=\mathrm{tr}_\zeta B\,\mathrm{tr}_\zeta C, \tag{40}$$

which extends the corresponding property known to hold in finite dimensions.

Now, consider the respective determinants. Recall, to begin with, that in the finite case we have

$$\det(B\otimes C)=(\det B)^{\dim C}(\det C)^{\dim B}, \tag{41}$$

where the dimensions refer to the spaces where the respective operators act. We will now prove that this equation is maintained in the infinite dimensional situation (we will drop the ζ label from the determinants, from now on). In fact, we have [recall that $\zeta_B(0)$ is the zeta *regularized dimension* of the space in which B acts, and the same for the rest]:

$$\det B=\exp[-\zeta_B'(0)], \quad \det C=\exp[-\zeta_C'(0)], \tag{42}$$

$$\det D=\exp[-\zeta_D'(0)]=\exp[-\zeta_B'(0)\zeta_C(0)-\zeta_B(0)\zeta_C'(0)], \tag{43}$$

and we thus see, that

$$\det(D)=(\det B)^{\zeta_C(0)}(\det C)^{\zeta_B(0)}. \tag{44}$$

In the particular case when $\zeta_B(s)$ and $\zeta_C(s)$ have the same value at zero (the two operators act on a space of the same dimension),[10] $\zeta_B(0)=\zeta_C(0)\equiv\tilde{\zeta}(0)$, we get

$$\det(D)=(\det B\det C)^{\tilde{\zeta}(0)}. \tag{45}$$

We have thus shown that the computation of $\det B\det C$ is, in a way, as close to that of $\det(B\otimes C)$ as it is to that of $\det(BC)$, provided when both operators act on the same space and can be multiplied. In fact, the determinant of their tensor product is given in terms of the product of the determinants of the individual operators by introducing the regularized dimension of the space where they act. Formally, it is a kind of exponential anomaly. But notice that this is actually no anomaly, since the exponent is constant (e.g., it does not depend on the particular operators B and C chosen) and it is always equal to the regularized dimension of the space (as it should). When $\zeta_B(0)=\zeta_C(0)=\tilde{\zeta}(0)$, let us compare in more detail the two expressions: the one for the multiplicative anomaly

$$\det(BC)=\det B\,\det C\,e^{a(B,C)}, \tag{46}$$

with the other for the exponential anomaly, thus

$$\exp(a(B,C))=\frac{\det(BC)}{\det B\,\det C}=\frac{\det A}{(\det D)^{1/\zeta(0)}}. \tag{47}$$

This equation seems somewhat artificial, no wonder since it links two nondirectly related quantities, as explained above. It can nevertheless be useful in practical determinations of the multiplicative anomaly.

Some consequences and examples: In general, if one is dealing with factorizations of the type

$$\zeta_A(s)=\prod_i \zeta_{A_i}(s), \tag{48}$$

the determinants are related as $\det A=\Pi_i(\det A_i)^{\Pi_{j\neq i}\zeta_j(0)}$. This can be useful for the computation of determinants of multidimensional zeta functions, once its factorization is known. For a general m-dimensional zeta function, we can write its factorization as $\zeta(s)=\Pi_i^m \zeta_i^{d_i}(s)$ where d_i specifies the dimension of the zeta function, with $m=\Sigma_i d_i$.

A number of different examples can be worked out. For instance, if the zeta functions factors are zero at the origin, then the associated multidimensional determinant is one. This is what happens, for example, for the product of harmonic oscillators,

$$\prod_{n_1=0}^{\infty}\cdots\prod_{n_k=0}^{\infty}\left(n_1+\frac{1}{2}\right)\cdots\left(n_k+\frac{1}{2}\right)=1. \tag{49}$$

Actually, with little more effort a more general case can be considered,

$$\lambda_{n_1\cdots n_k}=(n_1+c_1)\cdots(n_k+c_k),\quad n_1,\ldots,n_k=0,1,2,3,\ldots. \tag{50}$$

Here

$$\zeta(s)=\prod_{j=1}^{k}\zeta_j(s),\quad \zeta_j(s)\equiv\zeta_H(s,c_j). \tag{51}$$

Recalling that

$$\zeta_H(0,c_j)=\tfrac{1}{2}-c_j,\quad \zeta_H'(0,c_j)=\ln\Gamma(c_j)-\tfrac{1}{2}\ln(2\pi), \tag{52}$$

we get

$$\det A=\prod_{j=1}^{k}\det(A_j)^{\Pi_{i\neq j}\zeta_H(0,c_j)}=\prod_{j=1}^{k}\left(\frac{\sqrt{2\pi}}{\Gamma(c_j)}\right)^{\Pi_{i\neq j}(1/2-c_i)}, \tag{53}$$

which reduces to the expression above, Eq. (49), in the particular example considered. This is a nice result of the regularization method.

A second example is the case of a multiple factorization, $\zeta^{(N)}(s)=\Pi_{i=1}^{N}\zeta_i(s)$, in which at least one of the zeta functions evaluated at the origin is zero [without losing generality let us choose $\zeta_1(0)=0$]. Then, the determinant associated with $\zeta^{(N)}(s)$ is just

$$(e^{-\zeta_1'(0)})^{\Pi_{i=2}^{\infty}\zeta_i(0)}, \tag{54}$$

that is, the determinant of the zeta function which is zero at the origin, exponentiated with the product of the other zeta functions at zero. Different situations of this type could be discussed.

V. BEYOND ΨDOs: THE CASE OF COMPLEX POLES

In this concluding section, we want to comment on the appearance, in some important situations, of complex poles, and on its relationship with the multiplicative anomaly and with factorizations. We begin by paying some attention to the anomaly free case (20) and (21) studied in Sec. III. This case corresponds to two commuting operators, for which there is a simple expression for the multiplicative anomaly, due to Wodzicki,[1]

$$a(A,B)=\frac{\operatorname{res}[(\ln(A^bB^{-a}))^2]}{2ab(a+b)}, \tag{55}$$

where $a>0$ and $b>0$ are the orders of A and B, respectively.

In spite of the generality of (20) and (21), it is clear that this is not the most general case inside the class of commuting operators. To begin with, the fact that one is a function of the other is a sufficient but not a necessary condition for the commutation of the operators (think of the operators involved in the quantum mechanics of the hydrogen atom, for example). In addition, one may also argue that a more general function than $\mu_n=f(\lambda_n)=c\lambda_n^{\alpha}$ may be considered as well. For example, an exponential function $f(\lambda_n)=\exp(\lambda_n)$. It can be readily seen that with such a choice we are outside the realm of pseudodifferential operators. For instance, just with $\lambda_n=n$, then $\mu_n=\exp(n)$, and then the associated zeta function is a geometric series:

$$\zeta_B(s)=\sum_{n=1}^{\infty} e^{-ns}=\frac{1}{(e^s-1)}, \tag{56}$$

giving rise to infinitely many complex poles. Nevertheless, this spectra is indeed physical, as shown in Ref. 11, and related to q deformations[11] and to fractal geometry[12] as well. Thus, it is also rather reasonable to expect that associated regularized expressions (such as determinants) may be of physical interest as well. In principle, one can proceed identically—depending on the precise meromorphic structure of the corresponding zeta function—with the formal definition. Likewise, note that the case (20) and (21), not only holds for $\alpha\in\mathbf{R}$, but also for $\alpha\in\mathbf{C}$, as can be readily seen from (22)–(24). Therefore, it is still anomaly free but notice that a complex α introduces complex poles (just as a simple example, consider $\mu_n=n$, then the complex α rotates the pole at $s=1$ to $s=\alpha^{-1}$).

There are other circumstances where we are outside the pseudodifferential operator framework, but there is still interest in the short time asymptotics of the heat kernel or in zeta determinants. This is exactly the case, for instance, when considering heat kernels in noncommutative spaces[13] and when studying products of prime numbers,[14] respectively. Indeed, the zeta function associated to the prime numbers is known,[15]

$$\mathcal{P}(s)=\sum_p p^{-s}=\sum_{n=1}^{\infty}\frac{\mu(n)}{n}\log\zeta(ns), \tag{57}$$

where p are the prime numbers and $\mu(n)$ is the Möbius function. Note that this function has a rich pattern of logarithmic singularities in the complex plane but still the associated *determinant* is of interest and actually follows directly from the derivative of $\mathcal{P}(s)$.[14] Additionally, in this type of regularized products, one can look at multiplicative anomalies as well. For example, following Ref. 14 one can consider the Euler product representation of Riemann's zeta function,

$$\zeta(s)=\frac{\prod_p p^s}{\prod_p p^s-1}, \quad \operatorname{Re}s>1. \tag{58}$$

This expression, considered together with $\mathcal{P}(s)$, gives rise to the following result:[14]

$$\prod_p (p-1)=0 \quad \text{and} \quad \prod_p (p^2-1)=48\pi^2, \tag{59}$$

and the appearance of a multiplicative anomaly is manifest.

One of the author's (E.E.) investigation has been partially supported by DGI/SGPI (Spain), project BFM2000-0810, and by CIRIT (Generalitat de Catalunya), Contract No. 2001SGR-00427. M.T. is indebted to Michel Lapidus for many useful and interesting discussions on zeta functions, and also for warm hospitality at University of California at Riverside.

APPENDIX: REMARKS ON ZETA FACTORIZATIONS

We have seen how the discussion of the multiplicative anomaly of determinants, has lead us, in a natural way, to the construction of a zeta function from the product of other zeta functions. Generically, and following the previous notation, let us envisage

$$\zeta_D(s)=\zeta_B(s)\zeta_C(s)=\sum_i \lambda_i^{-s}\sum_j \mu_j^{-s}. \tag{A1}$$

This turns out to be an important construction in number theory. Actually, even with the simplest zeta functions as factors, important and sophisticated $\zeta_D(s)$ are obtained. For example, with the Riemann zeta function itself. In fact, from the Euler product of the Riemann zeta function, we know that it has local factors of degree 1 at each prime, while automorphic L functions have local factors of degree 2 at almost all places.[16] This suggests that we can denote such product as

$$L(s)=\zeta_R(s)\zeta_R(s-k+1), \tag{A2}$$

with $k\geqslant 2$. In Ref. 16 it is shown that the L function is actually

$$L(s)=\sum_{n=1}^{\infty} \sigma_{k-1}(n)n^{-s}, \tag{A3}$$

where σ_k is the arithmetic function (the generalized divisor function, or some over all the divisor of n to some power), given by

$$\sigma_k(n)=\sum_{d|n} d^k. \tag{A4}$$

This appears naturally in the Chowla–Selberg formula and its generalizations.[7]

This shows, in close relationship with the preceding section, how the product of even the simplest of the zeta functions lead to an interesting object by the process considered above, often with important arithmetic properties (and some of these L functions are useful in analytical approaches to the study of algorithms[17,18]). Even more, in general, increasingly complex L functions are very often constructed or represented by a generic product of simpler L functions.[16]

Nevertheless, it seems apparent that instead of exploiting the useful idea of constructing zeta functions, it may also be worth to look at this relation from the other side, that is, as a decomposition of the zeta function on the l.h.s. into several factors. To illustrate the approach for zeta functions, let us just take into account the two simple examples considered in detail in Ref. 19. The zeta function

$$\zeta(s)=\sum_{m,n\in\mathbf{Z}^2}{}' \ (m^2+n^2)^{-s}, \tag{A5}$$

with the summation extended over all pairs $(m,n)\neq(0,0)$ in $\mathbf{Z}^2$, can be expressed as

$$\zeta(s)=4\zeta_R(s)\cdot L(\chi_4,s). \tag{A6}$$

where $\zeta_R(s)$ is the Riemann zeta function and $L(\chi_4,s)$ is the Dirichlet zeta function corresponding to the character χ_4. Another interesting factorization is the following one, for a different particular case of the two-dimensional Epstein zeta function:

$$\zeta(s)=\sum_{m,n\in\mathbf{Z}^2}{}' \ (m^2+mn+n^2)^{-s}=6\zeta_R(s)\cdot L(\chi_3,s). \tag{A7}$$

Once again, we see the natural appearance of L functions, whose determinants are of much interest as well (mainly in a number theoretical context; see Ref. 20 for a review).

These factorizations are particular cases of a more general situation coming from algebraic considerations in number theory.[16] Very general statements are not always possible, but let us compare the previous with the classical results (due to Dirichlet) concerning primitive quadratic forms of any determinant,

$$Q(x)=ax_1^2+bx_1x_2+cx_2^2, \quad (a,b,c)=1 \tag{A8}$$

(the parentheses meaning here maximum common divisor), with $D=-\det Q=b^2-4ac<0$ (the discriminant of Q), and

$$\chi_D(d)=\left(\frac{D}{d}\right). \tag{A9}$$

Then, for $n>0$, $(n,D)=1$, the character sum

$$r(n;D)=\omega_D\sum_{d|n}\chi_D(d) \tag{A10}$$

gives the number of all representations of n by representatives of forms of all classes of discriminant D. Here ω_D stands for the number of automorphs,

$$\omega_D=\begin{cases}6 & \text{if } D=-3,\\ 4 & \text{if } D=-4,\\ 2 & \text{if } D<-4.\end{cases} \tag{A11}$$

Notice how the discriminant gives the right character for the L function and the number of automorphs the right prefactor in the previous example of factorization. Nevertheless, we must point out that these previous examples and the posterior discussion looks so simple, due to the fact that the examples correspond to discriminants D for which the class number $h(D)$ (the number of equivalence classes of primitive binary quadratic forms) is one.

Factorization at the level of the heat kernels: Now, we pay attention to the meaning of the zeta factorization at the level of the respective associated heat kernels. Since A^{-s} and $\exp(-tA)$ are related by the following expression:

$$A^{-s}=\frac{1}{\Gamma(s)}\int_0^\infty t^{s-1}\exp(-tA)\mathrm{d}t, \tag{A12}$$

then the zeta function is, up to a gamma function, the Mellin transform of the heat kernel. The interest of this expression, considered together with the factorization property, is that it allows, in a probabilistic context, the product of random variables to be directly performed in Mellin space (in contrast to the better known case of the addition of variables, where Fourier transform is used).[21] Therefore, the zeta factorization implies also a product for the respective heat kernels, but a product in the sense of probability theory, that is, the heat kernel (or in a number theoretical context, the theta function) denotes the probability distribution function of a random variable X_i, and then we have the product $X=\Pi_{i=1}^{n}X_i$. Nevertheless, for this to be exactly correct we should take into account the gamma function for each factor and for the resulting zeta function. For example, in the case of a zeta function with two factors:

$$\zeta(s)=\zeta_1(s)\zeta_2(s)\rightarrow\Gamma(s)\Gamma(s)\zeta(s)=\Gamma(s)\zeta_1(s)\Gamma(s)\zeta_2(s)\rightarrow K(t)\cdot\exp(-t)=K_1(t)\cdot K_2(t), \tag{A13}$$

where, in the last expressions, the products are in the sense explained above, and we have used the fact that $\Gamma(s)=\int_0^\infty t^{s-1}\exp(-t)\mathrm{d}t$. Thus, the necessary introduction of gamma factors implies that we have to take into account possible products of the main heat kernel with an exponential distribution.

This stochastic point of view seems both interesting from the mathematical point of view, where a probabilistic interpretation of zeta and theta functions is of interest,[22] and also from a physical point of view, where products of random variables very often constitute a role model of what is known with the name of multiplicative or cascade processes.[23]

Last but not least, the factorization is potentially interesting from the practical point of view in the asymptotic study of the trace of the heat kernel (9) and (10). The contributions can be considered separately, with the exception of the possible coincidence of poles or poles and zeros. This fact introduces interesting phenomena that can be seen with the following example. Consider the product of two Riemann zeta functions,

$$\zeta(s)=\zeta_R(s)\zeta_R(s), \tag{A14}$$

which yield the well-known L function,

$$\zeta(s)=L(s)=\sum_{k=1}^{\infty}\frac{d(k)}{k^s}, \tag{A15}$$

with $d(k)$ the divisor function again. Note the consistency with the previous case (A2)–(A4). The idea is now to construct another zeta function from two very similar factors,

$$\zeta_\varepsilon(s)=\zeta_R(s(1+\varepsilon))\zeta_R(s(1-\varepsilon)), \tag{A16}$$

with $\varepsilon>0$ a very small, real positive number. It seems that these two zeta functions should be almost identical in the whole complex plane, except for the fact that, in the first one, we have a double pole at $s=1$, while the second has two simple poles at $s=(1+\varepsilon)^{-1}$ and $s=(1-\varepsilon)^{-1}$, very close one from the other for ε small. Note that the pointlike structure of a pole allows to play that game. Now, from (9) and (10), it is clear how different the $t\rightarrow 0$ expansion of the associated trace of the heat kernel is, in the two cases. In the first case, we have

$$\mathrm{tr}\,e^{-tA_1}\sim-\frac{\log t}{t},\quad t\downarrow 0, \tag{A17}$$

in sharp contrast with the second case, where

$$\mathrm{tr}\,e^{-tA_2}\sim\Gamma\left(\frac{1}{1+\varepsilon}\right)t^{-[1/(1+\varepsilon)]}+\Gamma\left(\frac{1}{1-\varepsilon}\right)t^{-[1/(1-\varepsilon)]},\quad t\downarrow 0. \tag{A18}$$

We see that the case where the poles collide possesses a partition function which is much bigger the smaller the value of t is (the classical limit). Therefore, the associated partition functions differ considerably in the classical limit. A deeper physical understanding of this phenomena seems to be an interesting open question.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 45, NUMBER 3 MARCH 2004

On the Clebsch–Gordan problem for SU(1,1): Coupling nonstandard representations

Christopher C. Gerry
Department of Physics and Astronomy, Lehman College, City University of New York, Bronx, New York 10468-1589

(Received 14 June 2003; accepted 25 November 2003)

The Clebsch–Gordan coefficients coupling two unitary, irreducible, positive discrete series representations of SU(1,1), are constructed. In contrast to the Clebsch–Gordan coefficients obtained a long time ago by Holman and Biedenharn [Ann. Phys. (N.Y.) **39**, 1 (1966)], the derived coefficients are valid even when coupling nonstandard representations such as those for which the corresponding Bargmann indices k may be $k=\frac{1}{4}$ and/or $\frac{3}{4}$, values associated with the ''two-photon'' realization of the su(1,1) Lie algebra, the corresponding representations covering the even and odd number states, respectively, of the single-mode boson system. These nonstandard cases are actually representations associated with the covering group $\overline{\mathrm{SU}}(1,1)$. The results are extended to the coupling of three positive discrete series and the corresponding SU(1,1) Racah coefficients are obtained. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1643542]

I. INTRODUCTION

The Lie group SU(1,1) and its associated Lie algebra su(1,1) plays a prominent role in many areas of quantum mechanics. The Lie algebra su(1,1), and those to which it is isomorphic, $\mathrm{su}(1,1)\sim\mathrm{so}(2,1)\sim\mathrm{sp}(2,\mathrm{R})\sim\mathrm{sl}(2,\mathrm{R})$,[1] are known to be spectrum generating algebras (the corresponding Lie groups being spectrum generating groups) for a number of systems, among them being: the harmonic oscillator,[2] the radial part of the Coulomb and the two and three-dimensional harmonic oscillator problems,[3] the singular oscillator,[2,4] the Morse oscillator,[5] and superfluid helium.[6] Beyond its role in generating spectra, it serves as a dynamical group for certain Hamiltonians of importance in quantum optics. Specifically, the single and double boson mode realizations of the su(1,1) Lie algebra appear in the Hamiltonians for nonlinear interactions that generate the single- and two-mode vacuum states.[7] The states generated from the vacuum are specific types of SU(1,1) coherent states and they are associated with specific representations.

There has recently been some interest, particularly in the context of quantum optics, in the coherent states obtained by coupling together different discrete representations of SU(1,1). These are coherent states associated with the representations of the direct product group $\mathrm{SU}(1,1)\otimes\mathrm{SU}(1,1)$ which is locally isomorphic to SO(2,2) much in the same way as $\mathrm{SU}(2)\otimes\mathrm{SU}(2)$ is locally isomorphic to SO(4).[8] There are many realizations of the corresponding Lie algebra su(1,1) which in turn determine the allowed positive discrete unitary irreducible representations (UIRs) which we denote as $\mathcal{D}_k^+$, where k is the Bargmann index[9] and where $k>0$. For what we shall call the *standard* UIRs of the positive discrete series one has $k=\frac{1}{2},1,\frac{3}{2},\ldots$. To couple different representations and obtain the states of the direct product representation $\mathcal{D}_{k_1}^+\otimes\mathcal{D}_{k_2}^+$, we need the SU(1,1) Clebsch–Gordan coefficients (CGCs). The CCGs for the coupling $\mathrm{SU}(2)\otimes\mathrm{SU}(2)$ are, of course, the familiar coefficients of angular momentum theory. For the higher dimensional groups such as SU(3), de Swart[10] worked out a rather general scheme that can work for any irreducible representation of any Lie algebra. For SU(1,1) the CCGs were derived many years ago by a number of authors, at least for coupling two standard representations.[11] The realization of the su(1,1) Lie algebra in terms of bilinear products of two sets of bose operators is associated with the standard UIRs. Bambah and Agarwal[12] studied the four-mode coherent states of the

Barut–Girardello-type[13] obtained by coupling together two two-mode realizations of the Lie algebra su(1,1), i.e., coherent states of the Lie algebra $su(1,1)\oplus su(1,1)$, or, equivalently, of the direct product group $SU(1,1)\otimes SU(1,1)$, by making use of the tabulated SU(1,1) CGCs as given in Ref. 11. This works well because the relevant representations being coupled are the standard ones. (It is the standard representations that are relevant to the radial Coulomb and harmonic oscillator problems[3] and the superfluid helium problem.[13]) But the representations associated with the single-mode realizations, sometimes known as the ''two-photon'' algebra, are nonstandard in that the Bargmann index is required to take the values $k=\frac{1}{4},\frac{3}{4}$. These representations are actually those associated with representations of the covering group $\overline{SU(1,1)}$ for which any $k\geqslant 0$ is allowed. (The representations associated with the realizations for the singular oscillator[2,4] and the Morse oscillator[5] are also those of the covering group.) In attempting to couple these nonstandard representations, this author and Benmoussa[14] found that the tabulated SU(1,1) CG coefficients gave nonsensical results (see Appendix). Part of the problem may be that many of these older papers adopt a notation for the state labels identical to that used in the case of su(2), the algebra of angular momentum. That notation tends to obscure important differences between the representations of SU(2) and SU(1,1), quite apart from the fact that for the latter, the unitary representations are all infinite dimensional. We say a little more on this below and in the Appendix. In any case, we rederived the relevant SU(1,1) CGCs in such a manner that allows the coupling of both the standard and nonstandard representations. As in the familiar case of SU(2), one can obtain a recursion relation for the SU(1,1) CGCs.[11] But the method we adopted in Ref. 14 seems to be different than any of the previous methods used and therefore we believe it is worthwhile to elaborate on it apart from any specific application. The idea is to first construct a proper ''ground'' state in the coupled representation by first solving a simple recursion relation analytically. The ''excited'' states are then determined by the application of the coupled raising operator an arbitrary number of times on this ground state, along with the use of the binomial expansion. It is straightforward to extend the procedure to the coupling of three representations of SU(1,1) and to obtain the SU(1,1) Racah coefficients. We believe that the methods used here have the virtue of relative simplicity.

The paper is organized as follows: We first review, in Sec. II, the su(1,1) Lie algebra and relevant positive discrete UIRs. In Sec. III we couple two discrete series and derive the SU(1,1) Clebsch–Gordan coefficients. In Sec. IV we use the results of Sec. III to couple three discrete series and obtain the SU(1,1) Racah coefficients. Section V contains some concluding remarks. As mentioned above, an Appendix is included to illustrate what goes wrong with the tabulated SU(1,1) CGCs when attempting to couple nonstandard representations.

II. REVIEW OF SU(1,1) POSITIVE DISCRETE SERIES REPRESENTATIONS

The su(1,1) Lie algebra consists of the operators K_0, $K_\pm$, satisfying the commutation relations

$$[K_0,K_\pm]=\pm K_\pm,\quad [K_+,K_-]=-2K_0. \tag{1}$$

The operator K_0 generates compact (circular) SU(1,1) transformations, whereas the combinations $K_1=(K_++K_-)/2$ and $K_2=(K_+-K_-)/2i$ generate noncompact (hyperbolic) SU(1,1) transformations. The Casimir operator

$$\mathcal{C}=K_0^2-\tfrac{1}{2}(K_+K_-+K_-K_+) \tag{2}$$

commutes with all the elements of the Lie algebra. The relevant unitary irreducible representations (UIRs) are the positive discrete series $\mathcal{D}_k^+$, whose bases, which are eigenstates of K_0 and $\mathcal{C}$, we denote as $|k,m\rangle$, where k is the so-called Bargmann index taking on the values $k=\frac{1}{2},1,\frac{3}{2},2,\ldots$, and where $m=0,1,2,\ldots,\infty$. These states satisfy the relations

$$K_0|k,m\rangle=(m+k)|k,m\rangle, \tag{3}$$

$$\mathcal{C}|k,m\rangle = k(k-1)|k,m\rangle, \tag{4}$$

$$K_+|k,m\rangle = [(m+1)(m+2k)]^{1/2}|k,m+1\rangle, \tag{5}$$

$$K_-|k,m\rangle = [m(m+2k-1)]^{1/2}|k,m-1\rangle. \tag{6}$$

The states $|k,m\rangle$ may be generated from the "ground" state $|k,0\rangle$ according to

$$|k,m\rangle = \left[\frac{\Gamma(2k)}{m!\Gamma(2k+m)}\right]^{1/2}(K_+)^m|k,0\rangle. \tag{7}$$

We avoid the use of the alternative, pseudoangular mometum labeling of the states, $|j,n\rangle$, frequently encountered in the literature,[11,12] where the eigenvalue of $\mathcal{C}$ is now $j(j+1)$ and that of K_0 is n, where $n=-j,-j+1,-j+2,\ldots$. [We use n instead of m to avoid confusion with our labels adopted for the SU(1,1) bases.] The allowed values of j for the standard unitary irreducible representations are $j=-\frac{1}{2},-1,-\frac{3}{2},\ldots$. The CGCs derived in the $|j,n\rangle$ notation are, at best, confusing to use in coupling nonstandard representations, and, as said above, lead to nonsensical results (as discussed in the Appendix) owing to the peculiar fractional nature of j and of n required for these representations. But the notation $|k,m\rangle$ is convenient because m is *always* a positive integer or zero and the Bargmann index k contains the fractional part of the spectrum of K_0. This turns out to be of an advantage in deriving the Clebsch–Gordan coefficients in what follows.

Before proceeding to that, we briefly give examples of realizations of su(1,1) with standard and nonstandard UIRs. The first we consider is the Schwinger-type[15] two-boson realization given as

$$K_0=\tfrac{1}{2}(a^+a+b^+b+1)\ K_+=a^+b^+,\ K_-=ab, \tag{8}$$

where the operators a and b are the bose operators of the two independent modes. The Casimir operator for this realization can be written as

$$\mathcal{C}=\tfrac{1}{4}(\Delta^2-1), \tag{9}$$

where the operator $\Delta=a^+a-b^+b$ is just the difference between the number of particles in the two modes. With the eigenvalue of Δ denoted by q where q is an integer, the Bargmann index is given by $k=(1+|q|)/2$, where $|q|$ is the degeneracy parameter and $|q|=0,1,2,\ldots$. Thus we have $k=\frac{1}{2},1,\frac{3}{2},\ldots$, so we have the standard UIRs. Assuming that the a mode has q more particles than the b mode, the number states of the two modes, $|n_a\rangle\otimes|n_b\rangle=|n_a,n_b\rangle$, organize themselves into $\mathcal{D}_k^+$ representations of su(1,1) given by $|k,m\rangle=|n+q,n\rangle$, $n=0,1,2,\ldots,\infty$, k is given above and from Eqs. (3) and (8) we have $m=n$.

An example of a realization leading to nonstandard UIRs is[3]

$$K_0=\tfrac{1}{2}(a^\dagger a+\tfrac{1}{2}),\ K_+=\tfrac{1}{2}a^{\dagger 2},\ K_-=\tfrac{1}{2}a^2, \tag{10}$$

where a and $a^\dagger$ are Bose operators. The Casimir operator for this realization takes on the value $\mathcal{C}=-3/16$ meaning that the allowed values of the Bargmann index are restricted to $k=1/4$ and $k=3/4$, values clearly not included within the standard series of discrete UIRs. The correspondence between the usual number states of a harmonic oscillator, $|n\rangle$, and the SU(1,1) basis states $|k,m\rangle$ from Eq. (10) is $|n\rangle\Leftrightarrow|k,m\rangle$ for $n=2(m+k)-1/2$. Note that for $k=\frac{1}{4}$ we have $n=0,2,4,\ldots$, while for $k=\frac{3}{4}$ $n=1,3,5,\ldots$. Thus the Hilbert space $\mathcal{H}$ of the single boson mode is split into even and odd subspaces corresponding to the respective UIRs: $\mathcal{H}=\mathcal{D}_{1/4}^+\oplus\mathcal{D}_{3/4}^+$.

There is one other application of the su(1,1) Lie algebra, not related to the realization given in Eq. (10), but for which one may have $k=\frac{1}{4}$ (mod 1) or $\frac{3}{4}$ (mod 1) whose corresponding represen-

tations describe bosons and fermions, respectively, and which for general k describes particles with fractional statistics, e.g., anyons.[16] These representations, along with those for the "two-photon" algebra, are representations of the covering group $\overline{\mathrm{SU}}(1,1)$.

III. COUPLING TWO POSITIVE DISCRETE SERIES REPRESENTATIONS

Now suppose we have two sets of su(1,1) operators that we denote (1) and (2), i.e., $K_{0,\pm}^{(i)}$, $i=1,2$ such that

$$[K_0^{(i)},K_\pm^{(j)}]=\pm K_\pm^{(i)}\delta_{i,j},\ [K_+^{(i)},K_-^{(j)}]=-2K_0^{(i)}\delta_{i,j}. \tag{11}$$

We then define the operators

$$K_0:=K_0^{(1)}+K_0^{(2)},\ K_+:=_+^{(1)}+K_+^{(2)},\ K_-:=K_-^{(1)}+K_-^{(2)}, \tag{12}$$

which, of course, also satisfy the su(1,1) Lie algebra and generate the direct product group $\mathrm{SU}(1,1)\otimes\mathrm{SU}(1,1)$. Each of these algebras has its respective Casimir operator of the form of Eq. (2). Denoting the Bargmann indices of the representations relevant to the realizations of these two algebras as k_1 and k_2, the representations to be coupled we denote as $\mathcal{D}_{k_1}^+:\{|k_1,m_1\rangle\}$ and $\mathcal{D}_{k_2}^+:\{|k_2,m_2\rangle\}$. The basis of the coupled representation we denote as $|K,M;k_1,k_2\rangle$, which we may sometimes abbreviate as $|K,M\rangle$. The eigenvalue of K_0 is $M+K$ and that of the Casimir operator is $K(K-1)$; that is, the coupled states satisfy Eqs. (3)–(6) with the replacements $k\to K$ and $m\to M$. The Kronecker product of the two positive discrete series reduces to a sum over positive discrete series according to the Clebsch–Gordan decomposition

$$\mathcal{D}_{k_1}^+\otimes\mathcal{D}_{k_2}^+=\sum_{K=k_1+k_2}^{\infty}\mathcal{D}_K^+, \tag{13}$$

where the sum proceeds in integer steps. That is, the allowed values of K are $K=k_1+k_2+l$, where $l=0,1,2,...,\infty$.

We now write the basis of the $\mathrm{SU}(1,1)\otimes\mathrm{SU}(1,1)$ states as

$$|K,M;k_1,k_2\rangle=\sum_{m_1,m_2}C(k_1,k_2,K;m_1,m_2,M)|k_1,m_1\rangle|k_2,m_2\rangle, \tag{14}$$

where the numbers $C(k_1,k_2,K;m_1,m_2,M)$ are the SU(1,1) CG coefficients. We first consider the ground state of the coupled representation where $M=0$:

$$|K,0;k_1,k_2\rangle=\sum_{m_1,m_2}C_{m_1,m_2}|k_1,m_1\rangle|k_2,m_2\rangle, \tag{15}$$

where for the moment, and for convenience, we have set $C(k_1,k_2,K;m_1,m_2,0)=C_{m_1,m_2}$. Acting on the state of Eq. (15) with the operator K_- gives us, since we have a ground state,

$$K_-|K,0;k_1,k_2\rangle=0=\sum C_{m_1,m_2}(K_-^{(1)}+K_-^{(2)})|k_1,m_1\rangle|k_2,m_2\rangle \tag{16}$$

or, using Eq. (6), equivalently,

$$\begin{aligned}0=\sum_{m_1,m_2}C_{m_1,m_2}\{&[m_1(m_1+2k_1-1)]^{1/2}|k_1,m_1-1\rangle|k_2,m_2\rangle\\&+[m_2(m_2+2k_2-1)]^{1/2}|k_1,m_1\rangle|k_2,m_2-1\rangle\}.\end{aligned} \tag{17}$$

This last expression we may rewrite as

$$\sum_{m_1,m_2}\{C_{m_1+1,m_2}[(m_1+1)(m_1+2k_1)]^{1/2}+C_{m_1,m_2+1}[(m_2+1)(m_2+2k_2)]^{1/2}\}|k_1,m_1\rangle|k_2,m_2\rangle=0, \tag{18}$$

from which follows the recursion relation

$$C_{m_1+1,m_2}=-C_{m_1,m_2+1}\left[\frac{(m_2+1)(m_2+2k_2)}{(m_1+1)(m_1+2k_1)}\right]^{1/2}. \tag{19}$$

It is evident that only those states are coupled for which $m_1+m_2=\text{const}$. Setting $m_1+m_2=l$, $l=0,1,2,...,\infty$, the recursion relation can be solved to yield

$$C_{q,l-q}=(-1)^q\left[\binom{l}{q}\frac{\Gamma(2k_1)\Gamma(2k_2+l)}{\Gamma(2k_1+q)\Gamma(2k_2+l-q)}\right]^{1/2}C_{0,l}, \tag{20}$$

where $C_{0,l}$ is from normalization

$$C_{0,l}=\left[\sum_{r=0}^{l}\binom{l}{r}\frac{\Gamma(2k_1)\Gamma(2k_2+l)}{\Gamma(2k_1+r)\Gamma(2k_2+l-q)}\right]^{-1/2}. \tag{21}$$

Thus our ground state may now be written as

$$|K,0;k_1,k_2\rangle=\sum_{q=0}^{l}C(k_1,k_2,K;q,l-q,0)|k_1,q\rangle|k_2,l-q\rangle, \tag{22}$$

where $C(k_1,k_2,K;q,l-q,0)=C_{q,l-q}$. Applying the operator $K_0=K_0^{(1)}+K_0^{(2)}$ to this last equation, it is easy to show that the allowed values of K and hence the allowed representations of $SU(1,1)\otimes SU(1,1)$, are given by $K=k_1+k_2+l$, $l=0,1,2,...,\infty$. The result in Eq. (22) is the proper ''ground'' state for the coupling of any two positive discrete UIRs of SU(1,1).

To obtain the states for $M>0$, the ''excited'' states, we now apply to Eq. (22) the raising operator K_+ of Eq. (3.3b) M times. But we first, make use of Eq. (7) and rewrite Eq. (22) as

$$|K,0,k_1,k_2\rangle=\sum_{q=o}^{l}C(k_1,k_2,K;q,l-q,0)\left[\frac{\Gamma(2k_1)\Gamma(2k_2)}{q!(l-q)!\Gamma(2k_1+q)\Gamma(2k_2+l-q)}\right]^{1/2}$$
$$\times(K_+^{(1)})^q(K_+^{(2)})^{l-q}|k_1,0\rangle|k_2,0\rangle. \tag{23}$$

Now, writing

$$K_+^M=(K_+^{(1)}+K_+^{(2)})^M=\sum_{p=0}^{M}\binom{M}{p}(K_+^{(1)})^p(K_+^{(2)})^{M-p}, \tag{24}$$

applying it to Eq. (23), and making multiple uses of Eq. (7), we obtain

$$|K,M;k_1,k_2\rangle=\left[\frac{\Gamma(2K)}{M!\Gamma(2K+M)}\right]^{1/2}\sum_{q=0}^{l}\sum_{p=0}^{M}C(k_1,k_2,K;q,l-q,0)$$
$$\times\left[\frac{(p+q)!(l+M-p-q)!\Gamma(2k_1+p+q)\Gamma(2k_2+l+M-p-q)}{q!(l-q)!\Gamma(2k_1+q)\Gamma(2k_2+l-q)}\right]^{1/2}$$
$$\times|k_1,p+q\rangle|k_2,l+M-p-q\rangle. \tag{25}$$

Note that there is degeneracy with respect to p and q and therefore we need to collect the coefficients of identical $p+q$. We may then write our state as

$$|K,M;k_1,k_2\rangle=\sum_{m_1=0}^{l+M} C(k_1,k_2,K;m_1,l+M-m_1)|k_1,m_1\rangle|k_2,l+M-m_1\rangle, \tag{26}$$

where

$$C(k_1,k_2,K;m_1,l+M-m_1)$$

$$=\sum_{q=0}^{l}\sum_{p=0}^{M}\delta(m_1,p+q)(-1)^q\frac{1}{q!(l-q)!\Gamma(2k_1+q)\Gamma(2k_2+l-q)}$$

$$\times\left\{\frac{l!\Gamma(2K)\Gamma(2k_1)\Gamma(2k_2+l)(p+q)!(l+M-p-q)!\Gamma(2k_1+p+q)\Gamma(2k_2+l+M-p-q)}{M!\Gamma(2K+M)}\right\}^{1/2}$$

$$\times\left[\sum_{r=0}^{l}\binom{l}{r}\frac{\Gamma(2k_1)\Gamma(2k_2+l)}{\Gamma(2k_1+r)\Gamma(2k_2+l-r)}\right]^{-1/2}, \tag{27}$$

and where, of course, it is understood that $K=k_1+k_2+l$. Note that we have dropped the redundant M by setting

$$C(k_1,k_2,K;m_1,l+M-m_1)\equiv C(k_1,k_2,K;m_1,l+M-m_1,M). \tag{28}$$

Finally we can write our coupled state in the ''standard'' form

$$|K,M;k_1,k_2\rangle=\sum_{m_1=0}^{l+M}\sum_{m_2=0}^{\infty} C(k_1,k_2,K;m_1,m_2,M)|k_1,m_1\rangle|k_2,m_2\rangle, \tag{29}$$

where the SU(1,1) CGCs are now

$$C(k_1,k_2,K;m_1,m_2,M)=\delta(m_2,l+M-m_1)C(k_1,k_2,K;m_1,l+M-m_1). \tag{30}$$

The key to the method we used here in deriving the CGCs is the separation of the integer and fractional parts of the spectrum of the K_0 operators, natural in the notation $|k,m\rangle$, as this allows for simple binomial expansions of the form of Eq. (24), i.e., in finite sums.

Because the CGCs are elements of a unitary transformation they must satisfy the orthogonality condition:

$$\begin{aligned}\delta_{K'K}\delta_{M'M}&=\langle K',M';k_1,k_2|K,M;k_1,k_2\rangle\\&=\sum_{m_1}\sum_{m_1'} C(k_1,k_2,K';m_1',l'+M'-m_1')C(k_1,k_2,K;m_1,l+M-m_1)\\&\quad\times\delta_{m_1'm_1}\delta_{l'+M',l+M}\\&=\sum_{m_1} C(k_1,k_2,K';m_1,l'+M'-m_1)C(k_1,k_2,K;m_1,l+M-m_1)\times\delta_{l'+M',l+M}.\end{aligned} \tag{31}$$

The left-hand side vanishes unless $M'=M$ and since $K=k_1+k_2+l$ and $K'=k_1+k_2+l'$ the condition that $l'=l$ implies that $K'=K$. Thus we can write the orthogonality relation as

$$\sum_{m_1=0}^{K-k_1-k_2+M} C(k_1,k_2,K';m_1,K'-k_1-k_2+M-m_1)$$
$$\times C(k_1,k_2,K;m_1,K-k_1-k_2+M-m_1)=\delta_{K'K}. \tag{32}$$

We now list some results from coupling nonstandard representations. We consider only those representations associated with the realization of the ''two-photon'' algebra given in Eq. (10). For $k_1=\frac{1}{4}=k_2$ and for $l=0$ we have

$$|K=\tfrac{1}{2},M=0;\tfrac{1}{4},\tfrac{1}{4}\rangle=|\tfrac{1}{4},0\rangle_1|\tfrac{1}{4},0\rangle_2=|0\rangle_1|0\rangle_2,$$

$$|K=\tfrac{1}{2},M=1;\tfrac{1}{4},\tfrac{1}{4}\rangle=\frac{1}{\sqrt{2}}(|\tfrac{1}{4},1\rangle_1|\tfrac{1}{4},0\rangle_2+|\tfrac{1}{4},0\rangle_1|\tfrac{1}{4},1\rangle_2)=\frac{1}{\sqrt{2}}(|2\rangle_1|0\rangle_2+|0\rangle_1|2\rangle_2),$$

$$\begin{aligned}|K=\tfrac{1}{2},M=2;\tfrac{1}{4},\tfrac{1}{4}\rangle&=\sqrt{\tfrac{3}{8}}(|\tfrac{1}{4},2\rangle_1|\tfrac{1}{4},0\rangle_2+|\tfrac{1}{4},0\rangle_1|\tfrac{1}{4},2\rangle_2)+\tfrac{1}{2}|\tfrac{1}{4},1\rangle_1|\tfrac{1}{4},1\rangle_2\\&=\sqrt{\tfrac{3}{8}}(|4\rangle_1|0\rangle_2+|0\rangle_1|4\rangle_2)+\tfrac{1}{2}|2\rangle_1|2\rangle_2,\end{aligned} \tag{33}$$

the first three states in the coupled representation. For the upper part of the right-hand side we have used the notation $|k_i,m_i\rangle_i$, where the k_i and m_i have been replaced by their numerical values, and for the lower part we have used the oscillator number states as given by the equivalence $|n\rangle_i\Leftrightarrow|k_i,m_i\rangle$ with $n=2(m_i+k_i)-1/2$.

The sequence of states in Eq. (33) is already physically relevant. It is equivalent to the sequence of states

$$|\psi_{2N}\rangle=\left(\frac{1}{2}\right)^N\sum_{p=0}^{N}\left[\binom{2p}{p}\binom{2N-2p}{N-p}\right]^{1/2}|2p\rangle_1|2N-2p\rangle_2, \tag{34}$$

where number states are used on the right-hand side. These states are known as the arcsine states[17] as the associated joint photon number probabilities for finding $2p$ photons in mode 1 and $2N-2p$ photons in mode 2 form the distribution known in probability theory as the fixed-multiplicative arcsine law of order N.[18] In fact, for the case of two-mode light fields, the states $|\psi_{2N}\rangle$ will be generated by a 50:50 beamsplitter with twin input Fock states of the form $|N\rangle_1|N\rangle_2$. That is, $(|N\rangle_1|N\rangle_2)_{\text{in}}\overset{\text{BS}}{\rightarrow}|\psi_{2N}\rangle_{\text{out}}$.[17] The input twin Fock state, actually a superposition of twin Fock states, can be generate from a down-conversion process with initial vacuum states in these modes.[19] The superposition produced is just the two-mode squeezed vacuum state. The state $|\psi_2\rangle=|K=\frac{1}{2},M=1;\frac{1}{4},\frac{1}{4}\rangle$ was observed many years ago in a well known experiment performed by Hong *et al.*[20] In another, more recent experiment, Ou *et al.*[21] have observed the state $|\psi_4\rangle=|K=\frac{1}{2},M=2;\frac{1}{4},\frac{1}{4}\rangle$. Furthermore, these states may have a practical application in ultrahigh resolution interferometry.[22,23]

For $k_1=\frac{1}{4}=k_2$, but now with $l=1$ such that $K=\frac{3}{2}$, we have the sequence of states

$$|K=\tfrac{3}{2},M=0;\tfrac{1}{4},\tfrac{1}{4}\rangle=\frac{1}{\sqrt{2}}(|\tfrac{1}{4},0\rangle_1|\tfrac{1}{4},1\rangle_2-|\tfrac{1}{4},1\rangle_1|\tfrac{1}{4},0\rangle_2)=\frac{1}{\sqrt{2}}(|0\rangle_1|2\rangle_2-|2\rangle_1|0\rangle_2),$$

$$|K=\tfrac{3}{2},M=1;\tfrac{1}{4},\tfrac{1}{4}\rangle=\frac{1}{\sqrt{2}}(|\tfrac{1}{4},0\rangle_1|\tfrac{1}{4},2\rangle_2-|\tfrac{1}{4},2\rangle_1|\tfrac{1}{4},0\rangle_2)=\frac{1}{\sqrt{2}}(|0\rangle_1|4\rangle_2-|4\rangle_1|0\rangle_2),$$

$$|K=\tfrac{3}{2},M=2;\tfrac{1}{4},\tfrac{1}{4}\rangle=\frac{1}{\sqrt{32}}(|\tfrac{1}{4},1\rangle_1|\tfrac{1}{4},2\rangle_2-|\tfrac{1}{4},2\rangle_1|\tfrac{1}{4},1\rangle_2)+\sqrt{\frac{15}{32}}(|\tfrac{1}{4},0\rangle_1|\tfrac{1}{4},3\rangle_2-|\tfrac{1}{4},3\rangle_1|\tfrac{1}{4},0\rangle_2)$$

$$=\frac{1}{\sqrt{32}}(|2\rangle_1|4\rangle_2-|4\rangle_1|2\rangle_2)+\sqrt{\frac{15}{32}}(|0\rangle_1|6\rangle_2-|6\rangle_1|0\rangle_2). \tag{35}$$

Notice that in these two examples, only even number states appear. Had we coupled representations for $k_1=k_2=\frac{3}{4}$, only odd states would have appeared.

