and $\pi_{\alpha,\beta}(K_0)$ acts by scalar multiplications in every isotypic component, we see that $V_{\mathbf{k}}^-$ is a simple $U_q\mathfrak{sl}_n \otimes U_q\mathfrak{sl}_n$-module. Hence the $U_q\mathfrak{sl}_n \otimes U_q\mathfrak{sl}_n$-module $V_{\mathbf{k}}^-$ decomposes into a tensor product of $U_q\mathfrak{sl}_n$-modules: $V_{\mathbf{k}}^- \simeq V_{\mathbf{k}}^{(1)} \otimes V_{\mathbf{k}}^{(2)}$ with $V_{\mathbf{k}}^{(1)} = L(k_1 - k_2, \ldots, k_{n-1} - k_n)$, $V_{\mathbf{k}}^{(2)} = L^*(k_1 - k_2, \ldots, k_{n-1} - k_n)$, where we denote by $L(k_1 - k_2, \ldots, k_{n-1} - k_n)$ and $L^*(k_1 - k_2, \ldots, k_{n-1} - k_n)$ the simple finite dimensional $U_q\mathfrak{sl}_n$-modules with highest weights $(k_1 - k_2, \ldots, k_{n-1} - k_n)$ and $(k_{n-1} - k_n, \ldots, k_1 - k_2)$, respectively.

We can equip the vector spaces $V_{\mathbf{k}}^{(1)}$ and $V_{\mathbf{k}}^{(2)}$ with the structure of $U_q\mathfrak{sl}_n \otimes U_q\mathfrak{sl}_n$-modules as follows:

$$(\xi \otimes \eta)(v) = \xi \cdot (\varepsilon(\eta)v), \quad (\xi \otimes \eta)(v^*) = \eta \cdot (\varepsilon(\xi)v^*),$$

for all $\xi, \eta \in U_q\mathfrak{sl}_n$, $v \in V_{\mathbf{k}}^{(1)}$, $v^* \in V_{\mathbf{k}}^{(2)}$, where ε denotes the counit of $U_q\mathfrak{sl}_n$. Note that as $U_q\mathfrak{sl}_n \otimes U_q\mathfrak{sl}_n$-modules

$$\mathfrak{p}_q^+ \simeq \mathbb{C}^n \otimes (\mathbb{C}^n)^*, \quad \mathfrak{p}_q^- \simeq (\mathbb{C}^n)^* \otimes \mathbb{C}^n,$$

where $\mathbb{C}^n$ is the vector representation of $U_q\mathfrak{sl}_n$. Consider the natural maps

$$m_{\mathbf{k}}^+ : \mathfrak{p}_q^+ \otimes V_{\mathbf{k}}^- \to V, \quad m_{\mathbf{k}}^- : \mathfrak{p}_q^- \otimes V_{\mathbf{k}}^- \to V.$$

Since there exist the $U_q\mathfrak{sl}_n \otimes U_q\mathfrak{sl}_n$-homomorphisms

$$\mathfrak{p}_q^+ \otimes V_{\mathbf{k}}^- \simeq \mathbb{C}^n \otimes (\mathbb{C}^n)^* \otimes V_{\mathbf{k}}^{(1)} \otimes V_{\mathbf{k}}^{(2)} \simeq \mathbb{C}^n \otimes V_{\mathbf{k}}^{(1)} \otimes (\mathbb{C}^n)^* \otimes V_{\mathbf{k}}^{(2)},$$

$$\mathfrak{p}_q^- \otimes V_{\mathbf{k}}^- \simeq (\mathbb{C}^n)^* \otimes \mathbb{C}^n \otimes V_{\mathbf{k}}^{(1)} \otimes V_{\mathbf{k}}^{(2)} \simeq (\mathbb{C}^n)^* \otimes V_{\mathbf{k}}^{(1)} \otimes \mathbb{C}^n \otimes V_{\mathbf{k}}^{(2)},$$

we have the well-defined morphisms

$$\mathcal{M}_{\mathbf{k}}^+ : \mathbb{C}^n \otimes V_{\mathbf{k}}^{(1)} \otimes (\mathbb{C}^n)^* \otimes V_{\mathbf{k}}^{(2)} \to V,$$

$$\mathcal{M}_{\mathbf{k}}^- : (\mathbb{C}^n)^* \otimes V_{\mathbf{k}}^{(1)} \otimes \mathbb{C}^n \otimes V_{\mathbf{k}}^{(2)} \to V.$$

For instance, if we consider a $U_q\mathfrak{sl}_n$-highest vector $v_1 \in \mathbb{C}^n \otimes V^{(1)}_{\mathbf{k}}$ and a $U_q\mathfrak{sl}_n$-highest vector $v_2 \in (\mathbb{C}^n)^* \otimes V^{(2)}_{\mathbf{k}}$, then $\mathcal{M}^+_{\mathbf{k}}(v_1 \otimes v_2)$ is a $U_q\mathfrak{sl}_n \otimes U_q\mathfrak{sl}_n$-highest vector (or, equivalently, a $U_q\mathfrak{k}$-highest vector) in V.

In the sequel we are going to get explicit formulas for $U_q\mathfrak{sl}_n$-highest vectors $\zeta_j \in \mathbb{C}^n \otimes L(k_1-k_2,\dots,k_{n-1}-k_n)$, $j=1,\dots,n$ with weights $(k_1,\dots,k_j+1,\dots,k_n)$, respectively.

In the classical case auxiliary elements $F_{m,j}$ of the universal enveloping algebra $U\mathfrak{sl}_n$ are used in such formulas.

Lemma 1 (Ref. 8, lemma 3.4): Let $1 \leqslant k \leqslant n-1$ *and* $1 \leqslant m < j \leqslant n$.

(1) *If* $1 \leqslant k < m$ *or* $j < k \leqslant n$, *then* $E_k F_{m,j} = F_{m,j} E_k$;
(2) *If* $k=m$, *then* $E_m F_{m,j} \equiv F_{m+1,j}(H_m + \cdots + H_{j-1} + j - m - 1) \pmod{U\mathfrak{sl}_n \cdot E_m}$;
(3) *If* $m < k \leqslant j$, *then* $E_k F_{m,j} \equiv 0 \pmod{U\mathfrak{sl}_n \cdot E_k}$. □

Explicit formulas for the elements $F_{m,j}$ are used for the proof of lemma:

$$F_{m,j} = F_{m+1,j}F_m + \sum_{t=m+2}^{j} (-1)^{t+m+1} F_{t,j} \mathrm{ad}_{F_{t-1}} \cdots \mathrm{ad}_{F_{m+1}F_m} H(j; m+1, t-1),$$

where $H(j;p,s) = \Pi_{a=p}^{s}(H_a + \cdots + H_{j-1} + j - a)$.

We find quantum analogs of the previous lemma and the elements in $U_q\mathfrak{sl}_n$.

For $1 \leqslant m \leqslant j \leqslant n$ define $F_{m,j} \in U_q\mathfrak{sl}_n$ inductively as follows:

$$F_{j,j} = 1, \quad F_{j-1,j} = F_{j-1}K_{j-1},$$

$$F_{m,j} = F_{m+1,j}F_m K_m + \sum_{s=m+2}^{j} (-1)^{s+m+1} F_{s,j} \, \mathrm{ad}_{F_{s-1}} \cdots \mathrm{ad}_{F_{m+1}}(F_m K_m) K(j, m+1, s-1),$$

where $K(j,p,r) = \Pi_{a=p}^{r} q^{j-a} K_a \cdots K_{j-1}[H_a + \cdots + H_{j-1} + j - a]_q$.

Here and everywhere below we use the standard notation $[x]_q = (q^x - q^{-x})/(q - q^{-1})$.

Lemma 2: The following relations are satisfied:

$$(1)\ K_i F_{m,j} = F_{m,j} K_i \quad \textit{for } 1 \leqslant i < m-1 \textit{ or } j < i \leqslant n, \tag{9}$$

$$(2)\ K_j F_{m,j} = q F_{m,j} K_j, \quad K_{m-1} F_{m,j} = q F_{m,j} K_{m-1}, \tag{10}$$

$$(3)\ q K_{j-1} F_{m,j} = F_{m,j} K_{j-1}, \quad q K_m F_{m,j} = F_{m,j} K_m, \tag{11}$$

$$(4)\ E_i F_{m,j} = F_{m,j} E_i \quad \textit{for } 1 \leqslant i < m-1 \textit{ or } j < i \leqslant n, \tag{12}$$

$$(5)\ E_{m-1} F_{m,j} = q F_{m,j} E_{m-1}, \quad E_j F_{m,j} = q F_{m,j} E_j, \tag{13}$$

$$(6)\ E_i F_{m,j} \equiv 0 (\mathrm{mod}\ U_q\mathfrak{sl}_n \cdot E_i) \quad \textit{for } m < i < j, \tag{14}$$

$$(7)\ E_m F_{m,j} \equiv F_{m+1,j} q^{j-m} K_m \cdots K_{j-1} [H_m + \cdots + H_{j-1} + j - m - 1]_q \ (\mathrm{mod}\ U_q\mathfrak{sl}_n \cdot E_m). \tag{15}$$

This lemma is proved in the Appendix. □

Let $(\varepsilon_1,\dots,\varepsilon_n)$ be the standard basis for $\mathbb{C}^n$. Suppose $u \in L(k_1-k_2,\dots,k_{n-1}-k_n)$ *is a* $U_q\mathfrak{sl}_n$-highest vector with weight $(k_1-k_2,\dots,k_{n-1}-k_n)$.

Proposition 5: Define vectors $\{\zeta_j\}_{j=1}^n$ *as follows:*

$$\zeta_j = \sum_{m=1}^{j} (-q^2)^{m-1} \varepsilon_m \otimes F_{m,j} K_-(j,1,m-1)u \in \mathbb{C}^n \otimes L(k_1-k_2, \ldots, k_{n-1}-k_n),$$

where $K_-(j,p,r)=\Pi_{a=p}^{r} q^{j-a-1} K_a \cdots K_{j-1}[H_a+\cdots+H_{j-1}+j-a-1]_q$. *Then* ζ_j *is a* $U_q\mathfrak{sl}_n$*-highest vector* (i.e., $E_i\zeta_j=0$ for all $i=1,\ldots,n-1$) *with weight* $(k_1-k_2,\ldots,k_{j-1}-k_j-1,k_j+1-k_{j+1},\ldots,k_{n-1}-k_n)$ *for* $j=1,\ldots,n$.

Proof: Using Lemma 2, it is easy to prove that ζ_j are weight vectors. We claim that $E_i\zeta_j=0$ for all $1\leqslant i\leqslant n$, $1\leqslant j\leqslant n$. Indeed, by Lemma 2,

$$\begin{aligned} E_i\zeta_j &= E_i\left(\sum_{m=1}^{j} (-q^2)^{m-1}\varepsilon_m \otimes F_{m,j}K_-(j,1,m-1)u\right) \\ &= \sum_{m=1}^{j} (-q^2)^{m-1} E_i(\varepsilon_m \otimes F_{m,j}K_-(j,1,m-1)u) \\ &= (-q^2)^i \varepsilon_i \otimes F_{i+1,j}K_-(j,1,i)u + (-q^2)^{i-1}E_i(\varepsilon_i \otimes F_{i,j}K_-(j,1,i-1)u) \\ &= (-q^2)^{i-1}(-q^2\varepsilon_i \otimes F_{i+1,j}K_-(j,1,i)u + q\varepsilon_i \otimes F_{i+1,j}q^{j-i}K_i\cdots K_{j-1}[H_i+\cdots+H_{j-1}+j-i \\ &\quad -1]_q K_-(j,1,i-1)u) = 0. \end{aligned}$$

□

Similarly, we are going to get explicit formulas for $U_q\mathfrak{sl}_n$-highest vectors $\xi_j \in (\mathbb{C}^n)^* \otimes L^*(k_1-k_2,\ldots,k_{n-1}-k_n)$. For $1\leqslant r\leqslant t\leqslant n$ introduce the elements $S_{r,t}\in U_q\mathfrak{sl}_n$ as follows (classic analogs of these elements were investigated by Lee in Ref. 8):

$$S_{t,t}=1, \quad S_{t-1,t}=F_tK_t,$$

$$S_{r,t}=S_{r,t-1}F_tK_t+\sum_{s=r+1}^{t-1} S_{r,s-1}\,\mathrm{ad}_{F_s}\cdots\mathrm{ad}_{F_{t-1}}(F_tK_t)L(t,s,t-1),$$

where $L(j,p,r)=\Pi_{a=p}^{r} q^{a-j}K_{j+1}\cdots K_a[H_{j+1}\cdots+H_a+a-j]_q$.

Lemma 3: The following relations are satisfied:

(1) $K_iS_{r,t}=S_{r,t}K_i$ *for* $1\leqslant i<r$ *or* $t+1<i\leqslant n$,
(2) $K_rS_{r,t}=qK_rS_{r,t}$, $K_{t+1}S_{r,t}=qK_{t+1}S_{r,t}$,
(3) $K_{r+1}S_{r,t}=q^{-1}K_{r+1}S_{r,t}$, $K_tS_{r,t}=q^{-1}K_tS_{r,t}$,
(4) $E_iS_{r,t}=S_{r,t}E_i$ *for* $1\leqslant i<r$ *or* $t+1<i\leqslant n$,
(5) $E_rS_{r,t}=qS_{r,t}E_r$, $E_{t+1}S_{r,t}=qS_{r,t}E_{t+1}$,
(6) $E_iS_{r,t}\equiv 0 \pmod{U_q\mathfrak{sl}_n\cdot E_i}$ for $r<i<t$,
(7) $E_tS_{r,t}\equiv -S_{r,t-1}q^{t-r}K_{r+1}\cdots K_t[H_{r+1}+\cdots+H_t+t-r-1]_q \pmod{U_q\mathfrak{sl}_n\cdot E_t}$.

The proof of this lemma is completely analogous to the proof of Lemma 2.

Let $(\varepsilon_1^*,\ldots,\varepsilon_n^*)$ be the basis for $(\mathbb{C}^n)^*$ dual to the basis $(\varepsilon_1,\ldots,\varepsilon_n)$ for $\mathbb{C}^n$. Suppose that $u^*\in L^*(k_1-k_2,\ldots,k_{n-1}-k_n)$ is a $U_q\mathfrak{sl}_n$-highest vector with weight $(k_{n-1}-k_n,\ldots,k_1-k_2)$. The proof of the next statement is similar to the proof of Proposition 5.

Proposition 6: Define vectors $\{\xi_j\}_{j=1}^n$ *as follows:*

$$\xi_j=\sum_{m=j}^{n}\varepsilon_m^*\otimes S_{j,m}L_-(j,m+1,n)u^* \in (\mathbb{C}^n)^*\otimes L^*(k_1-k_2,\ldots,k_{n-1}-k_n),$$

where $L_-(j,p,r)=\Pi_{a=p}^{r} q^{a-j-1}K_{j+1}\cdots K_a[H_{j+1}+\cdots+H_a+a-j-1]_q$. *Then* ξ_j *is a* $U_q\mathfrak{sl}_n$*-highest vector with weight* $(k_{n-1}-k_n,\ldots,k_{n-j+1}+1-k_{n-j+2},k_{n-j}-k_{n-j+1}-1,\ldots,k_1-k_2)$ *for* $j=1,\ldots,n$. □

It follows from Propositions 5 and 6 that $\mathcal{M}^{+-}_{\mathbf{k}}: \mathbb{C}^n\otimes V^{(1)}_{-\mathbf{k}}\otimes(\mathbb{C}^n)^*\otimes V^{(2)}_{-\mathbf{k}}\to\oplus_{j=1}^n V_{-\mathbf{k}+\mathbf{e}_j}$. For all $j,k=1,\ldots,n$ the vectors $\mathcal{M}^{+-}_{\mathbf{k}}(\zeta_j\otimes\xi_k)$ are $U_q\mathfrak{sl}_n\otimes U_q\mathfrak{sl}_n$-highest vectors in V. By the action of

$\pi_{\alpha,\beta}(K_0)$ [see (8)], the vector $\mathcal{M}^+_{\overline{\mathbf{k}}}(\zeta_j \otimes \xi_k)$ is a $U_q\mathfrak{k}$-highest vector in $V_{\overline{\mathbf{k}+\mathbf{e}_j}}$ if and only if $k=n-j+1$. Since every isotypic component occurs with multiplicity one, $\mathcal{M}^+_{\overline{\mathbf{k}}}(\zeta_j \otimes \xi_{n-j+1}) = c_j \cdot v^h_{\overline{\mathbf{k}+\mathbf{e}_1}} = c_j \cdot (\mathbf{z}^{\wedge 1})^{k_1-k_2+1} \cdots (\mathbf{z}^{\wedge n-1})^{k_{n-1}-k_n} (\mathbf{z}^{\wedge n})^{k_n}$ for some $c_j \in \mathbb{C}$. (Here and below we suppose that if $\overline{\mathbf{m}}=(m_1,\ldots,m_n) \notin \hat{K}$, then $V_{\overline{\mathbf{m}}}=0$ and $v^h_{\overline{\mathbf{m}}}=0$.)

The proof of the next statement, reduced to computation of c_j, is given in the Appendix.

Proposition 7: For every $j=1,\ldots,n, \overline{\mathbf{k}} \in \hat{K}$,

$$\mathcal{M}^+_{\overline{\mathbf{k}}}(\zeta_j \otimes \xi_{n-j+1}) = c_j(\beta,k_j) v^h_{\overline{\mathbf{k}+\mathbf{e}_j}},$$

where $c_j(\beta,k_j)=q^{-\beta-n/2}[\beta-k_j+j-1]_q \omega_j(\overline{\mathbf{k}},q)$ *and* $\omega_j(\overline{\mathbf{k}},q) \neq 0$ *for all* $\overline{\mathbf{k}} \in \hat{K}$.

We deduce sufficient conditions for reducibility of $\pi_{\alpha,\beta}$ from Proposition 7.

Let α, β be fixed. For any $j=1,\ldots,n$ and $\overline{\mathbf{k}} \in \hat{K}$ if $c_j(\beta,k_j) \neq 0$, then there exist $v \in V_{\overline{\mathbf{k}}}$, $\xi \in \mathfrak{p}^+_q$ such that $\pi_{\alpha,\beta}(\xi)\cdot v \in V_{\overline{\mathbf{k}+\mathbf{e}_j}}$. That means $\pi_{\alpha,\beta}(U_q\mathfrak{sl}_{2n})\cdot V_{\overline{\mathbf{k}}} \supset V_{\overline{\mathbf{k}+\mathbf{e}_j}}$.

Let us consider in details other cases, i.e., let $c_j(\beta,k_j)=0$ for some k_j. For fixed β, by Proposition 7 and (6), the equation $c_j(\beta,k_j)=0$ is equivalent to $\beta-k_j+j-1=0$.

Corollary 1: For all $j=1,\ldots,n$, $\overline{\mathbf{k}} \in \hat{K}$, *the subspace* $V^j_{\leqslant k} \overset{\text{def}}{=} \oplus_{\{\overline{\mathbf{k}'} \in \hat{K} | k \geqslant k'_j\}} V_{\overline{\mathbf{k}'}}$ *is a* $U_q\mathfrak{sl}_{2n}$*-submodule in* V *iff* $\beta-k+j-1=0$.

Proof: Let $j=1$, the other cases are similar. The necessity easily follows from the above. Prove the sufficiency. If $\beta-k_1=0$, then $\mathcal{M}^+_{\overline{\mathbf{k}}}(\mathfrak{p}^+_q \otimes V_{\overline{\mathbf{k}}}) \subset \oplus^n_{j=2} V_{\overline{\mathbf{k}+\mathbf{e}_j}}$. Introduce the natural filtration on $U_q\mathfrak{p}^+$ (here $U_q\mathfrak{p}^+$ is the algebra generated by $\mathfrak{p}^+_q$) in the following way: $U_q\mathfrak{p}^+ = \cup_{n\geqslant 0} (U_q\mathfrak{p}^+)^{(n)}$. Then $\pi_{\alpha,\beta}((U_q\mathfrak{p}^+)^{(1)})(V_{\overline{\mathbf{k}}}) \subset V_{\overline{\mathbf{k}}} \oplus (\oplus^n_{j=2} V_{\overline{\mathbf{k}+\mathbf{e}_j}})$. In the same way, $\pi_{\alpha,\beta}((U_q\mathfrak{p}^+)^{(2)})(V_{\overline{\mathbf{k}}}) \subset \pi_{\alpha,\beta}((U_q\mathfrak{p}^+)^{(1)}) \times (V_{\overline{\mathbf{k}}} \oplus (\oplus^n_{j=2} V_{\overline{\mathbf{k}+\mathbf{e}_j}})) \subset V_{\overline{\mathbf{k}}} \oplus (\oplus^n_{j=2} V_{\overline{\mathbf{k}+\mathbf{e}_j}}) \oplus (\oplus_{n\geqslant j_1 \geqslant j_2 \geqslant 2} V_{\overline{\mathbf{k}+\mathbf{e}_{j_1}+\mathbf{e}_{j_2}}})$. Then $\pi_{\alpha,\beta}(U_q\mathfrak{p}^+)(V_{\overline{\mathbf{k}}}) \subset \oplus^\infty_{m=0} \times (\oplus_{n\geqslant j_1 \geqslant \cdots \geqslant j_m \geqslant 2} V_{\overline{\mathbf{k}+\mathbf{e}_{j_1}+\cdots+\mathbf{e}_{j_m}}})$, and $\pi_{\alpha,\beta}(U_q\mathfrak{sl}_{2n})(V_{\overline{\mathbf{k}}}) \subset \pi_{\alpha,\beta}(U_q\mathfrak{p}^-)\pi_{\alpha,\beta}(U_q\mathfrak{k}) \times (\pi_{\alpha,\beta}(U_q\mathfrak{p}^+)V_{\overline{\mathbf{k}}}) \subset \pi_{\alpha,\beta}(U_q\mathfrak{p}^-)\pi_{\alpha,\beta}(U_q\mathfrak{k})(\oplus^\infty_{m=0}(\oplus_{n\geqslant j_1 \geqslant \cdots \geqslant j_m \geqslant 2} V_{\overline{\mathbf{k}+\mathbf{e}_{j_1}+\cdots+\mathbf{e}_{j_m}}})) \subset \pi_{\alpha,\beta}(U_q\mathfrak{p}^-)(\oplus_{m\geqslant 0} \times (\oplus_{n\geqslant j_1 \geqslant \cdots \geqslant j_m \geqslant 2} V_{\overline{\mathbf{k}+\mathbf{e}_{j_1}+\cdots+\mathbf{e}_{j_m}}})) \subset V^1_{\leqslant k}$. Obviously the subspace $V^1_{\leqslant k}$ is a $U_q\mathfrak{sl}_{2n}$-submodule in V. □

By the same arguments as in Propositions 5, 6, and 7, one has the following.

Proposition 8: Define vectors $\{\xi'_j\}^n_{j=1}$ *as follows:*

$$\xi'_j = \sum_{m=j}^{n} \varepsilon^*_m \otimes S_{j,m} L_-(j,m+1,n) u \in (\mathbb{C}^n)^* \otimes L(k_1-k_2,\ldots,k_{n-1}-k_n),$$

where $L_-(j,p,r)=\Pi^r_{a=p} q^{a-j-1} K_{j+1} \cdots K_a [H_{j+1}+\cdots+H_a+a-j-1]_q$. *Then* ξ'_j *is a* $U_q\mathfrak{sl}_n$*-highest vector with weight* $(k_1-k_2,\ldots,k_{j-1}-k_j+1,k_j-1-k_{j+1},\ldots,k_{n-1}-k_n)$ *for* $j=1,\ldots,n$. □

Proposition 9: Define vectors $\{\zeta'_j\}^n_{j=1}$ *as follows:*

$$\zeta'_j = \sum_{m=1}^{j} (-q^2)^{m-1} \varepsilon_m \otimes F_{m,j} K_-(j,1,m-1) u^* \in \mathbb{C}^n \otimes L^*(k_1-k_2,\ldots,k_{n-1}-k_n),$$

where $K_-(j,p,r)=\Pi^r_{a=p} q^{j-a-1} K_a \cdots K_{j-1} [H_a+\cdots+H_{j-1}+j-a-1]_q$. *Then* ζ'_j *is a* $U_q\mathfrak{sl}_n$*-highest vector with weight* $(k_{n-1}-k_n,\ldots,k_{n-j+1}-k_{n-j}-1,k_{n-j}+1-k_{n-j-1},\ldots,k_1-k_2)$ *for* $j=1,\ldots,n$. □

The proof of the next statement, reduced as for Proposition 7 to the computation of d_j, is given in the Appendix.

Proposition 10: For every $j=1,\ldots,n$, $\overline{\mathbf{k}} \in \hat{K}$

$$\mathcal{M}^-_{\overline{\mathbf{k}}}(\xi'_j \otimes \zeta'_{n-j+1}) = d_j(\alpha,k_j) v^h_{\overline{\mathbf{k}-\mathbf{e}_j}},$$

where $d_j(\alpha,k_j)=q^{\alpha+n/2}[\alpha+k_j+n-j]_q \varpi_j(\overline{\mathbf{k}},q)$ *and* $\varpi_j(\overline{\mathbf{k}},q) \neq 0$ *for all* $\overline{\mathbf{k}} \in \hat{K}$. □

By (6) and Proposition 10, we see that the equations $d_j(\alpha,k_j)=0$ and $\alpha+k_j+n-j=0$ are equivalent.

Corollary 2: For all $j=1,\dots,n$, $\overline{\mathbf{k}}\in\hat{K}$ *the subspace* $V^j_{\geqslant k}\overset{\text{def}}{=}\oplus_{\{\overline{\mathbf{k}'}\in\hat{K}|k'_j\geqslant k\}}V_{\overline{\mathbf{k}'}}$ *is a* $U_q\mathfrak{sl}_{2n}$*-submodule in* V *iff* $\alpha+k_j+n-j=0$. □

V. REDUCIBILITY OF $\pi_{\alpha,\beta}$

Proposition 11: The representation $\pi_{\alpha,\beta}$ *is irreducible if and only if* α,β *satisfy the following equivalent conditions (since* $\alpha-\beta\in\mathbb{Z}$*, these conditions are equivalent):*

$$1.\ \alpha\notin\mathbb{Z};\ 2.\ \beta\notin\mathbb{Z}.$$

Proof: Suppose $\alpha\notin\mathbb{Z}$, $\beta\notin\mathbb{Z}$. Consider the system of equations

$$\begin{cases}\beta-k_1=0,\\ \beta-k_2+1=0,\\ \dots\\ \beta-k_n+n-1=0,\\ \alpha+k_1+n-1=0,\\ \dots\\ \alpha+k_n=0.\end{cases}$$

This system has no integral solution. Therefore $c_j(\beta,k_j)$ and $d_j(\alpha,k_j)$ do not vanish. Let W be a $U_q\mathfrak{sl}_{2n}$-submodule of V. Then $W=\oplus_{\overline{\mathbf{k}}\in I}V_{\overline{\mathbf{k}}}$ for some $I\subset\hat{K}$. Then, for all $\overline{\mathbf{k}}\in I$ and $j=1,\dots,n$, it follows that $\overline{\mathbf{k}}+\mathbf{e_j}$, $\overline{\mathbf{k}}-\mathbf{e_j}\in I$ (if the respective indexes belong to $\hat{K}$). Therefore if $I\neq\emptyset$, then $I=\hat{K}$, and the module V has no proper submodules, i.e., it is simple. Conversely, by Corollaries 1 and 2, if $\pi_{\alpha,\beta}$ is irreducible, then $\alpha\notin\mathbb{Z}$, $\beta\notin\mathbb{Z}$. □

Corollary 3: Let $\alpha,\beta\in\mathbb{Z}$*, and let* W *be the representation space of a subrepresentation of* $\pi_{\alpha,\beta}$*. Then* W *is a finite intersection of some of the* $U_q\mathfrak{sl}_{2n}$*-modules* $V^j_{\geqslant k}$, $V^j_{\leqslant k}$ *defined in Corollaries 1,2.*

The proof follows directly from the previous proof. □

Now suppose that $\alpha,\beta\in\mathbb{Z}$. We will investigate reducibility and proper subrepresentations of $\pi_{\alpha,\beta}$. We use figures as in Refs. 1 and 8 for a description.

Each $U_q\mathfrak{k}$-isotypic component $V_{\overline{\mathbf{k}}}$ is assigned to the point $(k_1,\dots,k_n)\in\mathbb{R}^n$. Thus $\hat{K}$ is assigned to the set $\mathbf{K}^+=\{(k_1,\dots,k_n)\,|\,k_1\geqslant\dots\geqslant k_n\}\subset\mathbb{R}^n$. Consider $2n$ hyperplanes:

$$\mathcal{L}^+_j:k_j=\beta+j-1;\ \ \mathcal{L}^-_j:k_j=-\alpha-n+j.$$

These hyperplanes are parallel to the coordinate axis and pass through points with integral coordinates. The distance between $\mathcal{L}^+_j$ and $\mathcal{L}^-_j$ is equal to $\alpha+\beta+n-1$.

By Corollaries 1 and 2,

$$\overline{\mathbf{k}}\in\mathcal{L}^+_j\ \text{iff}\quad U_q\mathfrak{sl}_{2n}\cdot V_{\overline{\mathbf{k}}}\supset V_{\overline{\mathbf{k}+\mathbf{e_j}}};\quad \overline{\mathbf{k}}\in\mathcal{L}^-_j\quad\text{iff } U_q\mathfrak{sl}_{2n}\cdot V_{\overline{\mathbf{k}}}\supset V_{\overline{\mathbf{k}-\mathbf{e_j}}}.$$

Investigate the example $n=2$. In this case $\mathcal{L}^\pm_j$, $j=1,2$ are just lines on the plane $\mathbb{R}^2$, parallel to the coordinate axis. Let us consider different values of $\alpha+\beta$.

Case 1: $\alpha+\beta\geqslant 0$. In this case the line $\mathcal{L}^+_1$ lies to the right of $\mathcal{L}^-_1$, $\mathcal{L}^+_2$ lies higher than $\mathcal{L}^-_2$. The lines $\mathcal{L}^\pm_1$, $\mathcal{L}^\pm_2$ are shown in Fig. 1. The intersection point of $\mathcal{L}^+_1$ and $\mathcal{L}^-_2$ has the coordinates $(\beta,-\alpha)$ and belongs to $\mathbf{K}^+$. Arrows attached to $\mathcal{L}^\pm_j$ show the direction of isotypic components "movement" under $\pi_{\alpha,\beta}$. There exists a unique simple submodule $V^s=\oplus_{\{\overline{\mathbf{k}}\in\hat{K}|k_1\leqslant\beta,k_2\geqslant-\alpha\}}V_{\overline{\mathbf{k}}}$ in V.

Case 2: $\alpha+\beta=-1$. In this case the lines $\mathcal{L}^+_1$ and $\mathcal{L}^-_1$, $\mathcal{L}^+_2$ and $\mathcal{L}^-_2$ coincide. The intersection point of the lines $\mathcal{L}^+_1$ and $\mathcal{L}^+_2$ does not belong to $\mathbf{K}^+$ (Fig. 2). There are two simple submodules in V: $V^s_1=\oplus_{\{\overline{\mathbf{k}}\in\hat{K}|k_1=-1-\alpha\}}V_{\overline{\mathbf{k}}}$ and $V^s_2=\oplus_{\{\overline{\mathbf{k}}\in\hat{K}|k_2=-\alpha\}}V_{\overline{\mathbf{k}}}$.

Case 3: $\alpha+\beta=-2$. In this case the line $\mathcal{L}^+_1$ lies to the left of $\mathcal{L}^-_1$, $\mathcal{L}^+_2$ lies lower than $\mathcal{L}^-_2$.

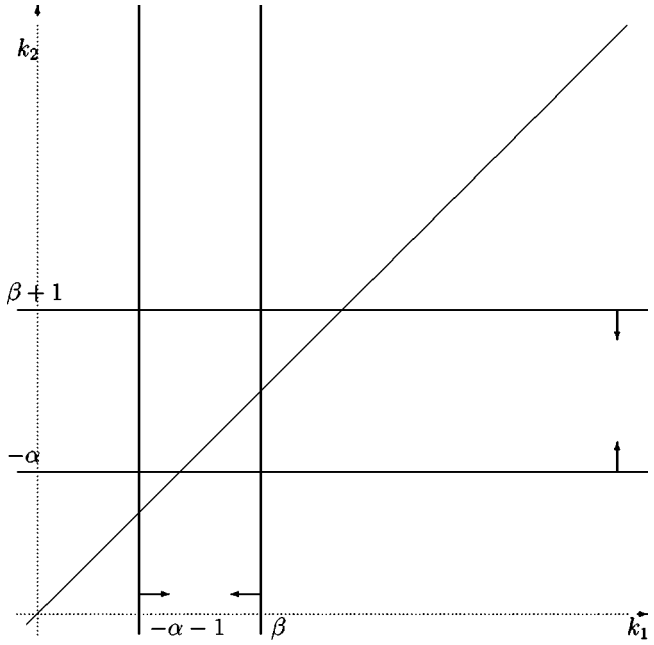

FIG. 1. Structure of $\pi_{\alpha,\beta}$ with $\alpha+\beta\geqslant 0$.

However, the lines $\mathcal{L}_1^-$ and $\mathcal{L}_2^+$ intersect in the point with coordinates $(-\alpha-1,\beta+1)$ (see Fig. 3). Besides, the distance between $\mathcal{L}_j^+$ and $\mathcal{L}_j^-$ is equal to 1. This shows that V is a direct sum of three submodules:

$$V_1^s=\bigoplus_{\{\bar{\mathbf{k}}\in\hat{K}|k_1\leqslant\beta\}} V_{\bar{\mathbf{k}}},\quad V_2^s=\bigoplus_{\{\bar{\mathbf{k}}\in\hat{K}|k_2\geqslant-\alpha\}} V_{\bar{\mathbf{k}}},\quad V_3^s=\bigoplus_{\{\bar{\mathbf{k}}\in\hat{K}|k_1\geqslant-\alpha-1,k_2\leqslant\beta+1\}} V_{\bar{\mathbf{k}}}.$$

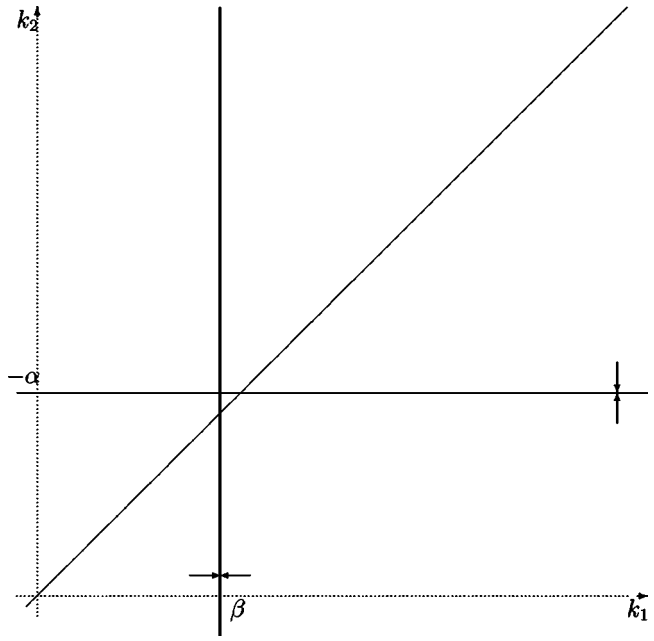

FIG. 2. Structure of $\pi_{\alpha,\beta}$ with $\alpha+\beta=-1$.

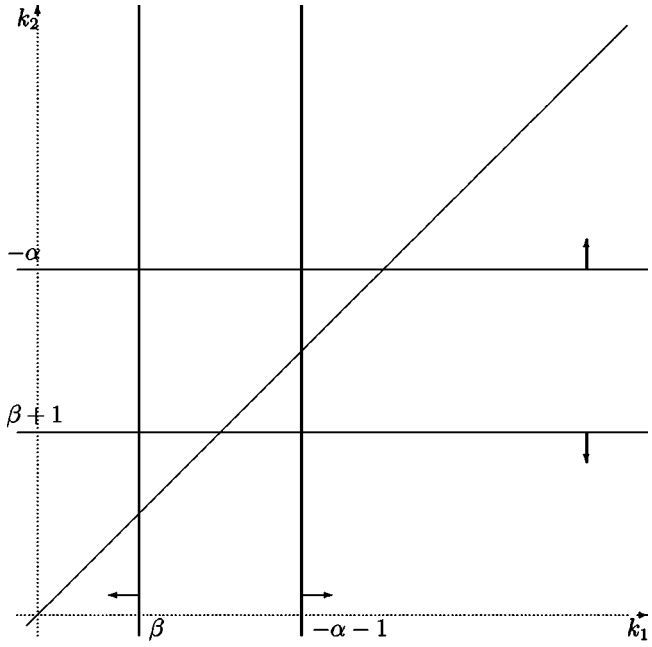

FIG. 3. Structure of $\pi_{\alpha,\beta}$ with $\alpha+\beta=-2$.

Case 4: $\alpha+\beta\leqslant -3$. In this case the intersection point of $\mathcal{L}_1^+$ and $\mathcal{L}_1^+$ belongs to $\mathbf{K}^+$ (see Fig. 4). Also, there are simple submodules V_1^s, V_2^s, V_3^s in V, but V does not decompose into their direct sum.

Turn now to the general case. Consider all possible values of $\alpha+\beta+n-1$.

Case 1: $\alpha+\beta+n-1\geqslant 1$. In this case the hyperplanes $\mathcal{L}_j^{\pm}$, $j=1,\ldots,n$ bound in $\mathbf{K}^+$ the subset that corresponds to a unique simple *finite dimensional* submodule

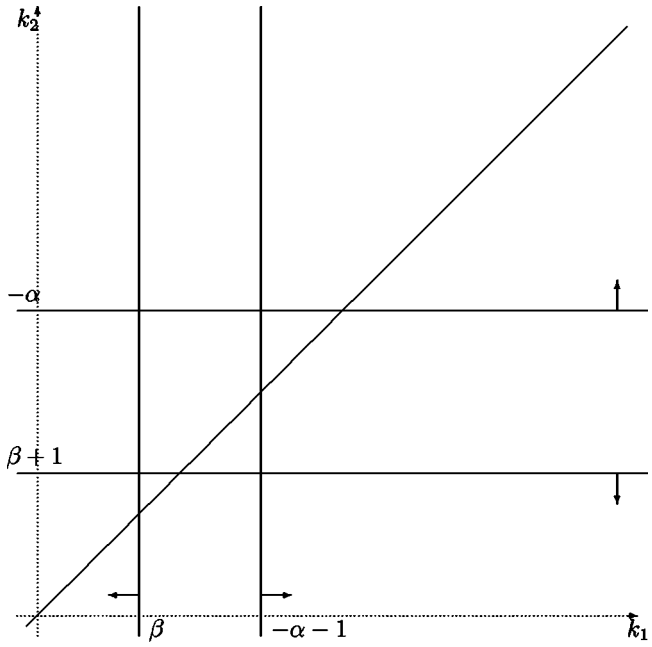

FIG. 4. Structure of $\pi_{\alpha,\beta}$ with $\alpha+\beta\leqslant -3$.

$$V^s = \bigoplus_{\{\overline{\mathbf{k}} \in \hat{K} \mid -\alpha-n+j \leqslant k_j \leqslant \beta+j-1 \text{ for all } j=1,\ldots,n\}} V_{\overline{\mathbf{k}}}^-.$$

Case 2: $\alpha+\beta+n-1=0$. In this case the hyperplanes $\mathcal{L}_j^+$ and $\mathcal{L}_j^-$ coincide. There are n simple submodules in V:

$$V_j^s = \bigoplus_{\{\overline{\mathbf{k}} \in \hat{K} \mid k_j = \beta+j-1\}} V_{\overline{\mathbf{k}}}^-, \quad j = 1, \ldots, n. \tag{16}$$

Case 3: $\alpha+\beta=-n$. Here the distance between $\mathcal{L}_j^+$ and $\mathcal{L}_j^-$ is equal to 1. This allows one to decompose the set $\hat{K}$ into a direct sum of $n+1$ subsets $\hat{K}_i$, $i=1,\ldots,n+1$, those correspond to the simple submodules: $V_i^s = \oplus_{\{\overline{\mathbf{k}} \in \overline{K}_i\}} V_{\overline{\mathbf{k}}}^- \subset V$. The subsets $\hat{K}_i$ are defined as follows:

$$\hat{K}_i = \{\overline{\mathbf{k}} \in \hat{K} \mid k_{i-1} \geqslant -\alpha - n + i - 1, \beta + i - 1 \geqslant k_i\}$$

(for $i=1$ and $i=n+1$ we put, respectively, $\hat{K}_1 = \{\overline{\mathbf{k}} \in \hat{K} \mid k_1 \leqslant \beta\}$ and $\hat{K}_{n+1} = \{\overline{\mathbf{k}} \in \hat{K} \mid k_n \geqslant -\alpha\}$).

Case 4: $\alpha+\beta+n-1 \leqslant -2$. Also, there are simple submodules corresponded to the subsets $\hat{K}_i$. However, V is not equal to their direct sum.

Thus we have proved the following:

Corollary 4: For $\alpha, \beta \in \mathbb{Z}$ *the only one from the representations* $\pi_{\alpha,\beta}$ *and* $\pi_{-n-\beta,-n-\alpha}$ *has an irreducible finite dimensional subrepresentation*. □

VI. INTERTWINING OPERATORS

In this section we construct the intertwining operators between the representations $\pi_{\alpha,\beta}$ and $\pi_{-n-\beta,-n-\alpha}$ for nonintegral α, β. This allows one to prove Proposition 2.

Let $A: V \to V$ be an intertwining operator, i.e., for all $\xi \in U_q\mathfrak{sl}_{2n}$, $v \in V$, we have $A\pi_{\alpha,\beta}(\xi)(v) = \pi_{-n-\beta,-n-\alpha}(\xi)(Av)$. The operators $\pi_{\alpha,\beta}(U_q\mathfrak{k}_{ss})$ are independent of α, β and $\pi_{\alpha,\beta}(K_n) = \pi_{-n-\beta,-n-\alpha}(K_n)$. Also, $V_{\overline{\mathbf{k}}}^-$ and $V_{\overline{\mathbf{m}}}^-$ are nonisomorphic $U_q\mathfrak{k}$-modules for $\overline{\mathbf{k}} \neq \overline{\mathbf{m}}$. Then $A(\alpha,\beta)|_{V_{\overline{\mathbf{k}}}^-} = a_{\overline{\mathbf{k}}}^-(\alpha,\beta)$, $a_{\overline{\mathbf{k}}}^-(\alpha,\beta) \in \mathbb{C}$. Let us find necessary conditions for A to be an intertwining operator in terms of $a_{\overline{\mathbf{k}}}^-(\alpha,\beta)$. By Propositions 5, 6, 8, and 9, it follows that for all $\overline{\mathbf{k}} \in \hat{K}$ there exist ϑ_j, $\eta_j \in U_q\mathfrak{sl}_{2n}$, $j=1,\ldots,n$, such that $\pi_{\alpha,\beta}(\eta_j)(v_{\overline{\mathbf{k}}}^h) = c_j(\beta,k_j)v_{\overline{\mathbf{k}+\mathbf{e_j}}}^h$ and $\pi_{\alpha,\beta}(\vartheta_j)(v_{\overline{\mathbf{k}}}^h) = d_j(\alpha,k_j)v_{\overline{\mathbf{k}-\mathbf{e_j}}}^h$. (Recall that $v_{\overline{\mathbf{k}}}^h$ is the $U_q\mathfrak{k}$-highest vector in $V_{\overline{\mathbf{k}}}^-$.) Therefore the necessary conditions look as follows: for all $j=1,\ldots,n, \overline{\mathbf{k}} \in \hat{K}$,

$$A\pi_{\alpha,\beta}(\eta_j)(v_{\overline{\mathbf{k}}}^h) = \pi_{-n-\beta,-n-\alpha}(\eta_j)(Av_{\overline{\mathbf{k}}}^h) \quad \text{and} \quad A\pi_{\alpha,\beta}(\vartheta_j)(v_{\overline{\mathbf{k}}}^h) = \pi_{-n-\beta,-n-\alpha}(\vartheta_j)(Av_{\overline{\mathbf{k}}}^h).$$

Equivalently, in terms of $a_{\overline{\mathbf{k}}}^-$,

$$a_{\overline{\mathbf{k}+\mathbf{e_j}}}^-(\alpha,\beta)c_j(\beta,k_j)v_{\overline{\mathbf{k}+\mathbf{e}_j}}^h = a_{\overline{\mathbf{k}}}^-(\alpha,\beta)c_j(-n-\alpha,k_j)v_{\overline{\mathbf{k}+\mathbf{e_j}}}^h,$$

$$a_{\overline{\mathbf{k}-\mathbf{e_j}}}^-(\alpha,\beta)d_j(\alpha,k_j)v_{\overline{\mathbf{k}-\mathbf{e_j}}}^h = a_{\overline{\mathbf{k}}}^-(\alpha,\beta)d_j(-n-\beta,k_j)v_{\overline{\mathbf{k}-\mathbf{e_j}}}^h.$$

Thus the coefficients $a_{\overline{\mathbf{k}}}^-$ of the intertwining operator A must satisfy the following conditions: for all $j=1,\ldots,n, \overline{\mathbf{k}} \in \hat{K}$,

$$\frac{a_{\overline{\mathbf{k}+\mathbf{e_j}}}^-(\alpha,\beta)}{a_{\overline{\mathbf{k}}}^-(\alpha,\beta)} = \frac{c_j(-n-\alpha,k_j)}{c_j(\beta,k_j)}, \quad \frac{a_{\overline{\mathbf{k}-\mathbf{e_j}}}^-(\alpha,\beta)}{a_{\overline{\mathbf{k}}}^-(\alpha,\beta)} = \frac{d_j(-n-\beta,k_j)}{d_j(\alpha,k_j)}.$$

We get from Propositions 7 and 10 that for all $j=1,\ldots,n, \overline{\mathbf{k}} \in \hat{K}$,

$$\frac{a^{-}_{\mathbf{k}+\mathbf{e_j}}(\alpha,\beta)}{a^{-}_{\mathbf{k}}(\alpha,\beta)} = q^{n+\alpha+\beta}\frac{[-n-\alpha-k_j+j-1]_q}{[\beta-k_j+j-1]_q}, \quad \frac{a^{-}_{\mathbf{k}-\mathbf{e_j}}(\alpha,\beta)}{a^{-}_{\mathbf{k}}(\alpha,\beta)} = q^{-n-\beta-\alpha}\frac{[-\beta+k_j-j]_q}{[\alpha+k_j+n-j]_q}.$$

As we see, the coefficients $a^{-}_{\mathbf{k}}(\alpha,\beta)$ are defined up to a scalar multiplier. By additional assumption $a^{-}_{\mathbf{0}}(\alpha,\beta)=1$, we get the explicit formulas for the coefficients $a^{-}_{\mathbf{k}}(\alpha,\beta)=A(\alpha,\beta)|_{V^{-}_{\mathbf{k}}}$ of the intertwining operator A,

$$a^{-}_{\mathbf{k}}(\alpha,\beta) = \prod_{j=1}^{n} P_j(\alpha,\beta), \tag{17}$$

where

$$P_j(\alpha,\beta) = \begin{cases} \prod\limits_{i=0}^{k_j-1} \dfrac{1-q^{2(\alpha+n+i-j+1)}}{1-q^{2(-\beta+i-j+1)}}, & \text{for } k_j > 0, \\ 1, \quad \text{for } k_j = 0, \\ \prod\limits_{i=1+k_j}^{0} \dfrac{1-q^{2(-\beta+i-j)}}{1-q^{2(\alpha+n+i-j)}}, & \text{for } k_j < 0. \end{cases}$$

For fixed $\alpha-\beta\in\mathbb{Z}$, the operator A is a meromorphic operator-function with simple poles in integral points.

VII. UNITARIZABLE REPRESENTATIONS OF THE DEGENERATE PRINCIPAL SERIES

In this section we find necessary and sufficient conditions for modules of the degenerate principal series and their simple submodules to be unitarizable.

Equip $U_q\mathfrak{sl}_{2n}$ with the involution $*$ as follows:

$$E_n^* = -K_nF_n, \quad F_n^* = -E_nK_n^{-1}, \quad K_n^* = K_n,$$

$$E_j^* = K_jF_j, \quad F_j^* = E_jK_j^{-1}, \quad K_j^* = K_j, \quad j=1,\dots,2n-1, \quad j\neq n.$$

The $*$-Hopf algebra $U_q\mathfrak{su}_{n,n} \overset{\text{def}}{=} (U_q\mathfrak{sl}_{2n},*)$ is a q-analog of $U\mathfrak{su}_{n,n}$, and its subalgebra $U_q\mathfrak{s}(\mathfrak{u}_n\times\mathfrak{u}_n) \overset{\text{def}}{=} (U_q\mathfrak{k},*)$ is a q-analog of $U\mathfrak{s}(\mathfrak{u}_n\times\mathfrak{u}_n)$.

Let us introduce two auxiliary $*$-algebras $\mathrm{Pol}(S(\mathbb{U}))_q$ and $\mathrm{Pol}(\widehat{S(\mathbb{U})})_q$ (a quantum analog of the Shilov boundary $S(\mathbb{U})$ of the matrix ball is introduced in Ref. 20). Equip the algebra $\mathbb{C}[\mathrm{Mat}_n]_{q,\det_q \mathbf{z}}$ with the involution $*$ defined by the formula

$$(z_a^b)^* = (-q)^{a+b-2n}(\det_q \mathbf{z})^{-1}\det_q \mathbf{z}_a^b,$$

where $\det_q \mathbf{z}_a^b$ is the q-determinant of the matrix derived from $\mathbf{z}$ by deleting the line b and the column a. Put $\mathrm{Pol}(S(\mathbb{U}))_q=(\mathbb{C}[\mathrm{Mat}_n]_{q,\det_q \mathbf{z}},*)$ and equip it with the natural structure of a $*$-module algebra over $U_q\mathfrak{su}_{n,n}$. The involutions in $\mathrm{Pol}(S(\mathbb{U}))_q$ and $U_q\mathfrak{su}_{n,n}$ are compatible, i.e., for all $f\in\mathrm{Pol}(S(\mathbb{U}))_q$, $\xi\in U_q\mathfrak{su}_{n,n}$ we have

$$(\xi f)^* = (S(\xi))^* f^*,$$

where S is the antipode in the Hopf algebra $U_q\mathfrak{sl}_{2n}$.

The $*$-algebra $\mathrm{Pol}(\widehat{S(\mathbb{U})})_q$ is generated by z_a^b, $a,b=1,\dots,n$, $(\det_q \mathbf{z})^{-1}$, t and t^{-1}. The relations between z_a^b and $(\det_q \mathbf{z})^{-1}$ are inherited from the $*$-algebra $\mathrm{Pol}(S(\mathbb{U}))_q$, the other relations are provided by the following:

$$t^{-1}t = tt^{-1} = 1, \quad tt^* = t^*t, \quad tz_a^b = q^{-1}z_a^b t, \quad t^* z_a^b = qz_a^b t^*, \quad a,b = 1, \ldots, n.$$

Consider an embedding of $U_q\mathfrak{su}_{n,n}$-module algebras $\mathrm{Pol}(\widehat{S(\mathbb{U})})_q \hookrightarrow \mathbb{C}[\mathrm{Pl}_{n,2n}]_{q,t}$ which maps t to t and z_a^b to $t^{-1}t^{\wedge n}_{\{1,\ldots,n\}J_a\ b}$ [see (3)]. Using this embedding, we can extend the $U_q\mathfrak{su}_{n,n}$-module structure from $\mathrm{Pol}(S(\mathbb{U}))_q$ onto $\mathrm{Pol}(\widehat{S(\mathbb{U})})_q$.

In Ref. 20, the invariant integral over the Shilov boundary of the quantum matrix ball $f \mapsto \int_{S(\mathbb{U})_q} f d\mu$ is defined and the following statement is actually proved.

Proposition 12: The linear subspace $(t^{-n})^* \cdot \mathrm{Pol}(S(\mathbb{U}))_q \cdot t^{-n} \subset \mathrm{Pol}(\widehat{S(\mathbb{U})})_q$ *is a* $U_q\mathfrak{su}_{n,n}$*-module. The linear functional*

$$(t^{-n})^* \cdot f \cdot t^{-n} \mapsto \int_{S(\mathbb{U})_q} f d\mu$$

is a $U_q\mathfrak{su}_{n,n}$*-invariant integral.*

The precise meaning of two next propositions will be given if we continue $\mathrm{Pol}(\widehat{S(\mathbb{U})})_q$ via adding to the list of generators t^λ, $(t^*)^\lambda$, $(\det_q \mathbf{z})^\lambda$ for all $\lambda \in \mathbb{C}$. The relations between the "new" generators and the action of E_j, F_j, $K_j^{\pm 1}$, $j = 1, \ldots, 2n-1$ can be derived from the corresponding formulas for t^m, $(\det_q \mathbf{z})^m$ and $(t^*)^m$, where $m \in \mathbb{Z}$. From the previous proposition it follows

Proposition 13 (cf. Ref. 13, lemma 3.2): Let $\mathrm{Re}\,\lambda = -n$*. Then the linear subspace*

$$((\det_q \mathbf{z})^{\lambda/2} t^\lambda)^* \cdot \mathrm{Pol}(S(\mathbb{U}))_q \cdot (\det_q \mathbf{z})^{\lambda/2} t^\lambda \subset \mathrm{Pol}(\widehat{S(\mathbb{U})})_q$$

is a $U_q\mathfrak{su}_{n,n}$*-module. The linear functional*

$$((\det_q \mathbf{z})^{\lambda/2} t^\lambda)^* \cdot f \cdot (\det_q \mathbf{z})^{\lambda/2} t^\lambda \mapsto \int_{S(\mathbb{U})_q} f d\mu$$

is a $U_q\mathfrak{su}_{n,n}$*-invariant integral.*

For each α, $\beta \in \mathbb{Z}$ define an embedding $i_{\alpha,\beta}$: $V = \mathbb{C}[\mathrm{Mat}_n]_{q,\det_q \mathbf{z}} \hookrightarrow \mathrm{Pol}(\widehat{S(\mathbb{U})})_q$ by the formula $i_{\alpha,\beta}(f) = f \cdot (\det_q \mathbf{z})^\alpha \cdot t^{\alpha+\beta}$ for all $f \in \mathbb{C}[\mathrm{Mat}_n]_{q,\det_q \mathbf{z}}$. Using these embeddings and the commutative relations between t, t^{-1} and $\det_q \mathbf{z}$, we get the following.

Corollary 5: Let $\mathrm{Re}(\alpha+\beta) = -n$*. Then the sesquilinear form* $V \times V \to \mathbb{C}$ *defined by*

$$\langle f_1, f_2 \rangle = \int_{S(\mathbb{U})_q} f_2^* f_1 d\mu$$

satisfies the condition $(\pi_{\alpha,\beta}(\xi)u, v) = (u, \pi_{\alpha,\beta}(\xi^*)v)$ *for all* $u, v \in V$, $\xi \in U_q\mathfrak{sl}_{2n}$.

Recall the definition of unitarizable module. Let A be a $*$-Hopf algebra, W an A-module. Then an A-module W is *unitarizable* if there exists a Hermitian form (i.e., sesquilinear Hermitian-symmetric positive definite form) $(\cdot,\cdot)$, which is A-invariant, i.e.,

$$(au, v) = (u, a^* v) \quad \text{for any } u, v \in W, a \in A.$$

Therefore the representation $\pi_{\alpha,\beta}$ is unitary if $\mathrm{Re}(\alpha+\beta) = -n$. Such representations form *the principal unitary series.*

Now we are going to find all unitarizable simple modules of the degenerate principal series and their unitarizable submodules.

Weight subspaces are pairwise orthogonal with respect to every $U_q\mathfrak{su}_{n,n}$-invariant scalar product. Therefore the isotypic components $V_{\overline{\mathbf{k}}}$ are pairwise orthogonal too. From Proposition 4 and the Burnside theorem (see Ref. 21, Sec. 27), it follows that in every component $V_{\overline{\mathbf{k}}}$ there exists a unique up to a constant $U_q\mathfrak{s}(\mathfrak{u}_n \times \mathfrak{u}_n)$-invariant scalar product. Fix such scalar products via the integral over the Shilov boundary of the quantum matrix ball[20]

$$\langle u,v\rangle_{\mathbf{k}}^{-}=\int_{S(\mathbb{U})_q} v^{*}u d\mu \quad u,v\in V_{\mathbf{k}}^{-}.$$

Hence each invariant scalar product $(\cdot,\cdot)$: $V\times V\to\mathbb{C}$ is assigned to a set $\{c_{\mathbf{k}}^{-}\}_{\mathbf{k}\in K^{+}}^{-}\subset\mathbb{R}_{+}$ such that $(u,v)=c_{\mathbf{k}}^{-}\langle u,v\rangle_{\mathbf{k}}^{-}$ for all $u,v\in V_{\mathbf{k}}^{-}$. Conversely, each $\{c_{\mathbf{k}}^{-}\}_{\mathbf{k}\in K^{+}}^{-}\subset\mathbb{R}_{+}$ defines a unique sesquilinear Hermitian-symmetric positive definite $U_q\mathfrak{s}(\mathfrak{u}_n\times\mathfrak{u}_n)$-invariant form in V.

Let us find explicit conditions for the coefficients $\{c_{\mathbf{k}}^{-}\}$ to define a $U_q\mathfrak{su}_{n,n}$-invariant form.

Using the decomposition $U_q\mathfrak{sl}_{2n}\simeq U_q\mathfrak{p}^{-}\otimes U_q\mathfrak{k}\otimes U_q\mathfrak{p}^{+}$ from Sec. IV and the definitions of $U_q\mathfrak{p}^{+}$ and $U_q\mathfrak{p}^{-}$, we see that it is sufficient to investigate the invariance of $(\cdot,\cdot)$ under the subspaces $\mathfrak{p}_q^{+}$ and $\mathfrak{p}_q^{-}$. Moreover, it is enough to prove $\mathfrak{p}_q^{+}$-invariance of $(\cdot,\cdot)$. We can see that if $(\cdot,\cdot)$ is $\mathfrak{p}_q^{+}$-invariant, then it is $\mathfrak{p}_q^{-}$-invariant. Indeed, for all $\eta\in\mathfrak{p}_q^{-}$, u, $v\in V$ we have $(\eta u,v)=\overline{(v,\eta u)}=\overline{(\eta^{*}v,u)}=(u,\eta^{*}v)$.

Investigate the $\mathfrak{p}_q^{+}$-invariance of the form $(\cdot,\cdot)$. From the results of Sec. IV it follows that $\pi_{\alpha,\beta}(\mathfrak{p}_q^{+})(V_{\mathbf{k}}^{-})\subset\oplus_{j=1}^{n}V_{\mathbf{k}+\mathbf{e}_j}^{-}$. Since the isotypic components $V_{\mathbf{k}}^{-}$ are pairwise orthogonal, one needs to check the invariance in "nonzero cases" only (that means for $u\in V_{\mathbf{k}}^{-}$, $v\in V_{\mathbf{k}+\mathbf{e}_j}^{-}$, $j=1,\dots,n$). In this case the invariant conditions are the following: for all $\xi\in U_q\mathfrak{sl}_{2n}$, $u\in V_{\mathbf{k}}^{-}$, $v\in V_{\mathbf{k}+\mathbf{e}_j}^{-}$, $j=1,\dots,n$,

$$(P_{\mathbf{k}+\mathbf{e}_j}^{-}(\pi_{\alpha,\beta}(\xi)u),v)\big|_{V_{\mathbf{k}+\mathbf{e}_j}^{-}}=(u,P_{\mathbf{k}}^{-}(\pi_{\alpha,\beta}(\xi^{*})v))\big|_{V_{\mathbf{k}}^{-}},$$

where $P_{\mathbf{k}}^{-}:V\to V_{\mathbf{k}}^{-}$ is an orthogonal projection onto $V_{\mathbf{k}}^{-}$. In other words,

$$c_{\mathbf{k}+\mathbf{e}_j}\langle P_{\mathbf{k}+\mathbf{e}_j}^{-}(\pi_{\alpha,\beta}(\xi)u),v\rangle_{\mathbf{k}+\mathbf{e}_j}^{-}=c_{\mathbf{k}}^{-}\langle u,P_{\mathbf{k}}^{-}(\pi_{\alpha,\beta}(\xi^{*})v)\rangle_{\mathbf{k}}^{-}.$$

First consider the case $\alpha,\ \beta\notin\mathbb{Z}$. Recall that from Propositions 5, 6, 8, and 9 it follows that in $(\mathfrak{p}_q^{-}\oplus\mathfrak{p}_q^{+})\otimes V_{\mathbf{k}}^{-}$ there exist $U_q\mathfrak{k}_{ss}$-highest vectors $\psi_{j,l}^{\pm}$, $j,\ l=1,\dots,n$ with weights $(k_1-k_2,\dots,k_{j-1}-(k_j\pm1),(k_j\pm1)-k_{j+1},\dots,k_{n-1}-k_n,2k_n+\alpha-\beta,k_{n-1}-k_n,\dots,(k_{n-l+1}\mp1)-k_{n-l+2},k_{n-1}-(k_{n-l+1}\mp1),\dots,k_1-k_2)$, respectively. Define $U_q\mathfrak{k}$-invariant maps

$$T_{\mathbf{k},j}^{\pm}:(\mathfrak{p}_q^{-}\oplus\mathfrak{p}_q^{+})\otimes V_{\mathbf{k}}^{-}\to V_{\mathbf{k}\pm\mathbf{e}_j}^{-}$$

by their values on the $U_q\mathfrak{k}_{ss}$-highest vectors as follows:

$$T_{\mathbf{k},j}^{+}(\psi_{j,l}^{+})=\begin{cases}\omega_j(\overline{\mathbf{k}},q)\cdot v_{\mathbf{k}+\mathbf{e}_j}^{h} & l=n-j+1;\\ 0 & l\neq n-j+1;\end{cases}$$

$$T_{\mathbf{k},j}^{-}(\psi_{j,l}^{-})=\begin{cases}\varpi_j(\overline{\mathbf{k}},q)\cdot v_{\mathbf{k}-\mathbf{e}_j}^{h} & l=n-j+1;\\ 0 & l\neq n-j+1.\end{cases}$$

Here $v_{\mathbf{k}}^{h}$, $\varpi_j(\overline{\mathbf{k}},q)$ and $\omega_j(\overline{\mathbf{k}},q)$ are introduced in Propositions 4, 7, and 10.

Lemma 4: For all $\xi\in\mathfrak{p}_q^{-}\oplus\mathfrak{p}_q^{+}$, $u\in V_{\mathbf{k}}^{-}$, $j=1,\dots,n$ the following holds:

$$P_{\mathbf{k}+\mathbf{e}_j}^{-}(\pi_{\alpha,\beta}(\xi)u)=q^{-\beta-n/2}[\beta-k_j+j-1]_qT_{\mathbf{k},j}^{+}(\xi\otimes u);$$

$$P_{\mathbf{k}-\mathbf{e}_j}^{-}(\pi_{\alpha,\beta}(\xi)u)=q^{\alpha+n/2}[\alpha+k_j+n-j]_qT_{\mathbf{k},j}^{-}(\xi\otimes u).$$

Proof: The proof completely repeats the proof of Lemma 9.10 of Ref. 8. □

Using the last lemma, we can rewrite the $U_q\mathfrak{su}_{n,n}$-invariance condition of the scalar product as follows: for all $\xi\in\mathfrak{p}_q^{-}\oplus\mathfrak{p}_q^{+}$, $u\in V_{\mathbf{k}}^{-}$, $v\in V_{\mathbf{k}+\mathbf{e}_j}^{-}$, $j=1,\dots,n$

$$q^{-\beta-n/2}[\beta-k_j+j-1]_qc_{\mathbf{k}+\mathbf{e}_j}^{-}\langle T_{\mathbf{k},j}^{+}(\xi\otimes u),v\rangle_{\mathbf{k}+\mathbf{e}_j}^{-}=\overline{q^{\alpha+n/2}[\alpha+(k_j+1)+n-j]_q}c_{\mathbf{k}}^{-}\langle u,T_{\mathbf{k}+\mathbf{e}_j,j}^{-}(\xi^{*}\otimes v)\rangle_{\mathbf{k}}^{-}.$$

Proposition 14: $\langle T^{+}_{\mathbf{k},j}(\xi\otimes u),v\rangle^{-}_{\mathbf{k}+\mathbf{e_j}}=-\langle u,T^{-}_{\mathbf{k}+\mathbf{e_j},j}(\xi^{*}\otimes v)\rangle^{-}_{\mathbf{k}}$ *for all* $j=1,\dots,n$.

Proof: Since the maps $T^{\pm}_{\mathbf{k},j}$ do not depend on $\alpha,\ \beta\in\mathcal{D}$, it is enough to consider only the special case $\mathrm{Re}(\alpha+\beta)=-n$. In this case the representation $\pi_{\alpha,\beta}$ is unitary, thus we can put $c^{-}_{\mathbf{k}}=1$ for all $\overline{\mathbf{k}}\in\hat{K}$. Since $\overline{q^{\alpha+n}}=q^{-\beta}$, we see that

$$q^{-\beta-n/2}\frac{q^{\beta-k_j+j-1}-q^{-\beta+k_j-j+1}}{q-q^{-1}}(\langle T^{+}_{\mathbf{k},j}(\xi\otimes u),v\rangle^{-}_{\mathbf{k}+\mathbf{e_j}}+\langle u,T^{-}_{\mathbf{k}+\mathbf{e_j},j}(\xi^{*}\otimes v)\rangle^{-}_{\mathbf{k}})=0.$$

If we consider nonintegral $\alpha,\ \beta$, then $q^{\beta-k_j+j-1}-q^{-\beta+k_j+1-j}$ does not vanish. This completes the proof. □

Recall that $\alpha,\ \beta\notin\mathbb{Z}$. Thus the $U_q\mathfrak{su}_{n,n}$-invariance condition of the scalar product can be rewritten as follows: for all $\overline{\mathbf{k}}\in\hat{K},\ j=1,\dots,n$

$$(1-q^{2(-\beta+k_j+1-j)})(\overline{1-q^{2(\alpha+(k_j+1)+n-j)}})^{-1}=+\frac{c^{-}_{\mathbf{k}}}{c^{-}_{\mathbf{k}+\mathbf{e_j}}}. \tag{18}$$

Since the scalar product must be positive definite, we have the following necessary conditions for the unitarizability of modules of the degenerate principal series (recall that $q=e^{-h/2}$): for all $\overline{\mathbf{k}}\in\hat{K},\ j=1,\dots,n$

$$\mathrm{sh}\,\frac{h}{2}(\beta-k_j+j-1)\overline{\left(\mathrm{sh}\,\frac{h}{2}(\alpha+(k_j+1)+n-j)\right)}^{-1}>0.$$

Using these inequalities, we can present the following series of simple unitary *representations of the degenerate principal series* related to the Shilov boundary.

The principal unitary series: $\mathrm{Re}(\alpha+\beta)=-n,\ \alpha,\ \beta\notin\mathbb{Z}$. In this case all representations are unitary. The invariant scalar product is provided by the $U_q\mathfrak{su}_{n,n}$-invariant integral.[20]

The complementary series: $\mathrm{Im}(\alpha+\beta)=0,\ |\mathrm{Re}\,\alpha+n|<1,\ |\mathrm{Re}\,\beta|<1,\ (\mathrm{Re}\,\alpha+n)\mathrm{Re}\,\beta<0,$ $\alpha,\beta\notin\mathbb{Z}$. In this case the representations $\pi_{\alpha,\beta}$ are unitary too. (The required invariant scalar product $(\cdot,\cdot)$ is defined by the coefficients $\{c^{-}_{\mathbf{k}}\}$ as follows: let $c^{-}_{\mathbf{0}}=1$, other coefficients are computed from recurrent relations such as (18).)

The strange series: $\mathrm{Im}\,\alpha=\pi/h$. For such values of the parameters the respective representations $\pi_{\alpha,\beta}$ are irreducible and unitary. This series of representations has no classical analog. For the first time it appears in unpublished works of Korogodsky and in Klimyk and Groza's paper (see Ref. 6).

Now let $\alpha,\beta\in\mathbb{Z}$. (Recall that in this case $\pi_{\alpha,\beta}$ is reducible.) For such α,β there might exist unitarizable simple submodules in the respective module (we will mention them below), although the module is not unitarizable. For each simple submodule the same arguments as in the "general case" on the $U_q\mathfrak{su}_{n,n}$-invariance of scalar product can be applied. In each case we have the necessary conditions like (18), however they must be satisfied only on a certain part of $\hat{K}$. Consider all possible cases:

Case 1: $\alpha+\beta\geqslant 2-n$. In this case the representation is not unitary and its unique irreducible subrepresentation is not unitary too.

Case 2: $\alpha+\beta=1-n$. In this case there exist n irreducible unitary subrepresentations of the representation $\pi_{\alpha,1-n-\alpha}$. Precisely, V^{s}_{j} (see (16)) is a simple submodule in V for any $j=1,\dots,n$. Notice that each V^{s}_{j} can be equipped with a $U_q\mathfrak{su}_{n,n}$-invariant scalar product $(\cdot,\cdot)$. Such modules are called small representations because they have "poor" decompositions into isotypic components.

Case 3: $\alpha+\beta=-n$. In this case the representations are completely reducible, their irreducible subrepresentations V^{s}_{i}, $i=1,\dots,n+1$ (see Sec. V) are unitary (actually, the required invariant scalar product is the same as for the principal unitary series).

Case 4: $\alpha+\beta\leqslant -1-n$. In this case the submodules V^{s}_{i}, $i=1,\dots,n+1$ are unitary although there exist nonunitarizable quotient modules in V.

ACKNOWLEDGMENT

The author is grateful to Professor L. L. Vaksman for constant attention to her work and helpful discussions.

APPENDIX

Let us prove Lemma 2. This proof is a q-analog of the proof of Lemma 3.4 from Ref. 8.

Proof of Lemma 2: Statements (9)–(12) can be easily checked.

For example, check the equality $K_jF_{m,j}=qF_{m,j}K_j$. For $j-m=1$, i.e., $m=j-1$, we see that $K_jF_{j-1,j}=K_jF_{j-1}K_{j-1}=F_{j-1}K_{j-1}K_j=qF_{j-1,j}K_j$. Assume that for $j-m<r$ Eqs. (9)–(12) are proved. Let $j-m=r$. Then,

$$\begin{aligned}
K_jF_{m,j} &= K_j(F_{m+1,j}F_mK_m + \sum_{s=m+2}^{j}(-1)^{s+m+1}F_{s,j}\mathrm{ad}_{F_{s-1}}\cdots\mathrm{ad}_{F_{m+1}}(F_mK_m)K(j,m+1,s-1))\\
&= K_jF_{m+1,j}F_mK_m + \sum_{s=m+2}^{j}(-1)^{s+m+1}K_jF_{s,j}\mathrm{ad}_{F_{s-1}}\cdots\mathrm{ad}_{F_{m+1}}(F_mK_m)K(j,m+1,s-1)\\
&= qF_{m+1,j}K_jF_mK_m + q\sum_{s=m+2}^{j-1}(-1)^{s+m+1}F_{s,j}K_j\mathrm{ad}_{F_{s-1}}\cdots\mathrm{ad}_{F_{m+1}}(F_mK_m)K(j,m+1,s-1)\\
&\quad + q(-1)^{j+m+1}\,\mathrm{ad}_{F_{j-1}}\cdots\mathrm{ad}_{F_{m+1}}(F_mK_m)K_j = qF_{m,j}K_j.
\end{aligned}$$

The proof is completed by induction.

Using (12), prove equality (14). Recall that $[x]_q=(q^x-q^{-x})/(q-q^{-1})$,

$$\begin{aligned}
E_mF_{m,j} &= \sum_{s=m+2}^{j}(-1)^{s+m+1}E_mF_{s,j}\,\mathrm{ad}_{F_{s-1}}\cdots\mathrm{ad}_{F_{m+1}}(F_mK_m)K(j,m+1,s-1) + E_mF_{m+1,j}F_mK_m\\
&\equiv \sum_{s=m+2}^{j}(-1)^{s+m+1}F_{s,j}E_m\,\mathrm{ad}_{F_{s-1}}\cdots\mathrm{ad}_{F_{m+1}}(F_mK_m)K(j,m+1,s-1) + qF_{m+1,j}E_mF_mK_m\\
&\equiv q\sum_{s=m+2}^{j}(-1)^{s+m}F_{s,j}\,\mathrm{ad}_{F_{s-1}}\cdots\mathrm{ad}_{F_{m+2}}(F_{m+1}K_{m+1})K_m^2K(j,m+1,s-1) + qF_{m+1,j}[H_m]_qK_m\\
&= \left(\sum_{s=m+2}^{j}(-1)^{s+m+2}F_{s,j}\,\mathrm{ad}_{F_{s-1}}\cdots\mathrm{ad}_{F_{m+2}}(F_{m+1}K_{m+1})K(j,m+2,s-1)\right)\\
&\quad \times K_m^2\cdot q^{j-m-1}\,K_{m+1}\cdots K_{j-1}[H_{m+1}+\cdots+H_{j-1}+j-m-1]_q) + qF_{m+1,j}[H_m]_qK_m\\
&= qF_{m+1,j}(q^{j-m-1}K_m^2K_{m+1}\cdots K_{j-1}[H_{m+1}+\cdots+H_{j-1}+j-m-1]_q + [H_m]_qK_m)\\
&= F_{m+1,j}q^{j-m}K_m\cdots K_{j-1}[H_m+\cdots+H_{j-1}+j-m-1]_q \ (\mathrm{mod}\ U_q\mathfrak{sl}_n\cdot E_m).
\end{aligned}$$

Prove equality (13) by induction. If $j-m=2$ and $m<i<j$, then $i=j-1$, and (13) means that $E_{j-1}F_{j-2,j}\equiv 0\ (\mathrm{mod}\ U_q\mathfrak{sl}_n\cdot E_{j-1})$. It can be proved as follows:

$$\begin{aligned}
E_{j-1}F_{j-2,j} &= E_{j-1}(F_{j-1,j}F_{j-2}K_{j-2}K(j,j-1,j-2) - \mathrm{ad}_{F_{j-1}}(F_{j-2}K_{j-2})K(j,j-1,j-1))\\
&\equiv [H_{j-1}]_qK_{j-1}F_{j-2}K_{j-2} - qF_{j-2}K_{j-2}K_{j-1}[H_{j-1}+1]_q = 0\ (\mathrm{mod}\ U_q\mathfrak{sl}_n\cdot E_{j-1}).
\end{aligned}$$

For the inductive step it is sufficient to check that for all $m<i<j$,

$$
\begin{aligned}
E_iF_{m,j} &= \sum_{s=m+2}^{j} (1-)^{s+m+1} E_iF_{s,j}\,\mathrm{ad}F_{s-1}\cdots \mathrm{ad}_{F_{m+1}}(F_mK_m)K(j,m+1,s-1) + E_iF_{m+1,j}F_mK_m \\
&\equiv \sum_{s=m+2}^{i-1} (-1)^{s+m+1} E_iF_{s,j}\,\mathrm{ad}_{F_{s-1}}\cdots \mathrm{ad}_{F_{m+1}}(F_mK_m)K(j,m+1,s-1) + E_iF_{m+1,j}F_mK_m \\
&\quad + \sum_{s=i+1}^{j} (-1)^{s+m+1} E_iF_{s,j}\,\mathrm{ad}_{F_{s-1}}\cdots \mathrm{ad}_{F_{m+1}}(F_mK_m)K(j,m+1,s-1) \\
&\quad + (-1)^{i+m+1} E_iF_{i,j}\,\mathrm{ad}_{F_{i-1}}\cdots \mathrm{ad}_{F_{m+1}}(F_mK_m)K(j,m+1,i-1) \pmod{U_q\mathfrak{sl}_n\cdot E_i}
\end{aligned}
$$

(we use (12) and (14)). By the inductive hypothesis, for $s<i$ we have $E_iF_{s,j}\equiv 0 \pmod{U_q\mathfrak{sl}_n\cdot E_i}$, therefore for all $m<s<i$ there exists an element $X_s\in U_q\mathfrak{sl}_n$ such that $E_iF_{s,j}=X_sE_i$. From (12), $E_iF_{s,j}=F_{s,j}E_i$. From (14), $E_iF_{i,j}=qF_{i+1,j}q^{j-i-1}K_i\cdots K_{j-1}[H_i+\cdots+H_{j-1}+j-i-1]_q$. Thus,

$$
\begin{aligned}
E_iF_{m,j} &\equiv \sum_{s=m+2}^{i-1} (-1)^{s+m+1} X_sE_i\,\mathrm{ad}_{F_{s-1}}\cdots \mathrm{ad}_{F_{m+1}}(F_mK_m)K(j,m+1,s-1) + X_{m+1}E_iF_mK_m \\
&\quad + \sum_{s=i+1}^{j} (-1)^{s+m+1} F_{s,j}E_i\,\mathrm{ad}_{F_{s-1}}\cdots \mathrm{ad}_{F_{m+1}}(F_mK_m)K(j,m+1,s-1) + (-1)^{i+m+1} \\
&\quad \times F_{i+1,j}q^{j-i}K_i\cdots K_{j-1}[H_i+\cdots+H_{j-1}+j-i-1]_q\,F_{i-1}\cdots \mathrm{ad}_{F_{m+1}}(F_mK_m)\cdot K(j,m+1,i-1) \\
&\equiv (-1)^{i+m+1} qF_{i+1,j}\,\mathrm{ad}_{F_{i-1}}\cdots \mathrm{ad}_{F_{m+1}}(F_mK_m)K(j,m+1,i) + (-1)^{i+m} \\
&\quad \times F_{i+1,j}E_i\,\mathrm{ad}_{F_i}\cdots \mathrm{ad}_{F_{m+1}}(F_mK_m)K(j,m+1,i) = 0 \pmod{U_q\mathfrak{sl}_n\cdot E_i}.
\end{aligned}
$$

□

The proof of Lemma 3 is similar.

Let us prove Proposition 7. We just have to compute the coefficients $c_j(\beta,k_j)$. Recall that there is a $U_q\mathfrak{sl}_n\otimes U_q\mathfrak{sl}_n$-isomorphism $j_1:\mathfrak{p}_q^+\simeq\mathbb{C}^n\otimes(\mathbb{C}^n)^*$, where $\mathbb{C}^n$ is the vector representation of $U_q\mathfrak{sl}_n$. The isomorphism j_1^{-1} on the elements of the standard basis for $\mathbb{C}^n\otimes(\mathbb{C}^n)^*$ is defined as follows:

$$
\begin{aligned}
&j_1^{-1}\begin{pmatrix} \varepsilon_1\otimes\varepsilon_1^* & \cdots & \varepsilon_1\otimes\varepsilon_n^* \\ \cdots & \cdots & \cdots \\ \varepsilon_{n-1}\otimes\varepsilon_1^* & \cdots & \cdots \\ \varepsilon_n\otimes\varepsilon_1^* & \cdots & \varepsilon_n\otimes\varepsilon_n^* \end{pmatrix} \\
&= \begin{pmatrix} \mathrm{ad}_{E_1}\cdots\mathrm{ad}_{E_{n-1}}E_n & \cdots & \cdots & (-1)^{n-1}\mathrm{ad}_{E_{2n-1}}\cdots\mathrm{ad}_{E_{n+1}}\mathrm{ad}_{E_1}\cdots\mathrm{ad}_{E_{n-1}}E_n \\ \cdots & \cdots & \cdots & \cdots \\ \mathrm{ad}_{E_{n-1}}E_n & \cdots & \cdots & \cdots \\ E_n & -\mathrm{ad}_{E_{n+1}}E_n & \cdots & (-1)^{n-1}\mathrm{ad}_{E_{2n-1}}\cdots\mathrm{ad}_{E_{n+1}}E_n \end{pmatrix}.
\end{aligned}
$$

(This follows from the equalities $\mathrm{ad}_{F_j}E_n=0$, $\mathrm{ad}^2_{E_j}E_n=0$ for $j=1,\ldots,2n-1, j\neq n$, $\mathrm{ad}_{K_j}E_n=E_n$ for $j=1,\ldots,n-2,n+2,\ldots,2n-1$, $\mathrm{ad}_{K_j}E_n=q^{-1}E_n$ for $j=n-1$ or $j=n+1$.) Consider the following embeddings of vector spaces:

$$\iota_1: U_q\mathfrak{sl}_n \hookrightarrow U_q\mathfrak{sl}_n \otimes U_q\mathfrak{sl}_n, \quad \xi \mapsto \xi \otimes 1;$$

$$\iota_2: U_q\mathfrak{sl}_n \hookrightarrow U_q\mathfrak{sl}_n \otimes U_q\mathfrak{sl}_n, \quad \xi \mapsto 1 \otimes \xi.$$

Set $\xi^{(1)} = \iota_1(\xi)$ and $\xi^{(2)} = \iota_2(\xi)$.

From Propositions 5 and 6, we deduce that for all $j = 1, \ldots, n, \overline{\mathbf{k}} \in \hat{K}$

$$\begin{aligned}\mathcal{M}^+_{\overline{\mathbf{k}}}(\zeta_j \otimes \xi_{n-j+1}) &= \mathcal{M}^+_{\overline{\mathbf{k}}}\Bigg(\sum_{m=1}^{j} (-q^2)^{m-1}\varepsilon_m \otimes F^{(1)}_{m,j}K^{(1)}_-(j,1,m-1)u \\ &\quad \otimes \sum_{m=n-j+1}^{n} \varepsilon^*_m \otimes S^{(2)}_{n-j+1,m}L^{(2)}_-(n-j+1,m+1,n)u^*\Bigg) \\ &= \mathcal{M}^+_{\overline{\mathbf{k}}}\Bigg(\sum_{m=1}^{j}\sum_{l=n-j+1}^{n} (-q^2)^{m-1}\varepsilon_m \otimes \varepsilon^*_l \otimes F_{m,j}K_-(j,1,m-1)u \\ &\quad \otimes S_{n-j+1,l}L_-(n-j+1,l+1,n)u^*\Bigg).\end{aligned}$$

Proposition 15: For all $j = 1, \ldots, n, \overline{\mathbf{k}} \in \hat{K}$

$$\mathcal{M}^+_{\overline{\mathbf{k}}}(\zeta_j \otimes \xi_{n-j+1}) = \lambda^-(n-j+1,n-j+2,n)\mathcal{M}^+_{\overline{\mathbf{k}}}(\zeta_j \otimes \varepsilon^*_{n-j+1} \otimes u^*),$$

where

$$L^{(2)}_-(n-j+1,n-j+2,n)(v^h_{\overline{\mathbf{k}}}) = \lambda^-(n-j+1,n-j+2,n)v^h_{\overline{\mathbf{k}}}.$$

Proof: In the same way as in Ref. 8, we have

$$\begin{aligned}\mathcal{M}^+_{\overline{\mathbf{k}}}(\zeta_j \otimes \xi_{n-j+1}) &= \mathcal{M}^+_{\overline{\mathbf{k}}}\Bigg(\sum_{m=1}^{j}\sum_{l=n-j+1}^{n} (-q^2)^{m-1}\varepsilon_m \otimes \varepsilon^*_l \otimes F^{(1)}_{m,j}K^{(1)}_-(j,1,m-1)u \\ &\quad \otimes S^{(2)}_{n-j+1,l}L^{(2)}_-(n-j+1,l+1,n)u^*\Bigg) \\ &= \mathcal{M}^+_{\overline{\mathbf{k}}}\Bigg(\sum_{m=1}^{j} (-q^2)^{m-1}\varepsilon_m \otimes \varepsilon^*_{n-j+1} \otimes F^{(1)}_{m,j}K^{(1)}_-(j,1,m-1)u \\ &\quad \otimes L^{(2)}_-(n-j+1,n-j+2+1,n)u^*\Bigg) + \mathcal{M}^+_{\overline{\mathbf{k}}}\Bigg(\sum_{m=1}^{j}\sum_{l=n-j+2}^{n} (-q^2)^{m-1}\varepsilon_m \otimes \varepsilon^*_l \\ &\quad \otimes F^{(1)}_{m,j}K^{(1)}_-(j,1,m-1)u \otimes S^{(2)}_{n-j+1,l}L^{(2)}_-(n-j+1,l+1,n)u^*\Bigg) \\ &= \lambda^-(n-j+1,n-j+2,n)\mathcal{M}^+_{\overline{\mathbf{k}}}\Bigg(\sum_{m=1}^{j} (-q^2)^{m-1}\varepsilon_m \otimes \varepsilon^*_{n-j+1} \\ &\quad \otimes F^{(1)}_{m,j}K^{(1)}_-(j,1,m-1)u \otimes u^*\Bigg) + \mathcal{M}^+_{\overline{\mathbf{k}}}\Bigg(\sum_{m=1}^{j}\sum_{l=n-j+2}^{n} (-q^2)^{m-1}\varepsilon_m \otimes \varepsilon^*_l \\ &\quad \otimes F^{(1)}_{m,j}K^{(1)}_-(j,1,m-1)u \otimes S^{(2)}_{n-j+1,l}L^{(2)}_-(n-j+1,l+1,n)u^*\Bigg)\end{aligned}$$

$$= \lambda^-(n-j+1,n-j+2,n)\mathcal{M}^+_{\overline{\mathbf{k}}}(\zeta_j \otimes \varepsilon^*_{n-j+1} \otimes u^*)$$
$$+ \mathcal{M}^+_{\overline{\mathbf{k}}}\Bigg(\sum_{l=n-j+2}^{n} \sum_{m=1}^{j} (-q^2)^{m-1} \varepsilon_m \otimes (\mathrm{ad}_{E_{n-l-2}} \cdots \mathrm{ad}_{E_j})^{(2)} \varepsilon^*_{n-j+1}$$
$$\otimes F^{(1)}_{m,j} K^{(1)}_-(j,1,m-1)u \otimes S^{(2)}_{n-j+1,l} L^{(2)}_-(n-j+1,l+1,n)u^* \Bigg)$$
$$= \lambda^-(n-j+1,n-j+2,n)\mathcal{M}^+_{\overline{\mathbf{k}}}(\zeta_j \otimes \varepsilon^*_{n-j+1} \otimes u^*)$$
$$+ \sum_{l=n-j+1}^{n} (\mathrm{ad}_{E_{n-l-2}} \cdots \mathrm{ad}_{E_j})^{(2)} S^{(2)}_{n-j+1,l} L^{(2)}_-(n-j+1,l+1,n)\mathcal{M}^+_{\overline{\mathbf{k}}}(\zeta_j \otimes \varepsilon^*_{n-j+1}$$
$$\otimes u^*).$$

The vector $\mathcal{M}^+_{\overline{\mathbf{k}}}(\zeta_j \otimes \varepsilon^*_{n-j+1} \otimes u^*) \in V_{\overline{\mathbf{k}+\mathbf{e}_j}}$ and is a $U_q\mathfrak{sl}_n \otimes 1$-highest vector. Therefore $\mathcal{M}^+_{\overline{\mathbf{k}}}(\zeta_j \otimes \varepsilon^*_{n-j+1} \otimes u^*) \in V_{\overline{\mathbf{k}+\mathbf{e}_j}}$, $\mathcal{M}^+_{\overline{\mathbf{k}}}(\zeta_j \otimes \varepsilon^*_{n-j+1} \otimes u^*) = c \cdot v^h_{\overline{\mathbf{k}+\mathbf{e}_j}}$ with some $c \in \mathbb{C}$. Now we conclude that in the obtained expression all summands except the first equal 0. □

To find $c_j(\beta,k_j)$ we must compute

$$\mathcal{M}^+_{\overline{\mathbf{k}}}(\zeta_j \otimes \varepsilon^*_{n-j+1} \otimes u^*) = \mathcal{M}^+_{\overline{\mathbf{k}}}\Bigg(\sum_{m=1}^{j} (-q^2)^{m-1} \varepsilon_m \otimes \varepsilon^*_{n-j+1} \otimes F^{(1)}_{m,j} K^{(1)}_-(j,1,m-1)u \otimes u^* \Bigg)$$
$$= \sum_{m=1}^{j} (-q^2)^{m-1} \pi_{\alpha,\beta}((-1)^{j-1} \mathrm{ad}_{E_{n+j-1}} \cdots \mathrm{ad}_{E_{n+1}} \mathrm{ad}_{E_m} \cdots \mathrm{ad}_{E_{n-1}} E_n) F^{(1)}_{m,j} K^{(1)}_-$$
$$\times (j,1,m-1)(v^h_k). \tag{A1}$$

We need some auxiliary lemmas. Recall that in this paper we introduce the notation for q-minors of the matrix $\mathbf{z}$ [see (4)]. Set $\mathbf{z}^{\wedge k}_{a_1,\ldots,a_k} = \mathbf{z}^{\wedge k\{1,\ldots,k\}}_{\{a_1,\ldots,a_k\}}$.

Lemma 5: For all $1 \leqslant m \leqslant k \leqslant j-2$,

$$(-q)^{j-k-1} \mathbf{z}^{\wedge j-1} \mathbf{z}^{\wedge k}_{1,\ldots,m-1,m+1,\ldots,j} - \sum_{s=k+1}^{j-2} (-q)^{s-k-1} \mathbf{z}^{\wedge j-1}_{1,\ldots,s-1,s+1,\ldots,j} \mathbf{z}^{\wedge k}_{1,\ldots,m-1,m+1,\ldots,s} = \mathbf{z}^{\wedge j-1}_{1,\ldots,m-1,m+1,\ldots,j} \mathbf{z}^{\wedge k}.$$

□

Lemma 6: For all $1 \leqslant m \leqslant j \leqslant n$ *we have* $F_{m,j} = q^{j-m-1} G_{m,j}$, *where*

$$G_{m,j} = F_m K_m F_{m+1,j} + \sum_{s=m+2}^{j} (-q)^{s-m-1} \mathrm{ad}_{F_{s-1}} \cdots \mathrm{ad}_{F_{m+1}} (F_m K_m) F_{s,j} K_-(j,m+1,s-1).$$

□

Lemma 7: For all $1 \leqslant m \leqslant j \leqslant n$

$$G_{m,j}(v^h_{\overline{\mathbf{k}}}) = (q^{1/2})^{j-m} \kappa_-(j,m,j-1) \mathbf{z}^{\wedge j-1}_{1,\ldots,m-1,m+1,\ldots,j} \frac{v^h_{\overline{\mathbf{k}}}}{\mathbf{z}^{\wedge j-1}},$$

where

$$K_-(j,m+1,j-1)(v^h_{\overline{\mathbf{k}}}) = \kappa_-(j,m,j-1) v^h_{\overline{\mathbf{k}}}.$$

Proof: We prove this lemma by induction. For $j-m=1$ the statement is obvious, since

$$G_{m,m+1}(v_{\mathbf{k}}^{\underline{h}}) = F_m K_m((\mathbf{z}^{\wedge 1})^{k_1-k_2}\cdots(\mathbf{z}^{\wedge n})^{k_n})$$
$$= q^{k_m-k_{m+1}}q^{1/2}[k_m-k_{m+1}]_q(\mathbf{z}^{\wedge 1})^{k_1-k_2}\cdots(\mathbf{z}^{\wedge m-1})^{k_{m-1}-k_m}\mathbf{z}^{\wedge m}_{1,\ldots,m-1,m+1}$$
$$\times(\mathbf{z}^{\wedge m})^{k_m-k_{m+1}-1}\cdot(\mathbf{z}^{\wedge m+1})^{k_{m+1}-k_{m+2}}\cdots(\mathbf{z}^{\wedge n})^{k_n}$$
$$= q^{1/2}\kappa_-(m+1,m,m)\mathbf{z}^{\wedge m}_{1,\ldots,m-1,m+1}v_{\mathbf{k}-\mathbf{e}_m}^{\underline{h}}.$$

For the proof of the inductive step we use two previous lemmas. By Lemma 6, we have

$$G_{m,j}(v_{\mathbf{k}}^{\underline{h}}) = \sum_{s=m+2}^{j}(-q)^{s-m-1}\,\mathrm{ad}_{F_{s-1}}\cdots\mathrm{ad}_{F_{m+1}}(F_mK_m)\cdot(F_{s,j}K_-(j,m+1,s-1))(v_{\mathbf{k}}^{\underline{h}}) + F_mK_mF_{m+1,j}(v_{\mathbf{k}}^{\underline{h}})$$
$$= F_mK_mF_{m+1,j}(v_{\mathbf{k}}^{\underline{h}}) + \sum_{s=m+2}^{j}(-q)^{s-m-1}\kappa_-(j,m+1,s-1)\mathrm{ad}_{F_{s-1}}\cdots\mathrm{ad}_{F_{m+1}}(F_mK_m)F_{s,j}(v_{\mathbf{k}}^{\underline{h}}).$$

By the inductive hypothesis, for all $j-s<j-m$

$$G_{m,j}(v_{\mathbf{k}}^{\underline{h}}) = q^{1/2(j-m-1)}\kappa_-(j,m+1,j-1)F_mK_m\left(\mathbf{z}^{\wedge j-1}_{1,\ldots,m-1,m+1,\ldots,j}\frac{v_{\mathbf{k}}^{\underline{h}}}{\mathbf{z}^{\wedge j-1}}\right)$$
$$+\sum_{s=m+2}^{j}(-q)^{s-m-1}\cdot q^{1/2(j-s)}\kappa_-(j,m+1,s-1)\kappa_-(j,s,j-1)\mathrm{ad}_{F_{s-1}}\cdots\mathrm{ad}_{F_{m+1}}(F_mK_m)$$
$$\times\left(\mathbf{z}^{\wedge j-1}_{1,\ldots,m-1,m+1,\ldots,j}\frac{v_{\mathbf{k}}^{\underline{h}}}{\mathbf{z}^{\wedge j-1}}\right)$$
$$= q^{1/2(j-m-1)}\kappa_-(j,m+1,j-1)\cdot(F_mK_m)\left(\mathbf{z}^{\wedge j-1}_{1,\ldots,m-1,m+1,\ldots,j}\frac{v_{\mathbf{k}}^{\underline{h}}}{\mathbf{z}^{\wedge j-1}}\right)$$
$$+\sum_{s=m+2}^{j}(-q^{1/2})^{s-m-1}\,\mathrm{ad}_{F_{s-1}}\cdots\mathrm{ad}_{F_{m+1}}(F_mK_m)\left(\mathbf{z}^{\wedge j-1}_{1,\ldots,s-1,s+1,\ldots,j}\frac{v_{\mathbf{k}}^{\underline{h}}}{\mathbf{z}^{\wedge j-1}}\right).$$

Using the explicit formulas for the $U_q\mathfrak{sl}_{2n}$-action in $\mathbb{C}[\mathrm{Mat}_n]_q$ and properties of the comultiplication (see Sec. II), we obtain that

$$\mathrm{ad}_{F_{s-1}}\cdots\mathrm{ad}_{F_{m+1}}(F_mK_m)\left(\mathbf{z}^{\wedge j-1}_{1,\ldots,s-1,s+1,\ldots,j}\frac{v_{\mathbf{k}}^{\underline{h}}}{\mathbf{z}^{\wedge j-1}}\right)$$
$$= (q^{1/2})^{s-m}(q^{k_m-k_{m+1}}[k_m-k_{m+1}]_q(\mathbf{z}^{\wedge 1})^{k_1-k_2}\cdot\ \cdots\ \cdot(\mathbf{z}^{\wedge m-1})^{k_{m-1}-k_m}\mathbf{z}^{\wedge m}_{1,\ldots,m-1,m+1,\ldots,s}$$
$$\cdot(\mathbf{z}^{\wedge m})^{k_m-k_{m+1}-1}\cdots(\mathbf{z}^{\wedge s-1})^{k_{s-1}-k_s}\mathbf{z}^{\wedge j-1}_{1,\ldots,s-1,s+1,\ldots,j}(\mathbf{z}^{\wedge s})^{k_s-k_{s+1}}\cdot\ \cdots\ \cdot(\mathbf{z}^{\wedge n})^{k_n}$$
$$+(-q)q^{k_m-k_{m+1}+k_{m+1}-k_{m+2}}[k_{m+1}-k_{m+2}]_q(\mathbf{z}^{\wedge 1})^{k_1-k_2}\cdot\ \cdots\ \cdot(\mathbf{z}^{\wedge m})^{k_m-k_{m+1}}$$
$$\cdot\mathbf{z}^{\wedge m+1}_{1,\ldots,m-1,m+1,\ldots,s}(\mathbf{z}^{\wedge m+1})^{k_{m+1}-k_{m+2}-1}\cdots(\mathbf{z}^{\wedge s-1})^{k_{s-1}-k_s}\mathbf{z}^{\wedge j-1}_{1,\ldots,s-1,s+1,\ldots,j}\cdot(\mathbf{z}^{\wedge s})^{k_s-k_{s+1}}\cdot\ \cdots\ \cdot(\mathbf{z}^{\wedge n})^{k_n}$$
$$+\ \cdots\ +(-q)^{s-2}q^{k_m-k_{m+1}+\cdots+k_{s-2}-k_{s-1}}[k_{s-2}-k_{s-1}]_q\cdot(\mathbf{z}^{\wedge 1})^{k_1-k_2}\cdot\ \cdots\ \cdot(\mathbf{z}^{\wedge s-2})^{k_{s-2}-k_{s-1}}$$
$$\times\mathbf{z}^{\wedge s-1}_{1,\ldots,m-1,m+1,\ldots,s}\cdot(\mathbf{z}^{\wedge s-1})^{k_{s-1}-k_s-1}\mathbf{z}^{\wedge j-1}_{1,\ldots,s-1,s+1,\ldots,j}$$
$$\cdot(\mathbf{z}^{\wedge s})^{k_s-k_{s+1}}\cdot\ \cdots\ \cdot(\mathbf{z}^{\wedge n})^{k_n}+(-q)^{s-1}q^{k_m-k_{m+1}+\cdots+k_{s-1}-k_s}[k_{s-1}-k_s]_q(\mathbf{z}^{\wedge 1})^{k_1-k_2}\cdot\ \cdots$$
$$\cdot(\mathbf{z}^{\wedge s-2})^{k_{s-2}-k_{s-1}}(\mathbf{z}^{\wedge s-1})^{k_{s-1}-k_s}\mathbf{z}^{\wedge j-1}_{1,\ldots,m-1,m+1,\ldots,j}(\mathbf{z}^{\wedge s})^{k_s-k_{s+1}}\cdot\ \cdots\ \cdot(\mathbf{z}^{\wedge n})^{k_n}).$$

Finally, by Lemma 5, we see that

$$G_{m,j}(v_{\mathbf{k}}^{h}) = (q^{1/2})^{j-m}\kappa_-(j,m+1,j-1)\cdot \mathbf{z}_{1,\ldots,m-1,m+1,\ldots,j}^{\wedge j-1}\frac{v_{\mathbf{k}}^{h}}{\mathbf{z}^{\wedge j-1}}\cdot\frac{q^{2(j-2+k_1-k_j)}-1}{q-q^{-1}}.$$

□

By the last lemma and (A1), we can compute the coefficients $c_j(\beta,k_j)$ introduced in Proposition 7.

Proposition 16: For all $1\leqslant j\leqslant n$,

$$\mathcal{M}^{+}_{\mathbf{k}}(\zeta_j\otimes\varepsilon^{*}_{n-j+1}\otimes u^{*}) = q^{-\beta-n/2+k_j+j}[\beta-k_j+j-1]_q\kappa_-(j,1,j-1)v_{\mathbf{k}+\mathbf{e_j}}^{h}.$$

Proof: We have

$$\begin{aligned}
&\mathcal{M}^{+}_{\mathbf{k}}(\zeta_j\otimes\varepsilon^{*}_{n-j+1}\otimes u^{*})\\
&=\sum_{m=1}^{j}(-q^2)^{m-1}\pi_{\alpha,\beta}((-1)^{j-1}\,\mathrm{ad}_{E_{n+j-1}}\cdots\mathrm{ad}_{E_{n+1}}\,\mathrm{ad}_{E_m}\cdots\mathrm{ad}_{E_{n-1}}E_n)\cdot F^{(1)}_{m,j}K^{(1)}_{-}(j,1,m-1)v_{\mathbf{k}}^{h}\\
&=\sum_{m=1}^{j}(-q^2)^{m-1}\kappa_-(j,1,m-1)\cdot\pi_{\alpha,\beta}((-1)^{j-1}\,\mathrm{ad}_{E_{n+j-1}}\cdots\mathrm{ad}_{E_{n+1}}\,\mathrm{ad}_{E_m}\cdots\mathrm{ad}_{E_{n-1}}E_n)F^{(1)}_{m,j}v_{\mathbf{k}}^{h}.
\end{aligned}$$

By Lemma 7,

$$\begin{aligned}
\mathcal{M}^{+}_{\mathbf{k}}(\zeta_j\otimes\varepsilon^{*}_{n-j+1}\otimes u^{*}) &= \sum_{m=1}^{j-1}(-q^2)^{m-1}q^{j-m-1}(q^{1/2})^{j-m}\kappa_-(j,m,j-1)\kappa_-(j,1,m-1)\cdot(-1)^{j-1}\\
&\quad\times\pi_{\alpha,\beta}(\mathrm{ad}_{E_{n+j-1}}\cdots\mathrm{ad}_{E_{n+1}}\,\mathrm{ad}_{E_m}\cdots\mathrm{ad}_{E_{n-1}}E_n)\left(\mathbf{z}_{1,\ldots,m-1,m+1,\ldots,j}^{\wedge j-1}\frac{v_{\mathbf{k}}^{h}}{\mathbf{z}^{\wedge j-1}}\right)\\
&\quad+(-q^2)^{j-1}\kappa_-(j,1,j-1)\pi_{\alpha,\beta}((-1)^{j-1}\,\mathrm{ad}_{E_{n+j-1}}\cdots\mathrm{ad}_{E_{n+1}}\,\mathrm{ad}_{E_j}\cdots\mathrm{ad}_{E_{n-1}}E_n)\\
&\quad\times(v_{\mathbf{k}}^{h})\\
&= q^{3/2j-3}\kappa_-(j,1,j-1)\sum_{m=1}^{j-1}(-1)^{j+m}q^{m/2}\\
&\quad\cdot\pi_{\alpha,\beta}(\mathrm{ad}_{E_{n+j-1}}\cdots\mathrm{ad}_{E_{n+1}}\,\mathrm{ad}_{E_m}\cdots\mathrm{ad}_{E_{n-1}}E_n)\\
&\quad\times\left(\mathbf{z}_{1,\ldots,m-1,m+1,\ldots,j}^{\wedge j-1}\frac{v_{\mathbf{k}}^{h}}{\mathbf{z}^{\wedge j-1}}\right)+q^{2j-2}\kappa_-(j,1,j-1)\\
&\quad\times\pi_{\alpha,\beta}(\mathrm{ad}_{E_{n+j-1}}\cdots\mathrm{ad}_{E_{n+1}}\,\mathrm{ad}_{E_j}\cdots\mathrm{ad}_{E_{n-1}}E_n)(v_{\mathbf{k}}^{h}).
\end{aligned}$$

In Sec. II the following morphism of $U_q\mathfrak{sl}_{2n}$-modules was defined:

$$\iota:\mathbb{C}[\mathrm{Mat}_n]_q\to\mathbb{C}[\mathrm{Pl}_{n,2n}]_{q,t},\quad \iota(z_{\{a_1,\ldots,a_k\}}^{\wedge k\{b_1,\ldots,b_k\}}) = t^{-1}t_{\{1,\ldots,n\}J}^{\wedge n},$$

with

$$J=\{n+1,\ldots,2n\}\setminus\{2n+1-b_1,\ldots,2n+1-b_k\}\cup\{a_1,\ldots,a_k\}.$$

Therefore $\iota(\mathbf{z}^{\wedge k})=t^{-1}t_{\{1,\ldots,n\}\{1,\ldots,k,n+1,\ldots,2n-k\}}^{\wedge n}$. It follows that

$$\iota(v_{\mathbf{k}}^{h}) = q^{c}t^{-k_1}(t_{\{1,\ldots,n\}\{1,n+1,\ldots,2n-1\}}^{\wedge n})^{k_1-k_2}\cdots(t_{\{1,\ldots,n\}\{1,\ldots n\}}^{\wedge n})^{k_n},$$

where some $c\in\mathbb{C}$. Using the definition of $\pi_{\alpha,\beta}$, we obtain that for all $\xi\in U_q\mathfrak{sl}_{2n}, f\in\mathbb{C}[\mathrm{Pl}_{n,2n}]_{q,t}$

$$\pi_{\alpha,\beta}(\xi)(f) = q^{c}t^{-\beta}\xi\cdot(t^{\beta}f(t^{\wedge n}_{\{1,\ldots,n\}\{1,\ldots,n\}})^{\alpha})(t^{\wedge n}_{\{1,\ldots,n\}\{1,\ldots,n\}})^{-\alpha}.$$

For $m<j$,

$$\begin{aligned}&(\mathrm{ad}_{E_{n+j-1}}\cdots\mathrm{ad}_{E_{n+1}}\mathrm{ad}_{E_m}\cdots\mathrm{ad}_{E_{n-1}}E_n)(t^{\wedge n\{1,\ldots,n\}}_{\{1,\ldots,m-1,m+1,\ldots,j,n+1,\ldots,2n-j,2n-m+1\}})\\ &\quad=(-1)^{m-j}(q^{-1/2})^{j+n-m}q^{m-j-1}t^{\wedge n}_{\{1,\ldots,n\}\{1,\ldots,j,n+1,\ldots,2n-j\}},\end{aligned}$$

and for $m=j$ $(\mathrm{ad}_{E_{n+j-1}}\cdots\mathrm{ad}_{E_{n+1}}\mathrm{ad}_{E_j}\cdots\mathrm{ad}_{E_{n-1}}E_n)(t^{\wedge n}_{\{1,\ldots,n\}\{1,\ldots,j-1,n+1,\ldots,2n-j+1\}})$ $=(q^{-1/2})^{n}t^{\wedge n}_{\{1,\ldots,n\}\{1,\ldots,j,n+1,\ldots,2n-j\}}$. For other summands we use an analog of Lemma 5. Finally, we have

$$\begin{aligned}\mathcal{M}^{+}_{-\mathbf{k}}(\zeta_j\otimes\varepsilon^{*}_{n-j+1}\otimes u^{*}) &= \kappa_{-}(j,1,j-1)q^{-n/2}\cdot\left(q^{2}\sum_{m=1}^{j-1}q^{2m-2}+\frac{1-q^{-2\beta+2k_1}}{1-q^{-2}}\right.\\ &\quad\left.+\sum_{m=1}^{j-1}q^{-2\beta+2k_m}\frac{1-q^{-2k_m+2k_{m+1}}}{1-q^{-2}}\right)\cdot v^{h}_{\mathbf{k}+\mathrm{e}_j}\\ &= q^{-\beta-n/2+k_j+j}\kappa_{-}(j,1,j-1)[\beta-k_j+j-1]_q v^{h}_{\mathbf{k}+\mathrm{e}_j}.\end{aligned}$$

□

Repeat the same arguments to prove Proposition 10. First, we have the explicit formulas for the isomorphism $j_2:\mathfrak{p}^{-}_{q}\simeq(\mathbb{C}^n)^{*}\otimes\mathbb{C}^n$:

$$j_2^{-1}\begin{pmatrix}\varepsilon^{*}_1\otimes\varepsilon_1 & \cdots & \varepsilon^{*}_n\otimes\varepsilon_1\\ \cdots & \cdots & \cdots\\ \varepsilon^{*}_1\otimes\varepsilon_n & \cdots & \varepsilon^{*}_n\otimes\varepsilon_n\end{pmatrix}$$

$$=\begin{pmatrix}(-1)^{n-1}\mathrm{ad}_{F_1}\cdots\mathrm{ad}_{F_{n-1}}(K_nF_n) & \cdots & -\mathrm{ad}_{F_{n-1}}(K_nF_n) & K_nF_n\\ \cdots & \cdots & \cdots & \mathrm{ad}_{F_{n+1}}(K_nF_n)\\ \cdots & & & \\ (-1)^{n-1}\mathrm{ad}_{F_{2n-1}}\cdots\mathrm{ad}_{F_{n+1}}\mathrm{ad}_{F_1}\cdots\mathrm{ad}_{F_{n-1}}(K_nF_n) & \cdots & \cdots & \mathrm{ad}_{F_{2n-1}}\cdots\mathrm{ad}_{F_{n+1}}(K_nF_n)\end{pmatrix}.$$

For the proof of Proposition 10 we must compute the following:

$$\begin{aligned}\mathcal{M}^{-}_{-\mathbf{k}}(\xi'_j\otimes\zeta'_{n-j+1}) &= \mathcal{M}^{-}_{-\mathbf{k}}\left(\sum_{m=j}^{n}\varepsilon^{*}_m\otimes S^{(1)}_{j,m}L^{(1)}_{-}(j,m+1,n)u\right.\\ &\quad\left.\otimes\sum_{m=1}^{n-j+1}(-q^2)^{m-1}\varepsilon_m\otimes F^{(2)}_{m,n-j+1}K^{(2)}_{-}(n-j+1,1,m-1)u^{*}\right)\\ &= \mathcal{M}^{-}_{-\mathbf{k}}\left(\sum_{m=j}^{n}\sum_{l=1}^{n-j+1}(-q^2)^{l-1}\varepsilon^{*}_m\otimes\varepsilon_l\otimes S^{(1)}_{j,m}L^{(1)}_{-}(j,m+1,n)u\right.\\ &\quad\left.\otimes F^{(2)}_{l,n-j+1}K^{(2)}_{-}(n-j+1,1,l-1)u^{*}\right).\end{aligned}$$

Proposition 17: For all $1\leqslant j\leqslant n$

$$\mathcal{M}^{-}_{-\mathbf{k}}(\xi'_j\otimes\zeta'_{n-j+1}) = \lambda_{-}(j,j+1,n)\mathcal{M}^{-}_{-\mathbf{k}}(\varepsilon^{*}_j\otimes u\otimes\zeta'_{n-j+1}),$$

where

$$L_{-}^{(1)}(j,j+1,n)u = \lambda_{-}(j,j+1,n)u.$$

The proof is similar to the proof of Proposition 15.

Therefore in order to find the coefficients $d_j(\alpha,k_j)$ introduced in Proposition 10 we must only compute

$$\mathcal{M}^{-}_{\mathbf{k}}(\varepsilon_j^* \otimes u \otimes \zeta'_{n-j+1}) = \mathcal{M}^{-}_{\mathbf{k}}\left(\sum_{l=1}^{n-j+1}(-q^2)^{l-1}\varepsilon_j^* \otimes \varepsilon_l \otimes u \otimes F_{l,n-j+1}K_{-}(n-j+1,1,l-1)u^*\right)$$

$$= \sum_{l=1}^{n-j+1}(-q^2)^{l-1}\pi_{\alpha,\beta}(\mathrm{ad}_{F_j}\cdots\mathrm{ad}_{F_{n-1}}\mathrm{ad}_{F_{n-1+l}}\cdots\mathrm{ad}_{F_{n+1}}(K_nF_n))$$

$$\cdot F^{(2)}_{l,n-j+1}K^{(2)}_{-}(n-j+1,1,l-1)(v^{h}_{\mathbf{k}}).$$

These computations are analogous to the ones from the proof of Proposition 16.

(Received 10 March 2004; accepted 7 June 2004; published 12 October 2004)

A bijective map r: $X^2 \to X^2$, where $X=\{x_1,\ldots,x_n\}$ is a finite set, is called a *set-theoretic solution of the Yang–Baxter equation* (YBE) if the braid relation $r^{12}r^{23}r^{12}=r^{23}r^{12}r^{23}$ holds in X^3. A nondegenerate involutive solution (X,r) satisfying $r(xx)=xx$, for all $x \in X$, is called *square-free solution*. There exist close relations between the square-free set-theoretic solutions of YBE, the semigroups of I-type, the semigroups of skew polynomial type, and the Bieberbach groups, as it was first shown in a joint paper with Michel Van den Bergh. In this paper we continue the study of square-free solutions (X,r) and the associated Yang–Baxter algebraic structures—the semigroup $S(X,r)$, the group $G(X,r)$ and the k-algebra $A(k,X,r)$ over a field k, generated by X and with quadratic defining relations naturally arising and uniquely determined by r. We study the properties of the associated Yang–Baxter structures, and prove a conjecture of the present author that the three notions: a square-free solution of (set-theoretic) YBE, a semigroup of I type, and a semigroup of skew-polynomial-type, are equivalent. This implies that the Yang–Baxter algebra $A(k,X,r)$ is a Poincaré–Birkhoff–Witt-type algebra, with respect to some appropriate ordering of X. We conjecture that every square-free solution of YBE is retractable, in the sense of Etingof–Schedler–Solovyev. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1788848]

I. INTRODUCTION

The Yang–Baxter equation appeared in 1967[36] in Statistical Mechanics and turned out to be one of the basic equations in mathematical physics, and more precisely for introducing the theory of quantum groups. At present the study of quantum groups, and, in particular, the solutions of the Yang–Baxter equation attracts the attention of a broad circle of scientists and mathematicians.

Let V be a vector space over a field k. We recall that a linear automorphism R of $V \otimes V$ *is a solution of the Yang–Baxter equation*, if the equality

$$(R \otimes id_V)(id_V \otimes R)(R \otimes id_V) = (id_V \otimes R)(R \otimes id_V)(id_V \otimes R) \tag{1.1}$$

holds in the automorphism group of $V \otimes V \otimes V$. R is a solution of the *quantum Yang–Baxter equation* (QYBE) if

$$R^{12}R^{13}R^{23} = R^{23}R^{13}R^{12}, \tag{1.2}$$

where R^{ij} means R acting on the ith and jth component.

Finding all solutions of the Yang–Baxter equation is a difficult task far from being resolved. Nevertheless many solutions of these equations have been found during the last 20 years and the related algebraic structures (Hopf algebras) have been studied (for example, see Ref. 20). Most of these solutions were "deformations" of the identity solution. In 1990 Drinfeld[5] posed the problem

[a)]Electronic mail: tatyana@aubg.bg, tatianagateva@yahoo.com, tatiana@math.harvard.edu

of studying a class of solutions that are obtained in a different way—the so-called *set-theoretic solutions*.

Definition 1.1: Let X be a nonempty set. Let $r: X\times X\to X\times X$ be a bijection of the Cartesian product $X\times X$ onto itself. The map r is called *a set-theoretic solution of the Yang–Baxter equation*, if

$$(r\times id_X)(id_X\times r)(r\times id_X)=(id_X\times r)(r\times id_X)(id_X\times r).$$

Each set-theoretic solution r of the Yang–Baxter equation induces an operator R on $V\otimes V$ for the vector space V spanned by X, which is, clearly, a solution of (1.1). Various works dealing with set-theoretic solutions appeared during the last decade, cf. Refs. 35, 18, 15, 6, 7, 33, 23, 26, and 30.

The purpose of this paper is first to present some recent conjectures on the set-theoretic solutions of the Yang–Baxter equation, and to give an account of the research in this area, and, second to continue the study of the general algebraic and homological properties of the algebraic structures related to the so-called square-free solutions. Our approach is combinatorial. To each solution (X,r) we associate a semigroup $S=S(X,r)$, a group $G=G(X,r)$ (the group was also studied in Ref. 6), and a quadratic algebra over a field k, $A(k,X,r)\simeq kS$, each of them with a set of n generators X and with quadratic defining relations $\mathfrak{R}(X,r)$ naturally arising and uniquely determined by r. We study the "behavior" of these relations, and use the obtained information for establishing structural and homological properties of the associated algebraic objects. This approach is natural, for usual linear solutions one has similar ideas for instance in Manin's work.[25] In the case of set-theoretic solutions to YBE it was initiated in the joint paper with Michel Van den Bergh,[15] and applied to the study of the close relations between different mathematical objects such as set-theoretic solutions of the Yang–Baxter equation, semigroups of I-type (which appeared in the study of Sklyanin algebras) and the semigroups S_0 associated with the class of skew-polynomial rings with binomial relations, introduced and studied in Refs. 8 and 9. The semigroups S_0, called *semigroups of skew-polynomial type* are standard finitely presented, more precisely, they are defined in terms of a finite number of generators and quadratic square-free relations, which form a Groebner basis (or equivalently, the algebra $A=kS$ is a PBW algebra) cf. 2.19. It is proven in Ref. 15 that each skew-polynomial semigroup S_0 defines a nondegenerate set-theoretic solution $r=r(S_0)$ of the Yang–Baxter equation. In connection with this result the present author made the conjecture that under the restriction that X is finite and r is *square-free*, i.e., $r(x,x)=(x,x)$ for each $x\in X$, all nondegenerate involutive solutions can be obtained in this way, cf. 2.18. The Main theorem 2.26 proves this conjecture, and shows that there exists an ordering on X, $X=\{x_1<x_2<\cdots<x_n\}$, such that the Yang–Baxter algebra $\mathcal{A}=\mathcal{A}(k,X,r)$ is a Poincaré–Birkhoff–Witt-type algebra, with a k-basis—the set of ordered monomials $\{x_1^{\alpha_1}x_2^{\alpha_2}\cdots x_n^{\alpha_n}\,|\,\alpha_i\geqslant 0, 1\leqslant i\leqslant n\}$. This result is used to show that each *binomial solution* of the Yang–Baxter equation is obtained from a *binomial skew-polynomial ring*, see 9.7. We show that the Yang–Baxter semigroup $S=S(X,r)$ is a distributive lattice. Finally we study generalized twisted unions of solutions and multipermutation solutions. We make a stronger conjecture, 2.28, that every square-free solution (X,r) is retractable, furthermore it is a multipermutation solution of level $m<n$.

In this work we will not be in a position to develop specific physical applications but already we can say that several of the structures we introduce are highly relevant for physics. For example, the groups $G(X,r)$ act on each other to form a matched pair of groups and are hence a natural source of quantum groups of bicrossproduct type. More details are to appear in our sequel.[16] Bicrossproduct quantum groups themselves are increasing importance in noncommutative geometry as for example the Connes–Kreimer quantum groups associated to renormalization, the κ-Poincaré quantum groups related to deformed spacetime, and the original "Planck-scale" quantum group; see Ref. 24 for this background.

II. BASIC NOTIONS AND RESULTS

In this section we first recall some basic notions, definitions, and results, from Refs. 6 and 15. They are related to both quantum group theory and noncommutative algebra, so we recall them for convenience of readers with various mathematical background. Next we formulate the main results of the paper and a conjecture about set-theoretic solutions of YBE.

We fix a finite nonempty set X with n elements. We shall often identify the sets $X\times X$ and X^2, the set of all monomials of length two in the free semigroup $\langle X\rangle$.

Definition 2.1 (Ref. 6): Let $r:X\times X\to X\times X$ be a bijective map, we shall refer to it as (X,r). The components of r are the maps $\mathcal{L}:X\times X\to X$ and $\mathcal{R}:X\times X\to X$ defined by the equality

$$r(x,y)=(\mathcal{L}_x(y),\mathcal{R}_y(x)).$$

(i) (X,r) is *left nondegenerate* if for each x the map $\mathcal{L}_x(y)$ is a bijective function of y; (X,r) is *right nondegenerate* if for each y the map $\mathcal{R}_y(x)$ is a bijective function of x; (X,r) is *nondegenerate* if it is left and right nondegenerate.

(ii) (X,r) is involutive if

$$r^2=id_{X\times X}. \tag{2.1}$$

(iii) (X,r) is *a braided set* if r satisfies the braid relation

$$r^{12}r^{23}r^{12}=r^{23}r^{12}r^{23}, \tag{2.2}$$

where $r^{12}=r\times id_X$ and $r^{23}=id_X\times r$.

(iv) (X,r) is *symmetric* if it is braided and involutive.

(v) If (X,r) is a braided, involutive and nondegenerate set we shall call it simply *a solution*.

Clearly, every braided set presents a set-theoretic solution of the Yang–Baxter equation. A general study of nondegenerate symmetric sets was given in Ref. 6.

In Ref. 15 was found a special class of solutions, here we call them *square-free solutions* (cf. 2.2), which are defined via the semigroups of skew-polynomial type. These semigroups were introduced and studied first in Ref. 8. The study continued in Refs. 9, 10, 15, and 19, cf. also Ref. 17.

Definition 2.2: A map $r:X^2\to X^2$ is *square-free* if it acts trivially on $\mathrm{diag}(X^2)$ i.e., $r(xx)=xx$, for all $x\in X$.

Example 2.3: Let X be a nonempty set and let $r(xy)=yx$. Then (X,r) is a square-free solution, which is called *the trivial solution*.

Example 2.4 (Permutational solution, Lyubashenko, Ref. 5): Let X be a nonempty set, let f,g be maps $X\to X$ and let $r(xy)=g(y)f(x)$. Then (a) (X,r) is nondegenerate if and only if f and g are bijective; (b) (X,r) is braided if and only if $fg=gf$; (c) (X,r) is involutive if and only if $f=g^{-1}$.

Remark 2.5: Note that for any permutation f of X, the map r defined as $r(xy)=f(y)f^{-1}(x)$, is a solution, but in general r is not square-free. In fact, a permutational involutive solution r is square-free if and only if $f=id_X$, i.e., $r=id_{X^2}$. Nevertheless, we prove in 3.7 that each square-free solution behaves "locally" as a permutational solution.

Clearly, when the order $|X|=2$, the only square-free solution (X,r) is the trivial one. The lowest order of X which allows a nontrivial, square-free solution is 3, as shown in the following:

Example 2.6: Let $X=\{x_1,x_2,x_3\}$. Up to renumerating of the set X there exists a unique nontrivial square-free solution (X,r), namely,

$$r(x_3x_1)=x_2x_3,\quad r(x_2x_3)=x_3x_1,$$

$$r(x_3x_2)=x_1x_3,\quad r(x_1x_3)=x_3x_2,$$

$$r(x_2x_1)=x_1x_2,\quad r(x_1x_2)=x_2x_1,\quad r(x_ix_i)=x_ix_i,\quad i=1,2,3.$$

Up to isomorphism of solutions, there exist 5 square-free solutions (X,r) with $|X|=4$. The one with the greatest number nontrivial relations is given in the following example.

Example 2.7: Let $X=\{x_1,x_2,x_3,x_4\}$ and let r be defined as

$$r(x_1x_3)=x_4x_2,\quad r(x_4x_2)=x_1x_3,\quad r(x_1x_4)=x_3x_2,\quad r(x_3x_2)=x_1x_4,$$

$$r(x_2x_3)=x_4x_1,\quad r(x_4x_1)=x_2x_3,\quad r(x_2x_4)=x_3x_1,\quad r(x_3x_1)=x_2x_4,$$

$$r(x_1x_2)=x_2x_1,\quad r(x_2x_1)=x_1x_2,\quad r(x_3x_4)=x_4x_3,\quad r(x_4x_3)=x_3x_4,$$

$$r(x_ix_i)=x_ix_i,\quad i=1,\ldots,4.$$

Then (X,r) is a square-free solution. Consider the permutation $\sigma=(12)(34)$. For x,y which belong to different orbits of σ one has $r(xy)=\sigma(y)\sigma^{-1}(x)$, and when x and y belong to the same orbit, then $r(xy)=\sigma^2(y)\sigma^{-2}(x)=yx$.

Definition 2.8: The braid group B_n is the group generated by n generators $b_1,\ldots,b_n$ and defining relations

$$b_ib_j=b_jb_i,|i-j|>1; \tag{2.3}$$

$$b_ib_{i+1}b_i=b_{i+1}b_ib_{i+1}. \tag{2.4}$$

Recall that the symmetric group S_n is isomorphic to the quotient of B_n by the relations $b_i^2=1$.

The following remark is obvious, see for example Ref. 6.

Remark 2.9: Let $m\geqslant 3$ be an integer. (i) The assignment $b_i\to r^{ii+1}$, $1\leqslant i\leqslant m-1$, extends to an action of B_m on X^m if and only if (X,r) is a braided set. (ii) The assignment $b_i\to r^{ii+1}$, $1\leqslant i\leqslant m-1$, extends to an action of S_m on X^m if and only if (X,r) is a symmetric set. (Here, as usual, $r^{ii+1}=id_{X^{(i-1)}}\times r\times id_{X^{(m-i-1)}}$.)

The next well-known fact (see Ref. 6), gives the relation between the braided sets (i.e., the set-theoretic solutions of the Yang–Baxter equation) and the set-theoretic solutions of the quantum Yang–Baxter equation.

Fact 2.10: Let $r:X^2\to X^2$ be a bijection, $\sigma:X^2\to X^2$ be the flip $\sigma(xy)=yx$, for all $x,y\in X$. Let $R=\sigma\circ r$ (i.e., R is the so called R-matrix *corresponding to r). Then r satisfies the set-theoretic Yang–Baxter equation if and only if R satisfies the quantum Yang–Baxter equation:*

$$R^{12}R^{13}R^{23}=R^{23}R^{13}R^{12}. \tag{2.5}$$

Furthermore, r is involutive if and only if R satisfies (2.5) and the unitarity condition

$$R^{21}R=1. \tag{2.6}$$

In the spirit of a recent trend called a *combinatorial approach in algebra*, to each bijective map $r:X^2\to X^2$ we associate canonically finitely presented algebraic objects (see precise definition in 2.12) generated by X and with quadratic defining relations $\mathfrak{R}$ naturally determined as

$$\mathfrak{R}=\mathfrak{R}(r)=\{(u=r(u))|u\in X^2,u\neq r(u)\text{ as words in }X^2\}. \tag{2.7}$$

We study the close relations between the combinatorial properties of the defining relations, e.g., of the map r, and the structural properties of the associated algebraic objects.

Notation 2.11: For a nonempty set X, as usual, we denote by $\langle X\rangle$ the free semigroup generated by X, and by $k\langle X\rangle$—the free associative k-algebra generated by X, where k is an arbitrary field. For a set $F\subseteq k\langle X\rangle$, (F) denotes the two sided ideal of $k\langle X\rangle$, generated by F.

Definition 2.12: Assume that $r:X^2\to X^2$ is an involutive, bijective map.

(i) The semigroup

$$S = S(X,r) = \langle X; \mathfrak{R}(r) \rangle,$$

with a set of generators X and a set of defining relations $\mathfrak{R}(r)$ is called *the semigroup associated with* (X,r).

(ii) *The group* $G=G(X,r)$ *associated with* (X,r) is defined as

$$G = G(X,r) = {}_{gr}\langle X; \mathfrak{R}(r) \rangle.$$

(iii) For arbitrary fixed field k, *the k-algebra associated with* (X,r) is defined as

$$\mathcal{A} = \mathcal{A}(k,X,r) = k\langle X \rangle / (\mathfrak{R}(r)). \tag{2.8}$$

Clearly $\mathcal{A}$ is a quadratic algebra, generated by X and with defining relations $\mathfrak{R}(r)$. Furthermore, $\mathcal{A}$ is isomorphic to the semigroup algebra $kS(X,r)$.

Manin[25] introduced the notion of a *Yang–Baxter algebra*. He calls *a Yang–Baxter algebra* a quadratic algebra A with defining relation determined via arbitrary fixed Yang–Baxter operator. In this spirit we give the following definition.

Definition 2.13: Assume (X,r) is a solution. Then $S(X,r)$, $G(X,r)$, and $\mathcal{A}(k,X,r)$ are called, respectively, *the Yang–Baxter semigroup, the Yang–Baxter group*, and *the Yang–Baxter k-algebra, associated with* (X,r). We shall also use the abbreviation "YB" for "Yang–Baxter."

In the case when (X,r) is a solution, $G(X,r)$ is also called *the structure group of* (X,r), see Ref. 6.

Example 2.14: Let (X,r) be the trivial solution, i.e., $r(xy)=yx$, for all $x,y \in X$, then clearly, $S(X,r)=[x_1,\ldots,x_n]$, is the free Abelian semigroup generated by X, $G(X,r)=Z^X$, is the free Abelian group generated by X, and $\mathcal{A}(k,X,r)=k[x_1,\ldots,x_n]$ is the commutative polynomial ring over k.

Definition 2.15: Let $S=\langle X;\mathfrak{R}\rangle$ be a semigroup with a set of generators X and a set of quadratic binomial defining relations

$$\mathfrak{R} = \{xy = y'x' | x,y,x',y' \in X\}.$$

We assume that each monomial $u \in X^2$, occurs in at most one relation in $\mathfrak{R}$. Define the map $r = r(S): X^2 \to X^2$ as follows:

(i) $r(xy)=xy$, if xy is a monomial of length 2 which does not occur in any relation in $\mathfrak{R}$; and
(ii) if $(xy=y'x') \in \mathfrak{R}$, then we set $r(xy)=y'x'$ and $r(y'x')=xy$. We call $r(S)$ *the map associated with the semigroup S*.

Note that if r is the map defined by the set of relations of a YB-semigroup $S=\langle X;\mathfrak{R}\rangle$, then the set $(X;r)$ is always symmetric, since clearly, $r^2=id_{X^2}$.

We give now an example of a Yang–Baxter semigroup S with 11 generators. In fact, S belongs to the class of semigroups of skew-polynomial type, 2.19, and the map $r(S)$ is a square-free solution.

Example 2.16: Let $S=\langle X;\mathfrak{R}\rangle$, where the set of generators is $X=\{1,2,\ldots,8,a,b,c\}$ and the defining relations are

$$1a = a2, \quad 2a = a1, \quad 2b = b3, \quad 3b = b2, \quad 3a = a4, \quad 4a = a3, \quad 4c = c1, \quad 1c = c4,$$

$$5a = a6, \quad 6a = a5, \quad 6b = b7, \quad 7b = b6, \quad 7a = a8, \quad 8a = a7, \quad 8c = c5, \quad 5c = c8,$$

$$1b = b5, \quad 5b = b1, \quad 2c = c6, \quad 6c = c2, \quad 3c = c7, \quad 7c = c3, \quad 4b = b8, \quad 8b = b4,$$

$$ab = ca, \quad ac = ba, \quad bc = cb, \quad ij = ji, \quad 1 \leqslant i,j \leqslant 8.$$

Remark 2.17: Let S_0 be a semigroup of skew-polynomial type (see 2.19). Let $r=r(S_0)$ be the map defined by the relations of S_0. Then (X,r) is a square-free solution (cf Ref. 15, Theorem 1.2,

also Theorem 2.26). Furthermore, S_0 is a cancelative semigroup, and has a group of quotients $\mathrm{gr}(S_0)$, which is a central localization of S_0, see Ref. 19. It is clear, that the groups $\mathrm{gr}(S_0)$ and the associated group $G(X,r)$ are isomorphic. Moreover, the set X is embedded in $G(X,r)$.

The semigroups of skew-polynomial type were discovered while the author was searching for a new class of Artin–Schelter regular rings. It turned out that *the skew-polynomial rings with binomial relations*, or shortly *binomial skew-polynomial rings* introduced and studied in Refs. 8–10, provide a class of Artin–Schelter regular rings of arbitrary global dimension, cf. Refs. 10, 14, and 15. Furthermore, with each ring $\mathcal{A}_0$ of this type we associate (uniquely) a semigroup $\mathcal{S}_0$ which defines (via its relations) a nondegenerate set-theoretic solution $r(\mathcal{S}_0)$ of the Yang–Baxter equation, cf. Ref. 15. It is easy to generalize this result by showing that each skew-polynomial ring with binomial relations defines a solution of the classical Yang–Baxter equation, see Theorem 9.7. The semigroup $\mathcal{S}_0$ is called a semigroup of skew-polynomial type. The results in Ref. 15 and further study of the combinatorial properties of the solutions inspired the following Conjecture, which we reported first in a talk at the International Conference in Ring Theory, Miskolc, 1996, see also Refs. 11 and 12.

Main Conjecture 2.18 (Ref. 13): Let (X,r) be a square-free (nondegenerate, involutive) solution of the Yang–Baxter equation. Then the set X can be ordered so, that the associated semigroup is of skew-polynomial type.

Definition 2.19: We say that the semigroup S_0 is *a semigroup of skew-polynomial type* (or shortly, *a skew-polynomial semigroup*) if it has a standard finite presentation as $S_0=\langle X;\mathfrak{R}_0\rangle$, where the set of generators X is ordered: $x_1<x_2<\cdots<x_n$, and the set

$$\mathfrak{R}_0=\{\, x_jx_i=x_{i'}x_{j'}\,|\,1\leqslant i<j\leqslant n,1\leqslant i'<j'\leqslant n\},$$

contains precisely $n(n-1)/2$ quadratic square-free binomial defining relations, each of them satisfying the following conditions:

(i) each monomial $xy\in X^2$, with $x\neq y$, occurs in exactly one relation in $\mathfrak{R}_0$; a monomial of the type xx does not occur in any relation in $\mathcal{R}_0$;
(ii) if $(x_jx_i=x_{i'}x_{j'})\in\mathcal{R}_0$, with $1\leqslant i<j\leqslant n$, then $i'<j'$, and $j>i'$ (further studies show that this also implies $i<j'$, see Ref. 9);
(iii) the monomials $x_kx_jx_i$ with $k>j>i,1\leqslant i,j,k,\leqslant n$ do not give rise to new relations in S_0, or equivalently, cf. Ref. 4, $\mathfrak{R}_0$ is a Groebner basis with respect to the degree-lexicographic ordering of the free semigroup $\langle X\rangle$.

Remark 2.20: Suppose S_0 is a semigroup of skew-polynomial type. It follows from the Diamond Lemma[4] that, each element w of S can be presented uniquely as an ordered monomial

$$w=x_1^{\alpha_1}x_2^{\alpha_2}\cdots x_n^{\alpha_n},$$

where $\alpha_i\geqslant 0,1\leqslant i\leqslant n$. This presentation is called *the normal form of w* and denoted as $\mathrm{Nor}(w)$. It follows from the Diamond lemma, that two monomials w_1,w_2 in the free semigroup $\langle X\rangle$ are equal in S if and only if their normal forms coincide, $\mathrm{Nor}(w_1)=\mathrm{Nor}(w_2)$. Thus S_0 can be identified as a set with the set of ordered monomials

$$\mathcal{N}_0=\{x_1^{\alpha_1}x_2^{\alpha_2}\cdots x_n^{\alpha_n}|\alpha_i\geqslant 0,1\leqslant i\leqslant n\}. \tag{2.9}$$

Furthermore, for an arbitrary field k, the set $\mathcal{N}_0$ is a k-basis of the quadratic algebra

$$A_0=k\langle X\rangle/(\mathfrak{R}_0)\simeq kS_0.$$

Clearly, A_0 is a Poincaré–Birkhoff–Witt-algebra in the sense of Priddy[27] with $\mathcal{N}_0$ as a PBW-basis.

Remark 2.21: In Ref. 19 the skew-polynomial semigroups S_0 are called *binomial semigroups*.

We now recall the definition of the semigroups of *I*-type, see Ref. 15, which are closely related to both—the semigroups of skew-polynomial type and the set-theoretic solutions of Yang–Baxter equation. The rings of *I*-type were introduced and studied by Tate and Van den Bergh in their work on the homological properties of Sklyanin Algebras.[34]

Notation 2.22: Until the end of the paper we shall denote by

$$\mathcal{U} = [u_1, \ldots, u_n], \tag{2.10}$$

the free commutative multiplicative semigroup generated by $u_1, \ldots, u_n$.

Definition 2.23 (Ref. 15): A semigroup S generated by $\{x_1, \ldots, x_n\}$ is said to be of *(left) I-type* if there exists a bijection $v: \mathcal{U} \to S$ called *(a left) I-structure*, such that $v(1)=1$, and such that for each $a \in \mathcal{U}$ there is an equality of sets $\{v(u_1a), v(u_2a), \ldots, v(u_na)\} = \{x_1v(a), x_2v(a), \ldots, x_nv(a)\}$. Analogously one defines *a right I-structure* $v_1: \mathcal{U} \to S$.

Remark 2.24: It can be extracted from Ref. 15, see also (4.1), that if (X,r) is a square-free solution, and $S=S(X,r)$ is the associated YB semigroup, then

(a) There exists a unique left *I*-structure $v: \mathcal{U} \to S$, such that $v(u_i)=x_i$, for $1 \leqslant i \leqslant n$.
(b) There exists a unique right *I*-structure $v_1: \mathcal{U} \to S$, such that $v_1(u_i)=x_i$ for $1 \leqslant i \leqslant n$.

In Sec. IV, Proposition 4.16, we show that a semigroup of *I*-type is a distributive lattice with respect to the order induced from "one-sided" divisibility, defined below.

Definition 2.25: For every pair $a, b \in S$ we set

(i) $a|_l b$, if and only if there exists a monomial $c \in S$, such that $b=ca$. We call this relation *divisibility with respect to the left multiplication.*
(ii) $a|_r b$, if and only if there exists a monomial $c \in S$, such that $b=ac$. This relation is called *divisibility with respect to the right multiplication.*

The following theorem proved in Sec. VI verifies the Main Conjecture 2.18.

Main Theorem 2.26: *Assume that X is a finite set of order $n \geqslant 1$, and $r: X \times X \to X \times X$ is a square-free involutive bijection. Let $S=S(X,r)$ be the semigroup associated with (X,r) and let $\mathcal{A}=\mathcal{A}(k,X,r)$ be the quadratic k-algebra associated with (X,r), where k is an arbitrary field. Then the following conditions are equivalent:*

(1) *(X,r) is a nondegenerate solution of the set-theoretic Yang–Baxter equation.*
(2) *$S=S(X,r)$ is a semigroup of I-type.*
(3) *There exists an ordering on X, $X=\{x_1 < x_2 < \cdots < x_n\}$, such that $S=S(X,r)$ is a semigroup of skew-polynomial type.*
(4) *There exists an ordering on X, $X=\{x_1 < x_2 < \cdots < x_n\}$ such that for every field k the quadratic k-algebra $\mathcal{A}=\mathcal{A}(k,X,r)$ is a Poincaré–Birkhoff–Witt algebra, with a k-basis—the set of ordered monomials $\mathcal{N}_0$.*

Moreover, each of these conditions implies that the solution (X,r) is decomposable, i.e., X a disjoint union of two nonempty r-invariant subsets.

Corollary 2.27: Let (X,r) be a square-free solution, with associated semigroup $S=S(X,r)$. Then $(S, |_l)$ is a distributive lattice. Furthermore the left I-structure $v: \mathcal{U} \to S$ is an isomorphism of lattices.

Condition 2.26.2 implies, cf. Refs. 14 and 15, various nice algebraic and homological properties of the algebra $\mathcal{A}=\mathcal{A}(k,X,r)$, like being a Noetherian domain, Koszul, Cohen–Macaulay, Artin–Schelter regular, etc. In particular the semigroup S is cancelative. Hence it is naturally embedded in its group of quotients $\mathrm{gr}(S)=G(X,r)$. We recall these results in Theorem 6.1.

My student, Garcia Roman shows in Ref. 29 that for an explicitly given solution (X,r), condition 2.26.3 is equivalent to a standard problem from Linear Programming.

In Ref. 16 is presented a matched pairs approach to the set-theoretic solutions of the Yang–Baxter equation. One of the main results in Ref. 16, given here as Theorem 5.6 covers all known constructions of solutions (X,r), restricted to the case of square-free solutions, with X a finite set.

In Sec. VIII we study retractability of solutions, generalized twisted unions of solutions, and multipermutation solutions.

Section IX gives an application of the Main Theorem to a particular class of solutions of the classical Yang–Baxter equation called *binomial solutions of YBE*. We show that each binomial solution of the classical Yang–Baxter equation is obtained from binomial skew polynomial rings. Therefore the associated Yang–Baxter algebra has a PBW type k-basis, and the nice algebraic and homological properties of binomial skew-polynomial rings. The study of these algebras continues in Ref. 14.

We close this section with the following conjecture:

Strong Conjecture 2.28: (I) Every square-free solution (X,r), where X is a finite set of order $n\geqslant 2$, is retractable, see 8.5. Furthermore (X,r) is a multipermutation solution of level $m<n$.

(II) Every multipermutation square-free solution of level m is a generalized twisted union of multipermutation solutions of levels $\leqslant m-1$.

III. THE CYCLIC CONDITION AND COMBINATORICS IN $S(X,r)$

In this section we introduce a combinatorial technique for non-degenerate square-free solutions (X,r), which associates cycles in $\mathrm{Sym}(X)$ to each pair of elements y,x in X. We call the corresponding property of r *cyclic condition*. The cyclic condition is the base for all combinatorial techniques in this paper. We use it here to deduce more precise pictures of the left and right actions of the group $G(X,r)$ on X, and to show that each involutive square-free solution acts "locally" as a permutational solution. Lemma 3.9 gives more precise information about the relations $\mathfrak{R}(r)$, which is used throughout the paper. We use the lengths of the cycles occurring in $S(X,r)$ to deduce some important relations of higher degrees in $S(X,r)$, and to introduce an invariant integer $M=M(X,r)$ called *the cyclic degree of* (X,r).

Definition 3.1: Let $r:X\times X\to X\times X$ be a bijection.

(1) We say that (X,r) satisfies *the weak cyclic condition*, if for every pair $y,x\in X$, there exist two disjoint cycles $\mathcal{L}_y^x=(x_1,\ldots,x_m)$ and $\mathcal{R}_x^y=(y_k,\ldots,y_1)$ in the symmetric group $\mathrm{Sym}(X)$, such that $x=x_1,y=y_1$, and for all $1\leqslant i\leqslant m$, $1\leqslant j\leqslant k$ there are equalities:

$$r(y_jx_i)=\mathcal{L}_y^x(x_i)\mathcal{R}_x^y(y_j)=x_{i+1}y_{j-1}, \tag{3.1}$$

where $x_{m+1}:=x_1$, and $y_0:=y_k$.

In particular, $r(yx)=\mathcal{L}_y^x(x)\mathcal{R}_x^y(y)=x_2y_k$.

In this case we also say that the semigroup $S(X,r)$ satisfies *the weak cyclic condition*.

(2) (X,r) satisfies *the cyclic condition*, if for every pair $y,x\in X$, there exist two disjoint cycles $\mathcal{L}_y^x=(x_1,\ldots,x_m)$ and $\mathcal{L}_x^y=(y_1,\ldots,y_k)$ in $\mathrm{Sym}(X)$, such that $x=x_1,y=y_1$, and for all $1\leqslant i\leqslant m$, $1\leqslant j\leqslant k$ there are equalities:

$$r(x_iy_j)=y_{j+1}x_{i-1} \text{ and } r(y_jx_i)=x_{i+1}y_{j-1}, \tag{3.2}$$

where $x_0=x_m,x_{m+1}:=x_1$, and $y_0:=y_k,y_{k+1}=y_1$.

In particular, for every pair $(y,x)\in X\times X$, the disjoint cycles $\mathcal{L}_y^x$ and $\mathcal{L}_x^y$ satisfy

$$r(y,x)=\mathcal{L}_y^x(x)(\mathcal{L}_x^y)^{-1}(y), \text{ and } r(x,y)=\mathcal{L}_x^y(y)(\mathcal{L}_y^x)^{-1}(x). \tag{3.3}$$

We call $\mathcal{L}_x^y$ and $\mathcal{L}_y^x$ *the pair of cycles associated with* (y,x).

If this is the case for (X,r) we also say that the semigroup $S(X,r)$ satisfies *the cyclic condition*.

Remark 3:2: Clearly, the (strong) cyclic condition implies that r is involutive. We will show that every involutive square-free solution (X,r) satisfies the cyclic condition and use this to study the left (and the right) action of $G(X,r)$ on X. Note that if the cyclic condition holds, and we set

$$\sigma=\sigma_{y,x}=\sigma_{x,y}=(x_1,\ldots,x_m)(y_1,\ldots,y_k)\in\mathrm{Sym}(X),$$

the map r is expressible "locally" as a permutational solution

$$r(y_jx_i)=\sigma(x_i)\sigma^{-1}(y_j) \quad \text{and} \quad r(x_iy_j)=\sigma(y_j)\sigma^{-1}(x_i).$$

If we do not assume involutiveness for r, then, in general, only the weak cyclic condition is satisfied. We give an example, see 3.3, of a noninvolutive solution in which the cyclic condition does not hold.

Example 3.3: Let $X=\{x_1,x_2,x_3,x_4,x_5,x_6\}$ and suppose the map $r:X^2\to X^2$ is defined as

$$x_1x_2\leftrightarrow x_2,x_1; \quad x_3x_4\leftrightarrow x_4x_3;$$

$$x_3x_5\leftrightarrow x_5x_3; \quad x_3x_6\leftrightarrow x_6x_3;$$

$$x_4x_5\leftrightarrow x_5x_4; \quad x_4x_6\leftrightarrow x_6x_4; \quad xx\leftrightarrow xx, \text{ for all } x\in X;$$

$$x_1x_3\to x_4x_2\to x_1x_5\to x_6x_2\to x_1x_3;$$

$$x_1x_4\to x_3x_2\to x_1x_6\to x_5x_2\to x_1x_4;$$

$$x_2x_3\to x_4x_1\to x_2x_5\to x_6x_1\to x_2x_3;$$

$$x_2x_4\to x_3x_1\to x_2x_6\to x_5x_1\to x_2x_4.$$

Then (X,r) is a noninvolutive solution, with $r^4=id_{X^2}$. Furthermore

$$\mathcal{L}_{x_1}=(x_3x_4)(x_5x_6), \quad \mathcal{R}_{x_1}=(x_3x_6)(x_4x_5), \quad \text{and } \mathcal{R}_{x_1}\neq(\mathcal{L}_{x_1})^{-1}.$$

Recall first a well known fact from Ref. 6.

Fact 3.4 (Ref. 6): Let (X,r) be nondegenerate, $G=G(X,r)$. Then (X,r) is a braided set if and only if the following three conditions are satisfied:

(1) *The assignment $x\to\mathcal{L}_x$ induces a left action of G on X;*
(2) *The assignment $x\to\mathcal{R}_x$ induces a right action of G on X;*
(3) *The following equality holds for any $x, y, z\in X$:*

$$\mathcal{L}_{\mathcal{R}_{\mathcal{L}_y(z)}(x)}(\mathcal{R}_z(y))=\mathcal{R}_{\mathcal{L}_{\mathcal{R}_y(x)}(z)}(\mathcal{L}_x(y)). \tag{3.4}$$

Notation 3.5: We shall denote by $O_G(x)$ the orbit of x, $x\in X$, under the left action of G on X.

Lemma 3.6: Let $r:X\times X\to X\times X$ be a bijection. Then in the notation of 3.1 the following holds:

(I) *Conditions (1), (2), and (3) are equivalent.* (II) *Conditions (4), (5), and (6) are equivalent. Each of them implies (1), (2), and (3).*

(1) *(X,r) satisfies the weak cyclic condition.*
(2) *For every $x,y\in X, x\neq y$, there are equalities*

$$\mathcal{L}_{\mathcal{R}_x(y)}(x)=\mathcal{L}_y(x) \quad \textit{and } \mathcal{R}_{\mathcal{L}_y(x)}(y)=\mathcal{R}_x(y). \tag{3.5}$$

(3) *For all $i,j, 1\leqslant i\leqslant m$, $1\leqslant j\leqslant k$, there are equalities*

$$\mathcal{L}^{x_i}_{y_j}=\mathcal{L}^x_y=(x_1,\ldots,x_m), \quad \textit{and } \mathcal{R}^{y_j}_{x_i}=\mathcal{R}^y_x=(y_1,\ldots,y_k). \tag{3.6}$$

(4) *(X,r) satisfies the cyclic condition.*
(5) *For all $x,y\in X$ there are equalities:*

$$\mathcal{R}_x(y)=\mathcal{L}_x^{-1}(y), \quad \text{and } \mathcal{L}_{\mathcal{R}_x(y)}(x)=\mathcal{L}_y(x). \tag{3.7}$$

(6) *For all $i,j, 1\leqslant i\leqslant m$, $1\leqslant j\leqslant k$, there are equalities*

$$\mathcal{L}_{y_j}^{x_i} = (\mathcal{R}_{y_j}^{x_i})^{-1} = \mathcal{L}_y^x = (x_1, \ldots, x_m), \tag{3.8}$$

and

$$\mathcal{L}_{x_i}^{y_j} = (\mathcal{R}_{x_i}^{y_j})^{-1} = \mathcal{L}_x^y = (y_1, \ldots, y_k). \tag{3.9}$$

The following theorem gives an account of various conditions on the bijective maps $r: X^2 \to X^2$ and the corresponding semigroup $S(X,r)$. For some of them we assume neither that r is necessarily a solution of the Yang–Baxter equation, nor we assume that r is involutivene.

Theorem 3.7: *Let $r: X^2 \to X^2$ be a bijective map, denoted by (X,r). Let $S = S(X,r)$ be the semigroup associated to (X,r). Let $\mathcal{L}_x$ and $\mathcal{R}_x$ be the left and right components of r, introduced in 2.1. Consider the following conditions:*

(1) *(a) (X,r) is left nondegenerate; (b) (X,r) is right nondegenerate.*
(2) *(a) (Right Ore condition) For every pair $a,b \in X$, there exists a unique pair $x,y \in X$, such that $ax = by$; (b) (Left Ore condition) For every pair $a,b \in X$ there exists a unique pair $z,t \in X$, such that $za = tb$.*
(3) *(X,r) is square-free and nondegenerate.*
(4) *$\mathcal{L}_x$ is a bijection and $\mathcal{L}_x(y) \neq x$, for each $y \neq x$; $\mathcal{R}_y$ is a bijection and $\mathcal{R}_y(x) \neq y$, for each $y \neq x$.*

Then the following is true:

(A) *The conditions 1(a) and 2(a) are equivalent; the conditions 1(b) and 2(b) are equivalent;*
(B) *The conditions 3 and 4 are equivalent.*
(C) *If (X,r) is a nondegenerate square-free solution of the Yang–Baxter equation (not necessarily involutive) then the weak cyclic condition 3.1.1 holds.*
(D) *If (X,r) is a nondegenerate involutive square-free solution of the Yang–Baxter equation, then the cyclic condition 3.1.2 holds.*

Proof: (A) $(1.a) \Rightarrow (2.a)$ Let $a,b \in X$. By our assumption the function $\mathcal{L}_a$ is a bijection of X onto itself, so there exists a unique y such that $\mathcal{L}_a(y) = b$, hence the equality $r(ay) = \mathcal{L}_a(y)\mathcal{R}_y(a)$ gives $r(ay) = bz$, for some $z \in X$. But r is a bijective map on X^2 onto itself, so z is also determined uniquely. The implication $(1.b) \Rightarrow (2.b)$ is analogous.

The implications $(2.a) \Rightarrow (1.a)$ and $(2.b) \Rightarrow (1.b)$ are obvious.

(B) $3 \Rightarrow 4$. Let $x,y \in X$, $x \neq y$. By assumption $r(xx) = xx$, so $\mathcal{L}_x(x) = x \neq \mathcal{L}_x(y)$. $4 \Rightarrow 3$. Let $x \in X$, clearly there is an equality of sets

$$\{\mathcal{L}_x(y) | y \in X, y \neq x\} = X \setminus \{x\}$$

so $\mathcal{L}_x(x) = x$. Similarly $\mathcal{R}_x(x) = x$, thus $r(xx) = xx$.

For the following lemmas we assume the hypothesis of the theorem.

Lemma 3.8: If (X,r) is nondegenerate and square-free, then $r(xy) \neq xy$ if and only if $x \neq y$.

Proof: The statement of the lemma follows immediately from B and from the equation $r(xy) = \mathcal{L}_x(y)\mathcal{R}_y(x)$. □

Lemma 3.9 gives important and explicit information about the relations $\mathfrak{R}(r)$. In fact relations (3.10) and (3.11) are used in almost every computation throughout the paper.

Lemma 3.9: If (X,r) is a nondegenerate and square-free solution of the Yang–Baxter equation (not necessarily involutive), then the following conditions hold in S:

$$[yx = x'y', x \neq y] \Rightarrow [yx' = x''y', y'x = x'y''], \tag{3.10}$$

for some $x'', y'' \in X$.

Furthermore, there are equalities:

$$yxx = x'x'y'', \quad \text{and } yyx = x''y'y'. \tag{3.11}$$

Proof: Let $x \neq y$ and let $yx = x'y'$, or equivalently, $r(yx) = x'y'$. It follows from (3.8) that $yx \neq x'y'$, as monomials in the free semigroup $\langle X \rangle$. Assume that

$$r(yx') = x''y''. \tag{3.12}$$

Now consider the "Yang–Baxter diagram"

$$\begin{array}{ccc} yyx & \overset{r\times id_X}{\longrightarrow} & yyx \\ id_X \times r \downarrow & & \downarrow id_X \times r \\ yx'y' & & yx'y' \\ r \times id_X \downarrow & & \downarrow r \times id_X \\ x''y''y' & \overset{id_X\times r}{\longrightarrow} & x''y''y' \end{array} . \tag{3.13}$$

It follows then that $r(y''y') = y''y'$, which, since r is square-free, is possible only if $y'' = y'$. We have shown that

$$(yx = x'y') \Rightarrow (yx' = x''y') \tag{3.14}$$

($y' = y$ is possible). Note that $x'' \neq y, y'$.

Similarly, we prove that

$$(yx = x'y') \Rightarrow (y'x = x'y'') \tag{3.15}$$

for some appropriate $y'' \in X$.

The equality $yyx = x''y'y'$ in S also follows from the diagram (3.13). □

The validity of conditions C and D can be deduced from the following lemma. Note that in the hypothesis of the lemma we do not assume that (X, r) is a solution.

Lemma 3.10: (i) (X, r) *satisfies the weak cyclic condition 3.1.1 if and only if r is nondegenerate and satisfies condition* (3.10).

(ii) Suppose (X, r) *satisfies the weak cyclic condition. Then r is involutive if and only if for every pair* $y, x \in X$ *one has* $\mathcal{L}_y^x = (\mathcal{R}_y^x)^{-1}$.

Proof: Clearly, the weak cyclic condition 3.1.1 implies (3.10) and r nondegenerate. Assume now that r is nondegenerate and condition (3.10) holds.

Suppose $y, x \in X$, $y \neq x$, and $r(yx) = x'y'$ ($x' = x$, or $y' = y$ are possible). We denote $x_1 = x$, $x_2 = x'$, and apply (3.10) successively to obtain a sequence of pairwise distinct elements $x_1, \ldots, x_m \in X$, such that

$$r(yx_i) = x_{i+1}y', \quad \text{for } 1 \leqslant i \leqslant m-1, \quad \text{and } r(yx_m) = x_1y'. \tag{3.16}$$

Similarly (after an appropriate re-numeration) we obtain $y_1 = y, y_2, \ldots, y_k = y' \in X$, such that

$$r(y_jx_1) = x_2y_{j-1}, \quad \text{for } 2 \leqslant j \leqslant k, \quad \text{and } r(y_1x_1) = x_2y_m. \tag{3.17}$$

We claim that

$$r(y_jx_i) = x_{i+1}y_{j-1}, \quad \text{for } 1 \leqslant i \leqslant m, \quad 1 \leqslant j \leqslant k, \tag{3.18}$$

where $x_{m+1} := x_1$, $y_0 := y_m$. We prove (3.18) by induction on j.

Step 1: $j = 1$. Clearly (3.16), with $y_k = y'$, give the base for the induction. Assume (3.18) is satisfied for all $j, 1 \leqslant j \leqslant j_0 - 1$. We shall prove (3.18) for $j = j_0$, $1 \leqslant i \leqslant m-1$, using induction on i. The base of the induction,

$$r(y_{j_0}x_1) = x_2y_{j_0-1}, \tag{3.19}$$

follows from (3.17). Assume now (3.18) is true for all $i < i_0$. In particular,

$$r(y_{j_0}x_{i_0-1}) = x_{i_0}y_{j_0-1}. \tag{3.20}$$

Then by (3.10) one has

$$r(y_{j_0}x_{i_0}) = ty_{j_0-1}, \quad \text{for some } t \in X, \tag{3.21}$$

we apply (3.10) again and obtain

$$r(y_{j_0-1}x_{i_0}) = tz, \tag{3.22}$$

for some $z \in X$. It follows from the inductive assumption that

$$r(y_{j_0-1}x_{i_0}) = x_{i_0+1} + y_{j_0-2}, \tag{3.23}$$

which together with (3.22) gives $t = x_{i_0+1}$ thus $r(y_{j_0}x_{i_0}) = x_{i_0+1}y_{j_0-1}$. We have proven that (3.18) holds for all i, $1 \leqslant i \leqslant m$, and $j = j_0$, which verifies (3.18). This proves (i).

We set $\mathcal{L}_y^x = (x_1, \ldots, x_m) \in \mathrm{Sym}(X)$, and $(\mathcal{R}_x^y)^{-1} = (y_1, \ldots, y_k) \in \mathrm{Sym}(X)$. Consider the permutation

$$\sigma_{y,x} = (x_1, \ldots, x_m)(y_1, \ldots, y_k).$$

Clearly,

$$r(y_jx_i) = \sigma_{y,x}(x_i)\sigma_{y,x}^{-1}(y_j). \tag{3.24}$$

Assume now that r is involutive, and apply r to (3.18) to obtain $r(x_{i+1}y_{j-1}) = y_jx_i$. This implies for $1 \leqslant i \leqslant m$ and $1 \leqslant j \leqslant k$:

$$\mathcal{L}_x^y = \mathcal{L}_{x_i}^y = (y_1, \ldots, y_k) = (\mathcal{R}_x^y)^{-1} = (\mathcal{R}_{x_i}^y)^{-1}, \tag{3.25}$$

$$\mathcal{L}_y^x = \mathcal{L}_{y_j}^x = (x_1, \ldots, x_m) = (\mathcal{R}_y^x)^{-1} = (\mathcal{R}_{y_j}^x)^{-1}. \tag{3.26}$$

Conversely, (3.25) and (3.26) imply that $\sigma_{y,x} = \sigma_{x,y}$ therefore r is involutive. This proves the lemma, and completes the proof of the theorem. □

Remark 3.11: Let (X, r) be an arbitrary square-free nondegenerate solution (not necessarily involutive). Consider the left and the right actions of G on X, see (3.4), extending the assignment $y \to \mathcal{L}_y$, respectively, $x \to \mathcal{R}_x$, where $\mathcal{L}_y$, $\mathcal{R}_x \in \mathrm{Sym}(X)$ are the permutations defined via $r(yx) = \mathcal{L}_y(x)\mathcal{R}_x(y)$. Since each permutation has a presentation as a product of disjoint cycles in $\mathrm{Sym}(X)$ (unique up to commutation of multiples) we obtain that the cycle $\mathcal{L}_y^x = (x_1, \ldots, x_m)$, $(x_1 = x)$ occurs as a multiple in such a presentation of $\mathcal{L}_y$ and the cycle $\mathcal{R}_x^y = (y_1, \ldots, y_k)$ is a multiple of the corresponding presentation for $\mathcal{R}_x$. The surprising part is that each pair y_i, x_i with $1 \leqslant j \leqslant k$ and $1 \leqslant i \leqslant m$, produces the same pair of cycles: $\mathcal{L}_{y_j}^{x_i} = \mathcal{L}_y^x = (x_1, \ldots, x_m)$, and $\mathcal{R}_{x_i}^{y_j} = \mathcal{R}_x^y = (y_1, \ldots, y_k)$. Therefore although in general $\mathcal{L}_{y_j} \neq \mathcal{L}_y$, each permutation $\mathcal{L}_{y_j}$, $1 \leqslant j \leqslant k$ contains the same cycle $(x_1, \ldots, x_m)$ in its presentation as products of disjoint cycles in $\mathrm{Sym}(X)$. Analogously, the cycle $(y_1, \ldots, y_k)$ participates in the presentation of each $\mathcal{R}_{x_i}$, $1 \leqslant i \leqslant m$, as a product of disjoint cycles. We do not know how the cycles L_y^x and R_y^x, are related to each other, in the general (noninvolutive) case of square-free nondegenerate solutions, besides the obvious property, that each of them contains x, see example 3.3. In the case of involutive solutions (X, r) there is a "symmetry" $\mathcal{L}_y^x = (\mathcal{R}_y^x)^{-1} = (x_1, \ldots, x_m)$ for each pair $y \neq x, y, x \in X$.

Notation 3.12: To avoid complicated expressions, sometimes we shall use also the notation ${}^xy = \mathcal{L}_x(y)$ and $y^x = \mathcal{R}_x(y)$.

The following corollary is a "translation" of the cyclic condition in the new notation. It can be extracted from a more general result in Ref. 16.

Corollary 3.13: Let $r: X \times X \to X \times X$ be a nondegenerate involutive bijection. Consider the following conditions:

(1) ${}^{x}x=x$ *for every* $x\in X$.
(2) $r(x,x)=(x,x)$ *for every* $x\in X$.
(3) (X,r) *satisfies the cyclic condition.*
(4) *For every* $x,y\in X$ *there are equalities:*

$$ {}^{({}^{x}y)}x = {}^{y}x; \quad ({}^{y}x)^{y} = {}^{y}(x^{y}) = x. \tag{3.27}$$

Then the following is true:

(a) *Conditions 1 and 2 are equivalent.*
(b) *Conditions 3 and 4 are equivalent.*

Convention 3.14: In the rest of the paper we shall consider only involutive nondegenerate square-free solutions (X,r) of the Yang–Baxter equation; they will be briefly called *square-free solutions*.

Let $x\in X$. Clearly, for $t\in X$ the cycle $\mathcal{L}_x^t$ is of length one if and only if $xt=tx'$.

Notation 3.15: We denote by $\mathcal{G}_L=\mathcal{G}_L(X,r)$ the image of $G(X,r)$ under the group homomorphism $\mathcal{L}:G\to\mathrm{Sym}(X)$, which extends the assignment $x\to\mathcal{L}_x$. $\mathcal{G}_R=\mathcal{G}_R(X,r)$ denotes the image of $G(X,r)$ under the group homomorphism $\mathcal{R}:G\to\mathrm{Sym}(X)$, which extends the assignment $x\to\mathcal{R}_x$.

Lemma 3.16: Let (X,r) *be a square-free solution,* $\mathcal{L}_x$*, and* $\mathcal{R}_x$ *be the left and right components of r, which are extended to a left, respectively right action of* $G(X,r)$ *on X. Then*

(1) *The permutation* $\mathcal{L}_x$ *is presented as a product of disjoint cycles in* $\mathrm{Sym}(X)$ *via the equality*

$$\mathcal{L}_x = \mathcal{L}_x^{t_1}\mathcal{L}_x^{t_2}\cdots\mathcal{L}_x^{t_s}, \tag{3.28}$$

where $t_1,\ldots,t_s$ *are representatives of all disjoint orbits of* $\mathcal{L}_x$ *in X.*

(2) *The permutations* $\mathcal{L}_x$ *and* $\mathcal{R}_x$ *satisfy the equality*

$$\mathcal{R}_x = (\mathcal{L}_x)^{-1}. \tag{3.29}$$

Furthermore, the two permutation groups determined by the left and right action of $G(X,r)$ *on X coincide:*

$$\mathcal{G}_R = \mathcal{G}_L.$$

(3) *The assignment* $x\to\mathcal{L}_x$, $x\in X$, *determines the solution r uniquely, via the formula*

$$r(x,y) = \mathcal{L}_x(y)(\mathcal{L}_y)^{-1}(x).$$

To each solution we associate an invariant integer number $M=M(X,r)$ defined as follows.

Definition 3.17: (1) For every $x\in X$ we denote by M_x the order of the permutation $\mathcal{L}_x$ in $\mathrm{Sym}(X)$, i.e. (in the notation of 3.16) the least common multiple of the lengths of the cycles $\mathcal{L}_x^{t_i}$, $1\leqslant i\leqslant s$.

(2) By $M=M(X,r)$ we denote the least common multiple of all M_x, where $x\in X$, and call M the *cyclic degree* of the solution (X,r).

Lemma 3.18: Suppose $ax=ya'$, *for some* $x,y,a,a'\in X$. *Then* $M_x=M_y$.

Proof: It will be enough to show that the length k of each cycle $\mathcal{L}_x^{\xi}$ occurring in $\mathcal{L}_x$ divides M_y. □

Proposition 3.19: Assume $x,y\in X$, *and* $O_G(x)=O_G(y)$. *Then* $M_y=M_x$.

Corollary 3.20: Suppose $M_x\neq M_y$, *for some* $x,y\in X$. *Then G acts nontransitively on X, and X is decomposable into a disjoint union of two r-invariant subsets.*

The following proposition follows easily from the cyclic condition, and 3.17.

Proposition 3.21: Let (X,r) *be a square-free solution of cyclic degree M. Let p, and q be arbitrary natural numbers. Suppose* $y,x\in X$, $y\neq x$, *and let k, m be the natural numbers defined in 3.1. Let* M_x *denote the order of* $\mathcal{L}_x$. *Then the following equalities hold:*

$$y^m x = x y_k^m, \tag{3.30}$$

$$y^p x^q = (x')^q (y')^p, \quad \text{where } x' = (\mathcal{L}_y)^p(x), \quad \text{and } y' = (\mathcal{L}_x)^{-q}(y), \tag{3.31}$$

$$x^{M_x} y = y (x_m)^{M_x}, \tag{3.32}$$

$$x^M y^M = y^M x^M. \tag{3.33}$$

The next corollary follows immediately from (3.33).

Corollary 3.22: Let (X,r) be a square-free solution, then the center of the Yang–Baxter algebra $\mathcal{A}(k,X,r)$ contains all symmetric functions in $x_1^M, x_2^M, \ldots, x_n^M$.

Corollary 3.23: Let (X,r) be a square-free solution. Then the group $A = gr[x_1^M, \ldots x_n^M]$ is a free Abelian subgroup of $G(X,r)$ of index M^n.

IV. THE LATTICE STRUCTURE OF $S(X,r)$

In this section we show that for a semigroup $\mathcal{S}$ of left I-type, the relation $|_l$ of left divisibility, defined in 2.25, and the left I-structure $v:\mathcal{U}\to S$, see 2.23, are compatible, and prove that $(S,|_l)$ is a distributive lattice. Analogous results are true for semigroups with right I-structure $v_1:\mathcal{U}\to S$. As a corollary we obtain that the Yang–Baxter semigroup $S=S(X,r)$ has a structure of distributive lattice, induced by its left I-structure v. We keep the notation from the previous sections. In particular,

$$\mathcal{U} = [u_1, \ldots, u_n] \tag{4.1}$$

is the free commutative multiplicative semigroup generated by $u_1, \ldots, u_n$, and $\langle X\rangle$ denotes the free semigroup generated by X. The definition of an I-structure is given in 2.23.

The following result can be extracted from Ref. 15, Theorem 1.3.

Theorem 4.1: *Let (X,r) be a square-free solution and $S=S(X,r)$ be the associated Yang–Baxter semigroup. Then*

(A) *There exists a unique left I-structure $v:\mathcal{U}\to S$, which is inductively defined by the following conditions:*

(1) $v_1(1)=1$, $v(u_i)=x_i$, *for* $1\leqslant i\leqslant n$.

(2) *For every* $b\in\mathcal{U}$ *and every* i, $1\leqslant i\leqslant n$, *there exists an* $x_{b,i}\in X$, *such that* $v(u_i b) = x_{b,i} v(b)$. *Moreover, there is an equality of sets*

$$\{x_{b,i} | 1 \leqslant i \leqslant n\} = \{x_1, \ldots, x_n\}. \tag{4.2}$$

(3) *For every* $b\in\mathcal{U}$, *and* $1\leqslant i,j\leqslant n$, *there is a relation in S*:

$$x_{u_j b,i} x_{b,j} = x_{u_i b,j} x_{b,i}. \tag{4.3}$$

(B) *There exists a unique right I-structure $v_1:\mathcal{U}\to S$, which satisfies the following conditions:*

(1) $v_1(1)=1$, $v_1(u_i)=x_i$, *for* $1\leqslant i\leqslant n$.

(2) *For every* $b\in\mathcal{U}$ *and every* i, $1\leqslant i\leqslant n$, *there exists an* $x_{i,b}\in X$, *such that* $v(b u_i) = v(b) x_{i,b}$. *Furthermore, there is an equality of sets*

$$\{x_{i,b} | 1 \leqslant i \leqslant n\} = \{x_1, \ldots, x_n\}. \tag{4.4}$$

(3) *For every* $b\in\mathcal{U}$, *and* $1\leqslant i,\ j\leqslant n$, *there is a relation in S*:

$$x_{i,b u_j} x_{j,b} = x_{j,b u_i} x_{i,b}. \tag{4.5}$$

Remark 4.2: Suppose $\mathcal{S}$, is a semigroup of (left) I-type generated by $x_1, \ldots, x_n$, with a left

I-structure $v:\mathcal{U}\to\mathcal{S}$. Then in general, v satisfies a modified version on condition A where condition 1 is modified to

$$v(u_j)=x_{i_j},\quad 1\leqslant j\leqslant n, \tag{4.6}$$

where $i_1,\ldots,i_n$ is a permutation of $1,\ldots,n$ and conditions 2 and 3 are unchanged. Moreover (4.6) determines the bijection v uniquely. Analogous statement is true for right I-structures. Without loss of generality we can consider only the special I-structure v and v_1 defined in theorem 4.1.

Notation 4.3: Throughout this section $\mathcal{S}$ will denote a semigroup of I-type generated by $x_1,\ldots,x_n$ with a left I-structure v and a right I-structure v_1. We assume that v and v_1 satisfy conditions 4.1(A) and 4.1(B), respectively.

Remark 4.4: Note that given $a\in\mathcal{U}$, in finitely many steps one can find effectively the monomials $v(a)$ and $v_1(a)$. In particular, it is easy to see that for any i, $1\leqslant i\leqslant n$, and any positive integer k there are equalities $v(u_i^k)=v_1(u_i^k)=x_i^k$. In general, for a monomial $u\in\mathcal{U}$ there might be inequality $v(u)\neq v_1(u)$ (as elements of $\mathcal{S}$), see 4.11.

We study first the properties of the relations "$|_l$"-*divisibility with respect to left multiplication* or shortly-*left divisibility* and "$|_r$"-*right divisibility* on $\mathcal{S}$, defined as

$$a|_l b,\quad \text{if there exists a } c\in\mathcal{S}, \text{ such that } b=ca, \tag{4.7}$$

$$a|_r b,\quad \text{if there exists a } d\in\mathcal{S}, \text{ such that } b=ad. \tag{4.8}$$

The following lemma shows that the left I-structure v is compatible with the left divisibility.

Lemma 4.5: $|_l$ is a partial order on $\mathcal{S}$, compatible with the left multiplication. Furthermore, this order is compatible with the left I-structure v. More precisely, the following two conditions hold:

(a) *If $a|b\in\mathcal{U}$ (i.e. $b=ca$ is an equality in $\mathcal{U}$) then $v(a)|_l v(b)$;*
(b) *Conversely, let $a,b,c\in\mathcal{S}$ satisfy $b=ca$. Let a_0, b_0 be the unique elements of $\mathcal{U}$ which satisfy $v(a_0)=a$ and $v(b_0)=b$. Then $b_0=c_0a_0$, for some $c_0\in\mathcal{U}$.*

Proof: First we show that $|_l$ is an ordering on $\mathcal{S}$ as a set. Clearly, $a|_l a$ for every $a\in S$. It is known that each semigroup $\mathcal{S}$ of I-type is with cancellation low, see Ref. 15. It follows then that $a|_l b$ and $b|_l a$ imply $a=b$. The transitiveness follows at once from the definition of $|_l$.

Next we prove (a). Assume $b=ca$, for $a,b,c\in\mathcal{U}$. We use induction on the length $|c|$ of c to find a monomial $c'\in\mathcal{S}$, such that $v(b)=c'v(a)$. If $c=u_i$, then by the definition of v we have $v(b)=v(u_ia)=x_{a,i}v(a)$. Assume that the statement of the proposition is true for all c of length $\leqslant m$. Let $b=ca$, where $|c|=m+1$. Then $c=u_id$, where $1\leqslant i\leqslant n$, and $|d|=m$. We have $v(b)=v(u_ida)=x_{da,i}v(da)$. By the inductive assumption $v(da)=d'v(a)$, so $v(b)=x_{da,i}d'v(a)$, which proves (a). Assume now that $a,b\in\mathcal{S}$ and $b=ca$, for a $c\in\mathcal{S}$. By definition, v is a bijection, so there are unique a_0 and b_0 in $\mathcal{U}$, such that $v(a_0)=a$, and $v(b_0)=b$. We have to find a $c_0\in\mathcal{U}$, such that $b_0=c_0a_0$. We show this again by induction on the length $|c|$ of c. If $|c|=1$, then $c=x_i\in X$. It follows from 4.1 that there is an equality of sets

$$\{v(u_1a_0),\ldots,v(u_na_0)\}=\{x_1v(a_0),\ldots,x_nv(a_0)\}. \tag{4.9}$$

Clearly, then there exists a j, such that $v(u_ja_0)=x_iv(a_0)=x_ia=b$. This gives $b_0=u_ja_0$. Assume (b) is true for all $c\in\mathcal{S}$ with length $|c|\leqslant k$. Let $b=ca$, where $|c|=k+1$. Then $c=xd$, for some $x\in X$ and $|d|=k$. It follows from the inductive assumption that there is a $d_0\in\mathcal{U}$, such that

$$v(d_0a_0)=dv(a). \tag{4.10}$$

In addition an equality of sets similar to (4.9) shows that there exists a u_j, such that $v(u_jd_0a_0)=xv(d_0a_0)$. The last equality together with (4.10) gives $v(u_jd_0a_0)=xv(d_0a_0)=xda=ca$, so $c_0=u_jd_0$ satisfies the desired equality $b_0=c_0a_0$. □

An analogous statement is true for the right I-structure v_1.

Lemma 4.6: Let $a,b\in\mathcal{S}$. (a) There exists a uniquely determined least common multiple of a and b, with respect to $|_l$, that is a monomial w of minimal length, such that $w=w_1a=w_2b$, for some $w_1, w_2\in S$. (b) There exists a uniquely determined least common multiple, of a and b, with respect to $|_r$, that is a monomial w' of minimal length, such that $w'=aw_1'=bw_2'$, for some $w_1', w_2'\in S$.

Proof: The map v is bijective, so $a=v(a_0)$, and $b=v(b_0)$, for some uniquely determined a_0 and b_0 in $\mathcal{U}$. Let w_0 be the least common multiple $a_0\sqcup b_0$ of a_0 and b_0 in $\mathcal{U}$. It follows from (4.5) that $v(w_0)=\xi v(a_0)=\eta v(b_0)$. Thus $w=v(w_0)$ satisfies

$$w=\xi a=\eta b, \tag{4.11}$$

is a common multiple of a and b (with respect to $|_l$). That w is of minimal possible length among the monomials satisfying (4.11) follows from (4.5). This proves (a). An analogous argument proves (b). □

Notation 4.7: By $a\sqcup b$ we denote the least common multiple of a and b with respect to $|_l$. $a\vee b$ denotes the least common multiple of a and b with respect to $|_r$.

Lemma 4.8: Let v, v_1 be the left and the right I-structures on $\mathcal{S}$, defined in 4.3. Then (a) v is a lattice isomorphism for $(\mathcal{U},|)$ and $(\mathcal{S},|_l)$; (b) v_1 is a lattice isomorphism for $(\mathcal{U},|)$ and $(\mathcal{S},|_r)$.

Definition 4.9: Let $u\in\mathcal{S}$. We say that $h\in X$ is a *head* of u (as an element of $\mathcal{S}$), if u can be presented as $u=hu'$, for some $u'\in\mathcal{S}$. The element $t\in X$ is called *a tail* of u (in $\mathcal{S}$) if $u=u''t$ is an equality in $\mathcal{S}$, for some $u''\in\mathcal{S}$.

Note that a monomial u has exactly one head (respectively: u has exactly one tail) if and only if it is of the shape $u=x^m$, for some $x\in X$, $m\geqslant 1$.

Example 4.10: The relation $(xy=y'x')\in\mathfrak{R}$ implies that the heads of xy are x and y', and its tails are y and x'. Furthermore, $xy=x\vee y'=y\sqcup x'$.

Example 4.11: Consider the YB semigroup $S=\langle X;\mathfrak{R}\rangle$, where $X=\{x_1,x_2,x_3,x_4\}$ and the set of relations is

$$x_4x_1=x_2x_3,\quad x_4x_2=x_1x_3,\quad x_3x_1=x_2x_4,\quad x_3x_2=x_1x_4,\quad x_1x_2=x_2x_1,\quad x_3x_4=x_4x_3.$$

Then

$$v(u_2u_4)=x_1x_4=x_3x_2=v_1(u_1u_3),\quad v_1(u_2u_4)=x_4x_1=x_2x_3=v(u_1u_3),$$

$$v(u_2^2u_4)=x_3x_2^2=x_1x_4x_2=x_1^2x_4=v_1(u_1^2u_3),$$

$$v_1(u_2^2u_4)=x_2^2x_4=x_2x_3x_1=x_4x_1^2.$$

Clearly, $v(u_2^2u_4)\neq v_1(u_2^2u_4)$ as elements of S. In fact, $v(u_2^2u_4)=v_1(u_1^2u_3)$. For $w=x_1^2x_4$ there are equalities in S

$$w=x_2^2\sqcup x_4=x_1^2\vee x_4.$$

Lemma 4.12: Let $w_0\in\mathcal{U}$. Suppose $w_0=u_{i_1}^{\alpha_1}u_{i_2}^{\alpha_2}\cdots u_{i_k}^{\alpha_k}$, where $1\leqslant i_1<i_2<\cdots i_k\leqslant n$, and all α_j are positive integers. Then,

(a) $v(w_0)=x_{i_1}^{\alpha_1}\sqcup x_{i_2}^{\alpha_2}\sqcup\cdots\sqcup x_{i_k}^{\alpha_k}$;
(b) $v_1(w_0)=x_{i_1}^{\alpha_1}\vee x_{i_2}^{\alpha_2}\vee\cdots\vee x_{i_k}^{\alpha_k}$.

Remark 4.13: In general, for $w\in\mathcal{U}$ there might be an inequality $v(w)\neq v_1(w)$ and it is not true that $a\sqcup b=a\vee b$, cf. (4.11). Still for the special monomial

$$W_0=u_1u_2\cdots u_n \tag{4.12}$$

one has

$$v(W_0)=v_1(W_0)=x_1\sqcup x_2\sqcup\cdots\sqcup x_n=x_1\vee x_2\vee\cdots\vee x_n. \tag{4.13}$$

Definition 4.14: The monomial $W=v(u_1u_2\cdots u_n)$ is called *the principal monomial of* $\mathcal{S}$.

Remark 4.15: The principal monomial W "encodes" important information about $\mathcal{S}$ and the solution (X,r). In particular, if (X,r) is a solution and $A=A(k,X,r)$, is the associated Yang–Baxter algebra, then the Koszul dual algebra $A^!$ is Frobenius and W projects to a basis of the socle of $A^!$. In Ref. 14 we study various properties of the principal monomial W, and their implication to the properties of A.

Proposition 4.16: Let $\mathcal{S}$ be a semigroup of I-type, let v and v_1 be the left and right structures on $\mathcal{S}$ as in 4.3. Then following conditions hold:

(1) *$(\mathcal{S},|_l)$ is a distributive lattice. More precisely, any monomial $w\in\mathcal{S}$ has a unique presentation as $w=x_1^{\alpha_1}\sqcup x_2^{\alpha_2}\sqcup\cdots\sqcup x_n^{\alpha_n}$, where α_i is a uniquely determined non-negative integer for each i, $1\leqslant i\leqslant n$. In particular, for each i, with $\alpha_i\geqslant 1$, there is an equality $w=w_ix_i^{\alpha_i}$, where $w_i\in\mathcal{S}$, and x_i does not occur as a tail of w_i.*

(2) *The properties of the lattice $(\mathcal{S},|_r)$ are analogous. In particular, every element $w\in\mathcal{S}$ has a unique presentation as $w=x_1^{\beta_1}\vee x_2^{\beta_2}\vee\cdots\vee x_n^{\beta_n}$, where all β_i are non-negative integers.*

(3) *The following are equalities in $\mathcal{S}$:*

$$W_0=v_1(u_1u_2\cdots u_n)=x_1\vee x_2\vee\cdots\vee x_n=x_1\sqcup x_2\sqcup\cdots\sqcup x_n=v(u_1u_2\cdots u_n).$$

Proof: It is well known that $\mathcal{U}$ is a distributive lattice with respect to the order of divisibility, $a|b$. In particular, every element $a\in\mathcal{U}$ has a unique presentation $a=u_1^{k_1}u_2^{k_2}\cdots u_n^{k_n}$, where $k_1,\ldots,k_n$ are non-negative integers, and $a=u_1^{k_1}\sqcup u_2^{k_2}\sqcup\cdots\sqcup u_n^{k_n}$ ($v\sqcup w$ denotes the least common multiple of v, w in $\mathcal{U}$). Lemma 4.8 implies condition (1). One can show using induction on k that a monomial of the shape $u_{i_1}u_{i_2}\cdots u_{i_k}$, where all u_{i_j} are pairwise distinct, has exactly k different heads and k distinct tails. Therefore the monomial $W_0=v(u_1u_2\cdots u_n)$ has exactly n distinct heads (respectively, n distinct tails) so the set of heads for W_0 coincides with X. □

V. UNIONS OF SOLUTIONS AND MATCHED PAIRS OF GROUPS

In this section we briefly recall some definitions and properties of unions of solutions. We also state a recent result from Ref. 16, in which matched pairs approach is used to describe extensions of solutions.

Definition 5.1 (Ref. 6): Let (X,r) be a solution. A subset $Y\subseteq X$ is *r-invariant*, if r restricts to a bijection $r_Y: Y\times Y\to Y\times Y$. (X,r) is *decomposable* if it can be presented as a union of two nonempty disjoint r-invariant subsets. A solution (Z,r) is *a union* of the solutions (X,r_X) and (Y,r_Y), if $X\cap Y=\emptyset$, $Z=X\cup Y$, as a set, and the bijection r extends r_X, and r_Y.

Clearly, (Z,r) is a union of two nonempty r-invariant subsets, if and only if it is decomposable.

Remark 5.2 (Ref. 6): Suppose the solution (Z,r) is a union of (X,r_X) and (Y,r_Y). Then the map r induces bijections

$$X\times Y\to Y\times X, \text{ and } Y\times X\to X\times Y.$$

Note that a (disjoint) union (Z,r) of two square-free solutions (X,r_X), and (Y,r_Y) is also a square-free solution. The cyclic condition implies then that for every $z\in Z$, there is an equality $\mathcal{R}_z=\mathcal{L}_z^{-1}$. Therefore the equality $r(x,y)=(\mathcal{L}_{x|Y}(y),\mathcal{L}_{y|X}^{-1}(x))$ defines a left action of the groups $G(X,r_X)$ on the set Y and a left action of the group $G(Y,r_Y)$ on the set X. Furthermore for every $z\in Z$ there is an equality of permutations in $\mathrm{Sym}(Z)$: $\mathcal{L}_z=\mathcal{L}_{z|X}\mathcal{L}_{z|Y}$. The following lemma is straightforward.

Lemma 5.3: Let (X,r) be a solution. Suppose $X_1,X_2,\ldots,X_k$ are all disjoint orbits of the left action of $G(X,r)$ on X. Then r induces solutions (X_i,r_i), $1\leqslant i\leqslant k$, where each r_i is the restriction of r on $X_i\times X_i$. Furthermore, X is a disjoint union of (X_i,r_i), $1\leqslant i\leqslant k$.

Clearly, (X,r) is decomposable if and only if $G(X,r)$ acts nontransitively on X.

Remark 5.4: Rump[30] proved that every square-free solution (X,r) is decomposable.

Therefore to understand the structure of a solution and also for constructing solutions it is essential to study extensions of solutions.

Definition 5.5 (Ref. 6): Suppose (X,r_X) and (Y,r_Y) are (disjoint) solutions. The set of *extensions of X by Y*, denoted by $\mathrm{Ext}(X,Y)$, is defined as the set of all decomposable solutions Z which are unions of X and Y.

It is shown in Ref. 6, that given (X,r_X), and (Y,r_Y), an element Z of $\mathrm{Ext}(X,Y)$ is uniquely determined by the function: $r_{X,Y}: X\times Y \to Y\times X$.

The fact that every square-free solution (Z,r) can be presented as a union of two disjoint solutions (X,r_X) and (Y,r_Y), where the bijective map $r: Z\times Z \to Z\times Z$ extends the maps r_X, and r_Y, implies that the following theorem covers all known constructions of solutions restricted to the square-free case.

Theorem 5.6 (Ref. 16): *Let (X,r_X) and (Y,r_Y) be disjoint solutions, $G_X=G(X,r_X)$, $G_Y=G(Y,r_Y)$ be the groups associated with (X,r_X), and (Y,r_Y), respectively. Suppose that $Z=X\cup Y$ and the bijective map $r: Z\times Z\to Z\times Z$ is an extension of the maps r_X and r_Y. Then (Z,r) is a solution if and only if (G_X,G_Y) is a matched pair of groups, in the sense of Majid.*[24] *Moreover (Z,r) is square-free if and only if (X,r_X) and (Y,r_Y) are square-free solutions.*

VI. THE EQUIVALENCE OF THE NOTIONS SQUARE-FREE SET-THEORETIC SOLUTION OF THE YANG–BAXTER EQUATION, SEMIGROUP OF I TYPE, AND SEMIGROUP OF SKEW-POLYNOMIAL-TYPE

We keep all notation and conventions from the previous sections. As usual (X,r) is a square-free solution, where $X=\{x_1,\ldots,x_n\}$ is a finite set with n elements, $S=S(X,r)$, $G=G(X,r)$, and $\mathcal{A}(k,X,r)$ are the associated Yang–Baxter semigroup, group and algebra over a field k, defined in 2.12. In this section we prove Theorem 2.26.

For convenience of the reader, we first recall some basic algebraic and homological properties of $S=S(X,r)$ and $\mathcal{A}(k,X,r)$.

Theorem 6.1 (**Ref. 15**): *Let X be a finite set of n elements, (X,r) be a square-free solution. Let $S=S(X,r)$, $G(X,r)$, and $\mathcal{A}=k\langle X;\mathfrak{R}(r)\rangle$ be the associated Yang–Baxter semigroup, group, and algebra over a field k, respectively. Then the following conditions hold:*

(1) *The semigroup S is of I-type*;
(2) *S is a semigroup with cancellation and $G(X,r)$ is its group of quotients*;
(3) *S is Noetherian*;
(4) *The algebra $\mathcal{A}$ is a Noetherian domain*;
(5) *The Hilbert series of $\mathcal{A}$ is $H_{\mathcal{A}}(t)=1/(1-t)^n$, the same as the Hilbert series of the commutative polynomial rings in n variables over k*;
(6) (Ref. 14) *$\mathcal{A}$ is Koszul*;
(7) *$\mathcal{A}$ satisfies the Auslander condition*;
(8) *$\mathcal{A}$ is Cohen–Macaulay*;
(9) *$\mathcal{A}$ is Artin–Schelter regular ring of global dimension n*;
(10) *The Koszul dual $\mathcal{A}^!$ of A is a Frobenius algebra*;
(11) (Ref. 17) *$\mathcal{A}$ satisfies a polynomial identity. Moreover, S satisfies a semigroup identity*;
(12) *$\mathcal{A}$ is catenary*.

Sketch of the proof: For the definition of "Cohen–Macaulay" and the "Auslander condition" see Ref. 22. Artin–Schelter regular rings are defined in Ref. 3. Conditions 6.1.1–6.1.9 can be extracted from Ref. 15 (cf. Ref. 15, Theorems 1.3, 1.4).

Condition 6.1.11 follows from a more general result in Ref. 17. It is proven (cf. Ref. 17, Theorem 3.1 and Corollary 3.2) that if a semigroup S has homogeneous defining relations, and the semigroup algebra $k[S]$ is right Noetherian and has finite Gelfand–Kirillov dimension, then $k[S]$ satisfies a polynomial identity, and S satisfies a semigroup identity.

Condition 6.1.12 follows from Ref. 31. A The Koszul dual algebra $A^!$ for arbitrary quadratic graded algebra A was introduced in Ref. 25. In Ref. 14 we give the precise defining relations for $A^!$ and a direct combinatorial proof that $A^!$ is Frobenius (in fact, we prove more: that $A^!$ is a

quantum Grassmanian algebra). Condition 6.1.10 follows also from the fact that a Koszul algebra A of finite global dimension is Gorenstein if and only if $A^!$ is Frobenius, see Ref. 32, Proposition 5.10.

The following theorem proves Conjecture 2.18.

Theorem 6.2: *Let (X,r) be a square-free solution, where X is a finite set with n elements, $n\geqslant 2$. Then there exists an ordering of $X=\{x_1<x_2<\cdots<x_n\}$, such that the Yang–Baxter semigroup $S(X,r)$ is of skew-polynomial type (with respect to this ordering), and the Yang–Baxter algebra $A(k,X,r)$, over an arbitrary field k is a PBW algebra with a k-basis the set of ordered monomials:*

$$\mathcal{N}_0=\{x_1^{\alpha_1}x_2^{\alpha_2}\cdots x_n^{\alpha_n}|\alpha_i\geqslant 0, 1\leqslant i\leqslant n\}.$$

Under the hypothesis of the theorem we first prove some lemmas.

Lemma 6.3: There exists an ordering on X, $X=\{x_1<x_2<\cdots<x_n\}$, such that for any pair $x,t\in X$ the following holds:

$$(tx=x't')\in\mathfrak{R}(X,r),\quad \text{and } (t>x)\Rightarrow(x'<t'). \tag{6.1}$$

Proof: We use induction on $n=|X|$. Assume that the statement of the lemma is true for all solutions (X,r), with $|X|\leqslant n-1$. It follows from a theorem of Rump,[30] that every square-free solution (X,r), where X is a finite set, is decomposable into a disjoint union $X=Y\cup Z$ of two nonempty r-invariant subsets Y,Z. Suppose $|Y|=k$, $|Z|=m$, $k+m=n$. Let r_Y and r_Z be the restrictions on r on Y^2 and Z^2, respectively. It follows from the inductive assumption that there exist orderings $Y=\{y_1<\cdots<y_k\}$, and $Z=\{z_1<\cdots<z_m\}$, which satisfy condition 6.1. We set $y_1<\cdots<y_k<z_1<\cdots<z_m$ and verify that this is an ordering on X, which satisfies 6.1. Assume

$$tx=x't'\in\mathfrak{R}(X,r),\ \text{and } t>x. \tag{6.2}$$

We have to show that $x'<t'$. Clearly if $t,x\in Y$, or $t,x\in Z$, then by the inductive assumption and by the choice of the ordering $<$, condition 6.1 is satisfied. Assume now $x\in Y$, and $t\in Z$. (Note that the case $t\in Y$, $x\in Z$ is impossible since we assume $t>x$.) The sets Y, and Z, are r-invariant, therefore by 5.2 r induces a map $Z\times Y\to Y\times Z$. In particular $tx=x't'\in\mathfrak{R}(X,r)$, and $t\in Z$, $x\in Y$, imply that $x'\in Y$, $t'\in Z$. Hence, by the choice of $<$, there is an inequality $x'<t'$, which proves 6.1. □

Lemma 6.4: Suppose condition 6.1 holds. Let x, $t\in X$, and let $\mathcal{L}_t^x=(x_1,\ldots,x_k)$, $\mathcal{L}_x^t=(t_1,\ldots,t_m)$ be their associated disjoint cycles, see 3.1. Then $t_1>x_1$ implies $t_j>x_i$, for all i, j, $1\leqslant i\leqslant k$, $1\leqslant j\leqslant m$.

Proof: Using induction on i, we first show that

$$t_1>x_i,\quad 1\leqslant i\leqslant k. \tag{6.3}$$

By hypothesis $t_1>x_1$, which gives the base for the induction. Assume

$$t_1>x_s,\quad \text{for } 1\leqslant s\leqslant i-1. \tag{6.4}$$

We claim $t_1>x_i$. Assume the contrary,

$$t_1<x_i. \tag{6.5}$$

Note that $t_1=x_i$ is impossible, since the cycles $\mathcal{L}_t^x$ and $\mathcal{L}_x^t$ are disjoint. By the cyclic condition, 3.1 one has

$$t_1x_{i-1}=x_it_m, \tag{6.6}$$

and

$$t_1 x_i = \begin{cases} x_{i+1} t_m & \text{if } i < k \\ x_1 t_m & \text{if } i = k. \end{cases} \tag{6.7}$$

In the case when $i=k$, we obtain immediately a contradiction with (6.1), since

$$t_1 x_k = x_1 t_m, \quad \text{and } x_1 < t_1 < x_k < t_m. \tag{6.8}$$

Assume now $i<k$. Then (6.1) and (6.7), and the assumption (6.5), imply

$$x_{i+1} > t_m. \tag{6.9}$$

At the same time, the equalities (6.6) and (6.4) give

$$t_m > x_i. \tag{6.10}$$

We have obtained

$$x_{i+1} > t_m > x_i > t_1 > x_1. \tag{6.11}$$

Induction on j and analogous argument show, that for $1 \leqslant j \leqslant k-i$, the following inequalities hold:

$$x_{i+j} > t_m > x_i > t_1 > x_1. \tag{6.12}$$

In particular,

$$x_k > t_m > x_i > t_1 > x_1. \tag{6.13}$$

Now the equality $t_1 x_k = x_1 t_m$ together with (6.13) give a contradiction with (6.1). We have shown that

$$t_1 > x_i, \quad \text{for all } i, \quad 1 \leqslant i \leqslant k. \tag{6.14}$$

Induction on j and analogous argument show that

$$t_j > x_i, \quad \text{for all } i, \quad 1 \leqslant i \leqslant k. \tag{6.15}$$

This proves the lemma. □

Lemma 6.5: Let (X,r) be a square-free solution, with an ordering $<$ on X which satisfies (6.1), $S=S(X,r)$ be the associated Yang–Baxter semigroup. Then the following two conditions are satisfied:

(1)

$$(tx = x't') \in \mathfrak{R}(X,r) \quad \text{and } (t > x) \Rightarrow (x' < t') \text{ and } (t > x'). \tag{6.16}$$

(2) *The relations $\mathfrak{R}(X,r)$ form a Groebner basis, with respect to the degree-lexicographic ordering in the free semigroup $\langle X \rangle$, induced by $<$, or equivalently the monomials txu, where $t,x,u \in X$ and $t>x>u$ do not give rise to new relations in $S(X,r)$.*

Proof: Condition (6.16) follows immediately from Lemma 6.4. Therefore the set of defining relations $\mathfrak{R}=\mathfrak{R}(X,r)$ for the Yang–Baxter semigroup $S(X,r)$ satisfies the following:

$$(x_j x_i = x_{i'} x_{j'}) \in \mathfrak{R} \quad \text{and } (j > i) \Rightarrow (i' < j'), \quad \text{and } (j > i'). \tag{6.17}$$

We have to show that $\mathfrak{R}$ is Groebner basis. It follows from the theory of Groebner bases, that each monomial $u \in \langle X \rangle$ has a unique normal form, denoted by $\mathrm{Nor}(u)$, with respect to the so called *reduced Groebner basis*, $\mathfrak{R}_0$, which is uniquely determined by the set $\mathfrak{R}$ and, $\mathfrak{R} \subseteq \mathfrak{R}_0$. As a set S can be identified with the set of normal monomials

$$\mathcal{N}(S) = \{\mathrm{Nor}(u) | u \in \langle X \rangle\}. \tag{6.18}$$

Knowing the normal monomials one can uniquely restore the set of obstructions, i.e., the set of highest monomials in the reduced Groebner basis, $\mathfrak{R}_0$. To verify the equality $\mathfrak{R}=\mathfrak{R}_0$, therefore $\mathfrak{R}$ is a Groebner basis, it will be enough to show that the "ambiguities" $x_k x_j x_i$, where $n \geqslant k > j > i \geqslant 1$, do not give rise to new relations in $S(X,r)$, or equivalently, that each monomial of the shape $x_i x_j x_k$, with $1 \leqslant i \leqslant j \leqslant k \leqslant n$ is normal, with respect to $\mathfrak{R}_0$. This will follow immediately from a stronger statement:

Lemma 6.6: Each ordered monomial $u = x_1^{\alpha_1} x_2^{\alpha_2} \cdots x_n^{\alpha_n}$, where $\alpha_i \geqslant 0$, $1 \leqslant i \leqslant n$ is in normal form with respect to the reduced Groebner basis $\mathfrak{R}_0$ in $\langle X \rangle$.

Proof: Each relation in $\mathfrak{R}$ satisfies (6.17), so its highest monomial is $x_j x_i$, with $j > i$, therefore the normal form $\mathrm{Nor}(u)$ of each $u \in \langle X \rangle$ does not contain $x_j x_i, j > i$ as a sub word. This shows that

$$S = \mathcal{N}(S) \subseteq \mathcal{N}_0, \tag{6.19}$$

where $\mathcal{N}_0$ is the set of ordered monomials $\mathcal{N}_0 = \{x_1^{\alpha_1} x_2^{\alpha_2} \cdots x_n^{\alpha_n} | \alpha_i \geqslant 0, 1 \leqslant i \leqslant n\}$.

The existence of the I-structure v on $S(X,r)$ (by definition $v: \mathcal{U} \to S$ is a bijection) implies the equality $\mathcal{N}(S) = \mathcal{N}_0$. □

We have proved 6.5. □

Proof of the theorem: The theorem follows from Lemma 6.5. Note that the Diamond Lemma 2.2 implies that the Yang–Baxter algebra $\mathcal{A} = \mathcal{A}(k,X,r)$ is PBW in the sense of Priddy,[27] and the set of ordered monomials $\mathcal{N}_0$ projects to a k-basis of $\mathcal{A}$ (as a k-vector space).

Proof of theorem A: The equivalence of 2.26.1 and 2.26.2 follow from Ref. 15, Theorem 1.4. The implications 2.26.1 $\Rightarrow$ 2.26.3, and 2.26.1 $\Rightarrow$ 2.26.4 follow from theorem 6.2. Clearly, the theory of Groebner basis implies the equivalence of conditions 2.26.3 and 2.26.4. Theorem 1.2 (Ref. 15), proves the implication 2.26.3 $\Rightarrow$ 2.26.1.

VII. MORE ABOUT $S(X,r)$ AND $G(X,r)$

In this section, as usual (X,r) denotes a square-free solution, where X is a finite set of n elements. We show that $G = G(X,r)$ acts by conjugation on the set $X^M = \{x_1^M, \ldots, x_n^M\}$, where $M = M(X,r)$ is the cyclic degree of (X,r) defined in 3.17. We compare this action with the left action of $G(X,r)$ on the set X. Next we prove that $G(X,r)$ contains a free Abelian subgroup A of index M^n, and prove that the quotient group $\overline{G} = G/A$ can be presented as a product of its Sylow subgroups (cf. 7.10). This implies a presentation of the group $\mathcal{G}_L(X,r)$ as a product of its Sylow subgroups. As a corollary we obtain a result of Etingof–Schedler–Solovyev,[6] that the group $G(X,r)$ is solvable.

Notation 7.1: For any positive integer k we set $X^{(k)} = \{x_1^k, \ldots, x_n^k\}$. By $S^k = \langle X^{(k)} \rangle$ we denote the submonoid of $S = S(X,r)$ generated by $X^{(k)}$. If $A, B \subset S$, then as usual, AB denotes the set of all elements u of the form $u = ab$, with $a \in A$, $b \in B$.

Proposition 7.2: Let k be a positive integer, $X^{(k)}$ and S^k as in 7.1. Then the following conditions hold:

(1) *The map r induces a map $r_k: X^{(k)} \times X^{(k)} \to X^{(k)} \times X^{(k)}$ such that $(X^{(k)}, r_k)$ is a square-free solution;*
(2) *S^k is of I-type;*
(3) *$S^k S^j = S^j S^k$ is an equality of sets in S, for every two positive integers k and j.*

It follows from 3.21 that for any pair $x, y \in X$ and $M = M(X,r)$ being the cyclic degree of the solution, there is an equality in S,

$$yx^M = x_2^M y, \text{ where } \mathcal{L}_y(x) = x_2.$$

This implies that G acts by conjugation on the set $X^{(M)}$. The following corollary follows easily from the existence of the I-structure v, and 3.21.

Corollary 7.3: Suppose (X,r) is a square-free solution. Then,

(1) *$S(X,r)$ contains the free Abelian semigroup $[x_1^M,\dots,x_n^M]=S^M$;*
(2) *$S(X,r)$ is left and right Noetherian*;
(3) *The group $A=gr[x_1^M,\dots,x_n^M]$ is a free Abelian normal subgroup of G of index M^n*;
(4) *The group $G=G(X,r)$ acts by conjugation on the set $X^{(M)}$. Moreover the action of A on $X^{(M)}$ is trivial, thus the quotient group $\overline{G}=G/A$ acts on $X^{(M)}$ by conjugation. Clearly, $\overline{G}$ is a finite group of order M^n*;
(5) *The group A is contained in the kernel* $\ker\mathcal{L}$ *of the homomorphism $\mathcal{L}:G\to Sym(X)$. Therefore there exists an epimorphism $\overline{\mathcal{L}}:\overline{G}\to\mathcal{G}_L$, induced by $\mathcal{L}$, satisfying the equality: $\mathcal{L}=\overline{\mathcal{L}}\circ\nu$, where ν is the natural epimorphism $\nu:G\to\overline{G}$*;
(6) *The order of $\mathcal{G}_L$ divides M^n.*

Notation 7.4: For every $y\in X$ we denote by $O(y^M)$ the orbit of y^M under the action if G on $X^{(M)}$. For $x, y\in X$ we define an equivalence on X by setting $x\approx y$ iff $O(x^M)=O(y^M)$. By $X(y)$ we denote the equivalence class of y, $y\in X$.

The lemma below follows straightforward from the definition of the actions of G on the sets X and X^M, and from Proposition 3.21.

Lemma 7.5: The following conditions hold:

(1) *There exists a one-to-one correspondence between the G-orbits of X^M and the G-orbits of X. More precisely for every $\xi\in X$, there are equalities $O_G(\xi)=X(\xi)=\{x\in X\,|\,x^M\in O(\xi^M)\}$. Furthermore, the orbits $O_G(\xi)$ can be obtained simply by acting with the "semigroup" elements of G,* i.e., *$y\in O_G(x)$ if and only if, there exist monomials $a,b\in S$, $a=a_1\cdots a_k$, and $b=b_1\cdots b_k$ $(a_i,b_i\in X)$ and elements $y_1,\dots,y_k\in X$, such that there are equalities:*

$$a_kx=y_kb_k,\quad a_{k-1}y_k=y_{k-1}b_{k-1},\quad\dots,\quad a_1y_1=yb_1. \tag{7.1}$$

(2) *If $x\in X(a)$, and $y\in X(b)$, for some $a, b\in X$ (not necessarily $a\neq b$) then there is an equality $xy=y'x'$, with $y'\in X(b)$, $x'\in X(a)$.*
(3) *Each orbit $O_G(\xi)$, $\xi\in X$ is r-invariant.*
(4) *X is r-decomposable if and only if $\overline{G}$ does not act transitively on X^M. More precisely, if $O_{\overline{G}}(\xi_i^M)$, $1\leqslant i\leqslant k$ are all disjoint orbits of this action then X splits into a disjoint union of k nonempty r-invariant subsets: $X_1=O_G(\xi_1),\dots,X_k=O_G(\xi_k)$.*

Remark 7.6: It is a routine fact, that the order of each orbit $O(x^M)$, $x\in X$ is a divisor of the order M^n of $\overline{G}$, see for example Ref. 2, 6.1.

A sufficient condition for r-decomposability of X follows immediately from 7.6. As a corollary we obtain a result from Ref. 6, that every solution (X,r), where X is of prime order p is decomposable.

Corollary 7.7: If M is not divisible by some prime divisor p of n, then the action of $\overline{G}$ (and of G) on $X^{(M)}$ is not transitive and X is a disjoint union of k r-invariant subsets, where $k\geqslant 2$ is the number of orbits in $X^{(M)}$.

Corollary 7.8 (Ref. 6): If $n=p$ is a prime number, then X is a disjoint union of two nonempty r-invariant subsets.

Next we study the relations between the cyclic degree $M=M(X,r)$, the Sylow subgroups of $\overline{G}$, and the cyclic properties of the semigroup $S(X,r)$. Note that

Notation 7.9: Let $M=M(X,r)$ be the cyclic degree of the solution (X,r) defined in 3.17. Suppose $M=p_1^{\alpha_1}p_2^{\alpha_2}\cdots p_k^{\alpha_k}$, where $p_1,\dots,p_k$ are distinct prime numbers, and $\alpha_1\cdots\alpha_k$ are positive integers. For $i=1,\dots,k$, we set

$$q_i=M/p_i^{\alpha_i},$$

$$S^{q_i} = \langle x_1^{q_i}, \ldots, x_n^{q_i} \rangle,$$

the submonoid of S generated by $x_1^{q_i}, \ldots, x_n^{q_i}$, $1 \leqslant i \leqslant k$. We denote by $\overline{S^{q_i}}$ the natural image of S^{q_i} in the quotient group $\overline{G}$, and by $\mathcal{L}(S^{q_i})$ the image of S^{q_i} under the homomorphism $\mathcal{L}: G \to \mathcal{G}_L \subset \mathrm{Sym}(X)$, defined by the left action of G on X.

Clearly, the integers $q_1, \ldots, q_k$ are pairwise coprime, and $\overline{S^{q_i}}$ are submonoids of $\overline{G}$.

The next theorem gives a presentation of $\overline{G}$ as a product of its Sylow subgroups. Surprisingly it also allows one to consider each element of $\overline{G}$ as an element of the monoid $\overline{S}$.

Theorem 7.10: *The following conditions hold:*

(1) *For every i, $1 \leqslant i \leqslant r$, the submonoid $\overline{S^{q_i}}$ is a subgroup of order $p_i^{n\alpha_i}$ in $\overline{G}$. In particular, it is a Sylow p_i-subgroup of $\overline{G}$.*
(2) *For every pair q_i, q_j, $1 \leqslant i, j \leqslant r$, there is an equality $\overline{S^{q_i}}.\overline{S^{q_j}} = \overline{S^{q_j}}.\overline{S^{q_i}}$.*
(3) *The group $\overline{G}$ is a product of its Sylow subgroups: $\overline{G} = \overline{S^{q_1}} \cdots \overline{S^{q_k}}$. In particular, $\overline{G} = \overline{S}$.*
(4) *For each i, $1 \leqslant i \leqslant k$, such that $\mathcal{L}(S^{q_i}) \neq id_X$, $\mathcal{L}(S^{q_i})$ is a p_i-Sylow subgroup of $\mathcal{G}_L$.*
(5) *Let $1 \leqslant i_1, \ldots, i_s \leqslant k$ be all indices, for which $\mathcal{L}(S^{q_{i_j}}) \neq \{id_X\}$, $1 \leqslant j \leqslant s$. Then the group $\mathcal{G}_L = \mathcal{G}_L(X, r)$ is a product of its Sylow subgroups:*

$$\mathcal{G}_L = \mathcal{L}(S^{q_{i_1}}) \cdots \mathcal{L}(S^{q_{i_s}}).$$

In particular, $\mathcal{G}_L = \mathcal{L}(S)$.
(6) *The groups $\mathcal{G}_L$, $\overline{G}$, and G are solvable.*

Proof: Consider $\overline{S^{q_i}}$, where $1 \leqslant i \leqslant k$. Note first that as a finite submonoid of the group $\overline{G}$, $\overline{S^{q_i}}$ is a subgroup of $\overline{G}$. We claim that the order of $\overline{S^{q_i}}$ is exactly $p_i^{n\alpha_i}$. The equalities 3.31 imply that every element w of $\overline{S^{q_i}}$ can be presented as

$$w = \overline{v((u_1^{q_i})^{\beta_1} \cdots (u_n^{q_i})^{\beta_n})}, \tag{7.2}$$

where $0 \leqslant \beta_s \leqslant p_i^{\alpha_i}$ for all $s, 1 \leqslant s \leqslant n$. We set $\beta = (\beta_1, \beta_2, \ldots, \beta_n)$, and $w = w(\beta)$, for the monomial w determined by (7.2). It follows from the properties of the I-structure v on S and from 3.31 that each inequality $\beta' \neq \beta''$ implies an inequality in $\overline{S}$,

$$w(\beta') \neq w(\beta''). \tag{7.3}$$

This implies that $\overline{S^{q_i}}$ is a group of order $(p_i^{\alpha_i})^n$ thus a Sylow p_i subgroup of $\overline{G}$, which proves 1.

Next we recall that for every pair of integers $i, j, 1 \leqslant i, j \leqslant k$, and for every pair $x, y \in X$ there exist $z, t \in X$, such that the equality

$$x^{q_i} y^{q_j} = z^{q_j} t^{q_i} \tag{7.4}$$

holds in S. This implies that $\overline{S^{q_i} S^{q_j}} = \overline{S^{q_j} S^{q_i}}$ for all i, j, which verifies 2. Let $S' = \langle S^{q_1}, \ldots, S^{q_k} \rangle$ be the submonoid of S, generated by $S^{q_1}, \ldots, S^{q_k}$. It follows from 7.4 that there is an equality

$$S' = S^{q_1} \cdots S^{q_k}. \tag{7.5}$$

Hence

$$\overline{S'} = \overline{S^{q_1}} \cdots \overline{S^{q_k}} \tag{7.6}$$

is a presentation of $\overline{S'}$ as a product of subgroups with pairwise co-prime orders: $p_1^{n\alpha_1}, \ldots, p_k^{n\alpha_k}$, respectively. It follows then that the order of $\overline{S'}$ is exactly $p_1^{n\alpha_1} \cdots p_k^{n\alpha_k} = M^n$, thus $\overline{G} = \overline{S^{q_1}} \cdots \overline{S^{q_k}}$. This proves 3. The proof of 4, and 5 is routine. □

Note that, in general the Sylow subgroups $\overline{S^{q_i}}$ might not be normal subgroups of $\overline{G}$, as shows the following example.

Example 7.11: Let $S=\langle X;\Re\rangle$, where $X=\{x_i|1\leqslant i\leqslant 6\}\cup\{y_j|1\leqslant j\leqslant 4\}$ and the relations $\Re$ are defined by the permutation

$$\sigma=(x_1x_2x_3x_4x_5x_6)(y_1y_2y_3y_4) \tag{7.7}$$

as follows:

$$y_jx_i=\sigma(x_i)\sigma^{-1}(y_j),\quad \text{and } x_iy_j=\sigma_1(y_j)\sigma^{-1}(x_i)\quad \text{for } 1\leqslant i\leqslant 6,\ 1\leqslant j\leqslant 4; \tag{7.8}$$

$$x_ix_k=\sigma^3(x_k)\sigma^{-3}(x_i),\quad \text{for all } i\neq k(\text{mod }3),\ 1\leqslant i,k\leqslant 6; \tag{7.9}$$

$$x_ix_k=x_kx_i,\quad \text{for all } i=k(\text{mod }3),\ 1\leqslant i,k\leqslant 6; \tag{7.10}$$

$$y_jy_k=\sigma^2(y_k)\sigma^{-2}(y_j),\quad \text{for all } j\neq k(\text{mod }2),\ 1\leqslant j,k\leqslant 4; \tag{7.11}$$

$$y_jy_k=y_ky_j,\quad \text{for all } j=k(\text{mod }2),\ 1\leqslant j,k\leqslant 4. \tag{7.12}$$

It is easy to verify that the set of relations $\Re$ defines naturally a square-free solution, r, thus S is a YB semigroup. The set of all lengths of cycles is 6, 4, 2, so $M=12=2^2.3$, and (in the notation 7.9), $q_1=3$, and $q_2=4$. Thus, by Theorem 7.10, $\overline{G}=\overline{S^3}\,\overline{S^4}$. Note that none of the subgroups $\overline{S^3}$, $\overline{S^4}$ is normal in $\overline{G}$.

One can use Theorem 7.10 to give a straightforward proof of the r-decomposability of (X,r) in all cases when the cycles are not enough "dense" on X. More precisely, the following corollary is true.

Corollary 7.12: Suppose that there exists a prime divisor p of n, and an $x\in X$, such that x does not belong to a cycle of length divisible by p. Then the action of $\overline{G}$ on X is nontransitive, therefore (X,r) is decomposable.

VIII. MULTIPERMUTATION SOLUTIONS AND GENERALIZED TWISTED UNIONS

We give a description of the generalized twisted unions of solutions $Z=X\cup Y$, showing that the group $G_Y=G(Y,r_Y)$ acts as automorphisms on X, and all the elements ξ of an orbit $O(x)=O_{G_Y}(x)$ have the same action on Y see 8.3. Lemma 8.10 generalizes the cyclic condition. We give a conjecture that every multipermutation solution of level m is a generalized twisted union of multipermutation solutions of level $\leqslant m-1$. We keep the notation and conventions from the previous sections. In particular, as before we shall use both notation ${}^xy=\mathcal{L}_x(y)$ and $y^x=\mathcal{R}_x(y)$.

Definition 8.1 (Ref. 6): Let (Z,r), be a disjoint union of the solutions (X,r_X), and (Y,r_Y).

(1) (Z,r) is called *a twisted union* of X and Y if the maps $r_{XY}:X\times Y\to Y\times X$ and $r_{YX}:Y\times X\to X\times Y$ are defined as

$$r_{XY}(x,y)=(g(y),f^{-1}(x)) \tag{8.1}$$

and

$$r_{YX}(y,x)=(f(x),g^{-1}(y)), \tag{8.2}$$

where $f\in\text{Sym}(X)$, and $g\in\text{Sym}(Y)$ are fixed.

(2) (Z,r) is *a generalized twisted union* of X and Y if the map r is determined by the formula

$$r_{XY}(x,y) = (\mathcal{L}_{x|Y}(y), \mathcal{R}_{y|X}(x)), \tag{8.3}$$

where the permutations $\mathcal{L}_{x|Y} \in \mathrm{Sym}(Y)$, and $\mathcal{R}_{y|X} \in \mathrm{Sym}(X)$ satisfy the following condition:

For every $y \in Y$ the permutation $\mathcal{L}_{x^y|Y}: Y \to Y$ is independent of y, and for every $x \in X$, the permutation $\mathcal{R}_{x_y|X}: X \to X$ is independent of x.

Notation 8.2: When the element $\xi \in Z$ is specified we shall simply write, as usual, $\mathcal{L}_x(\xi)$, or ${}^x\xi$ instead of $\mathcal{L}_{x|Y}(\xi)$, respectively, $\mathcal{L}_y(\xi)$, ${}^y\xi$ instead of $\mathcal{L}_{y|X}(\xi)$.

Proposition 8.3: Let (Z,r) be union of the disjoint solutions (X,r_X) and (Y,r_Y). Then (Z,r) is a generalized twisted union of X and Y if and only if for every pair x,y, $x \in X$, $y \in Y$ the following equalities hold:

$$\mathcal{L}_{x^y|Y} = \mathcal{L}_{x|Y} = \mathcal{L}_{y_x|Y}; \tag{8.4}$$

$$\mathcal{L}_{x_y|X} = \mathcal{L}_{y|X} = \mathcal{L}_{y^x|X}. \tag{8.5}$$

Proof: Note first that the equalities (8.4) and (8.5) imply that (Z,r) is a generalized twisted union of X and Y.

Assume now that (Z,r) is a generalized twisted union of X and Y. Let $x \in X$, $y \in Y$. We have to show that for every $z \in Y$ there is an equality

$$\mathcal{L}_{x^y}(z) = \mathcal{L}_x(z). \tag{8.6}$$

By definition 8.1 the map $\mathcal{L}_{x^y|Y}: Y \to Y$ is independent of $y \in Y$. Hence for every pair $y,z \in Y$ there is an equality

$$\mathcal{L}_{x^y}(z) = \mathcal{L}_{x^z}(z). \tag{8.7}$$

By the cyclic condition in (Z,r), see (3.27), one has

$$\mathcal{L}_{x^z}(z) = \mathcal{L}_x(z). \tag{8.8}$$

Now the Eqs. (8.7) and (8.8) imply

$$\mathcal{L}_{x^y}(z) = \mathcal{L}_x(z) \tag{8.9}$$

for every $z \in Y$. We have shown that

$$\mathcal{L}_{x^y|Y} = \mathcal{L}_{x|Y} \tag{8.10}$$

for arbitrary $x \in X$ and $y \in Y$. We apply this to the pair ${}^yx \in X$ and $y \in Y$ and obtain

$$\mathcal{L}_{({}^yx)^y|Y} = \mathcal{L}_{y_x|Y}. \tag{8.11}$$

By (3.27) there is an equality,

$$({}^yx)^y = x, \tag{8.12}$$

which together with (8.11) and (8.10) implies $\mathcal{L}_{y_x|Y} = \mathcal{L}_{x|Y} = \mathcal{L}_{x^y|Y}$.

This completes the proof of (8.4). Analogous argument proves (8.5). □

Theorem 8.4: *Let (Z,r) be a generalized twisted union of the solutions (X,r_X) and (Y,r_Y), and let $G_X = G(X,r_X)$, $G_Y = G(Y,r_Y)$ be the associated Yang–Baxter groups. Suppose $O_{G_Y}(\xi_1),\ldots, O_{G_Y}(\xi_p)$ are the (distinct) orbits of the action of the group G_Y on X, and $O_{G_X}(\eta_1),\ldots, O_{G_X}(\eta_q)$ are the (distinct) orbits of the action of G_X on Y. Then the following conditions are satisfied.*

(1) *The assignment*

$$x \to \mathcal{L}_{x|Y}, \quad \textit{for all } x \in X$$

extends to a group homomorphism

$$L_X : G(X, r_X) \to Aut(Y, r_Y).$$

(2) *Let H_X denote the kernel Ker L_X. Then each orbit $O_{G_Y}(\xi_i)$, is contained in the left coset $\xi_i H_X$, i.e., $O_{G_Y}(\xi_i) \subseteq \xi_i H_X$. In particular, for every $x \in O_{G_Y}(\xi_i)$, $1 \leqslant i \leqslant p$ there is an equality*

$$\mathcal{L}_{x|Y} = \mathcal{L}_{\xi_i|Y}. \tag{8.13}$$

(3) *The assignment*

$$y \to \mathcal{L}_{y|X}, \quad \textit{for all } y \in Y$$

extends to a group homomorphism

$$L_Y : G(Y, r_Y) \to Aut(X, r_X).$$

(4) *Let H_Y denote the kernel Ker L_Y. Then $O_{G_X}(\eta_j) \subseteq \eta_j H_Y$, for $1 \leqslant j \leqslant q$. In particular, for every $y \in O_{G_X}(\eta_j)$, there is an equality*

$$\mathcal{L}_{y|X} = \mathcal{L}_{\eta_j|X}. \tag{8.14}$$

Definition 8.5 (Ref. 6): Let (X, r) be a square-free solution. Define an equivalence relation on X as $x \sim y$ if and only if $\mathcal{L}_x = \mathcal{L}_y$.

Clearly, since $\mathcal{R}_x = \mathcal{L}_x^{-1}$, one has also $x \sim y$ iff $\mathcal{R}_x = \mathcal{R}_y$. Let $X^\sim = X/\sim$. It is known, see Ref. 6, that the solution $r : X \times X \to X \times X$ induces a bijection $r^\sim : X^\sim \times X^\sim \to X^\sim \times X^\sim$, so that $(X^\sim, r^\sim)$ is a solution. It is not difficult to see that this solution is also square-free. The solution $(X^\sim, r^\sim)$ is called the *retraction of* (X, r) and is denoted by $\mathrm{Ret}(X, r)$. The solution is *retractable* if $\sim$ is a nontrivial equivalence relation, or equivalently $\mathrm{Ret}(X, r) \neq (X, r)$. In the case when $\sim$ is the trivial equivalence on X, the solution (X, r) is called *irretractable*.

Lemma 8.6: For any $x, y \in X$ the equivalence $x \sim y$ implies $xy = yx$.

Definition 8.7: Inductively, for $1 < k$ we define the retractions of higher level as $\mathrm{Ret}^k(X, r) = \mathrm{Ret}(\mathrm{Ret}^{k-1}(X, r))$.

We denote by $x^{(k)}$ the image of x in $\mathrm{Ret}^k(X, r)$. The set

$$[x^{(k)}] := \{\xi \in X \mid \xi^{(k)} = x^{(k)}\} \tag{8.15}$$

is called *the k*th *retract orbit* of x.

Definition 8.8 (Ref. 6): A solution (X, r) is called *multipermutation solution of level m* if m is the minimal nonnegative integer, such that $\mathrm{Ret}^m(X, r)$ is finite of order 1.

*Lemma 8.9: For any positive integer k, and any $x \in X$ the k*th *retract orbit $[x^{(k)}]$ is r-invariant. Furthermore, if we denote by $\mathbf{r}_{x,k}$ the corresponding solution induced by r, then $([x^{(k)}], \mathbf{r}_{x,k})$ is a multipermutation solution of level k.*

Lemma 8.10: Let (X, r) be a square-free solution. Then the following conditions hold:

(1) *For every $x, y, t \in X$, and k a positive integer,*

$$y^{(k)} = t^{(k)} \Rightarrow \left({}^y x\right)^{(k-1)} = \left({}^t x\right)^{(k-1)}. \tag{8.16}$$

(2) *For every $x, y, t \in X$*

$$y^{(2)} = t^{(2)} \Rightarrow {}^y x \sim {}^t x, \quad \textit{in particular, } {}^y t \sim t, \textit{ and } {}^t y \sim y. \tag{8.17}$$

Proof: We first prove 1. By hypothesis, $y^{(k)} = t^{(k)}$, or equivalently

$$y^{(k-1)} \sim t^{(k-1)}. \tag{8.18}$$

Let $x \in X$. Clearly,

$$yx = \xi y_1, \quad tx = \xi_1 t_1, \quad \text{for some } \xi, \xi_1, y_1, t_1 \in X. \tag{8.19}$$

This implies the following equalities in $\mathrm{Ret}^{k-1}(X,r)$;

$$y^{(k-1)}x^{(k-1)} = \xi^{(k-1)}y_1^{(k-1)}, \tag{8.20}$$

and

$$t^{(k-1)}x^{(k-1)} = \xi_1^{(k-1)}t_1^{(k-1)}.$$

It follows then from (8.18) that

$$\xi^{(k-1)} = \xi_1^{(k-1)}, \quad \text{or equivalently, } \xi^{(k-2)} \sim \xi_1^{(k-2)}. \tag{8.21}$$

By (8.19), one has $\xi = {}^{y}x$, and $\xi_1 = {}^{t}x$, which proves 1. Condition 2 follows straightforward from 1, with $k=2$, and the cyclic condition. □

Corollary 8.11: Let (X,r) be a multipermutation solution of level m, $G_X = G(X,r)$ be the associated Yang–Baxter group. Then for every $y \in X$ one has

$$O_{G_X}(y) \subseteq [y^{(m-1)}],$$

*where $O_{G_X}(y)$ is the G_X orbit of y in X, and $[y^{(m-1)}]$ is the $(m-1)$*th *retract orbit of y. In particular, $O_{G_X}(y)$ is a multipermutation solution of level at most $m-1$.*

The cyclic condition, ${}^{({}^{y}x)}(y) = {}^{x}y$ is "extended" to the class $[y^{(2)}]$ by the following lemma.

Lemma 8.12: Let (X,r) be a solution. Then the following conditions hold.

(1) *For every $x \in X$, and $z \in [y^{(2)}]$ there is an equality*

$${}^{({}^{y}x)}(z) = {}^{x}z \tag{8.22}$$

and

$$\mathcal{L}_{y_{x|[y^{(2)}]}} = \mathcal{L}_{x|[y^{(2)}]}. \tag{8.23}$$

(2) *Suppose that $[x^{(2)}] \neq [y^{(2)}]$, and the set $[y^{(2)}]$ is invariant under the left action of $G([x^{(2)}], \mathbf{r}_{x,2})$, respectively, $[x^{(2)}]$ is invariant under the left action of $G([y^{(2)}], \mathbf{r}_{y,2})$. Then the disjoint union $Z = [x^{(2)}] \cup [y^{(2)}]$ is a generalized twisted union of $[x^{(2)}]$ and $[y^{(2)}]$. Moreover, (Z, r_Z) is a multipermutation solution of level 3, where r_Z is the restriction of r on $Z \times Z$.*

Proof: Let $x \in X$, and let $z \in y^{(2)}$. We will show that (8.22) holds. It follows from (8.17) that

$${}^{y}x \sim {}^{z}x. \tag{8.24}$$

So, by the definition of $\sim$, and by the cyclic condition,

$${}^{({}^{y}x)}(z) = {}^{({}^{z}x)}(z) = {}^{x}z. \tag{8.25}$$

We have shown (8.22). Clearly, (8.22) implies (8.23). Condition 2 follows easily from 1. □

Corollary 8.13: Let (X,r) be a multipermutation solution of level 3. Then (X,r) is a generalized twisted union of multipermutation solutions of level $\leqslant 2$.

Example 8.14: Let $X = \{x, x_1, \xi, \xi_1, t, t_1, \eta, \eta_1, y, y_1\}$ and let r be determined via

$$\mathcal{L}_x = \mathcal{L}_{x_1} = (tt_1)(\eta\eta_1)(yy_1); \tag{8.26}$$

$$\mathcal{L}_{\xi} = \mathcal{L}_{\xi_1} = (t\eta)(t_1\eta_1)(yy_1); \tag{8.27}$$

$$\mathcal{L}_{t} = \mathcal{L}_{t_1} = \mathcal{L}_{\eta} = \mathcal{L}_{\eta_1} = id_X; \tag{8.28}$$

$$\mathcal{L}_{y} = \mathcal{L}_{y_1} = (x\xi)(x_1\xi_1). \tag{8.29}$$

Then $\mathrm{Ret}(X,r)=(X^{\sim},r^{\sim})$, where $X^{\sim}=\{x^{\sim},\xi^{\sim},t^{\sim},y^{\sim}\}$, and $r^{\sim}$ is determined by $\mathcal{L}y^{\sim}=(x^{\sim}\xi^{\sim})$, $\mathcal{L}_{x^{\sim}}=\mathcal{L}_{\xi^{\sim}}=\mathcal{L}_{t^{\sim}}=id_{X^{\sim}}$. Clearly, $X^{(2)}=\{y^{(2)},x^{(2)}\}$, and $\mathrm{Ret}^2(X,r)$ is the trivial solution, therefore $\mathrm{Ret}^3(X,r)=1$. In this case (X,r) is a multipermutation solution of level 3.

IX. BINOMIAL SOLUTIONS OF THE CLASSICAL YANG–BAXTER EQUATION

In this section we study a particular class of solutions of the classical Yang–Baxter equation, we call them *binomial solutions*. We show that there is a close relation between the binomial solutions of the classical Yang–Baxter equation and the *binomial skew-polynomial rings*, a class of PBW algebras, which are Artin–Schelter regular domains. These rings were introduced in Ref. 8, and studied in Refs. 9, 10, 15, 14, 21, and 19.

Definition 9.1: Let V be a finite dimensional vector space over a field k with a k-basis $X=\{x_1,\ldots,x_n\}$. Suppose the linear automorphism $R: V\otimes V\to V\otimes V$ is a solution of the Yang–Baxter equation. We say that R is *a binomial solution of the (classical) Yang–Baxter equation* or shortly *binomial solution* if the following conditions hold:

(1) For every pair $i\neq j$, $1\leqslant i,\ j\leqslant n$,

$$R(x_j\otimes x_i)=c_{ij}x_{i'}\otimes x_{j'},\quad R(x_{i'}\otimes x_{j'})=\frac{1}{c_{ij}}x_j\otimes x_i, \tag{9.1}$$

where $c_{ij}\in k\backslash\{0\}$, $i'\neq j'$.

(2) For all i, $1\leqslant i\leqslant n$

$$R(x_i\otimes x_i)=x_i\otimes x_i. \tag{9.2}$$

(3) R is *nondegenerate*, that is *the associated set-theoretic solution* $(X,r(R))$ is nondegenerate, where $r=r(R): X\times X\to X\times X$ is defined as

$$r(x_j,x_i)=(x_{i'},x_{j'})\quad \text{if } R(x_j\otimes x_i)=c_{ij}x_{i'}\otimes x_{j'}. \tag{9.3}$$

Note that definition 9.1 implies that for each binomial solution R of the Yang–Baxter equation the associated set-theoretic solution $(X,r(R))$ is square-free.

Notation 9.2: By (k,X,R) we shall denote a binomial solution of the classical Yang–Baxter equation.

Each binomial solution (k,X,R) defines a quadratic algebra $\mathcal{A}_R=\mathcal{A}(k,X,R)$, namely *the associated Yang–Baxter algebra*, in the sense of Manin.[25] The algebra $\mathcal{A}(k,X,R)$ is generated by X and has quadratic defining relations, $\mathfrak{R}(R)$ determined by R similarly to (2.7):

$$\mathfrak{R}(R)=\{(x_jx_i-c_{ij}x_{i'}x_{j'})\,|\,R(x_j\otimes x_i)=c_{ij}x_{i'}\otimes x_{j'}\}_{1\leqslant i\neq j\leqslant n}. \tag{9.4}$$

Sometimes it is more convenient to work with the free associative algebra $k\langle X\rangle$, instead of working with the tensor algebra, generated by V. Similarly to the identification of $X\times X$ and the set of X^2, we identify the vector spaces $V^{\otimes m}$ and $\mathrm{Span}_k X^m$, $m\geqslant 1$.

Theorem 9.7 gives the close relation between the binomial solutions of the classical Yang–Baxter equation and the *binomial skew-polynomial rings*. It is an analog of Theorem 2.26.

Now we recall the definition of a binomial skew-polynomial ring.

Definition 9.3 (Ref. 8): Let $\mathcal{A}_0=\mathcal{A}_0(k,X,\mathfrak{R}_0)=k\langle X\rangle/(\mathfrak{R}_0)$ be a finitely presented quadratic algebra.

(a) We say that $\mathcal{A}_0(k,X,\mathfrak{R}_0)$ is *an algebra with binomial relations of skew-polynomial type,* if the set of generators X is ordered: $X=\{x_1<x_2<\cdots<x_n\}$, and the set of defining relations

$$\mathfrak{R}_0=\{x_jx_i=c_{ij}x_{i'}x_{j'}|1\leqslant i<j\leqslant n,\},$$

contains precisely $n(n-1)/2$ quadratic square-free binomial relations such that the following three conditions hold:

(1) Each monomial xy, with $x\neq y$, $x, y\in X$ occurs in exactly one relation in $\mathfrak{R}_0$; a monomial of the type xx does not occur in any relation in $\mathfrak{R}_0$;
(2) $c_{ij}\neq 0$, for all i,j with $1\leqslant i<j\leqslant n$;
(3) For every pair, i,j with $1\leqslant i<j\leqslant n$, there are inequalities: $j>i'$, $i'<j'$.

(b) An algebra $\mathcal{A}_0=\mathcal{A}_0(k,X,\mathfrak{R}_0)$ with binomial relations of skew-polynomial type is called *a binomial skew-polynomial ring* (we refer to it also as *a skew-polynomial ring with binomial relations*, see Ref. 8) if

(4) $\mathfrak{R}_0$ is a Groebner basis of the ideal $I=(\mathfrak{R}_0)$ in the free associative algebra $k\langle X\rangle$, with respect to the degree-lexicographic ordering of the free semigroup $\langle X\rangle$.

Remark 9.4: It follows from the Diamond Lemma, cf. Ref. 4, that condition 9.3.4 is equivalent to each of the conditions (4′) and (4″) below.

(4′) The set of ordered monomials,

$$\mathcal{N}_0=\{x_1^{\alpha_1}x_2^{\alpha_2}\cdots x_n^{\alpha_n}|\alpha_i\geqslant 0,1\leqslant i\leqslant n\}$$

is a k-basis of $\mathcal{A}_0$, as a k-vector space.

(4″) The monomials $x_kx_jx_i$, with $k>j>i$ do not give rise to new relations in $\mathcal{A}_0$.

Note that given the relations $\mathfrak{R}_0$, condition (4″) is recognizable.

Definition 9.5: Let $\mathcal{A}_0=\mathcal{A}_0(k,X,\mathfrak{R}_0)$ be an algebra with binomial relations of skew-polynomial-type.

Let V be the k-vector space with a basis $x_1,\ldots,x_n$. Consider the linear automorphism $R=R(\mathfrak{R}_0)$ of $V\otimes V$ defined as follows:

(a) for each pair i, j, $1\leqslant i<j\leqslant n$, we set

$$R(x_j\otimes x_i)=c_{ij}x_{i'}\otimes x_{j'},\quad 1\leqslant i<j\leqslant n,$$

$$R(x_{i'}\otimes x_{j'})=\frac{1}{c_{ij}}x_j\otimes x_i,\quad 1\leqslant i<j\leqslant n;$$

(b) for each i, $1\leqslant i\leqslant n$

$$R(x_i\otimes x_i)=x_i\otimes x_i.$$

We say that R is *the automorphism* associated with the relations $\mathfrak{R}_0$, and denote it by $R(\mathfrak{R}_0)$. We also define the bijection $r=r(\mathfrak{R}_0)$ of X^2 onto itself, as

$$r(x_jx_i)=x_{i'}x_{j'},\quad r(x_{i'}x_{j'})=x_jx_i,\quad \text{whenever } x_jx_i=c_{ij}x_{i'}x_{j'}\in\mathfrak{R}_0, \tag{9.5}$$

and

$$r(xx)=xx,\quad \text{for all } x\in X. \tag{9.6}$$

Lemma 9.6: Assume that $\mathcal{A}_0(k,X,\mathfrak{R}_0)=k\langle X\rangle/(\mathfrak{R}_0)$ is an algebra with binomial relations of skew-polynomial type, and let $R=R(\mathfrak{R}_0)$ be the automorphism of $V\otimes V$ associated with the rela-

tions $\mathfrak{R}_0$. Then R is a solution of the classical Yang–Baxter equation if and only if $\mathfrak{R}_0$ is Groebner basis.

Proof: Assume that $R=R(\mathfrak{R}_0)$ is a solution of the Yang–Baxter equation. We will prove that $\mathfrak{R}_0$ is a Groebner basis. It will be enough to show that each monomial $x_kx_jx_i$, with $k>j>i$, can be reduced by means of reductions defined via $\mathfrak{R}_0$ to a unique element of the shape $\alpha_{ijk}x_{i'}x_{j'}x_{k'}$, where $1\leqslant i'<j'<k'\leqslant n$, and α_{ijk} is a uniquely determined coefficient, $0\neq\alpha_{ijk}\in k$. Let $(X,r(R))$ be the associated set-theoretic solution, see (9.3). Denote $r^{12}=r\times id_X$, $r^{23}=id_X\times r$. Then the group ${}_{\mathrm{gr}}\langle r^{12},r^{23}\rangle$, which is isomorphic to the symmetric group S_3, acts on the set X^3. Consider the orbit $\mathcal{O}_0$ of $w=x_kx_jx_i$ under this action. It is not difficult to see that it has precisely 6 elements. By Lemma 6.5, the relations $\mathfrak{R}(r)$ form a Groebner basis, therefore the orbit $\mathcal{O}_0$ contains exactly one ordered monomial, namely some $w_0=x_{i'}x_{j'}x_{k'}$, such that $1\leqslant i'<j'<k'\leqslant n$.

Clearly, the orbit $\mathcal{O}$ of $x_kx_jx_i$ under the action of ${}_{\mathrm{gr}}\langle R^{12},R^{23}\rangle$ on kX^3 contains the same monomials of X^3 as $\mathcal{O}_0$, but, in general, they occur with nonzero coefficients which might be different from 1. In particular, $\mathcal{O}$ contains exactly one element in *normal form modulo* $\mathfrak{R}_0$, namely $\alpha x_{i'}x_{j'}x_{k'}$ where $\alpha\in k$, $\alpha\neq 0$. It is also clear that each sequence of reductions (in the sense of Ref. 4) reduces the monomial $x_kx_jx_i$ to some element of the orbit $\mathcal{O}$. It follows then, that the ambiguity $x_kx_jx_i$, $k>j>i$ is solvable, therefore $\mathfrak{R}_0$ is Groebner basis.

Conversely, let $\mathfrak{R}_0$ be a Groebner basis. Consider the associated linear automorphism $R(\mathfrak{R}_0)$ and the associated bijective map $r=r(R(\mathfrak{R}_0)):X^2\to X^2$. By Ref. 15, Theorem 1.4, r is a solution of the set-theoretic Yang–Baxter equation. Now one can easily deduce that $R(\mathfrak{R}_0)$ is a solution of the classical Yang–Baxter equation. □

Theorem 9.7: *Let V be finite-dimensional vector space over a field k, with a k-basis X. Suppose R is a linear automorphism of $V\otimes V$. Then the following conditions are equivalent:*

(1) *(k,X,R) is a binomial solution of the classical Yang–Baxter equation.*
(2) *There exists an ordering of X, $X=\{x_1<x_2<\cdots<x_n\}$, such that the associated quadratic algebra $\mathcal{A}=\mathcal{A}(k,X,R)=k\langle X\rangle/(\mathfrak{R}(R))$ is a binomial skew-polynomial ring.*

Furthermore, each of the above conditions implies that $\mathcal{A}$ is a Yang–Baxter algebra which satisfies conditions 4–11 of Theorem 6.1. In particular, $\mathcal{A}$ is PBW, a Noetherian domain, and an Artin–Schelter regular ring of global dimension n.[1,28]

Proof: (1)⇒(2). Assume (k,X,R) is a binomial solution of the classical Yang–Baxter equation. Consider the associated set-theoretic solution $(X,r(R))$. It follows from 2.26 that there exists an ordering $X=\{x_1<\cdots<x_n\}$ such that the relations $\mathfrak{R}(r(R))$ are of skew-polynomial type. Then the relations $\mathfrak{R}(R)$ of the Yang–Baxter algebra $\mathcal{A}$ associated to (k,X,R) are also of skew-polynomial-type. Now Lemma 9.6 implies that $\mathfrak{R}(R)$ is a Groebner basis, therefore $\mathcal{A}(k,X,R)$ is a skew-polynomial ring. The implication (1)⇒(2) follows from Lemma 9.6.

The remaining part of the theorem presents properties of the skew-polynomial rings with binomial relations, $\mathcal{A}_0$, which can be extracted from our previous works. The Noetherian properties were proven in Ref. 9, a combinatorial proof of the Artin–Schelter regularity of $\mathcal{A}_0$ was first given in Ref. 10. Conditions 4–11 of Theorem 6.1, have been deduced in Ref. 15 from algebraic and homological properties of the semigroups S of I-type and the associated semigroup algebras kS. □

ACKNOWLEDGMENTS

Part of this paper was written during my visit at Harvard in 2002. It is my pleasant duty to thank the Department of Mathematics of Harvard University for the invitation. The author was partially supported by the Department of Mathematics of Harvard University, Grant No. MM1106/2001 of the Bulgarian National Science Fund of the Ministry of Education and Science, and by the Programme "Noncommutative Geometry" of the European Science Foundation. I express my gratitude to David Kazhdan for our valuable and stimulating discussions. I thank Shahn Majid for his kind attention to my work and for our inspiring and fruitful discussions. My cordial thanks to

Michel Van den Bergh for our productive cooperation, for drawing my attention to the study of set-theoretic solutions of the Yang–Baxter equation, and for his moral support through the years. I am grateful to Wolfgang Rump for providing me with his preprint.

Recoupling Lie algebra and universal ω-algebra

William P. Joyce[a)]
Department of Physics and Astronomy, University of Canterbury, Private Bag 4800, Christchurch, New Zealand

(Received 2 March 2004; accepted 7 June 2004; published 12 October 2004)

We formulate the algebraic version of recoupling theory suitable for commutation quantization over any gradation. This gives a generalization of graded Lie algebra. Underlying this is the new notion of an ω-algebra defined in this paper. ω-algebra is a generalization of algebra that goes beyond nonassociativity. We construct the universal enveloping ω-algebra of recoupling Lie algebras and prove a generalized Poincaré–Birkhoff–Witt theorem. As an example we consider the algebras over an arbitrary recoupling of $\mathbb{Z}_n$ graded Heisenberg Lie algebra. Finally we uncover the usual coalgebra structure of a universal envelope and substantiate its Hopf structure. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1789281]

I. INTRODUCTION

Graded Lie algebra[1–3] is of fundamental importance in quantum theory. It is the algebraic structure necessary to introduce a commutator (for bosons) and anticommutator (for fermions) to achieve quantization of a physical system. The universal enveloping algebra provides creation and annihilation operators which generate ensembles of particles. These particles must form representations of symmetries present in the physical system and as such must satisfy an appropriate recoupling theory. In Joyce[4] from broad physical requirements the most general form of a recoupling theory was deduced. This leads to a complete representation theory[5–9] generalizing the Racah–Wigner calculus.[10–14] The process of recoupling could at best introduce recoupling phases for associativity, commutativity, and identity graded according to some Abelian group. For example, this Abelian group is $\mathbb{Z}_n$ for SU(n). Usually the identity and associativity are implicity taken to be unity. However, Joyce[4,15] demonstrated that for SU(3) color this restriction admitted no Bose–Fermi recoupling. Moreover, it was shown that nonassociative recoupling phases breaking the pentagon condition were crucial.

In the associative case the commutativity phase factors are precisely the color (or commutation) factors of color algebra.[16–21] The general case is a nontrivial extension which is necessary in order to accommodate SU(3) color. This paper reviews the recoupling phases and defines the extension of graded Lie algebra (or color algebra) embodying the general recoupling situation, called *recoupling Lie algebra*.

There is no acceptable notion of universal enveloping algebra. For example, Isaac *et al.*[22] investigated SU(3) color. Although an apparent confinement mechanism[23] analogous to the octonion confinement principle of Günaydin and Gürsey[24] applies the envelope itself is finite. For example, the Bose–Fermi deformativity phase for two mesons is $\xi_{1,2,1,2}=-1$ prohibiting the existence of such a composite. This would run contrary to the existence of boundless multiple mesonic (and baryonic) states observed in nature. The difficulty arises because any universal envelope based on the pentagon constraint, such as an algebra, is too restrictive. The solution is to be found in the new notion of an ω-algebra. This is an extension of algebra where such statements as $(ab)(cd)$, ambiguous in the sense that there is no unique order in which to evaluate, are avoided. In ω-algebra this example would be either $(ab)_1(cd)_2$ or $(ac)_2(cd)_1$. The first (respectively, second)

a)Electronic mail: w.joyce@phys.canterbury.ac.nz

evaluates *ab* after (respectively, before) *cd*. Using this notion we construct a universal enveloping ω-algebra and prove the corresponding ω-Poincaré–Birkhoff–Witt theorem under suitable conditions. Note that the proof does not utilize the notion of an ω-module which would parallel the standard proof. (See, for example, Knapp.[25]) We uncover the usual coalgebra structure of the universal enveloping ω-algebra and describe its Hopf structure.

Given the natural extension of algebra given by ω-algebra it is natural to consider in general omegafied structures. Particularly, ω-coalgebra, ω-bialgebra, Hopf ω-algebra, ω-modules, ω-comodules, and ω-tensor product. The last leading to a notion of ω-Fock space. All these require a general theory of ω-monoidal category theory.[26]

The last 20 years or so has seen the intense development of braided structures[27–29] in mathematics and physics. We suggest that any equally intense focus should be given to generalizations of nonassociative structures. Let us not forget the important role that nonassociative structures already play in physics. The most notable example being Lie alegbra.[25] For a survey of nonassociative structures in physics see Lõhmus *et al.*[30]

II. SYMMETRIC UNITAL PSEUDOMONOIDAL RECOUPLING

We begin with the constraints on the recoupling phase factors of a unital symmetric premonoidal recoupling as derived in Joyce.[4] This is a special case of the full premonoidal theory[31,32] and admits nonassociative recouplings. Given an Abelian group $\mathbb{A}$ then a recoupling is determined by its phase factors, compactly written as the maps

$$\xi:\mathbb{A}^4 \to S^1,\ \ (m,n,p,q) \mapsto \xi_{m,n,p,q}, \tag{1}$$

$$\alpha:\mathbb{A}^3 \to S^1,\ \ (m,n,p) \mapsto \alpha_{m,n,p}, \tag{2}$$

$$\gamma:\mathbb{A}^2 \to S^1,\ \ (m,n) \mapsto \gamma_{m,n}, \tag{3}$$

$$\lambda:\mathbb{A} \to S^1,\ \ m \mapsto \lambda_m, \tag{4}$$

$$\rho:\mathbb{A} \to S^1,\ \ m \mapsto \rho_m \tag{5}$$

for all $m,n,p,q \in \mathbb{A}$ where $S^1 \subset \mathbb{C}\backslash\{0\}$ is the unit circle. Note that the restriction to S^1 could be generalized to the invertible elements of any field. These phases define, respectively, recouplings for deformativity, associativity, commutativity, and left and right identity. It turns out to be useful to define a further phase map

$$\beta:\mathbb{A}^3 \to S^1,\ \ (n,m,p) \mapsto \beta_{n,m,p} = \frac{\alpha_{m,n,p}\alpha_{n,p,m}}{\alpha_{n,m,p}} \tag{6}$$

for all $m,n,p \in \mathbb{A}$. The phases are constrained by

$$\xi_{m,n,p,q} = \frac{\alpha_{m,n,p}\alpha_{m,n+p,q}\alpha_{n,p,q}}{\alpha_{m+n,p,q}\alpha_{m,n,p+q}}, \tag{7}$$

$$\xi_{m,n,p,q} = \xi_{n,m,p,q}, \tag{8}$$

$$\xi_{p,q,m,n} = \frac{1}{\xi_{m,n,p,q}}, \tag{9}$$

$$\gamma_{m,n+p} = \frac{\gamma_{m,n}\gamma_{m,p}}{\beta_{n,m,p}}, \tag{10}$$

$$\gamma_{n,m} = \frac{1}{\gamma_{m,n}}, \tag{11}$$

$$\lambda_{m+n} = \frac{\lambda_m}{\alpha_{0,m,n}}, \tag{12}$$

$$\rho_m = \alpha_{m,0,n}\lambda_n, \tag{13}$$

$$\rho_{m+n} = \alpha_{m,n,0}\rho_n \tag{14}$$

for all $m,n,p,q,r \in \mathbb{A}$. Note that (7) provides a formula for $\xi_{m,n,p,q}$ and (13) provides a formula for ρ_m. Thus ξ and ρ are entirely redundant, as of course is β. Finally we denote the $\mathbb{A}$ graded recoupling by the triplet (α,γ,λ). The set of recouplings for a given Abelian group $\mathbb{A}$ is denoted $R_{\mathbb{A}}$. This is itself an Abelian group with addition given by pointwise multiplication $(\alpha_1,\gamma_1,\lambda_1)+(\alpha_2,\gamma_2,\lambda_2)=(\alpha_1\cdot\alpha_2,\gamma_1\cdot\gamma_2,\lambda_1\cdot\lambda_2)$. Clearly the identity is the recoupling with all phases one and the inverse is given by $-(\alpha,\gamma,\lambda)=(1/\alpha,1/\gamma,1/\lambda)$.

We make the following observations. Due to (10) we have

$$\beta_{p,m,n} = \beta_{n,m,p}. \tag{15}$$

The constraints (8) and (9) imply the condition

$$\xi_{m,n,p,q} = \xi_{m,n,q,p}. \tag{16}$$

Taking $n=0$ in (12) gives

$$\alpha_{0,m,0} = 1. \tag{17}$$

Hence (13) with $m=n=0$ shows $\lambda_0=\rho_0$. Thus (12) with $m=0$ provides us with a formula for λ_m, and (13) with $n=0$ a formula for ρ_m, in terms of λ_0, $\alpha_{m,0,0}$, and $\alpha_{0,0,m}$,

$$\lambda_m = \frac{\lambda_0}{\alpha_{0,0,m}}, \tag{18}$$

$$\rho_m = \alpha_{m,0,0}\lambda_0. \tag{19}$$

Substituting these formulas back into (12), (13), and (14) gives formulas for α when one index is 0,

$$\alpha_{m,n,0} = \frac{\alpha_{m+n,0,0}}{\alpha_{n,0,0}}, \tag{20}$$

$$\alpha_{m,0,n} = \alpha_{m,0,0}\alpha_{0,0,n}, \tag{21}$$

$$\alpha_{0,m,n} = \frac{\alpha_{0,0,m+n}}{\alpha_{0,0,m}}, \tag{22}$$

for all m, $n \in \mathbb{A}$. Taking $n=p=0$ in (10) gives

$$\gamma_{m,0} = \alpha_{m,0,0}\alpha_{0,0,m}. \tag{23}$$

In particular $\gamma_{0,0}=1$. Substituting into (7) using (20), (21), and (22) gives

$$\xi_{m,n,p,q} = 1, \tag{24}$$

whenever $m=0$, $n=0$, $p=0$ or $q=0$. Thus we have the following two choices of independent phases given by λ_0, λ_m, and ρ_m where $m \in \mathbb{A}\backslash\{0\}$ or λ_0, $\alpha_{m,0,0}$, and $\alpha_{0,0,m}$ where $m \in \mathbb{A}\backslash\{0\}$.

Let **Rcp** be the category of recouplings whose objects are recouplings $(\alpha, \gamma, \lambda)$ and whose morphisms $(\alpha, \gamma, \lambda) \to (\alpha', \gamma', \lambda')$ are group homomorphisms $\phi: \mathbb{A}' \to \mathbb{A}$ satisfying

$$\alpha(\phi \times \phi \times \phi) = \alpha', \tag{25}$$

$$\gamma(\phi \times \phi) = \gamma', \tag{26}$$

$$\lambda\phi = \lambda'. \tag{27}$$

A recoupling $(\alpha, \gamma, \lambda)$ is called reducible if there is a group $\mathbb{A}'$ of lower cardinality than $\mathbb{A}$ and an epimorphism $\phi: (\alpha', \gamma', \lambda') \to (\alpha, \gamma, \lambda)$. (That is, $\phi: \mathbb{A} \to \mathbb{A}'$ is onto.) Whenever such a morphism exists the recoupling is constant on each fiber $\phi^{-1}(a')$. This gives an isomorphism between the typical fiber $\mathrm{Ker}\,\phi = \phi^{-1}(0)$ direct product the base space $\mathrm{coKer}\,\phi = \mathbb{A}'$ and $\mathbb{A}$. Equivalently, $\mathbb{A}/\mathrm{Ker}\,\phi \cong \mathbb{A}'$.

Example 1: Let $\mathbb{A}' \subset \mathbb{A}$ then we may extended any recoupling $(\alpha', \gamma', \lambda')$ on $\mathbb{A}'$ to a recoupling $(\alpha, \gamma, \lambda)$ on $\mathbb{A}$ as follows. Let $\phi: \mathbb{A}/\mathbb{A}' \to \mathbb{A}$ be a mapping satisfying $\phi(m+\mathbb{A}') \in m+\mathbb{A}'$, that is a choice function. Given $m \in \mathbb{A}$ there is a unique $\hat{m} \in \mathbb{A}'$ such that $m = \hat{m} + \phi(m+\mathbb{A}')$. Thus we define the reducible recoupling on $\mathbb{A}$ (reducible to $\mathbb{A}'$) by $\alpha_{m,n,p} = \alpha'_{\hat{m},\hat{n},\hat{p}}$, $\gamma_{m,n} = \gamma'_{\hat{m},\hat{n}}$, and $\lambda_m = \lambda'_{\hat{m}}$.

III. ALGEBRAIC RECOUPLING THEORY

We develop an extension of graded Lie algebra[1–3] utilizing the recoupling phase theory summerized in the preceding section. In this paper we let $\mathbb{N}_+ = \{1, 2, 3, \ldots\}$ be the multiplicative monoid of natural numbers, and $\mathbb{N} = \{0\} \cup \mathbb{N}_+ = \{0, 1, 2, \ldots\}$ the additive monoid of natural numbers.

Definition 1: A recoupling Lie algebra for a symmetric unital recoupling $(\alpha, \gamma, \lambda)$ over an Abelain group $\mathbb{A}$ is an $\mathbb{A}$ graded vector space

$$\mathcal{L} = \bigoplus_{m \in \mathbb{A}} \mathcal{L}_m, \tag{28}$$

and an $\mathbb{A}$ graded bilinear map $[\_, \_]: \mathcal{L} \otimes \mathcal{L} \to \mathcal{L}$ called the commutator taking $a \otimes b \mapsto [a, b]$ satisfying

(i) *Recoupling skew-symmetry,*

$$[a, b] = -\gamma_{m,n}[b, a] \tag{29}$$

for all $a \in \langle\mathcal{L}\rangle_m$ and $b \in \langle\mathcal{L}\rangle_n$.

(ii) *Recoupling Jacobi identity,*

$$\alpha_{m,p,n}[[a, b], c] - \alpha_{m,n,p}\gamma_{n,p}[[a, c], b] - \alpha_{m,n,p}\alpha_{m,p,n}[a, [b, c]] = 0 \tag{30}$$

for all $a \in \langle\mathcal{L}\rangle_m$, $b \in \langle\mathcal{L}\rangle_n$, and $c \in \langle\mathcal{L}\rangle_p$.

The commutator is a multiplication for $\mathcal{L}$ making it an algebra. The grade zero component $\langle\mathcal{L}\rangle_0$ is a Lie subalgebra of $\mathcal{L}$ and has the adjoint action on $\mathcal{L}$.

Given two recoupling Lie algebras $\mathcal{L}$ and $\mathcal{L}'$ over the same recoupling we can form the direct sum recoupling Lie algebra $\mathcal{L} \oplus \mathcal{L}'$ which is the direct sum of the underlying vector spaces with the bracket defined by

$$[a \oplus a', b \oplus b'] = [a,b] \oplus 0 + 0 \oplus [a',b'], \tag{31}$$

where a, b, a', $b' \in \mathcal{L}$. It is easy to see that the recoupling skew-symmetry and Jacobi identities hold.

If $\mathbb{A}=\mathbb{Z}_1$ there is only the trivial choice of recoupling and hence $\mathcal{L}$ (with the commutator) is a Lie algebra. For $\mathbb{Z}_2$ one can take all phases one except $\gamma_{1,1}=\pm 1$. If $\gamma_{1,1}=1$ then $\mathcal{L}$ is a Lie algebra, otherwise $\gamma_{1,1}=-1$ and $\mathcal{L}$ is a super Lie algebra. For $\mathbb{A}=\mathbb{Z}_N$ with α and λ trivial we obtain $\gamma_{m,n}=\gamma_{1,1}^{mn}$. If $\gamma_{1,1}=1$ we have a Lie algebra, otherwise $\gamma_{1,1}=-1$ and N is even giving the $\mathbb{Z}_N$ graded Lie algebras of Green.[16] Moreover, these recouplings are reducible to the $\mathbb{Z}_2$ recoupling with $\gamma_{1,1}=-1$.

IV. ω-ALGEBRA

Nonassociative recoupling requires a generalization of the notion of an algebra. This will allow us to define universal envelopes, prove a corresponding Poincaré–Birkhoff–Witt theorem and deduce a generalized Hopf structure.

Definition 2: A weak ω-algebra consists of a vector space $\mathcal{A}$, a family of symmetric subspaces $\mathcal{D}_n$ of $\mathcal{A}\otimes\mathcal{A}$ for all $n\in\mathbb{N}_+$ such that $\mathcal{D}_m\subset\mathcal{D}_n$ whenever $m<n$, and a family of linear maps $\mu_m:\mathcal{D}_m\to\mathcal{A}$ for all $m\in\mathbb{N}_+$.

To simplify notation we write $\mu_m(a\otimes b)$ as $(ab)_m$. Recall that symmetry of $\mathcal{D}_m$ means $a\otimes b \in \mathcal{D}_m$ if and only if $b\otimes a\in\mathcal{D}_m$.

An enhanced coupling tree is a rooted planar binary tree t whose set of nodes is a finite subset of $\mathbb{N}$ such that the root node is 0 and every sequence of nodes from the root node to a leaf node is an increasing sequence. Let $|t|$ represent the number of its leaves, $\{t\}_E\subset\mathbb{N}$ the set of nodes and $\{t\}\subset\{t\}_E$ the nodes of t that are not leaves nor the root. Let T_E denote the set of enhanced coupling trees. We define two useful families of cutting operations on T_E. Let $m\in\mathbb{N}$ then we define, respectively, the upper and lower cut operations $\vee_m$, $\wedge_m: T_E\to T_E$ as follows. Given $t\in T_E$ cut the edge joining m to its immediate descendent. The tree containing m is taken to be $\vee_m t$ (the empty tree if $m\notin\{t\}_E$) and $\wedge_m t$ the portion remaining. Two enhanced coupling trees s and t are equivalent, written $s\sim t$, if the trees with the leaf and root edges and nodes removed are identical. Each equivalence class is called a coupling tree. The set of coupling trees is denoted $T=T_E/\sim$.

Let $t\in T$ then we define $\mathcal{D}_t$ inductively to be the linear span of all $a_1\otimes\cdots\otimes a_{|t|}\in\mathcal{A}^{\otimes|t|}$ such that $a_j\otimes a_k\in\mathcal{D}_m$ for all $l\leqslant j<k\leqslant|t|$ and

$$a_1\otimes\cdots\otimes a_{i-1}\otimes\mu_m(a_i\otimes a_{i+1})\otimes a_{i+2}\otimes\cdots\otimes a_{|t|}\in\mathcal{D}_{\wedge_m t}, \tag{32}$$

where $m=\sup\{t\}$ and m was attached to the ith leaf of $\wedge_m t$. If t is the tree with two leaves and the single internal node m then $\mathcal{D}_t=\mathcal{D}_m$. If $t=|$ is the unique tree consisting of a single edge then $\mathcal{D}_t=\mathcal{A}$ or the empty tree $t=\emptyset$ then $\mathcal{D}_t=\{0\}$. Now we can define the product map $\mu_t:\mathcal{D}_t\to\mathcal{A}$ of $|t|$ factors given by t. Inductively this is defined by

$$\mu_t(a_1\otimes\cdots\otimes a_{|t|})=\mu_{\wedge_m t}(1^{\otimes i-1}\otimes\mu_m\otimes 1^{\otimes|t|-i-1}), \tag{33}$$

where $m=\sup\{t\}$ and m was attached to the ith leaf of $\wedge_m t$.

With this notation we can easily define the important notion of a (strong) ω-algebra.

Definition 3: A (strong) ω-algebra $\mathcal{A}$ is a weak ω-algebra such that given $s,t\in T$ and $m\in\mathbb{N}_+$ then whenever $\{s\}\cap\{t\}=\emptyset$ and $\inf\{s\}$, $\inf\{t\}>m$ we have $\mu_s(\mathcal{D}'_s)\otimes\mu_t(\mathcal{D}'_t)\subset\mathcal{D}_m$ whenever $\mathcal{D}'_s\otimes\mathcal{D}'_t\subset\mathcal{D}_{(st)_m}$. *The ω-algebra is called strict if whenever s,t are such that $\{s\}\cap\{t\}\neq\emptyset$ or* $\inf\{s\}$, $\inf\{t\}>m$ *then we have that the intersection of the span of $\{\mu_s(\mathcal{D}'_s)\otimes\mu_t(\mathcal{D}'_t):\mathcal{D}'_s\otimes\mathcal{D}'_t\subset\mathcal{D}_{(st)_m}\}$* with $\mathcal{D}_m$ is empty.

Define $\mathcal{A}_m=\{a\in\mathcal{A}:$ there is $b\in\mathcal{A}$ with $a\otimes b\in\mathcal{D}_m\}$. Thus $\mathcal{A}_n\subset\mathcal{A}_m$ whenever $m<n$ and $\mu_{m+1}(\mathcal{D}_{m+1})\subset\mathcal{A}_m$. An ω-algebra is called unital if there is $1\in\mathcal{A}_1$ such that $1\otimes a\in\mathcal{D}_m$ for all $a\in\mathcal{A}_m$ and

$$\mu_m(1 \otimes a) = \mu_m(a \otimes 1) = a \tag{34}$$

for all $a \in \mathcal{A}_m$ and $m \in \mathbb{N}_+$. We write this as $(1a)_m = a = (a1)_m$. Note that a unital ω-algebra cannot be strict. An ω-algebra is called associative if

$$\mu_m(\mu_n(a \otimes b) \otimes c) = \mu_m(a \otimes \mu_n(b \otimes c)), \tag{35}$$

for all $a \otimes b,\ b \otimes c \in \mathcal{D}_n$ and $m < n$. This may be written in the compact form $((ab)_n c)_m = (a(bc)_n)_m$. And commutative if

$$\mu_m(a \otimes b) = \mu_m(b \otimes a) \tag{36}$$

for all $a \otimes b \in \mathcal{D}_m$ and $m \in \mathbb{N}_+$.

Every algebra is an ω-algebra with $\mathcal{D}_m = \mathcal{A} \otimes \mathcal{A}$ and $\mu_m = \mu$ for all $m \in \mathbb{N}_+$. Given an algebra $\mathcal{A}$ then one may construct the ω-algebra $\omega[\mathcal{A}]$ over $\mathcal{A}$ as follows. Consider the vector space $\mathcal{A}\{\mathcal{P}(\mathbb{N}_+)\}$ built from the finite power Abelian monoid $\mathcal{P}(\mathbb{N}_+)$ of finite subsets of $\mathbb{N}_+$. A typical element is a finite formal sum $a = \Sigma_{P \in \mathcal{P}(\mathbb{N}_+)} a^P P$ with $a^P \in \mathcal{A}$. That is, only a finite number of the coefficients are nonzero. A multiplication is given by

$$ab = \sum_{P,Q \in \mathcal{P}(\mathbb{N}_+)} a^P b^Q P \cup Q. \tag{37}$$

Take $\omega[\mathcal{A}]$ to be the vector space $\mathcal{A}\{\mathcal{P}(\mathbb{N}_+)\}$. Let $\mathcal{D}_n$ be the linear span of $\{a \otimes b \in \omega[\mathcal{A}] \otimes \omega[\mathcal{A}] : a^P, b^Q \neq 0$ implies $P \cap Q = \varnothing$ and $(P \cup Q) \cap \{1, \ldots, n\} = \varnothing$ for all $P, Q \in \mathcal{P}(\mathbb{N}_+)\}$ then $\mathcal{A}_m = \{a \in \omega[\mathcal{A}] : a^P \neq 0$ implies $P \cap \{1, \ldots, m\} = \varnothing$ for all $P \in \mathcal{P}(\mathbb{N}_+)\}$. We define the bilinear maps $\mu_m : \mathcal{D}_m \to \omega[\mathcal{A}]$ by

$$(ab)_m = \sum_{P,Q \in \mathcal{P}(\mathbb{N}_+)\setminus\{\varnothing\}} a^P b^Q P \cup Q \cup \{m\} + \sum_{P \in \mathcal{P}(\mathbb{N}_+)\setminus\{\varnothing\}} (a^P b^\varnothing + a^\varnothing b^P) P + a^\varnothing b^\varnothing \varnothing \tag{38}$$

for all $a \otimes b \in \mathcal{D}_m$. If $\mathcal{A}$ is unital then so is $\omega[\mathcal{A}]$ with unit $\varnothing$. If $\mathcal{A}$ is associative (respectively, commutative) then so is $\omega[\mathcal{A}]$.

An important construction is the free ω-algebra over coupling trees. Let $\mathbb{C}\{T\}$ the vector space freely generated by T. Let $\mathcal{D}_m$ be the subspace spanned by the coupling trees $s \otimes t \in \mathbb{C}\{T\} \otimes \mathbb{C}\{T\}$ where s, t have no labels in common and all labels greater than m. We define $\mu_m : \mathcal{D}_m \to \mathbb{C}\{T\}$ to be given by joining the roots of the coupling trees s, t to the node m. Thus m is the root of the joined tree $(st)_m$. The unit is the tree with no leaves.

One may form the tensor product of two ω-algebras $\mathcal{A}$ and $\mathcal{A}'$ as follows. Let $\mathcal{A} \otimes \mathcal{A}'$ be the usual tensored vector space. Define the trivial symmetric braid $R : \mathcal{A}' \otimes \mathcal{A} \to \mathcal{A} \otimes \mathcal{A}'$ by $R(a' \otimes a) = a \otimes a'$ for all $a \in \mathcal{A}$ and $a' \in \mathcal{A}'$. The bilinear products $\mu'' : \mathcal{D}''_m \to \mathcal{A} \otimes \mathcal{A}'$ are given by $\mu''_m = (\mu_m \otimes \mu'_m)(1 \otimes R \otimes 1)$ and

$$\mathcal{D}''_m = \{f \otimes g \otimes h \otimes k \in (\mathcal{A} \otimes \mathcal{A}')^{\otimes 2} : f \otimes h \in \mathcal{D}_m \text{ and } g \otimes k \in D'_m\}. \tag{39}$$

In particular we have

$$\mu''_m(f \otimes g \otimes h \otimes k) = \mu_m(f \otimes h) \otimes \mu'_m(g \otimes k) \tag{40}$$

for all $g \in \mathcal{A}'$, $h \in \mathcal{A}$, and $m \in \mathbb{N}_+$. It is straightforward to check that this does indeed define an ω-algebra. If $\mathcal{A}$ and $\mathcal{A}'$ are unital then so is $\mathcal{A} \otimes \mathcal{A}'$ with unit $1 \otimes 1'$. If $\mathcal{A}$ and $\mathcal{A}'$ are associative (respectively, commutative) then $\mathcal{A} \otimes \mathcal{A}'$ is associative (respectively, commutative).

A morphism of ω-algebras is a linear map $\phi : \mathcal{A} \to \mathcal{A}'$ satisfying

$$(\phi \otimes \phi)\mathcal{D}_m \subset \mathcal{D}'_m, \tag{41}$$

$$\phi\mu_m = \mu'_m(\phi \otimes \phi) \tag{42}$$

for all $m \in \mathbb{N}_+$. It follows that $\phi\mathcal{A}_m \subset \mathcal{A}'_m$.

An ω-algebra $\mathcal{A}$ is called a derived ω-algebra $\mathcal{A}'$ if there is an isomorphism $\phi: \mathcal{A} \to \omega[\mathcal{A}']$. Moreover, this isomorphism is weakly universal from $\mathcal{A}$ to $\omega[\mathcal{A}']$. Hence given another algebra $\mathcal{B}$ such that $\mathcal{A} \cong \omega[\mathcal{B}]$ then $\mathcal{A}' \cong \mathcal{B}$. Similarly we can conclude that $\omega[\mathcal{A}' \otimes \mathcal{A}''] \subset \omega[\mathcal{A}'] \otimes \omega[\mathcal{A}'']$ for all algebras $\mathcal{A}'$ and $\mathcal{A}''$ by considering the subset $\mathcal{A}''\emptyset$ of $\omega[\mathcal{A}'']$.

An ω-algebra $\mathcal{A}$ is $\mathbb{A}$ graded if the underlying vector space and bilinear products are all $\mathbb{A}$ graded. In detail, if

$$\mathcal{A} = \bigoplus_{p \in \mathbb{A}} \mathcal{A}_p \tag{43}$$

then define $\langle \mathcal{D}_m \rangle_{p,q} = \{d \in \langle \mathcal{A} \rangle_p \otimes \langle \mathcal{A} \rangle_q : d \in \mathcal{D}_m\}$ for all $p, q \in \mathbb{A}$ and $m \in \mathbb{N}_+$, then we have that

$$\mathcal{D}_m = \bigoplus_{(p,q) \in \mathbb{A}^2} \langle \mathcal{D}_m \rangle_{p,q}. \tag{44}$$

The bilinear product is $\mathbb{A}$ graded if $\mu_m \langle \mathcal{D}_m \rangle_{p,q} \subset \langle \mathcal{A} \rangle_{p+q}$. In particular the free algebra $\mathbb{C}[T]$ over coupling trees is $\mathbb{Z}$ graded because the monoid T is $\mathbb{Z}$ graded by leaf number.

An $\mathbb{A}$ graded ω-algebra $\mathcal{A}$ is called a recoupling ω-algebra if there is a recoupling $(\alpha, \gamma, \lambda)$ and $\hbar \in \langle \mathcal{A}_1 \rangle_0$ over $\mathbb{A}$ such that

$$((ab)_n c)_m = \alpha_{k,l,p}(a(bc)_n)_m, \tag{45}$$

$$(ab)_m = \gamma_{k,l}(ba)_m, \tag{46}$$

$$(\hbar a)_m = \lambda_k a, \tag{47}$$

$$(a\hbar)_m = \rho_k a \tag{48}$$

for all $a \in \langle \mathcal{A} \rangle_k$, $b \in \langle \mathcal{A} \rangle_l$, $c \in \langle \mathcal{A} \rangle_p$, and $m, n \in \mathbb{N}_+$ such that $m < n$. No recoupling ω-algebra is strict.

V. UNIVERSAL ENVELOPING ω-ALGEBRA

In order to give the construction of universal enveloping ω-algebra we need some preliminary structures. Let $T^* \supset T$ be the set of coupling trees with nodules attached to some leaves. Given a set X, let $T^*(X)$ be the ω-monoid of (noduled) coupling trees over X. That is the set of coupling trees whose leaves are labeled by elements of $X \amalg \{\circ\}$ where $\circ$ denotes the nodule. Thus $(t, \mathbf{x}) \in T^* \times X^n$, where n is the number of leaves of t less the number of attached nodules, is composed of a coupling tree t whose nodule-free leaves are labeled (in order) by the n-tuple $\mathbf{x}$. $T^*(X)$ inherits the ω-multiplication from T^* given by

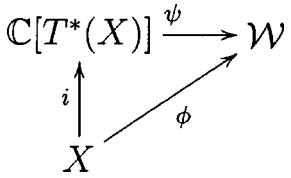
$$((s, \mathbf{x})(t, \mathbf{y}))_m = ((st)_m, \mathbf{xy}), \tag{49}$$

where $\mathbf{xy}$ is the concatenate of the tuples $\mathbf{x}$ and $\mathbf{y}$. The unit is the tree with no leaves. This ω-monoid is $\mathbb{Z} \times \mathbb{Z}$ graded by leaf and nodule number. In order to construct the free ω-algebra over $T^*(X)$ we need the notion of an ω-ideal.

Definition 4: Given an ω-algebra $\mathcal{A}$, a left (*respectively, right*) *ω-ideal $\mathcal{J}$ is a subspace of $\mathcal{A}$ such that for all $m \in \mathbb{N}_+$, $a \in \mathcal{A}$ and $b \in \mathcal{J}$ such that $a \otimes b \in \mathcal{D}_m$ we have $(ab)_m \in \mathcal{J}$* [*respectively, $(ba)_m \in \mathcal{J}$*]. *An ω-ideal is both a left and right ω-ideal.*

Let $\mathbb{C}[T^*(X)]$ be the vector space freely generated by $T^*(X)$. An ω-multiplication is given by $\mu_m(\Sigma_k a^k(s_k, \mathbf{x}_k), \Sigma_l b^l(t_l, \mathbf{y}_l)) = \Sigma_{k,l} a^k b^l((s_k t_l)_m, \mathbf{x}_k \mathbf{y}_l)$ where $a^k b^l \in \mathbb{C}$, $s_k \otimes t_l \in \mathcal{D}_m$, $\mathbf{x}_k \in X^{|s_k|}$ and $\mathbf{y}_l \in X^{|t_l|}$. Clearly $\mathbb{C}[T^*(X)]$ is a unital ω-algebra. We call it the free ω-algebra over X. Moreover, it

has the following universal property. Let $i:X\to\mathbb{C}[T^*(X)]$ be the insertion map $x\mapsto(|,x)$ where $|$ is the unique coupling tree with one leaf. Given any unital ω-algebra $\mathcal{W}$ and mapping $\phi:X\to\mathcal{W}$ there is a unique $\psi:\mathbb{C}[T^*(X)]\to\mathcal{W}$ such that



commutes. If $X=\oplus_{m\in A}\langle X\rangle_m$ is $\mathbb{A}$-graded then so is $T^*(X)$ and hence $\mathbb{C}[T^*(X)]$. Each coupling tree $t\in T^*$ defines a canonical map $t:X\to T^*(X)$ given by $t\mathbf{x}=(t,\mathbf{x})$. Given a coupling tree t with n leaves and $\mathbf{x}\in X^n$ where each x_k is of grade m_k then $t\mathbf{x}$ has grade $m_1+\cdots+m_n$.

Given a recoupling Lie algebra $\mathcal{L}$ let X be an $\mathbb{A}$-graded basis for $\mathcal{L}$. We write $X=X_+\amalg X_-$ where the grade m of any member of $X_\pm$ satisfies $\gamma_{m,m}=\pm1$, respectively. The universal enveloping algebra of $\mathcal{L}$ is defined to be

$$\mathcal{U}(\mathcal{L})=\mathbb{C}[T^*(X)]/\mathcal{J}, \tag{50}$$

where $\mathcal{J}$ is the ideal with generators

$$((r\mathbf{x}s\mathbf{y})_l t\mathbf{z})_k-\alpha_{m,n,p}(r\mathbf{x}(s\mathbf{y}t\mathbf{z})_l)_k, \tag{51}$$

$$(xy)_k-\gamma_{m,n}(yx)_k-[x,y], \tag{52}$$

$$(\circ r\mathbf{x})_k-\lambda_m r\mathbf{x}, \tag{53}$$

$$(r\mathbf{x}\circ)_k-\rho_m r\mathbf{x}, \tag{54}$$

where $r,s,t\in T^*(X)$ have, respectively, u, v, and w leaves, $\mathbf{x}\in X^u$, $\mathbf{y}\in X^v$, and $\mathbf{z}\in X^w$ are of grades m, n, and p, respectively, $x\in\langle X\rangle_m$, $y\in\langle X\rangle_n$, and $k<l$. The symbol $\circ$ represents the unique tree with a single leaf that has a nodule attached. The universal enveloping algebra $\mathcal{U}(\mathcal{L})$ has the following universal property.

Proposition 1: Given an ω-algebra $\mathcal{W}$ and linear map $\phi:\mathcal{L}\to\mathcal{W}$ satisfying

$$((r\phi^u(\mathbf{a})s\phi^v(\mathbf{b}))_l t\phi^w(\mathbf{c}))_k-\alpha_{m,n,p}(r\phi^u(\mathbf{a})(s\phi^v(\mathbf{b})t\phi^w(\mathbf{c}))_l)_k, \tag{55}$$

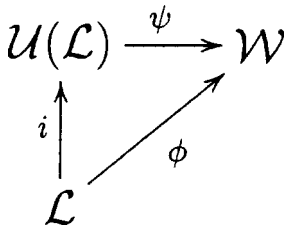
$$(\circ r\phi^u(\mathbf{a}))_k=\lambda_m r\phi^u(\mathbf{a}), \tag{56}$$

$$(r\phi^u(\mathbf{a})\circ)_k=\rho_m r\phi^u(\mathbf{a}) \tag{57}$$

for all $r,s,t\in T^*$ with, respectively, u, v, and w leaves, $\mathbf{a}\in\langle\mathcal{L}^u\rangle_m$, $\mathbf{b}\in\langle\mathcal{L}^v\rangle_n$, $\mathbf{c}\in\langle\mathcal{L}^w\rangle_p$ and $k<l$, and satisfying

$$\phi([a,b])=(\phi(a)\phi(b))_k-\gamma_{m,n}(\phi(b)\phi(a))_k \tag{58}$$

for all $a\in\langle\mathcal{L}\rangle_m$, $b\in\langle\mathcal{L}\rangle_n$ and $k\in\mathbb{N}_+$, then there is a unique morphism $\psi:\mathcal{U}(\mathcal{L})\to\mathcal{W}$ such that



commutes.

The universal $\mathcal{U}(\mathcal{L})$ is of course defined up to isomorphism. The universal envelope $\mathcal{U}(\mathcal{L})$ inherits an $\mathbb{A}\times\mathbb{Z}$ grading from the free ω-algebra $\mathbb{C}[T^*(X)]$ or equivalently the ω-monoid $T^*(X)$. The $\mathbb{Z}$ grading corrresponding to nodule number is lost because of (53) or (54). We write

$$\mathcal{U}(\mathcal{L}) = \bigoplus_{m\in Z} \mathcal{U}(\mathcal{L})_m, \tag{59}$$

where $\mathcal{U}(\mathcal{L})_m$ is generated by trees with m nodule free leaves.

VI. THE GROUPOID OF UNIVERSAL ω-ALGEBRA

In this section we reveal the combinatorics underlying universal ω-algebra. These results are fundamental to the proof of the ω-Poincaré–Birkhoff–Witt theorem in the next section. The ω-monoidal groupoid of interest is built from the ω-monoidal groupoid of noduled coupling trees **CpTr** and the exploded symmetric ω-monoidal groupoid **xS** of the symmetric groups. These groupoids are based on **NCpTree** and the exploded Artin braid groupoid **xB** defined in Joyce.[32]

The ω-monoidal groupoid **CpTr** is defined to have objects T^* with a unique arrow between $s,t\in T^*$ provided they have the same number of nodule free leaves. Thus

$$\mathbf{CpTr} = \coprod_{n\in\mathbb{N}} \mathbf{CpTr}_n, \tag{60}$$

where the objects of the full subcategory $\mathbf{CpTr}_n$ are T^*_n, the coupling trees with n nodule free leaves. Note that $\mathbf{NCpTree}_n$ is finite where as $\mathbf{CpTr}_n$ is infinite. Furthermore, there is a forgetful functor $U:\mathbf{CpTr}\to\mathbf{NCpTree}$ given by renaming the nodes of t by $1,\ldots,|\{t\}|$ in the unique way preserving order. The resultant tree Ut underlies premonoidal categories.

In addition to the upper and lower cutting operations defined earlier we define the left and right cutting operations. Given $t\in T^*$ the left (respectively, right) cut Lt (respectively, Rt) is the maximal subtree formed from the left (respectively, right) descedents of the root. Finally we note that a tree t is left (respectively, right) justified if $R\vee_m t$ (respectively, $L\vee_m t$) is a singleton set for every $m\in\{t\}$.

If we forget the ordering of nodes then we arrive at the groupoid of bracketing trees with nodules **NBrTree** and the evident forgetful functor $V:\mathbf{NCpTree}\to\mathbf{NBrTree}$. The groupoid of bracketing trees with nodules admits the functor $\otimes:\mathbf{NBrTree}\times\mathbf{NBrTree}\to\mathbf{NBrTree}$ given by joining roots. Thus two trees with m and n leaves join to give a tree with $m+n$ leaves. The identity object is the empty tree. Thus **NBrTree** is a strict monoidal category. Since **CpTr** is an ω-monoid then given $(s,t)\in\mathcal{D}_m$ we have $VU(st)_m=(VUs)\otimes(VUt)$. See Joyce[26] for the full theory of ω-monoidal category theory.

The exploded symmetric ω-monoidal groupoid **xS** has as objects all permutations. There is defined to be an arrow between two permutations π and σ whenever they have the same length. Moreover, this arrow is unique and given by $\sigma\pi^{-1}:\pi\to\sigma$. Thus

$$\mathbf{xS} = \coprod_{n\in\mathbb{N}} \mathbf{xS}_n, \tag{61}$$

where the objects of the full subcategory $\mathbf{xS}_n$ are S_n.

The ω-monoidal groupoid of universal ω-algebra is

$$\mathcal{U} = \coprod_{n\in\mathbb{N}} \mathbf{CpTr}_n \times \mathbf{xS}_n. \tag{62}$$

The set of *elementary* arrows spanning the category are given as follows.

(i) Arrows $(s,1)\to(t,1)$ that prune (or graft in opposite direction) a nodule. That is there is $m\in\{s\}$ such that $\wedge_m s=t$ with $L\vee_m s=\circ$ or $R\vee_m s=\circ$.
(ii) Arrows $(s,\pi)\to(s,(i\,i+1)\pi)$ that interchange two adjacent leafs and the i and $i+1$ leaves have the same descendants.
(iii) Arrows $(s,\pi)\to(t,\pi)$ which swing a single edge between two nodes with immediate descendant m. That is, for a left to right swing $\wedge_m s=\wedge_m t$ and $LL\vee_m s=L\vee_n t$, $RL\vee_m s=LR\vee_m t$, $R\vee_m s=RR\vee_m t$.

These arrows play a crucial role in the next section whereby each is associated with either left and right identitivity, commutativity or associativity, respectively.

VII. ω-POINCARÉ–BIRKHOFF–WITT THEOREM

The ω-Poincaré–Birkhoff–Witt theorem provides a basis for the universal envelope $\mathcal{U}(\mathcal{L})$ just constructed. We suppose that $\mathbb{A}$ is ordered by $<$. Given a recoupling Lie algebra $\mathcal{L}$ an important subalgebra is the commutator subalgebra $[\mathcal{L},\mathcal{L}]$. Let X_0 be an $\mathbb{A}$-graded basis for $[\mathcal{L},\mathcal{L}]$ then for each $x\in X_0$ there is $m,n\in\mathbb{A}$ such that $m\leqslant n$ and $x\in[\langle\mathcal{L}\rangle_m,\langle\mathcal{L}\rangle_n]$. We impose an order $<$ on X_0 satisfying $x<x'$ implies $m\leqslant m'$ where $x\in\langle\mathcal{L}\rangle_m$ and $x'\in\langle\mathcal{L}\rangle_{m'}$. We extend X_0 to an $\mathbb{A}$-graded basis X for $\mathcal{L}$. Let $X_1=X\backslash X_0$ then $X=X_0\amalg X_1$. We extend the order $<$ ensuring that $x<y$ whenever $x\in X_0$ and $y\in X_1$. The order on X_1 is required to satisfy $y<y'$ implies $n\leqslant n'$ where $y\in\langle\mathcal{L}\rangle_n$ and $y'\in\langle\mathcal{L}\rangle_{n'}$.

Next we characterize admissible tuples of X. A tuple $\mathbf{x}\in X_0^M$ is *admissible* if and only if $x_1<\cdots<x_M$ and for all $a\in\langle\mathcal{L}\rangle_m$, $b\in\langle\mathcal{L}\rangle_n$, $c\in\langle\mathcal{L}\rangle_p$, and $d\in\langle L\rangle_q$ with $[a,b]=x_i$ and $[c,d]=x_j$ $(1\leqslant i\neq j\leqslant M)$ we have $\xi_{m,n,p,q}=1$. A tuple $\mathbf{x}\in X^M$ is *admissible* if and only if $x_1<\cdots<x_M$, every subtuple $\mathbf{x}_0$ with components in X_0 is admissible and for all $1\leqslant i,j,k\leqslant N$ distinct, $a\in\langle\mathcal{L}\rangle_m$ and $b\in\langle\mathcal{L}\rangle_n$ with $[a,b]=x_i$ we have $\xi_{m,n,p,q}=1$ where $x_j\in\langle\mathcal{L}\rangle_p$ and $x_k\in\langle\mathcal{L}\rangle_q$. We denote the collection of admissible ordered tuples of X by $\mathrm{Adm}(X)$. This set is $\mathbb{A}$-graded given by adding grades of individual components and is the disjoint union of two important subsets

$$\mathrm{Adm}(X)=\mathrm{Adm}(X)_0\amalg\mathrm{Adm}(X)_1, \tag{63}$$

where $\mathrm{Adm}(X)_0$ is the set of tuples with at least three components one of which is in X_0. $\mathrm{Adm}(X)_1$ is the complement in $\mathrm{Adm}(X)$. Note that $\mathrm{Adm}(X)_1$ contains the empty tuple which has no components.

If we append a nodule to the basis X we extend the order $<$ on $X\amalg\{\circ\}$ by $\circ<x$ for all $x\in X$. Let $\mathcal{I}=\{x\in X^n:\text{for some } n\in\mathbb{N} \text{ such that } x_i\leqslant x_{i+1} \text{ for all } i=1,\ldots,n-1\}$. This set contains $\mathrm{Adm}(X)$. We partition $\mathcal{I}$ into $\mathcal{I}_+\amalg\mathcal{I}_-$ where $\mathcal{I}_-=\{x\in\mathcal{I}:\text{there exists } i \text{ such that } x_i=x_{i+1}\in X_-\}$ and clearly $\mathcal{I}_+=\mathcal{I}\backslash\mathcal{I}_-$. Consequently $\mathrm{Adm}(X)$ inherits this partition. The set of vectors in the theorem is $\mathrm{Adm}(X)_+$.

Theorem 1 (ω–Poincaré–Birkhoff–Witt): Let $\mathcal{L}$ be a recoupling Lie algebra. Let X be a basis for $\mathcal{L}$ constructed previously. A basis for the universal enveloping algebra $\mathcal{U}(\mathcal{L})$ is given by

$$(\cdots((x_1x_2)_{N-1}x_3)_{N-2}\cdots x_N)_1, \tag{64}$$

where $(x_1,\ldots,x_N)\in\mathrm{Adm}(X)_{+0}$, *and*

$$(\cdots((x_1x_2)_{k_1}x_3)_{k_2}\cdots x_N)_{k_{N-1}}, \tag{65}$$

where $(x_1,\ldots,x_N)\in Adm(X)_{+1}$ *and* $k_1>k_2>\cdots>k_{N-1}$.

The ideal $\mathcal{J}$ used in the construction of $\mathcal{U}(\mathcal{L})$ is given by

$$\mathcal{J} = \text{span}_{I \in I} \mathcal{J}_I, \tag{66}$$

where $\mathcal{J}_I$ is the subideal generated by (51)–(53) restricted to coupling trees of $n=|I|$ nodule free leaves that are a rearrangement of I. To prove spanning we require the next lemma. Let $L^* \subset T^*$ be the set of left-justified coupling trees. That is if $t \in L^*$ with nodes $n_1, \ldots, n_N$ (from left to right) then $n_1 > \cdots > n_N$. The set of labeled left-justified coupling trees is denoted $L^*(X)$. For each $n \in \mathbb{N}$ let $\tau_n \in L^*$ be the unique left-justified coupling tree with n leaves and no nodules.

Lemma 1: Let $I \in \mathcal{I}$, t a coupling tree with N leaves and $n=|I|$ nodule free leaves, and $\pi \in S_n$.

(i) *We have that*

$$t(\pi I) + \mathcal{J}_I = b_{t,I,\pi} \tau_n I + \mathbf{x}_{t,I,\pi} + \mathcal{J}_I \tag{67}$$

for some $b_{t,\pi,I} \in S^1$ and

$$\mathbf{x}_{t,\pi,I} \in \left(\bigoplus_{\substack{m<n \\ p \leqslant N-n}} \mathbb{C}[T^*(X)]_{m,p} \right) \oplus \left(\bigoplus_{p<N-n} \mathbb{C}[T^*(X)]_{n,p} \right). \tag{68}$$

(ii) *Moreover, if $I \in \mathcal{I}_-$ then*

$$t(\pi I) + \mathcal{J}_I = \mathbf{y}_{t,I,\pi} + \mathcal{J}_I \tag{69}$$

for some

$$\mathbf{y}_{t,I,\pi} \in \left(\bigoplus_{\substack{m<n \\ p \leqslant N-n}} \mathbb{C}[T^*(X)]_{m,p} \right) \oplus \left(\bigoplus_{p<N-n} \mathbb{C}[T^*(X)]_{n,p} \right). \tag{70}$$

(iii) *If $I \in \mathcal{I} \backslash Adm(X)$ then $t(\pi I) \in \mathcal{J}_I$.*

Proof: Let $\mathcal{E}$ be the set of elementary arrows in **CpTr**. Define the evaluation map $\text{eval}: \mathcal{E} \times \mathcal{I} \to \mathbb{C}[T^*(X)]$ given by mapping each elementary arrow $E:(s,\sigma) \to (s',\sigma')$ under $I \in \mathcal{I}$ to the generating function between $s(\sigma I)$ and $s'(\sigma' I)$ given by (51), (52), (53), and (54).

To prove (i) we note that there exists a composable sequence of elementary arrows $E_1, \ldots, E_N$ in **CpTr** from (t,π) to $(\tau_n, 1)$. Let the source of E_k be denoted (t_k, π_k) and the target (t_{k+1}, π_{k+1}) then $t_1 = t$, $\pi_1 = \pi$, $t_{N+1} = \tau_n$, and $\pi_{N+1} = 1$. We find that $t_k(\pi_k I) - \text{eval}(E_k, I) = b_k t_{k+1}(\pi_{k+1} I) + \mathbf{x}_k$ for some $b_k \in S^1$ and $\mathbf{x}_k$ in (68). Since $\text{eval}(E_k, I) \in \mathcal{J}_I$ then we have that

$$t_k(\pi_k I) + \mathcal{J}_I = b_k t_{k+1}(\pi_{k+1} I) + \mathbf{x}_k + \mathcal{J}_I \tag{71}$$

for $k = 1, \ldots, N$. Hence (67) holds with $b_{t,\pi,I} = \Pi_{k=1}^N b_k$ and

$$\mathbf{x}_{t,\pi,I} = \sum_{k=1}^{N} \left(\prod_{l=1}^{k-1} b_l \right) \mathbf{x}_k. \tag{72}$$

To prove (ii) let $\sigma \in S_n$ such that the first two entries of σI are in X_-. Then by (i) the evaluation of the arrow $(t,\sigma) \to (t,(12)\sigma)$ at I gives $t(\sigma I) + \mathcal{J}_I = -t((12)\sigma I) + \mathbf{x} + \mathcal{J}_I$ for some $\mathbf{x}$ in (68). Thus we have that

$$t(\sigma I) + \mathcal{J}_I = \tfrac{1}{2}\mathbf{x} + \mathcal{J}_I. \tag{73}$$

Also by (i) we can find a, $b \in S^1$ and $\mathbf{y}$, $\mathbf{z}$ in (68) satisfying

$$t(\pi I) + \mathcal{J}_I = a \tau_n I + \mathbf{y} + \mathcal{J}_I, \tag{74}$$

$$t(\sigma I) + \mathcal{J}_I = b \tau_n I + \mathbf{z} + \mathcal{J}_I. \tag{75}$$

A simple calculation substituting (75) then (73) into (74) yields

$$t(\pi I) + \mathcal{J}_I = \frac{a}{2b}\mathbf{x} + \mathbf{y} - \frac{a}{b}\mathbf{z} + \mathcal{J}_I. \tag{76}$$

The result follows with $\mathbf{y}_{t,\pi,I}=(a/2b)\mathbf{x}+\mathbf{y}-(a/b)\mathbf{z}$.

Finally to prove (iii) suppose $I \notin \mathrm{Adm}(X)$. Either there is $a \in \langle\mathcal{L}\rangle_m$, $b \in \langle\mathcal{L}\rangle_n$, $c \in \langle\mathcal{L}\rangle_p$, $d \in \langle\mathcal{L}\rangle_q$, and $i \neq j$ with $[a,b]=I_i$ and $[c,d]=I_j$ such that $\xi_{m,n,p,q} \neq 1$; or there is $a \in \langle\mathcal{L}\rangle_m$, $b \in \langle\mathcal{L}\rangle_n$, $I_j \in \langle\mathcal{L}\rangle_p$, $I_k \in \langle\mathcal{L}\rangle_q$ and $i \neq j \neq k \neq i$ with $[a,b]=I_i$ such that $\xi_{m,n,p,q} \neq 1$. In the first case we choose $s \in L$ and $\pi \in S_{|I|}$ such that there is an arrow $(s,\pi) \to (t,\pi)$ and $(\sigma\pi^{-1}I)_1=I_i$ and $(\sigma\pi^{-1}I)_2=I_j$. Thus it follows from Proposition 2 (this proposition, proved later, does not depend on this result) and (85) that

$$\vee_{\sup\{s\}} s(I_i,I_j) = \xi_{m,n,p,q} \vee_{\sup\{s\}} s(I_i,I_j). \tag{77}$$

Since $\xi_{m,n,p,q} \neq 1$ we have that $\vee_{\sup\{s\}} s(I_i,I_j) \in \mathcal{J}_{(a,b,c,d)} \subset \mathcal{J}$. Thus $(s,\sigma)I \in \mathcal{J}$ from which it follows that $(t,\pi)I \in \mathcal{J}$. In the second case we choose $s \in L$ and $\pi \in S_{|I|}$ such that there is an arrow $(s,\pi) \to (t,\pi)$ and $(\sigma\pi^{-1}I)_1=I_i$, $(\sigma\pi^{-1}I)_2=I_j$ and $(\sigma\pi^{-1}I)_3=I_k$. Thus it follows from Proposition 2 and (83) that

$$\vee_{\sup\{s\}\setminus\{\sup\{s\}\}} s(I_i,I_j,I_k) = \xi_{m,n,p,q} \vee_{\sup\{s\}\setminus\{\sup\{s\}\}} s(I_i,I_j,I_k). \tag{78}$$

Since $\xi_{m,n,p,q} \neq 1$ we have that $\vee_{\sup\{s\}\setminus\{\sup\{s\}\}} s(I_i,I_j,I_k) \in \mathcal{J}_{(a,b,c,d)} \subset \mathcal{J}$. Thus $(s,\sigma)I \in \mathcal{J}$ from it follows that $(t,\pi)I \in \mathcal{J}$. This completes the proof.

To prove that $\mathrm{Adm}(X)_+$ spans $\mathcal{U}(\mathcal{L})$ we use induction on $\oplus_{m<n}\mathcal{U}(\mathcal{L})_m$. Clearly it holds for $m=1$. Now suppose it holds for n and that $x \in \oplus_{m<n+1}\mathcal{U}(\mathcal{L})_m$ then we may decompose x as

$$x = \sum_{t,\pi,I} a^{t,\pi,I} t(\pi I), \tag{79}$$

where all but finitely many $a^{t,\pi,I}$ are zero. Thus we have by the lemma

$$x + \mathcal{J} = \sum_{t,\pi,I} a^{t,\pi,I} b^{t,\pi,I} \tau_n I + \sum_{t,\pi,I} a^{t,\pi,I} \mathbf{x}_{t,\pi,I} + \mathcal{J} \tag{80}$$

$$= \left(\sum_{t,\pi,I \in \mathrm{Adm}(X)_+} a^{t,\pi,I} b^{t,\pi,I} \tau_n I + \mathcal{J} \right) + \left(\sum_{t,\pi,I \in I} a^{t,\pi,I} b^{t,\pi,I} \mathbf{y}_{t,\pi,I} + \sum_{t,\pi,I} a^{t,\pi,I} \mathbf{x}_{t,\pi,I} + \mathcal{J} \right) \tag{81}$$

The first line by (i) and the second line by (ii) and (iii) of the lemma. The first term is in the span by definition, while the second term is in the span by the induction step. Hence $\mathrm{Adm}(X)_+$ spans $\mathcal{U}(\mathcal{L})$.

