Our key physical message is finally formulated in Sec. V emphasizing that our innovative geometric interpretation of the matching conditions offers the rigorous proof that in our example, an arbitrarily small imaginary shift $0\to i\omega$ of the matching point causes a non-perturbative, *sudden* complexification of *all* the high-energy part of the spectrum. In the currently accepted terminology this means that the vast majority of the wave functions encounters a spontaneous breakdown of *their* $\mathcal{PT}$-symmetry. We shall conclude in Sec. VI that this symmetry is *manifestly* fragile in our particular model.

II. $\mathcal{PT}$-SYMMETRY

A. Variational picture

In the early stages of study of $\mathcal{PT}$-symmetric quantum mechanics people tried to understand the complexified Schrödinger Hamiltonians of the type (4) as models on the real line, with a pair

of the real and imaginary potentials of a definite behavior with respect to the parity $\mathcal{P}$. Along these lines one arrives at an introduction of the two harmonic-oscillator-type bases $\{|n^{(\pm)}\rangle\}$ (with definite, fixed parities $^{(\pm)}$) and transforms the $\mathcal{PT}$-symmetric differential Schrödinger equations $H|\psi\rangle = E|\psi\rangle$ with a pre-selected normalization of $|\psi\rangle = \Sigma_n\ (|n^{(+)}\rangle\psi_n^{(+)} + i|n^{(-)}\rangle\psi_n^{(-)})$ into the variational-like real and partitioned matrix problems containing arrays $\vec{\psi}^{(\pm)}$ of the real wave function components $\psi_n^{(\pm)}$,

$$\begin{pmatrix} A & -C \\ C^T & D \end{pmatrix}\begin{pmatrix} \vec{\psi}^{(+)} \\ \vec{\psi}^{(-)} \end{pmatrix} = E\begin{pmatrix} \vec{\psi}^{(+)} \\ \vec{\psi}^{(-)} \end{pmatrix}. \tag{5}$$

The infinite-dimensional submatrices $A=A^T$ and $D=D^T$ are real and symmetric but the spectrum itself need not be real at all.[13] These considerations inspired Mostafazadeh who conjectured, in a series of papers,[14] that the Bender's and Boettcher's $\mathcal{PT}$-symmetric quantum mechanics should be classified as a mere special case of the more universal pseudo-Hermitian quantum mechanics, the origins and foundations of which might be traced back to Dirac *et al.*[15] In such an overall setting, he proposed to weaken the $\mathcal{PT}$ symmetry of the Hamiltonians to their mere pseudo-Hermiticity

$$H^\dagger = \eta H \eta^{-1}, \quad \eta = \eta^\dagger, \tag{6}$$

where we may set, in our particular example (5),

$$\eta = \eta_P = \begin{pmatrix} I & 0 \\ 0 & -I \end{pmatrix} = \eta_P^{-1}. \tag{7}$$

In the light of the well known[16] huge ambiguity of the assignment of the "metric" η to any given pseudo-Hermitian Hamiltonian $H \neq H^\dagger$, Mostafazadeh also proposed that the "natural" choices with the indeterminate parity-like metric operators [like $\eta_{\mathcal{P}}$ in Eq. (7)] should be *all* replaced by *any* (i.e., very often, nondiagonal and strongly Hamiltonian-dependent) positive definite alternative $\eta_+ > 0$. In parallel to Mostafazadeh, similar conclusions have been reached in Refs. 17 and 18 defining, in the present language, the particular positive definite metrics $\eta_+ = \mathcal{PQ}$ and $\eta_+ = \mathcal{CP}$ using the additional symmetry generators $\mathcal{Q}$ and $\mathcal{C}$ of quasi-parity and charge, respectively.

The latter procedure enables us to call all the similar non-Hermitian Hamiltonians H "quasi-Hermitian" because, in accord with the Ref. 16, the positivity of $\eta_+ > 0$ suppresses many interpretation difficulties and leaves the quasi-norm $\|\varphi\| = \sqrt{\langle\varphi|\,\eta_+|\varphi\rangle}$ real and nondegenerate. This makes the corresponding Hamiltonians compatible with their standard quantum-mechanical probabilistic tractability.[19]

B. Square-well illustration

One of the main sources of inspiration for the selection of potentials in Schrödinger equations (say, in the Coulombic form) is the principle of correspondence which allows us to extend and transfer to quantum mechanics the experimental experience gained during centuries in the common, macroscopic world. A counterintuitive character of many quantum phenomena allows us to search for some new and unusual Schrödinger equations, e.g., by a complexification of their axes of coordinates $\mathbb{R} \to \mathcal{C}$.[4] Alternatively, we may obtain manifestly $\mathcal{PT}$-symmetric equations

$$\left[-\frac{d^2}{dx^2} + V(x) + iW(x) \right]\psi(x) = E\psi(x) \tag{8}$$

by staying on the real line and "deforming" the shapes of $V(x) = +V(-x)$ and $W(x) = -W(-x)$. Samples of both these approaches may be found, e.g., in Ref. 10 (considering mainly the asymptotically power-law potentials) or Ref. 20 (paying attention to some exponentially confining forces) or Ref.12 (where an even steeper, infinitely deep square well has been complexified) or Ref. 21 (where the mathematical properties have been discussed for the next-step models with delta-functions mimicking the "infinitely thin" square wells).

The square-well model represents a reasonable phenomenological compromise exhibiting, as a bonus, an important merit of exact solvability. We shall pick up it in what follows, interpreting the infinitely deep real part of the potential

$$V(x)=\begin{cases}+\infty\\0\\+\infty\end{cases}\quad\text{for}\quad\begin{cases}x>1\\-1<x<1\\x<-1\end{cases}\tag{9}$$

as a requirement that all the wave functions vanish at $x=\pm 1$. We break the Hermiticity of our Hamiltonian by adding the imaginary and $\mathcal{PT}$-symmetric finite interaction term with coupling $Z>0$,

$$W(x)=\begin{cases}+Z,\\-Z\end{cases}\quad\text{for}\quad\begin{cases}\text{Re } x<0\\\text{Re } x>0.\end{cases}\tag{10}$$

Once we assume that the interval of the coordinates x remains purely real, the spectrum of energies $E_n=E_n(Z)$ proves discrete and real at all $Z<Z_{\text{critical}}\approx 4.48$ (cf. Ref. 22). It smoothly converges towards the well known square-well energy levels $E_n(0)=(n+1)^2\pi^2/4$ in the Hermitian limit $Z\to 0$.

In an extension of the above square-well model we shall now assume that the interval of the coordinates x will be deformed to complex plane, to a suitable curve $\mathcal{C}$ of integration of our complexified Schrödinger equation. More rigorously, we reinterpret our original differential Eq. (8) with nonanalytic potential $W(x)$ as two individual equations, each of which is only defined on the respective half-plane of x with $Re x>0$ and $Re x<0$. Both of them contain a constant, safely analytic potential, but their solutions must be matched at a point where the curve $\mathcal{C}$ intersects the boundary of the two domains. The corresponding generalized, $\mathcal{PT}$-symmetric (i.e., left-right–symmetric) curve $\mathcal{C}$ is sampled in Fig. 1.

III. EXACT SOLVABILITY OF THE NEW MODEL

Once we define our potential (10) in the whole complex plane of $x\in\mathbb{C}$, solutions $\psi(x)$ will be analytic in both its half-planes. The only distinctive feature of our present generalization $(-1,1)=\mathcal{I}\to\mathcal{C}$ lies in the requirement of the matching of the left and right branches $\psi_{\mp}(x)$ of our full wave function $\psi(x)$ at a point $x_0=i\omega$ on the imaginary axis. This enables us to postulate the matching rules

$$\psi_-(i\omega)=\psi_+(i\omega)=1,\quad \partial_x\psi_-(i\omega)=\partial_x\psi_+(i\omega)=iA\tag{11}$$

in terms of an auxiliary real parameter $A\in(-\infty,\infty)$.

A. Re-parametrization of the matching conditions

As long as our potentials V and W are constant almost everywhere, the general solution of our differential Schrödinger equation (8) may be put equal to a sum of the hyperbolic sine and cosine. The left and right solutions $\psi_{\mp}(x)$ are different, having to vanish at the different boundary points $x\to\mp 1$,

$$\psi_-(x)=R_-\sinh\kappa^*(1+x),\quad \psi_+(x)=R_+\sinh\kappa(1-x).\tag{12}$$

With $\kappa=s-it$, the values of the two free real parameters s and t will be determined by the differentiation in Eq. (8),

$$E=t^2-s^2,\quad Z=2\,st.\tag{13}$$

As long as a change of the sign of κ would influence just the (arbitrary) sign of the overall normalization coefficients $R_{\pm}$, we conveniently restrict our attention to the quadrant of $s>0$ and $t>0$ (note that we fixed the sign of $Z>0$ in advance). The insertion of the right and left solutions

(12) in the matching conditions (11) gives the following complex (and transcendental) algebraic equations,

$$L\ \sinh\ \kappa^{*}(1+i\omega)=R\ \sinh\ \kappa(1-i\omega)=1,$$

$$\kappa^{*}L\ \cosh\ \kappa^{*}(1+i\omega)=-\kappa\ R\ \cosh\ \kappa(1-i\omega)=iA.$$

Their solution is our main task. In the first step, we can get rid of the redundant constants by taking the ratios,

$$\kappa^{*}\ \mathrm{cotanh}\ \kappa^{*}(1+i\omega)=-\kappa\ \mathrm{cotanh}\ \kappa(1-i\omega)=iA. \tag{14}$$

The former equal sign is trivial while the latter one represents a complex equation which defines the real parameter A *and* inter-relates the two real and positive parameters s and t in addition. As long as we have $Z=2st$, this should determine all their admissible values.

Changing our notation and putting $\omega=\tan\ \varphi$ with $\varphi\in(-\pi/2,\pi/2)$, let us now introduce two auxiliary linear functions $S=S(s,t)$ and $T=T(s,t)$ defined by the elementary two-dimensional rotation

$$\begin{pmatrix} S \\ T \end{pmatrix}=\begin{pmatrix} \cos\ \varphi & -\sin\ \varphi \\ \sin\ \varphi & \cos\ \varphi \end{pmatrix}\begin{pmatrix} s \\ t \end{pmatrix} \tag{15}$$

where the angle of the rotation measures also the upward shift of the matching point in the complex plane of our complex coordinates. In this notation we may re-write our matching constraint (14) in the form

$$A\ \sinh\left(\frac{S}{\cos\ \varphi}-i\frac{T}{\cos\ \varphi}\right)=(t+is)\cosh\left(\frac{S}{\cos\ \varphi}-i\frac{T}{\cos\ \varphi}\right) \tag{16}$$

which admits a facilitated separation of its real and imaginary part. The value of A drops out of their ratio which may be further re-arranged to represent our matching condition in the most compact real form

$$s\ \sinh\left(\frac{2S}{\cos\ \varphi}\right)=-t\ \sin\left(\frac{2T}{\cos\ \varphi}\right). \tag{17}$$

In the limit $\varphi\to 0$ the latter equation coincides with the $\omega=0$ prescription of Ref. 12. At the generalized $\omega\neq 0$ the replacement of s and t by S and T via Eq. (15) converts our new and more complicated matching formula (17) into its final form

$$\tau=\sigma\frac{\omega+\varrho(\tau)\sinh\ \sigma}{1-\varrho(\tau)\omega\ \sinh\ \sigma},\quad \omega=\tan\ \varphi, \tag{18}$$

where we abbreviated $\sigma=2S/\cos\ \varphi$, $\tau=2T/\cos\ \varphi$ and $\varrho=\varrho(\tau)=-1/\sin\ \tau$. This equation is an implicit definition of a certain set of curves $\tau=\Theta(\sigma)$ in the $\sigma-\tau$ plane. In principle, the knowledge of these curves would enable us to find all their intersections $(\sigma_k,\ \tau_k)$, $k=0,1,\ldots$ with our original constraint $t=Z/(2s)$.

B. The lattice-moving method of solving Eq. (18)

Our present key idea is that the function $\varrho=\varrho(\tau)$ is periodic, i.e., it remains constant on a discrete lattice $\mathcal{L}$ of its argument τ. In this spirit we shall split the real axis of τ into intervals of the length 2π numbered by an integer k. Then we introduce the second variable $p=\pm 1$ marking the right and the left half of each of these intervals, respectively. This guarantees that at a fixed p the sign of the sine function remains the same and equal to $-p$. Finally, due to the symmetry of each of the sine-shaped curves we split the half-intervals in the quarter-intervals marked by another index $q=\pm 1$,

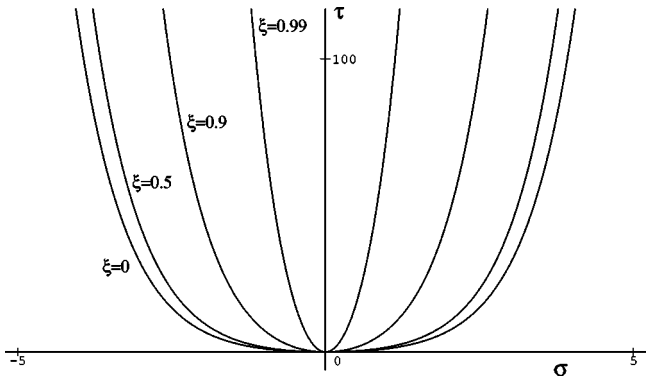

FIG. 2. The lattice-dependent curve (22) with $p=+1$ at a few ξ.

$$\tau=(2k+1)\pi+p\frac{\pi}{2}+q\frac{\pi}{2}\xi\equiv\tau_{(k,q)}(p,\xi),\quad \xi=\xi(\tau)\in(0,1). \tag{19}$$

As a consequence, our parameters $\varrho(\tau)$ become represented by the functions which are independent of k and q,

$$\Omega(p,\xi)=-\frac{1}{\sin\,\tau_{(k,q)}(p,\xi)}=+\frac{p}{\cos(\pi\xi/2)}. \tag{20}$$

The parameters ϱ remain constant over all the lattices $\mathcal{L}_{(p_0,\xi_0)}$ of points $\tau_{(k,q)}(p_0,\xi_0)$ where the sign p_0 and the parameter ξ_0 are temporarily fixed.

1. Verification: Straight-path solution re-visited

At $\omega=0$ and $\mathcal{C}=\mathcal{I}$, the use of the limiting, simplified version

$$\tau=\varrho(\tau)\sigma\,\sinh\,\sigma,\quad \omega=0 \tag{21}$$

of our matching condition (18) leads to an enormous simplification of the construction performed in Ref. 12. There, severe difficulties originated from a strong and pronounced τ-dependence of the factor $\varrho=\varrho(\tau)$ which is a very quickly changing function of its argument τ. In our present setting, the discretization (19) enables us to fix the value of $\varrho=\Omega$ by reducing our attention from all the values of τ to their lattices $\mathcal{L}_{(p,\xi)}$. Treating them separately, one at a time, we only have to keep in mind the overall range of our real constants $\Omega(p,\xi)=p|\Omega(p,\xi)|=p\Omega(+1,\xi)\notin(-1,1)$. This enables us to re-parametrize the matching condition (21),

$$\tau=\tau_{(k,q)}(p,\xi)=\Omega(p,\xi)\sigma\,\sinh\,\sigma,\quad p,\xi=fixed. \tag{22}$$

In the new language, the graph of the function $\Omega\,\sigma\,\sinh\,\sigma$ is a parabolic curve which is oriented up or down at the respective $p=+1$ and $p=-1$. As long as we are interested in the positive $\tau>0$, we may discard $p=-1$ and fix $\tau=\tau_{(k,q)}(+1,\xi)>0$ and $\varrho(\tau)=\Omega(p,\xi)=\Omega(+1,\xi)\geqslant 1$. The curves $\tau=\Omega(+1,\xi)\sigma\,\sinh\,\sigma\equiv\Theta_\xi(\sigma)$ then shrink in proportion to the growth of ξ, proceeding from their broadest $\xi=0$ version (where $|\Omega|=1$) via the narrowing parabolic curves until the degenerate single and upwards-oriented half-line in the limit $\xi\to 1$, i.e., $\Omega\to\infty$. This is illustrated in Fig. 2 where the unlimited shrinking of the curves is sampled at $\xi=0,0.5,0.9$, and $\xi=0.99$.

When we zoom out a stripe of $\tau=\tau_{(k,q)}(p,\xi)$ at a fixed $k=30$ in Fig. 2, we get Fig. 3. In Fig. 3 the variations of τ are determined solely by the changes of ξ and q which are sampled by a few horizontal lines. As long as the right-hand-side function $\Theta_\xi(\sigma)$ depends on both σ and ξ, Eq. (22) will be satisfied *only* at the points of intersection of each particular ξ-marked horizontal line with another particular, ξ-assigned parabolic curve. In this manner the points of intersection $(\sigma_{\xi_m},\tau_{\xi_m})$

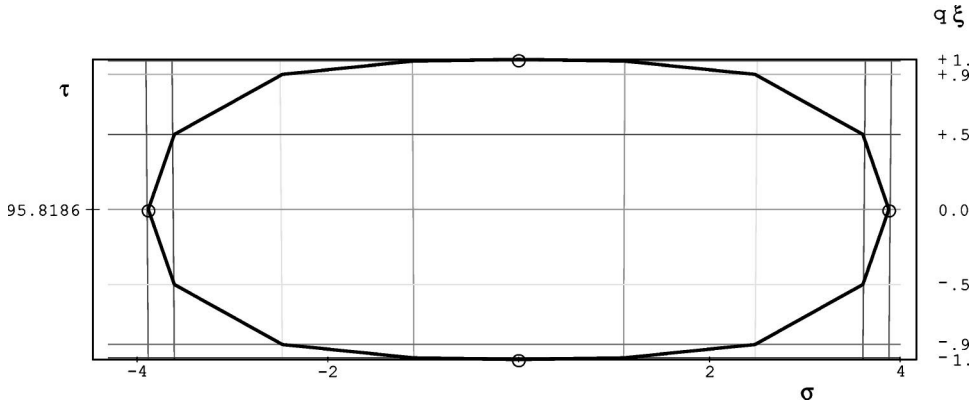

FIG. 3. The oval-shaped matching constraint $\tau=\Theta(\sigma)$ in its ξ-discretization at $\omega=0$ and $k=30$.

in Fig. 3 sample the graphical solution of the matching condition (22). As long as we choose a fairly large stripe number $k=30$, the parabolas of Fig. 2 are represented by the almost straight and almost vertical lines in Fig. 3. This makes the identification of all the intersections particularly easy. We see that the points of intersection form the horizontally prolate ovals, each of which being confined within its $k=k_0$ and $p=+1$ stripe, and not exceeding the interior of the "maximal," $|\Omega|=1$ parabola. It is obvious that the horizontal lines (= lattices of τ) as well as the more or less vertical parabolas move smoothly with the growth of ξ. The resulting picture reproduces precisely our old graphical proof[12] of the existence of solutions at $\omega=0$. Our present new discretization method appears to offer a feasible extension of this proof and analysis to $\omega\neq 0$.

IV. BOUND STATES AT $\omega\neq 0$ IN GRAPHICAL REPRESENTATION

Once we wish to determine the spectrum of the square-well energies $E_n=t_n^2-s_n^2$ at any $\omega\neq 0$, we have to find all the real values of $s=s_n$ and $t=t_n$ which satisfy *both* the constant-coupling constraint (13) *and* the matching condition (17). In the first step, let us re-express the former elementary hyperbolic-curve correlation $Z=2st$ in the new variables σ and τ.