As a final example, we consider the case for $k_1=\frac{1}{4}$ and $k_2=\frac{3}{4}$ and for $l=0$:

$$|K=1,M=0;\tfrac{1}{4},\tfrac{3}{4}\rangle=|\tfrac{1}{4},0\rangle_1|\tfrac{3}{4},0\rangle_2=|0\rangle_1|1\rangle_2,$$

$$|K=1,M=1;\tfrac{1}{4},\tfrac{3}{4}\rangle=\tfrac{1}{2}(|\tfrac{1}{4},1\rangle_1|\tfrac{3}{4},0\rangle_2+\sqrt{3}|\tfrac{1}{4},0\rangle_1|\tfrac{3}{4},1\rangle_2)=\tfrac{1}{2}(|2\rangle_1|1\rangle_2+\sqrt{3}|0\rangle_1|3\rangle_2),$$

$$|K=1,M=2;\tfrac{1}{4},\tfrac{3}{4}\rangle=\frac{1}{2\sqrt{2}}|\tfrac{1}{4},2\rangle_1|\tfrac{3}{4},0\rangle_2+\tfrac{1}{2}|\tfrac{1}{4},1\rangle_1|\tfrac{3}{4},1\rangle_2+\tfrac{1}{2}\sqrt{\frac{5}{2}}|\tfrac{1}{4},0\rangle_1|\tfrac{3}{4},2\rangle_2$$

$$=\frac{1}{2\sqrt{2}}|4\rangle_1|1\rangle_2+\tfrac{1}{2}|2\rangle_1|3\rangle_2+\tfrac{1}{2}\sqrt{\frac{5}{2}}|0\rangle_1|5\rangle_2,$$

$$\vdots, \tag{36}$$

where, of course, we notice the presence of both even and odd states and that the first in the product states is always even and the second odd.

Coherent states of the Perelomov[4] and Barut-Girardello[13] types based on these coupled states, and possible generation methods, have been discussed elsewhere.[14,24]

IV. COUPLING THREE POSITIVE DISCRETE SERIES

For the sake of completeness, we extend our considerations to the coupling of three SU(1,1) positive discrete series bases, i.e., the coupling $\mathcal{D}^+_{k_1}\otimes\mathcal{D}^+_{k_2}\otimes\mathcal{D}^+_{k_3}$. We first consider the grouping $(\mathcal{D}^+_{k_1}\otimes\mathcal{D}^+_{k_2})\otimes\mathcal{D}^+_{k_3}$. Denoting $k'=k_1+k_2+l$ and, using our previous result of Eq. (26) with an obvious change in the notation, we have

$$|k',m'\rangle\equiv|k',m';k_1,k_2\rangle=\sum_{m_1=0}^{l+m'}C(k_1,k_2,K;m_1,l+m'-m_1)|k_1,m_1\rangle|k_2,l+m'-m_1\rangle. \tag{37}$$

Then, coupling to the third basis we have

$$|K,M;k',k_3\rangle=\sum_{m'=0}^{l+M}C(k',k_3,K;m',L+M-m')|k',m'\rangle|k_3,l+M-m'\rangle, \tag{38}$$

where $K=k'+k_3+L=k_1+k_2+k_3+l+L$. Upon substituting Eq. (37) into Eq. (38) we have

$$|K,M;k',k_3\rangle=\sum_{m'=0}^{l+M}\sum_{m_1=0}^{l+m'}C(k_1,k_2,K;m_1,l+m'-m_1)C(k',k_3,K;m',L+M-m')$$
$$\times|k_1,m_1\rangle|k_2,l+m'-m_1\rangle|k_3,l+M-m'\rangle. \tag{39}$$

For the grouping $\mathcal{D}^+_{k_1}\otimes(\mathcal{D}^+_{k_2}\otimes\mathcal{D}^+_{k_3})$ we first have

$$|k'',m''\rangle \equiv |k'',m'';k_2,k_3\rangle = \sum_{m_2=0}^{l+m''} C(k_2,k_3,k'';m_2,l+m'-m_2)|k_2,m_2\rangle|k_3,l+m''-m_2\rangle, \tag{40}$$

where $k''=k_2+k_3+l'$. Then

$$|K,M;k'',k_1\rangle = \sum_{m''=0}^{L'+M} C(k'',k_1,K;m'',L'+M-m'')|k'',m''\rangle|k_1,L'+M-m''\rangle, \tag{41}$$

and substituting Eq. (40) into Eq. (41) we obtain

$$\begin{aligned}|K,M;k'',k_1\rangle = \sum_{m''=0}^{L'+M}\sum_{m_2=0}^{l+m''} & C(k_2,k_3,k'';m_2,l+m'-m_2)C(k'',k_1,K;m'',L'+M-m'') \\ & \times|k_1,L'+M-m''\rangle|k_2,m_2\rangle|k_3,l+m''-m_2\rangle,\end{aligned} \tag{42}$$

where now $K=k_1+k''+L'=k_1+k_2+k_3+l'+L'$. Evidently, we must require that $l+L=l'+L'$ as we must have the same value of K for either coupling scheme. The coupled bases must be related to each other by a unitary transformation of the form

$$|K,M;k',k_3\rangle = \sum_{k''} U(k'',k')|K,M;k_1,k''\rangle. \tag{43}$$

Following the standard procedures as used in the case of SU(2) (angular momentum),[25] it can be shown that

$$\begin{aligned}U(k'',k') = \sum_{\mu_1}\sum_{\mu_2} & C(k_1,k_2,k';\mu_1,\mu_2)C(k',k_3,K;\mu_1+\mu_2-l,\mu_3) \\ & \times C(k_2,k_3,k'';\mu_2,\mu_3)C(k_1,k',K;\mu_1,\mu_2+\mu_3-l').\end{aligned} \tag{44}$$

One can then define the SU(1,1) Racah coefficient W in the standard way according to

$$W(k_1,k_2,K,k_3;k',k'') = [(2k'+1)(2k''+1)]^{-1/2}U(k'',k'). \tag{45}$$

V. CONCLUSIONS

In this paper we have obtained Clebsch–Gordan coefficients allowing for the coupling of two unitary irreducible positive discrete series representations of SU(1,1) where one or both may be nonstandard, e.g., with Bargmann index $k=\frac{1}{4},\frac{3}{4}$, associated with the ''two-photon'' algebra, or of any case where the Bargmann index is not of the standard values $k=\frac{1}{2},1,\frac{3}{2},\ldots$. We have followed this by coupling three representations and have obtained the SU(1,1) Racah coefficients allowing for the transformation between different orders of couplings.

Possible applications, to be considered elsewhere, are to the coupling of, say, three single-mode (two-photon) representations. Such states, and the corresponding coherent states, might be of interest in quantum optics for three mode fields or in the three-dimensional motion of a trapped ion. Other possibilities, such as the coupling of the ''two-photon'' SU(1,1) states with the two-mode SU(1,1) states, are evident and are under investigation. Beyond applications in quantum optics, applications to the problem of coupling states of other systems associated with representations of SU(1,1), such as the case of the singular oscillator[2,4] also of anyons,[16] may be of interest and will be discussed elsewhere.

APPENDIX: WHEN GOOD CLEBSCH–GORDAN COEFFICIENTS GO BAD

In the work of Holman and Biedenharn,[11] the su(1,1) bases are labeled using angular momentumlike states $|j,n\rangle$ (we are using n as before) such that

$$K_0|j,n\rangle = n|j,n\rangle,\ C|j,n\rangle = j(j+1)|j,n\rangle, \tag{A1}$$

where, by comparison with Eqs. (3) and (4), $n=-j,-j+1,-j+2,...$ and $j=-k$. The coupled states of two UIRs are given by the relation

$$|J,N;j_1,j_2\rangle = \sum_{n_1=-j_1} C^{j_1,j_2,J}_{n_1,N-n_1,N}|j_1,n_1\rangle|j_2,N-n_1\rangle, \tag{A2}$$

where $J=j_1+j_2-s$, $s=0,1,2,...$, and the CG coefficients $C^{j_1,j_2,J}_{n_1,N-n_1,N}$ are given explicitly in the Appendix of Ref. 12. We consider the ''ground state'' of the representation coupled for which $s=0$ and $N=-j_1-j_2$. The corresponding CGCs are given by[11]

$$C^{j_1,j_2,J}_{-j_1,j_1-J,-J} = (-1)^{J-j_1-j_2}\sqrt{-2J-1}\left[\frac{(j_1-j_2-J-1)!(-j_1-j_2-J-2)}{(-2j_1-1)!(-2J-1)!}\right]^{1/2}. \tag{A3}$$

For the case of coupling two standard representations, say for $k_1=-j_1=\frac{1}{2}=k_2=-j_2$ the coupled state is just $|J=-1,M=1\rangle = |j_1=-\frac{1}{2},n_1=\frac{1}{2}\rangle|j_2=-\frac{1}{2},n_2=\frac{1}{2}\rangle$ and the corresponding CGC is unity as is easy to check. But for the case when coupling the nonstandard representations, say, for $k_1=-j_1=\frac{1}{4}=k_2=-j_2$ and for $s=0$ such that $J=-1/2$ we obtain

$$C^{-\frac{1}{4},-\frac{1}{4},-\frac{1}{2}}_{\frac{1}{4},\frac{1}{4},\frac{1}{2}} = \sqrt{0}\left[\frac{\left(-\frac{1}{2}!\right)(-1)!}{\left(-\frac{1}{2}!\right)0!}\right]^{1/2} = \sqrt{\pm\infty\cdot 0}, \tag{A4}$$

a nonsensical result. Further, as displayed in Holman and Biedenharn[11] the CGCs $C^{j_1,j_2,J}_{n_1,n_2,N}$ are all proportional to $C^{j_1,j_2,J}_{-j_1,j_2-J,-J}$ thus rendering all coefficients suspect for the coupling of nonstandard representations within this scheme. In contrast, the coefficients derived above are well behaved for the case in question. For $k_1=\frac{1}{4}=k_2$, with $l=0$ we have $K=\frac{1}{2}$. Then, from Eqs. (20)–(22) we have

$$|K=\tfrac{1}{2},M=0,k_1=\tfrac{1}{4},k_2=\tfrac{1}{4}\rangle = |k_1=\tfrac{1}{4},q=0\rangle|k_2=\tfrac{1}{4},l-q=0\rangle, \tag{A5}$$

where we have, from Eq. (21), $C_{0,0}=1$ as it should. Thus there is no difficulty in coupling the nonstandard cases and getting sensible results within the approach taken in this paper.

Singularity confinement and algebraic integrability

S. Lafortune[a] and A. Goriely[b]
Department of Mathematics, University of Arizona, Tucson, Arizona 85721-0089

(Received 11 October 2003; accepted 12 November 2003)

Two important notions of integrability for discrete mappings, algebraic integrability and singularity confinement, have been used for discrete mappings. Algebraic integrability is related to the existence of sufficiently many conserved quantities and singularity confinement is associated with the local analysis of singularities. In this article, the relationship between these two notions is explored for birational autonomous mappings. The main result of this article is that algebraically integrable mappings are shown to have the singularity confinement property. Using this result, the proof of the nonexistence of algebraic conserved quantities for a class of discrete systems is given. © *2004 American Institute of Physics.*

I. INTRODUCTION

One of the first notions of integrability was introduced by Liouville in the 19th century for Hamiltonian systems in classical mechanics. This type of integrability is based on quantities whose values do not change in time, the so-called *constants of the motion* or *first integrals*. For instance, in many mechanical systems the total energy and the linear and angular momenta are conserved through the dynamics and are examples of such constants. Liouville's fundamental contribution was to prove that if a given Hamiltonian systems admits enough first integrals, it can be solved explicitly by quadratures. More precisely, a $2n$-dimensional Hamiltonian system is said to be *Liouville-integrable* if it admits n functionally independent first integrals in involution (that is their Poisson brackets commute) and such systems can be integrated by quadrature and enjoy a particularly simple topology (the flow lives on products of tori and cylinders). For systems of n first-order ordinary differential equations (ODEs) *algebraic integrability* is defined as the existence $(n-1)$ functionally independent first integrals that are algebraic functions of the dependent variables. The existence of such first integrals is important for integrability as they can be used to reduce the dimensionality of the system.

In the particular case of Hamiltonian systems with more than one degree of freedom, algebraic integrability corresponds to the notion of superintegrability (see Refs. 6, 7, and 16 and references therein). For a $2n$-dimensional Hamiltonian system with $n>1$, the $2n-1$ first integrals needed for the property of algebraic integrability are more than the n ones needed for complete Liouville–Arnold integrability.

A different notion of integrability was introduced by Painlevé in the beginning of the 20th century.[8,25] Although Painlevé's goal was not to define a notion of integrability but rather to build new functions, his property is today widely used for the detection of integrable systems. An ODE is said to possess the *Painlevé property*[1,9,21] if its general solution is single-valued in its maximal domain of analytic continuation. The restrictions the Painlevé property impose on the solutions are so strong that an ODE exhibiting it may be considered for all practical purposes integrable. Many formal links between the Painlevé property and other notions of integrability have been established (see, for example, Refs. 9 and 10). Despite the fact that there is no general algorithmic way to obtain sufficient conditions for a given ODE to have the Painlevé property, necessary conditions can be derived. The algorithmic procedure to obtain such conditions is known as the *Painlevé test*

[a]Electronic mail: lafortus@math.arizona.edu
[b]Electronic mail: goriely@math.arizona.edu

or singularity analysis and is based on a local analysis of the solutions around movable isolated singularities.

The notions of algebraic integrability and singularity analysis of the solutions can be extended to finite difference equations. One of the most effective ways to perform singularity analysis in this context is given by *singularity confinement*[5,10–15,17,27–29] which, like the Painlevé test for ODEs, imposes conditions on the singularities of the solutions. Although there exist many striking particular examples which indicate that singularity confinement is closely related to other notions of integrability, there is no clear-cut result which establishes this relationship in a formal and general framework. This article explores the relationship between the notion of algebraic integrability and the property of singularity confinement in discrete mappings.

In the case of systems of ODEs, Yoshida[9,32,33] proved that the degree of a rational first integral is closely related to some exponents that can be obtained through the application of the Painlevé test. In this article, we establish an equivalent result for discrete systems by showing that singularity confinement analysis provides necessary conditions for the existence of an algebraic first integral. Moreover, a lower bound on the degree of rational first integrals can be obtained.

The rest of this article is organized as follows. In Sec. II, we define the notion of singularity and singularity confinement for birational autonomous discrete dynamical systems. In Sec. III, we study the local consequences of the existence of an algebraic first integral on the confinement of the singularities in the two-dimensional case. In Sec. IV, we extend the results of Sec. III to arbitrary dimensions. Applications are discussed in Sec. V.

II. FORMULATION OF THE PROBLEM

In this section we introduce and illustrate the notion of singularity confinement by considering a particular class of two-dimensional autonomous dynamical systems. These examples are used to motivate a formal definition valid in arbitrary dimensions.

Throughout the article the following notation will be used: If $\mathbf{g}$ is an analytic function from $\mathbb{C}^p$ to $\mathbb{C}^r$, then $D\mathbf{g}(\mathbf{x})$ is its *Jacobian* matrix evaluated at $\mathbf{x}\in\mathbb{C}^p$. When $p=r$, the *Jacobian* is denoted by $\det(D\mathbf{g}(\mathbf{x}))$. If f is a complex-valued rational function on $\mathbb{C}^p$, then $\mathrm{num}(f)$ and $\mathrm{den}(f)$ respectively denote the numerator and denominator of f.

A. Simple examples

The basic idea of singularity confinement is to consider the properties of solutions close to some singularities. To illustrate this concept, consider the class of two-dimensional complex dynamical systems of the form

$$\begin{pmatrix} x_{n+1} \\ y_{n+1} \end{pmatrix} = \mathbf{f}(x_n, y_n) = \begin{pmatrix} g(x_n, y_n) \\ x_n \end{pmatrix}, \tag{2.1}$$

where g is a complex-valued rational function on $\mathbb{C}^2$,

$$g(x,y) = \frac{p(x,y)}{q(x,y)},$$

and p, q are relatively prime polynomials. Two types of singularities can be distinguished for such systems. The singularities of *first type* are the roots of q in $\mathbb{C}^2$, that is, the values (x,y) at which the vector field $\mathbf{f}(x,y)$ in (2.1) has a singularity. The singularities of *second type* are the points where the Jacobian of $\mathbf{f}$ is zero (this type of singularity was first considered in Ref. 12). As an example, consider the following discrete dynamical system:

$$\begin{pmatrix} x_{n+1} \\ y_{n+1} \end{pmatrix} = \mathbf{f}(x_n, y_n) = \begin{pmatrix} -x_n - y_n + a + \dfrac{b}{x_n} \\ x_n \end{pmatrix}, \tag{2.2}$$

where a and b are complex numbers. The analysis is performed for generic values of the parameters a and b. Clearly the right-hand-side of (2.2) presents a singularity if $x_n=0$. To study this singularity we study the behavior of nearby solutions by introducing a small complex perturbation ϵ, with $|\epsilon|>0$. We then set y_0 to be any complex number and $x_0=\epsilon$. The iterates x_p and y_p are then determined for any positive nonzero integer p by the discrete dynamical system (2.2). After one iteration, we have

$$x_1=\frac{b}{\epsilon}+a-y_0+\mathcal{O}(\epsilon). \tag{2.3}$$

In the limit $\epsilon\to 0$, $|x_1|\to\infty$ and, using (2.2) again,

$$x_2=-\frac{b}{\epsilon}+y_0+\mathcal{O}(\epsilon), \tag{2.4}$$

$$x_3=-\epsilon+\mathcal{O}(\epsilon^2). \tag{2.5}$$

The limit $\epsilon\to 0$ of the next iterate x_4 is well defined and given by y_0. Despite the fact that the function $\mathbf{f}$ defined by (2.2) is not well defined on any point of $\mathbb{C}^2$ of the form $(0,y)$, the limit $(x,y)\to(0,y)$ of $\mathbf{f}^4(x,y)$ exists and is given by

$$\lim_{(x,y)\to(0,y)}\mathbf{f}^4(x,y)=\begin{pmatrix} y \\ 0 \end{pmatrix}. \tag{2.6}$$

Moreover, since the value of the limit (2.6) depends on y, the same limit applied on the Jacobian of $\mathbf{f}^4$ is nonzero. The singularity is thus ''confined'' between the iterates 0 and 4 and does not propagate further. This property of confinement is very particular and we show in this article that it is closely related to the existence of a first integral for the system. A first integral for a discrete dynamical system of the form (2.1) is defined to be an analytic nonconstant complex-valued function I defined almost everywhere on $\mathbb{C}^2$ which is preserved by $\mathbf{f}$, that is

$$I(\mathbf{f}(\mathbf{x}))=I(\mathbf{x}), \tag{2.7}$$

for every $\mathbf{x}\in\mathbb{C}^2$ for which (2.7) makes sense. It is important to note that if $\mathbf{f}$ is not defined at a point $\mathbf{x}^*$ where I is well-defined, then the value of I at $\mathbf{x}^*$ is still preserved under $\mathbf{f}$ in the limit sense, i.e.,

$$\lim_{\mathbf{x}\to\mathbf{x}^*} I(\mathbf{f}(\mathbf{x}))=I(\mathbf{x}^*). \tag{2.8}$$

This is a consequence of the fact that $\mathbf{f}$ and I are continuous and defined almost everywhere in $\mathbb{C}^2$. In the particular case of system (2.2), one can check that the following polynomial,

$$I(x,y)=xy(x+y-a)-b(x+y), \tag{2.9}$$

is a first integral. Moreover, following (2.8), the first integral I is preserved in the limit sense through the iterations of the singularity of (2.2). That is,

$$-by=I(0,y)=\lim_{(x,y)\to(0,y)} I(\mathbf{f}^i(x,y)), \quad i=1,2,3,4. \tag{2.10}$$

Note that most integrable systems studied in this article are particular cases of the so-called QRT-family of mappings.[15,26]

The confinement property for the solutions of (2.1) does not hold in general. Although there is no formal result establishing how rare this confinement property might be, the fact that it does not hold for most systems of the form (2.1) has been well established in the literature.[11,13,14,27–29]

The following system is an example where singularities are not confined:

$$\begin{pmatrix} x_{n+1} \\ y_{n+1} \end{pmatrix} = \mathbf{f}(x_n, y_n) = \begin{pmatrix} -x_n - y_n + a + \dfrac{b}{x_n^3} \\ x_n \end{pmatrix}. \tag{2.11}$$

Consider the singularity $(x^*, y^*) = (0, y)$ and, as before, introduce $x_0 = \epsilon$ and $y_0 \in \mathbb{C}$ nonvanishing. The next iterates are $x_1 = b/\epsilon^3 + (a - y_0) - \epsilon$, $x_2 = -b/\epsilon^3 + y_0 + \mathcal{O}(\epsilon^5)$, and $x_3 = \epsilon + \mathcal{O}(\epsilon^5)$. Further, we find that, unlike the previous example, the appropriate cancellations allowing for confinement do not occur and the next iterates are also diverging at $\epsilon = 0$, $x_4 = 2b/\epsilon^3 + (a - y_0) - \epsilon + \mathcal{O}(\epsilon^5)$, and $x_5 = -2b/\epsilon^3 + y_0 + \mathcal{O}(\epsilon^5)$. In general, the sequence of limits $\epsilon \to 0$ of the $|x_p|$ for $p > 0$ repeats the formal triplet $(\infty, \infty, 0)$ indefinitely. This assertion is proven by induction based on the equality

$$\mathbf{f}^3 \begin{pmatrix} -nb/\epsilon^3 + y_0 + \mathcal{O}(\epsilon^5) \\ nb/\epsilon^3 + (a - y_0) - \epsilon + \mathcal{O}(\epsilon^5) \end{pmatrix} = \begin{pmatrix} -(n+1)b/\epsilon^3 + y_0 + \mathcal{O}(\epsilon^5) \\ (n+1)b/\epsilon^3 + (a - y_0) - \epsilon + \mathcal{O}(\epsilon^5) \end{pmatrix} \tag{2.12}$$

for any positive integer n. Therefore, the singularity is not confined. It is generally believed that systems which lack the confinement property will not be integrable. However, there is no definite result attached to this belief. We prove in the next sections that the analysis of the dynamics near the singularities can be used to conclude that (2.11) does not admit an algebraic first integral.

The following example illustrates the occurrence of the second type of singularity. Consider

$$\begin{pmatrix} x_{n+1} \\ y_{n+1} \end{pmatrix} = \mathbf{f}(x_n, y_n) = \begin{pmatrix} \dfrac{x_n - 1}{y_n} + 2x_n \\ x_n \end{pmatrix}. \tag{2.13}$$

At first sight, the point $(x_n, 0)$ seems to be the only singularity. However, the Jacobian of $\mathbf{f}$ in (2.13) vanishes whenever $x_n = 1$. If $x_0 = 1$ and $y_0 \neq 0$, the next iterate as determined by (2.13) is given by $x_1 = 2$. We then have $x_2 = 5$, $x_3 = 12$. It is not difficult to see that x_i grows with respect to i, and that all iterates of $(1, y_0)$ under (2.13) with $y_0 \neq 0$ are independent of y_0. The singularity here only appears in the inverse of the Jacobian matrix and is not confined.

In the light of the previous examples, we can define the confinement property for singularities of discrete dynamical systems of the form (2.1). A general definition will be given in the next section. A *singularity* of the dynamical system (2.1) is defined to be any point (x^*, y^*) in $\mathbb{C}^2$ at which the right-hand-side of (2.1) is undefined or at which the Jacobian of $\mathbf{f}$ is zero. A singularity (x^*, y^*) is said to be *confined* if there exists a positive integer N such that both limits

$$\lim_{(x,y)\to(x^*,y^*)} \mathbf{f}^N(x,y), \qquad \lim_{(x,y)\to(x^*,y^*)} \det(\mathrm{D}\mathbf{f}^N(x,y)) \tag{2.14}$$

exist and the second limit is nonzero. The smallest number N having this property is referred to as the *confinement number*, that is the number of steps necessary for confinement.

The next example illustrates the case when a singularity of the second type is confined,

$$\begin{pmatrix} x_{n+1} \\ y_{n+1} \end{pmatrix} = \mathbf{f}(x_n, y_n) = \begin{pmatrix} \dfrac{(x_n - 1/a)(x_n - a)}{y_n (x_n - b)(x_n - 1/b)} \\ x_n \end{pmatrix}, \tag{2.15}$$

where a and b are two nonzero distinct complex numbers which are also both distinct from $1/a$ and $1/b$. The right-hand-side (RHS) of (2.15) presents a singularity of the second type if $x_n=a$ because the Jacobian of $\mathbf{f}$ vanishes. If $x_0=a$ and $y_0\neq 0$, the next iterate as determined by (2.15) will be $x_1=0$; then $x_2=1/a$ and x_3 takes an indeterminate form 0/0. Again, we introduce a small complex perturbation ϵ, $|\epsilon|>0$, then set $x_0=\epsilon$ to find that when $\epsilon\to 0$,

$$x_3\to y_0+a-\frac{1}{a}, \tag{2.16}$$

and we conclude that the singularity is confined. The dynamical system (2.15) has singularity of the first type if $x_n=b$. Applying the same procedure as before with a perturbation ϵ, one finds that the limit $\epsilon\to 0$ of $|x_1|$, x_2 and x_3 gives, respectively, ∞, $1/b$ and $by_0/(b+y_0(1-b^2))$. Thus, any singularity of the form (b,y_0) with $y_0\neq b/(b^2-1)$ is confined in three steps. System (2.15) admits the following rational first integral:

$$I(x,y)=\left(b+\frac{1}{b}\right)(x+y)+\left(a+\frac{1}{a}\right)\left(\frac{1}{x}+\frac{1}{y}\right)-\frac{(1+x^2)(1+y^2)}{xy}. \tag{2.17}$$

The following example shows that the existence of a first integral does not imply that all singularities are confined. The system

$$\begin{pmatrix} x_{n+1}\\ y_{n+1}\end{pmatrix}=\mathbf{f}(x_n,y_n)=\begin{pmatrix} x_n^2/y_n\\ x_n\end{pmatrix} \tag{2.18}$$

has the following first integral:

$$I(x,y)=\frac{xy}{x^2+y^2}. \tag{2.19}$$

The RHS of (2.18) has a pole of order 1 at any point of $\mathbb{C}^2$ of the form $(x,0)$ with $x\neq 0$. As before, if we study this singularity by perturbation we conclude that there is no confinement since the Laurent expansions of the iterations of (x,ϵ) under the discrete system (2.18) around $\epsilon=0$ are all divergent. Although this singularity is not confined, one notices that any point of the form $(x,0)$ with $x\neq 0$ does not have a unique preimage under (2.18). Indeed, the expression defining $\mathbf{f}^{-1}$ given by

$$\mathbf{f}^{-1}(x,y)=\begin{pmatrix} y\\ y^2/x\end{pmatrix} \tag{2.20}$$

has a singularity of second type at $(x,0)$ and all the points of this form are mapped to $(0,0)$ under $\mathbf{f}^{-1}$. This example shows that if one wishes to establish a relationship between singularity confinement and first integrals, particular care should be given in distinguishing different singularities.

B. Preliminaries

The notion of singularity confinement will now be defined in a more general setting. We consider p-dimensional autonomous discrete dynamical systems described by birational mappings on $\mathbb{C}^p$. A *birational mapping* on $\mathbb{C}^p$ is a $\mathbb{C}^p$-valued rational function which is one-to-one almost everywhere in $\mathbb{C}^p$ and whose inverse, where it exists, is also represented by a rational function. The corresponding discrete dynamical systems are written

$$\mathbf{x}_{n+1}=\mathbf{f}(\mathbf{x}_n),\qquad \mathbf{x}_n\in\mathbb{C}^p,\qquad n\in\mathbb{Z}, \tag{2.21}$$

where $\mathbf{f}$ is a birational mapping on $\mathbb{C}^p$ with no explicit dependence on n. The ith *iterate* of $\mathbf{x}_0\in\mathbb{C}^p$ under (2.21) is said to *exist* if the following limit,

$$\lim_{\mathbf{x}\to\mathbf{x}_0} \mathbf{f}^i(\mathbf{x}), \tag{2.22}$$

exists. The ith iterate is then defined to be that limit and is denoted $\mathbf{F}^i(\mathbf{x}_0)$.

Definition: A **singularity of type I** *for the discrete dynamical system* $\mathbf{x}_{n+1}=\mathbf{f}(\mathbf{x}_n)$ *is a point* $\mathbf{x}^* \in \mathbb{C}^p$ *at which* $\mathbf{f}$ *is not defined. The set of singularity of type I associated with the mapping* $\mathbf{f}$ *in* $\mathbb{C}^p$ *is denoted* $S_I(\mathbf{f})$.

Definition: A **singularity of type II** *for the discrete dynamical system* $\mathbf{x}_{n+1}=\mathbf{f}(\mathbf{x}_n)$ *is a point* $\mathbf{x}^* \in \mathbb{C}^p$ *such that* $\det(\mathrm{D}\mathbf{f}(\mathbf{x}^*))=0$. *The set of singularity of type II in* $\mathbb{C}^p$ *is denoted* $S_{II}(\mathbf{f})$.

In the particular case of birational mappings, we have

$$S_I(\mathbf{f})=\{\mathbf{x}^* \in \mathbb{C}^p | \mathrm{den}(f_i)(\mathbf{x}^*)=0, \quad \text{for some} \quad i \in \{1,2,\ldots,p\}\}, \tag{2.23}$$

$$S_{II}(\mathbf{f})=\{\mathbf{x}^* \in \mathbb{C}^p | \det(\mathrm{D}\mathbf{f}(\mathbf{x}^*))=0\}. \tag{2.24}$$

We call the sets $S_I(\mathbf{f})$ and $S_{II}(\mathbf{f})$ the *singular sets of first and second type*, respectively. The *singular set* $S(\mathbf{f})$ is defined as the union of both sets:

$$S(\mathbf{f})=S_I(\mathbf{f}) \cup S_{II}(\mathbf{f}). \tag{2.25}$$

For both types of singularity we can define the property of confinement.

Definition: Let $\mathbf{x}^* \in \mathbb{C}^p$ *be a singularity of type I or II for the system* $\mathbf{x}_{n+1}=\mathbf{f}(\mathbf{x}_n)$. *The singularity is said to be* **confined** *if, for some* $i_c \in \mathbb{N}^{>0}$, *the iterate* $\mathbf{F}^{i_c}(\mathbf{x}^*)$ *exists and* $\lim_{\mathbf{x}\to\mathbf{x}^*} \det(\mathrm{D}\mathbf{f}^{i_c}(\mathbf{x}))\neq 0$.

The lowest such i_c is referred to as the *confinement number* that is the number of steps necessary for confinement. From now on, we assume that $\mathbf{f}$ is a birational mapping. The following lemma proves to be useful.

Lemma 2.1: *The image of* $S_{II}(\mathbf{f})$ *under the mapping* $\mathbf{f}$ *lies inside an algebraic variety of codimension 2.*

That is, the birational mapping $\mathbf{f}$ is one-to-one only on the subset of $\mathbb{C}^p$ defined by

$$O_{\mathbf{f}} \equiv \mathbb{C}^p \backslash S(\mathbf{f}). \tag{2.26}$$

As a consequence, the function $\mathbf{f}$ restricted to $O_{\mathbf{f}}$ defines a rational diffeomorphism

$$\mathbf{f}: O_{\mathbf{f}} \to O'_{\mathbf{f}} \equiv \mathbf{f}(O_{\mathbf{f}}), \tag{2.27}$$

whose inverse is also a rational function.

Proof: Assume that $S_{II}(\mathbf{f})\neq\varnothing$. Let $\mathbf{x}_0 \in S_{II}(\mathbf{f})$ and let $\mathbf{x}_1=\mathbf{f}(\mathbf{x}_0)$. From the inverse function theorem, it follows that

$$\lim_{\mathbf{x}\to\mathbf{x}_1} \|\det(\mathrm{D}\,\mathbf{f}^{-1}(\mathbf{x}))\|=\infty. \tag{2.28}$$

Thus, for some i's in $\{1,2,\ldots,p\}$, the denominator of $(\mathbf{f}^{-1})_i$ evaluated at $\mathbf{x}_1$ is zero. Denote those i by i_k, $k=1,2,\ldots,r$. We now prove that at least for one i_k, $\mathrm{num}((\mathbf{f}^{-1})_{i_k})$ also vanishes at $\mathbf{x}_1$. By contradiction, suppose that none of these numerators vanishes at $\mathbf{x}_1$. Thus

$$\lim_{\mathbf{x}\to\mathbf{x}_1} \|\mathbf{f}^{-1}(\mathbf{x})\|=\infty. \tag{2.29}$$

On the other hand, we have

$$\lim_{\mathbf{x}\to\mathbf{x}_0} \|\mathbf{f}^{-1}(\mathbf{f}(\mathbf{x}))\|=\mathbf{x}_0, \tag{2.30}$$

which contradicts Eq. (2.29). Thus, $\mathbf{x}_1$ must be in one of the following sets:

$$A_i=\{\mathbf{x}\in\mathbb{C}^p|\mathrm{num}((\mathbf{f}^{-1})_i)(\mathbf{x})=\mathrm{den}((\mathbf{f}^{-1})_i)(\mathbf{x})=0\},\qquad i\in\{1,2,\ldots,p\}. \tag{2.31}$$

This concludes the proof since each set A_i is defined as the intersection of the zero level sets of two relatively prime polynomials. □

As mentioned earlier, the singularity confinement turns out to be closely related to the existence of a first integral. This relationship will be explored in the next section.

Definition: *A* **first integral** *of* $\mathbf{x}_{n+1}=\mathbf{f}(\mathbf{x}_n)$ *is an analytic function* $I:U\subset\mathbb{C}^p\to\mathbb{C}$ *where* U *is a dense subset of* $\mathbb{C}^p$ *such that*

(a) $\|(\partial I/\partial x_1,\partial I/\partial x_2,\ldots,\partial I/\partial x_p)\|\neq 0$ *almost everywhere in* U, *and*
(b) $I(\mathbf{f}(\mathbf{x}))=I(\mathbf{x})$.

A first integral can exist in several forms.

Definition: A first integral I *of* $\mathbf{x}_{n+1}=\mathbf{f}(\mathbf{x}_n)$ *is* **polynomial** (*resp.* **rational**) *if the function* $I(\mathbf{x})$ *is a polynomial (resp. rational) function of* $\mathbf{x}\in\mathbb{C}^p$. *A complex-valued function* $f(\mathbf{x})$ *is* **algebraic** *over* $\mathbb{C}$ *if there exist* $s>0$ *and* $q_0,\ldots,q_s$ *rational in* $\mathbf{x}$ *such that*

$$q_0+q_1f+\cdots+q_sf^s=0. \tag{2.32}$$

If s *is the smallest positive integer such that (2.32) holds, the relation (2.32) is referred to as the minimal polynomial of* f. *A first integral* I *is* **algebraic** *if the function* $I(\mathbf{x})$ *is algebraic*.

Many notions of integrability are used in the literature. In this article, we focus on algebraic integrability. We are interested in determining precisely ''how many'' algebraic first integrals a given discrete system must admit to be algebraically integrable. For instance, suppose that the algebraic functions $A_1(\mathbf{x}),A_2(\mathbf{x}),\ldots,A_r(\mathbf{x})$ defined on $\mathbb{C}^p$ are all first integrals for a given system and $F(z_1,z_2,\ldots,z_r)$ is algebraic on $\mathbb{C}^r$. Then, it is clear that $A(\mathbf{x})=F(A_1(\mathbf{x}),A_2(\mathbf{x}),\ldots,A_r(\mathbf{x}))$ is also a first integral. However, this new first integral adds no knowledge to the given problem since it depends on the other first integrals.

Definition: Let $A_1(\mathbf{x}),A_2(\mathbf{x}),\ldots,A_r(\mathbf{x})$ *be smooth complex-valued functions defined on a domain* $D\subset\mathbb{C}^p$. *Then*

(a) $A_1,A_2,\ldots,A_r$ *are* **functionally dependent** *if, for each* $\mathbf{x}\in D$, *there is a neighborhood* U *of* $\mathbf{x}$ *and a smooth complex-valued function* $F(z_1,z_2,\ldots,z_r)$ *not identically zero on any subset of* $\mathbb{C}^p$ *such that*

$$F(A_1(\mathbf{x}),A_2(\mathbf{x}),\ldots,A_r(\mathbf{x}))=0. \tag{2.33}$$

(b) $A_1,A_2,\ldots,A_r$ *are* **functionally independent** *if they are not functionally dependent when restricted to any open subset of* D.

A simple way to determine if a set of functions is functionally independent is given by the following theorem (see, for example, Ref. 24).

Theorem: *Let* $\mathbf{A}=(A_1,A_2,\ldots,A_r)$ *be a smooth function from a domain* $D\subseteq\mathbb{C}^p$ *to* $\mathbb{C}^r$. *Then,* $A_1(\mathbf{x}),A_2(\mathbf{x}),\ldots,A_r(\mathbf{x})$ *are functionally dependent if and only if* $D\mathbf{A}(\mathbf{x}^*)$ *has rank strictly less than* r *for all* $\mathbf{x}^*\in D$.

We introduce the notion of integrability considered in this article.

Definition: *The discrete dynamical system* $\mathbf{x}_{n+1}=\mathbf{f}(\mathbf{x}_n)$ *is said to be* **algebraically integrable** *if it admits* $(p-1)$ *algebraic functionally independent first integrals*.

The following theorem is a direct extension of Brun's[9,23] theorem to discrete systems and is useful to extend the results we obtain for rational to algebraic first integrals.

Theorem: *If a discrete dynamical system of* $\mathbf{x}_{n+1}=\mathbf{f}(\mathbf{x}_n)$ *has* k *functionally independent algebraic first integrals, then it has* k *functionally independent rational first integrals*.

Proof: Let I be an algebraic first integral and let

$$P(I)=q_0+q_1I+\cdots+q_{s-1}I^{s-1}+I^s \tag{2.34}$$

be its minimal polynomial, where q_i is a rational function of $\mathbf{x}$. Since I depends nontrivially on $\mathbf{x}$, there exists i such that q_i is a nonconstant rational function of $\mathbf{x}$. Since $I(\mathbf{f}(\mathbf{x}))=I(\mathbf{x})$, we have

$$q_0(\mathbf{f}(\mathbf{x}))-q_0(\mathbf{x})+(q_1(\mathbf{f}(\mathbf{x}))-q_1(\mathbf{x}))I(\mathbf{x})+\cdots+(q_{s-1}(\mathbf{f}(\mathbf{x}))-q_{s-1}(\mathbf{x}))I^{s-1}(\mathbf{x})=0. \tag{2.35}$$

Since P is minimal, we have $q_i(\mathbf{f}(\mathbf{x})))=q_i(\mathbf{x})$ and each q_i is a first integral. Now, let I' be another independent first integral whose minimal polynomial is

$$P(I')=q'_0+q'_1I'+\cdots+q'_{s'-1}I'^{s'-1}+I'^{s'}. \tag{2.36}$$

The independence between the two first integrals implies that there exist $i<s, i'<s'$ such that q_i, q'_i are two independent nonconstant rational first integrals. By induction, one can build k independent rational first integrals. □

Therefore, algebraic integrability implies rational integrability and it is sufficient to consider discrete dynamical systems of the form (2.21) which admit $(p-1)$ functionally independent rational first integrals $R_i(\mathbf{x})=P_i(\mathbf{x})/Q_i(\mathbf{x})$ where $i=1,2,\ldots,p-1$ and P_i and Q_i are relatively prime polynomials. Let $L_{i,c}$ be the level set of the first integral R_i corresponding to the value $c \in \mathbb{C}$. Since $\mathbf{f}$ is continuous, it leaves invariant the closure of the level set given by

$$\overline{L_{i,c}}=\{\mathbf{x}\in\mathbb{C}^p \,|\, P_i(\mathbf{x})-c\,Q_i(\mathbf{x})=0\}. \tag{2.37}$$

III. THE TWO-DIMENSIONAL CASE

In this section we study the local implications of algebraic integrability on the confinement of singularities for two-dimensional discrete dynamical systems. We consider a discrete dynamical systems of the form (2.21) which is algebraically integrable, that is, it possesses a nontrivial rational first integral $R(\mathbf{x})=P(\mathbf{x})/Q(\mathbf{x})$ where P and Q are some polynomials over $\mathbb{C}^2$. Let L_c be the level set of R corresponding to the value $c\in\mathbb{C}$.

We first focus our attention on singularities of the first type. The singular set of first type $S_I(\mathbf{f})$ is an algebraic variety since it is defined as the set of zeros of polynomials. We consider its irreducible decomposition is

$$S_I(\mathbf{f})=\bigcup_{i=1}^{d} S_I^{(i)}(\mathbf{f}), \tag{3.1}$$

where each irreducible component $S_I^{(i)}(\mathbf{f})$ is defined as the zero set of an irreducible polynomial on $\mathbb{C}^2$.

In example (2.18), we showed that the existence of a rational first integral does not ensure that all singularities are confined. However, in this case it is not possible to ''enter'' the singularity, meaning that it does not have a unique preimage under the mapping. Moreover, we know that confinement is a generic property, that is, it is only concerned with dense subsets of irreducible components of S_I. For instance, in example (2.15) all singularities of type I of the form (b,y_0) confine in three steps except a particular singularity defined by $y_0=b/(b^2-1)$. The next theorem relates the confinement of singularities to the existence of a rational first integral.

Theorem 3.1: *Consider a two-dimensional birational mapping* $\mathbf{x}_{n+1}=\mathbf{f}(\mathbf{x}_n)$ *and assume it has a rational first integral* $R(\mathbf{x})=P(\mathbf{x})/Q(\mathbf{x})$. *Then, for each irreducible component* $S_I^{(j)}(\mathbf{f})$, *we have either*

(a) *there exists* $k_j \in \mathbb{N}^{>0}$ *such that*

$$\lim_{\mathbf{x}\to\mathbf{x}^*} \mathbf{f}^{k_j}(\mathbf{x}) \tag{3.2}$$

exists for almost all $\mathbf{x}^* \in S_I^{(j)}(\mathbf{f})$, *or*

(b) *there exists* $l_j \in \mathbb{N}^{>0}$ *such that* $S_I^{(j)}(\mathbf{f})$ *lies inside the singular set of the birational mapping defining* $\mathbf{f}^{-l_j}$.

Proof: Without loss of generality, take $j=1$. Consider two cases:

(1) $S_I^{(1)}(\mathbf{f}) \not\subset \overline{L_c}$ for all $c \in \mathbb{C}$.

Let $\mathbf{x}^* \in S_I^{(1)}(\mathbf{f})$ such that $\lim_{\mathbf{x}\to\mathbf{x}^*} \|f_i(\mathbf{x})\|$ exists or is infinity (as opposed to undefined) for $i=1,2$. Suppose that $\mathbf{x}^* \in \overline{L_{c^*}}$ for only one $c^* \in \mathbb{C}$ and that there is a neighborhood of $\mathbf{x}^*$ on $\overline{L_{c^*}}$ whose only intersection with any of the singular sets associated with the mappings $\mathbf{f}^i$, $i=1,2,\ldots,q+1$, (q is defined below) is $\mathbf{x}^*$ itself. The set of points satisfying the above properties is dense in $S_I^{(1)}(\mathbf{f})$. Let $\mathbf{p}_i(\epsilon)$, $i=1,2,..,q$, be the paths in $\mathbb{C}^2$ such that

(*i*) $\mathbf{p}_i(\epsilon) \in \overline{L_{c^*}}$ for ϵ small enough, that is,

$$P(\mathbf{p}_i(\epsilon)) - c^* Q(\mathbf{p}_i(\epsilon)) = 0; \text{ and} \tag{3.3}$$

(*ii*) $\|\mathbf{p}_i(\epsilon)\| \to \infty$ as $\epsilon \to 0$ and at least one of the components of $\mathbf{p}_i(\epsilon)$ is of the form $1/\epsilon$.

Note that the number of paths q can depend on the complex number c^* but the values it can take for different c^* can be bounded above by a number depending only on the degrees of P and Q.