The other half of the theorem is to prove that $\mathrm{Adm}(X)_+$ is a linearly independent set in $\mathcal{U}(\mathcal{L})$. To this end we prove the next theorem below. We define the groupoid of noduled coupling trees labeled by X to be

$$\mathcal{U}(X) = \coprod_{n \in \mathbb{N}} \mathcal{U}_n \times X^n. \tag{82}$$

We also introduce the ω-monoid $\mathcal{J}_{00}$ defined by the generating relations

$$(|(||)_k)_h([a,b],c,d) - \xi_{m,n,p,q}(|(||)_l)_h([a,b],c,d), \tag{83}$$

$$((||)_k|)_h(a,b,[c,d]) - \xi_{m,n,p,q}((||)_l|)_h(a,b,[c,d]), \tag{84}$$

$$(||)_h([a,b],[c,d]) - \xi_{m,n,p,q}(||)_h([a,b],[c,d]) \tag{85}$$

for all a, b, c, $d \in X$ of grades m, n, p, q, respectively, and $h<k$, l. By construction one observes that $\mathbb{C}[T^*(X)]/\mathcal{J}_{00}$ is spanned by $\mathrm{Adm}(X)$.

Now we can state a Mac Lane coherence between $\mathcal{U}(X)$ and the one object category $\mathbb{C}[T^*(X)]$ with composition given by addition.

Theorem 2: *There is a functor*

$$F:\mathcal{U}(X) \to \mathbb{C}[T^*(X)]/\mathcal{J}_{00} \tag{86}$$

taking primitive arrows to their corresponding generating relations.

Proof: Premonoidal Mac Lane coherence implies F restricted to **CpTr**(X) is a functor. In remains to incorporate commutivity. Given a transposition $\sigma: s\mathbf{x} \to t((kk+1)\mathbf{x})$ where $i \leqslant k \leqslant |\mathbf{x}| - 1$, we can find arrows $f: s(\mathbf{x}) \to r(\mathbf{x})$ and $g: r((kk+1)\mathbf{x}) \to t((kk+1)\mathbf{x})$ in **CpTr** where $r \in T$ with k and $k+1$ siblings, such that $\sigma = g\sigma_{r,k} f$ where $\sigma_k: r\mathbf{x} \to r((kk+1)\mathbf{x})$. We define $F(\sigma) = F(g)F(\sigma_{r,k})F(f)$. This definition is independent of f, g, and r provided the squares

$$\begin{array}{ccc}
((||)_k(||)_l)_h\mathbf{x} & \longrightarrow & ((||)_k(||)_l)_h((12)\mathbf{x}) \\
\downarrow & & \downarrow \\
((||)_l(||)_k)_h\mathbf{x} & \longrightarrow & ((||)_l(||)_k)_h((12)\mathbf{x})
\end{array}$$

$$\begin{array}{ccc}
((||)_k(||)_l)_h\mathbf{x} & \longrightarrow & ((||)_k(||)_l)_h((34)\mathbf{x}) \\
\downarrow & & \downarrow \\
((||)_l(||)_k)_h\mathbf{x} & \longrightarrow & ((||)_l(||)_k)_h((34)\mathbf{x})
\end{array}$$

commute for all $h < k < l$ and $\mathbf{x} \in X^4$ under F. This may be seen from the proof of theorems 9 and 20 in Joyce.[32] A short calculation shows that these are the generating conditions (83) and (84) and so belong to $\mathcal{J}_{00}$. The proof is completed by showing symmetric braid conditions hold under F. That is,

$$F(\sigma_k)F(\sigma_k) = 1, \tag{87}$$

$$F(\sigma_k)F(\sigma_l) = F(\sigma_l)F(\sigma_k) \text{ whenever } |k-l| > 1, \tag{88}$$

$$F(\sigma_{k+1})F(\sigma_k)F(\sigma_{k+1}) = F(\sigma_k)F(\sigma_{k+1})F(\sigma_k) \text{ provided } k < |\mathbf{x}| \tag{89}$$

for all k, $l = 1, 2, \ldots, |\mathbf{x}|$. The first holds by the recoupling symmetry. The second by choosing $r \in T$ with k and $k+1$ siblings and l and $l+1$ siblings. The last condition follows by taking $r \in T$ such that k and $k+1$ are siblings and their parent node has sibling $k+2$. Thus the condition holds provided

$$\begin{array}{ccccc}
((||)_k|)_l(a,b,c) & \longrightarrow & ((||)_k|)_l(b,a,c) & \longrightarrow & ((||)_k|)_l(b,c,a) \\
\downarrow & & & & \downarrow \\
((||)_k|)_l(a,c,b) & \longrightarrow & ((||)_k|)_l(c,a,b) & \longrightarrow & ((||)_k|)_l(c,b,a)
\end{array}$$

commutes for all $k < l$ and a, b, $c \in X$ under F. Suppose a, b, and c are of grades m, n, and p, respectively, then the diagonal dashed arrow is well-defined if and only if

$$(||)_l([a,b],c) + \alpha_{n,m,p}\gamma_{m,n}(||)_l(b,[c,a]) + \frac{\alpha_{n,m,p}}{\alpha_{n,p,m}}\gamma_{m,n}\gamma_{m,p}(||)_l([b,c],a)$$

$$= \alpha_{m,n,p}(||)_l(a,[b,c]) + \frac{\alpha_{m,n,p}}{\alpha_{m,p,n}}\gamma_{n,p}(||)_l([a,c],b) + \frac{\alpha_{m,n,p}\alpha_{p,m,n}}{\alpha_{m,p,n}}\gamma_{n,p}\gamma_{m,p}(||)_l(c,[a,b]). \quad (90)$$

Substituting $(\|)_l([a,b],c)=\gamma_{m+n,p}(\|)_l(c,[a,b])+[[a,b],c]$ and similarly for $(\|)_l(b,[c,a])$ and $(\|)_l([b,c],a)$ reduces this condition to the recoupling Jacobi identity. Hence it vanishes.

This result has the obvious corollary.

Corollary 1: There is a unique extension of F to the ω-algebra morphism

$$\widetilde{F}:\mathbb{C}[\mathcal{U}(X)] \to \mathbb{C}[T^*(X)]/\mathcal{J}_{00}. \quad (91)$$

We have the following expected embedding.

Proposition 2: We have that $\mathcal{J}_{00} \subset \mathcal{J}$.

Proof: We must show that (83), (84), and (85) are a consequence of the generating relations for $\mathcal{J}$. As a direct result of these we have the square

$$\begin{array}{ccc} ((||)_k(||)_l)_h(a,b,c,d) & \longrightarrow & ((||)_k(||)_l)_h(b,a,c,d) \\ \downarrow & & \downarrow \\ ((||)_l(||)_k)_h(a,b,c,d) & \longrightarrow & ((||)_l(||)_k)_h(b,a,c,d) \end{array}$$

in $\mathcal{J}$ for all $a \in \langle\mathcal{L}\rangle_m$, $b \in \langle\mathcal{L}\rangle_n$, $c \in \langle\mathcal{L}\rangle_p$, $d \in \langle\mathcal{L}\rangle_q$ and $m, n, p, q \in \mathbb{A}$. This loop evaluates under F to give (83). Similarly we may obtain (84). Finally we have

$$(1-\xi_{m,n,p,q})(|(||)_k)_l([a,b],c,d) = (1-\xi_{m,n,p,q})\gamma_{p,q}(|(||)_k)_l([a,b],d,c) + (1-\xi_{m,n,p,q})(||)_l([a,b],[c,d]). \quad (92)$$

Since the first two terms are in $\mathcal{J}$ then the last must be also. Hence (85) is in $\mathcal{J}$.

A simple corollary is as follows.

Corollary 2: The subspace spanned by $Adm(X)_{0+}$ *is an algebra.*

Let $I \in \mathrm{Adm}(X)_+$ and $\mathcal{U}(X)_I$ the coupling trees with $|I|$ nodule free leaves labeled by I. We have that

$$\widetilde{F}(\mathbb{C}[\mathcal{U}(X)_I]) = \mathcal{J}_I. \quad (93)$$

Lemma 2: Let $I \in Adm(X)_+$ *and* $j \in \mathcal{J}_I$ *then whenever*

$$j \in \mathrm{span}_{I' \in I\setminus\{I\}, |I'| \leqslant |I|}\mathcal{J}_{I'} \quad (94)$$

we have that $j=0$.

Proof: Suppose $I \in \mathrm{Adm}(X)_{+1}$. The other case when $I \in \mathrm{Adm}(X)_{+0}$ will follow by a similar agrument using rooted planar binary trees. Let $(t,\pi) \to (t,\pi')$ be an arrow such that $I_{\pi i}=I_{\pi' i}$ for all $i=1,2,\ldots,|I|$. The tuple I is partitionable into constant maximal subtuples. Choose $s \in T$ such that the leaves corresponding to subtuples of length at least two are the descendents of a unique node. We have the diagram

$$\begin{array}{ccc} (t,\pi) & \longrightarrow & (t,\pi') \\ \downarrow & & \downarrow \\ (s,1) & \longrightarrow & (s,\pi'\pi^{-1}) \end{array}$$

in $\mathcal{U}$. If we evaluate this diagram at I and apply F then the side arrows are equal and if the bottom arrow is zero the top arrow is zero. Indeed the bottom arrow evaluates as zero because constant subtuples of I of at least length two are bosonic. That is the commutator vanishes and the phase is unity. Given $\pi, \sigma \in S_{|I|}$ we say they are equivalent applied to I if $I_{\pi i} - I_{\sigma i}$ for all $i = 1, \ldots, |I|$. The set of equivalence classes we denote S_I/I. Let r be the nodule free left-justified tree with $|I$ leaves then a spanning set for $\mathcal{J}_I$ is given by the arrows $rI \to r(\pi I)$ where $\pi \in S_{|I|}/I$ under F. That is, each element is of the form

$$rI - \phi_\pi r(\pi I) + b_\pi \tag{95}$$

for some $\phi_\pi \in S^1$ and

$$b_\pi \in \text{span}_{I' \in \mathcal{I}, |I'| < |I|} \mathcal{J}_{I'} \tag{96}$$

for all $\pi \in S_{|I|}/I$. This is clearly a basis since $rI - \phi_\pi r(\pi I)$ where $\pi \in S_{|I|}/I$ is a basis. This completes the proof of the lemma. Let $I_1, \ldots, I_N \in \text{Adm}(X)_+$ be any finite distinct collection with I_k of length n_k, and $a_1, \ldots, a_N \in \mathbb{C}\backslash\{0\}$ such that

$$\sum_{k=1}^{N} a_k \tau_{n_k} I_k = 0, \tag{97}$$

Choose I_m such that $n_k \leqslant n_m$ for all $k = 1, \ldots, N$. We have that

$$a_m \tau_{n_m} I_m = - \sum_{\substack{k=1 \\ k \neq m}}^{N} a_k \tau_{n_k} I_k \in \text{span}_{I' \in \mathcal{I}\backslash\{I_m\}, |I'| \leqslant |I_m|} \mathcal{J}_{I'} \tag{98}$$

Hence by the lemma $a_m = 0$ giving a contradiction. Thus $\text{Adm}(X)_+$ is a linearly independent set. This completes the proof of the ω-Poincaré–Birkhoff–Witt theorem.

VIII. $\mathbb{Z}_N$-GRADED HEISENBERG RECOUPLING LIE ALGEBRA

We consider in detail a generalized version of the Heisenberg algebra $\mathcal{H}$ for any $\mathbb{Z}_N$ graded recoupling. The recoupling Lie algebra is spanned by a grade 0 element h, grade 1 elements a_μ and grade $N-1$ elements $a_\mu^\dagger$ for all $\mu \in \mathcal{I}$ satisfying

$$[a_\mu, a_\nu] = 0, \quad [a_\mu, h] = 0,$$

$$[a_\mu^\dagger, a_\nu^\dagger] = 0, \quad [a_\mu^\dagger, h] = 0,$$

$$[a_\mu, a_\nu^\dagger] = \delta_{\mu,\nu} h, \quad [h, h] = 0$$

for all $\mu, \nu \in \mathcal{I}$. For simplicity suppose $\mathcal{I}$ is finite. We see that $\text{Adm}(\mathcal{H}) = \mathcal{H}$. Moreover, we usually identify the element h with $\hbar\circ$. Thus we work in the factored universal ω-algebra $\mathcal{U}(H)/h - \hbar\circ$.

The grade 0 component $\langle \mathcal{H} \rangle_0$ is a Lie algebra. Define $h_{\mu\nu} = a_\mu a_\nu^\dagger$ then a straight forward calculation in the universal enveloping algebra $\mathcal{U}(\mathcal{H})/h - \hbar\circ$ shows that

$$\begin{aligned}[h_{\mu\nu}, h_{\mu'\nu'}] = \hbar \frac{\alpha_{1,N-1,0}\lambda_0}{\alpha_{N-1,1,N-1}\alpha_{0,0,N-1}} \gamma_{N-1,1} \left(\delta_{\mu\nu'} h_{\mu'\nu} - \frac{\alpha_{0,0,1}}{\alpha_{1,0,0}} \gamma_{1,1}\gamma_{N-1,N-1} \delta_{\mu'\nu} h_{\mu\nu'} \right) \\ + (1 - \gamma_{1,1}\gamma_{N-1,N-1}) h_{\mu\nu} h_{\mu'\nu'}\end{aligned} \tag{99}$$

Closure requires $\gamma_{1,1}\gamma_{N-1,N-1} = 1$ and $\alpha_{1,0,0} = \alpha_{0,0,1}$ giving the Lie algebra $u(1) \oplus su(|\mathcal{I}|)$.

Two straightforward calculations in the universal enveloping algebra $\mathcal{U}(\mathcal{H})/h - \hbar\circ$ demonstrate

$$[h_{\mu\nu},a_\lambda]=-\hbar\alpha_{1,0,0}\lambda_0\gamma_{0,1}\gamma_{1,1}\delta_{\nu,\lambda}a_\mu+\left(1-\frac{\gamma_{0,1}\gamma_{1,1}\gamma_{1,N-1}}{\alpha_{1,N-1,1}}\right)h_{\mu\nu}a_\lambda, \tag{100}$$

$$[h_{\mu\nu},a_\lambda^\dagger]=\hbar\frac{\gamma_{0,N-1}\gamma_{N-1,1}\lambda_0}{\alpha_{N-1,1,N-1}\alpha_{0,0,N-1}}\delta_{\mu\lambda}a_\nu^\dagger+\left(1-\frac{\gamma_{0,N-1}\gamma_{N-1,1}\gamma_{N-1,N-1}}{\alpha_{N-1,1,N-1}}\right)h_{\mu\nu}a_\lambda^\dagger. \tag{101}$$

Closure requires the term of each to vanish. Furthermore, if a_μ and $a_\mu^\dagger$ are to be a pair of lowering and raising elements then $\gamma_{0,1}=\gamma_{0,N-1}=1$. The adjoint action on the space spanned by a_μ gives the fundamental representation, while on the space spanned by $a_\mu^\dagger$ gives the dual fundamental representation. We define the (standard) Bose–Fermi $\mathbb{A}$ graded recoupling as the following irreducible recoupling. We take $\lambda_m=\rho_m=1$ and

$$\gamma_{m,n}=\begin{cases}1, & m=0 \text{ or } n=0\\ -1, & \text{otherwise},\end{cases} \tag{102}$$

$$\alpha_{m,n,p}=\begin{cases}1, & m=0,n=0,p=0 \text{ or } m+n=0\\ -1, & \text{otherwise}.\end{cases} \tag{103}$$

The $m+n=0$ in the definition of $\alpha_{m,n,p}$ may equally well be replaced by $n+p=0$. These determine the deformativity phases to be

$$\xi_{m,n,p,q}=\begin{cases}1, & m=0,n=0,p=0,q=0,m+n=0 \text{ or } p+q=0,\\ -1, & \text{otherwise}.\end{cases} \tag{104}$$

Algebraic formulas for α,ξ, and γ utilizing Kronecker deltas are given in the Appendix. For this recoupling the Heisenberg algebra reduces to

$$[h_{\mu\nu},h_{\mu'\nu'}]=\hbar\delta_{\mu'\nu}h_{\mu\nu'}-\hbar\delta_{\mu\nu'}h_{\mu'\nu}, \tag{105}$$

$$[h_{\mu\nu},a_\lambda]=\hbar\delta_{\nu,\lambda}a_\mu, \tag{106}$$

$$[h_{\mu\nu},a_\lambda^\dagger]=\hbar\delta_{\mu\lambda}a_\nu^\dagger, \tag{107}$$

where $\mu,\nu,\mu',\nu',\lambda\in\mathcal{I}$. For SU(3) color with a $\mathbb{Z}_3$ graded Bose–Fermi recoupling Heisenberg Lie algebra the universal envelope is an ω-algebra satisfying the Pauli exclusion principle and avoiding the confinement outlined in Joyce.[4,15]

IX. HOPF STRUCTURE OF THE UNIVERSAL ENVELOPING ω-ALGEBRA

The universal ω-algebra of a recoupling Lie algebra possesses coalgebra and Hopf algebralike structures. Let $\mathcal{U}^0(\mathcal{L})$ be the maximal ω-subalgebra of $\mathcal{U}(\mathcal{L})$ excluding the unit.

Proposition 3: The universal ω-algebra $\mathcal{U}(\mathcal{L})$ is a coalgebra.

A comultiplication $\Delta:\mathcal{U}(\mathcal{L})\to\mathcal{U}(\mathcal{L})^{\otimes 2}$ is given by

$$\Delta(a)=1\otimes a+a\otimes 1, \tag{108}$$

$$\Delta(1)=1\otimes 1, \tag{109}$$

whenever $a\in\mathcal{U}^0(\mathcal{L})$. The corresponding counit $\epsilon:\mathcal{U}(\mathcal{L})\to\mathbb{C}$ is given by

$$\epsilon(a)=0, \tag{110}$$

$$\epsilon(1) = 1, \tag{111}$$

whenever $a \in \mathcal{U}^0(\mathcal{L})$.

Using the symmetric unital braid R we can construct a coalgebra structure for $\mathcal{U}(\mathcal{L})$. Comultiplication and counit are given by

$$\Delta(a \otimes b) = (\Delta \otimes \Delta)(a \otimes R(b \otimes a) \otimes b), \tag{112}$$

$$\epsilon(a \otimes b) = \epsilon(a) \otimes \epsilon(b), \tag{113}$$

for all $a, b \in \mathcal{U}(\mathcal{L})$. We say that the coalgebra and ω-algebra are compatible if $\mu_m : \mathcal{D}_m \to \mathcal{A}$ are coalgebra morphisms on the restricted domain $\mathcal{D}_m$ for each $m \in \mathbb{N}_+$. Equivalently, the comultiplication is a morphim between the ω-algebras $\mathcal{U}(\mathcal{L})$ and $\mathcal{U}(\mathcal{L})^{\otimes 2}$. Algebraically these conditions are

$$\Delta\mu_m(a \otimes b) = (\mu_m \otimes \mu_m)(1 \otimes R \otimes 1)(\Delta(a) \otimes \Delta(b)), \tag{114}$$

$$\epsilon\mu_m(a \otimes b) = \epsilon(a) \otimes \epsilon(b), \tag{115}$$

$$\Delta(1) = 1 \otimes 1 \tag{116}$$

whenever $a \otimes b \in \mathcal{D}_m$, for all $m \in \mathbb{N}_+$. One can easily check that these all hold.

Definition 5: A Hopf ω-algebra is a unital ω-algebra $\mathcal{A}$ with a compatible coalgebra structure and an antipode S. The antipode is a contravariant morphism $S : \mathcal{A} \to \mathcal{A}$ satisfying

$$\mu_m(S \otimes 1)\Delta(a) = \eta(a)\epsilon(a) = \mu_m(1 \otimes S)\Delta(a) \tag{117}$$

for all $a \in \mathcal{U}(\mathcal{L})$ such that $(S \otimes 1)\Delta(a) \in \mathcal{D}_m$, for all $m \in \mathbb{N}_+$.

One can easily check that an antipode for $\mathcal{U}(\mathcal{L})$ is the unique linear map given by $S(a) = -a$ whenever $a \in \mathcal{U}^0(\mathcal{L})$ and $S(1) = 1$.

X. CONCLUSION

We have extended the notion of a graded Lie algebra to include the recoupling phases of Joyce[4] necessary in the description of SU(3) color. In order to construct the appropriate notion of a universal envelope we required the new notion of an ω-algebra. One may think of this as a generalization of algebra where the order in which brackets are evaluated is unique, avoiding ambiguous statements such as $(ab)(cd)$. We constructed the universal enveloping ω-algebra and proved the corresponding ω-Poincaré–Birkhoff–Witt theorem. Finally we recovered the usual coalgebra structure and uncovered the Hopf structure of the universal enveloping ω-algebra.

The results of this paper provide motivation for the omegafication of a number of structures requiring the development of a general theory of ω-monoidal categories.[26] Of particular interest is an ω-tensor product (and ω-Fock space) which should be the appropriate setting for the representation theory of ω-algebra. This requires notions of ω-coalgebra, ω-bialgebra, and Hopf ω-algebra.

The known link of the division algebras to 10-dimensional spacetime and one leptoquark family is extended to encompass three leptoquark families. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1786682]

I. INTRODUCTION

No volume devoted to noncommutative mathematical structures of any sort would be complete without some attention paid to the quaternions (**H**) and octonions (**O**). These, together with the commutative algebras **R** (real numbers) and **C** (complex numbers), are the four real normed division algebras, linked to much that is elegant, noteworthy and exceptional in mathematics. The obviously central role of **R** and **C** in physics has also led many to believe that **H** and **O** should have an equally central role in fundamental physics as they do in mathematics. In this article we further develop the idea that in fact all of these algebras tensored together should play a role in constructing the Standard Model. Our observations are also relevant to recent developments in string theory, where the octonions are becoming increasingly of interest. We direct the reader to John Baez's excellent review for a broader discussion of quaternions and octonions.[1]

This article is an extension of work begun in Ref. 2, which builds on Ref. 3. There it is assumed that none of the three hypercomplex division algebras (**C**, **H** and **O**) is to be distinguished over any other, and all should play a role. Thus it was proposed to consider

$$\mathbf{T}=\mathbf{C}\otimes\mathbf{H}\otimes\mathbf{O}$$

as a starting point for a particle physics model. Here **T** is nothing more than the complexification of the quaternionization of the octonions. More precisely, we considered $\mathbf{T}^2=\mathbf{T}\oplus\mathbf{T}$ as follows.

Each of these algebras, **C**, **H**, **O**, the tensor product, **T** and $\mathbf{T}^2$, is a spinor space (see Ref. 2). A Dirac algebra spinor of a fundamental fermion like the electron is conventionally represented as an element of $\mathbf{C}^4$, and so is 8-dimensional over the reals. **T** is 64-dimensional, and $\mathbf{T}^2$, a complexified $\mathbf{R}^{1,9}$ spinor, is 128-dimensional. Since $128=(8+8)\times 8$, and associated with the first family of leptons and quarks there are 8 fermions and 8 antifermions (neutrinos treated as Dirac throughout), one might hope that $\mathbf{T}^2$ is the correct object to account for 16 Dirac spinors. This turns out to be a good point of view as shown in detail in Refs. 2 and 3, and elsewhere; many of the mathematical features of the Standard Model of quarks and leptons indeed fall naturally out of a theory based mathematically on this spinor space $\mathbf{T}^2$.

One feature that has, however, been missing, is how to account for the higher leptoquark families two and three in this picture. We propose a solution now.

II. PRELIMINARIES

Let PSO_k be a projective special orthogonal group. In Ref. 4 the following is noted.

(1) The existence of **C** implies that PSO_2 is commutative.
(2) The existence of **H** implies $PSO_4\cong PSO_3\times PSO_3$.
(3) The existence of **O** implies that PSO_8 has a triality automorphism of order 3.

a)Electronic mail: gdixon@7stones.com

We also have natural actions of the special orthogonal groups on the division algebras as spinor spaces.

(1) The special orthogonal group SO_2 acting on 2^1-dimensional **C** can be represented by multiplication by a single complex unit, $u+iv$, where $u^2+v^2=1$.
(2) Any element of the group SO_4 acting on the 2^2-dimensional **H** requires at most 16 quaternion doublets, (u,v), summing actions of the form

$$x \to u_L v_R[x] = uxv.$$

This becomes somewhat obvious when we realize that SO_4 is generated by the six elements q_{Li} and q_{Ri}, where q_i, $i=1,2,3$, are the three imaginary quaternion units, and q_{Li} and q_{Ri} are the maps

$$X \to q_i X, \quad X \to X q_i,$$

for X in **H**. A general element of SO_4 takes the form $u+v^i q_{Li}+r^j q_{Rj}+s^{ij} q_{Li} q_{Rj}$ $(1+3+3+9=16)$, with suitable conditions placed on the coefficients.
(3) Any element of the group SO_8 acting on the 2^3-dimensional **O** requires at most 64 octonion triples, (u,v,w), summing actions of the form

$$X \to u_L v_L w_L[X] = u(v(wX)).$$

This becomes somewhat obvious when we realize that SO_8 is generated by the 28 elements e_{La} and e_{Lab}, where e_a, $a=1,\ldots,7$, are the imaginary octonion units, and e_{La} and e_{Lab} (and e_{Labc}) are the maps

$$X \to e_a X, \quad X \to e_a(e_b X), \quad X \to e_a(e_b(e_c X)),$$

for X in **O** (no right multiplication is needed: see Ref. 2). A general element of SO_8 takes the form $u+v^a e_{La}+r^{ab} e_{Lab}+s^{abc} e_{Labc}$ $(1+7+21+35=64)$, with suitable conditions placed on the coefficients.

Finally, we make a key observation from p. 12 of the Conway and Sloane book on sphere packings (Ref. 5), where three laminated lattices are singled out for their density and simplicity. These are (1) $\Lambda_2=A_2$, which can be represented in $\mathbf{C^1}$; (2) $\Lambda_8=E_8$, which can be represented in $\mathbf{H^2}$ (and $\mathbf{O^1}$); (3) Λ_{24} (Leech lattice), which can be represented in $\mathbf{O^3}$.

In each case the representations are intimately related to certain integral elements over the underlying division algebras (Refs. 4 and 5).

We will also need some notations:

(i) $\mathbf{K}_L, \mathbf{K}_R$—the algebras of left and right actions of an algebra **K** on itself;
(ii) $\mathbf{K}_A$—the algebra of the combined left and right actions of an algebra **K** on itself;
(iii) $M_n(\mathbf{K})$—$n \times n$ matrices over the algebra **K**;
(iv) $\mathbf{K}^n$—and the $n \times 1$ column over **K**;
(v) $\mathcal{CL}(p,q)$—the Clifford algebra of the real spacetime with signature $(p+,q-)$.

III. THREE LEPTOQUARK FAMILES

One thing to note from the mathematical preliminaries is that $\mathbf{C^1}$, $\mathbf{H^2}$ and $\mathbf{O^3}$ are each associated to exceptional structures. Motivated particularly by the list of lattice representations, we therefore propose to consider as the spinor space for the Standard Model,

$$\mathbf{T^6} = \mathbf{C^1} \otimes \mathbf{H^2} \otimes \mathbf{O^3}.$$

Clearly, if $\mathbf{T^2}$ accounts for one full family and its antifamily, then $\mathbf{T^6}$ should account for three, which is the accepted number.

First of all, let $\mathbf{P}=\mathbf{C}\otimes\mathbf{H}$; then $\mathbf{P}_L$ is isomorphic to the Pauli algebra, so $M_2(\mathbf{P}_L)$ is isomorphic to the Dirac algebra, and $\mathbf{H}_R$, which commutes with $M_2(\mathbf{P}_L)$ (which acts on $\mathbf{H^2}$), provides an internal $SU(2)$ degree of freedom.

One can do much the same thing[2] with $\mathbf{T}$. $\mathbf{T}_L$ is a Pauli-like algebra, and $M_2(\mathbf{T}_L)$ is the Dirac algebra of 1,9-spacetime. Again there remains the internal $\mathbf{H}_R$ commuting with $M_2(\mathbf{T}_L)$, providing an isospin $SU(2)$. The associated spinor space ($\mathbf{T}^2$) transforms with respect to the standard symmetry as the direct sum of a leptoquark family and antifamily of 1,3-Dirac spinors.

We would like to proceed similarly with $\mathbf{T}^6$. However, in Ref. 2 the algebra $M_2(\mathbf{T}_L)$, which acts on $\mathbf{T}^2$, is isomorphic to a Clifford algebra [the complexification of $\mathcal{CL}(1,9)$], which is relevant to our interpretation above. But since all Clifford algebras are 2^k-dimensional, the $3^2 2^{13}$-dimensional $M_6(\mathbf{T}_A)$ (which is the full algebra of actions associated with $\mathbf{T}^6$) is not a Clifford algebra.

Let us plow ahead anyway, and first look at the 2^{15}-dimensional $M_4(\mathbf{T}_A)$, isomorphic to the complexification of $\mathcal{CL}(1,13)$. This acts on $\mathbf{T}^4$, which is a pair of leptoquark families (and their antifamilies). We let

$$\epsilon=\begin{bmatrix}1&0\\0&1\end{bmatrix},\quad \alpha=\begin{bmatrix}1&0\\0&-1\end{bmatrix},\quad \beta=\begin{bmatrix}0&1\\1&0\end{bmatrix},\quad \gamma=\begin{bmatrix}0&1\\-1&0\end{bmatrix}.$$

We define, for example, the following 4×4 real matrix:

$$[\beta\otimes\alpha]=\begin{bmatrix}0&\alpha\\\alpha&0\end{bmatrix}.$$

We will use the $\mathcal{CL}(1,13)$ 1-vector basis [let $\mathcal{CL}_k(p,q)$ be the $\boldsymbol{k}$-vector basis of $\mathcal{CL}(p,q)$]:

$$[\epsilon\otimes\beta](iq_{R3}),\quad [\epsilon\otimes\gamma]q_{Lk}e_{L7}(iq_{R3}),\quad k=1,2,3,\quad [\epsilon\otimes\gamma]ie_{Lp}(iq_{R3}),\quad p=1,\ldots,6,$$

$$[\beta\otimes\epsilon]q_{R1},\quad [\beta\otimes\epsilon]q_{R2},\quad [\beta\otimes\alpha]q_{R3},\quad [\gamma\otimes\alpha].$$

The first line contains 10 elements which generate a $\mathcal{CL}(1,9)$ subalgebra of $\mathcal{CL}(1,13)$. This is essentially the $\mathcal{CL}(1,9)$ that appeared in Ref. 2. The second line contains 4 elements which generate a $\mathcal{CL}(0,4)$ subalgebra. Under the commutator product the associated 2-vectors are a basis for $so(4)\sim su(2)\times su(2)$. The six generators are

$$\frac{1}{2}(1\pm[\alpha\otimes\epsilon])\{[\epsilon\otimes\alpha]q_{R1},[\epsilon\otimes\alpha]q_{R2},[\epsilon\otimes\epsilon]q_{R3}\}.$$

The 4×4 real matrix $[\alpha\otimes\epsilon]$ is the product of the last four 1-vectors above; hence it commutes with the $\mathcal{CL}(1,9)$ 1-vectors, but anticommutes with the $\mathcal{CL}(0,4)$ 1-vectors. Therefore it can be used to reduce the 1,13-spacetime to 1,9-spacetime. In particular, at the 1-vector level,

$$\frac{1}{2}(1\pm[\alpha\otimes\epsilon])\mathcal{CL}_1(1,13)\frac{1}{2}(1\pm[\alpha\otimes\epsilon])=\mathcal{CL}_1(1,9)\frac{1}{2}(1\pm[\alpha\otimes\epsilon]).$$

At the 2-vector level,

$$\frac{1}{2}(1\pm[\alpha\otimes\epsilon])so(1,13)\frac{1}{2}(1\pm[\alpha\otimes\epsilon])=(so(1,9)\times su(2))\frac{1}{2}(1\pm[\alpha\otimes\epsilon]),$$

each projector $\frac{1}{2}(1\pm[\alpha\otimes\epsilon])$ picking out a $su(2)$ half of $so(4)$, and projecting from the spinor space, $\mathbf{T}^4$, a $\mathbf{T}^2$ subspace. Hence this reduction results in exactly the scenario developed in Ref. 2, except doubled. Projection operators, $\rho_{L\pm}=\frac{1}{2}(1\pm ie_{L7})$ and $\rho_{R\pm}=\frac{1}{2}(1\pm ie_{R7})$, further reduce the $\mathcal{CL}_1(1,9)$ to $\mathcal{CL}_1(1,3)$, and yielding a total Lie algebra reduction:

$$so(1,13) \mapsto so(1,9) \times su(2) \mapsto so(1,3) \times u(1) \times su(2) \times su(3).$$

The associated $\mathbf{T}^2$ subspace is the direct sum of a family and antifamily of leptons and quarks, transforming appropriately with respect to $u(1) \times su(2) \times su(3)$.

With a Clifford algebra and spinors we can form a Dirac operator and Lagrangian. If there were 2^k families then $\mathbf{T}^{2k}$ would be the appropriate hyperspinor space, acted on by a conventional Clifford algebra. But it is believed there are exactly 3 families, and we will have to get a little creative in constructing a Dirac-like Lagrangian for this case.

A Dirac operator for the $\mathcal{CL}(1,13)$ 2-family model developed above would be

$$\begin{bmatrix} \partial\!\!\!/_{1,9} & \partial\!\!\!/^{+}_{0,4} \\ \partial\!\!\!/^{-}_{0,4} & \partial\!\!\!/_{1,9} \end{bmatrix},$$

built from the original set of 14 1-vectors. (As noted in Ref. 6, this leads to interfamily mixing, including neutrinos.) For the 3-family case, one suggestion is to incorporate 3 of these 2-family Dirac operators into something new, motivated by the form of matrices in the exceptional Jordan algebra. In particular, consider a Lagrangian term like

$$\bar{\Psi} D \Psi = [\bar{\psi}_1 \quad \bar{\psi}_2 \quad \bar{\psi}_3] \begin{bmatrix} \partial\!\!\!/_{1,9} & \partial\!\!\!/^{+}_{0,4} & \partial\!\!\!/^{-}_{0,4} \\ \partial\!\!\!/^{-}_{0,4} & \partial\!\!\!/_{1,9} & \partial\!\!\!/^{+}_{0,4} \\ \partial\!\!\!/^{+}_{0,4} & \partial\!\!\!/^{-}_{0,4} & \partial\!\!\!/_{1,9} \end{bmatrix} \begin{bmatrix} \psi_1 \\ \psi_2 \\ \psi_3 \end{bmatrix} = \bar{\psi}_1 \partial\!\!\!/_{1,9} \psi_1 + \bar{\psi}_1 \partial\!\!\!/^{+}_{0,4} \psi_2 + \cdots .$$

Each of the $\psi_k, k=1,2,3$, is a complete leptoquark family plus antifamily residing in a copy of $\mathbf{T}^2$. There are three terms like $\bar{\psi}_1 \partial\!\!\!/_{1,9} \psi_1$, from which we derive single family interactions (Refs. 2 and 3), and six of the form $\bar{\psi}_1 \partial\!\!\!/^{+}_{0,4} \psi_2$, which mixes two different families—on the assumption $\partial\!\!\!/^{+}_{0,4} \psi_2 \neq 0$ (see Ref. 6).

If this approach is valid there is much that needs to be done to complete the picture. In particular, there is no single conventional pseudo-orthogonal space associated with the operator $\mathcal{D}$. Should the three $\partial\!\!\!/_{1,9}$ on the diagonal, and three $\partial\!\!\!/^{+}_{0,4}$ off-diagonal, be distinct? How does one obtain bivectors leading to Lie group actions and internal symmetries?

There are other 3×3 structures that may be relevant in this context, including a kind of Fermionic Clifford algebra related to supersymmetry (Ref. 3, p. 25). This has not been pursued to this point.

APPENDIX

We list for completeness the explicit generators of the special orthogonal groups realized on the division algebras, as used above:

$$so_2 : i.$$

$$so_8 : \left\{ \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}, \begin{bmatrix} 1 & 0 \\ 0 & 0 \end{bmatrix}, \begin{bmatrix} 0 & 0 \\ 0 & 1 \end{bmatrix} \right\} \{q_{Li}, q_{Rj}\},$$

$$\begin{bmatrix} 0 & 1 \\ -1 & 0 \end{bmatrix} \{1, q_{Li} q_{Rj}\}.$$

$$so_{24} : \left\{ \begin{bmatrix} 0 & 1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix}, \begin{bmatrix} 0 & 0 & 1 \\ 0 & 0 & 0 \\ 1 & 0 & 0 \end{bmatrix}, \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 1 \\ 0 & 1 & 0 \end{bmatrix} \right\} \{e_{La}, e_{Lab}\},$$

$$\left\{\begin{bmatrix}1&0&0\\0&1&0\\0&0&0\end{bmatrix},\begin{bmatrix}1&0&0\\0&0&0\\0&0&1\end{bmatrix},\begin{bmatrix}0&0&0\\0&1&0\\0&0&1\end{bmatrix}\right\}\{e_{La},e_{Lab}\},$$

$$\left\{\begin{bmatrix}0&1&0\\-1&0&0\\0&0&0\end{bmatrix},\begin{bmatrix}0&0&-1\\0&0&0\\1&0&0\end{bmatrix},\begin{bmatrix}0&0&0\\0&0&1\\0&-1&0\end{bmatrix}\right\}\{1,e_{Labc}\}.$$

(Received 28 April 2004; accepted 7 June 2004; published 12 October 2004)

We use monoidal category methods to study the noncommutative geometry of nonassociative algebras obtained by a Drinfeld-type cochain twist. These are the so-called quasialgebras and include the octonions as braided-commutative but nonassociative coordinate rings, as well as quasialgebra versions $\mathcal{C}_q(G)$ of the standard q-deformation quantum groups. We introduce the notion of ribbon algebras in the category, which are algebras equipped with a suitable generalized automorphism σ, and obtain the required generalization of cyclic cohomology. We show that this *braided cyclic cohomology* is invariant under a cochain twist. We also extend to our generalization the relation between cyclic cohomology and differential calculus on the ribbon quasialgebra. The paper includes differential calculus and cyclic cocycles on the octonions as a finite nonassociative geometry, as well as the algebraic noncommutative torus as an associative example. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1787621]

I. INTRODUCTION

In the influential work,[1] Drinfeld extended quantum groups or Hopf algebras to a more general notion of quasi-Hopf algebras stable under conjugation of the coproduct by a "twist." In a dual form the cotwist element F is a cochain and modifies the product of the coquasi-Hopf algebra. In Ref. 2 this construction was formulated as a monoidal equivalence between the comodule category of the coquasi-Hopf algebra H and that of the cotwisted coquasi-Hopf algebra H^F. The differential geometry of quantum groups H^F from this point of view and assuming F was a cocycle (so that we stay in the associative setting) was studied in Ref. 3. The more general coquasi-Hopf setting was used recently in Ref. 4 and applied to the standard quantum groups $\mathbb{C}_q(G)$. This work proved that there is no associative differential algebra on the standard quantum groups with classical dimensions (i.e., deforming the classical case in a strict sense) but that this is possible as a supercoquasi-Hopf algebra $\Omega(\mathbb{C}_q(G))$. This could be considered a first hint that nonassociative geometry is necessary for a full understanding even of ordinary quantum groups. It also suggests that one should take seriously nonassociative coordinate algebras themselves (not just their exterior algebras) and moreover in much greater generality than just (coquasi-)Hopf algebras alone.

We do this in the present paper for algebras A in monoidal Abelian categories. The idea is that the nicest nonassociative algebras, which we call *quasialgebras*, should be ones which are nonassociative but which may be viewed as associative by deforming the tensor product to a monoidal category with nontrivial associator $\Phi_{U,V,W}: U\otimes(V\otimes W)\to(U\otimes V)\otimes W$ for the rebracketing of tensor products of objects U,V,W. This complements the established idea of using braided categories to view certain noncommutative algebras as "commutative" with respect to a nontrivial braiding $\Psi_{V,W}: V\otimes W\to W\otimes V$ for objects V,W, see Ref. 5. Similarly, building on work of Drinfeld[1] we will find quasialgebra versions $\mathcal{C}_q(G)$ of the standard quantum groups which are nonassociative but more commutative (i.e., one can trade one feature for the other).

In general terms, we study several key constructions borrowed from noncommutative geometry[6,7] but now in the setting of quasialgebras, i.e., of algebras in monoidal categories with nontrivial associator. The idea is to think of the quasialgebra geometrically as by definition the coordinates of a "quasiassociative" space, which may also be noncommutative (for example, commutative with respect to a nontrivial braiding) and hence a "quantum quasispace." Thus, in Sec. III we will associate a cocyclic module (see Ref. 6) to any algebra in a braided monoidal *Ab*-category. We show that the morphism

$$\lambda = (\sigma \otimes \mathrm{id})\Psi$$

provides for us a cyclicity morphism in this category and hence a "braided cyclic cohomology" theory. Here $\Psi: A^{\otimes(n+1)} \otimes A \to A \otimes A^{\otimes(n+1)}$ is the braiding isomorphism and $\sigma: A \to A$ is a "generalized algebra automorphism." For reasons which will become clear, we call it a *ribbon automophism* on the algebra A and call (A, σ) a *ribbon (quasi)algebra*. In the associative trivially braided case σ becomes an automorphism in the usual sense and our braided cyclic cohomology reduces to the "twisted" cohomology in Ref. 7 which has been successfully applied to quantum groups such as $\mathbb{C}_q(SL_2)$. We also study how braided cyclic cocycles relate to differential calculus in the monoidal category.

The other key goal of the paper concerns the provision of examples. Indeed, the need for some kind of nonassociative geometry is hinted at from several directions in mathematical physics including string theory. Its need is also indicated from Poisson geometry, where the idea of a generalized Poisson bracket violating the usual Jacobi identity is proposed.[8] It turns out that an adequate class that appears to cover such examples is based on the use of Drinfeld-type cotwists, but not for (coquasi-)Hopf algebras H as above. Rather, we consider an algebra A in the monoidal category of H-comodules. After applying the monoidal equivalence one has an algebra A_F in the category of H^F-comodules. Indeed, all algebras and algebraic constructions "gauge transform" in this way. The A_F construction was introduced in Ref. 9 (in a module version) and for our purposes takes the form[5]

$$A_F = A, \quad \text{with the new product } a \cdot_F b = F(a_{(1)}, b_{(1)}) a_{(2)} b_{(2)},$$

where $a_{(1)} \otimes a_{(2)}$ denotes the (left) coaction. It turns out that a great many noncommutative algebras of interest fit into this cotwist framework for suitable H and F. Indeed, switching on F is a useful formulation of quantization as an extension of the Moyal product: Even if A is commutative, A_F in general becomes noncommutative when F is not symmetric since

$$a \cdot_F b = F(a_{(1)}, b_{(1)}) F^{-1}(b_{(2)}, a_{(2)}) b_{(3)} \cdot_F a_{(3)}.$$

More relevant for us, even if A is associative, A_F in general becomes nonassociative unless F obeys a 2-cocycle condition.[5] Recent applications include Refs. 10–12 in the associative case and Ref. 13, in the nonassociative case.

Section IV contains theorems about how braided cyclic cohomology and differential geometry respond under such cotwists. Thus, suppose for the sake of discussion that A possesses a left covariant differential calculus, $\Omega = \oplus_{k=0}^{n} \Omega_k$ which is supercommutative, i.e., two homogeneous differential forms ω and ω' commute up to a sign $(-1)^{|\omega||\omega'|}$. Thus in particular functions (0-forms) and n-forms commute. Therefore if $\int: \Omega_n \to \mathbb{C}$ is a closed graded trace in the sense of Connes then its character is a cyclic cocycle.[6] Now if we cotwist the superalgebra of differential forms with the same cocycle from one side as above, we obtain a calculus Ω_F for A_F but now functions and n-forms no longer commute. The noncommutativity is controlled by

$$\omega\omega' = (-1)^{|\omega||\omega'|} F(\omega_{(1)}, \omega'_{(1)}) F^{-1}(\omega'_{(2)}, \omega_{(2)}) \omega'_{(3)} \omega_{(3)},$$

where the product is the cotwisted $\cdot_F$ one. Consequently the character $\varphi(a^0, \ldots, a^n) = \int a^0 da^1 \cdots da^n$ after cotwisting is no longer a cyclic cocycle but obeys

$$\sum_{i=0}^{n}(-1)^i\varphi(a^0,\ldots,a^ia^{i+1},\ldots,a^{n+1})$$
$$+(-1)^{n+1}F(a^0_{(1)}\cdots a^n_{(1)},a^{n+1}_{(1)})F^{-1}(a^{n+1}_{(2)},a^0_{(2)}\cdots a^n_{(2)})\varphi(a^{n+1}_{(3)}a^0_{(3)},a^1_{(3)},\ldots,a^n_{(3)})=0.$$

The corresponding formula in the case where F is just a cochain not a cocycle, is much more involved and contains the associator in its formula (see Sec. IV A). We obtain, rather, a braided cyclic cocycle in the "gauge equivalent" category of H^F-comodules. Section IV A also contains rather concrete formulas when the background Hopf algebra H is coquasitriangular. Section IV B specializes the theory to the important case where in fact H is the group algebra of an Abelian group, which is the setting needed for many examples including the octonions.

Finally, Sec. V presents a collection of key examples demonstrating the theory in our paper. We explicitly give the differential calculus and a cyclic cocycle on the octonions as a finite nonassociative geometry, as well as the usual (algebraic) noncommutative torus. Section V C also outlines the theory applied to formal deformation theory, where we obtain the quasialgebras $\mathcal{C}_q(G)$ as mentioned above, using Drinfeld's associator obtained from solving the Knizhnik–Zamalochikov equations. We can also in principle use cotwising to deformation-quantize the quasi-Poisson manifold structure on a G-manifold M proposed in Ref. 8 (which was not achieved before), which we do as a quasialgebra $\mathcal{C}_q(M)$. We also construct the differential calculus and braided cyclic cocycles on all these quasialgebras. Further details of these potential examples will be presented elsewhere.

On the technical side, we start in the preliminary Sec. II, by explicitly embedding, in a canonical way, any general (relaxed) braided monoidal *Ab*-category in a strict braided monoidal *Ab*-category. This underlies Mac Lane's coherence theorem[14] and ensures that one can work with a relaxed category like a strict one. We also recall the Drinfeld's "gauge transformation" (in a dual cotwist sense) at the level of braided monoidal *Ab*-categories as in Ref. 2.

We conclude the Introduction with the geometric motivation behind our theory. In what follows we will consider "branched ribbon tangles," a modification of the usual notion of ribbon tangles (see Ref. 15, and the references there). We are not going to give a precise meaning of a branched ribbon tangle, but limit ourselves to an informal discussion. Thus let us define d_i, $0\leqslant i\leqslant n$ and d_{n+1} to be the isotopy type of the branched ribbon tangles in the strip $\mathbb{R}^2\times[0,1]$ in Figs. 1(a) and 1(b), respectively. Here by isotopy we mean isotopy in $\mathbb{R}^2\times[0,1]$ constant in boundary intervals on the lines $z=0$ and $z=1$ in the plane $x=0$. Then intuitively we have the isotopies in Fig. 1 parts (c), (d), (e), and (f). In part (d) we used the isotopy in part (g). All these isotopies should be clear except (f) which may need more explanation; in fact ignoring vertical bands indexed from 1 to $n+1$ in part (f), the left-hand side of (f) is isotopic with the left-hand side of (h). Now considering the last diagram in (h), rotate the upper branch in this diagram by 360° to give the right-hand side of (f). Now as in Ref. 15 or 5 we define the composition of two branched ribbon tangles by putting one on top of the other one and compressing the resulting diagram to the strand $\mathbb{R}^2\times[0,1]$. Then parts (c), (d), (e), and (f) of Fig. 1 mean

$$d_id_j=d_{j-1}d_i.$$

These relations are the main content of the notion of a simplicial object in the category. Note that one can work essentially in the category of ribbon tangles as in Ref. 15, where roughly speaking, a morphism is just an isotopy type of a ribbon tangle. This would need, however, some geometric considerations whereas we prefer to work in a purely algebraic manner. Thus in Sec. III we axiomatize the precise assumptions which will lead us to above relations in the context of a general braided monoidal category. In this case, for braided categories we use the usual graphical calculus, which should not be confused with the above isotopy argument on actual ribbon graphs which are embedded surfaces in space. We recall that any braided category is the image of the

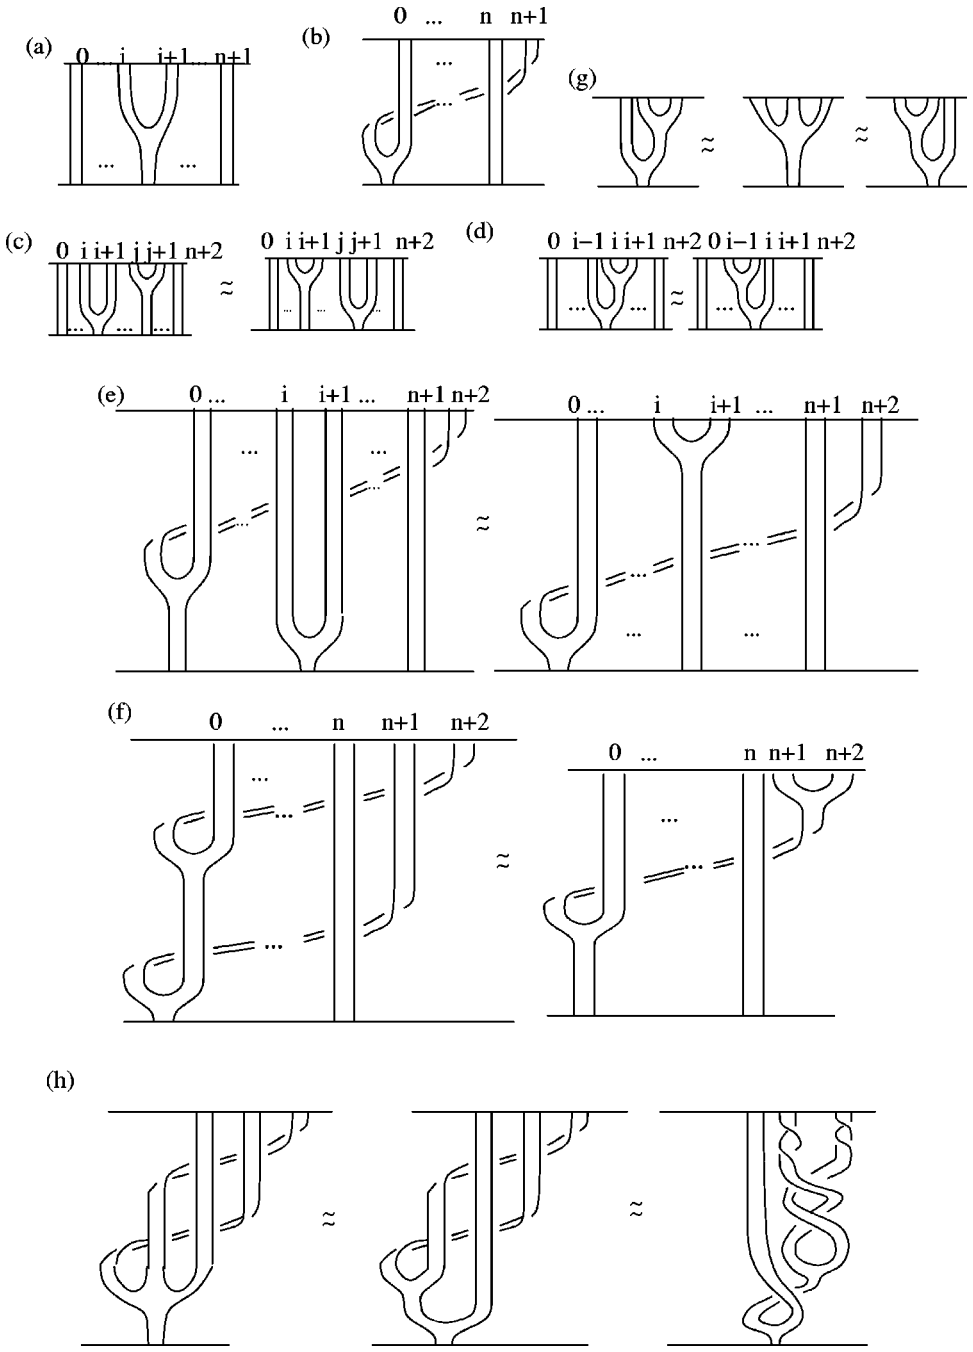

FIG. 1. Branched ribbon tangles, with (a), $0 \leqslant i \leqslant n$. (c), $0 \leqslant i < j-1 \leqslant n$. (d), $1 \leqslant j \leqslant n+1$. (e), $0 \leqslant i \leqslant n$.

category of braids which allows for the representation of the axiomatic properties of $\otimes, \Psi$ by strands and their braiding in the graphical notation (see the Preliminaries). In the same way, one can define a functor from the category of branched ribbon graphs (see Ref. 15) to our category in Sec. III such that two isotopic branched ribbon tangles have the same image under this functor, and the image of branched ribbon tangles under this functor can be considered as graphical symbols.

II. PRELIMINARIES: MONOIDAL CATEGORIES, COHERENCE, AND "GAUGE" EQUIVALENCE

Here we establish the basic notations and methods needed in the paper. In order to be able to work effectively with the nonassociativity, we need in particular to fix some conventions on bracketing and explain related issues. Then we recall the notion of monoidal equivalence used in the construction of our examples.

Let $(\mathcal{C},\otimes,\Phi,\Psi)$ be a braided monoidal Ab-category, where Φ is the associator and Ψ is the braiding. We refer to Refs. 15 and 5 for the axioms, but briefly $\otimes:\mathcal{C}\times\mathcal{C}\to\mathcal{C}$ is a functor and $\Phi\in\mathrm{Nat}(\otimes(\otimes),(\otimes)\otimes)$ and $\Psi\in\mathrm{Nat}(\otimes,\otimes^{\mathrm{op}})$ are natural isomorphisms obeying respectively the pentagon and two hexagon identities with regard to composite objects. The pentagon identifies two ways to go from $U\otimes(V\otimes(W\otimes Z))\to((U\otimes V)\otimes W)\otimes Z$ using two and three applications of Φ, respectively. The hexagons identify $(V\otimes W)\otimes Z\to Z\otimes(V\otimes W)$ in two ways and $V\otimes(W\otimes Z)\to(W\otimes Z)\otimes V$ in two ways, using Ψ,Φ. The coherence theorem of Mac Lane in the symmetric case (when $\Psi^2=\mathrm{id}$ is assumed) and of Joyal and Street[16] in the general braided case, ensures that once these are assumed, one may (a) drop brackets entirely, inserting Φ as needed for any composition to make sense, and (b) represent Ψ,Ψ^{-1} by braid crossings $\times$ and inverse braid crossings $\times$; if two braid compositions are equal then so are the compositions of Ψ,Ψ^{-1}. We assume the monoidal category is unital and denote the unit object by $\mathbf{1}$, where for simplicity we will assume that $U\otimes\mathbf{1}=\mathbf{1}\otimes U=U$, $\forall U\in\mathcal{C}$ and $\Phi_{U,V,W}=\mathrm{id}$ whenever at least one of the objects U,V or W is $\mathbf{1}$. Similarly for the braiding when present. By Ab-monoidal category we mean that for each pair of objects U and V the set $\mathrm{Hom}(U,V)$ is an additive Abelian group such that the composition and tensor product of morphisms are bilinear. Then one can easily show that $K:=\mathrm{Hom}(\mathbf{1},\mathbf{1})$ is a commutative ring with unit.

Next, in order to be completely explicit, we canonically extend any braided monoidal Ab-category $\mathcal{C}$ into a strict braided monoidal Ab-category. First of all, using induction on n we define a family Λ_n of sets as follows. Let for $n>0$, $\mathcal{C}^n$ be the n times Cartesian product of $\mathcal{C}$ with itself. Let Λ_1 be the single set whose element is the identity functor on $\mathcal{C}$ and let Λ_2 be the single set whose element is the functor $\otimes:\mathcal{C}\times\mathcal{C}\to\mathcal{C}$. Now suppose that $\Lambda_k, k<n$ has been defined already such that for each $\alpha\in\Lambda_k$ there is an associated functor $\overline{\alpha}:\mathcal{C}^k\to\mathcal{C}$, then we define Λ_n for $n>2$ to be the set of all pairs (α,β), $\alpha\in\Lambda_k$, $\beta\in\Lambda_l$, $k<n$, $l<n$, $k+l=n$ and we associate to the pair (α,β) the functor $\otimes(\overline{\alpha}\times\overline{\beta}):\mathcal{C}^n\to\mathcal{C}$. For $U_i\in\mathcal{C}$, $1\leqslant i\leqslant n$ and $\alpha\in\Lambda_n$ the symbol $(U_1\otimes\cdots\otimes U_n;\alpha)$ or $U_1\otimes_\alpha\cdots\otimes_\alpha U_n$ will denote the object $\overline{\alpha}(U_1,\ldots,U_n)$.

Now let $\overline{\mathcal{C}}$ be the category whose objects are symbols $U_1\otimes\cdots\otimes U_n$, $n=1,2,\ldots,U_i\in\mathcal{C}$ such that if $n>1$ then $U_i\neq\mathbf{1},\forall i$. The object $\mathbf{1}$ of $\overline{\mathcal{C}}$ is called the degree zero object and the objects $U_1\otimes\cdots\otimes U_n$, $n=1,2,\ldots,\mathbf{1}\neq U_i\in\mathcal{C}$ are called of degree n. To define morphisms in this category we recall that by Mac Lane's coherence theorem there exists a unique family of isomorphisms $I^\alpha_\beta=I^\alpha_\beta(U_1,\ldots,U_m):(U_1\otimes\cdots\otimes U_m;\alpha)\to(U_1\otimes\cdots\otimes U_m;\beta)$, $\alpha,\beta\in\Lambda_m,\mathbf{1}\neq U_i\in\mathcal{C}$, induced by the associator satisfying $I^\alpha_\beta=\mathrm{id}$ for $m=1,2$ and

$$I^\beta_\gamma I^\alpha_\beta=I^\alpha_\gamma,\qquad\forall\,\alpha,\ \beta,\ \gamma\in\Lambda_m, \tag{2.1}$$

$$I^{\alpha_1}_{\alpha_2}(U_1,\ldots,U_k)\otimes I^{\beta_1}_{\beta_2}(U_{k+1},\ldots,U_m)=I^{(\alpha_1,\beta_1)}_{(\alpha_2,\beta_2)}(U_1,\ldots,U_m),\quad\alpha_1,\alpha_2\in\Lambda_k,\ \beta_1,\ \beta_2\in\Lambda_{m-k}, \tag{2.2}$$

$$I^{(\mathrm{id},\otimes)}_{(\otimes,\mathrm{id})}(U_1,U_2,U_3)=\Phi_{U_1,U_2,U_3}. \tag{2.3}$$

We call these isomorphisms, the *higher degree associators* of $\mathcal{C}$.

Next we define an equivalence relation among the morphisms in $\cup_{\alpha\in\Lambda_m,\beta\in\Lambda_n}\mathrm{Hom}_{\mathcal{C}}((U_1\otimes\cdots\otimes U_m;\alpha),(V_1\otimes\cdots\otimes V_n;\beta))$ by

$$f_1 \sim f_2 \Leftrightarrow f_2 = I^{\beta_1}_{\beta_2}(V_1, \ldots, V_n) f_1 I^{\alpha_2}_{\alpha_1}(U_1, \ldots, U_m) \tag{2.4}$$

for $f_i:(U_1\otimes\cdots\otimes U_m;\alpha_i)\to(V_1\otimes\cdots\otimes V_n;\beta_i)$, $\alpha_i\in\Lambda_m,\beta_i\in\Lambda_n,i=1,2$. One can easily show that the above relation is an equivalence relation and each equivalence class contains one and only one representative in each set $\mathrm{Hom}_{\mathcal{C}}((U_1\otimes\cdots\otimes U_m;\alpha),(V_1\otimes\cdots\otimes V_n;\beta))$. We now define $\mathrm{Hom}_{\overline{\mathcal{C}}}(U_1\otimes\cdots\otimes U_m, V_1\otimes\cdots\otimes V_n)$ to be the equivalence classes of all morphisms in the set $\cup_{\alpha\in\Lambda_m,\beta\in\Lambda_n}\mathrm{Hom}_{\mathcal{C}}((U_1\otimes\cdots\otimes U_m;\alpha),(V_1\otimes\cdots\otimes V_n;\beta))$. We denote the equivalence classes by notation $[f]$.

For morphisms $f:U_1\otimes\cdots\otimes U_l\to V_1\otimes\cdots\otimes V_m$ and $g:V_1\otimes\cdots\otimes V_m\to W_1\otimes\cdots\otimes W_n$ in $\overline{\mathcal{C}}$ we define composition gf to be the class of morphism $g^{\beta}_{\gamma}f^{\alpha}_{\beta}$. Here f^{α}_{β} and g^{β}_{γ} are the representatives of f and g in $\mathrm{Hom}_{\mathcal{C}}((U_1\otimes\cdots\otimes U_l;\alpha),(V_1\otimes\cdots\otimes V_m;\beta))$ and $\mathrm{Hom}_{\mathcal{C}}((V_1\otimes\cdots\otimes V_m;\beta),(W_1\otimes\cdots\otimes W_n;\gamma))$ respectively, for arbitrary $\alpha\in\Lambda_l,\beta\in\Lambda_m,\gamma\in\Lambda_n$. One can easily show that this composition is well-defined and is associative, and that the classes of identity morphisms in $\mathcal{C}$ are identity morphisms in $\overline{\mathcal{C}}$.

To define a monoidal structure on $\overline{\mathcal{C}}$ we define $\mathbf{1}\otimes\mathbf{1}:=\mathbf{1}$ and $\mathbf{1}\otimes(U_1\otimes\cdots\otimes U_m):=U_1\otimes\cdots\otimes U_m=:(U_1\otimes\cdots\otimes U_m)\otimes\mathbf{1}$ and $(U_1\otimes\cdots\otimes U_m)\otimes(V_1\otimes\cdots\otimes V_n):=U_1\otimes\cdots\otimes U_m\otimes V_1\otimes\cdots\otimes V_n$ for $\mathbf{1}\neq U_i,V_i$. And for $f:U_1\otimes\cdots\otimes U_m\to V_1\otimes\cdots\otimes V_n$ and $f':U'_1\otimes\cdots\otimes U'_{m'}\to V'_1\otimes\cdots\otimes V'_{n'}$ we define $f\otimes f'$ to be the equivalence class of the morphism $f^{\alpha}_{\beta}\otimes f'^{\alpha'}_{\beta'}:(U_1\otimes\cdots\otimes U_m\otimes U'_1\otimes\cdots\otimes U'_{m'};(\alpha,\alpha'))\to(V_1\otimes\cdots\otimes V_n\otimes V'_1\otimes\cdots\otimes V'_{n'};(\beta,\beta'))$, $\alpha\in\Lambda_m,\alpha'\in\Lambda_{m'},\beta\in\Lambda_n,\beta\in\Lambda_{n'}$. Again one can show this is well-defined by using (2.2). From naturality of the associator, it is obvious that this tensor product is associative and the unit object of $\mathcal{C}$ is also unit object of this product. Therefore $\overline{\mathcal{C}}$ is a strict monoidal category. Similarly the addition of two morphisms $f,g:U_1\otimes\cdots\otimes U_m\to V_1\otimes\cdots\otimes V_n$ is defined to be the equivalence class of the morphism $f^{\alpha}_{\beta}+g^{\alpha}_{\beta}$, $\alpha\in\Lambda_m,\beta\in\Lambda_n$, and it is straightforward to show this is well-defined and $\overline{\mathcal{C}}$ is a strict monoidal *Ab*-category.

Finally, when $\mathcal{C}$ is braided, we define braid isomorphisms $\overline{\Psi}_{U_1\otimes\cdots\otimes U_m,V_1\otimes\cdots\otimes V_n}$ to be the equivalence class of morphism $\Psi_{(U_1\otimes\cdots\otimes U_m;\alpha),(V_1\otimes\cdots\otimes V_n;\beta)}$. It is easy to show that $\overline{\mathcal{C}}$ equipped with this isomorphisms becomes a strict braided monoidal *Ab*-category.

Note that the strict braided monoidal category $\overline{\mathcal{C}}$ is an extension of $\mathcal{C}$ as an *Ab*-category but not as a braided monoidal one. Nevertheless, the braided monoidal structure of $\mathcal{C}$ is used in building $\overline{\mathcal{C}}$ and allows us to replace any nonstrict $\mathcal{C}$ by the strict $\overline{\mathcal{C}}$ by regarding its objects and morphisms in $\overline{\mathcal{C}}$. Note that $\mathcal{C}$ does not inherit an associative tensor product from $\overline{\mathcal{C}}$ because if we regard two objects U and V in $\mathcal{C}$ as first degree objects of $\overline{\mathcal{C}}$ then their tensor product $U\otimes V$ in $\overline{\mathcal{C}}$ is a second degree object of $\overline{\mathcal{C}}$ and therefore it is not in $\mathcal{C}$ which is the set of objects of degree less than two in $\overline{\mathcal{C}}$. For example we know that an algebra in a strict monoidal category is defined to be an object A equipped with a morphism $m:A\otimes A\to A$ such that $m(\mathrm{id}\otimes m)=m(m\otimes\mathrm{id})$ as a morphism from $A\otimes A\otimes A$ to A. Now let $\mathcal{C}$ be a nonstrict monoidal category, but view it in $\overline{\mathcal{C}}$. We define similarly, an algebra A to be an object in $\mathcal{C}$ (a first degree object in $\overline{\mathcal{C}}$) equipped with a morphism $m:A\otimes A\to A$ (a morphism from a second degree object to a first degree object in $\overline{\mathcal{C}}$) such that $m(\mathrm{id}\otimes m)=m(m\otimes\mathrm{id})$ as an equality between morphisms from $A\otimes A\otimes A$ (a third degree object in $\overline{\mathcal{C}}$) to A (a first degree object in $\overline{\mathcal{C}}$). If in addition there exists a morphism $\eta:\mathbf{1}\to A$ such that $m(\mathrm{id}\otimes\eta)=m(\eta\otimes\mathrm{id})=\mathrm{id}$ then we call (A,m,η) a unital algebra in $\mathcal{C}$.

The above construction of the family $\{\Lambda_n\}_n$ can be done for any set equipped with a binary action on it. Explicitly let A be a set with a binary action $.:A\times A\to A$, then similarly, using induction, for each n we have a set of n-fold actions $A\times\cdots\times A\to A$. We denote this set again by $\{\Lambda_n\}_n$ and for $\alpha\in\Lambda_n$ and $a^i\in A$, $1\leqslant i\leqslant n$ we use the notation $a^1{}_{._\alpha}\cdots{}_{._\alpha}a^n$ for $\alpha(a^1,\ldots,a^n)$.

We also want to recall quite explicitly the notion of a tensor functor between braided monoidal categories. It is known[2] that equivalence by such tensor functors is the correct notion of "gauge transformation" relevant to the Drinfeld cotwist. At the moment, we give the general categorical

setting for this. Thus, let $(\mathcal{C},\otimes,\Phi,\Psi)$ and $(\mathcal{C}',\otimes',\Phi',\Psi')$ be two braided unital monoidal *Ab*-categories and let $T:\mathcal{C}\to\mathcal{C}'$ be an additive functor such that $T(\mathbf{1})=\mathbf{1}'$ and suppose that there exists a natural isomorphism $\mathcal{F}$ between the functors $\otimes'(T\times T), T\otimes:\mathcal{C}\times\mathcal{C}\to\mathcal{C}'$, i.e., there exists a family of isomorphisms $\mathcal{F}_{U,V}:T(U)\otimes' T(V)\to T(U\otimes V)$ in $\mathcal{C}'$, $\forall U,V\in\mathcal{C}$, such that $\mathcal{F}_{U,\mathbf{1}}=\mathcal{F}_{\mathbf{1},U}=\mathrm{id}_{T(U)}$ and for all objects U_i,V_i, $i=1,2$ and morphisms $f:U_1\to U_2, g:V_1\to V_2$ in $\mathcal{C}$ we have

$$T(f\otimes g)\mathcal{F}_{U_1,V_1}=\mathcal{F}_{U_2,V_2}(T(f)\otimes' T(g)). \tag{2.5}$$

Now suppose that

$$T(\Phi_{U,V,W})\mathcal{F}_{U,V\otimes W}(\mathrm{id}_{T(U)}\otimes'\mathcal{F}_{V,W})=\mathcal{F}_{U\otimes V,W}(\mathcal{F}_{U,V}\otimes\mathrm{id}_{T(W)})\Phi'_{T(U),T(V),T(W)} \tag{2.6}$$

and

$$T(\Psi_{U,V})\mathcal{F}_{U,V}=\mathcal{F}_{V,U}\Psi'_{T(U),T(V)} \tag{2.7}$$

$\forall U,V,W\in\mathcal{C}$.

Definition 1: A tensor functor between two braided monoidal Ab-categories $(\mathcal{C},\otimes,\Phi,\Psi)$ *and* $(\mathcal{C}',\otimes',\Phi',\Psi')$ *is a pair* $(T,\mathcal{F})$ *as above. A "gauge transformation" between braided monoidal Ab-categories is an invertible tensor functor, in which case we say that the categories are "gauge equivalent."*

Indeed, if T is an invertible functor, we set

$$\mathcal{F}'_{U',V'}:=T^{-1}(\mathcal{F}^{-1}_{T^{-1}(U'),T^{-1}(V')}),\quad \forall U',V'\in\mathcal{C}'.$$

Then $(T^{-1},\mathcal{F}')$ is a tensor functor from $(\mathcal{C}',\otimes',\Phi',\Psi')$ to $(\mathcal{C},\otimes,\Phi,\Psi)$. To prove this let U'_i, V'_i, U', V' and W' be objects in $\mathcal{C}'$, where $i=1,2$, and let $f':U'_1\to U'_2, g':V'_1\to V'_2$ be morphisms in $\mathcal{C}'$, then we set $U_i:=T^{-1}(U'_i)$, $V_i:=T^{-1}(V'_i)$, $i=1,2$, $f:=T^{-1}(f')$ and $g:=T^{-1}(g')$. Then from (2.5) we get $\mathcal{F}^{-1}_{U_2,V_2}T(f\otimes g)=(f'\otimes' g')\mathcal{F}^{-1}_{U_1,V_1}$. Thus applying T^{-1} to this relation we get

$$T^{-1}(f'\otimes' g')\mathcal{F}'_{U'_1,V'_1}=\mathcal{F}'_{U'_2,V'_2}(T^{-1}(f')\otimes' T^{-1}(g')) \tag{2.8}$$

which is the counterpart of (2.5) for pair $(T^{-1},\mathcal{F}')$. The counterpart of (2.7) for the pair $(T^{-1},\mathcal{F}')$ can be proved similarly. Let us prove (2.6) for $(T^{-1},\mathcal{F}')$. At first note that if we apply (2.8) for $f'=\mathrm{id}_{U'}, g'=\mathcal{F}^{-1}_{V,W}$ then we get $T^{-1}(\mathrm{id}_{U'}\otimes'\mathcal{F}^{-1}_{V,W})\mathcal{F}'_{U',T(V\otimes W)}=\mathcal{F}'_{U',V'\otimes W'}(\mathrm{id}_{T^{-1}(U')}\otimes' T^{-1}(\mathcal{F}^{-1}_{V,W}))=\mathcal{F}'_{U',V'\otimes W'}(\mathrm{id}_{T^{-1}(U')}\otimes'\mathcal{F}'_{V',W'})$, and similarly applying (2.8) for $f'=\mathcal{F}^{-1}_{U,V}, g'=\mathrm{id}_{W'}$ we get $T^{-1}(\mathcal{F}^{-1}_{U,V}\otimes'\mathrm{id}_{W'})\mathcal{F}'_{T(U\otimes V),W'}=\mathcal{F}'_{U'\otimes V',W'}(T^{-1}(\mathcal{F}^{-1}_{U,V})\otimes'\mathrm{id}_{T^{-1}(W')})=\mathcal{F}'_{U'\otimes V',W'}(\mathcal{F}'_{U',V'}\otimes'\mathrm{id}_{T^{-1}(W')})$. We call these two relations auxiliary relations. Now from (2.6) we deduce $\Phi'_{U',V',W'}(\mathrm{id}_{U'}\otimes'\mathcal{F}^{-1}_{V,W})\mathcal{F}^{-1}_{U,V\otimes W}=(\mathcal{F}^{-1}_{U,V}\otimes\mathrm{id}_{W'})\mathcal{F}^{-1}_{U\otimes V,W}T(\Phi_{U,V,W})$ and if we apply T^{-1} to this relation and use the auxiliary relations then we get the counterpart of (2.6).

We need to check how the above notions of tensor functor and gauge equivalence extend to $\overline{\mathcal{C}}$. Thus, given $(T,\mathcal{F})$, we construct a family of isomorphisms $S_\alpha=S_\alpha(U_1,\ldots,U_m):(T(U_1)\otimes'\cdots\otimes' T(U_m);\alpha)\to T(U_1\otimes\cdots\otimes U_m;\alpha)$, $\forall\alpha\in\Lambda_m$, $U_i\in\mathcal{C}$, by induction on m; for $m=1$ we set $S_\alpha(U)=\mathrm{id}_{T(U)}$ and for $m=2$ we set $S_\alpha(U_1,U_2)=\mathcal{F}_{U_1,U_2}$. Now let S_α have been defined already for $\alpha\in\Lambda_k$, $k<m$ and let $\gamma\in\Lambda_m$. Then by definition of the set Λ_m there exist unique integers k, $l<m$ and unique $\alpha\in\Lambda_k$, $\beta\in\Lambda_l$ such that $k+l=m$ and $\gamma=(\alpha,\beta)$. Then we set

$$S_{(\alpha,\beta)}(U_1,\ldots,U_m):=\mathcal{F}_{(U_1\otimes\cdots\otimes U_k;\alpha),(U_{k+1}\otimes\cdots\otimes U_m;\beta)}(S_\alpha(U_1,\ldots,U_k)\otimes' S_\beta(U_{k+1},\ldots,U_m)). \tag{2.9}$$

Now let I'^{α}_{β} denote the corresponding higher degree associators for $\mathcal{C}'$, then we claim that

$$S^{-1}_\beta T(I^\alpha_\beta(U_1,\ldots,U_m))S_\alpha=I'^{\alpha}_{\beta}(U'_1,\ldots,U'_m), \tag{2.10}$$

where $U'_i=T(U_i)$. To prove this, let us denote the left-hand side of the above relation by $J^\alpha_\beta(U'_1,\ldots,U'_m)$. We check that the relations (2.1)–(2.3) hold for this family and therefore by

uniqueness of higher degree associators the claim will be proven. We have

$$J^{\beta}_{\gamma}J^{\alpha}_{\beta}=S^{-1}_{\gamma}T(I^{\beta}_{\gamma})S_{\beta}S^{-1}_{\beta}T(I^{\alpha}_{\beta})S_{\alpha}=S^{-1}_{\gamma}T(I^{\beta}_{\gamma}I^{\alpha}_{\beta})S_{\alpha}=S^{-1}_{\gamma}T(I^{\alpha}_{\gamma})S_{\alpha}=J^{\alpha}_{\gamma}$$

and

$$\begin{aligned}J^{\alpha_1}_{\alpha_2}\otimes' J^{\beta_1}_{\beta_2}&=S^{-1}_{\alpha_2}T(I^{\alpha_1}_{\alpha_2})S_{\alpha_1}\otimes' S^{-1}_{\beta_2}T(I^{\beta_1}_{\beta_2})S_{\beta_1}=(S^{-1}_{\alpha_2}\otimes' S^{-1}_{\beta_2})(T(I^{\alpha_1}_{\alpha_2})\otimes' T(I^{\beta_1}_{\beta_2}))(S_{\alpha_1}\otimes' S_{\beta_1})\\&=S^{-1}_{(\alpha_2,\beta_2)}\mathcal{F}_{X_2,Y_2}(T(I^{\alpha_1}_{\alpha_2})\otimes' T(I^{\beta_1}_{\beta_2}))\mathcal{F}^{-1}_{X_1,Y_1}S_{(\alpha_1,\beta_1)}=S^{-1}_{(\alpha_2,\beta_2)}T(I^{\alpha_1}_{\alpha_2}\otimes I^{\beta_1}_{\beta_2})S_{(\alpha_1,\beta_1)}\\&=S^{-1}_{(\alpha_2,\beta_2)}T(I^{(\alpha_1,\beta_1)}_{(\alpha_2,\beta_2)})S_{(\alpha_1,\beta_1)}=J^{(\alpha_1,\beta_1)}_{(\alpha_2,\beta_2)},\end{aligned}$$

where for simplicity we wrote $X_i=(U_1\otimes\cdots\otimes U_k;\alpha_i)$, $Y_i=(U_{k+1}\otimes\cdots\otimes U_m;\beta_i)$, and we have

$$\begin{aligned}J^{(\mathrm{id},\otimes')}_{(\otimes',\mathrm{id})}(U'_1,U'_2,U'_3)&=S^{-1}_{(\otimes',\mathrm{id})}T(I^{(\mathrm{id},\otimes)}_{(\otimes,\mathrm{id})}(U_1,U_2,U_3))S_{(\mathrm{id},\otimes')}\\&=(\mathcal{F}^{-1}_{U_1,U_2}\otimes\mathrm{id}_{T(U_3)})\mathcal{F}^{-1}_{U_1\otimes U_2,U_3}T(\Phi_{U_1,U_2,U_3})\mathcal{F}_{U_1,U_2\otimes U_3}(\mathrm{id}_{T(U_1)}\otimes\mathcal{F}_{U_2,U_3})\\&=\Phi'_{U'_1,U'_2,U'_3},\end{aligned}$$

where we used $S_{(\mathrm{id},\otimes')}(U_1,U_2,U_3)=\mathcal{F}_{U_1,U_2\otimes U_3}(\mathrm{id}_{T(U_1)}\otimes\mathcal{F}_{U_2,U_3})$ which comes from (2.9), and similarly for $S_{(\otimes',\mathrm{id})}$.

Now let $\overline{\mathcal{C}}$ and $\overline{\mathcal{C}'}$ be the canonical extensions of $\mathcal{C}$ and $\mathcal{C}'$ to strict braided monoidal *Ab*-categories respectively. We define a functor $\overline{T}:\overline{\mathcal{C}}\to\overline{\mathcal{C}'}$ by $\overline{T}(U_1\otimes\cdots\otimes U_m):=T(U_1)\otimes'\cdots\otimes' T(U_m)$ and for morphism $f:U_1\otimes\cdots\otimes U_m\to V_1\otimes\cdots\otimes V_n$ in $\overline{\mathcal{C}}$ we define $\overline{T}(f)$ as follows: let $f^{\alpha}_{\beta}:(U_1\otimes\cdots\otimes U_m;\alpha)\to(V_1\otimes\cdots\otimes V_n;\beta)$ be the representative of f for any $\alpha\in\Lambda_m$, $\beta\in\Lambda_n$. We define $\overline{T}(f)$ be the equivalence class of the morphism $S^{-1}_{\beta}T(f^{\alpha}_{\beta})S_{\alpha}:(T(U_1)\otimes'\cdots\otimes' T(U_m);\alpha)\to(T(V_1)\otimes'\cdots\otimes' T(V_n);\beta)$. We must show that this definition does not depend to the choice of the representative. Thus let $f^{\alpha_i}_{\beta_i}$, $i=1,2$ be two representatives of f then we have

$$I'^{\beta_1}_{\beta_2}S^{-1}_{\beta_1}T(f^{\alpha_1}_{\beta_1})S_{\alpha_1}I'^{\alpha_2}_{\alpha_1}=S^{-1}_{\beta_2}T(I^{\beta_1}_{\beta_2})S_{\beta_1}S^{-1}_{\beta_1}T(f^{\alpha_1}_{\beta_1})S_{\alpha_1}S^{-1}_{\alpha_1}T(I^{\alpha_2}_{\alpha_1})S_{\alpha_2}=S^{-1}_{\beta_2}T(I^{\beta_1}_{\beta_2}f^{\alpha_1}_{\beta_1}I^{\alpha_2}_{\alpha_1})S_{\alpha_2}=S^{-1}_{\beta_2}T(f^{\alpha_2}_{\beta_2})S_{\alpha_2}.$$

Thus $\overline{T}(f)$ is well-defined.

Next, for composable morphisms f and g in $\overline{\mathcal{C}}$ we have

$$\overline{T}(gf)=[S^{-1}_{\gamma}T(g^{\beta}_{\gamma}f^{\alpha}_{\beta})S_{\alpha}]=[S^{-1}_{\gamma}T(g^{\beta}_{\gamma})S_{\beta}S^{-1}_{\beta}T(f^{\alpha}_{\beta})S_{\alpha}]=\overline{T}(g)\overline{T}(f)$$

and for addable morphisms f and g in $\overline{\mathcal{C}}$ we have $\overline{T}(f+g)=[S^{-1}_{\beta}T(f^{\alpha}_{\beta}+g^{\alpha}_{\beta})S_{\alpha}]=\overline{T}(f)+\overline{T}(g)$. Clearly for all objects $X=U_1\otimes\cdots\otimes U_m$, $Y=V_1\otimes\cdots\otimes V_n$ in $\mathcal{C}$ we have $T(X\otimes Y)=T(X)\otimes'T(Y)$ and if $X'=U'_1\otimes\cdots\otimes U'_{m'}$, $Y'=V'_1\otimes\cdots\otimes V'_{n'}$ are other objects in $\overline{\mathcal{C}}$ and $f:X\to Y$, $g:X'\to Y'$ are morphisms in $\overline{\mathcal{C}}$ we have

$$\begin{aligned}\overline{T}(f\otimes g)=[S^{-1}_{(\beta,\beta')}T(f^{\alpha}_{\beta}\otimes g^{\alpha'}_{\beta'})S_{(\alpha,\alpha')}]&=[(S^{-1}_{\beta}\otimes' S^{-1}_{\beta'})\mathcal{F}^{-1}_{Y_{\beta},Y'_{\beta'}}T(f^{\alpha}_{\beta}\otimes g^{\alpha'}_{\beta'})\mathcal{F}^{-1}_{X_{\alpha},X'_{\alpha'}}(S_{\alpha}\otimes' S_{\alpha'})]\\&=[(S^{-1}_{\beta}\otimes' S^{-1}_{\beta'})(T(f^{\alpha}_{\beta})\otimes' T(g^{\alpha'}_{\beta'}))(S_{\alpha}\otimes' S_{\alpha'})]\\&=[S^{-1}_{\beta}T(f^{\alpha}_{\beta})S_{\alpha}\otimes' S^{-1}_{\beta'}T(g^{\alpha'}_{\beta'})S_{\alpha'}]=\overline{T}(f)\otimes'\overline{T}(g),\end{aligned}$$

where $X_{\alpha}=(U_1\otimes\cdots\otimes U_m;\alpha)$, $X'_{\alpha'}=(U'_1\otimes\cdots\otimes U'_m;\alpha')$, $Y_{\beta}=(V_1\otimes\cdots\otimes V_n;\beta)$, $Y'_{\beta'}=(V'_1\otimes\cdots\otimes V'_n;\beta')$.

Now, with the above notation for X,Y,X_{α}, and Y_{β}, we show that

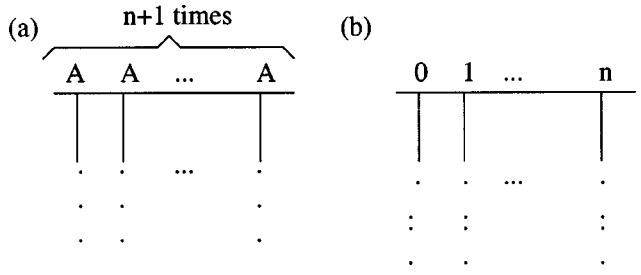

FIG. 2. Notation for multiple $\otimes$ products.

$$\overline{T}(\overline{\Psi}_{X,Y}) = \overline{\Psi}'_{\overline{T}(X),\overline{T}(Y)}. \tag{2.11}$$

Let us denote $\overline{\Psi}_{X,Y}$ by f for brevity. Then by definition for $\alpha \in \Lambda_m$, $\beta \in \Lambda_n$ we have $f^{(\alpha,\beta)}_{(\beta,\alpha)} = \Psi_{X_\alpha, Y_\beta}$. Thus,

$$\begin{aligned}\overline{T}(\overline{\Psi}_{X,Y}) &= [S^{-1}_{(\beta,\alpha)} T(f^{(\alpha,\beta)}_{(\beta,\alpha)}) S_{(\alpha,\beta)}] = [(S^{-1}_\beta \otimes' S^{-1}_\alpha)\mathcal{F}^{-1}_{Y_\beta, X_\alpha} T(\Psi_{X_\alpha, Y_\beta})\mathcal{F}^{-1}_{X_\alpha, Y_\beta}(S_\alpha \otimes' S_\beta)] \\ &= [(S^{-1}_\beta \otimes' S^{-1}_\alpha)\Psi'_{T(X_\alpha),T(Y_\beta)}(S_\alpha \otimes' S_\beta)] \\ &= [\Psi'_{\overline{T}(X)_\alpha, \overline{T}(Y)_\beta}] = \overline{\Psi}'_{\overline{T}(X),\overline{T}(Y)},\end{aligned}$$

where by $\overline{T}(X)_\alpha$ we mean $(T(U_1)\otimes' \cdots \otimes' T(U_m); \alpha)$ and by $\overline{T}(Y)_\beta$ we mean $(T(V_1)\otimes' \cdots \otimes' T(V_n); \beta)$ and in the fourth equality we used naturality of the braiding in $\mathcal{C}'$.

Summarizing the above argument, we have

Proposition 2: Any tensor functor $(T, \mathcal{F})$ from $(\mathcal{C}, \otimes, \Phi, \Psi)$ to $(\mathcal{C}', \otimes', \Phi', \Psi')$ induces a canonical additive functor $\overline{T}: \overline{\mathcal{C}} \to \overline{\mathcal{C}'}$ obeying

(i) $\overline{T}(X \otimes Y) = \overline{T}(X) \otimes' \overline{T}(Y)$, *for all objects X, Y in* $\overline{\mathcal{C}}$;

(ii) $\overline{T}(f \otimes g) = \overline{T}(f) \otimes' \overline{T}(g)$, *for all morphisms f, g in* $\overline{\mathcal{C}}$;

(iii) $\overline{T}(\overline{\Psi}_{X,Y}) = \Psi'_{\overline{T}(X),\overline{T}(Y)}$, *for all objects X, Y in* $\overline{\mathcal{C}}$.

III. BRAIDED HOCHSCHILD AND CYCLIC COHOMOLOGY

Before starting this section let us agree that if in a diagram all the bands are labeled by an object A, we label the bands by integers $0, 1, 2, 3, \ldots$. For examples we use the diagram (b) instead of diagram (a) in Fig. 2. We let $\mathcal{C}$ be a braided unital monoidal *Ab*-category.

Definition 3: A ribbon algebra in $\mathcal{C}$ is an algebra (A, m, η) (see the previous section) equipped with an isomorphism $\sigma: A \to A$ such that

$$m(\sigma \otimes \sigma)\Psi^2 = \sigma m, \quad \sigma\eta = \eta,$$

where $\Psi = \Psi_{A,A}$ is the braiding $A \otimes A \to A \otimes A$.

If the category $\mathcal{C}$ is the category of vector spaces over a field with trivial braiding i.e., the flip, then these relations mean that σ is just an algebra automorphism preserving the unit. In fact this Definition 3 is a combination of the axioms of an algebra homomorphism and the axiom for the relation between the braiding and the ribbon structure in a ribbon category. In particular, any algebra A in a ribbon category $\mathcal{C}$ is automatically ribbon with $\sigma = \nu_A$ where ν is the ribbon isomorphism. We recall that a ribbon category is a braided monoidal category equipped with natural isomorphisms ν_X for any object X such that

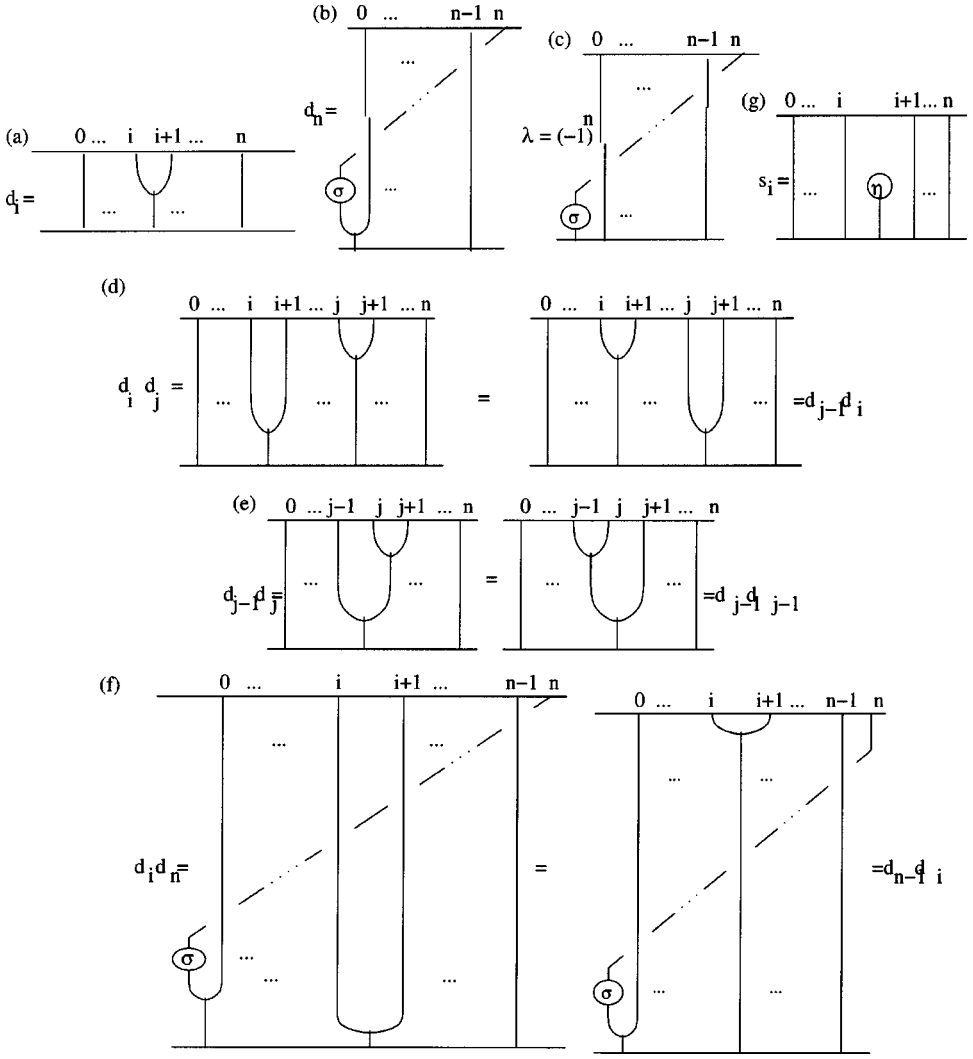

FIG. 3. Structure of C_n.

$$\nu_{X\otimes Y}=(\nu_X\otimes\nu_Y)\circ\Psi_{Y,X}\circ\Psi_{X,Y}$$

for all X, Y. Since the product of A is a morphism, we conclude by functoriality that $\nu_A\circ m=m\circ\nu_{A\otimes A}=m\circ(\nu_A\otimes\nu_A)\circ\Psi^2$ as required. There are also plenty of examples where $\mathcal{C}$ does not need to be a ribbon category. For example, if A is a braided group or Hopf algebra in a braided category $\mathcal{C}$, then its antipode $S:A\to A$ is known[5] to be braided-antimultiplicative with the result that $\sigma=S^2$ makes A into a ribbon algebra in the sense above.

This definition will be rather essential for us in the construction of braided Hochschild and cyclic cohomology. We call σ a *ribbon automorphism* for the algebra A. As mentioned in the previous section, we will work via the strict extension $\overline{\mathcal{C}}$ of $\mathcal{C}$.

We set $C_n=A^{\otimes(n+1)}$, $n\geqslant 0$ as an object of $\overline{\mathcal{C}}$ of degree $n+1$ and define morphisms

$$d_i=d_i^{(n)}:C_n\to C_{n-1},\quad s_i=s_i^{(n)}:C_n\to C_{n+1},\quad 0\leqslant i\leqslant n,\quad \lambda=\lambda_n:C_n\to C_n \tag{3.1}$$

in $\overline{\mathcal{C}}$ by diagrams (a), (b), (c), and (g) in Fig. 3, where all bands in all diagrams in Fig. 3 are labeled by object A in $\mathcal{C}$. We use a diagrammatic notation for morphisms as explained in the Preliminaries.

Theorem 4: *On C_n we have*

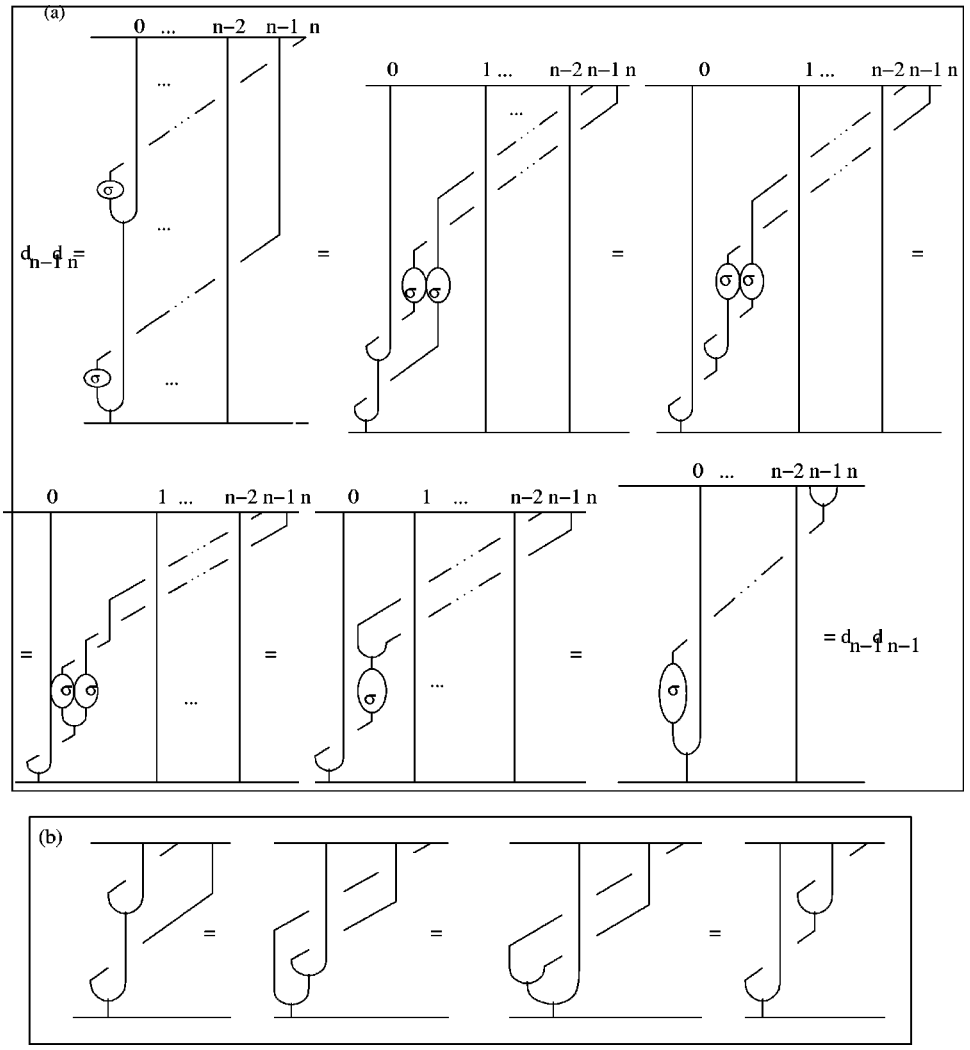

FIG. 4. Further diagrams in the structure of C_n.

$$(i)\ d_i d_j = d_{j-1} d_i, \quad 0 \leqslant i < j \leqslant n, \quad (ii)\ s_i s_j = s_{j+1} s_i, \quad 0 \leqslant i \leqslant j \leqslant n,$$

$$(iii)\ d_i s_j = \begin{cases} s_{j-1} d_i, & i < j \\ \mathrm{id}, & i = j \text{ or } i = j+1 \\ s_j d_{i-1}, & i > j+1, \end{cases}$$

$$(iv)\ d_i \lambda = -\lambda d_{i-1}, \quad 1 \leqslant i \leqslant n, \quad d_0 \lambda = (-1)^n d_n,$$

$$(v)\ s_i \lambda = -\lambda s_{i-1}, \quad 1 \leqslant i \leqslant n, \quad s_0 \lambda = (-1)^n \lambda^2 s_n,$$

$$(vi)\ d_i \lambda^{n+1} = \lambda^n d_i, \quad (vii)\ s_i \lambda^{n+1} = \lambda^{n+2} s_i, \quad 0 \leqslant i \leqslant n.$$

Proof: (i) The proof by means of graphical calculus is in Fig. 3 parts (d) (for $j<n, i<j-1$), (e) (for $j<n, i=j-1$), (f) (for $j=n, i<n-1$) and Fig. 4 part (a) (for $j=n, i=n-1$). Note that in the third equality of Fig. 4(a) we used the identity in Fig. 4(b) and in the fifth equality we used Definition 3.

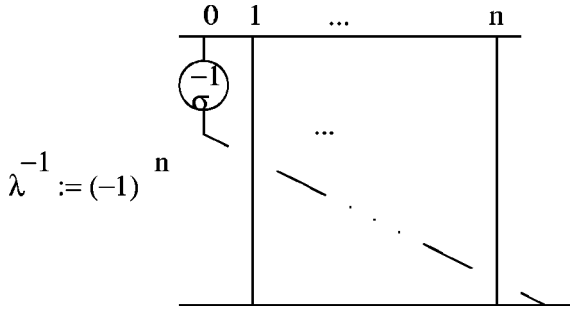

FIG. 5. Inverse of λ on C_n.

The proofs of parts (ii)–(v) are very straightforward and we leave them to the reader. (vi) At first note that λ is invertible with inverse given in Fig. 5. Now from the recursive relations in first part of (iv) it is easy to compute all the d_i in terms of d_n and λ and then using the last part of (iv) we compute d_i in terms of d_0 and λ as $d_i=(-1)^i\lambda^{-n+i}d_0\lambda^{n-i+1}$, $0\leqslant i\leqslant n$. In particular $d_0=\lambda^{-n}d_0\lambda^{n+1}$. Thus $d_i=(-1)^i\lambda^i d_0\lambda^{-i}$, $\forall i$. Hence we have

$$d_i\lambda^{n+1}=(-1)^i\lambda^i d_0\lambda^{n+1-i}=(-1)^i\lambda^i\lambda^n d_0\lambda^{-i}=(-1)^i\lambda^n\lambda^i d_0\lambda^{-i}=\lambda^n d_i.$$

Part (vii) is similar to (iv). ■

Following the strategy in Ref. 7, we now define

$$C^n(\mathcal{C};A,\sigma)=\{\varphi\in \mathrm{Hom}_{\overline{C}}(A^{\otimes(n+1)},\mathbf{1})\,|\,\varphi\lambda^{n+1}=\varphi\}. \tag{3.2}$$

By the above Theorem 4 the morphisms d_i, λ and s_i induce morphisms

$$d_i:C^{n-1}\to C^n,\quad \lambda:C^n\to C^n,\quad s_i:C^{n+1}\to C^n,\quad 0\leqslant i\leqslant n, \tag{3.3}$$

respectively, where we use same symbols. Hence for example $d_i(\varphi):=\varphi d_i$, $\varphi\in C^{n-1}$. Then we obtain a cocyclic module $\{C^n\}_{n\geqslant 0}$ with the above linear maps as face, cyclicity and degeneracy maps respectively. Namely we have

$$On\ C^{n-1};\quad d_jd_i=d_id_{j-1},\quad 0\leqslant i<j\leqslant n,$$

$$On\ C^{n+1};\quad s_js_i=s_is_{j+1},\quad 0\leqslant i\leqslant j\leqslant n,$$

$$On\ C^n;\quad s_jd_i=\begin{cases} d_is_{j-1}, & i<j\\ \mathrm{id}, & i=j\ or\ i=j+1\\ d_{i-1}s_j, & i>j+1,\end{cases}$$

$$On\ C^{n-1};\quad \lambda d_i=-d_{i-1}\lambda,\quad 1\leqslant i\leqslant n,\quad \lambda d_0=(-1)^n d_n,$$

$$On\ C^{n+1};\quad \lambda s_i=-s_{i-1}\lambda,\quad 1\leqslant i\leqslant n,\quad \lambda s_0=(-1)^n s_n\lambda^2,$$

$$On\ C^n;\quad \lambda^{n+1}=\mathrm{id}.$$

Therefore the general theory of Hochschild and cyclic cohomology[6] gives us a cochain complex (C^*,d), $d:=\Sigma_{i=0}^n(-1)^i d_i$ and we call the cohomology of this complex the *braided Hochschild cohomology* of the ribbon algebra (A,σ) in the category $\mathcal{C}$ and denote it by $HH^*(\mathcal{C};A,\sigma)$. We also have a subcomplex of the above complex defined as usual by

$$C^n_\lambda(\mathcal{C};A,\sigma)=\{\varphi\in \mathrm{Hom}_{\overline{C}}(A^{\otimes(n+1)},\mathbf{1})\,|\,\lambda(\varphi)=\varphi\}$$

and we call its cohomology the *braided cyclic cohomology* of the ribbon algebra (A,σ) in the category $\mathcal{C}$ and denote it by $HC^*(\mathcal{C};A,\sigma)$.

Now we suppose that the ring $K=\mathrm{Hom}(\mathbf{1},\mathbf{1})$ is a field containing $\mathbb{Q}$, the rational numbers. Then again the general theory of Hochschild and cyclic cohomology gives the SIB-long exact sequence

$$\cdots \to HC^{n-1} \overset{\mathcal{S}}{\to} HC^{n+1} \overset{\mathcal{I}}{\to} HH^{n+1} \overset{\mathcal{B}}{\to} HC^n \to \cdots,$$

where $\mathcal{I}$ is induced from the inclusion map $C^*_\lambda \hookrightarrow C^*$ and $\mathcal{B}$ is implemented by the Connes's boundary map $\mathcal{B}:C^{n+1}\to C^n$ defined by $\mathcal{B}=(-1)^n N(s_{-1}+s_n)$, where $N=\Sigma_{i=0}^n \lambda^i$ and $s_{-1}=(-1)^n s_0 \lambda^{-1}$ is the extra degeneracy map. Finally, $\mathcal{S}$ is the periodicity map which [see, for example Ref. 17, formula (10.15)], is given explicitly by

$$\mathcal{S}(\varphi) = \frac{-1}{n(n+1)} \sum_{1\leqslant i\leqslant j\leqslant n} (-1)^{i+j} d_{i-1}(d_{j-1}(\varphi)). \tag{3.4}$$

Let us now extend the notion of an ordinary "differential calculus" (DC) over an ordinary algebra (i.e., a DC over an algebra in the category of vector spaces) to an algebra A inside a monoidal *Ab*-category. Until now we have seen only the universal calculus treated in such generality,[18] using diagrammatic methods. In fact the axioms are the same as usual, namely part of a differential graded algebra[6] including A in degree zero; but this time all objects and morphisms must be inside the category. Thus, a *differential calculus of degree* $1\leqslant n\leqslant\infty$ *over algebra* (A,m,η), *in* $\mathcal{C}$ is a sequence of objects $\Omega=\{\Omega_i\}_{i=0}^n$ in $\mathcal{C}$ together with morphisms $\{m_{i,j}:\Omega_i\otimes\Omega_j \to \Omega_{i+j}\}_{i,j=0}^n$, called multiplication and morphisms $d=\{d_i:\Omega_i\to\Omega_{i+1}\}_{i=0}^n$, called exterior differentials, such that $\Omega_0=A$, $m_{0,0}=m$, all with the well-known axioms for an ordinary DC when viewed in the category $\overline{\mathcal{C}}$. For instance, the diagram of the Leibniz rule is in Fig. 6(c), where by labels i and j we mean Ω_i and Ω_j. We do need to say some words about the following axiom of an ordinary DC, where one usually requires that every k-form is a sum of k-forms of the form $a^0 da^1\cdots da^k$ for some $a^i\in A$. We translate this axiom for a DC in a category by requiring that for each k the morphisms

$$m(\mathrm{id}\otimes d):A\otimes\Omega_{k-1}\to\Omega_k \tag{3.5}$$

be epimorphisms. One can easily conclude by using induction on k, that the morphisms

$$m(\mathrm{id}_A\otimes d^{\otimes k}):A^{\otimes(k+1)}\to\Omega_k$$

are epimorphisms of $\overline{\mathcal{C}}$ (the converse is also true but we do not need it). We recall that a morphism $f:U\to V$ in a category is called an *epimorphism* if for each pair of morphisms $g,h:V\to W$ the equality $gf=hf$ implies $g=h$. We suppose in what follows that the tensor product of two epimorphisms in $\mathcal{C}$ is also an epimorphism.

Definition 5: A ribbon DC over a ribbon algebra (A,σ) *is a DC,* Ω, *together with a sequence of automorphisms* $\{\sigma_i:\Omega_i\to\Omega_i\}_{i=0}^n$ *such that* $\sigma_0=\sigma$ *and*

$$m_{i,j}(\sigma_i\otimes\sigma_j)\Psi_{j,i}\Psi_{i,j}=\sigma_{i+j}m_{i,j}, \quad d_i\sigma_i=\sigma_{i+1}d_i \tag{3.6}$$

for all i, j, where by $\Psi_{i,j}$ *we mean* Ψ_{Ω_i,Ω_j}.

This has been presented in Fig. 6(b). It means that σ extends to a ribbon structure on Ω in a manner compatible with d.

Definition 6: A ribbon graded trace *(r.g.t.) on a degree n ribbon DC is a morphism* $\int:\Omega_n \to \mathbf{1}$ *such that if* $i+j=n$, *then*

$$\int m_{i,j} = (-1)^{ij} \int m_{j,i}(\sigma_j\otimes \mathrm{id}_{\Omega_i})\Psi_{i,j}. \tag{3.7}$$

It is called closed *if* $\int d=0$.

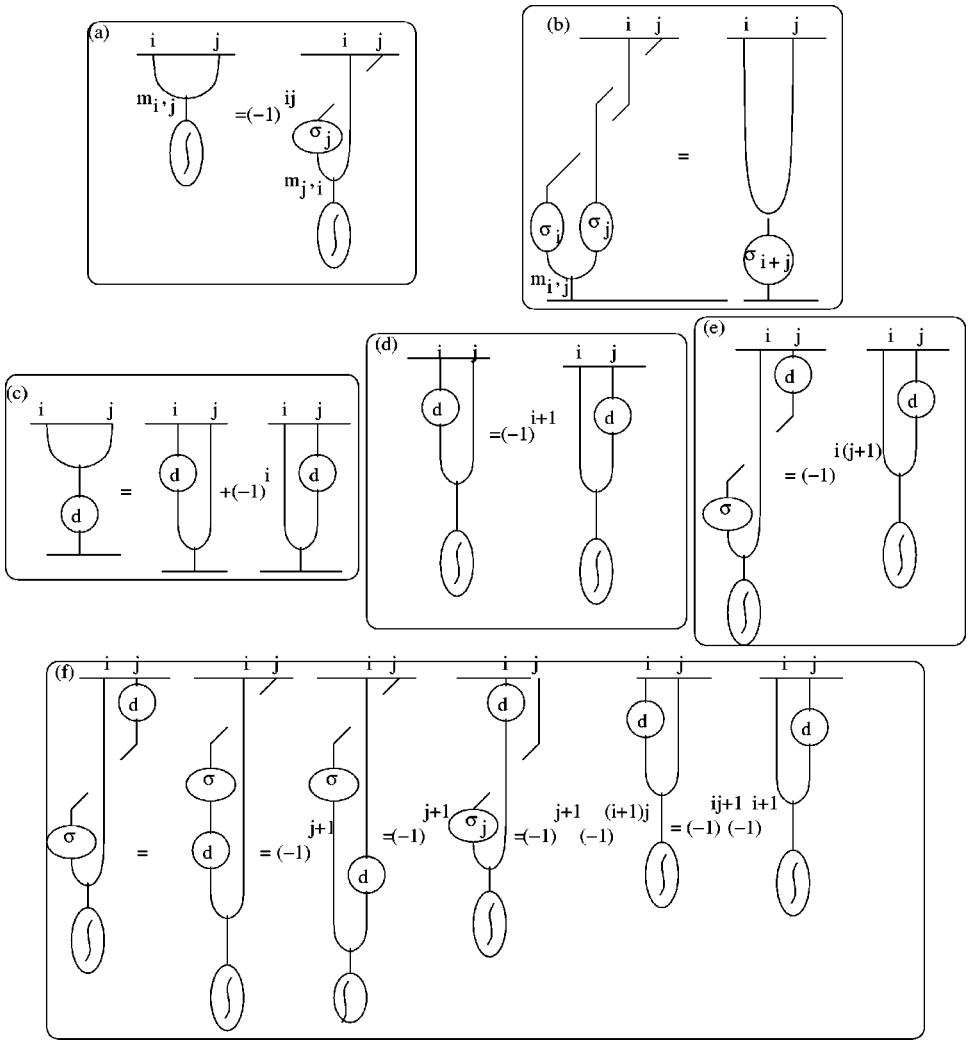

FIG. 6. Ribbon differential calculi and ribbon graded traces.

This has been presented in Fig. 6(a). If $\int$ satisfies (3.7) at least for $i=n$, $j=0$ on a (not necessarily ribbon) DC on a ribbon algebra in $\mathcal{C}$ then we call it a *weak ribbon graded trace* (w.r.g.t.). Following the strategy in Ref. 7 we have

Proposition 7: On a ribbon DC, any w.r.g.t. is also a r.g.t.

Proof: We use induction on j. Let (3.7) be true for j; we prove it for $j+1$. We have the identity in Fig. 6(e) as proven in part (f). In part (f) we used part (d) which is an immediate consequence of the Leibniz rule [represented by the diagrams in part (c)] and closedness of $\int$. In the fourth equality of part (f) we used the induction hypothesis. Now we have the identity in Fig. 7(a) as proven in part (b), where i means Ω_i, j means Ω_j and 0 means $\Omega_0=A$. Here in the third equality we used the equality in Fig. 6(e) and in the sixth equality we used (3.7). Now since the morphism $m(\mathrm{id}\otimes d):A\otimes\Omega_j\to\Omega_{j+1}$ is an epimorphism, then by our assumption, $\mathrm{id}\otimes(m(\mathrm{id}\otimes d)):\Omega_i\otimes A\otimes\Omega_j\to\Omega_i\otimes\Omega_{j+1}$, is also an epimorphism. Thus from the equality in Fig. 7(a) we conclude that the induction hypothesis holds for $j+1$. ■

Theorem 8: *Let Ω be a (not necessarily ribbon) DC of degree $0\leqslant n\leqslant\infty$ on the ribbon algebra (A,σ) in $\mathcal{C}$, and $\int$ a closed w.r.g.t. on Ω. Define the morphism in $\overline{\mathcal{C}}$*

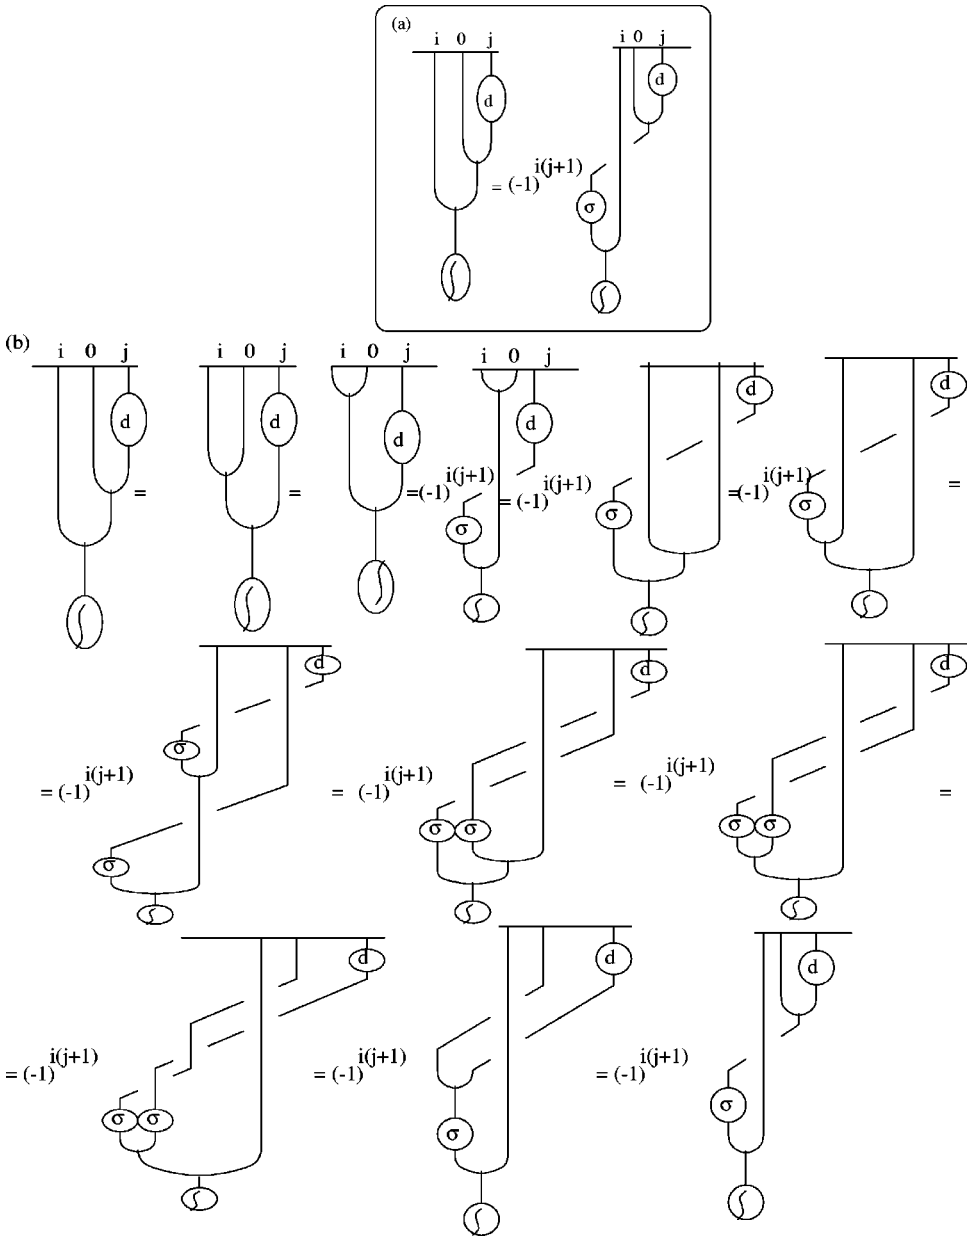

FIG. 7. Further diagrams in the construction of ribbon graded traces.

$$\varphi: A^{\otimes(n+1)} \to \mathbf{1}, \quad \varphi = \int m(id \otimes d^{\otimes n}) \tag{3.8}$$

[the diagram of φ is in Fig. 9(c)]. Then φ is a braided cyclic cocycle, i.e., $\varphi \in Z^n_\lambda(\mathcal{C}; A, \sigma)$. Here m is the morphism $A \otimes \Omega_1^{\otimes n} \to \Omega_n$ induced by the multiplication morphisms m_i (using associativity).

Proof: Let us denote the morphism $md^{\otimes k}$ by f_k. Then clearly we have $f_k = m(d \otimes f_{k-1}) = m(f_{k-1} \otimes d)$ and $df_k = 0$ and by definition we have $\varphi = \int m(\mathrm{id} \otimes f_n)$. Then the proof that $\lambda(\varphi) = \varphi$ is in Fig. 8, where the left-hand side diagram is by definition $\lambda(\varphi) = \varphi$ and by $[k]$ we mean $A^{\otimes k}$.

To prove that φ is cocycle we first note the identity in Fig. 9(a) as proven in part (b). Now

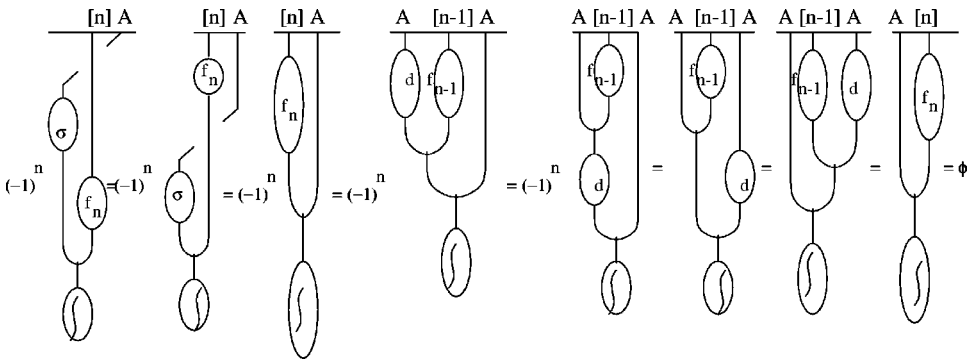

FIG. 8. Construction of a braided cyclic cocycle.

applying $\int$ to both sides of this identity and using the definition of φ, we just need to prove that the left-hand side is $d_n(\varphi)$, which is in part (d). ■

Finally, we study the behavior of braided cyclic cohomology with respect to gauge transformation between braided monoidal *Ab*-categories, using the definitions from the previous section.

Theorem 9: *Let* $(T,\mathcal{F})$ *be a tensor functor between braided monoidal Ab-categories* $(\mathcal{C}, \otimes, \Phi, \Psi)$ *and* $(\mathcal{C}', \otimes', \Phi', \Psi')$, *and let* (A, m, η, σ) *be a ribbon algebra in* $\mathcal{C}$. *Then* $A' := T(A)$ *is a ribbon algebra in* $\mathcal{C}'$ *with product* $m' := T(m)$, *unit* $\eta' := T(\eta)$ *and ribbon structure* $\sigma' := T(\sigma)$. *Moreover, there exists a morphism of cocyclic modules*

$$\overline{T}: C^n(\mathcal{C}; A, \sigma) \to C^n(\mathcal{C}'; A', \sigma').$$

If in addition $\mathcal{C}$ *and* $\mathcal{C}'$ *are gauge equivalent then the above morphism is a cocyclic module isomorphism and therefore induces an isomorphism between Hochschild and cyclic cohomologies of A and A′ in* $\mathcal{C}$ *and* $\mathcal{C}'$, *respectively*.

Proof: At first suppose $\mathcal{C}$, $\mathcal{C}'$ are strict categories and $\mathcal{F}$ is trivial i.e., $T(U \otimes V) = T(U) \otimes' T(V)$ and $\mathcal{F}_{U,V} = \mathrm{id}$ for all objects U, V in $\mathcal{C}$. Then from (2.5) and (2.7) we get $T(f \otimes g) = T(f) \otimes' T(g)$ for all morphisms f, g in $\mathcal{C}$, and $T(\Psi_{U,V}) = \Psi'_{T(U),T(V)}$. In this case it is obvious that (A', m', η', σ') is a ribbon algebra in $\mathcal{C}'$. Now if d_i, s_i, λ_i and d_i', s_i', λ_i' are the face, degeneracy and cyclicity maps for A and A', respectively, then since these maps are constructed by composition, addition or tensor product of the product of A, identity, braiding or ribbon morphisms and since T preserves composition, addition and tensor product of morphisms, we deduce easily that $d_i' = T(d_i)$, $s_i' = T(s_i)$, and $\lambda_i' = T(\lambda_i)$. Thus the theorem is proved in this case. Now since braided Hochschild and cyclic cohomology is defined inside the extended strict category $\overline{\mathcal{C}}$, the general nonstrict case follows using Proposition 2. ■

IV. BRAIDED CYCLIC COHOMOLOGY OF QUASIALGEBRAS OVER COQUASITRIANGULAR COQUASIBIALGEBRAS

In this section we use "gauge transformation" to construct nontrivial quasialgebras following the methods in Ref. 13, and see how the differential calculi and the braided cyclic cohomology behave in this case. We start with the general theory before specializing to the group algebra case of particular interest. Concrete examples then follow in Sec. V.

A. General construction by Drinfeld cotwists

We recall Refs. 2 and 5, cf. Ref. 1;

Definition 10: A coquasitriangular coquasibialgebra is a coalgebra (H, Δ, ϵ) *equipped with a linear map* $.: H \otimes H \to H$, *called product, an associated unit element, a convolution invertible "unital 3-cocycle," in the sense of a linear map* $\phi: H^{\otimes 3} \to \mathbb{C}$ *satisfying*

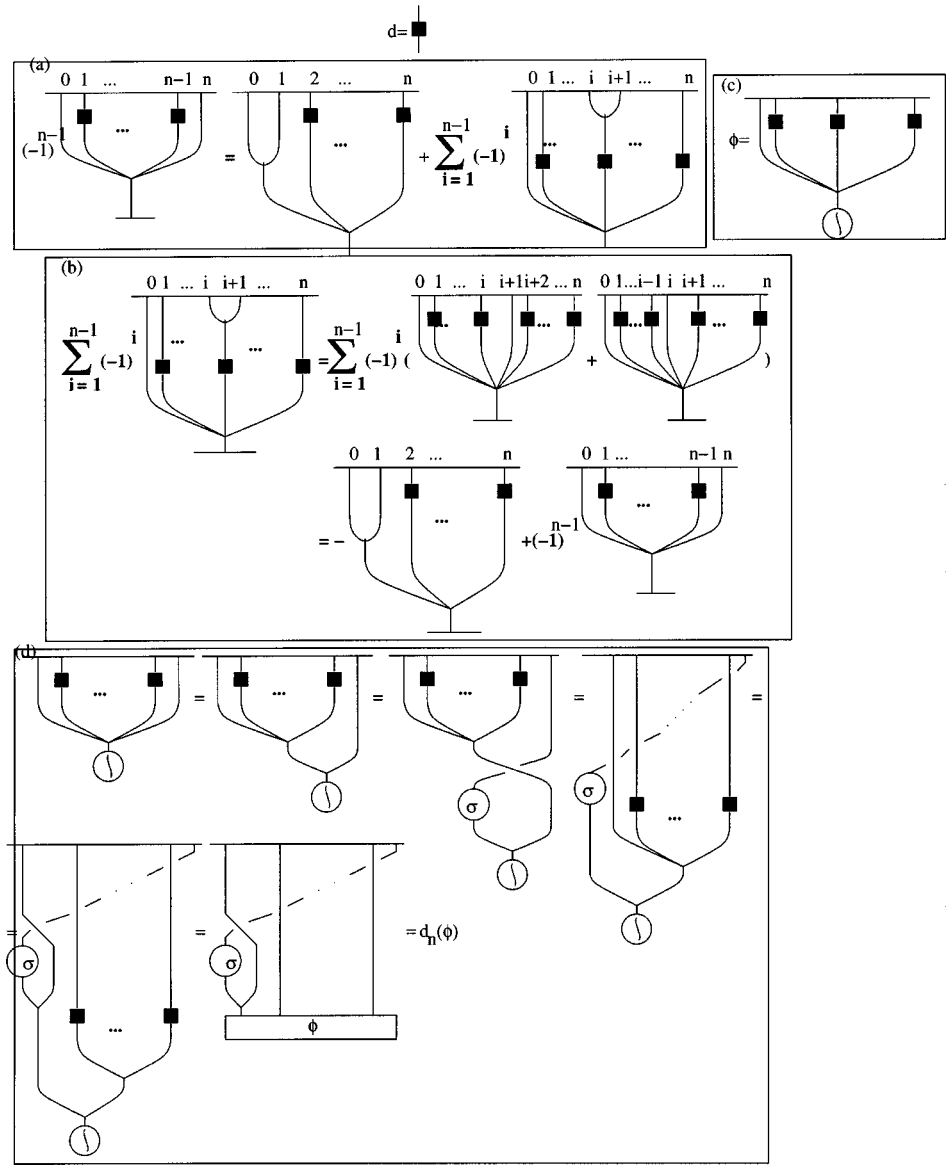

FIG. 9. Further diagrams in the construction of a braided cyclic cocycle.

$$\phi(b_{(1)},c_{(1)},d_{(1)})\phi(a_{(1)},b_{(2)}\,.\,c_{(2)},d_{(2)})\phi(a_{(2)},b_{(3)},c_{(3)}) = \phi(a_{(1)},b_{(1)},c_{(1)}\,.\,d_{(1)})\phi(a_{(2)}\,.\,b_{(2)},c_{(2)},d_{(2)}),$$

$$\phi(a,1,b) = \epsilon(a)\epsilon(b),$$

such that Δ,ϵ *are multiplicative and*

$$a_{(1)}\,.\,(b_{(1)}\,.\,c_{(1)})\phi(a_{(2)},b_{(2)},c_{(2)}) = \phi(a_{(1)},b_{(1)},c_{(1)})(a_{(2)}\,.\,b_{(2)})\,.\,c_{(2)},$$

$\forall a,b,c,d \in H$, *and finally a convolution invertible linear map* $\mathcal{R}:H\otimes H\to\mathbb{C}$, *satisfying*

$$\mathcal{R}(a\,.\,b,c) = \phi(c_{(1)},a_{(1)},b_{(1)})\mathcal{R}(a_{(2)},c_{(2)})\phi^{-1}(a_{(3)},c_{(3)},b_{(2)})\mathcal{R}(b_{(3)},c_{(4)})\phi(a_{(4)},b_{(4)},c_{(5)}),$$

$$\mathcal{R}(a,b\,.\,c) = \phi^{-1}(b_{(1)},c_{(1)},a_{(1)})\mathcal{R}(a_{(2)},c_{(2)})\phi(b_{(2)},a_{(3)},c_{(3)})\mathcal{R}(a_{(4)},b_{(3)})\phi^{-1}(a_{(5)},b_{(4)},c_{(4)}),$$

$$b_{(1)} \,.\, a_{(1)}\mathcal{R}(a_{(2)},c_{(2)}) = \mathcal{R}(a_{(1)},b_{(1)})a_{(2)} \,.\, b_{(2)}.$$

Also we recall that the category of (left) H-comodules (abbreviated as H-Com) is a braided monoidal Ab-category with

$$\Phi_{U,V,W}: U \otimes (V \otimes W) \to (U \otimes V) \otimes W, \quad u \otimes v \otimes w \mapsto \phi(u_{(1)},v_{(1)},w_{(1)})u_{(2)} \otimes v_{(2)} \otimes w_{(2)},$$

$$\Psi_{U,V}: U \otimes V \to V \otimes U, \quad u \otimes v \mapsto \mathcal{R}(v_{(1)},u_{(1)})v_{(2)} \otimes u_{(2)}$$

$\forall U,V,W \in H$-Com. An algebra A in this category is called a *left quantum quasispace* (or left H-comodule quasialgebra[13]). This means that we have a left H-comodule structure, $A \to H \otimes A$, $a \mapsto a_{(1)} \otimes a_{(2)}$, a linear map $.: A \otimes A \to A$, called product, which is unital, associative in the category and equivariant under the coaction of H. Specifically,

$$a \,.\, (b \,.\, c) = \phi(a_{(1)},b_{(1)},c_{(1)})(a_{(2)} \,.\, b_{(2)}) \,.\, c_{(2)}, \quad (a \,.\, b)_{(1)} \otimes (a \,.\, b)_{(2)} = a_{(1)} \,.\, b_{(1)} \otimes a_{(2)} \,.\, b_{(2)}, \quad a,b \in A.$$

Finally, a ribbon structure for A in the sense of Sec. III means a H-comodule isomorphism $\sigma: A \to A$ such that

$$\sigma(a \,.\, b) = \mathcal{R}(b_{(1)},a_{(1)})\mathcal{R}(a_{(2)},b_{(2)})\sigma(a_{(3)}) \,.\, \sigma(b_{(3)}). \tag{4.1}$$

Now let us describe explicitly a braided cyclic cocycle in this category. First of all by the argument in Sec. II, for H-comodules U_i, $1 \leqslant i \leqslant n$, a morphism $U_1 \otimes \cdots \otimes U_n \to \mathbb{C}$ in the category of H-Com, is an equivalence class of H-comodule intertwiners $U_1 \otimes_\alpha \cdots \otimes_\alpha U_n \to \mathbb{C}$ for all $\alpha \in \Lambda_n$. Here a H-comodule intertwiner $U_1 \otimes_\alpha \cdots \otimes_\alpha U_n \to \mathbb{C}$ means a linear map $f: U_1 \otimes \cdots \otimes U_n \to \mathbb{C}$ satisfying

$$f(u^1 \otimes \cdots \otimes u^n)1 = u^1_{(1)\cdot_\alpha} \cdots {}_{\cdot_\alpha} u^n_{(1)} f(u^1_{(2)} \otimes \cdots \otimes u^n_{(2)}), \quad \forall\, u_i \in U_i, \tag{4.2}$$

where we have used $U_1 \otimes \cdots \otimes U_n$ for the usual vector space tensor product, $u^1 \otimes \cdots \otimes u^n$ meaning an element of the vector space $U_1 \otimes \cdots \otimes U_n$ and the notation $u^1{}_{._\alpha} \cdots u^n$ as defined in Sec. II. Similarly, a morphism $U_1 \otimes \cdots \otimes U_m \to V_1 \otimes \cdots \otimes V_n$ is an equivalence class of H-comodule intertwiners $U_1 \otimes_\alpha \cdots \otimes_\alpha U_m \to V_1 \otimes_\beta \cdots \otimes_\beta V_n$, $\alpha \in \Lambda_m, \beta \in \Lambda_n$.

Now let us describe the morphisms $d_i: C_n = A^{\otimes(n+1)} \to C_{n-1} = A^{\otimes n}$, $0 \leqslant i \leqslant n-1$ in our particular category. These are represented by morphisms

$$A \otimes_\alpha \cdots \otimes_\alpha (A \otimes A) \otimes_\alpha \cdots \otimes_\alpha A \to A \otimes_\alpha \cdots \otimes_\alpha A,$$

$$(a^0 \otimes \cdots \otimes a^n) \mapsto (a^0 \otimes \cdots \otimes a^i \,.\, a^{i+1} \otimes \cdots \otimes a^n), \quad a^i \in A, \alpha \in \Lambda_n$$

while d_n by definition is $(m_A \otimes \mathrm{id}_{n-1})(\sigma_A \otimes \mathrm{id}_n)\Psi_{n,1}$, where $\Psi_{n,1} := \Psi_{A^{\otimes n},A}$ and $\mathrm{id}_k := \mathrm{id}_{A^{\otimes k}}$. Let us write for simplicity X for $A^{\otimes^{n-1}_\alpha}$, $\alpha \in \Lambda_{n-1}$. Then the representative of d_n from $(A \otimes X) \otimes A$ to $A \otimes X$ is $(m_A \otimes \mathrm{id}_X)\phi_{A,A,X}(\sigma \otimes \mathrm{id}_{A\otimes X})\Psi_{A\otimes X,A}$ which has value on $a^0 \otimes \cdots \otimes a^n$ equal to

$$\begin{aligned}
&\mathcal{R}(a^n_{(1)},a^0_{(1)} \,.\, (a^1_{(1)\cdot_\alpha} \cdots {}_{\cdot_\alpha} a^{n-1}_{(1)}))(m_A \otimes \mathrm{id}_X)\phi_{A,A,X}(\sigma \otimes \mathrm{id}_{A\otimes X})(a^n_{(2)} \otimes (a^0_{(2)} \otimes (a^1_{(2)} \otimes_\alpha \cdots \otimes_\alpha a^{n-1}_{(2)})))\\
&= \mathcal{R}(a^n_{(1)},a^0_{(1)} \,.\, (a^1_{(1)\cdot_\alpha} \cdots {}_{\cdot_\alpha} a^{n-1}_{(1)}))(m_A \otimes \mathrm{id}_X)\phi_{A,A,X}(\sigma(a^n_{(2)}) \otimes (a^0_{(2)} \otimes (a^1_{(2)} \otimes_\alpha \cdots \otimes_\alpha a^{n-1}_{(2)})))\\
&= \mathcal{R}(a^n_{(1)},a^0_{(1)} \,.\, (a^1_{(1)\cdot_\alpha} \cdots {}_{\cdot_\alpha} a^{n-1}_{(1)}))\phi(a^n_{(2)},a^0_{(2)},a^1_{(2)\cdot_\alpha} \cdots {}_{\cdot_\alpha} a^{n-1}_{(2)})(m_A \otimes \mathrm{id}_X)((\sigma(a^n_{(3)}) \otimes a^0_{(3)}) \otimes (a^1_{(3)}\\
&\quad \otimes_\alpha \cdots \otimes_\alpha a^{n-1}_{(3)}))\\
&= \mathcal{R}(a^n_{(1)},a^0_{(1)} \,.\, (a^1_{(1)\cdot_\alpha} \cdots {}_{\cdot_\alpha} a^{n-1}_{(1)}))\phi(a^n_{(2)},a^0_{(2)},a^1_{(2)\cdot_\alpha} \cdots {}_{\cdot_\alpha} a^{n-1}_{(2)})\sigma(a^n_{(3)}) \,.\, a^0_{(3)} \otimes a^1_{(3)} \otimes \cdots \otimes a^{n-1}_{(3)}.
\end{aligned}$$

Therefore the representative of d_n from $(A \otimes (A^{\otimes^{n-1}_\alpha})) \otimes A$ to $A \otimes (A^{\otimes^{n-1}_\alpha})$ is

$$d_n(a^0 \otimes \cdots \otimes a^n) = \mathcal{R}(a^n_{(1)}, a^0_{(1)} \,.\, (a^1_{(1)\cdot_\alpha} \cdots \cdot_\alpha a^{n-1}_{(1)}))\phi(a^n_{(2)}, a^0_{(2)}, a^1_{(2)\cdot_\alpha} \cdots \cdot_\alpha a^{n-1}_{(2)})\sigma(a^n_{(3)}) \,.\, a^0_{(3)} \otimes a^1_{(3)} \otimes \cdots \otimes a^{n-1}_{(3)}, \tag{4.3}$$

where $\alpha \in \Lambda_{n-1}$.

We can similarly represent λ with the representative $(A \otimes (A^{\otimes_\alpha^{n-1}})) \otimes A \to A \otimes (A \otimes (A^{\otimes_\alpha^{n-1}}))$ by

$$\lambda(a^0 \otimes \cdots \otimes a^n) = (-1)^n \mathcal{R}(a^n_{(1)}, a^0_{(1)} \,.\, (a^1_{(1)\cdot_\alpha} \cdots \cdot_\alpha a^{n-1}_{(1)}))\sigma(a^n_{(2)}) \otimes a^0_{(2)} \otimes \cdots \otimes a^{n-1}_{(2)}, \tag{4.4}$$

where $\alpha \in \Lambda_{n-2}$.

Next a DC, $\Omega(A) = \oplus_{i=0}^n \Omega_i(A)$, on A in this category is just a left H-covariant DC as in Ref. 19, except that the product of forms are associative up to the associator, namely,

$$\omega \,.\, (\omega' \,.\, \omega'') = \phi(\omega_{(1)}, \omega'_{(1)}, \omega''_{(1)})(\omega_{(2)} \,.\, \omega'_{(2)}) \,.\, \omega''_{(2)}, \quad \forall\, \omega, \omega', \omega'' \in \Omega.$$

A w.r.g.t. on $\Omega(A)$ is a left H-invariant functional $\Omega_n \to \mathbb{C}$ satisfying

$$\int \omega \,.\, a = \mathcal{R}(a_{(1)}, \omega_{(1)}) \int \sigma(a_{(2)}) \,.\, \omega_{(2)}. \tag{4.5}$$

Now we recall briefly the so-called Drinfeld cotwist and associated "gauge transformation." For this discussion we will denote the product of two elements a and b in H or A, just by ab and we keep the notation $a*b$ or $a \,.\, b$, respectively, for the new products defined as follows. Thus for $(H, \Phi, \mathcal{R})$ as above and any convolution invertible linear map $F: H \otimes H \to \mathbb{C}$ obeying $F(a,1) = F(1,a) = \epsilon(a)$, $\forall\, a \in H$ (a 2-cochain), we define a coquasitriangular coquasibialgebra H^F as follows; H^F as a coalgebra is, by definition, (H, Δ, ϵ) itself and the product for H^F is defined by[1]

$$a * b := F(a_{(1)}, b_{(1)}) a_{(2)} b_{(2)} F^{-1}(a_{(3)}, b_{(3)}), \tag{4.6}$$

the unital 3-cocycle for H^F is defined by

$$\phi_F(a,b,c) := F(b_{(1)}, c_{(1)}) F(a_{(1)}, b_{(2)} c_{(2)}) \phi(a_{(2)}, b_{(3)}, c_{(3)}) F^{-1}(a_{(3)} b_{(4)}, c_{(4)}) F^{-1}(a_{(4)}, b_{(5)}) \tag{4.7}$$

and the coquasitriangular structure for H^F is defined by

$$\mathcal{R}_F(a,b) := F(b_{(1)}, a_{(1)}) \mathcal{R}(a_{(2)}, b_{(2)}) F^{-1}(a_{(3)}, b_{(3)}) \tag{4.8}$$

$\forall\, a, b \in H$. This is the dual version of the Drinfeld twist (see Ref. 5). Then, as above, we have a braided monoidal Ab-category, namely H^F-Com, which is nothing other than H-Com, as an Ab-category but with new monoidal and braided structures. We denote the tensor product, the associator and the braiding of this category by $\otimes_F, \Phi_F, \psi_F$ respectively.

If A is a quantum quasispace over H then there is a gauge transformed copy of it in H^F-Com, namely we cotwist the product of A as[13]

$$a \,.\, b := F(a_{(1)}, b_{(1)}) a_{(2)} b_{(2)}, \quad \forall\, a, b \in A,$$

then A_F is by definition A as a left H-comodule equipped with the above product. It is easy to see that A_F is a (left) quantum quasispace over H^F, see Ref. 13.

Now let us show that if σ is a ribbon structure for A in H-Com, then σ is still a ribbon structure for A_F in the category of left H^F-Com. Indeed,

$$\begin{aligned}
&\mathcal{R}_F\,(b_{(1)},a_{(1)})\mathcal{R}_F(a_{(2)},b_{(2)})\sigma(a_{(3)})\,.\,\sigma(b_{(3)})\\
&\quad=F(a_{(1)},b_{(1)})\mathcal{R}(b_{(2)},a_{(2)})F^{-1}(b_{(3)},a_{(3)})F(b_{(4)},a_{(4)})\mathcal{R}(a_{(5)},b_{(5)})F^{-1}(a_{(6)},b_{(6)})\\
&\qquad\times F(a_{(7)},b_{(7)})\sigma(a_{(8)})\sigma(b_{(8)})\\
&\quad=F(a_{(1)},b_{(1)})\mathcal{R}(b_{(2)},a_{(2)})\mathcal{R}(a_{(3)},b_{(3)})\sigma(a_{(4)})\sigma(b_{(4)})\\
&\quad=F(a_{(1)},b_{(1)})\sigma(a_{(2)}b_{(2)})\\
&\quad=\sigma(a\,.\,b)
\end{aligned}$$

as required.

Next it is known that the cotwisted comodule algebra $\Omega(A_F):=\Omega(A)_F$ is a DC over the algebra A_F in the category of H^F-Com (see Ref. 12). We recall that differential forms in $\Omega(A_F)$ are the same as differential forms in $\Omega(A)$ with the same coaction of H on them and the differential operator, d, remaining unchanged, but the product of forms has been cotwisted to

$$\omega\,.\,\omega':=F(\omega_{(1)},\omega'_{(1)})\omega_{(1)}\omega'_{(2)}.$$

Therefore for left invariant forms this product does not change, i.e., we have

$$\omega\,.\,\omega'=\omega\omega',\quad a\,.\,\omega=a\omega,\quad \omega\,.\,a=\omega a,\quad \forall\,\omega\in\Omega^{inv},\ a\in A,$$

where Ω^{inv} denote the space of left invariant forms.

Let us show now that if $\int$ is a w.r.g.t. on $\Omega(A)$ then it is also a w.r.g.t. on $\Omega(A_F)$. Indeed,

$$\begin{aligned}
\mathcal{R}_F(a_{(1)},\omega_{(1)})\int\sigma(a_{(2)})\,.\,\omega_{(2)}&=F(\omega_{(1)},a_{(1)})\mathcal{R}(a_{(2)},\omega_{(2)})F^{-1}(a_{(3)},\omega_{(3)})F(a_{(4)},\omega_{(4)})\int\sigma(a_{(5)})\omega_{(5)}\\
&=\int F(\omega_{(1)},a_{(1)})\omega_{(2)}a_{(2)}=\int\omega\,.\,a
\end{aligned}$$

as required.

Remark: Observe that even if the associator and coquasitriangular structure are trivial before gauge transformation, they are typically no longer trivial after gauge transformation. Even if F is a Hopf algebra 2-cocycle,[5] the associator after gauge transformation becomes trivial but the coquasitriangular structure is not typically trivial but is cotriangular. Also note that the F needed for gauge transformation of classical semisimple Lie groups to their quantum counterpart are not Hopf algebra 2-cocycles but are 2-cochains, thus these observations imply that we do need to consider the class of braided cyclic cocycles during such transformations.

As for any monoidal category $\mathcal{C}$ the functor $\mathcal{C}^n\to\mathcal{C}$, $(U_1,\ldots,U_n)\mapsto(\cdots((U_1\otimes U_2)\otimes U_3)\otimes\cdots)\otimes U_n$ is called the *left-to-right arranger*. We can use this to give explicit left-to-right representatives of all formulas. Finally, the categories $(H\text{-Com},\otimes,\Phi,\Psi)$ and $(H^F\text{-Com},\otimes_F,\Phi_F,\psi_F)$ are gauge equivalent, which is the categorical meaning of the Drinfeld cotwist, see Ref. 2. We choose $T=\mathrm{id}$ and $\mathcal{F}_{U,V}(u\otimes v):=F(u_{(1)},v_{(1)})u_{(2)}\otimes v_{(2)}$. Here $\mathcal{F}_{U,V}$ is a morphism in H^F-Com since

$$\begin{aligned}
(u\otimes v)_{(1)}\otimes\mathcal{F}_{U,V}(u\otimes v)_{(2)}&=u_{(1)}*v_{(1)}\otimes F(u_{(2)},v_{(2)})u_{(3)}\otimes v_{(3)}\\
&=F(u_{(1)},v_{(1)})u_{(2)}v_{(2)}F^{-1}(u_{(3)},v_{(3)})\otimes F(u_{(4)},v_{(4)})u_{(5)}\otimes v_{(5)}\\
&=F(u_{(1)},v_{(1)})u_{(2)}v_{(2)}\otimes u_{(3)}\otimes v_{(3)}=(\mathcal{F}_{U,V}(u\otimes v))_{(1)}\otimes(\mathcal{F}_{U,V}(u\otimes v))_{(2)}.
\end{aligned}$$

Similarly, $\mathcal{F}^{-1}_{U,V}(u\otimes v)=F^{-1}(u_{(1)},v_{(1)})u_{(2)}\otimes v_{(2)}$ is a morphism in H^F-Com. Moreover, (2.5) is a consequence of the definition of a morphism in the category of H-Com and (2.6) and (2.7) are consequences of (4.7) and (4.8). Therefore by Theorem 9 we have:

Theorem 11: *There is an isomorphism of cocyclic modules*

$$\overline{\mathrm{id}}: C^k(H\text{-Com}; A, \sigma) \to C^k(H^F\text{-Com}; A_F, \sigma), \quad \varphi \mapsto \varphi_F.$$

For instance if φ^{lr} be the left-to-right representative of φ then the left-to-right representative of φ_F, which we denote by φ_F^{lr} is

$$\varphi_F^{lr}(a^0, \ldots, a^k) = F(a^0_{(1)}, a^1_{(1)}) F(a^0_{(2)} a^1_{(2)}, a^2_{(1)}) F((a^0_{(3)} a^1_{(3)}) a^2_{(2)}, a^3_{(1)}) \cdots \times F((\cdots((a^0_{(k)} a^1_{(k)}) a^2_{(k-1)}) \cdots) a^{k-1}_{(2)}, a^k_{(1)}) \varphi^{lr}(a^0_{(k+1)}, a^1_{(k+1)}, a^2_{(k)} \ldots, a^k_{(2)}). \quad (4.9)$$

Proof: This is Theorem 9 in our present case. In (4.9) we just used the definition of S_α (see Sec. II). ■

B. Braided cyclic cocycles on group algebras and *G*-graded quasialgebras

Let G be a group and $H = \mathbb{C}G$ the group algebra on G. This is a Hopf algebra with

$$\Delta g = g \otimes g, \quad \varepsilon(g) = 1, \quad S(g) = g^{-1}, \quad \forall\, g \in G$$

we recall that a unital 3-cocycle for $H = \mathbb{C}G$ is just the linear extension of a group cocycle $\phi: G^3 \to \mathcal{C} - \{0\}$ in the sense of a function $\phi: G^3 \to \mathbb{C} - \{0\}$ obeying

$$\phi(g_1, g_2, g_3)\phi(g_0, g_1 g_2, g_3)\phi(g_0, g_1, g_2) = \phi(g_0, g_1, g_2 g_3)\phi(g_0 g_1, g_2, g_3), \quad \phi(g_0, e, g_1) = 1, \quad \forall\, g_i \in G.$$

Of interest is the case when G is Abelian. Since H is cocommutative and associative, we can consider $\mathbb{C}G$ as a coquasibialgebra with any ϕ, including to start with the trivial $\phi \equiv 1$. Then in this standard case, since we assume G is Abelian, a coquasitriangular structure is just a group bicharacter $\mathcal{R}: G^2 \to \mathbb{C} - \{0\}$ in the sense of a function obeying

$$\mathcal{R}(g_0 g_1, g_2) = \mathcal{R}(g_0, g_2)\mathcal{R}(g_1, g_2), \quad \mathcal{R}(g_0, g_1 g_2) = \mathcal{R}(g_0, g_1)\mathcal{R}(g_0, g_2), \quad \forall\, g_i \in G.$$

Again to start with we can choose the trivial $\mathcal{R} \equiv 1$, so that $\mathbb{C}G$ is considered as a coquasitriangular coquasibialgebra with trivial associator and trivial coquasitriangular structure.

Next a left $\mathbb{C}G$-comodule means precisely a G-graded vector space V with coaction of $\mathbb{C}G$ on it given by $\alpha(v) = |v| \otimes v$, where $|v| \in G$ denotes the degree of a homogeneous vector $v \in V$.[5] An algebra A in the category of $\mathbb{C}G$-comodules is just a G-graded algebra (recall that we have chosen trivial associator for $\mathbb{C}G$). Now since for every bialgebra H (that is a coquasibialgebra with trivial associator), $A = H$ is an H-comodule algebra with the coproduct of H taken as coaction of H on A, we can consider the algebra $A = \mathbb{C}G$ in the category of $\mathbb{C}G$-comodules. Since we have chosen the trivial coquasitriangular structure for $H = \mathbb{C}G$, a ribbon structure $\sigma: A = \mathbb{C}G \to A = \mathbb{C}G$ is just a group homomorphism $\sigma: G \to G$ extended by linearity to $\mathbb{C}G$.

Finally, let $\{\chi_i: G \to \mathbb{C} - \{0\}\}_{i=1}^n$ be a finite set of group characters. We extend each χ_i on $\mathbb{C}G$ by linearity and denote the extended map still by χ_i. Clearly we have $\chi_i(ab) = \chi_i(a)\chi_i(b)$ $\forall a, b \in A$, $\forall i$. It is well-known that if Λ is an n-dimensional vector space with basis $\{\omega_i\}_{i=1}^n$ then there exists a unique left covariant FODC, Γ, on $A = \mathbb{C}G$ such that $\forall g \in G$, $\forall i$

$$\omega_i g = \chi_i(g) g \omega_i, \quad dg = \sum_{i=1}^n (\chi_i(g) - 1) g \omega_i. \quad (4.10)$$

In fact these calculi are bicovariant and the space of right invariant forms $\Gamma^{r.\mathrm{inv}}$, coincides with the space of left invariant forms, $\Gamma^{l.\mathrm{inv}} = \Lambda$. Thus the Woronowicz braiding $\Psi: \Gamma \otimes_A \Gamma \to \Gamma \otimes_A \Gamma$ is just the map, $\Psi(a\omega \otimes_A \omega') = a\omega' \otimes_A \omega$, $\forall \omega, \omega' \in \Gamma^{l.\mathrm{inv}}$. Hence the relations among basis 1-forms ω_i in the DC, $\Omega := T(\Gamma)/\ker(\Psi - id)$, are $\omega_i^2 = 0$, $\omega_i \omega_j = -\omega_j \omega_i$, $\forall i, j$, where $T(\Gamma)$ is the tensor algebra over Γ. Therefore we have a top form $\theta := \omega_1 \cdots \omega_n$ for the space of left invariant n-forms, i.e., the space of left invariant n-forms is one dimensional. Now let us define $\pi: \Omega_n \to A$ and $\rho: A \to A$ as follows; since $\{\theta\}$ is a free A-basis for Ω_n, for each $\omega \in \Omega_n$ and $a \in A$ there exist unique elements of A, $\pi(\omega)$ and $\rho(a)$ such that $\omega = \pi(\omega)\theta$ and $\theta a = \rho(a)\theta$. One can easily verify that both π and ρ are morphisms in the category of H-comodules, and ρ is an algebra automorphism and by very

definition we have $\pi(a\omega)=a\pi(\omega)$, $\pi(\omega a)=\pi(\omega)\rho(a)$. In our case of $A=\mathbb{C}G$ by (4.10) we have

$$\rho(g)=\chi_1(g)\cdots\chi_n(g)g.$$

Next there exists a unique left and right invariant functional on $\mathbb{C}G$ defined by

$$h(g)=0, \quad \forall\, g\neq e, \quad h(e)=1 \tag{4.11}$$

which defines a canonical left invariant functional

$$\int:\Omega_n\to\mathbb{C}, \quad \int\omega := h(\pi(\omega)). \tag{4.12}$$

Since $\omega a=\pi(\omega)\theta a=\pi(\omega)\rho(a)\theta=\rho(a)\pi(\omega)\theta=\rho(a)\omega$, we have $\int\omega a=\int\rho(a)\omega$. Thus $\int$ is a w.r.g.t. with ribbon morphism $\sigma(g)=\chi_1(g)\cdots\chi_n(g)g$. Let us show that it is closed. Since $\int$ is left covariant we have $(\int dg_1\cdots dg_n)e=g_1\cdots g_n\int dg_1\cdots dg_n$, $\forall g_i\in G$ thus if $g_1\cdots g_n\neq e$, then $\int dg_1\cdots dg_n=0$, and if $g_1\cdots g_n=e$ then we have

Proposition 12: If for $g_0,\ldots,g_k\in G$ we have $g_0\cdots g_k=e$, then $dg_0\cdots dg_k=0$.

Proof: We have $g^{-1}dg=\Sigma_{i=1}^n(\chi_i(g)-1)\omega_i$ and $(dg^{-1})g=\Sigma_{i=1}^n(\chi_i(g^{-1})-1)g^{-1}\omega_i g=\Sigma_{i=1}^n(\chi_i(g^{-1})-1)\chi_i(g)\omega_i=-\Sigma_{i=1}^n(\chi_i(g)-1)\omega_i$. Thus $dg^{-1}dg=(dg^{-1})gg^{-1}dg=-\Sigma_{i=1}^n(\chi_i(g)-1)(\chi_j(g)-1)\omega_i\omega_j=0$. Thus $dg^{-1}dg=0$ and $d\omega(g)=d(g^{-1}dg)=dg^{-1}dg=0$. Since every left invariant form $\omega\in\Omega_{\text{inv}}$ is generated by left invariant 1-forms, we deduce that $d\omega=0$, $\forall\,\omega\in\Omega_{\text{inv}}$. Now we show by induction on k that for arbitrary $g_1,\ldots,g_k\in G$ we have $(g_1\cdots g_k)^{-1}dg_1\cdots dg_k\in\Omega^k_{\text{inv}}$; for $k=1$ it is clear, and since for every $g\in G$ by (4.10) we have $g\Omega_{\text{inv}}=\Omega_{\text{inv}}g$ we conclude by using the induction hypothesis that $(g_1\cdots g_k)^{-1}dg_1\cdots dg_k=g_k^{-1}((g_1\cdots g_{k-1})^{-1}dg_1\cdots dg_{k-1})dg_k\in\Omega^k_{\text{inv}}$. Now since $g_0=(g_1\cdots g_k)^{-1}$ we see that $dg_0\cdots dg_k=d((g_1\cdots g_k)^{-1}dg_1\cdots dg_k)=0$. ■

Hence the character $\varphi(g_0,\ldots,g_n)=\int g_0dg_1\cdots dg_n$ is a trivially braided cyclic cocycle. Now we calculate φ explicitly. First of all, using (4.10) one has

$$dg_1\cdots dg_n=\sum_{i_1,\ldots,i_n=1}^{n}(\chi_{i_1}(g_1)-1)\cdots(\chi_{i_n}(g_n)-1)$$
$$\times\chi_{i_1}(g_2)\cdots\chi_{i_1}(g_n)\chi_{i_2}(g_3)\cdots\chi_{i_2}(g_n)\cdots\chi_{i_{n-1}}(g_n)g_1\cdots g_n\omega_{i_1}\cdots\omega_{i_n}.$$

Now for any permutation $\tau\in S_n$ we have $\omega_{\tau(1)}\cdots\omega_{\tau(n)}=\text{sgn}(\tau)\omega_1\cdots\omega_n$. Therefore $\varphi(g_0,\ldots,g_n)=0$, if $g_0\cdots g_n\neq e$ and if $g_0\cdots g_n=e$, then

$$\varphi(g_0,\ldots,g_n)=\sum_{\tau\in S_n}\text{sgn}(\tau)(\chi_{\tau(1)}(g_1)-1)\cdots(\chi_{\tau(n)}(g_n)-1)\chi_{\tau(1)}(g_2)\cdots\chi_{\tau(1)}(g_n)\chi_{\tau(2)}(g_3)$$
$$\cdots\chi_{\tau(2)}(g_n)\cdots\chi_{\tau(n-1)}(g_n).$$

Using the fact that χ_i are group characters we conclude that

$$\varphi(g_0,\ldots,g_n)=\sum_{\tau\in S_n}\text{sgn}(\tau)(\chi_{\tau(1)}(g_1\cdots g_n)-\chi_{\tau(1)}(g_2\cdots g_n))$$
$$(\chi_{\tau(2)}(g_2\cdots g_n)-\chi_{\tau(2)}(g_3\cdots g_n))\cdots(\chi_{\tau(n)}(g_n)-1). \tag{4.13}$$

Hence we have a braided monoidal *Ab*-category, namely the category of G-graded vector spaces with trivial braiding and trivial associator, and we have an algebra A in it, i.e., $A=\mathbb{C}G$ itself but with a nontrivial ribbon structure $\sigma:G\to G$, a group homomorphism given by $\sigma(g)=\chi_1(g)\cdots\chi_n(g)g$. Moreover, we have a DC on A and a closed w.r.g.t. and therefore the corresponding cyclic cocycle. This is therefore an example of the theory in Ref. 7.

Moreover, since we are working with a strict category we can suppress the subscript α in the expression $U_1\otimes_\alpha\cdots\otimes_\alpha U_n$ and $a^0\cdot_\alpha\cdots\cdot_\alpha a^n$. Therefore the maps d_i and λ become as usual. Let us

describe them in this case more explicitly. First of all a morphism $\varphi: A^{\otimes(k+1)} \to \mathbb{C}$ in this category is determined by a function $\varphi: G^{k+1} \to \mathbb{C}$ such that $\varphi(g_0, \dots, g_k)e = g_0 \cdots g_k \varphi(g_0, \dots, g_k)$, but since G is a vector space basis for $\mathbb{C}G$, we conclude

$$\mathrm{Hom}_{G\text{-Vec}}((\mathbb{C}G)^{\otimes(k+1)}, \mathbb{C}) = \{\varphi: G^{k+1} \to \mathbb{C} | \varphi(g_0, \dots, g_k) = 0, \text{ if } g_0 \cdots g_k \neq e\} \tag{4.14}$$

and

$$(b\varphi)(g_0, \dots, g_{k+1}) = \sum_{i=0}^{k} (-1)^i \varphi(g_0, \dots, g_i g_{i+1}, \dots, g_{k+1}) + (-1)^{k+1} \chi(g_{k+1}) \varphi(g_{k+1} g_0, \dots, g_k), \tag{4.15}$$

$$(\lambda\varphi)(g_0, \dots, g_k) = (-1)^k \chi(g_k) \varphi(g_k, g_0, \dots, g_{k-1}), \tag{4.16}$$

where $\chi = \chi_1 \cdots \chi_n$. Note that since $(\lambda^{k+1}\varphi)(g_0, \dots, g_k) = (-1)^{k(k+1)} \chi(g_0 \cdots g_k) \varphi(g_0, \dots, g_k)$ we conclude that

$$C^k(G - \mathrm{Vec}; \mathbb{C}G, \overline{\chi}) = \mathrm{Hom}_{G\text{-Vec}}((\mathbb{C}G)^{\otimes(k+1)}, \mathbb{C}) = \{\phi: G^{k+1} \to \mathbb{C} | \phi(g_0, \dots, g_k) = 0, \text{ if } g_0 \dots g_k \neq e\},$$

where $\overline{\chi}(g) := \chi_1(g) \cdots \chi_n(g) g$.

Now we are ready to cotwist all of the above to obtain a braided cyclic cocycle. Thus, let $F: G^2 \to \mathbb{C} - \{0\}$ be a function such that $F(g,e) = F(e,g) = 1$, $\forall g \in G$ and $H = \mathbb{C}G$ as above. Then after cotwisting, H^F has the same product as H, because

$$g_1 \,.\, g_2 = F(g_1, g_2) g_1 g_2 F(g_1, g_2)^{-1} = g_1 g_2, \quad \forall\, g \in G.$$

But we have nontrivial 3-cocycle

$$\phi_F(g_1, g_2, g_3) = F(g_2, g_3) F(g_1, g_2 g_3) F(g_1, g_2)^{-1} F(g_1 g_2, g_3)^{-1} \tag{4.17}$$

and nontrivial cotriangular structure

$$\mathcal{R}_F(g_1, g_2) = F(g_2, g_1) F(g_1, g_2)^{-1}. \tag{4.18}$$

Therefore we have a cotriangular coquasibialgebra which we denote by $\mathbb{C}^F G$ and an algebra in the category of $\mathbb{C}^F G$-comodules is called a *G-graded quasialgebra*[13] i.e., a G-graded algebra $A = \oplus_{g \in G} A_g$ such that

$$a(bc) = \phi_F(|a|, |b|, |c|)(ab)c \tag{4.19}$$

on homogeneous elements. Recall that we chose $A = \mathbb{C}G$ as an algebra in the category of G-graded vector spaces which cotwists to a G-graded quasialgebra $A_F = \mathbb{C}_F G$ with the product

$$g_1 \,.\, g_2 = F(g_1, g_2) g_1 g_2. \tag{4.20}$$

We also have

$$\int \omega \,.\, g = F(g, \omega_{(1)}) F(\omega_{(1)}, g)^{-1} \chi_1(g) \cdots \chi_n(g) \int g \,.\, \omega_{(2)}, \tag{4.21}$$

while the isomorphism of Theorem 12 becomes

$$\varphi_F(g_0, \dots, g_k) = F(g_0, g_1) F(g_0 g_1, g_2) \cdots F(g_0 \cdots g_{k-1}, g_k) \varphi(g_0, \dots, g_k). \tag{4.22}$$

V. EXAMPLES

In this section we collect examples that demonstrate key aspects of the theory above. They are all constructed using cotwisting on coquasitriangular Hopf algebras in Sec. IV. The first two are based on Abelian groups as in Sec. IV B.

A. Octonions

Let $G=\mathbb{Z}_2\times\mathbb{Z}_2\times\mathbb{Z}_2$. Thus $\mathbb{C}G$ is an associative algebra with generators $\{1,u,v.w\}$ and relations

$$u^2=1,\quad v^2=1,\quad w^2=1,\quad uv=vu,\quad uw=wu,\quad vw=wv.$$

For simplicity we will use the notation $\mathbf{i}=u^{i_1}v^{i_2}w^{i_3}$ and $\mathbf{i}+\mathbf{j}=u^{i_1+j_1}v^{i_2+j_2}w^{i_3+j_3}$ as well. In fact this notation is statement of the group $\mathbb{Z}_2^3$ as an additive group. Each $\mathbb{Z}_2$ has a unique nonzero differential calculus (the universal one) and it is natural to equip G with the "direct product" of three copies of this. To do this, we choose three characters

$$\chi_1(u^iv^jw^k)=(-1)^i,\quad \chi_2(u^iv^jw^k)=(-1)^j,\quad \chi_3(u^iv^jw^k)=(-1)^k,\quad i,j,k=0,1.$$

Then by (4.10) we have

$$\omega_1u=-u\omega_1,\quad \omega_2u=u\omega_2,\quad \omega_3u=u\omega_3,$$

$$\omega_1v=v\omega_1,\quad \omega_2v=-v\omega_2,\quad \omega_3v=v\omega_3,$$

$$\omega_1w=w\omega_1,\quad \omega_2w=w\omega_2,\quad \omega_3w=-w\omega_3,$$

and again by (4.10) we have

$$du=-2u\omega_1,\quad dv=-2v\omega_2,\quad dw=-2w\omega_3,$$

and

$$(du)u=-udu,\quad (dv)u=udv,\quad (dw)u=udw,$$

$$(du)v=vdu,\quad (dv)v=-vdv,\quad (dw)v=vdw,$$

$$(du)w=wdu,\quad (dv)w=wdv,\quad (dw)w=-wdw,$$

and therefore

$$(du)^2=(dv)^2=(dw)^2=0,$$

$$dudv=-dvdu,\quad dudw=-dwdu,\quad dvdw=-dwdv.$$

Now using the Leibniz rule and the above relations we have $d(uv)=-2uv(\omega_1+\omega_2)$, $d(uw)=-2uw(\omega_1+\omega_3)$, and $d(vw)=-2vw(\omega_2+\omega_3)$ and thus we have $d(uvw)=(du)vw+u(dvw)=-2uvw(\omega_1+\omega_2+\omega_3)$. Therefore, generally, we have

$$d(u^{i_1}v^{i_2}w^{i_3})=-2u^{i_1}v^{i_2}w^{i_3}(i_1\omega_1+i_2\omega_2+i_3\omega_3),\quad i_k=0,1,\quad k=1,2,3$$

or in additive notation

$$d\mathbf{i}=-2\mathbf{i}(i_1\omega_1+i_2\omega_2+i_3\omega_3).$$

Using this formula and the above commutation relations we obtain

$$\begin{aligned}\pi(\mathbf{i}d\mathbf{j}d\mathbf{k}d\mathbf{l})=&-8(\mathbf{i}+\mathbf{j}+\mathbf{k}+\mathbf{l})[(-1)^{l_2+l_3}l_1((-1)^{k_2}j_2k_3-(-1)^{k_3}j_3k_2)\\&+(-1)^{l_1+l_3}l_2((-1)^{k_3}j_3k_1-(-1)^{k_1}j_1k_3)+(-1)^{l_1+l_2}l_3((-1)^{k_1}j_1k_2-(-1)^{k_2}j_2k_1)].\end{aligned}$$

Thus we calculate the character of the trivially braided ribbon graded trace defined by (4.12) as

$$\varphi(\mathbf{i},\mathbf{j},\mathbf{k},\mathbf{l}) = -8[(-1)^{l_2+l_3}l_1((-1)^{k_2}j_2k_3 - (-1)^{k_3}j_3k_2) + (-1)^{l_1+l_3}l_2((-1)^{k_3}j_3k_1 - (-1)^{k_1}j_1k_3) + (-1)^{l_1+l_2}l_3((-1)^{k_1}j_1k_2 - (-1)^{k_2}j_2k_1)] \tag{5.1}$$

if $\mathbf{i}+\mathbf{j}+\mathbf{k}+\mathbf{l}=0$, and zero otherwise. One can compute this from the general formula (4.13) as well.

Now we study cotwisting of $G=\mathbb{Z}_2^3$ to the octonions. The complex numbers, the quaternions, the octonions and the higher Cayley algebras can be constructed by the Cayley–Dixon process. On the other hand it has been shown in Ref. 13 that these algebras are G-graded quasialgebras of the form $\mathbb{C}_F G$ for G a power of $\mathbb{Z}_2$ and for a suitable F.

For octonions we take[13] $G=\mathbb{Z}_2^3$ and

$$F(\mathbf{i},\mathbf{j}) = (-1)^{i_1(j_1+j_2+j_3)+i_2(j_2+j_3)+i_3j_3+j_1i_2i_3+i_1j_2i_3+i_1i_2j_3} \tag{5.2}$$

which has coboundary

$$\phi_F(\mathbf{i},\mathbf{j},\mathbf{k}) = (-1)^{|\mathbf{ijk}|}, \tag{5.3}$$

where $|\mathbf{i}\ \mathbf{j}\ \mathbf{k}|$ is a short notation for determinant of the matrix whose columns are the vectors $\mathbf{i}$, $\mathbf{j}$, and $\mathbf{k}$, respectively.

We denote the cotwisted product by $x.y=F(x,y)xy$, $\forall x,y\in\mathbb{C}G$. Then we have the following relations:

$$u\,.\,u=-1,\quad v\,.\,v=-1,\quad w\,.\,w=-1,\quad u\,.\,v=-v\,.\,u,\quad u\,.\,w=-w\,.\,u,$$

$$v\,.\,w=-w\,.\,v,\quad u\,.\,(v\,.\,w)=-(u\,.\,v)\,.\,w$$

and the relations between 0-forms and left invariant forms remain unchanged after twisting the above DC on $G=\mathbb{Z}_2\times\mathbb{Z}_2\times\mathbb{Z}_2$. But we have

$$du\,.\,u=-u\,.\,du,\quad dv\,.\,u=-u\,.\,dv,\quad dw\,.\,u=-u\,.\,dw,$$

$$du\,.\,v=-v\,.\,du,\quad dv\,.\,v=-v\,.\,dv,\quad dwv=-v\,.\,dw,$$

$$du\,.\,w=-w\,.\,du,\quad dv\,.\,w=-w\,.\,dv,\quad dw\,.\,w=-w\,.\,dw,$$

and

$$du\,.\,du=dv\,.\,dv=dw\,.\,dw=0,$$

$$du\,.\,dv=dv\,.\,du,\quad du\,.\,dw=dw\,.\,du,\quad dv\,.\,dw=dw\,.\,dv.$$

This is our natural differential calculus or "exterior algebra" for the octonions as obtained by cotwisting. Like the octonions themselves, it is a nonassociative quasialgebra. We see that now the function algebra generators and their differentials uniformly anticommute, while the latter mutually commute.

From the above, we have $d(u.v)=du.v+u.dv=-2u.\omega_1.v-2u.v.\omega_2=-2u.v.(\omega_1+\omega_2)$ and similarly we have $d(u.w)=-2u.w.(\omega_1+\omega_3)$ and $d(v.w)=-2v.w.(\omega_2+\omega_3)$ and $d((u.v).w)=d(u.v).w+(u.v).dw=-2(u.v.(\omega_1+\omega_2)).w-2(u.v).w.\omega_3=-2(u.v).w.(\omega_1+\omega_2)-2(u.v).w.\omega_3=-2(u.v).w.(\omega_1+\omega_2+\omega_3)$. Therefore, generally, we have

$$d((u^i\,.\,v^j)\,.\,w^k)=-2(u^i\,.\,v^j)\,.\,w^k(i\omega_1+j\omega_2+k\omega_3),\quad i,j,k=0,1.$$

Using formula (4.22) we can then calculate

$$\varphi_F(\mathbf{i},\mathbf{j},\mathbf{k},\mathbf{l}) = F(\mathbf{i},\mathbf{j})F(\mathbf{i}+\mathbf{j},\mathbf{k})F(\mathbf{i}+\mathbf{j}+\mathbf{k},\mathbf{l})\varphi(\mathbf{i},\mathbf{j},\mathbf{k},\mathbf{l})$$

as the left-to-right representative of the character.

Let us remark that the octonions presented in the above way can be viewed as a "nonassociative quantization" of $\mathbb{Z}_2\times\mathbb{Z}_2\times\mathbb{Z}_2$ as follows. Indeed, it is well-known that the Weyl algebra of canonical quantization in quantum mechanics can be formally presented as a "Moyal product" modifying the original algebra $A=C^\infty(\mathbb{R}^n)$ to a new algebra A_F with product

$$a\,.\,b = e^{\hbar\Sigma_{i,j}B_{ij}\partial_i\otimes\partial_j}(a\otimes b),$$

where $\hbar$ is a deformation parameter and B an antisymmetric tensor. The product in the original A is understood on the right. The F for the octonions similarly has a quadratic term in its exponent; cotwisting by this gives the Clifford algebra on $\mathbb{R}^3$ so this is like a "free field" quantization of $\mathbb{Z}_2\times\mathbb{Z}_2\times\mathbb{Z}_2$. The further cubic term in the F for the octonions is a bit like a "Chern–Simmons" interaction term and it is this which make $\phi_F=\partial F$ nontrivial. If we accept this analogy then we have the following proposal for physics: one might try to build cubic and higher interactions in quantum mechanics or quantum field theory by means of *nonassociative quantization* of the form

$$a\,.\,b = e^{\hbar\mathcal{L}_0+\hbar V}(a\otimes b),$$

where $\mathcal{L}_0$ is a bidifferential operator (as above) corresponding to a free particle and V is an additional term of joint degree three or higher to encode interactions. Another possibility is to take for F simply a phase factor $e^{\hbar S_0(a,b)+\hbar V(a,b)}$, where S_0 is the bilinear functional in the free field action and V is cubic or higher. The general idea, to be pursued elsewhere, is be to build such interaction terms into the algebra where their effect is a mild quasiassociativity; the system would still be equivalent to the the free case in the sense of being strictly related by cotwisting, allowing the theory to be solved as easily as the free case.

B. Noncommutative algebraic torus

Let $G=\mathbb{Z}\times\mathbb{Z}$. Thus $\mathbb{C}G$ is an associative algebra with free invertible commuting generators u,v. The standard calculus on algebra $\mathbb{C}G$, i.e., the two-dimensional bicovariant DC can be written with basis $\{\omega_1,\omega_2\}$ for left invariant 1-forms and relations

$$\omega_k a = a\omega_k,\quad d(u^iv^j) = u^iv^j(i\omega_1+j\omega_2),\quad \omega_k^2=0,\quad \omega_1\omega_2=-\omega_2\omega_1,$$

$\forall a\in\mathbb{C}G$, $\forall i,\ j\in\mathbb{Z}$. This is obtained from characters as in the finite group case via a limiting procedure.[12]

Then we have $\pi(u^{i_1}v^{i_2}d(u^{j_1}v^{j_2})d(u^{k_1}v^{k_2}))=(j_1k_2-j_2k_1)u^{i_1+j_1+k_1}v^{i_2+j_2+k_2}$ and hence

$$\varphi(u^{i_1}v^{i_2},u^{j_1}v^{j_2},u^{k_1}v^{k_2}) = j_1k_2-j_2k_1 \tag{5.4}$$

if $i_1+j_1+k_1=i_2+j_2+k_2=0$, and zero otherwise.

Next, as in Ref. 12 we chose the cocycle $F(u^{i_1}v^{i_2},u^{j_1}v^{j_2})=e^{\imath\theta i_2j_1}$ to gauge transform the category of $\mathbb{Z}\times\mathbb{Z}$-graded vector spaces. Then the algebra $\mathbb{C}_FG$ after cotwisting of the product has the relations $v\,.\,u=e^{\imath\theta}u\,.\,v$, which we call *algebraic noncommutative torus*. This observation itself is well-known already for the full noncommutative torus C^*-algebra in a more explicit (noncategorical) context.[20] From our point of view the algebra is associative since above F is a cocycle, but it still gives a nontrivial example of the theory of Sec. IV.

Now using (4.22) we compute the character of the above DC after gauge transformation as

$$\begin{aligned}\varphi_F(u^{i_1}v^{i_2},u^{j_1}v^{j_2},u^{k_1}v^{k_2}) &= F(u^{i_1}v^{i_2},u^{j_1}v^{j_2})F(u^{i_1}v^{i_2}u^{j_1}v^{j_2},u^{k_1}v^{k_2})\varphi(u^{i_1}v^{i_2},u^{j_1}v^{j_2},u^{k_1}v^{k_2})\\ &= e^{\imath\theta(i_2j_1+(i_2+j_2)k_1)}(j_1k_2-j_2k_1).\end{aligned} \tag{5.5}$$

Since, by the very definition of F, we have $u^{\cdot i}v^{\cdot j}=u^iv^j$, $\forall i,j\in\mathbb{Z}$, we conclude that

$$\varphi_F(u^{\cdot i_1}v^{\cdot i_2},u^{\cdot j_1}v^{\cdot j_2},u^{\cdot k_1}v^{\cdot k_2}) = e^{\imath\theta(i_2j_1+(i_2+j_2)k_1)}(j_1k_2-j_2k_1). \tag{5.6}$$

We remark that we have $v^{\cdot j}u^{\cdot i}=e^{\imath\theta ij}u^iv^j$, $\forall i,j\in\mathbb{Z}$. Note that σ is trivial in this example.

C. Quantum quasimanifolds covariant under quantum groups $\mathbb{C}_q(G)$

Here we take the initial Hopf algebra to be $H=\mathbb{C}(G)$, the algebraic version of a classical Lie group of complex simple Lie algebra g. More precisely, we need to work in a deformation-theoretic setting where $H=\mathbb{C}(G)[[\hbar]]$ is extended over this ring $\mathbb{C}[[\hbar]]$ of formal power series in a deformation parameter $\hbar$, rather than working over $\mathbb{C}$ itself. With this proviso, we are able to use the theory in Sec. IV A with F a cochain with values in $\mathbb{C}[[\hbar]]$. By essentially dualizing the theory in Ref. 1, one knows that there exists an F such that

$$\mathbb{C}_q(G) \cong (\mathbb{C}(G)[[\hbar]])^F,$$

i.e., such that after cotwisting one obtains the (formal power-series version of the) standard quantum group $\mathbb{C}_q(G)$. Here $q=e^{\hbar/2}$. Note that although the required F is not a cocycle so that the cotwist on the right-hand side here is in theory a coquasi-Hopf algebra, its coboundary $\phi_{\mathrm{KZ}}=\partial F$ [which is obtained by solving the Knizhnik–Zamolochikov (KZ) equations] happens to be central in the sense

$$abc = \phi_{\mathrm{KZ}}(a_{(1)},b_{(1)},c_{(1)})a_{(2)}b_{(2)}c_{(2)}\phi_{\mathrm{KZ}}^{-1}(a_{(3)},b_{(3)},c_{(3)})$$

so that the coquasi-Hopf algebra on the right-hand side happens to remain associative as indeed is $\mathbb{C}_q(G)$ on the left-hand side (since it is a usual Hopf algebra). This point of view has been expounded recently in Ref. 4. Let us note only that it is not exactly the one of Drinfeld even before dualization. For that one should start with $\mathbb{C}(G)[[\hbar]]$ as a nontrivial coquasi-Hopf algebra with a nontrivial initial coquasitriangular structure $\mathcal{R}_0$ built from the Killing form and a certain ϕ_0 as the initial associator, which is the object actually obtained by Drinfeld by solving the KZ-equations. Here ϕ_0 is closely related to ϕ_{KZ} above as its "inverse" in the sense that cotwisting it by F gives ε (the trivial associator). In this way, Drinfeld's theory in the cotwist form would cotwist a certain coquasi-Hopf algebra $(\mathbb{C}(G)[[\hbar]],\mathcal{R}_0,\phi_0)$ into the ordinary Hopf algebra $\mathbb{C}_q(G)$ with its usual quasitriangular structure and trivial associator. By contrast in Ref. 4 one starts with $\mathbb{C}(G)[[\hbar]]$ as completely classical with trivial coquasitriangular structure and trivial associator, and obtains after cotwisting $(\mathbb{C}_q(G),\mathcal{R}_F,\phi_{\mathrm{KZ}})$ as a cotriangular coquasi-Hopf algebra. Like in our examples based on Abelian groups, this happens to be an ordinary Hopf algebra in its algebra and coalgebra. Here $\mathcal{R}_F$ is given by (4.8) and ϕ_{KZ} by (4.7). This cotriangular coquasi-Hopf algebra $(\mathbb{C}_q(G),\mathcal{R}_F,\phi_{\mathrm{KZ}})$ is the object under which our examples of quantum quasispaces below are covariant. As an algebra and coalgebra it coincides with the usual quantum group $\mathbb{C}_q(G)$.

Thus, in Ref. 4 this $(\mathbb{C}_q(G),\mathcal{R}_F,\phi_{\mathrm{KZ}})$ construction was used to obtain a quantum differential calculus on $\mathbb{C}_q(G)$ as a supercoquasi-Hopf algebra $\Omega(\mathbb{C}(G))^F$. We extend this setting now to any manifold M on which the classical Lie group G acts. More precisely, we assume that there are algebraic versions $\mathbb{C}(M)$ for the coordinate algebra and for a coaction $\mathbb{C}(M)\to\mathbb{C}(G)\otimes\mathbb{C}(M)$. Thus $\mathbb{C}(M)$ is given as an algebra in our initial category of $\mathbb{C}(G)$-comodules. Moreover, we extend all this data to the formal power series setting (we adjoin $\hbar$).

Theorem 13: *Let M be a classical G-manifold in the sense above. Then there is a quasialgebra $\mathcal{C}_q(M)=(\mathbb{C}(M)[[\hbar]])_F$ in the category of $\mathbb{C}_q(G)$-comodules, where $\mathbb{C}_q(G)$ is the standard quantum group associated to G viewed as a cotriangular coquasi-Hopf algebra. Moreover, $\mathcal{C}_q(M)$ has a quasiassociative differential calculus $\Omega(\mathbb{C}(M))_F$.*

Proof: We apply the theory of Sec. IV A with $H=\mathbb{C}(G)[[\hbar]]$, F the cochain above and $A=\mathbb{C}(M)[[\hbar]]$. ■

Similarly, any classical data on M such as a cyclic cocycle twists to a braided cyclic one on the symmetric but nontrivially monoidal category of $\mathbb{C}_q(G)$-comodules.

Let us note also that when all of our data are obtained from exponentiating infinitesimal data, we can look at the structure of $\mathcal{C}_q(M)$ to lowest order. Then one finds

$$\{\{a,b\},c\}+\{\{b,c\},a\}+\{\{c,a\},b\}=2\tilde{n}(a\otimes b\otimes c),$$

where $n\propto[r_{+12},r_{+23}]\in g\otimes g\otimes g$ is the leading order part of ϕ_{KZ} as explained in Ref. 4. Here r_+ is the symmetric part of the standard classical r-matrix of g and is a multiple of the Killing form. In this case the left-invariant trivector field $\tilde{n}$ given by the action of n is some multiple of the canonical "Cartan tensor" that exists for any manifold M acted upon by a semisimple Lie algebra. We see that $\mathcal{C}_q(M)$ is not the quantization of a usual Poisson manifold but of a "quasi-Poisson" manifold. Such a weaker concept was proposed recently in Ref. 8 and we see that we have succeed in quantizing it using cotwisting. We see, moreover, that the quantum quasispace $\mathbb{C}_q(M)$ remains covariant but under the quantum group $\mathbb{C}_q(G)$ (viewed as a cotriangular coquasi Hopf algebra). Let us note, however, one technical difference from Ref. 8; our quasi-Poisson manifold is associated with an action of G not to a Poisson action of G (these are not quite the same thing).

Finally, we can apply all of this theory to $M=G$, i.e., to $A=\mathbb{C}(G)[[\hbar]]$, where G acts on itself by translation, i.e., $A=H$ and the coaction is via the coproduct. This is the same idea as for our examples with finite groups, but now with G a Lie group of a simple Lie algebra.

Corollary 14: The standard quantum groups $\mathbb{C}_q(G)$ *have quasialgebra versions* $\mathcal{C}_q(G)$ as algebras in the category of $\mathbb{C}_q(G)$*-comodules as a symmetric monoidal category*.

Proof: Here $\mathcal{C}_q(G)=(\mathbb{C}(G)[[\hbar]])_F$, where we use the one-sided cotwist, in contrast to the Drinfeld cotwist which gives $(\mathbb{C}_q(G),\mathcal{R}_F,\phi_{\mathrm{KZ}})$ as explained above. The former lives in the category of comodules of the latter. ■

If one wants to be concrete, let $\{t^i{}_j\}$ be the matrix of generators of the classical Lie group G. These generate the classical $\mathbb{C}(G)$ with the usual "matrix" coproduct. If we know F then we know in particular the tensors

$$F^{i\ j}_{k\ l}=F(t^i{}_k,t^j{}_l),\quad (\Delta_2F)^{i\ j\ k}_{l\ m\ n}=F(t^i{}_l,t^j{}_m t^k{}_n),\quad (\Delta_1F)^{i\ j\ k}_{l\ m\ n}=F(t^i{}_l t^j{}_m,t^k{}_n),$$

and so forth, where the product is in the classical $\mathbb{C}(G)[[\hbar]]$. Next, we denote the generators of $\mathcal{C}_q(G)$ by $\{x^i{}_j\}$ say. They are the same as the $t^i{}_j$ but with a new product which then enjoys the deformed relations

$$x_1x_2=FF_{21}^{-1}x_2x_1.$$

We use here the standard notation in quantum group theory, where the numerical indices refer to the position in a tensor product. These relations have to be combined with the nonassociativity relations

$$x_1(x_2x_3)=F_{23}(\Delta_2F)(\Delta_1F)^{-1}F_{12}^{-1}(x_1x_2)x_3.$$

The commutation relations reflect that the quasispace is braided-commutative with respect to the cotriangular structure $\mathcal{R}_F$, while the nonassociativity relations reflect the associator ϕ_{KZ} obtained from F.

We also have a calculus, cocycle etc. on $\mathcal{C}_q(G)$, with $\Omega(\mathcal{C}_q(G))=\Omega(\mathbb{C}(G)[[\hbar]])_F$. Choosing a matrix of invariant classical differential forms as generators of the classical calculus, one has similar "F-matrix" formulas for the relations in the deformed calculus on $\mathcal{C}_q(G)$, and so forth. Further details will be given elsewhere.

Modules over a quasialgebra (here, by quasialgebra we mean a left H-module algebra, where H is a quasi-Hopf algebra), as defined by Albuquerque and Majid, coincide with modules over a certain associative algebra, a quasi-Hopf smash product. As a consequence of this, we get that the category of modules over the octonions is isomorphic to the category of modules over the algebra of 8×8 real matrices. We provide a new approach to the endomorphism quasialgebra associated to a left H-module, which in the finite dimensional case yields the same results as the one of Albuquerque and Majid. We discuss possible definitions as endomorphism quasialgebras for Heisenberg doubles of a finite dimensional quasi-Hopf algebra. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1789280]

I. INTRODUCTION

The starting point of this paper was the following question we asked ourselves: What could be a module over the octonions? The usual approach to octonions (we refer to Ref. 2 for a recent survey of the existing theory for the octonions) does not provide an answer. However, it turned out that such an answer is possible using the recent Hopf-algebraic approach to octonions proposed by Albuquerque and Majid in Ref. 1. Namely, they first introduced the concept of a "quasialgebra," as being an algebra in a tensor category (in this paper we restrict the term to algebras in the tensor category of modules over a quasi-Hopf algebra) and then proved that the (nonassociative) algebra of octonions is such a quasialgebra; they defined also a module over a quasialgebra A as being an A-module in the same tensor category where A lives as an algebra and hence a suitable definition of modules over the octonions may be derived from this.

If H is a quasi-Hopf algebra and M is a *finite dimensional* left H-module, Albuquerque and Majid constructed the so-called "endomorphism quasialgebra" of M—which is built on the vector space $\mathrm{End}(M)$ and will be denoted below by $\mathrm{end}(M)$—using "tensor-categorical" techniques, that is by introducing first a quasialgebra structure on $M\otimes M^*$ and then transfering it to $\mathrm{End}(M)$ via the linear isomorphism $\mathrm{End}(M)\simeq M\otimes M^*$. Also, if A is an algebra in the category of left H-modules, they proved that setting a structure of an A-module on M is equivalent to giving a quasialgebra map $A\to \mathrm{end}(M)$.

There is an obvious analogy with what happens for other classes of algebras (associative or Lie), where setting a module structure on a vector space is equivalent to giving an algebra map from the algebra to a certain "endomorphism algebra" constructed out of the vector space, but in those cases one can construct the "endomorphism algebra" of any object (not necessarily finite dimensional), so it is natural to see whether this is possible also for the class of quasialgebras.

[a)]Electronic mail: florin.panaite@imar.ro
[b)]Electronic mail: francine.schoeters@ua.ac.be

In order to explain our contribution to this subject, let us first recall some results from Ref. 6. First, if H is a quasi-Hopf algebra, B an associative algebra and $v:H\to B$ an algebra map, then on B one can introduce a structure of an algebra in the tensor category of left H-modules (a left H-module algebra structure, in the terminology of Ref. 6), denoted by B^v. Second, if A is a left H-module algebra, an associative algebra, denoted by $A\#H$ and called the smash product, has been introduced in Ref. 6 and the left $A\#H$-modules were described. These turned out to coincide with the A-modules in the category of left H-modules (called left A, H-modules in Ref. 6).

The first aim of this paper is to point out that the modules over a quasialgebra, as defined by Albuquerque and Majid, coincide with modules over an associative algebra, namely, a quasi-Hopf smash product. As a consequence, we obtain that the category of modules over a twisted group quasialgebra kG_F is isomorphic to the category of modules over the algebra of $|G|$ by $|G|$ matrices over k (where $|G|$ is the order of the group G), and in particular that the category of modules over the octonions is isomorphic to the category of modules over the algebra of 8×8 real matrices.

The second aim is to provide a different approach to the endomorphism quasialgebra associated to an object, which works also in the *infinite dimensional case*. Namely, if H is a quasi-Hopf algebra, A a left H-module algebra and M a left H-module, we have the algebra map $v:H\to \mathrm{End}(M)$, $v(h)(m)=h\cdot m$, so we can consider the left H-module algebra $\mathrm{End}(M)^v$ (this will be the endomorphism quasialgebra associated to M); then we prove that setting a structure of a left A, H-module on M is equivalent to giving a morphism of left H-module algebras $\varphi:A\to \mathrm{End}(M)^v$ (the proof relies on the use of the smash product $A\#H$). Also, we prove that if M is a finite dimensional left H-module, then $\mathrm{End}(M)^v$ coincides with $\mathrm{end}(M)$ defined in Ref. 1 as left H-module algebras, and that if M is moreover a left A, H-module, then the map φ coincides with the similar map $A\to \mathrm{end}(M)$ defined by Albuquerque and Majid.

As an immediate consequence of the identification $\mathrm{End}(M)^v\equiv \mathrm{end}(M)$ and of results in Ref. 4, we obtain that if M is a finite dimensional Yetter–Drinfeld H-module, then $\mathrm{End}(M)^v$ is a Yetter–Drinfeld H-module algebra.

The analogy with the classes of associative or Lie algebras mentioned before can be pushed forward. Namely, the concepts of a *bimodule* over an associative or Lie algebra are a manifestation of a single concept, that of a bimodule over an algebra with respect to a class of algebras (see Ref. 18). We prove that if H is a quasi-bialgebra and A is a left H-module algebra, then an A-bimodule with respect to the class of left H-module algebras, in the sense of Ref. 18, is the same as an A-bimodule in the tensor category of left H-modules.

In the final section we discuss possible definitions as endomorphism quasialgebras for Heisenberg doubles of a finite dimensional quasi-Hopf algebra.

II. PRELIMINARIES

We work over a commutative field k. All algebras, linear spaces, etc., will be over k; unadorned $\otimes$ means $\otimes_k$. Following Drinfeld,[9] a quasi-bialgebra is a fourtuple $(H,\Delta,\varepsilon,\Phi)$, where H is an associative algebra with unit, Φ is an invertible element in $H\otimes H\otimes H$, and $\Delta:H\to H\otimes H$ and $\varepsilon:H\to k$ are algebra homomorphisms satisfying the identities

$$(\mathrm{id}\otimes\Delta)(\Delta(h))=\Phi(\Delta\otimes\mathrm{id})(\Delta(h))\Phi^{-1}, \tag{2.1}$$

$$(\mathrm{id}\otimes\varepsilon)(\Delta(h))=h\otimes 1,\quad (\varepsilon\otimes\mathrm{id})(\Delta(h))=1\otimes h, \tag{2.2}$$

for all $h\in H$, and Φ has to be a normalized 3-cocycle, in the sense that

$$(1\otimes\Phi)(\mathrm{id}\otimes\Delta\otimes\mathrm{id})(\Phi)(\Phi\otimes 1)=(\mathrm{id}\otimes\mathrm{id}\otimes\Delta)(\Phi)(\Delta\otimes\mathrm{id}\otimes\mathrm{id})(\Phi), \tag{2.3}$$

$$(\mathrm{id}\otimes\varepsilon\otimes\mathrm{id})(\Phi)=1\otimes 1\otimes 1. \tag{2.4}$$

The map Δ is called the coproduct or the comultiplication, ε the counit and Φ the reassociator. As for Hopf algebras[19] we denote $\Delta(h)=\Sigma h_1\otimes h_2$, but since Δ is only quasi-coassociative we adopt the further convention

$$(\Delta\otimes\mathrm{id})(\Delta(h))=\sum h_{(1,1)}\otimes h_{(1,2)}\otimes h_2,\ \ (\mathrm{id}\otimes\Delta)(\Delta(h))=\sum h_1\otimes h_{(2,1)}\otimes h_{(2,2)},$$

for all $h\in H$. We will denote the tensor components of Φ by capital letters, and those of Φ^{-1} by small letters, namely,

$$\Phi=\sum X^1\otimes X^2\otimes X^3=\sum T^1\otimes T^2\otimes T^3=\sum V^1\otimes V^2\otimes V^3=\cdots,$$

$$\Phi^{-1}=\sum x^1\otimes x^2\otimes x^3=\sum t^1\otimes t^2\otimes t^3=\sum v^1\otimes v^2\otimes v^3=\cdots.$$

The quasi-bialgebra H is called a quasi-Hopf algebra if there exists an antiautomorphism S of the algebra H and elements $\alpha,\beta\in H$ such that, for all $h\in H$, we have

$$\sum S(h_1)\alpha h_2=\varepsilon(h)\alpha\ \text{ and }\ \sum h_1\beta S(h_2)=\varepsilon(h)\beta, \tag{2.5}$$

$$\sum X^1\beta S(X^2)\alpha X^3=1\ \text{ and }\ \sum S(x^1)\alpha x^2\beta S(x^3)=1. \tag{2.6}$$

For a quasi-Hopf algebra the antipode is determined uniquely up to a transformation $\alpha\mapsto U\alpha$, $\beta\mapsto\beta U^{-1}$, $S(h)\mapsto US(h)U^{-1}$, where $U\in H$ is invertible. The axioms for a quasi-Hopf algebra imply that $\varepsilon(\alpha)\varepsilon(\beta)=1$, so, by rescaling α and β, we may assume without loss of generality that $\varepsilon(\alpha)=\varepsilon(\beta)=1$ and $\varepsilon\circ S=\varepsilon$. The identities (2.2)–(2.4) also imply that

$$(\varepsilon\otimes\mathrm{id}\otimes\mathrm{id})(\Phi)=(\mathrm{id}\otimes\mathrm{id}\otimes\varepsilon)(\Phi)=1\otimes 1\otimes 1. \tag{2.7}$$

Together with a quasi-bialgebra or a quasi-Hopf algebra $H=(H,\Delta,\varepsilon,\Phi,S,\alpha,\beta)$ we also have H^{op}, H^{cop} and $H^{\mathrm{op,cop}}$ as quasi-bialgebras (respectively, quasi-Hopf algebras), where "op" means opposite multiplication and "cop" means opposite comultiplication. The structures are obtained by setting $\Phi_{\mathrm{op}}=\Phi^{-1}$, $\Phi_{\mathrm{cop}}=(\Phi^{-1})^{321}$, $\Phi_{\mathrm{op,cop}}=\Phi^{321}$, $S_{\mathrm{op}}=S_{\mathrm{cop}}=(S_{\mathrm{op,cop}})^{-1}=S^{-1}$, $\alpha_{\mathrm{op}}=S^{-1}(\beta)$, $\beta_{\mathrm{op}}=S^{-1}(\alpha)$, $\alpha_{\mathrm{cop}}=S^{-1}(\alpha)$, $\beta_{\mathrm{cop}}=S^{-1}(\beta)$, $\alpha_{\mathrm{op,cop}}=\beta$, and $\beta_{\mathrm{op,cop}}=\alpha$.

Next we recall that the definition of a quasi-bialgebra or quasi-Hopf algebra is "twist covariant" in the following sense. An invertible element $F\in H\otimes H$ is called a *gauge transformation* or *twist* if $(\varepsilon\otimes\mathrm{id})(F)=(\mathrm{id}\otimes\varepsilon)(F)=1$. If H is a quasi-bialgebra or a quasi-Hopf algebra and $F=\Sigma F^1\otimes F^2\in H\otimes H$ is a gauge transformation with inverse $F^{-1}=\Sigma G^1\otimes G^2$, then we can define a new quasi-bialgebra (respectively, quasi-Hopf algebra) H_F by keeping the multiplication, unit, counit (and antipode in the case of a quasi-Hopf algebra) of H and replacing the comultiplication, reassociator and the elements α and β by

$$\Delta_F(h)=F\Delta(h)F^{-1}, \tag{2.8}$$

$$\Phi_F=(1\otimes F)(\mathrm{id}\otimes\Delta)(F)\Phi(\Delta\otimes\mathrm{id})(F^{-1})(F^{-1}\otimes 1), \tag{2.9}$$

$$\alpha_F=\sum S(G^1)\alpha G^2,\ \ \beta_F=\sum F^1\beta S(F^2). \tag{2.10}$$

It is well known that the antipode of a Hopf algebra is an anti-coalgebra morphism. For a quasi-Hopf algebra, we have the following statement: there exists a gauge transformation $f\in H\otimes H$ such that

$$f\Delta(S(h))f^{-1} = \sum (S \otimes S)(\Delta^{\mathrm{cop}}(h)) \quad \text{for all } h \in H. \tag{2.11}$$

The element f can be computed explicitly. First set

$$\sum A^1 \otimes A^2 \otimes A^3 \otimes A^4 = (\Phi \otimes 1)(\Delta \otimes \mathrm{id} \otimes \mathrm{id})(\Phi^{-1}), \tag{2.12}$$

$$\sum B^1 \otimes B^2 \otimes B^3 \otimes B^4 = (\Delta \otimes \mathrm{id} \otimes \mathrm{id})(\Phi)(\Phi^{-1} \otimes 1), \tag{2.13}$$

and then define $\gamma, \delta \in H \otimes H$ by

$$\gamma = \sum S(A^2)\alpha A^3 \otimes S(A^1)\alpha A^4 \text{ and } \delta = \sum B^1 \beta S(B^4) \otimes B^2 \beta S(B^3). \tag{2.14}$$

Then f and f^{-1} are given by the formulas

$$f = \sum (S \otimes S)(\Delta^{\mathrm{cop}}(x^1))\gamma\Delta(x^2\beta S(x^3)), \tag{2.15}$$

$$f^{-1} = \sum \Delta(S(x^1)\alpha x^2)\delta(S \otimes S)(\Delta^{\mathrm{cop}}(x^3)). \tag{2.16}$$

If H is a quasi-Hopf algebra, following Refs. 10 and 11 we may define the elements

$$p_R = \sum p^1 \otimes p^2 = \sum x^1 \otimes x^2 \beta S(x^3), \quad q_R = \sum q^1 \otimes q^2 = \sum X^1 \otimes S^{-1}(\alpha X^3)X^2, \tag{2.17}$$

$$p_L = \sum \tilde{p}^1 \otimes \tilde{p}^2 = \sum X^2 S^{-1}(X^1 \beta) \otimes X^3, \quad q_L = \sum \tilde{q}^1 \otimes \tilde{q}^2 = \sum S(x^1)\alpha x^2 \otimes x^3 \tag{2.18}$$

satisfying the relations (for all $h \in H$):

$$\sum q_1^1 p^1 \otimes q_2^1 p^2 S(q^2) = 1 \otimes 1, \quad \sum q^1 p_1^1 \otimes S^{-1}(p^2) q^2 p_2^1 = 1 \otimes 1, \tag{2.19}$$

$$\sum S(\tilde{p}^1)\tilde{q}^1\tilde{p}_1^2 \otimes \tilde{q}^2\tilde{p}_2^2 = 1 \otimes 1, \quad \sum \tilde{q}_1^2\tilde{p}^1 S^{-1}(\tilde{q}^1) \otimes \tilde{q}_2^2\tilde{p}^2 = 1 \otimes 1, \tag{2.20}$$

$$\sum \Delta(h_1)p_R[1 \otimes S(h_2)] = p_R[h \otimes 1], \quad \sum [1 \otimes S^{-1}(h_2)]q_R\Delta(h_1) = [h \otimes 1]q_R, \tag{2.21}$$

$$\sum \Delta(h_2)p_L[S^{-1}(h_1) \otimes 1] = p_L[1 \otimes h], \quad \sum [S(h_1) \otimes 1]q_L\Delta(h_2) = [1 \otimes h]q_L. \tag{2.22}$$

Suppose that $(H, \Delta, \varepsilon, \Phi)$ is a quasi-bialgebra. If U, V, W are left (right) H-modules, define $a_{U,V,W}$, $\mathbf{a}_{U,V,W}: (U \otimes V) \otimes W \to U \otimes (V \otimes W)$ by

$$a_{U,V,W}((u \otimes v) \otimes w) = \mathbf{\Phi} \cdot (u \otimes (v \otimes w)),$$

$$\mathbf{a}_{U,V,W}((u \otimes v) \otimes w) = (u \otimes (v \otimes w)) \cdot \mathbf{\Phi}^{-1}.$$

The category ${}_H\mathcal{M}$ ($\mathcal{M}_H$) of left (right) H-modules becomes a monoidal category (see Refs. 12 and 14 for the terminology) with tensor product $\otimes$ given via Δ, associativity constraints $a_{U,V,W}$ ($\mathbf{a}_{U,V,W}$), unit k as a trivial H-module and the usual left and right unit constraints.

Now, let H be a quasi-bialgebra. We say that a k-vector space A is a left H-module algebra if it is an algebra in the monoidal category ${}_H\mathcal{M}$, that is A has a multiplication and a usual unit 1_A satisfying the following conditions:

$$(aa')a'' = \sum (X^1 \cdot a)[(X^2 \cdot a')(X^3 \cdot a'')], \tag{2.23}$$

$$h \cdot (aa') = \sum (h_1 \cdot a)(h_2 \cdot a'), \tag{2.24}$$

$$h \cdot 1_A = \varepsilon(h)1_A, \tag{2.25}$$

for all $a, a', a'' \in A$ and $h \in H$, where $h \otimes a \to h \cdot a$ is the left H-module structure of A. Following Ref. 6 we define the smash product $A\#H$ as follows: as vector space $A\#H$ is $A \otimes H$ (elements $a \otimes h$ will be written $a\#h$) with multiplication given by

$$(a \# h)(a' \# h') = \sum (x^1 \cdot a)(x^2 h_1 \cdot a') \# x^3 h_2 h', \tag{2.26}$$

for all $a, a' \in A$, $h, h' \in H$. Then $A\#H$ is an associative algebra with unit $1_A\#1$.

If A' is another left H-module algebra, a map $f: A \to A'$ is a morphism of left H-module algebras if it is multiplicative, unital and a morphism of left H-modules.

For further use we need also the notion of right H-module algebra. Let H be a quasi-bialgebra. We say that a k-linear space C is a right H-module algebra if C is an algebra in the monoidal category $\mathcal{M}_H$, i.e., C has a multiplication and a usual unit 1_C satisfying the following conditions:

$$(cc')c'' = \sum (c \cdot x^1)[(c' \cdot x^2)(c'' \cdot x^3)], \tag{2.27}$$

$$(cc') \cdot h = \sum (c \cdot h_1)(c' \cdot h_2), \tag{2.28}$$

$$1_C \cdot h = \varepsilon(h)1_C, \tag{2.29}$$

for all $c, c', c'' \in C$ and $h \in H$, where $c \otimes h \to c \cdot h$ is the right H-module structure of C.

Let H be a quasi-bialgebra, $F \in H \otimes H$ a gauge transformation and A a left H-module algebra. Then, following Refs. 6 and 5, we can define a new multiplication on A, by

$$a \diamond b = \sum (G^1 \cdot a)(G^2 \cdot b), \quad \forall\, a, b \in A, \tag{2.30}$$

where $F^{-1} = \Sigma G^1 \otimes G^2$. If we denote by $A_{F^{-1}}$ the resulting structure, then $A_{F^{-1}}$ becomes a left H_F-module algebra, with the same unit and H-action as for A, and moreover the map

$$\lambda: A \# H \to A_{F^{-1}} \# H_F, \ \lambda(a \# h) = \sum F^1 \cdot a \# F^2 h,$$

is an algebra isomorphism.

If H is a quasi-Hopf algebra, B an associative algebra and $v: H \to B$ an algebra map, then, following Ref. 6, we can introduce on the vector space B a left H-module algebra structure, denoted by B^v in what follows, for which the multiplication, unit and left H-action are

$$b \star b' = \sum v(X^1) b v(S(x^1 X^2) \alpha x^2 X_1^3) b' v(S(x^3 X_2^3)), \quad \forall\, b, b' \in B, \tag{2.31}$$

$$1_{B^v} = v(\beta), \tag{2.32}$$

$$h \triangleright_v b = \sum v(h_1) b v(S(h_2)), \quad \forall\, h \in H, b \in B. \tag{2.33}$$

If H is a quasi-Hopf algebra and A is a left H-module algebra, define the following maps:

$$j: H \to A \# H, \ j(h) = 1 \# h, \quad \forall\, h \in H, \tag{2.34}$$

$$i_0: A \to A \# H, \quad i_0(a) = \sum x^1 \cdot a \# x^2 \beta S(x^3), \quad \forall\, a \in A. \tag{2.35}$$

Then, by Ref. 6, j is an algebra map and i_0 is a morphism of left H-module algebras from A to $(A\#H)^j$. Moreover, the following universal property of the smash product $A\#H$ holds (see Ref. 6, Proposition 2.9): if B is an associative algebra, $v: H \to B$ is an algebra map and $\varphi: A \to B^v$ is a morphism of left H-module algebras, then there exists a unique algebra map $\varphi \# v: A\#H \to B$ such that $(\varphi \# v) \circ i_0 = \varphi$ and $(\varphi \# v) \circ j = v$; this map may be described explicitly as follows:

$$(\varphi \# v)(a \# h) = \sum v(X^1)\varphi(a)v(S(X^2)\alpha X^3 h), \quad \forall\, a \in A, \ h \in H. \tag{2.36}$$

Now recall from Ref. 6 the following concept.

Definition 2.1: Let H be a quasi-bialgebra and A a left H-module algebra. We say that M, a k-linear space, is a left A, H-module if

(i) M is a left H-module with action denoted by $h \otimes m \mapsto h \cdot m$.
(ii) A acts weakly on M to the left, i.e., there exists a k-linear map $A \otimes M \to M$, denoted by $a \otimes m \mapsto a \triangleright m$, such that $1_A \triangleright m = m$ for all $m \in M$.
(iii) The following compatibility relations hold:

$$a \triangleright (b \triangleright m) = \sum [(x^1 \cdot a)(x^2 \cdot b)] \triangleright (x^3 \cdot m), \tag{2.37}$$

$$h \cdot (a \triangleright m) = \sum (h_1 \cdot a) \triangleright (h_2 \cdot m), \tag{2.38}$$

for all $h \in H$, a, $b \in A$ and $m \in M$ (these conditions may be expressed equivalently by saying that M is a left A-module in the tensor category ${}_H\mathcal{M}$).

The category of all left A, H-modules, morphisms being the maps that are H-linear and preserve the A-action, will be denoted by ${}_{A,H}\mathcal{M}$.

Let $A\#H$-mod be the category of left $A\#H$-modules; we have the following result (see Ref. 6).

Proposition 2.2: Let H be a quasi-bialgebra and A a left H-module algebra. Then the categories ${}_{A,H}\mathcal{M}$ and $A\#H$-mod are isomorphic.

The isomorphism is given as follows. If $M \in A\#H$-mod with $A\#H$-module structure given by $(a\#h) \otimes m \mapsto (a\#h) \cdot m$, then $M \in {}_{A,H}\mathcal{M}$ with A-action given by $a \triangleright m = (a\#1) \cdot m$ and H-action given by $h \cdot m = (1\#h) \cdot m$. Conversely, if $M \in {}_{A,H}\mathcal{M}$, then M becomes a left $A\#H$-module with action $(a\#h) \cdot m = a \triangleright (h \cdot m)$.

III. OCTONIONS AND OTHER TWISTED GROUP QUASIALGEBRAS

Let G be a finite group, kG its group algebra and $k(G)$ the dual Hopf algebra of kG. We recall first the setting in Ref. 1, but in a quasi-Hopf framework (not dual quasi-Hopf as in Ref. 1). Let $T: G \times G \to k^*$ be an invertible map, with inverse $F: G \times G \to k^*$, such that $T(1,x) = T(x,1) = 1$ for all $x \in G$, and regard T and F as extended to $kG \otimes kG$, so we can regard them as elements in $k(G) \otimes k(G)$, where they become gauge transformations. So, we have the Hopf algebra $k(G)$, T a gauge transformation on it, and we have the left $k(G)$-module algebra kG [with the left regular action of $k(G)$ on kG, that is $p \rightharpoonup x = p(x)x$ for all $p \in k(G)$ and $x \in G$]. From the preliminaries, we know that we can consider the left $k(G)_T$-module algebra kG_F, and also that we have an algebra isomorphism,

$$kG_F \# k(G)_T \simeq kG \# k(G).$$

Let us mention that the multiplication in kG_F (denoted in Ref. 1 by $k_F G$), which is given by

$$x \cdot_F y = F(x,y)xy, \quad \forall\ x,y \in G,$$

is in general nonassociative, and that $k(G)_T$, though is a Hopf algebra (being commutative), is regarded here as a quasi-Hopf algebra, with reassociator obtained by extending the map $\phi: G \times G \times G \to k^*$ given by

$$\phi(x,y,z) = \frac{T(x,yz)T(y,z)}{T(xy,z)T(x,y)} = \frac{F(x,y)F(xy,z)}{F(y,z)F(x,yz)},$$

so in general kG_F is a $k(G)_T$-module algebra *only* in the quasi-Hopf sense (*not* in the Hopf sense).

Now, it is well known (see Ref. 16) that $kG\#k(G)$, which is the Heisenberg double of kG, is isomorphic as an algebra to the matrix algebra $M_{|G|}(k)$, where $|G|$ is the order of G. Since left kG_F, $k(G)_T$-modules coincide to left $kG_F\#k(G)_T$-modules, we get the following result.

Proposition 3.1: *The category of left kG_F, $k(G)_T$-modules is isomorphic to the category of left $M_{|G|}(k)$-modules.*

In particular, as proved in Ref. 1, the algebra $\mathcal{O}$ of octonions is of the form kG_F, for $G = Z_2 \times Z_2 \times Z_2$ (where Z_2 is the group with two elements) and a certain map F, so we get the following as a consequence.

Corollary 3.2: The category of modules over the octonions is isomorphic to the category of modules over the algebra of 8×8 real matrices.

IV. THE ENDOMORPHISM QUASIALGEBRA ASSOCIATED TO A MODULE

Lemma 4.1: Let H be a quasi-Hopf algebra, B, C associative algebras, $\eta: B \to C$, $j: H \to B$, $v: H \to C$ algebra maps such that $\eta \circ j = v$. Then the map $\eta: B^j \to C^v$ is a morphism of left H-module algebras.

Proof: Follows by a direct computation, using the formulas (2.31)–(2.33). □

Let H be a quasi-Hopf algebra and M a left H-module, with action denoted by $h \otimes m \mapsto h \cdot m$. Consider the (usual) associative algebra $\mathrm{End}(M)$ (with composition) and define $v: H \to \mathrm{End}(M)$, $v(h)(m) = h \cdot m$, which is an algebra map, so we can consider the left H-module algebra $\mathrm{End}(M)^v$, whose multiplication, unit and H-action are given as follows [using the formulas (2.31)–(2.33)]:

$$(u \star u')(m) = \sum X^1 \cdot u(S(x^1X^2)\alpha x^2 X_1^3 \cdot u'(S(x^3X_2^3) \cdot m)), \tag{4.1}$$

$$1_{\mathrm{End}(M)^v}(m) = v(\beta)(m) = \beta \cdot m, \tag{4.2}$$

$$(h \triangleright_v u)(m) = \sum h_1 \cdot u(S(h_2) \cdot m), \tag{4.3}$$

for all $h \in H$, $u, u' \in \mathrm{End}(M)^v$, $m \in M$.

Suppose now that we have also a left H-module algebra A, with notation $h \otimes a \mapsto h \cdot a$ and $a \otimes a' \mapsto aa'$. Our first aim is to prove the following result.

Theorem 4.2: *Setting a structure of a left A, H-module on M is equivalent to giving a morphism of left H-module algebras $\varphi: A \to End(M)^v$. The correspondence is given as follows: if M is a left A, H-module (with A-action denoted by $a \otimes m \mapsto a \triangleright m$) then the map $\varphi: A \to End(M)^v$ is given by*

$$\varphi(a)(m) = \sum (p^1 \cdot a) \triangleright (p^2 \cdot m), \quad \forall\ a \in A,\ m \in M, \tag{4.4}$$

where $p_R = \Sigma p^1 \otimes p^2 = \Sigma x^1 \otimes x^2 \beta S(x^3)$. Conversely, if $\varphi: A \to End(M)^v$ is a morphism of left H-module algebras, then M becomes a left A, H-module, with A-action given by

$$a \triangleright m = \sum q^1 \cdot \varphi(a)(S(q^2) \cdot m), \quad \forall\ a \in A,\ m \in M, \tag{4.5}$$

where $q_R=\Sigma q^1\otimes q^2=\Sigma X^1\otimes S^{-1}(\alpha X^3)X^2$, *and the H-action being the original H-module structure of M*.

Proof: Suppose first that M is a left A, H-module, with A-action $a\otimes m\mapsto a\triangleright m$. As we know, this is equivalent to M being a left $A\#H$-module, with structure

$$(a\#h)\cdot m=a\triangleright(h\cdot m),\quad \forall\, a\in A,\ h\in H,\ m\in M.$$

So, considering the usual associative algebra $\mathrm{End}(M)$, we obtain an algebra map $\eta:A\#H\to\mathrm{End}(M)$, $\eta(a\#h)(m)=(a\#h)\cdot m$. We also have the canonical algebra map $j:H\to A\#H$, $j(h)=1\#h$; since we obviously have that $\eta\circ j=v$, we may apply the previous lemma and obtain that the map $\eta:(A\#H)^j\to\mathrm{End}(M)^v$ is a morphism of left H-module algebras. It follows from the preliminaries that the map $i_0:A\to(A\#H)^j$, $i_0(a)=\Sigma p^1\cdot a\#p^2$, where $p_R=\Sigma p^1\otimes p^2=\Sigma x^1\otimes x^2\beta S(x^3)$, is a morphism of left H-module algebras, so the composition

$$\varphi=\eta\circ i_0:A\to\mathrm{End}(M)^v$$

is also a morphism of left H-module algebras, and one can easily check that it is given by

$$\varphi(a)(m)=\sum(p^1\cdot a)\triangleright(p^2\cdot m),\quad \forall\, a\in A,\ m\in M.$$

Conversely, let $\varphi:A\to\mathrm{End}(M)^v$ be a morphism of left H-module algebras; by applying the universal property of the smash product $A\#H$ (see Sec. II) for $B=\mathrm{End}(M)$, we obtain the algebra map $\varphi\#v:A\#H\to\mathrm{End}(M)$, which [using the formula (2.36)] may be expressed as follows:

$$(\varphi\#v)(a\#h)(m)=\sum q^1\cdot\varphi(a)(S(q^2)h\cdot m),\quad \forall\, a\in A,\ h\in H,\ m\in M.$$

Hence, M becomes a left $A\#H$-module (i.e., a left A, H-module) with action

$$(a\#h)\cdot m=\sum q^1\cdot\varphi(a)(S(q^2)h\cdot m),\quad \forall\, a\in A,\ h\in H,\ m\in M.$$

In particular, the A-action is given by

$$a\triangleright m=(a\#1)\cdot m=\sum q^1\cdot\varphi(a)(S(q^2)\cdot m),\quad \forall\, a\in A,\ m\in M,$$

and, using the fact that $\Sigma q^1\beta S(q^2)=1$ [which follows from the relation (2.6)], we obtain that the H-action is given by

$$(1\#h)\cdot m=\sum q^1\beta S(q^2)h\cdot m=h\cdot m,\quad \forall\, h\in H,\ m\in M.$$

Now the only thing left to prove is that the two correspondences are inverse to each other.

If M is an A, H-module with A-action denoted by $\triangleright$, if φ is the associated map $\varphi:A\to\mathrm{End}(M)^v$ and we denote by $\triangleright'$ the A-action associated to φ, we have (for all $a\in A$ and $m\in M$):

$$a\triangleright' m=\sum q^1\cdot((p^1\cdot a)\triangleright(p^2S(q^2)\cdot m))$$

$$(2.38)=\sum(q_1^1p^1\cdot a)\triangleright(q_2^1p^2S(q^2)\cdot m)$$

$$(2.19)=a\triangleright m.$$

Conversely, if $\varphi:A\to\mathrm{End}(M)^v$ is a left H-module algebra map, if $\triangleright$ is the A-action obtained from φ and φ' is the map obtained from this A, H-module structure on M, we have (for all $a\in A$ and $m\in M$)

$$\begin{aligned}\varphi'(a)(m) &= \sum (p^1 \cdot a) \triangleright (p^2 \cdot m)\\ &= \sum q^1 \cdot \varphi(p^1 \cdot a)(S(q^2)p^2 \cdot m)\\ &= \sum q^1 \cdot ((p^1 \triangleright_v \varphi(a))(S(q^2)p^2 \cdot m))\end{aligned}$$

$$\begin{aligned}(4.3) &= \sum q^1 \cdot (p_1^1 \cdot \varphi(a)(S(p_2^1)S(q^2)p^2 \cdot m))\\ &= \sum q^1 p_1^1 \cdot \varphi(a)(S(S^{-1}(p^2)q^2 p_2^1) \cdot m)\end{aligned}$$

$$(2.19) = \varphi(a)(m),$$

and the proof is complete. □

By taking in the Theorem $A = \mathrm{End}(M)^v$ and $\varphi = \mathrm{id}$, we obtain the following consequence:

Corollary 4.3: If H is a quasi-Hopf algebra and M is a left H-module, then M becomes a left $\mathrm{End}(M)^v$*, H-module [i.e., a left* $\mathrm{End}(M)^v \# H$*-module], with* $\mathrm{End}(M)^v$*-action given by*

$$u \triangleright m = \sum q^1 \cdot u(S(q^2) \cdot m), \tag{4.6}$$

for all $u \in \mathrm{End}(M)^v$, $m \in M$.

We study now the behavior of the construction $\mathrm{End}(M)^v$ under twisting. Namely, let H be a quasi-Hopf algebra, $F \in H \otimes H$ a gauge transformation and M a left H-module. Then M is also a left H_F-module, with the same H-action. Denote by $v: H \to \mathrm{End}(M)$ and $v_F: H_F \to \mathrm{End}(M)$ the corresponding algebra maps, and consider the H-module algebra $\mathrm{End}(M)^v$ and the H_F-module algebra $\mathrm{End}(M)^{v_F}$; we also consider the H_F-module algebra $\mathrm{End}(M)^v_{F^{-1}}$. In view of similar results concerning invariance under twisting, one might expect to have $\mathrm{End}(M)^{v_F} \equiv \mathrm{End}(M)^v_{F^{-1}}$, but in general this is not true. Nevertheless, we will prove that they are isomorphic as left H_F-module algebras.

Actually, we will prove something more general. Let H be a quasi-Hopf algebra, $F \in H \otimes H$ a gauge transformation, B an associative algebra, $v: H \to B$ an algebra map, which will be denoted by v_F when considered as a map from H_F to B.

Proposition 4.4: The map

$$\psi: B^v_{F^{-1}} \to B^{v_F}, \quad \psi(b) = \sum v(F^1) b v(S(F^2)), \quad \forall\, b \in B,$$

is an isomorphism of left H_F*-module algebras*.

Proof: The map ψ is obviously bijective, with inverse given by $\psi^{-1}(b) = \Sigma v(G^1) b v(S(G^2))$, for all $b \in B$, where $F^{-1} = \Sigma G^1 \otimes G^2$. Then one checks by a direct computation that ψ is a morphism of left H_F-module algebras, using the formulas for Δ_F, Φ_F, α_F, β_F and for the multiplications, units and actions in B^{v_F} and $B^v_{F^{-1}}$. □

By taking $B = \mathrm{End}(M)$, we obtain the following.

Corollary 4.5: $\mathrm{End}(M)^{v_F}$ *and* $\mathrm{End}(M)^v_{F^{-1}}$ *are isomorphic as left* H_F*-module algebras*.

If H is a quasi-Hopf algebra, the left H-module algebra H^{id_H} was denoted in Ref. 6 by H_0; its multiplication is given by

$$g \star h = \sum X^1 g S(x^1 X^2) \alpha x^2 X_1^3 h S(x^3 X_2^3), \quad \forall\, g, h \in H,$$

the unit is β and the left H-action is $h \triangleright h' = \Sigma h_1 h' S(h_2)$, for all h, $h' \in H$. Then, from the above proposition, we get also the following consequence (by taking $B = H$, $v = \mathrm{id}_H$ in the proposition):

Corollary 4.6: $(H_0)_{F^{-1}} \simeq (H_F)_0$ *as left* H_F*-module algebras, with an isomorphism given by* $\psi: (H_0)_{F^{-1}} \to (H_F)_0$, $\psi(h) = \Sigma F^1 h S(F^2)$ *for all* $h \in H$, *where* $F = \Sigma F^1 \otimes F^2$ *is a gauge transformation on H*.

For completeness' sake and further use, we also treat the case of right A-modules in ${}_H\mathcal{M}$.

Let H be a quasi-bialgebra and A a left H-module algebra. If we let A^{op} be A with opposite multiplication, then it is easy to see that A^{op} becomes a left H^{cop}-module algebra, with the same unit and H-action as for A.

If H is a quasi-Hopf algebra, B an associative algebra and $v:H\to B$ an algebra map, consider v as algebra map from H^{cop} to B and denote it by v_{cop}; then we have the left H^{cop}-module algebra $B^{v_{\mathrm{cop}}}$, and by the above $(B^{v_{\mathrm{cop}}})^{\mathrm{op}}$ becomes a left H-module algebra, which will be denoted by B_v. Its multiplication, unit and H-action are

$$b\cdot b'=\sum v(x^3)b'v(S^{-1}(\alpha X^3x^2)X^2x_2^1)bv(S^{-1}(X^1x_1^1)),\quad \forall\, b,b'\in B, \tag{4.7}$$

$$1_{B_v}=v(S^{-1}(\beta)), \tag{4.8}$$

$$h\to b=\sum v(h_2)bv(S^{-1}(h_1)),\quad \forall\, h\in H,\ b\in B. \tag{4.9}$$

Consequently, if M is a left H-module and $v:H\to\mathrm{End}(M)$ is the algebra map as before, we can consider the left H-module algebra $\mathrm{End}(M)_v$, whose structure is

$$(u\cdot u')(m)=\sum x^3\cdot u'(S^{-1}(\alpha X^3x^2)X^2x_2^1\cdot u(S^{-1}(X^1x_1^1)\cdot m)), \tag{4.10}$$

$$1_{\mathrm{End}(M)_v}(m)=S^{-1}(\beta)\cdot m, \tag{4.11}$$

$$(h\to u)(m)=\sum h_2\cdot u(S^{-1}(h_1)\cdot m), \tag{4.12}$$

for all $u,\ u'\in\mathrm{End}(M)_v$, $m\in M$, $h\in H$.

Now, if H is a quasi-bialgebra and A is a left H-module algebra, we can define a right A, H-module M as being a right A-module in ${}_H\mathcal{M}$. That is, M must be a left H-module, together with a right A-action $M\otimes A\to M$, $m\otimes a\mapsto m\triangleleft a$, with $m\triangleleft 1=m$ for all $m\in M$, such that

$$(m\triangleleft a)\triangleleft b=\sum (X^1\cdot m)\triangleleft[(X^2\cdot a)(X^3\cdot b)], \tag{4.13}$$

$$h\cdot(m\triangleleft a)=\sum (h_1\cdot m)\triangleleft(h_2\cdot a), \tag{4.14}$$

for all $h\in H$, $m\in M$, $ab\in A$.

It is easy to see that M being a right A, H-module is equivalent to M being a left A^{op}, H^{cop}-module (i.e., a left $A^{\mathrm{op}}\#H^{\mathrm{cop}}$-module). Then, if H is moreover a quasi-Hopf algebra and using also the fact that the elements p_R and q_R for H^{cop} may be expressed as $p_R^{\mathrm{cop}}=p_L^{21}$ and $q_R^{\mathrm{cop}}=q_L^{21}$, where p_L and q_L are the ones for H, by applying the theorem for A^{op}, H^{cop}, M, $\mathrm{End}(M)^{v_{\mathrm{cop}}}$, we obtain the following result.

Proposition 4.7: Let H be a quasi-Hopf algebra, A a left H-module algebra and M a left H-module. Then setting a structure of a right A, H-module on M is equivalent to giving a morphism of left H-module algebras $\eta:A\to End(M)_v$. The correspondence is given as follows: if M is a right A, H-module (with A-action denoted by $m\otimes a\mapsto m\triangleleft a$) then the map $\eta:A\to End(M)_v$ is given by

$$\eta(a)(m)=\sum(\tilde{p}^1\cdot m)\triangleleft(\tilde{p}^2\cdot a),\quad \forall\, a\in A,\ m\in M, \tag{4.15}$$

where $p_L=\Sigma\tilde{p}^1\otimes\tilde{p}^2=\Sigma X^2S^{-1}(X^1\beta)\otimes X^3$. Conversely, if $\eta:A\to End(M)_v$ is a morphism of left H-module algebras, then M becomes a right A,H-module, with A-action given by

$$m\triangleleft a=\sum\tilde{q}^2\cdot\eta(a)(S^{-1}(\tilde{q}^1)\cdot m),\quad \forall\, a\in A,\ m\in M, \tag{4.16}$$

where $q_L=\Sigma\tilde{q}^1\otimes\tilde{q}^2=\Sigma S(x^1)\alpha x^2\otimes x^3$, *and the H-action being the original H-module structure of* M.

As we have seen, the construction of $\mathrm{End}(M)_v$ was obtained from the one of $\mathrm{End}(M)^v$ by taking opposites and co-opposites. However, there is also another relation between the two constructions. Namely, if M is a left H-module, it is well known that on the linear dual of M we can introduce two left H-module structures, denoted by M^* and ${}^*M$, with H-actions $(h\cdot m^*)(m)=m^*(S(h)\cdot m)$, for all $h\in H$, $m\in M$, $m^*\in M^*$, respectively, $(h\cdot {}^*m)(m)={}^*m(S^{-1}(h)\cdot m)$ for all $h\in H$, $m\in M$, ${}^*m\in {}^*M$ [the corresponding algebra maps $H\to\mathrm{End}(M^*)$ and $H\to\mathrm{End}({}^*M)$ are denoted by v^*, respectively, ${}^*v$].

If $u:M\to M$ is a linear map, we denote by u^* its transpose given by $u^*(\xi)=\xi\circ u$ for all $\xi\in M^*$.

We have then the following result, which generalizes a part of Proposition 4.7 in Ref. 8.

Proposition 4.8: Let H be a quasi-Hopf algebra and M a left H-module. Then the map $u\mapsto u^*$ *gives H-module algebra morphisms* $End(M)^v\to End(M^*)_{v^*}$ *and* $End(M)_v\to End({}^*M)^{{}^*v}$, *which are isomorphisms if M is finite dimensional.*

Proof: Follows by a direct computation, using the formulas for the structures of the H-module algebras $\mathrm{End}(M)_v$, $\mathrm{End}(M^*)_{v^*}$, etc. □

Let again H be a quasi-bialgebra and A a left H-module algebra. We introduce now the concept of an A, H-bimodule, as being an A-bimodule in ${}_H\mathcal{M}$. That is, M must be a left H-module which is a left and a right A, H-module (with A-actions denoted by $\triangleright$ and $\triangleleft$) and such that

$$(a\triangleright m)\triangleleft b=\sum (X^1\cdot a)\triangleright[(X^2\cdot m)\triangleleft(X^3\cdot b)],\quad \forall\, a,b\in A,\ m\in M. \tag{4.17}$$

Recall now from Ref. 18 the following concept. Let $\mathcal{C}$ be a class of (not necessarily associative) algebras, $A\in\mathcal{C}$ and M a linear space with two linear actions $a\otimes m\mapsto a\triangleright m$ and $m\otimes a\mapsto m\triangleleft a$ of A on M. Then on the direct sum $A\oplus M$ one can introduce an algebra structure (called the *semidirect sum or split null extension*) by defining a multiplication in $A\oplus M$ by

$$(a+m)(a'+m')=aa'+(m\triangleleft a'+a\triangleright m'), \tag{4.18}$$

for all a, $a'\in A$ and m, $m'\in M$. Then, if $A\oplus M$ with this algebra structure is in $\mathcal{C}$, we say that M is an A-bimodule with respect to $\mathcal{C}$. If $\mathcal{C}$ is the class of all associative algebras or of all Lie algebras, we obtain the usual concepts of bimodule for these types of algebras. We have then the following result.

Proposition 4.9: Let H be a quasi-bialgebra, A a left H-module algebra and M a k-linear space. Then M is an A-bimodule with respect to the class of left H-module algebras (that is, $A\oplus M$ *is a left H-module algebra) if and only if M is an A, H-bimodule.*

Proof: If M is an A, H-bimodule, one can prove by a direct computation that $A\oplus M$ becomes a left H-module algebra. Conversely, if $A\oplus M$ is a left H-module algebra, then first M becomes a left H-module with structure induced from the one of $A\oplus M$. Then, if the unit of $A\oplus M$ is an element of the form a_0+m_0, writing down the unit condition we obtain first that a_0 should be 1_A, then that $1_A\triangleright m=m\triangleleft 1_A=m$ for all $m\in M$ and finally that $m_0=0$. Similarly, writing down the conditions for $A\oplus M$ to be a left H-module algebra, by taking properly particular values of the elements involved we obtain finally the conditions expressing the fact that M is an A, H-bimodule. □

V. THE FINITE DIMENSIONAL CASE

Let H be a quasi-Hopf algebra, A a left H-module algebra and M a *finite dimensional* left H-module. Then, by using the identification $\mathrm{End}(M)\simeq M\otimes M^*$, Albuquerque and Majid introduced in Ref. 1 a left H-module algebra structure on $\mathrm{End}(M)$, and, if M is also a left A, H-module, a morphism of left H-module algebras $A\to\mathrm{End}(M)$. Our aim now is to prove that they actually coincide with $\mathrm{End}(M)^v$ and $\varphi:A\to\mathrm{End}(M)^v$, respectively (notation as in the preceding section).

Let us recall some well-known facts, cf. Refs. 12 and 14. If H is a quasi-Hopf algebra and M is a left H-module, we consider the two left H-modules M^* (the left dual) and ${}^*M$ (the right dual) as before. If M is moreover finite dimensional and we fix $\{e_1,\dots,e_n\}$ a basis in M with $\{e^1,\dots,e^n\}$ its dual basis in M^*, then we have the k-linear maps,

$$ev_M: M^* \otimes M \to k,\quad coev_M: k \to M \otimes M^*, \tag{5.1}$$

$$ev_M(e^i \otimes e_j) = e^i(\alpha \cdot e_j),\quad coev_M(1) = \sum_{i=1}^{n} \beta \cdot e_i \otimes e^i, \tag{5.2}$$

$$ev'_M: M \otimes {}^*M \to k,\quad coev'_M: k \to {}^*M \otimes M, \tag{5.3}$$

$$ev'_M(e_i \otimes e^j) = e^j(S^{-1}(\alpha) \cdot e_i),\quad coev'_M(1) = \sum_{i=1}^{n} e^i \otimes S^{-1}(\beta) \cdot e_i \tag{5.4}$$

(the evaluation and coevaluation maps), which are H-linear and make M a *rigid* object in ${}_H\mathcal{M}$.

With this notation, let us recall from Ref. 1 that $M \otimes M^*$ becomes a left H-module algebra, as follows: the left H-module structure is the tensor product of M and M^*, and the multiplication is given by the formula

$$(\mathrm{id}_M \otimes (ev_M \otimes \mathrm{id}_{M^*})) \circ (\mathrm{id}_M \otimes a^{-1}_{M^*,M,M^*}) \circ a_{M,M^*,M\otimes M^*} \tag{5.5}$$

[as a map $(M \otimes M^*) \otimes (M \otimes M^*) \to M \otimes M^*$]. On the other hand, the map

$$\lambda: \mathrm{End}(M) \to M \otimes M^*,\quad \lambda(u) = \sum_{i=1}^{n} u(e_i) \otimes e^i,\quad \forall\, u \in \mathrm{End}(M)$$

is a linear isomorphism, with inverse

$$\lambda^{-1}: M \otimes M^* \to \mathrm{End}(M),\quad \lambda^{-1}(m \otimes \xi)(m') = \xi(m')m,\quad \forall\, m,m' \in M,\ \xi \in M^*,$$

so we can transfer the H-module algebra structure of $M \otimes M^*$ to $\mathrm{End}(M)$ via λ; let us denote by $\mathrm{end}(M)$ this H-module algebra structure on $\mathrm{End}(M)$ (this is the one appearing, with different notation, in Ref. 1).

Proposition 5.1: With notation as above, $\mathrm{end}(M)$ *and* $\mathrm{End}(M)^v$ *coincide as left H-module algebras.*

Proof: The fact that $\mathrm{end}(M) = \mathrm{End}(M)^v$ as left H-modules follows from the fact, proved in Ref. 7, that the map λ given above, considered as a map $\lambda: \mathrm{End}(M)^v \to M \otimes M^*$, is H-linear. So, we only have to prove that the multiplications of $\mathrm{end}(M)$ and $\mathrm{End}(M)^v$ coincide. Let us compute the multiplication in $\mathrm{end}(M)$. By using the identification $\mathrm{end}(M) \simeq M \otimes M^*$ via λ and by considering the multiplication as a map $\mathrm{end}(M) \otimes \mathrm{end}(M) \to M \otimes M^*$, the sequence of compositions in formula (5.5) looks as follows [for $u\ u' \in \mathrm{end}(M)$]:

$$\begin{aligned}
u \otimes u' &\mapsto \sum (u(e_i) \otimes e^i) \otimes (u'(e_j) \otimes e^j) \\
&\mapsto \sum X^1 \cdot u(e_i) \otimes (X^2 \cdot e^i \otimes (X^3_1 \cdot u'(e_j) \otimes X^3_2 \cdot e^j)) \\
&\mapsto \sum X^1 \cdot u(e_i) \otimes ((x^1X^2 \cdot e^i \otimes x^2X^3_1 \cdot u'(e_j)) \otimes x^3X^3_2 \cdot e^j) \\
&\mapsto \sum (x^1X^2 \cdot e^i)(\alpha x^2X^3_1 \cdot u'(e_j))X^1 \cdot u(e_i) \otimes x^3X^3_2 \cdot e^j \\
&= \sum e^i(S(x^1X^2)\alpha x^2X^3_1 \cdot u'(e_j))X^1 \cdot u(e_i) \otimes x^3X^3_2 \cdot e^j
\end{aligned}$$

$$= \sum X^1 \cdot u(S(x^1X^2)\alpha x^2X_1^3 \cdot u'(e_j)) \otimes x^3X_2^3 \cdot e^j,$$

so, if $m \in M$, the multiplication of end(M) is

$$\begin{aligned}(u \cdot u')(m) &= \sum (x^3X_2^3 \cdot e^j)(m)X^1 \cdot u(S(x^1X^2)\alpha x^2X_1^3 \cdot u'(e_j)) \\ &= \sum e^j(S(x^3X_2^3) \cdot m)X^1 \cdot u(S(x^1X^2)\alpha x^2X_1^3 \cdot u'(e_j)) \\ &= \sum X^1 \cdot u(S(x^1X^2)\alpha x^2X_1^3 \cdot u'(S(x^3X_2^3) \cdot m)),\end{aligned}$$

and one can see that this is exactly the multiplication of $\mathrm{End}(M)^v$. Moreover, the unit of $\mathrm{End}(M)^v$ coincides with $coev_M(1)$ after the identification $\mathrm{End}(M)^v \equiv M \otimes M^*$ via λ. □

Suppose now that M is not only a left H-module, but also a left A, H-module, where A is a left H-module algebra. Then Albuquerque and Majid constructed in Ref. 1 a map $\rho: A \to \mathrm{end}(M)$, which is a morphism of left H-module algebras, and which is given as follows:

$$\rho = \lambda^{-1} \circ (\triangleright \otimes \mathrm{id}_{M^*}) \circ a^{-1}_{A,M,M^*} \circ (\mathrm{id} \otimes coev_M). \tag{5.6}$$

Proposition 5.2: The left H-module algebra maps $\varphi: A \to \mathrm{End}(M)^v$ and $\rho: A \to \mathrm{end}(M)$ *coincide*.

Proof: Let us describe the map ρ explicitly. For $a \in A$, we have

$$\begin{aligned}\rho(a) &= \lambda^{-1} \circ (\triangleright \otimes \mathrm{id}_{M^*}) \circ a^{-1}_{A,M,M^*}\Big(a \otimes \Big(\sum \beta \cdot e_i \otimes e^i\Big)\Big) \\ &= \sum \lambda^{-1} \circ (\triangleright \otimes \mathrm{id}_{M^*})((x^1 \cdot a \otimes x^2\beta \cdot e_i) \otimes x^3 \cdot e^i) \\ &= \sum \lambda^{-1}((x^1 \cdot a) \triangleright (x^2\beta \cdot e_i) \otimes x^3 \cdot e^i),\end{aligned}$$

so, for $m \in M$, we obtain

$$\begin{aligned}\rho(a)(m) &= \sum (x^3 \cdot e^i)(m)(x^1 \cdot a) \triangleright (x^2\beta \cdot e_i) \\ &= \sum e^i(S(x^3) \cdot m)(x^1 \cdot a) \triangleright (x^2\beta \cdot e_i) \\ &= \sum (x^1 \cdot a) \triangleright (x^2\beta S(x^3) \cdot m) = \sum (p^1 \cdot a) \triangleright (p^2 \cdot m),\end{aligned}$$

and this is exactly the formula for $\varphi(a)(m)$, hence we have $\rho = \varphi$. □

Moreover, Albuquerque and Majid proved that if H is a quasi-Hopf algebra and M is a finite dimensional left H-module, then we have an action of end(M) on M, which, using the identification $\mathrm{end}(M) \simeq M \otimes M^*$ via λ, is given by the map

$$(\mathrm{id}_M \otimes ev_M) \circ a_{M,M^*,M}: (M \otimes M^*) \otimes M \to M. \tag{5.7}$$

Then, using the formulas for λ, ev_M and $a_{M,M^*,M}$, one can verify that this action coincides with the one given by the formula (4.6).

Suppose again that H is a quasi-Hopf algebra and M is a finite dimensional left H-module. Then, similarly to the definition of end(M), we can define another left H-module algebra structure on $\mathrm{End}(M)$, by first introducing one on $^*M \otimes M$ by the formula

$$((\mathrm{id}_{^*M} \otimes ev'_M) \otimes \mathrm{id}_M) \circ (a_{^*M,M,^*M} \otimes \mathrm{id}_M) \circ a^{-1}_{^*M \otimes M,^*M,M}$$

for the multiplication and $coev'_M(1)$ for the unit, and then transfering it to $\mathrm{End}(M)$ via the canonical linear isomorphism $\mathrm{End}(M) \simeq {}^*M \otimes M$. Then a similar computation yields the following result.

Proposition 5.3: The H*-module algebra structure induced on* $\mathrm{End}(M)$ *by the one of* $^*M \otimes M$ *coincides with* $\mathrm{End}(M)_v$.

We give now an application of the identification $\mathrm{End}(M)^v \equiv \mathrm{end}(M)$. Let us first recall from Ref. 15 that a (left) Yetter–Drinfeld module over H is a left H-module M, together with a left H-coaction on M and some compatibility conditions between the two structures, ensuring that if we take the category of Yetter–Drinfeld modules, it is just the center of the monoidal category of left H-modules (we refer to Ref. 15 for detail).

Suppose now that H is a quasi-Hopf algebra and M is a finite dimensional Yetter–Drinfeld module. The following result generalizes the corresponding one for Hopf algebras proved in Ref. 8.

Proposition 5.4: *End*$(M)^v$ *and End*$(M)_v$ *are algebras in the category of Yetter–Drinfeld modules over* H.

Proof: We give the proof only for $\mathrm{End}(M)^v$, it is similar for $\mathrm{End}(M)_v$. It was proved in Ref. 4 that M^*, the left dual of M, becomes also a Yetter–Drinfeld module, so $M \otimes M^*$ is a Yetter–Drinfeld module too; by the identification $\mathrm{End}(M)^v \equiv M \otimes M^*$ via λ we obtain that $\mathrm{End}(M)^v$ is also a Yetter–Drinfeld module. Since we already know that $\mathrm{End}(M)^v$ is an algebra in ${}_H\mathcal{M}$, the only thing left to prove would be that the multiplication and unit of $\mathrm{End}(M)^v$ intertwine the corresponding H-coaction on $\mathrm{End}(M)^v$; a direct proof of these facts would be quite technical and difficult (even for the unit). However, we can give an immediate proof using the identification $\mathrm{End}(M)^v \equiv \mathrm{end}(M)$. Namely, it was proved in Ref. 4 that ev_M and $coev_M$ are morphisms not only in ${}_H\mathcal{M}$, but also in the Yetter–Drinfeld category, so the multiplication (5.5) of $\mathrm{end}(M)$ is a morphism in the Yetter–Drinfeld category, and similarly for the unit of $\mathrm{end}(M)$, which is exactly $coev_M$, and we are done. Alternatively, we can obtain the result as a particular case of general results on braided tensor categories in Ref. 20. □

VI. SOME EXAMPLES OF ENDOMORPHISM QUASIALGEBRAS: HEISENBERG DOUBLES

We start this section by giving an example taken from Ref. 3, which will turn out to be of the type $\mathrm{End}(M)^v$. If H is a finite dimensional quasi-Hopf algebra, in Ref. 3 was constructed the so-called *quasi-smash product* $H\overline{\#}H^*$, which is a left H-module algebra structure built on $H \otimes H^*$, with multiplication, unit and H-action given, for all $h, h' \in H$ and $\xi, \xi' \in H^*$, by

$$(h\overline{\#}\xi)(h'\overline{\#}\xi') = \sum hh'_1x^1\overline{\#}(\xi \leftharpoonup h'_2x^2)(\xi' \leftharpoonup x^3), \tag{6.1}$$

$$1_{H\overline{\#}H^*} = 1_H\overline{\#}\varepsilon, \tag{6.2}$$

$$h \cdot (h'\overline{\#}\xi) = h'\overline{\#}h \rightharpoonup \xi, \tag{6.3}$$

where $\rightharpoonup$ and $\leftharpoonup$ are the left and right regular actions of H on H^* given by

$$(h \rightharpoonup \xi)(h') = \xi(h'h), \quad (\xi \leftharpoonup h)(h') = \xi(hh'). \tag{6.4}$$

Then, in Ref. 3 was constructed a linear isomorphism,

$$\mu: H\overline{\#}H^* \simeq \mathrm{End}(H), \quad \mu(h\overline{\#}\xi)(h') = \sum \xi(h'_2\tilde{p}^2)hh'_1\tilde{p}^1, \tag{6.5}$$

for all $h, h' \in H$ and $\xi \in H^*$, where $p_L = \Sigma\tilde{p}^1 \otimes \tilde{p}^2 = \Sigma X^2S^{-1}(X^1\beta) \otimes X^3$, with inverse

$$\mu^{-1}: \mathrm{End}(H) \to H\overline{\#}H^*, \quad \mu^{-1}(u) = \sum u(\tilde{q}^2(e_i)_2)S^{-1}(\tilde{q}^1(e_i)_1)\overline{\#}e^i, \tag{6.6}$$

for all $u \in \mathrm{End}(H)$, where $\{e_i\}$ and $\{e^i\}$ are dual bases in H and H^*, and $q_L = \Sigma\tilde{q}^1 \otimes \tilde{q}^2 = \Sigma S(x^1)\alpha x^2 \otimes x^3$. Then, the H-module algebra structure of $H\overline{\#}H^*$ was transfered to $\mathrm{End}(H)$ via μ, where it looks as follows (the multiplication, unit and H-action):

$$(u \underline{\circ} u')(h) = \sum u(u'(hx^3X_2^3)S^{-1}(S(x^1X^2)\alpha x^2X_1^3))S^{-1}(X^1), \tag{6.7}$$

$$1_{\mathrm{End}(H)} = S^{-1}(\beta) \rightharpoonup \mathrm{id}_H, \quad (h \cdot u)(h') = u(h'h_2)S^{-1}(h_1), \tag{6.8}$$

for all $u, u' \in \mathrm{End}(H)$ and $h, h' \in H$. Then one can easily check that this H-module algebra structure on $\mathrm{End}(H)$ is exactly $\mathrm{End}(M)^v$, where M is H regarded as a left H-module with action $h \cdot m = mS^{-1}(h)$ for all $m, h \in H$. The quasismash product $H\overline{\#}H^*$ was called the Heisenberg double of H (its multiplication generalizes the one in the usual Heisenberg double of a Hopf algebra), cf. Ref. 3. For reasons to be discussed below, we call it the *first* Heisenberg double of H and denote it by $\mathcal{H}_1(H)$.

To motivate this terminology, we discuss the case of the Heisenberg double $\mathcal{H}(H)$ of a finite dimensional Hopf algebra H. It is built on $H \otimes H^*$ and has the following tensor-categorical properties: it is a left $D(H)$-module algebra and a right $D(H)^{\mathrm{cop}}$-module algebra [and hence a $D(H)$, $D(H)^{\mathrm{cop}}$-bimodule algebra], where $D(H)$ is the Drinfeld double of H and the actions of $D(H)$ on $\mathcal{H}(H)$ are the left and right regular actions if we regard $\mathcal{H}(H) \equiv D(H)^*$ as linear spaces, see Refs. 13 and 17 for all these. In particular, $\mathcal{H}(H)$ is a left H-module algebra [with action $h \cdot (h' \# \xi) = h' \# h \rightharpoonup \xi$] and a right H^{cop}-module algebra.

Now, if one tries to define a quasi-Hopf analogue of the Heisenberg double, one should obtain the same tensor-categorical properties as in the Hopf case. But since the three tensor-categorical properties of the Heisenberg double normally cannot be satisfied simultaneously in the quasi-Hopf case, it follows that one might be looking for (at least) *three* Heisenberg doubles of a finite dimensional quasi-Hopf algebra. The first one then should be $\mathcal{H}_1(H) = H\overline{\#}H^*$ defined in Ref. 3, which is a left H-module algebra, and a construction for the third was proposed in Ref. 17, providing a $D(H)$, $D(H)^{\mathrm{cop}}$-bimodule algebra. Now we propose a definition for the second one, which will be a right H^{cop}-module algebra and will be realized also as an endomorphism quasialgebra.

Again we start with a general construction. If H is a quasi-bialgebra and A is a left H-module algebra with action $h \otimes a \mapsto h \cdot a$, then one can prove that A^{op} becomes a right $H^{\mathrm{op\ cop}}$-module algebra, with action $a \cdot h = h \cdot a$. Then we have the following result.

Proposition 6.1: Let H be a quasi-Hopf algebra, B an associative algebra and $v: H \to B$ an algebra map. Define a new multiplication on B by

$$b \odot b' = \sum v(S^{-1}(x_2^3X^3))bv(x_1^3X^2S^{-1}(x^2X^1\beta))b'v(x^1), \quad \forall\, b, b' \in B, \tag{6.9}$$

and denote by ${}^vB$ this structure. Then ${}^vB$ becomes a right H^{cop}-module algebra, with unit $v(S^{-1}(\alpha))$ and right H-action on ${}^vB$ given by

$$b_v \triangleleft h = \sum v(S^{-1}(h_2))bv(h_1), \tag{6.10}$$

for all $h \in H$ and $b \in {}^vB$, where $\Delta(h) = \Sigma h_1 \otimes h_2$ is the comultiplication of H.

Proof: Since v is an algebra map, $v: H^{\mathrm{op}} \to B^{\mathrm{op}}$ is also an algebra map, which will be denoted by v^{op}. Then we can consider $(B^{\mathrm{op}})^{v^{\mathrm{op}}}$, which is a left H^{op}-module algebra, hence, by the above remark, we get that $((B^{\mathrm{op}})^{v^{\mathrm{op}}})^{\mathrm{op}}$ becomes a right $(H^{\mathrm{op}})^{\mathrm{op\ cop}} = H^{\mathrm{cop}}$-module algebra, and one can easily see that ${}^vB$ is exactly this $((B^{\mathrm{op}})^{v^{\mathrm{op}}})^{\mathrm{op}}$. □

In particular we may take $B = H$, $v = \mathrm{id}_H$, and obtain a right H^{cop}-module algebra structure on H, or we may take M to be a left H-module and the map $v: H \to \mathrm{End}(M)$ as before, and we get a right H^{cop}-module algebra ${}^v\mathrm{End}(M)$.

We are now interested in the case when $M = H$ with the left regular action on itself, so we have the algebra map $v: H \to \mathrm{End}(H)$, $v(h)(h') = hh'$, and we can consider the right H^{cop}-module algebra ${}^v\mathrm{End}(H)$. Let us record that the right H-action on ${}^v\mathrm{End}(H)$ is given by $(u_v \triangleleft h)(h') = \Sigma S^{-1}(h_2)u(h_1h')$, for all $h, h' \in H$ and $u \in {}^v\mathrm{End}(H)$, where $\Delta(h) = \Sigma h_1 \otimes h_2$ is the comultiplication

of H. We propose this ${}^v\mathrm{End}(H)$ as the *second* Heisenberg double of H and denote it by $\mathcal{H}_2(H)$. This proposal will be supported by the next results.

Suppose now that H is moreover finite dimensional. Then, besides the isomorphism μ introduced in Ref. 3, we can construct another linear isomorphism between $H\otimes H^*$ and $\mathrm{End}(H)$, namely,

$$\nu: H\otimes H^* \to \mathrm{End}(H),\quad \nu(h\otimes\xi)(h') = \sum \xi(X^2 h'_2 \tilde{p}^2) S^{-1}(X^3) h X^1 h'_1 \tilde{p}^1,$$

for all $h,h'\in H$ and $\xi\in H^*$; one can prove as in Ref. 3 that its inverse is given by

$$\nu^{-1}: \mathrm{End}(H) \to H\otimes H^*,\quad \nu^{-1}(u) = \sum S^{-1}(x^3) u(\tilde{q}^2 (e_i)_2) S^{-1}(\tilde{q}^1 (e_i)_1) x^1 \otimes e^i \leftharpoonup x^2,$$

for all $u\in\mathrm{End}(H)$.

Now, we consider on $\mathrm{End}(H)$ the right H^{cop}-module algebra structure ${}^v\mathrm{End}(H)$, and we can transfer it to $H\otimes H^*$ via the isomorphisms μ or ν, thus obtaining two (isomorphic) right H^{cop}-module algebra structures on $H\otimes H^*$.

Proposition 6.2: If we denote by $\leftharpoonup$, *respectively* $\leftharpoondown$, *the right H-module structures of* $H\otimes H^*$ *obtained by transfer via* μ, *respectively* ν, *then* $\leftharpoonup$ *and* $\leftharpoondown$ *look as follows*:

$$(h'\otimes\xi)\leftharpoonup h = \sum S^{-1}(h_2) h' h_{(1,1)} \otimes \xi \leftharpoonup h_{(1,2)}, \tag{6.11}$$

$$(h'\otimes\xi)\leftharpoondown h = \sum S^{-1}(h_{(2,2)}) h' h_1 \otimes \xi \leftharpoonup h_{(2,1)}, \tag{6.12}$$

for all $h,h'\in H$ *and* $\xi\in H^*$, *where* $\Delta(h)=\Sigma h_1\otimes h_2$ *is the comultiplication of H*.

Proof: We give the proof only for $\leftharpoonup$, the one for $\leftharpoondown$ is similar. We compute $(h'\otimes\xi)\leftharpoonup h \in H\otimes H^*$ by applying it to an element $g\in H$ on the second component. We have

$$\begin{aligned}((h'\otimes\xi)\leftharpoonup h)(g) &= \mu^{-1}(\mu(h'\otimes\xi)_v \triangleleft h)(g)\\ &= \sum (\mu(h'\otimes\xi)_v \triangleleft h)(\tilde{q}^2 g_2) S^{-1}(\tilde{q}^1 g_1)\\ &= \sum (v(S^{-1}(h_2))\mu(h'\otimes\xi) v(h_1))(\tilde{q}^2 g_2) S^{-1}(\tilde{q}^1 g_1)\\ &= \sum S^{-1}(h_2)\mu(h'\otimes\xi)(h_1\tilde{q}^2 g_2) S^{-1}(\tilde{q}^1 g_1)\\ &= \sum S^{-1}(h_2)\xi(h_{(1,2)}\tilde{q}^2_2 g_{(2,2)}\tilde{p}^2) h' h_{(1,1)}\tilde{q}^2_1 g_{(2,1)}\tilde{p}^1 S^{-1}(g_1) S^{-1}(\tilde{q}^1)\\ (2.22) &= \sum \xi(h_{(1,2)}\tilde{q}^2_2\tilde{p}^2 g) S^{-1}(h_2) h' h_{(1,1)}\tilde{q}^2_1\tilde{p}^1 S^{-1}(\tilde{q}^1)\\ (2.20) &= \sum \xi(h_{(1,2)} g) S^{-1}(h_2) h' h_{(1,1)} = \sum (S^{-1}(h_2) h' h_{(1,1)} \otimes \xi \leftharpoonup h_{(1,2)})(g),\end{aligned}$$

and the proof is finished. □

Now, let H be a finite dimensional quasi-Hopf algebra. We recall from Refs. 10 and 11 the two realizations of the quantum double of H built on $H^*\otimes H$, hereafter denoted by $D_1(H)$ and $D_2(H)$, whose multiplications are, respectively, given, for all $\xi,\xi'\in H^*$ and $h,h'\in H$, by

$$(\xi\otimes h)(\xi'\otimes h') = \sum (\Omega^1 \rightharpoonup \xi \leftharpoonup \Omega^5)(\Omega^2 h_{(1,1)} \rightharpoonup \xi' \leftharpoonup S^{-1}(h_2)\Omega^4) \otimes \Omega^3 h_{(1,2)} h',$$

$$(\xi\otimes h)(\xi'\otimes h') = \sum (\omega^1 \rightharpoondown \xi \leftharpoondown \omega^5)(\omega^2 h_1 \rightharpoondown \xi' \leftharpoondown S^{-1}(h_{(2,2)})\omega^4) \otimes \omega^3 h_{(2,1)} h',$$

where $\Omega=\Sigma\Omega^1\otimes\cdots\otimes\Omega^5$, $\omega=\Sigma\omega^1\otimes\cdots\otimes\omega^5\in H^{\otimes 5}$ are given by

$$\Omega = \sum X^1_{(1,1)} x^1 y^1 \otimes X^1_{(1,2)} x^2 y^2_1 \otimes X^1_2 x^3 y^2_2 \otimes S^{-1}(f^1 X^2 y^3) \otimes S^{-1}(f^2 X^3), \tag{6.13}$$

$$\omega = \sum x^1 \otimes x^2 Y^1 \otimes x_1^3 X^1 Y_1^2 \otimes S^{-1}(f^1 x_{(2,1)}^3 X^2 Y_2^2) \otimes S^{-1}(f^2 x_{(2,2)}^3 X^3 Y^3), \tag{6.14}$$

and where $f=\Sigma f^1 \otimes f^2$ is the twist defined in (2.15).

Using these formulas, one can prove that the comultiplications of $D_1(H)^*$ and $D_2(H)^*$ (both identified with $H \otimes H^*$ as linear spaces), dual to the above multiplications, are given by

$$\Delta_{D_1(H)^*}(h \otimes \xi) = \sum (\Omega^5 h_1 \Omega^1 \otimes [e^i(\xi_1 \leftharpoonup \Omega^3)]e^j) \otimes (S^{-1}(e_j)\Omega^4 h_2 \Omega^2 e_i \otimes \xi_2), \tag{6.15}$$

$$\Delta_{D_2(H)^*}(h \otimes \xi) = \sum (\omega^5 h_1 \omega^1 \otimes e^i[(\xi_1 \leftharpoonup \omega^3)e^j]) \otimes (S^{-1}(e_j)\omega^4 h_2 \omega^2 e_i \otimes \xi_2), \tag{6.16}$$

for all $h \in H$ and $\xi \in H^*$, where $\Delta(\xi)=\Sigma \xi_1 \otimes \xi_2$ is the comultiplication of H^* and $\{e_i\}$ and $\{e^i\}$ are dual bases in H and H^*. Using these formulas, one can prove that the right regular actions of $D_1(H)$ on $D_1(H)^*$ and of $D_2(H)$ on $D_2(H)^*$, respectively, look as follows:

$$(h' \otimes \xi) \leftharpoonup (\xi' \otimes h) = \sum \xi'(\Omega^5 h_1' \Omega^1) S^{-1}(h_2) \Omega^4 h_2' \Omega^2 h_{(1,1)} \otimes \xi \leftharpoonup \Omega^3 h_{(1,2)},$$

$$(h' \otimes \xi) \leftharpoonup (\xi' \otimes h) = \sum \xi'(\omega^5 h_1' \omega^1) S^{-1}(h_{(2,2)}) \omega^4 h_2' \omega^2 h_1 \otimes \xi \leftharpoonup \omega^3 h_{(2,1)},$$

for all $h, h' \in H$ and $\xi, \xi' \in H^*$. By taking $\xi' = \varepsilon$ in these formulas, we get two right H-module structures on $H \otimes H^*$, and one can easily see that they are exactly (6.11) and (6.12).

Let us mention that, if the proposed definitions of $\mathcal{H}_1(H)$ and $\mathcal{H}_2(H)$ are natural, they should be not only left H and, respectively, right H^{cop}-module algebras, but also left $D(H)$ and, respectively, right $D(H)^{\mathrm{cop}}$-module algebras, but so far we have not been able to prove this (direct computations are very cumbersome).

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 45, NUMBER 10 OCTOBER 2004

Frobenius monads and pseudomonoids

Ross Street[a)]
Centre of Australian Category Theory, Macquarie University, New South Wales 2109, Australia

(Received 26 February 2004; accepted 7 June 2004; published 12 October 2004)

Six equivalent definitions of Frobenius algebra in a monoidal category are provided. In a monoidal bicategory, a pseudoalgebra is Frobenius if and only if it is star autonomous. Autonomous pseudoalgebras are also Frobenius. What it means for a morphism of a bicategory to be a projective equivalence is defined; this concept is related to "strongly separable" Frobenius algebras and "weak monoidal Morita equivalence." Wreath products of Frobenius algebras are discussed. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1788852]

I. INTRODUCTION

Over the last two decades, the relevance of categories to physics has become widely acknowledged in at least two particular areas: quantum group theory (QGT) [see Joyal and Street (1991), Kassel (1995), Majid (1995)] and topological quantum field theory (TQFT) [see Kock (2003) and Kerler and Volodymyr (2001)]. Quantum groups arise from the Yang–Baxter equation of statistical mechanics, while each quantum group has a monoidal (or "tensor") category of representations. A two-dimensional TQFT can be regarded as a tensor-preserving functor from a monoidal category of 2-cobordisms to the category of vector spaces. Monoidal categories can be used to construct the known three-dimensional TQFTs while some four-dimensional TQFTs can be constructed using monoidal bicategories (see Baez). Both QGT and TQFT feature categories whose morphisms come from low-dimensional topology (braids, links, tangles, surfaces, and so on). Mainly for the benefit of readers from mathematical physics, in this introduction and the next section, we will warm up to the categorical notions just mentioned and a few others we require.

Of course, the use in physics of (classical) groups and their representations goes back many score years. A lot of information about a group G is contained in its characters. Characters are group morphisms from G into the multiplicative monoid of an appropriate field k. In other words, we find a category (in this case the category of monoids) where G and k both live as objects so that it makes sense to look at morphisms between these objects.

Representations reveal even more about G than characters yet can be introduced using the same philosophy. The group G can be regarded as a category ΣG having only one object and every morphism invertible. Although this could be taken as the definition of group, it is often helpful to maintain a notational distinction between the group and the one-object category (after all, groups can be defined in alternative categorical terms as discrete closed monoidal categories). We think of ΣG as a kind of suspension of G, where the morphisms of ΣG are the elements of G. Since we have put G into the category Cat of categories, we can look at morphisms from ΣG into other categories such as the category Vect_k of vector spaces over k. These are precisely linear representations of the group G: a morphism of categories $F:\Sigma G \to \mathrm{Vect}_k$ (functor) takes the one object of ΣG to the vector space underlying the representation and the morphisms of ΣG to action by those group elements.

This paper is concerned with the identification of mathematical structure on objects of interest. The structure of particular interest is an abstraction of Frobenius algebra; we will soon recall the

[a)]Electronic mail: street@math.mq.edu.au

basic concept. The connection between TQFT and Frobenius algebras is pointed out in Kock (2003) and we proceed to outline how that works. Some connection between quantum groups and Frobenius algebras is already apparent from the fact that quantum groups are Hopf algebras and finite-dimensional Hopf algebras are Frobenius [Larson and Sweedler (1969)]. We intend to deepen the connection between Frobenius algebras and quantum group theory.

A k-algebra A is called *Frobenius* when it is equipped with an exact pairing

$$\sigma: A \otimes A \to k$$

satisfying the condition

$$\sigma((ab) \otimes c) = \sigma(a \otimes (bc))$$

for all elements a, b and c of A. (The exact bilinear pairing in the sense of monoidal category theory here means that A is finite dimensional as a vector space and the pairing provides an isomorphism between A and its linear dual.) In fact, σ is determined by a linear function $\varepsilon: A \to k$ via the formulas $\varepsilon(a) = \sigma(1, a)$ and $\sigma(a, b) = \varepsilon(ab)$. The group algebra kG of any finite group G is Frobenius when equipped with the form σ that has $\sigma(x, y) = 1$ if and only if $xy = 1$.

We shall recall in Sec. II how each Frobenius algebra becomes a coalgebra. However, in the case where the Frobenius algebra comes from a finite-dimensional Hopf algebra, this coalgebra is not the same as the coalgebra underlying the Hopf algebra. For one thing, a morphism of Frobenius algebras (preserving the algebra and coalgebra structure) is invertible [see Kock (2003); Sec. III D], whereas Hopf algebra morphisms between group algebras are in bijection with group morphisms.

Each commutative Frobenius algebra determines (uniquely up to isomorphism) a two-dimensional TQFT; that is, a tensor-preserving functor from the monoidal category 2-Cob of two-dimensional cobordisms to Vect_k. More precisely, the category of commutative Frobenius k-algebras is equivalent to the category of symmetric strong-monoidal functors from 2-Cob to Vect_k [see Kock (2003), Theorem 3.3.2]. Both of these categories are actually groupoids: every morphism is invertible. We already mentioned this fact for Frobenius algebras, while the monoidal category 2-Cob is *autonomous* (that is, its objects all have both left and right duals) and this already implies that every morphism between 2D TQFTs is invertible.

A category $\mathcal{V}$ is *monoidal* when it is equipped with a functor $\otimes: \mathcal{V} \times \mathcal{V} \to \mathcal{V}$ (called the *tensor product*), an object I of V (called the *tensor unit*), and three natural families of isomorphisms

$$(A \otimes B) \otimes C \cong A \otimes (B \otimes C), \quad I \otimes A \cong A \cong A \otimes I$$

in $\mathcal{V}$ (called *associativity* and *unital constraints*), such that the pentagon, involving the five ways of bracketing four objects, commutes, and the associativity constraint with $B = I$ is compatible with the unit constraints. Call $\mathcal{V}$ *braided* when it is equipped with a natural family of isomorphisms

$$c_{A,B}: A \otimes B \cong B \otimes A$$

(called the *braiding*) satisfying two conditions (one expressing $c_{A \otimes B,C}$ in terms of associativity constraints, $1_A \otimes c_{B,C}$ and $c_{C,A} \otimes 1_B$, and a similar one for $c_{A,B \otimes C}$). A braiding is a *symmetry* when $c_{B,A} \circ c_{A,B} = 1_{A \otimes B}$. A monoidal category is called *strict* when the associativity and unital constraints are identities.

Monoids can be defined in any monoidal category $\mathcal{V}$. A *monoid* in $\mathcal{V}$ is an object A equipped with a multiplication $\mu: A \otimes A \to A$ and a unit $\eta: I \to A$ satisfying unital and associativity conditions. A monoid in the category Set of sets, where the tensor product is cartesian product, is a monoid in the usual sense. If we use the coproduct (disjoint union) in Set as tensor product, every set has a unique monoid structure. A monoid in Vect_k, with the usual tensor product of vector spaces, is precisely a k-algebra; monoids in monoidal k-linear categories are also sometimes called algebras. A monoid in the category Cat of categories (where the morphisms are functors and the tensor product is a Cartesian product) is a strict monoidal category. For any category $\mathcal{A}$, the category $[\mathcal{A}, \mathcal{A}]$ of endofunctors on A becomes strict monoidal by taking composition as the

tensor product: a monoid in $[\mathcal{A},\mathcal{A}]$ is called a *monad* on $\mathcal{A}$ [see MacLane (1971) for the theory of monads and their algebras].

Frobenius structure on a monoid makes sense in any monoidal category. We recall this in Sec. II, where we assemble some facts about Frobenius monoids. Many of the facts are scattered throughout the literature. To begin with, for a concrete case that denies us the luxury of symmetry, we express the results in terms of monads on categories; but clearly the results carry over to monoids in general monoidal categories.

In a symmetric (or even braided) monoidal category we can define commutative monoids. In fact, what is shown in Kock (2003) is that 2-Cob possesses a distinguished commutative Frobenius monoid and that every commutative Frobenius monoid in every symmetric monoidal category is the image, under an essentially unique symmetric monoidal functor, of the distinguished one.

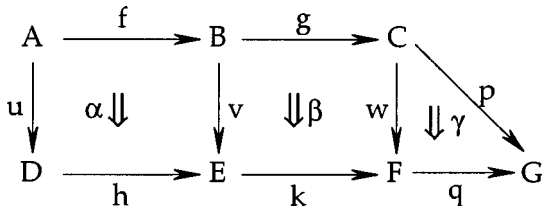
Notice from the above discussion that it is the strict monoidal categories, and not the general ones, that are genuinely examples of monoids in Cat. The reason nonstrictness arises is that Cat is a 2-category: natural transformations between the functors provide Cat with the two-dimensional structure of *2-morphisms* or *2-cells* and their compositions. Cartesian product is compatible with the 2-cells and so Cat is actually a *monoidal 2-category*.

Composition of functors is strictly associative so Cat itself is stricter than it might be in the two-dimensional setting. This leads to a weaker version of 2-category due to Bénabou (1967). A *bicategory* $\mathcal{B}$ has *objects*, and, for objects A and B, we have a category $\mathcal{B}(A,B)$ (called a *hom-category*) whose objects are called *morphisms* $f:A\to B$ of $\mathcal{B}$, whose morphisms are called *2-cells* $\theta:f\Rightarrow g:A\to B$ of $\mathcal{B}$, and whose composition is called *vertical composition* in B; there are functors

$$-\circ-:\mathcal{B}(B,C)\times\mathcal{B}(A,B)\to\mathcal{B}(A,C)$$

(called *horizontal composition*) and morphisms $1_A:A\to A$ (called *identity morphisms*). Horizontal composition is associative with units the identity morphisms: but only up to invertible 2-cells that are just like the associativity and unital constraints of a monoidal category. In fact, for each object A, the category $\mathcal{B}(A,A)$ becomes monoidal by using the horizontal composition as tensor product; this is the two-dimensional version of the fact that endomorphism sets in any category are monoids. An object A together with a monoid t, η, μ in the monoidal category $\mathcal{B}(A,A)$ is called a *monad* in $\mathcal{B}$. Each monoidal category $\mathcal{V}$ can be regarded as a bicategory $\Sigma\mathcal{V}$ with one object; the endohom of that object is $\mathcal{V}$ and the horizontal composition is the tensor product of $\mathcal{V}$.

In a bicategory, Bénabou introduced the operation of *pasting* which is applied to diagrams such as

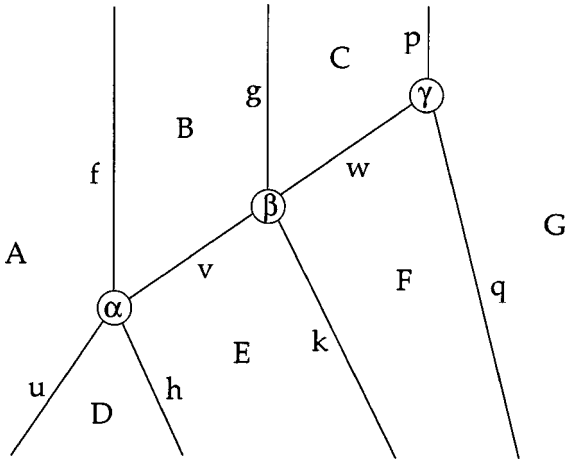


in which the left square depicts a 2-cell $\alpha:v\circ f\Rightarrow h\circ u$, the middle square depicts a 2-cell $\beta:w\circ g\Rightarrow k\circ v$ and the right triangle depicts a 2-cell $\gamma:p\Rightarrow q\circ w$. Once a bracketing is chosen for the upper path $p\circ g\circ f$ yielding a morphism $s:A\to G$ and a bracketing is chosen for the lower path $q\circ k\circ h\circ u$ yielding a morphism $t:A\to G$, there is a unique 2-cell $\sigma:s\Rightarrow t$ determined by the diagram using the compositions and constraints of the bicategory; we call σ the *pasting composite* of the diagram. In the exemplary diagram, taking $s=p\circ(g\circ f)$ and $t=q\circ(k\circ(h\circ u))$, we obtain σ as the composite

$$p\circ(g\circ f)\overset{\alpha\circ(g\circ f)}{\to}(q\circ w)\circ(g\circ f)\cong q\circ((w\circ g)\circ f)\overset{q\circ(\beta\circ f)}{\to}q\circ((k\circ v)\circ f)$$

$$\cong q\circ(k\circ(v\circ f))\overset{q\circ(k\circ\alpha)}{\to}q\circ(k\circ(h\circ u))$$

in the category $\mathcal{B}(A,G)$. For simplicity we sometimes ignore the brackets and constraints in describing such composites (that is, we act as if we were in a 2-category). String diagrams can also be used: suffice it to say here that the string diagram corresponding to our pasting diagram is as follows where the 2-cells label vertices, the morphisms label edges, and the objects label faces.



Each bicategory $\mathcal{B}$ has *duals* $\mathcal{B}^{\mathrm{op}}$, $\mathcal{B}^{\mathrm{co}}$, and $\mathcal{B}^{\mathrm{coop}}$: the first has morphisms reversed, the second has 2-cells reversed, while the third has both morphisms and 2-cells reversed.

In any bicategory B, we can define *adjoint morphisms*: we say $u:A\to B$ is right adjoint to $f:B\to A$ when there are 2-cells

$$\varepsilon:f\circ u\Rightarrow 1_A:A\to A \quad\text{and}\quad \eta:1_B\Rightarrow u\circ f:B\to B$$

(called the *counit* and *unit*) satisfying the following 2-cell equations: $(\varepsilon\circ f)(f\circ\eta)=1_f$ and $(u\circ\varepsilon)(\eta\circ u)=1_u$ (the reader might like to draw the pasting and string diagrams as an exercise). We say u is an *equivalence* when it is right adjoint to an f with invertible counit and unit (actually, in this case we do not need to have the 2-cell equations; the unit can always be rechosen so that they hold). If u is right adjoint to f, then B together with $t=u\circ f$ form a monad in B with unit η and multiplication $u\circ\varepsilon\circ f$.

For any morphism $f:X\to Y$ in the bicategory, we write $f^*:Y\to X$ for a right adjoint should there be one.

An object U of a monoidal category $\mathcal{V}$ is said to be *right dual* to an object V when the morphism U is right adjoint to V in the bicategory $\Sigma\mathcal{V}$. For example, a vector space U is a right dual in Vect_k if and only if U is finite dimensional; in this case, U is right dual to the space $\mathrm{Vect}_k(U,k)$ of linear functions from U to k. A monoidal category is called *right autonomous* when every object has a right dual; it is called *autonomous* when every object has both a left and right dual. If V is symmetric then every right dual is also a left dual.

There is a weaker kind of monoidal duality that was conceived by Barr [see Barr (1979, 1995, 1996)] based on examples in topological algebra yet the notion has received a lot of attention by computer scientists interested in Girard's "linear logic." A monoidal category $\mathcal{V}$ is said to be **-autonomous* when there is an equivalence of categories $S:\mathcal{V}\to\mathcal{V}^{\mathrm{op}}$ and a natural family of isomorphisms

$$\mathcal{V}(U \otimes V, I) \cong \mathcal{V}(V, SU).$$

Each autonomous monoidal $\mathcal{V}$ is *-autonomous with SU a right dual for U; the existence of left duals is needed for this S to be an equivalence.

If $\mathcal{B}$ and $\mathcal{D}$ are bicategories, a *lax functor* (or "morphism") $F: \mathcal{B} \to \mathcal{D}$ consists of a function between the sets of objects together with functors

$$F_{A,B}: \mathcal{B}(A,B) \to \mathcal{D}(FA, FB)$$

and 2-cells $F_{B,C}(g) \circ F_{A,B}(f) \Rightarrow F_{A,C}(g \circ f)$, natural in f and g, and $1_{FA} \Rightarrow F(1_A)$; these 2-cells satisfy three conditions very much like associativity and unital conditions for a monoid. When these structural 2-cells are all invertible the lax functor is called a *pseudofunctor* (or "homomorphism"). A *biequivalence* is a pseudofunctor F for which each $F_{A,B}$ is an equivalence of categories and, for each object D of $\mathcal{D}$, there is an object A of B and an equivalence $FA \xrightarrow{\sim} D$. Every bicategory is biequivalent to a 2-category (giving some justification for leaving out constraints when writing equations).

Between pseudofunctors there are *pseudonatural transformations*: these are a two-dimensional version of natural transformation in which the naturality equations are "broken" by asking them to hold only up to extra invertible 2-cells that satisfy some further conditions [see Kelly and Street (1974), for example]. There is a bicategory $\mathrm{Hom}(\mathcal{B}, \mathcal{D})$ whose objects are the pseudofunctors from $\mathcal{B}$ to $\mathcal{D}$, whose morphisms are the pseudonatural transformations, and whose 2-cells are called *modifications*. We shall only have need of modifications in one place in this paper (in defining "scalars") and there we shall spell out exactly what we mean.

A 2-category can be defined to be a strict bicategory: one in which the associativity and unital constraints are identities. So Cat is special among bicategories; it is strict. Cartesian product is also special among monoidal structures on bicategories; it is stricter in many ways than required of a general monoidal bicategory. A bicategory B is *monoidal* when it is equipped with a pseudofunctor $\otimes: \mathcal{B} \times \mathcal{B} \to \mathcal{B}$ and an object I together with associativity and unital constraints much like a monoidal category except that they need only be equivalences rather than isomorphisms and they need only satisfy the conditions up to further selected isomorphisms that themselves satisfy conditions. Monoidal bicategories are not all monoidally biequivalent to monoidal 2-categories but some degree of strictness can be attained. We do not need more detail than this; however, the interested reader can consult Day and Street (1997) and McCrudden (1999).

In any monoidal bicategory it is possible to define *pseudomonoids*; these are like monoids except that the associativity and unital conditions only hold up to invertible 2-cells that are called *associativity and unit constraints*; they are required to satisfy conditions that are said to express *coherence*; again, a reference is Day and Street (1997). In particular, a pseudomonoid in Cat is precisely a monoidal category. Hence a pseudomonoid is also called a "monoidal object" of the monoidal bicategory.

In Sec. III we continue this review of categorical structures highlighting enriched categories.

In Sec. IV we define what it means for a pseudomonoid in any monoidal bicategory to be Frobenius. It is an easy corollary of results of Day *et al.* (2003) that every autonomous pseudomonoid (whose unit has a right adjoint) is Frobenius. As we have mentioned, finite dimensional Hopf algebras are known to be Frobenius, yet our corollary provides a setting in which even the more general quasi-Hopf algebras of Drinfeld are Frobenius irrespective of dimension. Another example is any autonomous monoidal $\mathcal{V}$-category. In Day and Street (2004), we showed how quantum groups (and more generally "quantum groupoids") and star-autonomous monoidal categories are instances of the same mathematical structure. Although the term Frobenius was not used in Day and Street (2004), the star-autonomy defined there is precisely the higher-dimensional version of Frobenius structure.

Section V is largely inspired by the discussion of "weak monoidal Morita equivalence" in Müger (2003a, 2003b) where it is shown that monoidal categories that are equivalent in this weak sense still give rise to the same state sum invariants of closed oriented 3-manifolds [see Barrett and Westbury (1996, 1999)]. We define a notion of projective equivalence between objects in any

bicategory. In the same general setting, we define what it means for a Frobenius monad to be strongly separable and relate this to projective equivalence. Both concepts require the abstract notion of "scalar" determined by the bicategory. In the bicategory of k-linear categories for a commutative ring k, the scalars are in bijection with elements of k. Section VI says a little about Morita equivalence.

Finally, in Sec. VII, we discuss wreath products of Frobenius algebras. This is done at the level of generalized distributive laws between monads as developed in Lack and Street (2002).

II. FROBENIUS MONADS

Let $\mathbf{T}=(T,\eta,\mu)$ be a monad on a category $\mathcal{X}$. We write $\mathcal{X}^{\mathbf{T}}$ for the category of $\mathbf{T}$-algebras in the sense of Eilenberg and Moore (1965) (although those authors called monads "triples"). We write $U^{\mathbf{T}}:\mathcal{X}^{\mathbf{T}}\to\mathcal{X}$ for the forgetful functor and $F^{\mathbf{T}}:\mathcal{X}\to\mathcal{X}^{\mathbf{T}}$ for its left adjoint. Similarly, for a comonad $\mathbf{G}=(G,\varepsilon,\delta)$, we write $\mathcal{X}^{\mathbf{G}}$ for the category of $\mathbf{G}$-coalgebras, we write $V^{\mathbf{G}}:\mathcal{X}^{\mathbf{G}}\to\mathcal{X}$ for the forgetful functor, and we write $C^{\mathbf{G}}:\mathcal{X}\to\mathcal{X}^{\mathbf{G}}$ for the right adjoint of $V^{\mathbf{G}}$.

Before defining Frobenius monads and finding several equivalent definitions, we shall recall the results in Sec. 3 of Eilenberg and Moore (1965) on adjoint monads. Let $\mathbf{T}=(T,\eta,\mu)$ be a monad on a category $\mathcal{X}$ such that the endofunctor T has a right adjoint: our notation is $T\dashv G$ with counit $\sigma:TG\to 1$ and unit $\rho:1\to GT$. Eilenberg and Moore showed that:

AM1: $\mathbf{G}=(G,\varepsilon,\delta)$ is a comonad where ε and δ are the mates [in the sense of Kelly and Street (1974)] of η and μ under adjunction, with the explicit formulas being

$$\varepsilon=\sigma\circ\eta G \quad\text{and}\quad \delta=G^2\sigma\circ G^2\mu G\circ G\rho TG\circ\rho G,$$

and the comonad $\mathbf{G}$ is said to be *right adjoint* to the monad $\mathbf{T}$;

AM2: mateship under adjunction of action and coaction defines an isomorphism of categories $\mathcal{X}^{\mathbf{T}}\cong\mathcal{X}^{\mathbf{G}}$ that commutes with the forgetful functors $U^{\mathbf{G}}$ and $V^{\mathbf{G}}$ into $\mathcal{X}$;

AM3: each of the forgetful functors $U^{\mathbf{T}}$ and $V^{\mathbf{G}}$ has both left and right adjoints; and,

AM4: if $F\dashv U\dashv C$, then the comonad generated by $U\dashv C$ is right adjoint to the monad generated by $F\dashv U$.

We can add the following extra observation on adjoint monads; it is a trivial consequence of Beck's monadicity theorem [Beck (2003)].

AM5: if $F\dashv U\dashv C$ and U is conservative (that is, reflects invertibility of morphisms) then the comparison functor, into the category of Eilenberg–Moore algebras for the monad generated by $F\dashv U$, is an equivalence;

If $\mathbf{T}=(T,\eta,\mu)$ is a monad on a category $\mathcal{X}$ such that the endofunctor T has a left adjoint H, we can apply the duality explained in Street (1972) to obtain five corresponding results. In particular, there is a comonad $\mathbf{H}=(H,\varepsilon,\delta)$ for which there is an isomorphism $\mathcal{X}_{\mathbf{T}}\cong\mathcal{X}_{\mathbf{H}}$ where $\mathcal{X}_{\mathbf{T}}$ and $\mathcal{X}_{\mathbf{H}}$ are the Kleisli categories of the monad $\mathbf{T}$ and the comonad $\mathbf{H}$, respectively. Also, if a functor $F:\mathcal{X}\to\mathcal{K}$ has a left adjoint, a right adjoint, and is essentially surjective on objects, then $\mathcal{K}$ is equivalent to the Kleisli categories for the appropriately generated monad and comonad on $\mathcal{X}$.

Definition 1.1: A monad $\mathbf{T}=(T,\eta,\mu)$ is called *Frobenius* when it is equipped with a natural transformation $\varepsilon:T\to 1$ such that there exists a natural transformation $\rho:1\to T^2$ satisfying the equations

$$T\mu\circ\rho T=\mu T\circ T\rho \quad\text{and}\quad T\varepsilon\circ\rho=\eta=\varepsilon T\circ\rho.$$

Lemma 1.2: *For a Frobenius monad* $\mathbf{T}$, *put* $\delta:=T\mu\circ\rho T=\mu T\circ T\rho$. *Then*

(a) $T\mu\circ\delta T=\delta\circ\mu=\mu T\circ T\delta$,
(b) $T\varepsilon\circ\delta=1_T=\varepsilon T\circ\delta$,
(c) $\rho=\delta\circ\eta$.

Proof:

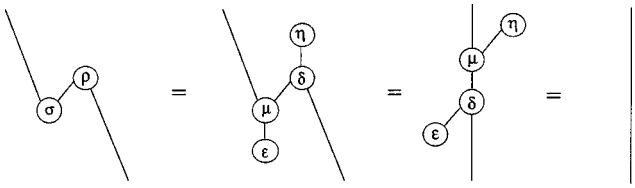
(a) $T\mu\circ\delta T = T\mu\circ T\mu T\circ\rho T^2 = T\mu\circ T^2\mu\circ\rho T^2 = T\mu\circ\rho T\circ\mu = \delta\circ\mu$
$\mu T\circ T\delta = \mu T\circ T\mu T\circ T^2\rho = \mu T\circ\mu T^2\circ T^2\rho = \mu T\circ T\rho\circ\mu = \delta\circ\mu$
(b) $T\varepsilon\circ\delta = T\varepsilon\circ\mu T\circ T\rho = \mu\circ T^2\varepsilon\circ T\rho = \mu\circ T\eta = 1_T$
$\varepsilon T\circ\delta = \varepsilon T\circ T\mu\circ\rho T = \mu\circ\varepsilon T^2\circ\rho T = \mu\circ\eta T = 1_T$
(c) $\delta\circ\eta = T\mu\circ\rho T\circ\eta = T\mu\circ T^2\eta\circ\rho = \rho.$ Q.E.D.

Remark: Condition (a) of Lemma 1.2 has occurred in the work of Carboni and Walters [see Carboni and Walters (1987) and Carboni (1991)] and of Boyer and Joyal [unfortunately Boyer and Joyal (1994) is unpublished, but see Street (1995) for some details]. The condition relates to separability of algebras and discreteness. Condition (b) expesses that ε is a counit for the comultiplication δ. Condition (c) suggests dually introducing $\sigma = \varepsilon\circ\mu$ as we shall now do.

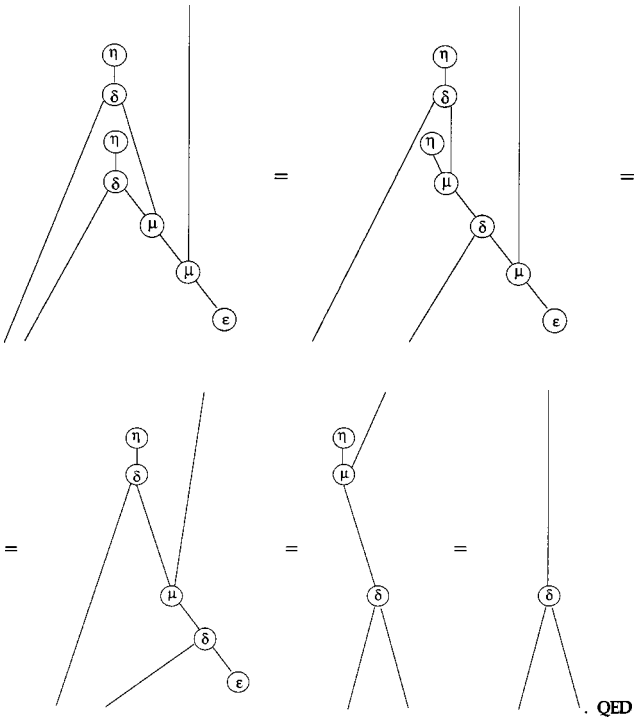
Lemma 1.3: *For a Frobenius monad* $\mathbf{T}$, *there is an adjunction* $T\dashv T$ *with counit* $\sigma = \varepsilon\circ\mu : T^2 \to 1$ *and unit* $\rho : 1 \to T^2$. *Moreover,* $\mathbf{G} = (T, \varepsilon, \delta)$ *is a right adjoint comonad for the monad* $\mathbf{T}$.

Proof: We shall do this using the string calculus [as justified by Joyal and Street (1991)]. We use Lemma 1.2.

One of the counit/unit identities is proved by the following calculation; look in a mirror for the proof of the other.



For the second sentence we need to show that $\delta = T^2\sigma\circ T^2\mu G\circ T\rho T^2\circ\rho T$ and $\varepsilon = \sigma\circ\eta T$. The latter is easy since $\sigma\circ\eta T = \varepsilon\circ\mu\circ\eta T = \varepsilon$. For the former we have



Q.E.D.

Remark: (a) It follows from the first sentence of Lemma 1.3 that ρ is uniquely determined by the monad $\mathbf{T} = (T, \eta, \mu)$ and ε. This is because the counit σ is determined by μ and ε, and the counit of any adjunction uniquely determines the unit.

(b) It is implicit (using AM1) in the second sentence of Lemma 1.3 that δ is coassociative.

Proposition 1.4: *For a Frobenius monad* $\mathbf{T}$, *the left adjoint* $F^{\mathbf{T}}:\mathcal{X}\to\mathcal{X}^{\mathbf{T}}$ *to the forgetful functor* $U^{\mathbf{T}}:\mathcal{X}^{\mathbf{T}}\to\mathcal{X}$ *is also a right adjoint to* $U^{\mathbf{T}}$ *with counit* ε.

Proof: By AM2 we know that there is an isomorphism of categories $K:\mathcal{X}^{\mathbf{T}}\cong\mathcal{X}^{\mathbf{G}}$ such that $V^{\mathbf{G}}K=U^{\mathbf{T}}$. The left adjoint $F^{\mathbf{T}}$ to $U^{\mathbf{T}}$ is given by $F^{\mathbf{T}}X=(\mathbf{T}^2X\xrightarrow{\mu_X}TX)$ and the right adjoint $C^{\mathbf{G}}$ to $V^{\mathbf{G}}$ is given by $C^{\mathbf{G}}X=(TX\xrightarrow{\delta_X}T^2X)$. Since $T\mu\cdot\rho T=\delta$, we see that μ and δ are mates as required to prove that $KF^{\mathbf{T}}=C^{\mathbf{G}}$. Since $V^{\mathbf{G}}\dashv C^{\mathbf{G}}$ with counit ε, we have $V^{\mathbf{G}}K\dashv K^{-1}C^{\mathbf{G}}$ with counit ε; that is, $U^{\mathbf{T}}\dashv F^{\mathbf{T}}$ with counit ε. Q.E.D.

Proposition 1.5: *Suppose* $F\dashv U\dashv F$ (written $F\vdash\!\dashv U$). *Then the monad* $\mathbf{T}$ *generated by the adjunction* $F\dashv U$ *together with the counit for* $U\dashv F$ is Frobenius.

Proof: Let $\lambda:FU\to 1$ be the counit and $\eta:1\to UF$ be the unit for $F\dashv U$. Let $\varepsilon:UF\to 1$ be the counit and $\kappa:1\to FU$ be the unit for $U\dashv F$. The multiplication for $\mathbf{T}$ is $\mu=U\lambda F$. Take $\rho=U\kappa F\circ\eta:1\to T^2$. Then $\mathbf{T}$ with ε is Frobenius since

$$T\mu\circ\rho T=UFU\lambda F\circ U\kappa FUF\circ\eta UF=U\kappa F\circ U\lambda F\circ\eta UF=U\kappa F=U\kappa F\circ U\lambda F\circ UF\eta$$
$$=U\lambda FUF\circ UFU\kappa F\circ UF\eta=\mu T\circ T\rho,$$

$$T\varepsilon\circ\rho=UF\varepsilon\circ U\kappa F\circ\eta=\eta,\quad\text{and}\quad\varepsilon T\circ\rho=\varepsilon UF\circ U\kappa F\circ\eta=\eta.$$

Q.E.D.

See Freyd *et al.* (1999) for a discussion of $F\vdash\!\dashv U$ in the special case where *inter alia* U is fully faithful.

Theorem 1.6: *Suppose* $\mathbf{T}=(T,\eta,\mu)$ *is a monad on a category* $\mathcal{X}$ *and suppose* $\varepsilon:T\to 1$ *is a natural transformation. Then the following conditions are equivalent*:

(a) *equipped with* ε, *the monad* $\mathbf{T}$ *is Frobenius*;
(b) *there exists a natural transformation* $\delta:T\to TT$ *such that*

$$T\mu\circ\delta T=\delta\circ\mu=\mu T\circ T\delta\quad\text{and}\quad T\varepsilon\circ\delta=1_T=\varepsilon T\circ\delta;$$

(c) *there exists a comonad* $\mathbf{G}=(T,\varepsilon,\delta)$ *such that*

$$T\mu\circ\delta T=\delta\circ\mu=\mu T\circ T\delta;$$

(d) *there exists a counit* $\sigma:T^2\to 1$ *for an adjunction* $T\dashv T$ *satisfying the equation*

$$\sigma\circ T\mu=\sigma\circ\mu T,$$

where $\varepsilon=\sigma\circ\mu T$;
(e) *the natural transformation* $\sigma=\varepsilon\circ\mu:T^2\to 1$ *is a counit for an adjunction* $T\dashv T$;
(f) *the functor* $F^{\mathbf{T}}:\mathcal{X}\to\mathcal{X}^{\mathbf{T}}$ is right adjoint to $U^{\mathbf{T}}:\mathcal{X}^{\mathbf{T}}\to\mathcal{X}$ with counit ε.

Proof: Equivalence of (a), (b), and (c).

We have proved that (a) implies (b) and (c). Clearly (c) implies (b). To see that (b) implies (a), put $\rho=\delta\circ\eta$. Then,

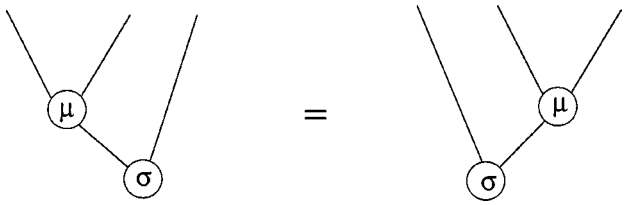
$$T\mu\circ\rho T=T\mu\circ\delta T\circ\eta T=\delta\circ\mu\circ\eta T=\delta=\delta\circ\mu\circ T\eta=\mu T\circ T\delta\circ T\eta=\mu T\circ T\rho\ \text{and}$$

$$T\varepsilon\circ\rho=T\varepsilon\circ\delta\circ\eta=\eta=\varepsilon T\circ\delta\circ\eta=\varepsilon T\circ\rho.$$

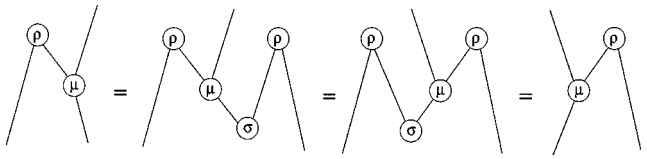
Equivalence of (a) and (d).

Assuming (a), we know that $\sigma=\varepsilon\circ\mu:T^2\to 1$ is a counit for $T\dashv T$ by (b). But then $\sigma\circ T\mu=\sigma\circ\mu T$ is obvious by associativity of μ.

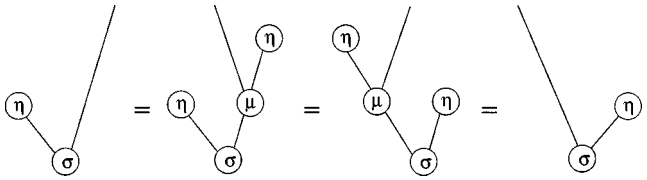
Assume (d) and note that $\sigma\circ T\mu=\sigma\circ\mu T$, in string notation, becomes



Let ρ be the unit corresponding to the counit σ. The following proves $T\mu\circ\rho T=\mu T\circ T\rho$.



Now notice that $\sigma\circ\eta T=\sigma\circ T\eta$ by the following calculation.



So put $\varepsilon=\sigma\circ\eta T=\sigma\circ T\eta$ and notice that

$$T\varepsilon\circ\rho=T\sigma\circ T^2\eta\circ\rho=T\sigma\circ\rho T\circ\eta=\eta=\sigma T\circ T\rho\circ\eta=\sigma T\circ\eta T^2\circ\rho=\varepsilon T\circ\rho.$$

So (a) holds.

Equivalence of (a) and (e).

Lemma 1.3 provides one direction. Conversely, if (e) holds then (d) holds since $\sigma\circ T\mu=\sigma\circ\mu T$ by associativity of μ. So (a) holds.

Equivalence of (a) and (f).

This is an immediate consequence of Propositions 1.4 and 1.5. Q.E.D.

It is clear from Theorem 1.6 that our definition agrees with Lawvere's definition of Frobenius monad [see Lawvere (1969), pp. 151 and 152]. Using the "algebra" terminology, it also agrees for example with Chap. 5 of Carmody (1995), Sec. 6 of Bichon and Street (2003) and Definition 3.1 of Müger (2003a, 2003b).

It follows also that the notion of Frobenius monad is self-dual in the sense that it is the same as a comonad $\mathbf{G}=(G,\varepsilon,\delta)$ with a natural transformation $\eta:1_X\to G$ such that $\delta\circ\eta$ is a unit for $G\dashv G$.

III. REVIEW OF ENRICHED CATEGORIES

References for enriched categories are Kelly (1982) and Lawvere (1974). Let $\mathcal{V}$ denote a particularly familiar symmetric monoidal category. The reader really only needs to keep in mind the category Set of sets with Cartesian product as tensor product and the category Vect_k of k-linear spaces with usual tensor product. There are other nice examples such as Cat with Cartesian product or the category DGVect_k of chain complexes of (that is, differential graded) vector spaces.

We call $\mathcal{V}$ our *base* monoidal category. A *category $\mathcal{A}$ enriched in the base $\mathcal{V}$*, also called a *$\mathcal{V}$-category*, consists of:

(i) a set $\mathrm{ob}\,\mathcal{A}$ whose elements are called *objects*;
(ii) for each pair of objects A and B of $\mathcal{A}$, an object $\mathcal{A}(A,B)$ of $\mathcal{V}$ (that some people write as $\mathrm{Hom}_{\mathcal{A}}(A,B)$);
(iii) morphisms $\mathcal{A}(B,C)\otimes\mathcal{A}(A,B)\to\mathcal{A}(A,C)$ in $\mathcal{V}$ called *composition*; and
(iv) morphisms $I\to\mathcal{A}(A,A)$ in $\mathcal{V}$ called *identity morphisms of $\mathcal{A}$*;

subject to associativity and unital conditions. There is an underlying ordinary category whose objects are the same as those of $\mathcal{A}$ and whose morphisms $f:A\to B$ (we call them *morphisms of* $\mathcal{A}$) are morphisms $f:I\to\mathcal{A}(A,B)$ in $\mathcal{V}$. Each object A of $\mathcal{A}$ determines a monoid $\mathcal{A}(A,A)$ in $\mathcal{V}$. Each monoid M in $\mathcal{V}$ determines a $\mathcal{V}$-category ΣM with one object whose endohom is M. Taking the other view, we can think of $\mathcal{V}$-categories as "monoids in $\mathcal{V}$ with several objects."

When $\mathcal{V}=\mathrm{Set}$, a $\mathcal{V}$-category is a category. When $\mathcal{V}=\mathrm{Vect}_k$, a $\mathcal{V}$-category is a k-linear category (this is simply an ordinary category whose homs are k-vector spaces and whose composition is bilinear). Each k-algebra E determines a Vect_k-category ΣE with one object. A 2-category is a Cat-category!