A. The *Z*-dependent hyperbolic-curve constraint

Rotation (15) implies that under the assumption $\omega>0$ we have $\tau>0$ while the sign of σ may be both positive and negative. Alternatively, the choice of $\omega<0$ would imply that we must keep $\sigma>0$ while the sign of τ is allowed to vary. This means that one of the two hyperbolas defined by the rule $Z=2st$ may be discarded immediately. Of course, in our innovated notation we must describe these hyperbolas by the slightly less transparent rotated quadratic equation

$$\tau^2+2\tau\sigma\frac{\cos 2\varphi}{\sin 2\varphi}-\sigma^2-\frac{4Z}{\sin 2\varphi\,\cos^2\varphi}=0. \tag{23}$$

At $\omega=\tan\varphi>0$ it is easy to select the correct branch defined by the formula

$$\tau=\Xi(\sigma)=\frac{1}{2}\left(\omega-\frac{1}{\omega}\right)\sigma+\frac{1}{2}\sqrt{\left(\omega+\frac{1}{\omega}\right)^2\sigma^2+4X^2},\quad X^2=\frac{4Z}{\sin 2\varphi\,\cos^2\varphi}. \tag{24}$$

In parallel, at $\omega=\tan\varphi=-\tilde{\omega}<0$ we must use the *different* formula

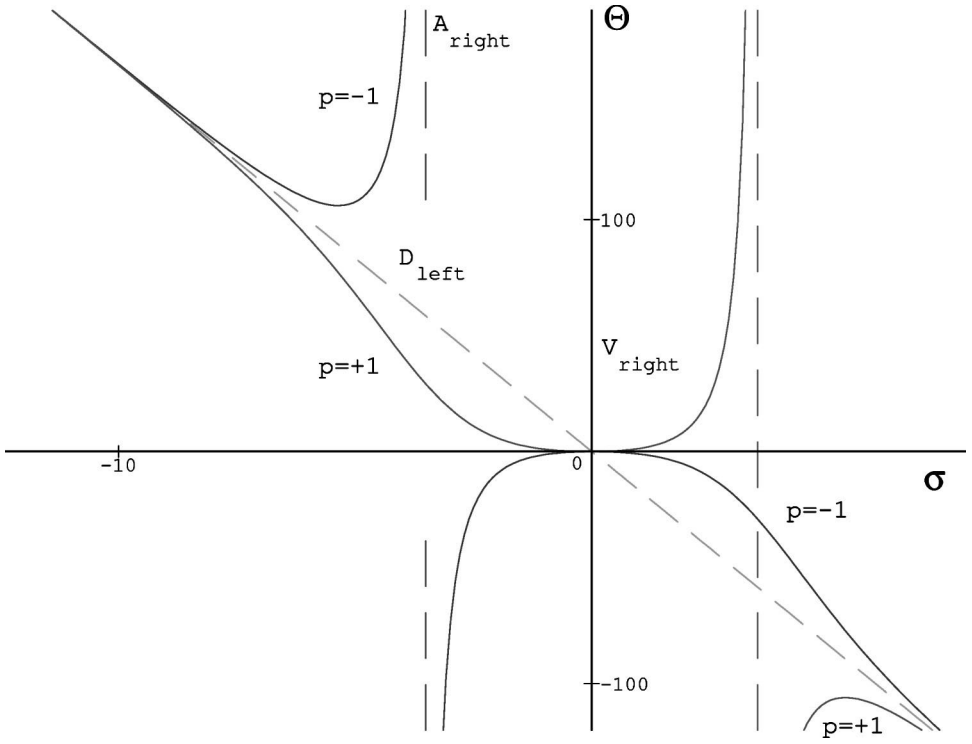

FIG. 4. Two lattice-dependent functions $\tau=\Theta_{(p,0)}(\sigma)$ at $\omega=0.06$.

$$\sigma=\Upsilon(\tau)=\frac{1}{2}\left(\frac{1}{\omega}-\omega\right)\tau+\frac{1}{2}\sqrt{\left(\omega+\frac{1}{\omega}\right)^2\tau^2+4Y^2},\quad Y^2=\frac{-4Z}{\sin 2\varphi\,\cos^2\varphi}. \tag{25}$$

In other words, we must treat the up and down shifts $i\omega$ of the matching point separately, reflecting the fact that we already broke the symmetry between the half-planes of coordinates $x\in\mathbb{C}$ by having chosen the positive coupling $Z>0$ in advance.

B. The second, matching constraint

The application of the lattice-shifting technique of Sec. III B may be extended to both the positive and negative ω. The variable $\tau=\tau_{(k,q)}(p,\xi)$ remains represented by the same function of the interval selector k, of the two sign-variables $q=\pm1$ and $p=\pm1$ and of the continuous ξ varying in the compact interval $(0,1)$.

1. Moving lattices

Let us now select $\omega>0$ and keep the two auxiliary variables p and ξ fixed. This restricts the range of our variable τ to the lattice $\mathcal{L}=\mathcal{L}(p,\xi)$ where the function $\Omega=\Omega(p,\xi)=p/\cos(\pi\xi/2)$ remains constant. This leads to a decisive simplification of our matching condition (18),

$$\tau=\Theta_{(p,\xi)}(\sigma)=\sigma\frac{\omega+\Omega\,\sinh\,\sigma}{1-\Omega\,\omega\,\sinh\,\sigma},\quad p,\xi=fixed. \tag{26}$$

A typical graph of the function $\Theta_{(p,\xi)}(\sigma)$ at both $p=\pm1$ and at the minimal $\xi=0$ and/or $|\Omega|=1$ is displayed in Fig. 4. With respect to the growth of the lattice-characterizing parameter ξ from 0 to 1 it is trivial to see from Eq. (26) that

- at $p=+1$ and $\sigma>0$, the right branch of the well-shaped curve $\Theta_{(+1,\xi)}(\sigma)>0$ is bounded by its perpendicular asymptote at $\sigma_\infty(\xi)=\text{arcsinh}(1/[\omega\Omega(+1,\xi)])$. With the growth of ξ and Ω it inadvertently moves to the left and in the limit of $\xi\to 1$ it coincides with the vertical half-axis $V_{\text{right}}(\sigma_\infty(1)=0)$;
- in parallel, the left branch of the same well moves upwards and coincides with its diagonal asymptote D_{left} in the same limit, $\lim_{\xi\to 1}\Theta_{(+1,\xi)}(\sigma)=-\sigma/\omega$;
- at $p=-1$ and $\sigma<-\sigma_\infty(\xi)<0$, there exists another hyperbolic well sampled in Fig. 4, with definition $\tau=\Theta_{(-1,\xi)}(\sigma)$ and asymptotes D_{left} and (ξ-dependent) A_{right}. With the growth of ξ this well moves downwards and to the right and coincides with the wedge formed by D_{left} and V_{right} at $\xi=1$.

This geometric picture has several consequences. The most important one is that at the minimal $\xi=0$ the curves of Fig. 4 contain the initial points of all the ovals of the solutions in the manner indicated by the $\xi=0$ point in Fig. 3 above. With the growth of ξ the similar oval-shaped curves are then being formed at any ω.

2. Four families of half-ovals

In a continuing description of the structure of solutions of Eq. (26) we must distinguish between the positive and negative σ. For $\sigma\geqslant 0$, the analysis is simpler since the ovals (or rather half-ovals) as sampled in Fig. 3 at $\omega=0$ can solely exist in the stripes with $p=+1$. With the growth of ξ they open their two $q=\pm 1$ branches to the left until they attain their maximal width and reach the boundaries of their stripes on the vertical axis V_{right} in the limit $\xi\to 1$.

At $\sigma<0$ we have to parallel the above half-ovals by their $p=+1$ partners which start to open to the right at the leftmost curve with $\xi=0$. They end their growth at $\xi=1$ while touching the boundaries of their $p=+1$ stripes on the diagonal D_{left}.

In contrast to our above $\omega=0$ exercise in Sec. III B 1, the choice of $\sigma<0$ admits the existence of another family of the half-ovals within the $D_{\text{left}}-V_{\text{right}}$ wedge. Of course, they can only exist within the stripes where $p=-1$ and in the domain of the sufficiently large $\tau\gtrsim\tau_0$ (i.e., at $k\geqslant k_{\text{minimal}}$) where they can originate on the curve $\tau=\Theta_{(-1,0)}(\sigma)\geqslant\tau_0$. In this domain they form the two subfamilies again, depending on whether they originated on the left or right branch of the $\xi=0$ curve.

3. Two patterns of gluing the half-ovals

With the growth of ξ, the left half-ovals within the wedge $D_{\text{left}}-V_{\text{right}}$ open to the left, ending their growth at $\xi=1$ in the intersections of the boundaries of their $p=-1$ stripes with the left diagonal straight line D_{left}. At these points these half-ovals meet their $p=+1$ partners so that in contrast to the $\omega=0$ pattern (with a series of the separated and closed ovals—cf. their picture in Ref. 12), the resulting locus of the solutions forms a wavy, sine-like-shaped line which oscillates to the left and right and moves up to the left along the diagonal D_{left}. As long as this curve remains confined between its two envelopes $\Theta_{(\pm 1,0)}(\sigma)$, the asymptotic decrease of the amplitude of this wobbling is exponential. A schematic example of such a wavy curve appears in Fig. 5.

In the same range of the sufficiently large τ, the second, similar wavy pattern is formed along the axis V_{right}. In exactly the same manner it results from the gluing of the right $p=-1$ half-ovals which open to the right and reach the line V_{right} where they find a continuation in the above-mentioned $p=+1$ half-ovals at $\sigma>0$. In contradistinction to the previous case, the amplitude of the wobbling is asymptotically constant. Still, this fact alone is sufficient to exclude this branch from further consideration because the $Z=2st$ constraint is asymptotically a hyperbola with asymptotes at the angles $\varphi=\arctan\omega$ and $\varphi'=\arctan\omega-\pi/2$ with respect to the axis V_{right}.

In all the remaining domain of the not too large values of τ, just smooth perturbations ocur of the $\omega=0$ pattern of disconnected ovals. At $\omega>0$ the height of the ovals exceeds the height of a single stripe. This is consistent with the fact that an inner part of the ovals lies within the $D_{\text{left}}-V_{\text{right}}$ wedge and must belong, therefore, to a $p=-1$ stripe. This also does not contradict to the steady decrease of the minimum of the graph of the curve $\Theta_{(-1,\xi)}(\sigma)$ since with the growth of ξ the

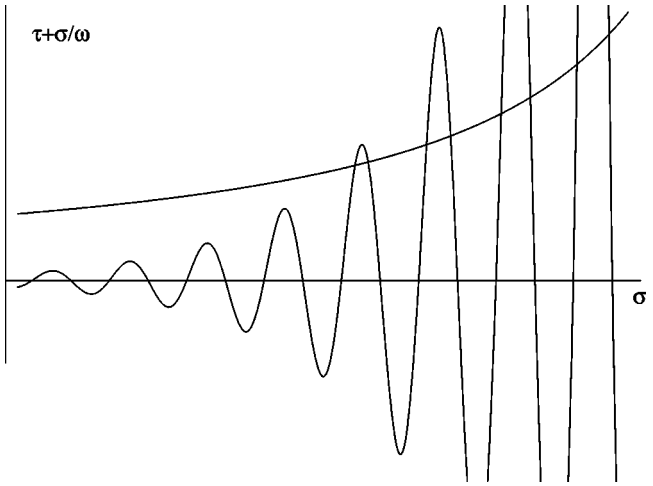

FIG. 5. Damped oscillations of $\Theta(\sigma)$ vs constraint $2st=Z$.

solutions of Eq. (26) start to exist in the lower and lower $p=-1$ stripes within the wedge. In this way, the resulting loci of solutions of Eq. (26) are allowed to form the separate ovals in a fully consistent manner, indeed.

V. ENERGIES

The ultimate goal of our considerations is achieved. We clarified that an optimal strategy of the determination of all the parameters $s=s_n$ and $t=t_n$ in the bound-state formula $E_n=t_n^2-s_n^2$, $n=0,1,\ldots$ is based on a suitable change of variables $(s,t)\to(\sigma,\tau)$ which merely re-scales and rotates the original hyperbolic constraint $Z=2st$ and re-expresses all the real deformed-path square-well energies by the "rotated" formula

$$E=E_n(Z,\varphi)=\tfrac{1}{4}\,[(\tau_n^2-\sigma_n^2)\cos 2\varphi-2\,\sigma_n\tau_n\sin 2\varphi]\cos^2\varphi. \tag{27}$$

This leads to a vital simplification of the matching of wave functions. In the real $\sigma-\tau$ plane, the construction of all the physical bound states (if any) is reduced to an identification of all the admissible parameters (σ_n,τ_n) with all the intersections of a certain pair of curves. One of them is the elementary Z-dependent hyperbola (the smooth curve in Fig. 5). A sufficiently transparent graphical representation of the shape of the second one is more difficult and required in fact the greater portion of our previous text. This curve is sampled by its quickly oscillating asymptotic part in Fig. 5.

A. A comment on asymmetry between $\omega>0$ and $\omega<0$

We mainly paid attention to the positive values of the shift $\omega>0$ pertaining to the generic form of the family of the hyperbolae given by Eq. (24). They are sampled by the smoother curve in Fig. 5. The figure also illustrates a generic pattern of the intersection of these hyperbolas with half-oval families confined within areas specified by their envelope curves exemplified in Fig. 4.

We did not notice in Sec. IV B 1 that after reflection of Fig. 4 with respect to the origin of coordinates σ and τ, its $p=-1$ and $p=+1$ envelope curves are mapped upon each other. This simplifies marginally the construction and follows from the invariance of Eq. (26) *on the lattices* since the simultaneous replacements $\tau\to-\tau$ and $\sigma\to-\sigma$ are equivalent to $\Omega\to-\Omega$ while the latter change of sign merely means that we have to transform $p\to-p$.

We did not deduce, *ibidem*, that another simultaneous sign-change of $\sigma\to-\sigma$ and $\omega\to-\omega$ preserves the form of the original, lattice-independent matching condition (18). This is more important because at the negative $\omega=-\tilde{\omega}<0$ we would be forced to replace the most complicated

pattern of Fig. 4 (where we always employ the positive $\tilde{\omega}=|\omega|$) by its left-right-reflected copy complemented by the corresponding correct hyperbolic branch of curve $Z=2st$ in its alternative form (25). After the left-right mirroring transform it enables us to simplify the situation by returning to the original Fig. 4 complemented by the trivially modified reflected hyperbola

$$\sigma=\Sigma(\tau)=\frac{1}{2}\left(\frac{1}{\tilde{\omega}}-\tilde{\omega}\right)\tau-\frac{1}{2}\sqrt{\left(\tilde{\omega}+\frac{1}{\tilde{\omega}}\right)^2\tau^2+4Y^2},\quad Y^2=\frac{+4Z}{\sin 2\tilde{\varphi}\cos^2\tilde{\varphi}}. \tag{28}$$

Hence, all what we have derived at the positive ω may *immediately* be transferred to the case where ω is negative, *without* changing the half-oval curves and with the mere addition of the second branch (28) of the hyperbola. In Fig. 5 this would just mean a replacement of the upper hyperbola by its minus-sign partner. Of course, such an extension of the whole picture is essentially trivial and it need not be discussed separately at all.

B. The breakdown of $\mathcal{PT}$ symmetry at high energies

Our construction of a closed form of the bound states is transparent and, undoubtedly, potentially useful. For the straight path $\mathcal{C}$ with $\omega=\varphi=0$ and for all the values of $Z>0$ which are not too large, the square-well model already found interesting applications in the study of the spontaneous $\mathcal{PT}$-symmetry breaking at the sufficiently large Z.[22] An even more important role of this model seems to have emerged within the supersymmetric quantum mechanics.[23] In all these and similar applications, our present results simply mean that all the changes caused by a shift of a small size $|\omega|$ remain smooth if and only if we do not move to the very high energies.

In contrast to that, an introduction of *any* nonvanishing shift ω changes the high-energy region completely and abruptly. In place of infinitely many real and positive energies $E_n(Z)$, $n=0,1,\ldots$ which formed the complete spectrum at $\omega=0$, the choice of *any* $\omega=\tan\varphi\neq 0$ makes the number of the real intersections (σ_n,τ_n) *finite*, $n=0,1,\ldots,n_{\max}(Z,\varphi)$ with a certain maximal real energy at $n_{\max}(Z,\varphi)<\infty$. The mathematical foundation of this conclusion is almost trivial: Up to a finite number of exceptions, the energies may only be generated by the intersections in the domain of the large $\tau\gg 1$ where both the Z-dependent hyperbolas with $\omega>0$ and $\omega=-|\omega|<0$ have almost the same asymptotic representation,

$$\tau=-\frac{1}{|\omega|}\sigma\mp\frac{|X^2|}{(|\omega|+1/|\omega|)\sigma}+\mathcal{O}(\sigma^{-3}),\quad \text{sign }\omega=\pm 1,\quad \sigma\ll -1. \tag{29}$$

This means that both of them share the dominant term (representing just the straight line of their common asymptote D_{left}) and approach this asymptote at an inverse-power rate from above or below, respectively (the former case is illustrated in Fig. 5 displaying just the deviation from the asymptote).

The same asymptote D_{left} is further shared by both the upper and lower envelopes $\Theta_{(\mp 1,0)}\times(\sigma)$ of the second, quickly wobbling curve. Nevertheless, from definition (26) we easily derive their leading-order asymptotic form

$$\tau=-\frac{1}{|\omega|}\sigma\mp\frac{|\omega|+1/|\omega|}{\sinh\sigma}+\mathcal{O}(\sinh^{-2}\sigma),\quad \text{sign }\omega=\pm 1,\quad \sigma\ll -1. \tag{30}$$

This implies that the *quick, exponential* decrease of *both* the envelopes in Eq. (30) *guarantees* that the wobbling line cannot have *any* real intersections with *neither* of the two hyperbolic Z-dependent curves (29) with their too slow, power-law rate of approach to the asymptote. This is illustrated in Fig. 5 as a key message of the whole construction and implies that the number of the real energies remains finite at *any* nonvanishing $\omega\neq 0$ and Z. In the other words, infinitely many real energies which existed at $\omega=0$ become "lost" and "dissolved" in complex conjugate pairs. This occurs precisely at the moment when (say, in Fig. 5) the intersecting Z-dependent hyperbola moves (say, due to a slight increase of Z) to the top of a particular half-oval (there, the two energies merge at a "Bender–Wu singularity"[1] or "exceptional point"[3]) and, in the next stage,

TABLE I. Cardinalities $N^{(\text{real})}$ and $N^{(\text{complex})}$ of the square-well energies E with Im $E=0$ and Im $E\neq 0$, respectively.

ω	Z	$N^{(\text{real})}$	$N^{(\text{complex})}$	Comment
0	0	∞	0	Hermitian case
0	$0<Z<4.475\ldots$	∞	0	$\mathcal{PT}$-symmetric case of Ref. 12
0	$4.475\ldots<Z<12.8015\ldots$	∞	2	$\mathcal{PT}$-symmetry broken Ref. 22
0	$Z_N<Z<Z_{N+1}$	∞	2N	$\mathcal{PT}$-symm. br. at $E<E_{\text{crit}}(N)$
$\neq 0$	$\neq 0$	finite	∞	$\mathcal{PT}$-symm. br. at $E>E_{\text{crit}}(Z,\omega)$
$\neq 0$	0	∞	0	new $\mathcal{PT}$-symmetric case

separates from the half-oval completely (Ref. 22 studied this type of a pairwise complexification of the square-well energies at $\omega=0$ in more detail).

The disappearance of the real intersections of the two curves in Fig. 5 occurs at any $Z\neq 0$ and implies that the $\mathcal{PT}$ symmetry of our wave functions becomes broken at all the sufficiently large energies. In the other words, our initial choice of the form of the wave functions does not suddenly represent *all* the possible bound-state solutions. In a way discussed in full detail in our previous $\omega=0$ study[22] this means that all the "missing" bound states must be sought in a certain more-parametric and manifestly $\mathcal{PT}$-symmetry-breaking form.

The only exception in encountered at $Z=0$ where the message offered by Fig. 5 is different because in the limit $Z\to 0$ the upper hyperbolic curve moves down and coincides *strictly* with the horizontal axis. This forces us to return to the very origin of our present construction and repeat all its steps under the new explicit postulate that $t=0$. In this case, the kind reader may easily verify that the $Z=0$ result *proves* in fact *independent* of the value of ω so that all the repeated $Z=0$ and $\omega\neq 0$ (i.e., non-Hermitian though still $\mathcal{PT}$-symmetric) construction returns us back to the energies which *coincide* with the well known Hermitian square-well spectrum.

VI. SUMMARY

All our results are summarized in Table I which may be read, first of all, as an advertisement of our almost involuntary discovery of an extremely elementary and transparent new $\mathcal{PT}$-symmetric model with real energies (cf. the last line). On a more general level, the main item in the review Table I (viz., its last but one line) warns against all the noncritical intuition which might prove misleading in the realm of $\mathcal{PT}$ symmetric models. In this sense, our results may be perceived as a nonnumerical complement to numerical experiments of paper[10] where several "not entirely smooth" potentials clearly inclined towards a spontaneous $\mathcal{PT}$-symmetry breakdown at high energies.