Now, consider another path $\mathbf{x}(\sigma) \in \overline{L_{c^*}}$ $\forall \sigma$ such that

$$\lim_{\sigma\to 0} \mathbf{x}(\sigma) = \mathbf{x}^*. \tag{3.4}$$

Since there is a neighborhood of $\mathbf{x}^*$ on $\overline{L_{c^*}}$ whose only intersection with $S(\mathbf{f})$ is $\mathbf{x}^*$, $\mathbf{f}(\mathbf{x}(\sigma))$ is well-defined for σ nonzero and small enough. Moreover, since $\mathbf{f}$ preserves $\overline{L_{c^*}}$, $\mathbf{f}(\mathbf{x}(\sigma))$ also lies in $\overline{L_{c^*}}$, and

$$\lim_{\sigma\to 0} \|\mathbf{f}(\mathbf{x}(\sigma))\| = \infty. \tag{3.5}$$

Therefore, there exists a change of variable $\sigma = \sigma(\epsilon)$ of order $\mathcal{O}(\epsilon^s)$ for some $s>0$, so that $\mathbf{f}(\mathbf{x}(\sigma))$ is one of the paths $\mathbf{p}_i$ defined above:

$$\mathbf{f}(\mathbf{x}(\sigma(\epsilon))) = \mathbf{p}_i(\epsilon), \tag{3.6}$$

for some $1 \leqslant i \leqslant q$. Our claim is that there exists m with $m \leqslant q+1$ such that the limit as $\sigma \to 0$ of $\mathbf{f}^m(\mathbf{x}(\sigma))$ exists and is finite. Suppose, by contradiction, that the iterates $\mathbf{f}^k(\mathbf{x}(\sigma))$, $k=1,2,3,\ldots,q+1$, are all divergent at $\sigma=0$. Each iterate $\mathbf{f}^k(\mathbf{x}(\sigma))$ is associated with a unique path $\mathbf{p}_{i_k}(\epsilon)$. This implies that the kth preimage of $\mathbf{p}_{i_k}(\epsilon)$ is finite in the limit $\epsilon \to 0$ and no other $\mathbf{f}^l(\mathbf{x}(\sigma))$ for $1 \leqslant k < l \leqslant q+1$ corresponds to the same $\mathbf{p}_{i_k}(\epsilon)$. Hence the relation between the $q+1$ iterates that are divergent at $\sigma=0$ and the paths $\mathbf{p}_i(\epsilon)$ is injective. This is a contradiction since there are only q paths $\mathbf{p}_i(\epsilon)$.

(2) There exists $c \in \mathbb{C}$ such that $S_I^{(1)}(\mathbf{f}) \subset \overline{L_c}$. Let

$$\overline{L_c} = \bigcup_{i=1}^{r} \overline{L_c^{(i)}} \tag{3.7}$$

be the irreducible decomposition of $\overline{L_c}$ for any $c \in \mathbb{C}$. If $S_I^{(1)}(\mathbf{f})$ lies inside the singular set of $\mathbf{f}^{-1}$, then the theorem is proved. Otherwise, let $k \in \mathbb{N}^{>0}$ be such that $S_I^{(1)}(\mathbf{f})$ does not lie in a singular set associated with the mappings $\mathbf{f}^{-m}$, $m=1,2,\ldots,k$. Then,

$$\overline{\mathbf{f}^{-m}(S_I^{(1)}(\mathbf{f}))} = \bigcup_{i \in B_m} \overline{L_c^{(i)}}, \qquad 1 \leqslant l \leqslant k, \tag{3.8}$$

where each B_m is a subset of $\{1,2,\ldots,r\}$. The k sets in (3.8) are distinct, otherwise, by contradiction, there exist $m_1, m_2 \in \mathbb{N}^{>0}$ such that

$$\overline{\mathbf{f}^{-m_1}(S_I^{(1)}(\mathbf{f}))} = \overline{\mathbf{f}^{-m_2}(S_I^{(1)}(\mathbf{f}))}, \qquad 1 \leqslant m_1 < m_2 \leqslant k. \tag{3.9}$$

This implies that

$$S_I^{(1)}(\mathbf{f}) = \overline{\mathbf{f}^{-1}(\mathbf{f}^{(m_1-m_2+1)}(S_I^{(1)}(\mathbf{f})))}, \tag{3.10}$$

which is a contradiction since $\mathbf{f}$ is undefined almost everywhere on $S_I^{(1)}(\mathbf{f})$. Hence the k sets in (3.8) are distinct. However, there are only finitely many possibilities for the sets B_m in (3.8). Hence $S_I^{(1)}(\mathbf{f})$ must lie inside the singular set of $\mathbf{f}^{-l_1}$ for some l_1. □

Notice that condition (3.2) does not imply that the singularity is confined since the condition that the Jacobian be nonzero must be satisfied. In order to solve this problem, singularities of type II have to be considered. The singular set of second type is not, in general, an algebraic variety but its closure,

$$\overline{S_{II}(\mathbf{f})} = \{\mathbf{x}^* \in \mathbb{C}^p \,|\, \mathrm{num}(\det(\mathrm{D}\mathbf{f}(\mathbf{x}^*))) = 0\}, \tag{3.11}$$

is. Hence, it is possible to introduce the irreducible decomposition

$$\overline{S_{II}(\mathbf{f})} = \bigcup_{i=1}^{s} \overline{S_{II}^{(i)}(\mathbf{f})}, \tag{3.12}$$

where each $S_{II}^{(i)}(\mathbf{f})$ is a subset of $S_{II}(\mathbf{f})$. It is now possible to state the general theorem for singularities of second type.

Theorem 3.2: *Consider a two-dimensional birational mapping* $\mathbf{x}_{n+1} = \mathbf{f}(\mathbf{x}_n)$ *and assume it has a rational first integral* $R(\mathbf{x}) = P(\mathbf{x})/Q(\mathbf{x})$. *Then, for each irreducible component* $\overline{S_{II}^{(j)}(\mathbf{f})}$, *we have either*

(*a*) *there exists* $k_j \in \mathbb{N}^{>0}$ *such that*

$$\lim_{\mathbf{x} \to \mathbf{x}^*} \det(\mathrm{D}\mathbf{f}^{k_j}(\mathbf{x})) \tag{3.13}$$

exists and is nonzero for almost all $\mathbf{x} \in S_{II}^{(j)}(\mathbf{f})$, *or*

(*b*) *there exists* $l_j \in \mathbb{N}^{>0}$ *such that* $S_{II}^{(j)}(\mathbf{f})$ *lies inside the singular set of* $\mathbf{f}^{-l_j}$.

Proof: The proof is similar to the proof of Theorem 3.1. Again, without loss of generality, we take $j = 1$ and consider two cases.

(1) $\overline{S_{II}^{(1)}(\mathbf{f})} \not\subset \overline{L_c}$ for all $c \in \mathbb{C}$.

The image of $S_{II}^{(1)}(\mathbf{f})$ under the mapping $\mathbf{f}$ is a finite subset of $\mathbb{C}^2$, thanks to Lemma 2.1. Moreover, $S_{II}^{(1)}(\mathbf{f})$ is not contained inside any level set. For any point in the image of $S_{II}^{(1)}(\mathbf{f})$ it is therefore possible to choose two distinct preimages in $S_{II}^{(1)}(\mathbf{f})$ which lie in two different level sets. Since $\mathbf{f}$ preserves $\overline{L_c}$, every point in the image of $S_{II}^{(1)}(\mathbf{f})$ must lie in the set

$$\bigcap_{c \in \mathbb{C}} \overline{L_c} = \{\mathbf{x} \in \mathbb{C}^2 \,|\, P(\mathbf{x}) = Q(\mathbf{x}) = 0\}. \tag{3.14}$$

The elements of this finite set are denoted $\mathbf{s}_i$, $i = 1,2,\ldots,m$. Note that in the case of a polynomial first integral, $Q(\mathbf{x}) = 1$ and this set is empty.

Now, choose $\mathbf{x}^* \in S_{II}^{(1)}(\mathbf{f})$ such that $\mathbf{x}^* \in \overline{L_{c^*}}$ for only one $c^* \in \mathbb{C}$ and there is a neighborhood of $\mathbf{x}^*$ on $\overline{L_{c^*}}$ whose only intersection with any of the singular sets associated with the mappings $\mathbf{f}^i$, $i=1,2,\ldots,q+r+1$, (q and r are defined below) is $\mathbf{x}^*$ itself. The set of points satisfying the above properties is dense in $S_{II}^{(1)}(\mathbf{f})$. Consider the q paths $\mathbf{p}_i(\epsilon)$ described in the proof of Theorem 3.1. Consider also the r paths $\mathbf{w}_i(\epsilon)$, $i=1,2,...,r$, in $\mathbb{C}^2$ satisfying

(i) $\mathbf{w}_i(\epsilon) \in \overline{L_{c^*}}$ for ϵ small enough.
(ii) $\mathbf{w}_i(\epsilon) \to \mathbf{s}_{j_i}$ as $\epsilon \to 0$ and one of the components ($k=1$ or 2) of $\mathbf{w}_i(\epsilon)$ is of the form $(\mathbf{s}_{j_i})_k + \epsilon$ for some $1 \leqslant j_i \leqslant m$.

Now, consider another path $\mathbf{x}(\sigma) \in \overline{L_{c^*}}$ such that

$$\lim_{\sigma \to 0} \mathbf{x}(\sigma) = \mathbf{x}^*. \tag{3.15}$$

Since there is a neighborhood of $\mathbf{x}^*$ on $\overline{L_{c^*}}$ whose only intersection with $S(\mathbf{f})$ is $\mathbf{x}^*$, $\mathbf{f}(\mathbf{x}(\sigma))$ is well-defined for σ nonzero and small enough. Moreover, since $\mathbf{f}$ preserves $\overline{L_{c^*}}$, $\mathbf{f}(\mathbf{x}(\sigma)) \in \overline{L_{c^*}}$, and

$$\lim_{\sigma \to 0} \mathbf{f}(\mathbf{x}(\sigma)) = \mathbf{s}_i \tag{3.16}$$

for some i such that $1 \leqslant i \leqslant r$. Following the proof of Theorem 3.1, $\mathbf{f}(\mathbf{x}(\sigma))$ can be associated with a path $\mathbf{w}_j(\epsilon)$ (whose limit as $\sigma \to 0$ is $\mathbf{s}_i$). Suppose by contradiction that the $d+r+1$ iterates $\mathbf{f}^k(\mathbf{x}(\sigma))$, $k=1,2,\ldots,d+r+1$, are either divergent at $\sigma=0$ or have a limit $\sigma \to 0$ equal to one of the $\mathbf{s}_i$. Each iterate $\mathbf{f}^k$ is associated with a path $\mathbf{p}_{i_k}(\epsilon)$ or $\mathbf{w}_{i_k}(\epsilon)$. This implies that the unique kth preimage of $\mathbf{p}_{i_k}(\epsilon)$ or $\mathbf{w}_{i_k}(\epsilon)$ must converge to $\mathbf{x}^*$ as $\epsilon \to 0$. The preimage is unique because there is a neighborhood of $\mathbf{x}^*$ on $\overline{L_{c^*}}$ whose only intersection with any of the singular sets associated with the mappings $\mathbf{f}^i$, $i=1,2,\ldots,q+r+1$, (q and r are defined below) is $\mathbf{x}^*$ itself. Since $\mathbf{x}^*$ is not one of the $\mathbf{s}_i$, there cannot be two iterates $\mathbf{f}^{k_1}(\mathbf{x}(\sigma))$ and $\mathbf{f}^{k_2}(\mathbf{x}(\sigma))$, $k_1, k_2 \leqslant q+r+1$, associated with the same path. Since there are only $q+r+1$ paths $\mathbf{p}_i(\epsilon)$ and $\mathbf{w}_i(\epsilon)$, there exists a $k \leqslant q+r+1$ such that the limit $\sigma \to 0$ of the kth iterate of $\mathbf{x}(\sigma)$ must be finite and not equal to one $\mathbf{s}_i$ as $\sigma \to 0$. Therefore, the limit $\sigma \to 0$ of the Jacobian of $\mathbf{f}^{k_1}$ evaluated at $\mathbf{x}(\sigma)$ must be a finite nonvanishing number. This ends the proof in the first case.

(2) There exists $c \in \mathbb{C}$ such that $S_I^{(1)}(\mathbf{f}) \subset \overline{L_c}$. The argument leading to the conclusion that $S_{II}^{(j)}(\mathbf{f})$ lies inside the singular set of $\mathbf{f}^{-l_1}$ for some l_1 is identical to the second case considered in the proof of the preceding theorem. □

With Theorem 3.2, it is now easy to see that singularities of type I satisfying the condition (3.2) are confined. Indeed, suppose k_j is the number considered in the first part of Theorem 3.1. If the Jacobian of $\mathbf{f}^{k_j}$ is zero almost everywhere on $S_I^{(j)}(\mathbf{f})$, then $S_I^{(j)}(\mathbf{f})$ becomes a subset of $\overline{S_{II}(\mathbf{f}^{k_j})}$. According to the proof of Theorem 3.1 we know that $S_I^{(j)}(\mathbf{f}) \not\subset \overline{L_c}$ for all $c \in \mathbb{C}$. Thus, as a consequence of Theorem 3.2, the singularities in $S_I^{(j)}(\mathbf{f})$ must be confined. We can state a general theorem including both types of singularities. To do so, we introduce the irreducible decomposition associated with $S(\mathbf{f})$

$$S(\mathbf{f}) = \bigcup_{i=1}^{d+s} S^{(i)}(\mathbf{f}), \tag{3.17}$$

where d and s are defined in (3.1) and (3.12).

Theorem 3.3: *Consider a two-dimensional birational mapping* $\mathbf{x}_{n+1} = \mathbf{f}(\mathbf{x}_n)$ *and assume it has a rational first integral* $R(\mathbf{x}) = P(\mathbf{x})/Q(\mathbf{x})$. *Let* $S(\mathbf{f})$ *be its singular set with irreducible components* $S^{(j)}(\mathbf{f})$. *Then, for each* j, *either*

(a) *almost all singularities of* $S^{(j)}(\mathbf{f})$ *are confined in the same number of steps, or*
(b) *there exists* $l_j \in \mathbb{N}^{>0}$ *such that* $S^{(j)}(\mathbf{f})$ *lies inside the singular set of* $\mathbf{f}^{-l_j}$.

IV. ARBITRARY DIMENSIONS

In this section, we extend the results of the previous section to birational mappings of arbitrary dimension p. The mappings are assumed to be algebraically integrable, that is, they admit $(p-1)$ functionally independent first integrals $R_i(\mathbf{x})=P_i(\mathbf{x})/Q_i(\mathbf{x})$, $i=1,2,\ldots,p-1$. Then, the closure of the level sets associated with $\mathbf{c}\in\mathbb{C}^{p-1}$ is given by

$$\overline{L_{\mathbf{c}}}=\{\mathbf{x}\in\mathbb{C}^p \,|\, P_i(\mathbf{x})-c_i\,Q_i(\mathbf{x})=0, \quad \text{for } 1\leqslant i\leqslant p-1\}=\bigcap_{i=1}^{p-1}\overline{L_{i,c_i}}, \tag{4.1}$$

with $\overline{L_{i,c_i}}$ defined in (2.37). A set of constants $\mathbf{c}\in\mathbb{C}^{p-1}$ is said to be *regular* for the first integrals $\mathbf{R}=(R_1,R_2,\ldots,R_{p-1})$ if $\mathrm{D}\mathbf{R}(\mathbf{x})$ has rank equal to $(p-1)$ almost everywhere on $\mathbf{R}^{-1}(\mathbf{c})$. The set $\overline{L_{\mathbf{c}}}$ is then an algebraic variety of codimension $(p-1)$.

Our main Theorems 3.1–3.3 can be readily generalized to arbitrary dimensions and we only give here an outline of the proofs.

Theorem 4.1: *Consider a p-dimensional birational mapping* $\mathbf{x}_{n+1}=\mathbf{f}(\mathbf{x}_n)$ *and assume it is algebraically integrable with first integrals* $R_i(\mathbf{x})=P_i(\mathbf{x})/Q_i(\mathbf{x})$, $i=1,2,\ldots,p-1$. *Then for each irreducible component* $S_I^{(j)}(\mathbf{f})$, *we have either*

(*a*) *there exists* $k_j\in\mathbb{N}^{>0}$ *such that*

$$\lim_{\mathbf{x}\to\mathbf{x}^*}\mathbf{f}^{k_j}(\mathbf{x}) \tag{4.2}$$

exists for almost all $\mathbf{x}\in S_I^{(j)}(\mathbf{f})$, or

(*b*) *there exists* $l_j\in\mathbb{N}^{>0}$ *such that* $S_I^{(j)}(\mathbf{f})$ *lies inside the singular set of the birational mapping defining* $\mathbf{f}^{-l_j}$.

Proof: Without loss of generality, take $j=1$. Consider two cases:

(1) $S_I^{(1)}(\mathbf{f})\not\subset\overline{L_{i,c}}$ for all $c\in\mathbb{C}$ and $1\leqslant i\leqslant p-1$.

Let $\mathbf{x}^*\in S_I^{(1)}(\mathbf{f})$ such that $\lim_{\mathbf{x}\to\mathbf{x}^*}\|f_i(\mathbf{x})\|$ exists or is infinite (as opposed to undefined) for $i=1,\ldots,p$. Suppose that $\mathbf{x}^*\in\overline{L_{\mathbf{c}^*}}$ for only one $\mathbf{c}^*\in\mathbb{C}^{p-1}$ which is regular and that there is a neighborhood of $\mathbf{x}^*$ on $\overline{L_{\mathbf{c}^*}}$ whose only intersection with the singular sets associated with the mappings $\mathbf{f}^i$, $i=1,2,\ldots,q+1$, (q is defined below) is $\mathbf{x}^*$ itself. The set of points satisfying the above properties is dense in $S_I^{(1)}(\mathbf{f})$. Let q be the number of paths $\mathbf{p}_i(\epsilon)$, $i=1,2,..,q$, in $\mathbb{C}^p$ such that

(i) $\mathbf{p}_i(\epsilon)\in\overline{L_{\mathbf{c}^*}}$ for ϵ small enough. That is,

$$P_k(\mathbf{p}_i(\epsilon))-c_k^*\,Q_k(\mathbf{p}_i(\epsilon))=0, \quad k=1,2,\ldots,p-1. \tag{4.3}$$

(ii) $\|\mathbf{p}_i(\epsilon)\|\to\infty$ as $\epsilon\to 0$ and at least one of the components of $\mathbf{p}_i(\epsilon)$ is of the form $1/\epsilon$.

Using the fact that $\overline{L_{\mathbf{c}^*}}$ is of codimension $p-1$, the rest of the proof follows exactly the similar case in the proof of Theorem 3.1.

(2) There exists $c\in\mathbb{C}$ and i, $1\leqslant i\leqslant p-1$, such that $S_I^{(1)}(\mathbf{f})\subset\overline{L_{i,c}}$. This part of the proof is identical to the corresponding part in the proof of Theorem 3.1 except that $\overline{L_{i,c}}$ is considered instead of $\overline{L_c}$. □

Theorem 4.2: *Consider a p-dimensional birational mapping* $\mathbf{x}_{n+1}=\mathbf{f}(\mathbf{x}_n)$ *and assume it is algebraically integrable with rational first integrals* $R_i(\mathbf{x})=P_i(\mathbf{x})/Q_i(\mathbf{x})$, $i=1,2,\ldots,p-1$. *Then, for each irreducible component* $\overline{S_{II}^{(j)}(\mathbf{f})}$, *we have either*

(*a*) *there exists* $k_j\in\mathbb{N}^{>0}$ *such that*

$$\lim_{\mathbf{x}\to\mathbf{x}^*}\det(D\mathbf{f}^{\mathbf{k_j}}(\mathbf{x})) \tag{4.4}$$

exists and is nonzero for almost all $\mathbf{x}\in S_{II}^{(j)}(\mathbf{f})$, *or*

(*b*) *there exists* $l_j\in\mathbb{N}^{>0}$ *such that* $S_{II}^{(j)}(\mathbf{f})$ *lies inside the singular set of* $\mathbf{f}^{-l_j}$.

Proof: The proof is similar to the proof of Theorem 3.2 and the only difference comes in the first case, when $\overline{S_{II}^{(1)}(\mathbf{f})}\not\subset\overline{L}_{i,c}$ for all $c\in\mathbb{C}$ and $1\leqslant i\leqslant p-1$. Following the proof of Theorem 3.2, for any point in the image of $S_{II}^{(1)}(\mathbf{f})$ it is possible to choose two distinct preimages in $S_{II}^{(1)}(\mathbf{f})$ which lie in two different level sets. Indeed, from Lemma 2.1, the image of $S_{II}^{(1)}(\mathbf{f})$ under the mapping $\mathbf{f}$ lies in a subset of codimension 2 inside $\mathbb{C}^p$. Since $\mathbf{f}$ preserves $\overline{L}_{i,c}$, the points in the image of $S_{II}^{(1)}(\mathbf{f})$ must lie in the set

$$\bigcap_{c\in\mathbb{C},i\leqslant p-1}\overline{L}_{i,c}=\{\mathbf{x}\in\mathbb{C}^2|P_i(\mathbf{x})=Q_i(\mathbf{x})=0\}. \tag{4.5}$$

Since the first integrals are functionally independent, the set defined above is finite. The rest of the proof is similar to the proof of Theorem 3.2 except that one should specify that $\mathbf{c}^*$ has to be regular. □

Theorem 4.3: *Consider a p-dimensional birational mapping* $\mathbf{x}_{n+1}=\mathbf{f}(\mathbf{x}_n)$ *and assume it is algebraically integrable. Let* $S(\mathbf{f})$ *be its singular set with irreducible components* $S^{(j)}(\mathbf{f})$. *Then, for each* j, *either*

(a) *almost all singularities of* $S^{(j)}(\mathbf{f})$ *are confined in the same number of steps, or*
(b) *there exists* $l_j\in\mathbb{N}^{>0}$ *such that* $S^{(j)}(\mathbf{f})$ *lies inside the singular set of* $\mathbf{f}^{-l_j}$.

V. COROLLARIES AND APPLICATIONS

In the previous two sections, the existence of first integrals was assumed to obtain local information on the confinement property. Here, the information given by the singularity confinement property is used to obtain global information on the discrete dynamical systems such as the nonexistence of algebraic first integral and the degree of possible rational first integrals. The results of this section can be considered as a discrete analog of Yoshida's theorem[9,32,33] which, for ODEs, relates the Kovalevskaya exponents given by the Painlevé test to the degree of a rational first integral. The first corollary is a direct consequence of Theorem 4.3.

Corollary 5.1: Consider a p-dimensional birational mapping $\mathbf{x}_{n+1}=\mathbf{f}(\mathbf{x}_n)$ *with a nonempty singular set* $S(\mathbf{f})$. *If there exists an irreducible components* $S^{(j)}(\mathbf{f})$ *in which almost all singularities are not confining and such that* $S^{(j)}(\mathbf{f})\not\subset S(\mathbf{f}^{-k})$ *for any positive* k, *then the system is not algebraically integrable.*

As an example of this corollary, we show that system (2.11), defined by

$$\mathbf{f}(x,y)=\begin{pmatrix}-x-y+a+\dfrac{b}{x^3}\\ x\end{pmatrix}, \tag{5.1}$$

is not algebraically integrable. Recall that singularities of the form $(0,y)$ are nonconfining. In order to use Corollary 5.1 and prove that this mapping does not admit an algebraic first integral, one must show that points of the form $(0,y)$ are not generically in the singular set of $\mathbf{f}^{-l}$ for some

$l>0$. The singular set of $\mathbf{f}^{-1}$ consists of points of the form $(x,0)$. Thus, we must prove that generic iterates of $(0,y)$ under $\mathbf{f}^{-1}$ do not belong to the set of points of the form $(x,0)$. The inverse of the mapping (5.1) is given by

$$\mathbf{f}^{-1}(x,y)=\begin{pmatrix} y \\ -x-y+a+\dfrac{b}{y^3} \end{pmatrix}. \tag{5.2}$$

This mapping can be obtained from $\mathbf{f}$ of (5.1) by interchanging x and y. Therefore, we can follow the analysis performed in (2.12) to perform a Laurent expansion in y to show that

$$\mathbf{f}^{-2}(x_0,y_0)=\begin{pmatrix} b/y_0^3+(a-x_0)-y_0+\mathcal{O}(y_0^5) \\ -b/y_0^3+x_0+\mathcal{O}(y_0^5) \end{pmatrix}. \tag{5.3}$$

Moreover, we have

$$\mathbf{f}^{-3}\begin{pmatrix} nb/y_0^3+(a-x_0)-y_0+\mathcal{O}(y_0^5) \\ -nb/y_0^3+x_0+\mathcal{O}(y_0^5) \end{pmatrix}=\begin{pmatrix} (n+1)b/y_0^3+(a-x_0)-y_0+\mathcal{O}(y_0^5) \\ -(n+1)b/y_0^3+x_0+\mathcal{O}(y_0^5) \end{pmatrix}, \tag{5.4}$$

where n is any positive integer. Hence, points of the form $(0,y)$ are not generically sent to points of the form $(x,0)$ by applications of $\mathbf{f}^{-1}$ and, from Corollary 5.1, system (2.11) does not admit an algebraic first integral.

In general, algebraic integrability restricts the possible *local* behavior of singularities. Theorem 4.3 gives two possible local behaviors but, in each case, the singularity can have several different *global* behaviors. Consider an irreducible component of the singular set $S^{(1)}(\mathbf{f})$. In the proofs of Theorems 3.3 and 4.3, we considered two cases: $S^{(1)}(\mathbf{f})\not\subset\overline{L_{\mathbf{c}}}$ and $S^{(1)}(\mathbf{f})\subset\overline{L_{\mathbf{c}}}$. When $S^{(1)}(\mathbf{f})\not\subset\overline{L_{\mathbf{c}}}$ the singularities of $S_I^{(1)}(\mathbf{f})$ are generically confined. In this case, two different types of global behavior can be expected. First, after meeting a finite number singularities, the mapping generically never meets other singularities (note that this must also be true in the backward direction, that is for $\mathbf{f}^{-1}$). We will refer to such a behavior as *global confinement*. Second, the singularities may be confined but not globally. Because, for each dynamical system of the form (2.21), there are only finitely many irreducible parts to $S(\mathbf{f})$, the mapping must, at one point, come back to the initial singularity and take $S_I^{(1)}(\mathbf{f})$ into itself. We say that such singularities are *periodic*. We now define formally these two types of global behavior and illustrate them.

Definition: A singularity $\mathbf{x}^*\in\mathbb{C}^p$ *for a birational mapping* $\mathbf{x}_{n+1}=\mathbf{f}(\mathbf{x}_n)$ *is said to be* **globally confined** *if there exist* $k',k''\in\mathbb{N}^{>0}$ *such that* $\mathbf{x}^*\notin S(\mathbf{f}^k)$ *for any* $k>k'$ *and* $\mathbf{x}^*\notin S(\mathbf{f}^{-k})$ *for any* $k>k''$.

An example of such a behavior is given by system (2.2). For this system, points of the form $(x,0)$ are not sent to points of the form $(0,y)$ through successive applications of $\mathbf{f}$. To prove this, let (x_n,y_n) be the nth iterate of $(x,0)$. If $n=4k$, an expansion of $\mathbf{f}^4(x,0)$ reveals that $(x_{4k},y_{4k})=(kx+\mathcal{O}(x^2),(-k+1)x+\mathcal{O}(x^2))$, $k=1,2,\ldots$. This fact also implies that $x_{4k+3}=-kx+\mathcal{O}(x^2)$ and we conclude that x_{4k+3} and x_{4k} are neither infinite nor vanishing. By contradiction assume that there exists n such that $(x_n,y_n)=(0,y)$. Therefore, either $n=4k+1$ or $n=4k+2$. However, from Eq. (2.4) we know that x_{n+2} is infinite which is a contradiction. We conclude that no iterate of $(x,0)$ falls onto a point of the form $(0,y)$ and singularities of the form $(0,y)$ are globally confined.

Definition: Consider the singular set of a birational mapping $\mathbf{x}_{n+1}=\mathbf{f}(\mathbf{x}_n)$ *and one of its irreducible component* $S^{(j)}(\mathbf{f})$. *If there is a* $k\in\mathbb{N}^{>0}$ *such that* $\mathbf{f}^k(S^{(j)}(\mathbf{f}))=S^{(j)}(\mathbf{f})$, *then the elements of* $S^{(j)}(\mathbf{f})$ *are said to be* **periodic singularities** *of period* k.

An example of such a behavior is given by a particular case of the Gambier system[13,14]

$$\begin{pmatrix} x_{n+1} \\ y_{n+1} \end{pmatrix} = \mathbf{f}(x_n, y_n) = \begin{pmatrix} \dfrac{(y_n + (1/a - a - 1))x_n - a + 1}{x_n + y_n} \\ 1 - 1/y_n \end{pmatrix}, \tag{5.5}$$

where a is a nonzero complex constant. The system (5.5) admits a singularity of type II at any point of the form (x,a). Then the first iterate of a point of this form is given by $(1/a-1,1-1/a)$. But the Jacobians of $\mathbf{f}^2$ and $\mathbf{f}^3$ at (x,a) are nonzero and the singularity is confined. It is not globally confined since $\mathbf{f}^4(x,a)=\mathbf{f}(x,a)=(1/a-1,1-1/a)$ and the singularity is periodic. The system admits the following first integral:

$$I(x,y) = \frac{y^3 - 3y + 1}{y(y-1)}. \tag{5.6}$$

Now, consider the second case considered in the proofs of Theorems 3.3 and 4.3: $S^{(1)}(\mathbf{f}) \subset \overline{L_{i,c}}$ for some c. If the singularities of $S^{(1)}(\mathbf{f})$ are generically confined in k steps, then $\mathbf{f}^k(S^{(1)}(\mathbf{f}))$ has to be a set of the form of the RHS of (3.8). Since there are only finitely many of those, the singularities cannot be globally confined. So, either they are periodic, or $S^{(1)}(\mathbf{f})$ lies inside the singular set of $\mathbf{f}^k$ for all k greater than a certain k'. It must also be true in the backward direction and if the singularities are not periodic $S^{(1)}(\mathbf{f})$ lies inside the singular set of $\mathbf{f}^{-k}$ for all k greater than a certain k''. We will refer to these singularities as *ubiquitous singularities*. An example of such a behavior is given by the singularities of Eq. (2.18) of the form $(x,0)$. These singularities are not confined but they are in the singular set of $\mathbf{f}^{-l}$ for any $l>0$ and, therefore, these singularities are ubiquitous. Note that singularities of the form $(0,y)$ are also ubiquitous.

Definition: A singularity $\mathbf{x}^* \in \mathbb{C}^p$ *of a birational mapping is said to be* **ubiquitous** *if there exist a* $k' \in \mathbb{N}^{>0}$ *such that* $\mathbf{x}^* \in S(\mathbf{f}^k)$ *for any* $k > k'$ *and a* $k'' \in \mathbb{N}^{>0}$ *such that* $\mathbf{x}^* \in S(\mathbf{f}^{-k})$ *for any* $k > k''$.

Given a discrete dynamical system of the form (2.21) and an irreducible component $S^{(j)}(\mathbf{f})$ of the singular set, one would like to be able to obtain information on the first integrals. The only way one can know if a given irreducible component of the singular set lies inside a level set is by studying the global behavior of the singularity. If the singularity is globally confined, then $S^{(j)}(\mathbf{f})$ does not lie inside a level set, but if it is ubiquitous, then it does. If the singularities are periodic, no conclusion can be reached.

Information on first integrals can be obtained by studying singularities of type I. Consider the paths $\mathbf{p}_i$ defined in the two-dimensional case in the proof of Theorem 3.1. The number of these paths is bounded above by the maximum of the degrees of P and Q. Moreover, for each $S_I^{(j)}(\mathbf{f}) \not\subset \overline{L_c}$ for all c, consider k_j', the lowest value k_j can take. Then $k_j' - 1$ is the number of different paths $\mathbf{p}_i$ realized by iterating a point close to the singularity under the mapping. Hence, the following corollary holds.

Corollary 5.2: Consider a two-dimensional birational mapping with rational first integral $R = P/Q$. *Consider also the irreducible components of the singular set of the first type* $S_I^{(j)}(\mathbf{f})$ *for which the singularities are globally confined. Then the maximum of the degrees of* P *and* Q *is bounded below by the number*

$$\sum_j (k_j' - 1), \tag{5.7}$$

where k_j' *is given by the lowest value* k_j *of Theorem 3.1.*

In example (2.2), the singular set has a unique component in which singularities are globally confined with $k=4$ and the degree of the first integral is exactly $k-1=3$. Note, however, that the corollary only provides a lower bound as shown in the following example,

$$\begin{pmatrix} x_{n+1} \\ y_{n+1} \end{pmatrix} = \mathbf{f}(x_n, y_n) = \begin{pmatrix} -y_n + x_n + \dfrac{a}{x_n} \\ x_n \end{pmatrix}, \tag{5.8}$$

where a is a nonvanishing complex number. Here again, one can check that singularities of the form $(0,y)$ are confined in four steps and since confinement is global, the lower bound for the numerator and denominator of a first integral is 3. However, the rational first integral $I=P/Q$ with lowest degree possible on P and Q is given by

$$I=(x_n-y_n)^2(x_n y_n-a)^2, \tag{5.9}$$

which is of degree 6, not 3 (note, however, the rather degenerate nature of the first integral).

Next, we turn our attention to singularities of type II in the case when $S_{II}^{(j)}(\mathbf{f}) \not\subset \overline{L_{i,c}}$ for all c and all i. From the proof of Theorems 3.2 and 4.2, one sees that, as long as the singularities are not confined, the iterates of $S_{II}^{(j)}(\mathbf{f}) \not\subset \overline{L_{\mathbf{c}}}$ must be roots of both P_i and Q_i for all rational first integrals P_i/Q_i. Therefore, we have the following corollary.

Corollary 5.3: Consider an algebraically integrable p-dimensional birational mapping with the rational first integral $R=P/Q$. Consider also an irreducible component of the singular set of the second type $S_{II}^{(j)}(\mathbf{f})$ whose singularities are globally confined. Let k_j be the corresponding confinement number. Then the finite elements of the set

$$\bigcup_{i=1}^{k_j-1} \mathbf{f}^i(S_I^{(j)}(\mathbf{f}))$$

are roots of both P and Q.

This corollary is best illustrated in example (2.15) where $(0,a)$ and $(1/a,0)$ are roots of both the numerator and denominator of the rational function (2.17).

The previous corollary has an immediate consequence for the existence of polynomial first integrals.

Corollary 5.4: Consider an algebraically integrable p-dimensional birational mapping. If this system admits singularities of the second type which are globally confined, then there is no polynomial first integral.

The last result concerns the case when the irreducible component of the singular set lies inside the closure of a level set of the first integral. In Secs. III and IV, it was found that if $\mathbf{f}^k$ (for $k \in \mathbb{N}$) is well-defined on $S^{(j)}(\mathbf{f})$ and its Jacobian is nonzero, then $\mathbf{f}^k(S^{(j)}(\mathbf{f}))$ must be a set of the form of the RHS of (3.8), hence it lies on a level set. This is stated in the following corollary.

Corollary 5.5: Consider a p-dimensional birational mapping $\mathbf{x}_{n+1}=\mathbf{f}(\mathbf{x}_n)$ together with an irreducible component of the singular set $S^{(j)}(\mathbf{f})$ for which the singularities are ubiquitous. If $\mathbf{f}^k$ is well-defined almost everywhere on $S^{(j)}(\mathbf{f})$ and its Jacobian is nonzero, then $\mathbf{f}^k(S^{(j)}(\mathbf{f}))$ lies inside the closure of a level set of the first integrals.

Note that the case $k=0$ should also be included meaning that $S^{(j)}(\mathbf{f})$ itself lies inside the closure of a level set of the first integrals.

This corollary can be applied to example (2.18). Since the two sets of singularities ($(x,0)$ and $(0,y)$) are ubiquitous, they are level sets of the first integral (2.19).

As a final example, consider the system

$$\begin{pmatrix} x_{n+1} \\ y_{n+1} \end{pmatrix} = \mathbf{f}(x_n, y_n) = \begin{pmatrix} -y_n + x_n + \dfrac{a}{x_n^2} \\ x_n \end{pmatrix}, \tag{5.10}$$

where a is a nonzero complex number. This example was first used in Ref. 17 to show that singularity confinement is not sufficient for integrability. Following example (2.2), it is easy to

show that singularities of the form $(0,y)$ are generically globally confined. However, numerical analysis performed on this system strongly suggests that it exhibits chaotic behavior.[17]

VI. CONCLUSIONS

In this article, we defined different types of singularities and their confinement property for autonomous discrete birational dynamical systems. The theory of singularity confinement was developed more than 10 years ago[11,12,27] and different types of singularities have been implicitly used. Here, in order to relate algebraic integrability to singularity confinement we have found necessary to give a formal definition of different singularities and their confinement property.

In Secs. III and IV, we showed that algebraic integrability for birational mappings implies that singularities are either locally confined or some preimages are not well-defined.

In Sec. V, we studied global properties of birational mappings and showed that there are three types of behavior for singularities compatible with algebraic integrability. Namely, singularities are either globally confined, periodic, or ubiquitous. Remarkably, in the seminal papers describing singularity confinement, similar behaviors were found heuristically to be compatible with integrability.[11–13,15,27,28] However, the classical approach relies mostly on a local analysis of the singularities. An important aspect of the results shown in this article is that global properties have to be satisfied for a system to be algebraically integrable. To unify these different concepts, we define the confinement property for a discrete system in the following way:

Definition: A birational mapping is said to have the **confinement property** *if its singularities are, generically, globally confined, periodic, or ubiquitous*.

Then the most important result of this article can be rephrased as follows.

Theorem: *An algebraically integrable birational mapping has the confinement property*.

In particular, this result shows that every mapping in the QRT-family[15,26] has the confinement property both in the symmetric and asymmetric cases. This fact also holds for the recently discovered class of integrable birational discrete systems discovered in Ref. 22. Moreover, from examples such as system (5.10), we have strong numerical evidence that the confinement property is necessary but not sufficient for algebraic integrability.

In this article, we also found sufficient conditions for nonintegrability. Essentially, if singularities are confined in one direction and not in the other, the system cannot be algebraically integrable.

Finally, the remaining corollaries of Sec. V provide information on the existence and degree of rational first integrals directly from the singularity confinement procedure.

All the examples of integrable discrete systems considered in this article have a first integral of genus 0 or 1. It is not possible to find a birational mapping of infinite order preserving an algebraic curve of genus 2 or higher. The argument proving this fact is due to Veselov (Ref. 31, p. 35). It makes use of the Hurwitz theorem which tells us that the automorphic group of an algebraic curve of genus 2 or higher is finite.

Another important question concerns the relation between the confinement property and other types of integrability for discrete dynamical systems (see, for example, Refs. 2, 4, 5, 17, and 30). In particular, in a work by Bellon,[3] the proof that two-dimensional birational mappings admitting a first integral satisfy the *algebraic entropy*[4,17] integrability condition is given.

Since the only mappings studied here were birational, we could have made use of the projective space in which the point at infinity plays no particular role. Hence only singularities of type II should be studied. However, the ideas presented in this article could not be extended for the case of nonautonomous or discrete dynamical systems that are not birational. For instance, the integrable nonrational mapping derived in Refs. 18–20 could not be studied. It is therefore crucial to give a definition of singularity confinement that can be applied to general discrete systems.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 45, NUMBER 3 MARCH 2004

Mathematical properties of a new Levin-type sequence transformation introduced by Čížek, Zamastil, and Skála. I. Algebraic theory

Ernst Joachim Weniger[a)]
Institut für Physikalische und Theoretische Chemie, Universität Regensburg, D-93040 Regensburg, Germany

(Received 25 June 2003; accepted 2 December 2003)

Čížek, Zamastil, and Skála [J. Math. Phys. **44**, 962–968 (2003)] introduced in connection with the summation of the divergent perturbation expansion of the hydrogen atom in an external magnetic field a new sequence transformation which uses as input data not only the elements of a sequence $\{s_n\}_{n=0}^{\infty}$ of partial sums, but also explicit estimates $\{\omega_n\}_{n=0}^{\infty}$ for the truncation errors. The explicit incorporation of the information contained in the truncation error estimates makes this and related transformations potentially much more powerful than, for instance, Padé approximants. Special cases of the new transformation are sequence transformations introduced by Levin [Int. J. Comput. Math. B **3**, 371–388 (1973)] and Weniger [Comput. Phys. Rep. **10**, 189–371 (1989), Secs. 7–9; Numer. Algor. **3**, 477–486 (1992)] and also a variant of Richardson extrapolation [Philos. Trans. R. Soc. London, Ser. A **226**, 299–349 (1927)]. The algebraic theory of these transformations—explicit expressions, recurrence formulas, explicit expressions in the case of special remainder estimates, and asymptotic order estimates satisfied by rational approximants to power series—is formulated in terms of hitherto unknown mathematical properties of the new transformation introduced by Čížek, Zamastil, and Skála. This leads to a considerable formal simplification and unification. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1643787]

I. INTRODUCTION

The most important and most versatile systematic approximation method in quantum physics is eigenvalue perturbation theory (see, for example, Ref. 137). Thus, the question, whether perturbation expansions converge or diverge, is of principal importance. Already in 1952, Dyson[56] had argued that perturbation expansions in quantum electrodynamics should diverge. Around 1970, Bender and Wu[10–12] showed in their work on anharmonic oscillators that factorially divergent perturbation expansions occur also in nonrelativistic quantum mechanics. In the following years, many other quantum systems were investigated, and in the overwhelming majority factorially divergent perturbation expansions were found (see, for example, Ref. 65, Table I or the articles reprinted in Ref. 98). Consequently, summation methods are needed to give the divergent perturbation series of quantum physics any meaning beyond mere formal expansions and to extract numerical information from them. A very readable discussion of the usefulness of summation and related techniques from a physicist's point of view can be found in the monograph by Bender and Orszag.[8]

Factorially divergent power series occur also in asymptotic expansions for special functions. However, special functions can normally be computed via a variety of different representations. Accordingly, in mathematics there is usually no compelling need to use divergent series for computational purposes, whereas in quantum physics it is frequently quite difficult or even impossible to find alternatives to divergent perturbation expansions. Consequently, summation tech-

[a)]Electronic mail: joachim.weniger@chemie.uni-regensburg.de

niques are far more important in physics than in mathematics. Nevertheless, the evaluation of special functions by summing divergent asymptotic expansions can be remarkably effective (see, for example, Refs. 147, 150, 154, 161).

In physics, the best known and most widely used summation techniques are Borel summation,[16,17] which replaces a divergent perturbation expansion by a Laplace-type integral, and the method of Padé approximants,[110] which transforms the partial sums of a power series to a rational function. Both approaches have been remarkably successful, but they have—like all other numerical techniques—certain shortcomings and limitations. For example, the Borel method is very powerful, but conceptually and computationally very demanding. From a technical point of view, Padé approximants can be applied remarkably easily, but they are not necessarily powerful enough to sum all perturbation series of interest. For example, Graffi and Grecchi[70] showed rigorously that Padé approximants are not able to sum the perturbation expansion of the octic anharmonic oscillator whose series coefficients grow roughly like $(3n)!/n^{1/2}$ [Ref. 11, Eq. (3)]. Accordingly, it is worth while to look for alternative techniques which are at least in some cases capable of producing better summation results.

Padé approximants accomplish an acceleration of convergence or a summation by converting the partial sums of a power series to a doubly indexed sequence of rational functions. This is also done by other, albeit less well known nonlinear transformations (see, for example, Refs. 20, 21, 33, 146, 166). It is not so well known among nonspecialists that some of these transformations sum many strongly divergent power series much more effectively than Padé approximants can do it. Particularly suited for the summation of strongly divergent series is a class of sequence transformations introduced by Levin[99] in 1973. These transformations use as input data not only the elements of a slowly convergent or divergent sequence $\{s_n\}_{n=0}^{\infty}$, whose elements may for instance be the partial sums $s_n=\sum_{k=0}^{n}a_k$ of an infinite series, but also explicit remainder estimates $\{\omega_n\}_{n=0}^{\infty}$. Several generalizations and extensions of Levin's transformation were derived later, for instance in Refs. 146, Secs. 7–9 or in Ref. 148. Further details as well as the description of several other Levin-type transformations can be found in a recent review by Homeier.[82]

The explicit incorporation of the information contained in the remainder estimates $\{\omega_n\}_{n=0}^{\infty}$ makes all Levin-type transformation potentially very powerful (see for example the numerical examples in Refs. 140, 141, 146). In the case of divergent alternating series, the so-called delta transformation [Ref. 146, Eq. (8.4-4)] was found to be particularly useful.[18,48–50,85,91,146–153,155,156,158,162,163]

However, sequence transformations in general or the Levin-type transformations mentioned above in particular are not only useful for the summation of divergent perturbation expansions. In recent years, many other successful applications of Levin-type transformations have been reported in the literature (see, for example, Refs. 2, 4–6, 13–15, 19, 39, 48, 49, 54, 55, 57, 63, 66, 71–74, 77–84, 86–90, 92, 94, 95, 97, 100, 103, 108, 109, 111–114, 116–119, 127–130, 132, 138, 139, 142, 144–152, 154, 158, 161, 164, 165). This list does not claim to be complete, but it suffices to show that Levin-type transformations are extremely useful computational tools which deserve to be more widely known.

In connection with the summation of the perturbation series for a hydrogen atom in an external magnetic field, Čížek, Zamastil, and Skála introduced a new sequence transformation [Ref. 50, Eq. (10)], which in the notation of Ref. 146 can be expressed as follows:

$$\mathcal{G}_k^{(n)}(q_m,s_n,\omega_n) = \frac{\sum_{j=0}^{k}(-1)^j\binom{k}{j}\left\{\prod_{m=1}^{k-1}\frac{(n+j+q_m)}{(n+k+q_m)}\right\}\frac{s_{n+j}}{\omega_{n+j}}}{\sum_{j=0}^{k}(-1)^j\binom{k}{j}\left\{\prod_{m=1}^{k-1}\frac{(n+j+q_m)}{(n+k+q_m)}\right\}\frac{1}{\omega_{n+j}}}, \quad k,n\in\mathbb{N}_0. \tag{1.1}$$

Here as well as later in the text it is always assumed that $\prod_{k=l}^{n}a_k=1$ holds if it is a so-called empty product with $l>n$.