The nice bases $\mathcal{V}$ we have in mind are *closed*: for each pair of objects X and Y of $\mathcal{V}$ there is an object $[X,Y]$ (called the *internal hom* of X and Y) and a natural bijection

$$\mathcal{V}(W\otimes X,Y)\cong\mathcal{V}(W,[X,Y]).$$

In this case $\mathcal{V}$ itself becomes a $\mathcal{V}$-category; so sometimes we write $\mathcal{V}(X,Y)$ for the object $[X,Y]$ rather than merely its underlying set. In a nonsymmetric monoidal category $\mathcal{V}$ this $[X,Y]$ would be called a *left internal hom*. A *right internal hom* $[X,Y]_r$ satisfies

$$\mathcal{V}(X\otimes W,Y)\cong\mathcal{V}(W,[X,Y]_r).$$

In any monoidal category $\mathcal{V}$ then, if U is right dual to V, then there is a right internal hom of V and any Y given by $[V,Y]_r=U\otimes Y$.

The *opposite* $\mathcal{A}^{\mathrm{op}}$ of a $\mathcal{V}$-category $\mathcal{A}$ is the $\mathcal{V}$-category with the same objects as $\mathcal{A}$ and with $\mathcal{A}^{\mathrm{op}}(A,B)=\mathcal{A}(B,A)$; the composition uses that of $\mathcal{A}$ but "in the reverse order" as allowed by the symmetry of $\mathcal{V}$. We will see that, in the appropriate context, $\mathcal{A}^{\mathrm{op}}$ is a dual of $\mathcal{A}$ in the same way that for finite-dimensional vector spaces V, the space V^* of linear functionals is a dual of V.

The definition of $\mathcal{V}$-*functor* $T:\mathcal{A}\to\mathcal{B}$ between $\mathcal{V}$-categories $\mathcal{A}$ and $\mathcal{B}$ is made in the obvious way: it consists of a function $T:\mathrm{ob}\,\mathcal{A}\to\mathrm{ob}\,\mathcal{B}$ and morphisms

$$T=T_{A,B}:\mathcal{A}(A,B)\to\mathcal{B}(TA,TB)$$

in $\mathcal{V}$ (called *the effect of T on homs*) compatible with composition and identities. The definition of $\mathcal{V}$-*natural transformation* $\theta:T\Rightarrow T':\mathcal{A}\to\mathcal{B}$ needs a little more care in general, however, for the cases $\mathcal{V}=\mathrm{Set}$ and $\mathcal{V}=\mathrm{Vect}_k$, it amounts to an ordinary natural transformation.

With compositions that are straightforward (especially in the examples), we obtain a 2-category $\mathcal{V}$-Cat whose objects are (small) $\mathcal{V}$-categories, whose morphisms are $\mathcal{V}$-functors and whose 2-cells are $\mathcal{V}$-natural transformations. As a technical point concerning size, we allow ourselves to write $\mathcal{V}$-Cat $(\mathcal{A},\mathcal{B})$ for the category of $\mathcal{V}$-functors from $\mathcal{A}$ to $\mathcal{B}$ even when $\mathcal{A}$ and $\mathcal{B}$ are not small.

There is a *tensor product* $\mathcal{A}\otimes\mathcal{B}$ of $\mathcal{V}$-categories with $\mathrm{ob}(\mathcal{A}\otimes\mathcal{B})=\mathrm{ob}\,\mathcal{A}\times\mathrm{ob}\,\mathcal{B}$ and

$$(\mathcal{A}\otimes\mathcal{B})((A,B),(A',B'))=\mathcal{A}(A,A')\otimes\mathcal{B}(B,B');$$

the composition uses the compositions of $\mathcal{A}$ and $\mathcal{B}$ and the symmetry of $\mathcal{V}$. The unit for this tensor product is the $\mathcal{V}$-category $\mathcal{I}$ with one object, denoted by $\cdot$, and with $\mathcal{I}(\cdot,\cdot)=I$. Equipped with this, $\mathcal{V}$-Cat becomes a symmetric monoidal 2-category. Actually it is also closed; we now describe the internal hom.

For $\mathcal{V}$-categories $\mathcal{A}$ and $\mathcal{B}$, there is a $\mathcal{V}$-*functor category* $[\mathcal{A},\mathcal{B}]$: it is the $\mathcal{V}$-category whose objects are $\mathcal{V}$-functors from $\mathcal{A}$ to $\mathcal{B}$ and whose homs are given by the ends

$$[\mathcal{A},\mathcal{B}](T,T') = \int_A \mathcal{B}(TA,T'A)$$

[see MacLane (1971) for Yoneda–Day–Kelly integral notation]. In the examples of bases of interest here, it is clear that the $\mathcal{V}$-natural transformations from T to T' form an object of $\mathcal{V}$. There is a canonical isomorphism of categories

$$V\text{-Cat}(\mathcal{C},[\mathcal{A},\mathcal{B}]) \cong \mathcal{V}\text{-Cat}(\mathcal{C}\otimes\mathcal{A},\mathcal{B}).$$

There is another monoidal bicategory $\mathcal{V}$-Mod whose objects are also the (small) $\mathcal{V}$-categories; in this case however, the hom-categories are defined by

$$\mathcal{V}\text{-Mod}(\mathcal{A},\mathcal{B}) = \mathcal{V}\text{-Cat}(\mathcal{B}^{\mathrm{op}}\otimes\mathcal{A},\mathcal{V}).$$

In other words, the morphisms of $\mathcal{V}$-Mod are $\mathcal{V}$-functors $M:\mathcal{B}^{\mathrm{op}}\otimes\mathcal{A}\to\mathcal{V}$ and the 2-cells are $\mathcal{V}$-natural transformations. These objects M of $\mathcal{V}$-Mod $(\mathcal{A},\mathcal{B})$ are called *modules* from $\mathcal{A}$ to $\mathcal{B}$ (or "left $\mathcal{A}$-, right $\mathcal{B}$-bimodules") because of the actions (albeit a "several object version" of action)

$$\mathcal{A}(A,A')\otimes M(B,A)\otimes\mathcal{B}(B',B)\to M(B',A')$$

that correspond to the effect of M on homs. The composite of modules $M:\mathcal{A}\to\mathcal{B}$ and $N:\mathcal{B}\to\mathcal{C}$ is defined by the coend

$$(N\circ M)(C,A) = \int^B M(B,A)\otimes N(C,B);$$

this colimit can be constructed by taking a sum (coproduct) in $\mathcal{V}$ over all objects B and factoring out the left action of $\mathcal{B}$ on N and the right action of $\mathcal{B}$ on M (instead of a composition we can think of it as a tensor product over $\mathcal{B}$: in that spirit we can write $N\circ M = M\underset{\mathcal{B}}{\otimes} N$. This composition (like tensor product) is only associative up to isomorphism (which is allowed in a bicategory). The identity module of $\mathcal{A}$ is the module $1_{\mathcal{A}}$ defined by $1_{\mathcal{A}}(A,A') = \mathcal{A}(A,A')$.

Each $\mathcal{V}$-functor $T:\mathcal{A}\to\mathcal{B}$ yields modules $T_*:\mathcal{A}\to\mathcal{B}$ and $T^*:\mathcal{B}\to\mathcal{A}$ defined by $T_*(B,A) = \mathcal{B}(B,TA)$ and $T^*(A,B) = \mathcal{B}(TA,B)$. In fact, T^* is right adjoint to T_* in the bicategory $\mathcal{V}$-Mod: the unit $1_{\mathcal{A}}\to T^*\circ T_*$ has components

$$\mathcal{A}(A,A')\to\int^B \mathcal{B}(TA,B)\otimes\mathcal{B}(B,TA') = \mathcal{B}(TA,TA')$$

given by the effect of T on homs. We obtain an "inclusion" pseudofunctor

$$\mathcal{V}\text{-Cat}\to\mathcal{V}\text{-Mod}$$

that takes each $\mathcal{V}$-category to itself, takes each $\mathcal{V}$-functor T to T_*, and is bijective on 2-cells; so we sometimes write T for the module T_*.

So we can think of $\mathcal{V}$-Mod as an expansion of $\mathcal{V}$-Cat designed to provide the morphisms in $\mathcal{V}$-Cat with right adjoints. Not only adjoints but equivalences in $\mathcal{V}$-Mod are also of interest.

Equivalence in $\mathcal{V}$-Mod is called *Cauchy equivalence of $\mathcal{V}$-categories*. In the particular case where $\mathcal{V}$ is the monoidal category of Abelian groups with the usual tensor product, we obtain the notion of Cauchy equivalence for additive categories. Rings R can be regarded as additive categories ΣR with a single object; in this way, Cauchy equivalence is none other than ordinary Morita equivalence of rings.

Each $\mathcal{V}$-category $\mathcal{A}$ has a *Cauchy completion* $Q\mathcal{A}$: it is the smallest full sub-$\mathcal{V}$-category of the $\mathcal{V}$-functor $\mathcal{V}$-category $P\mathcal{A}=[\mathcal{A}^{\mathrm{op}},\mathcal{V}]$ that contains the representable $\mathcal{V}$-functors $\mathcal{A}(-,A)$ and is closed under absolute $\mathcal{V}$-colimits. [Absolute $\mathcal{V}$-colimits are those preserved by all $\mathcal{V}$-functors; see Street (1983).] For example, if $\mathcal{V}=\mathrm{Set}$ then $Q\mathcal{A}$ is the completion of the category $\mathcal{A}$ under splitting of idempotents; and if $\mathcal{V}=\mathrm{Vect}_k$, then $Q\mathcal{A}$ is the completion of the additive category $\mathcal{A}$ under

direct sums and splitting of idempotents. For reasonable $\mathcal{V}$, if $\mathcal{A}$ is small, so is $Q\mathcal{A}$ [see Johnson (1989b)].

It is easy to see that $\mathcal{V}$-categories $\mathcal{A}$ and $\mathcal{B}$ are Cauchy equivalent if and only if $P\mathcal{A}$ and $P\mathcal{B}$ are equivalent $\mathcal{V}$-categories (that is, equivalent in the 2-category $\mathcal{V}$-Cat). It is well known [see Street (1983) for a proof in a very general context] that $\mathcal{V}$-categories $\mathcal{A}$ and $\mathcal{B}$ are Cauchy equivalent if and only if $Q\mathcal{A}$ and $Q\mathcal{B}$ are equivalent $\mathcal{V}$-categories. The inclusion of $Q\mathcal{A}$ in $QQ\mathcal{A}$ is an equivalence, so $\mathcal{A}$ is Cauchy equivalent to $Q\mathcal{A}$. We say $\mathcal{A}$ is *Cauchy complete* when it admits all absolute $\mathcal{V}$-colimits; that is, when the inclusion of $\mathcal{A}$ in $Q\mathcal{A}$ is an equivalence.

Tensor product of $\mathcal{V}$-categories extends to $\mathcal{V}$-Mod making $\mathcal{V}$-Mod a symmetric monoidal bicategory and the inclusion of $\mathcal{V}$-Cat in $\mathcal{V}$-Mod strict monoidal. We have seen that $\mathcal{V}$-Cat is closed. However, there is a much stronger structure possessed by $\mathcal{V}$-Mod; it is "autonomous" like the category of finite-dimensional vector spaces, and we shall now make this precise.

We work in a monoidal bicategory $\mathcal{B}$. A morphism $e:A\otimes B\to I$ is called a *biexact pairing* when the functor

$$\mathcal{B}(C,B\otimes D)\to\mathcal{B}(A\otimes C,D),$$

taking $C\xrightarrow{f}B\otimes D$ to $A\otimes C\xrightarrow{A\otimes f}A\otimes B\otimes D\xrightarrow{e\otimes D}D$, is an equivalence of categories for all objects C and D. In this case, there is a unique (up to isomorphism) morphism $n:I\to B\otimes A$ such that the composite $A\xrightarrow{A\otimes n}A\otimes B\otimes A\xrightarrow{e\otimes A}A$ is isomorphic to the identity of A. We say that B is a *right bidual* for A with *counit* e and *unit* n. Of course, A is called a *left bidual* for B.

The monoidal bicategory $\mathcal{B}$ is called *autonomous* when each object has both a left and a right bidual. A choice of right bidual of an object A is denoted by A°: with unit $n:I\to A^\circ\otimes A$ and counit $e:A\otimes A^\circ\to I$.

In the case of $\mathcal{V}$-Mod, a right bidual for the $\mathcal{V}$-category $\mathcal{A}$ is provided by $\mathcal{A}^{\mathrm{op}}$ since

$$\mathcal{V}\text{-Mod}(\mathcal{A}\otimes\mathcal{B},\mathcal{C})\cong\mathcal{V}\text{-Cat}(\mathcal{C}^{\mathrm{op}}\otimes\mathcal{A}\otimes\mathcal{B},\mathcal{V})\cong\mathcal{V}\text{-Mod}(\mathcal{B},\mathcal{A}^{\mathrm{op}}\otimes\mathcal{C}).$$

The counit $e:\mathcal{A}\otimes\mathcal{A}^{\mathrm{op}}\to I$ is the module defined by $e(\cdot,A,A')=\mathcal{A}(A',A)$. Since $\mathcal{V}$-Mod is symmetric, it is autonomous.

IV. FROBENIUS PSEUDOMONOIDS

We consider a pseudomonoid (or monoidal object) A in a monoidal bicategory $\mathcal{B}$: the underlying object is also denoted by A, the unit is $j:I\to A$, the multiplication is $p:A\otimes A\to A$, and there are invertible coherent associativity and unital constraints. When the unit constraints are identities, the pseudomonoid is said to be *normalized*. When the unit and associativity constraints are identities, the pseudomonoid is said to be *strict*; it is then just a monoid.

Motivated by Theorem 1.6(e) we make a natural higher-dimensional extension of the Frobenius notion.

Definition 3.1: A pseudomonoid A is *Frobenius* when it is equipped with a morphism $l:A\to I$ such that the composite

$$A\otimes A\xrightarrow{p}A\xrightarrow{l}I$$

is a biexact pairing.

Proposition 1.1 of Day *et al.* (2003) states that the pseudomonoid A is *left autonomous* with dualization $d:A^\circ\to A$ if and only if

$$p^*\cong(p\otimes A)\circ(A\otimes d\otimes A)\circ(A\otimes n),$$

and this holds if and only if

$$(p \circ (d \otimes A))^* \cong (A^\circ \otimes p) \circ (n \otimes A).$$

Proposition 1.2 of Day *et al.* (2003) gives the formula

$$d \cong (A \otimes e) \circ (p^* \otimes A^\circ) \circ (j \otimes A^\circ).$$

Furthermore, in the case where j has a right adjoint, Proposition 1.4 of Day *et al.* (2003) states that A is also right autonomous, and then simply called autonomous, if and only if d is an equivalence. Then the right adjoint d^* of d is an inverse equivalence and [Proposition 1.2 of Day *et al.* (2003)] is given by the formula

$$d^* \cong (A^\circ \otimes j^*) \circ (A^\circ \otimes p) \circ (n \otimes A).$$

Proposition 3.1: *Every autonomous pseudomonoid* (A, j, p), *for which* j *has a right adjoint, is Frobenius with* $l = j^*$.

Proof: In an autonomous monoidal bicategory, the composite $\sigma: A \otimes A \xrightarrow{p} A \xrightarrow{l} I$ is a biexact pairing if and only if the corresponding morphism

$$\hat{\sigma}: A \xrightarrow{n \otimes A} A^\circ \otimes A \otimes A \xrightarrow{A^\circ \otimes \sigma} A^\circ$$

is an equivalence. So, with $l = j^*$, we have

$$\hat{\sigma} = (A^\circ \otimes j^*) \circ (A^\circ \otimes p) \circ (n \otimes A) \cong d^*,$$

an equivalence. Q.E.D.

A pseudocomonoidal structure on A in Proposition 3.1 is provided by j^* and p^*; compare Theorem 1.6(c). We also note that there are isomorphisms

$$p^* \cong (d \otimes A) \circ (A^\circ \otimes p) \circ (n \otimes A) \cong (A \otimes p) \circ (\rho \otimes A) \cong (p \otimes A) \circ (A \otimes \rho),$$

where $\rho = (I \xrightarrow{j} A \xrightarrow{p^*} A \otimes A)$.

Example: *Quasi-Hopf algebras*

A *quasibialgebra* (over a field k) is a k-algebra H equipped with algebra morphisms

$$\Delta: H \to H \otimes H \quad \text{and} \quad E: H \to k,$$

and with an invertible element $\phi \in H \otimes H \otimes H$, such that

$$(E \otimes 1_H)(\Delta(a)) = a = (1_H \otimes E)(\Delta(a)) \quad \text{and} \quad \phi(\Delta \otimes 1_H)(\Delta(a)) = (1_H \otimes \Delta)(\Delta(a))\phi$$

for all $a \in H$; furthermore, ϕ satisfies the *pentagon condition*

$$(1 \otimes 1 \otimes \Delta)(\phi) \cdot (\Delta \otimes 1 \otimes 1)(\phi) = (1 \otimes \phi) \cdot (1 \otimes \Delta \otimes 1)(\phi) \cdot (\phi \otimes 1).$$

(A quasibialgebra reduces to an ordinary bialgebra when ϕ is the identity element $1 \otimes 1 \otimes 1$.) We can make $H \otimes H$ into a left $H \otimes H$-, right H-bimodule by means of the actions

$$(a \otimes b) \cdot (x \otimes y) \cdot c = \sum_i axc_i^1 \otimes byc_i^2,$$

where $\Delta(c) = \sum_i c_i^1 \otimes c_i^2$; for the time being, let us call this bimodule M. Given an algebra antimorphism $S: H \to H$, there is another left $H \otimes H$-, right H-bimodule structure defined on $H \otimes H$ by the actions

$$(a \otimes b) \cdot (x \otimes y) \cdot c = \sum_j axS(b_j^1) \otimes b_j^2 yc,$$

where $\Delta(b) = \sum_j b_j^1 \otimes b_j^2$; for the time being, let us call this bimodule N. A *quasi-Hopf algebra* is a

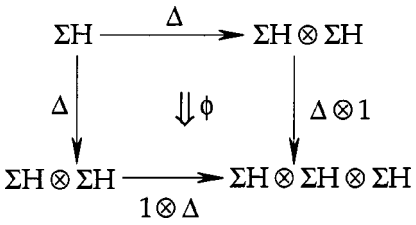
quasibialgebra H together with an algebra antimorphism $S:H\to H$ (called the *antipode*) and a bimodule isomorphism $\pi:M\cong N$. This is equivalent to the original definition of Drinfel'd (1990) that, instead of the isomorphism π, involved two elements α and β of H satisfying the equations

$$E(c)\alpha=\sum_i S(c_i^1)\alpha c_i^2,\quad E(c)\beta=\sum_i c_i^1\beta S(c_i^2),$$

$$\sum_i \phi_i^1\beta S(\phi_i^2)\alpha\phi_i^3=1,\quad \text{and}\quad \sum_i S(\phi_i^{-1})\alpha\phi_i^{-2}\beta S(\phi_i^{-3})=1$$

[see Sec. 2.4 of Majid (1995)]. We shall say a bit more about the equivalence of the definitions soon.

Take $\mathcal{V}=\mathrm{Vect}_k$ and recall that a k-algebra A is a one-object V-category ΣA. It is obvious that an algebra morphism $f:A\to B$ is the same as a $\mathcal{V}$-functor $f:\Sigma A\to\Sigma B$. So what is a $\mathcal{V}$-natural transformation $\sigma:f\Rightarrow g$ in terms of the algebra morphisms f and g from A to B ? It is nothing other than an element α of B such that $\alpha f(a)=g(a)\alpha$ for all elements a of A. Therefore we see that ϕ belongs in the square



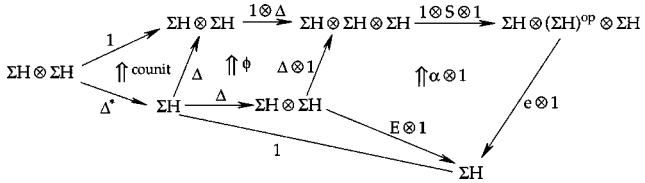
in $\mathcal{V}$-Cat. From this it follows easily that: *a quasibialgebra structure on an algebra H is precisely a normalized pseudomonoid structure on* ΣH *in* $(\mathcal{V}\text{-Cat})^{\mathrm{coop}}$.

Now we move from $(\mathcal{V}\text{-Cat})^{\mathrm{coop}}$ to $(\mathcal{V}\text{-Mod})^{\mathrm{coop}}$ where $\mathcal{V}$-functors have right adjoints and the object ΣH^{op} is a bidual for ΣH. Here we can observe that the right adjoint $\Delta^*:\Sigma H\otimes\Sigma H\to\Sigma H$ of Δ is the bimodule M above and the composite module

$$\Sigma H\otimes\Sigma H\xrightarrow{\Sigma H\otimes\Delta}\Sigma H\otimes\Sigma H\otimes\Sigma H\xrightarrow{\Sigma H\otimes S\otimes\Sigma H}\Sigma H\otimes\Sigma H^{\mathrm{op}}\otimes\Sigma H\xrightarrow{e\otimes\Sigma H}\Sigma H$$

is N. It follows that: *a quasi-Hopf structure on the quasialgebra H is precisely a left autonomous structure on the normalized pseudomonoid* ΣH *in* $(\mathcal{V}\text{-Mod})^{\mathrm{coop}}$. Therefore Proposition 3.1 applies to yield a Frobenius structure on ΣH in $(\mathcal{V}\text{-Mod})^{\mathrm{coop}}$ using E^*. This means that ΣH becomes a pseudomonoid in $\mathcal{V}$-Mod using E^* and Δ^*; of course, this is not the original algebra structure on H.

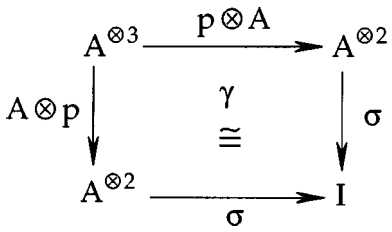
Finally in this example, we can say something about the equivalent definitions of quasi-Hopf algebra: specifically about how π is obtained from α and ϕ. The above-mentioned equation satisfied by the element α of H says precisely that it is a (bi)module morphism from E to $e\circ(1\otimes S)\circ\Delta$ (note that E is k and $e\circ(1\otimes S)\circ\Delta$ is H with appropriate actions). Then π is the pasting composite of the following diagram.



Similarly, β is used to define a 2-cell in the opposite direction; the further conditions on α, β, and ϕ say that this really is the inverse of π. Further details can be found in the general results of Day *et al.* (2003). This ends our example.

In Sec. 9 of Day and Street (2004) a *form* for a pseudomonoid A in a monoidal bicategory $\mathcal{B}$

is defined to be a morphism $\sigma: A \otimes A \to I$ together with an invertible 2-cell γ as below.



Then the authors define the pseudomonoid to be $*$-*autonomous* when σ is a biexact pairing. **(**There was an extra condition in [Day and Street (2004)] requiring σ to be "representable"; however, this is automatic under a mild completeness condition on the pseudomonoid.**)**

Proposition 3.2: A pseudomonoid is $*$-autonomous if and only if it is Frobenius.

Proof: Suppose σ and γ is a form on the pseudomonoid A with σ a biexact pairing. Put $l = (A \xrightarrow{j \otimes A} A \otimes A \xrightarrow{\sigma} I)$ so that

$$\sigma \cong \sigma \circ (p \otimes A) \circ (j \otimes A) \cong \sigma \circ (A \otimes p) \circ (j \otimes A) \cong \sigma \circ (j \otimes A) \circ p \cong l \circ p,$$

where the second isomorphism involves γ. So A equipped with l is Frobenius. Conversely, put $\sigma = l \circ p$ which is a biexact pairing by definition of Frobenius; the isomorphism γ is obtained by composing the associativity constraint

$$p \circ (p \otimes A) \cong p \circ (A \otimes p)$$

on the left with l. Q.E.D.

Corollary 3.3: For any object X of $\mathcal{B}$ and any equivalence $v: X \to X^{\circ\circ}$, the pseudomonoid $X^{\circ} \otimes X$ is Frobenius when equipped with $l: X^{\circ} \otimes X \xrightarrow{1 \otimes v} X^{\circ} \otimes X^{\circ\circ} \xrightarrow{e} I$.

Example: Star-autonomous monoidal enriched categories

A $\mathcal{V}$-category $\mathcal{A}$ is *monoidal* when it is equipped with the structure of pseudomonoid in $\mathcal{V}$-Cat; we write $\#: \mathcal{A} \otimes \mathcal{A} \to \mathcal{A}$ for the "multiplication" $\mathcal{V}$-functor (to distinguish it from the tensor product $\otimes$ of $\mathcal{V}$) and J for the unit object. We say that $\mathcal{A}$ is $*$-*autonomous* when it is equipped with an equivalence of $\mathcal{V}$-categories $S: \mathcal{A} \to \mathcal{A}^{\mathrm{op}}$ and a $\mathcal{V}$-natural family of isomorphisms

$$\mathcal{A}(A \# B, J) \cong \mathcal{A}(B, SA).$$

This is a straightforward enrichment of the concept due to Barr (1996) and considered more generally in Day and Street (2004) in connection with quantum groupoids. Here we want to emphasize the Frobenius aspect. In order to obtain an autonomous monoidal bicategory, we need to move from $\mathcal{V}$-Cat to $\mathcal{V}$-Mod. Because of the way we have defined $\mathcal{V}$-Mod, it is better to consider $\mathcal{A}^{\mathrm{op}}$ rather than $\mathcal{A}$; to say one is monoidal is the same as saying the other is. For simplicity, we also suppose $\mathcal{A}$ is Cauchy complete (see Sec. VI); then any equivalence $\mathcal{A} \to \mathcal{A}^{\mathrm{op}}$ in $\mathcal{V}$-Mod is automatically of the form S_* for an equivalence $S: \mathcal{A} \to \mathcal{A}^{\mathrm{op}}$ in $\mathcal{V}$-Cat. As a consequence of Proposition 3.2 we have that: *the monoidal $\mathcal{V}$-category $\mathcal{A}$ is $*$-autonomous if and only if $\mathcal{A}^{\mathrm{op}}$ is Frobenius in* $\mathcal{V}$-Mod. If we write $\check{S}: \mathcal{A}^{\mathrm{op}} \otimes \mathcal{A}^{\mathrm{op}} \to \mathcal{I}$ for the module defined by $\check{S}(A,B) = \mathcal{A}(B, SA)$, we see that the isomorphism defining $*$-autonomy is precisely $J^* \circ \#_* \cong \check{S}$. Corollary 3.3 implies a result of Day and Street (2004) that, for any $\mathcal{V}$-category $\mathcal{X}$, the monoidal $\mathcal{V}$-category $\mathcal{X}^{\mathrm{op}} \otimes \mathcal{X}$ is $*$-autonomous.

V. PROJECTIVE EQUIVALENCES

This section was inspired to a large extent by the discussion of "weak monoidal Morita equivalence" in Müger (2003a, 2003b).

It is well known what it means for a morphism to be an equivalence in any bicategory and that every equivalence can be made an adjoint equivalence. We wish to discuss a more general notion of equivalence. For this we need to clarify a concept of scalar.

A *scalar* for a bicategory $\mathcal{D}$ is a modification

$$\omega: 1_{1_{\mathcal{D}}} \to 1_{1_{\mathcal{D}}}: 1_{\mathcal{D}} \to 1_{\mathcal{D}}: \mathcal{D} \to \mathcal{D}.$$

That is, ω assigns to each object A of $\mathcal{D}$ a 2-cell $\omega_A: 1_A \to 1_A$ such that, for all morphisms $f: A \to B$,

$$f\omega_A = \omega_B f.$$

Scalars form a commutative monoid under composition. By abuse of language, 2-cell $\theta: f \Rightarrow f: X \to Y$ will be called a *scalar* when there exists an actual scalar ω such that

$$\theta = f\omega_X;$$

we say θ is an *invertible scalar* when ω is invertible.

Take the example of enriched categories; that is, in the case where $\mathcal{D} = \mathcal{V}$-Mod. It is easy to see that the commutative monoid of scalars is isomorphic to the endomorphism monoid $\mathcal{V}(I, I)$ of the unit object I. In particular, when $\mathcal{V}$ is the category of sets, the monoid is trivial (consisting only of the identity). More interestingly, if $\mathcal{V}$ is the monoidal category of modules over a commutative ring k then the scalars for $\mathcal{V}$-Mod are precisely the elements of k.

Remark: The braided monoidal category $\mathrm{Hom}(\mathcal{D}, \mathcal{D})(1_{\mathcal{D}}, 1_{\mathcal{D}})$ whose objects are pseudonatural transformations of the identity of $\mathcal{D}$, whose morphisms are modifications, and whose tensor product is either of the two compositions, is called the *center* of the bicategory $\mathcal{D}$. So scalars are endomorphisms of the unit of the centre. If $\mathcal{D}$ is the one-object bicategory $\Sigma\mathcal{C}$ with hom monoidal category $\mathcal{C}$ then $\mathrm{Hom}(\mathcal{D}, \mathcal{D})(1_{\mathcal{D}}, 1_{\mathcal{D}})$ is the center $Z\mathcal{C}$ of $\mathcal{C}$ in the sense of Joyal and Street (1991).

Definition 4.1: A morphism $u: A \to X$ in a bicategory $\mathcal{D}$ is called a *projective equivalence* when there is a morphism $f: X \to A$ adjoint to u on both sides (that is, $f \dashv u$) and there are invertible scalars ω and ϖ such that the composites

$$1_X \overset{\eta}{\to} uf \overset{\varepsilon}{\to} 1_X \quad \text{and} \quad 1_A \overset{\kappa}{\to} fu \overset{\lambda}{\to} 1_A$$

are equal to ω_X and ϖ_A, respectively, where η, λ and κ, ε are the unit-counit pairs for the adjunctions.

In any projective equivalence, by suitable rescaling of units and counits, we can ensure that either ω or ϖ is an identity. Equivalences are precisely the projective equivalences in which both ω and ϖ can be chosen to be identities.

Proposition 4.1: A composite of projective equivalences is a projective equivalence.

Proof: Suppose $f \dashv u$ with $u: A \to X$ and $f' \dashv u'$ with $u': X \to K$ where η, λ and κ, ε are the unit-counit pairs for the adjunctions $f \dashv u$ and those for $f' \dashv u'$ are similar except that they have primes. The counit for $u'u \dashv ff'$ is

$$u'uff' \overset{u'\varepsilon f'}{\to} u'f' \overset{\varepsilon'}{\to} 1_K$$

while the unit for $ff' \dashv u'u$ is

$$1_K \overset{\eta'}{\to} u'f' \overset{u'\eta f'}{\to} u'uff'.$$

But $\varepsilon \circ \eta = \omega_X$ and $\varepsilon' \circ \eta' = \omega'_K$. So,

$$\varepsilon' \circ (u'\varepsilon f') \circ (u'\eta f') \circ \eta' = \varepsilon' \circ (u'(\varepsilon \circ \eta)f') \circ \eta' = \varepsilon' \circ (u'\omega_X f') \circ \eta' = \varepsilon' \circ (\omega_K u'f') \circ \eta'$$
$$= \varepsilon' \circ \eta' \circ \omega_K = \omega'_K \circ \omega_K = (\omega' \circ \omega)_K.$$

A similar argument applies for the other composite. Q.E.D.

Definition 4.2: A Frobenius monad $\mathbf{t} = (t, \eta, \mu, \varepsilon, \delta)$ on an object X of $\mathcal{D}$ is *strongly separable* when there exist invertible scalars ω and ϖ such that the composites

$$1_X \overset{\eta}{\longrightarrow} t \overset{\varepsilon}{\longrightarrow} 1_X \quad \text{and} \quad t \overset{\delta}{\longrightarrow} tt \overset{\mu}{\longrightarrow} t$$

are equal to ω_X and $\varpi_X t$, respectively.

Proposition 4.2: A morphism in $\mathcal{D}$ is a projective equivalence if and only if it is monadic via a strongly separable Frobenius monad.

Proof: A projective equivalence $u: A \to X$ is conservative since the counit λ for its left adjoint is a retraction (split epimorphism). Since u also has a right adjoint, it is monadic. The composites $\varepsilon \circ \eta$ and $\mu \circ \delta = u\lambda f \circ u\kappa f = u(\lambda \circ \kappa)f$ are invertible scalars from Definition 4.1. So u generates a strongly separable Frobenius monad on X.

Conversely, suppose we have a strongly separable Frobenius monad $\mathbf{t} = (t, \eta, \mu, \varepsilon, \delta)$ on X and $u: A \to X$ together with action $\xi: tu \to u$ provide an Eilenberg–Moore construction for $\mathbf{t}$. So there exists $f \dashv u$, where uf is isomorphic to t and ξf transports to μ. We can replace t by uf so that $\xi f = \mu$. Then η is the unit for $f \dashv u$ and ε is the counit for $u \dashv f$. So we have that $\varepsilon \circ \eta$ is an invertible scalar. The counit κ for $f \dashv u$ is determined by $u\kappa = \xi$ and unit λ for $u \dashv f$ is determined by

$$u\lambda = t\xi \circ \delta u \circ \eta u.$$

So,

$$u(\kappa \circ \lambda) = \xi \circ t\xi \circ \delta u \circ \eta u = \xi \circ \mu u \circ \delta u \circ \eta u = \xi \circ \varpi_X u \circ \eta u = \varpi_X u \circ \xi \circ \eta u = \varpi_X u = u\varpi_A,$$

which implies that $\kappa \circ \lambda = \varpi_A$. Therefore u is a projective equivalence. Q.E.D.

VI. VARIATIONS ON MORITA EQUIVALENCE

Suppose $\mathcal{A}$ is a monoidal $\mathcal{V}$-category (that is, a pseudomonoid in $\mathcal{V}$-Cat). Then $P\mathcal{A}$ becomes a cocomplete monoidal $\mathcal{V}$-category via the convolution tensor product

$$(M * N)(A) = \int^{XY} \mathcal{A}(A, X \otimes Y) \otimes MX \otimes NY$$

of Day (1970). Monoidal $\mathcal{V}$-categories $\mathcal{A}$ and $\mathcal{B}$ are defined to be *Cauchy equivalent* when $P\mathcal{A}$ and $P\mathcal{B}$ are equivalent monoidal $\mathcal{V}$-categories (that is, equivalent in the 2-category of monoidal $\mathcal{V}$-categories and monoidal $\mathcal{V}$-functors). Johnson (1989a) showed that the convolution tensor product on $P\mathcal{A}$ restricts to $Q\mathcal{A}$ and that monoidal $\mathcal{V}$-categories $\mathcal{A}$ and $\mathcal{B}$ are Cauchy equivalent if and only if $Q\mathcal{A}$ and $Q\mathcal{B}$ are equivalent monoidal $\mathcal{V}$-categories. Moreover $\mathcal{A}$ is Cauchy equivalent to $Q\mathcal{A}$ as monoidal $\mathcal{V}$-categories.

From this we see in particular that Cauchy equivalence, monoidal or not, is a special case of equivalence once we find the appropriate ambient bicategory. Having in Sec. IV weakened the notion of equivalence to projective equivalence, we can now contemplate projective Cauchy equivalence. Two $\mathcal{V}$-categories $\mathcal{A}$ and $\mathcal{B}$ are *projectively Cauchy equivalent* when $P\mathcal{A}$ and $P\mathcal{B}$ are projectively equivalent $\mathcal{V}$-categories. For $\mathcal{V}$ equal to the category of sets or the category of Abelian groups, this concept is the same as Cauchy equivalence. However, if $\mathcal{V}$ is the category of vector spaces over a field, for example, we do obtain a weaker kind of equivalence; in particular, this applies to associative unital algebras over the field. In general, $\mathcal{A}$ and $\mathcal{B}$ are projectively Cauchy equivalent if and only if $Q\mathcal{A}$ and $Q\mathcal{B}$ are projectively equivalent $\mathcal{V}$-categories.

Similarly, two monoidal $\mathcal{V}$-categories $\mathcal{A}$ and $\mathcal{B}$ are *projectively Cauchy equivalent* when $P\mathcal{A}$ and $P\mathcal{B}$ are projectively equivalent monoidal $\mathcal{V}$-categories. If $\mathcal{V}$ is the category of vector spaces over a field k, we do obtain a weaker kind of Cauchy equivalence for monoidal k-linear categories. In general, monoidal $\mathcal{V}$-categories $\mathcal{A}$ and $\mathcal{B}$ are projectively Cauchy equivalent if and only if $Q\mathcal{A}$ and $Q\mathcal{B}$ are projectively equivalent monoidal $\mathcal{V}$-categories.

VII. WREATH PRODUCTS OF FROBENIUS ALGEBRAS

As in Sec. II, we express our results in terms of monads rather than algebras.

We shall begin by recalling some notions from Lack and Street (2002). Given a 2-category $\mathcal{K}$, there is a 2-category $\mathrm{EM}(\mathcal{K})$ which turns out to be the free completion of $\mathcal{K}$ with respect to the Eilenberg–Moore construction on monads. Explicitly, an object of $\mathrm{EM}(\mathcal{K})$ is a pair (A,t) where A is an object of $\mathcal{K}$ and t is a monad on A in $\mathcal{K}$. A morphism $(f,\phi):(A,t)\to(B,s)$ consists of a morphism $f:A\to B$ and 2-cell $\phi:s\circ f\Rightarrow f\circ t$ in $\mathcal{K}$ satisfying two compatibility conditions with the units η and multiplications μ of the monads t and s. A 2-cell $\rho:(f,\phi)\Rightarrow(g,\psi)$ is a 2-cell $\rho:f\Rightarrow g\circ t$ in $\mathcal{K}$ such that

$$(g\circ\mu)(\rho\circ t)\phi=(g\circ\mu)(\psi\circ t)(s\circ\rho).$$

Composition in the category $\mathrm{EM}(\mathcal{K})((A,t),(B,s))$ involves using the multiplication μ of t. Horizontal composition is straightforward.

A *wreath* in $\mathcal{K}$ is defined in Lack and Street (2002) to be a monad in $\mathrm{EM}(\mathcal{K})$. Explicitly, a wreath consists of an object A of $\mathcal{K}$, monad t on A, a morphism $s:A\to A$, and 2-cells $\lambda:t\circ s\Rightarrow s\circ t$, $\iota:1_A\Rightarrow s\circ t$, and $\nu:s\circ s\Rightarrow s\circ t$ satisfying seven conditions (on top of those that say t is a monad). Notice that s need not itself be a monad, but it could be while ι and ν could be obtained from the unit and multiplication: in this case λ is called a *distributive law* between the monads t and s.

For any wreath, we obtain a monad structure on the composite endomorphism $s\circ t$. The unit is ι and the multiplication is the composite

$$s\circ t\circ s\circ t\xrightarrow{s\circ\lambda\circ t}s\circ s\circ t\circ t\xrightarrow{\nu\circ\mu}s\circ t\circ t\xrightarrow{s\circ\mu}s\circ t.$$

This composite monad is the *wreath product*.

A wreath is called *Frobenius* when the monad (s,λ) on (A,t) in $\mathrm{EM}(\mathcal{K})$ is equipped with a Frobenius structure. We leave this to the reader to make more explicit [Johnson (1989b)].

Proposition 6.1: *The wreath product of a Frobenius wreath on a Frobenius monad* (A,t) *is Frobenius*.

Proof: Without loss of generality we may suppose $\mathcal{K}$ admits the Eilenberg–Moore construction. We use Theorem 1.6(f). Since (A,t) is Frobenius, the left adjoint f^t to $u^t:A^t\to A$ is also right adjoint. The Eilenberg–Moore construction on the wreath, as a monad in $\mathrm{EM}(\mathcal{K})$, is the wreath product. So the left adjoint of the underlying $(A,s\circ t)\to(A,t)$ is also a right adjoint. Since all 2-functors preserve adjunctions, the 2-functor $\mathrm{EM}(\mathcal{K})\to\mathcal{K}$ assigning to each monad its Eilenberg–Moore construction, assigns to $(A,s\circ t)\to(A,t)$, a morphism $A^{s\circ t}\to A^t$ whose left adjoint is also its right adjoint. The underlying $A^{s\circ t}\to A$ is the composite of the underlyings $A^{s\circ t}\to A^t\to A$, and so has a two-sided adjoint. It follows then that $s\circ t$ is Frobenius. Q.E.D.

Higher gauge theory—differential versus integral formulation

Florian Girelli[a)]

(Received 12 April 2004; accepted 11 June 2004; published 12 October 2004)

The term higher gauge theory refers to the generalization of gauge theory to a theory of connections at two levels, essentially given by 1- and 2-forms. So far, there have been two approaches to this subject. The differential picture uses non-Abelian 1- and 2-forms in order to generalize the connection 1-form of a conventional gauge theory to the next level. The integral picture makes use of curves and surfaces labeled with elements of non-Abelian groups and generalizes the formulation of gauge theory in terms of parallel transports. We recall how to circumvent the classic no-go theorems in order to define non-Abelian surface ordered products in the integral picture. We then derive the differential picture from the integral formulation under the assumption that the curve and surface labels depend smoothly on the position of the curves and surfaces. We show that some aspects of the no-go theorems are still present in the differential (but not in the integral) picture. This implies a substantial structural difference between nonperturbative and perturbative approaches to higher gauge theory. We finally demonstrate that higher gauge theory provides a geometrical explanation for the extended topological symmetry of *BF*-theory in both pictures. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1790048]

I. INTRODUCTION

Gauge theory can be formulated in two ways which we term the differential and the integral picture. As an illustration, recall, for example, Maxwell's equations which can be formulated either in terms of integral equations relating electric and magnetic fluxes through surfaces and currents through solenoids (this is actually the form which corresponds to experimental setups and in which the laws of electrodynamics were originally discovered) (integral picture) or alternatively in terms of the familiar differential equations (differential picture).

Similarly, any gauge theory can be formulated in two ways. Let M be some space–time manifold and the gauge group G be a Lie group with Lie algebra $\mathfrak{g}$. In the differential formulation of gauge theory, one considers a connection of some principal G-bundle $P \to M$. In local coordinates, i.e., using a local trivialization of the bundle, the connection is given by a $\mathfrak{g}$-valued connection 1-form A which transforms under changes of the coordinates as

$$A \mapsto A' = g^{-1}Ag + g^{-1}\,\mathrm{d}g, \tag{1.1}$$

where $g: U_1 \cap U_2 \to G$ denotes a transition function on the overlap of the coordinate patches $U_1, U_2 \subseteq M$.

[a)]Electronic mail: fgirelli@perimeterinstitute.ca
[b)]Electronic mail: hpfeiffer@perimeterinstitute.ca

The connection is usually taken to be the basic field of the theory, i.e., the variation in the action principle is with respect to A, and in a path integral quantum theory, one must integrate over all possible connections. The Lagrangian and the action of the theory depend on the curvature,

$$F = \mathrm{d}A + \tfrac{1}{2}[A,A], \tag{1.2}$$

which is a $\mathfrak{g}$-valued 2-form. It transforms under coordinate changes in a gauge covariant way,

$$F \mapsto F' = g^{-1}Fg. \tag{1.3}$$

As an alternative to this differential picture, there exists the integral formulation. In this formulation, one uses the group valued parallel transports,

$$U_\gamma = P\exp\left(\int_\gamma A\right) \in G, \tag{1.4}$$

along curves $\gamma:[0,1]\to M, \tau\mapsto\gamma(\tau)$ as the basic variables. Locally, the parallel transport always exists, and it is uniquely determined as the solution of the first order matrix differential equation,

$$\frac{\mathrm{d}}{\mathrm{d}t}U_\gamma(t) = [A_\mu(\gamma(t))\,\dot\gamma^\mu(t)]U_\gamma(t), \tag{1.5}$$

where we have written

$$U_\gamma(t) = P\exp\left(\int_0^t A_\mu(\gamma(\tau))\,\dot\gamma^\mu(\tau)\mathrm{d}\tau\right), \tag{1.6}$$

for the parallel transport along γ from $\tau=0$ to $\tau=t$. The initial condition is $U_\gamma(0)=1\in G$.

The curvature can then be calculated from the holonomy U_γ of a closed loop γ in the limit in which the loop shrinks to infinitesimal size. This integral picture of gauge theory closely resembles what is done in lattice gauge theory, but without the restriction that the curves must live on some fixed lattice. Note that in the integral formulation, the parallel transports satisfy various relations.

Now let us illustrate the basic idea of higher gauge theory. Suppose first that the gauge group in conventional gauge theory is Abelian, say $G=\mathrm{U}(1)$. Then the connection 1-form A is imaginary and the transition functions are of the form $g(x)=e^{\varphi(x)}$, where $\varphi:\mathrm{U}\to i\mathbb{R}$ is a suitable imaginary valued function, and (1.1) becomes

$$A \mapsto A' = A + \mathrm{d}\varphi, \tag{1.7}$$

so that the curvature 2-form (1.2) is just the exterior derivative,

$$F = \mathrm{d}A. \tag{1.8}$$

Abelian gauge theory with (1.7) and (1.8) now admits the following higher level generalization. Let A be some (imaginary valued) p-form which becomes the basic field of the theory. The Lagrangian and the action depend only on the curvature $(p+1)$-form $F=\mathrm{d}A$. The theory therefore enjoys a local gauge symmetry with the transformation law (1.7) for some $(p-1)$-form φ. This is a consequence of the Poincaré lemma because locally any closed p-form $A-A'$ is of the form $\mathrm{d}\varphi$. The Abelian theory at level p is therefore completely governed by the de Rham cohomology of M.

The Abelian theory at level $p=2$ is known in the physics literature as Kalb–Ramond fields,[1] and at generic level p as p-form electrodynamics.[2] Both refer to the differential picture of the theory. The corresponding integral picture makes use of p-dimensional surfaces labeled with elements of the Abelian group U(1). If the p-surfaces were restricted to a fixed hypercubic lattice, we would have at level $p=0$ the xy model of statistical mechanics, at $p=1$, U(1)-lattice gauge theory, and at higher p the models of Ref. 3.

We refer to these higher level theories as *higher gauge theory*. Does there exist a non-Abelian higher gauge theory, at least at level $p=2$? Many authors[4–8] have attempted to construct such models, but the necessity to find an underlying geometrical picture by suitably generalizing fiber bundles seems to impose serious constraints. To our knowledge, the most thoroughly studied model was the Freedman–Townsend model[4] which, however, has only an Abelian local symmetry and lacks a geometrical understanding of why this must be Abelian.

What precisely are the geometrical conditions involved in higher gauge theory? The coboundary condition $d\circ d=0$ of the Abelian case is, of course, no longer useful as the curvature F is in general no longer just dA, but rather given by (1.2). Assume we have some non-Abelian connection 2-form and wish to define its curvature 3-form. Geometrically, the 2-form would be associated with surfaces labeled by elements of some non-Abelian group H, and the curvature 3-form should be some group element associated with a closed surface, composed from several constituent surfaces that are all labeled with elements of H. Since the group H is non-Abelian and there is no canonical surface order available, we simply do not know how to compose the various non-Abelian labels.

Recall that the points of a curve have a natural order, and the definition of the parallel transport along a given curve indeed makes use of this order. For higher dimensional submanifolds, however, such a canonical order is not available. This lack of natural order has led Teitelboim[9] to the formulation of a no-go theorem ruling out the existence of non-Abelian gauge theories for extended objects. This applies essentially to any gauge theory whose connection is a non-Abelian p-form, $p\geqslant 2$.

With the introduction of 2-categories in mathematics, it recently became possible to sidestep this no-go theorem at $p=2$. On the mathematical side, there is the construction of non-Abelian gerbes generalizing fiber bundles, see, for example, Ref. 10. It is expected that gerbes provide the desired generalization of fiber bundles. They are, for example, conjectured to play a role in theories on coincident 5-branes is string theory, see for example, Refs. 11 and 12. In the present paper, we prefer a slightly different approach based on the definition of Lie 2-groups by Baez[13] which generalize ordinary Lie groups to a higher level and which include the symmetries of gerbes at least in the case of strict categories. This will allow us to explicitly solve the surface ordering problem, thereby providing a rigorous basis for Chepelev's conjectures,[7] and to see in detail how Teitelboim's no-go theorem is avoided. Our results finally provide the geometrical background to most of the traditional approaches to non-Abelian 2-forms, at least as long as strict categories are sufficient, and explain geometrically why there are some restrictions that become effective only if one requires smooth 1- and 2-forms, but not necessarily in a nonperturbative approach. It comes as a surprise that *BF*-theory which is usually not mentioned in the context of non-Abelian 2-forms, does form a nontrivial example of higher gauge theory.

Let us now briefly outline our approach. Starting from the notion of Lie 2-groups, Baez has defined Lie 2-algebras and started to generalize the differential picture of gauge theory to a theory involving non-Abelian connection 1- and 2-forms.[13] Open questions in this approach are the precise form of the local gauge transformations and of the gauge invariant expressions which are required in order to define Lagrangians and actions in physics.

Also starting from the notion of Lie 2-groups, we have generalized the integral picture of gauge theory to a theory involving curves and surfaces labeled with elements of non-Abelian groups.[14] This formulation has the advantage that the theory of 2-categories dictates the form of the local gauge transformations and the expressions for the gauge invariant quantities. The no-go theorems can be avoided because the underlying 2-categorical structure leads to a nontrivial interplay of the curve and surface labels.

An important question is how the differential[13] and the integral approach[14] are related. In this paper, we start from the integral picture of Ref. 14 and systematically derive the corresponding differential expressions by studying the non-Abelian curve and surface labels of the theory in the infinitesimal limit, assuming that the labels depend smoothly on the curves and surfaces. In the smooth case, we find an additional flatness condition at level 1 which has not yet appeared in the

literature. It implies in particular that the non-Abelian part of the connection 2-form agrees with the curvature of the connection 1-form, that the curvature 2-form vanishes and that the curvature 3-form is Abelian.

We show that an interesting example of higher gauge theory is given by *BF*-theory with non-Abelian gauge group[15] in which the level-1 flatness is a key feature of the theory, in fact encoded in the field equations. The theory of 2-categories then provides the explanation for the extended local (topological) symmetry. Otherwise, the resulting conditions show that the classic no-go theorems reappear only in the differential picture in which they rule out the naive generalization of the Yang–Mills action. The algebraic structure of the integral picture, however, still allows us to have nontrivial central group elements that characterize the 2-curvature associated with closed labeled surfaces which we call 2-holonomies. If the center of the gauge group is discrete such as, for example, for SU(N), the differential picture would require these central elements to be trivial, but in the integral picture and in any nonperturbative quantum theory based on it, no such restriction applies. The integral picture is therefore more general than the differential one and is in some sense essentially nonperturbative.

Since the nontrivial central elements can be interpreted as the presence of singularities of codimension 2, one can say that the integral picture of higher gauge theory rather predicts the existence of topological defects in the differential formulation.

The present paper is structured as follows. In Sec. II, we recall the construction of higher gauge theory in the integral formulation as it was developed in Ref. 14. Our presentation is self-contained. We emphasize the calculational aspects and try to hide as much as possible of the 2-category theory in our notation. In Sec. III, we then derive the differential formulation of higher gauge theory starting from the integral picture and compare the result with Ref. 13. We conclude in Sec. IV with comments on interesting questions for further investigations.

II. THE INTEGRAL FORMULATION

In this section, we review the integral picture of higher gauge theory following Ref. 14. We call the higher level model a 2-*gauge theory* whereas we refer to conventional gauge theory as a 1-*gauge theory* in view of the hierarchy of models sketched in Ref. 14. The theory is formulated at the integral level, i.e., it describes curves and surfaces which are labeled with data from some algebraic structure, supplementing the parallel transports of conventional 1-gauge theory by additional group elements which are used to label surfaces.

A. Lie 2-groups

The algebraic structure required to describe a 1-gauge theory is just some gauge group G, usually taken to be a Lie group. The geometric objects that are labeled with algebraic data, are the curves giving rise to the parallel transports of the theory. The group structure ensures that we can consistently compose (multiply) parallel transports and also reverse their direction (inversion).

The algebraic structure for a 2-gauge theory is a so-called 2-group.[13,16] This is a pair G, H of groups with two maps. (We define here a *crossed module*, a structure from which we can construct a strict 2-group.[13,16]) The first map is a group homomorphism $t: H \to G$, i.e.,

$$t(h_1 \cdot h_2) = t(h_1) \cdot t(h_2), \tag{2.1}$$

$$t(1) = 1, \tag{2.2}$$

for all $h_1, h_2 \in H$. The second map is an action of G on H by automorphisms. This is an operation $g \triangleright h$ taking values in H, which is a group action, i.e.,

$$(g_1 \cdot g_2) \triangleright h = g_1 \triangleright (g_2 \triangleright h), \tag{2.3}$$

$$1 \triangleright h = h, \tag{2.4}$$

for all $g_1, g_2 \in G$ and $h \in H$, such that $h \mapsto g \triangleright h$ is a homomorphism for each $g \in G$, i.e.,

$$g \triangleright (h_1 \cdot h_2) = (g \triangleright h_1) \cdot (g \triangleright h_2), \tag{2.5}$$

$$g \triangleright 1 = 1, \tag{2.6}$$

for all $h_1, h_2 \in H$. These maps are required to satisfy the following two compatibility conditions:

$$t(g \triangleright h) = g \cdot t(h) \cdot g^{-1}, \tag{2.7}$$

$$t(h) \triangleright h' = h \cdot h' \cdot h^{-1}, \tag{2.8}$$

for all $g \in G, h, h' \in H$. A Lie 2-group is a 2-group in which G and H are Lie groups and both maps t and $\triangleright$ are smooth.

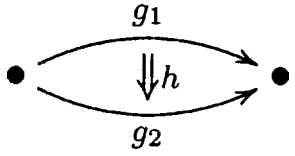
Plenty of examples of Lie 2-groups are known.[13,14] Here we mention the following cases.

(1) The *Euclidean* and *Poincaré 2-groups*. Here $H = \mathbb{R}^n$ is Euclidean or Minkowski space and $G = \mathrm{SO}(n)$ or $\mathrm{SO}(n-1,1)$. The map t is trivial, i.e., $t(h) = 1$ for all $h \in H$, and $\triangleright$ is the obvious action by rotation.
(2) More generally, one can choose H to be any vector space on which the Lie group G is represented. The map t is trivial in this case, and $\triangleright$ and is the action of G on its representation H. In this way, one defines, for example, the *adjoint* and the *co-adjoint* 2*-groups* in which $H = \mathfrak{g}$ or $H = \mathfrak{g}^*$ where $\mathfrak{g}$ denotes the Lie algebra of G.
(3) The *automorphism* 2*-groups*. Let H be any Lie group and G its group of automorphisms. The action $g \triangleright h$ is the application of the particular automorphism, and $t: H \to G$ associates with each element h the corresponding *inner automorphism* $h' \mapsto hh'h^{-1}$. This example is related to non-Abelian gerbes.[13] For example, if $H = \mathrm{SU}(2)$, we have $G = \mathrm{SU}(2)/\mathbb{Z}_2 \cong \mathrm{SO}(3)$ where $\mathbb{Z}_2$ is the centre of SU(2). In general, $\ker t \subseteq Z(H)$ is always contained in the center of H.

B. 2-gauge theory

In a 2-gauge theory, we have to label geometric objects at two levels. Curves are labeled by elements of G. Their composition and orientation reversal is defined as in conventional gauge theory.

In addition, surfaces are labeled with elements of H. For each surface (the elementary surfaces are chosen to have the topology of a disk), we choose two reference points on the boundary (full dots in the diagram below, we are going to suppress them later on) and split the boundary into two curves with labels $g_1 \in G$ (*source*) and $g_2 \in G$ (*target*) as follows:



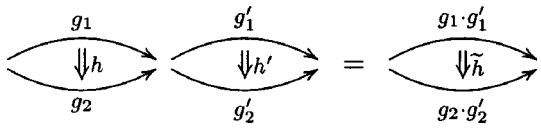
(2.9)

The label h of the surface is required to satisfy

$$t(h) = = g_2 \cdot g_1^{-1}, \tag{2.10}$$

i.e., $t(h)$ is the (inverse) holonomy along the boundary curve. This condition appears when we use the Lie crossed module in order to construct a Lie 2-group.[13,14,16] The first reference point is the base point of this holonomy and therefore plays a role in (2.10) whereas the second reference point does not enter this condition.

We can now compose surfaces in two different ways. First, we can join them *horizontally* in one common reference point,

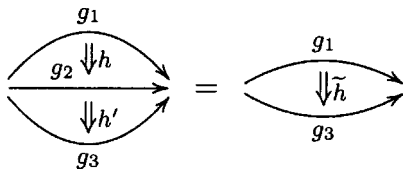


(2.11)

where the label of the composition is given by

$$\tilde{h} = h \cdot (g_1 \triangleright h'). \tag{2.12}$$

Note the asymmetry: the source of the first surface acts on the label of the second one. [The pairs (h, g_1) of surface label and source curve label form the semidirect product $H \rtimes G$ under horizontal composition.] As required, it follows that $t(\tilde{h}) = (g_2 g_2')(g_1 g_1')^{-1}$. Alternatively, we can glue the surfaces *vertically* along a common curve,



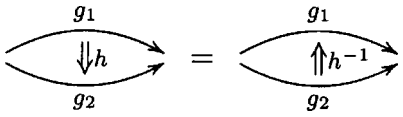
(2.13)

where the composition is simply given by

$$\tilde{h} = h' \cdot h. \tag{2.14}$$

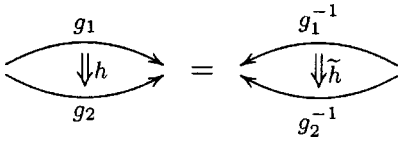
Observe that $t(\tilde{h}) = g_3 g_1^{-1}$ as expected.

The orientation of a surface can be reversed if it is labeled by the inverse element h^{-1} instead,



(2.15)

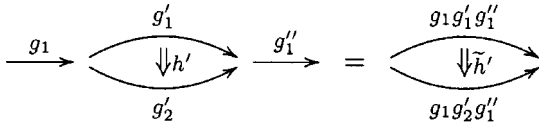
Both source and target curve of some surface can be reversed,



(2.16)

if the surface label is replaced by $\tilde{h} = g_1^{-1} \triangleright h^{-1}$. Observe that $t(\tilde{h}) = g_2^{-1}(g_1^{-1})^{-1}$ as required.

An important operation is known as *whiskering*. By attaching whiskers to a surface h, for example, attaching whiskers g_1 and g_1'' to some surface h' with source g_1' and target g_2',



(2.17)

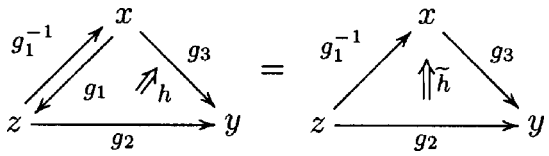
we can construct a surface with source $g_1 g_1' g_1''$ and target $g_1 g_2' g_1''$, carrying the label

$$\tilde{h}' = g_1 \triangleright h'. \tag{2.18}$$

The attachment of the left whisker can be understood as a special case of the horizontal composition (2.11) in which $g_1 = g_2$ and $h = 1$ so that the left surface collapses to a line. A similar

argument is available for the right whisker. The asymmetry in the expression (2.18) originates from the asymmetry of the horizontal composition (2.12).

Whiskering allows us to change the reference points of a surface. For example, starting from a surface h with reference points x and y, i.e., source $g_1 \cdot g_2$ and target g_3,



(2.19)

we can whisker from the left by g_1^{-1} and obtain the surface $\tilde{h}=g_1^{-1}\triangleright h$ with reference points z and y, i.e., source g_2 and target $g_1^{-1}\cdot g_3$.

Given any collection of curves and surfaces, a *configuration* of 2-gauge theory is an assignment of elements of G to the curves and of elements of H to the surfaces so that the following conditions hold. Compositions of curves are labeled by the product of elements in G, curves of opposite orientation are labeled by the inverse group element. For each surface labeled by $h \in H$, we have $t(h)=g_2\cdot g_1^{-1}$ where g_1 and g_2 are the source and target curve, respectively. Finally, compositions of surfaces, and surfaces whose reference points have been changed, are labeled as described above in this section. The configurations thus defined can be viewed as the classical configurations of 2-gauge theory or, in a path integral quantum theory, these are the configurations over which we sum in the path integral. The path integral was given in detail in Ref. 14.

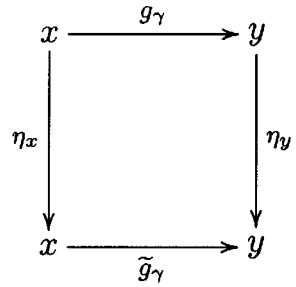
C. Local 2-gauge transformations

The 2-gauge theory defined in the preceding section enjoys an extended local gauge symmetry which we call a *local* 2*-gauge symmetry*.

First recall the conventional local 1-gauge symmetry in a formulation of gauge theory in the language of parallel transports. A local gauge transformation is given by a *generating function* assigning group elements $\eta_x, \eta_y \in G$ to the points. For each curve γ from point x to point y with label $g_\gamma \in G$, the transformed parallel transport is then calculated by

$$\tilde{g}_\gamma = \eta_x^{-1} g_\gamma \eta_y, \tag{2.20}$$

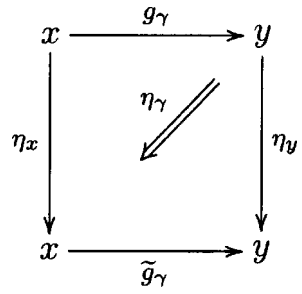
which we visualize by the following diagram:



(2.21)

We say that the diagram *commutes*, i.e., it does not matter which way a round we go from one corner to another. If we view all four labeled curves g_γ, $\tilde{g}_\gamma$, η_x, and η_y as a gauge connection, then this connection is *flat*, i.e., the parallel transport is path independent.

In 2-gauge theory, the local gauge transformation (2.20) is weakened by extending the generating function to the next level. The 2*-generating function* not only assigns group elements $\eta_x, \eta_y \in G$ to the points, but there is the additional freedom of choosing elements $\eta_\gamma \in H$ for the curves. (These curve labels are in general path dependent.) Diagram (2.21) is generalized to



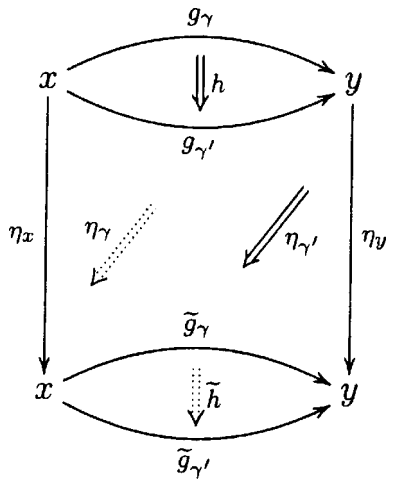
(2.22)

where we require $t(\eta_\gamma)=(\eta_x\tilde{g}_\gamma)(g_\gamma\eta_y)^{-1}$. The full diagram involving g_γ, $\tilde{g}_\gamma$, η_x, η_y, and η_γ can therefore be viewed as a configuration of 2-gauge theory in which the surface labeled with η_γ has the source $g_\gamma\cdot\eta_y$ and the target $\eta_x\cdot\tilde{g}_\gamma$. We can thus calculate the gauge transformed parallel transport by

$$\tilde{g}_\gamma = \eta_x^{-1}t(\eta_\gamma)g_\gamma\eta_y, \tag{2.23}$$

which generalizes the conventional local gauge transformation (2.20).

This is the prescription of how to transform the curve labels. In 2-gauge theory, we must specify in addition how to transform the surface labels. Therefore we write down the surface analogue of the diagram (2.21) and require that for each surface labeled $h\in H$ with source and target curves γ, γ' labeled by g_γ and $g_{\gamma'}$, the following "tin can" diagram:



(2.24)

2-*commutes*. This means that it does not matter which way round we compose the labeled surfaces, i.e., the configuration of 2-gauge theory shown in diagram (2.24) is 2-*flat*. The top of this "tin can" is the old configuration and the bottom the new one with curve labels $\tilde{g}_\gamma$, $\tilde{g}_{\gamma'}$ and surface label $\tilde{h}$. The transformed surface label is thus given by

$$\tilde{h} = \eta_x^{-1}\triangleright(\eta_{\gamma'}h\eta_\gamma^{-1}). \tag{2.25}$$

We can summarize this paragraph as follows. The local 2-gauge transformations are given by 2-generating functions which assign elements of G to the points and elements of H to the curves. The transformed curve and surface labels are then determined by (2.23) and (2.25). Although, at first sight, these transformation rules look quite artificial, they follow immediately from the underlying 2-categorical structure.[14]

D. Pure 2-gauge and 2-flatness

In conventional 1-gauge theory, we say that a configuration is *pure gauge* if it is gauge equivalent to the trivial connection in which all curves are assigned the group unit. A configuration

is therefore pure gauge if there exists a generating function associating group elements $\eta_j \in G$ with all points so that the parallel transports are given by

$$g_{12} = \eta_1^{-1}\eta_2, \tag{2.26}$$

for any curve from 1 to 2, cf. (2.20). Observe that any configuration which is pure gauge, is also *flat*, i.e., its parallel transports are path independent.

In complete analogy, we say that a configuration of 2-gauge theory is *pure* 2-*gauge* if it is 2-gauge equivalent to the trivial configuration in which all curves are labeled by the group unit of G and all surfaces by the group unit of H. A configuration with curve labels $g_\gamma, g_{\gamma'} \in G$ and surface labels $h \in H$ is therefore pure 2-gauge if there exists a 2-generating function that assigns elements $\eta_x, \eta_y \in G$ to the points and $\eta_\gamma, \eta_{\gamma'} \in H$ to the curves such that for any curve γ from x to y,

$$g_\gamma = \eta_x^{-1} t(\eta_\gamma)\eta_y, \tag{2.27}$$

and for any surface with source curve g_γ and target curve $g_{\gamma'}$,

$$h = \eta_x^{-1} \triangleright (\eta_{\gamma'}\eta_\gamma^{-1}), \tag{2.28}$$

cf. (2.23) and (2.25).

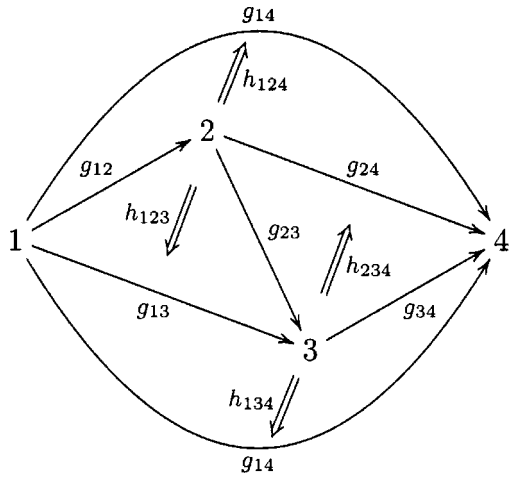
A configuration of 2-gauge theory is called 2-*flat* if the surface label on any surface of topology S^2 which is the boundary of a 3-ball, is just the group unit $1 \in H$. As a consequence, in 2-flat configurations, the surface label of any disk shaped surface depends only on the boundary (source and target) curve labels in G. Note also that being pure 2-gauge implies 2-flatness.

E. Composition of labeled surfaces

In this section, we describe how the language of 2-gauge theory can be used in order to define compositions of labeled surfaces. We will make use of this surface composition in Sec. II F in order to construct gauge invariant quantities that are associated with closed surfaces, and in Sec. III in order to derive the differential formulation.

In Sec. II B, we have introduced a number of operations by which we can modify and combine labeled surfaces: vertical and horizontal composition, two types of orientation reversal and the change of reference point by whiskering. These rules can be employed in order to calculate the composition of elementary surfaces to arbitrarily large ones.

We illustrate this procedure for the boundary surface of a tetrahedron,



(2.29)

We have numbered the vertices by 1, 2, 3, 4. The edges (j,k), $j<k$, are labeled by group elements $g_{jk} \in G$ and the triangles (j,k,ℓ), $j<k<\ell$, by elements $h_{jk\ell} \in H$. We have oriented the triangles

(j,k,ℓ) so that they have the source $g_{jk}\cdot g_{k\ell}$ and the target $g_{j\ell}$, i.e., $t(h_{jk\ell})=g_{j\ell}(g_{jk}g_{k\ell})^{-1}$.

We choose reference points, here 1 and 4, and cut the tetrahedron surface along the edge (14). This *base edge* forms both the source and the target curve of the surface. Imagine that a curve starting from the source sweeps out the entire surface until it reaches the target. This determines the ordering of the vertical composition of the constituent surfaces. We just have to make sure that all surfaces are composable, i.e., they have the suitable reference points and the correct orientation in order to compose them vertically by (2.13).

Consider the diagram (2.29). We first move the curve from g_{14} to $g_{12}g_{24}$ via h_{124}^{-1}. At this stage we cannot compose the result with the triangle (123) because source and target would not match, but we can use the orientation reversed triangle (234), whiskered from the left by g_{12}. This moves our curve to $g_{12}g_{23}g_{34}$ using the label $g_{12}\triangleright h_{234}^{-1}$ of the whiskered and reversed surface. In the next step, we can use the triangle (123), whiskered from the right by g_{34} which does not change the label h_{123}. Finally, we move our curve from $g_{13}g_{34}$ to g_{14} along h_{134}.

The label associated to the boundary surface of the tetrahedron is therefore the vertical composition, cf. (2.13),

$$\tilde{h}=h_{134}h_{123}(g_{12}\triangleright h_{234}^{-1})h_{124}^{-1}. \tag{2.30}$$

This is a useful notation for the automorphism 2-group in which typically both G and H are non-Abelian. In the case of the Euclidean and the Poincaré 2-groups, it is preferable to write the group structure of H additively, i.e.,

$$\tilde{h}=h_{134}+h_{123}-g_{12}\triangleright h_{234}-h_{124}. \tag{2.31}$$

The following geometrical picture illustrates the surface composition. Imagine the surface labels $h_{jk\ell}$ are interpreted in a local coordinate system associated with their first reference point j, the common starting point of their source and target curves. If we vertically compose surfaces that are based at the same reference point, i.e., whose labels are given in the same coordinate system, the composition is just the group product in H, cf. (2.14). If the reference points and therefore the coordinate systems are different, however, then we must parallel transport before we can compare and multiply their surface labels. In the example (2.30), this is relevant for the surface h_{234}, the only surface that is not based at point 1 but rather at 2. We have to whisker h_{234}^{-1} from the left by g_{12} in order to obtain a surface $g_{12}\triangleright h_{234}^{-1}$ with reference point 1.

For a closed surface of topology S^2, i.e., of genus zero, source and target curve agree so that $t(\tilde{h})=1$. Recall that $\ker t\subseteq Z(H)$ is always contained in the center $Z(H)$ of H and therefore Abelian. We call the labels $h\in\ker t$ of closed surfaces the 2-*holonomies* of the theory.

F. Gauge invariant expressions

For all the assignments of algebraic data to geometric objects, we should understand how they depend on the choices made. Consider, for example, the holonomy along a closed loop (*Wilson loop*) in conventional gauge theory. It still depends on the base point of the loop. It does so, however, in a well-understood way. Changing the base point leads to the conjugation of the holonomy with the parallel transport from the old to the new base point. Any group character applied to the holonomy yields an invariant. Observe that the independence of the base point and the invariance under local gauge transformations are both implemented by the same operation, namely by calculating the character. Due to its gauge invariance, the character can then serve as the Lagrangian or as the action of a physical theory.

An analogous result can be shown for the integral picture of 2-gauge theory.[14] Consider a closed surface of topology S^2, for example, the surface of the tetrahedron (2.29). We must choose a *base edge* at which we start and finish the surface composition. In our tetrahedron example this was the edge (14). When we change the base edge, holding its two end points fixed, then the 2-holonomy h' of such a closed surface (*Wilson surface*) is conjugated,

$$h' \mapsto hh'h^{-1}, \tag{2.32}$$

by the label $h \in H$ associated with the surface enclosed between the old and the new base edge. If we change the reference point of a closed surface (the starting point of its base edge) by whiskering with $g \in G$, then the 2-holonomy is acted upon by the corresponding parallel transport,

$$h' \mapsto g \triangleright h'. \tag{2.33}$$

We have seen that the 2-holonomies, i.e., the labels h' associated with closed surfaces, are contained in $\ker t$. The functions s: $\ker t \to \mathbb{R}$ that are independent of the base edge and of the reference points, i.e., that satisfy for all $g \in G$, $h \in H$, and $h' \in \ker t$,

$$\begin{aligned} s(hh'h^{-1}) &= s(h'), \\ s(g \triangleright h') &= s(h'), \end{aligned} \tag{2.34}$$

are called *2-actions*. We have shown in Ref. 14 that these are precisely the functions of the 2-holonomy that are invariant under the local 2-gauge transformations (2.23) and (2.25), hence the name. They form the generalization of the Wilson action to 2-gauge theory.

For the Euclidean and Poincaré 2-groups, the 2-actions are the maps $s: H \to \mathbb{R}$ that are constant on the orbits of G on $H = \mathbb{R}^n$, i.e., they are functions of the invariant Euclidean or Minkowski norm, $s(v) = f(\eta(v,v))$ where $f: \mathbb{R} \to \mathbb{R}$ is any function, $v \in \mathbb{R}^n$, and η denotes the Euclidean or Minkowski scalar product. For the automorphism 2-group, any map $s: Z(H) \to \mathbb{R}$ gives rise to an acceptable 2-action.

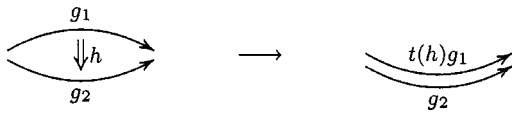
Even though there exists no canonical surface ordering, we have shown, using ideas from the theory of 2-categories, that the interplay of curves and surfaces not only circumvents the no-go theorems, but also provides us with an unambiguous and gauge covariant composition of labeled surfaces.

Whereas in conventional gauge theory, the gauge invariant expressions are associated with closed loops, we have seen that in 2-gauge theory, we can form 2-gauge invariant expressions for closed surfaces. Is there a also a 2-gauge invariant expression associated with loops, i.e., a direct generalization of the Wilson loop to 2-gauge theory?

Recall that in a 1-gauge theory, we would just calculate the (real part of a unitary) character,

$$\chi(g_2^{-1} g_1), \tag{2.35}$$

of the holonomy $g_2^{-1} g_1 \in G$ in order to obtain a locally 1-gauge invariant expression. If we take into account a possibly nontrivial transport of curves along surfaces, then we cannot directly compare the two curve labels g_1 and g_2, but rather we must surface transport one curve onto the other,



(2.36)

Rather than the usual holonomy $g_2^{-1} g_1$, we should therefore consider the expression,

$$\mathcal{F} = g_2^{-1} t(h) g_1, \tag{2.37}$$

which takes the surface transport into account. Due to condition (2.10), however, this expression always gives the group unit of G, $\mathcal{F} = 1$.

There is therefore no loop based gauge invariant expression in 2-gauge theory which would generalize the Wilson loop of 1-gauge theory, but only the surface based construction with the invariance (2.34).

III. THE DIFFERENTIAL FORMULATION

In this section, we derive the differential formulation of 2-gauge theory which corresponds to the integral picture of the preceding section. We therefore study the integral formulation of 2-gauge theory on squares, cubes, and hypercubes, assume that the labels depend smoothly on the positions of the curves and surfaces and consider the limit in which these shrink to infinitesimal size.

The theory we derive uses the same connection 1- and 2-forms as Baez[13] which have also been found independently by Hofman,[8] but with a flatness condition at level 1 which has not yet appeared in the literature. As a bonus, we can also derive the local gauge transformations.

A. Lie 2-algebras

Just as the differential picture of conventional gauge theory involves the Lie algebra $\mathfrak{g}$ of the gauge group G, we need here the appropriate generalized notion of a Lie algebra associated with the gauge 2-group.

A *Lie 2-algebra* consists of two Lie algebras $\mathfrak{g}$ and $\mathfrak{h}$ with two maps. (We describe here a differential crossed module, a structure from which we can construct a strict Lie 2-algebra.[13,17]) The first map, $\tau:\mathfrak{h}\to\mathfrak{g}$, is a homomorphism of Lie algebras, i.e., a linear map that satisfies

$$\tau([Y_1,Y_2])=[\tau(Y_1),\tau(Y_2)], \tag{3.1}$$

for all $Y_1,Y_2\in\mathfrak{h}$. The second map is an action of $\mathfrak{g}$ on $\mathfrak{h}$ by derivations, i.e., a bilinear operation $X\triangleright Y$ for $X\in\mathfrak{g}$, $Y\in\mathfrak{h}$, taking values in $\mathfrak{h}$, such that it is an action, i.e.,

$$[X_1,X_2]\triangleright Y=X_1\triangleright(X_2\triangleright Y)-X_2\triangleright(X_1\triangleright Y), \tag{3.2}$$

for all $X_1,X_2\in\mathfrak{g}$ and $Y\in\mathfrak{h}$, and such that for any $X\in\mathfrak{g}$, the map $Y\mapsto X\triangleright Y$ is a derivation on $\mathfrak{h}$, i.e., linear and,

$$X\triangleright[Y_1,Y_2]=[X\triangleright Y_1,Y_2]+[Y_1,X\triangleright Y_2], \tag{3.3}$$

for all $Y_1,Y_2\in\mathfrak{h}$. These maps are required to satisfy the following two compatibility conditions:

$$\tau(X\triangleright Y)=[X,\tau(Y)], \tag{3.4}$$

$$\tau(Y)\triangleright Y'=[Y,Y'], \tag{3.5}$$

for all $X\in\mathfrak{g}$, $Y,Y'\in\mathfrak{h}$.

Given some Lie 2-group in terms of the Lie groups G, H and the maps t and $\triangleright$ (Sec. II A), one can construct its Lie 2-algebra as follows.[17] The Lie algebras $\mathfrak{g}$ and $\mathfrak{h}$ are the Lie algebras of the Lie groups G and H. The map $\tau:\mathfrak{h}\to\mathfrak{g}$ is the derivative $\tau=\mathrm{d}t$ of the map $t:H\to G$. Finally, let the map,

$$\alpha:G\to \mathrm{Aut}\,H,\quad \alpha(g)[h]:=g\triangleright h, \tag{3.6}$$

associate an automorphism $\alpha(g)$ of H with each element $g\in G$. Then the derivative of α,

$$\mathrm{d}\alpha:\mathfrak{g}\to \mathrm{Der}\ \mathfrak{h},\quad X\mapsto \mathrm{d}\alpha(X), \tag{3.7}$$

associates with each element $X\in\mathfrak{g}$ a derivation $\mathrm{d}\alpha(X)$ of $\mathfrak{h}$. The operation $\triangleright$ in the definition of the Lie 2-algebra is chosen to be $X\triangleright Y:=\mathrm{d}\alpha(X)[Y]$.

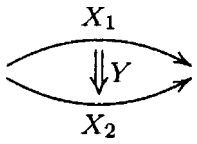
Consider first the Lie 2-algebra of the Euclidean and Poincaré 2-groups. In this case, $\mathfrak{g}=\mathfrak{so}(n)$ or $\mathfrak{g}=\mathfrak{so}(n-1,1)$, and $\mathfrak{h}=\mathbb{R}^n$. The action of $\mathfrak{g}$ on $\mathfrak{h}$ is in the defining representation of $\mathfrak{g}$, and the map $\tau:\mathfrak{h}\to\mathfrak{g}$ is the null map.

For the automorphism 2-group of $H=\mathrm{SU}(2)$, we have $G=\mathrm{SU}(2)/\mathbb{Z}_2$. In this case, both Lie algebras agree, $\mathfrak{g}=\mathfrak{h}$, and we have $t(Y)=Y$ for all $Y\in\mathfrak{h}$. Finally, the action of $\mathfrak{g}$ on $\mathfrak{h}=\mathfrak{g}$ is the adjoint action, $X\triangleright Y=[X,Y]$.

Let us conclude this section with a remark on the category theory underlying the construction of Lie 2-algebras. When we construct a Lie 2-algebra from the differential crossed module, there is the condition [analogous to (2.10)],

$$\tau(Y) = X_2 - X_1, \tag{3.8}$$

for each 2-cell,



(3.9)

$X_i \in \mathfrak{g}$, $Y \in \mathfrak{h}$, of the 2-category which is defined by the Lie 2-algebra. In the gauge theory language, this would correspond to an infinitesimally small surface. The condition (3.8) is in fact already present in the 2-vector spaces of Ref. 17.

B. Notation

For the discussion of the differential picture of higher gauge theory, we restrict ourselves to trivial bundles and present the theory in the language of the $\mathfrak{g}$- and $\mathfrak{h}$-valued connection 1- and 2-forms. As we will see in the following section, the basic fields of the differential picture are a $\mathfrak{g}$-valued connection 1-form A and an $\mathfrak{h}$-valued connection 2-form B.

We denote by d_A the exterior covariant derivative for the connection A which acts on $\mathfrak{g}$-valued p-forms φ by

$$\mathrm{d}_A(\varphi) = \mathrm{d}\varphi + [A, \varphi]. \tag{3.10}$$

Here the bracket of a 1-form A with a p-form φ, both taking values in $\mathfrak{g}$, is defined by

$$[A, \varphi] := A^a \wedge \varphi^b [T_a, T_b], \tag{3.11}$$

where we have chosen a basis (T_a) of $\mathfrak{g}$ and written $A = A^a T_a$, $\varphi = \varphi^b T_b$ with coefficient forms A^a and φ^b. Summation over repeated indices is understood. Similarly, we define the action of d_A on $\mathfrak{h}$-valued p-forms ψ, using the action of $\mathfrak{g}$ on $\mathfrak{h}$ via the operation $\triangleright$,

$$\mathrm{d}_A(\psi) = \mathrm{d}\psi + A \triangleright \psi, \tag{3.12}$$

where the $\triangleright$ of a $\mathfrak{g}$-valued 1-form with an $\mathfrak{h}$-valued p-form is defined by

$$A \triangleright \psi := A^a \wedge \psi^b (T_a \triangleright T'_b), \tag{3.13}$$

where (T_a) denotes a basis of $\mathfrak{g}$ and (T'_b) a basis of $\mathfrak{h}$. We calculate for $\mathfrak{g}$-valued p-forms φ,

$$(\mathrm{d}_A \circ \mathrm{d}_A)(\varphi) = [F, \varphi], \tag{3.14}$$

and for $\mathfrak{h}$-valued p-forms ψ,

$$(\mathrm{d}_A \circ \mathrm{d}_A)(\psi) = F \triangleright \psi. \tag{3.15}$$

C. Configuration variables and their curvature

We shall first identify the basic fields and their associated curvature. We then compute their respective transformations under the local 2-gauge transformations.

We assume that all labels depend smoothly on the curves and surfaces. The key idea for the derivation of the differential picture is to write down the integral formulation on squares and cubes

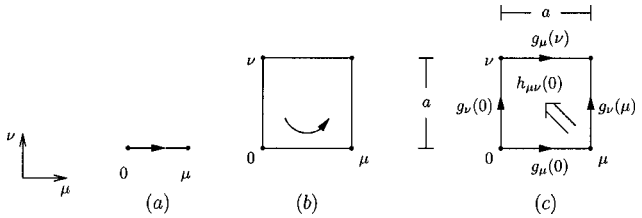


FIG. 1. Conventions for the integral formulation of 2-gauge theory on the squares, in particular (c) the generalized holonomy (3.22).

and then to study the limit in which these shrink to infinitesimal size. We write the labels $g \in G$, $h \in H$ as exponentiated curve and surface integrals over approximately constant differential forms,

$$g_\mu(0) = e^{\int_\gamma A} \sim e^{aA_\mu},$$
$$h_{\mu\nu}(0) = e^{\int_S B} \sim e^{a^2 B_{\mu\nu}}. \tag{3.16}$$

Here γ denotes a curve of length a from $x=0$ to $x=\mu$ and S a square of area a^2 in the $(\mu\nu)$-plane. We abbreviate the coordinates by $x=\mu := ae_\mu$ where e_μ is a vector of unit length. All A_μ, etc., without argument are at $x=0$.

The basic fields in the differential picture are the $\mathfrak{g}$-valued connection 1-form $A=A_\mu\,\mathrm{d}x^\mu$ and the $\mathfrak{h}$-valued connection 2-form $B=\frac{1}{2}B_{\mu\nu}\,\mathrm{d}x^\mu\wedge\mathrm{d}x^\nu$. Note that $h_{\mu\nu}=h_{\nu\mu}^{-1}$.

We will make use of the usual Taylor expansion,

$$g_\mu(\alpha) \sim e^{aA_\mu + a^2\partial_\alpha A_\mu}, \tag{3.17}$$

$$h_{\mu\nu}(\alpha) \sim e^{a^2 B_{\mu\nu} + a^3 \partial_\alpha B_{\mu\nu}}. \tag{3.18}$$

When we have a product of Lie group elements, the Baker–Hausdorff formula allows us to get the corresponding operation at the Lie algebra level,

$$e^x e^y = e^{x+y+(1/2)[x,y]+\cdots}. \tag{3.19}$$

The action $\mathrm{d}\alpha$ of $\mathfrak{g}$ on $\mathfrak{h}$ is the infinitesimal version of the action of G over H,

$$g_\beta(0) \triangleright h_{\mu\nu}(\beta) \sim e^{a^2 B_{\mu\nu} + a^3 \partial_\beta B_{\mu\nu} + a^3\, \mathrm{d}\alpha(A_\beta)(B_{\mu\nu})}. \tag{3.20}$$

The map $\tau:\mathfrak{h}\to\mathfrak{g}$ is the infinitesimal version of the map $t:H\to G$,

$$t(h_{\mu\nu}) \sim e^{a^2 \tau(B_{\mu\nu})}. \tag{3.21}$$

As mentioned earlier, they satisfy the compatibility conditions (3.5) and (3.4). The approximations (3.16)–(3.20) together with (3.4) and (3.5) are all we need in order to derive the differential picture.

So far we have identified as the basic fields the generalized connection (A,B) in agreement with Ref. 13. Let us now calculate a curvature 2-form, using the holonomy around an infinitesimal square, and a curvature 3-form, using the 2-holonomy around an infinitesimal cube.

In 1-gauge theory, the curvature 2-form is given by an infinitesimal Wilson loop. In the context of 2-gauge theory, it depends also on the B-field because of (2.37). The expression $\mathcal{F}$ of (2.37) reads for the square of Fig. 1(c),

$$e^{a^2\tilde{F}_{\mu\nu}} \sim \mathcal{F}_{\mu\nu} = g_\mu^{-1}(\nu) g_\nu(0)^{-1} t(h_{\mu\nu}(0)) g_\mu(0) g_\nu(\mu). \tag{3.22}$$

Using the approximations (3.16)–(3.19) and dropping all terms of order a^3 in the exponent, we obtain the curvature 2-form $\tilde{F}_{\mu\nu}=\frac{1}{2}\tilde{F}_{\mu\nu}\,\mathrm{d}x^\mu\wedge\mathrm{d}x^\nu$ as follows:

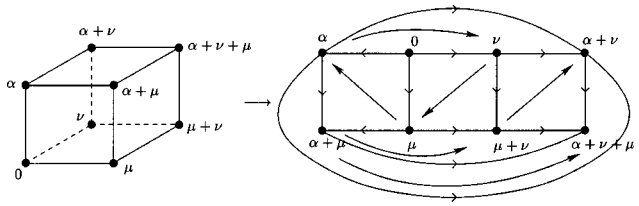

FIG. 2. A flattend cube in order to read off the 2-holonomy (3.26)

$$\tilde{F}_{\mu\nu} = \partial_\mu A_\nu - \partial_\nu A_\mu + [A_\mu, A_\nu] + \tau(B_{\mu\nu}) = F_{\mu\nu} + \tau(B_{\mu\nu}), \tag{3.23}$$

where F denotes the conventional curvature of A. This agrees with Baez's expression[13] (up to a sign which is matter of convention),

$$\tilde{F} = \mathrm{d}A + \frac{1}{2}[A,A] + \tau(B) = F + \tau(B). \tag{3.24}$$

We have therefore found a geometrical interpretation for the generalized curvature $\tilde{F}$ from the surface transport of the curve (2.36).

It is important here to remember that in the definition of a strict Lie 2-group, we have $\mathcal{F} = 1 \in H$ in (2.37) and therefore at the differential level,

$$\tau(B) = -F. \tag{3.25}$$

This condition is the alter ego of the equations (2.10) and (3.8) and has some drastic consequences: it means that the curvature 2-form $\tilde{F}$ is always zero.

Let us now compute the curvature 3-form $G = \frac{1}{6} G_{\alpha\mu\nu}\, \mathrm{d}x^\alpha \wedge \mathrm{d}x^\mu \wedge \mathrm{d}x^\nu$ associated with A and B. It is the differential counterpart of the 2-holonomy around a cube (Fig. 2).

To calculate it, we use the same technique as for the tetrahedron in (2.29) and (2.30). We obtain

$$e^{a^3 G_{\alpha\mu\nu}} \sim \mathcal{G}_{\alpha\mu\nu} = [g_\alpha(0) \triangleright h_{\mu\nu}(\alpha)] h_{\mu\alpha}(0) [g_\mu(0) \triangleright h_{\nu\alpha}(\mu)] h_{\nu\mu}(0) [g_\nu(0) \triangleright h_{\alpha\mu}(\nu)] h_{\alpha\nu}(0). \tag{3.26}$$

Let us use once again the approximations (3.16)–(3.19) and drop all terms of order a^4 in the exponent, so that we get

$$G_{\alpha\mu\nu} = \partial_\alpha B_{\mu\nu} + \mathrm{d}\alpha(A_\alpha)(B_{\mu\nu}) + \partial_\nu B_{\alpha\mu} + \mathrm{d}\alpha(A_\nu)(B_{\alpha\mu}) + \partial_\mu B_{\nu\alpha} + \mathrm{d}\alpha(A_\mu)(B_{\nu\alpha}), \tag{3.27}$$

and using the simplified notation,

$$G = \mathrm{d}B + A \triangleright B = \mathrm{d}_A(B). \tag{3.28}$$

This coincides with Baez's definition of the curvature 3-form.[13]

D. Differential gauge transformations

In order to derive the differential form of the local 2-gauge transformations (2.23) and (2.25), we draw the analogous diagrams for a square and a cube, respectively, cf. Figs. 1 and 2. Here the old configuration corresponds to the bottom of the diagram, the new one to the top. We parametrize differential gauge transformations by the height ε of these diagrams, i.e., the 2-generating function,

$$\eta_\alpha(0) \sim e^{\varepsilon X}, \tag{3.29}$$

$$\eta_{\mu\alpha}(0) \sim e^{\varepsilon a Y_\mu}, \tag{3.30}$$

is parametrized by a $\mathfrak{g}$-valued function X and by an $\mathfrak{h}$-valued 1-form $Y = Y_\mu \, \mathrm{d}x^\mu$. Similarly to Sec. III C, we use the Taylor expansion,

$$\eta_\alpha(\mu) \sim e^{\varepsilon(X + a\partial_\mu X)}, \tag{3.31}$$

$$\eta_{\mu\alpha}(\nu) \sim e^{\varepsilon(aY_\mu + a^2 \partial_\nu Y_\mu)}, \tag{3.32}$$

the convention $\eta_{\mu\alpha} = \eta^{-1}_{\alpha\mu}$, the derivative $\tau = \mathrm{d}t$,

$$t(\eta_{\mu\alpha}(0)) \sim e^{a\varepsilon\tau(Y_\mu)}, \tag{3.33}$$

and the group actions,

$$g_\nu(0) \triangleright \eta_{\mu\alpha}(\nu) \sim e^{\varepsilon(aY_\mu + a^2\partial_\nu Y_\mu + a^2 \, \mathrm{d}\alpha(A_\nu)(Y_\mu))}, \tag{3.34}$$

$$\eta_\alpha(0) \triangleright h_{\mu\nu}(0) \sim e^{a^2(B_{\mu\nu} + \varepsilon \, \mathrm{d}\alpha(X)(B_{\mu\nu}))}. \tag{3.35}$$

The gauge transformation for the connection 1-form A is read off from the square of Fig. 1 and the formula (2.20),

$$e^{aA_\mu + a\varepsilon\delta A_\mu} \sim \tilde{g}_\mu(\alpha) = \eta_\alpha^{-1}(0) t(\eta_{\mu\alpha}(0)) g_\mu(0) \, \eta_\alpha(\mu). \tag{3.36}$$

Using the approximations (3.16)–(3.19) and dropping terms of order ε^2 and a^2 in the exponent, we get the gauge transformation,

$$A_\mu \mapsto A_\mu + \varepsilon \, \delta A_\mu, \quad \delta A_\mu = \partial_\mu X + [A_\mu, X] + \tau(Y_\mu), \tag{3.37}$$

that is

$$\delta A = \mathrm{d}_A(X) + \tau(Y). \tag{3.38}$$

The 2-gauge transformations of the B-field can be deduced from the flattened cube (Fig. 2) whose height in α-direction is ε for the gauge transformation,

$$e^{a^2 B_{\mu\nu} + a^2\varepsilon\delta B_{\mu\nu}} \sim \tilde{h}_{\mu\nu}(\beta) = \eta_\alpha(0)^{-1} \triangleright \{\eta_{\nu\alpha}(0)[g_\nu(0) \triangleright \eta_{\mu\alpha}(\nu)] h_{\mu\nu}(0) [g_\mu(0) \triangleright \eta^{-1}_{\nu\alpha}(\mu)] \eta^{-1}_{\mu\alpha}(0)\}. \tag{3.39}$$

The infinitesimal transformation is calculated as usual with the help of (3.16)–(3.19), dropping terms of order ε^2 and a^3 in the exponent, and we get

$$B_{\mu\nu} \mapsto B_{\mu\nu} + \varepsilon \, \delta B_{\mu\nu},$$

$$\delta B_{\mu\nu} = -\partial_\mu Y_\nu + \partial_\nu Y_\mu - \mathrm{d}\alpha(A_\mu)(Y_\nu) + \mathrm{d}\alpha(A_\nu)(Y_\mu) - \mathrm{d}\alpha(X)(B_{\mu\nu}). \tag{3.40}$$

So by using the shorthand notation, we have

$$\delta B = -\mathrm{d}Y - A \triangleright Y - X \triangleright B = -\mathrm{d}_A(Y) - X \triangleright B. \tag{3.41}$$

From the gauge transformations (3.37) and (3.40) for A and B, we can deduce the transformation of the curvature 2-form,

$$\tilde{F} \mapsto \tilde{F} + \varepsilon \, \delta\tilde{F}, \quad \delta\tilde{F} = [\tilde{F}, X], \tag{3.42}$$

up to terms of order ε^2. This means that $\tilde{F}$ transforms covariantly even without the assumption $\tilde{F} = 0$, and on the other hand, that the transformation preserves the condition $\tilde{F} = 0$.

For the curvature 3-form G, we obtain after a rather lengthy calculation,

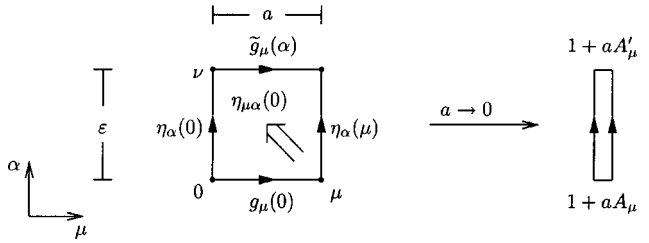

FIG. 3. The local gauge transformation of the edge labels in the integral picture, cf. (3.50). The bottom layer is the old configuration, the top layer the new one. In order to pass to the differential picture, we shrink the rectangle to infinitesimal width, $a \to 0$, but keep its height ε fixed.

$$G \mapsto G + \varepsilon \delta G, \quad \delta G = -\tilde{F} \triangleright Y - X \triangleright G, \tag{3.43}$$

up to terms of order ε^2. This transformation shows that G transforms covariantly if and only if $\tilde{F} = 0$. However, if we are considering the case of a strict Lie 2-algebra, then this flatness condition is naturally present, and G transforms covariantly, moreover it sees only the level 1 of the generating function,

$$\delta G = -X \triangleright G. \tag{3.44}$$

E. Large gauge transformations

In the preceding section, we have derived the differential gauge transformations in the differential picture. What can we conclude from their existence?

Recall first the role of large and differential gauge transformations in conventional non-Abelian gauge theory with gauge group G. A large gauge transformation is a bundle automorphism of the principal bundle $P \to M$. In a local trivialization on $U \subseteq M$, it is given by a G-valued generating function $g: U \to G$. The connection 1-form and the curvature 2-form transform as

$$A \mapsto g^{-1} A g + g^{-1}\, \mathrm{d}g, \tag{3.45}$$

$$F \mapsto g^{-1} F g. \tag{3.46}$$

It is often convenient to consider only the tangents to the above transformations which means to parametrize g in terms of the Lie algebra,

$$g = e^{\varepsilon X}, \tag{3.47}$$

where $X: U \to \mathfrak{g}$ is a Lie algebra valued function. If G is compact and connected, then the exponential map is surjective, see for example, Ref. 18, and any generating function is of this form. If G is noncompact or not connected, this is in general no longer true. Usually, one considers the parametrization (3.47) only for small ε and finds

$$A \mapsto A + \varepsilon(\mathrm{d}X + [A, X]) = A + \varepsilon \mathrm{d}_A(X), \tag{3.48}$$

$$F \mapsto F + \varepsilon[F, X], \tag{3.49}$$

dropping terms of order ε^2. Since we know that we can always integrate these differential gauge transformations, we can recover the large transformations as long as the exponential map is surjective.

Let us now try to derive the large counterparts of the differential 2-gauge transformations of Sec. III D. Therefore, we again consider the integral formulation on squares and cubes, but this time we keep the height ε fixed and consider only the limit $a \to 0$, see Fig. 3.

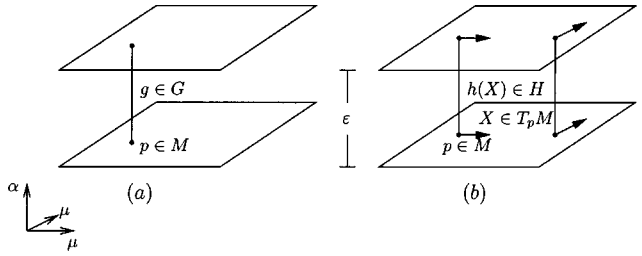

FIG. 4. (a) After shrinking the square of Fig. 3 to infinitesimal width $a \to 0$, its vertical edges carry a group label $g(p) = \eta_\alpha(p) \in G$ at each point $p \in M$. (b) The vertical surface label $\eta_{\mu\alpha}(p)$ would ideally yield an H-valued 1-form $h_\mu(p)\mathrm{d}x^\mu = \eta_{\mu\alpha}(p)\mathrm{d}x^\mu$ which associates with each vector $X \in T_pM$ an element $h(X) \in H$. The linear structure of T_pM here imposes a serious constraint as we explain in the text.

First we restrict ourselves to the case in which the curve labels of the gauge generating transformation are trivial, i.e., the surface in Fig. 3 has the trivial label $\eta_{\mu\alpha}(0) = 1 \in H$. Rather than (3.36), we now write $e^{aA_\mu} \sim g_\mu(0)$ and $e^{aA'_\mu} \sim \tilde{g}_\mu(\alpha)$ and obtain

$$(1 + aA'_\mu) \sim e^{aA'_\mu} \sim \eta_\alpha(0)^{-1} e^{aA_\mu} \eta_\alpha(\mu) \sim \eta_\alpha(0)^{-1}(1 + aA_\mu)(\eta_\alpha(0) + a\partial_\mu \eta_\alpha(0)). \tag{3.50}$$

Dropping terms of order a^2, this gives the familiar transformation rule (3.45) for the G-valued function $g(p) = \eta_\alpha(p)$, $p \in U$. The index α was just used in order to denote the vertical gauge direction in our figure.

All the data required in order to describe the gauge transformation are associated with vertical curves or surfaces which link the bottom with the top layer of Fig. 3. If the surface label is trivial, i.e., if the gauge generating transformation assigns the group unit $1 \in H$ to each curve, we have to deal only with vertical lines labeled by elements,

$$\eta_\alpha(p) = g(p) \in G, \tag{3.51}$$

at each point $p \in U$, Fig. 4(a). Indeed, the gauge generating function,

$$g{:}\mathrm{U} \to G, \tag{3.52}$$

can be visualized by a bunch of such vertical lines between the old configuration (bottom) and the new one (top). It poses no problem that the labels are in the group G. The transformation is just a change of coordinates.

Let us now consider the case in which the curve labels of the 2-generating function are nontrivial, i.e., the square in Fig. 3 has a nontrivial label $\eta_{\mu\alpha}(0) \in H$. The index α just indicates that the surface is vertical, but the index μ has indeed a geometrical meaning. In order to derive the differential gauge transformations we have expanded (3.30) in terms of both a and ε in order to obtain a 1-form $Y_\mu \, \mathrm{d}x^\mu$ as the differential expression.

If we expand only in terms of a, but keep ε fixed, we run into the following geometrical obstruction as depicted in Fig. 4(b). By expansion in terms of a, we wish to obtain a 1-form, say $h_\mu \, \mathrm{d}x^\mu$, from the vertical surface. For any tangent vector $X \in T_pM$ at some point $p \in U$, we should therefore be able to evaluate $h(X) = h_\mu X^\mu$. On the other hand, from the surface label, $\eta_{\mu\alpha}(0) \in H$, there remains for each choice of μ a group element in H. We are tempted to write,

$$\eta_{\mu\alpha}(p) = h_\mu(p) \in H. \tag{3.53}$$

Since T_pM is a linear space, however, this is possible only if h_μ gives rise to a linear map,

$$h{:}TM \to H. \tag{3.54}$$

This condition is stronger than that in (3.51) and (3.52).

The construction of the large gauge transformations in the differential picture is therefore possible only if $H=\mathbb{R}^n$ for some n. In this case, the action $\triangleright$ of G on H is actually a representation of the Lie group G and induces a representation $\triangleright$ of the Lie algebra $\mathfrak{g}$ on H.

We parametrize the large gauge transformations by $h_\mu(p) \in H$, $p \in M$, i.e.,

$$\eta_{\mu\alpha}(p) = a h_\mu(p), \tag{3.55}$$

identifying H with its Lie algebra and indicating that h_μ is already a quantity of order a. Rather than (3.36), we obtain for the transformation of the connection 1-form,

$$A \mapsto A' = g^{-1}Ag + g^{-1}\,\mathrm{d}g + \tau(h). \tag{3.56}$$

In order to derive the large gauge transformations for the connection 2-form $B_{\mu\nu}$, we replace (3.39) by

$$e^{a^2 B'_{\mu\nu}} \sim \eta_\alpha^{-1}(0) \triangleright [\eta_{\nu\alpha}(0)(e^{aA_\nu} \triangleright \eta_{\mu\alpha}(\nu)) e^{a^2 B_{\mu\nu}} (e^{aA_\mu} \triangleright \eta_{\nu\alpha}^{-1}(\mu))\, \eta_{\mu\alpha}^{-1}(0)]. \tag{3.57}$$

Expanding everything up to order a^2, using $\eta_\alpha(0)=g(0)$, (3.55), and $h_\mu(\nu)=h_\mu(0)+a\partial_\nu h_\mu(0)$, we obtain the transformation

$$B \mapsto B' = g^{-1} \triangleright B - \mathrm{d}_A(h). \tag{3.58}$$

From the large gauge transformations (3.56) and (3.58) one can recover the differential transformations (3.38) and (3.41) using the parametrizations (3.47) and (3.55).

We conclude that we have a full extended local gauge symmetry only if $H \cong \mathbb{R}^n$. In general, it is not possible to integrate the differential gauge transformations and to obtain proper (large) transformations. The large transformations are given by (3.56) and (3.58), and

$$G \mapsto G' = g^{-1} \triangleright G. \tag{3.59}$$

F. Pure 2-gauge and 2-flatness

For the case $H \cong \mathbb{R}^n$, we can now express the condition of being pure 2-gauge (Sec. II D) in the differential language. A generalized connection (A,B) is pure gauge if there exists (locally) a G-valued function $g: \mathrm{U} \to G$ and an H-valued 1-form $h: T^*M|_U \to H$ such that,

$$A = g^{-1}\,\mathrm{d}g + \tau(h), \tag{3.60}$$

$$B = -\,\mathrm{d}h. \tag{3.61}$$

It is straightforward to show that these configurations are also 2-flat.

G. Flatness at level 1

The level-1 flatness condition $\tilde{F}=0$, cf (3.25), has the following effect on the curvature 3-form. The definition $G=\mathrm{d}_A(B)$ implies $\tau(G)=\mathrm{d}_A(\tau(B))=-\mathrm{d}_A(F)=0$ by the Bianchi identity for the conventional curvature F of A. This implies that G takes values in $\ker\tau \lhd \mathfrak{h}$ which is an Abelian ideal of $\mathfrak{h}$. This is the differential counterpart of the result[14] that the 2-holonomy of an S^2 surface in the integral picture takes values in the Abelian normal subgroup $\ker t \lhd H$ (Sec. II F).

We can always decompose the $\mathfrak{h}$-valued connection 2-form $B = z \oplus B'$ where $z \in \ker\tau$ and $\mathfrak{h} = \ker\tau \oplus \mathfrak{h}'$ is split into a direct sum of vector spaces. The non-Abelian part of B is therefore contained in $B' \in \mathfrak{h}'$ and related to the conventional curvature F of A by $F=-\tau(B')$ due to (3.25). The only contribution to B unrelated to the curvature of A is contained in some Abelian subalgebra of $\mathfrak{h}$.

H. Higher Bianchi identities

As a generalization of the Bianchi identity $d_A(F)=0$ of conventional 1-gauge theory, we have in 2-gauge theory,

$$d_A(\tilde{F}) = d_A(F) + \tau(d_A(B)) = \tau(G) = 0, \tag{3.62}$$

where we have used the condition (3.25) only in the last step, and

$$d_A(G) = F \triangleright B = -\tau(B) \triangleright B = -[B,B] = 0, \tag{3.63}$$

where we have used (3.25) in the second step. They can be derived from the integral picture by drawing the square and cube from the definition of the curvature 2- and 3-form and by parallel transporting the entire diagram in an independent direction.

I. Examples

BF-theory: Consider first the special example in which we use the adjoint 2-group of some Lie group G, i.e., $H=\mathfrak{g}$ is the Lie algebra, G acts on $H=\mathfrak{g}$ by the adjoint action, and the map $t:H\to G$ is $t(h)=1$ for all $h\in H$. The corresponding Lie 2-algebra is given by the Lie algebras $\mathfrak{g}=\mathfrak{h}$, the adjoint action of $\mathfrak{g}$ on $\mathfrak{h}$ and the null map $\tau=dt=0$.

In this case, the differential forms A, B, F, $\tilde{F}$, and G are all $\mathfrak{g}$-valued. In four dimensions, one can therefore consider the Lagrangian of BF-theory,[15]

$$\mathcal{L} = \mathrm{tr}_{\mathfrak{g}}(B \wedge F). \tag{3.64}$$

The local 2-gauge transformations are generated by a $\mathfrak{g}$-valued function X and a $\mathfrak{g}$-valued 1-form Y,

$$\delta A = d_A(X), \tag{3.65}$$

$$\delta B = d_A(Y) - [X,B], \tag{3.66}$$

$$\delta F = -[X,F], \tag{3.67}$$

$$\delta G = -[X,G]. \tag{3.68}$$

They encompass both the ordinary local gauge symmetry (generated by X) and the extended, so-called topological, local symmetry which is a special feature of BF-theory (generated by Y). Both are unified in the local 2-gauge symmetry. We have therefore discovered the actual geometrical reason for the topological symmetry of BF-theory. Notice that the level-1 flatness condition (3.25) reads in this case $F=0$ which is actually one of the field equations of BF-theory.

Notice that in the case of BF-theory, the Abelian ideal is $\ker t=\mathfrak{g}$ which is an Abelian group using the addition of elements of $\mathfrak{g}$, even though $\mathfrak{g}$ as a Lie algebra can be non-Abelian if the gauge group G is non-Abelian.

Yang–Mills theory: Let us now try to construct a higher level analogue of the Yang–Mills action. In conventional gauge theory, the Yang–Mills Lagrangian reads

$$\mathcal{L} = \mathrm{tr}_g(F \wedge {*F}), \tag{3.69}$$

where $\mathrm{tr}_{\mathfrak{g}}$ denotes the Cartan–Killing form of $\mathfrak{g}$. A candidate for a Lagrangian density in higher gauge theory is therefore given by the expression

$$\mathcal{L} = \mathrm{tr}_{\mathfrak{h}}(G \wedge {*G}). \tag{3.70}$$

We could have tried $\mathrm{tr}_{\mathfrak{g}}(\tilde{F} \wedge {*\tilde{F}})$ which, however, vanishes because of (3.25) in the case of strict Lie 2-groups. We have seen that the curvature 3-form G is always Abelian.

If we choose the Euclidean or Poincaré 2-group, we have $\mathfrak{g}=\mathfrak{so}(n)$ or $\mathfrak{so}(n-1,1)$, $\mathfrak{h}=\mathbb{R}^n$ and $\tau:\mathfrak{h}\to\mathfrak{g}$ the null map. This implies in particular that $\tilde{F}=F$, and the condition (3.25) furthermore states that the connection A is flat. In addition, we have a connection 2-form B taking values in $\mathfrak{h}=\mathbb{R}^n$ with a curvature 3-form $G=\mathrm{d}_A(B)$. Locally, the flatness of A implies that it is pure gauge, i.e., gauge equivalent to $A=0$, so that locally G is just the exterior derivative, $G=\mathrm{d}B$. The Yang–Mills Lagrangian (3.70) therefore agrees locally with that of Abelian 2-form electrodynamics.

A similar result can be shown for all 2-groups in which $H=V$ is a vector space on which G is represented. The connection 1-form A is locally pure gauge and the Yang–Mills Lagrangian (3.70) reduces to that of Abelian 2-form electrodynamics.

Consider finally the automorphism 2-group of $H=\mathrm{SU}(2)$, i.e., $\mathfrak{g}=\mathfrak{h}=\mathfrak{su}(2)$, τ is the identity map, and $\mathfrak{g}$ acts on $\mathfrak{h}=\mathfrak{g}$ by the adjoint action. In this case, the condition (3.25) implies that $B=-F$ is just (minus) the ordinary curvature 2-form of A. The Yang–Mills Lagrangian (3.70) therefore vanishes because of the conventional Bianchi identity $G=\mathrm{d}_A(B)=-\mathrm{d}_A(F)=0$.

With the known Lie 2-groups alone, it is therefore not possible to find a nontrivial generalization of the Yang–Mills action. This is in outright contrast to the integral picture for which we have shown[14] that nontrivial generalizations exist. This result points towards a genuine discrepancy between perturbative and nonperturbative formulations of higher gauge theory on which we comment in the conclusion.

IV. CONCLUSION AND OUTLOOK

In this paper, we have reviewed both the integral and the differential picture of higher gauge theory. One main result is the appearance of the condition (3.25) at the differential level as soon as the curve and surface labels depend smoothly on the positions of the curves and surfaces.

Another main result is that we are able to construct large (as opposed to differential) 2-gauge transformations in the differential picture only in the case in which $H\cong\mathbb{R}^n$ as an Abelian group. This seriously restricts the applications of the differential formulation and prevents us from obtaining an interesting level-2 generalization of Yang–Mills theory. *BF*-theory, however, forms an interesting example of a 2-gauge theory. The local 2-gauge transformations unify the two types of local symmetries of *BF*-theory and thereby provide a structural explanation for the existence of the topological symmetry of *BF*-theory.

We have chosen the language of 2-groups[13] in order to study higher gauge theory. The categorical structure of 2-groups leads directly to the integral picture[14] and as a consequence to the differential formulation as derived in the present paper. Alternatively it would be possible to use the language of gerbes and to start with a differential formulation of higher gauge theory. One can then ask under which conditions it is possible to integrate the connection 1-form along curves and the connection 2-form along surfaces in a consistent way. The result of the present article suggests the conjecture that (3.25) is the required integrability condition.

How serious are the restrictions we have found, in particular the Abelianness of the curvature 3-form?

First note that all the Lie 2-groups and Lie 2-algebras used in the present paper are *strict*. They form only the simplest examples of these structures which can be constructed in a general 2-categorical framework, but there exist the more general notions of *weak* and *coherent* 2-groups and their Lie 2-algebras. For 2-groups, see, for example, Refs. 19 and 20 and for Lie 2-algebras.[17] One can hope that the differential picture becomes less restrictive once we generalize from strict Lie 2-groups and 2-algebras to weak ones. Since the origin of the level-1 flatness is the very basic condition (2.10), a fully successful weakening should therefore allow for a non-Abelian kernel of the map $t:H\to G$.

We also observe that the nontrivial 2-holonomies are ruled out in the differential picture only if one requires the connection 1- and 2-forms to be both smooth and well defined everywhere in space–time. In particular, in the integral picture with the automorphism 2-group of SU(2), we can have $\mathbb{Z}_2$-valued 2-holonomies associated with surfaces of topology S^2. If we assume that a smooth

deformation of the surface changes the 2-holonomy only smoothly, then the nontrivial $\mathbb{Z}_2$-element indicates that the S^2 is not smoothly contractible. This can be interpreted as an indication that there are singularities of codimension 2 in the theory which are actually *predicted* by the algebraic structure. Solitonlike solutions of some classical field equations come to mind. In fact, the integral picture for the inner automorphism group of SU(3) is related to the symmetries of center vortices in QCD as sketched in Ref. 14.

The difference of the differential and the integral picture is much deeper, though. As an illustration, we refer to a result in the context of the path integral quantization of conventional gauge theory. For simplicity, assume that we work in the Euclidean setting (i.e., with imaginary time) on some Riemannian manifold M.

The obvious naive choice is to consider the set $\mathcal{A}$ of all smooth connections A on M which form an affine space, and then to divide out the action of the gauge transformations. This step, however, destroys the linear structure so that the standard techniques fail to construct a useful path integral measure on the quotient $\mathcal{A}/\mathcal{G}$. This failure to implement the gauge symmetry correctly can be seen as a main reason why perturbative QCD does not predict confinement as observed in nature.

A nonperturbative approach, see, for example, Ref. 21, is to consider the collection of all graphs embedded in M, to study gauge theory in the integral picture on these graphs, i.e., all connections that are given by group labels attached to the edges of the graph, and finally to make use of a refinement relation on the class of all graphs which facilitates the construction of a projective continuum limit for the set of connections. Not only does this set of generalized connections form a compact Hausdorff space, it is also possible to fully divide out the gauge symmetry. This set of generalized connections modulo gauge transformations is a huge space that includes not only smooth or continuous connections, but rather mainly distributional ones. In order to appreciate the physical significance of this space of generalized connections it is useful to recall the most basic example of a field theory which admits a rigorous Euclidean path integral quantization, the free relativistic scalar field. Its path integral measure[22] is supported mainly on nonsmooth scalar fields. In fact, the subsets of smooth fields form sets of measure zero.

This is a strong indication that a restriction to smooth fields does not yield an adequate description of the corresponding quantum theory and that we should take the integral formulation seriously. In a proper continuum limit, constructed from a suitable refinement of the integral formulation of higher gauge theory, the above-mentioned codimension-2 singularities will not only be allowed, they may actually be abundant in the path integral.

(Received 27 January 2004; accepted 7 June 2004; published 12 October 2004)

We discuss the possible relationship of homological mirror symmetry with deformation quantization. We speculate that after certain nonlinear "twist" the Fukaya category becomes equivalent to the category of holonomic modules over a quantized algebra of functions. © *2004 American Institute of Physics.*
[DOI: 10.1063/1.1786350]

I. INTRODUCTION

The mathematical foundation of mirror symmetry belongs both to geometry (the Strominger-Yau-Zaslow conjecture; see Strominger *et al.*, 1996) and algebra (Kontsevich's homological mirror symmetry program; see Kontsevich, 1994). In the present paper we deal with some aspects of the latter. Our methods and conjectures have an algebraic (categorical) nature. On the other hand, based on the ideas of Kontsevich (1994) and Kontsevich and Soibelman (2000, in press), we stress the role of *noncommutative* geometry of mirror symmetry, making an attempt to connect it with deformation quantization. The latter is a generalization of the theory of (pseudo)-differential operators (or D-modules) to arbitrary symplectic manifolds.

In homological mirror symmetry and in the theory of D-modules one meets similar objects. They are pairs (L,ρ) where L is a Lagrangian manifold, and ρ is a flat bundle on L (local system). In the framework of homological mirror symmetry such pairs are objects of the so-called Fukaya category, which is the principal mathematical structure of the genus zero part of the A-model. In the framework of D-modules they are holonomic D-modules (in the C^∞ category). It is natural to compare the categories themselves. This comparison is the main theme of the present paper.

One can object any relationship between mirror symmetry and deformation quantization. Indeed we have the following.

(a) Theory of D-modules works well in an algebraic or complex analytic framework, while the Fukaya category (and in general Floer theory) exists in the C^∞-category only.
(b) In mirror symmetry one considers a series in an exponentially small (with respect to the symplectic structure) parameter, while in deformation quantization the parameter "is of the size" of the symplectic structure.

From our point of view these are rather research problems than objections.

In regard to point (a) we remark that the finding of a complex analog of the Floer theory is an interesting problem. At this time we can only speculate in this direction.

Our aim in the present paper is to summarize our present understanding of the topic and make some conjectures. Our main conjecture can be briefly formulated such as follows.

[a)]Electronic mail: bressler@hedgehog.math.arizona.edu
[b)]Electronic mail: soibel@math.ksu.edu

(i) There is a category of holonomic modules over the quantized algebra of smooth functions on a symplectic manifold.
(ii) It is possible to change morphisms in this category by a kind of integral transformation, so that it becomes equivalent (at least locally) to the Fukaya category of the same symplectic manifold.

Let us mention two possible applications of this idea. First, it can help in the construction of an algebraic model of the Fukaya category (analogy: de Rham complex is an algebraic model of Morse complex). Second, it might help to resolve some difficulties in the definition of the Fukaya category (nontransversality of supports, nonexistence of identity morphisms, etc.). In our opinion the current situation is not completely satisfactory despite the recent progress (cf., for example, Fukaya *et al.*, 2000). Third, one can go beyond Lagrangian submanifolds by considering coisotropic submanifolds or even nonsmooth varieties (cf. Kapustin and Orlov, 2001). Finally, one hopes to achieve a deeper understanding of the relationship at the level of chiral algebras (see Beilinson and Drinfeld, 1999; Malikov *et al.*, 1998; Kapranov and Vasserot, 2001). Hence the subject of this paper is just the first approximation to the full picture.

The paper is organized as follows. In Sec. II we briefly recall basics on the deformation theory and A_∞-categories. Our purpose in this section is to fix the language. Details of the formalism will be explained in Kontsevich and Soibelman (in press).

In Sec. III we recall the main facts about the Fukaya category, which is one of the main structures of homological mirror symmetry. Section IV is a reminder on the deformation quantization of symplectic manifolds. Section V is devoted to the comparison of the Fukaya category with the category of holonomic modules over the quantized algebra of functions.

The main idea of Sec. III goes back to the pioneering paper (Kontsevich, 1994). As explained in loc. cit., homological mirror symmetry is not a statement about individual categories, but rather about families of A_∞-categories over $\mathbf{Z}$-graded formal schemes. Geometrically this structure is modeled by a "family of noncommutative differential-graded manifolds over a commutative differential-graded base." The framework in which the latter phrase has a precise meaning will be explained in Kontsevich and Soibelman (in press). The reader can keep in mind the example of the deformation theory of an associative algebra. In this case one has a family of associative algebras parametrized by the formal moduli space $\mathcal{M}_A$ of deformations of a given algebra A. The moduli space $\mathcal{M}_A$ is a formal pointed differential-graded manifold (dg-manifold for short) (see, for example, Kontsevich, 1997 and Kontsevich and Soibelman, 2000). By definition $\mathcal{M}_A$ is a base of a family of associative algebras A_γ, $\gamma \in \mathcal{M}_A$. Each algebra gives rise to a "noncommutative scheme" $\mathrm{Spec}(A_\gamma)$, hence one has the desired structure.

II. REMINDER ON A_∞-CATEGORIES AND DEFORMATION THEORY

In this section we recall some facts about the homological algebra of mirror symmetry. Full details including the necessary language of noncommutative geometry will appear in Kontsevich and Soibelman (in press). Some of the material can be found in the existing literature, for example, in Kontsevich (1994). We are not going to discuss in detail motivations for all of the definitions and notions below. The main purpose of this section is to fix the language.

Let A be a free $\mathbf{Z}$-graded k-module over a unital commutative ring k of characteristic zero (the main applications deal with the case when k is a field).

Definition 1: *An A_∞-algebra A over k is given by the following data*.

(a) *A $\mathbf{Z}$-graded free k-module A.*
(b) *A codifferential d on the cofree coalgebra $T(A[1]) = \oplus_{n \geqslant 1} A[1]^{\otimes n}$, where $A[1]$ denotes the graded free k-module such that $A[1]^i = A^{i+1}$ (A with shifted grading).*

(We recall that a codifferential means a derivation d of the coalgebra satisfying the condition $d^2 = 0$).

Since d is uniquely defined on generators, it gives rise to "higher multiplications" $m_n: A^{\otimes n} \to A, n \geqslant 1$ of degrees $2-n$ satisfying a system of quadratic equations which follows from the equation $d^2=0$.

Definition 2: *An L_∞-algebra on A is given by the following data*.

(a) *A* **Z***-graded vector space A.*
(b) *A codifferential on the cofree cocommutative coalgebra $C(A[1])=\oplus_{n\geqslant 1} S^n(A[1])$, where $S^n(V)$ denotes the nth symmetric power in the symmetric monoidal category of* **Z***-graded k-modules*.

The codifferential d defines a sequence of "higher Lie brackets" $m_n: A^{\otimes n} \to A, n \geqslant 1$ of degrees $2-n$ satisfying a system of quadratic equations which follows from the equality $d^2=0$.

It is useful to have in mind a geometric picture for both algebraic structures defined above. We start with L_∞-algebras.

An L_∞-algebra gives rise to a *formal pointed* **Z***-graded manifold X*, which carries a vector field d_X of degree +1 such that d_X vanishes at the marked point, and satisfies the condition $[d_X, d_X]=0$. This structure is called *formal pointed differential-graded manifold* in Kontsevich (1997) and Kontsevich and Soibelman (in press, 2000) (it was introduced by Schwarz under the name of the Q-manifold). The algebra of formal functions of X is isomorphic to the graded dual to the coalgebra $C(A[1])$. Thus we can write $X=Spf((C[1])^*)$, where Spf stands for the formal spectrum.

Remark 1: (a) One should remember that formal **Z***-graded manifolds have only nilpotent points*.

(b) It is useful to interpret maps m_n as a Taylor coefficient of the vector field d_X at the marked point.

Let us consider two examples.

Example 1: *Let A be an associative algebra. Then its truncated Hochschild complex $C^\bullet_+(A,A)[1]=\oplus_{n\geqslant 1}\mathrm{Hom}_k(A^{\otimes n},A)[1]$ carries a structure of differential-graded Lie algebra, hence defines a formal pointed dg-manifold (see Kontsevich, 1997)*.

One can interpret the DGLA from the example as a DGLA of derivations of the tensor coalgebra generated by $A[1]$. Equivalently, it is the DGLA of vector fields on the formal pointed graded manifold X vanishing at the marked point. Then the DGLA structure is the natural one on vector fields.

One also has the notion of a *formal differential-graded manifold*, where the condition of vanishing at the marked point is dropped. Algebraically this means that we allow the condition $m_0 \neq 0$.

Example 2: *In the previous example we consider the full Hochschild complex $C^\bullet(A,A)[1]=\oplus_{n\geqslant 0}\mathrm{Hom}_k(A^{\otimes n},A)[1]$. It gives rise to a formal dg-manifold*.

The importance of L_∞-algebras and formal dg-manifolds in deformation theory is based on the fact that they define deformation functors (see, for example Kontsevich, 1997, and Kontsevich and Soibelman, 2000). Let us briefly recall the construction. If $g=\oplus_{n\geqslant 0} g^n$ is an L_∞-algebra (g^n is the nth graded component) then one has the deformation functor from commutative nilpotent algebras (possibly graded) to groupoids. Namely to a commutative nilpotent ring R one assigns the groupoid $\mathrm{Def}_g(R)$ consisting of $\gamma \in g^1 \otimes R$ which satisfy the Maurer-Cartan equation,

$$m_1(\gamma) + m_2(\gamma,\gamma)/2\,! + \cdots + m_n(\gamma,\ldots,\gamma)/n\,! + \cdots = 0,$$

where m_n are the higher Lie brackets.

Formal deformations of many algebraic and geometric structures give rise to formal pointed dg-manifolds. Formal dg-manifolds without marked points arise, for example, when one deforms categories (i.e., when objects of a category are deformed). In Example 2 the corresponding dg-manifold controls deformations of the category with one object X such that $\mathrm{Hom}(X,X)=A$.

One can develop a similar geometric language for A_∞-algebras. Namely, an A_∞-algebra gives rise to a *noncommutative formal pointed dg-manifold*. It is modeled by the cofree coalgebra $T(A[1])$ which carries a codifferential d_X. One also has the notion of a *noncommutative formal dg-manifold* (no marked point is specified). In this case one can have a nonzero map $m_0: k \to A$.

Geometrically this structure corresponds to a vector field d_X of degree +1 such that $[d_X, d_X]=0$, without any condition at the marked point. The corresponding algebraic structure is defined in the following way.

Definition 3: *We say that a codifferential on the coalgebra* $k \oplus T(A[1])$ *defines a structure of generalized* A_∞*-algebra on* A.

The notion of a small A_∞-category is a natural generalization of the notion of A_∞-algebra. Traditionally, such a category is defined by a set of objects $Ob(\mathcal{C})$, **Z**-graded free k-modules of morphisms $\mathrm{Hom}(X,Y)$, and structures of A_∞-algebras on the spaces $\oplus_{0\leqslant i,j\leqslant n}\mathrm{Hom}(X_i,X_j)$ for any collection of objects $X_0,\ldots,X_n, n\geqslant 1$. These structures are given by the higher compositions,

$$m_n: \otimes_{0\leqslant i\leqslant n}\mathrm{Hom}(X_i,X_{i+1}) \to \mathrm{Hom}(X_0,X_n),$$

which are maps of **Z**-graded free k-modules of degrees $2-n$ satisfying quadratic relations similar to those for A_∞-algebras. The structures of A_∞-algebras are compatible with inclusions of collections of objects.

One can think of an A_∞-category $\mathcal{C}$ as of the large A_∞-algebra $\mathrm{End}(\oplus_{X\in Ob(\mathcal{C})}X)$ (compare with the relation between additive categories and associative algebras). The Hochschild complex and Hochschild cohomology of an A_∞-category can be defined in terms of this A_∞-algebra.

For any object X the k-module $\mathrm{End}(X)=\mathrm{Hom}(X,X)$ is an A_∞-algebra. Its truncated Hochschild complex gives rise to a formal pointed dg-manifold $\mathcal{M}_X$. Then the formal dg-manifold $\mathcal{M}=\sqcup_{X\in Ob(C)}\mathcal{M}_X$ "controls" A_∞-deformations of the category $\mathcal{C}$ with the fixed set of objects.

Replacing in the above discussion the truncated Hochschild complex by the full Hochschild complex one obtains a new structure called *generalized* A_∞*-category*. Generalized A_∞-categories do not have a fixed set of objects. This is due to the fact that now for the A_∞-algebra $\mathrm{End}(X)$ one can have $m_0\neq 0$. As before, one can derive the formal dg-manifold $\mathcal{M}$ [now using the generalized A_∞-algebras $\mathrm{End}(X)$]. For a commutative nilpotent k-algebra R one can consider k-points $\mathcal{M}(R)$. If $\mathcal{M}_0\subset\mathcal{M}$ is the subset of zeros of the odd vector field $d_{\mathcal{M}}$ then one can speak about objects of some A_∞-category. The objects are parametrized by $\mathcal{M}_0$. We omit here the description which can be given in terms of R-points of $\mathcal{M}_0$ and $\mathcal{M}$.

We will keep the name of the generalized A_∞-category for a slightly more general structure. The point is that we allow the higher compositions m_n be defined not for all collections of objects, but only for some of them (transversal collections). The Fukaya category discussed in the next section will be this kind of generalized A_∞-category.

We summarize without details the data defining a generalized A_∞-category in the following way.

(a) We are given a formal dg-manifold $Ob(\mathcal{C})=\mathcal{M}$.
(b) For any $n\geqslant 1$ we are given a formal dg-submanifold $\mathcal{M}^n_{\mathrm{tr}}\subset\mathcal{M}^n$ called the space of transversal n-families. It is assumed that $\mathcal{M}^1_{\mathrm{tr}}\subset\mathcal{M}$ (i.e., every object is transversal to itself).
(c) For a point $(X,Y)\in\mathcal{M}^2_{\mathrm{tr}}$ we are given a **Z**-graded free k-module $\mathrm{Hom}_{\mathcal{C}}(X,Y)$ called a space of morphisms between X and Y. These k-modules are organized in a formal dg-bundle $\mathrm{Hom}^{\mathcal{C}}\to\mathcal{M}^2_{\mathrm{tr}}$.
(d) For $n\geqslant 1$ and any $(X_0,\ldots,X_n)\in\mathcal{M}^n_{\mathrm{tr}}$ we are given a higher composition map $m_n^{(X_0,\ldots,X_n)}$ which gives rise to a morphism of the obvious pullbacks of $\mathrm{Hom}^{\mathcal{C}}$ to $\mathcal{M}^n_{\mathrm{tr}}$. The composition maps give rise to a structure of generalized A_∞-algebra $A(X_0,\ldots,X_n)$, or, equivalently to a noncommutative formal dg-manifold $\mathcal{M}(X_0,\ldots,X_n)$.
(e) Let $\mathcal{M}(\mathcal{C})$ be the inductive limit of $\mathcal{M}(X_0,\ldots,X_n)$ taken over increasing collections of transversal objects. This is a noncommutative formal dg-ind-scheme (it can be properly defined as an inductive limit in the appropriate category).
(f) Finally $\mathcal{M}(\mathcal{C})$ is a noncommutative formal dg-manifold over the commutative scheme $\mathrm{Spec}(k)$.

The structure defined in (a)–(e) is called the generalized A_∞-category. It gives rise to the usual

k-linear A_∞-category, which we will call associated to $\mathcal{C}$. The latter is defined by a noncommutative formal dg-ind-subscheme $\mathcal{M}(\mathcal{C})_0 \subset \mathcal{M}(\mathcal{C})$ of zeros of the odd vector field $d_{\mathcal{M}(\mathcal{C})}$.

Remark 2:(a) One can define the Hochschild complex of a generalized A_∞-category. It gives rise to a formal dg-manifold. The corresponding deformation functor describes the formal deformation theory of the generalized A_∞-category in the class of generalized A_∞-categories. If the category has one object X we have the full Hochschild complex of the corresponding generalized A_∞-algebra $\mathrm{End}(X)$.

(b) We do not discuss the delicate problem of unital A_∞-algebras (more generally, A_∞-categories with identity morphisms). It is an interesting question because in practice identity morphisms may be defined up to a homotopy only. All this can be formulated in the language of noncommutative geometry.

There is a notion of an A_∞-functor between two generalized A_∞-categories. A_∞-functors form themselves a generalized A_∞-category. Using A_∞-functors one defines the notion of equivalence of A_∞-categories (see Kontsevich and Soibelman, 2000).

Let us illustrate the notion of equivalence in the case when both categories have only one object. Then we are dealing with generalized A_∞-algebras, say A and B. Assume in addition that $m_0^A=0$ and $m_0^B=0$ (i.e., we have ordinary A_∞-algebras). If A is equivalent to B then the complexes (A,m_1^A) and (B,m_1^B) are quasi-isomorphic. Geometrically this means that the tangent spaces at marked points of equivalent noncommutative formal pointed dg-manifolds are quasi-isomorphic. The converse is also true (this is the A_∞-version of the inverse function theorem). A generalized A_∞-algebra with $m_0 \neq 0$ is equivalent to one which has $m_0 \neq 0$, and $m_{n\geqslant 1}=0$ (cf. the vector field which is nontrivial at a point is locally equivalent to a constant one). The latter observation explains why generalized A_∞-categories should be studied in families rather than individually. Indeed generalized A_∞-categories with $m_0 \neq 0$ are trivial in the sense that all higher compositions can be killed by an appropriate equivalence functor.

Similarly to the case of formal pointed dg-manifolds there is a theory of minimal models of noncommutative formal pointed dg-manifolds. For such a theory one needs to assume that the ground ring k is a field of characteristic zero (there is more complicated theory for nonpointed dg-manifolds).

If two A_∞-categories are equivalent then the formal pointed dg-manifolds of their deformations are quasi-isomorphic (i.e., tangent complexes at the marked points are quasi-isomorphic).

Finally, there is a theory of generalized A_∞-categories over a formal dg-base. In the above discussion we discussed the case when the base was an ordinary scheme $\mathrm{Spec}(k)$. We can also assume that the base is a formal scheme. As we will see in the next section the latter case is important in symplectic geometry.

III. FUKAYA CATEGORY

A. Fukaya category and noncommutative geometry

The Fukaya category $F(X)$ of a smooth symplectic manifold X is a generalized A_∞-category over a base. It can be constructed as an A_∞-deformation of the following trivial $\mathbf{C}$-linear category $F_0(X)$. Objects of $F_0(X)$ are pairs (L,ρ), where L is a Lagrangian submanifold of X and ρ is a local system on L. Transversal collections of objects correspond to transversal collections of Lagrangian submanifolds [in fact we need a more sophisticated transversality condition; see Kontsevich and Soibelman (2000)]. We set $\mathrm{Hom}_{F_0(X)}((L_0,\rho_0),(L_1,\rho_1)) = \oplus_{x\in L_0\cap L_1}\mathrm{Hom}(\rho_{0x},\rho_{1x})$ and $\mathrm{Hom}_{F_0(X)}((L,\rho),(L,\rho)) = \Omega^\bullet(L,\mathrm{End}(\rho))$. All compositions $m_n, n\geqslant 1$ are trivial for collections of different objects. Otherwise $m_{n\geqslant 3}=0$, and m_2 is the natural product on the differential-graded algebra $\Omega^\bullet(L,\mathrm{End}(\rho))$.

To a pair (L,ρ) one can associate a generalized A_∞-algebra $A(L,\rho)$. Let us assume for simplicity that ρ is a trivial rank one local system. Then the corresponding generalized A_∞-algebra $A(L)$ is generated by geometric cycles in L. Higher multiplications $m_n(C_1,\ldots,C_n)$ between generic cycles C_i are given by a kind of quantum cohomology construction. Namely, one counts with some weight pseudo-holomorphic maps $f:(D^2,\partial D^2)\to(X,L)$ with marked points $x_1,\ldots,x_n \in \partial D^2$.

Here $D^2 \subset \mathbf{C}$ is the standard disk. It is required that the point x_i is mapped to C_i. The weight is $\exp(-1/\epsilon \int_{D^2} f^*(\omega))$, where ω is the symplectic form on X, and ϵ is a parameter. The idea of this construction of $A(L)$ was suggested by Kontsevich. Difficult analytic details have been worked out in Fukaya, Oh, Ohta, and Ono (2000). In what follows we will assume the conditions on the data imposed in Fukaya, Oh, Ohta, and Ono (2000). The resulting generalized A_∞-algebra $A(L)$ is defined over the valuation ring $\mathbf{C}_\epsilon^{\geqslant 0} = \{f = \Sigma_{i \geqslant 1} a_i e^{-\lambda_i/\epsilon}\}$, where $a_i \in \mathbf{C}, a_1 \neq 0$, and $\lambda_i \geqslant 0$ is a monotonically increasing sequence of real numbers such that $\lim_{i \to +\infty} \lambda_i = +\infty$. The valuation map is given by $v(f) = \lambda_1$. The corresponding valuation field $\mathbf{C}_\epsilon$ consists of series f as above, with $\lambda_i \in \mathbf{R}$. It is useful to notice that $\mathbf{C}_\epsilon^{\geqslant 0}$ contains the maximal ideal $\mathbf{C}_\epsilon^{>0}$ consisting of series with all $\lambda_i > 0$. One observes that the composition $m_0 = 0$ modulo $\mathbf{C}_\epsilon^{>0}$, but in general $m_0 \neq 0$.

It can be proved that the disjoint union of noncommutative dg-manifolds associated with generalized A_∞-algebras $A(L, \rho)$ gives rise to a generalized A_∞-category $F_\epsilon(X)$ over the formal spectrum of the ring $\mathbf{C}_\epsilon^{\geqslant 0}$. Its reduction modulo the ideal $\mathbf{C}_\epsilon^{>0}$ is equivalent to $F_0(X)$. If the symplectic form ω satisfies certain rationality conditions then one can introduce a new parameter $q = \exp(-1/\epsilon)$, thus replacing the ring $\mathbf{C}_\epsilon^{\geqslant 0}$ by the ring of formal series $\mathbf{C}[[q]]$. Then the maximal ideal is just $q\mathbf{C}[[q]]$, and the field $\mathbf{C}_\epsilon$ coincides with the field of Laurent series $\mathbf{C}((q))$.

The Fukaya category $F(X)$ is defined as an A_∞-category obtained from $F_\epsilon(X)$ by restriction to zeros of the odd vector field. In particular, for an object A of $F(X)$ the composition m_0 vanishes: $m_0^A = 0$. The condition $m_0^A = 0$ defines a "subvariety" of the noncommutative moduli space $M^{\mathrm{NC}}_{\mathrm{Ob}(F_\epsilon(X))}$. Objects of the Fukaya category exist only along this "subvariety." This geometric picture explains why it is too naive to work with the Fukaya category for fixed ϵ, even if one can prove convergence of the series defining m_n (the latter is still an open problem).

Let us assume for simplicity the above-mentioned rationality conditions of ω. Then the Fukaya category is defined over the formal spectrum $Spf(\mathbf{C}[[q]])$. In fact one can extend the definition so that the base will be $Spf(\mathbf{C}[[q]] \otimes (\otimes_{i \neq 2} \mathbf{C}[t_{i,\mu}]))$, where q has degree zero, and $t_{i,\mu}$ are parameters of degrees $2-i$ corresponding to some basis in the graded vector space of cohomology $H^i(X, \mathbf{C})$. We introduce new parameters z, t of degree zero by setting $z = qe^t$. Then, inverting z we obtain a family of A_∞-categories over the field $\mathbf{C}((z))$ parametrized by $Spf(\mathbf{C}[[t]] \otimes (\otimes_{i \neq 2} \mathbf{C}[t_{i,\mu}]))$. This family should be thought of as the formal deformation of a certain A_∞-category over $\mathbf{C}((z))$. The tangent space to the moduli space of the formal deformations of this category is isomorphic to the cohomology $H^\bullet(X, \mathbf{C}((z)))$. The latter cohomology group is isomorphic to $\oplus_{i \geqslant 0} \mathrm{Ext}^i(\mathrm{Id}, \mathrm{Id})$, where Id is the identity functor, and the extensions are taken in the properly defined A_∞-category of endofunctors. This description is useful for the purposes of quantum cohomology (the Yoneda product on functors gives rise to the quantum product on the cohomology group).

B. Conventional approach to the Fukaya category

Below we briefly recall the "naive" definition of the Fukaya category, when the composition m_0 is ignored. It is useful in some questions, for example, in mirror symmetry for Abelian varieties (see Kontsevich and Soibelman, 2000). As we will discuss below, this "naive" Fukaya category is related to deformation quantization.

Objects of $F^{\mathrm{naive}}(X)$ are pairs (L, ρ), where $L \subset X$ is a Lagrangian submanifold and ρ is a local system on L. Morphisms between (L_0, ρ_0) and (L_1, ρ_1) are defined only if L_0 and L_1 intersect transversally. In this case $\mathrm{Hom}((L_0, \rho_0), (L_1, \rho_1)) = \oplus_{x \in L_0 \cap L_1} \mathrm{Hom}(\rho_{0x}, \rho_{1x}) \otimes \mathbf{C}_\epsilon$. The space of morphisms is $\mathbf{Z}$-graded by means of the Maslov index. Thus we are dealing with graded Lagrangian manifolds (cf. Seidel, 2000). There are higher compositions $m_n, n \geqslant 1$, which are linear maps of degrees $2-n$:

$$m_n : \otimes_{0 \leqslant i \leqslant n} \mathrm{Hom}((L_i, \rho_i), (L_{i+1}, \rho_{i+1})) \to \mathrm{Hom}((L_0, \rho_0), (L_n, \rho_n)).$$

They are defined by means of the Floer-type construction associated with the "transversal" collection of Lagrangian submanifolds $L_i, 0 \leqslant i \leqslant n$. It is usually said that the maps m_n give rise to an A_∞-structure on $F^{\mathrm{naive}}(X)$. We refer the reader to Kontsevich and Soibelman (2000) about the

details of this definition, and to Fukaya, Oh, Ohta, and Ono (2000) about definitions of the related moduli spaces.

There are several problems with the naive definition of the Fukaya category. One of the most essential is the presence of pseudo-holomorphic disks with the boundary mapped to a Lagrangian submanifold. This amounts to nontrivial maps $m_0: \mathbf{C}_\epsilon \to \mathrm{Hom}(X,X)$. As a result, the axioms of the A_∞-category are not satisfied, and one has to work with generalized A_∞-categories. It was explained in the preceeding sections [for all details see Kontsevich and Soibelman (2000)] how a consistent theory of such can be developed in the framework of noncommutative formal geometry. One can still work with $F^{\mathrm{naive}}(X)$ with understanding that it is only a part of the "true" Fukaya category $F(X)$.

IV. REMINDER ON DEFORMATION QUANTIZATION

We recall that a symplectic 2n-dimensional manifold (X,ω) gives rise to an Abelian category $C(X)$ of modules over a noncommutative algebra $A(X)$ (deformation quantization of the algebra $C^\infty(X)$ of smooth functions on X). Such a deformation quantization is nonunique. We will use the one which has the characteristic class $[\omega]/t$ [see Deligne (1995)]. The algebra $A(X)$ is a topological algebra over the ring of formal series $\mathbf{C}[[t]]$. As a $\mathbf{C}[[t]]$-module it is isomorphic to the algebra of formal series $C^\infty(X)[[t]]$. The algebra $A(X)$ consists of global sections of a sheaf of noncommutative algebras A_X, such that locally A_X is isomorphic to the sheaf of t-pseudo-differential operators on $\mathbf{R}^n$ [the latter are locally series $P=\Sigma_{|I|\geqslant 0} a_I(x)(t\partial_x)^I$]. The Poisson structure induced on $C^\infty_X \simeq A_X/tA_X$ coincides with the one given by the symplectic form.

One has a category of $A(X)$-modules M such that M is t-adically complete, flat as a $\mathbf{C}[[t]]$-module, and M/tM is the space of sections of a sheaf of modules over the sheaf of smooth functions C^∞_X. The category of A_X-modules will be denoted by $\mathcal{C}(X)$. Morphisms are defined as $\mathbf{C}[[t]]$-linear homomorphisms of topological modules. We will keep the same notation for the related category defined over the field $\mathbf{C}((t))$. It is obtained from $\mathcal{C}(X)$, respectively, $\mathcal{C}_X$ by adding t^{-1}, so that modules V and tV become equivalent.

Let $\mathrm{hol}(X)$ be a full subcategory of $\mathcal{C}(X)$ which consists of modules M such that the support $\mathrm{Supp}(M/tM)$ is a Lagrangian submanifold.

We will call objects of $\mathrm{hol}(X)$ *holonomic*. The Lagrangian support $\mathrm{Supp}(M)$ of a holonomic module will be sometimes called its *characteristic variety* of M and denoted by $Ch(M)$. The category $\mathrm{hol}(X)$ contains objects $V_{(L,\rho)}$ which correspond to pairs (L,ρ) where $L\subset X$ is a Lagrangian submanifold and ρ is a local system on L. In what follows only such objects will be considered.

Remark 3: In [Karasev and Maslov (1983)] the authors constructed (for every Lagrangian submanifold L satisfying some topological conditions) an A_X-module V_L such that $Ch(V_L)=L$. One can easily generalize their construction including local systems on L. We will call the corresponding objects Karasev–Maslov modules.

We will need symplectic manifolds $X^n, n\geqslant 2$. The corresponding symplectic forms are given by $(\omega,-\omega,-\omega,\ldots,-\omega)$.

The identity functor $\mathrm{Id}_{A_X-\mathrm{mod}}$ is represented by the $A_{X\times X}$-module K_Δ supported on the diagonal $\Delta\subset X\times X$. It can be identified with the sheaf A_X. Deformations of $A_X-\mathrm{mod}$ as an A_∞-category has the tangent complex quasi-isomorphic (after a shift) to the tangent complex to the deformations of the identity functor $\mathrm{Id}_{A_X-\mathrm{mod}}$. The latter deformations are described by the deformations of K_Δ as an object of $\mathrm{A}_{X\times X}-\mathrm{mod}$. The tangent space at K_Δ to the moduli space of its deformations is isomorphic to $\oplus_{i\geqslant 0}\mathrm{Ext}^i_{A_{X\times X}-\mathrm{mod}}(K_\Delta,K_\Delta)$. After changing scalars to $\mathbf{C}((t))$ the latter sum can be identified with $H^\bullet(X,\mathbf{C}((t)))$. We can restrict the deformation functor to the subcategory $\mathrm{hol}(X)$. It is not difficult to see that the support of a holonomic module remains Lagrangian. These observations lead to the following result.

Proposition 1:

(a) *The Hochschild cohomology of the category $A_X-\mathrm{mod}$ is isomorphic to $H^\bullet(X,\mathbf{C}((t)))$. (Here*

we consider $A_X-\mathrm{mod}$ *as an* A_∞*-category with* $m_{n\neq 2}=0$ *and* m_2 *given by the usual composition of morphisms).*

(b) *The tangent space to the deformations of an object* $(L,\rho)\in \mathrm{hol}(X)$ is isomorphic to $H^\bullet(L,\mathrm{End}(\rho))\otimes \mathbf{C}((t))$.

We also mention the following proposition [see Soibelman (2001)]. It should be compared with the definition of Hom's in the Fukaya category.

Proposition 2: *Let* $V_{(L,\rho)}$ *denotes the object of* hol_X *corresponding to the pair* (L,ρ). *If* L_0 *is transversal to* L_1 *then*

(a) $\mathrm{Ext}^i(V_{(L_0,\rho_0)},V_{(L_1,\rho_1)})$ *is trivial if* $i\neq n$, *where* $n=1/2\ \dim X$;

(b) $\mathrm{Ext}^n(V_{(L_0,\rho_0)},V_{(L_1,\rho_1)})\simeq \oplus_{x\in L_0\cap L_1}\mathrm{Hom}(\rho_{0x},\rho_{1x})\otimes \mathbf{C}((t))$;

(c) *the algebra* $\mathrm{Ext}^\bullet(V_{(L,\rho)},V_{(L,\rho)})$ *is isomorphic to the cohomology* $H^\bullet(L,\mathrm{End}(\rho))\otimes \mathbf{C}((t))$ *[cf. part (b)] of the previous Proposition).*

Let $D^b_\infty(\mathrm{hol}(X))$ be the A_∞-category associated with the category $\mathrm{hol}(X)$. It is in fact a dg-category. In order to construct it one chooses injective resolutions of A_X-modules I_M and I_N of two holonomic modules M and N. Then one defines $\mathrm{Hom}_{D^b_\infty(\mathrm{hol}(X))}(M,N)=\mathrm{Hom}^\bullet(I_M,I_N)$. In this way one obtains an A_∞-model for the derived category of the category of holonomic modules.

The discussion above shows a certain similarity between $D^b_\infty(\mathrm{hol}(X))$ and $F^{\mathrm{naive}}(X)$. At the same time their deformation theories induce different products on the cohomology of X. In case of the Fukaya category it is the quantum product, while in case of $\mathrm{hol}(X)$ it is the usual cup product. The reader will also notice that the Maslov index is not visible in the case of $\mathrm{hol}(X)$.

On the other hand we will explain in the next section that

(a) The algebras $\mathrm{End}_{D^b_\infty(\mathrm{hol}(X))}((L,\rho))$ and $\mathrm{End}_{F^{\mathrm{naive}}(X)}((L,\rho))$ are A_∞-equivalent.

(b) If L and L' are Hamiltonian isotopic, then we can "twist" the space $\mathrm{Hom}_{D^b_\infty(\mathrm{hol}(X))}((L,\rho),(L',\rho'))$ in such a way that it becomes quasi-isomorphic to the corresponding complex of morphisms in $F^{\mathrm{naive}}(X)$.

V. COMPARISON OF THE CATEGORIES

Let (L,ρ) be a pair as before, i.e., L is a Lagrangian submanifold of X and ρ is a local system on L. Let us denote by $E_{(L,\rho)}$ the corresponding object of $F(X)$, and by $V_{(L,\rho)}$ the corresponding object of $\mathrm{hol}(X)$. We assume that $m_0=0$ in the A_∞-algebra $A(L,\rho)$. This means that in fact we are dealing with the category $F^{\mathrm{naive}}(X)$. We also assume the conditions imposed on L in Fukaya, Oh, Ohta, and Ono (2000). This allows us to make necessary choices without further explanations. In particular L is relatively spin in the sense of Fukaya, Oh, Ohta, and Ono (2000), so the moduli spaces of pseudo-holomorphic discs are orientable. Taking the Hochschild complex of $A(L,\rho)$ we can construct the formal pointed dg-manifold $\mathcal{M}_{E_{(L,\rho)}}$ of deformations of $E_{(L,\rho)}$. Similarly, we can start with the Lie algebra $\mathrm{Hom}_{D^b_\infty(\mathrm{hol}(X))}(V_{(L,\rho)},V_{(L,\rho)})$ and construct the formal pointed dg-manifold $\mathcal{M}_{V_{(L,\rho)}}$ of deformations of $V_{(L,\rho)}$.

Let us imagine that both $F^{\mathrm{naive}}(X)$ and $D^b_\infty(\mathrm{hol}(X))$ are "sheaves of A_∞-categories" on the "moduli space of objects". Let us also imagine that there is a well-defined moduli space $Lagr_X$ of Lagrangian submanifolds of X. Then we should have a natural projection $\pi:\mathcal{M}_X\to \mathrm{Lagr}_X$. If L is a Lagrangian submanifold, and $[L]\in \mathrm{Lagr}_X$, the corresponding point of the moduli space then the fiber $\pi^{-1}([L])$ consists of local systems supported on L (or on any Lagrangian submanifold representing the same equivalence class in the moduli space). We would like to compare $F^{\mathrm{naive}}(X)$ and $\mathrm{hol}(X)$ in a "small neighborhood of $[(L,\rho)]$". From the categorical point of view we have two A_∞-categories $\mathcal{A}$ and $\mathcal{B}$ with the same "space" of objects, and such that for any object X the A_∞-algebras $\mathrm{End}_{\mathcal{A}}(X)$ and $\mathrm{End}_{\mathcal{B}}(X)$ are equivalent. We would like to find a functor $\Phi:\mathcal{A}\to\mathcal{A}$ such that changing morphisms in $\mathcal{A}$ to $\mathrm{Hom}^{\mathrm{new}}_{\mathcal{A}}(X,Y)=\mathrm{Hom}_{\mathcal{A}}(X,\Phi(Y))$ one gets a new A_∞-category equivalent to $\mathcal{B}$.

A. Main conjecture

We will denote by $\mathrm{hol}(L)$ the full subcategory of $\mathrm{hol}(X)$ consisting of holonomic modules with the given support L. For simplicity we will assume the rationality condition imposed on the symplectic form ω. Hence the Fukaya category is defined over $\mathbf{C}((q))$ (this is not a serious restriction because one can consider deformation quantization over any pro-nilpotent algebra, in particular $\mathbf{C}_\varepsilon$).

Our main idea can be explained such as follows. Having in mind the intuitive picture of the previous subsection we consider both $F^{\mathrm{naive}}(X)$ and $D^b_\infty(\mathrm{hol}(X))$ in a small neighborhood of a given $[L]\in \mathrm{Lagr}_X$. For a pair L_1, L_2 sufficiently close to L we would like to find a functor $\Phi_{L_1,L_2}: D^b_\infty(\mathrm{hol}(L_2)) \to D^b_\infty(\mathrm{hol}(L_1))$, such that $\mathrm{Hom}(\rho_1, \Phi_{L_1,L_2}(\rho_2))$ [morphism as objects of $D^b_\infty(\mathrm{hol}(L_1))$] is quasi-isomorphic to $\mathrm{Hom}_{F^{\mathrm{naive}}(X)}((L_1,\rho_1),(L_2,\rho_2))$. Such a functor should be represented by a bimodule. Let us describe all this more precisely.

Let $M_i = V_{(L_i,\rho_i)} \in \mathrm{hol}(L_i), i=1,2$. We expect that there exists a Lagrangian submanifold $\Lambda_{12} = \Lambda(L_1,L_2) \subset X\times X$ and $K(L_1,L_2) = K_{\Lambda_{12}} \in \mathrm{hol}(X\times X)$ such that the following occurs.

(1) If L_1 and L_2 have a nonempty intersection then $\Lambda_{12}\circ L_1 = L_2$. Here $\Lambda\circ L = \pi_2(\pi_1^{-1}(L)\cap\Lambda)$, where $\pi_i: X\times X\to X, i=1,2$ are the natural projections. In particular we assume that the restrictions of $\pi_i, i=1,2$ to Λ are coverings.

(2) $\mathrm{Hom}_{D^b_\infty(\mathrm{hol}(X))}(M_1, K(L_1,L_2)\circ M_2) \simeq \mathrm{Hom}_{F^{\mathrm{naive}}(X)}((L_1,\rho_1),(L_2,\rho_2))$, where $\simeq$ means a quasi-isomorphism of complexes, and we consider both categories over the field $\mathbf{C}((q))$ [i.e., $q=t$ in the case of $\mathrm{hol}(X)$]. The composition $\circ$ for modules is given by the formula $K\circ M = \pi_{2*}[K\otimes \pi_1^*(M)]$.We denote by $\mathrm{Hom}^{\mathrm{new}}(M_1,M_2)$ the left hand side of (2).

(3) For a generic sequence of Lagrangian submanifolds $L_1, L_2, \ldots, L_n, n\geqslant 2$ and holonomic modules $M_1,\ldots,M_n$ such that $M_i = V_{(L_i,\rho_i)}$ for all i, we expect to have an isomorphism of A_{X^n}-modules:

$$K(L_1,L_2)\circ K(L_2,L_3)\circ\cdots\circ K(L_{n-1},L_n)\to K(L_1,L_n).$$

Such an isomorphism defines a linear map,

$$m_n^{\mathrm{new}}: \otimes_{1\leqslant i\leqslant n-1}\mathrm{Hom}^{\mathrm{new}}(M_i,M_{i+1}) \to \mathrm{Hom}^{\mathrm{new}}(M_1,M_n).$$

We expect the above data to satisfy the following.

Conjecture 1: (i) Higher compositions $m_n^{\mathrm{new}}, n\geqslant 1$ give rise to a structure of an A_∞ -category on $D^b_\infty(\mathrm{hol}(X))$.

(ii) This category is A_∞-equivalent to $F^{\mathrm{naive}}(X,\omega)$ (with $q=t$).

B. The conjecture in the case of cotangent bundle

Let us fix a Lagrangian submanifold $L\subset X$, and consider only those L' which are "very close" to L. More precisely we assume that they are not only close to L but also Hamiltonian isotopic to L. We want to "restrict" $F^{\mathrm{naive}}(X)$ to this "neighborhood of L." This means that we consider an A_∞-subcategory with the objects taken from the above-mentioned subset, and morphisms the same as in $F^{\mathrm{naive}}(X)$. We do the same thing with $\mathrm{hol}(X)$ and $D^b_\infty(\mathrm{hol}(X))$. We would like to compare these categories in the case when $X=T^*Y$ is the cotangent bundle with the standard symplectic structure (notice that a neighborhood of a Lagrangian submanifold L can be identified by a symplectomorphism with a neighborhood of the zero section in T^*L). We are going to consider Lagrangian submanifolds of the type $L_i = \{(x, df_i(x)) | x\in Y\}$. Let ρ_i be local systems on L_i.

For a pair of such Lagrangian submanifolds we have a symplectomorphism $\phi: X\to X$ such that $(x,\xi)\mapsto (x, \xi + df_2(x) - df_1(x))$. Clearly it maps isomorphically L_1 into L_2.

Let us define $\Lambda = \Lambda_{12}$ as $\mathrm{graph}(\phi)\subset X\times X$. The corresponding bimodule K_Λ is the quotient of $A_X \boxtimes A_X^{op}$ by the left ideal generated by the relation $a\otimes 1 = 1\otimes e^{(1/t)ad(f_2-f_1)}(a)$, $a\in A_X$. Here $ad(a)\times(b) = ab-ba$ (clearly A_X contains C^∞_Y as a subalgebra, so the ideal is well-defined).

Notice that $\exp 1/t(ad(f_2-f_1))\exp 1/t(ad(f_3-f_2))\cdots\exp 1/t(ad(f_n-f_{n-1}))=\exp 1/t(ad(f_n-f_1))$. Hence we have an isomorphism $K(L_1,L_2)\circ K(L_2,L_3)\circ\cdots\circ K(L_{n-1},L_n)\to K(L_1,L_n)$.

In order to check the conjecture we may assume that $f_1=0$. Then we observe that

$$\mathrm{Hom}_{D^b_\infty(\mathrm{hol}(X))}(\rho_1,K(L_1,L_2)\circ\rho_2)=\Omega^\cdot(Y,\rho_1^*\otimes\rho_2),$$

where the rhs is the complex of de Rham forms with values in the local system. Let $\nabla_i, i=1,2$ denote the flat connection on $\rho_i, i=1,2$. Then the differential is given by $\nabla_1^*\otimes 1+1\otimes\nabla_2+df_2\wedge(\cdot)$. The latter complex is equivalent to the standard de Rham complex (without df_2) if one twists the sections by $\exp((1/t)f_2)$, i.e., $s\mapsto s\exp((1/t)f_2)$. Then according to Kontsevich and Soibelman (2000), in Sec. IV the resulting complex is quasi-isomorphic to $\mathrm{Hom}_{F^{\mathrm{naive}}(X)}((L_1,\rho_1),(L_2,\rho_2))$. We remark that in the notation of Kontsevich and Soibelman (2000), one has $q=\exp(-1/\varepsilon)$.

Remark 4:. *The case of a general symplectic manifold does not follow automatically from the results of this section. Indeed, in order to define morphisms in the Fukaya category for Lagrangian submanifolds in a small neighborhood of a given L one has to consider pseudo-holomorphic disks which do not belong entirely to the neighborhood (we are restricted by the boundary conditions only). Nevertheless, if our main conjecture is true, one can find a family of kernels $K(L_1,L_2)$ which takes care of such disks.*

C. Complex structure on the moduli space of holonomic modules

We observe that the tangent space to the moduli space of deformations of a module $M\in\mathrm{hol}(X),\mathrm{supp}(M)=L$ is isomorphic to $\mathrm{Hom}_{D^b_\infty(\mathrm{hol}(X))}(M,M)$ [derived deformations of $\mathrm{Hom}_{\mathrm{hol}(X)\times(\mathrm{Id}_X,\mathrm{Id}_X)}$]. There is a natural embedding $\mathrm{Hom}_{D^b_\infty(\mathrm{hol}(L))}(M,M)\to\mathrm{Hom}_{D^b_\infty(\mathrm{hol}(X))}(M,M)$, corresponding to the deformations with the fixed support L. On the other hand there is a natural projection $\mathrm{Hom}_{D^b_\infty(\mathrm{hol}(X))}(M,M)\to\Omega^\cdot(L)$, where $\Omega^\cdot(L)$ denotes the de Rham complex of L. Indeed, a deformation of the module M induces the deformation of the support of M. The latter are controlled by differential forms on the support. We can perform computations in the derived categories. Then we have an exact sequence of the tangent spaces to the formal moduli spaces of deformations:

$$\mathrm{Ext}^\cdot_{\mathrm{hol}(L)}(M,M)\to\mathrm{Ext}^\cdot_{\mathrm{hol}(X)}(M,M)\to H^\cdot_{DR}(L).$$

Suppose that M is a simple module. Then

$$R\,\mathrm{Hom}_{\mathrm{hol}(L)}(M,M)\simeq R\Gamma(L,R\underline{\mathrm{Hom}}(M,M))\simeq R\Gamma(L,\mathbf{C}_L)\simeq\Omega^\cdot(L).$$

Taking the first cohomology (this corresponds to "classical" tangent space) we obtain in this case an exact sequence,

$$H^1_{DR}(L)\to\mathrm{Ext}^1_{\mathrm{hol}(X)}(M,M)\to H^1_{DR}(L).$$

This means that the tangent space to the "classical" deformations of M inside of $\mathrm{hol}(X)$ is twice as big as the tangent space to the "classical" deformations of L inside of Lagr_X. If X is a Calabi–Yau manifold then one hopes to obtain a complex structure on the moduli space of formal deformations of a simple holonomic module M. We expect that it is isomorphic to a subvariety in the dual Calabi-Yau manifold. In order to describe the complex structure explicitly we need to identify the tangent space $T_L(\mathrm{Lagr}_X)$ with the tangent space $T_M(\mathrm{hol}(L))$. It is sufficient to describe the lifting of paths from Lagr_X to $\mathrm{hol}(L)$. Given a path $L(t)\subset\mathrm{Lagr}_X$ such that $L(0)=L$, we define a path $M(t)\subset\mathrm{hol}(L),M(0)=M$ in the following way: $M(t)=M\otimes\rho(t)$. Here $\rho(t)$ is the restriction to $L(t)$ of the unitary bundle over X with a connection ∇ such that $\mathrm{curv}(\nabla)=\omega_X$ (it is often called the pre-quantum line bundle). The restriction of ∇ to $L(t)$ is a flat connection.

VI. CONCLUSION

We have suggested the way to compare the Fukaya category with the category of holonomic modules over the quantized algebra of smooth functions. The idea is for a pair of Lagrangian submanifolds L_1, L_2 to find a kernel $K(L_1, L_2)$ which transforms local systems (or more general A_X-modules) supported on L_2 to local systems supported on L_1. We have conjectured that it is possible to make these choices in such a way that the counting of instantons (i.e., higher compositions in the Fukaya category) can be replaced by pure algebraic operation of taking homomorphisms between local systems having the same Lagrangian support. We have checked the conjecture in the simplest case. It would be interesting to check it in other cases as well as "globalize" this picture, finding kernels $K(L_1, L_2)$ for Lagrangian submanifolds which are not close to each other.

(Received 4 January 2004; accepted 7 June 2004; published 12 October 2004)

We present a method of quantizing analytic spaces X immersed in an arbitrary smooth ambient manifold M. Remarkably our approach can be applied to singular spaces. We begin by quantizing the cotangent bundle of the manifold M. Using a supermanifold framework we modify the Fedosov construction in a way such that the $\star$-product of the functions lifted from the base manifold turns out to be the usual commutative product of smooth functions on M. This condition allows us to lift the ideals associated to the analytic spaces on the base manifold to form left (or right) ideals on $(\mathcal{O}_{\Omega^1 M}[[\hbar]],\star_\hbar)$ in a way independent of the choice of generators and leading to a finite set of PDEs defining the functions in the quantum algebra associated with X. Some examples are included. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1788847]

I. INTRODUCTION

Deformation quantization is mathematically speaking a way of defining noncommutative associative products on a Poisson manifold, called $\star$-products, in a way such that the noncommutativity is controlled by a deformation parameter. The usual pointwise product is recovered as a limit case when this deformation parameter is negligible and the Poisson structure is found to be in the same fashion a limit case of the $\star$-commutator in accordance with the quantum correspondence principle.

Formally speaking, consider a smooth manifold N. A star product on $\mathcal{O}_N[[\hbar]]$ is an associative $\mathbb{R}[[\hbar]]$-linear product

$$f\star_\hbar g := \sum_{k=0}^{\infty} \left(-\frac{i\hbar}{2}\right)^k m_k(f,g),$$

where any m_k is a bidifferential operator of finite total order and $m_0(f,g)=fg$. It then can be shown that the operation on $\mathcal{O}_N[[\hbar]]$ defined by $\{f,g\}=\lim_{\hbar\to 0}(1/i\hbar)[f,g]$ is indeed a Poisson structure on M. (For a review from the mathematical perspective see Ref. 1.)

From the physics point of view deformation quantization is a new autonomous reformulation of quantum mechanics. Although still in development nowadays it is capable of reproducing numerous examples from the ordinary operator formulation and has been found to be closely related to the path integral formulation. (For a review from the physics perspective, see Refs. 2 and 3.)

One of the most powerful trends of work in mathematical physics during the last century was the generalization of the formulation of physical theories from the Euclidean case to the manifold framework. In this way classical mechanics was formulated in terms of a Poisson structure generalizing the classical notion of the Poisson bracket. Another example of this has been the gener-

a)Electronic mail: cm@maths.gla.ac.uk

alization of the operator formulation of quantum mechanics to the nonflat case. Different answers have been found e.g., geometric quantization, group theoretic quantization. (For an extended discussion, see Ref. 4.)

Deformation quantization has followed a similar way going from the first $\star$-product found by Moyal following physical ideas and then generalized by Fedosov, who gave an explicit construction of a $\star$-product in an arbitrary symplectic manifold.[5,6]

The quantization of singular spaces has been somewhat rejected until very recently. This is one of the new possibilities provided by deformation quantization, since the traditional approaches breakdown in this case. Merkulov proposed in Ref. 7 a way of quantizing algebraic varieties immersed in some $\mathbb{R}^n$. This included the possibility of a nonempty set of singular points.

In this work we provide a general construction to quantize arbitrary analytic spaces (including the singular case), immersed in any smooth analytic real manifold. (A different approach can be found in Ref. 8.) We summarize the general context of this work in the following:

	Euclidean	Manifold framework
Classical mechanics	Poisson bracket	Poisson structure
Quantum mechanics	Heisenberg's formulation	e.g., group quantization
Deformation quantization	Moyal $\star$-product	Fedosov construction
Deformation quantization of singular spaces	Merkulov's work	This article

II. QUANTIZATION OF ANALYTIC SPACES

Consider a smooth analytic manifold M and $\mathcal{O}_M[[\hbar]]$, the ring of formal power series with global analytic functions as coefficients equipped with the usual commutative product. Classically an analytic space $(X,\mathcal{O}_X[[\hbar]])$ immersed on M is defined by choosing a finitely generated vanishing ideal I. Then the subspace X, which in general is not a smooth submanifold, corresponds to the set of solutions of the system of equations $\phi_i=0$, for any set $\phi_1,\ldots,\phi_n$ of generators of I. The associated ring of functions is defined then as $\mathcal{O}_X[[\hbar]]=\mathcal{O}_M[[\hbar]]/I$. (For a detailed exposition see, for example, Ref. 9.)

Now consider the cotangent bundle $\pi:\Omega^1M\to M$. The ideal I can be lifted via $\pi^{-1}(I)$ and in this way an analytic space $(X,\mathcal{O}_X[[\hbar]])$ can be defined. This time $\mathcal{O}_X[[\hbar]]=\mathcal{O}_{\Omega^1M}[[\hbar]]/\pi^{-1}(I)$ and $X\subset\Omega^1M$. In physical terms this would describe a system with a set of constrictions in the configuration space. Our goal is to define a quantum version of this structure capable of dealing with singular spaces.

Note that if one tries to replace naively the pointwise product of functions by the star product on Ω^1M (which can be found via the standard Fedosov construction for symplectic manifolds), one finds two possible scenarios. If one fixes a set of generators of the vanishing ideal $\pi^{-1}(I)$ before quantizing, the construction will depend on this choice since the star product depends on the smoothness around the vanishing points of the possible choices of generators. On the other hand, if one avoids this choice and defines a left (or right) ideal and proceeds to determine the normalizer, one finds an infinite number of equations.

In our approach, we modify the Fedosov construction[5,6] in a way that allows us to find a quantum algebra independently of the choice of generators and corresponding to the solutions of a finite set of partial differential equations.

The quantization procedure goes as follows:

Step 1. Initial data: The necessary data to begin the construction are

(1) *A smooth manifold M*;
(2) *A torsion free affine connection ∂ defined on M*;
(3) *The vanishing ideal I associated to the classical analytic space*.

Step 2. Quantization of $\Omega^1 M$: Before discussing the details we give in rough terms an overview of this step (for a related material on the deformation quantization of cotangent bundles with a different approach, see Ref. 10). The goal is to construct a star product on the ring of functions $\mathcal{O}_{\Omega^1 M}[[\hbar]]$ which coincides with the pointwise multiplication when restricted to functions lifted from the base, which is not the case in general for the standard Fedosov construction. The main tool is an auxiliary algebra $\mathcal{W}$ where a star product $\star_\hbar$ can be defined in a straightforward manner. Then a subalgebra $\mathcal{W}_D \subset \mathcal{W}$ with a one to one correspondence that we will denote as $\phi: \mathcal{O}_{\Omega^1 M}[[\hbar]] \to \mathcal{W}_D$ is found. The star product $\star'_\hbar$ for $\mathcal{O}_{\Omega^1 M}[[\hbar]]$ is defined as the one making the following diagram commute:

$$\begin{array}{ccc} \mathcal{O}_{\Omega^1 M}[[\hbar]] \otimes \mathcal{O}_{\Omega^1 M}[[\hbar]] & \overset{\star'_\hbar}{\rightarrow} & \mathcal{O}_{\Omega^1 M}[[\hbar]] \\ \phi \otimes \phi \downarrow & & \downarrow \phi \\ \mathcal{W}_D \otimes \mathcal{W}_D & \underset{\star_\hbar}{\rightarrow} & \mathcal{W}_D \end{array}$$

Then the key point in this step is to find the subalgebra $\mathcal{W}_D$, which turns out to be the set of flat sections of a connection, and the correspondent map ϕ.

Now we proceed with the exposition in detail. We shall use the language of supermanifolds which makes it more simple and makes the nature of the objects used more transparent.

Consider a $(3n|n)$-dimensional supermanifold $\mathcal{M} := \Omega^1 M \times_M TM \times_M \Pi(TM)$ (where we have used the parity change operator Π). For a coordinate system in $\Omega^1 M$ of the form $(x^1 \ldots x^n, p_1 \ldots p_n)$ we have an associated coordinate system on $\mathcal{M}$ of the form

$$(x^1 \cdots x^n, p_1 \cdots p_n, y^1 \cdots y^n, \psi^1 \cdots \psi^n).$$

Definition 2.1: The Weyl algebra $\mathcal{W}$ *on the supermanifold* $\mathcal{M}$ *is the usual supercommutative algebra* $\mathcal{O}_{\mathcal{M}}[[\hbar]]$*, and a typical element of* $\mathcal{W}$ *has locally the form*

$$a(x,p,y,\psi) = \sum_{k,p,r=0}^{\infty} \hbar^k a^{k_1 \cdots k_r}_{k,i_1 \cdots i_p, j_1 \cdots j_q}(x) y^{i_1} \cdots y^{i_p} p_{k_1} \cdots p_{k_r} \psi^{j_1} \cdots \psi^{j_q}, \tag{1}$$

where the tensor $a^{k_1 \cdots k_r}_{k,i_1 \cdots i_p, j_1 \cdots j_q}$ *is symmetric in the* $i_1 \cdots i_p$ *and* $k_1 \cdots k_r$ *indices and antisymmetric in the* $j_1 \cdots j_r$ *indices.*

There is a natural $\star$-product defined on $\mathcal{W}$ given as follows:

$$f \star_\hbar g = \exp\left(-\frac{i\hbar}{2} \left(\frac{\partial^2}{\partial y^a \partial \tilde{p}_a} - \frac{\partial^2}{\partial \tilde{y}^a \partial p_a} \right) \right) f(x,p,y,\psi) g(x,\tilde{p},\tilde{y},\psi)\big|_{p=\tilde{p}, y=\tilde{y}},$$

where $f, g \in \mathcal{W}$. This product is manifestly covariant and is easy to check it is associative. Note also that $f \star_\hbar g = g \star_{-\hbar} f$.

Then some auxiliary vector fields on $\mathcal{M}$ are defined:

$$\text{(i)} \quad \delta := \psi^a \frac{\partial}{\partial y^a},$$

$$\text{(ii)} \quad \delta^\star := y^a \frac{\partial}{\partial \psi^a},$$

$$\text{(iii)} \quad d := \psi^a \frac{\partial}{\partial x^a},$$

$$\text{(iv)}\ \ \delta^{-1}a := \frac{\delta^*}{p+q}a,$$

$$\text{(v)}\ \ \partial a := \psi^j \partial_i a,$$

where $a \in \mathcal{W}$ is a homogeneous element of order p in the variable y^a and of order q in the anticommutative variable ψ^a.

Lemma 2.2: Let $a \in \mathcal{W}$ be a homogeneous element as in the last paragraph and define $a_{00} := a(x,p,0,0)$, then

$$\text{(i)}\ \ \delta^2 a = 0,$$

$$\text{(ii)}\ \ \delta^{*2} a = 0,$$

$$\text{(iii)}\ \ \delta a = -\frac{i}{\hbar}[p_j\psi^j, a]_*,$$

$$\text{(iv)}\ \ a = a_{00} + \frac{1}{p+q}(\delta\delta^* a + \delta^* \delta a).$$

Proof is done by direct calculation, to illustrate we show the check for (iii) which goes as follows:

$$\begin{aligned}-\frac{i}{\hbar}[p_i\psi^i, a]_* &= -\frac{i}{\hbar}\left(p_i\psi^i a + \left(\frac{-i\hbar}{2}\right)\left(\frac{\partial^2}{\partial y^a \partial \tilde{p}_a} - \frac{\partial^2}{\partial \tilde{y}^a \partial p_a}\right) p_i\psi^i a(x,\tilde{y},\tilde{p},\psi) - (-1)^{\tilde{a}}\left(a p_i\psi^i + \left(\frac{-i\hbar}{2}\right)\right.\right.\\ &\quad \left.\left.\times\left(\frac{\partial^2}{\partial y^a \partial \tilde{p}_a} - \frac{\partial^2}{\partial \tilde{y}^a \partial p_a}\right) a(x,y,p,\psi)\tilde{p}_i\psi^i\right)\right)\\ &= -\frac{i}{\hbar}\left(\frac{-i\hbar}{2}\right)\left(-\psi^i\frac{\partial a}{\partial y^i} - (-1)^{\tilde{a}}\frac{\partial a}{\partial y^i}\psi^i\right) = \psi^i\frac{\partial a}{\partial y^i} = \delta a.\end{aligned}$$

□

Note that property (iv) implies that for all $a \in \mathcal{W}$ there is a decomposition

$$a = \delta\delta^{-1}a + \delta^{-1}\delta a + a_{00}. \tag{2}$$

The local expression of ∂ is

$$\partial a = \psi^a\left(\frac{\partial}{\partial x^a} + \Gamma^c_{ab}p_c\frac{\partial}{\partial p_b} - \Gamma^c_{ab}y^b\frac{\partial}{\partial y_c}\right)a. \tag{3}$$

Lemma 2.3: It is possible to express ∂a as

$$\partial a = da + \frac{i}{\hbar}[\Gamma, a]_*$$

for some $\Gamma \in \mathcal{W}$ of odd parity.

Proof: This can be shown as follows. Consider, for some constant α, the expression

$$da + [\alpha\Gamma, a]_* = da + i\hbar\alpha\left(-\frac{\partial\Gamma}{\partial y^b}\frac{\partial a}{\partial p_b} + \frac{\partial\Gamma}{\partial p_c}\frac{\partial a}{\partial y^c}\right) + O(\hbar^2).$$

Comparing this equation with Eq. (3) leads us to the equations

$$\psi^a\Gamma^c_{ab}p_c = -i\hbar\frac{\partial\alpha\Gamma}{\partial y^b}, \quad -\psi^a\Gamma^c_{ab}y^b = i\hbar\frac{\partial\alpha\Gamma}{\partial p_c}.$$

This implies that we must take $\Gamma=\Gamma^c_{ab}y^bp_c\psi^a$ and $\alpha=i/\hbar$ and the result follows. □

The auxiliary algebra is defined as the set $\mathcal{W}_D:=\{a\in\mathcal{W}:Da=0\}$, for some connection $D=\psi^aD_a$ that must satisfy the integrability condition $D^2=0$. It turns out that taking $D=\partial$ is not a good choice as the following proposition shows.

Proposition 2.4: The integrability condition for the connection ∂ can be expressed as

$$\partial^2 a = \frac{i}{\hbar}[R,a]_* \tag{4}$$

where $R:=\frac{1}{2}\psi^b\psi^cR^d_{abc}p_dy^a$.

Proof:

$$\begin{aligned}\frac{1}{2}[\partial,\partial]_*a &= \frac{1}{2}\left[\psi^a\left(\frac{\partial}{\partial x^a}+\Gamma^c_{ab}p_c\frac{\partial}{\partial p_b}-\Gamma^c_{ab}y^b\frac{\partial}{\partial y^c}\right),\psi^d\left(\frac{\partial}{\partial x^d}+\Gamma^f_{de}p_f\frac{\partial}{\partial p_e}-\Gamma^f_{de}y^e\frac{\partial}{\partial y^f}\right)\right]_{*a}\\ &= \frac{1}{2}\psi^a\psi^d\left(\left(\frac{\partial\Gamma^f_{de}}{\partial x^a}-\frac{\partial\Gamma^f_{ae}}{\partial x^d}\right)p_f\frac{\partial}{\partial p_e}+\left(\frac{\partial\Gamma^f_{ae}}{\partial x^d}-\frac{\partial\Gamma^f_{de}}{\partial x^a}\right)y^e\frac{\partial}{\partial y^f}+(\Gamma^f_{am}\Gamma^m_{de}-\Gamma^m_{ae}\Gamma^f_{dm})p_f\frac{\partial}{\partial p_e}\right.\\ &\quad\left.+(\Gamma^m_{ae}\Gamma^f_{dm}-\Gamma^m_{de}\Gamma^f_{am})y^e\frac{\partial}{\partial y^f}\right)a.\end{aligned}$$

And since

$$R^i_{jkl}=\frac{\partial\Gamma^i_{jl}}{\partial x^k}-\frac{\partial\Gamma^i_{jk}}{\partial x^l}+\Gamma^i_{mk}\Gamma^m_{jl}-\Gamma^i_{ml}\Gamma^m_{jk},$$

we have that

$$\partial^2=\frac{1}{2}\psi^b\psi^c\left(R^d_{abc}p_d\frac{\partial}{\partial p_a}-R^d_{abc}y^a\frac{\partial}{\partial y^d}\right)$$

and, on the other hand, we have

$$\frac{i}{\hbar}[R,a]_*=\frac{\partial R}{\partial y^a}\frac{\partial a}{\partial p_a}-\frac{\partial R}{\partial p_d}\frac{\partial a}{\partial y^d}.$$

This implies that we must take

$$R=\tfrac{1}{2}\psi^b\psi^cR^d_{abc}p_dy^a,$$

in order to have $\partial^2=(i/\hbar)[R,\cdot]_*$. This completes the proof. □

In other words the connection ∂ should be flat to fulfill the condition, which is far too restrictive. The way out is to define a new generalized connection of the form

$$Da=da+\frac{i}{\hbar}[-\psi^ap_a+\Gamma+\gamma,a]_*=\partial a+\frac{i}{\hbar}[-\psi^ap_a+\gamma,a]_*,$$

where γ is

$$\gamma=\sum_{n=3}^{\infty}\Gamma^a_{i_1\cdots i_n,b}y^{i_1}\cdots y^{i_n}p_a\psi^b, \tag{5}$$

to be determined to fulfill the integrability condition. Further calculation shows

$$D^2a=\frac{i}{\hbar}[R,a]_*+\frac{i}{\hbar}\partial[-\psi^\mu p_a+\gamma,a]_*+\frac{i}{\hbar}[-\psi^\mu p_a+\gamma,\partial a]_*+\left(\frac{i}{\hbar}\right)^2[-\psi^\mu p_a+\gamma,[-\psi^\mu p_a+\gamma,a]_*]_*$$
$$=\frac{i}{\hbar}[R,a]_*+\frac{i}{\hbar}[\partial\gamma,a]_*+\left(\frac{i}{\hbar}\right)^2\frac{1}{2}[[\psi^\mu p_a+\gamma,-\psi^\mu p_a+\gamma]_*,a]_*=\frac{i}{\hbar}\left[R+\partial\gamma-\delta\gamma+\frac{i}{\hbar}\gamma\star_\hbar\gamma,a\right]_*.$$

Then the equivalent condition for having $D^2=0$ is

$$\delta\gamma=R+\partial\gamma+\frac{i}{\hbar}\gamma^2. \tag{6}$$

Proposition 2.5: γ is a solution of Eq. (6) if and only if

$$\gamma=\delta^{-1}R+\delta^{-1}\left(\partial\gamma+\frac{i}{\hbar}\gamma^2\right) \tag{7}$$

and the condition $\delta^{-1}\gamma=0$ is fulfilled.

Fedosov's proof[6] can be applied here so we shall not include it.

Substitution of the general form of γ given in (5) into Eq. (7) leads to an iterative process with initial condition $\delta^{-1}R$. The first terms of the solution are

$$\gamma=\tfrac{1}{3}R^d_{abc}y^ay^b\psi^cp_d+\tfrac{1}{12}\partial_lR^d_{abc}y^ly^ay^b\psi^cp_d+\cdots.$$

The subalgebra $\mathcal{W}_D$ is defined by the condition $Da=0$, i.e.,

$$\delta a=\partial a+\frac{i}{\hbar}[\gamma,a]_*. \tag{8}$$

Proposition 2.6: There is a one to one correspondence $\phi:\mathcal{O}_{\Omega^1M}[[\hbar]]\to\mathcal{W}_D$.

Proof: This can be shown as follows. Condition (8) is equivalent to

$$a=a_{00}+\delta^{-1}\left(\partial a+\left[\frac{i}{\hbar}\gamma,a\right]_*\right). \tag{9}$$

The equivalence of these two equations is proved as in the Fedosov construction. Indeed, since $D^2a=0$

$$\delta Da=\partial Da+\left[\frac{i}{\hbar}\gamma,Da\right]_*. \tag{10}$$

On the other hand, using (9) $\delta^{-1}Da=0$ and so

$$Da=\delta^{-1}\left(\partial Da+\left[\frac{i}{\hbar}\gamma,Da\right]_*\right).$$

Solution of this equation by an iterative process implies that $Da=0$. The converse assertion is trivial.

These are the first few terms of the solution for Eq. (9)

$$a=a_{00}+\partial_ia_{00}y^i+\frac{1}{2}\partial_i\partial_ja_{00}y^iy^j+\frac{1}{6}\partial_i\partial_j\partial_ka_{00}y^iy^jy^k-\frac{1}{12}R^d_{abc}y^ay^bp_d\frac{\partial a_{00}}{\partial p_c}+\cdots$$

giving the one to one map $a_{00}\mapsto\phi(a_{00}):=a$. □

The star product for $f_{00},g_{00}\in\mathcal{O}_{\Omega^1M}[[\hbar]]$ is finally defined as

$$f_{00}\star'_\hbar g_{00} = \phi^{-1}(f\star_\hbar g),$$

where $\phi^{-1}(f\star_\hbar g)=f\star_\hbar g(x,p,y,0)_{|y=0}$. The star product $\star'_\hbar$ inherits from $\star_\hbar$ the natural shift from left to right multiplication $f_{00}\star_\hbar g_{00}=g_{00}\star_{-\hbar}f_{00}$, implying that our construction will not depend on our choice to use left ideals instead of right ideals.

We find our key result for this step

Theorem 2.7: *Let* $f_{00},g_{00}\in\pi^*(\mathcal{O}_M[[\hbar]])$, then

$$f_{00}\star'_\hbar g_{00} = f_{00}g_{00}.$$

Proof: Suppose that in Eq. (9) the starting condition $a_{00}(x,p)$ does not depend on p, therefore the commutator $[\gamma,a_{00}]$ vanishes and one can check that this happens for every step in the iterative solution. We are left then with the equation

$$a = a_{00}(x,p) + \delta^{-1}(\psi^i\partial_i a).$$

Solutions of this equation are

$$a = a_{00} + \sum_{i=1}^{n}\frac{1}{n!}\partial_{i_1}\cdots\partial_{i_n}a_{00}y^{i_1}\cdots y^{i_n}.$$

Star products of functions of this type are clearly just the usual commutative product. Now let f_{00},g_{00} be two functions not depending on p then

$$f_{00}(x)\star'_\hbar g_{00}(x) = \phi^{-1}(f\star_\hbar g) = \phi^{-1}(fg) = f_{00}(x)g_{00}(x).$$

□

From this point we denote the star product on Ω^1M simply as $\star_\hbar$.

Step 3. Define the left ideal $\mathcal{J}_l$ *and compute the normalizer* $\mathcal{N}_l$: With the natural projection $\pi:\Omega^1M\to M$ the ideal $I\subset\mathcal{O}_M[[\hbar]]$ can be lifted to Ω^1M giving a set $\pi^*(I)\subset\mathcal{O}_{\Omega^1M}$ which defines a left ideal

$$\mathcal{J}_l = \{\mathcal{O}_{\Omega^1M}[[\hbar]]\star_\hbar\pi^*(I)\}.$$

Consider now the normalizer $\mathcal{N}_l\subset A_{\mathcal{M}}$ for the left ideal $\mathcal{J}_l$,

$$\mathcal{N}_l = \{h\in\mathcal{O}_{\Omega^1M}[[\hbar]]:\pi^*(I)\star_\hbar h\subset\mathcal{J}_l\}.$$

Clearly $\mathcal{J}_l\subset\mathcal{N}_l$ and moreover $\mathcal{J}_l$ is a double sided ideal of $\mathcal{N}_l$, this is

$$f\star_\hbar s\in\mathcal{J}_l,\quad s\star_\hbar f\in\mathcal{J}_l,$$

for all $f\in\mathcal{N}_l$, $s\in\mathcal{J}_l$.

Step 4. Take the quotient $\mathcal{Q}_X:=\mathcal{N}_l/\mathcal{J}_l$: *The result is a well defined noncommutative associative algebra which we call the quantum algebra of observables of X.*

Computing the normalizer of a one-sided ideal and taking the quotient to find a noncommutative ring is a rather common procedure which in general leads to conditions difficult to solve, but in our case, remarkably we have

Theorem 2.8: *The algebra* $\mathcal{Q}_X$ *corresponds to the quotient solution space of a finite number of partial differential equations and it does not depend on the choice of generators of the ideal I.*

Proof: The key point of the proof is given by theorem 2.7. This implies that for any $g\in\mathcal{O}_{\Omega^1M}$ the condition to be in the normalizer

$$\pi^{-1}(I)\star_\hbar g = 0 \bmod \mathcal{J}_l$$

is equivalent to

$$\left(\sum_{i=1}^{n}\alpha_i\phi_i\right)\star_\hbar g=\sum_{i=1}^{n}\alpha_i\star_\hbar(\phi_i\star_\hbar g)=0 \bmod \mathcal{J}_l. \tag{11}$$

In other words to the condition that $\phi_i\star_\hbar g=0 \bmod \mathcal{J}_l$ for the n generators ϕ_i of $\pi^{-1}(I)$. Each equation being in fact a partial differential equation for functions in $\mathcal{O}_{\Omega^1 M}[[\hbar]]$. The independence of the choice of generators of the ideal follows trivially from the fact that any new set of generators $\tilde{\phi}_i$ can be rewritten as a combination of the original ones leading again to Eq. (11). □

III. EXAMPLES

We shall develop next several examples of the explained technique when the ambient configuration space is $\mathbb{R}^2$. The natural choice of star product is the Moyal product on $\Omega^1\mathbb{R}^2$, given by

$$f*_\lambda g=e^{\lambda\Sigma_{i=1}^{2}(\partial/\partial_{x_i}\,\partial/\partial_{\tilde{p}_i}-\partial/\partial_{\tilde{x}_i}\,\partial/\partial_{p_i})}f(x_1,x_2,p_1,p_2)g(\tilde{x}_1,\tilde{x}_2,\tilde{p}_1,\tilde{p}_2)_{|\tilde{x}=x,\tilde{p}=p}$$

with $f,g\in\mathcal{O}_{\Omega^1\mathbb{R}^2}[[\lambda]]$. Clearly the Moyal product of functions not depending on the momentum variables coincides with the pointwise product. We shall be using the following:

Lemma 3.1: Every analytic function $f(x_1,x_2,p_1,p_2)\in\Omega^1\mathbb{R}^2$ can be uniquely decomposed as

$$f(x_1,x_2,p_1,p_2)=\sum_{i,j=0}^{\infty}f_{ij}(p_1,p_2)*_\lambda x_1^i *_\lambda x_2^j. \tag{12}$$

Proof: It is sufficient to note that

$$h(p_1,p_2)x_1^M x_2^N=h(p_1,p_2)*_\lambda x_1^M x_2^N-\sum_{n=1}^{M}\sum_{k=0}^{\min(N,n)}\frac{(-\lambda)^n}{(n-k)!\,k!}\frac{M!\,N!}{(M-n+k)!\,(N-k)!}x_1^{M-n+k}x_2^{N-k}\frac{\partial^n h}{\partial p_1^{(n-k)}\partial p_2^k}$$

implying that the Taylor expansion can be re-expressed in terms of the Moyal product. □

A. The cross

Consider now the analytic variety of the cross defined by the equation $x_1x_2=0$. Any function on the quantum algebra $\mathcal{Q}=\mathcal{N}_l/\mathcal{J}_l$ can be expressed as

$$h(x_1,x_2,p_1,p_2)=h_0(p_1,p_2)+h_1(x_1,p_1,p_2)*_\lambda x_1+h_2(x_2,p_1,p_2)*_\lambda x_2.$$

The left ideal is

$$\mathcal{J}_l=\{f*_\lambda x_1x_2 : f\in\mathcal{O}_{\Omega^1\mathbb{R}^2}\}.$$

The condition for the function h to be in the normalizer $\mathcal{N}_l$ is $x_1x_2*_\lambda h\in\mathcal{J}_l$, i.e.,

$$\begin{aligned}0 \bmod \mathcal{J}_l &= x_1x_2*_\lambda h_0+x_1x_2*_\lambda h_1*_\lambda x_1+x_1x_2*_\lambda h_2*_\lambda x_2\\ &=[x_1x_2,h_0]+[x_1x_2,h_1]*_\lambda x_1+[x_1x_2,h_2]*_\lambda x_2\\ &=2\lambda\frac{\partial^2 h_0}{\partial p_1\partial p_2}+\left(\frac{\partial h_0}{\partial p_2}+\lambda\frac{\partial^2 h_1}{\partial p_1\partial p_2}+x_1\frac{\partial h_1}{\partial p_2}\right)*_\lambda x_1+\left(\frac{\partial h_0}{\partial p_1}+\lambda\frac{\partial^2 h_2}{\partial p_1\partial p_2}+x_2\frac{\partial h_2}{\partial p_1}\right)*_\lambda x_2.\end{aligned}$$

Solutions have the form

$$h_1(x_1,p_1,p_2)=-\frac{h_0^2(p_2)}{x_1}+\xi(x_1,p_2)e^{-x_1p_1/\lambda}+a(x_1,p_1),$$

$$h_2(x_2,p_1,p_2) = -\frac{h_0^1(p_1)}{x_2} + \zeta(x_2,p_1)e^{-x_2p_2/\lambda} + b(x_2,p_2),$$

where $h_0^1(p_1), h_0^2(p_2)$ are arbitrary functions. The solutions of the form $h_0^2(p_2)/x_1, h_0^1(p_1)/x_2$ are not defined on the cross, therefore we do not consider them, similarly the terms $\xi(x_1,p_2)e^{-x_1p_1/\lambda}$ and $\zeta(x_2,p_1)e^{-x_2p_2/\lambda}$ must be rejected as they are not meromorphic in λ. (However such solutions may have a physical interpretation which we hope to elucidate later.)

We have then a family of functions for the quantum algebra of the cross given by

$$\mathcal{Q}_C := \{h \in \mathcal{O}_{\Omega^1\mathbb{R}^2}[[\lambda]]: h(x_1,x_2,p_1,p_2) = a(x_1,p_1)*_\lambda x_1 + b(x_2,p_2)*_\lambda x_2\}.$$

Computing the Moyal product of two elements h, $\tilde{h} \in \mathcal{Q}_C$ and eliminating terms with the factor x_1x_2 we find

$$h*_\lambda\tilde{h} = (a*_\lambda x_1 + b*_\lambda x_2)*_\lambda(\tilde{a}*_\lambda x_1 + \tilde{b}*_\lambda x_2) = a*_\lambda x_1*_\lambda\tilde{a} + b*_\lambda x_2*_\lambda\tilde{b}.$$

In other words the quantum algebra of the cross has then elements of the form

$$h = (a(x_1,p_1), b(x_2,p_2)),$$

where a, b are arbitrary functions and the noncommutative product is

$$h\star_C\tilde{h} = (a*_\lambda x_1*_\lambda\tilde{a}, b*_\lambda x_2*_\lambda\tilde{b}).$$

B. The double line

Consider now the analytic space of the double line defined by the equation $x_2^2=0$. Functions of the quantum algebra $\mathcal{N}_l/\mathcal{J}_l$ can be represented as

$$h(x_1,x_2,p_1,p_2) = h_0(x_1,p_1,p_2) + h_1(x_1,p_1,p_2)*_\lambda x_2.$$

The condition for h to be in the normalizer of the left ideal $\mathcal{J}_l=\{f*_\lambda x_2^2; f \in \mathcal{O}_{\Omega^1\mathbb{R}^2}\}$ is

$$0 \bmod \mathcal{J}_l = [x_2^2,h_0] + [x_2^2,h_1]*_\lambda x_2.$$

Leading to the differential equation

$$x_2\frac{\partial h_0}{\partial p_2} + \lambda x_2\frac{\partial^2 h}{\partial p_2^2} + \lambda^2\frac{\partial^3 h}{\partial p_2^3} = 0$$

whose general solution is

$$h(x_1,x_2,p_1,p_2) = a(x_1,p_1) + b(x_1,p_1)p_2 + \left(c(x_1,p_1) + d(x_1,p_1)p_2 - \frac{b(x_1,p_1)}{2\lambda}p_2^2\right)*_\lambda x_2.$$

The product of two of these functions can be represented as a matrix star product denoted as $\star$, in the following way:

$$\phi(h) := \begin{pmatrix} a+2\lambda d & b \\ 2\lambda c & a \end{pmatrix} \equiv \begin{pmatrix} A & B \\ C & D \end{pmatrix}.$$

Then

$$\phi(h)\star\phi(\tilde{h})) = \begin{pmatrix} A & B \\ C & D \end{pmatrix}*_\lambda\begin{pmatrix} \tilde{A} & \tilde{B} \\ \tilde{C} & \tilde{D} \end{pmatrix} = \begin{pmatrix} A*_\lambda\tilde{A} + B*_\lambda\tilde{C} & A*_\lambda\tilde{B} + B*_\lambda\tilde{D} \\ C*_\lambda\tilde{A} + D*_\lambda\tilde{C} & C*_\lambda\tilde{B} + D*_\lambda\tilde{D} \end{pmatrix}$$

is equal to $\phi(h*_\lambda\tilde{h})$.

C. Line with a double point

We shall proceed now with the quantization of the line with a double point defined as the quotient of the quantum algebra of the double line quotient by the ideal generated by $x_1x_2=0$ which has the form

$$\phi(h*_\lambda x_1x_2)=\phi(h)\star\phi(x_1x_2)=\begin{pmatrix}A & B\\ C & D\end{pmatrix}*_\lambda\begin{pmatrix}0 & 0\\ x_1 & 0\end{pmatrix}=\begin{pmatrix}B*_\lambda x_1 & 0\\ D*_\lambda x_1 & 0\end{pmatrix},$$

where B, D are arbitrary functions depending on x_1, p_1. The corresponding normalizer will be the set of solutions of the equation

$$\begin{pmatrix}0 & 0\\ x_1 & 0\end{pmatrix}*_\lambda\begin{pmatrix}a & b\\ c & d\end{pmatrix}=0 \bmod \mathcal{J}_l, \tag{13}$$

where a, b, c, d are a different set of arbitrary functions depending on x_1, p_1. This implies in turn that $b=0$ since the only solutions of the differential equation $x_1b+\lambda\partial_{p_1}b=0$ are not in the space of acceptable formal functions. Then $a(x_1,p_1)$ must be a solution of the equation

$$x_1*_\lambda a=0(\bmod D*_\lambda x_1).$$

Decomposing $a=\Sigma_{i=0}^{\infty}a_i(p_1)*_\lambda x_1^i$ and factoring out we can rewrite this as

$$x_1*_\lambda a_0(p_1)=0(\bmod D*_\lambda x_1).$$

Lemma 3.2:

$$A(x,p)*_\lambda B(p)=\sum_{n=0}^{\infty}(2\lambda)^nA_n(p)B^{(n)}(p)(\bmod D*_\lambda x),$$

where $A(x,p)=\Sigma A_n(p)*_\lambda x^n$ *and* $B^{(n)}$ *is the nth derivative of* B.

Proof:

$$\sum_{i=0}^{\infty}A_i(p)*_\lambda x^{i-1}*_\lambda x*_\lambda B(p)=\sum_{i=0}^{\infty}A_i(p)*_\lambda x^{i-1}*_\lambda 2\lambda B^{(1)}(\bmod D*_\lambda x)=\sum_{i=0}^{\infty}(2\lambda)^iA_i(p)*_\lambda B^{(i)}(p).$$

□

In particular this implies that the second equation means that $a=k$ for some constant. Then the normalizer has the form

$$\begin{pmatrix}k & 0\\ c(x_1,p_1) & d(x_1,p_1)\end{pmatrix}.$$

The last step is to factor out the members of the left ideal from this normalizer. This means to take

$$c(x_1,p_1)\bmod D*_\lambda x_1.$$

The resulting quantum algebra for the line with a double point is the set of matrices of the form

$$\begin{pmatrix}k & 0\\ c(p_1) & d(x_1,p_1)\end{pmatrix}$$

with multiplication law

$$\begin{pmatrix} k & 0 \\ c(p_1) & d(x_1,p_1) \end{pmatrix} \star' \begin{pmatrix} \tilde{k} & 0 \\ \tilde{c}(p_1) & \tilde{d}(x_1,p_1) \end{pmatrix}$$
$$= \begin{pmatrix} k\tilde{k} & 0 \\ \tilde{k}c(p_1) + \sum_{n=0}^{\infty} (2\lambda)^n d_n(p_1)\tilde{c}^{(n)}(p_1) & d(x_1,p_1) *_\lambda \tilde{d}(x_1,p_1) \end{pmatrix},$$

where we have used Lemma 3.2.

D. The doubly fattened circle

Let us consider now the space associated to the ideal generated by $x_1^2+x_2^2$, that we refer to as the "doubly fattened" circle. Although the zero set of this polynomial is just the origin the resulting quantum algebra, as we shall show, is nontrivial. Any function in this quantum algebra can be represented as

$$h(x_1,x_2,p_1,p_2) = h_0(x_1,p_1,p_2) + h_1(x_1,p_1,p_2) *_\lambda x_2.$$

The left ideal is

$$\mathcal{J}_l = \{f *_\lambda (x_1^2 + x_2^2) : f \in \mathcal{O}_{\Omega^1\mathbb{R}^2}[[\lambda]]\}.$$

The condition for a function $h(x_1,x_2,p_1,p_2)$ to be in the normalizer is

$$0 \bmod \mathcal{J}_l = (x_1^2 + x_2^2) *_\lambda h = -\frac{\partial h_1}{\partial p_2} x_1^2 + 2\lambda x_1 \frac{\partial^2 h_1}{\partial p_1 \partial p_2} - \lambda^2 \frac{\partial^3 h_1}{\partial p_1^2 \partial p_2} + \lambda \frac{\partial^2 h_0}{\partial p_2^2} + x_1 \frac{\partial h_0}{\partial p_1} + \left(\frac{\partial h_0}{\partial p_2} + \lambda \frac{\partial^2 h_1}{\partial p_2^2} + x_1 \frac{\partial h_1}{\partial p_1} \right) *_\lambda x_2.$$

Manipulations in the last equation lead to the condition

$$x_1^2(\Delta h_1) - \lambda^2 \frac{\partial^2}{\partial p_2^2}(\Delta h_1) = 0,$$

where $\Delta = \partial_{p_1}^2 + \partial_{p_2}^2$, is the Laplacian operator. Therefore the two-dimensional spherical harmonics give a family of solutions h_1.

E. Conclusion

We have shown a way to define noncommutative associative products to analytic spaces immersed in analytic manifolds. The procedure works for smooth spaces and more remarkably it works for singular spaces. This opens new possibilities in the field of deformation quantization and leaves many open questions. One such question is how the singularity affects the resulting algebra, or more generally how the singularity type affects it. Questions like these can be studied through the introduction of parameters deforming the analytic spaces which will enter the partial differential equations defining the associated algebras. These equations turn out to be complex in most cases. New techniques need to be developed to find the representation of the algebras to make possible the study of such questions.

Another interesting possibility is to develop a comparative study of the different quantization programs. The common goal of all such programs is to give a quantized version of classical physical systems. Naturally for any given classical system there should be a unique physical quantum version, thus one would expect the different approaches to be equivalent in some sense. Having an affirmative answer to this would give a hint of some deep mathematical relations between the different approaches.

Another important line of work is to develop proper physical applications of the program. A rather interesting question to be studied is to find out how the singularity affects the physics of the space.

We expect to elucidate these and other questions in the future.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 45, NUMBER 10 OCTOBER 2004

Classification of extensions of principal bundles and transitive Lie groupoids with prescribed kernel and cokernel

Iakovos Androulidakis[a)]
Departamento di Mathemática, Instituto Superior Técnico, Lisbon 1049-001, Portugal

(Received 1 February 2004; accepted 7 June 2004; published 12 October 2004)

The equivalence of principal bundles with transitive Lie groupoids due to Ehresmann is a well-known result. A remarkable generalization of this equivalence, given by Mackenzie, is the equivalence of principal bundle extensions with those transitive Lie groupoids over the total space of a principal bundle, which also admit an action of the structure group by automorphisms. In this paper the existence of suitably equivariant transition functions is proved for such groupoids, generalizing consequently the classification of principal bundles by means of their transition functions, to extensions of principal bundles by an equivariant form of Čech cohomology. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1786349]

INTRODUCTION

Lie groupoids are categories where every arrow has an inverse, plus a smooth structure. They generalize at the same time the notion of a manifold and a group, and are widely understood to be part of the general context of noncommutative geometry. First, because groupoids are inherently noncommutative objects, to a greater extent than are groups. Second, Lie groupoids provide a modern context for the understanding of the geometry of symplectic and Poisson manifolds, which are equipped with noncommutative structures. Following a result of Mackenzie, it was shown in Ref. 1, that the prequantization problem for a symplectic manifold amounts to the existence of a suitable transitive Lie groupoid. Furthermore, given a Poisson manifold, the existence of a (nontransitive) symplectic groupoid provides a way to quantize it.

A rough and descriptive definition of a Lie groupoid is a pair of manifolds Ω and M such that the elements of Ω are arrows between points of M. The functions $\alpha,\beta:\Omega\to M$ mapping every arrow to its source and target points in M are differentiable. Moreover there is a differentiable way to multiply suitable arrows (such that the source of one is exactly the target of the other), and the inversion of arrows is also differentiable. In this setting, for $x,y\in M$ we denote Ω_x the set of arrows in Ω with source x, Ω^y the arrows with target y and Ω_x^y the arrows with source x and target y. In particular, Ω_x^x is a Lie group called the *orbit* of Ω at x. A Lie groupoid is denoted by $\Omega\rightrightarrows M$.

The simplest example of a Lie groupoid is the product $M\times M\rightrightarrows M$ of a manifold M, with the obvious groupoid structure. This is called the "pair" groupoid. If Ω and Ξ are Lie groupoids over the same base manifold M, then a smooth map $\varphi:\Omega\to\Xi$ is a *morphism* of Lie groupoids if $\alpha\circ\varphi=\alpha$, $\beta\circ\varphi=\beta$ and $\varphi(\eta\cdot\xi)=\varphi(\eta)\cdot\varphi(\xi)$ for any pair of composable arrows in Ω. For example, given any Lie groupoid $\Omega\rightrightarrows M$, the map $(\beta,\alpha):\Omega\to M\times M$ is a morphism of Lie groupoids. This particular morphism is called the *anchor*.

The most well-known classification of Lie groupoids is the one of the transitive case. Transitive Lie groupoids are the ones whose anchor is a surjective submersion, in other words there is an arrow between any two points in M. The choice of a basepoint $x\in M$ for a transitive Lie groupoid $\Omega\rightrightarrows M$ gives rise to the principal bundle $\Omega_x(M,\Omega_x^x,\beta_x)$. The principal bundles arising

a)Electronic mail: iakovos@math.ist.utl.pt

from different choices of elements in M are isomorphic. Given a principal bundle $P(M,G,\pi)$ on the other hand, the associated transitive Lie groupoid is the quotient $(P\times P)/G \rightrightarrows M$. The groupoid structure here is as follows: For an element $\langle u_2,u_1\rangle$, the source is $\pi(u_1)$ and the target $\pi(u_2)$. Suitable arrows $\langle u_2,u_1\rangle$ and $\langle u_2',u_1'\rangle$ such that there exists a $g\in G$ with $u_1=u_2'g$ can be multiplied by

$$\langle u_2,u_1\rangle\langle u_2',u_1'\rangle=\langle u_2,u_1'g\rangle.$$

The inverse of $\langle u_2,u_1\rangle$ is $\langle u_1,u_2\rangle$ and the unit element over an $x\in M$ is $\langle u,u\rangle$ for any $u\in P$ such that $\pi(u)=x$. It is shown in Ref. 8, Vol. II, Sec. I that the two processes are mutually inverse.

So transitive Lie groupoids are classified by the well-known classification of principal bundles by Čech cohomology.

A different classification of the transitive case was given by Mackenzie in Ref. 9. It was shown that if we shift the point of view from the prescription of Ω_x^x (for any given basepoint) to the prescription of the Lie group bundle $I\Omega$ over M, of orbits, then transitive Lie groupoids are classified by Čech cohomology with Abelian coefficients. This classification is always possible to calculate in contrast with the often non-Abelian classification of principal bundles. To achieve this classification, a transitive Lie groupoid is considered as an extension,

$$I\Omega \rightarrowtail \overset{(\beta,\alpha)}{\Omega} \twoheadrightarrow M\times M,$$

of the Lie groupoid $M\times M\rightrightarrows \mathrm{M}$ (with the obvious groupoid structure) by the Lie group bundle $I\Omega$, instead of the principal bundle $\Omega_x(M,\Omega_x^x,\beta_x)$. For example, the groupoid extension associated to a principal bundle $P(M,G)$ is

$$\frac{P\times G}{G} \rightarrowtail \frac{P\times P}{G} \twoheadrightarrow M\times M, \tag{1}$$

where $(P\times G)/G\to M$ is the well-known gauge group bundle of $P(M,G)$ (where the G-action on itself implied is the adjoint). The usual classification of principal bundles by $\check{H}^1(M,G)$ is the answer to the problem "given a Lie group G and a manifold M, classify all principal bundles $P(M,G)$." Mackenzie's results imply that if we shift the problem to "given a Lie group bundle $F\to M$ classify all groupoid extensions of $M\times M$ by this bundle," then we get a classification by Čech cohomology with coefficients in an Abelian group which is always computable, instead of $\check{H}^1(M,G)$.

Another classification appeared recently by Moerdijk. In Ref. 11 regular Lie groupoids are classified, i.e., those whose orbits have a constant dimension. Many Lie groupoids are regular, for example those arising from regular Poisson manifolds; moreover all transitive Lie groupoids are regular. Extensions appear in this classification as well. Namely, it is shown that regular Lie groupoids are extensions of foliation groupoids by bundles of connected Lie groups, and they are classified as such. In the case of transitive Lie groupoids, the results in Ref. 9 are a variation of the results of Moerdijk in Ref. 11.

The main result of the present paper is the classification of extensions of transitive Lie groupoids by bundles of Lie groups. Denote such an extension,

$$F \rightarrowtail \Omega \twoheadrightarrow \Xi, \tag{2}$$

where F is a bundle of Lie groups and Ω,Ξ are Lie groupoids, all of them over the same connected manifold M. Due to the equivalence of transitive Lie groupoids with principal bundles, such extensions are equivalent to extensions of principal bundles,

$$N \rightarrowtail Q(M,H) \twoheadrightarrow P(M,G). \tag{3}$$

Here N is a Lie group and the notation implies the existence of an extension of Lie groups,

$$N \rightarrowtail H \twoheadrightarrow G.$$

On the other hand, an extension of principal bundles (3) gives rise to the extension of transitive Lie groupoids over M,

$$\frac{Q \times N}{H} \rightarrowtail \frac{Q \times Q}{H} \twoheadrightarrow \frac{P \times P}{G}.$$

Here the quotient $(Q \times N)/H \rightarrow M$ is the bundle of Lie groups associated to the principal bundle $Q(M,H)$ through the action of H on N by (the restrictions of) inner automorphisms. It is shown in Ref. 7 that the two processes are mutually inverse.

From this point of view, the importance of such a classification is more than the generalization of the classification of transitive Lie groupoids to extensions. The central problem it deals with is the classification of the covering bundles of a given principal bundle $P(M,G)$ with connected base manifold M. Less abstract uses of such a classification arise from an abundance of paradigms of extensions of principal bundles (see for example Ref. 6).

The classification of extensions (2) is made possible using a result of Mackenzie.[7] It was proved that such extensions are equivalent to a special kind of transitive Lie groupoids, the so-called PBG-groupoids. These are transitive Lie groupoids over the total space of a principal bundle which admit an action of the Lie group of the bundle by Lie groupoid isomorphisms. A description of this equivalence is given in Sec. II of this paper. Roughly speaking, the PBG-groupoid that corresponds to (2) is a Lie groupoid over the principal bundle $P(M,G)$, together with a G-action by (Lie groupoid) automorphisms. Thinking in terms of the extension of principal bundles (3) corresponding to (2), this is a remarkable result; because although the Lie group G does not always act on the kernel N (unless N is Abelian), due to Mackenzie's result there always exists a Lie groupoid which admits an action of G.

Once this result is well understood, the problem shifts to the classification of PBG-groupoids. The classification we give here is similar to the one given for general transitive Lie groupoids. In that case, the equivalence with principal bundles ensures the existence of transition functions for Lie groupoids, which suffice to classify them by the usual Čech cohomology. In the case of PBG-groupoids though, it is necessary to encode the group action as well, and the existence of transition functions which keep track of the action is not established.

In this paper it is shown that there exist transition functions for PBG-groupoids which are equivariant in a certain sense. This is a nonstandard notion of equivariance which we call *isometablicity*. In turn, a nonstandard form of equivariance in Čech cohomology arises. The first isometablic Čech cohomology then classifies PBG-groupoids.

Furthermore, a rather old problem is answered. Lie algebroids are the infinitesimal objects that arise from Lie groupoids, remotely related to them like Lie algebras are related to Lie groups. Mackenzie in Ref. 8 gave a classification of transitive Lie algebroids, but it is not clear how this classification integrates to the groupoid level. A reformulation of the isometablic transition functions is given here, which clearly differentiates to the equivariant analog of the classification given in Ref. 8.

This paper is structured in the following way: Section I is an account of PBG-groupoids and their relation with extensions of Lie groupoids and principal bundles. In Sec. II the relevant connection theory is described, emphasizing on the material that is of use for the scope of this paper. In Sec. III we prove the existence of transition functions which keep track of the group action, and clarify the notion of isometablicity. In Sec. IV we give the classification of PBG-Lie group bundles. A remarkable result yielding from this is that the local G-actions which give rise to the notion of isometablicity are local expressions of the action of G on the Lie group bundle $I\Omega$ of a given PBG-groupoid $\Omega \rightrightarrows P(M,G)$. Section V contains the proof of the fact that isometablic transition functions indeed classify PBG-groupoids. In Sec. VI we provide the reformulation of iosmetablic transition functions to a form that differentiates to the equivariant analog of the classification of Lie algebroids given in Ref. 8. Finally, the formulation of the suitable cohomology groups where the cocycles of isometablic transition functions live is given in Sec. VII.

I. LIE GROUPOID EXTENSIONS AND PBG-GROUPOIDS

In this section we recall in short the material from Ref. 7 on the correspondence of extensions of transitive Lie groupoids to PBG-groupoids.

Definition 1.1: A PBG-groupoid *is a Lie groupoid* $\Omega \rightrightarrows P$ *whose base is the total space of a principal bundle* $P(M,G)$ *together with a right action of* G *on the manifold* Ω *such that for all* $(\xi,\eta)\in\Omega*\Omega$ *and* $g\in G$ *we have*

(i) $\beta(\xi\cdot g)=\beta(\xi)\cdot g$ and $\alpha(\xi\cdot g)=\alpha(\xi)\cdot g$;
(ii) $1_{u\cdot g}=1_u\cdot g$;
(iii) $(\xi\eta)\cdot g=(\xi\cdot g)(\eta\cdot g)$;
(iv) $(\xi\cdot g)^{-1}=\xi^{-1}\cdot g$.

The notation $\Omega*\Omega$ stands for the pairs $(\xi,\eta)\in\Omega\times\Omega$ such that $\alpha(\xi)=\beta(\eta)$. We denote a PBG-groupoid Ω over the principal bundle $P(M,G)$ by $\Omega\rightrightarrows P(M,G)$ and the right-translation in Ω coming from the G-action by $\widetilde{R}_g$ for any $g\in G$. The right-translation in P will be denoted by R_g. The previous definition implies that $\widetilde{R}_g$ is an automorphism of the Lie groupoid Ω over the diffeomorphism R_g for all $g\in G$. A morphism φ of Lie groupoids between two PBG-groupoids Ω and Ω' over the same principal bundle is called a morphism of PBG-groupoids if it preserves the group actions, namely if $\varphi\circ\widetilde{R}_g=\widetilde{R}'_g\circ\varphi$ for all $g\in G$. In the same fashion, a PBG-Lie group bundle (PBG-LGB) is a Lie group bundle F over the total space P of a principal bundle $P(M,G)$ such that the group G acts on F by Lie group bundle automorphisms. We denote a PBG-LGB by $F\to P(M,G)$. It is easy to see that the gauge Lie group bundle $I\Omega\to P$ associated with a PBG-groupoid $\Omega\rightrightarrows P(M,G)$ is a PBG-LGB.

Numerous examples of transitive PBG-groupoids and their corresponding extensions can be found in Ref. 6. In Ref. 2 nontransitive examples are given as well. Transitive PBG-groupoids are the concern of this paper, due to their equivalence with extensions of transitive Lie groupoids (or, equivalently, extensions of principal bundles[7]). Let us give an outline of this equivalence.

Given an extension of Lie groupoids (2), the choice of a basepoint gives rise to its corresponding principal bundle extension (3) as was discussed in the Introduction. With the notation of (3), the Lie group N acts on the manifold Q by the restriction of the H-action on Q to the embedding of N in H. It is immediate that $Q(P,N,\pi)$ is a principal bundle. Here the projection $\pi:Q\twoheadrightarrow P$ is the surjective submersion given with the extension (3). In Ref. 7 this was called the *transverse bundle*.

Denote Ω the (transitive) Lie groupoid $(Q\times Q)/N\rightrightarrows P$ associated to the transverse bundle, and define a right action of the Lie group G on Ω by

$$\langle q_2,q_1\rangle g=\langle q_2h,q_1h\rangle,$$

where $h\in H$ is any element which projects to g. It is trivial to see that this action is well defined and makes Ω a transitive PBG-groupoid over the principal bundle $P(M,G)$.

It is shown in Ref. 7, Sec. 1.3 that the Lie group bundle $I\Omega\to P$ of the orbits of Ω is isomorphic to the pullback bundle $\pi*((Q\times N)/H)$. Therefore the PBG-groupoid $\Omega\rightrightarrows P(M,G)$ can be presented canonically in the following form:

$$\pi*\left(\frac{Q\times N}{H}\right)\rightarrowtail\Omega\twoheadrightarrow P\times P.$$

Here the injection is

$$(p,\langle q,n\rangle)\mapsto\langle qnh^{-1},qh^{-1}\rangle,$$

where the element $h\in H$ is chosen so that $\pi(q)=p\pi(h)$. Moreover, it is shown in Ref. 7, Sec. 1.6, that $I\Omega$ is a PBG-Lie group bundle over $P(M,G)$, the action of G defined as

$$(p,\langle q,n\rangle)_g = (pg,\langle q,n\rangle).$$

Conversely, consider given a transitive PBG-groupoid $\Upsilon \rightrightarrows P(M,G)$. It follows easily from (i) of Definition 1.1 that the action of G is free. In Ref. 7, Sec. 2.2 it is shown that the criterion of Godement (see Ref. 4, Sec. 16.10.3) applies, therefore the quotient manifold Υ/G exists and the projection $\sharp:\Upsilon\to\Upsilon/G$ is a surjective submersion.

This manifold has a natural Lie groupoid structure with base M defined as follows: Since the source and target projections of Υ are G-equivariant, they induce maps $\alpha',\beta':\Upsilon/G\to M$, which are surjective submersions because the projection $\sharp$, the projection of the principal bundle $P(M,G)$, as well as the source and target maps of Υ are submersions as well. Take $u_1,u_2\in\Upsilon$ such that $\alpha'(\langle u_1\rangle)=\beta'(\langle u_2\rangle)$. Then there exists $g\in G$ such that $\alpha(u_1)=\beta(u_2)g$, so it is meaningful to define

$$\langle u_1\rangle\langle u_2\rangle = \langle u_1u_2g\rangle.$$

Finally, the map $(\beta,\alpha):\Upsilon\to P\times P$ is equivariant, so it induces a smooth submersion $\pi:\Upsilon/G \to (P\times P)/G$. It is clear that this is a groupoid morphism over M, and its kernel is $I\Upsilon/G$. Therefore

$$\frac{I\Upsilon}{G} \rightarrowtail \frac{\Upsilon}{G} \overset{\pi}{\twoheadrightarrow} \frac{P\times P}{G}$$

is an extension of Lie groupoids over M. Finally, it is easy to see that the two processes are mutually inverse. In Ref. 7 the following theorem is proven.

Theorem 1.2: *The category of transitive Lie groupoid extensions is equivalent to the category of transitive PBG-groupoids.*

II. CONNECTIONS OF PBG-GROUPOIDS

An alternative formulation of the connection theory of principal bundles is by using the Atiyah sequence. Given a principal bundle $P(M,G,p)$, it follows from the fact that the bundle projection p is G-invariant, that the vector bundle morphism $Tp:TP\to TM$ quotients to a map $p*:TP/G \to TM$ which, like Tp, is a fiberwise surjective vector bundle morphism, therefore a surjective submersion. The kernel of this map is of course T^pP/G, where T^pP is the vertical subbundle of TP, i.e., the kernel of Tp. Now the map $j:(P\times\mathfrak{g})/G\to T^pP/G$, induced by

$$P\times\mathfrak{g}\to TP,(u,X)\mapsto T_1(m_u)(X)$$

(where $m_u:G\to P$ is $g\mapsto ug$), is a vector bundle isomorphism (see Ref. 8, Appendix A, Sec. 3.2). Note that the G-action on $\mathfrak{g}$ implied here is the adjoint. Therefore the principal bundle $P(M,G,p)$ gives rise to the extension of vector bundles,

$$\frac{P\times\mathfrak{g}}{G} \overset{j}{\rightarrowtail} \frac{TP}{G} \overset{p^*}{\twoheadrightarrow} TM, \tag{4}$$

which is known as the *Atiyah sequence*.

The properties of a connection 1-form $\tilde{\gamma}:TP\to M\times\mathfrak{g}$ allow it to quotient to a left-splitting $\overline{\gamma}:TP/G\to(P\times\mathfrak{g})/G$ of (4). In turn, the rule

$$j\circ\overline{\gamma}+\gamma\circ p^* = 0$$

corresponds $\overline{\gamma}$ to a right-splitting $\gamma:TM\to TP/G$ of (4). This way the connection forms of a principal bundle correspond to the right-splittings of its Atiyah sequence. Respectfully, the curvature of the connection 1-form $\tilde{\gamma}$ corresponds to the 2-form $R_\gamma:TM\times TM\to(P\times\mathfrak{g})/G$ defined by $C_\gamma(X,Y)=\gamma[X,Y]-[\gamma(X),\gamma(Y)]$.

The module of sections of the vector bundle $TP/G \to M$ can be identified with the G-invariant vector fields of P (see Ref. 8, Appendix A), thus inheriting a Lie bracket which, together with p^*, satisfy the properties of the following definition.

Definition 2.1: A Lie algebroid *is a vector bundle A on base M together with a vector bundle map $\sharp: A \to TM$, called the* anchor *of A, and a bracket $[,]: \Gamma A \times \Gamma A \to \Gamma A$ which is $\mathbb{R}$-bilinear, alternating, satisfies the Jacobi identity, and is such that we have the following:*

(i) $\sharp([X,Y]) = [\sharp X, \sharp Y]$;
(ii) $[X, fY] = f[X,Y] + (\sharp X)(f)Y$;

for all $X, Y \in \Gamma A$ and $f \in C^\infty(M)$.

Basic material on Lie algebroids can be found in Refs. 8 and 5. The notion of a Lie algebroid generalizes that of the tangent bundle TM of a given manifold M, which can be thought of as a Lie algebroid with the well-known Lie bracket of vector fields and the identity as the anchor map. Moreover, any bundle of Lie algebras is a Lie algebroid with zero as the anchor map.

If A and A' are Lie algebroids over the same base M, then a morphism of Lie algebroids $\varphi: A \to A'$ over M is a vector bundle morphism such that $\sharp' \circ \varphi = \sharp$ and $\varphi([X,Y]) = [\varphi(X), \varphi(Y)]$ for $X, Y \in \Gamma A$. A Lie algebroid is called *transitive* if its anchor map is a surjective submersion. In this case the kernel of the anchor map is a bundle of Lie algebras, called the *adjoint bundle*, and the Lie algebroid can be presented as an extension of vector bundles,

$$L \rightarrowtail A \overset{\sharp}{\twoheadrightarrow} TM, \tag{5}$$

where the injection of L into A and the anchor map are morphisms of Lie algebroids.

Definition 2.2: Let A, A' be Lie algebroids over the manifold M and $L \to M$. An extension of vector bundles,

$$K \rightarrowtail A \twoheadrightarrow A',$$

is called an extension of Lie algebroids *if the injection and surjection maps are morphisms of Lie algebroids*.

Extensions such as (5) are the simplest form of Lie algebroid extensions, in fact, they are just an alternative way to present a transitive Lie algebroid A over a manifold M. In this setting, the connection theory of principal bundles gives rise to the following notions.

Definition 2.3: Let $L \rightarrowtail A \overset{\sharp}{\twoheadrightarrow} TM$ be a transitive Lie algebroid.

(i) *A connection of A is a vector bundle morphism $\gamma: TM \to A$ such that $\sharp \circ \gamma = 0$.*
(ii) *The* curvature *of a connection γ is the 2-form $C_\gamma: TM \times TM \to L$ defined by*

$$C_\gamma(X,Y) = \gamma[X,Y] - [\gamma(X), \gamma(Y)],$$

for all $X, Y \in \Gamma A$.

A connection γ is called flat *if $C_\gamma = 0$.*

Note that a flat connection is evidently a morphism of Lie algebroids $\gamma: TM \to A$.

All Lie groupoids differentiate to Lie algebroids. A full account of this process can be found in Ref. 8, Vol. III, Sec. 3. The reader can get a rough idea by comparing the extension (1) to the Atiyah sequence (4). Lie III does not apply for groupoids and algebroids though. The integrability of Lie algebroids has a cohomological obstruction in the transitive case, which was given by Mackenzie in Ref. 8, Vol. V. In the nontransitive case, integrability of Lie algebroids is a problem of different order which was tackled by Crainic and Fernandes in Ref. 3. In general, a Lie algebroid that integrates to a Lie groupoid $\Xi \rightrightarrows M$ is denoted by $A\Xi$. Note that the tangent bundle TM of a manifold M integrates to the "pair" groupoid $M \times M \rightrightarrows M$.

Analogously with the reformulation of principal bundle connections as right-splittings of the Atiyah sequence, it is legitimate to regard the *connections* of a transitive Lie groupoid $\Xi \rightrightarrows M$ as

the connections of the Lie algebroid $A\Xi$ it differentiates to, and the same is valid for the curvature 2-forms. This terminology will be used in the remainder of this paper.

Once again though, the concern of this paper is extensions of transitive Lie groupoids, so let us make a fresh start by giving the notion of a PBG-algebroid.

Definition 2.4: A PBG-algebroid *over the principal bundle $P(M,G)$ is a Lie algebroid A over P together with a right action of G on A denoted by $(X,g)\mapsto \hat{R}_g(X)$ for all $X\in A, g\in G$ such that each $\hat{R}_g: A\to A$ is a Lie algebroid automorphism over the right translation R_g in P.*

We denote a PBG-algebroid A over $P(M,G)$ by $A\Rightarrow P(M,G)$. The G-action on A induces an action of G on the module ΓA of sections of the vector bundle $A\to M$, namely

$$X\cdot g=\hat{R}_g\circ X\circ R_{g^{-1}}.$$

The right-translation with respect to this action is denoted by $\hat{R}^{\Gamma}_g:\Gamma A\to\Gamma A$ for all $g\in G$. With this notation Definition 2.4 implies that

$$\hat{R}^{\Gamma}_g([X,Y])=[\hat{R}^{\Gamma}_g(X),\hat{R}^{\Gamma}_g(Y)].$$

Given a *transitive* PBG-algebroid $A\Rightarrow P(M,G,p)$, its adjoint bundle $L\to P$ inherits a G-action by automorphisms, thus making

$$L\rightarrowtail A\overset{\sharp}{\twoheadrightarrow} TP$$

an extension of PBG-algebroids. That is to say it is an extension of Lie algebroids such that the injection and surjection maps are moreover equivariant. It is shown in Ref. 2, Sec. 3.4 that the Godement criterion applies, so the quotient manifold A/G exists. Therefore the previous extension quotients to a vector bundle extension,

$$\frac{L}{G}\rightarrowtail\frac{A}{G}\overset{\sharp^{/G}}{\twoheadrightarrow}\frac{TP}{G},\tag{6}$$

of the (integrable) Lie algebroid TP/G by the quotient Lie algebra bundle L/G. Observe that since the quotient manifold A/G exists, the vector bundle structure of A quotients to $A/G\to M$. Moreover, the natural projection $\natural^A:A\to A/G$ is a pullback over $p:P\to M$.

The vector bundle A/G has the following Lie algebroid structure: The anchor is the composition of vector bundle morphisms $p_*\circ\sharp^{/G}$. Moreover, the sections of A/G are isomorphic to the G-invariant sections of A, therefore $\Gamma(A/G)$ inherits the Lie bracket from $\Gamma^G A$. The verification that this bracket together with the anchor map $p_*\circ\sharp^G$ satisfy the properties of a Lie algebroid can be found in Ref. 7, Sec. 3.2. It is immediate that A/G is transitive. A more elaborate presentation of the extension 6 is given in Fig. 1, which helps to keep track of all the structures related to the Lie algebroid extension. Note that the adjoint bundle K of A/G is an extension of $(P\times g)/G$ by L/G. This diagram makes it clear that the cokernel of the extension (6) is in fact the Atiyah sequence of the bundle $P(M,G,p)$.

On the other hand, pulling back (6) by the map $Tp:TP\to TM$ we recover the given PBG-algebroid (see Ref. 7, Sec. 4). This consists of the proof of the following theorem.

Theorem 2.5: *The category of transitive PBG-algebroids over a manifold M is equivalent to the category of Lie algebroid extensions,*

$$K\rightarrowtail A\twoheadrightarrow A\Xi,\tag{7}$$

of an integrable transitive Lie algebroid by a Lie algebra bundle (over M).

Now extensions of Lie groupoids differentiate to extensions (7). The connection theory of Lie groupoid extensions (2) is encoded by the right-splittings of extensions (7). These in turn correspond to the following notion of connection for the equivalent PBG-algebroid (see Refs. 6 and 7).

Definition 2.6: Let $A\Rightarrow P(M,G,p)$ be a transitive PBG-algebroid. A connection $\gamma:TP\to A$ is

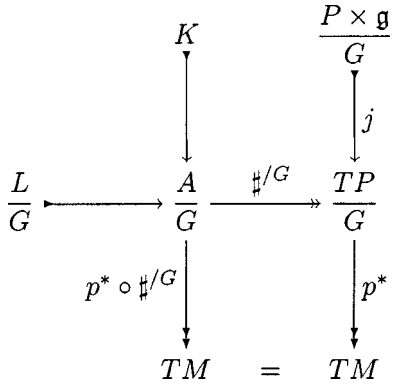

FIG. 1. The extension of Lie algebroids induced by a PBG-algebroid.

called isometablic, *if it satisfies*

$$\gamma \circ TR_g = \hat{R}_g \circ \gamma. \tag{8}$$

An account of isometablic connections and their holonomy is given in Ref. 2, however in this paper we are interested in a different problem. The groupoid extensions that we intend to classify have a prescribed kernel and cokernel. In other words, *given* a transitive Lie groupoid $\Xi \rightrightarrows M$ and a Lie algebra bundle $F \to M$, we classify all transitive Lie groupoids $\Phi \to M$ which fit into a Lie groupoid extension,

$$F \rightarrowtail \Phi \twoheadrightarrow \Xi.$$

In this sense, we are interested in the connections of Φ rather than the splittings of the extension of the Lie algebroid extension $AF \rightarrowtail A\Phi \twoheadrightarrow A\Xi$. The following theorem clarifies exactly what these connections correspond to in the relevant PBG-algebroid.

Theorem 2.7: *Suppose we are given a transitive PBG-algebroid* $A \Rightarrow P(M,G,p)$ *and consider its corresponding extension of Lie algebroids (6) over* M. *The connections of the (transitive) Lie algebroid* $A/G \to M$ *are equivalent to the isometablic connections of* A *which vanish on the kernel* T^pP *of* $Tp: TP \to TM$.

Proof: Consider an isometablic connection $\gamma: TP \to A$ such that $\gamma(X) = 0$ if $X \in T^pP$. This quotients to a splitting $\gamma^{/G}: TP/G \to A/G$. Given a connection $\delta: TM \to TP/G$ of the principal bundle $P(M,G)$, define

$$\widetilde{\gamma} = \gamma^{/G} \circ \delta: TM \to \frac{A}{G}.$$

The assumption that γ vanishes on the kernel of Tp makes the definition of $\tilde{\gamma}$ independent from the choice of δ. It follows immediately from the assumption that δ is a connection of $P(M,G)$ and $\gamma^{/G}$ is a splitting of (6) that this is a connection of the Lie algebroid A/G.

Conversely, given a connection $\theta: TM \to A/G$ of the Lie algebroid A/G, compose it with the anchor map $p^*: TP/G \twoheadrightarrow TM$ of the Atiyah sequence corresponding to the bundle $P(M,G,p)$ [see (4)] to the vector bundle morphism,

$$\overline{\theta} = \theta \circ p^*: \frac{TP}{G} \to \frac{A}{G}.$$

Denote $\natural: TP \to TP/G$ and $\natural^A: A \to A/G$ the natural projections. Since $\natural^A$ is a pullback over $p: P \to M$, there is a unique vector bundle morphism $\gamma: TP \to A$ such that

$$\natural^A \circ \gamma = \overline{\theta} \circ \natural .$$

Due to the G-invariance of $\natural$ and $\natural^A$ the morphism of vector bundles $\hat{R}_{g^{-1}} \circ \gamma \circ TR_g$ also satisfies the previous equation for every $g \in G$; therefore it follows from the uniqueness argument that γ is isometablic. It is an immediate consequence of the previous equation that γ vanishes at T^pP.

To see that it is indeed a connection of A, let us recall the fact that θ is a connection of A/G. This gives $p^* \circ \sharp^{/G} \circ \theta = \mathrm{id}_{TM}$. Now $\sharp^{/G} = \natural \circ \sharp$ and by definition we have $p^* \circ \natural = Tp$, therefore $Tp \circ \sharp \circ \theta = \mathrm{id}_{TM}$. Now take an element $X \in TP$. Then $Tp(X) \in TM$, and it follows from this equation that there exists an element $g \in G$ such that

$$(\sharp \circ \theta)(Tp(X)) = X \cdot g.$$

Multiplying this by g^{-1} and using the G-invariance of Tp we get

$$\sharp \circ (\theta \circ Tp) = \mathrm{id}_{TP}.$$

Finally, from the properties of the pullback, it follows immediately that γ is the map $(\pi, \overline{\theta} \circ \natural)$, where $\pi : TP \to P$ is the natural projection of the tangent bundle. It is straightforward to check that this reformulates to $(\pi, \theta \circ Tp)$, and this proves that γ is a connection. ■

Definition 2.8: The isometablic connections of a PBG-algebroid $A \Rightarrow P(M,G,p)$ which vanish at the kernel T^pP of p^* are called basic connections.

It is therefore necessary to focus on basic connections of PBG-groupoids for the purpose of this paper. The following result follows from Proof 2.7.

Corollary 2.9: Let $A \Rightarrow P(M,G)$ be a transitive PBG-algebroid. A flat connection of the Lie algebroid $A/G \to M$ gives rise to a unique flat basic connection of A.

Note that the Proof 2.7 does not give force to the converse of this result. That is because the connection of A/G corresponding to a given flat basic connection of A arises by composition with an arbitrary connection of TP/G, which is not necessarily a flat one, unless the bundle $P(M,G)$ is flat.

III. TRANSITION FUNCTIONS FOR TRANSITIVE PBG-GROUPOIDS

This section is concerned with the study of those transition functions of transitive PBG-groupoids which encode the group action.

Let us start with a principal bundle $P(M,G)$ and a simple open cover $\mathcal{U} = \{U_i\}_{i \in I}$ of M. This is an open cover such that each U_i is contractible, and the intersection of two as well as three open sets is also contractible. Then a cover $\mathcal{P} = \{P_i\}_{i \in I}$ of P by principal bundle charts such that $P_i \cong U_i \times G$ exists.

Consider now a PBG-groupoid $\Omega \rightrightarrows P(M,G)$ over this bundle and its corresponding Lie algebroid $A\Omega \Rightarrow P(M,G)$ with adjoint bundle $L\Omega$. The extension of Lie algebroids corresponding to that is

$$\frac{L\Omega}{G} \rightarrowtail \frac{A\Omega}{G} \twoheadrightarrow \frac{TP}{G}.$$

It follows from Ref. 8, Vol. IV, Sec. 4 that the Lie algebroid $A\Omega/G$ (over M) has local flat connections $\tilde{\theta}_i^* : TU_i \to (A\Omega/G)_{U_i}$. Due to 2.9 these give rise to flat *basic* connections $\theta_i^* : TP_i \to A\Omega_{P_i}$.

Since the connections $\tilde{\theta}_i^*$ are flat, they can be regarded as morphisms of Lie algebroids. Now consider the following theorem from Ref. 10.

Theorem 3.1: *Let Ω, Ξ be Lie groupoids over the same manifold M and $\mu : A\Omega \to A\Xi$ a Lie algebroid morphism. If Ω is α-simply connected, then there exists a unique morphism of Lie groupoids $\varphi : \Omega \to \Xi$ which differentiates to μ,* i.e., *$\varphi^* = \mu$.*

With the assumption that every U_i is contractible, and by force of the previous result, it follows that the $\tilde{\theta}_i^*$'s integrate uniquely to morphisms of Lie groupoids $\tilde{\theta}_i : U_i \times U_i \to \Omega_{U_i}^{U_i}/G$. It was

shown in Proof 2.7 that the basic flat connections θ_i^* corresponding to the $\widetilde{\theta}_i^*$'s are in essence the maps $\widetilde{\theta}_i^* \circ T_p$, therefore they also integrate uniquely to morphisms of Lie groupoids,

$$\theta_i : P_i \times P_i \to \Omega_{P_i}^{P_i}.$$

Proposition 3.2: The θ_i's are morphisms of PBG-groupoids.

Proof: It suffices to prove the equivariance of the θ_i's. For every $g \in G$, the map θ_i^g: $P_i \times P_i \to \Omega_{P_i}^{P_i}$ defined by

$$\theta_i^g(u,v) = \theta_i(ug, vg)g^{-1}$$

is clearly a morphism of Lie groupoids and it differentiates to θ_i^*. It therefore follows from the uniqueness of θ_i that $\theta_i^g = \theta_i$ for all $g \in G$; consequently θ_i is equivariant. ■

For every $i \in I$ choose an element $u_i \in P_i$ and define $\overline{\sigma_i}$: $P_i \to \Omega_{P_i}$ by $\overline{\sigma_i}(u) = \theta_i(u, u_i)$. We call these maps *schisms*. Note that $\overline{\sigma_i}(u_i) = 1_{u_i}$. The following proposition clarifies the behavior of the schisms with respect to the G-action. We call this notion of equivariance *isometablicity* because it follows directly from the isometablicity property of the local flat connections of the PBG-groupoid we discussed above.

Proposition 3.3: The schisms $\overline{\sigma_i}$ are isometablic *in the sense that*

$$\overline{\sigma_i}(ug) = (\overline{\sigma_i}(u)g) \cdot \overline{\sigma_i}(u_i g),$$

for all $u \in P_i$ and $g \in G$.

Proof: From the definition of the $\overline{\sigma_i}$'s and the equivariance of the morphisms θ_i we get $(\overline{\sigma_i}(u)g) \cdot \overline{\sigma_i}(u_i g) = (\theta_i(u, u_i)g) \cdot \theta_i(u_i g, u_i) = \theta_i(ug, u_i g) \cdot \theta_i(u_i g, u_i) = \theta_i(ug, u_i) = \overline{\sigma_i}(ug)$. ■

For every choice of a $u_i \in P_i$, consider the Lie group $H_i = \Omega_{u_i}^{u_i}$. In order to refer to a unique Lie group independent to the index $i \in I$, we need to fix a $u_0 \in P$ and define $H = \Omega_{u_0}^{u_0}$. Then, for every $i \in I$ choose a $\xi_i \in \Omega_{u_0}^{u_i}$ and consider the maps τ_i: $H_i \to H$ defined by $\tau_i(\eta) = \xi^{-1} \cdot \eta \cdot \xi$. These are isomorphisms of Lie groups. Now define σ_i: $P_i \to \Omega_{u_0}$ by

$$\sigma = \overline{\sigma_i} \cdot \xi_i.$$

These are sections of the Lie groupoid Ω. Note that $\sigma_i(u_i) = \xi_i$. The isometablicity of these sections is described in the following proposition:

Proposition 3.4: The sections σ_i are isometablic *in the sense that*

$$\sigma_i(ug) = [\sigma_i(u)g] \cdot (\xi_i^{-1} g) \cdot \sigma_i(u_i g),$$

for all $i \in I$, $u \in P_i$ and $g \in G$.

The proof is a straightforward calculation.

Now we look at the isometablicity of the transition functions. We denote $\{\overline{s_{ij}} : P_{ij} \to \Omega_{u_j}^{u_i}\}_{i,j \in I}$ the transition functions of the schisms $\{\overline{\sigma_i}\}_{i \in I}$ and $\{s_{ij} : P_{ij} \to \Omega_{u_0}^{u_0}\}_{i,j \in I}$ the transition functions of the sections $\{\sigma_i\}_{i \in I}$. The following proposition is an immediate consequence of the isometablicity of the schisms and the sections.

Proposition 3.5: For every $i, j \in I$ such that $P_{ij} \neq \emptyset$, $u \in P_{ij}$ and $g \in G$ we have the following.

(i) $\overline{s_{ij}}(ug) = \overline{\sigma_i}(u_i g)^{-1} \cdot (\overline{s_{ij}}(u)g) \cdot \overline{\sigma_j}(u_j g)$.
(ii) $s_{ij}(ug) = \sigma_i(u_i g)^{-1} \cdot (\xi_i g) \cdot (s_{ij}(u)g) \cdot (\xi_j g)^{-1} \cdot \sigma_j(u_j g)$.

This gives rise to the following formulation of G-actions:

Definition 3.6: Denote $\Omega_{u_i}^{u_i} = H_i$ and $\Omega_{u_0}^{u_0} = H$. The following formulas:

(i) $\overline{\rho_{ij}} : G \times H_i \to H_i$, $\overline{\rho_{ij}}(g^{-1})(h_i) = \overline{\sigma_i}(u_i g)^{-1} \cdot (h_i g) \cdot \overline{\sigma_j}(u_j g)$, *and*
(ii) $\rho_{ij} : G \times H \to H$, $\rho_{ij}(g^{-1})(h) = \sigma_i(u_i g)^{-1} \cdot (\xi_i g) \cdot (hg) \cdot (\xi_j g)^{-1} \cdot \sigma_j(u_j g)$, *define families of G-actions on H_i and H, respectively.*

With this notation, it is legitimate to reformulate the isometablicity equations of 3.5 to

$$\overline{s_{ij}}(ug) = \overline{\rho_{ij}}(g^{-1})(\overline{s_{ij}}(u))$$

and

$$s_{ij}(ug) = \rho_{ij}(g^{-1})(s_{ij}(u)).$$

Let us now examine the properties of the G-actions $\overline{\rho_{ij}}$ and ρ_{ij}. The proof of the following proposition is, again, straightforward.

Proposition 3.7: Let $\Omega \rightrightarrows P(M,G)$ be a PBG-groupoid. Then the families of G-actions $\{\overline{\rho_{ij}}\}_{i,j\in I}$ and $\{\rho_{ij}\}_{i,j\in I}$ satisfy the following identities:

$$\rho_{ij}(g^{-1})(h_1h_2) = \rho_{ik}(g^{-1})(h_1)\rho_{kj}(g^{-1})(h_2), \tag{9}$$

for all $i,j,k \in I$ such that $P_{ijk} \neq \emptyset$ and $h_1, h_2 \in H$:

$$\begin{aligned}\rho_{ij}(g^{-1})(h) &= \rho_{ii}(g^{-1})(h) \cdot \sigma_i(u_ig)^{-1} \cdot (\xi_ig) \cdot (\xi_jg)^{-1} \cdot \sigma_j(u_jg) \\ &= \sigma_i(u_ig)^{-1} \cdot (\xi_ig) \cdot (\xi_jg)^{-1} \cdot \sigma_j(u_jg) \cdot \rho_{jj}(g^{-1})(h),\end{aligned} \tag{10}$$

$$\tau_i(\overline{\rho_{ii}}(g^{-1})(h_i)) = \rho_{ii}(g^{-1})(\tau_i(h_i)), \tag{11}$$

for all $h_i \in H_i$.

Due to (10), it is possible to say that the family of actions $\{\rho_{ij}\}_{i,j\in I}$ is fully determined by the subset of those actions with $i=j$. Now (11) shows that for all $i \in I$ the isomorphism $\tau_i: H_i \to H$ maps every G-action $\overline{\rho_{ii}}$ on H_i exactly to the G-action ρ_{ii} on H.

Last, notice that (9) is a nonstandard property. From this it follows immediately that $\rho_{ii}(g^{-1})(e_H) = e_H$ for all $i \in I$. These two properties almost make the ρ_{ij}'s representations in a certain sense. We single out (9) by giving the following definition.

Definition 3.8: Let G and H be Lie groups. If a family $\{\rho_{ij}\}_{i,j\in I}$ of G-actions on H satisfy

$$\rho_{ij}(g^{-1})(h_1h_2) = \rho_{ik}(g^{-1})(h_1)\rho_{kj}(g^{-1})(h_2),$$

for all $g \in G$, $h_1, h_2 \in H$ and $i,j,k \in I$, then G is said to be acting on H by cocycle morphisms.

A. Equivalence of transition functions

So far we have demonstrated that PBG-groupoids have sections which are suitably equivariant. These sections arise naturally from the local flat basic connections that exist on the algebroid level. But what happens if we start with a different family of local flat basic connections?

Let us start with two families $\{\theta_i^*\}_{i\in I}$ and $\{\theta'^*_i\}_{i\in I}$ of flat basic connections over the same cover $\mathcal{P} = \{P_i\}_{i\in I}$ of P by principal bundle charts. Then there exist maps $\ell_i^*: TP_i \to P_i \times \mathfrak{h}_i$ such that

$$\theta'^*_i = \theta_i^* + \ell_i^*,$$

for every $i \in I$. Here $\mathfrak{g}_i$ denotes the Lie algebra of the Lie group H_i. Therefore every ℓ_i^* must also be isometablic, that is to say

$$\ell_i^*(Xg) = \ell_i^*(X)g,$$

for all $X \in TP_i$ and $g \in G$. Moreover, the ℓ_i^*'s integrate to PBG-groupoid morphisms $\ell_i: P_i \times P_i \to H_i$ such that $\theta'_i = \theta_i \cdot \ell_i$. As far as the isometablicity of the ℓ_i's is concerned, it follows that

$$\ell_i(ug, vg) = \overline{\rho_{ii}}(g^{-1})(\ell_i(u,v)). \tag{12}$$

Now define $\overline{r_i}: P_i \to H_i$ by

$$\overline{r_i}(u) = \ell_i(u, u_i),$$

and $r_i : P_i \to H$ by $r_i = \tau_i \circ \overline{r_i}$. That is to say,

$$r_i(u) = \xi_i^{-1} \cdot \overline{r_i}(u) \cdot \xi_i,$$

for all $u \in P_i$. We call the $\overline{r_i}$'s and the r_i's *conjugation* maps. The proof of the following proposition is a simple calculation.

Proposition 3.9: The schisms, sections and the respective transition data induced by $\{\theta_i^*\}_{i\in I}$ *and* $\{\theta'^*_i\}_{i\in I}$ *are related by the following:*

(i) $\overline{\sigma'}_i = \overline{\sigma_i} \cdot \overline{r_i}$,
(ii) $\overline{s'}_{ij} = \overline{r_i}^{-1} \cdot \overline{s_{ij}} \cdot \overline{r_j}$,
(iii) $\sigma'_i = \sigma_i \cdot r_i$,
(iv) $s'_{ij} = r_i^{-1} \cdot s_{ij} \cdot r_j$.

Corollary 3.10: The families of G-actions $\rho = \{\rho_{ij}\}_{i,j\in I}$ *and* $\rho' = \{\rho'_{ij}\}_{i,j\in I}$ *arising from the connections* θ_i^* *and* $\theta_i'^*$*, respectively, are related by*

$$\rho'_{ij}(g^{-1})(h) = r_i(u_i g)^{-1} \cdot \rho_{ij}(g^{-1})(h) \cdot r_j(u_j g),$$

for all $h \in H$ *and* $g \in G$.

Now let us examine the isometablicity of the conjugation maps.

Proposition 3.11: The conjugation maps satisfy the following:

(i) $\overline{r_i}(ug) = \overline{\rho_{ii}}(g^{-1})\big(\overline{r_i}(u)\big) \cdot \overline{r_i}(u_i g)$,
(ii) $r_i(ug) = \rho_{ii}(g^{-1})\big(r_i(u)\big) \cdot r_i(u_i g)$,

for all $u \in P_i$ *and* $g \in G$.

Proof: Note that (ii) follows by applying the isomorphisms τ_i to (i) and taking into account (11). For (i) we have

$$\overline{r_i}(ug) = \ell_i(ug, u_i) = \ell_i(ug, u_i g) \cdot \ell(u_i g, u_i).$$

Because of (12) the last part of the above equation becomes $\overline{\rho_{ii}}(g^{-1})\big(\ell(u, u_i)\big) \cdot \ell(u_i g, u_i)$, and the result follows. ■

IV. THE CLASSIFICATION OF PBG-LIE GROUP BUNDLES

Consider the adjoint bundle $I\Omega \to P(M, G)$ associated with a given PBG-groupoid $\Omega \rightrightarrows P(M, G)$. This section is concerned with the isometablic transition data that classifies this bundle. Apart from this classification, another result given here is that the G-actions ρ_{ij} given in the previous section are local expressions of the action of G on the Lie group bundle $I\Omega$.

Proposition 4.1: Let $\{U_i\}_{i\in I}$ *be a simple open cover of* M *and* $P_i \cong U_i \times G$ *charts of the principal bundle* $P(M, G)$*. The maps* $\psi_i : P_i \times H \to I\Omega_{P_i}$ *defined by*

$$\psi_i(u, h) = \sigma_i(u) \cdot h \cdot \sigma_i(u)^{-1}$$

are local charts for the Lie group bundle $I\Omega$*. They are isometablic in the sense that*

$$\psi_i\big(ug, \rho_{ii}(g^{-1})(h)\big) = \psi_i(u, h) \cdot g.$$

Proof: The fact that ψ_i is a bijection and $\psi_{i,u} : H \to \Omega_u^u$ is a morphism of Lie groups for all $u \in P_i$ are simple calculations. For the isometablicity we have

$$\begin{aligned}\psi_i\big(ug, \rho_{ii}(g^{-1})(h)\big) &= \sigma_i(ug) \cdot \rho_{ii}(g^{-1})(h) \cdot \sigma_i(ug)^{-1} \\ &= \big(\sigma_i(u)g\big) \cdot (\xi_i^{-1} g) \cdot \sigma_i(u_i g) \cdot \sigma_i(u_i g)^{-1} \cdot (\xi_i g) \cdot (hg) \cdot (\xi_i^{-1} g) \\ &\quad \cdot \sigma_i(u_i g) \cdot \sigma_i(u_i g)^{-1} \cdot (\xi_i g) \cdot \big(\sigma_i(u)^{-1} g\big)\end{aligned}$$

$$= (\sigma_i(u)g) \cdot (\xi_i g) \cdot (\sigma_i(u)^{-1}g) = \psi_i(u,g) \cdot g.$$

■

The transition functions of these charts are $\alpha_{ij}: P_{ij} \to \mathrm{Aut}(H)$ defined by

$$\alpha_{ij}(u)(h) = s_{ij}(u) \cdot h \cdot s_{ij}(u)^{-1}.$$

As far as the isometablicity of the respective transition functions is concerned, the following proposition is a straightforward calculation.

Proposition 4.2: The transition functions α_{ij} are isometablic in the sense that

$$\alpha_{ij}(ug)(\rho_{jj}(g^{-1})(h)) = \rho_{ii}(g^{-1})(\alpha_{ij}(u)(h)). \tag{13}$$

Theorem 4.3: *Let $P(M,G)$ be a principal bundle, $\mathcal{P}=\{P_i\}_{i\in I}$ be an open cover of P by principal bundle charts and H a Lie group. Let $\rho=\{\rho_i\}_{i\in I}$ be a family of actions of G on H. Given a cocycle $\alpha=\{\alpha_{ij}: P_{ij} \to \mathrm{Aut}(H)\}_{i,j\in I}$ which satisfies* (13)*, there exists a PBG-Lie group bundle over $P(M,G)$ with transition functions the given ones.*

Proof: Let $F_i = U_i \times H$ and on the union of the F_i define the following equivalence relation:

$$(i,(u_1,h_1)) \sim (j,(u_2,h_2)) \Leftrightarrow u_1 = u_2 = u \text{ and } h_2 = \alpha_{ij}(u)(h_1).$$

This is an equivalence relation because we assumed that the α_{ij}'s form a cocycle. Denote the quotient set by F and equivalence classes $\langle i,(u,h)\rangle$. Define a map $\pi: F \to P$ by $\pi\langle i,(u,h)\rangle = u$ and a G-action by

$$\langle i,(u,h)\rangle \cdot g = \langle i,(ug, \rho_i(g^{-1})(h))\rangle.$$

It is easy to see that the map $\psi_i: P_i \times H \to \pi^{-1}(P_i)$ defined by $(u,h) \mapsto \langle i,(u,h)\rangle$ is an equivariant bijection. Give F the smooth structure induced from the manifolds $P_i \times H$ via the ψ_i's. Clearly $F \to P(M,G)$ is a PBG-Lie algebra bundle, and its transition functions are

$$\psi_{i,u}^{-1}(\psi_{j,u}(h)) = \psi_{i,u}^{-1}(\langle j,(u,h)\rangle) = \psi_{i,u}^{-1}(\langle i,(u,\alpha_{ij}(u)(h))\rangle) = \alpha_{ij}(u)(h).$$

■

It will be shown in Sec. VI that the construction of a PBG-LGB given in Theorem 4.3 is well defined. The family of G-actions $\{\rho_{ij}\}_{i,j\in I}$ arises naturally from the local flat basic connections that every PBG-groupoid has. A remarkable result, which is presented here, is that these actions are really only local expressions of the G-action on the groupoid. We prove this for the subset of the ρ_{ij}s for which $i=j$. This is enough, as it was shown in (10) that these actions determine the whole family. To this end, it is necessary to establish the notion of an action groupoid.

Definition 4.4: Given a manifold M together with a right action of a Lie group G on M, the action groupoid $M \rtimes G \rightrightarrows M$ associated with this action is the product manifold $M \times G$, together with the following groupoid structure:

(i) *The source map is $\alpha(x,g)=x$, and the target map $\beta(x,g)=xg$.*
(ii) *Multiplication is defined by $(xg,h)\cdot(x,g)=(x,gh)$.*
(iii) *The unit element over any $x \in M$ is $1_x=(x,e_G)$.*
(iv) *The inverse of an element $(x,g) \in M \rtimes G$ is (xg,g^{-1}).*

Note that the action groupoid is transitive if and only if the G-action on M is transitive.

Now suppose given a PBG-groupoid $\Omega \rightrightarrows P(M,G)$ and a cover $\mathcal{P}=\{P_i\}_{i\in I}$ of P by principal bundle charts. For every $i \in I$, consider the action groupoid $P_i \rtimes G \rightrightarrows P_i(U_i,G)$ and define a map $\tilde{\rho}_i: P_i \rtimes G * I\Omega_{P_i} \to I\Omega_{P_i}$ by

$$\tilde{\rho}_i((u,g), \eta \in \Omega_u^u) = \psi_i(ug, \rho_{ii}(g^{-1})(\psi_{i,u}^{-1}(\eta))).$$

Obviously, $\pi(\tilde{\rho}_i((u,g),\eta)) = ug = \beta(u,g)$ and $\tilde{\rho}_i((u,e_G),\eta) = \eta$. It is easily verified that

$$\widetilde{\rho}_i((ug_1,g_2)\cdot(u,g_1),\eta)=\widetilde{\rho}_i((ug_1,g_2),\widetilde{\rho}_i(u,g_1),\eta).$$

Also, each $\widetilde{\rho}_i(u,g)$ is an automorphism of Ω^u_u; therefore it is a representation of the Lie groupoid $P_i\twoheadrightarrow G$ on the Lie group bundle $I\Omega_{P_i}$, in the sense of Ref. 9. The following proposition allows us to "glue" the $\widetilde{\rho}_i$'s together to a global map.

Proposition 4.5: For all $i,j\in I$ such that $P_{ij}\neq\emptyset$, $u\in P_{ij}$, $g\in G$ and $\eta\in\Omega^u_u$ we have

$$\widetilde{\rho}_i((u,g),\eta)=\widetilde{\rho}_j((u,g),\eta).$$

Proof: The isometablicity of the α_{ij}'s gives

$$\begin{aligned}\widetilde{\rho}_i((u,g),\eta)&=\psi_i(ug,\rho_{ii}(g^{-1})(\psi^{-1}_{i,u}(\eta)))=\psi_i(ug,\rho_{ii}(g^{-1})(\alpha_{ij}(u)(\psi^{-1}_{j,u}(\eta))))\\&=\psi_i(ug,\alpha_{ij}(ug)(\rho_{jj}(g^{-1})(\psi^{-1}_{i,u}(\eta))))\\&=\psi_j(ug,\rho_{jj}(g^{-1})(\psi^{-1}_{i,u}(\eta)))=\widetilde{\rho}_j((u,g),\eta).\end{aligned}$$

■

Now we can define $\rho:(P\twoheadrightarrow G)*I\Omega\to I\Omega$ by $\rho((u,g),\eta\in\Omega^u_u)=\widetilde{\rho}_i((u,g),\eta)$, if $u\in P_i$. The previous proposition shows that it is well defined. More than that, it is a representation because each $\widetilde{\rho}_i$ is. As a matter of fact, ρ is a lot simpler than it seems. Since the charts $\{\psi_i\}_{i\in I}$ are isometablic we have

$$\rho((u,g),\eta)=\psi_i(ug,\rho_{ii}(g^{-1})(\psi^{-1}_{i,u}(\eta)))=\psi_i(u,\psi^{-1}_{i,u}(\eta))\cdot g=\eta\cdot g.$$

So ρ is, in fact, just the PBG structure of $I\Omega$.

Conversely, it is possible to retrieve the local representations $\{\rho_{ii}\}_{i\in I}$ from the PBG structure of $I\Omega$. Suppose $\{\sigma_i:P_i\to\Omega_{u_0}\}_{i\in I}$ is a family of sections of Ω. Consider the charts $\psi_i:P_i\times H\to I\Omega_{P_i}$ defined as $\psi_{i,u}(h)=I_{\sigma_i(u)}(h)$ and define $\widetilde{\rho}_i:P_i\twoheadrightarrow G\to\mathrm{Aut}(H)$ by

$$\widetilde{\rho}_i(u,g)(h)=\psi^{-1}_{i,ug}(\psi_{i,u}(h)\cdot g),$$

for all $g\in G$, $h\in H$ and $u\in P_i$. This is a morphism of Lie groupoids over $P_i\to\cdot$. For every $i\in I$ choose $u_i\in P_i$ and define

$$\rho_{ii}(g^{-1})(h)=\widetilde{\rho}_i(u_i,g)(h)=\psi^{-1}_{i,u_ig}(\psi_{i,u}(h)\cdot g).$$

Then

$$\rho_{ii}(g^{-1})(h)=I_{\sigma_i(u_ig)^{-1}}(I_{\sigma_i(u_i)}(h)\cdot g)=\sigma_i(u_ig)^{-1}\cdot(\sigma_i(u_i)g)\cdot(hg)\cdot(\sigma_i(u_i)^{-1}g)\cdot\sigma_i(u_ig).$$

The latter is exactly the original definition of the ρ_{ii}'s. Since the ρ_{ii}'s determine the ρ_{ij}'s, the previous considerations are the proof of the following theorem.

Theorem 4.6: *Given a PBG-groupoid $\Omega\rightrightarrows P(M,G)$, the representations $\{\rho_{ij}\}_{i\in I}$ are local expressions of the PBG structure of $I\Omega$.*

V. THE CLASSIFICATION OF TRANSITIVE PBG-GROUPOIDS

In this section we deal with a single result: It is shown that the isometablic transition functions classify transitive PBG-groupoids.

Theorem 5.1: *Let $P(M,G)$ be a principal bundle and $\mathcal{P}=\{P_i\}_{i\in I}$ an open cover of P by principal bundle charts. Consider a Lie group H and a family of actions $\rho=\{\rho_{ij}\}_{i,j\in I}$ of G on H which has the property of the cocycle morphism. Given a ρ-isometablic cocycle $\{s_{ij}:P_{ij}\to H\}_{i,j\in I}$ there is a PBG-groupoid Ω over $P(M,G)$ whose PBG-Lie group bundle $I\Omega$ of orbits is the one produced by $\{\alpha_{ij}=I_{s_{ij}}\}_{i,j\in I}$.*

Proof: For every $i,j\in I$ consider the sets $\Sigma^j_i=P_i\times H\times P_j$ and let $\Sigma=\cup_{i,j\in I}\Sigma^j_i$. Consider the equivalence relation

$$(i,u,h,v,j) \sim (i',u',h',v',j') \Leftrightarrow u = u', v = v' \text{ and } h' = s_{i'i}(u) \cdot h \cdot s_{jj'}(v).$$

Then it is shown in Ref. 8, Vol.II, Sec. 2.19 that the following defines a groupoid structure on the quotient $\Omega = \Sigma/\sim$: The source and target projections are $\langle i,u,h,v,j\rangle = v$, $\langle i,u,h,v,j\rangle = u$, the object inclusion map is $1: u \mapsto 1_u = \langle i,u,e_H,u,i\rangle$ (any $i \in I$ such that $u \in P_i$), and the multiplication is

$$\langle i,u,h_1,v,j_1\rangle \cdot \langle j_2,v,h_2,w,k\rangle = \langle i,u,h_1 \cdot s_{j_1j_2}(v) \cdot h_2,w,k\rangle.$$

The inversion is $\langle i,u,h,v,j\rangle^{-1} = \langle j,v,h^{-1},u,i\rangle$. This groupoid becomes a PBG-groupoid with action

$$\langle i,u,h,v,j\rangle \cdot g = \langle i,ug,\rho_{ij}(g^{-1})(h),vg,j\rangle.$$

This is well defined because if $\langle i,u,h,v,j\rangle = \langle i',u,h',v',j'\rangle$; then $h' = s_{i'i}(u) \cdot h \cdot s_{jj'}(v)$. The cocycle morphism condition then gives

$$\rho_{i'j'}(g^{-1})(h') = \rho_{i'i}(g^{-1})(s_{i'i}(u)) \cdot \rho_{ij}(g^{-1})(h) \cdot \rho_{jj'}(g^{-1})(s_{jj'}(u)) = s_{i'i}(ug) \cdot \rho_{ij}(g^{-1})(h) \cdot s_{jj'}(ug).$$

So, $\langle i,u,h,v,j\rangle \cdot g = \langle i',u,h',v,j'\rangle \cdot g$. It is straightforward that this action makes Ω a PBG-groupoid. For instance, we prove here that this action preserves the multiplication. Again, because of the cocycle morphism property, we have

$$\begin{aligned}
(\langle i,u,h_1,v,j_1\rangle \cdot \langle j_2,v,h_2,w,k\rangle) \cdot g &= \langle i,u,h_1 \cdot s_{j_1j_2} \cdot h_2,w,k\rangle \cdot g \\
&= \langle i,ug,\rho_{ik}(g^{-1})(h_1 \cdot s_{j_1j_2} \cdot h_2),w,k\rangle \\
&= \langle i,ug,\rho_{ij_1}(g^{-1})(h_1) \cdot \rho_{j_1j_2}(g^{-1})(s_{j_1j_2}(v)) \cdot \rho_{j_2k}(g^{-1})(h_2),wg,k\rangle \\
&= \langle i,ug,\rho_{ij_1}(g^{-1})(h_1) \cdot s_{j_1j_2}(vg) \cdot \rho_{j_2k}(g^{-1})(h_2),wg,k\rangle \\
&= (\langle i,u,h_1,v,j_1\rangle \cdot g) \cdot (\langle j_2,v,h_2,w,k\rangle \cdot g).
\end{aligned}$$

Proposition 5.2: Let $P(M,G)$ be a principal bundle, $\{P_i\}_{i\in I}$ an open cover of P by principal bundle charts, H a Lie group and ρ', ρ be two families of actions of G on H by cocycle morphisms which are conjugate under a family of maps $r = \{r_i: P_i \to H\}_{i\in I}$ such that $r_i(ug) = \rho_{ii}(g^{-1})(r_i(u)) \cdot r_i(u_ig)$ for all $u \in P_i$, $g \in G$ and $i \in I$. Let $\{s_{ij}\}_{i,j\in I}$ and $\{s'_{ij}\}_{i,j\in I}$ be ρ'-isometablic and ρ-isometablic systems of transition data over $\{P_i\}_{i\in I}$ with values in H, respectively, which are equivalent under the family of maps r. Let Ω' and Ω be the PBG-groupoids constructed from $\{s_{ij}\}_{i,j\in I}$ and $\{s'_{ij}\}_{i,j\in I}$, respectively. Then the map $\varphi: \Omega' \to \Omega$ defined by

$$\langle i,u,v,h\rangle \mapsto \langle i,u,r_i(u) \cdot h \cdot r_j(v)^{-1},v,j\rangle$$

is an isomorphism of PBG-groupoids over $P(M,G)$.

Proof: It is shown in Ref. 8, Vol. II, Sec. 2.19 that φ is an isomorphism of Lie groupoids. To show that it is an isomorphism of PBG-groupoids, take any $g \in G$. Then

$$\begin{aligned}
\varphi(\langle i,u,h,v,j\rangle \cdot g) &= \varphi(\langle i,ug,\rho'_{ij}(g^{-1})(h),vg,j\rangle) \\
&= \langle i,ug,r_i(ug) \cdot ri(u_ig)^{-1}\rho_{ij}(g^{-1})(h) \cdot r_j(u_jg) \cdot r_j(vg)^{-1},vg,j\rangle \\
&= \langle i,ug,\rho_{ii}(g^{-1})(r_i(u)) \cdot r_i(u_ig) \cdot r_i(u_ig)^{-1}\rho_{ij}(g^{-1})(h) \cdot r_j(u_jg) \cdot r_j(u_jg)^{-1}\rho_{jj}(g^{-1}) \\
&\quad \times (r_j(v)^{-1}),vg,j\rangle \\
&= \langle i,ug,\rho_{ij}(g^{-1})(r_i(u) \cdot h \cdot r_j(v)^{-1}),vg,j\rangle = \varphi(\langle i,u,h,v,j\rangle) \cdot g.
\end{aligned}$$

■

VI. ISOMETABLIC TRANSITION DATA

Let us move to the Lie algebroid level for a while. In Ref. 8, Vol. IV, Sec. 4, it is shown that a transitive Lie algebroid $L \rightarrowtail A \twoheadrightarrow TM$ is locally described by the following data: If $\mathfrak{h}$ denotes the fiber type of L, then for a simple open cover $\{U_i\}_{i\in I}$ of M there exists a family of differential-2-forms $\chi=\{\chi_{ij}: TU_{ij}\times TU_{ij}\to U_{ij}\times\mathfrak{h}\}_{i,j\in I}$ and a cocycle $\alpha=\{\alpha_{ij}: U_{ij}\to \mathrm{Aut}(\mathfrak{h})\}_{i,j\in I}$ such that we have the following:

(i) The χ_{ij}s are Maurer-Cartan forms, i.e., $\delta\chi_{ij}+[\chi_{ij},\chi_{ij}]=0$, whenever $U_{ij}\neq\emptyset$;
(ii) $\chi_{ik}=\chi_{ij}+\alpha_{ij}(\chi_{jk})$, whenever $U_{ijk}\neq\emptyset$;
(iii) $\Delta(\alpha_{ij})=\mathrm{ad}\circ\chi_{ij}$, whenever $U_{ij}\neq\emptyset$.

The α_{ij}'s here are the transition functions of the Lie algebra bundle L. The notation Δ stands for the Darboux derivative. More than that, it is shown that this data classifies transitive Lie algebroids.

Since transitive Lie groupoids differentiate to transitive Lie algebroids, it is reasonable to expect that so does the respective classification data. Mackenzie in Ref. 8, Vol. III, Sec. 5 gives a full account of this process, however it is expected that the transition functions that classify a transitive Lie groupoid can be reformulated in a fashion which makes their correspondence to the pair (χ,α) on the algebroid level immediate.

In this section we give this reformulation for transitive PBG-groupoids. For any PBG-groupoid $\Omega\to P(M,G)$ such that the fiber bundle of the associated PBG-Lie group bundle $I\Omega$ is H, we have the following definition.

Definition 6.1: The Lie groupoid morphisms χ_{ij}: $P_{ij}\times P_{ij}\to H$ *defined by*

$$\chi_{ij}(u,v)=s_{ij}(u)\cdot s_{ji}(v)$$

(*over the map* $P_{ij}\to\cdot$) *are called transition morphisms.*

Let us see now how the transition morphisms intertwine with the transition functions α_{ij}.

Proposition 6.2: The transition morphisms χ_{ij} *and the transition functions* α_{ij} *satisfy the following:*

(i) $\chi_{ik}(u,v)=\chi_{ij}(u,v)\cdot\alpha_{ij}(v)\big(\chi_{jk}(u,v)\big)$.
(ii) *For a choice of* $u_{ij}\in P_{ij}$,

$$\alpha_{ij}(u)=I_{\chi_{ij}(u,u_{ij})}\circ I_{s_{ij}(u_{ij})}.$$

(iii) $\rho_{ii}(g^{-1})\big(\chi_{ij}(u,v)\big)=\chi_{ij}(ug,vg)$.

Again, the proof is straightforward. Note that these conditions differentiate to the respective ones on the Lie algebroid level.

Definition 6.3: Let $P(M,G)$ *be a principal bundle,* $\mathcal{P}=\{P_i\}_{i\in I}$ *a cover of* P *by principal bundle charts,* H *a Lie group and* $\rho=\{\rho_i\}_{i\in I}$ *a family of* G*-actions on* H. *Let* $\chi=\{\chi_{ij}: P_{ij}\times P_{ij}\to H\}_{i,j\in I}$ *be a family of Lie groupoid morphisms and* $\alpha=\{\alpha_{ij}: P_{ij}\to \mathrm{Aut}(H)\}_{i,j\in I}$ *a cocycle, such that we have the following:*

(i) $\rho_{ii}(g^{-1})\big(\chi_{ij}(u,v)\big)=\chi_{ij}(ug,vg)$;
(ii) $\alpha_{ij}(ug)\big(\rho_{jj}(g^{-1})(h)\big)=\rho_{ii}(g^{-1})\big(\alpha_{ij}(u)(h)\big)$;
(iii) $\chi_{ik}(u,v)=\chi_{ij}(u,v)\cdot\alpha_{ij}(v)\big(\chi_{jk}(u,v)\big)$;
(iv) *For a choice of* $u_{ij}\in P_{ij}$,

$$\alpha_{ij}(u)=I_{\chi_{ij}(u,u_{ij})}\circ I_{s_{ij}(u_{ij})}.$$

Then the pair (χ,α) *is called a* ρ-isometablic system of transition data over $P(M,G)$ with values in H.

Let us now examine the relation of systems of transition data when we start with different

families of flat isometablic basic connections. Denote (χ,α) and (χ',α') the respective systems of isometablic transition data. Again, the proof of the following proposition is just a matter of calculations.

Proposition 6.4: Two ρ-isometablic and ρ'-isometablic systems of transition data (χ,α) and (χ',α'), respectively, are related by

$$\chi'_{ij}(u,v) = r_i(u)^{-1}[\chi_{ij}(u,v)\cdot\alpha_{ij}(v)(r_i(u)\cdot r_j(v)^{-1})]\cdot r_i(v) \tag{14}$$

and

$$\alpha'_{ij}(u) = I_{r_i(u)^{-1}}\circ\alpha_{ij}(u)\circ I_{r_j(u)}. \tag{15}$$

Definition 6.5: Two isometablic systems of transition data which satisfy (14) and (15) are called equivalent.

Finally we prove that the PBG-Lie group bundles induced by equivalent transition functions are isomorphic, thus showing that the classification of PBG-Lie group bundles we gave in 4.3 is well defined.

Theorem 6.6: *Let $P(M,G)$ be a principal bundle, $\mathcal{P}=\{P_i\}_{i\in I}$ a cover of P by principal bundle charts and H a Lie group. Let $\rho=\{\rho_i\}_{i\in I}$ and $\rho'=\{\rho'_i\}_{i\in I}$ be two families of actions of G on H such that we have the following:*

(i) $\rho_i(g^{-1})(h_1h_2)=\rho_i(g^{-1})(h_1)\cdot\rho_i(g^{-1})(h_2)$

(ii) *There exists a family of maps $\{r_i:P_i\to H\}_{i\in I}$ which are ρ-isometablic [i.e. $r_i(ug)=\rho_i(g^{-1})(r_i(u))\cdot r_i(u_ig)$] such that*

$$\rho'_i(g^{-1})(h) = r_i(u_ig)^{-1}\cdot\rho_i(g^{-1})(h)\cdot r_i(u_ig).$$

If α and α' are cocycles which satisfy (15) which give rise to the PBG-Lie group bundles F and F', respectively, then the map $\varphi:F\to F'$,

$$\langle i,(u,h)\rangle \mapsto \langle i,(u,r_i(u)^{-1}\cdot h\cdot r_i(u))\rangle$$

is an isomorphism of PBG-Lie algebra bundles.

The proof of this is analogous to the one given in 5.2.

VII. ISOMETABLIC COHOMOLOGY

In this section we give a formulation of the cohomology that classifies PBG-groupoids. In general, consider a principal bundle $P(M,G)$, a cover $\mathcal{P}=\{P_i\}_{i\in I}$ of P by principal bundle charts and a Lie group H. We also suppose given a family $\rho=\{\rho_{ij}\}_{i,j\in I}$ of G-actions on H with the property of the cocycle morphism.

For $n\geqslant 3$ we denote by $\check{C}^n_G(P,H)$ the set of differentiable maps $e_{i_0,\ldots,i_n}:P_{i_0,\ldots,i_n}\to H$ such that for every $u\in P_{i_0,\ldots,i_n}$ and $g\in G$ we have the following:

(i) $e_{i_0,\ldots,i_n}(ug)=\rho_{i_{n-1},i_{n-2}}(g^{-1})(e_{i_0,\ldots,i_n}(u))$, if n is odd, and

(ii) $e_{i_0,\ldots,i_n}(ug)=\rho_{i_{n-1},i_{n-3}}(g^{-1})(e_{i_0,\ldots,i_n}(u))$, if n is even.

For $n=0$ define $\check{C}^0_G(P,H)$ to be the set of $e_i:P_i\to H$ such that $e_i(ug)=\rho_{ii}(g^{-1})(e_i(u))$. For $n=1$ define $\check{C}^1_G(P,H)$ to be the set of $e_{ij}:P_{ij}\to H$ such that $e_{ij}(ug)=\rho_{ij}(g^{-1})(e_{ij}(u))$. Finally, define $\check{C}^2_G(P,H)$ to be the set of e_{ijk}'s such that $e_{ijk}(ug)=\rho_{jj}(g^{-1})(e_{ijk}(u))$ and identify $\check{C}^{-1}_G(P,H)$ with H.

Then the usual Čech differential $\delta:\check{C}^n(P,H)\to\check{C}^{n+1}(P,H)$, defined by

$$\delta(e)_{i_0,\ldots,i_n} = \prod_{k=0}^{n}[e_{i_0,\ldots,\hat{i_k},\ldots,i_n}]^{(-1)^{k+1}},$$

is *isometablic* in the sense that

(i) $\delta(e)_{i_0,\ldots,i_n}(ug)=\rho_{i_{n-1}i_{n-2}}(g^{-1})(\delta(e)_{i_0,\ldots,i_n}(u))$ if n is odd, and
(ii) $\delta(e)_{i_0,\ldots,i_n}(ug)=\rho_{i_{n-1}i_{n-3}}(g^{-1})(\delta(e)_{i_0,\ldots,i_n}(u))$ if n is even.

Definition 7.1: The cohomology of the complex,

$$\ldots\xrightarrow{\delta}\check{C}^n_G(P,H)\xrightarrow{\delta}\check{C}^{n+1}_G(P,H)\xrightarrow{\delta}\ldots,$$

is called an isometablic Čech *cohomology and is denoted by* $\check{H}^n_G(P,H)$.

The next theorem follows immediately from 5.1.

Theorem 7.2: *With the notation above, PBG-groupoids are classified by* $\check{H}^1_G(P,H)$.

(Received 15 December 2003; accepted 6 July 2004; published 19 October 2004)

We demonstrate that a class of torus-shaped Hopf maps with arbitrary linking number obeys the static complex eikonal equation. Further, we explore the geometric structure behind these solutions, explaining thereby the reason for their existence. As this equation shows up as an integrability condition in certain nonlinear field theories, the existence of such solutions is of some interest. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1792931]

I. INTRODUCTION

In this article we want to report on a class of Hopf maps with arbitrary linking number, which are, at the same time, static solutions to the complex eikonal equation. Further, we want to explore the geometric structure which is behind these solutions and explains, in fact, their existence.

The eikonal equation reads

$$(\partial^\mu \chi)(\partial_\mu \chi) = 0, \tag{1}$$

and describes, for a real scalar function χ, the propagation of wave fronts (field discontinuities) in Minkowski space. Its generalization to complex χ has some applications in optics and quantum mechanics, as well as in general relativity (see Ref. 1 and the literature cited there). In Ref. 1 an algebraic procedure (based on twistor methods) for the construction of complex solutions to Eq. (1) was developed, and some examples of singular solutions were provided. The complex eikonal equation admits even static solutions, i.e., solutions to the equation

$$(\nabla \chi) \cdot (\nabla \chi) = 0, \tag{2}$$

in contrast to the case of real χ.

The complex eikonal equation (1) has also appeared, in quite a different context, as an integrability condition in some nonlinear field theories. In the last few years there has been rising interest in integrable field theories in higher (i.e., more than two) dimensions, where solitonic solutions are, in many cases, provided by certain Hopf maps, see, e.g., Refs. 2–5. In addition, some nonlinear field theories which are, in general, not integrable, contain *integrable subsectors* where certain integrability conditions are satisfied. Specifically, the complex eikonal equation (1) defines integrable subsectors in the Skyrme and Skyrme–Faddeev models.[6,7] For static, solitonic solutions, this condition reduces to the static complex eikonal equation (2). Finite energy solitons in these integrable subsectors correspond to static solutions defined on one-point compactified $\mathbb{R}^3$ and may, therefore, be identified with functions on S^3 via stereographic projection. Further, the target space of the fields χ in the integrable subsectors can be identified with the Riemann sphere S^2 (i.e., χ is a holomorphic variable on $\mathbb{C}$). Therefore, the fields χ in the integrable subsectors of these models are Hopf maps $S^3 \to S^2$, and can be classified by the Hopf index (the homotopy group $\pi_3(S^2) = \mathbb{Z}$). Consequently, solutions of the complex, static eikonal equation which are, at the same time, Hopf maps, are of some interest for these nonlinear field theories, because they provide finite energy field configurations in their integrable subsectors.

In addition, the static complex eikonal equation (2) has appeared as an integrability condition for the existence of multiple zero modes of the static, Abelian Dirac operator.[8–10] In this case, solutions χ to Eq. (2) are again required to be Hopf maps. The Hopf maps described below will indeed give rise to the construction of new classes of zero modes with new and interesting properties, but this issue shall be discussed elsewhere.

In Sec. II we show that certain toroidal Hopf maps $\chi^{(m,n)}$ obey the static eikonal equation for arbitrary integer m and n (here m and n count the number of times the level curves of χ wrap around the two circular directions of a certain torus). Further, we briefly discuss the symmetries of the static eikonal equation, which enables us to construct new solutions from the ones just mentioned.

In Sec. III we explain the geometric structure which lies behind the existence of these solutions. It turns out that the solutions of Sec. II may be understood as pullbacks of trivial solutions of the complex eikonal equation in two dimensions which preserve some metric properties, providing thereby nontrivial three-dimensional solutions. Further, we give a sufficient condition for the existence of solutions of the geometric type discussed in this paper.

II. THE SOLUTIONS

In the sequel, we will express Hopf maps as complex-valued functions which depend on three variables like, e.g., (x,y,z). Here, the space spanned by these variables may be interpreted either as one-point compactified $\mathbb{R}^3$ or as the three-sphere S^3, where a stereographic projection has been performed. The solutions to the static eikonal equation described below do not depend on this interpretation, i.e., they may be interpreted as solutions on $\mathbb{R}^3$ or on S^3. This result is related to the fact that the metrics on $\mathbb{R}^3$ and S^3 are conformally equivalent (i.e., equal up to a local, space-dependent scale transformation), as will become clear in the next section.

The simplest Hopf map is

$$\chi^{(1,1)} = i\frac{2(x+iy)}{2z+i(r^2-1)} \tag{3}$$

[the meaning of the superscript $(1,1)$ is explained below in Eq. (10)]. Further, $r^2 \equiv x^2+y^2+z^2$, and the irrelevant pre-factor i has been chosen for later convenience. The simplest Hopf map is well-known to obey the static eikonal equation (2), see, e.g., Ref. 8. Before demonstrating this fact, we want to introduce toroidal coordinates (η,ξ,φ) via

$$x = q^{-1}\sinh\,\eta\cos\,\varphi, \quad y = q^{-1}\sinh\,\eta\sin\,\varphi,$$

$$z = q^{-1}\sin\,\xi; \quad q = \cosh\,\eta - \cos\,\xi. \tag{4}$$

Further, we need the gradient in terms of the toroidal coordinates,

$$\nabla = (\nabla\eta)\partial_\eta + (\nabla\xi)\partial_\xi + (\nabla\varphi)\partial_\varphi = q\left(\hat{e}_\eta\partial_\eta + \hat{e}_\xi\partial_\xi + \frac{1}{\sinh\,\eta}\hat{e}_\varphi\partial_\varphi\right), \tag{5}$$

where $(\hat{e}_\eta,\hat{e}_\xi,\hat{e}_\varphi)$ form an orthonormal frame in $\mathbb{R}^3$. In terms of toroidal coordinates, the simplest Hopf map reads

$$\chi^{(1,1)} = \sinh\,\eta\, e^{i\varphi+i\xi}. \tag{6}$$

Here, surfaces of $\eta=$const are tori in $\mathbb{R}^3$. These tori are rotation symmetric around the z axis, and all of them enclose the circle $C=\{\vec{x}\in\mathbb{R}^3 : z=0\wedge r^2=1\}$. The coordinates φ and ξ are angular coordinates along the two circular directions on each torus. Each level curve of $\chi^{(1,1)}$ (i.e., each curve $\chi^{(1,1)}=$const) is located on one torus. It is, in fact, a circle that winds once around each circular direction of the torus. Further, any two different level curves are linked with linking number one, and this linking number is the geometric definition of the Hopf index [which is equal to one for the simplest Hopf map (3)].

For a simple demonstration of the fact that the Hopf map (6) really obeys the eikonal equation it is useful to re-express a general Hopf map χ in terms of two real functions (modulus S and phase σ) like

$$\chi = S\, e^{i\sigma}. \tag{7}$$

In terms of these real functions, the static eikonal equation (2) leads to the conditions

$$(\nabla S)\cdot(\nabla \sigma) = 0, \qquad (\nabla S)^2 = S^2(\nabla \sigma)^2. \tag{8}$$

For the simplest Hopf map (6) we find, with $S=\sinh\,\eta$, $\sigma=\xi+\varphi$,

$$\nabla S = q\,\cosh\,\eta\,\hat{e}_\eta, \qquad \nabla\,\sigma = q\left(\hat{e}_\xi + \frac{1}{\sinh\,\eta}\hat{e}_\varphi\right), \tag{9}$$

which indeed obey Eqs. (8). The important point here is that the equations (8) are expressed only in terms of the target space coordinates S and σ, making the problem essentially two-dimensional. This is precisely what happens for the simplest Hopf map. The factor q, which is present in (9) and cannot be expressed in terms of the target space coordinates, cancels in the relations (8).

A simple generalization to higher Hopf maps is provided by the functions

$$\chi^{(m,n)} = f(\eta)\, e^{in\varphi+im\xi}, \quad m,n \in \mathbb{Z}, \tag{10}$$

which are true Hopf maps if the real function f obeys certain regularity conditions like, e.g., $f(0)=0$ and $f(\infty)=\infty$ (what we assume in the sequel). The level curves of these Hopf maps still lie on the same tori as above, but now they wind n times around the φ direction and m times around the ξ direction. Further, the Hopf index N_{H} (i.e., the linking number of any two different level curves) is $N_{\mathrm{H}}=nm$.

We find for the gradient

$$\nabla\chi^{(m,n)} = q\, e^{im\xi+in\varphi}\left(f'\hat{e}_\eta + imf\hat{e}_\xi + \frac{in}{\sinh\,\eta}f\hat{e}_\varphi\right), \tag{11}$$

where $f'\equiv\partial_\eta f$, and Eq. (2) leads to the simple differential equation

$$\frac{f'}{f} = \left(m^2 + \frac{n^2}{\sinh^2\,\eta}\right)^{1/2} \tag{12}$$

with the solution

$$f = \sinh^{|n|}\,\eta\frac{(|m|\cosh\,\eta + \sqrt{n^2+m^2\,\sinh^2\,\eta})^{|m|}}{(|n|\cosh\,\eta + \sqrt{n^2+m^2\,\sinh^2\,\eta})^{|n|}}. \tag{13}$$

These solutions are genuine Hopf maps for all nonzero, integer m,n, because f obeys $f(0)=0$, $f(\infty)=\infty$.

At this point it is of interest to briefly consider the symmetries of the complex static eikonal equation (2). This will lead to some further understanding of these solutions and allow to construct more solutions from the ones obtained so far. The symmetry group of Eq. (2) is a direct product of base space and target space symmetries, where the group of base space symmetries is the conformal group in three-dimensional Euclidean space. The group of target space symmetries is given locally by the maps $\chi\to F(\chi)$, where F is an arbitrary complex function of χ, but not of its complex conjugate $\overline{\chi}$. The requirement that the solutions $\chi'=F(\chi)$ are single-valued again restricts the allowed functions $F(\cdot)$ to the set of holomorphic functions on $\mathbb{C}$.

The presence of the conformal symmetry on base space implies that the ansatz (10) is an "educated guess" for a solution to Eq. (2) in the sense of the Lie theory of symmetry. That is to say, if we choose a rotation about the z axis and a certain combination of proper conformal transformation along the z axis and translation along the z axis as a maximal set of two commuting

base space transformations, then the corresponding infinitesimal symmetry generators (vectors $\mathbf{v}^i$) are precisely given by the tangent vectors along φ and ξ, $\mathbf{v}^1=\partial_\varphi$, and $\mathbf{v}^2=\partial_\xi$. The ansatz (10) is invariant under a combination of these base space transformations and phase transformations of the target space variable χ, i.e., under the action of the vector fields $\tilde{\mathbf{v}}^1=\partial_\varphi - in\chi\partial_\chi$ and $\tilde{\mathbf{v}}^2=\partial_\xi - im\chi\partial_\chi$, which provides precisely the educated guess according to Lie. A concise discussion of these points can be found in Ref. 4, where the symmetries of an integrable model with infinitely many Hopf solitons are discussed in detail.

Further, we may use the target space symmetries to construct more solutions from the ones given in (13). In fact, each field $\chi'=F(\chi)$ is a solution, where χ is a solution and F is a holomorphic function on $\mathbb{C}$.

III. GEOMETRIC BACKGROUND

Here we want to explain the geometric structure behind the solutions (13), which will, in fact, allow to understand the reason why they exist. For this purpose, let us first observe that there exist trivial solutions to the complex eikonal equation in $\mathbb{R}^2$ or, equivalently, in $\mathbb{C}$. Indeed, for real, cartesian coordinates $(u,v)\in\mathbb{R}^2$ with $w=u+iv$ and gradient

$$\nabla^{(2)} \equiv \hat{e}_u\partial_u + \hat{e}_v\partial_v, \tag{14}$$

the complex eikonal equation $(\nabla^{(2)}f(w))^2=0$ is equivalent to the Cauchy–Riemann equations, which are obeyed by arbitrary holomorphic functions $f(w)$. So, obviously, the complex coordinate $w=u+iv$ itself obeys the eikonal equation,

$$(\nabla^{(2)}w)^2 = 0. \tag{15}$$

By introducing the modulus ρ and phase ϕ of w,

$$w = \rho e^{i\phi}, \tag{16}$$

this equation leads to the conditions

$$(\nabla^{(2)}\rho)\cdot(\nabla^{(2)}\phi) = 0, \qquad (\nabla^{(2)}\rho)^2 = \rho^2(\nabla^{(2)}\phi)^2. \tag{17}$$

It holds in fact also that

$$(\nabla^{(2)}\rho)^2 = \rho^2(\nabla^{(2)}\phi)^2 = 1. \tag{18}$$

Conditions (17) are completely analogous to the conditions (8) in three dimensions. This leads to the natural assumption that the conditions (8) in three dimensions are just the pullbacks under the Hopf map χ of the two-dimensional conditions (17). In the sequel we want to show that this is true in a specific sense.

For this purpose, we want to re-express the above remarks in a more geometric fashion, where we introduce the metrics of the spaces under consideration and replace the gradients by exterior derivatives.

The metric on the space $\mathbb{R}^2$ is

$$g^{(2)} = d\rho\otimes d\rho + \rho^2 d\phi\otimes d\phi, \tag{19}$$

and the dual metric is

$$G^{(2)} = \partial_\rho\otimes\partial_\rho + \frac{1}{\rho^2}\partial_\phi\otimes\partial_\phi. \tag{20}$$

The conditions (17) translate into

$$G^{(2)}(d\rho,d\phi) = 0, \quad G^{(2)}(d\rho,d\rho) = \rho^2 G^{(2)}(d\phi,d\phi) = 1, \tag{21}$$

and are obviously true.

The metric in $\mathbb{R}^3$ is

$$g = q^{-2}(d\eta \otimes d\eta + d\xi \otimes d\xi + \sinh^2 \eta\, d\varphi \otimes d\varphi)$$
$$= \frac{q^{-2}}{1+t^2}[dt \otimes dt + (1+t^2)d\xi \otimes d\xi + t^2(1+t^2)d\varphi \otimes d\varphi], \tag{22}$$

where (η, ξ, φ) are the toroidal coordinates [see (4)] and the coordinate

$$t = \sinh \eta \tag{23}$$

was introduced for later convenience. The dual metric is

$$G = (1+t^2)q^2\left(\partial_t \otimes \partial_t + \frac{1}{1+t^2}\partial_\xi \otimes \partial_\xi + \frac{1}{t^2(1+t^2)}\partial_\varphi \otimes \partial_\varphi\right). \tag{24}$$

As a next step we need the observation that a Hopf map χ introduces a fiber-bundle structure on one-point compactified $\mathbb{R}^3$ (or, equivalently, on S^3). Here, the fibers are the level curves of the Hopf map. The fiber has the topology of the circle S^1, and the base space has the topology of the sphere S^2 for all Hopf maps, but the induced metric properties depend on the specific Hopf map.

Further, the Hopf map allows for a decomposition of the tangent bundle TM of the fiber bundle $M=\mathbb{R}^3$ (or S^3) into vertical and horizontal directions at each point of M. Thereby two subbundles of the full tangent bundle TM are induced, which are called the vertical distribution V and the horizontal distribution H. The vertical direction at each point points along the fiber and is spanned (in our case) by one vertor field e_3 which is pushed forward to zero under the Hopf map, $\chi_* e_3 = 0$. The horizontal directions are spanned (in our case) by two vector fields e_1, e_2, which are perpendicular to the vertical vector e_3. Obviously, the vertical direction only depends on the Hopf map, whereas the horizontal directions depend on the bundle metric, as well. Further, we will choose all three vectors e_i to have unit length (this condition depends, of course, on the metric). This decomposition leads to an analogous decomposition at each point $p \in M$ of the cotangent space T_p^*M into a vertical direction spanned by ω_3 and horizontal directions spanned by ω_1 and ω_2, where the ω_i are defined via

$$(\omega_i, e_j) = \delta_{ij}, \tag{25}$$

and $(\cdot,\cdot)$ denotes the canonical inner product.

Finally, the decomposition of the tangent space (and the cotangent space) into vertical and horizontal directions allows for a corresponding decomposition of the metric and its dual into a vertical and a horizontal component, $g = g_\mathrm{v} + g_\mathrm{h}$. They may be expressed like

$$g_\mathrm{h} = \omega_1 \otimes \omega_1 + \omega_2 \otimes \omega_2, \quad g_\mathrm{v} = \omega_3 \otimes \omega_3, \tag{26}$$

$$G_\mathrm{h} = e_1 \otimes e_1 + e_2 \otimes e_2, \quad G_\mathrm{v} = e_3 \otimes e_3, \tag{27}$$

in terms of the above vector fields and one-forms (observe that this notation just expresses the metric in terms of vielbeins in a coordinate-independent way).

Now we are in a position, eventually, to formulate sufficient conditions for the existence of solutions to the conditions (8).

One sufficient condition is like follows: Obviously, the push-forward χ_* of the Hopf map defines an isomorphism from vectors in the horizontal distribution H of TM at points $\vec{x}$ to vectors in TN at points $\chi(\vec{x})$ (here N is the target space manifold, i.e., $\mathbb{C}$ or S^2, and M is the fiber bundle). Now assume that this isomorphism is, at the same time, an isometry, i.e., the length $|\chi_* v|$ of a pushed-forward vector field $\chi_* v$ in TN w.r.t. the metric $g^{(2)}$ on N at points $\chi(\vec{x})$ is equal to the length $|v|$ of an arbitrary horizontal vector field v in H with respect to the horizontal metric g_h at points $\vec{x}$. Then, obviously, the lengths of one-forms remain invariant under the pull-back χ^*. For a Hopf map $w = \chi(\vec{x})$, which reads, in terms of real coordinates, like

$$\rho = S(\vec{x}), \quad \phi = \sigma(\vec{x}), \tag{28}$$

this means that the lengths should pull back like

$$|d\rho| = |dS|, \quad |d\phi| = |d\sigma|, \tag{29}$$

and the target space metric $g^{(2)}$ expressed in coordinates ρ, ϕ should be identical to the horizontal metric $g_{\rm h}$ expressed in coordinates S, σ. Obviously, length relations are now conserved under the pull-back, as well,

$$|d\rho|^2 = \rho^2 |d\phi|^2 \quad \Rightarrow \quad |dS|^2 = S^2 |d\sigma|^2, \tag{30}$$

$$G^{(2)}(d\rho, d\phi) = 0 \quad \Rightarrow G_{\rm h}(dS, d\sigma) = 0, \tag{31}$$

which is precisely what we need in order to have solutions to the conditions (8). (Maps χ such that the push-forward $\chi_*: H \to TN$ is an isometry are called Riemannian submersions and are described at length, e.g., in Ref. 11.)

It turns out that the condition on the Hopf map χ to be a Riemannian submersion is too strong for our purposes. But there is a simple generalization which does just what we want. Suppose that the lengths of horizontal vector fields are multiplied by a *common* factor at each point under the push-forward, instead of being invariant. Then the lengths of one-forms will be multiplied by a common factor under the pull-back, and this is sufficient for the conservation of the length relations (30) and (31) under the pull-back. For the horizontal metric $g_{\rm h}$ and the target space metric $g^{(2)}$ this implies that they should be conformally equivalent, i.e., equal up to a local scale factor. This is precisely what happens for our solutions, as we want to demonstrate now explicitly.

First, we want to demonstrate it for the simplest Hopf map (6). We re-display the metric in $\mathbb{R}^3$,

$$g = [dt \otimes dt + (1+t^2) d\xi \otimes d\xi + t^2 (1+t^2) d\varphi \otimes d\varphi], \tag{32}$$

where we already ignored an irrelevant local scale factor, see (22). For the Hopf map $\chi = Se^{i\sigma}$ with $S = t$, $\sigma = \xi + \varphi$, the vertical unit vector field e_3 is

$$e_3 = \frac{1}{1+t^2}(\partial_\xi - \partial_\varphi) \tag{33}$$

(remember that $e_3(\sigma) = e_3(S) = 0$). The horizontal unit vector fields may be chosen as

$$e_1 = \partial_t, \quad e_2 = \frac{t}{1+t^2}(\partial_\xi + t^{-2}\partial_\varphi). \tag{34}$$

The corresponding vertical and horizontal one-forms are

$$\omega_1 = dt, \quad \omega_2 = t(d\xi + d\varphi), \tag{35}$$

$$\omega_3 = d\xi - t^2 d\varphi, \tag{36}$$

and the horizontal metric is

$$g_{\rm h} = \omega_1 \otimes \omega_1 + \omega_2 \otimes \omega_2 = dt \otimes dt + t^2 (d\xi + d\varphi) \otimes (d\xi + d\varphi). \tag{37}$$

Obviously, this is identical to the target space metric (19) once the identification $\rho \to t$, $\phi \to \sigma = \xi + \varphi$ is made.