On this background we believe that in the nearest future, attention will be re-attracted to the real role of non-analyticity in the $\mathcal{PT}$ symmetric potentials and models, with inspiration by our present rigorous proof that any nonvanishing shift of ω at $Z\neq 0$ *makes* the $\mathcal{PT}$-symmetry of our square-well model *suddenly* to break down. This breakdown involves infinitely many levels at once, i.e., it occurs in a way which seems characteristic for virtually all the exactly solvable *analytic* models.[11,24] At the same time, the discontinuity of the breakdown might reflect its *nonanalytic* origin, contrasting with the robust survival of the reality of spectra under path-deformations in many not too strongly singular analytic potentials.[25]

We have seen that the square-well model is exceptional in representing a solvable laboratory which seems to lie on a very boundary between "robust" and "fragile" models with $\mathcal{PT}$-symmetry. In this sense, our present key message is encouraging since the geometric language of our innovated "moving-lattice" method proved extremely efficient and seems productive. Its former aspect becomes clear when we compare the $\omega=0$ discussion here and in Ref. 12, while its second property is still to be verified in the future.

(Received 30 June 2004; accepted 27 July 2004; published 4 November 2004)

We consider the convex set of positive operator valued measures (POVM) which are covariant under a finite dimensional unitary projective representation of a group. We derive a general characterization for the extremal points, and provide bounds for the ranks of the corresponding POVM densities, also relating extremality to uniqueness and stability of optimized measurements. Examples of applications are given. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1806262]

I. INTRODUCTION

An essential step in the design of the new quantum information technology[1] is to assess the ultimate precision limits achievable by quantum measurements in extracting information from physical systems. For example, the security analysis of a quantum cryptographic protocol[2] is based on the evaluation of the limits posed in principle by the quantum laws to any possible eavesdropping strategy. A general method to establish such limits is to optimize a quantum measurement according to a suitable criterion, and this is the general objective of the so-called *quantum estimation theory*.[3,4] Different criteria can be adopted for optimizing the measurement, the choice of a particular one depending on the particular problem at hand. Moreover, many different optimization problems often share the same form, e.g., they resort to the maximization of a concave function on the set of the possible measurements. We remind that measurements form a convex set, the convex combination corresponding to the random choice between two different apparatuses. Since a concave function attains its maximum in an extremal point, it is clear that the optimization problem is strictly connected to the problem of characterizing the extremal points of the convex set.

The quantum measurements interesting in most applications are *covariant*[4] with respect to a group of physical transformations. In a purely statistical description of a quantum measurement in terms of the outcome probability only—i.e., without considering the state-reduction—the measurement is completely described by a positive operator valued measure (POVM) on its probability space. In terms of POVM's, "group covariant" means that there is an action of the transformation group on the probability space which maps events into events, in such a way that when the measured system is transformed according to a group transformation, the probability of a given event becomes the probability of the transformed event. Such a scenario naturally occurs in the estimation of an unknown group transformation performed on a known input state, e.g., in the estimation of an unknown unitary transformation,[5,6] in the measurement of a phase shift in the radiation field,[4,7] or in the estimation of rotations on a system of spins.[8] A first technique for characterizing extremal covariant POVM's and quantum operations has been presented in Ref. 9

inspired by the method for characterizing extremal correlation matrices of Ref. 10, in particular, classification of extremal POVM's has been presented for the case of trivial stability group, i.e., when the only transformation which leaves the input state unchanged is the identity. Here we solve the characterization problem for extremal covariant POVM's in the general case of nontrivial stability group, providing a simple criterion for extremality in Theorem 1 in terms of minimality of the support of the *seed* of the POVM, presenting iff conditions for extremality in Theorem 3, and providing bounds for the rank of extremal POVM's [in the following we will define the rank of a POVM as the rank of its respective density: see Eq. (6) for its definition]. We show that, contrarily to the usual credo, the optimal covariant POVM can have rank larger than one. Indeed, there are group representations for which covariant POVM cannot have unit rank, since this would violate a general bound for the rank of the POVM in relation to dimensions and multiplicity of the invariant subspaces of the group. In the present paper we adopt the maximum likelihood optimality criterion, which, however, as we will show, is formally equivalent to the solution of the optimization problem in a very large class of optimality criteria. Other issues of practical interest that we address are the uniqueness and the stability of the optimal covariant POVM. The whole derivation is given for finite dimensional Hilbert spaces: as we will show in a simple example, it can be generalized to infinite dimensions, however, at the price of making the theory much more technical.

The paper is organized as follows. After introducing covariant POVM's and their convex structure in Sec. II, the main group theoretical tools that will be used for the characterization of covariant POVM's are presented in Sec. III. In Sec. IV we give a characterization of extremal covariant POVM's in finite dimension with a general stability group, deriving an algebraic extremality criterion, along with a general bound for the rank of the extremal POVM's in terms of the dimensions of the invariant subspaces of the group and of the stability subgroup. Properties of extremal POVM's in relation with optimization problems are analyzed in Sec. V, where also the issues of uniqueness and stability of the optimal covariant POVM's are addressed. Finally, examples of application of the theory to estimation of rotation, state, phase shift, etc., are given in Sec. VI, providing extremal POVM's with a nontrivial stability group and giving examples of optimization problems with solution consisting of extremal POVM with rank greater than one.

II. CONVEX STRUCTURE OF COVARIANT POVM'S

The general description of the statistics of a measurement is given in terms of a probability space $\mathcal{X}$—the set of all possible measurement *outcomes*—equipped with a σ-algebra $\sigma(\mathcal{X})$ of subsets $\mathsf{B}\subseteq\mathcal{X}$ and with a probability measure p on $\sigma(\mathcal{X})$. Each subset $\mathsf{B}\in\sigma(\mathcal{X})$ describes the event "the outcome x belongs to B" and the statistics of the measurement is fully specified by the probability measure p, which associates to any event B its probability $p(\mathsf{B})$.

In quantum mechanics the probability $p(\mathsf{B})$ is given by the Born rule,

$$p(\mathsf{B}) \doteq \mathrm{Tr}[\rho P(\mathsf{B})], \tag{1}$$

where ρ is a density operator (i.e., a positive semidefinite operator with unit trace) on the Hilbert space $\mathcal{H}$ of the measured system, representing its state, whereas P is the POVM of the apparatus, giving the probability measure p for every given state ρ of the quantum system. Mathematically a POVM $P:\sigma(\mathcal{X})\to\mathcal{B}(\mathcal{H})$ is a *positive operator valued measure* on $\sigma(\mathcal{X})$, namely it satisfies the following defining properties:

$$0 \leqslant P(\mathsf{B}) \leqslant I \quad \forall\, \mathsf{B}\in\sigma(\mathcal{X}), \tag{2}$$

$$P(\cup_{i=1}^{\infty}\mathsf{B}_i) = \sum_{i=1}^{\infty} P(\mathsf{B}_i) \quad \forall\, \{\mathsf{B}_i\} \text{ disjoint}, \tag{3}$$

$$P(\mathfrak{X}) = I. \tag{4}$$

Notice that the set of POVM's for $\sigma(\mathfrak{X})$ is a convex set, namely, if P_1 and P_2 are POVM's for $\sigma(\mathfrak{X})$, then also $\lambda P_1 + (1-\lambda)P_2$ is a POVM for $\sigma(\mathfrak{X})$ for any $0 \leqslant \lambda \leqslant 1$. The measurement described by the POVM $\lambda P_1 + (1-\lambda)P_2$ corresponds to randomly choosing between two different measuring apparatuses described by the POVM's P_1 and P_2, respectively. The extremal points of such convex set of POVM's—the so-called *extremal POVM's*—correspond to measurements that cannot result from a random choice between different measuring apparatuses.

In the following we will focus attention to the case of probability space $\mathfrak{X}$ given by the quotient $\mathbf{G}/\mathbf{G}_0$ of a compact Lie group $\mathbf{G}$ with respect to a subgroup $\mathbf{G}_0$. Physically, this situation arises when the POVM is designed to estimate a state in the group-orbit $\{U_g \rho U_g^\dagger | g \in \mathbf{G}\}$ of a given state ρ, with the group $\mathbf{G}$ acting on the Hilbert space $\mathcal{H}$ of a quantum system via the unitary projective representation $\mathsf{R}(\mathbf{G}) \doteq \{U_g | g \in \mathbf{G}\}$. In such a case, in fact, the probability space of the POVM is exactly $\mathfrak{X} = \mathbf{G}/\mathbf{G}_0$, and $\mathbf{G}_0 = \{h \in \mathbf{G} | U_h \rho U_h^\dagger = \rho\}$ is the stability group of ρ, whence the points of the orbit are in one-to-one correspondence with the elements of $\mathfrak{X} = \mathbf{G}/\mathbf{G}_0$. Notice that in the following the fact that the representation is projective is inconsequential, whence there will be no need for reminding.

An important class of measurements with $\mathfrak{X} = \mathbf{G}/\mathbf{G}_0$ is described by the *covariant* POVM's,[4] namely those POVM's which enjoy the property

$$P(g\mathsf{B}) = U_g P(\mathsf{B}) U_g^\dagger \quad \forall\, \mathsf{B} \in \sigma(\mathfrak{X}), \quad \forall\, g \in \mathbf{G}, \tag{5}$$

where $g\mathsf{B} \doteq \{gx | x \in \mathsf{B}\}$. Any POVM P in this class is absolutely continuous with respect to the measure $\mathrm{d}x$ induced on $\mathfrak{X}$ by the normalized Haar measure $\mathrm{d}g$ on the group $\mathbf{G}$, and admits an operator density M, namely

$$M : \mathfrak{X} \to \mathcal{B}(\mathcal{H}), \quad P(\mathsf{B}) = \int_{\mathsf{B}} \mathrm{d}x\, M(x). \tag{6}$$

For a covariant POVM, the operator density has the form[4]

$$M(x) = U_{g(x)} \Xi U_{g(x)}^\dagger, \tag{7}$$

where $g(x) \in \mathbf{G}$ is any element in the equivalence class $x \in \mathfrak{X} = \mathbf{G}/\mathrm{G}_0$, and Ξ is an Hermitian operator satisfying the constraints

$$\Xi \geqslant 0, \quad \int_{\mathbf{G}} \mathrm{d}g\, U_g \Xi U_g^\dagger = I, \tag{8}$$

$$[\Xi, U_h] = 0 \quad \forall\, h \in \mathbf{G}_0. \tag{9}$$

The operator Ξ is usually referred to as the *seed* of the covariant POVM.[11]

Notice that the constraints (8) are needed for positivity and normalization of the probability density, whereas identity (9) guarantees that $M(x) = U_{g(x)} \Xi U_{g(x)}^\dagger$ does not depend on the particular element $g(x)$ in the equivalence class x. It is easy to see that the constraints (8) and (9) still define a convex set C, namely, for any $\Xi_1, \Xi_2 \in \mathsf{C}$ and for any $0 \leqslant \lambda \leqslant 1$ one has $\lambda \Xi_1 + (1-\lambda)\Xi_2 \in \mathsf{C}$. Precisely, the convex set C is the intersection of the cone of positive semidefinite operators with the two affine hyperplanes given by identity (9) and by the normalization condition in Eq. (8). Since a covariant POVM is completely specified by its seed Ξ as in Eq. (7), the classification of the the extremal covariant POVM's resorts to the classification of the extremal points in the convex set C.

III. GROUP THEORETIC TOOLS

Let $\mathbf{G}$ be a compact Lie group, with invariant Haar measure $\mathrm{d}g$ normalized as $\int_{\mathbf{G}}\mathrm{d}g=1$, and consider a unitary representation $\mathsf{R}(\mathbf{G})=\{U_g|g\in\mathbf{G}\}$ on a finite dimensional Hilbert space $\mathcal{H}$. Then $\mathcal{H}$ is decomposed as direct sum of orthogonal irreducible subspaces as follows:

$$\mathcal{H}=\bigoplus_{\mu\in\mathsf{S}}\bigoplus_{i=1}^{m_\mu}\mathcal{H}_i^{(\mu)}, \tag{10}$$

S denoting the collection of equivalence classes of irreducible components of the representation, the classes being labeled by the greek index μ, whereas the italic index i numbers equivalent representations in the same class. Let $T_{ij}^{(\mu)}:\mathcal{H}_j^{(\mu)}\to\mathcal{H}_i^{(\mu)}$ denote invariant isomorphisms connecting the irreducible representations of the equivalence class μ of dimension d_μ, namely for any $i,j=1,\ldots,m_\mu$ $T_{ij}^{(\mu)}:\mathcal{H}_j^{(\mu)}\to\mathcal{H}_i^{(\mu)}$ is an invertible operator satisfying the identity

$$U_gT_{ij}^{(\mu)}U_g^\dagger=T_{ij}^{(\mu)},\quad\forall\, g\in\mathbf{G}. \tag{11}$$

Consistently with this notation $T_{ii}^{(\mu)}$ will denote the projection operator on $\mathcal{H}_i^{(\mu)}$. Since all subspaces $\mathcal{H}_i^{(\mu)}$ are isomorphic, we can equivalently write

$$\bigoplus_{i=1}^{m_\mu}\mathcal{H}_i^{(\mu)}\equiv\mathcal{H}_\mu\otimes\mathcal{M}_\mu, \tag{12}$$

where $\mathcal{H}_\mu$ denotes the *representation space*, i.e., an abstract d_μ-dimensional subspace where a representation of the class μ acts, while $\mathcal{M}_\mu$ denotes the *multiplicity space*, i.e., a m_μ-dimensional space which is unaffected by the action of the group. In this way, the decomposition (10) can be written in the Wedderburn's form,[12]

$$\mathcal{H}=\bigoplus_{\mu\in\mathsf{S}}\mathcal{H}_\mu\otimes\mathcal{M}_\mu. \tag{13}$$

Due to Schur lemmas, an operator O in the commutant of the representation $\mathsf{R}(\mathbf{G})$ can be decomposed as follows:[13]

$$O=\sum_\mu\sum_{i,j=1}^{m_\mu}\frac{\mathrm{Tr}[T_{ji}^{(\mu)}O]}{d_\mu}T_{ij}^{(\mu)}, \tag{14}$$

whereas, in terms of the decomposition (13) one has

$$O=\oplus_{\mu\in\mathsf{S}}(I_\mu\otimes O_\mu), \tag{15}$$

I_μ denoting the identity on the representation space $\mathcal{H}_\mu$, and $O_\mu\in\mathcal{B}(\mathcal{M}_\mu)$ being a suitable set of operators on the multiplicity spaces $\mathcal{M}_\mu$.

In this paper we will consider covariant POVM's with $\mathcal{X}=\mathbf{G}/\mathbf{G}_0$ where both $\mathbf{G}$ and $\mathbf{G}_0$ are compact Lie groups, represented on the Hilbert space $\mathcal{H}$ by the unitary representations $\mathsf{R}(\mathbf{G})=\{U_g|g\in\mathbf{G}\}$ and $\mathsf{R}(\mathbf{G}_0)=\{U_h|h\in\mathbf{G}_0\}$. We will denote with S and S_0 the equivalence classes of irreducible representations of $\mathsf{R}(\mathbf{G})$ and $\mathsf{R}(\mathbf{G}_0)$, respectively. The constraints (8) and (9) can be rewritten in a remarkably simple form using the decompositions of $\mathcal{H}$ in irreducible subspaces under the action of $\mathbf{G}$ and $\mathbf{G}_0$. In fact, due to the invariance of the Haar measure $\mathrm{d}g$, the integral in (8) belongs to the commutant of $\mathsf{R}(\mathbf{G})$. Rewriting the constraint (8) by using (14), one obtains easily,

$$\mathrm{Tr}[T_{ij}^{(\mu)}\Xi]=d_\mu\delta_{ij},\quad\forall\,\mu\in\mathsf{S},\quad\forall\, i,j=1,\ldots,m_\mu. \tag{16}$$

Moreover, according to (8) and (9), the operator Ξ must be a positive semidefinite operator in the commutant of $R(\mathbf{G}_0)$ (9), then we have

$$\Xi = \oplus_{\nu \in \mathsf{S}_0} (I_\nu \otimes X_\nu^\dagger X_\nu), \tag{17}$$

where X_ν is an operator on the multiplicity subspace $\mathcal{M}_\nu$.

IV. EXTREMAL COVARIANT POVM'S WITH A NONTRIVIAL STABILITY GROUP

In this section we will classify the extremal points of the convex set C of covariant seeds, namely the convex set of operators that satisfy both conditions (8) and (9). For the characterization of the extremal points of a convex set we will use the well-known method of perturbations. We will say that the operator $\Theta \in \mathcal{B}(\mathcal{H})$ is a "perturbation" of a given $\Xi \in \mathsf{C}$ if and only if there exists an $\epsilon > 0$ such that $\Xi + t\Theta \in \mathsf{C}$ for any $t \in [-\epsilon, \epsilon]$. With such definition one has that an operator Ξ is extremal if and only if its unique perturbation is the trivial one, namely if Θ is a perturbation of Ξ then $\Theta = 0$.

Let us start with a simple lemma which is useful for the characterization of the perturbations of a given seed Ξ.

Lemma 1: Let $\Xi \in \mathcal{B}(\mathcal{H})$ be a positive semidefinite operator. Then, for any Hermitian $\Theta \in \mathcal{B}(\mathcal{H})$ the condition

$$\exists \epsilon > 0: \quad \forall\, t \in [-\epsilon, \epsilon]\ \Xi + t\Theta \geqslant 0 \tag{18}$$

is equivalent to

$$\mathsf{Supp}(\Theta) \subseteq \mathsf{Supp}(\Xi). \tag{19}$$

Proof: Suppose that the condition (18) holds. Then for any $|\phi\rangle \in \mathsf{Ker}(\Xi)$ one necessarily has $\langle\phi|\Theta|\phi\rangle = 0$. Therefore, for any vector $|\psi\rangle \in \mathcal{H}$ one has

$$|\langle\psi|\Theta|\phi\rangle| = \frac{1}{t}|\langle\psi|(\Xi + t\Theta)|\phi\rangle| \leqslant \frac{1}{t}\sqrt{\langle\psi|(\Xi + t\Theta)|\psi\rangle\langle\phi|(\Xi + t\Theta)|\phi\rangle} = 0.$$

Hence $\mathsf{Ker}(\Xi) \subseteq \mathsf{Ker}(\Theta)$, implying that $\mathsf{Supp}(\Theta) \subseteq \mathsf{Supp}(\Xi)$. Conversely, suppose that (19) holds. Let us denote by λ the smallest nonzero eigenvalue of Ξ and by $\|\Theta\|$ the norm of Θ, then condition (18) holds with $\epsilon = \lambda / \|\Theta\|$. ■

Using the previous lemma we can state that an Hermitian operator Θ is a perturbation for a given seed Ξ if and only if the following conditions are satisfied:

$$\mathsf{Supp}(\Theta) \subseteq \mathsf{Supp}(\Xi), \tag{20}$$

$$\mathrm{Tr}[\Theta T_{ij}^{(\mu)}] = 0 \quad \forall\, \mu \in \mathsf{S}, \quad \forall\, i,j = 1, \ldots, m_\mu, \tag{21}$$

$$[\Theta, U_h] = 0 \quad \forall\, h \in \mathbf{G}_0 \tag{22}$$

[conditions (21) and (22) follow directly from the normalization constraints (16) and (17)].

This set of conditions leads to an interesting property of extremal seeds.

Theorem 1: *Ξ is an extremal point of C if and only if for any $\zeta \in \mathsf{C}$ one has*

$$\mathsf{Supp}(\zeta) \subseteq \mathsf{Supp}(\Xi) \Rightarrow \zeta = \Xi. \tag{23}$$

Proof: To prove necessity it is sufficient to define $\Theta \doteq \Xi - \zeta$ and note that it is a perturbation of Ξ. In fact, Θ is in the commutant of $\mathsf{R}(\mathbf{G}_0)$, $\mathsf{Supp}(\Theta) \subseteq \Xi$, and $\mathrm{Tr}[\Theta T_{ij}^{\mu}] = 0\ \forall \mu \in \mathsf{S}$, $\forall i, j = 1, \ldots, m_\mu$. But, since Ξ is extremal, then Θ must be zero.