The sequence transformation (1.1) contains the as yet unspecified parameters q_m with $1\leqslant m\leqslant k-1$. As discussed in Sec. II in more details, several other sequence transformations can be

obtained by specifying the parameters q_m. If we for instance choose $q_m=\beta$ with $\beta>0$, we obtain Levin's transformation $\mathcal{L}_k^{(n)}(\beta,s_n,\omega_n)$ (Ref. 99) in the notation of Ref. 146 [Eq. (7.1-7)], if we choose $q_m=\beta+m-1$, we obtain $\mathcal{S}_k^{(n)}(\beta,s_n,\omega_n)$ [Ref. 146, Eq. (8.2-7)], which is the parent transformation of the so-called delta transformation [Ref. 146, Eq. (8.4-4)] mentioned above, and if we choose $q_m=\xi-m+1$ with $\xi>0$, we obtain $\mathcal{M}_k^{(n)}(\xi,s_n,\omega_n)$ [Ref. 146, Eq. (9.2-6)]. Then, there is a sequence transformation $\mathcal{C}_k^{(n)}(\alpha,\beta,s_n,\omega_n)$ [Ref. 148, Eq. (3.2)] which—depending on the value of the parameter α—interpolates between Levin's transformation $\mathcal{L}_k^{(n)}(\beta,s_n,\omega_n)$ and $\mathcal{S}_k^{(n)}(\beta,s_n,\omega_n)$. It is obtained by choosing $q_m=\beta+[m-1]/\alpha$.

Thus, the transformation $\mathcal{G}_k^{(n)}(q_m,s_n,\omega_n)$ introduced by Čížek, Zamastil, and Skála provides a unifying concept for a large and practically important class of sequence transformations, and all results derived for $\mathcal{G}_k^{(n)}(q_m,s_n,\omega_n)$ can immediately be translated to the analogous results for its various special cases. However, so far only the explicit expression for this transformation as the ratio of two finite sums according to (1.1) is known [Ref. 50, Eq. (10)], and many other mathematical properties of interest are unknown.

In Sec. II, the explicit expression for $\mathcal{G}_k^{(n)}(q_m,s_n,\omega_n)$ is rederived by applying a suitable annihilating difference operator to the model sequence (2.12) according to (2.9). This annihilation operator approach was originally introduced in Ref. 146, Sec. 3.2 in connection with a simplified derivation of the explicit expression for Levin's transformation[99] and the construction of explicit expressions for other, closely related sequence transformations (Ref. 146, Secs. 7–9). This annihilation operator approach does not only produce the explicit expression (1.1), but it also provides a convenient starting point for the derivation of a recursive scheme for the numerators and denominators in (1.1), which is done in Sec. III, and for a theoretical convergence analysis, which will be done in Ref. 160.

In Sec. IV, simple explicit remainder estimates introduced by Levin[99] and Smith and Ford,[140] which in the terminology of Ref. 146 yield the u, t, v, and d variants of Levin's sequence transformation, are used in combination with $\mathcal{G}_k^{(n)}(q_m,s_n,\omega_n)$. The effectiveness of these remainder estimates is motivated and studied via some model sequences. Surprisingly, the v type remainder estimate produces more effective asymptotic estimates for the truncation errors of these model sequences than the other simple remainder estimates. Moreover, it is shown that all t type variants considered in this article are actually analogous d type variants in disguise.

In Sec. V, variants of $\mathcal{G}_k^{(n)}(q_m,s_n,\omega_n)$ are studied which closely resemble the Richardson extrapolation process.[115] These variants can be used in the case of logarithmic convergence ($\rho=1$ in (4.7)), whose acceleration constitutes a formidable computational problem.

In Sec. VI, the u, t, d, and v variants of $\mathcal{G}_k^{(n)}(q_m,s_n,\omega_n)$ are applied to the partial sums of a (formal) power series. This produces rational approximants that resemble Padé approximants, which are defined via the accuracy-through-order relationship (6.3). In the case of the u and d variants, the resulting rational expressions are actually Padé-type approximants, which satisfy the modified accuracy-through-order relationship (6.16).[22,23] In the case of the t and v variants, the resulting expressions are slight generalizations of a Padé-type approximant. With the help of the accuracy-through-order relationship (6.16), which defines Padé-type approximants, the accuracy-through-order relationships satisfied by these rational functions can be derived easily. These accuracy-through-order relationships are needed if the rational approximants derived from $\mathcal{G}_k^{(n)}(q_m,s_n,\omega_n)$ are to be used for the prediction of unknown power series coefficients.

This article is concluded in Sec. VII by a short summary and a critical assessment of the essential features of the new Levin-type transformation introduced recently by Čížek, Zamastil, and Skála.[50]

Only the mathematical properties of $\mathcal{G}_k^{(n)}(q_m,s_n,\omega_n)$ and its various special cases are treated in this article, albeit in a relatively detailed way. Anybody interested in other sequence transformations should consult the monograph by Brezinski and Redivo Zaglia.[33] It contains a wealth of material and provides a very readable introduction to a rapidly growing subfield of numerical mathematics. The older history of sequence transformations up to about 1945 is treated in a monograph by Brezinski,[26] and the more recent history is discussed in two articles, also by Brezinski.[27,31]

Finally, one should not forget that the study of sequence transformations remains incomplete without the simultaneous study of Padé approximants. Here, I recommend the book by Baker and Graves-Morris.[3]

II. EXPLICIT EXPRESSIONS VIA ANNIHILATION OPERATORS

Let us assume that $\{s_n\}_{n=0}^{\infty}$ is a slowly convergent or divergent sequence, whose elements may for instance be the partial sums $s_n=\sum_{k=0}^{n}a_k$ of an infinite series. A *sequence transformation* is a rule which maps a sequence $\{s_n\}_{n=0}^{\infty}$ to a new sequence $\{s_n'\}_{n=0}^{\infty}$ with hopefully better numerical properties.

The basic step for the construction of a sequence transformation is the assumption that the elements of a convergent or divergent sequence $\{s_n\}_{n=0}^{\infty}$ can be partitioned into a (generalized) limit s and a remainder r_n according to

$$s_n = s+r_n, \quad n\in\mathbb{N}_0. \tag{2.1}$$

A sequence transformation tries to accomplish an acceleration of convergence or a summation by eliminating the remainders r_n as effectively as possible from the input data s_n with the help of numerical techniques. In realistic problems, a sequence transformation can only eliminate approximations to the remainders. Consequently, the transformed sequence $\{s_n'\}_{n=0}^{\infty}$ will also be of the type of (2.1), which means that s_n' can also be partitioned into the (generalized) limit s and a transformed remainder r_n' according to

$$s_n' = s+r_n', \quad n\in\mathbb{N}_0. \tag{2.2}$$

The transformed remainders $\{r_n'\}_{n=0}^{\infty}$ are in general different from zero for all finite values of n. However, convergence is accelerated if the transformed remainders $\{r_n'\}_{n=0}^{\infty}$ vanish more rapidly than the original remainders $\{r_n\}_{n=0}^{\infty}$ according to

$$\lim_{n\to\infty}\frac{s_n'-s}{s_n-s} = \lim_{n\to\infty}\frac{r_n'}{r_n} = 0, \tag{2.3}$$

and a divergent sequence is summed if the transformed remainders r_n' vanish as $n\to\infty$.

In practice, an in principle unlimited variety of different types of remainders can occur. Therefore, it is essential to make some assumptions—either explicitly or implicitly—which provide the basis for the construction of a sequence transformation.

Let us assume that we have sufficient reason to believe that the elements of a sequence $\{s_n\}_{n=0}^{\infty}$ can for all $n\in\mathbb{N}_0$ be expressed by an expansion of the following type:

$$s_n = s+\sum_{j=0}^{\infty} c_j\,\psi_j(n). \tag{2.4}$$

The $\psi_j(n)$ are assumed to be *known* functions of n, but otherwise essentially arbitrary, and the c_j are unspecified coefficients independent of n. Hence, the ansatz (2.4) incorporates convergent as well as divergent sequences, depending upon the behavior of the functions $\psi_j(n)$ as $n\to\infty$.

If we want to accelerate the convergence of $\{s_n\}_{n=0}^{\infty}$ to its limit s or to sum it in the case of divergence with the help of a sequence transformation, we have to compute approximations to the remainders $\sum_{j=0}^{\infty}c_j\psi_j(n)$ and to eliminate them from the input data. However, the remainders of the sequence (2.4) contain an infinite number of unspecified coefficients c_j. Consequently, a complete determination of the remainders and their subsequent elimination cannot be accomplished by purely numerical means.

Let us also assume that the functions $\{\psi_j(n)\}_{j=0}^{\infty}$ form an asymptotic sequence as $n\to\infty$, i.e., that they satisfy for all $j\in\mathbb{N}_0$,

$$\psi_{j+1}(n) \;=\; o(\psi_j(n)), \quad n\to\infty. \tag{2.5}$$

The best, which a purely numerical process can accomplish, is the elimination of a finite number of the leading terms of (2.4). Obviously, this corresponds to the transformation of the sequence (2.4) to a new sequence $\{s_n'\}_{n=0}^{\infty}$ whose elements satisfy

$$s_n' \;=\; s+\sum_{j=0}^{\infty} c_j'\,\psi_{k+j}(n), \quad n\in\mathbb{N}_0, \quad k\in\mathbb{N}. \tag{2.6}$$

The c_j' are numerical coefficients that depend on k as well as on the coefficients c_j in (2.4).

In (2.6), the original remainders $\Sigma_{j=0}^{\infty}c_j\psi_j(n)$ are not completely eliminated from the elements of the input sequence (2.4). Since, however, the functions $\{\psi_j(n)\}_{j=0}^{\infty}$ are by assumption an asymptotic sequence according to (2.5), the transformed remainders $\Sigma_{j=0}^{\infty}c_j'\psi_{k+j}(n)$ in (2.6) should at least for sufficiently large values of $k\in\mathbb{N}$ have significantly better numerical properties than the original remainders $\Sigma_{j=0}^{\infty}c_j\psi_j(n)$.

Assumptions about the n-dependence of the truncation errors r_n can be incorporated into the transformation process via model sequences. In this approach, a sequence transformation is constructed which produces the (generalized) limit s of the model sequence

$$s_n \;=\; s+r_n \;=\; s+\sum_{j=0}^{k-1} c_j\,\psi_j(n), \quad k\in\mathbb{N}, \quad n\in\mathbb{N}_0, \tag{2.7}$$

if it is applied to $k+1$ consecutive elements $s_n, s_{n+1},\ldots, s_{n+k}$ of this model sequence. Since the $\psi_j(n)$ are assumed to be known functions of n, an element of this model sequence contains $k+1$ unknowns, the (generalized) limit s and the k unspecified coefficients $c_0, c_1,\ldots, c_{k-1}$. Accordingly, it follows from Cramer's rule that a sequence transformation, which is exact for the model sequence (2.7), can be expressed as the ratio of two determinants (see, for example, Ref. 33, Sect. 1.5). However, determinantal representations will not be considered here since they are computationally unattractive. Fortunately, the sequence transformation, which is exact for the general model sequence (2.7), can also be computed recursively, as shown independently by Schneider,[131] Håvie,[75] and Brezinski.[24] An alternative recursive scheme, which is more economical than the original recursive scheme, was later obtained by Ford and Sidi.[67]

A detailed discussion of the construction of sequence transformations via model sequences as well as many examples can for instance be found in the book by Brezinski and Redivo Zaglia[33] or in Ref. 146.

Levin-type sequence transformations try to make the transformation process more efficient by explicitly utilizing the information contained in remainder estimates $\{\omega_n\}_{n=0}^{\infty}$. Thus, a sequence transformation is constructed which is exact for the elements of the model sequence [Ref. 146, Eq. (3.2-9)]

$$s_n \;=\; s+\omega_n z_n, \quad n\in\mathbb{N}_0. \tag{2.8}$$

The remainder estimates ω_n are assumed to be known, and the correction terms z_n should be chosen in such a way that the products $\omega_n z_n$ provide sufficiently accurate and rapidly convergent approximations to actual remainders. The principal advantage of this approach is that only the correction terms $\{z_n\}_{n=0}^{\infty}$ have to be determined. If good remainder estimates can be found, the determination of z_n and the subsequent elimination of $\omega_n z_n$ from s_n often leads to substantially better results than the construction and subsequent elimination of other approximations to r_n.

The model sequence (2.8) has another indisputable advantage: There exists a systematic approach for the construction of a sequence transformation which is exact for this model sequence. Let us assume that a *linear* operator $\hat{T}$ can be found which annihilates for all $n\in\mathbb{N}_0$ the correction term z_n according to $\hat{T}(z_n)=0$. Then, a sequence transformation, which is exact for the model

sequence (2.8), can be obtained by applying $\hat{T}$ to $[s_n - s]/\omega_n = z_n$. Since $\hat{T}$ annihilates z_n and is by assumption linear, the following sequence transformation $\mathcal{T}$ is exact for the model sequence (2.8) [Ref. 146, Eq. (3.2-11)]:

$$\mathcal{T}(s_n, \omega_n) = \frac{\hat{T}(s_n/\omega_n)}{\hat{T}(1/\omega_n)} = s. \tag{2.9}$$

The construction of sequence transformations via annihilation operators was introduced in Ref. 146, Sec. 3.2 in connection with a rederivation of Levin's transformation[99] and the construction of some other, closely related sequence transformations (Refs. 146, Secs. 7–9).

Later, this annihilation operator approach was discussed and extended in books by Brezinski[28] and Brezinski and Redivo Zaglia[33] and in articles by Brezinski,[27,29–31] Brezinski and Matos,[32] Brezinski and Redivo Zaglia,[34–36] Brezinski and Salam,[37] Homeier,[82] Matos,[102] and Weniger.[148]

Simple and yet very powerful sequence transformations result (Ref. 146, Secs. 7–9) if the annihilation operator $\hat{T}$ in (2.9) is based upon the finite difference operator Δ defined by $\Delta f(n) = f(n+1) - f(n)$. In the following text, it will always be tacitly assumed that Δ acts on the variable n only. As is well known, the kth power of the finite difference operator annihilates a polynomial $P_{k-1}(n)$ of degree $k-1$ in n according to $\Delta^k P_{k-1}(n) = 0$. Thus, the correction terms z_n in (2.8) should be chosen in such a way that multiplication of z_n by some suitable quantity $w_k(n)$ yields a polynomial $P_{k-1}(n)$ of degree $k-1$ in n. If such a $w_k(n)$ can be found, then

$$\Delta^k [w_k(n)\, z_n] = \Delta^k P_{k-1}(n) = 0 \tag{2.10}$$

and the weighted difference operator $\hat{T} = \Delta^k w_k(n)$ annihilates z_n. Thus, the corresponding sequence transformation (2.9) is given by the ratio

$$\mathcal{T}_k^{(n)}(w_k(n)|s_n, \omega_n) = \frac{\Delta^k[w_k(n) s_n/\omega_n]}{\Delta^k[w_k(n)/\omega_n]}. \tag{2.11}$$

The sequence transformation (1.1) introduced by Čížek, Zamastil, and Skála can be constructed via the model sequence [Ref. 50, Eq. (9)]

$$s_n = s + \omega_n \sum_{j=0}^{k-1} \frac{c_j}{\prod_{m=1}^{j} (n+q_m)}, \quad k \in \mathbb{N}, \quad n \in \mathbb{N}_0, \tag{2.12}$$

for which it is exact.

It will become clear later (compare (4.5) and the discussion related to it) that in (2.12) as well as in the model sequences (2.16), (2.19), (2.23), and (2.27), which can be derived from (2.12), it makes sense to assume $c_0 \neq 0$.

Both in the model sequence (2.12) as well as in the sequence transformation, which is derived from it, we want to admit $n = 0$. Moreover, this model sequence should have a consistent behavior for all $n \in \mathbb{N}_0$. In particular, the signs of the terms in (2.12) should not depend on n. Thus, we normally require $q_m > 0$ for $1 \leqslant m \leqslant k-1$, but otherwise these parameters are essentially arbitrary.

Multiplication of the sum in (2.12) by $\Pi_{m=1}^{k-1}(n+q_m)$ yields $\Sigma_{j=0}^{k-1} c_j \Pi_{m=j+1}^{k-1}(n+q_m)$, which is a polynomial of degree $k-1$ in n. Thus, $\hat{T} = \Delta^k \Pi_{m=1}^{k-1}(n+q_m)$ is the operator which annihilates the correction term in (2.12), and we obtain from (2.9) the following difference operator representation for the sequence transformation introduced by Čížek, Zamastil, and Skála [Ref. 50, Eq. (10)]:

$$\mathcal{G}_k^{(n)}(q_m,s_n,\omega_n) = \frac{\Delta^k\left\{\prod_{m=1}^{k-1}(n+q_m)\right\}\frac{s_n}{\omega_n}}{\Delta^k\left\{\prod_{m=1}^{k-1}(n+q_m)\right\}\frac{1}{\omega_n}}, \quad k,n\in\mathbb{N}_0. \tag{2.13}$$

It will become clear later that this difference operator representation is in some sense more fundamental and more important than the explicit expression which can be derived easily from it. We only have to insert the well-known relationship

$$\Delta^k f(n) = (-1)^k\sum_{j=0}^{k}(-1)^j\binom{k}{j}f(n+j) \tag{2.14}$$

into the numerator and denominator of (2.13) to obtain

$$\mathcal{G}_k^{(n)}(q_m,s_n,\omega_n) = \frac{\sum_{j=0}^{k}(-1)^j\binom{k}{j}\left\{\prod_{m=1}^{k-1}(n+j+q_m)\right\}\frac{s_{n+j}}{\omega_{n+j}}}{\sum_{j=0}^{k}(-1)^j\binom{k}{j}\left\{\prod_{m=1}^{k-1}(n+j+q_m)\right\}\frac{1}{\omega_{n+j}}}, \quad k,n\in\mathbb{N}_0. \tag{2.15}$$

In the case of large transformation orders k, terms that are large in magnitude occur in the binomial sums in the numerator and denominator of (2.15). The same problem occurs also in explicit expressions for other Levin-type sequence transformation discussed later. In the case of some FORTRAN compilers, this can easily lead to overflow. To decrease the magnitude of the terms, it has become customary to include an additional normalization factor. Thus, we divide numerator and denominator of (2.15) by $\Pi_{m=1}^{k-1}(n+k+q_m)$ and obtain (1.1). Such an approach is always possible since the coefficients of a ratio like (2.15) are only defined up to a common nonzero factor.

If we choose in (2.12) $q_m=\beta$ with $\beta>0$, we obtain the model sequence for Levin's transformation[99] in the notation of Ref. 146, Eq. (7.1-2),

$$s_n = s+\omega_n\sum_{j=0}^{k-1}\frac{c_j}{(\beta+n)^j}, \quad k\in\mathbb{N}, \quad n\in\mathbb{N}_0. \tag{2.16}$$

Thus, the corresponding annihilation operator is given by $\hat{T}=\Delta^k(\beta+n)^{k-1}$ and Levin's transformation[99] can in the notation of Ref. 146, Eq. (7.1-7) be expressed as follows:

$$\mathcal{L}_k^{(n)}(\beta,s_n,\omega_n)=\mathcal{G}_k^{(n)}(\beta,s_n,\omega_n)=\frac{\Delta^k[(\beta+n)^{k-1}s_n/\omega_n]}{\Delta^k[(\beta+n)^{k-1}/\omega_n]} \tag{2.17}$$

$$=\frac{\sum_{j=0}^{k}(-1)^j\binom{k}{j}\frac{(\beta+n+j)^{k-1}}{(\beta+n+k)^{k-1}}\frac{s_{n+j}}{\omega_{n+j}}}{\sum_{j=0}^{k}(-1)^j\binom{k}{j}\frac{(\beta+n+j)^{k-1}}{(\beta+n+k)^{k-1}}\frac{1}{\omega_{n+j}}}, \quad k,n\in\mathbb{N}_0. \tag{2.18}$$

If we choose in (2.12) $q_m=\beta+m-1$ with $\beta>0$, we obtain the following model sequence [Ref. 146, Eq. (8.2-1)] for the sequence transformation $\mathcal{S}_k^{(n)}(\beta,s_n,\omega_n)$ which is a truncated factorial series involving Pochhammer symbols $(\beta+n)_j=\Gamma(\beta+n+j)/\Gamma(\beta+n)$:

$$s_n = s+\omega_n\sum_{j=0}^{k-1}\frac{c_j}{(\beta+n)_j}, \quad k\in\mathbb{N}, \quad n\in\mathbb{N}_0. \tag{2.19}$$

The fundamental properties of factorial series are for instance discussed in books by Nielsen[105] and Nörlund.[106,107]

The annihilation operator for the model sequence (2.19) is given by $\hat{T}=\Delta^k(\beta+n)_{k-1}$ and the sequence transformation $\mathcal{S}_k^{(n)}(\beta,s_n,\omega_n)$, which is exact for the model sequence (2.19), can be expressed as follows [Ref. 146, Eq. (8.2-7)]:

$$\mathcal{S}_k^{(n)}(\beta,s_n,\omega_n)=\mathcal{G}_k^{(n)}(\beta+m-1,s_n,\omega_n)=\frac{\Delta^k[(\beta+n)_{k-1}s_n/\omega_n]}{\Delta^k[(\beta+n)_{k-1}/\omega_n]} \tag{2.20}$$

$$=\frac{\sum_{j=0}^{k}(-1)^j\binom{k}{j}\frac{(\beta+n+j)_{k-1}}{(\beta+n+k)_{k-1}}\frac{s_{n+j}}{\omega_{n+j}}}{\sum_{j=0}^{k}(-1)^j\binom{k}{j}\frac{(\beta+n+j)_{k-1}}{(\beta+n+k)_{k-1}}\frac{1}{\omega_{n+j}}},\quad k,n\in\mathbb{N}_0\,. \tag{2.21}$$

The ratio (2.21) was originally derived by Sidi[134] for the construction of explicit expressions for Padé approximants of some special hypergeometric series. However, Sidi's article[134] provides no evidence that he intended to use this ratio as a sequence transformation. Moreover, I am not aware of any article of Sidi where the properties of the sequence transformation $\mathcal{S}_k^{(n)}(\beta,s_n,\omega_n)$ were discussed or where it was applied. Later, $\mathcal{S}_k^{(n)}(\beta,s_n,\omega_n)$ was used in the Master's thesis of Shelef[133] for the numerical inversion of Laplace transforms, but it seems that this Master's thesis was not published elsewhere. The first refereed and generally accessible article, where an application of (2.21) as a sequence transformation was described, is,[165] where the u-variant (4.13) was employed [Ref. 165, Eq. (9)]. The mathematical properties of (2.21) as a sequence transformation and in particular its connection with factorial series were developed independently of Sidi and Shelef in (Ref. 146, Secs. 8 and 13) (compare also Ref. 8 of Ref. 165).

If we choose in (2.12) $q_m=\xi-m+1$ with $\xi>0$, we obtain the following model sequence [Ref. 146, Eq. (9.2-1)] for the sequence transformation $\mathcal{M}_k^{(n)}(\xi,s_n,\omega_n)$:

$$s_n = s+\omega_n\sum_{j=0}^{k-1}\frac{c_j}{\prod_{m=1}^{j}(\xi+n-m+1)} \tag{2.22}$$

$$= s+\omega_n\sum_{j=0}^{k-1}\frac{(-1)^j c_j}{(-\xi-n)_j} = s+\omega_n\sum_{j=0}^{k-1}\frac{c_j'}{(-\xi-n)_j},\quad k\in\mathbb{N},\quad n\in\mathbb{N}_0\,. \tag{2.23}$$

Thus, the corresponding annihilation operator is given by $\hat{T}=\Delta^k(-\xi-n)_{k-1}$ and the sequence transformation $\mathcal{M}_k^{(n)}(\xi,s_n,\omega_n)$ can be expressed as follows [Ref. 146, Eq. (9.2-6)]:

$$\mathcal{M}_k^{(n)}(\xi,s_n,\omega_n)=\mathcal{G}_k^{(n)}(\xi-m+1,s_n,\omega_n)=\frac{\Delta^k[(-\xi-n)_{k-1}s_n/\omega_n]}{\Delta^k[(-\xi-n)_{k-1}/\omega_n]} \tag{2.24}$$

$$=\frac{\sum_{j=0}^{k}(-1)^j\binom{k}{j}\frac{(-\xi-n-j)_{k-1}}{(-\xi-n-k)_{k-1}}\frac{s_{n+j}}{\omega_{n+j}}}{\sum_{j=0}^{k}(-1)^j\binom{k}{j}\frac{(-\xi-n-j)_{k-1}}{(-\xi-n-k)_{k-1}}\frac{1}{\omega_{n+j}}},\quad k,n\in\mathbb{N}_0\,. \tag{2.25}$$

If we choose in (2.12) $q_m=\beta+[m-1]/\alpha$ with $\alpha,\beta>0$, we obtain the following model sequence [Ref. 148, Eq. (3.1)] for the sequence transformation $\mathcal{C}_k^{(n)}(\alpha,\beta,s_n,\omega_n)$:

$$s_n = s + \omega_n \sum_{j=0}^{k-1} \frac{c_j}{\prod_{m=1}^{j} (\beta+n+[m-1]/\alpha)} \tag{2.26}$$

$$= s + \omega_n \sum_{j=0}^{k-1} \frac{\alpha^j c_j}{(\alpha[\beta+n])_j} = s + \omega_n \sum_{j=0}^{k-1} \frac{c_j'}{(\alpha[\beta+n])_j}, \quad k \in \mathbb{N}, \quad n \in \mathbb{N}_0 . \tag{2.27}$$

Thus, the corresponding annihilation operator is given by $\hat{T}=\Delta^k(\alpha[\beta+n])_{k-1}$ and the sequence transformation $\mathcal{C}_k^{(n)}(\alpha,\beta,s_n,\omega_n)$ can be expressed as follows [Ref. 148, Eq. (3.2)]:

$$\mathcal{C}_k^{(n)}(\alpha,\beta,s_n,\omega_n)=\mathcal{G}_k^{(n)}(\beta+[m-1]/\alpha,s_n,\omega_n)=\frac{\Delta^k[(\alpha[\beta+n])_{k-1}s_n/\omega_n]}{\Delta^k[(\alpha[\beta+n])_{k-1}/\omega_n]} \tag{2.28}$$

$$=\frac{\sum_{j=0}^{k} (-1)^j \binom{k}{j} \frac{(\alpha[\beta+n+j])_{k-1}}{(\alpha[\beta+n+k])_{k-1}} \frac{s_{n+j}}{\omega_{n+j}}}{\sum_{j=0}^{k} (-1)^j \binom{k}{j} \frac{(\alpha[\beta+n+j])_{k-1}}{(\alpha[\beta+n+k])_{k-1}} \frac{1}{\omega_{n+j}}},$$

$$k,n \in \mathbb{N}_0 . \tag{2.29}$$

Depending upon the value of $\alpha>0$, the sequence transformation $\mathcal{C}_k^{(n)}(\alpha,\beta,s_n,\omega_n)$ interpolates between $\mathcal{S}_k^{(n)}(\beta,s_n,\omega_n)$ and Levin's sequence transformation $\mathcal{L}_k^{(n)}(\beta,s_n,\omega_n)$. If we choose $\alpha=1$ in (2.29) and compare the resulting expression with (2.21), we find

$$\mathcal{C}_k^{(n)}(1,\beta,s_n,\omega_n) = \mathcal{S}_k^{(n)}(\beta,s_n,\omega_n), \tag{2.30}$$

and if we use

$$\lim_{\alpha\to\infty} \frac{(\alpha[\beta+n+j])_{k-1}}{\alpha^{k-1}} = \lim_{\alpha\to\infty} \prod_{m=1}^{k-1} (\beta+n+j+[m-1]/\alpha) = (\beta+n+j)^{k-1} \tag{2.31}$$

in (2.29) and compare the resulting expression with (2.18), we find

$$\lim_{\alpha\to\infty} \mathcal{C}_k^{(n)}(\alpha,\beta,s_n,\omega_n) = \mathcal{L}_k^{(n)}(\beta,s_n,\omega_n) . \tag{2.32}$$

Thus, the construction of explicit expressions for the Levin-type sequence transformations $\mathcal{G}_k^{(n)}(q_m,s_n,\omega_n)$, $\mathcal{L}_k^{(n)}(\beta,s_n,\omega_n)$, $\mathcal{S}_k^{(n)}(\beta,s_n,\omega_n)$, $\mathcal{M}_k^{(n)}(\xi,s_n,\omega_n)$, and $\mathcal{C}_k^{(n)}(\alpha,\beta,s_n,\omega_n)$ with the help of annihilation operators is almost trivial. However, the annihilation operator approach does not only work in the case of the comparatively simple annihilating difference operators in (2.13), (2.17), (2.20), (2.24), and (2.28). In Ref. 146, Sec. 7.4 it was shown that Richardson extrapolation[115] and Sidi's generalized Richardson extrapolation process[135] can be derived by using divided differences as annihilation operators. Then, it was shown by Brezinski and Redivo Zaglia,[34,35] Brezinski and Matos,[32] and Matos[102] that the majority of the currently known transformations for scalar sequence can be derived via the annihilation operator approach. The generalization of this approach to vector and matrix sequences was discussed by Brezinski and Redivo Zaglia[36] and Brezinski and Salam.[37]

III. RECURRENCE FORMULAS

In the theory of sequence transformations it is relatively uncommon that closed form expressions of the type of (1.1), (2.18), (2.21), (2.25), and (2.29) are known. The majority of the currently known sequence transformations are defined and computed via recursive schemes. From a computational point of view, the lack of an explicit expression is normally no disadvantage. The use of recurrence formulas is in most cases (much) more efficient, in particular if a whole sequence of transforms must be computed simultaneously.

It is an additional advantage of the annihilation operator approach described in Sec. II that it permits a convenient construction of a recursive scheme for the numerators and denominators of $\mathcal{G}_k^{(n)}(q_m, s_n, \omega_n)$. For that purpose, let us define

$$\Gamma_k^{(n)} = \Gamma_k^{(n)}(q_m, u_n) = \Delta^k X_k^{(n)}, \quad k,n \in \mathbb{N}_0, \tag{3.1}$$

$$X_k^{(n)} = X_k^{(n)}(q_m, u_n) = \prod_{m=1}^{k-1} (n+q_m)\, u_n, \quad k,n \in \mathbb{N}_0. \tag{3.2}$$

Comparison with (2.13) shows that $\Gamma_k^{(n)}$ corresponds apart from a missing phase factor $(-1)^k$ to the numerator in (2.15) if we choose $u_n = s_n/\omega_n$, and to the denominator in (2.15) if we choose $u_n = 1/\omega_n$.

The quantities $X_k^{(n)}$ satisfy for $k \geqslant 2$ the two-term recursion

$$X_k^{(n)} = (n+q_{k-1})\, X_{k-1}^{(n)}. \tag{3.3}$$

Next, we use the commutator relationship [see Ref. 64 or Ref. 146, Eq. (7.2-2)]

$$\Delta^k (n+q_{k-1}) - (n+q_{k-1})\, \Delta^k = k\, E\, \Delta^{k-1}, \tag{3.4}$$

which can be proven by complete induction. This commutator can be rewritten as follows:

$$\Delta^k (n+q_{k-1}) = [(n+k+q_{k-1})\, E - (n+q_{k-1})]\, \Delta^{k-1}. \tag{3.5}$$

Here, E is the shift operator defined by $Ef(n) = f(n+1)$.

The combination of (3.1), (3.2), (3.3), and (3.5) yields

$$\Gamma_k^{(n)} = \Delta^k (n+q_{k-1})\, X_{k-1}^{(n)} \tag{3.6}$$

$$= [(n+k+q_{k-1})\, E - (n+q_{k-1})]\, \Delta^{k-1} X_{k-1}^{(n)} \tag{3.7}$$

$$= (n+k+q_{k-1})\, \Gamma_{k-1}^{(n+1)} - (n+q_{k-1})\, \Gamma_{k-1}^{(n)}, \quad k \geqslant 2, \quad n \in \mathbb{N}_0. \tag{3.8}$$

Finally, we rescale $\Gamma_k^{(n)}$ according to

$$G_k^{(n)} = G_k^{(n)}(q_m, u_n) = \frac{\Gamma_k^{(n)}(q_m, u_n)}{\prod_{m=1}^{k-1} (n+k+q_m)}, \quad k,n \in \mathbb{N}_0. \tag{3.9}$$

If we combine (3.8) and (3.9) and take into account that (3.1) and (3.2) imply $\Gamma_0^{(n)} = u_n$ and $\Gamma_1^{(n)} = u_{n+1} - u_n$, respectively, we obtain the following recursive scheme for the numerators and denominators of the sequence transformation (1.1) introduced by Čížek, Zamastil, and Skála [Ref. 50, Eq. (10)]:

$$G_0^{(n)} = u_n, \quad n \in \mathbb{N}_0, \tag{3.10a}$$

$$G_1^{(n)} = u_{n+1} - u_n, \quad n \in \mathbb{N}_0, \tag{3.10b}$$

$$G_{k+1}^{(n)} = G_k^{(n+1)} - \frac{n+q_k}{n+k+q_k+1} \prod_{m=1}^{k-1} \frac{n+k+q_m}{n+k+q_m+1} G_k^{(n)}, \quad k \in \mathbb{N}, \quad n \in \mathbb{N}_0. \tag{3.10c}$$

If we choose $u_n = s_n/\omega_n$, this recursive scheme produces the numerator of (1.1), and if we choose $u_n = 1/\omega_n$, we obtain the denominator of (1.1).

As shown in Ref. 146, Secs. 7.3, 8.3, and 9.3, recursive schemes for the numerator and denominator sums of the sequence transformations $\mathcal{L}_k^{(n)}(\beta,s_n,\omega_n)$. $\mathcal{S}_k^{(n)}(\beta,s_n,\omega_n)$, and $\mathcal{M}_k^{(n)}(\xi,s_n,\omega_n)$ can be derived in the same way. The recursive scheme [Ref. 146, Eq. (7.2-8)]

$$L_0^{(n)} = u_n, \quad n\in\mathbb{N}_0, \tag{3.11a}$$

$$L_{k+1}^{(n)} = L_k^{(n+1)} - \frac{(\beta+n)(\beta+n+k)^{k-1}}{(\beta+n+k+1)^k} L_k^{(n)}, \quad k,n\in\mathbb{N}_0, \tag{3.11b}$$

produces the numerator and denominator sums in (2.18) if we choose $u_n=s_n/\omega_n$ and $u_n=1/\omega_n$, respectively. We obtain (3.11) from (3.10) by choosing $q_m=\beta$.

Similarly, the recursive schemes [Ref. 146, Eq. (8.3-7)]

$$S_0^{(n)} = u_n, \quad n\in\mathbb{N}_0, \tag{3.12a}$$

$$S_{k+1}^{(n)} = S_k^{(n+1)} - \frac{(\beta+n+k-1)(\beta+n+k)}{(\beta+n+2k-1)(\beta+n+2k)} S_k^{(n)}, \quad k,n\in\mathbb{N}_0, \tag{3.12b}$$

and [Ref. 146, Eq. (9.3-6))]

$$M_0^{(n)} = u_n, \quad n\in\mathbb{N}_0, \tag{3.13a}$$

$$M_{k+1}^{(n)} = M_k^{(n+1)} - \frac{\xi+n-k+1}{\xi+n+k+1} M_k^{(n)}, \quad k,n\in\mathbb{N}_0, \tag{3.13b}$$

produce the numerator and denominator sums in (2.21) and (2.25), respectively. The recursive schemes (3.12) and (3.13) can be obtained from (3.10) by setting $q_m=\beta+m-1$ and $q_m=\xi-m+1$, respectively.

If we set $q_m=\beta+[m-1]/\alpha$ in (3.10), we obtain the recursive scheme for the interpolating transformation $\mathcal{C}_k^{(n)}(\alpha,\beta,s_n,\omega_n)$:

$$C_0^{(n)} = u_n, \quad n\in\mathbb{N}_0, \tag{3.14a}$$

$$C_1^{(n)} = u_{n+1}-u_n, \quad n\in\mathbb{N}_0, \tag{3.14b}$$

$$C_{k+1}^{(n)} = C_k^{(n+1)} - \frac{(\alpha[\beta+n]+k-1)(\alpha[\beta+n+k])_{k-1}}{(\alpha[\beta+n+k+1])_k} C_k^{(n)}, \quad k\in\mathbb{N},n\in\mathbb{N}_0. \tag{3.14c}$$

This scheme produces the numerator and denominator sums of (2.29) if we choose $u_n=s_n/\omega_n$ and $u_n=1/\omega_n$, respectively. The recurrence formula published in Ref. 148, Eq. (3.3) contains errors.

IV. LEVIN'S EXPLICIT REMAINDER ESTIMATES

It follows from (2.13), (2.14), (2.17), (2.20), (2.24), and (2.28) that all sequence transformations considered in this article can be expressed as follows:

$$T_k^{(n)}(s_n,\omega_n) = \frac{\Delta^k\{P_{k-1}(n)\, s_n/\omega_n\}}{\Delta^k\{P_{k-1}(n)/\omega_n\}}, \quad k\in\mathbb{N}, \quad n\in\mathbb{N}_0. \tag{4.1}$$

Here, $P_{k-1}(n)$ is a polynomial of degree $k-1$ in n. Obviously, the remainder estimates $\{\omega_n\}_{n=0}^{\infty}$ have to satisfy the minimal requirement that $\Delta^k\{P_{k-1}(n)/\omega_n\}\neq 0$ for all *finite* $k,n\in\mathbb{N}_0$. In the following text, this will always be assumed.

The weighted difference operator $\Delta^k P_{k-1}(n)$ in (4.1) is linear. Accordingly, such a sequence transformation satisfies

$$T_k^{(n)}(s_n,\omega_n) \;=\; s+\frac{\Delta^k\{P_{k-1}(n)\,[s_n-s]/\omega_n\}}{\Delta^k\{P_{k-1}(n)/\omega_n\}},\quad k\in\mathbb{N},\quad n\in\mathbb{N}_0\,. \tag{4.2}$$

This property of Levin-type transformations has some far-reaching consequences. Let us assume that we can find for a given sequence $\{s_n\}_{n=0}^{\infty}$ a sequence $\{\omega_n\}_{n=0}^{\infty}$ of *perfect* remainder estimates such that

$$s_n \;=\; s+r_n \;=\; s+c\,\omega_n,\quad c\neq 0,\quad n\in\mathbb{N}_0\,. \tag{4.3}$$

The polynomial $P_{k-1}(n)$ in (4.1) is of degree $k-1$ in n, which implies that it is annihilated by Δ^k according to $\Delta^k P_{k-1}(n)=0$. Thus, the transformation problem is now trivial since (4.2) produces the (generalized) limit s of the sequence (4.3) (Ref. 146, Theorem 12-8),

$$T_k^{(n)}(s_n,\omega_n) \;=\; s+\frac{c\Delta^k P_{k-1}(n)}{\Delta^k\{P_{k-1}(n)/\omega_n\}} \;=\; s,\quad k\in\mathbb{N},\quad n\in\mathbb{N}_0\,. \tag{4.4}$$

Unfortunately, the perfect remainder estimates satisfying (4.3) can only be found for practically more or less irrelevant model problems. In the case of realistic problems, we have to be more modest and can only hope to find remainder estimates that reproduce the leading order asymptotics of the actual remainders [Ref. 146, Eq. (7.3-1)],

$$r_n \;=\; s_n-s \;=\; \omega_n[c+\mathrm{O}(1/n)],\quad c\neq 0,\quad n\to\infty\,. \tag{4.5}$$

This asymptotic condition does not fix remainder estimates uniquely. All Levin-type transformations considered in this article are invariant under the transformation $\omega_n\to\gamma\omega_n$ with $\gamma\neq 0$. Accordingly, all Levin-type transformations considered here are homogeneous functions of degree one in the sequence elements and of degree zero in the remainder estimates [compare Ref. 146, Eq. (12.3-1)]. Moreover, given a sequence $\{r_n\}_{n=0}^{\infty}$ of remainders it is usually possible to find a variety of genuinely different sequences $\{\omega_n\}_{n=0}^{\infty}$, $\{\omega_n'\}_{n=0}^{\infty}$, $\{\omega_n''\}_{n=0}^{\infty}$,... of remainder estimates which all satisfy the asymptotic condition (4.5).

In some exceptional cases, explicit analytical expressions for remainder estimates can be found. Let us for instance assume that the elements of the sequence to be transformed are the partial sums $s_n=\Sigma_{k=0}^{n}a_k$ of an infinite series and that the terms a_k have a sufficiently simple analytical structure. Then it may be possible to derive an explicit expression for the truncation error, from which explicit remainder estimates satisfying (4.5) can be derived.

In principle, such an analytical approach would be highly desirable, in particular since it should then be possible to construct for a given sequence $\{s_n\}_{n=0}^{\infty}$ more effective remainder estimates $\{\tilde{\omega}_n^{(l)}\}_{n=0}^{\infty}$ that do not only reproduce the leading order asymptotics of the remainders according to (4.5), but several of the leading orders according to

$$r_n \;=\; s_n-s \;=\; \tilde{\omega}_n^{(l)}[c+\mathrm{O}(n^{-l})],\quad c\neq 0,\quad n\to\infty\,, \tag{4.6}$$

where $l>1$ is a fixed positive integer. Improved remainder estimates of that kind should lead to more efficient Levin-type transformations. Unfortunately, only relatively little work has been done on the asymptotics of truncation errors $\Sigma_{k=n+1}^{\infty}a_k$ of infinite series as $n\to\infty$ beyond the leading order. Moreover, in many applications of Levin-type transformations in particular in physics, only the numerical values of a finite string of sequence elements or series coefficients are available, but no explicit analytical expressions. In such a case, remainder estimates have to be constructed from the numerical values of the input data via simple rules.

Levin-type sequence transformations are not limited to strongly divergent perturbation expansions. They are able to accelerate the convergence of many series and sequences if suitable remainder estimates are used. In this context, it is helpful to introduce first some terminology which is common in the literature on convergence acceleration methods. Many practically relevant sequences $\{s_n\}_{n=0}^{\infty}$, which converge to some limit s, satisfy

$$\lim_{n\to\infty}\frac{s_{n+1}-s}{s_n-s} \;=\; \lim_{n\to\infty}\frac{r_{n+1}}{r_n} \;=\; \rho\,. \tag{4.7}$$

If $0<|\rho|<1$ holds, we say that the sequence $\{s_n\}_{n=0}^{\infty}$ converges *linearly*, if $\rho=1$ holds, we say that this sequence converges *logarithmically*, and if $\rho=0$ holds, we say that it converges *hyperlinearly*. Of course, $|\rho|>1$ implies that the sequence $\{s_n\}_{n=0}^{\infty}$ diverges.

In this article, only linearly and logarithmically convergent as well as divergent sequences are considered. Hyperlinearly convergent sequences as for example the partial sums of the power series for the exponential $\exp(z)$ normally converge so well that it is not worth while using sequence transformations.

On the basis of purely heuristic arguments Levin[99] and later Smith and Ford[140] suggested some simple remainder estimates which according to experience nevertheless work remarkably well in a large variety of cases. These simple remainder estimates can be motivated by considering simple model problems. For that purpose, let us assume that the elements of a sequence $\{s_n\}_{n=0}^{\infty}$ of partial sums $\Sigma_{\nu=0}^{n}a_\nu$ behave as follows:

$$s_n \;\sim\; s+z^{n+1}\,n^{\theta}\left[\alpha_0+\frac{\alpha_1}{n}+\frac{\alpha_2}{n^2}+\cdots\right],\quad n\to\infty\,. \tag{4.8}$$

This is a fairly general model sequence, which is able to describe the asymptotics of many practically relevant sequences as $n\to\infty$ and which Levin[99] probably had in mind when he introduced his simple remainder estimates. For $|z|<1$, the sequence (4.8) converges linearly to its limit s, for $z=1$ and $\mathrm{Re}(\theta)<0$, it converges logarithmically, and for $|z|>1$ it diverges.