Now we repeat this procedure for the class of Hopf maps $S = t$, $\sigma = m\xi + n\varphi$ which are genuine Hopf maps with toroidal symmetry, but not yet the solutions (13). We find for the horizontal and vertical unit vector fields

$$e_1 = \partial_t, \quad e_2 = \frac{t}{\sqrt{(n^2 + m^2t^2)(1 + t^2)}}(m\partial_\xi + nt^{-2}\partial_\varphi), \tag{38}$$

$$e_3 = \frac{1}{\sqrt{(n^2 + m^2t^2)(1 + t^2)}}(n\partial_\xi - m\partial_\varphi), \tag{39}$$

and for the corresponding one-forms

$$\omega_1 = dt, \quad \omega_2 = t\sqrt{\frac{1 + t^2}{n^2 + m^2t^2}}(md\xi + nd\varphi), \tag{40}$$

$$\omega_3 = \sqrt{\frac{1 + t^2}{n^2 + m^2t^2}}(nd\xi - mt^2d\varphi). \tag{41}$$

The horizontal metric now is

$$g_{\mathrm{h}} = dt \otimes dt + t^2\frac{1 + t^2}{n^2 + m^2t^2}(md\xi + nd\varphi) \otimes (md\xi + nd\varphi), \tag{42}$$

and is not yet manifestly conformally equivalent to the target space metric. However, the horizontal metric only depends on the "horizontal" coordinates $S=t$ and $\sigma=m\xi+n\varphi$ and, therefore, certainly *is* conformally equivalent to the target space metric, because it is a well-known fact that two different metrics on a two-dimensional surface with a given topology are always conformally equivalent (see, e.g., Theorem 13.1.1 in Ref. 12). All we have to do is to find the coordinate transformation from the horizontal coordinates (S, σ) to some new coordinates $(\tilde{S}, \tilde{\sigma})$ such that the conformal equivalence becomes manifest. This shows that the initial problem must have a solution, i.e., higher Hopf maps, related to the Hopf maps (10), which solve the static eikonal equation, *must* exist.

Explicitly, a transformation $(t, \sigma) \to (\tilde{t}(t), \sigma)$ is sufficient such that

$$g_{\mathrm{h}} = \frac{t^2}{\tilde{t}^2}\frac{1 + t^2}{n^2 + m^2t^2}[d\tilde{t} \otimes d\tilde{t} + \tilde{t}^2(md\xi + nd\varphi) \otimes (md\xi + nd\varphi)]. \tag{43}$$

Therefore, $\tilde{t}$ has to obey

$$(dt)^2 = \frac{(1 + t^2)t^2}{(n^2 + m^2t^2)\tilde{t}^2}(d\tilde{t})^2 \quad \Rightarrow \quad \frac{1}{\tilde{t}}\frac{d\tilde{t}}{dt} = \frac{1}{t}\sqrt{\frac{n^2 + m^2t^2}{1 + t^2}}. \tag{44}$$

Re-introducing the variable η and using $\tilde{t}(t)=\tilde{t}(\sinh\ \eta) \equiv f(\eta)$, Eq. (44) leads to Eq. (12) with the solution (13).

We want to close with two remarks. Firstly, the geometric setting developed above easily leads to more Hopf maps which solve the static eikonal equation. Obviously, the sufficient condition for the existence of a solution related to a given Hopf map is that the induced horizontal metric should be expressible—up to a local scale factor—in terms of the horizontal coordinates (S, σ) (where the Hopf map is $\chi=Se^{i\sigma}$). Once this condition is met, the solution can be found by transforming to new horizontal coordinates $(\tilde{S}, \tilde{\sigma})$ such that the horizontal metric is manifestly conformally equivalent to the target space metric. This transformation is always possible for genuine Hopf maps. The simplest example of this type for the generation of new solutions is the composition of existing solutions with maps $S^2 \to S^2$, i.e., the choice of new complex-valued functions $\chi' = F(\chi)$, where $F(\cdot)$ is a holomorphic function (e.g., a rational map), and χ is a solution. However, we already found these solutions from the symmetries of the static eikonal equation in Sec. II.

Second, we want to remark that the above Hopf maps (10) do, in fact, provide genuine Riemannian submersions from the three-sphere S^3 to some two-dimensional target spaces with the

topology of the two-sphere but, in general, metrics different from the two-sphere (except for the simplest case $m=n=1$, which provides a Riemannian submersion from S^3 to S^2, see, e.g., Refs. 10 and 11). This may be understood from what we said above by noting that the local scale factor q^{-2}, which is present in the metric on $\mathbb{R}^3$ (see (22)), and which cannot be expressed in terms of the horizontal coordinates alone, is absent for the metric on S^3.

(Received 21 April 2004; accepted 6 July 2004; published 19 October 2004)

We consider a nearest-neighbor p-adic λ-model with spin values ±1 on the Cayley tree of order $k \geqslant 1$. We prove that a p-adic Gibbs measure is unique for $p \geqslant 3$. If $p=2$ then we find a condition which guarantees uniqueness of p-adic Gibbs measure. Besides, the results are applied to the p-adic Ising model. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1792932]

I. INTRODUCTION

The p-adic numbers were first introduced by the German mathematician K. Hensel. For about a century after the discovery of p-adic numbers, they were mainly considered objects of pure mathematics. However, numerous applications of these numbers to theoretical physics have been proposed in papers.[1,2,6,7,13,18] It is known[7] that number of p-adic models in physics cannot be described using ordinary probability theory based on the Kolmogorov axioms.[12] New probability models- p-adic probability models were investigated in Refs. 7 and 8. This is non-Kolmogorovean model, since probabilities take values in fields of p-adic numbers.

In Refs. 9 and 10 the theory of stochastic processes with values in p-adic and more general non-Archimedean fields having probability distributions with non-Archimedean values, has been developed. The non-Archimedean analog of the Kolmogorov theorem that gives the possibility to construct wide classes of stochastic processes by using finite dimensional probability distributions, was proved.

It is known that the theory of statistical mechanics lies in the base of the theory of probability and stochastic processes. Since the theory of probabilities and stochastic processes in a non-Archimedean setting has been introduced, it is natural to begin the study and initiate further the development of the problems of statistical mechanics in the context of the p-adic theory of probability.

One of the central problems in the theory of Gibbs measures is to describe infinite-volume Gibbs measures corresponding to a given Hamiltonian. However, a complete analysis of the set of Gibbs measures for a specific Hamiltonian is often a difficult problem. If for a given Hamiltonian there are at least two Gibbs measures then it is said that a *phase transition* occurs for the model.

The existence of a phase transition for the Ising model (real case) on the Cayley tree of order $k \geqslant 2$ was established by Katsura and Takisawa.[5] The analysis of the Cayley tree Ising model can be extended in several directions (see Refs. 14, 15, and 4).

In this paper we develop the p-adic probability theory approaches to the study of some statistical mechanics models on a Cayley tree in the field of p-adic numbers. In Ref. 3 we have proved the existence of the phase transition for the homogeneous p-adic Potts model with $q \geqslant 2$

spin variables on the set of integers $\mathbb{Z}$. The present paper deals with a nonhomogeneous p-adic λ-model on the Cayley tree of order k, $k \geqslant 1$. The aim of this paper is to show the uniqueness of Gibbs measures for the considered model.

II. DEFINITIONS AND PRELIMINARY RESULTS

A. *p*-adic numbers and measures

Let $\mathbb{Q}$ be the field of rational numbers. Every rational number $x \neq 0$ can be represented in the form $x = p^r(n/m)$, where $r, n \in \mathbb{Z}$, m is a positive integer, $(p,n)=1$, $(p,m)=1$ and p is a fixed prime number. The p-adic norm of x is given by

$$|x|_p = \begin{cases} p^{-r} & \text{for } x \neq 0 \\ 0 & \text{for } x = 0. \end{cases}$$

It satisfies the following properties:

1) $|xy|_p = |x|_p |y|_p$,
2) the strong triangle inequality

$$|x+y|_p \leqslant \max\{|x|_p, |y|_p\},$$

this is a non-Archimedean norm.

The completion of $\mathbb{Q}$ with respect to p-adic norm is called p-adic field which is denoted by $\mathbb{Q}_p$.

The well-known Ostrovsky's theorem asserts that norms $|x|_\infty = |x|$ and $|x|_p$, $p = 2,3,5,\ldots$ exhaust all nonequivalent norms on $\mathbb{Q}$ (see Ref. 11). Any p-adic number $x \neq 0$ can be uniquely represented in the canonical series:

$$x = p^{\gamma(x)}(x_0 + x_1 p + x_2 p^2 + \cdots),$$

where $\gamma = \gamma(x) \in \mathbb{Z}$ and x_j are integers, $0 \leqslant x_j \leqslant p-1$, $x_0 > 0$, $j = 0,1,2,\ldots$ (for more details see Refs. 11 and 17). In this case $|x|_p = p^{-\gamma(x)}$.

Let $B(a,r) = \{x \in \mathbb{Q}_p : |x-a|_p \leqslant r\}$, where $a \in \mathbb{Q}_p$, $r > 0$. The p-adic logarithm is defined by series

$$\log_p(x) = \log_p(1 + (x-1)) = \sum_{n=1}^{\infty} (-1)^{n+1} \frac{(x-1)^n}{n},$$

which converges for $x \in B(1,1)$. And p-adic exponential is defined by

$$\exp_p(x) = \sum_{n=1}^{\infty} \frac{x^n}{n!},$$

which converges for $x \in B(0, p^{-1/(p-1)})$.

Lemma 2.1:[11,17] *Let $x \in B(0, p^{-1/(p-1)})$ then we have*

$$|\exp_p(x)|_p = 1, \quad |\exp_p(x) - 1|_p = |x|_p < 1, \quad |\log_p(1+x)|_p = |x|_p < p^{-1/(p-1)}$$

and

$$\log_p(\exp_p(x)) = x, \quad \exp_p(\log_p(1+x)) = 1 + x.$$

Let $(X, \mathcal{B})$ be a measurable space, where $\mathcal{B}$ is an algebra of subsets X. A function $\mu : \mathcal{B} \to \mathbb{Q}_p$ is said to be a p-adic measure if for any $A_1, \ldots, A_n \subset \mathcal{B}$ such that $A_i \cap A_j = \varnothing$ $(i \neq j)$ the equality holds

$$\mu\left(\bigcup_{j=1}^{n} A_j\right) = \sum_{j=1}^{n} \mu(A_j).$$

A p-adic measure is called a probability measure if $\mu(X)=1$.

For more detailed information about p-adic measures please refer to Refs. 7 and 8.

B. The Cayley tree

The Cayley tree Γ^k of order $k \geqslant 1$ is an infinite tree, i.e., a graph without cycles, such that each vertex of which lies on $k+1$ edges. Let $\Gamma^k=(V,\Lambda)$, where V is the set of vertices of Γ^k, Λ is the set of edges of Γ^k. The vertices x and y are called *nearest neighbors*, which is denoted by $l=\langle x,y\rangle$ if there exists an edge connecting them. A collection of the pairs $\langle x,x_1\rangle,\ldots,\langle x_{d-1},y\rangle$ is called *path* from the point x to the point y. The distance $d(x,y), x,y \in V$, on the Cayley tree, is the length of the shortest path from x to y.

We set

$$W_n=\{x \in V | d(x,x^0)=n\},$$

$$V_n=\bigcup_{m=1}^{n} W_m=\{x \in V | d(x,x^0) \leqslant n\},$$

$$L_n=\{l=\langle x,y\rangle \in L | x,y \in V_n\},$$

for an arbitrary point $x^0 \in V$.

Denote

$$S(x)=\{y \in W_{n+1} : d(x,y)=1\} \quad x \in W_n,$$

this set is called the set *direct successors* of x. Observe that any vertex $x \neq x^0$ has k direct successors and x^0 has $k+1$.

C. The *p*-adic λ-model

We consider a p-adic λ-model, where the spin takes values in the set $\Phi=\{-1,1\}\subset\mathbb{Q}_p$ and is assigned to the vertices of the tree. A configuration σ on V is then defined as a function $x \in V \to \sigma(x) \in \Phi$; in a similar fashion one defines a configuration σ_n and $\sigma^{(n)}$ on V_n and W_n, respectively. The set of all configurations on V (resp. V_n, W_n) coincides with $\Omega=\Phi^V$ (resp. $\Omega_{V_n}=\Phi^{V_n}, \Omega_{W_n}=\Phi^{W_n}$). One can see that $\Omega_{V_n}=\Omega_{V_{n-1}}\times\Omega_{W_n}$. Using this, for given configurations $\sigma_{n-1} \in \Omega_{V_{n-1}}$ and $\sigma^{(n)} \in \Omega_{W_n}$ we define their concatenations by the formula

$$\sigma_{n-1}\vee\sigma^{(n)}=\{\{\sigma_n(x),x \in V_{n-1}\},\{\sigma^{(n)}(y),y \in W_n\}\}.$$

It is clear that $\sigma_{n-1}\vee\sigma^{(n)} \in \Omega_{V_n}$. Let functions $\lambda_{x,y}:(u,v) \in \Phi\times\Phi \to \lambda_{x,y}(u,v) \in \mathbb{Q}_p$. be given for each pairs of neighboring vertices x,y. The Hamiltonian $H_n:\Omega_{V_n}\to\mathbb{Q}_p$ of the p-adic inhomogeneous λ-model has the form

$$H_n(\sigma_n)=\sum_{\langle x,y\rangle \in L_n}\lambda_{x,y}(\sigma_n(x),\sigma_n(y)), \quad n \in \mathbb{N}, \tag{2.1}$$

where the sum is taken over all pairs of neighboring vertices $\langle x,y\rangle$ and $\sigma_n \in \Omega_{V_n}$.

We say that (2.1) is *homogeneous* λ-*model* if all functions $\lambda_{xy}(u,v)$ do not depend on x,y and in this case we put $\lambda(u,v):=\lambda_{x,y}(u,v), \forall\langle x,y\rangle \in L$.

We note that λ-model of this type were firstly considered in Ref. 15.

III. CONSTRUCTION OF GIBBS MEASURES

In this subsection we give a construction of a special class of Gibbs measures for p-adic λ-model on the Cayley tree.

To define Gibbs measure we need in the following

Lemma 3.1: Let $h_x, x \in V$ be a $\mathbb{Q}_p$-valued function such that $h_x \in B(0, p^{-1/(p-1)})$ for all $x \in V$ and $|\lambda_{x,y}(u,v)|_p < p^{-1/(p-1)}$ for all $u, v \in \Phi$. Then the relation

$$H_n(\sigma) + \sum_{x \in W_n} h_x \sigma(x) \in B(0, p^{-1/(p-1)}),$$

is valid for any $n \in \mathbb{N}$.

The proof easily follows from the strong triangle inequality for the norm $|\cdot|_p$.

Let $h: x \in V \to h_x \in \mathbb{Q}_p$ be a function of $x \in V$ such that $|h_x|_p < p^{-1/(p-1)}$ for all $x \in V$. Given $n = 1, 2, \ldots$ consider a p-adic probability measure $\mu^{(n)}$ on Φ^{V_n} defined by

$$\mu_h^{(n)}(\sigma_n) = Z_n^{-1} \exp_p \left\{ H_n(\sigma_n) + \sum_{x \in W_n} h_x \sigma(x) \right\}. \tag{3.1}$$

Here, as before, $\sigma_n: x \in V_n \to \sigma_n(x)$ and Z_n is the corresponding partition function:

$$Z_n = \sum_{\tilde{\sigma}_n \in \Omega_{V_n}} \exp_p \left\{ H(\tilde{\sigma}_n) + \sum_{x \in W_n} h_x \tilde{\sigma}(x) \right\}.$$

Note that according to Lemma 3.1 the measures $\mu^{(n)}$ exist.

The compatibility conditions for $\mu_h^{(n)}(\sigma_n), n \geqslant 1$ are given by the equality

$$\sum_{\sigma^{(n)} \in \Omega_{W_n}} \mu_h^{(n)}(\sigma_{n-1} \vee \sigma^{(n)}) = \mu_h^{(n-1)}(\sigma_{n-1}), \tag{3.2}$$

where $\sigma_{n-1} \in \Omega_{V_{n-1}}$.

We note that an analog of the Kolmogorov extension theorem for distributions can be proved for p-adic distributions given by (3.1) (see Ref. 10). Then according to the Kolmogorov theorem there exists a unique p-adic measure μ_h on $\Omega = \Phi^V$ such that for every $n = 1, 2, \ldots$ and $\sigma_n \in \Phi^{V_n}$ the equality holds

$$\mu_h(\{\sigma|_{V_n} = \sigma_n\}) = \mu_h^{(n)}(\sigma_n),$$

which will be called *p-adic Gibbs measure* for the considered λ-model. It is clear that the measure μ_h depends on the function h_x. By $\mathcal{S}_\lambda$ we denote the set of all p-adic Gibbs measures associated with functions $h = (h_x, x \in V)$. If $|\mathcal{S}_\lambda| \geqslant 2$, then we can say that, for this model, there exists *a phase transition*, otherwise, we say there is *no phase transition* (here $|A|$ means the cardinality of a set A). In other words, the phase transition means that there are two different functions $h = (h_x, x \in V)$ and $s = (s_x, x \in V)$ for which there exists two μ_h and μ_s p-adic Gibbs measures on Ω, respectively.

The following statement describes conditions on h_x guaranteeing the compatibility condition of measures $\mu^{(n)}(\sigma_n)$.

Theorem 3.2: *The measures $\mu^{(n)}(\sigma_n), n = 1, 2, \ldots$ satisfy the compatibility condition (3.2) if and only if for any $x \in V$ the following equation holds:*

$$h_x = \sum_{y \in S(x)} F_{x,y}(h_y; \lambda) \tag{3.3}$$

where $S(x)$ is the set of all direct successors of $x \in V$ and

$$F_{x,y}(h, \lambda) = \frac{1}{2} \log_p \left(\frac{\exp_p(\lambda_{x,y}(1,1)) \exp_p(2h) + \exp_p(\lambda_{x,y}(1,-1))}{\exp_p(\lambda_{x,y}(-1,1)) \exp_p(2h) + \exp_p(\lambda_{x,y}(-1,-1))} \right).$$

Proof: *Necessity*. According to the compatibility condition (3.2) we have

$$Z_n^{-1}\sum_{\sigma^{(n)}}\exp_p\left[\sum_{\langle x,y\rangle\in L_n}\lambda_{x,y}(\sigma(x),\sigma(y))+\sum_{x\in W_n}h_x\sigma(x)\right]$$
$$=Z_{n-1}^{-1}\exp_p\left[\sum_{\langle x,y\rangle\in L_{n-1}}\lambda_{x,y}(\sigma(x),\sigma(y))+\sum_{x\in W_{n-1}}h_x\sigma(x)\right]. \quad (3.4)$$

It yields

$$\frac{Z_{n-1}}{Z_n}\sum_{\sigma(n)}\exp_p\left[\sum_{x\in W_{n-1}}\sum_{y\in S(x)}\lambda_{x,y}(\sigma(x),\sigma(y))+\sum_{x\in W_{n-1}}\sum_{y\in S(x)}h_y\sigma(y)\right]=\prod_{x\in W_{n-1}}\exp_p(h_x\sigma(x)). \quad (3.5)$$

From this equality we find

$$\frac{Z_{n-1}}{Z_n}\prod_{x\in W_{n-1}}\prod_{y\in S(x)}\sum_{\sigma(y)\in\Phi}\exp_p(\lambda_{x,y}(\sigma(x),\sigma(y))+h_y\sigma(y))=\prod_{x\in W_{n-1}}\exp_p(h_x\sigma(x)). \quad (3.6)$$

Now fix $x\in W_{n-1}$ and dividing the equalities (3.6) with $\sigma(x)=1$ and $\sigma(x)=-1$ we obtain

$$\prod_{y\in S(x)}\frac{\sum_{\sigma(y)\in\Phi}\exp_p(\lambda_{x,y}(1,\sigma(y))+h_y\sigma(y))}{\sum_{\sigma(y)\in\Phi}\exp_p(\lambda_{x,y}(-1,\sigma(y))+h_y\sigma(y))}=\exp_p(2h_x), \quad (3.7)$$

hence we get

$$\prod_{y\in S(x)}\frac{\exp_p(\lambda_{x,y}(1,1))\exp_p(2h_y)+\exp_p(\lambda_{x,y}(1,-1))}{\exp_p(\lambda_{x,y}(-1,1))\exp_p(2h_y)+\exp_p(\lambda_{x,y}(-1,-1))}=\exp_p(2h_x), \quad (3.8)$$

which implies (3.3).

Sufficiency: Now assume that (3.3) is valid, then it implies (3.8), and hence (3.7). From (3.7) we obtain the following equality:

$$a(x)\exp_p(h_x\sigma)=\prod_{y\in S(x)}\sum_{\tilde\sigma(y)\in\Phi}\exp_p(\lambda_{x,y}(\sigma,\tilde\sigma(y))+h_y\tilde\sigma(y)),\quad \sigma\in\{-1,1\};$$

this equality implies

$$\prod_{x\in W_{n-1}}a(x)\exp_p(h_x\sigma(x))=\prod_{x\in W_{n-1}}\prod_{y\in S(x)}\sum_{\tilde\sigma(y)\in\Phi}\exp_p(\lambda_{x,y}(\sigma(x),\tilde\sigma(y))+h_y\tilde\sigma(y)), \quad (3.9)$$

where

$$\sigma(z)=\begin{cases}\sigma, & z=x\\ \sigma(z), & z\neq x\end{cases}\qquad \sigma\in\{-1,1\}.$$

Denoting $A_n(x)=\Pi_{x\in W_n}a(x)$ from (3.9) and (3.2) we find

$$Z_{n-1}A_{n-1}\mu_h^{(n-1)}(\sigma_{n-1})=Z_n\sum_{\tilde\sigma^{(n)}}\mu_h^{(n)}(\sigma_{n-1}\vee\tilde\sigma^{(n)}).$$

Since each $\mu_h^{(n)}$, $n\geqslant 1$ measure is a *p*-adic probability measure, so we should have

$$\sum_{\sigma_{n-1}}\sum_{\tilde\sigma^{(n)}}\mu_h^{(n)}(\sigma_{n-1}\vee\tilde\sigma^{(n)})=1,\quad \sum_{\sigma_{n-1}}\mu_h^{(n-1)}(\sigma_{n-1})=1.$$

Therefore, from these equalities we find $Z_{n-1}A_{n-1}=Z_n$ which means that (3.2) is valid.

Observe that according to this Theorem the problem of describing of *p*-adic Gibbs measures is reduced to the description of solutions of functional equation (3.3).

IV. THE UNIQUENESS OF GIBBS MEASURE FOR THE *p*-ADIC λ-MODEL

In this section we will show that the phase transition does not occur for the p-adic λ-model. Put

$$\Xi = \{h = (h_x, x \in V) : h_x \text{ satisfies the equation (3.3)}\}.$$

According to Theorem 3.2 the description of Gibbs measures is reduced to the description of elements of the set Ξ.

A. Nonhomogeneous case

In this subsection we will consider nonhomogeneous λ-model. We claim that the function $\lambda_{x,y}$ satisfies the following condition: for all nearest-neighbor vertices $x, y \in V$ the equality

$$\exp_p(\lambda_{x,y}(1,1)) + \exp_p(\lambda_{x,y}(1,-1)) = \exp_p(\lambda_{x,y}(-1,1)) + \exp_p(\lambda_{x,y}(-1,-1)), \tag{4.1}$$

is valid.

This condition implies that the function $h_x = 0, \forall x \in V$ is a solution of (3.3).

Let $S(x) = \{x_1, \ldots, x_k\}$, here as before $S(x)$ is the set of direct successors of x. Then the equation (3.3) can be rewritten as follows:

$$z_x = \prod_{i=1}^{k} \alpha_{x,i}, \tag{4.2}$$

where $z_x = \exp_p(h_x)$, $z_{x_i} = \exp_p(h_{x_i})$,

$$\alpha_{x,i} = \frac{a_{x,x_i} z_{x_i} + b_{x,x_i}}{c_{x,x_i} z_{x_i} + d_{x,x_i}},$$

$$\begin{aligned} a_{x,x_i} &= \exp_p(\lambda_{x,x_i}(1,1)), \quad & b_{x,x_i} &= \exp_p(\lambda_{x,x_i}(1,-1)), \\ c_{x,x_i} &= \exp_p(\lambda_{x,x_i}(-1,1)), \quad & d_{x,x_i} &= \exp_p(\lambda_{x,x_i}(-1,-1)) \end{aligned} \tag{4.3}$$

for every $i = 1, \ldots, k$, here as before $|h_x|_p \leqslant 1/p$ for all $x \in V$.

Lemma 4.2: If $|a_i - 1|_p \leqslant M$ *and* $|a_i|_p = 1$, $i = 1, \ldots, n$, *then*

$$\left| \prod_{i=1}^{n} a_i - 1 \right|_p \leqslant M. \tag{4.4}$$

Proof: We prove by induction on n. The case $n = 1$ is the condition of lemma. Suppose that (4.4) is valid at $n = m$. Now let $n = m + 1$. Then we have

$$\left| \prod_{i=1}^{m+1} a_i - 1 \right|_p = \left| \prod_{i=1}^{m+1} a_i - \prod_{i=1}^{m} a_i + \prod_{i=1}^{m} a_i - 1 \right|_p \leqslant \max\left\{ \left| \prod_{i=1}^{n} a_i (a_{n+1} - 1) \right|_p, \left| \prod_{i=1}^{n} a_i - 1 \right|_p \right\} \leqslant M.$$

This completes the proof.

Lemma 4.3: For every $x \in V$ *the following inequality holds*

$$|h_x|_p \leqslant \frac{1}{p} \max_{1 \leqslant i \leqslant k} \{|h_{x_i}|_p\}.$$

Proof: For every $m \in \{1, 2, \ldots, k\}$ we have

$$|\alpha_{x,m}-1|_p=\left|\frac{(a_{x,x_m}-c_{x,x_m})(z_{x_m}-1)}{c_{x,x_m}z_{x_m}+d_{x,x_m}}\right|_p\leqslant\frac{1}{p}|h_{x_m}|_p.$$

Here we have used (4.1) and the following relations: for $p\geqslant 3$

$$|a_{x,x_m}-c_{x,x_m}|_p\leqslant\frac{1}{p},\quad |c_{x,x_m}z_{x_m}+d_{x,x_m}|_p=1,$$

for $p=2$

$$|a_{x,x_m}-c_{x,x_m}|_p\leqslant\frac{1}{2^2},\quad |c_{x,x_m}z_{x_m}+d_{x,x_m}|_p=\frac{1}{2},$$

which follow from (4.3) and the equality $|\exp_p(x)-1|_p=|x|_p$ (see Lemma 2.1). Then according to Lemma 4.2 and (4.2) we obtain

$$|h_x|_p=|z_x-1|_p\leqslant\frac{1}{p}\max_{1\leqslant i\leqslant k}\{|h_{x_i}|_p\}.$$

Lemma is proved.

Theorem 4.4: *Let* $k\geqslant 1$, $|\lambda_{x,y}(u,v)|_p\leqslant 1/p$ *for all* $<x,y>\in L$, $u,v\in\Phi$ *and (4.1) be satisfied. Then for the p-adic nonhomogeneous* λ*-model (2.1) on the Cayley tree of order k there is no phase transition for any prime p.*

Proof: To obtain the proof it is enough to show that $\Xi=\{h_x\equiv 0\}$. In order to do so it is enough to show that for arbitrary $\varepsilon>0$ and every $x\in V$ the inequality $\|h_x\|_p<\varepsilon$ is valid. Let $n_0\in\mathbb{N}$ be such that $1/p^{n_0}<\varepsilon$. According to Lemma 4.3 we have

$$|h_x|_p\leqslant\frac{1}{p}|h_{x_{i_0}}|_p\leqslant\frac{1}{p^2}|h_{x_{i_0,i_1}}|_p\leqslant\cdots\leqslant\frac{1}{p^{n_0-1}}|h_{x_{i_0,\ldots,i_{n_0-2}}}|_p\leqslant\frac{1}{p^{n_0}}<\varepsilon,$$

here $x_{i_0,\ldots,i_n,j}$, $j=\overline{1,k}$ are direct successors of $x_{i_0,\ldots,i_n}$, where

$$|h_{x_{i_0,\ldots,i_m}}|_p=\max_{1\leqslant j\leqslant k}\{|h_{x_{i_0,\ldots,i_{m-1},j}}|_p\}.$$

This completes the proof.

B. Homogeneous case

In this subsection we will consider the homogeneous λ-model, i.e., $\lambda_{xy}(u,v)=\lambda(u,v)$, $\forall\langle x,y\rangle\in L$.

In this subsection at first we restrict ourselves to the description of translation-invariant ($h_x=h\in\mathbb{Q}_p$, $\forall x\in V$) elements of Ξ.

Let $h_x=h$ for all $x\in V$. Then (3.3) implies

$$\left(\frac{\exp_p(\lambda(1,1))\exp_p(2h)+\exp_p(\lambda(1,-1))}{\exp_p(\lambda(-1,1))\exp_p(2h)+\exp_p(\lambda(-1,-1))}\right)^k=\exp_p(2h).\tag{4.5}$$

Denoting

$$\begin{gathered}z=\exp_p(2h),\quad a=\exp_p(\lambda(1,1)),\quad b=\exp_p(\lambda(1,-1)),\\ c=\exp_p(\lambda(-1,1)),\quad d=\exp_p(\lambda(-1,-1)),\end{gathered}\tag{4.6}$$

from (4.5) we obtain

$$\left(\frac{az+b}{cz+d}\right)^k = z. \tag{4.7}$$

Denote

$$f(x) = \left(\frac{ax+b}{cx+d}\right)^k.$$

Let $S_1=\{x \in \mathbb{Q}_p : |x|_p=1\}$. Then it is clear that $f(S_1) \subset S_1$. Using this fact for every $x \in S_1$ we find

$$|f(x)-1|_p = \left|\frac{(a-c)x+b-d}{cx+d}\right|_p \left|\sum_{m=0} k-1\left(\frac{ax+b}{cx+d}\right)^m\right|_p \leqslant \frac{1}{p}, \tag{4.8}$$

here we have used (4.6) and Lemma 2.1.

Let $x,y \in S_1$, then

$$|f(x)-f(y)|_p = \left|\frac{ax+b}{cx+d}-\frac{ay+b}{cy+d}\right|_p \left|\sum_{m=0}^{k-1}\left(\frac{ay+b}{cy+d}\right)^m\left(\frac{ax+b}{cx+d}\right)^{k-m-1}\right|_p \leqslant \frac{|ad-bc|_p|x-y|_p}{|cx+d|_p|cy+d|_p}. \tag{4.9}$$

Now consider two different cases with respect to p.

Let us assume that $p \geqslant 3$. In this case we have

$$|ad-bc|_p \leqslant \frac{1}{p}, \quad |cx+d|_p = 1, \quad |cy+d|_p = 1,$$

which are obtained from (4.6) and Lemma 2.1. Using these equalities from (4.9) it can be found

$$|f(x)-f(y)|_p \leqslant \frac{1}{p}|x-y|_p. \tag{4.10}$$

Now suppose $p=2$. Then

$$|ad-bc|_p \leqslant \frac{1}{2^2}, \quad |cx+d|_p = \frac{1}{2}, \quad |cy+d|_p = \frac{1}{2}.$$

We claim that $|ad-bc|_p \leqslant 1/2^3$ is satisfied. It follows from (4.9) that

$$|f(x)-f(y)|_2 \leqslant \frac{1}{2}|x-y|_2. \tag{4.11}$$

Thus the equalities (4.10) and (4.11) imply that f is a contraction of S_1, hence f has a unique fixed point $\zeta \in S_1$ such that $|\zeta-1|_p \leqslant 1/p$ (see (4.8)). So we have proved the following

Proposition 4.5: (i) Let $p \geqslant 3$ and $|\lambda(u,v)|_p \leqslant 1/p$ for all $\langle x,y\rangle \in L$, $u,v \in \Phi$. Then for the p-adic homogeneous λ-model (2.1) on the Cayley tree of order k $(k \geqslant 1)$ the Eq. (4.5) has a unique solution.

(ii) Let $p=2$, $|\lambda(u,v)|_2 \leqslant 1/2^2$ for all $\langle x,y\rangle \in L$, $u,v \in \Phi$ and the following condition be satisfied:

$$|\exp_p(\lambda(1,1))\exp_p(\lambda(-1,-1)) - \exp_p(\lambda(-1,1))\exp_p(\lambda(1,-1))|_2 \leqslant \frac{1}{2^3}. \tag{4.12}$$

Then for the 2-adic homogeneous λ-model (2.1) on the Cayley tree of order k $(k \geqslant 1)$ the Eq. (4.5) has a unique solution.

Theorem 4.6: *Let the condition of the previous Proposition be satisfied. Then for the p-adic*

homogeneous λ*-model (2.1) on the Cayley tree of order k there is no phase transition for any prime p*.

Proof: In the homogeneous model (4.2) is written as

$$z_x = \prod_{i=1}^{k} \alpha_{x,i}, \tag{4.13}$$

here

$$\alpha_{x,i} = \frac{az_{x_i}+b}{cz_{x_i}+d},$$

where as before $z_x = \exp_p(h_x), z_{x_i} = \exp_p(h_{x_i})$, and the coefficients a,b,c,d are defined by (4.6).

Let ζ be a solution of (4.7). Then using (4.13) we have

$$\begin{aligned}
|z_x-\zeta|_p &= \left|\prod_{i=1}^{k}\left(\frac{az_{x_i}+b}{cz_{x_i}+d}\right)-\left(\frac{a\zeta+b}{c\zeta+d}\right)^k\right|_p \\
&= \left|\prod_{i=1}^{k}\left(\frac{az_{x_i}+b}{cz_{x_i}+d}\right)-\left(\frac{az_{x_k}+b}{cz_{x_k}+d}\right)\left(\frac{a\zeta+b}{c\zeta+d}\right)^{k-1}+\left(\frac{az_{x_k}+b}{cz_{x_k}+d}\right)\left(\frac{a\zeta+b}{c\zeta+d}\right)^{k-1}-\left(\frac{a\zeta+b}{c\zeta+d}\right)^k\right|_p \\
&\leqslant \max\left\{\left|\frac{az_{x_k}+b}{cz_{x_k}+d}\right|_p\left|\prod_{i=1}^{k-1}\left(\frac{az_{x_i}+b}{cz_{x_i}+d}\right)-\left(\frac{a\zeta+b}{c\zeta+d}\right)^{k-1}\right|_p, \left|\frac{a\zeta+b}{c\zeta+d}\right|_p^{k-1}\left|\frac{az_{x_k}+b}{cz_{x_k}+d}-\frac{a\zeta+b}{c\zeta+d}\right|_p\right\} \\
&= \max\left\{\left|\frac{az_{x_k}+b}{cz_{x_k}+d}\right|_p\left|\prod_{i=1}^{k-1}\left(\frac{az_{x_i}+b}{cz_{x_i}+d}\right)-\left(\frac{a\zeta+b}{c\zeta+d}\right)^{k-1}\right|_p, \frac{|z_{x_k}-\zeta|_p|ad-bc|_p}{|cz_{x_k}+d|_p|c\zeta+d|_p}\right\} \\
&\leqslant \cdots \leqslant \max\left\{\frac{|z_{x_k}-\zeta|_p|ad-bc|_p}{|cz_{x_k}+d|_p|c\zeta+d|_p}\right\} \leqslant \frac{1}{p}\max_{1\leqslant m\leqslant k}\{|z_{x_m}-\zeta|_p\}.
\end{aligned}$$

Now repeating the argument of the proof of Theorem 4.4 we obtain $z_x=\zeta$ for all $x\in V$. This completes the proof.

V. APPLICATIONS TO *p*-ADIC ISING MODEL

In this section we will show that the phase transition does not occur for the *p*-adic Ising model.

Recall the *p*-adic Ising model. This model is a particular case of λ-model, namely it corresponds to the function:

$$\lambda_{x,y}(u,v) = J_{x,y}uv + \eta(u+v), \tag{5.1}$$

here $|J_{x,y}|\leqslant p^{-1/(p-1)}$, $|\eta|_p \leqslant p^{-1/(p-1)}$ and $\langle x,y\rangle \in L$, $u,v\in\{-1,1\}$.

First consider the case $\eta=0$, this corresponds to the inhomogeneous *p*-adic Ising model without external field. For the considered model it is easy to see that the condition (4.1) is satisfied. So according to Theorem 4.4 we infer that the following

Theorem 5.1: *Let* $k\geqslant 1$, $|J_{x,y}|_p \leqslant p^{-1/(p-1)}$ *for all* $\langle x,y\rangle \in L$. *Then for the p-adic inhomogeneous Ising model on the Cayley tree of order k there is no phase transition for any prime p*.

Now consider a case $J_{x,y}=J$ for all $\langle x,y\rangle\in L$ and $\eta\neq 0$. This corresponds to the homogeneous *p*-adic Ising model with an external field.

Let $p=2$, then the condition (4.12) can be written as follows:

$$|\exp_p(J+2\eta)\exp_p(J-2\eta)-\exp_p(-J)\exp_p(-J)|_2=|\exp_p(4J)-1|_2=|4J|_2\leqslant\frac{1}{2^4},$$

here we have used Lemma 2.1. Hence (4.12) is satisfied. So we can formulate the following.

Theorem 5.2: *Let* $k\geqslant 1$, $|\eta|_p\leqslant p^{-1/(p-1)}$ *and* $|J|_p\leqslant p^{-1/(p-1)}$ *for all* $\langle x,y\rangle\in L$. *Then for the p-adic homogeneous Ising model on the Cayley tree of order k there is no phase transition for any prime p*.

Remark: It is known[5,16] that for the Ising model on the Cayley tree of order $k\geqslant 2$ over $\mathbb{R}$ on some condition upon parameter $J_{x,y}$ there is a phase transition. Theorems 5.1 and 5.2 show the difference between the real Ising model and the considered *p*-adic one.

On extremal quantum states of composite systems with fixed marginals

Oliver Rudolph
Quantum Information Theory Group, Dipartimento di Fisica "A. Volta," Università degli Studi di Pavia, via Bassi 6, I-27100 Pavia, Italy

(Received 5 March 2004; accepted 1 June 2004; published 19 October 2004)

We study the convex set $\mathcal{C}(\rho_1,\rho_2)$ of all bipartite quantum states with fixed marginal states ρ_1 and ρ_2. The extremal states in this set have recently been characterized by Parthasarathy [Ann. Henri Poincaré (to appear), quant-ph/0307182]. Here we present an alternative necessary and sufficient condition for a state in $\mathcal{C}(\rho_1,\rho_2)$ to be extremal. Our approach is based on a canonical duality between bipartite states and a certain class of completely positive maps and has the advantage that it is easier to check and to construct explicit examples of extremal states. In dimension 2×2 we give a simple new proof for the fact that all extremal states in $\mathcal{C}(\frac{1}{2}\mathbb{1},\frac{1}{2}\mathbb{1})$ are precisely the projectors onto maximally entangled wave functions. We also prove that in higher dimension this does not hold and construct an explicit example of an extremal state in $\mathcal{C}(\frac{1}{3}\mathbb{1},\frac{1}{3}\mathbb{1})$ that is not maximally entangled. Generalizations of this result to higher dimensions are also discussed. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1776642]

I. INTRODUCTION

In the paradigmatic situation encountered in quantum information processing, two or more (often spatially separated) parties share the different parts of a composite quantum system. The parties are able to perform arbitrary operations on their respective parts "locally" and to communicate classically among each other to orchestrate their actions. The fundamental realization in quantum information theory is that sharing the parts of a composite quantum system can enable the parties to perform certain communication or information processing tasks more efficiently than classically (see Ref. 1 for an introduction). Mathematically this setting raises a number of new and interesting structural questions. Among them the study of quantum channels and the characterization of quantum entanglement play a central role.[2–4] The present work is devoted to the characterization of the set of quantum states with fixed marginal states. This problem was recently posed and studied in detail by Parthasarathy.[5] Let $\mathcal{H}_1$ and $\mathcal{H}_2$ be two finite dimensional complex Hilbert spaces, corresponding to two finite level quantum systems S_1 and S_2. Without loss of generality we assume that $d:=\dim(\mathcal{H}_1)=\dim(\mathcal{H}_2)$. (Otherwise we embed the lower dimensional Hilbert space into the larger one.) The states for S_i are given by the positive operators on $\mathcal{H}_i$ with trace one. We denote the set of all states on $\mathcal{H}_i$ by $\mathsf{S}(\mathcal{H}_i)$. The composite quantum system S_{12} of S_1 and S_2 is described by the tensor product $\mathcal{H}_1\otimes\mathcal{H}_2$. A *state* for S_{12} is a positive operator on $\mathcal{H}_1\otimes\mathcal{H}_2$ with trace one. The space of all states is denoted by $\mathsf{S}(\mathcal{H}_1\otimes\mathcal{H}_2)$. Consider $\rho\in\mathsf{S}(\mathcal{H}_1\otimes\mathcal{H}_2)$. The *reductions* or *marginal states* of ρ are given by $\rho_1:=\mathrm{tr}_2(\rho)\in\mathsf{S}(\mathcal{H}_1)$ and $\rho_2:=\mathrm{tr}_1(\rho)\in\mathsf{S}(\mathcal{H}_2)$. Here tr_1 and tr_2 denote the partial traces over $\mathcal{H}_1$ and $\mathcal{H}_2$, respectively. Now fix $\rho_1\in\mathsf{S}(\mathcal{H}_1)$ and $\rho_2\in\mathsf{S}(\mathcal{H}_2)$. We denote by $\mathcal{C}(\rho_1,\rho_2)$ the convex set of all states $\rho\in\mathsf{S}(\mathcal{H}_1\otimes\mathcal{H}_2)$ whose marginal states are equal to ρ_1 and ρ_2, respectively. The set of extreme points of $\mathcal{C}(\rho_1,\rho_2)$ will be denoted by $\mathcal{E}(\rho_1,\rho_2)$. Throughout this paper we will denote the set of all operators on a Hilbert space $\mathcal{H}$ by $\mathsf{L}(\mathcal{H})$. The identity in $\mathsf{L}(\mathcal{H})$ is denoted by $\mathbb{1}$, or, when $\mathcal{H}$ is d-dimensional, by $\mathbb{1}_d$. Slightly abusing the notation we will also denote the identity map from $\mathsf{L}(\mathcal{H})$ into itself by $\mathbb{1}$.

In his work[5] Parthasarathy presented a necessary and sufficient condition for an element $\rho\in\mathcal{C}(\rho_1,\rho_2)$ to be an extreme point. This was then used to derive an upper bound on the rank of such an extremal state. In the special case $\mathcal{H}_1=\mathcal{H}_2=\mathbb{C}^2$ and $\rho_1=\rho_2=\frac{1}{2}\mathbb{1}_2$, Parthasarathy found that

a state $\rho \in \mathcal{C}(\frac{1}{2}\mathbb{1}_2, \frac{1}{2}\mathbb{1}_2)$ is extremal if and only if it is a projector onto the subspace spanned by a maximally entangled wave function. A wave function in $\mathbb{C}^2 \otimes \mathbb{C}^2$ is called maximally entangled if it is of the form $|\psi_+\rangle = (1/\sqrt{2})(|0\rangle|\phi_0\rangle + |1\rangle|\phi_1\rangle)$ where $\{|0\rangle, |1\rangle\}$ denotes the canonical basis of $\mathbb{C}^2$ and where $\{|\phi_0\rangle, |\phi_1\rangle\}$ is any other orthonormal basis of $\mathbb{C}^2$. For higher dimensions the question of whether or not there are extremal states with maximally mixed marginals—i.e., states in $\mathcal{E}(\frac{1}{d}\mathbb{1}, \frac{1}{d}\mathbb{1})$—that are not projectors onto maximally entangled wave functions was left open in Ref. 5.

In the present work we present an alternative approach to the characterization of $\mathcal{E}(\rho_1, \rho_2)$ that transforms the problem into that of finding the extreme points of a certain convex set of completely positive maps that satisfy an additional requirement. This will allow us to derive an alternative necessary and sufficient condition for a state $\rho \in \mathcal{C}(\rho_1, \rho_2)$ to be extremal. We will then study the special case of states with maximally mixed marginals, i.e., when $\rho_1 = \rho_2 = (1/d)\mathbb{1}$. For $d = 2$ we will give a simple proof for Parthasarathy's result that the extremal states are exactly the projectors onto maximally entangled wave functions. For $d > 2$ our results imply that there are extremal states in $\mathcal{E}(\mathbb{1}/d, \mathbb{1}/d)$ that are not projectors onto maximally entangled pure states. We give an explicit example for an extremal state on $\mathbb{C}^3 \otimes \mathbb{C}^3$ with maximally mixed marginals that is not equal to a projector onto a maximally entangled wave function. Finally, we discuss generalizations of this result to higher dimensions.

II. DUALITY BETWEEN BIPARTITE STATES AND COMPLETELY POSITIVE MAPS

The approach in the present paper relies upon a duality between bipartite quantum states on $\mathcal{H}_1 \otimes \mathcal{H}_2$ and completely positive maps $\Lambda : \mathsf{L}(\mathcal{H}_2) \to \mathsf{L}(\mathcal{H}_1)$ that preserve the trace of the completely mixed state, i.e., that satisfy $\mathrm{tr}(\Lambda((1/d)\mathbb{1})) = 1$ (this is very often called the *Jamiołkowski isomorphism*, see Ref. 6 and, for a related duality, Ref. 2). A map $\Lambda : \mathsf{L}(\mathcal{H}_2) \to \mathsf{L}(\mathcal{H}_1)$ is called completely positive if $\Lambda \otimes \mathbb{1} : \mathsf{L}(\mathcal{H}_2 \otimes \mathcal{K}) \to \mathsf{L}(\mathcal{H}_1 \otimes \mathcal{K})$ is positive for any finite dimensional ancilla Hilbert space $\mathcal{K}$.

We make the identification $\mathcal{H}_1 \simeq \mathbb{C}^d$ and $\mathcal{H}_2 \simeq \mathbb{C}^d$. In other words, we pick orthonormal bases in $\mathcal{H}_1$ and $\mathcal{H}_2$ and identify them with the canonical real basis in $\mathbb{C}^d$ and $\mathbb{C}^d$, respectively. We denote these bases by $\{|i\rangle_1\}_{i=1}^d$ and $\{|i\rangle_2\}_{i=1}^d$, respectively. Finally, we introduce the maximally entangled pure wave function

$$|\psi_+\rangle := \frac{1}{\sqrt{d}} \sum_{i=1}^{d} |i\rangle_2 |i\rangle_2 \in \mathcal{H}_2 \otimes \mathcal{H}_2.$$

The duality between bipartite state and completely positive maps depends explicitly on this choice for the canonical bases. Let $\Lambda : \mathsf{L}(\mathcal{H}_2) \to \mathsf{L}(\mathcal{H}_1)$ be a completely positive map with $\mathrm{tr}(\Lambda((1/d)\mathbb{1})) = 1$. Then

$$\rho_\Lambda := \Lambda \otimes \mathbb{1}(|\psi_+\rangle\langle\psi_+|) \tag{1a}$$

defines a bipartite state on $\mathcal{H}_1 \otimes \mathcal{H}_2$. The complete positivity of Λ ensures that $\rho \geqslant 0$ while the condition $\mathrm{tr}(\Lambda((1/d)\mathbb{1})) = 1$ ensures that $\mathrm{tr}(\rho_\Lambda) = 1$.

Conversely, let ρ be a bipartite state on $\mathcal{H}_1 \otimes \mathcal{H}_2$. Then

$$\Lambda_\rho(\sigma) := d\,\mathrm{tr}_2[(\mathbb{1} \otimes \sigma^{\mathsf{T}}\rho)] \tag{1b}$$

defines a completely positive map $\Lambda_\rho : \mathsf{L}(\mathcal{H}_2) \to \mathsf{L}(\mathcal{H}_1)$ that satisfies $\mathrm{tr}(\Lambda_\rho((1/d)\mathbb{1})) = 1$. Here $^{\mathsf{T}}$ denotes the transposition with respect to the canonical real basis. By explicit calculation one checks that for a given Λ we have $\Lambda_{\rho_\Lambda} = \Lambda$ and for a given ρ we have $\rho_{\Lambda_\rho} = \rho$. Thus the correspondence $\Lambda \leftrightarrow \rho$ described by Eqs. (1a) and (1b) is bijective.[6]

III. JOINT LINEAR INDEPENDENCE

To formulate the main result in this paper it is useful to introduce the concept of *joint linear independence* of two families of vectors. In the following definition $X^{\times r}$ denotes the r-fold Cartesian product of the set X by itself.

Definition 1: *Let V and W be complex vector spaces. Then two ordered r-tuples $(v_i)_{i=1}^r \in V^{\times r}$ and $(w_i)_{i=1}^r \in W^{\times r}$ are called* jointly linearly independent *if the family $\{v_i \oplus w_i\}_{i=1}^r$ in the direct sum $V \oplus W$ is a linearly independent family*.

Notice that this definition depends on the order of the r-tuples. The following is an immediate consequence of the definition.

Lemma 1: *Let V and W be complex vector spaces and let $(v_i)_{i=1}^r \in V^{\times r}$ and $(w_i)_{i=1}^r \in W^{\times r}$ be two ordered r-tuples of vectors. If $\{v_i\}_{i=1}^r$ is linearly independent in V or if $\{w_i\}_{i=1}^r$ is linearly independent in W, then $(v_i)_{i=1}^r$ and $(w_i)_{i=1}^r$ are jointly linearly independent.*

Notice that the converse implication does not hold in general. If $\{v_i\}_{i=1}^r$ is linearly dependent in V and if $\{w_i\}_{i=1}^r$ is linearly dependent in W, then $\{v_i \oplus w_i\}_{i=1}^r$ is not necessarily linearly dependent in $V \oplus W$.

Lemma 2: *Let V be a complex *-algebra and let $(v_j)_{j=1}^r \in V^{\times r}$ be an ordered r-tuple of elements. If $\{v_j\}_j$ is linearly dependent, then the r^2-tuples $(v_i^* v_j)_{ij}$ and $(v_j v_i^*)_{ij}$ cannot be jointly linearly independent.*

Proof: Since $\{v_j\}_j$ is linearly dependent, there exist $(\lambda_j)_j \in \mathbb{C}^r$ such that $\lambda_{j_0} \neq 0$ for some j_0 and $\Sigma_{j=1}^r \lambda_j v_j = 0$. Therefore also $\Sigma_{ij} \delta_{ii_0} \lambda_j (v_i^* v_j, v_j v_i^*) = 0$ for all i_0. □

IV. EXTREMAL STATES IN $\mathcal{C}(\rho_1, \rho_2)$

Let $\rho \in \mathcal{C}(\rho_1, \rho_2)$. In $\mathcal{H}_2$ consider an orthonormal basis of eigenvectors of ρ_2, i.e., $\rho_2 = \Sigma_i r_i |r_i\rangle\langle r_i|$. We identify the basis $\{|r_i\rangle\}_{i=1}^d$ of eigenvectors of ρ_2 with the canonical real basis of $\mathcal{H}_2 \simeq \mathbb{C}^d$. Further, we write

$$|\psi_+\rangle := \frac{1}{\sqrt{d}} \sum_i |r_i\rangle \otimes |r_i\rangle. \tag{2}$$

In the sequel it is always understood that the bijection between states and completely positive maps from Sec. II is with respect to this choice of the canonical basis and that the maximally entangled state in Eq. (1a) is the state from Eq. (2). To every state $\rho \in \mathcal{C}(\rho_1, \rho_2)$ Eq. (1b) gives a unique completely positive map Λ_ρ that satisfies

$$\Lambda_\rho(\mathbb{1}) = d\rho_1, \tag{3a}$$

$$\Lambda'_\rho(\mathbb{1}) = d\rho_2. \tag{3b}$$

Here Λ'_ρ denotes the canonical dualization of Λ_ρ defined by $\mathrm{tr}(\Lambda'_\rho(x)y) = \mathrm{tr}(x\Lambda_\rho(y))$ for all y. In terms of the Kraus representation of $\Lambda_\rho(x) = \Sigma_j V_j^\dagger x V_j$ the conditions (3a) and (3b) can be expressed as

$$\sum_j V_j^\dagger V_j = d\rho_1, \tag{4a}$$

$$\sum_j V_j V_j^\dagger = d\rho_2. \tag{4b}$$

We denote the set of all completely positive maps $\Lambda : \mathsf{L}(\mathcal{H}_2) \to \mathsf{L}(\mathcal{H}_1)$ satisfying the conditions (3a) and (3b) by $\mathrm{CP}(\mathcal{H}_2, \mathcal{H}_1, \rho_1, \rho_2)$. It is clear that $\mathrm{CP}(\mathcal{H}_2, \mathcal{H}_1, \rho_1, \rho_2)$ is a convex set. The bijection described in (1a) and (1b) obviously respects the convex structure. In particular it establishes a bijection between $\mathcal{E}(\rho_1, \rho_2)$ and the extreme points of $\mathrm{CP}(\mathcal{H}_2, \mathcal{H}_1, \rho_1, \rho_2)$.

We are now ready to state our main result.

Theorem 1: *Let* $\Lambda:\mathsf{L}(\mathcal{H}_2)\to\mathsf{L}(\mathcal{H}_1)$ *be a completely positive map in* $\mathrm{CP}(\mathcal{H}_2,\mathcal{H}_1,\rho_1,\rho_2)$. *Then* Λ *is extreme in* $\mathrm{CP}(\mathcal{H}_2,\mathcal{H}_1,\rho_1,\rho_2)$ *if and only if* Λ *admits an expression* $\Lambda(x)=\Sigma_j V_j^\dagger x V_j$ *for all* $x\in\mathsf{L}(\mathcal{H}_2)$, *where* V_i *are* $d\times d$ *matrices, satisfying the following conditions*:

(i) $\Sigma_j V_j^\dagger V_j = d\rho_1$,
(ii) $\Sigma_j V_j V_j^\dagger = d\rho_2$, *and*
(iii) $(V_i^\dagger V_j)_{ij}$ *and* $(V_j V_i^\dagger)_{ij}$ *are jointly linearly independent.*

For the proof of Theorem 1 we need the following lemma. For a proof see Remark 4 in Ref. 7.

Lemma 3: Let Λ *be a completely positive map with Kraus representation* $\Lambda(x)=\Sigma_j V_j^\dagger x V_j$ *with* $\{V_j\}_j^\ell$ *linearly independent. Let* $\{W_p\}_p^{\ell'}$ *be a class of* $d\times d$ *matrices, then* Λ *has the expression* $\Lambda(x)=\Sigma_p^{\ell'} W_p^\dagger x W_p$ *if and only if there exists an isometric* $\ell'\times\ell$ *matrix* $(\mu_{pi})_{pi}$, *such that* $W_p=\Sigma_i\mu_{pi}V_i$ *for all* p.

Proof of Theorem 1: The proof is an only slight modification and generalization of the proof of Theorem 5 in Ref. 7. We include it for the convenience of the reader. First assume that Λ is extremal in $\mathrm{CP}(\mathcal{H}_2,\mathcal{H}_1,\rho_1,\rho_2)$. We express Λ in Kraus form $\Lambda(x)=\Sigma_j V_j^\dagger x V_j$. Without loss of generality we can assume that $\{V_j\}_j$ is linearly independent.[7] Now suppose that $\Sigma\lambda_{ij}V_i^\dagger V_j=0$ and $\Sigma_{ij}\lambda_{ij}V_jV_i^\dagger=0$. We need to show that $\lambda_{ij}=0$. Without loss of generality we can assume that $(\lambda_{ij})_{ij}$ is a Hermitian matrix and $-\mathbb{1}\leqslant(\lambda_{ij})_{ij}\leqslant\mathbb{1}$ (for details see Ref. 7).

Define $\Phi_\pm:\mathsf{L}(\mathcal{H}_2)\to\mathsf{L}(\mathcal{H}_1)$ by $\Phi_\pm(x):=\Sigma_j V_j^\dagger x V_j\pm\Sigma_{ij}\lambda_{ij}V_i^\dagger x V_j$. Hence $\Phi_\pm(\mathbb{1})=d\rho_1$ and $\Phi'_\pm(\mathbb{1})=d\rho_2$ We set $\mathbb{1}+(\lambda_{ij})_{ij}=(\alpha_{ij})_{ij}^\dagger(\alpha_{ij})_{ij}\geqslant 0$ and $W_i:=\Sigma_j\alpha_{ij}V_j$ By direct computation, $\Phi_+(x)=\Sigma_i W_i^\dagger x W_i$. Hence Φ_+ is completely positive. Similarly it can be shown that Φ_- is completely positive. Since Λ is extremal, we find that $\Lambda=\Phi_+$. Therefore by Lemma 3 $(\alpha_{ij})_{ij}$ is an isometry and $\mathbb{1}+(\lambda_{ij})_{ij}=\mathbb{1}$. This implies $(\lambda_{ij})_{ij}=0$.

Now assume that Λ admits a representation of the form $\Lambda(x)=\Sigma_j V_j^\dagger x V_j$ for all $x\in\mathsf{L}(\mathcal{H}_2)$ where $\Sigma_j V_j^\dagger V_j=d\rho_1$, $\Sigma_j V_j V_j^\dagger=d\rho_2$, and $(V_i^\dagger V_j)_{ij}$ and $(V_jV_i^\dagger)_{ij}$ are jointly linearly independent. By Lemma 2 also $\{V_j\}_j$ is linearly independent. Now suppose $\Lambda=\frac{1}{2}(\Phi_1+\Phi_2)$ with $\Phi_1(x)=\Sigma_p W_p^\dagger x W_p$, $\Phi_2(x)=\Sigma_q Z_q^\dagger x Z_q$, and $\Sigma_p W_p^\dagger W_p=\Sigma_q Z_q^\dagger Z_q=d\rho_1$, $\Sigma_p W_p W_p^\dagger=\Sigma_q Z_q Z_q^\dagger=d\rho_2$ Since $\Lambda(x)=\frac{1}{2}\Sigma_p W_p^\dagger x W_p+\frac{1}{2}\Sigma_q Z_q^\dagger x Z_q$, it follows by Lemma 3 that W_p and Z_q can be expressed as a linear combination of the V_j. Let $W_p=\Sigma_i\mu_{pi}V_i$ for all p. Then $\Sigma_j V_j^\dagger V_j=\Sigma_p W_p^\dagger W_p=\Sigma_{pij}\mu_{pi}^*\mu_{pj}V_i^\dagger V_j$ and $\Sigma_j V_jV_j^\dagger=\Sigma_p W_pW_p^\dagger=\Sigma_{pij}\mu_{pi}^*\mu_{pj}V_jV_i^\dagger$. The joint linear independence of $(V_i^\dagger V_j)_{ij}$ and $(V_jV_i^\dagger)_{ij}$ implies $\Sigma_p\mu_{pi}^*\mu_{pj}=\delta_{ij}$. In other words $(\mu_{pi})_{pi}$ is an isometry. By Lemma 3, we conclude that $\Lambda=\Phi_1$ Thus Λ is extremal in $\mathrm{CP}(\mathcal{H}_2,\mathcal{H}_1,\rho_1,\rho_2)$. □

Corollary 1: Let $\rho\in\mathcal{C}(\rho_1,\rho_2)$. *Write the spectral decomposition of* ρ_2 *as* $\rho_2=\Sigma_i r_i|r_i\rangle\langle r_i|$. *Then* $\rho\in\mathcal{E}(\rho_1,\rho_2)$ *if and only if there exists a family of* $d\times d$ *matrices* $\{V_j\}$ *such that* ρ *can be expressed as*

$$\rho=\frac{1}{d}\sum_{ijk}V_j^\dagger|r_i\rangle\langle r_k|V_j\otimes|r_i\rangle\langle r_k|,$$

where $\{V_j\}_j$ *satisfy the following conditions:*

(i) $\Sigma_j V_j^\dagger V_j=d\rho_1$,
(ii) $\Sigma_j V_j V_j^\dagger=d\rho_2$, *and*
(iii) $(V_i^\dagger V_j)_{ij}$ *and* $(V_jV_i^\dagger)_{ij}$ *are jointly linearly independent.*

Remark 1: Suppose $\Lambda:\mathsf{L}(\mathcal{H}_2)\to\mathsf{L}(\mathcal{H}_1)$ *is completely positive. Then we can write* $\Lambda(x)=\Sigma_j V_j^\dagger x V_j$ *where* $\{V_j\}_{i=1}^\ell$ *is a class of linearly independent* $d\times d$ *matrices. Therefore* $\ell\leqslant d^2$. *If* Λ *is extremal in* $\mathrm{CP}(\mathcal{H}_2,\mathcal{H}_1,\rho_1,\rho_2)$, *we can conclude that* $\ell\leqslant\sqrt{2}d$. *Indeed,* $(V_i^\dagger V_j)_{ij}$ *and* $(V_jV_i^\dagger)_{ij}$ *are jointly linearly independent only if the cardinal number of* $\{V_i^\dagger V_j\oplus V_jV_i^\dagger\}_{ij}$ *is smaller than* $\dim(\mathsf{L}(\mathcal{H}_2))+\dim(\mathsf{L}(\mathcal{H}_1))$. *In other words,* $\ell^2\leqslant 2d^2$, i.e., $\ell\leqslant\sqrt{2}d$. *Parthasarathy found a slightly stronger bound in* Ref. 5. $\ell\leqslant\sqrt{2d^2-1}$ *It is not known whether this bound is tight.*

Remark 2: The bound $\ell\leqslant\sqrt{2}d$ *also implies that for any* $\rho\in\mathcal{E}(\rho_1,\rho_2)$ *we have* $\mathrm{rank}(\rho)\leqslant\sqrt{2}d$. *In all dimensions* $d\geqslant 2$ *this implies that any* $\rho\in\mathcal{E}(\rho_1,\rho_2)$ *is singular.*

V. EXAMPLES

A. A two dimensional example

Consider $\mathbb{C}^2\otimes\mathbb{C}^2$ and the convex set $\mathcal{C}(\frac{1}{2}\mathbb{1},\frac{1}{2}\mathbb{1})$ of states on $\mathbb{C}^2\otimes\mathbb{C}^2$ with maximally mixed marginals. This is a physically interesting example. It was previously studied in Ref. 5.

Assume that $\rho\in\mathcal{E}(\frac{1}{2}\mathbb{1},\frac{1}{2}\mathbb{1})$, i.e., that ρ is extremal in $\mathcal{C}(\frac{1}{2}\mathbb{1},\frac{1}{2}\mathbb{1})$. By Corollary 1 there is a linearly independent family of 2×2 matrices $\{V_i\}_{i=1}^{\ell}$ such that

$$\rho=\frac{1}{2}\sum_{ijk} V_j^\dagger|r_i\rangle\langle r_k|V_j\otimes|r_i\rangle\langle r_k|,$$

where $\{V_j\}$ satisfy the following conditions:

$$\sum_j V_j^\dagger V_j=\mathbb{1}_2, \tag{5a}$$

$$\sum_j V_j V_j^\dagger=\mathbb{1}_2, \tag{5b}$$

and where $(V_i^\dagger V_j)_{ij}$ and $(V_jV_i^\dagger)_{ij}$ are jointly linearly independent.

By Remark 1 either $\ell=1$ or $\ell=2$. In the case $\ell=1$, the matrix V_1 is unitary and it follows from Corollary 1 that ρ is equal to the projector onto the subspace spanned by a maximally entangled wave function.

Now consider the case $\ell=2$. Consider the singular value decompositions of V_1 and V_2, respectively, i.e., $V_1=\Sigma_{s=1}^2\sqrt{\nu_s(1)}|\varphi_s\rangle\langle\psi_s|$ and $V_2=\Sigma_{s=1}^2\sqrt{\nu_s(2)}|\varphi_s'\rangle\langle\psi_s'|$, where $\nu_s(i)$ are non-negative coefficients and where $\{|\psi_s\rangle\}_{s=1}^2$, $\{|\psi_s'\rangle\}_{s=1}^2$, $\{|\varphi_s\rangle\}_{s=1}^2$ and $\{|\varphi_s'\rangle\}_{s=1}^2$ are four orthonormal bases of $\mathbb{C}^2$. Then $V_1^\dagger V_1=\Sigma_{s=1}^2\nu_s(1)|\psi_s\rangle\langle\psi_s|$, $V_2^\dagger V_2=\Sigma_{s=1}^2\nu_s(2)|\psi_s'\rangle\langle\psi_s'|$, $V_1V_1^\dagger=\Sigma_{s=1}^2\nu_s(1)|\varphi_s\rangle\langle\varphi_s|$ and $V_2V_2^\dagger=\Sigma_{s=1}^2\nu_s(2)|\varphi_s'\rangle\langle\varphi_s'|$.

First consider the case of degenerate singular values, i.e., assume $\nu_1(1)=\nu_2(1)$. Then $V_1^\dagger V_1=V_1V_1^\dagger=\nu_1(1)\mathbb{1}$ and $V_2^\dagger V_2=V_2V_2^\dagger=\nu_1(2)\mathbb{1}$. Moreover, (5a) and (5b) imply that $\nu_1(1)=1-\nu_1(2)$. However, this implies that $(V_i^\dagger V_j)_{ij}$ and $(V_jV_i^\dagger)_{ij}$ are not jointly linearly independent. By Corollary 1 ρ is not extremal in $\mathcal{C}(\frac{1}{2}\mathbb{1},\frac{1}{2}\mathbb{1})$. This is a contradiction.

Second, consider the case of nondegenerate singular values, i.e., $\nu_1(1)\neq\nu_2(1)$. In this case Eqs. (5a) and (5b) imply that $\nu_s(1)=1-\nu_s(2)$, $|\varphi_s\rangle=|\varphi_s'\rangle$ and $|\psi_s\rangle=|\psi_s'\rangle$ for $s=1$, 2. By direct computation it is easily verfied that $V_1^\dagger V_2=V_2^\dagger V_1$ and $V_1V_2^\dagger=V_2V_1^\dagger$. This implies that $(V_i^\dagger V_j)_{ij}$ and $(V_jV_i^\dagger)_{ij}$ are not jointly linearly independent. Again by Corollary 1 ρ is not extremal in $\mathcal{C}(\frac{1}{2}\mathbb{1},\frac{1}{2}\mathbb{1})$. A contradiction.

We summarize our results in the following proposition.

Proposition 1: In dimension 2×2 the extremal states in $\mathcal{C}(\frac{1}{2}\mathbb{1},\frac{1}{2}\mathbb{1})$ are precisely the projectors onto the subspaces spanned by maximally entangled pure wave functions.

Proposition 1 has previously been found, using different methods, by Parthasarathy in Ref. 5.

B. A three dimensional example

From the preceding example it is clear that also in higher dimensions all projectors onto the subspaces spanned by maximally entangled wave functions are extremal elements in $\mathcal{C}((1/d)\mathbb{1},(1/d)\mathbb{1})$. However, in the present section we show that the extension of Proposition 1 to higher dimensions does not hold. In other words the set of extremal states in $\mathcal{C}((1/d)\mathbb{1},(1/d)\mathbb{1})$ is not exhausted by the projectors onto maximally entangled pure states. Here we use our characterization of extremal states in $\mathcal{C}((1/d)\mathbb{1},(1/d)\mathbb{1})$ to construct an explicit counterexample in dimension 3×3.

Denote by $\{|i\rangle\}_{i=1}^3$ the canonical real orthonormal basis of $\mathbb{C}^3$. Define the following operators:

$$V_1 = \frac{1}{\sqrt{2}}(|1\rangle\langle 1| + |2\rangle\langle 3|), \tag{6a}$$

$$V_2 = \frac{1}{\sqrt{2}}(|2\rangle\langle 2| + |3\rangle\langle 1|), \tag{6b}$$

$$V_3 = \frac{1}{\sqrt{2}}(|3\rangle\langle 3| + |1\rangle\langle 2|). \tag{6c}$$

By explicit calculation one checks that $\Sigma_{j=1}^3 V_j^\dagger V_j = \Sigma_j^3 V_j V_j^\dagger = \mathbb{1}$. Moreover,

$$V_1^\dagger V_2 = V_3 V_1^\dagger = \tfrac{1}{2}|3\rangle\langle 2|, \tag{7a}$$

$$V_1^\dagger V_3 = V_3 V_2^\dagger = \tfrac{1}{2}|1\rangle\langle 2|, \tag{7b}$$

$$V_2^\dagger V_3 = V_1 V_2^\dagger = \tfrac{1}{2}|1\rangle\langle 3|, \tag{7c}$$

$$V_2^\dagger V_1 = V_1 V_3^\dagger = \tfrac{1}{2}|2\rangle\langle 3|, \tag{7d}$$

$$V_3^\dagger V_1 = V_2 V_3^\dagger = \tfrac{1}{2}|2\rangle\langle 1|, \tag{7e}$$

$$V_2^\dagger V_2 = V_2 V_3^\dagger = \tfrac{1}{2}|3\rangle\langle 1|. \tag{7f}$$

Hence $\{V_i^\dagger V_j\}_{ij}$ and $\{V_j V_i^\dagger\}_{ij}$ are both linearly independent and thus by Lemma 1 jointly linearly independent. By Corollary 1 the state

$$\rho := \frac{1}{3}\sum_{ijk=1}^{3} V_j^\dagger |i\rangle\langle k| V_j \otimes |i\rangle\langle k| \tag{8}$$

is extremal in $\mathcal{C}(\frac{1}{3}\mathbb{1}, \frac{1}{3}\mathbb{1})$. An explicit calculation gives the following matrix representation of ρ in the canonical product basis in lexicographic order:

$$\rho = \frac{1}{6}\begin{pmatrix} 1 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 1 \\ 0 & 0 & 1 & 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 1 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 1 \end{pmatrix}. \tag{9}$$

This state is entangled but not maximally entangled and an extremal element of $\mathcal{C}(\frac{1}{3}\mathbb{1}, \frac{1}{3}\mathbb{1})$.

C. Higher dimensions

It is possible to construct counterexamples to Proposition 1 also in higher dimensions. For instance, consider $\mathbb{C}^2 \otimes \mathbb{C}^2$. We denote the canonical basis of $\mathbb{C}^4$ as usual by $\{|1\rangle, |2\rangle, |3\rangle, |4\rangle\}$. The three dimensional example above can be generalized to dimension 4×4 by letting

$$V_1 = \frac{1}{\sqrt{3}}(|1\rangle\langle 1| + |2\rangle\langle 4| + |3\rangle\langle 2|),$$

$$V_2 = \frac{1}{\sqrt{3}}(|2\rangle\langle 2| + |3\rangle\langle 1| + |4\rangle\langle 3|),$$

$$V_3 = \frac{1}{\sqrt{3}}(|3\rangle\langle 3| + |4\rangle\langle 2| + |1\rangle\langle 4|),$$

$$V_4 = \frac{1}{\sqrt{3}}(|4\rangle\langle 4| + |1\rangle\langle 3| + |2\rangle\langle 1|).$$

It is straightforward to show that both $(V_i^\dagger V_j)_{ij}$ and $(V_j V_i^\dagger)_{ij}$ are linearly independent families. Thus an analysis similar to the one given above shows that

$$\rho := \frac{1}{4}\sum_{ijk=1}^{4} V_j^\dagger |i\rangle\langle k| V_j \otimes |i\rangle\langle k| \tag{10}$$

is extremal in $\mathcal{C}(\frac{1}{4}\mathbb{1}, \frac{1}{4}\mathbb{1})$ but is not a maximally entangled pure state. It is easy to construct similar counterexamples also in higher dimensions. It seems therefore likely that there are counterexamples to Proposition 1 in all dimensions greater than 2.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 45, NUMBER 11 NOVEMBER 2004

The Newtonian limit of the relativistic Boltzmann equation

Simone Calogero[a)]
Max Planck Institut für Gravitationphysik, Albert Einstein Institut Am Mühlenberg 1, 14476 Golm bei Potsdam, Germany,

(Received 28 April 2004; accepted 12 July 2004; published 19 October 2004)

The relativistic Boltzmann equation for a constant differential cross section and with periodic boundary conditions is considered. The speed of light appears as a parameter $c > c_0$ for a properly large and positive c_0. A local existence and uniqueness theorem is proved in an interval of time independent of $c > c_0$ and conditions are given such that in the limit $c \to +\infty$ the solutions converge, in a suitable norm, to the solutions of the nonrelativistic Boltzmann equation for hard spheres. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1793328]

I. INTRODUCTION

Our purpose in this paper is to show that solutions of the relativistic Boltzmann equation are well-approximated by solutions of the classical (nonrelativistic) Boltzmann equation. A more precise statement will be given later in the Introduction.

The relativistic Boltzmann equation can be written in the form

$$\partial_t f + \hat{p} \cdot \nabla_x f = Q_{\mathrm{rel}}(f,f), \tag{1.1}$$

where the various symbols have the following meaning. $f = f(t,x,p)$ is the distribution function in phase-space of a single nondegenerate relativistic gas. $\hat{p} = cp/p_0$ is the relativistic velocity, with c denoting the speed of light and $y_0 = \sqrt{c^2 + |y|^2}$. The molecular rest-mass is set to unity and the convention for the signature of Minkowski's metric is $(+---)$, so that $p_0 = p^0$. Finally, Q_{rel} is the relativistic collision operator defined by

$$Q_{\mathrm{rel}}(f,g) = \int_{\mathbb{R}^3} \int_{S^2} \mathcal{K}_c(p,q,\omega)[f(p')g(q') - f(p)g(q)]\mathrm{d}\omega\, \mathrm{d}q. \tag{1.2}$$

In the previous definition, p', q' are the momenta after the elastic collision of two particles with pre-collisional momenta p, q. These quantities are subjected to the conservation of momentum and energy, which read as

$$p + q = p' + q', \quad \mathcal{E}_c(p) + \mathcal{E}_c(q) = \mathcal{E}_c(p') + \mathcal{E}_c(q'), \quad \mathcal{E}_c(y) = cy_0. \tag{1.3}$$

A solution of (1.3) can be represented as

$$p' = p - a(p,q,\omega)\omega, \quad q' = q + a(p,q,\omega)\omega, \tag{1.4}$$

where

$$a(p,q,\omega) = \frac{2(p_0 + q_0)[c^{-1}\omega \cdot (\hat{p} - \hat{q})]p_0 q_0}{(p_0 + q_0)^2 - [\omega \cdot (p + q)]^2}.$$

Using this representation, the relativistic collision kernel $\mathcal{K}_c$ takes the form

a)Electronic mail: simcall@aei-potsdam.mpg.de

$$\mathcal{K}_c(p,q,\omega) = 16\sigma(c^2+\mathfrak{g}^2)\frac{(p_0+q_0)^2|\omega\cdot(\hat{p}-\hat{q})|}{[(p_0+q_0)^2-(\omega\cdot(p+q))^2]^2}, \tag{1.5}$$

$$\mathfrak{g} = \frac{1}{\sqrt{2}}(p_0q_0 - p\cdot q - c^2)^{1/2}. \tag{1.6}$$

Here $\mathfrak{g}$ is a Lorentz invariant defined so that $-2\mathfrak{g}$ is the relative momentum in the center of mass system and σ denotes the differential cross section. In general σ is a function of $\mathfrak{g}$ and of a second Lorentz invariant quantity which in the center of mass system reduces to the cosine of the scattering angle of the collision. In this article the differential cross section is assumed to be constant. As usual, the local dependence on (t,x) in (1.2) is omitted. This formulation of the relativistic Boltzmann equation for $c=1$ is derived for instance in Refs. 6,7. We refer to Refs. 1,3,5,10 for more background on the subject.

In this paper, the solutions of (1.1) will be directly compared to the solutions of the classical Boltzmann equation for hard spheres, which is

$$\partial_t f_\infty + p\cdot\nabla_x f_\infty = Q_{\mathrm{cl}}(f_\infty, f_\infty), \tag{1.7}$$

where

$$Q_{\mathrm{cl}}(f,g) = d\int_{\mathbb{R}^3}\int_{S^2}|\omega\cdot(p-q)|[f(\overline{p})g(\overline{q}) - f(p)g(q)]\mathrm{d}\omega\,\mathrm{d}q. \tag{1.8}$$

The meaning of the various symbols in (1.7) is the same as in the relativistic case. The post-collisional momenta are now denoted by $\overline{p},\overline{q}$, the conservation of momentum and energy take the form $p+q=\overline{p}+\overline{q}$ and $\frac{1}{2}|p|^2+\frac{1}{2}|q|^2=\frac{1}{2}|\overline{p}|^2+\frac{1}{2}|\overline{q}|^2$, respectively, while the analog of (1.4) in the classical case is

$$\overline{p} = p - \omega\cdot(p-q)\omega, \quad \overline{q} = q + \omega\cdot(p-q)\omega. \tag{1.9}$$

The factor d in (1.8) is the differential cross section for hard spheres interaction, which is a constant with the same dimensions as σ, namely $[length]^2$. A standard mathematical reference for the classical Boltzmann equation is Ref. 4.

In this paper it is shown that there is a class of solutions to the relativistic Boltzmann equation which have a Newtonian limit, i.e., which tend to solutions of the classical Boltzmann equation (in the corresponding class) as the speed of light goes to infinity. For this purpose, the speed of light will be treated as a parameter $c>c_0$—where c_0 is a fixed and properly large positive constant—and the difference between the classical and the relativistic solution will be estimated as $c\to+\infty$. (No loss of generality arises in letting $c>c_0$, since only the limit behavior as $c\to+\infty$ is of interest here.) In order to obtain the correct Newtonian limit it is also necessary to relate the constants d and σ in a proper way. From (1.5) it follows that $\mathcal{K}_c(p,q,\omega)\to 4\sigma|\omega\cdot(p-q)|$ as $c\to+\infty$. This leads to *postulate* the relation $4\sigma=d$. By further choosing units such that $d=1$, the classical collision kernel reduces to $|\omega\cdot(p-q)|$, while the relativistic collision kernel becomes

$$\mathcal{K}_c(p,q,\omega) = 2(p_0q_0 - p\cdot q + c^2)\frac{(p_0+q_0)^2|\omega\cdot(\hat{p}-\hat{q})|}{[(p_0+q_0)^2-(\omega\cdot(p+q))^2]^2}. \tag{1.10}$$

The precise formulation of the result will be now given. The conditions on the distribution functions mentioned in the theorem are introduced thereafter. The symbol $\mathbb{T}^3$ denotes the three-torus and the norm $\|\ \|_{0,1}$ is defined as follows:

$$\|g(t)\|_{0,1} = \int_{\mathbb{R}^3}|g(t,p)|_0\mathrm{d}p, \quad |g(t,p)|_0 = \sup_{x\in\mathbb{T}^3}|g(t,x,p)|.$$

Theorem 1: *Let $f_\infty(t)$ be a solution of* (1.7) *which satisfies the properties (C1), (C2) and with initial datum $f_\infty^{\mathrm{in}} \in C^1$ such that $|\nabla_p f_\infty^{\mathrm{in}}|_0 \in L^1(\mathbb{R}^3)$. Let $f_c(t)$ be a solution of* (1.1), *depending on $c > c_0$, which satisfies the properties (R1)–(R3) and with the c-dependent initial datum f_c^{in}. Assume $\|f_\infty^{\mathrm{in}} - f_c^{\mathrm{in}}\|_{0,1} = O(c^{-1})$ as $c \to +\infty$. Then*

$$\lim_{c \to +\infty} \|f_\infty(t) - f_c(t)\|_{0,1} = 0, \quad t \in [0,T].$$

The following notation will be used. Given two functions g and h on $\mathbb{R}^n$ we write $g \lesssim h$ if the estimate $g \leqslant Dh$ holds for a positive constant D independent of $c > c_0$. The constant D may also depend on the length of some time interval $[0,T]$, in which case we write $g \lesssim h$ for $t \in [0,T]$. Whenever necessary or convenient, the constant D will be recovered in the computations.

The classes of solutions of the Boltzmann equations to be considered are defined by the following properties. In the classical case it is required that, in some interval $[0,T_1]$:

$$\text{(C1)}\ f_\infty \in C([0,T_1] \times \mathbb{T}^3 \times \mathbb{R}^3),$$

$$\text{(C2)}\ \exists\, \alpha_0 > 0 : f_\infty(t,x,p) \lesssim \exp(-\alpha_0 |p|^2), \quad t \in [0,T_1], \quad x \in \mathbb{T}^3, \quad p \in \mathbb{R}^3.$$

In the relativistic case let f_c denote a (one parameter family of) solution(s) of (1.1) and require that, for all $c > c_0$ and in some interval $[0,T_c]$,

$$\text{(R1)}\ f_c \in C([0,T_c] \times \mathbb{T}^3 \times \mathbb{R}^3),$$

$$\text{(R2)}\ \exists\, \beta_0 > 0 : f_c(t,x,p) \lesssim \exp[-\beta_0(\mathcal{E}_c(p) - c^2)], \quad t \in [0,T_c], \quad x \in \mathbb{T}^3, \quad p \in \mathbb{R}^3,$$

$$\text{(R3)}\ T_2 := \inf_{c > c_0} T_c > 0.$$

Let us briefly comment on the above conditions. The existence of solutions to the classical Boltzmann equation satisfying the properties (C1), (C2) is proved in Ref. 9—see also Refs. 2,8 for questions concerning the global existence of such solutions. A similar argument applies to the relativistic Boltzmann equation to prove the local existence and uniqueness of solutions satisfying (R1)—(R3). A short sketch of the proof is given in Sec. III to show that the property (R3) is satisfied. The latter is necessary for studying the Newtonian limit, since it assures that the existence interval of a solution of the relativistic Boltzmann equation does not shrink to zero as $c \to +\infty$. The time T in Theorem 1 is defined as the minimum between T_1 and T_2.

Note also that the assumption $x \in \mathbb{T}^3$ allows one to neglect technical difficulties not related to the problem under discussion, such us the choice of boundary or fall-off conditions. The generalization of the result when x lies in a region of $\mathbb{R}^3$ with a smooth boundary—or simply $x \in \mathbb{R}^3$—is not attempted here but it should not be too difficult.

II. PROOF OF THE MAIN THEOREM

The following lemma collects some estimates which are required in the proof of the main theorem.

Lemma 1: The following estimates hold:

$$\text{(a)}\ |q' - \overline{q}| + |p' - \overline{p}| \lesssim \frac{(|q| + |p|)^3}{c^2},$$

$$\text{(b)}\ |\mathcal{K}_c(p,q,\omega) - |\omega \cdot (p-q)|| \lesssim \frac{(1 + |p| + |q|)^9}{c^2},$$

$$\text{(c)} \quad \iint \mathcal{K}_c(p,q,\omega)\exp\left[-\beta_0(\mathcal{E}_c(q)-c^2)\right]\mathrm{d}\omega\,\mathrm{d}q \lesssim (1+|p|).$$

Proof: From (1.4) and (1.9) we have

$$|q'-\overline{q}| = |p'-\overline{p}| = |\omega\cdot(p-q)-a|,$$

and a computation shows that

$$\omega\cdot(p-q)-a = \frac{\omega\cdot(p+q)(|p|^2-|q|^2+(\omega\cdot p)^2-(\omega\cdot q)^2)}{(p_0+q_0)^2-[\omega\cdot(p+q)]^2} = \frac{\text{Num}}{\text{Den}}.$$

Moreover,

$$\begin{aligned}\text{Den} &= 2c^2+|p|^2+|q|^2+2\sqrt{c^2+|p|^2}\sqrt{c^2+|q|^2}-(\omega\cdot p)^2-(\omega\cdot q)^2-2(\omega\cdot p)(\omega\cdot q)\\ &\geqslant 2c^2+2\sqrt{c^2+|p|^2}\sqrt{c^2+|q|^2}-2|p||q| \geqslant 2c^2+\frac{c^2(c^2+|p|^2+|q|^2)}{\sqrt{c^2+|p|^2}\sqrt{c^2+|q|^2}}. \qquad (2.11)\end{aligned}$$

In particular $\text{Den} > 2c^2$ and since $\text{Num} \lesssim (|p|+|q|)^3$, the estimate (a) is proved. Next, from (1.10) we have

$$\begin{aligned}|\mathcal{K}_c(p,q,\omega)-|\omega\cdot(p-q)|| &\lesssim \left|\frac{2(p_0q_0-p\cdot q+c^2)(p_0+q_0)^2(\omega\cdot\hat{p}-\omega\cdot\hat{q})}{[(p_0+q_0)^2-(\omega\cdot(p+q))^2]^2}-\omega\cdot(p-q)\right|\\ &\lesssim |\omega\cdot p|\left|\frac{2c(p_0q_0-p\cdot q+c^2)(p_0+q_0)^2}{p_0[(p_0+q_0)^2-(\omega\cdot(p+q))^2]^2}-1\right|+(q\leftrightarrow p), \qquad (2.12)\end{aligned}$$

where $(q\leftrightarrow p)$ denotes the expression obtained by exchanging p and q in the first term. Recall the definition of "Den" in (2.11). The first term in (2.12) is estimated as

$$\begin{aligned}&\frac{|p|}{p_0(\text{Den})^2}|2c(p_0q_0+c^2)(p_0+q_0)^2-2cp\cdot q(p_0+q_0)^2-p_0(p_0+q_0)^4-p_0[\omega\cdot(p+q)]^4\\ &\quad+2p_0(p_0+q_0)^2[\omega\cdot(p+q)]^2|\\ &\lesssim \frac{|p|}{p_0(\text{Den})^2}|(p_0+q_0)^2(2cp_0q_0+2c^3-p_0^3-p_0q_0^2-2p_0^2q_0)+c^3(1+|p|+|q|)^5|.\end{aligned}$$

Here $p_0(\text{Den})^2 \geqslant 4c^5$ and so to prove (b) one needs to estimate only the expression containing the fifth order powers of c, which is given by

$$\mathcal{P}(p,q) = (p_0+q_0)^2[2cp_0q_0+2c^3-p_0^3-p_0q_0^2-2p_0^2q_0].$$

We have

$$\frac{|\mathcal{P}(p,q)|}{p_0(\text{Den})^2} \lesssim \frac{(1+|p|+|q|)^2}{c^3}|2cp_0q_0+2c^3-p_0^3-p_0q_0^2-2p_0^2q_0|.$$

Using that

$$2cp_0q_0-2p_0^2q_0 = \frac{2p_0q_0}{c+p_0}(c^2-p_0^2) \leqslant 2c|p|^2(1+|q|),$$

$$c^3-p_0q_0^2 = c^2(c-p_0)-c|q|^2(1+|p|) \leqslant \frac{c^2(c^2-p_0^2)}{c+p_0}+c|q|^2(1+|p|) \leqslant c(|p|^2+|q|^2)(1+|p|),$$

$$c^3 - p_0^3 = c^3\left(1 - \left(1 + \frac{|p|^2}{c^2}\right)^{3/2}\right) \leqslant c(1+|p|)^6,$$

and repeating the argument for the second term in (2.12) concludes the proof of (b). To prove (c) consider the following pointwise estimate on $\mathcal{K}_c$:

$$\begin{aligned}\mathcal{K}_c &\lesssim \frac{cp_0q_0}{(\mathrm{Den})^2}(p_0^2+q_0^2+2p_0q_0)(|p|/p_0+|q|/q_0)\\ &\lesssim \frac{c}{(\mathrm{Den})^2}[|p|p_0^2q_0+|p|q_0^3+2|p|p_0q_0^2+p_0^3|q|+p_0|q|q_0^2+2p_0^2q_0|q|]\\ &\lesssim \frac{c^4}{(\mathrm{Den})^2}(1+|p|)(1+|q|^2)^{3/2}\left(1+\frac{|p|^2}{c^2}\right).\end{aligned}$$

From (2.11) it follows that

$$\mathrm{Den} \geqslant c^2\frac{\sqrt{1+|p|^2/c^2}}{\sqrt{1+|q|^2/c^2}}.$$

Moreover, since $\sqrt{c^4+c^2|q|^2}-c^2 \geqslant \frac{1}{2}(\sqrt{1+|q|^2}-1)$, then

$$\exp[-\beta_0(\mathcal{E}_c(q)-c^2)] \lesssim \exp\left[-\frac{\beta_0}{2}\sqrt{1+|q|^2}\right], \tag{2.13}$$

and so

$$\iint \mathcal{K}_c(p,q,\omega)e^{-\beta_0(\mathcal{E}_c(q)-c^2)}\,\mathrm{d}\omega\,\mathrm{d}q \lesssim (1+|p|)\int (1+|q|^2)^{5/2}e^{(-\beta_0/2)\sqrt{1+|q|^2}}\mathrm{d}q,$$

by which the claim follows. □

Remark 1: The simple estimate (2.13) will be often used in the sequel for the same purpose as in Lemma 1, i.e., to obtain an estimate independent of $c > c_0$ of the integrals containing the factor $\exp[-\beta_0(\mathcal{E}_c(q)-c^2)]$.

In the class of solutions that we are considering, the distribution functions satisfy the Boltzmann equations in the mild form

$$f_c(t,x,p) = f_c^{\mathrm{in}}(x-\hat{p}t,p) + \int_0^t Q_{\mathrm{rel}}(s,x+\hat{p}(s-t),p)\mathrm{d}s, \tag{2.14}$$

$$f_\infty(t,x,p) = f_\infty^{\mathrm{in}}(x-pt,p) + \int_0^t Q_{\mathrm{cl}}(s,x+p(s-t),p)\mathrm{d}s. \tag{2.15}$$

We use this representation to estimate the following quantity:

$$F_\eta[f_\infty] = \int \sup_{|h|<\eta}|f_\infty(p+h)-f_\infty(p)|_0\mathrm{d}p, \quad \eta > 0.$$

Lemma 2: For all $\eta_0, T > 0$, $\eta \in [0,\eta_0]$ *and* $t \in [0,T]$, *there exists a positive constant* $C = C(T,\eta_0,\alpha_0)$ *such that*

$$F_\eta[f_\infty] \leqslant C\sqrt{F_\eta[f_\infty^{\mathrm{in}}]}.$$

Proof: By (1.8),

$$Q_{\mathrm{cl}}(f_\infty,f_\infty)(p+h)=\iint |\omega\cdot(p-q)|[f_\infty(\overline{p}+h)f_\infty(\overline{q}+h)-f_\infty(p+h)f_\infty(q+h)]\mathrm{d}\omega\,\mathrm{d}q.$$

Therefore by (2.15),

$$\begin{aligned}|f_\infty(p+h)-f_\infty(p)|_0 \le |f_\infty^{\mathrm{in}}(p+h)-f_\infty^{\mathrm{in}}(p)|_0 &+\int_0^t\iint |\omega\cdot(p-q)||f_\infty(q)|_0|f_\infty(p+h)\\ &-f_\infty(p)|_0\,\mathrm{d}\omega\,\mathrm{d}q\,\mathrm{d}s+\int_0^t\iint |\omega\cdot(p-q)||f_\infty(\overline{q})|_0|f_\infty(\overline{p}+h)\\ &-f_\infty(\overline{p})|_0\,\mathrm{d}\omega\,\mathrm{d}q\,\mathrm{d}s+\int_0^t\iint |\omega\cdot(p-q)||f_\infty(p+h)|_0|f_\infty(q+h)\\ &-f_\infty(q)|_0\,\mathrm{d}\omega\,\mathrm{d}q\,\mathrm{d}s+\int_0^t\iint |\omega\cdot(p-q)||f_\infty(\overline{p}+h)|_0|f_\infty(\overline{q}+h)\\ &-f_\infty(\overline{q})|_0\,\mathrm{d}\omega\,\mathrm{d}q\,\mathrm{d}s.\end{aligned}$$

Hence changing to the post-collisional variables,

$$\begin{aligned}F_\eta[f_\infty] &\le F_\eta[f_\infty^{\mathrm{in}}]+\int_0^t\iiint |\omega\cdot(p-q)|e^{-\alpha_0|q|^2}\sup_{|h|<\eta}|f_\infty(p+h)-f_\infty(p)|_0\,\mathrm{d}\omega\,\mathrm{d}q\,\mathrm{d}p\,\mathrm{d}s\\ &\quad+\int_0^t\sup_{|h|<\eta}\iiint |\omega\cdot(p-h-q)|e^{-\alpha_0|p|^2}|f_\infty(q+h)-f_\infty(q)|_0\,\mathrm{d}\omega\,\mathrm{d}q\,\mathrm{d}p\,\mathrm{d}s\\ &= F_\eta[f_\infty^{\mathrm{in}}]+\mathrm{A}+\mathrm{B}.\end{aligned}$$

For $R>0$ we write

$$\begin{aligned}\mathrm{A} &\le \int_0^t\int_{|p|\le R}(1+|p|)\sup_{|h|<\eta}|f_\infty(p+h)-f_\infty(p)|_0\,\mathrm{d}p\,\mathrm{d}s+\int_0^t\int_{|p|>R}(1+|p|)\\ &\quad\times\exp[-\alpha_0(|p|^2-2\eta|p|)]\mathrm{d}p\,\mathrm{d}s\le (1+R)\int_0^t F_\eta[f_\infty](s)\mathrm{d}s+Ce^{-\alpha_0R^2/2}.\end{aligned}$$

The estimate for B is obtained in the same way,

$$\mathrm{B}\le[1+(R+\eta_0)]\int_0^t F_\eta[f_\infty](s)\mathrm{d}s+Ce^{-\alpha_0R^2/2}.$$

Hence, finally,

$$F_\eta[f_\infty](t)\le F_\eta[f_\infty^{\mathrm{in}}]+Ce^{-\alpha_0R^2/2}+[1+(R+\eta_0)]\int_0^t F_\eta[f_\infty](s)\mathrm{d}s.$$

Choose R such that $e^{-\alpha_0R^2/2}=(1+F_{\eta_0}[f_\infty^{\mathrm{in}}])^{-1}F_\eta[f_\infty^{\mathrm{in}}]$, so that

$$F_\eta[f_\infty](t)\le Ce^{-\alpha_0R^2/2}+[1+(R+\eta_0)]\int_0^t F_\eta[f_\infty](s)\mathrm{d}s.$$

Hence, by the Grönwall Lemma,

$$F_\eta[f_\infty](t) \lesssim C\exp\left[-\frac{\alpha_0 R^2}{2}+(R+\eta_0)t\right] \lesssim C\exp\left(-\frac{\alpha_0 R^2}{4}\right)\sup_{R>0}\exp\left[-\frac{\alpha_0 R^2}{4}+(R+\eta_0)T\right]$$
$$\lesssim C\exp\left(-\frac{\alpha_0 R^2}{4}\right)=C\sqrt{F_\eta[f_\infty^{\mathrm{in}}]}.$$

□

Note also that for an initial datum as given in Theorem 2 the estimate $F_\eta[f_\infty^{\mathrm{in}}]\lesssim\eta$ holds. Then Lemma 2 implies

$$F_\eta[f_\infty]\lesssim\sqrt{\eta}. \tag{2.16}$$

The next goal is to estimate the difference $Q_{\mathrm{rel}}-Q_{\mathrm{cl}}$ in the norm $\|\ \|_{0,1}$.

Lemma 3: The following estimate holds:

$$\|Q_{\mathrm{rel}}(t)-Q_{\mathrm{cl}}(t)\|_{0,1}\lesssim c^{-1}(\log c)^{5/4}+\exp[-\beta_0(\sqrt{c^4+c^2\log c}-c^2)]+\exp[-\alpha_0\log c]$$
$$+\sqrt{\log c}\|f_\infty(t)-f_c(t)\|_{0,1}.$$

Proof: From (1.2) and (1.8),

$$\|Q_{\mathrm{rel}}(t)-Q_{\mathrm{cl}}(t)\|_{0,1}\lesssim\iiint|\mathcal{K}_c(p,q,\omega)[f(p')f(q')-f(p)f(q)]-|\omega\cdot(p-q)|[f_\infty(\overline{p})f_\infty(\overline{q})$$
$$-f_\infty(p)f_\infty(q)]|_0\mathrm{d}\omega\,\mathrm{d}q\,\mathrm{d}p=\iiint_{|p|+|q|\le\sqrt{\log c}}\cdots+\iiint_{|p|+|q|>\sqrt{\log c}}\cdots.$$

Observing the conservation of energy and using (c) of Lemma 1, the integral in the exterior region is dominated by

$$\iiint_{|p|+|q|>\sqrt{\log c}}\mathcal{K}_c(p,q,\omega)\exp[-\beta_0(\mathcal{E}_c(p)+\mathcal{E}_c(q)-2c^2)]\mathrm{d}\omega\,\mathrm{d}q\,\mathrm{d}p+\int\int\int_{|p|+|q|>\sqrt{\log c}}|\omega\cdot(p-q)|$$
$$\times\exp[-\alpha_0(|p|^2+|q|^2)\mathrm{d}p\,\mathrm{d}\omega\,\mathrm{d}q\,\mathrm{d}p\lesssim\exp[-\beta_0(\sqrt{c^4+c^2\log c}-c^2)]+\exp(-\alpha_0\log c).$$

For the integral over the interior part consider the splitting,

$$\iiint_{|p|+|q|\le\sqrt{\log c}}\cdots\lesssim\mathrm{I}+\mathrm{II}+\cdots+\mathrm{VIII},$$

where

$$\mathrm{I}=\iiint_{|p|+|q|\le\sqrt{\log c}}|f_c(p)|_0|f_c(q)|_0||\omega\cdot(p-q)|-\mathcal{K}_c|\mathrm{d}\omega\,\mathrm{d}q\,\mathrm{d}p,$$

$$\mathrm{II}=\iiint_{|p|+|q|\le\sqrt{\log c}}|f_\infty(\overline{p})|_0|f_\infty(\overline{q})|_0||\omega\cdot(p-q)|-\mathcal{K}_c|\mathrm{d}\omega\,\mathrm{d}q\,\mathrm{d}p,$$

$$\mathrm{III}=\iiint_{|p|+|q|\le\sqrt{\log c}}|\omega\cdot(p-q)||f_\infty(p)|_0|f_\infty(q)-f_c(q)|_0\,\mathrm{d}\omega\,\mathrm{d}q\,\mathrm{d}p,$$

$$\mathrm{IV}=\iiint_{|p|+|q|\le\sqrt{\log c}}|\omega\cdot(p-q)||f_c(q)|_0|f_\infty(p)-f_c(p)|_0\,\mathrm{d}\omega\,\mathrm{d}q\,\mathrm{d}p,$$

$$\mathrm{V} = \iiint_{|p|+|q|\leqslant\sqrt{\log c}} \mathcal{K}_c |f_c(p')|_0 |f_c(q') - f_\infty(q')|_0 \,\mathrm{d}\omega\,\mathrm{d}q\,\mathrm{d}p,$$

$$\mathrm{VI} = \iiint_{|p|+|q|\leqslant\sqrt{\log c}} \mathcal{K}_c |f_c(p')|_0 |f_\infty(q') - f_\infty(\overline{q})|_0 \,\mathrm{d}\omega\,\mathrm{d}q\,\mathrm{d}p,$$

$$\mathrm{VII} = \iiint_{|p|+|q|\leqslant\sqrt{\log c}} \mathcal{K}_c |f_\infty(\overline{q})|_0 |f_c(p') - f_\infty(p')|_0 \,\mathrm{d}\omega\,\mathrm{d}q\,\mathrm{d}p,$$

$$\mathrm{VIII} = \iiint_{|p|+|q|\leqslant\sqrt{\log c}} \mathcal{K}_c |f_\infty(\overline{q})|_0 |f_\infty(p') - f_\infty(\overline{p})|_0 \,\mathrm{d}\omega\,\mathrm{d}q\,\mathrm{d}p.$$

It follows directly from the estimate (b) of Lemma 1 that

$$\mathrm{I} + \mathrm{II} \lesssim c^{-2}.$$

The integrals III and IV satisfy the estimate

$$\mathrm{III} + \mathrm{IV} \lesssim \int_{|q|\leqslant\sqrt{\log c}} (1 + |q|)|f_\infty(q) - f_c(q)|_0 \,\mathrm{d}q \lesssim (1 + \sqrt{\log c})\|f_\infty(t) - f_c(t)\|_{0,1}.$$

In the integral V we change to the post-collisional variables. Since $\mathcal{K}_c(p,q,\omega)\mathrm{d}q\,\mathrm{d}p = \mathcal{K}_c(p',q',\omega)\mathrm{d}q'\,\mathrm{d}p'$ and, by (1.3), $|p'|+|q'| \leqslant 4\sqrt{\log c}$ for $|p|+|q| \leqslant \sqrt{\log c}$, then

$$\mathrm{V} \lesssim \iiint_{|p|+|q|\leqslant 4\sqrt{\log c}} \mathcal{K}_c(p,q,\omega)|f_c(p)|_0 |f_c(q) - f_\infty(q)|_0 \mathrm{d}\omega\,\mathrm{d}q\,\mathrm{d}p \lesssim \sqrt{\log c}\|f_\infty(t) - f(t)\|_{0,1}.$$

For the integral VI we have, by the estimate (a) of Lemma 1, Lemma 2, and (2.16),

$$\begin{aligned}
\mathrm{VI} &\lesssim \iiint_{|p|+|q|\leqslant\sqrt{\log c}} \mathcal{K}_c |f_c(p')|_0 \sup_{|h|\leqslant(\log c)^{3/2}/c^2} |f_\infty(q'+h) - f_\infty(q')|_0 \,\mathrm{d}\omega\,\mathrm{d}q\,\mathrm{d}p \\
&\lesssim \iiint_{|p|+|q|\leqslant 4\sqrt{\log c}} \mathcal{K}_c e^{-\beta_0(\mathcal{E}(p)-c^2)} \sup_{|h|\leqslant(\log c)^{3/2}/c^2} |f_\infty(q+h) - f_\infty(q)|_0 \,\mathrm{d}\omega\,\mathrm{d}q\,\mathrm{d}p \\
&\lesssim \int_{|q|\leqslant 4\sqrt{\log c}} (1 + |q|) \sup_{|h|\leqslant(\log c)^{3/2}/c^2} |f_\infty(q+h) - f_\infty(q)|_0 \\
&\lesssim \sqrt{\log c} F_{(\log c)^{3/2}/c^2}[f_\infty] \lesssim c^{-1}(\log c)^{5/4}.
\end{aligned}$$

It is now straightforward to estimate VII and VIII; therefore we merely state the result

$$\mathrm{VII} + \mathrm{VIII} \lesssim c^{-1}(\log c)^{5/4} + \sqrt{\log c}\|f_\infty(t) - f(t)\|_{0,1}.$$

Collecting the various bounds, the claim follows. □

The proof of Theorem 1 is now almost complete. From (2.14) and (2.15) we have

$$\|f_c(t) - f_\infty(t)\|_{0,1} \leqslant \|f_c^{\mathrm{in}} - f_\infty^{\mathrm{in}}\|_{0,1} + \int_0^t \|Q_{\mathrm{rel}}(s) - Q_{\mathrm{cl}}(s)\|_{0,1}.$$

Using Lemma 3 and applying Grönwall's inequality one obtains, for $t \in [0,T]$,

$$\|f_c(t)-f_\infty(t)\|_{0,1} \lesssim \|f_c^{\mathrm{in}}-f_\infty^{\mathrm{in}}\|_{0,1} e^{D\sqrt{\log c}} + c^{-1}(\log c)^{5/4} e^{D\sqrt{\log c}} + \exp[-\beta_0\sqrt{c^4+c^2\log c}+\beta_0 c^2 + D\sqrt{\log c}] + \exp[-\alpha_0 \log c + D\sqrt{\log c}].$$

The expression on the right hand side tends to zero as $c\to\infty$ and this concludes the proof of Theorem 1.

III. EXISTENCE IN A UNIFORM SHORT TIME INTERVAL

The equation to be studied reads explicitly as

$$f_c(t,x,p) = f_c^{\mathrm{in}}(x-\hat{p}t,p) + \int_0^t [Q_{\mathrm{rel}}^+(f_c,f_c) - Q_{\mathrm{rel}}^-(f_c,f_c)](s,x-\hat{p}(t-s),p)\mathrm{d}s, \tag{3.17}$$

where Q_{rel}^+ and Q_{rel}^- refer to the gain and loss part of the relativistic collision operator (1.2), respectively. Given two functions $u_0(t)$ and $l_0(t)$, the approximation sequences $\{u_n\}_{n\geqslant 0}$, $\{l_n\}_{n\geqslant 0}$ are defined recursively by

$$l_{n+1}(t,x,p) = f_c^{\mathrm{in}}(x-\hat{p}t,p) + \int_0^t [Q_{\mathrm{rel}}^+(l_n,l_n) - Q_{\mathrm{rel}}^-(l_{n+1},u_n)](s,x-\hat{p}(t-s),p)\mathrm{d}s,$$

$$u_{n+1}(t,x,p) = f_c^{\mathrm{in}}(x-\hat{p}t,p) + \int_0^t [Q_{\mathrm{rel}}^+(u_n,u_n) - Q_{\mathrm{rel}}^-(u_{n+1},l_n)](s,x-\hat{p}(t-s),p)\mathrm{d}s,$$

and as in Lemma 5.1 in Ref. 9 one can prove the following.

Proposition 1: Assume the beginning condition is satisfied:

$$0 \leqslant l_0(t) \leqslant l_1(t) \leqslant u_1(t) \leqslant u_0(t); \tag{3.18}$$

then $0\leqslant l_n(t)\leqslant l_{n+1}(t)\leqslant u_{n+1}(t)\leqslant u_n(t)$ *for all* $n\geqslant 0$.

Next assume that $u_0 \lesssim \exp[-\beta_0(\mathcal{E}_c(p)-c^2)]$; it follows by the previous proposition that u_n, l_n are also dominated by $\exp[-\beta_0(\mathcal{E}_c(p)-c^2)]$. Moreover $l_n(t)\uparrow l(t), u_n(t)\downarrow u(t)$, and $|u(t)|, |l(t)| \lesssim \exp[-\beta_0(\mathcal{E}_c(p)-c^2)]$. All these preliminary facts are valid for any collision kernel. When the latter is given by (1.10) one can also prove that (i) $u(t)=l(t)$ and (ii) the limit is a continuous solution of (3.17). The second statement is an obvious consequence of the first one, so only the proof of (i) will be given. By the dominated convergence theorem, $u(t), l(t)$ satisfy

$$l(t,x,p) = f_c^{\mathrm{in}}(x-\hat{p}t,p) + \int_0^t [Q_{\mathrm{rel}}^+(l,l) - Q_{\mathrm{rel}}^-(l,u)](s,x-\hat{p}(t-s),p)\mathrm{d}s,$$

$$u(t,x,p) = f_c^{\mathrm{in}}(x-\hat{p}t,p) + \int_0^t [Q_{\mathrm{rel}}^+(u,u) - Q_{\mathrm{rel}}^-(u,l)](s,x-\hat{p}(t-s),p)\mathrm{d}s.$$

Estimating the difference $u(t)-l(t)$ in the norm $\|\ \|_{0,1}$ and using (c) of Lemma 1 we get

$$\begin{aligned}\|u(t)-l(t)\|_{0,1} &\lesssim \int_0^t \int (1+|p|)|u(s,p)-l(s,p)|_0\,\mathrm{d}p\,\mathrm{d}s \\ &\lesssim \int_0^t \int_{|p|\leqslant R} (1+|p|)|u(s,p)-l(s,p)|_0\,\mathrm{d}p\,\mathrm{d}s \\ &\quad + \int_0^t \int_{|p|>R} (1+|p|)\exp[-\beta_0(\sqrt{c^4+c^2|p|^2}-c^2)]\mathrm{d}p\,\mathrm{d}s\end{aligned}$$

$$\lesssim (1+R)\int_0^t \|u(s)-l(s)\|_{0,1} + te^{(-\beta_0/2)(\sqrt{c^4+c^2R^2}-c^2)}.$$

Hence by the Grönwall inequality

$$\|u(t)-l(t)\|_{0,1} \lesssim te^t \exp\left[DtR - \frac{\beta_0}{2}\sqrt{c^4+R^2c^2} + \frac{\beta_0}{2}c^2\right],$$

for some constant D independent of the speed of light. For $t\in[0,T]$ and $c>\sqrt{48}DT/\beta_0 := c_0$, this implies

$$\|u(t)-l(t)\|_{0,1} \lesssim e^{(-DTR)}, \quad \text{for } R > \frac{12DT}{\beta_0},$$

and so the claim $u(t)=l(t)$, for $t\in[0,T]$ and $c>c_0$ follows by letting $R\to+\infty$.

It remains to show that the beginning condition (3.18) is attained in some interval $[0,T_c]$ satisfying the property (R3) (indeed it will be shown that T_c is independent of $c>1$). Following Ref. 9 we choose $l_0\equiv 0$ and $u_0(t)$ of the form

$$u_0(t) = \omega(t)e^{-\beta(t)[\mathcal{E}_c(p)-c^2]},$$

where β and ω are positive functions and $\beta(0)=\beta_0$. We also set $\omega_0=\omega(0)$. Then u_1 are l_1 are given by

$$l_1(t,x,p) = f_c^{\text{in}}(x-\hat{p}t,p)\exp\left[-\omega(t)\iint \mathcal{K}_c(q,p,\omega)e^{-\beta(t)[\mathcal{E}_c(q)-c^2]}\mathrm{d}\omega\,\mathrm{d}q\right],$$

$$u_1(t,x,p) = f_c^{\text{in}}(x-\hat{p}t,p) + \int_0^t \omega(s)^2 \iint \mathcal{K}_c(q,p,\omega)e^{-\beta(s)[\mathcal{E}_c(p)+\mathcal{E}_c(q)-2c^2]}\mathrm{d}\omega\,\mathrm{d}q\,\mathrm{d}s.$$

Hence $0\leqslant l_1(t)\leqslant u_1(t)$. Moreover,

$$u_1(0)-u_0(0) = f_c^{\text{in}} - \omega_0 e^{-\beta_0[\mathcal{E}_c(p)-c^2]} \lesssim e^{-\beta_0[\mathcal{E}_c(p)-c^2]} - \omega_0 e^{-\beta_0[\mathcal{E}_c(p)-c^2]} \leqslant 0,$$

for ω_0 large enough and

$$\frac{d}{dt}[u_1(t,x+\hat{p}t,p)-u_0(t,x+\hat{p}t,p)] \leqslant [D(1+|p|)\omega^2 - \dot{\omega} + \omega\dot{\beta}(\sqrt{c^4+c^2|p|^2}-c^2)] \times \exp[-\beta(t)(\mathcal{E}_c(p)-c^2)],$$

where an upper dot has been used to denote differentiation in time. Hence the proof of (3.18) is complete if one can choose ω,β such that

$$D(1+|p|)\omega^2 - \dot{\omega} + \omega\dot{\beta}(\sqrt{c^4+c^2|p|^2}-c^2) \leqslant 0. \tag{3.19}$$

Let

$$\omega(t) = \frac{\omega_0}{1-3D\omega_0 t}, \quad \beta(t) = \beta_0 + \tfrac{2}{3}\log(1-3D\omega_0 t),$$

so that $\dot{\omega}=3D\omega^2$ and $\dot{\beta}=-2D\omega$. Here $t\in[0,T]$, where $T=(6D\omega_0)^{-1}(1-e^{-(3/2)\beta_0})$ so that ω and β are well-defined positive functions in $[0,T]$. In this way, the left hand side of (3.19) is dominated by $-D\omega^2\leqslant 0$ and this concludes the proof of the following

Theorem 2: *Let $f_c^{\text{in}}\in C(\mathbb{T}^3\times\mathbb{R}^3)$ such that $f_c^{\text{in}}\lesssim\exp[-\beta_0(\mathcal{E}_c(p)-c^2)]$. There exist $c_0,T>0$ such that for all $c>c_0$, the relativistic Boltzmann equation, Eq. (1.1) with $\mathcal{K}_c(p,q,\omega)$ given by*

(1.5) and initial datum f_c^{in}*, has a unique solution* $f \in C([0,T]\times\mathbb{T}^3\times\mathbb{R}^3)$ *which also satisfies* $f \lesssim \exp[-\beta_0(\mathcal{E}_c(p)-c^2)]$*; in particular the class of solutions satisfying (R1)–(R3) is not empty.*

(Received 12 April 2004; accepted 7 July 2004; published 19 October 2004)

In this paper, we present a real nonlinear differential equation for the two flavor neutrino oscillation problem in matter with an arbitrary density profile. We also present an exact series solution to this nonlinear differential equation. In addition, we investigate numerically the convergence of this solution for different matter density profiles such as constant and linear profiles as well as the Preliminary Reference Earth Model describing the Earth's matter density profile. Finally, we discuss other methods used for solving the neutrino flavor evolution problem. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1793330]

I. INTRODUCTION

In general, there are several phenomena and processes in physics, but also in other fields of science such as chemistry, that can be described in terms of a system with two (quantum mechanical) states and a time-dependent Hamiltonian, i.e., so-called two-level systems—neutrino oscillations with two flavors being one such system. Other representatives of such systems are, for example, a spin $1/2$ particle in a time-dependent electromagnetic field having the states "spin up" and "spin down," K^0-$\overline{K}^0$ mixing, a Josephson device, nuclear magnetic resonance used for encoding bits of information (i.e., quantum bits for a quantum computer), the left and right chirality states of molecules in chemistry, etc. The problem of neutrino oscillations in matter, which we are concerned with in this paper, is mathematically equivalent to a spin $1/2$ particle in a magnetic field that is constant in one direction, zero in another direction, and time-dependent in the last direction.[1]

Neutrino oscillations have recently been extensively studied in the literature[2–6] and they act as the most plausible description of both the solar[2] and atmospheric[3] neutrino problems. At an early stage, neutrino oscillations were mainly investigated with two flavors and without including matter effects. Nowadays, we know that there are at least three neutrino flavors and that matter effects are important. For example, in matter, the so-called Mikheyev–Smirnov–Wolfenstein (MSW) effect[7,8] can take place, which is an amplifying resonant effect due to the presence of matter. However, in most situations, neutrino oscillations can be effectively investigated with two flavors, since the leptonic mixing in the 1–3 sector is indeed small,[4,5] leading to the fact that the full three flavor scenario can be decoupled into two effective two flavor scenarios, each of which can be studied separately.

In this paper, we present an exact analytic solution to the two flavor neutrino oscillation problem in matter. Since there are many similar two-level systems, as discussed above, our solution will also be interesting and applicable to this kind of system. However, before we proceed to present our solution, we will give a brief overview of what has previously been done in this field. Note that this overview is not presented in chronological order. First, in Refs. 9,10, the neutrino flavor evolution has been investigated by a discretization of the effective potential.

[a]Electronic mail: mbl@theophys.kth.se
[b]Electronic mail: tommy@theophys.kth.se

Second, exact solutions exist for a number of specific effective potentials.[7,11–13] Third, in Refs. 14,15, the evolution was studied by using an adiabatic approximation. Fourth, approximate solutions valid for small effective potentials have recently been studied in detail.[16] Finally, there have also been other attempts to write the evolution in terms of a second order nonlinear ordinary differential equation.[17] However, this has been done for the neutrino oscillation probability amplitudes and not for the neutrino oscillation probabilities. The advantage of working with a nonlinear differential equation for the oscillation probability rather than a linear system of differential equations for the probability amplitudes is that we only have one real variable instead of two complex variables. The disadvantage is that the resulting differential equation is nonlinear.

This paper is organized as follows. In Sec. II, the neutrino flavor evolution in matter with two flavors is studied and a second order nonlinear ordinary differential equation for the neutrino oscillation probability is derived. Then, in Sec. III, we perform series expansions of both the neutrino oscillation probability and the effective potential in order to solve the differential equation presented in Sec. II. Next, in Sec. IV, we continue by studying the numerical convergence of the solution for a number of different effective potentials and baselines. In Sec. V, we present a brief summary of other methods for solving the neutrino evolution in matter. Finally, in Sec. VI, we summarize our results and give our conclusions.

II. NEUTRINO FLAVOR EVOLUTION IN MATTER

When neutrinos propagate in matter, neutrino flavors are affected differently by coherent forward scattering against the matter constituents. Assuming that there are no sterile neutrinos, the effect of matter is to add an effective potential to ν_e; this effective potential is given by $V(t) = \sqrt{2}G_F N_e(t)$, where G_F is the Fermi coupling constant and $N_e(t)$ is the electron number density.

In the two flavor case, the time evolution of a neutrino state $|\nu(t)\rangle = (|\nu_e(t)\rangle |\nu_x(t)\rangle)^T$ is given by

$$\mathrm{i}\frac{\mathrm{d}|\nu(t)\rangle}{\mathrm{d}t} = (H_{\mathrm{vac}} + H_{\mathrm{mat}}(t))|\nu(t)\rangle, \tag{1}$$

where $H_{\mathrm{vac}} = U\,\mathrm{diag}(m_1^2, m_2^2)U^\dagger/2E$ is the free Hamiltonian in vacuum, $H_{\mathrm{mat}}(t) = \mathrm{diag}(V(t), 0)$ is the addition to the free Hamiltonian due to matter effects, and

$$U = \begin{pmatrix} c & s \\ -s & c \end{pmatrix} \tag{2}$$

is the leptonic mixing matrix in vacuum. Here $c \equiv \cos\theta, s \equiv \sin\theta$, and θ is the leptonic mixing angle. Adding or subtracting terms proportional to the unity operator to the total Hamiltonian $H(t) = H_{\mathrm{vac}} + H_{\mathrm{mat}}(t)$ will only contribute with an overall phase to the neutrino state $|\nu(t)\rangle$, and thus, does not affect the neutrino oscillation probabilities. Using this fact, the total Hamiltonian may be written as

$$H(t) = \frac{1}{2}\begin{pmatrix} V(t) - \dfrac{\Delta m^2}{2E}\cos 2\theta & \dfrac{\Delta m^2}{2E}\sin 2\theta \\ \dfrac{\Delta m^2}{2E}\sin 2\theta & \dfrac{\Delta m^2}{2E}\cos 2\theta - V(t) \end{pmatrix} = \frac{1}{2}\left[\sigma_1 \frac{\Delta m^2}{2E}\sin 2\theta + \sigma_3\left(V(t) - \frac{\Delta m^2}{2E}\cos 2\theta\right)\right], \tag{3}$$

where the σ_i's ($i = 1, 2, 3$) are the Pauli matrices and $\Delta m^2 \equiv m_2^2 - m_1^2$ is the mass squared difference between the two mass eigenstates in vacuum.

The density matrix $\rho(t) = |\nu(t)\rangle\langle\nu(t)|$ can be parametrized as $\rho(t) = (\mathbf{1} + \mathbf{S}(t)\cdot\boldsymbol{\sigma})/2$, where $\mathbf{1}$ is the unity matrix, $\boldsymbol{\sigma} = (\sigma_1\ \sigma_2\ \sigma_3)^T$ is the vector of Pauli matrices, and $\mathbf{S}(t)$ is a vector such that $\mathbf{S}(t)^2 = 1$. Differentiating the density matrix ρ with respect to time t, the equation of motion for $\mathbf{S}(t)$ becomes

$$\dot{\mathbf{S}}(t) = \mathbf{S}(t) \times \mathbf{B}(t), \tag{4}$$

where $\mathbf{B}(t) \equiv g\mathbf{e}_1 + f(t)\mathbf{e}_3$ and we have defined $g \equiv -\sin(2\theta)\Delta m^2/2E$ and $f(t) \equiv \cos(2\theta)\Delta m^2/2E - V(t)$. Note that g is independent of time t. The probability of neutrinos produced as ν_e to oscillate into ν_x (where ν_x is some linear combination of ν_μ and ν_τ) is now given by $P(\nu_e \to \nu_x) \equiv P_{ex} = (1 - S_3(t))/2$. With the parametrization

$$\mathbf{S}(t) \equiv \begin{pmatrix} \sin\alpha\cos\beta \\ \sin\alpha\sin\beta \\ \cos\alpha \end{pmatrix}, \tag{5}$$

where $\alpha = \alpha(t)$ and $\beta = \beta(t)$, we obtain the following nonlinear system of ordinary differential equations:

$$\dot{\beta} = g\cot\alpha\cos\beta - f, \tag{6}$$

$$\dot{\alpha} = g\sin\beta. \tag{7}$$

Eliminating β from the above expressions, we obtain the differential equation

$$[\ddot{\alpha} + \cot\alpha(\dot{\alpha}^2 - G)]^2 = F(t)(G - \dot{\alpha}^2), \tag{8}$$

where $F(t) \equiv f(t)^2$ and $G \equiv g^2$.

Now, we make the substitution $p = S_3(t) = \cos\alpha$ after which Eq. (8) becomes

$$(\ddot{p} + Gp)^2 = F(t)[G(1 - p^2) - \dot{p}^2]. \tag{9}$$

Note that $F = 0$ corresponds to the so-called MSW resonance condition $\cos(2\theta)\Delta m^2/2E = V$. In this case, Eq. (9) takes the simple form

$$\ddot{p} + Gp = 0, \tag{10}$$

with the trivial solutions $p = A\cos(gt) + B\sin(gt)$ just as expected.

In general, the expression for P_{ex} is known for constant matter density and is given by[7]

$$P_{ex} = \sin^2(2\tilde{\theta})\sin^2\left(\frac{\Delta\tilde{m}^2}{4E}t\right) = \frac{G}{F+G}\sin^2\left(\frac{\sqrt{F+G}}{2}t\right), \tag{11}$$

where $\tilde{\theta}$ is the effective leptonic mixing angle in matter and $\Delta\tilde{m}^2$ is the effective mass squared difference in matter. Using that $p = 1 - 2P_{ex}$, it is a matter of trivial computation to show that this is the solution to Eq. (9) with constant F, which corresponds to any constant matter density.

In the three (n) flavor case, the density matrix can be parametrized by four $[2(n-1)]$ real parameters. If we would adopt our approach to the three (n) flavor case, then we would end up with a system of seven $[2(n-1)]$ nonlinear ordinary differential equations, which, in principle, can be solved in a manner analogous to the one described above for the two flavor case.

III. SERIES EXPANSION OF THE SOLUTION

In order to solve the propagation of neutrinos in matter with arbitrary density profiles, we adopt the method of series expansion. We suppose that neutrinos are produced as ν_e and then propagate through a given effective potential $V(t)$; this gives the initial values $p(0) = 1$ and $\dot{p}(0) = 0$. Series expanding the effective potential $V(t)$ and the quantity $p(t)$, we obtain the following expressions:

$$V(t) = \sum_{n=0}^{\infty} V_n t^n, \tag{12}$$

$$p(t) = \sum_{n=0}^{\infty} p_n t^n, \tag{13}$$

where the coefficients V_n $(n=0,1,\ldots)$ define the effective potential and where we wish to compute the coefficients p_n $(n=0,1,\ldots)$. By using the relation between f and V, we obtain

$$f(t) = \sum_{n=0}^{\infty} f_n t^n, \quad f_n = \delta_{n0}\frac{\Delta m^2}{2E}\cos(2\theta) - V_n, \tag{14}$$

$$F(t) = \sum_{n=0}^{\infty} F_n t^n, \quad F_n = \sum_{k=0}^{n} f_k f_{n-k}. \tag{15}$$

Inserting the above expressions into Eq. (9) and identifying terms of the same order in t gives the relation

$$F_n G = \sum_{s=0}^{n} (s+2)(s+1)(n-s+2)(n-s+1)p_{s+2}p_{n-s+2} + \sum_{s=0}^{n} [2G(s+2)(s+1)p_{s+2}p_{n-s} + G^2 p_s p_{n-s}] + \sum_{s=0}^{n} F_{n-s}\sum_{k=0}^{s} G p_k p_{s-k} + (k+1)(s-k+1)p_{k+1}p_{s-k+1}. \tag{16}$$

For $n=0$ with the given initial conditions, Eq. (16) is a second order equation in p_2 with $p_2 = -G/2$ as a double root. This corresponds well to the fact that at $t=0$, the right-hand side of Eq. (9) vanishes for the given initial conditions and we are left with the equation $\ddot{p}(0) = -Gp(0)$. For $n=1$, Eq. (16) is trivially fulfilled (given the assumed initial conditions, terms with p_{n+2} will appear with the prefactor $Gp_0 + 2p_2$ only), while the solution to the equation for $n=2$ is simply $p_3 = 0$.

Also the solution for $n=3$ is now trivially fulfilled, since the terms including p_{n+1} also cancel for $n \geqslant 3$. For $n=4$, the equation is a second order equation in p_4 with the solutions

$$p_4 = \frac{G^2}{24} \text{ and } p_4 = \frac{G(G+F_0)}{24}. \tag{17}$$

Of these two solutions, only the latter will be a solution to our problem; this is easily checked by inserting the known solution in the case of constant effective potential from Eq. (11).

For $n \geqslant 5$, Eq. (16) is now linear in p_n. For $n \geqslant 6$, we obtain a solution for p_n in terms of lower order p_k, G, and F_s, where $k < n$ and $s \leqslant n-4$. This expression is the following recurrence relation:

$$p_n = -\frac{1}{G(n^2-3n+2)F_0}\Bigg[F_1\sum_{s=1}^{n-2}(s+1)(n-s)p_{s+1}p_{n-s} + G(G+F_0)\sum_{s=2}^{n-2}p_s p_{n-s} + F_0\sum_{s=3}^{n-3}(s+1)(n-s+1)p_{s+1}p_{n-s+1} + 2G\sum_{s=2}^{n-4}(s+2)(s+1)p_{n-s}p_{s+2} + G\sum_{s=4}^{n-1}F_{n-s}\sum_{k=0}^{s}p_k p_{s-k} + \sum_{s=4}^{n-2}F_{n-s}\sum_{k=0}^{s}(k+1)(s-k+1)p_{k+1}p_{s-k+1} + \sum_{s=3}^{n-3}(n-s+2)(n-s+1)(s+2)(s+1)p_{n-s+2}p_{s+2}\Bigg]. \tag{18}$$

For the first few coefficients we obtain

$$p_0 = 1,$$

$$p_1 = 0,$$

$$p_2 = -\frac{G}{2},$$

$$p_3 = 0,$$

$$p_4 = \frac{G}{24}(G + F_0),$$

$$p_5 = \frac{GF_1}{48},$$

$$p_6 = -\frac{G(4G^2F_0 + 8GF_0^2 + 4F_0^3 + F_1^2 - 36F_0F_2)}{2880F_0},$$

$$p_7 = -\frac{G(8GF_0^2F_1 + 8F_0^3F_1 - F_1^3 + 4F_0F_1F_2 - 48F_0^2F_3)}{5760F_0^2},$$

$$p_8 = \frac{G}{645120F_0^3}\{48GF_0^5 + 16F_0^6 - 63F_1^4 + 16F_0^4(3G^2 - 34F_2) + 312F_0F_1^2F_2 + 8F_0(GF_1^2 - 30F_2^2 - 48F_1F_3) + 4F_0^3[4(G^3 - 34GF_2 + 240F_4) - 53F_1]\}. \quad (19)$$

As can be observed by setting $F_k = 0$, the solution for $F = 0$, i.e., at the MSW resonance, is just the series expansion for $p = \cos(gt)$, which is clearly as expected.

IV. CONVERGENCE OF THE SOLUTION

In order to test our solution, we perform a number of numerical tests. First of all, we give an overview of how we approximate the electron number density (i.e., in principle, the effective potential) by a polynomial. Then, we proceed by confirming that our solution really converges nicely towards the simple trigonometric function that is the exact solution for a constant electron number density. In this case, we also study the convergence of the energy dependence of the neutrino oscillation probability $P_{ex}(L)$ for a baseline of $L = 3000$ km. After the constant electron number density case, we investigate the case of a linear effective potential, and finally, we study the case of the Preliminary Reference Earth Model (PREM).[18]

In the numerical calculations, we have used the mixing angle $\theta = 13°$ and the mass squared difference $\Delta m^2 = 2 \times 10^{-3}$ eV^2.[19] The value of θ approximately corresponds to the upper limit on the leptonic mixing angle θ_{13} from the CHOOZ experiment with $\Delta m^2 = 2 \times 10^{-3}$ eV^2.[5] The reason to use this particular choice of parameters is that θ_{13} and the large mass squared difference give the main effects to neutrino oscillations from ν_e into other flavors for the baselines and energies we have studied (for $L = 3000$ km and $E = 1$ GeV, the neutrino oscillations governed by the small mass squared difference contribute with an approximate addition of 0.05 to the neutrino oscillation probability P_{ex}, for shorter baselines and higher energies, this effect decreases); see, for example, Ref. 20. The reason for using the upper bound value for the mixing angle θ and not some smaller value is that we wish to study the behavior of our solution rather than to make any precise predictions about the neutrino oscillation probabilities.

A. Series expansion of the effective potential

In order to use the series solution, which was obtained in the previous section, we will need the coefficients V_n. In general, for a given baseline length L, the effective potential $V(t)$ can be expanded in terms of Legendre polynomials, i.e.,

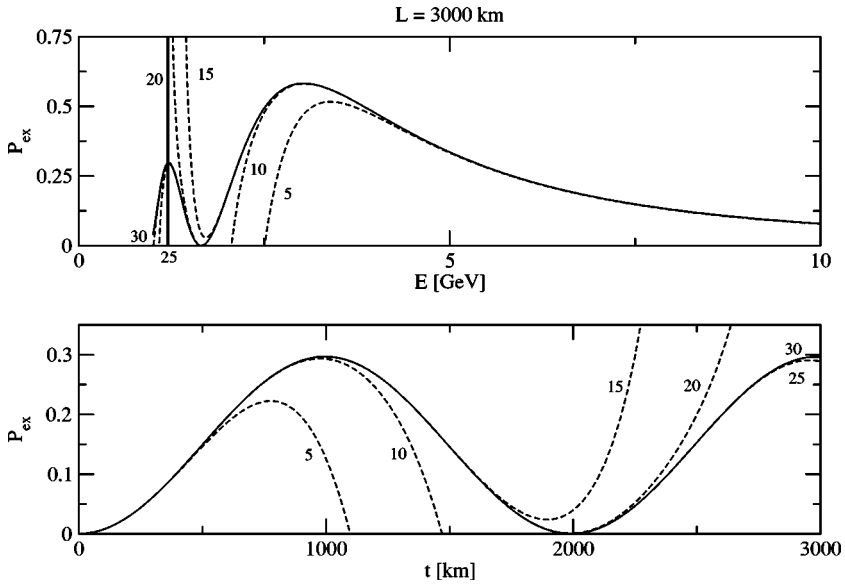

FIG. 1. The neutrino oscillation probability P_{ex} as a function of energy and time, respectively. Upper panel: The convergence of the energy spectrum given by our series expansion for a constant electron number density profile with $N_e = N_{e,\mathrm{core}}/3$. Lower panel: The convergence of the series expansion for $E = 1.2$ GeV, corresponding to the bold line in the energy spectrum. The solid curves correspond to the exact solutions and the dashed curves correspond to the series expansion. The numbers correspond to the number of terms used in the series expansion. The solid vertical line in the upper panel corresponds to the energy used for the lower panel.

$$V(x) = \sum_{n=0}^{\infty} c_n P_n(x), \quad P_n(x) = \frac{1}{n!\,2^n}\frac{\mathrm{d}^n}{\mathrm{d}x^n}[(x^2-1)^n], \quad c_n = \frac{2n+1}{2}\int_{-1}^{1} V(x)P_n(x)\mathrm{d}x, \tag{20}$$

where $x \equiv 2t/L - 1$. For numerical treatments, we cannot use the entire expansion in Legendre polynomials because of finite computer memory and finite computer time. However, if we assume that the coefficients c_n are negligible for $n > N$, where N is some integer, then we have a polynomial approximation,

$$V(x) \simeq \sum_{n=0}^{N} c_n P_n(x), \tag{21}$$

of the effective potential. Clearly, given any polynomial $V(t)$, it is a trivial matter to extract the coefficients V_n. This approach turns out to be quite handy in the case of the PREM profile, which is discussed below.

B. Constant matter density

The first case we study numerically is the case of a constant effective potential. We use the baseline length $L = 3000$ km and the electron number density $N_e = N_{e,\mathrm{core}}/3$, where $V_{\mathrm{core}} = \sqrt{2}G_{\mathrm{F}}N_{e,\mathrm{core}} \simeq 5.6 \times 10^{-19}$ MeV corresponds to a matter density of about 13 g/cm^3, which is the maximum matter density in the Earth's core.[18] In this case, the coefficients V_n are easily obtained as $V_0 = V(t)$ and $V_n = 0$ for $n > 0$. Since the exact solution to this problem is known,[7] we focus on the convergence of our solution for P_{ex}, both in the energy spectrum and the time evolution. The numerical results are shown in Fig. 1. In this figure, we can observe that approximately 20 terms are needed to reconstruct one period of oscillation and that the convergence is indeed the same as for a simple trigonometric function.

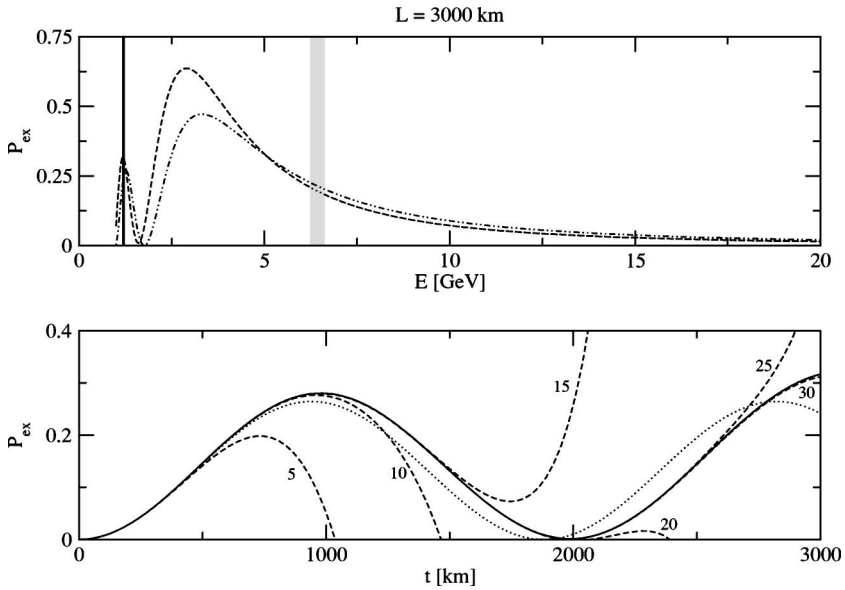

FIG. 2. The energy spectrum of the neutrino oscillation probability P_{ex} for a linear profile (upper panel) with $N_e = N_{e,\mathrm{core}}(1+t/L)/4$ along with the convergence of the solution for $E=1.2$ GeV (lower panel). In the energy spectra, the dotted curve corresponds to the numerical solution for the given profile, the dashed curve corresponds to our series solution, where we have included the first 35 terms, and the dash–dotted curve corresponds to an approximation of constant matter density. The solid vertical line corresponds to the energy used in the lower panel and the series solution is not plotted in the shaded region where it breaks down numerically. In the time evolution plot, the solid curve corresponds to the numerical solution, the dotted curve corresponds to the approximation of constant matter density, the dashed curves correspond to our series solution for different numbers of included terms, and the numbers correspond to the number of terms used for each of these curves.

C. Linearly varying matter density

Now, we turn our interest towards the case of a linearly varying effective potential. In particular, we study a baseline of $L=3000$ km, where the electron number density is given by $N_e(t)=N_{e,\mathrm{core}}(t/L+1)/4$. As in the case of constant effective potential, it is again easy to obtain the coefficients V_n from our equation for $V(t)$. Performing the numerical calculations results in Fig. 2. In this figure, we have excluded the plot for our solution in the shaded region, which roughly corresponds to an energy equal to the resonance energy of the effective potential $V=V_0$, where the solution breaks down numerically. The reason for this breakdown can be found in Eq. (18), where we repeatedly divide by F_0. For the resonance energy corresponding to $V=V_0$, we have $F_0 \sim 0$, which leads to large absolute values of numbers that should add up to a number between zero and one. Due to finite machine precision, we have numerical errors as a result.

Apart from neutrino energies near the resonance energy, we can observe that we again obtain a nice convergence of both the energy spectrum and the time evolution, where we reproduce one full oscillation by approximately 20 terms of our series expansion. It should be pointed out that this case of linearly varying matter density has no known application to experiments and only serves as an illustrative example.

D. PREM profile

For the PREM electron number density profile, which is the interesting profile in, for example, long-baseline neutrino oscillation experiments, we use the expansion in Legendre polynomials and truncate the series using $N=2$ for definiteness. In effect, this corresponds to projecting the function $V(t)$, which is an element in the vector space of real functions on the interval $[0,L]$, onto the subspace of second order polynomial functions on $[0,L]$, using the inner product

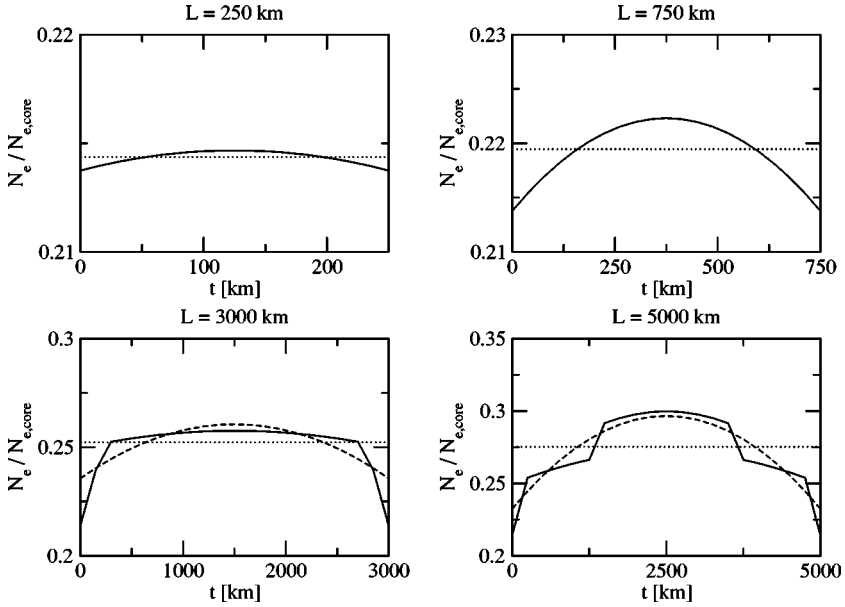

FIG. 3. The matter density profiles for different baseline lengths L according to the PREM. The solid curves are the exact profiles, the dashed curves are profiles approximated by a second order polynomial, and the dotted lines are the average matter densities, i.e., the matter density of approximations using constant electron number density. For $L=250$ km and 750 km the exact profiles and the approximations using a second order polynomial are practically the same and as a result they are not distinguishable in the figure.

$$\langle f,g\rangle = \int_0^L f(x)g(x)\mathrm{d}x. \tag{22}$$

In Fig. 3, we plot the electron number density profiles for the baseline lengths $L=250$ km, 750 km, 3000 km, and 5000 km along with the second order polynomial approximations and the constant approximations. In Fig. 4, we plot the energy spectra and time evolution at $E=1.2$ GeV for a baseline of $L=3000$ km for the PREM profile. Again, our solution is not plotted in the shaded region in which it breaks down numerically for the same reasons as discussed previously. In this case, it is apparent that if the number of terms used in the series expansion is large enough, our solution is a significant improvement from the constant matter density approximation.

Clearly, the approximation of using a second order polynomial for the electron number density gives a very good reproduction of the numerical solution (which uses the profiles obtained from the PREM). As can be seen in the time evolution plot, the error made is barely noticeable until approximately one and a half oscillations, i.e., for lower neutrino energies if the baseline length L is kept fixed. This is in good agreement with the results obtained in Ref. 21, where the effective potential is expanded in a Fourier series, as well as Ref. 22, which shows that details of the effective potential that are smaller than the oscillation length cannot be resolved by neutrino oscillations. As noticed in both of the earlier cases, about 20 terms are needed in the series expansion in order to reproduce one full oscillation.

For the PREM profile, we are also interested in a number of other baseline lengths. In particular, in Fig. 5, we plot the energy spectra for the baseline lengths $L=250$ km, 750 km, 3000 km, and 5000 km. For the baseline lengths $L=250$ km and 750 km, there is no noticeable difference between the numerical solution, our exact solution, and the approximation using constant electron number density. This is to be expected as the electron number density does not vary significantly for these baseline lengths (see Fig. 3). However, for both $L=3000$ km and 5000 km, we do observe a difference between the constant electron number density approximations and the other two solutions. Again, we can conclude that the approximation with a second order polyno-

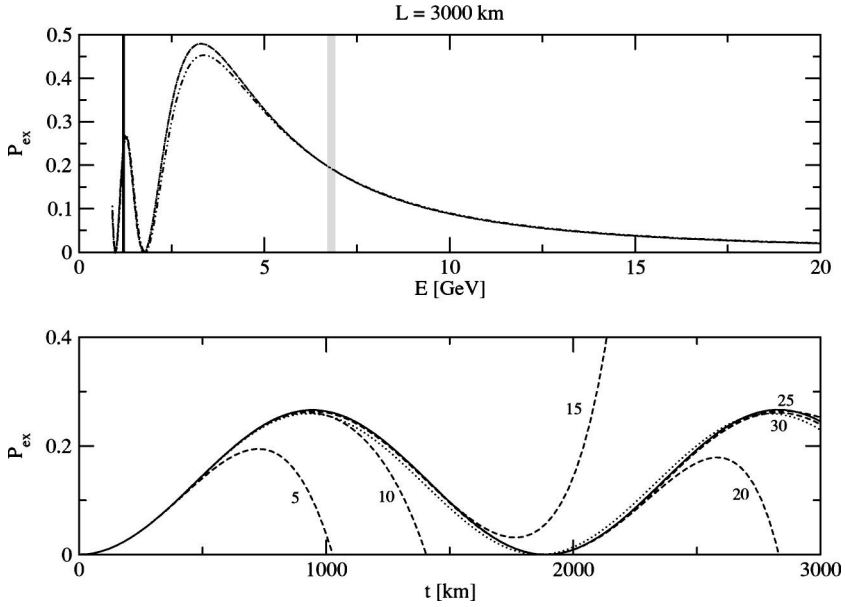

FIG. 4. The energy spectrum for the neutrino oscillation probability P_{ex} using 35 terms of our series solution (upper panel) and the convergence of the time evolution for $E=1.2$ GeV (lower panel). Here we assume a baseline of $L=3000$ km and using the PREM profile for the electron number density. In the energy spectrum, the dashed curve corresponds to the numerical solution using the PREM profile, the dotted curve corresponds to our series solution, and the dash-dotted curve corresponds to the approximation using constant matter density. The solid vertical line corresponds to the energy used in the lower panel and the series solution is not plotted in the shaded region where it breaks down numerically. In the time evolution plot, the solid curve corresponds to the numerical solution, the dotted curve to the solution for the constant matter density approximation, the dashed curves correspond to our series solution using different numbers of terms, and the numbers correspond to the number of terms used for each of these curves.

mial for the electron number density agrees remarkably well with the numerical calculation using the profile obtained directly from the PREM. Note that the comparison of the energy spectra for different matter density profiles and baselines has been studied before.[23]

For baselines longer than $L=5000$ km, the region near the resonance for $V=V_0$ tends to expand and ruin the numerical convergence of our solution. Also, this region expands if we include more terms of the series expansion. For the baseline lengths below $L=5000$ km, this can be somewhat compensated by using fewer terms of the series expansion for high energies to avoid the numerical cancellation effects and more terms for lower energies to obtain a nice convergence.

V. OTHER METHODS OF SOLVING THE NEUTRINO FLAVOR EVOLUTION

In general, there have been numerous methods on how to solve the problem of neutrino flavor evolution in matter.[7,9–17] First of all, there is the obvious formal solution using a time-ordered exponential, i.e.,

$$|\nu(t)\rangle = T\left[\exp\left(-\mathrm{i}\int_0^t H(\tau)\mathrm{d}\tau\right)\right]|\nu(0)\rangle. \tag{23}$$

This solution is exact, but it is not very helpful in actual calculations due to the nature of the time-ordered exponential. A way of solving this problem is to use a discretization of the effective potential.[9,24] The effective potential is then divided into a finite number of layers with constant effective potentials (i.e., constant electron number density), which approximate a given effective potential. Clearly, when the number of layers goes to infinity, one regains the time-ordered exponential.

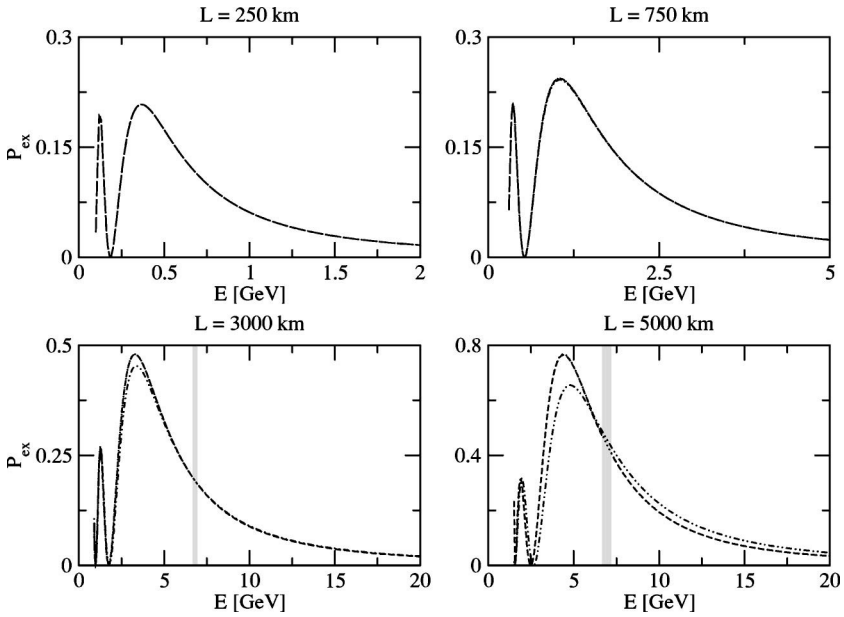

FIG. 5. The energy spectra of the neutrino oscillation probability P_{ex} for different baselines using the PREM profile for the electron number density. Again, we have used 35 terms from our series solution for each of these energy spectra and the dashed curves correspond to the numerical solutions, the dotted curves correspond to our series solution, and the dash-dotted curves correspond to the constant density approximations. The series solution is not plotted in the shaded regions where it breaks down numerically.

There is also the pure numerical approach to the problem, where the neutrino flavor evolution is easily solved numerically for any effective potential. While this gives the possibility of actually calculating numerical values for the neutrino oscillation probabilities, it does not offer any insight into how these probabilities vary with different parameters.

In addition, the neutrino flavor evolution can be analytically solved for some specific effective potentials. Examples are the constant (two flavors[7] and three flavors[11]), linearly[12] and exponentially[13] varying effective potentials.

Moreover, a widely used solution is the adiabatic solution,[14,15] where the effective potential is assumed to change slowly, so that there are no transitions between different matter eigenstates of the full Hamiltonian. This approximation can be derived by, for example, using the Wentzel–Kramers–Brillouin (WKB) method,[15] where also higher order corrections due to nonadiabatic transitions can be calculated.

There have also been earlier efforts to write the neutrino evolution equations as ordinary nonlinear differential equations; see, for example, Ref. 17. However, such equations have generally been complex differential equations for the probability amplitudes and not, as in the present case, real differential equations for the probabilities. Also, the solutions in such cases have been made for special cases of the effective potential and not as series solutions valid for all effective potentials.

Lately, approximate solutions, valid when the effective potential $V \ll \Delta m^2/(2E)$, have been presented[16] and applied to oscillations of solar neutrinos and the solar neutrino day–night effect. However, these solutions are not valid for the baseline lengths and neutrino energies which we have treated numerically.

VI. SUMMARY AND CONCLUSIONS

We have shown that solving the general problem of two flavor neutrino oscillations with an arbitrary effective potential is equivalent with solving the nonlinear ordinary differential equation,

$$(\ddot{p} + Gp)^2 = F(t)[G(1 - p^2) - \dot{p}^2], \tag{24}$$

where $G \equiv [\Delta m^2/(2E)]^2 \sin^2(2\theta), F(t) \equiv [\Delta m^2 \cos(2\theta)/(2E) - V(t)]^2$, and the neutrino oscillation probability P_{ex} is given by

$$P_{ex} = \frac{1}{2}(1 - p). \tag{25}$$

We have presented an exact solution [see Eqs. (18) and (19)] to this equation by adopting the method of series expansion of both the solution and the effective potential $V(t)$ and demonstrated the numerical convergence of this solution for a number of different effective potentials. In all cases investigated, about 20 terms in the series expansion are required to reproduce one period of oscillation. We have also seen that for the neutrino energies and baselines considered, the energy spectra of the neutrino oscillation probability is well reproduced by approximating the effective potential by a second order polynomial.

The asymptotic behavior of the stochastic Ginzburg–Landau equation is studied. We obtain the stochastic Ginzburg–Landau equation as a finite-dimensional random attractor. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1794365]

I. INTRODUCTION

Let us consider the following stochastic Ginzburg–Landau equation perturbed by a multiplicative white noise of Itô form:

$$du = (\lambda + i\alpha)\Delta u\, dt + \nu u\, dt - (k + i\beta)|u|^2 u\, dt + \sigma u\, dW(t). \tag{1}$$

As one of the nonlinear Schrodinger equation, it can be found in many areas of physics and chemistry (Ref. 9). The white noise described by a Wiener process $W(t)$ results from the fact that small irregularity has to be taken account in some circumstances. Due to the special linear multiplicative noise, the equation (1) can be reduced to an equation with random coefficients and thus solved pathwise. As the solution of the stochastic Ginzburg–Landau equation exists globally, a natural problem is the qualitative analysis of the solution, and from which, to understand the noise effect on the deterministic differential system.

As it is well known, the equation (1) can be rewritten as the Stratonovich form (Ref. 8)

$$du = (\lambda + i\alpha)\Delta u\, dt + \left(\nu - \frac{\sigma^2}{2}\right)u\, dt - (k + i\beta)|u|^2 u\, dt + \sigma u \circ dW. \tag{2}$$

We find, if $\nu \leqslant \lambda\lambda_1 + \sigma^2/2$, the trivial solution is stable with probability one. For an unperturbed system, the stationary solution is stable if $\nu \leqslant \lambda\lambda_1$. The similar fact can also be found in the stochastic reaction-diffusion equation (Ref. 2). If $\nu > \lambda\lambda_1 + \sigma^2/2$, we need the random attractor to study the long-time behavior of our problem. The notion of an attractor of the semigroup for the associated deterministically differential system is well known to be a compact invariant set in the phase space which attracts all bounded sets of the initial state. Recently, the corresponding generalization of this concept to the stochastic case was introduced by Crauel and Flandoli (Ref. 4) and Schmalfuss (Ref. 6) independently. Since a stochastic differential equation is driven by a Wiener process, the equation is nonautonomous and the trajectory of the solution cannot be attracted by some bounded set. They exploited successfully a random attractor to tackle these difficulties by introducing a cocycle and redefining the absorption concept. It is shown that the random attractor is a proper extension and some important information on the asymptotic behavior of the stochastic system can be obtained (Ref. 3). Their framework is suitable for our problem. First, the linear multiplicative noise makes us construct a random dynamical system modeling our stochastic differential equation. By assuming that $|\beta| < k$, we verify the compactness of the absorbing set. Finally, we obtain the existence of the random attractor for the stochastic Ginzburg–Landau equation.

[a)]Electronic mail: dsyang@mail.csu.edu.cn

Another important problem is the Hausdorff dimension of the random attractor. A finite dimension of the attractor characterize the number of degrees of freedom present in the long term dynamics of the system. Since the random attractor is not uniformly bounded, some relative restrictive assumptions must be imposed to guarantee the generalization of the theory of deterministic system to the stochastic case (Refs. 5,6). Applying the approach developed by Debussche in Ref. 5 to the stochastic Ginzburg–Landau equation, we prove that the random attractor has a finite Hausdorff dimension. The key is to prove that the cocycle associated with the stochastic equation is uniformly differentiable. It needs the bound of the solution in L^p for $\forall p \in Z^+$, which is not easy to obtain for the stochastic Ginzburg–Landau equation. We have to assume that $|\alpha| < \lambda$ to obtain the bound of the solution in L^p for $1 \leqslant p \leqslant 8$, and then to choose proper parameters to prove the differentiability.

This paper is arranged as follows. In Sec. II, we will present some preliminaries and the stability conclusion for the unperturbed system. The stability of the stationary solution for the stochastic system will be included in Sec. III. In Sec. IV, we introduce the framework of the theory of a random dynamical system and random attractor and prove the existence of the random attractor for the stochastic Ginzburg–Landau equation. In the end, we prove that the random attractor has a finite Hausdorff dimension.

II. PRELIMINARIES

Let $D \subset R^n$ $(n=1,2)$ be an open bounded set with a boundary ∂D sufficiently regular. We consider the following the stochastic Ginzburg–Landau equation in D perturbed by a multiplicative white noise:

$$du = (\lambda + i\alpha)\Delta u dt + \nu u dt - (k + i\beta)|u|^2 u dt + \sigma u dW(t), \quad \text{in} \quad D;$$

$$u(t) = 0, \quad \text{on} \quad D;$$

$$u(0) = u_0; \tag{3}$$

where $\lambda, \alpha, \nu, k, \beta, \sigma \in R, \lambda > |\alpha|, k > |\beta|, \sigma > 0$, and $W(t): \Omega \to R$ is a two-sided standard Wiener process. The unknown function u is a complex valued function defined on $D \times R^+$. We now introduce the following complex Sobolev space. Denoted by $\mathbb{X}$ with the norm $|\cdot|_{\mathbb{X}}$, the complexified space of a functional space X with the norm $|\cdot|_X$, by $(\cdot,\cdot)$ and $|\cdot|$ the inner product and the norm in $\mathbb{L}^2(D)$, respectively, by $\mathbf{((\cdot))}$ and $\|\cdot\| + |\cdot|$, the inner product and the norm in $\mathbb{H}_0^1(D)$, respectively, where

$$(u,v) = \mathrm{Re} \int_D u(x)\overline{v}(x)dx$$

for $u, v \in \mathbb{L}^2(D)$ and for $u, v \in \mathbb{H}_0^1(D)$,

$$((u,v)) = \mathrm{Re} \sum_{i=1}^{n} \int_D D_i u D_i \overline{v}\, dx, \quad \|u\| = (((u,u)))^{1/2}.$$

We always write $H = \mathbb{L}^2(D), V = \mathbb{H}_0^1(D)$, $Au = -\Delta u$, and $f(u) = |u|^2 u$. The operator A is an isomorphism from $D(A) = V \cap \mathbb{H}^2(D)$ onto H. Let $\{e_n\}$ be the orthonormal basis in H of its eigenvectors with the corresponding eigenvalues $\lambda_n, \lambda_n > 0, \lambda_n \nearrow \infty$. For the first eigenvalue, we have the inequality $\lambda_1 |u|^2 \leqslant \|u\|^2$. The stochastic Ginzburg–Landau equation (3) can be rewritten as follows in the abstract form:

$$du + (\lambda + i\alpha)Au\, dt - \nu u\, dt + (k + i\beta)f(u)dt = \sigma u\, dW(t),$$

$$u(0) = u_0. \tag{4}$$

For the unperturbed system (i.e., $\sigma=0$), the stabilization of the trivial solution and the existence of the global attractor is well known (Ref. 9). For convenience, we will give a concise statement. First the Ginzburg–Landau equation has a unique solution,

$$u \in C([0,T];H) \cap L^2(0,T;V), \quad \forall\, T<\infty \quad \text{for} \quad u_0 \in H$$

and

$$u \in C([0,T];V) \cap L^2(0,T;D(A)), \quad \forall\, T<\infty \quad \text{for} \quad u_0 \in V.$$

The energy equation can be given as

$$\frac{1}{2}\frac{d}{dt}|u|^2 + \lambda\|u\|^2 - \nu|u|^2 + k|u|_{L^4}^4 = 0. \tag{5}$$

If $\nu<\lambda\lambda_1$, (5) leads to

$$|u(t)| \leqslant |u_0|\exp\{(\nu-\lambda\lambda_1)t\},$$

which follows the stationary solution $u=0$ is exponentially stable.

If $\nu=\lambda\lambda_1$, we have from (5),

$$|u(t)| \leqslant Ct^{1/2},$$

for some constant C dependent on the initial u_0, k, and the domain D. So the stationary solution $u=0$ is asymptotically stable.

If $\nu>\lambda\lambda_1$, the dynamical system associated with the Ginzburg–Landau possesses a finite-dimensional global attractor.

The analysis above shows that, if $\nu\leqslant\lambda\lambda_1$, all the trajectories converge to 0 as $t\to\infty$. Hence, the global attractor is reduced to the stationary solution $\{0\}$.

III. STABILITY

In this section, we continue to consider the asymptotic behavior of the deterministic Ginzburg–Landau equation perturbed by a multiplicative white noise in the Itô sense. First, due to special linear multiplicative noise, the stochastic Ginzburg–Landau equation can be reduced to an equation with random coefficients by a suitable change of variable. Then the same method as the deterministic theory leads to the existence and uniqueness of the solution to (4). Consider the process

$$z(t) = e^{-\sigma W(t)},$$

which satisfies the stochastic differential equation

$$dz(t) = \frac{1}{2}\sigma^2 z\, dt - \sigma z\, dW(t).$$

The process $v(t)=z(t)u(t)$ follows the random differential equation,

$$dv(t) + (\lambda + i\alpha)Av\, dt - \left(\nu - \frac{\sigma^2}{2}\right)v\, dt + (k+i\beta)zf(u)dt = 0.$$

Since $z(t)$ is a real-valued process, the equation above can be rewritten as a more explicit form,

$$dv(t) + (\lambda + i\alpha)Av\, dt - \left(\nu - \frac{\sigma^2}{2}\right)v\, dt + (k+i\beta)z^{-2}f(v)dt = 0, \tag{6}$$

this equation can be solved pathwise. Exploiting the Galerkin approximation and *a priori* esti-

mates, the same conclusion as Theorem 5.1 in Temam[9] can be derived as folllows. For P-almost every $\omega \in \Omega$, the equation (6) possesses a unique strong solution,

$$v \in C([s,t];H) \cap L^2(s,t;V), \quad \forall\, s < t \quad \text{for } v(s) \in H$$

and

$$v \in C([s,t];V) \cap L^2(s,t;D(A)), \quad \forall\, s < t \quad \text{for } v(s) \in V.$$

Then $u(t)=Z(t)v(t)$ with $Z(t)=e^{\sigma W(t)}$ is a solution to the equation (4). We now state the stability conclusion.

Theorem 1: *Assume* $\nu < \lambda\lambda_1 + \frac{1}{2}\sigma^2$. *Then there is a P-full set* Ω_1 *such that for all* $\omega \in \Omega_1$,

$$|u(t,\omega,u_0)| \leqslant |u_0| e^{(1/2)[\nu - \lambda\lambda_1 - (1/2)\sigma^2]t}, \tag{7}$$

holds for each $u_0 \in H$, *and* $t \geqslant T(\omega)$ *for some* $T(\omega) > 0$.

Proof: Applying the Itô formula to $|u(t)|^2$, we have

$$|u(t)|^2 = |u_0|^2 + 2\int_0^t \left(-\lambda \|u(s)\|^2 + \left(\nu + \frac{\sigma^2}{2}\right)|u(s)|^2 - k|u(s)|_{L^4}^4 \right) ds + 2\int_0^t \sigma |u(s)|^2\, dW(s).$$

Let us apply once again the Itô formula to the function $\log|u(t)|^2$. It follows that

$$\begin{aligned} \log|u(t)|^2 &= \log|u_0|^2 - 2\int_0^t \frac{1}{|u(s)|^2}(\lambda\|u(s)\|^2 + k|u(s)|_{L^4}^4) ds + (2\nu - \sigma^2)t + 2\sigma W(t) \\ &\leqslant \log|u_0|^2 + (2\nu - \lambda\lambda_2 - \sigma^2)t + 2\sigma W(t). \end{aligned} \tag{8}$$

As $\lim_{t\to\infty}(W(t)/t)=0$, P-a.s., there exists a P-full set Ω_1 such that for $\omega \in \Omega_1$ there exists $T(\omega) > 0$ such that

$$\frac{2\sigma W(t)}{t} \leqslant \left(\lambda\lambda_1 + \frac{\sigma^2}{2} - \nu\right) \quad \text{for} \quad t \geqslant T(\omega),$$

holds. It leads to

$$\log|u(t)|^2 \leqslant \log|u_0|^2 + \left(\nu - \lambda\lambda_2 - \frac{1}{2}\sigma^2\right)t, \tag{9}$$

which completes the proof. □

We have proved that the trivial solution is asymptotically exponentially stable with probability one. The stability interval on ν is extended from $(-\infty, \lambda\lambda_1]$ in the unperturbed system to $(-\infty, \lambda\lambda_1 + \sigma^2/2]$ in the system perturbed by the Itô noise. Note that it is the extra term appearing in the Itô formula that leads to the longer part $[\lambda\lambda_1, \lambda\lambda_1 + \sigma^2/2]$. In fact, Stratonovich noise is the correct one in the usual idealization from smooth perturbations to rough ones, while Itô noise is artificial. Considering the Itô equation is equivalent to adding two terms: a multiplicative noise and a deterministic damping; the resulting stabilization is a trivial consequence of the addition of damping, not of the noise. Similar to the deterministic case, as $\nu > \lambda\lambda_1 + \sigma^2/2$, we will exploit the random attractor to study the long-term behavior of the stochastic Ginzburg–Landau equation.

IV. EXISTENCE OF RANDOM ATTRACTORS

Let us begin with the definitions of a random dynamical system (RDS) and a random attractor developed by Arnold (Ref. 1), Crauel and Flandoli (Ref. 4) and Schmalfuss (Ref. 6), and then prove the existence of the random attractor for the stochastic Ginzburg–Landau equation.

Let $(\Omega,\mathcal{F},P)$ be a probability space and $\{\theta_t:\Omega\to\Omega, t\in R\}$ a family of measure-preserving transformations such that $\theta_0=id_\Omega$, and $\theta_{t+s}=\theta_t\circ\theta_s$, for all $t,s\in R$. We say $\{\theta_t\}$ is a metric dynamical system on $(\Omega,\mathcal{F},P)$. We assume that θ is ergodic under P.

Definition 2: Let (X,d) be a Polish space. A measurable map,

$$\varphi:R^+\times\Omega\times X\to X,(t,\omega,x)\to\varphi(t,\omega)x,$$

is called a random dynamical system (RDS) if φ satisfies the cocycle property: $\varphi(0,\omega)=id_X$, $\varphi(t+s,\omega)=\varphi(t,\theta_s\omega)\varphi(s,\omega)$, for all $t,s\in R^+$ and P-a.s. $\omega\in\Omega$.

A RDS is continuous if $\varphi(t,\omega):X\to X$ is continuous. In order to define the random attractor, some crucial notions are needed.

Definition 3: A set-valued map $K:\Omega\to 2^X$, the set of all subsets of X, is called a random compact set if $K(\omega)$ is a compact P-almost surely and if $\omega\to d(x,K(\omega))$ is measurable for each $x\in X$, where $d(x,M):=\inf_{y\in M}d(x,y)$.

Definition 4: Let $A(\omega)$ and $B(\omega)$ be two random sets. We say the following.

(1) *$A(\omega)$ attracts $B(\omega)$ if*

$$\lim_{t\to\infty}\operatorname{dist}(\varphi(t,\theta_{-t}\omega)B(\theta_{-t}\omega),A(\omega))=0,\quad P\text{-a.s.}$$

where $\operatorname{dist}(\cdot,\cdot)$ *denotes the Hausdorff semidistance in X.*

(2) *$A(\omega)$ absorbs $B(\omega)$ if there exists $t_B(\omega)$ such that for all $t\geqslant t_B(\omega)$,*

$$\phi(t,\theta_{-t}\omega)B(\theta_{-t}\omega)\subset A(\omega),\quad P\text{-a.s.}$$

Definition 5: A random set $\mathcal{A}(\omega)$ is said to be a random attractor for the RDS φ if P-a.s.

(1) *$\mathcal{A}(\omega)$ is a random compact set.*
(2) *$\mathcal{A}(\omega)$ is invariant, that is, $\varphi(t,\omega)\mathcal{A}(\omega)=\mathcal{A}(\theta_t\omega)$, for $\forall t\geqslant 0$.*
(3) *$\mathcal{A}(\omega)$ attracts all deterministic bounded sets $B\in X$.*

Similar to the deterministic theory, the existence result of random attractors can be stated as follows (Refs. 4 and 6).

Theorem 6: *If there exists a random compact set absorbing every bounded nonrandom set $B\subset X$, the RDS φ possesses a random attractor $\mathcal{A}(\omega)$,*

$$\mathcal{A}(\omega)=\overline{\bigcup_{B\subset X}\Lambda_B(\omega)},$$

where $\Lambda_B(\omega):=\cap_{s\geqslant 0}\overline{\cup_{t\geqslant s}\varphi(t,\theta_{-t}\omega)B}$ is the omega-limit set of B.

Remark 7: (1) The random attractor in Definition 5 is in fact a global random set attractor. It is unique (Ref. 4).

(2) $\varphi(t,\theta_{-t})x$ can be interpreted as the position at $t=0$ of the trajectory which was at x at time $-t$, that is, while time t is moving, the trajectory $\varphi(t,\theta_{-t}\omega)x$ is always at the position at time zero. Therefore, the random attractor in Definition 5 is also called the "pullback attractor."

Now we construct a RDS modeling the stochastic Ginzburg–Landau equation. For example, consider the set of continuous functions with value 0 at 0,

$$\Omega=\{\omega\in C(R,R):\omega(0)=0\}.$$

Let $\mathcal{F}$ be the Borel sigma-algebra induced by the compact-open topology of Ω, and let P be a Wiener measure on $(\Omega,\mathcal{F})$. Writing $W(t,\omega)=\omega(t)$, we define

$$\theta_t\omega(s)=\omega(t+s)-\omega(t),\tag{10}$$

which satisfies $\theta_t\circ\theta_s=\theta_{t+s}$. Then $(\Omega,\mathcal{F},P,(\theta_t)_{t\in R})$ is an ergodic metric dynamical system which models white noise. We set

$$u(t,\omega) = \psi(t,s;\omega)u_s, v(t,\omega) = \phi(t,s;\omega)v_s,$$

where $u(t)$ is a solution to the equation (4) with the initial value $u(s)=u_s$ and $v(t)$ satisfies (6) with $v(s)=v_s$. Obviously, for $s\leqslant r\leqslant t$, we have

$$\psi(t,s;\omega) = \psi(t,r;\omega)\psi(r,s;\omega).$$

Thanks to (10), for any $s,t\in R^+, u_0\in H$, we have P-a.s.,

$$\psi(t+s,0;\omega)u_0 = \psi(t,0;\theta_s\omega)\psi(s,0;\omega)u_0.$$

Therefore, the process $\varphi: R^+\times\Omega\times H\to H$, defined by

$$\varphi(t,\omega)u_0 = \psi(t,0;\omega)u_0, \tag{11}$$

is a cocycle. It is a continuous RDS on H over $(\Omega,\mathcal{F},P,(\theta_t)_{t\in R})$ and models the dynamical system associated with the stochastic equation (4).

In order to prove the existence of a compact absorbing set, we give first the following estimates:

Lemma 8: Given any ball of $H, B(0,\rho)$ centered at 0 of radius ρ, there exists random variables $r_t(\omega)$ and $t(\omega,\rho)\leqslant -1$ such that for any $s\leqslant t(\omega,\rho), u_s\in B(0,\rho), v_s=z(s)u_s$ and $-1\leqslant t\leqslant 0$,

$$|\phi(t,s;\omega)v_s| \leqslant r_t(\omega), \quad P\text{-a.s.}, \tag{12}$$

holds. Hence, we have

$$|\psi(0,s;\omega)u_s| \leqslant r_0(\omega).$$

Proof: Let $v(t)=v(t,s,v_s;\omega)$ be the solution of (6) with the initial value v_s. We have

$$\frac{d}{dt}|v|^2 + \lambda\|v\|^2 = -\lambda\|v\|^2 + (2\nu-\sigma^2)|v|^2 - 2kz^{-2}|v|_{\mathbb{L}^4}^4 \leqslant -(\lambda\lambda_1+\sigma^2)|v|^2 + 2\nu|v|^2 - 2kz^{-2}|v|_{\mathbb{L}^4}^4. \tag{13}$$

Taking into account that $|v|\leqslant|D|^{1/4}|v|_{\mathbb{L}^4}$, we get

$$\begin{aligned}\frac{d}{dt}|v|^2 + \lambda\|v\|^2 &\leqslant -(\lambda\lambda_1+\sigma^2)|v|^2 + 2\nu|D|^{1/2}|v|_{\mathbb{L}^4}^2 - 2kz^{-2}|v|_{\mathbb{L}^4}^4\\ &\leqslant -(\lambda\lambda_1+\sigma^2)|v|^2 + \nu^2|D|k^{-1}z^2 - kz^{-2}|v|_{\mathbb{L}^4}^4\\ &\leqslant -(\lambda\lambda_1+\sigma^2)|v|^2 + \nu^2|D|k^{-1}z^2.\end{aligned} \tag{14}$$

It follows that, for $t\geqslant s$,

$$\begin{aligned}|v(t)|^2 &\leqslant |v(s)|^2 e^{-(\lambda\lambda_1+\sigma^2)(t-s)} + \nu^2|D|k^{-1}\int_s^t e^{-(\lambda\lambda_1+\sigma^2)(t-\tau)}z^2(\tau)d\tau\\ &\leqslant e^{-(\lambda\lambda_1+\sigma^2)t}\left(e^{(\lambda\lambda_1+\sigma^2)s}z^2(s)|u_s|^2 + \nu^2|D|k^{-1}\int_s^t e^{(\lambda\lambda_1+\sigma^2)\tau}z^2(\tau)d\tau\right).\end{aligned} \tag{15}$$

Since $e^{(\lambda\lambda_1+\sigma^2)s}z^2(s) = e^{(\lambda\lambda_1+\sigma^2)s-2\sigma W(s)}\to 0, P$-a.s. as $s\to-\infty$, we can find, for $u_s\in B(0,\rho)\subset H$, a time $t(\omega,\rho)\leqslant -1$ such that

$$e^{(\lambda\lambda_1+\sigma^2)s}z^2(s)\rho^2 \leqslant 1,$$

holds P-a.s. for $s\leqslant t(\omega,\rho)$. Hence, choosing the positive variable $r_t(\omega)$,

$$r_t^2(\omega) = e^{-(\lambda\lambda_1+\sigma^2)t}\left(1 + \nu^2|D|k^{-1}\int_{-\infty}^{t} e^{(\lambda\lambda_1+\sigma^2)\tau}z^2(\tau)d\tau\right),$$

we obtain P-a.s.$|v(t)| \leqslant r_t(\omega)$. □

Note that if $\nu < \lambda\lambda_1 + \sigma^2/2$, from (13), we obtain

$$|v(t)| \leqslant |v(0)|e^{(\nu-\lambda\lambda_1-\sigma^2/2)t}.$$

It follows that

$$|u(t,\omega)| \leqslant |u_0|e^{(\nu-\lambda\lambda_1-\sigma^2/2+\sigma[W(t)/t])t}.$$

Since $\lim_{t\to\infty}[W(t)/t]=0, P$-a.s., there exits $t(\omega)$ such that for all $t \geqslant t(\omega)$,

$$\sigma\frac{W(t)}{t} \leqslant \frac{1}{2}\left(\lambda\lambda_1 + \frac{\sigma^2}{2} - \nu\right).$$

It leads to the same result as Theorem 1. From the view of the attractor, since for $s \leqslant 0$,

$$|u(0)| \leqslant |u_s|e^{-(\nu-\lambda\lambda_1-\sigma^2/2)s-\sigma W(s)},$$

we have $|u(0)| \to 0, P$-a.s. as $s \to -\infty$. Hence the global random attractor is reduced to $\{0\}$. From now on, we will assume that $\nu \geqslant \lambda\lambda_1 + \sigma^2/2$.

Lemma 8 shows there exists an absorbing set $B(0, r_0(\omega))$ in H. In order to obtain the existence of the absorbing set in V, we need the assumption $|\beta| \leqslant k$.

First, integrating (14) between -1 and 0, we have

$$\int_{-1}^{0}\|v\|^2\,ds \leqslant \frac{1}{\lambda}\left(|v(-1)|^2 + \nu^2|D|k^{-1}\int_{-1}^{0} z^2(s)ds\right).$$

Multiplying (6) by $-\Delta\overline{v}$, integrating over D, and taking the real part, we obtain

$$\frac{1}{2}\frac{d}{dt}\|v\|^2 + \lambda|\Delta v|^2 - \left(\nu - \frac{1}{2}\sigma^2\right)\|v\|^2 = z^{-2}\,\mathrm{Re}(k+i\beta)\int f(v)\Delta\overline{v}\,dx. \tag{16}$$

Using $|\beta| \leqslant k$, the right of (16) is nonpositive,

$$\begin{aligned}\mathrm{Re}(k+i\beta)\int f(v)\Delta\overline{v}\,dx &= -\,\mathrm{Re}(k+i\beta)\int (|v|^2|\nabla v|^2 + v\,\nabla\overline{v}\nabla|v|^2)dx\\ &= -k\int |v|^2|\nabla v|^2\,dx - \frac{k}{2}\int(\nabla|v|^2)^2\,dx + \beta\,\mathrm{Im}\int v^2(\nabla\overline{v})^2\,dx\\ &\leqslant (|\beta|-k)\int |v|^2|\nabla v|^2\,dx \leqslant 0.\end{aligned}$$

So (16) can be rewritten as

$$\frac{d}{dt}\|v\|^2 \leqslant -2\lambda|\Delta v|^2 + 2\left(\nu - \frac{\sigma^2}{2}\right)\|v\|^2 \leqslant 2\left(\nu - \lambda\lambda_1 - \frac{\sigma^2}{2}\right)\|v\|^2.$$

For any $s \in [-1,0]$, we have

$$\|v(0)\|^2 \leqslant \|v(s)\|^2 + 2\left(\nu - \lambda\lambda_1 - \frac{\sigma^2}{2}\right)\int_s^0 \|v(\tau)\|^2\,d\tau.$$

Integrating again in $[-1,0]$,

$$\|v(0)\|^2 \leqslant 2\left(\frac{1}{2}+\nu-\lambda\lambda_1-\frac{\sigma^2}{2}\right)\int_{-1}^{0}\|v(s)\|^2\,ds$$
$$\leqslant \frac{2}{\lambda}\left(\frac{1}{2}+\nu-\lambda\lambda_1-\frac{\sigma^2}{2}\right)\left(|v(-1)|^2+\nu^2|D|k^{-1}\int_{-1}^{0}z^2(s)ds\right). \tag{17}$$

Therefore, given $\rho>0$, there exists $T(\omega)\leqslant -1$ such that for $s\leqslant T(\omega)$ and $u_s\in B(0,\rho)\subset H$,

$$\|u(0)\|^2=\|v(0)\|^2\leqslant R_0^2(\omega), \tag{18}$$

holds P-a.s., where

$$R_0^2=\frac{2}{\lambda}\left(\frac{1}{2}+\nu-\lambda\lambda_1-\frac{\sigma^2}{2}\right)(e^{\lambda\lambda_1+\sigma^2}+\nu^2|D|k^{-1})\left(1+\int_{-\infty}^{0}e^{(\lambda\lambda_1+\sigma^2)\tau}z^2(\tau)d\tau+\int_{-1}^{0}z^2(s)ds\right).$$

In the end, applying Theorem 6, we conclude the following.

Theorem 9: *Under the assumption $|\beta|\leqslant k$, the random dynamical system associated with the stochastic Ginzburg–Landau equation possesses a global random attractor $\mathcal{A}(\omega)$. If $\nu<\lambda\lambda_1+\sigma^2/2$, the attractor $\mathcal{A}(\omega)$ is reduced to $\{0\}$.*

Although we have obtained a compact absorbing set which guarantees the existence of the random attractor, the union in ω of $\mathcal{A}(\omega)$ is not compact in general. However, as $\sigma\to 0$, the $\mathcal{A}(\omega)$ may converge to the corresponding deterministic attractor with probability one (Ref. 3).

Since P is invariant under θ_t, the asymptotic behavior with an attraction property from 0 to ∞ can be obtained in a weaker convergence in probability, that is,

$$\lim_{t\to\infty}P(\mathrm{dist}(\varphi(t,\omega)B,\mathcal{A}(\theta_t\omega))<\varepsilon)=1,$$

holds for all $\varepsilon>0$ and all deterministic bounded set $B\subset H$. Especially, if $\nu<\lambda\lambda_1+\sigma^2/2$, the attraction as $t\to\infty$ holds not only in probability and not also ω-wise.

V. HAUSDORFF DIMENSION OF THE RANDOM ATTRACTOR

Although the random attractor is not uniformly bounded, it is expected that the theory on the Hausdorff dimension of a global attractor of a deterministic system can be generalized to the stochastic case under some assumption (Refs. 5,7). The following conclusion is due to Debussche (Ref. 5).

Theorem 10: *Let $\mathcal{A}(\omega)$ be a compact measurable set which is invariant under a random map $S(\omega),\omega\in\Omega$, for some ergodic metric dynamical system $(\Omega,\mathcal{F},P,(\theta_t)_{t\in R})$. Assume the following.*

(1) *$S(\omega)$ is almost surely uniformly differentiable on $\mathcal{A}(\omega)$, that is, for every $u,u+h\in\mathcal{A}(\omega)$ there exists $D(S(\omega,u))$ in $\mathcal{L}(\mathcal{H})$, the space of the bounded linear operator from H to H, such that*

$$|S(\omega)(u+h)-S(\omega)u-DS(\omega,u)h|\leqslant\overline{k}(\omega)|h|^{1+\mu},$$

where $\mu>0$, $\overline{k}(\omega)$ is a random variable satisfying $\overline{k}(\omega)\geqslant 1, E(\log\overline{k})<\infty$.

(2) *$\omega_d(DS(\omega,u))\leqslant\overline{\omega}_d(\omega)$ for $u\in\mathcal{A}(\omega)$ and some random variable $\overline{\omega}_d(\omega)$ satisfying $E(\log(\overline{\omega}_d))<0$, where*

$$\omega_d(L)=\alpha_1(L)\cdots\alpha_d(L),\alpha_i(L)=\sup_{\substack{F\subset H\\ \dim F\leqslant n-1}}\inf_{\varphi\in F}|L\varphi| \quad \text{for } L\in\mathcal{L}(\mathcal{H}).$$

(3) *$\alpha_1(DS(\omega,u))\leqslant\overline{\alpha}_1(\omega)$, for $u\in\mathcal{A}(\omega)$ and a random variable $\overline{\alpha}_1(\omega)\geqslant 1$ with $E(\log\overline{\alpha}_1)<\infty$.*

Then the Hausdorff dimension $d_H(\mathcal{A}(\omega))$ of $\mathcal{A}(\omega)$ is less than d almost surely.

According to this theorem, in fact, the main task is to verify that the cocycle defined by (11) has the uniform differentiability. We set

$$S(\omega) = \varphi(1,\omega), \quad T(\omega)v_0 = \phi(1,0,v_0;\omega); \tag{19}$$

then the random attractor $\mathcal{A}(\omega)$ is a compact measurable set invariant by S. Since $S(\omega) = e^{\sigma W(1)}T(\omega)$, it is easy to see that if $T(\omega)$ is almost surely uniformly differentiable with the Fréchet derivative DT, then $S(\omega)$ is also almost surely uniformly differentiable with the Fréchet derivative $DS = e^{\sigma W(1)}DT$. Consequently, we turn to prove the following.

Lemma 11: $T(\omega)$ is almost surely uniformly differentiable on $\mathcal{A}(\omega)$: for $v, v+h \in \mathcal{A}(\omega)$, there exists $DT(\omega,v) \in \mathcal{L}(\mathcal{H})$ such that

$$|T(\omega)(v+h) - T(\omega)v - DT(\omega,v)h| \leqslant \overline{k}(\omega)|h|^{1+\mu},$$

holds P-a.s., *where* $\mu > 0, \overline{k}(\omega) \geqslant 1, E(\log \overline{k}(\omega)) < \infty$ *and* $DT(\omega,v_0)h = V(1), V(t)$ *solves the first variation equation for (6),*

$$\frac{dV}{dt} = L(t,v)V,$$

$$V(0) = h, \tag{20}$$

where $v(t) = \phi(t,0,v_0;\omega), L(t,v) = -(\lambda + i\alpha)A + (\nu - \sigma^2/2) - (k + i\beta)z^{-2}f'(v)$.

The proof will be given in the Appendix.

From Eq. (20), we have

$$\frac{1}{2}\frac{d}{dt}|V|^2 = -\lambda\|V\|^2 + \left(\nu - \frac{\sigma^2}{2}\right)|V|^2 - \mathrm{Re}(k + i\beta)z^{-2}\int_D (|v|^2|V|^2 + 2v\overline{V}\,\mathrm{Re}(\overline{v}V))dx.$$

The third term of the right is nonpositive,

$$\begin{aligned} &-\mathrm{Re}(k + i\beta)\int (|v|^2|V|^2 + 2v\overline{V}\,\mathrm{Re}(\overline{v}V))dx \\ &\quad \leqslant -k\int |v|^2|V|^2\,dx - 2\int \mathrm{Re}(\overline{v}V)\{k\,\mathrm{Re}(v\overline{V}) - \beta\,\mathrm{Im}(v\overline{V})\}dx \\ &\quad \leqslant -k\int |v|^2|V|^2\,dx + 2\beta\int \mathrm{Im}(v\overline{V})\mathrm{Re}(v\overline{V})dx \leqslant (|\beta| - k)\int |v|^2|V|^2\,dx \leqslant 0. \end{aligned}$$

Hence $|V(t)| \leqslant |V(0)|e^{(\nu - \lambda\lambda_1 - \sigma^2/2)t}$. Since $\alpha_1(DT(\omega,v))$ is equal to the norm of $DT(\omega,v) \in \mathcal{L}(\mathcal{H})$, it is not difficult, choosing $\overline{\alpha_1}(\omega) = \max\{e^{\sigma W(1) + \nu - \lambda\lambda_1 - \sigma^2/2}, 1\}$, to get

$$\alpha_1(DS(\omega,u)) \leqslant \overline{\alpha_1}(\omega),$$

and $E(\log \overline{\alpha_1}) < \infty$.

Note that we can write

$$DT(\omega,v) = \exp\left\{\int_0^1 L(s,v(s))ds\right\}$$

and

$$DS(\omega,u)=\exp\left\{\sigma W(1)+\int_0^1 L(s,v(s))ds\right\}.$$

Following Ref. 9, we have

$$\omega_d(DS(\omega,u))=\sup_{\substack{|\xi_i|\in H\\ |\xi_i|\leqslant 1,i=1,\cdot,d}}\exp\left\{\sigma W(1)+\int_0^1 \mathrm{Tr}(L(s,v(s))\circ Q_d(s))ds\right\},$$

where $Q_d(s)$ is the orthogonal projector in H onto the space spanned by $V_1(s),\ldots,V_d(s)$, and $V_i(s)$ is the solution of (20) with $V(0)=\xi_i$.

Let $\varphi_i(s), i\in N$ be an orthonormal basis of H such that $Q_d(s)H=\mathrm{Span}[\varphi_1(s),\ldots,\varphi_d(s)]$; then

$$\begin{aligned}\mathrm{Tr}(L(s,v(s))\circ Q_d(s))&=\textstyle\sum_{i=1}^d (L(s,v(s))\varphi_i(s),\varphi_i(s))\\ &\leqslant -\lambda\textstyle\sum_{i=1}^d\|\varphi_i\|^2+\left(\nu-\frac{\sigma^2}{2}\right)d\leqslant -\lambda\sum_{i=1}^d\lambda_i^2+\left(\nu-\frac{\sigma^2}{2}\right)d.\end{aligned}$$

Denoting $\overline{\omega}_d(\omega)=\exp\{\sigma W(1)-\lambda\Sigma_{i=1}^d\lambda_i^2+[\nu-(\sigma^2/2)]d\}$ and choosing d such that

$$\nu-\frac{\sigma^2}{2}<\frac{\lambda}{d}\sum_{i=1}^d\lambda_i^2,$$

then we have $\omega_d(DS)\leqslant\overline{\omega}_d(\omega)$ and $E(\log(\overline{\omega}_d))<0$.

In conclusion, we have the following result.

Theorem 12: *If there exists d such that $\nu\leqslant(\sigma^2/2)+\frac{\lambda}{d}\Sigma_{i=1}^d\lambda_i$ then P-*a.s. *$d_H(\mathcal{A}(\omega))<d$.*

Note that if $\nu<\lambda\lambda_1+(\sigma^2/2)$, the random attractor $\mathcal{A}(\omega)$ consists of one point which may be a random point.

APPENDIX: PROOF OF LEMMA 11

In this appendix, we prove the differentiability of $T(\omega)$. The proof will be divided into three steps.

Step 1. Bound in $\mathbb{L}^p, p\in Z^+,\ 1\leqslant p\leqslant 8$.

Lemma 13: Assume that $\lambda\geqslant|\alpha|$ and let $v(t)$ be the solution of (6); then for $p\in Z^+, 1\leqslant p\leqslant 4$, there exists a random variable $I_{2p}(\omega)$ such that

$$\int_0^1|v(s)|_{\mathbb{L}^{2p}}^{2p}\,ds\leqslant I_{2p}(\omega),\tag{A1}$$

where we use the notation $|\cdot|_{\mathbb{L}^p}=|\cdot|_p$, and for $\forall m\geqslant 0$,

$$E(I_{2p}^m)<\infty.$$

Proof: Due to the invariance of the random attractor $\mathcal{A}(\omega)$, for $v_0\in\mathcal{A}(\omega)$, there exists the solution $v(t)$ of (6) with $v(0)=v_0$ such that $v(t)\in\mathcal{A}(\theta_t\omega)$ for $\forall t\in R$. In order to obtain (A1), we show first that for $p\in Z^+, 1\leqslant p\leqslant 3$ and $r>0$,

$$\int_{t-r}^t|v(s)|_{2p+2}^{2p+2}\,ds\leqslant C\sup_{t-r\leqslant s\leqslant t}e^{-2\sigma W(s)}\int_{t-r-1}^t|v(s)|_{2p}^{2p}\,ds,\tag{A2}$$

where C is a deterministic constant which may be changed from one line to another; sometimes we denote by $C(\omega)$ a random constant dependent on $\omega\in\Omega$. Taking the scalar product of (6) with $\overline{v}|v|^{2p-2}(p\geqslant 1)$, and using the estimate

$$\mathrm{Re}(\lambda + i\alpha)\int_D \Delta v\overline{v}|v|^{2p-2}\,dx = -\lambda p\int_D |\nabla v|^2|v|^{2p-2}\,dx - (p-1)\mathrm{Re}(\lambda + i\alpha)\int_D (\overline{v}\nabla v)^2|v|^{2p-4}\,dx$$

$$\leqslant -\lambda(p - \sqrt{2}p + \sqrt{2})\int_D |\nabla v|^2|v|^{2p-2}\,dx \leqslant 0,$$

we obtain

$$\frac{1}{2p}\frac{d}{dt}|v|_{2p}^{2p} + e^{2\sigma W(t)}|v|_{2p+2}^{2p+2} \leqslant \left(\nu - \frac{\sigma^2}{2}\right)|v|_{2p}^{2p}. \tag{A3}$$

Integrating (A3) between s and t, we have

$$\frac{1}{2p}|v(t)|_{2p}^{2p} \leqslant \frac{1}{2p}|v(s)|_{2p}^{2p} + \left(\nu - \frac{\sigma^2}{2}\right)\int_s^t |v(\tau)|_{2p}^{2p}\,d\tau.$$

Let us integrate on s once again between $t-1$ and t to give

$$|v(t)|_{2p}^{2p} \leqslant \int_{t-1}^t |v(s)|_{2p}^{2p}\,ds + 2p\left(\nu - \frac{\sigma^2}{2}\right)\int_{t-1}^t |v(s)|_{2p}^{2p}\,ds. \tag{A4}$$

Using (A4), we then integrate (A3) between $t-r$ and t to give

$$\begin{aligned}\int_{t-r}^t e^{2\sigma W(s)}|v(s)|_{2p+2}^{2p+2}\,ds, &\leqslant \frac{1}{2p}|v(t-r)|_{2p}^{2p} + \left(\nu - \frac{\sigma^2}{2}\right)\int_{t-r}^t |v(s)|_{2p}^{2p}\,ds\\ &\leqslant \frac{1}{2p}\int_{t-r-1}^{t-r} |v(s)|_{2p}^{2p}\,ds + \left(\nu - \frac{\sigma^2}{2}\right)\int_{t-r-1}^{t-r} |v(s)|_{2p}^{2p}\,ds\\ &\quad + \left(\nu - \frac{\sigma^2}{2}\right)\int_{t-r}^t |v(s)|_{2p}^{2p}\,ds \leqslant (1 + 2\nu - \sigma^2)\int_{t-r-1}^t |v(s)|_{2p}^{2p}\,ds.\end{aligned}$$

It leads to

$$\int_{t-r}^t |v(s)|_{2p+2}^{2p+2}\,ds \leqslant (1 + 2\nu - \sigma^2)\sup_{t-r\leqslant s\leqslant t} e^{-2\sigma W(s)}\int_{t-r-1}^t |v(s)|_{2p}^{2p}\,ds.$$

Writing $S_i = \sup_{1-i\leqslant s\leqslant 1} e^{-2\sigma W(s)}$, we have

$$\begin{aligned}\int_0^1 |v(s)|_{2p+2}^{2p+2}\,ds &\leqslant (1 + 2\nu - \sigma^2)S_1\int_{-1}^1 |v(s)|_{2p}^{2p}\,ds \leqslant (1 + 2\nu - \sigma^2)^2 S_1 S_2\int_{-2}^1 |v(s)|_{2p-2}^{2p-2}\,ds\\ &\leqslant (1 + 2\nu - \sigma^2)^p S_1 S_2 S_p\int_{-p}^1 |v(s)|^2\,ds.\end{aligned}$$

Since $v(-3) \in \mathcal{A}(\theta_{-3}\omega)$, we have

$$|v(-3)| \leqslant r_{-3}(\theta_{-3}\omega)$$

Finally, using (15), we obtain the bound in H of $v(t)$ for $-3 \leqslant t \leqslant 1$, and hence complete the proof. □

Step 2. Lipschitz property for the solution. Let $v_i(t)$ $(i=1,2)$ be two solution of (6) with $v_i(0) = v_i^0$ and denote $g(t) = v_1(t) - v_2(t)$. Then $g(t)$ solves

$$\frac{dg}{dt} + (\lambda + i\alpha)Ag - \left(\nu - \frac{\sigma^2}{2}\right)g + (k + i\beta)z^{-2}(f(v_1) - f(v_2)) = 0.$$

Taking the scalar product of the equation with g, we get

$$\frac{1}{2}\frac{d}{dt}|g|^2 + \lambda\|g\|^2 - \left(\nu - \frac{\sigma^2}{2}\right)|g|^2 = -\operatorname{Re}(k + i\beta)z^{-2}\int_D (f(v_1) - f(v_2))(\overline{v_1} - \overline{v_2})dx. \tag{A5}$$

Note that the right side of Eq. (A5) is bounded by

$$Cz^{-2}(|v_1|_6^3 + |v_2|_6^3)|g|^2.$$

Hence we obtain

$$|g(t)|^2 \leqslant |g(0)|^2 \exp\left\{\left(\nu - \lambda\lambda_1 - \frac{\sigma^2}{2}\right)t + C\int_0^t z^{-2}(s)(|v_1(s)|_6^3 + |v_2(s)|_6^3)ds\right\}. \tag{A6}$$

From (A1), it leads to

$$|g(1)|^2 \leqslant |g(0)|^2 \exp\left\{\nu - \lambda\lambda_1 - \frac{\sigma^2}{2} + C\sup_{0\leqslant s\leqslant 1} z^{-2}(s)I_6(\omega)\right\}.$$

Finally, we get

$$|v_1(1) - v_2(1)| \leqslant C(\omega)|v_1^0 - v_2^0|,$$

with $E(C(\omega)) < \infty$. □

Step 3. Differentiability of $T(\omega)$.

Let $r(t) = v_1(t) - v_2(t) - V(t)$, where $v_i(t)(i = 1, 2)$ be two solutions of (6) with $v_i(0) = v_i^0$ and $V(t)$ satisfies the linear equation (20) with $L(t, v_2)$ and $h = v_1^0 - v_2^0$. Then $r(t)$ satisfies the equation

$$\frac{dr}{dt} + (\lambda + i\alpha)Av - \left(\nu - \frac{\sigma^2}{2}\right)r = -(k + i\beta)z^{-2}(f(v_1) - f(v_2) - f'(v_2)(v_1 - v_2 - r)).$$

Taking the scalar product this equation with r, we get

$$\frac{1}{2}\frac{d}{dt}|r|^2 + \lambda\|r\|^2 \leqslant \left(\nu - \frac{\sigma^2}{2}\right)|r|^2 - \operatorname{Re}(k + i\beta)z^{-2}\int_D f'(v_2)|r|^2\,dx - \operatorname{Re}(k + i\beta)z^{-2}\int_D (f(v_1) - f(v_2) - f'(v_2)(v_1 - v_2))\overline{r}\,dx. \tag{A7}$$

The second term of the right side is nonpositive,

$$\begin{aligned} -\operatorname{Re}(k + i\beta)z^{-2}\int_D f'(v_2)|r|^2\,dx &= -\operatorname{Re}(k + i\beta)\int (|v_2|^2|r|^2 + 2v_2\overline{r}\operatorname{Re}(v_2\overline{r}))dx \\ &= -k\int (|v_2|^2|r|^2\,dx - 2k\int (\operatorname{Re}(v_2\overline{r}))^2\,dx + 2\beta\int \operatorname{Re}(v_2\overline{r}) \\ &\quad \times (\operatorname{Im}(v_2\overline{r}))dx \leqslant (|\beta| - k)\int |v_2|^2|r|^2\,dx \leqslant 0. \end{aligned}$$

We continue to estimate the third of (A7). First, the nonlinearity f satisfies the estimate

$$|f(v_1) - f(v_2) - f'(v_2)(v_1 - v_2)| \leqslant C(|v_1|^2 + |v_2|^2)|v_1 - v_2|.$$

By the Hölder estimate and the Sobelev embedding theorems, we have

$$-\mathrm{Re}(k+i\beta)z^{-2}\int_D (f(v_1)-f(v_2)-f'(v_2)(v_1-v_2))\bar{r}\,dx$$
$$\leqslant Cz^{-2}|(|v_1|^2+|v_2|^2)(v_1-v_2)|_s|r|_{s^*}\leqslant Cz^{-4}|(|v_1|^2+|v_2|^2)(v_1-v_2)|_s^2+\varepsilon\|r\|^2,$$

where $\varepsilon>0, s>1$ and s^* is the conjugate exponent of s. Let

$$0<\delta<\frac{2}{3},\quad 1<s<\frac{8}{6+3\delta}.$$

It follows easily that

$$1<s<\frac{2}{1+\delta},\quad s_1:=\frac{2s(2-\delta)}{2-s(1+\delta)}<8.$$

Therefore, we have

$$|(|v_1|^2+|v_2|^2)(v_1-v_2)|_s^s\leqslant C\int_D (|v_1|+|v_2|)^{3s-s(1+\delta)}|v_1-v_2|^{s(1+\delta)}\,dx$$
$$\leqslant C(|v_1|_{s_1}^{s(2-\delta)}+|v_2|_{s_1}^{s(2-\delta)})|v_1-v_2|^{s(1+\delta)}.$$

Returning to (A7), for ε small enough, we get

$$\frac{1}{2}\frac{d}{dt}|r|^2\leqslant\left(\nu-\frac{\sigma^2}{2}\right)|r|^2+Cz^{-4}(|v_1|_{s_1}^{2(2-\delta)}+|v_2|_{s_1}^{2(2-\delta)})|v_1-v_2|^{2(1+\delta)}.$$

This yields

$$|r(1)|^2\leqslant C(\omega)\int_0^1 z^{-4}(s)(|v_1(s)|_{s_1}^{2(2-\delta)}+|v_2(s)|_{s_1}^{2(2-\delta)})ds\,h^{2(1+\delta)}.$$

Writing

$$\overline{k_1^2}(\omega)=C(\omega)\sup_{0\leqslant t\leqslant 1} z^{-4}(t)\int_0^1 (|v_1(s)|_{s_1}^{2(2-\delta)}+|v_2(s)|_{s_1}^{2(2-\delta)})ds,$$

and choosing $\overline{k}(\omega)=\max\{k_1(\omega),1\}$, which satisfies $E(\log\overline{k}(\omega))<\infty$, we conclude the proof of Lemma 11.

In this paper, we discuss umbral calculus as a method of systematically discretizing linear differential equations while preserving their point symmetries as well as generalized symmetries. The method is then applied to the Schrödinger equation in order to obtain a realization of nonrelativistic quantum mechanics in discrete space–time. In this approach a quantum system on a lattice has a symmetry algebra isomorphic to that of the continuous case. Moreover, systems that are integrable, superintegrable or exactly solvable preserve these properties in the discrete case. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1780612]

I. INTRODUCTION

A sizable literature exists on discrete quantum mechanics, that is on quantum mechanics in discrete space–time. We refer to a recent review for motivation and for an extensive list of references.[20] There are many reasons for considering quantum systems in discrete space–time. One is that physical space–time may indeed be discrete, involving an elementary length related to the Planck length and some minimal time interval. Then continuous theories would only be approximations to the real world. This is the scenario proposed, for instance, in loop quantum gravity. In its recent formulation, a fundamentally discrete evolution law has been derived.[59,1,6] Further conditions must be imposed in order to provide a consistent quantum theory.[7] Another reason is the usual one: on a lattice one can avoid some of the divergence problems occuring in quantum field theories. On the other hand, some properties of quantum systems are lost in any discretization. The aim of this paper is to discuss a discretization of space–time in which the Schrödinger equation is replaced by a difference equation. This is done in such a manner that many of the essential properties of the continuous system are preserved. In particular, we preserve the Lie algebraic and integrability properties of the Schrödinger equation. This is true for the time dependent, as well as the stationary equation. The free equations, as well as those with potentials, after discretization have symmetry algebras, isomorphic to those of the continuous case. Lie point symmetries, after discretization, may however act at several points of the lattice. An application of

our approach is to preserve Lorentz and Galilei invariance in a classical or even quantum field theory on a lattice, via a suitable discretization of the infinitesimal operators generating these symmetries.[35]

Another property that we wish to preserve is that of integrability, and also superintegrability. By integrability, for an n dimensional quantum system, we mean the existence of n well defined algebraically independent Hermitian operators $\{X_1, \ldots, X_n\}$ (including the Hamiltonian H) commuting pairwise. Superintegrability means that there exist further independent operators, $\{Y_1, \ldots, Y_k\}$, $1 \leqslant k \leqslant n-1$, commuting with the Hamiltonian H, but not necessarily with the other operators X_i, nor Y_i.[19,64,43,56,58,51,23,48,30]

Finally, we wish to preserve exact solvability in the discretization, i.e., the fact that for certain systems (like the harmonic oscillator, or hydrogen atom) it is possible to calculate all energy levels algebraically.

A mathematical tool that we shall use for the study of symmetries and exact solutions of linear equations is the so-called "umbral calculus." This calculus, which originated in 19th century with the work of Sylvester, Cayley, and others, was used for a long time as a useful tool to derive combinatorial identities (see, for instance, Ref. 50). Nevertheless, it was only with Rota *et al.*[55,54,53,52] that this calculus was set on an axiomatic basis using the language of linear algebra of operators. In Ref. 9, the interested reader can find an up to date survey concerning the origins of umbral calculus and its many applications in several branches of mathematics, like combinatorics, functional analysis, algebraic topology, theory of special functions and orthogonal polynomials, etc.

Umbral calculus has recently been used explicitly,[11] or implicitly,[22,60,57,10] to provide discrete representations of canonical commutation relations, specially in the context of exactly solvable and quasiexactly solvable quantum systems.[61–63] Linear differential equations have been discretized in a symmetry preserving manner using commuting difference operators.[17,44,18] An alternative approach[38] to symmetries of linear difference equations makes use of a discretized version of the prolongation theory of evolutionary vector fields. Finally, umbral calculus was used in an implicit manner, to obtain several different symmetry preserving discretizations of the linear heat equation.[32]

Symmetries of difference equations, mainly nonlinear ones, have recently received a lot of attention (see, e.g., Refs. 17, 44, 18, 38, 32, 41, 39, 24, 36, 37, 40, and 12–15, and references therein). What has emerged for purely difference equations is that in order to capture the essential features and usefulness of symmetries of differential equations it is necessary to make serious adjustments. Either one must go beyond point transformations to generalized ones,[25,24] or one must use symmetry adapted and transforming lattices (as proposed initially by Dorodnitsyn).[36,37,40,12–15]

In this paper we follow the first approach. We consider a fixed lattice and use umbral calculus to obtain symmetries acting simultaneously on more than one point of the lattice. We apply this approach to quantum mechanics. In Sec. II we provide a very short summary of umbral calculus. In addition to standard definitions and known facts, we obtain some new results on the relation between umbral calculus, linear difference operators and solutions of linear difference equations. Section III is devoted to an "umbral" discretization of the Schrödinger equation in a manner that preserves the algebraic features of all point symmetries. In particular, for the free Schrödinger equation we construct a realization of the Schrödinger Lie algebra in terms of difference operators. Sections IV and V are devoted to discrete analogs of quantum superintegrable systems, their spectral properties and exact solvability are discussed. Some conclusions are drawn in the final Sec. VI. In the Appendix we consider a discrete relativistic wave equation in two dimensions. We use the discrete version of Lorentz invariance to obtain solutions of the discrete wave equations and discuss their convergence properties.

II. UMBRAL CALCULUS

To make this paper self-contained let us sum up in Sec. II A some known definitions and also some results proven as theorems by Rota,[54] Roman,[52] and Dimakis *et al.*.[11]

We shall actually need umbral calculus on spaces of many variables in order to study multidimensional difference equations. However, for simplicity of exposition and notation we shall in this section restrict to the case of one variable x.

Sections II B and II C contain results that are, to our knowledge, new.

A. General theory

Let $\mathfrak{J}$ be the algebra of formal power series in a variable x, and $\mathcal{P}$ the algebra of polynomials in the same variable. The algebras will be considered over a field $\mathbb{F}$ of characteristic zero. This field in the subsequent considerations will be identified with $\mathbb{R}$ or $\mathbb{C}$. An element of $\mathfrak{J}$ is of the form

$$\sum_k a_k x^k \equiv f(x). \tag{2.1}$$

The operations defined in $\mathfrak{J}$ are the addition of series

$$\sum_{k=0}^{\infty} a_k x^k + \sum_{k=0}^{\infty} b_k x^k = \sum_{k=0}^{\infty} (a_k + b_k) x^k, \tag{2.2}$$

and the multiplication

$$\left(\sum_{k=0}^{\infty} a_k x^k\right)\left(\sum_{l=0}^{\infty} b_l x^l\right) = \sum_{m=0}^{\infty} \left(\sum_{j=0}^{m} a_j b_{m-j}\right) x^m. \tag{2.3}$$

The algebra $\mathfrak{J}$ is also called the *umbral algebra.*[52]

A polynomial sequence $p_n(x) \in \mathcal{P}$ is a sequence whose nth element is a polynomial of degree n. We will denote by $\mathcal{L}$ the algebra of linear operators acting on $\mathfrak{J}$ or $\mathcal{P}$.

Definition 2.1: A shift operator $T \in \mathcal{L}$ is a linear operator such that

$$Tp(x) = p(x + \sigma), \tag{2.4}$$

where $p(x)$ is a polynomial and $\sigma \in \mathbb{F}$.

Definition 2.2: An operator $F \in \mathcal{L}$ is said to be shift invariant if it commutes with all shift operators (i.e., with T for all values of σ).

Definition 2.3: An operator U is said to be a delta operator if it is shift invariant and

$$Ux = c \neq 0, \tag{2.5}$$

where $c \in \mathbb{F}$.

Using Definition 2.1 and the linearity of shift-invariant operators one can prove the following result. If U is a delta operator, for every $c \in \mathbb{F}$ we have

$$Uc = 0. \tag{2.6}$$

Definition 2.4: A polynomial sequence $p_n(x)$, $n = 0, 1, 2, \ldots$, is called a sequence of basic polynomials for the delta operator U if

$$p_0(x) = 1, \quad p_n(0) = 0 \quad \forall n > 0, \tag{2.7}$$

and

$$Up_n(x) = np_{n-1}(x). \tag{2.8}$$

It is easy to show that every delta operator has a unique sequence of basic polynomials. We will denote by $\mathfrak{I}$ the one-to-one correspondence between basic sequences and delta operators.

Let $\mathcal{A}$ be the algebra of shift-invariant operators, endowed with the usual operations of sum of two operators, product of a scalar with an operator, and product of two operators. We introduce a multiplication operation $*: \mathcal{A} \times \mathcal{L} \to \mathcal{L}$, defined by

$$F * O = [F,O] = FO - OF, \tag{2.9}$$

where F is a shift-invariant operator and $O \in \mathcal{L}$. In particular, if x denotes the multiplication operator $x: p(x) \to xp(x)$, then $F * x$ corresponds to what in the umbral literature is known as the Pincherle derivative of F. In this case we will write

$$F' = F * x = [F,x]. \tag{2.10}$$

Using the $*$ multiplication the Leibnitz rule becomes

$$F * (fg) = (F * f)g + f(F * g) \tag{2.11}$$

and the Jacobi identity is expressed by

$$F * G * H + G * H * F + H * F * G = 0. \tag{2.12}$$

Let us now consider a pair of shift-invariant operators: a *delta* operator $U \in \mathcal{L}$ and its conjugate operator $\beta \in \mathcal{L}$, defined in such a way that the *Heisenberg–Weyl algebra* is satisfied,

$$[U,x\beta] = 1. \tag{2.13}$$

If U is a delta operator, then the inverse of U' exists (Ref. 54, p. 18). Therefore, the operator β is determined by the relation

$$\beta = (U')^{-1}. \tag{2.14}$$

To prove this it suffices to notice that

$$1 = [U,x\beta] = [U,x]\beta = U'\beta,$$

where the property $[U,\beta]=0$ has been exploited. Equation (2.14) follows.

Let us present some specific examples of realizations of the conjugate operators U and β in terms of derivatives and shifts, respectively.

Example 2.1: The continuous case. We have

$$U = \partial_x, \quad \beta = 1. \tag{2.15}$$

Example 2.2: The discrete case. The variable x is defined over an equally spaced lattice, with spacing σ. Two of the most common choices for the discrete derivative are as follows:

(a) The right discrete derivative,

$$U = \Delta^+ = \frac{T-1}{\sigma}, \quad \beta = T^{-1}. \tag{2.16}$$

(b) The left discrete derivative,

$$U = \Delta^- = \frac{1-T^{-1}}{\sigma}, \quad \beta = T. \tag{2.17}$$

Other cases will be considered below.

Using the $*$ multiplication of Eq. (2.9) it is easy to construct the basic sequence for the operator U. Let us introduce the polynomial sequence of operators

$$P_n = (x\beta)^n, \quad n \in \mathbb{N}. \tag{2.18}$$

The delta operator U satisfies the relation

$$[U,(x\beta)^n]=n(x\beta)^{n-1},\ \ n\in N. \tag{2.19}$$

This is an immediate consequence of the definition (2.13) and of the Leibnitz rule (2.11). A proof is obtained by induction. From (2.19) we immediately obtain

$$U*P_n=nP_{n-1},\ \ n\in\mathbb{N}. \tag{2.20}$$

This shows that $\{(x\beta)^n\}_{n\in\mathbb{N}}$ is the basic sequence for the operator U, under the $*$ multiplication.

Definition 2.5: An umbral correspondence is a map $\mathcal{R}:\mathcal{L}\to\mathcal{L}$ defined by

$$(x\beta_1)^n\overset{\mathcal{R}}{\to}(x\beta_2)^n, \tag{2.21}$$

where $P_n^1=\{(x\beta_1)^n\}$ and $P_n^2=\{(x\beta_2)^n\}$ are basic sequences of operators for two delta operators U_1 and U_2, respectively.

The umbral correspondence (2.21) naturally induces a correspondence between the two operators U_1 and U_2, according to the following scheme:

$$\begin{array}{ccc}(x\beta_1)^n & \overset{\mathcal{R}}{\leftrightarrow} & (x\beta_2)^n\\ \Im\updownarrow & & \Im\updownarrow\\ U_1 & \overset{R}{\leftrightarrow} & U_2.\end{array} \tag{2.22}$$

We shall also denote the induced correspondence between delta operators by the symbol $\mathcal{R}$.

Systems of equations connected by the umbral map (2.21) share many algebraic properties. A particular case of the umbral correspondence is when U_1 is the standard derivative ∂_x, and U_2 is a discrete derivative Δ. Then according to the scheme (2.22) we have

$$\begin{array}{ccc}x^n & \overset{\mathcal{R}}{\leftrightarrow} & (x\beta)^n\\ \Im\updownarrow & & \Im\updownarrow\\ \partial_x & \overset{\mathcal{R}}{\leftrightarrow} & \Delta.\end{array} \tag{2.23, 2.24}$$

Let us observe that Definition (2.5) generalizes the notion of an umbral operator introduced in Ref. 54: an umbral operator $R:\mathcal{P}\to\mathcal{P}$ is an operator (in general not necessarily shift-invariant) which maps some basic sequence of polynomials $p_n(x)$ into another basic sequence $q_n(x)$:

$$p_n(x)\overset{R}{\leftrightarrow}q_n(x). \tag{2.25}$$

Indeed, we observe that, since β is a function of shifts and any constant is invariant under the action of a shift operator, an umbral operator R is deduced from the action of $\mathcal{R}$ simply applying the sequence of operators $(x\beta)^n$ onto 1:

$$(x\beta_1)^n\cdot 1\overset{R}{\leftrightarrow}(x\beta_2)^n\cdot 1. \tag{2.26}$$

From (2.19) we also get

$$U_i(x\beta_i)^n\cdot 1=n(x\beta_i)^{n-1}\cdot 1,\ \ i=1,2. \tag{2.27}$$

An important consequence is that the umbral correspondence (2.22) preserves commutation relations between operators in $\mathcal{L}$. In particular, it preserves Lie algebras.

Indeed, let A_1 be a m-dimensional Lie algebra, generated by vector fields $\{\mathbf{v}_i\}_{i=1,\ldots,m}$ of the form

$$\mathbf{v}_i = \sum_j a_j(x_1, \ldots, x_p)\partial_{x_j}. \tag{2.28}$$

The umbral correspondence (2.22) maps A_1 isomorphically into an algebra A_2, generated by the vector fields $\{\mathbf{v}_i^U\}_{i=1,\ldots,m}$, with

$$\mathbf{v}_i^U = \sum_j a_j(x_1\beta_{x_1}, \ldots, x_p\beta_{x_p})\Delta_{x_j}. \tag{2.29}$$

This follows from the fact that the umbral correspondence (2.22) preserves the Heisenberg–Weyl algebra.

B. Umbral calculus and linear difference operators

The umbral approach reveals its power in the study of linear difference operators.

For our purposes, namely the study of difference equations and their continuous limits, we shall need only two types of delta operators. The first is simply the derivative $U=\partial_x$, with $\beta=1$. The second is a general difference operator that has ∂_x as its continuous limit. We set

$$U \equiv \Delta = \frac{1}{\sigma}\sum_{k=l}^{m} a_k T_\sigma^k, \quad l,m \in \mathbb{Z}, \quad l < m, \tag{2.30}$$

where a_k and σ are constants and $T_\sigma \equiv T$ is the shift operator of Eq. (2.4). In order for Δ in (2.30) to be a delta operator, it must satisfy Eq. (2.5). For any function $f(x) \in \mathfrak{F}$ Eq. (2.30) implies

$$\Delta f(x) = \frac{1}{\sigma}\sum_{k=l}^{m} a_k T^k f(x) = \frac{1}{\sigma}\sum_{k=l}^{m} a_k f(x + k\sigma). \tag{2.31}$$

Using a Taylor expansion around $\sigma=0$ we get

$$\Delta f(x) = \frac{1}{\sigma}\sum_{q=0}^{\infty} \frac{f^{(q)}(x)}{q!}\sigma^q \sum_{k=l}^{m} a_k k^q. \tag{2.32}$$

Choosing $f(x)=x$ we immediately see that Eq. (2.5) implies

$$\sum_{k=l}^{m} a_k = 0, \tag{2.33}$$

and $\Sigma_{k=l}^m a_k k = c$. We require that in the continuous limit Δ be the derivative ∂_x; this implies $c=1$, i.e.

$$\sum_{k=l}^{m} a_k k = 1. \tag{2.34}$$

Equation (2.30) involves $m-l+1$ constants a_k, subject to two conditions (2.33) and (2.34). To fix all constants a_k we must impose $m-l-1$ further conditions, for instance,

$$\gamma_q \equiv \sum_{k=l}^{m} a_k k^q = 0, \quad q = 2,3, \ldots, m-l. \tag{2.35}$$

Conditions (2.33) and (2.34) are necessary and sufficient for $U=\Delta$ to be a delta operator which has the derivative ∂_x as its continuous limit.

Definition 2.6: A difference operator of order $p=m-l$ is a delta operator of the form (2.30) satisfying Eqs. (2.33) and (2.34).

Theorem 2.1: *If the difference operator Δ of order $(m-l)\geqslant 2$ satisfies the supplementary conditions (2.35) it provides an approximation of order σ^{m-l} of the derivative ∂_x.*

Proof: We immediately have from Eq. (2.32) and Eqs. (2.33)–(2.35),

$$\Delta f \underset{\sigma\to 0}{\sim} f'(x) + \frac{\sigma^{m-l}}{(m-l+1)!} f^{(m-l-1)}(x) \sum_{k=l}^{m} a_k q^{m-l-1}. \tag{2.36}$$

Q.E.D.

Remark: Formula (2.30) defines U as an operator parametrized by σ, where $\sigma\in\mathbb{F}$. It may happen that for specific values of σ the operator U could involve less than p points, and consequently its order would be less than p. Once a representation of U as a difference operator is chosen, these points can be easily determined by solving a linear system of algebraic equations.

By way of an example, let us consider the following equation:[31]

$$\Delta^3 f(x) + 3\Delta^2 f(x) + \Delta f(x) - f(x) = 0. \tag{2.37}$$

If $\Delta=(T-1)/\sigma$, for $\sigma=1$ Eq. (2.37) becomes

$$f(x+3) - f(x+1) = 0,$$

which is of second order, in an appropriate domain.

In the following, U will be assumed to be an operator of order p parametrically depending on σ, and we shall omit the simple analysis of the specific cases in which the order could be less than maximal.

Theorem 2.2: *If Δ is a difference operator of order p, then $\widetilde{\Delta}=T^j\Delta$, $j\in\mathbb{Z}$ is a difference operator of the same order.*

Proof: Let us first prove the result for $j=1$. We have

$$T\Delta = \frac{1}{\sigma}\sum_{k=l}^{m} a_k T^{k+1} = \frac{1}{\sigma}\sum_{k=l-1}^{m+1} \widetilde{a}_k T^k, \quad \widetilde{a}_k = a_{k-1}.$$

Hence

$$\sum_{k=l+1}^{m+1} \widetilde{a}_k = \sum_{k=l}^{m} a_k = 0,$$

$$\sum_{k=l+1}^{m+1} k\widetilde{a}_k = \sum_{k=l}^{m} (k+1)a_k = \sum_{k=l}^{m} k a_k = 1.$$

Thus, conditions (2.31) and (2.33) are satisfied for $\widetilde{U}$ and that is all that is needed. The proof for $j=-1$ is analogous and for j arbitrary the result follows by induction. Q.E.D.

Conditions (2.35) are not shift invariant. However, once m and l are chosen, Eqs. (2.35) can always be imposed. Their solution depends on m and l, not only on the shift invariant difference $m-l$.

Theorem 2.3: *The operator β conjugate to the difference operator Δ of Eq. (2.30) is*

$$\beta = \left(\sum_{k=l}^{m} a_k k T^k\right)^{-1}. \tag{2.38}$$

Proof: Using Eq. (2.14) we have

$$\beta = (\Delta')^{-1} = [\Delta, x]^{-1}.$$

Moreover

$$[\Delta, x] = \frac{1}{\sigma}\left(\sum_{k=l}^{m} a_k(x + k\sigma)T^k - x\sum_{k=l}^{m} a_k T^k\right) = \sum_{k=l}^{m} a_k k T^k$$

and (2.38) follows. Q.E.D.

Examples of difference operators and the corresponding operators β are Δ^+ and Δ^- of Eqs. (2.16) and (2.17). Both are of order 1. Higher order examples are

$$\Delta^s = \frac{T - T^{-1}}{2\sigma}, \quad \beta = \left(\frac{T + T^{-1}}{2}\right)^{-1}, \tag{2.39}$$

$$\Delta^{(\mathrm{III})} = -\frac{1}{6\sigma}(T^2 - 6T + 3 + 2T^{-1}), \quad \beta = \left(-\frac{T^2 - 3T - T^{-1}}{3}\right)^{-1}, \tag{2.40}$$

$$\Delta^{(\mathrm{IV})} = -\frac{1}{12\sigma}(T^2 - 8T + 8T^{-1} - T^{-2}), \quad \beta = \left(-\frac{T^2 - 4T - 4T^{-1} + T^{-2}}{6}\right)^{-1}. \tag{2.41}$$

The operators Δ^s, $\Delta^{(\mathrm{III})}$, and $\Delta^{(\mathrm{IV})}$ approximate the derivative to order σ^2, σ^3, and σ^4, respectively.

Theorem 2.4: *The expression*

$$P_n(x) \equiv (x\beta)^n \cdot 1 \tag{2.42}$$

is a well-defined polynomial in x of order n with finite coefficients depending on a finite number of nonnegative powers of the shifts σ for any difference operator Δ. The expression for P_n is

$$P_n(x) = \sum_{k=1}^{n} A_k \sigma^{n-k} x^k, \quad A_n = 1, \tag{2.43}$$

where all coefficients A_k are finite and depend only on the coefficients a_k in the definition of Δ [see Eq. (2.30)]. In particular, they do not depend on σ.

Proof: Let us consider the difference operator Δ of Eq. (2.30) and define the quantities

$$\gamma_j = \sum_{k=l}^{m} a_k k^j, \quad \gamma_0 = 0, \quad \gamma_1 = 1, \quad j = 0, 1, 2, \ldots . \tag{2.44}$$

Let us now prove Eq. (2.43) by induction. Let P_n be a basic sequence of polynomials for any Δ, as given by Eq. (2.27). Thus we set

$$P_{n+1}(x) = \sum_{a=1}^{n+1} B_a x^a, \tag{2.45}$$

and must prove that the coefficients B_a are finite and depend on σ in the proper way (i.e., $B_a = \tilde{B}_a \sigma^{n+1-a}$, where $\tilde{B}_a$ is finite and does not depend on σ).

We rewrite Eq. (2.8) (with n substituted by $n+1$) as

$$\Delta P_{n+1} = (n + 1)P_n. \tag{2.46}$$

The left-hand side is

$$\Delta P_{n+1} = \frac{1}{\sigma}\sum_{b=l}^{m} a_b \sum_{a=1}^{n+1} B_a (x+b\sigma)^a = \sum_{a=1}^{n+1} B_a \sum_{k=0}^{a} \binom{a}{k} x^k \sigma^{a-k-1}\gamma_{a-k} = \sum_{k=0}^{n+1}\sum_{a=k}^{n+1} B_a \binom{a}{k} x^k \sigma^{a-k-1}\gamma_{a-k}.$$

Comparing powers on the left- and right-hand side of Eq. (2.46), we obtain a system of linear algebraic equations for the coefficient B_k,

$$\sum_{a=k}^{n+1} B_a \binom{a}{k} \sigma^{a-k-1}\gamma_{a-k} = (n+1)A_k \sigma^{n-k}. \tag{2.47}$$

The system (2.47) has a triangular structure. For $k=n+1$, we get the identity $0=0$. For $k=n$, only one term is present on the left and we get $B_{n+1}=1$ (since we have $\gamma_0=0$ and $A_n=1$). The value $k=n-1$ gives

$$B_n = \sigma\frac{n+1}{n}\left(A_{n-1} - \frac{n}{2}\right).$$

In general, the system (2.47) implies

$$B_{n-j} = \sigma^{j+1} \sum_{k=n-j-1}^{n} \mu_k A_k, \tag{2.48}$$

where the coefficients μ_k are easy to calculate, but are cumbersome (and of little interest), so we do not spell them out. Q.E.D.

Let us present the first few basic polynomials $P_k(x)=(x\beta)^k 1$ for arbitrary Δ as given by Eq. (2.30) with γ_j defined in terms of a_k by Eq. (2.44). We obtain

$$P_0 = (x\beta)^0 \cdot 1 = 1,$$

$$P_1 = (x\beta)^1 \cdot 1 = x,$$

$$P_2 = (x\beta)^2 \cdot 1 = x^2 - \sigma\gamma_2 x, \tag{2.49}$$

$$P_3 = (x\beta)^3 \cdot 1 = x^3 - 3\sigma\gamma_2 x^2 - \sigma^2(\gamma_3 - 3\gamma_2^2)x,$$

$$P_4 = (x\beta)^4 \cdot 1 = x^4 - 6\sigma\gamma_2 x^3 + \sigma^2(-4\gamma_3 + 15\gamma_2^2)x^2 + \sigma^3(-\gamma_4 + 10\gamma_2\gamma_3 - 15\gamma_2^3)x.$$

For $\sigma\to 0$, we obviously reobtain the basic series (sequence) for $\Delta=\partial_x$.

For $\Delta^+=(T-1)/\sigma$ we have only two values of a_j, namely $a_1=1$, $a_0=-1$, hence $\gamma_j=1$, $j=2,3,\ldots$. The polynomials (2.49) in this case reduce to the well-known factorial powers $P_n = x(x-\sigma)(x-2\sigma)\cdots(x-(n-1)\sigma)$.

C. Linear difference equations and umbral equations

Let us introduce the notation $\hat{f}=f(x\beta)$, i.e., to each function $f(x)\in\mathfrak{F}$ we associate an operator $\hat{f}\in\mathfrak{L}$. We shall consider an operator equation of the form

$$\sum_{k=0}^{n} \hat{A}_k U^k \hat{f} = \hat{g}, \tag{2.50}$$

where U is a delta operator and β is its conjugate operator defined in Eqs. (2.13) and (2.14). We assume that the operators $\hat{A}_k$ and $\hat{g}$ can be expanded into formal power series in $(x\beta)$.

Definition 2.7: An umbral equation of order n is an operator equation of the form (2.50) in which the operators $\hat{A}_k$ and $\hat{g}$ are given. The unknown is the operator $\hat{f}$.

If U is specified to be $U=\partial_x$, then $\beta=1$ and Eq. (2.50) reduces to a differential equation of order n. If U is a difference operator, (2.50) is still an operator equation. Projecting both sides onto a space of functions, i.e., applying them to a constant, we obtain a difference equation. The order of the difference equations obtained projecting Eq. (2.50) may vary depending on the structure of the operator $\hat{A}_k$ (since it acts on the operator $\hat{f}$) and on the choice of the operator Δ (and consequently of β) in terms of shift operators.

Let us first take $U=\partial_x$, $\beta=1$ in Eq. (2.50). The obtained linear ODE will have n linearly independent solutions $f_i(x)$. We can expand them into formal power series about any point x_0, where x_0 is not a singular point of the equation. Now let $U=\Delta$ be a difference operator and β the corresponding conjugate operator. Then $f_i(x\beta)\cdot 1$ viewed as a formal power series, will be a solution of the corresponding difference equation.

Definition 2.8: We shall call $\hat{f}\cdot 1$ *an* "umbral solution" *of the difference equation*

$$\sum_{k=0}^{n} \hat{A}_k U^k \hat{f}\cdot 1 = \hat{g}\cdot 1 \tag{2.51}$$

if the real valued function $f(x)$ *is a solution of the differential equation*

$$\sum_{k=0}^{n} A_k \partial_x^k f(x) = g(x). \tag{2.52}$$

Thus each solution of the ODE (2.52) provides a formal power solution of the difference equation (2.51) [and of the umbral equation (2.50)]. However, Eq. (2.51) and (2.50) may have other solutions. Indeed, for a linear difference equation with constant coefficients we have the following theorem.

Theorem 2.5: *Let U be a difference operator of order p and let us assume that the operators* $\hat{A}_k$ *in Eq. (2.50) are constant. Equation (2.51) will then have np linearly independent solutions, n of them umbral ones.*

Proof: Equation (2.51) in this case is a difference equation involving $np+1$ different points. Hence to obtain a solution in a new point we must specify initial conditions in np points. This provides np linearly independent solutions, uniquely defined in the lattice points $x_n=x_0+n\sigma$.[16,31] Now, let us consider the continuous limit of Eq. (2.51). It is a linear partial differential equation of order n, possessing analytic solutions which can be expanded around any nonsingular point. Applying the umbral correspondence to the series expansion of these solutions, we obtain n solutions of Eq. (2.51) which are expressed as formal power series in $(x\beta)^k$, and therefore are elements of the algebra $\mathfrak{F}$. These are the umbral solutions admitted by Eq. (2.51). The remaining $(n-1)p$ do not belong to $\mathfrak{F}$. Q.E.D.

When $\hat{A}_k$ are polynomials in $(x\beta)$, then additional shifts may appear in the explicit form of the equations coming from the umbral equation (2.50) via projection and their order may be different than np.

As an example, let us consider the "umbral Airy equation,"

$$[\Delta^2 + ax\beta]\hat{\Psi} = 0, \quad a = \text{const}. \tag{2.53}$$

For $\Delta^+=(T-1)/\sigma$, $\beta=T^{-1}$, and $\tilde{\Psi}(x)=\hat{\Psi}\cdot 1$ we have

$$\frac{1}{\sigma^2}[\tilde{\Psi}(x+2\sigma) - 2\tilde{\Psi}(x+\sigma) + \tilde{\Psi}(x)] + ax\tilde{\Psi}(x-\sigma) = 0.$$

This is a third order difference equation since it involves the function $\tilde{\Psi}(x)$ at the points $x+2\sigma$, $x+\sigma$, x and $x-\sigma$. For $\Delta=\Delta^s$ Eq. (2.53) would seem to involve infinitely many points,

$$\frac{1}{4\sigma^2}[\tilde{\Psi}(x+2\sigma)-2\tilde{\Psi}(x)+\tilde{\Psi}(x-2\sigma)]+ax\left(\frac{T+T^{-1}}{2}\right)^{-1}\tilde{\Psi}(x)=0. \tag{2.54}$$

However, multiplying Eq. (2.54) by β^{-1} we obtain

$$\frac{1}{4\sigma^2}[\tilde{\Psi}(x+3\sigma)-\tilde{\Psi}(x+\sigma)-\tilde{\Psi}(x-\sigma)+\tilde{\Psi}(x-3\sigma)]+ax\tilde{\Psi}(x)=0. \tag{2.55}$$

This equation is a sixth order difference equation.

As a simple example of umbral and nonumbral solutions, let us consider a first order homogeneous umbral equation with constant coefficients,

$$U\hat{f}=a\hat{f},\quad a\neq 0. \tag{2.56}$$

For $U=\partial_x$, the solution is

$$f(x)=Ae^{ax}. \tag{2.57}$$

Now, let us consider the first order difference operator Δ^+. Equation (2.56) reduces to

$$f(x+\sigma)-f(x)=a\sigma f(x). \tag{2.58}$$

We look for a solution in the form $f(x)=\lambda^x$ and find

$$\lambda=(1+a\sigma)^{1/\sigma}. \tag{2.59}$$

Thus we obtain a single solution

$$f_1(x)=A(1+a\sigma)^{x/\sigma} \tag{2.60}$$

and of course we have

$$\lim_{\sigma\to 0} f(x)=Ae^{ax}. \tag{2.61}$$

The umbral correspondence provides the solution

$$f_u(x)=Ae^{axT^{-1}}\cdot 1. \tag{2.62}$$

Expanding (2.60) and (2.62) in formal power series in a, we find that the two series coincide, i.e., $f_1=f_u$.

For comparison, let us consider the second order difference operator Δ^s. Equation (2.56) in this case yields

$$f(x+\sigma)-f(x-\sigma)=2\sigma a f(x). \tag{2.63}$$

Setting $f(x)=\lambda^x$ we obtain two values of λ and the general solution of Eq. (2.63) in this case is

$$f=A_1(\sqrt{1+a^2\sigma^2}+a\sigma)^{x/\sigma}+A_2(-1)^{x/\sigma}(\sqrt{1+a^2\sigma^2}-a\sigma)^{x/\sigma}=A_1f_1+A_2f_2. \tag{2.64}$$

The first solution has e^{ax} as its continuous limit. The second one does not have a limit for $\sigma\to 0$. The umbral correspondence provides the solution

$$f_u(x)=Ae^{ax[T+T^{-1}/2]^{-1}}\cdot 1 \tag{2.65}$$

[see Eq. (2.39)]. Expanding into formal power series in a we find $f_u=f_1$ and f_2 is nonumbral.

The question arises whether an expression of the type

$$\hat{f} = e^{ax\beta} \tag{2.66}$$

is meaningful, at least in the sense of a formal power series. The problem is that for a general difference operator Δ, the expression for β, given in Eq. (2.38), is quite complicated. If we expand β into a power series in T, it will for $m-l \geqslant 3$ involve infinitely many shifts. Convergence problems may arise. Luckily, it is not Eq. (2.66) itself that provides the umbral solution of a difference equation. Rather, it is the projection of the operator $\hat{f}$ onto a space of functions, or formal power series. The expressions that appear in the corresponding expansions are $P_n(x) = (x\beta)^n \cdot 1$ and these are finite polynomials in x, and in the shifts σ, with well-defined finite coefficients (see Theorem 2.4). As a matter of fact these are the basic polynomials for the difference operator Δ defined in Eq. (2.30).

It follows that if we know a solution of the umbral equation (2.50) for $U=\partial_x$, and have

$$f(x) = \sum_{n=0}^{\infty} \frac{f^{(n)}(0)}{n!} x^n,$$

then for $U=\Delta$ as in (2.30) the corresponding umbral solution will be

$$\hat{f} \cdot 1 = \sum_{n=0}^{\infty} \frac{f^{(n)}(0)}{n!} P_n(x).$$

The matter of convergence is a separate issue.

Umbral calculus and especially the umbral correspondence also provide us with a powerful tool with which to handle symmetries of linear difference equations, both ordinary and partial ones. On the one hand, we can discretize a linear differential equation, in particular the linear Schrödinger equation, via the (multidimensional) umbral substitutions

$$\partial_{x_i} \overset{\mathcal{R}}{\longrightarrow} \Delta_{x_i}, \quad x_i \overset{\mathcal{R}}{\longrightarrow} x_i \beta_{x_i}, \quad \partial_t \overset{\mathcal{R}}{\longrightarrow} \Delta_t, \quad t \overset{\mathcal{R}}{\longrightarrow} t\beta_t.$$

Lie symmetries, both point and generalized ones, of linear differential equations can be expressed in terms of commuting operators. Since the umbral correspondence preserves commutation relations, it will also preserve symmetries. On the other hand, we may have more symmetries than in the continuous case due to the nonumbral solutions of the determining equations.

III. DISCRETIZATION OF THE TIME-DEPENDENT SCHRÖDINGER EQUATION PRESERVING ALL POINT SYMMETRIES

Before considering discrete space–time, let us first give a detailed and rigorous analysis of the point symmetries of the time-dependent Schrödinger equation in continuous space–time. The results will be presented in a form well suited for the discretization.

A. Point symmetries and commuting operators in continuous space–time

We write the Schrödinger equation in $\mathbb{R}^{n+1}$ as

$$L\psi = 0, \qquad L = i\partial_t - H, \quad H = -\frac{1}{2}\sum_{k=1}^{n} \frac{\partial^2}{\partial x_k^2} + \mathrm{V}(\vec{x},t). \tag{3.1}$$

A local Lie point symmetry transformation is generated by a vector field that we write in evolutionary form[47] as

$$\mathbf{v}^E = Q\partial_\psi + Q^* \partial_{\psi^*}, \tag{3.2}$$

$$Q = \eta - \tau\frac{\partial\psi}{\partial t} - \xi_k\frac{\partial\psi}{\partial x_k}. \tag{3.3}$$

The functions η, τ, and ξ_κ depend on t, $\vec{x}$, ψ, and ψ^* where the star denotes complex conjugation. These functions are determined from the requirement

$$pr^{(2)}\mathbf{v}^E(L\psi)|_{L\psi=L^*\psi^*=0} = 0, \quad pr^{(2)}\mathbf{v}^E(L^*\psi^*)|_{L\psi=L^*\psi^*=0} = 0. \tag{3.4}$$

The following theorem will provide a basis for studying the symmetries of a nonrelativistic quantum system.

Theorem 3.1: *All Lie point symmetries of the time-dependent Schrödinger equation (3.1) are generated by evolutionary vector fields of the form (3.2) with*

$$Q = \chi(\vec{x},t) + iX\psi, \tag{3.5}$$

$$X = i(\tau(t)\partial_t + \xi_k(\vec{x},t)\partial_{x_k} - i\phi(\vec{x},t)), \tag{3.6}$$

$$\xi_k(\vec{x},t) = \tfrac{1}{2}x_k\tau' - A_{kl}x_l + f_k(t), \tag{3.7}$$

$$\phi(\vec{x},t) = \frac{1}{4}\tau''r^2 + x_k f_k' + g(t) + i\left[\frac{n}{4}\tau' - B\right], \tag{3.8}$$

where the prime denotes a derivative. The function $\chi(\vec{x},t)$ satisfies the Schrödinger equation (3.1), $A_{kl}=-A_{lk}$ and B are real constants. The real functions $\tau(t)$, $f_k(t)$, $g(t)$ and the constants A_{kl} depend on the potential and satisfy the equation

$$\tau(t)\mathrm{V}_t + \xi_k(\vec{x},t)\mathrm{V}_{x_k} + \tau'\mathrm{V} + \tfrac{1}{4}\tau'''r^2 + x_k f_k'' + g' = 0, \tag{3.9}$$

with $r^2=\Sigma_{k=1}^n x_k^2$. Moreover, the linear operator X commutes with L on the solutions of the Schrödinger equation

$$[L,X]\psi|_{L\psi=0} = 0. \tag{3.10}$$

Proof: Equation (3.4) implies a system of determining equations. Those among them that come from terms involving derivatives of ψ, e.g., $\psi_x\psi_{xx}$, ψ_{xx}, ψ_x^k, $k\geqslant 1$ do not depend on the potential $\mathrm{V}(\vec{x},t)$. From them we obtain the fact that the corresponding transformations are fiber preserving and linear (inhomogeneous). That is, Q has the form (3.3) with τ and ξ_k independent of ψ and ψ^*. From the same equations we find that τ depends only on t and that $\xi_k(\vec{x},t)$ are linear in $\vec{x}$. Thus ξ_k and ϕ have the form (3.7) and (3.8), respectively.

Once these conditions are satisfied, only one determining equation remains, namely Eq. (3.9), involving the potential in a crucial manner.

To prove the commutativity relation (3.10) we use the compatibility of the two flows,

$$i\frac{\partial\psi}{\partial t} = H\psi, \quad \frac{\partial\psi}{\partial\lambda} = Q, \tag{3.11}$$

where λ is a group parameter and Q is the characteristic of the vector field [see Eqs. (3.5)–(3.8)]. Equating the cross derivatives $\psi_{t\lambda}=\psi_{\lambda t}$ and using the equation $L\chi(\vec{x},t)=0$, we obtain

$$[H,X]\psi = -iX_t\psi, \tag{3.12}$$

where ψ is any solution of the Schrödinger equation. This is equivalent to Eq. (3.10). Simply stated, finding point symmetries of the Schrödinger equation is equivalent to finding linear self-adjoint operators X commuting with L on the solution set of L. Q.E.D.

Comments:

(1) For any potential $V_k(\vec{x},t)$, the function $\chi(\vec{x},t)$, the constant B, and a constant $g=g_0$ are solutions of Eq. (3.9). Hence we always have a "trivial" symmetry algebra

$$S(\chi)=\chi(\vec{x},t)\partial_\psi+\chi^*(\vec{x},t)\partial_{\psi^*},\ L\chi=0,$$

$$N=\psi\partial_\psi+\psi^*\partial_{\psi^*}, \tag{3.13}$$

$$E=i(\psi\partial_\psi-\psi^*\partial_{\psi^*}),$$

due to the linearity of the Schrödinger equation.

(2) Each symmetry generator $\mathbf{v}^E$ provides us with a flow that is by construction compatible with the time flow (3.1), that is, we can simultaneously solve the equations (3.11). The fixed point $\partial\psi/\partial\lambda=0$ corresponds to group invariant solutions.

(3) While the result presented in Theorem 3.1 is quite simple and natural, we have not found it explicitly in the literature, so we have sketched a proof. For other results on point symmetries of linear differential equations, see, e.g., Refs. 5, 42, and 8.

Let us consider the implications of Theorem 3.1 for special cases of the potential $V(\vec{x},t)$. We shall omit the operators (3.13) that are present for any potential $V(\vec{x},t)$.

Let us first consider the free Schrödinger equation (for further discussions, see also Ref. 49). For $V(\vec{x},t)=0$ in $\mathbb{R}^{3+1}$ the so-called "Schrödinger group" was first obtained by Niederer.[45] For n arbitrary we obtain its generalization, i.e., the group Sch (n). Its Lie algebra can be written as

$$P_0=\partial_t,\ D=2t\partial_t+x_k\partial_{x_k}-\tfrac{1}{2}(\psi\partial_\psi+\psi^*\partial_{\psi^*}),$$

$$C=t^2\partial_t+tx_k\partial_{x_k}-\frac{1}{2}t(\psi\partial_\psi+\psi^*\partial_{\psi^*})+\frac{in}{4}r^2(\psi\partial_\psi-\psi^*\partial_{\psi^*}),$$

$$L_{ik}=x_i\partial_{x_k}-x_k\partial_{x_i},\ P_k=\partial_{x_k}, \tag{3.14}$$

$$B_k=t\partial_{x_k}+\frac{i}{2}x_k(\psi\partial_\psi-\psi^*\partial_{\psi^*}),$$

$$E=i(\psi\partial_\psi-\psi^*\partial_{\psi^*}).$$

The Levi decomposition[28] of this algebra for $n\geqslant 3$ is

$$\mathfrak{L}\sim[\mathrm{sl}(2,\mathbb{R})\oplus \mathrm{O}(n)]\rhd H_n, \tag{3.15}$$

where the radical H_n is the n-dimensional Heisenberg algebra. Explicitly we have

$$\mathrm{sl}(2,\mathbb{R})\sim\{P_0,D,C\},\ \mathrm{O}(n)\sim\{L_{ik}\},\ H_n\sim\{P_k,B_k,E\}. \tag{3.16}$$

We included the central element E explicitly in (3.14) since it appears in the derived algebra of the Schrödinger algebra [it is also present in (3.13)].

Equation (3.9) implies that for a general time-independent potential $V(\vec{x})$ we have only one additional symmetry generator to the set given by Eqs. (3.13), namely time translations $P_0=\partial_t$.

For a central potential $V=V(r)$, the additional elements are time translations and rotations

$$P_0=\partial_t,\ L_{ik}=x_i\partial_{x_k}-x_k\partial_{x_i},\ 1\leqslant i\leqslant k\leqslant n. \tag{3.17}$$

In the case of a translationally invariant potential $V=V(x_n)$, the additional symmetry elements are

$$P_0 = \partial_t, P_j = \partial_{x_j}, B_j = t\partial_{x_j} - ix_j(\psi\partial_\psi - \psi^* \partial_{\psi^*}),\ \ 1 \leqslant j \leqslant n-1,$$
$$L_{ik} = x_i\partial_{x_k} - x_k\partial_{x_i},\ \ 1 \leqslant i \leqslant k \leqslant n-1. \tag{3.18}$$

B. Symmetries of the discrete time-dependent Schrödinger equation

The umbral correspondence, together with Theorem 3.1 provide the tools necessary for a symmetry preserving discretization of quantum mechanics.

Indeed, let us consider a discrete space–time, more precisely an $n+1$ dimensional orthogonal and equally spaced lattice with time step σ_t and space steps σ_k, $1 \leqslant k \leqslant n$. In this space we write a "Schrödinger difference equation"

$$L_D\psi = 0,\ \ L_D = i\Delta_t - H_D,$$
$$H_D = -\frac{1}{2}\sum_{k=1}^{n} \Delta_{x_k x_k} + V(x_1\beta_1, \ldots, x_n\beta_n, t\beta_t), \tag{3.19}$$

where we have

$$[\Delta_{x_k}, x_k\beta_k] = 1,\ \ [\Delta_t, t\beta_t] = 1. \tag{3.20}$$

Each Δ_{x_k}, Δ_t is some chosen difference operator and β_k, β_t are the corresponding conjugate operators satisfying the Heisenberg commutation relations (3.20).

The continuous limit of Eq. (3.19) is Eq. (3.1), obtained by taking $\sigma_k \to 0$, $\sigma_t \to 0$, i.e.,

$$\Delta_{x_k x_k} \to \frac{\partial^2}{\partial x_k^2},\ \ \Delta_t \to \partial_t,\ \ \beta_i \to 1,\ \ \beta_t \to 1. \tag{3.21}$$

Let us assume that in the continuous limit the obtained Schrödinger equation (3.1) is invariant under some Lie point symmetry group generated by some evolutionary vector field (3.2). Symmetries of linear difference equations on fixed lattices can also be expressed in terms of evolutionary vector fields.[38,40] For Eq. (3.19) we set

$$\mathbf{v}_D^E = Q_D\partial_\psi + Q_D^*\partial_{\psi^*},$$
$$Q_D = \eta_D - \tau_D\Delta_t\psi - \xi_{k_D}\Delta_{x_k}\psi, \tag{3.22}$$

where η_D, τ_D, and ξ_{k_D} are functions of $x_i\beta_i$, $t\beta_t$, ψ, and ψ^*. The functions ψ and ψ^* are to be evaluated at the points $x_i\beta_i$, $t\beta_t$.

The prolongation of the vector field (3.22) must act on the dependent variables ψ and ψ^* and on their discrete derivatives $\Delta_t\psi$, $\Delta_{x_k x_k}\psi$. As in the continuous case, we require that an infinitesimal transformation

$$\tilde{x}_k\tilde{\beta}_k = x_k\beta_k,\ \ \tilde{t}\tilde{\beta}_t = t\beta_t,$$
$$\tilde{\psi}(\tilde{x}_k\tilde{\beta}_k, \tilde{t}\tilde{\beta}_t) = \psi(x_k\beta_k, t\beta_t) + \lambda Q_D,\ \ \lambda \ll 1 \tag{3.23}$$

should take a solution ψ into a solution $\tilde{\psi}$ of the same equation. First of all, we have

$$\tilde{\beta}_k = \beta_k,\ \ \tilde{\beta}_t = \beta_t, \tag{3.24}$$

since β_k and β_t are expressed in terms of shifts operators and we are considering equations on a fixed (not transforming) lattice. Equation (3.23) is an infinitesimal transformation in the evolu-

tionary formalism, hence only the dependent variables transform. The transformation of the discrete derivatives is given by

$$\Delta_t\tilde{\psi} = \Delta_t\psi + \lambda\Delta_t Q_D,$$
$$\Delta_{x_k x_k}\tilde{\psi} = \Delta_{x_k x_k}\psi + \lambda\Delta_{x_k x_k} Q_D, \tag{3.25}$$

where Δ_t, Δ_{x_k}, etc., are discrete total derivatives. One can of course also introduce discrete partial derivatives,[40] but we shall not need them here.

In terms of the vector fields $\mathbf{v}_D^E$of Eq. (3.22) the prolongation of $\mathbf{v}_D^E$ is

$$pr\mathbf{v}_D^E = Q_D\partial_\psi + Q_D^t\partial_{\Delta_t\psi} + Q_D^{x_k x_k}\partial_{\Delta_{x_k x_k}\psi} + \cdots + \text{c.c.}, \tag{3.26}$$

where c.c. denotes the complex conjugate terms and we have

$$Q_D^t = \Delta_t Q_D, \quad Q_D^{x_k x_k} = \Delta_{x_k x_k} Q_D. \tag{3.27}$$

The determining equations for the characteristic Q_D are obtained as in the continuous case, i.e., from the invariance condition

$$pr\mathbf{v}_D^E(L_D\psi)|_{L_D\psi=L_D^*\psi^*=0} = 0, \quad pr\mathbf{v}_D^E(L_D^*\psi^*)|_{L_D\psi=L_D^*\psi^*=0} = 0. \tag{3.28}$$

From this we conclude that the following theorem holds.

Theorem 3.2: *The discrete time-dependent Schrödinger equation (3.19) allows a Lie algebra of "umbral symmetries" isomorphic to that of its continuous limit (3.1). This Lie algebra is realized by vector fields (3.22) with*

$$Q_D = \chi(x_k\beta_k, t\beta_t) + iX_D\psi, \tag{3.29}$$

$$X_D = i\left[\tau(t\beta_t)\Delta_t + \sum_k \xi_k\Delta_{x_k} - i\phi\right], \tag{3.30}$$

$$\xi_k = \frac{1}{2}x_k\beta_k\Delta_t\tau - \sum_{l=1}^n A_{kl}x_l\beta_l + f_k(t\beta_t), \tag{3.31}$$

$$\phi = \left[\frac{1}{4}\Delta_{tt}\tau\sum_{k=1}^n (x_k\beta_k)^2 + \sum_{k=1}^n x_k\beta_k\Delta_t f_k + g(t\beta_t)\right] + i\left[\frac{n}{4}(\Delta_t\tau) - B\right]. \tag{3.32}$$

The function χ satisfies the discrete Schrödinger equation (3.19), $A_{kl}=-A_{lk}$ and B are real constants. The real functions τ, f_k and g all depend only on $t\beta_t$ and the potential $\mathrm{V}(x_k\beta_k, t\beta_t)$ satisfies

$$\tau\Delta_t\mathrm{V} + \sum_{k=1}^n \xi_k\Delta_{x_k}\mathrm{V} + (\Delta_t\tau)\mathrm{V} + \frac{1}{4}(\Delta_{ttt}\tau)\sum_{k=1}^n (x_k\beta_k)^2 + \sum_{k=1}^n x_k\beta_k\Delta_{tt}f_k + \Delta_t g = 0. \tag{3.33}$$

Finally, the difference operator X_D commutes with L_D on the solutions of the discrete Schrödinger equation (3.19):

$$[L_D, X_D]\psi|_{L_D\psi=0} = 0. \tag{3.34}$$

Proof: The proof of Theorem 3.2 is quite analogous to that of Theorem 3.1 in the continuous case. To see the similarities and differences, let us restrict ourselves to the case $n=2$.

The invariance condition (3.28) implies the following determining equations:

$$\xi_{k,\psi} = \xi_{k,\psi^*} = \tau_\psi = \tau_{\psi^*} = 0, \quad \Delta_{x_i}\tau = 0, \quad \phi_{\psi^*} = 0, \quad \phi_{\psi\psi} = 0, \tag{3.35}$$

$$\Delta_{x_1}\xi_2 + \Delta_{x_2}\xi_1 = 0, \tag{3.36}$$

$$\Delta_t\tau - 2\Delta_{x_1}\xi_1 = 0, \quad \Delta_t\tau - 2\Delta_{x_2}\xi_2 = 0, \tag{3.37}$$

$$\begin{aligned} 2i\Delta_t\xi_1 + 2\Delta_{x_1}\phi_{1\psi} + \Delta_{x_1x_1}\xi_1 + \Delta_{x_2x_2}\xi_1 = 0, \\ 2i\Delta_t\xi_2 + 2\Delta_{x_2}\phi_{1\psi} + \Delta_{x_1x_1}\xi_2 + \Delta_{x_2x_2}\xi_2 = 0, \end{aligned} \tag{3.38}$$

$$2\psi\{\tau\Delta_t V + \xi_1\Delta_{x_1}V + \xi_2\Delta_{x_2}V + V\Delta_t\tau + V\phi_\psi\} - 2V\phi + 2i\Delta_t\phi + \Delta_{x_1x_1}\phi + \Delta_{x_2x_2}\phi = 0. \tag{3.39}$$

It is now obvious that Eq. (3.30)–(3.32) (for $n=2$) provide a solution to Eq. (3.35),…, (3.38) and that (3.39) reduces to Eq. (3.33), once (3.35),…, (3.38) are solved. Equation (3.34) then follows in exactly the same manner as in the continuous case. Q.E.D.

Comment:

There is an important difference between the continuous and the discrete case. In Theorem 3.1 we presented the most general solution of the determining equations. In Theorem 3.2 we presented a solution and added the requirement that the solution should have the correct continuous limit. Take for instance the function τ. Equations (3.35) for any Δ_t, Δ_x allow the solution $\tau(t,\beta_t)$, i.e., an arbitrary function of time t and the "shift" operator β_t independently. For first order operators $\Delta^{\pm}$ (see Sec. II), the function τ will depend only on $(t\beta_t)$. This follows from the determining equations, and agrees with the result of umbral correspondence. Moreover, the result will have the correct continuous limit. Thus the discretization and the continuous equation have isomorphic symmetry algebras. For other choices of the discrete derivatives we may get more general solutions. For instance, let us consider the case of a "symmetric" derivative,

$$\Delta_x^s\tau = \frac{T_x - T_x^{-1}}{2\sigma}\tau = \frac{\tau(x+\sigma) - \tau(x-\sigma)}{2\sigma} = 0. \tag{3.40}$$

Equation (3.40) has the general solution

$$\tau = \tau_0(t) + \tau_1(t)e^{i\pi x/\sigma}, \tag{3.41}$$

$$x = x_n = x_0 + n\sigma. \tag{3.42}$$

We see that Eq. (3.40) actually allows an x-dependence in τ. However, the second term in (3.42) does not have a continuous limit (for $\sigma = x_{n+1} - x_n \to 0$). See Ref. 37 for further discussions.

C. Examples

As in the continuous case, for any discrete potential we have the "trivial" symmetries (3.13) (with $\vec{x}$, t, replaced by $x_k\beta_k$, $t\beta_t$).

Let us consider the case $V=0$, i.e., a free quantum particle in discrete space–time of dimension $n+1$. Operators commuting with the operator L_D of Eq. (3.19) are obtained from (3.14) by the umbral correspondence. We obtain the "discrete" Schrödinger algebra

$$P_0 = \Delta_t, \quad D = 2(t\beta_t)\Delta_t + \sum_{k=1}^{n}(x_k\beta_k)\Delta_{x_k} - \frac{1}{2}(\psi\partial_\psi + \psi^*\partial_{\psi^*}),$$

$$C=(t\beta_t)^2\Delta_t+\sum_{k=1}^{n}(t\beta_t)(x_k\beta_k)\Delta_{x_k}-\frac{1}{2}(t\beta_t)(\psi\partial_\psi+\psi^*\partial_{\psi^*})+\frac{in}{4}\sum_{k=1}^{n}(x_k\beta_k)^2(\psi\partial_\psi-\psi^*\partial_{\psi^*}),$$

$$L_{ik}=(x_i\beta_i)\Delta_{x_k}-(x_k\beta_k)\Delta_{x_i},\quad P_k=\Delta_{x_k},\tag{3.43}$$

$$B_k=(t\beta_t)\Delta_{x_k}+\frac{i}{2}(x_k\beta_k)(\psi\partial_\psi-\psi^*\partial_{\psi^*}),$$

$$E=i(\psi\partial_\psi-\psi^*\partial_{\psi^*}).$$

For a general time-independent potential $V(x_i\beta_i)$ we have only one additional [to (3.13)]. symmetry generator, namely time translations $P_0=\Delta_t$.

For a time-independent central potential $V=V(\Sigma_i(x_i\beta_i)^2)$ the additional symmetries are expressed by the operators

$$P_0=\Delta_t,\ L_{ik}=x_i\beta_i\Delta_{x_k}-x_k\beta_k\Delta_{x_i},\ 1\leqslant i\leqslant k\leqslant n.\tag{3.44}$$

For a translationally invariant potential $V=V(x_n\beta_n)$ the additional symmetry operators are

$$P_0=\Delta_t,$$

$$P_j=\Delta_{x_j},\quad B_j=t\beta_t\Delta_{x_j}-ix_j\beta_j(\psi\Delta_\psi-\psi^*\Delta_{\psi^*}),\quad 1\leqslant j\leqslant n-1,\tag{3.45}$$

$$L_{ik}=x_i\beta_i\Delta_{x_k}-x_k\beta_k\Delta_{x_i},\quad 1\leqslant i\leqslant k\leqslant n-1.$$

IV. DISCRETE SUPERINTEGRABLE SYSTEMS

The umbral calculus provides a systematic method for transfering results from standard quantum mechanics to quantum mechanics in a discrete space–time. This is particularly simple if the results are formulated in terms of commuting differential operators. It has been shown elsewhere[56] that there is a direct relation between generalized symmetries in quantum mechanics and higher order differential operators, commuting with the Hamiltonian. Here we shall briefly sum up the results and then adapt them to the discrete case.

A. Generalized symmetries in quantum mechanics

Let us consider the stationary Schrödinger equation in real two-dimensional Euclidean space,

$$H\psi=E\psi,\quad H=-\tfrac{1}{2}\Delta+V(x,y),\tag{4.1}$$

and look for second order generalized symmetries in their evolutionary form $\mathbf{v}^E$ (3.2) with characteristic Q satisfying

$$Q=Q(x,y,\psi,\psi_x,\psi_y,\psi_{xx},\psi_{xy},\psi_{yy}).\tag{4.2}$$

We require that the second prolongation of the vector field $\mathbf{v}^E$ should annihilate Eq. (4.1) on its solution space, i.e.,

$$pr^{(2)}\mathbf{v}^E\,(H-E)\psi\big|_{\substack{H\psi=E\psi\\ H\psi^*=E\psi^*}}=0,\quad pr^{(2)}\mathbf{v}^E\,(H-E)\psi\big|_{\substack{H\psi=E\psi\\ H\psi^*=E\psi^*}}=0.\tag{4.3}$$

If we also require that Q be energy independent, we obtain the following result.

Theorem 4.1: *The characteristic Q of the evolutionary vector field $\mathbf{v}^E=Q\partial_\psi+Q^*\partial_{\psi^*}$, corresponding to a second order generalized symmetry of the Schrödinger equation (4.1) has the form*

$$Q = X\psi + \chi(x,y), \tag{4.4}$$

$$X = aL_3^2 + b(L_3P_1 + P_1L_3) + c(L_3P_2 + P_2L_3) + d(P_1^2 - P_2^2) + 2eP_1P_2 + \alpha L_3 + \beta P_1 + \gamma P_2 + \phi(x,y). \tag{4.5}$$

The function $\chi(x,y)$ satisfies the Schrödinger equation (4.1). The operator X commutes with the Hamiltonian H,

$$[H,X] = 0. \tag{4.6}$$

The quantities $a,\ldots,e,\alpha,\beta,\gamma$ are constants and

$$P_1 = \partial_x,\ \ P_2 = \partial_y,\ \ L_3 = y\partial_x - x\partial_y \tag{4.7}$$

are generators of the Euclidean group E_2.

For a proof of Theorem 4.1, see Ref. 56.

The commutativity relation (4.6) is equivalent to the following linear partial differential equations satisfied by the potential $V(x,y)$ and the function $\phi(x,y)$,

$$[\alpha(y\partial_x - x\partial_y) + \beta\partial_x + \gamma\partial_y]V(x,y) = 0, \tag{4.8}$$

$$\begin{aligned}(-axy - bx + cy + e)(V_{xx} - V_{yy}) + [a(x^2 - y^2) - 2by - 2cx - 2d]V_{xy}\\ - 3(ay + b)V_x + 3(ax - c)V_y = 0,\end{aligned} \tag{4.9}$$

$$\phi_x = -2(ay^2 + 2by + d)V_x + 2(axy + bx - cy - e)V_y, \tag{4.10}$$

$$\phi_y = 2(axy + bx - cy - e)V_x + 2(-ax^2 + 2cx + d)V_y. \tag{4.11}$$

Here Eq. (4.9) is the compatibility condition for the two equations (4.10) and (4.11). Equation (4.8) is easily solved.

For $\alpha \neq 0$ we can translate x and y to transform $\beta \to 0,\ \gamma \to 0$. Then the potential is rotationally invariant, $V = V(r)$.

For $\alpha = 0,\ \beta^2 + \gamma^2 \neq 0$ we can rotate to obtain $\beta \to 0$. Then the potential is translationally invariant, $V = V(x)$.

To avoid the geometric symmetries (4.7) we solve Eq. (4.8) trivially by imposing $\alpha = \beta = \gamma = 0$. We then simplify the second order operator X of Eq. (4.5) by rotations, translations, and linear combinations with the Hamiltonian H.

These transformations leave two expressions in the space of the coefficients $a,\ldots,e$ invariant, namely

$$I_1 = a,\ \ I_2 = [(2ad - b^2 + c^2)^2 + 4(ae - bc)^2]. \tag{4.12}$$

In the nongeneric case when $I_1 = I_2 = 0$, a third invariant exists, namely

$$I_3 = d^2 + e^2. \tag{4.13}$$

Using these invariants, one obtains four equivalence classes of operators X and correspondingly, four classes of potentials allowing for the existence of an operator X, commuting with the Hamiltonian.[64,56] The existence of one second order operator X, satisfying (4.6) makes the system integrable. Moreover, the corresponding Schrödinger equation will allow separation of variables in Cartesian, polar, parabolic or elliptic coordinates. Which is the separable system depends on the values of the invariants (4.12) and (4.13).

We are interested in the case of superintegrable Hamiltonians, when two operators X_1 and X_2 exist, satisfying

$$[H,X_1]=[H,X_2]=0,\ \ [X_1,X_2]\neq 0. \tag{4.14}$$

Four classes of such potentials exist, each allowing the separation of variables in at least two coordinate systems. The Hamiltonians and corresponding integrals of motion are

(1)

$$\begin{aligned} H_{\mathrm{I}} &= -\frac{1}{2}(\partial_x^2+\partial_y^2)+\frac{\omega^2}{2}(x^2+y^2)+\frac{a}{2x^2}+\frac{b}{2y^2},\\ \hat{X}_1 &= P_1^2-P_2^2-\left[\omega^2(x^2-y^2)+\frac{a}{x^2}-\frac{b}{y^2}\right],\\ \hat{X}_2 &= L_3^2-\left(\frac{a}{\cos^2\phi}+\frac{b}{\sin^2\phi}\right),\\ x &= r\cos\phi,\ \ y=r\sin\phi. \end{aligned} \tag{4.15}$$

(2)

$$\begin{aligned} H_{\mathrm{II}} &= -\frac{1}{2}\left(\partial_x^2+\partial_y^2\right)+\omega^2\left(2x^2+\frac{y^2}{2}\right)+\frac{a}{2y^2}+bx,\\ \hat{X}_1 &= P_1^2-P_2^2-\left[\omega^2(4x^2-y^2)+bx-\frac{a}{y^2}\right],\\ \hat{X}_2 &= L_3P_2+P_2L_3-2\omega^2xy^2+\frac{2ax}{y^2}-by^2. \end{aligned} \tag{4.16}$$

The remaining two systems are best written in parabolic coordinates,

$$x=\tfrac{1}{2}(\xi^2-\eta^2),y=\xi\eta. \tag{4.17}$$

(3)

$$\begin{aligned} H_{\mathrm{III}} &= -\frac{1}{2}\frac{1}{\xi^2+\eta^2}(\partial_\xi^2+\partial_\eta^2)+\frac{1}{\xi^2+\eta^2}\left(2a+\frac{b}{\xi^2}+\frac{c}{\eta^2}\right),\\ X_1 &= L_3^2-2(\xi^2+\eta^2)\left(\frac{b}{\xi^2}+\frac{c}{\eta^2}\right),\\ X_2 &= L_3P_2+P_2L_3+\frac{2}{\xi^2+\eta^2}\left(a(\xi^2-\eta^2)-b\frac{\eta^2}{\xi^2}+c\frac{\xi^2}{\eta^2}\right). \end{aligned} \tag{4.18}$$

(For $b=c=0$, $a\neq 0$ this is the Coulomb atom.) The system allows separation of variables in polar and parabolic coordinates (and also in elliptic coordinates).

(4)

$$\begin{aligned} H_{\mathrm{IV}} &= -\frac{1}{2}\frac{1}{\xi^2+\eta^2}(\partial_\xi^2+\partial_\eta^2)+\frac{2a+b\xi+c\eta}{\xi^2+\eta^2},\\ \hat{X}_1 &= L_3P_1+P_1L_3+\frac{b\eta(\eta^2-\xi^2)+c\xi(\xi^2-\eta^2)-4a\eta\xi}{(\xi^2+\eta^2)}, \end{aligned} \tag{4.19}$$

$$\hat{X}_2 = L_3P_2 + P_2L_3 + 2\frac{a(\xi^2 - \eta^2) + \eta\xi(c\xi - b\eta)}{(\xi^2 + \eta^2)}.$$

The equation separates in two mutually orthogonal parabolic coordinate systems, namely (4.17) and a similar system with x and y interchanged. For $a \neq 0$, $b=c=0$ we again obtain the Coulomb atom.

We shall call the systems H_{I} and H_{II} the *generalized isotropic* and *generalized nonisotropic harmonic oscillators*, respectively. Similarly, H_{III} and H_{IV} can both be called *generalized Coulomb systems.*

The Schrödinger equations for H_{III} and H_{IV} can be rewritten as

$$\left\{-\frac{1}{2}(\partial_\xi^2 + \partial_\eta^2) - E(\xi^2 + \eta^2) + \frac{b}{2\xi^2} + \frac{c}{2\eta^2}\right\}\psi = -a\psi, \tag{4.20}$$

$$\left\{-\frac{1}{2}(\partial_\xi^2 + \partial_\eta^2) - E\left[\left(\xi - \frac{b}{2E}\right)^2 + \left(\eta - \frac{c}{2E}\right)^2\right]\right\}\psi = \left(-2a - \frac{b^2 + c^2}{4E^2}\right)\psi, \tag{4.21}$$

respectively. Thus, the system H_{III} is reduced to H_{I} with the energy $(-E)$ and coupling constant ω^2 interchanged. The system H_{IV} is reduced to a "shifted" harmonic oscillator. This interchange of the energy and a coupling constant has been called "metamorphosis of the coupling constant."[26]

B. Discrete generalized harmonic oscillators

The umbral correspondence immediately provides us with discrete versions of these systems. Let us first consider the potential V_{I} of Eq. (4.15). The discrete version of this system is

$$H_{\mathrm{I}}^D = -\frac{1}{2}(\Delta_x^2 + \Delta_y^2) + \frac{\omega^2}{2}[(x\beta_x)^2 + (y\beta_y)^2] + \frac{a}{2}(x\beta_x)^{-2} + \frac{b}{2}(y\beta_y)^{-2} \tag{4.22}$$

with the integrals of motion

$$X_1 = [-\tfrac{1}{2}\Delta_x^2 + \omega^2(x\beta_x)^2 + a(x\beta_x)^{-2}] - [-\tfrac{1}{2}\Delta_y^2 + \omega^2(y\beta_y)^2 + b(y\beta_y)^{-2}] \tag{4.23}$$

and

$$X_2 = (x\beta_x\Delta_y - y\beta_y\Delta_x)^2 - [a(1 + (x\beta_x)^{-2}(y\beta_y)^2) + b(1 + (x\beta_x)^2(y\beta_y)^{-2})]. \tag{4.24}$$

Similarly, the discrete version of the system with potential V_{II} is

$$H_{\mathrm{II}}^D = -\frac{1}{2}(\Delta_x^2 + \Delta_y^2) + \omega^2\left[2(x\beta_x)^2 + \frac{1}{2}(y\beta_y)^2\right] + \frac{a}{2}(y\beta_y)^{-2} + bx\beta_x. \tag{4.25}$$

The second order operators commuting with the Hamiltonian (4.25) are

$$X_1 = \Delta_x^2 - \Delta_y^2 - [\omega^2(4(x\beta_x)^2 - (y\beta_y)^2) + b(x\beta_x) - a(y\beta_y)^{-2}] \tag{4.26}$$

and

$$X_2 = [(y\beta_y)\Delta_x - (x\beta_x)\Delta_y]\Delta_y + \Delta_y[(y\beta_y)\Delta_x - (x\beta_x)\Delta_y] - 2\omega^2(x\beta_x)(y\beta_y)^2 + 2a(x\beta_x)(y\beta_y)^{-2} - b(y\beta_y)^2. \tag{4.27}$$

The model (4.15) has also been discretized in Ref. 62 using the formalism of raising and lowering operators.

C. Discrete generalized Coulomb potentials

To discretize the systems H_{III} and H_{IV} we again use the umbral correspondence, this time using parabolic coordinates. Thus, we replace

$$\partial_\xi \to \Delta_\xi,\ \partial_\eta \to \Delta_\eta,\ \xi \to \xi\beta_\xi,\ \eta \to \eta\beta_\eta. \tag{4.28}$$

With these replacements it is a simple matter to write the discrete versions of the systems corresponding to the potentials V_{III} and V_{IV}. Indeed, we have

$$H_{\mathrm{III}} = -\tfrac{1}{2}[(\xi\beta_\xi)^2 + (\eta\beta_\eta)^2]^{-1}[\Delta_\xi^2 + \Delta_\eta^2 - 4a - 2b(\xi\beta_\xi)^{-2} - 2c(\eta\beta_\eta)^{-2}], \tag{4.29}$$

$$X_1 = [(\xi\beta_\xi)\Delta_\eta - (\eta\beta_\eta)\Delta_\xi]^2 - 2[(\xi\beta_\xi)^2 + (\eta\beta_\eta)^2][b(\xi\beta_\xi)^{-2} + c(\eta\beta_\eta)^{-2}], \tag{4.30}$$

$$\begin{aligned} X_2 = {} & [(\xi\beta_\xi)^2 + (\eta\beta_\eta)^2]^{-1}\{(\eta\beta_\eta)^2\Delta_\xi^2 - (\xi\beta_\xi)^2\Delta_\eta^2 + 2a[(\xi\beta_\xi)^2 - (\eta\beta_\eta)^2] - 2b(\eta\beta_\eta)^2(\xi\beta_\xi)^{-2} \\ & + 2c(\xi\beta_\xi)^2(\eta\beta_\eta)^{-2}\}, \end{aligned} \tag{4.31}$$

and

$$H_{\mathrm{IV}} = -\tfrac{1}{2}[(\xi\beta_\xi)^2 + (\eta\beta_\eta)^2]^{-1}[\Delta_\xi^2 + \Delta_\eta^2 - 4a - 2b(\xi\beta_\xi) - 2c(\eta\beta_\eta)], \tag{4.32}$$

$$\begin{aligned} X_1 = {} & [(\xi\beta_\xi)^2 + (\eta\beta_\eta)^2]^{-1}\{(\xi\beta_\xi)(\eta\beta_\eta)(\Delta_\xi^2 + \Delta_\eta^2) + [-b(\eta\beta_\eta) + c(\xi\beta_\xi)][(\xi\beta_\xi)^2 - (\eta\beta_\eta)^2] \\ & - 4a(\xi\beta_\xi)(\eta\beta_\eta)\} - \Delta_{\xi\eta}^2, \end{aligned} \tag{4.33}$$

$$\begin{aligned} X_2 = {} & \tfrac{1}{2}[(\xi\beta_\xi)^2 + (\eta\beta_\eta)^2]^{-1}\{(\eta\beta_\eta)^2\Delta_\xi^2 - (\xi\beta_\xi)^2\Delta_\eta^2 + 2a[(\xi\beta_\xi)^2 - (\eta\beta_\eta)^2] \\ & + 2(\xi\beta_\xi)(\eta\beta_\eta)[c(\xi\beta_\xi) - b(\eta\beta_\eta)]\}. \end{aligned} \tag{4.34}$$

V. EXACT SOLVABILITY AND SPECTRAL PROPERTIES OF DISCRETE SUPERINTEGRABLE SYSTEMS

We have shown that certain important properties of the Schrödinger equation, such as point and generalized symmetries, and hence also integrability, are preserved when we pass from continuous to discrete space–time via an umbral correspondence.

Another important property of some quantum systems is their "exact solvability." This means that their Hamiltonian can be transformed into a block diagonal form with finite-dimensional blocks. In other words, their complete energy spectrum can be calculated algebraically. In more mathematical terms, we give the following definition.

Definition 5.1: A quantum mechanical system with Hamiltonian H is called exactly solvable if its Hilbert space S of bound states consists of a flag of finite-dimensional subspaces,

$$S_0 \subset S_1 \subset S_2 \subset \cdots \subset S_n \subset \cdots \tag{5.1}$$

preserved by the Hamiltonian

$$HS_i \subseteq S_i. \tag{5.2}$$

All known exactly solvable systems also have the following properties.

(1) In appropriate coordinates and in an appropriate gauge, the bound state wave functions $\Psi_N(\vec{x})$ are polynomials,

$$\Psi_N(\vec{x}) = g(\vec{x})P_N(\vec{s}),\ \ s_i = s_i(\vec{x}). \tag{5.3}$$

The gauge factor $g(\vec{x})$ is *a priori* defined and can be energy dependent. The function $P_N(\vec{s})$

are polynomials of order N in the variables s_i. The integer N labels the subspaces S_i in the flag.

(2) In the same gauge g and same variables s_i the Hamiltonian H can be written as

$$H = ghg^{-1}, \quad hP_N = E_N P_N \tag{5.4}$$

with

$$h = a_{ik}^{\alpha} T_{ik}^{\alpha} + a_{ik,lm}^{\alpha\beta} T_{ik}^{\alpha} T_{lm}^{\beta}, \tag{5.5}$$

where a_{ik}^{α} and $a_{ik,lm}^{\alpha\beta}$ are constants (subject to some further conditions[21]) and

$$T_{ik}^{\alpha} = s_i^{\alpha} \partial_{s_k}, \quad \alpha = 0,1, \quad i,k = 1, \ldots, n. \tag{5.6}$$

In other words, the gauge rotated Hamiltonian h is an element of the enveloping algebra of an affine Lie algebra aff$(n,\mathbb{R})$ (or one of its subalgebras). It is clear that (5.5) guarantees that the Hamiltonian H will preserve, or decrease the order of the polynomials P_N. This is a concrete realization of the flag condition (5.2).

We mention that all known quadratically superintegrable systems are exactly solvable, in particular those of Sec. IV.[58] For the generalized harmonic oscillators the gauge factor g is equal to the ground state wave function and is energy independent. The generalized Coulomb systems have been reduced to the harmonic oscillator ones [see (4.20) and (4.21)]. However, due to the interchange of the energy and the coupling constant, the gauge factor g will be energy dependent.

The aim of this section is to show how exact solvability manifests itself in discrete space–time. First of all, let us consider an arbitrary one-dimensional linear spectral problem

$$L(\partial_x, x)\psi(x) = \lambda\psi(x). \tag{5.7}$$

Let $x=0$ be a regular point of this equation. Then any solution can be expanded into a Taylor series

$$\psi(x) = \sum_{k=0}^{\infty} a_k x^k. \tag{5.8}$$

Using the umbral correspondence we write the umbral equation

$$L(\Delta, x\beta)\psi(x\beta) = \lambda\psi(x\beta) \tag{5.9}$$

with the same eigenvalue λ as in the ODE (5.7). Viewed as a difference equation, Eq. (5.9) will have a formal power series solution,

$$\psi(x\beta)1 = \sum_{k=0}^{\infty} a_k^k (x\beta)^k \cdot 1. \tag{5.10}$$

In particular, if (5.8) is a polynomial solution, then Eq. (5.10) will also be a finite sum of terms involving the basic polynomials of the operator Δ. Thus, (5.10) will also be a polynomial and all convergence problems disappear.

Now let us turn to the specific case of the generalized harmonic oscillator system with Hamiltonian H_{I} [see Eq. (4.15)] and its discretization (4.22). The gauge factor g of Eq. (5.3) and (5.4) is

$$g = x^{p_1} y^{p_2} \exp\left[-\frac{\omega(x^2+y^2)}{2} \right], \quad a = p_1(p_1-1), \quad b = p_2(p_2-1). \tag{5.11}$$

We set $\omega x^2 = s_1$, $\omega y^2 = s_2$ and in these variables the aff$(2,\mathbb{R})$ operators of Eq. (5.6) reduce to

$$J_1 = \partial_{s_1}, \quad J_2 = \partial_{s_2}, \quad J_3 = s_1\partial_{s_1}, \quad J_4 = s_2\partial_{s_2},$$

$$J_5 = s_2\partial_{s_1},\ \ J_6 = s_1\partial_{s_2}. \tag{5.12}$$

The gauge rotated Hamiltonian h and gauge rotated integrals of motion $\hat{x_1}=g\hat{X}_1g^{-1}$, $\hat{x_2}=g\hat{X}_2g^{-1}$ can now be written as[58]

$$h = -2J_3J_1 - 2J_4J_2 + 2J_3 + 2J_4 - (2p_1+1)J_1 - (2p_2+1)J_2,$$

$$\hat{x_1} = 2J_3J_1 - 2J_4J_2 - 2J_3 + 2J_4 + (2p_1+1)J_1 - (2p_2+1)J_2, \tag{5.13}$$

$$\hat{x_2} = 4J_3J_5 + 4J_4J_6 - 8J_3J_4 + 2(2p_1+1)J_5 - 2(2p_2+1)J_3 - 2(2p_1+1)J_4 + 2(2p_2+1)J_6.$$

By construction, all three of these operators will conserve the flag of polynomials

$$P_n(s_1,s_2) = \langle (s_1)^{N_1}(s_2)^{N_2} | 0 \leqslant N_1 + N_2 \leqslant n \rangle \tag{5.14}$$

and this is the reason why the superintegrable system with Hamiltonian H_{I} is exactly solvable. The actual solutions of Eq. (5.4) are Laguerre polynomials,

$$\begin{gathered} HP_{nm} = E_{nm}P_{nm},\ \ E_{mn} = n+m, \\ P_{nm}(x,y) = L_n^{(-1/2+p_1)}(\omega x^2)L_m^{(-1/2+p_2)}(\omega y^2). \end{gathered} \tag{5.15}$$

The umbral discretization will preserve the above properties and will give umbral Laguerre polynomial expressed in terms of $x\beta_x$ and $y\beta_y$. The algebra aff$(2,\mathbb{R})$ is represented by difference operators,

$$\begin{gathered} \tilde{J}_1 = \Delta_{s_1},\ \ \tilde{J}_2 = \Delta_{s_2},\ \ \tilde{J}_3 = (s_1\beta_1)\Delta_{s_1},\ \ \tilde{J}_4 = (s_2\beta_2)\Delta_{s_2}, \\ \tilde{J}_5 = (s_2\beta_2)\Delta_{s_1},\ \ \tilde{J}_6 = (s_1\beta_1)\Delta_{s_2}. \end{gathered} \tag{5.16}$$

The formulas (5.13) remain the same (with $J_i \to \widetilde{J_i}$) and all commutation relations are preserved, as are polynomial solutions. For similar results formulated in terms of operators acting in Fock spaces and the notion of isospectral discretization see Turbiner *et al.* (Refs. 60–63, 57, and 10), and Ref. 11 for further discussions.

We mention here that other discretizations of superintegrable systems, especially the harmonic oscillator, exist in the literature.[2–4,27] They are either related to quantum groups, or the discretization is based on noncommuting coordinates in configuration space.

VI. CONCLUSIONS

Much, if not all of nonrelativistic quantum mechanics can be viewed as the "theory of the enveloping algebra of the Heisenberg algebra."

Indeed, let us define the Heisenberg algebra H_n by the relations

$$[X_j, Y_k] = \delta_{jk}C,\ \ j,k = 1,\ldots,n, \tag{6.1}$$

and then set

$$X_j = x_j,\ Y_k = -i\hbar\partial_{x_k},\ C = i\hbar. \tag{6.2}$$

We can say that all quantum mechanical operators lie in the enveloping algebra of H_n, or in an extension of the enveloping algebra obtained by adding all formal power series in $x_1,\ldots,x_n$, $p_1,\ldots,p_n$.

If we replace the coordinates x_j and the momenta p_j by some other quantities satisfying the relations (6.1) then all polynomials and all power series in these objects will commute in the same way as the corresponding quantum mechanical quantities.

Indeed, the umbral correspondence $x_i \to x_i \beta_i$, $\partial_{x_i} \to \Delta_{x_i}$ preserves the commutation relations (6.1) between quantum mechanical operators. Thus, the umbral correspondence allows us to consider quantum mechanics on a lattice and to preserve all properties of quantum mechanics in continuous space and time that are expressed in terms of the commutation properties of physical quantities (quantum mechanical operators). In particular, infinitesimal point symmetries and generalized symmetries are preserved, as shown in Secs. III and IV, respectively. Exact solvability is reduced to an algebraic property and then discretized in Sec. V (and also in Refs. 57, 62, and 63).

Some nonalgebraic properties are lost in the discretization. For instance, the "umbral vector fields" (2.29), obtained by the umbral correspondence, do not generate global transformations (like rotations, or dilations). The solutions of umbral equations (obtained by the umbral correspondence) are often formal, i.e., they may diverge.

The physical content of this paper is based on the results contained in Sec. II, where we presented and proved several theorems that, to our knowledge, extend the previously known umbral formalism to linear difference equations. In particular we associate with a linear differential equation an abstract operator equation, written in terms of delta operators, using the umbral correspondence (2.23). Any representation of Δ and β in terms of shift-invariant operators provides a difference equation, whose analytic solutions can be obtained from the solutions $\hat{f}$ of the operator equation (2.50) via the projection $\hat{f} \cdot 1 = f(x\beta) \cdot 1$. These are the umbral solutions admitted by a given difference equation. The other possible solutions do not have a continuous limit and are not provided by the umbral approach.

Many of the results presented here can be considered also in the case of q-difference operators.[34] The delta operator U in this case is defined in terms of a q-shift operator satisfying

$$T_q f(x) = f(qx). \tag{6.3}$$

In the simplest case, the q-difference operator reads

$$\Delta_q = \frac{1}{(q-1)x}(T_q - 1), \quad \lim_{q \to 1} \Delta_q f = f_x \tag{6.4}$$

and its conjugate operator, obtained imposing the Heisenberg commutation relation,

$$[\Delta_q, x\beta_q] = 1, \tag{6.5}$$

is written in terms of a q shift and differential operators as

$$\beta_q = (q-1)(qT - 1)^{-1} x \partial_x. \tag{6.6}$$

In this case we can still consider the umbral correspondence, but the Δ_q operator is not a shift invariant operator, as $[\Delta_q, T_q] \neq 0$.

Among open questions, presently under consideration, we mention the following.

(i) This paper deals with the Lie-algebraic aspects of the discretization of the Schrödinger equation. The analytic aspects, like the self-adjointness properties of the discrete Hamiltonians, and the convergence properties of the formal power series remain to be investigated.

(ii) The umbral correspondence has lead us to various linear umbral equations and difference equations. It would be of considerable interest to study their solutions directly and in the case of polynomial solutions, establish their relation to orthogonal polynomials of discrete variables, known in the literature.[50,46]

(iii) Although many of the results presented in this paper can also be carried out in the q-difference case,[34,29,33] a reformulation of the umbral theory in this case is necessary.

(iv) The connection between umbral calculus, delay equations and functional analysis should be studied.

(v) The simultaneous diagonalization of commuting sets of second order differential operators is intimately related to the separation of variables in the Schrödinger equation. It would be important to further investigate common solutions of commuting sets of difference operators from this point of view. An example of such a study is given in the Appendix, where we present solutions of an "umbral Klein–Gordon equation."

(vi) A related problem is that of establishing a connection between umbral formalisms introduced in different coordinate systems, e.g., the Cartesian quantities Δ_x, Δ_y, β_x, β_y and the corresponding polar ones, or parabolic ones Δ_ξ, Δ_η, β_ξ, β_η introduced in Secs. IV and V.

APPENDIX: DISCRETIZATION OF A RELATIVISTIC WAVE EQUATION

Let us consider a relativistic wave equation in two dimensions,

$$\left(\frac{\partial^2}{\partial t^2} - \frac{\partial^2}{\partial z^2}\right)\phi = k\phi. \tag{A1}$$

In light-cone coordinates

$$x = \frac{z+t}{2},\ y = \frac{z-t}{2},$$

we write this equation as

$$R\phi = \frac{\partial^2}{\partial x \partial y}\phi(x,y) = -k\phi. \tag{A2}$$

Equation (A2) is invariant under the Poincaré group of two-dimensional Minkowski space. Its symmetry algebra is given by

$$P_0 = \partial_x,\ P_1 = \partial_y,\ M = x\partial_x - y\partial_y. \tag{A3}$$

Since the operators R and M commute, we can construct common eigenfunctions satisfying

$$M\phi = \lambda\phi, \tag{A4}$$

in addition to Eq. (A2). The solution of Eq. (A4) can be written as monomials $x^{n+\lambda}y^n$, or more generally

$$\phi_\lambda(x,y) = \sum_{n=0}^{\infty} a_n x^{n+\lambda} y^n \tag{A5}$$

(we choose not to follow the standard procedure of separating variables). Substituting (A5) into Eq. (A2) we obtain the recursion relation

$$a_{n+1}(n+\lambda+1)(n+1) = -ka_n, \tag{A6}$$

i.e.,

$$a_n = (-k)^n a_0 \frac{\Gamma(\lambda+1)}{\Gamma(\lambda+n+1)n!}. \tag{A7}$$

With a_n as in Eq. (A7) we write the (unnormalized) solution (A5) as

$$\phi_{\lambda k} = x^\lambda \sum_{n=0}^{\infty} (-k)^n \frac{1}{\Gamma(\lambda+n+1)n!}(xy)^n. \tag{A8}$$

This can be rewritten as

$$\phi_{\lambda k}(x,y) = \frac{1}{(k)^{\lambda/2}}\left(\frac{x}{y}\right)^{\lambda/2} J_\lambda(2\sqrt{kxy}), \tag{A9}$$

where $J_\nu(z)$ is a cylindrical function. The umbral version of the system (A2) and (A4) is

$$\Delta_x \Delta_y \psi = -k\psi, \tag{A10}$$

$$(x\beta_x \Delta_x - y\beta_y \Delta_y)\psi = \lambda\psi. \tag{A11}$$

Since Eq. (A5) is a power series we can immediately write the corresponding solution of Eq. (A1) as

$$\psi_\lambda(x,y) = \sum_{n=0}^{\infty} a_n (x\beta_x)^{n+\lambda}(y\beta_y)^n \cdot 1. \tag{A12}$$

Setting $\psi_\lambda(x,y)$ into Eq. (A10), we reobtain the two-term recursion relation (A6) with the solution (A7). The solution of the umbral system (A10) and (A11), is hence

$$\psi_\lambda(x,y) = (x\beta_x)^\lambda \sum_{n=0}^{\infty} \frac{(-k)^n}{\Gamma(\lambda+n+1)n!}(x\beta_x)^n(y\beta_y)^n \cdot 1. \tag{A13}$$

Equation (A13) provides a formal power series solution for any choice of the difference operators Δ_x, Δ_y and the corresponding conjugate operators β_x, β_y. If the series converges, then Eq. (A13) is a solution of the system (A10) and (A11).

Let us fix the values of x and y and apply the ratio test of convergence to the series (A13). The ratio of two consecutive terms is

$$\frac{a_{n+1}}{a_n} = -k \frac{1}{(\lambda+n+1)(n+1)} \frac{(x\beta_x)^{n+1}}{(x\beta_x)^n} \frac{(y\beta_y)^{n+1}\cdot 1}{(y\beta_y)^n \cdot 1}.$$

The value of this limit depends on our choice of Δ_x and Δ_y, and hence of β_x and β_y.

For the right and left derivatives Δ^+ and Δ^-, we have $\beta = T^{-1}$ and T, respectively, and hence

$$\lim_{n\to\infty}\left|\frac{a_{n+1}}{a_n}\right| = |k| \lim_{n\to\infty}\left|\frac{(x \mp n\sigma_x)(y \mp n\sigma_y)}{(\lambda+n+1)(n+1)}\right| = |k\sigma_x\sigma_y|. \tag{A14}$$

We see that the series (A13) converges (absolutely) for any finite values of x and y, provided we have

$$|k\sigma_x\sigma_y| < 1. \tag{A15}$$

It is interesting to compare the two series expansions (A8) and (A13). In the continuous case we can introduce "polar" coordinates (ρ, α)

$$x = \frac{\rho}{2}e^{\alpha}, \quad y = \frac{\rho}{2}e^{-\alpha}, \tag{A16}$$

and Eq. (A8) then corresponds to the separation of variables

$$\phi_{\lambda k}(x,y) = e^{\lambda\alpha}\sum_{n=0}^{\infty}(-k)^n \frac{1}{n!\Gamma(\lambda+n+1)}\left(\frac{\rho}{2}\right)^{2n+\lambda} = e^{\lambda\alpha}k^{-\lambda/2}J_{\lambda}(\sqrt{k\rho}). \tag{A17}$$

In the discrete case we obtain a solution of the difference scheme by applying ψ_λ of Eq. (A13) to a constant. This is however not a separated solution, since $[(x\beta_x)(y\beta_y)]^n$ is not a function of xy alone. For example, for $\beta_i = T_i^{-1}$ and $n=2$ we have

$$[(xT_x^{-1})(yT_y^{-1})]^2 = x(x-\sigma_x)y(y-\sigma_y)T_x^{-2}T_y^{-2}.$$

Thus, separation of variables techniques in the discrete case lead to very specific "umbral" solutions like (A13). They only separate in the continuum limit. See also Refs. 17, 18, and 44 on simultaneous eigenfunctions of commuting difference operators.

(Received 6 April 2004; accepted 15 June 2004; published 20 October 2004)

The Γ-convergence theory shows that under certain conditions the diblock copolymer equation has spot and ring solutions. We determine the asymptotic properties of the critical eigenvalues of these solutions in order to understand their stability. In two dimensions a threshold exists for the stability of the spot solution. It is stable if the sample size is small and unstable if the sample size is large. The stability of the ring solutions is reduced to a family of finite dimensional eigenvalue problems. In one study no two-interface ring solutions are found by the Γ-convergence method if the sample is small. A stable two-interface ring solution exists if the sample size is increased. It becomes unstable if the sample size is increased further. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1782280]

I. INTRODUCTION

A diblock copolymer is a soft material, characterized by fluidlike disorder on the molecular scale and a high degree of order at longer length scales. A molecule in a diblock copolymer is a linear subchain of *A* monomers grafted covalently to another subchain of *B* monomers. Because of the repulsion between the unlike monomers, the different type subchains tend to segregate, but as they are chemically bonded in chain molecules, segregation of subchains cannot lead to a macroscopic phase separation. Only a local microphase separation occurs: microdomains rich in *A* and *B* emerge. These microdomains form morphology patterns/phases in a larger scale.

The Ohta–Kawasaki[21] free energy of an incompressible diblock copolymer melt is a functional of the *A* monomer density field. Let $u(x)$ be the relative *A* monomer number density at point x in the sample D. When there is high *A* monomer concentration at x, $u(x)$ is close to 1; when there is high concentration of *B* monomers at x, $u(x)$ is close to 0. A value of $u(x)$ between 0 and 1 means that a mixture of *A* and *B* monomers occupies x. The re-scaled, dimensionless free energy of the system is

$$I(u) = \int_D \left\{ \frac{\epsilon^2}{2} |\nabla u|^2 + \frac{\epsilon\gamma}{2} |(-\Delta)^{-1/2}(u-a)|^2 + W(u) \right\} dx, \tag{1.1}$$

which is defined in the admissible set

$$X_a = \{u \in W^{1,2}(D) : \overline{u} = a\}, \tag{1.2}$$

where $\overline{u} = (1/|D|)\int_D u\, dx$ is the average of u in D. a is a fixed constant in (0,1). It is the ratio of the number of the *A* monomers to the number of all the monomers in a chain molecule.

In (1.1) ϵ is a small positive parameter and γ is a fixed positive constant, i.e.,

$$\epsilon \to 0, \quad \gamma \sim 1. \tag{1.3}$$

The term $W(u)$ is the internal energy field. Originally in Choksi and Ren[8] it is taken to be

$$W(u) = \begin{cases} u - u^2 & \text{if } u \in [0,1] \\ \infty & \text{otherwise.} \end{cases} \tag{1.4}$$

Here we change it to a smooth function so that W is a double well potential of equal depth. It has global minimum value 0 achieved at 0 and 1. We assume for simplicity that W is smooth, grows at least quadratically at $\pm\infty$, and symmetric about 1/2: $W(u)=W(1-u)$. 0 and 1 are nondegenerate: $W''(0)=W''(1)>0$. An example of W is $W(u)=\frac{1}{4}(u^2-u)^2$.

The other two terms in (1.1) give the entropy of the system. The peculiar nonlocal term is due to the fact that molecules in a diblock copolymer are connected long cains. It models a type of nonlocal interaction known as the Coulomb interaction (Muratov[17]). Mathematically we view $(-\Delta)^{-1}$ as a bounded positive operation from $\{\zeta \in L^2(D): \overline{\zeta}=0\}$ to $\{\xi \in W^{2,2}(D): \overline{\xi}=0\}: \xi=(-\Delta)^{-1}\zeta$ if

$$-\Delta\xi = \zeta \text{ in } D, \quad \partial_v \xi = 0 \text{ on } \partial D, \quad \overline{\xi} = 0.$$

Then $(-\Delta)^{-1/2}$ is the positive square root of $(-\Delta)^{-1}$.

To understand the parameter range (1.3) we recall the physical parameters in a diblock copolymer system (cf. Ref. 8).

(1) The polymerization index N that is the number of all the monomers in a chain molecule. We consider the ideal situation where this N is the same in all molecules;
(2) The Kuhn statistical length l measuring the average distance between two adjacent monomers in a chain molecule, which is the same regardless the monomer types;
(3) The Flory–Huggins parameter χ that measures the repulsion between unlike monomers and is inversely proportional to the absolute temperature;
(4) Relative A monomer ratio a mentioned earlier;
(5) The volume V of the sample.

They are related to the mathematical dimensionless parameters ϵ and γ by

$$\epsilon^2 = \frac{\pi^{2/3} l^2}{12a(1-a)\chi V^{2/3}}, \quad \gamma = \frac{18\sqrt{3}V}{\pi a^{3/2}(1-a)^{3/2}\chi^{1/2}N^2 l^3}. \tag{1.5}$$

Among the physical parameters a and χ are dimensionless and order 1. So we focus on l, V, and N. N is necessarily large in a polymer system. By taking ϵ small we have assumed that the sample is large compared to l. On the other hand having $\gamma \sim 1$ means that $V \sim l^3 N^2$. After we find spot and ring solutions of a finite number of microdomains separated by interfaces whose width is of order ϵ in the parameter range (1.3), we conclude that the size of a microdomain is of order l^3N^2 and the thickness of the interfaces is of order l, facts very well matched by experiments.[21]

Another choice of γ was used in Müller,[16] Nishiura and Ohnishi,[19] and Ren and Wei:[26] $\gamma \sim \epsilon^{-1}$, i.e., $V \sim l^3 N^3$. In this larger sample one finds that the number of the microdomains is of order ϵ^{-1}. Then again the size of a microdomain is of order l^3N^2.

The diblock copolymer equation

$$-\epsilon^2 \Delta u + f(u) + \epsilon\gamma(-\Delta)^{-1}(u-a) = \eta \text{ in } D, \quad \partial_\nu u = 0 \text{ on } \partial D, \quad \overline{u} = a \tag{1.6}$$

is the Euler–Lagrange equation of (1.1), where $f=W'$. For the example of W, $f(u)=u(u-1/2)(u-1)$. The unknown constant η is a Lagrange multiplier due to the constraint $\overline{u}=a$. If we integrate (1.6) over D, then

$$\eta = \overline{f(u)}. \tag{1.7}$$

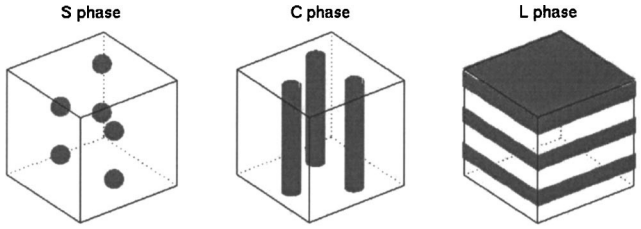

FIG. 1. The spherical, cylindrical, and lamellar morphology phases commonly observed in diblock copolymer melts. The white color indicates the concentration of type *A* monomer, and the dark color indicates the concentration of type *B* monomer.

Many morphology patterns are observed in diblock copolymers. See Bates and Fredrickson,[4] Hamley,[11] and the references therein. The most popular ones are the spherical, cylindrical, and lamellar phases, Fig. 1. The existence of the lamellar phase was shown in Ren and Wei,[24] and its stability in three dimensions was studied in Ren and Wei.[27] Surprisingly we found that the lamellar phase is only *marginally* stable. Physicists believe that defects should appear commonly in the lamellar phases, Tsori *et al.*, Refs. 36 and 17.

One type of defect is the wriggled lamellar pattern studied in Ren and Wei,[33] where interfaces separating microdomains oscillate like the sinusoidal curve. Here we study another type of defect: spot and ringlike microdomains, Fig. 2. We consider (1.6) in the unit disk $D=\{x\in R^2:|x|<1\}$. Let $v=(-\Delta)^{-1}(u-a)$. If u and v are radially symmetric, then (1.6) may be written in the radial coordinates, $r=|x|$, as

$$\begin{cases} -\epsilon^2 u_{rr}-\dfrac{\epsilon^2}{r}u_r+f(u)+\epsilon\gamma v=\eta, \\ -v_{rr}-\dfrac{1}{r}v_r=u-a, \\ u_r(0)=u_r(1)=v_r(0)=v_r(1)=0, \\ \overline{u}-a=\overline{v}=0. \end{cases} \tag{1.8}$$

The average now becomes $\overline{u}=2\int_0^1 u(r)rdr$. We are interested in radial solutions of (1.6) that show the phenomenon of microphase separation. They are close to 0 or 1 in most of D but change between 0 and 1 in small regions. These small transition regions are called the interfaces. For a radial solution u an interface may be identified by a number r_j, where $u(r_j)=1/2$. The following theorem was proved in Ren and Wei[25] using the Γ-convergence theory (cf. De Giorgi,[9] Modica,[15] and Kohn and Sternberg[14]).