Vice versa, assume (23). If Θ is a perturbation for Ξ, then there exists some $t \neq 0$ such that $\zeta \doteq \Xi + t\Theta \in \mathsf{C}$. But a perturbation must satisfy (19), then $\mathsf{Supp}(\zeta) \subseteq \mathsf{Supp}(\Xi)$. Using (23) it is then clear that $\Theta = t^{-1}(\zeta - \Xi) = 0$. ■

The proposition tells us that extremal seeds have "minimal support," in the sense that there is no element $\zeta \in \mathsf{C}$ with $\mathsf{Supp}(\zeta) \subseteq \mathsf{Supp}(\Xi)$ which is different from Ξ.

Theorem 2: *Let be* $\Xi \in \mathsf{C}$. *Write* Ξ *in the form* (17). *Then an operator* Θ *is a perturbation of* Ξ *if and only if*

$$\mathrm{Tr}[\Theta T_{ij}^{(\mu)}] = 0 \quad \forall\, \mu \in \mathsf{S}, \quad \forall\, i,j = 1, \ldots, m_\mu \tag{24}$$

and Θ *can be written as follows:*

$$\Theta = \oplus_{\nu \in \mathsf{S}_0} (I_\nu \otimes X_\nu^\dagger A_\nu X_\nu), \tag{25}$$

with $X_\nu \in \mathcal{B}(\mathcal{M}_\nu)$ *and* $A_\nu \in \mathcal{B}(\mathsf{Rng}(X_\nu))$ *Hermitian* $\forall\, \nu \in \mathsf{S}_0$.

Proof: Suppose Θ is a perturbation. Condition (21) is the same as (24). Due to the condition (22), Θ must be an Hermitian operator in the commutant of $\mathsf{R}(\mathbf{G}_0)$, then we can write it in the block form $\Theta = \oplus_{\nu \in \mathsf{S}_0} (I_\nu \otimes O_\nu)$, with each $O_\nu \in \mathcal{B}(\mathcal{M}_\nu)$ Hermitian. Moreover, condition (20) along with (17) imply that each operator O_ν must have $\mathsf{Supp}(O_\nu) \subseteq \mathsf{Supp}(X_\nu^\dagger X_\nu) = \mathsf{Supp}(X_\nu)$. Using the singular value decomposition $X_\nu = \sum_{i=1}^{r_\nu} \lambda_i^{(\nu)} |w_i^{(\nu)}\rangle\langle v_i^\nu|$ [$\{|v_i^\nu\rangle\}$ and $\{|w_i^{(\nu)}\rangle\}$ are orthonormal bases for $\mathsf{Supp}(X_\nu)$ and $\mathsf{Rng}(X_\nu)$, respectively] one can see that any Hermitian operator O_ν with $\mathsf{Supp}(O_\nu) \subseteq \mathsf{Supp}(X_\nu)$ admit the decomposition $O_\nu = X_\nu^\dagger A_\nu X_\nu$, with A_ν Hermitian operator in $\mathcal{B}(\mathsf{Rng}(X_\nu))$. Conversely, if both conditions (24) and (25) hold, then conditions (20)–(22) are obviously fulfilled. ■

Theorem 3: *Let* P_ν *be the projection operator onto the subspace* $\mathcal{H}_\nu \otimes \mathcal{M}_\nu \subseteq \mathcal{H}$ *corresponding to the class* $\nu \in \mathsf{S}_0$. *An operator* $\Xi \in \mathsf{C}$ *written in the form* $\Xi = \oplus_{\nu \in \mathsf{S}_0} (I_\nu \otimes X_\nu^\dagger X_\nu)$ *is extremal if and only if*

$$\oplus_{\nu \in \mathsf{S}_0} \mathcal{B}(\mathsf{Rng}(X_\nu)) = \mathsf{Span}\{F_{ij}^{(\mu)} | \mu \in \mathsf{S},\ i,j = 1, \ldots, m_\mu\}, \tag{26}$$

where

$$F_{ij}^{(\mu)} \doteq \oplus_{\nu \in \mathsf{S}_0} X_\nu \, \mathrm{Tr}_{\mathcal{H}_\nu}[P_\nu T_{ij}^{(\mu)} P_\nu] X_\nu^\dagger.$$

Proof: Using the characterization of Theorem 2, we know that Ξ is extremal if and only if for any operator Θ satisfying (24) and (25) one has $\Theta = 0$. Let us take Θ in the form (25), and rewrite the direct sum as an ordinary sum

$$\Theta = \sum_{\nu \in \mathsf{S}_0} P_\nu (I_\nu \otimes X_\nu^\dagger A_\nu X_\nu) P_\nu, \tag{27}$$

using the projectors P_ν onto $\mathcal{H}_\nu \otimes \mathcal{M}_\nu$. Using invariance of trace under cyclic permutations, we can write

$$\mathrm{Tr}[\Theta T_{ij}^{(\mu)}] = \sum_{\nu \in \mathsf{S}_0} \mathrm{Tr}[(I_\nu \otimes A_\nu)(I_\nu \otimes X_\nu) P_\nu T_{ij}^{(\mu)} P_\nu (I_\nu \otimes X_\nu^\dagger)] = \sum_{\nu \in \mathsf{S}_0} \mathrm{Tr}[A_\nu X_\nu \mathrm{Tr}_{\mathcal{H}_\nu}[P_\nu T_{ij}^{(\mu)} P_\nu] X_\nu^\dagger]. \tag{28}$$

Define the space $\mathcal{R} \doteq \oplus_{\nu \in \mathsf{S}_0} \mathsf{Rng}(X_\nu)$ and denote as $\oplus_{\nu \in \mathsf{S}_0} \mathcal{B}(\mathsf{Rng}(X_\nu))$ the linear space of operators acting on $\mathcal{R}$ which are block diagonal on the subspaces $\mathsf{Rng}(X_\nu)$, $\nu \in \mathsf{S}_0$. Then, the extremality condition for Ξ becomes: for any Hermitian operator $A \in \oplus_{\nu \in \mathsf{S}_0} \mathcal{B}(\mathsf{Rng}(X_\nu))$ one has

$$\mathrm{Tr}[A F_{ij}^{(\mu)}] = 0 \ \ \forall\, \mu \in \mathsf{S}, \quad \forall\, i,j = 1, \ldots, m_\mu \Rightarrow A = 0. \tag{29}$$

In terms of the Hilbert–Schmidt product $(A,B) \doteq \mathrm{Tr}[A^\dagger B]$ this condition says that the unique Hermitian operator $A \in \oplus_{\nu \in \mathsf{S}_0} \mathcal{B}(\mathsf{Rng}(X_\nu))$ which is orthogonal to the whole set of operators $\mathsf{F} \doteq \{F_{ij}^{(\mu)} | \mu \in \mathsf{S},\ i,j = 1, \ldots, m_\mu\}$ is the null operator. Orthogonality to the set F is equivalent to orthogonality to the set of Hermitian operators $\mathsf{F}' = \{(F_{ij}^{(\mu)} + F_{ji}^{(\mu)}), i(F_{ij}^{(\mu)} - F_{ji}^{(\mu)}) | \mu \in \mathsf{S},\ i,j = 1, \ldots, m_\mu\}$. Such orthogonality holds if and only if F' is a spanning set for the real space of Hermitian operators in $\oplus_{\nu \in \mathsf{S}_0} \mathcal{B}(\mathsf{Rng}(X_\nu))$. Nevertheless, using the Cartesian decomposition we see that any complex block operator $O \in \oplus_{\nu \in \mathsf{S}_0} \mathcal{B}(\mathsf{Rng}(X_\nu))$ can be written as a sum of two Hermitian

ones, whence the extremality condition is equivalent to $\mathsf{Span}(\mathsf{F}') = \oplus_{\nu\in\mathsf{S}_0}\mathcal{B}(\mathsf{Rng}(X_\nu)$. Finally, the observation $\mathsf{Span}(\mathsf{F}') = \mathsf{Span}(\mathrm{F})$ completes the proof. ■

Notice that for trivial stability group $\mathbf{G}_0 = \{e\}$ (e denotes the identity element), we recover the characterization of Ref. 9: there, one has indeed a single equivalence class $\overline{\nu}$ in S_0 with one-dimensional representation space $\mathcal{H}_{\overline{\nu}}$ so that the whole Hilbert space $\mathcal{H}$ is isomorphic to the multiplicity space $\mathcal{M}_{\overline{\nu}}$ and the extremality condition (26) reduces to $\mathsf{Span}\{XT_{ij}^{(\mu)}X^\dagger \,|\, \mu\in\mathsf{S},\ i,j = 1,\ldots,m_\mu\} = \mathcal{B}(\mathsf{Rng}(X))$.

Corollary 1: Any rank-one seed is extremal.

Proof: Let Ξ be a rank-one seed. In this case there is only one class ν_0 in the decomposition (17) of Ξ (otherwise Ξ could not have unit rank), and the space $\mathcal{B}(\mathsf{Rng}(X_{\nu_0}))$ to be spanned is one dimensional, whence the condition (26) is always satisfied. ■

An alternative proof of Corollary 1 follows by observing that any rank-one element of the cone D of positive semidefinite operators is necessarily extremal for such cone: since the convex set C is a subset of D, a rank-one seed $\Xi\in\mathsf{C}$ is necessarily an extreme point of C.

Corollary 2: Let $\Xi\in\mathsf{C}$ be an extremal seed and write it in the form $\Xi = \oplus_{\nu\in\mathsf{S}_0}(I_\nu\otimes X_\nu^\dagger X_\nu)$. Define $r_\nu \doteq \mathrm{rank}(X_\nu)$. Then

$$\sum_{\nu\in\mathsf{S}_0} r_\nu^2 \leqslant \sum_{\mu\in\mathsf{S}} m_\mu^2. \tag{30}$$

Proof: This relation follows directly from the extremality condition by noting that the left-hand side is the dimension of the complex linear space of block operators $\oplus_{\nu\in\mathsf{S}_0}\mathcal{B}(\mathsf{Rng}(X_\nu))$, while the right-hand side is the cardinality of the spanning set $\mathsf{F} = \{F_{ij}^{(\mu)} \,|\, \mu\in\mathsf{S},\ i,j = 1,\ldots,m_\mu\}$. ■

In Sec. VI we will see an explicit example of extremal POVM which achieves this bound.

V. EXTREMAL POVM'S AND OPTIMIZATION PROBLEMS

A crucial step in a quantum estimation approach is the optimization of the estimation strategy for a given figure of merit. This consists in finding the POVM which maximizes some linear (more generally concave) functional $\mathcal{F}$—e.g., the average fidelity of the estimated state with the true one. Then, the convex structure of the set of POVM's plays a fundamental role in this problem, since, due to concavity of $\mathcal{F}$, one can restrict the optimization procedure to the extremal POVM's only.

In the covariant case, the problem resorts to optimize the state estimation in the orbit $\{U_g\rho U_g^\dagger \,|\, g\in\mathbf{G}\} \simeq \mathbf{G}/\mathbf{G}_0$ of a given state ρ under the action of a group $\mathbf{G}$, $\mathbf{G}_0$ being the stability group of ρ. The optimization typically is the maximization of a linear functional corresponding to the average value of a positive function $f(x,x_*)$, where the average is taken over all the couples (x,x_*) of measured and true values x, $x_*\in\mathcal{X}\doteq\mathbf{G}/\mathbf{G}_0$, respectively. The joint probability density $p(x,x_*)$ is connected to the conditional density $p(x\,|\,x_*)$ given by the Born rule via Bayes, assuming an *a priori* probability distribution of the true value x_*. In the covariant problem the function f enjoys the invariance property $f(gx,gx_*) = f(x,x_*)\ \forall g\in\mathbf{G}$, and is taken as a decreasing function of the distance $|x-x_*|$ of the measured value x from the true one x_*. In the case of compact $\mathbf{G}$ one can assume a uniform *a priori* distribution for x_* values, so that the functional corresponding to the average can be written as follows:

$$\mathcal{F}_\rho[\Xi] = \int_{\mathbf{G}} \mathrm{d}g \int_{\mathbf{G}} \mathrm{d}g_*\, f(gx_0,g_*x_0)\mathrm{Tr}[U_{g_*}\rho U_{g_*}^\dagger U_g \Xi U_g^\dagger] \tag{31}$$

$$= \int_{\mathbf{G}} \mathrm{d}g\, f(x_0,gx_0)\mathrm{Tr}[U_g\rho U_g^\dagger \Xi], \tag{32}$$

where x_0 is the equivalence class containing the identity. In the following, we will consider as the prototype optimization problem the maximization of the likelihood functional[3,4]

$$\mathcal{L}_\rho[\Xi] \doteq \mathrm{Tr}[\rho\Xi], \tag{33}$$

corresponding to the choice $f(x,x_*)=\delta(x-x_*)$ in Eq. (31). Maximizing $\mathcal{L}_\rho[\Xi]$ means maximizing the probability density that the measured value x coincides with the true value x_*. For such estimation strategy the optimization problem has a remarkably simple form, enabling a general treatment for a large class of group representations.[13] Moreover, the solution of the maximum likelihood is formally equivalent to the solution of any optimization problem with a positive (which, a part from an additive constant, means bounded from below) summable function $f(x,x_*)$. Indeed, we can define the map

$$\mathcal{M}(\rho) = k^{-1}\int_{\mathbf{G}} \mathrm{d}g\, f(x_0,gx_0)U_g\rho U_g^\dagger, \tag{34}$$

where $k=\int_{\mathbf{G}}\mathrm{d}g\, f(x_0,gx_0)$. This map is completely positive, unital and trace preserving, and, in particular, $\mathcal{M}(\rho)$ is a state. With this definition, we have

$$\mathcal{F}_\rho[\Xi] = k\mathcal{L}_{\mathcal{M}(\rho)}[\Xi], \tag{35}$$

whence the maximization of $\mathcal{F}_\rho$ is equivalent to the maximization of the likelihood for the transformed state $\mathcal{M}(\rho)$.

Essentially all optimal covariant measurements known in the literature are represented by rank-one operators. The rank-one assumption often provides a useful instrument for simplifying calculations. Nevertheless, as we will show in the following, the occurrence of POVM's with rank grater than one is unavoidable in some relevant situations.

Proposition 1: For any $\Xi\in\mathsf{C}$,

$$\mathrm{rank}[\Xi] \geqslant \max_{\mu\in\mathsf{S}}\left(\frac{m_\mu}{d_\mu}\right). \tag{36}$$

Proof: Let us decompose $\mathcal{H}$ into irreducible subspaces for the representation $\mathsf{R}(\mathbf{G})$ of $\mathbf{G}$ as follows:

$$\mathcal{H} = \oplus_{\mu\in\mathsf{S}}\oplus_{i=1}^{m_\mu}\mathcal{H}_i^{(\mu)}. \tag{37}$$

Take an orthonormal basis $\mathsf{B}_i^{(\mu)}=\{|(\mu,i),n\rangle\,|\,n=1,\ldots,d_\mu\}$ for each subspace $\mathcal{H}_i^{(\mu)}$ in such a way that $|(\mu,i),n\rangle = T_{ij}^{(\mu)}|(\mu,j),n\rangle$ for any n, $T_{ij}^{(\mu)}:\mathcal{H}_j\to\mathcal{H}_i$ being the invariant isomorphism which intertwines the equivalent representations (μ,i) and (μ,j). Diagonalize Ξ as

$$\Xi = \sum_{k=1}^{\mathrm{rank}(\Xi)} |\eta_k\rangle\langle\eta_k| \tag{38}$$

and write

$$|\eta_k\rangle = \sum_{\mu\in\mathsf{S}}\sum_{i=1}^{m_\mu}\sum_{n=1}^{d_\mu} c^k_{(\mu,i),n}|(\mu,i),n\rangle. \tag{39}$$

Since $\langle\eta_k|T_{ij}^{(\mu)}|\eta_k\rangle=\sum_{n=1}^{d_\mu}c^{k*}_{(\mu,i),n}c^k_{(\mu,j),n}$, the normalization constraints (16) become

$$\sum_{k=1}^{\mathrm{rank}(\Xi)}\sum_{n=1}^{d_\mu} c^{k*}_{(\mu,i),n}c^k_{(\mu,j),n} = d_\mu\delta_{ij}. \tag{40}$$

This relation implies that for any $\mu\in\mathsf{S}$ the vectors $\{\mathbf{c}_{(\mu,i)}\,|\,i=1,\ldots,m_\mu\}$ defined by $(\mathbf{c}_{(\mu,i)})_{k,n}\doteq c^k_{(\mu,i),n}$ are orthogonal: since they are m_μ orthogonal vectors in a linear space whose dimension is $d_\mu\times\mathrm{rank}(\Xi)$, it follows that $m_\mu\leqslant d_\mu\times\mathrm{rank}(\Xi)$, hence $\mathrm{rank}(\Xi)\geqslant m_\mu/d_\mu\ \forall\,\mu\in\mathsf{S}$. ■

Summarizing, every times $m_\mu > d_\mu$ for some class $\mu \in \mathsf{S}$, a covariant POVM cannot be represented by a rank-one seed, due to the normalization constraints.

The previous proposition exhibits a structural reason for which, in the presence of equivalent representations, the set C of covariant seeds may contain only elements with rank greater than one. On the other hand, in the following we will discuss the occurrence of covariant POVM's with rank greater than one in explicit optimization problems, independently of the presence of equivalent representations.

Proposition 2: Let Ξ be an extremal point of C. *Denote by P the projector onto* $\mathsf{Supp}(\Xi)$, *and let* $r \doteq \mathrm{rank}(P)$. *Then Ξ is the unique seed which maximizes the likelihood for the state* $\rho = P/r$.

Proof: First, we need to prove that Ξ commutes with the representation $\mathsf{R}(\mathbf{H}_0) \doteq \{U_k | k \in \mathbf{H}_0\}$, where $\mathbf{H}_0$ is the stability group of ρ. Define the group average

$$\xi \doteq \frac{\int_{\mathbf{H}_0} \mathrm{d}h\, U_h \Xi U_h^\dagger}{\int_{\mathbf{H}_0} \mathrm{d}h}. \tag{41}$$

Since $\mathsf{R}(\mathbf{H}_0)$ is the stability group of the projector onto $\mathsf{Supp}(\Xi)$, clearly $\mathsf{Supp}(\Xi)$ is invariant under $\mathsf{R}(\mathbf{H}_0)$, whence ξ satisfies $\mathsf{Supp}(\xi) \subseteq \mathsf{Supp}(\Xi)$. Moreover, using the invariance of the Haar measure it is easy to see that ξ commutes with $\mathsf{R}(\mathbf{H}_0)$. Finally, ξ is an element of C. In fact, it is positive semidefinite, satisfies (16) and commutes with $\mathsf{R}(\mathbf{G}_0)$, which is by definition a subset of $\mathsf{R}(\mathbf{H}_0)$. Since Ξ is extremal, using Theorem 1 we can conclude that $\Xi = \xi$, whence Ξ commutes with $\mathsf{R}(\mathbf{H}_0)$.

Let us prove now optimality. For any arbitrary seed $\zeta \in \mathsf{C}$, the following bound holds:

$$\mathcal{L}_\rho[\zeta] = \mathrm{Tr}[\rho\zeta] = \frac{\mathrm{Tr}[P\zeta]}{r} \leqslant \frac{\mathrm{Tr}[\zeta]}{r} = \frac{\dim(\mathcal{H})}{r}, \tag{42}$$

where the last equality follows from the normalization constraints (16). Clearly Ξ achieves the bound, whence it is optimal. Notice that the inequality $\mathrm{Tr}[P\zeta] \leqslant \mathrm{Tr}[\zeta]$ becomes equality if and only if $\mathsf{Supp}(\zeta) \subseteq \mathsf{Supp}(\Xi)$, then using Theorem 1 we can see that Ξ represents the unique optimal POVM. ■

Consider now a density matrix σ with support in the orthogonal complement of $\mathsf{Supp}(\Xi)$, and consider the randomization

$$\rho = (1-\alpha)\frac{P}{r} + \alpha\sigma, \tag{43}$$

with $0 \leqslant \alpha \leqslant 1$. In the following we prove that, for sufficiently small $\alpha > 0$, Ξ is still optimal for the maximum likelihood strategy. In other words, the extremal POVM represented by Ξ is stable under randomization, and the same measuring apparatus can be used for a larger class of mixed states.