From (4.8) we obtain via $a_n=\Delta s_{n-1}$ the leading orders of the asymptotic expansion of the terms of the infinite series $\Sigma_{\nu=0}^{\infty}a_\nu$. For $z=1$ and $\mathrm{Re}(\theta)<0$ (logarithmic convergence), we find with the help of the computer algebra system MAPLE

$$a_n=n^{\theta}\left\{\frac{\theta\alpha_0}{n}+\frac{(\theta-1)[2\alpha_1-\theta\alpha_0]}{2n^2}+\frac{(\theta-2)[6\alpha_2+(\theta-1)\{\theta\alpha_0-3\alpha_1\}]}{6n^3}+\mathrm{O}(n^{-3})\right\},$$
$$n\to\infty\,, \tag{4.9}$$

and for $|z|<1$ (linear convergence), we find

$$a_n=z^n\,n^{\theta}\left\{(z-1)\alpha_0+\frac{\theta\alpha_0+(z-1)\alpha_1}{n}+\frac{(\theta-1)[2\alpha_1-\theta\alpha_0]+2(z-1)\alpha_2}{2n^2}+\mathrm{O}(n^{-3})\right\},$$
$$n\to\infty\,. \tag{4.10}$$

If we compare (4.8) and (4.9), we see that in the case of logarithmic convergence the term $a_n=\Delta s_{n-1}=\mathrm{O}(n^{\theta-1})$ cannot reproduce the leading order of the remainder $r_n=s_n-s=\mathrm{O}(n^{\theta})$. However, the product $na_n=\mathrm{O}(n^{\theta})$ reproduces the leading order of the remainder of the model sequence (4.8). Thus, it is an obvious idea to use the remainder estimate[99]

$$\omega_n \;=\; (\beta+n)\Delta s_{n-1} \;=\; (\beta+n)a_n \tag{4.11}$$

in Levin's general transformation (2.18), yielding Levin's u transformation in the notation of [Ref. 146, Eq. (7.3-5)]:

$$u_k^{(n)}(\beta,s_n) \;=\; \mathcal{L}_k^{(n)}(\beta,s_n,(\beta+n)\Delta s_{n-1})\,,\quad k,n\in\mathbb{N}_0\,. \tag{4.12}$$

Since Levin's remainder estimate (4.11) reproduces the leading order of the remainder of the model sequence (4.8) for $z=1$ and $\mathrm{Re}(\theta)<0$ (logarithmic convergence), it is not surprising that the u transformation is an effective accelerator for many monotone, logarithmically convergent sequences and series.

In the case of linear convergence ($|z|<1$ in (4.8)), the asymptotic expansion (4.10) indicates that the term a_n itself and not the product na_n would be a natural estimate for the truncation error in (4.8). However, the Levin-type transformations considered in this article nevertheless accelerate convergence if instead of the "right" sequence $\{\omega_n\}_{n=0}^{\infty}$ of remainder estimates satisfying (4.5) "wrong" remainder estimates $\omega_n'=(n+\beta)^l\omega_n$ with $l\in\mathbb{N}_0$ are used (see Theorems 12-14–12-16 and the discussion on pp. 310–311 of Ref. 146). The use of "wrong" remainder estimates only leads—depending on the magnitude of l—to a decrease of the efficiency of the transformation process (compare for instance Ref. 146, Theorem 13-12). With the help of a generalization of Germain-Bonne's formal theory of convergence acceleration[68] it can be proved rigorously that the u transformation accelerates linear convergence (Ref. 146, Theorems 12-10, 12-11, and 12-16).

Moreover, the u transformation is also capable of summing effectively many alternating divergent series. According to Smith and Ford[140,141] the u transformation is among the most versatile and powerful sequence transformations that are currently known. This explains why Levin's u transformation is used internally in the computer algebra system Maple in the case of convergence problems (see for example Ref. 51, pp. 51 and 125 or Ref. 76, p. 258).

The remainder estimate (4.11) can also be inserted into the explicit expressions (2.21), (2.25), and (2.29) for $\mathcal{S}_k^{(n)}(\beta,s_n,\omega_n)$, $\mathcal{M}_k^{(n)}(\xi,s_n,\omega_n)$, and $\mathcal{C}_k^{(n)}(\alpha,\beta,s_n,\omega_n)$, yielding the u-type variants [Ref. 146, Eqs. (8.4-2) and (9.4-2)]

$$y_k^{(n)}(\beta,s_n) = \mathcal{S}_k^{(n)}(\beta,s_n,(\beta+n)\Delta s_{n-1}), \quad k,n\in\mathbb{N}_0, \tag{4.13}$$

$$Y_k^{(n)}(\xi,s_n) = \mathcal{M}_k^{(n)}(\xi,s_n,(-\xi-n)\Delta s_{n-1}), \quad k,n\in\mathbb{N}_0, \tag{4.14}$$

$${}_u\mathcal{C}_k^{(n)}(\alpha,\beta,s_n) = \mathcal{C}_k^{(n)}(\alpha,\beta,s_n,(\beta+n)\Delta s_{n-1}), \quad k,n\in\mathbb{N}_0. \tag{4.15}$$

In the case of the sequence transformation $\mathcal{G}_k^{(n)}(q_m,s_n,\omega_n)$ introduced by Čížek, Zamastil, and Skála [Ref. 50, Eq. (10)] we choose the u-type remainder estimates according to

$$\omega_n = (n+q_0)\Delta s_{n-1} = (n+q_0)a_n, \tag{4.16}$$

where $q_0\geqslant 0$ is a suitable constant. Inserting this into (1.1) yields

$$\begin{aligned}{}_u\mathcal{G}_k^{(n)}(q_m,s_n) &= \mathcal{G}_k^{(n)}(q_m,s_n,(n+q_0)\Delta s_{n-1})\\ &= \frac{\displaystyle\sum_{j=0}^{k}(-1)^j\binom{k}{j}\left\{\prod_{m=1}^{k-1}\frac{(n+j+q_m)}{(n+k+q_m)}\right\}\frac{s_{n+j}}{(n+j+q_0)\Delta s_{n+j-1}}}{\displaystyle\sum_{j=0}^{k}(-1)^j\binom{k}{j}\left\{\prod_{m=1}^{k-1}\frac{(n+j+q_m)}{(n+k+q_m)}\right\}\frac{1}{(n+j+q_0)\Delta s_{n+j-1}}}, \quad k,n\in\mathbb{N}_0.\end{aligned} \tag{4.17}$$

As discussed in more detail in Sec. VI (see the discussion following (6.14)), this u-type transformation loses some important exactness properties if $q_0>0$ is essentially arbitrary and does not satisfy $q_0\in\{q_1,\ldots,q_m\}$ because then $[\Pi_{m=1}^{k-1}(n+q_m)]/(n+q_0)$ is rational in n and does not simplify to a polynomial of degree $k-2$ in n. Thus, an obvious idea would be to choose $q_0=q_1$. The other u-type transformations (4.12), (4.13), (4.14), and (4.15) all satisfy $q_0=q_1$.

The asymptotic expansion (4.10) indicates that in the case linear convergence the term a_n is a natural estimate for the truncation error of the sequence (4.8) with $|z|<1$. Thus, Levin[99] proposed for linearly convergent sequences and series the remainder estimate

$$\omega_n = \Delta s_{n-1} = a_n, \tag{4.18}$$

which yields Levin's t transformation in the notation of [Ref. 146, Eq. (7.3-7)]:

$$t_k^{(n)}(\beta,s_n) = \mathcal{L}_k^{(n)}(\beta,s_n,\Delta s_{n-1}), \quad k,n\in\mathbb{N}_0. \tag{4.19}$$

The t transformation is an effective accelerator for linear convergence and in particular for alternating series.[140,141] With the help of a generalization of Germain–Bonne's formal theory of convergence acceleration[68] it can be proved rigorously that Levin's t transformation accelerates linear convergence (Ref. 146, Theorems 12-10, 12-11, and 12-16). It is also able to sum many alternating divergent series. However, a comparison of (4.8) and (4.9) indicates that the t transformation should fail to accelerate logarithmic convergence (for more details, see Ref. 146, Theorem 14-1).

The use of the remainder estimate (4.18) in the explicit expressions (2.21), (2.25), and (2.29) for $\mathcal{S}_k^{(n)}(\beta,s_n,\omega_n)$, $\mathcal{M}_k^{(n)}(\xi,s_n,\omega_n)$, and $\mathcal{C}_k^{(n)}(\alpha,\beta,s_n,\omega_n)$ yields the t-type variants [Ref. 142, Eqs. (8.4-3) and (9.4-3)]

$$\tau_k^{(n)}(\beta,s_n) = \mathcal{S}_k^{(n)}(\beta,s_n,\Delta s_{n-1}), \quad k,n\in\mathbb{N}_0, \tag{4.20}$$

$$T_k^{(n)}(\xi,s_n) = \mathcal{M}_k^{(n)}(\xi,s_n,\Delta s_{n-1}), \quad k,n\in\mathbb{N}_0, \tag{4.21}$$

$${}_t\mathcal{C}_k^{(n)}(\alpha,\beta,s_n) = \mathcal{C}_k^{(n)}(\alpha,\beta,s_n,\Delta s_{n-1}), \quad k,n\in\mathbb{N}_0. \tag{4.22}$$

In the case of the sequence transformation $\mathcal{G}_k^{(n)}(q_m,s_n,\omega_n)$ we obtain in this way,

$${}_t\mathcal{G}_k^{(n)}(q_m,s_n) = \mathcal{G}_k^{(n)}(q_m,s_n,\Delta s_{n-1}) = \frac{\displaystyle\sum_{j=0}^{k}(-1)^j\binom{k}{j}\left\{\prod_{m=1}^{k-1}\frac{(n+j+q_m)}{(n+k+q_m)}\right\}\frac{s_{n+j}}{\Delta s_{n+j-1}}}{\displaystyle\sum_{j=0}^{k}(-1)^j\binom{k}{j}\left\{\prod_{m=1}^{k-1}\frac{(n+j+q_m)}{(n+k+q_m)}\right\}\frac{1}{\Delta s_{n+j-1}}},$$

$$k,n\in\mathbb{N}_0. \tag{4.23}$$

Inspired by Aitken's Δ^2 formula,[1] Levin[99] introduced as a third simple remainder estimate

$$\omega_n = \frac{\Delta s_{n-1}\Delta s_n}{\Delta s_{n-1}-\Delta s_n} = \frac{a_n a_{n+1}}{a_n-a_{n+1}}. \tag{4.24}$$

The usefulness of this remainder estimate can be demonstrated by applying it to the model sequence (4.8). For $\zeta=1$ and $\mathrm{Re}(\theta)<0$ (logarithmic convergence) we obtain

$$\frac{a_n a_{n+1}}{a_n-a_{n+1}} = n^{\theta}\left\{-\frac{\theta\alpha_0}{\theta-1}-\frac{\theta\alpha_1}{(\theta-1)n}+\left[(\theta+1)\left\{\frac{\theta\alpha_0}{12}-\frac{(\theta-2)\alpha_2}{\theta-1}\right\}-\frac{{\alpha_1}^2}{\theta\alpha_0}\right]\frac{1}{(\theta-1)n^2}+\mathrm{O}(n^{-3})\right\}, \quad n\to\infty, \tag{4.25}$$

and for $|z|<1$ (linear convergence) we obtain

$$\frac{a_n a_{n+1}}{a_n-a_{n+1}} = z^{n+1}n^{\theta}\left\{-\alpha_0-\frac{\alpha_1}{n}-\left[\frac{z\theta\alpha_0}{(z-1)^2}+\alpha_2\right]\frac{1}{n^2}+\mathrm{O}(n^{-3})\right\}, \quad n\to\infty. \tag{4.26}$$

It is a remarkable feature of the remainder estimate (4.24) that it does not only reproduce the leading order of the model sequence (4.8), but both in the case of linear and logarithmic convergence also the next one. Thus, in the case of the model sequence (4.8) the reminder estimate (4.24) satisfies (4.6) with $l=2$, whereas Levin's other two remainder estimates (4.11) and (4.18) only satisfy (4.5). Of course, it would be desirable to find other remainder estimate which are also able to reproduce more than the leading order asymptotics of the truncation error. Further research into this direction should be of considerable interest.

The use of the remainder estimate (4.24) in (2.18) yields Levin's v transformation in the notation of [Ref. 146, Eq. (7.3-11)]:

$$v_k^{(n)}(\beta,s_n) = \mathcal{L}_k^{(n)}(\beta,s_n,\Delta s_{n-1}\Delta s_n/[\Delta s_{n-1}-\Delta s_n]), \quad k,n\in\mathbb{N}_0. \tag{4.27}$$

Levin's v transformation is an effective accelerator for many linearly and logarithmically convergent sequences and series. With the help of a generalization of Germain–Bonne's formal theory of convergence acceleration[68] it can be proved rigorously that the v transformation accelerates linear convergence (Ref. 146, Theorems 12-10 and 12-11). The v transformation is also able to sum many alternating divergent series. According to Smith and Ford,[140,141] the v transformation has similar properties as the u transformation, which means that it is among the most versatile and powerful sequence transformations that are currently known.

The use of the remainder estimate (4.24) in the explicit expressions (2.21), (2.25), and (2.29) for $\mathcal{S}_k^{(n)}(\beta,s_n,\omega_n)$, $\mathcal{M}_k^{(n)}(\xi,s_n,\omega_n)$, and $\mathcal{C}_k^{(n)}(\alpha,\beta,s_n,\omega_n)$ yields the v-type variants [Ref. 146, Eqs. (8.4-5) and (9.4-5)]

$$\varphi_k^{(n)}(\beta,s_n) = \mathcal{S}_k^{(n)}(\beta,s_n,\Delta s_{n-1}\Delta s_n/[\Delta s_{n-1}-\Delta s_n]), \quad k,n\in\mathbb{N}_0, \tag{4.28}$$

$$\Phi_k^{(n)}(\xi,s_n) = \mathcal{M}_k^{(n)}(\xi,s_n,\Delta s_{n-1}\Delta s_n/[\Delta s_{n-1}-\Delta s_n]), \quad k,n\in\mathbb{N}_0, \tag{4.29}$$

$${}_v\mathcal{C}_k^{(n)}(\alpha,\beta,s_n) = \mathcal{C}_k^{(n)}(\alpha,\beta,s_n,\Delta s_{n-1}\Delta s_n/[\Delta s_{n-1}-\Delta s_n]), \quad k,n\in\mathbb{N}_0. \tag{4.30}$$

In the case of the sequence transformation $\mathcal{G}_k^{(n)}(q_m,s_n,\omega_n)$ we obtain

$$\begin{aligned} {}_v\mathcal{G}_k^{(n)}(q_m,s_n) &= \mathcal{G}_k^{(n)}(q_m,s_n,\Delta s_{n-1}\Delta s_n/[\Delta s_{n-1}-\Delta s_n]) \\ &= \frac{\displaystyle\sum_{j=0}^{k}(-1)^j\binom{k}{j}\left\{\prod_{m=1}^{k-1}\frac{(n+j+q_m)}{(n+k+q_m)}\right\}\frac{(\Delta s_{n+j-1}-\Delta s_{n+j})s_{n+j}}{\Delta s_{n+j-1}\Delta s_{n+j}}}{\displaystyle\sum_{j=0}^{k}(-1)^j\binom{k}{j}\left\{\prod_{m=1}^{k-1}\frac{(n+j+q_m)}{(n+k+q_m)}\right\}\frac{\Delta s_{n+j-1}-\Delta s_{n+j}}{\Delta s_{n+j-1}\Delta s_{n+j}}}, \quad k,n\in\mathbb{N}_0. \end{aligned} \tag{4.31}$$

The best simple estimate for the truncation error of a strictly alternating convergent series is the first term not included in the partial sum (Ref. 96, p. 259). Moreover, the first term neglected is also an estimate of the truncation error of a divergent hypergeometric series ${}_2F_0(a,b,-z)$ with $a,b,z>0$ (Ref. 40, Theorem 5.12-5). Accordingly, Smith and Ford[140] proposed the remainder estimate

$$\omega_n = \Delta s_n = a_{n+1}. \tag{4.32}$$

This remainder estimate can also be motivated via the model sequence (4.8). For $z=1$ and $\mathrm{Re}(\theta)<0$ (logarithmic convergence), we find

$$a_{n+1}=n^\theta\left\{\frac{\theta\alpha_0}{n}+\frac{(\theta-1)[2\alpha_1+\theta\alpha_0]}{2n^2}+\frac{(\theta-2)[6\alpha_2+(\theta-1)\{\theta\alpha_0+3\alpha_1\}]}{6n^3}+\mathrm{O}(n^{-3})\right\}, \quad n\to\infty, \tag{4.33}$$

and for $|z|<1$ (linear convergence), we find

$$a_{n+1}=z^{n+1}n^\theta\left\{(z-1)\alpha_0+\frac{z\theta\alpha_0+(z-1)\alpha_1}{n}+\frac{z(\theta-1)[2\alpha_1+\theta\alpha_0]+2(z-1)\alpha_2}{2n^2}+\mathrm{O}(n^{-3})\right\}, \quad n\to\infty. \tag{4.34}$$

The use of the remainder estimate (4.32) yields Levin's d transformation in the notation of [Ref. 146, Eq. (7.3-9)],

$$d_k^{(n)}(\beta,s_n) = \mathcal{L}_k^{(n)}(\beta,s_n,\Delta s_n), \quad k,n\in\mathbb{N}_0. \tag{4.35}$$

If we compare (4.33) with (4.9) and (4.34) with (4.10), we see that Levin's d transformation should have similar properties as Levin's t transformation. This is confirmed by experience: The d transformation is a powerful accelerator for linear convergence and in particular for alternating series, and is also able to sum many alternating divergent series, but fails to accelerate logarithmic convergence. With the help of a generalization of Germain–Bonne's formal theory of convergence acceleration[68] it can be proved rigorously that the d transformation accelerates linear convergence (Ref. 146, Theorems 12-10, 12-11, and 12-16).

The use of the remainder estimate (4.32) in the explicit expressions (2.21), (2.25), and (2.29) for $\mathcal{S}_k^{(n)}(\beta,s_n,\omega_n)$, $\mathcal{M}_k^{(n)}(\xi,s_n,\omega_n)$, and $\mathcal{C}_k^{(n)}(\alpha,\beta,s_n,\omega_n)$ yields the d-type variants [Ref. 146, Eqs. (8.4-4) and (9.4-4)]

$$\delta_k^{(n)}(\beta,s_n) = \mathcal{S}_k^{(n)}(\beta,s_n,\Delta s_n), \quad k,n\in\mathbb{N}_0, \tag{4.36}$$

$$\Delta_k^{(n)}(\xi,s_n) = \mathcal{M}_k^{(n)}(\xi,s_n,\Delta s_n), \quad k,n\in\mathbb{N}_0, \tag{4.37}$$

$${}_d\mathcal{C}_k^{(n)}(\alpha,\beta,s_n) = \mathcal{C}_k^{(n)}(\alpha,\beta,s_n,\Delta s_n), \quad k,n\in\mathbb{N}_0. \tag{4.38}$$

As already mentioned in Sec. I, the delta transformation (4.36) was found to be particularly powerful in the case of factorially and hyperfactorially divergent alternating power series as they for instance occur in the perturbation expansions of quantum physics[18,48–50,85,91,146–153,155,156,158,162,163] or in asymptotic expansions for special functions.[147,150,154,161]

In the case of the sequence transformation $\mathcal{G}_k^{(n)}(q_m,s_n,\omega_n)$ we obtain

$${}_d\mathcal{G}_k^{(n)}(q_m,s_n) = \mathcal{G}_k^{(n)}(q_m,s_n,\Delta s_n) = \frac{\displaystyle\sum_{j=0}^{k}(-1)^j\binom{k}{j}\left\{\prod_{m=1}^{k-1}\frac{(n+j+q_m)}{(n+k+q_m)}\right\}\frac{s_{n+j}}{\Delta s_{n+j}}}{\displaystyle\sum_{j=0}^{k}(-1)^j\binom{k}{j}\left\{\prod_{m=1}^{k-1}\frac{(n+j+q_m)}{(n+k+q_m)}\right\}\frac{1}{\Delta s_{n+j}}}, \quad k,n\in\mathbb{N}_0. \tag{4.39}$$

In practical applications it happens relatively often that asymptotic expressions $a_n^{(\infty)}$ for the terms a_n of a series are known that reproduce the leading order of a_n as $n\to\infty$. For example, the coefficients c_n of many divergent perturbation expansions, which are power series in some coupling constant g, satisfy (see for example, Ref. 65, Table I)

$$c_n = (-1)^n\,\Gamma(an+b)\,R^n\,[C+\mathrm{O}(1/n)], \quad n\to\infty, \tag{4.40}$$

where a, b, C, and R are known constants.

The remainder estimate (4.24), which leads to Levin's v transformation, is in some sense exceptional since reproduces not only the leading order of the truncation errors of the model sequence (4.8) as $n\to\infty$, but also the next one. Normally, we can only expect that the simple remainder estimates (4.11), (4.18), (4.24), and (4.32) reproduce the leading order of the remainder s_n-s. However, the leading order of the truncation error is also reproduced if we use in (4.11), (4.18), (4.24), and (4.32) not a_n and a_{n+1} but their limiting expressions $a_n^{(\infty)}$ and $a_{n+1}^{(\infty)}$. Whether this improves the transformation results or not, depends on the problem under consideration and cannot be decided by simple considerations. Nevertheless, it may well be worth a try. Ideas of that kind were discussed in more detail in Refs. 83, 149 and also by Čížek, Zamastil, and Skála.[50]

The t-type transformations (4.19), (4.20), (4.21), (4.22), and (4.23) use the last term a_n of the partial sum $s_n=\Sigma_{k=0}^{n}a_k$ as an estimate for the truncation error $r_n=-\Sigma_{k=n+1}^{\infty}a_k$, whereas the analogous d-type transformations (4.35), (4.36), (4.37), (4.38), and (4.39) use the first term a_{n+1} not included in the partial sum as the remainder estimate. Thus, it looks that t-type transformation utilize the available information in some sense more effectively than d-type transformation since they use a_{n+1} also for the construction of the next partial sum s_{n+1}. This is, however, a superficial judgment and it can be shown easily that t-type transformations are actually d-type transformations is disguise.

It follows from (2.13) that the t-type variant (4.23) of $\mathcal{G}_k^{(n)}(q_m,s_n,\omega_n)$ can be expressed as follows:

$$ {}_t\mathcal{G}_k^{(n)}(s_n,\Delta s_{n-1}) = \frac{\Delta^k\left\{\prod_{m=1}^{k-1}(n+q_m)\right\}\dfrac{s_n}{\Delta s_{n-1}}}{\Delta^k\left\{\prod_{m=1}^{k-1}(n+q_m)\right\}\dfrac{1}{\Delta s_{n-1}}}, \quad k,n\in\mathbb{N}_0 . \tag{4.41}$$

Next, we use $s_n=s_{n-1}+\Delta s_{n-1}$ in the numerator on the right-hand side and take into account that Δ^k annihilates polynomials of degree $k-1$ in n. Thus,

$$ \Delta^k\left\{\prod_{m=1}^{k-1}(n+q_m)\right\}\frac{s_n}{\Delta s_{n-1}} = \Delta^k\left\{\prod_{m=1}^{k-1}(n+q_m)\right\}\left[\frac{s_{n-1}}{\Delta s_{n-1}}+\frac{\Delta s_{n-1}}{\Delta s_{n-1}}\right] \tag{4.42}$$

$$ = \Delta^k\left\{\prod_{m=1}^{k-1}(n+q_m)\right\}\frac{s_{n-1}}{\Delta s_{n-1}}. \tag{4.43}$$

Inserting this into (4.41) shows that the t-type variant (4.23) of $\mathcal{G}_k^{(n)}(q_m,s_n,\omega_n)$ actually corresponds to the d-type variant (4.39) with a shifted index $n'=n-1$ and modified parameters $q'_m=q_m+1$:

$$ {}_t\mathcal{G}_k^{(n)}(q_m,s_n)=\mathcal{G}_k^{(n-1)}(q_m+1,s_{n-1},\Delta s_{n-1})={}_d\mathcal{G}_k^{(n-1)}(q_m+1,s_{n-1}) \tag{4.44}$$

$$ =\frac{\sum_{j=0}^{k}(-1)^j\binom{k}{j}\left\{\prod_{m=1}^{k-1}\dfrac{(n+j+q_m)}{(n+k+q_m)}\right\}\dfrac{s_{n+j-1}}{\Delta s_{n+j-1}}}{\sum_{j=0}^{k}(-1)^j\binom{k}{j}\left\{\prod_{m=1}^{k-1}\dfrac{(n+j+q_m)}{(n+k+q_m)}\right\}\dfrac{1}{\Delta s_{n+j-1}}}, $$

$$ k,n\in\mathbb{N}. \tag{4.45}$$

The other t-type transformations (4.19), (4.20), (4.21), and (4.22) can also be expressed by the corresponding d-type transformations (4.35), (4.36), (4.37), and (4.38) according to

$$ t_k^{(n)}(\beta,s_n) = \mathcal{L}_k^{(n-1)}(\beta+1,s_{n-1},\Delta s_{n-1}) = d_k^{(n-1)}(\beta+1,s_{n-1}), \tag{4.46}$$

$$ \tau_k^{(n)}(\beta,s_n) = \mathcal{S}_k^{(n-1)}(\beta+1,s_{n-1},\Delta s_{n-1}) = \delta_k^{(n-1)}(\beta+1,s_{n-1}), \tag{4.47}$$

$$ T_k^{(n)}(\xi,s_n) = \mathcal{M}_k^{(n-1)}(\xi+1,s_{n-1},\Delta s_{n-1}) = \Delta_k^{(n-1)}(\xi+1,s_{n-1}), \tag{4.48}$$

$$ {}_t\mathcal{C}_k^{(n)}(\alpha,\beta,s_n) = \mathcal{C}_k^{(n-1)}(\alpha,\beta+1,s_{n-1},\Delta s_{n-1}) = {}_d\mathcal{C}_k^{(n-1)}(\alpha,\beta+1,s_{n-1}). \tag{4.49}$$

In these expressions, the case $n=0$ deserves special consideration. Since we tacitly assume $s_{-m}=0$ with $m\in\mathbb{N}$, the term with $j=0$ in the numerator sum of (4.45) vanishes for $n=0$. This can also be proved directly from the numerator sum in (4.23). If we write there $\Delta s_{n+j-1}=a_{n+j}$ and $s_{n+j}=\Sigma_{\nu=0}^{n+j}a_\nu$, we obtain for $n=0$:

$$\sum_{j=0}^{k} (-1)^j \binom{k}{j} \left\{ \prod_{m=1}^{k-1} (j+q_m) \right\} \sum_{\nu=0}^{j} \frac{a_\nu}{a_j}$$

$$= \sum_{j=0}^{k} (-1)^j \binom{k}{j} \left\{ \prod_{m=1}^{k-1} (j+q_m) \right\} \left[\sum_{\nu=0}^{j-1} \frac{a_\nu}{a_j} + \frac{a_j}{a_j} \right] \tag{4.50}$$

$$= \sum_{j=1}^{k} (-1)^j \binom{k}{j} \left\{ \prod_{m=1}^{k-1} (j+q_m) \right\} \sum_{\nu=0}^{j-1} \frac{a_\nu}{a_j}. \tag{4.51}$$

Here, we made use of the fact that $\Sigma_{\nu=0}^{j-1} a_\nu$ is for $j=0$ an empty sum which is zero. Thus, we obtain for the t-type variant of $\mathcal{G}_k^{(0)}(q_m, s_0, \omega_0)$ the following expression:

$${}_t\mathcal{G}_k^{(0)}(q_m, s_0) = \mathcal{G}_k^{(-1)}(q_m+1, s_{-1}, \Delta s_{-1}) = {}_d\mathcal{G}_k^{(-1)}(q_m+1, s_{-1}) \tag{4.52}$$

$$= \frac{\sum_{j=1}^{k} (-1)^j \binom{k}{j} \left\{ \prod_{m=1}^{k-1} \frac{(j+q_m)}{(k+q_m)} \right\} \frac{s_{j-1}}{\Delta s_{j-1}}}{\sum_{j=0}^{k} (-1)^j \binom{k}{j} \left\{ \prod_{m=1}^{k-1} \frac{(j+q_m)}{(k+q_m)} \right\} \frac{1}{\Delta s_{j-1}}}, \quad k \in \mathbb{N}. \tag{4.53}$$

The fact that t-type transformations are actually d-type transformations in disguise can also be deduced from the recursive scheme (3.10) which contains all the other recursive schemes of Sec. III as special cases. If we choose the initial conditions in (3.10a) according to $u_n = s_n/\Delta s_{n-1}$, then (3.10b) implies $G_1^{(n)} = \Delta[s_n/\Delta s_{n-1}] = \Delta[s_{n-1}/\Delta s_{n-1}]$. Thus, (3.10c) with $k \geqslant 1$ yields the same results as if we had started the recursion with the d-type initial conditions $u_n = s_{n-1}/\Delta s_{n-1}$.

Numerical cancellation increases the risk of losing accuracy. Therefore, it is probably wiser not to use the t-type initial conditions $u_n = s_n/\Delta s_{n-1}$ in the recursive scheme (3.10) or in any of its special cases, but instead the d-type initial conditions $u_n = s_{n-1}/\Delta s_{n-1}$.

V. RICHARDSON-TYPE TRANSFORMATIONS

Some of the most effective accelerators for logarithmically convergent sequences and series ($\rho = 1$ in (4.7)), which abound in scientific applications and which constitute formidable computational problems, can be derived with the help of interpolation theory. Thus, the existence of a function S of a continuous variable is postulated which coincides on a set of discrete arguments $\{x_n\}_{n=0}^{\infty}$ with the elements of the sequence $\{s_n\}_{n=0}^{\infty}$ to be transformed:

$$S(x_n) = s_n, \quad n \in \mathbb{N}_0. \tag{5.1}$$

This ansatz reduces the convergence acceleration problem to an extrapolation problem. If a finite string s_n, s_{n+1}, …, s_{n+k} of $k+1$ sequence elements is known, one can construct an approximation $S_k(x)$ to $S(x)$ which satisfies the $k+1$ interpolation conditions $S_k(x_{n+j}) = s_{n+j}$ with $0 \leqslant j \leqslant k$. Next, the value of $S_k(x)$ has to be determined for $x \to x_\infty$. If this can be done, $S_k(x_\infty)$ should provide a better approximation to the limit $s = s_\infty$ of the sequence $\{s_n\}_{n=0}^{\infty}$ than the last sequence element s_{n+k} used for its construction.

The most important interpolating functions are either polynomials or rational functions which lead to different convergence algorithm (see, for example, Ref. 146, Sec. 6). Here, only polynomial interpolation will be considered. Thus, it is assumed that the kth order approximant $S_k(x)$ is a polynomial of degree k in x,

$$S_k(x) = \gamma_0 + \gamma_1 x + \cdots + \gamma_k x^k, \quad k \in \mathbb{N}, \tag{5.2}$$

or equivalently that the model sequence for the Richardson extrapolation scheme,[115] whose construction will be sketched below, is a polynomial of degree k in the interpolation points x_n,

$$s_n = s + \sum_{j=0}^{k-1} c_j x_n^{j+1}, \quad k \in \mathbb{N}, \quad n \in \mathbb{N}_0. \tag{5.3}$$

For polynomials, the most natural extrapolation point is $x_\infty = 0$. Accordingly, we assume that the interpolation points x_n satisfy the conditions

$$x_0 > x_1 > \cdots > x_m > x_{m+1} > \cdots > 0, \tag{5.4a}$$

$$\lim_{n\to\infty} x_n = 0. \tag{5.4b}$$

The choice $x_\infty = 0$ implies that the approximation to the limit $s = s_\infty$ in (5.3) is to be identified with the constant term γ_0 of the polynomial (5.2).

Several different methods for the construction of interpolating polynomials $S_k(x)$ are known (see, for example, Ref. 52, Chap. III). Since we are only interested in the constant term γ_0 of an interpolating polynomial $S_k(x)$ and since in most applications it is desirable to compute simultaneously a whole string of approximants $S_0(0), S_1(0), S_2(0), \ldots$ with increasing polynomial degree, the most economical choice is Neville's scheme[104] for the recursive computation of interpolating polynomials. If we set $x = 0$ in Neville's scheme, we obtain the following recursive scheme [see, for example, Ref. 33, p. 73 or Ref. 146, Eq. (6.1-5)]

$$\mathcal{N}_0^{(n)}(s_n, x_n) = s_n, \quad n \in \mathbb{N}_0, \tag{5.5a}$$

$$\mathcal{N}_{k+1}^{(n)}(s_n, x_n) = \frac{x_n \mathcal{N}_k^{(n+1)}(s_{n+1}, x_{n+1}) - x_{n+k+1} \mathcal{N}_k^{(n)}(s_n, x_n)}{x_n - x_{n+k+1}}, \quad k, n \in \mathbb{N}_0. \tag{5.5b}$$

In the literature on convergence acceleration, this variant of Neville's scheme is called Richardson extrapolation.[115] In Ref. 146, Sec. 7.4 it was shown that this recursive scheme can also be derived with the help of the of the annihilation operator approach described in Sec. II by using divided differences as annihilation operators.

In most applications, Richardson extrapolation is used in combination with the interpolation points $x_n = 1/(n+\beta)$ with $\beta > 0$. Then, the model sequence (5.3) assumes the following form:

$$s_n = s + \frac{1}{\beta+n} \sum_{j=0}^{k-1} \frac{c_j}{(\beta+n)^j}, \quad k \in \mathbb{N}, \quad n \in \mathbb{N}_0. \tag{5.6}$$

This model sequence can be obtained from the model sequence (2.16) for Levin's sequence transformation by setting $\omega_n = 1/(\beta+n)$. Consequently, $\mathcal{N}_k^{(n)}$ with $x_n = 1/(\beta+n)$ is a special Levin transformation and can be expressed as the ratio of two finite sums according to (2.18). Since, however, the denominator of the ratio (2.18) can for $\omega_n = 1/(\beta+n)$ be expressed in closed form, $\mathcal{N}_k^{(n)}$ possesses an even simpler closed form expression as a finite sum [see, for example, Ref. 101, Lemma 2.1 on p. 313, or Ref. 146, Eq. (7.3-20)]

$$\begin{aligned} \Lambda_k^{(n)}(\beta, s_n) &= \mathcal{N}_k^{(n)}(s_n, 1/(\beta+n)) = \mathcal{L}_k^n(\beta, s_n, 1/(\beta+n)) \\ &= (-1)^k \sum_{j=0}^{k} (-1)^j \frac{(\beta+n+j)^k}{j!\,(k-j)!} s_{n+j}, \quad k, n \in \mathbb{N}_0. \end{aligned} \tag{5.7}$$

Moreover, the recursive scheme (5.5) assumes the following form [Ref. 146, Eq. (7.3-21)]:

$$\Lambda_0^{(n)}(\beta, s_n) = s_n, \quad n \in \mathbb{N}_0, \tag{5.8a}$$

$$\Lambda_{k+1}^{(n)}(\beta,s_n) = \Lambda_k^{(n+1)}(\beta,s_{n+1}) + \frac{\beta+n}{k+1}\Delta\Lambda_k^{(n)}(\beta,s_n), \quad k,n\in\mathbb{N}_0. \tag{5.8b}$$

In the case of doubly indexed quantities like $\Lambda_k^{(n)}$ it is always assumed that Δ only acts on the superscript n but not on the subscript k, i.e., $\Delta\Lambda_k^{(n)}=\Lambda_k^{(n+1)}-\Lambda_k^{(n)}$.

A Richardson-type variant of the sequence transformation (1.1) introduced by Čížek, Zamastil, and Skála [Ref. 50, Eq. (10)] can be constructed easily. We only have set in (2.12) $\omega_n=1/(n+q_0)$, where q_0 is a suitable constant. This yields the model sequence

$$s_n = s + \sum_{j=0}^{k-1} \frac{c_j}{\prod_{m=1}^{j}(n+q_m)}, \quad k,n\in\mathbb{N}_0. \tag{5.9}$$

Thus, $\Delta^k\Pi_{m=0}^{k-1}(n+q_m)$ is the annihilation operator for the remainder of this model sequence, yielding the following Richardson-type variant of the sequence transformation introduced by Čížek, Zamastil, and Skála [Ref. 50, Eq. (10)]:

$${}_R\mathcal{G}_k^{(n)}(q_m,s_n) = \mathcal{G}_k^{(n)}(q_m,s_n,n+q_0) = \frac{\Delta^k\left\{\prod_{m=1}^{k-1}(n+q_m)\right\}s_n}{\Delta^k\left\{\prod_{m=1}^{k-1}(n+q_m)\right\}}, \quad k,n\in\mathbb{N}_0. \tag{5.10}$$

Of course, this transformation can be expressed as the ratio of two finite sums according to (1.1). However, the denominator of (5.10) can be expressed in closed form. First, we observe that the products in the difference operator representation (5.10) are polynomials of degree k in n, satisfying

$$\prod_{m=0}^{k-1}(n+q_m) = n^k + (q_0+q_1+\cdots+q_{k-1})n^{k-1} + \cdots. \tag{5.11}$$

Next, we use the well known relationship $\Delta^k n^k=k!$, which can for instance be derived by iterating the commutator relationship (3.4), and take into account that all polynomials of degree $0,1,\ldots,k-1$ in n are annihilated by Δ^k. Thus,

$$\Delta^k\prod_{m=0}^{k-1}(n+q_m) = k!. \tag{5.12}$$

With the help of (2.14) we then obtain from (5.10),

$${}_R\mathcal{G}_k^{(n)}(q_m,s_n) = \mathcal{G}_k^{(n)}(q_m,s_n,1/(n+q_0)) = (-1)^k\sum_{j=0}^{k-1}(-1)^j\frac{\prod_{m=1}^{k-1}(n+j+q_m)}{j!(k-j)!}s_{n+j}, \quad k,n\in\mathbb{N}_0. \tag{5.13}$$

If we set here $q_m=\beta$, we obtain the sequence transformation (5.7) according to

$${}_R\mathcal{G}_k^{(n)}(\beta,s_n) = \mathcal{G}_k^{(n)}(\beta,s_n,1/(\beta+n)) = \Lambda_k^{(n)}(\beta,s_n), \quad k,n\in\mathbb{N}_0. \tag{5.14}$$

We can derive a recursive scheme for ${}_R\mathcal{G}_k^{(n)}(q_m,s_n)$ by means of the techniques described in Sec. III. For that purpose, we express the numerator of the ratio on the right-hand side of (5.10) as follows:

$$Q_k^{(n)} = Q_k^{(n)}(q_m,s_n) = \Delta^k Y_k^{(n)}, \quad k,n\in\mathbb{N}_0, \tag{5.15}$$

$$Y_k^{(n)} = Y_k^{(n)}(q_m,s_n) = \prod_{m=0}^{k-1}(n+q_m)\,s_n, \quad k,n\in\mathbb{N}_0. \tag{5.16}$$

The quantities $Y_k^{(n)}$ satisfy for $k \geqslant 1$ the two-term recursion

$$Y_k^{(n)} = (n+q_{k-1})\, Y_{k-1}^{(n)}. \tag{5.17}$$

Next, we combine (5.15)–(5.17) with the commutator relationship (3.5), yielding

$$Q_k^{(n)} = \Delta^k (n+q_{k-1})\, Y_{k-1}^{(n)} \tag{5.18}$$

$$= [(n+k+q_{k-1})\, E - (n+q_{k-1})]\, \Delta^{k-1}\, Y_{k-1}^{(n)} \tag{5.19}$$

$$= (n+k+q_{k-1})\, Q_{k-1}^{(n+1)} - (n+q_{k-1})\, Q_{k-1}^{(n)}, \quad k \in \mathbb{N}, \quad n \in \mathbb{N}_0. \tag{5.20}$$

Now, we only have to divide the recurrence formula (5.20) for the numerator of (5.10) by the denominator according to (5.12) to obtain the recursive scheme

$${}_R\mathcal{G}_k^{(0)}(q_m, s_n) = s_n, \quad n \in \mathbb{N}_0, \tag{5.21a}$$

$${}_R\mathcal{G}_{k+1}^{(n)}(q_m, s_n) = {}_R\mathcal{G}_k^{(n+1)}(q_m, s_{n+1}) + \frac{n+q_k}{k+1} \Delta\, {}_R\mathcal{G}_k^{(n)}(q_m, s_n), \quad k,n \in \mathbb{N}_0. \tag{5.21b}$$

If we choose in (5.21) $q_m = \beta$, we obtain the recursive scheme (5.8) for $\Lambda_k^{(n)}(\beta, s_n)$.

By specializing the parameters q_m in (5.13) and (5.21), other Richardson-type transformations and their recursive schemes can be obtained. If we choose $q_m = \chi + m$ with $\chi > 0$, we obtain the Richardson-type variant of the sequence transformation (2.21) [Ref. 146, Eq. (8.4-11)],

$$\mathcal{F}_k^{(n)}(\chi, s_n) = {}_R\mathcal{G}_k^{(n)}(\chi+m, s_n) = \mathcal{S}_k^{(n)}(\chi+1, s_n, 1/(\chi+n))$$

$$= (-1)^k \sum_{j=0}^{k} (-1)^j \frac{(\chi+n+j)_k}{j!\,(k-j)!}\, s_{n+j}, \quad k,n \in \mathbb{N}_0, \tag{5.22}$$

and its recursive scheme [Ref. 146, Eq. (8.4-12)]

$$\mathcal{F}_0^{(n)}(\chi, s_n) = s_n, \quad n \in \mathbb{N}_0, \tag{5.23a}$$

$$\mathcal{F}_{k+1}^{(n)}(\chi, s_n) = \mathcal{F}_k^{(n+1)}(\chi, s_{n+1}) + \frac{\chi+n+k}{k+1} \Delta\, \mathcal{F}_k^{(n)}(\chi, s_n), \quad k,n \in \mathbb{N}_0. \tag{5.23b}$$

If we choose in (5.13) and (5.21) $q_m = \zeta - m$ with $\zeta > 0$, we obtain the Richardson-type variant of the sequence transformation (2.25) [Ref. 146, Eq. (9.4-11)],

$$\mathcal{P}_k^{(n)}(\zeta, s_n) = {}_R\mathcal{G}_k^{(n)}(\zeta-m, s_n) = \mathcal{M}_k^{(n)}(\zeta-1, s_n, -1/(\zeta+n))$$

$$= \sum_{j=0}^{k} (-1)^j \frac{(-\zeta-n-j)_k}{j!\,(k-j)!}\, s_{n+j}, \quad k,n \in \mathbb{N}_0, \tag{5.24}$$

and its recursive scheme [Ref. 146, Eq. (9.4-12)]

$$\mathcal{P}_0^{(n)}(\zeta, s_n) = s_n, \quad n \in \mathbb{N}_0, \tag{5.25a}$$

$$\mathcal{P}_{k+1}^{(n)}(\zeta, s_n) = \mathcal{P}_k^{(n+1)}(\zeta, s_{n+1}) + \frac{\zeta+n-k}{k+1} \Delta\, \mathcal{P}_k^{(n)}(\zeta, s_n), \quad k,n \in \mathbb{N}_0. \tag{5.25b}$$

If we choose in (5.13) and (5.21) $q_m = \chi + m/\alpha$ with $\chi, \alpha > 0$, we obtain the Richardson-type variant of the sequence transformation (2.29),

$$
\begin{aligned}
{}_R\mathcal{C}_k^{(n)}(\alpha,\chi,s_n) &= {}_R\mathcal{G}_k^{(n)}(\chi+m/\alpha,s_n) = \mathcal{C}_k^{(n)}(\alpha,\chi+1,s_n,1/(\chi+n)) \\
&= \frac{(-1)^k}{\alpha^k}\sum_{j=0}^{k}(-1)^j\frac{(\alpha[\chi+n+j])_k}{j!(k-j)!}s_{n+j}, \quad k,n\in\mathbb{N}_0,
\end{aligned}
\tag{5.26}
$$

and its recursive scheme

$$
{}_R\mathcal{C}_0^{(n)}(\alpha,\chi,s_n) = s_n, \quad n\in\mathbb{N}_0, \tag{5.27a}
$$

$$
{}_R\mathcal{C}_{k+1}^{(n)}(\alpha,\chi,s_n) = {}_R\mathcal{C}_k^{(n+1)}(\alpha,\chi,s_{n+1}) + \frac{\chi+n+k/\alpha}{k+1}\Delta\,{}_R\mathcal{C}_k^{(n)}(\alpha,\chi,s_n), \quad k,n\in\mathbb{N}_0. \tag{5.27b}
$$

Depending upon the value of $\alpha>0$, ${}_R\mathcal{C}_k^{(n)}(\alpha,\chi,s_n)$ interpolates between the Richardson-type transformations $\Lambda_k^{(n)}(\beta,s_n)$ and $\mathcal{F}_k^{(n)}(\chi,s_n)$. If we choose in (5.26) $\alpha=1$ and compare the resulting expression with (5.22), we find

$$
{}_R\mathcal{C}_k^{(n)}(1,\chi,s_n) = \mathcal{F}_k^{(n)}(\chi,s_n), \tag{5.28}
$$

and if we use in (5.26),

$$
\lim_{\alpha\to\infty}\frac{(\alpha[\chi+n+j])_k}{\alpha^k} = \lim_{\alpha\to\infty}\prod_{m=0}^{k-1}(\chi+n+j+m/\alpha) = (\chi+n+j)^k \tag{5.29}
$$

together with $\chi=\beta$ and compare the resulting expression with (5.7), we find

$$
\lim_{\alpha\to\infty}{}_R\mathcal{C}_k^{(n)}(\alpha,\beta,s_n) = \Lambda_k^{(n)}(\beta,s_n). \tag{5.30}
$$

VI. RATIONAL APPROXIMANTS

In theoretical physics and in applied mathematics, Padé approximants[106] have become the standard tool to overcome problems with slowly convergent or divergent power series. Padé approximants can also be viewed as a special class of sequence transformations since they transform the partial sums

$$
f_n(z) = \sum_{\nu=0}^{n}\gamma_\nu z^\nu, \quad n\in\mathbb{N}_0, \tag{6.1}
$$

of a (formal) power series for some function f into a doubly indexed sequence of rational functions (see, for example, Ref. 3, Chap. 1):

$$
[l/m]_f(z) = \frac{P^{[l/m]}(z)}{Q^{[l/m]}(z)} = \frac{p_0+p_1z+\cdots+p_lz^l}{1+q_1z+\cdots+q_mz^m}, \quad l,m\in\mathbb{N}_0. \tag{6.2}
$$

We also obtain rational approximants if the u, t, d, and v variants considered in Sec. IV are applied to the partial sums (6.1). Nevertheless, there are some substantial differences between most sequence transformations and Padé approximants. Levin-type transformations can be computed via their explicit expressions, although it is normally preferable to compute them recursively. The coefficients $p_0,\ldots,p_l$ and $q_1,\ldots,q_m$ of the two Padé polynomials $P^{[l/m]}$ and $Q^{[l/m]}$ in (6.2) are, however, chosen in such a way that the Taylor expansion of the ratio $P^{[l/m]}(z)/Q^{[l/m]}(z)$ at $z=0$ agrees with the power series for f as far as possible:

$$Q^{[l/m]}(z)\,f(z) - P^{[l/m]}(z) \;=\; \mathrm{O}(z^{l+m+1})\,, \quad z\to 0\,. \tag{6.3}$$

This asymptotic condition leads to a system of $l+m+1$ linear equations. If this system of equations has a solution, it yields the coefficients of the polynomials $P^{[l/m]}(z)$ and $Q^{[l/m]}(z)$ (see, for example, Ref. 3, Chap. 1).