Theorem 1.1 (Ren and Wei[25]): *For any $\gamma>0$, there exist two radial solutions of (1.6) on the unit disk with one circular interface when ϵ is small. If $K\geqslant 2$ and γ is large enough there exist two radial solutions with K circular interfaces when ϵ is small.*

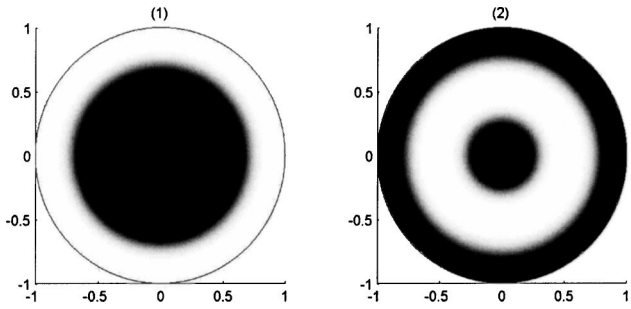

FIG. 2. (1) A spot solution. (2) A $K=2$ ring solution. In both cases $a=1/2$ and $\gamma=25$.

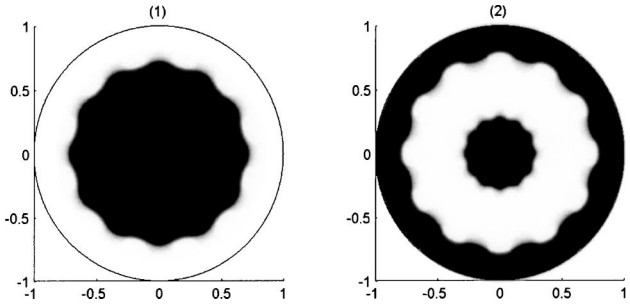

FIG. 3. Bifurcation solutions for $K=1$ and $K=2$.

For each K one of the solutions, which we simply denote by u, in Theorem 1.1 is close to 0 near the origin and the other one is close to 1 near the origin, which we denote by $\tilde{u}$. However the two solutions are related. If we change a to $1-a$ in (1.1) and (1.2), then $1-\tilde{u}$ is a solution of the new problem which is close to 0 near the origin, and $1-u$ is a solution of the new problem which is close to 1 near the origin. So it suffices to study u. u is a spot solution if $K=1$, and a ring solution if $K\geqslant 2$, Fig. 2. Throughout this paper $v=(-\Delta)^{-1}(u-a)$.

The spot solution is also useful in the study of the cylindrical phase, Fig. 1(2). A cross section of the cylindrical phase has a pattern of many spots. It is believed that these spots pack in a hexagonal way.[4] A good understanding of a single spot is essential before one can mathematically prove the existence of the cylindrical phase.

In this paper we derive a criterion for the stability of the spot and ring solutions by obtaining detailed information on the eigenvalues and eigenfunctions of the linearized problem,

$$L\varphi:=-\epsilon^2\Delta\varphi+f'(u)\varphi-\overline{f'(u)\varphi}+\epsilon\gamma(-\Delta)^{-1}\varphi=\lambda\phi \text{ in } D,\quad \partial_\nu\varphi=0 \text{ on } \partial D,\quad \overline{\phi}=0. \quad (1.9)$$

It is easy to see, Lemma 2.4, that $\lim\inf_{\epsilon\to 0}\lambda\geqslant 0$. To determine the stability we need to study the λ's that tend to 0 as $\epsilon\to 0$. These λ's are called the critical eigenvalues. They are found in Theorems 3.1 and 4.1. Consequently we show in Theorem 5.1 that the spot solution is stable if γ is small and unstable if γ is large. The threshold of γ is denoted by $\hat{\gamma}$. It is calculated numerically for various a.

To better appreciate this theorem let us recall the stationary Cahn–Hilliard equation,[5] which is (1.6) with $\gamma=0$, the local counterpart. It is known that the Cahn–Hilliard equation on the unit disk has an unstable spot solution. Once the nonlocal term with a small γ, which encourages oscillation, is added, the spot solution becomes stable. The abrupt change of stability here is discussed after the proof of Theorem 5.1. If γ is further increased, more oscillation is required and the spot solution, which only has one interface, becomes unstable.

The second change of stability has a simple physical explanation. According to (1.5) γ is proportional to the size of the sample. When the sample is sufficiently large, one big spot is unstable in two dimensions. It should break into multiple spots to form a cylindrical phase, Fig. 1(2). The value V corresponding to $\hat{\gamma}$ in $(1.5)_2$ suggests a scale for a cell with one spot in a multispot cylindrical phase.

For the ring solution ($K\geqslant 2$), we will use Theorems 3.1 and 4.1 to numerically study a case of $K=2$. When γ is small, we cannot find a ring solution by the Γ-convergence method. When γ is increased, there exists a ring solution that is stable in two dimensions. When γ is further increased over $\hat{\gamma}$, a ring solution exists but is no longer stable.

This change of stability of the ring solution and the second change of stability of the spot solution lead to a bifurcation phenomenon near $\hat{\gamma}$. Following Ref. 33 one should be able to find bifurcation solutions. They are depicted in Fig. 3. Based on our experience in Ref. 33 we suspect that most of them are stable.

More information on the model (1.1) and its extension to triblock copolymers may be found in Nakazawa and Ohta,[18] and Ren and Wei.[29] The mathematical study of stable domain structures

with multiple sharp interfaces started rather recently. On the block copolymer problem the literature includes Ohnishi *et al.*,[20] Ren and Wei,[30] Choksi,[7] Fife and Hilhorst,[10] Henry,[13] and Teramoto and Nishiura.[35] Elsewhere Ren and Truskinovsky[23] study the phenomenon in elastic bars, Ren and Wei[32,28,31] in the Seul–Andelman membrane, charged monolayers, and smectic liquid crystal films, respectively. Taniguchi[34] and Chen and Taniguchi[6] study spot and ring patterns in a free boundary problem.

The paper is organized as follows: In Sec. II we review the construction of the spot and ring solutions u, give some properties of u, and explain the classification into λ_m where $m=0,1,2,3,\ldots$ of the eigenvalues of the linearized operator at u. The properties of λ_m are given in Theorems 3.1 and 4.1 in Sec. III and IV, respectively. In Sec. V we show the stability property of the spot solution, calculate the second threshold $\hat{\gamma}$, and use Theorems 3.1 and 4.1 to study a $K=2$ ring solution. This section also includes some remarks. The Appendix contains the proof of a technical lemma.

II. PRELIMINARIES

To make the paper more readable a quantity's dependence on ϵ is usually not reflected in its notation but implied in the context. On the other hand, a quantity's independence of ϵ is often emphasized with a superscript 0. For instance the spot or ring solution u is not denoted by u_ϵ, while the $L^2(D)$-limit of u as $\epsilon\to 0$ is denoted by u^0.

Throughout the paper, the L^∞ norm of a function is denoted simply by $\|\cdot\|$. Other norms are more explicitly written, like $\|\cdot\|_2$.

We define some frequently used quantities. H is the heteroclinic solution of

$$-H''+f(H)=0,\quad H(-\infty)=0,\quad H(\infty)=1,\quad H(0)=1/2. \tag{2.1}$$

Our assumption that $W(u)=W(1-u)$ implies that $H(t)=1-H(-t)$. The interface tension τ is a constant defined by

$$\tau := \int_R (H'(t))^2\,dt. \tag{2.2}$$

In the special case $W(u)=\frac{1}{4}(u^2-u)^2$, $\tau=\sqrt{2}/12$.

Theorem 1.1 was proven in Ref. 25 by locally minimizing I in the radial class

$$X_a^R=\{u\in W^{1,2}(D): u(x)=u(|x|), \overline{u}=a\}. \tag{2.3}$$

To do so we used the Γ-convergence theory in the perturbation variational analysis. $(\epsilon\pi)^{-1}I$ converges in a particular sense to a singular limit J. J is defined in the class $\mathcal{A}$ which may be decomposed to

$$\mathcal{A}=\bigcup_{K=1}^{\infty}(\mathcal{A}_K\cup\tilde{\mathcal{A}}_K). \tag{2.4}$$

A function $\mathcal{U}$ is in $\mathcal{A}_K$ if $\overline{\mathcal{U}}=a$ and there exist $q_1,q_2,\ldots,q_K$, satisfying $0<q_1<q_2<\cdots<q_K<1$, such that $\mathcal{U}(r)=0$ if $r\in(0,q_1)$, $=1$ if $r\in(q_1,q_2)$, $=0$ if $r\in(q_2,q_3)\ldots$. Similarly a function $\tilde{\mathcal{U}}\in\tilde{\mathcal{A}}_K$ if $\overline{\tilde{\mathcal{U}}}=a$ and there exist $q_1,q_2,\ldots,q_K$, satisfying $0<q_1<q_2<\cdots<q_K<1$, such that $\tilde{\mathcal{U}}(r)=1$ if $r\in(0,q_1)$, $=0$ if $r\in(q_1,q_2)$, $=1$ if $r\in(q_2,q_3),\ldots$. By the remark after Theorem 1.1 we will not consider J in $\tilde{\mathcal{A}}$. In each $\mathcal{A}_K$ the function J depends on $\mathbf{q}=(q_1,q_2,\ldots,q_K)$ only

$$J(\mathbf{q})=2\tau(q_1+q_2+\cdots+q_K)+\gamma\int_0^1 \mathcal{V}'(r)^2 r\,dr. \tag{2.5}$$

In (2.5) $\mathbf{q}$ determines $\mathcal{U}\in\mathcal{A}_K$. We emphasize that $\mathcal{U}$ depends on all q_j. We sometimes use the notation $\mathcal{U}=\mathcal{U}(r;\mathbf{q})$. Let $\mathcal{V}$ be the solution of

$$-\mathcal{V}''-\frac{\mathcal{V}'}{r}=\mathcal{U}-a,\quad \mathcal{V}'(1)=0,\quad \overline{\mathcal{V}}=0. \tag{2.6}$$

We define G_0 to be the solution operator of (2.6) so that $\mathcal{V}=G_0[\mathcal{U}-a]$. Again we may write $\mathcal{V}=\mathcal{V}(r;\mathbf{q})$. The constraint $\overline{\mathcal{U}}=a$ becomes a constraint on $\mathbf{q}$,

$$S(\mathbf{q}):=-q_1^2+q_2^2-q_3^2+\cdots+(-1)^K q_K^2+\frac{1-(-1)^K}{2}=a. \tag{2.7}$$

To incorporate the constraint (2.7) we define $F:=J+\nu S$, where ν is the Lagrange multiplier in accordance to the constraint.

Using ideas from Refs. 15 and 14 the following result is obtained in Ref. 25.

Lemma 2.1: *If J has a strict local minimizer $\mathcal{U}(\cdot;\mathbf{r}^0)\in\mathcal{A}_K$, then there exists $\hat{\epsilon}>0$ such that for all $\epsilon\in(0,\hat{\epsilon})$,* (1.6) *has a solution u with the properties* $\lim_{\epsilon\to 0}\|u-\mathcal{U}(\cdot;\mathbf{r}^0)\|_2=0$ *and* $\lim_{\epsilon\to 0}(\epsilon\pi)^{-1}I(u)=J(\mathcal{U}(\cdot;\mathbf{r}^0))$.

Lemma 2.1 reduces I to J which is finite dimensional in each $\mathcal{A}_K$ and $\tilde{\mathcal{A}}_K$. To study J we define from the operator G_0 the Green function

$$G_0(r,s)=G_0[\delta(\cdot-s)-2s](r), \tag{2.8}$$

where $2s$ is the average of $\delta(\cdot-s)$. More explicitly

$$G_0(r,s)=\begin{cases}\dfrac{sr^2}{2}-\dfrac{3s-2s^3}{4}-s\log s & \text{if } r<s\\[2ex] \dfrac{sr^2}{2}-s\log r-\dfrac{3s-2s^3}{4} & \text{if } r\geqslant s.\end{cases} \tag{2.9}$$

Note that $G_0(r,s)$ is not symmetric in r and s, although $rG_0(r,s)$ is. Also note $\overline{\delta(\cdot-s)}=2s$. Then we may write

$$\mathcal{V}(r)=\int_0^1 G_0(r,s)(\mathcal{U}(s)-a)ds=\int_0^1 G_0(r,s)\mathcal{U}(s)ds.$$

We calculate the derivatives of J and F. J may be rewritten as

$$J(\mathbf{q})=2\tau\sum_{j=1}^{k}q_j+\gamma\int_0^1\mathcal{U}(r)\mathcal{V}(r)r\,dr.$$

Then

$$\begin{aligned}\frac{\partial J}{\partial q_j}&=2\tau+\gamma\frac{\partial}{\partial q_j}\left[\int_{q_1}^{q_2}\mathcal{V}(r)r\,dr+\int_{q_3}^{q_4}\mathcal{V}(r)r\,dr+\cdots\right]\\&=2\tau+(-1)^j\gamma q_j\mathcal{V}(q_j)+\gamma\int_0^1\mathcal{U}(r)\frac{\partial}{\partial q_j}\mathcal{V}(r)r\,dr.\end{aligned}$$

Note that

$$\frac{\partial}{\partial q_j}\mathcal{V}(r)=\frac{\partial}{\partial q_j}\left[\int_{q_1}^{q_2}G_0(r,s)ds+\int_{q_3}^{q_4}G_0(r,s)ds+\cdots\right]=(-1)^jG_0(r,q_j).$$

Hence

$$\frac{\partial J}{\partial q_j} = 2\tau + 2(-1)^j \gamma q_j \mathcal{V}(q_j),$$

and

$$\frac{\partial F}{\partial q_j} = 2\tau + 2(-1)^j \gamma q_j \mathcal{V}(q_j) + 2\nu(-1)^j q_j.$$

Let $\mathbf{r}^0=(r_1^0, r_2^0, \ldots, r_K^0)$ be a solution of $\partial F/\partial q_j=0$, $j=1,2,\ldots,K$, i.e.,

$$2\tau + 2(-1)^j \gamma r_j^0 \mathcal{V}(r_j^0) + 2\nu(-1)^j r_j^0 = 0, \quad j=1,2,\ldots,K. \tag{2.10}$$

The second derivatives of J are

$$\frac{\partial^2 J}{\partial q_j \partial q_k} = 2(-1)^{j+k} \gamma q_j G_0(q_j, q_k), \quad \text{if } j \neq k,$$

$$\begin{aligned}\frac{\partial^2 J}{\partial q_j^2} &= 2(-1)^j \gamma \mathcal{V}(q_j) + 2(-1)^j \gamma q_j ((-1)^j G_0(q_j, q_j) + \mathcal{V}'(q_j)) \\ &= 2\gamma q_j G_0(q_j, q_j) + 2(-1)^j \gamma (\mathcal{V}(q_j) + q_j \mathcal{V}'(q_j)).\end{aligned}$$

Hence

$$\frac{\partial^2 F}{\partial q_j \partial q_k} = \begin{cases} 2\gamma q_j G_0(q_j, q_j) + 2(-1)^j \gamma (\mathcal{V}(q_j) + q_j \mathcal{V}'(q_j)) + 2\nu(-1)^j & \text{if } j=k \\ 2(-1)^{j+k} \gamma q_j G_0(q_j, q_k) & \text{if } j \neq k. \end{cases} \tag{2.11}$$

At $\mathbf{r}^0$, because of (2.10), we have

$$\frac{\partial^2 F}{\partial q_j \partial q_k}(\mathbf{r}^0) = \begin{cases} 2\gamma r_j^0 G_0(r_j^0, r_j^0) + 2(-1)^j \gamma r_j^0 \mathcal{V}'(r_j^0) - \dfrac{2\tau}{r_j^0} & \text{if } j=k \\ 2(-1)^{j+k} \gamma r_j^0 G_0(r_j^0, r_k^0) & \text{if } j \neq k. \end{cases} \tag{2.12}$$

We emphasize that the function $\mathcal{V}$ in (2.12) is associated with $\mathbf{r}^0$, i.e., $\mathcal{V}=\mathcal{V}(\cdot;\mathbf{r}^0)$.

Whether a critical point $\mathbf{r}^0$ is a local minumum is determined by the matrix (2.12) in the subspace

$$T = \{\mathbf{b} = (b_1, b_2, \ldots, b_K)^T \in R^K : \sum_{j=1}^{K} (-1)^j b_j r_j^0 = 0\}. \tag{2.13}$$

T is the tangent space of the domain of J at $\mathbf{r}^0$. When (2.12) is positive definite in T, i.e.,

$$\sum_{j,k=1}^{K} \frac{\partial^2 F}{\partial q_j \partial q_k}(\mathbf{r}^0) b_j b_k > 0, \quad \text{if } \mathbf{b} \in T \text{ and } \mathbf{b} \neq 0, \tag{2.14}$$

the critical point $\mathbf{r}^0$ is a strict local minimum.

The condition (2.14) may be rephrased as follows. Define a K by K matrix $\mathbf{M}^0$ whose kj entry is

$$M_{kj}^0 = \delta_{kj}\left(-\frac{\tau}{(r_k^0)^2} + \gamma(-1)^k \mathcal{V}'(r_k^0)\right) + \gamma(-1)^{k+j} G_0(r_k^0, r_j^0), \tag{2.15}$$

where $\delta_{kj}=1$ if $k=j$ and 0 otherwise. M_{kj}^0 is not symmetric in j and k but $r_k^0 M_{kj}^0$ is. Let g^0 be a non-standard inner product on R^K defined by

$$g^0(\mathbf{A},\mathbf{B}) = \sum_{j=1}^{K} A_j B_j r_j^0, \quad \mathbf{A} = (A_1, A_2, \ldots, A_K)^T, \quad \mathbf{B} = (B_1, B_2, \ldots, B_K)^T. \tag{2.16}$$

With respect to g^0, the matrix $\mathbf{M}^0$ represents a symmetric linear operator on R^K. Also with respect by g^0 we choose an orthonormal basis $\mathbf{e}_1^0, \mathbf{e}_2^0, \ldots, \mathbf{e}_K^0$ with

$$\mathbf{e}_1^0 = \frac{1}{\sqrt{r_1^0 + r_2^0 + \cdots + r_K^0}}(-1, 1, -1, 1, \cdots, (-1)^K)^T. \tag{2.17}$$

Since

$$\frac{1}{2}\sum_{j,k=1}^{K} \frac{\partial F}{\partial q_j \partial q_k}(\mathbf{r}^0) b_j b_k = \sum_{j,k=1}^{K} M_{kj}^0 b_j b_k r_k^0 = g^0(\mathbf{M}^0\mathbf{b}, \mathbf{b}),$$

(2.14) is equivalent to the condition that $\mathbf{M}^0$ is positive definite in the $K-1$ dimensional subspace perpendicular to $\mathbf{e}_1^0$ with respect to g^0. This form of (2.14) is closer to the contents of Sec. III.

Lemma (2.1) now implies the following theorem:

Theorem 2.2: *If J has a critical point $\mathbf{r}^0$ at which* (2.12) *is positive definite in T, then there exists $\hat{\epsilon} > 0$ such that for all $\epsilon \in (0, \hat{\epsilon})$ there is a solution u of* (1.6) *with the properties* $\lim_{\epsilon\to 0}\|u - \mathcal{U}(\cdot;\mathbf{r}^0)\|_2 = 0$ *and* $\lim_{\epsilon\to 0}(\epsilon\pi)^{-1} I(u) = J(\mathcal{U}(\cdot;\mathbf{r}^0))$.

Only when $K=1$, $\mathbf{r}^0 = (r_1^0)$ alsways exists and equals $\sqrt{1-a}$. It is regarded trivially as a strict local minimizer of J. Hence when ϵ is small, a spot solution of (1.6) exists unconditionally.

When $K \geqslant 2$, J may not have a strict local minimizer. Another perturbation argument can be used. Note that when γ is large, J may be viewed as a perturbation of

$$J^*(\mathbf{q}) = \gamma \int_0^1 (\mathcal{V}'(r))^2 r dr. \tag{2.18}$$

It was proved in Ref. 25 that J^* has a unique critical point $\mathbf{r}^* = (r_1^*, r_2^*, \ldots, r_k^*)$. When γ is large, (2.12) is dominated by

$$\begin{cases} 2\gamma r_j^* G(r_j^*, r_j^*) + 2(-1)^j \gamma r_j^* \mathcal{V}'(r_j^*) & \text{if} \quad j = k \\ 2(-1)^{j+k} \gamma r_j^* G(r_j^*, r_K^*) & \text{if} \quad j \neq k. \end{cases} \tag{2.19}$$

It was shown in Ref. 25 that (2.19) is positive definite in T. For large γ $\mathbf{r}^*$ perturbs to $\mathbf{r}^0$, a strict local minimizer of J. Theorem 1.1 hence is a consequence of Theorem 2.2. In this paper we assume that the condition (2.14) is satisfied and hence u exists.

We denote the function $\mathcal{U}(\cdot;\mathbf{r}^0)$ by u^0 and set $v^0 = G_0[u^0 - \overline{u^0}]$. u^0 takes values 0 and 1, and it jumps between these two values at $r_1^0, r_2^0, \ldots, r_k^0$. The Γ-convergence theory asserts that u converges to u^0 in $L^2(D)$. Then there exist $r_1, r_2, \ldots, r_k$ such that $u(r_j) = 1/2, j = 1, 2, \ldots, K$, and $\mathbf{r} = (r_1, r_2, \ldots, r_K)^T \to \mathbf{r}_0$ as $\epsilon \to 0$. These r_j's are called the interfaces of u. We will see that they are the only interfaces.

We also need to know the asymptotic behavior of u. First we construct an *inner* expansion. Around each r_j we introduce the scaled variable $r = r_j + \epsilon t$ so to expand

$$u(r) = u(r_j + \epsilon t) = H_j(t) + \epsilon P_j(t) + \epsilon^2 Q_j(t) + \cdots. \tag{2.20}$$

Correspondingly

$$v(r) = v(r_j) + \epsilon t v'(r_j) + \cdots. \tag{2.21}$$

As we insert (2.20) and (2.21) into (1.8) we find the leading term

$$H_j(t) = H(t) \quad \text{if } j \text{ is odd}, \quad H_j(t) = H(-t) \quad \text{if } j \text{ is even}. \tag{2.22}$$

The next term is $P_j(t)$ defined to be the solution of

$$-P'' + f'(H_j)P - \frac{H_j'}{r_j} + \xi_j = 0, \quad P(0) = 0. \tag{2.23}$$

P_j is even. The constant ξ_j is chosen so that $(H_j'/r_j) + \xi_j$ is perpendicular to H_j' for solvability. Therefore

$$\xi_j = \frac{(-1)^{j+1}}{r_j} \int_R (H'(t))^2 \, dt = \frac{(-1)^{j+1}\tau}{r_j}. \tag{2.24}$$

In our rigorous setting of asymptotic expansions P_j depends on ϵ because r_j and ξ_j do so. This way we avoid expanding r_j. The third term in the inner expansion is $Q_j(t)$ which is the solution of

$$-Q'' + f'(H_j)Q - \frac{P_j'}{r_j} + \frac{tH_j'}{r_j^2} + \frac{f''(H_j)P_j^2}{2} + \gamma v'(r_j)t = 0, \quad Q(0) = 0. \tag{2.25}$$

Q_j is odd. Again Q_j depends on ϵ, via r_j and $v'(r_j)$. We set the inner approximation of u near r_j to be

$$z_j(r) = H_j\left(\frac{r - r_j}{\epsilon}\right) + \epsilon P_j\left(\frac{r - r_j}{\epsilon}\right) + \epsilon^2 Q_j\left(\frac{r - r_j}{\epsilon}\right). \tag{2.26}$$

The outer approximation is done in one step. It is denoted by z and defined for all r not equal to $r_1, r_2, \ldots, r_K$ by the equation

$$f(z) + \epsilon\gamma v(r) - \eta = 0. \tag{2.27}$$

Since $\eta = O(\epsilon)$ and $v = O(1)$, facts proved in the Appendix, z is chosen to be close to 0 or 1 on each (r_j, r_{j+1}) nonambiguously, in agreement with the shape of u, i.e., z is close to 0 on $(0, r_1)$, close to 1 on (r_1, r_2), close to 0 on (r_2, r_3), etc.

The inner approximation is used in each $(r_j - \epsilon^\alpha, r_j + \epsilon^\alpha)$ where $\alpha \in (1/2, 1)$. The outer approximation is used in $(0,1) \setminus (\cup_{j=1}^K (r_j - 2\epsilon^\alpha, r_j + 2\epsilon^\alpha))$. The inner approximation is matched to the outer approximation in the matching intervals $(r_j - 2\epsilon^\alpha, \ r_j - \epsilon^\alpha)$ and $(r_j + \epsilon^\alpha, r_j + 2\epsilon^\alpha)$, $j = 1, 2, \ldots, K$. Let χ_j be smooth cut-off functions so that

$$\chi_j(r) = \begin{cases} 0 & \text{if } r \notin (r_j - 2\epsilon^\alpha, r_j + 2\epsilon^\alpha) \\ 1 & \text{if } r \in (r_j - \epsilon^\alpha, r_j + \epsilon^\alpha), \end{cases}$$

and moreover $(\chi_j)_r = O(\epsilon^{-\alpha})$ $(\chi_j)_{rr} = O(\epsilon^{-2\alpha})$ in $(r_j - 2\epsilon^\alpha, r_j - \epsilon^\alpha)$ and $(r_j + \epsilon^\alpha, r_j + 2\epsilon^\alpha)$.

We then glue the two approximations to form a uniform approximation

$$w(r) = \sum_{j=1}^K \chi_j z_j + \left(1 - \sum_{j=1}^K \chi_j\right) z. \tag{2.28}$$

Lemma 2.3: $w - u = o(\epsilon^2)$.

According to this lemma, whose proof is left to the appendix, the uniform approximation w is accurate up to order ϵ^2. This lemma also implies that the r_j's are the only interfaces of u.

To understand the stability of a spot or a ring solution in two dimensions we need to find the spectrum, which only contains eigenvalues, of the linearized operator L defined in (1.9). We separate variables in the polar coordinates to let

$$\varphi(x) = \varphi(r\cos\theta, r\sin\theta) = \sum_{m=0}^{\infty} \phi_m(r)(A_m \cos(m\theta) + B_m \sin(m\theta)). \tag{2.29}$$

After substituting (2.29) into (1.9), we deduce that $\varphi(x)$ is a linear combination of $\phi_m(r)\cos(m\theta)$ and $\phi_m(r)\sin(m\theta)$ for some non-negative integer m. The corresponding eigenvalue λ is thus

classified into $\lambda=\lambda_m, m=0,1,2,\ldots$. The pair (λ_m,ϕ_m) satisfies the following equations:

(1) If $m=0$,

$$L_0\phi_0 := -\epsilon^2\phi_0'' - \frac{\epsilon^2}{r}\phi_0' + f'(u)\phi_0 - \overline{f'(u)\phi_0} + \epsilon\gamma G_0[\phi_0] = \lambda_0\phi_0, \quad \phi'(0)=\phi'(1)=0, \quad \overline{\phi_0} = 0; \tag{2.30}$$

(2) if $m\geq 1$,

$$L_m\phi_m := -\epsilon^2\phi_m'' - \frac{\epsilon^2}{r}\phi_m' + \frac{\epsilon^2 m^2}{r^2}\phi_m + f'(u)\phi_m + \epsilon\gamma G_m[\phi_m] = \lambda_m\phi_m, \quad \phi_m(0)=\phi_m'(1)=0. \tag{2.31}$$

The operator G_0 is defined in (2.6), and when $m\geq 1$, G_m is the inverse of the differential operator $-(d^2/dr^2)-(1/r)(d/dr)+(m^2/r^2)$ with the Neumann boundary condition at $r=1$ and the Dirichlet boundary condition at $r=0$.

Lemma 2.4: Let λ *be an eigenvalue of L. Then* $\liminf_{\epsilon\to 0}\lambda\geq 0$.

Proof: Suppose that the lemma is false. We may assume that $\lim_{\epsilon\to 0}\lambda=\lambda^0<0$. Since λ is classified in to λ_m, $m=0,1,2,\ldots$, we consider the case that λ is one of λ_0. The case $m\geq 1$ may be handled similarly and we omit the proof.

Let ϕ be an eigenfunction of (2.30) associated with λ. Without the loss of generality we assume that $\|\phi\|=\phi(r_*)=1$. First we claim that there is a r_j whose distance to r_* is of order $O(\epsilon)$. Otherwise $-\epsilon^2\phi''(r_*)\geq 1$ since r_* is a maximum; $(\epsilon^2/r)\phi'(r_*)=0$ whether or not r_* is on the boundary; $f'(u(r_*))\phi(r_*)>0$ since $f'(u(r_*))>0$ outside any ϵ-neighborhood of r_j; $\overline{f'(u)\phi} = \overline{(f'(u)-f'(0))\phi} = O(\epsilon)$ by the uniform estimate of u in Lemma 2.3; $\epsilon\gamma G_0[\phi](r_*)=O(\epsilon)$, and $\lambda\phi(r_*)=\lambda<0$. Then

$$-\epsilon^2\phi''(r_*) - \frac{\epsilon^2}{r}\phi'(r_*) + f'(u(r_*))\phi(r_*) - \overline{f'(u)\phi} + \epsilon\gamma G_0[\phi](r_*) > \lambda\phi(r_*),$$

and (2.30) is not satisfied at r_*.

If r_* is in a size $O(\epsilon)$ neighborhood of r_j, then $\phi(r_j+\epsilon t)\to\Phi\not\equiv 0$ in $C^2_{\mathrm{loc}}(R)$, and Φ satisfies $-\Phi''+f'(H_j)\Phi=\lambda^0\Phi$. However this equation has no nonzero, bounded solution when $\lambda^0<0$, since H_j is a minimizer of $E(U):=\int_R\left(\frac{1}{2}(U')^2+W(U)\right)dt$. Here U is in the class $W^{1,2}_{\mathrm{loc}}(R)$ and $\lim_{t\to\pm\infty}(U(t)-H_j(t))=0$. □

Hence to understand the stability of u we must analyze all the eigenvalues that tend to 0 as $\epsilon\to 0$. They are called the critical eigenvalues.

III. THE CRITICAL EIGENVALUES λ_0

Recall $\mathbf{M}^0$ and g^0 defined in (2.15) and (2.16), respectively, and $\mathbf{e}_j^0$ with $\mathbf{e}_1^0$ defined in (2.17).

Theorem 3.1: *When* ϵ *is sufficiently small, there exist exactly K eigenpairs* (λ_0,ϕ_0), *of* (2.30) *with* $\lambda_0=o(1)$. *One* λ_0 *is positive and of order* ϵ. *This* λ_0 *and its eigenfunction expand like*

$$\lambda_0 = \frac{2f'(0)\sum_{k=1}^{K} r_k^0}{\tau}\epsilon + o(\epsilon), \quad \phi_0 = \sum_{j=1}^{K} c_j(H_j' - \overline{H_j'}) + O(\epsilon|\mathbf{c}|).$$

where $\mathbf{c}=(c_1,c_2,\ldots c_K)^T\to\mathbf{c}^0$, *as* ϵ *tends to* 0. $\mathbf{c}^0$ *is a nonzero scaler multiple of* $\mathbf{e}_1^0$.

The remaining $K-1$ λ_0's *are positive and of order* ϵ^2. *Each of them and its corresponding eigenfunction expand like*

$$\lambda_0 = \mu_0^0 \epsilon^2 + o(\epsilon^2), \quad \phi_0 = \sum_{j=1}^{K} c_j (H_j' - \overline{H_j'} + \epsilon(P_j' - \overline{P_j'})) + O(\epsilon^2 |\mathbf{c}|).$$

Let $\mathbf{c}^0 = \lim_{\epsilon \to 0} \mathbf{c}$. *Then* $\mathbf{c}^0 = \Sigma_{n=2}^{K} \tilde{c}_n^0 \mathbf{e}_n^0$, *and* μ_0^0 *and* $(\tilde{c}_2^0, \tilde{c}_3^0, \ldots, \tilde{c}_K^0)^T$ *form an eigenpair of the* $K-1$ *dimensional eigenvalue problem*

$$\sum_{m=2}^{K} \tilde{c}_m^0 g^0(\mathbf{M}^0 \mathbf{e}_m^0, \mathbf{e}_n^0) = \mu_0^0 r \tilde{c}_n^0, \quad n = 2, 3, \ldots, K.$$

We expect that the eigenfunctions associated with small eigenvalues may be approximated by combinations of

$$H_j' - \overline{H_j'} + \epsilon(P_j' - \overline{P_j'}). \tag{3.1}$$

Here H_j' is the derivative of $H_j = H_j(t)$ with respect to t evaluated at $t = (r - r_j)/\epsilon$. In this section we write (λ, ϕ) for an eigenpair (λ_0, ϕ_0). We decompose

$$\phi = \sum_{j=1}^{K} c_j (H_j' - \overline{H_j'} + \epsilon(P_j' - \overline{P_j'})) + \phi^{\perp} \tag{3.2}$$

in the $L^2(D)$ space where $H_j' - \overline{H_j'} + \epsilon(P_j' - \overline{P_j'}) \perp \phi^{\perp}$ for $j = 1, 2, \ldots, K$. First we estimate

$$L_0(H_j' - \overline{H_j'}) = -\epsilon^2 (H_j')_{rr} - \frac{\epsilon^2}{r}(H_j')_r + f'(u)(H_j' - \overline{H_j'}) - \overline{f'(u)(H_j' - \overline{H_j'})} + \epsilon \gamma G_0[H_j' - \overline{H_j'}],$$

in which

$$\begin{aligned} \overline{f'(u) H_j'} &= 2 \int_0^1 (f'(H_j) + \epsilon P_j f''(H_j)) H_j' r \, dr + O(\epsilon^3) \\ &= 2\epsilon \int_R [f'(H_j) H_j' r_j + \epsilon t f'(H_j) H_j' + \epsilon P_j f''(H_j) H_j' r_j] dt + O(\epsilon^3) = O(\epsilon^3) \end{aligned} \tag{3.3}$$

since $\int_R f'(H_j) H_j' dt = \int_R t f'(H_j) H_j' dt = \int_R P_j f''(H_j) H_j' dt = 0$ ($t f'(H_j) H_j'$ and $P_j f''(H_j) H_j'$ are odd). Then

$$\begin{aligned} L_0(H_j' - \overline{H_j'}) &= (f'(u) - f'(H_j)) H_j' - \frac{\epsilon}{r} H_j'' + (\overline{f'(u)} - f'(u)) \overline{H_j'} + \epsilon^2 \gamma (-1)^{j+1} G_0(r, r_j) + O(\epsilon^3) \\ &= \epsilon f''(H_j) P_j H_j' + \epsilon^2 \left(f''(H_j) Q_j + \frac{f'''(H_j) P_j^2}{2} \right) H_j' - \frac{\epsilon}{r} H_j'' \\ &\quad + \epsilon^2 \gamma (-1)^{j+1} G_0(r, r_j) + (\overline{f'(u)} - f'(u)) \overline{H_j'} + O(\epsilon^3). \end{aligned}$$

By differentiating (2.23) we have

$$-P_j''' + f'(H_j) P_j' + f''(H_j) H_j' P_j - \frac{H_j''}{r_j} = 0.$$

Then

$$L_0(P_j' - \overline{P_j'}) = -\epsilon^2 (P_j')_{rr} - \frac{\epsilon^2}{r}(P_j')_r + f'(u)(P_j' - \overline{P_j'}) - \overline{f'(u)(P_j' - \overline{P_j'})} + \epsilon\gamma G_0[P_j' - \overline{P_j'}]$$

$$= (f'(u) - f'(H_j))P_j' - f''(H_j)H_j'P_j + \frac{H_j''}{r_j} - \frac{\epsilon}{r}P_j'' + (\overline{f'(u)} - f'(u))\overline{P_j'} + O(\epsilon^2)$$

$$= \epsilon f''(H_j)P_jP_j' - f''(H_j)H_j'P_j + \frac{H_j''}{r_j} - \frac{\epsilon}{r}P_j'' + (\overline{f'(u)} - f'(u))\overline{P_j'} + O(\epsilon^2),$$

where we have used the fact

$$\overline{f'(u)P_j'} = 2\int_0^1 f'(u)P_j' r\, dr = 2\epsilon \int_R f'(H_j)P_j' r_j dt + O(\epsilon^2) = O(\epsilon^2) \tag{3.4}$$

since $f'(H_j)P_j'$ is odd. Therefore

$$L_0(H_j' - \overline{H_j'} + \epsilon(P_j' - \overline{P_j'})) = \epsilon^2 \Bigg[\left(f''(H_j)Q_j + \frac{f'''(H_j)P_j^2}{2} \right) H_j' + f''(H_j)P_jP_j' + \left(\frac{1}{\epsilon r_j} - \frac{1}{\epsilon r} \right) H_j'' - \frac{P_j''}{r} + \gamma($$
$$- 1)^{j+1} G_0(r, r_j) \Bigg] + (\overline{f'(u)} - f'(u))\overline{H_j' + \epsilon P_j'} + O(\epsilon^3).$$

On the other hand,

$$\overline{H_j'} = 2\int_0^1 H_j' r\, dr = 2\epsilon \int_R H_j'(t)(r_j + \epsilon t)dt = 2\epsilon r_j \int_R H_j'(t)dt + 2\epsilon^2 \int_R H_j'(t)t dt = 2\epsilon(-1)^{j+1} r_j$$

since $H_j'(t)t$ is odd, and

$$\overline{P_j'} = 2\int_0^1 P_j' r\, dr = 2\epsilon r_j \int_R P_j' dt + O(\epsilon^2) = O(\epsilon^2)$$

since P_j' is odd. We find

$$\overline{H_j' + \epsilon P_j'} = 2\epsilon(-1)^{j+1} r_j + O(\epsilon^3). \tag{3.5}$$

Hence we deduce that

$$L_0(H_j' - \overline{H_j'} + \epsilon(P_j' - \overline{P_j'})) = \epsilon^2 \Bigg[\left(f''(H_j)Q_j + \frac{f'''(H_j)P_j^2}{2} \right) H_j' + f''(H_j)P_jP_j' + \left(\frac{1}{\epsilon r_j} - \frac{1}{\epsilon r} \right) H_j'' - \frac{P_j''}{r}$$
$$+ \gamma(-1)^{j+1} G_0(r, r_j) \Bigg] + 2\epsilon(-1)^{j+1} r_j (\overline{f'(u)} - f'(u)) + O(\epsilon^3). \tag{3.6}$$

Note that in (3.6)

$$\left(\frac{1}{\epsilon r_j} - \frac{1}{\epsilon r} \right) H_j'' = \frac{tH''(t)}{r_j r} = O(1).$$

Rewrite the equation $L_0\phi = \lambda\phi$ as

$$\sum_{j=1}^{K} c_j L_0(H_j' - \overline{H_j'} + \epsilon(P_j' - \overline{P_j'})) + L_0\phi^\perp = \lambda \left(\sum_{j=1}^{K} c_j (H_j' - \overline{H_j'} + \epsilon(P_j' - \overline{P_j'})) + \phi^\perp \right). \tag{3.7}$$

Then $\phi^\perp$ satisfies

$$L_0\phi^\perp = O\left(\epsilon|\sum_{j=1}^{K}(-1)^j r_j c_j|\right) + O(\epsilon^2)|\mathbf{c}| + O(|\lambda|)(|\mathbf{c}| + \|\phi^\perp\|). \tag{3.8}$$

Here $\|\phi^\perp\|$ is the L^∞ norm of $\phi^\perp$ on (0,1). The following lemma estimates $\phi^\perp$.

Lemma 3.2: *There exists $C>0$ independent of ϵ such that for all ψ in the domain of L_0 and $\psi \perp H_j' - \overline{H_j'} + \epsilon(P_j' - \overline{P_j'})$, $j=1,2,\cdots,K$, $\|\psi\| \leqslant C\|L_0\psi\|$.*

Proof: Suppose that the lemma is false. There exist ψ and some r_* such that $\|\psi\| = \psi(r_*) = 1$, $\psi \perp H_j' - \overline{H_j'} + \epsilon(P_j' - \overline{P_j'})$, $j=1,2,\cdots,K$, and $L_0\psi = o(1)$. Then r_* must lie in a neighborhood of r_j for some j. The size of this neighborhood must be of order ϵ. Otherwise we argue as in the proof of Lemma 2.4: $-\epsilon^2\psi''(r_*) \geqslant 0$; $(-\epsilon^2/r)\psi'(r_*) = 0$; $\epsilon\gamma G_m[\psi](r_*) = O(\epsilon)$; $\overline{f'(u)\psi} = (\overline{f'(u) - f'(0)})\psi = O(\epsilon)$; and $f'(u)\psi(r_*)$ is positive and bounded away from 0 independent of ϵ. Then the equation $L_0\psi = o(1)$ is not satisfied at r_*.

So let us assume that r_* is in a neighborhood, of size ϵ, of r_j. Then $\psi(r_j + \epsilon t) \to \Psi_0(t)$ in $C^2_{\text{loc}}(R)$ as ϵ tends to 0. Ψ_0 satisfies $-\Psi_0'' + f'(H_j)\Psi_0 = 0$. Therefore $\Psi_0 = cH_j'$ for some constant $c \neq 0$. On the other hand if we denote the inner product in $L^2(D)$ by $\langle \cdot, \cdot \rangle$, then $\psi \perp H_j' - \overline{H_j'} + \epsilon(P_j' - \overline{P_j'})$ implies

$$0 = \langle \psi, H_j' - \overline{H_j'} + \epsilon(P_j' - \overline{P_j'}) \rangle = 2\pi\epsilon c r_j \int_R (H')^2 dt + o(\epsilon),$$

which is possible only if $c = 0$. □

We obtain by Lemma 3.2 that

$$\phi^\perp = O(\epsilon|\sum_{j=1}^{K}(-1)^j r_j c_j|) + O(\epsilon^2)|\mathbf{c}| + O(|\lambda|)(|\mathbf{c}| + \|\phi^\perp\|)$$

which implies, since $\lambda = o(1)$,

$$\phi^\perp = O(\epsilon|\sum_{j=1}^{K}(-1)^j r_j c_j|) + O(\epsilon^2)|\mathbf{c}| + O(|\lambda|)|\mathbf{c}|. \tag{3.9}$$

We multiply (3.7) by $H_k' - \overline{H_k'} + \epsilon(P_k' - \overline{P_k'})$ and integrate with respect to $2\pi r\, dr$ over (0, 1) to find the equations

$$\sum_{j=1}^{K} \langle c_j L_0(H_j' - \overline{H_j'} + \epsilon(P_j' - \overline{P_j'})), H_k' - \overline{H_k'} + \epsilon(P_k' - \overline{P_k'}) \rangle + \langle \phi^\perp, L_0(H_k' - \overline{H_k'} + \epsilon(P_k' - \overline{P_k'})) \rangle$$
$$= \lambda \sum_{j=1}^{K} c_j \langle H_j' - \overline{H_j'} + \epsilon(P_j' - \overline{P_j'}), H_k' - \overline{H_k'} + \epsilon(P_k' - \overline{P_k'}) \rangle.$$

In these equations

$$\langle \phi^\perp, L_0(H_k' - \overline{H_k'} + \epsilon(P_k' - \overline{P_k'})) \rangle = O(\|\phi^\perp\| \cdot \|L_0(H_k' - \overline{H_k'} + \epsilon(P_k' - \overline{P_k'}))\|_1),$$

where $\|\cdot\|_1$ denotes the $L^1(D)$ norm. By (3.6) we find

$$\|L_0(H_k' - \overline{H_k'} + \epsilon(P_k' - \overline{P_k'}))\|_1 = O(\epsilon^2).$$

Then by (3.9) we deduce the equations

$$\sum_{j=1}^{K} c_j\langle L_0(H_j' - \overline{H_j'} + \epsilon(P_j' - \overline{P_j'})), H_k' - \overline{H_k'} + \epsilon(P_k' - \overline{P_k'})\rangle + O\left(\epsilon^3\Big|\sum_{j=1}^{K}(-1)^j r_j c_j\Big|\right) + O(\epsilon^4)|\mathbf{c}|$$
$$+ O(\epsilon^2|\lambda|)|\mathbf{c}| = \lambda\sum_{j=1}^{K} c_j\langle H_j' - \overline{H_j'} + \epsilon(P_j' - \overline{P_j'}), H_k' - \overline{H_k'} + \epsilon(P_k' - \overline{P_k'})\rangle, \tag{3.10}$$

for $k=1,2,\ldots,K$. The inner products in (3.10) are given in the next lemma.

Lemma 3.3: In Eq. (3.10):

(1) $\langle H_j' - \overline{H_j'} + \epsilon(P_j' - \overline{P_j'}), H_k' - \overline{H_k'} + \epsilon(P_k' - \overline{P_k'})\rangle = 2\pi\epsilon r_k \tau\delta_{jk} + O(\epsilon^2)$;

(2) $\langle L_0(H_j' - \overline{H_j'} + \epsilon(P_j' - \overline{P_j'})), H_k' - \overline{H_k'} + \epsilon(P_k' - \overline{P_k'})\rangle$
$$= 4\pi\epsilon^2(-1)^{k+j} r_j r_k \overline{f'(u)} + 2\pi\epsilon^3 r_k\left\{\delta_{jk}\left[-\frac{\tau}{r_k^2} + (-1)^k\gamma v'(r_k)\right] + \gamma(-1)^{k+j}G_0(r_k,r_j)\right\} + O(\epsilon^4).$$

Proof: (1) is obvious. To prove (2) we note that P' decays exponentially fast. Then (3.6) implies that

$$\begin{aligned}
&\langle L_0(H_j' - \overline{H_j'} + \epsilon(P_j' - \overline{P_j'})), H_k' - \overline{H_k'} + \epsilon(P_k' - \overline{P_k'})\rangle \\
&= \langle L_0(H_j' - \overline{H_j'} + \epsilon(P_j' - \overline{P_j'})), H_k' - \overline{H_k'} + \epsilon P_k'\rangle \\
&= \epsilon^2\left\langle\left(f''(H_j)Q_j + \frac{f'''(H_j)P_j^2}{2}\right)H_j' + f''(H_j)P_jP_j' + \frac{tH_j''}{r_j r} - \frac{P_j''}{r} + \gamma(-1)^{j+1}G_0(r,r_j), H_k' + \epsilon P_k'\right\rangle \\
&\quad + 2\epsilon(-1)^{j+1} r_j\langle\overline{f'(u)} - f'(u), H_k' + \epsilon P_k'\rangle + O(\epsilon^4) \\
&= \epsilon^2\left\langle\left(f''(H_j)Q_j + \frac{f'''(H_j)P_j^2}{2}\right)H_j' + f''(H)P_jP_j' + \frac{t}{r_j r}H_j'' - \frac{P_j''}{r} + \gamma(-1)^{j+1}G_0(r,r_j), H_k'\right\rangle \\
&\quad + 2\epsilon\pi(-1)^{j+1} r_j\overline{f'(u)}\,\overline{H_k' + \epsilon P_k'} + O(\epsilon^4)
\end{aligned} \tag{3.11}$$

$$\begin{aligned}
&= 2\pi\epsilon^3 r_k\left\{\delta_{jk}\int_R\left[\left(f''(H_k)Q_k + \frac{f'''(H_k)P_k^2}{2}\right)H_k' + f''(H_k)P_kP_k' + \frac{tH_k''}{r_k^2} - \frac{P_k''}{r_k}\right]H_k' dt\right. \\
&\quad \left. + \gamma(-1)^{k+1}G_0(r_k,r_j)\right\} + 4\epsilon^2\pi(-1)^{k+j} r_j r_k\overline{f'(u)} + O(\epsilon^4).
\end{aligned} \tag{3.12}$$

Note that we have again used (3.3) and (3.4) to reach (3.11), and used (3.5) to reach (3.12). To find the integral in (3.12), we differentiate (2.25) to obtain

$$-Q_k''' + f'(H_k)Q_k' + f''(H_k)H_kQ_k - \frac{P_k''}{r_k} + \frac{H_k' + tH_k''}{r_k^2} + \frac{f'''(H_k)H_k'P_k^2}{2} + f''(H_k)P_kP_k' + \gamma v'(r_k) = 0.$$

Multiplying by H_k' and integrating over $(-\infty,\infty)$ yield

$$\int_R\left[f''(H_k)Q_k(H_k')^2 - \frac{P_k''H_k'}{r_k} + \frac{(H_k')^2 + tH_k''H_k'}{r_k^2} + \frac{f'''(H_k)P_k^2(H_k')^2}{2} + f''(H_k)P_kP_k'H_k'\right]dt$$
$$+ (-1)^{k+1}\gamma v'(r_k) = 0.$$

The integral in (3.12) now becomes

$$-\frac{1}{r_k^2}\int_R (H')^2 dt + (-1)^k \gamma v'(r_k).$$

□

With Lemma 3.3 we will write (3.10) in the vector form. We view $\mathbf{c}=(c_1,c_2,\cdots,c_K)^T$ as a column vector in R^K. Let $\mathbf{R}$ be a K by K rank one matrix:

$$\mathbf{R} = 2\overline{f'(u)}\begin{bmatrix} r_1 & -r_2 & r_3 & -r_4 & \cdots & (-1)^{1+k}r_K \\ -r_1 & r_2 & -r_3 & r_4 & \cdots & (-1)^{2+k}r_K \\ r_1 & -r_2 & r_3 & -r_4 & \cdots & (-1)^{3+k}r_K \\ (-1)^{K+1}r_1 & (-1)^{K+2}r_2 & (-1)^{K+3}r_3 & (-1)^{K+4}r_4 & \cdots & r_K \end{bmatrix}, \tag{3.13}$$

and $\mathbf{M}$ be a K by K matrix whose kj entry is

$$M_{kj} = \delta_{jk}\left(-\frac{\tau}{r_k^2} + (-1)^k \gamma v'(r_k)\right) + \gamma(-1)^{k+j} G_0(r_k,r_j).$$

In R^K we define a nonstandard inner product g by

$$g(\mathbf{A},\mathbf{B}) = \sum_{j=1}^{K} A_j B_j r_j, \quad \mathbf{A} = (A_1,A_2,\ldots,A_K)^T, \quad \mathbf{B} = (B_1,B_2,\ldots,B_K)^T. \tag{3.14}$$

The matrices $\mathbf{R}$ and $\mathbf{M}$ represent symmetric linear operators on R^K with respect to this inner product. The symmetry of $\mathbf{M}$ under g is a consequence of the fact that $r_k G_0(r_k,r_j)=r_j G_0(r_j,r_k)$. Let $\{\mathbf{e}_n\}$ be an orthonormal basis under g in which

$$\mathbf{e}_1 = \sqrt{r_1+r_2+\cdots+r_K}(-1,1,-1,1\cdots,(-1)^K)^T. \tag{3.15}$$

$\mathbf{e}_1$ is an eigenvector vector of $\mathbf{R}$ with eigenvalue $2\overline{f'(u)}(r_1+r_2+\cdots+r_K)$. $\mathbf{e}_2,\mathbf{e}_3,\cdots,\mathbf{e}_K$ span the eigenspace of the eigenvalue 0, which has multiplicity $K-1$.

Now we rewrite (3.10) as

$$\epsilon^2\mathbf{R}\mathbf{c} + \epsilon^3\mathbf{M}\mathbf{c} + O(\epsilon^3|g(\mathbf{c},\mathbf{e}_1)|) + O(\epsilon^4|\mathbf{c}|) + O(\epsilon^2|\lambda||\mathbf{c}|) = \epsilon\tau\lambda\mathbf{c}. \tag{3.16}$$

In (3.16) $|\mathbf{c}|$, the norm of $\mathbf{c}$, may be understood as either the norm under the standard inner product or the norm under g, because the two norms are equivalent uniformly in ϵ.

We must consider two cases:

$$(1)\ g\left(\frac{\mathbf{c}}{|\mathbf{c}|},\mathbf{e}_1\right) \nrightarrow 0; \quad (2)\ g\left(\frac{\mathbf{c}}{|\mathbf{c}|},\mathbf{e}_1\right) = o(1).$$

Of course when $K=1$, the second case does not occur.

In the first case we use a rough form of (3.16):

$$\epsilon^2\mathbf{R}\mathbf{c} + O(\epsilon^3|\mathbf{c}|) + O(\epsilon^2|\lambda||\mathbf{c}|) = \epsilon\tau\lambda\mathbf{c}. \tag{3.17}$$

Take the g-inner product of (3.17) and $\mathbf{e}_1$:

$$2\epsilon^2\overline{f'(u)}\left(\sum_{j=1}^{K} r_j\right) g(\mathbf{c},\mathbf{e}_1) + O(\epsilon^3|\mathbf{c}|) + O(\epsilon^2|\lambda||\mathbf{c}|) = \epsilon\tau\lambda g(\mathbf{c},\mathbf{e}_1). \tag{3.18}$$

Since $g(\mathbf{c}/|\mathbf{c}|,\mathbf{e}_1) \nrightarrow 0$, (3.18) implies that

$$\lambda = \frac{\epsilon}{\tau}\left(\sum_{k=1}^{K} 2r_k\overline{f'(u)}\right) + O(\epsilon^2). \tag{3.19}$$

This eigenvalue is positive for small ϵ and of order ϵ. Consequently (3.9) implies that

$$\phi^{\perp} = O(\epsilon|\mathbf{c}|). \tag{3.20}$$

If we take the g-inner product of (3.17) and $\mathbf{e}_n$, $n \geqslant 2$, then

$$g(\mathbf{c},\mathbf{e}_n) = O(\epsilon|\mathbf{c}|), \quad n \geqslant 2. \tag{3.21}$$

The asymptotic properties of λ and ϕ in the first case follows from (3.19)–(3.21).

In the second case we take the g-inner product of (3.16) and $\mathbf{e}_n$, $n \geqslant 2$, to deduce

$$\epsilon^3 g(\mathbf{Mc},\mathbf{e}_n) + O(\epsilon^3|g(\mathbf{c},\mathbf{e}_1)|) + O(\epsilon^4|\mathbf{c}|) + O(\epsilon^2|\lambda||\mathbf{c}|) = \epsilon\tau\lambda g(\mathbf{c},\mathbf{e}_n), \quad n = 2,3,\ldots,K. \tag{3.22}$$

Note that $g(\mathbf{c}/|\mathbf{c}|,\mathbf{e}_1) = o(1)$ and (3.22) imply that $\lambda = O(\epsilon^2)$.

Then we take the g-inner product of (3.16) and $\mathbf{e}_1$:

$$2\epsilon^2\overline{f'(u)}\left(\sum_{j=1}^{K} r_j\right)g(\mathbf{c},\mathbf{e}_1) + O(\epsilon^3|\mathbf{c}|) + O(\epsilon^3|g(\mathbf{c},\mathbf{e}_1)|) + O(\epsilon^2|\lambda||\mathbf{c}|) = \epsilon\tau\lambda g(\mathbf{c},\mathbf{e}_1). \tag{3.23}$$

(3.23) and $\lambda = O(\epsilon^2)$ imply that

$$g(\mathbf{c},\mathbf{e}_1) = O(\epsilon|\mathbf{c}|), \tag{3.24}$$

which turns (3.9) to

$$\phi^{\perp} = O(\epsilon^2|\mathbf{c}|), \tag{3.25}$$

and (3.22) is simplified to

$$\epsilon^3 g(\mathbf{Mc},\mathbf{e}_n) + O(\epsilon^4|\mathbf{c}|) = \epsilon\tau\lambda g(\mathbf{c},\mathbf{e}_n), \quad n = 2,3,\ldots,K. \tag{3.26}$$

We pass limit in (3.26) and (3.24). Let $\mathbf{M}^0 = \lim_{\epsilon\to 0}\mathbf{M}$, $\mathbf{R}^0 = \lim_{\epsilon\to 0}\mathbf{R}$, $g^0 = \lim_{\epsilon\to 0} g$, $\mathbf{e}_j^0 = \lim_{\epsilon\to 0}\mathbf{e}_j$, and $\mu_0^0 = \lim_{\epsilon\to 0}\lambda/\epsilon^2$, and $\mathbf{c}^0 = \lim_{\epsilon\to 0}\mathbf{c}$, where $|\mathbf{c}^0| \neq 0$. Then

$$g^0(\mathbf{M}^0\mathbf{c}^0,\mathbf{e}_n^0) = \mu_0^0\tau g^0(\mathbf{c}^0,\mathbf{e}_n^0), \quad (n = 2,3\ldots,K), \quad g^0(\mathbf{c}^0,\mathbf{e}_1^0) = 0. \tag{3.27}$$

The second equation implies that we can decompose $\mathbf{c}^0$ as

$$\mathbf{c}^0 = \sum_{n=2}^{K} \tilde{c}_n^0\mathbf{e}_n^0. \tag{3.28}$$

The first equation in (3.27) becomes

$$\sum_{m=2}^{K} \tilde{c}_m^0 g^0(\mathbf{M}^0\mathbf{e}_m^0,\mathbf{e}_n^0) = \mu_0^0\tau\tilde{c}_n^0, \quad n = 2,3,\ldots,K. \tag{3.29}$$

Here (3.29) is a $K-1$ dimensional eigenvalue problem from which we find $K-1$ pairs of μ_0^0 and $(\tilde{c}_2^0,\tilde{c}_3^0,\ldots,\tilde{c}_K^0)$. This proves the asymptotic properties of λ and ϕ in the second case.

As we have explained in Sec. II that the construction of u via the Γ-convergence theory assumes that (2.12) is positive definite in T. The paragraph after (2.12) shows that this condition, (2.14), is equivalent to the condition that μ_0^0 in (3.29) are all positive. Hence λ_0 are all positive when ϵ is sufficiently small.

In summary, we have proven that if (λ_0,ϕ_0) is an eigenpair of (2.30) with the property $\lambda_0 = o(1)$ then λ_0 and ϕ_0 must possess the asymtotic properties described in Theorem 3.1. We still need to show that there indeed exist exactly K eigenparis of (2.30) with the properties. The proof

of this fact uses some ideas from the linear perturbation theory. Not to prolong this section we omit the proof. Instead we will give a full proof in the next section for the $m \geqslant 1$ case, which is similar to the one for the $m=0$ case.

IV. THE CRITICAL EIGENVALUES λ_m

Theorem 4.1: *When ϵ is sufficiently small, there exist exactly K eigenparis (λ_m, ϕ_m) of* (2.31) *with $\lambda_m = o(1)$. Each λ_m and ϕ_m have the asymptotic expansion*

$$\lambda_m = \epsilon^2 \mu_m^0 + o(\epsilon^2), \phi_m = \sum_{j=1}^{K} c_j (H_J' + \epsilon P_j') + O(\epsilon^2 |\mathbf{c}|).$$

μ_m^0 and the limit $\mathbf{c}^0 = \lim_{\epsilon \to 0}(c_1, c_2, \ldots, c_K)$ form an eigenpair of the K-dimensional eigenvalue problem

$$\left\{ \frac{(m^2-1)\tau}{(r_k^0)^2} + (-1)^k \gamma (v^0)'(r_k^0) \right\} c_k^0 + \gamma \sum_{j=1}^{K} (-1)^{k+j} G_m(r_k^0, r_j^0) c_j^0 = \mu_m^0 \tau c_k^0, \quad k = 1,2, \ldots, K.$$

G_m is defined after (2.31): $G_m(r,s) = G_m[\delta(\cdot - s)](r)$. More explicitly

$$G_m(r,s) = \begin{cases} \left(\dfrac{s^{1-m}}{2m} + \dfrac{s^{1+m}}{2m} \right) r^m & \text{if } r < s \\ \dfrac{s^{1+m}}{2m} (r^m + r^{-m}) & \text{if } r \geqslant s. \end{cases} \tag{4.1}$$

Note that $G_m(r,s)$ is not symmetric in r and s, although $rG_m(r,s)$ is. So with respect to g^0 the matrix in the K dimensional eigenvalue problem represents a symmetric operator.

In the proof of Theorem 4.1 we write (λ, ϕ) for (λ_m, ϕ_m) for simplicity. We decompose in $L^2(D)$

$$\phi(r) = \sum_{j=1}^{K} c_j (H_j' + \epsilon P_j') + \phi^{\perp}, \quad \text{where } \phi^{\perp} \perp H_j' + \epsilon P_j' \quad (j = 1,2, \ldots, K). \tag{4.2}$$

First we compute

$$\begin{aligned} L_m H_j' &= -\epsilon^2 (H_j')_{rr} - \frac{\epsilon^2}{r} (H_j')r + \frac{\epsilon^2 m^2}{r^2} H_j' + f'(u) H_j' + \epsilon \gamma G_m[H_j'] \\ &= (f'(u) - f'(H_j)) H_j' - \frac{\epsilon}{r} H_j'' + \frac{\epsilon^2 m^2}{r^2} H_j' + \epsilon^2 \gamma (-1)^{j+1} G_m(r, r_j) + O(\epsilon^3) \\ &= \epsilon f''(H_j) P_j H_j' + \epsilon^2 \left(f''(H_j) Q_j + \frac{f'''(H_j) P_j^2}{2} \right) H_j' - \frac{\epsilon}{r} H_j'' + \frac{\epsilon^2 m^2}{r^2} H_j' + \epsilon^2 \gamma (-1)^{j+1} G_m(r, r_j) \\ &\quad + O(\epsilon^3). \end{aligned}$$

By differentiating (2.23) we have

$$-P_j''' + f'(H_j) P_j' + f''(H_j) H_j' P_j - \frac{H_j''}{r_j} = 0.$$

Then

$$L_m P_j' = -\epsilon^2 (P_j')rr - \frac{\epsilon^2}{r}(P_j')_r + \frac{\epsilon^2 m^2}{r^2} P_j' + f'(u)P_j' + \epsilon\gamma G_m[P_j']$$

$$= (f'(u) - f'(H_j))P_j' - f''(H_j)H_j' P_j + \frac{H_j''}{r_j} - \frac{\epsilon}{r}P_j'' + O(\epsilon^2)$$

$$= \epsilon f''(H_j)P_j P_j' - f''(H_j)H_j' P_j + \frac{H_j''}{r_j} - \frac{\epsilon}{r}P_j'' + O(\epsilon^2).$$

Therefore,

$$L_m(H_j' + \epsilon P_j') = \epsilon^2 \left[\left(f''(H_j)Q_j + \frac{f'''(H_j)P_j^2}{2} \right) H_j' + f''(H_j)P_j P_j' + \frac{tH_j''}{r_j r} + \frac{m^2 H_j'}{r^2} - \frac{P_j''}{r} + \gamma(-1)^{j+1} G_m(r, r_j) \right] + O(\epsilon^3). \tag{4.3}$$

In particular,

$$L_m(H_j' + \epsilon P_j') = O(\epsilon^2). \tag{4.4}$$

Rewrite the equation $L_m\phi = \lambda\phi$ as

$$\sum_{j=1}^{K} c_j L_m(H_j' + \epsilon P_j') + L_m\phi^\perp = \lambda\left(\sum_{j=1}^{K} c_j(H_j' + \epsilon P_j') + \phi^\perp \right). \tag{4.5}$$

Then $\phi^\perp$ satisfies

$$L_m\phi^\perp = O(\epsilon^2)|\mathbf{c}| + O(|\lambda|)(|\mathbf{c}| + \|\phi^\perp\|).$$

Lemma 4.2: There exists $C>0$ independent of ϵ such that for all $\psi \perp H_j' + \epsilon P_j'$, $j = 1, 2, \ldots, K$, $\|\psi\| \leqslant C\|L_m\psi\|$.

The proof of this lemma is similar to that of Lemma 3.2, so we omit it. We obtain by Lemma 4.2 that

$$\phi^\perp = O(\epsilon^2)|\mathbf{c}| + O(|\lambda|)(|\mathbf{c}| + \|\phi^\perp\|),$$

which implies, since $\lambda = o(1)$, that

$$\phi^\perp = O(\epsilon^2)|\mathbf{c}| + O(|\lambda|)|\mathbf{c}|. \tag{4.6}$$

We multiply (4.5) by $H_k' + \epsilon P_k'$ and integrate with respect to $2\pi r\, dr$ over $(0,1)$. Then

$$\sum_{j=1}^{K} \langle c_j L_m(H_j' + \epsilon P_j'), H_k' + \epsilon P_k' \rangle + \langle \phi^\perp, L_m(H_k' + \epsilon P_k') \rangle = \lambda \sum_{j=1}^{K} c_j \langle H_j' + \epsilon P_j', H_k' + \epsilon P_k' \rangle,$$

which, by (4.6) and (4.4), may be written as

$$\sum_{j=1}^{K} c_j \langle L_m(H_j' + \epsilon P_j'), H_k' + \epsilon P_k' \rangle + O(\epsilon^4)|\mathbf{c}| + O(\epsilon^2|\lambda|)|\mathbf{c}| = \lambda \sum_{j=1}^{K} c_j \langle H_j' + \epsilon P_j', H_k' + \epsilon P_k' \rangle \tag{4.7}$$

for $k = 1, 2 \ldots, K$.

Lemma 4.3: In Eq. (4.7):

(1) $\langle H_j' + \epsilon P_j', H_k' + \epsilon P_k' \rangle = 2\pi\epsilon r_k \tau \delta_{jk} + O(\epsilon^2)$,

(2) $\langle L_m(H_j' + \epsilon P_j'), H_k' + \epsilon P_k' \rangle = 2\pi\epsilon^3 r_k \{ \delta_{jk}[(m^2 - 1)\tau / r_k^2 + (-1)^k \gamma v'(r_k)] + \gamma(-1)^{k+j} G_m(r_k, r_j) \} + O(\epsilon^4)$.

Proof: (1) is obvious. To prove (2) we note that P' decays exponentially fast. Then (4.3) implies that

$$\begin{aligned}\langle L_m(H_j'+\epsilon P_j'),H_k'+\epsilon P_k'\rangle &= \langle L_m(H_j'+\epsilon P_j'),H_k'\rangle + O(\epsilon^4)\\ &= 2\pi\epsilon^3 r_k\Bigg\{\delta_{jk}\int_R\Bigg[\left(f''(H_k)Q_k+\frac{f'''(H_k)P_k^2}{2}\right)H_k'+f''(H_k)P_kP_k'+\frac{tH_k''}{r_k^2}\\ &\quad+\frac{m^2H_k'}{r_k^2}-\frac{P_k''}{r_k}\Bigg]H_k'dt+\gamma(-1)^{k+j}G_m(r_k,r_j)\Bigg\}+O(\epsilon^4).\end{aligned}$$

To find the integral in the last line we follow the argument used in the proof of Lemma 3.3. □

This lemma simplifies (4.7) to

$$\left(\frac{(m^2-1)\tau}{r_k^2}+(-1)^k\gamma v'(r_k)\right)c_k+\gamma\sum_{j=1}^{K}(-1)^{k+j}G_m(r_k,r_j)c_j+O(\epsilon|\mathbf{c}|)+O\left(\frac{|\lambda||\mathbf{c}|}{\epsilon}\right)=\frac{\tau\lambda c_k}{\epsilon^2}. \tag{4.8}$$

Hence λ is of order ϵ^2. (4.6) now becomes

$$\phi^{\perp}=O(\epsilon^2|\mathbf{c}|). \tag{4.9}$$

After passing limit in (4.8) we deduce the asymptotic properties in Theorem 4.1 for λ and ϕ.

We have proved that if (λ_m,ϕ_m) is an eigenpair associated with m with $\lambda=o(1)$, then it must have the asymptotic behavior described in Theorem 4.1. To complete the proof of the theorem we proceed to show that there exist exactly K simple eigenpairs of (2.31) with the properties.

Let F be the linear subspace spanned by critical eigenfunctions. It is defined unambiguously by $F=\mathrm{span}\{\phi\in L^2(0,1):L_m(\phi)=\lambda\phi,|\lambda|<\epsilon^{1/2}\}$. Since the critical eigenvalues of L_m are of order ϵ^2, F includes all the critical eigenfunctions.

First dim F, the dimension of F, is at most K. Suppose that this is not the case. There exist two distinct eigenpairs (λ,ϕ) and (λ',ϕ') with the same asymptotic behavior. That is

$$\lambda=\epsilon^2\eta+o(\epsilon^2),\quad \lambda'=\epsilon^2\eta+o(\epsilon^2),\quad \phi=\sum_j c_j(H_j'+\epsilon P_j')+\psi,$$

$$\phi'=\sum_j c_j'(H_j'+\epsilon P_j')+\psi',\quad \lim_{\epsilon\to 0}c_j=\lim_{\epsilon\to 0}c_j'=c_j^0.$$

But the two eigenfunctions must be orthogonal, so

$$0=\langle\phi,\phi'\rangle=2\epsilon\pi g^0(\mathbf{c}^0,\mathbf{c}^0)\int_{-\infty}^{\infty}(H'(t))^2dt+o(\epsilon)|\mathbf{c}^0|^2.$$

This is obviously impossible when ϵ is sufficiently small.

Next dim F is at least K. Suppose otherwise that dim $F<K$. Define a subspace of $L^2(0,1)$: $S=\mathrm{span}\{\Sigma_j c_j^0(H_j'+\epsilon P_j')\}$, where c_j^0 are the K eigenvectors of the K-dimensional eigenvalue problem in the statement of the theorem. We use a perturbation argument. The asymmetric distance between the closed subspaces S and F is

$$d(S,F)=\sup\{d(\varphi,F):\varphi\in S,\|\varphi\|_2=1\},$$

where $d(x,F)=\inf\{\|x-y\|_2:y\in F\}$. Since dim $F<$ dim S, there exists $\Sigma_j b_j^0(H_j'+\epsilon P_j')\in S$ such that for every eigenvector in F which may be written as $\Sigma_j c_j(H_j'+\epsilon P_j')+\psi$ with $\|\psi\|=O(\epsilon^2|\mathbf{c}|)$, $g^0(\mathbf{c}/|\mathbf{c}|,\mathbf{b}^0/|\mathbf{b}^0|)=o(1)$. Then straight calculations show that

$$\left\langle \frac{\sum_j c_j(H_j'+\epsilon P_j')+\psi}{\left\|\sum_j c_j(H_j'+\epsilon P_j')+\psi\right\|_2}, \frac{\sum_j b_j^0(H_j'+\epsilon P_j')}{\left\|\sum_j b_j^0(H_j'+\epsilon P_j')\right\|_2} \right\rangle = o(1).$$

So if we use $\varphi=\Sigma_j b_j^0(H_j'+\epsilon P_j')/\|\Sigma_j b_j^0(H_j'+\epsilon P_j')\|_2$, $d(\varphi,F)=1-o(1)$ and $d(S,F)=1-o(1)$. The following lemma due to Helffer and Sjöstrand[12] will give us a contradiction.

Lemma 4.4: Let L be a self-adjoint operator on a Hilbert space H, Q a compact interval in $(-\infty,\infty)$ *and* $e_1,e_2,\ldots,e_K$ *normalized linearly independent elements in the domain of L. Assume that the following are true.*

(1) $L(e_k)=p_k e_k+r_k, \|r_k\|_H \leqslant \epsilon'$ *and* $p_k \in Q, k=1,2,\ldots,K$.
(2) *There is* $\omega>0$ *so that Q is* ω*-isolated in the spectrum of L,* i.e., $(\sigma(L)\backslash Q)\cap(Q+(-\omega,\omega))=\emptyset$.

Then $d(S,F)\leqslant K^{1/2}\epsilon'/(\omega\kappa^{1/2})$, *where* $S=span\{e_1,\ldots,e_K\}$ $F=$ *the closed subspace associated to* $\sigma(L)\cap Q$, *and* $\kappa=$ *the smallest eigenvalue of the matrix* $[\langle e_j,e_k\rangle]$.

Here we take $L=L_m$, each e_k is normalized and proportional to $\Sigma_j c_j^0(H_j'+\epsilon P_j')$ for each one of the K vectors $\mathbf{c}^0$, and S, F as before. ω and κ are positive and bounded away from 0 as $\epsilon\to 0$. Set $p_k=\eta\epsilon^2$ and $Q=[-\epsilon^{1/2},\epsilon^{1/2}]$. From (4.3) we find

$$L_m\left(\sum_j c_j^0(H_j'+\epsilon P_j')\right)-p_k\sum_j c_j^0(H_j'+\epsilon P_j')=O(\epsilon^2|\mathbf{c}^0|),$$

and on the other hand $\|\Sigma_j c_j^0(H_j'+\epsilon P_j')\|_2\sim\epsilon^{1/2}|\mathbf{c}^0|$. Therefore $\|r_k\|_2=O(\epsilon^{3/2})$, Consequently $d(S,F)=o(1)$, a contradiction.

V. THE CASES OF $K=1$ AND $K=2$

We know from Theorem 1.1 that the spot solution ($K=1$) exists for all γ. However the stability of the solution in two dimensions depends on γ. For small ϵ, the spot solution is stable if γ is small and unstable if γ is large. More precisely we have

Theorem 5.1: *Let* $K=1$. *There exists* $\hat\gamma>0$ *such that when* $\gamma\in(0,\hat\gamma)$ *there exists* $\hat\epsilon$ *such that for every* $\epsilon\in(0,\hat\epsilon)$ *all* $\lambda_m>0$, i.e., *the spot solution u is stable. On the other hand if* $\gamma>\hat\gamma$, *there exist* $\tilde\epsilon>0$ *and* $m\geqslant 2$ *such that for all* $\epsilon\in(0,\tilde\epsilon)$, $\lambda_m<0$, i.e., *u is unstable.*

Proof: Theorem 3.1 shows that when $K=1$, there is only one λ_0 with the property $\lambda=o(1)$. This λ_0 is positive and of order ϵ for all γ if ϵ is sufficiently small.

When $m=1$, in Theorem 4.1:

$$\gamma\{-(v^0)'(r_1^0)+G_1(r_1^0,r_1^0)\}=\mu_1^0\tau. \tag{5.1}$$

According to (4.1), $G_1(r_1^0,r_1^0)=((r_1^0)^3+r_1^0)/2$. When $K=1$, $a=1-(r_1^0)^2$ by (2.7) and $(v^0)'(r_1^0)=(r_1^0-(r_1^0)^3)/2$ by solving the equation

$$-(v^0)''-\frac{1}{r}(v^0)'=u^0-a,\quad (v^0)'(0)=(v^0)'(1)=0.$$

Therefore $\mu_1^0=\gamma(r_1^0)^3/\tau>0$ and $\lambda_1>0$.

When $m\geqslant 2$, let $K=1$ in Theorem 4.1:

$$\frac{(m^2-1)\tau}{(r_1^0)^2}+\gamma\left\{\frac{(r_1^0)^3-r_1^0}{2}+\frac{(r_1^0)^{2m+1}+r_1^0}{2m}\right\}=\mu_m^0\tau. \tag{5.2}$$

Clearly when γ is small, the first term on the left side dominates and μ_m^0 is positive for all $m\geqslant 2$. On the other hand we find that the quantity in the braces is negative if m is sufficiently large. Fixing such m and taking γ large enough, we find that the entire left-hand side of (5.2) becomes negative. □

The borderline value $\hat\gamma$ for γ can be calculated easily from (5.2) in two steps.

TABLE I. The value of $\hat{\gamma}$ for various a and the corresponding mode $\hat{m}$ of the principal eigenvalue $\lambda_{\hat{m}}$ which varnishes up to order ϵ^2. Here $\tau=\sqrt{2}/12$.

a	0.1	0.2	0.3	0.4	0.5	0.6	0.7	0.8	0.9
$\hat{m}$	19	9	6	4	3, 4	3	2	2	2
$\hat{\gamma}$	2468.56	356.23	123.86	64.69	42.67	30.38	27.76	28.23	56.61

(1) For each integer $m\geqslant 2$ find $\hat{\gamma}_m$ by setting the right-hand side of (5.2) to be 0 and solving the equation for γ. If the resulting $\hat{\gamma}_m$ is less than or equal to 0, this mode m does not yield a zero eigenvalue. Discard such $\hat{\gamma}_m$.
(2) Minimize the $\hat{\gamma}_m$'s from the last step with respect to $m\geqslant 2$. The minimum is $\hat{\gamma}$, achieved at $m=\hat{m}$ where $\lambda_{\hat{m}}$, the principal eigenvalue, vanishes up to order ϵ^2.

The values $\hat{\gamma}$ for several a are reported in Table I. Curiously when $a=1/2$ the borderline $\hat{\gamma}$ occurs at two modes $\hat{m}=3$ and $\hat{m}=4$. In this case if $\gamma=\hat{\gamma}$ both λ_3 and λ_4 are of order $o(\epsilon^2)$ while the other λ_m's$(m\geqslant 2)$ are positive and $\sim\epsilon^2$.

One gains more insight into the diblock copolymer equation by comparing with the Cahn–Hilliard equation, which is (1.6) with $\gamma=0$. The Cahn–Hilliard equation also has a spot solution. Its critical eigenvalues are again classified into λ_m for non-negative integers m. If we formally set $\gamma=0$ in Theorem 3.1 and (5.2) it appears that for the Cahn–Hilliard equation λ_0 is positive and of order ϵ, and λ_m with $m\geqslant 2$ is also positive and of order ϵ^2. From (5.1) with $\gamma=0$, one thinks that up to order ϵ^2, λ_1 vanishes. These statements are actually all correct, although the exact value of λ_1 is negative, and the spot solution is unstable in the Cahn–Hilliard problem. Therefore Theorem 5.1 does not cover the Cahn–Hilliard equation. Nevertheless the distance between λ_1 and 0 is exponentially small there and is not visible in (5.1). The smallness of λ_1 is related to the phenomenon of the slow motion of a bubble profile in a general domain (see Alikakos and Fusco,[2,3] Ward,[37] and Alikakos, Bronsard and Fusco[1]). One may feel uneasy about the abrupt change from negative λ_1 to positive λ_1 as we add a nonlocal term with a small γ. This is a result of our setting of fixing γ while taking ϵ small. To find the threshold where $\lambda_1=0$ one must take γ to vary with ϵ. We suspect that a borderline lies where γ is exponentially small compared to ϵ.

When we further increase γ, we reach the second threshold where one of λ_m with $m\geqslant 2$ becomes 0. Beyond this critical γ value the spot solution is unstable. It no longer has enough oscillation demanded by the stronger nonlocal term now. Note that the first stability threshold occurs because of λ_1 which is related to the translation of the spot, while the second threshold occurs because of some λ_m with $m\geqslant 2$ which is related to the oscillation of the boundary of the spot.

The situation is more complex when $K\geqslant 2$, because the existence of u is conditional. According to Theorem 2.2, we have u if (2.12) is positive definite in T. This condition requires two things. First (2.10) must have a solution $\mathbf{r}^0$. From this $\mathbf{r}^0$ we construct $\mathcal{U}(\cdot;\mathbf{r}^0)$, $\mathcal{V}(\cdot;\mathbf{r}^0)$, g^0, $\mathbf{e}_j^0$, and finally the matrix $\mathbf{M}^0$. The second requirement is that the eigenvalues of the $K-1$ by $K-1$ matrix $g^0(\mathbf{M}^0\mathbf{e}_n^0,\mathbf{e}_m^0),n,m=2,3,\ldots,K$, in Theorem 3.1 must all be positive. When these two requirements are met, u exists and its stability in two dimensions is determined by the eigenvalues λ_m, $m\geqslant 1$. Their leading order approximations μ_m^0 are calculated from the K by K matrix in Theorem 4.1.

The determination of $\mathbf{r}^0$ and the analysis of the matrices have to be done numerically. As an example we consider $K=2$. Let $a=1/2$, $\tau=\sqrt{2}/12$, and try various values of γ. Instead of considering q_1 and q_2 under the constraint $-q_1^2+q_2^2=a$, we let $y=q_1^2$ and $q_2=\sqrt{y+a}$. Then as done in Ref. 25, J may be treated as a function, of y without constraint, $J(y)=J(q_1(y),q_2(y))$.

According to Sec. II for given y we find q_1 and q_2, $\mathcal{U}(\cdot;q_1,q_2)$, $\mathcal{V}(\cdot;q_1,q_2)$, and $J(y)$. When γ is small, e.g., $\gamma=1$, J is increasing in y, Fig. 4(1), and (2.10) has no solution.

When γ is increased to 25, J has a critical point at $y=0.0802$, Fig. 4(2), i.e., (2.10) has a solution $\mathbf{r}^0=(0.2832,0.7616)$. We calculate $g^0(\mathbf{M}^0\mathbf{e}_2^0,\mathbf{e}_2^0)$ which turns out to be positive. Hence μ_0^0

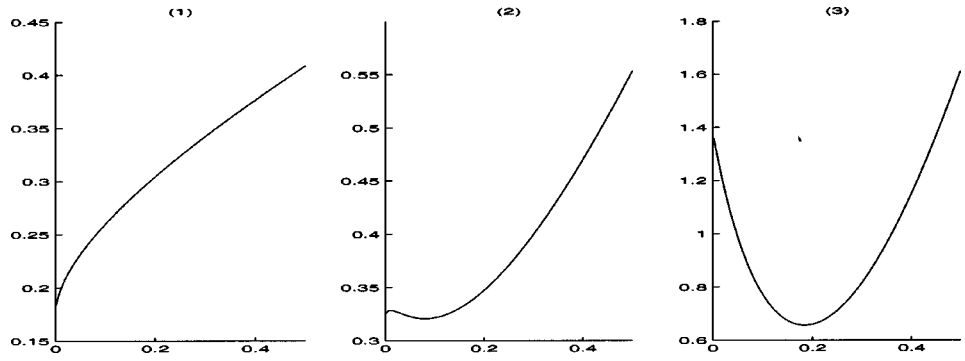

FIG. 4. (1) When $\gamma=1$, $J(y)$ is increasing in y. No $\mathbf{r}^0$ exists. (2) When $\gamma=25$, a local minimum of $J(y)$ appears and $\mathbf{r}^0$ exists. The $K=2$ ring solution is stable. (3) When $\gamma=200$, $\mathbf{r}^0$ still exists, but the $K=2$ ring solution is unstable. In all three cases $a=1/2$ and $\tau=\sqrt{2}/12$.

is positive, $y=0.0802$ is a local minimum of J, and a solution u exists. Then we compute the eigenvalues μ_m^0 of the matrix in Theorem 4.1. They are all positive, Table II. So u is a stable solution in two dimensions.

When γ is further increased to 200, J has a critical point at $y=0.1841$, Fig. 4(3), corresponding to $\mathbf{r}^0=(0.4290,0.8271)$, $g^0(\mathbf{M}^0\mathbf{e}_2^0,\mathbf{e}_2^0)$ is positive, so a solution u exists. However some $\mu_m^0(m\geqslant 1)$ are negative, Table III. Hence u is unstable in two dimensions.

There is something interesting in Fig. 4(2) and (3). If we blow them up near $y=0$, Fig. 5, then in each case we find a local *maximum* near $y=0$. This is because that $J(y)$ is increasing in y near $y=0$ and near $y=1-a$. So whenever there is a local minimum, there must be a local maximum before the local minimum. This local maximum gives rise to a solution $\hat{\mathbf{r}}^0$ of (2.10). However we cannot use the Γ-convergence theory to find a solution of (1.6) near $\mathcal{U}(\cdot;\hat{\mathbf{r}}^0)$. We conjecture that such a solution exists.

When the critical eigenvalues of a spot or a ring solution, determined from Theorems 3.1 and 4.1, are nonzero, we may expect to have a similar solution of (1.6) on a slightly perturbed domain. However finding solutions of (1.6) on a general domain $\Omega\subset R^N$ is rather difficult. It was noted in Ref. 19 that (1.6) has a singular limit as $\epsilon\to 0$. One looks for a function $u^0\in BV(\Omega)$ defined such that for a.e. $x\in\Omega$, $u^0(x)=0$ or $u^0(x)=1$ and $\overline{u^0}=a$. Let S be the union of the hypersurfaces that separate the regions $u^0=0$ from the regions $u^0=1$, and $v^0=(-\Delta)^{-1}(u^0-a)$. Then one requires that at every $x\in S$,

$$\tau\kappa(x)+\gamma v^0(x)=\eta, \tag{5.3}$$

where $\kappa(x)$ is the mean curvature of S at x viewed from the $u^0=1$ side, and η is a Lagrange multiplier to be determined. If the free boundary problem (5.3) admits an isolated stable solution u^0, then near u^0, in the $L^2(\Omega)$ sense, there exists a local minimizer solution u of (1.6) by the Γ-convergence theory. However (5.3) is a challenging nonlocal geometric problem. Even though Fig. 1(2) and (3) suggest we look for solutions with multiple spots, (5.3) implies that for such a solution the curvature of the boundary of a spot is in general not constant (there is the impact of v^0), i.e., the spots are not exactly round, unless we deal with the one spot or the ring solutions in a disk as in this paper. Nevertheless if we consider the situation where a is close to 0 (or 1), then

v^0 is near constant throughout Ω and hence κ becomes close to a constant and the spots are approximately round. The cylindrical and spherical phases in Fig. 1 are thus heuristically explained. Note that in the singular limit of the Cahn–Hilliard equation, which is (5.3) without the $\gamma v^0(x)$ term, κ is constant.

APPENDIX: PROOF OF LEMMA 2.3

Since $\eta=\overline{f(u)}$, we obtain a rough estimate for η,

$$|\eta| = |\overline{f(u)}| \leqslant C\left(\int_D W(u)dx\right)^{1/2} = O(\epsilon^{1/2}), \tag{A1}$$

since $I(u)=O(\epsilon)$. $||u||_2=O(1)$ implies that $||v||_{2,2}=O(1)$ and in particular $v=O(1)$. A maximum principle argument shows that

$$-O(\epsilon^{1/2}) = -(O(\epsilon)+O(|\eta|)) \leqslant u \leqslant 1+O(\epsilon)+O(|\eta|) = 1+O(\epsilon^{1/2}). \tag{A2}$$

In the Γ-convergence theory u satisfies $u\to u^0$ in $L^2(D)$ and $(\epsilon\pi)^{-1}I(u)\to J(u^0)$.[25] The fact $u\to u^0$ in $L^2(D)$ implies the existence of r_j where $u(r_j)=1/2$ and that $r_j\to r_j^0$ for $j=1,2,\ldots,K$. We construct a preliminary approximation h of u,

$$h(r) = H\left(\frac{r-r_1}{\epsilon}\right) + \left[H\left(-\frac{r-r_2}{\epsilon}\right)-1\right] + H\left(\frac{r-r_3}{\epsilon}\right) + \left[H\left(-\frac{r-r_4}{\epsilon}\right)-1\right] + \cdots, r\in(r_1,1),$$

and let $d=u-h$.

If we consider h on $(r_1,1)$, the argument in Proposition 8.2 (Ref. 26) shows that $d=o(1)$ on $[r_1,1]$. Next we improve (A1) to

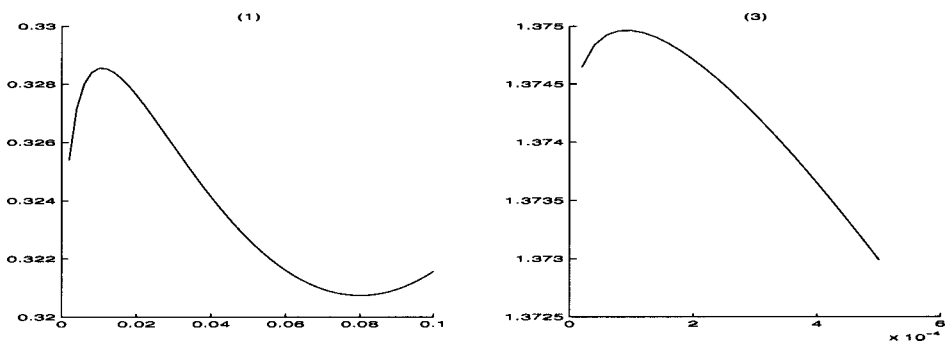

FIG. 5. (1) The enlarged Fig. 4(2) near $y=0$. (2) The enlarged Fig. 4(3) near $y=0$.

$$\eta = O(\epsilon), \tag{A3}$$

and show that

$$d = O(\epsilon) \text{ in } [r_1, 1]. \tag{A4}$$

Note that $d = u - h$ satisfies the equation

$$-\epsilon^2 d_{rr} + f'(h)d + O(||d||^2) + O(\epsilon) = \eta, \quad d(r_j) = 0 \quad (j = 1,2,\ldots,K), \quad d'(1) = 0$$

on $(r_1, 1)$. Then $d = O(\epsilon + |\eta|)$ in $[r_1, 1]$. Now we use an idea of Pohozaev.[22] Multiply the first equation of (1.8) by $r^2 u_r$ and integrate with respect to dr on (0, 1). Then

$$\int_0^1 [-\epsilon^2 (ru_r)_r (ru_r) + r^2 f(u) u_r + \epsilon\gamma r^2 v u_r] dr = \eta \int_0^1 r^2 u_r dr.$$

The first term on the left-hand side becomes 0 after integration. Applying integration by parts to the second and third terms on the left-hand side and the right-hand side shows that

$$r^2 W(u)|_{r=0}^{r=1} - 2\int_0^1 W(u) r\, dr + \epsilon\gamma r^2 v u|_{r=0}^{r=1} - \epsilon\gamma \int_0^1 u (r^2 v)_r dr = \eta(r^2 u|_{r=0}^{r=1} - 2\int_0^1 u\, r dr),$$

which is simplified to

$$W(u(1)) - \frac{1}{\pi}\int_D W(u) dx + O(\epsilon) = \eta(u(1) - a)$$

since $\epsilon\gamma v(1) u(1) = O(\epsilon)$ and $\epsilon\gamma \int_0^1 u (r^2 v)_r dr = O(\epsilon)$. The integral in the last equation is of order $O(\epsilon)$ since it is a part of $I(u)$ and $I(u) = O(\epsilon)$ by $(\epsilon\pi)^{-1} I(u) \to J(u^0)$. Moreover $u(1) \to 0$ or 1 to which a is not equal, so the last equation reads

$$\eta = O(\epsilon) + O(W(u(1))).$$

However $d = O(\epsilon + |\eta|)$ on $[r_1, 1]$ proved earlier implies that $u(1) = O(\epsilon + |\eta|)$ or $u(1) = 1 + O(\epsilon + |\eta|)$. Then $W(u(1)) = W(O(\epsilon + |\eta|)) = O((\epsilon + |\eta|)^2)$, or $W(u(1)) = W(1 + O(\epsilon + |\eta|)) = O((\epsilon + |\eta|)^2)$. Hence we derive

$$\eta = O(\epsilon) + O((\epsilon + |\eta|)^2), \quad \text{i.e., } \eta = O(\epsilon).$$

Consequently $d = O(\epsilon)$ in $[r_1, 1]$.

Now we consider u, h, and d on $(0, r_1)$. We proceed to show that $d = o(1)$ on $(0, r_1)$. Suppose that this is false. Then there exist a small $\delta > 0$, independent of ϵ, and $r_* \in [0, r_1)$ such that $|d(r_*)| = \delta$ and $|d(r)| < \delta$ if $r \in (r_*, r_1)$. δ is so small that 0 is the only critical point of W in $(-\delta, \delta)$. Since $u(\epsilon t + r_1) \to H(t)$ in $C^2_{\text{loc}}(R)$, $(r_1 - r_*)/\epsilon \to \infty$. Moreover the argument in Proposition 8.2 Ref. 26 shows that $r_* = o(1)$. There are two cases left: (1) $r_*/\epsilon \to \infty$ and $r_* = o(1)$, and (2) $r_* = O(\epsilon)$.

In the first case we multiply the first equation of (1.8) by u_r and integrate with respect to dr:

$$-\int_0^1 \frac{\epsilon^2}{r} u_r^2\, dr + W(u(1)) - W(u(0)) + \epsilon\gamma \int_0^1 v u_r\, dr = \eta(u(1) - u(0)).$$

Here $W(u(1))$ is of order $O(\epsilon^2)$ by (A4). The right-hand side is of order $O(\epsilon)$ by (A3). $\epsilon\gamma \int_0^1 v u_r\, dr$ is of order $O(\epsilon)$ after integration by parts. Hence

$$\int_0^1 \frac{\epsilon^2}{r} u_r^2 \, dr + W(u(0)) = O(\epsilon).$$

Since $W(u(0)) \geqslant 0$,

$$\int_0^1 \frac{\epsilon^2}{r} u_r^2 \, dr = O(\epsilon). \tag{A5}$$

On the other hand if we scale u at r_* so that $U(t) := u(r_* + \epsilon t) \to H(t)$ locally in C^2, then

$$\int_0^1 \frac{\epsilon^2}{r} u_r^2 \, dr = \frac{\epsilon}{r_*} \int_{-r_*/\epsilon}^{(1-r_*)/\epsilon} \frac{1}{1 + (\epsilon t + r_*)} (U')^2 \, dt \geqslant \frac{\epsilon}{r_*} \left(\int_R (H')^2 \, dt + o(1) \right). \tag{A6}$$

However (A5) and (A6) are inconsistent if $r_* = o(1)$.

In the second case we scale u so that $U(t) := u(\epsilon t) \to U^0(t)$ locally in C^2 and

$$-U^0_{tt} - \frac{U^0_t}{t} + f(U^0) = 0 \text{ in } R, \quad U^0(\infty) = 1, \quad ||U^0|| \leqslant 1.$$

Moreover $U(r_*/\epsilon) \to \delta$. We multiply the equation for U^0 by U^0_t and integrate with respect to dt over $(0, \infty)$. Then

$$-W(U^0(0)) - \int_0^\infty \frac{(U^0_t)^2}{t} dt = 0,$$

which implies that $U^0 \equiv 0$ or $U^0 \equiv 1$. Neither case is consistent with $U(r_*/\epsilon) \to \delta \in (0,1)$.

We have shown that $d = u - h = o(1)$ on (0,1). In particular we know that there are exactly K interfaces $r_1, r_2, \ldots, r_K$. Now we consider the more accurate approximation w of u defined in Sec. II. We call $(r_j - \epsilon^\alpha, r_j + \epsilon^\alpha)$ an inner region, $(0,1) \setminus (U_{j=1}^K (r_j - 2\epsilon^\alpha, r_j + 2\epsilon^\alpha))$ the outer region, and $(r_j - 2\epsilon^\alpha, r_j - \epsilon^\alpha)$ and $(r_j + \epsilon^\alpha, r_j + 2\epsilon^\alpha)$ matching regions. Recall that $\alpha \in (1/2, 1)$.

In the inner and matching regions, using (2.22), (2.23), and (2.25) we find that

$$\begin{aligned}
-\epsilon^2 \Delta z_j + f(z_j) &= -\epsilon^2 \Delta (H_j + \epsilon P_j + \epsilon^2 Q_j) + f(H_j + \epsilon P_j + \epsilon^2 Q_j) \\
&= -\left[f(H_j) + \epsilon \left(\frac{H_j'}{r} + f'(H_j) P_j - \frac{H_j'}{r_j} + \xi_j \right) + \epsilon^2 \left(\frac{P_j'}{r} + f'(H_j) Q_j - \frac{P_j'}{r_j} + \frac{t H_j'}{r_j^2} \right.\right. \\
&\quad \left.\left. + \frac{f''(H_j) P_j^2}{2} + \gamma v'(r_j) t \right) \right] + f(H_j) + \epsilon f'(H_j) P_j + \epsilon^2 \left(\frac{f''(H_j) P_j^2}{2} + f'(H_j) Q_j \right) + O(\epsilon^3) \\
&= \epsilon \xi_j - \epsilon^2 \gamma v'(r_j) t + \frac{\epsilon^2 t}{r_j} \left(\frac{1}{r} - \frac{1}{r_j} \right) H_j' + \epsilon^3 \frac{t P_j'}{r_j r} + O(\epsilon^3) = \epsilon \xi_j - \epsilon^2 \gamma v'(r_j) t + O(\epsilon^3).
\end{aligned}$$

Therefore

$$-\epsilon^2 \Delta z_j + f(z_j) + \epsilon \gamma v - \eta = \epsilon \xi_j + \epsilon \gamma v(r_j) - \eta + O(\epsilon^3 t^2) + O(\epsilon^3) = \sigma_j + O(\epsilon^{1+2\alpha}), \tag{A7}$$

where we have defined

$$\sigma_j = \epsilon \xi_j + \epsilon \gamma v(r_j) - \eta. \tag{A8}$$

By (A3) implicit differentiation of (2.27) and $v'' = O(1)$ yield that

$$-\epsilon^2 \Delta z + f(z) + \epsilon \gamma v - \eta = -\epsilon^2 \Delta z = O(\epsilon^3), \tag{A9}$$

which is valid on $(0.1) \setminus \{r_1, r_2, \ldots, r_K\}$.

We now estimate the difference of z_j and z on a matching region. First using (2.23) and (2.25) we find

$$\epsilon^2 \Delta z_j = O(\epsilon^3).$$

Then (A7) implies that

$$f(z_j) + \epsilon\gamma v - \eta = \sigma_j + O(\epsilon^{1+2\alpha}).$$

Comparing this to (2.27) we deduce that

$$z_j - z = O(|\sigma_j|) + O(\epsilon^{1+2\alpha}) \tag{A10}$$

on the matching regions $(r_j - 2\epsilon^\alpha, r_j - \epsilon^\alpha)$ and $(r_j + \epsilon^\alpha, r_j + 2\epsilon^\alpha)$. Then we consider w in the matching region. Here by (A10)

$$\begin{aligned} -\epsilon^2 \Delta w + f(w) + \epsilon\gamma v - \eta &= -\epsilon^2 \Delta w + f(z) + \epsilon\gamma v - \eta + O(\|z_j - z\|) \\ &= -\epsilon^2 \Delta w + O(|\sigma_j|) + O(\epsilon^{1+2\alpha}) \\ &= -\epsilon^2 \Delta z - \epsilon^2 \Delta(\chi_j(z_j - z)) + O(|\sigma_j|) + O(\epsilon^{1+2\alpha}) \\ &= -\epsilon^2((\chi_j)_{rr}(z_j - z) + 2(\chi_j)_r(z_j - z)_r + \chi_j(z_j - z)_{rr}) \\ &\quad - \frac{\epsilon^2}{r}((\chi_j)_r(z_j - z) + \chi_j(z_j - z)_r) + O(|\sigma_j|) + O(\epsilon^{1+2\alpha}) \\ &= O(|\sigma_j|) + O(\epsilon^{1+2\alpha}) + O(\epsilon^{3-\alpha}). \end{aligned} \tag{A11}$$

If we let $g = u - w$, then (A7), (A9), and (A11) imply that

$$-\epsilon^2 \Delta g + f'(w)g + O(\|g\|^2) = \begin{cases} -\sigma_j + O(\epsilon^{1+2\alpha}) & \text{in an inner region} \\ O(|\sigma|) + O(\epsilon^{1+2\alpha}) + O(\epsilon^{3-\alpha}) & \text{in a matching region} \\ O(\epsilon^3) & \text{in the outer region.} \end{cases} \tag{A12}$$

We deduce from (A12) and $g(r_j) = 0$ that

$$g = O(|\sigma_j|) + O(\epsilon^{1+2\alpha}) + O(\epsilon^{3-\alpha}). \tag{A13}$$

On the other hand, if we multiply (A12) by H_j' and integrate with respect to $r\,dr$ on (0,1), then

$$\int_0^1 [-\epsilon^2 (r g_r)_r H_j' + f'(w) g H_j' r] dr + O(\epsilon \|g\|^2) = (-1)^j \epsilon \sigma_j r_j + O(\epsilon^2 |\sigma_j|) + O(\epsilon^{2+2\alpha}).$$

But the integral on the left-hand side after integration by parts becomes

$$\int_0^1 [-\epsilon g H_j'' + (f'(w) - f'(H_j)) g H_j' r] dr = O(\epsilon^2 \|g\|),$$

from which we conclude that

$$\sigma_j = O(\epsilon \|g\|) + O(\|g\|^2) + O(\epsilon^{1+2\alpha}). \tag{A14}$$

Inserting (A14) into (A13) we find that

$$g = O(\epsilon^{1+2\alpha}) + O(\epsilon^{3-\alpha}); \tag{A15}$$

substituting(A15) into (A14) we deduce that

$$\sigma_j = O(\epsilon^{1+2\alpha}). \tag{A16}$$

Since $\alpha \in (1/2, 1)$, (A15) implies that $g = o(\epsilon^2)$.

The Avez–Seifert theorem for the relativistic Lorentz force equation

Erasmo Caponio[a] and Antonio Masiello[b]
Dipartimento di Matematica, Politecnico di Bari, Bari, Italy

(Received 9 March 2004; accepted 18 June 2004; published 20 October 2004)

In this paper we prove an extension of the Avez–Seifert theorem to the relativistic Lorentz force equation. Let (M,g) be a globally hyperbolic space–time, F an exact 2-form on M representing the electromagnetic field, $\hat{F}$ the Lorentz force associated to F, and q a charge for a test particle. Let p_0 and p_1 be two chronologically related points on M, then there exists a future-pointing timelike solution of the Lorentz force equation $D_s\dot{z}=q\hat{F}(z)[\dot{z}]$, connecting p_0 and p_1. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1782673]

I. INTRODUCTION

The Avez and Seifert theorem is the first classical result in Global Lorentzian Geometry; see Refs. 1, 2, and 7. It can be considered as the extension to globally hyperbolic space–times of the Hopf–Rinow Theorem in Riemannian Geometry, stating that any couple of points in a complete Riemannian manifold are joined by a minimizing geodesic. It states that on a globally hyperbolic space–time (M,g), any two causally related points p_0 and p_1 on M are connected by (at least) one future-pointing causal maximizing geodesic. In particular, if p_0 and p_1 are chronologically related then there exists a timelike future-pointing geodesic connecting p_0 and p_1.

This result has a clear geometric meaning but its importance comes from General Relativity. Indeed lightlike and timelike geodesics on a space–time represent, respectively, the trajectories of light rays and of freely falling particles (i.e., particles subjected only to the gravitational field).

Our aim in this paper is to extend the above result to the trajectories of charged particles under the action of gravitational and electromagnetic fields.

Let (M,g) be a space–time, let $\Lambda^k(M)$, $k\in\{1,2,3,4\}$, be the fiber bundle of k-forms and consider the *differential operator* $d:\Lambda^k(M)\to\Lambda^{k+1}(M)$ and the Hodge operator $*:\Lambda^k(M)\to\Lambda^{4-k}(M)$ acting on differential forms on the manifold M. An *electromagnetic field* F on the space–time (M,g), is a smooth 2-form on M satisfying the Maxwell equations of the electromagnetism; see, for instance, Refs. 4 and 6,

$$\mathrm{d}F=0,$$

$$\mathrm{d}(F^*)=4\pi J^*,$$

where J is a smooth 1-form on M called the *charge-current density*. In particular the first Maxwell equation means that the 2-form F is closed.

The *Lorentz force* associated to the electromagnetic field is the map $\hat{F}$ on TM defined for any $z\in M$ as $\hat{F}(z):T_zM\to T_zM$ and

[a]Electronic mail: caponio@poliba.it
[b]Electronic mail: masiello@poliba.it

$$g(z)[v,\hat{F}(z)[w]] = F(z)[v,w]. \tag{1}$$

Thus for every $z \in M$, $\hat{F}(z)$ is a linear map on T_zM and, in local coordinates, the components of $\hat{F}$ are given by $\hat{F}^i_j = g^{ik}F_{kj}$, where g^{ik} is the inverse matrix of the metric tensor g_{ij}.

The Lorentz force equation governing the motion of a particle with charge q is (cf. Ref. 6)

$$D_s\dot{z} = q\hat{F}(z)[\dot{z}], \tag{2}$$

where $D_s\dot{z}$ is the covariant derivative of $\dot{z}$ along $z(s)$ associated to the Levi–Civita connection.

We will assume that F is exact and we will denote by ω a *potential form* for F, that is $d\omega = F$. Since the electromagnetic field F is exact, Eq. (2) is the Euler–Lagrange equation of the functional

$$\frac{1}{2}\int (g(z)[\dot{z},\dot{z}] + q\omega(z)[\dot{z}])ds, \tag{3}$$

where ω is a potential form of the electromagnetic field F.

Before stating our main result, we shortly recall some basic notions about causality (for details see Ref. 2).

The *causality relations* on M are defined as follows. Let $p_0\ p_1 \in M$; we call p_0 and p_1 *chronologically related* and we write $p_0 \ll p_1$, if there is a smooth future-pointing timelike curve from p_0 to p_1. Furthermore, we say p_0 and p_1 are *causally related* and we write $p_0 \leqslant p_1$, if either $p_0 = p_1$ or there is a future-pointing (hence nowhere vanishing) causal curve from p_0 to p_1.

Let $\gamma :]\!]a,b[\![\to M$ be a curve on M. A point $p \in M$ is said to be the *end point of* γ corresponding to $s=b$ if $\lim_{s\to b^-}\gamma(s) = p$. If γ is a future-pointing (respectively, past-pointing) causal curve with end point p corresponding to $s=b$, the point p is called a *future* (respectively, *past*) *end point* of γ. A causal curve is said to be *future inextendible* (respectively, *past inextendible, inextendible*) if it has no future (respectively, past, nor future neither past) end point.

A *Cauchy surface* S is a subset of M such that every inextendible causal curve meets S exactly once. A Lorentzian manifold M is said to be *globally hyperbolic* if M admits a Cauchy surface. The main result of this paper is stated in the following theorem.

Theorem 1: Let (M,g) *be a globally hyperbolic space–time, endowed with an exact* 2*-form* F, p_0, p_1 *two points on* M, $p_0 \ll p_1$. *Then for any* $q \in \mathbb{R}$ *there exists a timelike future-pointing solution of Eq. (2), connecting* p_0 *and* p_1.

The theorem will be proved by using a five-dimensional (5-D) Kaluza–Klein framework. Kaluza–Klein theories have been developed in the last century as attempts to build up a unified approach to the fundamental interactions. They are based on a higher-dimensional geometry than the 4-D geometry of Einstein relativistic gravity theory (see Ref. 5 for a survey about Kaluza–Klein theories).

According to the Kaluza–Klein framework, we will consider the 5-D manifold $\boldsymbol{M} = M \times \mathbb{R}$, endowed with the Lorentzian metric,

$$\boldsymbol{k} = g + (dy + \omega)^2, \tag{4}$$

where y is the canonical coordinate on $\mathbb{R}$. It is well known (see, for instance, Ref. 3) that the projection on M of any timelike geodesic $\boldsymbol{\gamma}$ of $(\boldsymbol{M},\boldsymbol{k})$ represents a trajectory for test particles subjected to the action of the external field ω.

The charge q_0 of the particle is determined by the constant of the motion (coming from the fact that the vector field ∂_y on $\boldsymbol{M}$ is a Killing field for the metric $\boldsymbol{k}$):

$$\boldsymbol{k}(\boldsymbol{\gamma})[\dot{\boldsymbol{\gamma}},\partial_y] = \text{const} \equiv q_0. \tag{5}$$

On any Lorentzian manifold (N,h), the timelike geodesics $\gamma = \gamma(s)$ connecting two points p_0 and p_1 on N can be characterized as the critical points of the *energy functional*,

$$\frac{1}{2}\int h(\gamma)[\dot\gamma,\dot\gamma]\mathrm{d}s,$$

on the set of the piecewise smooth timelike curves joining p_0 and p_1. In the case of the Kaluza–Klein metric (4), the Euler–Lagrange equations of the energy functional (i.e., the geodesic equations) are

$$D_s\dot z = (\dot y + \omega(z)[\dot z])\hat F(z)[\dot z],$$

$$\dot y + \omega(z)[\dot z] = \text{const}. \tag{6}$$

From (2) and (6), we see that $\dot y+\omega(z)[\dot z]$ plays effectively the role of the charge of the particle moving along the trajectory $z=z(s)$.

Thus in order to establish the existence of timelike connecting trajectories for charged particles on M, we may study the existence of the timelike connecting geodesic on $\boldsymbol{M}$.

In Sec. II we will show that if (M,g) is globally hyperbolic then $(\boldsymbol{M},\boldsymbol{k})$ is as well. The Avez and Seifert Theorem provides the existence of a timelike geodesic $\boldsymbol{z}$ for the 5-D Kaluza–Klein manifold, connecting two chronologically related points on $\boldsymbol{M}$. Thus we gain the existence of a timelike connecting trajectory $z=\pi_M(\boldsymbol{z})$ (π_M is the canonical projection on M) for a particle carrying a charge q_0, which depends on the 5-D timelike geodesic $\boldsymbol{z}$. If $q_0\neq 0$ we can reparametrize the curve z, considering the new map $c(s)=z\boldsymbol{(}(q/q_0)s\boldsymbol{)}$, where q is the fixed test charge. The map c solves Eq. (2), in fact,

$$D_{\dot c(s)}\dot c(s) = \left(\frac{q}{q_0}\right)^2 D_{\dot z((q/q_0)s)}\dot z\left(\frac{q}{q_0}s\right) = \left(\frac{q}{q_0}\right)^2 q_0\hat F\left(z\left(\frac{q}{q_0}s\right)\right)\left[\dot z\left(\frac{q}{q_0}s\right)\right] = q\hat F(c(s))[\dot c(s)].$$

Finally an analysis based on the relations between causality on the 4-D space-time (M,g) and the 5-D space-time $(\boldsymbol{M},\boldsymbol{k})$, allows us to prove the existence of a 5-D future-pointing timelike connecting geodesic having a constant of the motion $q_0\neq 0$ (in other words a 5-D future-pointing timelike geodesic $\boldsymbol{z}$, such that its projection on M is not a 4-D geodesic).

II. KALUZA–KLEIN METRICS

Let (M,g) be a space–time [i.e., (M,g) is a smooth time-oriented Lorentzian manifold] and ω a smooth 1-form on M. The Kaluza-Klein metric $\boldsymbol{k}$ associated to (M,g,ω) is defined on $\boldsymbol{M}=M\times\mathbb{R}$ as follows:

$$\boldsymbol{k}(\boldsymbol{z})[(\zeta,\eta),(\zeta',\eta')] = g(z)[\zeta,\zeta'] + (\eta+\omega(z)[\zeta])(\eta'+\omega(z)[\zeta']), \tag{7}$$

for all $\mathbf{z}\equiv(z,y)\in\boldsymbol{M}$, and for all $(\zeta,\eta),(\zeta',\eta')\in T_{\mathbf{z}}\boldsymbol{M}\equiv T_zM\times\mathbb{R}$ (throughout the paper bold symbols will refer to 5-D manifold $\boldsymbol{M}$).

Consider the canonical projections maps $\pi_M:\boldsymbol{M}\to M$, $\pi_{\mathbb{R}}:\boldsymbol{M}\to\mathbb{R}$ and denote by π_M^* and $\pi_{\mathbb{R}}^*$ the corresponding pullback maps. From (7) we see that $\boldsymbol{k}$ is given by

$$\boldsymbol{k} = \pi_M^*(g) + [\pi_{\mathbb{R}}^*(\mathrm{d}y) + \pi_M^*(\omega)]\otimes[\pi_{\mathbb{R}}^*(\mathrm{d}y) + \pi_M^*(\omega)]. \tag{8}$$

Proposition 2: $\boldsymbol{k}$ is a symmetric nondegenerate bilinear form.

Proof: $\boldsymbol{k}$ is clearly symmetric and bilinear. In order to prove that $\boldsymbol{k}(\mathbf{z})$ is nondegenerate, for any $\mathbf{z}$ in $\boldsymbol{M}$, let $\boldsymbol{\zeta}\equiv(\zeta,\eta)\in T_{\mathbf{z}}\boldsymbol{M}$ be such that for any $\boldsymbol{\zeta}'\equiv(\zeta',\eta')\in T_{\mathbf{z}}\boldsymbol{M}$:

$$\boldsymbol{k}(\mathbf{z})[\boldsymbol{\zeta},\boldsymbol{\zeta}'] = g(z)[\zeta,\zeta'] + (\eta+\omega(z)[\zeta])(\eta'+\omega(z)[\zeta']) = 0.$$

Choosing $\boldsymbol{\zeta}'\equiv(0,1)$, we obtain

$$0 = \boldsymbol{k}(\mathbf{z})[(\zeta,\eta),(0,1)] = (\eta+\omega(z)[\zeta]). \tag{9}$$

On the other hand, for any $\zeta'\in T_zM$:

$$0 = \boldsymbol{k}(\mathbf{z})[(\zeta,\eta),(\zeta',0)] = g(z)[\zeta,\zeta'] + (\eta + \omega(z)[\zeta])\omega(z)[\zeta']. \tag{10}$$

From (9) and (10) we deduce that $g(z)[\zeta,\zeta']=0$, for any $\zeta' \in T_zM$. Thus it results $\zeta=0$ and, from (9), $\eta=0$ too. □

Proposition 3: $\boldsymbol{k}$ is a Lorentzian metric.

Proof: We will show that for any $\mathbf{z} \in \boldsymbol{M}$, $\boldsymbol{k}(\mathbf{z})$ has index 1. Indeed $\boldsymbol{k}$ is positive definite on any subspace $F \subset T_{\mathbf{z}}\boldsymbol{M}$ of the form $F=F_0 \times \{0\}$, with F_0 spacelike with respect to g. On the subspace spanned by the vector $(0,1) \in T_{\mathbf{z}}\boldsymbol{M}$, it results that

$$\boldsymbol{k}(\mathbf{z})[(0,\lambda),(0,\lambda)] = \lambda^2 > 0.$$

Now let $\zeta \in T_zM$ be a timelike vector with respect to g and for any $\lambda \in \mathbb{R}$ consider the vector $\boldsymbol{\zeta} = (\zeta,\lambda) \in T_{\mathbf{z}}\boldsymbol{M}$. It results that

$$\boldsymbol{k}(\mathbf{z})[(\zeta,\lambda),(\zeta,\lambda)] = g(z)[\zeta,\zeta'] + (\lambda + \omega(z)[\zeta])^2 = \lambda^2 + 2\omega(z)[\zeta]\lambda + g(z)[\zeta,\zeta] + (\omega(z)[\zeta])^2. \tag{11}$$

From (11) we see that there exist two real numbers λ_1 and λ_2 such that, for any $\lambda \in]\!]\lambda_1,\lambda_2[\![$, $\boldsymbol{k}(\mathbf{z})[(\zeta,\lambda),(\zeta,\lambda)]<0$, that is the vector (ζ,λ) is timelike and $\boldsymbol{k}(\mathbf{z})$ has index 1. □

Let V be a timelike vector field on M which gives a time-orientation to M (i.e., V is continuous and timelike). Then consider the vector field $\boldsymbol{V}=(V,-\omega[V])$ on $\boldsymbol{M}$. Clearly $\boldsymbol{V}$ is continuous and timelike with respect to $\boldsymbol{k}$. Thus we can state the following.

Proposition 4: $(\boldsymbol{M},\boldsymbol{k})$ is time-oriented.

It is natural to consider if causality conditions satisfied by (M,g) are preserved by $(\boldsymbol{M},\boldsymbol{k})$.

Proposition 5: Assume that $\mathbf{z}=\mathbf{z}(s)$ is a smooth timelike (causal) future-pointing curve on $\boldsymbol{M}$. Then $z(s)=\pi_M(\mathbf{z}(s))$ is a smooth timelike (causal) future-pointing curve on M.

Proof: Clearly z is a smooth curve on M. Let $y=y(s)$ be the function $y(s)=\pi_{\mathbb{R}}(\mathbf{z}(s))$. From

$$0 > \boldsymbol{k}(\mathbf{z})[\dot{\boldsymbol{z}},\dot{\boldsymbol{z}}] = g(z)[\dot{z},\dot{z}] + (\dot{y} + \omega(z)[\dot{z}])^2,$$

we have that $g(z)[\dot{z},\dot{z}]<0$, that is z is timelike. Since

$$\boldsymbol{k}(\mathbf{z})[\dot{\boldsymbol{z}},\boldsymbol{V}(\mathbf{z})] = g(z)[\dot{z},V(z)],$$

and $\boldsymbol{k}(\mathbf{z})[\dot{\boldsymbol{z}},\boldsymbol{V}(\mathbf{z})]<0$, z is future-pointing. □

Another result about causality is the following.

Proposition 6: If (M,g) is globally hyperbolic, then $(\boldsymbol{M},\boldsymbol{k})$ is globally hyperbolic.

Proof: Let S be a Cauchy surface for M. We will prove that $\boldsymbol{S}=S\times\mathbb{R}$ is a Cauchy surface for $\boldsymbol{M}=M\times\mathbb{R}$. By contradiction assume that there exists an inextendible smooth future-pointing causal curve $\mathbf{z}:]\!]a,b[\![\to\boldsymbol{M}$ $(-\infty\leqslant a<b\leqslant+\infty)$, which does not intersect $\boldsymbol{S}$. Consider $z(s)=\pi_M(\mathbf{z}(s))$. Clearly z does not intersect S otherwise $\mathbf{z}$ would meet $\boldsymbol{S}$. By Proposition 5, z is a smooth future-pointing causal curve on M and, being S a Cauchy surface for M, we deduce that z must be extendible. So let p be a future end point for z corresponding to $s=b$. Now since $\mathbf{z}$ is causal we deduce that

$$|\dot{y} + \omega(z)[\dot{z}]| \leqslant \sqrt{-g(z)[\dot{z},\dot{z}]},$$

and, integrating from $c>a$ to $d<b$, we get

$$\int_c^d |\dot{y} + \omega(z)[\dot{z}]|\mathrm{d}s \leqslant \int_c^d \sqrt{-g(z)[\dot{z},\dot{z}]}\mathrm{d}s. \tag{12}$$

Now consider the Lorentzian distance function d on M associated to the metric g. Since M is globally hyperbolic and z is causal, the right-hand side of (12) is less than $d(z(c),z(d))<+\infty$. As z has future end point p corresponding to $s=b$, it results that $d(z(c),p)<+\infty$. So there exists the limit as $d\to b^-$ of the right-hand side of (12). Therefore the left-hand side of (12) has a finite limit

as $d \to b^-$. Now consider the term $\int_c^d \omega(z)[\dot{z}]\mathrm{d}s$. It is well known that, for any $q \in M$ there exists a neighborhood $U_q \subset M$ of q and a coordinate system $\varphi=(x_1,x_2,x_3,t)$ on U_q such that $V=\partial_t$ and $U_q=\Sigma \times]\!]a_1,b_1[\![$, where Σ is a spacelike hypersurface parametrized by x_1,x_2,x_3. Moreover in the coordinate system $x=(x_1,x_2,x_3) \in \Sigma$ and $t \in]\!]a_1,b_1[\![$ the metric g is given by

$$g(x,t)[(\xi,\tau),(\xi,\tau)] = \langle \alpha(x,t)\xi,\xi\rangle + 2\langle \delta(x,t),\xi\rangle\tau - \beta(x,t)\tau^2,$$

where $(\xi,\tau) \in T_x\Sigma \times \mathbb{R}$, $\langle\cdot,\cdot\rangle$ is the restriction of g to Σ, α is a smooth, symmetric positive definite operator, δ is a smooth vector field on U_q and β is a smooth, positive real function on U_q. Pick a coordinate system (U_p,φ) as above for the future end point p. Without loss of generality we can assume that $z(c) \in U_p$ and $z(d) \in U_p$, for any $c<d\leqslant b$. Denote $z(s)$ by $(x(s),t(s))$ for any $s \in]\!]c,b]\!]$. Since z is causal, we have

$$\langle \alpha(x,t)\dot{x},\dot{x}\rangle + 2\langle \delta(x,t),\dot{x}\rangle\dot{t} \leqslant \beta(x,t)\dot{t}^2. \tag{13}$$

Moreover as z is future-pointing, $\dot{t}(s) \neq 0$ on $]\!]c,b[\![$, thus $t(s)$ is strictly monotone on $]\!]c,b[\![$. Since $\omega(z(s))$ is a linear form on $T_{z(s)}M$, it results that

$$|\omega(z(s))[\dot{z}(s)]| \leqslant C(z(s))\sqrt{\langle \alpha(x(s),t(s))\dot{x}(s),\dot{x}(s)\rangle + \beta(x(s),t(s))\dot{t}(s)^2},$$

for any $s \in]\!]c,b]\!]$. But the field $\omega(z(s))$ is continuous on $]\!]c,b]\!]$, so the positive function $C(z(s))$ is uniformly bounded on $]\!]c,b]\!]$. Thus, by (13), we have

$$\int_c^d |\omega(z)[\dot{z}]|\mathrm{d}s \leqslant C_1\int_c^d \sqrt{\langle \alpha(x,t)\dot{x},\dot{x}\rangle + \beta(x,t)\dot{t}^2}\mathrm{d}s \leqslant C_2\int_c^d |\dot{t}|\mathrm{d}s = \pm C(t(d)-t(c)).$$

Passing to the limit as $d \to b^-$, we conclude that $|\omega(z)[\dot{z}]|$ is integrable on $]\!]c,b]\!]$. As

$$\lim_{d\to b^-}\int_c^d (\dot{y} - \omega(z)[\dot{z}])\mathrm{d}s \in \mathbb{R},$$

we conclude that

$$\lim_{d\to b^-} y(d) - y(c) = \lim_{d\to b^-}\int_c^d \dot{y}\mathrm{d}s \in \mathbb{R}.$$

Let $\overline{y}=\lim_{d\to b^-} y(d)$. Clearly the point $(p,\overline{y}) \in \boldsymbol{M}$ is a future end point for $\boldsymbol{z}$ corresponding to $s=b$. This fact yields the desired contradiction. Now assume that an inextendible smooth future-pointing causal curve $\boldsymbol{z}$ meets $\boldsymbol{S}$ at least twice. So the maximal causal future-pointing extension of $z(s)=\pi_M(\boldsymbol{z}(s))$ meets S at least two times. This contradiction concludes the proof. □

III. PROOF OF THEOREM 1

Let us consider the set $\mathcal{T}_{p_0,p_1}$ of the smooth future-pointing timelike curves $z:]\!]0,1]\!] \to M$ on (M,g), such that $z(0)=p_0$ and $z(1)=p_1$.

Lemma 7: Let (M,g) be globally hyperbolic and $p_0 \leqslant p_1$. Then

$$\sup_{z\in\mathcal{T}_{p_0,p_1}}\int_0^1 |\omega(z)[\dot{z}]|\mathrm{d}s < +\infty. \tag{14}$$

Proof: Denote by D the quantity $\sup_{z\in\mathcal{T}_{p_0,p_1}}\int_0^1|\omega(z)[\dot{z}]|\mathrm{d}s$ and let $\{z_n\}_{n\in\mathbb{N}} \subset \mathcal{T}_{p_0,p_1}$ be a sequence such that

$$\int_0^1 |\omega(z_n)[\dot{z}_n]|\mathrm{d}s \to D.$$

Since (M,g) is globally hyperbolic, we can extract a subsequence, denoted by z_n too, such that z_n converges to a continuous curve $z:[\![0,1]\!]\to M$ in the C^0 topology of curves (see Ref. 2, Corollary 3.32 and Proposition 3.34). Cover z by a finite number of coordinate neighborhoods $\{U_k\}_{1\leqslant k\leqslant m}$ of the same type as in the proof of Proposition 6. So $U_k=\Sigma_k\times]\!]a_k,b_k[\![$. Let $\Delta=\max_{1\leqslant k\leqslant m}(b_k-a_k)$. In the coordinate system $x_k=(x_{1k},x_{2k},x_{3k})\in\Sigma_k$ and $t_k\in]\!]a_k,b_k[\![$, the metric g is given by

$$g(x_k,t_k)[(\xi,\tau),(\xi,\tau)]=\langle\alpha_k(x_k,t_k)\xi,\xi\rangle_k+2\langle\delta_k(x_k,t_k),\xi\rangle_k\tau-\beta_k(x_k,t_k)\tau^2,$$

for any $(\xi,\tau)\in T_{x_k}\Sigma_k\times\mathbb{R}$. Consider a partition $\{[\![s_{k-1},s_k]\!]\}_{1\leqslant k\leqslant m}$, $s_0=0<s_1<\cdots<s_m=1$, of the interval $[\![0,1]\!]$, such that $z([\![s_{k-1},s_k]\!])\subset U_k$. As z_n converges to z in the C^0 topology of curves, it results definitively, up to reparametrize the curves z_n, $z_n([\![s_{k-1},s_k]\!])\subset U_k$. Now arguing as in Proposition 6, we have

$$\langle\alpha_k(x_{nk},t_{nk})\dot{x}_{nk},\dot{x}_{nk}\rangle_k+2\langle\delta_k(x_{nk},t_{nk}),\dot{x}_{nk}\rangle_k\dot{t}_{nk}<\beta_k(x_{nk},t_{nk})\dot{t}_{nk}^2;$$

furthermore $\dot{t}_{nk}(s)\neq 0$ on $[\![s_{k-1},s_k]\!]$ and

$$\begin{aligned}\int_0^1|\omega(z_n(s))[\dot{z}_n(s)]|\mathrm{d}s&=\sum_{k=1}^m\int_{s_{k-1}}^{s_k}|\omega(z_{nk}(s))[\dot{z}_{nk}(s)]|\mathrm{d}s\\&\leqslant C\sum_{k=1}^m\int_{s_{k-1}}^{s_k}\sqrt{\langle\alpha_k(x_{nk},t_{nk})\dot{x}_{nk},\dot{x}_{nk}\rangle_k+\beta_k(x_{nk},t_{nk})\dot{t}_2^{nk}}\mathrm{d}s\\&\leqslant C\sum_{k=1}^m\int_{s_{k-1}}^{s_k}|\dot{t}_{nk}|\mathrm{d}s\leqslant Cm\Delta.\end{aligned}$$

Passing to the limit on n, we conclude. □

Proof of Theorem 1: We begin by considering the case $q>0$. Since $p_0\ll p_1$, there exists a smooth future-pointing timelike curve $z:[\![0,1]\!]\to M$ on (M,g), such that $z(0)=p_0$ and $z(1)=p_1$. So consider the curve $\boldsymbol{z}:[\![0,1]\!]\to\boldsymbol{M}$ defined as $\boldsymbol{z}(s)=(z(s),-\int_0^s\omega(z)[\dot{z}]\mathrm{d}s)$. Clearly $\boldsymbol{z}(0)=(p_0,0)$, $\boldsymbol{z}(1)=(p_1,-\int_0^1\omega(z)[\dot{z}]\mathrm{d}s)$, $\boldsymbol{z}$ is a future-pointing timelike curve on $(\boldsymbol{M},\boldsymbol{k})$, and the points $(p_0,0)$ and $(p_1,-\int_0^1\omega(z)[\dot{z}]\mathrm{d}s)$ are chronologically related on $(\boldsymbol{M},\boldsymbol{k})$. Thus set

$$\upsilon_1=\sup_{z\in\mathcal{T}_{p_0,p_1}}\left(-\int_0^1\omega(z)[\dot{z}]\mathrm{d}s\right).$$

Let $\varepsilon>0$ and consider the points $(p_0,-\varepsilon)$ $(p_1,\upsilon_1-\varepsilon/2)$. Since the relation $\ll$ is open, $(p_0,-\varepsilon)\ll(p_1,\upsilon_1-\varepsilon/2)$ for ε small enough. Hence there exists a 5-D future-pointing timelike geodesic $\boldsymbol{\gamma_1}$ connecting $(p_0,-\varepsilon)$ and $(p_1,\upsilon_1-\varepsilon/2)$. Let $q_1=\boldsymbol{k}(\boldsymbol{\gamma_1})[\dot{\boldsymbol{\gamma}}_{\boldsymbol{1}},\partial_y]$. It results that $q_1=\dot{y}_1+\omega(\gamma_1)[\dot{\gamma}_1]$, with $y_1=\pi_{\mathbb{R}}(\boldsymbol{\gamma_1})$ and $\gamma_1=\pi_{\boldsymbol{M}}(\boldsymbol{\gamma_1})\in\mathcal{T}_{p_0,p_1}$. Therefore

$$q_1=y_1(1)-y_1(0)+\int_0^1\omega(\gamma_1)[\dot{\gamma}_1]\mathrm{d}s=\upsilon_1-\frac{\varepsilon}{2}+\varepsilon+\int_0^1\omega(\gamma_1)[\dot{\gamma}_1]\mathrm{d}s\geqslant\frac{\varepsilon}{2}>0.$$

As $q_1=\dot{y}_1+\omega(\gamma_1)[\dot{\gamma}_1]>0$, we can conclude, by (6), that γ_1 is not a 4-D geodesic. Then consider the curve c_1, defined on $[\![0,q_1/q]\!]$ as $c_1(s)=\gamma_1(q/q_1s)$. Clearly c_1 connects p_0 and p_1, is timelike, future-pointing and solves Eq. (2).

Now assume that $q<0$. Arguing as above, we find a 5-D future-pointing timelike geodesic $\boldsymbol{\gamma_2}$ connecting (p_0,ε) and $(p_1,\upsilon_2+\varepsilon/2)$, where now

$$\upsilon_2 = \inf_{z \in \mathcal{T}_{p_0,p_1}} \left(- \int_0^1 \omega(z)[\dot{z}]ds \right).$$

Now it results that $q_2 = \dot{y}_2 + \omega(\gamma_2)[\dot{\gamma}_2] \leqslant -\varepsilon/2 < 0$. So $c_2 = \gamma_2((q/q_2)s)$ is the desired solution. □

Covariants, joint invariants and the problem of equivalence in the invariant theory of Killing tensors defined in pseudo-Riemannian spaces of constant curvature

Roman G. Smirnov[a] and Jin Yue[b]
Department of Mathematics and Statistics, Dalhousie University, Halifax, Nova Scotia, Canada B3H 3J5

(Received 2 June 2004; accepted 3 August 2004; published 25 October 2004)

The invariant theory of Killing tensors (ITKT) is extended by introducing the new concepts of covariants and joint invariants of (product) vector spaces of Killing tensors defined in pseudo-Riemannian spaces of constant curvature. The covariants are employed to solve the problem of classification of the orthogonal coordinate webs generated by nontrivial Killing tensors of valence two defined in the Euclidean and Minkowski planes. Illustrative examples are provided. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1805728]

I. INTRODUCTION

The second half of the 19th century saw the development of the post-"Theorema Egregium of Gauss" differential geometry going in two major directions. Thus, Riemann[1] generalized Gauss's geometry of surfaces in the Euclidean space by introducing the concept of a differentiable manifold of arbitrary dimension and defining the inner product in terms of the metric tensor on the spaces of tangent vectors. This remarkable work has evolved in time into what is known today as (Riemannian) differential geometry. The other direction originated in the celebrated "Erlangen Program" of Klein.[2,3] According to his manifesto any branch of geometry can be interpreted as an invariant theory with respect to a specific transformation group. Moreover, the main goal of any geometry is the determination of those properties of geometrical figures that remain unchanged under the action of a transformation group. One of the main contributions of Cartan to differential geometry, in particular with his moving frames method,[4] is the blending of these two directions into a single theory. An excellent exposition of this fact can be found in Sharpe[5] (see also, for example, Arvanitoyeorgos[6]). The following diagram presented in Ref. 5 elucidates the relationship among the different approaches to geometry described above:

$$\begin{array}{ccc} \text{Euclidean Geometry} & \overset{\text{generalization}}{\longrightarrow} & \text{Klein Geometries} \\ \downarrow\text{generalization} & & \text{generalization}\downarrow \\ \text{Riemannian Geometry} & \overset{\text{generalization}}{\longrightarrow} & \text{Cartan Geometries} \end{array} \tag{1}$$

Being a result of the natural fusion of classical invariant theory (CIT) and the (geometric) study of Killing tensors defined in pseudo-Riemannian manifolds of constant curvature, the invariant theory of Killing tensors (ITKT) formed recently a new direction of research,[7–16] which, in view of the above, can be rightfully placed into the theory initiated by Cartan. This is especially

[a]Electronic mail: smirnov@mathstat.dal.ca
[b]Electronic mail: jyue@dal.ca

evident in the study of vector spaces of Killing tensors of valence two. Indeed, by now a number of vector spaces of Killing tensors have been investigated from this viewpoint by means of determining the corresponding sets of fundamental *invariants* and, much like in CIT, using them to solve the problem of equivalence in each case. These results have been employed in applications arising in the *theory of orthogonal coordinate webs*,[17–25,16,12,7] where Killing tensors of valence two play a pivotal role (see Ref. 22 for a complete list of references). Admittedly, an orthogonal coordinate web is an integral part of the geometry of the underlying pseudo-Riemmanian manifold. Therefore the problem of group invariant classification of orthogonal coordinate webs in a specific pseudo-Riemannian space of constant curvature is a problem of Klein's approach to geometry, as well as that of Riemann, both leading to the theory due to Cartan [see the diagram (1)].

The main goal of this paper is to further the development of the invariant theory of Killing tensors by introducing the concepts of a *covariant* and a *joint invariant*. In this setting they can be introduced by establishing a natural extension of the main ideas of CIT to the geometric study of Killing tensors in pseudo-Riemannian geometry. Furthermore, we employ the latest generalization of Cartan's method of moving frames due to Fels and Olver[26,27] (see also Refs. 4 and 28–32 for more details and references) to determine complete systems of fundamental covariants for the vector spaces of Killing tensors of valence two defined in the Euclidean and Minkowski planes. The covariants are employed to classify in both cases orthogonal coordinate webs generated by Killing tensors. We also compare the results with the classifications of the orthogonal webs defined in the Minkowski plane obtained in McLenaghan *et al.*[12,15] by means of invariants only.

II. INVARIANT THEORY OF KILLING TENSORS (ITKT)

In this section we establish the requisite language and recall the basic notions of the invariant theory of Killing tensors (ITKT) defined in pseudo-Riemannian spaces of constant curvature. More specifically, we review what is known about isometry group invariants and extend the theory by introducing the concepts of *covariants* and *joint invariants* of product vector spaces of Killing tensors in ITKT. Let $(M,\mathbf{g})$ be a pseudo-Riemannian manifold, dim $M=n$.

Definition 2.1: A Killing tensor $\mathbf{K}$ of valence p defined in $(M,\mathbf{g})$ *is a symmetric* $(p,0)$ *tensor satisfying the Killing tensor equation,*

$$[\mathbf{K},\mathbf{g}]=0, \tag{2}$$

where $[,]$ *denotes the Schouten bracket.*[33] *When* $p=1$, $\mathbf{K}$ *is said to be a* Killing vector (infinitesimal isometry) *and the equation (2) reads*

$$\mathcal{L}_{\mathbf{K}}\mathbf{g}=0,$$

where $\mathcal{L}$ *denotes the Lie derivative operator.*

Remark 2.1: Throughout this paper, unless otherwise specified, $[,]$ denotes the Schouten bracket, which is a generalization of the usual Lie bracket of vector fields.

Killing tensors appear naturally in many problems of classical mechanics, general relativity, field theory, and other areas. To demonstrate this fact, let us consider the following example.

Example 2.1: Let $(\mathbf{X}_H,\mathbf{P}_0,H)$ be a Hamiltonian system defined on $(M,\mathbf{g})$ by a natural Hamiltonian H of the form

$$H(\mathbf{q},\mathbf{p})=\tfrac{1}{2}g^{ij}p_ip_j+V(\mathbf{q}),\quad i,j=1,\ldots,n, \tag{3}$$

where g^{ij} are the contravariant components of the corresponding metric tensor $\mathbf{g}$, $(\mathbf{q},\mathbf{p})\in T^*M$ are the canonical position-momenta coordinates and the Hamiltonian vector field $\mathbf{X}_H$ is given by

$$\mathbf{X}_H = [\mathbf{P}_0, H] \tag{4}$$

with respect to the canonical Poisson bi-vector $\mathbf{P}_0 = \Sigma_{i=1}^{n} \partial/\partial q^i \wedge \partial/\partial p_i$. Assume also that the Hamiltonian system defined by (3) admits a first integral of motion F which is a polynomial function of degree m in the momenta:

$$F(\mathbf{q},\mathbf{p}) = K^{i_1 i_2 \cdots i_m}(\mathbf{q}) p_{i_1} p_{i_2} \cdots p_{i_m} + U(\mathbf{q}), \tag{5}$$

where $1 \leqslant i_1, \ldots, i_m \leqslant n$. Since the functions H and F are in involution, the vanishing of the Poisson bracket defined by $\mathbf{P}_0$:

$$\{H,F\}_0 = \mathbf{P}_0 \,\mathrm{d}\, H \,\mathrm{d}\, F = [[\mathbf{P}_0, H], F] = 0 \tag{6}$$

yields

$$[\mathbf{K}, \mathbf{g}] = 0 \quad \text{(Killing tensor equation)} \tag{7}$$

and

$$K^{i_1 i_2 \cdots i_m} \frac{\partial V}{\partial q^{i_1}} p_{i_2} \cdots p_{i_m} = g^{ij} \frac{\partial U}{\partial q^i} p_j \quad \text{(compatibility condition)}, \tag{8}$$

where the symmetric $(m,0)$-tensor $\mathbf{K}$ has the components $K^{i_1 i_2 \cdots i_m}$ and $1 \leqslant i, j, i_1, \ldots, i_m \leqslant n$. Clearly, in view of Definition 2.1 the equation (7) confirms that $\mathbf{K}$ is a Killing tensor. Furthermore, in the case $m=2$ (see Benenti[22]) the compatibility condition (8) reduces to $\mathbf{K} \,\mathrm{d}\, V = \mathbf{g} \,\mathrm{d}\, U$ or $\mathrm{d}(\hat{\mathbf{K}} \,\mathrm{d}\, V) = 0$, where the (1,1)-tensor $\hat{\mathbf{K}}$ is given by $\hat{\mathbf{K}} = \mathbf{K}\mathbf{g}^{-1}$. We also note that the vanishing of the Poisson bracket (6) and the assumed form of the first integral F (5) imply the following additional conditions:

$$\partial_i U = 0, \quad K^{i_1 i_2 \cdots i_m} \partial_{i_1} V = 0.$$

Indeed, the right-hand side (RHS) of (5) does not have the terms which are polynomials of $\mathbf{p}$ of degrees less than m.

In view of linear properties of the Schouten bracket the sets of Killing tensors of the same valence form vector spaces in $(M,\mathbf{g})$. Let $\mathcal{K}^p(M)$ denote the vector space of Killing tensors of valence $p \geqslant 1$ defined in $(M,\mathbf{g})$. Assume also $\dim M = n$. Then if $(M,\mathbf{g})$ is a pseudo-Riemannian space of constant curvature, the dimension d of the corresponding vector space $\mathcal{K}^p(M)$ for a given $p \geqslant 1$ is determined by the *Delong–Takeuchi–Thompson (DTT) formula*,[34–36]

$$d = \dim \mathcal{K}^p(M) = \frac{1}{n}\binom{n+p}{p+1}\binom{n+p-1}{p}, \quad p \geqslant 1. \tag{9}$$

That being the case, a Killing tensor of valence $p \geqslant 1$ defined in a pseudo-Riemannian space $(M,\mathbf{g})$ of constant curvature can be viewed as an algebraic object, or, an element of $\mathcal{K}^p(M)$. Note the vector space $\mathcal{K}^p(M)$ for a fixed $p \geqslant 1$ is determined by d arbitrary parameters $(\alpha_1, \ldots, \alpha_d)$, where $d = \dim \mathcal{K}^p(M)$ is given by (9). This approach to the study of Killing tensors introduced in Ref. 15 differs significantly from the more conventional approach based on the property that Killing tensors defined in pseudo-Riemannian spaces of constant curvature are sums of symmetrized tensor products of Killing vectors (see, for example, Ref. 36). Moreover, the idea leads to a natural link between the study of vector spaces of Killing tensors and the classical theory of invariants of vector spaces of homogeneous polynomials, which has become in the last decade a growth industry once again (see Olver[39] and the references therein). Thus, it has been shown in a series of recent papers[11,16,10,12–15] that one can utilize the basic ideas of classical invariant theory in the study of Killing tensors defined in pseudo-Riemannian spaces of constant curvature. The concept of an *invariant* of $\mathcal{K}^p(M)$ was introduced in Ref. 16 in the study of nontrivial Killing tensors of the vector space $\mathcal{K}^2(\mathbb{R}^2)$ generating orthogonal coordinate webs in the Euclidean plane.

A. Invariants

It has been shown that one can determine the action of the isometry group $I(M)$ in the d-dimensional space $\Sigma \simeq \mathbb{R}^d$ defined by the parameters $\alpha_1, \ldots, \alpha_d$. In this view, the action is induced by the corresponding action of $I(M)$ in $\mathcal{K}^p(M)$, which, in turn, is induced by the action of $I(M)$ in M. More specifically, it induces the corresponding transformation laws for the parameters $(\alpha_1, \ldots, \alpha_d)$ given by

$$\begin{aligned} \tilde{\alpha}_1 &= \tilde{\alpha}_1(\alpha_1, \ldots, \alpha_d, g_1, \ldots, g_r), \\ \tilde{\alpha}_2 &= \tilde{\alpha}_2(\alpha_1, \ldots, \alpha_d, g_1, \ldots, g_r), \\ &\vdots \\ \tilde{\alpha}_d &= \tilde{\alpha}_d(\alpha_1, \ldots, \alpha_d, g_1, \ldots, g_r), \end{aligned} \tag{10}$$

where $g_1, \ldots, g_r$ are local coordinates on $I(M)$ that parametrize the group and $r = \dim I(M) = \frac{1}{2}n(n+1)$. The formulas (10) can be obtained in each case by making use of the standard transformation rules for tensor components. We note that the action of $I(M)$ can be considered in the spaces M and Σ concurrently, provided there is an isomorphism between the corresponding group actions (see below).

Definition 2.2: Let $(M, \mathbf{g})$ *be a pseudo-Riemannian manifold of constant curvature. For a fixed* $p \geqslant 1$ *consider the corresponding space* $\mathcal{K}^p(M)$ *of Killing tensors of valence p defined in* $(M, \mathbf{g})$. *A smooth function* $\mathcal{I}: \Sigma \to \mathbb{R}$ *defined in the space of functions on the parameter space* Σ *is said to be an* $I(M)$ invariant of the vector space $\mathcal{K}^p(M)$ *iff it satisfies the condition*

$$\mathcal{I} = F(\alpha_1, \ldots, \alpha_d) = F(\tilde{\alpha}_1, \ldots, \tilde{\alpha}_d) \tag{11}$$

under the transformation laws (10) induced by the isometry group $I(M)$.

The main problem of invariant theory is to describe the whole space of invariants (covariants, joint invariants) for a given vector space under the action of a group. To solve this problem one has to find a set of *fundamental invariants (covariants, joint invariants)* with the property that any other invariant (covariant, joint invariant) is a (analytic) function of the fundamental invariants (covariants, joint invariants). The fundamental theorem on invariants of a regular Lie group action[39] determines the number of fundamental invariants required to define the whole of the space of $I(M)$ invariants.

Theorem 2.1: *Let G be a Lie group acting regularly on an m-dimensional manifold X with s-dimensional orbits. Then, in a neighborhood N of each point* $x_0 \in X$, *there exist* $m-s$ *functionally independent G invariants* $\Delta_1, \ldots, \Delta_{m-s}$. *Any other G-invariant* $\mathcal{I}$ *defined near* x_0 *can be locally uniquely expressed as an analytic function of the fundamental invariants through* $\mathcal{I} = F(\Delta_1, \ldots, \Delta_{m-s})$.

Hence, if we assume that the group $I(M), \dim I(M) = r = \frac{1}{2}n(n+1)$ acts in a subspace Σ_r of the parameter space Σ defined by the corresponding $\mathcal{K}^p(M)$, $p \geqslant 1$ regularly with r-dimensional orbits, then, according to Theorem 2.1, the number of fundamental invariants required to describe the whole space of $I(M)$ invariants of $\mathcal{K}^p(M)$ is $d-r$, where d is given by (9) (note $d \geqslant r$). This has been shown to be the case for the vector spaces $\mathcal{K}^2(\mathbb{R}^2)$,[16] $\mathcal{K}^2(\mathbb{R}^2_1)$,[12] $\mathcal{K}^3(\mathbb{R}^2)$,[10] and $\mathcal{K}^2(\mathbb{R}^3)$,[7] where $\mathbb{R}^2, \mathbb{R}^2_1$, and $\mathbb{R}^3$ denote the Euclidean, Minkowski planes and the Euclidean space, respectively. The dimension of the orbits of the isometry group $I(M)$ acting in Σ is not always the same as the dimension of the group. For example, this is the case for the vector space $\mathcal{K}^1(\mathbb{R}^3)$.[11] To determine the dimension of the orbits one can use the infinitesimal generators of the group $I(M)$ in Σ.

In what follows we use the approach introduced in Ref. 15. Let $\mathbf{X}_1, \ldots, \mathbf{X}_r \in \mathcal{X}(M)$ be the infinitesimal generators (Killing vector fields) of the Lie group $I(M)$ acting on M. Note $\mathrm{Span}\{\mathbf{X}_1, \ldots, \mathbf{X}_r\} = \mathcal{K}^1(M) = i(M)$, where $i(M)$ is the Lie algebra of the Lie group $I(M)$. For a fixed $p \geqslant 1$, consider the corresponding vector space $\mathcal{K}^p(M)$. To determine the action of $I(M)$ in the

space Σ, we find first the infinitesimal generators of $I(M)$ in Σ. Consider Diff Σ, it defines the corresponding space Diff $\mathcal{K}^p(M)$, whose elements are determined by the elements of Diff Σ in an obvious way. Let $\mathbf{K}^0 \in \text{Diff}\,\mathcal{K}^p(M)$. Note $\mathbf{K}^0$ is determined by d parameters $\alpha_i^0(\alpha_1,\ldots,\alpha_d)$, $i=1,\ldots,d$, which are functions of $\alpha_1,\ldots,\alpha_d$—the parameters of Σ. Define now a map $\pi:\text{Diff}\,\mathcal{K}^p(M)\to\mathcal{X}(\Sigma)$, given by

$$\mathbf{K}^0 \to \sum_{i=1}^{d} \alpha_i^0(\alpha_1,\ldots,\alpha_d)\frac{\partial}{\partial\,\alpha_i}. \tag{12}$$

To specify the action of $I(M)$ in Σ, we must find the counterparts of the generators $\mathbf{X}_1,\ldots,\mathbf{X}_r$ in $\mathcal{X}(\Sigma)$. Consider the composition $\pi\circ\mathcal{L}$, where π is defined by (12) and $\mathcal{L}$ is the Lie derivative operator. Let $\mathbf{K}$ be the general Killing tensor of $\mathcal{K}^p(M)$, in other words $\mathbf{K}$ is the general solution to the Killing tensor equation (2). Note, for $p=2$ we have $\mathbf{K}=\text{Span}\{\mathbf{g},\mathbf{K}_1,\ldots,\mathbf{K}_{d-1}\}$, where $\{\mathbf{g},\mathbf{K}_1,\ldots,\mathbf{K}_{d-1}\}$ is a basis of the vector space $\mathcal{K}^2(M)$ and $\mathbf{g}$ is the metric of $(M,\mathbf{g})$. Next, define

$$\mathbf{V}_i = \pi\mathcal{L}_{\mathbf{X}_i}\mathbf{K}, \quad i=1,\ldots,r. \tag{13}$$

The composition map $\pi\circ\mathcal{L}:i(M)\to\mathcal{X}(\Sigma)$ maps the generators $\mathbf{X}_1,\ldots,\mathbf{X}_r$ to $\mathcal{X}(\Sigma)$.

Conjecture 2.1 (Ref. 10): Suppose the generators $\mathbf{X}_1,\ldots,\mathbf{X}_r$ of $i(M)$ satisfy the following commutator relations:

$$[\mathbf{X}_i,\mathbf{X}_j] = c_{ij}^k\mathbf{X}_k, \quad i,j,k=1,\ldots,r, \tag{14}$$

where c_{ij}^k, $i,j,k=1,\ldots,r$ are the structural constants. Then the corresponding vector fields $\mathbf{V}_i \in \mathcal{X}(\Sigma)$, defined by (13) satisfy the same commutator relations,

$$[\mathbf{V}_i,\mathbf{V}_j] = c_{ij}^k\mathbf{V}_k, \quad i,j,k=1,\ldots,r. \tag{15}$$

Therefore the map $F_* := \pi\circ\mathcal{L}:i(M)\to i_\Sigma(M)$ is a Lie algebra isomorphism, where $i_\Sigma(M)$ is the Lie algebra generated by $\mathbf{V}_1,\ldots,\mathbf{V}_r$.

We emphasize that the technique of the Lie derivative deformations used here is a very powerful tool. It was used before, for example, in Ref. 37 to generate compatible Poisson bivectors in the theory of bi-Hamiltonian systems. The idea introduced in Ref. 37 was utilized in Ref. 38 and applied to a different class of integrable systems. The validity of the formula (15) can be confirmed directly on a case by case basis, provided that the general form of a Killing tensor $\mathbf{K}^p \in \mathcal{K}^p(M)$ is available. The proof of the general statement of Conjecture 2.1 will be published elsewhere.[8]

Remark 2.2: Alternatively, the generators (13) can be obtained from the formulas for the action of the group (10) in the usual way taking into account that a Lie algebra is the tangent space at the unity of the corresponding Lie group. We note, however, that in this way the formulas (10) are not easy to derive in general.

In view of the isomorphism exhibited in the conjecture and the fact that invariance of a function under an entire Lie group is equivalent to the infinitesimal invariance under the infinitesimal generators of the corresponding Lie algebra one can determine a set of fundamental invariants by solving the system of PDEs

$$\mathbf{V}_i(F) = 0, \quad i=1,\ldots,r \tag{16}$$

for an analytic function $F:\Sigma\to\mathbb{R}$, where the vector fields $\mathbf{V}_i$, $i=1,\ldots,r$ are the generators defined by (13). As is specified by Theorem 2.1, the general solution to the system (16) is an analytic function F of the fundamental invariants. The number of fundamental invariants is $d-s$, where d is specified by the DTT formula (9) and s is the dimension of the orbits of $I(M)$ acting regularly in the parameter space Σ. To determine s and the subspaces of Σ where the isometry group acts with orbits of the same dimension, one employs the result of the following proposition.[39]

Proposition 2.1: *Let a Lie group G act on X, $\mathfrak{g}$ is the corresponding Lie algebra and let $x \in X$. The vector space $S|_x = \mathrm{Span}\{\mathbf{V}_i(x) \,|\, \mathbf{V_i} \in \mathfrak{g}\}$ spanned by all vector fields determined by the infinitesimal generators at x coincides with the tangent space to the orbit $\mathcal{O}_x$ of G that passes through x, so $S|_x = T\mathcal{O}_x|_x$. In particular, the dimension of $\mathcal{O}_x$ equals the dimension of $S|_x$. Moreover, the isotropy subgroup $G_x \subset G$ has dimension* $\dim G - \dim \mathcal{O}_x = r - s$.

Example 2.2: Consider the action of the isometry group $I(\mathbb{R}^2_1)$ on the vector space $\mathcal{K}^2(\mathbb{R}^2_1)$. More information about the geometry of Minkowski plane $\mathbb{R}^2_1$ can be found in the monograph by Thompson.[40] The general form of the elements of $\mathcal{K}^2(\mathbb{R}^2_1)$ in terms of the standard pseudo-Cartesian coordinates (t,x) is given by

$$\mathbf{K} = (\alpha_1 + 2\alpha_4 x + \alpha_6 x^2)\frac{\partial}{\partial t} \odot \frac{\partial}{\partial t} + (\alpha_3 + \alpha_4 t + \alpha_5 x + \alpha_6 t x)\frac{\partial}{\partial t} \odot \frac{\partial}{\partial x} + (\alpha_2 + 2\alpha_5 t + \alpha_6 t^2)\frac{\partial}{\partial x} \odot \frac{\partial}{\partial x}. \tag{17}$$

The isometry group $I(\mathbb{R}^2_1)$ acts in the Minkowski plane $\mathbb{R}^2_1$ parametrized by (t,x) as follows:

$$\begin{pmatrix} \tilde{t} \\ \tilde{x} \end{pmatrix} = \begin{pmatrix} \cosh\phi & \sinh\phi \\ \sinh\phi & \cosh\phi \end{pmatrix}\begin{pmatrix} t \\ x \end{pmatrix} + \begin{pmatrix} a \\ b \end{pmatrix}, \tag{18}$$

where $\phi, a, b \in \mathbb{R}$ are local coordinates that parametrize the group $I(\mathbb{R}^2_1)$. The generators of the Lie algebra $i(\mathbb{R}^2_1)$ of the isometry group with respect to the coordinates (t,x) take the following form:

$$\mathbf{T} = \frac{\partial}{\partial t}, \quad \mathbf{X} = \frac{\partial}{\partial x}, \quad \mathbf{H} = x\frac{\partial}{\partial t} + t\frac{\partial}{\partial x} \tag{19}$$

corresponding to t and x translations and (hyperbolic) rotation, given with respect to the standard pseudo-Cartesian coordinates (t,x). Note the generators (19) of the Lie algebra $i(\mathbb{R}^2_1)$ enjoy the following commutator relations:

$$[\mathbf{T},\mathbf{X}] = 0, \quad [\mathbf{T},\mathbf{H}] = \mathbf{X}, \quad [\mathbf{X},\mathbf{H}] = \mathbf{T}. \tag{20}$$

We use the formula (18) and the transformation laws for the components of (2, 0) tensors

$$\tilde{K}^{ij}(\tilde{y}^1,\tilde{y}^2,\tilde{\alpha}_1,\ldots,\tilde{\alpha}_6) = K^{k\ell}(y^1,y^2,\alpha_1,\ldots,\alpha_6)\frac{\partial \tilde{y}^i}{\partial y^k}\frac{\partial \tilde{y}^j}{\partial y^\ell}, \quad i,j,k,\ell = 1,2, \tag{21}$$

where the tensor components K^{ij} are given by (17), $y^1 = t, y^2 = x$. In view of (17), (18), and (21) the transformation laws (10) for the parameters α_i, $i = 1,\ldots,6$ take in this case the following form (see also Refs. 23 and 12),

$$\begin{aligned}
\tilde{\alpha}_1 &= \alpha_1 \cosh^2\phi + 2\alpha_3 \cosh\phi \sinh\phi + \alpha_2 \sinh^2\phi + \alpha_6 b^2 - 2(\alpha_4 \cosh\phi + \alpha_5 \sinh\phi)b, \\
\tilde{\alpha}_2 &= \alpha_1 \sinh^2\phi + 2\alpha_3 \cosh\phi \sinh\phi + \alpha_2 \cosh^2\phi + \alpha_6 a^2 - 2(\alpha_5 \cosh\phi + \alpha_4 \sinh\phi)a, \\
\tilde{\alpha}_3 &= \alpha_3(\cosh^2\phi + \sinh^2\phi) + (\alpha_1 + \alpha_2)\cosh\phi \sinh\phi - (a\alpha_4 + b\alpha_5)\cosh\phi \\
&\quad - (a\alpha_5 + b\alpha_4)\sinh\phi + \alpha_6 ab, \\
\tilde{\alpha}_4 &= \alpha_4 \cosh\phi + \alpha_5 \sinh\phi - \alpha_6 b, \\
\tilde{\alpha}_5 &= \alpha_4 \sinh\phi + \alpha_5 \cosh\phi - \alpha_6 a, \\
\tilde{\alpha}_6 &= \alpha_6.
\end{aligned} \tag{22}$$

We note that the corresponding transformation formulas for the parameters obtained in Ref. 12

were derived for *covariant* Killing tensors. Accordingly, they differ somewhat from (22) presented above [compare with (7.6) in Ref. 12]. According to Proposition 2.1, in order to determine the subspaces of Σ where the orbits have the same dimensions, one must check the subspaces of Σ where the system (16) retains its rank. In many cases the system of PDEs (16) can be solved by the method of characteristics. The determination of fundamental invariants by solving (16) is the key idea used in Ref. 15 to adapt the *method of infinitesimal generators* to the problem of finding fundamental invariants of Killing tensors under the action of the isometry group. When the method of characteristic fails, one can employ the *method of undetermined coefficients* to find a set of fundamental invariants.[11,7] Alternatively, a set of fundamental invariants can be determined by using the *method of moving frames* (see Sec. III for more details). To determine the space of $I(\mathbb{R}^2_1)$ invariants, we employ the procedure described above and derive the corresponding infinitesimal generators $\mathbf{V}_i$, $i=1, 2, 3$ by the formula (13),

$$\mathbf{V}_1 = \alpha_4\frac{\partial}{\partial\,\alpha_3} + 2\alpha_5\frac{\partial}{\partial\,\alpha_2} + \alpha_6\frac{\partial}{\partial\,\alpha_5},$$

$$\mathbf{V}_2 = \alpha_5\frac{\partial}{\partial\,\alpha_3} + 2\alpha_4\frac{\partial}{\partial\,\alpha_1} + \alpha_6\frac{\partial}{\partial\,\alpha_4}, \tag{23}$$

$$\mathbf{V}_3 = -2\alpha_3\frac{\partial}{\partial\,\alpha_1} - \alpha_5\frac{\partial}{\partial\,\alpha_4} - (\alpha_1+\alpha_2)\frac{\partial}{\partial\,\alpha_3} - 2\alpha_3\frac{\partial}{\partial\,\alpha_2} - \alpha_4\frac{\partial}{\partial\,\alpha_5},$$

and then solve by the method of characteristic the corresponding system of PDEs (16) with respect to (23). Note the vector fields $-\mathbf{V}_i$, $i=1, 2, 3$ satisfy the same commutator relations as (19) [see (20)], which confirms Conjecture 2.1. Ultimately, this leads to the following theorem.

Theorem 2.2: *Any algebraic $I(\mathbb{R}^2_1)$-invariant I of the subspace of the parameter space Σ of $\mathcal{K}^2(\mathbb{R}^2_1)$ defined by the condition that the vector fields (23) are linearly independent can be (locally) uniquely expressed as an analytic function,*

$$I = F(\mathcal{I}_1,\mathcal{I}_2,\mathcal{I}_3),$$

where the fundamental invariants $\mathcal{I}_i$, $i=1, 2, 3$ are given by

$$\mathcal{I}_1 = (\alpha_4^2+\alpha_5^2-\alpha_6(\alpha_1+\alpha_2))^2 - 4(\alpha_3\alpha_6-\alpha_4\alpha_5)^2,$$

$$\mathcal{I}_2 = \alpha_6(\alpha_1-\alpha_2) - \alpha_4^2 + \alpha_5^2, \tag{24}$$

$$\mathcal{I}_3 = \alpha_6.$$

The fact that $\mathcal{I}_3=\alpha_6$ is a fundamental $I(\mathbb{R}^2_1)$ invariant of the vector space $\mathcal{K}^2(\mathbb{R}^2_1)$ trivially follows from the transformation formulas (22). The fundamental $I(\mathbb{R}^2_1)$-invariant $\mathcal{I}_1$ was derived in Refs. 12 and 15 in the study of the five-dimensional subspace of nontrivial Killing tensors of $\mathcal{K}^2(\mathbb{R}^2_1)$. As expected, in this case by Theorem 2.1, we have obtained 6 (dimension of the space) -3 (dimension of the orbits) $=3$ fundamental $I(\mathbb{R}^2_1)$ invariants of the vector space $\mathcal{K}^2(\mathbb{R}^2_1)$.

B. Covariants

Consider now the action of the isometry group $I(M)$ on the product space $\mathcal{K}^p(M)\times M$, $p\geqslant 1$. As above it induces the transformation laws on the *extended parameter space* $\Sigma\times M$, where Σ is the parameter space of the vector space $\mathcal{K}^p(M)$,

$$\begin{gathered}\tilde{\alpha}_1 = \tilde{\alpha}_1(\alpha_1,\ldots,\alpha_d,g_1,\ldots,g_r),\\ \tilde{\alpha}_2 = \tilde{\alpha}_2(\alpha_1,\ldots,\alpha_d,g_1,\ldots,g_r), \quad \ldots,\\ \tilde{\alpha}_d = \tilde{\alpha}_d(\alpha_1,\ldots,\alpha_d,g_1,\ldots,g_r),\\ \tilde{x}_1 = \tilde{x}_1(x_1,\ldots,x_n,g_1,\ldots,g_r),\\ \tilde{x}_2 = \tilde{x}_2(x_1,\ldots,x_n,g_1,\ldots,g_r), \quad \ldots,\\ \tilde{x}_n = \tilde{x}_n(x_1,\ldots,x_n,g_1,\ldots,g_r),\end{gathered} \tag{25}$$

where as before $\alpha_1,\ldots,\alpha_d$ are the parameters of $\mathcal{K}^p(M)$ that define $\Sigma, g_1,\ldots,g_r$, $r=\frac{1}{2}n(n+1)$ are local parameters parametrizing the group $I(M)$ and $x_1,\ldots,x_n$ are local coordinates on the manifold M.

Definition 2.3: An $I(M)$ covariant of the vector space $\mathcal{K}^p(M)$ $p\geqslant 1$ is a function $C:\Sigma\times M\rightarrow\mathbb{R}$ satisfying the condition

$$C = F(\alpha_1,\ldots,\alpha_d,x_1,\ldots,x_n) = F(\tilde{\alpha}_1,\ldots,\tilde{\alpha}_d,\tilde{x}_1\ldots,\tilde{x}_n) \tag{26}$$

under the transformation laws (25) induced by the isometry group $I(M)$, where Σ is the parameter space of $\mathcal{K}^p(M)$.

Conjecture 2.1 entails the following corollary.

Corollary 2.1: Consider the product vector space $\mathcal{K}^p(M)\times M$, $p\geqslant 1$. Define the vector fields

$$\mathbf{V}_i' := \mathbf{V}_i + \mathbf{X}_i, \quad i=1,\ldots,r, \tag{27}$$

where $\mathbf{V}_i, i=1,\ldots,r$ are the infinitesimal generators of the Lie algebra $i(M)$ in the parameter space Σ of the vector space $\mathcal{K}^p(M)$ obtained via (13) and $\mathbf{X}_i, i=1,\ldots,r$ are the generators of $i(M)$. Then the vector fields $\mathbf{V}_1',\ldots,\mathbf{V}_r'$ enjoy the same commutator relations as the generators $\mathbf{X}_1,\ldots,\mathbf{X}_r$ of $i(M)$ in $\mathcal{X}(M)$:

$$[\mathbf{V}_i',\mathbf{V}_j'] = c_{ij}^k\mathbf{V}_k', \quad i,j,k=1,\ldots,r, \tag{28}$$

where the structural constants c_{ij}^k are as in (14).

Proof: Straightforward. □

Therefore, in view of the above, $I(M)$ covariants of a vector space $\mathcal{K}^p(M)$ can be obtained by solving the corresponding system of PDEs generated by the vector fields (27):

$$\mathbf{V}_i'(F) = 0, \quad i=1,\ldots,r. \tag{29}$$

Alternatively, one can employ the method of moving frames. To demonstrate how it works in the framework of ITKT we shall employ the method in Sec. III to compute the covariants of the vector spaces $\mathcal{K}^2(\mathbb{R}^2)$ and $\mathcal{K}^2(\mathbb{R}_1^2)$.

C. Joint invariants

Consider now the action of the isometry group $I(M)$ on the product space $\mathcal{K}^\ell(M)\times\mathcal{K}^m(M)\times\cdots\times\mathcal{K}^q(M)$, $\ell,m,\ldots,q\geqslant 1$. Let $\alpha_1,\ldots,\alpha_d,\beta_1,\ldots,\beta_e,\ldots,\gamma_1,\ldots,\gamma_f$ be the parameters of the vector spaces $\mathcal{K}^\ell(M),\mathcal{K}^m(M),\ldots,\mathcal{K}^q(M)$, respectively, where $d,e,\ldots,f$ are the corresponding dimensions determined by (9). Then the action of the isometry group $I(M)$ induces the corresponding transformation laws for the parameters $\alpha_1,\ldots,\alpha_d,\beta_1,\ldots,\beta_e,\ldots,\gamma_1,\ldots,\gamma_f$:

$$\tilde{\alpha}_1 = \tilde{\alpha}_1(\alpha_1,\ldots,\alpha_d,g_1,\ldots,g_r),$$

$$\tilde{\alpha}_2 = \tilde{\alpha}_2(\alpha_1,\ldots,\alpha_d,g_1,\ldots,g_r), \quad \ldots,$$

$$\tilde{\alpha}_d = \tilde{\alpha}_d(\alpha_1,\ldots,\alpha_d,g_1,\ldots,g_r), \quad \ldots,$$

$$\tilde{\beta}_1 = \tilde{\beta}_1(\beta_1,\ldots,\beta_e,g_1,\ldots,g_r), \quad \ldots,$$

$$\tilde{\beta}_2 = \tilde{\beta}_2(\beta_1,\ldots,\beta_e,g_1,\ldots,g_r), \quad \ldots, \tag{30}$$

$$\tilde{\beta}_e = \tilde{\beta}_e(\beta_1,\ldots,\beta_e,g_1,\ldots,g_r), \quad \ldots,$$

$$\tilde{\gamma}_1 = \tilde{\gamma}_1(\gamma_1,\ldots,\gamma_f,g_1,\ldots,g_r),$$

$$\tilde{\gamma}_2 = \tilde{\gamma}_2(\gamma_1,\ldots,\gamma_f,g_1,\ldots,g_r), \quad \ldots,$$

$$\tilde{\gamma}_f = \tilde{\gamma}_f(\gamma_1,\ldots,\gamma_f,g_1,\ldots,g_r),$$

where as before $g_1,\ldots,g_r$ are local coordinates on $I(M)$ that parametrize the group and $r = \dim I(M) = \frac{1}{2}n(n+1)$. This observation leads us to introduce the concept of a *joint $I(M)$-invariant*.

Definition 2.4: *A* joint $I(M)$ invariant *of the product space $\mathcal{K}^\ell(M)\times\mathcal{K}^m(M)\times\cdots\times\mathcal{K}^q(M)$, is a function $J:\Sigma^\ell\times\Sigma^m\times\cdots\times\Sigma^q\to\mathbb{R}$ satisfying the condition*

$$J = F(\alpha_1,\ldots,\alpha_d,\beta_1\ldots,\beta_e,\ldots,\gamma_1\ldots,\gamma_f)$$

$$= F(\tilde{\alpha}_1,\ldots,\tilde{\alpha}_d,\tilde{\beta}_1\ldots,\tilde{\beta}_e,\ldots,\tilde{\gamma}_1\ldots,\tilde{\gamma}_f) \tag{31}$$

under the transformation laws (30) induced by the isometry group $I(M)$.

In this case again Conjecture 2.1 entails the following corollary.

Corollary 2.2: Consider the product vector space,

$$\mathcal{K} = \mathcal{K}^\ell(M)\times\mathcal{K}^m(M)\times\cdots\times\mathcal{K}^q(M), \tag{32}$$

where $\ell,m,\ldots,q\geqslant 1$. Define the vector fields

$$\tilde{\mathbf{V}}_i := \mathbf{V}_i^\ell + \mathbf{V}_i^m + \cdots + \mathbf{V}_i^q, \quad i=1,\ldots,r, \tag{33}$$

where $\{\mathbf{V}_i^\ell\},\{\mathbf{V}_i^m\},\ldots,\{\mathbf{V}_i^q\}$, $i=1,\ldots,r$ are the sets of infinitesimal generators of the Lie algebra $i(M)$ in the parameter spaces $\Sigma^\ell,\Sigma^m,\ldots,\Sigma^q$ of the vector spaces $\mathcal{K}^\ell(M),\mathcal{K}^q(M),\ldots,\mathcal{K}^n(M)$, respectively, obtained via (13). Then the vector fields $\tilde{\mathbf{V}}_1,\ldots,\tilde{\mathbf{V}}_r$ enjoy the same commutator relations as the generators $\mathbf{X}_1\ldots,\mathbf{X}_r$ of $i(M)$ in $\mathcal{X}(M)$:

$$[\tilde{\mathbf{V}}_i,\tilde{\mathbf{V}}_j] = c_{ij}^k\tilde{\mathbf{V}}_k, \quad i,j,k=1,\ldots,r, \tag{34}$$

where the structural constants c_{ij}^k are as in (14).

Proof: Straightforward. □

Example 2.3: Consider the product vector space $\mathcal{K}^1(\mathbb{R}^2)\times\mathcal{K}^2(\mathbb{R}^2)$. The general form of the elements of $\mathcal{K}^1(\mathbb{R}^2)$ (Killing vectors) with respect to the Cartesian coordinates is given by

$$\mathbf{K}^1 = (\alpha_1 + \alpha_3 y)\frac{\partial}{\partial x} + (\alpha_2 - \alpha_3 x)\frac{\partial}{\partial y}, \tag{35}$$

while the (contravariant) elements of $\mathcal{K}^2(\mathbb{R}^2)$ assume the following general form with respect to the same coordinate system:

$$\mathbf{K}^2 = (\beta_1 + 2\beta_4 y + \beta_6 y^2)\frac{\partial}{\partial x} \odot \frac{\partial}{\partial x} + (\beta_3 - \beta_4 x - \beta_5 y - \beta_6 xy)\frac{\partial}{\partial x} \odot \frac{\partial}{\partial y}$$
$$+ (\beta_2 + 2\beta_5 x + \beta_6 x^2)\frac{\partial}{\partial y} \odot \frac{\partial}{\partial y}, \tag{36}$$

where $\odot$ denotes the symmetric tensor product. The formulas (35) and (36) put in evidence that the corresponding parameter spaces Σ^1 and Σ^2 are determined by the three parameters $\alpha_i, i=1,\ldots,3$ and the six parameters $\beta_i, i=1,\ldots,6$, respectively. Let $I(\mathbb{R}^2)$ be the proper Euclidean group that consists of the orientation-preserving isometries of $\mathbb{R}^2$ (rigid motions). Its action in $\mathbb{R}^2$ can be described as the semidirect product of rotations and translations. In view of its standard parametrization, we have the transformation of the Cartesian coordinates $\mathbf{x}=(x,y)$,

$$\tilde{\mathbf{x}} = R_\theta \mathbf{x} + \mathbf{a}, \quad R_\theta = \begin{bmatrix} \cos\theta & -\sin\theta \\ \sin\theta & \cos\theta \end{bmatrix} \in \mathrm{SO}(2), \quad \mathbf{a} = (a,b) \in \mathbb{R}^2. \tag{37}$$

Note, the generators of $i(\mathbb{R}^2)=\mathcal{K}^1(\mathbb{R}^2)$, which is the Lie algebra of the Lie group $I(\mathbb{R}^2)$, are given with respect to the Cartesian coordinates by

$$\mathbf{X} = \frac{\partial}{\partial x}, \quad \mathbf{Y} = \frac{\partial}{\partial y}, \quad \mathbf{R} = x\frac{\partial}{\partial y} - y\frac{\partial}{\partial x}, \tag{38}$$

whose flows are translations and a rotation, respectively. Employing the construction (13), we derive two triples of the vector fields representing the generators (38) in $\mathcal{X}(\Sigma^1)$

$$\mathbf{V}_1^1 = -\alpha_3\frac{\partial}{\partial \alpha_2},$$

$$\mathbf{V}_2^1 = \alpha_3\frac{\partial}{\partial \alpha_1}, \tag{39}$$

$$\mathbf{V}_3^1 = \alpha_1\frac{\partial}{\partial \alpha_2} - \alpha_2\frac{\partial}{\partial \alpha_1},$$

and $\mathcal{X}(\Sigma^2)$,

$$\mathbf{V}_1^2 = -2\beta_5\frac{\partial}{\partial \beta_2} - \beta_4\frac{\partial}{\partial \beta_3} + \beta_6\frac{\partial}{\partial \beta_5},$$

$$\mathbf{V}_2^2 = 2\beta_4\frac{\partial}{\partial \beta_1} - \beta_5\frac{\partial}{\partial \beta_3} + \beta_6\frac{\partial}{\partial \beta_6}, \tag{40}$$

$$\mathbf{V}_3^2 = -2\beta_3\left(\frac{\partial}{\partial \beta_1} - \frac{\partial}{\partial \beta_2}\right) + (\beta_1 - \beta_2)\frac{\partial}{\partial \beta_3} + \beta_5\frac{\partial}{\partial \beta_4} - \beta_4\frac{\partial}{\partial \beta_5},$$

respectively. We note that in view of Conjecture 2.1 both the vector fields (39) and the vector fields (40) satisfy the same commutator relations as the generators of $i(\mathbb{R}^2)$ (38). By Corollary 2.2

this fact entails immediately that the vector fields $\{\tilde{\mathbf{V}}_i\}$, $i=1, 2, 3$ defined by

$$\tilde{\mathbf{V}}_i := \mathbf{V}_i^1 + \mathbf{V}_i^2, \quad i = 1,2,3 \tag{41}$$

also enjoy the same commutator relations. This property can be also verified directly. Therefore we have determined the action of $I(\mathbb{R}^2)$ in the product space $\Sigma^1 \times \Sigma^2$. To determine the dimension of the orbits of the group we use the result of Propositon 2.1. Thus, the orbits of the isometry group $I(\mathbb{R}^2)$ acting in $\Sigma^1 \times \Sigma^2$ are three dimensional in the subspace $\mathcal{S}_3 \subset \Sigma^1 \times \Sigma^2$, where the generators (41) are linearly independent. According to Theorem 2.1, the number of fundamental invariants in $\mathcal{S}_3$ is 9 (dimension of $\Sigma^1 \times \Sigma^2$) -3 (dimension of the orbits in $\mathcal{S}_3$) $=6$. Some of these fundamental invariants may be the fundamental invariants of the group action in the vector spaces $\mathcal{K}^1(\mathbb{R}^2)$ and $\mathcal{K}^2(\mathbb{R}^2)$. Indeed, it is instructive at this point to review the transformations imposed on the nine parameters $(\alpha_1, \alpha_2, \alpha_3, \beta_1, \beta_2, \beta_3, \beta_4, \beta_5, \beta_6)$ of the product space $\Sigma^1 \times \Sigma^2$ by the group action:

$$\tilde{\alpha}_1 = \alpha_1 \cos\theta - \alpha_2 \sin\theta - b\alpha_3,$$

$$\tilde{\alpha}_2 = \alpha_1 \sin\theta + \alpha_2 \cos\theta + a\alpha_3,$$

$$\tilde{\alpha}_3 = \alpha_3,$$

$$\tilde{\beta}_1 = \beta_1 \cos^2\theta - 2\beta_3 \cos\theta \sin\theta + \beta_2 \sin^2\theta - 2b\beta_4 \cos\theta - 2b\beta_5 \sin\theta + \beta_6 b^2,$$

$$\tilde{\beta}_2 = \beta_1 \sin^2\theta - 2\beta_3 \cos\theta \sin\theta + \beta_2 \cos^2\theta - 2a\beta_5 \cos\theta + 2a\beta_4 \sin\theta + \beta_6 a^2, \tag{42}$$

$$\tilde{\beta}_3 = (\beta_1 - \beta_2)\sin\theta \cos\theta + \beta_3(\cos^2\theta - \sin^2\theta) + (a\beta_4 + b\beta_5)\cos\theta + (a\beta_5 - b\beta_4)\sin\theta - \beta_6 ab,$$

$$\tilde{\beta}_4 = \beta_4 \cos\theta + \beta_5 \sin\theta - \beta_6 b,$$

$$\tilde{\beta}_5 = \beta_5 \cos\theta - \beta_4 \sin\theta - \beta_6 a,$$

$$\tilde{\beta}_6 = \beta_6,$$

where (θ, a, b) given by (37) parametrize the isometry group $I(\mathbb{R}^2)$. Hence, the dimension of the orbits in this subspace coincides with the dimension of the group. We also observe that α_3 and β_6 are fundamental $I(\mathbb{R}^2)$ invariants of the group action in $\Sigma^1 \times \Sigma^2$.

To determine the remaining four fundamental invariants we use the method of characteristics to solve the system of linear PDEs,

$$\tilde{\mathbf{V}}_i(F) = 0, \quad i = 1,2,3, \tag{43}$$

where $F: \Sigma^1 \times \Sigma^2 \to \mathbb{R}$ and the vector fields $\tilde{\mathbf{V}}_i$, $i=1, 2, 3$ are given by (41). Having solved the system of PDEs (43), we have therefore proven the following result.

Theorem 2.3: *Any algebraic joint $I(\mathbb{R}^2)$-invariant I defined over the subspace of $\Sigma^1 \times \Sigma^2$ where the vector fields (41) are linearly independent can be locally uniquely expressed as an analytic function,*

$$I = F(\mathcal{I}_1, \mathcal{I}_2, \mathcal{I}_3, \mathcal{I}_4, \mathcal{J}_1, \mathcal{J}_2),$$

where the fundamental joint $I(\mathbb{R}^2)$-invariants $\mathcal{I}_i, \mathcal{J}_j$, $i=1,\ldots, 4$, $j=1, 2$ are given by

$$\mathcal{I}_1 = [\beta_6(\beta_1 - \beta_2) + \beta_5^2 - \beta_4^2]^2 + 4(\beta_3\beta_6 + \beta_4\beta_5)^2,$$

$$\mathcal{I}_2 = \beta_6(\beta_1 + \beta_2) - \beta_4^2 - \beta_5^2,$$

$$\mathcal{I}_3 = \beta_6, \qquad \mathcal{I}_4 = \alpha_3, \tag{44}$$

$$\mathcal{J}_1 = (\beta_6\alpha_2 + \beta_5\alpha_3)^2 + (\beta_6\alpha_1 - \beta_4\alpha_3)^2,$$

$$\mathcal{J}_2 = (\beta_6\alpha_2 + \alpha_3\alpha_5)(\beta_6\beta_2 - \beta_5^2) + 2(\beta_3\beta_6 + \beta_4\beta_5)(\beta_6\alpha_1 - \beta_4\alpha_3).$$

The fundamental joint $I(\mathbb{R}^2)$ invariants $\mathcal{I}_i$, $i=1, 2, 3$ are the fundamental $I(\mathbb{R}^2)$ invariants of the vector space $\mathcal{K}^2(\mathbb{R}^2)$ ($\mathcal{I}_1$ was derived in Ref. 15), while $\mathcal{I}_4$ is the fundamental $I(\mathbb{R}^2)$ invariant of the vector space $\mathcal{K}^1(\mathbb{R}^2)$. Note the fundamental $I(\mathbb{R}^2)$ invariants $\mathcal{J}_1$ and $\mathcal{J}_2$ are "truly" joint $I(\mathbb{R}^2)$ invariants of the vector spaces $\mathcal{K}^1(\mathbb{R}^2)$ and $\mathcal{K}^2(\mathbb{R}^2)$. Therefore we have introduced an analogue of the concept of a joint invariant in the classical invariant theory of homogeneous polynomials (refer to Ref. 41 for more details). The problem of the determination of fundamental invariants, solved in this section for a particular (product) vector space of Killing tensors (Theorem 2.3) by the *method of infinitesimal generators*, can also be solved by the purely algebraic *method of moving frames*. This is the subject of the considerations that follow.

III. THE METHOD OF MOVING FRAMES

The method of moving frames, introduced originally by Cartan,[4] is a powerful technique that can be employed to solve a wide range of equivalence-type problems. In its original interpretation it is based on an equivariant map from the space of submanifolds to a bundle of frames. The simplest example of a moving frame is the Frenet frame $\{\mathbf{t}, \mathbf{n}\}$ of a regular curve $\gamma \in \mathbb{R}^2$ parametrized by its arc length. In this case the equivariant map assigns to each point on the curve $\gamma(s)$ the corresponding frame $\{\mathbf{t}(s), \mathbf{n}(s)\}$. Clearly, the moving frame along γ can be obtained from a fixed frame via a combination of rotations and/or translations. This puts in evidence that there is a natural isomorphism between the moving frame and the orientation-preserving isometry group (Euclidean group) $I(\mathbb{R}^2)$. This is the essence of the later generalizations of the moving frame method,[28–30] where the moving frame was viewed as an equivariant map from the space of submanifolds to the group itself. In recent works by Fels and Olver[26,27] the classical moving frame method was further generalized to completely general transformation groups, including infinite-dimensional Lie pseudogroups (see also Kogan[32]). Ultimately, the authors have succeeded in bringing the theory up to the level where the bundle of frames is no longer needed. We very briefly review the basic definitions and results of the moving frames theory in its modern formulation (for a complete review, see Ref. 39).

Definition 3.1: A moving frame *is a smooth, G-equivariant map $\rho: M \to G$, where G is an r-dimensional group acting smoothly on an n-dimensional underlying manifold M.*

Theorem 3.1: *A moving frame exists in a neighborhood of a point $\mathbf{x} \in M$ iff G acts freely and regularly near* $\mathbf{x}$.

To construct a moving frame, one employs Cartan's *normalization method*.[4]

Theorem 3.2: *Let G act freely and regularly on M and let $K \subset M$ be a (local) cross section to the group orbits. Given $\mathbf{x} \in M$, let $\mathbf{g} = \rho(\mathbf{x})$ be the unique group element that maps $\mathbf{x}$ to the cross section: $\mathbf{g} \cdot \mathbf{x} = \rho(\mathbf{x}) \cdot \mathbf{x} \in K$. Then $\rho: M \to G$ is a right moving frame.*

More specifically, let $\mathbf{x} = (x_1, \ldots, x_n) \in M$ be local coordinates. Consider the explicit formulas

for the coordinate transformations induced by the action of $G:\omega(\mathbf{g},\mathbf{x})=\mathbf{g}\cdot\mathbf{x}$. The right moving frame $\mathbf{g}=\rho(\mathbf{x})$ can be constructed by making use of a *coordinate cross section*,

$$K=\{x_1=c_1,x_2=c_2,\ldots,x_r=c_r\},$$

where c_i, $i=1,\ldots,r$ are some constants and solving the corresponding *normalization equations*

$$\omega_1(\mathbf{g},\mathbf{x})=c_1,\quad \omega_2(\mathbf{g},\mathbf{x})=c_2,\quad \ldots,\quad \omega_r(\mathbf{g},\mathbf{x})=c_r, \tag{45}$$

for the group G locally parametrized by $\mathbf{g}=(g_1,\ldots,g_r)$ in terms of the local coordinates $(x_1,\ldots,x_n)$. Substituting the resulting expressions for $g_1,\ldots,g_r$ in terms of the local coordinates $(x_1,\ldots x_n)$ into the remaining $n-r$ formulas for the transformation rules $\omega(\mathbf{g},\mathbf{x})=\mathbf{g}\cdot\mathbf{x}$ yields a complete set of fundamental invariants for the action of G on M.

Theorem 3.3: *If* $\mathbf{g}=\rho(\mathbf{x})$ *is the moving frame solution to the normalization equations (45), then the functions*

$$\mathcal{I}_1(\mathbf{x})=\omega_{r+1}(\rho(\mathbf{x}),\mathbf{x}),\ldots,\mathcal{I}_{n-r}(\mathbf{x})=\omega_n(\rho(\mathbf{x}),\mathbf{x}) \tag{46}$$

form a complete system of functionally independent fundamental G invariants.

Let us now illustrate the procedure and demonstrate how the method of moving frames can be effectively applied to the problem of the determination of the fundamental invariants of the isometry group in the invariant theory of Killing tensors.

Example 3.1: Consider the extended vector space $\mathcal{K}^2(\mathbb{R}^2)\times\mathbb{R}^2$. The corresponding extended parameter space $\Sigma\times\mathbb{R}^2$ is determined by the parameters $\beta_1,\ldots,\beta_6,x,y$, where β_i, $i=1,\ldots,6$ are as in (36) and x,y are the standard Cartesian coordinates. The isometry group $I(\mathbb{R}^2)$ acting on $\mathcal{K}^2(\mathbb{R}^2)\times\mathbb{R}^2$ induces the corresponding transformations on the extended parameter space $\Sigma\times\mathbb{R}^2$ (25), which in this case take the following form:

$$\tilde{\beta}_1=\beta_1\cos^2\theta-2\beta_3\cos\theta\sin\theta+\beta_2\sin^2\theta-2b\beta_4\cos\theta-2b\beta_5\sin\theta+\beta_6b^2,$$

$$\tilde{\beta}_2=\beta_1\sin^2\theta-2\beta_3\cos\theta\sin\theta+\beta_2\cos^2\theta-2a\beta_5\cos\theta+2a\beta_4\sin\theta+\beta_6a^2,$$

$$\tilde{\beta}_3=(\beta_1-\beta_2)\sin\theta\cos\theta+\beta_3(\cos^2\theta-\sin^2\theta)+(a\beta_4+b\beta_5)\cos\theta+(a\beta_5-b\beta_4)\sin\theta-\beta_6ab,$$

$$\begin{aligned}\tilde{\beta}_4&=\beta_4\cos\theta+\beta_5\sin\theta-\beta_6b,\\ \tilde{\beta}_5&=\beta_5\cos\theta-\beta_4\sin\theta-\beta_6a,\end{aligned} \tag{47}$$

$$\tilde{\beta}_6=\beta_6,$$

$$\tilde{x}=x\cos\theta-y\cos\theta+a,$$

$$\tilde{y}=x\sin\theta+y\cos\theta+b.$$

Next, we construct a moving frame by using the cross section (for example),

$$K=\{\beta_3=\beta_4=\beta_5=0\}, \tag{48}$$

which yields the corresponding normalization equations,

$$0 = (\beta_1 - \beta_2)\sin\theta\cos\theta + \beta_3(\cos^2\theta - \sin^2\theta) + (a\beta_4 + b\beta_5)\cos\theta + (a\beta_5 - b\beta_4)\sin\theta - \beta_6 ab,$$

$$0 = \beta_4\cos\theta + \beta_5\sin\theta - \beta_6 b, \tag{49}$$

$$0 = \beta_5\cos\theta - \beta_4\sin\theta - \beta_6 a.$$

Solving (49) for the parameters $a, b,$ and θ, we obtain the moving frame map $\rho: \Sigma \times \mathbb{R}^2 \to I(\mathbb{R}^2)$ determined by the following formulas:

$$a = \frac{\beta_5\cos\theta - \beta_4\sin\theta}{\beta_6},$$

$$b = \frac{\beta_4\cos\theta + \beta_5\sin\theta}{\beta_6}, \tag{50}$$

$$\theta = \frac{1}{2}\arctan\frac{2(\beta_3\beta_6 + \beta_4\beta_5)}{\beta_6(\beta_1 - \beta_2) - \beta_4^2 + \beta_5^2}.$$

It was observed in Ref. 11 that the method of moving frames could be used to solve the problem of the determination of fundamental invariants of vector spaces of Killing tensors under the action of the isometry group. Indeed, having derived the moving frame map (50) and the transformation laws (47), we can now make use of the result of Theorem 3.3 and determine a set of fundamental $I(\mathbb{R}^2)$ covariants of $\mathcal{K}^2(\mathbb{R}^2)$. Substituting (50) into (47), by Theorem 3.3, we arrive at the following result.

Theorem 3.4: *Consider the vector space $\mathcal{K}^2(\mathbb{R}^2)$. Any algebraic $I(\mathbb{R}^2)$-covariant C defined over the subspace of $\Sigma \times \mathbb{R}^2$ where the isometry group $I(\mathbb{R}^2)$ acts freely and regularly with three-dimensional orbits can be locally uniquely expressed as an analytic function,*

$$C = F(\mathcal{I}_1, \mathcal{I}_2, \mathcal{I}_3, \mathcal{C}_1, \mathcal{C}_2),$$

where the fundamental $I(\mathbb{R}^2)$-covariants $\mathcal{I}_i, \mathcal{C}_j$, $i = 1, 2, 3$, $j = 1, 2$ are given by

$$\mathcal{I}_1 = [\beta_6(\beta_1 - \beta_2) + \beta_5^2 - \beta_4^2]^2 + 4(\beta_3\beta_6 + \beta_4\beta_5)^2,$$

$$\mathcal{I}_2 = \beta_6(\beta_1 + \beta_2) - \beta_4^2 - \beta_5^2,$$

$$\mathcal{I}_3 = \beta_6, \tag{51}$$

$$\mathcal{C}_1 = (\beta_6 x + \beta_5)^2 + (\beta_6 y + \beta_4)^2,$$

$$\mathcal{C}_2 = [(\beta_6 x + \beta_5)^2 - (\beta_6 y + \beta_4)^2](\beta_5^2 - \beta_4^2 + \beta_6(\beta_1 - \beta_2)) + 4(\beta_6 x + \beta_5)(\beta_6 y + \beta_4)(\beta_6\beta_3 + \beta_4\beta_5),$$

where Σ is the parameter space of $\mathcal{K}^2(\mathbb{R}^2)$.

We immediately observe that the functions $\mathcal{I}_1, \mathcal{I}_2, \mathcal{I}_3$ constitute in fact a set of fundamental $I(\mathbb{R}^2)$ invariants of the vector space $\mathcal{K}^2(\mathbb{R}^2)$, while the functions $\mathcal{C}_1$ and $\mathcal{C}_2$ are "truly" fundamental $I(\mathbb{R}^2)$ covariants of the vector space $\mathcal{K}^2(\mathbb{R}^2)$. We also observe that the fundamental covariant $\mathcal{C}_1$ can be expressed as

$$\mathcal{C}_1 = \mathcal{I}_3 \operatorname{tr} \hat{\mathbf{K}} - \mathcal{I}_2,$$

where the (1, 1)-tensor $\hat{\mathbf{K}}$ is given by $\hat{\mathbf{K}} = \mathbf{K}\mathbf{g}^{-1}$. This observation immediately suggests that $\operatorname{tr} \hat{\mathbf{K}}$ is a fundamental $I(\mathbb{R}^2)$ covariant of $\mathcal{K}^2(\mathbb{R}^2)$. We note, however, that the function $\det \hat{\mathbf{K}}$ is not a fundamental $I(\mathbb{R}^2)$ covariant of $\mathcal{K}^2(\mathbb{R}^2)$.

Consider a similar example.

Example 3.2: Let $\mathcal{K}^2(\mathbb{R}^2_1) \times \mathbb{R}^2_1$ be the extended vector space of $\mathcal{K}^2(\mathbb{R}^2_1)$. The action of the isometry group $I(\mathbb{R}^2_1)$ in the Minkowski plane $\mathbb{R}^2_1$ is given by (18), while the corresponding action in the parameter space Σ of $\mathcal{K}^2(\mathbb{R}^2_1)$ is given by (22). The transformation laws (22) combined with the transformations (18) yield an analogue of (47). Next, we proceed as in Example 3.1. The resulting moving frame map $\rho: \Sigma \times \mathbb{R}^2_1 \to I(\mathbb{R}^2_1)$ is given by

$$a = \frac{\alpha_4 \sinh \phi + \alpha_5 \cosh \phi}{\alpha_6},$$

$$b = \frac{\alpha_4 \cosh \phi + \alpha_5 \sinh \phi}{a_6}, \tag{52}$$

$$\phi = \frac{1}{2} \operatorname{arctanh} \frac{2(\alpha_3\alpha_6 - \alpha_4\alpha_5)}{\alpha_4^2 + \alpha_5^2 - \alpha_6(\alpha_1 + \alpha_2)}.$$

Now we can continue as in the previous example to determine a set of fundamental $I(\mathbb{R}^2_1)$ covariants of the vector space $\mathcal{K}^2(\mathbb{R}^2_1)$.

Theorem 3.5: *Consider the vector space $\mathcal{K}^2(\mathbb{R}^2_1)$. Any algebraic $I(\mathbb{R}^2_1)$ covariant C defined over the subspace of $\Sigma \times \mathbb{R}^2_1$ where the isometry group $I(\mathbb{R}^2_1)$ acts freely and regularly with three-dimensional orbits can be locally uniquely expressed as an analytic function*

$$C = F(\mathcal{I}_1, \mathcal{I}_2, \mathcal{I}_3, \mathcal{C}_1, \mathcal{C}_2),$$

where the fundamental $I(\mathbb{R}^2_1)$ covariants $\mathcal{I}_i, \mathcal{C}_j$, $i = 1, 2, 3$, $j = 1, 2$ are given by

$$\mathcal{I}_1 = [\alpha_4^2 + \alpha_5^2 - \alpha_6(\alpha_1 + \alpha_2)]^2 - 4(\alpha_3\alpha_6 - \alpha_4\alpha_5)^2,$$

$$\mathcal{I}_2 = (\alpha_1 - \alpha_2)\alpha_6 - \alpha_4^2 + \alpha_5^2,$$

$$\mathcal{I}_3 = \alpha_6, \tag{53}$$

$$\mathcal{C}_1 = (\alpha_6 t + \alpha_5)^2 - (\alpha_6 x + \alpha_4)^2,$$

$$\mathcal{C}_2 = [(\alpha_6 t + \alpha_5)^2 + (\alpha_6 x + \alpha_4)^2](\alpha_4^2 + \alpha_5^2 - \alpha_6(\alpha_1 + \alpha_2)) + 4(\alpha_6 t + \alpha_5)(\alpha_6 x + \alpha_4)(\alpha_3\alpha_6 - \alpha_4\alpha_5),$$

where Σ is the parameter space of $\mathcal{K}^2(\mathbb{R}^2_1)$.

The conclusion is similar to that following Theorem 3.4. Thus, we observe again that the functions $\mathcal{I}_1, \mathcal{I}_2, \mathcal{I}_3$ constitute in fact a set of fundamental $I(\mathbb{R}^2_1)$ invariants of the vector space $\mathcal{K}^2(\mathbb{R}^2_1)$, while the functions $\mathcal{C}_1$ and $\mathcal{C}_2$ are "truly" fundamental $I(\mathbb{R}^2_1)$ covariants of the vector space $\mathcal{K}^2(\mathbb{R}^2_1)$.

IV. EQUIVALENCE CLASSES OF VECTOR SPACES $\mathcal{K}^2(\mathbb{R}^2)$ AND $\mathcal{K}^2(\mathbb{R}^2_1)$

In this section we use the results obtained in the preceding section to solve the problems of equivalence for the vector subspaces of *nontrivial* Killing tensors of $\mathcal{K}^2(\mathbb{R}^2)$ and $\mathcal{K}^2(\mathbb{R}^2_1)$. As is well-known[22] the elements of these subspaces generate *orthogonal coordinate webs* in $\mathbb{R}^2$ and $\mathbb{R}^2_1$,

TABLE I. Invariant classification of the orthogonal coordinate webs in $\mathbb{R}^2$ by means of $I(\mathbb{R}^2)$ invariants.

Equivalence class	$\mathcal{I}_1$	$\mathcal{I}_3$	Orthogonal web
EC1	0	0	Cartesian
EC2	0	$\neq 0$	Polar
EC3	$\neq 0$	0	Parabolic
EC4	$\neq 0$	$\neq 0$	Elliptic–hyperbolic

respectively, provided the Killing tensors in question have distinct (and real) eigenvalues. The problem of equivalence in this case is the problem of classification of orthogonal coordinate webs. On the other hand, from the invariant theory point of view the problem of equivalence and the related canonical form problem are intimately related to the problem of the determination of fundamental invariants (covariants, joint invariants).

A. The vector space $\mathcal{K}^2(\mathbb{R}^2)$

Let $\mathcal{K}^2_{nt}(\mathbb{R}^2) \subset \mathcal{K}^2(\mathbb{R}^2)$ be the vector subspace of nontrivial Killing two tensors defined in the Euclidean plane $\mathbb{R}^2$. "Nontrivial" in this context means that none of the elements of $\mathcal{K}^2_{nt}(\mathbb{R}^2)$ is a multiple of the metric of $\mathbb{R}^2$. Clearly $\dim \mathcal{K}^2_{nt}(\mathbb{R}^2) = 5$. It has been established in Refs. 13,14,16 that the functions $\mathcal{I}_1$ and $\mathcal{I}_3$ given by (51) are the fundamental $I(\mathbb{R}^2)$ invariants of $\mathcal{K}^2_{nt}(\mathbb{R}^2)$. Moreover, they can be used to solve the problem of classification of orthogonal coordinate webs in the Euclidean plane. The fundamental $I(\mathbb{R}^2)$ invariants divide the vector subspace $\mathcal{K}^2_{nt}(\mathbb{R}^2)$ into four equivalence classes. The elements within each equivalence class generate a particular orthogonal web (see Ref. 13 for more details). These results are summarized in Table I. Clearly, any (analytic) $I(\mathbb{R}^2)$ covariant of the vector subspace $\mathcal{K}^2_{nt}(\mathbb{R}^2)$ takes the following general form:

$$C = F(\mathcal{I}_1, \mathcal{I}_3, \mathcal{C}_1, \mathcal{C}_2),$$

where the functions $\mathcal{I}_1, \mathcal{I}_3, \mathcal{C}_1$, and $\mathcal{C}_2$ are given by (51).

The same classification can be done by means of the fundamental $I(\mathbb{R}^2)$ covariants $\mathcal{C}_1$ and $\mathcal{C}_2$ given by (51). The results are summarized in Table II.

Recall that in most of the problems studied so far within ITKT the associated *canonical form problem* has been solved for vector spaces of Killing tensors of valence two via transforming the corresponding Killing tensors in orthogonal coordinates back to the original (pseudo-)Cartesian coordinates by using the standard transformations from the orthogonal coordinates to (pseudo-) Cartesian coordinates (see, for example, Refs. 7,12,13,16). In the problems involving Killing tensors of valence two (with distinct eigenvalues and integrable eigenvectors) the equivalence classes (ECs) of the corresponding vector spaces are associated with the corresponding orthogonal coordinate webs and so such an approach seems to be natural.

However, one may wish to solve the canonical form problem for vector spaces of Killing tensors of valences higher than two, in which case a connection with the theory of orthogonal

TABLE II. Invariant classification of the orthogonal coordinate webs in $\mathbb{R}^2$ by means of $I(\mathbb{R}^2)$ covariants.

Equivalence class	$\mathcal{C}_1$	$\mathcal{C}_2$	Orthogonal web
EC1	0	0	Cartesian
EC2	Positive–definite	0	Polar
EC3	1	1	Parabolic
EC4	Positive–definite	Indefinite	Elliptic–hyperbolic

coordinate webs is not evident. In such a case, another, more general approach can be adapted from CIT[39] to the study of Killing tensors. Indeed, recall first the following definitions and results.[39]

Definition 4.1: Two submanifolds $N,P\subset X$ are said to intersect transversally *at a common point $x_0\in N\cap P$ if they have no nonzero tangent vectors in common: $TN|_{x_0}\cap TP|_{x_0}=\{0\}$.*

Definition 4.2: Let G be a Lie transformation group that acts regularly on an m-dimensional manifold X with s-dimensional orbits. A (local) cross section *is an $(m-s)$-dimensional submanifold $K\subset X$ such that K intersects each orbit transversally and at most once.*

Proposition 4.1: If a Lie group G acts regularly on a manifold X, then one can construct a local cross section K passing through any point $x\in X$.

One can define a *coordinate cross section K*, in which case the first *s* coordinates themselves define a coordinate cross section[39]

$$K=\{x_1=c_1,\ldots,x_s=c_s\} \tag{54}$$

iff

$$\frac{\partial(\Delta_1,\ldots,\Delta_{m-s})}{\partial(x_{s+1},\ldots,x_m)}\neq 0, \tag{55}$$

where $\Delta_1,\ldots,\Delta_{m-s}$ are the fundamental invariants of the group action. Then, in view of the above, we can obtain canonical forms of the equivalence classes set by the fundamental invariants as intersections of the coordinate cross sections and the level sets (invariant submanifolds) defined by the fundamental group invariants. To illustrate this simple procedure consider the following example.

Example 4.1: Consider $\mathcal{K}^2_{nt}(\mathbb{R}^2)\subset\mathcal{K}^2(\mathbb{R}^2)$. Without loss of generality we can assume that the elements of the vector subspace $\mathcal{K}^2_{nt}(\mathbb{R}^2)$ enjoy the following general form:

$$\mathbf{K}^2_{nt}=(\beta_1'+2\beta_4y+\beta_6y^2)\frac{\partial}{\partial x}\odot\frac{\partial}{\partial x}+(\beta_3-\beta_4x-\beta_5y-\beta_6xy)\frac{\partial}{\partial x}\odot\frac{\partial}{\partial y}+(2\beta_5x+\beta_6x^2)\frac{\partial}{\partial y}\odot\frac{\partial}{\partial y}, \tag{56}$$

where $\beta_1'=\beta_1-\beta_2$ and the parameters β_i, $i=1,\ldots,6$ are as in (36). The four equivalence classes EC1–4 of $\mathcal{K}^2_{nt}(\mathbb{R}^2)$ have been classified in Table I and Table II. The Killing tensors within each equivalence class share the same geometrical properties, that is they define the same orthogonal coordinate webs equivalent up to the action of the isometry group $I(\mathbb{R}^2)$. This fact can be used to select appropriate canonical forms for each of the four equivalence classes. Thus, one can consider the Killing tensors in terms of the orthogonal coordinates (u,v) (see Ref. 16) and then use the standard coordinate transformations from the orthogonal (u,v) coordinates to the Cartesian coordinates (x,y) in order to determine the corresponding canonical forms for EC1–4. Alternatively, one can proceed by using the coordinate cross sections. The procedure is outlined below.

EC1: In this case the parameter space Σ' defined by the five parameters of (56) can be intersected by the coordinate cross section,

$$K_1=\{\beta_3=\beta_4=\beta_5=0\}. \tag{57}$$

Taking into account (56) and the corresponding formulas for $\mathcal{I}_1$ and $\mathcal{I}_3$ given by (51), we conclude that all but one (β_1') parameters vanish in this case. The parameter β_1' is arbitrary, without loss of generality we can set $\beta_1'=1$, which leads to the canonical form

$$\mathbf{K}_{\mathrm{I}}=\frac{\partial}{\partial x}\odot\frac{\partial}{\partial x}. \tag{58}$$

Alternatively, we could have used the coordinate cross section,

$$K_2 = \{\beta_1' = \beta_4 = \beta_5 = 0\}, \tag{59}$$

which would have led to the canonical form

$$\mathbf{K}_{\mathrm{I}}' = \frac{\partial}{\partial x} \odot \frac{\partial}{\partial y}. \tag{60}$$

Note the canonical forms (58) and (60) are equivalent up to a rotation.

EC2: Reason as in EC1 above. Either of the coordinate cross sections (57) or (59) leads to the canonical form

$$\mathbf{K}_{\mathrm{II}} = y^2 \frac{\partial}{\partial x} \odot \frac{\partial}{\partial x} - xy \frac{\partial}{\partial x} \odot \frac{\partial}{\partial y} + x^2 \frac{\partial}{\partial y} \odot \frac{\partial}{\partial y}. \tag{61}$$

EC3: First, note that the condition $\mathcal{I}_1 \neq 0, \mathcal{I}_3 = 0$ (see Table I) prompts $\beta_4^2 + \beta_5^2 \neq 0$. Therefore the coordinate cross sections that can be used in this case are

$$K_3 = \{\beta_1' = \beta_3 = \beta_4 = 0\} \tag{62}$$

and

$$K_4 = \{\beta_1' = \beta_3 = \beta_5 = 0\}, \tag{63}$$

which lead to the canonical forms

$$\mathbf{K}_{\mathrm{III}} = -y \frac{\partial}{\partial x} \odot \frac{\partial}{\partial y} + 2x \frac{\partial}{\partial y} \odot \frac{\partial}{\partial y} \tag{64}$$

and

$$\mathbf{K}_{\mathrm{III}}' = 2y \frac{\partial}{\partial x} \odot \frac{\partial}{\partial x} - x \frac{\partial}{\partial x} \odot \frac{\partial}{\partial y}, \tag{65}$$

respectively. Note the canonical forms (64) and (65) are equivalent up to a rotation.

EC4: In this case we can use either of the coordinate cross sections (57) or (59). Intersecting the common level set defined by $\mathcal{I}_1 \neq 0, \mathcal{I}_3 \neq 0$ (see Table I) with (57) yields the canonical form

$$\mathbf{K}_{\mathrm{IV}} = (\beta_1' + y^2) \frac{\partial}{\partial x} \odot \frac{\partial}{\partial x} - xy \frac{\partial}{\partial x} \odot \frac{\partial}{\partial y} + x^2 \frac{\partial}{\partial y} \odot \frac{\partial}{\partial y}, \tag{66}$$

while with (59)—the canonical form

$$\mathbf{K}_{\mathrm{IV}}' = y^2 \frac{\partial}{\partial x} \odot \frac{\partial}{\partial x} + (\beta_3 - xy) \frac{\partial}{\partial x} \odot \frac{\partial}{\partial y} + x^2 \frac{\partial}{\partial y} \odot \frac{\partial}{\partial y}. \tag{67}$$

Note the canonical forms (66) and (67) are equivalent up to a rotation and rescaling.

B. The vector space $\mathcal{K}^2(\mathbb{R}_1^2)$

The problem of classification of the 10 orthogonal coordinate webs defined in the Minkowski plane $\mathbb{R}_1^2$ was initially solved by Kalnins[23] in 1975. The approach used in Ref. 23 is based on the property that the Killing tensors defined in pseudo-Riemannian spaces of constant curvature are the sums of symmetrized tensor products of Killing vectors. In Ref. 23 different combinations (as symmetric tensor products) of the basic Killing vectors (19) were analyzed modulo the action of the eight-dimensional discrete group $\mathcal{R}$ of permutations of coordinates and reflections of the signature of the Minkowski metric $\mathbf{g} = \mathrm{diag}(1, -1)$ given in terms of the pseudo-Cartesian coordinates (t, x) (see below). A different approach was used in Rastelli,[42] where the 10 orthogonal webs were classified based on the algebraic properties of the nontrivial Killing tensors of $\mathcal{K}^2(\mathbb{R}_1^2)$. More

specifically, the author made use of the points where the eigenvalues of such Killing tensors coincide (singular points). Finally, McLenaghan *et al.*[12,15] employed a set of the fundamental $I(\mathbb{R}_1^2)$ invariants of the vector subspace of nontrivial Killing tensors of $\mathcal{K}^2(\mathbb{R}_1^2)$ to classify the 10 orthogonal webs defined in $\mathbb{R}_1^2$. The problem appeared to be incommensurably more challenging than the problem of classification of the orthogonal coordinate webs in $\mathbb{R}^2$.[13,16] The reason is simple: In both cases one has two fundamental invariants at one's disposal, while the number of orthogonal coordinate webs is four (Euclidean plane) and 10 (Minkowski plane). In the latter case the problem was solved[12,15] by introducing the concept of a *conformal* $I(\mathbb{R}_1^2)$ *invariant*, which was used to generate additional *discrete* $I(\mathbb{R}_1^2)$ invariants. To solve the problem, the authors had to investigate the effect of the eight-dimensional discrete group $\mathcal{R}$ on the discrete $I(\mathbb{R}_1^2)$ invariants. Unordered pairs (as the objects preserved by the discrete group) of discrete invariants along with one of the fundamental invariants were used to solve the problem. In what follows, we propose a simpler solution based on the fundamental $I(\mathbb{R}_1^2)$ covariants obtained in the preceding section.

Let $\mathcal{K}_{nt}^2(\mathbb{R}_1^2)\subset\mathcal{K}^2(\mathbb{R}_1^2)$ be the vector subspace of nontrivial Killing two tensors defined in the Minkowski plane $\mathbb{R}_1^2$. Here "nontrivial" has the same meaning as above. Again $\dim\mathcal{K}_{nt}^2(\mathbb{R}_1^2)=5$. Without loss of generality we can assume that in terms of the pseudo-Cartesian coordinates (t,x) the general form of the elements of $\mathcal{K}_{nt}^2(\mathbb{R}_1^2)$ is given by

$$\mathbf{K}=(\alpha_1'+2\alpha_4x+\alpha_6x^2)\frac{\partial}{\partial t}\odot\frac{\partial}{\partial t}+(\alpha_3+\alpha_4t+\alpha_5x+\alpha_6tx)\frac{\partial}{\partial t}\odot\frac{\partial}{\partial x}+(2\alpha_5t+\alpha_6t^2)\frac{\partial}{\partial x}\odot\frac{\partial}{\partial x},\tag{68}$$

where $\alpha_1'=\alpha_1+\alpha_2$ and the parameters α_i, $i=1,\ldots,6$ are as in (17). Note that in this case the parameter space Σ' is determined by the five parameters $\alpha_1',\alpha_3,\alpha_4,\alpha_5$, and α_6. Our next observation is that by Theorem 3.5 any $I(\mathbb{R}_1^2)$ covariant of $\mathcal{K}_{nt}^2(\mathbb{R}_1^2)$ enjoys the form

$$C=F(\mathcal{I}_1,\mathcal{I}_3,\mathcal{C}_1,\mathcal{C}_2),$$

where the functions $\mathcal{I}_1,\mathcal{I}_3,\mathcal{C}_1$, and $\mathcal{C}_2$ are given by (53). As in the case of $\mathcal{K}_{nt}^2(\mathbb{R}^2)$ we can use $\mathcal{I}_1,\mathcal{I}_3,\mathcal{C}_1$, and $\mathcal{C}_2$ to classify the 10 orthogonal webs. However, in view of the number of cases we must use these functions concurrently. Before doing so, we check the effect of $\mathcal{R}$ on $\mathcal{I}_1,\mathcal{I}_3,\mathcal{C}_1$, and $\mathcal{C}_2$. Recall[23,12] that the group (under composition) $\mathcal{R}=\langle R_1,R_2\rangle$ consists of eight discrete transformations generated by

$$R_1:\quad \tilde{t}=t,\quad \tilde{x}=-x\quad\text{(spatial reflections)},$$

$$R_2:\quad \tilde{t}=x,\quad \tilde{x}=t\quad\text{(permutation)}.\tag{69}$$

Note the group $\mathcal{R}$ [along with the isometry group $I(\mathbb{R}_1^2)$] preserves the geometry of the 10 orthogonal webs defined in the Minkowski plane. Recall next[12] that R_1 and R_2 induce the following transformations on the parameters α_i, $i=1,\ldots,6$ of $\mathcal{K}^2(\mathbb{R}_1^2)$ [see (36)]:

$$R_1:\quad \tilde{\alpha}_1=\alpha_1,\quad \tilde{\alpha}_2=\alpha_2,\quad \tilde{\alpha}_3=-\alpha_3,\quad \tilde{\alpha}_4=-\alpha_4,\quad \tilde{\alpha}_5=\alpha_5,\quad \tilde{\alpha}_6=\alpha_6,$$

$$R_2:\quad \tilde{\alpha}_1=\alpha_2,\quad \tilde{\alpha}_2=\alpha_1,\quad \tilde{\alpha}_3=\alpha_3,\quad \tilde{\alpha}_4=\alpha_5,\quad \tilde{\alpha}_5=\alpha_4,\quad \tilde{\alpha}_6=\alpha_6.\tag{70}$$

It follows immediately that the fundamental $I(\mathbb{R}_1^2)$ covariants $\mathcal{I}_1,\mathcal{I}_3,\mathcal{C}_1$, and $\mathcal{C}_2$ remain unchanged under the transformations (70) induced by the group $\mathcal{R}$. We conclude therefore that we can use them in the classification of the 10 orthogonal webs. Recall that the vector subspace $\mathcal{K}_{nt}^2(\mathbb{R}_1^2)$ can be divided into 10 equivalence classes EC1–10 within each of which the corresponding elements generate the *same orthogonal coordinate web* (for more details see Refs. 23 and 12). We consider next the 10 *canonical elements* determined in Ref. 12 representing each class EC1–10 by transforming them to contravariant form and making them compatible with the general form (68) by adding multiples of the metric when necessary. The latter operation does not affect the geometry

of the coordinate webs generated by the canonical elements. We arrive at the following list:

$$\text{EC1} \quad \mathbf{K}_1 = \frac{\partial}{\partial t} \odot \frac{\partial}{\partial t}, \tag{71}$$

$$\text{EC2} \quad \mathbf{K}_2 = x^2 \frac{\partial}{\partial t} \odot \frac{\partial}{\partial t} + tx \frac{\partial}{\partial t} \odot \frac{\partial}{\partial x} + t^2 \frac{\partial}{\partial x} \odot \frac{\partial}{\partial x}, \tag{72}$$

$$\text{EC3} \quad \mathbf{K}_3 = \left(\frac{1}{2} - x\right) \frac{\partial}{\partial t} \odot \frac{\partial}{\partial t} + \left(\frac{1}{4} - \frac{1}{2}t + \frac{1}{2}x\right) \frac{\partial}{\partial t} \odot \frac{\partial}{\partial x} + t \frac{\partial}{\partial x} \odot \frac{\partial}{\partial x}, \tag{73}$$

$$\text{EC4} \quad \mathbf{K}_4 = x \frac{\partial}{\partial t} \odot \frac{\partial}{\partial x} + 2t \frac{\partial}{\partial x} \odot \frac{\partial}{\partial x}, \tag{74}$$

$$\text{EC5} \quad \mathbf{K}_5 = \left(2k^2 - \frac{1}{4}x^2\right) \frac{\partial}{\partial t} \odot \frac{\partial}{\partial t} - \frac{1}{4}tx \frac{\partial}{\partial t} \odot \frac{\partial}{\partial x} - \frac{1}{4}t^2 \frac{\partial}{\partial x} \odot \frac{\partial}{\partial x}, \tag{75}$$

$$\text{EC6} \quad \mathbf{K}_6 = \left(\frac{1}{4} + \frac{1}{4}x^2\right) \frac{\partial}{\partial t} \odot \frac{\partial}{\partial t} + \left(\frac{1}{4} + \frac{1}{4}tx\right) \frac{\partial}{\partial t} \odot \frac{\partial}{\partial x} + \frac{1}{4}t^2 \frac{\partial}{\partial x} \odot \frac{\partial}{\partial x}, \tag{76}$$

$$\text{EC7} \quad \mathbf{K}_7 = \left(-\frac{1}{2} + \frac{1}{4}x^2\right) \frac{\partial}{\partial t} \odot \frac{\partial}{\partial t} + \left(-\frac{1}{4} + \frac{1}{4}tx\right) \frac{\partial}{\partial t} \odot \frac{\partial}{\partial x} + \frac{1}{4}t^2 \frac{\partial}{\partial x} \odot \frac{\partial}{\partial x}, \tag{77}$$

$$\text{EC8} \quad \mathbf{K}_8 = \frac{1}{4}x^2 \frac{\partial}{\partial t} \odot \frac{\partial}{\partial t} + \left(-k^2 + \frac{1}{4}tx\right) \frac{\partial}{\partial t} \odot \frac{\partial}{\partial x} + \frac{1}{4}t^2 \frac{\partial}{\partial x} \odot \frac{\partial}{\partial x}, \tag{78}$$

$$\text{EC9} \quad \mathbf{K}_9 = \left(2k^2 + \frac{1}{4}x^2\right) \frac{\partial}{\partial t} \odot \frac{\partial}{\partial t} + \frac{1}{4}tx \frac{\partial}{\partial t} \odot \frac{\partial}{\partial x} + \frac{1}{4}t^2 \frac{\partial}{\partial x} \odot \frac{\partial}{\partial x}, \tag{79}$$

$$\text{EC10} \quad \mathbf{K}_{10} = \left(-2k^2 + \frac{1}{4}x^2\right) \frac{\partial}{\partial t} \odot \frac{\partial}{\partial t} + \frac{1}{4}tx \frac{\partial}{\partial t} \odot \frac{\partial}{\partial x} + \frac{1}{4}t^2 \frac{\partial}{\partial x} \odot \frac{\partial}{\partial x}, \tag{80}$$

where the parameter k is a $I(\mathbb{R}_1^2)$ invariant of $\mathcal{K}_{nt}^2(\mathbb{R}_1^2)$. In view of Theorem 2.2 (see also Theorem 3.5), it can be represented via the fundamental $I(\mathbb{R}_1^2)$ invariants. Indeed, the corresponding formulas were found in Ref. 12,

$$\text{EC5, EC9, EC10:} \quad k^2 = \frac{\sqrt{\mathcal{I}_1}}{\mathcal{I}_3} \quad (\mathcal{I}_1 > 0),$$

$$\text{EC8:} \quad k^2 = \frac{\sqrt{-\mathcal{I}_1}}{\mathcal{I}_3} \quad (\mathcal{I}_1 < 0). \tag{81}$$

Note the canonical forms (71)–(80) are compatible with the general form given by (68). Following the procedure devised in Ref. 12, we use the canonical forms (71)–(80) to evaluate the corresponding values of the fundamental $I(\mathbb{R}_1^2)$ covariants $\mathcal{I}_1, \mathcal{I}_3, \mathcal{C}_1, \mathcal{C}_2$ and employ the results to distinguish the elements belonging to different equivalence classes EC1–10. The elements of $\mathcal{K}_{nt}^2(\mathbb{R}_1^2)$ must have the same values of $\mathcal{I}_1, \mathcal{I}_3, \mathcal{C}_1$, and $\mathcal{C}_2$. We note however that these functions do not distinguish EC1 from EC3 and EC6 from EC8. Therefore we have to derive some auxiliary $I(\mathbb{R}_1^2)$

invariants to complete the classification scheme. Indeed, consider the vector space $\mathcal{K}^2(\mathbb{R}^2_1)$ under the action of the isometry group $I(\mathbb{R}^2_1)$. Since $\mathcal{I}_3$ is a fundamental $I(\mathbb{R}^2_1)$ invariant, we can consider the level set

$$\mathcal{S}_{\mathcal{I}_3} = \{(\alpha_1, \ldots, \alpha_5) \in \Sigma | \quad \mathcal{I}_3 = 0\}. \tag{82}$$

Note $\mathcal{S}_{\mathcal{I}_3}$ is an $I(\mathbb{R}^2_1)$-invariant submanifold in Σ defined by the parameters α_i, $i=1,\ldots,5$. Next we prove the following result by using the techniques exhibited in Sec. II.

Lemma 4.1: Any algebraic $I(\mathbb{R}^2_1)$ invariant I of the $I(\mathbb{R}^2_1)$-invariant submanifold $\mathcal{S}_{\mathcal{I}_3}$ defined by (82) can be (locally) uniquely expressed as an analytic function

$$I = F(\mathcal{I}'_1, \mathcal{I}'_2),$$

where the fundamental invariants $\mathcal{I}'_i$, $i=1, 2$ are given by

$$\mathcal{I}'_1 = \alpha_4^2 - \alpha_5^2,$$

$$\mathcal{I}'_2 = 2\alpha_3\alpha_4\alpha_5 - \alpha_2\alpha_4^2 - \alpha_1\alpha_5^2, \tag{83}$$

provided the group acts in $\mathcal{S}_{\mathcal{I}_3}$ with three-dimensional orbits.

We note that the fundamental $I(\mathbb{R}^2_1)$ invariants $\mathcal{I}'_1$ and $\mathcal{I}'_2$ still cannot be used in the problem of classification of the elements of $\mathcal{K}^2_{nt}(\mathbb{R}^2_1)$. In particular, $\mathcal{I}'_2$ appears to be a function of $\alpha_1, \alpha_2, \alpha_3, \alpha_4$, and α_5 (not $\alpha'_1, \alpha_3, \alpha_4, \alpha_5$). However, under the additional *invariant* condition

$$\mathcal{I}'_1 = \alpha_4^2 - \alpha_5^2 = 0 \tag{84}$$

it assumes the following form:

$$\mathcal{I}'_2 = 2\alpha_3\alpha_4\alpha_5 - \alpha'_1\alpha_4^2, \tag{85}$$

where $\alpha'_1 = \alpha_1 + \alpha_2$. We immediately recognize the $I(\mathbb{R}^2_1)$-invariant (85) to be an $I(\mathbb{R}^2_1)$ invariant of the submanifold in $\mathcal{S}_{\mathcal{I}_3}$ determined by the condition (84). Hence, $\mathcal{I}'_2$ given by (85) can be used to distinguish between EC1 and EC3.

Next, in order to distinguish between the elements of EC6 and EC8, introduce the following auxiliary $I(\mathbb{R}^2_1)$ invariant:

$$\mathcal{I}^* := k^4\mathcal{I}_3 + \mathcal{I}_1, \tag{86}$$

where k is given by (81) (the formula for EC8). We note that $\mathcal{I}^*$ given by (86) is an $I(\mathbb{R}^2_1)$ invariant. The values of $\mathcal{I}_1$ and $\mathcal{I}_3$ evaluated with respect to the parameters of the canonical form EC8 given by (78) are

$$\mathcal{I}_1 = -\frac{k^4}{4}, \quad \mathcal{I}_3 = \frac{1}{4}.$$

Therefore the $I(\mathbb{R}^2_1)$ invariant $\mathcal{I}^* = 0$, whenever the Killing tensor in question belongs to EC8. The classification scheme is now complete. We summarize the results in Table III.

Using the results obtained we can devise a general algorithm of classification for the elements of the vector spaces $\mathcal{K}^2(\mathbb{R}^2)$ and $\mathcal{K}^2(\mathbb{R}^2_1)$. It consists of the following two steps. Let $\mathbf{K} \in \mathcal{K}^2(\mathbb{R}^2) \times (\mathcal{K}^2(\mathbb{R}^2_1))$.

(i) If $\mathbf{K}$ has arbitrary constants, decompose $\mathbf{K}$ as follows:

TABLE III. Invariant classification of the orthogonal coordinate webs in $\mathbb{R}_1^2$ by means of $I(\mathbb{R}_1^2)$ invariants and covariants.

Equivalence class	$\mathcal{I}_1$	$\mathcal{I}_3$	$\mathcal{C}_1$	$\mathcal{C}_2$	$\mathcal{I}_1'$	$\mathcal{I}_2'$	$\mathcal{I}^*$
EC1	0	0	0	0	0	0	
EC2	0	$\neq 0$	Indefinite	0			
EC3	0	0	0	0	0	$\neq 0$	
EC4	$\neq 0$	0	1	1			
EC5	$\neq 0$	$\neq 0$	Indefinite	Positive–definite			
EC6	$\neq 0$	$\neq 0$	Indefinite	Indefinite			$\neq 0$
EC7	0	$\neq 0$	Indefinite	Positive–definite			
EC8	$\neq 0$	$\neq 0$	Indefinite	Indefinite			0
EC9	$\neq 0$	$\neq 0$	Indefinite	Negative–definite			
EC10	$\neq 0$	$\neq 0$	Indefinite	Positive–definite			

$$\mathbf{K} = \ell_0 \mathbf{g} + \sum_{i=1}^{5} \ell_i \mathbf{K}_i, \tag{87}$$

where ℓ_i, $i=1,\ldots,5$ are the arbitrary constants. Note $\Sigma_{i=1}^5 \ell_i \mathbf{K}_i \in \mathcal{K}_{nt}^2(\mathbb{R}^2)(\mathcal{K}_{nt}^2(\mathbb{R}_1^2))$. Clearly, $\mathbf{K} \in \mathcal{K}_{nt}^2(\mathbb{R}^2)(\mathcal{K}_{nt}^2(\mathbb{R}_1^2))$ iff $\ell_0 = 0$.

(ii) Each Killing tensor in the representation (87) represents one of the equivalence classes (and thus, an orthogonal coordinate web), provided it has real eigenvalues in the case of the vector space being $\mathcal{K}^2(\mathbb{R}_1^2)$. We can determine which one by evaluating the corresponding $I(\mathbb{R}^2)$ and $I(\mathbb{R}_1^2)$ invariants and covariants and then using the information provided in Table I or Table II for the Killing tensors defined in the Euclidean plane and Table III defined in the Minkowski plane.

The problem of classification is therefore solved.

Remark 4.1: We note that EC5 and EC10 are characterized by the same values of the fundamental $I(\mathbb{R}_1^2)$ convariants. It agrees with the geometry of the corresponding orthogonal webs, namely they determine two distinct coordinate systems that cover two disjoint areas of the same space (see Miller[25] for more details).

On perturbations of Dirac operators with variable magnetic field of constant direction

Serge Richard[a] and Rafael Tiedra de Aldecoa[b]
Département de Physique Théorique, Université de Genève, 24, quai E. Ansermet, 1211 Genève 4, Switzerland

(Received 5 May 2004; accepted 26 June 2004; published 25 October 2004)

We carry out the spectral analysis of matrix valued perturbations of three-dimensional Dirac operators with variable magnetic field of constant direction. Under suitable assumptions on the magnetic field and on the pertubations, we obtain a limiting absorption principle, we prove the absence of singular continuous spectrum in certain intervals and state properties of the point spectrum. Various situations, for example, when the magnetic field is constant, periodic or diverging at infinity, are covered. The importance of an internal-type operator (a two-dimensional Dirac operator) is also revealed in our study. The proofs rely on commutator methods. © *2004 American Institute of Physics.*

I. INTRODUCTION AND MAIN RESULTS

We consider a relativistic spin-$\frac{1}{2}$ particle evolving in $\mathbb{R}^3$ in presence of a variable magnetic field of constant direction. By virtue of the Maxwell equations, we may assume with no loss of generality that the magnetic field has the form $\vec{B}(x_1,x_2,x_3)=(0,0,B(x_1,x_2))$. So the unperturbed system is described, in the Hilbert space $\mathsf{L}^2(\mathbb{R}^3;\mathbb{C}^4)$, by the Dirac operator

$$H_0 := \alpha_1\Pi_1 + \alpha_2\Pi_2 + \alpha_3 P_3 + \beta m,$$

where $\beta\equiv\alpha_0,\alpha_1,\alpha_2,\alpha_3$ are the usual Dirac–Pauli matrices, m is the strictly positive mass of the particle and $\Pi_j := -i\partial_j - a_j$ are the generators of the magnetic translations with a vector potential $\vec{a}(x_1,x_2,x_3)=(a_1(x_1,x_2),a_2(x_1,x_2),0)$ that satisfies $B=\partial_1 a_2-\partial_2 a_1$. Since $a_3=0$, we have written $P_3 := -i\partial_3$ instead of Π_3.

In this paper we study the stability of certain parts of the spectrum of H_0 under matrix valued perturbations V. More precisely, if V satisfies some natural hypotheses, we shall prove the absence of singular continuous spectrum and the finiteness of the point spectrum of $H := H_0+V$ in intervals of $\mathbb{R}$ corresponding to gaps in the symmetrized spectrum of the operator $H^0 := \sigma_1\Pi_1+\sigma_2\Pi_2+\sigma_3 m$ in $\mathsf{L}^2(\mathbb{R}^2;\mathbb{C}^2)$. The matrices σ_j are the Pauli matrices and the symmetrized spectrum σ^0_{sym} of H^0 is the union of the spectra of H^0 and $-H^0$. We stress that our analysis does not require any restriction on the behavior of the magnetic field at infinity. Nevertheless, the pertinence of our work depends on a certain property of the internal-type operator H^0; namely, the size and the number of gaps in σ^0_{sym}. We refer to Refs. 2, 7, 10, 12, and 16 for various results on the spectrum of H^0, especially in the situations of physical interest, for example, when B is constant, periodic or diverges at infinity.

Technically, this work relies on commutator methods initiated by Mourre[14] and extensively developed in Ref. 1. For brevity we shall constantly refer to the latter reference for notations and definitions. Our choice of a conjugate operator enables us to treat Dirac operators with general

[a]Electronic mail: richard@kalymnos.unige.ch
[b]Electronic mail: rafael.tiedra@physics.unige.ch

magnetic fields provided they point in a constant direction. On the other hand, as already put into evidence in Ref. 9, the use of a conjugate operator with a matrix structure has a few "rather awkward consequences" for long-range perturbations. We finally mention that this study is the counterpart for Dirac operators of Ref. 13, where only Schrödinger operators are considered. Unfortunately, the intrinsic structure of the Dirac equation prevents us from using the possible magnetic anisotropy to control the perturbations (see Remark 3.2 for details).

We give now a more precise description of our results. For simplicity we impose the continuity of the magnetic field and avoid perturbations with local singularities. Hence we assume that B is a $C(\mathbb{R}^2;\mathbb{R})$-function and choose any vector potential $\vec{a}=(a_1,a_2,0)\in C(\mathbb{R}^2;\mathbb{R}^3)$, e.g. the one obtained by means of the transversal gauge.[16] The definitions below concern the admissible perturbations. In the long-range case, we restrict them to the scalar type in order not to impose unsatisfactory constraints. In the sequel, $\mathcal{B}_{\mathrm{h}}(\mathbb{C}^4)$ stands for the set of 4×4 Hermitian matrices, and $\|\cdot\|$ denotes the norm of the Hilbert space $\mathcal{H}:=\mathsf{L}^2(\mathbb{R}^3;\mathbb{C}^4)$ as well as the norm of $\mathcal{B}(\mathcal{H})$, the set of bounded linear operators on $\mathcal{H}$. $\mathbb{N}:=\{0,1,2,\ldots\}$ is the set of natural numbers. ϑ is an arbitrary $C^\infty([0,\infty))$-function such that $\vartheta=0$ near 0 and $\vartheta=1$ near infinity. Q_j is the multiplication operator by the coordinate x_j in $\mathcal{H}$, and the expression $\langle\cdot\rangle$ corresponds to $\sqrt{1+(\cdot)^2}$.

Definition 1.1: Let V be a multiplication operator associated with an element of $\mathsf{L}^\infty(\mathbb{R}^3;\mathcal{B}_{\mathrm{h}}(\mathbb{C}^4))$.

(a) *V is small at infinity if* $\lim_{r\to\infty}\|\vartheta(\langle Q\rangle/r)V\|=0$,
(b) *V is short-range if* $\int_1^\infty\|\vartheta(\langle Q_3\rangle/r)V\|\mathrm{d}r<\infty$,
(c) *Let V_L be in $C^1(\mathbb{R}^3;\mathbb{R})$ with $x\mapsto\langle x_3\rangle(\partial_j V_{\mathrm{L}})(x)$ in $\mathsf{L}^\infty(\mathbb{R}^3;\mathbb{R})$ for $j=1,2,3$, then $V:=V_{\mathsf{L}}$ is* long-range if

$$\int_1^\infty\left\|\vartheta\left(\frac{\langle Q_3\rangle}{r}\right)\langle Q_3\rangle(\partial_j V)\right\|\frac{\mathrm{d}r}{r}<\infty \text{ for } j=1,2,3.$$

Note that Definitions 1.1.(b) and 1.1.(c) differ from the standard ones: The decay rate is imposed only in the x_3 direction.

We are in a position to state our results. Let $\mathcal{D}(\langle Q_3\rangle)$ denote the domain of $\langle Q_3\rangle$ in $\mathcal{H}$, then the limiting absorption principle for H is expressed in terms of the Banach space $\mathcal{G}:=(\mathcal{D}(\langle Q_3\rangle),\mathcal{H})_{1/2,1}$ defined by real interpolation.[1] For convenience, we recall that $\mathcal{D}(\langle Q_3\rangle^s)$ is contained in $\mathcal{G}$ for each $s>1/2$.

Theorem 1.2: *Assume that B belongs to $C(\mathbb{R}^2;\mathbb{R})$, and that V belongs to $\mathsf{L}^\infty(\mathbb{R}^3;\mathcal{B}_{\mathrm{h}}(\mathbb{C}^4))$, is small at infinity and can be written as the sum of a short-range and a long-range matrix valued function. Then*

(a) *The point spectrum of the operator H in $\mathbb{R}\setminus\sigma^0_{\mathrm{sym}}$ is composed of eigenvalues of finite multiplicity and with no accumulation point in $\mathbb{R}\setminus\sigma^0_{\mathrm{sym}}$.*
(b) *The operator H has no singular continuous spectrum in $\mathbb{R}\setminus\sigma^0_{\mathrm{sym}}$.*
(c) *The limits $\lim_{\varepsilon\to+0}\langle\psi,(H-\lambda\mp i\varepsilon)^{-1}\psi\rangle$ exist for each $\psi\in\mathcal{G}$, uniformly in λ on each compact subset of $\mathbb{R}\setminus\{\sigma^0_{\mathrm{sym}}\cup\sigma_{\mathrm{pp}}(H)\}$.*

The limiting absorption principle (c), together with the inclusions mentioned before the theorem, lead to locally H-smooth operators. They imply the existence of local wave operators.

Corollary 1.3: Let V belong to $\mathsf{L}^\infty(\mathbb{R}^3;\mathcal{B}_{\mathrm{h}}(\mathbb{C}^4))$ and be small at infinity. Assume there exists some $s>1$ such that $\langle Q_3\rangle^s V\in\mathcal{B}(\mathcal{H})$. Then for each open set $J\subset\mathbb{R}\setminus\{\sigma^0_{\mathrm{sym}}\cup\sigma_{\mathrm{pp}}(H)\}$, the local wave operators $\text{s-}\lim_{t\to\pm\infty}e^{itH_0}e^{-itH}E^H(J)$ *exist and their ranges are equal to $E^{H_0}(J)$, where E^H and E^{H_0} are the spectral measures of H and H_0, respectively.*

Remark 1.4: H_0-bounded perturbations (with relative bound less than one) may also be treated with some slight adaptations of Definition 1.1. In particular Coulomb-type potentials and Zeeman effect [11] could be considered for certain magnetic fields and vector potentials. However, to our knowledge, there is not any explicit class of H_0-bounded perturbations for arbitrary continuous magnetic fields. For this reason, we concentrate on bounded potentials V only, and thus

present a simplified version of a more general, and more complicated, perturbation theory.

The above statements seem to be new for such a general magnetic field. In the special but important case of a nonzero constant magnetic field B_0, the admissible perturbations introduced in Definition 1.1 are more general than those allowed in Ref. 17. We stress that in this situation σ^0_{sym} is equal to $\{\pm\sqrt{2nB_0+m^2}: n\in\mathbb{N}\}$, which implies that there are plenty of gaps where our analysis gives results. On the other hand, if $B(x_1,x_2)\to 0$ as $|(x_1,x_2)|\to\infty$, our treatment gives no information since both $(-\infty,-m]$ and $[m,\infty)$ belong to σ^0_{sym}. We finally mention Ref. 3 for related work on perturbations of magnetic Dirac operators.

II. MOURRE ESTIMATE FOR THE OPERATOR H_0

A. Preliminaries

Let us start by recalling some known results. The operator H_0 is essentially self-adjoint on $\mathcal{D}:=C_0^\infty(\mathbb{R}^3;\mathbb{C}^4)$ [Ref. 5, Thm. 2.1]. Its spectrum is symmetric with respect to 0 and does not contain the interval $(-m,m)$ [Ref. 16, Cor. 5.14]. Thus the subset $H_0\mathcal{D}$ is dense in $\mathcal{H}$ since $\mathcal{D}$ is dense in $\mathcal{D}(H_0)$ (endowed with the graph topology) and H_0 is a homeomorphism from $\mathcal{D}(H_0)$ onto $\mathcal{H}$.

We now introduce a suitable representation of the Hilbert space $\mathcal{H}$. We consider the partial Fourier transformation

$$\mathcal{F}:\mathcal{D}\to\int_{\mathbb{R}}^{\oplus}\mathcal{H}_{12}\mathrm{d}\xi,\quad (\mathcal{F}\psi)(\xi):=\frac{1}{\sqrt{2\pi}}\int_{\mathbb{R}}e^{-i\xi x_3}\psi(\cdot,x_3)\mathrm{d}x_3, \tag{2.1}$$

where $\mathcal{H}_{12}:=\mathsf{L}^2(\mathbb{R}^2;\mathbb{C}^4)$. This map extends uniquely to a unitary operator from $\mathcal{H}$ onto $\int_{\mathbb{R}}^{\oplus}\mathcal{H}_{12}\mathrm{d}\xi$, which we denote by the same symbol $\mathcal{F}$. As a first application, one obtains the following direct integral decomposition of H_0:

$$\mathcal{F}H_0\mathcal{F}^{-1}=\int_{\mathbb{R}}^{\oplus}H_0(\xi)\mathrm{d}\xi,$$

where $H_0(\xi)$ is a self-adjoint operator in $\mathcal{H}_{12}$ acting as $\alpha_1\Pi_1+\alpha_2\Pi_2+\alpha_3\xi+\beta m$ on $C_0^\infty(\mathbb{R}^2;\mathbb{C}^4)$. In the following remark we draw the connection between the operator $H_0(\xi)$ and the operator H^0 introduced in Sec. I. It reveals the importance of the internal-type operator H^0 and shows why its negative $-H_0$ also has to be taken into account.

Remark 2.1: The operator $H_0(0)$ acting on $C_0^\infty(\mathbb{R}^2;\mathbb{C}^4)$ is unitarily equivalent to the direct sum operator $\left(\begin{smallmatrix} m & \Pi_- \\ \Pi_+ & -m\end{smallmatrix}\right)\oplus\left(\begin{smallmatrix} m & \Pi_+ \\ \Pi_- & -m\end{smallmatrix}\right)$ acting on $C_0^\infty(\mathbb{R}^2;\mathbb{C}^2)\oplus C_0^\infty(\mathbb{R}^2;\mathbb{C}^2)$, where $\Pi_\pm:=\Pi_1\pm i\Pi_2$. Now, these two matrix operators act in $\mathsf{L}^2(\mathbb{R}^2;\mathbb{C}^2)$ and are essentially self-adjoint on $C_0^\infty(\mathbb{R}^2;\mathbb{C}^2)$ [Ref. 5, Thm. 2.1]. However, the first one is nothing but H^0, while the second one is unitarily equivalent to $-H^0$ (this can be obtained by means of the abstract Foldy–Wouthuysen transformation [Ref. 16, Thm. 5.13]). Therefore, $H_0(0)$ is essentially self-adjoint on $C_0^\infty(\mathbb{R}^2;\mathbb{C}^4)$ and

$$\sigma[H_0(0)]=\sigma(H^0)\cup\sigma(-H^0)\equiv\sigma^0_{\mathrm{sym}}.$$

Moreover, there exists a relation between $\sigma[H_0(\xi)]$ and σ^0_{sym}. Indeed, for $\xi\in\mathbb{R}$ *fixed, one can show that $H_0(\xi)^2=H_0(0)^2+\xi^2$ on $\mathcal{D}(H_0(\xi)^2)=\mathcal{D}(H_0(0)^2)$, so that*

$$\sigma[H_0(\xi)^2]=\sigma[H_0(0)^2+\xi^2]=(\sigma[H_0(0)])^2+\xi^2=(\sigma^0_{\mathrm{sym}})^2+\xi^2, \tag{2.2}$$

where the spectral theorem has been used for the second equality. Since the spectrum of $H_0(\xi)$ is symmetric with respect to 0 [Ref. 16, Cor. 5.14], it follows that

$$\sigma[H_0(\xi)]=-\sqrt{(\sigma^0_{\mathrm{sym}})^2+\xi^2}\cup\sqrt{(\sigma^0_{\mathrm{sym}})^2+\xi^2}.$$

Define $\mu_0:=\inf|\sigma^0_{\mathrm{sym}}|$ (which is bigger or equal to m because H^0 has no spectrum in $(-m,m)$ [Ref. 16, Cor. 5.14]). Then from the direct integral decomposition of H_0, one readily gets

$$\sigma(H_0) = (-\infty, -\mu_0] \cup [\mu_0, +\infty). \tag{2.3}$$

We conclude the section by giving two technical lemmas in relation with the operator H_0^{-1}. Proofs can be found in an Appendix.

Lemma 2.2:

(a) *For each* $n \in \mathbb{N}$, $H_0^{-n}\mathcal{D}$ *belongs to* $\mathcal{D}(Q_3)$,
(b) $P_3 H_0^{-1}$ *is a bounded self-adjoint operator equal to* $H_0^{-1}P_3$ *on* $\mathcal{D}(P_3)$. *In particular,* $H_0^{-1}\mathcal{H}$ *belongs to* $\mathcal{D}(P_3)$.

One may observe that, given a $C^1(\mathbb{R};\mathbb{C})$-function f with f' bounded, the operator $f(Q_3)$ is well-defined on $\mathcal{D}(Q_3)$. Thus $f(Q_3)H_0^{-n}\mathcal{D}$ is a subset of $\mathcal{H}$ for each $n \in \mathbb{N}$. The preceding lemma and the following simple statement are constantly used in the sequel.

Lemma 2.3: Let f *be in* $C^1(\mathbb{R};\mathbb{C})$ *with* f' *bounded, and* $n \in \mathbb{N}$. *Then*

(a) $iH_0^{-1}f(Q_3) - if\,(Q_3)H_0^{-1}$ *is equal to* $-H_0^{-1}\alpha_3 f'(Q_3)H_0^{-1}$ *on* $H_0^{-n}\mathcal{D}$,
(b) $P_3H_0^{-1}f(Q_3) - f(Q_3)P_3H_0^{-1}$ *is equal to* $i(P_3H_0^{-1}\alpha_3 - 1)f'(Q_3)H_0^{-1}$ *on* $\mathcal{D}$.

Both right terms belong to $\mathcal{B}(\mathcal{H})$. For shortness we shall denote them by $[iH_0^{-1}, f(Q_3)]$ and $[P_3H_0^{-1}, f(Q_3)]$, respectively.

B. The conjugate operator

The aim of the present section is to define an appropriate operator conjugate to H_0. To begin with, one observes that $Q_3P_3H_0^{-1}\mathcal{D} \subset \mathcal{H}$ as a consequence of Lemma 2.2. In particular, the formal expression

$$A := \frac{1}{2}(H_0^{-1}P_3Q_3 + Q_3P_3H_0^{-1}) \tag{2.4}$$

leads to a well-defined symmetric operator on $\mathcal{D}$.

Proposition 2.4: The operator A is essentially self-adjoint on $\mathcal{D}$ *and its closure is essentially self-adjoint on any core for* $\langle Q_3\rangle$.

Proof: The claim is a consequence of Nelson's criterion of essential self-adjointness [Ref. 15 Thm. X.37] applied to the triple $\{\langle Q_3\rangle, A, \mathcal{D}\}$. Let us simply verify the two hypotheses of that theorem. By using Lemmas 2.2 and 2.3, one first obtains that for all $\psi \in \mathcal{D}$:

$$\|A\psi\| = \left\| \left(P_3H_0^{-1}Q_3 - \frac{1}{2}[P_3H_0^{-1}, Q_3] \right)\psi \right\| \leqslant c\|\langle Q_3\rangle\psi\|,$$

for some constant $c > 0$ independent of ψ. Then, for all $\psi \in \mathcal{D}$ one has

$$\langle A\psi, \langle Q_3\rangle\psi\rangle - \langle \langle Q_3\rangle\psi, A\psi\rangle = i\,\mathrm{Im}\langle Q_3\psi, [P_3H_0^{-1}, \langle Q_3\rangle]\psi\rangle = i\,\mathrm{Re}\langle(\alpha_3P_3H_0^{-1} - 1)Q_3\psi, Q_3\langle Q_3\rangle^{-1}H_0^{-1}\psi\rangle.$$

A few more commutator calculations, using again Lemma 2.3 with $f(Q_3) = \langle Q_3\rangle^{1/2}$, lead to the following result: For all $\psi \in \mathcal{D}$, there exists a constant $d > 0$ independent of ψ such that

$$|\langle A\psi, \langle Q_3\rangle\psi\rangle - \langle \langle Q_3\rangle\psi, A\psi\rangle| \leqslant d\|\langle Q_3\rangle^{1/2}\psi\|^2.$$

□

As far as we know, the operator (2.4) has never been employed before for the study of magnetic Dirac operators. In Ref. 17, a slightly different conjugate operator has been introduced for Dirac operators with constant magnetic field, namely

$$A = \frac{1}{2} U_{\mathrm{FW}}^{-1} (\langle P_3 \rangle^{-1} P_3 Q_3 + Q_3 P_3 \langle P_3 \rangle^{-1}) \beta U_{\mathrm{FW}},$$

where U_{FW} is the Foldy–Wouthuysen transformation that diagonalizes H_0. Though this operator could also be used in our more general context, it presents the major drawback of making the perturbation theory somewhat more complicated.

C. Strict Mourre estimate for H_0

We now gather some results on the regularity of H_0 with respect to A. We recall that $\mathcal{D}(H_0)^*$ is the adjoint space of $\mathcal{D}(H_0)$ and that one has the continuous dense embeddings $\mathcal{D}(H_0) \hookrightarrow \mathcal{H} \hookrightarrow \mathcal{D}(H_0)^*$, where $\mathcal{H}$ is identified with its adjoint through the Riesz isomorphism.

Proposition 2.5:

(a) *The quadratic form* $\mathcal{D}(A) \ni \psi \mapsto \langle H_0^{-1}\psi, iA\psi\rangle - \langle A\psi, iH_0^{-1}\psi\rangle$ *extends uniquely to the bounded form defined by the operator* $-H_0^{-1}(P_3 H_0^{-1})^2 H_0^{-1} \in \mathcal{B}(\mathcal{H})$.

(b) *The group* $\{e^{itA}\}_{t\in\mathbb{R}}$ *leaves* $\mathcal{D}(H_0)$ *invariant.*

(c) *The quadratic form*

$$\mathcal{D}(A) \ni \psi \mapsto \langle H_0^{-1}(P_3 H_0^{-1})^2 H_0^{-1}\psi, iA\psi\rangle - \langle A\psi, iH_0^{-1}(P_3 H_0^{-1})^2 H_0^{-1}\psi\rangle, \tag{2.5}$$

extends uniquely to a bounded form on $\mathcal{H}$.

In the framework of Ref. 1, the statements of (a) and (c) mean that H_0 is of class $C^1(A)$ and $C^2(A)$, respectively.

Proof:

(a) For any $\psi \in \mathcal{D}$, one gets

$$\begin{aligned} 2(\langle H_0^{-1}\psi, iA\psi\rangle - \langle A\psi, iH_0^{-1}\psi\rangle) &= \langle [iH_0^{-1}, Q_3]\psi, P_3 H_0^{-1}\psi\rangle + \langle P_3 H_0^{-1}\psi, [iH_0^{-1}, Q_3]\psi\rangle \\ &= -\langle H_0^{-1}\psi, (\alpha_3 P_3 H_0^{-1} + H_0^{-1}\alpha_3 P_3) H_0^{-1}\psi\rangle, \end{aligned} \tag{2.6}$$

where we have used Lemmas 2.2 and 2.3. Furthermore, one has

$$H_0^{-1}\alpha_3 = -\alpha_3 H_0^{-1} + 2H_0^{-1} P_3 H_0^{-1}, \tag{2.7}$$

as an operator identity in $\mathcal{B}(\mathcal{H})$. When inserting (2.7) into (2.6), one obtains the equality

$$\langle H_0^{-1}\psi, iA\psi\rangle - \langle A\psi, iH_0^{-1}\psi\rangle = -\langle \psi, H_0^{-1}(P_3 H_0^{-1})^2 H_0^{-1}\psi\rangle. \tag{2.8}$$

Since $\mathcal{D}$ is a core for A, the statement is obtained by density. We shall write $[iH_0^{-1}, A]$ for the bounded extension of the quadratic form $\mathcal{D}(A) \ni \psi \mapsto \langle H_0^{-1}\psi, iA\psi\rangle - \langle A\psi, iH_0^{-1}\psi\rangle$.

(b) Since $\mathcal{D}(H_0)$ is not explicitly known, one has to invoke an abstract result in order to show the invariance. Let $[iH_0, A]$ be the operator in $\mathcal{B}(\mathcal{D}(H_0), \mathcal{D}(H_0)^*)$ associated with the unique extension to $\mathcal{D}(H_0)$ of the quadratic form $\psi \mapsto \langle H_0\psi, iA\psi\rangle - \langle A\psi, iH_0\psi\rangle$ defined for all $\psi \in \mathcal{D}(H_0) \cap \mathcal{D}(A)$. Then $\mathcal{D}(H_0)$ is invariant under $\{e^{itA}\}_{t\in\mathbb{R}}$ if H_0 is of class $C^1(A)$ and if $[iH_0, A]\mathcal{D}(H_0) \subset \mathcal{H}$ [Ref. 8, Lemma 2]. From Eq. (2.8) and [Ref. 1, Eq. (6.2.24)], one obtains the following equalities valid in form sense on $\mathcal{H}$:

$$-H_0^{-1}(P_3 H_0^{-1})^2 H_0^{-1} = [iH_0^{-1}, A] = -H_0^{-1}[iH_0, A]H_0^{-1}.$$

Thus $[iH_0, A]$ and $(P_3 H_0^{-1})^2$ are equal as operators in $\mathcal{B}(\mathcal{D}(H_0), \mathcal{D}(H_0)^*)$. But since the latter belongs to $\mathcal{B}(\mathcal{H})$, $[iH, A]\mathcal{D}(H_0)$ is included in $\mathcal{H}$.

(c) The boundedness on $\mathcal{D}$ of the quadratic form (2.5) follows by inserting (2.4) into the r.h.s. term of (2.5) and by applying repeatedly Lemma 2.3 with $f(Q_3) = Q_3$. Then one concludes by using the density of $\mathcal{D}$ in $\mathcal{D}(A)$. □

From now on we shall simply denote the closure in $\mathcal{H}$ of $[iH_0,A]$ by $T=(P_3H_0^{-1})^2\in\mathcal{B}(\mathcal{H})$. One interest of this operator is that $\mathcal{F}T\mathcal{F}^{-1}$ is boundedly decomposable [Ref. 6, Prop. 3.6], more precisely:

$$\mathcal{F}T\mathcal{F}^{-1}=\int_{\mathbb{R}}^{\oplus}T(\xi)\mathrm{d}\xi \text{ with } T(\xi)=\xi^2H_0(\xi)^{-2}\in\mathcal{B}(\mathcal{H}_{12}).$$

In the following definition, we introduce two functions giving the optimal value to a Mourre-type inequality. Remark that slight modifications have been done with regard to the usual definition [Ref. 1, Sec. 7.2.1].

Definition 6: Let H be a self-adjoint operator in a Hilbert space $\mathcal{H}$ and assume that S is a symmetric operator in $\mathcal{B}(\mathcal{D}(H),\mathcal{D}(H)^*)$. Let $E^H(\lambda;\varepsilon):=E^H((\lambda-\varepsilon,\lambda+\varepsilon))$ be the spectral projection of H for the interval $(\lambda-\varepsilon,\lambda+\varepsilon)$. Then, for all $\lambda\in\mathbb{R}$ and $\varepsilon>0$, we set

$$\varrho_H^S(\lambda;\varepsilon):=\sup\{a\in\mathbb{R}:E^H(\lambda;\varepsilon)SE^H(\lambda;\varepsilon)\geqslant aE^H(\lambda;\varepsilon)\},$$

$$\varrho_H^S(\lambda):=\sup_{\varepsilon>0}\varrho_H^S(\lambda;\varepsilon).$$

Let us make three observations: The inequality $\varrho_H^S(\lambda;\varepsilon')\leqslant\varrho_H^S(\lambda;\varepsilon)$ holds whenever $\varepsilon'\geqslant\varepsilon$, $\varrho_H^S(\lambda)=+\infty$ if λ does not belong to the spectrum of H, and $\varrho_H^S(\lambda)\geqslant 0$ for all $\lambda\in\mathbb{R}$ if $S\geqslant 0$. We also mention that in the case of two self-adjoint operators H and A in $\mathcal{H}$, with H of class $C^1(A)$ and $S:=[iH,A]$, the function $\varrho_H^S(\cdot)$ is equal to the function $\varrho_H^A(\cdot)$ defined in [Ref. 1, Eq. 7.2.4]. Taking advantage of the direct integral decomposition of H_0 and T, one obtains for all $\lambda\in\mathbb{R}$ and $\varepsilon>0$:

$$\varrho_{H_0}^T(\lambda;\varepsilon)=\operatorname*{ess\,inf}_{\xi\in\mathbb{R}}\varrho_{H_0(\xi)}^{T(\xi)}(\lambda;\varepsilon). \tag{2.9}$$

Now we can deduce a lower bound for $\varrho_{H_0}^T(\cdot)$.

Proposition 2.7: One has

$$\varrho_{H_0}^T(\lambda)\geqslant\inf\left\{\frac{\lambda^2-\mu^2}{\lambda^2}:\mu\in\sigma_{\mathrm{sym}}^0\cap[0,|\lambda|]\right\}, \tag{2.10}$$

with the convention that the infimum over an empty set is $+\infty$.

Proof: We first consider the case $\lambda\geqslant 0$.

(i) Recall from (2.3) that $\mu_0\equiv\inf|\sigma_{\mathrm{sym}}^0|=\inf\{\sigma(H_0)\cap[0,+\infty)\}$. Thus, for $\lambda\in[0,\mu_0)$ the l.h.s. term of (2.10) is equal to $+\infty$, since λ does not belong to the spectrum of H_0. Hence (2.10) is satisfied on $[0,\mu_0)$.

(ii) If $\lambda\in\sigma_{\mathrm{sym}}^0$, then the r.h.s. term of (2.10) is equal to 0. However, since T is positive, $\varrho_{H_0}^T(\lambda)\geqslant 0$. Hence the relation (2.10) is again satisfied.

(iii) Let $0<\varepsilon<\mu_0<\lambda$. Direct computations using the explicit form of $T(\xi)$ and the spectral theorem for the operator $H_0(\xi)$ show that for ξ fixed, one has

$$\varrho_{H_0(\xi)}^{T(\xi)}(\lambda;\varepsilon)=\inf\left\{\frac{\xi^2}{\rho^2}:\rho\in(\lambda-\varepsilon,\lambda+\varepsilon)\cap\sigma[H_0(\xi)]\right\}\geqslant\frac{\xi^2}{(\lambda+\varepsilon)^2}. \tag{2.11}$$

On the other hand, one has $\varrho_{H_0(\xi)}^{T(\xi)}(\lambda;\varepsilon)=+\infty$ if $(\lambda-\varepsilon,\lambda+\varepsilon)\cap\sigma[H_0(\xi)]=\emptyset$, and *a fortiori*

$$\varrho_{H_0(\xi)}^{T(\xi)}(\lambda;\varepsilon)=+\infty \text{ if } ((\lambda-\varepsilon)^2,(\lambda+\varepsilon)^2)\cap\sigma[H_0(\xi)^2]=\emptyset.$$

Thus, by taking into account Eqs. (2.9) and (2.11), the previous observation and relation (2.2), one obtains that

$$\varrho^T_{H_0}(\lambda;\varepsilon) \geqslant \operatorname{ess\,inf}\left\{ \frac{\xi^2}{(\lambda+\varepsilon)^2} : \xi^2 \in ((\lambda-\varepsilon)^2,(\lambda+\varepsilon)^2) - (\sigma^0_{\rm sym})^2 \right\}. \tag{2.12}$$

Suppose now that $\lambda \notin \sigma^0_{\rm sym}$, define $\mu := \sup\{\sigma^0_{\rm sym} \cap [0,\lambda]\}$ and choose $\varepsilon > 0$ such that $\mu < \lambda - \varepsilon$. Then the inequality (2.12) implies that

$$\varrho^T_{H_0}(\lambda;\varepsilon) \geqslant \frac{(\lambda-\varepsilon)^2 - \mu^2}{(\lambda+\varepsilon)^2}.$$

Hence the relation (2.10) follows from the above formula when $\varepsilon \to 0$.

For $\lambda < 0$, similar arguments lead to the inequality

$$\varrho^T_{H_0}(\lambda) \geqslant \inf\left\{ \frac{\lambda^2 - \mu^2}{\lambda^2} : \mu \in \sigma^0_{\rm sym} \cap [\lambda,0] \right\}.$$

The claim is then a direct consequence of the symmetry of $\sigma^0_{\rm sym}$ with respect to 0. □

The above proposition implies that we have a strict Mourre estimate, i.e., $\varrho^T_{H_0}(\cdot) > 0$, on $\mathbb{R} \setminus \sigma^0_{\rm sym}$. Moreover it is not difficult to prove that $\varrho^T_{H_0}(\lambda) = 0$ whenever $\lambda \in \sigma^0_{\rm sym}$. It follows that the conjugate operator A does not allow to get spectral informations on H_0 in the subset $\sigma^0_{\rm sym}$.

III. MOURRE ESTIMATE FOR THE PERTURBED HAMILTONIAN

In the sequel, we consider the self-adjoint operator $H := H_0 + V$ with a potential V that belongs to $\mathsf{L}^\infty(\mathbb{R}^3;\mathcal{B}_{\rm h}(\mathbb{C}^4))$. The domain of H is equal to the domain $\mathcal{D}(H_0)$ of H_0. We first give a result on the difference of the resolvents $(H-z)^{-1} - (H_0-z)^{-1}$ and, as a corollary, we obtain the localization of the essential spectrum of H.

Proposition 3.1: Assume that V is small at infinity. Then for all $z \in \mathbb{C} \setminus (\sigma(H) \cup \sigma(H_0))$ the difference $(H-z)^{-1} - (H_0-z)^{-1}$ is a compact operator. It follows in particular that $\sigma_{\rm ess}(H) = \sigma_{\rm ess}(H_0)$.

Proof: Since V is bounded and small at infinity, it is enough to check that H_0 is locally compact [Ref. 16, Sec. 4.3.4]. However, the continuity of $\vec{a}$ implies that $\mathcal{D}(H_0) \subset \mathcal{H}^{1/2}_{\rm loc}$ [Ref. 4, Thm. 1.3]. Hence the statement follows by usual arguments. □

Remark 3.2: In the study of an analogous problem for Schrödinger operators,[13] the authors prove a result similar to Proposition 3.1 without assuming that the perturbation is small at infinity (it only has to be small with respect to B in a suitable sense). Their proof mainly relies on the structural inequalities $H_{\rm Sch} := \Pi_1^2 + \Pi_2^2 + P_3^2 \geqslant \pm B$. In the Dirac case, the counterpart of these turn out to be

$$H_0^2 \geqslant 2B \cdot \operatorname{diag}(0,1,0,1) \text{ and } H_0^2 \geqslant -2B \cdot \operatorname{diag}(1,0,1,0),$$

where diag(…) *stands for a diagonal matrix. If we assume that the magnetic field is bounded from below, the first inequality enables us to treat pertubations of the type* $\operatorname{diag}(V_1,V_2,V_3,V_4)$ *with V_2, V_4 small with respect to the magnetic field and V_1, V_3 small at infinity in the original sense. If the magnetic field is bounded from above, the second inequality has to be used and the role of V_2, V_4 and V_1, V_3 are interchanged. However, the unnatural character of these perturbations motivated us not to include their treatment in this paper.*

In order to obtain a limiting absorption principle for H, one has to invoke some abstract results. An optimal regularity condition of H with respect to A has to be satisfied. We refer to Ref. 1, Chap. 5 for the definitions of $\mathcal{C}^{1,1}(A)$ and $\mathcal{C}^{1,1}(A;\mathcal{D}(H_0),\mathcal{D}(H_0)^*)$, and for more explanations on regularity conditions.

Proposition 3.3: Let V be a short-range or a long-range potential. Then H is of class $\mathcal{C}^{1,1}(A)$.

Proof: Since $\{e^{itA}\}_{t\in\mathbb{R}}$ leaves $\mathcal{D}(H) = \mathcal{D}(H_0)$ invariant, it is equivalent to prove that H belongs to $\mathcal{C}^{1,1}(A;\mathcal{D}(H_0),\mathcal{D}(H_0)^*)$ [Ref. 1, Thm. 6.3.4.(b)]. But in Proposition 2.5.(c), it has already been shown that H_0 is of class $C^2(A)$, so that H_0 is of class $\mathcal{C}^{1,1}(A;\mathcal{D}(H_0),\mathcal{D}(H_0)^*)$. Thus it is enough to

prove that V belongs to $\mathcal{C}^{1,1}(A;\mathcal{D}(H_0),\mathcal{D}(H_0)^*)$. In the short-range case, we shall use Ref. 1, Thm. 7.5.8, which implies that V belongs to $\mathcal{C}^{1,1}(A;\mathcal{D}(H_0),\mathcal{D}(H_0)^*)$. The conditions needed for that theorem are obtained in points (i) and (ii) below. In the long-range case, the claim follows by Ref. 1, Thm. 7.5.7, which can be applied because of points (i), (iii), (iv), and (v) below.

(i) We first check that $\{e^{it\langle Q_3\rangle}\}_{t\in\mathbb{R}}$ is a polynomially bounded C_0-group in $\mathcal{D}(H_0)$ and in $\mathcal{D}(H_0)^*$. Lemma 2.3.(a) (with $n=0$ and $f(Q_3)=\langle Q_3\rangle$) implies that H_0 is of class $C^1(\langle Q_3\rangle)$. Furthermore, by an argument similar to that given in part (b) of the proof of Proposition 2.5, one shows that $\{e^{it\langle Q_3\rangle}\}_{t\in\mathbb{R}}$ leaves $\mathcal{D}(H_0)$ invariant. Since $H_0e^{it\langle Q_3\rangle}-e^{it\langle Q_3\rangle}H_0$, defined on $\mathcal{D}$, extends continuously to the operator $t\alpha_3Q_3\langle Q_3\rangle^{-1}e^{it\langle Q_3\rangle}\in\mathcal{B}(\mathcal{H})$, one gets that $\|e^{it\langle Q_3\rangle}\|_{\mathcal{B}(\mathcal{D}(H_0))}\leqslant \mathrm{Const.}\langle t\rangle$ for all $t\in\mathbb{R}$, i.e., the polynomial bound of the C_0-group in $\mathcal{D}(H_0)$. By duality, $\{e^{it\langle Q_3\rangle}\}_{t\in\mathbb{R}}$ extends to a polynomially bounded C_0-group in $\mathcal{D}(H_0)^*$ [Ref. 1, Prop. 6.3.1]. The generators of these C_0-groups are densely defined and closed in $\mathcal{D}(H_0)$ and in $\mathcal{D}(H_0)^*$, respectively; both are simply denoted by $\langle Q_3\rangle$.

(ii) Since $\{e^{itA}\}_{t\in\mathbb{R}}$ leaves $\mathcal{D}(H_0)$ invariant, one may also consider the C_0-group in $\mathcal{D}(H_0)$ obtained by restriction and the C_0-group in $\mathcal{D}(H_0)^*$ obtained by extension. The generator of each of these C_0-groups will be denoted by A. Let $\mathcal{D}(A;\mathcal{D}(H_0)):=\{\varphi\in\mathcal{D}(H_0)\cap\mathcal{D}(A):A\varphi\in\mathcal{D}(H_0)\}$ be the domain of A in $\mathcal{D}(H_0)$, and let $\mathcal{D}(A^2;\mathcal{D}(H_0)):=\{\varphi\in\mathcal{D}(H_0)\cap\mathcal{D}(A^2):A\varphi,A^2\varphi\in\mathcal{D}(H_0)\}$ be the domain of A^2 in $\mathcal{D}(H_0)$. We now check that $\langle Q_3\rangle^{-1}A$ and $\langle Q_3\rangle^{-2}A^2$, defined on $\mathcal{D}(A;\mathcal{D}(H_0))$ and on $\mathcal{D}(A^2;\mathcal{D}(H_0))$, respectively, extend to operators in $\mathcal{B}(\mathcal{D}(H_0))$. After some commutator calculations performed on $\mathcal{D}$ and involving Lemma 2.3, one first obtains that $\langle Q_3\rangle^{-1}A$ and $\langle Q_3\rangle^{-2}A$ are, respectively, equal on $\mathcal{D}$ to some operators S_1 and $S_2\langle Q_3\rangle^{-1}$ in $\mathcal{B}(\mathcal{H})$, where S_1 and S_2 are polynomials in H_0^{-1}, $P_3H_0^{-1}$, α_3 and $f(Q_3)$ for bounded functions f with bounded derivatives. Since $\mathcal{D}$ is a core for A, these equalities even hold on $\mathcal{D}(A)$. Hence one has on $\mathcal{D}(A^2)$:

$$\langle Q_3\rangle^{-2}A^2=(\langle Q_3\rangle^{-2}A)A=S_2\langle Q_3\rangle^{-1}A=S_2S_1.$$

In consequence, $\langle Q_3\rangle^{-1}A$ and $\langle Q_3\rangle^{-2}A^2$ are equal on $\mathcal{D}(A)$ and on $\mathcal{D}(A^2)$, respectively, to operators expressed only in terms of H_0^{-1}, $P_3H_0^{-1}$, α_3, and $f(Q_3)$ for bounded functions f with bounded derivatives. Moreover, one easily observes that these operators and their products belong to $\mathcal{B}(\mathcal{D}(H_0))$. Thus, it follows that $\langle Q_3\rangle^{-1}A$ and $\langle Q_3\rangle^{-2}A^2$ are equal on $\mathcal{D}(A;\mathcal{D}(H_0))$ and on $\mathcal{D}(A^2;\mathcal{D}(H_0))$, respectively, to some operators belonging to $\mathcal{B}(\mathcal{D}(H_0))$.

(iii) By duality, the operator $(\langle Q_3\rangle^{-1}A)^*$ belongs to $\mathcal{B}(\mathcal{D}(H_0)^*)$. Now, for $\psi\in\mathcal{D}(H_0)^*$ and $\varphi\in\mathcal{D}(A;\mathcal{D}(H_0))$, one has

$$\langle(\langle Q_3\rangle^{-1}A)^*\psi,\varphi\rangle=\langle\psi,\langle Q_3\rangle^{-1}A\varphi\rangle=\langle\langle Q_3\rangle^{-1}\psi,A\varphi\rangle, \tag{3.13}$$

where $\langle\cdot,\cdot\rangle$ denotes the duality between $\mathcal{D}(H_0)$ and $\mathcal{D}(H_0)^*$. Since $\langle Q_3\rangle^{-1}$ is a homeomorphism from $\mathcal{D}(H_0)^*$ to the domain of $\langle Q_3\rangle$ in $\mathcal{D}(\mathcal{H}_0)^*$, it follows from (3.13) that the domain of $\langle Q_3\rangle$ in $\mathcal{D}(H_0)^*$ is included in the domain of A in $\mathcal{D}(H_0)^*$ (the adjoint of the operator A in $\mathcal{D}(H_0)$ is equal to the operator $-A$ in $\mathcal{D}(H_0)^*$).

(iv) The inequality $r\|(\langle Q_3\rangle+ir)^{-1}\|_{\mathcal{B}(\mathcal{D}(H_0)^*)}\leqslant\mathrm{Const.}$ for all $r>0$ is obtained from relation (A1), given in the proof of Lemma 2.3, with $f(Q_3)=(\langle Q_3\rangle+ir)^{-1}$.

(v) Assume that V is a long-range (scalar) potential. Then the following equality holds in form sense on $\mathcal{D}$:

$$2[iV,A]=-Q_3(\partial_3V)H_0^{-1}-H_0^{-1}Q_3(\partial_3V)+[iV,H_0^{-1}]Q_3P_3+P_3Q_3[iV,H_0^{-1}], \tag{3.14}$$

with $[iV,H_0^{-1}]=\Sigma_{j=1}^3H_0^{-1}\alpha_j(\partial_jV)H_0^{-1}$. Using Lemma 2.3a, one gets that the last two terms in (3.14) are equal in form sense on $\mathcal{D}$ to

$$2\ \mathrm{Re}\sum_{j=1}^{3} H_0^{-1}\alpha_j Q_3(\partial_j V)P_3 H_0^{-1} - 2\ \mathrm{Im}\sum_{j=1}^{3} H_0^{-1}\alpha_j(\partial_j V)H_0^{-1}\alpha_3 P_3 H_0^{-1}.$$

It follows that $[iV,A]$, defined in form sense on $\mathcal{D}$, extends continuously to an operator in $\mathcal{B}(\mathcal{H})$. Now let ϑ be as in Definition 1.1. Then a direct calculation using the explicit form of $[iV,A]$ obtained above implies that

$$\left\| \vartheta\left(\frac{\langle Q_3\rangle}{r}\right)[iV,A] \right\| \leqslant \mathrm{C}\sum_{j=1}^{3} \left\| \vartheta\left(\frac{\langle Q_3\rangle}{r}\right)\langle Q_3\rangle(\partial_j V) \right\| + \frac{\mathrm{D}}{r},$$

for all $r>0$ and some positive constants C and D. □

As a direct consequence, one obtains that

Lemma 3.4: If V satisfies the hypotheses of Theorem 1.2, then A is conjugate to H on $\mathbb{R}\setminus\sigma^0_{\mathrm{sym}}$.

Proof: Proposition 3.3 implies that both H_0 and H are of class $\mathcal{C}^{1,1}(A)$. Furthermore, the difference $(H+i)^{-1}-(H_0+i)^{-1}$ is compact by Proposition 3.1, and $\varrho^T_{H_0}>0$ on $\mathbb{R}\setminus\sigma^0_{\mathrm{sym}}$ due to Proposition 2.7. Hence the claim follows by [Ref. 1, Thm. 7.2.9 & Prop. 7.2.6]. □

We can finally give the proof of Theorem 1.2.

Proof of Theorem 1.2: Since A is conjugate to H on $\mathbb{R}\setminus\sigma^0_{\mathrm{sym}}$ by Lemma 3.4, the assertions (a) and (b) follow by the abstract conjugate operator method [Ref. 1, Cor. 7.2.11 & Thm. 7.4.2].

The limiting absorption principle directly obtained via Ref. 1, Thm. 7.4.1 is expressed in terms of some interpolation space, associated with $\mathcal{D}(A)$, and of its adjoint. Since both are not standard spaces, one may use Ref. 1, prop. 7.4.4 for the Friedrichs couple $(\mathcal{D}(\langle Q_3\rangle),\mathcal{H})$ to get the statement (c). In order to verify the hypotheses of that proposition, one has to check that for each $z\in\mathbb{C}\setminus\sigma(H)$ the inclusion $(H-z)^{-1}\mathcal{D}(\langle Q_3\rangle)\subset\mathcal{D}(A)$ holds. However, since $\mathcal{D}(\langle Q_3\rangle)$ is included in $\mathcal{D}(A)$ by Proposition 2.4, it is sufficient to prove that for each $z\in\mathbb{C}\setminus\sigma(H)$ the operator $(H-z)^{-1}$ leaves $\mathcal{D}(\langle Q_3\rangle)$ invariant. Since $\mathcal{D}(H)=\mathcal{D}(H_0)$ is left invariant by the group $\{e^{it\langle Q_3\rangle}\}_{t\in\mathbb{R}}$ (see Proposition 3.3 (i)) one easily gets from Ref. 1, Thm. 6.3.4.(a) that H is of class $C^1(\langle Q_3\rangle)$, which implies the required invariance of $\mathcal{D}(\langle Q_3\rangle)$ [Ref. 1, Thm. 6.2.10.(b)]. □

ACKNOWLEDGMENTS

We thank M. Măntoiu for having suggested to us the present study. We are also grateful to W. Amrein, H. D. Cornean, and B. Thaller for their helpful remarks. This work was partially supported by the Swiss National Science Foundation.

APPENDIX

Proof of Lemma 2.2: (a) Let φ, ψ be in $\mathcal{D}$. Using the transformation (2.1), one gets

$$\langle H_0^{-n}\varphi, Q_3\psi\rangle = \int_{\mathbb{R}} \langle H_0(\xi)^{-n}(\mathcal{F}\varphi)(\xi), (i\partial_\xi\mathcal{F}\psi)(\xi)\rangle_{\mathcal{H}_{12}}\mathrm{d}\xi.$$

Now the map $\mathbb{R}\ni\xi\mapsto H_0(\xi)^{-n}\in\mathcal{B}(\mathcal{H}_{12})$ is norm differentiable with its derivative equal to $-\Sigma_{j=1}^{n}H_0(\xi)^{-j}\alpha_3 H_0(\xi)^{j-n-1}$. Hence $\{\partial_\xi[H_0(\xi)^{-n}(\mathcal{F}\varphi)(\xi)]\}_{\xi\in\mathbb{R}}$ belongs to $\int_{\mathbb{R}}^{\oplus}\mathcal{H}_{12}\mathrm{d}\xi$. Thus one can perform an integration by parts (with vanishing boundary contributions) and obtain

$$\langle H_0^{-n}\varphi, Q_3\psi\rangle = \int_{\mathbb{R}} \langle i\partial_\xi[H_0(\xi)^{-n}(\mathcal{F}\varphi)(\xi)], (\mathcal{F}\psi)(\xi)\rangle_{H_{12}}\mathrm{d}\xi.$$

It follows that $|\langle H_0^{-n}\varphi, Q_3\psi\rangle|\leqslant \mathrm{const.}\|\psi\|$ for all $\psi\in\mathcal{D}$. Since Q_3 is essentially self-adjoint on $\mathcal{D}$, this implies that $H_0^{-n}\varphi$ belongs to $\mathcal{D}(Q_3)$.

(b) The boundedness of $P_3H_0^{-1}$ is a consequence of the estimate

$$\operatorname*{ess\,sup}_{\xi\in\mathbb{R}}\|\xi H_0(\xi)^{-1}\|_{\mathcal{B}(\mathcal{H}_{12})}=\operatorname*{ess\,sup}_{\xi\in\mathbb{R}}\left\|\frac{|\xi|}{[H_0(0)^2+\xi^2]^{1/2}}\right\|_{\mathcal{B}(\mathcal{H}_{12})}<\infty$$

and of the direct integral formalism [Ref. 6, Prop. 3.6 & 3.7]. The remaining assertions follow by standard arguments. □

Proof of Lemma 2.3: (a) One first observes that the following equality holds on $\mathcal{D}$:

$$iH_0^{-1}f(Q_3)H_0=-H_0^{-1}\alpha_3 f'(Q_3)+if(Q_3). \tag{A1}$$

Now, for $\varphi,\psi\in\mathcal{D}$ and $\eta\in H_0^n\mathcal{D}$, one has

$$\begin{aligned}
&\langle\varphi,iH_0^{-1}f(Q_3)\,\eta\rangle-\langle\varphi,if(Q_3)H_0^{-1}\eta\rangle\\
&\quad=\langle\varphi,iH_0^{-1}f(Q_3)H_0\psi\rangle+\langle\varphi,iH_0^{-1}f(Q_3)(\eta-H_0\psi)\rangle-\langle\overline{f}(Q_3)\varphi,iH_0^{-1}\eta\rangle\\
&\quad=-\langle\varphi,H_0^{-1}\alpha_3 f'(Q_3)H_0^{-1}\eta\rangle-\langle\varphi,H_0^{-1}\alpha_3 f'(Q_3)H_0^{-1}(H_0\psi-\eta)\rangle\\
&\qquad+\langle\overline{f}(Q_3)\varphi,iH_0^{-1}(H_0\psi-\eta)\rangle+\langle\overline{f}(Q_3)H_0^{-1}\varphi,i(\eta-H_0\psi)\rangle,
\end{aligned}$$

where we have used (A1) in the last equality for the term $\langle\varphi,iH_0^{-1}f(Q_3)H_0\psi\rangle$. Hence there exists a constant c (depending on φ) such that

$$\left|\langle\varphi,iH_0^{-1}f(Q_3)\,\eta\rangle-\langle\varphi,if(Q_3)H_0^{-1}\eta\rangle+\langle\varphi,H_0^{-1}\alpha_3 f'(Q_3)H_0^{-1}\eta\rangle\right|\leqslant c\|\eta-H_0\psi\|.$$

Then the statement is a direct consequence of the density of $H_0\mathcal{D}$ and $\mathcal{D}$ in $\mathcal{H}$.

(b) This is a simple corollary of the point (a). □

We consider a spinless particle coupled to a quantized Bose field and show that such a system has a ground state for two classes of short-range potentials which are alone too weak to have a zero-energy resonance. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1793329]

I. INTRODUCTION AND MAIN RESULTS

Our aim in this paper is to prove the existence of the ground state for a spinless nonrelativistic particle interacting with a short-range potential and coupled to a quantized radiation field. We want to show that this can be achieved using the threshold-coupling behavior of the corresponding Schrödinger operator, without using explicitly the zero-energy resonance property.

Let us begin by specifying the classes of potentials to be considered. Throughout the paper we suppose that (i) $V \in L^\infty$ is nonzero and attractive, $V \leqslant 0$, and (ii) V belongs to $L^{3/2}(\mathbb{R}^3)$, which is well known to ensure, in particular, that V lies in the Rollnik class, i.e.,

$$\|V\|_R^2 := \iint_{\mathbb{R}^6} \frac{|V(x)||V(y)|}{|x-y|^2} dx\, dy < +\infty.$$

Finally, we adopt one of the following assumptions: (iii) V is *strictly* attractive, $V < 0$, and satisfies the inequality

$$|\Delta V| \leqslant C|V|, \tag{1.1}$$

with a positive constant C, or alternatively (iii′) V is compactly supported with ΔV integrable. We will say more on the meaning of these assumptions in the remarks following Theorem 1 below. Here we just comment that our goal is to explain the above indicated idea, rather than to push for an optimal result, and therefore the stated assumptions leave ample room for improvements.

We denote by H_λ the family of Schrödinger operators $H_\lambda := p^2 + \lambda V$ on $L^2(\mathbb{R}^3)$ for positive parameters λ. Its eigenvalues are monotonically decreasing functions of λ in $[0, +\infty)$, and it is

a)Electronic mail: catto@ceremade.dauphine.fr
b)Electronic mail: exner@ujf.cas.cz
c)Electronic mail: hainzl@ceremade.dauphine.fr

well known that at some positive critical value λ_0, which is called the "coupling-constant threshold" an eigenvalue emerges from the continuum. More precisely, if $\lambda \leqslant \lambda_0$, H_λ has no negative eigenvalues, whereas when $\lambda > \lambda_0$ it has at least one bound state.

We now couple this Schrödinger operator to the radiation field and consider the so-called *Pauli–Fierz operator,*

$$H_\alpha^V = (p + \sqrt{\alpha}\, A(x))^2 + H_f + \lambda V, \tag{1.2}$$

acting on the Hilbert space,

$$\mathcal{H} = L^2(\mathbb{R}^3;\mathbb{C}) \otimes \mathcal{F},$$

where $\mathcal{F} = \oplus_{n=0}^{+\infty} L_b^2(\mathbb{R}^{3n};\mathbb{C})$ is the Fock space for the photon field and $L_b^2(\mathbb{R}^{3n})$ is the space of symmetric functions in $L^2(\mathbb{R}^{3n})$ representing n-photon states, with $n=0$ corresponding to the one-dimensional vacuum sector. Following the usual convention we abuse notation and use the same symbol for H_f and $I \otimes H_f$, etc. The operator H_α^V is essentially self-adjoint on $\mathcal{D}(\Delta) \cap \mathcal{D}(H_f)$, where the symbol $\mathcal{D}$ denotes the operator domain—see Bach, Fröhlich, and Sigal (1999) and Hiroshima (2002).

We denote the ground state energy as

$$E(\alpha, \lambda V) := \inf \text{ spec } H_\alpha^V, \tag{1.3}$$

and the spectrum is then the half-line $[E(\alpha, \lambda V), +\infty)$. In Griesemer, Lieb, and Loss (2001), Theorem 3.1, the authors show under rather weak assumptions about the potential V that, in the case when $\lambda > \lambda_0$, i.e. when the Schrödinger operator $-\Delta + \lambda V$ has a ground state, it persists after coupling to the radiation field. Moreover, in Hainzl, Vougalter, and Vugalter (2003), the authors prove for a particular class of potentials that in the case when $\lambda = \lambda_0$, the coupling to the field can create a ground state for small coupling constant α, despite the fact that the underlying Schrödinger operator $-\Delta + \lambda_0 V$ has no ground state. Recall also that in the case of a particle with spin the same result was proved by two of the present authors in Catto and Hainzl (2004); a different proof is given in Chen, Vougalter, and Vugalter (2003).

Our goal here is to show that $E(\alpha, \lambda V)$ is an eigenvalue of H_α^V for coupling in some interval $(\gamma, \lambda_0]$, with $\lambda_0 - \gamma = \mathcal{O}(\alpha)$ for α small. It means that we do not require the existence of a zero-energy resonance in the absence of the field. This is due to the fact that, in contrast to the other existing work quoted above, we employ a tool adopted from Klaus and Simon (1980) which makes it possible to estimate "how much" the binding is enhanced.

The strategy of proof will be based on the expansion of the self-energy in powers of α, as provided in Hainzl (2003), Hainzl (2002), Hainzl, Vougalter, and Vugalter (2003), and Catto and Hainzl (2004), and by checking that the Griesemer–Lieb–Loss criterium [i.e., inequality (2.1) below] is satisfied for α small enough. To this aim we use the coupling constant threshold expansion of Klaus and Simon (1980), which will allow us to demonstrate the enhanced binding for the class of potentials indicated above. For any ultraviolet cutoff Λ our result holds true for α sufficiently small. In fact for a large class of potentials (see Remark 3) the physical value of α is in the range of validity, since we will fix the photon energy cutoff to be mc^2. This is physically reasonable, since for larger values nonrelativistic QED might no longer be applicable due to the fact that pair-production can take place.

Recall that in the dipole approximation, in the case of a large coupling α the enhanced binding was shown earlier by Hiroshima and Spohn (2001); see also Arai and Kawano (2003) in the context of linear coupling.

We fix units in such a way that the Planck constant $\hbar = 1$, the speed of light $c = 1$, and the electron mass $m = \frac{1}{2}$. The electron charge is then given by $e = \sqrt{\alpha}$, with $\alpha \approx 1/137$ being the fine structure constant. In the present paper α plays the role of a small, dimensionless number which measures the coupling to the radiation field. Our results hold for *sufficiently small values* of α. The operator $p = -i\nabla$ is the electron momentum while A is the quantized magnetic vector potential, which is given by

$$A(x) = \sum_{\lambda=1,2} \int_{\mathbb{R}^3} \frac{\chi(|k|)}{2\pi|k|^{1/2}} \varepsilon^\lambda(k)[a_\lambda(k)e^{ik\cdot x} + a_\lambda^*(k)e^{-ik\cdot x}]\mathrm{d}k,$$

where the annihilation and creation operators a_λ and a_λ^*, respectively, satisfy the usual commutation relations,

$$[a_\nu(k), a_\lambda^*(q)] = \delta(k-q)\,\delta_{\lambda,\nu},$$

and

$$[a_\lambda(k), a_\nu(q)] = 0, \quad [a_\lambda^*(k), a_\nu^*(q)] = 0.$$

In the following we use the notation

$$A(x) = D(x) + D^*(x). \tag{1.4}$$

The vectors $\varepsilon^\lambda(k) \in \mathbb{R}^3$ in $A(x)$ are orthonormal polarization vectors perpendicular to k which are chosen in a such a way that

$$\varepsilon^2(k) = \frac{k}{|k|} \wedge \varepsilon^1(k). \tag{1.5}$$

The function $\chi(|k|)$ describes the ultraviolet cutoff for the interaction at large wave-numbers k. For the sake of simplicity we choose for χ the Heaviside function $\Theta(\Lambda - |k|)$; more general cutoff functions would work, however, let us emphasize the fact that we shall sometimes use the radial symmetry of χ in the proofs. Throughout the paper we assume $\Lambda = 1$. This corresponds to the energy mc^2 in our system of units and represents a natural upper bound to which the validity of the nonrelativistic QED can be extended.

The photon field energy H_f is given by

$$H_f = \sum_{\lambda=1,2} \int_{\mathbb{R}^3} |k| a_\lambda^*(k) a_\lambda(k)\mathrm{d}k, \tag{1.6}$$

and the field momentum reads

$$P_f = \sum_{\lambda=1,2} \int_{\mathbb{R}^3} k a_\lambda^*(k) a_\lambda(k)\mathrm{d}k. \tag{1.7}$$

Since $\mathcal{H}$ can be also written as $\oplus_{n=0}^{+\infty} L^2(\mathbb{R}^3;\mathbb{C}) \otimes L_b^2(\mathbb{R}^{3n};\mathbb{C}^{2n})$ we can express a general vector $\Psi \in \mathcal{H}$ as a direct sum,

$$\Psi = \bigoplus_{n=0}^{\infty} \psi_n, \tag{1.8}$$

where $\psi_n = \psi_n(x, k_1, \ldots, k_n)$ is an n-photon state. For simplicity, we do not include the variables corresponding to the polarization of the photons.

To simplify further the notation, we introduce the unitary transformation

$$U = \mathrm{e}^{\mathrm{i}P_f \cdot x} \tag{1.9}$$

acting on $\mathcal{H}$. Since

$$UA(x)U^* = A(0)$$

and

$$UpU^* = p - P_f, \tag{1.10}$$

we obtain

$$UH_\alpha^V U^* = (p - P_f + \sqrt{\alpha}A)^2 + H_f + \lambda V, \tag{1.11}$$

where $A=A(0)$. The operator U preserves spectral properties, in particular,

$$\inf \operatorname{spec}[UH_\alpha^V U^*] = \inf \operatorname{spec} H_\alpha^V. \tag{1.12}$$

Thus we shall rather work with $UH_\alpha^V U^*$ in the following; abusing the notation we will use again the symbol H_α^V for it.

Our main result is the following.

Theorem 1: *Adopt the assumptions (i), (ii), and either (iii) or (iii′). Then there exists a function* $g:\mathbb{R}^+ \to (0,1)$ *such that for any small enough* α *and all* $\lambda \in (\lambda_0(1-g(\alpha)), \lambda_0]$, *the spectral threshold* $E(\alpha, \lambda V)$ *is an eigenvalue of* H_α^V.

Remark 1: The assumptions about the potential combine different types of requirements. For instance, hypotheses involving the Laplacian, i.e., (1.1) or $\Delta V \in L^1$ impose restrictions mainly on local regularity of the potential. On the other hand, the integrability condition (ii) which guarantees the Rollnik property regulates the potential decay; on a heuristic level one may say that it should behave as $|x|^{-2-\epsilon}$ at infinity.

Remark 2: It comes out of the proof that $g(\alpha)$ is of order of α, more specifically, the relation (2.37) shows that $g(\alpha)=c\alpha+\mathcal{O}(\alpha^2 \ln \alpha)$ with $c>0$ holds as $\alpha \to 0$. It is important that we get in this way an asymptotical *lower* bound to $g(\alpha)$ which allows us to assess how much the binding is enhanced.

Remark 3: In connection with the previous remark we want to emphasize that all the constants appearing in the proof can be evaluated explicitly. Assuming that we choose a potential V such that the constants $C, b(V)$ in (1.1) and (2.39), respectively, are of the order of one, it turns out that Theorem 1 holds for $\alpha \lesssim 10^{-2}$ which covers the physically important case.

Remark 4: We have recalled above the results of Griesemer, Lieb, and Loss (2001) and Hainzl, Vougalter, and Vugalter (2003), the latter using the existence of a zero-energy resonance state together with a continuity argument which shows that H_α^V has a bound state for values of λ slightly below λ_0. As we have said our strategy is similar but the proof is more constructive, in particular, it provides a rough estimate on how far below λ_0 one can descend to still ensure the existence of a ground state. In addition our method covers a different and in several respects a wider class of potentials V, in particular, we require neither a compact support nor the radial symmetry of the potential.

Remark 5: Using the methods of Catto and Hainzl (2004), Theorem 1 can also be proven for the case of particles with spin. Unfortunately the numbers of inequalities needed increase dramatically. For that reason we restricted our attention to the more convenient case of bosons.

II. PROOF OF THEOREM I

Let $0<\lambda \leq \lambda_0$. According to Griesemer, Lieb, and Loss (2001), the ground state exists provided

$$E(\alpha, \lambda V) < E(\alpha, 0), \tag{2.1}$$

where $E(\alpha,0)$ is the electron self-energy. Thus we are going to construct a trial state $\Psi \in L^2(\mathbb{R}^3) \otimes \mathcal{F}$ which ensures that the last inequality is satisfied,

$$(\Psi; H_\alpha^V \Psi) < E(\alpha,0)\|\Psi\|^2. \tag{2.2}$$

The strategy of proof is as follows: we will compare the respective expansions of $E(\alpha,0)$ and $(\Psi; H_\alpha^V \Psi)$ for the trial state Ψ in terms of the coupling constant α. From Hainzl (2003) and

Hainzl, Vougalter, and Vugalter (2003) we already know the first three terms in the Taylor expansion of the former, namely

$$|E(\alpha,0) - \alpha\pi^{-1} + \alpha^2\langle 0|DD\mathcal{A}_\alpha^{-1}D*D*|0\rangle| \leqslant C_{\mathrm{self}}\alpha^3, \tag{2.3}$$

for some positive constant C_{self}, where $|0\rangle$ is the vacuum vector, $\langle\cdot;\cdot\rangle$ denotes the scalar product in the photon Fock space $\mathcal{F}$, and with

$$\mathcal{A}_\alpha = P_f^2 + H_f + 2\alpha D*D. \tag{2.4}$$

Recall that actually in Hainzl, Vougalter, and Vugalter (2003) the proof is given for $\mathcal{A}_0$ instead of $\mathcal{A}_\alpha$ in the second-order term in (2.3), but the same argument carries through *mutatis mutandis* to the present case.

Consider now a quantity $g(\alpha) \in (0,1)$, to be determined later, and observe that when the coupling parameter λ satisfies

$$(1 - g(\alpha))\lambda_0 < \lambda \leqslant \lambda_0,$$

then the Schrödinger operator,

$$h_\alpha^\lambda := (1 - g(\alpha))p^2 + \lambda V,$$

has a negative eigenvalue $e_\lambda(\alpha) := -|e_\lambda|$ at the bottom of the spectrum. This trivially follows from the inequality $\lambda/[1-g(\alpha)] > \lambda_0$ and our choice of λ_0 to be critical. We denote by ψ_λ a corresponding eigenstate which may be chosen without loss of generality as real-valued and normalized in L^2. Our trial function, to be inserted into (2.2), will involve only two photons being of the form

$$\Psi = \psi_\lambda \oplus \psi_1 \oplus \psi_2 \oplus \cdots, \tag{2.5a}$$

with

$$\psi_1 = -2\sqrt{\alpha}L^{-1}D*p\psi_\lambda \tag{2.5b}$$

and

$$\psi_2 = -\alpha L^{-1}D*D*\psi_\lambda. \tag{2.5c}$$

The operator L on $L^2(\mathbb{R}^3)\otimes\mathcal{F}$ appearing in here is defined by

$$L = (1 - g(\alpha))(p - P_f)^2 + \lambda V + |e_\lambda| + H_f + 2\alpha D*D; \tag{2.6}$$

the definitions (2.5b) and (2.5c) make sense because L is invertible on the orthogonal complement of the vacuum sector $L^2(\mathbb{R}^3)\otimes\mathbb{C}|0\rangle$; this follows from the fact that it is unitarily equivalent to $h_\alpha^\lambda + |e_\lambda| + H_f + 2\alpha D*(x)D(x)$ by means of the operator (1.9). Note that, with the abuse of notation mentioned in the opening, we often use ψ_λ as a shorthand for $\psi_\lambda\otimes|0\rangle$.

The canonical commutation relations yield the identity

$$A^2 = D*D* + DD + 2D*D + \frac{1}{\pi};$$

using it together with commutativity of P_f with D, $D*$, we find that

$$(\Psi;H_\alpha^V\Psi) = g(\alpha)\|P\Psi\|^2 + \left[\frac{\alpha}{\pi} - |e_\lambda|\right]\|\Psi\|^2 + (\Psi;L\Psi) + 2\Re(\Psi;[2\sqrt{\alpha}PD* + \alpha D*D*]\Psi)$$
$$+ (\psi_\lambda;(h_\alpha^\lambda + |e_\lambda|)\psi_\lambda), \tag{2.7}$$

where $P := p - P_f$ denotes the total momentum; the last term on the right-hand side of (2.7) cancels by definition of e_λ, h_α^λ, and ψ_λ.

Let us further remark that it will be convenient in the following to replace the field Hamiltonian H_f by $\widetilde{H}_f := H_f + \alpha^3$ in order to avoid dealing with the logarithmically divergent infrared terms; this trick was already used in Hainzl and Seiringer (2002), Catto and Hainzl (2004), and Hainzl, Hirokawa, and Spohn (2003). It amounts to adding an extra $-\alpha^3\|\Psi\|^2$ term at the right-hand side of (2.7) which does not change, of course, the expansion up to the second order in α. Observe that by our choice of Ψ the identity

$$\begin{aligned}(\Psi; L\Psi) + 2\Re(\Psi; [2\sqrt{\alpha}PD^* + \alpha D^* D^*]\Psi) \\ = (\psi_\lambda; L\psi_\lambda) - 2\Re(\psi_\lambda; -\alpha DDL^{-1}(-2\sqrt{\alpha}PD)^* L^{-1}(-2\sqrt{\alpha}PD)^*\psi_\lambda) \\ - \|L^{-1/2}[2\sqrt{\alpha}PD^* + \alpha D^* D^*]\psi_\lambda\|^2, \end{aligned} \tag{2.8}$$

holds, and the same is true if we replace L in the last relation by $\widetilde{L}$ referring to $\widetilde{H}_f$. Thus we obtain

$$\begin{aligned}(\Psi; \widetilde{H}_\alpha^V \Psi) = g(\alpha)\|P\Psi\|^2 + \left[\frac{\alpha}{\pi} - |e_\lambda| - \alpha^3\right]\|\Psi\|^2 - 4\alpha\|\widetilde{L}^{-1/2}D^* p\psi_\lambda\|^2 - \alpha^2(\psi_\lambda; DD\widetilde{L}^{-1}D^* D^*\psi_\lambda) \\ + 8\alpha^2\Re(\widetilde{L}^{-1}D^* D^*\psi_\lambda; PD^*\widetilde{L}^{-1}D^* p\psi_\lambda), \end{aligned} \tag{2.9}$$

where $\widetilde{H}_\alpha^V$ refers again to $\widetilde{H}_f$. On the other hand, apart from taming the infrared singularity the extra term is irrelevant, as long as we are looking for an effect of an order of α^2. This is why we will abuse notation writing nontilded quantities everywhere except the one place where this Hamiltonian shift indeed matters, that is, in the proof of Lemma 2.4.

To estimate the last term at the right-hand side of (2.9), notice that the Cauchy–Schwarz inequality yields

$$8\alpha^2|(L^{-1}D^* D^*\psi_\lambda; PD^* L^{-1}D^* p\psi_\lambda)| \leqslant \frac{4\alpha^3}{a}\|L^{-1/2}PDL^{-1}D^* D^*\psi_\lambda\|^2 + 4\alpha a\|L^{-1/2}D^* p\psi_\lambda\|^2, \tag{2.10}$$

with a positive constant a to be chosen later. The last term can be combined with the similar term in (2.9) giving

$$\begin{aligned}(\Psi; H_\alpha^V \Psi) \leqslant g(\alpha)\|P\Psi\|^2 - |e_\lambda|\|\Psi\|^2 + \frac{\alpha}{\pi}\|\Psi\|^2 - 4\alpha(1-a)\|L^{-1/2}D^* p\psi_\lambda\|^2 \\ - \alpha^2(\psi_\lambda; DDL^{-1}D^* D^*\psi_\lambda) + \frac{4\alpha^3}{a}\|L^{-1/2}PDL^{-1}D^* D^*\psi_\lambda\|^2. \end{aligned} \tag{2.11}$$

To estimate further the terms appearing in (2.10) we need a series of technical lemmata.