Proposition 3: Consider the randomized state ρ in (43) and denote by $\overline{q}$ the maximum eigenvalue of σ. If $\alpha < 1/(1+r\overline{q})$, then Ξ is the unique seed which maximizes the likelihood for the state ρ.

Proof: First, notice that Ξ commutes with the representation $\mathsf{R}(\mathbf{H}_0)$ of the stability group of ρ. This follows from the observation that the condition $\alpha < 1/(1+r\overline{q})$ implies that $(1-\alpha)/r$ is strictly the largest eigenvalue of ρ. Then, P is the projector on the eigenspace with maximum eigenvalue of ρ, while, for any $h \in \mathbf{G}$, $P_h \doteq U_h P U_h^\dagger$ is the projector on the eigenspace with maximum eigenvalue of $\rho_h \doteq U_h \rho U_h^\dagger$. If $h \in \mathbf{H}_0$ then it must be $\rho_h = \rho$, and, necessarily, $P_h = P$. Therefore $\mathbf{H}_0$ is a subgroup of the stability group of P. But Ξ commutes with the representation of the stability group of P, as proven in Proposition 2, then it commutes also with $\mathsf{R}(\mathbf{H}_0)$.

Now we prove optimality of Ξ. Let us denote by Q the projection onto $\mathsf{Supp}(\sigma)$. The following bound holds for any $\zeta \in \mathsf{C}$:

$$\mathcal{L}_\rho[\zeta] = \frac{(1-\alpha)}{r}\,\mathrm{Tr}[P\zeta] + \alpha\,\mathrm{Tr}[\sigma\zeta] \tag{44}$$

$$\leqslant \frac{(1-\alpha)}{r}\,\mathrm{Tr}[P\zeta] + \alpha\overline{q}\,\mathrm{Tr}[Q\zeta] \tag{45}$$

$$\leqslant \frac{(1-\alpha)}{r}\,\mathrm{Tr}[(P+Q)\zeta] \tag{46}$$

$$\leqslant \frac{(1-\alpha)}{r}\,\mathrm{Tr}[\zeta] = \frac{(1-\alpha)}{r}\,\dim(\mathcal{H}). \tag{47}$$

This bound is achieved by Ξ, proving its optimality. Notice that Ξ is the unique optimal seed. In fact, equality in (46) is attained if and only if $\mathrm{Tr}[Q\zeta]=0$, namely when $\mathsf{Supp}(Q)\subseteq\mathsf{Ker}(\zeta)$, while in (47) equality is attained if and only if $\mathsf{Supp}(\zeta)\subseteq\mathsf{Supp}(P)\oplus\mathsf{Supp}(Q)$. Therefore the bound is achieved if and only if $\mathsf{Supp}(\zeta)\subseteq\mathsf{Supp}(P)=\mathsf{Supp}(\Xi)$, implying $\zeta=\Xi$. ■

VI. EXAMPLES

A. Extremal POVM's with a nontrivial stability group

Example 1: Consider the group of rotations, represented in a $(2j+1)$-dimensional Hilbert space $\mathcal{H}_j$ by the irreducible representation $R_{\mathbf{n},\varphi} \doteq e^{i\varphi\mathbf{n}\cdot\mathbf{j}}$, where φ is an angle, $\mathbf{n}$ is a unit vector, and $\mathbf{j}\doteq(j_x,j_y,j_z)$ is the angular momentum operator. In this case a covariant estimation in the orbit of a pure state $|\psi\rangle$ generally may involve a nontrivial stability group. This is actually the case when $|\psi\rangle \doteq |jm\rangle_{\mathbf{n_0}}$, is an eigenvector of $\mathbf{n_0}\cdot\mathbf{j}$ for some unit vector $\mathbf{n_0}$. Clearly in such case the stability group $\mathbf{G}_0$ consists of rotations around $\mathbf{n_0}$, and the state estimation in the orbit reduces to the estimation of a rotated direction $\mathbf{n}'$. The same situation arises for any state ρ mixture of eigenvectors of $\mathbf{n_0}\cdot\mathbf{j}$. Without loss of generality, let us take $\mathbf{n_0}$ as the direction of the z axis, and write $\rho=\Sigma_{m=-j}^{j} p_m |jm\rangle\langle jm|$ with $p_m \geqslant 0\ \forall m$. Let us denote by P the projector onto $\mathsf{Supp}(\rho)$, and take $\overline{m}$ such that $p_{\overline{m}}=\max_m\{p_m\}$. Then, since

$$\mathrm{Tr}[\rho\zeta] \leqslant p_{\overline{m}}\,\mathrm{Tr}[P\Xi] \leqslant p_{\overline{m}}\,\mathrm{Tr}[\Xi] = p_{\overline{m}}(2j+1),$$

one has that $\Xi=(2j+1)|j\overline{m}\rangle\langle j\overline{m}|$ is the optimal POVM. Notice that such POVM commutes with the stability group $\mathsf{R}(\mathbf{G}_0)$ and is extremal, as a consequence of Corollary 1.

Example 2: Consider the group $\mathbb{SU}(d)$ of unitary $d\times d$ matrices with unit determinant, acting on the space $\mathcal{H}\doteq\mathbb{C}^d$. It is easy to see that each vector $|\psi\rangle\in\mathcal{H}$ has a nontrivial stability group $\mathbf{G}_0\equiv\mathbb{U}(d-1)$. In fact, by introducing an orthonormal basis $\mathsf{B}_\perp\doteq\{|n\rangle\,|\,n=1,\ldots,d-1\}$ for the orthogonal complement $\mathcal{H}^\perp$ of the line $\mathsf{Span}\{|\psi\rangle\}$, and the basis $\mathsf{B}\doteq|\psi\rangle\cup\mathsf{B}_\perp$ for $\mathcal{H}$, the stability group $\mathbf{G}_0$ consists on matrices of the form

$$U_h = \begin{pmatrix} \omega_h & \mathbf{0} \\ \mathbf{0} & V_h \end{pmatrix}, \tag{48}$$

where $\omega_h\in\mathbb{C}$, $|\omega_h|=1$, and V_h is a unitary $(d-1)\times(d-1)$ matrix with $\mathrm{Det}(V_h)=\omega_h^*$. Let us consider now the tensor representation $\mathsf{R}(\mathbf{G})=\{U_g^{\otimes 2}\,|\,U_g\in\mathbb{SU}(d)\}$ on the space $\mathcal{H}^{\otimes 2}$. This representation has two irreducible subspaces, the symmetric and the antisymmetric ones $\mathcal{H}_+$ and $\mathcal{H}_-$, with dimensions $d_+=d(d+1)/2$ and $d_-=d(d-1)/2$, respectively. Denote by P_+ and P_- the projectors on $\mathcal{H}_+$ and $\mathcal{H}_-$. Let us apply the representation $\mathsf{R}(\mathbf{G})$ on the state $|\psi\rangle^{\otimes 2}\in\mathcal{H}^{\otimes 2}$. Clearly the stability group is the same $\mathbf{G}_0$ as before, and it is represented by $\mathsf{R}(\mathbf{G}_0)=\{U_h^{\otimes 2}\,|\,h\in\mathbf{G}_0\}$. It is easy to see that

$\mathsf{R}(\mathbf{G}_0)$ contains five irreducible components, carried by the subspaces $\mathcal{H}_1=\mathsf{Span}\{|\psi\rangle^{\otimes 2}\}$, $\mathcal{H}_2=\mathsf{Span}\{|\psi\rangle\}\otimes\mathcal{H}^{\perp}$, $\mathcal{H}_3=\mathcal{H}^{\perp}\otimes\mathsf{Span}\{|\psi\rangle\}$, $\mathcal{H}_4=P_+(\mathcal{H}^{\perp\otimes 2})$, and $\mathcal{H}_5=P_-(\mathcal{H}^{\perp\otimes 2})$. Notice that $\mathcal{H}_2$ and $\mathcal{H}_3$ carry equivalent representations, corresponding to a two-dimensional multiplicity space. An example of extremal POVM is given by

$$\Xi=\frac{d(d+1)}{2}|\psi\rangle\langle\psi|^{\otimes 2}\oplus\frac{d}{d-2}P_-QP_-,$$

where Q is the projection on $\mathcal{H}^{\perp\otimes 2}$. Since the two summands are proportional to $|\psi\rangle\langle\psi|^{\otimes 2}$ and P_-QP_-, which are the projectors on $\mathcal{H}_1$ and $\mathcal{H}_5$, respectively, then Ξ belongs to the commutant of $\mathsf{R}(\mathbf{G}_0)=\{U_h^{\otimes 2}|h\in\mathbf{G}_0\}$. Notice that the subspaces $\mathcal{H}_1$ and $\mathcal{H}_5$ have multiplicities $m_1=m_5=1$, corresponding to one-dimensional multiplicity spaces $\mathcal{M}_1\equiv\mathcal{M}_5\equiv\mathbb{C}$ (whence the partial traces over $\mathcal{H}_{1,5}$ will be c numbers). Moreover, using the fact that $\mathrm{Tr}_{\mathcal{H}_1}[P_+]=1$, $\mathrm{Tr}_{\mathcal{H}_1}[P_-]=0$, $\mathrm{Tr}_{\mathcal{H}_5}[P_+]=0$, $\mathrm{Tr}_{\mathcal{H}_5}[P_-]=(d-1)(d-2)/2$ one can check extremality using the condition (26). Let us observe that in this example we have $r_1=r_5=1$ and $m_+=m_-=1$, where r_1 and r_5 are defined as in Corollary 2, while m_+ and m_- are the multiplicities of the two irreducible representations of $\mathsf{R}(\mathbf{G})$. Then the bound of (30) is saturated. Finally, we remark that this POVM is optimal for discriminating states in the orbit of $|\psi\rangle^{\otimes 2}$,[13] in the orbit of $\rho=(1/r)(|\psi\rangle\langle\psi|^{\otimes 2}+P_-QP_-)$ where $r=1+[(d-1)(d-2)/2]$ because of Proposition 2, and also in the orbit of any randomization $\rho'=(1-\alpha)\rho+\alpha\sigma$ where σ is density matrix with $\mathsf{Supp}(\sigma)\subseteq\mathsf{Ker}(P)$, and $\alpha<1/(1+r)$, because of Proposition 3.

B. Extremal POVM's with rank greater than one

Example 1: Consider the Abelian group $\mathbf{G}=\mathbb{U}(1)$ of phase shifts, acting in the space $\mathcal{H}=\mathbb{C}^d$ by the representation $\mathsf{R}(\mathbf{G})=\{U(\varphi)=\exp(i\varphi N)|\ \varphi\in[-\pi,\pi]\}$, where the generator N is given by $N=\sum_{n=0}^{d-1}n|n\rangle\langle n|$ for some orthonormal basis $\{|n\rangle|n=0,1,\ldots,d-1\}$. The stability group $\mathbf{G}_0$ may be either the whole $\mathbb{U}(1)$ (for ρ diagonal on the eigenstates of the generator), or a discrete subgroup $\mathbf{G}_0=\mathbb{Z}_k$ for some integer k, including the case $k=1$ of trivial stability group. We exclude the degenerate case $\mathbf{G}_0=\mathbb{U}(1)$ of shift invariant states. The parameter space $\mathfrak{X}=\mathbb{U}(1)/\mathbb{Z}_k$ will be a circle, parametrized by an angle $\theta\in[-\pi,\pi]$, and the action of a group element $g(\varphi)\in\mathbf{G}$ on an element $\theta\in\mathfrak{X}$ will be given by $g(\varphi)\theta=\theta+k\varphi$.

Due to constraint (16), a seed Ξ is represented in the eigenbasis of the generator by a correlation matrix, namely by a positive semidefinite matrix with unit diagonal entries. Vice versa, any correlation matrix corresponds to a seed in the case of trivial stability group $\mathbf{G}_0$. In Ref. 10 one can find a constructive method which provides extremal correlation matrices with rank $r>1$: here we show that any of such matrices can be viewed as the optimal seed for the estimation problem in the orbit of a particular state. Let us choose as optimality criterion the maximization of the average value of a positive summable function $f:\mathfrak{X}\times\mathfrak{X}\to\mathbb{R}_+$ depending only on the difference $\theta-\theta_*$ between the measured and the true value. Suppose ρ a state with stability group $\mathbf{G}_0=\mathbb{Z}_k$. As we noted at the beginning of Sec. V, the maximization of $\mathsf{F}_\rho[\Xi]$—the average value of $f(\theta-\theta_*)$—corresponds to the maximization of the likelihood $\mathcal{L}_{\mathcal{M}(\rho)}[\Xi]$ for the transformed state $\mathcal{M}(\rho)=f_0^{-1}\int_{-\pi}^{\pi}(\mathrm{d}\varphi/2\pi)f(-k\varphi)U_\varphi\rho U_\varphi^\dagger$ [from Eq. (34)]. Notice that the map $\mathcal{M}$ is trivially covariant—i.e., $\mathcal{M}(U_\phi\rho U_\phi^\dagger)=U_\phi\mathcal{M}(\rho)U_\phi^\dagger$—since the group is Abelian. For simplicity here we require that the map $\mathcal{M}$ is invertible, whence also $\mathcal{M}^{-1}$ is covariant and trace preserving (but generally not positive). Covariance of $\mathcal{M}$ implies that the stability group of $\mathcal{M}(\rho)$ contains the stability group of ρ, and covariance of $\mathcal{M}^{-1}$ implies the reverse inclusion, whence the stability group is not changed by the maps.

Let us take now an extremal correlation matrix Ξ with $\mathrm{rank}(\Xi)=r\geqslant 1$ and denote by P the projector onto $\mathsf{Rng}(\Xi)$. Using Proposition 2, we can see that Ξ commutes with the representation $\mathsf{R}(\mathbf{H}_0)$, where $\mathbf{H}_0$ is the stability group of P. Call λ the modulus of the minimum eigenvalue of $\mathcal{M}^{-1}(P/r)$, then

$$\rho = \frac{\lambda}{1+d\lambda} I + \frac{1}{1+d\lambda} \mathcal{M}^{-1}(P/r)$$

is a density operator. Notice that the stability group $\mathbf{G}_0$ of ρ is the same stability group of $\mathcal{M}^{-1}(P)$, which coincides with $\mathbf{H}_0$, the stability group of P. Therefore Ξ commutes with the representation $\mathsf{R}(\mathbf{G}_0)$. It is easy to show that Ξ is the unique seed commuting with $\mathsf{R}(\mathbf{G}_0)$ which is also optimal for the estimation of states in the orbit of ρ. In fact, for any ζ in the convex set C of the seeds with stability group $\mathbf{G}_0$, we have

$$\mathsf{F}_\rho[\zeta] = f_0 \operatorname{Tr}[\zeta \mathcal{M}(\rho)] = f_0\left(\frac{\lambda}{1+d\lambda} \operatorname{Tr}[\zeta] + \frac{1}{r(1+d\lambda)} \operatorname{Tr}[\zeta P] \right) \leqslant f_0\left(\frac{d}{r}\right)\left(\frac{1+r\lambda}{1+d\lambda}\right).$$

This bound is achieved choosing $\zeta = \Xi$, moreover, as in Proposition 2, we can observe that the functional $\operatorname{Tr}[\zeta P]$ with $\zeta \in \mathsf{C}$ is maximum if and only if $\zeta = \Xi$, then the maximum is unique.

Example 2: We provide now an example with a noncompact group represented in an infinite dimensional Hilbert space. This example is out of the general treatment of the present paper—which considers only finite dimensions—and is given only with the purpose of showing that our results could be generalized to infinite dimensions, however at the price of much more technical proofs.

Take $\mathcal{H}$ as the Fock space, and consider the projective representationon $\mathcal{H}$ of the group of translations on the complex plane $\mathbb{C}$ in terms of the Weyl–Heisenberg operators $\mathsf{R}(\mathbf{G}) = \{D(\alpha) = e^{\alpha a^\dagger - \bar{\alpha} a} | \alpha \in \mathbb{C}\}$, where $[a, a^\dagger] = 1$. Here we will consider the twofold tensor representation $\{D(\alpha)^{\otimes 2} | \alpha \in \mathbb{C}\}$ on $\mathcal{H}^{\otimes 2}$. Using the unitary operator $V = e^{(\pi/4)(a_1 a_2^\dagger - a_1^\dagger a_2)}$, one can write $D(\alpha)^{\otimes 2} = V(D(\sqrt{2}\alpha) \otimes I) V^\dagger$ and see that the irreducible subspaces of this representation are $\mathcal{H}_n = V(\mathcal{H} \otimes \mathsf{Span}\{|\phi_n\rangle\})$, where $\{|\phi_n\rangle | n = 1, 2, \ldots, \infty\}$ is any orthonormal basis for $\mathcal{H}$. All these subspaces carry equivalent representations, the isomorphism between $\mathcal{H}_m$ and $\mathcal{H}_n$ being

$$T_{mn} = V(I \otimes |\phi_m\rangle\langle\phi_n|) V^\dagger. \tag{49}$$

In terms of these isomorphisms, the normalization constraints (16) for a seed operator become[13]

$$\operatorname{Tr}[T_{mn} \zeta] = 2 \delta_{mn}. \tag{50}$$

Notice that the number 2 in this formula has nothing to do with the dimension of $\mathcal{H}_n$ which is infinite: in the noncompact case the dimensions are replaced by positive numbers depending only on the equivalence class of representations. In principle, since the space $\mathcal{H}^{\otimes 2}$ is infinite dimensional, there is the possibility of extremal covariant POVM's with an infinite rank. Actually we can provide the remarkable example

$$\Xi = 2V(|0\rangle\langle 0| \otimes I) V^\dagger, \tag{51}$$

where $|0\rangle$ is the vacuum state of the Fock basis $\{|m\rangle | a^\dagger a |m\rangle = m |m\rangle\}$. The corresponding POVM can be realized by averaging the outcomes of two independent measurements with $\Xi_1 = |0\rangle\langle 0| \otimes I$ and $\Xi_2 = I \otimes |0\rangle\langle 0|$,[13] which in quantum optics correspond to two heterodyne measurements.[14]

We can observe that Ξ maximizes the likelihood functional for any state of the form $\rho = V(|0\rangle\langle 0| \otimes \sigma) V^\dagger$, where $\sigma = \sum_{n=0}^\infty p_n |\phi_n\rangle\langle\phi_n|$, is a mixed state with $p_n > 0 \, \forall \, n$. In fact, for any seed ζ, one has the bound

$$\begin{aligned} \operatorname{Tr}[V(|0\rangle\langle 0| \otimes \sigma) V^\dagger \zeta] &= \sum_{n=0}^\infty p_n \operatorname{Tr}[V(|0\rangle\langle 0| \otimes |\phi_n\rangle\langle\phi_n|) V^\dagger \zeta] \\ &\leqslant \sum_{n=0}^\infty p_n \operatorname{Tr}[V(I \otimes |\phi_n\rangle\langle\phi_n|) V^\dagger \zeta] = \sum_n p_n \operatorname{Tr}[T_{nn} \zeta] = 2, \end{aligned} \tag{52}$$

and since Ξ achieves the bound (52), it is optimal. Moreover Ξ is the unique optimal seed. In fact,

the equality in (52) is achieved if and only if $\mathrm{Tr}[V(|0\rangle\langle 0|\otimes|\phi_n\rangle\langle\phi_n|)V^\dagger\zeta]=\mathrm{Tr}[V(I\otimes|\phi_n\rangle\times\langle\phi_n|)V^\dagger\zeta]$ for any n: by expanding the identity on the Fock basis, the positivity of ζ implies $\langle m|\langle\phi_n|V^\dagger\zeta V|m\rangle|\phi_n\rangle=0$ for any $m\neq 0$. Hence the unique nonzero diagonal elements of ζ are on the vectors $V|0\rangle|\phi_n\rangle$. On the other hand, the positivity of ζ along with the normalization constraint $\mathrm{Tr}[T_{mn}\zeta]=0\ \forall m\neq n$ imply that all the off diagonal elements of ζ are zero. Hence $\zeta=2V\Sigma_{n=1}^{\infty}(|0\rangle\times\langle 0|\otimes|\phi_n\rangle\langle\phi_n|)V^\dagger=2V(|0\rangle\langle 0|\otimes I)V^\dagger=\Xi$. The fact that Ξ is the unique optimal seed ensures that it is also extremal, otherwise there would be two different seeds which are equally optimal. Notice that Ξ is extremal also according to our characterization (26).