In most practical applications, Padé approximants are not computed via the defining system of equations, but with the help of recursive algorithms as for example, Wynn's epsilon algorithm.[167] Nevertheless, the accuracy-through-order relationship (6.3) guarantees that the Taylor expansion of $[l/m]_f(z)$ reproduces the partial sum $f_{l+m}(z)$ from which it was constructed. If a sequence transformation is applied to the partial sums of a (formal) power series, it is by no means obvious whether the resulting expression satisfies an accuracy-through-order relationship of the type of (6.3) (see, for example, the discussion in Ref. 157).

The accuracy-through-order relationship (6.3) is essential if Padé approximants are to be used for the prediction of unknown series coefficients, which was first described and utilized by Gilewicz.[69] This so-called Padé prediction is based on the fact that a Padé approximant is by construction analytic at the origin. Accordingly, the power series

$$[l/m]_f(z) \;=\; \sum_{\nu=0}^{\infty} \gamma_\nu^{[l/m]}\, z^\nu \tag{6.4}$$

converges in a neighborhood of $z=0$. The accuracy-through-order relationship (6.3) implies $\gamma_\nu^{[l/m]}=\gamma_\nu$ for $0\leqslant\nu\leqslant l+m$. The remaining coefficients $\gamma_{l+m+\mu+1}^{[l/m]}$ with $\mu\geqslant 0$ are in general different from the corresponding coefficients $\gamma_{l+m+\mu+1}$ of the power series for $f(z)$. If, however, the Padé approximants $[l/m]_f(z)$ converge more rapidly to $f(z)$ than the partial sums $f_{l+m}(z)$ from which they are constructed, then the coefficients $\gamma_{l+m+\mu+1}^{[l/m]}$ provide in particularly for smaller values of μ approximants to the corresponding series coefficients. It is important to note that Padé prediction is not restricted to convergent power series. Thus, Padé prediction can produce useful results even if the power series is a factorially divergent perturbation expansion.

In certain subfields of theoretical physics, the computation of more than a few coefficients of a perturbation expansion can be extremely difficult. Moreover, these coefficients are often affected by comparatively large relative errors. Under such adverse conditions, Padé approximants can be used to make predictions about the leading unknown coefficients of perturbation expansions as well as to make consistency checks for previously calculated coefficients. Further details as well as many examples can be found in Refs. 9, 38, 41–47, 53, 58–62, 85, 91, 93, 120–126, 143, 157, and references therein. Padé prediction can also be quite helpful in different contexts. For example, Padé prediction techniques developed in Ref. 157 were used in Ref. 9 to provide numerical evidence that the factorially divergent perturbation expansion for an anharmonic oscillator, whose Hamiltonian is non-Hermitian but $\mathcal{PT}$-symmetric,[7] is a Stieltjes series.

The prediction of unknown power series coefficients is not restricted to Padé approximants. In principle, any other rational approximant, that also satisfies an accuracy-through-order relationship of the type of (6.3), can be used. It seems that this idea was first formulated by Sidi and Levin[136] and by Brezinski.[25] Recently, it was found that Levin-type transformation like (4.35) and (4.36), which satisfy for $k\in\mathbb{N}$ and $n\in\mathbb{N}_0$ the following asymptotic order estimates as $z\to 0$ [Ref. 163, Eqs. (4.28) and (4.29)],

$$f(z) - d_k^{(n)}(\beta, f_n(z)) \;=\; \mathrm{O}(z^{k+n+2})\,, \tag{6.5}$$

$$f(z) - \delta_k^{(n)}(\beta, f_n(z)) \;=\; \mathrm{O}(z^{k+n+2})\,, \tag{6.6}$$

produce at least in some cases significantly more accurate predictions for unknown power series coefficients than Padé approximants.[85,91,156] Accordingly, it should be of interest to analyze not only the rational approximants, which result if Levin-type transformations are applied to power series, but also their accuracy-through-order relationships. In the case of Levin's t transformation,

this was already done by Sidi and Levin,[136] and the accuracy-through-order relationships for the u, t, v, and d variants of $\mathcal{L}_k^{(n)}(\beta,s_n,\omega_n)$, $\mathcal{S}_k^{(n)}(\beta,s_n,\omega_n)$, and $\mathcal{M}_k^{(n)}(\xi,s_n,\omega_n)$ were studied in Ref. 150, Sec. 5.7, albeit by a less elegant method.

In this section, the u, t, v, and d variants of the sequence transformation $\mathcal{G}_k^{(n)}(q_m,s_n,\omega_n)$ introduced by Čížek, Zamastil, and Skála [Ref. 50, Eq. (10)] are applied to (formal) power series and the accuracy-through-order properties of the resulting rational approximants are studied. Since the sequence transformations $\mathcal{L}_k^{(n)}(\beta,s_n,\omega_n)$, $\mathcal{S}_k^{(n)}(\beta,s_n,\omega_n)$, $\mathcal{M}_k^{(n)}(\xi,s_n,\omega_n)$, and $\mathcal{C}_k^{(n)}(\alpha,\beta,s_n,\omega_n)$ can be obtained from $\mathcal{G}_k^{(n)}(q_m,s_n,\omega_n)$ by specializing the parameters q_m, all results for ${}_u\mathcal{G}_k^{(n)}(q_m,f_n(z))$, ${}_t\mathcal{G}_k^{(n)}(q_m,f_n(z))$, ${}_d\mathcal{G}_k^{(n)}(q_m,f_n(z))$, and ${}_v\mathcal{G}_k^{(n)}(q_m,f_n(z))$ derived here can immediately be translated to the analogous results for the u, t, d, and v variants of the transformations mentioned above.

If we use the partial sums (6.1) of a (formal) power series $f(z)=\sum_{\nu=0}^{\infty}\gamma_\nu z^\nu$ as input data, the simple remainder estimates (4.16), (4.18), (4.24), and (4.32) for the u, t, v, and d variants of $\mathcal{G}_k^{(n)}(q_m,s_n,\omega_n)$ translate to $\omega_n=(n+q_0)\gamma_n z^n$, $\omega_n=\gamma_n z^n$, $\omega_n=\gamma_n\gamma_{n+1}z^{n+1}/[\gamma_n-z\gamma_{n+1}]$, and $\omega_n=\gamma_{n+1}z^{n+1}$. Of course, these remainder estimates can only be used if the coefficients of the power series for f satisfy $\gamma_n\neq 0$ for all $n\in\mathbb{N}_0$. In the following text, this will be tacitly assumed.

If we apply the u variant (4.17) of $\mathcal{G}_k^{(n)}(q_m,s_n,\omega_n)$ to the partial sums (6.1) of the (formal) power series for f, we obtain

$$
\begin{aligned}
{}_u\mathcal{G}_k^{(n)}(q_m,f_n(z)) &= \mathcal{G}_k^{(n)}(q_m,f_n(z),(n+q_0)\gamma_n z^n)\\
&= \frac{\displaystyle\sum_{j=0}^{k}(-1)^j\binom{k}{j}\left\{\prod_{m=1}^{k-1}\frac{(n+j+q_m)}{(n+k+q_m)}\right\}\frac{z^{k-j}f_{n+j}(z)}{(n+j+q_0)\gamma_{n+j}}}{\displaystyle\sum_{j=0}^{k}(-1)^j\binom{k}{j}\left\{\prod_{m=1}^{k-1}\frac{(n+j+q_m)}{(n+k+q_m)}\right\}\frac{z^{k-j}}{(n+j+q_0)\gamma_{n+j}}},\quad k,n\in\mathbb{N}.
\end{aligned}
\tag{6.7}
$$

${}_u\mathcal{G}_k^{(n)}(q_m,f_n(z))$ is the ratio of two polynomials of degrees $k+n$ and k in z, and for its computation the partial sums $f_n(z)$, $f_{n+1}(z),\ldots,f_{n+k}(z)$ are needed. It resembles the Padé approximant $[k+n/k]$, whose computation with the help of Wynn's epsilon algorithm[167] requires, however, the partial sums $f_n(z),f_{n+1}(z),\ldots,f_{n+2k}(z)$.

In the case of the (modified) t variant (4.45) of $\mathcal{G}_k^{(n)}(q_m,s_n,\omega_n)$, we obtain for $n\geqslant 1$

$$
\begin{aligned}
{}_t\mathcal{G}_k^{(n)}(q_m,f_n(z)) &= \mathcal{G}_k^{(n-1)}(q_m+1,f_{n-1}(z),\gamma_n z^n)\\
&= \frac{\displaystyle\sum_{j=0}^{k}(-1)^j\binom{k}{j}\left\{\prod_{m=1}^{k-1}\frac{(n+j+q_m)}{(n+k+q_m)}\right\}\frac{z^{k-j}f_{n+j-1}(z)}{\gamma_{n+j}}}{\displaystyle\sum_{j=0}^{k}(-1)^j\binom{k}{j}\left\{\prod_{m=1}^{k-1}\frac{(n+j+q_m)}{(n+k+q_m)}\right\}\frac{z^{k-j}}{\gamma_{n+j}}},\quad k\in\mathbb{N}_0,\quad n\in\mathbb{N},
\end{aligned}
\tag{6.8}
$$

and for $n=0$, we obtain from (4.53),

$$
\begin{aligned}
{}_t\mathcal{G}_k^{(0)}(q_m,f_0(z)) &= \mathcal{G}_k^{(-1)}(q_m+1,f_{-1}(z),\gamma_0 z^0)\\
&= \frac{\displaystyle\sum_{j=0}^{k}(-1)^j\binom{k}{j}\left\{\prod_{m=1}^{k-1}\frac{(j+q_m)}{(k+q_m)}\right\}\frac{z^{k-j}f_{j-1}(z)}{\gamma_j}}{\displaystyle\sum_{j=0}^{k}(-1)^j\binom{k}{j}\left\{\prod_{m=1}^{k-1}\frac{(j+q_m)}{(k+q_m)}\right\}\frac{z^{k-j}}{\gamma_j}},\quad k\in\mathbb{N}.
\end{aligned}
\tag{6.9}
$$

For $n\geqslant 1$, ${}_t\mathcal{G}_k^{(n)}(q_m,f_n(z))$ is the ratio of two polynomials of degrees $k+n-1$ and k in z, and for its computation the partial sums $f_{n-1}(z)$, $f_n(z),\ldots,f_{n+k}(z)$ are needed. For $n=0$, the degrees of

the numerator and denominator polynomials are $k-1$ and k, respectively. In that respect, ${}_t\mathcal{G}_k^{(0)}(q_m,f_0(z))$ resembles the Padé approximant $[k-1/k]$, which is of importance in the convergence theory of Stieltjes series (see, for example, Ref. 3, Theorem 5.2.3).

In the case of the d variant (4.39) of $\mathcal{G}_k^{(n)}(q_m,s_n,\omega_n)$, we obtain

$$\begin{aligned} {}_d\mathcal{G}_k^{(n)}(q_m,f_n(z)) &= \mathcal{G}_k^{(n)}(q_m,f_n(z),\gamma_{n+1}z^{n+1}) \\ &= \frac{\displaystyle\sum_{j=0}^{k}(-1)^j\binom{k}{j}\left\{\prod_{m=1}^{k-1}\frac{(n+j+q_m)}{(n+k+q_m)}\right\}\frac{z^{k-j}f_{n+j}(z)}{\gamma_{n+j+1}}}{\displaystyle\sum_{j=0}^{k}(-1)^j\binom{k}{j}\left\{\prod_{m=1}^{k-1}\frac{(n+j+q_m)}{(n+k+q_m)}\right\}\frac{z^{k-j}}{\gamma_{n+j+1}}}, \quad k,n\in\mathbb{N}_0\,. \end{aligned} \tag{6.10}$$

${}_d\mathcal{G}_k^{(n)}(q_m,f_n(z))$ is the ratio of two polynomials of degrees $k+n$ and k in z, and for its computation the partial sums $f_n(z)$, $f_{n+1}(z),\ldots,f_{n+k+1}(z)$ are needed.

In the case of the v variant (4.31) of $\mathcal{G}_k^{(n)}(q_m,s_n,\omega_n)$, we obtain

$$\begin{aligned} {}_v\mathcal{G}_k^{(n)}(q_m,f_n(z)) &= \mathcal{G}_k^{(n)}(q_m,f_n(z),\gamma_n\gamma_{n+1}z^{n+1}/[\gamma_n-z\gamma_{n+1}]) \\ &= \frac{\displaystyle\sum_{j=0}^{k}(-1)^j\binom{k}{j}\left\{\prod_{m=1}^{k-1}\frac{(n+j+q_m)}{(n+k+q_m)}\right\}\frac{z^{k-j}(\gamma_{n+j}-z\gamma_{n+j+1})f_{n+j}(z)}{\gamma_{n+j}\gamma_{n+j+1}}}{\displaystyle\sum_{j=0}^{k}(-1)^j\binom{k}{j}\left\{\prod_{m=1}^{k-1}\frac{(n+j+q_m)}{(n+k+q_m)}\right\}\frac{z^{k-j}(\gamma_{n+j}-z\gamma_{n+j+1})}{\gamma_{n+j}\gamma_{n+j+1}}}, \\ & k,n\in\mathbb{N}_0\,. \end{aligned} \tag{6.11}$$

${}_v\mathcal{G}_k^{(n)}(q_m,f_n(z))$ is the ratio of two polynomials of degrees $k+n+1$ and $k+1$ in z, and for its computation the partial sums $f_n(z)$, $f_{n+1}(z),\ldots,f_{n+k+1}(z)$ are needed.

Next, asymptotic order estimates of the type of (6.3) will be constructed for the rational approximants (6.7)–(6.11). Here, it must be taken into account that an accuracy-through-order relationship does not make any sense if the rational function reproduces exactly the function f represented by the power series. This is for instance the case if u, t, d, and v variants of $\mathcal{G}_k^{(n)}(q_m,s_n,\omega_n)$ are applied to the partial sums $\Sigma_{\nu=0}^{n}z^\nu=(1-z^{n+1})/(1-z)$ of the geometric series. For an analysis of these complications, let us consider the u variant (6.7). If we introduce the remainders of the partial sums (6.1) according to

$$r_n(z) = f_n(z)-f(z) = -\sum_{\nu=0}^{\infty}\gamma_{n+\nu+1}\,z^{n+\nu+1}, \tag{6.12}$$

then the difference between f and the u variant (6.7) can according to (4.2) be expressed as follows:

$$f(z)-{}_u\mathcal{G}_k^{(n)}(q_m,f_n(z)) = -z^{k+n}\,\frac{\displaystyle\sum_{j=0}^{k}(-1)^j\binom{k}{j}\left\{\prod_{m=1}^{k-1}(n+j+q_m)\right\}\frac{r_{n+j}(z)}{(n+j+q_0)\gamma_{n+j}z^{n+j}}}{\displaystyle\sum_{j=0}^{k}(-1)^j\binom{k}{j}\left\{\prod_{m=1}^{k-1}(n+j+q_m)\right\}\frac{z^{k-j}}{(n+j+q_0)\gamma_{n+j}}}. \tag{6.13}$$

The denominator of this expression is by assumption of order O(1) as $z\to 0$. For the derivation of an order estimate of the numerator, we can use (2.14) to obtain

$$\sum_{j=0}^{k}(-1)^j\binom{k}{j}\left\{\prod_{m=1}^{k-1}(n+j+q_m)\right\}\frac{r_{n+j}(z)}{(n+j+q_0)\gamma_{n+j}z^{n+j}}$$

$$=(-1)^k\left[\Delta^k\left\{\prod_{m=1}^{k-1}(n+q_m)\right\}\frac{r_n(z)}{(n+q_0)\gamma_n z^n}\right]. \tag{6.14}$$

We now have to distinguish some special cases.

Let us first assume that the u type remainder estimate $\omega_n=(n+q_0)\gamma_n z^n$ is a perfect remainder estimate according to (4.3). Then, Δ^k acts on a polynomial of degree $k-1$ in n, which means that the right-hand side of (6.13) is annihilated. Accordingly, ${}_u\mathcal{G}_k^{(n)}(q_m,f_n(z))$ is exact for $k\geqslant 1$ and an accuracy-through-order relationship of the type of (6.3) makes no sense.

Let us now assume that the t type remainder estimate $\omega_n=\gamma_n z^n$ is a perfect remainder estimate according to (4.3), which is the case if the input data $\{f_n(z)\}_{n=0}^{\infty}$ are the partial sums $\Sigma_{\nu=0}^{n}z^\nu=(1-z^{n+1})/(1-z)$ of the geometric series. Then, we again have to distinguish two cases. If $q_0\in\{q_1,\ldots,q_{k-1}\}$, the ratio $\Pi_{m=1}^{k-1}(n+q_m)/(n+q_0)$ simplifies to yield a polynomial of degree $k-2$ in n which is annihilated by Δ^k. Accordingly, ${}_u\mathcal{G}_k^{(n)}(q_m,f_n(z))$ is for $k\geqslant 2$ exact for the partial sums of the geometric series and an accuracy-through-order relationship makes no sense. If $q_0\notin\{q_1,\ldots,q_{k-1}\}$, the ratio $\Pi_{m=1}^{k-1}(n+q_m)/(n+q_0)$ does not simplify to yield a polynomial and is not annihilated by Δ^k. Accordingly, ${}_u\mathcal{G}_k^{(n)}(q_m,f_n(z))$ is in this case not exact for the geometric series.

The exactness for the geometric series is probably the most fundamental requirement for a sequence transformation in the case of linear convergence ($0<|\rho|<1$ in (4.7)). This follows from Germain–Bonne's formal theory of convergence acceleration[68] and its extension to Levin-type transformations (Ref. 146, Sec. 12). Consequently, it is probably a good idea that to choose q_0 in in $\omega_n=(n+q_0)\Delta s_{n-1}$ according to $q_0\in\{q_1,\ldots,q_m\}$. An obvious idea would be to choose $q_0=q_1$. The remainder estimates of the other u-type transformations (4.12), (4.13), (4.14), and (4.15) all satisfy $q_0=q_1$. Accordingly, these u variants are for $k\geqslant 1$ exact for the geometric series. This is also true for the t, d, and v variants (6.8)–(6.11) of $\mathcal{G}_k^{(n)}(q_m,s_n,\omega_n)$.

By analyzing expressions of the type of (6.13), accuracy-through-order relationships for ${}_u\mathcal{G}_k^{(n)}(q_m,f_n(z))$, ${}_t\mathcal{G}_k^{(n)}(q_m,f_n(z))$, ${}_d\mathcal{G}_k^{(n)}(q_m,f_n(z))$, and ${}_v\mathcal{G}_k^{(n)}(q_m,f_n(z))$ can be derived (see, for example, Ref. 150, Sec. 5.7). However, this can be done more elegantly this via the theory of Padé-type approximants which were introduced by Brezinski in Ref. 22 and fully developed in the monograph.[23]

As is well known, the coefficients of the numerator and the denominator polynomials of a Padé approximants are chosen in such a way that the asymptotic order estimate (6.3) is satisfied, but it is not so well known that generalizations and modifications of Padé approximants can be obtained by suitably modifying the asymptotic condition (6.3). For example, let us consider the rational approximants

$$(l/m)_f(z)=\frac{\mathcal{U}^{(l/m)}(z)}{\mathcal{V}^{(l/m)}(z)}=\frac{u_0+u_1z+\cdots+u_lz^l}{v_0+v_1z+\cdots+v_mz^m},\quad l,m\in\mathbb{N}_0. \tag{6.15}$$

We assume that the two polynomials $\mathcal{U}^{(l/m)}(z)$ and $\mathcal{V}^{(l/m)}(z)$ are exactly of degrees l and m in z, or equivalently that $u_l\neq 0$ and $v_m\neq 0$. Let us now assume that the $m+1$ coefficients v_0, $v_1,\ldots,$ v_m of the denominator polynomial $\mathcal{V}^{(l/m)}(z)$ are chosen according to some rule. Then, only the $l+1$ coefficients u_0, $u_1,\ldots,$ u_l of the numerator polynomial $\mathcal{U}^{(l/m)}(z)$ have to be determined via the modified asymptotic condition

$$\mathcal{V}^{(l/m)}(z)\,f(z)-\mathcal{U}^{(l/m)}(z)=\mathrm{O}(z^{l+1}),\quad z\to 0, \tag{6.16}$$

yielding

$$\mathcal{U}^{(l/m)}(z) = \sum_{\lambda=0}^{l} v_\lambda z^\lambda f_{l-\lambda}(z) . \tag{6.17}$$

The rational function $(l/m)_f(z)$ is a so-called Padé-type approximant.[22,23]

Let us now set $l=k+n$ and $m=k$ with $k,n, \in \mathbb{N}_0$ in (6.15). Then, (6.17) implies

$$(k+n/k)_f(z) = \frac{\mathcal{U}^{(k+n/k)}(z)}{\mathcal{V}^{(k+n/k)}(z)} = \frac{\sum_{j=0}^{k} v_j z^j f_{k+n-j}(z)}{\sum_{j=0}^{k} v_j z^j} = \frac{\sum_{j=0}^{k} v_{k-j} z^{k-j} f_{n+j}(z)}{\sum_{j=0}^{k} v_{k-j} z^{k-j}} . \tag{6.18}$$

It follows from (6.7) and (6.10) that ${}_u\mathcal{G}_k^{(n)}(q_m,f_n(z))$ and ${}_d\mathcal{G}_k^{(n)}(q_m,f_n(z))$ possess the following general structure:

$$\mathbf{T}_k^{(n)}(z) = \frac{\sum_{j=0}^{k} \lambda_j^{(k,n)} z^{k-j} f_{n+j}(z)}{\sum_{j=0}^{k} \lambda_j^{(k,n)} z^{k-j}} = \frac{\sum_{j=0}^{k} \lambda_{k-j}^{(k,n)} z^{j} f_{n+k-j}(z)}{\sum_{j=0}^{k} \lambda_{k-j}^{(k,n)} z^{j}}, \quad k,n \in \mathbb{N}_0 . \tag{6.19}$$

Thus, ${}_u\mathcal{G}_k^{(n)}(q_m,f_n(z))$ and ${}_d\mathcal{G}_k^{(n)}(q_m,f_n(z))$ are Padé-type approximants of the type of $(k+n/k)_f(z)$ with $v_j=\lambda_{k-j}^{(k,n)}$.

It is a direct consequence of the defining asymptotic condition (6.16) that the Padé-type approximant $\mathbf{T}_k^{(n)}(z)$ satisfies the accuracy-through-order relationship

$$f(z) - \mathbf{T}_k^{(n)}(z) = O(z^{k+n+1}), \quad k,n \in \mathbb{N}_0, \quad z \to 0 . \tag{6.20}$$

This implies that ${}_u\mathcal{G}_k^{(n)}(q_m,f_n(z))$ as well as all the other u-type transformations satisfies the asymptotic order estimate

$$f(z) - {}_u\mathcal{G}_k^{(n)}(q_m,f_n(z)) = O(z^{k+n+1}), \quad k,n \in \mathbb{N}_0, \quad z \to 0 . \tag{6.21}$$

Thus, all coefficients $\gamma_0, \gamma_1, \ldots, \gamma_{k+n}$ of the power series $f(z)=\sum_{\nu=0}^{\infty}\gamma_\nu z^\nu$, that are used for the construction of ${}_u\mathcal{G}_k^{(n)}(q_m,f_n(z))$, are reproduced by a Taylor expansion around $z=0$.

For ${}_d\mathcal{G}_k^{(n)}(q_m,f_n(z))$ we obtain the same asymptotic order estimate:

$$f(z) - {}_d\mathcal{G}_k^{(n)}(q_m,f_n(z)) = O(z^{k+n+1}), \quad k,n \in \mathbb{N}_0, \quad z \to 0 . \tag{6.22}$$

In the context of the prediction of unknown power series coefficients, this is a highly unwelcome result: For the computation of ${}_d\mathcal{G}_k^{(n)}(q_m,f_n(z))$ we need the series coefficients $\gamma_0, \gamma_1, \ldots, \gamma_{n+k+1}$. Thus, the order term $O(z^{k+n+1})$ implies that a Taylor expansion of ${}_d\mathcal{G}_k^{(n)}(q_m,f_n(z))$ does not reproduce all coefficients used for its construction. Moreover, the order estimates (6.5) and (6.6), which were derived in Ref. 163 by directly analyzing the corresponding expressions without using the theory of Padé-type approximants, indicate that we should instead get the order estimate

$$f(z) - {}_d\mathcal{G}_k^{(n)}(q_m,f_n(z)) = O(z^{k+n+2}), \quad k \in \mathbb{N}, \quad n \in \mathbb{N}_0, \quad z \to 0 . \tag{6.23}$$

It is indeed possible to derive this seemingly irregular accuracy-through-order relationship by analyzing the Padé-type approximant $\mathbf{T}_k^{(n)}(z)$ more carefully. For that purpose, we rewrite (6.19) as follows:

$$\mathbf{T}_k^{(n)}(z) = f(z) - z^{k+n+1}\frac{\sum_{j=0}^{k}\lambda_j^{(k,n)}\sum_{\nu=0}^{\infty}\gamma_{n+j+\nu+1}z^{\nu}}{\sum_{j=0}^{k}\lambda_j^{(k,n)}z^{k-j}}. \tag{6.24}$$

The denominator on the right-hand side is by assumption of order O(1) as $z\to 0$. Accordingly, the asymptotic estimate (6.20) is normally optimal, and the improved asymptotic estimate (6.23) can only hold if the z-independent part of the numerator vanishes, or equivalently if $\Sigma_{j=0}^{k}\lambda_j^{(k,n)}\gamma_{n+j+1}=0$. For essentially arbitrary coefficients $\lambda_j^{(k,n)}$ this is certainly not true. However, in the case of all d-type transformations of this article we have $\lambda_j^{(k,n)}=(-1)^j\binom{k}{j}P_{k-1}(n+j)/\gamma_{n+j+1}$, where $P_{k-1}(n)$ is a suitable polynomial of degree $k-1$ in n. Then, we have for $k\geqslant 1$

$$\sum_{j=0}^{k}\lambda_j^{(k,n)}\gamma_{n+j+1} = \sum_{j=0}^{k}(-1)^j\binom{k}{j}P_{k-1}(n+j) = (-1)^k\Delta^k P_{k-1}(n) = 0. \tag{6.25}$$

This proofs the refined accuracy-through-order relationship (6.23).

As discussed in more detail in Sec. IV, t-type transformations are actually d-type transformations in disguise, and (4.44) implies

$${}_t\mathcal{G}_k^{(n)}(q_m,f_n(z)) = {}_d\mathcal{G}_k^{(n-1)}(q_m+1,f_{n-1}(z)). \tag{6.26}$$

Accordingly, for $n\geqslant 1$ the asymptotic order estimate of ${}_t\mathcal{G}_k^{(n)}(q_m,f_n(z))$ follows from the asymptotic order estimate (6.23) of ${}_d\mathcal{G}_k^{(n)}(q_m,f_n(z))$:

$$f(z) - {}_t\mathcal{G}_k^{(n)}(q_m,f_n(z)) = f(z) - {}_d\mathcal{G}_k^{(n-1)}(q_m+1,f_{n-1}(z)) = \mathrm{O}(z^{k+n+1}),$$
$$k,n\in\mathbb{N},\quad z\to 0. \tag{6.27}$$

Thus, all coefficients $\gamma_0, \gamma_1,\ldots,\gamma_{k+n}$ of the power series $f(z)=\Sigma_{\nu=0}^{\infty}\gamma_\nu z^\nu$, that are used for the construction of ${}_t\mathcal{G}_k^{(n)}(q_m,f_n(z))$ with $n\geqslant 1$, are reproduced by a Taylor expansion around $z=0$.

Next, we analyze the case $n=0$ which is not covered by (6.27). A comparison of (6.9) and (6.19) shows that ${}_t\mathcal{G}_k^{(0)}(q_m,f_0(z))$ is not a Padé-type approximant—the term proportional to z^k is missing in the numerator sum—but a closely related rational function of the following kind:

$$\mathbf{T}_k^{(-1)}(z) = \frac{\sum_{j=0}^{k}\lambda_j^{(k,-1)}z^{k-j}f_{j-1}(z)}{\sum_{j=0}^{k}\lambda_j^{(k,-1)}z^{k-j}},\quad k\in\mathbb{N}. \tag{6.28}$$

Accordingly, the defining accuracy-through-order relationship (6.16) of Padé-type approximants cannot help us. However, $\mathbf{T}_k^{(-1)}(z)$ can be reformulated as follows:

$$\mathbf{T}_k^{(-1)}(z) = f(z) - z^k\frac{\sum_{j=0}^{k}\lambda_j^{(k,-1)}\sum_{\nu=0}^{\infty}\gamma_{j+\nu}z^{\nu}}{\sum_{j=0}^{k}\lambda_j^{(k,-1)}z^{k-j}},\quad k\in\mathbb{N}. \tag{6.29}$$

The ratio on the right-hand side is of order $\mathrm{O}(z^k)$ as $z\to 0$. This implies the asymptotic oder estimate $f(z)-{}_t\mathcal{G}_k^{(0)}(q_m,f_0(z))=\mathrm{O}(z^k)$ as $z\to 0$, which does not agree with (6.27) and which would be unsatisfactory since it indicates that not all coefficients $\gamma_0, \gamma_1,\ldots,\gamma_k$ are reproduced by a Taylor expansion of ${}_t\mathcal{G}_k^{(0)}(q_m,f_0(z))$. Instead, we need an order term $\mathrm{O}(z^{k+1})$. Accordingly, we have to show that the z-independent part $\Sigma_{j=0}^{k}\lambda_j^{(k,-1)}\gamma_j$ of the numerator on the right-hand side of (6.29) vanishes.

For that purpose, we take into account that a t-type transformations with $n=0$ is according to (4.44) or (6.26) actually a d-type transformations with $n=-1$. As remarked above, all d-type transformations satisfy $\lambda_j^{(k,n)}=(-1)^j\binom{k}{j}P_{k-1}(n+j)/\gamma_{n+j+1}$, where $P_{k-1}(n)$ is a suitable polynomial of degree $k-1$ in n. Thus, we obtain for $k\geqslant 1$ and $n=-1$:

$$\sum_{j=0}^{k}\lambda_j^{(k,-1)}\gamma_j = \sum_{j=0}^{k}(-1)^j\binom{k}{j}P_{k-1}(j-1) = (-1)^k\Delta^k P_{k-1}(n)\big|_{n=-1} = 0. \tag{6.30}$$

Inserting this into (6.29) yields

$$\mathbf{T}_k^{(-1)}(z) = f(z)-z^{k+1}\frac{\sum_{j=0}^{k}\lambda_j^{(k,-1)}\sum_{\nu=0}^{\infty}\gamma_{j+\nu+1}z^\nu}{\sum_{j=0}^{k}\lambda_j^{(k,-1)}z^{k-j}}, \quad k\in\mathbb{N}, \tag{6.31}$$

which proves the asymptotic order estimate

$$f(z)-{}_t\mathcal{G}_k^{(0)}(q_m,f_0(z)) = O(z^{k+1}), \quad k\in\mathbb{N}, \quad z\to 0. \tag{6.32}$$

Consequently, the asymptotic order estimate (6.27) holds also for $n=0$, and all series coefficients $\gamma_0,\ \gamma_1,\ldots,\ \gamma_{k+n}$ are reproduced by a Taylor expansion of ${}_t\mathcal{G}_k^{(n)}(q_m,f_n(z))$ which were used for its construction.

It follows from (6.11) that the rational approximant ${}_v\mathcal{G}_k^{(n)}(q_m,f_n(z))$ possesses like all other v-type transformations of this article the following general structure:

$$\mathbf{V}_k^{(n)}(z) = \frac{\sum_{j=0}^{k}\lambda_j^{(k,n)}z^{k-j}f_{n+j}(z)+z\sum_{j=0}^{k}\mu_j^{(k,n)}z^{k-j}f_{n+j}(z)}{\sum_{j=0}^{k}\lambda_j^{(k,n)}z^{k-j}+z\sum_{j=0}^{k}\mu_j^{(k,n)}z^{k-j}}, \quad k,n\in\mathbb{N}_0. \tag{6.33}$$

Comparison with (6.19) shows that $\mathbf{V}_k^{(n)}(z)$ is no Padé-type approximant. Accordingly, the defining asymptotic condition (6.16) of Padé-type approximants cannot be applied. Fortunately, an analogous asymptotic order estimate for $\mathbf{V}_k^{(n)}(z)$ can be derived easily. For that purpose, we rewrite (6.33) as follows:

$$\mathbf{V}_k^{(n)}(z) = f(z)-z^{k+n+1}\frac{\sum_{j=0}^{k}\lambda_j^{(k,n)}\sum_{\nu=0}^{\infty}\gamma_{n+j+\nu+1}z^\nu+z\sum_{j=0}^{k}\mu_j^{(k,n)}\sum_{\nu=0}^{\infty}\gamma_{n+j+\nu+1}z^\nu}{\sum_{j=0}^{k}\lambda_j^{(k,n)}z^{k-j}+z\sum_{j=0}^{k}\mu_j^{(k,n)}z^{k-j}}. \tag{6.34}$$

The denominator on the right-hand side is by assumption of order O(1) as $z\to 0$. Accordingly, we obtain the asymptotic order estimate

$$f(z)-\mathbf{V}_k^{(n)}(z) = O(z^{k+n+1}), \quad k,n\in\mathbb{N}_0, \quad z\to 0, \tag{6.35}$$

which implies

$$f(z)-{}_v\mathcal{G}_k^{(n)}(q_m,f_n(z)) = O(z^{k+n+1}), \quad k,n\in\mathbb{N}_0, \quad z\to 0. \tag{6.36}$$

Now, we have the same problem as in the case of the suboptimal order estimate (6.22) for ${}_d\mathcal{G}_k^{(n)}(q_m,f_n(z))$: The order term $O(z^{k+n+1})$ in (6.36) implies that a Taylor expansion of ${}_v\mathcal{G}_k^{(n)}(q_m,f_n(z))$ reproduces only $\gamma_0, \gamma_1,\ldots, \gamma_{n+k}$, whereas $\gamma_0, \gamma_1,\ldots, \gamma_{n+k+1}$ are needed for the computation of ${}_v\mathcal{G}_k^{(n)}(q_m,f_n(z))$. Thus, we need instead the order estimate

$$f(z) - {}_v\mathcal{G}_k^{(n)}(q_m,f_n(z)) = O(z^{k+n+2}), \quad k\in\mathbb{N}, \quad n\in\mathbb{N}_0, \quad z\to 0. \tag{6.37}$$

This refined asymptotic estimate can only be true if the z-independent part of the first numerator sum in (6.34) vanishes, or equivalently if $\Sigma_{j=0}^{k}\lambda_j^{(k,n)}\gamma_{n+j+1}=0$. For essentially arbitrary coefficients $\lambda_j^{(k,n)}$ this is certainly not true. However, in the case of the v-type transformations of this article we have just like in the case of the d-type transformations $\lambda_j^{(k,n)}=(-1)^j\binom{k}{j}P_{k-1}(n+j)/\gamma_{n+j+1}$ but $\mu_j^{(k,n)}=(-1)^{j+1}\binom{k}{j}P_{k-1}(n+j)/\gamma_{n+j}$, where $P_{k-1}(n)$ is a suitable polynomial of degree $k-1$ in n. Thus, (6.25) holds which proves the accuracy-through-order relationship (6.37).

In Sec. IV, it was mentioned that in some cases asymptotic expressions $a_n^{(\infty)}$ for the terms a_n of an infinite series $s=\Sigma_{\nu=0}^{\infty}a_\nu$ are known which reproduce the leading order asymptotics of a_n as $n\to\infty$, and that these asymptotic expressions can also be used in the simple remainder estimates (4.11), (4.18), (4.24), and (4.32) since they also reproduce the leading order asymptotics of the remainders $r_n=s_n-s$ as $n\to\infty$.

Thus, we now assume that asymptotic expressions $\gamma_n^{(\infty)}$ are known that reproduce the leading order asymptotics of the coefficients of the power series $f(z)=\Sigma_{\nu=0}^{\infty}\gamma_\nu z^\nu$ according to

$$\gamma_n = \gamma_n^{(\infty)}[c+O(1/n)], \quad c\neq 0, \quad n\to\infty. \tag{6.38}$$

If we use in $\mathcal{G}_k^{(n)}(q_m,s_n,\omega_n)$ the u-, t-, v-, and d-type remainder estimates $\omega_n=(n+q_0)\gamma_n^{(\infty)}z^n$, $\omega_n=\gamma_n^{(\infty)}z^n$, $\omega_n=\gamma_n^{(\infty)}\gamma_{n+1}^{(\infty)}z^{n+1}/[\gamma_n^{(\infty)}-z\gamma_{n+1}^{(\infty)}]$, and $\omega_n=\gamma_{n+1}^{(\infty)}z^{n+1}$, we obtain rational approximants which closely resemble the u, t, v, and d variants (6.7), (6.8), (6.10), and (6.11), and which are also special cases of the rational functions $\mathbf{T}_k^{(n)}(z)$ and $\mathbf{V}_k^{(n)}(z)$ defined in (6.19) and (6.33), respectively. Consequently, these rational approximants satisfy for all $k,n\in\mathbb{N}_0$ the following asymptotic estimates as $z\to 0$:

$$f(z) - \mathcal{G}_k^{(n)}(q_m,f_n(z),(n+q_0)\gamma_n^{(\infty)}z^n) = O(z^{k+n+1}), \tag{6.39}$$

$$f(z) - \mathcal{G}_k^{(n)}(q_m,f_n(z),\gamma_n^{(\infty)}z^n) = O(z^{k+n+1}), \tag{6.40}$$

$$f(z) - \mathcal{G}_k^{(n)}(q_m,f_n(z),\gamma_{n+1}^{(\infty)}z^n) = O(z^{k+n+1}), \tag{6.41}$$

$$f(z) - \mathcal{G}_k^{(n)}(q_m,f_n(z),\gamma_n^{(\infty)}\gamma_{n+1}^{(\infty)}z^{n+1}/[\gamma_n^{(\infty)}-z\gamma_{n+1}^{(\infty)}]) = O(z^{k+n+1}). \tag{6.42}$$

Accordingly, all coefficients $\gamma_0, \gamma_1,\ldots, \gamma_{k+n}$ of the power series for $f(z)$, which were used for the construction of these rational approximants are reproduced by Taylor expansion.

Improved asymptotic estimates of the type of (6.23) or (6.37) for the d- and v-type variants do not hold here. The reason is that the coefficients $\lambda_j^{(k,n)}$ in (6.19) and (6.33) now satisfy $\lambda_j^{(k,n)}=(-1)^j\binom{k}{j}P_{k-1}(n+j)/\gamma_{n+j+1}^{(\infty)}$. In general, we have $\gamma_{n+j+1}^{(\infty)}\neq\gamma_{n+j+1}$, which implies that $\Sigma_{j=0}^{k}\lambda_j^{(k,n)}\gamma_{n+j+1}=0$ does not hold.

If we use in $\mathcal{G}_k^{(n)}(q_m,s_n,\omega_n)$ the remainder estimates $\omega_n=(n+q_0)\gamma_n^{(\infty)}z^n$, $\omega_n=\gamma_n^{(\infty)}z^n$, $\omega_n=\gamma_n^{(\infty)}\gamma_{n+1}^{(\infty)}z^{n+1}/[\gamma_n^{(\infty)}-z\gamma_{n+1}^{(\infty)}]$, and $\omega_n=\gamma_{n+1}^{(\infty)}z^{n+1}$, the poles of the resulting rational approximants are determined by the parameters q_m in the products $\Pi_{m=1}^{k-1}(n+q_m)$ and by the remainder estimates, but they do not depend on the coefficients γ_n of the power series for f. This highlights once more the crucial importance of the remainder estimates for the success or the failure of Levin-type transformations. In contrast, both the numerator and the denominator coefficients of a Padé approximant $[l/m]_f(z)$ depend via (6.3) on the coefficients of the partial sum $f_{l+m}(z)$ which was used for its construction.

VII. SUMMARY AND OUTLOOK

Levin[99] deserves credit for realizing that the efficiency of convergence acceleration and summation processes can be enhanced considerably by using as input data not only the elements of the sequence $\{s_n\}_{n=0}^{\infty}$ to be transformed, but also explicit estimates $\{\omega_n\}_{n=0}^{\infty}$ for the truncation errors of this sequence.

If the input data are the partial sums of an infinite series, and if sufficiently simple analytical expressions for the terms of this series are known, then it is possible to derive analytical estimates for the truncation errors of these series. In principle, the use of specially designed analytical remainder estimates would be highly desirable, although the resulting expressions are no longer generally applicable sequence transformations, but rather (optimized) approximation schemes for specific problems (see, for instance, the discussion in Ref. 159).

However, convergence acceleration and summation methods are needed most if only relatively few elements of a slowly convergent or divergent sequence are available, and if apart from the numerical values of the input data virtually nothing is known. This is a scenario which happens only too often if we try to sum divergent perturbation expansions of quantum physics. In such a situation there is obviously no chance of constructing analytical expressions for remainder estimates. Instead, we must construct the remainder estimates from the numerical values of the input data via simple rules. Fortunately, the simple remainder estimates proposed by Levin[99] and later Smith and Ford,[140] which are discussed in Sec. IV, normally do the job. In spite of their simplicity, they often work remarkably well.

If we approximate the remainder r_n of a sequence element s_n by the product $\omega_n z_n$ according to (2.8), where z_n is a so-called correction term, then we should take into account that our approximation scheme actually has two degrees of freedom. Levin[99] originally assumed that z_n is a truncated inverse power series according to (2.16). This is certainly a very natural idea, and it leads to a very powerful sequence transformation.

Nevertheless, in some cases Levin's transformation fails horribly for reasons which we do not completely understand. For example, it was found in Refs. 162 and 163 that Levin's transformation diverges if it is used for the summation of the perturbation expansions for the ground state energies of the anharmonic oscillators (compare also Ref. 148, Table II or the discussion in Ref. 150, Sec. 10.7). A similar divergence of Levin's transformation was observed by Čížek, Zamastil, and Skála (Ref. 50, p. 965) in the case of the hydrogen atom in an external magnetic field. Fortunately, Levin's choice for z_n is not the only possibility, and at least for some problems, alternative correction terms produce significantly better results. For example, the so-called delta transformation defined in (4.36) is based on the assumption that z_n is a truncated factorial series according to (2.19). As mentioned before, this delta transformation is a very effective transformation for slowly convergent and divergent alternating series. In particular, it produces very good summation results both in the case of the anharmonic oscillators[147,148,150,149,153,155,162,163] as well as in the case of the hydrogen atom in an external magnetic field (Ref. 50, Tables I and II).

The sequence transformation $\mathcal{G}_k^{(n)}(q_m, s_n, \omega_n)$ introduced by Čížek, Zamastil, and Skála[50] permits a unified treatment of the mathematical properties of all sequence transformations, whose correction terms are annihilated by difference operators of the type of

$$\hat{T} = \Delta^k P_{k-1}(n). \tag{7.1}$$

Here, $P_{k-1}(n)$ is a suitable polynomial of degree $k-1$ in n that can be obtained by specializing the parameters q_m in $\Pi_{m=1}^{k-1}(n+q_m)$. All Levin-type transformations considered in this article belong to this class of sequence transformations. Consequently, all their mathematical properties such as explicit expressions (Secs. II and V), recurrence formulas (Sec. III), and accuracy-through-order properties (Sec. VI) can be deduced from the corresponding properties of $\mathcal{G}_k^{(n)}(q_m, s_n, \omega_n)$ by specializing the parameters q_m.

In addition, new sequence transformations can be constructed by specializing the parameters q_m in $\mathcal{G}_k^{(n)}(q_m, s_n, \omega_n)$. For example, Čížek, Zamastil, and Skála (Ref. 50, Tables I and II) found that in the case of the hydrogen atom in an external magnetic field at least for some coupling

constants better summation results can be obtained by choosing $q_m = m^2$ instead of choosing $q_m = m$ which yields the delta transformation with $\beta = 1$. Such a quadratic dependence of the parameters q_m on m leads to a completely new sequence transformation. Thus, the sequence transformation $\mathcal{G}_k^{(n)}(q_m, s_n, \omega_n)$ introduced by Čížek, Zamastil, and Skála[50] does not only permit a unification of already known transformations, but it also opens up the path for promising new research.