Lemma 2.1: The following inequality holds:

$$(\psi_\lambda; DDL^{-1}D^* D^*\psi_\lambda) \geqslant \langle 0|DD\mathcal{A}_\alpha^{-1}D^* D^*|0\rangle + g(\alpha)C_1, \tag{2.12}$$

where

$$C_1 := \|P_f\mathcal{A}_\alpha^{-1}D^* D^*|0\rangle\|^2.$$

Proof: We denote $L = \mathcal{Q} + b$, with

$$\mathcal{Q} = (1-g(\alpha))(p^2 + P_f^2) + \lambda V + |e_\lambda| + H_f + 2\alpha D^* D,$$

and $b = -2(1-g(\alpha))pP_f$, and we use twice the second resolvent equation,

$$(\mathcal{Q}+b)^{-1}=\mathcal{Q}^{-1}-\mathcal{Q}^{-1}b\mathcal{Q}^{-1}+\mathcal{Q}^{-1}b(\mathcal{Q}+b)^{-1}b\mathcal{Q}^{-1}\geqslant\mathcal{Q}^{-1}-\mathcal{Q}^{-1}b\mathcal{Q}^{-1}, \tag{2.13}$$

where the inverse of $\mathcal{Q}+b$ and the last inequality makes sense in the complement to the vacuum sector where the operator is strictly positive as we have remarked above. Hence we have

$$(\psi_\lambda;DDL^{-1}D*D*\psi_\lambda)\geqslant(\psi_\lambda;DD\mathcal{Q}^{-1}D*D*\psi_\lambda)+2(1-g(\alpha))(\psi_\lambda;DD\mathcal{Q}^{-1}pP_f\mathcal{Q}^{-1}D*D*\psi_\lambda). \tag{2.14}$$

Furthermore, the second term at the right-hand side vanishes. To check this claim, recall that ψ_λ belongs by construction to the null-space of $h_\alpha^\lambda+|e_\lambda|$, and that h_α^λ commutes with the operator

$$\mathcal{K}:=(1-g(\alpha))P_f^2+H_f+2\alpha D*D.$$

It follows easily that

$$\mathcal{Q}^{-1}D*D*\psi_\lambda=\mathcal{K}^{-1}D*D*\psi_\lambda, \tag{2.15}$$

and therefore

$$(\psi_\lambda;DD\mathcal{Q}^{-1}pP_f\mathcal{Q}^{-1}D*D*\psi_\lambda)=(\psi_\lambda;p\psi_\lambda)\langle 0|DD\mathcal{K}^{-1}P_f\mathcal{K}^{-1}D*D*|0\rangle=0,$$

because ψ_λ is real-valued as indicated above making the first factor zero.

Using (2.15) again, we find that the first term reads as

$$\begin{aligned}(\psi_\lambda;DD\mathcal{Q}^{-1}D*D*\psi_\lambda)&=(\psi_\lambda;DD\mathcal{K}^{-1}D*D*\psi_\lambda)\\&=\|\psi_\lambda\|^2\langle 0|DD\mathcal{K}^{-1}D*D*|0\rangle\geqslant\langle 0|DD\mathcal{A}_\alpha^{-1}D*D*|0\rangle+g(\alpha)\\&\quad\times\langle 0|DD\mathcal{A}_\alpha^{-1}P_f^2\mathcal{A}_\alpha^{-1}D*D*|0\rangle,\end{aligned} \tag{2.16}$$

where in the last line we used the fact that ψ_λ is normalized together with the second resolvent equation and positivity of $\mathcal{K}$ in the complement of the vacuum sector. Hence we have the following claim. □

Lemma 2.2: For any positive constant μ we have

$$\|L^{-1/2}D*p\psi_\lambda\|^2\geqslant[C_4(\mu)+\mu C_3(\mu)]\|p\psi_\lambda\|^2-\frac{\lambda}{2}C_3(\mu)(\psi_\lambda;\Delta V\psi_\lambda), \tag{2.17}$$

with

$$C_3(\mu)=\tfrac{2}{3}\langle 0|D(\mathcal{K}+\mu)^{-2}D*|0\rangle \tag{2.18}$$

and

$$C_4(\mu)=\tfrac{2}{3}\langle 0|D(\mathcal{K}+\mu)^{-1}D*|0\rangle. \tag{2.19}$$

Proof: Using the relation analogous to (2.13), we find

$$\begin{aligned}pDL^{-1}D*p\geqslant{}&pD(\mathcal{K}+\mu)^{-1}D*p-pD(\mathcal{K}+\mu)^{-1}[-2pP_f(1-g(\alpha))+h_\alpha^\lambda+|e_\lambda|-\mu]\\&\times(\mathcal{K}+\mu)^{-1}D*p.\end{aligned}$$

Again, since ψ_λ is real valued the term containing pP_f vanishes; notice that the same conclusion can also be made using symmetry of the cutoff function. Since $\mathcal{K}$ acts on photon variables whereas h_α^λ acts on those of the electron, the two operators commute and the second term at the right-hand side of the last estimate can be rewritten as

$$(\psi_\lambda; pD(\mathcal{K}+\mu)^{-1}[-2pP_f(1-g(\alpha))+h_\alpha^\lambda+|e_\lambda|-\mu](\mathcal{K}+\mu)^{-1}D*p\psi_\lambda)$$
$$= C_3(\mu)(p\psi_\lambda; (h_\alpha^\lambda+|e_\lambda|-\mu)p\psi_\lambda), \tag{2.20}$$

with $C_3(\mu)$ given by (2.18). Observing that ψ_λ belongs to the null-space of $h_\alpha^\lambda+|e_\lambda|$ we can further cast a part of the last expression into the form

$$(p\psi_\lambda; (h_\alpha^\lambda+|e_\lambda|)p\psi_\lambda) = -\tfrac{1}{2}(\psi_\lambda; [p,[p,h_\alpha^\lambda+|e_\lambda|]]\psi_\lambda) = \frac{\lambda}{2}(\psi_\lambda; \Delta V\psi_\lambda), \tag{2.21}$$

to obtain

$$(p\psi_\lambda; (h_\alpha^\lambda+|e_\lambda|-\mu)p\psi_\lambda) = -\mu\|p\psi_\lambda\|^2+\frac{\lambda}{2}(\psi_\lambda; \Delta V\psi_\lambda).$$

On the other hand,

$$(\psi_\lambda; pD(\mathcal{K}+\mu)^{-1}D*p\psi_\lambda) = C_4(\mu)\|p\psi_\lambda\|^2,$$

with $C_4(\mu)$ given by (2.19), which concludes the proof. □

Our next auxiliary result is the following.

Lemma 2.3: Let $\alpha>0$ and $0<\lambda\leq\lambda_0$, then for any positive number $g(\alpha)<1-\lambda/\lambda_0$ there are positive constants β and $C(V)$ such that

$$p^2 \leqslant \beta(h_\alpha^\lambda+|e_\lambda|)+C(V). \tag{2.22}$$

Proof: For the inequality (2.22) to hold, the constant β which appears at the right-hand side has obviously to satisfy the inequality $\beta>1/[1-g(\alpha)]$, or equivalently $\beta(1-g(\alpha))-1>0$. We fix an arbitrary β with this property, to be specified later. Next we notice that inequality (2.22) will follow from

$$p^2+\lambda\tilde{V}\geqslant -\tilde{C}(V),$$

with

$$\tilde{V}:=\frac{1}{1-g(\alpha)-\beta^{-1}}V, \quad \tilde{C}(V):=\frac{C(V)}{\beta(1-g(\alpha))-1},$$

because the last inequality is equivalent to (2.22) with the term $|e_\lambda|$ at the right-hand side neglected. In other words, it is sufficient that the Schrödinger operator $p^2+\lambda\tilde{V}$ has no spectrum below $-\tilde{C}(V)$. From the proof of the Birman-Schwinger bound in Reed and Simon (1975), Theorem XIII.10, and the fact that $\tilde{V}$ is nonpositive it follows that this happens if and only if

$$\frac{\lambda^2}{16\pi^2}\iint_{\mathbb{R}^6}\frac{|\tilde{V}(x)||\tilde{V}(y)|}{|x-y|^2}e^{-2\sqrt{\tilde{C}(V)}|x-y|}\,dx\,dy<1. \tag{2.23}$$

Let us denote by $\mathcal{K}_m$ the function $x\mapsto e^{-\sqrt{m}|x|}/4\pi|x|^2$ with a fixed positive m which represents the resolvent kernel in the above expression; it is clear that $\mathcal{K}_m$ belongs to $L^1(\mathbb{R}^3)$ and $\int_{\mathbb{R}^3}\mathcal{K}_m(x)dx=1/\sqrt{m}$. We employ these observations in the following chain of inequalities:

$$\frac{\lambda^2}{16\pi^2}\iint_{\mathbb{R}^6}\frac{|\tilde{V}(x)||\tilde{V}(y)|}{|x-y|^2}e^{-2\sqrt{\tilde{C}(V)}|x-y|}\,dx\,dy=\frac{\lambda^2}{4\pi(1-g(\alpha)-\beta^{-1})^2}\int_{\mathbb{R}^3}(V\star K_{4\tilde{C}(V)})(x)V(x)dx$$
$$\leqslant\frac{\lambda^2}{4\pi(1-g(\alpha)-\beta^{-1})^2}\|V\|_{L^2}^2\|K_{4\tilde{C}(V)}\|_{L^1}$$
$$\leqslant\frac{\lambda^2}{8\pi(1-g(\alpha)-\beta^{-1})^2\sqrt{\tilde{C}(V)}}\|V\|_{L^2}^2,$$

where in the second and third line we used Cauchy–Schwarz and Young inequalities, respectively. Thus the bound (2.23) will be satisfied if the last expression is smaller than one. For a fixed $\beta>2(1-g(\alpha))^{-1}$ we can estimate $(1-g(\alpha)-\beta^{-1})^{-1/2}$ by $\sqrt{\beta}$, and consequently, the inequality (2.22) will hold uniformly in $\lambda\in[0;\lambda_0)$, as long as the positive constant $C(V)$ is chosen large enough to satisfy

$$\frac{\lambda_0^2\sqrt{\beta}\|V\|_{L^2}^2}{8\pi(1-g(\alpha)-\beta^{-1})^{3/2}}<\sqrt{\tilde{C}(V)}, \tag{2.24}$$

which we set out to prove. □

Note that the constants can be chosen explicitly. The left-hand side of (2.24) diverges as $\beta\to\infty$ and in the allowed interval it has a unique minimum at $\beta=4/[1-g(\alpha)]$ where it attains the value $2\lambda_0^2\|V\|_{L^2}^2/3\sqrt{3}\pi(1-g(\alpha))^2$. In other words, the lemma is valid for this β and

$$C(V)=\left(\frac{2\lambda_0^2\|V\|_{L^2}^2}{3\pi(1-g(\alpha))^2}\right)^2.$$

The reader may wonder that we have not used here fully our assumptions about the potential because for a bounded function $V\in L^2$ is a weaker requirement than $V\in L^{3/2}$, however, without the latter our main premise about the existence of the coupling constant threshold may not be valid.

Lemma 2.4 : The following estimates hold:

$$\|PL^{-1}D*D*\psi_\lambda\|^2\leqslant C_5 \tag{2.25}$$

and

$$\|PL^{-1}D*p\psi_\lambda\|^2\leqslant C_6(\alpha)\|p\psi_\lambda\|^2, \tag{2.26}$$

with positive C_5 and $C_6(\alpha)$ given in (2.28) and (2.29) below, depending on β and $C(V)$ of the previous lemma. Using the shifted Hamiltonian $\tilde{H}_f:=H_f+\alpha^3$, we have $C_6(\alpha)\sim\ln(\alpha^{-3})$ as $\alpha\to 0+$.

Proof: By means of (2.22) we get the estimates

$$L^{-1}P^2L^{-1}\leqslant L^{-1}[\beta(h_\alpha^\lambda+|e_\lambda|)+C(V)]L^{-1}\leqslant\frac{\beta}{2}H_f^{-1}+C(V)H_f^{-2}, \tag{2.27}$$

valid in the appropriate part of the state space, namely, when sandwiched between vectors annulated by P_f; in the second inequality we used the fact that for any pair of commuting operators B,C with C strictly positive we have $(B+C)^{-1}B(B+C)^{-1}\leqslant\frac{1}{2}C^{-1}$. In this way we arrive at

$$\|PL^{-1}D*D*\psi_\lambda\|^2\leqslant\left[\frac{\beta}{2}\langle 0|DDH_f^{-1}D*D*|0\rangle+C(V)\langle 0|DDH_f^{-2}D*D*|0\rangle\right]:=C_5 \tag{2.28}$$

and

$$\|PL^{-1}D*p\psi_\lambda\|^2 \leqslant \|p\psi_\lambda\|^2\frac{2}{3}\left[\frac{\beta}{2}\langle 0|DH_f^{-1}D*|0\rangle + C(V)\langle 0|DH_f^{-2}D*|0\rangle\right] := \|p\psi_\lambda\|^2 C_6(\alpha). \tag{2.29}$$

Now we come to the place where the shift matters because without it the right-hand side of (2.29) is infrared divergent. With the replacement $H_f \to H_f + \alpha^3$ we have

$$\langle 0|D[H_f+\alpha^3]^{-2}D*|0\rangle = 8\pi\int_0^1 d|k|\frac{|k|}{[|k|+\alpha^3]^2} = 8\pi(\ln(\alpha^{-3}) + \alpha^3 - 1), \tag{2.30}$$

which concludes the argument. Let us stress that this trick is mainly used for convenience since even without it the term on the left-hand side of (2.29) is finite, which can be seen by repeating the argument in Hainzl and Seiringer (2002), Eq. (4.4). □

Finally we come to our last technical result.

Lemma 2.5: Under the assumption (iii′) there is a positive constant C such that

$$|(\psi_\lambda; \Delta V\psi_\lambda)| \leqslant C(\psi_\lambda; |V|\psi_\lambda). \tag{2.31}$$

Proof: Since $V \in L^\infty$ the ground state is represented on $G := \mathrm{supp}V$ by a positive smooth function. Hence $\rho(\lambda) := \sup_G \psi_\lambda (\inf_G \psi_\lambda)^{-1}$ makes sense and satisfies $1 \leqslant \rho(\lambda) < \infty$; the same is true for $\lambda = (1-g(\alpha))\lambda_0$ corresponding to the zero-energy resonance. Using the standard estimate [Reed and Simon (1975), Thm. IX.28] one can check that $\lambda \mapsto \psi_\lambda$ is continuous in the $\|\cdot\|_\infty$ norm which implies continuity of the function ρ. Consequently, there are positive m and M such that

$$0 < m \leqslant \tilde{\psi}_\lambda(x) \leqslant M < \infty \tag{2.32}$$

holds for all $x \in G$, $\lambda \in]\lambda_0(1-g(\alpha)); \lambda_0]$, and a suitable family of non-normalized solutions (for ψ_λ both the infimum and supremum vanish, of course, as we approach the zero-energy resonance). It follows that

$$(\tilde{\psi}_\lambda; \Delta V\tilde{\psi}_\lambda) \leqslant M^2\|\Delta V\|_{L^1}, \tag{2.33}$$

while $(\tilde{\psi}_\lambda; |V|\tilde{\psi}_\lambda) \geqslant m^2\|V\|_{L^1}$ is positive, so it can majorize (2.33) when multiplied by a sufficiently large C. □

Now we are ready to complete the proof of the theorem. From the definitions of ψ_1 and ψ_2 and with the help of (2.25) and (2.26) we get

$$g(\alpha)\|P\Psi\|^2 \leqslant g(\alpha)(1 + 4\alpha C_6(\alpha))\|p\psi_\lambda\|^2 + \alpha^2 g(\alpha)C_5. \tag{2.34}$$

Using our assumptions about V we can write

$$(\psi_\lambda; |V|\psi_\lambda) = -(\psi_\lambda; V\psi_\lambda) = (1-g(\alpha))\|p\psi_\lambda\|^2 + |e_\lambda|,$$

which yields an estimate to the last term at the right-hand side of (2.17),

$$\|L^{-1/2}D*p\psi_\lambda\|^2 \geqslant \left[C_4(\mu) + \mu C_3(\mu) - \frac{\lambda}{2}C_3(\mu)C(1-g(\alpha))\right]\|p\psi_\lambda\|^2 - \frac{\lambda}{2}C_3(\mu)C|e_\lambda|; \tag{2.35}$$

in case of (iii) this follows from (1.1), whereas for (iii′) we employ Lemma 2.5. Next we insert into (2.11) from (2.34) and (2.35); in combination with Lemma 2.1 we obtain

$$(\Psi;H_\alpha^V\Psi) \leqslant \frac{\alpha}{\pi}\|\Psi\|^2 - \alpha^2\langle 0|DD\mathcal{A}_\alpha^{-1}D*D*|0\rangle \tag{2.36a}$$

$$-|e_\lambda|\|\Psi\|^2 + \alpha|e_\lambda|2\lambda C_3(\mu)C(1-a) \tag{2.36b}$$

$$+\left[g(\alpha)(1+4\alpha C_6(\alpha)-2\alpha(1-a)\lambda C_3(\mu)C)-4\alpha(1-a)\right.$$
$$\left.\times\left[C_4(\mu)+\mu C_3(\mu)-\frac{\lambda}{2}C_3(\mu)C\right]\right]\|p\psi_\lambda\|^2 \tag{2.36c}$$

$$+\alpha^2 g(\alpha)C_5 - \alpha^2 g(\alpha)C_1 + \tag{2.36d}$$

$$+\frac{4\alpha^3}{a}\|L^{-1/2}PDL^{-1}D*D*\psi_\lambda\|^2. \tag{2.36e}$$

Notice first that the term (2.36e) behaves as $\mathcal{O}(\alpha^3)$ for $\alpha\to 0$ which follows, e.g., from Hainzl, Hirokawa, and Spohn (2003), Lemma 15(v); thus it is irrelevant for the argument in the same way as the shift coming from the infrared regularization.

The main idea is now to choose the function $g(\alpha)$ in such a way that it cancels the factor in front of $\|p\psi_\lambda\|^2$ in (2.36c); this yields

$$g(\alpha) = \frac{4\alpha(1-a)\left[C_4(\mu)+\mu C_3(\mu)-\frac{\lambda}{2}C_3(\mu)C\right]}{1+4\alpha C_6(\alpha)-2\alpha(1-a)\lambda C_3(\mu)C}. \tag{2.37}$$

We choose also $\mu=(\lambda/2)C$ and fix the parameter in (2.10) by setting

$$1-a := \min\{(4C_4(\mu))^{-1}, C_6(\alpha)(\mu C_3(\mu))^{-1}, 3/4\};$$

this yields $g(\alpha)\leqslant\alpha$ which means that (2.36d) $=\mathcal{O}(\alpha^3)$.

On the other hand, since

$$\|\Psi\|^2 = 1 + 4\alpha\|L^{-1}D*p\psi_\lambda\|^2 + \alpha^2\|L^{-1}D*D*\psi_\lambda\|^2 = 1+\mathcal{O}(\alpha), \tag{2.38}$$

we deduce from (2.3) that

$$(2.36a) = E(\alpha,0)\|\Psi\|^2 + \mathcal{O}(\alpha^3).$$

We denote by $E(\beta)$ the bottom of the spectrum of $p^2+\beta V$, i.e.,

$$E(\beta) := \inf \operatorname{spec}(p^2+\beta V).$$

We have $E(\lambda_0)=0$ by assumption, and since the ground state represents always case (A) in the terminology of Klaus and Simon (1980); in other words, zero is not an eigenvalue of $p^2+\lambda_0 V$; we know that

$$E(\beta) = -b(V)(\beta-\lambda_0)^2 + \mathcal{O}((\beta-\lambda_0)^3), \tag{2.39}$$

holds for $\beta\geqslant\lambda_0$, close to λ_0, and for some positive constant $b(V)$ depending only on the potential V. Notice that the above asymptotic expansion coming from Klaus and Simon (1980), Theorem 2.3 was derived there for $V\in C_0^\infty(\mathbb{R}^3)$, however, an extension to the Rollnik class is straightforward. Recall now that

$$|e_\lambda| = -(1-g(\alpha))E(\lambda(1-g(\alpha))^{-1}).$$

Since $(1-g(\alpha))\lambda_0 < \lambda \leqslant \lambda_0$ holds by assumption and $g(\alpha)=\mathcal{O}(\alpha)$, we have

$$\lambda(1-g(\alpha))^{-1} - \lambda_0 \leqslant \lambda_0 g(\alpha)(1-g(\alpha))^{-1} = \mathcal{O}(\alpha),$$

and therefore

$$|e_\lambda| = b(V)\left(\frac{\lambda}{1-g(\alpha)} - \lambda_0\right)^2 + \mathcal{O}(\alpha^3),$$

where the first term at the right-hand side is $\mathcal{O}(\alpha^2)$. Returning to (2.36) we conclude from the last claim that the second term in (2.36b) is of order of α^3. This yields for all λ in the considered range and for small α the asymptotic inequality,

$$E(\alpha,\lambda V) \leqslant E(\alpha,0) - |e_\lambda| + \mathcal{O}(\alpha^3).$$

Since $b(V)>0$ the second term at the right-hand side is negative and dominates over the error for α sufficiently small. This demonstrates that the sought inequality (2.1) is valid under the assumptions we have made and thus it proves Theorem 1.

Two-dimensional Riemannian and Lorentzian geometries from second-order ODE's

Emanuel Gallo[a)]
FaMAF, Universidad Nacional de Córdoba, 5000 Córdoba, Argentina

(Received 29 June 2004; accepted 3 August 2004; published 25 October 2004)

In this paper we give an alternative geometrical derivation of the results recently presented by García-Godínez, Newman, and Silva-Ortigoza on the class of all two-dimensional Riemannian and Lorentzian metrics from second-order ODE's which are in duality with the two-dimensional Hamilton–Jacobi equation. We show that, as it happens in the null surface formulation of general relativity, the Wünschmann-type condition can be obtained as a requirement of a vanishing torsion tensor. Furthermore, from these second-order ODE's we obtain the associated Cartan connections. © *2004 American Institute of Physics.*

I. INTRODUCTION

In a couple of recent works, García-Godínez, Newman, and Silva-Ortigoza (GNS) presented the (pseudo-)Riemannian geometries which are hidden in a certain class of differential equations (those which satisfy a Wünschmann-type condition, $I_{\mathrm{GNS}}=0$). In the first of these works,[1] they studied how to obtain all two-dimensional Riemannian and Lorentzian metrics from a certain class of second-order ODE's. Furthermore, in Ref. 2, they extended their work and showed how to get all three-dimensional metrics from a certain class of three second-order PDE's and also from a certain class of third-order ODE's. From now on, we will say that these equations are in the GNS class.

The special status of these ODE's and PDE's is that they are in duality with the Hamilton–Jacobi equation. For example, if we have a second-order ODE in the GNS class,

$$u''=\Lambda(u,u',s), \tag{1}$$

and if we know a solution $u=Z(x^a,s)$, with $x^a=(x^1,x^2)$ integration constants, then this solution automatically satisfies the two-dimensional Hamilton–Jacobi equation:

$$g^{ab}\nabla_a Z\nabla_b Z=1, \tag{2}$$

where ∇_a means a differentiation with respect to x^a, and g^{ab}, is a (pseudo-)Riemannian metric constructed from Λ and its derivatives.

All these problems share similar characteristics with the problem of the null surface formulation (NSF) of general relativity in three and four dimensions.[3–6] In NSF, from a certain class of differential equations, known as the Wünschmann class, one can construct all three- and four-dimensional conformal Lorentzian metrics. The three-dimensional conformal metrics are obtained from a class of third-order ODE,

$$u'''=F(u,u',u'',s), \tag{3}$$

with F satisfying the so-called Wünschmann condition $I[F]=0$. Likewise, the four-dimensional metrics are obtained from a pair of second-order PDE's,

[a)]Electronic mail: egallo@fis.uncor.edu

$$u_{ss} = \Lambda(s, s^*, u, u_s, u_{s^*}, u_{ss^*}),$$
$$u_{s^*s^*} = \Lambda^*(s, s^*, u, u_s, u_{s^*}, u_{ss^*}), \tag{4}$$

where s and s^* are complex variables, and Λ and Λ^* satisfy the generalized Wünschmann condition $W[\Lambda, \Lambda^*]=0$ and its complex conjugate. It can be shown that $I[F]$ and $W[\Lambda, \Lambda^*]$ are invariant under contact transformations.[7–9] Again, these equations are in duality with another equation, namely the eikonal equation,

$$g^{ab}\nabla_a Z \nabla_b Z = 0. \tag{5}$$

and the level surfaces of the solution $u=Z(x^a, s)$ to (3), or $u=Z(x^a, s, s^*)$ to (4) are null surfaces of the respective metrics that they generate.

In NSF, the Wünschmann condition can be obtained in several ways.[3,10–12] Two of these were used by GNS to obtain the Wünschmann-type condition for differential equations in duality with the Hamilton–Jacobi equation. There exists a third method which is used in NSF, the torsion-free method, and from which one can obtain not only the Wünschmann class and its respective metrics, but also more geometrical structures associated to the equations, in particular all normal Cartan conformal connections.[13,12] In this paper we show that this method can also be applied to the problem of (pseudo-)Riemannian metrics discussed by GNS. In particular, we show how the torsion-free condition restricts the class of second-order ODE's to those belonging to the GNS class and such that we get all two-dimensional Riemannian and Lorentzian metrics, and respective Cartan connections.

In Sec. II we briefly present the notation and basic concepts about the geometry of second-order ODE's. In Sec. III, we show how to get the GNS class from the torsion-free condition, and construct the associated Cartan connections. Finally, in the conclusions, we discuss the extension of this approach to the problem of the GNS class of third-order ODE's.

II. NOTATION AND BASIC NOTIONS

Let the second-order ODE be

$$u'' = \Lambda(u, u', s), \tag{6}$$

where $s \in \mathbb{R}$ is the independent variable, and the primes denote derivative of the dependent variable u with respect to s.

On the jet-space J^1 with local coordinates (s, u, u') we consider the Pfaffian system $\mathcal{P}$

$$\omega^1 = \mathrm{d}u - u'\,\mathrm{d}s, \tag{7}$$

$$\omega^2 = \mathrm{d}u' - \Lambda\,\mathrm{d}s. \tag{8}$$

Local solutions of (6) are in one-to-one correspondence with integral curves γ: $\mathbb{R} \to J^1$ of $\mathcal{P}$ satisfying $\gamma^*\,\mathrm{d}s \neq 0$. These curves are generated by the vector field on J^1 given by

$$e_s \equiv D = \frac{\partial}{\partial s} + u'\frac{\partial}{\partial u} + \Lambda\frac{\partial}{\partial u'}. \tag{9}$$

We will restrict the domain of Λ to a open neighborhood U of J^1 where Λ is C^∞ and the Cauchy problem is well posed. Then, it follows from Frobenius theorem that the solution space M is a two-dimensional C^∞ manifold, and we will denote a given local coordinates system on it by $x^a = (x^1, x^2)$. It means that we can construct a map Z: $M \times \mathbb{R} \to \mathbb{R}$, $u=Z(x^a, s)$, such that by a given $x_0^a \in M$ the map $u=Z(x_0^a, s)$ is a solution of (6).

Then, if on $M \times \mathbb{R}$ we define a Pfaffian system $\mathcal{S}$ generated by

$$\beta^1 = Z_a \, \mathrm{d}x^a,$$

$$\beta^2 = Z'_a \, \mathrm{d}x^a$$

(where primes mean derivatives on s, and $Z_a = \partial_a Z$), it follows that there exist a diffeomorphism $\zeta\colon J^1 \to M \times \mathbb{R}$ which pulls back the Pfaffian system $\mathcal{S}$ on the system $\mathcal{P}$, i.e.,

$$\zeta^* \mathcal{S} = \mathcal{P}. \tag{10}$$

We will make use of this diffeomorphism later.

III. RIEMANNIAN AND LORENTZIAN GEOMETRIES FROM SECOND-ORDER ODE's

From ω^1, ω^2 which generate the Pfaffian system $\mathcal{P}$, we construct the following one-forms:

$$\theta^1 = \frac{1}{\sqrt{2}}(\omega^1 + a\omega^2), \tag{11}$$

$$\theta^2 = \frac{1}{\sqrt{2}}(\omega^1 - a\omega^2), \tag{12}$$

where $a = a(s, u, u')$ is a nonvanishing function to be determined. Next, we construct a degenerate metric on J^1,

$$h(u, u', s) = 2\theta^{(1} \otimes \theta^{2)} = \eta_{ij} \theta^i \otimes \theta^j, \tag{13}$$

where

$$\eta_{ij} = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}.$$

Note that if $a^2 > 0$, then θ^1 and θ^2 behave as null real vectors, and if $a^2 < 0$, they are complex null vectors.

Let ω^i_j be a connection such that we have the following.

(A) The connection is skew-symmetric,

$$\omega_{ij} = \omega_{[ij]}, \tag{14}$$

where $\omega_{ij} = \eta_{ik}\omega^k{}_j$.

(B) The one-forms θ^1 and θ^2 satisfy the Cartan's torsion-free first structure equations,

$$T^i \equiv \mathrm{d}\theta^i + \omega^k{}_j \wedge \theta^j = 0. \tag{15}$$

Now, we state and prove the following theorem.

Theorem: *The Torsion-free condition on the skew-symmetric connection:*

(1) *uniquely determines the connection, with the only nonvanishing component given by*

$$\omega_{[12]} = -\frac{1}{\sqrt{2}}(\ln a)_u \theta^1 + \frac{1}{\sqrt{2}}(\ln a)_u \theta^2 + \frac{1}{a}\mathrm{d}s, \tag{16}$$

(2) *uniquely determines the function a in terms of* Λ,

$$a^2 = \frac{1}{\Lambda_u}, \tag{17}$$

(3) *impose a Wünschmann-type condition on* Λ,

$$I_{\mathrm{GNS}} = Da + a\Lambda_{u'} = 0. \tag{18}$$

Proof: From (11) and (12) we have

$$\mathrm{d}\theta^1 = -\frac{1}{\sqrt{2}a}a_u\theta^1\wedge\theta^2 - \frac{1}{2a}(1 + Da + a^2\Lambda_u + a\Lambda_{u'})\theta^1\wedge\mathrm{d}s - \frac{1}{2a}(-1 - Da + a^2\Lambda_u - a\Lambda_{u'})\theta^2\wedge\mathrm{d}s, \tag{19}$$

$$\mathrm{d}\theta^2 = \frac{1}{\sqrt{2}a}a_u\theta^1\wedge\theta^2 + \frac{1}{2a}(-1 + Da + a^2\Lambda_u + a\Lambda_{u'})\theta^1\wedge\mathrm{d}s + \frac{1}{2a}(1 - Da + a^2\Lambda_u - a\Lambda_{u'})\theta^2\wedge\mathrm{d}s. \tag{20}$$

The condition of free torsion (15) reads

$$\mathrm{d}\theta^1 - \omega_{[12]}\wedge\theta^1 = 0, \tag{21}$$

$$\mathrm{d}\theta^2 + \omega_{[12]}\wedge\theta^2 = 0, \tag{22}$$

and by solving these equations we get

$$\omega_{[12]} = -\frac{1}{\sqrt{2}}(\ln a)_u\theta^1 + \frac{1}{\sqrt{2}}(\ln a)_u\theta^2 + \frac{1}{2a}(1 + Da + a^2\Lambda_u + a\Lambda_{u'})\mathrm{d}s, \tag{23}$$

together for the three conditions,

$$(-1 - Da + a^2\Lambda_u - a\Lambda_{u'}) = 0, \tag{24}$$

$$(-1 + Da + a^2\Lambda_u + a\Lambda_{u'}) = 0, \tag{25}$$

$$(Da + a\Lambda_{u'}) = 0. \tag{26}$$

Finally, from (23), and the conditions (24), (25), and (26) we get the results stated in the theorem. Q.E.D.

Note now, that with the map ζ: $J^1\to M\times\mathbb{R}$ discussed in Sec. II, we have a one-parameter family of (pseudo-)Riemannian metrics in the solution space M (Riemannian metrics if $\Lambda_u<0$, and Lorentzian metrics if $\Lambda_u>0$), i.e., we have the following family of metrics:

$$g(x^a,s) = (\zeta^{-1})^* h, \tag{27}$$

or written in coordinates,

$$g(x^a,s) = \beta^1\otimes\beta^1 - \frac{1}{\Lambda_u}\beta^2\otimes\beta^2 = \left[Z_aZ_b - \frac{1}{\Lambda_u}Z'_aZ'_b\right]\mathrm{d}x^a\,\mathrm{d}x^b. \tag{28}$$

In fact, they are equivalents, because it is easy to show that h satisfies

$$\mathfrak{L}_{e_s}h = 0. \tag{29}$$

Finally, let us collect the one-forms θ^i and ω^i_j into the matrix-valued one-form

$$\omega_c = \begin{pmatrix} 0 & 0 & 0 \\ \theta^1 & -\omega_{[12]} & 0 \\ \theta^2 & 0 & \omega_{[12]} \end{pmatrix},$$

and let us study two cases.

(a) $\Lambda_u > 0$: In this case we have a Lorentzian metric, and ω_c takes its values in the Lie algebra of $\mathrm{SO}(1,1) \rtimes \mathrm{R}^2$.

This matrix valued one-form can be regarded as a $\mathrm{SO}(1,1) \rtimes \mathrm{R}^2$ Cartan connection[14] on the principal bundle $\mathrm{SO}(1,1) \to \mathrm{P} \to M$ with associated curvature $\Omega_c = \mathrm{d}\omega_c + \omega_c \wedge \omega_c$ given by

$$\Omega_c = \begin{pmatrix} 0 & 0 & 0 \\ T^1 & \Omega_1^1 & \Omega_2^1 \\ T^2 & \Omega_1^2 & \Omega_2^2 \end{pmatrix} = \begin{pmatrix} 0 & 0 & 0 \\ 0 & -R & 0 \\ 0 & 0 & R \end{pmatrix}, \tag{30}$$

where $\Omega_j^i = \mathrm{d}\omega_j^i + \omega_k^i \wedge \omega_j^k$ is the standard curvature, and

$$R = -\frac{1}{a} a_{uu} \theta^1 \wedge \theta^2. \tag{31}$$

(b) $\Lambda_u < 0$: In this case we have a Riemannian metric, and ω_c takes its values in the Lie algebra of $\mathrm{SO}(2) \rtimes \mathrm{R}^2$.

This construction gives a $\mathrm{SO}(2) \rtimes \mathrm{R}^2$ Cartan connection on the principal bundle $\mathrm{SO}(2) \to \mathrm{P} \to M$ with associated curvature $\Omega_c = \mathrm{d}\omega_c + \omega_c \wedge \omega_c$ given by a similar formula to (30).

IV. CONCLUSIONS

In this paper we show that, as it happens in NSF, all two-dimensional Riemannian and Lorenztian metrics can be obtained from the geometrical condition of a torsion-free connection. Furthermore, we construct all associated Cartan connections to these equations. This approach can be extended to the study of third-order ODE and a pair of second-order PDE's, but the choice of the differential quadratic form h, is not *a priori* so clear. In fact, all these problems should be studied with the Cartan's equivalence method[15] applied to differential equation under a subgroup of contact transformations: the canonical transformations. With this algorithmic method, the group arising from these equations can be naturally obtained as the group of allowed transformations in the study of the equivalence problem. Work in this area has begun.

Comments on matter collineations of plane symmetric, cylindrically symmetric, and spherically symmetric space–times

(Received 24 June 2004; accepted 6 July 2004; published 25 October 2004)

[DOI: 10.1063/1.1793331]

Recently matter collineations (MCs) of plane symmetric static[1] and cylindrically symmetric static space–times[2] have been presented. Earlier, the same author also classified spherically symmetric static space–times according to their MCs.[3] For an energy-momentum tensor $\mathbf{T}$, we call $\boldsymbol{\xi}$ an MC if

$$\pounds_{\boldsymbol{\xi}}\mathbf{T} = 0. \tag{1}$$

In component form, Eq. (1) becomes the MC equation

$$T_{ab,c}\xi^{c} + T_{ac}\xi^{c}{}_{,b} + T_{bc}\xi^{c}{}_{,a} = 0.$$

In these equations, if $\mathbf{T}$ is replaced by the Ricci tensor $\mathbf{R}$ then the vector $\boldsymbol{\xi}$ is called a Ricci collineation (RC). Noting the apparently similar form of the equations and the role of the matter and Ricci tensors in the Einstein field equations (EFEs)

$$R_{ab} - \tfrac{1}{2}Rg_{ab} = \kappa T_{ab}, \tag{2}$$

the author merely replaced the Ricci tensor by the matter tensor in Refs. 4–6 for the classification according to RCs of plane symmetric, cylindrically symmetric, and spherically symmetric static space–times, respectively. All that remains to be done is to check that the RCs satisfy the MC equations. Even if he has done so, errors persist in his papers. For example, because of the error in calculations the Lie algebra for a case, as given in Eq. (B47) of Ref. 4, does not close. This error has been carried over in Eqs. (43) of his paper (Ref. 1). (A typographical error there is carried over as well.) Now, as plane symmetry can locally be considered as a special case of cylindrical symmetry, this particular case appears in Ref. 5 also, where it has been corrected. This correction has been carried over into Eqs. (27) of his paper (Ref. 2) as well, but the author has not cited these papers.

It is worth mentioning a serious misconception in the three subject papers (Refs. 1–3) that was not imported from the Ricci collineation papers. The author says that there are "three, four, five, six, seven, or ten MCs out of which three are isometries and the rest are proper."[1,2] He has assumed that the isometry group is minimal. This is simply incorrect as there are numerous cases of nonminimal isometry groups. It is possible that all the four, five, six, seven, or ten MCs may be isometries and there may be no proper MCs. A similar problem arises for the spherically symmetric case.[3]

[b)]Electronic mail: saifullah@qau.edu.pk

We also mention here that Ref. 7, on the same subject as Ref. 1, does not only classify the plane symmetric space–times (with the correct Lie algebras provided) but it discusses the issue of the relationship between the RCs and MCs and also provides a number of explicit examples for that purpose. We will not go into further detail on this because this is the subject of a separate full-length study[8] in itself.

Addendum: Symmetries of the energy-momentum tensor

M. Sharif[a)]
Department of Mathematics, University of the Punjab,
Quaid-e-Azam Campus Lahore-54590, Pakistan

(Received 21 May 2004; accepted 31 May 2004; published 25 October 2004)

In recent papers [J. Math. Phys. **44**, 5142 (2003); **45**, 1518 (2003); **45**, 1532 (2004)] we have discussed matter symmetries of nonstatic spherically symmetric space–times, static plane symmetric space–times, and cylindrically symmetric static space–times. These have been classified for both cases when the energy-momentum tensor is nondegenerate and also when it is degenerate. Here we add up some consequences and the missing references about the Ricci tensor. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1777404]

Recently, we have presented a detailed analysis of matter collineations (MCs) for nonstatic spherically symmetric space–times,[1] static plane symmetric space–times,[2] and cylindrically symmetric static space–times.[3] We have discussed in detail the matter symmetries for each of the metrics and have found the corresponding constraint equations. In general, it is not easy to solve these constraint equations, sometimes the solution of the constraint equations may not exist. We have constructed some examples which help us in exploring the difference between RCs and MCs.

It is usually believed that matter and Ricci symmetries are the similar symmetries and one can find MCs directly from the RCs. However, this is not true in general. This has been shown in many papers on this topic.[1–9] In this short communication, we express this difference with examples. Further, we add up some references missing in Refs. 1–3 which should have been inserted there.

Let (M,g) be a space–time manifold with signature $(+,-,-,-)$. It is assumed that the manifold M, and the metric g, are smooth. Einstein's field equations (EFEs), which relate the geometry and matter, are given by

$$R_{ab} - \tfrac{1}{2}Rg_{ab} \equiv G_{ab} = \kappa T_{ab} \quad (a,b = 0,1,2,3), \tag{1}$$

where κ is the gravitational constant, G_{ab} is the Einstein tensor, R_{ab} is the Ricci, and T_{ab} is the matter (energy-momentum) tensor. Also, $R=g^{ab}R_{ab}$ is the Ricci scalar. It is obvious from EFEs that for vacuum space–times, $R_{ab}=T_{ab}$ and consequently, RCs and MCs are similar in this special case.

We define a differentiable vector field ξ on M to be a matter collineation if $\pounds_\xi T_{ab}=0$ which can be written in component form as

$$T_{ab,c}\xi^c + T_{ac}\xi^c_{,b} + T_{cb}\xi^c_{,a} = 0, \tag{2}$$

where $\pounds$ is the Lie derivative operator, ξ^a is the symmetry or collineation vector. Since the Einstein tensor is related to the matter content of the space–time by the EFEs, the investigation of MCs seems to be more relevant from the viewpoint of physics. Here we would not give details of the calculations as the procedure has been explicitly given in the papers.[1–3] Rather we would explore the difference of RCs and MCs for nonstatic spherically symmetric, static plane symmetric, and cylindrically symmetric static space–times with the help of examples.

The most general form of the metric for a spherically symmetric space–time is given by

[a)]Electronic mail: hasharif@yahoo.com

$$ds^2 = e^{\nu(t,r)}\,dt^2 - e^{\mu(t,r)}\,dr^2 - e^{\lambda(t,r)}\,d\Omega^2, \tag{3}$$

where $d\Omega^2 = d\theta^2 + \sin^2\theta\, d\phi^2$. The surviving components of the energy-momentum tensor are $T_{00}, T_{01}\ T_{11}, T_{22}, T_{33}$, where $T_{33} = \sin^2\theta T_{22}$. We have found[1] that, for the nondegenerate case, there exist either four, six, seven or ten independent MCs in which four are isometries and the rest are the proper. For the degenerate case, most of the cases give the infinite-dimensional MCs. The worth-noting cases are those where the energy-momentum tensor is degenerate but the group of MCs is finite dimensional, i.e., four or ten. Similar analysis has been given in the paper[10] for the Ricci tensor. It can be seen from the comparison of the two papers[1,10] that MCs and RCs turn out to be the same but the constraint equations are entirely different. For example, in the Einstein/anti-Einstein metric, we obtain seven MCs[5] but RCs are infinite dimensional.

The metric for static plane symmetric space–times is given in the form[11]

$$ds^2 = e^{\nu(x)}\,dt^2 - dx^2 - e^{\mu(x)}(dy^2 + dz^2). \tag{4}$$

The surviving components of the energy-momentum tensor are T_0, T_1, T_2, T_3, where $T_3 = T_2$. When we solve MC equations for the static plane symmetric space–times it turns out[2] that the nondegenerate case yields either four, five, six, seven or ten independent MCs in which four are isometries and the rest are proper. We have also obtained three interesting cases where the energy-momentum tensor is degenerate but the group of MCs is finite dimensional which are either four, six or ten.

Again when we compare the analysis given in the two papers,[2,12] it is concluded that RCs and MCs are similar but with different constraint equations. We can construct some examples by solving these constraint equations which exhibit the difference between RCs and MCs admitted by the space–time. Consider the following plane symmetric static space–time:

$$ds^2 = (ax + b)^2\,dt^2 - dx^2 - (cx + d)^2(dy^2 + dz^2), \tag{5}$$

where $a, b, c, d \in \Re, ac \neq 0 \neq ad - bc$. In this example, we obtain five MCs in which three are the usual isometries and the remaining two are proper MCs but the RCs are infinite dimensional.

The most general form of cylindrically symmetric static space–time is given by

$$ds^2 = e^{\nu(r)}\,dt^2 - dr^2 - e^{\lambda(r)}\,d\theta^2 - e^{\mu(r)}\,dz^2. \tag{6}$$

The only nonzero components of the energy-momentum tensor turn out to be $T_{00}, T_{11}, T_{22}, T_{33}$. We have found[3] that the nondegenerate energy-momentum tensor gives either three, four, five, six, seven or ten independent MCs in which three are isometries and the rest are proper. There are four worth-mentioning cases where we have obtained the group of MCs finite dimensional, even the energy-momentum tensor is degenerate, i.e., either three, four, five or ten. It can be seen from the two papers[3,13] that RCs and MCs become similar but the constraints are different. Here we present examples by solving these constraints which give different space–times for the two collineations.

The following cylindrically symmetric metric,

$$ds^2 = \cosh^2 cr\,dt^2 - dr^2 - (\cosh cr)^{-1}\,d\theta^2 - (\cosh cr)^{-1}\,dz^2, \tag{7}$$

where c is an arbitrary constant, admits four MCs and also four isometries but it has seven RCs. The space–time

$$ds^2 = (r/r_0)^{2a}\,dt^2 - dr^2 - (r/r_0)^{2a}\,d\theta^2 - (r/r_0)^{2a}\,dz^2, \tag{8}$$

where a and r_0 are arbitrary constants such that $a \neq 0, 1$, admits ten MCs with six KVs but seven RCs. Taking $\nu = \lambda = \mu$ in Eq. (6), this metric admits six MCs and also six KVs but seven RCs. The following space–time,

$$ds^2 = (\cosh cr)^{-1}\,dt^2 - dr^2 - \cosh^2 cr\,d\theta^2 - (\cosh cr)^{-1}\,dz^2, \tag{9}$$

has four MCs and also four KVs but seven RCs.

In this addendum, we have provided examples which clearly indicate the difference of the symmetries for the Ricci and matter tensors. Also, we have incorporated the missing references in the previous papers.[1–3] It is mentioned here that RCs and MCs will exactly be similar for those space–times where $R_{ab}=T_{ab}$ or equivalently for vacuum space–times. For example, in the case of Schwarzschild metric, every direction is RC/MC.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 45, NUMBER 11 NOVEMBER 2004

Almost sharp quantum effects

Alvaro Arias and Stan Gudder
Department of Mathematics, The University of Denver, Denver, Colorado 80208

(Received 22 April 2004; accepted 17 August 2004; published 25 October 2004)

Quantum effects are represented by operators on a Hilbert space satisfying $0 \leqslant A \leqslant I$, and sharp quantum effects are represented by projection operators. We say that an effect A is almost sharp if $A=PQP$ for projections P and Q. We give simple characterizations of almost sharp effects. We also characterize effects that can be written as longer products of projections. For generality we first work in the formalism of von Neumann algebras. We then specialize to the full operator algebra $B(H)$ and to finite dimensional Hilbert spaces. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1806532]

I. INTRODUCTION

Let H be a complex Hilbert space that represents the state space of a quantum system $\mathcal{S}$. The set of *effects* $\mathcal{E}(H)$ for $\mathcal{S}$ is the set of operators on H satisfying $0 \leqslant A \leqslant I$. Effects represent yes–no measurements that may be unsharp (imprecise, fuzzy). It is interesting that many of the important classes of quantum operators are given by subsets of $\mathcal{E}(H)$. For example, the *sharp* yes–no measurements are represented by the set of projection operators $\mathcal{P}(H) \subset \mathcal{E}(H)$. A *state* for $\mathcal{S}$ is represented by an operator $W \in \mathcal{E}(H)$ satisfying $\mathrm{tr}(W)=1$. We call W a *density operator* and denote the set of density operators by $\mathcal{D}(H)$. The *pure states* for $\mathcal{S}$ are given by $\mathcal{D}(H) \cap \mathcal{P}(H)$.

The probability that $A \in \mathcal{E}(H)$ has values yes (or is true) in the state $W \in \mathcal{D}(H)$ is given by $p_W(A)=\mathrm{tr}(WA)$. If W happens to be a pure state corresponding to the unit vector ψ, then $p_W(A) = \langle A\psi, \psi \rangle$. In particular, sharp effects are called *quantum events* and the probability that event $Q \in \mathcal{P}(H)$ occurs in the state $W \in \mathcal{D}(H)$ is $p_W(Q)=\mathrm{tr}(WQ)$. For $P, Q \in \mathcal{P}(H)$ we define the *conditional probability of Q given P* in the state W by

$$p_W(Q|P) = \frac{\mathrm{tr}(PWPQ)}{\mathrm{tr}(WP)} = \frac{\mathrm{tr}(WPQP)}{\mathrm{tr}(WP)}$$

from which we obtain

$$p_W(PQP) = \mathrm{tr}(WPQP) = p_W(P)p_W(Q|P). \tag{1.1}$$

Now (1.1) is analogous to the traditional probability formula

$$p(A \cap B) = p(A)p(B|A)$$

so in some sense PQP corresponds to an intersection of events. However, in general $p_W(PQP) \neq p_W(QPQ)$ so the order of measurements is relevant. In fact, $P \circ Q = PQP$ corresponds to a sequential measurement in which we measure P first and Q second. We call $P \circ Q$ the *sequential product* of P and Q (see Refs. 2 and 3). More generally, we define the *sequential product* $A \circ B = A^{1/2}BA^{1/2} \in \mathcal{E}(H)$ for any $A, B \in \mathcal{E}(H)$ but our main interest is in sequential products of sharp effects. The form $P \circ Q = PQP$ for projective measurements is well established, but the general form $A \circ B = A^{1/2}BA^{1/2}$ is not unique and depends on the particular measurement technique. In general, we may have a sequential product given by C^*BC where C is any operator satisfying $C^*C=A$. Note however that $C=A^{1/2}$ is the simplest such operator and moreover in this case $C \in \mathcal{E}(H)$. The next result gives some of the important properties of the sequential product.

Theorem 1 (Ref. 3): *Let $A, B \in \mathcal{E}(H)$, $P, Q \in \mathcal{P}(H)$. Then*

(1) $A\circ B=B\circ A$ *if and only if* $AB=BA$.
(2) *If* $A\circ B\in\mathcal{P}(H)$ *then* $AB=BA$.
(3) $P\circ Q\in\mathcal{P}(H)$ *if and only if* $PQ=QP$.

If $AB=BA$ we say that A and B are *compatible*. Physically, compatible effects correspond to effects that are simultaneously measurable. Thus, A and B are simultaneously measurable if and only if their order of measurement is irrelevant. A state $W\in\mathcal{D}(H)$ is *faithful* if $\mathrm{tr}(WA)=0$ for $A\in\mathcal{E}(H)$ implies that $A=0$. The next result gives an interesting probabilistic characterization of compatible sharp effects.

Corollary 2: For $P,Q\in\mathcal{P}(H)$ *and faithful* $W\in\mathcal{D}(H)$, $PQ=QP$ *if and only if* $p_W(Q\circ P)\leqslant p_W(Q\circ(P\circ Q))$.

Proof: Suppose that $p_W(Q\circ P)\leqslant p_W(Q\circ(P\circ Q))$. Then

$$\mathrm{tr}[W(QPQ-QPQPQ)]\leqslant 0.$$

It is easy to check that $PQP\leqslant P$ and it follows that $QPQPQ\leqslant QPQ$. Hence, $QPQ-QPQPQ\in\mathcal{E}(H)$ so that

$$\mathrm{tr}[W(QPQ-QPQPQ)]=0.$$

Since W is faithful, we conclude that

$$QPQ=QPQPQ=(QPQ)^2.$$

Thus, $Q\circ P=QPQ\in\mathcal{P}(H)$ so by part 3 of Theorem 1, $PQ=QP$. The converse is trivial. ■

The next corollary solves Problem 11028 in the American Mathematical Monthly [Vol. 110, p. 636 (2003)].

Corollary 3: Let $\dim(H)=n<\infty$ *and let* $P,Q\in\mathcal{P}(H)$. *Then* $PQ\in\mathcal{P}(H)$ *if and only if* $\mathrm{tr}(PQ)=\mathrm{tr}(PQPQ)$.

Proof: Notice that $W=(1/n)I\in\mathcal{D}(H)$ is faithful and

$$p_W(Q\circ P)=\mathrm{tr}(WQPQ)=\frac{1}{n}\mathrm{tr}(QPQ)=\frac{1}{n}\mathrm{tr}(PQ).$$

Assuming that $\mathrm{tr}(PQ)=\mathrm{tr}(PQPQ)$ we have that

$$p_W(Q\circ P)=\frac{1}{n}\mathrm{tr}(QPQP)=p_W(Q\circ(P\circ Q)).$$

By Corollary 1.2 we have $PQ=QP$ so that $PQ\in\mathcal{P}(H)$. The converse is trivial. ■

One of our main concerns is to characterize effects of the form $A=P\circ Q$ for $P,Q\in\mathcal{P}(H)$. Such effects are called *almost sharp* because they may be obtained by measuring two sharp effects. In a sense, almost sharp effects are "close" to being sharp and we shall present a simple characterization of such effects. Defining the *negation* of $A\in\mathcal{E}(H)$ by $A'=I-A$, we see immediately that $A'\in\mathcal{E}(H)$. We say that A is *nearly sharp* if both A and A' are almost sharp. We shall show that the set of nearly sharp effects has the structure of an orthocomplemented partially ordered set.

Letting $\mathcal{P}_1(H)=\mathcal{P}(H)$ and $\mathcal{P}_2(H)$ be the set of almost sharp elements we see that

$$\mathcal{P}_2(H)=\{A\in\mathcal{E}(H):A=P_1\circ P_2,P_1,P_2\in\mathcal{P}(H)\}$$

and it follows from part 3 of Theorem 1 that $\mathcal{P}_2(H)$ strictly contains $\mathcal{P}_1(H)$. We shall show that

$$\mathcal{P}_3(H)=\{A\in\mathcal{E}(H):A=P_1\circ(P_2\circ P_3),P_1,P_2,P_3\in\mathcal{P}(H)\}$$

strictly contains $\mathcal{P}_2(H)$ if dim (H) is sufficiently large. This suggests the natural problem of when $A\in\mathcal{E}(H)$ has the form

$$A = P_1 \circ (P_2 \circ \cdots \circ (P_{n-1} \circ P_n)). \tag{1.2}$$

Writing (1.2) in terms of operator products gives

$$A = P_1 P_2 \cdots P_{n-1} P_n P_{n-1} \cdots P_2 P_1.$$

We shall also characterize effects that have the form (1.2)

For generality we shall first work in the formalism of a von Neumann algebra. We then consider the full operator algebra $B(H)$ for H separable. Finally, we show that simplifications and further insights can be obtained from considering finite dimensional Hilbert spaces.

II. EFFECTS ON VON NEUMANN ALGEBRAS

Let M be a von Neumann algebra on a Hilbert space H. The set of effects in M is

$$\mathcal{E}(M) = \{A \in M : 0 \leqslant A \leqslant I\}$$

and the set of projections or sharp effects in M is

$$\mathcal{P}(M) = \{P \in M : P = P^* = P^2\} \subset \mathcal{E}(M).$$

For $P, Q \in \mathcal{P}(M)$, according to the usual comparison of projections we define $P \leqslant Q$ if there exists a partial isometry $U \in M$ such that $U^*U = P$ and $UU^* \leqslant Q$. Notice that UU^* is a projection whose range is contained in the range of Q.

For $A \in \mathcal{E}(M)$ we define P_A to be the projection onto the closure of the range of A. It can be shown that

$$P_A = \lim_{n \to \infty} A^{1/n}$$

in the strong operator topology so that $P_A \in M$. Moreover, $P_A A = A P_A = A$. Letting N_A be the projection onto the null space of A we have that

$$N_A = I - P_A = (P_A)'.$$

It is easy to check that P_A is the smallest projection satisfying $A \leqslant P_A$, $N_{A'}$ is the largest projection satisfying $N_{A'} \leqslant A$ and that

$$N_{A'} = \lim_{n \to \infty} A^n.$$

It follows that $N_A = \lim_{n \to \infty} (A')^n$ and hence

$$N_{A'} A = A N_{A'} = N_{A'}.$$

Notice that if $A \in \mathcal{E}(M)$ has the form $A = PQP$ for some $P, Q \in \mathcal{P}(M)$, then we also have that $A = P_A Q P_A$.

Lemma 4: For $A \in \mathcal{E}(M)$ we have that $P_{AA'} = P_A - N_{A'}$.

Proof: It is clear that $AA' \in \mathcal{E}(M)$, $AA' \leqslant A$, and $AA' \leqslant A'$. Hence, $P_{AA'} \leqslant P_A$, $P_{AA'} \leqslant P_{A'}$, and it follows that $N_A \leqslant N_{AA'}$ and $N_{A'} \leqslant N_{AA'}$. Since N_A and $N_{A'}$ are mutually orthogonal we conclude that $N_A + N_{A'} \leqslant N_{AA'}$. To prove the reverse inequality, let $x \neq 0$ satisfying $N_{AA'} x = x$. Write $x = Ax + A'x$ and notice that $A'(Ax) = 0$ and $A(A'x) = 0$. Then $Ax = N_{A'}(Ax)$ and $A'x = N_A(A'x)$. Since $N_{A'} A = N_{A'}$ and $N_A A' = N_A$, we have that $x = N_A x + N_{A'} x$. We conclude that $N_A + N_{A'} = N_{AA'}$. Therefore

$$P_{AA'} = I - N_{AA'} = I - N_A - N_{A'} = P_A - N_{A'}.$$

■

In the process of proving Lemma 4 we also obtained the interesting result $N_A + N_{A'} = N_{AA'}$.

The motivation for the next theorem is the following: If $0 \leqslant A \leqslant I$, then

$$\begin{pmatrix} A & \sqrt{AA'} \\ \sqrt{AA'} & A' \end{pmatrix}$$

is a projection whose compression to the (1,1) component is A.

Theorem 5: *An effect $A\in\mathcal{E}(M)$ is almost sharp if and only if $P_{AA'}\leqslant N_A$.*

Proof: Suppose that $P_{AA'}\leqslant N_A$. Then there exists a partial isometry $U\in M$ such that $U^*U=P_{AA'}$ and $UU^*\leqslant N_A$. Then U maps the range of $P_{AA'}$ into the range of N_A and U^* maps the range of N_A into the range of $P_{AA'}$. Notice that $N_{A'}=P_A-P_{AA'}$, $P_{AA'}$, and N_A are mutually orthogonal projections satisfying

$$N_A+N_{A'}+P_{AA'}=I. \tag{2.1}$$

Define Q_1 by the formula

$$Q_1=P_{AA'}AP_{AA'}+P_{AA'}\sqrt{AA'}U^*N_A+N_AU\sqrt{AA'}P_{AA'}+N_AUA'U^*N_A.$$

It is clear that $Q_1=Q_1^*$ and to show that $Q_1\in\mathcal{P}(M)$ we have

$$\begin{aligned} Q_1^2=&P_{AA'}(A^2+\sqrt{AA'}U^*N_AU\sqrt{AA'})P_{AA'}+P_{AA'}(AP_{AA'}\sqrt{AA'}U^*+\sqrt{AA'}U^*N_AUA'U^*)N_A\\ &+N_A(U\sqrt{AA'}P_{AA'}A+UA'U^*N_AU\sqrt{AA'})P_{AA'}+N_A(U\sqrt{AA'}P_{AA'}\sqrt{AA'}U^*\\ &+UA'U^*N_AUA'U^*)N_A. \end{aligned} \tag{2.2}$$

Notice that

$$U=N_AU=UP_{AA'}=N_AUP_{AA'} \tag{2.3}$$

and hence

$$P_{AA'}=U^*N_AU. \tag{2.4}$$

By (2.4) the first term in (2.2) becomes

$$P_{AA'}(A^2+AA')P_{AA'}=P_{AA'}AP_{AA'}.$$

By (2.4) again, the second term in (2.2) becomes

$$P_{AA'}(A\sqrt{AA'}U^*+A'\sqrt{AA'}U^*)N_A=P_{AA'}\sqrt{AA'}U^*N_A.$$

In a similar way, the third term in (2.2) becomes

$$N_A(UA\sqrt{AA'}+UA'\sqrt{AA'})P_{AA'}=N_AU\sqrt{AA'}P_{AA'}.$$

Finally, by (2.3) and (2.4) the fourth term in (2.2) becomes

$$N_AU(AA'+P_{AA'}A'A')U^*N_A=N_AU(AA'+A'A')U^*N_A=N_AUA'U^*N_A.$$

We conclude that $Q_1\in\mathcal{P}(M)$. To show that $Q_1\leqslant P_{AA'}+N_A$ we have that

$$Q_1(P_{AA'}+N_A)=(P_{AA'}+N_A)Q_1=Q_1.$$

Since $N_{A'}$ is orthogonal to $P_{AA'}$ and N_A we see that

$$Q=N_{A'}+Q_1\in\mathcal{P}(M).$$

Since $N_{A'}\leqslant A\leqslant P_A$, $P_{AA'}\leqslant P_A$, and $P_AN_A=0$ we have by Lemma 4 that

$$P_AQP_A = P_AN_{A'}P_A + P_AQ_1P_A = N_{A'} + P_{AA'}Q_1P_{AA'} = N_{A'} + P_{AA'}AP_{AA'}$$
$$= N_{A'} + (P_A - N_{A'})A(P_A - N_{A'}) = N_{A'} + (P_A - N_{A'})A$$
$$= N_{A'} + P_AA - N_{A'}A = N_{A'} + A - N_{A'} = A.$$

Conversely, suppose that there exists a $Q \in \mathcal{P}(M)$ such that $A = P_AQP_A$. Letting $B = P_AQN_A$ we have that $BB^* \geqslant 0$ and

$$BB^* = P_AQN_AQP_A = P_AQ(I - P_A)QP_A = P_AQP_A - P_AQP_AQP_A = A - A^2 = AA'.$$

Using the polar decomposition of B we find a partial isometry $U \in M$, with initial space P_{B^*}, the range of B^*, and final space P_B, the range of B, such that $B = \sqrt{AA'}U$. Now

$$P_B = P_{BB^*} = P_{AA'}$$

and since $P_{B^*} \leqslant N_A$ we obtain that $UU^* = P_{AA'}$ and $U^*U \leqslant N_A$. Hence, $P_{AA'} \leqslant N_A$. ■

We can gain an intuitive feeling for Theorem 5 as follows. Since $AA' = A - A^2$ we see that A is sharp iff $AA' = 0$ or equivalently $P_{AA'} = 0$. Now Theorem 5 states that A is almost sharp if and only if $P_{AA'}$ is not too big in the sense that $P_{AA'}$ is dominated by N_A. Recall that a *factor* is a von Neumann algebra with trivial center and that in this case all projections are comparable relatively to $\leqslant$. It follows that projections have a well-defined dimension $\dim(P)$ in a factor.

Corollary 6: If M is a factor, then an effect $A \in \mathcal{E}(M)$ is almost sharp if and only if $\dim(P_{AA'}) \leqslant \dim(N_A)$.

Corollary 6 is not true if M is not a factor even when there is a well-defined dimension function. To show this, let M_n be the matrix algebra of $n \times n$ complex matrices and let M be the von Neumann algebra $M = M_n \oplus M_n$. Let $I_n \in M_n$ be the identity matrix and let

$$A = \frac{1}{2}I_n \oplus 0 = \begin{bmatrix} 1/2 & \cdots & 0 \\ \vdots & \ddots & \vdots \\ 0 & \cdots & 1/2 \end{bmatrix} \begin{bmatrix} 0 & \cdots & 0 \\ \vdots & \ddots & \vdots \\ 0 & \cdots & 0 \end{bmatrix} \in M_n \oplus M_n.$$

Then $\dim(P_{AA'}) = \dim(N_A) = n$ but A cannot be written in the form P_AQP_A for some projection Q in $M = M_n \oplus M_n$.

Applying Corollary 6, a moment thought shows that $A \in \mathcal{E}(M)$ is almost sharp if and only if A^n is almost sharp for every positive integer n. This gives the nontrivial result that if $A = P_AQP_A$ for $Q \in \mathcal{P}(M)$, then $A^n = P_AQ_nP_A$ for some $Q_n \in \mathcal{P}(M)$.

In a type III factor, all proper projections are equivalent (have the same dimension). Recall that if A is not invertible, then A is *singular*.

Corollary 7: Let M be a type III factor and let $A \in \mathcal{E}(M)$ with $A \neq I$. Then A is almost sharp if and only if A is singular.

Proof. Suppose A is invertible and $A = P_AQP_A$ for some $Q \in \mathcal{P}(M)$. Since $A \leqslant P_A$, P_A is also invertible which implies that $P_A = I$. Hence, $A = Q$ which implies that $A = I$. Conversely, suppose that $A \neq 0$ and that A is singular. Then $P_{AA'} \neq I$ and $N_A \neq 0$. The result follows from Corollary 6. ■

Recall that an effect $A \in \mathcal{E}(M)$ is *nearly sharp* if A and A' are both almost sharp.

Corollary 8: An effect $A \in \mathcal{E}(M)$ is nearly sharp if and only if $P_{AA'} \leqslant N_A$ and $P_{AA'} \leqslant N_{A'}$. If M is a factor, then $A \in \mathcal{E}(M)$ is nearly sharp if and only if $\dim(P_{AA'}) \leqslant \dim(N_A)$ *and* $\dim(P_{AA'}) \leqslant \dim(N_{A'})$.

An *orthoposet* is a system $(\mathcal{P}, \leqslant, ', 0, 1)$ where $(\mathcal{P}, \leqslant, 0, 1)$ is a bounded poset and $': \mathcal{P} \to \mathcal{P}$ satisfies $a'' = a$, $a \leqslant b$ implies $b' \leqslant a'$ and $a \wedge a' = 0$. An orthoposet $\mathcal{P}$ is *orthomodular* if $a \leqslant b'$ implies $a \vee b$ exists and $a \leqslant b$ implies $b = a \vee (b \wedge a')$. It is well known that $\mathcal{P}(M)$ forms an orthomodular lattice.[1]

Corollary 9: If $\mathcal{E}(M)_{ns}$ is the set of nearly sharp elements in $\mathcal{E}(M)$, then $(\mathcal{E}(M)_{ns}, \leqslant, ', 0, 1)$ is an orthoposet.

Proof: All the properties of an orthoposet are clear except for the condition $A \wedge A' = 0$ for every $A \in \mathcal{E}(M)_{ns}$. To verify this condition suppose that $B \in \mathcal{E}(M)_{ns}$ with $B \leqslant A$ and $B \leqslant A'$. Then $B \leqslant (A + A')/2 = \frac{1}{2}I$. Since $(\frac{1}{2}I)' = \frac{1}{2}I$, it follows that $\frac{1}{2}I \leqslant B'$ so that $N_{B'} = 0$. Since $B \in \mathcal{E}(M)_{ns}$, by Theorem 5, $P_{BB'} \leqslant N_{B'}$ so that $P_{BB'} = 0$. Hence, $BB' = 0$. Since $B' \geqslant \frac{1}{2}I$ we conclude that $B = 0$ and it follows that $A \wedge A' = 0$. ■

III. EFFECTS ON $B(H)$

Let H be a separable Hilbert space and let M be the factor $B(H)$ consisting of all bounded linear operators on H. As in Sec. I, we use the notation $\mathcal{E}(H)$, $\mathcal{P}(H)$ for $\mathcal{E}(M)$, $\mathcal{P}(M)$, respectively. For $P \in \mathcal{P}(H)$ we define

$$[0, P] = \{A \in \mathcal{E}(H) : 0 \leqslant A \leqslant P\}.$$

Theorem 10:

(1) *If $P \in \mathcal{P}(H)$ with $\dim(P') = \infty$, then*

$$[0, P] = \{P_1 Q P_1 : Q, P_1 \in \mathcal{P}(H), P_1 \leqslant P\}.$$

(2) *If $P \in \mathcal{P}(H)$ with $\dim(P) = \dim(P') = \infty$, then $A \in \mathcal{E}(H)$ satisfies $AP = PA$ if and only if $A = P_1 Q P_1 + P_2 R P_2$ with $P_1, P_2, Q, R \in \mathcal{P}(H)$ and $P_1 \leqslant P$, $P_2 \leqslant P'$.*

Proof: (1) If $A = P_1 Q P_1$, then $0 \leqslant A \leqslant P_1 \leqslant P$ so $A \in [0, P]$. Conversely, if $0 \leqslant A \leqslant P$, then $P_A \leqslant P$ and hence $N_A \geqslant P'$. Thus $\dim(N_A) = \infty$ and the result follows from Corollary 6.

(2) If $A = P_1 Q P_1 + P_2 R P_2$ with the given properties, it is clear that $AP = PA$. Conversely, suppose that $AP = PA$. Then we can write $A = PAP + P'AP'$. Since $PAP \in [0, P]$ and $P'AP' \in [0, P']$ the result follows from part (1). ■

A projection P is an example of a simple *superselection rule* and an $A \in \mathcal{E}(H)$ satisfying $AP = PA$ is said to satisfy the superselection rule P. Part (2) of Theorem 10 states that if $\dim(P) = \dim(P') = \infty$, then $A \in \mathcal{E}(H)$ satisfies the superselection rule P if and only if A is the sum of two nearly sharp elements, $A = A_1 + A_2$, where A_1 is contained in the *superselection sector* $[0, P]$ and A_2 is contained in the superselection sector $[0, P']$.

Suppose $P \in \mathcal{P}(H)$ with $\dim(P) = \dim(P') = \infty$. If $A \in [0, P]$ then by Part (1) of Theorem 10, A is almost sharp. If $A, B \in [0, P]$ and $A + B \in \mathcal{E}(H)$, then $A + B \in [0, P]$. It follows that $[0, P]$ is an *effect algebra with unit P* (see Refs. 1 and 2). If $A \in [0, P]$, then $\lambda A \in [0, P]$ for every $\lambda \in [0, 1]$ and it follows that $[0, P]$ is a *convex* effect algebra.[1] Finally, if $A, B \in [0, P]$ then $A \circ B \leqslant A \leqslant P$ where $A \circ B = A^{1/2} B A^{1/2}$. Hence, $A \circ B \in [0, P]$ and we conclude that $[0, P]$ is a *sequential effect algebra*[2] of almost sharp effects. Notice however, that if $A \in [0, P]$ then $A = P_A Q P_A$ where $P_A \in [0, P]$ but $Q \notin [0, P]$ in general.

We now consider the question of when $A \in \mathcal{E}(H)$ has the form

$$A = P_1 P_2 \cdots P_n Q P_n \cdots P_2 P_1 \tag{3.1}$$

for $\mathcal{P}_i, Q \in P(H)$ for $i = 1, \ldots, n$. To answer this question we shall need some preliminary results. If $\dim(N_A) = \infty$, then by Corollary 6, A is almost sharp so that A certainly has the form (3.1). We therefore assume that $\dim(N_A) < \infty$.

Lemma 11:

(1) *Suppose that $A, B \in \mathcal{E}(H)$ satisfy $A = P_A B P_A$, $\dim(N_A) < \infty$, and $\dim(P_{AA'}) = \infty$. Then $\dim(N_B) < \infty$ and $\dim(P_{BB'}) = \infty$.*

(2) *If $A \in \mathcal{E}(H)$ satisfies $\dim(N_A) < \infty$ and $\dim(P_{AA'}) = \infty$, then A does not have the form* (3.1).

Proof: (1) We first show that $\dim(N_B) \leqslant \dim(N_A)$. If this is not true, then there exists a nonzero vector $x \in \ker(B) \ominus \ker(A)$. But then $P_A x = x$ and we have that $Ax = P_A B P_A x = P_A B x = 0$. Hence

$x \in \ker(A)$ which is a contradiction. We now show that $\dim(P_{BB'}) = \infty$. If $\dim(P_{BB'}) < \infty$, then by (2.1) we have that

$$\dim(P_{B'}) = \dim(I - N_{B'}) = \dim(N_B + P_{BB'}) < \infty.$$

Hence, B' is a finite rank operator and it follows that $B = I - B'$ is the identity plus a finite rank map. Since $P_A = I - N_A$ and N_A has finite rank, we conclude that $A = P_A B P_A$ is also the identity plus a finite rank operator. But this contradicts the fact that $\dim(P_{AA'}) = \infty$.

(2) Suppose on the contrary that A has the form (3.1) for some integer n. For each $i = 1, 2, \ldots, n-1$, let

$$B_i = P_{i+1} P_{i+2} \cdots P_n Q P_n \cdots P_{i+2} P_{i+1}.$$

Then $A = P_1 B P_1$, $B_i = P_{i+1} B_{i+1} P_{i+1}$ for $i = 1, \ldots, n-2$, and $B_{n-1} = P_n Q P_n$. By Corollary 6

$$\dim(P_{B_{n-1} B'_{n-1}}) \leqslant \dim(N_{B_{n-1}}).$$

On the other hand, by successive applications of part (1) of this theorem we deduce that $\dim(N_{B_{n-1}}) < \infty$ and $\dim(P_{B_{n-1} B'_{n-1}}) = \infty$. ■

For the remaining case, assume that $\dim(N_A) = k < \infty$ and $\dim(P_{AA'}) = m < \infty$.

Lemma 12: Suppose that $A, B \in \mathcal{E}(H)$, *that* $\dim(N_A) = k < \infty$, $\dim(P_{AA'}) = m > k$ *and* $A = P_A B P_A$. *Then* $\dim(N_B) \leqslant k$ *and* $\dim(P_{BB'}) \geqslant m - k$. *Moreover, there exists a* $B \in \mathcal{E}(H)$ *such that* $A = P_A B P_A$, $\dim(N_B) = k$, *and* $\dim(P_{BB'}) = m - k$.

Proof: That $\dim(N_B) \leqslant k$ follows from part (1) of Lemma 11. To show that $\dim(P_{BB'}) \geqslant m - k$, define

$$\widetilde{A} = (N_A + P_{AA'}) A (N_A + P_{AA'}) = P_{AA'} A P_{AA'},$$

$$\widetilde{B} = (N_A + P_{AA'}) B (N_A + P_{AA'}),$$

and think of them as being defined in the range of $N_A + P_{AA'}$ which is a $k+m$ dimensional Hilbert space. It is easy to check that $P_{\widetilde{A}} = P_{AA'}$ and that $P_{\widetilde{A}} \widetilde{B} P_{\widetilde{A}} = P_{AA'} B P_{AA'} = P_{AA'} A P_{AA'} = \widetilde{A}$. The eigenvalues of $\widetilde{A}$ are

$$\lambda_1 \geqslant \lambda_2 \geqslant \cdots \geqslant \lambda_m > 0,$$

where 0 has multiplicity k and $1 > \lambda_1$. The eigenvalues of $\widetilde{B}$ are

$$s_1 \geqslant \cdots \geqslant s_k \geqslant s_{k+1} \geqslant \cdots \geqslant s_m \geqslant s_{m+1} \geqslant \cdots \geqslant s_{m+k},$$

where $1 \geqslant s_1$ and $s_{m+k} \geqslant 0$. Since $\widetilde{A}$ is the compression of $\widetilde{B}$ to a k-codimensional space, it follows from Cauchy's interlacing theorem[4] that

$$s_j \geqslant \lambda_j \geqslant s_{j+k} \qquad \text{for } j = 1, \ldots, m.$$

We then obtain that $0 < \lambda_m \leqslant s_m$ and $s_{k+1} \leqslant \lambda_1 < 1$. This implies that $1 > s_{k+1} \geqslant \cdots \geqslant s_m > 0$ and it follows that $\dim(P_{\widetilde{B}\widetilde{B}'}) \geqslant m - k$. To see that $\dim(P_{BB'}) = \dim(P_{\widetilde{B}\widetilde{B}'})$, consider $\widetilde{A}$ and $\widetilde{B}$ as operators on $N_A + P_{AA'}$ and represent A and B by the block matrices

$$A = \begin{pmatrix} I_{N_{A'}} & 0 \\ 0 & \widetilde{A} \end{pmatrix} \quad \text{and} \quad B = \begin{pmatrix} I_{N_{A'}} & 0 \\ 0 & \widetilde{B} \end{pmatrix}.$$

Then notice that

$$BB' = \begin{pmatrix} I_{N_{A'}} & 0 \\ 0 & \widetilde{B} \end{pmatrix} \begin{pmatrix} 0 & 0 \\ 0 & \widetilde{B}' \end{pmatrix} = \begin{pmatrix} 0 & 0 \\ 0 & \widetilde{B}\widetilde{B}' \end{pmatrix}.$$

To check the second assertion, consider the effect defined on $P_{AA'}+N_A$,

$$\widetilde{B} = \begin{pmatrix} \lambda_1 & \cdots & 0 & \cdots & 0 & \sqrt{\lambda_1(1-\lambda_1)} & \cdots & 0 \\ \vdots & \ddots & \vdots & \vdots & \vdots & \vdots & \ddots & \vdots \\ 0 & \cdots & \lambda_k & \cdots & 0 & 0 & \cdots & \sqrt{\lambda_k(1-\lambda_k)} \\ \vdots & \vdots & \vdots & \ddots & \vdots & \vdots & \vdots & \vdots \\ 0 & \cdots & 0 & \cdots & \lambda_m & 0 & \cdots & 0 \\ \sqrt{\lambda_1(1-\lambda_1)} & \cdots & 0 & \cdots & 0 & 1-\lambda_1 & \cdots & 0 \\ \vdots & \ddots & \vdots & \ddots & \vdots & \vdots & \ddots & \vdots \\ 0 & \cdots & \sqrt{\lambda_k(1-\lambda_k)} & \cdots & 0 & 0 & \cdots & 1-\lambda_k \end{pmatrix}.$$

It is easy to check that $\widetilde{A}=P_{\widetilde{A}}\widetilde{B}P_{\widetilde{A}}$. Since

$$\begin{pmatrix} \lambda_i & \sqrt{\lambda_i(1-\lambda_i)} \\ \sqrt{\lambda_i(1-\lambda_i)} & I-\lambda_i \end{pmatrix}$$

is unitarily equivalent to $\left(\begin{smallmatrix} 1 & 0 \\ 0 & 0 \end{smallmatrix}\right)$ for every $i\leqslant k$, it follows that $\widetilde{B}$ has eigenvalues

$$0,\ldots,0,\lambda_{k+1},\lambda_{k+2},\ldots,\lambda_m,1,\ldots,1,$$

where the multiplicity of 0 and 1 are each k. Since $A=N_{A'}+\widetilde{A}$ we define $B=N_{A'}+\widetilde{B}$ and we are finished. ■

Lemma 13: Suppose that $\dim(N_A)=k>0$, $\dim(P_{AA'})=m$ *and* A *has the form (3.1). Then* $n\geqslant m/k$.

Proof: The case $n=1$ follows from Corollary 6. Assume that the result is true for $n-1$ and suppose that A has the form (3.1). Then

$$B = P_2\cdots P_nQP_n\cdots P_2$$

satisfies the hypothesis and we conclude that

$$n-1 \geqslant \frac{\dim(P_{BB'})}{\dim(N_B)}.$$

By Lemma 12 we have that $\dim(N_B)\leqslant k$ and $\dim(P_{BB'})\geqslant m-k$. Hence, $n-1\geqslant m-k/k$ so that $n\geqslant m/k$. ■

Lemma 14: Suppose that $A\in\mathcal{E}(H)$ *with* $\dim(N_A)=k>0$ and $\dim(P_{AA'})=m$. *Then for any* $n\geqslant m/k$, A *has a representation of the form* (3.1).

Proof: If $m\leqslant k$, by Corollary 6 we can write $A=PQP$ and we are finished. We now assume that $m>k$. By Lemma 12 we can find $B_1\in\mathcal{E}(H)$ such that $A=P_AB_1P_A$, $\dim(N_{B_1})=k$ and $\dim(P_{B_1B_1'})=m-k$. If $m-k\leqslant k$, by Corollary 6 we can write $B_1=PQP$ which implies that

$$A = P_APQPP_A.$$

In this case $m/k\leqslant 2$ and we again are finished. If on the other hand, $m-k>k$, by Lemma 12 we find $B_2\in\mathcal{E}(H)$ such that $B_1=P_{B_1}B_2P_{B_1}$, $\dim(N_{B_2})=k$ and $\dim(P_{B_2B_2'})=m-2k$. If $m-2k\leqslant k$ we are again finished, otherwise there exists $B_3\in\mathcal{E}(H)$ such that $B_2=P_{B_2}B_3P_{B_2}$, $\dim(N_{B_3})=k$ and $\dim(P_{B_3B_3'})=m-3k$. Proceeding this way, we can find n such that $m-(n-1)k\leqslant k$ and we prove the result. ■

Applying these lemmas, we obtain the following.

Theorem 15: *Let $A\in\mathcal{E}(H)$ with H separable and $A\neq I$. Then A has the form (3.1) if and only if* $\dim(N_A)=\infty$ or $0<\dim(N_A)<\infty$ *and* $\dim(P_{AA'})<\infty$.

For $A\in\mathcal{E}(H)$ we define the *fuzzy index* $f(A)$ to be the smallest integer n so that A has the form (3.1). Then A is sharp if and only if $f(A)=0$ and A is almost sharp if and only if $f(A)$ is 0 or 1. By convention, if no such n exists then $f(A)=\infty$. For m,k positive integers we denote the smallest integer greater than or equal to m/k by $\lceil m/k\rceil$. We extend this definition to include values 0 and ∞ for m and k by defining

$$\left\lceil\frac{m}{k}\right\rceil=\begin{cases}\infty & \text{if} \quad k=0 \text{ and } m\neq 0,\\ 0 & \text{if} \quad m=0,\\ 1 & \text{if} \quad k=\infty \text{ and } m\neq 0,\\ \infty & \text{if} \quad m=\infty \text{ and } k\neq\infty.\end{cases}$$

The next result again follows from the previous lemmas.

Theorem 16: *Let $A\in\mathcal{E}(H)$ with H separable. Then*

$$f(A)=\left\lceil\frac{\dim(P_{AA'})}{\dim(N_A)}\right\rceil.$$

The fuzzy index $f(A)$ designates the fewest number of sharp effects whose sequential product gives $A\in\mathcal{E}(H)$. Since sharp effects are frequently thought of as filters such as polarization filters on an optical bench, $f(A)$ is the fewest number of filters that can be placed in series to give the same effect A. Theorem 15 characterizes when $f(A)$ is finite and Theorem 16 provides the value of $f(A)$ as a simple function of A.

IV. FINITE DIMENSIONAL EFFECTS

We now show that we can obtain further insights and some simpler proofs for the set $\mathcal{E}(H)$ on a finite dimensional Hilbert space. Although finite dimensional Hilbert spaces may seem restrictive for quantum systems, there are important fields such as quantum computation and information theory that are based on such spaces.[5]

Let $A\in\mathcal{E}(H)$ where $\dim(H)<\infty$. We define the following non-negative integers:

$$n_0(A)=\dim(N_A),$$

$$n_1(A)=\dim(N_{A'}),$$

$$n(A)=\dim(H)-n_0(A)-n_1(A).$$

Notice that $n_0(A)$ is the multiplicity of the eigenvalue 0, $n_1(A)$ is the multiplicity of the eigenvalue 1, and $n(A)$ is the number of eigenvalues λ with $0<\lambda<1$ including multiplicity.

Lemma 17: If $A\in\mathcal{E}(H)$ with $\dim(H)<\infty$, *then* $n(A)=\dim(P_{AA'})=rank(P_A-A)$.

Proof: By diagonalizing A we can assume without loss of generality that A has the form

$$A=\operatorname{diag}(\lambda_1,\ldots,\lambda_m,1,\ldots,1,0,\ldots,0), \tag{4.1}$$

where $0<\lambda_i<1$ for $i=1,\ldots,m$. We then have that

$$AA'=\operatorname{diag}(\lambda_1(1-\lambda_1),\ldots,\lambda_m(1-\lambda_m),0,\ldots,0,0,\ldots,0),$$

and

$$P_A-A=\operatorname{diag}(1-\lambda_1,\ldots,1-\lambda_m,0,\ldots,0,0,\ldots,0).$$

It follows that $\dim(P_{AA'})=\operatorname{rank}(P_A-A)=n(A)=m$. ■

The next result follows from Corollary 6 and Lemma 17. However, we give a much shorter proof which relies on the fact that $\dim(H)<\infty$.

Theorem 18: *Let* $A\in\mathcal{E}(H)$ *with* $\dim(H)<\infty$.

(1) *A is almost sharp if and only if* $n(A)\leqslant n_0(A)$.
(2) *A is nearly sharp if and only if* $n(A)\leqslant\min\{n_0(A),n_1(A)\}$.

Proof: (1) Suppose $A=P_AQP_A$ for $Q\in\mathcal{P}(H)$. Then by Lemma 17 we have that

$$\begin{aligned} n(A)&=\operatorname{rank}(P_A-A)=\operatorname{rank}(P_A(I-Q)P_A)\leqslant\operatorname{rank}(I-Q)\\ &=\dim(N_Q)\leqslant\dim(N_{P_AQP_A})=\dim(N_A)=n_0(A). \end{aligned}$$

Conversely, suppose that $m=n(A)\leqslant n_0(A)$. Without loss of generality we can represent A as a diagonal matrix (4.1) Let.

$$\Lambda=\operatorname{diag}(\lambda_1,\ldots,\lambda_m)=\begin{pmatrix}\lambda_1&\cdots&0\\ \vdots&\ddots&\vdots\\ 0&\cdots&\lambda_m\end{pmatrix}\in M_m,$$

and represent A by the block matrix,

$$A=\begin{pmatrix}\Lambda&0&0\\ 0&I_{n_1(A)}&0\\ 0&0&0_{n_0(A)}\end{pmatrix}.$$

Since $m\leqslant n_0(A)$, we can split the last block into a $m\times m$ block and an $l\times l$ block, where $l=n_0(A)-m$. Let Q be the block matrix

$$Q=\begin{pmatrix}\Lambda&0&\sqrt{\Lambda(I_m-\Lambda)}&0\\ 0&I_{n_1(A)}&0&0\\ \sqrt{\Lambda(I_m-\Lambda)}&0&I_m-\Lambda&0\\ 0&0&0&0_l\end{pmatrix}.$$

It is easy to check that $P_AQP_A=A$ and that $Q\in\mathcal{P}(H)$.

The proof of (2) follows directly from (1). ■

We may think of $n(A)$ as the number of fuzzy eigenvalues of A and $n_0(A)+n_1(A)$ as the number of sharp eigenvalues. As one might expect, the almost (or nearly) sharpness of A depends on $n(A)$ compared to $n_0(A)$ and $n_1(A)$ and this is the content of Theorem 18. Moreover, it follows from Theorem 16 and Lemma 17 that if $\dim(H)<\infty$ then

$$f(A)=\left\lceil\frac{n(A)}{n_0(A)}\right\rceil.$$

We now consider some examples in $\mathcal{E}(\mathbb{C}^3)$. Let $0<\lambda_i<1$ for $i=1,2,3$, and consider the following effects:

$$A=\begin{pmatrix}\lambda_1&0&0\\ 0&\lambda_2&0\\ 0&0&\lambda_3\end{pmatrix},\quad B=\begin{pmatrix}\lambda_1&0&0\\ 0&\lambda_2&0\\ 0&0&0\end{pmatrix},$$

$$D=\begin{pmatrix}\lambda_1 & 0 & 0\\ 0 & 0 & 0\\ 0 & 0 & 0\end{pmatrix}, \quad \text{and } E=\begin{pmatrix}\lambda_1 & 0 & 0\\ 0 & 1 & 0\\ 0 & 0 & 0\end{pmatrix}.$$

Then A and B are not almost sharp, D is almost sharp but it is not nearly sharp and E is nearly sharp. The fuzzy indexes are $f(A)=\infty$, $f(B)=2$, $f(D)=f(E)=1$. The decomposition $E=P_EQP_E$ has the following form:

$$\begin{pmatrix}\lambda_1 & 0 & 0\\ 0 & 1 & 0\\ 0 & 0 & 0\end{pmatrix}=\begin{pmatrix}1 & 0 & 0\\ 0 & 1 & 0\\ 0 & 0 & 0\end{pmatrix}\begin{pmatrix}\lambda_1 & 0 & \sqrt{\lambda_1(1-\lambda_1)}\\ 0 & 1 & 0\\ \sqrt{\lambda_1(1-\lambda_1)} & 0 & 1-\lambda_1\end{pmatrix}\begin{pmatrix}1 & 0 & 0\\ 0 & 1 & 0\\ 0 & 0 & 0\end{pmatrix}.$$

Although E is almost sharp, λE for $0<\lambda<1$ is not almost sharp. Our last result follows from Theorem 18.

Theorem 19: *Let $A\in\mathcal{E}(H)$, $A\neq I$, with* $\dim(H)<\infty$. *Then A has the form (3.1) if and only if A is singular*.

Inhomogeneous quantum groups for particle algebras

M. Arik and A. Baykal[a)]
Department of Physics, Boğaziçi University, 80815 Bebek, Istanbul, Turkey

(Received 15 April 2004; accepted 13 July 2004; published 25 October 2004)

We construct the inhomogeneous quantum groups FIO(d) and BISp($2d$) and investigate their Hopf algebra structure. FIO(d) and BISp($2d$) leave the algebra of fermion and boson creation/annihilation operators invariant, respectively. We also present the corresponding R-matrices. © *2004 American Institute of Physics.*
[DOI: 10.1063/1.1794367]

I. INTRODUCTION

The importance of inhomogeneous groups in physics cannot be overestimated. Well known examples are the Poincaré and Galilean groups. Deformations of inhomogeneous Lie groups lead to inhomogeneous quantum groups. This procedure entails the deformation of the function algebra over the classical group and/or the deformation of the enveloping algebra of the Lie algebra.[1,2]

In the present paper we will construct a different type of inhomogeneous quantum groups by considering their action on the algebra of fermionic and bosonic creation/annihilation operators. The algebra of such operators for particles obeying fermionic and bosonic statistics are defined by

$$[c_i, c_j^*]_\pm = \mathbf{1}\delta_{ij},$$

$$[c_i, c_j]_\pm = 0. \tag{1.1}$$

All known particles in physics are bosons and fermions and thus obey (1.1). In Quantum Field Theory the discrete indices are replaced by continuous momentum indices.

As a motivation for the next section, in which we clothe our calculation with compact and standard notation using the language of Hopf algebra, we investigate the nature of the transformation parameters which mixes up the creation and annihilation operators together with the identity element of the algebra as

$$c_i \mapsto c_i' = \alpha_{ik} \otimes c_k + \beta_{ik} \otimes c_k^* + \gamma_i \otimes \mathbf{1},$$

$$c_i^* \mapsto c_i'^* = \alpha_{ik}^* \otimes c_k^* + \beta_{ik}^* \otimes c_k + \gamma_i^* \otimes \mathbf{1}, \quad i,k = 1,2,\ldots,d. \tag{1.2}$$

Here, the minimal assumption we presume is that the homogeneous parameters $\alpha_{ik}, \alpha_{ik}^*, \beta_{ik}, \beta_{ik}^*$ commute among themselves in accordance with the results found in Ref. 3 for FIO(2). Note that the $*$ structure is of some physical significance and will be discussed in Sec. III. We directly impose the invariance of the above algebras under the above transformation. As they stand, they are defined equally for fermions and bosons. As we will see, this seemingly simple transformation consists of parameters which turn out to belong to a Hopf algebra with respective numerical R-matrices.

Now, using the algebra of the original operators, we calculate the (anti-)commutator of the transformed operators, for example, for the first commutation relation, we have

a)Electronic mail: baykala@boun.edu.tr

$$[c_i', c_j'^*]_\pm = [(\alpha_{ik} \otimes c_k + \beta_{ik} \otimes c_k^* + \gamma_i \otimes \mathbf{1}), (\alpha_{jl}^* \otimes c_l^* + \beta_{jl}^* \otimes c_l + \gamma_j^* \otimes \mathbf{1})]_\pm$$
$$= \{\{\alpha_{ik}\alpha_{jl}^* \pm \beta_{ik}\beta_{jl}^*\}\delta_{kl} + [\gamma_i, \gamma_j^*]_\pm\} \otimes \mathbf{1} + \{[\gamma_i, \beta_{jk}^*]_\pm + [\alpha_{ik}, \gamma_j^*]_\pm\} \otimes c_k + \{[\gamma_i, \alpha_{jk}^*]_\pm$$
$$+ [\beta_{ik}, \gamma_j^*]_\pm\} \otimes c_k^*. \tag{1.3}$$

Exploiting the canonical isomorphism $\mathbb{C} \otimes \mathcal{A} \cong \mathcal{A}$ for the tensor product defined over the field $\mathbb{C}$, for the vector space $\mathcal{A}$, this must be equal to

$$\delta_{ij}\mathbf{1} \cong \delta_{ij} \otimes \mathbf{1} = [c_i', c_j'^*]_\pm \otimes \mathbf{1}. \tag{1.4}$$

Upon requiring the transformations to be an algebra homomorphism, one assumes the relations

$$\alpha_{ik}\alpha_{jk}^* \pm \beta_{ik}\beta_{jk}^* + [\gamma_i, \gamma_j^*]_\pm = \delta_{ij}, \tag{1.5}$$

together with

$$[\gamma_i, \beta_{jk}^*]_\pm = 0, \quad [\alpha_{ik}, \gamma_j^*]_\pm = 0,$$

$$[\gamma_i, \alpha_{jk}^*]_\pm = 0, \quad [\beta_{ik}, \gamma_j^*]_\pm = 0, \tag{1.6}$$

among the elements that parametrize the transformations.

Similarly, for the invariance of the second set of the transformed (anti-) commutators, the straightforward calculation,

$$[c_i', c_j']_\pm = [(\alpha_{ik} \otimes c_k + \beta_{ik} \otimes c_k^* + \gamma_i \otimes \mathbf{1}), (\alpha_{jl} \otimes c_l + \beta_{jl} \otimes c_l^* + \gamma_j \otimes \mathbf{1}\ )]_\pm = \{\alpha_{ik}\beta_{jl} \pm \beta_{ik}\alpha_{jl}\}$$
$$\otimes [c_k, c_l^*]_\pm + [\gamma_i, \gamma_j]_\pm \otimes \mathbf{1} + \{[\beta_{ik}, \gamma_j]_\pm + [\gamma_i, \beta_{jk}]_\pm\} \otimes c_k^* + \{[\alpha_{ik}, \gamma_j]_\pm + [\gamma_i, \alpha_{jk}]_\pm\} \otimes c_k, \tag{1.7}$$

is consistent with the (anti-)commutation relations

$$\alpha_{ik}\beta_{jk} \pm \beta_{ik}\alpha_{jk} + [\gamma_i, \gamma_j]_\pm = 0, \tag{1.8}$$

$$[\beta_{ik}, \gamma_j]_\pm = 0, \quad [\alpha_{ik}, \gamma_j]_\pm = 0. \tag{1.9}$$

These calculations show that it is the inhomogeneous transformation parameters that result in the nontrivial algebraic relations. Collecting all the relations defining the algebra of the transformation parameters we have

$$\alpha_{ik}\beta_{jk} \pm \beta_{ik}\alpha_{jk} + [\gamma_i, \gamma_j]_\pm = 0, \tag{1.10}$$

$$\alpha_{ik}\alpha_{jk}^* \pm \beta_{ik}\beta_{jk}^* + [\gamma_i, \gamma_j^*]_\pm = \delta_{ij}, \tag{1.11}$$

$$[\beta_{ik}, \gamma_j]_\pm = 0, \quad [\alpha_{ik}, \gamma_j]_\pm = 0, \tag{1.12}$$

$$[\beta_{ik}, \gamma_j^*]_\pm = 0, \quad [\alpha_{ik}, \gamma_j^*]_\pm = 0, \tag{1.13}$$

together with the $*$-conjugates of all the relations.

The derivation of the quantum invariance group given above, in fact, mimics the derivation of other matrix quantum groups, such as $GL_q(2)$ or $SL_q(2)$ that leave the underlying quantum plane with coordinates (x,y) and the 1-forms, the differentials of x and y, (ξ, η) having the (anti-)commutations

$$xy = qyx, \quad \xi\eta = -q^{-1}\eta\xi, \quad \xi^2 = 0, \quad \eta^2 = 0, \tag{1.14}$$

invariant. In this way, the study of the automorphisms of noncommutative spaces naturally leads to the notion of the quantum groups.[4] In our case the matrix quantum group acts, exclusively, on the vector space which is either fermionic or bosonic in nature.

Intending to emphasize the action of the transformations on the creation/annihilation operators rather than the algebra of creation/annihilation operators, we write the transformation parameters as a quantum matrix and the elements of the particle algebra as a column vector.

II. QUANTUM GROUPS, FIO($2d$) AND BISp($2d$)

If we are to emphasize that the action of the quantum matrix group on the algebra of creation/annihilation operators, we form $(2d+1)$-dimensional column vectors $\mathbf{C} \equiv [c_i, c_i^*, \mathbf{1}]^t$ on which the action is defined via

$$\mathbf{C}' = \mathbf{M} \dot{\otimes} \mathbf{C}, \tag{2.1}$$

or supplying the indices,

$$\mathbf{C}'^i = M^i_k \otimes \mathbf{C}^k, \tag{2.2}$$

where $\mathbf{C}^k$ is the kth entry of the column vector $\mathbf{C}$ and the quantum matrix $\mathbf{M}$ is given by

$$\mathbf{M} = \left[\begin{array}{cc|c} \alpha_{ij} & \beta_{ij} & \gamma_i \\ \beta^*_{ij} & \alpha^*_{ij} & \gamma^*_i \\ \hline \mathbf{0} & \mathbf{0} & \mathbf{1} \end{array}\right] \equiv \left[\begin{array}{c|c} \mathbf{A} & \Gamma \\ \hline 0 & \mathbf{1} \end{array}\right]. \tag{2.3}$$

If the elements of the matrix $\mathbf{M}$ satisfy the relations (1.10)–(1.13) we will name the corresponding quantum groups as the Fermionic Inhomogeneous Orthogonal Group (FIO) and the Bosonic Inhomogeneous Symplectic Quantum Group (BISp), respectively, for the upper and the lower signs. In this section this definition will be made more rigorous by defining the corresponding R-matrices.

The space of vectors $\mathbf{C}$, built out of the generators of the algebras (1.1), is therefore a left M-comodule for the bialgebra defined by all the relations among the transformation parameters obtained in the first section. In order to be able to make the algebra of the transformation parameters (1.10)–(1.13) into a bialgebra, it is convenient to define the vectors

$$\mathbf{C}_1\mathbf{C}_2 = \begin{bmatrix} c_1\mathbf{C} \\ c_2\mathbf{C} \\ \vdots \\ c_d\mathbf{C} \\ c_1^*\mathbf{C} \\ c_2^*\mathbf{C} \\ \vdots \\ c_d^*\mathbf{C} \\ \mathbf{1}\cdot\mathbf{C} \end{bmatrix}, \quad \mathbf{C}_2\mathbf{C}_1 = \begin{bmatrix} \mathbf{C}c_1 \\ \mathbf{C}c_2 \\ \vdots \\ \mathbf{C}c_d \\ \mathbf{C}c_1^* \\ \mathbf{C}c_2^* \\ \vdots \\ \mathbf{C}c_d^* \\ \mathbf{C}\cdot\mathbf{1} \end{bmatrix}, \tag{2.4}$$

where both $\mathbf{C}_1\mathbf{C}_2$ and $\mathbf{C}_2\mathbf{C}_1$ carry double indices as $(\mathbf{C}_1\mathbf{C}_2)^{ij}$, for example, $(\mathbf{C}_1\mathbf{C}_2)^{(d+1)k} = c_1^* \cdot \mathbf{C}^k$, etc. Since these two indexed column vectors cover all possible "multiplications" in the algebra of creation/annihilation operators, it is possible to write Eqs. (1.1) as a matrix equation in the form

$$R\mathbf{C}_1\mathbf{C}_2 = \mathbf{C}_2\mathbf{C}_1, \tag{2.5}$$

where the entries of the $(2d+1)\times(2d+1)$ matrix R are also labeled by double indices as R^{ik}_{lm}. With all these new conventions, the invariance of the algebras defined by Eqs. (1.1) under the action (2.1) boils down to

$$R^{ij}_{kl}(\mathbf{C}'_1\mathbf{C}'_2)^{kl} = (\mathbf{C}'_2\mathbf{C}'_1)^{ij}. \tag{2.6}$$

Given the relation between $\mathbf{C}$ and $\mathbf{C}'$ as $\mathbf{C}'=\mathbf{M}\dot{\otimes}\mathbf{C}$ and the original algebra (1.10)–(1.13), eventually, Eqs. (2.1) and (2.5) are consistent with

$$RM_1M_2 = M_2M_1R, \tag{2.7}$$

where $M_1=\mathbf{M}\otimes 1$, $M_2=1\otimes\mathbf{M}$, and the numerical matrices $R^{-1},R\in M_{(2d+1)^2}(\mathbb{C})\otimes M_{(2d+1)^2}(\mathbb{C})$. Actually, Eq. (2.7) is a just proper way of writing the algebra defined in Eqs. (1.10)–(1.13). It also reflects the fact that the R matrix is of fundamental importance for quantum groups; in that it expresses how the multiplication $(M_1M_2)^{ij}_{kl}=M^i_kM^j_l$ is related to the opposite multiplication, that is, $(M_2M_1)^{ij}_{kl}=M^j_lM^i_k$. As the consistency conditions for the associativity of the multiplication in the algebra generated by M^i_k, the R matrix satisfies the quantum Yang–Baxter equation,

$$R_{12}R_{13}R_{23} = R_{23}R_{13}R_{12}, \tag{2.8}$$

where, $R_{12},R_{13},R_{23}\in(M_{(2d+1)^2})^{\otimes 3}$ and $(R_{12})^{ijk}_{lmn}=R^{ij}_{lm}\delta^k_n$, etc.

A quantum group is a noncommutative and noncocommutative Hopf algebra $\mathbf{H}$ with quasitriangular structure $\mathcal{R}\in\mathbf{H}\otimes\mathbf{H}$ (Drinfel'd).[5] There are different lines of approach to the quantum groups depending on the usage and/or the purpose. For example, the commutative algebra of functions on a group manifold, for which the noncocommutative coproduct defined by pointwise multiplication, carries a natural Hopf algebra setting (together with appropriate antipode and counit).[6,7]

The vector fields on the group manifold are dual to the functions on the manifold, in the sense that they act on the function algebra as derivations. As for the algebra of functions, the universal enveloping algebra, $U(\mathfrak{g})$ can also be equipped with the Hopf algebra setting by defining an appropriate (primitive) bialgebra structure and an antipode. The noncommutative (Lie) product on $U(\mathfrak{g})$, inherited from $\mathfrak{g}$, corresponds to the noncocommutative coproduct on the algebra of functions, whereas the cocommutative product on $U(\mathfrak{g})$ corresponds to the commutative product on the algebra of functions. In the case of complex semisimple Lie algebra $\mathfrak{g}$, there is a standard way of defining the deformed quantum enveloping algebra $U_q(\mathfrak{g})$.[8,9]

The duality of two different approaches, crudely mentioned above, turn out to hold when the respective algebras are deformed. The simplest nontrivial example is that $SL_q(2)$ is dual to $U_q(\mathfrak{sl}_2)$. However, there are examples of quantum groups that do not belong to any of the above two types;[6] the quantum groups presented here can be considered to fit into the former construction. As in the example presented here, both the use and the importance of abstract Hopf algebras (quantum groups) in applications to physics emerges when they act on other structures, carrying concrete physical relevance.[10] If a Hopf algebra has a quasitriangular structure $\mathcal{R}\in\mathbf{H}^{\otimes 2}$, which controls the noncocommutativity of the coproduct, in the dual Hopf algebra (if it can be found) the noncommutativity of the multiplication is controlled by the numerical R matrix. The quasitriangular structure $\mathcal{R}$ is often called the universal R matrix, probably for the reason that it produces the matrix solutions of the quantum Yang–Baxter equation on all of its modules, and while the dual producing solutions of the Yang–Baxter on all of its comodules.[7]

Returning to our presentation, we need to prove that the coassociative coproduct $\Delta:\mathbf{M}\mapsto\mathbf{M}\otimes\mathbf{M}$ defined by

$$\Delta(\mathbf{M}) = \mathbf{M}\dot{\otimes}\mathbf{M}, \tag{2.9}$$

together with the antipode $S:\mathbf{M}\mapsto\mathbf{M}, S(\mathbf{M})=\mathbf{M}^{-1}$ as an anti-algebra map and the counit map $\varepsilon:\mathbf{M}\mapsto\mathbb{C}$ given by $\varepsilon(\mathbf{M})=I_{(2d+1)\times(2d+1)}$, defines the matrix quantum groups which we name as the fermionic orthogonal and the bosonic symplectic inhomogeneous quantum groups without referring to any $*$ structure. We denote these quantum groups as FIO$(2d,\mathbb{C})$, and BISp$(2d,\mathbb{C})$, respectively. The coproduct $\Delta:\mathbf{M}\mapsto\mathbf{M}\otimes\mathbf{M}$ should be an algebra homomorphism, in order to make the algebra (2.7) into a bialgebra: $\Delta(\mathbf{M}\mathbf{M}')=\Delta(\mathbf{M})\Delta(\mathbf{M}')$ for all the elements in the algebra (2.7). We will come back to this point after we present the different $*$-conjugation choices for FIO and BISp in the following section.

III. $*$-STRUCTURE AND REAL FORMS

In this section, we will obtain FIO$(2d,\mathbb{R})$ and BISp$(2d,\mathbb{R})$ by changing the $*$-conjugation relations among the M^i_k, for $d=1$ and generalize what we find to the $(2d+1)$-dimensional case for fermions.

The boson algebra in Eqs. (1.1), unlike the fermion algebra, has a corresponding classical counterpart, the Poisson algebra of functions over the cotangent bundle of the configuration space of the corresponding classical system. The Poisson bracket makes the algebra of functions becomes an ∞-dimensional Lie algebra and the definition of the Poisson bracket requires a nondegenerate, closed 2-form Ω, the symplectic form. In terms of canonical coordinates p^i, q_i, it has constant components $\Omega=\Sigma dp^i\wedge dq_i$ so that $\{p^i,q_j\}=\delta^i_j$. An odd dimensional manifold cannot accommodate a nondegenerate symplectic two form and the quantum counterpart must also be even dimensional.

After this digression, we first take the simplest example FIO$(2,\mathbb{C})$ and its action on the fermion algebra (1.1). It acts on the column vector $\mathbf{C}=[c,c^*,\mathbf{1}]^t$ via (2.1) and the conjugation in the entries of $\mathbf{M}$ is forced by the fermion algebra defined in Eqs. (1.1). Hence, the $*$-conjugation in the Hopf algebra $\mathbf{M}$ directly reflects the choice of the vector $\mathbf{C}$. What if one begins with another choice of the column vector $\mathbf{C}$? If we begin with the column vector $\hat{\mathbf{C}}=[1/\sqrt{2}(c+c^*), i/\sqrt{2}(c-c^*),\mathbf{1}]^t$, accordingly the $*$-conjugation relations among $\{M^i_k\}_{i,k=1,2,3}$ changes. It is easy to see that the vectors $\hat{\mathbf{C}}$ and $\mathbf{C}$ are related by

$$\hat{\mathbf{C}} = \frac{1}{\sqrt{2}}\left[\begin{array}{cc|c} 1 & 1 & 0 \\ i & -i & 0 \\ \hline 0 & 0 & \sqrt{2} \end{array}\right]\mathbf{C} \equiv U\mathbf{C}, \tag{3.1}$$

where $U^\dagger=U^{-1}$. If one relabels the entries of $\hat{\mathbf{C}}$ as

$$a_1 \equiv \frac{1}{\sqrt{2}}(c+c^*),$$

$$a_2 \equiv \frac{i}{\sqrt{2}}(c-c^*), \tag{3.2}$$

the anti-commutation relations for these new operators can be derived from the anti-commutation relations among the original operators c,c^*. This is the same thing as the corresponding quantum matrices $\hat{\mathbf{M}}$ and $\mathbf{M}$ are related by a similarity transformation. Therefore, in turn, it is possible to obtain the algebra of $\{\hat{M}^i_k\}_{i,k=1,2,3}$ from those of $\{M^i_k\}_{i,k=1,2,3}$. If we denote the entries of the new matrix as

$$\hat{\mathbf{M}} \equiv \left[\begin{array}{c|c} \mathbf{A} & \mathbf{\Gamma} \\ \hline 0 & \mathbf{1} \end{array}\right], \quad \mathbf{A} \equiv \begin{bmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{bmatrix} \quad \mathbf{\Gamma} \equiv \begin{bmatrix} \Gamma_1 \\ \Gamma_2 \end{bmatrix}, \tag{3.3}$$

we have

$$\hat{\mathbf{M}} = \left[\begin{array}{cc|c} A_{11} & A_{12} & \Gamma_1 \\ A_{21} & A_{22} & \Gamma_2 \\ \hline 0 & 0 & 1 \end{array}\right] = \left[\begin{array}{cc|c} \mathrm{Re}(\alpha+\beta) & \mathrm{Im}(\alpha-\beta) & \sqrt{2}\mathrm{Re}\ \gamma \\ -\mathrm{Im}(\alpha+\beta) & \mathrm{Re}(\alpha-\beta) & \sqrt{2}\mathrm{Im}\ \gamma^* \\ \hline 0 & 0 & 1 \end{array}\right]. \tag{3.4}$$

If we invert the above relations we obtain

$$\alpha = 1/2(A_{11} + A_{22}) + i/2(A_{12} - A_{21}),$$

$$\beta = 1/2(A_{11} - A_{22}) - i/2(A_{12} + A_{21}). \tag{3.5}$$

Now calculating the anticommutators $[\Gamma_i, \Gamma_j]_+$, using (3.4) and the algebra of $\alpha, \alpha^*, \beta, \beta^*, \gamma, \gamma^*$, we have

$$[\Gamma_1, \Gamma_2]_+ = \frac{1}{2}(\alpha + \beta^*)(\alpha^* + \beta) - \frac{1}{2}(\alpha - \beta^*)(\alpha^* - \beta),$$

$$2\Gamma_1^2 = 1 - (\alpha + \beta^*)(\alpha^* + \beta),$$

$$2\Gamma_2^2 = 1 - (\alpha - \beta^*)(\alpha^* - \beta). \tag{3.6}$$

Using (3.5), we can convert rhs of the above anticommutators also in terms of the self conjugate variables as

$$[\Gamma_1, \Gamma_2]_+ = -A_{11}A_{21} - A_{12}A_{22},$$

$$2\Gamma_1^2 = 1 - A_{11}^2 - A_{12}^2,$$

$$2\Gamma_2^2 = 1 - A_{22}^2 - A_{21}^2, \tag{3.7}$$

all of which combine into the equation

$$[\Gamma_i, \Gamma_j]_+ = \delta_{ij} - A_{ik}A_{jk}, \quad i,j = 1,2. \tag{3.8}$$

For BISp$(2,\mathbb{R})$, similar linear algebra calculations yields

$$[\Gamma_1, \Gamma_2]_- = i\{1 - A_{11}A_{22} + A_{12}A_{21}\}. \tag{3.9}$$

Moreover, since the transformations by U do not mix the homogeneous parameters with the inhomogeneous ones, the (anti-)commutation relations involving the homogeneous parts remain intact. Eventually, for the BISp(2), by introducing the matrix

$$G^- \equiv \begin{bmatrix} 0 & i \\ -i & 0 \end{bmatrix}, \tag{3.10}$$

the (anti-)commutation relations with real parameters bosonic transformation parameters can be written as

$$[\Gamma_i,\Gamma_j]_- = (G^- - \mathbf{A}G^-\mathbf{A}^t)_{ij}. \tag{3.11}$$

As mentioned in the digression in the beginning of this section, the matrix G^- is related to the symplectic form Ω and generalizes to even dimensions only.

Our aim is to treat both FIO and BISp on the same footing, thus rewritten as in Eq. (3.11), both real forms FIO$(2d,\mathbb{R})$ and BISp$(2d,\mathbb{R})$ can be fused into a single set of equations by denoting $G^+ \equiv \mathbf{1}_{2\times 2}$ as

$$[\Gamma_i,\Gamma_j]_\pm = G^\pm - \mathbf{A}G^\pm\mathbf{A}^t{}_{ij}. \tag{3.12}$$

By the "real form" we refer to the particular $*$-conjugation relation among the algebra transformation, not to the elements of the corresponding R-matrices. With the additional ingredients $G^\pm$, the coproduct defined as $\Delta(\hat{\mathbf{M}})=\hat{\mathbf{M}}\dot{\otimes}\hat{\mathbf{M}}$ extends as an algebra homomorphism to make the algebras defined in Eqs. (3.12) bialgebras. Explicitly, for the real forms, the coproducts for the elements of the matrix $\hat{\mathbf{M}}$,

$$\Delta(\Gamma_i) = \sum_k A_{ik}\otimes\Gamma_k + \Gamma_i\otimes 1, \quad \Delta(A_{ij}) = \sum_n A_{in}\otimes A_{nj}, \tag{3.13}$$

respect the relations (3.12):

$$\begin{aligned}
\Delta([\Gamma_i,\Gamma_j]_\pm) &= \sum_{k,n} A_{ik}A_{jk}\otimes[\Gamma_i,\Gamma_j]_\pm + [\Gamma_i,\Gamma_j]_\pm \otimes \mathbf{1} \\
&= \sum_{k,n} A_{ik}A_{jn}\otimes\{(G^\pm)_{kn} - A_{kp}A_{nr}(G^\pm)_{pr}\} + \{(G^\pm)_{ij} - A_{ik}A_{jn}(G^\pm)_{kn}\}\otimes\mathbf{1} \\
&= (G^\pm)_{ij}\otimes\mathbf{1} - \sum_{k,n} A_{ik}A_{jn}\otimes(G^\pm)_{pr}A_{kp}A_{nr} \\
&= (G^\pm)_{ij}\Delta(\mathbf{1}) - \sum_{p,r}(G^\pm)_{pr}\Delta(A_{ip})\Delta(A_{jr}) = \Delta((G^\pm - \mathbf{A}G^\pm\mathbf{A}^t)_{ij}),
\end{aligned} \tag{3.14}$$

where we have exploited the coproduct

$$\Delta\left(\sum_k A_{ik}A_{jk}\right) = \sum_k \Delta(A_{ik}A_{jk}) = \sum_k \Delta(A_{ik})\Delta(A_{jk}) = \sum_{k,n,p} A_{in}A_{jp}\otimes A_{nk}A_{pk}, \tag{3.15}$$

reading it from right to left. As a result, both FIO(2) and BISp(2) satisfy the Hopf Algebra axioms independent of the $*$-structure, with the antipode

$$S(\hat{\mathbf{M}}) = \hat{\mathbf{M}}^{-1} \equiv \left[\begin{array}{c|c} \mathbf{A}^{-1} & -\mathbf{A}^{-1}\mathbf{\Gamma} \\ \hline \mathbf{0} & \mathbf{1} \end{array}\right], \tag{3.16}$$

and the counit $\varepsilon(\hat{\mathbf{M}})=I_{4\times 4}$. For the fermions, the arguments of this section concerning the $*$-structures do not touch upon the dimensionality of the vectors $\mathbf{C}$ and can easily be extended to any dimension d that can be either odd or even. But in the case of bosons different $*$-conjugation choices exist in even dimensions only. The next section is devoted to the systematic calculation of their numerical R-matrices.

IV. *R*-MATRICES FOR FIO(*d*), BISp(2*d*)

Because the R-matrices of the quantum groups FIO(d) and BISp$(2d)$ follow a pattern that is easy to figure out for increasing d, we will present only the R-matrices for $d=2$ and for both $*$-choices in the previous section as 9×9 matrices. In light of these, we give the nonzero elements of the R-matrices for $d>2$, which are not easy to display as matrices fitting to the page.

For the convenience of the notation and ease for calculation, we relabel the elements of FIO(2,$\mathbb{C}$) and BISp(2,$\mathbb{C}$) as

$$\mathbf{M} = [M_k^i] = \begin{bmatrix} M_1^1 & M_2^1 & M_3^1 \\ M_1^2 & M_2^2 & M_3^2 \\ M_1^3 & M_2^3 & M_3^3 \end{bmatrix} \equiv \begin{bmatrix} \alpha & \beta & \gamma \\ \beta^* & \alpha^* & \gamma^* \\ 0 & 0 & \mathbf{1} \end{bmatrix}, \tag{4.1}$$

and similarly for the real forms which we denoted by $\hat{\mathbf{M}}$. If we supply the indices to Eq. (2.7), we have

$$R_{kl}^{ij}(M_1)_{cd}^{kl}(M_2)_{ab}^{cd} = (M_2)_{cd}^{ij}(M_1)_{kl}^{cd}R_{ab}^{kl},$$

$$R_{kl}^{ij}M_c^k\delta_d^l\delta_a^cM_b^d = \delta_c^iM_d^jM_k^c\delta_l^dR_{ab}^{kl},$$

$$R_{ab}^{ik}M_j^aM_l^b = M_b^kM_a^iR_{jl}^{ab}, \tag{4.2}$$

where all the indices runs over the same range, $i,j,k,l,a,b=1, 2, 3$. From this matrix equation it is possible to extract the R-matrices using (1.10)–(1.13) as

$$R = \begin{bmatrix} -1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & -1 & 0 & 0 & 0 & 0 & 0 & 0 & 1 \\ 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & -1 & 0 & 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 & -1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 \end{bmatrix}, \tag{4.3}$$

$$R = \begin{bmatrix} 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & -1 \\ 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 \end{bmatrix}, \tag{4.4}$$

for the FIO(2,$\mathbb{C}$) and the BISp(2,$\mathbb{C}$), respectively. Because the real forms are just a particular choice of the $*$-structure, it is possible to guess the numerical R-matrices for the FIO(2,$\mathbb{R}$) and the BISp(2,$\mathbb{R}$) by inspecting those of FIO(2,$\mathbb{C}$) and the BISp(2,$\mathbb{C}$) together with their corresponding algebra (3.12). Besides, since FIO(2) can be extended to FIO(d) for both even and odd d, it is practical to work with its real forms.

The only nontrivial (anti-)commutation relations involve the inhomogeneous parameters, therefore the only difference between the R-matrices of the real forms and those above also involve R_{33}^{ik} components. In fact, the $d=2$ real forms have the R-matrices are

$$R=\begin{bmatrix} -1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 \\ 0 & -1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & -1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & -1 & 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 \end{bmatrix}, \tag{4.5}$$

$$R=\begin{bmatrix} 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & -\mathrm{i} \\ 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & \mathrm{i} \\ 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 \end{bmatrix}, \tag{4.6}$$

for the FIO$(2,\mathbb{R})$ and the BISp$(2,\mathbb{R})$, respectively. Note that the R-matrix for FIO(2) is a 9×9 matrix, likewise the R-matrix for FIO(d) is $(d+1)^2\times(d+1)^2$-dimensional, etc. In all the R-matrices given above the places of the nonzero elements of their last columns refer to the (anti-)commutation relations of the pairwise $*$-conjugate elements of the vector **C**. For example, for FIO$(2,\mathbb{C})$, the equations,

$$R^{12}_{ab}M^a_3M^b_3=M^2_bM^1_aR^{ab}_{33}, \tag{4.7}$$

$$R^{21}_{ab}M^a_3M^b_3=M^1_bM^2_aR^{ab}_{33}, \tag{4.8}$$

dictate that the nonzero elements of the last column to be R^{12}_{33}, R^{21}_{33}, and R^{33}_{33}. Similarly for FIO$(2,\mathbb{R})$ it is easy to see that

$$R^{11}_{ab}M^a_3M^b_3=M^1_bM^1_aR^{ab}_{33}, \tag{4.9}$$

$$R^{22}_{ab}M^a_3M^b_3=M^2_bM^2_aR^{ab}_{33}, \tag{4.10}$$

dictate the nonzero elements to be R^{11}_{33}, R^{22}_{33}, and R^{33}_{33}. However, the relative signs of all the nonzero entries can be obtained by inspecting the other components in matrix equations (4.2). One can show that these observations also hold for BISp and for higher dimensions. Keeping these considerations in mind, it can be shown that the nonzero diagonal elements of the $(2d+1)^2\times(2d+1)^2$ R-matrix for FIO$(2d,\mathbb{C})$ are

$$R^{ik}_{ik}=\begin{cases} -1, & \text{if } \forall\, i,k<2d, \\ +1, & \text{if}\begin{cases} i\leqslant(2d+1), & \text{with } k=(2d+1), \\ k\leqslant(2d+1), & \text{with } i=(2d+1), \end{cases} \end{cases} \tag{4.11}$$

whereas the nonzero off-diagonal entries are

$$R^{i}{}_{(2d+1)(2d+1)}^{k}=\begin{cases}+1, & \text{if}\begin{cases} i=k+d, & k<i<d,\\ k=i+d, & i<k<d,\end{cases}\\ 0, & \text{otherwise}.\end{cases} \tag{4.12}$$

Now, for the real forms FIO$(d,\mathbb{R})$, with which we refer to the fact that its elements are equal to their $*$-conjugates, R-matrices can be given in a unified manner in arbitrary dimension d. In accordance with this choice of $*$-conjugation, only the position of the off-diagonal nonzero elements change places. The nonzero elements of the $(d+1)^2\times(d+1)^2$ R-matrices for FIO$(d,\mathbb{R})$ are

$$R_{ik}^{ik}=\begin{cases}-1, & \text{if } \forall\, i,k<(d+1),\\ +1, & \text{if}\begin{cases} i\leqslant(d+1), & \text{with } k=(d+1),\\ k\leqslant(d+1), & \text{with } i=(d+1),\end{cases}\end{cases} \tag{4.13}$$

$$R^{i}{}_{(d+1)(d+1)}^{k}=\begin{cases}+1, & \text{if } i=k,\\ 0, & \text{otherwise}.\end{cases} \tag{4.14}$$

Similarly, the off-diagonal nonzero elements the R-matrices for BISp$(2d,\mathbb{C})$ are

$$R^{i}{}_{(2d)(2d)}^{k}=\begin{cases}+1, & \text{if } i=k+d, \quad k<i<d,\\ -1, & \text{if } k=i+d, \quad i<k<d,\\ 0, & \text{otherwise},\end{cases} \tag{4.15}$$

with all the diagonal entries $R_{ik}^{ik}=1$. Last, for the BISp$(2d,\mathbb{R})$, with the elements having self $*$- conjugation relations, the nonzero off-diagonal elements turn out to be a complex unit number up to sign. The relative sign of these terms are also inherited from the $*$-conjugate pairs of operators. They are given by

$$R^{l}{}_{(2d)(2d)}^{k}=\begin{cases}+i, & \text{if } l=k+d, \quad k<l<d,\\ -i, & \text{if } k=l+d, \quad l<k<d,\\ 0, & \text{otherwise},\end{cases} \tag{4.16}$$

in addition to the elements along the diagonal all of which are equal to 1.

V. CONCLUSION AND FUTURE PERSPECTIVE

The inhomogeneous quantum groups we obtained constructively in a somewhat more generalized form than they appear in Refs. 3 and 11 are richer, in content, than one expects.

Considering the matrix quantum group FIO(2), the homogeneous part of the matrix can be identified with the group $SU(1,1)\simeq Sp(2,\mathbb{R})$ and it is the inhomogeneous parameters that makes the algebra (2.7) noncommutative. The noncommutativity is controlled by the numerical matrix R. Moreover, the partitioning the quantum matrix $\mathbf{M}$ indicated by Eqs. (3.12), makes it possible to define various subgroups of the quantum groups FIO(d) and BISp$(2d)$, yielding as well the different classical groups in appropriate limits.[12] Also, dropping all the homogeneous parameters, the algebra of the remaining inhomogeneous parameters is equivalent to the algebra on which they act (1.1).

To construct a quantum group that act on systems carrying both fermions and bosons at the same framework may be a valuable construction, since interesting and also physically realizable mathematical models involve interaction. In this respect, it may be interesting to look for a scheme which can combine the FIO and BISp, as a supersymmetry theory.

A two-dimensional irreducible representation of the fermion algebra (1.1) is the algebra of the Pauli matrices $\sigma_{\mp}=1/2(\sigma_1\mp i\sigma_2)$. Since the inhomogeneous parameters can be identified with the algebra (1.1) setting the homogeneous parameters zero, if one pursues this correspondence for

arbitrary dimensions, in terms of the Clifford algebra, similar to those given in Ref. 3, this may help to put a differential geometric structure on the quantum groups FIO(d).[13]

By means of complex representation and companion vector, in this paper we introduce a definition of rank of a quaternion matrix, study the problems of quaternionic linear equations, and obtain an algorithm for quaternionic linear equations in quaternionic quantum theory. © *2004 American Institute of Physics.*
[DOI: 10.1063/1.1794368]

I. INTRODUCTION

In the study of theory of quaternionic quantum mechanics and some applied disciplines (Finkelstein *et al.*, 1962; Adler and co-workers, 1985, 1986, 1988, 1995, 1997; Sutcliffe, 2003), one often encounters a problem of solution of quaternionic linear equations. Because of the noncommutation of quaternions, the solution of quaternionic linear equations is more difficult. In order to solve quaternionic linear equations, the author (Adler, 1995) changed the quaternionic linear equations into a two-component complex quaternionic linear equations, and turned the problem of quaternionic linear equations into that of complex linear equations. This paper, by means of complex representation and companion vector, studies the problems of quaternionic linear equations, and gives a technique of computing quaternionic linear equations in quaternionic quantum theory.

Let $\mathbf{R}$ denote the real number field, $\mathbf{C}=\{a+b\sqrt{-1}\,|\,a,b\in\mathbf{R}\}$ the complex number field, $\mathbf{Q}$ the quaternion number field. Let $\mathbf{F}^{m\times n}$ denote the set of $m\times n$ matrices on a field $\mathbf{F}$. For any $A\in\mathbf{C}^{m\times n}$, $\overline{A}$ and A^T denote the conjugate and the transpose of the matrix A, respectively.

For any quaternion $x=x_0+x_1i+x_2j+x_3k=y+zj\in\mathbf{Q}$, in which $x_i\in\mathbf{R}$, and $i^2=j^2=k^2=-1$, $ij=-ji=k$, and quaternion matrix $A\in\mathbf{Q}^{m\times n}$, the complex representation of quaternion x and A are, respectively, defined to be

$$x^f=\begin{pmatrix} x_0+x_1\sqrt{-1} & x_2+x_3\sqrt{-1} \\ -x_2+x_3\sqrt{-1} & x_0-x_1\sqrt{-1}\end{pmatrix}=\begin{pmatrix} y & z \\ -\overline{z} & \overline{y}\end{pmatrix}\in\mathbf{C}^{2\times 2}, \tag{1.1}$$

and

$$A^f=(a_{ij}^f)=\left(\begin{pmatrix} y_{ij} & z_{ij} \\ -\overline{z}_{ij} & \overline{y}_{ij}\end{pmatrix}\right)\in\mathbf{C}^{2m\times 2n}. \tag{1.2}$$

Let $A\in\mathbf{Q}^{m\times n}$, $B\in\mathbf{Q}^{n\times s}$; by the definition of complex representation we easily get the following results:

$$(AB)^f=A^fB^f, \tag{1.3}$$

a)Electronic mail: tsjemail@163.com

$$\overline{A^f} = P_m^T A^f P_n, \tag{1.4}$$

where

$$P_t = \mathrm{diag}(J, J, \ldots, J), \quad J = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix},$$

and $PP^T = I$.

If $\alpha = (x_1, x_2, \ldots, x_{2n})^T \in \mathbf{C}^{2n\times 1}$, then the companion vector α^c of vector α is defined to be $\alpha^c = (-\overline{x_2}, \overline{x_1}, -\overline{x_4}, \overline{x_3}, \ldots, -\overline{x_{2n}}, \overline{x_{2n-1}})^T \in \mathbf{C}^{2n\times 1}$.

For any quaternion matrix $A \in \mathbf{Q}^{m\times n}$, by the definition of the complex representation of a quaternion matrix there exist complex vectors $\alpha_1, \alpha_2, \ldots, \alpha_n$ such that $A = (\alpha_1, \alpha_1^c, \alpha_2, \alpha_2^c, \ldots, \alpha_n, \alpha_n^c)$.

By the definition of the companion vector we easily prove that if complex vectors $\alpha_1, \alpha_1^c, \alpha_2, \alpha_2^c, \ldots, \alpha_s$ are linearly independent, then complex vectors $\alpha_1, \alpha_1^c, \alpha_2, \alpha_2^c, \ldots, \alpha_s, \alpha_s^c$ are also linearly independent.

From the statement above we get the following result.

Proposition 1.1: Let $A \in \mathbf{Q}^{n\times n}$. Then the rank of complex representation matrix A^f is even.

II. RANK OF QUATERNION MATRICES

In this section, we introduce a definition of rank of quaternion matrices by means of complex representation and a companion vector.

For any quaternion matrix $A \in \mathbf{Q}^{m\times n}$, from Proposition 1.1 we know that the rank of A^f is even, the rank of A is defined to be $\mathrm{rank}(A) = \frac{1}{2}\mathrm{rank}(A^f)$.

By the definition of rank and (1.3) we easily know that almost all the equalities and inequalities of rank to complex matrices hold to quaternion matrices. For instance, if $A \in \mathbf{Q}^{m\times n}$, $B \in \mathbf{Q}^{n\times s}$, then

$$\mathrm{rank}(AB) \leqslant \min\{\mathrm{rank}(A), \mathrm{rank}(B)\}.$$

But $\mathrm{rank}(A)$ and $\mathrm{rank}(A^T)$ are not always the same. For example,

$$A = \begin{pmatrix} 1 & i \\ j & k \end{pmatrix}, \quad \mathrm{rank}(A) \neq \mathrm{rank}(A^T).$$

III. QUATERNIONIC LINEAR EQUATIONS

In this section, we study the solution of quaternionic linear equations $Ax = \beta$ and $AXB = C$, and give a technique of finding a solution of the quaternionic linear equations in quaternionic quantum mechanics and quantum fields.

If $A \in \mathbf{Q}^{m\times n}$, $\beta \in \mathbf{Q}^{m\times 1}$, then by the definition of complex representation and (1.3), $Ax = \beta$ if and only if $A^f x^f = \beta^f$. That is $Ax = \beta$ has a solution x if and only if $A^f Y = \beta^f$ has a solution $Y = x^f$.

If Y is a solution of $A^f Y = \beta^f$, by (1.4),

$$A^f Y = \beta^f \Leftrightarrow \overline{A^f}(P_n^T Y P_1) = \overline{\beta^f} \Leftrightarrow A^f(P_n^T \overline{Y} P_1) = \beta^f, \tag{3.1}$$

i.e., $P_n^T \overline{Y} P_1$ is a solution of $A^f Y = \beta^f$, therefore

$$\hat{Y} = \frac{1}{2}(Y + P_n^T \overline{Y} P_1) \tag{3.2}$$

is also a solution of $A^f Y = \beta^f$. Let

$$Y=(Y_{l1})\in \mathbf{C}^{2n\times 2},\quad Y_{l1}=\begin{pmatrix} z_{l1} & z_{l2}\\ z_{l3} & z_{l4}\end{pmatrix}\in \mathbf{C}^{2\times 2},\quad l=1,2,\ldots,n. \tag{3.3}$$

It is easy to get, by direct calculation,

$$\hat{Y}=(\hat{Y}_{l1})\in \mathbf{C}^{2n\times 2},\quad \hat{Y}_{l1}=\begin{pmatrix} \hat{z}_{l1} & \hat{z}_{l2}\\ -\overline{\hat{z}_{l2}} & \overline{\hat{z}_{l1}}\end{pmatrix}\in \mathbf{C}^{2\times 2},\quad l=1,2,\ldots,n, \tag{3.4}$$

in which

$$\hat{z}_{l1}=\frac{1}{2}(z_{l1}+\overline{z_{l4}}),\quad \hat{z}_{l2}=\frac{1}{2}(z_{l2}-\overline{z_{l3}}). \tag{3.5}$$

From (3.4) we construct a quaternion matrix,

$$x=(x_{l1})\in \mathbf{C}^{n\times 1},\quad x_{l1}=\hat{z}_{l1}+\hat{z}_{l2}j=\frac{1}{2}(1,-j)\hat{Y}_{l1}\begin{pmatrix}1\\ j\end{pmatrix},\quad l=1,2,\ldots,n. \tag{3.6}$$

Therefore we have

$$x=\frac{1}{2}(1,-j,1,-j,\ldots,1,-j)\hat{Y}\begin{pmatrix}1\\ j\end{pmatrix}=\frac{1}{4}(1,-j,1,-j,\ldots,1,-j)(Y+P_n^T\overline{Y}P_1)\begin{pmatrix}1\\ j\end{pmatrix}.$$

Clearly $x_{l1}^f=\hat{Y}_{l1}$, and $x^f=\hat{Y}$. This means that $x^f=\hat{Y}$ is a solution of $A^fY=\beta^f$, so x is a solution of $Ax=\beta$.

From the statement above we get following result.

Theorem 3.1: Let $A\in \mathbf{Q}^{m\times n}$, $\beta\in \mathbf{Q}^{m\times 1}$. Then quaternionic linear equations $Ax=\beta$ have a solution if and only if $\mathrm{rank}(A)=\mathrm{rank}(A,\beta)$, i.e., $Ax=\beta$ has a solution if and only if $A^fY=\beta^f$ has a solution, in which case, if Y is a solution to $A^fY=\beta^f$, then the following quaternion is a solution to $Ax=\beta$:

$$x=\frac{1}{4}(1,-j,1,-j,\ldots,1,-j)(Y+P_n^T\overline{Y}P_1)\begin{pmatrix}1\\ j\end{pmatrix}. \tag{3.7}$$

Moreover, if $\mathrm{rank}(A)=\mathrm{rank}(A,\beta)=n$, then quaternionic linear equations $Ax=\beta$ have a unique solution.

Remark: Theorem 3.1 gives not only sufficient and necessary conditions for quaternionic linear equations $Ax=\beta$ to have a solution, but also a technique of finding a solution to quaternionic linear equations $Ax=\beta$. When the quaternionic linear equations $Ax=\beta$ have a solution, we can find a solution by a solution of complex representation equation $A^fY=\beta^f$ from the formula (3.7). Theorem 3.1 turns the problem of the solution of quaternionic linear equations into that of the solution of complex linear equations by means of complex representations of quaternion matrices.

Similarly we easily get the following result.

Theorem 3.2: Let $A\in \mathbf{Q}^{m\times n}$, $B\in \mathbf{Q}^{p\times q}$, $C\in \mathbf{Q}^{m\times q}$. Then quaternionic matrix equation $AXB=C$ has a solution if and only if $\mathrm{rank}(A)=\mathrm{rank}(A,C)$ and $\mathrm{rank}(B)=\mathrm{rank}\binom{B}{C}$, i.e., quaternionic matrix equation $AXB=C$ has a solution if and only if complex matrix equation $A^fYB^f=C^f$ has a solution, in which case, if Y is a solution to complex matrix equation $A^fYB^f=C^f$, then the following matrix is a solution to $AXB=C$:

$$x=\frac{1}{4}(1,-j,1,-j,\ldots,1,-j)(Y+P_n^T\overline{Y}P_q)(1,j,1,j,\ldots,1,j)^T. \tag{3.8}$$

Moreover, if $\mathrm{rank}(A)=\mathrm{rank}(A,C)=n$ and $\mathrm{rank}(B)=\mathrm{rank}\binom{B}{C}=p$, then quaternionic matrix equation $AXB=C$ has a unique solution.

IV. EXAMPLE

Example: Let

$$A=\begin{pmatrix} i & 1+j \\ -1+j & -k \end{pmatrix}, \quad \beta=\begin{pmatrix} i \\ -1 \end{pmatrix}.$$

Find all solutions of quaternionic linear equations $Ax=\beta$.

It is easy to find the A^f and β^f by the definition of complex representation, and

$$A^f=\begin{pmatrix} i & 0 & 1 & 1 \\ 0 & -i & -1 & 1 \\ -1 & 1 & 0 & -i \\ -1 & -1 & -i & 0 \end{pmatrix}, \quad \beta^f=\begin{pmatrix} i & 0 \\ 0 & -i \\ -1 & 0 \\ 0 & -1 \end{pmatrix},$$

and $\mathrm{rank}(A^f)=\mathrm{rank}(A^f,\beta^f)=4$, i.e., $\mathrm{rank}(A)=\mathrm{rank}(A,\beta)=2$, then quaternionic linear equations $Ax=\beta$ have a unique solution.

Since $\mathrm{rank}(A^f)=\mathrm{rank}(A^f,\beta^f)=4$, so $A^fY=\beta^f$ has a unique solution. The unique solution is easily found to be

$$Y=\begin{pmatrix} \frac{2}{3} & \frac{1}{3} \\ -\frac{1}{3} & \frac{2}{3} \\ \frac{i}{3} & 0 \\ 0 & -\frac{i}{3} \end{pmatrix}.$$

By (3.7), we easily find the unique solution x of quaternionic linear equations $Ax=\beta$, and

$$x=\frac{1}{4}(1,-j,1,-j)(Y+P_2^T\overline{Y}P_1)\begin{pmatrix} 1 \\ j \end{pmatrix}=\begin{pmatrix} \frac{2}{3}+\frac{1}{3}j \\ \frac{1}{3}i \end{pmatrix}.$$

By means of a complex representation and companion vector, this paper introduces a definition of rank of a quaternion matrix, studies the solutions of quaternionic linear equations, gives sufficient and necessary conditions for the quaternionic linear equations to have a solution, and obtains a technique of finding a solution to quaternionic linear equations. This paper turns the problem of quaternionic linear equations into that of complex linear equations, changes noncommutative quaternion problems to a complex question, and provides a practical algorithm of the solution of quaternionic linear equations in quaternionic quantum theory.

Intersecting hypersurfaces in dimensionally continued topological density gravitation

Elias Gravanis and Steven Willison[a)]
Department of Physics, King's College London, Strand, London WC2R 2LS, United Kingdom

(Received 15 September 2003; accepted 7 July 2004; published 25 October 2004)

We consider intersecting hypersurfaces in curved spacetime with gravity governed by a class of actions which are topological invariants in lower dimensionality. Along with the Chern–Simons boundary terms there is a sequence of intersection terms that should be added in the action functional for a well defined variational principle. We construct them in the case of Characteristic Classes, obtaining relations which have a general topological meaning. Applying them on a manifold with a discontinuous connection 1-form we obtain the gravity action functional of the system and show that the junction conditions can be found in a simple algebraic way. At the sequence of intersections there are localized independent energy tensors, constrained only by energy conservation. We work out explicitly the simplest nontrivial case. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1794841]

I. INTRODUCTION

General relativity can be generalized to a manifold with a boundary. The inclusion of a certain boundary term (Gibbons–Hawking) makes the action principle well defined on the boundary. Also, singular hypersurfaces of matter[1] can be incorporated into a manifold with piece-wise differentiable metric.[2] We will see that these are part of the general properties of actions built out of dimensionally continued topological invariants. The Einstein–Hilbert action of General Relativity is the dimensionally continued form of the two-dimensional Euler Characteristic. A linear combination of terms which are dimensionally continued Euler densities in arbitrary dimensions is known variously as Lovelock or Lanczos–Lovelock or Gauss–Bonnet gravity. It has been studied extensively[3–6] and the boundary action has been constructed.[7–9]

An interesting problem in gravity is the study of collisions of shells of matter.[10–12] Brane-world models of matter on the intersection of co-dimension 1 branes were studied and it was found that the Gauss–Bonnet term was needed in order to get a tension on the intersection in a natural way.[13] The Gauss–Bonnet term is the dimensionally continued 4-dimensional Euler density. We address this problem of intersections and collisions of co-dimension 1 hypersurfaces in a more generalized way, motivated by the properties of the topological invariants.

A topological invariant "action" contains no local degrees of freedom. The only information it encodes is topological. As such, it is independent of the local form of the metric. We consider actions which are topological in a certain dimensionality and then generalize to higher dimensions. These actions have the property that the independent infinitesimal variation of the action with respect to the connection is a total derivative.

We consider a smooth manifold with embedded arbitrarily intersecting hypersurfaces of singular matter. We can view a hypersurface as the shared boundary of two adjacent regions. The gravity of localized matter can be described by a boundary action. As in Ref. 13, we allow for the possibility of matter being localized on the surfaces of intersection also. The spacetime is divided

[a)]Electronic mail: steven.willison@kcl.ac.uk

up into polyhedral regions bounded by piece-wise smooth hypersurfaces—like a matrix of cells. We show that this situation is compatible with any theory of gravity based on a dimensionally continued topological invariant.

We exploit the topological nature of the theory to write the action in terms of different connections in different regions. This generates our surface actions remarkably simply. We can derive the Israel junction conditions and the junction conditions for any intersections in a purely algebraic way.

In Sec. II we review basic material on topological densities, introducing Characteristic Classes on a manifold with boundary. In Sec. III A we derive the intersection forms generalizing Chern–Simons forms and in Sec. III B we construct the action functional of gravity in the presence of intersecting hypersurfaces employing the properties of the intersection forms. The topological theory is dealt with in Sec. III B 1 and the dimensionally continued case of interest is dealt with in Sec. III B 2. In Sec. IV we work out a simple example along with the energy exchange relations in that case.

II. TOPOLOGICAL DENSITIES AND GRAVITATION

Let M be a manifold with a Riemannian or Lorentzian metric g and a Levi-Cività connection. Let ω be the connection 1-form and Ω the curvature form. For dim $M=2n$ consider the integral

$$\int_M f(\Omega,\ldots\Omega), \quad f(\Omega,\ldots,\Omega)=\Omega^{a_1a_2}\wedge\cdots\wedge\Omega^{a_{2n-1}a_{2n}}\epsilon_{a_1\cdots a_{2n}}, \tag{1}$$

where $\epsilon_{\ldots}$ is the fully anti-symmetric symbol and $\epsilon_{1\cdots 2n}=+1$ and the integral is assumed to exist. The frame E is ortho-normal in the sense that $g(E^a,E^b)=\delta^{ab}$ in the Riemannian case and $g(E^a,E^b)=\eta^{ab}=\mathrm{diag}(-1,1,\ldots,1)$ in the Lorentzian case.

When g is Riemannian and M is compact and oriented $f(\Omega,\ldots,\Omega)$ represents the Euler class. The integral over M, normalized properly, gives the Euler number of M, according to the renowned Gauss–Bonnet–Chern Theorem.[14] There are more general (and precise) definitions than the one we give here. The details are in the textbooks[15–17] but we only need to point out the similarity and make intelligible borrowing of tools from global differential geometry. $f(\Omega,\ldots,\Omega)$ will be called the Euler density. In general an invariant whose integral over M gives a topological invariant of M will be called topological density.

Let us now repeat the Chern–Weil construction and show that under a continuous change of the connection, $\omega\to\omega'$, $f(\Omega,\ldots,\Omega)$ changes by an exact form. In fact we are only going to need f to be invariant, symmetric and multi-linear. These general properties are provided by the invariant polynomials and lead to the so-called Characteristic Classes, of which the Euler class is an example. The following applies globally on the principal bundle but it is sufficient for our purpose to work on the manifold.

Define

$$\omega_t=t\omega+(1-t)\omega'.$$

Call

$$\theta=\omega-\omega'$$

and note that

$$\theta=\frac{d}{dt}\omega_t,$$

and for the curvature associated with ω_t,

$$\Omega_t = d\omega_t + \omega_t \wedge \omega_t, \tag{2}$$

that

$$\frac{d}{dt}\Omega_t = D_t\theta, \tag{3}$$

where D_t is the covariant derivative associated with ω_t. Then

$$\begin{aligned} f(\Omega, \ldots, \Omega) - f(\Omega', \ldots, \Omega') &= \int_0^1 dt \frac{d}{dt} f(\Omega_t, \ldots, \Omega_t) = n \int_0^1 dt f(d\Omega_t/dt, \Omega_t, \ldots, \Omega_t) \\ &= n \int_0^1 dt f(D_t\theta, \Omega_t, \ldots, \Omega_t) = n \int_0^1 dt df(\theta, \Omega_t, \ldots, \Omega_t), \end{aligned} \tag{4}$$

where symmetry and multi-linearity of f have been used, as well as $D_t\Omega_t = 0$.

If we define

$$\mathcal{L}(\omega) = f(\Omega, \ldots, \Omega) \tag{5}$$

and

$$\mathcal{L}(\omega, \omega') = -n \int_0^1 dt f(\omega - \omega', \Omega_t, \ldots, \Omega_t), \tag{6}$$

we can write

$$\mathcal{L}(\omega) = \mathcal{L}(\omega') - d\mathcal{L}(\omega, \omega'). \tag{7}$$

Now, assume that, for example, M is noncompact and without a boundary. If $\mathcal{L}(\omega, \omega')$ vanishes fast enough asymptotically,

$$\int_M \mathcal{L}(\omega) \tag{8}$$

(assumed to exist) does not depend on ω. It is this property that makes $\mathcal{L}(\omega)$ so useful when, with a little modification, it is used as a Lagrangian for gravity for dim $M > 2n$.

Define the $(d\text{-}r)$-form [which is a natural $(d\text{-}r)$-dimensional volume element]:

$$e_{a_1 a_2 \cdots a_r} = \frac{1}{(d-r)!} \epsilon_{a_1 a_2 \cdots a_d} E^{a_{r+1}} \wedge \cdots \wedge E^{a_d}. \tag{9}$$

The associated dimensionally continued Euler density for $d > 2n$ is

$$\mathcal{L}_g(\omega, e) = f(\Omega, \ldots, \Omega, e) = \Omega^{a_1 b_1} \wedge \Omega^{a_2 b_2} \wedge \cdots \wedge \Omega^{a_n b_n} \wedge e_{a_1 b_1 a_2 b_2 \cdots a_n b_n}, \tag{10}$$

which is also an invariant.

Then, the Euler–Lagrange variation with respect to ω in

$$\int_M \mathcal{L}_g(\omega, e), \tag{11}$$

noting that $\delta\Omega = D(\delta\omega)$, vanishes by the Bianch identity and the assumed zero torsion condition $DE^a = 0$.[18] The equations of motion are obtained simply by the Euler–Lagrange variation of the frame, applying the formula

$$\delta e_{a_1\cdots a_r} = \delta E^{a_{r+1}} \wedge e_{a_1\cdots a_r a_{r+1}}, \tag{12}$$

in a purely algebraic way.

In the next section we find how the action (10) is re-expressed in the presence of hypersurfaces and their intersections, by generalizing (7) appropriately, and show that the equations of motion (junction conditions) are still obtained from the mere variation of the frame.

III. TOPOLOGICAL DENSITIES ON MANIFOLDS CONTAINING INTERSECTING HYPERSURFACES

A hypersurface is understood as a smooth co-dimension 1 subspace of the manifold where the connection form exhibits discontinuity or as a (higher co-dimension) intersection of such discontinuities.

Integrating $\mathcal{L}(\omega)$ over the manifold, when ω is the discontinuous connection form, one has to add a Chern–Simons term integrated over the discontinuity for the final result to have well-defined variations with respect to ω (and to be diffeomorphism invariant). If discontinuities intersect, in all possible ways, one should, in general, add appropriate generalizations of the Chern–Simons forms integrated over the intersections.

A discontinuity can be thought of as the common boundary of two d-dimensional (bulk) regions. The intersection of discontinuities can be thought of as common subspaces of the (not smooth) boundaries of a larger number of bulk regions. It is also helpful to think of them as singular overlaps (at the boundaries) or intersections of two or more bulk regions.

With this in mind, we first find generalizations of the Chern–Simons forms.

A. From boundary to intersection action terms

Given an invariant polynomial, we found in the previous section a relation of the form of (7) by interpolating between the given connection ω and an arbitrary one ω'. We can continue by interpolating between the latter and a new connection. In general, let us define the p-parameter family of connections, interpolating between $p+1$ connections, $\omega^1, \ldots, \omega^{p+1}$,

$$\omega_p = \omega_{t_1\cdots t_p} = \omega^1 - (1-t_1)\theta^1 - \cdots - (1-t_1)\cdots(1-t_p)\theta^p, \tag{13}$$

where

$$\theta^r = \omega^r - \omega^{r+1}, \quad r = 1, \ldots, p. \tag{14}$$

Note: For the purposes of Sec. III A and Eqs. (38)–(44) only, the subscript p refers to a function of $t_1, \ldots, t_p$.

Define

$$\frac{\partial}{\partial t_q}\omega_p = \frac{\partial}{\partial t_q}\omega_{t_1\cdots t_p} = \sum_{r\geqslant q}^{p} (1-t_1)\cdots\widehat{(1-t_q)}\cdots(1-t_r)\theta^r = \theta^q_{t_1\cdots\widehat{t_q}\cdots t_p} = \theta^q_p, \tag{15}$$

where the over caret means that the index is omitted. Note that

$$\omega_{t_1\cdots t_p}\big|_{t_r=0} = \omega_{t_1\cdots t_{r-1}t_{r+1}\cdots t_p}, \tag{16}$$

setting the connection $\omega^r = 0$. This will be useful below. Let Ω_p be the p-parameter curvature 2-form associated with ω_p. Then

$$\frac{\partial}{\partial t_q}\Omega_p = \frac{\partial}{\partial t_q}\Omega_{t_1\cdots t_p} = D_{t_1\cdots t_p}\theta^q_{t_1\cdots\widehat{t_q}\cdots t_p} = D_p\theta^q_p. \tag{17}$$

There is also a "Bianchi identity" for Ω_p,

$$D_p\Omega_p = 0; \tag{18}$$

D_p is the covariant derivative associated with ω_p.

Proposition 1: We introduce a $(p+1)$-point term with $p+1$ connection entries. We now show that the $(p+1)$-point generalization of the 2-point Chern–Simons term takes the form

$$\mathcal{L}(\omega^1, \ldots, \omega^{p+1}) = \eta_p \frac{n!}{(n-p)!} \int_0^1 dt_1 \cdots dt_p f(\theta_p^1, \theta_p^2, \ldots, \theta_p^p, \Omega_p, \ldots, \Omega_p), \tag{19}$$

where $\eta_p = (-1)^{p(p+1)/2}$. These terms obey the following rule:

$$\sum_{s=1}^{p+1} (-1)^{s-p-1} \mathcal{L}(\omega^1, \ldots, \widehat{\omega^s}, \ldots, \omega^{p+1}, \omega^{p+2}) = \mathcal{L}(\omega^1, \ldots, \omega^{p+1}) + d\mathcal{L}(\omega^1, \ldots, \omega^{p+1}, \omega^{p+2}). \tag{20}$$

Proof: If we define

$$\omega_{t_{p+1}}^{p+1} = t_{p+1}\omega^{p+1} + (1 - t_{p+1})\omega^{p+2}, \tag{21}$$

then

$$\mathcal{L}(\omega^1, \ldots, \omega_{t_{p+1}}^{p+1}) = \eta_p \frac{n!}{(n-p)!} \int_0^1 dt_1 \cdots dt_p f(\theta_{p+1}^1, \theta_{p+1}^2, \ldots, \theta_{p+1}^p, \Omega_{p+1}, \ldots, \Omega_{p+1}).$$

We have

$$\begin{aligned}\mathcal{L}(\omega^1, \ldots, \omega^p, \omega^{p+1}) - \mathcal{L}(\omega^1, \ldots, \omega^p, \omega^{p+2}) &= \int_0^1 dt_{p+1} \frac{\partial}{\partial t_{p+1}} \mathcal{L}(\omega^1, \ldots, \omega^p, \omega_{t_{p+1}}^{p+1}) \\ &= \eta_p \frac{n!}{(n-p)!} \int_0^1 dt_1 \cdots dt_p dt_{p+1} \frac{\partial}{\partial t_{p+1}} \\ &\quad \times f(\theta_{p+1}^1, \theta_{p+1}^2, \ldots, \theta_{p+1}^p, \Omega_{p+1}, \ldots, \Omega_{p+1}).\end{aligned}$$

From the multi-linearity of the invariant polynomial f we have

$$\begin{aligned}\frac{\partial}{\partial t_{p+1}} f(\theta_{p+1}^1, \theta_{p+1}^2, \ldots, \theta_{p+1}^p, \Omega_{p+1}, \ldots, \Omega_{p+1}) &= \sum_{r=1}^{p} f\left(\theta_{p+1}^1, \ldots, \frac{\partial}{\partial t_{p+1}} \theta_{p+1}^r, \ldots, \theta_{p+1}^p, \Omega_{p+1}, \ldots, \Omega_{p+1}\right) \\ &\quad + (n-p) f\left(\theta_{p+1}^1, \theta_{p+1}^2, \ldots, \theta_{p+1}^p, \frac{\partial}{\partial t_{p+1}} \Omega_{p+1}, \ldots, \Omega_{p+1}\right).\end{aligned}$$

Using (17), we can write the last term as

$$\begin{aligned}&(n-p)(-1)^p df(\theta_{p+1}^1, \theta_{p+1}^2, \ldots, \theta_{p+1}^p, \theta_{p+1}^{p+1}, \Omega_{p+1}, \ldots, \Omega_{p+1}) \\ &- (n-p) \sum_{s=1}^{p} (-1)^{p+s-1} f(\theta_p^1, \ldots, D_{p+1}\theta_{p+1}^s, \ldots, \theta_{p+1}^{p+1}, \Omega_{p+1}, \ldots, \Omega_{p+1}),\end{aligned}$$

and using again (17) in the last term we obtain

$$-\sum_{s=1}^{p}(-1)^{p+s-1}\frac{\partial}{\partial t_s}f(\theta^1_{p+1},\ldots,\widehat{\theta^s_{p+1}},\ldots,\theta^{p+1}_{p+1},\Omega_{p+1},\ldots,\Omega_{p+1})$$
$$+\sum_{s=1}^{p}(-1)^{p+s-1}\sum_{r=1,\neq s}^{p+1}f\left(\theta^1_{p+1},\ldots,\frac{\partial}{\partial t_s}\theta^r_{p+1},\ldots,\widehat{\theta^s_{p+1}},\ldots,\theta^p_{p+1},\theta^{p+1}_{p+1},\Omega_{p+1},\ldots,\Omega_{p+1}\right).$$

In all

$$(n-p)(-1)^p df(\theta^1_{p+1},\theta^2_{p+1},\ldots,\theta^p_{p+1},\theta^{p+1}_{p+1},\Omega_{p+1},\ldots,\Omega_{p+1})$$
$$-\sum_{s=1}^{p}(-1)^{p+s-1}\frac{\partial}{\partial t_s}f(\theta^1_{p+1},\ldots,\widehat{\theta^s_{p+1}},\ldots,\theta^{p+1}_{p+1},\Omega_{p+1},\ldots,\Omega_{p+1})$$
$$+\sum_{s=1}^{p+1}(-1)^{p+s-1}\sum_{r=1,\neq s}^{p+1}f\left(\theta^1_{p+1},\ldots,\frac{\partial}{\partial t_s}\theta^r_{p+1},\ldots,\widehat{\theta^s_{p+1}},\ldots,\theta^p_{p+1},\theta^{p+1}_{p+1},\Omega_{p+1},\ldots,\Omega_{p+1}\right).$$

Note now that

$$\frac{\partial}{\partial t_s}\theta^r_{p+1}=\frac{\partial}{\partial t_s}\frac{\partial}{\partial t_r}\omega_{p+1}=\frac{\partial}{\partial t_r}\theta^s_{p+1};\tag{22}$$

then, in the last term, if we split the sum into $r<s$ and $r>s$, changing variables $r\leftrightarrow s$ in the latter and using this identity we see that the term vanishes. We have shown then that $(p+1)$-point $\mathcal{L}_{p+1}$ defined in (19) obeys a rule,

$$\sum_{s=1}^{p+1}(-1)^{s-p-1}\mathcal{L}(\omega^1,\ldots,\widehat{\omega^s},\ldots,\omega^{p+1},\omega^{p+2})=\mathcal{L}(\omega^1,\ldots,\omega^{p+1})+d\mathcal{L}(\omega^1,\ldots,\omega^{p+1},\omega^{p+2}).$$

The relation (16) has been used. □

It is not hard to show that $\mathcal{L}$ is fully anti-symmetric in its entries, so we can write the above in the form

$$\sum_{s=1}^{p+1}\mathcal{L}(\omega^1,\ldots,\omega^{s-1},\omega',\omega^{s+1},\ldots,\omega^{p+1})=\mathcal{L}(\omega^1,\ldots,\omega^{p+1})+d\mathcal{L}(\omega^1,\ldots,\omega^{p+1},\omega'),\tag{23}$$

where ω' is arbitrary.

As θ^r is a 1-form we have $f(\ldots,\theta^r,\ldots,\theta^r,\ldots,\Omega_p,\ldots\Omega_p)=0$ and we can write (19) explicitly in terms of $\theta^r=\omega^r-\omega^{r+1}$, $r=1\ldots p$ in the form

$$\mathcal{L}(\omega^1,\ldots,\omega^{p+1})=\int_0^1 dt_1\cdots dt_p\zeta_p f(\theta^1,\theta^2,\ldots\theta^p,\Omega_p,\ldots,\Omega_p),\tag{24}$$

$$\zeta_p=(-1)^{p(p+1)/2}\frac{n!}{(n-p)!}\prod_{r=1}^{p-1}(1-t_r)^{p-r}.\tag{25}$$

Let us show that $\mathcal{L}_p$'s, constructed from Characteristic Classes, are invariant under local Lorentz transformations. The connections transform as

$$\omega^r_{(g)}=g^{-1}\omega^r g+g^{-1}\,dg,\tag{26}$$

for all $r=1,\ldots,p+1$, where g belongs to the adjoint representation of SO(d-1,1). Then, $\theta^r_{(g)}=g^{-1}\theta^r g$ and $\Omega_{p(g)}=g^{-1}\Omega_p g$, so [20]

$$\mathcal{L}(\omega^1_{(g)}, \ldots, \omega^{p+1}_{(g)}) = \mathcal{L}(\omega^1, \ldots, \omega^{p+1}). \tag{27}$$

In fact, one can derive (23) without reference to the invariant polynomial, by use of the Poincare lemma and the following observation [inspired by the form of (23)]. If $f(x_1, \ldots, x_n)$ is an anti-symmetric function of n variables and

$$Af(x_1, \ldots x_p, x_{p+1}) = f(x_1, \ldots x_p) - \sum_{i=1}^{p} f(x_1, \ldots, x_{i-1}, x_{p+1}, x_{i+1}, \ldots, x_p) \tag{28}$$

(antisymmetrizing over $n+1$ variables) then $AAf(x_1, \ldots, x_{p+2}) = 0$. The proof is trivial.

We can now show (23) by induction, assuming only that $\mathcal{L}(\omega)$ obeys (7). That is, it is true for the $p=0$ case. Assume (23) for $p=k-1$ [let us use the symbol $\mathcal{L}_k(\omega^1 \ldots \omega^k)$ for the intersection forms in this proof],

$$A\mathcal{L}_k(\omega^1 \cdots \omega^{k+1}) = -\, d\mathcal{L}_{k+1}(\omega^1 \cdots \omega^{k+1}). \tag{29}$$

Then $dA\mathcal{L}_{k+1}(\omega^1 \cdots \omega^{k+2}) = 0$. By the Poincare lemma we have that there exists an invariant form, locally, such that

$$A\mathcal{L}_{k+1}(\omega^1 \cdots \omega^{k+2}) = -\, d\mathcal{L}_{k+2}(\omega^1 \cdots \omega^{k+2}), \tag{30}$$

which completes the induction. (19) is *a* solution of the general relation (23).

There is similarity between our composition rule and Stora–Zumino descent equations.[21] The reason is the existence in both cases of a nilpotent operator, A in our case and the fermionic BRST operator there, which commutes and anticommutes, respectively, with the derivative operator d.

B. Manifolds with discontinuous connection 1-form

We now construct the action functional of gravity on a manifold containing intersecting surfaces. It will also enable us to draw conclusions for arbitrary intersections of hypersurfaces for a general dimensionally continued topological density.

1. Topological density

If the functional $\int_M \mathcal{L}$ is independent of the C^0 metric of the manifold M, then it can be evaluated using a continuous connection as well as a connection that is discontinuous at some subspaces (namely there are hypersurfaces involved). That is, the result will be the same. We use this formal equivalence to give a meaning to $\int_M \mathcal{L}(\omega)$ when ω is discontinuous.

Let us start with the case of a topological density $\mathcal{L}(\omega_0)$ of a continuous connection ω_0 integrated over M which contains a single hypersurface. Label 1 and 2 the regions of M separated by the hypersurface. Introduce two connections, ω_1 and ω_2, which are smooth in the regions 1 and 2, respectively. We now write

$$\int_M \mathcal{L}(\omega_0) = \int_1 \mathcal{L}(\omega_1) + d\mathcal{L}(\omega_1, \omega_0) + \int_2 \mathcal{L}(\omega_2) + d\mathcal{L}(\omega_2, \omega_0). \tag{31}$$

Label the surface, oriented with respect to region 1, with 12 (formally $\int_{12} = -\int_{21}$):

$$\begin{aligned}\int_M \mathcal{L}(\omega_0) &= \int_1 \mathcal{L}(\omega_1) + \int_2 \mathcal{L}(\omega_2) + \int_{12} \mathcal{L}(\omega_1, \omega_0) - \mathcal{L}(\omega_2, \omega_0) \\ &= \int_1 \mathcal{L}(\omega_1) + \int_2 \mathcal{L}(\omega_2) + \int_{12} \mathcal{L}(\omega_1, \omega_2) + d\mathcal{L}(\omega_1, \omega_2, \omega_0).\end{aligned} \tag{32}$$

That is, for a smooth surface the rhs is independent of ω_0.

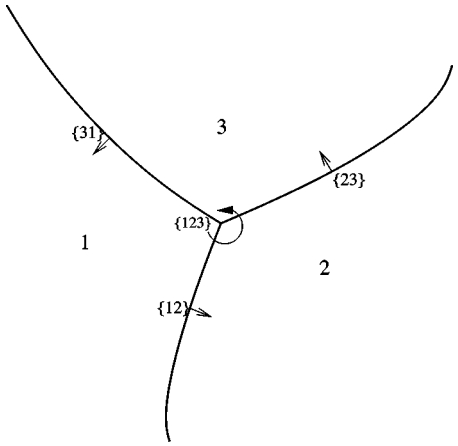

FIG. 1. The simplicial intersection of co-dimension 2 ($h=2$). The totally antisymmetric symbol {123} specifies the intersection including the orientation.

Consider now a sequence of co-dimension $p=1,2,3,\ldots,h$ hyper-surfaces which are intersections of $p+1=2,3,\ldots,h+1$ bulk regions, respectively. We will use the terms intersection and hypersurface alternatively. A co-dimension p hyper-surface is labeled by $i_0\cdots i_p$ where $i_0,\ldots,i_p$ are the labels of the bulk regions which intersect there. We call this configuration a simplicial intersection.

We take the example $h=2$ (Fig. 1), where the intersections are {12}, {13}, {23}, {123}. An exact form integrated over {12} will contribute at {123} the opposite that when integrated over {21}, that is, for the latter integration the intersection can be labeled by $-123=213$, if we assume anti-symmetry of the label. The arrows of positive orientations in Fig. 1 tell us that a fully anti-symmetric symbol {123} will adequately describe the orientations of the intersection 123. This is in contrast to the nonsimplicial intersection (Fig. 2).

Definition 2 (for a simplicial intersection): $\{i_0\cdots i_p\}$ is the set $\overline{i_0}\cap\cdots\cap\overline{i_p}$ where $\overline{i_r}$ is the closure of the open set i_r (a bulk region). $\overline{i_r}$ overlap such that $\partial i_r=\Sigma_{s=0,\neq r}^{h}\,\overline{i_r}\cap\overline{i_s}$ and $i_r\cap i_s=\varnothing$ for all $s\neq r$. This formalises our definitions at the beginning of Sec. II. By $\partial(\overline{A}\cap\overline{B})=(\partial\overline{A}\cap\overline{B})\cup(\overline{A}\cap\partial\overline{B})$, for A, B open sets, we can write

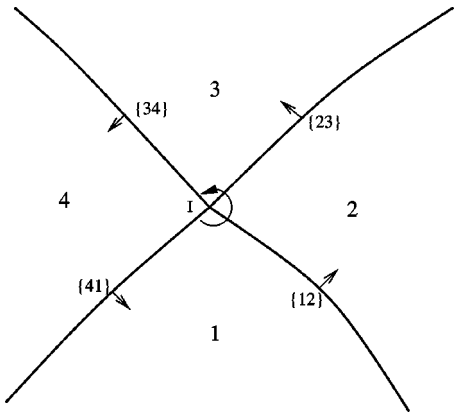

FIG. 2. A nonsimplicial intersection of co-dimension 2 ($h=2$). The intersection, including the orientation, would not be properly represented by the totally anti-symmetric symbol {1234}.

$$\partial\{i_0\cdots i_p\}=\sum_{i_{p+1}}\{i_0\cdots i_{p+1}\}. \tag{33}$$

Full anti-symmetry of the symbol $\{i_0\cdots i_p\}$ keeps track of the orientations properly in (33). As a check,

$$\partial^2\{i_0\cdots i_p\}=\sum_{i_{p+1},i_{p+2}}\{i_0\cdots i_{p+1}i_{p+2}\}=0.$$

Lemma 3: When all intersections are simplicial intersections, with no localized curvature, the contribution from each intersection $\{i_1\cdots i_k\}$ is

$$\int_{\{i_1\cdots i_k\}}\mathcal{L}(\omega_{i_1},\ldots,\omega_{i_k}), \tag{34}$$

up to a boundary term on ∂M.

By "no localized curvature," it is meant that the distributional part of the Riemann curvature tensor must have its support only on co-dimension 1 hypersurfaces and not on lower-dimensional intersections. This is an important condition. We require this in order to have a well-defined ortho-normal frame at the intersections.

Proof: Assume, for $l<h$, we can write

$$\int_M\mathcal{L}(\omega_0)=\sum_{k=1}^{l-1}\frac{1}{k!}\sum_{i_1\cdots i_k}\int_{\{i_1\cdots i_k\}}\mathcal{L}(\omega_{i_1}\cdots\omega_{i_k})+\frac{1}{l!}\sum_{i_1\cdots i_l}\int_{\{i_1\cdots i_l\}}\mathcal{L}(\omega_{i_1}\cdots\omega_{i_l})+d\mathcal{L}(\omega_{i_1}\cdots\omega_{i_l},\omega_0). \tag{35}$$

We have already seen that this is true for $l=1$ and $l=2$. The exact form gives

$$\frac{1}{l!}\sum_{i_1\cdots i_li_{l+1}}\int_{\{i_1\cdots i_li_{l+1}\}}\mathcal{L}(\omega_{i_1}\cdots\omega_{i_l},\omega_0),$$

+ a term on ∂M. From the anti-symmetry of $\{i_1\cdots i_li_{l+1}\}$ and of $\mathcal{L}$ we have

$$\frac{1}{l!}\sum_{i_1\cdots i_{l+1}}\int_{\{i_1\cdots i_li_{l+1}\}}\frac{1}{l+1}\sum_{r=1}^{l+1}\mathcal{L}(\omega_{i_1}\cdots\omega_{i_{r-1}},\omega_0,\omega_{i_{r+1}}\cdots\omega_{i_{l+1}}).$$

Applying the composition rule we get

$$\int_M\mathcal{L}(\omega_0)=\sum_{k=1}^{l}\frac{1}{k!}\sum_{i_1\cdots i_k}\int_{\{i_1\cdots i_k\}}\mathcal{L}(\omega_{i_1}\cdots\omega_{i_k})+\frac{1}{(l+1)!}\sum_{i_1\cdots i_{l+1}}\int_{\{i_1\cdots i_{l+1}\}}\mathcal{L}(\omega_{i_1}\cdots\omega_{i_{l+1}})+d\mathcal{L}(\omega_{i_1}\cdots\omega_{i_{l+1}},\omega_0). \tag{36}$$

Finally we note that the total derivative term on the highest co-dimension intersections (order h), can only contribute to ∂M. So by induction we have proved the Lemma.

Note that apart from our composition formula we have used only Stokes's theorem, which is valid on a topologically nontrivial manifold M assuming a partition of unity f_i subordinated to a chosen covering. By (27) each of the terms appearing will be invariant w.r.t. the structure group. So the last formula is valid over M understanding each $\mathcal{L}$ as $\Sigma_i\, f_i\mathcal{L}$. □

We began with a smooth manifold with an Euler Density action which is completely independent of the choice of ω_0. This gives only a topological invariant of the manifold and is entirely independent of any embedded hypersurfaces. The ω_i's, as well as their number, are arbitrary also. So we see that we have constructed a "theory of gravity," in the presence of arbitrarily intersecting hypersurfaces of discontinuity in the connection, which is a topological invariant. It is a trivial

theory in that the action is completely insensitive to these hypersurfaces. The "gravitational" equations of motion vanish identically, regardless of the geometry, providing no way to relate geometry to energy–momentum.

2. Dimensionally continued Euler densities

Now we consider the dimensionally continued Euler density for arbitrarily intersecting hypersurfaces separating bulk regions counted by i. We postulate the action

$$S_g = \sum_i \int_i \mathcal{L}_g(\omega_i, e) + \sum_{k=2}^{h} \frac{1}{k!} \sum_{i_1 \cdots i_k} \int_{\{i_1 \cdots i_k\}} \mathcal{L}_g(\omega_{i_1}, \ldots, \omega_{i_k}, e). \tag{37}$$

We will show that this action is "one and a half order" in the connection. We will need to revisit our derivation of the composition rule in Sec. III A, this time interpolating between the different metric functions $E^i(x)$, where the index represents the region (the local Lorentz index being suppressed). Physically, we require the metric being continuous at a surface $\Sigma_{1\cdots p+1}$: $i^* E^i = E$ which implies $i^*(e^i) = e$. Here i^* is the pullback of the embedding of $\Sigma_{1\cdots p+1}$ into M. We will see that this continuity condition arises naturally from the action principle. Define the Lagrangian on the surface $\Sigma_{1\cdots p+1}$ to be

$$\mathcal{L}(\omega^1, \ldots, \omega^{p+1}, e) = \int_0^1 dt_1 \cdots dt_p \zeta_p f(\theta^1, \theta^2, \ldots, \theta^p, \Omega_p, \ldots, \Omega_p, e_p),$$

$$(e_p)_{a_1 \cdots a_{2n}} = \frac{1}{(d-2n)!} (E_p)^{a_{2n+1}} \wedge \cdots \wedge (E_p)^{a_d} \epsilon_{a_1 \cdots a_d}, \tag{38}$$

where $E_p = E^1 - (1-t_1)(E^1 - E^2) - \cdots - (1-t_1)\cdots(1-t_p)(E^p - E^{p+1})$ and ζ_p is given by (25).

Following through the calculation of Sec. III A, we pick up extra terms, involving derivatives of E_{p-1}, from using the Leibnitz Rule on f:

$$\begin{aligned} &\frac{\partial}{\partial t_{p+1}} f(\theta^1_{p+1}, \theta^2_{p+1}, \ldots, \theta^p_{p+1}, \Omega_{p+1}, \ldots, \Omega_{p+1}, e_{p+1}) \\ &\quad = \sum_{s=1}^{p+1} f\left(\theta^1_{p+1}, \ldots, \widehat{\theta^s_{p+1}}, \ldots, \theta^{p+1}_{p+1}, \Omega_{p+1}, \ldots, \Omega_{p+1}, \frac{\partial e_{p+1}}{\partial t_s}\right) \\ &\qquad + (n-p) f(\theta^1_{p+1}, \theta^2_{p+1}, \cdot\, \theta^{p+1}_{p+1}, \Omega_{p+1}, \ldots, \Omega_{p+1}, D_{p+1} e_{p+1}) + (\cdots). \end{aligned}$$

The $(\cdots)$ are terms which appear just as in Sec. III A.

We will verify our assertion that the action is one-and-a-half order by infinitesimally varying the metric and connection in one region. We vary them as independent fields. Using t_{p+1} to interpolate between E^{p+1} and $E^{p+1} + \delta E^{p+1}$ and the corresponding variation of ω^{p+1}:

$$\delta\mathcal{L}(\omega^1, \ldots, \omega^{p+1}, e) = \int_0^1 dt_1 \cdots dt_{p+1} \zeta_p \Xi + (\cdots), \tag{39}$$

$$\begin{aligned} \Xi = &\prod_{i=1}^{p} (1-t_i) \sum_{s=1}^{p} f\left(\theta^1_{p+1}, \ldots, \widehat{\theta^s_{p+1}}, \ldots, \delta\omega^{p+1}, \Omega_{p+1}, \ldots, \Omega_{p+1}, \frac{\partial e_{p+1}}{\partial t_s}\right) \\ &- f\left(\theta^1_{p+1}, \ldots, \theta^p_{p+1}, \Omega_{p+1}, \ldots, \Omega_{p+1}, \frac{\partial e_{p+1}}{\partial t_{p+1}}\right) + \prod_{i=1}^{p} (1-t_i)(n-p+1) \\ &\times f(\theta^1_{p+1}, \ldots, \theta^p_{p+1}, \delta\omega^{p+1}, \Omega_{p+1}, \ldots, \Omega_{p+1}, D_{p+1} e_{p+1}). \end{aligned} \tag{40}$$

The $(\cdots)$ are terms which will cancel when intersections are taken into account, just as in the topological theory (provided that the metric is continuous). Above, we have made use of $\theta^{p+1}_{p+1} = -(1-t_1)\cdots(1-t_p)\,\delta\omega^{p+1}$.

We require the vanishing of the terms in (40) involving $\delta\omega^{p+1}$. Now $E_{p+1} = E^1 - (1-t_1)(E^1 - E^2) - \cdots + (1-t_1)\cdots(1-t_{p+1})\,\delta E^{p+1}$. Making use of formula (12),

$$\frac{\partial}{\partial t_s}(e_{p+1})_{a_1\cdots a_{2n}} = \frac{\partial}{\partial t_s}(E_{p+1})^b \wedge (e_{p+1})_{a_1\cdots a_{2n}b}$$
$$= \sum_{i=1}^{p} (1-t_1)\cdots\widehat{(1-t_s)}\cdots(1-t_i)(E^i - E^{i+1})^b \wedge (e_p)_{a_1\cdots a_{2n}b} + \mathcal{O}(\delta E^{p+1}). \quad (41)$$

So we see the first term in (40) vanishes if $i^*(E^{i+1}) = i^*(E^i)$ for all $i = 1\cdots p+1$, i.e., the metric is continuous. Given this, we see that

$$\begin{aligned} i^*(D_{p+1}E_{p+1}) = i^*(dE_{p+1} + \omega_{p+1}\wedge E_{p+1}) &= i^*\big(d\{E^1 + t_1(E^2 - E^1) + \cdots t_1\cdots t_{p+1}\delta E^{p+1}\} \\ &\quad + \{\omega_1 + t_1\theta^1 + \cdots + t_1\cdots t_p\delta\omega_{p+1}\}\wedge(E \\ &\quad + t_1\cdots t_{p+1}\delta E^{p+1})\big) \\ &= i^*\Bigg(D(\omega^1)E^1 + \sum_{i=1}^{p} t_1\cdots t_i(D(\omega^{i+1})E^{i+1} - D(\omega^i)E^i) \\ &\quad + \mathcal{O}(\delta\omega^{p+1}) + \mathcal{O}(\delta E^{p+1})\Bigg). \end{aligned} \quad (42)$$

The third term in (40) already contains a $\delta\omega^{p+1}$ apart from the $D_{p+1}e_{p+1}$. $D_{p+1}e_{p+1}$ is proportional to $D_{p+1}E_{p+1}$ so to first order in δE^p, this term vanishes if $D(\omega^i)E^i = 0$ for all $i = 1\ldots p$.[23]

The only nonvanishing term in (40) is the second which involves

$$\frac{\partial}{\partial t_{p+1}}(e_{p+1})_{a_1\cdots a_{2n}} = -(1-t_1)\cdots(1-t_p)(\delta E^{p+1})^b \wedge (e_{p+1})_{a_1\cdots a_{2n}b} = -(\delta e_p)_{a_1\cdots a_{2n}}.$$

So we arrive at a simple expression for the variation of the action, once the equation of motion for the connection and continuity of the metric have been substituted:

$$\delta\mathcal{L}(\omega^1, \ldots, \omega^{p+1}, e) = \int_0^1 dt_1\cdots dt_p\zeta_p f(\theta^1, \ldots, \theta^p, \Omega_p, \ldots, \Omega_p, \delta e) + (\cdots).$$

Then, variation of an ω_i will vanish automatically upon imposing the zero torsion condition and the continuity of the metric at the intersections.[24] Second, from the variation of the frame E^a we obtain a field equation for gravitation and its relation to the matter present, by

$$\delta_E S_g + \delta_E S_{\text{matter}} = 0. \quad (43)$$

The field equations are actually algebraically obtained, on the gravity side, using (12). Note that although intersections describe physically a situation such as collisions, there is a nonzero energy momentum tensor at the intersection when the theory is not linear in the curvature 2-form. The dimensionally continued nth Euler density produces a nonzero energy tensor down to d-n dimensional intersections. Explicitly, the gravitational equation of motion for a fundamental intersection $\Sigma_{1\cdots p+1}$, carrying localized matter $\mathcal{L}_{m(1\cdots p+1)}$ is

$$\int_0^1 dt_1\cdots dt_p\zeta_p\theta^1\wedge\cdots\wedge\theta^p\wedge(\Omega_p)^{n-p}\wedge\delta E\wedge e = \delta_E\mathcal{L}_{m(1\cdots p+1)}. \quad (44)$$

We have dropped the local frame index and $(\Omega_p)^{n-p} = \Omega_p\wedge\cdots\wedge\Omega_p$.

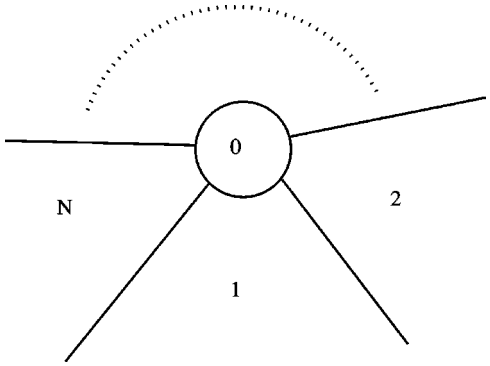

FIG. 3. The nonfundamental intersection viewed as the limit $\{0\}\to I$, where I is a co-dimension 2 surface.

IV. AN EXPLICIT EXAMPLE

We calculate the Lagrangian of the simplest intersection, that of N d-1-dimensional (non-null) surfaces intersecting at the same d-2-dimensional (non-null) surface. We then find explicitly the equations of motion for the intersection in the simplest topological density such that equations of motion are nontrivial, the $n=2$ Euler density (Gauss–Bonnet term). We also express the energy conservation in the form of relations among the energy tensors involved in this case.

A. Equation of motion

We can treat the nonsimplicial intersection with a 2-dimensional normal space as follows. We divide the space–time into $N+1$ regions formed by N surfaces intersecting a cylinder in the middle. Taking the cross section of the system, we see a circle with N outgoing lines, without further intersections (Fig. 3). We call ω the connection inside the circle and ω_i the connections of the N regions formed outside between the lines. We are going to take the limit of the circle to zero size. The intersections are N lowest-dimensional simplicial intersections. We calculate the contributions at the intersections implying that they are integrated over the same surface.

The action functional of the hypersurfaces is

$$\int_{12}\mathcal{L}(\omega_1\omega_2)+\int_{23}\mathcal{L}(\omega_2\omega_3)+\cdots+\int_{N1}\mathcal{L}(\omega_N\omega_1). \tag{45}$$

In order to calculate the equation of motion explicitly in terms of intrinsic and extrinsic curvature tensors we should introduce the connection ω_{ij} associated with the induced metric at the common boundaries. Using the composition rule

$$\mathcal{L}(\omega_i\omega_j)=\mathcal{L}(\omega_i\omega_{ij})+\mathcal{L}(\omega_{ij}\omega_j)-d\mathcal{L}(\omega_i\omega_j\omega_{ij}), \tag{46}$$

we obtain one set of contributions at the intersection, when the common boundary connections are involved.

From the N fundamental intersection, $k=3$ terms in (37), we have

$$\mathcal{L}(\omega_1\omega_2\omega)+\mathcal{L}(\omega_2\omega_3\omega)+\cdots+\mathcal{L}(\omega_N\omega_1\omega). \tag{47}$$

Up to total derivatives, the expression is independent of the connection ω, but depends only on the bulk region connections ω_i. Adding trivially a set of terms $\mathcal{L}(\omega_i\omega_1\omega)+\mathcal{L}(\omega_1\omega_i\omega)=0$, $i=3\ldots N$, and using the composition rule we have

$$\mathcal{L}(\omega_1\omega_2\omega_3)+\mathcal{L}(\omega_1\omega_3\omega_4)+\cdots+\mathcal{L}(\omega_1\omega_{N-1}\omega_N), \tag{48}$$

plus an exact form containing ω. The variation of (47) with respect to the frame gives us the equation of motion.

If we want to express things in terms of extrinsic curvatures, we can use

$$\mathcal{L}(\omega_i\omega_j\omega) + \mathcal{L}(\omega_i\omega\omega_{ij}) + \mathcal{L}(\omega\omega_j\omega_{ij}) = \mathcal{L}(\omega_i\omega_j\omega_{ij}) \tag{49}$$

(dropping the exact forms integrated on the smooth infinite intersection) and (46) and (47) to obtain finally

$$\mathcal{L}_{d-2} = (12) + (23) + \cdots + (N1); \quad (ij) = \mathcal{L}(\omega_i\omega_{ij}\omega) - \mathcal{L}(\omega_j\omega_{ij}\omega). \tag{50}$$

Clearly ω can be taken as the connection associated with the induced metric of the intersection. Now we can express everything in terms of the bulk region connections, the second fundamental forms $\theta_{i|ij}$ of the surface $\{ij\}$ induced by the region i and the χ_{ij}, the second fundamental form of the intersection regarded as the boundary of $\{ij\}$:

$$\theta_{iij} = \omega_i - \omega_{ij}, \quad \chi_{ij} = \omega_{ij} - \omega. \tag{51}$$

Note that, as the form of the Lagrangian suggests, we could directly try to build the Lagrangian by applying the method Sec. II directly without the use of a simplicial intersection and limiting cases. That is, there is nothing singular in the limit taken.

In order to write the simplest nontrivial equation of motion for the common intersection of N d-1-dimensional surfaces, we consider the $n=2$ dimensionally continued Euler density. Applying (19) or (24) we find easily

$$\mathcal{L}(\omega_i\omega_{ij}\omega) = f(\theta_{i\,ij}, \chi_{ij}). \tag{52}$$

As noted above, formula (48), the equation of motion for $\mathcal{L}_{d-2}$ w.r.t. the connection which remains vanished via the assumed zero torsion condition in the dimensionally continued theory. Varying the frame E^a we obtain the equations of motion. We define the gravity Lagrangian as $\mathcal{L}_g = \mathcal{L}^{(1)} + \alpha_1 \mathcal{L}^{(2)}$, where $\mathcal{L}^{(n)}$ is the n-th Euler Density and α_1 is the constant of dimension (length)^2, the coupling of the Gauss–Bonnet term. We express the second fundamental form θ^{ab} in terms of the extrinsic curvature K_{ab} by

$$\theta^{ab} = \theta^{cab} E_c, \quad \text{where} \quad \theta^{cab} = -\epsilon(n) 2 n^{[a} \boldsymbol{\nabla}^{\,b]} n^c = -\epsilon(n) 2 n^{[a} K^{\,b]c}, \tag{53}$$

where n^μ is the normal vector of a $(d$-1)-dimensional surface embedded in a given bulk and it carries the same indices as the θ^{ab} [see (51)] and $K_{\mu\nu} = h^\rho_\mu \boldsymbol{\nabla}_\rho n_\nu$ with $h_{\mu\nu} = g_{\mu\nu} - \epsilon(n) n_\mu n_\nu$, $\epsilon(n) = n_\mu n^\mu = \pm 1$. The vielbein e^μ_a and its inverse e^a_μ is used to change from spacetime to local frame indices. χ^{ab} is defined similarly for v^μ, the normal vector of the intersection embedded in a given $(d$-1)-dimensional hypersurface and it carries the same indices as χ^{ab}, and the extrinsic curvature $C_{\mu\nu} = \gamma^\rho_\mu h^\sigma_\nu \boldsymbol{\nabla}_\rho v_\sigma$ with $\gamma_{\mu\nu} = h_{\mu\nu} - \epsilon(v) v_\mu v_\nu$. We have

$$2\alpha_1 \sum \epsilon(n)\epsilon(v) \left\{ (\mathcal{K}\overline{C})^{ab} + (\overline{\mathcal{K}}C)^{ab} - \frac{1}{2}\gamma^{ab} \mathrm{Tr}(\mathcal{K}\overline{C} + \overline{\mathcal{K}}C) \right\} = -T^{ab}_{d-2}, \tag{54}$$

where $\mathcal{K}_{ab}$ is the projection of K_{ab} on the intersection. Clearly the sum in (54) is over all terms in (50), one for each embedding of each $(d$-1)-surface in the adjacent bulk region. We use the notation $\overline{\mathcal{K}}_{ab} = \mathcal{K}_{ab} - \gamma_{ab}\mathcal{K}$, where $\mathcal{K} = \gamma^{ab}\mathcal{K}_{ab}$, and compact matrix multiplication, for example $(\mathcal{K}\overline{C})^{ab} = \mathcal{K}^c_a \overline{C}^{cb}$. T^{ab}_{d-2} is the energy momentum tensor which in general should be localized at the intersection.

B. Energy conservation at the intersection

Let us see the implications of these results for the question of energy conservation. We recall that the local expression of the energy-momentum tensor conservation is related to the diffeomorphism invariance of the action, under which the metric tensor changes as $\delta g_{ab} = 2\boldsymbol{\nabla}_{(a}\,\xi_{\,b)}$ where $\xi^a = \delta x^a(x)$ are infinitesimal coordinate transformations. Note that $2\boldsymbol{\nabla}_{(a}\xi_{b)} = \delta g_{ab}$ has to be continuous.

Let us first consider the case of an intersection whose action term is zero. Let N regions intersect, labeled by i, at a common intersection I. We write the energy exchange relations in the system as

$$\delta_\xi S_{\text{matter}} = \sum_i \int_i T_d^{ab} \boldsymbol{\nabla}_a \xi_b + \frac{1}{2} \sum_{i,j=i\pm1} \int_{ij} T_{d-1}^{ab} \boldsymbol{\nabla}_a \xi_b = 0, \tag{55}$$

where the normal vectors obey $n_{ij} = -n_{ji}$, $j = i \pm 1$. Then by $\xi_b = \xi_{\|b} + \epsilon(n) n_b n^c \xi_c$ with $\xi_{\|b} = h_b^c \xi_c$ we obtain

$$\begin{aligned} &- \sum_i \int_i \boldsymbol{\nabla}_a T_d^{ab} \xi_b + \sum_{ij} \int_{ij} \epsilon(n) n_a T_d^{ab} h_b^c \xi_c - \frac{1}{2} D_a T_{d-1}^{ab} \xi_b + \sum_{ij} \int_{ij} n_a T_d^{ab} n_b n^c \xi_c \\ &\quad + \frac{1}{2} T_{d-1}^{ab} K(n)_{ab} \epsilon(n) n^c \xi_c + \int_I \sum_{ij} \frac{1}{2} \epsilon(v) v_a T_{d-1}^{ab} \xi_b = 0, \end{aligned} \tag{56}$$

where $K(n)_{ab} = h_a^c \boldsymbol{\nabla}_c n_b$ and $n^a; K_{ab}$ carries an index ij. Also $j = i \pm 1$; the same for v^a which is the normal on I induced by ij pointing outwards. Recall that integrals are taken over the interiors of the sets. Along with the known relations we then obtain the ones related with the intersection

$$\sum \epsilon(v) v_a T_{d-1}^{ab} \gamma_b^c = 0, \quad \sum v_a T_{d-1}^{ab} v_b v^c = 0, \tag{57}$$

where the sum is over all shared boundaries. γ_{ab} is the induced metric at I.

Equation (57) implies that the total energy current density at the intersection or collision is zero. This is valid though when the energy tensor at the intersection vanishes identically. On the other hand, as we have learned, the energy tensor is not zero in general and the energy conservation has to take into account this lower-dimensional energy tensor existing at the intersection hypersurface. In such a case there is an additional term in (55) that can be written as

$$\frac{1}{2N} \int_I \sum_{ij} T_{d-2}^{ab} \boldsymbol{\nabla}_a \xi_b, \tag{58}$$

where we sum over the contribution from each side of every shared boundary for N regions. T_{d-2}^{ab} is the total energy momentum tensor on I. We decompose $\xi_b = \xi_{\|b} + \epsilon(n) n_b n^c \xi_c + \epsilon(v) v_b v^c \xi_c$ where $\xi_{\|b} = \gamma_b^c \xi_c$. We then have

$$- \int_I \mathcal{D}_a T_{d-2}^{ab} \xi_{\|b} + \int_I \mathcal{D}_a (T_{d-2}^{ab} \xi_{\|b}) + \int_I T_{d-2}^{ab} \frac{1}{N} \sum_{ij} (\epsilon(n) \mathcal{K}_{ab} n^c + \epsilon(v) C_{ab} v^c) \xi_c; \tag{59}$$

$\mathcal{D}$ is the covariant derivative associated with γ. The second term is useful when the intersection is not smooth itself. The energy exchange relation are then

$$\sum \epsilon(v) v_a T_{d-1}^{ab} \gamma_b^c = \mathcal{D}_a T_{d-2}^{ac} \sum v_a T_{d-1}^{ab} v_b v^c + T_{d-2}^{ab} \frac{1}{N} \sum_{ij} (\epsilon(n) \mathcal{K}_{ab} n^c + \epsilon(v) C_{ab} v^c) = 0, \tag{60}$$

where the first sums are over all shared boundaries.

For a collision of hypersurfaces, the intersection surface will be space-like. The v vectors are time-like (velocity) vectors. We assume the hypersurface matter of the form

$$v^a v^b T_{ab} = \rho, \quad \gamma_c^a T_{ab} v^b = 0. \tag{61}$$

The first of (57) is satisfied automatically while the second becomes

$$\sum_{\Lambda} \rho_{\Lambda} v_{\Lambda}^{a} = 0, \tag{62}$$

where the upper case greek index counts the hypersurfaces. We can recover the results of Langlois, Maeda, and Wands[11] by first introducing the ortho-normal basis at the intersection. The basis is taken to line up with the two vectors v_{Λ} and n_{Λ} of one of the hypersurfaces:

$$E_{(0)} = v_{\Lambda}, \quad E_{(1)} = n_{\Lambda}. \tag{63}$$

We can write the other v vectors in the following way, motivated by special relativity,

$$v_{\Xi} = \gamma_{\Xi|\Lambda} E_{(0)} + \gamma_{\Xi|\Lambda} \beta_{\Xi|\Lambda} E_{(1)}, \tag{64}$$

where the β and γ have the usual interpretation from S.R. Hence, the two components of Eq. (62) are

$$\sum_{\Xi} \rho_{\Xi} \gamma_{\Xi|\Lambda} = 0, \tag{65}$$

$$\sum_{\Xi} \rho_{\Xi} \gamma_{\Xi|\Lambda} \beta_{\Xi|\Lambda} = 0. \tag{66}$$

These are the results found in Ref. 11; they are conservation of energy and momentum, respectively.

The hypersurfaces obey the same rules in terms of the local inertial frame as do point particle collisions in two dimensions. This is true for quite general bulk backgrounds. The only essential feature is the absence of a deficit angle at the collision. This means that there is a well-defined local inertial frame at the collision and the S.R. addition of velocities applies.

We have calculated the contribution to the energy–momentum tensor at the collision due to the junction conditions. Our calculation implicitly assumed that there was no conical singularity (see the footnote to Lemma 3). There may be some correction to this from a conical singularity. If we impose some reasonable energy condition such as the dominant energy condition, this space-like matter should vanish—the two contributions should cancel. The assumption of no conical deficit is then justified for the *Einstein* theory, because we have seen that there is no contribution due to the junction conditions. But this would not be so for the Gauss–Bonnet theory. In that case, the cancellation would demand that there be a conical singularity at the collision. Conversely, if we impose that there be no such singularity, we must have space-like matter localized at the collision.

Since completion of this work, intersecting branes in Lovelock gravity have been studied by Lee and Tasinato[25] and by Navarro and Santiago.[26] A further analysis of the geometry of intersections has been done by us in Ref. 27.

[23] The general gravitation theory we consider is built as a sum of a desired set of dimensionally continued topological densities. The coefficients can be taken to be functions of scalar fields, making the theory dilatonic. The variation with respect to the connection leads to a nonzero torsion in this case. The torsion equation is a constraint on the variation of the scalar fields. Solving it for the connection and substituting in the Lagrangian one obtains explicitly an action for the dilatonic fields.
[24] The equations of motion for ω are satisfied by the zero torsion condition but are not, for $n \geqslant 1$, identical to it. There are potentially solutions of nonvanishing torsion; see Ref. 19.

We give an asymptotic upper bound as $n\to\infty$ for the entropy integral, $E_n(w) = -\int p_n^2(x)\log(p_n^2(x))w(x)dx$, where p_n is the nth degree orthonormal polynomial with respect to a weight $w(x)$ on $[-1,1]$ which belongs to the Szegő class. We also study two functionals closely related to the entropy integral. First, their asymptotic behavior is completely described for weights w in the Bernstein class. Then, as for the entropy, we obtain asymptotic upper bounds for these two functionals when $w(x)$ belongs to the Szegő class. In each case, we give conditions for these upper bounds to be attained. © *2004 American Institute of Physics.*

I. INTRODUCTION

In the framework of the density functional theory (see, e.g., Refs. 6 and 11), the physical and chemical properties of fermionic systems are described by means of the single-particle probability densities. If $\Psi(\vec{r})$ is the wave function of a single-particle system in a (D-dimensional) position space, and $\hat{\Psi}(\vec{p})$ is the corresponding wave function in momentum space [that is, the Fourier transform of $\Psi(\vec{r})$], then the position and momentum densities of the system are given by

$$\rho(\vec{r}) = |\Psi(\vec{r})|^2, \quad \gamma(\vec{p}) = |\hat{\Psi}(\vec{p})|^2,$$

respectively. It is known that the Boltzmann–Gibbs–Shannon position–space entropy,

$$S(\rho) = -\int \rho(\vec{r})\log\,\rho(\vec{r})d\vec{r},$$

measures the uncertainty in the localization of the particle in space (lower entropy indicates a more concentrated wave function, with the associated higher accuracy in predicting the localization of the particle). The similar is true for the momentum–space entropy,

a)Corresponding author. Electronic mail: andrei@ual.es

$$S(\gamma) = -\int \gamma(\vec{p})\log\ \gamma(\vec{p})d\vec{p}.$$

These quantities have importance in the study of the structure and dynamics of atomic and molecular systems; we refer the reader to the survey[5] and to references therein. Both $S(\rho)$ and $S(\gamma)$ also play a role in a generalization of the Heisenberg uncertainty relation: it has been established[3] that for any pair of densities $\rho(\vec{r})$ and $\gamma(\vec{p})$ in D-dimensional space, we have the sharp inequality

$$S(\rho) + S(\gamma) \geqslant D(1 + \log\ \pi), \tag{1}$$

which expresses quantitatively the impossibility of the simultaneous localization of a pair of observables with no common eigenstates.

It is well known that the wave function of many important systems, such as D-dimensional harmonic oscillator and hydrogen atom, are expressible in terms of families of orthogonal polynomials. It is not surprising that, as it has been shown in Refs. 4 and 13, the computation of the entropies $S(\rho)$ and $S(\gamma)$ usually can be reduced to integrals involving these polynomials.

Let ν be a positive unit Borel measure on $\Delta := [-1,1]$ and let

$$p_n(x) = \gamma_n \prod_{j=1}^{n} (x - \zeta_j^{(n)}), \quad \gamma_n > 0, \quad n \in \mathbb{N},$$

denote the corresponding sequence of *orthonormal* polynomials such that

$$\int p_n(x)p_m(x)d\nu(x) = \delta_{mn}, \quad m,n \in \mathbb{N}.$$

We define the *information entropy* of the polynomials $p_n(x)$ as

$$E_n = E_n(\nu) = -\int p_n^2(x)\log(p_n^2(x))d\nu(x). \tag{2}$$

Throughout the paper, we will assume that the orthogonality measure ν is absolutely continuous with respect to the Lebesgue measure λ on Δ with the Radon–Nikodym derivative

$$d\nu/d\lambda = \nu'(x) = w(x), \quad w \in L^1(\Delta).$$

For normalization purposes, we will always assume that the weight w is unitary, i.e.,

$$\int_{\Delta} w(x)dx = 1. \tag{3}$$

The information entropy will be indistinctly denoted by $E_n(\nu)$ and $E_n(w)$. We follow this convention below for other notations.

The asymptotic behavior of E_n as $n \to \infty$ has a special interest in the study of the so-called Rydberg states of quantum-mechanical systems. Besides physical motivations, there are some fascinating aspects of this problem because of a certain universal behavior of related integrals, and because of a close connection of the entropy E_n with important functionals of the normalized zero counting measures of the polynomials p_n,

$$\mu_n = \frac{1}{n}\sum_{j=1}^{n} \delta_{\zeta_j^{(n)}}, \quad n > 0,$$

and of the following probability measures ν_n:

$$d\nu_n(x) = p_n^2(x)d\nu(x), \quad n \geqslant 0$$

(note that $\nu_0 = \nu$). Both measures are standard objects of study in the analytic theory of orthogonal polynomials. For instance, the normalized zero counting measure μ_n is closely connected with the nth root asymptotics of p_n, and as was shown in Ref. 12, ν_n is associated with the behavior of the ratio p_{n+1}/p_n as $n \to \infty$.

If μ and ν are positive Borel measures on $\mathbb{C}$, then their *mutual entropy* is defined as

$$S(u,v) = \begin{cases} -\infty & \text{if } \mu \text{ is not } \nu\text{-absolutely continuous,} \\ -\int \log\left(\dfrac{d\mu}{d\nu}\right)d\mu & \text{if } \mu \text{ is } \nu\text{-absolutely continuous,} \end{cases}$$

and their *mutual logarithmic energy* as

$$I(\nu,\mu) = -\int\int \log|z-t|d\nu(t)d\mu(z).$$

With these notations the entropy (2) is equivalently rewritten as

$$E_n(\nu) = S(\nu_n,\nu) = -2\log\gamma_n + 2n\, I(\mu_n,\nu_n). \tag{4}$$

In particular, from a classical Jensen's inequality for integrals, it follows immediately that if both μ and ν are unit measures on Δ, then $S(\mu,\nu) \leqslant 0$, with equality if and only if $\mu = \nu$. Hence,

$$E_n(\nu) \leqslant 0,$$

with equality if and only if $n = 0$.

Aptekarev *et al.*[1] considered two subfamilies of the usual Szegő class of weights on Δ, namely the Jacobi weights and the Bernstein-Szegő class (weights being bounded above, bounded away from zero, and satisfying a Dini–Lipschitz condition). In this last case it is known that the asymptotic formula for the orthogonal polynomials p_n holds uniformly in Δ, as n tends to infinity. With these assumptions it has been proved in Ref. 1 that

$$\lim_{n\to\infty} E_n(w) = S(\rho,w) + \log(2) - 1, \tag{5}$$

where

$$\rho(x) = 1/(\pi\sqrt{1-x^2})$$

denotes the Chebyshev unit weight on Δ. We are concerned here with the problem of whether a weaker form of this equality holds in the Szegő class of weights. We will show that the right-hand side of (5) is actually an asymptotic upper bound for the entropy $E_n(w)$ when the weight w satisfies the Szegő condition [see assumption (6) below]. Furthermore, the expression (2) for the entropy can be naturally split into two functionals, which have simple asymptotic behaviors when w belongs to the Bernstein class (see Proposition 1). The situation with the Bernstein class is in a sense optimal: the corresponding limits provide asymptotic upper bounds for w in the whole Szegő class. We also give conditions for the entropy and the two functionals to tend to their upper bounds as the degree n becomes large.

Finally, we must mention that in the case of an unbounded support of the weight of orthogonality interesting results concerning the asymptotics of the E_n and related functionals have been obtained recently in Ref. 9.

II. STATEMENTS OF RESULTS

The weighted L^p norm of a function f with respect to a weight k on Δ will be denoted by

$$\|f\|_{L^p(k)} = \left(\int_\Delta |f(x)|^p k(x) dx \right)^{1/p}, \quad 1 \leqslant p \leqslant \infty.$$

We will simply write L^p when $k \equiv 1$ on Δ.

Though our main interest in this paper lies in the Szegő class of weights, some other classes appear at different places. We recall the definitions of these classes now.

The *Erdős–Turan class* $\mathcal{ET}$ consists of weights $w \in L^1$ such that $w > 0$ almost everywhere on Δ.

The *Szegő class* $\mathcal{S}$ consists of weights $w \in L^1$ such that

$$\log(w_0) \in L^1(\rho), \tag{6}$$

where

$$w_0(x) := w(x)/\rho(x) = \pi\sqrt{1-x^2}w(x)$$

denotes the trigonometric weight corresponding to w. The fact that $w_0 \in L^1(\rho)$ implies $\log^+(w_0) \in L^1(\rho)$, where, as usual, we denote

$$\log^+(x) = \max\{\log(x), 0\}, \quad x > 0.$$

Hence, condition (6) is actually equivalent to

$$S(\rho, w) = \int_\Delta \log(w_0(x))\rho(x)dx > -\infty. \tag{7}$$

Note that (6) and (7) can equivalently be rewritten as $\log(w) \in L^1(\rho)$ and

$$\int_\Delta \log(w(x))\rho(x)dx > -\infty,$$

respectively.

Finally, the *Bernstein class* $\mathcal{B}$ consists of weights w such that w_0 is given by the reciprocal of a positive polynomial on Δ. As it is well-known, the class $\mathcal{B}$ is an important class useful for establishing asymptotic properties in the Szegő theory of orthogonal polynomials. Obviously, one has the following inclusions $\mathcal{B} \subset \mathcal{S} \subset \mathcal{ET}$.

We will also use the notations

$$f_n(x) := p_n(x)\sqrt{w_0(x)}, \tag{8}$$

and for $M > 0$,

$$\Delta_n(M) := \{x \in \Delta : |f_n(x)| \geqslant M\}. \tag{9}$$

One of the main results of the paper is the following theorem.

Theorem 1: *Assume that the weight w belongs to the Szegő class* $\mathcal{S}$*. Then, for all* $M > \sqrt{2}$,

$$E_n(w) = S(\rho, w) + \log(2) - 1 - \int_{\Delta_n(M)} p_n^2(x)\log^+(p_n^2(x))w(x)dx + o(1), \quad n \to \infty. \tag{10}$$

As a simple consequence of the above formula, we obtain the following asymptotic upper bound together with necessary and sufficient conditions for equality.

Corollary 1: Assume that the weight w belongs to the Szegő class $\mathcal{S}$*. Then the following asymptotic upper bound for the entropy holds:*

$$\limsup_{n\to\infty} E_n(w) \leqslant S(\rho, w) + \log(2) - 1. \tag{11}$$

Moreover, for a subsequence $n \in \Lambda \subset \mathbb{N}$,

$$\lim_{n\in\Lambda} E_n(w) = S(\rho,w) + \log(2) - 1, \tag{12}$$

if and only if there exists a constant $M > \sqrt{2}$, *such that*

$$\lim_{n\in\Lambda} \int_{\Delta_n(M)} p_n^2(x)\log^+(p_n^2(x))w(x)dx = 0. \tag{13}$$

In this case (13) is valid for all $M > \sqrt{2}$.

Furthermore, (13) holds if there exists $\varepsilon > 0$ *such that either*

$$\sup_{n\in\Lambda} \int_\Delta (\log^+(p_n^2(x)))^{1+\varepsilon} p_n^2(x)w(x)dx < \infty \quad or \quad \sup_{n\in\Lambda} \int_\Delta (p_n^2(x))^{1+\varepsilon} w(x)dx < \infty. \tag{14}$$

Remark 1: Notice that the findings of Ref. 1 on Bernstein–Szegő polynomials are included in Corollary 1 since for $w \in \mathcal{B}$, $\log(w_0)$ is bounded and the f_n are uniformly bounded in $[-1,1]$. In contrast, the case of Jacobi polynomials requires some extra considerations. One knows that for the orthonormal Jacobi polynomials there exists a constant c such that for $n \geqslant 0$ and $x \in [-1,1]$,

$$|P_n^{(\alpha,\beta)}(x)| \cdot \left(\sqrt{1-x} + \frac{1}{n}\right)^{\alpha+1/2} \left(\sqrt{1+x} + \frac{1}{n}\right)^{\beta+1/2} \leqslant c/\sqrt{\pi}.$$

Taking into account that here $w_0(x) = \pi(1-x)^{\alpha+1/2}(1+x)^{\beta+1/2}$, we find that for $p_n = P_n^{(\alpha,\beta)}$,

$$(p_n(x))^{2+\varepsilon} w_0(x) \leqslant c\sqrt{\pi} \left(\frac{1-x}{(\sqrt{1-x}+1/n)^{2+\varepsilon}}\right)^{\alpha+1/2} \left(\frac{1+x}{(\sqrt{1+x}+1/n)^{2+\varepsilon}}\right)^{\beta+1/2},$$

and the second condition in (14) is satisfied.

Remark 2: An inequality weaker than (11) is a straightforward consequence of the asymptotic behavior of the measures ν_n. Indeed, if $w \in \mathcal{ET}$, we know from Rakhmanov's Theorem[12] that $d\nu_n(x) \to \rho(x)dx$ as $n \to \infty$ in the weak-* topology. It follows from the weak upper semicontinuity of the mutual entropy (Ref. 7, Corollary 5.3) that lim sup $E_n(w) =$ lim sup $S(\nu_n, w) \leqslant S(\rho, w)$. In particular, it shows that if the weight w is in $\mathcal{ET}\backslash\mathcal{S}$,

$$\lim_{n\to\infty} E_n(w) = -\infty.$$

Nevertheless, it seems that a semicontinuity argument for the entropy does not allow us to explain the additional term $\log(2)-1$ occurring on the right-hand side of (12).

The information entropy for Chebyshev polynomials orthonormal with respect to ρ has been computed in Refs. 4,14:

$$E_n(\rho) = \log(2) - 1, \quad \text{for} \quad n \geqslant 1. \tag{15}$$

Intuitively, Chebyshev polynomials are the most "uniformly" distributed polynomials, both for each n and asymptotically as $n \to \infty$. This fact is formally set in the next corollary.

Corollary 2: If

$$\limsup_{n\to\infty} E_n(w) \geqslant \log(2) - 1, \tag{16}$$

then $w = \rho$ *and* $E_n(w) = \log(2) - 1$, $n \geqslant 1$.

The proof is a simple consequence of inequality (11). Indeed, from this inequality, we see that (16) can only happen if $S(\rho,w) = 0$ that is $\rho = w$.

Now we exploit the connection between the entropy $E_n(w)$ and the mutual energy $I(\mu_n, \nu_n)$ given in (4). It is well known that in the class $\mathcal{ET}$ both μ_n and ν_n tend (as $n \to \infty$) to the Chebyshev (equilibrium) distribution given by the weight ρ on Δ. In particular, from the convexity properties of the mutual energy it follows that

$$\lim_{n\to\infty} I(\mu_n, \nu_n) = I(\rho, \rho) = \log(2).$$

What is more surprising is that the next term of the asymptotic expansion of $I(\mu_n, \nu_n)$ also exhibits a "universal" behavior, in the sense that it does not depend on the choice of the weight w. Namely, if the entropy $E_n(w)$ satisfies (12), then the following result is a direct consequence of (4) and the well known asymptotic behavior of the leading coefficient of p_n [see (29)].

Corollary 3: Assume w is a weight in the Szegő class $\mathcal{S}$ and condition (13) is satisfied. Then the mutual energy $I(\mu_n, \nu_n)$ has the following asymptotic expansion:

$$I(\mu_n, \nu_n) = \log(2) - \frac{1}{2n} + o\left(\frac{1}{n}\right), \quad n \in \Lambda, \quad n \to \infty.$$

This remarkable fact certainly deserves further study.

Another aim of the paper is to study two related functionals F_n and G_n, whose sum equals the entropy,

$$E_n(w) = F_n(w) + G_n(w),$$

and which are defined by

$$F_n(w) = -\int_\Delta \log(p_n^2(x) w_0(x)) p_n^2(x) w(x) dx = S(f_n^2 \rho, \rho), \tag{17}$$

and

$$G_n(w) = \int_\Delta \log(w_0(x)) p_n^2(x) w(x) dx = -S(p_n^2 w, p_n^2 \rho). \tag{18}$$

We will see that the functional F_n also exhibits a "universal" behavior, while G_n is sensitive to a particular choice of the weight w, and is related naturally with the mutual entropy $S(\rho, w)$. Functionals F_n and G_n have a particularly nice behavior for w in the Bernstein class $\mathcal{B}$:

Proposition 1: Let S be a polynomial of degree $2N$ $(N \geqslant 0)$ such that $S(x) > 0$ for $x \in \Delta$, and assume that the orthogonality weight satisfies

$$w_0(x) = \frac{1}{S(x)}, \quad x \in \Delta.$$

Then

$$F_n(w) = \log(2) - 1, \quad \textit{for} \quad n > N. \tag{19}$$

Moreover,

$$\lim_{n\to\infty} G_n(w) = S(\rho, w), \tag{20}$$

and this limit takes place with a geometric rate. Consequently, the same holds true for the limit in (5).

The conjecture that constant entropy $E_n(w)$ is a (yet another) characterization of Chebyshev polynomials [cf. (15)] belongs to Golinsky. We were able to prove it in the Bernstein class $\mathcal{B}$.

Proposition 2: Let $w \in \mathcal{B}$ such that $E_n(w)$ is constant for all sufficiently large n. Then $w = \rho$.

Since Bernstein weights are suitable as approximation tool for the whole Szegő class, we could expect the asymptotic behavior from Proposition 1 to hold in a more general setting. Nevertheless, the behavior of the entropy, as well as the behavior of the two functionals F_n and G_n is extremely sensitive to the growth of $p_n^2 w$, which may affect convergence. In general, the following expression for the first functional F_n holds true:

Theorem 2: *Assume the weight w belongs to the Szegő class $\mathcal{S}$. Then, for all $M>\sqrt{2}$,*

$$F_n(w) = \log(2) - 1 - \int_{\Delta_n(M)} \log(f_n^2(x)) f_n^2(x)\rho(x)dx + o(1), \quad n \to \infty. \tag{21}$$

Again, as a simple consequence of the above formula, we get the following corollary.

Corollary 4: Assume the weight w belongs to the Szegő class $\mathcal{S}$. Then, the following asymptotic upper bound for F_n holds:

$$\limsup_{n\to\infty} F_n(w) \leqslant \log(2) - 1. \tag{22}$$

Moreover, for a subsequence $n \in \Lambda \subset \mathbb{N}$,

$$\lim_{n\in\Lambda} F_n(w) = \log(2) - 1, \tag{23}$$

if and only if there exists a constant $M>\sqrt{2}$, such that

$$\lim_{n\in\Lambda} \int_{\Delta_n(M)} f_n^2(x)\log(f_n^2(x))\rho(x)dx = 0, \tag{24}$$

for f_n and $\Delta_n(M)$ defined in (8) and (9), respectively. In this case, (24) is valid for every $M>\sqrt{2}$.

Furthermore, (24) holds if there exists an $\varepsilon>0$ such that either

$$\sup_{n\in\Lambda} \int_{\Delta} (\log^+(f_n^2(x)))^{1+\varepsilon} f_n^2(x)\rho(x)dx < \infty \quad \text{or} \quad \sup_{n\in\Lambda} \int_{\Delta} (f_n^2(x))^{1+\varepsilon}\rho(x)dx < \infty. \tag{25}$$

Remark 3: The method of proof of Theorem 2 can be applied to larger classes of weights. In fact, we only need an L^2 asymptotics of the polynomials p_n on the support Δ of the measure ν, and that has been extended beyond the Szegő class. For instance, using our technique we can prove that (11) is valid for weights $w \in \mathcal{F}(dini)$, introduced in Ref. 8.

Remark 4: Apparently, a necessary condition for (25) is that $w_0 \log(w_0) \in L^1(\rho)$ [cf. with (6)]. If $\log(w_0) \in L^\infty$ then there is equivalence between conditions (13) and (24), and between (14) and (25), respectively.

Concerning the second functional G_n, we use a result from Ref. 10 to deduce the following proposition.

Proposition 3: Assume the weight w belongs to the Szegő class $\mathcal{S}$ and $\log^+(w_0) \in L^\infty$; *then*

$$\limsup_{n\to\infty} G_n(w) \leqslant S(\rho,w) = \int_{\Delta} \log(w_0(x))\rho(x)dx. \tag{26}$$

Similarly, assume that $\log^-(w_0) \in L^\infty$; then

$$\liminf_{n\to\infty} G_n(w) \geqslant S(\rho,w) = \int_{\Delta} \log(w_0(x))\rho(x)dx. \tag{27}$$

Hence, if $\log(w_0) \in L^\infty$, *then*

$$\lim_{n\to\infty} G_n(w) = S(\rho,w).$$

Furthermore, if the weight w belongs to the set $\mathcal{ET}\backslash\mathcal{S}$, *the assumption* $\log^+(w_0)\in L^\infty$ *still implies inequality (26). In this case, (26) simplifies to* $\lim_{n\to\infty}G_n(w)=-\infty$.

III. PROOFS OF THEOREMS 1 AND 2, COROLLARIES 1 AND 4

Before entering the proofs of our results, let us state two preliminary lemmas. The first one is borrowed from Ref. 1.

Lemma 1 (Ref. 1, Lemma 2.1): Let g be a continuous function on $\mathbb{R}$, $g(\theta+\pi)=g(\theta)$, $f\in L^1([0,\pi])$, *and let* $\gamma(\theta)$ *be a function that is measurable and almost everywhere finite on* $[0,\pi]$. *Then, as* $n\to\infty$,

$$\int_0^\pi g(n\theta+\gamma(\theta))f(\theta)d\theta\to\frac{1}{\pi}\int_0^\pi g(\theta)d\theta\int_0^\pi f(\theta)d\theta.$$

As remarked in Ref. 1, when $\gamma(\theta)=0$ and $g\in L^\infty[0,\pi]$, the statement of the lemma becomes a well-known result of Fejer; cf. Ref. 2, Chap. I, Sec. 20.

As the second main ingredient in our proofs let us recall the Szegő asymptotics for $f_n(x)=\sqrt{w_0(x)}p_n(x)$: if

$$g_n(x)=\sqrt{2}\cos(n\arccos x+\gamma(x)),$$

where

$$\gamma(x)=\frac{1}{2\pi}\int_\Delta\frac{\log w_0(x)-\log w_0(t)}{x-t}\sqrt{\frac{1-x^2}{1-t^2}}dt$$

is the harmonic conjugate function to $\log w_0$; then in the Szegő class $\mathcal{S}$, one has

$$\lim_{n\to\infty}\|f_n-g_n\|_{L^2(\rho)}=0, \tag{28}$$

and

$$\lim_{n\to\infty}\log\left(\frac{\gamma_n}{2^n}\right)=-\frac{1}{2}(\log(2)+S(\rho,w)). \tag{29}$$

The mutual entropy on the right-hand side of (29) is known as the Szegő constant for the weight w. Since the entropy integral is very sensitive to the growth of $f_n^2=p_n^2w_0$, the following lemma will be useful; roughly speaking, it shows that the subsets $\Delta_n(M)$, defined in (9), have no influence on the L^2 asymptotics (28):

Lemma 2: For $w\in\mathcal{S}$,

$$\lim_{n\to\infty}\int_{\Delta_n(M)}\rho(x)dx=0, \tag{30}$$

for every $M>\sqrt{2}$. *Furthermore, let* $\widetilde{f}_n$, $n\geqslant 0$, *be the sequence of truncated functions,*

$$\widetilde{f}_n(x):=\begin{cases}f_n(x), & \text{for } x\in\Delta\setminus\Delta_n(M),\\ 1, & \text{for } x\in\Delta_n(M).\end{cases} \tag{31}$$

Then

$$\lim_{n\to\infty}\|\widetilde{f}_n-g_n\|_{L^2(\rho)}=0. \tag{32}$$

Proof: Observe first that by the Cauchy–Schwarz inequality,

$$\int_\Delta |f_n^2(x) - g_n^2(x)|\rho(x)dx \leqslant \|f_n + g_n\|_{L^2(\rho)} \cdot \|f_n - g_n\|_{L^2(\rho)} \leqslant (\|f_n\|_{L^2(\rho)} + \|g_n\|_{L^2(\rho)}) \cdot \|f_n - g_n\|_{L^2(\rho)},$$

so that

$$\int_\Delta |f_n^2(x) - g_n^2(x)|\rho(x)dx \leqslant (1 + \sqrt{2})\|f_n - g_n\|_{L^2(\rho)}. \tag{33}$$

Now we can show that the Chebyshev (and hence, Lebesgue) measure of $\Delta_n(M)$ is asymptotically vanishing: by (33),

$$\begin{aligned}(M^2 - 2)\int_{\Delta_n(M)} \rho(x)dx &\leqslant \int_{\Delta_n(M)} (f_n^2(x) - 2)\rho(x)dx \\ &\leqslant \int_{\Delta_n(M)} |f_n^2(x) - g_n^2(x)|\rho(x)dx \leqslant (1 + \sqrt{2})\|f_n - g_n\|_{L^2(\rho)},\end{aligned}$$

the right-hand side tending to zero as $n \to \infty$ by (28); this proves (30). Moreover, since $|\tilde{f}_n(x)| = 1$ and $|g_n(x)| \leqslant \sqrt{2}$ for $x \in \Delta_n(M)$, we have by (33),

$$\begin{aligned}\|\tilde{f}_n - g_n\|_{L^2(\rho)}^2 &= \int_{\Delta \setminus \Delta_n(M)} |f_n(x) - g_n(x)|^2\rho(x)dx + \int_{\Delta_n(M)} |\tilde{f}_n(x) - g_n(x)|^2\rho(x)dx \\ &\leqslant (1 + \sqrt{2})\|f_n - g_n\|_{L^2(\rho)} + 3\int_{\Delta_n(M)} \rho(x)dx.\end{aligned}$$

It remains to use (28) and (30) to see that (32) is satisfied. □

A. Proof of Theorem 1

Fix arbitrary $M > \sqrt{2}$ and let $\Delta_n(M)$ and $\tilde{f}$ be as defined in (9) and (31), respectively. We write the entropy as

$$E_n(w) = S(f_n^2\rho, w) = S(g_n^2\rho, w) + [S(\tilde{f}_n^2\rho, w) - S(g_n^2\rho, w)] + [S(f_n^2\rho, w) - S(\tilde{f}_n^2\rho, w)]. \tag{34}$$

In three steps let us prove that the first term on the right has as a limit the first three terms on the right-hand side of (1), the second term tends to 0, and the third term is asymptotically negative and related to the integral in (1).

Let

$$\mathcal{R}(y) = y^2 \log(y^2), \quad y \in \mathbb{R}.$$

From Lemma 1 we get

$$\begin{aligned}\lim_{n\to\infty} S(g_n^2\rho, w) &= -\lim_{n\to\infty}\int_0^\pi \mathcal{R}(g_n(\cos(\theta)))\frac{d\theta}{\pi} + \lim_{n\to\infty}\int_0^\pi \log(w_0(\cos(\theta)))g_n^2(\cos(\theta))\frac{d\theta}{\pi} \\ &= -\int_0^\pi \mathcal{R}(\sqrt{2}\cos(\theta))\frac{d\theta}{\pi} + \int_0^\pi 2\cos^2(\theta)\frac{d\theta}{\pi}\int_0^\pi \log(w_0(\cos(\theta)))\frac{d\theta}{\pi} \\ &= E_1(\rho) + S(\rho, w) = \log(2) - 1 + S(\rho, w).\end{aligned} \tag{35}$$

Hence the first term on the right-hand side of (34) has the required limit. The second term in (34) can be written as

$$S(\widetilde{f}_n^2\rho,w)-S(g_n^2\rho,w)=\int_\Delta\left[\mathcal{R}\left(\frac{\widetilde{f}_n(x)}{\sqrt{w_0(x)}}\right)-\mathcal{R}\left(\frac{g_n(x)}{\sqrt{w_0(x)}}\right)\right]w(x)dx. \tag{36}$$

Recall that both $\widetilde{f}_n$ and g_n are uniformly bounded on Δ by M, and hence for $x\in\Delta$,

$$\left|\mathcal{R}\left(\frac{\widetilde{f}_n(x)}{\sqrt{w_0(x)}}\right)\right|w_0(x)\leqslant|\mathcal{R}(\widetilde{f}_n(x))|+|\log(w_0(x))|\widetilde{f}_n^2(x)\leqslant M^2\log M^2+M^2|\log(w_0(x))|=:h(x),$$

where $h\in L^1(\rho)$ by assumption (6). Similarly,

$$\left|\mathcal{R}\left(\frac{g_n(x)}{\sqrt{w_0(x)}}\right)\right|w_0(x)\leqslant h(x),\quad x\in\Delta.$$

The integral in (36) will be split into two parts depending on whether w_0 is small or large. Fix an arbitrary $0<\varepsilon<1$; by the monotone convergence theorem there exists a constant $C=C(\varepsilon)$ such that

$$0\leqslant\int_{h(x)>C}h(x)\rho(x)dx=\int_\Delta h(x)\rho(x)dx-\int_{h(x)\leqslant C}h(x)\rho(x)dx<\varepsilon.$$

Defining $\tau:=M^2\exp(-C/M^2)$ we see that $w_0(x)<\tau$ implies that $h(x)>C$, and hence

$$\left|\int_{w_0(x)<\tau}\left[\mathcal{R}\left(\frac{\widetilde{f}_n(x)}{\sqrt{w_0(x)}}\right)-\mathcal{R}\left(\frac{g_n(x)}{\sqrt{w_0(x)}}\right)\right]w(x)dx\right|\leqslant 2\int_{w_0(x)<\tau}h(x)\rho(x)dx\leqslant 2\varepsilon.$$

On the other hand, if $w_0(x)\geqslant\tau$, then

$$\left|\frac{\widetilde{f}_n(x)}{\sqrt{w_0(x)}}\right|\leqslant\frac{M}{\sqrt{w_0(x)}}\leqslant\frac{M}{\sqrt{\tau}}=e^{C/(2M^2)}=:C_1,$$

and the same inequality is valid for $g_n/\sqrt{w_0}$. Taking into account that $\mathcal{R}$ is smooth,

$$\begin{aligned}\left|\mathcal{R}\left(\frac{\widetilde{f}_n(x)}{\sqrt{w_0(x)}}\right)-\mathcal{R}\left(\frac{g_n(x)}{\sqrt{w_0(x)}}\right)\right|&\leqslant\max_{|y|\leqslant C_1}|\mathcal{R}'(y)|\left|\frac{\widetilde{f}_n(x)}{\sqrt{w_0(x)}}-\frac{g_n(x)}{\sqrt{w_0(x)}}\right|\\&\leqslant\max_{|y|\leqslant C_1}|2y(1+\log(y^2))|\left|\frac{\widetilde{f}_n(x)}{\sqrt{w_0(x)}}-\frac{g_n(x)}{\sqrt{w_0(x)}}\right|\\&\leqslant C_2\left|\frac{\widetilde{f}_n(x)}{\sqrt{w_0(x)}}-\frac{g_n(x)}{\sqrt{w_0(x)}}\right|,\end{aligned}$$

with $C_2:=\max\{4e^{-3/2},2C_1(1+\log(C_1^2))\}$. Hence, using the Cauchy–Schwarz inequality,

$$\left|\int_{w_0(x)\geqslant\tau}\left[\mathcal{R}\left(\frac{\widetilde{f}_n(x)}{\sqrt{w_0(x)}}\right)-\mathcal{R}\left(\frac{g_n(x)}{\sqrt{w_0(x)}}\right)\right]w(x)dx\right|\leqslant C_2\|(\widetilde{f}_n-g_n)\sqrt{w_0(x)}\|_{L^1(\rho)}\leqslant C_2\|\widetilde{f}_n-g_n\|_{L^2(\rho)},$$

which by (32) tends to 0 as $n\to\infty$. Taking into account that $\varepsilon\in(0,1)$ was chosen arbitrarily, we conclude that

$$S(\widetilde{f}_n^2\rho,w)-S(g_n^2\rho,w)\to 0,\quad n\to\infty. \tag{37}$$

Thus, for establishing the expression for the entropy in Theorem 1, it only remains to examine the last bracket on the right-hand side of (34). Notice that since $\widetilde{f}_n=f_n$ on $\Delta\setminus\Delta_n(M)$,

$$S(f_n^2\rho,w)-S(\tilde{f}_n^2\rho,w)=-\int_{\Delta_n(M)}p_n^2(x)\log(p_n^2(x))w(x)dx+\int_{\Delta_n(M)}\log\left(\frac{1}{w_0(x)}\right)\rho(x)dx$$
$$=-\int_{\Delta_n(M)}p_n^2(x)\log^+(p_n^2(x))w(x)dx+\int_{\tilde{\Delta}_n(M)}p_n^2(x)|\log(p_n^2(x))|w(x)dx$$
$$-\int_{\Delta_n(M)}\log(w_0(x))\rho(x)dx,$$

where

$$\tilde{\Delta}_n(M)=\{x\in\Delta_n(M):p_n^2(x)<1\}\subset\Delta_n(M).$$

Observing that, for $p_n^2(x)\leqslant 1$, we have $0\leqslant p_n^2(x)\,|\log(p_n^2(x))|\leqslant 1$, we obtain

$$0\leqslant\int_{\tilde{\Delta}_n(M)}p_n^2(x)|\log(p_n^2(x))|w(x)dx\leqslant\int_{\Delta_n(M)}w(x)dx=\int_{\Delta_n(M)}w_0(x)\rho(x)dx.$$

Since $w_0\in L^1(\rho)$, $\log(w_0)\in L^1(\rho)$, by the absolute continuity of the Lebesgue integral, relation (30) implies that

$$\lim_{n\to\infty}\int_{\Delta_n(M)}w_0(x)\rho(x)dx=0,\quad\text{and}\quad\lim_{n\to\infty}\int_{\Delta_n(M)}\log(w_0(x))\rho(x)dx=0,\tag{38}$$

showing that

$$S(f_n^2\rho,w)-S(\tilde{f}_n^2\rho,w)=-\int_{\Delta_n(M)}p_n^2(x)\log^+(p_n^2(x))w(x)dx+o(1),\quad n\to\infty.\tag{39}$$

Hence, gathering (35), (37), and (39) in (34), we get (10). □

B. Proof of Corollary 1

Since

$$\int_{\Delta_n(M)}p_n^2(x)\log^+(p_n^2(x))w(x)dx\geqslant 0,$$

relation (11) is a trivial consequence of Theorem 1. Suppose now that (13) holds for some $M>\sqrt{2}$, then (12) follows immediately from (10). Conversely, if (12) is true then it follows from Theorem 1 that (13) holds for all $M>\sqrt{2}$.

In order to prove that (14) is sufficient for (13), notice that, by Hölder's inequality,

$$\int_{\Delta_n(M)}p_n^2(x)\log^+(p_n^2(x))w(x)dx\leqslant\left(\int_{\Delta_n(M)}p_n^2(x)(\log^+(p_n^2(x)))^{1+\varepsilon}w(x)dx\right)^{1/(1+\varepsilon)}$$
$$\times\left(\int_{\Delta_n(M)}p_n^2(x)w(x)dx\right)^{1-1/(1+\varepsilon)}.\tag{40}$$

Furthermore,

$$\int_{\Delta_n(M)} p_n^2(x)w(x)dx \leqslant \int_{\Delta_n(M)} [f_n^2(x) - g_n^2(x)]\rho(x)dx + \int_{\Delta_n(M)} g_n^2(x)\rho(x)dx$$
$$\leqslant \int_{\Delta_n(M)} [f_n^2(x) - g_n^2(x)]\rho(x)dx + 2\int_{\Delta_n(M)} \rho(x)dx$$
$$\leqslant (1+\sqrt{2})\|f_n - g_n\|_{L^2(\rho)} + 2\int_{\Delta_n} \rho(x)dx = o(1), \quad n \to \infty,$$

where we have used (28), (30), and (33).

If we assume that the first condition in (14) holds, then the first factor on the right-hand side of (40) is uniformly bounded in n, and (13) follows.

Finally, notice that the second condition in (14) implies the first one since $\log^+(z) \leqslant z$ for $z \geqslant 0$, and hence

$$(\log^+(y))^{1+\varepsilon} = \left(\frac{1+\varepsilon}{\varepsilon}\right)^{1+\varepsilon} (\log^+(y^{\varepsilon/(1+\varepsilon)}))^{1+\varepsilon} \leqslant \left(\frac{1+\varepsilon}{\varepsilon}\right)^{1+\varepsilon} y^{\varepsilon}, \quad y \geqslant 0.$$

□

C. Proof of Theorem 2

Our proof for Theorem 2 follows closely the arguments of the proof of Theorem 1, but some parts simplify. As before let $\mathcal{R}(y) = y^2 \log(y^2)$, $y \in \mathbb{R}$, and fix $M > \sqrt{2}$. We write the functional as follows:

$$F_n(w) = \int_\Delta [-\mathcal{R}(g_n(x))]\rho(x)dx + \int_\Delta [\mathcal{R}(g_n(x)) - \mathcal{R}(\tilde{f}_n(x))]\rho(x)dx + \int_\Delta [\mathcal{R}(\tilde{f}_n(x))$$
$$- \mathcal{R}(f_n(x))]\rho(x)dx. \tag{41}$$

Here the first integral on the right-hand side of (41) has the limit $E_1(\rho) = \log(2) - 1$ by Lemma 1. The last one can be written as

$$\int_\Delta [\mathcal{R}(\tilde{f}_n(x)) - \mathcal{R}(f_n(x))]\rho(x)dx = -\int_{\Delta_n(M)} \log(f_n^2(x)) f_n^2(x)\rho(x)dx \leqslant 0,$$

the right-hand side coinciding with the integral in (21). Thus Theorem 2 follows by showing that the second integral on the right-hand side of (41) is asymptotically vanishing. Recalling that $|\tilde{f}_n(x)|$ and $|g_n(x)|$ are uniformly bounded by M for all $n \geqslant 0$ and $x \in \Delta$, we obtain

$$\left| \int_\Delta [\mathcal{R}(g_n(x)) - \mathcal{R}(\tilde{f}_n(x))]\rho(x)dx \right|$$
$$\leqslant \max_{y \in [-M,M]} |\mathcal{R}'(y)| \int_\Delta |g_n(x) - \tilde{f}_n(x)|\rho(x)dx$$
$$\leqslant M^2(1 + \log M^2)\|g_n - \tilde{f}_n\|_{L^1(\rho)} \leqslant M^2(1 + \log M^2)\|g_n - \tilde{f}_n\|_{L^2(\rho)},$$

the term on the right tending to zero as $n \to \infty$ by (32). □

D. Proof of Corollary 4

Since

$$\int_{\Delta_n(M)} f_n^2(x)\log(f_n^2(x))\rho(x)dx \geqslant 0,$$

relation (22) is a trivial consequence of Theorem 2. Suppose now that (24) holds for some $M>\sqrt{2}$; then (23) follows immediately from (21). Conversely, if (23) is true then it follows from Theorem 2 that (24) holds for all $M>\sqrt{2}$.

In order to prove that the first condition in (25) (which clearly is weaker than the second one) is sufficient for (24), notice that, by Hölder's inequality,

$$\int_{\Delta_n} f_n^2(x)\log^+(f_n^2(x))\rho(x)dx \leqslant \left(\int_{\Delta_n} f_n^2(x)(\log^+(f_n^2(x)))^{1+\varepsilon}\rho(x)dx\right)^{1/(1+\varepsilon)}\left(\int_{\Delta_n} f_n^2(x)\rho(x)dx\right)^{1-1/(1+\varepsilon)},$$

and we may conclude as in the proof of Corollary 1 that the second factor on the right-hand side tends to zero. □

IV. PROOFS OF PROPOSITIONS 1, 2, AND 3

A. Proof of Proposition 1

Let us make the change of variables $x=(z+1/z)/2$. It is well known that since $S(x)>0$ on Δ we may write S as

$$S(x) = |q(z)|^2 = q(z)q(1/z), \tag{42}$$

with q a polynomial of degree $2N$ with real coefficients having all its zeros outside the disk and $q(0)>0$. Moreover,

$$p_n(x) = \frac{1}{\sqrt{2}}(z^n q(z^{-1}) + z^{-n}q(z)) \tag{43}$$

is the orthonormal polynomial of degree $n>N$ with respect to the Bernstein weight ρ/S. Introducing the Blaschke product,

$$B_n(z) = z^{2n}q(1/z)/q(z), \quad n \geqslant N, \tag{44}$$

we find that

$$p_n^2(x)w_0(x) = \tfrac{1}{2}|1+B_n(z)|^2 = 1 + \tfrac{1}{2}(B_n(z)+B_n(1/z)), \quad |z|=1.$$

Since, for $n>N$, $B_n(0)=0$, and B_n is analytic in the disk, we have

$$\begin{aligned}\log(2) - F_n(w) &= \log(2) + \int \log(p_n^2(x)w_0(x))p_n^2(x)w_0(x)\rho(x)dx \\ &= \frac{1}{2\pi}\int_{|z|=1}\log(|1+B_n(z)|^2)\left[1+\frac{1}{2}(B_n(z)+B_n(1/z))\right]|dz| \\ &= \mathrm{Re}\left(\frac{1}{2\pi i}\int_{|z|=1}\log(1+B_n(z))[2+B_n(z)+B_n(1/z)]\frac{dz}{z}\right).\end{aligned}$$

Since $|B_n(z)|<1$ for $|z|<1$, the function $\log(1+B_n)[2+B_n]$ is holomorphic inside the disk and vanishes at the origin. Thus,

$$\log(2) - F_n(w) = \mathrm{Re}\left(\frac{1}{2\pi i}\int_{|z|=1}\log(1+B_n(z))B_n(1/z)\frac{dz}{z}\right) \tag{45}$$

$$= \mathrm{Re}\left(\frac{1}{2\pi i} \int_{|z|=1} \frac{\log(1+B_n(z))}{B_n(z)} \frac{dz}{z} \right), \tag{46}$$

where we have used that $B_n(1/z) = 1/B_n(z)$. Observe that the last integrand is analytic in a neighborhood of the unit circle, and we can integrate along a smaller circle $|z| = r < 1$, where $|B_n(z)| < 1$. Replacing the log by its uniformly convergent Taylor expansion we get finally that this integral equals 1, which proves (19).

On the other hand, by a similar reasoning we have

$$\begin{aligned} G_n(w) &= \int_{-1}^{1} \log(w_0(x)) p_n(x)^2 w(x) dx \\ &= -2\mathrm{Re}\left(\frac{1}{2\pi i} \int_{|z|=1} \log(q(z)) \left[1 + \frac{1}{2}(B_n(z) + B_n(1/z)) \right] |dz| \right) \\ &= -2 \log(q(0)) - \frac{1}{2\pi i} \int_{|z|=1} \log(q(z)) B_n(1/z) \frac{dz}{z}. \end{aligned} \tag{47}$$

Note that in the last expression of (47), taking the real part is not necessary since q and B_n are real functions. Integrating now along $|z| = R > 1$, we observe that $|B_n(1/z)|$ becomes geometrically small, there which yields a geometric rate of convergence for

$$\lim_{n\to\infty} G_n(w) = -2 \log(q(0)) = -\mathrm{Re} \frac{1}{\pi} \int_{|z|=1} \log(q(z)) \frac{dz}{z} = S(\rho, w),$$

which proves (20). □

B. Proof of Proposition 2

From the computations of $F_n(w)$ and $G_n(w)$ in the proof of Proposition 1, see (45) and (47), we know that $E_n(w)$ is constant for n large, say $n > N_0 > N$, if and only if

$$\frac{1}{2\pi i} \int_{|z|=1} \frac{B_N(1/z) \log(q(z))}{z^{2n-2N}} \frac{dz}{z} = 0, \quad n > N_0, \tag{48}$$

where the polynomial q and the Blaschke product B_N are defined by (42) and (44), respectively. Since $\log(q(z))$ is analytic in some neighborhood $\mathcal{U}$ of the unit disk, we may conclude that $\log(q(z)) B_N(1/z)$ is meromorphic in $\mathcal{U}$, and thus can be written as

$$B_N(1/z) \log(q(z)) = r(z) + f(z), \quad z \in \mathcal{U}, \tag{49}$$

where r is a rational function such that $z^{2N} q(1/z) r(z)$ is a polynomial of degree at most $2N-1$, and f is analytic in $\mathcal{U}$. Since r is analytic outside the unit disk and grows like at most $1/z$ at infinity, we deduce

$$\frac{1}{2\pi i} \int_{|z|=1} \frac{r(z)}{z^{2n-2N}} \frac{dz}{z} = 0, \quad n > N_0,$$

which implies, together with (48) and (49), that

$$\frac{1}{2\pi i} \int_{|z|=1} \frac{f(z)}{z^{2n-2N}} \frac{dz}{z} = 0, \quad n > N_0.$$

Hence, all sufficiently high even Taylor coefficients of f vanish. As a consequence, $f(z) + f(-z) = P(z)$ is a polynomial, and

$$B_N(1/z)\log(q(z)) + B_N(-1/z)\log(q(-z)) = r(z) + r(-z) + P(z), \quad |z| \leqslant 1. \tag{50}$$

Since the right-hand side of (50) is a rational function, the principle of analytic continuation applies, showing that (50) actually holds everywhere in $\mathbb{C}$. First, assume that the polynomial q is even, that is $q(z)=q(-z)$, $z \in \mathbb{C}$. Then, it follows from (50) that $\log(q(z))$ is a rational function so that q can only be a constant, namely 1 by the normalization (3) of the weight w. Second, assume that the polynomial q is not even (hence different from a constant). It implies the existence of some root $\alpha \in \mathbb{C}$ of q such that either $q(-\alpha) \neq 0$ or $-\alpha$ is a root of q of different multiplicity than that of α. Note that $\alpha \neq 0$ since, by assumption, $q(0) > 0$. Then we get a contradiction. Indeed, in view of the definition (44) of B_N, we readily observe that the left-hand side of (50) has a branch point at α while the right-hand side has not. Hence, $q(z)$ is constant, equal to 1, and the proof of Proposition 2 is finished. □

C. Proof of Proposition 3

Choosing $p=2$ and $g=|\log(w_0)w|^{1/2} \in L^1$ in Theorem 2 of Ref. 10 shows that

$$\liminf_{n\to\infty} \int_\Delta |\log(w_0(x))| p_n^2(x) w(x) dx \geqslant \int_\Delta |\log(w_0(x))| \rho(x) dx, \tag{51}$$

for any weight w in the Erdős–Turan class $\mathcal{ET}$. If $\log^+(w_0) \in L^\infty$, there exists a constant $C>1$ such that $w_0(x) \leqslant C$, $x \in \Delta$. Hence $|\log(w_0/C)| = -\log(w_0/C)$ and substracting $\log(C)$ to both sides of (51), we get (26) since

$$\int_\Delta \rho(x) dx = \int_\Delta p_n^2(x) w(x) dx = 1.$$

A similar reasoning shows (27) when $\log^-(w_0) \in L^\infty$. Since this argument applies for any weight in the Erdős–Turan class, the last assertion in the proposition also follows. □

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 45, NUMBER 11 NOVEMBER 2004

Recovering the M-channel Sturm-Liouville operator from M+1 spectra

V. M. Chabanov[a)]
Laboratory of Theoretical Physics, JINR, Dubna, 141980, Russia

(Received 2 June 2004; accepted 20 July 2004; published 25 October 2004)

For a system of M coupled Schrödinger equations, the relationship is found between the vector-valued norming constants and $M+1$ spectra corresponding to the same potential matrix but different boundary conditions. Under a special choice of particular boundary conditions, this equation for norming vectors has a unique solution. The double set of norming vectors and associated spectrum of one of the $M+1$ boundary value problems uniquely specifies the matrix of potentials in the multichannel Schrödinger equation. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1794844]

I. INTRODUCTION

Consider the system of coupled one-dimensional Schrödinger equations

$$-\frac{d^2}{dx^2}\Psi_\alpha(x)+\sum_\beta V_{\alpha\beta}(x)\Psi_\beta(x)=(E-\varepsilon_\alpha)\Psi_\alpha(x),\quad \alpha=1,\ldots,M. \tag{1}$$

In this system, each equation is referred to as a "channel" and ε_α's are the energies of channel "thresholds." Once $E\geqslant\varepsilon_\alpha$, it is said that α's threshold becomes open. The system (1) is a matrix generalization of the ordinary one-dimensional Schrödinger equation. The coupled Schrödinger equations originate in the Feshbach's unified theory, see Ref. 1, of nuclear reactions and correspond to so-called approximation of the strong coupling [when a finite number of equations in (1) is left]. Now, that method, renewed and generalized (see, e.g., Ref. 2), finds a lot of applications and, rightfully, is one of the most universal tools for microscopic description of systems with many degrees of freedom (nuclear structure, reactions, molecules, etc).

The inverse problem for multichannel Schrödinger Eq. (1) has also been developed.[3–5] As in one-channel case, one can uniquely restore the potential matrix $V_{\alpha\beta}(x)$ from the spectral measure that, e.g., for the case of bounded interval, is specified by the complete set of eigenvalues E_n and so-called norming vectors (spectral weight vectors) $\gamma_\alpha(E_n)$. These vectors characterize the behavior of the normalized wave functions $\Psi_\alpha(x,E_n)$ at one of the boundaries of interval (or at the origin for a half-axis problem, etc.), see also below.

At the same time, in the one-channel case we have more variants of the inverse problem. Among them, there is a statement of an inverse eigenvalue problem on a bounded interval where no norming constants occur. Namely, the potential is uniquely recovered from a knowledge of only two different spectra, each for a distinct pair of homogeneous boundary conditions (with the same potential).[6] There were established necessary and sufficient conditions of the solvability of the inverse Sturm–Liouville problem from two-spectra, see, e.g., Ref. 7.

Until now, one attempt to generalize this theorem to the multichannel Sturm–Liouville operator has been known to the author—see Ref. 8 (the case of a finite-difference operator). Though not complete, this work gave an idea of the existence of such a generalization in principle. No doubt, the possibility of deriving potential matrix from a certain set of spectra would contribute to the

[a)]Electronic mail: chabanov@thsun1.jinr.ru

multichannel inverse problem theory. In the present article, results concerning that problem are obtained. It is found that $M+1$ spectra determine the $V_{\alpha\beta}(x)$ and, under special conditions, it is possible to uniquely restore multichannel Sturm–Liouville operator.

The central idea of this article is to derive the relationship between $M+1$ spectra and M-component norming vector $\gamma_\alpha(E_n)$ associated with one of the $M+1$ boundary value problems on a finite interval (which may be a good model for a description of the compacted system with bound states). Then, having the double set of eigenvalues and norming vectors, one can uniquely restore an interaction matrix by the Gel'fand–Levitan inversion procedure on finite interval. The reader can get acquainted with a multichannel extension of the inverse problem in, e.g., Ref. 5, p. 135 (Sec. IX.4 "Coupled Channels").

The next section is devoted to setting forth these results. We shall find the sought expression which, however, does not guarantee the uniqueness in itself. Only under a special choice of boundary conditions can it be represented in a form of system of linear algebraic equations which give a simple criterion of the uniqueness and solvability. For the sake of the reader's convenience, the narrative is organized so that it goes partially in parallel with standard derivation of two spectra formulas given in Ref. 7, Chap. 3.

II. DERIVATION OF THE FORMULA FOR NORMING VECTOR

We are beginning this section with preliminary notations. Let us rewrite the system (1) in a more symbolic form as follows:

$$-\frac{d^2}{dx^2}y(x)+\hat{V}(x)y(x)=\lambda y(x), \quad x\in[0,a], \tag{2}$$

where y stands for the whole vector-column solution

$$y(x)\equiv\begin{pmatrix}\Psi_1(x)\\ \vdots\\ \Psi_M(x)\end{pmatrix},$$

and

$$\hat{V}\equiv V_{\alpha\beta}+\varepsilon_\alpha\delta_{\alpha\beta}, \quad \lambda\equiv E.$$

The potential matrix is the real symmetric matrix of continuous functions, $x\in[0,a]$. In this article, the hat will always stand for the matrix. Next, we add to Eq. (2) the following boundary conditions:

$$\begin{cases} y'(0)-\hat{h}y(0)=0, & y'(a)+\hat{H}y(a)=0,\\ y_i'(0)-\hat{h}_i y_i(0)=0, & y_i'(a)+\hat{H}y_i(a)=0, \quad i=1,\ldots,M, \end{cases} \tag{3}$$

where we take $\hat{h}$, $\hat{h}_i$, and $\hat{H}$ to all be the real symmetric matrices. We denote the spectra of the M+1 problems (2) and (3) by $\{\lambda_n\}_{n=1}^{\infty}$ and $\{\lambda_n^i\}_{n=1}^{\infty}$, respectively. There is no theorem of interlacing of the spectra in the M-channel case, $M>1$. So, we additionally require that no spectrum degeneracy should occur.

Let us denote by $\hat{\phi}(x,\lambda)$ and $\hat{\chi}_i(x,\lambda)$ the matrix solutions of Eq. (2) satisfying the initial conditions

$$\hat{\phi}(0,\lambda)=\hat{1}, \quad \hat{\phi}'(x,\lambda)|_{x=0}=\hat{h}, \quad \hat{\chi}_i(0,\lambda)=\hat{1}, \quad \hat{\chi}_i'(x,\lambda)|_{x=0}=\hat{h}_i, \tag{4}$$

where the prime stands for the derivative with respect to x. In what follows we shall use the prime to denote this derivative. A matrix solution of (2) means that each column of the matrix is a vector-solution, only satisfying a specific initial (boundary) condition. Eigenvalues of the boundary value problems (2) and (3) coincide with zeros of determinants of the matrices

$$\begin{cases} \hat{\Phi}(\lambda) = \overline{\hat{\phi}}'(x,\lambda)|_{x=a} + \overline{\hat{\phi}}(a,\lambda)\hat{H}, \\ \hat{\Phi}_i(\lambda) = \overline{\hat{\chi}}_i'(x,\lambda)|_{x=a} + \overline{\hat{\chi}}_i(a,\lambda)\hat{H}, \end{cases} \tag{5}$$

where the bar sign denotes transpose.

Now we introduce the norming vectors associated with the spectrum $\{\lambda_n\}_{n=1}^{\infty}$

$$\gamma_{\lambda_n} \equiv \begin{pmatrix} \gamma_1(\lambda_n) \\ \vdots \\ \gamma_M(\lambda_n) \end{pmatrix},$$

such that

$$\hat{\phi}(x,\lambda_n)\gamma_{\lambda_n} = y(x,\lambda_n) \tag{6}$$

with $y'(x,\lambda_n)|_{x=a} + \hat{H}y(a,\lambda_n) = 0$ and $\int_0^a \Sigma_{\alpha=1}^M [\Psi_\alpha(x,\lambda_n)]^2 dx = 1$. Likewise, for the spectra $\{\lambda_n^i\}_{n=1}^{\infty}$

$$\gamma_{\lambda_n^i} \equiv \begin{pmatrix} \gamma_1(\lambda_n^i) \\ \vdots \\ \gamma_M(\lambda_n^i) \end{pmatrix},$$

such that

$$\hat{\chi}_i(x,\lambda_n^i)\gamma_{\lambda_n^i} = y_i(x,\lambda_n^i) \tag{7}$$

with $y_i'(x,\lambda_n^i)|_{x=a} + \hat{H}y_i(a,\lambda_n^i) = 0$ and $\int_0^a \Sigma_{\alpha=1}^M [\Psi_\alpha(x,\lambda_n^i)]^2 dx = 1$. Let us also introduce the function γ_λ (versus λ) such that $\gamma_\lambda = \gamma_{\lambda_n}$ when $\lambda = \lambda_n$ and $\gamma_\lambda = \gamma_{\lambda_n^i}$ when $\lambda = \lambda_n^i$. That function makes sense at the points λ_n and λ_n^i only. In between, we have the freedom to specify it arbitrarily. We can only require this function to be continuously differentiable and have no singularities, $\gamma_\lambda \neq 0$.

We take

$$f_i(x,\lambda) \equiv \overline{\gamma_\lambda}\overline{\hat{\chi}}_i(x,\lambda) + m_i(\lambda)\overline{\gamma_\lambda}\overline{\hat{\phi}}(x,\lambda), \tag{8}$$

where $m_i(\lambda)$ is scalar and we require that

$$f_i'(x,\lambda)_{x=a} + f_i(a,\lambda)\hat{H} = 0 \Rightarrow \tag{9}$$

$$m_i(\lambda)[\overline{\gamma_\lambda}\overline{\hat{\phi}}'(x,\lambda)|_{x=a} + \overline{\gamma_\lambda}\overline{\hat{\phi}}(a,\lambda)\hat{H} = -[\overline{\gamma_\lambda}\overline{\hat{\chi}}_i'(x,\lambda)|_{x=a} + \overline{\gamma_\lambda}\overline{\hat{\chi}}_i(a,\lambda)\hat{H}. \tag{10}$$

Comparing with (5) we have

$$m_i(\lambda) = -\frac{\overline{\Phi}_i(\lambda)\Phi(\lambda)}{\overline{\Phi}(\lambda)\Phi(\lambda)}, \tag{11}$$

where we denote $\Phi(\lambda) \equiv \overline{\hat{\Phi}}(\lambda)\gamma_\lambda$ and $\Phi_i(\lambda) \equiv \overline{\hat{\Phi}}_i(\lambda)\gamma_\lambda$.

Next, employing the well known Green formula we have

$$(\lambda - \lambda_n)\int_0^a f_i(x,\lambda)\hat{\phi}(x,\lambda_n)\gamma_{\lambda_n}dx = f_i'(x,\lambda)|_{x=0}\hat{\phi}(0,\lambda_n)\gamma_{\lambda_n} - f_i(0,\lambda)\hat{\phi}'(x,\lambda)|_{x=0}\gamma_{\lambda_n} = \overline{\gamma_\lambda}(\hat{h}_i - \hat{h})\gamma_{\lambda_n}.$$

From the other hand,

$$(\lambda-\lambda_n)\int_0^a f_i(x,\lambda)\hat{\phi}(x,\lambda_n)\gamma_{\lambda_n}dx=(\lambda-\lambda_n)\int_0^a \overline{\gamma_\lambda}\overline{\hat{\chi}}_i(x,\lambda)\hat{\phi}(x,\lambda_n)\gamma_{\lambda_n}dx-(\lambda-\lambda_n)$$
$$\times\int_0^a \frac{\overline{\Phi}_i(\lambda)\Phi(\lambda)}{\overline{\Phi}(\lambda)\Phi(\lambda)}\overline{\gamma_\lambda}\overline{\hat{\phi}}(x,\lambda)\hat{\phi}(x,\lambda_n)\gamma_{\lambda_n}dx=\overline{\gamma_\lambda}(\hat{h}_i-\hat{h})\gamma_{\lambda_n}, \tag{12}$$

where we used, in the two last formulas, the definitions (4), (8), and (11). The last equality follows from the fact that the matrices in (3) are symmetric.

Let us pass to the limit $\lambda\to\lambda_n$. Then the Eq. (12) goes over into

$$-\frac{\frac{d}{d\lambda}[\overline{\Phi}(\lambda)\Phi(\lambda)]|_{\lambda=\lambda_n}}{\overline{\Phi}_i(\lambda_n)\Phi(\lambda_n)}\overline{\gamma_{\lambda_n}}(\hat{h}_i-\hat{h})\gamma_{\lambda_n}=1, \tag{13}$$

where we used the L' Hospital rule and definition (6).

We shall prove that this formula can be represented as

$$(\lambda_n^i-\lambda_n)^{-1}\prod_{\substack{\mu=1\\ \mu\neq n}}^{\infty}\frac{\lambda_\mu-\lambda_n}{\lambda_\mu^i-\lambda_n}\overline{\gamma_{\lambda_n}}(\hat{h}_i-\hat{h})\gamma_{\lambda_n}=1. \tag{14}$$

Since $\Phi(\lambda)$ and $\Phi_i(\lambda)$ are the entire holomorphic functions they are determined (to within constant multipliers) by their zeros and, hence, can be represented as follows:

$$\Phi(\lambda)=C\prod_{\mu=1}^{\infty}\left(1-\frac{\lambda}{\lambda_\mu}\right);\quad \Phi_i(\lambda)=C_i\prod_{\nu=1}^{\infty}\left(1-\frac{\lambda}{\lambda_\nu^i}\right). \tag{15}$$

Substituting (15) into (13) we have

$$\frac{\frac{1}{\lambda_n}\prod_{\substack{\mu=1\\ \mu\neq n}}^{\infty}\left(1-\frac{\lambda_n}{\lambda_\mu}\right)\overline{C}C}{\prod_{\nu=1}^{\infty}\left(1-\frac{\lambda_n}{\lambda_\nu^i}\right)\overline{C}_iC}\overline{\gamma_{\lambda_n}}(\hat{h}_i-\hat{h})\gamma_{\lambda_n}=1. \tag{16}$$

Now we have to ascertain the expression for the $\overline{C}C/\overline{C}_iC$. We shall need some knowledge about an asymptotic behavior of the solutions of (2). First of all, these equations become uncoupled in the limit $\lambda\to\infty$. So, as in the one-channel case, we have $\lim_{\lambda\to\infty}\hat{\Phi}(\lambda)\{\hat{\Phi}_i(\lambda)\}^{-1}=1$, and the same for the transpose of these matrices. Here the limit is taken for the diverging sequence $\lambda\equiv\lambda(k)=k^{2\pm\varepsilon}+O(1)$ for any $\varepsilon>0$ and k being integer and sufficiently large [we choose such a sequence lest $\lambda(k)$ should coincide with M+1 spectra at even if one point].

Taking this into account we obtain

$$\frac{\overline{C}C}{\overline{C}_iC}\prod_{\mu=1}^{\infty}\frac{\lambda_\mu^i}{\lambda_\mu}\lim_{\lambda\to\infty}\prod_{\mu=1}^{\infty}\frac{\lambda_\mu-\lambda}{\lambda_\mu^i-\lambda}=1. \tag{17}$$

We have the following asymptotic formulas for λ and λ^i: $\lambda_\mu=(\pi/a)^2\mu^2+O(1)$ and the same for λ^i. Then $\lambda_\mu^i-\lambda_\mu=O(1)$ and the series $\Sigma_\mu^\infty|(\lambda_\mu-\lambda_\mu^i)/(\lambda_\mu^i-\lambda)|$ converges uniformly as $\lambda\to\infty$ on the set $\mathbb{R}\setminus(\lambda_\mu\cup\lambda_\mu^i)$. Hence, we can pass to the limit in each term of the infinite product

$$\lim_{\lambda\to\infty}\prod_{\mu=1}^{\infty}\frac{\lambda_\mu-\lambda}{\lambda_\mu^i-\lambda}=\lim_{\lambda\to\infty}\prod_{\mu=1}^{\infty}\left(1+\frac{\lambda_\mu-\lambda_\mu^i}{\lambda_\mu^i-\lambda}\right)=1. \tag{18}$$

We see from (18) and (17) that

$$\frac{\overline{C}C}{\overline{C_i}C}\prod_{\mu=1}^{\infty}\frac{\lambda_\mu^i}{\lambda_\mu}=1. \tag{19}$$

At last, we can obtain the final expression for γ_{λ_n}. Substituting (19) into (16) we have the formula (14)—the system of M equations ($i=1,\dots,M$) for determining M components of γ_{λ_n}.

In the one-channel case the formula (14) goes over into the known expression for two spectra

$$(\lambda_n^2-\lambda_n^1)^{-1}\prod_{\substack{\mu=1\\ \mu\neq n}}^{\infty}\frac{\lambda_\mu^1-\lambda_n^1}{\lambda_\mu^2-\lambda_n^1}(h_2-h_1)\gamma_{\lambda_n}^2=1, \tag{20}$$

where the matrix values become scalars, and we denote, by indices 1 and 2, two spectra determining scalar norming factor γ_{λ_n}.

The system (14) is not linear one: Each row in it contains the quadratic form $\overline{\gamma}_{\lambda_n}(\hat{h}_i-\hat{h})\gamma_{\lambda_n}$. Hence, these equations cannot be solved uniquely in general (including solvability itself). In other words, we have to impose some constraint on choosing the matrices $\hat{h}_i$, i.e., the difference $\hat{h}_i-\hat{h}$. Among other possibilities, we give several realizations which will allow a unique solvability of the system (14).

(i) The symmetric matrix $\hat{h}_i-\hat{h}\equiv\hat{\xi}^{(i)}$ has the form of a Jacobi matrix

$$\hat{\xi}^{(i)}=\begin{pmatrix}\xi_{11}^{(i)} & \xi_{12}^{(i)} & 0 & 0 & . & . & 0\\ \xi_{12}^{(i)} & 0 & \xi_{23}^{(i)} & 0 & . & . & .\\ 0 & \xi_{23}^{(i)} & 0 & \xi_{34}^{(i)} & . & . & .\\ . & . & . & . & . & . & .\\ . & . & . & . & . & . & \xi_{M-1M}^{(i)}\\ 0 & . & . & . & 0 & \xi_{M-1M}^{(i)} & 0\end{pmatrix}, \tag{21}$$

where the main diagonal contains only one nonzero element, $\xi_{11}^{(i)}$. Then

$$\overline{\gamma}_{\lambda_n}(\hat{h}_i-\hat{h})\gamma_{\lambda_n}=\xi_{11}^{(i)}\gamma_1(\lambda_n)^2+2\sum_{k\neq 1}^{M}\xi_{k-1k}^{(i)}\gamma_{k-1}(\lambda_n)\gamma_k(\lambda_n). \tag{22}$$

Introducing the variables $\omega_1\equiv\gamma_1(\lambda_n)^2$ and $\omega_k\equiv\gamma_{k-1}(\lambda_n)\gamma_k(\lambda_n), k=2,\dots,M$ we can rewrite the last expression as follows:

$$\overline{\gamma}_{\lambda_n}(\hat{h}_i-\hat{h})\gamma_{\lambda_n}=\xi_{11}^{(i)}\omega_1+2\sum_{k\neq 1}^{M}\xi_{k-1k}^{(i)}\omega_k. \tag{23}$$

Then (14) becomes the system of linear algebraic equations for the variables ω. If $\omega_1=\gamma_1(\lambda_n)^2>0$, then $\gamma_1(\lambda_n)=\pm\omega_1^{1/2}$, $\gamma_2(\lambda_n)=\mp\omega_2/\omega_1^{1/2}$ and so forth. The sign in front of $\omega_1^{1/2}$ in the expression for $\gamma_1(\lambda_n)$ determines the common sign for γ_{λ_n} and, hence, is inessential: The whole vector-valued wave function is determined to within sign ($\pm$). With the nonzero element $\xi_{ll}^{(i)}\neq 0, l\neq 1$ positioned in arbitrary place of the main diagonal, the scheme is analogous.

(ii) The matrix $\hat{h}_i-\hat{h}\equiv\hat{\zeta}^{(i)}$ is represented as follows:

$$\hat{\zeta}^{(i)} = \begin{pmatrix} 0 & . & 0 & \zeta_{1l}^{(i)} & 0 & . & 0 \\ . & . & . & . & . & . & . \\ . & . & 0 & \zeta_{l-1l}^{(i)} & 0 & . & . \\ \zeta_{l1}^{(i)} & . & \zeta_{ll-1}^{(i)} & \zeta_{ll}^{(i)} & \zeta_{ll+1}^{(i)} & . & \zeta_{lM}^{(i)} \\ . & . & 0 & \zeta_{l+1l}^{(i)} & 0 & . & 0 \\ . & . & . & . & . & . & . \\ 0 & . & 0 & \zeta_{Ml}^{(i)} & 0 & . & 0 \end{pmatrix}, \tag{24}$$

i.e., the matrix contains one nonzero row and one nonzero column which cross each other in a place of the entry $\zeta_{ll}^{(i)}$. For the quadratic form we have (using the symmetry of $\hat{h}_i - \hat{h}$)

$$\overline{\gamma}_{\lambda_n}(\hat{h}_i - \hat{h})\gamma_{\lambda_n} = \zeta_{ll}^{(i)}\gamma_l(\lambda_n)^2 + 2\sum_{k\neq l}^{M} \zeta_{lk}^{(i)}\gamma_l(\lambda_n)\gamma_k(\lambda_n). \tag{25}$$

Introducing new variables $\theta_k \equiv \gamma_l(\lambda_n)\gamma_k(\lambda_n)$, $k \neq l$, and $\theta_l \equiv \gamma_l(\lambda_n)^2$ we can now look upon (14) as a linearized system again

$$(\lambda_n^i - \lambda_n)^{-1}\prod_{\substack{\mu=1 \\ \mu\neq n}}^{\infty} \frac{\lambda_\mu - \lambda_n}{\lambda_\mu^i - \lambda_n}\left\{ \zeta_{ll}^{(i)}\theta_l + 2\sum_{k\neq l}^{M} \zeta_{lk}^{(i)}\theta_k \right\} = 1. \tag{26}$$

After deriving θ_i, one can obtain $\gamma_i(\lambda_n)$ trivially. Of course, the solvability in this case depends on whether the corresponding determinant for the system (26) is nonzero and $\theta_l > 0$.

In all the cases, the knowledge of the complete set $\{\lambda_n, \gamma_{\lambda_n}\}_{n=1}^{\infty}$ allows a unique restoration of the potential matrix by the standard Gel'fand–Levitan theory (its multichannel generalization).

III. CONCLUSIONS

In this article, the relationship is established between components of the norming vector γ_{λ_n} associated with a certain boundary value problem (with the spectrum $\{\lambda_n\}_{n=1}^{\infty}$) and the spectra (including $\{\lambda_n\}_{n=1}^{\infty}$) of $M+1$ multichannel Sturm-Liouville operators with the same potential matrix $V_{\alpha\beta}(x)$ but different boundary conditions. As a matter of fact, the central result is formula (14). Though giving no unique solutions in general, it can get linear if we require the matrices $\hat{h}_i$ to be of special type. Hence, the uniqueness of the multichannel inverse eigenvalue problem from $M+1$ spectra is however possible for a particular class of boundary conditions. The problem of specifying the necessary and sufficient conditions needs a special examination. It is clear that scrutinizing the asymptotic behavior of the spectra with different boundary conditions will be required. It is closely associated with specifying the class of differentiable functions the $V_{\alpha\beta}(x)$ pertain to. So, the results given present only an intermediate stage in investigations on the subject.

(Received 6 May 2004; accepted 21 May 2004; published 25 October 2004)

We prove that under short range potentials a semiclassical wave packet's propagation is accurate for infinite times in the $\hbar \to 0$ limit. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1780613]

I. INTRODUCTION

Semiclassical analysis is the study of the connections between the quantum dynamics and the corresponding classical dynamics in the $\hbar \to 0$ limit. Consider the quantum dynamics determined by the time dependent Schrödinger equation

$$i\hbar \frac{\partial}{\partial t}\psi(x,t) = \left\{ -\frac{\hbar^2}{2}\Delta_x + V(x) \right\} \psi(x,t). \tag{1}$$

Following the prescription defined in Refs. 1–5 one can construct approximate solutions to this equation whose time propagation is determined by the corresponding classical mechanics. These wave packets depend explicitly on the corresponding classical dynamics of the system, $\hbar$, and position. These semiclassical wave packets can be used to approximate the quantum dynamics.[1–5] Here we present a result for the semiclassical wave packets that is uniform in time. This result is an extension of a known result[1] to one and two space dimensions.

The organization of the paper is as follows: In Sec. II we present the construction of the semiclassical wave packets. In Sec. III we introduce the needed results from classical scattering theory. In Sec. IV we state and prove Theorem 1, the main result of the paper for $n=1$, referring the reader to some technical lemmas from Sec. V. In Sec. VI we provide the necessary tools needed to extend the proof to two dimensions.

Throughout we adopt standard multi-index notation.[7] The inner products are linear in the second term, conjugate linear in the first. Furthermore, we assume that our potential is "short range," i.e., $V(x)$ satisfies the short-range assumption (D) if for any multi-index α such that $|\alpha| = 0,1,2,3$, there exists $C_{|\alpha|} > 0$, $0 < \nu < 1$, such that

$$|(D^\alpha V)(x)| \leqslant C_{|\alpha|}(1+|x|)^{-1-|\alpha|-\nu}.$$

Notice that if a potential is short range then

$$V(x) \in L^p(\mathbb{R}^n) \text{ for } p > \max\left\{ \frac{n}{1+\nu}, 1 \right\}$$

and

$$V(x)(1+x)^{-[(n/2)-1]+(\nu/2)} \in L^2(\mathbb{R}^n).$$

So, for $n=1,2$ our potentials are in $L^2(\mathbb{R}^n)$.

II. SEMICLASSICAL WAVE PACKETS

Here we present a definition of the semiclassical wave packets. Our construction is analogous to the standard construction of the harmonic oscillator eigenstates using raising and lowering operators. Greater detail on the construction presented here can be found in Ref. 4. Let $a,\ \eta \in \mathbb{R}^n$, and $\hbar > 0$. Furthermore assume that A and B are complex $n \times n$ matrices satisfying

$$A^t B - B^t A = 0, \tag{2}$$

$$A^* B + B^* A = 2I. \tag{3}$$

Conditions (2) and (3) are known to be equivalent to the following four conditions assumed in Ref. 1:

(i) A and B are invertible;
(ii) the real and imaginary parts of BA^{-1} are both real symmetric;
(iii) $\mathrm{Re}\, BA^{-1}$ is strictly positive definite;
(iv) $(\mathrm{Re}\, BA^{-1})^{-1} = AA^*$.

Let $p = -i\hbar\nabla_x$ be the momentum operator. For any $v \in \mathbb{C}^n$ we define associated raising and lowering operators by

$$\mathcal{A}(A,B,\hbar,a,\eta,v)^* = \frac{1}{\sqrt{2\hbar}}[\langle B\overline{v},(x-a)\rangle - i\langle A\overline{v},(p-\eta)\rangle]$$

and

$$\mathcal{A}(A,B,\hbar,a,\eta,v) = \frac{1}{\sqrt{2\hbar}}[\langle \overline{B}v,(x-a)\rangle + i\langle \overline{A}v,(p-\eta)\rangle].$$

Let $\{e_j\}$ be any orthonormal basis for $\mathbb{R}^n$, and define

$$\mathcal{A}_j(A,B,\hbar,a,\eta)^* = \mathcal{A}(A,B,\hbar,a,\eta,e_j)^*,$$

$$\mathcal{A}_j(A,B,\hbar,a,\eta) = \mathcal{A}(A,B,\hbar,a,\eta,e_j).$$

Then we can define

$$\mathcal{A}(A,B,\hbar,a,\eta)^* = \frac{1}{\sqrt{2\hbar}}[B^*(x-a) - iA^*(p-\eta)],$$

$$\mathcal{A}(A,B,\hbar,a,\eta) = \frac{1}{\sqrt{2\hbar}}[B^t(x-a) + iA^t(p-\eta)],$$

where the representation is in terms of the above basis. Define $\phi_0(A,B,\hbar,a,\eta,\cdot)$ to be a normalized vector with respect to $L^2(\mathbb{R}^n)$ such that

$$\mathcal{A}(A,B,\hbar,a,\eta)\phi_0(A,B,\hbar,a,\eta,\cdot) = 0.$$

It is seen that

$$\phi_0(A,B,\hbar,a,\eta,x) = (\pi\hbar)^{-n/4}(\det(A))^{-1/2}\exp\{-\langle (x-a),BA^{-1}(x-a)\rangle/(2\hbar) + i\langle \eta,(x-a)\rangle/\hbar\}.$$

Here a particular choice of phase is being made. For any multi-index k, we define

$$\phi_k(A,B,\hbar,a,\eta,x) = \frac{1}{\sqrt{k!}}(\mathcal{A}_1(A,B,\hbar,a,\eta)^*)^{k_1} \times \cdots \times (\mathcal{A}_n(A,B,\hbar,a,\eta)^*)^{k_n}\phi_0(A,B,\hbar,a,\eta,x).$$

Remark: The only ambiguity here is in the choice of sign on $(\det(A))^{-1/2}$, it is chosen depending on the initial conditions and continuity.

Remark: The functions $\phi_k(A,B,\hbar,a,\eta,\cdot)$ form an orthonormal basis of $L^2(\mathbb{R}^n)$.[4]

Let $S(t)$ be in $\mathbb{R}$, $a(t)$, $\eta(t)$ be vectors in $\mathbb{R}^n$, $A(t)$, $B(t)$ be complex $n\times n$ matrices all governed by the following system of ordinary differential equations:

$$\dot{a}(t) = \eta(t),$$

$$\dot{\eta}(t) = -\vec{\nabla} V(a(t)),$$

$$\dot{A}(t) = iB(t), \tag{4}$$

$$\dot{B}(t) = iV^{(2)}(a(t))A(t),$$

$$\dot{S}(t) = \frac{(\eta(t))^2}{2} - V(a(t)),$$

suppose the initial conditions given such that $A(0)$, $B(0)$ together satisfy (2) and (3) and $S(0)=0$. It is known that $A(t)$, $B(t)$ together still satisfy (2) and (3).[4]

Remark: Let

$$W_{a(t)}(x) = V(a(t)) + \langle V^{(1)}(a(t)),(x-a(t))\rangle + \tfrac{1}{2}\langle (x-a(t)),V^{(2)}(a(t))(x-a(t))\rangle,$$

the functions $\psi(x,t)=e^{iS(t)/\hbar}\phi_k(A(t),B(t),\hbar,a(t),\eta(t),x)$ provide exact solutions to the time dependent Schrödinger equation,

$$i\hbar\frac{\partial}{\partial t}\psi(x,t) = -\frac{\hbar^2}{2}\Delta_x\psi(x,t) + W_{a(t)}(x)\psi(x,t).$$

We state a result about the wave packets that will be used later. The reference is Ref. 4.

Lemma 1: Suppose $V\in C^3(\mathbb{R}^n)$ *satisfies* $-C_1\leqslant V(x)\leqslant C_2e^{Mx^2}$ *for some* C_1, C_2 *and* M. *Let* $(A(t),B(t),a(t),\eta(t),S(t))$ *be a solution to the system (4) with appropriate initial conditions. Let* $H(\hbar)=-(\hbar^2/2)\Delta+V(x)$. *Then there exists some* $C(k,t)$ *such that*

$$\|e^{-itH(\hbar)/\hbar}\phi_k(A(0),B(0),\hbar,a(0),\eta(0),x) - e^{-iS(t)/\hbar}\phi_k(A(t),B(t),\hbar,a(t),\eta(t),x)\| \leqslant C(k,t)\hbar^{1/2}. \tag{5}$$

Using these semiclassical wave packets one can now attempt to provide a construction for approximate solutions to the Schrödinger equation and prove accuracy estimates. For details on this see Refs. 1–5.

III. CLASSICAL SCATTERING

Existence of scattering states in classical mechanics is crucial to our study.

Lemma 2: Let $V(x)$ *satisfy the short-range assumption* (D). *Given any* $(a_-,\eta_-)\in\mathbb{R}^{2n}$ *such that* $\eta_-\neq 0$. *Let* A_-, *and* B_- *be complex* $n\times n$ *matrices satisfying conditions (2) and (3) then there exist a unique solution* $[a(t),\eta(t),A(t),B(t),S(t)]$ *to the system (4) such that*

$$\lim_{t\to-\infty}|a(t) - a_- - \eta_- t| = 0,$$

$$\lim_{t\to-\infty}|\eta(t) - \eta_-| = 0,$$

$$\lim_{t\to-\infty}|S(t)-t\eta_-^2/2|=0, \tag{6}$$

$$\lim_{t\to-\infty}\|A(t)-A_--iB_-t\|=0,$$

$$\lim_{t\to-\infty}\|B(t)-B_-\|=0.$$

Moreover, there exists $n\times n$ *complex matrices* A_+, B_+ *satisfying (2) and (3) and a closed set* E *of measure zero contained in* $\mathbb{R}^{2n}$ *such that* $(a_-,\eta_-)\in\mathbb{R}^{2n}\backslash E$ *implies the existence of* $(a_+,\eta_+)\in\mathbb{R}^{2n}$ *with* $\eta_+\neq 0$, $S_+\in R$ *such that*

$$\lim_{t\to\infty}|a(t)-a_+-\eta_+t|=0,$$

$$\lim_{t\to\infty}|\eta(t)-\eta_+|=0,$$

$$\lim_{t\to\infty}\|A(t)-A_+-iB_+t\|=0, \tag{7}$$

$$\lim_{t\to\infty}\|B(t)-B_+\|=0,$$

$$\lim_{t\to\infty}|S(t)-S_+-t\eta_+^2/2|=0.$$

This result basically says that given an incoming free state we can find an interacting state that approaches it at infinite negative time. Then for almost any free incoming state there exists a free outgoing state that approximates the interaction state at infinite time. In the language of scattering, the above theorem is existence, uniqueness of scattering operators coupled with asymptotic completeness. The proof of this for the position and momentum variables $a(t)$, $\eta(t)$, is given in Ref. 8, the proof for the spreading variables $A(t)$, $B(t)$ and the action variable $S(t)$, is given in Ref. 1.

IV. STATEMENT AND PROOF OF THE MAIN RESULT FOR $N=1$

Let

$$H(\hbar)=-\frac{\hbar^2}{2}\Delta_x+V(x)$$

and

$$H_1(t,\hbar)=-\frac{\hbar^2}{2}\Delta_x+W_{a(t)}(x),$$

with corresponding unitary propagators $U(t)$ and $U_1(t,0)$, respectively. Recall

$$U_1(t,0)\phi_0(A(0),B(0),\hbar,a(0),\eta(0),x)=e^{iS(t)/\hbar}\phi_0(A(t),B(t),\hbar,a(t),\eta(t),x).$$

Theorem 1: *If* $V(x)$ *satisfies the short-range assumption* (D), *then there exists* C, $\lambda>0$, *both independent of* t *and* $\hbar$ *such that*

$$\|U(t)\phi_0(A(0),B(0),\hbar,a(0),\eta(0),\cdot)-e^{iS(t)/\hbar}\phi_0(A(t),B(t),\hbar,a(t),\eta(t),\cdot)\|_2\leqslant C\hbar^{\lambda}$$

for all $t\in(-\infty,\infty)$, $\hbar\in(0,1)$, *any* $A(0)$, $B(0)$ *satisfying Eqs. (2) and (3) and almost all* $a(0)$, $\eta(0)$.

Remark: The theorem is an analogous statement to that of lemma 2 for the semiclassical wave packets.

The proof given in Ref. 1 that is restricted to $n \geqslant 3$ uses the fact that the wave packet decays as $t^{-n/2}$, and thus the wave packet is itself in L^1 when $n \geqslant 3$. For $n=1$ and $n=2$ we remove the portion of the state that has small asymptotic momentum. This portion of the wave packet is $O(\hbar^{1/2})$. The remaining portion of the wave packet decays fast enough in t to prove the estimates we need. Our idea is to write the wave packet as

$$\phi_0(A(t),B(t),\hbar,a(t),\eta(t),x) = \frac{p}{\eta}\phi_0(A(t),B(t),\hbar,a(t),\eta(t),x) + \frac{\eta - p}{\eta}\phi_0(A(t),B(t),\hbar,a(t),\eta(t),x)$$

and then drop the second term at time 0 in order to get the asymptotics to cancel out correctly. The intuition is that the second term above is on the order of $\sqrt{\hbar}$ at time zero and can be disregarded in the semiclassical limit. The idea to write the wave packet in this way was inspired by Ref. 6 and many ideas from this paper can be seen in the proof. We need the portion of the wave packet that is not disregarded to be propogated exactly by the semiclassics given in Sec. II, therefore we write the wave packet as

$$\begin{aligned}
\phi_0(A(\tau),B(\tau),\hbar,a(\tau),\eta(\tau),x) &= \left\{1 + \frac{(x-a(\tau))iB_+}{A(\tau)\eta_+}\right\}\phi_0(A(\tau),B(\tau),\hbar,a(\tau),\eta(\tau),x) \\
&\quad - \frac{(x-a(\tau))iB_+}{A(\tau)\eta_+}\phi_0(A(\tau),B(\tau),\hbar,a(\tau),\eta(\tau),x) \\
&= \left\{1 + \frac{(x-a(\tau))iB_+}{A(\tau)\eta_+}\right\}\phi_0(A(\tau),B(\tau),\hbar,a(\tau),\eta(\tau),x) \\
&\quad - \sqrt{\frac{\hbar}{2}}\frac{iB_+}{\eta_+}\phi_1(A(\tau),B(\tau),\hbar,a(\tau),\eta(\tau),x) \\
&= \tilde{\phi}_0(A(\tau),B(\tau),\hbar,a(\tau),\eta(\tau),x) \\
&\quad - \sqrt{\frac{\hbar}{2}}\frac{iB_+}{\eta_+}\phi_1(A(\tau),B(\tau),\hbar,a(\tau),\eta(\tau),x). \qquad (8)
\end{aligned}$$

We have used the fact that in one dimension

$$\phi_1(A(t),B(t),\hbar,a(t),\eta(t),x) = \sqrt{\frac{2}{\hbar}}\frac{(x-a(t))}{A(t)}\phi_0(A(t),B(t),\hbar,a(t),\eta(t),x). \qquad (9)$$

The argument of the theorem almost exactly follows the argument in Ref. 1. Besides the introduction of the modified wave packet the changes that we have made are imbedded in technical lemmas 3 and 4.

Proof of Theorem 1 for $n=1$: Let $\mu < 1$, $\epsilon \in (0, \frac{1}{6})$, and define

$$\chi_1(\hbar,a(t),x) = \begin{cases} 1 & \text{if } |x-a(t)| \leqslant (1+|a(t)|)\mu\hbar^{1/2-\epsilon}, \\ 0 & \text{otherwise.} \end{cases}$$

Define $\chi_2(\hbar,a(t),x) = 1 - \chi_1(\hbar,a(t),x)$. Now define $\tilde{\phi}_0(A(\tau),B(\tau),\hbar,a(\tau),\eta(\tau),x)$ as above and proceed to calculate. By (8) and since $\{U(t) - U_1(t,0)\}$ is bounded by lemma 2 it is clear that

$$\begin{aligned}
&\|\{U(t) - U_1(t,0)\}\phi_0(A(0),B(0),\hbar,a(0),\eta(0),\cdot)\|_2 \\
&\quad \leqslant \|\{U(t) - U_1(t,0)\}\tilde{\phi}_0(A(0),B(0),\hbar,a(0),\eta(0),\cdot)\|_2 + k\sqrt{\hbar}, \qquad (10)
\end{aligned}$$

where

$$k = \frac{|B_+|}{\sqrt{2}|\eta_+|}.$$

By the fundamental theorem of calculus,

$$\begin{aligned}
&\|\{U(t) - U_1(t,0)\}\tilde{\phi}_0(A(0),B(0),\hbar,a(0),\eta(0),\cdot)\|_2 \\
&\quad = \left\| \int_0^t \frac{d}{ds}\{U(s) - U_1(s,0)\}\tilde{\phi}_0(A(0),B(0),\hbar,a(0),\eta(0),\cdot)ds \right\|_2 \\
&\quad \leqslant \hbar^{-1}\int_0^t \|\{V(\cdot) - W_{a(s)}(\cdot)\}\tilde{\phi}_0(A(s),B(s),\hbar,a(s),\eta(s),\cdot)\|_2\, ds. \qquad (11)
\end{aligned}$$

Analyzing the integrand in the last expression,

$$\begin{aligned}
&\|\{V(x) - W_{a(s)}(x)\}\tilde{\phi}_0(A(s),B(s),\hbar,a(s),\eta(s),x)\|_2 \\
&\quad \leqslant \|\{V(x) - W_{a(s)}(x)\}\chi_1(\hbar,a(s),x)\tilde{\phi}_0(A(s),B(s),\hbar,a(s),\eta(s),x)\|_2 \\
&\qquad + \|V(x)\chi_2(\hbar,a(s),x)\tilde{\phi}_0(A(s),B(s),\hbar,a(s),\eta(s),x)\|_2 \\
&\qquad + \|W_{a(s)}(x)\chi_2(\hbar,a(s),x)\tilde{\phi}_0(A(s),B(s),\hbar,a(s),\eta(s),x)\|_2 = \mathrm{I}(s) + \mathrm{II}(s) + \mathrm{III}(s). \qquad (12)
\end{aligned}$$

If $|x-a(s)| \leqslant (1+|a(s)|)\mu\hbar^{1/2-\epsilon}$ then following the analysis from Ref. 1 we let $z_* \in \mathcal{Z} = \{z = rx + (1-r)y\}$ such that $|z_*| \leqslant |z|$ for all $z \in \mathcal{Z}$. By the fundamental theorem of calculus and the triangle inequality it can be seen that

$$|V_2(x) - V_2(y)| \leqslant C_3(1+|z|)^{-4-\nu}|x-y| \leqslant C_3(1+|y|-|y-z|)^{-4-\nu} \leqslant C_3[(1-\mu)(1+|y|)^{-4-\nu}|x-y| \ , \qquad (13)$$

where C_3 is taken from the short-range assumption. From here it follows that

$$\|\chi_1(\hbar,a(s),x)(V(x) - W_{a(s)}(x))\|_\infty \leqslant C_3(1+|a(s)|)^{-1-\nu}\hbar^{3/2-3\epsilon}. \qquad (14)$$

Hence

$$\mathrm{I}(s) \leqslant C_3(1+|a(s)|)^{-1-\nu}\hbar^{3/2-3\epsilon}\left(1 + k\sqrt{\frac{\hbar}{2}}\right).$$

Again we follow the argument in Ref. 1. Due to continuity and asymptotics of the classical quantities $a(s)$, $A(s)$ that

$$\begin{aligned}
\mathrm{II}(s) &\leqslant \left\| \chi_2(\hbar,a(s),x)\exp\left\{\frac{-(x-a(s))^2}{4|A(s)|^2\hbar}\right\}\right\|_\infty \left\| \chi_2(\hbar,a(s),x)V(x)\left(1 + \frac{(x-a(s))iB_+}{A(s)\eta_+}\right)\right. \\
&\quad \left. \times(\pi\hbar)^{-1/4}(A(s))^{-1/2}\exp\left\{\frac{-(x-a(s))^2}{4|A(s)|^2\hbar}\right\}\right\|_2 \\
&\leqslant \exp\{-C'\hbar^{-2\epsilon}\}\left\| \chi_2(\hbar,a(s),x)V(x)\left(1 + \frac{(x-a(s))iB_+}{A(s)\eta_+}\right)\right. \\
&\quad \left. \times(\pi\hbar)^{-1/4}(A(s))^{-1/2}\exp\left\{\frac{-(x-a(s))^2}{4|A(s)|^2\hbar}\right\}\right\|_2, \qquad (15)
\end{aligned}$$

where C' is some constant independent of s and $\hbar$. By lemma 5.1 and dividing by $A(s)\eta_+$ there exists C_V, T_1 such that for $s > T_1$,

$$\mathrm{II}(s) \leqslant C_V \hbar^{-1/2-\nu/2} \exp\{-C'\hbar^{-2\epsilon}\}|s|^{-1-\nu/2}.$$

We can do the same thing with $\mathrm{III}(s)$ as well. By lemma 5.2 there exists T_2, C_W such that for $s > T_2$,

$$\mathrm{III}(s) \leqslant C_W \hbar^{-1} \exp\{-C'\hbar^{-2\epsilon}\}|s|^{-1-\nu}.$$

The theorem is now proven by taking $T = \max\{T_1, T_2\}$ and writing for $t > T$,

$$\hbar^{-1}\int_0^t (\mathrm{I}(s) + \mathrm{II}(s) + \mathrm{III}(s))\mathrm{d}s = \hbar^{-1}\left\{\int_0^T (\mathrm{I}(s) + \mathrm{II}(s) + \mathrm{III}(s))\mathrm{d}s + \int_0^t (\mathrm{I}(s) + \mathrm{II}(s) + \mathrm{III}(s))\mathrm{d}s\right\}.$$

The first term is bounded by some $C_T\hbar^{1/2}$ by lemma 1. The second term is bounded by some $C\hbar^{-2}\exp\{-C'\hbar^{-2\epsilon}\} + C_3\hbar^{1/2-3\epsilon}$ by the work shown here. In order to propagate to large negative times we write the modified wave packet with η_-, B_- in place of η_+, B_+ and the details are the same. □

V. TECHNICAL LEMMAS

Lemma 3: In space dimension one if $V(x)$ satisfies the short-range assumption (D), then there exists some constant C such that for t sufficiently large, $\hbar \in (0,1)$,

$$\left\| \chi_2(\hbar, a(t), x) V(x)\{\eta_+ A(t) + (x - a(t))iB_+\}(\pi\hbar)^{-1/4}(A(t))^{-1/2} \exp\left\{\frac{-(x-a(t))^2}{4|A(t)|^2\hbar}\right\}\right\|_2 \leqslant C\hbar^{-1/2-\nu/2}t^{-\nu/2},$$

where $\chi_2(\hbar, a(t), x)$ is as defined in the proof of Theorem 1.

Proof: Let $k_1 > 0$. By lemma 2 there exists T such that $t > T$ implies that

$$\begin{aligned}&\left\| \chi_2(\hbar, a(t), x) V(x)\{\eta_+ A(t) + (x - a(t))iB_+\}(\pi\hbar)^{-1/4}(A(t))^{-1/2} \exp\left\{\frac{-(x-a(t))^2}{4|A(t)|^2\hbar}\right\}\right\|_2 \\ &\quad \leqslant \left\| \chi_2(\hbar, a(t), x) V(x) \cdot \{\eta_+(A_+ + iB_+t) + (x - a_+ - \eta_+ t)iB_+\} \right. \\ &\qquad \left. \times (\pi\hbar)^{-1/4}(A(t))^{-1/2} \exp\left\{\frac{-(x-a(t))^2}{4|A(t)|^2\hbar}\right\}\right\|_2 + k_1\hbar^{-1/4}|A(t)|^{-1/2}. \end{aligned} \tag{16}$$

Using the triangle inequality we find that

$$\begin{aligned}&\left\| \chi_2(\hbar, a(t), x) V(x) \cdot \{\eta_+(A_+ + iB_+t) + (x - a_+ - \eta_+ t)iB_+\}(\pi\hbar)^{-1/4}(A(t))^{-1/2} \exp\left\{\frac{-(x-a(t))^2}{4|A(t)|^2\hbar}\right\}\right\|_2 \\ &\quad \leqslant \left\| V(x)[\eta_+ A_+](\pi\hbar)^{-1/4}(A^{-1/2}(t)) \exp\left\{\frac{-(x-a(t))^2}{4|A(t)|^2\hbar}\right\}\right\|_2 + \left\| \chi_2(\hbar, a(t), x) V(x)[iB_+(x - a_+)] \right. \\ &\qquad \left. \times (\pi\hbar)^{-1/4}(A^{-1/2}(t)) \exp\left\{\frac{-(x-a(t))^2}{4|A(t)|^2\hbar}\right\}\right\|_2. \end{aligned} \tag{17}$$

Since $V(x) \in L^2(\mathbb{R})$ we have some constant k_2 such that for large enough t,

$$\left\| V(x)[\eta_+ A_+](\pi\hbar)^{-1/4}(A^{-1/2}(t)) \exp\left\{\frac{-(x-a(t))^2}{4|A(t)|^2\hbar}\right\}\right\|_2 \leqslant k_2\hbar^{-1/4}t^{-1/2}. \tag{18}$$

Similarly,

$$\left\| \chi_2(\hbar,a(t),x)V(x)[iB_+(x-a_+)](\pi\hbar)^{-1/4}(A^{-1/2}(t))\exp\left\{\frac{-(x-a(t))^2}{4|A(t)|^2\hbar}\right\}\right\|_2$$
$$\leqslant \|iB_+V(x)(x-a_+)^{1/2+\nu/2}\|_2 \left\| \chi_2(\hbar,a(t),x)(\pi\hbar)^{-1/4}(A(t))^{-1/2}(x-a_+)^{1/2-\nu/2} \times\exp\left\{\frac{-(x-a(t))^2}{4|A(t)|^2\hbar}\right\}\right\|_\infty. \tag{19}$$

The first factor is a constant independent of t and $\hbar$. Evaluating the second term further we see that

$$\left\| \chi_2(\hbar,a(t),x)(\pi\hbar)^{-1/4}(A(t))^{-1/2}(x-a_+)^{1/2-\nu/2}\exp\left\{\frac{-(x-a(t))^2}{4|A(t)|^2\hbar}\right\}\right\|_\infty$$
$$= \left\| \chi_2(\hbar,a(t),x)\frac{(x-a_+)^{1/2-\nu/2}}{(x-a(t))^{1/2-\nu/2}}\frac{(x-a(t))^{1/2-\nu/2}}{(\pi\hbar)^{1/4}(A(t))^{1/2}}\exp\left\{\frac{-(x-a(t))^2}{4|A(t)|^2\hbar}\right\}\right\|_\infty$$
$$\leqslant \left\| \chi_2(\hbar,a(t),x)\frac{(x-a_+)^{1/2-\nu/2}}{(x-a(t))^{1/2-\nu/2}}\right\|_\infty \left\| \chi_2(\hbar,a(t),x)\frac{(x-a(t))^{1/2-\nu/2}}{(\pi\hbar)^{1/4}(A(t))^{1/2}}\exp\left\{\frac{-(x-a(t))^2}{4|A(t)|^2\hbar}\right\}\right\|_\infty$$
$$\leqslant \left\| \chi_2(\hbar,a(t),x)\frac{(x-a_+)^{1/2-\nu/2}}{(x-a(t))^{1/2-\nu/2}}\right\|_\infty \frac{\hbar^{-\nu/4+\epsilon\nu/2}}{(\mu(1+|a(t)|))^{\nu/2}}\left\| \frac{(x-a(t))^{1/2}}{(\pi\hbar)^{1/4}(A(t))^{1/2}}\exp\left\{\frac{-(x-a(t))^2}{4|A(t)|^2\hbar}\right\}\right\|_\infty. \tag{20}$$

The second norm in the last expression is bounded by a constant. For the first norm we see that

$$\left\| \chi_2(\hbar,a(t),x)\frac{(x-a_+)^{1/2-\nu/2}}{(x-a(t))^{1/2-\nu/2}}\right\|_\infty \leqslant \max\left\{1,\left\| \chi_2(\hbar,a(t),x)\frac{(x-a_+)}{(x-a(t))}\right\|_\infty\right\}. \tag{21}$$

Now we see that

$$\left\| \chi_2(\hbar,a(t),x)\frac{(x-a_+)}{(x-a(t))}\right\|_\infty \leqslant \left\| \chi_2(\hbar,a(t),x)\frac{(x-a(t)+a(t)-a_+)}{(x-a(t))}\right\|_\infty 1+\left\| \chi_2(\hbar,a(t),x)\frac{(a(t)-a_+)}{(x-a(t))}\right\|_\infty$$
$$\leqslant 1+\left\| \chi_2(,a(t),x)\frac{(a(t)-a_+)}{(1+a(t))\mu\hbar^{1/2-\nu/2}}\right\|_\infty \leqslant 1+k_3\hbar^{-1/2+\nu/2}, \tag{22}$$

where k_3 is a constant independent of t and $\hbar$. The lemma now follows. □

Lemma 4: If $V(x)$ satisfies the short-range assumption (D), then there exists some constant C such that for large enough t, and $\hbar\in(0,1)$,

$$\left\| W_{a(t)}(x)\left[1+\sqrt{\frac{\overline{A}(t)}{A(t)}}\frac{(x-a(t))iB_+}{|A(t)|\eta_+}\right](\pi\hbar)^{-1/4}(A^{-1/2}(t))\exp\left\{\frac{-(x-a(t))^2}{4|A(t)|^2\hbar}\right\}\right\|_2 \leqslant C\hbar^{-1}t^{-1-\nu}.$$

Proof: Since $V(x)$ satisfies the short-range condition there exists C_j, $j=0,1,2$ such that

$$\left\| W_{a(t)}(x)\left[1+\sqrt{\frac{\overline{A(t)}}{A(t)}}\frac{(x-a(t))iB_+}{|A(t)|\eta_+}\right](\pi\hbar)^{-1/4}(A^{-1/2}(t))\exp\left\{\frac{-(x-a(t))^2}{4|A(t)|^2\hbar}\right\}\right\|_2$$
$$\leqslant \sum_{j=0}^{2} C_j(1+|a(t)|)^{-1-j-\nu}\cdot|A(t)|^j\cdot 2^j\cdot\hbar^{j/2}\left\|\left(\frac{(x-a(t))}{2|A(t)|\hbar^{1/2}}\right)^j\cdot\left\{1+\sqrt{\frac{\overline{A(t)}}{A(t)}}\frac{(x-a(t))iB_+}{|A(t)|\eta_+}\right\}\right.$$
$$\left.\times(\pi\hbar)^{-1/4}(A(t))^{-1/2}\exp\left\{\frac{-(x-a(t))^2}{4|A(t)|^2\hbar}\right\}\right\|_2. \tag{23}$$

By explicit evaluation, we see that the norms in the last expression are bounded by constants independent of t and $\hbar$. □

VI. EXTENSION TO TWO DIMENSIONS

The extension of this result to two dimensions has a few complications due to the structure of higher order states in more than one dimension. Here we point out the changes that need to be made in the proof of Theorem 1 in order to extend it to $n=2$. The techniques follow the construction given in Ref. 3. We present this in a less general manner for the sake of clarity. Let $\{e_1,e_2\}$ be the standard basis for $\mathbb{R}^2$. By the polar decomposition theorem for all t there exists a unique unitary matrix $U_A(t)$ such that $A(t)=|A(t)|U_A(t)$. We then define

$$\tilde{H}_1(v,x)=2\langle v,x\rangle$$

and

$$H_{e_j}(A(t);x)=\tilde{H}_1(U_A(t)e_j,x).$$

Now we proceed to define the higher order wave packet,

$$\phi_{e_j}(A(t),B(t),\hbar,a(t),\eta(t),x)=2^{-1/2}H_{e_j}(A(t);\hbar^{-1/2}|A(t)|^{-1}(x-a(t)))\phi_0(A(t),B(t),\hbar,a(t),\eta(t),x) \tag{24}$$

$$=2^{1/2}\langle U_A(t)e_j,\hbar^{-1/2}|A(t)|^{-1}(x-a(t))\rangle\phi_0(A(t),B(t),\hbar,a(t),\eta(t),x). \tag{25}$$

Now define

$$\tilde{\phi}_0(A(t),B(t),\hbar,a(t),\eta(t),x)=\left\{1+\left\langle U_A(t)e_1,\frac{i|A(t)|^{-1}B_+(x-a(t))}{\langle e_1,\eta_+\rangle}\right\rangle\right\}\phi_0(A(t),B(t),\hbar,a(t),\eta(t),x) \tag{26}$$

and the modified wave packet is again propagated as in Theorem 1. Since we have assumed that $\eta_+\neq 0$ we can use e_2 instead of e_1 if $\langle e_1,\eta_+\rangle=0$. Recall

$$U_A(t)=|A(t)|^{-1}A(t),$$

implying

$$U_A^*(t)=A^{-1}(t)|A(t)|,$$

and so similar to the analysis in one dimension we have

$$\tilde{\phi}_0(A(t),B(t),\hbar,a(t),\eta(t),x) = \left\{ \frac{\langle e_1,\eta_+\rangle}{\langle e_1,\eta_+\rangle} + \left\langle e_1, \frac{iA^{-1}(t)B_+(x-a(t))}{\langle e_1,\eta_+\rangle} \right\rangle \right\} \phi_0(A(t),B(t),\hbar,a(t),\eta(t),x)$$

$$= \frac{1}{\langle e_1,\eta_+\rangle} \langle e_1, \eta_+ + A^{-1}(t)(x-a(t))iB_+\rangle \phi_0(A(t),B(t),\hbar,a(t),\eta(t),x)$$

$$= \frac{1}{\langle e_1,\eta_+\rangle} \langle e_1, A^{-1}(t)\{A(t)\eta_+ + (x-a(t))iB_+\}\rangle \phi_0(A(t),B(t),\hbar,a(t),\eta(t),x). \tag{27}$$

Noting that

$$V(x)(1+x)^{\nu/2} \in L^2(\mathbb{R}^2)$$

and thus

$$\|iB_+V(x)(x-a_+)^{\nu/2}\|_2$$

is constant in place of

$$\|iB_+V(x)(x-a_+)^{1/2+\nu/2}\|_2$$

in the one dimensional case, the proof is now analogous to the proof for $n=1$.