(Received 2 July 2004; accepted 12 August 2004; published 4 November 2004)

A new geometrical framework for tetrad-affine formulation of gravity, pure or coupled with Yang–Mills fields, is proposed. After analyzing the geometrical properties of the new mathematical setting, field equations are deduced from a variational principle in the Poincaré–Cartan formalism. A generalized Noether Theorem is stated and classical relationship between symmetries and conserved quantities are recovered in the newer scheme. Some explicit examples are given. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1806536]

I. INTRODUCTION

In recent papers,[1,2] we developed a geometrical framework for the description of Lagrangian field theories depending on the derivatives of the fields, only through their antisymmetric combinations.

For example, for Yang–Mills theories,[3–7] where one can interpret the dynamical field A as a connection on a suitable principal fiber bundle, and the strength field F as the associated curvature, only the antisymmetric part of the gradient of A is involved in the construction of F; in this case, the approach outlined in Refs. 1 and 2 allows to cut away the "inessential" coordinates from the geometrical construction, so getting some important results: Taking care from the beginning only of the physical degrees of freedom of the theory, regularizing Yang–Mills Lagrangians and obtaining a simpler action of gauge transformations on the "derivatives" of the dynamical field A.

The aim of this paper is to extend the mathematical machinery to gravity, in a tetrad-affine formulation.

The mathematical arena we chose to formulate our theory is the gauge natural bundle framework for gravity (see, for example, Refs. 8–13). Dynamical fields are metric connections (*a priori* not necessarily torsion-free) and pseudo-orthonormal tetrads. More precisely, metric connections are viewed as principal connections on the structure bundle $[P, M, \pi, \mathrm{SO}(1,3)]$ over the space–time manifold M, while tetrads turn out to be sections of a suitable associated bundle, locally diffeomorphic to the co-frames bundle.

The resulting geometrical framework automatically embodies the Lorentz invariance of the theory; here, in fact, tetrads are truly gauge natural objects, subject to the transformations of the structure bundle P. Moreover, the use of the gauge natural bundle framework also avoids the necessity of assuming the existence of a globally defined tetrad field.

Following the lines traced in Refs. 1 and 2, we construct a new affine bundle over the configuration space of the theory, by changing the standard definition of jet-equivalence.

In the resulting mathematical setting, we describe a class of interaction between the gravitational and the Yang–Mills fields, including minimal coupling, in the Poincaré–Cartan formalism.

[a]Electronic mail: vignolo@dipem.unige.it
[b]Electronic mail: cianci@dipem.unige.it

This is achieved by adopting as preferred coordinates in the new space directly the components of the curvature and torsion tensor fields, thereby gauging away all unphysical degrees of freedom.

The paper is organized as follows. In Sec. II, we construct the new bundle as an appropriate quotient space of the standard jet-bundle. In order to implement a variational calculus, we extend to the newly defined space some classical geometrical structures of jet-bundle theory. For simplicity, we develop in detail the purely gravitational case only. The geometrical setting suitable for describing coupled gravitational and Yang–Mills fields is easily obtained joining together the present geometrical framework with the one proposed in Refs. 1 and 2. The argument is entirely straightforward and is left to the reader.

In Sec. III, we define the Poincaré–Cartan form associated with a Lagrangian on the new bundle. We derive the field equations from a variational principle. Both purely gravitational and coupled with Yang–Mills fields cases are explicitly worked out.

In Sec. IV, making use of the Poincaré–Cartan formalism, we state a generalized Nöther Theorem and investigate the relationships between symmetries and conserved currents in the newer scheme. We analyze explicitly the coupled gravitational Yang–Mills Lagrangian in curved space–time and get the conserved quantities related to gauge and diffeomorphism invariance.

The supersymmetric extension of this formalism and the description of the interaction with spinor fields are, at the moment, under investigation and will form the subject of a future work.

II. THE GEOMETRICAL FRAMEWORK

A mathematical scenario suitable for globally describing gravity in the tetrad formalism is the gauge natural bundle framework, where the structure bundle of the theory is a principal fiber bundle $[P,M,\pi,\mathrm{SO}(1,3)]$ over space–time M (see, for example, Refs. 8–12 and references therein).

In this context, denoting by $L(M)$ the frame bundle over M, a tetrad field turns out to be a section of a $GL(4,\Re)$ bundle $\mathcal{E}$, which is the bundle associated with $P\times L(M)$ through the left action

$$\lambda:(\mathrm{SO}(1,3)\times GL(4,\Re))\times GL(4,\Re)\to GL(4,\Re),\quad \lambda(\Lambda,J;X)=\Lambda\cdot X\cdot J^{-1}.$$

Accordingly, local fibered coordinates on $\mathcal{E}\to M$ are functions of the kind x^i, e_i^μ $(i,\mu=1,\ldots,4)$ undergoing the transformation laws

$$\overline{x^j}=\overline{x^j}(x^i),\quad \overline{e_j^\mu}=e_i^\sigma\Lambda^\mu{}_\sigma(x)\frac{\partial x^i}{\partial\overline{x^j}}, \tag{2.1}$$

where $\Lambda^\mu{}_\sigma(x)\in\mathrm{SO}(1,3)$, $\forall x\in M$.

The assignment of a tetrad field $x\to e^\mu(x)=e_i^\mu(x)dx^i$ allows to define a metric over M by setting $g:=\eta_{\mu\nu}e^\mu\otimes e^\nu(g_{ij}:=\eta_{\mu\nu}e_i^\mu e_j^\nu)$, with $\eta:=\mathrm{diag}(-1,1,1,1)$. By construction, g is invariant under transformations (2.1).

In this way, the structure bundle $[P,M,\pi,\mathrm{SO}(1,3)]$ becomes the bundle of orthonormal frames associated with the metric g: For each tetrad e there is an isomorphism between P and $\mathrm{SO}(M,g)$.

Therefore, the quotient bundle $\mathcal{C}:=J_1P/\mathrm{SO}(1,3)$ of principal connections over the structure bundle P is naturally identified with the bundle of g-metric compatible linear connections over M.

As is well known, every connection one-form on P may be expressed locally as

$$\omega(x,\Lambda)=\omega^\mu{}_\nu(x,\Lambda)\otimes\underline{\mathrm{u}}_\mu{}^\nu:=[\Lambda^\mu{}_\sigma\Lambda_\nu{}^\gamma\omega_i{}^\sigma{}_\gamma(x)dx^i-\Lambda_\nu{}^\eta d\Lambda^\mu{}_\eta]\otimes\underline{\mathrm{u}}_\mu{}^\nu, \tag{2.2}$$

where $\omega_i{}^\mu{}_\nu(x)$ are the connection coefficients, $\underline{\mathrm{u}}_\mu{}^\nu$ denote a basis of the Lie algebra $\mathfrak{so}(1,3)$ of SO(1, 3), and $\Lambda_\mu{}^\eta:=(\Lambda^{-1})^\eta{}_\mu$. In view of this, we can put on $\mathcal{C}$ local coordinates of the form x^i, $\omega_i{}^{\mu\nu}(:=\omega_i{}^\mu{}_\sigma\eta^{\sigma\nu})$ with $\mu<\nu$.

Because of the above identification, given a (local) tetrad field $e_i^\mu(x)dx^i$ the transformations (2.1) can be viewed as changes of (local) sections $e^\nu \to \overline{e^\mu} = \Lambda^\mu{}_\nu(x)e^\nu$ of $P \to M$. The latter induce associated changes of (local) trivialization of P itself, in turn yielding corresponding coordinate transformations in $\mathcal{C}$ of the form

$$\overline{x^i} = \overline{x^i}(x^j), \quad \overline{\omega_i}^{\mu\nu} = \Lambda^\mu{}_\sigma(x)\Lambda^\nu{}_\gamma(x)\frac{\partial x^j}{\partial \overline{x^i}}\omega_j{}^{\sigma\gamma} - \Lambda_\sigma{}^\eta(x)\frac{\partial \Lambda^\mu{}_\eta(x)}{\partial x^h}\frac{\partial x^h}{\partial \overline{x^i}}\eta^{\sigma\nu}, \tag{2.3}$$

where $\omega_j{}^{\sigma\gamma} := -\omega_j{}^{\gamma\sigma}$ whenever $\sigma > \gamma$.

Now, let us consider the fibered product $\mathcal{E} \times_M \mathcal{C}$ ($\mathcal{E}\times\mathcal{C}$ for short) over M, between the bundles $\mathcal{E}$ and $\mathcal{C}$.

We apply to the study of the bundle $\mathcal{E}\times\mathcal{C} \to M$ and its sections the whole geometrical machinery developed in Refs. 1 and 2. Referring systematically to Refs. 1 and 2 for proofs, comments and notations, we outline here the main results, especially useful for the present purposes.

First of all, let $J_1(\mathcal{E}\times\mathcal{C}, M)$ be the first jet-bundle associated with $\mathcal{E}\times\mathcal{C} \to M$, referred to jet-coordinates x^i, e_i^μ, $\omega_i{}^{\mu\nu}$, $e_{ij}^\mu (\simeq \partial e_i^\mu / \partial x^j)$, $\omega_{ij}{}^{\mu\nu} (\simeq \partial \omega_i{}^{\mu\nu} / \partial x^j)$. The latter are subject to the transformation laws (2.1) and (2.3) together with

$$\overline{e}_{jk}^\mu = e_{ih}^\sigma \frac{\partial x^h}{\partial \overline{x^k}}\Lambda^\mu{}_\sigma \frac{\partial x^i}{\partial \overline{x^j}} + e_i^\sigma \frac{\partial \Lambda^\mu{}_\sigma}{\partial x^h}\frac{\partial x^h}{\partial \overline{x^k}}\frac{\partial x^i}{\partial \overline{x^j}} + e_i^\sigma \Lambda^\mu{}_\sigma \frac{\partial^2 x^i}{\partial \overline{x^k}\partial \overline{x^j}} \tag{2.4a}$$

and

$$\begin{aligned}\overline{\omega}_{ik}{}^{\mu\nu} = {} & \Lambda^\mu{}_\sigma\Lambda^\nu{}_\gamma \frac{\partial x^j}{\partial \overline{x^i}}\frac{\partial x^h}{\partial \overline{x^k}}\omega_{jh}{}^{\sigma\gamma} + \frac{\partial \Lambda^\mu{}_\sigma}{\partial x^h}\frac{\partial x^h}{\partial \overline{x^k}}\Lambda^\nu{}_\gamma \frac{\partial x^j}{\partial \overline{x^i}}\omega_j{}^{\sigma\gamma} + \Lambda^\mu{}_\sigma \frac{\partial \Lambda^\nu{}_\gamma}{\partial x^h}\frac{\partial x^h}{\partial \overline{x^k}}\frac{\partial x^j}{\partial \overline{x^i}}\omega_j{}^{\sigma\gamma} \\ & + \Lambda^\mu{}_\sigma\Lambda^\nu{}_\gamma \frac{\partial^2 x^j}{\partial \overline{x^k}\partial \overline{x^i}}\omega_j{}^{\sigma\gamma} + - \frac{\partial \Lambda_\sigma{}^\eta}{\partial x^s}\frac{\partial x^s}{\partial \overline{x^k}}\frac{\partial \Lambda^\mu{}_\eta}{\partial x^h}\frac{\partial x^h}{\partial \overline{x^i}}\eta^{\sigma\nu} - \Lambda_\sigma{}^\eta \frac{\partial^2 \Lambda^\mu{}_\eta}{\partial x^s \partial x^h}\frac{\partial x^s}{\partial \overline{x^k}}\frac{\partial x^h}{\partial \overline{x^i}}\eta^{\sigma\nu} \\ & - \Lambda_\sigma{}^\eta \frac{\partial \Lambda^\mu{}_\eta}{\partial x^h}\frac{\partial^2 x^h}{\partial \overline{x^k}\partial \overline{x^i}}\eta^{\sigma\nu}.\end{aligned} \tag{2.4b}$$

Following the main idea of Refs. 1 and 2, we introduce the following equivalence relation on the bundle $J_1(\mathcal{E}\times\mathcal{C}, M)$: Given two points $z = (x^i, e_i^\mu, \omega_i{}^{\mu\nu}, e_{ij}^\mu, \omega_{ij}{}^{\mu\nu})$ and $\hat{z} = (\hat{x}^i, \hat{e}_i^\mu, \hat{\omega}_i{}^{\mu\nu}, \hat{e}_{ij}^\mu, \hat{\omega}_{ij}{}^{\mu\nu}) \in J_1(\mathcal{E}\times\mathcal{C}, M)$, we set $z \sim \hat{z} \Leftrightarrow x^i = \hat{x}^i$, $e_i^\mu = \hat{e}_i^\mu$, $\omega_i{}^{\mu\nu} = \hat{\omega}_i{}^{\mu\nu}$, and $(e_{ij}^\mu - e_{ji}^\mu) = (\hat{e}_{ij}^\mu - \hat{e}_{ji}^\mu)$, $(\omega_{ij}{}^{\mu\nu} - \omega_{ji}{}^{\mu\nu}) = (\hat{\omega}_{ij}{}^{\mu\nu} - \hat{\omega}_{ji}{}^{\mu\nu})$ (the geometrical meaning of the above equivalence relation is explained in Ref. 2).

Transformation laws (2.1), (2.3), (2.4a), and (2.4b) ensure that the above equivalence relation is independent of the choice of local coordinates and, therefore, geometrically significant.

We denote by $\mathcal{J}(\mathcal{E}\times\mathcal{C})$ the quotient space $J_1(\mathcal{E}\times\mathcal{C}, M)/\sim$ and by $\rho : J_1(\mathcal{E}\times\mathcal{C}, M) \to \mathcal{J}(\mathcal{E}\times\mathcal{C})$ the corresponding canonical projection. We may refer $J_1(\mathcal{E}\times\mathcal{C}, M)$ to local $\mathcal{J}$-coordinates x^i, e_i^μ, $\omega_i{}^{\mu\nu}$, $E_{ij}^\mu := \frac{1}{2}(e_{ij}^\mu - e_{ji}^\mu)$, $\Omega_{ij}{}^{\mu\nu} := \frac{1}{2}(\omega_{ij}{}^{\mu\nu} - \omega_{ji}{}^{\mu\nu})$ $(i<j)$, whose transformation laws are given by Eqs. (2.1) and (2.3) together with

$$\overline{E}_{jk}^\mu = E_{ih}^\sigma \Lambda^\mu{}_\sigma \frac{\partial x^h}{\partial \overline{x^k}}\frac{\partial x^i}{\partial \overline{x^j}} + \frac{1}{2}e_i^\sigma \frac{\partial \Lambda^\mu{}_\sigma}{\partial x^h}\frac{\partial x^h}{\partial \overline{x^k}}\frac{\partial x^i}{\partial \overline{x^j}} - \frac{1}{2}e_i^\sigma \frac{\partial \Lambda^\mu{}_\sigma}{\partial x^h}\frac{\partial x^h}{\partial \overline{x^j}}\frac{\partial x^i}{\partial \overline{x^k}} \tag{2.5a}$$

and

$$\overline{\Omega}_{ik}{}^{\mu\nu} = \Lambda^{\mu}{}_{\sigma}\Lambda^{\nu}{}_{\gamma}\frac{\partial x^j}{\partial \overline{x}^i}\frac{\partial x^h}{\partial \overline{x}^k}\Omega_{jh}{}^{\sigma\gamma} + \frac{1}{2}\frac{\partial \Lambda^{\mu}{}_{\sigma}}{\partial x^h}\frac{\partial x^h}{\partial \overline{x}^k}\Lambda^{\nu}{}_{\gamma}\frac{\partial x^j}{\partial \overline{x}^i}\omega_j{}^{\sigma\gamma} - \frac{1}{2}\frac{\partial \Lambda^{\mu}{}_{\sigma}}{\partial x^h}\frac{\partial x^h}{\partial \overline{x}^i}\Lambda^{\nu}{}_{\gamma}\frac{\partial x^j}{\partial \overline{x}^k}\omega_j{}^{\sigma\gamma}$$
$$+ \frac{1}{2}\Lambda^{\mu}{}_{\sigma}\frac{\partial \Lambda^{\nu}{}_{\gamma}}{\partial x^h}\frac{\partial x^h}{\partial \overline{x}^k}\frac{\partial x^j}{\partial \overline{x}^i}\omega_j{}^{\sigma\gamma} - \frac{1}{2}\Lambda^{\mu}{}_{\sigma}\frac{\partial \Lambda^{\nu}{}_{\gamma}}{\partial x^h}\frac{\partial x^h}{\partial \overline{x}^i}\frac{\partial x^j}{\partial \overline{x}^k}\omega_j{}^{\sigma\gamma} - \frac{1}{2}\frac{\partial \Lambda_{\sigma}{}^{\eta}}{\partial x^s}\frac{\partial x^s}{\partial \overline{x}^k}\frac{\partial \Lambda^{\mu}{}_{\eta}}{\partial x^h}\frac{\partial x^h}{\partial \overline{x}^i}\eta^{\sigma\nu}$$
$$+ \frac{1}{2}\frac{\partial \Lambda_{\sigma}{}^{\eta}}{\partial x^s}\frac{\partial x^s}{\partial \overline{x}^i}\frac{\partial \Lambda^{\mu}{}_{\eta}}{\partial x^h}\frac{\partial x^h}{\partial \overline{x}^k}\eta^{\sigma\nu}, \tag{2.5b}$$

with the identifications $E^{\mu}_{ij}=-E^{\mu}_{ji}$ and $\Omega_{ij}{}^{\mu\nu}=-\Omega_{ji}{}^{\mu\nu}$ (implicitly understood) whenever $i>j$.

Still following Refs. 1 and 2, we may endow the affine bundle $\mathcal{J}(\mathcal{E}\times\mathcal{C})\to\mathcal{E}\times\mathcal{C}$ with the following geometrical structures, reproducing some standard results of jet-bundle geometry in $\mathcal{J}(\mathcal{E}\times\mathcal{C})$:

• *$\mathcal{J}$-extension of sections*. Given a (local) section $\sigma: M\to\mathcal{E}\times\mathcal{C}$, we define its *$\mathcal{J}$-extension* $\mathcal{J}\sigma: M\to\mathcal{J}(\mathcal{E}\times\mathcal{C})$ as $\mathcal{J}\sigma := \rho\circ j_1\sigma$, $j_1\sigma: M\to j_1(\mathcal{E}\times\mathcal{C}, M)$ denoting the standard first jet-extension of σ.

Any section $\gamma: M\to\mathcal{J}(\mathcal{E}\times\mathcal{C})$ is said *holonomic* if there exists a section $\sigma: M\to\mathcal{E}\times\mathcal{C}$ such that $\gamma=\mathcal{J}\sigma$. Every holonomic section γ is then expressed locally as $\gamma: x\to\big(x^i, e^{\mu}_i(x), \omega_i{}^{\mu\nu}(x), E^{\mu}_{ij}(x) = \frac{1}{2}(\partial e^{\mu}_i(x)/\partial x^j - \partial e^{\mu}_j(x)/\partial x^i), \Omega_{ij}{}^{\mu\nu}(x) = \frac{1}{2}(\partial\omega_i{}^{\mu\nu}(x)/\partial x^j - \partial\omega_j{}^{\mu\nu}(x)/\partial x^i)\big)$.