As discussed in more details in the following article,[160] our current level of theoretical understanding does not permit to predict which one of the numerous variants of $\mathcal{G}_k^{(n)}(q_m, s_n, \omega_n)$ will give best results for a given convergence acceleration or summation problem. So, if we for example use one of the numerous Levin-type transformation for the summation of a divergent perturbation expansion, we are essentially conducting a numerical experiment. As every good experimentalist knows, a single experiment is only rarely able to provide a definite answer. Normally, a whole set of related experiments is needed to obtain convincing evidence. Of course, this applies also to our numerical experiments. Therefore, we should not insist with a quasireligious zeal on using only a single (Levin-type) transformation which we for some reason may prefer. Instead, it is usually a much better idea to compare the performance of several different transformations.

Levin-type transformations are not only very powerful but also very flexible. Experience shows that they can handle successfully a large variety of different convergence acceleration or summation problems. This is a direct consequence of the fact that the ansatz $\omega_n z_n$ for r_n according to (2.8) has two degrees of freedom which allows a considerable amount of fine-tuning. Nevertheless, Levin-type transformations are not a cure for all evils. Consequently, a good experimentalist should also take into account the possibility that Levin-type transformations may not work at all or that other transformations could produce better results.

(Received 10 March 2003; accepted 18 January 2004)

General Natanzon potentials related to the SO(2,2) group are studied. The S-matrices for systems under consideration are related to intertwining operators between Weyl equivalent most degenerate principal series representations of SO(2,2). © *2004 American Institute of Physics.* [DOI: 10.1063/1.1669057]

I. INTRODUCTION

The existence of Hamiltonians with nontrivial potentials which are exactly solvable is one of the most interesting problems in nonrelativistic quantum mechanics. By exactly solvable, one means those Hamiltonians for which the spectrum, eigenfunctions and the scattering matrices can be found explicitly. Apart from their beautiful mathematical structure, these models provide excellent tools for studying various physical phenomena.

In particular, the Hamiltonians with Natanzon potentials[1] are known to be exactly solvable, and much literature has been devoted to the study of these models.[2–11] An important point to stress is that they possess hidden algebraic structures responsible for solvability. Moreover, it has been shown by Wu *et al.*[5] that both bound and scattering problems for Natanzon potentials can be reduced to a representation theory problem of $\mathfrak{so}(2,2)$. It appears that knowledge of the interrelation between $\mathfrak{so}(2,2)$ algebra and an Euclidean algebra $\mathfrak{e}(2)\oplus\mathfrak{e}(2)$, which describes the asymptotic properties of the system, allows pure algebraic calculation of S-matrices. (This technique[12] is referred to as the Euclidean connection.) However, Natanzon potentials constructed in Ref. 5 is not the most general one related to $\mathfrak{so}(2,2)$. As we shall see, this lack of generality is due to the fact that only $\mathfrak{so}(2,2)\supset\mathfrak{so}(2)\oplus\mathfrak{so}(2)$ subgroup reduction were considered in that paper. It is also worth to point out that the Euclidean connection technique works out only in cases in which the reduction with respect to compact algebra is appropriate.

In a recent paper by one of the present authors[13] was proposed a way which allows pure algebraic calculation of S-matrices for the systems whose Hamiltonians are related to the Casimir operator C of some noncompact group G. In that paper the S-matrices for the systems under consideration are associated with intertwining operators A between Weyl equivalent principal series representations of G. At this stage we note that the operator A is said to intertwine the representations U^{χ} and $U^{\tilde{\chi}}$ of the group G (Ref. 14) if relation

$$AU^{\chi}(g)=U^{\tilde{\chi}}(g)A \quad \text{for all } g\in G \tag{1.1}$$

or

$$AdU^{\chi}(b)=dU^{\tilde{\chi}}(b)A \quad \text{for all } b\in\mathfrak{g} \tag{1.2}$$

holds, where dU^{χ} and $dU^{\tilde{\chi}}$ are the corresponding representations of the algebra $\mathfrak{g}$ of G.

It turns out that if Hamiltonian H of the system belongs to the center of the enveloping algebra of G, i.e.,

$$H=f(C), \tag{1.3}$$

then the S matrix coincide with intertwining operator between Weyl equivalent principal series representations of G. Moreover, it follows from Eq. (1.1) or (1.2) that if the matrix of the representation operator is diagonal in some subgroup basis then the matrix of the intertwining operator is also diagonal. This fact leads to the suggestion that there might exist a class of scattering systems for which

$$H=f(C)|_{\mathcal{H}}, \tag{1.4}$$

where $\mathcal{H}$ are the subspaces occurring in the subgroup reductions. This is exactly what happens in the algebraic approaches proposed in Refs. 15, 16, 17, 12. (As usual, H is linear on the second-order Casimir operator of G.) In this case the group G describes fixed energy states of a family of dynamical systems with different potential strength. This is why the present group G is called ''the potential group.'' [17,12]

It is clear that the scattering operators S for such systems are also related to the intertwining operators, but now

$$S=A|_{\mathcal{H}}. \tag{1.5}$$

Moreover, there also exist other solvable models for which scattering operators are given by (1.5) while the Hamiltonian of the systems are related to the Casimir operator C as[15]

$$Q(H-E)=(C-q)|_{\mathcal{H}}, \tag{1.6}$$

where q is an eigenvalue of C and Q is some nontrivial operator. Observe that if we choose $Q=\text{const}$ Eq. (1.6) reduces to (1.4) provided that H is linear on C.

Equations (1.1) and (1.2) have much restriction power, determining the intertwining operator up to a constant. Therefore, one can evaluate the S-matrix without writing a Schrödinger equation, or wave functions. Moreover, one can use the well-developed theory of intertwining operators for semisimple Lie groups[18–21] to obtain stringent restriction upon the structure of the scattering matrices for many-body systems associated with semisimple Lie groups, or even to determine it completely.[22]

In a previous paper[23] we gave the simple example of how the scattering problem for systems with the SO(2,2) ''potential group'' structure can be solved within the framework of group theory. We discussed the one-dimensional potential scattering of systems for which the Hamiltonians H can be written as

$$H\propto(C+1)|_{\mathcal{H}}, \tag{1.7}$$

where C is the Casimir operator of SO(2,2) and $\mathcal{H}$ is a subspace occurring in the $\mathrm{SO}(2,2)\supset\mathrm{SO}(2)\otimes\mathrm{SO}(2)$, $\mathrm{SO}(2,2)\supset\mathrm{SO}(2)\otimes E(1)$, $\mathrm{SO}(2,2)\supset\mathrm{SO}(2)\otimes\mathrm{SO}(1,1)$, $\mathrm{SO}(2,2)\supset\mathrm{SO}(1,1)\otimes E(1)$ or $\mathrm{SO}(2,2)\supset E(1)\otimes E(1)$ reduction. Here we show that the solution of the scattering problem in the case of models with algebraic structure proposed in (1.6) is also possible within this framework.

The content of the paper is arranged as follows: After the introduction, in Sec. II, we set out the basis of our approach. In Secs. III, IV, and V we discuss a class of quantum scattering problems related to most degenerate principal series representations of the group SO(2,2) in the reductions with respect to $\mathrm{SO}(2)\otimes\mathrm{SO}(2)$, $\mathrm{SO}(2)\otimes E(1)$, and $\mathrm{SO}(2)\otimes\mathrm{SO}(1,1)$. Finally, we have included in the Appendix some technical details of the calculation that for clarity were omitted from the main text.

II. MAIN IDEA

Let $R^{2,2}$ be a four-dimensional pseudo-Euclidean space with the bilinear form

$$[\xi,\eta]=\xi_1\eta_1+\xi_2\eta_2-\xi_3\eta_3-\xi_4\eta_4. \tag{2.1}$$

By SO(2,2) we denote the connected component of the group of linear transformation of $R^{2,2}$ preserving the form (2.1). We consider SO(2,2) as acting on $R^{2,2}$ on the right. In accordance with this we shall write the vector in the row form $\xi=(\xi_1,\xi_2,\xi_3,\xi_4)$.

Let us denote $\{g_{ij}(\theta)\}$ $i<j$, $i,j=1,2,3,4$ the one-parameter subgroups of SO(2,2) consisting of rotations or pseudorotations in the $\xi_i-\xi_j$-planes, that is, of transformations of the form

$$\xi_k'=\xi_k,\quad k\neq i,j,\quad \xi_i'=\xi_i\cos\theta+\xi_j\sin\theta,\quad \xi_j'=-\xi_i\sin\theta+\xi_j\cos\theta \tag{2.2}$$

or

$$\xi_k'=\xi_k,\ k\neq i,j,\quad \xi_i'=\xi_i\cosh\theta+\xi_j\sinh\theta,\quad \xi_j'=\xi_i\sinh\theta+\xi_j\cosh\theta, \tag{2.3}$$

respectively. The matrices

$$a_{ij}=\frac{d}{d\theta}g_{ij}(\theta)\bigg|_{\theta=0},\quad i<j \tag{2.4}$$

form a basis of the Lie algebra $\mathfrak{so}(2,2)$ of the group SO(2,2). Defining

$$\begin{aligned} a_1&=(a_{13}+a_{24})/2,\quad b_1=(a_{13}-a_{24})/2,\\ a_2&=(a_{23}-a_{14})/2,\quad b_2=(a_{23}+a_{14})/2,\\ a_3&=(a_{34}-a_{12})/2,\quad b_3=-(a_{12}+a_{34})/2, \end{aligned} \tag{2.5}$$

one has

$$\begin{aligned} [a_1,a_2]&=a_3,\quad [b_1,b_2]=b_3,\\ [a_2,a_3]&=-a_1,\quad [b_2,b_3]=-b_1,\\ [a_3,a_1]&=-a_2,\quad [b_3,b_1]=-b_2. \end{aligned} \tag{2.6}$$

The generators a_i and b_i separately form a Lie algebra of SO(2,1). In other words SO(2,2) is the product group of two SO(2,1) groups, i.e., $\mathrm{SO}(2,2)=\mathrm{SO}(2,1)\otimes\mathrm{SO}(2,1)$. Let us note at this point that the group SO(2,1) has three subgroups SO(2), SO(1,1), and $E(1)$ generated, for example, by a_3, a_1, and a_2+a_3, respectively, where $E(1)$ is an Euclidean group in one dimension. It is also worth noting that each UIR of SO(1.1) is doubly degenerate in principal series of UIR of SO(2.1).

The most degenerate UIR of SO(2,2) are known to form three series:[24,25] principal, supplementary, and discrete. It is also known that only the principal series of SO(2,2) describe scattering states. Consequently, the relevant unitary representations will be the principal series and we restrict the discussion to it.

The principal degenerate representation of SO(2,2) are characterized by the pair $\chi=(\rho,\varepsilon)$ where ε is equal to 0 or 1, while $0\leqslant\rho<\infty$. The representations specified by labels $\chi=(\rho,\varepsilon)$ and $\tilde{\chi}=(-\rho,\varepsilon)$ are equivalent. (The representations labeled by χ and $\tilde{\chi}$ have the same Casimir eigenvalues. Such representations are called Weyl equivalent.) For the sake of simplicity, we consider the representations with $\varepsilon=0$, although the case $\varepsilon=1$ can be also easily treated. We now return to our main theme.

We want to construct the Hamiltonians for which the relation

$$Q(H-E)=[C-j(j+2)]|_{\mathcal{H}} \tag{2.7}$$

holds, where j specifies the most degenerate principal series of SO(2,2) and $\mathcal{H}$ is a subspace occurring in subgroup reductions. The key to the construction of it lies in the observation that the Schrödinger energy eigenvalue equation for such systems is nothing but the condition imposed on

the carrier space of SO(2,2) to be irreducible. Thus in order to find the Hamiltonians for the systems under considerations we should look for a reducible representation of SO(2,2) containing the principal series.

Let us consider a quasiregular representation $T(g)$ of SO(2,2) realized in the Hilbert space of square-integrable functions $f(\xi)$ on hyperboloid Ξ,

$$\xi_1^2+\xi_2^2-\xi_3^2-\xi_4^2=1. \tag{2.8}$$

Generally, one can use for the construction of the quasiregular representation the carrier space $L^2(\Xi,d\mu)$ with any quasi-invariant measure $d\mu(\xi)$ on Ξ. The representations with different measure are unitarily equivalent. They are given by[26]

$$T(g)f(\xi)=(d\mu(\xi g)/d\mu(\xi))^{1/2}f(\xi g), \tag{2.9}$$

with the inner product

$$(f,f')=\int \overline{f(\xi)}f'(\xi)d\mu(\xi), \tag{2.10}$$

where $d\mu(\xi g)/d\mu(\xi)$ is the Radon–Nikodym derivative.

We can, without loss of generality, put

$$d\mu(\xi)=h(\xi)d\xi, \tag{2.11}$$

where $d\xi=d\xi_1 d\xi_2 d\xi_3/|\xi_4|$ is an invariant measure on Ξ. The requirement that the measure is quasi-invariant implies only the condition

$$h(\xi)\geqslant 0. \tag{2.12}$$

Then the (Hermitian) infinitesimal operators $A_{ij}=-i\,(d/d\theta)\,T(g_{ij}(\theta))|_{\theta=0}$ of the representation $T(g)$ corresponding to the one-parameter subgroups $g_{ij}(\theta)$ are given by

$$iA_{12}=\xi_2\frac{\partial}{\partial\xi_1}-\xi_1\frac{\partial}{\partial\xi_2}+\frac{1}{2h}\left(\xi_2\frac{\partial h}{\partial\xi_1}-\xi_1\frac{\partial h}{\partial\xi_2}\right),\quad iA_{14}=\xi_4\frac{\partial}{\partial\xi_1}+\frac{\xi_4}{2h}\frac{\partial h}{\partial\xi_1},$$

$$iA_{13}=\xi_3\frac{\partial}{\partial\xi_1}+\xi_1\frac{\partial}{\partial\xi_3}+\frac{1}{2h}\left(\xi_3\frac{\partial h}{\partial\xi_1}+\xi_1\frac{\partial h}{\partial\xi_3}\right),\quad iA_{24}=\xi_4\frac{\partial}{\partial\xi_2}+\frac{\xi_4}{2h}\frac{\partial h}{\partial\xi_2},$$

$$iA_{23}=\xi_3\frac{\partial}{\partial\xi_2}+\xi_2\frac{\partial}{\partial\xi_3}+\frac{1}{2h}\left(\xi_3\frac{\partial h}{\partial\xi_2}+\xi_2\frac{\partial h}{\partial\xi_3}\right),\quad iA_{34}=\xi_4\frac{\partial}{\partial\xi_3}+\frac{\xi_4}{2h}\frac{\partial h}{\partial\xi_3}.$$

We are taking ξ_1, ξ_2, and ξ_3 as the independent variables on Ξ.

We now require the representation space to be irreducible. (We note that the representation (2.9) is decomposed onto principal and discrete series of most degenerate UIR of SO(2,2).[24,25]) Such a restriction is obtained if all functions are eigenfunctions of the Casimir operator C

$$Cf=j(j+2)f, \tag{2.13}$$

where $C=A_{12}^2+A_{34}^2-A_{13}^2-A_{14}^2-A_{23}^2-A_{24}^2$. Since we are interested only in the continuous spectrum, we will put $j=-1-i\rho$. Next, imposing the reduction condition, one can extract corresponding one-dimensional potentials from the Casimir operator.

III. CLASS OF POTENTIALS RELATED TO $SO(2,2)\supset SO(2)\otimes SO(2)$ REDUCTION

As we mentioned above the quasiregular representations with different measure are unitarily equivalent. Although the representations with different measure are mathematically equivalent, they may be related to different physical problems. For this reason, we shall consider the quasiregular representation with different measure.

We want to diagonalize the $SO(2)\otimes SO(2)$ subgroup. Then, the reduction conditions are

$$A_3 f^{(1)}_{mk}=m f^{(1)}_{mk}, \quad B_3 f^{(1)}_{mk}=k f^{(1)}_{mk}, \tag{3.1}$$

where A_3 and B_3 are defined as

$$A_3=(A_{34}-A_{12})/2, \quad B_3=-(A_{12}+A_{34})/2. \tag{3.2}$$

(Here and in the following infinitesimal operators corresponding to generators a_i, b_i are denoted by A_i, B_i, respectively.) According to this we want $d\mu$ to be invariant under $SO(2)\otimes SO(2)$. We can, without loss of generality, put $d\mu(\xi)=h(r)d\xi$, where $r=\xi_1^2+\xi_2^2$. Then the generators A_{12} and A_{34} are given by

$$A_{12}=-i\left(\xi_2\frac{\partial}{\partial\xi_1}-\xi_1\frac{\partial}{\partial\xi_2}\right), \quad A_{34}=-i\xi_4\frac{\partial}{\partial\xi_3} \tag{3.3}$$

while

$$C=-\frac{\partial^2}{\partial\xi_1^2}-\frac{\partial^2}{\partial\xi_2^2}+\frac{\partial^2}{\partial\xi_3^2}+\left(\frac{\xi_1^2+\xi_2^2}{\xi_1 h}\frac{\partial h}{\partial\xi_1}+I\right)(I+2)-\frac{1}{\xi_1 h}\frac{\partial h}{\partial\xi_1}\left(\xi_1\frac{\partial}{\partial\xi_1}+\xi_2\frac{\partial}{\partial\xi_2}+1\right)$$
$$+\frac{(\xi_1^2+\xi_2^2)(\xi_1^2+\xi_2^2-1)}{2\xi_1\xi_2 h}\frac{\partial^2 h}{\partial\xi_1\partial\xi_2}-\frac{(\xi_1^2+\xi_2^2)(\xi_1^2+\xi_2^2-1)}{4\xi_1^2 h^2}\left(\frac{\partial h}{\partial\xi_1}\right)^2 \tag{3.4}$$

with

$$I=\xi_1\frac{\partial}{\partial\xi_1}+\xi_2\frac{\partial}{\partial\xi_2}+\xi_3\frac{\partial}{\partial\xi_3}, \tag{3.5}$$

where we have used

$$\frac{\partial h}{\partial\xi_2}=\frac{\xi_2}{\xi_1}\frac{\partial h}{\partial\xi_1}. \tag{3.6}$$

Since A_3 and B_3 are sought to be diagonal, we introduce in place of ξ_1, ξ_2, ξ_3 the variables x, α, β via

$$\xi_1=\frac{1}{\sqrt{1-z(x)}}\cos\frac{\alpha+\beta}{2}, \quad \xi_2=\frac{1}{\sqrt{1-z(x)}}\sin\frac{\alpha+\beta}{2},$$
$$\xi_3=\sqrt{\frac{z(x)}{1-z(x)}}\cos\frac{\beta-\alpha}{2}, \quad 0\leqslant\alpha, \quad \beta<2\pi, \quad 0\leqslant x<\infty, \tag{3.7}$$

where z is a differentiable function on R^+ with values in [0,1]. Then

$$A_3=-i\frac{\partial}{\partial\alpha}, \quad B_3=-i\frac{\partial}{\partial\beta} \tag{3.8}$$

as we expected. If we compute the Casimir operator C for this parametrization, it becomes

$$C=4\frac{z(1-z)^2}{\dot{z}^2}\left\{\frac{\partial^2}{\partial x^2}+\left(\frac{\dot{h}}{h}-\frac{\ddot{z}}{\dot{z}}+\frac{\dot{z}}{z}\right)\frac{\partial}{\partial x}\right.$$
$$\left.+\frac{\dot{z}^2}{4z^2}\left[\frac{\partial^2}{\partial\alpha^2}-2\frac{1+z}{1-z}\frac{\partial^2}{\partial\alpha\partial\beta}+\frac{\partial^2}{\partial\beta^2}\right]+\frac{1}{2h}\left[\ddot{h}-\frac{\dot{h}^2}{2h}-\left(\frac{\ddot{z}}{\dot{z}}-\frac{\dot{z}}{z}\right)\dot{h}\right]\right\}, \tag{3.9}$$

where dots represent derivatives with respect to x, i.e., $\dot{z}=dz/dx$, $\ddot{z}=d^2z/dx^2$, etc. In order to eliminate the term containing the first derivative we require

$$\frac{\dot{h}}{h}-\frac{\ddot{z}}{\dot{z}}+\frac{\dot{z}}{z}=0. \tag{3.10}$$

The solution to this equation is given by

$$h=\dot{z}z^{-1}. \tag{3.11}$$

(Since h must be positive we require that $\dot{z}>0$.) Substituting Eq. (3.11) into Eq. (3.9), one gets

$$C=\frac{4z(1-z)^2}{\dot{z}^2}\left[\frac{\partial^2}{\partial x^2}+\frac{\dot{z}^2}{4z^2}\left(\frac{\partial^2}{\partial\alpha^2}-2\frac{1+z}{1-z}\frac{\partial^2}{\partial\alpha\partial\beta}+\frac{\partial^2}{\partial\beta^2}+1\right)+\frac{1}{2}\frac{\dddot{z}}{\dot{z}}-\frac{3}{4}\left(\frac{\ddot{z}}{\dot{z}}\right)^2\right]. \tag{3.12}$$

Thus, the principal series of SO(2,2) in SO(2)×SO(2) basis can be realized in the Hilbert space spanned by eigenfunctions of C, A_3, and B_3.

Let $\mathcal{H}^{(1)}_{mk}$ be a one-dimensional subspace spanned by $f^{(1)}_{mk}$ with fixed m and k. Then the Casimir operator restricted to $\mathcal{H}^{(1)}_{mk}$ becomes a differential operator in x alone; it is found that

$$C_{mk}=\frac{4z(1-z)^2}{\dot{z}^2}\left[\frac{\partial^2}{\partial x^2}+\dot{z}^2\frac{(1-z)+2mk(1+z)+(1-m^2-k^2)(1-z)}{4z^2(1-z)}+\frac{1}{2}\frac{\dddot{z}}{\dot{z}}-\frac{3}{4}\left(\frac{\ddot{z}}{\dot{z}}\right)^2\right], \tag{3.13}$$

where C_{mk} denote the restriction of C to $\mathcal{H}^{(1)}_{mk}$. Then it is not difficult to see that a class of Natanzon hypergeometric potentials[1]

$$V(x)=-\frac{d^2}{dx^2}+\frac{fz(z-1)+h_o(1-z)+h_1z+1}{R}$$
$$+\left(a+\frac{a+(c_1-c_o)(2z-1)}{z(z-1)}-\frac{5\Delta}{4R}\right)\frac{z^2(1-z)^2}{R^2}, \tag{3.14}$$

which are defined in terms of six parameters f, h_o, h_1, a, c_o, c_1 and a function $z(x)$ satisfying

$$\dot{z}^2=\frac{4z^2(1-z)^2}{R(z)}, \tag{3.15}$$

where $\Delta=c_1^2-4c_oc_1$, $R(z)=a(z-1)z+c_o(1-z)+c_1z$, are related to C_{mk} as

$$(C_{mk}+\rho^2+1)=-\frac{4z(1-z)^2}{\dot{z}^2}(H-E),\quad H=-\frac{d^2}{dx^2}+V(x) \tag{3.16}$$

provided

$$1-(m+k)^2=aE-f,$$

$$1-(m-k)^2=c_0E-h_0, \tag{3.17}$$

$$1+\rho^2=c_1E-h_1.$$

(For details see Refs. 5 and 27.)

As a consequence, one find exactly solvable Hamiltonians (3.14) which have a ''broken symmetry'' in the sense that $H\neq f(C)|_{\mathcal{H}^{(1)}_{mk}}$. However, the Hamiltonians (3.14) have another kind of algebraic structure. It follows from (3.16) that

$$(C+\rho^2+1)|_{\mathcal{H}^{1}_{mk}}=Q(x)(H-E) \tag{3.18}$$

with m, k, and ρ given by (3.17) and

$$Q(x)=-\frac{4z(1-z)^2}{\dot{z}^2}. \tag{3.19}$$

Thus, the wave function of the Natanzon hypergeometric potential is related to the basis function $f^{(1)}_{mk}(\xi)$, while the S-matrix is (up to a ρ-dependent phase factor)

$$S=\frac{\Gamma\left(\frac{1}{2}-\frac{i\rho}{2}+m\right)\Gamma\left(\frac{1}{2}-\frac{i\rho}{2}+k\right)}{\Gamma\left(\frac{1}{2}+\frac{i\rho}{2}+m\right)\Gamma\left(\frac{1}{2}+\frac{i\rho}{2}+k\right)} \tag{3.20}$$

(see Eq. (A17) of Ref. 23) where m, k, and ρ are given by (3.17). Moreover, from (A3), (A10), (3.11), and (3.7) follows that

$$f^{(1)}_{mk}(\xi)=\exp(im\alpha+ik\beta)\sqrt{\frac{z}{\dot{z}}}\int_0^{2\pi}\int_0^{2\pi}\left|\frac{\cos\frac{\theta+\varphi}{2}}{\sqrt{1-z}}-\frac{\sqrt{z}\cos\frac{\theta-\varphi}{2}}{\sqrt{1-z}}\right|^{-2-j} e^{im\varphi+ik\theta}d\varphi d\theta, \tag{3.21}$$

where $j=-1-i\rho$. Hence for the wave functions of the Natanzon potentials given in (3.14) we have

$$\Psi(x)\propto(\dot{z})^{-(1/2)}z^{(1+m-k)/2}(1-z)^{(2+j)/2}\,{}_2F_1\left(1+\frac{j}{2}-k,1+\frac{j}{2}+m;1+m-k;z\right), \tag{3.22}$$

where ${}_2F_1$ is the hypergeometric function.[28]

IV. CLASS OF POTENTIALS RELATED TO SO(2,2)⊃SO(2)⊗E(1) REDUCTION

Now, the reduction conditions are

$$A_3f^{(2)}_{m\lambda}=mf^{(2)}_{m\lambda}, \quad (B_2+B_3)f^{(2)}_{m\lambda}=\lambda f^{(2)}_{m\lambda}.$$

Hence we require the quasi-invariant measure $d\mu$ to be invariant under the transformations

$$\exp(a_3\varphi)=\begin{pmatrix} \cos\frac{\varphi}{2} & \sin\frac{\varphi}{2} & 0 & 0 \\ -\sin\frac{\varphi}{2} & \cos\frac{\varphi}{2} & 0 & 0 \\ 0 & 0 & \cos\frac{\varphi}{2} & -\sin\frac{\varphi}{2} \\ 0 & 0 & \sin\frac{\varphi}{2} & \cos\frac{\varphi}{2} \end{pmatrix} \in \mathrm{SO}(2) \tag{4.1}$$

and

$$\exp[(b_2+b_3)t]=\begin{pmatrix} 1 & \frac{t}{2} & 0 & \frac{t}{2} \\ -\frac{t}{2} & 1 & \frac{t}{2} & 0 \\ 0 & \frac{t}{2} & 1 & \frac{t}{2} \\ \frac{t}{2} & 0 & -\frac{t}{2} & 1 \end{pmatrix} \in E(1). \tag{4.2}$$

According to this, we put $d\mu=h(r)d\xi$, where now $r=(\xi_1+\xi_3)^2+(\xi_2-\xi_4)^2$. As a check, one can immediately verify that such defined r is indeed invariant under the transformations given by (4.1) and (4.2). Then

$$2A_3=-i\left(\xi_4\frac{\partial}{\partial\xi_3}-\xi_2\frac{\partial}{\partial\xi_1}+\xi_1\frac{\partial}{\partial\xi_2}\right) \tag{4.3}$$

and

$$2(B_2+B_3)=-i\left[(\xi_4-\xi_2)\frac{\partial}{\partial\xi_1}+(\xi_3+\xi_1)\frac{\partial}{\partial\xi_2}+(\xi_2-\xi_4)\frac{\partial}{\partial\xi_3}\right]. \tag{4.4}$$

Since A_3 and B_2+B_3 are sought to be diagonal we introduce in place of ξ_1, ξ_2, ξ_3 the new variables x,φ,t by

$$\begin{aligned} \xi_1&=\frac{1+z}{2\sqrt{z}}\cos\frac{\varphi}{2}-\frac{t}{2\sqrt{z}}\sin\frac{\varphi}{2}, \\ \xi_2&=\frac{1+z}{2\sqrt{z}}\sin\frac{\varphi}{2}+\frac{t}{2\sqrt{z}}\cos\frac{\varphi}{2}, \\ \xi_3&=\frac{1-z}{2\sqrt{z}}\cos\frac{\varphi}{2}+\frac{t}{2\sqrt{z}}\sin\frac{\varphi}{2}, \end{aligned} \tag{4.5}$$

with $0\leqslant x<\infty$, $0<\varphi<2\pi$, $-\infty<t<\infty$, where $z(x)$ is a differentiable function on R^+ with values in $[0,1]$. Then $A_3=-i(\partial/\partial\varphi)$, $B_2+B_3=-i(\partial/\partial t)$, while

$$C=\frac{4z^2}{\dot{z}^2}\left\{\frac{\partial^2}{\partial x^2}+\left(\frac{\dot{h}}{h}-\frac{\ddot{z}}{\dot{z}}\right)\frac{\partial}{\partial x}+\dot{z}^2\left(\frac{\partial^2}{\partial t^2}-\frac{2}{z}\frac{\partial^2}{\partial\varphi\partial t}\right)+\frac{\dot{h}}{2h}\left[\frac{\ddot{h}}{\dot{h}}-\frac{\dot{h}}{2h}-\frac{\ddot{z}}{\dot{z}}\right]\right\}. \tag{4.6}$$

We now require

$$\frac{\dot{h}}{h}-\frac{\ddot{z}}{\dot{z}}=0,$$

which yields

$$h=-\dot{z}. \tag{4.7}$$

(Since h must be positive we require that $\dot{z}<0$.) Putting Eq. (4.7) into Eq. (4.6), one gets

$$C=\frac{4z^2}{\dot{z}^2}\left[\frac{\partial^2}{\partial x^2}+\dot{z}^2\left(\frac{\partial^2}{\partial t^2}-\frac{2}{z}\frac{\partial^2}{\partial\varphi\partial t}\right)+\frac{1}{2}\frac{\dddot{z}}{\dot{z}}-\frac{3}{4}\left(\frac{\ddot{z}}{\dot{z}}\right)^2\right]. \tag{4.8}$$

Denote by $C_{m\lambda}$ a restriction of C on the one-dimensional subspace $\mathcal{H}^{(2)}_{m\lambda}$ spanned by $f^{(2)}_{m\lambda}$ with fixed m and λ,

$$C_{m\lambda}=\frac{4z^2}{\dot{z}^2}\left[\frac{\partial^2}{\partial x^2}-\dot{z}^2\left(\lambda^2-\frac{2m\lambda}{z}\right)+\frac{1}{2}\frac{\dddot{z}}{\dot{z}}-\frac{3}{4}\left(\frac{\ddot{z}}{\dot{z}}\right)^2\right]. \tag{4.9}$$

Before proceeding further, note from (4.9) that $C_{m\lambda}$ is the Schrödinger-type if

$$\frac{z^2}{\dot{z}^2}=1.$$

The solution to this equation is given by

$$z=\exp(-x),\quad 0\leqslant x<\infty.$$

If we compute $C_{m\lambda}$ for this z, it becomes

$$C_{m\lambda}=4\frac{d^2}{dx^2}-4\lambda^2\exp(-2x)+8m\lambda\exp(-x)-1.$$

Hence the Hamiltonian

$$H=-\frac{d^2}{dx^2}+\lambda^2\exp(-2x)-2m\lambda\exp(-x)$$

is related to the Casimir operator as

$$H=-\tfrac{1}{4}(C+1)\big|_{\mathcal{H}^{(2)}_{m\lambda}}.$$

(We are using units with $2M=\hbar=1$.) Thus, the Mors Hamiltonian[29] has the SO(2,2) potential group structure; the scattering states that have the same energy but belong to different potential strengths are related to the UIR of the principal series of SO(2,2). However for a class of Hamiltonians the relation (2.7) can be satisfied by a proper choice of m, λ, and ρ as a function of the energy. It is not difficult to see that for Hamiltonians

$$H=-\frac{d^2}{dx^2}+\frac{g_2z^2+g_1z+h_o+1}{R}+\left(\frac{\sigma_1}{z}-\sigma_2-\frac{5\Delta}{R}\right)\frac{z^2}{R^2}, \tag{4.10}$$

where $R(z)=\sigma_2 z^2+\sigma_1 z+c_o$, $\Delta=\sigma_1^2-4\sigma_2 c_o$ and $z(x)$ satisfies

$$\dot{z}^2=\frac{4z^2}{R(z)} \tag{4.11}$$

the following relation holds:

$$C_{m\lambda}+\rho^2+1=-\frac{4z^2}{\dot{z}^2}(H-E), \tag{4.12}$$

provided

$$-8m\lambda=g_1-\sigma_1 E, \quad 4\lambda^2=g_2-\sigma_2 E, \quad 1+\rho^2=c_o E-h_o. \tag{4.13}$$

The interaction potentials given in (4.10) are Natanzon confluent potentials[1] which depends on six parameters h_o, c_o, g_1, σ_1, g_2, and σ_2. [In (4.10) we closely following the notation of Ref. 1.]

Thus, Natanzon confluent potentials in (4.11) are associated with the reduction into $\mathfrak{so}(2)\oplus\mathfrak{e}(1)$ in the sense that

$$(C+\rho^2+1)|_{\mathcal{H}^{(2)}_{m\lambda}}=Q(x)(H-E), \tag{4.14}$$

where

$$Q(x)=-\frac{4z^2}{\dot{z}^2}. \tag{4.15}$$

Hence S-matrices for these potentials are (up to a ρ-dependent phase factor)

$$S=|\lambda|^{-i\rho}\frac{\Gamma\left(\frac{1}{2}-\frac{i\rho}{2}+m\right)}{\Gamma\left(\frac{1}{2}+\frac{i\rho}{2}+m\right)} \tag{4.16}$$

(see Eq. (A22) of Ref. 23). Moreover, it follows from (A3), (A16), (4.7), and (4.5) that

$$\Psi(x)\propto\sqrt{\dot{z}}\int_0^{2\pi}\int_{-\infty}^{\infty}\left|\sqrt{z}\cos\frac{\varphi}{2}-\frac{t}{\sqrt{z}}\sin\frac{\varphi}{2}\right|^{-2-j}e^{im\varphi+i\lambda t}d\varphi dt. \tag{4.17}$$

Hence, for the scattering solutions we have

$$\Psi(x)\propto\begin{cases}\dfrac{1}{\sqrt{\dot{z}}}W_{m,-(1+j)/2}(2z\lambda), & \text{if} \quad \lambda>0\\[2ex] \dfrac{1}{\sqrt{\dot{z}}}W_{-m,-(1+j)/2}(-2z\lambda), & \text{if} \quad \lambda<0,\end{cases} \tag{4.18}$$

where $W_{mn}(z)$ is the Whittaker function.[28]

It is also worth mentioning that the solution to the condition $Q=\text{const}$ is $\sigma_1=\sigma_2=0$. This gives rise to the Morse potential, which was already known to possess SO(2,2) as the potential group.

V. CLASS OF POTENTIALS RELATED TO SO(2,2)⊃SO(1,1)⊗SO(2) REDUCTION

The basis functions corresponding to the considered reduction are the eigenfunctions of C, A_1, and B_3, with

$$A_1 f^{(3)}_{m\nu\tau} = \nu f^{(3)}_{m\nu\tau}, \quad B_3 f^{(3)}_{m\nu\tau} = m f^{(3)}_{m\nu\tau}, \tag{5.1}$$

where $\tau = \pm 1$ is the multiplicity label. We now choose the quasi-invariant measure in (2.9) as $d\mu = h(r)d\xi$, with $r = \xi_1\xi_4 - \xi_2\xi_3$. Such a defined measure is invariant under the transformations given by

$$\exp(a_1 t) = \begin{pmatrix} \cosh\frac{t}{2} & 0 & \sinh\frac{t}{2} & 0 \\ 0 & \cosh\frac{t}{2} & 0 & \sinh\frac{t}{2} \\ \sinh\frac{t}{2} & 0 & \cosh\frac{t}{2} & 0 \\ 0 & \sinh\frac{t}{2} & 0 & \cosh\frac{t}{2} \end{pmatrix} \in \mathrm{SO}(1,1) \tag{5.2}$$

and

$$\exp(b_3 \varphi) = \begin{pmatrix} \cos\frac{\varphi}{2} & \sin\frac{\varphi}{2} & 0 & 0 \\ -\sin\frac{\varphi}{2} & \cos\frac{\varphi}{2} & 0 & 0 \\ 0 & 0 & \cos\frac{\varphi}{2} & \sin\frac{\varphi}{2} \\ 0 & 0 & -\sin\frac{\varphi}{2} & \cos\frac{\varphi}{2} \end{pmatrix} \in \mathrm{SO}(2). \tag{5.3}$$

Then

$$2A_1 = -i\left(\xi_3 \frac{\partial}{\partial \xi_1} + \xi_4 \frac{\partial}{\partial \xi_2} + \xi_1 \frac{\partial}{\partial \xi_3} \right), \tag{5.4}$$

and

$$2B_3 = -i\left(\xi_2 \frac{\partial}{\partial \xi_1} - \xi_1 \frac{\partial}{\partial \xi_2} + \xi_4 \frac{\partial}{\partial \xi_3} \right). \tag{5.5}$$

The parametrization that we see for hyperboloid (2.8) must be such as to make A_1, B_3, particularly simple

$$x_1=\frac{1}{\sqrt{1-z^2}}\cosh\frac{t}{2}\cos\frac{\varphi}{2}-\frac{z}{\sqrt{1-z^2}}\sinh\frac{t}{2}\sin\frac{\varphi}{2},$$

$$x_2=\frac{1}{\sqrt{1-z^2}}\sinh\frac{t}{2}\cos\frac{\varphi}{2}+\frac{z}{\sqrt{1-z^2}}\cosh\frac{t}{2}\sin\frac{\varphi}{2}, \tag{5.6}$$

$$x_3=\frac{1}{\sqrt{1-z^2}}\sinh\frac{t}{2}\cos\frac{\varphi}{2}-\frac{z}{\sqrt{1-z^2}}\cosh\frac{t}{2}\sin\frac{\varphi}{2}.$$

Then

$$A_1=-i\frac{\partial}{\partial t},\quad B_3=-i\frac{\partial}{\partial\varphi}, \tag{5.7}$$

while

$$C=\frac{(1-z^2)^2}{\dot z^2}\left\{\frac{\partial^2}{\partial x^2}+\left(\frac{\dot h}{h}-\frac{\ddot z}{\dot z}+\frac{2\dot z z}{1+z^2}\right)\frac{\partial}{\partial x}+\frac{4\dot z^2}{(1+z^2)^2}\left(\frac{\partial^2}{\partial t^2}-\frac{4z}{1-z^2}\frac{\partial^2}{\partial\varphi\partial t}-\frac{\partial^2}{\partial\varphi^2}\right)\right.$$
$$\left.+\frac{\dot h}{2h}\left[\frac{\ddot h}{\dot h}-\frac{\dot h}{2h}-\left(\frac{\ddot z}{\dot z}-\frac{2\dot z z}{1+z^2}\right)\right]\right\}. \tag{5.8}$$

Since we want the first derivative to vanish, we require

$$\frac{\dot h}{h}-\frac{\ddot z}{\dot z}+\frac{2\dot z z}{1+z^2}=0. \tag{5.9}$$

Hence the function h must be chosen to be

$$h=\frac{\dot z}{1+z^2}. \tag{5.10}$$

Substituting (5.10) into (5.8), one gets

$$C=\frac{(1-z^2)^2}{\dot z^2}\left\{\frac{\partial^2}{\partial x^2}+\frac{4\dot z^2}{(1+z^2)^2}\left(\frac{\partial^2}{\partial t^2}-\frac{4z}{1-z^2}\frac{\partial^2}{\partial\varphi\partial t}-\frac{\partial^2}{\partial\varphi^2}\right)-\frac{\dot z^2}{(1+z^2)^2}+\frac{1}{2}\frac{\dddot z}{\dot z}-\frac{3}{4}\left(\frac{\ddot z}{\dot z}\right)^2\right\}. \tag{5.11}$$

The restriction of C to a subspace $\mathcal{H}^{(3)}_{m\nu}$ spanned by $f^{(3)}_{m\nu\tau}, \tau=\pm1$, for given m and ν yields the differential operator $C_{m\nu}$,

$$C_{m\nu}=\frac{(1-z^2)^2}{\dot z^2}\left\{\frac{\partial^2}{\partial x^2}-\frac{\dot z^2}{(1+z^2)^2}\left(1+4\nu^2-4m^2-\frac{16zm\nu}{1-z^2}\right)+\frac{1}{2}\frac{\dddot z}{\dot z}-\frac{3}{4}\left(\frac{\ddot z}{\dot z}\right)^2\right\}. \tag{5.12}$$

Because of (2.7) we put

$$1+\nu^2-m^2=a_1E+b_1,$$

$$1+\rho^2/4=a_2E+b_2, \tag{5.13}$$

$$2m\nu=a_3E+b_3.$$

Then it is not difficult to see that the systems governed by Hamiltonians

$$H=-\frac{d^2}{dx^2}+\frac{(b_1-1)(1-v^2)-b_3v\sqrt{1-v^2}-b_2+5/4}{R}$$
$$+\frac{1}{2}\left(a_1-2a_2-\frac{a_2}{2(1-v^2)}-\frac{5\Delta}{8R}\right)\frac{(1-v^2)}{R^2}, \tag{5.14}$$

where $\Delta=a_3^2+4a_2(a_1-a_2)$, are related to SO(2,2) in the sense that

$$\left(C_{m\nu}+\rho^2+\frac{1}{4}\right)=-\frac{4(1-v^2)^2}{\dot{v}^2}[H-E] \tag{5.15}$$

provided

$$\dot{v}^2=\frac{(1-v^2)^2}{R}, \tag{5.16}$$

where $R=a_3v\sqrt{1-v^2}+a_1v^2+(a_2-a_1)$. To simplify notation we have put

$$v=\frac{2z}{(1+z^2)}. \tag{5.17}$$

Moreover, for the scattering solutions we have

$$\Psi_{\pm}(x)\propto\frac{(1-v^2)^{1/4}}{\sqrt{\dot{v}}}\mathfrak{Q}^{j/2+1}_{\pm i\nu,m}\left(\frac{\pm iv}{\sqrt{1-v^2}}\right), \tag{5.18}$$

where $\mathfrak{Q}^{j}_{m,n}(z)$ is the generalized Legendre function of the second kind as defined by Azimov.[30] The solution Ψ_+ describes waves incident from the left while Ψ_- describes waves that are incident from the right.

It should be noted that the potential functions of this class admit a double degeneracy of the wave function for every positive value of energy. The main reason for this is the fact that each UIR of SO(1,1) is twofold degenerate in principal series of UIR of SO(2,1). The scattering matrices can now be obtained as restriction of the intertwining operator onto $\mathcal{H}^{(3)}_{m\nu}$,

$$S=\begin{pmatrix}R & T\\ T & R\end{pmatrix}, \tag{5.19}$$

where

$$R=\frac{1}{\pi}\cosh\pi\nu\,\Gamma\left(\frac{1}{2}-\frac{i\rho}{2}+i\nu\right)\Gamma\left(\frac{1}{2}-\frac{i\rho}{2}-i\nu\right)\frac{\Gamma\left(\frac{1}{2}-\frac{i\rho}{2}+m\right)}{\Gamma\left(\frac{1}{2}+\frac{i\rho}{2}+m\right)},$$

$$T=\frac{-i}{\pi}\sinh\frac{\pi\rho}{2}\,\Gamma\left(\frac{1}{2}-\frac{i\rho}{2}+i\nu\right)\Gamma\left(\frac{1}{2}-\frac{i\rho}{2}-i\nu\right)\frac{\Gamma\left(\frac{1}{2}-\frac{i\rho}{2}+m\right)}{\Gamma\left(\frac{1}{2}+\frac{i\rho}{2}+m\right)}$$

(see Eq. (A27) of Ref. 23). According to this, the reflection and transmission coefficients are

$$|R|^2=\frac{\cosh^2\pi\nu}{\cosh^2\pi\nu+\sinh^2\pi\rho},\quad |T|^2=\frac{\sinh^2\pi\rho}{\cosh^2\pi\nu+\sinh^2\pi\rho}.$$

This class of solvable potentials includes as special cases important families of Ginocchio potentials.[2] Indeed, putting

$$a_1=\frac{1}{\gamma^4}-\frac{1}{\gamma^2},\ a_2=\frac{1}{\gamma^4},\ a_3=0,\ b_1=\delta(\delta+1)+\frac{3}{4},\ b_2=1,\ b_3=0$$

with $0<\gamma\leqslant 1$ and introducing Ginocchio's variable y

$$y=\frac{v}{\sqrt{v^2+\gamma^2(1-v^2)}} \tag{5.20}$$

we have

$$H=-\frac{d^2}{dx^2}+\gamma^2\delta(\delta+1)(1-y^2)+\frac{(1-y^2)(1-\gamma^2)}{4}[2-y^2(7-\gamma^2)+5(1-\gamma^2)y^4]. \tag{5.21}$$

Moreover, it follows from (5.16) and (5.20) that

$$\frac{dy}{dx}=(1-y^2)[1-(1-\gamma^2)y^2]. \tag{5.22}$$

We also mention that in the special case of $\gamma=1$ the Hamiltonian (5.21) reduces to the Pöschl–Teller Hamiltonian,[31]

$$H=-\frac{d^2}{dx^2}+\frac{\delta(\delta+1)}{\cosh^2 x}.$$

Observe that in this case $Q(x)=-4$. Moreover the solution to the condition $Q=\text{const}$ gives rise to the Scarf potential ($a_1=a_3=0$).[32]

VI. CONCLUSION

In this paper we have shown how the group theory can be used to obtain a class of one-dimensional Hamiltonians related to SO(2,2) in the sense of (2.7) and to solve the scattering problems. Using the quasiregular representation with any quasi-invariant measure, it was possible to treat a more general class of Natanzon potentials. We have seen how all the Natanzon potentials can quite easily be extracted from the Casimir operator. The relationship between the Hamiltonian and Casimir operators on the one hand and the scattering and intertwining operators on the other enabled us to write down an explicit expression for wave functions and scattering matrices for the systems under consideration. We have only considered $\mathrm{SO}(2,2)\supset\mathrm{SO}(2)\otimes\mathrm{SO}(2)$, $\mathrm{SO}(2,2)\supset\mathrm{SO}(2)\otimes E(1)$, and $\mathrm{SO}(2,2)\supset\mathrm{SO}(2)\otimes\mathrm{SO}(1,1)$ reductions but in a manner amenable to be immediately extended to other subgroup reductions.