(Received 26 May 2003; accepted 21 July 2004; published 25 October 2004)

An exact solution of the time-dependent master equation that describes the evolution of two two-level qubits (ions or atoms) within a perfect cavity for the case of multiphoton transition and in the presence of both the Stark shift and phase shift is obtained. Employing this solution, the significant features of the entanglement when a second qubit is allowed to interact with cavity mode and becomes entangled with the first qubit are investigated in the context of the measure defined by negative eigenvalues for the partial transposition of the density operator. The effects of Stark shift, distance between the two qubits, and an instantaneous phase shift experienced by the second qubit on the entanglement and probability amplitudes are indicated. It has been shown that the entanglement as well as the intensity are markedly affected by different parameters when the nonlinear two-photon process is involved. Moreover, the quasiprobability distribution function is investigated before and after the sudden phase shift experienced by the second qubit. We believe that this may throw some light on the question of the entanglement of multi-qubit systems. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1795986]

I. OVERVIEW

Investigations into the emerging science of quantum information has led to the widespread belief that entanglement in states shared between two systems can be used as a resource in nonclassical applications.[1–3] The theory of quantum entanglement has occupied a central place in modern research because of its promise of enormous utility in quantum computing, cryptography, etc.[4–8] A major thrust of current research is to find a quantitative measure of entanglement for general states. One of the most intriguing problems of quantum mechanics is the interpretation of the measurement process (for an overview of fundamental problems in quantum measurement, see, for example, Refs. 9–11). The reason for this central role of the measurement process is the absence of fundamental, elements of reality, that would simultaneously characterize both the dynamics and the measurement results. At this end, in quantum information, the maximally entangled states have a special significance.

For the experiments in the newest fields of physics, quantum computing, quantum communication, and quantum cryptography[4–8] the quantitative analysis of the multiqubit or ion is of substantial interest.[12] The dipole-dipole interaction between two atoms can be understood through the exchange of virtual photons and depends on the transition dipole moment of the levels involved. It can be characterized by complex coupling constants, or by their real and imaginary parts, where the former affect decay constants and the latter lead to level shifts.[13] There is an inherent interest in analytical and nonperturbative solutions of multiatom interacting with the cavity field problems, all the more considering quantum systems with more than one particle. One example of such a

[a)]Electronic mail: abdelatyquant@yahoo.co.uk

kind is the system of two two-level qubits in an electromagnetic field.[14–20] Entanglement of identical particles is a property dependent on which single-particle basis is chosen, as any operation should act on each identical particle in the same way. Indeed, individual particles are excitations of a quantum field, and the single-particle basis defines which set of particles are used in representing the many-particle state.[21]

One aim of the present article is to extend the previous models to a much more general model. To be more precise, we assume that two two-level atoms (two qubits) share a bipartite system, taking into account the multiphoton transition and the presence of Stark shift with the second qubit undergoing phase shift. Another principal aim is to elucidate the extent to which mixed entangled states can affect the entanglement. The emphasis being put on the investigation of the entanglement in a more general situation in which the two atoms (qubits) share a mixed state, rather than a pure state. The issue of attributing objective properties to the constituents of a quantum system composed of identical atoms, does not turn out to be a straightforward generalization of just the analyzed case involving distinguishable atoms, and the problem of entanglement has to be reconsidered. If a system interacts unitarily with an imperfectly known environment, the subdynamics of the system, averaged over the unknown states of the environment is nonunitary, and can take a pure state to a mixed state. In general it is known that there are also cases when entangled states are mixed with other entangled states and where the sum is separable.

The outline of this article is arranged as follows: In Sec. II, we give notation and definitions of the model and its analytical solution to be used in the rest of the article. The entanglement measure calculation is presented in Sec. III. By a numerical computation, we examine the influence of distance between the qubits, Stark shift, and phase shift on the evolution of the measure of entanglement which will be defined in terms of the negative eigenvalues of the partial transposition. Finally, Sec. IV has few concluding remarks, and few avenues for further investigations are indicated.

II. TWO QUBITS MODEL

To set the stage, we first begin with a discussion of where the two-qubit model comes from. Therefore, the physical system on which we focus is a two three-level harmonically trapped ions with its center-of-mass motion quantized. The ions are subjected to a laser field. This model differs from the standard micromaser setup in that instead of a single qubit we have assumed a pair of qubits interacting with a single mode of the cavity field. The position of the first qubit in the cavity is fixed and the second qubit is at some distance L from it. This distance will be a variable parameter of the problem.[9–11] Our interest lies in the case where the Stark shift and phase shift are included. The electronic levels $|a\rangle$ and $|b\rangle$ are assumed to be metastable and coupled via a laser field of the form

$$E(\hat{x},t) = E_0 \exp[i(\hat{k}\,.\,\hat{x} - \omega t + \phi(t))], \tag{1}$$

where E_0 is the strength of the electric field, $\hat{k}$ is the wave vector of the driving laser field, $\hat{x}$ is the position operator associated with the center-of-mass motion, and ω is the laser frequency. We denote by $\phi(t)$ the fluctuations in the laser phase. Therefore, we can express the center-of-mass position in terms of the creation and annihilation operators of the one-dimensional trap, namely,

$$\hat{x} = \sqrt{\frac{\hbar}{2M\omega_s}}(\hat{a}^\dagger + \hat{a}) = \Delta x(\hat{a}^\dagger + \hat{a}). \tag{2}$$

We denote by $\hat{a}$ and $\hat{a}^\dagger$ the annihilation and creation operators and ω_s is the vibrational frequency related to the center-of-mass harmonic motion along the direction $\hat{x}$. In the absence of the rotating wave approximation, the trapped ions Hamiltonian that describes the system between detections may be written as

$$\hat{H} = \hat{H}_0 + \hat{H}_1, \tag{3}$$

where

$$\hat{H}_0 = \hbar\omega_s \hat{a}^\dagger \hat{a} + \sum_{i=a,b,c} \hbar\omega_i |i\rangle\langle i|,$$

$$\hat{H}_1 = \hbar \sum_{i=1}^{2} \{(\lambda_1^{(i)} e^{-i(k_i.\hat{x}-\omega t+\phi_i)} S_{bc}^{(i)} + \text{H.c.}) + (\lambda_2^{(i)} e^{-i(k_i.\hat{x}-\omega t+\phi_i)} S_{ac}^{(i)} + \text{H.c.})\}. \tag{4}$$

The transition in the three-level ions is characterized by the dipole matrix element $\lambda_j^{(i)}$ where $S_{lm}^{(i)} = |l^{(i)}\rangle\langle m^{(i)}|$ $(l,m=a,b,c)$ being the considered three atomic levels. For the sake of simplicity (but without loss of generality), we have assumed to deal with the case in which $\phi_1 = 0$, $\phi_2 = \phi$ and the level $|c\rangle$ is assumed to be dipole-coupled to both the levels $|a\rangle$ and $|b\rangle$ via a far detuned laser field. While this is straightforward, it is often the case that it is simpler to work in the interaction picture in which the Hamiltonian (4) evolves in time according to the interaction with the vacuum field. If we express the center-of-mass position in terms of the creation and annihilation operators, the interaction part of Eq. (4) becomes

$$\begin{aligned}\hat{H}_{\text{int}} = &-\hbar\Delta \sum_{i=1}^{2} (S_{bb}^{(i)} + S_{aa}^{(i)}) + \hbar(\lambda_1^{(1)} e^{-i\eta(\hat{a}^\dagger+\hat{a})} S_{bc}^{(1)} + \text{H.c.}) + \hbar(\lambda_2^{(1)} e^{-i\eta(\hat{a}^\dagger+\hat{a})} S_{ac}^{(1)} + \text{H.c.}) \\ &+ \hbar(\lambda_1^{(2)} e^{-i\eta(\hat{a}^\dagger+\hat{a})} S_{bc}^{(2)} e^{-i\phi} + \text{H.c.}) + \hbar(\lambda_2^{(2)} e^{-i\eta(\hat{a}^\dagger+\hat{a})} S_{ac}^{(2)} e^{-i\phi} + \text{H.c.}),\end{aligned} \tag{5}$$

where $\eta = k\sqrt{\hbar/2M\omega_s}$, is the Lamb–Dicke parameter. In Eq. (5) the time-dependent factor is eliminated in the interaction picture, since $\omega_c - (\omega_b + \Delta) = m\omega_s$ and $\omega_c - (\omega_a + \Delta) = m\omega_s$. We assume the Lamb–Dicke regime with small η. In order to obtain this we detune the laser frequency ω to the mth vibrational red sideband. Also, we apply the rotating wave approximation discarding the rapidly oscillating terms and selecting the terms that oscillate with minimum frequency.[22] In these limits we can expand the interaction Hamiltonian to lowest order in η. The resulting effective Hamiltonian may be written as

$$\begin{aligned}\hat{H}_{\text{int}} = &-\hbar\Delta \sum_{i=1}^{2} (S_{bb}^{(i)} + S_{aa}^{(i)}) + \hbar\gamma_1^{(1)}(\hat{a}^{\dagger m} S_{bc}^{(1)} + \text{H.c.}) + \hbar\gamma_2^{(1)}(\hat{a}^{\dagger m} S_{ac}^{(1)} + \text{H.c.}) + \hbar\gamma_1^{(2)}(\hat{a}^{\dagger m} S_{bc}^{(2)} e^{-i\phi} + \text{H.c.}) \\ &+ \hbar\gamma_2^{(2)}(\hat{a}^{\dagger m} S_{ac}^{(2)} e^{-i\phi} + \text{H.c.}),\end{aligned} \tag{6}$$

with new coupling parameter $\gamma_i^{(j)}$ including the Dicke parameter in its definition. The analysis of such a Hamiltonian model can be carried out, providing eliminating of the nonresonantly coupled atomic level $|c\rangle$ adiabatically in the same manner as the standard JCM. Indeed, due to the large detuning, the transitions for instance from the level $|a\rangle$ to the level $|c\rangle$ are very fast and immediately followed by decays on the atomic level $|b\rangle$. Therefore, considering only coarse grained observables, meaning that the system is observed at a rough enough time scale, effectively eliminates the far detuned level, namely, at such a time scale, the only observables and hence meaningful dynamical behaviors, involve levels $|a\rangle$ and $|b\rangle$ as a result of time averaging second-order processes having $|c\rangle$ as an intermediate virtual level. This procedure hence suppresses the fine dynamics, that is it sacrifices any information concerning the fast dynamics the third level is involved in. So that the effective Hamiltonian of the system for $m=1$ in Eq. (6), including the ac-Stark shift, in the dipole and rotating wave approximation, can be written as[14–20] $(\hbar = 1)$

$$\hat{H} = \hat{a}^{\dagger}\hat{a}(\beta_1 S_{ba}^{(1)} S_{ab}^{(1)} + \beta_2 S_{ab}^{(1)} S_{ba}^{(1)}) + \hat{a}^{\dagger}\hat{a}(\beta_1 S_{ba}^{(2)} S_{ab}^{(2)} + \beta_2 S_{ab}^{(2)} S_{ba}^{(2)}) + \omega\hat{a}^{\dagger}\hat{a} + \omega(S_{aa}^{(1)} - S_{bb}^{(1)}) + \omega(S_{aa}^{(2)} - S_{bb}^{(2)}) + \gamma_1(S_{ab}^{(1)}\hat{a}^2 + \text{H.c.}) + \gamma_2(e^{i\phi} S_{ab}^{(2)}\hat{a}^2 + \text{H.c.}). \tag{7}$$

We denote by β_1 and β_2 the intensity-dependent Stark shifts, that are due to the virtual transitions to the intermediate relay level and $\gamma_i = \eta^2 \gamma_1^{(i)} \gamma_2^{(i)} / \Delta$.

It has been shown that entangled states in a two-atom system can be created by a continuous driving of the atoms with a coherent or chaotic thermal field, or by a pulse excitation followed by a continuous observation of radiative decay.[23] To begin with, we shall choose the following mixed state:

$$\rho = r|e_1, g_2\rangle\langle e_1, g_2| + (1-r)|g_1, e_2\rangle\langle g_1, e_2| \in \mathfrak{S}_A. \tag{8}$$

We may write the initial state of the field in vacuum state as

$$\varpi = |0\rangle\langle 0| \in \mathfrak{S}_F. \tag{9}$$

The continuous map $\mathcal{E}_t^*$ describing the time evolution between the qubits and the field is defined by the unitary evolution operator generated by $\hat{H}$ such that

$$\mathcal{E}_t^* : \mathfrak{S}_A \rightarrow \mathfrak{S}_A \otimes \mathfrak{S}_F,$$

$$\mathcal{E}_t^* \rho = \hat{U}_t(\rho \otimes \varpi)\hat{U}_t^*. \tag{10}$$

The interaction Hamiltonian, in this case, leads to an exactly solvable time evolution operator. Resuming our analysis, the time evolution operator can be written as

$$\hat{U}_t \equiv \exp\left(-\frac{i}{\hbar}\int_0^t \hat{H}(t')dt'\right), \tag{11}$$

i.e., $\hat{U}_t$ satisfies the interaction picture Schrödinger equation. Most of the authors who have treated multiqubits systems interacting with cavity fields have dealt with the case in which the Stark shift has been ignored.[9–11] However, in reality it cannot be ignored. Our interest in the current article lies in looking for a time dependent analytical solution even when the Stark shift and phase shift are nonzero. Using the above equations, in the interaction picture and after some algebraic manipulations we find that the final state $\mathcal{E}_t^*\rho$ at any time $t > 0$ is given by

$$\mathcal{E}_t^* \rho = \sum_{i=1}^{3}\sum_{j=1}^{3} U_{ij}(t)|\psi_i\rangle\langle\psi_j|, \tag{12}$$

where

$$U_{11}(t) = rA_tA_t^* + (1-r)B_tB_t^*, \quad U_{12}(t) = rA_tC_t^* + (1-r)B_tC_t^*,$$

$$U_{13}(t) = rA_tB_t^* + (1-r)B_tA_t^*, \quad U_{22}(t) = C_tC_t^*,$$

$$U_{23}(t) = rC_tB_t^* + (1-r)C_tA_t^*, \quad U_{33}(t) = rB_tB_t^* + (1-r)A_tA_t^*, \tag{13}$$

$\rho_{ij}(t) = \rho_{ji}^*(t)$, and

$$A_t = -\frac{\gamma_2^2}{\mu_1} - \frac{\gamma_1^2 \exp(-i2\beta_1 t)}{\mu_1}\left(\cos \mu t + i2\beta_1 \frac{\sin \mu t}{\mu}\right),$$

$$B_t = -\frac{\gamma_1^* \gamma_2 \exp(i\phi)\exp(-i2\beta_1 t)}{\mu_1}\left(\cos \mu t + 2\beta_1 \frac{\sin \mu t}{\mu}\right) + \frac{\gamma_1^* \gamma_2 \exp(i\phi)}{\mu_1},$$

$$C_t = -i2\gamma_1^* \exp(-i2\beta_1 t)\frac{\sin \mu t}{\mu}, \tag{14}$$

and

$$\mu = \sqrt{4\beta_1^2 + 2(\gamma_1^2 + \gamma_2^2)}, \quad \mu_1 = (\gamma_1^2 + \gamma_2^2),$$

$$\psi_1 = |e_1, g_2, 0\rangle, \quad \psi_2 = |g_1, e_2, 0\rangle, \quad \psi_3 = |g_1, g_2, 2\rangle. \tag{15}$$

We have therefore obtained an analytical solution of the final state of the system for this general model. Having obtained the explicit form of the final state of the system under consideration, we are therefore in a position to discuss the statistical properties of the system.

III. ENTANGLEMENT

The characterization and classification of entanglement in quantum mechanics is one of the cornerstones of the emerging field of quantum information theory. Although an entangled two-qubit state $\mathcal{E}_t^* \rho$ is not equal to the product $\mathcal{E}_t^* \rho_1$ and $\mathcal{E}_t^* \rho_2$ of the two single-qubit states contained in it, it may very well be a convex sum of such products. In general it is known that microscopic entangled states are found that to be very stable, for example electron-sharing in atomic bonding and two-qubit entangled photon states generated by parametric down conversion. Entanglement as one of the most nonclassical features of quantum mechanics is usually arisen from quantum correlations between separated subsystems which cannot be created by local actions on each subsystem. By definition, a mixed state of a bipartite system is said to be nonentangled if it can be written as a convex combination of pure product states. Although, in the case of pure states of bipartite systems it is easy to check whether a given state is entangled or not, the question is yet an open problem in the case of mixed states. There is also an increasing attention in quantifying entanglement, particularly for mixed states of a bipartite system.[24–38]

In this article, we take the measure of negative eigenvalues for the partial transposition of the density operator. It was proved that the negativity is an entanglement monotone,[38] hence, the negativity is a good entanglement measure. According to the Peres[39] and Horodecki *et al.*[40] condition for separability,[39,40] a two-qubit state for the given set of parameter values is entangled if and only if its partial transpose is negative. The measure of entanglement can be defined in terms of the negative eigenvalues of the partial transposition in the following form[36,37]

$$I_{\mathcal{E}_t^* \rho}(t) = 2 \max(0, -\lambda_{\text{neg}}), \tag{16}$$

where λ_{neg} is the sum of the negative eigenvalues of the partial transposition of the time-dependent reduced atomic density matrix ρ^a, which can be obtained by tracing out the field variables

$$\rho^a = \text{Tr}_f(\mathcal{E}_t^* \rho). \tag{17}$$

In the two qubit system $(C^2 \otimes C^2)$ it can be shown that the partial transpose of the density matrix can have at most one negative eigenvalue.[40] The partial transposition of ρ^{aT} has four eigenvalues one of which is negative, then the entanglement is given by

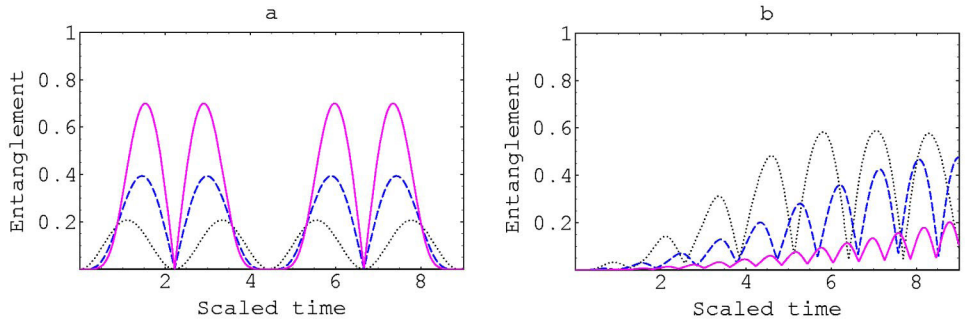

FIG. 1. This figure presents the results of a numerical calculation of the time evolution of the negativity as a measure of entanglement. The parameters $\phi=0$, and $L=0$, where (a) $r=0.2$ (solid curve), $r=0.6$ (dashed curve), and $r=1$ (dotted curve) and (b) $r=0.2$, $\beta_1=5\gamma$ (solid curve), $\beta=3\gamma$ (dashed curve), and $\beta_1=2\gamma$ (dotted curve).

$$I_{\varepsilon_t^*\rho}(t)=\sqrt{U_{33}^2(t)+4U_{21}(t)U_{12}(t)}-U_{33}(t).$$

The entanglement measure then ensures the scale between 0 and 1 and monotonously increases as entanglement grows. An important situation is that, when $I_{\varepsilon_t^*\rho}(t)=0$ the two qubits are separable and $I_{\varepsilon_t^*\rho}(t)=1$ indicates maximum entanglement between the two qubits. It was proved[38] that the negativity is an entanglement monotone, and hence is a good entanglement measure.

An interesting question is whether or not the entanglement is affected by the different parameters of the present system with the initial state in which one of the qubits is prepared in its excited state and the other in the ground state. In particular, the mixed state parameter r, the Stark shift parameter β_1, the distance between the qubits L, and the phase shift ϕ. A numeric evaluation of the entanglement measure leads to the plot in Fig. 1(a). We consider the coupling of the first qubit is taken to be constant $\gamma_1=\gamma$. Although we allow the second qubit to be at a distance L away and experience a variable qubit field coupling $\gamma_2=\gamma\cos kL$ (where we set $\beta_1=0$, $L=0$, $\phi=0$, and $r=1$). It is shown that the two qubits are entangled in this case, with the maximum value $I_{\varepsilon_t^*\rho}(t)\approx 0.2$ for $r=1$, $I_{\varepsilon_t^*\rho}(t)\approx 0.4$ for $r=0.6$ and $I_{\varepsilon_t^*\rho}(t)\approx 0.7$ for $r=0.2$. In all these cases we see that for some interaction times the entanglement is equal to zero, this period is increased with decreasing the parameter r. We now consider the two qubits interacting with the cavity field in the presence of Stark shift parameter β_1, where we set three different values of β_1 for the sake of comparison [see Fig. 1(b)]. It is remarkable to see that with the value of the Stark shift parameter, $\beta_1=2\gamma$ the entanglement is nearly zero for the initial period of the interaction time. This period increases with increasing the Stark shift. Also, the maximum value of the entanglement is decreased with increasing β_1. In this case we can say that, when the system is allowed to evolve without applying a phase shift, the entanglement degree is a periodic function of time. This is particularly because of the nonlinear nature of the coupling in this case (two-photon process).

We now pause to touch on certain entanglement features when a phase shift is applied to the second qubit at the time τ. To this end we consider the same values of the other parameters similar to Fig. 1(a). Three important values for the timing of the phase shift, namely, $\tau=\pi(J\pm 0.25)$, 3π, and $J\pi$ (here $J=3$) corresponding to the maximum and minimum values of the probability of emission of photon pair. This is illustrated in Fig. 2, where we have shown the time evolution of the entanglement for different values of the timing of the phase shift and $\phi=\pi/2$. First of all, we note that the regular behavior has been seen only for the case when $\tau=3\pi$. While for the other two values, i.e., for $\tau=\pi(J\pm 0.25)$, we see that there are two maximum values of the entanglement $I_{\varepsilon_t^*\rho}(t)\approx 0.5$ and 0.97. This situation is quite different from the maximum values of the entanglement at $\tau=3\pi$, where the two peaks have the same maximum value at $I_{\varepsilon_t^*\rho}(t)\approx 0.85$. It should be noted that the entanglement vanish for some period of the interaction time only when $\tau=3\pi$. These properties show that the role played by the timing of the phase shift on the entanglement is essential. Interestingly, when r is taken to be nonzero $(r=0.2)$, the values of the maximum en-

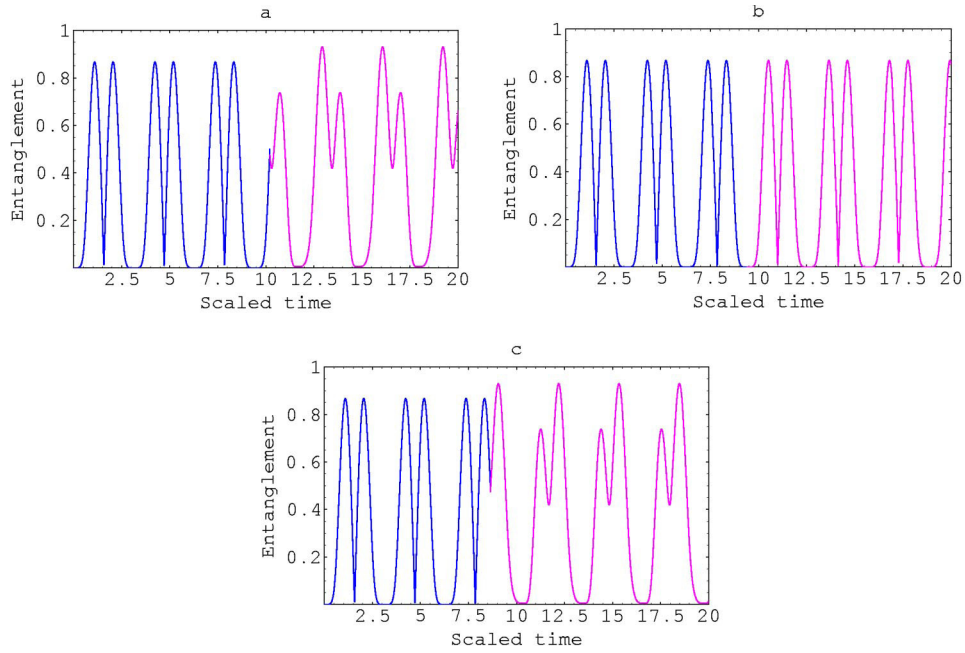

FIG. 2. This figure presents the results of a numerical calculation of the time evolution of the negativity as a measure of entanglement. $\phi=\pi/4$, $\beta_1=0$, $L=0$ and for different values of the timing of an applied phase step τ, where (a) $\tau=13\pi/4$, (b) $\tau=4\pi$, and (c) $\tau=11\pi/4$.

tanglement are decreased, indicating that the mixed state setting leads to a decreasing of the qubit-qubit entanglement. While the qubit-qubit entanglement has the same feature for different values of the mixed state parameter r, the change only occurs on the amplitude of the oscillations (see Fig. 2).

In the previous discussion, we have discussed different excitation processes which can prepare two qubits in the asymmetric state and we have assumed that both the qubits in the same position, i.e., $L=0$. This assumption is only valid if the coupling parameters $\gamma_1=\gamma_2$. The analysis involved single mode cavities, but ignored spontaneous emission from the qubits and the cavity damping. Here, we will extend this analysis to consider that two qubits separated by an arbitrary distance L, and we would like to highlight briefly why the qubit-qubit entanglement measure might have different features in the presence of the distance between the qubits. Figure 3(a) shows the basic features of the behavior of the qubit-qubit entanglement with different values of the distance between the qubits L. We remark that the entanglement has some kind of periodicity [see Fig. 3(a)] when $L=\pi/2k$. It is important to note here that, the minimum value of the entanglement is

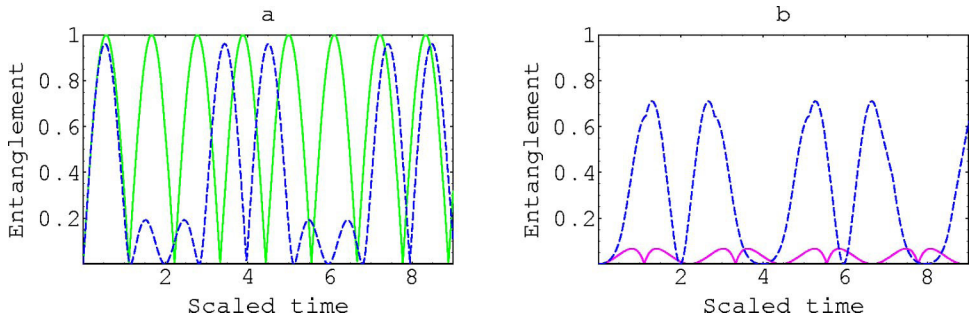

FIG. 3. Plot of the negativity as a measure of entanglement against the scaled time γt, the parameters $\beta_1=0$, $\phi=0$, and $r=1$, where (a) $kL=\pi/2$ (solid curve), and $kL=\pi/3$ (dotted curve). (b) The same as (a) but $r=0.2$.

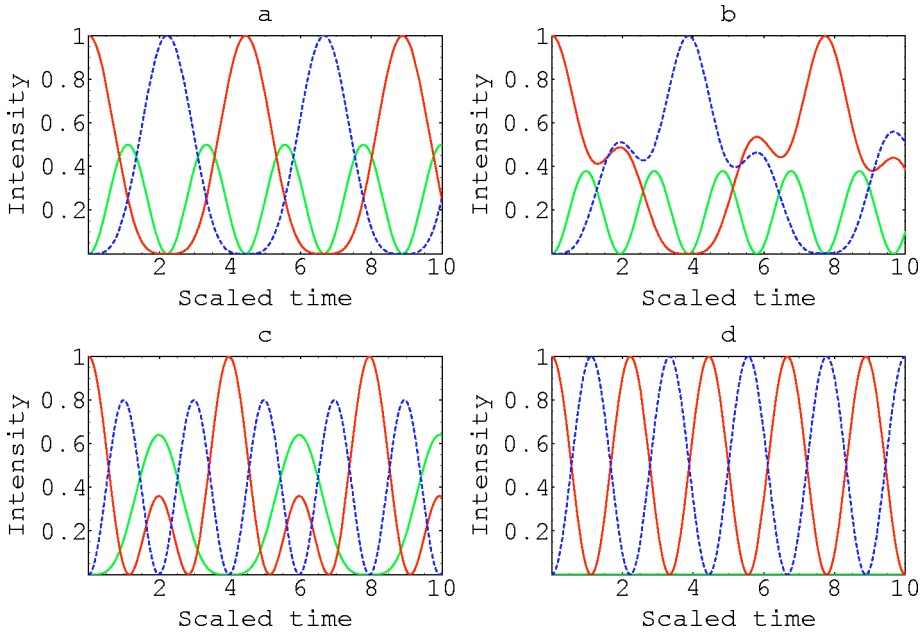

FIG. 4. This figure presents the results of the numerical calculations of the time evolution of the probability of the first qubit in excited state (solid line), probability of the second qubit in excited state (dotted line), and probability of emission of photon pair (dashed line), where (a) $\phi=0$, $\beta_1=0$, $kL=0$, $r=1$, (b) $\beta_1=0.8\gamma$, (c) $\phi=0$, $\beta_1=0$, $kL=\pi/3$, $r=1$, and (d) $\phi=0$, $\beta_1=0$, $kL=\pi/2$, $r=1$.

achieved, i.e., $I_{\mathcal{E}_t^*\rho}(t)\approx 0$ which means that the two qubits are separable and also the maximum values $I_{\mathcal{E}_t^*\rho}(t)=1$ is reached which indicates maximum entanglement between the two qubits. Therefore, one can say that an appropriate choice of distance between the two qubits leads to, on one hand, a complete separability between the qubits at other values of the interaction time and on the other hand maximum entanglement in other intervals of the interaction time. Meanwhile, the general feature of the entanglement in the case $L=\pi/3k$ is dramatically changed [see Fig. 3(a)]. This behavior is affected once the mixed state parameter r is decreased [see Fig. 3(b)]. It is noticed that the amount of entanglement is strongly decreased due to setting $L=\pi/2k$ and $r=0.2$, while it increased again when $L=\pi/3k$. Generally speaking, because of the influence of a mixed state parameter on entanglement, the amplitude of local maxima and minima decrease with increasing the deviation of r from the unity. However, as r takes values close to the unity we return to the same behavior in the initial pure state setting, i.e., $\rho=|e_1,g_2\rangle\otimes\langle e_1,g_2|$. However a slight change in r therefore, dramatically alters the entanglement. This is remarkable as the entanglement is strongly dependent on the initial state, which can be entangled or unentangled. Here, we clarify that it can be done by using a different initial state, which is strongly affected by the qubit number representation. This naturally leads to the use of occupation numbers of different single-qubit basis states in quantifying identical-qubits entanglement even when the number of qubits is conserved. The occupation-numbers of different modes have already been used in quantum computing.[41]

To this end, we devote the discussion in Fig. 4 to consider the effect of these different parameters on the probability of the first qubit (or atom) in excited state, the probability of the second qubit in excited state and probability of emission of photon pair. We would like to remark that when qubit 2 is initially prepared in either $|g_2\rangle$ $(r=1)$ or $|e_2\rangle$ $(r=0)$, which are stationary states for qubit 2, there will be substantial changes to the evolution of qubit 1 due to phase shifts introduced in the field through the dispersive interaction. The subsystem qubit 2 plays the role of a single qubit reservoir,[42] in the sense that it will induce modifications in the subsystem qubit 1 without having its state changed. If we increase the value of Stark shift parameter $\beta_1=0.8\gamma$, we have the situation shown in Fig. 4(b). We note a stronger modulation in the oscillations and a clear departure from ordinary Rabi oscillations is verified (see Fig. 4). The populations clearly exhibit

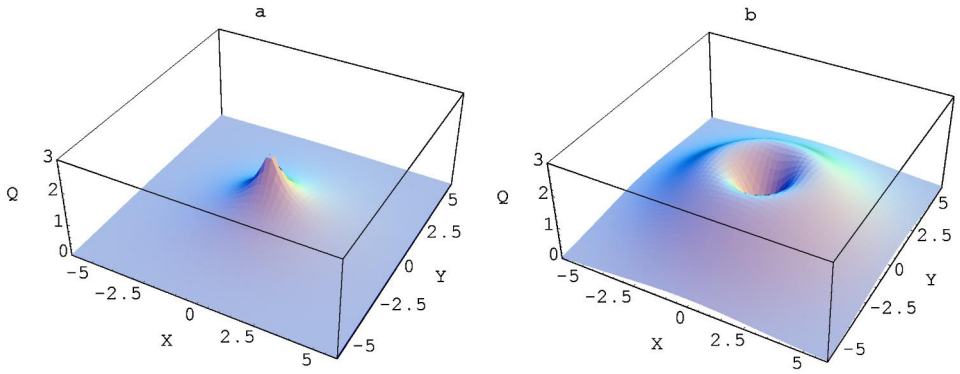

FIG. 5. Plot of quasiprobability function (Q-function) as a function of $X=\mathrm{Re}(\alpha)$ and $Y=\mathrm{Im}(\alpha)$, where the coherent state here is given by $|\alpha\rangle=\exp[-|\alpha|^2/2]\alpha^n/\sqrt{n!}|n\rangle$, $\alpha=X+iY$. The scaled time $\gamma t=\pi/2$, $L=0$, $\beta_1=0$, $r=1$. (a) corresponds to the case where the phase shift $\phi=\pi/2$, the timing of phase shift $\tau=13\pi/4$ and (b) the same as in (a) but $\tau=3\pi$.

the characteristic features observed in the entanglement behavior and provide us with information about the discrete nature of the quantized atom-field interaction. The remaining task is to identify and compare the results presented above for the entanglement degree with another accepted entanglement measure such as the concurrence.[43] One, possibly not very surprising, principal observation is that the numerical calculations corresponding to the same parameters, which have been considered above, give nearly the same behavior. This means that both the entanglement due to the negativity and concurrence measures are qualitatively the same.

There exists a neat explanation from the phase space point of view. Next, we will compute the relevant field quasiprobability in phase space. The Q-function computed for the field reduced density matrix $\rho^f(t)$ in the following form:

$$Q(\alpha)=\frac{1}{\pi}\langle\alpha|\rho^f(t)|\alpha\rangle,$$

where $|\alpha\rangle$ is a coherent state. The quasiprobability will be obtained in terms of probability amplitudes and photon occupation amplitudes. We now attempt to identify regions in the three-dimensional space spanned by the quasiprobability function that is inhabited by physical states, i.e., characterized by legitimate density matrices. Since the timing of an applied phase step has a large influence on the result, therefore to complete our work we shall consider in this discussion the quasiprobability function and how it is affected by the phase step in two different cases. For this purpose we have plotted Figs. 5 taking into consideration the same values of all parameters as in the above figures. For instance we have depicted the Q-function in Fig. 5(a) for $\beta_1=0$, $L=0$, $r=1$, and $\gamma t=\pi/2$, when the timing of an applied phase step $\tau=11\pi/4$ and $\phi=\pi/2$. We observe in general there is no change in the figure shape, i.e., there is no influence on the Q-function. The Q-function feature is exactly similar to that observed in the absence of the phase shift. As soon as we increase the values of τ such that $\tau=3\pi$, which means that the phase step is applied at the moment of maximum probability of pair photon emission, then we can observe a drastic change occurring in the function behavior. Therefore the shape of the quasiprobability is very sensitive to the choice of the application time of the phase step. Meanwhile, the general feature of the quasiprobability distribution function in the case $\tau=13\pi/4$, is almost identical to that in the previous case in which the timing of an applied phase step $\tau=11\pi/4$.

IV. CONCLUSION

We have investigated the entanglement in the context of an ensemble of two identical qubits (or atoms) coupled to a cavity field which can become entangled with one another, even when they do not interact directly with each other. We have treated the more general case where initial states

of the two qubits can be mixed with any state of the field. We have obtained an exact solution of the density operator taking into account the presence of Stark shift and an instantaneous phase shift experienced by one of the atoms that can be easily interpreted physically, and thus provides insight into the behavior of more complicated multiqubit systems. It is found that entangled pure states for this generalized case did not have the same entanglement as the mixed state case. Entanglement is measured via the negativity, currently defined only for an arbitrary system of two qubits, but similar analysis can in principle be applied to other systems such as a bipartite system with arbitrary dimensions. The influences of the Stark shift and the distance between the two-qubits have been presented. We have elucidated our studies by giving a detailed analysis and explanation of the predicted entanglement, intensity, and quasiprobability phenomena with nonzero values of the phase shift. The effect of phase shift is discussed when we apply a phase step at the moment of the maximum or minimum probability of photon pair emission. Finally, we have noted that the inclusion of the Stark shift in the present model, under suitable conditions, could lead to zero values of the entanglement, an effect that may have important consequences in other nonlinear processes. Finally, in addition to quantum computing implementations involving identical particles, the result here is also useful for many-body physics.

(Received 4 March 2004; accepted 26 April 2004; published 25 October 2004)

Based on the standard fact that any matrix potential $u=u(x)$ determines a family of Jost solutions whose parameter runs analytically (continuously) on the (closed) half planes, respectively, the zeros of a suitable matrix valued Wronskian of a Jost solution pair are explored. © *2004 American Institute of Physics.*
[DOI: 10.1063/1.1795987]

I. INTRODUCTION

Jost and Faddeev and their Wronskians play a crucial role in the direct and inverse scattering theory of the usual Schrödinger equation on the line (see, e.g., Deif and Trubowitz in Ref. 1). The fact that the Jost solutions are scalar functions allows one to prove that their Wronskians depend only of the spectral variable, to relate it to the entries of the scattering matrix and to the bound states as well as to use it as a tool for studying asymptotic properties for small values of the spectral variable.

All of this changes when studying the matrix equation of Schrödinger-type where the Jost solutions generalize and become matrix functions. One can define the Wronskian following Wadati and Kamijo in Ref. 2, Martínez Alonso and Olmedilla in Ref. 3, and Aktosun, Klaus and Van der Mee in Ref. 4. The basic facts such as dependence upon the spectral variable, relationship to scattering matrix coefficients and bound states and facilitation of the study of asymptotic behavior as the spectral variable tends to zero, still go through. The major inconvenience is the need to study the direct and inverse theory for the matrix equation of Schrödinger-type on the line for matrix potentials together with its adjoint at the same time, or to restrict oneself to self-adjoint potentials.

Here we shall consider a different way to define a Wronskian that only involves data pertaining to the matrix potential but not to its adjoint. It has the disadvantage that depends not only on the spectral variable and does not satisfy an antisymmetry relation but allows one to relate its zeros to the bound states. The goal of this work is to show that, under suitable conditions, the number of zeros is finite.

There will be four additional sections. Section II will be dedicated to quoting issues about the existence and asymptotic behavior for large values of both spatial and spectral variables of the Jost and Faddeev matrix solutions of Schrödinger-type for any matrix potential. Section III will deal with the analyticity and continuity on the half planes and the closed half planes, respectively, of the Faddeev and Jost matrix solutions and their derivatives with respect to the spectral variable including the asymptotic behavior for small values. All of this material in these sections is standard. Its formulation and proofs are as those for the usual Faddeev and Jost solutions (see Ref. 4). In Sec. IV we shall define a Wronskian for the Jost matrix solutions, state and prove its properties that imply that, under certain conditions its zeros form a discrete set in the upper half plane. In the last section (Sec. V), we shall give some comments and conclude from the results of Sec. IV that the number of bound state wave numbers is finite for suitable non-self-adjoint matrix potential.

II. JOST AND FADDEEV SOLUTIONS

By a matrix potential u of Faddeev type we shall mean a square-matrix-valued function $u=(u_{ij})_{1\leqslant i,j\leqslant n}$, where n is a positive integer fixed, defined on the real line whose entry functions u_{ij} are complex valued integrable functions satisfying the Faddeev condition (see Ref. 5): $\int_{-\infty}^{\infty}(1+|x|)|u_{ij}|<\infty, 1\leqslant i,j\leqslant n$

For these (nonself-adjoint) matrix potentials of Faddeev-type there exists a one-parametric family of solutions for the spectral problem for the matrix equation of Schrödinger-type.

Proposition 2.1: *Let u be a matrix potential of Faddeev-type. Then the spectral problem*

$$\varphi_{xx}+k^2\varphi=u\varphi, \tag{2.1}$$

has a solution for each complex number k, i.e., a C^1-square matrix valued function $x\mapsto\phi(x,k)$ with second derivative defined on the real line satisfying the differential matrix equation in (2.1).

The second order linear differential matrix equation (2.1) may be converted into an integral matrix equation of Volterra-type for which we need a classification of solutions according to their asymptotic behavior. For instance,

$$e^{-kix}\psi_+(x,k)=\int_x^{\infty}\frac{1-e^{2ik(y-x)}}{2ik}e^{-kiy}u(y)\psi_+(y,k)dy.$$

For all real k the iterates are dominated in the spectral norm by the corresponding iterate of the scalar equation $s(x,\kappa)=1+\int_x^{\infty}(y-x)\|u(y)\|s(y,\kappa)dy$, implying (see Ref. 1)

$$\begin{aligned}\left\|e^{-i\kappa x}\psi_+(x,k)-I_{n\times n}\right\|<s(x,k)-1&=\sum_{\ell=1}^{\infty}\frac{1}{\ell}\left[(1+\max(0,-x))\int_x^{\infty}(1+|y|)\|u(y)\|dy\right]^{\ell}\\&=\exp([1+\max(0,-x)]\int_x^{\infty}(1+|y|)\|u(y)\|dy)-1\\&\leqslant\exp\left(\int_x^{\infty}(1+|y|)\|u(y)\|dy\right)-1, x\geqslant 0,\end{aligned} \tag{2.2}$$

where we used that $\max(0,-x)=0$ for $x\geqslant 0$ and $\|\cdot\|$ is any norm over the complex $n\times n$ matrices. Since u is a matrix potential of Faddeev-type, we have $\int_x^{\infty}(1+|y|)\|u(y)\|dy\to 0$ as $x\to+\infty$. Hence given a positive number $\epsilon>0$, there exists a positive number N such that $\|e^{-i\kappa x}\psi_+(x,k)-\mathrm{I}_{n\times n}\|<\epsilon$, for all k, Im $k\geqslant 0$ and $x>N$. All of this is summarized as follows.

Proposition 2.2: *Let u be a matrix potential of Faddeev-type. Then there exist unique C^1 matrix solutions with second derivative, $x\mapsto\phi_{\pm}(x,k)$, $x\mapsto\psi_{\pm}(x,k)$ for the spectral (2.1) problem with the following asymptotic behavior.*

On the closed upper half k plane,

$\phi_+(x,k)\sim e^{-ixkI_{n\times n}}$ *as* $x\to-\infty$, $\psi_+(x,k)\sim e^{ixkII_{n\times n}}$ *as* $x\to\infty$.

On the closed lower half k plane,

$\phi_-(x,k)\sim e^{ixkI_{n\times n}}$ *as* $x\to-\infty$, $\psi_-(x,k)\sim e^{-ixkI_{n\times n}}$ *as* $x\to\infty$, *and are called the Jost solutions.*

The Jost solutions $\psi_{\pm}$, $\phi_{\pm}$ without the factors $e^{\pm ixk}$, for example $m_+(x,k)=e^{-2kix}\psi_+(x,k)$, are here denoted by $m_{\pm}$, $\hat{m}_{\pm}$ and called the Faddeev solutions (see Ref. 4), respectively.

In the sequel, the statements will be formulated in terms of the Jost and Faddeev solutions pertaining to the matrix potential u of Faddeev-type.

Corollary 2.3: *There exist a number $\mathcal{N}$ and a neighborhood $V(x_0)$ for each real number x_0 in the interval $(\mathcal{N},+\infty)$ such that the function $k\mapsto[\psi_+(x,k)]^{-1}$ is well-defined on the whole closed upper half plane for all $x\in V(x_0)$, or equivalently, the function $x\mapsto[\psi_+(x,k)]^{-1}$ is well defined on $V(x_0)$ for all k, Im $k\geqslant 0$.*

Proof: It is enough to prove that there exist a number $\mathcal{N}$ and a neighborhood $V(x_0)$ for each real number x_0 in the interval $(\mathcal{N},+\infty)$ such that the $n\times n$ matrix $\psi_+(x,\kappa)$ is invertible for all k, Im $k\geqslant 0$ and for all $x\in V(x_0)$. First of all define $G(x)=(1+\max(0,-x))\int_x^{\infty}(1+|y|)\|u(y)\|dy$. We

have just seen that for $k, \operatorname{Im} k \geqslant 0$ $\|e^{-i\kappa x}\psi_+(x,k) - \mathrm{I}_{n\times n}\| < \exp[G(x)] - 1$ [see inequality in (2.2)]. Thus $\psi_+(x,k)$ is a nonsingular $n\times n$ matrix for every $k, \operatorname{Im} k \geqslant 0$ if the last member of this estimate is strictly less than 1. The latter is equivalent to requiring that the expression $G(x) < \ln(2)$. However, $G(x)$ is monotonically nonincreasing in x, tends to $+\infty$ as $x \to -\infty$ (unless $u(x) = 0$ almost everywhere) and vanishes as $x \to \infty$. Letting $\mathcal{N}$ stand for the supremum of all real x for which $G(x) = \ln(2)$, we see that $[\psi_+(x,k)]^{-1}$ is well-defined for all $x > \mathcal{N}$, irrespective of the choice of $k, \operatorname{Im} k \geqslant 0$. Thus for any real fixed $x_0 \in (\mathcal{N}, \infty)$, by choosing as $V(x_0)$, the entire interval itself $(\mathcal{N}, \infty)$ or any open subset of it containing x_0, we get the claim. □

The Jost solutions have the following asymptotic behavior of the spectral variable and asymptotic relations.

Proposition 2.4: *For x on the real line,*

$\phi_+(x,k) \sim e^{-ix\mathrm{k}\mathrm{I}_{n\times n}}$, $\psi_+(x,k) \sim e^{ix\mathrm{k}\mathrm{I}_{n\times n}}$ *as* $k \to \infty$, $\operatorname{Im} k \geqslant 0$

$\phi_-(x,k) \sim e^{ix\mathrm{k}\mathrm{I}_{n\times n}}$, $\psi_-(x,k) \sim e^{-ix\mathrm{k}\mathrm{I}_{n\times n}}$ *as* $k \to \infty$, $\operatorname{Im} k \leqslant 0$.

Proposition 2.5: *There exist unique matrix functions* a_ℓ, a_r, $b_\ell b_r$ *such that we have the asymptotic relations* $\psi_+(x,\kappa) \sim (e^{i\kappa x}a_\ell(k) + e^{-i\kappa x}b_\ell(\kappa))$ *as* $x \to -\infty$ *and* $\phi_+(x,\kappa) \sim e^{-i\kappa x}a_r(\kappa) + e^{i\kappa x}b_r(\kappa)$ *as* $x \to +\infty$ *for* $\kappa \neq 0$ *on the real line.*

III. ANALYTICITY AND CONTINUITY OF THE JOST AND FADDEEV SOLUTIONS

Theorem 3.1: *Let u a matrix potential of Faddeev type. Then*

(1) *The functions* $k \mapsto (d^\ell m_+/dx^\ell)(x,k)$, $k \mapsto (d^\ell \hat{m}_+/dx^\ell)(x,k)$ *are analytic on the open upper half plane. Fix a complex number* k_0 $\operatorname{Im} k_0 \geqslant 0$.

(2) *On* $[\alpha, +\infty)$, $(d^\ell m_+/dx^\ell)(x,k) \sim (d^\ell m_+/dx^\ell)(x,k_0)$ *as* $k \to k_0, \operatorname{Im} k \geqslant 0$, *and on* $(-\infty, \beta]$, $(d^\ell \hat{m}_+/dx^\ell)(x,k) \sim (d^\ell \hat{m}_+/dx^\ell)(x,k_0)$ *as* $k \to k_0, \operatorname{Im} k \geqslant 0$, *where* α, β *are any real numbers fixed and* $\ell = 0, 1$.

(3) *Similar results hold for the maps* $k \mapsto (d^\ell m_-/dx^\ell)(x,k)$, $k \mapsto (d^\ell \hat{m}_-/dx^\ell)(x,k)$, $\ell = 0, 1$.

Remark: The proof for $\ell = 1$ follows at once from establishing the result for $\ell = 0$. For the Jost solutions, the conclusion of Theorem 3.1 can only be true on the close half planes uniformly for x in any finite interval of the real line, respectively. Note $\lim_{x\to\infty}\psi_+(x,\kappa) = \lim_{x\to\infty}\lim_{\substack{k\to\kappa \\ \operatorname{Im} k>0}} \psi_+(x,k)$ does not exist for real $\kappa \neq 0$ and for $\kappa = 0$ such limit is equal to $\mathrm{I}_{n\times n}$ because $\psi_+(x,\kappa) \sim e^{x\kappa\mathrm{I}_{n\times n}}$ as x goes to ∞, but $\lim_{\substack{k\to\kappa \\ \operatorname{Im} k>0}} \lim_{x\to\infty}\psi_+(x,k) = 0_{n\times n}$. Hence for Jost solutions the uniform convergence as in Theorem 3.1 is only true for any real κ and x in a finite interval.

Theorem 3.1 has a straightforward consequence for the Faddeev and Jost solutions.

Corollary 3.2: *The Faddeev and Jost solutions together with their derivatives respect to the spatial variable x are analytic on the open half planes and continuous on the closed upper half planes, respectively.*

IV. A WRONSKIAN OF THE JOST SOLUTIONS

Let us consider the Wronskian (see Ref. 6)

$$W(\psi,\varphi) = \psi\psi'\psi^{-1}\varphi - \psi\varphi' = -\psi^2\frac{d}{dx}(\psi^{-1}\varphi), \tag{4.1}$$

where a prime indicates derivative respect the variable x.

In contrast to the Wronskian 2-4, $W(\psi,\varphi) = [\psi']^\dagger\varphi - [\psi]^\dagger\varphi'$, ours depends on where ψ^{-1} is defined and on the variable x, and does not satisfy the usual antisymmetry relation $W(\psi,\phi) = -W(\phi,\psi)^\dagger$ but allows one to relate it to the bound states for sufficiently large real numbers x_0 which is sufficient for the purposes of this work.

By virtue Corollary 2.3, the Wronskian is defined on the closed upper half plane for any real number fixed x_0 large enough and Corollary 3.2 implies its analyticity and continuity.

Proposition 4.1: Let x_0 *be a fixed real number large enough according to the Corollary 2.3.*

Then the Wronskian $k\mapsto W(\psi_+(\cdot,k),\phi_+(\cdot,k))(x_0)$ *is defined on the closed upper half plane, analytic on the open upper half plane and continuous on the closed upper half plane.*

Similar results for the matrix Wronskian $W(\psi_-,\phi_-)$ can be obtained in the same way. In the sequel, we generate results only for the matrix Wronskian in (4.1) for the Jost solution ψ_+, ϕ_+.

Proposition 4.2: The set $\mathcal{W}_{x_0}=\{k,\operatorname{Im}k\geqslant 0: W(\psi_+(\cdot,k),\phi_+(\cdot,k))(x_0)=0\}$ *is bounded for any fixed real number* x_0 *large enough as in the previous proposition.*

Proof: By Proposition 2.3, $W(\psi_+(\cdot,k),\phi_+(\cdot,k))(x_0)\sim(-2ik)\mathrm{I}_{n\times n}$ as $k\to\infty$, $\operatorname{Im}k\geqslant 0$. Therefore, the set $\mathcal{W}_{x_0}$ is bounded as a set of the closed upper half plane for any real number x_0 large enough.

From now on x_0 will be a fixed real number large enough which means a real number chosen according to Corollary 2.3.

Proposition 4.3: The set $\mathcal{W}_{x_0}$ *satisfies that*

$$\mathcal{W}_{x_0}=\{k,\operatorname{Im}k\geqslant 0:\exists\ \text{a matrix } c=c(k)\ \text{such that}\ \phi_+(\cdot,k)\equiv\psi_+(\cdot,k)c\}.$$

Proof: Fix x_0 a real number as the statement, i.e., as in Corollary 2.3.

Let k_0 a complex number in the closed upper half plane ($\operatorname{Im}k_0\geqslant 0$) where $\phi_+(\cdot,k_0)\equiv\psi_+(\cdot,k_0)c$ being $c=c(k_0)$ a constant matrix. It is straightforward to see that by replacing this identity in the expression of the Wronskian given in (5.1) $W(\psi_+(\cdot,k_0),\phi_+(\cdot,k_0))(x)=0_{n\times n}$ for any x on the real line, where $\psi_+(x,k_0)$ is defined (Corollary 2.3) in particular for $x=x_0$. Thus $\mathcal{W}_{x_0}$ contains the set.

Take $k_0\in\mathcal{W}_{x_0}$. By Corollary 2.3, $x\mapsto[\psi_+(x,k_0)]^{-1}$ is well-defined on a neighborhood $V(x_0)$ $(k_0,\operatorname{Im}k_0\geqslant 0)$. Thus write $\phi_+(x,k_0)=\psi_+(x,k)c(x,k_0)$ for $x\in V(x_0)$, where $x\mapsto c(x,k_0)$ is differentiable at $x=x_0$ and the Wronskian $x\mapsto W(\psi(\cdot,k_0),\phi(\cdot,k_0))(x)$ is well-defined on $V(x_0)$. Since $W(\psi_+(\cdot,k_0),\phi_+(\cdot,k_0))(x_0)$ vanishes, then in view of (4.1), $W(\psi_+(\cdot,k_0),\phi_+(\cdot,k_0))(x_0)=\psi_+(x_0,k_0)c'(x_0,k_0)=0_{n\times n}$. From this and the choice of $x\mapsto c(x,k_0)$,

$$\phi_+(x_0,k_0)=\psi_+(x_0,k_0)c$$

$$\phi'_+(x_0,k_0)=\psi'_+(x_0,k_0)c,$$

being $c=c(x_0,k_0)$. Thus ϕ_+, ψ_+c are two solutions of the second order linear diferential equation (2.1) that agree at x_0 as well as their derivatives. By uniqueness, we have that $\phi_+(\cdot,k_0)\equiv\psi_+(\cdot,k_0)c$. Hence $\mathcal{W}_{x_0}$ is contained in the set, which finally proves the claim. □

Proposition 4.4: $\mathcal{W}_{x_0}$ *is a discrete set of the open upper half plane.*

Proof: This follows at once because the Wronskian $k\mapsto W(\psi_+(\cdot,k),\phi_+(\cdot,k))(x_0)$ is analytic on the open upper half plane (Proposition 4.1), therefore, its zeros are isolated in the upper half plane showing the claim. □

Proposition 4.5: Let $\kappa_0\neq 0$ *be a real number where the zeros in the open upper half plane of the Wronskian* $k\mapsto W(\psi_+(\cdot,k),\phi_+(\cdot,k))(x_0)$ *accumulate. Then* $a_r(\kappa_0)=0$.

Proof: Let κ_0 be as in the statement. By Proposition 4.5 the Wronskian is continuous on the closed upper half plane which shows that $W(\psi_+(\cdot,\kappa_0),\phi_+(\cdot,\kappa_0))(x_0)=0$. By virtue of Proposition there exists a constant $c=c(\kappa_0)$ such that $\phi_+(x_0,\kappa_0)=\psi_+(x_0,\kappa_0)c$. This together with Proposition 2.5 imply $\phi_+(x,\kappa_0)\sim e^{ix\kappa_0}c$ and $\phi_+(x_0,\kappa_0)\sim(e^{-ix\kappa}a_r(\kappa_0)+e^{ix\kappa_0}b_r(\kappa_0))$ as $x\to+\infty$. Thus $a_r(\kappa_0)=0$. □

Proposition 4.6: Assume the existence of $\lim_{k\to 0} W(\psi_+(\cdot,k),\phi_+(\cdot,k))(x_0)/k$ *and the accumulation of zeros of the Wronskian* $k\overset{\operatorname{Im}k\geqslant 0}{\mapsto}W(\psi_+(\cdot,k),\phi_+(\cdot,k))(x_0)$ *to* $k_0=0$. *Then* $(d/d\kappa)W(\psi_+(\cdot,\kappa),\phi_+(\cdot,\kappa))(x_0)\big|_{\kappa_0=0}=0$.

Proof: Let $\{k_n\}_n$ be a sequence of complex numbers in the upper half plane ($\operatorname{Im}k_n>0$) which accumulates to 0 and where $k\mapsto W(\psi_+(\cdot,k),\phi_+(\cdot,k))(x_0)$ vanishes. Then $W(\psi_+(\cdot,k_n),\phi_+(\cdot,k_n))\times(x_0)/k_n=0$ for all n. Hence by the first part of the hypothesis $(d/d\kappa)W(\psi_+(\cdot,\kappa),\phi_+(\cdot,\kappa))\times(x_0)\big|_{\kappa_0=0}=\lim_{k\to 0} W(\psi_+(\cdot,k),\phi_+(\cdot,k))(x_0)/k=0_{n\times n}$ where we use the fact that $W(\psi_+(\cdot,0),\phi_+(\cdot,0))(x_0)=0$. □

V. CONCLUSIONS

The usual Schrödinger equation has scalar Jost solutions $\psi_+(x,k)\sim e^{ikx}$ as $x\to+\infty$, $\phi_+(x,k)\sim e^{-ikx}$ as $x\to-\infty$. This fact allows to prove that their Wronskian $W(\psi_+,\phi_+)=\psi_+'\phi_+-\psi_+\phi_+'$ is independent of the real variable x and to relate it to the scattering coefficients by using the asymptotic relations for κ in the real line $\psi_+(x,\kappa)\sim a_\ell(k)e^{i\kappa x}+b_\ell(\kappa)e^{-i\kappa x}$ as $x\to-\infty$ and $\phi_+(x,\kappa)\sim a_r(\kappa)e^{-i\kappa x}+b_r(\kappa)e^{i\kappa x}$ as $x\to-\infty$, $\kappa\neq0$. It also allows one to relate bound state wave-numbers to the Wronskian which arise as zeros of $a_\ell(k)=a_r(k)$ on the positive imaginary axis and to use it as a tool for studying asymptotic properties as $k\to0$, $\mathrm{Im}\,k\geqslant0$. Since, in addition, $|a_\ell(\kappa)|^2-|b_\ell(\kappa)|^2=1$ for real $\kappa\neq0$, the continuity of $k\mapsto a_\ell(k)$ in the closed upper half plane implies the finiteness of the number of bound state wave numbers (it also implies that they cannot accumulate to any real number $\kappa\neq0$).

As we have seen this changes when studying the $n\times n$ matrix equation of Schrödinger type where the Jost solutions generalize and become $n\times n$ matrix functions. One may consider the Wronskian $W(\psi_+,\phi_+)=[\psi_+']^\dagger\phi_+-[\psi_+]^\dagger\phi_+'$, where † denotes the conjugate transpose, ϕ_+ is a Jost solution pertaining to the $n\times n$ matrix potential $u(x)$, and ψ_+ is a Jost solution pertaining to the matrix potential $u(x)^\dagger$. The basic stuff such as x-independence, relationships to scattering coefficients and bound states and facilitation of the study of small k asymptotic, still go through (see Ref. 4). The major drawback is the need to study the direct and inverse scattering theory for the matrix Schrödinger equations on the line for the potentials u and $u^\dagger$ at the same time, or to restrict oneself to self-adjoint potentials. On the other hand, one may consider the Wronskian $W(\psi,\varphi)=-\psi^2(d/dx)(\psi^{-1}\varphi)$ to obtain a Wronskian which is not well-defined for all ψ, not independent of the spatial variable x and does not satisfy an usual antisymmetry relation $W(\psi,\phi)=-W(\phi,\psi)^\dagger$ but only involves data pertaining to u (and not data pertaining to $u^\dagger$) and allows to relate it to the bound states (also to the scattering matrix coefficients).

It is indicated by Boris Pavlov (see Refs. 7 and 8) that the (scalar) Schrödinger equation on the half-line with complex potential has finitely many discrete eigenvalues if the potential decays exponentially, but often infinitely many discrete eigenvalues if the potential decays algebraically. It is a standard argument, involving the observation that the resolvent of the full-line Schrödinger equation is a rank one perturbation of the direct sum of the resolvents of the Schrödinger equations on the positive and negative half-lines, to see that this result goes through for the Schrödinger equation with complex potential on the full line. The standard result that Schrödinger equations with a Faddeev class potential [i.e., one where $(1+|x|)q(x)$ belongs to L^1] has only finitely many discrete eigenvalues, is only true for real potentials. Here it has been studied a generalization of the class of Schrödinger equations considered by Boris Pavlov, but has assumed a Faddeev-type of condition on the matrix potential. Unfortunately, the standard argument of excluding accumulation of discrete eigenvalues on the real line requires that $\|a_l(k)\|\geqslant1$. However, the identity $a_l(k)^\dagger a_l(k)-b_l(k)^\dagger b_l(k)=I_{n\times n}$ on which this can be based, has only been proved for selfadjoint matrix potentials (see Ref. 4). For complex potentials ($n=2$) this identity would imply that $a_l(k_0)=0$ and $b_l(k_0)=\pm i$ at a real numbers k_0 where the discrete eigenvalues accumulate (here it is used that $k\mapsto a_l(k)$ is continuous in the closed upper half plane). Thus even in the case that this identity will hold, we cannot conclude that the number of discrete eigenvalues is finite for a matrix potential which is not self-adjoint.

It is well-known that the norm of Jost solution $\phi_+(\cdot,k_0)$ which is a bound state is a square integrable function, therefore, the complex number k_0 belongs to the open upper half plane, i.e., $\mathrm{Im}\,k_0>0$ and there exists a constant matrix $c=c(k_0)$ such that $\phi_+(\cdot,k_0)\equiv\psi_+(\cdot,k_0)c$. This fact together with the discussion in the previous section yield to the following conclusion.

Theorem 5.1: Assume the existence of $\lim_{\substack{k\to0\\ \mathrm{Im}\,k\geqslant0}} W(\psi_+(\cdot,k),\phi_+(\cdot,k))(x_0)/k\neq0$ *and* $a_r(\kappa)\neq0$ *for real* $\kappa\neq0$. *Then the number of bound state wave numbers is finite.*

Proof: Let x_0 be a number large enough as indicated in the Corollary 2.3. In view of Proposition 4.3, we only need to consider the cardinality of $\mathcal{W}_{x_0}$. Given a complex number $k_0\in\mathcal{W}_{x_0}$, $\mathrm{Im}\,k_0>0$, the discreteness of $\mathcal{W}_{x_0}$ (Proposition 4.4) shows that there exist a neighborhood $V(k_0)$,

such that $\mathcal{W}_{x_0} \cap V(k_0) = \{k_0\}$ (the zeros of the Wronskian cannot accumulate to complex numbers in the upper half plane).

Consider a real number $\kappa_0 \neq 0$. In view of Proposition 4.5 and $a(\kappa_0) \neq 0$ by hypothesis, the zeros of the Wronskian cannot accumulate to κ_0. In addition, by virtue of Proposition 4.6 and $\lim_{\substack{k\to 0 \\ \text{Im } k\geqslant 0}} W(\psi_+(\cdot,k), \phi_+(\cdot,k))(x_0)/k \neq 0$ by hypothesis, the zeros of the Wronskian cannot accumulate to 0. Thus the zeros of the Wronskian in the upper half plane cannot accumulate to a real numbers. In consequence, for each real number k_0, we can find a neighborhood $V(k_0)$ such that $\mathcal{W}_{x_0} \cap V(k_0) = \emptyset$, $k_0 \neq 0$ and $\mathcal{W}_{x_0} \cap V(0) = \{0\}$. Note that $\cup_{k,\text{Im } k>0} V(k) \cup \cup_{k,\text{Im } k=0} V(k)$ is an open covering for $\overline{\mathcal{W}_{x_0}}$ which is a compact set of the closed upper half plane (Proposition 4.2). Hence there exist a finite collection of complex numbers $k_i, \text{Im } k_i > 0, i = 1, \ldots, \ell_1$, and real numbers $\kappa_j, j = 1, \ldots, \ell_2$, such that $\cup_{i=1}^{\ell_1} V(k_i) \cup \cup_{j=1}^{\ell_2} V(\kappa_j) \supseteqq \overline{\mathcal{W}_{x_0}}$. By the choice of the covering, we must have $\{k_1, \ldots, k_{\ell_1}\} \cup \{\kappa_1, \ldots, \kappa_{\ell_2}\} \supseteqq \mathcal{W}_{x_0}$. Since the set of the bound state wave numbers is a subset of both the open upper half plane and $\mathcal{W}_{x_0}$ sets, it is totally contained in $\{k_1, \ldots, k_{\ell_1}\}$, which shows the claim. □

On the Bose condensation in some model of a nonideal Bose gas

D. P. Sankovich
V. A. Steklov Institute of Mathematics, Gubkin str. 8, 119991 Moscow, Russia

(Received 25 March 2004; accepted 15 July 2004; published 25 October 2004)

A model of a nonideal Bose gas with a repulsive interaction is considered. It is proved that there is not macroscopic occupation of the ground state in the thermodynamic limit in this model, but nevertheless the generalized condensation occurs. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1795971]

I. INTRODUCTION

The experimental creation of Bose condensates (for a review of the theory of trapped Bose-condensed gases with extensive references in the literature see Ref. 1) has sparked interest in their properties. One of the most important and knotty problems is connected with the rigorous proof of the existence (or absence) of Bose condensation for nonideal (imperfect) Bose systems. Another aspect which in particular has received much attention is the relation between nature of interparticle interaction and Bose condensation.

Schröder[2] considered a model of a nonideal Bose gas contained in a d-dimensional ($d \geqslant 3$) cubical box with Dirichlet boundary conditions on two opposite faces and periodic boundary conditions on the remaining surface. From the results of this work the absence of macroscopic occupation of the zero momentum one particle state was ensued. In Ref. 3 the model formally looking like Schröder's model has been studied. The Hamiltonian of Michoel and Verbeure[3] differs from the Huang–Yang–Luttinger Hamiltonian[4] by the plus sign in the additional term, which is purely quantum mechanical contribution to the mean-field interaction energy. Michoel and Verbeure, referring to the approximation theorem proved in Ref. 5 showed that their model has so-called nonextensive Bose condensation, i.e., there is generalized condensation[6,7] without macroscopic occupation of the ground state level.

In the following a model of a nonideal Bose gas, which is some minimal generalization of the Michoel–Verbeure model, is considered. By the Bogoliubov method[8–10] we prove that there is no Bose condensation,[11] in which the total condensate is in the ground state so that the ground state is macroscopically occupied. The aim of this article is to analyze the simple diagonal model within the framework of the general ideas and methods, which are referred to as the Bogoliubov theory of superfluidity. They were introduced in Refs. 8 and 9 and later further extended by Ginibre.[10]

In Sec. II we give a definition of the model and present the main result. In Sec. III we prove the main theorem. Section IV contains a few concluding remarks. In particular, using the method of Ref. 3 we prove that the model has the generalized condensation.

II. MODEL AND MAIN RESULT

We consider a system of spinless identical nonrelativistic bosons of mass m enclosed in a centered hypercubic box $\Lambda \subset \mathbb{R}^d$, $d \geqslant 3$, of volume $V=|\Lambda|=L^d$ with periodic boundary conditions for the wave functions. The Hamiltonian of the model is given by

$$\hat{H}_\Lambda = \sum_{p \in \Lambda^*} \epsilon_p \hat{n}_p + \frac{\lambda}{V} \hat{N}_\Lambda^2 + \frac{g}{2V} \sum_{p \in \Lambda^*} \hat{n}_p^2, \tag{1}$$

where $\epsilon_p = p^2/(2m)$, positive constants λ and g do not depend on V,

$$\hat{N}_\Lambda = \sum_{p \in \Lambda^*} \hat{n}_p, \hat{n}_p = \hat{a}_p^\dagger \hat{a}_p.$$

Here $\hat{a}_p^\# = \{\hat{a}_p^\dagger \text{ or } \hat{a}_p\}$ are the usual boson creation (annihilation) operators for the one-particle state $\psi_p(x) = V^{-1/2} \exp(ipx)$, $p \in \Lambda^*$, $x \in \Lambda$, acting on the Fock space $F_\Lambda = \oplus_{n=0}^\infty \mathcal{H}_{\mathrm{B}}^{(n)}$, where $\mathcal{H}_{\mathrm{B}}^{(n)} \equiv [L^2(\Lambda^n)]_{\mathrm{symm}}$ is the symmetrized n-particle Hilbert space appropriate for bosons, and $\mathcal{H}_{\mathrm{B}}^{(0)} \equiv \mathbb{C}$. The sums in (1) run over the dual set

$$\Lambda^* = \left\{ p \in \mathbb{R}^d : p_j = \frac{2\pi}{L} n_j, n_j = 0, \pm 1, \pm 2, \ldots, j = 1, 2, \ldots, d \right\}.$$

The Michoel-Verbeure model is a special case of (1) where $g = \lambda$. Obviously, the Hamiltonian (1) is superstable.[12]

Let us prove, that in the case of model (1) for every $p \in \Lambda^* \setminus \{0\}$

$$\lim_{V \to \infty} \frac{\langle \hat{n}_p \rangle_{\hat{H}_\Lambda(\mu)}}{V} = 0, \tag{2}$$

where $\langle \cdots \rangle_{\hat{H}_\Lambda(\mu)}$ denotes the finite-volume grand-canonical Gibbs state for the Hamiltonian $\hat{H}_\Lambda(\mu) \equiv \hat{H}_\Lambda - \mu \hat{N}_\Lambda$ and μ is the chemical potential.

First, we define the Bogoliubov inner product[13–15] (or the Duhamel two-point function) for the Hamiltonian $\hat{\Gamma}$ and for any two operators $\hat{A}$, $\hat{B}$ by

$$(\hat{A}, \hat{B})_{\hat{\Gamma}} = \int_0^1 dx \langle e^{x\beta\Gamma} \hat{A} e^{-x\beta\Gamma} \hat{B} \rangle_{\hat{\Gamma}}. \tag{3}$$

Here $\langle \cdots \rangle_{\hat{\Gamma}}$ denotes the appropriate thermal average with respect to the Hamiltonian $\hat{\Gamma}$ and the inverse temperature β. The Bogoliubov inner product is positive semidefinite. It also satisfies the symmetry property, so

$$(\hat{A}, \hat{B})_{\hat{\Gamma}} = (\hat{B}, \hat{A})_{\hat{\Gamma}}, (\hat{A}^\dagger, \hat{A})_{\hat{\Gamma}} \geqslant 0. \tag{4}$$

The properties (4) follow from the definition (3). Noting that

$$\mathrm{tr}(e^{-x\beta\Gamma}[\hat{A}, \beta\hat{\Gamma}] e^{-(1-x)\beta\hat{\Gamma}} \hat{B}) = \frac{d}{dx} \mathrm{tr}(e^{-x\beta\Gamma} \hat{A} e^{-(1-x)\beta\hat{\Gamma}} \hat{B})$$

we have the relation

$$\langle [\hat{A}, \hat{B}] \rangle_{\hat{\Gamma}} = ([\hat{A}, \beta\hat{\Gamma}], \hat{B})_{\hat{\Gamma}}. \tag{5}$$

We then prove the following result.

Lemma 1: In the case of model (1) for every $p \in \Lambda^* \setminus \{0\}$ one has

$$(\hat{a}_p^\dagger, \hat{a}_p)_{\hat{H}_\Lambda} \leqslant (\beta\epsilon_p)^{-1}, \tag{6}$$

with the Bogoliubov inner product defined in the canonical ensemble.

Proof: Take $\hat{A} = \hat{a}_p$, $\hat{B} = \hat{a}_p^\dagger$, $\hat{\Gamma} = \hat{H}_\Lambda$ in the equality (5). Then it becomes

$$1 = \beta\epsilon_p (\hat{a}_p^\dagger, \hat{a}_p)_{\hat{H}_\Lambda} + \beta (\hat{a}_p^\dagger, \hat{C}_p \hat{a}_p)_{\hat{H}_\Lambda}, \tag{7}$$

where

$$\hat{C}_p \equiv \frac{2}{V}\left(\frac{g}{2}\hat{n}_p + \lambda\hat{N}\right) + \frac{1}{V}\left(\lambda + \frac{g}{2}\right). \tag{8}$$

Note that $\hat{C}_p$ is a positive Hermitian operator and it commutes with $\hat{H}_\Lambda$. Then, because of (4), the second term in the right-hand side of (7) is non-negative. This completes the proof of Lemma 1.

Note that the inequality (6) has a highly general nature, expressing a so-called local Gaussian domination property.[16]

Lemma 2: In the case of model (1) the condition

$$\lim_{V\to\infty}\frac{1}{V}\langle\hat{n}_p\rangle_{\hat{H}_\Lambda} = 0 \tag{9}$$

is satisfied for every $p \in \Lambda^* \setminus \{0\}$, *where* $\langle\cdots\rangle_{\hat{H}_\Lambda}$ *denotes the finite-volume canonical Gibbs state for the Hamiltonian* $\hat{H}_\Lambda$.

Proof: Use the Falk-Bruch inequality.[14,17] Then

$$\langle\hat{n}_p\rangle_{\hat{H}_\Lambda} \leqslant \frac{1}{2}\left[\sqrt{c_p^{(0)}b_p^{(0)}}\coth\sqrt{\frac{c_p^{(0)}}{4b_p^{(0)}}} - 1\right], \tag{10}$$

where

$$b_p \equiv (\hat{a}_p^\dagger, \hat{a}_p)_{\hat{H}_\Lambda} \leqslant b_p^{(0)} = (\beta\epsilon_p)^{-1},$$

$$c_p \equiv \langle[\hat{a}_p^\dagger, [\beta\hat{H}_\Lambda, \hat{a}_p]]\rangle_{\hat{H}_\Lambda} \leqslant c_p^{(0)} = \beta\left(\epsilon_p + 2\lambda\rho + \frac{2}{V}(\lambda+g)\langle\hat{n}_p\rangle_{\hat{H}_\Lambda} + \frac{1}{V}\left(\lambda + \frac{g}{2}\right)\right),\ c_p^{(0)} \geqslant 0$$

and ρ is the mean number of particles per unit volume for model (1). From $\coth x < 1 + 1/x$, $x > 0$, one deduces

$$\frac{1}{V}\langle\hat{n}_p\rangle_{\hat{H}_\Lambda} \leqslant \frac{1}{2V}\left[\sqrt{\frac{\epsilon_p + 2\lambda\rho + (\lambda+g)\langle\hat{n}_p\rangle_{\hat{H}_\Lambda}/V + (\lambda+g/2)/V}{\epsilon_p}} + \frac{2}{\beta\epsilon_p} - 1\right].$$

Since

$$\inf_{p\in\Lambda^*\setminus\{0\}}\epsilon_p = \frac{2\pi^2}{m}V^{-2/3},$$

we obtain $\langle\hat{n}_p\rangle_{\hat{H}_\Lambda}/V \sim V^{-1/3}$. The Lemma 2 is proved.

Condition (2) is a consequence of condition (9). It follows from the formula

$$\langle\hat{n}_p\rangle_{\hat{H}_\Lambda(\mu)} = \Xi_\Lambda^{-1}\sum_{N=0}^{\infty}\exp\left[-\beta V\left(f_N - \mu\frac{N}{V}\right)\right]\langle\hat{n}_p\rangle_{\hat{H}_\Lambda}, \tag{11}$$

where the grand canonical partition function is given by

$$\Xi_\Lambda = \sum_{N=0}^{\infty}\exp\left[-\beta V\left(f_N - \mu\frac{N}{V}\right)\right]$$

and N-particle free energy is

$$f_N = -\frac{1}{\beta V}\ln\mathrm{tr}_{\mathcal{H}_{\mathrm{B}}^{(N)}}e^{-\beta\hat{H}_\Lambda}.$$

Namely, let us define $\overline{\rho}$ by the condition

$$\inf_{N/V} F_N\left(\frac{N}{V}\right) = F_N(\overline{\rho}) \equiv \overline{F}_N.$$

In virtue of convexity of the free energy as a function of ρ[12] for $N/V - \overline{\rho} > \xi > 0$ one gets

$$F_N\left(\frac{N}{V}\right) \geqslant a_1 + a_2\left(\frac{N}{V} - \overline{\rho} - \xi\right),$$

where $a_1 = F_N(\overline{\rho}+\xi) \geqslant \overline{F}_N + \sigma$, $\sigma > 0$, $a_2 = F_N'(\overline{\rho}+\xi) > 0$. Furthermore, for $|N/V - \overline{\rho}| < \xi' < \xi$ we have $F_N \leqslant \overline{F}_N + \sigma/2$. Then we can write the following lower bound:

$$\Xi_\Lambda \geqslant \sum_{|N/V-\overline{\rho}|<\xi'} \exp(-\beta V F_N) \geqslant 2\xi' V \exp\left[-\beta V\left(\overline{F}_N + \frac{\sigma}{2}\right)\right].$$

From Lemma 2 and (11) we get, for every $p \in \Lambda^* \setminus \{0\}$ and V large enough,

$$\begin{aligned}
\langle \hat{n}_p \rangle_{\hat{H}_\Lambda(\mu)} &\leqslant c_1 \Xi_\Lambda^{-1} \sum_{N=0}^{\infty} N^{2/3} \exp(-\beta V F_N) \\
&= c_1 \Xi_\Lambda^{-1} \sum_{0 \leqslant N \leqslant V(\overline{\rho}+\xi)} N^{2/3} \exp(-\beta V F_N) + c_1 \Xi_\Lambda^{-1} \sum_{N \geqslant V(\overline{\rho}+\xi)} N^{2/3} \exp(-\beta V F_N) \\
&\leqslant c_1 (\overline{\rho}+\xi)^{2/3} V^{2/3} + c_1 \Xi_\Lambda^{-1} \sum_{N \geqslant V(\overline{\rho}+\xi)} N^{2/3} \exp\left\{-\beta V\left[a_1 + a_2\left(\frac{N}{V} - \overline{\rho} - \xi\right)\right]\right\} \\
&\leqslant c_1 (\overline{\rho}+\xi)^{2/3} V^{2/3} + c_2 \exp\left(-\frac{\sigma V}{2}\right),
\end{aligned}$$

where c_1 and c_2 are some positive constants. (2) follows from the last relation.

To study the behavior of $\langle \hat{n}_0 \rangle_{\hat{H}_\Lambda(\mu)}/V$ we are concerned with the Bogoliubov–Ginibre approach. Let us first rewrite the Hamiltonian $\hat{H}_\Lambda(\mu)$ in the form

$$\begin{aligned}
\hat{H}_\Lambda(\mu) = &-\mu \hat{a}_0^\dagger \hat{a}_0 + \sum_{p \in \Lambda^*, p \neq 0} (\epsilon_p - \mu) \hat{n}_p + \frac{\lambda}{V}\left[\hat{a}_0^\dagger \hat{a}_0^\dagger \hat{a}_0 \hat{a}_0 + \hat{a}_0^\dagger \hat{a}_0 + 2\hat{a}_0^\dagger \hat{a}_0 \sum_{p \in \Lambda^*, p \neq 0} \hat{n}_p + \left(\sum_{p \in \Lambda^*, p \neq 0} \hat{n}_p\right)^2\right] \\
&+ \frac{a}{2V}\left(\hat{a}_0^\dagger \hat{a}_0^\dagger \hat{a}_0 \hat{a}_0 + \hat{a}_0^\dagger \hat{a}_0 + \sum_{p \in \Lambda^*, p \neq 0} \hat{n}_p^2\right). \qquad (12)
\end{aligned}$$

According to the Bogoliubov method,[18] we now replace

$$\hat{a}_0 \to c V^{1/2}, \quad \hat{a}_0^\dagger \to \overline{c} V^{1/2}, \qquad (13)$$

where $c \in \mathbb{C}$ and the bar means complex conjugation. So we have the approximating Hamiltonian

$$\hat{H}_\Lambda(\mu, c) = \hat{H}_\Lambda^{(0)}(\mu, c) + \hat{H}_\Lambda'(\mu), \qquad (14)$$

where

$$\hat{H}_\Lambda^{(0)}(\mu, c) = V\left(\lambda |c|^2 - \mu + \frac{g}{2}|c|^2\right)|c|^2 + \left(\lambda + \frac{g}{2}\right)|c|^2 + 2\lambda |c|^2 \hat{N}_\Lambda',$$

$$\hat{H}'_\Lambda(\mu) = \sum_{p\in\Lambda^*,p\neq 0} (\epsilon_p - \mu)\hat{n}_p + \frac{\lambda}{V}\hat{N}'^2_\Lambda + \frac{g}{2V}\sum_{p\in\Lambda^*,p\neq 0}\hat{n}^2_p, N'_\Lambda \equiv \sum_{p\in\Lambda^*,p\neq 0}\hat{n}_p.$$

After the canonical gauge transformation to boson operators $\hat{a}^{\#}_p \to \exp(\pm i \arg c)\hat{a}^{\#}_p$ note that Hamiltonian (14) depends only on $c=|c|\equiv\sqrt{\rho_0}$, $\rho_0 \geqslant 0$.

Define the grand-canonical pressures

$$p_\Lambda = (\beta V)^{-1} \ln \mathrm{tr}_{F_\Lambda} \exp[-\beta\hat{H}_\Lambda(\mu)]$$

and

$$p_\Lambda(c) = (\beta V)^{-1} \ln \mathrm{tr}_{F_\Lambda} \exp[-\beta\hat{H}_\Lambda(\mu,c)]$$

associated with Hamiltonians $\hat{H}_\Lambda(\mu)$ and $\hat{H}_\Lambda(\mu,c)$, respectively.

Theorem: *The model Hamiltonian (1) and the approximating Hamiltonian (14) are thermodynamically equivalent in accordance to Wentzel,*[19] *i.e.,*

$$\lim_{V\to\infty}\sup_c p_\Lambda(c) = \lim_{V\to\infty} p_\Lambda \equiv p.$$

The proof of this theorem is given in Sec. III.

Theorem states that the self-consistency parameter c in the Bogoliubov-Ginibre method is determined by the condition that the approximate pressure $p_\Lambda(c)$ be maximal. If an appropriate equation (self-consistency equation) has the nontrivial solution (this equation always has the trivial solution $c=0$ for gauge invariant Hamiltonians), then we prove that Bose condensation actually occurs in the system under consideration[20]

$$\rho_0 = \lim_{V\to\infty} \frac{\langle \hat{a}^\dagger_0 \hat{a}_0\rangle_{\hat{H}_\Lambda(\mu)}}{V} > 0. \tag{15}$$

An absence of the nontrivial solution implies an absence of the Bose condensate. Let us prove, that the last just and is realized in a considered case.

A necessary condition for $p_\Lambda(c)$ to be maximum is

$$\left\langle \frac{\partial \hat{H}^{(0)}_\Lambda(\mu,c)}{\partial c} \right\rangle_{\hat{H}_\Lambda(\mu,c)} = 0.$$

By explicit calculations we get the following equation to obtain a nontrivial solution

$$g\rho_0 = \mu - 2\lambda\rho_0 - \frac{2\lambda}{V}\sum_{p\in\Lambda^*,p\neq 0}\langle\hat{n}_p\rangle_{\hat{H}_\Lambda(\mu,c)} - \frac{1}{V}\left(\lambda + \frac{g}{2}\right). \tag{16}$$

Prove that for V sufficiently large (16) does not have a positive solution $\rho_0 > 0$. Use the inequality[13,21]

$$\langle[\hat{A},[\hat{H},\hat{A}^\dagger]]\rangle_{\hat{H}} \geqslant 0, \tag{17}$$

which is valid for any operator $\hat{A}$ and for any self-conjugate superstable Hamiltonian $\hat{H}$. Take $\hat{A} = \hat{a}^\dagger_p (p\neq 0)$, $\hat{H}=\hat{H}_\Lambda(\mu,c)$. One gets

$$\mu - 2\lambda\rho_0 - \frac{2\lambda}{V}\sum_{p\in\Lambda^*,p\neq 0}\langle\hat{n}_p\rangle_{\hat{H}_\Lambda(\mu,c)} - \frac{1}{V}\left(\lambda + \frac{g}{2}\right) \leqslant \epsilon_p + \frac{2}{V}(\lambda+g)\langle\hat{n}_p\rangle_{\hat{H}_\Lambda(\mu,c)} \tag{18}$$

for all $p\in\Lambda^*\setminus\{0\}$. As in the case of Hamiltonian (1) (see Lemma 2) we get

$$\lim_{V\to\infty} \frac{1}{V}\langle \hat{n}_p\rangle_{\hat{H}_\Lambda(\mu,c)} = 0$$

for all $p \in \Lambda^* \setminus \{0\}$. Hence the right-hand side of (18) can be made arbitrarily small for V sufficiently large. Thus we conclude that for $V\to\infty$ and for any $g>0$ Eq. (16) does not have a positive solution $\rho_0 > 0$.

III. PROOF OF THEOREM

The following fact[10] will be needed below.

Lemma 3: $p_\Lambda \geqslant p_\Lambda(c)$ *for all* $c \in \mathbb{C}$.

For later purpose, we remind a convenient definition of the Bogoliubov approximation, which was proposed by Ginibre. The boson Fock space F_Λ is isomorphic to the tensor product $F_{0\Lambda} \otimes F'_\Lambda$, where $F_{0\Lambda}$ and F'_Λ are the symmetric tensor algebras constructed on the one-dimensional subspace of the constant functions $\psi_0 = V^{-1/2}$, and on its orthogonal complement, respectively. For any complex $c \in \mathbb{C}$, we consider in $F_{0\Lambda}$ the coherent vector

$$|c\rangle = \exp\left(-V\frac{|c|^2}{2}\right)\sum_{n=0}^{\infty}\frac{1}{n!}(V^{1/2}c)^n(\hat{a}_0^\dagger)^n|0\rangle,$$

where $|0\rangle$ is the vacuum vector of F_Λ. Then $\hat{a}_0|c\rangle = c|c\rangle$. To every operator $\hat{A}$ on F_Λ and any complex number c, we can associate the operator $\hat{A}(c)$ on F'_Λ defined by its quadratic form

$$\langle \varphi'_1|\hat{A}(c)|\varphi'_2\rangle = \langle \varphi'_1 \otimes c|\hat{A}|\varphi'_2 \otimes c\rangle,$$

where the vectors $|\varphi'_1\rangle$, $|\varphi'_2\rangle$ lie in F'_Λ. The transformation from the operator $\hat{A}$ to operator $\hat{A}(c)$ is called by Bogoliubov approximation of $\hat{A}$. This transformation consists in replacing $\hat{a}_0$ and $\hat{a}_0^\dagger$ by $c\sqrt{V}$ and $\bar{c}\sqrt{V}$ in $\hat{A}$, after $\hat{A}$ has been expanded as a normal Vick form. Taking into account these definitions, we have

$$\begin{aligned}
\mathrm{tr}_{F'_\Lambda} \exp[-\beta\hat{H}_\Lambda(\mu,c)] &= \sup_{\{|\varphi'_n\rangle\}} \sum_n \exp[-\beta\langle \varphi'_n|\hat{H}_\Lambda(\mu,c)|\varphi'_n\rangle] \\
&= \sup_{\{|\varphi'_n\rangle\}} \sum_n \exp[-\beta\langle \varphi'_n \otimes c|\hat{H}_\Lambda(\mu)|\varphi'_n \otimes c\rangle] \\
&\leqslant \sup_{\{|\varphi'_n\rangle\}} \sum_n \langle \varphi'_n \otimes c|\exp[-\beta\hat{H}_\Lambda(\mu)]|\varphi'_n \otimes c\rangle \leqslant \mathrm{tr}_{F_\Lambda} \exp[-\beta\hat{H}_\Lambda(\mu)].
\end{aligned}$$

The sup in these relations is taken over all possible orthonormal bases of F'_Λ contained in the form domain of $\hat{H}_\Lambda(\mu,c)$. The former inequality is the Peierls's inequality. The latter is the immediate consequence of the definition of Bogoliubov's approximation, since, as the coherent vector $|c\rangle$ can be taken as the first vector of an orthonormal basis in $F_{0\Lambda}$. This ends the proof of Lemma 3.

We prove the Theorem.

(1) By the Bogoliubov inequality[13] and Lemma 3 one gets

$$0 \leqslant p_\Lambda - p_\Lambda(c) \leqslant \frac{1}{V}\langle \hat{H}_\Lambda(\mu,c) - \hat{H}_\Lambda(\mu)\rangle_{\hat{H}_\Lambda(\mu)}. \tag{19}$$

In order to write the average in the right-hand side of (19), it will be helpful to express the Hamiltonian $\hat{H}_\Lambda(\mu,c)$ by a Taylor expansion around $\hat{a}_0^\#$. Then

$$\hat{H}_\Lambda(\mu,c)-\hat{H}_\Lambda(\mu)=-\hat{A}^\dagger[\hat{a}_0,\hat{H}_\Lambda(\mu)]+\text{H.c.}+\frac{1}{2}\hat{A}^\dagger\hat{A}^\dagger[\hat{a}_0,[\hat{a}_0,\hat{H}_\Lambda(\mu)]]+\text{H.c.}+\hat{A}^\dagger[\hat{a}_0,[\hat{H}_\Lambda(\mu),\hat{a}_0^\dagger]]\hat{A}$$
$$-\frac{1}{2}\hat{A}^\dagger\hat{A}^\dagger[\hat{a}_0,[\hat{a}_0,[\hat{H}_\Lambda(\mu),\hat{a}_0^\dagger]]]\hat{A}+\text{H.c.}+\frac{1}{4}\hat{A}^\dagger\hat{A}^\dagger[\hat{a}_0,[\hat{a}_0,[[\hat{H}_\Lambda(\mu),\hat{a}_0^\dagger],\hat{a}_0^\dagger]]]\hat{A}\hat{A}, \tag{20}$$

where $\hat{A}\equiv\hat{a}_0-c\sqrt{V}$, $\hat{A}^\dagger\equiv\hat{a}^\dagger-\bar{c}\sqrt{V}$. The third- and fourth-order terms in (20) are bounded by

$$-\frac{1}{2}\hat{A}^\dagger\hat{A}^\dagger[\hat{a}_0,[\hat{a}_0,[\hat{H}_\Lambda(\mu),\hat{a}_0^\dagger]]]\hat{A}+\text{H.c.}+\frac{1}{4}\hat{A}^\dagger\hat{A}^\dagger[\hat{a}_0,[\hat{a}_0,[[\hat{H}_\Lambda(\mu),\hat{a}_0^\dagger],\hat{a}_0^\dagger]]]\hat{A}\hat{A}$$
$$=-\frac{3}{2V}(2\lambda+g)\left(\hat{A}^2+\frac{2}{3}c\sqrt{V}\hat{A}\right)^\dagger\left(\hat{A}^2+\frac{2}{3}c\sqrt{V}\hat{A}\right)+\frac{2}{3}(2\lambda+g)|c|^2\hat{A}^\dagger\hat{A}\leqslant\frac{2}{3}(2\lambda+g)|c|^2\hat{A}^\dagger\hat{A}. \tag{21}$$

The terms of first and second order can be combined to give

$$-\hat{A}^\dagger[\hat{a}_0,\hat{H}_\Lambda(\mu)]+\text{H.c.}+\frac{1}{2}\hat{A}^\dagger\hat{A}^\dagger[\hat{a}_0,[\hat{a}_0,\hat{H}_\Lambda(\mu)]]+\text{H.c.}+\hat{A}^\dagger[\hat{a}_0,[\hat{H}_\Lambda(\mu),\hat{a}_0^\dagger]]\hat{A}$$
$$=-\frac{1}{2}[\hat{A}^\dagger\hat{A},[\hat{H}_\Lambda(\mu),\hat{A}^\dagger\hat{A}]]+2\hat{A}^\dagger[\hat{A},[\hat{H}_\Lambda(\mu),\hat{A}^\dagger]]\hat{A}-\frac{3}{2}\hat{A}^\dagger[\hat{A},\hat{H}_\Lambda(\mu)]-\frac{3}{2}[\hat{H}_\Lambda(\mu),\hat{A}^\dagger]\hat{A}. \tag{22}$$

Because of (17), the Gibbs average of the first term in the right-hand side of (22) is negative and can be dropped, since we are looking for an upper bound in (19). Since

$$[\hat{A},[\hat{H}_\Lambda(\mu),\hat{H}^\dagger]]=-\mu+\frac{1}{V}(2\lambda+g)+\frac{1}{V}(2\lambda+g)2\hat{a}_0^\dagger\hat{a}_0+\frac{2\lambda}{V}\hat{N}'_\Lambda\leqslant-\mu+\frac{1}{V}(2\lambda+g)+\frac{2}{V}(2\lambda+g)\hat{N}_\Lambda,$$

we have

$$2\hat{A}^\dagger[\hat{A},[\hat{H}_\Lambda(\mu),\hat{A}^\dagger]]\hat{A}\leqslant2\left(\frac{2\lambda+g}{V}-\mu\right)\hat{A}^\dagger\hat{A}+4\frac{2\lambda+g}{V}\hat{A}\hat{N}_\Lambda\hat{A}. \tag{23}$$

We consider the last two terms in the right-hand side of (22). Their averages with respect to $\hat{H}_\Lambda(\mu)$ do not depend on c, and are real and equal. Furthermore,

$$-2\langle\hat{A}^\dagger[\hat{A},\hat{H}_\Lambda(\mu)]\rangle_{\hat{H}_\Lambda(\mu)}=\langle[\hat{A}^\dagger,[\hat{H}_\Lambda(\mu),\hat{A}]]\rangle_{\hat{H}_\Lambda(\mu)}+\langle[\hat{A}^\dagger,[\hat{H}_\Lambda(\mu),\hat{A}]]_+\rangle_{\hat{H}_\Lambda(\mu)}, \tag{24}$$

where $[\ldots,\ldots]_+$ is the anticommutator. The first term in (24) is bounded by

$$\langle[\hat{A}^\dagger,[\hat{H}_\Lambda(\mu),\hat{A}]]\rangle_{\hat{H}_\Lambda(\mu)}\leqslant-\mu+\frac{1}{V}(2\lambda+g)+2\frac{2\lambda+g}{V}\rho, \tag{25}$$

where $\rho\equiv\langle\hat{N}_\Lambda\rangle_{\hat{H}_\Lambda(\mu)}$. Using a spectral decomposition of $\hat{H}_\Lambda(\mu)$ one can estimate the second term in (24) as[10]

$$\langle[\hat{A}^\dagger,[\hat{H}_\Lambda(\mu),\hat{A}]]_+\rangle_{\hat{H}_\Lambda(\mu)}\leqslant\langle[\hat{A},[\hat{H}_\Lambda(\mu),\hat{A}^\dagger]]\rangle_{\hat{H}_\Lambda(\mu)}+2\beta^{-1}\langle[\hat{A},\hat{A}^\dagger]_+\rangle_{\hat{H}_\Lambda(\mu)}. \tag{26}$$

Therefore, it follows from (24)–(26) that

$$-\frac{3}{2}\langle\hat{A}^\dagger[\hat{A},\hat{H}_\Lambda(\mu)]\rangle_{\hat{H}_\Lambda(\mu)}-\frac{3}{2}\langle[\hat{H}_\Lambda(\mu),\hat{A}^\dagger]\hat{A}\rangle_{\hat{H}_\Lambda(\mu)}\leqslant-3\mu+\frac{3}{V}(2\lambda+g)+\frac{6}{V}(2\lambda+g)\rho$$
$$+3\beta^{-1}\langle[\hat{A},\hat{A}^\dagger]_+\rangle_{\hat{H}_\Lambda(\mu)}. \tag{27}$$

Collecting (21), (23), and (27) we obtain finally the following upper bound for the average in the right-hand side of the Bogoliubov inequality (19):

$$\langle\hat{H}_\Lambda(\mu,c)-\hat{H}_\Lambda(\mu)\rangle_{\hat{H}_\Lambda(\mu)}\leqslant\frac{2}{3}(2\lambda+g)|c|^2\langle\hat{A}^\dagger\hat{A}\rangle_{\hat{H}_\Lambda(\mu)}+2\left(-\mu+\frac{1}{V}(2\lambda+g)\right)\langle\hat{A}^\dagger\hat{A}\rangle_{\hat{H}_\Lambda(\mu)}+\frac{4}{V}(2\lambda+g)$$
$$\times\langle\hat{A}^\dagger\hat{N}_\Lambda\hat{A}\rangle_{\hat{H}_\Lambda(\mu)}+3\beta^{-1}\langle[\hat{A},\hat{A}^\dagger]_+\rangle_{\hat{H}_\Lambda(\mu)}-3\mu+\frac{3}{V}(2\lambda+g)+\frac{6}{V}(2\lambda+g)\rho. \tag{28}$$

(2) The next step in the proof of Theorem is to obtain an upper bound for $\langle\hat{N}_\Lambda\hat{A}^\dagger\hat{A}\rangle_{\hat{H}_\Lambda(\mu)}$. We write this average as

$$\langle\hat{N}_\Lambda\hat{A}^\dagger\hat{A}\rangle_{\hat{H}_\Lambda(\mu)}=Q_\Lambda+\overline{\rho}\langle\hat{A}^\dagger\hat{A}\rangle_{\hat{H}_\Lambda(\mu)},$$

where

$$Q_\Lambda\equiv\left\langle\left(\frac{\hat{N}_\Lambda}{V}-\overline{\rho}\right)\hat{A}^\dagger\hat{A}\right\rangle_{\hat{H}_\Lambda(\mu)}$$

denotes the grand-canonical average and the positive number $\overline{\rho}$ will be defined below. The average Q_Λ can be written as

$$Q_\Lambda=\Xi_\Lambda^{-1}\sum_{N=0}^{\infty}\left(\frac{N}{V}-\overline{\rho}\right)\exp(-\beta VF_N)\langle\hat{A}^\dagger\hat{A}\rangle_{\hat{H}_\Lambda}, \tag{29}$$

where $F_N\equiv f_N-\mu N/V$, f_N represents the free-energy density and Ξ_Λ is the grand-canonical partition function associated with the Hamiltonian $\hat{H}_\Lambda$.

Let us partition the set $\{N\}$ and write the average (29) as

$$Q_\Lambda\equiv Q_\Lambda^{(1)}+Q_\Lambda^{(2)}+Q_\Lambda^{(3)}.$$

Now, we have to estimate from above the every term in this decomposition.

$$Q_\Lambda^{(1)}\equiv\Xi_\Lambda^{-1}\sum_{0\leqslant N<V\overline{\rho}}\left(\frac{N}{V}-\overline{\rho}\right)\exp(-\beta VF_N)\langle\hat{A}^\dagger\hat{A}\rangle_{\hat{H}_\Lambda}\leqslant 0,$$

$$Q_\Lambda^{(2)}\equiv\Xi_\Lambda^{-1}\sum_{V\overline{\rho}\leqslant N\leqslant V(\overline{\rho}+\xi)}\left(\frac{N}{V}-\overline{\rho}\right)\exp(-\beta VF_N)\langle\hat{A}^\dagger\hat{A}\rangle_{\hat{H}_\Lambda}\leqslant\xi\langle\hat{A}^\dagger\hat{A}\rangle_{\hat{H}_\Lambda(\mu)}.$$

Here $\xi>0$. Finally, we estimate the last term $Q_\Lambda^{(3)}$. The free energy is the convex function of ρ, so we have

$$F_N\left(\frac{N}{V}\right)\geqslant a_1+a_2\left(\frac{N}{V}-\overline{\rho}-\xi\right), \tag{30}$$

where $a_1=F_N(\overline{\rho}+\xi)$, $a_2=F_N'(\overline{\rho}+\xi)>0$ and $\overline{\rho}$ is defined by the condition

$$\inf_{N/V} F_N\left(\frac{N}{V}\right) = F_N(\overline{\rho}) \equiv \overline{F}_N.$$

Using (30), we obtain

$$\begin{aligned}
Q_\Lambda^{(3)} &\equiv \Xi_\Lambda^{-1} \sum_{N>V(\overline{\rho}+\xi)} \left(\frac{N}{V}-\overline{\rho}\right)\exp(-\beta V F_N)\langle \hat{A}^\dagger \hat{A}\rangle_{\hat{H}_\Lambda} \\
&\leqslant \Xi_\Lambda^{-1} \sum_{N>V(\overline{\rho}+\xi)} \left(\frac{N}{V}-\overline{\rho}\right)\exp\left\{-\beta V\left[a_1 + a_2\left(\frac{N}{V}-\overline{\rho}-\xi\right)\right]\right\}\langle \hat{A}^\dagger \hat{A}\rangle_{\hat{H}_\Lambda} \\
&\leqslant \Xi_\Lambda^{-1} \sum_{N>V(\overline{\rho}+\xi)} \left(\frac{N}{V}-\overline{\rho}\right)\exp\left\{-\beta V\left[a_1 + a_2\left(\frac{N}{V}-\overline{\rho}-\xi\right)\right]\right\}(N+|c|^2 V) \\
&= \Xi_\Lambda^{-1}\frac{1}{V}\exp(-\beta V a_1) \sum_{N>V(\overline{\rho}+\xi)} (N-V\overline{\rho})^2 \exp\{-\beta a_2[N-V(\overline{\rho}+\xi)]\} + \Xi_\Lambda^{-1}(\overline{\rho}+|c|^2) \\
&\quad \times \exp(-\beta V a_1) \sum_{N>V(\overline{\rho}+\xi)} (N-V\overline{\rho})^2 \exp\{-\beta a_2[N-V(\overline{\rho}+\xi)]\} \\
&= \Xi_\Lambda^{-1}\exp(-\beta V a_1)\left[\frac{1}{V}\frac{e^{-\beta a_2}(1+e^{-\beta a_2})}{(1-e^{-\beta a_2})^2} + 2\xi\frac{e^{-\beta a_2}}{(1-e^{-\beta a_2})^2} + \xi^2 V\frac{1}{1-e^{-\beta a_2}}\right. \\
&\quad \left. + (\overline{\rho}+|c|^2)\left(\frac{e^{-\beta a_2}}{(1-e^{-\beta a_2})^2} + \ + \xi V\frac{1}{1-e^{-\beta a_2}}\right)\right].
\end{aligned} \tag{31}$$

Let us find the lower bound for Ξ_Λ. The convexity implies that for any $\sigma>0$ and any sufficiently small ξ', $|N/V-\overline{\rho}|<\xi'<\xi$, one has $\overline{F}_N \leqslant F_N \leqslant \overline{F}_N + \sigma/2$. Then

$$\Xi_\Lambda \geqslant \sum_{|N/V-\overline{\rho}|<\xi'} \exp(-\beta V F_N) \geqslant 2\xi' V \exp\left[-\beta V\left(\overline{F}_N + \frac{\sigma}{2}\right)\right]. \tag{32}$$

Putting together the bounds (31) and (32), we obtain

$$Q_\Lambda^{(3)} \leqslant a_3 \exp\left[-\beta V\left(a_1 - \overline{F}_N - \frac{\sigma}{2}\right)\right] \leqslant a_3 \exp\left(-\beta V\frac{\sigma}{2}\right),$$

with some positive constant a_3.

Collecting the estimates above, we obtain that there exist some positive constants u and v, independent on V, such that

$$\frac{1}{V}\langle \hat{A}^\dagger \hat{N}_\Lambda \hat{A}\rangle_{\hat{H}_\Lambda(\mu)} \leqslant u + v\langle \hat{A}^\dagger \hat{A}\rangle_{\hat{H}_\Lambda(\mu)}. \tag{33}$$

Therefore, it follows from (33) that there exist two positive constants σ_1 and σ_2, independent on V, such that

$$\langle \hat{H}_\Lambda(\mu,c) - \hat{H}_\Lambda(\mu)\rangle_{\hat{H}_\Lambda(\mu)} \leqslant \sigma_1 + \frac{\sigma_2}{2}\langle \hat{A}^\dagger \hat{A}\rangle_{\hat{H}_\Lambda(\mu)}. \tag{34}$$

(3) It remains to prove that

$$\lim_{V\to\infty} \inf_c \left[\frac{1}{V}\langle \hat{H}_\Lambda(\mu,c) - \hat{H}_\Lambda(\mu)\rangle_{\hat{H}_\Lambda(\mu)}\right] = 0. \tag{35}$$

The proof is a standard application of the Bogoliubov method.[21] Since in the approximating Hamiltonian the gauge symmetry is broken, we introduce

$$\hat{H}_\Lambda^{(\nu)}(\mu) \equiv \hat{H}_\Lambda(\mu) - \sqrt{V}(\overline{\nu}\hat{a}_0 + \nu\hat{a}_0^\dagger),$$

$$\hat{H}_\Lambda^{(\nu)}(\mu, c) \equiv \hat{H}_\Lambda(\mu, c) - V(\overline{\nu c} + \nu\overline{c})$$

with sources $\nu \in \mathbb{C}$ breaking the symmetry of $\hat{H}_\Lambda(\mu)$. The best bound in (34) is obtained for $c^* = \langle \hat{a}_0/\sqrt{V}\rangle_{\hat{H}_\Lambda^{(\nu)}(\mu)}$, $|c^*| \leqslant M < \infty$. By the Harris inequality[22] one gets

$$\frac{1}{2}\langle [\delta\hat{a}_0^\dagger, \delta\hat{a}_0]_+\rangle_{\hat{H}_\Lambda^{(\nu)}(\mu)} \leqslant (\delta\hat{a}_0^\dagger, \delta\hat{a}_0)_{\hat{H}_\Lambda^{(\nu)}(\mu)} + \frac{\beta}{12}\langle [\delta\hat{a}_0, [\hat{H}_\Lambda^{(\nu)}(\mu), \delta\hat{a}_0^\dagger]]\rangle_{\hat{H}_\Lambda^{(\nu)}(\mu)}, \tag{36}$$

where $\delta\hat{a}_0^\# = \hat{a}_0^\# - \langle \hat{a}_0^\#\rangle_{\hat{H}_\Lambda^{(\nu)}(\mu)}$. The second term in the right-hand side of (36) is bounded by

$$\langle [\delta\hat{a}_0, [\hat{H}_\Lambda^{(\nu)}(\mu), \delta\hat{a}_0^\dagger]]\rangle_{\hat{H}_\Lambda^{(\nu)}(\mu)} \leqslant -\mu + 4\left(\lambda + \frac{g}{2}\right)\rho_\Lambda^{(\nu)}, \tag{37}$$

where $\rho_\Lambda^{(\nu)} \equiv \langle \hat{N}_\Lambda\rangle_{\hat{H}_\Lambda^{(\nu)}}/V < \infty$. To get an upper estimate for the first term in the right-hand side of (36), use the formula

$$(\delta\hat{a}_0^\dagger, \delta\hat{a}_0)_{\hat{H}_\Lambda^{(\nu)}(\mu)} = \beta^{-1}\frac{\partial^2 p_\Lambda^{(\nu)}}{\partial\overline{\nu}\partial\nu},$$

with $p_\Lambda^{(\nu)} \equiv (\beta V)^{-1}\ln \mathrm{tr}_{F_\Lambda} \exp[-\beta\hat{H}_\Lambda^{(\nu)}(\mu)]$. Without restriction we may assume that $\overline{\nu} = \nu = r \geqslant 0$. Then

$$(\delta\hat{a}_0^\dagger, \delta\hat{a}_0)_{\hat{H}_\Lambda^{(\nu)}(\mu)} = \frac{1}{4\beta r}\frac{d}{dr}\left(r\frac{dp_\Lambda^{(\nu)}}{dr}\right). \tag{38}$$

Denoting

$$\Delta(r) \equiv p_\Lambda^{(\nu)} - \sup_c p_\Lambda^{(\nu)}(c),$$

and using relations (19), (34), (36), and (37), we get

$$\Delta(r) \leqslant V^{-1}[\sigma_3 + \sigma_2(\delta\hat{a}_0^\dagger, \delta\hat{a}_0)_{\hat{H}_\Lambda^{(\nu)}(\mu)}], \tag{39}$$

where $\sigma_3 = \sigma_1 + \sigma_2\beta[4(\lambda + g/2)\rho_\Lambda^{(\nu)} - \mu]/12$. Multiply both sides of (39) by r, integrate over r from R to $R+\varepsilon$, and use the formula (38). Then

$$\int_R^{R+\varepsilon} r\Delta(r)dr \leqslant V^{-1}\left[\sigma_3\frac{(R+\varepsilon)^2 - R^2}{2} + \frac{\sigma_2}{4\beta}\left(r\frac{dp_\Lambda^{(\nu)}}{dr}\right)\Bigg|_R^{R+\varepsilon}\right].$$

Note now, that

$$\frac{dp_\Lambda^{(\nu)}}{dr} = \frac{2}{V}\langle \hat{a}_0\rangle_{\hat{H}_\Lambda^{(\nu)}(\mu)} \leqslant 2\sqrt{\rho_\Lambda^{(\nu)}}. \tag{40}$$

Therefore,

$$\int_R^{R+\varepsilon} r\Delta(r)dr \leqslant V^{-1}\left[\sigma_3\frac{(R+\varepsilon)^2 - R^2}{2} + \frac{\sigma_2}{2\beta}\sqrt{\rho_\Lambda^{(\nu)}}(2R+\varepsilon)\right]. \tag{41}$$

Take into account, that

$$\left|\frac{d\Delta(r)}{dr}\right| \leqslant 2(\sqrt{\rho_\Lambda^{(\nu)}}+M). \tag{42}$$

This estimate follows from the definition of $\Delta(r)$ and (40). The last inequality gives

$$\Delta(R) \leqslant \Delta(r) + 2(r-R)(\sqrt{\rho_\Lambda^{(\nu)}}+M), \tag{43}$$

where $r \in [R, R+\varepsilon]$. Multiplying (38) by r and integrating, we have

$$\Delta(R)\frac{(R+\varepsilon)^2-R^2}{2} \leqslant \int_R^{R+\varepsilon} r\Delta(r)dr + 2(\sqrt{\rho_\Lambda^{(\nu)}}+M)\left(\frac{r^3}{3}-R\frac{r^2}{2}\right)\Bigg|_R^{R+\varepsilon}.$$

Using (41), we get

$$\Delta(R) \leqslant \frac{1}{V}\left[\sigma_3 + \frac{\sigma_2}{\beta\varepsilon}\sqrt{\rho_\Lambda^{(\nu)}} + (\sqrt{\rho_\Lambda^{(\nu)}}+M)\varepsilon\frac{R+\frac{2\varepsilon}{3}}{R+\frac{\varepsilon}{2}}\right]. \tag{44}$$

Minimizing the right-hand side of (44) one obtains that for $V\to\infty$ the best choice of ε is $\varepsilon \sim 1/\sqrt{V}$, which gives $\Delta(R) \leqslant \eta V^{-1/2}$, where η is independent of V and can be taken independent of R in any bounded interval. For $\nu=0$ this implies (35). This finishes the proof of the Theorem.

IV. CONCLUSION

For $\lambda=0$ the Bogoliubov method implies the absence of Bose condensation also. In this case an appropriate self-consistency equation has the trivial solution only. On the other hand, for $g=0$ and $\lambda>0$ (mean field model) a self-consistency equation in the thermodynamic limit takes the degenerate form $(\mu-2\lambda\rho)c=0$ as for free bosons. Condensation can occur only at $\mu=2\lambda\rho$, and the density ρ_0 of the condensate is not determined by the equation.

The results of Michoel and Verbeure[3] on the nonextensive Bose condensation can be extended to our case. Let us take into account the correlation inequality[23,24]

$$\beta\langle\hat{A}[\hat{H},\hat{A}]\rangle_{\hat{H}} \geqslant \langle\hat{A}^\dagger\hat{A}\rangle_{\hat{H}} \ln\frac{\langle\hat{A}^\dagger\hat{A}\rangle_{\hat{H}}}{\langle\hat{A}\hat{A}^\dagger\rangle_{\hat{H}}} \tag{45}$$

for all local observables $\hat{A}$ belonging to the domain of $[\hat{H},\ldots]$. Taking $\hat{A}=\hat{a}_k$, $\hat{H}=\hat{H}_\Lambda(\mu)$ in (45), one gets

$$\langle\hat{n}_k\rangle_{\hat{H}_\Lambda(\mu)} \ln(1+\langle\hat{n}_k\rangle^{-1}_{\hat{H}_\Lambda(\mu)}) \geqslant \beta\Bigg[(\varepsilon_k-\mu)\langle\hat{n}_k\rangle_{\hat{H}_\Lambda(\mu)} + \frac{g}{V}\langle\hat{n}_k^2\rangle_{\hat{H}_\Lambda(\mu)} + \frac{2\lambda}{V}\langle\hat{n}_k\hat{N}_\Lambda\rangle_{\hat{H}_\Lambda(\mu)} - \frac{1}{V}\left(\lambda+\frac{g}{2}\right) \times\langle\hat{n}_k\hat{N}_\Lambda\rangle_{\hat{H}_\Lambda(\mu)}\Bigg]. \tag{46}$$

Referring to (17) with $\hat{H}=\hat{H}_\Lambda(\mu)$, $\hat{A}=\hat{n}_k^{1/2}\hat{a}_p$, $p\neq k$, we have

$$\left\langle\left(\mu-\frac{2\lambda}{V}\hat{N}_\Lambda\right)\hat{n}_k\right\rangle_{\hat{H}_\Lambda(\mu)} \leqslant \epsilon_p\langle\hat{n}_k\rangle_{\hat{H}_\Lambda(\mu)} + \frac{1}{V}\left(\lambda+\frac{g}{2}\right)\langle\hat{n}_k\rangle_{\hat{H}_\Lambda(\mu)} + \frac{2}{V}(\lambda+g)\langle\hat{n}_p\hat{n}_k\rangle_{\hat{H}_\Lambda(\mu)}, \quad p\neq k. \tag{47}$$

Inserting (47) into (46) and using the bound $\langle\hat{n}_k^2\rangle_{\hat{H}_\Lambda(\mu)} \geqslant 0$, we get for $p\neq k$

$$\langle \hat{n}_k \rangle_{\hat{H}_\Lambda(\mu)} \ln(1 + \langle \hat{n}_k \rangle^{-1}_{\hat{H}_\Lambda(\mu)}) \geqslant \beta \left[\left(\epsilon_k - \epsilon_p - \frac{2\lambda + g}{V} \right) \langle \hat{n}_k \rangle_{\hat{H}_\Lambda(\mu)} - \frac{2(\lambda + g)}{V} \langle \hat{n}_p \hat{n}_k \rangle_{\hat{H}_\Lambda(\mu)} \right].$$

Take $\delta > 0$ arbitrary, $|k| \geqslant \delta$ and $|p| \leqslant \delta/2$. Then for every V,

$$\langle \hat{n}_k \rangle_{\hat{H}_\Lambda(\mu)} \ln(1 + \langle \hat{n}_k \rangle^{-1}_{\hat{H}_\Lambda(\mu)}) \geqslant c_k \langle \hat{n}_k \rangle_{\hat{H}_\Lambda(\mu)} - \frac{2\beta}{V}(\lambda + g) \langle \hat{n}_p \hat{n}_k \rangle_{\hat{H}_\Lambda(\mu)},$$

where

$$c_k \equiv \beta \left(\epsilon_k - \frac{\delta^2}{8m} - \frac{2\lambda + g}{V} \right).$$

Solving the last inequality with respect to $\langle \hat{n}_k \rangle_{\hat{H}_\Lambda(\mu)}$, one has

$$\langle \hat{n}_k \rangle_{\hat{H}_\Lambda(\mu)} \leqslant (e^{c_k} - 1)^{-1} + \frac{2\beta}{V}(\lambda + g) \langle \hat{n}_p \hat{n}_k \rangle_{\hat{H}_\Lambda(\mu)} (1 - e^{-c_\delta})^{-1}, \tag{48}$$

where $c_\delta \equiv c_k|_{|k|=\delta}$. (46) gives

$$\beta \left[\left(-\epsilon_p + \mu + \frac{1}{V} \left(\lambda + \frac{g}{2} \right) \right) \langle \hat{n}_p \rangle_{\hat{H}_\Lambda(\mu)} - \frac{2\lambda}{V} \langle \hat{n}_p \hat{N}_\Lambda \rangle_{\hat{H}_\Lambda(\mu)} \right] \geqslant -1. \tag{49}$$

Taking $\hat{H} = \hat{H}_\Lambda(\mu)$, $\hat{A} = \hat{a}^\dagger_p$ in the inequality (17), we have

$$\mu \leqslant \epsilon_p + 2\lambda\rho + \frac{2}{V}(\lambda + g) \langle \hat{n}_p \rangle_{\hat{H}_\Lambda(\mu)} + \frac{1}{V} \left(\lambda + \frac{g}{2} \right).$$

Putting this into (49) gives

$$\frac{2\lambda}{V^2} \langle \hat{n}_p \hat{N}_\Lambda \rangle_{\hat{H}_\Lambda(\mu)} \leqslant \frac{1}{\beta V} + \left[2\lambda\rho + \frac{1}{V}(2\lambda + g) \right] \frac{\langle \hat{n}_p \rangle_{\hat{H}_\Lambda(\mu)}}{V} + \frac{2(\lambda + g)}{V^2} \langle \hat{n}_p \rangle^2_{\hat{H}_\Lambda(\mu)}.$$

Using Theorem and formula (2), we get

$$\frac{1}{V^2} \langle \hat{n}_p \hat{N}_\Lambda \rangle_{\hat{H}_\Lambda(\mu)} < \varepsilon \tag{50}$$

for every $\varepsilon > 0$, V large enough and $p \in \Lambda^*$. Since

$$\frac{1}{V} \sum_{k \in \Lambda^*, |k| < \delta} \langle \hat{n}_k \rangle_{\hat{H}_\Lambda(\mu)} = \rho - \frac{1}{V} \sum_{k \in \Lambda^*, |k| \geqslant \delta} \langle \hat{n}_k \rangle_{\hat{H}_\Lambda(\mu)},$$

the inequality (48) implies that for $|p| \leqslant \delta/2$

$$\frac{1}{V} \sum_{k \in \Lambda^*, |k| < \delta} \langle \hat{n}_k \rangle_{\hat{H}_\Lambda(\mu)} \geqslant \rho - \frac{1}{V} \sum_{k \in \Lambda^*, |k| \geqslant \delta} (e^{c_k} - 1)^{-1} - \frac{2\beta(\lambda + g)}{V} \sum_{k \in \Lambda^*, |k| \geqslant \delta} \langle \hat{n}_p \hat{n}_k \rangle_{\hat{H}_\Lambda(\mu)} (1 - e^{-c_\delta})^{-1}. \tag{51}$$

Take $\varepsilon > 0$ arbitrary and V large enough such that (50) is satisfied. Then

$$\frac{1}{V^2} \sum_{k \in \Lambda^*, |k| \geqslant \delta} \langle \hat{n}_p \hat{n}_k \rangle_{\hat{H}_\Lambda(\mu)} \leqslant \frac{1}{V^2} \langle \hat{n}_p \hat{N}_\Lambda \rangle_{\hat{H}_\Lambda(\mu)} < \varepsilon.$$

Finally, we have from (51) that

$$\lim_{\delta\to 0}\lim_{V\to\infty}\frac{1}{V}\sum_{k\in\Lambda^*,|k|<\delta}\langle\hat{n}_k\rangle_{\hat{H}_\Lambda(\mu)}\geqslant\rho-\int_{\mathbb{R}^d}\frac{dk}{(2\pi)^d}\frac{1}{e^{\beta\epsilon_k}-1}.$$

Hence for every $\rho>0$ there exists $\beta_c>0$, defined by

$$\rho=\int_{\mathbb{R}^d}\frac{dk}{(2\pi)^d}\frac{1}{e^{\beta_c\epsilon_k}-1},$$

such that for all $\beta>\beta_c$ the generalized condensation, also called frgmentation, takes place.

We obtain a diagonal solution of the *dual reflection* equation for the elliptic $A_{n-1}^{(1)}$ solid-on-solid model. The isomorphism between the solutions of the reflection equation and its dual is studied. © *2004 American Institute of Physics.*

I. INTRODUCTION

Two-dimensional lattice spin models in statistical mechanics have traditionally been solved by imposing periodic boundary condition. The Yang–Baxter equation[1,2]

$$R_{12}(u_1-u_2)R_{13}(u_1-u_3)R_{23}(u_2-u_3)=R_{23}(u_2-u_3)R_{13}(u_1-u_3)R_{12}(u_1-u_2), \tag{1.1}$$

together with such boundary condition then leads to families of commuting row *transfer matrices* and hence solvability.[2] The work of Sklyanin[3] shows that, by using the reflection equation (RE) introduced by Cherednik[4]

$$R_{12}(u_1-u_2)K_1(u_1)R_{21}(u_1+u_2)K_2(u_2)=K_2(u_2)R_{12}(u_1+u_2)K_1(u_1)R_{21}(u_1-u_2), \tag{1.2}$$

it is also possible to construct families of commuting *double-row transfer matrices* for vertex models with open boundary conditions. Then such a scheme has been generalized to *face-type* solid-on-solid (SOS) models.[5,6]

In order to construct the *double-row transfer matrices*, besides the RE, one needs the dual reflection equation whose explicit form is related with the crossing-unitarity relation of the R-matrix.[3,7,5,6] For the $\mathbb{Z}_n$ Belavin model,[8] the dual RE reads[6]

$$R_{12}(u_2-u_1)\tilde{K}_1(u_1)R_{21}(-u_1-u_2-nw)\tilde{K}_2(u_2)=\tilde{K}_2(u_2)R_{12}(-u_1-u_2-nw)\tilde{K}_1(u_1)R_{21}(u_2-u_1), \tag{1.3}$$

where w is the crossing parameter of the R-matrix. Moreover, there exists a *simple-form* isomorphism between the solution of the RE (1.2) and that of its dual (1.3)

$$\tilde{K}(u)=K\left(-u-\frac{nw}{2}\right). \tag{1.4}$$

However, for integrable SOS models, due to the complicated crossing-unitarity relation of R-matrix (Boltzmann weight) (2.18),[9,10] the dual RE (3.2) contains the face-type parameters $\{\lambda_j\}$ in addition to the spectral parameter. A generalized isomorphism between the solutions to the RE and its dual for SOS models, if exists, is yet to be found. In this sense, the dual RE for the

[a)]Present address: Department of Mathematics, The University of Queensland, Brisbane 4072, Australia.

face-type models has got its own *independent* role in contrast with the vertex model.

The RE of SOS models has been solved to give the diagonal K-matrices for the $A_n^{(1)}$, $B_n^{(1)}$, $C_n^{(1)}$, $D_n^{(1)}$, $A_{2n}^{(2)}$, and $A_{2n+1}^{(2)}$ SOS models.[11] But the generic (nondiagonal) K-matrix is known only for the $A_1^{(1)}$ SOS model.[12,5] However, the dual RE of the face type was solved only for the $A_1^{(1)}$ SOS model.[5] In this article, we consider the dual RE for the $A_{n-1}^{(1)}$ SOS model. After briefly reviewing the face-vertex correspondence between the $\mathbb{Z}_n$ Belavin model and the $A_{n-1}^{(1)}$ SOS model,[14] we construct the isomorphism between the solution of the RE and its dual for the $A_{n-1}^{(1)}$ SOS model in Sec. III. In Sec. IV, we derive a diagonal solution to the dual RE by solving directly. Then we prove that our diagonal solution to the dual RE can be obtained through the isomorphism transformation (3.16) from the diagonal solution[11] of RE by a special choice of the free parameter λ'. The final section is for conclusions.

II. REFLECTION EQUATION AND ITS DUAL FOR $A_{n-1}^{(1)}$ SOS MODEL

A. $\mathbb{Z}_n$ Belavin R-matrix

Let us fix τ such that $\mathrm{Im}(\tau)>0$ and a generic complex number w. Introduce the following elliptic functions:

$$\theta\begin{bmatrix} a \\ b \end{bmatrix}(u,\tau) = \sum_{m=-\infty}^{\infty} \exp\{\sqrt{-1}\pi[(m+a)^2\tau + 2(m+a)(u+b)]\}, \tag{2.1}$$

$$\theta^{(j)}(u) = \theta\begin{bmatrix} \frac{1}{2} - \frac{j}{n} \\ \frac{1}{2} \end{bmatrix}(u, n\tau), \quad \sigma(u) = \theta\begin{bmatrix} \frac{1}{2} \\ \frac{1}{2} \end{bmatrix}(u,\tau). \tag{2.2}$$

Among them the σ-function satisfies the following identity:

$$\begin{aligned} &\sigma(u+x)\sigma(u-x)\sigma(v+y)\sigma(v-y) - \sigma(u+y)\sigma(u-y)\sigma(v+x)\sigma(v-x) \\ &\quad = \sigma(u+v)\sigma(u-v)\sigma(x+y)\sigma(x-y), \end{aligned} \tag{2.3}$$

which will be useful in the following. [Our σ-function is the ϑ-function $\vartheta_1(u)$.[13] It has the following relation with the *Weierstrassian* σ-function if denoted by $\sigma_w(u)$: $\sigma_w(u) \propto e^{\eta_1 u^2}\sigma(u)$, $\eta_1 = \pi^2\left(\frac{1}{6} - 4\Sigma_{n=1}^{\infty} nq^{2n}/(1-q^{2n})\right)$ and $q = e^{\sqrt{-1}\tau}$.]

Let $R^B(u) \in \mathrm{End}(\mathbb{C}^n \otimes \mathbb{C}^n)$ be the $\mathbb{Z}_n$ Belavin R-matrix[8] given by

$$R^B(u) = \sum_{i,j,k,l} R_{ij}^{kl}(u) E_{ik} \otimes E_{lj}, \tag{2.4}$$

in which E_{ij} is the matrix with elements $(E_{ij})_k^l = \delta_{jk}\delta_{il}$. The coefficient functions are[9]

$$R_{ij}^{kl}(u) = \begin{cases} \dfrac{h(u)\sigma(w)\theta^{(i-j)}(u+w)}{\sigma(u+w)\theta^{(i-k)}(w)\theta^{(k-j)}(u)} & \text{if } i+j = k+l \bmod n, \\ 0 & \text{otherwise.} \end{cases} \tag{2.5}$$

Here we have set

$$h(u)=\frac{\prod_{j=0}^{n-1}\theta^{(j)}(u)}{\prod_{j=1}^{n-1}\theta^{(j)}(0)}. \tag{2.6}$$

The R-matrix satisfies the quantum Yang–Baxter Eq. (1.1) and the following unitarity and crossing-unitarity relations:[15]

$$\text{Unitarity: } R^B{}_{12}(u)R^B_{21}(-u)=id, \tag{2.7}$$

$$\text{Crossing-unitarity: } (R^B)^{t_2}_{21}(-u-nw)(R^B)^{t_2}_{12}(u)=\frac{e^{\sqrt{-1}nw}\sigma(u)\sigma(u+nw)}{\sigma(u+w)\sigma(u+nw-w)}id, \tag{2.8}$$

where t_i denotes the transposition in the ith space.

B. $A^{(1)}_{n-1}$ SOS R-matrix and face-vertex correspondence

Let $\{\epsilon_i|i=1,2,\ldots,n\}$ be the orthonormal basis of the vector space $\mathbb{C}^n$ such that $\langle\epsilon_i,\epsilon_j\rangle=\delta_{ij}$. The A_{n-1} simple roots are $\{\alpha_i=\epsilon_i-\epsilon_{i+1}|i=1,\ldots,n-1\}$ and the fundamental weights $\{\Lambda_i|i=1,\ldots,n-1\}$ satisfying $\langle\Lambda_i,\alpha_j\rangle=\delta_{ij}$ are given by

$$\Lambda_i=\sum_{k=1}^{i}\epsilon_k-\frac{i}{n}\sum_{k=1}^{n}\epsilon_k.$$

Set

$$\hat{i}=\epsilon_i-\overline{\epsilon},\ \overline{\epsilon}=\frac{1}{n}\sum_{k=1}^{n}\epsilon_k,\ i=1,\ldots,n,\ \text{then}\ \sum_{i=1}^{n}\hat{i}=0. \tag{2.9}$$

For each dominant weight $\Lambda=\Sigma_{i=1}^{n-1}a_i\Lambda_i$, $a_i\in\mathbb{Z}^+$, there exists an irreducible highest weight finite-dimensional representation V_Λ of A_{n-1} with the highest vector $|\Lambda\rangle$. For example the fundamental vector representation is V_{Λ_1}.

Let $\mathfrak{h}$ be the Cartan subalgebra of A_{n-1} and $\mathfrak{h}^*$ be its dual. A finite-dimensional diagonalizable $\mathfrak{h}$-module is a complex finite-dimensional vector space W with a weight decomposition $W=\oplus_{\mu\in\mathfrak{h}^*}W[\mu]$, so that $\mathfrak{h}$ acts on $W[\mu]$ by $xv=\mu(x)v$, $(x\in\mathfrak{h},v\in W[\mu])$. For example, the fundamental vector representation $V_{\Lambda_1}=\mathbb{C}^n$, the nonzero weight spaces $W[\hat{i}]=\mathbb{C}\epsilon_i$, $i=1,\ldots,n$.

For a generic $\lambda\in\mathbb{C}^n$, define

$$\lambda_i=\langle\lambda,\epsilon_i\rangle,\ \lambda_{ij}=\lambda_i-\lambda_j,\ |\lambda|=\sum_{l=1}^{n}\lambda_l,\ i,j=1,\ldots,n. \tag{2.10}$$

Let $R(z,\lambda)\in\mathrm{End}(\mathbb{C}^n\otimes\mathbb{C}^n)$ be the R-matrix of the $A^{(1)}_{n-1}$ SOS model given by

$$R(z,\lambda)=\sum_{i=1}^{n}R^{ii}_{ii}(z,\lambda)E_{ii}\otimes E_{ii}+\sum_{i\neq j}\{R^{ij}_{ij}(z,\lambda)E_{ii}\otimes E_{jj}+R^{ji}_{ij}(z,\lambda)E_{ji}\otimes E_{ij}\}. \tag{2.11}$$

The coefficient functions are

$$R^{ii}_{ii}(z,\lambda)=1,\ R^{ij}_{ij}(z,\lambda)=\frac{\sigma(z)\sigma(\lambda_{ij}w-w)}{\sigma(z+w)\sigma(\lambda_{ij}w)}, \tag{2.12}$$

$$R_{ij}^{ji}(z,\lambda)=\frac{\sigma(w)\sigma(z+\lambda_{ij}w)}{\sigma(z+w)\sigma(\lambda_{ij}w)}, \tag{2.13}$$

and λ_{ij} is defined in (2.10). The R-matrix satisfies the dynamical (modified) quantum Yang–Baxter equation

$$\begin{aligned}&R_{12}(z_1-z_2,\lambda-h^{(3)})R_{13}(z_1-z_3,\lambda)R_{23}(z_2-z_3,\lambda-h^{(1)})\\&\quad=R_{23}(z_2-z_3,\lambda)R_{13}(z_1-z_3,\lambda-h^{(2)})R_{12}(z_1-z_2,\lambda),\end{aligned} \tag{2.14}$$

with unitarity relation

$$R_{12}(u,\lambda)R_{21}(-u,\lambda)=id. \tag{2.15}$$

We adopt the notation: $R_{12}(z,\lambda-h^{(3)})$ acts on a tensor $v_1\otimes v_2\otimes v_3$ as $R(z,\lambda-\mu)\otimes id$ if $v_3\in W[\mu]$. Let us introduce

$$\tilde{R}(u,\lambda)_{ij}^{kl}=R(u,\lambda)_{ij}^{kl}\left\{\frac{f_2(\lambda;k)}{f_2(\lambda+\hat{k};k)}\frac{f_2(\lambda+\hat{i}+\hat{j};i)}{f_2(\lambda+\hat{j};i)}\right\}, \tag{2.16}$$

$$f_2(\lambda;j)=\prod_{k\neq j}\frac{\sigma(\lambda_{jk}w)}{\sigma(w)}. \tag{2.17}$$

The R-matrix satisfies the following crossing-unitarity relation[6]

$$\sum_{i_2,j_2=1}^{n}\tilde{R}(-u-nw,\lambda-\hat{j}_2)_{j_1\ j_2}^{i_1\ i_2}R(u,\lambda-\hat{j}_2)_{i_3\ j_2}^{i_2\ j_3}=\frac{e^{\sqrt{-1}nw}\sigma(u)\sigma(u+nw)}{\sigma(u+w)\sigma(u+nw-w)}\delta_{i_3}^{i_1}\delta_{j_3}^{j_1}. \tag{2.18}$$

Let us introduce an intertwiner—a n-component column vector $\phi_{\lambda,\lambda-\hat{j}}(u)$ whose kth element is

$$\phi_{\lambda,\lambda-\hat{j}}^{(k)}(u)=\theta^{(k)}(u+nw\lambda_j). \tag{2.19}$$

Using the intertwiner, the face-vertex correspondence can be written as[14]

$$R_{12}^{B}(u_1-u_2)\phi_{\lambda,\lambda-\hat{i}}(u_1)\otimes\phi_{\lambda-\hat{i},\lambda-\hat{i}-\hat{j}}(u_2)=\sum_{kl}R(u_1-u_2,\lambda)_{ij}^{kl}\phi_{\lambda-\hat{l},\lambda-\hat{l}-\hat{k}}(u_1)\otimes\phi_{\lambda,\lambda-\hat{l}}(u_2). \tag{2.20}$$

Then the Yang–Baxter equation of the $\mathbb{Z}_n$ Belavin R-matrix $R^B(u)$ (1.1) is equivalent to the dynamical Yang–Baxter equation of the $A_{n-1}^{(1)}$ SOS R-matrix $R(u,\lambda)$ (2.14).

III. RE AND DUAL RE FOR $A_{n-1}^{(1)}$ SOS MODEL

In this section, using the intertwiner between the $\mathbb{Z}_n$ Belavin R-matrix and that of the $A_{n-1}^{(1)}$ SOS model, we construct the isomorphism between the solution of the RE for the $A_{n-1}^{(1)}$ SOS model and that of its dual from the isomorphism (1.4).

A. RE and its dual for SOS model

The RE of the K-matrix $\mathcal{K}(\lambda|u)$ for the face-type SOS model was given as follows:[5,12,16,17]

$$\sum_{i_1,i_2}\sum_{j_1,j_2} R(u_1-u_2,\lambda)_{i_1}^{i_0}{}_{j_1}^{j_0}\mathcal{K}(\lambda+\hat{j}_1+\hat{i}_2|u_1)_{i_2}^{i_1}R(u_1+u_2,\lambda)_{j_2}^{j_1}{}_{i_3}^{i_2}\mathcal{K}(\lambda+\hat{j}_3+\hat{i}_3|u_2)_{j_3}^{j_2}$$
$$=\sum_{i_1,i_2}\sum_{j_1,j_2}\mathcal{K}(\lambda+\hat{j}_1+\hat{i}_0|u_2)_{j_1}^{j_0}R(u_1+u_2,\lambda)_{i_1}^{i_0}{}_{j_2}^{j_1}\mathcal{K}(\lambda+\hat{j}_2+\hat{i}_2|u_1)_{i_2}^{i_1}R(u_1-u_2,\lambda)_{j_3}^{j_2}{}_{i_3}^{i_2}. \quad (3.1)$$

The dual RE of the K-matrix $\tilde{\mathcal{K}}(\lambda|u)$ was written down by[5,6]

$$\sum_{i_1,i_2}\sum_{j_1,j_2} R(u_2-u_1,\lambda)_{i_1}^{i_0}{}_{j_1}^{j_0}\tilde{\mathcal{K}}(\lambda+\hat{j}_1+\hat{i}_1|u_1)_{i_2}^{i_1}\tilde{R}(-u_1-u_2-nw,\lambda)_{j_2}^{j_1}{}_{i_3}^{i_2}\tilde{\mathcal{K}}(\lambda+\hat{j}_2+\hat{i}_3|u_2)_{j_3}^{j_2}$$
$$=\sum_{i_1,i_2}\sum_{j_1,j_2}\tilde{\mathcal{K}}(\lambda+\hat{j}_0+\hat{i}_0|u_2)_{j_1}^{j_0}\tilde{R}(-u_1-u_2-nw,\lambda)_{i_1}^{i_0}{}_{j_2}^{j_1}\tilde{\mathcal{K}}(\lambda+\hat{j}_2+\hat{i}_1|u_1)_{i_2}^{i_1}R(u_2-u_1,\lambda)_{j_3}^{j_2}{}_{i_3}^{i_2}, \quad (3.2)$$

where $\tilde{R}(u,\lambda)$ is defined in (2.16) for the $A_{n-1}^{(1)}$ SOS model. The explicit expressions of $\tilde{R}(u,\lambda)$ for other types of SOS models were given in Ref. 6. Because of the *nontrivial* dependence on the face-type parameters $\{\lambda_j\}$, the dual RE of SOS models should be treated separately in contrast with those of the vertex models.

As in the Sklyanin scheme for the vertex models, one can construct families of commuting *double-row transfer matrices* for the SOS model with open boundary condition in terms of the K-matrices $\mathcal{K}(\lambda|u)$ and $\tilde{\mathcal{K}}(\lambda|u)$.[5,6]

B. Isomorphism between the solutions of the RE and its dual for $A_{n-1}^{(1)}$ SOS model

Thanks to the face-vertex correspondence between the $\mathbb{Z}_n$ Belavin vertex model and the $A_{n-1}^{(1)}$ SOS model (2.20), we can construct the isomorphism between the solutions of the RE and its dual for the $A_{n-1}^{(1)}$ SOS model from the isomorphism (1.4) of the $\mathbb{Z}_n$ Belavin vertex model.

Let us introduce other types of intertwiners $\overline{\phi}$ and $\tilde{\phi}$ satisfying the following orthogonality conditions:

$$\sum_k \overline{\phi}^{(k)}_{\lambda,\lambda-\hat{i}}(u)\phi^{(k)}_{\lambda,\lambda-\hat{j}}(u)=\delta_{ij}, \quad (3.3)$$

$$\sum_k \tilde{\phi}^{(k)}_{\lambda+\hat{i},\lambda}(u)\phi^{(k)}_{\lambda+\hat{j},\lambda}(u)=\delta_{ij}. \quad (3.4)$$

One can derive the "completeness" relations from the above conditions

$$\sum_k \overline{\phi}^{(i)}_{\lambda,\lambda-\hat{k}}(u)\phi^{(j)}_{\lambda,\lambda-\hat{k}}(u)=\delta_{ij}, \quad (3.5)$$

$$\sum_k \tilde{\phi}^{(i)}_{\lambda+\hat{k},\lambda}(u)\phi^{(j)}_{\lambda+\hat{k},\lambda}(u)=\delta_{ij}, \quad (3.6)$$

and the following relation between the intertwiners $\overline{\phi}$ and $\tilde{\phi}$ from their definitions (3.3) and (3.4):[6]

$$\overline{\phi}_{\lambda+\hat{j},\lambda}(u)=\frac{\sigma\left(u+w|\lambda|-\frac{n-1}{2}-w\right)}{\sigma\left(u+w|\lambda|-\frac{n-1}{2}\right)}\left\{\prod_{k\neq j}\frac{\sigma(\lambda_{jk}w)}{\sigma(\lambda_{jk}w+w)}\right\}\tilde{\phi}_{\lambda+\hat{j},\lambda}(u-nw). \quad (3.7)$$

Noting the fact $\langle\overline{\epsilon},\epsilon_j\rangle=1/n$ and the definition of the intertwiner (2.19), one can derive the following relations: for $\forall\alpha\in\mathbb{C}$

$$\phi_{\lambda+\alpha\bar{\epsilon}_{\hat{i}},\lambda+\alpha\bar{\epsilon}_{\hat{j}}}(u)=\phi_{\lambda,\lambda-\hat{j}}(u+\alpha w), \tag{3.8}$$

$$\overline{\phi}_{\lambda+\alpha\bar{\epsilon}_{\hat{i}},\lambda+\alpha\bar{\epsilon}_{\hat{j}}}(u)=\overline{\phi}_{\lambda,\lambda-\hat{j}}(u+\alpha w), \tag{3.9}$$

$$\tilde{\phi}_{\lambda+\alpha\bar{\epsilon}_{\hat{i}},\lambda+\alpha\bar{\epsilon}_{\hat{j}}}(u)=\tilde{\phi}_{\lambda,\lambda-\hat{j}}(u+\alpha w). \tag{3.10}$$

Define

$$\mathcal{K}(\lambda|u)_i^j=\sum_{s,t}\tilde{\phi}^{(s)}_{\lambda-\hat{i}+\hat{j},\lambda-\hat{i}}(u)K(u)_t^s\phi^{(t)}_{\lambda,\lambda-\hat{i}}(-u), \tag{3.11}$$

$$\tilde{\mathcal{K}}(\lambda|u)_i^j=\sum_{s,t}\overline{\phi}^{(s)}_{\lambda,\lambda-\hat{j}}(-u)\tilde{K}(u)_t^s\phi^{(t)}_{\lambda-\hat{j}+\hat{i},\lambda-\hat{j}}(u). \tag{3.12}$$

Then we have

Theorem 1 (Ref. 6): *The above relations (3.11) and (3.12) map the solutions $K(u)$ and $\tilde{K}(u)$ to the RE (1.2) and the dual (1.3) for the $\mathbb{Z}_n$ Belavin R-matrix to the solutions $\mathcal{K}(\lambda|u)$ and $\tilde{\mathcal{K}}(\lambda|u)$ to the RE (3.1) and the dual (3.2) for the $A^{(1)}_{n-1}$ SOS R-matrix, and vice versa.*

Using the relations (3.5) and (3.6), one can invert (3.11)

$$K(u)_t^s=\sum_{i,j}\phi^{(s)}_{\lambda-\hat{i}+\hat{j},\ \lambda-\hat{i}}(u)\mathcal{K}(\lambda|u)_i^j\overline{\phi}^{(t)}_{\lambda,\lambda-\hat{i}}(-u). \tag{3.13}$$

Using the isomorphism (1.4) between the solutions of the RE and the dual RE for the $\mathbb{Z}_n$ Belavin R-matrix, the relations (3.5), (3.6), and (3.12), we have

$$\begin{aligned}\tilde{\mathcal{K}}(\lambda|u)_\mu^\nu&=\sum_{s,t}\overline{\phi}^{(s)}_{\lambda,\lambda-\hat{\nu}}(-u)\tilde{K}(u)_t^s\phi^{(t)}_{\lambda-\hat{\nu}+\hat{\mu},\lambda-\hat{\nu}}(u)\\&=\sum_{s,t}\overline{\phi}^{(s)}_{\lambda,\ \lambda-\hat{\nu}}(-u)K\left(-u-\frac{nw}{2}\right)_t^s\phi^{(t)}_{\lambda-\hat{\nu}+\hat{\mu},\ \lambda-\hat{\nu}}(u)\\&=\sum_{i,j}\sum_{s,t}\overline{\phi}^{(s)}_{\lambda,\ \lambda-\hat{\nu}}(-u)\phi^{(s)}_{\lambda'-\hat{i}+\hat{j},\ \lambda'-\hat{i}}\left(-u-\frac{nw}{2}\right)\mathcal{K}\left(\lambda'|-u-\frac{nw}{2}\right)_i^j\\&\quad\times\overline{\phi}^{(t)}_{\lambda',\ \lambda'-\hat{i}}\left(u+\frac{nw}{2}\right)\phi^{(t)}_{\lambda-\hat{\nu}+\hat{\mu},\ \lambda-\hat{\nu}}(u)\\&=\sum_{i,j}M(\lambda,\lambda'-\hat{i}|-u)_j^\nu\mathcal{K}\left(\lambda'|-u-\frac{nw}{2}\right)_i^jM\left(\lambda',\lambda-\hat{\nu}|u+\frac{nw}{2}\right)_\mu^i,\end{aligned} \tag{3.14}$$

where $\lambda'\in\mathbb{C}^n$ is arbitrary and a *crossing matrix* $M(\lambda,\lambda'|u)_j^\nu$ is defined by

$$M(\lambda,\lambda'|u)_j^\nu=\sum_t\overline{\phi}^{(t)}_{\lambda,\ \lambda-\hat{\nu}}(u)\phi^{(t)}_{\lambda'+\hat{j},\lambda'}\left(u-\frac{nw}{2}\right). \tag{3.15}$$

Finally, we obtain

Theorem 2: *The solutions to the RE (3.1) and the dual (3.2) for the $A^{(1)}_{n-1}$ SOS R-matrix have the following isomorphism:*

$$\tilde{\mathcal{K}}(\lambda|u)_\mu^\nu=\sum_{i,j}M(\lambda,\lambda'-\hat{i}|-u)_j^\nu\mathcal{K}\left(\lambda'|-u-\frac{nw}{2}\right)_i^jM\left(\lambda',\lambda-\hat{\nu}|u+\frac{nw}{2}\right)_\mu^i, \tag{3.16}$$

where $\lambda'\in\mathbb{C}^n$ is arbitrary.

We remark that the crossing matrix (3.15) is generally *nondiagonal*. Hence, the corresponding

$\tilde{\mathcal{K}}(\lambda|u)$ of the solution to the dual RE (3.2) obtained by the isomorphism (3.16) from the diagonal solution[11] to RE is generally nondiagonal, too, except for the case that a special choice of "*moduli*" parameter λ' is chosen as (4.5) (this special case will be clarified later in the next section). However, in order to diagonalize the corresponding *double-row transfer matrices* for the $A_{n-1}^{(1)}$ SOS model by the algebraic Bethe ansatz method, one needs $\mathcal{K}(\lambda|u)$ and $\tilde{\mathcal{K}}(\lambda|u)$ both diagonal.[18,19] In the next section, we shall search for a diagonal $\tilde{\mathcal{K}}(\lambda|u)$.

IV. DIAGONAL SOLUTION OF THE DUAL RE FOR $A_{n-1}^{(1)}$ SOS MODEL

In this section we look for the diagonal solution to the dual RE (3.2) for the $A_{n-1}^{(1)}$ SOS model, namely, the *K*-matrix $\tilde{\mathcal{K}}(\lambda|u)$ of following form:

$$\tilde{\mathcal{K}}(\lambda|u)_i^j = \tilde{k}(\lambda|u)_i \delta_i^j, \tag{4.1}$$

where $\{\tilde{k}(\lambda|u)_i\}$ are the functions of the face parameters $\{\lambda_j\}$ and the spectral parameter u. From directly solving the Eq. (3.2), we have

Theorem 3: For

$$\tilde{k}(\lambda|u)_i = \left\{ \prod_{k\neq i} \frac{\sigma(\lambda_{ik}w - w)}{\sigma(\lambda_{ik}w)} \right\} \frac{\sigma\left(\lambda_i w + \overline{\xi} + u + \frac{nw}{2}\right)}{\sigma\left(\lambda_i w + \overline{\xi} - u - \frac{nw}{2}\right)} f(u,\lambda), \tag{4.2}$$

in which $\overline{\xi}$ is a free parameter and $f(u,\lambda)$ is any nonvanishing function of λ and u, the diagonal K-matrix $\tilde{\mathcal{K}}(\lambda|u)$ with entries (4.1) and (4.2) is a solution to the dual RE (3.2) for the $A_{n-1}^{(1)}$ SOS model.

Proof: Substituting $\tilde{\mathcal{K}}(\lambda|u)$ of form (4.1) into the dual RE (3.2) for the $A_{n-1}^{(1)}$ SOS model, one finds the only nontrivial conditions of $\tilde{k}(\lambda|u)_i$ are

$$\begin{aligned}
&R(u_2-u_1,\lambda)_{ji}^{ji}\tilde{k}(\lambda+\hat{i}+\hat{j}|u_1)_j\tilde{R}(-u_1-u_2-nw,\lambda)_{ji}^{ij}\tilde{k}(\lambda+\hat{i}+\hat{j}|u_2)_j \\
&\quad + R(u_2-u_1,\lambda)_{ij}^{ji}\tilde{k}(\lambda+\hat{i}+\hat{j}|u_1)_i\tilde{R}(-u_1-u_2-nw,\lambda)_{ji}^{ji}\tilde{k}(\lambda+\hat{i}+\hat{j}|u_2)_j \\
&= R(u_2-u_1,\lambda)_{ji}^{ji}\tilde{k}(\lambda+\hat{i}+\hat{j}|u_1)_i\tilde{R}(-u_1-u_2-nw,\lambda)_{ij}^{ji}\tilde{k}(\lambda+\hat{i}+\hat{j}|u_2)_i \\
&\quad + R(u_2-u_1,\lambda)_{ji}^{ij}\tilde{k}(\lambda+\hat{i}+\hat{j}|u_1)_j\tilde{R}(-u_1-u_2-nw,\lambda)_{ji}^{ji}\tilde{k}(\lambda+\hat{i}+\hat{j}|u_2)_i,\ i\neq j.
\end{aligned}$$

Substituting (2.16) and (4.2) into the above equation, the dual RE (3.2) is equivalent to the following equation:

$$\begin{aligned}
&\left\{ \sigma(u_- + \lambda_{ij}w)\sigma(u_+) - \sigma(u_-)\sigma(u_+ - \lambda_{ij}w)\frac{\sigma(\lambda_j w + \overline{\xi'} - u_1')\sigma(\lambda_i w + \overline{\xi'} + u_1')}{\sigma(\lambda_j w + \overline{\xi'} + u_1')\sigma(\lambda_i w + \overline{\xi'} - u_1')} \right\} \\
&\quad \times \frac{\sigma(\lambda_j w + \overline{\xi'} - u_2')\sigma(\lambda_i w + \overline{\xi'} + u_2')}{\sigma(\lambda_j w + \overline{\xi'} + u_2')\sigma(\lambda_i w + \overline{\xi'} - u_2')} \\
&= \sigma(u_+ + \lambda_{ij}w)\sigma(u_-) - \sigma(u_+)\sigma(u_- - \lambda_{ij}w)\frac{\sigma(\lambda_j w + \overline{\xi'} - u_1')\sigma(\lambda_i w + \overline{\xi'} + u_1')}{\sigma(\lambda_j w + \overline{\xi'} + u_1')\sigma(\lambda_i w + \overline{\xi'} - u_1')},
\end{aligned} \tag{4.3}$$

where $u_- = u_1' - u_2'$, $u_+ = u_1' + u_2'$, $u_i' = -u_i - nw/2$, $\overline{\xi'} = \overline{\xi} + (n-2)/nw$. Equation (4.3) is a consequence of the identity (2.3). Then we complete our proof.

Now we shall study the relation between our solution of the dual RE and the diagonal solution of RE which was given as follows:[11]

$$\mathcal{K}(\lambda|u)_i^j = k(\lambda|u)_i \delta_i^j = g(u,\lambda)\frac{\sigma(\lambda_i w+\xi-u)}{\sigma(\lambda_i w+\xi+u)}\delta_i^j. \tag{4.4}$$

Here, $g(\lambda|u)$ is any nonvanishing function of λ and u, and ξ is a free parameter. Let us choose

$$\lambda' = \lambda + \frac{n}{2}\overline{\epsilon} \Rightarrow \lambda_i' = \lambda_i + \tfrac{1}{2}, \tag{4.5}$$

the vector $\overline{\epsilon}$ is defined in (2.9). Using the relation (3.8), the crossing matrix $M(\lambda,\lambda+(n/2)\overline{\epsilon}-\hat{i}|u)_i^\nu$ defined in (3.15) becomes simple

$$M\left(\lambda,\lambda+\frac{n}{2}\overline{\epsilon}-\hat{i}|u\right)_i^\nu = \sum_t \overline{\phi}^{(t)}_{\lambda,\lambda-\hat{\nu}}(u)\phi^{(t)}_{\lambda+(n/2)\overline{\epsilon},\lambda+(n/2)\overline{\epsilon}-\hat{\nu}}\left(u-\frac{nw}{2}\right) = \sum_t \overline{\phi}^{(t)}_{\lambda,\lambda-\hat{i}}(u)\phi^{(t)}_{\lambda,\lambda-\hat{i}}(u) = \delta_i^\nu. \tag{4.6}$$

The resulting solution to the dual RE by the isomorphism transformation (3.16) from the diagonal solution to RE is

$$\widetilde{\mathcal{K}}(\lambda|u)_\mu^\nu = k\left(\lambda+\frac{n}{2}\overline{\epsilon}|-u-\frac{nw}{2}\right)_\nu M\left(\lambda+\frac{n}{2}\overline{\epsilon},\lambda-\hat{\nu}|u+\frac{nw}{2}\right)_\mu^\nu. \tag{4.7}$$

The relations (3.7) and (4.5) enable us to further simplify the expression of the crossing matrix $M(\lambda+(n/2)\overline{\epsilon},\lambda-\hat{\nu}|u+nw/2)_\mu^\nu$:

$$\begin{aligned}
M\left(\lambda+\frac{n}{2}\overline{\epsilon},\lambda-\hat{\nu}|u+\frac{nw}{2}\right)_\mu^\nu &= \frac{\sigma\left(u+|\lambda-\hat{\nu}|w+\frac{n-2}{2}w-\frac{n-1}{2}\right)}{\sigma\left(u+|\lambda-\hat{\nu}|w+\frac{n}{2}w-\frac{n-1}{2}\right)}\left\{\prod_{k\neq\nu}\frac{\sigma(\lambda_{\nu k}w-w)}{\sigma(\lambda_{\nu k}w)}\right\}\\
&\quad\times\sum_t \widetilde{\phi}^{(t)}_{\lambda+(n/2)\overline{\epsilon},\lambda+(n/2)\overline{\epsilon}-\hat{\nu}}\left(u-\frac{nw}{2}\right)\phi^{(t)}_{\lambda-\hat{\nu}+\hat{\mu},\lambda-\hat{\nu}}(u)\\
&= \frac{\sigma\left(u+|\lambda-\hat{\nu}|w+\frac{n-2}{2}w-\frac{n-1}{2}\right)}{\sigma\left(u+|\lambda-\hat{\nu}|w+\frac{n}{2}w-\frac{n-1}{2}\right)}\left\{\prod_{k\neq\nu}\frac{\sigma(\lambda_{\nu k}w-w)}{\sigma(\lambda_{\nu k}w)}\right\}\\
&\quad\times\sum_t \widetilde{\phi}^{(t)}_{\lambda,\lambda-\hat{\nu}}(u)\phi^{(t)}_{\lambda-\hat{\nu}+\hat{\mu},\lambda-\hat{\nu}}(u)\\
&= \frac{\sigma\left(u+|\lambda-\hat{\nu}|w+\frac{n-2}{2}w-\frac{n-1}{2}\right)}{\sigma\left(u+|\lambda-\hat{\nu}|w+\frac{n}{2}w-\frac{n-1}{2}\right)}\left\{\prod_{k\neq\nu}\frac{\sigma(\lambda_{\nu k}w-w)}{\sigma(\lambda_{\nu k}w)}\right\}\delta_\mu^\nu.
\end{aligned}$$

Finally, the resulting solution to the dual RE by the isomorphism transformation (3.16) from the diagonal solution to RE is given by

$$\widetilde{\mathcal{K}}(\lambda|u)_{\mu}^{\nu}=\frac{\sigma\left(u+|\lambda-\hat{\nu}|w+\frac{n-2}{2}w-\frac{n-1}{2}\right)}{\sigma\left(u+|\lambda-\hat{\nu}|w+\frac{n}{2}w-\frac{n-1}{2}\right)}\left\{\prod_{k\neq\nu}\frac{\sigma(\lambda_{\nu k}w-w)}{\sigma(\lambda_{\nu k}w)}\right\}k\left(\lambda+\frac{n}{2}\overline{|\varepsilon|}-u-\frac{nw}{2}\right)_{\nu}\delta_{\mu}^{\nu}. \tag{4.8}$$

Substituting the diagonal solution of RE (4.4) into the above equation and after redefining the boundary parameter $\overline{\xi}$ and the free nonvanishing function $f(u,\lambda)$, one finds that the resulting diagonal solution (4.8) to the dual RE is exactly the same as (4.2).

V. CONCLUSION AND COMMENTS

By using the face-vertex correspondence (2.20) and the isomorphism (1.4) between the solutions to the RE and its dual for the $\mathbb{Z}_n$ Belavin *R*-matrix, we construct the isomorphism between the solutions to the RE and its dual for the $A_{n-1}^{(1)}$ SOS *R*-matrix. By directly solving the equation, we obtain a diagonal solution to the dual RE. Our solution to the dual RE can also be obtained through the isomorphism transformation (3.16) from the diagonal solution to RE obtained in Ref. 11 by a special choice of the free parameter λ' (4.5). Furthermore, the diagonal $\widetilde{\mathcal{K}}(\lambda|u)$ obtained in this article enables us to diagonalize the *double-row transfer matrices* of the $\mathbb{Z}_n$ Belavin model with open boundary condition described by the diagonal $\mathcal{K}(\lambda|u)$ and the diagonal $\widetilde{\mathcal{K}}(\lambda|u)$.[19]

Alternatively in Ref. 20, the very isomorphism with the special choice of the free parameter λ' (4.5) from the diagonal solution of RE to the diagonal solution of the dual RE was constructed by fusion procedure. However, our *generic* isomorphism transformation (3.16) gives a way to construct a *nondiagonal* solution of the dual RE with additional free parameters $\{\lambda_i'\}$.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 45, NUMBER 11 NOVEMBER 2004

Approximation of sums of oscillating summands in certain physical problems

Ekatherina A. Karatsuba[a)]
Computing Centre of RAS, Vavilova 40, Moscow, 119991, Russia

(Received 15 January 2004; accepted 27 July 2004; published 25 October 2004)

The motion of a one-dimensional harmonic oscillator caused by recurring pushes in the absence of friction is considered. In particular, two cases are studied: the case when the pushes become more frequent and the other one when the pushes become less frequent. By means of an application of the Hardy–Littlewood–Vinogradov–Van der Corput theorem on the approximation of exponential sums by shorter ones, new asymptotic formulas for the solution of the problem are obtained. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1797552]

I. INTRODUCTION

In some fields of mathematics and mathematical physics the sums of the form

$$S=\sum_{a<k\leqslant b}\varphi(k)e^{2\pi i f(k)} \tag{1}$$

are studied. Here $\varphi(x)$ and $f(x)$ are real functions of real argument, $i^2=-1$. Such sums appear, for example, in number theory in the analysis of the Riemann zeta function, in the solution of the problems, connected with integer points in the domains on plane and in space, in the study of the Fourier series, in the solution of such differential equations as the wave equation, the potential equation, the heat conductivity equation and so on.

We call the number $b-a$ *the length of the sum* S (for the integers a and b, this is the number of the summands in S).

When $\varphi(x)$ and $f(x)$ satisfy certain conditions, the sum S can be replaced with good accuracy by another sum S_1,

$$S_1=\sum_{\alpha<k\leqslant\beta}\Phi(k)e^{2\pi i F(k)}, \tag{2}$$

with the length $\beta-\alpha$, which is much smaller then $b-a$. First relations of the form

$$S=S_1+R, \tag{3}$$

where S, S_1 are the sums (1) and (2), respectively, R is a remainder term, with concrete functions $\varphi(x)$ and $f(x)$, were obtained by Hardy and Littlewood,[1] when they deduced approximate functional equation for the Riemann zeta function $\zeta(s)$ and by Vinogradov,[2] in the study of total numbers of integer points in the domains on plane. In the general form the theorem was proved by Van der Corput[3] (for the recent results connected with the Van der Corput theorem, see Ref. 4).

In each of the above-mentioned papers, some restrictions on the functions $\varphi(x)$ and $f(x)$ were imposed. With certain restrictions on $\varphi(x)$ and $f(x)$ which are convenient for applications, the theorem was proved by Karatsuba in Ref. 5 (see also Ref. 6).

We shall use the following notations:

a)Electronic mail: ekar@ccas.ru; fax: +7-095-1356159.

(1) *For* $B>0$, $B\to+\infty$, *or* $B\to 0$, *we write*

$$1 \ll \frac{A}{B} \ll 1,$$

if there are constants $C_1>0$ *and* $C_2>0$, *such that*

$$C_1 \leqslant \frac{|A|}{B} \leqslant C_2.$$

(2) *For a real number* α, *the notation* $\|\alpha\|$, *is understood in the following sense:*

$$\|\alpha\| = \min(\{\alpha\}, 1-\{\alpha\}),$$

where $\{\alpha\}$ *is the fractional part of* α.

We formulate the main theorem about replacing of an exponential sum by shorter one in accordance with the equality (3).

Theorem: *Assume that the real functions* $f(x)$ *and* $\varphi(x)$ *satisfy the following conditions on the segment* $[a,b]$ *:*

(1) $f''''(x)$ *and* $\varphi''(x)$ *are continuous;*
(2) *there exist numbers* H, U *and* V *such that* $H>0$, $1\ll U\ll V$, $0<b-a\leqslant V$ *and*

$$\frac{1}{U} \ll f''(x) \ll \frac{1}{U}, \quad \varphi(x) \ll H,$$

$$f'''(x) \ll \frac{1}{UV}, \quad \varphi'(x) \ll \frac{H}{V},$$

$$f''''(x) \ll \frac{1}{UV^2}, \quad \varphi''(x) \ll \frac{H}{V^2}.$$

Then, if we define the numbers x_μ *by the equation*

$$f'(x_\mu) = \mu,$$

we obtain

$$\sum_{a<\mu\leqslant b} \varphi(\mu) e^{2\pi i f(\mu)} = \sum_{f'(a)\leqslant\mu\leqslant f'(b)} C(\mu) Z(\mu) + R, \tag{4}$$

where

$$R = O\left(\frac{HU}{b-a} + HT_a + HT_b + H\log(f'(b) - f'(a) + 2)\right);$$

$$T_j = \begin{cases} 0, & \text{if } f'(j) \text{ is an integer;} \\ \min\left(\dfrac{1}{\|f'(j)\|}, \sqrt{U}\right), & \text{if } \|f'(j)\| \neq 0; \end{cases}$$

$j=a,b$;

$$C(\mu) = \begin{cases} 1, & \text{if } f'(a) < \mu < f'(b); \\ \dfrac{1}{2}, & \text{if } \mu = f'(a) \text{ or } \mu = f'(b); \end{cases}$$

$$Z(\mu)=\frac{1+i}{\sqrt{2}}\frac{\varphi(x_\mu)}{\sqrt{f''(x_\mu)}}e^{2\pi i(f(x_\mu)-\mu x_\mu)}.$$

It is possible to prove this theorem with slightly weaker restrictions on $f(x)$ and $\varphi(x)$, replacing the condition (1) by the following condition

(1^*) *The finite derivatives* $f''''(x)$ *and* $\varphi''(x)$ *exist at every point of the segment* $[a,b]$.

The simplest version of the formulated theorem is the statement, which is called *the Van der Corput lemma* (see Ref. 7, for example).

Lemma (Van der Corput): Let $f(x)$ *be a real differentiable function on the interval* $a<x\leqslant b$. *Moreover, assume that inside this interval it's derivative* $f'(x)$ *is a monotonic and of a constant sign function, and for a constant* δ *such that* $0<\delta<1$ *the function* $f'(x)$ *satisfies the inequality* $|f'(x)|\leqslant\delta$.

Then

$$\sum_{a<k\leqslant b}e^{2\pi if(k)}=\int_a^b e^{2\pi if(x)}dx+\theta\left(3+\frac{2\delta}{1-\delta}\right), \tag{5}$$

where $|\theta|\leqslant 1$.

Remark: If the parameters a and b are integers, then it is possible to replace the relation (5) by the following one:

$$\sum_{a<k\leqslant b}e^{2\pi if(k)}=\int_a^b e^{2\pi if(x)}\,dx+\frac{1}{2}e^{2\pi if(b)}-\frac{1}{2}e^{2\pi if(a)}+\theta\frac{2\delta}{1-\delta}, \tag{6}$$

where $|\theta|\leqslant 1$.

II. STATEMENT OF THE PROBLEM

Our aim in the present paper is to apply the theorem (the lemma) to the solution of the problem of description of dynamics of the harmonic oscillator under the action of recurring pushes. Such an oscillator is an exact or approximate model in many problems of classical and quantum physics.

We consider the simplest example of vibrations of the one-dimensional harmonic oscillator in the absence of friction. The equation of the motion of such an oscillator is (see Ref. 8, for example)

$$\ddot{x}+\omega_0^2x=0, \tag{7}$$

where $\omega_0>0$ is a constant which is called the fundamental frequency of the oscillator vibrations; (7) describes the free oscillations of the harmonic oscillator without the friction:

$$x_0(t)=x_0\,\sin(\omega_0t-\varphi_0), \tag{8}$$

where $x_0=$const and $\varphi_0=$const are the given initial amplitude and phase.

Assume that the pushes act on the oscillator in the successive time moments $0<t_0<t_1<t_2<\cdots<t_n<\cdots$, $t_n\to+\infty$. These pushes give the positive increments the velocity of the oscillator motion: $V_0,V_1,\ldots,V_n,\ldots$. The mathematical description of such a problem presents the Cauchy problem with initial conditions

$$x(0)=X_0;\quad \dot{x}(0)=X_1. \tag{9}$$

For $t>0$, $x(t)$ satisfies the equation (see Ref. 9)

$$\ddot{x} + \omega_0^2 x = \sum_{k=0}^{\infty} V_k \delta(t - t_k), \tag{10}$$

where $\delta(t)$ is the Dirac delta-function:

$$\delta(x) = 0, \quad x \neq 0, \quad \int_{-\infty}^{+\infty} \delta(x)dx = 1.$$

The solution of this problem for $t_{n-1} < t < t_n$ has the following form:

$$x(t) = x_0(t) + S(t) = x_0(t) + \sum_{k=0}^{n-1} V_k \frac{\sin\ \omega_0(t - t_k)}{\omega_0}. \tag{11}$$

Here and below, $x_0(t)$ is the free harmonic vibrations of the oscillator (8).

III. PERIODIC PUSHES OF EQUAL VALUE ACT ON THE OSCILLATOR

The case when the pushes of the form

$$V_k = V,\ t_k = k\tau; \quad \tau = \text{const} > 0; \quad k = 0,1,2, \ldots, n; \quad n \to +\infty; \tag{12}$$

act on the one-dimensional harmonic oscillator is explicitly investigated in Ref. 9. There the solution of the problem (9), (10), (12) in the form

$$x(t) = x_0(t) + \frac{V}{\omega_0} \frac{\sin \dfrac{n\omega_0\tau}{2}}{\sin \dfrac{\omega_0\tau}{2}} \sin\ \omega_0 \left(t - \frac{n-1}{2}\tau \right)$$

is obtained for $t_{n-1} < t < t_n$. It is noted in Ref. 9 that "it is impossible to simplify the sum (11) for arbitrary t_k, V_k." We demonstrate below how applying the theorem (lemma) it is possible to obtain new asymptotic formulas for the solution of the problem (9), (10) also in the case of more complicated, nonperiodic pushes.

IV. THE PUSHES ACTING ON THE OSCILLATOR BECOME MORE FREQUENT

Consider the following example: in the absence of friction the pushes of the form

$$V_k = V,\ t_k = \tau(k + D)^{\beta}; \quad k = 0,1,2, \ldots, n; \quad n \to +\infty; \tag{13}$$

act on the harmonic oscillator, where $V; \tau; \beta; D$ are positive constants, with $D \geqslant 1$, and

$$0 < \beta < 1. \tag{14}$$

Note that the condition (14) means that the pushes become more frequent. For the pushes (13), (14) the sum $S = S(t)$ in (11) takes the form

$$S = \frac{V}{\omega_0} \mathrm{Im} \sum_{k=0}^{n-1} e^{i\omega_0(t - t_k)} = \frac{V}{\omega_0} \mathrm{Im}(e^{i\omega_0 t} S_0), \tag{15}$$

where

$$S_0 = \sum_{k=0}^{n-1} e^{-2\pi i(\omega_0/(2\pi))t_k}.$$

Set

$$f(x) = \frac{\omega_0}{2\pi} t_x = \frac{\omega_0}{2\pi} \tau (x + D)^{\beta}.$$

We note that

$$0 < f'(x) = \frac{\omega_0}{2\pi} \beta \tau (x + D)^{-1+\beta},$$

and for $x \to +\infty, f'(x) \to 0$ monotonically. That is why, defining the number x_1 by the equality

$$\frac{\omega_0}{2\pi} \beta \tau (x_1 + D)^{-1+\beta} = \frac{1}{2},$$

that is

$$x_1 = \left(\frac{\omega_0 \beta \tau}{\pi} \right)^{(1/(1-\beta))} - D,$$

we find that for $x \geqslant x_1$ the derivative $f'(x)$ satisfies the relation

$$0 < f'(x) \leqslant \frac{1}{2}.$$

Let $n_1 = [\max(0, x_1)] + 1, n > n_1$ (here and below $[X]$ means the integer part of the number X). We represent $S_0(t)$ in the form of the sum of two summands

$$S_0(t) = S_1(t) + S_2(t), \tag{16}$$

where

$$S_1(t) = \sum_{0 \leqslant k \leqslant n_1} e^{-2\pi i f(k)}, \tag{17}$$

$$S_2(t) = \sum_{n_1 < k \leqslant n-1} e^{-2\pi i f(k)}. \tag{18}$$

To estimate the sum $S_2(t)$ we apply the Van der Corput lemma; from (6) we obtain

$$S_2(t) = \int_{n_1}^{n-1} e^{-2\pi i f(x)}\, dx + \frac{1}{2} e^{-2\pi i f(n-1)} - \frac{1}{2} e^{-2\pi i f(n_1)} + \theta \frac{2\delta}{1-\delta}, \quad |\theta| \leqslant 1, \tag{19}$$

where

$$0 < \delta = \frac{\omega_0}{2\pi} \beta \tau (n_1 + D)^{-1+\beta} \leqslant \frac{1}{2}.$$

Consider the integral from (19):

$$J = J(n-1) = \int_{n_1}^{n-1} e^{-2\pi i f(x)}\, dx = \int_{n_1}^{n-1} e^{-i\omega_0 \tau (x+D)^{\beta}}\, dx. \tag{20}$$

Making the following change of variables of integration:

$$y = \omega_0 \tau (x + D)^{\beta},$$

we find from (20),

$$J = \beta^{-1}(\omega_0\tau)^{-1/\beta}\int_{\omega_0\tau(n_1+D)^\beta}^{\omega_0\tau(n+D-1)^\beta} y^{1/\beta-1}e^{-iy}\,dy = \beta^{-1}(\omega_0\tau)^{-1/\beta}J_1, \tag{21}$$

where

$$J_1 = \int_A^B y^{1/\beta-1}e^{-iy}\,dy,$$

$$A = \omega_0\tau(n_1+D)^\beta, \quad B = \omega_0\tau(n-1+D)^\beta. \tag{22}$$

Integrating J_1 by parts one time, we obtain

$$J_1 = iB^{1/\beta-1}e^{-iB} - iA^{1/\beta-1}e^{-iA} - i(\beta^{-1}-1)J_2, \tag{23}$$

where

$$J_2 = \int_A^B y^{1/\beta-2}e^{-iy}\,dy. \tag{24}$$

Since from (14) $1/\beta - 1 > 0$, in (23) we get $B^{1/\beta-1} > A^{1/\beta-1}$.

Let us get an upper bound for the integral J_2. Assume at first that $\beta \neq \frac{1}{2}$. From (24) we have

$$J_2 = \; i\int_A^B y^{1/\beta-2}\,de^{-iy} = iy^{1/\beta-2}e^{-iy}\Big|_A^B - i\left(\frac{1}{\beta}-2\right)\int_A^B y^{1/\beta-3}e^{-iy}\,dy.$$

From here,

$$|J_2| \leqslant B^{1/\beta-2} + A^{1/\beta-2} + \left|\frac{1}{\beta}-2\right|\int_A^B y^{1/\beta-3}\,dy \leqslant 2B^{1/\beta-2} + 2A^{1/\beta-2}, \quad \beta \neq \frac{1}{2}.$$

If $\beta = \frac{1}{2}$, then $J_2 = \int_A^B e^{-iy}\,dy$, and $|J_2| \leqslant 2$. Hence, for any $\beta, 0 < \beta < 1$, the inequality

$$|J_2| \leqslant 2B^{1/\beta-2} + 2A^{1/\beta-2} + 2 \tag{25}$$

is valid. From (23)–(25) we obtain

$$J_1 = iB^{1/\beta-1}e^{-iB} - iA^{1/\beta-1}e^{-iA} + \theta_1\frac{2(1-\beta)}{\beta}(B^{1/\beta-2} + A^{1/\beta-2} + 1), \tag{26}$$

$|\theta_1| \leqslant 1$.

From (18)–(22) and (26) we find the following approximation of the sum $S_2(t)$:

$$\begin{aligned} S_2(t) = {} & i(\omega_0\tau\beta)^{-1}(n-1+D)^{1-\beta}e^{-i\omega_0 t_{n-1}} + \theta_1 2(1-\beta)(\omega_0\tau\beta)^{-2}(n-1+D)^{1-2\beta} - i(\omega_0\tau\beta)^{-1}(n_1 \\ & + D)^{1-\beta}e^{-i\omega_0 t_{n_1}} + \theta_1 2(1-\beta)(\omega_0\tau\beta)^{-2}(n_1+D)^{1-2\beta} + \frac{1}{2}e^{-i\omega_0 t_{n-1}} - \frac{1}{2}e^{-i\omega_0 t_{n_1}} \\ & + \theta_1 2(1-\beta)(\omega_0\tau)^{-1/\beta}\beta^{-2} + \theta\frac{2\delta}{1-\delta}, \end{aligned} \tag{27}$$

where $|\theta| \leqslant 1$, $|\theta_1| \leqslant 1$, $0 < \delta \leqslant \frac{1}{2}$, $t_{n_1} = \tau(n_1+D)^\beta$, $t_{n-1} = \tau(n-1+D)^\beta$.

The sum $S_1(t)$ from (17) is estimated in the trivial way by the amount of its summands, that is,

$$S_1(t) = \theta_2(n_1+1), \quad |\theta_2| \leqslant 1. \tag{28}$$

From (16), (27), and (28) we have

$$e^{i\omega_0 t}S_0(t) = i(\omega_0\tau\beta)^{-1}(n-1+D)^{1-\beta}e^{i\omega_0(t-t_{n-1})} + \theta_3 R, \tag{29}$$

where $|\theta_3| \leqslant 1$,

$$R = 2(1-\beta)(\omega_0\tau\beta)^{-2}(n-1+D)^{1-2\beta} + (\omega_0\tau\beta)^{-1}(n_1+D)^{1-\beta} + 2(1-\beta)(\omega_0\tau\beta)^{-2}(n_1+D)^{1-2\beta}$$
$$+ n_1 + 2 + \theta_1 2(1-\beta)\beta^{-2}(\omega_0\tau)^{-1/\beta} + \frac{2\delta}{1-\delta}, \tag{30}$$

$0 < \delta \leqslant \frac{1}{2}$.

The imaginary part of the expression (29) is

$$\mathrm{Im}(e^{i\omega_0 t}S_0(t)) = (\omega_0\tau\beta)^{-1}(n-1+D)^{1-\beta}\cos\,\omega_0(t-t_{n-1}) + \theta_3 R,$$

$|\theta_3| \leqslant 1$.

From here and from (11) and (15) we find the general solution of the problem (9), (10), (13), (14): for $t_{n-1} < t < t_n$,

$$x(t) = x_0(t) + \frac{V}{\omega_0^2\tau\beta}(n-1+D)^{1-\beta}\sin\left(\omega_0 t + \frac{\pi}{2} - \omega_0\tau(n-1+D)^{\beta}\right) + \theta_4 R_0, \tag{31}$$

where $|\theta_4| \leqslant 1, R_0 = (V/\omega_0)R$.

Remark: It is possible to make (27), and therefore the solution of the problem (31), more precise, integrating by parts (22) not once, as it was done above, but several times (see the next paragraph).

V. A SPECIAL CASE OF THE PROBLEM IN WHICH THE PUSHES ACTING ON THE OSCILLATOR BECOME MORE FREQUENT

We consider again the problem (9), (10), (13), (14), but now with such values of the parameters β, τ, D, ω_0, that for the function

$$f'(x) = \frac{\omega_0}{2\pi}\beta\tau(x+D)^{-1+\beta}$$

the relation

$$f'(x)|_{x=0} = \frac{\omega_0}{2\pi}\beta\tau D^{-1+\beta} = \delta < 1 \tag{32}$$

holds. In this case we can apply the Van der Corput lemma to the asymptotic evaluation of the sum S_0 in (15). According to (6) we have

$$S_0 = e^{-i\omega_0 t_0} + \sum_{0<k\leqslant n-1} e^{-i\omega_0 t_k} = J + \theta\left(1 + \frac{2\delta}{1-\delta}\right),$$

where $|\theta| \leqslant 1$,

$$J = J(n-1) = \int_0^{n-1} e^{-i\omega_0 t_x}\,dx = \beta^{-1}(\omega_0\tau)^{-1/\beta}\int_{\omega_0 t_0}^{\omega_0 t_{n-1}} y^{1/\beta\,-1}e^{-iy}\,dy. \tag{33}$$

As before, here $y = \omega_0\tau(x+D)^{\beta}$, $t_0 = \tau D^{\beta}$, $t_{n-1} = \tau(n-1+D)^{\beta}$.

We assume at first that $1/\beta = m \geqslant 2, m$ is an integer. Then from (33) we find

$$\int_{\omega_0 t_0}^{\omega_0 t_{n-1}} y^{m-1}e^{-iy}\,dy = e^{-iy}(iy^{m-1} - i^2(m-1)y^{m-2} + \cdots + i^{3m-2}(m-1)!)\Big|_{\omega_0 t_0}^{\omega_0 t_{n-1}}.$$

From here we obtain

$$\begin{aligned}\mathrm{Im}(e^{i\omega_0 t}S_0) = \beta^{-1}(\omega_0\tau)^{-1/\beta}((\omega_0 t_{n-1})^{m-1}\cos\,\omega_0(t-t_{n-1}) + (\omega_0 t_{n-1})^{m-2}(m-1)\sin\,\omega_0(t-t_{n-1})\\ -(\omega_0 t_{n-1})^{m-3}(m-1)(m-2)\cos\,\omega_0(t-t_{n-1}) - (\omega_0 t_{n-1})^{m-4}(m-1)(m-2)\\ \times(m-3)\sin\,\omega_0(t-t_{n-1}) + \cdots + (m-1)\,!\,\mathrm{Im}(i^{3m-2}e^{i\omega_0(t-t_{n-1})})) + \theta_1 m((\omega_0 t_0)^{m-1}\\ +(m-1)^{m-1}) + \theta\left(1+\frac{2\delta}{1-\delta}\right),\end{aligned}$$

where $|\theta|\leqslant 1$, $|\theta_1|\leqslant 1$. It is possible to rewrite the last expression in the form

$$\mathrm{Im}(e^{i\omega_0 t}S_0) = m(\omega_0\tau)^{-m}A\,\sin(\omega_0(t-t_{n-1})+\varphi) + \theta_2 R, \tag{34}$$

where $|\theta_2|\leqslant 1$,

$$R = m((\omega_0 t_0)^{m-1} + (m-1)^{m-1}) + 1 + \frac{2\delta}{1-\delta}, \tag{35}$$

$$A = \sqrt{A_1^2 + A_2^2}, \tag{36}$$

$$A_1 = (\omega_0 t_{n-1})^{m-1} - (\omega_0 t_{n-1})^{m-3}(m-1)(m-2) + \cdots \sim (\omega_0 t_{n-1})^{m-1}, \tag{37}$$

$$A_2 = (\omega_0 t_{n-1})^{m-2}(m-1) - (\omega_0 t_{n-1})^{m-4}(m-1)(m-2)(m-3) + \cdots \sim (m-1)(\omega_0 t_{n-1})^{m-2}, \tag{38}$$

$$\varphi = \arctan\frac{A_1}{A_2} = \frac{\pi}{2} - \arctan\frac{A_2}{A_1} \sim \frac{\pi}{2}, \tag{39}$$

$m=1/\beta$, $t_0=\tau D^\beta$, $t_{n-1}=\tau(n-1+D)^\beta$, $n\to+\infty$.

From (11), (15), (34) we find the solution of the problem (9), (10), (13), (14), (32): for $t_{n-1}<t<t_n$,

$$x(t) = x_0(t) + \frac{V}{\omega_0\beta}(\omega_0\tau)^{-1/\beta}A\,\sin(\omega_0 t - \omega_0\tau(n-1+D)^\beta + \varphi) + \theta_0 R_0, \tag{40}$$

where $|\theta_0|\leqslant 1$, $R_0=(V/\omega_0)R$, and the values A and φ are defined by (36)–(39).

Remark: We obtained the solution of the problem of the form (40) in the assumption that $1/\beta=m$ is an integer. If $1/\beta$ is not an integer, then defining m by the equality $[1/\beta]=m$, we integrate (33) by parts $m+1$ times, and then we estimate from above by the absolute value of the last "remainder" integral. After that the solution is obtained in the same way as in the case when $1/\beta$ is an integer. The remainder (35) also includes the estimate of the "remainder" integral.

Remark: In the solution (40) the remainder expressed via (35) does not depend on n [compare with the remainder (30) obtained in the previous paragraph].

Remark: Substituting in (40) not the exact values of A and φ, but using the equivalences (37) and (39), we obtain, instead of the forced oscillations (40):

$$\frac{V}{\omega_0\beta}(\omega_0\tau)^{-1/\beta}A\,\sin(\omega_0 t - \omega_0\tau(n-1+D)^\beta + \varphi),$$

the forced oscillations of the problem considered before:

$$\frac{V}{\omega_0^2\tau\beta}(n-1+D)^{1-\beta}\,\sin\left(\omega_0 t + \frac{\pi}{2} - \omega_0\tau(n-1+D)^\beta\right),$$

see (31).

VI. THE PUSHES ACTING ON THE OSCILLATOR BECOME LESS FREQUENT

Consider the following example: the pushes of the form

$$V_k = V, \quad t_k = \tau(k+D)^{\beta}; \quad k = 0,1,2,\dots,n; \quad n \to +\infty; \tag{41}$$

act on the harmonic oscillator in the absence of friction, where V, τ, β, D are positive constants, and also $D \geqslant 1$,

$$1 < \beta < 2. \tag{42}$$

It is easy to see that under the condition (42) the pushes become less frequent. To obtain the solution of the problem (9), (10), (41), (42), we transform the sum S_0 from (15) in the following way. We divide the interval of summation in k into $m+1$ intervals of the form

$$\frac{n-1}{2} < k \leqslant n-1; \quad \frac{n-1}{4} < k \leqslant \frac{n-1}{2}; \dots; \quad 0 \leqslant k \leqslant \frac{n-1}{2^m},$$

where m is a natural number such that

$$2^m \leqslant n-1 < 2^{m+1}.$$

We represent S_0 in the form

$$S_0 = \sum_{0 \leqslant k \leqslant (n-1)2^{-m}} e^{-i\omega_0 t_k} + \sum_{\nu=0}^{m-1} \sum_{(n-1)2^{-\nu-1} < k \leqslant (n-1)2^{-\nu}} e^{-i\omega_0 t_k} = S_1 + S_2, \tag{43}$$

where

$$S_1 = \sum_{0 \leqslant k \leqslant (n-1)2^{-m}} e^{-i\omega_0 t_k} = e^{-i\omega_0 t_0} + e^{-i\omega_0 t_1}, \tag{44}$$

$$S_2 = \sum_{\nu=0}^{m-1} S(\nu), \quad S(\nu) = \sum_{(n-1)2^{-\nu-1} < k \leqslant (n-1)2^{-\nu}} e^{-i\omega_0 t_k}. \tag{45}$$

We transform the sum $S(\nu)$ using a simple variant of the main theorem. We set $\varphi(x)=1$, $H=1$, $T_a = T_b = \sqrt{U}$. Since in the theorem the estimate

$$|Z(\mu)| \leqslant H\sqrt{U} = \sqrt{U},$$

holds, then it is possible to suppose that in the relation (4) each factor $C(\mu)$ is equal to 1. We have

$$S(\nu) = \sum_{A < x \leqslant 2A} e^{-2\pi i f(x)}, \quad \overline{S}(\nu) = \sum_{A < x \leqslant 2A} e^{2\pi i f(x)},$$

where

$$f(x) = \frac{\omega_0 \tau}{2\pi}(x+D)^{\beta}, \tag{46}$$

$A = (n-1)2^{-\nu-1}, 0 \leqslant \nu \leqslant m-1$.

From (46) it follows that

$$f'(x) = \frac{\omega_0 \tau \beta}{2\pi}(x+D)^{\beta-1}, \quad f''(x) = \frac{\omega_0 \tau \beta(\beta-1)}{2\pi}(x+D)^{\beta-2}.$$

If we set $U = d^{-1}(A+D)^{2-\beta}$, where $d = \omega_0 \tau \beta(\beta-1)/(2\pi)$, then for $A \leqslant x \leqslant 2A$ the inequalities $1/(2U) \leqslant f''(x) \leqslant 1/U$ are satisfied.

We define the numbers x_μ by the equality

$$f'(x_\mu) = \frac{\omega_0 \tau \beta}{2\pi}(x_\mu + D)^{\beta-1} = \mu,$$

that is

$$x_\mu = \left(\frac{2\pi}{\omega_0 \tau \beta}\right)^{1/(\beta-1)} \mu^{1/(\beta-1)} - D.$$

Then

$$f(x_\mu) - \mu x_\mu = \frac{\omega_0 \tau}{2\pi}\left(\frac{2\pi}{\omega_0 \tau \beta}\right)^{\beta/(\beta-1)} \mu^{\beta/(\beta-1)} - \left(\frac{2\pi}{\omega_0 \tau \beta}\right)^{1/(\beta-1)} \mu^{1+1/(\beta-1)} + D\mu = -D_1 \mu^{1+1/(\beta-1)} + D\mu,$$

where

$$D_1 = \left(1 - \frac{1}{\beta}\right)\left(\frac{2\pi}{\omega_0 \tau \beta}\right)^{1/(\beta-1)}.$$

Besides,

$$f''(x_\mu) = \frac{\omega_0 \tau \beta(\beta-1)}{2\pi}\left(\frac{2\pi}{\omega_0 \tau \beta}\right)^{(\beta-2)/(\beta-1)} \mu^{(\beta-2)/(\beta-1)} = (\beta-1)\left(\frac{\omega_0 \tau \beta}{2\pi}\right)^{1/(\beta-1)} \mu^{1-1/(\beta-1)}.$$

Since in our example $b=2A$, $a=A$, $U=d^{-1}(A+D)^{2-\beta}$, we get

$$f'(b) - f'(a) = (b-a)f''(\xi) \leqslant \frac{A}{U} = \frac{Ad}{(A+D)^{2-\beta}} \leqslant d(A+D)^{\beta-1}.$$

This implies that the remainder term from (4) takes the form

$$R_\nu = O(UA^{-1} + \sqrt{U} + \log(2 + d(A+D)^{\beta-1})) = O(d^{-1}A^{-1}(A+D)^{2-\beta} + d^{-1/2}(A+D)^{1-\beta/2} + \log(2 + d(A+D)^{\beta-1})) = O(d^{-1/2}(A+D)^{1-\beta/2}) = O(d^{-1/2}A^{1-\beta/2}) = O(d^{-1/2}2^{-\nu(1-\beta/2)}n^{1-\beta/2}).$$

We apply the theorem to the asymptotic evaluation of the sum $\overline{S(\nu)}$. We find

$$\overline{S(\nu)} = \sum_{A<x\leqslant 2A} e^{2\pi i(\omega_0 \tau/(2\pi))(x+D)^\beta} = e^{i(\pi/4)} \sum_{\mu_1<\mu\leqslant\mu_2} (\beta-1)^{-1/2}\left(\frac{\omega_0 \tau \beta}{2\pi}\right)^{-1/(2(\beta-1))} \mu^{-1/2+1/(2(\beta-1))} e^{-2\pi i(D_1\mu^{1+1/(\beta-1)} - D\mu)} + O(R_\nu),$$

or using the complex conjugated sum we get

$$S(\nu) = e^{-i(\pi/4)}(\beta-1)^{-1/2}\left(\frac{\omega_0 \tau \beta}{2\pi}\right)^{-1/(2(\beta-1))} \sum_{\mu_1<\mu\leqslant\mu_2} \mu^{-1/2+1/(2(\beta-1))} e^{2\pi i(D_1\mu^{1+1/(\beta-1)} - D\mu)} + O(R_\nu), \tag{47}$$

where μ are the integers, and also

$$\mu_1 = f'(A) = \frac{\omega_0 \tau \beta}{2\pi}(A+D)^{\beta-1},$$

$$\mu_2 = f'(2A) = \frac{\omega_0 \tau \beta}{2\pi}(2A + D)^{\beta-1}.$$

Substituting (47) into (45) and summing over all ν, or what is the same, over all μ,

$$1 \leqslant \mu \leqslant \frac{\omega_0 \tau \beta}{2\pi}(n - 1 + D)^{\beta-1},$$

we obtain

$$S_2 = e^{-i(\pi/4)}(\beta-1)^{-1/2}\left(\frac{\omega_0\tau\beta}{2\pi}\right)^{-1/(2(\beta-1))} \sum_{1\leqslant\mu\leqslant\omega_0\tau\beta/(2\pi)(n\,-\,1\,+\,D)^{\beta-1}} \mu^{-1/2+1/(2(\beta-1))} e^{2\pi i(D_1\mu^{1+1/(\beta-1)}-D\mu)} + O\left(\sum_{\nu=0}^{m-1} R_\nu\right). \tag{48}$$

From (48) and (43)–(45) we obtain for the sum S_0 the following asymptotic expression:

$$S_0 = e^{-i(\pi/4)}(\beta-1)^{-1/2}\left(\frac{\omega_0\tau\beta}{2\pi}\right)^{-1/(2(\beta-1))} \sum_{1\leqslant\mu\leqslant\omega_0\tau\beta/(2\pi)(n\,-\,1\,+\,D)^{\beta-1}} \mu^{-1/2+1/(2(\beta-1))} \times e^{2\pi i((\beta-1)/\beta(2\pi/(\omega_0\tau\beta))^{1/(\beta-1)}\mu^{1+1/(\beta-1)}-D\mu)} + O(d^{-1/2}n^{1-\beta/2}). \tag{49}$$

Comparing (43) and (49) we see that applying the theorem we approximate the initial sum of n summands by the sum of $n^{\beta-1}, 1<\beta<2$, summands $n\to+\infty$ From (11), (16), and (49) we find the general solution of the problem (9), (10), (41), and (42) in the following form: for $t_{n-1}<t<t_n$,

$$x(t) = x_0(t) + \frac{V}{\omega_0}(\beta-1)^{-1/2}\left(\frac{\omega_0\tau\beta}{2\pi}\right)^{-1/(2(\beta-1))} \mathrm{Im}\left(e^{i(\omega_0 t-\pi/4)} \sum_{1\leqslant\mu\leqslant\omega_0\tau\beta/(2\pi)(n\,-\,1\,+\,D)^{\beta-1}} \mu^{-1/2+1/(2(\beta-1))} \times e^{2\pi i((\beta-1)/\beta(2\pi/(\omega_0\tau\beta))^{1/(\beta-1)}\mu^{1+1/(\beta-1)}-D\mu)}\right) + O(n^{1-\beta/2}). \tag{50}$$

Replacing in (50) the variable of summation μ by k and introducing new parameters,

$$N = \left[\frac{\omega_0\tau\beta}{2\pi}(n - 1 + D)^{\beta-1}\right] + 1;$$

$$A_k = (k+1)^{-1/2+1/(2(\beta-1))};$$

$$T_k = 2\pi\frac{\beta-1}{\beta}\left(\frac{2\pi}{\omega_0\tau\beta}\right)^{1/(\beta-1)}(k+1)^{1+1/(\beta-1)} - 2\pi(k+1)D;$$

$$W = V(\beta-1)^{-1/2}\left(\frac{\omega_0\tau\beta}{2\pi}\right)^{-1/(2(\beta-1))},$$

we obtain the solution of the problem in the following more compact form: for $t_{n-1}<t<t_n$,

$$x(t) = x_0(t) + \frac{W}{\omega_0}\sum_{k=0}^{N-1} A_k \sin\left(\omega_0 t - \frac{\pi}{4} + T_k\right) + O(N^{-1/2+1/(2(\beta-1))}).$$

Remark: In the results obtained above, it is assumed that τ, ω_0, β, and D are constants, and the constants in the remainders of the approximate solutions depend on the parameters τ, ω_0, β and D. In the examples considered above, it is assumed also that the total number of pushes n

must be great enough, that is $n \geqslant n_1(\tau, \omega_0, \beta, D)$.

Remark: It is possible to obtain the asymptotic approximation of the solution $x(t)$*, which is uniform not only in* n*,* $n \to +\infty$ *, but also in the parameters* τ, ω_0, β, D*. However, to obtain such formulas one needs very cumbersome calculations.*

(Received 26 March 2004; accepted 21 July 2004; published 25 October 2004)

For realizing a quantum memory the encoded quantum information can be protected against decoherence via repeated decoding and re-encoding operations. This requires us to perform fast encoding and decoding operations. The computational model underlying the one-way quantum computer provides a suitable concept for a fast implementation, which has been solved in a previous article for the encoding operation. In the present paper we show that the missing part, the decoding operation, can also be realized on a one-way quantum computer. This is based on the graph code representation for stabilizer codes, on the one hand, and the relation between cluster states and graph codes, on the other hand. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1797533]

I. INTRODUCTION

The concept of quantum error correcting codes plays a central role for the realization of quantum computational processes. In particular, quantum information, that is stored in a quantum system, has to be protected against decoherence. The states of the "input system" describe the quantum information we wish to store. These input states are given by density operators $\rho \in \mathcal{L}_1(\mathcal{K})$ acting on an "input Hilbert space" $\mathcal{K}$. The second system under consideration is the "output system" whose states are the density operators on an "output Hilbert space" $\mathcal{H}$.

The output system is the one which is present in nature, and in which we wish to encode quantum information. All relevant decoherence processes operating on the output system due to the coupling with the environment. A possible description of decoherence is the following: Consider a one parameter semi-group $t \mapsto T_t, T_t \circ T_s = T_{t+s}$, of channels acting on the observable algebra of all linear operators on $\mathcal{H}$. (In the Heisenberg picture, a channel T is a completely positive map that preserves unit operator.) The channel T_t is interpreted as the process of decoherence (error) that is present at the "time" t. A quantum computational process is only sufficiently reliable if the effect of errors is below a threshold ϵ. We define the "decoherence time" of the system to be the largest time s for which the cb-norm $\|T_s - \mathrm{id}\| \leq \epsilon$ is below the tolerable threshold. For most of the systems, which can be realized in experiments, the decoherence time s is too small for a sensible quantum memory.

In order to protect quantum information, we encode quantum states of the input system into quantum states of the output system. In the Heisenberg picture, which is preferably used here, an encoding operation is described by a channel E that maps the observable algebra $\mathcal{B}(\mathcal{H})$ of the output system into the observable algebra $\mathcal{B}(\mathcal{K})$ of the input system. For receiving the encoded quantum information back, we also need a decoding operation which is a channel D that maps the input observable algebra into the output observable algebra.

We encode states of the input system via a channel E to realize a quantum memory. After a certain time t, the encoded quantum information is corrupted due to the decoherence process T_t. The stored information is recovered by an application of an appropriate decoding operation D. The

a)Electronic mail: d.schlingemann@tu-bs.de

total channel that has been performed operates on the input system and it is given by the composition $E \circ T_t \circ D$. If this channel is close to the identity $\|E \circ T_t \circ D - \mathrm{id}\| \leq \epsilon$, we would have stored our quantum information successfully during the time t. For a reasonable coding scheme, the storing time t is much larger than the decoherence time s of the output system. The ratio t/s can be increased by increasing the ratio $\dim(\mathcal{H})/\dim(\mathcal{K})$ of the dimension of the output system and the dimension of the input system. Thus, increasing the storing time requires a larger amount of resources.

An alternative idea for obtaining large storing times is to concatenate decoding and re-encoding operations. Suppose we are able to store quantum information successfully for a time t. Then we just re-encode the corrected quantum information again, which corresponds to the operation $E \circ T_t \circ D \circ E$. Again the system undergoes decoherence for a further time t. Then the decoding operation is applied once more. The channel $E \circ T_t \circ D \circ E \circ T_t \circ D$ is close to the identity and we have stored our quantum information successfully for a time period $2t$. This heuristic picture is only realistic, if we assume that the decoding re-encoding operation $D \circ E$ can be performed much faster than the typical decoherence time s of the output system.

For realizing a quantum memory, we are therefore interested in "fast implementations" for encoding and decoding operations. The model of one-way quantum computing, introduced by Raussendorf and Briegel,[1–8] suggest being an appropriate base for realizing fast operations due to the intrinsic parallelism of this model. A one-way quantum computer operates on a system of qudits (quantum digits). Elementary operations within this scheme are (a) *local preparation procedures* which address every qudit individually, (b) one *elementary step of a dynamics* that corresponds to two-qudit next-neighbor interactions, (c) *local measurement operations* which operate independent on each qudit, and (d) *conditional local unitary operations*, depending on the measurement outcomes. The parallelism of a one-way quantum computer is based on the dynamics which is a global operation that addresses all qudits at the same time.

The pattern of two-qudit interactions defines a "weighted graph" on the set of qudit positions. Namely, two positions are connected by an edge, if the corresponding qudits interact with each other. The "weight," attached to an edge, is the "strength" of the qudit coupling (which is an integral number for suitable interactions).

As we have discussed in previous articles,[9,10] quantum error correcting codes associated with "graphs" are closely related to one-way quantum computing. The qudits under consideration are grouped into "input" qudits and "output qudits." In Ref. 11 we have shown that every encoding procedure for a graph code can be implemented on a one-way quantum computer by four elementary operations: (1) First one applies an appropriate local preparation procedure: Every output qudit is prepared in the "standard state" $(1/\sqrt{d})(\Sigma_{q \in \mathbb{F}_d}|q\rangle$, where $|q\rangle, q \in \mathbb{F}_d$ is an orthonormal basis labeled by the elements of a finite field $\mathbb{F}$ of order d, that is, d is a power of a prime. (2) One elementary step of a discrete dynamics is performed. This dynamics corresponds to the interaction pattern which is given by the underlying graph. (3) The input qudits are measured independently in the "x-basis," the nonbinary generalization of the σ_x-eigenbasis. (4) Depending on the measurement outcome, a suitable local unitary operation is performed. This scheme can be applied to all stabilizer codes over finite fields,[12] since any such code is equivalent to a graph code.[10,13]

The main result of the present paper is concerned with an implementation of the "decoding operation" of a graph code. It is based on a suitable extension of the coding graph by adding "syndrome vertices" and edges that connect the syndrome vertices with the output vertices in an appropriate manner. The syndrome vertices are the positions of the syndrome qudits which are used to measure the "error syndrome."

Theorem: *For every graph code over a finite field, the syndrome calculation can be implemented one a one-way quantum computer by a sequence of three elementary operations: (1) The input qudits as well as the syndrome qudits are individually prepared in the "standard state." (2) One inverse elementary step of the discrete dynamics, which corresponds to the extended coding graph, is performed. (3) The output qudits are measured independently in the x-basis and the syndrome qudits are measured independently in the z-basis which generalizes the σ_z-eigenbasis to the nonbinary case.*

Remark: The decoding operation can be completed by a conditional local unitary operation: (4) Depending on the measurement outcome of the output and syndrome qudits, a suitable local unitary operation is performed. This correction operation depends on the calculated syndromes and therefore on the class of errors that yield the same syndrome. Recall that the error syndrome is only uniquely determined by the error if the code is nondegenerate. We prove here that for any calculated error syndrome an appropriate local correction operation exists. However, to calculate it explicitly may be an NP hard problem concerning the length of the code.

We mention at this point that both operations, the encoding and the decoding, are based on the same dynamics. This is of course what one expects as far as the implementation of stabilizer codes by quantum circuits (consisting of one- and two-qudit elementary gates) is concerned:[14] The decoding one just uses the reversed circuit.

The paper is organized as follows: In Sec. II, we give some mathematical preliminaries as well as notations and conventions which are used in the subsequent sections. A precise description of the elementary operations that can be performed on a one-way quantum computer is given in Sec. III. The realization of a decoding operation on a one-way quantum computer is presented in Sec. IV. Some technical proofs are given in the Appendix and Sec. IV C in order to keep the article more comprehensive.

II. MATHEMATICAL PRELIMINARIES

The classical configuration space of a "digit" is given by a finite "alphabet" which is a finite field $\mathbb{F}$ of order d. For binary systems we are concerned with the field of two elements $\mathbb{F}_2=\{0,1\}$. A classical register is described by its configurations which are given by tuples $q^I=(q^i)_{i\in I}$ in the vector space $\mathbb{F}^I$. Each position $i\in I$ of the register is given by a "letter q^i" from the alphabet $\mathbb{F}$. It is convenient to identify a vector $a^K=(a^k)_{k\in K}\in\mathbb{F}^K$ with the vector in $\mathbb{F}^I$ that has only nonvanishing components in the subset $K\subset I$. The *phase space* of a register I is modeled by the vector space $\Xi^I=\mathbb{F}^I\oplus\mathbb{F}^I$.

The Hilbert space, describing a quantum register of qudits, is the space $\mathcal{L}_2(\mathbb{F}^I)$ of complex valued functions on $\mathbb{F}^I$ and its complex dimension is $d^{|I|}$ where $|I|$ is the number of elements in I. The scalar product of two functions ψ_1,ψ_2 is given by $\langle\psi_1,\psi_2\rangle=d^{-|I|}\Sigma_{q^I}\overline{\psi_1}(q^I)\psi_2(q^I)$. The algebra $\mathfrak{A}(I)$ of all linear operators on $\mathcal{L}_2(\mathbb{F}^I)$ is the "observable algebra" of the quantum register.

A useful basis of unitary operators in $\mathfrak{A}(I)$ is given by the unitary "Weyl" operators $\mathbf{w}(\xi^I),\xi^I\in\Xi^I$. For a given vector $\xi^I=(p^I,q^I)\in\Xi^I$ in phase space the corresponding Weyl operator is defined by

$$(\mathbf{w}(\xi^I)\psi)(q_1^I)=\chi(p^I,q_1^I)\psi(q_1^I-q^I), \tag{1}$$

with $\psi\in\mathcal{L}_2(\mathbb{F}^I)$. The phases $\chi(p^I,q^I)$ form a symmetric bicharacter of the additive group $\mathbb{F}^I$.[9] If the field $\mathbb{F}$ has characteristic d, then the bicharacter is given by $\chi(p^I,q^I)=\exp(2\pi i d^{-1}\Sigma_{i\in I}p^iq^i)$. By construction, the Weyl operators satisfy a discrete version of the canonical commutation relations,

$$\mathbf{w}(\xi_1^I)\mathbf{w}(\xi_2^I)=\chi(p_2^I,q_1^I)\mathbf{w}(\xi_1^I+\xi_2^I). \tag{2}$$

For a phase space vector $\xi^I=(0^I,q^I)$, the Weyl operator $\mathbf{x}(q^I):=\mathbf{w}(0^I,q^I)$ is a pure *shift* by q^I. On the other hand, the phase space vector $\xi^I=(p^I,0^I)$ corresponds to a *multiplier operator* $\mathbf{z}(p^I):=\mathbf{w}(p^I,0^I)$.

III. ONE-WAY QUANTUM COMPUTING

After a brief introduction into the basic elementary operations of one-way quantum computing, we apply the results of Ref. 11 to derive an implementation of both the encoding and decoding operation, on a one-way quantum computer.

It is convenient to fix one normalized "standard vector" $\Omega_K\in\mathcal{L}_2(\mathbb{F}^K)$ which we choose to be the constant function on $\mathbb{F}^K$. The application of multiplier operators yields an orthonormal basis $(\mathbf{z}(p^K)\Omega_K)_{p^K\in\mathbf{F}^K}$. This basis is called the "x-basis," which is the joint eigenbasis of the shift

operators. Any other product basis can be obtained by applying a local unitary operator $U_K = \otimes_k U_k$ to the x-basis. In particular, the local Fourier transform F_K, which is given by

$$(F_K\psi)(p^K) = \frac{1}{\sqrt{d}^{|K|}} \sum_{q^K} \chi(p^K, q^K)\psi(q^K), \tag{3}$$

transforms the x-basis to the so called z-basis which is nothing else but the joint eigenbasis of the multiplier operators.

The elementary operations are successively applied to a system of multiple qudits, which are grouped into three different types, according to their role. The "input qudits," "output qudits," as well as the "measuring qudits." They are labeled by the sets of vertices I, J, and K, respectively. The corresponding observable algebra (of the full quantum system) is given by $\mathfrak{A}(IJK) = \mathfrak{A}(I) \otimes \mathfrak{A}(J) \otimes \mathfrak{A}(K)$. In order to arrange formulas more clearly, we write $IJKL\cdots$ for the disjoint union $I \cup J \cup K \cup L \cup \cdots$ of sets of qudit positions (vertices).

A. Local preparation

Mathematical description: To each local unitary operator $U_{JK} = \otimes_{j \in JK} U_j$ in $\mathfrak{A}(JK)$ we associate the channel $\mathbf{E}_{U_{JK}}$ which maps an operator $A \in \mathfrak{A}(IJK)$ to

$$\mathbf{E}_{U_{JK}}(A) = \Phi_{JK}^* U_{JK}^* A\, U_{JK} \Phi_{JK} \in \mathfrak{A}(I). \tag{4}$$

Here Φ_{JK} is the isometry which assigns to a vector ψ the tensor product $\Phi_{JK}\psi = \psi \otimes \Omega_{JK}$.

Interpretation: The channel $\mathbf{E}_{U_{JK}}$ describes the *local preparation* which prepares each qudit at position $j \in J$ individually in the state which corresponds to the unit-vector $U_j\Omega_j$.

B. Elementary step of a discrete dynamics

Mathematical description: Let $\Lambda = (\Lambda_j^i)_{i,j \in IJK}$ be the adjacency matrix of a weighted graph with vertices IJK. We define the unitary multiplication operator $u(\Lambda)$ according to

$$(u(\Lambda)\psi)(q^{IJK}) := \tau(q^{IJK})\psi(q^{IJK}), \tag{5}$$

which implements an automorphism α_Λ of $\mathfrak{A}(IJK)$. An operator A is mapped to

$$\boldsymbol{\alpha}_\Lambda(A) = u(\Lambda)^* A u(\Lambda). \tag{6}$$

The phase-valued function $q^{IJK} \to \tau(q^{IJK})$ is chosen in such a way that

$$\tau(q^{IJK} + q_1^{IJK}) = \tau(q^{IJK})\tau(q_1^{IJK})\chi(q_1^{IJK}, \Lambda q^{IJK}) \tag{7}$$

holds for $q^{IJK} + q_1^{IJK} \in \mathbb{F}^{IJK}$.

Remark: For all graphs Λ a phase valued function τ that fulfills (7) exists. To see this, we build the finite-dimensional Abelian C*-algbra which is generated by unitary operators $\mathbf{u}(q^{IJK})$ that fulfill the relations

$$\mathbf{u}(q^{IJK} + q_1^{IJK}) = \mathbf{u}(q^{IJK})\mathbf{u}(q_1^{IJK})\chi(q_1^{IJK}, \Lambda q^{IJK}). \tag{8}$$

Each pure state (character) of this C*-algebra ζ induces a function τ that fullfills (7) by putting $\tau(q^{IJK}) := \zeta(\mathbf{u}(q^{IJK}))$.

To be more concrete, we can give an explicite formula for an appropriate function τ provided the graph Λ has no self-links. In this case, a solution for (7) is given by

$$\tau(q^{IJK}) := \exp\left(\frac{i\pi}{d} \sum_{i,j \in IJK} \Lambda_j^i q^i q^j\right). \tag{9}$$

Interpretation: The weighted graph Λ describes a next-neighbor interaction pattern subject to the dynamics $\boldsymbol{\alpha}_\Lambda$. Two positions i, j are neighbored if the corresponding matrix element of the

adjacency matrix does not vanish $\Lambda^i_j \neq 0$. The value of Λ^i_j corresponds to the strength of the coupling between qudit i and j.

C. Local measurements

Mathematical description: A local measurement operation is determined by a local unitary operator $U_{IK}=U_I\otimes U_K$. The corresponding operation is the channel $\mathbf{M}_{U_{IK}}$ which maps the C*-algebra $\mathcal{C}(\mathbb{F}^{IK},\mathfrak{A}(J))$ of operator valued functions $A:\mathbb{F}^{IK}\to\mathfrak{A}(J)$ to the operator

$$\mathbf{M}_{U_{IK}}(A)=\sum_{p^{IK}} U_{IK}\mathbf{z}(p^{IK})\Phi_{IK}A(p^{IK})\Phi^*_{IK}\mathbf{z}(p^{IK})^*U^*_{IK}, \tag{10}$$

in $\mathfrak{A}(IJK)$. The operators $U_{IK}\mathbf{z}(p^{IK})\Phi_{IK}, p^{IK}\in\mathbb{F}^{IK}$, are a complete family of mutually orthogonal isometries. This implies, in particular, that $\mathbf{M}_{U_{IK}}$ is an algebra homomorphism. Concerning the Heisenberg picture, this is the characteristic property of a projection valued measure. For our purposes, there are two interesting measurement bases: The x-basis corresponding to $U_{IK}=\mathbf{1}_{IK}$ and the z-basis corresponding to $U_{IK}=F_{IK}$.

Interpretation: Local measurements are dual to the local preparation schemes. They describe the individual measurement of a certain subset of qudits which consists here of input and measuring qudits IK. After the measurement operation has been performed, the remaining output qudits at positions J are in a quantum state that depends on the measurement outcome.

D. Conditional phase space translations

Mathematical description: Let f^J_{IK} be a function that maps a configuration $q^{IK}\in\mathbb{F}^{IK}$ to a phase space vector $f^J_{IK}q^{IK}\in\Xi^{IK}$. We associate to f^J_{IK} the *conditional phase space translation* $\mathbf{C}_{f^J_{IK}}$. It is the channel that assigns to an observable $A\in\mathfrak{A}(J)$ the operator valued function $\mathbf{C}_{f^J_{IK}}(A)\in\mathcal{C}(\mathbb{F}^{IK},\mathfrak{A}(J))$ by

$$q^{IK}\mapsto \mathbf{C}_{f^J_{IK}}(A)(q^{IK})=\mathbf{w}(f^J_{IK}q^{IK})A\mathbf{w}(f^J_{IK}q^{IK})^*. \tag{11}$$

Interpretation: After the qudits at the positions IK are measured, a measurement result $q^{IK}\in\mathbb{F}^{IK}$ is received. Depending on this outcome, a phase space translation is performed. The function f^J_{IK} describes a role which the phase space translation $f^J_{IK}q^{IK}$ one has to perform in case a randomly produced measurement result q^{IK} is received.

IV. IMPLEMENTING THE DECODING OPERATION BY A ONE-WAY QUANTUM COMPUTER

The encoding and decoding operation of a quantum error correcting code can be implemented as "quasi-free operations." Concerning the Heisenberg picture, quasi-free operations are channels T from the output algebra $\mathfrak{A}(J)$ into the input algebra $\mathfrak{A}(I)$ that map Weyl operators $\mathbf{w}(\xi^J)$ to a multiples of Weyl operators $T(\mathbf{w}(\xi^J))=\zeta(\xi^J)\mathbf{w}(\xi^I)$. As we have shown in Ref. 11, each quasi-free operation can be implemented on a one-way quatum computer by local preparation, one elementary step of a discrete dynamics (acting globally), a local measurement, and finally a phase space translation conditioned by the measurement outcome. The following definition expresses this in precise mathematical terms.

Definition IV.1: Let Λ be the adjacency matrix of a graph on the union of input vertices I, output vertices J, and syndrome vertices K, let $U_{IK}=\otimes_{i\in IK}U_i\in\mathfrak{A}(IK)$ be a local unitary operator, and let $f^J_{IK}:\mathbb{F}^{IK}\to\Xi^J$ be a function. We associate to the triple $(\Lambda,U_{IK},f^J_{IK})$ the channel $\mathbf{T}_{[\Lambda,U_{IK},f^J_{IK}]}:\mathfrak{A}(J)\to\mathfrak{A}(I)$, which is defined by

$$\mathbf{T}_{[\Lambda,U_{IK},f^J_{IK}]}:=\mathbf{E}_{1_{JK}}\circ\boldsymbol{\alpha}_\Lambda\circ\mathbf{M}_{U_{IK}}\circ\mathbf{C}_{f^J_{IK}}. \tag{12}$$

Interpretation: (1) The channel $\mathbf{E}_{1_{JK}}$ describes the preparation of the output and measuring qudits in the shift invariant standard state. (2) The next-neighbor interaction, which is described by

the graph Λ, is switched on for a definite period of time. This corresponds to the application of one elementary step of the discrete dynamics $\boldsymbol{\alpha}_\Lambda$ which acts globally on "all" qudits IJK. (3) The input and measuring qudits IK are measured in the product basis $(U_{IK}\mathbf{z}(p^{IK})\Omega_{IK})_{p^{IK}\in\mathbb{F}^{IK}}$. For quasi-free operations, the measurement of the input qudits is performed in the x-basis whereas the measurement qudits are either measured in a z- or an x-basis. This corresponds to the choice $U_i=\mathbf{1}_i$ for $i\in I$ and $U_k\in\{\mathbf{1}_k,F_k\}$ for $k\in K$. (4) After the measurement has been performed, one has produced a quantum state of the output qudits J which depends on the measurement outcome $p^{IK}\in\mathbb{F}^{IK}$. In order to realize a pure quantum operation, one has to perform, on the output qudits J, a phase space translation by the vector $f^J_{IK}p^{IK}$ which depends on the measurement outcome p^{IK}.

Note that in general the channels, given by Definition IV.1, are not pure. This requires additional conditions on the graph, on one hand, and on the conditional phase space translation, on the other hand.

A. Quantum error correction

We briefly recall here the concept of a quantum error correcting code that is able to correct errors that occur at a particular number e of qudits. A channel $T:\mathfrak{A}(J)\to\mathfrak{A}(J)$ is localized at a subset $E\subset J$ of qudit positions, if $T(A)=A$ holds for all operators $A\in\mathfrak{A}(J\backslash E)$ that are localized in the complement of E. This means that only the qubits at the positions E are affected by errors. A quantum error correcting code, that is able to correct e errors, is a pair (E,D) that consists of an encoding operation $E:\mathfrak{A}(J)\to\mathfrak{A}(I)$ and a decoding operation $D:\mathfrak{A}(I)\to\mathfrak{A}(J)$ such that the composition $E\circ T\circ D=\mathrm{id}$ is the ideal channel for all T that are localized at any subset E that contains e elements.

B. How to realize the decoder

The encoder and decoder can be related to the same adjacency matrix Λ of a graph on the union of input vertices I, output vertices J, and syndrome vertices L. For the implementation of a reasonable quantum error correcting code, which is able to correct e-errors, the matrix Λ has to fulfill the subsequent three conditions. [The following notation is used: For a matrix Θ^N_M and for two subsets $K\subset M,L\subset N$, we write $\Theta^L_K=(\Theta^l_k)_{l\in L,k\in K}$ for the corresponding sub-block. For a vector a^K we define $\Theta^L_K a^K=(\Sigma_k\Theta^l_k a^k)_{l\in L}$.]

Definition IV.2: The set of e-error correcting graphs $\mathcal{G}_e(I,J,L)$ is defined to consist of all graphs on the union of input vertices I, output vertices J, and syndrome vertices L whose adjacency matrix $\Lambda=(\Lambda^i_j)_{i,j\in IJL}$ fulfills the following conditions.

G-1: The block matrix Λ^J_{IL} is invertible with an inverse $\overline{\Lambda}^{IL}_J$.
G-2: There are no edges that connect input and syndrome vertices, i.e., the block matrix $\Lambda^{IL}_{IL}=0$ vanishes.
G-3: For all sets $E\subset J$ that contain at most $2e$ elements the condition

$$\Lambda^{J\backslash E}_{IE}q^{IE}=0 \text{ implies } q^I=0 \text{ and } \Lambda^I_E q^E=0 \tag{13}$$

is fulfilled.

Description of the encoding operation: As we have shown in Ref. 11, to an e-error correcting graph $\Lambda\in\mathcal{G}_e(I,J,L)$ corresponds the encoding channel $E_\Lambda=\mathbf{T}_{[\Lambda^{IJ}_{IJ},1_I,e^J_I]}$ of an e-error correcting code. Here e^J_I is the function from $\mathbb{F}^I$ to Ξ^J which is defined by

$$e^J_I p^I=(\Lambda^J_J\overline{\Lambda}^J_I p^I,-\overline{\Lambda}^J_I p^I). \tag{14}$$

The encoding scheme only operates on the input and output qudits and depends just on the subgraph Λ^{IJ}_{IJ} where the syndrome vertices are removed.

Interpretation: (1) The output qudits are prepared in the shift invariant state. (2) One step of the discrete dynamics, associated with the subgraph Λ^{IJ}_{IJ} is applied. (3) The input qudits are measured in x-basis. (4) Depending on the measurement outcome, a phase space translation is

done. The relation between the measurement outcome and the phase space translation is described by the "classical device" e_I^J.

Description of the decoding operation: The decoding operation makes use of the same graph $\Lambda \in \mathcal{G}_e(I,J,L)$ as the encoding operation but the vertices are interpreted differently. The output vertices J are now interpreted as inputs and, *vice versa*, the input vertices I as outputs. The syndrome vertices L are measuring vertices, to fix the error syndrome. However, the conditional phase space translation, which is performed after the measurement procedure, is more subtle as for the encoding case and relies on the following theorem:

Theorem IV.1: *Let $\Lambda \in \mathcal{G}_e(I,J,L)$ be an e-error correcting graph (see Definition IV.2). For each $q^L \in \mathbb{F}^L$ there is at most one solution $f_L^I q^L = (p^I, q^I) \in \Xi^I$ of the system of equations,*

$$p^E - \Lambda_{IEL}^J q^{IEL} = 0^J,$$

$$p^I - \Lambda_E^I q^E = 0^I, \tag{15}$$

for some $(p^E, q^E) \in \Xi^J$, provided E contains at most e elements.

Proof: Let us assume that for the two vectors $b^L, q^L \in \mathbb{F}^L$ there are solutions (a^I, b^I) and (p^I, q^I) of the system of equations,

$$a^E = \Lambda_{IEL}^J b^{IEL} \text{ and } a^I = \Lambda_E^I b^E,$$

$$p^E = \Lambda_{IEL}^J q^{IEL} \text{ and } p^I = \Lambda_E^I q^E, \tag{16}$$

respectively. The vectors (a^E, b^E) and (p^E, q^E) have components in a common set $E \subset J$ that contains at most $2e$ elements. This is true if $(a^E, b^E) = (a^K, b^K)$ and $(p^E, q^E) = (p^F, q^F)$ are independently supported in sets K and F that contain at most e elements. The set E is then their union $E = KF$. If $b^L = q^L$ holds, then the identity,

$$a^E - p^E = \Lambda_{IE}^J (b^{IE} - q^{IE}), \tag{17}$$

follows. We split the system of equations (17) into the components, belonging to the subset $E \subset J$ and its complement $J \setminus E$. This yields the identity

$$\Lambda_{IE}^{J \setminus E} (b^{IE} - q^{IE}) = 0^{J \setminus E}, \tag{18}$$

for the components in the complement $J \setminus E$. We conclude, by making use of the condition **G-3** in Definition IV.2, that $b^I = q^I$ holds as well as $\Lambda_E^I b^E = \Lambda_E^I q^E = a^I = p^I$. This implies that for a given vector $q^L = b^L$ there is indeed at most one solution $f_L^I q^L = (p^I, q^I) \in \Xi^I$ of (15). □

With the help of Theorem IV.1, we are able to define the function $d_{JL}^I : \mathbb{F}^{JL} \to \Xi^I$, which determines which conditional phase space translation $d_{JL}^I m^{JL}$ one has to perform if the measurement outcome m^{JL} has been received.

Definition IV.3: The function $d_{JL}^I : \mathbb{F}^{JL} \to \Xi^I$ assigns to each measurement outcome $m^{JL} \in \mathbb{F}^{JL}$ the phase space vector

$$d_{JL}^I m^{JL} := (p^I, q^I - \overline{\Lambda_J^I} m^J), \tag{19}$$

if (p^I, q^I) is the unique solution of (15) for $q^L = m^L + \overline{\Lambda_J^L} m^J$ and

$$d_{JL}^I m^{JL} := 0^I \tag{20}$$

if (15) has no solution for $q^L = m^L + \overline{\Lambda_J^L} m^J$.

The subsequent theorem gives a description of the decoder in terms of elementary operations on a one-way quantum computer.

Theorem IV.2: *Let $\Lambda \in \mathcal{G}_e(I,J,L)$ be an e-error correcting graph and let $D_\Lambda : \mathfrak{A}(I) \to \mathfrak{A}(J)$ be the channel,*

$$D_\Lambda := \mathbf{T}_{[-\Lambda,1_J\otimes F_L,d^I_{JL}]}, \tag{21}$$

where the function d^I_{JL} is given by Definition IV.3. Then the pair (E_Λ, D_Λ) is an e-error correcting code.

Before going into the details of the proof, we comment here how to interprete the operation D_Λ concerning one-way quantum computing. The proof of Theorem IV.2 is postponed to the next subsection "Verifying the correction property" since it requires some technical tools which are provided therein.

Interpretation: We describe now the implementation of the decoder as a four-step procedure of elementary operations on a one-way quantum computer.

Step 1: The input qudits I and the syndrome qudits L are individually prepared in the shift invariant state.
Step 2: One elementary step of the dynamics with respect to the graph $-\Lambda$ is performed.
Step 3: The syndrome qudits L are measured in z-basis and the output qudits J are measured in x-basis which produces a measurement result m^{JL} the "error syndrome."
Step 4: Depending on the "error syndrome" m^{JL} the phase space translation with respect to the vector $d^I_{JL}m^{JL}$ is performed which is the final "correction operation."

C. Verifying the correction property

We can verify that the pair (E_Λ, D_Λ) is an e-error correcting code by making use of the following useful lemmas, where we choose, for the subsequent, a fixed e-error correcting graph $\Lambda \in \mathcal{G}_e(I,J,L)$ with inputs I, outputs J, and syndrome vertices L.

Lemma IV.1: For each $(p^I,q^I) \in \Xi^I$, for each $(p^J,q^J) \in \Xi^J$, and for each $q^L \in \mathbb{F}^L$ the following identities hold:

$$\mathbf{v}_{[\Lambda,q^L]}\mathbf{x}(q^I) = \mathbf{z}(\Lambda^J_I q^I)\mathbf{v}_{[\Lambda,q^L]}, \tag{22}$$

$$\mathbf{w}(p^J,q^J)\mathbf{v}_{[\Lambda,0^L]} = \tau(q^J)\mathbf{z}(p^J - \Lambda^J_J q^J)\mathbf{v}_{[\Lambda,0^L]}\mathbf{z}(-\Lambda^I_J q^J), \tag{23}$$

$$\mathbf{v}_{[\Lambda,q^L]} = \mathbf{z}(\Lambda^J_L q^L)\mathbf{v}_{[\Lambda,0^L]}. \tag{24}$$

Proof of (22): We observe for a vector $\psi \in \mathcal{L}_2(\mathbb{F}^I), (p^I,q^I)$ and q^L that the identity,

$$[\mathbf{v}_{[\Lambda,q^L]}\mathbf{x}(q^I)\psi](b^J) = \sqrt{d}^{|I|-|J|}\sum_{b^I}\tau(b^{IJ}+q^{IL})\psi(b^I), \tag{25}$$

is valid for all b^J. Now, we make use of the fact that the relation $\tau(b^{IJ}+q^{IJ}) = \tau(b^{IJ}+q^L)\chi(\Lambda^J_I q^I, b^J)$ holds where we have used the assumption that $\Lambda^{IL}_{IL}=0$. This implies that the identity (22) is true.

Proof of (23): For a vector $\psi \in \mathcal{L}_2(\mathbb{F}^I)$ and for each p^J,q^J we apply the operator $\mathbf{w}(p^J,q^J)\mathbf{v}_{[\Lambda,0^L]}$ to $\psi \in \mathcal{L}_2(\mathbb{F}^I)$. We find for all $b^J \in \mathbb{F}^J$:

$$[\mathbf{w}(p^J,q^J)\mathbf{v}_{[\Lambda,0^L]}\psi](b^J) = \sqrt{d}^{|I|-|J|}\chi(p^J,b^J)\sum_{b^I}\tau(b^{IJ}-q^J)\psi(b^I). \tag{26}$$

We compute the term $\chi(p^J,b^J)\tau(b^{IJ}-q^J)$ as a product of four phases:

$$\chi(p^J,b^J)\tau(b^{IJ}-q^J) = \tau(q^J)\tau(b^{IJ})\chi(p^J-\Lambda^J_J q^J,b^J)\chi(-\Lambda^I_J q^J,b^I). \tag{27}$$

By means of this decomposition, the vector $\mathbf{w}(p^J,q^J)\mathbf{v}_{[\Lambda,0^L]}\psi$ can be obtained by the following sequence of operations: First we apply the multiplier operator $\psi \mapsto \psi_1 := \mathbf{z}(-\Lambda^I_J q^J)\psi$ which corresponds to multiplying the phases $\chi(-\Lambda^I_J q^J, b^I)$ for all b^I. Then we apply the isometry $\psi_1 \mapsto \psi_2 := \mathbf{v}_{[\Lambda,0^L]}\psi_1$ which corresponds to multiplying the phases $\tau(b^{IJ})$ and summation over the

b^I-variables. In the next step, the multiplier $\psi_2 \mapsto \psi_3 := \mathbf{z}(p^J - \Lambda_J^J q^J)\psi_2$ is performed due to multiplication by the phases $\chi(b^J, p^J - \Lambda_J^J q^J)$. Finally, the constant phase $\tau(q^J)$ remains and we obtain the relation $\mathbf{w}(p^J, q^J)\mathbf{v}_{[\Lambda,0^L]}\psi = \tau(q^J)\psi_3$. More explicitly, the identity

$$\mathbf{w}(p^J, q^J)\mathbf{v}_{[\Lambda,0^L]}\psi = \tau(q^J)\mathbf{z}(p^J - \Lambda_J^J q^J)\mathbf{v}_{[\Lambda,0^L]}\mathbf{z}(-\Lambda_J^I q^J)\psi, \tag{28}$$

is true which proves (23).

Proof of (24): The third identity just follows directly from the definition of the isometries $\mathbf{v}_{[\Lambda,q^L]}$. □

We prove in the Appendix that the channel D_Λ has a representation by Kraus operators $S_{q^L}, q^L \in \mathbb{F}^L$, which are labeled by syndrome configurations. By making use of Lemma A.3, we can formulate the following statement.

Lemma IV.2: If $E \subset J$ is a set that contains at most e elements. For each (p^E, q^E) there exists a $q^L \in \mathbb{F}^L$ such that the identity

$$\tau(q^E)^{-1}\mathbf{w}(p^E, q^E)\mathbf{v}_{[\Lambda,0^L]} = \mathbf{v}_{[\Lambda,q^L]}\mathbf{w}(-f_L^I q^L)^* = S_{q^L}, \tag{29}$$

holds where $f_L^I q^L = (p^I, q^I)$ is the unique solution of the system of equations $p^I = \Lambda_E^I q^E$ and $p^E = \Lambda_{IEL}^J q^{IEL}$.

Proof: We make use of Lemma IV.1 in order to prove (29). Combining the identities (22)–(24) we conclude that

$$\tau(q^E)^{-1}\mathbf{w}(p^E, q^E)\mathbf{v}_{[\Lambda,0^L]} = \mathbf{z}(p^E - \Lambda_{EIL}^J q^{IEL})\mathbf{v}_{[\Lambda,q^L]}\mathbf{w}(\Lambda_E^I q^E, -q^I)^*, \tag{30}$$

is valid for each $(p^E, q^E) \in \Xi^J$, for each $q^I \in \mathbb{F}^I$, and for each $q^L \in \mathbb{F}^L$. This can be verified as follows: First we conclude from (23) that the left hand side of (29) is equal to $\mathbf{z}(p^E - \Lambda_E^J q^E)\mathbf{v}_{[\Lambda,0^L]}\mathbf{z}(-\Lambda_E^I q^E)$. Then we apply (22) for some $q^I \in \mathbb{F}^I$ which implies that the left hand side of (29) coincides with $\mathbf{z}(p^E - \Lambda_{EI}^J q^{IE})\mathbf{v}_{[\Lambda,0^L]}\mathbf{x}(q^I)\mathbf{z}(-\Lambda_E^I q^E)$. According to (24), we derive for $q^L \in \mathbb{F}^L$ that (30) is indeed true.

We observe that for each (p^E, q^E) there exist a q^L such that that the range of $\mathbf{w}(p^E, q^E)\mathbf{v}_{[\Lambda,0^L]}$ coincides with the range of $\mathbf{v}_{[\Lambda,q^L]}$. In fact, we have shown in Ref. 11 that the ranges of isometries $(\mathbf{v}_{[\Lambda,q^L]})_{q^L \in \mathbb{F}^L}$ are the multiplicity spaces of characters of the Abelian algebra, the *stabilizer algebra*, that is generated by the Weyl operators $\mathbf{w}(\Lambda_J^J b^J, b^J)$ with $\Lambda_J^I b^J = 0^I$. This corresponds to the eigenvalue equation $\mathbf{w}(\Lambda_J^J b^J, b^J)\mathbf{v}_{[\Lambda,q^L]} = \tau(b^J - q^L)\mathbf{v}_{[\Lambda,q^L]}$ which can also be verfied by combining (23) and (24) in a suitable way. Since the Weyl operators $\mathbf{w}(p^E, q^E)$ and $\mathbf{w}(\Lambda_J^J b^J, b^J)$ commute up to a phase, the range of the operator $\mathbf{w}(p^E, q^E)\mathbf{v}_{[\Lambda,0^L]}$ is a multiplicity space of some character and therefore coincides with the range of $\mathbf{v}_{[\Lambda,q^L]}$ for some q^L, which can be computed in terms of (p^E, q^E) form (23) and (24) and the assumption **G-1** that Λ_{IL}^J is invertible with an inverse $\overline{\Lambda_J^{IL}}$. Namely q^L fulfills the identity $q^L = \overline{\Lambda_J^L}(p^E - \Lambda_E^J q^E)$. We choose $p^I := \Lambda_E^I q^E$ and $q^I := \overline{\Lambda_J^I}(p^E - \Lambda_E^J q^E)$ which implies that the system of equations $p^I = \Lambda_E^I q^E$ and $p^E = \Lambda_{IEL}^J q^{IEL}$ has a solution (p^I, q^I).

We have assumed that the set E contains at most e elements which implies, by Theorem IV.1, that $f_L^I q^L = (p^I, q^I)$ is the *unique* solution of the system of equations, which is completely determined by q^L. Thus the identity (30) becomes

$$\tau(q^E)^{-1}\mathbf{w}(p^E, q^E)\mathbf{v}_{[\Lambda,0^L]} = \mathbf{v}_{[\Lambda,q^L]}\mathbf{w}(-f_L^I q^L)^* = S_{q^L}, \tag{31}$$

which concludes the proof. □

Proof of Theorem IV.2: With help of Lemma IV.2 we can prove that the encoder E_Λ and the decoder D_Λ are indeed an e-error correcting code. The Kraus operators of a channel $T: \mathfrak{A}(J) \to \mathfrak{A}(J)$ that are localized in a set $E \subset J$ with at most e elements are spanned by Weyl operators $\mathbf{w}(p^E, q^E)$. In order to verify the identity $E_\Lambda \circ T \circ D_\Lambda = \mathrm{id}$ it is sufficient to show that the operators $S_{q^L}^* \mathbf{w}(p^E, q^E)\mathbf{v}_{[\Lambda,0^L]}, (p^E, q^E) \in \Xi^E, q^L \in \mathbb{F}^L$, are multiples of the identiy. By Lemma IV.2 for each (p^E, q^E) there exists a $b^L \in \mathbb{F}^L$ such that

$$S^*_{q^L}\mathbf{w}(p^E,q^E)\mathbf{v}_{[\Lambda,0^L]} \cong S^*_{q^L}S_{b^L} = \delta(q^L - b^L)\mathbf{1}, \tag{32}$$

where we have used the fact that $(S_{q^L})_{q^L\in\mathbb{F}^L}$ is a complete family of mutually orthogonal isometries. □

Interpretation of the correction procedure: We conclude by making a few remarks on the decoding procedure. The system of equation $p^I = \Lambda^I_E q^E$ and $p^E = \Lambda^J_{IEL} q^{IEL}$ has a unique solution (p^I, q^I), provided the components of the vector (p^E, q^E) has nonvanishing components for a subset E with at most e elements. This fact (Theorem IV.1) is essential for a successful decoding procedure since it identifies the effect of an error operator $\mathbf{w}(p^E, q^E)$ uniquely with an error syndrome q^L. The phase space translation by $f^I_L q^L$ is then the corresponding correction operation which eliminates the effect of the error.

However, if we relax the condition that the error occurs at a set E of at most e qudits, then the decoding operation can fail. For a general error operator $\mathbf{w}(a^J, b^J)$ the identity

$$\tau(b^J)^{-1}\mathbf{w}(a^J,b^J)\mathbf{v}_{[\Lambda,0^L]} = \mathbf{v}_{[\Lambda,q^L]}\mathbf{w}(-a^I,-b^I)^* \tag{33}$$

holds where the error syndrome is related to the error by $q^L = \overline{\Lambda^L_J}(a^J - \Lambda^J_J b^J)$. The protected subspace is affected by the effective error (a^I, b^I) which is given by $a^I := \Lambda^I_E q^E$ and $b^I := \overline{\Lambda^I_J}(a^J - \Lambda^J_J b^J)$. The solution $f^I_L q^L$, which corresponds to some other error (p^E, q^E) on $e = |E|$ qudits, may be different from $(a^I, b^I) \neq f^I_L q^L$. Thus the error (a^J, b^J) causes a nontrivial effective error $\mathbf{w}(-f^I_L q^L)\mathbf{w}(-a^I, -b^I)^*$ on the protected subspace which cannot be corrected by the decoding operation. Namely we have

$$S^*_{q^L}\mathbf{w}(a^J,b^J)\mathbf{v}_{[\Lambda,0^L]} = \tau(b^J)\mathbf{w}(-f^I_L q^L)\mathbf{w}(-a^I,-b^I)^* \neq \mathbf{1}, \tag{34}$$

and the correction procedure fails.

ACKNOWLEDGMENTS

I am very grateful to Hans Briegel and Robert Raussendorf for supporting this investigation with many ideas. I would also like to acknowledge Reinhard Werner for his support and interesting and helpful discussions. This research project is funded by the "Deutsche Forschungsgemeinschaft" which is also gratefully acknowledged.

APPENDIX: KRAUS REPRESENTATIONS FOR THE ENCODER AND THE DECODER

The encoding and decoding operations are channels of the type given by Definition IV.1. We give here a Kraus representation for a general channel of this kind.[15]

Lemma A.1: Let Λ be the adjacency matrix of a graph with input vertices I, output vertices J, and measuring vertices K. Let $U_{IK} \in \mathfrak{A}(IK)$ be a local unitary opertor and let f^I_{KL} be a function form $\mathbb{F}^{IK}$ to Ξ^J. The channel $\mathbf{T}_{[\Lambda,U_{IK},f^J_{IK}]}$ can be represented by d^{IK} Kraus operators,

$$\mathbf{T}_{[\Lambda,U_{IK},f^J_{IK}]}(A) = \sum_{p^{IK}} T^*_{p^{IK}} A T_{p^{IK}}, \tag{A1}$$

where for each $p^{IK} \in \mathbb{F}^{IK}$ the corresponding Kraus operator is given by

$$T_{p^{IK}} = \mathbf{w}(f^J_{IK}p^{IK})\Phi^*_{IK}\mathbf{z}(-p^{IK})U^*_{IK}u(\Lambda)\Phi_{JK}. \tag{A2}$$

Proof: The preparation channel $\mathbf{E}_{1_{JK}}$ is pure and implemented by the isometry Φ_{JK}. The dynamics $\boldsymbol{\alpha}_\Lambda$ is implemented by the unitary operator $u(\Lambda)$. The Kraus operators for the local measurement operation $\mathbf{M}_{U_{IK}}$ are given by the co-isometries $\Phi^*_{IK}\mathbf{z}(-p^{IK})U^*_{IK}$; each of them corresponds to the measurement outcome $p^{IK} \in \mathbb{F}^{IK}$. Finally, the Kraus operators for the conditional phase space translation are the Weyl operators $\mathbf{w}(f^J_{IK}p^{IK}), p^{IK} \in \mathbb{F}^{IK}$. Thus a Kraus representation for the channel $\mathbf{T}_{[\Lambda,U_{IK},f^J_{IK}]}$ is indeed given by the operators

$$T_{p^{IK}} = \mathbf{w}(f^J_{IK} p^{IK})^* \Phi^*_{IK} \mathbf{z}(-p^{IK}) U^*_{IK} u(\Lambda) \Phi_{JK}, \tag{A3}$$

with $p^{IK} \in \mathbb{F}^{IK}$. □

In Ref. 11 it is shown how to associate to an e-error correcting graph $\Lambda \in \mathcal{G}_e(I,J,L)$ (Definition IV.2) a complete family of mutually orthogonal isometries $(\mathbf{v}_{[\Lambda,q^L]})_{q^L \in \mathbb{F}^L}$. Each of the isometries map the input Hilbert space $\mathcal{L}_2(\mathbb{F}^I)$ into the output Hilbert space $\mathcal{L}_2(\mathbb{F}^J)$. For $q^L \in \mathbb{F}^L$, the corresponding isometry is given by

$$(\mathbf{v}_{[\Lambda,q^L]}\psi)(q^J) = \frac{1}{\sqrt{d}^{|J|}} \sum_{q^I} \tau(q^{IJL}) \psi(q^I), \tag{A4}$$

with $\psi \in \mathcal{L}_2(\mathbb{F}^I)$ and $q^J \in \mathbb{F}^J$. The range of $\mathbf{v}_{[\Lambda,q^L]}$ is the protected subspace of a graph code.[9] To point out the relation to the Kraus representation of Lemma A.1 we claim that the the isometry $\mathbf{v}_{[\Lambda,q^L]}$ can also be represented by

$$\mathbf{v}_{[\Lambda,q^L]} = \sqrt{d}^{|I|} \Phi^*_{IL} u(\Lambda) \mathbf{x}(q^L) F_L \Phi_{JL}. \tag{A5}$$

In Ref. 11 we have shown that the following is true.

Lemma A.2: The encoding operation $E_\Lambda = \mathbf{T}_{[\Lambda^{IJ}_{IJ}, 1_I, e^J_I]} : \mathfrak{A}(J) \to \mathfrak{A}(I)$ *is pure and for all* $A \in \mathfrak{A}(J)$ *the identity,*

$$E_\Lambda(A) = \mathbf{v}^*_{[\Lambda,0^L]} A \mathbf{v}_{[\Lambda,0^L]}, \tag{A6}$$

is valid.

By making use of Lemma A.1, we also obtain a useful Kraus representation for the decoding channel in terms of the isometries $\mathbf{v}_{[\Lambda,q^L]}, q^L \in \mathbb{F}^L$. For this purpose, we introduce the function function $f^I_L : \mathbb{F}^L \to \Xi^I$ by $f^I_L q^L = 0^I$ if the equation (15) has no solution for q^L. Otherwise, we put

$$f^I_L q^L = (p^I, q^I), \tag{A7}$$

where the phase space vector (p^I, q^I) is the *unique* solution (Theorem IV.1) of the equation (15), that is, $p^I = \Lambda^I_E q^E$ and $p^E = \Lambda^J_{IEL} q^{IEL}$ holds for some vector (p^E, q^E) which has nonvanishing components in for a set $E \subset J$ which contains at most e elements.

Lemma A.3: The decoding channel $D_\Lambda : \mathfrak{A}(I) \to \mathfrak{A}(J)$ *has a Kraus representation,*

$$D_\Lambda(B) = \sum_{q^L} S_{q^L} B S^*_{q^L}, \tag{A8}$$

where for $q^L \in \mathbb{F}^L$ *the Kraus operator* S_{q^L} *is given by*

$$S_{q^L} = \mathbf{v}_{[\Lambda,q^L]} \mathbf{w}(-f^I_L q^L)^*. \tag{A9}$$

In particular, the operators $(S_{q^L})_{q^L \in \mathbb{F}^L}$ *form a complete family of mutually orthogonal isometries and* D_Λ *is* an **-algebra homomorphism.*

Proof: By Lemma A.1 we conclude that D_Λ has a representation by the Kraus operators,

$$\widetilde{S}_{m^{JL}} := \Phi^*_{IL} u(\Lambda) F_L \mathbf{z}(m^{JL}) \Phi_{JL} \mathbf{w}(d^I_{JL} m^{JL}), \tag{A10}$$

with $m^{JL} \in \mathbb{F}^{JL}$. By the definition of the function d^I_{JL}, the identity $d^I_{JL} m^{JL} = (p^I, q^I - \overline{\Lambda^I_J} m^J)$ holds for $(p^I, q^I) = f^I_L q^L$ and for $m^L = q^L - \overline{\Lambda^L_J} m^J$. Inserting this into (A10) yields

$$\widetilde{S}_{m^{JL}} = \Phi^*_{IL} u(\Lambda) \mathbf{z}(m^J) \mathbf{x}(-q^L + \overline{\Lambda^L_J} m^J) F_L \Phi_{JL} \mathbf{w}(p^I, q^I - \overline{\Lambda^I_J} m^J), \tag{A11}$$

where we have used the relation $F_L \mathbf{z}(q^L) = \mathbf{x}(q_L) F_L$. Since $\mathbf{x}(\overline{\Lambda^I_J} m^J)$ is localized in I and commutes with $F_L \Phi_{JL}$. This yields

$$\tilde{S}_{m^{JL}} \cong \Phi^*_{IL}\mathbf{z}(m^J)u(\Lambda)\mathbf{x}(q^L - \overline{\Lambda}^{IL}_J m^J)F_L\Phi_{JL}\mathbf{w}(p^I,q^I)^*, \tag{A12}$$

where we write $S \cong S'$ if $S = e^{i\theta}S'$ holds for some phase $e^{i\theta}$. In the next step we use the commutation relation $u(\Lambda)\mathbf{x}(a^{IL}) = \mathbf{w}(\Lambda^J_{IL}a^{IL}, a^{IL})u(\Lambda)$ and the fact that Φ^*_{IL} has the invariance property $\Phi^*_{IL}\mathbf{x}(a^{IL}) = \Phi^*_{IL}$. This implies

$$\tilde{S}_{m^{JL}} \cong \Phi^*_{IL}u(\Lambda)F_L\mathbf{z}(q^L)\Phi_{JL}\mathbf{w}(-p^I,-q^I)^* = \frac{1}{\sqrt{d}^{|J|}}S_{q^L}, \tag{A13}$$

where we have used the identity (A5) for the isometry $\mathbf{v}_{[\Lambda,q^L]}$. Thus D_Λ has a representation by the Kraus operators $(S_{q^L})_{q^L\in\mathbb{F}^L}$. We have shown in Ref. 11 that $(\mathbf{v}_{[\Lambda,q^L]})_{q^L\in\mathbb{F}^L}$ is a family of mutually orthogonal isometries and thus the same holds for Kraus operators $(S_{q^L})_{q^L\in\mathbb{F}^L}$ too. That is, $S^*_{q^L}S_{a^L} = \delta(q^L - a^L)\mathbf{1}$ and $\Sigma_{q^L}S_{q^L}S^*_{q^L} = \mathbf{1}$ holds and D_Λ is a homomorphism. □

Non-null Lie quadratics in E^3

Lyle Noakes[a)]
School of Mathematics and Statistics, The University of Western Australia, Nedlands WA 6009, Australia

(Received 23 October 2003; accepted 27 July 2004; published 25 October 2004)

Interpolation problems in the space SO(3) of rotations of Euclidean 3-space E^3 are reviewed in Secs. I and II as background and motivation to a study of curves in E^3 called Lie quadratics. Except for a special class called null, Lie quadratics have resisted analysis until now. The rest of the present paper is devoted to new results showing non-null Lie quadratics have rich analytical, geometrical, and asymptotic structures: rates of growth are studied using differential equations and inequalities, Lie quadratics are proved to be extendible over the whole of $\mathbb{R}$, and existence of axes is proved under fairly general conditions. Examples show sharpness of many results. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1803609]

I. INTRODUCTION

Interpolating in the group SO(3) of rotations of Euclidean 3-space E^3, and in Riemannian manifolds generally, is a more significant task, in terms of applications and mathematics, than might at first be suspected. To place the new mathematical results of the present paper in context, we first say something about applications and previous mathematical work. Interpolation in SO(3) is very different to the standard problem of interpolation in E^3.

Example 1: *A rigid body K, perhaps a camera, is free to rotate about the origin* **0** *in Euclidean 3-space* E^3. *Configurations* x_i, *and possibly angular velocities* v_i, *are specified at times* $i=0, T$. *The problem is to move K accordingly. At time t the configuration* $x(t)$ *is given by a positively oriented orthonormal frame* $(x_1(t), x_2(t), x_3(t))$ *fixed relative to K. Equivalently,* $x(t)$ *is the rotation matrix*

$$\begin{bmatrix} x_1(t) & x_2(t) & x_3(t) \end{bmatrix} \in \mathrm{SO}(3),$$

and so we have an interpolation problem for a curve $x:[0,T]\to \mathrm{SO}(3)$. *In the simplest case, where angular velocities are not specified at endpoints, the interpolation conditions are*

$$x(0)=x_0, \quad x(T)=x_T. \tag{1}$$

If our elementary problem was posed in E^3, *instead of SO(3), the affine line segment from* x_0 *to* x_T *would probably be chosen as interpolant. However, although SO(3) is contained in the Euclidean space* $M_{3\times 3}\cong E^9$ *of real* 3×3 *matrices, an affine line in* E^9 *intersects SO(3) in at most two points. So line segments are not available for interpolation in SO(3). However SO(3) is covered by open subsets U diffeomorphic to open subsets of* E^3. *Such covers must contain several open sets, because U cannot be the whole of SO*(3). *For instance, rotations may be mapped to Euler angles* $(\psi,\theta,\phi)\in[0,2\pi)\times[0,\pi)\times[0,2\pi)\subset E^3$. *Chart-based interpolation proceeds by mapping* x_0, x_T *to points in* E^3, *interpolating in* E^3 *then mapping the interpolant back into SO(3). This prescription is less straightforward than it sounds. For instance, if the Euler angle of* x_i *are* $(\psi_i,\theta_i,\phi_i)=\Phi(x_i)$ *for* $i=0, T$, *small perturbations in* x_i *can give large changes in* ψ_i, ϕ_i *when* $\theta_i\approx 0$. *Also, whether the* θ_i *are small or not, the chart-based interpolant x may be a very unnatural choice. For example, taking*

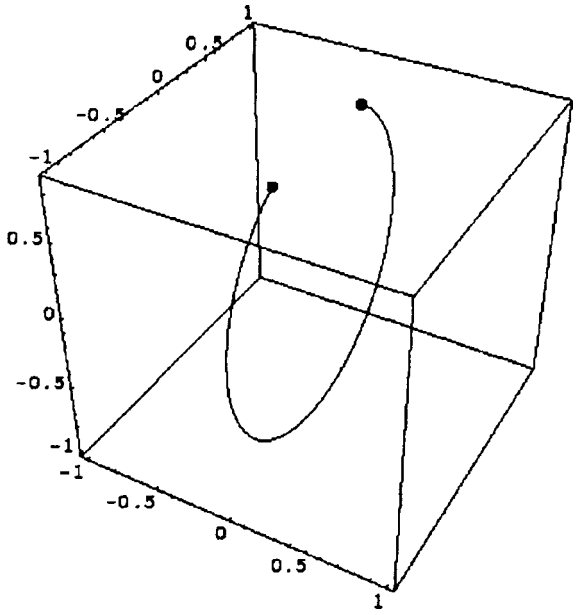

FIG. 1. Lens directions with chart-based linear interpolation.

$$x_{jT} = \begin{bmatrix} 1 & 0 & 0 \\ 0 & \sqrt{3}/2 & (-1)^j/2 \\ 0 & (-1)^{j+1}/2 & \sqrt{3}/2 \end{bmatrix},$$

where $j=0, 1$, *the curve of directions of the camera lens takes the long way around (Fig. 1).*

Although these difficulties can be ameliorated by switching between charts, this complicates implementation and has unwelcome side effects: the interpolant from x_T *to* x_0 *may be different to that from* x_0 *to* x_T. □

The geometrical difficulties in Example 1 suggest using a more geometrical interpolation scheme, like the following simple method from Riemannian geometry. A *Riemannian metric* on a C^∞ manifold M such as SO(3) is a smooth assignment of inner products to the tangent spaces at each point in M. The *length* $L(x)$ and *energy* $J_1(x)$ *of a smooth curve* $x:[0,T]\to \mathrm{SO}(3)$ are then defined as

$$L(x) = \int_0^T \|x^{(1)}(t)\| \mathrm{d}t \quad \text{and } J_1(x) = \int_0^T \|x^{(1)}(t)\|^2 \, \mathrm{d}t,$$

where the norm $\|\,\|$ is calculated using the Riemannian metric, and superscript (n) means n-fold derivative. Curves satisfying (1) of minimum length and uniform speed are called *minimal geodesics*. They also minimize energy. Geodesics on SO(3) can sometimes be written down in closed form, notably when the metric is *bi-invariant*. In this case rotations are represented by unit quaternions, namely points in the three-dimensional unit sphere $S^3 \subset E^4$, with geodesics represented by arcs of great circles. Interpolation by geodesics effectively deals with the problems raised in Example 1, but is inadequate for most applications.

In Example 1 only two camera configurations x_0, $x_T \in \mathrm{SO}(3)$ are prescribed, whereas in practice x may need to satisfy many such constraints. Piecewise geodesics are inappropriate because, like piecewise-linear curves in E^3, they are usually nondifferentiable at junctions. A simple way to ensure this does not occur is to prescribe derivatives of x at junctions, replacing (1) by

$$x(0)=x_0,\ \ x^{(1)}(0)=v_0,\ \ x(T)=x_T,\ \ x^{(1)}(T)=v_T. \tag{2}$$

If the problem was posed in E^3 a cubic polynomial could satisfy (2), but SO(3) has no nonconstant polynomial curves, and chart-based cubic polynomials are problematic in the same ways as chart-based line segments. On the other hand, geodesics in SO(3) are readily calculable, at least for a bi-invariant metric, and correspond to lines in E^3. This reminds us of the classical *deCastlejau algorithm* for generating polynomial curves in E^3 from line segments.

Replacing line segments by geodesic arcs in the cubic deCastlejau algorithm gives curves in SO(3) capable of satisfying (2), as in Refs. 29 and 12. This elegant and effective method is frequently applied, and has been investigated further in Ref. 11. A recursive form of the deCastlejau algorithm also adapts to Hermite interpolation in SO(3).[19–23] Unlike the Euclidean versions, the adapted nonrecursive and recursive deCastlejau schemes generate different curves in SO(3). Yet another kind of curve results when we insist on an analogue of the important *variation diminishing property*, that cubics in E^3 minimize

$$\int_0^T \|x^{(2)}(t)\|^2\,\mathrm{d}t$$

among curves $x:[0,T]\to E^3$ satisfying (2).

II. RIEMANNIAN CUBICS AND LIE QUADRATICS

A Riemannian manifold comes equipped with a *Levi–Cività covariant derivative* ∇, which is a procedure for differentiating vector fields, whose associated *parallel translation* respects the Riemannian metric. *Riemannian cubics* are critical points of the functional J_2 given by

$$J_2(x)=\int_0^T \|\nabla_{d/\mathrm{d}t}\,x^{(1)}\|^2\,\mathrm{d}t, \tag{3}$$

where $x:[0,T]\to M$ satisfies (2). As shown in Refs. 13 and 26, the Euler–Lagrange equation of J_2 is

$$\nabla^3_{d/\mathrm{d}t}\,x^{(1)}+R(\nabla_{d/\mathrm{d}t}\,x^{(1)},x^{(1)})x^{(1)}=\mathbf{0}, \tag{4}$$

where R is the *Riemannian curvature* of ∇. Let M be SO(3) with a bi-invariant Riemannian metric. Then, as it stands, (4) amounts to 36 nonlinear first order ODEs for 36 scalar functions, with 24 equality constraints, and 36 scalar boundary conditions. The first step in solving this system is the reduction in Ref. 26 of (4) to a second order system of ODEs for $V:[0,T]\to E^3$,

$$V^{(2)}(t)=V^{(1)}(t)\times V(t)+C\ \text{ where } C\in E^3, \tag{5}$$

together with the first order equation

$$x^{(1)}(t)=x(t)B(V(t)), \tag{6}$$

where $B:E^3\to so(3)$ is the linear isomorphism from E^3 onto the space of skew-symmetric 3×3 real matrices given by $B(v)(w)=v\times w$, and $\times$ denotes the vector product in E^3. In Sec. IV of the present paper Eqs. (5) and (6) are shown to be solvable over the whole real line. In Ref. 25, Eq. (6) is solved using at most one quadrature. For any interval $S\subseteq\mathbb{R}$, a curve $V:S\to E^3$ satisfying (5) is called a *Lie quadratic* in E^3. Defining $F:S\to[0,\infty)$ by $F(t)=\|V(t)\|^2$, it follows easily from (5) that

$$F^{(2)}(t)=6\langle C,V(t)\rangle+2b, \tag{7}$$

$$\|V^{(1)}(t)\|^2=2\langle C,V(t)\rangle+b, \tag{8}$$

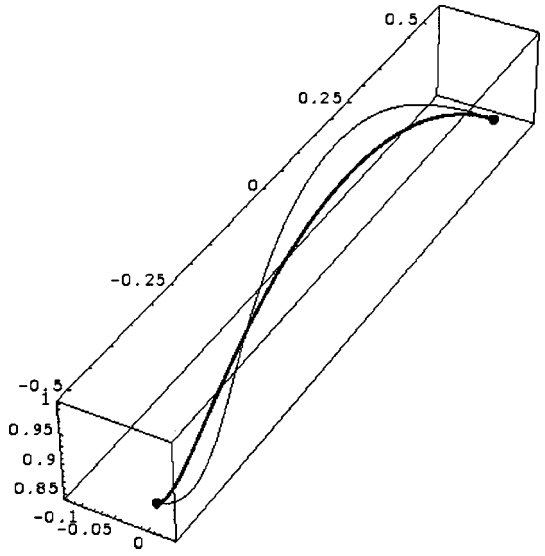

FIG. 2. Lens directions for the Riemannian cubic.

$$\|V^{(2)}(t)\|^2 = c, \tag{9}$$

where b, $c \in \mathbb{R}$ are constant. Set $d = 3(\|C\|^2 + c)$ and $\delta_\pm = 3(\|C\| \pm \sqrt{c})^2$.

Example 2: *Taking* v_0, v_T *as*

$$\begin{bmatrix} 0.0000 & 0.9280 & -0.3725 \\ -0.6175 & -0.1225 & 0.2121 \\ 0.7866 & -0.2121 & -0.1225 \end{bmatrix}, \begin{bmatrix} 0.0000 & -0.2708 & -0.2380 \\ 0.1155 & -0.0224 & -0.0388 \\ 0.3415 & 0.0388 & -0.0224 \end{bmatrix},$$

the curve of lens directions for the Riemannian cubic shown (thick) in Fig. 2 is less wavy in appearance than the curve for the adapted nonrecursive deCastlejau algorithm of Sec. I. These curves were generated in about 7 seconds on a 2 GHz PC running Mathematica. □

There is a special class of Lie quadratics for which quite a lot is known: the Lie quadratic $V: S \to E^3$ is called *null* when its constant C is $\mathbf{0}$. In Ref. 24 null Lie quadratics in E^3 are shown to have constant (usually nonzero) curvature, linearly varying torsion, and two *axes*. The axes are rays through $\mathbf{0}$, to which V becomes C^0 close as $t \to \pm\infty$. The space of null Lie quadratics has rotational symmetry, and individual null quadratics have *internal symmetry*. A Riemannian cubic in SO(3) associated with a null Lie quadratic also has internal symmetries and is asymptotic to a pair of geodesics.

Example 3: Figure 3 shows the null Lie quadratic $V: [0, 26] \to E^3$ *with* $V(0)$, $V^{(1)}(0)$ *taken as*

$$\begin{bmatrix} 3.2734 & 0.6697 & -5.1300 \end{bmatrix}^{\mathbf{T}}, \begin{bmatrix} -0.2320 & -0.0935 & 0.3427 \end{bmatrix}^{\mathbf{T}},$$

where $\mathbf{T}$ *means transpose. The Lie quadratic starts in the lower right, spiralling outwards along an axis pointing upwards and to the left. Around* $V(14)$ *the curve spirals inwards along the other axis, which points to the left and slightly downwards.*

Figure 4 shows the curve x_1 *in* S^2 *of first columns of* $x: [0, 26] \to SO(3)$ *associated with the null Lie quadratic V.*

x_1 *spirals downwards from a closed curve in the upper left, switches, then spirals upwards towards a closed curve in the lower right (note the change in sense of spiralling). The limiting*

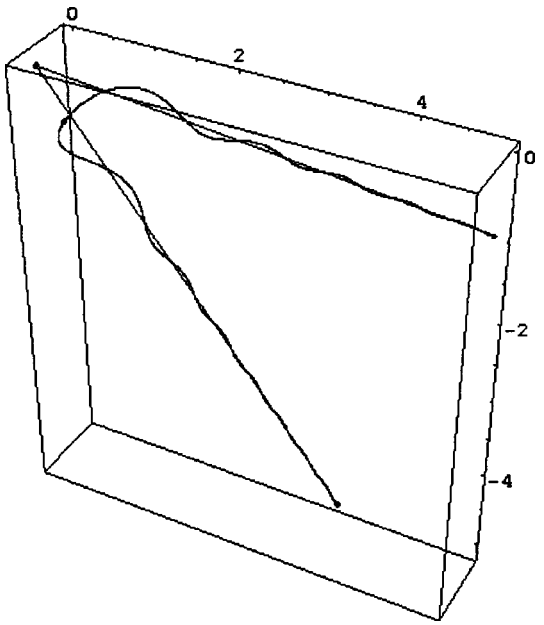

FIG. 3. Null Lie quadratic V in E^3, showing $V(0)$, $V(14.3)$, $V(26)$, and axes.

curves are projections of geodesics in SO(3), namely circles in S^2. Self-symmetry of x is not evident on casual inspection. □

In addition to references already cited, for further background on null Lie quadratics, Riemannian cubics, variational problems, reduction to Lie quadratics, generalizations, and alternatives see Refs. 6, 16, 28, 14, 15, 33–35, 10, 18, 8, 9, 30, and 2. For engineering applications see Refs. 17, 4, 27, 5, 3, 31, and 32.

For the larger class of non-null Lie quadratics V we note that if $A \in \mathrm{SO}(3)$ then $t \mapsto AV(t)$ is a non-null Lie quadratic with constant AC, if $t_0 \in \mathbb{R}$ then $t \mapsto V(t-t_0)$ is a non-null Lie quadratic with

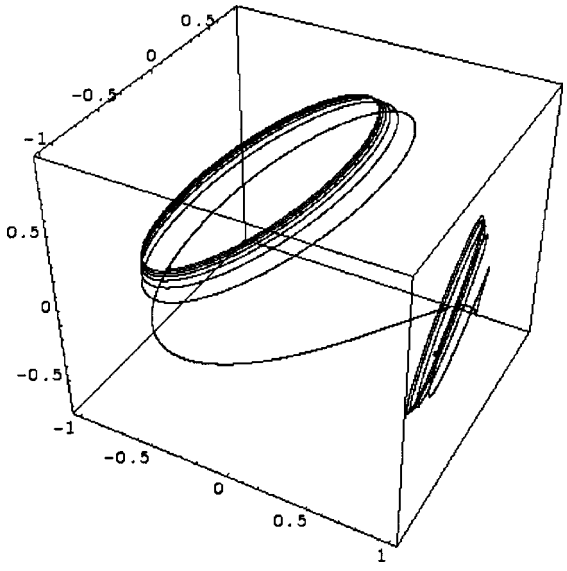

FIG. 4. $x_1:[0,26] \to S^2$, $x_1(0)$, $x_1(14.3)$, $x_1(26)$.

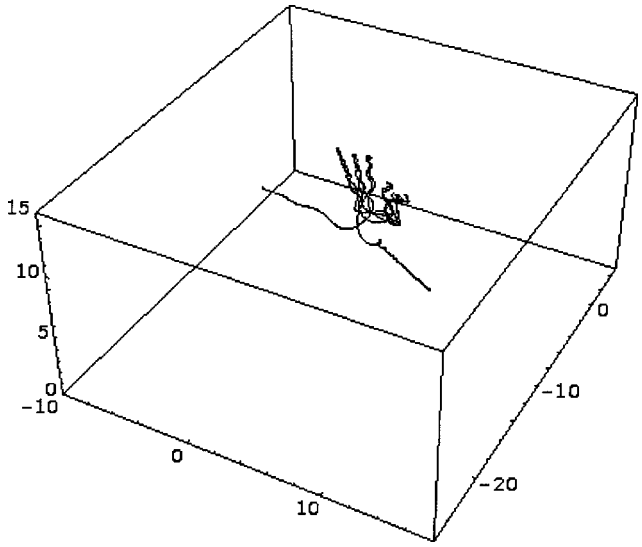

FIG. 5. $V:[-45,30]\to E^3$ computed with 16 significant figures in Example 4.

constant C, and if $0\neq a_1\in\mathbb{R}$ then $t\mapsto a_1V(a_1t)$ is a non-null Lie quadratic with constant a_1^3C. So after a rotation, change of origin, and change of scale a non-null Lie quadratic $V:\mathbb{R}\to E^3$ can be made to satisfy

$$C=\begin{bmatrix}1 & 0 & 0\end{bmatrix}^{\mathbf{T}},\quad V_1(0)=0,\quad \langle V(0),V^{(1)}(0)\rangle=0.$$

The geometry of Lie quadratics is much more complicated in the non-null case.

Example 4: Taking $V(0)=[1.0\ 2.0\ 2.0]^{\mathbf{T}}$, $V^{(1)}(0)=[-1.0\ 1.0\ 1.0]^{\mathbf{T}}$, *and* $C=-[0.4\ 0.5\ 0.75]^{\mathbf{T}}$, *we find*

$$b=8.800\,00,\quad c=20.4742,\quad d=64.34,\quad \delta_-=37.5669,\quad \delta_+=91.1131.$$

Numerical simulation with Mathematica's default 16 *significant figures working precision gives Fig. 5 for* $V:[-45,30]\to E^3$. *The curve appears to spiral backwards and forwards along rays through the origin.* □

From this point onwards the results are new, emphasizing the squared-norm function F of a Lie quadratic V. There are seven theorems, all central to the paper. These emphasize asymptotic properties of V, through a detailed analysis of F and its relationship to the constants $b,c,d,\delta_\pm$.

(i) Lie quadratics in E^3 (whether null or not) extend to Lie quadratics defined on the whole of $\mathbb{R}$ (Corollary 5), as do Riemannian cubics (Theorem 2), and can be sensitive to initial data (Example 5).
(ii) F satisfies various differential inequalities and differential equations (Theorem 1).
(iii) F satisfies a nonlinear third-order differential equation (11) from which follow further inequalities (Corollaries 1 and 2), and a second order equation (14) for $G\equiv(F^{(1)})^2$.
(iv) When $b<0$ F is strictly convex, with $F(t)$ increasing as t^4 for $t\to\pm\infty$ (Theorem 3).
(v) For $b>0$ V can be periodic (Example 6) and sometimes F is multimodal (Example 5).
(vi) For $b\geqslant 0$ V is often unbounded (Theorem 5) and then $F(t)$ increases as t^2 or t^4.
(vii) For $b\geqslant 0$ there are relationships between critical values of F (Theorem 5, Example 9).
(viii) When V is unbounded the angular part $U(t)$ of $V(t)$ converges to a limit $\alpha_\pm(V)$ as $t\to\pm\infty$ (Theorem 6) with $a_\pm\equiv\langle C,\alpha_\pm(V)\rangle\geqslant 0$ (Corollary 9).
(ix) When V is unbounded $F(t)=O(t^2)$ as $t\to\pm\infty$ if and only if $a_\pm=0$ (Theorem 7).
(x) The asymptotic directions $\alpha_\pm(V)$ may be difficult to determine (Example 11).

Properties of F, as well as being of interest in their own right, are the key to the rest of our analysis. Whereas in the null case F is a quadratic polynomial, the possibilities when V is non-null are more various and take a little longer to unfold, starting with some differential equations and inequalities.

III. DIFFERENTIAL EQUATIONS AND INEQUALITIES

Let $V:S\to E^3$ be a Lie quadratic defined on an open interval S, with constant vector C, $F:S\to[0,\infty)$, and associated constants $b,c,d,\delta_\pm$ as defined in Sec. II. A result similar to the following theorem appeared independently in Ref. 1.

Theorem 1: $F\geqslant 0$, $F^{(2)}+b=3\|V^{(1)}\|^2\geqslant 0$,

$$\delta_-\leqslant (F^{(2)}+b)F-\tfrac{3}{4}(F^{(1)})^2=d-F^{(4)}\leqslant\delta_+, \tag{10}$$

and

$$\begin{aligned}48F(F^{(3)})^2-48F^{(1)}(F^{(2)}-2b)F^{(3)}+64b^3+48d^2-96bdF+48b^2F^2+72d(F^{(1)})^2-72bF(F^{(1)})^2\\ +27(F^{(1)})^4-96dFF^{(2)}+96bF^2F^{(2)}-72F(F^{(1)})^2F^{(2)}-48b(F^{(2)})^2+48F^2(F^{(2)})^2+16(F^{(2)})^3\\ -576d\|C\|^2+1728\|C\|^4=0.\end{aligned} \tag{11}$$

Proof: Eliminating $\langle C,V\rangle$ between (7) and (8), $\|V^{(1)}\|^2=\frac{1}{3}(F^{(2)}+b)$. By (9) and (5), $\|V^{(1)}\|^2F-\langle V^{(1)},V\rangle^2+2\langle C,V^{(1)}\times V\rangle+\|C\|^2=c$. Then

$$\tfrac{1}{3}(F^{(2)}+b)F-\tfrac{1}{4}(F^{(1)})^2+2\langle C,V^{(1)}\times V\rangle+\|C\|^2=c.$$

Differentiating (7) twice, and by (5), $F^{(4)}=6\langle C,V^{(1)}\times V+C\rangle$ and consequently

$$\langle C,V^{(1)}\times V\rangle=\tfrac{1}{6}F^{(4)}-\|C\|^2. \tag{12}$$

For (10), it remains to prove $\delta_-\leqslant d-F^{(4)}\leqslant\delta_+$: by (7), $|F^{(4)}|=6|\langle C,V^{(2)}\rangle|\leqslant 6\|C\|\sqrt{c}$. So

$$\delta_-=3(\|C\|-\sqrt{c})^2\leqslant d-F^{(4)}\leqslant 3(\|C\|+\sqrt{c})^2=\delta_+,$$

and this proves (10). Now $F^{(4)}=6\langle C,C\rangle+6\langle C,V^{(1)}\times V\rangle$ by (5), and then

$$\begin{aligned}\left(\frac{F^{(4)}}{6}-\|C\|^2\right)^2&=\|C\|^2(\|V^{(1)}\|^2\|V\|^2-\langle V^{(1)},V\rangle^2)-\|\langle C,V\rangle V^{(1)}-\langle C,V^{(1)}\rangle V\|^2\\ &=\|C\|^2\left(\left(\frac{F^{(2)}+b}{3}\right)F-\frac{(F^{(1)})^2}{4}\right)-\left(\frac{F^{(2)}-2b}{6}\right)^2\left(\frac{F^{(2)}+b}{3}\right)\\ &\quad-\left(\frac{F^{(3)}}{6}\right)^2F+\left(\frac{F^{(2)}-2b}{6}\right)\frac{F^{(3)}}{6}F^{(1)}.\end{aligned}$$

Eliminating $F^{(4)}$ with (10) gives (11). □

Corollary 1: $64b^3F+48d^2F-96bdF^2+48b^2F^3-48b^2(F^{(1)})^2+72dF(F^{(1)})^2-72bF^2(F^{(1)})^2+27F(F^{(1)})^4-96dF^2F^{(2)}+96bF^3F^{(2)}+48b(F^{(1)})^2F^{(2)}-72F^2(F^{(1)})^2F^{(2)}-48bF(F^{(2)})^2+48F^3(F^{(2)})^2-12(F^{(1)})^2(F^{(2)})^2+16F(F^{(2)})^3-576d\|C\|^2F+1728\|C\|^4F\leqslant 0$.

Proof: Equation (11) is quadratic in $F^{(3)}$, with discriminant -192 times the left-hand side. □

Corollary 2: At a critical point t_0 of F where $F(t_0)>0$,

$$(F^{(2)})^3-3b(F^{(2)})^2+3(d-bF-FF^{(2)})^2-108\|C\|^2c+4b^3\leqslant 0.$$

Proof: Set $F^{(1)}=0$ in Corollary 1 and divide both sides by $16F$. □

Writing $G=(F^{(1)})^2$ for $F^{(1)}\neq 0$,

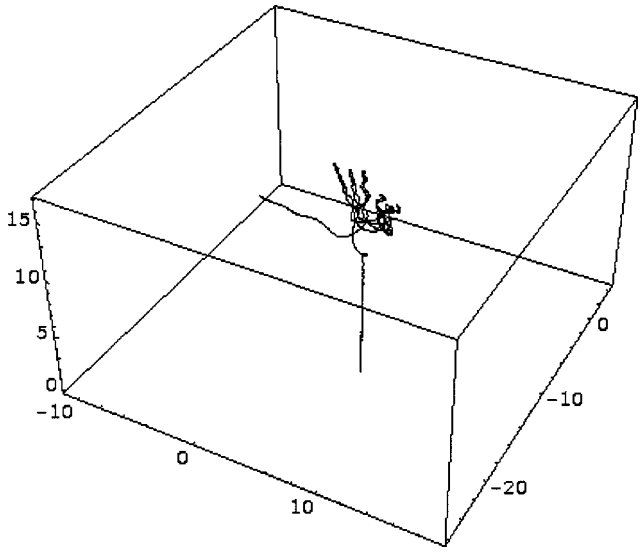

FIG. 6. $V:[-45,30]\to E^3$ computed with 25 significant figures in Example 5.

$$F^{(2)}=\frac{1}{2}\frac{\mathrm{d}G}{\mathrm{d}F},\quad F^{(3)}=\frac{\epsilon}{2}G^{1/2}\frac{\mathrm{d}^2G}{\mathrm{d}F^2},\quad F^{(4)}=\frac{1}{2}G\frac{\mathrm{d}^3G}{\mathrm{d}F^3}+\frac{1}{4}\frac{\mathrm{d}G}{\mathrm{d}F}\frac{\mathrm{d}^2G}{\mathrm{d}F^2},$$

where ϵ is the sign of $F^{(1)}$. Then, from (10) and (11), we have the following.

Corollary 3: In any open interval where $F^{(1)}\neq 0$,

$$2G^2\frac{\mathrm{d}^3G}{\mathrm{d}F^3}+\frac{\mathrm{d}G}{\mathrm{d}F}\frac{\mathrm{d}^2G}{\mathrm{d}F^2}+2F\frac{\mathrm{d}G}{\mathrm{d}F}-3G+4bF-4d=0, \tag{13}$$

and

$$12\frac{\mathrm{d}^2G}{\mathrm{d}F^2}\left(4bG-G\frac{\mathrm{d}G}{\mathrm{d}F}+FG\frac{\mathrm{d}^2G}{\mathrm{d}F^2}\right)+2\left(\frac{\mathrm{d}G}{\mathrm{d}F}\right)^3-12\frac{\mathrm{d}G}{\mathrm{d}F}\left(4F-4bF^2+b\frac{\mathrm{d}G}{\mathrm{d}F}+3FG-F^2\frac{\mathrm{d}G}{\mathrm{d}F}\right)$$
$$+9G(8d-8bF+3G)+48bF(bF-2d)+16(4b^3+3d^2-36d\|C\|^2+108\|C\|^4)=0. \tag{14}$$

□

Despite extreme sensitivity of solutions of (5) to numerical measurements, the evidence suggests these inequalities are sharp.

Example 5: In Example 4, numerical simulation with 16 significant figures working precision gives Fig. 5 for $V:[-45,30]\to E^3$. *Figure 6, using 25 significant figures (our default from now on), is noticeably different, although the two figures share some similarities in general appearance.*

In particular, both Figs. 5 and 6 suggest F is multimodal. The graph of $F|[-45,30]$ *in Fig. 7 shows more detail: eight points of local minimum and seven of local maximum. In Fig. 6, the curve starts from around the right of the front panel, spirals outwards then, after sporadic spiralling in the middle range, spirals outwards to the panel on the left.*

In Fig. 8 $d-F^{(4)}$ *is plotted together with the horizontal lines through* $\delta_\pm$. $F^{(4)}$ *appears is highly oscillatory, and the inequalities in (10) seem sharp.*

Corollary 1 is also sharp, as illustrated by the plot in Fig. 9 of the left-hand side of the inequality.

However, for a null Lie quadratic F is a quadratic polynomial.[24] □

Another basic fact is the extendibility of Riemannian cubics and Lie quadratics from intervals S to the whole of $\mathbb{R}$. The following inequality is needed for the proof in Sec. IV.

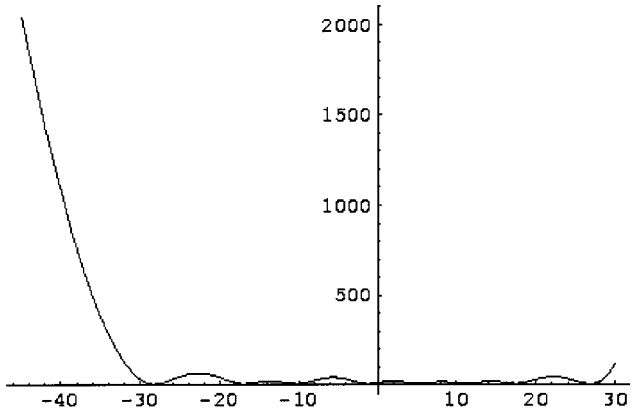

FIG. 7. F in Example 5.

Corollary 4: Given $t_0 \in S$, there are constants $\kappa_0, \kappa_2 > 0$ depending only on $V(t_0)$, $V^{(1)}(t_0)$, $V^{(2)}(t_0)$ such that, for all $t \in S$,

$$\|V(t)\|, \|V^{(1)}(t)\|^2 \leqslant \kappa_2^2 t^2 + \kappa_0^2.$$

Proof: For $t \in S$, $|F^{(4)}(t)| \leqslant 6\|C\|\sqrt{c}$. So when $t \geqslant t_0$, $|F^{(3)}(t)| \leqslant |F^{(3)}(t_0)| + 6\|C\|\sqrt{c}(t-t_0)$. Then $|F^{(2)}(t)| \leqslant k_0 + k_1(t-t_0) + k_2(t-t_0)^2$ where k_0, k_1, k_2 depend only on $V(t_0)$, $V^{(1)}(t_0)$, $V^{(2)}(t_0)$, and so on: $F(t)$ is bounded by a quartic in t, at least for $t \geqslant t_0$, and a similar argument applies for $t < t_0$. So $\|V\|$ is bounded by a quadratic. Because $F^{(2)}$ is bounded by a quadratic so is $\|V^{(1)}\|^2$. □

IV. EXTENDING RIEMANNIAN CUBICS AND LIE QUADRATICS

We prove an extendibility result for Riemannian cubics in SO(3), then use it to prove extendibility for Lie quadratics in E^3. Reference 7 also contains results on extendibility of cubics.

Lemma 1: For some $\delta > 0$, given $t_0 \in \mathbb{R}$, $x_0 \in SO(3)$, and $v_i \in TSO(3)_{x_0}$ with $\|B^{-1}(x_0^{-1}v_i)\| \leqslant 1$ for $0 \leqslant i \leqslant 2$, there is a unique Riemannian cubic $x: (t_0 - \delta, t_0 + \delta) \to SO(3)$ satisfying

$$x(t_0) = x_0, \quad x^{(1)}(t_0) = v_0, \quad \nabla_{d/dt} x^{(1)}\big|_{t_0} = v_1, \quad \text{and} \quad \nabla^2_{d/dt} x^{(1)}\big|_{t_0} = v_2. \tag{15}$$

Proof: Picard's theorem on local unique solvability of ordinary differential equations almost asserts this, but with δ depending on x_0, v_0, v_1, v_2. However SO(3) is compact. Restricting v_0, v_1, v_2 also to lie in a compact set permits a uniform choice of δ. □

Lemma 2: For δ as in Lemma 1, given $t_0 \in \mathbb{R}$, $x_0 \in SO(3)$, and $v_i \in TSO(3)_{x_0}$ for $0 \leqslant i \leqslant 2$, if

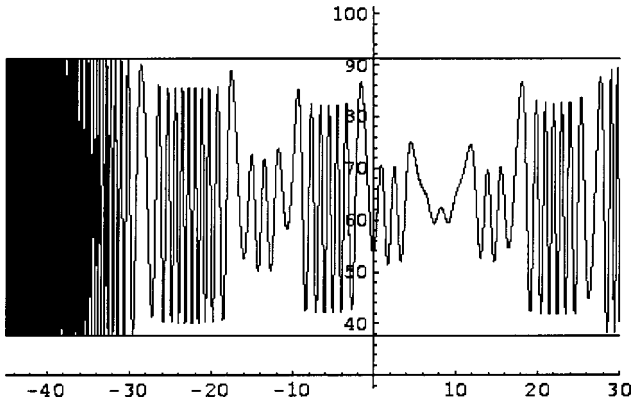

FIG. 8. $d - F^{(4)}$ and $\delta_\pm$ in Example 5.

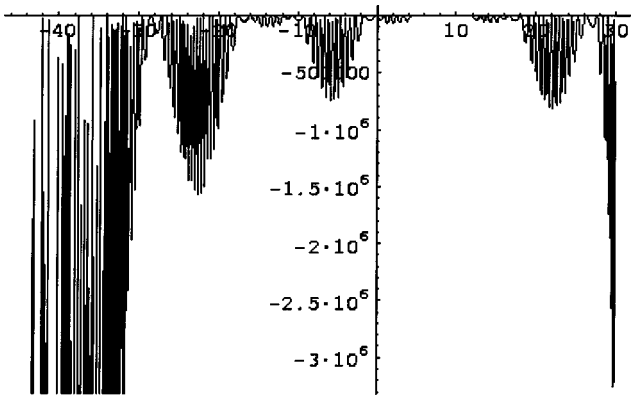

FIG. 9. Corollary 1 in Example 5.

$\lambda \geqslant 1+\max_i \|v_i\|$ *then there is a unique Riemannian cubic* $x:(t_0-\delta/\lambda, t_0+\delta/\lambda)\to SO(3)$ *satisfying (15).*

Proof: Using Lemma 1, let $\hat{x}:(t_0-\delta, t_0+\delta)\to \mathrm{SO}(3)$ be the Riemannian cubic satisfying

$$\hat{x}(t_0)=x_0,\ \ \hat{x}^{(1)}(t_0)=v_0/\lambda,\ \ \ \nabla_{d/dt}\,\hat{x}^{(1)}\big|_{t_0}=v_1/\lambda^2,\ \text{ and }\ \nabla^2_{d/dt}\,\hat{x}^{(1)}\big|_{t_0}=v_2/\lambda^3.$$

Then set $x(t)=\hat{x}(t_0+\lambda(t-t_0))$. □

Theorem 2: *Given* $t_0\in\mathbb{R}$, $x_0\in SO(3)$, *and* v_0, v_1, $v_2\in TSO(3)_{x_0}$, *there is a unique Riemannian cubic* $x:\mathbb{R}\to SO(3)$ *satisfying (15).*

Proof: By Lemma 1, for some $\tilde{\delta}>0$ there is a (Riemannian) cubic $\tilde{x}:(t_0-\tilde{\delta}, t_0+\tilde{\delta})\to \mathrm{SO}(3)$ satisfying (15). If $\tilde{x}$ is not extendible to a cubic on $(t_0-\tilde{\delta},\infty)$, let $\mathcal{T}$ be the set of real numbers T for which $\tilde{x}$ extends to a cubic on $(t_0-\tilde{\delta}, T]$. Set $\overline{T}=\sup\mathcal{T}$ and

$$\lambda=(\kappa_2^2\overline{T^2}+\kappa_0^2+1)^2+\|V^{(2)}(t_0)\|+1.$$

Choose $T\in\mathcal{T}$ with $T>\overline{T}-(\delta/2\lambda)$ and δ as in Lemma 1. By (9) and Corollary 4, the Lie quadratic V associated with a cubic extension $x:(t_0-\delta_0, T]\to \mathrm{SO}(3)$ of $\tilde{x}$ satisfies

$$\|V(t)\|\leqslant \kappa_2^2t^2+\kappa_0^2,\ \ \|V^{(1)}(t)\|\leqslant\sqrt{\kappa_2^2t^2+\kappa_0^2},\ \ \|V^{(2)}(t)\|=\|V^{(2)}(t_0)\|,\ \text{ for } t\in(t_0-\delta_0, T),$$

where κ_0, κ_2 depend only on $\tilde{x}$. By Ref. 26 Lemma 2,

$$\|B^{-1}(x(t)^{-1}x^{(1)}(t))\|=\|V(t)\|\leqslant\lambda-1,$$

$$\|B^{-1}(x(t)^{-1}\nabla_{d/dt}\,x^{(1)})\|=\|V^{(1)}(t)\|\leqslant\lambda-1,$$

$$\|B^{-1}(x(t)^{-1}\nabla^2_{d/dt}\,x^{(1)})\|=\left\|V^{(2)}(t)+\tfrac{1}{2}V(t)\times V^{(1)}(t)\right\|\leqslant\|V^{(2)}(t_0)\|+\tfrac{1}{2}(\kappa_2^2t^2+\kappa_0^2)^{3/2}\leqslant\lambda-1.$$

Applying Lemma 2, with $\hat{T}\equiv T-(\delta/4\lambda)$ in place of t_0, $x\big|[\hat{T}-(\delta/4\lambda), T]$ extends to a cubic defined on $[\hat{T}-(\delta/\lambda), \hat{T}+(3\delta/4\lambda)]$. So x, and therefore $\tilde{x}$, extends to a Riemannian cubic on $[t_0-\tilde{\delta}, \overline{T}+(\delta/4\lambda)]$, namely $\overline{T}+(\delta/4\lambda)\in\mathcal{T}$, contradicting $\overline{T}=\sup\mathcal{T}$. So $\tilde{x}$ is right extendible after all. Left extendibility is proved similarly. Uniqueness follows from Picard's local uniqueness. □

Corollary 5: Given $C\in E^3$, $t_0\in\mathbb{R}$ *and* w_0, $w_1\in E^3$, *there is a unique Lie quadratic* $V:\mathbb{R}\to E^3$ *with constant* C, *satisfying*

$$V(t_0)=w_0\ \text{ and }\ V^{(1)}(t_0)=w_1.$$

Proof: Set $w_2 = w_1 \times w_0 + C$, $x_0 = \mathbf{1}$, $v_0 = B^{-1}w_0$, $v_1 = B^{-1}w_1$, $v_2 = B^{-1}w_2$, apply Theorem 2, and let V be the Lie quadratic associated with the Riemannian cubic $x: \mathbb{R} \to \mathrm{SO}(3)$. □

So there is no loss in restricting attention to Lie quadratics in E^3 defined on the whole of $\mathbb{R}$. We may then ask about rates of growth of $V(t)$, or equivalently of $F(t)$, as $t \to \pm\infty$.

V. RATES OF GROWTH I

By Theorem 1, for a Lie quadratic, $V: \mathbb{R} \to E^3$,

$$F^{(4)} + (F^{(2)} + b)F = \tfrac{3}{4}(F^{(1)})^2 + d, \text{ where } d \geqslant 0. \tag{16}$$

When $d=0$ V is null of the form $V(t) = (t - t_0)\beta$, where $t_0 \in \mathbb{R}$ and $\beta \in E^3$. For $d > 0$, $\tilde{F}$ given by $F(t) = d^{1/3}\tilde{F}(d^{1/6}t)$ satisfies (16) with b replaced by $d^{-2/3}b$ and d by 1. So there would be no real loss of generality in taking $d=1$, but we continue with only the assumption $d > 0$. By Corollary 4, $\limsup_{t\to\pm\infty}[F(t)/t^4] < \infty$ and $\limsup_{t\to\pm\infty}[\|V^{(1)}(t)\|^2/t^2] < \infty$. Sharper results follow from Theorem 1.

Corollary 6: We have $\max\{0, -b/2\} \leqslant \liminf_{t\to\pm\infty}[F(t)/t^2]$ *and* $\limsup_{t\to\pm\infty}[F(t)/t^4] \leqslant \|C\|\sqrt{c}/4$.

Proof: Because $F^{(2)}(t) \geqslant -b$, $F^{(1)}(t) - F^{(1)}(t_0) \geqslant -b(t - t_0)$ for any $t \geqslant t_0 \in \mathbb{R}$. Integrating again,

$$F(t) \geqslant F(t_0) + (t - t_0)F^{(1)}(t_0) - \frac{b}{2}(t - t_0)^2. \tag{17}$$

For $t < t_0$, $F^{(1)}(t) - F^{(1)}(t_0) \leqslant -b(t - t_0)$, and again (17) holds on second integration. Similarly, because

$$F^{(4)}(t) \leqslant d - \delta_- = 6\|C\|\sqrt{c}, \text{ we have } \limsup_{t\to\pm\infty}\frac{F(t)}{t^4} \leqslant \frac{\|C\|\sqrt{c}}{4}.$$

□

Corollary 7: Let t_0 be a point of local minimum of F. Then $bF(t_0) \leqslant \delta_+$.

(1) If $F(t_0) = 0$ then $\delta_- = 0$.
(2) If t_0 is a degenerate critical point then $bF(t_0) \geqslant \delta_-$.

Proof: By (10), $\delta_- \leqslant (F^{(2)}(t_0) + b)F(t_0) \leqslant \delta_+$, where $F^{(2)}(t_0) \geqslant 0$. □

By Theorem 1, for $F^{(1)}F \neq 0$, we have $2\delta_- F^{-5/2} \leqslant 2bF^{-3/2} + (d/dF)(F^{-3/2}G) \leqslant 2\delta_+ F^{-5/2}$ and, integrating over $[F(t_1), F(t_2)]$ where $F^{(1)} > 0$ on $[t_1, t_2]$,

$$\frac{4\delta_-}{3}(\rho^{3/2} - 1) \leqslant 4bF(t_1)\rho(\rho^{1/2} - 1) + G(t_2) - \rho^{3/2}G(t_1) \leqslant \frac{4\delta_+}{3}(\rho^{3/2} - 1), \tag{18}$$

where $\rho \equiv F(t_2)/F(t_1) > 1$.

Theorem 3: *Suppose $b \leqslant 0$. Then F is convex. If $b < 0$ or $\delta_- > 0$ then F is strictly convex and* $\liminf_{t\to\pm\infty}[F(t)/t^4] > 0$.

Proof: By Theorem 1, $F^{(2)} + b \geqslant 0$, and F is convex because $b \leqslant 0$. Similarly, if $b < 0$ then F is strictly convex. For $b \leqslant 0$ and $\delta_- > 0$, $(F^{(2)} + b)F \geqslant \delta_- + \frac{3}{4}(F^{(1)})^2 > 0$ by (10), and again F is strictly convex.

Because F is strictly convex, it is unbounded, has a point t_0 of global minimum, and t_0 is the only critical point. Take $[t_1, t_2] \subset (t_0, \infty)$ in (18), let $t_1 \to t_0^+$, and write $t_2 = t$,

$$G(t) \geqslant 4(\rho^{1/2} - 1)\left(\left(\frac{\delta_-}{3} - bF(t_0)\right)\rho + \frac{\delta_-}{3}\rho^{1/2} + \frac{\delta_-}{3}\right).$$

Given $0 < \epsilon < 1$, choose $t_3 > t_0$ so large that $\rho > \epsilon^2$ for all $t \geqslant t_3$. Then $\rho^{1/2} - 1 \geqslant (1 - \epsilon)\rho^{1/2}$, and

$$F^{(1)}(t) = \sqrt{G(t)} \geqslant \gamma\rho^{3/4}, \text{ where } \gamma \equiv 2\sqrt{(1-\epsilon)\left(\frac{\delta_-}{3} - bF(t_0)\right)}.$$

So $F(t)^{-3/4}(dF/dt) \geqslant \gamma F(t_0)^{-3/4}$ and, integrating again, $F(t)^{1/4} - F(t_3)^{1/4} \geqslant 4\gamma F(t_0)(t-t_0)$, so that $\liminf_{t\to\infty}[F(t)/t^4] \geqslant \gamma$. Now if $F(t_0)=0$ we have $V(t_0)=V^{(1)}(t_0)=\mathbf{0}$, and the unique solution of (5) satisfying these conditions is $V(t)=\frac{1}{2}(t-t_0)^2C$, for which $b=0$. So either $F(t_0)>0$ or $b=0$, and either $b>0$ or $\delta_->0$ by hypothesis. So in any case we have $\gamma>0$, completing the proof for $t \to \infty$. For $t\to-\infty$ consider the Lie quadratic $s\mapsto -V(-s)$. □

VI. POLYNOMIAL SOLUTIONS FOR *F*

Comparing Corollary 6 and Theorem 3, if $b\delta_-<0$ then $F(t)=O(t^4)$ but $F(t)\neq O(t^3)$. On the other hand, F is sometimes bounded when $b>0$.

Example 6: Given a_0, c_0, $t_0 \in \mathbb{R}$, $A \in SO(3)$, define a Lie quadratic,

$$V(t) = a_0 A(-c_0, \cos a_0c_0(t-t_0), \sin a_0c_0(t-t_0)). \tag{19}$$

Then $C=a_0^3c_0A(1,0,0)$, F is constant with value $a_0^2(1+c_0^2)$,

$$b = 3a_0^4c_0^2, \ c = a_0^6c_0^4, \ d = 3a_0^6c_0^2(1+c_0^2) \text{ and } \delta_\pm = 3a_0^6c_0^2(1\pm c_0)^2.$$

If $a_0c_0=0$ then V is constant. Otherwise V is periodic and non-null (the only bounded null Lie quadratics in E^3 are constants).

Conversely, let V be any Lie quadratic in E^3 with F constant. If $C=\mathbf{0}$ then $b=0$ by (7) and then $\|V^{(1)}\|=0$ by (8), namely V is constant. If $C\neq\mathbf{0}$ then, after rotation in E^3 and time dilation, we can suppose $C=(1,0,0)$, so that the first component V_1 of V is $-c_0$. By (5), the other components satisfy

$$V_2^{(2)} = -c_0V_3^{(1)}, \ V_3^{(2)} = c_0V_2^{(1)},$$

giving $V_2=\cos c_0(t-t_0)$, $V_3=\sin c_0(t-t_0)$ for some $t_0\in\mathbb{R}$. So, in any case where F is constant, V has the form (19) after rotation and dilation. □

Example 7: For $b>0$, $c\geqslant 0$, $A\in SO(3)$ and $t_0\in\mathbb{R}$, let V be the null quadratic for which

$$V(t_0) = A(\sqrt{c},0,0), \ V^{(1)}(t_0) = A(0,\sqrt{b},0).$$

Then $F(t)=b(t-t_0)^2+c$, and $d=\delta_+=\delta_-=3c$. Alternatively, F is also realized by the affine Lie quadratic

$$t \mapsto -A(\sqrt{b}(t-t_0), \sqrt{c}, 0),$$

which is non-null for $c>0$. □

Example 8: For $a_0>0$, $c_0\in\mathbb{R}$, $A\in SO(3)$ and $t_0\in\mathbb{R}$, set

$$V(t) = (a_0(t-t_0)^2 + c_0)A(1,0,0).$$

Then V is a Lie quadratic in E^3 with $C=2a_0A(1,0,0)$, $F(t)=(a_0(t-t_0)^2+c_0)^2$,

$$b = -4a_0c_0, \ c = 4a_0^2, \ d = 24a_0^2, \ \delta_+ = 48a_0^2, \text{ and } \delta_- = 0.$$

□

In particular, Examples 6, 7, and 8 give constant, quadratic and quartic solutions of (16) with $F\geqslant 0$, $F^{(2)}+b\geqslant 0$, and $d\geqslant 0$. There are no other examples: all polynomial solutions of (16) have the form

$$a_0(t-t_0)^2 + c_0 \text{ or } (b_0(t-t_0)^2 + d_0)^2, \tag{20}$$

where

(i) $a_0=b$ and $3bc_0=d$, or $a_0=0$ and $bc_0=-d$,
(ii) $24b_0^2=d$ and $4b_0d_0=-b$, or $b_0=0$ and $bd_0^2=d$.

When $b<0$ the solution $F(t)=b(t-t_0)^2+d/(3b)$ of (16) satisfies neither $F\geqslant 0$ nor $F^{(2)}+b\geqslant 0$. In Examples 6, 7, and 8, t_0 is a point of global minimum of F. In Example 6, and in Example 8 when $c_0=0$, t_0 is degenerate.