• *Contact forms*. We may introduce in $\mathcal{J}(\mathcal{E}\times\mathcal{C})$ the concept of contact form by defining the following two-forms

$$\theta^{\mu} := de^{\mu}_j\wedge dx^j + E^{\mu}_{ij}dx^i\wedge dx^j, \quad \theta^{\mu\nu} := d\omega_j{}^{\mu\nu}\wedge dx^j + \Omega_{ij}{}^{\mu\nu}dx^i\wedge dx^j, \quad \mu,\nu = 1,\ldots,4. \tag{2.6}$$

It is easily seen that the behavior of the two-forms (2.6) under changes of coordinates (2.1), (2.3), and (2.5) is given by the equations

$$\overline{\theta^{\mu}} := d\overline{e}^{\mu}_j\wedge d\overline{x}^j + \overline{E}^{\mu}_{ij}d\overline{x}^i\wedge d\overline{x}^j = \Lambda^{\mu}_{\sigma}\theta^{\sigma} \tag{2.7a}$$

and

$$\overline{\theta^{\mu\nu}} := d\overline{\omega}^{\mu\nu}_j\wedge d\overline{x}^j + \overline{\Omega}^{\mu\nu}_{ij}d\overline{x}^i\wedge d\overline{x}^j = \Lambda^{\mu}_{\sigma}\Lambda^{\nu}_{\gamma}\theta^{\sigma\gamma}, \tag{2.7b}$$

showing the invariance of the module generated locally by the two-forms (2.6). The bundle spanned locally by the forms (2.6) is called *contact bundle* over $\mathcal{J}(\mathcal{E}\times\mathcal{C})$ and it is denoted by $\mathcal{C}(\mathcal{J}(\mathcal{E}\times\mathcal{C}))$; every section $\eta: \mathcal{J}(\mathcal{E}\times\mathcal{C})\to\mathcal{C}(\mathcal{J}(\mathcal{E}\times\mathcal{C}))$ is called a *contact two-form* on $\mathcal{J}(\mathcal{E}\times\mathcal{C})$. As it happens for standard jet-bundles, the contact forms (2.6) characterize the holonomic sections of $\mathcal{J}(\mathcal{E}\times\mathcal{C})\to M$, namely

Proposition 2.1: A section $\gamma: M\to\mathcal{J}(\mathcal{E}\times\mathcal{C})$ is holonomic if and only if $\gamma^*(\theta^{\mu})=0$ and $\gamma^*(\theta^{\mu\nu})=0\ \forall\,\mu,\nu=1,\ldots,4$.

• *$\mathcal{J}$-prolongation of morphisms*. We want to construct a sort of $\mathcal{J}$-prolongation for bundle morphisms Φ of $\mathcal{E}\times\mathcal{C}$

$$\begin{array}{ccc} \mathcal{E}\times\mathcal{C} & \xrightarrow{\ \Phi\ } & \mathcal{E}\times\mathcal{C} \\ \downarrow & & \downarrow \\ M & \xrightarrow{\ \chi\ } & M \end{array}$$

projecting to diffeomorphisms χ of M. As we shall see, this is possible for a particular family of bundle morphisms only, but general enough for our purposes.

Once again borrowing from Ref. 1, we start by singling out those bundle morphisms (Φ,χ) whose ordinary jet-prolongations $j_1\Phi$ on $J_1(\mathcal{E}\times\mathcal{C}, M)$ satisfy the requirement

$$\rho \circ j_1\Phi(w_1) = \rho \circ j_1\Phi(\omega_2) \quad \forall\, w_1, w_2 \in \rho^{-1}(z), \tag{2.8}$$

for any $z \in \mathcal{J}(\mathcal{E}\times\mathcal{C})$. In a local chart, we may repeat the same arguments stated in Ref. 1 and end up with the conclusion that the most general bundle morphism (ϕ, χ) satisfying the ansatz (2.8) has necessarily the local form

$$y^i = \chi^i(x),$$

$$b_i^\nu = \Phi_i^\nu(x,e,\omega) = \Gamma_\mu^\nu(x)\frac{\partial x^r}{\partial y^i}e_r^\mu + \Gamma_{\gamma\eta}^\mu(x)\frac{\partial x^r}{\partial y^i}\omega_r{}^{\gamma\eta} + f_i^\nu(x), \tag{2.9}$$

$$\eta_i{}^{\nu\gamma} = \Phi_i{}^{\nu\gamma}(x,e,\omega) = \Gamma_\mu^{\nu\gamma}(x)\frac{\partial x^r}{\partial y^i}e_r^\mu + \Gamma_{\mu\sigma}^{\nu\gamma}(x)\frac{\partial x^r}{\partial y^i}\omega_r{}^{\mu\sigma} + f_i{}^{\nu\gamma}(x),$$

where $\Gamma_\mu^\nu(x)$, $\Gamma_{\gamma\eta}^\nu(x)$, $\Gamma_\mu^{\nu\gamma}(x)$, $\Gamma_{\mu\sigma}^{\nu\gamma}(x)$, $f_i^\nu(x)$, and $f_i{}^{\nu\gamma}(x)$ are arbitrary local functions on M (with $\Gamma_{\gamma\eta}^\nu = -\Gamma_{\eta\gamma}^\nu$ and $\Gamma_{\mu\sigma}^{\nu\gamma} = -\Gamma_{\sigma\mu}^{\nu\gamma}$). Moreover, a direct calculation shows that the characterization (2.9) is invariant under changes of coordinates (2.1) and (2.3), and then geometrically well set. Indeed, it is easily seen that the formal expressions (2.9) transform as

$$\overline{y^i} = \overline{\chi}^i(\overline{x}),$$

$$\overline{b_i^\nu} = \overline{\Gamma}_\mu^\nu(\overline{x})\frac{\partial \overline{x^r}}{\partial \overline{y^i}}\overline{e_r^\mu} + \overline{\Gamma}_{\gamma\eta}^\nu(\overline{x})\frac{\partial \overline{x^r}}{\partial \overline{y^i}}\overline{\omega_r}^{\gamma\eta} + \overline{f_i^\nu}(\overline{x}),$$

$$\overline{\eta_i}^{\nu\gamma} = \overline{\Gamma}_\mu^{\nu\gamma}(\overline{x})\frac{\partial \overline{x^r}}{\partial \overline{y^i}}\overline{e_r^\mu} + \overline{\Gamma}_{\mu\sigma}^{\nu\gamma}(\overline{x})\frac{\partial \overline{x^r}}{\partial \overline{y^i}}\overline{\omega_r}^{\mu\sigma} + \overline{f_i}^{\nu\gamma}(\overline{x}),$$

where

$$\overline{\Gamma}_\mu^\nu(\overline{x}) := \Gamma^\lambda_{\eta|x(\overline{x})}\Lambda^\nu{}_{\lambda|\chi(x(\overline{x}))}\Lambda_\mu{}^\eta{}_{|\overline{x}},$$

$$\overline{\Gamma}_{\gamma\eta}^\nu(\overline{x}) := \Gamma^\sigma_{\mu\rho|x(\overline{x})}\Lambda^\nu{}_{\sigma|\chi(x(\overline{x}))}\Lambda_\eta{}^\rho{}_{|\overline{x}}\Lambda_\gamma{}^\mu{}_{|\overline{x}},$$

$$\overline{f_i^\nu}(\overline{x}) := \frac{\partial x^j}{\partial \overline{x^i}}f^\lambda_{j|x(\overline{x})}\Lambda^\nu{}_{\lambda|\chi(x(\overline{x}))} - \Lambda^\nu{}_{\sigma|\chi(x(\overline{x}))}\Gamma^\sigma_{\gamma\lambda|x(\overline{x})}\Lambda^\rho{}_{\mu|\overline{x}}\frac{\partial \Lambda_\rho{}^\gamma}{\partial \overline{x^k}}{}_{|\overline{x}}\frac{\partial \overline{x^k}}{\partial \overline{y^i}}\eta^{\mu\lambda},$$

$$\overline{\Gamma}_\mu^{\nu\gamma}(\overline{x}) := \Gamma^{\lambda\tau}_{\sigma\ |x(\overline{x})}\Lambda^\nu{}_{\lambda|\chi(x(\overline{x}))}\Lambda^\gamma{}_{\tau|\chi(x(\overline{x}))}\Lambda_\mu{}^\sigma{}_{|\overline{x}},$$

$$\overline{\Gamma}_{\mu\sigma}^{\nu\gamma}(\overline{x}) := \Lambda^\nu{}_{\rho|\chi(x(\overline{x}))}\Lambda^\gamma{}_{\eta|\chi(x(\overline{x}))}\Gamma^{\rho\eta}_{\beta\alpha|x(\overline{x})}\Lambda_\mu{}^\beta{}_{|\overline{x}}\Lambda_\sigma{}^\alpha{}_{|\overline{x}},$$

and

$$\overline{f_i}^{\nu\gamma}(\overline{x}) := \Lambda^\nu{}_{\rho|\chi(x(\overline{x}))}\Lambda^\gamma{}_{\eta|\chi(x(\overline{x}))}\left[-\Gamma^{\rho\eta}_{\beta\alpha|x(\overline{x})}\frac{\partial \overline{x^h}}{\partial \overline{y^i}}\Lambda^\mu{}_{\sigma|\overline{x}}\frac{\partial \Lambda_\mu{}^\beta}{\partial \overline{x^h}}{}_{|\overline{x}}\eta^{\sigma\alpha} + \frac{\partial x^j}{\partial \overline{x^i}}f_j{}^{\rho\eta}\right]$$
$$-\Lambda_\sigma{}^\mu{}_{|\chi(x(\overline{x}))}\frac{\partial \Lambda^\nu{}_\mu}{\partial x^h}{}_{|\chi(x(\overline{x}))}\frac{\partial x^h}{\partial \overline{x^j}}\eta^{\sigma\gamma},$$

thus proving the required invariance.

Condition (2.8) being satisfied, given any bundle morphism (2.9) we may define its

$\mathcal{J}$-prolongation $\mathcal{J}\Phi:\mathcal{J}(\mathcal{E}\times\mathcal{C})\to\mathcal{J}(\mathcal{E}\times\mathcal{C})$ as

$$\mathcal{J}\Phi(z) \coloneqq \rho\circ j_1\Phi(w) \quad \forall\, w\in\rho^{-1}(z), z\in\mathcal{J}(\mathcal{E}\times\mathcal{C})$$

In local coordinates, the explicit expression of $\mathcal{J}\Phi$ is given by (see Ref. 1 for details)

$$\mathcal{J}\Phi:\begin{cases} y^i=\chi^i(x) \\ b_i^\nu=\Gamma_\mu^\nu(x)\dfrac{\partial x^r}{\partial y^i}e_r^\mu+\Gamma_{\gamma\eta}^\nu(x)\dfrac{\partial x^r}{\partial y^i}\omega_r{}^{\gamma\eta}+f_i^\nu(x) \\ \eta_i^{\nu\gamma}=\Gamma_\mu^{\nu\gamma}(x)\dfrac{\partial x^r}{\partial y^i}e_r^\mu+\Gamma_{\mu\sigma}^{\nu\gamma}(x)\dfrac{\partial x^r}{\partial y^i}\omega_r{}^{\mu\sigma}+f_i{}^{\nu\gamma}(x) \\ B_{ij}^\nu=(\Gamma_\mu^\nu E_{ks}^\mu+\Gamma_{\sigma\gamma}^\nu\Omega_{ks}^{\sigma\gamma})\dfrac{\partial x^k}{\partial y^i}\dfrac{\partial x^s}{\partial y^j}+\dfrac{1}{2}\Bigg[\dfrac{\partial\Gamma_\mu^\nu}{\partial x^k}\left(\dfrac{\partial x^k}{\partial y^j}\dfrac{\partial x^r}{\partial y^i}-\dfrac{\partial x^k}{\partial y^i}\dfrac{\partial x^r}{\partial y^j}\right)e_r^\mu \\ \quad+\dfrac{\partial\Gamma_{\sigma\gamma}^\nu}{\partial x^k}\left(\dfrac{\partial x^k}{\partial y^j}\dfrac{\partial x^r}{\partial y^i}-\dfrac{\partial x^k}{\partial y^i}\dfrac{\partial x^r}{\partial y^j}\right)\omega_r{}^{\sigma\gamma}+\dfrac{\partial f_i^\nu}{\partial x^k}\dfrac{\partial x^k}{\partial y^j}-\dfrac{\partial f_j^\nu}{\partial x^k}\dfrac{\partial x^k}{\partial y^i}\Bigg] \\ \Delta_{ij}{}^{\nu\gamma}=(\Gamma_\mu^{\nu\gamma}E_{ks}^\mu+\Gamma_{\mu\sigma}^{\nu\gamma}\Omega_{ks}{}^{\mu\sigma})\dfrac{\partial x^k}{\partial y^i}\dfrac{\partial x^s}{\partial y^j}+\dfrac{1}{2}\Bigg[\dfrac{\partial\Gamma_{\mu\sigma}^{\nu\gamma}}{\partial x^k}\left(\dfrac{\partial x^k}{\partial y^j}\dfrac{\partial x^r}{\partial y^i}-\dfrac{\partial x^k}{\partial y^i}\dfrac{\partial x^r}{\partial y^j}\right)\omega_r{}^{\mu\sigma} \\ \quad+\dfrac{\partial\Gamma_\mu^{\nu\gamma}}{\partial x^k}\left(\dfrac{\partial x^k}{\partial y^j}\dfrac{\partial x^r}{\partial y^i}-\dfrac{\partial x^k}{\partial y^i}\dfrac{\partial x^r}{\partial y^j}\right)e_r^\mu+\dfrac{\partial f_i{}^{\nu\gamma}}{\partial x^k}\dfrac{\partial x^k}{\partial y^j}-\dfrac{\partial f_j{}^{\nu\gamma}}{\partial x^k}\dfrac{\partial x^k}{\partial y^i}\Bigg] \end{cases}.$$

As it happens for standard jet-prolongations in ordinary jet-bundles,[16] $\mathcal{J}$-prolongations are characterized by the property of preserving contact forms and $\mathcal{J}$-extensions. More precisely we have

Proposition 2.2: A bundle automorphism (Ψ,χ) *of* $\mathcal{J}(\mathcal{E}\times\mathcal{C})\to M$ *satisfies* $\Psi^*(\eta)\in Span\{\theta^\sigma,\theta^{\sigma\nu};\ \sigma,\nu=1,\dots,4\}\,\forall\,\eta\in Span\{\theta^\sigma,\theta^{\sigma\nu};\ \sigma,\nu=1,\dots,4\}\Leftrightarrow\Psi=\mathcal{J}\Phi$ *for some bundle morphism* (Φ,χ) *of* $\mathcal{E}\times\mathcal{C}\to M$.

Proposition 2.3: Given a bundle automorphism (Ψ,χ) *of* $\mathcal{J}(\mathcal{E}\times\mathcal{C})\to M$, *one has* $\Psi\circ\mathcal{J}\sigma\circ\chi^{-1}$ *is a* $\mathcal{J}$*-extension for every section* $\sigma:\mathcal{E}\times\mathcal{C}\to M\Leftrightarrow\Psi=\mathcal{J}\Phi$ *for some bundle morphism* (Φ,χ) *of* $\mathcal{E}\times\mathcal{C}\to M$.

The proofs of the above Propositions are strictly analogous to the corresponding ones given in Ref. 1 and will be omitted.

• *$\mathcal{J}$-prolongation of vector fields*. As made for bundle morphisms, we want to define a sort of $\mathcal{J}$-prolongation for vector fields X on $\mathcal{E}\times\mathcal{C}$, projecting to M.

To this end, still following Ref. 1, we first single out those vector fields X on $\mathcal{E}\times\mathcal{C}$, projecting to M, whose first jet-prolongations $J_1(X)$ on $J_1(\mathcal{E}\times\mathcal{C},M)$ pass to the quotient $\mathcal{J}(\mathcal{E}\times\mathcal{C})$.

Indeed, given any such vector field X, it is well defined the *$\mathcal{J}$-prolongation* $\mathcal{J}(X):\mathcal{J}(\mathcal{E}\times\mathcal{C})\to T\mathcal{J}(\mathcal{E}\times\mathcal{C})$ as

$$\mathcal{J}(X)(z) \coloneqq \rho_{*\rho^{-1}(z)}(j_1(X)) \quad \forall\, z\in\mathcal{J}(\mathcal{E}\times\mathcal{C}), \tag{2.10}$$

amounting to taking the standard first jet-prolongation $J_1(X)$ and to projecting it on $\mathcal{J}(\mathcal{E}\times\mathcal{C})$.

Proceeding as in Ref. 1, we may conclude that the most general vector field satisfying the required ansatz is expressed locally as

$$X=\epsilon^i(x)\frac{\partial}{\partial x^i}+\left(-\frac{\partial\epsilon^k}{\partial x^q}e_k^\mu+D_\nu^\mu(x)e_q^\mu+D_{\gamma\sigma}^\mu(x)\omega_q{}^{\gamma\sigma}+G_q^\mu(x)\right)\frac{\partial}{\partial e_q^\mu}+\sum_{\mu<\nu}\left(-\frac{\partial\epsilon^k}{\partial x^q}\omega_k{}^{\mu\nu}+D_\sigma^{\mu\nu}(x)e_q^\sigma\right.$$
$$\left.+D_{\gamma\sigma}^{\mu\nu}(x)\omega_q{}^{\gamma\sigma}+G_q{}^{\mu\nu}(x)\right)\frac{\partial}{\partial\omega_q{}^{\mu\nu}}, \tag{2.11}$$

where $\epsilon^i(x)$, $D_\nu^\mu(x)$, $D_{\gamma\sigma}^\mu(x)$, $G_q^\mu(x)$, $D_\sigma^{\mu\nu}(x)$, $D_{\gamma\sigma}^{\mu\nu}(x)$, and $G_q{}^{\mu\nu}(x)$ are arbitrary local functions on M (with $D_{\gamma\sigma}^\mu=-D_{\sigma\gamma}^\mu$ and $D_{\gamma\sigma}^{\mu\nu}=-D_{\sigma\gamma}^{\mu\nu}$). A straightforward check shows that the representations (2.11)

are invariant under changes of coordinates (2.1) and (2.3). In fact, it is easily seen that they undergo the transformation law

$$X = \overline{\epsilon}^i \frac{\partial}{\partial \overline{x}^i} + \left(- \frac{\partial \overline{\epsilon}^k}{\partial \overline{x}^q} \overline{e}_k^\mu + \overline{D}_\nu^\mu \overline{e}_q^\nu + \overline{D}_{\gamma\sigma}^\mu \overline{\omega}_q{}^{\gamma\sigma} + \overline{G}_q^\mu \right) \frac{\partial}{\partial \overline{e}_q^\mu} + \sum_{\mu<\nu} \left(- \frac{\partial \overline{\epsilon}^k}{\partial \overline{x}^q} \overline{\omega}_k{}^{\mu\nu} + \overline{D}_\sigma^{\mu\nu} \overline{e}_q^\sigma + \overline{D}_{\gamma\sigma}^{\mu\nu} \overline{\omega}_q{}^{\gamma\sigma} + \overline{G}_q{}^{\mu\nu} \right) \frac{\partial}{\partial \overline{\omega}_q{}^{\mu\nu}},$$

where

$$\overline{\epsilon}^i := \epsilon^k \frac{\partial \overline{x}^i}{\partial x^k},$$

$$\overline{D}_\nu^\mu := D_\rho^\eta \Lambda_\nu{}^\rho \Lambda^\mu{}_\eta + \Lambda_\nu{}^\eta \epsilon^i \frac{\partial \Lambda^\mu{}_\eta}{\partial x^i},$$

$$\overline{D}_{\gamma\sigma}^\mu := D_{\xi\nu}^\eta \Lambda^\mu{}_\eta \Lambda_\gamma{}^\xi \Lambda_\sigma{}^\nu,$$

$$\overline{G}_q^\mu := G_j^\nu \frac{\partial x^j}{\partial \overline{x}^q} \Lambda^\mu{}_\nu - D_{\gamma\sigma}^\eta \Lambda^\xi{}_\nu \frac{\partial \Lambda_\xi{}^\gamma}{\partial \overline{x}^q} \eta^{\nu\sigma} \Lambda^\mu{}_\eta,$$

$$\overline{D}_\sigma^{\mu\nu} := D_\eta^{\alpha\beta} \Lambda_\sigma{}^\eta \Lambda^\mu{}_\alpha \Lambda^\nu{}_\beta,$$

$$\overline{D}_{\gamma\sigma}^{\mu\nu} := \left[\xi^i \frac{\partial (\Lambda^\mu{}_\alpha \Lambda^\nu{}_\beta)}{\partial x^i} + \Lambda^\mu{}_\rho \Lambda^\nu{}_\eta D_{\alpha\beta}^{\rho\eta} \right] \Lambda_\gamma{}^\alpha \Lambda_\sigma{}^\beta,$$

and

$$\overline{G}_q{}^{\mu\nu} := G_j{}^{\alpha\beta} \Lambda^\mu{}_\alpha \Lambda^\nu{}_\beta \frac{\partial x^j}{\partial \overline{x}^q} - \xi^i \frac{\partial}{\partial x^i} \left(\Lambda_\rho{}^\eta \frac{\partial \Lambda^\mu{}_\eta}{\partial \overline{x}^q} \eta^{\rho\nu} \right) - \frac{\partial \overline{\xi}^h}{\partial \overline{x}^q} \Lambda_\rho{}^\eta \frac{\partial \Lambda^\mu{}_\eta}{\partial \overline{x}^h} \eta^{\rho\nu} - \left[\xi^i \frac{\partial (\Lambda^\mu{}_\alpha \Lambda^\nu{}_\beta)}{\partial x^i} + \Lambda^\mu{}_\rho \Lambda^\nu{}_\eta D_{\alpha\beta}^{\rho\eta} \right] \Lambda^\lambda{}_\gamma \frac{\partial \Lambda_\lambda{}^\alpha}{\partial \overline{x}^q} \eta^{\gamma\beta}.$$