Finally we note that the scattering problems related to the reductions $\mathrm{SO}(2,2)\supset\mathrm{SO}(2)\otimes\mathrm{SO}(1,1)$, $\mathrm{SO}(2,2)\supset E(1)\otimes\mathrm{SO}(1,1)$ and $\mathrm{SO}(2,2)\supset\mathrm{SO}(2,1)$ are somewhat more complicated than the one related to $\mathrm{SO}(2,2)\supset\mathrm{SO}(2)\otimes\mathrm{SO}(2)$, $\mathrm{SO}(2,2)\supset\mathrm{SO}(2)\otimes E(1)$ and $\mathrm{SO}(2,2)\supset E(1)\otimes E(1)$ reductions since the S-matrix in the former case is a unitary 2×2 matrix while in the latter it is a complex number of unit modulus. The reason for this is the fact that the subgroups SO(1,1) and SO(2,1) are degenerate in the principal series of SO(2,2).

APPENDIX: THE BASIS FUNCTIONS OF THE PRINCIPAL SERIES REPRESENTATIONS ASSOCIATED WITH THE HYPERBOLOID

In this appendix we will give the integral representation for the basis functions of the most degenerate principal series representations induced by (2.9) which are related to the wave functions of the systems under consideration. The procedure will go as follows. We shall start with the most degenerate principal series representations of SO(2,2) associated with the cone.[24] For such realization of the principal series the basis functions have particularly simple form. Then the interrelation between two alternative realizations of the principal series allows us to obtain the integral representation mentioned above.

Since the representations (2.8) with different measure are unitarily equivalent we can, without loss of generality, put $d\mu(\xi)=d\xi$, where $d\xi=d\xi_1 d\xi_2 d\xi_3/|\xi_4|$ is an invariant measure on Ξ. In this case the Radon–Nikodym derivative equals to one and the representation, call it $\check{T}$, has the simple form

$$\check{T}(g)\check{f}(\xi)=\check{f}(\xi g) \tag{A1}$$

with inner product

$$(\check{f},\check{f}')=\int \overline{\check{f}(\xi)}\check{f}'(\xi)d\xi. \tag{A2}$$

Such defined quasiregular representation of course is unitarily equivalent to (2.9). The unitary mapping W which realizes the equivalence is given by

$$W: f\to\check{f}=h^{1/2}f. \tag{A3}$$

The principal series of most degenerate representation of SO(2,2) characterized by the pair $\chi=(\rho,\varepsilon)$, where ε is equal to 0 or 1, while $0\leqslant\rho<\infty$ can be realized in the space of infinitely differentiable functions $F(\zeta)$ on the cone $B=\{\zeta:\zeta\in R^{2,2},\ \zeta_1^2+\zeta_2^2-\zeta_3^2-\zeta_4^2=0\}$, homogeneous of degree $j=-1-i\rho$ and with parity ε

$$F(a\zeta)=|a|^j \operatorname{sign}^{\varepsilon} a F(\zeta). \tag{A4}$$

A representation operator U^χ is defined by

$$U^\chi(g)F(\zeta)=F(\zeta g). \tag{A5}$$

It is worth mentioning that the homogeneous functions on the cone are uniquely determined by their values on any contour Γ intersecting each generator at one point. Hence, U^χ can be realized in spaces of functions on these contours.

The interrelation between $U^\chi,\chi=(\rho,0)$, and the principal series representation induced by (A1) are given by integral transform[24,25]

$$\check{f}(\xi)=\int_\Gamma |[\xi,n]|^{-2-j}F(n)dn\equiv(IF)(\xi), \tag{A6}$$

where $[\cdot,\cdot]$ is given by (2.1) and Γ is arbitrary contour on the cone B which intersects every generator once; and dn is a quasi-invariant measure on Γ. Moreover the following intertwining relation is held:

$$IU=\check{T}I. \tag{A7}$$

Thus, Eq. (A6) allows us to obtain the integral representation for the basis functions of the principal series representations induced by (A1).

(i) The $SO(2,2)\supset SO(2)\times SO(2)$ reduction. According to this we introduce the spherical coordinate systems on the cone

$$\zeta=\omega n,\quad n=\left(\cos\frac{\psi+\varphi}{2},\ \sin\frac{\psi+\varphi}{2},\ \cos\frac{\psi-\varphi}{2},\ \sin\frac{\psi-\varphi}{2}\right),\tag{A8}$$

with $0\leqslant\omega<\infty$, $0<\psi\leqslant 2\pi$, $0<\varphi\leqslant 2\pi$. It follows from (A4) that the functions $F(\zeta)$ is uniquely determined by its values on the direct product of two circles Γ_S,

$$\Gamma_S=\left\{n:n\in B,n=\left(\cos\frac{\psi+\varphi}{2},\ \sin\frac{\psi+\varphi}{2},\ \cos\frac{\psi-\varphi}{2},\ \sin\frac{\psi-\varphi}{2}\right)\right\}.$$

Then

$$U^{\chi}(g)F(n)=(\omega_g)^j F(n_g),\tag{A9}$$

where ω_g and n_g are determined from parametrization (A5) of ng, i.e., from $ng=\omega_g n_g$. The Casimir $\acute{C}$ operator of the representation (A9) is identically a multiple of the unit $\acute{C}\equiv-\rho^2-\frac{1}{4}$, while $\acute{A}_3=-i(\partial/\partial\varphi)$, $\acute{B}_3=-i(\partial/\partial\psi)$. Therefore, the basis functions of (A9) in $SO(2,2)\supset SO(2)\times SO(2)$ reduction are $F^{(1)}_{mk}(n)=\exp(im\varphi+ik\psi)$. Then, due to (A6), we come to the following integral representation for the basis functions of the principal series representations induced by (A1),

$$\check{f}^{(1)}_{mk}(\xi)=\int_0^{2\pi}\left|\xi_1\cos\frac{\psi+\varphi}{2}+\xi_2\sin\frac{\psi+\varphi}{2}-\xi_3\cos\frac{\psi-\varphi}{2}-\xi_4\sin\frac{\psi-\varphi}{2}\right|^{-1-j}$$
$$\times\exp(im\varphi+ik\psi)d\varphi d\psi,\tag{A10}$$

where the upper index 1 refers to the $SO(2,2)\supset SO(2)\times SO(2)$ reduction. It is not difficult to see that the basis functions $\check{f}^{(1)}_{mk}$ are indeed the eigenfunctions of the set of commuting operators $\check{C}$, $\check{A}_3$, and $\check{B}_3$,

$$\check{C}\check{f}^{(1)}_{mk}=j(j+2)\check{f}^{(1)}_{mk},\quad \check{A}_3\check{f}^{(1)}_{mk}=m\check{f}^{(1)}_{mk},\quad \check{B}_3\check{f}^{(1)}_{mk}=k\check{f}^{(1)}_{mk},\tag{A11}$$

where

$$\check{C}=-\frac{\partial^2}{\partial\xi_1^2}-\frac{\partial^2}{\partial\xi_2^2}+\frac{\partial^2}{\partial\xi_3^2}+I(I+2),\quad I=\xi_1\frac{\partial}{\partial\xi_1}+\xi_2\frac{\partial}{\partial\xi_2}+\xi_3\frac{\partial}{\partial\xi_3},\tag{A12}$$

and

$$2\check{A}_3=-i\left(\xi_3\frac{\partial}{\partial\xi_1}+\xi_4\frac{\partial}{\partial\xi_2}+\xi_1\frac{\partial}{\partial\xi_3}\right),\quad 2\check{B}_3=-i\left(\xi_2\frac{\partial}{\partial\xi_1}-\xi_1\frac{\partial}{\partial\xi_2}+\xi_4\frac{\partial}{\partial\xi_3}\right).\tag{A13}$$

(ii) The reduction $SO(2,2)\supset SO(2)\times E(1)$. According to this, we introduce new coordinates on cone as follows:

$$\zeta=\omega n,n=\left(\cos\frac{\varphi}{2}-t\sin\frac{\varphi}{2},\ \sin\frac{\varphi}{2}+t\cos\frac{\varphi}{2},\ \cos\frac{\varphi}{2}+t\sin\frac{\varphi}{2},\ -\sin\frac{\varphi}{2}+t\cos\frac{\varphi}{2}\right),\tag{A14}$$

where $0\leqslant\omega<\infty$, $0<\varphi\leqslant 2\pi$, $-\infty<t<\infty$. Then the infinitesimal operators $\acute{A}_3$ and $\acute{B}_2+\acute{B}_3$ have the forms

$$\acute{A}_3=-i\frac{\partial}{\partial\varphi},\quad \acute{B}_2+\acute{B}_3=-i\frac{\partial}{\partial t}. \tag{A15}$$

By arguments very similar to those used to obtain (A10) we can show that

$$\check{f}^{(2)}_{m\lambda}(\xi)=\int_{-\infty}^{\infty}\int_0^{2\pi}\left|\xi_1\left(\cos\frac{\varphi}{2}-t\sin\frac{\varphi}{2}\right)+\xi_2\left(\sin\frac{\varphi}{2}+t\cos\frac{\varphi}{2}\right)-\left(\xi_3\cos\frac{\varphi}{2}+t\sin\frac{\varphi}{2}\right)\right.$$
$$\left.-\xi_4\left(-\sin\frac{\varphi}{2}+t\cos\frac{\varphi}{2}\right)\right|^{-1-j}e^{im\varphi}e^{i\lambda t}d\varphi dt, \tag{A16}$$

where the upper index 2 refers to the $\mathrm{SO}(2,2)\supset\mathrm{SO}(2)\times E(1)$ reduction. We note that

$$\check{C}\check{f}^{(2)}_{m\lambda}=j(j+2)\check{f}^{(2)}_{m\lambda},\quad \check{A}_3\check{f}^{(2)}_{m\lambda}=m\check{f}^{(2)}_{m\lambda},\quad (\check{B}_2+\check{B}_3)\check{f}^{(2)}_{m\lambda}=\lambda\check{f}^{(2)}_{m\lambda}, \tag{A17}$$

where

$$2\check{A}_3=-i\left(\xi_4\frac{\partial}{\partial\xi_3}-\xi_2\frac{\partial}{\partial\xi_1}+\xi_1\frac{\partial}{\partial\xi_2}\right),$$

$$2(\check{B}_2+\check{B}_3)=-i\left[(\xi_4-\xi_2)\frac{\partial}{\partial\xi_1}+(\xi_3+\xi_1)\frac{\partial}{\partial\xi_2}+(\xi_2-\xi_4)\frac{\partial}{\partial\xi_3}\right]$$

and $\check{C}$ is given by (A12).

(iii) The $\mathrm{SO}(2,2)\supset\mathrm{SO}(2)\times\mathrm{SO}(1,1)$ reduction. This case is somewhat more complicated than the previous one. We find that the parametrization $\zeta=\omega n$, $\omega>0$ covers only with two choices of n,

$$n^{\tau}=\left(\cosh\frac{\beta}{2}\cos\frac{\varphi}{2}-\tau\sinh\frac{\beta}{2}\sin\frac{\varphi}{2},\ \tau\sinh\frac{\beta}{2}\cos\frac{\varphi}{2}+\cosh\frac{\beta}{2}\sin\frac{\varphi}{2},\sinh\frac{\beta}{2}\cos\frac{\varphi}{2}\right.$$
$$\left.-\tau\cosh\frac{\beta}{2}\sin\frac{\varphi}{2},\ \tau\cosh\frac{\beta}{2}\cos\frac{\varphi}{2}+\sinh\frac{\beta}{2}\sin\frac{\varphi}{2}\right),$$

$$\tau=\pm1,\ -\infty<\beta<\infty,0<\varphi\leqslant2\pi, \tag{A18}$$

while the expressions for $\acute{A}_1$ and $\acute{B}_3$ are given in both regions by $\acute{A}_1=-i(\partial/\partial\beta)$ and $\acute{B}_3=-i(\partial/\partial\varphi)$. Hence, we have the following integral representation for the basis functions corresponding to $\mathrm{SO}(2,2)\supset\mathrm{SO}(2)\times\mathrm{SO}(1,1)$ reduction:

$$\check{f}^{(3)}_{m\nu\tau}=\int_{-\infty}^{\infty}\int_0^{2\pi}|[\xi,n^{\tau}]|^{-2-j}\exp(im\varphi)\exp(i\nu\beta)d\varphi d\beta, \tag{A19}$$

where $\tau=\pm1$ is the multiplicity label and n^{τ} is given by (A18). Indeed, the functions $\check{f}^{(3)}_{m\nu\tau}$ are eigenfunctions of the set of commuting operators $\check{C}$, $\check{A}_1$, and $\check{B}_3$,

$$\check{C}f^{(3)}_{m\nu\tau}=j(j+2)f^{(3)}_{m\nu\tau},\quad \check{A}_1f^{(3)}_{m\nu\tau}=\nu f^{(3)}_{m\nu\tau},\quad \check{B}_3f^{(3)}_{m\nu\tau}=mf^{(3)}_{m\nu\tau}, \tag{A20}$$

where

$$2\check{A}_1 = -i\left(\xi_3\frac{\partial}{\partial\xi_1}+\xi_4\frac{\partial}{\partial\xi_2}+\xi_1\frac{\partial}{\partial\xi_3}\right),$$

$$2\check{B}_3 = -i\left(\xi_2\frac{\partial}{\partial\xi_1}-\xi_1\frac{\partial}{\partial\xi_2}+\xi_4\frac{\partial}{\partial\xi_3}\right),$$

and $\check{C}$ is given by (A12).

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 45, NUMBER 4 APRIL 2004

Spectral properties of a short-range impurity in a quantum dot

J. Brüning,[a] V. Geyler,[b] and I. Lobanov[c]
Institut für Mathematik, Humboldt-Universität zu Berlin, Unter den Linden 6, 10099 Berlin, Germany

(Received 21 October 2003; accepted 15 December 2003)

The spectral properties of the quantum mechanical system consisting of a quantum dot with a short-range attractive impurity inside the dot are studied in the zero-range limit. The Green function of the system is obtained in an explicit form. In the case of a spherically symmetric quantum dot, the dependence of the spectrum on the impurity position and strength of the impurity potential is analyzed in detail. The recovering of the confinement potential of the dot from the spectroscopy data is proven; the consequences of the hidden symmetry breaking by the impurity are considered. The effect of the positional disorder is analyzed. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1647693]

I. INTRODUCTION

Quantum dots (i.e., nanostructures with charge carriers confinement in all spatial directions) have an atom-like energy spectrum and, therefore, make possible to fabricate quantum devices with energy level spacing much greater than the temperature smearing kT at work temperature T (see, e.g., Ref. 1). Moreover, dimension and shape of a quantum dot affect considerably the most important characteristics of the corresponding devices: Relaxation and recombination time, Auger recombination coefficient etc, thus a possibility arises to control such characteristics in manufacturing the devices.[2–4] Another way to control the properties of a quantum dot is instilling an impurity into the dot. Therefore, the investigation of spectral properties of a quantum dot with impurities as well as the dependence of the spectrum on the geometric parameters of the dot and physical characteristics of the impurity is an important problem of nano- and mesoscopic physics (see, e.g., in Refs. 5–7, and references therein). The case of a hydrogen-like impurity is one of the most extensively studied up to now; however, the spectral problem in this case has no exact solution. On the other hand, short-range impurities can be investigated in the framework of the point potential theory (also called the zero-range potential theory). An important peculiarity of the point potential method is that the spectral problem for a point perturbed Hamiltonian is explicitly soluble as soon as the Green function for the unperturbed operator is known in an explicit form.[8,9]

For modeling the geometric confinement of a quantum dot, quadratic (in other words, parabolic) potentials are successfully used[10] (see also examples of applications in Refs. 5–7, 11–15). The reason is that the self-consistent solution to the corresponding system of the Poisson and Schrödinger equations leads to the confinement potential having the form of a truncated parabolic potential.[16] Moreover, the Green function of the corresponding Hamiltonian $\hat{H}^0$,

$$\hat{H}^0 = -\frac{\hbar^2}{2\mu}\Delta + \frac{\mu\Omega^2}{2}r^2, \tag{1}$$

can be explicitly calculated[17–19] (here Ω is the frequency of the oscillator, μ denotes over the

[c]Electronic mail: lobanov@mathematik.hu-berlin.de

paper the mass of the considered charged particle). This makes possible to perform an exhaustive spectral analysis of the perturbation of $\hat{H}^0$ by a point potential of arbitrary position $\mathbf{q}$ and strength α [we denote this perturbation by $\hat{H}_\alpha(\mathbf{q})$] and to analyze the behavior of the eigenvalues of $\hat{H}_\alpha(\mathbf{q})$ as functions of $\mathbf{q}$ and α. This analysis is the main goal of the paper. Note that a quite particular case of the point perturbation of $\hat{H}^0$ at $\mathbf{q}=0$ (without obtaining any explicit form for the Green function) has been considered in Ref. 20. Point potential for modeling an impurity in a spherically symmetric quantum dot has been studied in the series of papers using the Green function representation by means of the Laplace transform of the propagator kernel, but this approach allows to analyze (with numerical methods) the lowest impurity level only.[6,13–15]

It should be noted that point perturbations of the one-dimensional harmonic oscillators have been studied in detail earlier. This study was started in Ref. 21, where the spectral properties of the point perturbed harmonic oscillator have been considered in the context of the one-dimensional models for the toponium physics and the Bose–Einstein condensation.[22] A strict mathematical justification of results from Ref. 21 was done in Refs. 23 and 24; see also in Ref. 25. Undoubtedly, our approach using the three-dimensional harmonic oscillator is more adequate for the analyzing the spectral properties of three-dimensional systems, in particular, the toponium. It should be noted also that the one-dimensional harmonic oscillator perturbed by a point potential with varying position and strength has been investigated in Refs. 26 and 27. A series of phenomena of low-dimensional condensed matter physics can be analyzed by means of the Hamiltonian of the perturbed oscillator: Impurity in a one-dimensional quantum well, one-dimensional channel in a two-dimensional heterostructure subjected to a perpendicular uniform magnetic field etc., see the bibliography in the cited papers for details. However, the analysis given in Refs. 26, and 27 is based on the properties of one-dimensional second-order differential operators and is not extended to the three-dimensional case.

The paper is organized as follows. Preliminary results are collected in Sec. II. In Sec. III we consider point perturbations of the operator

$$\hat{H}^0 = -\frac{\hbar^2}{2\mu}\Delta + V, \tag{2}$$

with an infinitely growing potential V. It turns out that the operator $\hat{H}_\alpha(\mathbf{q})$ can be defined and investigated for the more generic case when $\hat{H}^0$ is defined by Eq. (2). In Sec. IV some important properties of $\hat{H}_\alpha(\mathbf{q})$ are established. In particular, a complete description of the spectrum and eigenfunctions of $\hat{H}_\alpha(\mathbf{q})$ is given in Theorem 1. As a consequence of this theorem we get the falling of the considered particle on the attractive center as the potential strength α tends to $-\infty$; for a very particular case of the one-dimensional harmonic oscillator perturbed at the potential minimum this phenomenon was observed in Ref. 21. In Sec. V we define at fixed α a family of continuous functions such that the values of these functions at the point $\mathbf{q}$ form the complete family of the eigenvalues of $\hat{H}_\alpha(\mathbf{q})$. Some elementary properties of these functions are established in Theorem 2. The main results of the paper are contained in Sec. VI, where the point perturbations of the Hamiltonian of the harmonic oscillator are studied; the case of the isotropic harmonic oscillator (1) is considered in detail. These results are based on an explicit form of the Green function for the operator (1). The detailed analysis of the dependence of the point levels on the position $\mathbf{q}$ and on the strength α is given in Theorem 3. In particular, if $\mathbf{q}\neq 0$, then the point levels never coincide with the eigenvalues of the unperturbed operator $\hat{H}^0$. Therefore, we have here no accidental degeneracy of the levels, which is a peculiarity of the one-dimensional model for the toponium.[21,26] Hence, this degeneracy is an artifact of the one-dimensional model. Another interesting result is the asymptotic expression for the bound state of $\hat{H}_\alpha(\mathbf{q})$ [Eqs. (33), and (34)]. These equations show that at least for the isotropic harmonic oscillator its potential (i.e., the frequency Ω) can be recovered from the dependence of the ground state of the point perturbation on the support of the perturbation. Moreover, we argue that the form of the parabolic potential V may be recovered from the behavior of the excited energy for the ground state. Our conjecture is that this

property is true for a more general form of the potential V. In this connection it is of interest to note that the study of the excited energy is one of the main problems of the quantum dot physics.[6] The methods of Sec. VI allow us to analyze rigorously the phenomenon of so-called ''positional disorder'' in quantum dots (including nonisotropic ones). The relation of the degeneracy properties of the eigenvalues of $\hat{H}_\alpha(\mathbf{q})$ at $\mathbf{q}=0$ to the symmetry properties of the unperturbed operator $\hat{H}^0$ in the phase space is briefly discussed in the conclusion of Sec. VI. In particular, the appearance of states with nonzero dipole momentum is noted.

II. PRELIMINARIES

Here we present for the convenience of readers some basic properties of point perturbations of Schrödinger operators in $L^2(\mathbb{R}^3)$ (see, e.g., Refs. 8, 28–31 for details). We will consider only Schrödinger operators $\hat{H}^0$ of the form (2), where the potential V is subordinated to the conditions

(P1) $V\in L^p_{\mathrm{loc}}(\mathbb{R}^3)$ *for some* $p>3$;
(P2) $V_-=\min(V,0)\in L^2(\mathbb{R}^3)+L^\infty(\mathbb{R}^3)$.

Conditions (P1), (P2) are weaker than commonly used in applications conditions $V\in L^\infty_{\mathrm{loc}}(\mathbb{R}^3)$ and $V\geqslant c$ with $c\in\mathbb{R}$ but making use of (P1), (P2) requires no change in proving of main results below. It is well known that under these conditions $\hat{H}^0$ is semibounded from below and essentially self-adjoint on $C_0^\infty(\mathbb{R}^3)$ (see in Ref. 32 Theorem X.28). Further we put, as a rule, $\hbar=1$, $\mu=1/2$ and denote the obtained operator $-\Delta+V$ by H^0. For the domain $\mathcal{D}(H^0)$ of H^0 we have $C_0^\infty(\mathbb{R}^3)\subset\mathcal{D}(H^0)\subset C(\mathbb{R}^3)$. This inclusion implies that the Green function $G^0(\mathbf{x},\mathbf{y};\zeta)$ for H^0 (the integral kernel of the resolvent $R(\zeta)=(H^0-\zeta)^{-1}$) is a Carleman operator, this means that

$$\int_{\mathbb{R}^3}|G^0(\mathbf{x},\mathbf{y};\zeta)|^2\,d\mathbf{y}<+\infty \quad \text{for a.e. } \mathbf{x}\in\mathbb{R}^3. \tag{3}$$

Moreover, according to Theorem B.7.2 from Ref. 31, for every fixed ζ, $\zeta\in\mathbb{C}\backslash\mathrm{spec}\,(H^0)$, the function G^0 obeys the following properties:

(G1) *For every* $\zeta\in\mathrm{spec}(\mathrm{H}^0)$ *the function* $G^0(\mathbf{x},\mathbf{y};\zeta)$ *is continuous in the domain* $\{(\mathbf{x},\mathbf{y})\in\mathbb{R}^3\times\mathbb{R}^3:\mathbf{x}\neq\mathbf{y}\}$;
(G2) $|G^0(\mathbf{x},\mathbf{y};\zeta)|\leqslant c_2(\zeta)|\mathbf{x}-\mathbf{y}|^{-1}$;
(G3) *if* $|\mathbf{x}-\mathbf{y}|\geqslant d>0$, *then* $|G^0(\mathbf{x},\mathbf{y};\zeta)|\leqslant c_3(d,\delta,\zeta)\exp(-\delta|\mathbf{x}-\mathbf{y}|)$ *for some* $\delta>0$. *Moreover, if* $\mathrm{Re}\,\zeta<\Sigma\equiv\mathrm{infspec}(H^0)$, *then arbitrary* δ *with* $\delta^2/2<\Sigma-\mathrm{Re}\,\zeta$ *is suitable for this estimate.*

From (G1) we get, in particular, that (3) is valid for *every* $\mathbf{x}\in\mathbb{R}^3$.

The crucial role in the point potential theory is played by the regularized Green function

$$G^0_{\mathrm{reg}}(\mathbf{x},\mathbf{y};\zeta)=G^0(\mathbf{x},\mathbf{y};\zeta)-\frac{1}{4\pi}\frac{1}{|\mathbf{x}-\mathbf{y}|}. \tag{4}$$

In the particular cases, e.g., if $V\in C^\infty(\mathbb{R}^3)$, it is known that at fixed ζ this function has a continuous extension on the whole space $\mathbb{R}^3\times\mathbb{R}^3$ (see, e.g., Ref. 33 or Theorem III.5.1 in Ref. 34). We need this property in the general situation and prove it under conditions (P1), (P2).

It is sufficient to prove that $G^0_{\mathrm{reg}}(\mathbf{x},\mathbf{y};\zeta)$ is continuous with respect to $(\mathbf{x},\mathbf{y})$ for some $\zeta=E_0<0$. Indeed, then for every $\zeta\in\mathbb{C}\backslash\mathrm{spec}\,(H^0)$

$$G^0(\mathbf{x},\mathbf{y};\zeta)=\int_{E_0}^{\zeta}\frac{\partial}{\partial\lambda}G^0(\mathbf{x},\mathbf{y};\lambda)\,d\lambda+G^0(\mathbf{x},\mathbf{y};E_0),$$

where the path of integration lies in the resolvent set $\mathbb{C}\backslash\mathrm{spec}\,(H^0)$. The function $(\partial G^0/\partial\lambda)(\mathbf{x},\mathbf{y};\lambda)$ is jointly continuous with respect to $(\mathbf{x},\mathbf{y})$ since it coincides with the integral kernel of $(H^0-\lambda)^{-2}$ and this kernel is continuous according to Theorem B.7.1 from Ref. 31.

It is easy to see that V can be represented in the form $V=V_1+W$, where $V_1\in C^\infty(\mathbb{R}^3)$ and obeys the property (P2) and $W\in L^p(\mathbb{R}^3)\cap L^1(\mathbb{R}^3)$. Denote $H^1=-\Delta+V_1$, $\Sigma_1=\mathrm{infspec}\,(H^1)$ and

by G^1 the Green function of H^1. Fix E_0, $E_0<\min(\Sigma,\Sigma^1)$, and introduce the function $F(\mathbf{x},\mathbf{y},\mathbf{z})=G^0(\mathbf{x},\mathbf{z};E_0)W(\mathbf{z})G^1(\mathbf{z},\mathbf{y};E_0)$. Using properties (G2), (G3), and the estimate

$$\int_{|\mathbf{y}-\mathbf{a}|\leqslant r}\frac{d\mathbf{y}}{|\mathbf{x}-\mathbf{y}|^{\nu}}\leqslant\tilde{c}_{\nu}r^{3-\nu}, \tag{5}$$

where $0<\nu<3$, $r>0$, $\mathbf{a},\mathbf{x}\in\mathbb{R}^3$, it is easy to prove that $F(\mathbf{x},\mathbf{y},\cdot)\in L^1(\mathbb{R}^3)$ for all $\mathbf{x},\mathbf{y}\in\mathbb{R}^3$. In virtue of the Lippmann–Schwinger relation

$$G^0(\mathbf{x},\mathbf{y};E_0)=G^1(\mathbf{x},\mathbf{y};E_0)+\int_{\mathbb{R}^3}G^0(\mathbf{x},\mathbf{z};E_0)W(\mathbf{z})G^1(\mathbf{z},\mathbf{y};E_0)\,d\mathbf{z},$$

and the continuity of the regularized Green function for H^1, it remains to prove that the function

$$I(\mathbf{x},\mathbf{y})=\int_{\mathbb{R}^3}F(\mathbf{x},\mathbf{y},\mathbf{z})\,d\mathbf{z}$$

is continuous on $\mathbb{R}^3\times\mathbb{R}^3$. Moreover, (G1) shows that it remains to prove the continuity of I at points of the form $(\mathbf{x}_0,\mathbf{x}_0)$. To do this fix $\varepsilon>0$ and find $\eta>0$ such that the relations $|\mathbf{x}-\mathbf{x}_0|<\eta$, $|\mathbf{y}-\mathbf{x}_0|<\eta$ imply $|I(\mathbf{x},\mathbf{y})-I(\mathbf{x}_0,\mathbf{x}_0)|\leqslant\varepsilon$. Introduce the sets $B_1(\eta)=\{\mathbf{z}:|\mathbf{z}-\mathbf{x}_0|<\eta\}$, $B_2(\eta)=\mathbb{R}^3\backslash B_1(\eta)$, and for a measurable set $B\subset\mathbb{R}^3$ denote $I_B(\mathbf{x},\mathbf{y})=\int_B F(\mathbf{x},\mathbf{y},\mathbf{z})\,d\mathbf{z}$. Then

$$|I(\mathbf{x},\mathbf{y})-I(\mathbf{x}_0,\mathbf{y}_0)|\leqslant|I_{B_1(\eta)}(\mathbf{x},\mathbf{y})|+|I_{B_1(\eta)}(\mathbf{x}_0,\mathbf{y}_0)|+|I_{B_2(\eta)}(\mathbf{x},\mathbf{y})-I_{B_2(\eta)}(\mathbf{x}_0,\mathbf{y}_0)|\,.$$

If $\mathbf{x},\mathbf{y},\mathbf{z}\in B_1(\eta)$, then by (G2)

$$|F(\mathbf{x},\mathbf{y},\mathbf{z})|\leqslant f(\mathbf{z})\,|\mathbf{x}-\mathbf{y}|^{-1}|\mathbf{z}-\mathbf{y}|^{-1},$$

where $f\in L^p$, therefore relation (5) and the Cauchy–Schwartz inequality lead to the estimate $|I_{B_1(\eta)}(\mathbf{x},\mathbf{y})|+|I_{B_1(\eta)}(\mathbf{x}_0,\mathbf{y}_0)|\leqslant\text{const}\,\eta$. On the other hand, if $\mathbf{x},\mathbf{y}\in B_1(\eta/2)$, $\mathbf{z}\in B_2(\eta)$, then we have from (G3): $|F(\mathbf{x},\mathbf{y},\mathbf{z})|\leqslant g(\mathbf{z})\exp(-\delta|\mathbf{z}|)$, where $\delta>0$ and $g\in L^p$. Thus by (G1) and the Lebesgue majorization theorem, $I_{B_2(\eta)}(\mathbf{x},\mathbf{y})$ is a continuous function on $B_1(\eta/2)\times B_1(\eta/2)$, and the proof of continuity of G^0_{reg} is completed.

Let $\mathbf{q}\in\mathbb{R}^3$, then the restriction of H^0 to the domain $\{f\in\mathcal{D}(H^0):f(\mathbf{q})=0\}$ is a closed symmetric operator S with the deficiency indices (1,1). By definition, the *point perturbation of* H^0, *supported on* $\mathbf{q}$ is a self-adjoint extension of S different from H^0. All the point perturbations of H^0 supported on a given $\mathbf{q}\in\mathbb{R}^3$ form a one-parameter family $H_\alpha(\mathbf{q})$, $\alpha\in\mathbb{R}$, of self-adjoin operators such that the Green function G_α of $H_\alpha(\mathbf{q})$ is given by the formula

$$G_\alpha(\mathbf{x},\mathbf{y};\zeta)=G^0(\mathbf{x},\mathbf{y};\zeta)-[Q(\zeta;\mathbf{q})-\alpha]^{-1}G^0(\mathbf{x},\mathbf{q};\zeta)G^0(\mathbf{q},\mathbf{y};\zeta)\,, \tag{6}$$

which is a consequence of the Krein resolvent formula. Here $Q(\zeta;\mathbf{q})=G^0_{\mathrm{reg}}(\mathbf{q},\mathbf{q};\zeta)$ is the so-called Krein $\mathcal{Q}$-function. The operator H^0 corresponds formally to $\alpha=\infty$; moreover, H^0 is the Friedrichs extension of S.

The extension parameter α has an important physical meaning, namely, H_α can be treated as the Hamiltonian H^0 perturbed by a zero-range potential, in this case α is the strength of this potential.[8,35,36] In place of the strength α, it is more convenient to use for applications so-called "scattering length" ℓ_s, $\ell_s=1/(4\pi\alpha)$ (see in Refs. 8, 35, and 36 again). More precisely,

$$\ell_s=\frac{\mu}{2\pi\hbar^2\alpha},$$

and we see that ℓ_s has actually the dimension of the length.

Note that according to the general results of the Krein self-adjoint extension theory, the function $\zeta \mapsto Q(\zeta;\mathbf{q})$ is analytic in the domain $\mathbb{C}\backslash\mathrm{spec}(H^0)$ for each $\mathbf{q}\in\mathbb{R}^3$ and $\partial Q(E;\mathbf{q})/\partial E>0$ if $E\in\mathbb{R}\backslash\mathrm{spec}(H^0)$.[37] Remark that $Q(\zeta;\mathbf{q})$ can be continuously extended to some points of $\mathrm{spec}(H^0)$. Further we assume that $Q(\zeta;\mathbf{q})$ is continuously extended to all regular points.

It is easy to prove that for every $\mathbf{q}\in\mathbb{R}^3$ the mapping $\zeta\mapsto G^0(\cdot,\mathbf{q};\zeta)$ is an analytic function from the domain $\mathbb{C}\backslash\mathrm{spec}\,(H^0)$ to the Hilbert space $L^2(\mathbb{R}^3)$. Denote $G^0(\cdot,\mathbf{q};\zeta)$ by $g_{\mathbf{q}}(\zeta)$, then we can rewrite (6) in an operator form

$$R_\alpha(\zeta)=R^0(\zeta)-[Q(\zeta;\mathbf{q})-\alpha]^{-1}|g_{\mathbf{q}}(\zeta)\rangle\langle g_{\mathbf{q}}(\zeta)|\,, \tag{7}$$

where $R_\alpha(\zeta)=(H_\alpha-\zeta)^{-1}$ and $R^0(\zeta)=(H^0-\zeta)^{-1}$.

Note, that $g_{\mathbf{q}}(\zeta)$ is a nonzero function for every $\mathbf{q}\in\mathbb{R}^3$ and $\zeta\in\mathbb{C}\backslash\mathrm{spec}\,(H^0)$. Indeed, otherwise we have $\varphi(\mathbf{q})=0$ for every $\varphi\in\mathcal{D}(H^0)$ that contradicts the inclusion $C_0^\infty(\mathbb{R}^3)\subset\mathcal{D}(H^0)$.

In conclusion we mention a possibility to approximate the zero-range perturbation by potentials with decreasing support. For $V=0$ the corresponding procedure is described in Ref. 8 (Theorem 1.2.5). We sketch here the proof for H^0 with potential V having properties (P1), (P2).

Let $W\in L^2_{\mathrm{comp}}(\mathbb{R}^3)$, in particular, W is a Rollnik function (see in Ref. 32, Sec. X.2). Denote $v=|W|^{1/2}$, $u=v\,\mathrm{sign}(V)$, and let $\lambda(\varepsilon)$ be a real-analytic function in a neighborhood of zero such that $\lambda(0)=1$. For $\varepsilon>0$ consider the operator $H^\varepsilon\equiv H^\varepsilon(\mathbf{q})=H^0+\varepsilon^{-2}\lambda(\varepsilon)W(\varepsilon^{-1}(\mathbf{x}-\mathbf{q}))$. Then the resolvent $R^\varepsilon(\zeta)=(H^\varepsilon-\zeta)^{-1}$ $(\varepsilon>0)$ has the form

$$R^\varepsilon(\zeta)=R^0(\zeta)-\varepsilon\lambda(\varepsilon)A^\varepsilon[1+B^\varepsilon]^{-1}C^\varepsilon\,,$$

where A^ε, B^ε, C^ε are integral operators with the kernels $A^\varepsilon(\mathbf{x},\mathbf{y};\zeta)=G^0(\mathbf{x},\varepsilon\mathbf{y}+\mathbf{q};\zeta)v(\mathbf{y})$, $C^\varepsilon(\mathbf{x},\mathbf{y};\zeta)=G^0(\varepsilon\mathbf{x}+\mathbf{q},\mathbf{y};\zeta)u(\mathbf{x})$, $B^\varepsilon(\mathbf{x},\mathbf{y};\zeta)=\varepsilon\lambda(\varepsilon)G^0(\varepsilon\mathbf{x}+\mathbf{q},\varepsilon\mathbf{y}+\mathbf{q};\zeta)u(\mathbf{x})v(\mathbf{y})$. Define A^0 and C^0 putting $\varepsilon=0$ in the formulas above, and define B^0 by the integral kernel $B^0(\mathbf{x},\mathbf{y})=(4\pi|\mathbf{y}-\mathbf{x}|)^{-1}u(\mathbf{x})v(\mathbf{y})$. All the operators A^ε, B^ε and C^ε $(\varepsilon\geqslant 0)$ belong to the Hilbert–Schmidt class and $A^\varepsilon\to A^0$, $B^\varepsilon\to B^0$, $C^\varepsilon\to C^0$ with respect to the Hilbert–Schmidt norm as $\varepsilon\to+0$. Moreover, using (4) we can prove that with respect to this norm

$$B^\varepsilon=B^0+\varepsilon(\lambda'(0)B^0+Q(\zeta;\mathbf{q})|u\rangle\langle v|)+o(\varepsilon)\,.$$

Hence, the arguments using for the proof of Theorem 1.2.5 from Ref. 8 give the following result.

Theorem A:

(1) Let $\langle v|\varphi\rangle=0$ for all L^2-solutions φ of the equation $B^0\varphi=-\varphi$ (in particular, let -1 be not an eigenvalue of B_0). Then $H^\varepsilon(\mathbf{q})\to H^0$ in the norm-resolvent sense as $\varepsilon\to+0$;

(2) let -1 be a simple eigenvalue of B^0 and φ be a corresponding eigenfunction normalized by the condition $\langle\tilde{\varphi}|\varphi\rangle=-1$, where $\tilde{\varphi}=\varphi\,\mathrm{sign}(\mathrm{V})$. If $\langle v|\varphi\rangle\neq 0$, then $\lim_{\varepsilon\to+0}H^\varepsilon(\mathbf{q})=H_\alpha(\mathbf{q})$ in the norm-resolvent sense, where $\alpha=-\lambda'(0)|\langle v|\varphi\rangle|^{-2}$;

(3) let -1 be a multiple eigenvalue of B^0 with eigenfunctions $\varphi_1,\ldots,\varphi_n$ normalized by the conditions $\langle\tilde{\varphi}_j|\varphi_k\rangle=-\delta_{jk}$ $(\tilde{\varphi}_j=\varphi_j\,\mathrm{sign}(\mathrm{V}))$. If $\langle v|\varphi_j\rangle\neq 0$ for some j and $\lambda'(0)\neq 0$, then $\lim_{\varepsilon\to+0}H^\varepsilon(\mathbf{q})=H_\alpha(\mathbf{q})$ in the norm-resolvent sense, where

$$\alpha=-\lambda'(0)\left[\sum_{j=1}^{n}|\langle v|\varphi_j\rangle|^2\right]^{-1}.$$

■

III. POINT PERTURBATION IN THE CASE OF UNBOUNDED POTENTIAL *V*

Starting with this section we suppose additionally that

(P3) $\lim_{|\mathbf{r}|\to\infty}V(\mathbf{r})=+\infty$.

In this case $R^0(\zeta)$ is a compact operator for all $\zeta\in\mathbb{C}\backslash\mathrm{spec}(H^0)$ (the Strichartz theorem; see, e.g.,

in Ref. 38, Theorem XIII.69). Therefore, $\mathrm{spec}(H^0)$ consists of an unbounded sequence $\lambda_0<\lambda_1<\cdots<\lambda_n<\cdots$ of eigenvalues with finite multiplicity k_n. Consequently, $Q(\zeta;\mathbf{q})$ is a meromorphic function of ζ. We are going to find the poles of this function.

Denote by L_n the eigenspace associated with λ_n, and choose in L_n an orthonormal basis $F_{n,k}(\mathbf{r})$, $k=1,\ldots,k_n$. For every $\mathbf{q}\in\mathbb{R}^3$ we denote

$$\sigma(\mathbf{q})=\{\lambda_n\in\mathrm{spec}(H^0):\exists f\in L_n \quad \text{s.t.} \quad f(\mathbf{q})\neq 0\}$$

Lemma 1: The set of all poles of the function $\zeta\mapsto Q(\zeta;\mathbf{q})$ *coincides with* $\sigma(\mathbf{q})$.

Proof: Since $(\partial G^0/\partial\zeta)(\mathbf{x},\mathbf{y};\zeta)$ is the integral kernel for the operator $(H^0-\zeta)^{-2}$, we have according to the Mercer theorem

$$\frac{\partial}{\partial\zeta}G^0(\mathbf{x},\mathbf{y};\zeta)=\sum_{n=0}^{\infty}\sum_{k=1}^{k_n}(\lambda_n-\zeta)^{-2}F_{n,k}(\mathbf{x})\overline{F_{n,k}(\mathbf{y})},$$

where the series converges locally uniformly on $\mathbb{R}^3\times\mathbb{R}^3\times(\mathbb{C}\backslash\mathrm{spec}(H^0))$. Therefore,

$$\frac{\partial}{\partial\zeta}Q(\zeta;\mathbf{q})=\sum_{n=0}^{\infty}\sum_{k=1}^{k_n}(\lambda_n-\zeta)^{-2}|F_{n,k}(\mathbf{q})|^2, \tag{8}$$

and the series converges locally uniformly on $(\mathbb{C}\backslash\mathrm{spec}(H^0))\times\mathbb{R}^3$. The lemma follows from (8) immediately. ■

Lemma 2: For each $\mathbf{q}\in\mathbb{R}^3$ *the set* $\sigma(\mathbf{q})$ *is infinite. If* V *is bounded from below, then* $\lambda_0\in\sigma(\mathbf{q})$.

Proof: Consider the space of continuous functions $C(\mathbb{R}^3)$ with the topology of compact convergence. Due to the closed graph theorem and the relation $\mathcal{D}(H^0)\subset C(\mathbb{R}^3)$, the operator $R^0(-1):L^2(\mathbb{R}^3)\to C(\mathbb{R}^3)$ is continuous. Therefore, for every $f\in\mathcal{D}(H^0)$ the Fourier expansion for f with respect to the basis $(F_{n,k})_{n,k}$ converges locally uniformly. Assume that the set $\sigma(\mathbf{q})$ is finite; let $N=\max\{n:\lambda_n\in\sigma(\mathbf{q})\}$ and P be the orthogonal projection of $L^2(\mathbb{R}^3)$ on the subspace $M=L_0+\ldots+L_N$. Then for every $\varphi\in\mathcal{D}(H^0)$ the conditions $\varphi(\mathbf{q})=0$ and $(P\varphi)(\mathbf{q})=0$ are equivalent. Since M is finite dimensional, there is $h\in M$ such that for every $\varphi\in M$ the conditions $\varphi(\mathbf{q})=0$ and $\langle h\,|\,\varphi\rangle=0$ are also equivalent. Using the inclusion $C_0^\infty(\mathbb{R}^3)\subset\mathcal{D}(H^0)$ we see that there is a function $h\in L^2(\mathbb{R}^3)$ such that for every $\varphi\in C_0^\infty(\mathbb{R}^3)$ the conditions $\varphi(\mathbf{q})=0$ and $\langle h\,|\,\varphi\rangle=0$ are equivalent. Obviously, this is impossible, hence $\sigma(\mathbf{q})$ is infinite. If V is bounded from below, then by Theorem XIII.48 from Ref. 38 the eigenfunctions of H^0 corresponding to the ground state λ_0 have no zeros therefore $\lambda_0\in\sigma(\mathbf{q})$. ■

Another property of the function $\zeta\mapsto Q(\zeta;\mathbf{q})$ we need further follows.

Lemma 3: The function $Q(\zeta;\mathbf{q})$ *tends to* $-\infty$ *as* $\zeta\to-\infty$, $\zeta\in\mathbb{R}$.

Proof: Since H^0 is the Friedrichs extension of S, the statement follows from Proposition 4 of Ref. 39. ■

IV. SPECTRAL PROPERTIES OF H_α AT FIXED POSITION OF THE POINT PERTURBATION