Theorem 4: *Unless V is one of the periodic Lie quadratics in Example 6,*

(1) the critical points of F are isolated, and
(2) if $F(t_0)>0$ and $F^{(1)}(t_0)=F^{(3)}(t_0)=0$ then $F(t)=(a_0(t-t_0)^2+c_0)^2$ where a_0, $c_0\in\mathbb{R}$,
(3) if t_0 is a degenerate critical point of F either $F^{(3)}(t_0)\neq 0$ or $F(t)=(d/24)(t-t_0)^4$.

Proof: For (2), $F(t_0)$, $F^{(2)}(t_0)$ determine F uniquely as a solution of (16), and all $(F(t_0),F^{(2)}\times(t_0))\in(0,\infty)\times\mathbb{R}$ are realized in Example 8. For (3), F is determined by $F(t_0)\geqslant 0$. Positive values are realized by taking F constant, and 0 is achieved in Example 8 by setting $c_0=0$. If F is constant V appears in Example 6. For (1), if F is nonconstant a critical point then, by (3), t_0 satisfies $F^{(i)}(t_0)\neq 0$ for some $i=2$, 3, 4. So t_0 is isolated. □

Corollary 8: If F is nonconstant its points of local maximum are nondegenerate. □

VII. RATES OF GROWTH II: $b\geqslant 0$

Theorem 5: *Suppose $b\geqslant 0$. If t_0 is a point of local maximum of F, then $\delta_-\leqslant bF(t_0)$. If t_0 is a point of local minimum of F then $bF(t_0)\leqslant\delta_+$, and*

(1) if $F|(t_0,\infty)$ has no critical points and is unbounded, then $3bF(t_0)\leqslant\delta_+$, and either

$$\lim_{t\to\infty}\frac{F(t)}{t^2}=b \text{ or } \liminf_{t\to\infty}\frac{F(t)}{t^4}>0;$$

(2) if $F|(-\infty,t_0)$ has no critical points and is unbounded, then $3bF(t_0)\leqslant\delta_+$, and either

$$\lim_{t\to-\infty}\frac{F(t)}{t^2}=b \text{ or } \liminf_{t\to-\infty}\frac{F(t)}{t^4}>0;$$

(3) if $3bF(t_0)\leqslant\delta_-$ and $\delta_->0$, then t_0 is the only critical point of F, is nondegenerate, and F is unbounded on $[0,\infty)$ and on $(-\infty,0]$;
(4) if $3bF(t_0)<\delta_-$ then

$$\liminf_{t\to\pm\infty}\frac{F(t)}{t^4}>0;$$

(5) for $\delta_->0$, let t_1 be another critical point of F, where F has no critical points between t_0,t_1. Then $3bF(t_0)>\delta_-$ and

$$F(t_1)\geqslant\left(\frac{\mu F(t_0)^{1/2}+\sqrt{4\mu F(t_0)^2-3\mu^2F(t_0)}}{2(F(t_0)-\mu)}\right)^2,\quad \text{where } \mu=\frac{\delta_-}{3b}. \tag{21}$$

If also $3bF(t_0)>\delta_+$ then

$$F(t_1)\leqslant\left(\frac{\mu F(t_0)^{1/2}+\sqrt{4\mu F(t_0)^2-3\mu^2F(t_0)}}{2(F(t_0)-\mu)}\right)^2,\quad \text{where } \mu=\frac{\delta_+}{3b}. \tag{22}$$

Proof: For t_0 a critical point of F, $\delta_-\leqslant(F^{(2)}(t_0)+b)F(t_0)\leqslant\delta_+$, by (10). If t_0 is a point of local maximum then $F^{(2)}(t_0)\leqslant 0$ and therefore $\delta_-\leqslant(F^{(2)}(t_0)+b)F(t_0)\leqslant bF(t_0)$. Similarly, if t_0 is a point of local minimum $F^{(2)}(t_0)\geqslant 0$ and $bF(t_0)\leqslant\delta_+$. For *(1)*, by (18), with $[t_1,t_2]\subset(t_0,\infty)$,

$$\rho^{3/2}\left(4bF(t_1) - G(t_1) - \frac{4\delta_+}{3}\right) - 4bF(t_1)\rho \leqslant -\left(G(t_2) + \frac{4\delta_+}{3}\right), \tag{23}$$

$$\rho^{3/2}\left(4bF(t_1) - G(t_1) - \frac{4\delta_-}{3}\right) - 4bF(t_1)\rho \geqslant -\left(G(t_2) + \frac{4\delta_-}{3}\right). \tag{24}$$

By hypothesis, $\limsup_{t_2\to\infty}\rho=\infty$. By (23), and because $G(t_2)+(4\delta_+/3)\geqslant 0$,

$$4bF(t) - G(t) \leqslant \frac{4\delta_+}{3} \text{ for all } t > t_0.$$

So $3bF(t_0)\leqslant\delta_+$. By (24) if, for any $t_1\geqslant t_0$, $k(t_1)\equiv 4bF(t_1)-G(t_1)-(4\delta_-/3)<0$, then for all $t\geqslant t_1$,

$$G(t) \geqslant -k(t_1)\rho^{3/2} + 4bF(t_1)\rho - \frac{4\delta_-}{3}, \text{ where } \rho = F(t)/F(t_1).$$

Then, as in the proof of Theorem 3, $\liminf_{t\to\infty}[F(t)/t^4]>0$. Alternatively if $k(t)\geqslant 0$ for all $t\geqslant t_0$, then $G(t)<4bF(t)$ and $0\leqslant F^{(1)}(t)<2\sqrt{b}F(t)^{1/2}$. So

$$0 \leqslant F(t) < (F(t_0)^{1/2} + \sqrt{b}(t-t_0))^2,$$

and $\limsup_{t\to\infty}[F(t)/t^2]\leqslant b$. When $b=0$ this proves (*1*), and when $b>0$ we argue as follows. By (23), since ρ is unbounded, $G(t)\geqslant 4bF(t)-(4\delta_+/3)$, for all $t\geqslant t_0$. Eventually the right-hand side is positive, when $t=t_1$ say, and

$$F^{(1)}(t) \geqslant 2(bF - \delta_+)^{1/2},$$

for all $t\geqslant t_1$. Integrating $(bF(t)-\delta_+)^{1/2}\geqslant b(t-t_1)+(bF(t_1)-\delta_+)^{1/2}$, which completes the proof of (*1*).

Now (*2*) follows by applying (*1*) to the Lie quadratic W where $W(s)=-V(2t_0-s)$. The parameters $b,c,d,\delta_\pm$ are the same for W, and C is replaced by $-C$.

For (*3*) $F(t_0)\neq 0$ and t_0 is nondegenerate, by Corollary 7. Taking $t_1\to t_0^+$ in (24),

$$G(t) \geqslant \tfrac{4}{3}(\rho^{1/2}-1)((\delta_- - 3bF(t_0))\rho + \delta_-\rho^{1/2} + \delta_-) \geqslant \tfrac{4}{3}(\rho-1)\delta_-, \tag{25}$$

where $\rho(t)=F(t)/F(t_0)$. In particular $F^{(1)}(t)\neq 0$ for $t\in(t_0,t_1]$ and, since t_0 is a point of local minimum of F, $F^{(1)}$ is positive on $(t_0,t_1]$. So $F|(t_0,t_1]$ is increasing, and $F(t_1)F^{(1)}(t_1)>0$. So $F(t)F^{(1)}(t)>0$ for all $t>t_0$, and (25) still holds. Since F is strictly increasing on (t_0,∞), so is ρ. Also

$$F^{(1)}(t) \geqslant 2\sqrt{\frac{\delta_-}{3}}(\rho-1)^{1/2} = 2\sqrt{\frac{\delta_-}{3}}(F(t)/F(t_0)-1)^{1/2}.$$

Then integration gives $\liminf_{t\to\infty}[F(t)/t^2]>0$, and (*3*) follows by applying this to W in place of V.

For (*4*), given $\lambda\in(0,1)$, choose ρ so large (and t accordingly) so that (25) gives

$$\rho(t)^{-3/4}F^{(1)}(t) \geqslant \lambda\sqrt{\frac{4(\delta_- - 3bF(t_0))}{3}}, \text{ namely } F(t)^{-3/4}F^{(1)}(t) \geqslant \lambda\sqrt{\frac{4(\delta_- - 3bF(t_0))}{3}}F(t_0)^{-3/4}.$$

Integration then proves (*4*) for $t\to\infty$, and applying this to W proves the rest of (*4*).

For (*5*), $bF(t_0)>0$ by (*3*). Also (18) gives $\delta_-(\rho+\rho^{1/2}+1)\leqslant 3bF(t_1)\leqslant\delta_+(\rho+\rho^{1/2}+1)$, where $\rho=F(t_1)/F(t_0)$. Writing $f_i=F(t_i)^{1/2}$,

$$f_1^2(\mu - f_0^2) + f_1(\mu f_0) + \mu f_0^2 \leqslant 0, \tag{26}$$

where $\mu=\delta_-/3b$ and $\mu-f_0^2<0$ by (*3*). So either

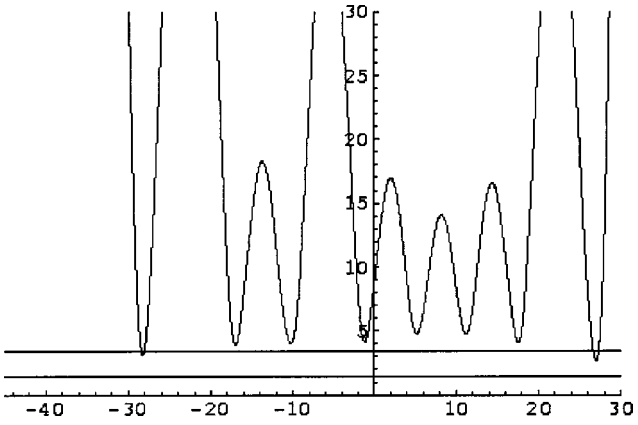

FIG. 10. F in Examples 5 and 9.

$$f_1 \leqslant \frac{\mu f_0 - \sqrt{4\mu f_0^4 - 3\mu^2 f_0^2}}{2(f_0^2 - \mu)} \quad \text{or } f_1 \geqslant \frac{\mu f_0 + \sqrt{4\mu f_0^4 - 3\mu^2 f_0^2}}{2(f_0^2 - \mu)}.$$

Now $(\mu f_0)^2 - (4\mu f_0^4 - 3\mu^2 f_0^2) = 4\mu f_0^2(\mu - f_0^2) < 0$ and, since $f_1 \geqslant 0$, this proves (21). Taking $\mu = \delta_+/3b$, the direction of the inequality in (26) reverses. When also $3bF(t_0) > \delta_+$, namely $\mu - f_0^2 < 0$, (22) follows in similar fashion to (21). □

Notice that when $3bF(t_0) < 2\delta_-$, (21) in (5) of Theorem 5 is stronger than $F(t_0) < F(t_1)$.

Example 9: *Figure 10 plots F in Example 5, with horizontal lines of heights* $\delta_\pm/3b$. *As in, Theorem 5,* $F(t_0) \leqslant \delta_+/3b$ *for every point* t_0 *of local minimum of F. Also notice that* $F(t_0) \leqslant \delta_+/3b$ *only for the first and last observed points* t_0 *of local minimum. Even if we only know* $F|[-20,20]$, *it follows from Part 1 of Theorem 5 that the restriction of F to each of* $(-\infty,-20)$ *and* $(20,\infty)$ *is either bounded or has a point of local minimum.* □

Under fairly general conditions $F(t)$ grows faster than linearly and V can be shown to possess *axes*, generalizing a result for null Lie quadratics. The axes of a non-null Lie quadratic V have non-negative components in the direction of the constant vector C.

VIII. SUPERLINEARITY

Whether $b > 0$ or not, for $V(t) \neq \mathbf{0}$ write $U(t) = V(t)/\|V(t)\|$. Then $U^{(1)} = (V^{(1)}/F^{1/2}) - (F^{(1)}U/2F)$.

Lemma 3: $\|U^{(1)}\| = \sqrt{(d - F^{(4)})/3}/F \leqslant (\|C\| + \sqrt{c})/F$.

Proof: $\|U^{(1)}\|^2 = [4F\|V^{(1)}\|^2 - (F^{(1)})^2]/4F^2 = \left[F(F^{(2)} + b) - \frac{3}{4}(F^{(1)})^2\right]/3F^2 = (d - F^{(4)})/3F^2 \leqslant \delta_+/3F^2$, by Theorem 1. □

Definition 1: *For* $\sigma = \pm$, F *is said to be* σ-superlinear *when, for some* $\epsilon > 0$, *we have* $0 < \liminf_{t \to \sigma\infty}[F(t)/|t|^{1+\epsilon}] < \infty$. □

In Example 6, V is not superlinear. In general,

(i) if F is superlinear then $\epsilon \leqslant 3$, by Corollary 6,
(ii) if $b < 0$ then F is $\pm$ superlinear with $\epsilon = 3$, by Theorem 3,
(iii) for $b \geqslant 0$, if $F(t)$ is unbounded for $\sigma t > 0$, with finitely many critical points t_i satisfying $\sigma t_i > 0$, then F is σ superlinear with ϵ either 1 or 3, by Theorem 5,
(iv) if V is null and nonconstant then F is $\pm$ superlinear with $\epsilon = 1$.

Definition 2: *Let* $\sigma = \pm$, $p \in \mathbb{R}$ *and* $h: \mathbb{R} \to \mathbb{R}$ *be given. A function* $g: \mathbb{R} \to \mathbb{R}$ *is said to be* $O_\sigma(h)$ *when* $\limsup_{t \to \sigma\infty}[g(t)/h(t)] < \infty$. □

Theorem 6: *If F is* σ*-superlinear then* $\alpha_\sigma(V) \equiv \lim_{t \to \sigma\infty} U(t)$ *exists, and*

$$U(t) = \alpha_\sigma(V) + O_\sigma(|t|^{-\epsilon}).$$

Proof: For $r<s$,

$$\|U(s)-U(r)\| \leqslant \int_r^s \|U^{(1)}(t)\|\mathrm{d}t \leqslant \int_r^s \frac{\|C\|+\sqrt{c}}{F(t)}\mathrm{d}t.$$

For $\sigma=+$, the right-hand side is bounded above by $k(r^{-\epsilon}-s^{-\epsilon})$ for some constant $k>0$, at least for r sufficiently large. So $\{U(j): j\geqslant 1\}\subset S^2$ is Cauchy, therefore convergent, then $\lim_{s\to\infty} U(s)$ exists, in the limit as $s\to\infty$ $\|\alpha_+(V)-U(r)\|\leqslant kr^{-\epsilon}$, and similarly for $\sigma=-$. □

Example 10: *Let V be a null Lie quadratic V with $b=1$, $c>0$, and $F(t)=c+t^2$. Set $\tau(t)=\int_0^t[\sqrt{c}/F(t)]\mathrm{d}t=(1/\sqrt{c})\arctan(t/c)$ and $W_2(\tau)\equiv U(t)=(c+t^2)^{-1/2}V(t)$. Differentiating with respect to τ, set $W_1(\tau)\equiv W_2'(\tau)=c^{-1/2}((c+t^2)^{1/2}V^{(1)}-t(c+t^2)^{-1/2}V)$, and $W_3(\tau)\equiv W_1(\tau)\times W_2(\tau)$. Then $W\equiv[W_1\ W_2\ W_3]\in SO(3)$, and*

$$W'(\tau)=\begin{bmatrix} 0 & -1 & c\sec^3(\sqrt{c}\tau) \\ 1 & 0 & 0 \\ -c\sec^3(\sqrt{c}\tau) & 0 & 0 \end{bmatrix} W(\tau),$$

where $\tau\in(-\pi/(2\sqrt{c}),\pi/(2\sqrt{c}))$. So U and therefore V can be found by solving the third-order homogeneous linear differential equation with variable coefficients

$$\cos^3(\sqrt{c}\tau)\frac{d}{d\tau}((y''(\tau)+y(\tau))\cos^3(\sqrt{c}\tau))+c^2y'(\tau)=0,$$

for $y:(-\pi/(2\sqrt{c}),\pi/(2\sqrt{c}))\to\mathbb{R}$. □

Theorem 7: *Let F be σ superlinear. Then*

$$\frac{f(t)}{t^2}=\frac{a_\sigma}{2}+O_\sigma(|t|^{-1}),$$

where $f\equiv F^{1/2}$ and $a_\sigma\equiv\langle C,\alpha_\sigma(V)\rangle$.

Proof: Suppose $\sigma=+$. By (5), $fU^{(2)}+2f^{(1)}U^{(1)}+f^{(2)}U=f^2U^{(1)}\times U+C$, and, since $\|U\|\equiv 1$, taking inner products of both sides with U gives

$$0\leqslant f^{(2)}-\langle C,U\rangle=f\langle U^{(1)},U^{(1)}\rangle\leqslant\frac{\delta_+}{3f^3}=O_+(t^{-3(1+\epsilon)/2}),$$

by Lemma 3 and because F is $+$ superlinear. Then $f^{(2)}(t)=a_++O_+(t^{-\epsilon})$, by Theorem 6. Integrating, for large $t_0<t$,

$$f^{(1)}(t)=a_+(t-t_0)+f^{(1)}(t_0)+O_+(K_1(t)-K_1(t_0)),$$

where $K_1(t)$ is $\ln t$ or $t^{1-\epsilon}/(1-\epsilon)$, according to $\epsilon=1$ or not. Integrating again,

$$f(t)=\frac{a_+(t-t_0)^2}{2}+(t-t_0)f^{(1)}(t_0)+f(t_0)+O_+(K_2(t)-(t-t_0)K_1(t_0)),$$

where $K_2(t)=t\ln t-t_0\ln t_0-t+t_0$, $t_0^{-1}-t^{-1}$, or $(t^{2-\epsilon}-t_0^{2-\epsilon})/((1-\epsilon)(2-\epsilon))$, according to ϵ is 1, 2 or neither. In any case, $f(t)/t^2=(a_+/2)+O_+(t^{-1})$. For $\sigma=-$ apply what has already been proved to the Lie quadratic W given by $W(s)=-V(-s)$, noting that W has constant $-C$ and $\alpha_+(W)=-\alpha_-(V)$. □

Corollary 9: Let F be σ superlinear. Then $\langle C,\alpha_\sigma\rangle\geqslant 0$, and either

(i) $\epsilon=1$, $\langle C,\alpha_\sigma\rangle=0$, *and* $b\geqslant 0$, *or*
(ii) $\epsilon=3$, *or*
(iii) $\langle C,\alpha_\sigma\rangle=0$, $b\geqslant 0$, *and F has critical points t_0 with σt_0 arbitrarily large.*

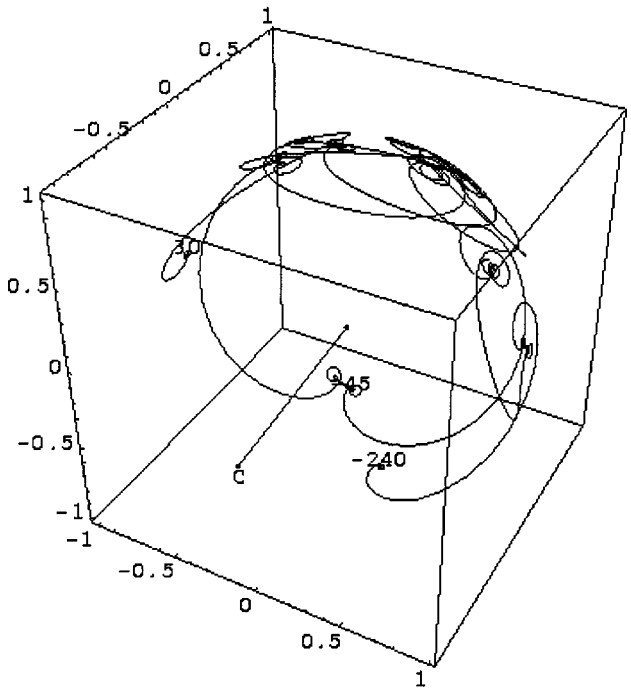

FIG. 11. U in Examples 5, 11.

Proof: If $a_+>0$ then $\epsilon=3$, by Theorem 7. Alternatively, if $a_\sigma=0$ then $b\geqslant 0$ by Theorem 3. Then, by Theorem 5, either $\epsilon=1$ or F has critical points t_0 with σt_0 arbitrarily large. □

Unlike the null case, where convergence to axes is more or less steady, unbounded non-null Lie quadratics in E^3 may explore numerous possibilities before settling on an asymptotic direction, at least when $b>0$.

Example 11: In Example 5, $\langle C,U(-45)\rangle=-0.032\,55$ *and* $\langle C,U(30)\rangle=0.2915$. *So, by Corollary 9,* $U(-45)$ *is far from* $\alpha_-(V)$, *which is not apparent from Figs. 6 and 7. Solving (5) numerically for V over the larger domain* $[-240,30]$, $U:[-240,30]\to S^2$ *is shown in Fig. 11, together with the line segment from* (0,0,0) *to C and labels when* $t=-240,-45,30$. *We find* $\langle C,U(-240)\rangle=0.62375$, *and Corollary 9 permits* $\alpha_-(V)\approx U(-240)$, $\alpha_+(V)\approx U(30)$. □

q-deformation of $z \to (\alpha z+\beta)/(\gamma z+\delta)$

Ctirad Klimčík
Institute de mathématiques de Luminy, 163, Avenue de Luminy, 13288 Marseille, France

(Received 30 October 2003; accepted 29 July 2004; published 25 October 2004)

We construct the action of the quantum double of $U_q(su(2))$ on the standard Podleś sphere and interpret it as the quantum projective formula generalizing to the q-deformed setting the action of the Lorentz group of global conformal transformations on the ordinary Riemann sphere. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1803610]

I. INTRODUCTION

As it is well known, the Lorentz group $SL(2,\mathbf{C})$ naturally acts on the Riemann sphere S^2 by the conformal transformations

$$z \to \frac{\alpha z+\beta}{\gamma z+\delta}, \quad \alpha,\beta,\gamma,\delta \in \mathbf{C}, \quad \alpha\delta-\beta\gamma=1. \tag{1}$$

The q-deformation of S^2 is referred to as the Podleś sphere (Podleś, 1987). One of the goals of this paper is to find the corresponding q-deformation of the conformal transformations (1). We note that the restriction $\overline{\alpha}=\delta$, $\overline{\gamma}=-\beta$ gives the action of the group SU(2) on S^2 which just corresponds to the standard geometrical rotations of the two-sphere embedded into three-dimensional Euclidean space. The q-deformed version of this SU(2) action was studied in detail by Podleś (1987). However, to our best knowledge, the q-conformal action of the full q-Lorentz group on the Podleś sphere has not yet been reported.

Recall, that the algebra of functions $\mathrm{Fun}(S^2)$ on ordinary two sphere can be viewed as the algebra of those functions on the group SU(2) which are invariant with respect to the right action of the maximal torus U(1) on SU(2). This gives the dual description of the coset $SU(2)/U(1) \equiv S^2$. The group SU(2) acts naturally from the left on this coset and this action can be extended to the action (1) of the Lorentz group $SL(2,\mathbf{C})$ on S^2 since we have a well-known identification $SU(2)/U(1) \equiv SL(2,\mathbf{C})/B$ with B being the Borel subgroup (consisting of upper triangular matrices) of $SL(2,\mathbf{C})$.

In order to construct the q-deformation of the picture just described, we take some inspiration from the theory of Poisson–Lie groups (see Semenov-Tian-Shansky, 1985, and Klimčík, 2004 for the elements). There is the Iwasawa decomposition $SL(2,\mathbf{C})=SU(2)AN$ of the Lorentz group where AN is the subgroup of upper triangular complex 2×2 matrices with real positive numbers on diagonal and unit determinant. AN turns out to be the dual Poisson–Lie group of SU(2) and $SL(2,\mathbf{C})$ is the Drinfeld double of SU(2) in the Poisson–Lie sense of this word. Now the Drinfeld double $SL(2,\mathbf{C})$ acts on Fun(SU(2)): the action of its subgroup SU(2) is induced just by the left multiplication of SU(2) on itself and the subgroup AN acts by the so-called dressing tranformations. This action of the $SL(2,\mathbf{C})$ on Fun(SU(2)) descends to $\mathrm{Fun}(SU(2)/U(1)(\equiv S^2))$ and it turns out to be given by the projective action (1), where z is the standard complex coordinate on the Riemann sphere.

The theory of Poisson–Lie groups is a sort of the semiclassical limit of the theory of q-deformed Hopf algebras for the deformation parameter q approaching 1. Many Poisson–Lie concepts can be directly generalized to the Hopf algebra setting like, e.g., the Drinfeld double or the dressing transformations. In particular, the Poisson–Lie concept of the duality translates into

the famous (Drinfeld, 1986) duality in the world of Hopf algebras. Having in mind the parallels between the Poisson–Lie and the Hopf worlds, it is not difficult to find the q-deformation of the projective formula. We proceed as follows.

The Podleś sphere $\mathrm{Fun}_q(S^2)$ is a one-parameter deformation of the algebra $\mathrm{Fun}(S^2)$. It is generated by the U(1) right-invariant elements of the quantum group $\mathrm{Fun}_q(\mathrm{SU}(2))$. The deformed enveloping algebra $\mathrm{U}_q(\mathrm{su}(2))$ naturally acts on the deformed $\mathrm{Fun}_q(\mathrm{SU}(2))$. [This corresponds to the left action of SU(2) on Fun(SU(2)) just described above.] The Hopf dual $\mathrm{U}_q(an)$ of $\mathrm{U}_q(\mathrm{su}(2))$ acts on $\mathrm{Fun}_q(\mathrm{SU}(2))$ in the Hopf-dressing way. This corresponds to the dressing action of AN on Fun(SU(2)). As noted by Korogodsky (unpublished), the Hopf analogue of the dressing action of $\mathrm{U}_q(an)$ on $\mathrm{Fun}_q(\mathrm{SU}(2))$ is the adjoint action of the Hopf algebra $\mathrm{Fun}_q(\mathrm{SU}(2))$ on itself. This statement is consistent due to the Drinfeld duality isomorphism between $\mathrm{U}_q(an)$ and $\mathrm{Fun}_q(\mathrm{SU}(2))$. The respective actions of $\mathrm{U}_q(an)$ and $\mathrm{U}_q(\mathrm{su}(2))$ on $\mathrm{Fun}_q(\mathrm{SU}(2))$ combine to the action of the Drinfeld double $D(\mathrm{U}_q(\mathrm{su}(2)))$ on $\mathrm{Fun}_q(\mathrm{SU}(2))$. This Drinfeld double is nothing but the q-Lorentz group (see Podleś and Woronowicz, 1990) and the only consistency check of the construction consists in verifying that the action of the q-Lorentz group descends from $\mathrm{Fun}_q(\mathrm{SU}(2))$ on $\mathrm{Fun}_q(S^2)$. It turns out to be the case and thus we obtain the q-deformation of the projective formula (1).

In Sec. II, we describe the action of the quantum double $D(\mathrm{U}_q(\mathrm{su}(2)))$ on the Podleś sphere and in Sec. III we show that it leads to the projective formula (1) in the limit $q\to 1$. We finish with a short outlook.

II. ACTION OF THE DRINFELD DOUBLE $D(\mathrm{U}_q(\mathrm{su}(2)))$ ON THE PODLEŚ SPHERE

First we recall some relevant facts concerning (the $*$-actions of) the Drinfeld double. The reader can mostly find them also in Majid (1995), however, our exposition between Eqs. (9) and (11) is original.

Thus let H be a Hopf algebra, $\tilde{H}$ its dual and H^{cop} the co-opposite Hopf algebra of H. The Drinfeld double $D(H)$ is another Hopf algebra which is generated by its two sub-Hopf algebras H^{cop} and $\tilde{H}$. The coalgebra structure of $D(H)$ is just that of $H^{\mathrm{cop}}\otimes\tilde{H}$, the antipode S_D is given by

$$S_D(U\otimes f)\equiv(1\otimes Sf)(S^{\mathrm{cop}}U\otimes 1)=(S^{\mathrm{cop}}U)''\otimes(Sf)''\langle(S^{\mathrm{cop}}U)',(Sf)'\rangle\langle S^{\mathrm{cop}}(S^{\mathrm{cop}}U)''',(Sf)'''\rangle, \quad (2)$$

and the product is defined by the following cross relations (Majid, 1995):

$$\langle U',f'\rangle(U''\otimes 1)(1\otimes f'')=\langle U'',f''\rangle(1\otimes f')(U'\otimes 1). \quad (3)$$

Here $U\in H^{\mathrm{cop}}$, $f\in\tilde{H}$, $\langle .,.\rangle$ is the duality pairing between H and $\tilde{H}$ and we use the Sweedler notation for the coproduct

$$\Delta^{\mathrm{cop}}(U)=\sum_p U'_p\otimes U''_p\equiv U'\otimes U'', \quad \Delta(f)=f'\otimes f''. \quad (4)$$

The formula (3) is particularly useful if we know the generators and their relations for both algebras H^{cop} and $\tilde{H}$ separately. The set of relations for the algebra structure of $D(H)$ can be then directly obtained from (3) and (4).

If, moreover, H and $\tilde{H}$ are equipped with compatible star structures, then the quantum double $D(H)$ can be also naturally made a $*$-Hopf algebra. Recall that a star $*$ on H is an antilinear antihomorphism of H satisfying $S*S*=Id$, $*^2=Id$, $(*\otimes *)\Delta=\Delta*$, and $*\varepsilon=\varepsilon*$. The standard compatibility relation (cf. Majid, 1995) between the stars on H and $\tilde{H}$ reads

$$\langle U*,f\rangle=\overline{\langle U,(Sf)*\rangle}, \quad U\in H, \quad f\in\tilde{H}. \quad (5)$$

The explicit formula for the star $*$ on $D(H)$ is then uniquely determined as follows:

$$(U \otimes f)^* \equiv (1 \otimes f^*)(U^* \otimes 1) = U^{*\prime\prime} \otimes f^{*\prime\prime}\langle U^{*\prime}, f^{*\prime}\rangle\langle S^{\mathrm{cop}}U^{*\prime\prime\prime}, f^{*\prime\prime\prime}\rangle, \quad U \in H^{\mathrm{cop}}, \quad f \in \tilde{H}, \tag{6}$$

where the star on H^{cop} is the same as that on H.

The algebras H^{cop} and $\tilde{H}$ act (from the left) on $\tilde{H}$, respectively, as

$$U \triangleright h = \langle S^{\mathrm{cop}}(U), h^{\prime}\rangle h^{\prime\prime}, \quad U \in H^{\mathrm{cop}}, \quad h \in \tilde{H}, \tag{7a}$$

$$f \triangleright h = f^{\prime} h S(f^{\prime\prime}), \quad f, h \in \tilde{H}. \tag{7b}$$

We note that $S^{\mathrm{cop}} = S^{-1}$, where S is the antipode of H. Using the basic axioms of Hopf algebras, it is easy to check that the definitions (7a) and (7b) imply

$$\langle U^{\prime}, f^{\prime}\rangle U^{\prime\prime} \triangleright (f^{\prime\prime} \triangleright h) = \langle U^{\prime\prime}, f^{\prime\prime}\rangle f^{\prime} \triangleright (U^{\prime} \triangleright h), \quad U \in H^{\mathrm{cop}}, \quad f, h \in \tilde{H}.$$

By comparing with the defining relation (3), this means that (7a) and (7b) describe in fact the left action of the quantum double $D(H)$ on $\tilde{H}$. Explicitly,

$$(U \otimes f) \triangleright h \equiv U \triangleright (f \triangleright h), \quad U \in H^{\mathrm{cop}}, \quad f, h \in \tilde{H}. \tag{8}$$

It can be also directly checked [with the help of the condition (5)], that this action is compatible with the algebra structure of $\tilde{H}$ and with the $*$-structure on $\tilde{H}$. Explicitly,

$$x \triangleright (fh) = (x^{\prime} \triangleright f)(x^{\prime\prime} \triangleright h), \quad x \in D(H), \; f, h \in \tilde{H}, \tag{9a}$$

$$(x \triangleright f)^* = (S_D(x))^* \triangleright f^*, \quad x \in D(H), \; f \in \tilde{H}. \tag{9b}$$

Now let $k \in H^{\mathrm{cop}}$ be a grouplike self-adjoint element, i.e., $k^* = k$, $\Delta^{\mathrm{cop}}k = k \otimes k$, $\varepsilon(k) = 1$. We can then define a linear space A consisting of invariant elements of $\tilde{H}$ with respect to the right action of k and $S(k)$ on $\tilde{H}$,

$$A = \{f \in \tilde{H}, \; \langle f^{\prime\prime}, k\rangle f^{\prime} \equiv f \triangleleft k = f, \; f \triangleleft S(k) = f\}. \tag{10}$$

We have for $f, g \in A$

$$(fg) \triangleleft k = \langle f^{\prime\prime}g^{\prime\prime}, k\rangle f^{\prime}g^{\prime} = \langle f^{\prime\prime}, k\rangle\langle g^{\prime\prime}, k\rangle f^{\prime}g^{\prime} = fg$$

and, in the same way, $(fg) \triangleleft S(k) = 1$ which means that A is the subalgebra of $\tilde{H}$. We obtain easily also the $*$-stability of A, since for $f \in A$ we have

$$f^* \triangleleft k = \langle f^{*\prime\prime}, k\rangle f^{*\prime} = (\langle f^{\prime\prime}, (S(k))^*\rangle f^{\prime})^* = (f \triangleleft S(k))^* = f^*$$

and, in the same way, $f^* \triangleleft S(k) = (f \triangleleft k)^* = f^*$.

It is not difficult to prove that A is also stable with respect to the action (7a) and (7b) of the quantum double $D(H)$ on $\tilde{H}$. Indeed, we have for the H^{cop} action (7a),

$$U \triangleright (f \triangleleft k) = \langle S^{\mathrm{cop}}(U), f^{\prime}\rangle f^{\prime\prime}\langle f^{\prime\prime\prime}, k\rangle = (U \triangleright f) \triangleleft k, \quad U \in H^{\mathrm{cop}}, \quad f \in \tilde{H}.$$

The proof of stability for $\tilde{H}$ action (7b) is slightly more involved,

$$(h \triangleright f) \triangleleft k = \langle (h^{\prime} f S(h^{\prime\prime}))^{\prime\prime}, k\rangle ((h^{\prime} f S(h^{\prime\prime}))^{\prime} = \langle h^{\prime\prime} f^{\prime\prime} S h^{\prime\prime\prime}, k\rangle h^{\prime} f^{\prime} S h^{\prime\prime\prime\prime} = \langle h^{\prime\prime}, k\rangle\langle f^{\prime\prime}, k\rangle\langle S h^{\prime\prime\prime}, k\rangle h^{\prime} f^{\prime} S h^{\prime\prime\prime\prime}$$

$$= \langle h^{\prime\prime}, kS(k)\rangle\langle f^{\prime\prime}, k\rangle h^{\prime} f^{\prime} S h^{\prime\prime\prime} = \langle f^{\prime\prime}, k\rangle h^{\prime} f^{\prime} S h^{\prime\prime} = h \triangleright (f \triangleleft k), \quad h, f \in \tilde{H}.$$

The same formulas hold true upon replacing $k \to S(k)$.

In the context of our paper, the *-Hopf algebra H will be the standard deformation $U_q(su(2))$ of $U(su(2))$, $\tilde{H}$ will be the corresponding dual deformation $Fun_q(SU(2))$ of $Fun(SU(2))$ and A will be the Podleś sphere $Fun_q(S^2)$. For the sake of mathematical rigor, we should pay attention to the fact that the notion of the dual Hopf algebra needs some clarification in the infinite-dimensional case. Actually, $U_q(su(2))$ and $Fun_q(SU(2))$ are in duality in the sense of Chaps. V.7 and VII.4 of the book by Kassel (1995). The general Drinfeld double formulas (2)–(10) then work with this notion of duality with the bilinear pairing given by Eq. (12d).

For the description of the Hopf algebras $Fun_q(SU(2))$ and $U_q(su(2))$, we use the conventions of Dąbrowski and Sitarz (2003) and Dąbrowski *et al.* (unpublished). Thus let $q\neq 1$ be a real positive number and denote $Fun_q(SU(2))$ a *-Hopf algebra generated by a and b, subject to relations

$$ba=qab,\quad b^*a=qab^*,\ bb^*=b^*b,\quad a^*a+q^2b^*b=1,\quad aa^*+bb^*=1, \tag{11a}$$

equipped with a coproduct

$$\Delta a=a\otimes a-qb\otimes b^*,\quad \Delta b=b\otimes a^*+a\otimes b, \tag{11b}$$

a counit $\varepsilon(a)=1$, $\varepsilon(b)=0$ and an antipode

$$Sa=a^*,\quad Sa^*=a,\quad Sb=-qb,\quad Sb^*=-q^{-1}b^*. \tag{11c}$$

The algebra $Fun_q(SU(2))$ is thus well defined but it is perhaps useful to comment its name. As everywhere in this paper, the symbol $Fun_q(M)$ indicates the deformation of the algebra of a certain class of functions on the ordinary manifold M. If the manifold M is the Lie group then the typical functions in this class are the matrix elements of the finite-dimensional representations of this group (cf. Levendorskii and Soibelman, 2001).

The *-Hopf algebra $U_q(su(2))$ is generated by elements e and (invertible self-adjoint) k, subject to relations

$$ek=qke,\quad k^2-k^{-2}=(q-q^{-1})(e^*e-ee^*), \tag{12a}$$

equipped with a coproduct

$$\Delta k=k\otimes k,\quad \Delta e=e\otimes k+k^{-1}\otimes e, \tag{12b}$$

a counit $\varepsilon(k)=1$, $\varepsilon(e)=0$ and an antipode

$$Se=-q^{-1}e,\quad Se^*=-qe^*,\quad Sk=k^{-1}. \tag{12c}$$

The (nondegenerate) duality pairing between $U_q(su(2))$ and $Fun_q(SU(2))$ is given by the two-dimensional representation of $U_q(su(2))$, i.e.,

$$\langle k,a\rangle=q^{1/2},\quad \langle k,a^*\rangle=q^{-1/2},\quad \langle e,-qb^*\rangle=\langle e^*,b\rangle=1 \tag{12d}$$

with all other couples of generators pairing to 0. It is easy to verify that the star structures on $Fun_q(SU(2))$ and $U_q(su(2))$ are compatible in the sense of Eq. (5).

The Podleś sphere is the algebra $Fun_q(S^2)$ viewed as the subalgebra of $Fun_q(SU(2))$ of right invariant elements with respect to the action of the self-adjoint grouplike elements k and k^{-1} [cf. (10)]. It is generated by

$$B=ab,\quad B^*=b^*a^*,\quad A=bb^*,$$

obeying the following relations:

$$AB=q^2BA,\quad AB^*=q^{-2}B^*A,\quad BB^*=q^{-2}A(1-A),\quad B^*B=A(1-q^2A).$$

The action of the q-Lorentz group $D(U_q(su(2)))$ on $Fun_q(S^2)\subset Fun_q(SU(2))$ is described by the formulas (7a) and (7b). We obtain explicitly

$$k\triangleright B = q^{-1}B, \quad k\triangleright B^* = qB^*, \quad k\triangleright A = A,$$

$$k^{-1}\triangleright B = qB, \quad k^{-1}\triangleright B^* = q^{-1}B^*, \quad k^{-1}\triangleright A = A,$$

$$e\triangleright B = 0, \quad e\triangleright B^* = q^{-1/2} - (q^{3/2} + q^{-1/2})A, \quad e\triangleright A = q^{1/2}B,$$

$$e^*\triangleright B = -q^{-3/2} + (q^{1/2} + q^{-3/2})A, \quad e^*\triangleright B^* = 0, \quad e^*\triangleright A = -q^{-1/2}B^*, \tag{13a}$$

$$a\triangleright B = q^{-1}B + (q - q^{-1})BA, \quad a\triangleright B^* = q^{-1}B^* + (q - q^{-1})AB^*,$$

$$a\triangleright A = q^{-2}A + (1 - q^{-2})A^2,$$

$$a^*\triangleright B = qB + (q - q^3)AB, \quad a^*\triangleright B^* = qB^* + (q - q^3)B^*A,$$

$$a^*\triangleright A = q^2A + (q^2 - q^4)A^2,$$

$$b\triangleright B = (q^2 - 1)B^2, \quad b\triangleright B^* = (1 - q^2)A^2, \quad b\triangleright A = (q^3 - q)BA,$$

$$b^*\triangleright B = (q - q^{-1})A^2, \quad b^*\triangleright B^* = -(q - q^{-1})B^{*2}, \quad b^*\triangleright A = (1 - q^2)AB^*. \tag{13b}$$

We note, that the notion of *-structure is crucial for our paper because the group $SL(2,\mathbf{C})$ (in the context of the conformal transformations acting on the Riemann sphere) is viewed as the *real* group. It is this fact which is the starting point of our strategy to deform the projective formula (1), since the real group $SL(2,\mathbf{C})$ is the Poisson–Lie Drinfeld double of the group SU(2). The concept of reality in the deformed Hopf picture is encoded in the *-structure. Thus we need a star * on our quantum double $D(U_q(su(2))) = SL_q(2,\mathbf{C})$. It is in fact given by the formula (6) uniquely in terms of the standard stars on $U_q(su(2))$ and $Fun_q(SU(2))$ (see Majid, 1995; Dąbrowski *et al.*, unpublished). The star-compatible action of the *-Hopf algebra $D(U_q(su(2)))$ on the *-algebra $Fun_q(SU(2))$ [and on its subalgebra $Fun_q(S^2)$] is the q-deformed version of the statement that the real group $SL(2,\mathbf{C})$ acts on the real algebra Fun(SU(2)) and on its subalgebra $Fun(S^2)$.

III. THE LIMIT $q\to 1$

In this section, we want to show that the action (7a) and (7b) of the quantum double $D(U_q(su(2)))$ on $Fun_q(S^2)$ described explicitly by the formulas (13a) and (13b) gives in the limit $q\to 1$ the same result as the action of the group $SL(2,\mathbf{C})$ on $Fun(S^2)$ induced by the projective formula (1). First of all, the limit $q\to 1$ of $Fun_q(S^2)$ gives the commutative algebra of complex functions on the sphere S^2, generated by

$$\mathcal{B} = \frac{z}{z\bar{z} + 1}, \quad \mathcal{B}^* = \frac{\bar{z}}{z\bar{z} + 1}, \quad \mathcal{A} = \frac{1}{z\bar{z} + 1},$$

where z is the standard complex coordinate on the Riemann sphere given by the stereographic projection.

The subgroup SU(2) of $SL(2,\mathbf{C})$ acts on S^2 via formula (1),

$$z \to \frac{\alpha z + \beta}{-\bar{\beta}z + \bar{\alpha}}, \quad \bar{z} \to \frac{\bar{\alpha}\bar{z} + \bar{\beta}}{-\beta\bar{z} + \alpha}.$$

Its Lie algebra Lie(SU(2)) therefore acts on $Fun(S^2)$ via three vector fields $\mathcal{R}_j$, $j=1,2,3$,

$$\mathcal{R}_3 = i(z\partial_z - \overline{z}\partial_{\overline{z}}), \quad \mathcal{R}_1 + i\mathcal{R}_2 = i(\partial_z + \overline{z}^2\partial_{\overline{z}}), \quad -\mathcal{R}_1 + i\mathcal{R}_2 = i(z^2\partial_z + \partial_{\overline{z}}).$$

The subgroup AN of $\mathrm{SL}(2,C)$ is formed by complex upper-triangular 2×2 matrices with real positive numbers on the diagonal. Its action on S^2 is obtained from the projective formula (1) for the following choice of parameters: $\gamma=0$, Im $\alpha=0$, Re $\alpha>0$, and β an arbitrary complex number. Thus

$$z \to \alpha(\alpha z + \beta), \quad \overline{z} \to \alpha(\alpha\overline{z} + \overline{\beta}).$$

The Lie algebra Lie(AN) therefore acts on Fun(S^2) via three vector fields $\mathcal{T}_j$, $j=0,1,2$,

$$\mathcal{T}_0 = z\partial_z + \overline{z}\partial_{\overline{z}}, \quad \mathcal{T}_2 + i\mathcal{T}_1 = -2\partial_{\overline{z}}, \quad -\mathcal{T}_2 + i\mathcal{T}_1 = 2\partial_z.$$

It is now straightforward to calculate

$$\mathcal{R}_3\mathcal{B} = i\mathcal{B}, \quad \mathcal{R}_3\mathcal{B}^* = -i\mathcal{B}^*, \quad \mathcal{R}_3\mathcal{A} = 0.$$

$$(\mathcal{R}_1 + i\mathcal{R}_2)\mathcal{B} = i(2\mathcal{A}-1), \quad (\mathcal{R}_1 + i\mathcal{R}_2)\mathcal{B}^* = 0, \quad (\mathcal{R}_1 + i\mathcal{R}_2)\mathcal{A} = -i\mathcal{B}^*, \tag{14a}$$

$$(-\mathcal{R}_1 + i\mathcal{R}_2)\mathcal{B} = 0, \quad (-\mathcal{R}_1 + i\mathcal{R}_2)\mathcal{B}^* = i(2\mathcal{A}-1), \quad (-\mathcal{R}_1 + i\mathcal{R}_2)\mathcal{A} = -i\mathcal{B},$$

$$\mathcal{T}_0\mathcal{B} = \mathcal{B}(2\mathcal{A}-1), \quad \mathcal{T}_0\mathcal{B}^* = \mathcal{B}^*(2\mathcal{A}-1), \quad \mathcal{T}_0\mathcal{A} = 2\mathcal{A}(\mathcal{A}-1),$$

$$(\mathcal{T}_2 + i\mathcal{T}_1)\mathcal{B} = 2\mathcal{B}^2, \quad (\mathcal{T}_2 + i\mathcal{T}_1)\mathcal{B}^* = -2\mathcal{A}^2, \quad (\mathcal{T}_2 + i\mathcal{T}_1)\mathcal{A} = 2\mathcal{A}\mathcal{B}, \tag{14b}$$

$$(-\mathcal{T}_2 + i\mathcal{T}_1)\mathcal{B} = 2\mathcal{A}^2, \quad (-\mathcal{T}_2 + i\mathcal{T}_1)\mathcal{B}^* = -2\mathcal{B}^{*2}, \quad (-\mathcal{T}_2 + i\mathcal{T}_1)\mathcal{A} = -2\mathcal{A}\mathcal{B}^*.$$

We recall, that the formulas (14a) and (14b) describe the infinitesimal projective action (1) of the Lie algebra Lie($\mathrm{SL}(2,\mathbf{C})$) on Fun($S^2$). We wish to show that they can be obtained from the formulas (13a) and (13b) in the limit $q\to 1$.

In the limit $q\to 1$, the Hopf algebra $\mathrm{U}_q(\mathrm{su}(2))$ reduces to the enveloping algebra of Lie(SU(2)). Upon the standard identification

$$-ie = -R_1 + iR_2, \quad ie^* = R_1 + iR_2, \quad k = q^{iR_3}, \quad k^{-1} = q^{-iR_3},$$

we indeed obtain in the limit the standard definition of the U(su(2)) (viewed as the Hopf algebra) from the defining relations (12a)–(12c) of $\mathrm{U}_q(\mathrm{su}(2))$. In particular, the commutations relations (12a) give in the limit $[R_j,R_k]=\epsilon_{jkl}R_l$. (Note that $R_j^*=-R_j$.) In the limit $q\to 1$, the action (13a) of $\mathrm{U}_q(\mathrm{su}(2))$ thus gives

$$(R_3\triangleright B)_{q\to 1} = \lim_{q\to 1}\frac{k-1}{i\ln q}\triangleright B = iB, \quad (R_3\triangleright B^*)_{q\to 1} = -iB^*, \quad (R_3\triangleright A)_{q\to 1} = 0.$$

$$\begin{gathered}((R_1 + iR_2)\triangleright B)_{q\to 1} = \lim_{q\to 1}(ie^*\triangleright B) = i(2A-1), \quad ((R_1 + iR_2)\triangleright B^*)_{q\to 1} = 0,\\ ((-R_1 + iR_2)\triangleright B)_{q\to 1} = 0, \quad ((-R_1 + iR_2)\triangleright B^*)_{q\to 1} = \lim_{q\to 1}(-ie\triangleright B^*) = i(2A-1),\end{gathered} \tag{15a}$$

$$((R_1 + iR_2)\triangleright A)_{q\to 1} = -iB^*, \quad ((-R_1 + iR_2)\triangleright A)_{q\to 1} = -iB.$$

Comparing (15a) with (14a), we immediately observe that the $q\to 1$ limit of the $\mathrm{U}_q(\mathrm{su}(2))$ action on the Podleś sphere indeed coincides with the Lie(SU(2)) action induced by the projective formula.

Now we turn our attention to the q-deformation of the action of Lie(AN). We define the following elements of $\mathrm{Fun}_q(\mathrm{SU}(2))$:

$$ {}^qT_0 = \frac{a - a^*}{2(\ln q)}, \quad i^qT_1 + {}^qT_2 = \frac{b}{(\ln q)}, \quad i^qT_1 - {}^qT_2 = \frac{b^*}{(\ln q)} \tag{16a} $$

and calculate

$$ \lim_{q\to 1}({}^qT_0 \triangleright B) = B(2A-1), \quad \lim_{q\to 1}({}^qT_0 \triangleright B^*) = B^*(2A-1), \quad \lim_{q\to 1}({}^qT_0 \triangleright A) = 2A(A-1), $$

$$ \begin{aligned} &\lim_{q\to 1}(i^qT_1 + {}^qT_2) \triangleright B = 2B^2, \quad \lim_{q\to 1}(i^qT_1 + {}^qT_2) \triangleright B^* = -2A^2, \\ &\lim_{q\to 1}(i^qT_1 - {}^qT_2) \triangleright B = 2A^2, \quad \lim_{q\to 1}(i^qT_1 - {}^qT_2) \triangleright B^* = -2B^{*2}, \\ &\lim_{q\to 1}(i^qT_1 + {}^qT_2) \triangleright A = 2AB, \quad \lim_{q\to 1}(i^qT_1 - {}^qT_2) \triangleright A = -2AB^*. \end{aligned} \tag{15b} $$

Comparing (15b) with (14b), we immediately observe that the $q\to 1$ limit of the $\mathrm{Fun}_q(\mathrm{SU}(2))$ action on the Podleś sphere indeed gives the Lie(AN) action induced by the projective formula (1).

The reader may find somewhat mysterious why the $q\to 1$ limit of $\mathrm{Fun}_q(\mathrm{SU}(2))$ contains Lie(AN) generators. The explanation of this fact resides in the famous Drinfeld duality principle which states that there is a natural identification of Hopf algebras $\mathrm{Fun}_g(G)$ and $\mathrm{U}_q(\mathcal{G}^*)$. Here G is a Poisson–Lie group and $\mathcal{G}^*$ is the Lie algebra of its dual Poisson–Lie group G^*. Let us indicate [a rigorous proof would require to give meaning to nonpolynomial functions appearing in (16b)] why the Drinfeld duality takes place in the case $G=\mathrm{SU}(2)$ and $G^*=AN$. The Lie algebra Lie(AN) is generated by three generators T_j, $j=0,1,2$, $T_j^*=-T_j$ obeying the following commutation relations:

$$ [T_0,T_1] = -T_1, \quad [T_0,T_2] = -T_2, \quad [T_1,T_2] = 0. \tag{17} $$

We set

$$ a = q^{T_0}\sqrt{1+q^2(\ln q)^2(T_1^2+T_2^2)}, \quad a^* = \sqrt{1+q^2(\ln q)^2(T_1^2+T_2^2)}\,q^{-T_0}, $$

$$ b = (\ln q)(iT_1 + T_2), \quad b^* = (\ln q)(iT_1 - T_2). \tag{16b} $$

Then it is not difficult to check two things: (1) the formulas (16b) and (17) imply the defining commutation relations (11a) of the Hopf algebra $\mathrm{Fun}_q(\mathrm{SU}(2))$; (2) it holds $\lim_{q\to 1}({}^qT_j) = T_j$.

Remark 1: Note that this explicit relation (16b) between $\mathrm{U}_q(\mathrm{Lie}(AN))$ and $\mathrm{Fun}_q(\mathrm{SU}(2))$ *degenerates* when $q\to 1$. This fact was important for establishing the limit $q\to 1$ of the Hopf adjoint action of $\mathrm{Fun}_q(\mathrm{SU}(2))$ on $\mathrm{Fun}_q(S^2)\subset\mathrm{Fun}_q(\mathrm{SU}(2))$. Indeed, it appears superficially that in the $q\to 1$ limit, the algebra $\mathrm{Fun}_q(\mathrm{SU}(2))$ becomes commutative and the adjoint action trivial. This observation is too naive, however, and the explanation of the paradox resides in the degeneration of the relation (16b) between the sets of generators T_j and a, a^*, b, b^* in the limit $q\to 1$.

Remark 2: We have established the correct $q\to 1$ limit of the quantum double action (7a) and (7b) by performing the detailed calculations with the generators, relations, etc. However, it is also possible to establish it on the conceptual level. First of all, the experts in Poisson–Lie groups and Hopf algebras know that the $q\to 1$ of the adjoint action (7b) of $\mathrm{U}_q(\mathcal{G}^*)$ on itself is indeed the dressing transformation of the Poisson–Lie group G by its dual Poisson–Lie group G^* [here $G=\mathrm{SU}(2)$ and $G^*=AN$]. The reader can find the detailed proof of this fact in the paper of Korogodsky (unpublished). The conceptual proof of the correct $q\to 1$ limit of the formula (7a) is even simpler. Indeed we have the following.

The standard left action of the enveloping algebra U(su(2)) on Fun(SU(2)) is given by left derivations, i.e., if X is an element of su(2) and $h(g)$ is in Fun(SU(2)) then we have

$$(X\triangleright h)(g)=\left.\frac{d}{dt}h(e^{-tX}g)\right|_{t=0}. \tag{18}$$

Recall the coproduct and the counit of the Hopf algebra structure of the nondeformed Fun(SU(2)),

$$(\Delta h)(g_1,g_2)=h(g_1g_2),\quad \varepsilon(h)=h(e),$$

where e is the group unit. Recall also that $S(X)=-X$ for $X\in\mathrm{su}(2)\subset\mathrm{U}(\mathrm{su}(2))$. Finally note the standard formula for the pairing $\langle .,.\rangle$ between $X\in\mathrm{su}(2)$ and $h\in\mathrm{Fun}(\mathrm{SU}(2))$:

$$-\langle X,h\rangle=\varepsilon(X\triangleright h).$$

Setting all of these pieces of information together, we see that (18) can be written as

$$(X\triangleright h)(g)=\left.\frac{d}{dt}h(e^{-tX}g)\right|_{t=0}=\langle S^{-1}(X),h'\rangle h''(g).$$

This is indeed the formula (7a) for $H=\mathrm{U}(\mathrm{su}(2))$ and $\tilde{H}=\mathrm{Fun}(\mathrm{SU}(2))$. In this way, we have verified that the action (7a) of $\mathrm{U}_q(\mathrm{su}(2))$ on $\mathrm{Fun}_q(\mathrm{SU}(2))$ [and, consequently on $\mathrm{Fun}_q(S^2)\subset\mathrm{Fun}_q(\mathrm{SU}(2))$] has the correct $q\to1$ limit, because it is well known that the left action of SU(2) on $S^2=\mathrm{SU}(2)/\mathrm{U}(1)$ is induced by the projective formula (1) for $\overline{\alpha}=\delta$, $\overline{\gamma}=-\beta$.

IV. CONCLUSIONS AND OUTLOOK

We have constructed the q-Lorentz group extension of the natural action of $\mathrm{U}_q(\mathrm{su}(2))$ on the Podleś sphere and shown that it can be naturally interpreted as the q-deformation of the projective formula $z\to(\alpha z+\beta)/(\gamma z+\delta)$ describing the global conformal transformation of the Riemann sphere. Our results are rather mathematical in nature but we believe that they can be used mainly in mathematical physics, e.g., in further studies of braided field theories (cf. Oeckl, 2001) and also in studies of q-differential operators (cf. the q-Dirac operator by Dąbrowski and Sitarz, 2003) on the Podleś sphere. Indeed, our studies suggest to investigate the symmetry properties of those objects not only from the point of view of the action of the $\mathrm{U}_q(\mathrm{su}(2))$ quantum group but also from the point of view of the action of its quantum double.

(Received 12 May 2004; accepted 29 July 2004; published 25 October 2004)

We consider a classical model in the kinetic theory of plasma—the Vlasov–Maxwell–Landau system. Global in time classical solutions near Maxwellians are constructed for hard potential and soft potential, i.e., $\gamma \geqslant -1$. The construction of global solution is based on an energy method. Meanwhile, global classical solutions of the Vlasov–Poisson–Landau system near Maxwellians for $\gamma \geqslant -1$ and the exponential decay of such solutions are obtained. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1803611]

I. INTRODUCTION

The dynamics of charged dilute particles in plasma physics can be described by the Vlasov–Maxwell–Landau system (see Refs. 1–3),

$$\partial_t F + v \cdot \nabla_x F + \frac{e}{m}\left\{E + \frac{v}{c} \times B\right\} \cdot \nabla_v F = Q[F,F], \quad F(0,x,v) = F_0(x,v), \tag{1.1}$$

where $F(t,x,v)$ is the spatially periodic distribution function for the particles at time $t \geqslant 0$, with spatial coordinates $x=(x_1,x_2,x_3) \in [-\pi,\pi]^3 = T^3$ and velocity $v=(v_1,v_2,v_3) \in R^3$. And e, m, and c denote the magnitude of their charges and mass, the light speed, respectively. The collision between particles is described by the following Landau operator:

$$\begin{aligned} Q[F,G] &= \nabla_v \cdot \left\{ \int_{R^3} \varphi(v-v_*)[F(v_*)\nabla_v G(v) - G(v)\nabla_v F(v_*)]\mathrm{d}v_* \right\} \\ &= \partial_i \int_{R^3} \varphi^{ij}(v-v_*)[F(v_*)\partial_j G(v) - G(v)\partial_j F(v_*)]\mathrm{d}v_*. \end{aligned}$$

In the case of an interaction force $\mathfrak{R}$ between the particles which depends on the interparticle distance r according to an inverse power law $\mathfrak{R}=r^{-s}$ with $s \geqslant 2$, $\varphi^{ij}(v)=\{\delta_{ij}-v_i v_j/|v|^2\}|v|^{\gamma+2}$ where $\gamma=(s-5)/(s-1)$. This leads to the usual classification in terms of hard potential ($\gamma>0$), Maxwellian molecules ($\gamma=0$) or soft potential ($\gamma<0$) (see Ref. 4). The present study is restricted to the case $\gamma \geqslant -1$.

The self-consistent, spatially periodic electromagnetic field $[E(t,x),B(t,x)]$ in (1.1) is coupled with $F(t,x,v)$ through the Maxwell system,

a)Electronic mail: yuhj@amss.ac.cn

$$\partial_t E - c\nabla \times B = -4\pi J = -4\pi \int_{R^3} ev F \, dv, \quad \nabla \cdot B = 0,$$

$$\partial_t B + c\nabla \times E = 0, \quad \nabla \cdot E = \rho = 4\pi \int_{R^3} e\{F - \mu\} dv, \tag{1.2}$$

$$E(0,x) = E_0(x), \quad B(0,x) = B_0(x).$$

The Vlasov–Maxwell–Landau system is a classical model in the kinetic theory of plasma and also arises in several branches of continuum physics. This system provides a statistical description of a plasma, in terms of its density $F(t,x,v)$, when the collisions moving particles are taken into account. There are two reduced descriptions of a high-temperature, low-density plasma. One is obtained by assuming that collisions are so rare that they are neglected. The associated model constitutes the Vlasov–Maxwell system, which is investigated by many authors (see Refs. 1 and 5–7). By neglecting the magnetic field ($B \equiv 0$ and $E = \nabla_x \phi$), one obtains the second reduced system, that is, the Vlasov–Poisson–Landau system,

$$\partial_t F + v \cdot \nabla_x F + \frac{c}{m} \nabla_x \phi \cdot \nabla_v F = Q[F,F],$$

$$\Delta \phi = 4\pi \int_{R^3} e\{F - u\} dv, \quad \int_{T^3} \phi \, dx = 0,$$

$$F(0,x,v) = F_0(x,v).$$

There are some investigations about the Vlasov–Poisson–Landau system (see Refs. 1,2,8,9,3). The purpose of this paper is to construct global classical solutions for (1.1) and (1.2) near a global Maxwellian $\mu = (n_0/e)(m/2\pi k T_0)^{3/2} e^{-m|v|^2/2kT_0}$. For convenience, we normalize all the physical constants involved in (1.1) and (1.2) to be one and let the global Maxwellian be $\mu(v) = e^{-|v|^2}$. We define the standard perturbation $f(t,x,v)$ to μ as $F = \mu + \mu^{1/2} f$. It is well known that $Q[\mu,\mu] = 0$. By expanding $Q[\mu + \mu^{1/2} g_1, \mu + \mu^{1/2} g_2]$, we define

$$Q[\mu + \mu^{1/2} g_1, \mu + \mu^{1/2} g_2] \equiv Q[\mu,\mu] + \mu^{1/2}\{K g_1 + A g_2 + \Gamma[g_1,g_2]\}.$$

The system (1.1) for $f(t,x,v)$ turns into

$$[\partial_t + v \cdot \nabla_x + (E + v \times B) \cdot \nabla_v] f - 2E \cdot v \mu^{1/2} + Lf = E \cdot v f + \Gamma[f,f], \tag{1.3}$$

with $f(0,x,v) = f_0(x,v)$ and $L = -A - K$. Notice that A, K, and Γ are defined in the same way as in Ref. 10, namely, $\sigma^i = \varphi^{ij} * [v_j \mu], \sigma^{ij} = \varphi^{ij} * \mu$,

$$Ag = \mu^{-1/2} \partial_i \{\mu^{1/2} \sigma^{ij} [\partial_j g + v_j g]\}, \quad Kg = -\mu^{1/2} \partial_i \{\mu [\varphi^{ij} * \{\mu^{1/2} [\partial_j g + v_j g]\}]\},$$

$$\begin{aligned} \Gamma[g_1,g_2] = {} & \partial_i [\{\varphi^{ij} * [\mu^{1/2} g_1]\} \partial_j g_2] - \{\varphi^{ij} * [v_i \mu^{1/2} g_1]\} \partial_j g_2 - \partial_i [\{\varphi^{ij} * [\mu^{1/2} \partial_j g_1]\} g_2] \\ & + \{\varphi^{ij} * [v_i \mu^{1/2} \partial_j g_1]\} g_2. \end{aligned}$$

The coupled Maxwell system takes the form

$$\partial_t E - c\nabla \times B = -J = -\int_{R^3} fv\mu^{1/2}\,\mathrm{d}v, \quad \nabla \cdot B = 0,$$

$$\partial_t B + c\nabla \times E = 0, \quad \nabla \cdot E = \rho = \int_{R^3} \mu^{1/2} f\,\mathrm{d}v, \tag{1.4}$$

$$E(0,x) = E_0(x), \quad B(0,x) = B_0(x).$$

Obviously, the conservation laws of mass, momentum, and energy of (1.1) hold

$$\frac{d}{\mathrm{d}t}\int_{R^3\times T^3} F(t) = \frac{d}{\mathrm{d}t}\left[\int_{R^3\times T^3} vF(t) + \int_{T^3} E(t)\times B(t)\right] = 0,$$

$$\frac{d}{\mathrm{d}t}\left[\int_{R^3\times T^3} |v|^2 F(t) + \int_{T^3} |E(t)|^2 + |B(t)|^2\right] = 0.$$

Notice that from the Maxwell system and the periodic boundary condition of $E(t,x), (d/\mathrm{d}t)\int_{T^3} B(t,x)\mathrm{d}x \equiv 0$. Thus we have a constant $\overline{B}$ such that $(1/|T^3|)\int_{T^3} B(t,x)\mathrm{d}x = \overline{B}$. By assuming that initially $[F_0, E_0, B_0]$ has the same mass, total momentum, and total energy as the steady state $[\mu, 0, \overline{B}]$, we can rewrite the conservation laws in the terms of the perturbation $[f, E, B]$ as

$$\int_{R^3\times T^3} f(t)\mu^{1/2} = \int_{R^3\times T^3} vf(t)\mu^{1/2} + \int_{T^3} E(t)\times B(t) = 0, \tag{1.5}$$

$$\int_{R^3\times T^3} |v|^2 f(t)\mu^{1/2} + \int_{T^3} |E(t)|^2 + |B(t) - \overline{B}|^2 = 0. \tag{1.6}$$

We shall use $(\cdot,\cdot)$ to denote either the standard L^2 inner product in T^3 or in $T^3\times R^3$. We shall use $\|\cdot\|$ to denote the corresponding norms. Let the multi-indices α and β be $\alpha = [\alpha_0, \alpha_1, \alpha_2, \alpha_3], \beta = [\beta_1, \beta_2, \beta_3]$ with $|\alpha| = \Sigma_{k=0}^3 \alpha_k$ and $|\beta| = \Sigma_{k=1}^3 \beta_k$. We define $\partial_\beta^\alpha \equiv \partial_t^{\alpha_0}\partial_{x_1}^{\alpha_1}\partial_{x_2}^{\alpha_2}\partial_{x_3}^{\alpha_3}\partial_{v_1}^{\beta_1}\partial_{v_2}^{\beta_2}\partial_{v_3}^{\beta_3}$. If each component of β is not greater than that of $\overline{\beta}$'s, we denote it by $\beta \leqslant \overline{\beta}$. We define $\beta < \overline{\beta}$ if $\beta \leqslant \overline{\beta}$, and $|\beta| < |\overline{\beta}|$. We denote $\binom{\beta}{\overline{\beta}}$ by $C_{\overline{\beta}}^{\beta}$.

We define the weighted norm and the high order energy norm as

$$|g|_\sigma^2 = \int_{R^3} [\sigma^{ij}\partial_i g\partial_j g + \sigma^{ij} v_i v_j g^2]\mathrm{d}v, \quad \|g\|_\sigma^2 = \int_{R^3\times T^3} [\sigma^{ij}\partial_i g\partial_j g + \sigma^{ij} v_i v_j g^2]\mathrm{d}x\,\mathrm{d}v,$$

$$E(f(t,x,v)) \equiv \sum_{|\alpha|+|\beta|\leqslant N}\left[\frac{1}{2}\|\partial_\beta^\alpha f(t)\|^2 + \int_0^t \|\partial_\beta^\alpha f(s)\|_\sigma^2\,\mathrm{d}s\right] + \sum_{|\alpha|\leqslant N}[\|\partial^\alpha E(t)\|^2 + \|\partial^\alpha B(t)\|^2],$$

with the initial energy

$$E(f_0) = E(f(0)) \equiv \sum_{|\alpha|+|\beta|\leqslant N}\frac{1}{2}\|\partial_\beta^\alpha f_0\|^2 + \sum_{|\alpha|\leqslant N}[\|\partial^\alpha E_0\|^2 + \|\partial^\alpha B_0\|^2].$$

Throughout this paper, $N \geqslant 8$. The main result in this paper is as follows.

Theorem 1.1: *Assume that $[f_0, E_0, B_0]$ satisfies the conservation laws (1.5) and (1.6). Let $F_0(x,v) = \mu + \mu^{1/2} f_0 \geqslant 0$. There exist $C_0 > 0$ and $M > 0$ such that if $E(f_0) \leqslant M$, then there exists a unique global solution $f(t,x,v)$ to the system (1.3) and (1.4). Moreover, $F(t,x,v) = \mu$*

$+\mu^{1/2}f(t,x,v)\geqslant 0$ *and* $\sup_{0\leqslant t\leqslant\infty}E(f(t))\leqslant C_0E(f_0)$.

For the simpler Vlasov–Poisson–Landau system from (1.3) and (1.4), we have

$$[\partial_t + v\cdot\nabla_x + \nabla_x\phi\cdot\nabla_v]f - 2\nabla_x\phi\cdot v\mu^{1/2} + Lf = \nabla_x\phi\cdot vf + \Gamma[f,f],$$

$$\Delta\phi = \int_{R^3}\mu^{1/2}f\,dv, \quad \int_{T^3}\phi\,dx = 0, \tag{1.7}$$

$$f(0,x,v) = f_0(x,v).$$

We define the same energy norm as the above with $B\equiv 0$ and $E=\nabla_x\phi$. The conservation laws of mass, momentum, and total energy are

$$\int_{R^3\times T^3} f(t)\mu^{1/2} = \int_{R^3\times T^3} vf(t)\mu^{1/2} = 0, \tag{1.8}$$

$$\int_{R^3\times T^3}|v|^2f(t)\mu^{1/2} + \int_{T^3}|\nabla_x\phi(t)|^2 = 0. \tag{1.9}$$

We have the following result for the decay of such a simpler system.

Theorem 1.2: *Assume that f_0 satisfies (1.8) and (1.9). Let $F_0(x,v)=\mu+\mu^{1/2}f_0\geqslant 0$. There exist $C_0>0$ and $M>0$ such that if $E(f_0)\leqslant M$, then there exists a unique global solution $f(t,x,v)$ to the system (1.7). Moreover, $F(t,x,v)=\mu+\mu^{1/2}f(t,x,v)\geqslant 0$ and $\sup_{0\leqslant t\leqslant\infty}E(f(t))\leqslant C_0E(f_0)$.*

Moreover, there is a $\delta^*>0$ such that

$$\sum_{|\alpha|+|\beta|\leqslant N}\|\partial_\beta^\alpha f(t)\|\leqslant E^{1/2}(f_0)e^{-\delta^* t}.$$

Although there are some research about the dynamical problems of the Landau equation (see Refs. 1,4,2,11,12,10,13,14,8,9,3), but few global classical solutions have been constructed except for Refs. 11,12,10, especially little for soft potential, i.e., $\gamma<0$ as pointed out by Desvillettes and Villani in Refs. 11,12, where they have constructed global classical solutions to the spatially homogeneous Landau equation for hard potential $0<\gamma\leqslant 1$. Guo first obtains the global classical solution of the Vlasov–Poisson–Boltzmann near Maxwellians under the hard sphere condition in the pioneering paper, Ref. 15. And then he also shows in Ref. 16 that under the hard sphere condition, global classical solution of the Vlasov–Maxwell–Boltzmann near Maxwellians can be constructed, which is the first result of global solution in this direction. In Ref. 10, the first global classical solution of the Landau equation with $\gamma\geqslant -3$ near Maxwellians can be obtained by original energy method. Zhan establishes the local existence of weak solution of the system (1.1) and (1.2) with initial data of unrestricted size in Ref. 3.

Motivated by the framework used in Ref. 16, we establish the existence and uniqueness of global in time classical solution of the system (1.1) and (1.2) near Maxwellians for both hard potential and soft potential, i.e., $\gamma\geqslant -1$. Although our construction of global solutions is based on an energy method developed in Refs. 15,16,10, we cannot obtain the crucial positivity of the linearized Landau operator L by using the similar argument developed in Refs. 15,17,10. This is because either $-\int E\times B$ in the momentum conservation in (1.5) or $-\|E(t)\|-\|B(t)-\overline{B}\|$ in the reduced energy conservation (1.6) cannot be controlled by $o(1)\|\partial_\beta^\alpha f(t)\|$, due to the presence of the magnetic field $[E(t,x),B(t,x)]$. Instead, we revised the methods in Ref. 16 to obtain it. Furthermore, we introduce the norm $\|\cdot\|_\sigma$ in the total energy and use the following inequality (1.14) with $\gamma\geqslant -1$ in order to control the product of the term $\partial_\beta[vf]$ and the term $\partial_\beta f$ in the energy estimate. However, we cannot control this product by (1.14) when $\gamma<-1$. As for this problem, we consider it in the future.

In the following we give some lemmas which can be found in Ref. 10.

Lemma 1.3: *Let* $|\beta|>0, |\alpha|+|\beta|\leqslant N$. *Then for small* $\eta>0$, *there exists* $C>0$ *and* $C_\eta>0$ *such that*

$$-(\partial_\beta[Ag],\partial_\beta g)\geqslant \|\partial_\beta g\|_\sigma^2-\eta\sum_{|\beta_1|\leqslant|\beta|}\|\partial_{\beta_1} g\|_\sigma^2-C_\eta\|\mu g\|^2, \tag{1.10}$$

$$|(\partial_\beta[Kg_1],\partial_\beta g_2)|\leqslant\left\{\eta\sum_{|\beta_1|\leqslant|\beta|}\|\partial_{\beta_1} g_1\|_\sigma+C_\eta\|\mu g_1\|\right\}\|\partial_\beta g_2\|_\sigma, \tag{1.11}$$

$$\begin{aligned}(\partial_\beta^\alpha\Gamma[g_1,g_2],\partial_\beta^\alpha g_3)\leqslant C\Bigg[&\left\{\sum_{\alpha_1\leqslant\alpha,\beta_1\leqslant\beta}\|\partial_{\beta_1}^{\alpha_1} g_1\|\right\}\left\{\sum_{\alpha_1\leqslant\alpha,\beta_1\leqslant\beta}\|\partial_{\beta_1}^{\alpha_1} g_2\|_\sigma\right\}+\left\{\sum_{\alpha_1\leqslant\alpha,\beta_1\leqslant\beta}\|\partial_{\beta_1}^{\alpha_1} g_1\|_\sigma\right\}\\&\times\left\{\sum_{\alpha_1\leqslant\alpha,\beta_1\leqslant\beta}\|\partial_{\beta_1}^{\alpha_1} g_2\|\right\}\Bigg]\|\partial_\beta^\alpha g_3\|_\sigma.\end{aligned} \tag{1.12}$$

It is well known that the linearized collision operator L is non-negative. And for fixed (t,x), the null space of L is the five dimensional space of $N=\mathrm{span}\{1,v_i,|v|^2\}\mu^{1/2}$, where $1\leqslant i\leqslant 3$. We denote $\{1,v_i,|v|^2\}\mu^{1/2}$ as $\{e_1,e_2,e_3,e_4,e_5\}$ in Ref. 7. We define a projection P_0 in $L^2(R^3)$ for any fixed x as $P_0g(x,v)=\Sigma(g(x,\cdot),e_j)e_j$ and $P_1=I-P_0$ where I is the identity operator.

Lemma 1.4: For any $m>1$, *there is* $0<C(m)<\infty$, *such that*

$$|(\partial_i\sigma^j g_1,g_2)|+|(Kg_1,g_2)|\leqslant\frac{C}{m}|g_1|_\sigma|g_2|_\sigma+C(m)\left\{\int_{|v|\leqslant C(m)}|g_1|^2\,\mathrm{d}v\right\}^{1/2}\left\{\int_{|v|\leqslant C(m)}|g_2|^2\,\mathrm{d}v\right\}^{1/2}. \tag{1.13}$$

Moreover, we have that there exists $c>0$ *and* $\delta>0$ *such that*

$$\|g\|_\sigma^2\geqslant c\|[1+|v|]^{(\gamma+2)/2}g\|^2, \tag{1.14}$$

$$(Lg,g)\geqslant\delta\|P_1g\|_\sigma^2. \tag{1.15}$$

Lemma 1.5: Let $\chi(v)$ *be a smooth function so that* $\{|\chi|+|\nabla\chi|+|\nabla^2\chi|\leqslant C\mu(v/4)$, *then*

$$\left\|\int\partial^\alpha\Gamma[g_1,g_2]\chi\,\mathrm{d}v\right\|\leqslant C\left\{\sum_{|\alpha_1|\leqslant N}\|\partial^{\alpha_1} g_1\|\right\}\left\{\sum_{|\alpha_1|\leqslant N}\|\partial^{\alpha_1} g_2\|_\sigma\right\}. \tag{1.16}$$

II. ENERGY ESTIMATES

The goal in this section is to construct local in time solutions to the system (1.3) and (1.4). The construction is based on a uniform energy estimate for the following sequence of iterating approximate solutions:

$$[\partial_t+v\cdot\nabla_x+(E^n+v\times B^n)\cdot\nabla_v]F^{n+1}=Q[F^n,F^{n+1}],$$

$$F^{n+1}(0,x,v)=F_0(x,v),$$

together with the coupled Maxwell system:

$$\partial_t E^n - \nabla \times B^n = -J^n = -\int_{R^3} v F^n \, dv, \quad \nabla \cdot B^n = 0,$$

$$\partial_t B^n + \nabla \times E^n = 0, \quad \nabla \cdot E^n = \rho^n = \int_{R^3} \{F^n - \mu\} dv,$$

$$E^n(0,x) = E_0(x), \quad B^n(0,x) = B_0(x).$$

We start with $F^0(t,x,v) = F_0(x,v)$. And then $[E^0(t,x), B^0(t,x)]$ is solved through the Maxwell system with initial datum $[E_0(x), B_0(x)]$. Since $F^{n+1} = \mu + \mu^{1/2} f^{n+1}$, we need to solve f^{n+1} such that

$$\begin{aligned} &[\partial_t + v \cdot \nabla_x + (E^n + v \times B^n) \cdot \nabla_v - (E^n \cdot v) - A] f^{n+1} - 2E^n \cdot v \mu^{1/2} - K f^n = \Gamma[f^n, f^{n+1}], \\ &\partial_t E^n - \nabla \times B^n = -J^n = -\int_{R^3} v f^n \mu^{1/2} \, dv, \quad \nabla \cdot B^n = 0, \end{aligned} \tag{2.1}$$

$$\begin{aligned} &\partial_t B^n + \nabla \times E^n = 0, \quad \nabla \cdot E^n = \rho^n = \int_{R^3} f^n \mu^{1/2} \, dv, \\ &E^n(0,x) = E_0(x), \quad B^n(0,x) = B_0(x), \quad f^{n+1}(0,x,v) = f_0(x,v), \end{aligned} \tag{2.2}$$

starting with $f^0(t,x,v) = f_0(x,v)$. Our goal is to get a uniformly in n estimate for $E(f^{n+1}(t))$. The crucial energy estimate is as follows:

Lemma 2.1: The sequence $\{F^n\}$ is well defined and non-negative. Moreover, there exist $T^*(E(f_0)) > 0$ and $C > 0$ such that for $0 \leq t \leq T^*$ and $E(f_0)$ sufficiently small, then

$$\sup_k E(f^k(t)) \leq C E(f_0). \tag{2.3}$$

Proof: The proof is based on an induction over k. Clearly (2.3) holds when $k = 0$. Assume (2.3) is valid for $k = n$ so that $F^n \geq 0$. We notice that $Q[F^n, F^{n+1}]$ can be written as the linear form on F^{n+1} (see Ref. 10) and then (2.1) is a linear equation on F^{n+1}. For given $F^n \geq 0$, there exists a solution F^{n+1} to the linear equation (2.1). Moreover, $F^{n+1} \geq 0$ since $F_0(x,v) \geq 0$.

To prove (2.3) for $k = n+1$, the first step is to estimate the ∂_β^α derivatives of f^{n+1}. Taking ∂_β^α $(\beta \neq 0)$ of (2.1), multiplying $\partial_\beta^\alpha f^{n+1}$, and then integrating over $T^3 \times R^3$, we obtain

$$\begin{aligned} &\frac{1}{2} \frac{d}{dt} \|\partial_\beta^\alpha f^{n+1}\|^2 - (\partial_\beta A[\partial^\alpha f^{n+1}], \partial_\beta^\alpha f^{n+1}) - (\partial_\beta K[\partial^\alpha f^n], \partial_\beta^\alpha f^{n+1}) \\ &\quad = (\partial_\beta^\alpha \Gamma[f^n, f^{n+1}], \partial_\beta^\alpha f^{n+1}) - \sum_{j, \beta_1 < \beta} (C_\beta^{\beta_1} \partial_{\beta - \beta_1} v_j \partial^j \partial_{\beta_1}^\alpha f^{n+1}, \partial_\beta^\alpha f^{n+1}) + (\partial_\beta^\alpha [E^n \cdot v f^{n+1}], \partial_\beta^\alpha f^{n+1}) \\ &\qquad + 2(\partial^\alpha E^n \cdot \partial_\beta [v \mu^{1/2}], \partial_\beta^\alpha f^{n+1}) - \sum_{0 \neq \alpha_1 \leq \alpha} C_\alpha^{\alpha_1} (\partial^{\alpha_1} E^n \cdot \partial_\beta^{\alpha - \alpha_1} \nabla_v f^{n+1}, \partial_\beta^\alpha f^{n+1}) \\ &\qquad - \sum_{0 \neq \alpha_1 \leq \alpha, 0 \neq \beta_1 \leq \beta} C_\alpha^{\alpha_1} C_\beta^{\beta_1} (\partial_{\beta_1} v \times \partial^{\alpha_1} B^n \cdot \partial_\beta^{\alpha - \alpha_1} \nabla_v f^{n+1}, \partial_\beta^\alpha f^{n+1}). \end{aligned} \tag{2.4}$$

We now estimate (2.4) term by term. For any $\eta > 0$, applying Lemma 1.3 and $\|\mu g\| \leq C \|g\|_\sigma$, we deduce

$$
\begin{aligned}
-(\partial_\beta A[\partial^\alpha f^{n+1}],\partial_\beta^\alpha f^{n+1}) &\geqslant \|\partial_\beta^\alpha f^{n+1}\|_\sigma^2 - \eta \sum_{|\beta_1|\leqslant|\beta|} \|\partial_{\beta_1}^\alpha f^{n+1}\|_\sigma^2 - C_\eta \|\partial^\alpha f^{n+1}\|_\sigma^2,\\
-(\partial_\beta K[\partial^\alpha f^n],\partial_\beta^\alpha f^{n+1}) &\geqslant -\left\{\eta \sum_{|\beta_1|\leqslant|\beta|} \|\partial_{\beta_1}^\alpha f^n\|_\sigma + C_\eta \|\mu\partial^\alpha f^n\|\right\}\|\partial_\beta^\alpha f^{n+1}\|_\sigma\\
&\geqslant -\eta \sum_{|\beta_1|\leqslant|\beta|} \|\partial_{\beta_1}^\alpha f^n\|_\sigma^2 - \eta\|\partial_\beta^\alpha f^{n+1}\|_\sigma^2 - C_\eta\|\mu\partial^\alpha f^n\|^2.
\end{aligned}
\tag{2.5}
$$

We now estimate the second term on the right-hand side of (2.4).

$$
\begin{aligned}
\sum_{j,\beta_1<\beta} (C_\beta^{\beta_1}\partial_{\beta-\beta_1} v_j \partial^j \partial_{\beta_1}^\alpha f^{n+1}, \partial_\beta^\alpha f^{n+1}) &\leqslant C \sum_{j,\beta_1<\beta} \|\partial_\beta^\alpha f^{n+1}\|\,\|\partial^j \partial_{\beta-\beta_1}^\alpha f^{n+1}\|\\
&\leqslant \sum_{j,\beta_1<\beta} [\eta\|\partial_\beta^\alpha f^{n+1}\|^2 + C_\eta\|\partial^j\partial_{\beta-\beta_1}^\alpha f^{n+1}\|^2].
\end{aligned}
\tag{2.6}
$$

The fourth term on the right-hand side of (2.4) is bounded by

$$
2(\partial^\alpha E^n \cdot \partial_\beta[v\mu^{1/2}],\partial_\beta^\alpha f^{n+1}) \leqslant C\|\partial^\alpha E^n\|\,\|\partial_\beta^\alpha f^{n+1}\|. \tag{2.7}
$$

We now estimate the fifth term on the right-hand side of (2.4). Recalling that $W^{4,1}(T^3)\subset L^\infty(T^3)$, we have

$$
\begin{aligned}
\sup_x\left[\int_{R^3} |g(x,u)|^2\,\mathrm{d}u\right] &\leqslant C\sum_{|\ell|\leqslant 4}\int_{T^3}\left|\partial^\ell\int_{R^3} g(x,u)\mathrm{d}u\right|^2\mathrm{d}x\\
&\leqslant C\sum_{|\ell_1|+|\ell_2|\leqslant 4}\int_{T^3\times R^3}|\partial^{\ell_1}g(x,u)\partial^{\ell_2}g(x,u)|\mathrm{d}u\,\mathrm{d}x \leqslant C\sum_{|\ell|\leqslant 4}\|\partial^\ell g(x,u)\|^2.
\end{aligned}
\tag{2.8}
$$

We separate two cases. If $|\alpha_1|\geqslant 5$, then $|\alpha-\alpha_1|+4\leqslant|\alpha|-1$. From (2.8), we have

$$
\begin{aligned}
-\sum_{0\neq\alpha_1\leqslant\alpha} C_\alpha^{\alpha_1}(\partial^{\alpha_1}E^n\cdot\partial_\beta^{\alpha-\alpha_1}\nabla_v f^{n+1},\partial_\beta^\alpha f^{n+1}) &\leqslant C\sum_{0\neq\alpha_1\leqslant\alpha}\int_{T^3}|\partial^{\alpha_1}E^n|\\
&\quad\times\left\{\int|\partial_\beta^{\alpha-\alpha_1}\nabla_v f^{n+1}|^2\,\mathrm{d}v\right\}^{1/2}\left\{\int|\partial_\beta^\alpha f^{n+1}|^2\,\mathrm{d}v\right\}^{1/2}\mathrm{d}x\\
&\leqslant C\sum_{0\neq\alpha_1\leqslant\alpha}\|\partial^{\alpha_1}E^n\|\sup_x\left\{\int|\partial_\beta^{\alpha-\alpha_1}\nabla_v f^{n+1}|^2\,\mathrm{d}v\right\}^{1/2}\|\partial_\beta^\alpha f^{n+1}\|\\
&\leqslant C\left\{\sum_{0\neq\alpha_1\leqslant\alpha}\|\partial^{\alpha_1}E^n\|\right\}\cdot\sum_{|\ell|\leqslant|\alpha-\alpha_1|+4}\|\partial_\beta^\ell\nabla_v f^{n+1}\|\cdot\|\partial_\beta^\alpha f^{n+1}\|\\
&\leqslant C\left\{\sum_{0\neq\alpha_1\leqslant\alpha}\|\partial^{\alpha_1}E^n\|\right\}\cdot\sum_{|\ell|\leqslant|\alpha|-1}\|\partial_\beta^\ell\nabla_v f^{n+1}\|\cdot\|\partial_\beta^\alpha f^{n+1}\|.
\end{aligned}
$$

On the other hand, if $|\alpha_1|\leqslant 4$ and $|\alpha_1|+1\leqslant 5$, we have

$$
\begin{aligned}
-\sum_{0\neq\alpha_1\leqslant\alpha} C_\alpha^{\alpha_1}(\partial^{\alpha_1}E^n\cdot\partial_\beta^{\alpha-\alpha_1}\nabla_v f^{n+1},\partial_\beta^\alpha f^{n+1}) &\leqslant C\sum_{0\neq\alpha_1\leqslant\alpha}\sup_x|\partial^{\alpha_1}E^n|\cdot\|\partial_\beta^{\alpha-\alpha_1}\nabla_v f^{n+1}\|\cdot\|\partial_\beta^\alpha f^{n+1}\|\\
&\leqslant C\sum_{0\neq\alpha_1\leqslant\alpha}\|\partial^{\alpha_1}E^n\|_{H^2}\|\partial_\beta^{\alpha-\alpha_1}\nabla_v f^{n+1}\|\cdot\|\partial_\beta^\alpha f^{n+1}\|\\
&\leqslant C\Big\{\sum_{|\ell|\leqslant|\alpha_1|+2}\|\partial^\ell E^n\|\Big\}\cdot\sum_{0\neq\alpha_1\leqslant\alpha}\|\partial_\beta^{\alpha-\alpha_1}\nabla_v f^{n+1}\|\cdot\|\partial_\beta^\alpha f^{n+1}\|.
\end{aligned}
$$

We thus have a unified estimate ($N\geqslant 8$) for the fifth term as

$$
-\sum_{0\neq\alpha_1\leqslant\alpha} C_\alpha^{\alpha_1}(\partial^{\alpha_1}E^n\cdot\partial_\beta^{\alpha-\alpha_1}\nabla_v f^{n+1},\partial_\beta^\alpha f^{n+1})\leqslant C\Big\{\sum_{|\ell|\leqslant N}\|\partial^\ell E^n\|\Big\}\cdot\Big\{\sum_{|\ell|+|\lambda|\leqslant N}\|\partial_\lambda^\ell f^{n+1}\|\Big\}\cdot\|\partial_\beta^\alpha f^{n+1}\|. \tag{2.9}
$$

We now estimate the third term on the right-hand side of (2.4). In the case $|\alpha_1|\geqslant 5, |\alpha-\alpha_1|+4\leqslant|\alpha|-1$. From (1.14) in Lemma 1.4 with $\gamma\geqslant -1$, we have

$$
\begin{aligned}
&\sum_{\alpha_1\leqslant\alpha} C_\alpha^{\alpha_1}(\partial^{\alpha_1}E^n\cdot\partial_\beta^{\alpha-\alpha_1}[vf^{n+1}],\partial_\beta^\alpha f^{n+1})\\
&\quad\leqslant C\sum_{\alpha_1\leqslant\alpha}\int_{T^3}|\partial^{\alpha_1}E^n|\Big\{\sum_{\beta_1\leqslant\beta}\int(1+|v|)|\partial_{\beta_1}^{\alpha-\alpha_1}f^{n+1}|^2\,dv\Big\}^{1/2}\cdot\Big\{\int(1+|v|)|\partial_\beta^\alpha f^{n+1}|^2\,dv\Big\}^{1/2}dx\\
&\quad\leqslant C\Big\{\sum_{\alpha_1\leqslant\alpha}\|\partial^{\alpha_1}E^n\|\Big\}\sup_x\Big\{\sum_{\beta_1\leqslant\beta}\int(1+|v|)|\partial_{\beta_1}^{\alpha-\alpha_1}f^{n+1}|^2\,dv\Big\}^{1/2}\cdot\|\partial_\beta^\alpha f^{n+1}\|_\sigma\\
&\quad\leqslant C\Big\{\sum_{\alpha_1\leqslant\alpha}\|\partial^{\alpha_1}E^n\|\Big\}\cdot\Big\{\sum_{|\ell|\leqslant|\alpha-\alpha_1|+4,\beta_1\leqslant\beta}\|(1+|v|)^{1/2}\partial_{\beta_1}^\ell f^{n+1}\|\Big\}\cdot\|\partial_\beta^\alpha f^{n+1}\|_\sigma\\
&\quad\leqslant C\Big\{\sum_{\alpha_1\leqslant\alpha}\|\partial^{\alpha_1}E^n\|\Big\}\cdot\Big\{\sum_{|\ell|\leqslant|\alpha-\alpha_1|+4,\beta_1\leqslant\beta}\|\partial_{\beta_1}^\ell f^{n+1}\|_\sigma\Big\}\cdot\|\partial_\beta^\alpha f^{n+1}\|_\sigma.
\end{aligned}
$$

Similarly, for $|\alpha_1|\leqslant 4$,

$$
\begin{aligned}
\sum_{\alpha_1\leqslant\alpha} C_\alpha^{\alpha_1}(\partial^{\alpha_1}E^n\cdot\partial_\beta^{\alpha-\alpha_1}[vf^{n+1}],\partial_\beta^\alpha f^{n+1}) &\leqslant C\sum_{\alpha_1\leqslant\alpha}\sup_x|\partial^{\alpha_1}E^n|\cdot\Big\{\sum_{\beta_1\leqslant\beta}\|(1+|v|)^{1/2}\partial_{\beta_1}^{\alpha-\alpha_1}f^{n+1}\|\Big\}\\
&\quad\times\{\|(1+|v|)^{1/2}\partial_\beta^\alpha f^{n+1}\|\}\\
&\leqslant C\Big\{\sum_{|\ell|\leqslant|\alpha_1|+2}\|\partial^\ell E^n\|\Big\}\cdot\Big\{\sum_{\alpha_1\leqslant\alpha,\beta_1\leqslant\beta}\|\partial_{\beta_1}^{\alpha-\alpha_1}f^{n+1}\|_\sigma\Big\}\cdot\|\partial_\beta^\alpha f^{n+1}\|_\sigma.
\end{aligned}
$$

We thus conclude from $N\geqslant 8$ that the third term is bounded by

$$
\sum_{\alpha_1\leqslant\alpha} C_\alpha^{\alpha_1}(\partial^{\alpha_1}E^n\cdot\partial_\beta^{\alpha-\alpha_1}[vf^{n+1}],\partial_\beta^\alpha f^{n+1})\leqslant C\Big\{\sum_{|\ell|\leqslant N}\|\partial^\ell E^n\|\Big\}\cdot\Big\{\sum_{|\ell|+|\lambda|\leqslant N}\|\partial_\lambda^\ell f^{n+1}\|_\sigma\Big\}\cdot\|\partial_\beta^\alpha f^{n+1}\|_\sigma. \tag{2.10}
$$

By the estimate similar to the above, we have that the sixth term on the right-hand side of (2.4) is bounded by

$$
C\Big\{\sum_{|\ell|\leqslant N}\|\partial^\ell B^n\|\Big\}\cdot\Big\{\sum_{|\ell|+|\lambda|\leqslant N}\|\partial_\lambda^\ell f^{n+1}\|_\sigma\Big\}\cdot\|\partial_\beta^\alpha f^{n+1}\|_\sigma. \tag{2.11}
$$

Finally, we estimate the nonlinear collision terms in (2.4). Applying (1.12) in Lemma 1.3, we have

$$(\partial_\beta^\alpha \Gamma[f^n, f^{n+1}], \partial_\beta^\alpha f^{n+1}) \leqslant C\Big[\Big\{\sum \|\partial_{\beta_1}^{\alpha_1} f^n\|\Big\}\Big\{\sum \|\partial_{\beta_1}^{\alpha_1} f^{n+1}\|_\sigma\Big\} + \Big\{\sum \|\partial_{\beta_1}^{\alpha_1} f^n\|_\sigma\Big\}\Big\{\sum \|\partial_{\beta_1}^{\alpha_1} f^{n+1}\|\Big\}\Big]\|\partial_\beta^\alpha f^{n+1}\|_\sigma. \tag{2.12}$$

Integrating over $[0,t]$ of (2.4), collecting the above estimate, and applying the elementary inequality, we have

$$\begin{aligned}
&\frac{1}{2}\|\partial_\beta^\alpha f^{n+1}(t)\|^2 + [\|\partial^\alpha E^{n+1}(t)\|^2 + \|\partial^\alpha B^{n+1}(t)\|^2] + \int_0^t \|\partial_\beta^\alpha f^{n+1}(s)\|_\sigma^2 ds \\
&\leqslant \frac{1}{2}\|\partial_\beta^\alpha f_0\|^2 + [\|\partial^\alpha E_0\|^2 + \|\partial^\alpha B_0\|^2] + C\int_0^t \Big\{\sum_{|\alpha|\leqslant N} \|\partial^\alpha E\|\Big\} \cdot \Big\{\sum_{|\alpha|+|\lambda|\leqslant N} \|\partial_\lambda^\alpha f^{n+1}(s)\|\Big\} ds \\
&\quad + C\int_0^t \sum_{|\alpha_1|\leqslant N} \|\partial^{\alpha_1} f^n(s)\|^2\, ds + C_\eta \int_0^t \sum_{|\alpha_1|\leqslant N} \|\mu \partial^{\alpha_1} f^n(s)\|^2\, ds + \int_0^t C\Big\{\sum_{|\ell|\leqslant N} [\|\partial^\ell E^n\| + \|\partial^\ell B^n\|]\Big\} \\
&\quad \times \Big\{\sum_{|\ell|+|\lambda|\leqslant N} \|\partial_\lambda^\ell f^{n+1}\|_\sigma\Big\} \cdot \|\partial_\beta^\alpha f^{n+1}\|_\sigma\, ds + C\eta \int_0^t \sum_{|\alpha_1|+|\beta_1|\leqslant N} \|\partial_\beta^\alpha f^{n+1}(s)\|_\sigma^2\, ds \\
&\quad + C_\eta \int_0^t \sum_{|\alpha_1|\leqslant N} \|\partial^{\alpha_1} f^{n+1}(s)\|_\sigma^2\, ds + C\int_0^t \Big\{\sum_{|\alpha_1|+|\beta_1|\leqslant N} \|\partial_{\beta_1}^{\alpha_1} f^n(s)\|\Big\}\Big\{\sum_{|\alpha_1|+|\beta_1|\leqslant N} \|\partial_{\beta_1}^{\alpha_1} f^{n+1}(s)\|_\sigma\Big\} \\
&\quad \times \|\partial_\beta^\alpha f^{n+1}(s)\|_\sigma\, ds + C\int_0^t \Big\{\sum_{|\alpha_1|+|\beta_1|\leqslant N} \|\partial_{\beta_1}^{\alpha_1} f^n(s)\|_\sigma\Big\}\Big\{\sum_{|\alpha_1|+|\beta_1|\leqslant N} \|\partial_{\beta_1}^{\alpha_1} f^{n+1}(s)\|\Big\}\|\partial_\beta^\alpha f^{n+1}(s)\|_\sigma\, ds.
\end{aligned} \tag{2.13}$$

In the following we consider ∂^α derivatives. Taking ∂^α of (2.1), we get

$$\begin{aligned}
&[\partial_t + v\cdot\nabla_x + (E^n + v\times B^n)\cdot\nabla_v - A]\partial^\alpha f^{n+1} - K[\partial^\alpha f^n] - 2[\partial^\alpha E^n \cdot v]\mu^{1/2} + \partial^\alpha[E^n \cdot v f^{n+1}] \\
&\quad + \sum_{0\neq\alpha_1\leqslant\alpha} C_\alpha^{\alpha_1}[\partial^{\alpha_1} E^n + v\times\partial^{\alpha_1} B^n]\partial^{\alpha-\alpha_1}\nabla_v f^{n+1} = \partial^\alpha \Gamma[f^n, f^{n+1}],
\end{aligned} \tag{2.14}$$

Applying (1.12) in Lemma 1.3 yields

$$\begin{aligned}
(\partial^\alpha \Gamma[f^n, f^{n+1}], \partial^\alpha f^{n+1}) \leqslant C\Bigg[\sum_{|\alpha_1|\leqslant N} \|\partial^{\alpha_1} f^{n+1}\|_\sigma\Bigg]\Bigg\{\Bigg[\sum_{|\alpha_1|\leqslant N} \|\partial^{\alpha_1} f^n\|\Bigg]\Bigg[\sum_{|\alpha_1|\leqslant N} \|\partial^{\alpha_1} f^{n+1}\|_\sigma\Bigg] \\
+ \Bigg[\sum_{|\alpha_1|\leqslant N} \|\partial^{\alpha_1} f^n\|_\sigma\Bigg]\Bigg[\sum_{|\alpha_1|\leqslant N} \|\partial^{\alpha_1} f^{n+1}\|\Bigg]\Bigg\}.
\end{aligned} \tag{2.15}$$

We notice, from Lemma 1.3 and (1.13) (see Ref. 10), that for any $\eta > 0$ small,

$$\begin{aligned}
-\int_0^t (A[\partial^\alpha f^{n+1}], \partial^\alpha f^{n+1}) - \int_0^t (K[\partial^\alpha f^n], \partial^\alpha f^{n+1}) \geqslant \frac{3}{4}\int_0^t \|\partial^\alpha f^{n+1}(s)\|_\sigma^2\, ds - C\int_0^t \|\partial^\alpha f^{n+1}(s)\|^2\, ds \\
- \eta\int_0^t \|\partial^\alpha f^n(s)\|_\sigma^2\, ds - C_\eta \int_0^t \|\mu\partial^\alpha f^n(s)\|^2\, ds.
\end{aligned} \tag{2.16}$$

It is easily founded that

$$-2[\partial^\alpha E^n \cdot v]\mu^{1/2} = -2[\partial^\alpha E^{n+1}\cdot v]\mu^{1/2} - 2[\partial^\alpha E^{n+1} - \partial^\alpha E^n]\cdot v\mu^{1/2}.$$

Notice that from Maxwell system, the inner product of the first term on the right-hand side of the above equality with $\partial^\alpha f^{n+1}$ is

$$-\int 2\partial^\alpha E^{n+1}\cdot v\mu^{1/2}\partial^\alpha f^{n+1} = -\int 2\partial^\alpha E^{n+1}\partial^\alpha J^{n+1}\,dx = \frac{d}{dt}[\|\partial^\alpha E^{n+1}(t)\|^2 + \|\partial^\alpha B^{n+1}(t)\|^2]. \tag{2.17}$$

And the inner product of the second term with $\partial^\alpha f^{n+1}$ is bounded by

$$C[\|\partial^\alpha E^n\| + \|\partial^\alpha E^{n+1}\|]\|\partial^\alpha_\beta f^{n+1}\|.$$

Multiplying both sides of (2.14) by $\partial^\alpha f^{n+1}$ and using (2.9), (2.11), and (2.15)–(2.17), then integrating over $T^3\times R^3$, we are able to obtain

$$\begin{aligned}
&\frac{1}{2}\|\partial^\alpha f^{n+1}\|^2 + [\|\partial^\alpha E^{n+1}(t)\|^2 + \|\partial^\alpha B^{n+1}(t)\|^2] + \frac{3}{4}\int_0^t \|\partial^\alpha f^{n+1}(s)\|_\sigma^2\,ds \\
&\leqslant \frac{1}{2}\|\partial^\alpha f_0\|^2 + [\|\partial^\alpha E_0\|^2 + \|\partial^\alpha B_0\|^2] + C\int_0^t \|\partial^\alpha f^{n+1}(s)\|^2\,ds + C\int_0^t [\|\partial^\alpha E^n\| + \|\partial^\alpha E^{n+1}\|]\|\partial^\alpha_\beta f^{n+1}(s)\|ds \\
&\quad + \eta\int_0^t \|\partial^\alpha f^n(s)\|_\sigma^2\,ds + C_\eta\int_0^t \|\mu\partial^\alpha f^n(s)\|^2\,ds + \int_0^t C\Big[\sum_{|\alpha_1|\leqslant N}\|\partial^{\alpha_1} f^{n+1}\|_\sigma\Big]\Big\{\Big[\sum_{|\alpha_1|\leqslant N}\|\partial^{\alpha_1} f^n\|\Big] \\
&\quad \times\Big[\sum_{|\alpha_1|\leqslant N}\|\partial^{\alpha_1} f^{n+1}\|_\sigma\Big] + \Big[\sum_{|\alpha_1|\leqslant N}\|\partial^{\alpha_1} f^n\|_\sigma\Big]\Big[\sum_{|\alpha_1|\leqslant N}\|\partial^{\alpha_1} f^{n+1}\|\Big]\Big\}ds.
\end{aligned} \tag{2.18}$$

Combining this with (2.13) implies, for any $\eta>0$ small,

$$\begin{aligned}
E(f^{n+1}(t)) &\leqslant CE(f_0) + Ct\sup_{0\leqslant s\leqslant t}E(f^{n+1}(s)) + Ct\sup_{0\leqslant s\leqslant t}E(f^n(s)) + Ct\sup_{0\leqslant s\leqslant t}E(f^{n+1}(s))\sup_{0\leqslant s\leqslant t}E^{1/2}(f^n(s)) \\
&\quad + Ct\sup_{0\leqslant s\leqslant t}E^{1/2}(f^{n+1}(s))\sup_{0\leqslant s\leqslant t}E(f^n(s)).
\end{aligned}$$

Since $\sup_{0\leqslant s\leqslant t}E(f^n(s))\leqslant CE(f_0)$, we have

$$(1 - CT^*E^{1/2}(f_0) - CT^*E(f_0))\sup_{0\leqslant s\leqslant T^*(M)}E(f^{n+1}(s)) \leqslant CE(f_0) + CT^*E(f_0).$$

Choosing T^* and $E(f_0)$ small enough, we conclude the proof of Lemma 2.1.

Theorem 2.2: *For any sufficiently small $M>0$, there exists $T^*(M)>0$ and $M_1>0$ such that if $E(f_0)\leqslant M_1$, then there is a unique classical solution $f(t,x,v)$ to (1.2) in $[0,T^*(M))\times T^3\times R^3$ such that $\sup_{0\leqslant t\leqslant T^*}E(f(t))\leqslant M$ and $E(f(t))$ is continuous over $[0,T^*(M))$. If $F_0(x,v)=\mu+\mu^{1/2}f_0\geqslant 0$, then $F(t,x,v)=\mu+\mu^{1/2}f(t,x,v)\geqslant 0$. Furthermore, the conservation laws (1.5) and (1.6) hold for all $0<t<T^*$ if they are valid initially at $t=0$.*

Proof: Let $F^0(t,x,v)\equiv F_0(x,v)$. Take $n\to\infty$ in Lemma 2.1 to obtain a classical solution f so that $F(x,t,v)=\mu+\mu^{1/2}f(t,x,v)\geqslant 0$.

In order to prove the uniqueness, we assume that there exists another solution g such that $\sup_{0\leqslant s\leqslant T^*}E(g(s))\leqslant M$. Taking the difference, we have

$$\begin{aligned}
\{\partial_t + v\cdot\nabla_x + (E_f + v\times B_f)\cdot\nabla_v + L\}[f-g] &= -[E_f - E_g + v\times(B_f - B_g)]\nabla_v g \\
&\quad + 2[E_f - E_g]\cdot v\mu^{1/2} + E_f\cdot v[f-g] \\
&\quad + [E_f - E_g]\cdot vg + \Gamma[f-g,g] + \Gamma[g,f-g],
\end{aligned}$$

$$\partial_t(E_f-E_g)-\nabla\times(B_f-B_g)=-\int_{R^3}v\mu^{1/2}(f-g)\mathrm{d}v,\quad \nabla\cdot(E_f-E_g)=\int_{R^3}(f-g)\mu^{1/2}\,\mathrm{d}v,$$
$$\partial_t(B_f-B_g)+\nabla\times(E_f-E_g)=0,\quad \nabla\cdot(B_f-B_g)=0, \tag{2.19}$$

with $f(0,x,v)=g(0,x,v)$, $E_f(0,x)=E_g(0,x)$, and $B_f(0,x)=B_g(0,x)$ as well as $L=-A-K$.

By an argument similar to (2.8), we obtain $\sup_x|g|_\sigma^2\leqslant C\Sigma_{|\alpha|\leqslant 4}\|\partial^\alpha g\|_\sigma^2$ (see Ref. 10). We apply Lemma 1.3 and the above estimate to get

$$|([E_f-E_g+v\times(B_f-B_g)]\nabla_v g,f-g)|\leqslant C\left\{\sum_{|\alpha|\leqslant 4}\|\partial^\alpha g\|_\sigma^2\right\}\{\|E_f-E_g\|^2+\|B_f-B_g\|^2\}+\frac{1}{4}\|f-g\|_\sigma^2,$$

$$\begin{aligned}(\Gamma[f-g,g]+\Gamma[g,f-g],f-g)&\leqslant\sum_{|\alpha|\leqslant 4}[\|\partial^\alpha f\|+\|\partial^\alpha g\|]\|f-g\|_\sigma^2\\&\quad+\sum_{|\alpha|\leqslant 4}[\|\partial^\alpha f\|_\sigma+\|\partial^\alpha g\|_\sigma]\|f-g\|_\sigma\|f-g\|\\&\leqslant CM^{1/2}\|f-g\|_\sigma^2+\frac{1}{8}\|f-g\|_\sigma^2+C\sum_{|\alpha|\leqslant 4}[\|\partial^\alpha f\|_\sigma^2+\|\partial^\alpha g\|_\sigma^2]\|f-g\|^2,\end{aligned}$$

$$|([E_f-E_g]\cdot vg,f-g)|\leqslant\frac{1}{4}\|f-g\|_\sigma^2+C\sum_{|\alpha|\leqslant 4}\|\partial^\alpha g\|_\sigma^2\|E_f-E_g\|^2,$$

$$(|E_f\cdot v(f-g)|,|f-g|)\leqslant CM^{1/2}\|f-g\|_\sigma^2.$$

From the Maxwell system in (2.19), we deduce from (2.17) that

$$2([E_f-E_g]\cdot v\mu^{1/2},f-g)=-\frac{\mathrm{d}}{\mathrm{d}t}[\|E_f-E_g\|^2+\|B_f-B_g\|^2].$$

Moreover, from (2.16), we easily know,

$$(L[f-g],f-g)\geqslant\tfrac{1}{2}\|f-g\|_\sigma^2-C\|f-g\|^2.$$

Multiplying (2.19) by $(f-g)$, and collecting the above estimates, we have

$$\begin{aligned}\frac{\mathrm{d}}{\mathrm{d}t}\left[\frac{1}{2}\|f-g\|^2+\|E_f-E_g\|^2+\|B_f-B_g\|^2\right]+\frac{1}{2}\|f-g\|_\sigma^2&\leqslant C\left\{\sum_{|\alpha|\leqslant 4}[\|\partial^\alpha f\|_\sigma^2+\|\partial^\alpha g\|_\sigma^2+1\}\right.\\&\quad\times[\|f-g\|^2+\|E_f-E_g\|^2+\|B_f-B_g\|^2]\\&\quad+\left[CM^{1/2}+\frac{3}{8}\right]\|f-g\|_\sigma^2.\end{aligned}\tag{2.20}$$

If we choose M small enough, the last term on the right-hand side of (2.20) can be absorbed by $\frac{1}{2}\|f-g\|_\sigma^2$. It is easy to know that $\int_0^t\{\Sigma_{|\alpha|\leqslant 4}[\|\partial^\alpha f\|_\sigma^2+\|\partial^\alpha g\|_\sigma^2]\}\mathrm{d}s\leqslant 2M$. Then, we deduce $f\equiv g$ from the Gronwall inequality.

To show the continuity of $E(f(t))$ with respect to t, we use the summation of (2.13) and (2.18) (with $f^n=f^{n+1}=f$) to get

$$|E(f(t))-E(f(s))| \leqslant C[1+\sup_{s\leqslant y\leqslant t} E^{1/2}(f(y))]\int_s^t \sum [\|\partial_\beta^\alpha f(y)\|_\sigma^2]\mathrm{d}y \to 0$$

as $t\to s$. By $F=\mu+\mu^{1/2}f$, it is straightforward to verify that the mass, total momentum, and total energy conservations hold for such solution constructed.

III. POSITIVITY OF *L*

In this section, we shall establish the positivity of the linear operator L for any small solution $[f(t,x,v),E(t,x),B(t,x)]$ to the system (1.3) and (1.4). Together with the Maxwell system, the conservation laws of mass, momentum, and energy play an important role.

Then for $f(t,x,v)$ and fixed (t,x), we know in the introduction that $P_0f=a(t,x)\mu^{1/2}+b(t,x)\cdot v\mu^{1/2}+c(t,x)|v|^2\mu^{1/2}$ for some $a(t,x),c(t,x)$ and vector function $b(t,x)$. Thus we split f as $f=P_0f+P_1f$ in the system (1.3) and (1.4) and we have

$$[\partial_t+v\cdot\nabla_x]P_0f-2E\cdot v\mu^{1/2}=l(P_1f)+h(f), \tag{3.1}$$

where

$$l(P_1f)\equiv-[\partial_t+v\cdot\nabla_x+L]P_1f, \tag{3.2}$$

$$h(f)\equiv-(E+v\times B)\cdot\nabla_v f+E\cdot vf+\Gamma[f,f]. \tag{3.3}$$

Lemma 3.1: Let $\partial^\alpha=\partial_t^{\alpha_0}\partial_{x_1}^{\alpha_1}\partial_{x_2}^{\alpha_2}\partial_{x_3}^{\alpha_3}$, *then* $\partial^\alpha P_0f=P_0\partial^\alpha f$ *and* $\|\partial^\alpha P_0f\|_\sigma^2+\|\partial^\alpha P_1f\|_\sigma^2\geqslant\|\partial^\alpha f\|_\sigma^2$. *There exists* $C>1$ *such that for any* $f\in C_c^\infty(R\times T^3\times R^3)$

$$\frac{1}{C}\|\partial^\alpha P_0f\|_\sigma^2\leqslant\|\partial^\alpha a\|^2+\|\partial^\alpha b\|^2+\|\partial^\alpha c\|^2\leqslant C\|\partial^\alpha P_0f\|^2. \tag{3.4}$$

Proof: A direct computation implies $\partial^\alpha P_0f=P_0\partial^\alpha f$. It is easy to get the second result from the triangle inequality. We substitute $\|\cdot\|_\sigma$ with $P_0\partial^\alpha f=\partial^\alpha a(t,x)\mu^{1/2}+\partial^\alpha b(t,x)\cdot v\mu^{1/2}+\partial^\alpha c(t,x)|v|^2\mu^{1/2}$. Using $\sigma^{ij}\leqslant C[1+|v|]^{\gamma+2}$ and the exponential decay of e_j, we can obtain the first half of (3.4) by a direct computation. For the second half of (3.4), since a,b, and c are the coefficients of a basis to the finite dimensional space N, $|\partial^\alpha a|^2+|\partial^\alpha b|^2+|\partial^\alpha c|^2$ is bounded by $C\int|\partial^\alpha P_0f|^2\,\mathrm{d}v$ for any (t,x). We then deduce (3.4) by a further integration over x.

Lemma 3.2: Let $[f(t,x,v),E(t,x),B(t,x)]$ *be the solution constructed in Theorem 2.2 to (1.3) and (1.4). Then we have*

$$\rho_2\int_{T^3} b(t,x)=-\int_{T^3} B(t,x)\times E(t,x), \tag{3.5}$$

$$\left|\int_{T^3} a(t,x)\right|+\left|\int_{T^3} c(t,x)\right|\leqslant C[\|E\|^2+\|B-\overline{B}\|^2], \tag{3.6}$$

where $\rho_2=\int|v|^2\mu$.

Proof: Plugging $f=P_0f+P_1f$ into the momentum equation (1.5). For fixed (t,x), notice that $(P_1f,e_j)=0$ and $P_0f=a(t,x)\mu^{1/2}+b(t,x)\cdot v\mu^{1/2}+c(t,x)|v|^2\mu^{1/2}$, we have $\int vf\mu^{1/2}\,\mathrm{d}v=b(t,x)\int|v|^2\mu\,\mathrm{d}v$. Hence (3.5) follows from (1.5). Similarly, we have

$$\int f\mu^{1/2}\,\mathrm{d}v=\rho_0a(t,x)+\rho_2c(t,x)\quad\text{and}\quad\int|v|^2f\mu^{1/2}\,\mathrm{d}v=\rho_2a(t,x)+\rho_4c(t,x),$$

where $\rho_i=\int|v|^i\mu\,\mathrm{d}v$. Further integration over T^3, we have (3.6) from the above equations and the Schwartz inequality.

We plug $P_0 f = a(t,x)\mu^{1/2} + b(t,x)\cdot v\mu^{1/2} + c(t,x)|v|^2\mu^{1/2}$ into the left-hand side of (3.1) and expand it as the products of a polynomial in v and $\mu^{1/2}$,

$$\sum_i \left[v_i \partial^i c|v|^2 + [\partial^0 c + \partial^i b]v_i^2 + \sum_{j>i} [\partial^i b_j + \partial^j b_i]v_i v_j + [\partial^0 b_i + \partial^i a - 2E_i]v_i + \partial^0 a \right]\mu^{1/2},$$

where $\partial^0 = \partial_t, \partial^j = \partial_{x_j}$. For any fixed (t,x), this is an expansion of the left-hand side of (3.1) with respect to the basis of $\mu^{1/2}, v_i\mu^{1/2}, v_i^2\mu^{1/2}, v_i v_j \mu^{1/2}$, and $|v|^2 v_i \mu^{1/2}$ denoted by ϵ_j where $1 \leqslant i \neq j \leqslant 3$. Expand the right-hand side of (3.1) with respect to the same basis, and compare with their coefficients on two sides. Then we have

$$(1)\ \nabla_x c = l_c + h_c, \quad (2)\ \partial^0 c + \partial^i b_i = l_i + h_i, \quad (3)\ \partial^0 a = l_a + h_a,$$

$$(4)\ \partial^i b_j + \partial^j b_i = l_{ij} + h_{ij}, \quad i \neq j, \quad (5)\ \partial^0 b_i + \partial^i a - 2E_i = l_{bi} + h_{bi},$$

where $\partial^0 = \partial_t$ and $\partial^j = \partial_{x_j}$. Here $l_c(t,x), l_i(t,x), l_{ij}(t,x), l_{bi}(t,x)$, and $l_a(t,x)$ are the corresponding coefficients of such an expansion of the linear term $l(P_1 f)$, and $h_c(t,x), h_i(t,x), h_{ij}(t,x), h_{bi}(t,x)$, and $h_a(t,x)$ are the corresponding coefficients of the same expansion of the higher order term $h(f)$.

Let ϵ_j^* be the corresponding orthogonal basis of ϵ_j such that for some constants $\lambda^{ij}, \epsilon_j^* = \sum_{i=1}^{13} \lambda^{ij}\epsilon_j$. Then for any fixed $(t,x), l_c(t,x), l_i(t,x), l_{ij}(t,x), l_{bi}(t,x)$, and $l_a(t,x)$ take the form $\sum_{i,n=1}^{13} \lambda^{ij}\lambda^{in}\int_{R^3} l(P_1 f)\epsilon_n(v)\mathrm{d}v$. The same is true after we take ∂^α. Let $|\alpha| \leqslant N-1$. By (3.2), we have that

$$\left\| \int (-[\partial_t + v\cdot\nabla_x]) P_1 \partial^\alpha f \cdot \epsilon_n(v)\mathrm{d}v \right\|^2 \leqslant \int |\epsilon_n(v)|\mathrm{d}v \int_{R^3\times T^3} |\epsilon_n(v)|(|P_1\partial^0\partial^\alpha f|^2 + |v|^2|P_1\nabla_x\partial^\alpha f|^2)\mathrm{d}x\,\mathrm{d}v \leqslant C[\|P_1\partial^0\partial^\alpha f\| + \|P_1\nabla_x\partial^\alpha f\|]^2, \tag{3.7}$$

$$\int LP_1\partial^\alpha f\epsilon_n(v)\mathrm{d}v = \int (-A-K)P_1\partial^\alpha f\epsilon_n(v)\mathrm{d}v.$$

Recalling the expressions of A, K, and ϵ_n, integration by parts and the Schwartz inequality will result in

$$\left\| \int LP_1\partial^\alpha f\epsilon_n(v)\mathrm{d}v \right\|^2 \leqslant C\|P_1\partial^\alpha f\|^2. \tag{3.8}$$

Combining (3.7) and (3.8), we have

$$\left\| \int \partial^\alpha l(P_1 f)\cdot\epsilon_n(v)\mathrm{d}v \right\|^2 \leqslant C[\|P_1\partial^0\partial^\alpha f\| + \|P_1\nabla_x\partial^\alpha f\| + \|P_1\partial^\alpha f\|]^2.$$

Here $\partial^0 = \partial_t$ and we have used the facts that $\partial^\alpha P_1 f = P_1\partial^\alpha f$ and the exponential decay of $\epsilon_n(v)$. The above proof is summarized in the following lemma.

Lemma 3.3: Let $\alpha = [\alpha_0, \alpha_1, \alpha_1, \alpha_2]$, *then for any* $1 \leqslant i, j \leqslant 3$,

$$\sum_{|\alpha|\leqslant N-1} [\|\partial^\alpha l_c\| + \|\partial^\alpha l_i\| + \|\partial^\alpha l_{ij}\| + \|\partial^\alpha l_{bi}\| + \|\partial^\alpha l_a\|] \leqslant C \sum_{|\alpha|\leqslant N} \|P_1\partial^\alpha f\|.$$

Since $\partial^\alpha J = \int_{R^3}\partial^\alpha f v\mu^{1/2}\,\mathrm{d}v$, we easily know that $\|\partial^\alpha J\| \leqslant C\|\partial^\alpha f\|$. Thus, by (1.16) and (1.14) with $\gamma \geqslant -1$, the arguments similar to Lemma 8 in Ref. 16 will imply that the following two lemmas hold.

Lemma 3.4: Let $[f(t,x,v), E(t,x), B(t,x)]$ *be the solution constructed in Theorem 2.2 to (1.3) and (1.4) such that*

$$\sum_{|\alpha|\leqslant N}\left[\tfrac{1}{2}\|\partial^\alpha f(t)\|^2+\|\partial^\alpha E(t)\|^2+\|\partial^\alpha B(t)\|^2\right]\leqslant M, \tag{3.9}$$

with the constant $M>0$ small enough. Then we have

$$\sum_{|\alpha|\leqslant N-1}\left[\|\partial^\alpha h_c\|+\|\partial^\alpha h_i\|+\|\partial^\alpha h_{ij}\|+\|\partial^\alpha h_{bi}\|+\|\partial^\alpha h_a\|\right]\leqslant CM^{1/2}\sum_{|\alpha|\leqslant N}\|\partial^\alpha f\|_\sigma.$$

Lemma 3.5: Let $[f(t,x,v),E(t,x),B(t,x)]$ be the solution constructed in Theorem 2.2 to (1.3) and (1.4). Let the small assumption (3.9) be valid for some $M\leqslant 1$. Then there is a constant $C>0$ such that

$$\sum_{|\alpha|\leqslant N-1}\left[\|\partial^\alpha E(t)\|+\|\partial^\alpha[B(t)-\bar{B}]\|\right]\leqslant C\sum_{|\alpha|\leqslant N}\|\partial^\alpha f\|_\sigma.$$

Theorem 3.6: *Let $[f(t,x,v),E(t,x),B(t,x)]$ be the solution constructed in Theorem 2.2 to (1.3) and (1.4). If the small amplitude assumption (3.9) holds. Then there exists $\delta_M>0$ such that*

$$\sum_{|\alpha|\leqslant N}(L\partial^\alpha f,\partial^\alpha f)\geqslant\delta_M\sum_{|\alpha|\leqslant N}\|\partial^\alpha f\|_\sigma^2.$$

Using Lemmas 3.1–3.5, (1.15), equations (1.1)–(1.5) and (1.14) with $\gamma\geqslant -1$, the arguments similar to those in the proof of Theorem 3 of Ref. 16, except for several differences, will imply Theorem 3.6.

The first difference is to prove the estimate of the purely spatial derivative of $a(t,x)$. The direct calculation implies $\nabla\cdot\partial^\alpha E=\int\partial^\alpha f\ \mu^{1/2}=\rho_0\partial^\alpha a(t,x)+\rho_2\partial^\alpha c(t,x)$. Since $\partial^\alpha c(t,x)$ is controlled by the argument similar to those in Ref. 16, we thus obtain the estimate of the purely spatial derivative of $a(t,x)$ by the same method as in Ref. 16.

The second difference is to prove the estimate of the higher purely temporal derivative $\partial^\alpha b_j$ with $|\alpha|\geqslant 3$. It is clear that the direct calculation implies $J=\rho_2 b(t,x)$. The Maxwell system leads to

$$\partial^{\alpha-1}E-\nabla\times\partial^{\alpha-2}B=-\partial^{\alpha-2}J,\quad \nabla\times\partial^{\alpha-2}B+\nabla\times[\nabla\times\partial^{\alpha-3}E]=0.$$

It is easy to get

$$\partial^{\alpha-1}E+\nabla\times[\nabla\times\partial^{\alpha-3}E]=-\partial^{\alpha-2}J=-\rho_2\partial^{\alpha-2}b.$$

Together with $\partial^{\alpha-1}$ on Eq. (5), we get

$$\begin{aligned}\|\partial^\alpha b_i\|=\|-\partial^i\partial^{\alpha-1}a+2\partial^{\alpha-1}E_i+\partial^{\alpha-1}[l_{bi}+h_{bi}]\|&\leqslant\|\partial^i\partial^{\alpha-1}a\|+2\rho_2\|\partial^{\alpha-2}b_i\|+2\|\nabla\times[\nabla\times\partial^{\alpha-3}E]\|\\&\quad+\|\partial^{\alpha-1}[l_{bi}+h_{bi}]\|.\end{aligned}$$

Thus we have

$$\|\partial^\alpha b_i\|-2\rho_2\|\partial^{\alpha-2}b_i\|\leqslant\|\partial^i\partial^{\alpha-1}a\|+2\|\nabla\times[\nabla\times\partial^{\alpha-3}E]\|+\|\partial^{\alpha-1}[l_{bi}+h_{bi}]\|.$$

The right-hand side of the above inequality is bounded by $C\Sigma_{|\alpha|\leqslant N}\|P_1\partial^\alpha f\|+CM^{1/2}\Sigma_{|\alpha|\leqslant N}\|\partial^\alpha f\|_\sigma$, which can be proved by the same arguments as in Ref. 16. Then we can obtain the estimate of the higher purely temporal derivative $\partial^\alpha b_j$ by a bootstrap argument.

IV. GLOBAL EXISTENCE

In this section, we will prove the existence of global classical solution to the system (1.3) and (1.4). We first derive a refined energy estimate for (1.3) and (1.4).

Theorem 4.1: *Let $[f(t,x,v),E(t,x),B(t,x)]$ be the solution constructed in Theorem 2.2 to (1.3) and (1.4). Let the small amplitude assumption (3.9) be valid. For any given $0\leqslant m\leqslant N$, $|\beta|\leqslant m$, there are constants $C_{|\beta|}>0, C_m^*>0$ and $\delta_m>0$ such that*

$$\sum_{|\beta|\leqslant m,|\alpha|+|\beta|\leqslant N}\left[\frac{\mathrm{d}}{\mathrm{d}t}(C_{|\beta|}\|\partial_\beta^\alpha f\|^2+\|\partial^\alpha E(t)\|^2+\|\partial^\alpha B(t)\|^2)+\delta_m\|\partial_\beta^\alpha f\|_\sigma^2\right]\leqslant C_m^* E^{1/2}(f(t))\sum_{|\alpha|+|\beta|\leqslant N}\|\partial_\beta^\alpha f\|_\sigma^2. \tag{4.1}$$

Proof: We use an induction over m, the order of the v-derivatives. For $m=0$, by taking the pure ∂^α derivatives of (1.3), we obtain

$$\begin{aligned}&[\partial_t+v\cdot\nabla_x+(E+v\times B)\cdot\nabla_v-(E\cdot v)]\partial^\alpha f+L[\partial^\alpha f]-2[\partial^\alpha E\cdot v]\mu^{1/2}\\&\quad=\partial^\alpha\Gamma[f,f]-\sum_{0\neq\alpha_1\leqslant\alpha}C_\alpha^{\alpha_1}[\partial^{\alpha_1}E+v\times\partial^{\alpha_1}B]\partial^{\alpha-\alpha_1}\nabla_v f+\sum_{0\neq\alpha_1\leqslant\alpha}C_\alpha^{\alpha_1}\partial^{\alpha_1}E\cdot v\,\partial^{\alpha-\alpha_1}f.\end{aligned} \tag{4.2}$$

Take the inner product with $\partial^\alpha f$ of Eq. (4.2). Recalling estimates (2.15) and (2.17) in Lemma 2.1 with $f^n=f^{n+1}=f$, applying Theorem 3.6 to $L[\partial^\alpha f]$ and summing over $|\alpha|\leqslant N$, we deduce, for some constant $C>0$, that

$$\sum_{|\alpha|\leqslant N}\frac{\mathrm{d}}{\mathrm{d}t}\left(\frac{1}{2}\|\partial^\alpha f\|^2+\|\partial^\alpha E(t)\|^2+\|\partial^\alpha B(t)\|^2\right)+\delta_0\sum_{|\alpha|\leqslant N}\|\partial^\alpha f\|_\sigma^2\leqslant CE^{1/2}(f(t))\sum_{|\alpha|\leqslant N}\|\partial^\alpha f\|_\sigma^2.$$

This concludes the case for $m=0$ with $C_0=1/2$ and $C_0^*=C$.

Assume the theorem is valid for m. For $|\beta|=m+1$, taking ∂_β^α of (1.3), we obtain

$$\begin{aligned}&[\partial_t+v\cdot\nabla_x+(E+v\times B)\cdot\nabla_v]\partial_\beta^\alpha f-2\partial^\alpha E\cdot\partial_\beta[v\mu^{1/2}]+\partial_\beta[L\partial^\alpha f]+\sum_{\beta_1\neq 0}C_\beta^{\beta_1}\partial_{\beta_1}v\cdot\nabla_x\partial_{\beta-\beta_1}^\alpha f\\&=\sum C_\alpha^{\alpha_1}C_\beta^{\beta_1}\partial^{\alpha_1}E\cdot\partial_{\beta_1}v\,\partial_{\beta-\beta_1}^{\alpha-\alpha_1}f-\sum_{\alpha_1\neq 0}C_\alpha^{\alpha_1}\partial^{\alpha_1}E\nabla_v\partial_\beta^{\alpha-\alpha_1}f-\sum_{\alpha_1\neq 0,\beta_1\neq 0}C_\alpha^{\alpha_1}C_\beta^{\beta_1}\partial_{\beta_1}v\\&\quad\times\partial^{\alpha_1}B\cdot\nabla_v\partial_{\beta-\beta_1}^{\alpha-\alpha_1}f+\sum C_\alpha^{\alpha_1}\partial_\beta\Gamma[\partial^{\alpha_1}f,\partial^{\alpha-\alpha_1}f].\end{aligned} \tag{4.3}$$

From (2.5) in Lemma 2.1, for any $\eta>0$, there is a constant $C_\eta>0$ such that

$$(\partial_\beta[L\partial^\alpha f],\partial_\beta^\alpha f)\leqslant\|\partial_\beta^\alpha f\|_\sigma^2-\eta\sum_{\beta'\leqslant\beta}\|\partial_{\beta'}^\alpha f\|_\sigma^2-C_\eta\|\partial^\alpha f\|_\sigma^2.$$

We can further choose $C_\eta>0$ such that the inner product of the last term on the left-hand side of (4.3) with $\partial_\beta^\alpha f$ is bounded by

$$\eta\|\partial_\beta^\alpha f\|_\sigma^2+C_\eta\sum_{|\beta_1|=1}\|\nabla_x\partial_{\beta-\beta_1}^\alpha f\|_\sigma^2.$$

Since $|\beta|=m+1,|\alpha|\leqslant N-1$ and by Lemma 3.5 and $\|f\|\leqslant\|f\|_\sigma$, we have

$$(2\partial^\alpha E\cdot\partial_\beta[v\mu^{1/2}],\partial_\beta^\alpha f)=(-1)^{|\beta|}(2\partial^\alpha E\cdot\partial_\beta^2[v\mu^{1/2}],\partial^\alpha f)\leqslant C_\mu\|\partial^\alpha E\|\cdot\|\partial^\alpha f\|\leqslant C_\mu\sum_{|\alpha'|\leqslant N}\|\partial^{\alpha'}f\|_\sigma^2.$$

By the arguments similar to those in Lemma 2.1, the inner product of other terms on the right-hand side of (4.3) with $\partial_\beta^\alpha f$ is bounded by $CE^{1/2}(f(t))\Sigma_{|\alpha|+|\beta|\leqslant N}\|\partial_\beta^\alpha f\|_\sigma^2$. We have, by collecting terms and summing over $|\beta|=m+1$ and $|\alpha|+|\beta|\leqslant N$,

$$\sum_{|\beta|=m+1,|\alpha|+|\beta|\leqslant N}\left[\frac{1}{2}\frac{\mathrm{d}}{\mathrm{d}t}\|\partial_\beta^\alpha f(t)\|^2+\|\partial_\beta^\alpha f(t)\|_\sigma^2\right]$$
$$\leqslant \sum_{|\beta|=m+1,|\alpha|+|\beta|\leqslant N}\left[\sum_{|\beta|=m+1}2\eta\|\partial_\beta^\alpha f(t)\|_\sigma^2+(2\eta+C_\mu+C_\eta)\right.$$
$$\left.\times\sum_{|\beta|\leqslant m,|\alpha|+|\beta|\leqslant N}\|\partial_\beta^\alpha f(t)\|_\sigma^2+CE^{1/2}(f(t))\sum_{|\alpha|+|\beta|\leqslant N}\|\partial_\beta^\alpha f\|_\sigma^2\right]$$
$$\leqslant Z_{m+1}\left[\sum_{|\beta|=m+1}2\eta\|\partial_\beta^\alpha f(t)\|_\sigma^2+(2\eta+C_\mu+C_\eta)\right.$$
$$\left.\times\sum_{|\beta|\leqslant m,|\alpha|+|\beta|\leqslant N}\|\partial_\beta^\alpha f(t)\|_\sigma^2+CE^{1/2}(f(t))\sum_{|\alpha|+|\beta|\leqslant N}\|\partial_\beta^\alpha f\|_\sigma^2\right].$$

Here we have used that $\|\partial_\beta^\alpha f(t)\|\leqslant C\|\partial_\beta^\alpha f(t)\|_\sigma$ and Z_{m+1} denotes the number of all possible (α,β) such that $|\beta|\leqslant m+1, |\alpha|+|\beta|\leqslant N$.

By choosing $\eta=1/4Z_{m+1}$, we have, for some constant $C(Z_{m+1})>0$,

$$\sum_{|\beta|=m+1,|\alpha|+|\beta|\leqslant N}\left[\frac{1}{2}\frac{\mathrm{d}}{\mathrm{d}t}\|\partial_\beta^\alpha f(t)\|^2+\frac{1}{2}\|\partial_\beta^\alpha f(t)\|_\sigma^2\right]\leqslant C(Z_{m+1})\left[\sum_{|\beta|\leqslant m,|\alpha|+|\beta|\leqslant N}\|\partial_\beta^\alpha f(t)\|_\sigma^2\right.$$
$$\left.+CE^{1/2}(f(t))\sum_{|\alpha|+|\beta|\leqslant N}\|\partial_\beta^\alpha f\|_\sigma^2\right]. \tag{4.4}$$

We may assume $C(Z_{m+1})\geqslant 1$. Multiply (4.3) by $\delta_m/2C(Z_{m+1})$ and add it to (4.1) for $|\beta|\leqslant m$ to get

$$\sum_{|\beta|=m+1,|\alpha|+|\beta|\leqslant N}\left[\frac{\delta_m}{4C(Z_{m+1})}\frac{\mathrm{d}}{\mathrm{d}t}\|\partial_\beta^\alpha f(t)\|^2+\frac{\delta_m}{4C(Z_{m+1})}\|\partial_\beta^\alpha f(t)\|_\sigma^2\right]$$
$$+\sum_{|\beta|\leqslant m,|\alpha|+|\beta|\leqslant N}\left[\frac{\mathrm{d}}{\mathrm{d}t}(C_{|\beta|}\|\partial_\beta^\alpha f\|^2+\|\partial^\alpha E(t)\|^2+\|\partial^\alpha B(t)\|^2)+\delta_m\|\partial_\beta^\alpha f\|_\sigma^2\right]$$
$$\leqslant\frac{\delta_m}{2}\sum_{|\beta|\leqslant m,|\alpha|+|\beta|\leqslant N}\|\partial_\beta^\alpha f(t)\|_\sigma^2+\left(C_m^*+\frac{\delta_m}{2}\right)E^{1/2}(f(t))\sum_{|\alpha|+|\beta|\leqslant N}\|\partial_\beta^\alpha f\|_\sigma^2.$$

Absorb the first term on the right-hand side by the last term on the left-hand side. We thus conclude the lemma by letting

$$C_{m+1}^*=C_m^*+\frac{\delta_m}{2},\quad C_{m+1}=\frac{\delta_m}{4C(Z_{m+1})},\quad \delta_{m+1}=\frac{\delta_m}{4C(Z_{m+1})}\leqslant\frac{\delta_m}{2}.$$

Proof of Theorems 1.1 and 1.2: The proof of Theorems 1.1 and 1.2 can be obtained by Theorem 4.1 and the arguments similar to those in the proof of Theorem 1 and Theorem 2 in Ref. 16.

ACKNOWLEDGMENTS

The author acknowledges Professor Guo Yan for giving us a wonderful talk. The author is grateful to Professor Hsiao Ling and Professor Zhang Ping for their interesting comments.

(Received 12 November 2003; accepted 28 July 2004; published 25 October 2004)

We introduce a definition of upper Lyapunov exponent for quantum systems in the Heisenberg representation, and apply it to parametric quantum oscillators. We provide a simple proof that the upper quantum Lyapunov exponent ranges from zero to a positive value, as the parameters range from the classical system's region of stability to the instability region. It is also proved that in the instability region the parametric quantum oscillator satisfies the discrete quantum Anosov relations defined by Emch, Narnhofer, Sewell, and Thirring. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1803926]

I. INTRODUCTION

Several definitions of quantum Lyapunov exponents have been proposed (see Refs. 1–6 and references therein). Due to the fact that there are few examples on which these definitions can be explicitly tested in detail, their range of applicability is not well established. Emch and co-workers[1,2] formulated a definition of quantum Anosov systems, and the associated quantum Lyapunov exponents. This definition of the Lyapunov exponents is however too rigid, and it is not applicable to systems that do not have a global structure with a constant hyperbolicity property. Majewski and Kuna[5] extracted from Ref. 1 a more general definition, that is still too restrictive, since it assumes the existence of certain limits that one cannot expect to be well defined in general. In a quite different approach, Vilela Mendes[6] introduced a definition of the quantum Lyapunov exponents based on the probability density $\rho(x,t)=|\psi(x,t)|^2$ in the position representation. The limitation of this approach is that it singles out the position representation, and thus it is not easily related to the dependence on initial conditions in phase space (x, and p).

In the present paper we propose a definition of the upper quantum Lyapunov exponent that is close in spirit to the ones of Refs. 1 and 5, but is more general and with a wider range of applicability. It is formulated in terms of the evolution of observables in an algebraic setting, and based by analogy on the classical upper Lyapunov exponent, as defined in the general context of cocycles.[7,8] An essential ingredient is the behavior with respect to changes in the initial conditions. In Refs. 1, 3, and 5 these are taken in a very general framework, by considering the variations generated by all the derivations on the algebra of observables. For our definition we restrict the class of variations of initial conditions to those derivations that correspond to translations in phase space, i.e., in x and in p. We illustrate this definition with the example of a parametric quantum oscillator, which shows the utility of the extension.

II. DEFINITION OF THE UPPER QUANTUM LYAPUNOV EXPONENT

Consider a quantum mechanical particle and let $\hat{x}$ and $\hat{p}$ denote its coordinate and momentum operators, on the Hilbert space $\mathcal{H}=L_2(\mathbb{R},\mathrm{d}x)$, with $[\hat{x},\hat{p}]=i\hbar$. We choose the units such that $\hbar=1$. We define the self-adjoint operator

$$L_{\underline{\alpha}} := \alpha_p \hat{p} + \alpha_x \hat{x}, \quad \text{with } \underline{\alpha} \equiv (\alpha_p, \alpha_x) \in \mathbb{R}^2. \tag{1}$$

It defines a derivation[1] $\delta_{\underline{\alpha}}$, acting on operators $A \in \mathcal{A}$, where $\mathcal{A}$ denotes the algebra of observables, by

$$\delta_{\underline{\alpha}} A = [L_{\underline{\alpha}}, A], \ \forall A \in \mathrm{Dom}(\delta_{\underline{\alpha}}), \tag{2}$$

where

$$\mathrm{Dom}(\delta_{\underline{\alpha}}) \equiv \{A \in \mathcal{A} \text{ such that} [L_{\underline{\alpha}}, A] \in \mathcal{A}\}. \tag{3}$$

This derivation may be interpreted as a derivation in the direction of phase space determined by (α_p, α_x) and is thus naturally suggested by classical mechanics.

Let $U(t, t_0)$ denote the unitary propagator which defines the dynamics, with initial time t_0. In order to proceed we must also specify the algebra of observables. Experience with examples[2] suggests the choice of the Weyl algebra $\mathcal{W}$, which consists of finite linear combinations of the operators

$$W(\beta, \gamma) = \exp[i(\beta \hat{x} + \gamma \hat{p})], \quad (\beta, \gamma) \in \mathbb{R}^2. \tag{4}$$

This is particularly natural because $\mathcal{W} \subset \mathrm{Dom}\ \delta_{\underline{\alpha}}$, since

$$[L_{\underline{\alpha}}, W(\beta, \gamma)] = (\alpha_p \beta - \alpha_x \gamma) W(\beta, \gamma). \tag{5}$$

Equivalently,[2] one can consider polynomials in $W = \exp[i(\beta \hat{x} + \gamma \hat{p})]$ with the multiplication law $W(z)W(z') = \exp(i\sigma(z, z'))W(z+z')$, with $z := (\beta, \gamma)$, $z' := (\beta', \gamma')$, and the symplectic form $\sigma(z, z') = (\beta\gamma' - \beta'\gamma)/2$. Note that once the equations (20) and (21) of Theorem 2 have been established, the C^* character of the algebra is inessential: a $*$-algebra is sufficient (see Ref. 1, Remark 3.7, No. 6).

We also assume that the dynamics defines an automorphism of $\mathcal{W}$,

$$U^\dagger(t, t_0) A U(t, t_0) \in \mathcal{W}, \quad \forall A \in \mathcal{W}, \forall t, t_0 \in \mathbb{R}. \tag{6}$$

Under the above assumptions, we can formulate the following.

Definition: The *upper quantum Lyapunov exponent* is defined as

$$\overline{\lambda} = \sup_{\underline{\alpha} \in \mathbb{R}^2} \overline{\lambda}_{\underline{\alpha}}, \tag{7}$$

where

$$\overline{\lambda}_{\underline{\alpha}}(U, L_{\underline{\alpha}}, A, t_0) := \limsup_{t \to \infty} \frac{1}{t} \ln \| [L_{\underline{\alpha}}, A(t, t_0)] \| \tag{8}$$

and

$$A(t, t_0) := U^\dagger(t, t_0) A U(t, t_0) \tag{9}$$

and $A \in \mathcal{W}$. The norm is chosen as $\|A\| = \sup_{\psi \in \mathcal{H}} \|A\psi\| / \|\psi\|$.

Remarks:

(1) This definition is adapted from the general formulation for cocycles described, e.g., in Ref. 8. $\overline{\lambda}$ is expected to be independent of t_0 and of the choice of the observable A, under suitable conditions, e.g.,

$$[L, A(t, t_0)] \neq 0. \tag{10}$$

(2) If the limit in (8) exists, then it is called the Lyapunov exponent $\lambda_{\underline{\alpha}}(U, L, A, t_0)$.

(3) Because of the unitarity of the time evolution, the exponent $\overline{\lambda}_{\underline{\alpha}}$ can also be expressed as

$$\overline{\lambda}_{\underline{\alpha}}(U,L_{\underline{\alpha}},A,t_0) = \limsup_{t\to\infty}\frac{1}{t}\ln\|[L_{\underline{\alpha}}(t_0,t),A]\| \tag{11}$$

with

$$L_{\underline{\alpha}}(t_0,t) := U^{\dagger}(t_0,t)L_{\underline{\alpha}}U(t_0,t). \tag{12}$$

(4) The main differences with the earlier definitions of Refs. 1, 2, and 5 are the lim sup in Eq. (8) and the restriction to the derivations (1) corresponding to directions in phase space.

III. APPLICATION TO PARAMETRICALLY DRIVEN QUANTUM OSCILLATORS

In order to show the usefulness of the above definition, we consider the parametric quantum oscillator,[9–11] one of the simplest paradigms of the transition from regular to unstable behavior in classical mechanics.[12,13] The Hamiltonian (we take the mass=1) is

$$H(t) = \tfrac{1}{2}\hat{p}^2 + \tfrac{1}{2}f(t)\hat{x}^2, \tag{13}$$

where f is a periodic function of period T,

$$f(t+T) = f(t). \tag{14}$$

It is convenient to decompose f as $f(t)=E+f_{za}$ with $E=(1/T)\int_0^T dt\, f(t)$ [and thus $(1/T)\int_0^T dt\, f_{za}(t)=0$]. We will analyze the one parameter family of systems defined by varying the average $E\in\mathbb{R}$.

The classical equation corresponding to (13) is Hill's equation,[14,15]

$$\ddot{x} + f(t)x = 0, \tag{15}$$

which is well known (Ref. 14, Chap. 4, and Ref. 15) to have bands of stability regions S, and instability regions I ("gaps"), when the parameter E is varied.

For the quantum parametric oscillators we will prove the following results:

Theorem 1: For any observable $A=W(\beta,\gamma)$ of the form (4), in the stability region $E\in S$ one has

$$\overline{\lambda}_{\underline{\alpha}}(U,L_{\underline{\alpha}},A,t_0) = 0,\ \forall\ \underline{\alpha},\quad \forall\ t_0. \tag{16}$$

In the instability region $E\in I$, there is a stable direction $\underline{\alpha}_s$, which depends on t_0, for which

$$\overline{\lambda}_{\underline{\alpha}_s}(U,L_{\underline{\alpha}_s},A,t_0) = -\lambda_r < 0, \tag{17}$$

whereas for all other directions $\underline{\alpha}$,

$$\overline{\lambda}_{\underline{\alpha}}(U,L_{\underline{\alpha}},A,t_0) = \lambda_r > 0, \tag{18}$$

where λ_r is the absolute value of the real part of the Floquet exponent of the corresponding classical oscillator defined below in Eq. (32). Thus the upper Lyapunov exponent is

$$\overline{\lambda} = \sup_{\underline{\alpha}}\overline{\lambda}_{\underline{\alpha}} = \lambda_r > 0. \tag{19}$$

There is thus a transition in the upper quantum Lyapunov exponent $\overline{\lambda}$ as the parameter E ranges from the classical system's region of stability to the instability region.

Theorem 2: If we consider the time evolution in the instability region $E\in I$ at discrete times $t_n=n2T$ given by even integer multiples of the period T, there is an unstable eigendirection $\underline{\alpha}_+ \equiv(\alpha_{p^+},\alpha_{x^+})$ such that the corresponding derivation $L_{\underline{\alpha}_+}$ satisfies for all t_n,

$$e^{iL_{\underline{\alpha}_+}s}\, e^{-\lambda_r t_n} U^\dagger(t_n,0) = U^\dagger(t_n,0) e^{iL_{\underline{\alpha}_+}s}, \tag{20}$$

and a stable eigendirection $\underline{\alpha}_- \equiv (\alpha_{p-}, \alpha_{x-})$ such that

$$e^{iL_{\underline{\alpha}_-}s}\, e^{\lambda_r t_n} U^\dagger(t_n,0) = U^\dagger(t_n,0) e^{iL_{\underline{\alpha}_-}s}, \tag{21}$$

where $\lambda_r > 0$ is the real part of the classical Floquet exponent. Thus the system satisfies the discrete quantum Anosov relations defined by Emch, Narnhofer, Sewell, and Thirring.[1–3]

Remarks: This system satisfies the quantum Anosov relations but it lacks two other properties that enter in the definition of quantum Anosov systems as formulated in Refs. 1–3: There is no state that is invariant with respect to $U(t_n,0)$, nor with respect to $e^{iL_{\underline{\alpha}_\pm}s}$ [$U(t_n,0)$ has no eigenvalues for $E \in I$ and there are no translation invariant states in $\mathcal{H} = L_2(\mathbb{R}, dx)$]. However, as it was remarked in Ref. 1 (Remark 3.7, No. 7) the requirement of the invariant state may be dispensed with, depending on the intended application.

The relations (20) and (21) can be written equivalently, by changing $t_n \to -t_n$ as

$$e^{iL_{\underline{\alpha}_+}s}\, e^{\lambda_r t_n} U(t_n,0) = U(t_n,0) e^{iL_{\underline{\alpha}_+}s}, \tag{22}$$

$$e^{iL_{\underline{\alpha}_-}s}\, e^{-\lambda_r t_n} U(t_n,0) = U(t_n,0) e^{iL_{\underline{\alpha}_-}s}. \tag{23}$$

With this representation (22) one can give an intuitive interpretation for the Lyapunov exponent in the Schrödinger picture: We compare the forward time evolution ($t_{n+1} > t_n$) of two initial states ψ and $\psi + \delta\psi$ that are related to each other by a translation in phase space in direction $\underline{\alpha}_+$ of size s. The time evolution $U(t_n,0)[\psi + \delta\psi]$ to time t_n will yield a state $\phi + \delta\phi$, that can be related to $\phi = U(t_n,0)\psi$ by a translation in phase space in the same direction $\underline{\alpha}_+$ but of a size s' that is exponentially amplified $s' = s\, e^{\lambda_r t_n}$. This can be visualized by the following diagram:

$$\begin{array}{ccc} \psi & \overset{U(t_n,0)}{\longrightarrow} & \phi \\ e^{iL_{\underline{\alpha}_+}s}\downarrow & & \downarrow e^{iL_{\underline{\alpha}_+}s\, e^{\lambda_r t_n}} \\ \psi + \delta\psi & \overset{U(t_n,0)}{\longrightarrow} & \phi + \delta\phi \end{array} \tag{24}$$

For Anosov systems this property is satisfied globally for any size s of the translation. The definition of the Lyapunov exponent (11) can be interpreted on the basis of this picture but taking infinitesimally small translations.

In order to determine the upper quantum Lyapunov exponent according to Eq. (11) we first need to calculate $L_{\underline{\alpha}}(t_0,t)$.

Lemma 1:

$$L_{\underline{\alpha}}(t_1;t_2) = \alpha_p(t_1;t_2)\hat{p} + \alpha_x(t_1;t_2)\hat{x} \tag{25}$$

with

$$\alpha_p(t_1;t_2) = e^{(t_1-t_2)\lambda_+} h_{p+}(t_1;t_2) + e^{(t_1-t_2)\lambda_-} h_{p-}(t_1;t_2), \tag{26}$$

$$\alpha_x(t_1;t_2) = e^{(t_1-t_2)\lambda_+} h_{x+}(t_1;t_2) + e^{(t_1-t_2)\lambda_-} h_{x-}(t_1;t_2), \tag{27}$$

and $h_{p\pm}(t_1;t_2)$, $h_{x\pm}(t_1;t_2)$ are periodic functions of the same period T of the function f, and $\lambda_\pm$ are the Floquet exponents associated to the classical dynamics [defined below in Eq. (32)]. In the stability bands $E \in S$, $\lambda_\pm$ are purely imaginary, whereas in the instability regions $E \in I$, $\lambda_\pm$ has a nonvanishing real part, that we will denote $\pm\lambda_r$.

Proof of Lemma 1: The classical equation (15) may be written

$$\frac{d}{dt}\begin{pmatrix} p \\ x \end{pmatrix} = \begin{pmatrix} 0 & -f(t) \\ 1 & 0 \end{pmatrix}\begin{pmatrix} p \\ x \end{pmatrix}. \tag{28}$$

The propagator $F(t,t_0)$ of the classical equation, defined by

$$\begin{pmatrix} p(t) \\ x(t) \end{pmatrix} = F(t,t_0)\begin{pmatrix} p(t_0) \\ x(t_0) \end{pmatrix}, \quad F(t,t) = 1 \ \forall \ t, \tag{29}$$

may be written, by Floquet's theorem[15] as the following.

Lemma 2:

$$F(t,t_0) = G(t)e^{(t-t_0)B}G^{-1}(t_0), \tag{30}$$

where

$$G(t+T) = G(t) \tag{31}$$

is an invertible differentiable matrix, and B a constant traceless matrix.

Thus B is of one of the following three forms:

(1) B has two complex eigenvalues

$$\lambda_{\pm} = \pm(\lambda_r + i\lambda_i) \neq 0 \tag{32}$$

(we choose the notation such that $\lambda_r \geqslant 0$): Thus B is diagonalizable and there are two cases,

(1a) $\lambda_r = 0$ (stable case, band),
(1b) $\lambda_r \neq 0$ (unstable case, gap).

In these two cases one can write

$$F(t,t_0) = G(t)Se^{(t-t_0)\begin{pmatrix} \lambda_+ & 0 \\ 0 & \lambda_- \end{pmatrix}}S^{-1}G^{-1}(t_0), \tag{33}$$

where S is some invertible matrix.

(2) $\lambda_{\pm} = 0$.

In this case B is not diagonalizable, and has Jordan canonical form $\left(\begin{smallmatrix} 0 & 1 \\ 0 & 0 \end{smallmatrix}\right)$. It corresponds to a band edge, which we shall not discuss further in this paper.

Using the fact that the Heisenberg equations of motion for the operators $\hat{x}(t)$ and $\hat{p}(t)$ have the same form as the classical equations for $p(t)$ and $x(t)$, we can write

$$\begin{pmatrix} U^{\dagger}(t,t_0) & \hat{p} & U(t,t_0) \\ U^{\dagger}(t,t_0) & \hat{x} & U(t,t_0) \end{pmatrix} = F(t,t_0)\begin{pmatrix} \hat{p} \\ \hat{x} \end{pmatrix} = g(t)\begin{pmatrix} e^{(t-t_0)\lambda_+} & 0 \\ 0 & e^{(t-t_0)\lambda_-} \end{pmatrix}g^{-1}(t_0)\begin{pmatrix} \hat{p} \\ \hat{x} \end{pmatrix}, \tag{34}$$

with $g(t) \equiv G(t)S$. Writing explicitly the matrix elements $g(t_1) \equiv (g_{ij}(t_1)), g^{-1}(t_2) \equiv (g_{ij}^{-1}(t_2))$, we find, by (26), (27), and (34) that the functions in Eq. (26) are given by

$$h_{p+}(t_1;t_2) = (\alpha_p g_{11}(t_1) + \alpha_x g_{21}(t_1))g_{11}^{-1}(t_2), \tag{35}$$

$$h_{p-}(t_1;t_2) = (\alpha_p g_{12}(t_1) + \alpha_x g_{22}(t_1))g_{21}^{-1}(t_2), \tag{36}$$

$$h_{x+}(t_1;t_2) = (\alpha_p g_{11}(t_1) + \alpha_x g_{21}(t_1))g_{12}^{-1}(t_2), \tag{37}$$

$$h_{x-}(t_1;t_2) = (\alpha_p g_{12}(t_1) + \alpha_x g_{22}(t_1))g_{22}^{-1}(t_2), \tag{38}$$

which are periodic in t_1 and in t_2 since $g(t)$ is periodic.

Proof of Lemma 2: The time evolution is symplectic, thus the Jacobi matrix $F(t,t_0)$ of the map (21) satisfies[12]

$$FJF^T = J, \quad J = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix} \tag{39}$$

and hence $\det F = 1$. Thus we may define $e^{BT} := F(T,0)$, i.e., $B := (1/T)\ln F(T,0)$, and define $G(t) := F(t,0)e^{-Bt}$. Then

$$G(t+T) = F(t+T,0)e^{-B(t+T)} = F(t+T,T)F(T,0)e^{-B(t+T)} = F(t,0)e^{-Bt} = G(t),$$

which is Floquet's theorem.[15]

It follows that

$$F(t,t_0) = F(t,0)F(0,t_0) = F(t,0)F^{-1}(t_0,0) = G(t)e^{B(t-t_0)}G^{-1}(t_0),$$

which is (30).

Now $F(T,0) = G(T)e^{BT}G^{-1}(0)$ and $1 = \det F(T,0) = \det(G(T))\det(e^{BT})(\det G(0))^{-1} = \det e^{BT}$ because $G(T) = G(0)$, hence $\mathrm{Tr}\, B = 0$.

Proof of Theorem 1: The Weyl algebra of observables is in the domain of the family of derivations defined as

$$\tilde{\delta}_{\underline{\alpha}}^{t_0,t} A := [L_{\underline{\alpha}}(t_0,t), A] \tag{40}$$

parametrized by the time variable,

$$\mathcal{W} \subset \mathrm{Dom}(\tilde{\delta}_{\underline{\alpha}}^{t_0,t}), \quad \forall\, t_0, t \in \mathbb{R}.$$

Indeed, by (5) and (25), if $A = e^{i(\beta\hat{x}+\gamma\hat{p})}$ then

$$[L_{\underline{\alpha}}(t_0,t), A] = (\alpha_p(t_0,t)\beta - \alpha_x(t_0,t)\gamma)A \in \mathcal{W}. \tag{41}$$

In order to determine the Lyapunov exponent we calculate

$$\|[L_{\underline{\alpha}}(t_0,t), A]\| = |\alpha_p(t_0,t)\beta - \alpha_x(t_0,t)\gamma|, \tag{42}$$

where we have used $\|A\| = 1$. By (26), (27), and (35)–(38) we may write, for $t, t_0 \in \mathbb{R}_+$,

$$\|[L_{\underline{\alpha}}(t_0,t), A]\| = |e^{(t-t_0)\lambda_+}[\{\alpha_p g_{12}(t_0) + \alpha_x g_{22}(t_0)\}(\beta g_{21}^{-1}(t) - \gamma g_{22}^{-1}(t))] + e^{(t-t_0)\lambda_-}[(\alpha_p g_{11}(t_0) + \alpha_x g_{21}(t_0)) \times (\beta g_{11}^{-1}(t) - \gamma g_{12}^{-1}(t))]|, \tag{43}$$

where we have used $\lambda_- = -\lambda_+$. The stable direction $\underline{\alpha}_s$ is determined by the condition that the curly bracket in the first term vanishes,

$$\{\alpha_p g_{12}(t_0) + \alpha_x g_{22}(t_0)\} = 0, \tag{44}$$

which leads to

$$\underline{\alpha}_s \equiv (\alpha_{ps}, \alpha_{xs}) = \eta_s(-g_{22}(t_0), g_{12}(t_0)), \tag{45}$$

where η_s is an arbitrary constant. We remark that the second term in (43) is not identically zero since

$$\alpha_p g_{11}(t_0) + \alpha_x g_{21}(t_0) = \eta_s(-g_{22}(t_0)g_{11}(t_0) + g_{12}(t_0)g_{21}(t_0)) = -\eta_s \det g \neq 0. \tag{46}$$

In this case we can write

$$\|[L_{\underline{\alpha}_s}(t_0,t), A]\| = e^{-t\lambda_r} S(t), \tag{47}$$

where λ_r is the absolute value of the real part of $\lambda_\pm$, and $S(t)$ is a periodic function of t. There is thus a sequence of times $\{t_k \to \infty\}$, such that $S(t_k) > \delta > 0$, for some constant δ, and therefore

$$\bar{\lambda}_{\underline{\alpha}_s}(U,L_{\underline{\alpha}_s},A,t_0) = -\lambda_r + \limsup_{t\to\infty}\frac{1}{t}\ln S(t) = -\lambda_r. \tag{48}$$

For all other directions $\underline{\alpha}$ we can write

$$\|[L_{\underline{\alpha}}(t_0,t),A]\| = e^{t\lambda_r}R(t), \tag{49}$$

where $R(t)$ is the sum of a periodic function and one that is either exponentially decreasing or identically zero. Thus there is a sequence of times $\{t_k\to\infty\}$, such that $R(t_k)>\delta>0$, for some constant δ, and therefore

$$\bar{\lambda}_{\underline{\alpha}}(U,L_{\underline{\alpha}},A,t_0) = \lambda_r + \limsup_{t\to\infty}\frac{1}{t}\ln R(t) = \lambda_r. \tag{50}$$

In the stability bands $E\in S,\lambda_\pm$ are imaginary, and thus $\bar{\lambda}_{\underline{\alpha}}=0$ for all directions $\underline{\alpha}$.

Remark: A simple extension of this proof shows that Theorem 1 is also true for any observable $A\in\mathcal{W}$ provided that $[L_{\underline{\alpha}},A]\neq 0$.

Proof of Theorem 2: We remark first that (20) and (21) are equivalent, by deriving with respect to s at $s=0$ to

$$U^\dagger(t_n,0)L_{\underline{\alpha}_+}U(t_n,0) = e^{-\lambda_r t_n}L_{\underline{\alpha}_+}, \tag{51}$$

$$U^\dagger(t_n,0)L_{\underline{\alpha}_-}U(t_n,0) = e^{\lambda_r t_n}L_{\underline{\alpha}_-}. \tag{52}$$

The eigendirections are thus determined by the conditions

$$L_{\underline{\alpha}_\pm}(t_n,0) = e^{\mp\lambda_\pm t_n}L_{\underline{\alpha}_\pm}(0,0). \tag{53}$$

According to Eqs. (25)–(27), since $h_{p\pm}(t,0)$ and $h_{x\pm}(t,0)$ are T periodic and since $\lambda_-=-\lambda_+$, these conditions will be satisfied.

For $\underline{\alpha}_+$, if $h_{p+}(t_n,0)=h_{p+}(0,0)=0$ and $h_{x+}(t_n,0)=h_{x+}(0,0)$, i.e., according to (35) and (37), if

$$(\alpha_{p+}g_{11}(0)+\alpha_{x+}g_{21}(0))g_{12}^{-1}(0) = 0, \tag{54}$$

$$(\alpha_{p+}g_{11}(0)+\alpha_{x+}g_{21}(0))g_{22}^{-1}(0) = 0. \tag{55}$$

For $\underline{\alpha}_-$, if $h_{p-}(t_n,0)=h_{p-}(0,0)=0$ and $h_{x-}(t_n,0)=h_{x-}(0,0)$, i.e., according to (36) and (38), if

$$(\alpha_{p-}g_{12}(0)+\alpha_{x-}g_{22}(0))g_{22}^{-1}(0) = 0, \tag{56}$$

$$(\alpha_{p-}g_{12}(0)+\alpha_{x-}g_{22}(0))g_{21}^{-1}(0) = 0. \tag{57}$$

Since g^{-1} is nonsingular, g_{12}^{-1} and g_{22}^{-1} cannot both be zero, and therefore for $\underline{\alpha}_-$ we obtain the condition

$$\alpha_{p-}g_{12}(0)+\alpha_{x-}g_{22}(0) = 0, \tag{58}$$

which has the solution

$$\underline{\alpha}_- \equiv (\alpha_{p-},\alpha_{x-}) = \eta_-(-g_{22}(0),g_{12}(0)), \tag{59}$$

where η_- is an arbitrary constant. Since g is nonsingular, g_{12} and g_{22} cannot both be zero, and thus (59) determines the unique stable eigendirection. It coincides for t_0 with the stable $\underline{\alpha}_s$ of Theorem 1, Eq. (45).

By the same type of argument we obtain the unstable eigendirection as

$$\underline{\alpha}_+ \equiv (\alpha_{p+}, \alpha_{x+}) = \eta_+(-g_{21}(0), g_{11}(0)). \tag{60}$$

We remark that

$$e^{2T\lambda_\pm} = e^{\pm 2T\lambda_r} e^{\pm i2T\lambda_i} = e^{\pm 2T\lambda_r}, \tag{61}$$

since in the gaps $E \in I$ the imaginary part λ_i of the Floquet eigenvalues takes constant values of the form

$$\lambda_i = k\frac{2\pi}{2T}, \quad k \in \mathbb{Z}. \tag{62}$$

This can be shown as follows: $\Lambda_\pm \equiv e^{\lambda_\pm T}$ are the eigenvalues of the propagator matrix $F(T,0)$ defined in Eq. (30). Since it is a real matrix with $\det F(T,0)=1$, its eigenvalues are either real or complex conjugate to each other $\Lambda_- = \Lambda_+^*$, in which case $|\Lambda_\pm| = 1$. Therefore, in the instability region $E \in I$ the eigenvalues $\Lambda_\pm = e^{\pm(\lambda_r + i\lambda_i)}$ are necessarily real, and thus $\lambda_i T = k\pi$, $k \in \mathbb{Z}$.

This completes the proof of the Anosov property (51) and (52).

Remark 1: The factor $1/2$ in Eq. (62) explains the need to take time intervals that are multiples of $2T$ in order to have the Anosov property. For the gaps with even k one has the Anosov property also in the discrete times $t_n' = nT$, $n \in \mathbb{Z}$.

Remark 2: We have set $t_0 = 0$ above, but, although the eigenvalues $\lambda_\pm$ do not vary upon variation of t_0, the eigendirections do. This is the reason why we have an Anosov system in discretized time but not in continuous time.

Remark 3: The above example of a quantum Anosov structure is interesting because it is not global in the space of parameters E, i.e., if $E \in S$ it is not realized. For $E \in S$, the upper quantum Lyapunov exponent equals zero, a case which is included in our definition, but not by Refs. 1–3.

Remark 4: The parametric quantum oscillator (13) is, of course, very special, being quadratic in $\hat{x}$ and $\hat{p}$. We have used the fact that the Heisenberg equations of motion for $\hat{x}, \hat{p}$ have the same form as the classical Hamiltonian equations. The dynamics are, however, rich and nontrivial and not explicitly soluble both classically and quantum mechanically: the complexity manifests itself in the fact that the symmetry group of (13) is SU (1,1) rather than the Heisenberg group.[16] The transition in the theorem has a physical interpretation in a model of quadrupole radio-frequency traps (Paul–Penning traps), see Refs. 9, 10, and 17 and references given there.

Remark 5: The case of a quasiperiodic time dependence has a very interesting structure (Refs. 18 and 19), and our approach is, in principle, applicable to this case.

Fluctuation statistics in networks: A stochastic path integral approach

Andrew N. Jordan, Eugene V. Sukhorukov, and Sebastian Pilgram
Département de Physique Théorique, Université de Genève, CH-1211 Genève 4, Switzerland

(Received 13 February 2004; accepted 21 July 2004; published 25 October 2004)

We investigate the statistics of fluctuations in a classical stochastic network of nodes joined by connectors. The nodes carry generalized charge that may be randomly transferred from one node to another. Our goal is to find the time evolution of the probability distribution of charges in the network. The building blocks of our theoretical approach are (1) known probability distributions for the connector currents, (2) physical constraints such as local charge conservation, and (3) a time scale separation between the slow charge dynamics of the nodes and the fast current fluctuations of the connectors. We integrate out fast current fluctuations and derive a stochastic path integral representation of the evolution operator for the slow charges. The statistics of charge fluctuations may be found from the saddle-point approximation of the action. Once the probability distributions on the discrete network have been studied, the continuum limit is taken to obtain a statistical field theory. We find a correspondence between the diffusive field theory and a Langevin equation with Gaussian noise sources, leading nevertheless to nontrivial fluctuation statistics. To complete our theory, we demonstrate that the cascade diagrammatics, recently introduced by Nagaev, naturally follows from the stochastic path integral. By generalizing the principle of minimal correlations, we extend the diagrammatics to calculate current correlation functions for an arbitrary network. One primary application of this formalism is that of full counting statistics (FCS), the motivation for why it was developed in the first place. We stress however, that the formalism is suitable for general classical stochastic problems as an alternative approach to the traditional master equation or Doi–Peliti technique. The formalism is illustrated with several examples: Both instantaneous and time averaged charge fluctuation statistics in a mesoscopic chaotic cavity, as well as the FCS and new results for a generalized diffusive wire. © *2004 American Institute of Physics.*

I. INTRODUCTION

Consider an exclusive nightclub with a long line at the entrance. A bouncer is at the front of the line to keep out the riffraff. At every time step, a person is accepted inside the club with probability p, or rejected with probability $1-p$. Inside the club, people stay for a while and eventually leave. At every time step, the probability a person leaves is q. We want to answer a question such as "what is the probability that Q people leave the club after t time steps?"

Assuming that p and q remain constant, the situation is simple and we can easily solve the relevant probabilistic problem. However, in realistic situations this rarely happens: The management wants to make money. If the club is almost empty, they instruct the bouncer to be less discriminating, while if the club is almost full, the bouncer is to be more discriminating. Thus, p becomes a function of the number of people in the club. People will be more likely to leave if the club is very crowded, so q is also a function of the number of people inside the club. The problem posed now is much more difficult because of the presence of feedback: The elementary processes change in response to the cumulative effect of what they have accomplished in the past.

This simple example captures all the basic features of the problems we wish to consider. Although the example was given with people, the actors in the probability game may be any quantity such as charge, energy, heat, or particles, which we will refer to simply as generalized charge. Similarly, the nightclub can be a mesoscopic chaotic cavity,[1] a birth-death process,[2] a biological membrane channel,[3] etc.

Historically, general stochastic problems are solved with the master equation. The time rate of change of the probability to be in a particular state is given in terms of transition rates to other states. This approach has had great success and leads naturally to the Fokker–Planck and Langevin equations.[4] However, once the master equation is given, the solution is often quite difficult to obtain.

This paper takes a different approach. Rather than beginning with a master equation describing the probability of all processes happening in a unit of time, we make several assumptions from which we can reformulate the problem. Although these assumptions limit the applicability of the theory, when they apply, the problems are much easier to solve. The assumptions are:

- The system we are interested in is a composite system made out of constituent parts. In the nightclub example, the system is made up of three physical regions: Outside the front door, the interior of the club, and outside the back door. The decomposition of a larger system into smaller interacting parts is only meaningful for us if there is a separation of time scales. This means that the charge inside the constituent parts changes on a slower time scale than the fluctuations at the boundaries. In the nightclub example, this simply means that the average time a person spends in the club will be much longer than the typical time needed to enter the door.
- Taken alone, the parts of the composite system have a finite number of simple properties or parameters. The only property of the nightclub that was relevant for the problem was the total number of people in it at any given time. The important element of the line out in front is that it never runs out. All other details are irrelevant.
- In the limit where all parts of the network are very large (so that the elementary transport processes do not affect themselves in the short run), the transport probability distributions between elements are known. In the nightclub example, the probability of getting Q people through the front door after t time steps (given a constant, large number of people inside) is easy to find, because we have assumed that the elementary probability p does not change from trial to trial. The transport probability distribution is simply the binomial distribution[4] where the probability p is a function of the (approximately unchanging) number of people inside. The back door distribution is obtained in the same way.
- There are conservation laws that govern the probabilistic processes. No matter what probability distributions we have, there are certain rules that must be obeyed. The net number of people that enter, stay, and leave the club must be a constant. This means that the time rate of change of the club's occupancy is given by the people-current in minus the people-current out. The people in the line outside are a special case. There is in principle always a replacement, so moving one person inside the club does not affect the properties of the line.

Now, the strategy is to use this information as the starting point to find transport statistics for the combined interacting system. The main result derived is a path integral expression for the conditional probability (taking conservation laws into account) for starting and ending with a given amount of charge at each location after some time has passed. From this conditional probability, specific quantities such as transport statistics through the system, fluctuation statistics of charge at a particular location and the like may be found.

One primary application of this formalism is that of full counting statistics (FCS),[5,6] the motivation for why it was developed in the first place.[7] FCS describes the fluctuations of currents in electrical conductors. It gives the distribution of the probability that a certain number of electrons pass a conductor in a certain amount of time. Mean current flow and shot noise[1] correspond to the first and second cumulant of this distribution. The full distribution (defined by all cumulants) provides a full characterization of the transport properties of an electrical conductor in the long time limit. In the past, FCS was mainly addressed with quantum mechanical tools such as

the scattering theory[5,6,8,9] of coherent conductors, the circuit theory based on Keldysh Green functions,[10–13] or the nonlinear σ model.[14] However, a number of works realized that for semi-classical systems with a large number of conductance channels, shot noise may be calculated without accounting for the phase coherence of the electron.[15–18] These works treat the basic sources of noise quantum mechanically, but calculate the spread of the noise throughout the conductor classically. For specific conductors like diffusive wires and chaotic cavities, this idea has been extended to the calculation of third and fourth cumulants via the cascade principle[19,20] and to the full generating function of FCS.[7,21–23] In the present work, we consider an abstract model instead of any particular example and develop the mathematical foundations of the proposed semi-classical procedure to obtain FCS. We introduce and investigate networks of elements with known transport statistics and show how the FCS of the entire network can be constructed systematically.

The formalism we present is related to a different approach in nonequilibrium statistical physics called the Doi–Peliti technique.[24] The idea is that once the basic master equation governing the time evolution of probability distributions is given, it may be interpreted as a Schrödinger equation which may be cast into a second-quantized language. This quantum problem is then converted into a quantum mechanical path integral (often obeying bosonic or fermionic statistics) from which one may take the continuum limit and use a field theory renormalization group approach with diagrammatic perturbation expansion.[25] This approach is useful in many situations far from equilibrium and has several parallels to our approach. It has been pointed out that this technique is in some sense the classical limit of the quantum mechanical Keldysh formalism,[26] the same tool used in the past to calculate FCS, so this gives another connection with the subject matter we are concerned with.

There are several advantages of our approach. First, we skip the master equation step. If the probability distributions of the connector fluctuations are given, we may immediately construct network distributions. Second, from a computational view, our formulation of the problem is much simpler than starting from first principles for situations where the ingredients we need are available, and results are much easier to obtain than beginning with the master equation alone. Thirdly, our formulation also applies to situations where temporal transition probabilities may be large. Finally, the formalism's physical origin is clear, so the needed mathematical objects are well motivated.

The rest of the paper is organized as follows. In Sec. II, we introduce and develop the general theory. After reviewing elements of probability theory, we derive the stochastic path integral for a network of nodes as well as explore the relationship to the master equation and Doi–Peliti formalism. In Sec. III, the continuum limit is taken to derive a stochastic field theory and link our formalism with the Langevin equation point of view. In Sec. IV, we develop diagrammatics rules to calculate cumulants of the current distribution as well as current correlation functions for an arbitrary network. Section V gives several applications of the theory to different physical situations. We solve the field theory for the mesoscopic wire and demonstrate universality in multiple dimensions as well as present new results for the conditional occupation function and probability distribution. We also consider the problem of charge fluctuation statistics (both instantaneous and time-averaged) in a mesoscopic chaotic cavity. Section VI contains our conclusions.

II. GENERAL FORMALISM

Once we have the basic elements of our theory (the generalized charges), we must specify some spatial structure that they move around on. As we noted in the introduction, the essential structure needed to state the problem are simply points we refer to as nodes, joined by connectors. This defines a network (see Fig. 1). The state of each node α is described by one (effectively continuous) charge Q_α,[27] and $\mathbf{Q}$ is the charge vector describing the charge state of the network. The node's state may be changed by transport: Flow of charges between nodes takes place via the connectors carrying currents $I_{\alpha\beta}$ from node α to node β. The variation of these charges Q_α is given by

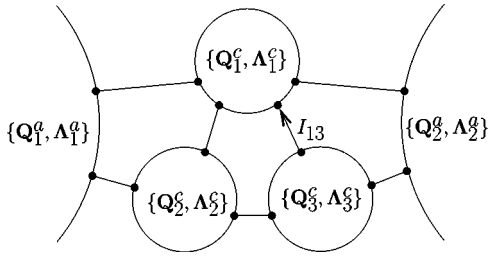

FIG. 1. An arbitrary network. Each node has charge and counting variables $\{\mathbf{Q}_\alpha, \mathbf{\Lambda}_\alpha\}$. The nodes transfer charge via currents $I_{\alpha\beta}$ through the connectors. The absorbed counting fields $(\mathbf{\Lambda}_\alpha^a)$ are constants by definition of the absorbed charges $\mathbf{Q}_\alpha^a$ (see text). Each node may have an arbitrary number of different charge species, $\mathbf{Q}_\alpha = \{Q_\alpha^1, Q_\alpha^2, \ldots, Q_\alpha^j\}$.

$$Q_\alpha(t+\Delta t) - Q_\alpha(t) = \sum_\beta Q_{\alpha\beta}, \tag{1}$$

where the transmitted charges $Q_{\alpha\beta}(t) = \int_0^{\Delta t} dt' I_{\alpha\beta}(t+t')$ are distributed according to $P_{\alpha\beta}(Q_{\alpha\beta}(t))$. The fact that the probabilities $P_{\alpha\beta}(t)$ also depend on the charges $\mathbf{Q}(t)$ is one source of the difficulty of the problem.

Assuming that the probability distributions $P_{\alpha\beta}$ (which depend parametrically on the state of nodes α and β) of the transmitted charges $Q_{\alpha\beta}$ are known, we seek the time evolved probability distribution $\Gamma(\mathbf{Q}, t)$ of the set of charges $\mathbf{Q}$ for a given initial distribution $\Gamma(\mathbf{Q}, 0)$. In other words, one has to find the conditional probability (which we refer to as the evolution operator) $U(\mathbf{Q}, \mathbf{Q}', t)$ such that

$$\Gamma(\mathbf{Q}, t) = \int d\mathbf{Q}' U(\mathbf{Q}, \mathbf{Q}', t) \Gamma(\mathbf{Q}', 0). \tag{2}$$

We assume that there is a separation of time scales, $\tau_0 \ll \tau_C$, between the correlation time of current fluctuations, τ_0, and the slow relaxation time of charges in the nodes, τ_C. As we will show in the next section, this separation of time scales allows us to derive a stochastic path integral representation for the evolution operator,

$$U(\mathbf{Q}_f, \mathbf{Q}_i, t) = \int \mathcal{D}\mathbf{Q}\mathcal{D}\mathbf{\Lambda} \exp\{S(\mathbf{Q}, \mathbf{\Lambda})\}, \tag{3a}$$

$$S(\mathbf{Q}, \mathbf{\Lambda}) = \int_0^t dt' \left[-i\mathbf{\Lambda} \cdot \dot{\mathbf{Q}} + (1/2) \sum_{\alpha\beta} H_{\alpha\beta}(\mathbf{Q}, \lambda_\alpha - \lambda_\beta) \right], \tag{3b}$$

where the vector $\mathbf{\Lambda}$ has components λ_α: Node variables conjugated to the Q_α that impose charge conservation in the network.

In the following, we define the functions $H_{\alpha\beta}$ as the generating functions of the fast currents between nodes α and β. On the time scale $\Delta t \gg \tau_0$, the currents through isolated connectors are Markovian, so that all cumulants (irreducible correlators which are denoted by double angle brackets) of the transmitted charge $\langle\langle (Q_{\alpha\beta})^n \rangle\rangle$ are linear in Δt. Following the standard notation in mesoscopic physics,[28] we define the current cumulants $\langle\langle (\tilde{I}_{\alpha\beta})^n \rangle\rangle$ as the coefficients in

$$\langle\langle (Q_{\alpha\beta})^n \rangle\rangle = \Delta t \langle\langle (\tilde{I}_{\alpha\beta})^n \rangle\rangle, \tag{4}$$

where the tilde symbol has been introduced to distinguish the bare currents of each connector (the sources of noise) from the physical currents $I_{\alpha\beta}$ flowing through that same connector when it is placed into the network. Then the generators $H_{\alpha\beta}$ are defined via the equation

$$\langle\langle(\tilde{I}_{\alpha\beta})^n\rangle\rangle = \left.\frac{\partial^n H_{\alpha\beta}(\mathbf{Q},\lambda_{\alpha\beta})}{(i\,\partial\lambda_{\alpha\beta})^n}\right|_{\lambda_{\alpha\beta}=0}, \tag{5}$$

and thus contain complete information about the statistics of the noise sources. The $\lambda_{\alpha\beta}$ [eventually to be replaced with with $\lambda_\alpha-\lambda_\beta$ in Eq. (3)] is the generating variable for the current $\tilde{I}_{\alpha\beta}$. The notion of current cumulants is useful because they are the time independent objects, and thus have time independent generators, Eq. (5). The generators $H_{\alpha\beta}(\mathbf{Q},\lambda_{\alpha\beta})$ depend in general on the full vector $\mathbf{Q}$ and not just on the generalized charges of the neighboring nodes Q_α and Q_β. This may serve to incorporate long range interactions between distant nodes.

The charge $Q_{\alpha\beta}$ transferred through the connectors [characterized by Eqs. (4) and (5)] may be discrete. However, the charge in the nodes Q_α is treated as an effectively continuous variable in Eqs. (1)–(3). This is justified if many charges in the node participate in transport. Formally, this limit allows a saddle-point evaluation of the propagator (3a).

A. Derivation of the path integral

To derive the path integral Eq. (3), we follow the usual procedure[29] and first discretize time, $t=n\Delta t$ to derive an expression for U that is valid for propagation over one time step Δt. Because of the separation of time scales $\tau_0 \ll \tau_C$, we can consider Δt as an intermediate time scale,

$$\tau_0 \ll \Delta t \ll \tau_C. \tag{6}$$

The left inequality, $\tau_0 \ll \Delta t$, implies that the transmitted charges $Q_{\alpha\beta}$ are Markovian.[4] This means that charges transmitted in separate time intervals are uncorrelated with each other. While it is not necessary to specify the source of the current correlation in the general formulation, it is worth noting two examples. In a mesoscopic point contact, the correlation time τ_0 has the interpretation of the time taken by an electron wavepacket to pass the point contact. In chemical dynamics, it could be the time taken for a long molecule in solution to traverse a filter.

In a time Δt, the probability that charge $Q_{\alpha\beta}$ is transmitted between nodes α and β can be written as the Fourier transform of the exponential of a generating function $S_{\alpha\beta}$:

$$P_{\alpha\beta}(Q_{\alpha\beta},\Delta t) = \int \frac{d\lambda_{\alpha\beta}}{2\pi}\exp\{-i\lambda_{\alpha\beta}Q_{\alpha\beta} + S_{\alpha\beta}(\lambda_{\alpha\beta})\}. \tag{7}$$

The definition of the cumulant of transmitted charge is

$$\langle\langle(Q_{\alpha\beta})^n\rangle\rangle = \left.\frac{\partial^n S_{\alpha\beta}(\lambda_{\alpha\beta})}{(i\,\partial\lambda_{\alpha\beta})^n}\right|_{\lambda_{\alpha\beta}=0}. \tag{8}$$

The Markovian assumption implies that the probability of transmitting charge $Q_{\alpha\beta}$ in time Δt followed by charge $Q'_{\alpha\beta}$ in time $\Delta t'$ through any connector is given by the product of independent probability distributions. This implies that the probability of transmitting charge $Q_{\alpha\beta}$ in time $\Delta t + \Delta t'$ may be calculated by finding all ways of independently transferring charge $Q'_{\alpha\beta}$ in the first step and $Q_{\alpha\beta}-Q'_{\alpha\beta}$ in the second step,

$$P(Q_{\alpha\beta},\Delta t+\Delta t') = \int dQ'_{\alpha\beta}P(Q_{\alpha\beta}-Q'_{\alpha\beta},\Delta t')P(Q'_{\alpha\beta},\Delta t), \tag{9}$$

which takes the form of a convolution of probabilities. Applying a Fourier transform to both sides of Eq. (9) with argument $\lambda_{\alpha\beta}$ decouples the convolution into a product of the two Fourier transformed distributions. Equation (7) implies $S_{\alpha\beta}(\Delta t+\Delta t',\lambda_{\alpha\beta})=S_{\alpha\beta}(\Delta t,\lambda_{\alpha\beta})+S_{\alpha\beta}(\Delta t',\lambda_{\alpha\beta})$. It then immediately follows that the generating function must be linear in time. Therefore, a time independent $H_{\alpha\beta}$ may be introduced: $S_{\alpha\beta}=\Delta t\, H_{\alpha\beta}$. The linear dependence of $S_{\alpha\beta}$ on time implies that all charge cumulants (8) will be proportional to time. Therefore, we define the time independent current cumulants, Eq. (5).

Different connectors are clearly uncorrelated for $\Delta t \ll \tau_C$, which indicates that the total probability distribution of transmitted charges is a product of the independent probabilities in each connector:[30]

$$P[\{Q_{\alpha\beta}\}] = \prod_{\alpha>\beta} P_{\alpha\beta}[Q_{\alpha\beta}, \Delta t]. \tag{10}$$

Thus far, the analysis is only valid for times much smaller than τ_C. For this case, the charges in the nodes will only slightly change. Since we wish to consider longer times, we need to take into account the fact that charge transfer between different nodes will be correlated as charge piles up inside the nodes. This may be accounted for by imposing charge conservation Eq. (1) during the time interval with a delta function,

$$\delta\left(Q_\alpha - Q'_\alpha - \sum_\beta Q_{\alpha\beta}\right) = \int \frac{d\lambda_\alpha}{2\pi} \exp\left\{-i\lambda_\alpha\left[Q_\alpha - Q'_\alpha - \sum_\beta Q_{\alpha\beta}\right]\right\}. \tag{11}$$

Here, Q'_α is the charge in the node before the time interval while Q_α is the charge accumulated in the node after the time interval is over. In Eq. (11), λ_α (referred to as a *counting variable*) plays the role of a Lagrange multiplier. The propagator is obtained by multiplying the constraint (11) and the independent probability distribution (10). Representing the probabilities in their Fourier form (7) then yields

$$\tilde{U}(\mathbf{Q}, \mathbf{Q}', Q_{\alpha\beta}, \Delta t) = \prod_\alpha \int \frac{d\lambda_\alpha}{2\pi} \prod_{\alpha>\beta} \int \frac{d\lambda_{\alpha\beta}}{2\pi} \exp(S),$$

$$S = -i\sum_\alpha \lambda_\alpha \left(Q_\alpha - Q'_\alpha - \sum_\beta Q_{\alpha\beta}\right) + \sum_{\alpha>\beta} [-i\lambda_{\alpha\beta} Q_{\alpha\beta} + \Delta t H_{\alpha\beta}(\mathbf{Q}', \lambda_{\alpha\beta})]. \tag{12}$$

The full propagator $\tilde{U}(\mathbf{Q}, \mathbf{Q}', Q_{\alpha\beta}, \Delta t)$ still keeps track of each individual connector contribution $Q_{\alpha\beta}$. We now integrate out the fast fluctuations to obtain the dynamics of the slow variables. This may be done by using the identity $\Sigma_\alpha \lambda_\alpha \Sigma_\beta Q_{\alpha\beta} = \Sigma_{\alpha>\beta}(\lambda_\alpha Q_{\alpha\beta} + \lambda_\beta Q_{\beta\alpha})$ and $Q_{\alpha\beta} = -Q_{\beta\alpha}$. The integration over $Q_{\alpha\beta}$ gives a delta function of argument $\lambda_{\alpha\beta} - (\lambda_\alpha - \lambda_\beta)$, so that the $\lambda_{\alpha\beta}$ integrals may be trivially done. We obtain

$$U(\mathbf{Q}, \mathbf{Q}', \Delta t) = \prod_\alpha \int \frac{d\lambda_\alpha}{2\pi} \exp\left\{-i\sum_\alpha \lambda_\alpha (Q_\alpha - Q'_\alpha) + \Delta t \sum_{\alpha>\beta} H_{\alpha\beta}(\mathbf{Q}', \lambda_\alpha - \lambda_\beta)\right\}. \tag{13}$$

This is the general result for the one step propagator. If any two nodes are unconnected, $H_{\alpha\beta}$ is zero.

An important comment is in order: Because $H_{\alpha\beta}$ changes slightly over the time period, which in turn affects the probability of transmitting charge through the contacts, it is not clear at what part of the time step $H_{\alpha\beta}$ should be evaluated. This ambiguity exists because our theory is not microscopic. Rather, it takes the microscopic noise generators as an input. This ambiguity gives the freedom of stochastic quantization.[31] The same problem also occurs in quantum mechanical path integrals, and its source there is an ambiguity in operator ordering.[32] As we are interested in the large transporting charge limit, $\gamma \gg 1$, and evaluate the integrals in leading order saddle-point approximation, this ambiguity will not affect the results.[7] For calculations beyond the large transporting charge limit, the canonical variables $\mathbf{Q}$ and $\mathbf{\Lambda}$ need to be properly ordered, which can only be done with a microscopic theory. For example, the master equation discretized in time as discussed in Sec. II D requires the placement of $\mathbf{\Lambda}$ operators in front of $\mathbf{Q}$ operators, since the generating functions $H_{\alpha\beta}$ of the transition probabilities depend on the state of the system at the beginning of the time period.

To extend the propagator (13) to longer times $t = n\Delta t$, we use the composition property of the evolution operator (also known as the Chapman–Kolmogorov equation[4]). This requires separate

$\{Q_\alpha\}$ integrals at each time step, so that for n time steps there will be $n-1$ integrals over $\mathbf{Q}$, while each of the n one-step propagators comes with its own $\mathbf{\Lambda}$ integral, $\mathbf{\Lambda}=\{\lambda_\alpha\}$. Inserting our expression for the Δt step propagator Eq. (13), we find

$$U(\mathbf{Q}_f,\mathbf{Q}_i,t)=\int d\mathbf{\Lambda}_0\prod_{k=1}^{n-1}\int d\mathbf{Q}_k d\mathbf{\Lambda}_k \exp\left[\sum_{k=0}^{n-1} -i\mathbf{\Lambda}_k\cdot(\mathbf{Q}_{k+1}-\mathbf{Q}_k)+\Delta t H(\mathbf{Q}_k,\mathbf{\Lambda}_k)\right], \quad (14a)$$

with

$$H(\mathbf{Q}_k,\mathbf{\Lambda}_k)=\sum_{\alpha>\beta} H_{\alpha\beta}[Q_{\alpha,k};\lambda_{\alpha,k}-\lambda_{\beta,k}], \quad (14b)$$

where we have introduced the notations $d\mathbf{Q}_k=\Pi_\alpha\, dQ_{\alpha,k}$ and $d\mathbf{\Lambda}_k=\Pi_\alpha(d\lambda_{\alpha,k}/2\pi)$. We are now in a position to take the continuous time limit. Writing $\mathbf{Q}_{k+1}-\mathbf{Q}_k=\Delta t\dot{\mathbf{Q}}$, which is valid because the charge in any node changes only slightly over the time scale Δt, the action of this discrete path integral has the form $S=\Delta t\Sigma_{k=1}^{n} S_k$, which goes over into a time integral in the continuous limit. Using the standard path integral notation $\int\mathcal{D}\mathbf{Q}\mathcal{D}\mathbf{\Lambda}=\int d\mathbf{\Lambda}_0\Pi_{k=1}^{n-1}\int d\mathbf{Q}_k d\mathbf{\Lambda}_k$, and invoking the symmetry $H_{\alpha\beta}(\lambda_\alpha-\lambda_\beta)=H_{\beta\alpha}(\lambda_\beta-\lambda_\alpha)$ we recover Eq. (3). The only explicit constraint on the path integral comes with the charge configurations at the start and finish, $\mathbf{Q}_i$ and $\mathbf{Q}_f$. We also note that $H_{\alpha\beta}$ depends on any external parameters such as voltages or chemical potentials driving the charge $\mathbf{Q}$.

In the simplest case of one charge and counting variable, the form of the path integral is the same as the (Euclidian time) path integral representation of a quantum mechanical propagator in phase space with position coordinate Q and momentum coordinate λ.[32] The differences with the quantum version are that the propagator evolves probability distributions, not amplitudes (similarly to Ref. 25), as well as the fact that the "Hamiltonian" $H=(1/2)\Sigma_{\alpha\beta}H_{\alpha\beta}(\mathbf{Q},\lambda_\alpha-\lambda_\beta)$ is not really a Hamiltonian, but rather a current cumulant generating function and, therefore, is not Hermitian in general. Even so, because of the similarity we shall refer to H as the Hamiltonian from now on.

B. Absorbed charges, boundary conditions, and correlation functions

A useful special case occurs when one has absorbed charges. These are charges that vanish into (or are injected from) absorbing nodes without altering the system dynamics. In mesoscopics, for example, the absorbing nodes are metallic reservoirs. Formally, we divide the charges into those that are conserved and those that are absorbed: $\mathbf{Q}=\{\mathbf{Q}^c,\mathbf{Q}^a\}$, where the subset of absorbed charges $\mathbf{Q}^a=\{Q_\alpha^a\}$ does not appear in $H_{\alpha\beta}$. We do the same for the corresponding counting variables: $\mathbf{\Lambda}=\{\mathbf{\Lambda}^c,\mathbf{\Lambda}^a\}$. Because $H_{\alpha\beta}$ does not depend on $\mathbf{Q}^a$, these charges may be integrated out by integrating the action by parts,

$$i\int_0^t dt'\mathbf{\Lambda}^a\cdot\dot{\mathbf{Q}}^a=-i\int_0^t dt'\mathbf{Q}^a\cdot\dot{\mathbf{\Lambda}}^a+i(\mathbf{\Lambda}_f^a\cdot\mathbf{Q}_f^a-\mathbf{\Lambda}_i^a\cdot\mathbf{Q}_i^a), \quad (15)$$

and then functionally integrating over $\mathbf{Q}^a$ to obtain $\delta(\dot{\mathbf{\Lambda}}^a)$, where δ is a functional delta function. This immediately constrains the $\mathbf{\Lambda}^a$ to be constants of motion so the functional integration over $\mathbf{\Lambda}^a$ becomes a normal integration, $\mathcal{D}\mathbf{\Lambda}^a\to d\mathbf{\Lambda}^a$. The absorbed kinetic terms in the action may then be integrated to obtain

$$U(\mathbf{Q}_f,\mathbf{Q}_i,t)=\int d\mathbf{\Lambda}^a\int\mathcal{D}\mathbf{Q}^c\mathcal{D}\mathbf{\Lambda}^c\exp\{S(\mathbf{Q},\mathbf{\Lambda})\}, \quad (16a)$$

$$S(\mathbf{Q},\mathbf{\Lambda})=\int_0^t dt'\left[-i\mathbf{\Lambda}^c\cdot\dot{\mathbf{Q}}^c+(1/2)\sum_{\alpha\beta}H_{\alpha\beta}(\lambda_\alpha-\lambda_\beta)\right]-i\mathbf{\Lambda}^a\cdot(\mathbf{Q}_f^a-\mathbf{Q}_i^a). \quad (16b)$$

Often one is interested in the probability to transmit some amount of charge through each of the absorbing nodes. By applying a Fourier transform to Eq. (16a) with respect to $\mathbf{Q}^a(t)-\mathbf{Q}^a(0)$ we remove the last term in Eq. (16b) and obtain the path integral representation for the characteristic function Z which generates current moments at every absorbing node

$$Z(\mathbf{\Lambda}^a)=\int \mathcal{D}\mathbf{Q}^c\mathcal{D}\mathbf{\Lambda}^c \exp\{S(\mathbf{Q},\mathbf{\Lambda})\}, \tag{17a}$$

$$S(\mathbf{Q},\mathbf{\Lambda})=\int_0^t dt'\left[-i\mathbf{\Lambda}^c\cdot\dot{\mathbf{Q}}^c+(1/2)\sum_{\alpha\beta}H_{\alpha\beta}(\lambda_\alpha-\lambda_\beta)\right]. \tag{17b}$$

Note that the counting variables $\mathbf{\Lambda}^a$ enter the action (17b) only as a set of constant parameters. The initial condition in the path integral (17) is given by the initial charge states $\mathbf{Q}^c(0)$. There is a choice of the final condition: By fixing the final $\mathbf{Q}^c(t)$ one obtains the distribution of the conserved charge subject to this constraint, while by fixing $\mathbf{\Lambda}^c(t)$ the corresponding characteristic function is obtained. The choice of $\mathbf{\Lambda}^c(t)=0$ in Eq. (17) gives the characteristic function of the absorbed charge under the condition that the conserved charge is not being monitored, i.e., the final charge state is integrated over. Therefore, $\ln Z$ becomes the generator of the FCS, defining the charge cumulants at the absorbing node,

$$\langle\langle[Q_\alpha^a(t)-Q_\alpha^a(0)]^n\rangle\rangle=\left.\frac{\partial^n \ln Z}{(\partial i\lambda_\alpha^a)^n}\right|_{\mathbf{\Lambda}^a=0}. \tag{18}$$

In the long time limit, this quantity is proportional to time, independent of the details of the boundary conditions.

Alternatively, in the short time limit one may calculate irreducible correlation functions of absorbed and conserved current fluctuations, $\mathbf{I}=\dot{\mathbf{Q}}$. These correlation functions can be obtained by extending the time integral in (3b) to infinity, introducing sources[32] in the action, $S\to S+i\int dt\ \chi(t)\cdot\mathbf{I}(t)$, and applying functional derivatives with respect to χ. Repeating the steps leading to Eqs. (17), we find that variables λ_α in the Hamiltonian in Eq. (17b) have to be shifted $\lambda_\alpha\to\lambda_\alpha+\chi_\alpha$. Then, the irreducible current correlation function is given by

$$\langle\langle I_{\alpha_1}(t_1)\cdots I_{\alpha_n}(t_n)\rangle\rangle=\left.\frac{\delta^n \ln Z[\chi]}{\delta i\chi_{\alpha_1}(t_1)\cdots\delta i\chi_{\alpha_n}(t_n)}\right|_{\chi=0}. \tag{19}$$

With these correlation functions, one may calculate, for example, the frequency dependence of current cumulants.[33]

C. The saddle point approximation

If the Hamiltonian has some dimensionless large prefactor, then the path integral (3) may be evaluated using the saddle point approximation, which is justified below. At the saddle point, (where the first variation of the action vanishes), we can write equations of motion analogous to the Hamiltonian equations of classical mechanics:

$$i\dot{\mathbf{Q}}^c=\frac{\partial}{\partial\mathbf{\Lambda}^c}H(\mathbf{Q}^c,\mathbf{\Lambda}),\quad i\dot{\mathbf{\Lambda}}^c=-\frac{\partial}{\partial\mathbf{Q}^c}H(\mathbf{Q}^c,\mathbf{\Lambda}), \tag{20}$$

where $H(\mathbf{Q}^c,\mathbf{\Lambda})=(1/2)\Sigma_{\alpha\beta}H_{\alpha\beta}(\mathbf{Q}^c;\lambda_\alpha-\lambda_\beta)$. There may be many saddle point solutions in general, and one has to sum over all of them. Equations (20) are solved subject to the temporal boundary conditions and generally describe the relaxation of the conserved charges from the initial state to a stationary state $\{\overline{\mathbf{Q}^c},\overline{\mathbf{\Lambda}^c}\}$ on a time scale given by τ_C, the dynamical time scale of the nodes. These stationary coordinates are functions of any external parameters as well as the (constant) absorbed counting variables $\mathbf{\Lambda}^a$. In the saddle point approximation, the action takes the form

$S=S_{sp}+S_{\mathrm{fluc}}$.[7] The term S_{sp} is the contribution to the action from the solution of the Eqs. (20), which describes the evolution of the system from the initial to the final state. The term S_{fluc} describes fluctuations around the saddle point and is suppressed compared to the saddle-point contribution, if the Hamiltonian has a large prefactor (in analogy to the $\hbar$-expansion of quantum mechanics). Physically, the validity condition for the saddle point approximation is that there should be many (transporting) charge carriers in the nodes. For times longer than the charge relaxation time of the node, the dominant contribution is from the stationary state only, where the saddle-point part of the action is simply linear in time:

$$S_{sp}(\overline{\mathbf{Q}},\overline{\mathbf{\Lambda}}) = tH(\overline{\mathbf{Q}},\overline{\mathbf{\Lambda}}), \quad t \gg \tau_C. \tag{21}$$

The linear time dependence of Eq. (21) indicates that the dynamics are Markovian on a long time scale. It is the fact that the contribution S_{sp} emerges in a dominant way which makes the approach given here a powerful tool to analyze the counting statistics of transmitted charge.

We now discuss the large parameter that justifies the saddle point approximation. The boundary conditions on the charge in the absorbing nodes fix a (dimensionless) charge scale of the system, γ. All charges in the network are scaled accordingly, $\mathbf{Q}\to\gamma\mathbf{Q}$. We make the assumption that there is a one parameter scaling of the Hamiltonian, $H\to\gamma H$. The time is also scaled by τ_C, the time scale of charge relaxation in the nodes. The dimensionless action is now $S=\gamma\int_0^{t/\tau_C}dt'$ $\times(-i\dot{Q}\lambda+\tau_C H)$. The saddle point action is proportional to $\gamma t/\tau_C$, while the fluctuation contribution will be of order t/τ_C. We note that the parameter γ is related to (though not necessarily the same as) the separation of time scales, τ_C/τ_0, needed to derive the path integral. For the mesoscopic conductors considered in the example section V B of this paper, the charge scale is set by the maximum number of semiclassical states on the cavity involved in transport, $\gamma=\Delta\mu N_F\gg 1$, the bias times the density of states at the Fermi level. On the other hand, for the chaotic cavity, $\tau_C/\tau_0=\gamma/(G_L+G_R)$, where $G_{L,R}\gg 1$ are the dimensionless conductances of the left and right point contact.

D. Relation to the master equation and Doi–Peliti technique

The evolution operator $U(\mathbf{Q},\mathbf{Q}',t)$ may be interpreted as a Green function of a differential equation which determines the propagation in time of an initial probability distribution $\Gamma(\mathbf{Q})$. In the theory of stochastic processes, such a differential equation is called a master equation. A natural question that arises is the relationship of the formalism presented here to other approaches to stochastic problems.

The most general type of Markovian master equation for discrete states and discrete time is of the form

$$\Gamma_n(t_{k+1}) = \sum_m P_{nm}(t_{k+1},t_k)\Gamma_m(t_k), \tag{22}$$

where $\Gamma_m(t_k)$ is the probability to be in state m at time t_k and P_{nm} is the transition probability from state m to state n. The state is described by a vector $n=(n_1,\ldots,n_N)$ whose components are the charges n_α of each node α. The Markovian assumption implies that $t_{k+1}-t_k=\Delta t$ is greater than the correlation time, τ_0. If we further assume that the probability to make a transition to another state is small, $P_{nm}\ll 1$ for $n\neq m$, so that the transition probability is only linear in Δt, a transition rate $W_{nm}=P_{nm}/\Delta t$ may be defined. It then follows that we may write a differential master equation,

$$\dot{\Gamma}_n(t) = \sum_m [W_{nm}\Gamma_m(t) - W_{mn}\Gamma_n(t)]. \tag{23}$$

Equation (23) is the starting point for the Doi–Peliti technique,[24] where one formally maps the space of physical states to the Fock space of states $|n\rangle=(a_1^\dagger)^{n_1}\cdots(a_N^\dagger)^{n_N}|0\rangle$, where n is the number of charges. The entire state of the system is expressed by a vector $|\Psi\rangle=\Sigma_n\Gamma_n|n\rangle$ which weights the states $|n\rangle$ with their probabilities Γ_n. Thus, the master equation (23) may be interpreted as a

many-body Schrödinger equation where the rates W_{mn} are incorporated into a Hamiltonian in a second-quantized form. One may then write a coherent-state path integral over the variables a, and $a^{\dagger}$ for this many-body quantum system and perform perturbation expansions along with the renormalization group.[25] This procedure eventually involves taking the continuum limit so the discrete charge states become continuous.

Let us now consider how our formalism is related to the master equation or the Doi–Peliti technique. According to the results of Sec. II, our stochastic path integral, Eq. (3) solves the continuum variable version of Eq. (22) with the transition probabilities given by the one step propagator $U(\mathbf{Q},\mathbf{Q}',\Delta t)$. *In general, the transition probabilities are neither small nor linear in time* for $\Delta t > \tau_0$. It is instructive nevertheless to consider the special case of processes where $H\tau_0 \ll 1$, when we can expand the one-step propagator (13) to first order in Δt,

$$U(\mathbf{Q},\mathbf{Q}',\Delta t) \approx \delta(\mathbf{Q}-\mathbf{Q}') + \Delta t \int d\mathbf{\Lambda} e^{-i\mathbf{\Lambda}\cdot(\mathbf{Q}-\mathbf{Q}')} H(\mathbf{Q}',\mathbf{\Lambda}). \tag{24}$$

Defining the Fourier transform of the generating function as $\tilde{H}(\mathbf{Q},\mathbf{Q}')$, the differential equation governing the evolution of a probability distribution of charges $\Gamma(\mathbf{Q})$ is then

$$\dot{\Gamma}(\mathbf{Q},t) = \int d\mathbf{Q}' \tilde{H}(\mathbf{Q},\mathbf{Q}')\Gamma(\mathbf{Q}',t). \tag{25}$$

Comparison with the continuous version of the master equation (23),

$$\dot{\Gamma}(\mathbf{Q},t) = \int d\mathbf{Q}' [W(\mathbf{Q},\mathbf{Q}')\Gamma(\mathbf{Q}',t) - W(\mathbf{Q}',\mathbf{Q})\Gamma(\mathbf{Q},t)], \tag{26}$$

indicates that $\tilde{H}$ is related to W. The Hamiltonian may be expressed in terms of the transition kernel[34] as,

$$H(\mathbf{Q}',\mathbf{\Lambda}) = \int d\mathbf{Q} [e^{i(\mathbf{Q}-\mathbf{Q}')\cdot\mathbf{\Lambda}} - 1] W(\mathbf{Q},\mathbf{Q}'), \tag{27}$$

where the normalization of probability is expressed by $H(\mathbf{Q}',0)=0$. Equation (27) is an important result, because it allows the conversion of the master equation (26) into the stochastic path integral (3).

We would like to stress that our formalism is not simply equivalent to the differential master equation (26) (and, therefore, the Doi–Peliti technique), but that it allows the treatment of a complementary class of problems. Our formalism assumes effectively continuous charge, and thus cannot resolve effects due to the discreteness of charge on the nodes. Such effects are present in the master equation (23). In contrast, the differential master equation assumption, $H\tau_0 \ll 1$ (which simply states that transition probabilities are small in the time interval τ_0) is not required. Our formalism is especially important when this is not the case, i.e., $H\tau_0 \sim 1$.

This is illustrated by the simple example from mesoscopics of two metallic reservoirs connected by a single electron barrier with hopping probability p and bias $\Delta\mu$ at zero temperature. For a time interval Δt larger than the correlation time $\tau_0 = \hbar/\Delta\mu$ (the time scale for an electron wavepacket to transverse the barrier), $\Delta t/\tau_0$ electrons approach the barrier and either are transmitted or reflected. Mathematically, this is a classical binomial process with the generator

$$S = (\Delta t/\tau_0)\ln[1 + p(e^{ie\lambda} - 1)]. \tag{28}$$

As this action is the starting point of many mesoscopic implementations of the formalism, it is an important example. Since the action is proportional to the large parameter $\Delta t/\tau_0 > 1$, for $p \sim 1$ the expansion of $\exp(S)$ to first order in Δt is strictly forbidden, effectively not allowing a first order differential master equation. Only in the limit $p \ll 1$, (i.e., when Eq. (28) describes a Poissonian process) may the logarithm be expanded to first order. This suggests that Eq. (26) describes the

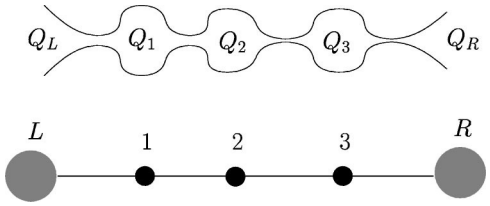

FIG. 2. A one-dimensional lattice of nodes connected on both ends to absorbing reservoirs. This situation could represent a series of mesoscopic chaotic cavities connected by quantum point contacts.

slow dynamics of systems whose fast transitions are Poissonian in nature. A more general type of dynamics such as the binomial distribution may only be found using the continuous charge state master equation in discrete time (22).

III. THE FIELD THEORY

From the stochastic network, Fig. 1, it is straightforward to go to spatially continuous systems as the spacing between the nodes is taken to zero. The goal is to introduce a Hamiltonian functional $h(\rho,\lambda)$ whose arguments are the charge density ρ and the counting field functions λ, that are themselves functions of space and time. We may then replace $(1/2)\Sigma_{\alpha,\beta}H_{\alpha,\beta}\rightarrow\int dz h(\rho,\lambda)$. Our description is local, so in the model each node is only connected to its nearest neighbors. We first derive the one-dimensional field theory with one charge species in detail, and then generalize to multiple dimensions and charge species.

Consider a series of identical, equidistant nodes separated by a distance Δz. This nodal chain could represent a chain of chaotic cavities, Fig. 2, in a mesoscopic context.[35,36] The sum over α and β becomes a sum over each node in space connected to its neighbors. The action for this arrangement is

$$S=\int_0^t dt'\sum_\alpha\{-\lambda_\alpha\dot{Q}_\alpha+H(Q_\alpha,Q_{\alpha-1};\lambda_\alpha-\lambda_{\alpha-1})\},\tag{29}$$

where for simplicity we have chosen real counting variables, $i\lambda_\alpha\rightarrow\lambda_\alpha$. The imaginary counting variables will be restored at the end of the section. The only constraint made on H is that probability is conserved, $H(\lambda_\alpha-\lambda_{\alpha-1})=0$ for $\lambda_\alpha=\lambda_{\alpha-1}$. We now derive a lattice field theory by formally expanding H in $\lambda_\alpha-\lambda_{\alpha-1}$ and $Q_\alpha-Q_{\alpha-1}$. Only differences of the counting variables will appear in the series expansion, while we must keep the full Q dependence of the Hamiltonian. If there are $N\gg1$ nodes in the lattice, for fixed boundary conditions the difference between adjacent variables, $\lambda_\alpha-\lambda_{\alpha-1}$ and $Q_\alpha-Q_{\alpha-1}$ will be of order $1/N$, and therefore, provides a good expansion parameter. The expansion of the Hamiltonian (29) to second order in the difference variables gives

$$H=\frac{\partial H}{\partial\lambda_\alpha}(\lambda_\alpha-\lambda_{\alpha-1})+\frac{1}{2}\frac{\partial^2H}{\partial\lambda_\alpha^2}(\lambda_\alpha-\lambda_{\alpha-1})^2+\frac{\partial^2H}{\partial Q_\alpha\partial\lambda_\alpha}(Q_\alpha-Q_{\alpha-1})(\lambda_\alpha-\lambda_{\alpha-1}),\tag{30}$$

where the expansion coefficients are evaluated at $\lambda_\alpha=\lambda_{\alpha-1}$ and $Q_\alpha=Q_{\alpha-1}$ and are functions of $Q_{\alpha-1}$. Terms involving only differences of $Q_\alpha-Q_{\alpha-1}$ are zero because $H(\lambda_\alpha-\lambda_{\alpha-1})=0$ for $\lambda_\alpha=\lambda_{\alpha-1}$. All terms in Eq. (30) need explanation. First, the expression $\partial H/\partial\lambda_\alpha$ is the local current at zero bias (because the charges in adjacent nodes are equal) which will usually be zero. There may be circumstances where this term should be kept,[37] but we do not consider them here. The term $\partial^2H/\partial Q_\alpha\partial\lambda_\alpha=-G(Q_{\alpha-1})$ is the linear response of the current to a charge difference. Hence, G is the generalized conductance[38] of the connector between nodes α and $\alpha-1$. $\partial^2H/\partial\lambda_\alpha^2=C(Q_{\alpha-1})$ is the current noise through the same connector because H is the generator of current cumulants.

We are now in a position to take the continuum limit by replacing the node index α with a coordinate z, introducing the fields $Q(z),\lambda(z)$, and making the expansions

$$\lambda_\alpha - \lambda_{\alpha-1} \to \lambda' \Delta z + (1/2)\lambda''(\Delta z)^2 + \mathcal{O}(\Delta z)^3, \tag{31a}$$

$$Q_\alpha - Q_{\alpha-1} \to Q' \Delta z + (1/2)Q''(\Delta z)^2 + \mathcal{O}(\Delta z)^3. \tag{31b}$$

The action may now be written in terms of intensive fields by scaling away Δz,

$$H \to h(\rho,\lambda)\Delta z, \quad Q_\alpha \to \rho(z)\Delta z, \quad G_\alpha(\Delta z)^2 \to D(\rho), \quad C_\alpha \Delta z \to F(\rho), \tag{32}$$

and taking the limit $\Sigma_\alpha H \to \int dz h(\rho,\lambda)$. One may check that expanding the Hamiltonian to higher than second order in Δz will result in terms suppressed by powers of $\Delta z/L$ and consequently vanish as $\Delta z \to 0$. This scaling argument for the field theory is analogous to Van Kampen's size expansion.[39] Though the lattice spacing Δz does not appear in the continuum limit, it provides a physical cutoff for any ultra-violet divergences that might appear in a loop expansion.

These considerations leave the one-dimensional action as

$$S = -\int_0^t dt' \int_0^L dz[\lambda\dot{\rho} + D\rho'\lambda' - \tfrac{1}{2}F(\lambda')^2]. \tag{33}$$

Here D is the local diffusion constant and F is the local noise density which are discussed in detail below. It is very important that these two functionals D, F are all that is needed to calculate current statistics. Classical field equations may be obtained by taking functional derivatives of the action with respect to the charge and counting fields: $\delta S/\delta\rho(z) = \delta S/\delta\lambda(z) = 0$ to obtain the equations of motion,

$$\dot{\lambda} = -\frac{1}{2}\frac{\delta F}{\delta\rho}(\lambda')^2 - D\lambda'', \quad \dot{\rho} = [-F\lambda' + D\rho']'. \tag{34}$$

From the charge equation, one can see immediately that the term inside the derivative may be interpreted as a current density so that local charge conservation is guaranteed. We have to solve these coupled differential equations subject to the boundary conditions

$$\rho(t,0) = \rho_L(t), \quad \rho(t,L) = \rho_R(t), \quad \lambda(t,0) = \lambda_L(t), \quad \lambda(t,L) = \lambda_R(t), \tag{35}$$

where $\rho_L(t)$, $\rho_R(t)$, $\lambda_L(t)$, and $\lambda_R(t)$ are arbitrary time dependent functions. Functions $\rho_L(t)$ and $\rho_R(t)$ are the charge densities at the far left and right end of the system which may be externally controlled. Functions $\lambda_L(t)$ and $\lambda_R(t)$ are the counting variables of the absorbed charges at the far left and right end which count the current that passes them.

Once Eqs. (34) are solved subject to the boundary conditions (35), the solutions $\rho(z,t)$ and $\lambda(z,t)$ should be substituted back into the action (33) and integrated over time and space. The resulting function, $S_{sp}[\rho_L(t),\rho_R(t),\lambda_L(t),\lambda_R(t),t,L]$ is the generating function for time-dependent cumulants of the current distribution. Often, the relevant experimental quantities are the stationary cumulants. These are given by neglecting the time dependence, finding static solutions, $\dot{\rho} = \dot{\lambda} = 0$, and imposing static boundary conditions. Similarly to Sec. II D, we can also introduce sources $\int dtdz\chi(z,t)\rho(z,t)$ and calculate density correlation functions.

To estimate the contribution of the fluctuations to the action, it is useful to define dimensionless variables. The boundary conditions ρ_L, and ρ_R provide the charge density scale ρ_0 in the problem, so we define $\rho(z) = \rho_0 f(z)$, where $f \sim 1$ is an occupation. We furthermore rescale $z \to Lz$, and $t \to \tau_D t$, where $\tau_D = L^2/D$ is the diffusion time, thus obtaining

$$S = -L\rho_0 \int_0^t dt' \int_0^1 dz' \left[\lambda\dot{f} + f'\lambda' - \frac{F}{2D\rho_0}(\lambda')^2\right]. \tag{36}$$

We assume that the combination $F/D\rho_0$ is of order 1. From Eq. (36), the dimensionless large parameter is $\gamma = \rho_0 L \gg 1$, i.e., the number of transporting charge carriers. As in Sec. II C, the saddle point contribution is of order $\gamma t/\tau_D$, while the fluctuation contribution is of order t/τ_D.

Repeating this derivation in multiple dimensions with N charge species $\rho=\{\rho_i(\mathbf{r})\}$ and counting fields $\mathbf{\Lambda}=\{\lambda_i(\mathbf{r})\}$, $i=1,\ldots,N$ yields the action

$$S=-\int_0^t dt'\int_\Omega d\mathbf{r}[\mathbf{\Lambda}\dot{\rho}+\nabla\mathbf{\Lambda}\hat{D}\nabla\rho-(1/2)\nabla\mathbf{\Lambda}\hat{F}\nabla\mathbf{\Lambda}], \tag{37}$$

where tensor notation is used and we have introduced $\hat{F}_{ij}=\partial_{\lambda_i}\partial_{\lambda_j}h$ and $\hat{D}_{ij}=-\partial_{\rho_i}\partial_{\lambda_j}h$ as general matrix functionals of the field vector ρ and coordinate $\mathbf{r}$ which should be interpreted as noise and diffusion matrices. If the medium is isotropic, then the vector gradients simply form a dot product. It should be emphasized that the vectors appearing are vectors of different species of charge fields, as all node delimitation has been accounted for in the spatial integration. The functional integral now runs over all field configurations that obey the imposed boundary conditions at the surface $\partial\Omega$. Classical field equations may be formally obtained by taking functional derivatives of the action with respect to the charge and counting fields as in the one-dimensional (1D) case.

As in any field theory, symmetries of the action play an important role because they lead to conserved quantities. We first note that the Hamiltonian $h(\rho,\nabla\rho,\nabla\mathbf{\Lambda})$ is a functional of $\nabla\mathbf{\Lambda}$ alone with no $\mathbf{\Lambda}$ dependence. This symmetry is analogous to gauge invariance, and leads to the equation of motion

$$\dot{\rho}+\nabla\cdot\mathbf{j}=0,\quad \mathbf{j}=-\hat{D}\nabla\rho+\hat{F}\nabla\mathbf{\Lambda}, \tag{38}$$

which can be interpreted as conservation of the conditional current $\mathbf{j}$. The next symmetry is related to the invariance under a shift in the space and time coordinates $\{\delta\mathbf{r},\delta t\}$. This symmetry leads to equations analogous to the conservation of the local energy/momentum tensor.[40] We do not explicitly give this quantity because it is rather cumbersome in the general case. However, for the stationary limit (where $\dot{\rho}$ and $\dot{\lambda}$ vanish) and for symmetric diffusion and noise tensors, the one charge species conservation law is relatively simple and is given by

$$\sum_m \nabla_m T_{mn}=0,\quad T_{mn}=j_m(\nabla_n\lambda)-(\nabla_n\rho)(\hat{D}\nabla\lambda)_m-h\delta_{mn}. \tag{39}$$

For the special case of a one-dimensional geometry, the Hamiltonian itself is the conserved quantity (see Sec. V A).

In the continuum limit, all terms of higher order in Λ are suppressed so that the action is quadratic in the Λ variables. This fact may be viewed as a consequence of the central limit theorem and confirms the observation made by Nagaev that local noise in the mesoscopic diffusive wire (see Sec. V A) is Gaussian.[19] To further clarify the physical meaning of D and F, and also to make connection with previous work,[32] we restore the complex variables, $\Lambda\to i\Lambda$, and make a Hubbard–Stratonovich transformation by introducing an auxiliary vector field ν,

$$\exp\{-(1/2)\nabla\mathbf{\Lambda}\hat{F}\nabla\mathbf{\Lambda}\}=(\det\hat{F})^{-1/2}\int\mathcal{D}\nu\exp\{-(1/2)\nu\hat{F}^{-1}\nu+i\nu\nabla\mathbf{\Lambda}\}. \tag{40}$$

We may then integrate out the Λ variables, taking account of the boundary terms to obtain,

$$U=\exp\left\{\int_0^t dt'\int_{\partial\Omega}d\mathbf{s}\cdot(i\Lambda^a\mathbf{J})\right\}\int\mathcal{D}\rho\mathcal{D}\nu\delta(\dot{\rho}+\nabla\cdot\mathbf{J})(\det\hat{F})^{-1/2}\exp\left\{-\frac{1}{2}\int_0^t dt'\int_\Omega d\mathbf{r}'\,\nu\hat{F}^{-1}\nu\right\}, \tag{41}$$

where the δ above is a functional delta function, imposing the Langevin equation

$$\dot{\rho}+\nabla\cdot\mathbf{J}=0, \tag{42a}$$

$$\mathbf{J} = -\hat{D}\nabla\rho + \nu, \tag{42b}$$

with a current noise source ν, whose correlator[41] is given by

$$\langle \nu(\mathbf{r},t)\nu(\mathbf{r}',t')\rangle = \delta(t-t')\delta(\mathbf{r}-\mathbf{r}')\hat{F}(\rho). \tag{42c}$$

J may be interpreted as the physical current density [not to be confused with the conditional current density (38)] so that local current conservation is guaranteed, and the $(\det \hat{F})^{-1/2}$ serves to normalize the ν probability distribution. The role of the boundary term is to count the current **J** flowing out of the boundary with the counting variable Λ^a, which serves as a Lagrange multiplier. This formula gives an immediate translation between the Langevin approach and full counting statistics, a connection not previously known. The algorithm is as follows:

(1) Given a Langevin equation of the form (42), write the average of the boundary term with source Λ^a as a path integral (41) over noise and density fields;[42]
(2) introduce an auxiliary field Λ that takes on the value Λ^a at the boundaries and represents the delta function in Eq. (41) imposing current conservation (42a) in Fourier form;
(3) integrate out the Gaussian noise to obtain an action of the form of Eq. (37);
(4) find where the first variation of the action is zero and solve the equations of motion subject to the boundary conditions;
(5) insert the solutions back into the action, and do the space and time integrals. The answer is the current cumulant generating function.

IV. PERTURBATION THEORY

We have shown in Sec. II C that a large number of participating elementary charges justifies the saddle point approximation for the generator of counting statistics. While the generator may sometimes be found in closed form,[7] in general, it has no compact expression and the cumulants should be found separately at every order. This may be done by expanding $S_{sp}(Q,\lambda,\chi)$ as a series in χ and solving the saddle point equations to a given order in χ directly. However, there is another approach for evaluating the higher cumulants, the cascade diagrammatics representing higher-order cumulants in terms of the lower ones. It has been introduced by Nagaev in the context of mesoscopic charge statistics in the diffusive wire[19] and later extended to the chaotic cavity,[20] but without proof. The basic idea is that lower order cumulants mix in to yield corrections to the bare fluctuations of higher order cumulants. This method was used successfully in Ref. 43 to explain the recent experiment of Ref. 44. In this section, we demonstrate that these rules follow naturally from the stochastic path integral in the same way as Feynman diagrams follow from the quantum mechanical functional integral. In Sec. IV C we present another (simpler) method for computing cumulants based completely on differential operators obtained from the Hamiltonian equations of motion. In Sec. IV D we generalize the cascade diagrammatics to an arbitrary network, and to the case of time-dependent correlators.

A. The principle of minimal correlations

To motivate the cascade diagrammatics, we refer to a specific physical system (see the inset of Fig. 8), the mesoscopic chaotic cavity.[1] For the purposes of this section, the cavity is a conserving node carrying charge Q, the electronic reservoirs correspond to the left and right are absorbing nodes, and the two point contacts are the connectors described by Hamiltonians H_L, H_R (see Fig. 3). Although a detailed description of this system is given in Sec. V B, we would like to mention that the mesoscopic cavity is described by an electron distribution function f, which is fluctuating around its mean value, f_0. The actual electrical charge in the cavity Q and the occupation f are related via the large parameter γ through $Q=\gamma(f-f_0)$, where $\gamma=\Delta\mu N_F \gg 1$ (the density of states at the Fermi energy N_F times the bias $\Delta\mu$) is the maximum possible number of electrons on the cavity which contribute to the transport (see Sec. II C).

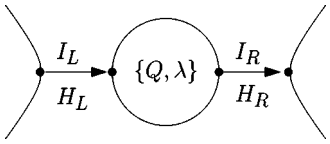

FIG. 3. Network representing a chaotic cavity. The state of the internal node is described by the variable Q, the charge on the cavity. The statistics of the connectors are characterized by the two generating functions $H_{L,R}$.

The cascade approach builds on the principle of minimal correlations developed in Ref. 18: The point contacts create bare noise $\langle\langle \tilde{I}_L^2\rangle\rangle = \partial^2 H_L/(\partial i\lambda_L)^2$, and $\langle\langle \tilde{I}_R^2\rangle\rangle = \partial^2 H_R/(\partial i\lambda_R)^2$ with no correlation, $\langle\langle \tilde{I}_L \tilde{I}_R\rangle\rangle = 0$ [see Eq. (5)]. However, for times longer than the average dwell time of electrons in the cavity, the current conservation requirement imposes "minimal correlations" on the fluctuations of the physical currents I_L and I_R, which can be expressed in the form of the Langevin equations,

$$I_L = \tilde{I}_L - G_L Q, \quad I_R = \tilde{I}_R + G_R Q, \tag{43}$$

where $\tilde{I}_{L,R}$ are now the sources of bare noise, $G_{L,R}$ are the generalized conductances of the left and right point contact, and Q is the fluctuating charge in the cavity. Current conservation of the physical currents, $I_L = I_R = I$, can now be used to obtain

$$I = \frac{G_R \tilde{I}_L + G_L \tilde{I}_R}{G_L + G_R}, \quad Q = \frac{\tilde{I}_L - \tilde{I}_R}{G_L + G_R}. \tag{44}$$

Combining powers of I and Q and averaging over the bare noise, we obtain the minimal correlation result for arbitrary cumulants $\langle\langle Q^k I^l\rangle\rangle_m$. In particular, using $\langle\langle \tilde{I}_L \tilde{I}_R\rangle\rangle = 0$, we find the second cumulant of current is[17,18]

$$\langle\langle I^2\rangle\rangle = \langle\langle I^2\rangle\rangle_m = \frac{G_R^2 \langle\langle \tilde{I}_L^2\rangle\rangle + G_L^2 \langle\langle \tilde{I}_R^2\rangle\rangle}{(G_L + G_R)^2}, \tag{45}$$

where the subscript m denotes the minimal correlation result. We stress that the bare correlators $\langle\langle \tilde{I}_{L,R}^2\rangle\rangle$ are fully determined by the average occupation function f_0 of the cavity.

This example demonstrates that a simple redefinition of the current fluctuations makes it straightforward to find the noise. Therefore, it came as a surprise[45] that the minimal correlation approach is not sufficient to correctly obtain higher-order cumulants of current. The reason for the failure of the minimal correlation approach has been found recently by Nagaev,[19] who showed that from the third order cumulant on, there are "cascade corrections" to the minimal correlation result, which may be interpreted as "noise of noise." For example, the third cumulant of current through the mesoscopic cavity,[20]

$$\langle\langle I^3\rangle\rangle = \langle\langle I^3\rangle\rangle_m + 3\langle\langle IQ\rangle\rangle_m \frac{\partial}{\partial Q} \langle\langle I^2\rangle\rangle_m, \tag{46}$$

contains a contribution from fluctuations of the charge in the cavity that couples back into the current fluctuations. The factor of 3 comes from the fact that there are 3 independent currents that the charge fluctuation may be correlated with. For higher cumulants, there will be more cascade corrections that may be represented in a diagrammatic form.[19,20]

B. Derivation of diagrammatic rules

We now present a derivation of these diagrammatic rules for a single node attached between two absorbing nodes. Generalizations to an arbitrary network will subsequently be given in Sec.

IV D. As we have shown in Sec. II C, the charge scale imposed by the boundary conditions, γ, gives a dimensionless large parameter which justifies the saddle point approximation of the path integral, so that fluctuations around the saddle point are suppressed by $1/\gamma$. In the diagrammatic language, we will show that loop diagrams are suppressed by the same factor $1/\gamma$. The diagrammatic approach given here is based on perturbation theory originally developed in quantum mechanics.[29]

Consider the path integral expression of the generating function for the charge absorbed in the left (L) and right (R) node:

$$Z(\chi_L,\chi_R)=\int \mathcal{D}Q\mathcal{D}\lambda\ \exp\left\{\int_0^t dt'[-i\dot{Q}\lambda+H(Q,\lambda,\chi_L,\chi_R)]\right\}, \tag{47}$$

where $H=H_L(Q,\lambda-\chi_L)+H_R(Q,\chi_R-\lambda)$. The perturbation theory is formulated as follows. First, the external counting variables are set to zero, $\chi_L=\chi_R=0$. The Hamiltonian $H\to H_L(Q,\lambda)+H_R(Q,-\lambda)$ has a stationary saddle point located at $\{Q_0,\lambda_0\}$ that we wish to define as the origin of coordinates. The probability distributions of transferred charge are normalized, so

$$\partial_Q^n H_{L,R}(Q,\lambda)|_{\lambda=0}=0, \quad \forall\, n. \tag{48}$$

In particular, $\partial_Q H_L(\lambda)|_{\lambda=0}=\partial_Q H_R(\lambda)|_{\lambda=0}=0$, and therefore $\lambda_0=0$. Next, $\partial_{i\lambda}H(\lambda)|_{\lambda=0}=\langle I_L(Q)\rangle-\langle I_R(Q)\rangle=0$, since H_L and H_R are the generators of the left and right current respectively. Therefore, Q_0 is fixed as the charge in the node such that left and right connector currents are equal on average. The stability of the saddle point is guaranteed by the fact that the bare noise correlators, $\langle\langle\tilde{I}^2_{L,R}\rangle\rangle$, are positive. The derivatives $\partial_{i\lambda}\partial_Q H_L=-G_L$, $\partial_{i\lambda}\partial_Q H_R=-G_R$ define the generalized conductance of each connector, where the current flows from left to right in both connectors.

The principle of minimal correlation plays an important role in the cascade diagrammatics. We will show that this principle is equivalent to exploiting certain freedoms in the path integral in order to postpone the cascade corrections to third and higher order cumulants. In the long-time limit, $t\gg\tau_C$ (where $1/\tau_C=G_L+G_R$ is the relaxation rate of the charge in the node), the absorbed current is conserved, $I_R=I_L$. Therefore, the current through the node can be defined as weighted average of the left and right connector currents $I=(1-v)I_L+vI_R$, where v is an arbitrary constant. The corresponding counting variable χ is introduced by substituting $\chi_R=v\chi$ and $\chi_L=(v-1)\chi$. Consider now the second derivative

$$\left.\frac{\partial^2 H}{\partial\, i\chi\,\partial Q}\right|_{\chi=0}=(v-1)G_L+vG_R. \tag{49}$$

We may set it to zero by fixing $v=G_L/(G_L+G_R)$. This is equivalent to imposing conservation of current fluctuations as in Eq. (44). If we consider further the derivative

$$\left.\frac{\partial^2 H}{\partial\, i\lambda\,\partial Q}\right|_{\chi=0}=-(G_L+G_R), \tag{50}$$

we have the freedom to scale λ to make the right hand side of Eq. (50) equal to -1 [this scaling only alters the χ independent prefactor of Eq. (47)]. The Hamiltonian takes the new form

$$H=H_L\left(Q,\frac{G_R\chi+\lambda}{G_L+G_R}\right)+H_R\left(Q,\frac{G_L\chi-\lambda}{G_L+G_R}\right). \tag{51}$$

We refer to these new variables as minimal correlation coordinates and will see that they simplify the diagrammatic expansion.

Define $\delta Q(t)=Q(t)-Q_0$ and $\delta\lambda(t)=\lambda(t)-\lambda_0$. If we expand the Hamiltonian in a power series in χ, δQ, and $\delta\lambda$, the terms linear in δQ and $\delta\lambda$ vanish at the saddle point, as well as the $(\delta Q)^2$ coefficient by Eq. (48) with $n=2$. As argued above, in the minimal correlation coordinates, $\partial_{i\lambda}\partial_Q H(Q_0,\lambda_0)=-1$. With these transformations, we may split the action S as

$$S = S_0 + \int_0^t dt' V(t'), \quad S_0 = -i \int_0^t dt' \delta\lambda(\tau_C \delta\dot{Q} + \delta Q), \tag{52}$$

where V represents the rest of the H power series and will be treated perturbatively. It should be emphasized that V is a general nonlinear function of $\delta\lambda$, so unlike most quantum examples, the full momentum dependence must be kept.

In order to formulate the perturbation theory, we add two sources, J and K to the action, $S \to S + \int dt'[J\delta Q + iK\delta\lambda]$, so that any average of a function of the variables $\delta Q, \delta\lambda$ may be evaluated by taking functional derivatives with respect to the sources J, and K, and then setting the sources to zero. In particular, for the generating function we can write

$$\begin{aligned} Z(\chi) &= \int \mathcal{D}Q\mathcal{D}\lambda \, \exp\left\{ \int_0^t dt' V(\delta Q, \delta\lambda, \chi) \right\} \exp\left\{ S_0 + \int_0^t dt'[J\delta Q + iK\delta\lambda] \right\} \Bigg|_{J,K=0} \\ &= \exp\left\{ \int_0^t dt' V\left(\frac{\delta}{\delta J}, \frac{\delta}{\delta iK}, \chi \right) \right\} \int \mathcal{D}Q\mathcal{D}\lambda \, \exp\left\{ S_0 + \int_0^t dt'[J\delta Q + iK\delta\lambda] \right\} \Bigg|_{J,K=0}. \end{aligned} \tag{53}$$

Using S_0. from Eq. (52) we evaluate the integral over Q and λ and obtain

$$Z(\chi) = \exp\left\{ \int_0^t dt' V\left(\frac{\delta}{\delta J}, \frac{\delta}{\delta iK}, \chi \right) \right\} W(J,K) \Bigg|_{J,K=0}, \tag{54}$$

where the functional $W(J,K)$ is

$$W(J,K) = \exp\left\{ \int \int_0^t dt' dt'' J(t') D(t',t'') K(t'') \right\}. \tag{55}$$

The operator $D = (\tau_C \partial_t + 1)^{-1}$ is the retarded propagator, and may be found explicitly by inverting the kernel in frequency space,

$$D(t,t') = \int_{-\infty}^{\infty} \frac{d\omega}{2\pi} \frac{e^{-i\omega(t-t')}}{-i\tau_C\omega + 1} = \tau_C^{-1} \Theta(t-t') \exp[-(t-t')/\tau_C]. \tag{56}$$

It describes the relaxation of the charge $Q(t)$ to the stationary state Q_0 with the rate $1/\tau_C = G_L + G_R$.

Expanding the exponential in Eq. (54) and taking the $t \gg \tau_C$ limit, we arrive at the following expression for the nth current cumulant

$$\langle\langle I^n \rangle\rangle = t^{-1} \frac{\delta^n}{\delta(i\chi)^n} \sum_{m=1}^{\infty} \frac{1}{m!} \left[\int_0^t dt' V\left(\frac{\delta}{\delta J}, \frac{\delta}{\delta iK}, \chi \right) \right]^m W(J,K) \Bigg|_{\substack{\chi = J = K = 0 \\ \text{connected}}}. \tag{57}$$

According to the linked cluster expansion,[32] by considering $\ln Z(\chi)$ rather than $Z(\chi)$, we have eliminated all disconnected terms. In order to compare with the results of Ref. 20, we introduce a new notation by defining

$$\partial_Q^j \langle\langle Q^k I^l \rangle\rangle_m \equiv \partial_Q^j \partial_{i\lambda}^k \partial_{i\chi}^l V(Q_0, \lambda_0, \chi = 0). \tag{58}$$

Here $\langle\langle Q^k I^l \rangle\rangle_m$ is the irreducible correlator expressed in terms of the noise sources, i.e., the minimal correlation cumulant. In this notation, the expansion of V in a Taylor series of all variables takes the form:

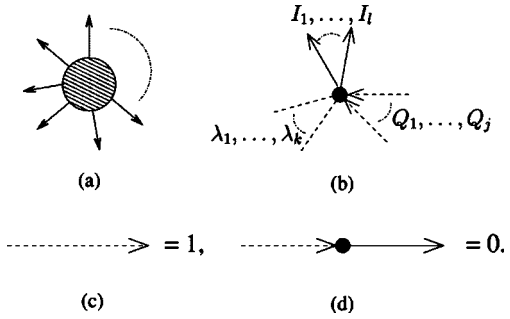

FIG. 4. (a) An n-point current cumulant. (b) The vertex connecting l external lines with j internal Q lines and k internal λ lines. (c) The propagator connecting λ to Q, equal to 1 in the stationary limit. (d) The vanishing vertex $\partial_Q\langle I\rangle$ in minimal correlation coordinates.

$$V(\delta Q, \delta\lambda, \chi) = \sum_{j,k,l} \frac{1}{j!\,k!\,l!} \partial_Q^j \langle\langle Q^k I^l\rangle\rangle_m [\delta Q(t)]^j [i\delta\lambda(t)]^k [i\chi]^l. \tag{59}$$

Inserting the expansion Eq. (59) into the formula for the current cumulants Eq. (57) gives the formal solution to the problem. From the form of $W(J,K)$ and V, we can immediately read off the diagrammatic rules with the internal lines given by the propagators (56), and the expansion coefficients $\partial_Q^j\langle\langle Q^k I^l\rangle\rangle_m$ playing the role of vertices.

The following simplifications can be done before the rules are finally formulated. First, it is straightforward to see that loop diagrams are suppressed by powers of γ^{-1}. Indeed, according to our single-parameter scaling assumption, the action (52) has a large prefactor γ, which can be explicitly displayed, $S \to \gamma S$, by rescaling the charge, $Q \to \gamma Q$. Then it becomes clear that each propagator D, represented by an internal line, comes with a factor of γ^{-1}. Each vertex comes from V and therefore has a factor of γ. If a diagram has I internal lines, E external legs, V vertices and L loops, it will come with a total γ power of $V-I$. Furthermore, Euler's formula tells us that $V+L-I=1$. Therefore, diagrams with no loops ("tree" diagrams) come with a power of γ, while loop diagrams are suppressed by the number of loops, γ^{1-L}. From now on we will concentrate on tree-level diagrams, since they represent current cumulants at the level of the saddle-point approximation.

Second, in the long time limit, $t \gg \tau_C$, each propagator (56) integrated over time gives 1. As a result, since every vertex is connected to at least one other vertex, all the time integrals together simply give a factor of t, and the time dependence cancels on the right hand side of the Eq. (57). There are no time integrals in the vertices and the propagators just give a factor of 1 as in Ref. 20. We are now able to formulate the diagrammatic rules for high-order current cumulants:

(1) The nth order cumulant $\langle\langle I^n\rangle\rangle$ is a connected n-point function of n external legs I represented by solid arrows [see Fig. 4(a)];
(2) the external legs must be connected by using vertices [see Fig. 4(b)] and linking internal dashed lines to internal dashed arrows;
(3) the vertices $\partial_Q^j\langle\langle I^l Q^k\rangle\rangle_m$ are represented by a circle with l external legs, k internal outgoing dashed lines, and j internal incoming dashed arrows [see Fig. 4(b)].
(4) Multiply each diagram by the number of inequivalent permutations (NIP).

Formally, the vertices $\partial_Q^j\langle\langle I^l Q^k\rangle\rangle_m$ are the expansion coefficients in (59). However, it is important to note that they can also be easily evaluated by solving the Langevin equations (43) and expressing the minimal correlation cumulants $\langle\langle I^l Q^k\rangle\rangle_m$ in terms of cumulants of the noise sources, $\langle\langle \tilde{I}_L^{l+k}\rangle\rangle$ and $\langle\langle \tilde{I}_R^{l+k}\rangle\rangle$. Some vertices are zero, $\partial^p H/\partial Q^p(Q_0,\lambda_0)|_{\chi=0}=0$ because of probability conservation, but other may or may not be zero depending on the physical system. Here, the advantage of the minimal correlation coordinates is made clear: the vertex $\partial_Q\langle\langle I\rangle\rangle_m=0$, and therefore any diagram that contains this vertex is zero [see Fig. 4(d)].

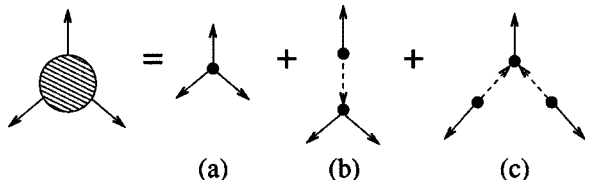

FIG. 5. Tree level contributions to the third cumulant of transmitted current.

To obtain the overall prefactor of a diagram, one can write out all the numerical constants and count the number of different ways of producing the same diagram.[32] For example, there is the $n!$ from the χ derivatives, the $1/m!$ from the Taylor series of e^V, a binomial coefficient from expanding V^m, and the $1/(j!k!l!)$ from every vertex with $j+k+l$ attachments for the different lines. To compensate these factors, we have to do the combinatorics of the number of equivalent terms: Interchange the vertices, find the number of different placements of lines on a vertex, etc. Often, the number of permutations of the n external legs will cancel the $m!$, and the $j!k!l!$ number of permutations of the internal legs attaching to the vertex will cancel that factor arising from the Taylor expansion.

Rather than making this expansion, there is a simpler method which exploits these cancellations given by counting the number of inequivalent permutations of the diagram (NIP). The NIP of the diagram is defined by how many ways the external legs of the diagram may be relabeled, such that the diagram is not topologically equivalent under deformation of the external legs. In other words, a diagram with n external legs has $n!$ ways of labeling them. If this diagram with a given labeling of the legs may be topologically deformed to give the diagram back with a different labeling, these two sets of labelings are equivalent permutations. If we write out all the different labelings the external legs can have, and cross out every labeling that is an equivalent permutation of another, then the number of labelings that remain is the NIP. This number is most easily found by dividing $n!$ by the number of equivalent permutations of the diagram. The number of equivalent permutations of the diagram is also called the symmetry factor of the diagram.

We illustrate these two approaches with the third cumulant, see Fig. 5. With the simplifications discussed above, these diagrams may be written as

$$\langle\langle I^3\rangle\rangle = \langle\langle I^3\rangle\rangle_m + 3\langle\langle IQ\rangle\rangle_m \frac{\partial}{\partial Q}\langle\langle I^2\rangle\rangle_m + 3\langle\langle IQ\rangle\rangle_m^2 \frac{\partial^2}{\partial Q^2}\langle\langle I\rangle\rangle_m. \tag{60}$$

Note that diagram (c) does not appear in Ref. 20, because it happens to vanish for the chaotic cavity [see also Eq. (46)]. Referring to the formula (57), the contributions in Eq. (60) are from $m=1,2,3$ respectively. Each diagram must have a χ^3 term in the expansion. We first show the combinatorial method to obtain the prefactor: Diagram (a) has a factor of $1/3!$ from the number of permutations of the χ variables, canceling the $3!$ from the χ derivatives. Diagram (b) has a factor of $1/2!$ from the number of permutations of the χ variables, a factor of $1/2!$ from the Taylor series of the exponential, a factor of 2 from the binomial expansion of V^2, and the $3!$ from the χ derivatives, leaving a factor of 3. Diagram (c) has a factor of $1/3!$ from the Taylor series of the exponential, a factor of 3 from the binomial expansion of V^3, a factor of $1/2!$ from the number of permutations of the δQ variables, a factor of 2 from the functional derivatives acting on W, and the $3!$ from the χ derivatives, leaving a factor of 3. The NIP is simpler to derive: We divide the number of permutations of the external legs, $m!$, by the number of equivalent permutation of the elements of the diagram that leave it unchanged. The number of equivalent permutations of diagrams (a,b,c) are $3!,2!,2!$, leaving the overall factors 1, 3, 3.

The computation of these diagrammatic contributions is best understood by a little practice on some examples. Consider three of the diagrams that contribute to the fourth cumulant drawn in Fig. 6. The diagrams symbolically represents the combinations:

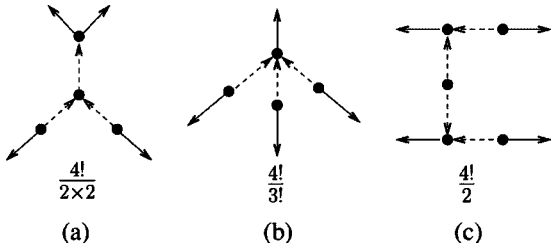

FIG. 6. Three examples of diagrams contributing to the fourth cumulant.

$$(a) = \frac{\partial}{\partial Q}\langle\langle I^2\rangle\rangle_m \frac{\partial^2}{\partial Q^2}\langle\langle Q\rangle\rangle_m \langle\langle IQ\rangle\rangle_m^2, \tag{61a}$$

$$(b) = \frac{\partial^3}{\partial Q^3}\langle\langle I\rangle\rangle_m \langle\langle IQ\rangle\rangle_m^3, \tag{61b}$$

$$(c) = \langle\langle Q^2\rangle\rangle_m \left(\frac{\partial^2}{\partial Q^2}\langle\langle I\rangle\rangle_m\right)^2 \langle\langle IQ\rangle\rangle_m^2. \tag{61c}$$

To figure out the numerical prefactors, we divide 4! (4 is the number of external legs) by the symmetry factor of the diagram. We first consider the symmetry factor of (a): The upper two legs may be flipped, and the lower two legs may be independently flipped where the dotted arrows join without altering the topology of the diagram. Therefore, the symmetry factor is $2\times 2=4$, and the NIP is $4!/4=6$. Moving on to diagram (b), the three lower legs may be permuted amongst themselves to give a symmetry factor 3!, and therefore, the NIP is $4!/3!=4$. Finally, diagram (c) may be flipped about its center for a symmetry factor of 2, giving a NIP of $4!/2=12$.

C. Operator approach

In the stationary limit, $t \gg \tau_C$, the action takes the form $S=tH(Q,\lambda,\chi)$ so that the evaluation of the cumulant generating function reduces to finding the stationary point of the Hamiltonian H as a function of the variables λ and Q. This can be done by solving the equations $\partial_Q H=0$ and $\partial_\lambda H=0$. The generating function is then obtained by substituting the solutions $\{\bar{Q},\bar{\lambda}\}$ into the Hamiltonian. In the previous section we have shown that this problem can be solved using path integral methods, and the solution can be represented diagrammatically. In the next section we will exploit the full strength of the path integral formalism in order to generalize the diagrammatics to an arbitrary network, and for the case of time-dependent charges. However, in the stationary limit, the conceptual simplicity of the problem of finding the stationary point of the function H indicates that there should exist a simple iterative procedure for evaluating the cumulants up to a given order. In this section we use classical mechanics methods to prove that this is indeed the case.

We first make the variable transformation $i\lambda\to\lambda$, and $i\chi\to\chi$, so that the Hamiltonian becomes a real function. For $\chi=0$ the saddle point is located at $\{Q_0,\lambda_0\}$. For nonzero χ the saddle point moves to a new position $\{\bar{Q},\bar{\lambda}\}$, which depends on χ, and the Hamiltonian $H(\bar{Q},\bar{\lambda},\chi)$ becomes the generator of cumulants of the current,

$$\langle\langle I^n\rangle\rangle = d^n H(\bar{Q},\bar{\lambda},\chi)/d\chi^n|_{\chi=0}\,. \tag{62}$$

By expressing the total χ derivative in terms of partial derivatives, the average current can be written as

$$\langle I\rangle = (\partial_\chi + Q'\partial_Q + \lambda'\partial_\lambda)H\,(Q,\lambda,\chi)\big|_{\{\chi=0,Q_0,\lambda_0\}}, \tag{63}$$

where $Q'=dQ/d\chi, \lambda'=d\lambda/d\chi$ are χ dependent. We wish to eliminate the functions Q' and λ' and to express the cumulant in terms of the partial derivatives of H. This is done by applying a total derivative to the equations of motion: $[\partial_Q H]'=[\partial_\lambda H]'=0$ and leads to two equations for Q' and λ' which may be solved,

$$Q' = \frac{\{\partial_\lambda H, \partial_\chi H\}}{\{\partial_Q H, \partial_\lambda H\}}, \quad \lambda' = -\frac{\{\partial_Q H, \partial_\chi H\}}{\{\partial_Q H, \partial_\lambda H\}}, \tag{64}$$

where $\{A,B\}$ is the Poisson bracket, defined as $\{A,B\}=\partial_\lambda A\,\partial_Q B-\partial_Q A\,\partial_\lambda B$. The solutions have to be inserted into the Eq. (63).

The advantage of this representation is clear: Now the right hand side of the Eq. (63) (before taking the $\chi=0$ saddle point) depends only on variables λ, Q, and χ. Therefore, we can apply the procedure again in order to express the high-order cumulant in terms of partial derivatives. This procedure solves the problem by giving a single operator,

$$\mathrm{D} = \partial_\chi + \frac{\{\partial_\lambda H, \partial_\chi H\}\partial_Q - \{\partial_Q H, \partial_\chi H\}\partial_\lambda}{\{\partial_Q H, \partial_\lambda H\}}, \tag{65}$$

which, being applied n times to a given Hamiltonian H and evaluating the resulting expression at the $\chi=0$ saddle point, gives cumulants of current:

$$\langle\langle I^n\rangle\rangle = \mathrm{D}^n H\,(Q,\lambda,\chi)\big|_{\{\chi=0,Q_0,\lambda_0\}}. \tag{66}$$

This approach is obviously more simple compared to the diagrammatic method, since in the diagrammatics, after drawing all of the diagrams, they have to be evaluated individually by taking many partial derivatives of the Hamiltonian and evaluating them at the $\chi=0$ saddle point. With this new approach, given the Hamiltonian H, the operator D may be constructed (65) and with a mathematical program, an arbitrary cumulant may be easily computed (66).

It is easy to see the importance of the minimal correlation coordinates in this solution. After applying D several times, the derivative quotient rule generates a large number of denominators, $\{\partial_Q H, \partial_\lambda H\}=(\partial_Q\partial_\lambda H)(\partial_\lambda\partial_Q H)-(\partial_Q\partial_Q H)(\partial_\lambda\partial_\lambda H)$. At $\chi=0$, as we argued previously, $\partial_Q\partial_Q H=0$, and it is possible to change coordinates so that $\partial_Q\partial_\lambda H=-1$. As a result, the denominator in (66) is equal to 1, which greatly simplifies the expansion. Finally, we would like to stress that the operator approach, introduced in this section for the one node case, can be easily generalized to a network.

D. Network cascade diagrammatics: Correlation functions

Consider now a general network. In the Sec. IV B, we saw that the dominant contribution to Eq. (47) arises from tree-level diagrams. On time scales $t \gg \tau_C$, the time dependence drops out, and the current cumulants are static. We now generalize the diagrammatic rules presented in the Sec. IV B to investigate time- and node-dependent correlation functions of conserved and absorbed charges, Eq. (19). To define the network, we must arbitrarily label the current flow, yielding a directed network. By doing so we fix the signs of the elements $H_{\alpha\beta}=-H_{\beta\alpha}$ of the Hamiltonian. In particular, the elements of the generalized conductance matrix $\hat{G}$,

$$G_{\alpha\beta} = \frac{\partial^2 H}{\partial(i\lambda_\alpha)\,\partial Q_\beta} \tag{67}$$

(evaluated at $\mathbf{Q}=\mathbf{Q}_0, \mathbf{\Lambda}=0$) are negative or positive depending on the chosen direction. If we segregate absorbing (a) and conserving (c) nodes, the conductance matrix $\hat{G}$ may be put in block form. Two of them, the blocks $\hat{G}_{cc}$ (real symmetric) and $\hat{G}_{ac}$ will be relevant. This gives us the necessary tool to define the generalized minimal correlation coordinates. We consider the frequency dependent response by letting the evolution time extent to infinity, and introduce the time

Fourier transform of the variables $\{\mathbf{Q}^c,\mathbf{\Lambda}^c,\chi^c,\chi^a\}$, where the vector $\{\chi^c,\chi^a\}$ is a time-dependent source term introduced to produce correlation functions of the conserved and absorbed currents [see Eq. (19)].

Following the steps of Sec. IV B, we again split the action into two parts, $S=S_0+\int dtV$, where

$$S_0 = i\int dt[-\mathbf{\Lambda}^c\dot{\mathbf{Q}}^c + \mathbf{\Lambda}^c\hat{G}_{cc}\mathbf{Q}^c + (\chi^c\hat{G}_{cc}+\chi^a\hat{G}_{ac})\mathbf{Q}^c]$$
$$= i\int\int \frac{d\omega d\omega'}{2\pi}[\mathbf{\Lambda}^c(i\omega'+\hat{G}_{cc})\mathbf{Q}^c + (\chi^c\hat{G}_{cc}+\chi^a\hat{G}_{ac})\mathbf{Q}^c]\delta(\omega+\omega'), \tag{68}$$

and where we have dropped the δ in front of the variables for simplicity. As in Sec. IV B, the generalized minimal correlation coordinates are defined by shifting and rescaling the $\mathbf{\Lambda}^c$ variables in order to eliminate the χ variables in Eq. (68). However, because χ is now a vector, the proportionality factor must be a frequency dependent matrix,

$$\mathbf{\Lambda}^c(\omega)\rightarrow\hat{D}^\dagger(\omega)[\mathbf{\Lambda}^c(\omega)+\hat{G}^\dagger_{cc}\chi^c(\omega)+\hat{G}^\dagger_{ca}\chi^a(\omega)]. \tag{69}$$

Here $\hat{D}(\omega)$ is the matrix network propagator,

$$\hat{D}(\omega) = -(i\omega\hat{E}+\hat{G}_{cc})^{-1}, \tag{70}$$

and $\hat{E}$ is the identity matrix. It is straightforward to verify that after the shift, the functional $\int dtV$ becomes the generator of cumulants of minimal correlation currents, i.e., of the currents which are solutions of the Langevin equations:

$$I^c_\alpha = -i\omega Q^c_\alpha = -i\omega\sum_{\beta\gamma} D_{\alpha\beta}(\omega)\tilde{I}_{\beta\gamma}, \tag{71a}$$

$$I^a_\alpha = \sum_{\beta\gamma\alpha'} G_{\alpha\alpha'}D_{\alpha'\beta}(\omega)\tilde{I}_{\beta\gamma}+\sum_\gamma \tilde{I}_{\alpha\gamma}, \tag{71b}$$

where $\tilde{I}_{\alpha\beta}$ are the bare noise sources as defined in Eq. (5). We finally rescale $\chi^c(\omega)\rightarrow\chi^c(\omega)/(i\omega)$ in order to replace conserved currents with charges, $\mathbf{I}^c\rightarrow\mathbf{Q}^c$.

The total action now acquires the following form

$$S = (2\pi i)^{-1}\int d\omega\mathbf{\Lambda}^c(-\omega)\mathbf{Q}^c(\omega)+\int dtV[\mathbf{Q}^c,\hat{D}^\dagger(\mathbf{\Lambda}^c+\chi^c)+\hat{D}^\dagger\hat{G}^\dagger_{ca}\chi^a,\chi^a], \tag{72}$$

where the simplified form of the $\mathbf{\Lambda}$ argument of V follows after composing the various transformations. Following the plan of the previous section, we replace the charge and counting variables $\{\mathbf{Q}(\omega),\mathbf{\Lambda}(\omega)\}$ by functional derivatives with respect to the charge and counting sources $\{\mathbf{J}(\omega),\mathbf{K}(\omega)\}$, and take the V term outside of the functional integral. The functional integrals may now be performed to obtain

$$W(\mathbf{J},\mathbf{K}) = \exp\left\{\int\int\frac{d\omega d\omega'}{2\pi}\mathbf{J}(\omega')\mathbf{K}(\omega)\delta(\omega+\omega')\right\}. \tag{73}$$

The perturbation V must now be expanded in a Taylor series with respect to all variables. The time dependence only appears through the variables themselves, so the expansion coefficients will be time independent, with the exception of the propagator $D_{\alpha\beta}(\omega)$ multiplying the counting variables.

$$V=\sum_{\{i_\alpha,j_\alpha,k_\alpha,l_\alpha\}=0}^{\infty}\frac{\delta^{j_1+\cdots+j_n}}{\delta(Q_1^c)^{j_1}\cdots\delta(Q_n^c)^{j_n}}\langle\langle(I_1^a)^{l_1}\cdots(I_r^a)^{l_r}(Q_1^c)^{i_1}\cdots(Q_q^c)^{i_q}(Q_1^c)^{k_1}\cdots(Q_p^c)^{k_p}\rangle\rangle_m$$
$$\times\frac{(\chi_1^a)^{l_1}}{l_1!}\cdots\frac{(\chi_r^a)^{l_r}}{l_r!}\times\frac{(\chi_1^c)^{i_1}}{i_1!}\cdots\frac{(\chi_r^c)^{i_q}}{i_q!}\times\frac{\lambda_1^{k_1}}{k_1!}\cdots\frac{\lambda_p^{k_p}}{k_p!}\times\frac{(Q_1^c)^{j_1}}{j_1!}\cdots\frac{(Q_n^c)^{j_n}}{j_n!}. \tag{74}$$

As in the one node case, the vertices $\delta_{Q_\alpha^c}\langle I_\beta^a\rangle$ vanish. We note again that the notation chosen for the expansion coefficients in Eq. (74) connects the formalism described here with the Langevin equation point of view. The minimal correlation cumulant $\langle\langle\cdots\rangle\rangle_m$ may be calculated either by the expansion procedure described by Eqs. (72) and (74), or by expressing the physical currents and charges in terms of the current source cumulants by solving the Langevin equations for currents and charges, given by Eq. (71).

The nth order irreducible correlator $\langle\langle I_1^a(\omega_1)\cdots Q_n^c(\omega_n)\rangle\rangle$ may be expressed as a tree-level diagram with n external lines representing absorbed currents I_α^a and conserved charges Q_α^c. Every vertex is local in time, so if there are p legs at a vertex, each is assigned an independent frequency, while the time integral imposes overall frequency conservation, $\delta(\Sigma_i\,\omega_i)$. The cascade rules are generalized as follows:

(1) Every vertex represents the object

$$\delta_{Q_1^c(\omega_1)}\cdots\delta_{Q_l^c(\omega_l)}\langle\langle I_{l+1}^a(\omega_{l+1})\cdots Q_n^c(\omega_n)\rangle\rangle_m,$$

which is multiplied by a δ-function conserving overall frequency, $\delta(\Sigma_{i=1}^n\,\omega_i)$;
(2) the minimal correlation cumulants $\langle\langle I_{l+1}^a(\omega_{l+1})\cdots Q_n^c(\omega_n)\rangle\rangle_m$ may be evaluated by expressing them in terms of cumulants of sources $\langle\langle\tilde{I}_{\alpha\beta}^n\rangle\rangle$ via the solutions (71) of the Langevin equations, or by Eq. (74) if the Hamiltonian is known;
(3) the internal dashed arrow goes from $Q_\alpha^c(\omega)$ to $\delta_{Q_\alpha^c(\omega)}$. It conserves the node index α and the frequency ω;[46]
(4) external lines for absorbed currents and conserved charges originate from $I_\alpha^a(\omega)$ or $Q_\alpha^c(\omega)$ of the vertexes. They conserve the node index and the frequency;
(5) sum over all internal node indices, and integrate over all internal frequencies to remove all but one of the frequency delta functions;
(6) the result has to be multiplied by the total number of inequivalent permutations.

The cascade rules are easily extended to the field theory (see Sec. III). The functional analog to the inverse conductance matrix is the operator

$$\hat{G}^{-1}(\mathbf{r}-\mathbf{r}')\equiv\frac{\delta^2 h}{\delta\lambda(\mathbf{r})\delta\rho(\mathbf{r}')}=-\,\delta(\mathbf{r}-\mathbf{r}')\,\nabla\,\hat{D}\,\nabla\,. \tag{75}$$

The diffusion propagator $(i\omega+\hat{G}^{-1})^{-1}$ can be used to solve the Langevin equations (42) for the density $\rho(\omega,\mathbf{r})$ and current $I(\omega)$ in order to evaluate minimal correlation cumulants. We would like to stress that these cumulants are limited to second order only, because in the diffusion limit the noise sources are Gaussian. The summation over node indices is replaced with an integration over the coordinate $\mathbf{r}$.

V. APPLICATIONS

The formalism presented above is intentionally abstract and general. This is to facilitate maximum applicability and not to tie it to a particular field. However, it is important to give concrete examples. For this reason, we give a detailed treatment of two problems. As a first problem, we consider the saddle-point equations of the 1D field theories for D and F being arbitrary functions of the density ρ [see Eq. (33)]. We apply the results of this analysis to the transport in a diffusive mesoscopic wire at zero temperature, rederive the FCS generating function of the transmitted charge obtained in Refs. 8 and 10, and give new results. We also prove the

conjecture made in Ref. 22 that the current noise of the diffusive symmetric exclusion process at half-filling is Gaussian, i.e., all high-order cumulants of transmitted charge vanish. In the end of the Sec. V A we generalize our results to multi-dimensional diffusion models and prove the universality of their transport statistics. As a second problem, we address the statistics of charge fluctuations in a mesoscopic chaotic cavity. We explicitly find the probability distributions for different physical configurations.

A. FCS for one-dimensional field theories. The mesoscopic diffusive wire

Before demonstrating our solution for the FCS of the mesoscopic diffusive wire specifically, we first consider the general 1D field theory with the action (33). In the stationary limit, $\dot{\rho}=\dot{\lambda}=0$ the action can be written as

$$S = t\int_0^L dz\left[- D\rho'\lambda' + \frac{1}{2}F(\lambda')^2 \right]. \tag{76}$$

The stationary saddle-point equations

$$(F\lambda' - D\rho')' = 0, \quad 2D\lambda'' + \frac{\delta F}{\delta \rho}(\lambda')^2 = 0, \tag{77}$$

can be partially integrated leading to the following two equations:

$$D\rho' = \pm\sqrt{\mathcal{I}^2 - 2\mathcal{H}F}, \tag{78a}$$

$$\lambda' = 2\mathcal{H}/(\mathcal{I} - D\rho'). \tag{78b}$$

The two integration constants $\mathcal{I}=-D\rho'+F\lambda'$ and $\mathcal{H}=-D\rho'\lambda'+(F/2)(\lambda')^2$ are the conserved (conditional) current and the Hamiltonian density, respectively. These conservation laws follow from the symmetries of our 1*D* field theory [see Eqs. (38) and (39) and the surrounding discussion]. Thus we obtain the following result for the action (76),

$$S = tL\mathcal{H}. \tag{79}$$

Equations (78) and (79) represent the formal solution of the FCS problem for 1D diffusion models with $D(\rho)$ and $F(\rho)$ being arbitrary functions of ρ. The following procedure has to be done in order to obtain the cumulant generating function $S(\chi)$ of the transmitted charge:

(1) The differential equation (78a) has to be solved for $\rho(z)$ with the boundary conditions $\rho(z)|_{z=0}=\rho_L$ and $\rho(z)|_{z=L}=\rho_R$. The constant $\mathcal{I}$ should be expressed through the constants ρ_L, ρ_R, and $\mathcal{H}$;
(2) next, $\rho(z)$ is substituted into Eq. (78b) which is integrated to obtain $\lambda(z)$ with the boundary conditions $\lambda_L=0$ and $\lambda_R=\chi$;
(3) finally, using the solution for $\lambda(z)$ the constant $\mathcal{H}$ is expressed in terms of ρ_L, ρ_R, χ, and substituted into the action (79).

We note that by expressing $\mathcal{H}$ and χ in terms of $\mathcal{I}$, we may also formally obtain the logarithm of the current distribution,

$$\ln P(I) = S(\mathcal{I}) - t\mathcal{I}\chi(\mathcal{I}), \quad \mathcal{I}\to I, \tag{80}$$

as a result of the stationary phase approximation for the integral $P(I)=\int d\chi \exp[S(\chi)-tI\chi]$ and because $\partial\mathcal{H}/\partial\chi=\mathcal{I}/L$.

As an example of the 1D field theory, we consider the FCS of the electron charge transmitted through the mesoscopic diffusive wire. When the chemical potential difference $\Delta\mu=\mu_L-\mu_R>0$ is applied to the wire, the electrons flow from the left lead to the right lead with the average current

$I_0 = e^{-1} G \Delta\mu$, where G is the conductance of the wire. The elastic electron scattering causes nonequilibrium fluctuations of the current. At zero temperature, and for noninteracting electrons (the cold electron regime), the zero-frequency current noise power has been found[15,47,48] to be equal to $\langle\langle I^2 \rangle\rangle = (1/3) e I_0$, i.e., the noise is suppressed compared to the Poissonian value. The suppression factor $1/3$ was shown to be universal,[49,50] i.e., it does not depend on the character of the disorder or on the shape of the wire. The FCS of the transmitted charge has been studied in Refs. 8 and 10 using quantum-mechanical methods, and recently in Ref. 22 using a classical method with the following result for the generating function of cumulants of the dimensionless charge Q/e:

$$S(\chi) = (tI_0/e) \operatorname{arcsinh}^2[\sqrt{\exp(\chi) - 1}]. \tag{81}$$

Here we will rederive this result using our classical method.

On the classical level, the electrons in the diffusive wire are described by the distribution function $f(z)$. Under transport conditions (and at zero temperature), this distribution $f(z)$ varies from $f_L = 1$ in the left lead to $f_R = 0$ in the right lead. Starting from the Langevin equation[32] as described in Sec. III or, alternatively, taking the continuum limit for the series of mesoscopic cavities,[36] we arrive at the action (76) with the form[51]

$$S = (tI_0/e) \int_{-1/2}^{1/2} dz [- f' \lambda' + f(1 - f)(\lambda')^2], \tag{82}$$

where we have rescaled the coordinate z, $\rho(z)$ has been replaced with the distribution $f(z)$, and where $D = 1$, and $F = 2f(1-f)$ up to the overall constant I_0/e. This form of F is quite general for fermionic systems. It originates from the Pauli blocking factors, i.e., the transition probability is proportional to the probability that the initial state is populated times the probability that the final state is empty.[15] Applying now the procedure described in the beginning of this section, we solve the saddle-point equations and find the fields f and λ,

$$f(z, \chi) = \frac{1}{2} \left[1 - \frac{\sinh(2\alpha z)}{\sinh \alpha} \right], \tag{83a}$$

$$\lambda(z, \chi) = 2 \operatorname{arctanh}[\tanh(\alpha/2) \tanh(\alpha z)], \tag{83b}$$

$$\alpha = \operatorname{arcsinh}[\sqrt{\exp(\chi) - 1}], \tag{83c}$$

where $\mathcal{H} = \alpha^2$, so that according to the Eq. (79) we immediately obtain the result (81).

The logarithm of the current distribution $\ln[P(I)]$ can be now found from Eq. (80). We obtain the following result:

$$\ln[P(I)] = - (tI_0/e)[2\alpha \coth \alpha \ln(\cosh \alpha) - \alpha^2], \tag{84}$$

where α has to be expressed in terms of $\mathcal{I} = I/I_0$ by solving the equation

$$\alpha \coth \alpha = I/I_0. \tag{85}$$

The last equation has real positive solutions, $0 < \alpha < \infty$, for $I > I_0$, and pure imaginary solutions $\alpha = i\beta$ with $0 < \beta < \pi/2$, for $I < I_0$. The distribution $P(I)$ is strongly asymmetric around the average current $I = I_0$ (see Fig. 7). It has the following asymptotics: $\ln P = -(tI_0/e)[\mathcal{I}^2 - (2 \ln 2)\mathcal{I}]$, for $\mathcal{I} = I/I_0 \gg 1$, i.e., P has a Gaussian tail, and $\ln P = -(\pi^2/4)(tI_0/e)$, for $I = 0$.

We also plot the conditional electron occupation $f(z, I)$, Eq. (83a), for different values of the normalized current I/I_0. There are several interesting points to stress. (i) For large currents, $I > I_0$, the function f drops mostly at the ends of the wire, while for small currents, $I < I_0$, the drop of f is mostly concentrated in the center of the wire. This effect has a simple explanation. At the end points of the wire, $z = \pm 1/2$, the occupation $f(z)$ is fixed independent of the particular value of the current I. On the other hand, its derivative takes the value $f' = -\mathcal{I} = -I/I_0$ at $z = \pm 1/2$, which can be

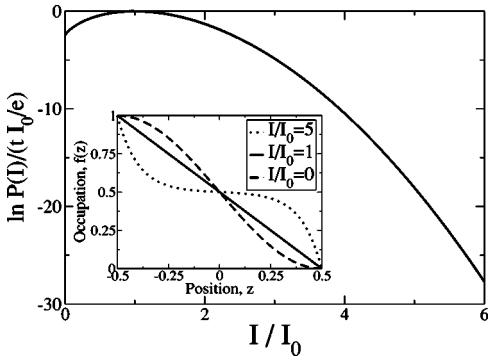

FIG. 7. The logarithm of the distribution of the current through a mesoscopic diffusive wire as a function of the ratio I/I_0 of the current to its average value I_0. The distribution is strongly asymmetric, with the Gaussian tale at $I \gg I_0$. Inset: The electron occupation f inside the wire as a function of the rescaled coordinate z, under the condition that the average current $I=I_0$, no current $I=0$, and large current $I=5I_0$ has been measured.

easily verified using Eqs. (83a) and (85). As a result, $f(z)$ deviates from its linear behavior, $f(z) = 1/2 - z$, characteristic of the average value of current, $\mathcal{I}=1$. The actual reason for this effect is that according to Eq. (42b) the total current $\mathcal{I}=-f'+\nu$ contains a contribution from the source of noise, ν. The greatest contribution is concentrated at the center of the wire, where the noise power $F=2f(1-f)$ has its maximum, while it vanishes at the ends of the wire. Since the current $\mathcal{I}$ is conserved, f' has to be redistributed in such a way as to partially compensate the effect of the source ν. (ii) Fluctuations of f are strongly suppressed at the ends of the wire, which is imposed by the boundary conditions, and at the center of the wire, as a result of the discrete symmetry, $\{z \to -z; f \to 1-f\}$. (iii) Eq. (85) has additional solutions with $\beta > \pi/2$. These solutions are not physical however, since f becomes negative or larger than 1 leading to $I<0$, which is impossible at $T=0$.

Returning to the saddle-point equations (77), we note that if $\delta F/\delta\rho = 0$ for a particular density ρ_0, then the fields $\rho(z)=\rho_0$, and $\lambda(z)=\chi z/L$ solve these equations. The fluctuations of the current become Gaussian with the noise power $\langle\langle I^2\rangle\rangle = F(\rho_0)/L$. This generalizes and proves the conjecture made in Ref. 22 that the noise of the diffusive symmetric exclusion process is Gaussian at half-filling, $f=1/2$.

As a final remark we note that the whole class of multi-dimensional field theories,

$$S = t\int_{\Omega} d\mathbf{r}[-\nabla\lambda\,\hat{D}\,\nabla\rho + (1/2)\,\nabla\lambda\,\hat{F}\,\nabla\lambda], \tag{86}$$

with $\hat{D}=D(\rho)\hat{T}$, $\hat{F}=F(\rho)\hat{T}$, and $\hat{T}$ being an arbitrary constant symmetric tensor,[52] bear the same kind of the universality as the shot noise in diffusive conductors discussed above (see Refs. 49 and 50). The reason is that the field theory with the action (86) can be mapped on the 1D theory with the action (76) by making use of the parameterization

$$\rho(\mathbf{r}) = \rho[\varphi(\mathbf{r})], \quad \lambda(\mathbf{r}) = \lambda[\varphi(\mathbf{r})], \tag{87}$$

where the function $\varphi(\mathbf{r})$ satisfies the equation

$$\nabla\cdot[\hat{T}\,\nabla\,\varphi(\mathbf{r})] = 0. \tag{88}$$

Using Eqs. (77) for ρ and λ as functions of φ, it is straightforward to verify that the fields $\rho(\mathbf{r})$ and $\lambda(\mathbf{r})$ given by (87) and (88) satisfy the saddle-point equations for the action (86). One of the equations is the conservation of current:

$$\mathbf{j} = -\hat{D}\nabla\rho + \hat{F}\nabla\lambda = \mathcal{I}\hat{T}\nabla\varphi. \tag{89}$$

Since the 1D Hamiltonian density is conserved, the action takes the following form

$$S = t\mathcal{G}\mathcal{H}, \tag{90}$$

where the constant $\mathcal{G}$ depends only on the geometry of the boundary $\partial\Omega$ by Eq. (88):

$$\mathcal{G} = \int_{\Omega} d\mathbf{r}\,\nabla\varphi\hat{T}\nabla\varphi = \int_{\partial\Omega} d\mathbf{s}\cdot\varphi\hat{T}\nabla\varphi. \tag{91}$$

Consider now a two-terminal diffusive wire, so that the surface $\partial\Omega$ consists of the left $\partial\Omega_L$ and right $\partial\Omega_R$ contact surfaces, and the open surface $\partial\Omega_0$ with no current through it. We choose the boundary conditions for φ to be

$$\varphi(\mathbf{r})_{\partial\Omega_L} = 0, \quad \varphi(\mathbf{r})_{\partial\Omega_R} = 1, \quad d\mathbf{s}\cdot\hat{T}\nabla\varphi(\mathbf{r})_{\partial\Omega_0} = 0, \tag{92}$$

so that $\rho(\mathbf{r})|_{\partial\Omega_L} = \rho_L$, $\rho(\mathbf{r})|_{\partial\Omega_R} = \rho_R$, $\lambda(\mathbf{r})|_{\partial\Omega_L} = 0$, $\lambda(\mathbf{r})|_{\partial\Omega_R} = \chi$, and $d\mathbf{s}\cdot\mathbf{j}(\mathbf{r})|_{\partial\Omega_0} = 0$. Then $\mathcal{H}$ becomes a function of ρ_L, ρ_R, and χ, and the action is the generator of the cumulants of the transmitted charge. If instead, $\mathcal{H}$ and χ are expressed in terms of $\mathcal{I}$ (as above for the 1D theory), then one obtains the logarithm of the distribution of the current, $\ln[P(I)] = S(I) - tI\chi(I)$, where $I = \mathcal{G}\mathcal{I}$, according to Eqs. (89), (91), and (92). The constant $\mathcal{G}$ may be interpreted as a "geometrical conductance" of a wire. In particular, in the "ohmic" regime, i.e., when D is independent of ρ, we have $I_0 = \mathcal{I}(\chi)|_{\chi=0} = D(\rho_L - \rho_R)$, and therefore $\mathcal{G} = I_0/[D(\rho_L - \rho_R)]$. In this case, the ratio S/I_0 does not contain $\mathcal{G}$ and becomes fully universal, proving also the universality of the result (81) as a special case.

To summarize, we have proven the universality of the FCS of the transmitted charge for a two-terminal multi-dimensional generalized wire described by the action (86) with the noise tensor $F(\rho)\hat{T}$, being an arbitrary function of the charge density ρ, and with the constant diffusion tensor $D\hat{T}$. The universality means that the FCS depends neither on the shape of the conductor, nor on its dimensionality.[53] The FCS of a mesoscopic wire given by Eq. (81) is a particular example of universal FCS. In the more general case, when $\hat{D}$ is a function of ρ, the FCS depends on the geometry through only one parameter $\mathcal{G}$, the geometrical conductance given by Eq. (91).

B. Charge fluctuations in a chaotic cavity

As another example of the applicability of the stochastic path integral approach, we now consider transport through a chaotic cavity. This problem is often investigated in mesoscopic physics because of its simplicity and conceptual clarity. A cavity consists of a large conducting island of irregular shape that is connected to two metallic leads through quantum point contacts (see inset of Fig. 8). The distinctive property of the chaotic cavity separating it from diffusive conductors is that the conductance is determined solely by the ballistic point contacts. The chaotic cavity itself may be either disordered or ballistic. Chaotic cavities can be described by a semiclassical theory if the point contacts have conductances much larger than e^2/h. The statistics of current flow through the cavity have been addressed using various methods. The zero-frequency noise power has been calculated using random matrix theory[54] and the minimal correlation principle.[18] The higher order current cumulants have been obtained in Refs. 7 and 20. The results are in complete agreement with random matrix theory.

In this section we will address another type of statistics. In a typical experimental setup, the cavity is connected to the electrical circuit not only through the leads, but also through nearby metallic gates via the electrostatic interaction. Observing potential fluctuations at these additional gates gives direct insight into the statistics of charge on the cavity. The noise power of the charge fluctuations in this system has been calculated in Ref. 55. The full statistics have been recently

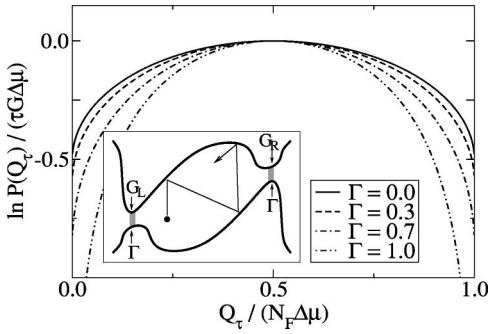

FIG. 8. The logarithm of the distribution of charge Q_τ in a symmetric cavity, $G_L=G_R$, averaged over measurement time τ in the long time limit $\tau \gg \tau_D$ and at zero temperature. The results are presented for several transparencies Γ of the point contacts. It is clearly seen that the tails of the distribution grow in the tunneling limit $\Gamma \ll 1$. The distribution is symmetric, i.e., odd cumulants vanish.

addressed using a random matrix theory.[56] Here, we rederive these results using the stochastic path integral, show new results on the temperature dependence of these statistics, and also investigate the instantaneous fluctuation statistics.

In a semiclassical approach, both leads L,R and the cavity are described by electron distribution functions f_L, f_R, and f. The Fermi functions in the leads $f_\alpha = f_F(E-\mu_\alpha)$ are characterized by their chemical potential μ_α and their temperature T. The chaotic electron motion inside the cavity makes the cavity distribution function $f(E,t)$ isotropic and position independent. Only its energy dependence must be retained. From now on we set the electron charge to one, $e=1$. Then the charge Q in the cavity is given in terms of the electron distribution function and density of states N_F as $Q=N_F\int dEf$. The average value of charge is determined by the low-energy cutoff of the integral and is not relevant for the present discussion. The charge and electrostatic potential of the cavity are related by a geometrical capacitance C_g. In the following, we restrict ourselves to the case $C_g \gg e^2 N_F$ which describes complete screening of the charge in the cavity. A more general discussion can be found in Ref. 56. To analyze the time evolution of the charge, we note that if the size of the cavity is smaller than the electron–electron and electron–phonon scattering length, every electron entering the cavity at a certain energy leaves it at the same energy. The single electron energy is thus conserved and we can formulate a current conservation law separately for each energy interval dE,

$$N_F \dot{f}(E,t) = J_L(E,t) + J_R(E,t), \tag{93}$$

where J_α denote ingoing particle currents per energy interval dE in the left and right contacts. These currents are described by binomial processes with the cumulant generating function given by[5]

$$H_\alpha(f, i\lambda_\alpha)dE = \Gamma^{-1} G_\alpha dE \, \ln[1 + \Gamma f_\alpha (1-f)(e^{i\lambda_\alpha}-1) + \Gamma f(1-f_\alpha)(e^{-i\lambda_\alpha}-1)], \tag{94}$$

where we have introduced the conductances of the point contacts G_α, $\alpha = L,R$, and their transparency Γ.

The quantity of interest is the total number of electrons in the cavity averaged over the measurement time τ,

$$Q_\tau = (N_F/\tau)\int_0^\tau dt \int dEf(E,t). \tag{95}$$

We first consider the long time limit, $\tau \gg \tau_D$, where $\tau_D = N_F/(G_L+G_R)$ is the average dwell time of an electron in the cavity. In this limit, the action is stationary with respect to the variables f and λ,

$$S = \tau \int dE[H(f,i\lambda) + i(N_F/\tau)\chi f], \quad H = H_L + H_R, \tag{96}$$

where the external variable χ generates the statistics of the desired quantity Q_τ.

At zero temperature $T=0$, the variables λ and f are independent of the energy E, and the integration in Eq. (96) amounts to a multiplication by $\Delta\mu=\mu_L-\mu_R$. Evaluating the Fourier transform of the characteristic function $Z(i\chi)$,

$$Z(i\chi) = (2\pi)^{-1} \int dQ d\lambda \, \exp(S), \tag{97}$$

we express the full probability distribution $P(Q_\tau)$ of charge on the cavity as an integral

$$P(Q_\tau) = (2\pi)^{-1} \int d\lambda \, \exp[\tau\Delta\mu H(f,i\lambda)], \quad f = Q_\tau/(N_F\Delta\mu). \tag{98}$$

This integral will be calculated in the saddle-point approximation. For the tunneling limit $\Gamma \ll 1$ and for open point contacts $\Gamma=1$ we obtain

$$\ln P(Q_\tau)_{\Gamma\ll 1} = -\tau G\Delta\mu[\sqrt{f(1-f_0)} - \sqrt{f_0(1-f)}]^2, \tag{99a}$$

$$\ln P(Q_\tau)_{\Gamma=1} = \tau G\Delta\mu\left[f_0 \ln\left(\frac{f}{f_0}\right) + (1-f_0)\ln\left(\frac{1-f}{1-f_0}\right)\right], \tag{99b}$$

where $G=G_L+G_R$, and where we have introduced the average distribution function $f_0=G_L/(G_L+G_R)$ in the cavity. We summarize that the results (99) have been obtained under the conditions $T=0$, $\tau \gg \tau_D$, and for $\Gamma \ll 1$ and $\Gamma=1$. These results can be easily generalized to the case of a multi-terminal cavity.

Although the general case of an arbitrary transparency Γ has been also solved analytically, the final expression for the charge distribution is too lengthy to be presented here. The Fig. 8 shows the distribution $P(Q_\tau)$ at zero temperature for various transparencies Γ of the point contacts. The cavity is taken to be symmetric $G_L=G_R$. It is clearly seen that the tails of the distribution grow towards the tunneling limit.

At finite temperature, further analytical progress can be made by considering the first few cumulants of the charge Q_τ. The integral (96) for the cumulant generating function has to be evaluated at the saddle point. For $\chi=0$ the solution of the saddle-point equations $\partial S/\partial\lambda=0$ and $\partial S/\partial f=0$ are simply given by $\lambda=0$ and $f=f_0$, where $f_0=(G_Lf_L+G_Rf_R)/(G_L+G_R)$ is the average electron distribution function in the cavity. From the diagrammatic technique discussed in Sec. IV we derive analytical expressions for the first few cumulants. The second cumulant has been obtained in Ref. 55. As an example, we present here the result for the third cumulant for the case of open point contacts, $\Gamma=1$:

$$\langle\langle Q_\tau^3\rangle\rangle = -\frac{2\tau_D^3}{\tau^2}\frac{G_LG_R(G_L-G_R)}{(G_L+G_R)^2}\left[\Delta\mu + 3\frac{\Delta\mu - k_BT\sinh(\Delta\mu/k_BT)}{\cosh(\Delta\mu/k_BT)-1}\right]. \tag{100}$$

The first few cumulants are plotted in Fig. 9 as a function of the dimensionless bias $\Delta\mu/k_BT$. Note that the fourth cumulant may change its sign as one goes from a symmetric cavity ($\beta=0$) to an asymmetric cavity ($\beta=0.9$).

So far we have considered the time of measurement τ longer than the dwell time τ_D. Next we consider the opposite limit $\tau \ll \tau_D$ (but still larger than $\tau_0=\hbar/\Delta\mu$) and study the instantaneous fluctuations of the charge Q in the cavity at zero temperature, $T=0$. For this purpose we will use the stochastic path integral (3) for the propagator $U(Q_f,Q_i,t)$ of the cavity charge. The distribution $P(Q)$ of instantaneous fluctuations can be obtained by taking the $t\to\infty$ limit of the propagator $U(Q_f,Q_i,t)$ and setting $Q_f=Q$. We note that in the long time limit, $t \gg \tau_D$, the initial state Q_i

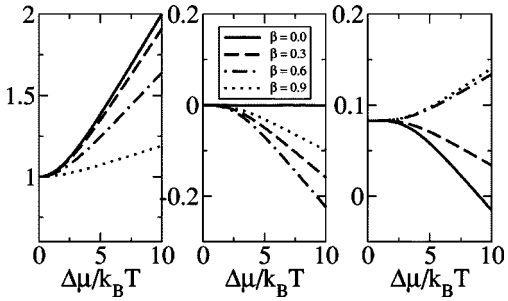

FIG. 9. Cumulants of the charge inside a chaotic cavity, $\langle\langle Q_\tau^n\rangle\rangle$, $n=2,3,4$ (in arbitrary units) as functions of the dimensionless potential difference $\Delta\mu/k_BT$. The parameter $\beta=(G_L-G_R)/(G_L+G_R)$ characterizes the asymmetry of the cavity.

relaxes to the stationary state $\overline{Q}$, and as a result the saddle-point expression of the propagator $U=\exp(S_{sp})$ factorizes according to $S_{sp}=S_0(\overline{Q})+S_i(Q_i)+S_f(Q_f)$. Here the stationary contribution to the action is zero, $S_0=0$, since there is no charge accumulation on a long time scale. We will show that the initial state contribution vanishes, $S_i=0$, so the system looses its memory about the initial state. Thus we obtain $\ln P(Q)=S_f(Q)$.

We now focus on the case of a cavity with two tunneling contacts ($\Gamma\ll 1$). Using the Hamiltonians in Eq. (94), and replacing the counting variable $\lambda\to i\lambda$, we write the action as

$$S=G\Delta\mu\int dt[\tau_D\lambda\dot{f}+h_s(\lambda,f)], \tag{101a}$$

$$h_s=(1-f_0)f(e^{\lambda}-1)+f_0(1-f)(e^{-\lambda}-1), \tag{101b}$$

where h_s is the scaled Hamiltonian. The saddle point equations take the following form

$$\tau_D\dot{f}=-(1-f_0)fe^{\lambda}+f_0(1-f)e^{-\lambda}, \tag{102a}$$

$$\tau_D\dot{\lambda}=\sinh(\lambda)+(1-2f_0)[\cosh(\lambda)-1]. \tag{102b}$$

The solution of the Eq. (102b) for λ reads

$$\lambda(t)=\ln\left[\frac{1+Af_0\exp(t/\tau_D)}{1-A(1-f_0)\exp(t/\tau_D)}\right], \tag{103}$$

where A is the integration constant.

To show that the initial contribution to the action S_i is zero, we note that independent of the constant A, the absolute value of λ is a growing function with the stationary state given by $\overline{\lambda}=0$ at $t=-\infty$. This means that starting from early times $t_0\to-\infty$, the solutions are $\lambda(t)=0$ and $f(t)-f_0=[f(t_0)-f_0]\exp[-(t-t_0)/\tau_D]$. They describe the relaxation of the initial state $f(t_0)$ to the stationary state $\overline{f}=f_0$. Substituting these solutions to Eqs. (101) we immediately find that $S_i=0$.

After making this point we skip the rest of the details and present the final result for $\ln P(Q)=S_f(Q)$:

$$\ln P(Q)_{\Gamma\ll 1}=-\tau_DG\Delta\mu\left[f\ln\left(\frac{f}{f_0}\right)+(1-f)\ln\left(\frac{1-f}{1-f_0}\right)\right], \tag{104}$$

which can now be compared to the results (99). The cumulant generating function for the distribution (104) is given by $S(\chi)=\tau_DG\Delta\mu\ln[1+f_0(e^{\chi}-1)]$. Note that $\tau_DG\Delta\mu=N_F\Delta\mu$ is the total number of the semi-classical states in the cavity which participate in transport. Therefore the distribution (104) can be interpreted as being a result of uncorrelated binomial fluctuations of the

Fermi occupations of each semi-classical state. We would like to mention that the same result can be obtained by solving the stationary master equation.

VI. CONCLUSIONS

We have put forth a stochastic path integral formulation of fluctuation statistics in networks. The mathematical building blocks of the theory are (1) the probability distributions of transport processes through the connectors, (2) a continuity equation linking the connector currents to the charge accumulation in nodes (charge conservation), and (3) a separation of time scales between nodal dynamics and connector fluctuations. The relevant action of the path integral is derived from these considerations and is related to the probability of (charge conserving) paths in phase space. The dominant contribution to the statistics comes from the saddle point approximation to the path integral, and the generating function for the interacting system is simply the action at the saddle point. Fluctuations are suppressed by the number of transporting elementary charges in the network. We have considered the continuum limit to obtain a field theory, and mapped it onto a Langevin equation with Gaussian noise. Cascade diagrammatic rules were found in agreement with Nagaev for the one node case, and extended to general current correlation functions in an arbitrary network. Applications to the current statistics of the diffusive wire and fluctuation statistics of the charge inside a mesoscopic cavity were also discussed. As the building blocks of the theory are classical probability theory, the potential application of this formalism is very broad and applicable to any field where fluctuations are important, including mesoscopics, biology, economics, fluid and chemical dynamics.

Note added. After this paper was submitted for publication, the authors learned of previous related work by Bertini *et al.*[57] Although they did not consider transport statistics, they did consider the probability to manifest a given macroscopic fluctuation of the particle density in diffusive lattice gas models and arrive at the action Eq. (33). However, the Gaussian nature of the local fluctuations was assumed *a priori*. We thank B. Derrida for bringing these papers to our attention.

[37] Mathematically, this term is a vector, and because the action must be scalar in nature, it must be dotted into some natural vector of the system. Physically, this simply states that at zero bias, there is no preferred current direction; the retention of this term demands some broken symmetry in the problem

[41] Gaussian noise with nontrivial correlations in space and time may be included by introducing two time and space integrals in the probability weight Eq. (41).
[42] In the process of converting the Langevin equation into the path integral, there is additionally a functional Jacobian between $\nabla\nu$ and ρ. This may be written as a determinant of an operator $M=[d/dt-\nabla\cdot(\delta/\delta\rho(D\nabla_\rho))]\delta(t-t')\delta(\mathbf{r}-\mathbf{r}')$. If D is independent of ρ, this simply alters the overall normalization. If this is not the case, one may often use the freedom of stochastic quantization to render it a constant (Ref. 29). To systemically investigate fluctuations, the determinant may be written as a fermionic functional integral (Ref. 32)

[51] If diffusion coefficient D and noise coefficient F do not explicitely depend on energy (which is usually the case for metals), it can be shown that the electrostatic potential along the wire can be absorbed into the electron energy and does not influence the action (82) in the zero frequency limit. Finite frequency effects due to fluctuations of the electrostatic potential are discussed in Ref. 59.
[52] It is crucial for the universality of the statistics that $D(\rho)$ and $F(\rho)$ multiply the same tensor $\hat{T}$.
[53] This proof of the universality can be easily generalized to include the coordinate dependence of $\hat{D}$ and $\hat{F}$, in the same way as it has been done for the noise power in Ref. 50.

Fragile $\mathcal{PT}$-symmetry in a solvable model

Miloslav Znojil[a)]

(Received 17 March 2004; accepted 21 July 2004; published 25 October 2004)

One of the simplest pseudo-Hermitian models with real spectrum (viz., square-well on a real interval $\mathcal{I}$ of coordinates) is re-examined. A $\mathcal{PT}$-symmetric complex deformation $\mathcal{C}$ of $\mathcal{I}$ is introduced and shown tractable via an innovated approach to matching conditions. The result is surprising: An *arbitrarily small* deformation $\mathcal{I} \to \mathcal{C}$ implies a sudden collapse (i.e., the spontaneous $\mathcal{PT}$-symmetry breaking) of virtually *all* the spectrum (i.e., up to its low-energy part). © *2004 American Institute of Physics.* [DOI: 10.1063/1.1803928]

I. NON-HERMITIAN HAMILTONIANS AND THEIR SPECTRA

Thirty-five years ago, Bender and Wu[1] published an extremely exciting discovery that certain bound-state problems may be much better understood when one drops the "obligatory" Hermiticity assumption $H=H^\dagger$ and admits that a coupling constant $g>0$ in Schrödinger equation

$$H(g)|\psi_n(g)\rangle = E_n(g)|\psi_n(g)\rangle, \quad n=0,1,\ldots \tag{1}$$

is analytically continued to a complex value $g \in \mathbb{C}$. In this perspective Bender and Wu worked, for definiteness, with the quartic anharmonic-oscillator Hamiltonians

$$H(g) = H^{(4)}(g) = \hat{p}^2 + f^2\hat{x}^2 + g\,\hat{x}^4, \tag{2}$$

and demonstrated that the separate (though, in general, complex) spectra $\{E_n(g)\}$ may *all* be interpreted as the sets of an intersection of *all* the Riemann sheets of a *single* analytic function $\mathbb{E}^{(4)}(g)$ with a corresponding "line" of a constant g. Many years later, similar observations were made and verified for the cubic model

$$H(g) = H^{(3)}(g) = \hat{p}^2 + f^2\hat{x}^2 + i\,g\,\hat{x}^3 \tag{3}$$

(see Ref. 2 for more details), etc. In all of these models, the costs of the generalization $H \neq H^\dagger$ proved much lower than expected. For all the nonzero couplings $g \neq 0$, all of their complex "exceptional points" (EP)[3] proved well separated in the complex plane of g for both Eqs. (2) and (3).

A new important development of the subject emerged cca six years ago when Bender and Boettcher published their letter.[4] Having extended their attention to the whole class of the power-law models

$$H(g) = H^{(2+\delta)}(g) = \hat{p}^2 + f^2\hat{x}^2 + g\,\hat{x}^2\,(i\hat{x})^\delta, \quad \delta>0, \quad g>0 \tag{4}$$

[reproducing the above special cases (2) and (3) at $\delta=2$ and $\delta=1$, respectively], they summarized several existing perturbative and numerical experiments (for illustration one could cite, e.g., Refs. 5–7), complemented them by numerous new WKB arguments and conjectured that after one introduces a suitable Hilbert space, *all* the Hamiltonians (4) (with, for simplicity, $f=0$) will possess the *purely real* (and discrete and, from below, bounded, i.e., "observable-like") spectra, in spite of their *manifestly* non-Hermitian origin.

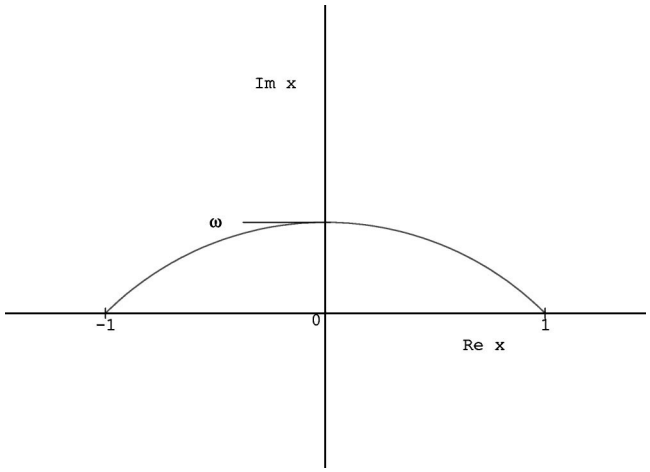

FIG. 1. Integration path $\mathcal{C}$ with an upwards deformation $\omega>0$.

For the pioneering conjecture of this type, several rigorous proofs [cf., e.g., the Fourier-transformation results[7] for Eq. (2) at $g<0$, or the manifest reality of perturbative energies after re-summation for Eq. (3) at the real g[5]] were already available and many other had only to come [cf., for illustration, proofs in the difficult case of Eq. (3) in Ref. 8]. Nevertheless, the core of the message delivered by Bender and Boettcher lied in the emphasis attributed to the parity-plus-complex-conjugation symmetry (conveniently called $\mathcal{PT}$-symmetry) of their sample non-Hermitian Hamiltonians $H^{(2+\delta)}(g)$ with real spectra. This inspired an extensive subsequent study of the structure of the relationship between the reality of the spectrum and the $\mathcal{PT}$-symmetry of the underlying non-Hermitian Hamiltonian.[9]

We intend to contribute to the latter effort by the description of an exactly solvable example which exhibits a rather counterintuitive enhanced sensitivity to a very small change of its coordinate domain. We shall start from an overall review of the state of the art in Sec. II where we emphasize the theoretical importance as well as some practical weaknesses of the pseudo-Hermitian constraint imposed upon the non-Hermiticity of the Hamiltonians.

In Sec. III we return to the study of quantitative characteristics of the specific, differential-equation models where the current and robust property of Hermiticity $H=H^{\dagger}$ is being replaced by the $\mathcal{PT}$-symmetry which may be fragile.[10,11] We restrict our attention to the most elementary non-Hermitian square-well model (of Ref. 12, with real spectrum) and extend its scope slightly by the replacement of its usual domain (viz., a finite interval $\mathcal{I}$) by a broken line (or by any other smoothly deformed curve $\mathcal{C}$—cf. Fig. 1) in the complex plane of coordinates.

Our main mathematical results are presented in Sec. IV where our new method of solving the matching conditions is shown applicable to an explicit qualitative description of the structure of the bound states in the broken-path regime. We explain in detail how our "moving-lattice" method decisively facilitates the global analysis of the matching conditions.