Still referring to Ref. 1 for details, in local coordinates we have the explicit expression

$$\mathcal{J}(X) = \epsilon^i \frac{\partial}{\partial x^i} + \left(- \frac{\partial \epsilon^k}{\partial x^q} e_k^\mu + D_\nu^\mu e_q^\nu + D_{\gamma\sigma}^\mu \omega_q{}^{\gamma\sigma} + G_q^\mu \right) \frac{\partial}{\partial e_q^\mu} + \sum_{\mu<\nu} \left(- \frac{\partial \epsilon^k}{\partial x^q} \omega_k{}^{\mu\nu} + D_\sigma^{\mu\nu} e_q^\sigma + D_{\gamma\sigma}^{\mu\nu} \omega_q{}^{\gamma\sigma} + G_q{}^{\mu\nu} \right) \frac{\partial}{\partial \omega_q{}^{\mu\nu}} + \sum_{i<j} h_{ij}^\mu \frac{\partial}{\partial E_{ij}^\mu} + \sum_{\mu<\nu} \sum_{i<j} h_{ij}{}^{\mu\nu} \frac{\partial}{\partial \Omega_{ij}{}^{\mu\nu}}, \tag{2.12}$$

where

$$h_{ij}^\mu := \frac{1}{2} \left(\frac{\partial D_\nu^\mu}{\partial x^j} e_i^\nu - \frac{\partial D_\nu^\mu}{\partial x^i} e_j^\nu + \frac{\partial D_{\sigma\gamma}^\mu}{\partial x^j} \omega_i{}^{\sigma\gamma} - \frac{\partial D_{\sigma\gamma}^\mu}{\partial x^i} \omega_j{}^{\sigma\gamma} + \frac{\partial G_i^\mu}{\partial x^j} - \frac{\partial G_j^\mu}{\partial x^i} \right) + D_\nu^\mu E_{ij}^\nu + D_{\sigma\gamma}^\mu \Omega_{ij}{}^{\sigma\gamma} + \left(E_{ki}^\mu \frac{\partial \epsilon^k}{\partial x^j} - E_{kj}^\mu \frac{\partial \epsilon^k}{\partial x^i} \right),$$

and

$$h_{ij}{}^{\mu\nu} := \frac{1}{2}\left(\frac{\partial D_\sigma^{\mu\nu}}{\partial x^j} e_i^\sigma - \frac{\partial D_\sigma^{\mu\nu}}{\partial x^i} e_j^\sigma + \frac{\partial D_{\gamma\sigma}^{\mu\nu}}{\partial x^j} \omega_i{}^{\gamma\sigma} - \frac{\partial D_{\gamma\sigma}^{\mu\nu}}{\partial x^i} \omega_j{}^{\gamma\sigma} + \frac{\partial G_i{}^{\mu\nu}}{\partial x^j} - \frac{\partial G_j{}^{\mu\nu}}{\partial x^i} \right) + D_\sigma^{\mu\nu} E_{ij}^\sigma + D_{\sigma\gamma}^{\mu\nu} \Omega_{ij}{}^{\sigma\gamma}$$
$$+ \left(\Omega_{ki}{}^{\mu\nu} \frac{\partial \epsilon^k}{\partial x^j} - \Omega_{kj}{}^{\mu\nu} \frac{\partial \epsilon^k}{\partial x^i} \right).$$

According to ordinary jet-prolongations,[16] $\mathcal{J}$-prolongations (2.10) are characterized by preserving contact forms and are a Lie algebra. More specifically, we have the following (see Ref. 1 for proofs).

Proposition 2.4: Let $\pi: \mathcal{J}(\mathcal{E}\times\mathcal{C}) \to \mathcal{E}\times\mathcal{C}$ denote the natural projection. Given a vector field Y on $\mathcal{J}(\mathcal{E}\times\mathcal{C})$, projectable on $\mathcal{E}\times\mathcal{C}$, such that its projection $X(z) := \pi_{*\pi^{-1}(z)}(Y)$ $(\forall z \in \mathcal{E}\times\mathcal{C})$ defines a vector field on $\mathcal{E}\times\mathcal{C}$ of the form (2.11), then

$$Y = \mathcal{J}(X) \Leftrightarrow L_Y\theta^\mu, L_Y\theta^{\mu\nu} \in Span\{\theta^\sigma, \theta^{\sigma\mu}; \sigma, \mu = 1, \ldots, 4\}$$

Corollary 2.1: The $\mathcal{J}$-prolongations (2.10) from a Lie algebra.

For later use, we introduce new fibered coordinates on $\mathcal{J}(\mathcal{E}\times\mathcal{C})$ of the form

$$x^i = x^i, \quad e_i^\mu = e_i^\mu, \quad \omega_i{}^{\mu\nu} = \omega_i{}^{\mu\nu}, \quad T_{ij}^\mu := 2E_{ji}^\mu + \omega_i{}^\mu{}_\nu e_j^\nu - \omega_j{}^\mu{}_\nu e_i^\nu \tag{2.13a}$$

and

$$R_{ij}{}^{\mu\nu} := 2\Omega_{ji}{}^{\mu\nu} + \tfrac{1}{2}(\omega_i{}^\mu{}_\lambda \omega_j{}^{\lambda\nu} - \omega_j{}^\mu{}_\lambda \omega_i{}^{\lambda\nu} - \omega_i{}^\nu{}_\lambda \omega_j{}^{\lambda\mu} + \omega_j{}^\nu{}_\lambda \omega_i{}^{\lambda\mu}), \tag{2.13b}$$

where $\omega_i{}^\mu{}_\nu := \omega_i{}^{\mu\sigma}\eta_{\sigma\nu}$. The idea is to take the components of the torsion tensor $T^\mu = de^\mu + \omega^\mu{}_\nu \wedge e^\nu$ and the curvature tensor $R^{\mu\nu} = d\omega^{\mu\nu} + \omega^\mu{}_\lambda \wedge \omega^{\lambda\nu}$ as $\mathcal{J}$-coordinates.

Taking Eqs. (2.1), (2.3), and (2.5) into account, it is a straightforward matter to verify the validity of the expected transformation laws

$$\overline{T}_{ij}^\mu = T_{hk}^\sigma \Lambda^\mu{}_\sigma \frac{\partial x^h}{\partial \overline{x}^i} \frac{\partial x^k}{\partial \overline{x}^j} \quad \text{and } \overline{R}_{ij}{}^{\mu\nu} = R_{hk}{}^{\sigma\gamma} \Lambda^\mu{}_\sigma \Lambda^\nu{}_\gamma \frac{\partial x^h}{\partial \overline{x}^i} \frac{\partial x^k}{\partial \overline{x}^j}. \tag{2.14}$$

Now, we define the following two-forms on $\mathcal{J}(\mathcal{E}\times\mathcal{C})$

$$T^\mu := \tfrac{1}{2} T_{ij}^\mu dx^i \wedge dx^j \quad \text{and } R^{\mu\nu} := \tfrac{1}{2} R_{ij}{}^{\mu\nu} dx^i \wedge dx^j, \tag{2.15}$$

henceforth referred to as the *torsion* and the *curvature* two-forms on $\mathcal{J}(\mathcal{E}\times\mathcal{C})$, respectively. In view of Eqs. (2.14), the latter undergo the transformation laws

$$\overline{T} = T^\sigma \Lambda^\mu{}_\sigma \quad \text{and } \overline{R}^{\mu\nu} = R^{\sigma\gamma} \Lambda^\mu{}_\sigma \Lambda^\nu{}_\gamma \tag{2.16}$$

showing the invariance of the module locally generated by the forms (2.15).

We conclude this section by introducing suitable bases of the tangent and cotangent bundles $T\mathcal{J}(\mathcal{E}\times\mathcal{C})$ and $T^*\mathcal{J}(\mathcal{E}\times\mathcal{C})$, respectively, which will be useful in the subsequent discussion. To this end, we preliminarily define the forms

$$\tau_i^\mu := de_i^\mu + \omega_j{}^\mu{}_\nu e_i^\nu dx^j \quad \text{and } \rho_i{}^{\mu\nu} := d\omega_i{}^{\mu\nu} + \tfrac{1}{2}(\omega_j{}^\mu{}_\lambda \omega_i{}^{\lambda\nu} - \omega_j{}^\nu{}_\lambda \omega_i{}^{\lambda\mu}) dx^j.$$

Then we choose the 1-forms

$$Dx^i := dx^i, \ \tau_i^\mu, \ \rho_i{}^{\mu\nu}, \ DT_{ij}^\mu := dT_{ij}^\mu + \omega_k{}^\mu{}_\lambda T_{ij}^\lambda dx^k \tag{2.17a}$$

and

$$DR_{ij}{}^{\mu\nu} := dR_{ij}{}^{\mu\nu} + \omega_k{}^\mu{}_\lambda R_{ij}{}^{\lambda\nu} dx^k - \omega_k{}^{\lambda\nu} R_{ij}{}^\mu{}_\lambda dx^k, \tag{2.17b}$$

as a local basis of $T^*\mathcal{J}(\mathcal{E}\times\mathcal{C})$; the vectors

$$\frac{D}{Dx^k} := \frac{\partial}{\partial x^k} - \omega_k{}^\mu{}_\nu e_i^\nu \frac{\partial}{\partial e_i^\mu} - \frac{1}{2}\omega_k{}^\mu{}_\lambda \omega_i{}^{\lambda\nu} \frac{\partial}{\partial \omega_i{}^{\mu\nu}} - \frac{1}{2}\omega_k{}^\mu{}_\lambda T_{ij}^\lambda \frac{\partial}{\partial T_{ij}^\mu}$$
$$+ \frac{1}{4}(-\omega_k{}^\mu{}_\lambda R_{ij}{}^{\lambda\nu} + \omega_k{}^{\lambda\nu} R_{ij}{}^\mu{}_\lambda) \frac{\partial}{\partial R_{ij}{}^{\mu\nu}}, \quad \frac{D}{De_i^\mu} := \frac{\partial}{\partial e_i^\mu}, \tag{2.18a}$$

$$\frac{D}{D\omega_i{}^{\mu\nu}} := \frac{\partial}{\partial \omega_i{}^{\mu\nu}}, \quad \frac{D}{DT_{ij}^\mu} := \frac{\partial}{\partial T_{ij}^\mu}, \quad \frac{D}{DR_{ij}{}^{\mu\nu}} := \frac{\partial}{\partial R_{ij}{}^{\mu\nu}},$$

form the local dual basis of $T\mathcal{J}(\mathcal{E}\times\mathcal{C})$.

We also notice that, if we set

$$\tau^\mu := \tau_i^\mu \wedge dx^i \text{ and } \rho^{\mu\nu} := \rho_i{}^{\mu\nu} \wedge dx^i, \tag{2.19}$$

then we can represent the contact forms as

$$\theta^\mu = \tau^\mu - T^\mu \quad \text{and} \quad \theta^{\mu\nu} = \rho^{\mu\nu} - R^{\mu\nu}. \tag{2.20}$$

III. THE FIELD EQUATIONS

In this section we shall derive the field equations of the theory from a variational principle.

To this end, we notice that a Lagrangian on $\mathcal{J}(\mathcal{E}\times\mathcal{C})$ is a horizontal four-form, locally expressed in terms of the coordinates (2.13) as

$$L = \mathcal{L}(x, e, \omega, T, R)ds, \tag{3.1}$$

with $ds := dx^1 \wedge dx^2 \wedge dx^3 \wedge dx^4$ and $\mathcal{L}$ is a scalar density.

Borrowing from Refs. 1 and 2, we associate with any Lagrangian (3.1) a corresponding Poincaré–Cartan four-form on $\mathcal{J}(\mathcal{E}\times\mathcal{C})$, locally described as

$$\Theta_L := \mathcal{L}ds - \tfrac{1}{2}\theta^\mu \wedge P_\mu - \tfrac{1}{4}\theta^{\mu\nu} \wedge P_{\mu\nu}, \tag{3.2}$$

where $P_\mu := (\partial\mathcal{L}/\partial T_{ij}^\mu)ds_{ij}$ and $P_{\mu\nu} := (\partial\mathcal{L}/\partial R_{ij}{}^{\mu\nu})ds_{ij}$ (with $ds_{ij} := \partial/\partial x^i \rfloor \partial/\partial x^j \rfloor ds$).

To every Lagrangian L we associate the action functional

$$A_L(\sigma) := \int_D \mathcal{J}\sigma^*(L) = \int_D \mathcal{J}\sigma^*(\Theta_L),$$

$\forall$ section $\sigma: D \subset M \to \mathcal{E}\times\mathcal{C}$, D compact domain.

Now, let Φ_ξ be a one-parameter group of $\mathcal{J}$-prolongable diffeomorphisms (2.9) on $\mathcal{E}\times\mathcal{C}$, projecting (for simplicity) on the identity map of M. Let X denote the infinitesimal generator of Φ_ξ; it follows that X is a $\mathcal{J}$-prolongable vector field (2.11) on $\mathcal{E}\times\mathcal{C}$, vertical with respect to the fibration $\mathcal{E}\times\mathcal{C}\to M$.

Given a section $\sigma: M \to \mathcal{E}\times\mathcal{C}$, we can deform it along X by setting $\sigma_\xi := \Phi_\xi \circ \sigma$; then we have $\mathcal{J}\sigma_\xi = \mathcal{J}(\Phi_\xi \circ \sigma) = \mathcal{J}\Phi_\xi \circ \mathcal{J}\sigma$.

We call *first variation* of A_L at σ in the direction X, the expression

$$\frac{\delta A_L}{\delta X}(\sigma) := \frac{d}{d\xi}\int_D \mathcal{J}\sigma_\xi^* \Theta_{L|_{\xi=0}} = \int_D \mathcal{J}\sigma^*(\mathcal{J}(X) \rfloor d\Theta_L) + \int_{\partial D} \mathcal{J}\sigma^*(\mathcal{J}(X) \rfloor \Theta_L). \tag{3.3}$$

In connection with this, a section σ is said *critical* if $\delta A_L/\delta X(\sigma) = 0$ for all compact domains D and all deformations $\mathcal{J}\sigma_\xi$ constant on the boundary ∂D. Due to this last condition at the boundary, it follows that a section σ is critical if and only if the equation

$$\mathcal{J}\sigma^*(\mathcal{J}(X)\rfloor d\Theta_L)=0 \tag{3.4}$$

holds true, for all $\mathcal{J}$-prolongable vector fields X.

In order to develop the calculations about Eq. (3.4), let us introduce the following differential operators acting on tensor-valued forms on $\mathcal{J}(\mathcal{E}\times\mathcal{C})$:

$$D\eta^\mu = d\eta^\mu + \omega_i{}^\mu{}_\nu dx^i\wedge\eta^\nu, \tag{3.5a}$$

$$D\eta_\mu = d\eta_\mu - \omega_i{}^\nu{}_\mu dx^i\wedge\eta_\nu, \tag{3.5b}$$

$$D\eta^\mu{}_\nu = d\eta^\mu{}_\nu + \omega_i{}^\mu{}_\lambda dx^i\wedge\eta^\lambda{}_\nu - \omega_i{}^\lambda{}_\nu dx^i\wedge\eta^\mu{}_\lambda, \tag{3.5c}$$

$$D\eta_\nu{}^\mu = d\eta_\nu{}^\mu - \omega_i{}^\lambda{}_\nu dx^i\wedge\eta_\lambda{}^\mu + \omega_i{}^\mu{}_\lambda dx^i\wedge\eta_\nu{}^\lambda. \tag{3.5d}$$

Making use of the bases (2.17) and taking Eqs. (2.20) and (3.5) as well as the identities $D\tau^\mu = \rho_j{}^{\mu\nu}\eta_{\nu\sigma}e_i^\sigma\wedge dx^j\wedge dx^i$, $D\rho^{\mu\nu}=0$, $(\partial\mathcal{L}/\partial T_{ij}^\mu)ds=\frac{1}{2}dx^j\wedge dx^i\wedge P_\mu$ and $(\partial\mathcal{L}/\partial R_{ij}{}^{\mu\nu})ds=\frac{1}{2}dx^j\wedge dx^i\wedge P_{\mu\nu}$ into account (we notice that the identities $D\tau^\mu=\rho_j{}^{\mu\nu}\eta_{\nu\sigma}e_i^\sigma\wedge dx^j$ and $D\rho^{\mu\nu}=0$ are nothing but a restatement of the Bianchi identities in the present geometrical setting), it is easily seen that

$$d\Theta_L = D\Theta_L = (D\mathcal{L}/De_i^\mu)\tau_i^\mu\wedge ds + \tfrac{1}{2}(D\mathcal{L}/D\omega_i{}^{\mu\nu})\rho_i{}^{\mu\nu}\wedge ds - (D\mathcal{L}/DT_{ji}^\mu)e_j^\sigma\eta_{\sigma\nu}\rho_i{}^{\mu\nu}\wedge ds - \tfrac{1}{2}\theta^\mu\wedge DP_\mu - \tfrac{1}{4}\theta^{\mu\nu}\wedge DP_{\mu\nu}.$$

Choosing infinitesimal deformations X of the special form

$$X = G_i^\mu(x)\frac{D}{De_i^\mu} + \frac{1}{2}G_i{}^{\mu\nu}(x)\frac{D}{D\omega_i{}^{\mu\nu}},$$

for simplicity, we have then

$$\mathcal{J}(X)\rfloor D\Theta_L = \frac{D\mathcal{L}}{De_i^\mu}G_i^\mu ds + \frac{1}{2}\frac{D\mathcal{L}}{D\omega_i{}^{\mu\nu}}G_i{}^{\mu\nu}ds - \frac{1}{2}G_i^{\mu\nu}\left(\frac{D\mathcal{L}}{DT_{ji}^\mu}e_j^\sigma\eta_{\sigma\nu} - \frac{D\mathcal{L}}{DT_{ji}^\nu}e_j^\sigma\eta_{\sigma\mu}\right)ds + \\ - \frac{1}{2}G_i^\mu dx^i\wedge DP_\mu - \frac{1}{4}G_i{}^{\mu\nu}dx^i\wedge DP_{\mu\nu} - \frac{1}{2}\theta^\mu\wedge\mathcal{J}(X)\rfloor DP_\mu - \frac{1}{4}\theta^{\mu\nu}\wedge\mathcal{J}(X)\rfloor DP_{\mu\nu}. \tag{3.6}$$

Pulling-back Eq. (3.6) through $\mathcal{J}\sigma$, we obtain the expression

$$\mathcal{J}\sigma^*(\mathcal{J}(X)\rfloor D\Theta_L) = G_i^\mu(x)\mathcal{J}\sigma^*\left(\frac{D\mathcal{L}}{De_i^\mu}ds - \frac{1}{2}dx^i\wedge DP_\mu\right) + \frac{1}{2}G_i{}^{\mu\nu}(x)\mathcal{J}\sigma^*\left(\frac{D\mathcal{L}}{D\omega_i{}^{\mu\nu}}ds - \frac{D\mathcal{L}}{DT_{ji}^\mu}e_j^\sigma\eta_{\sigma\nu}ds + \frac{D\mathcal{L}}{DT_{ji}^\nu}e_j^\sigma\eta_{\sigma\mu}ds - \frac{1}{2}dx^i\wedge DP_{\mu\nu}\right).$$

Due to the arbitrariness of X, by imposing the requirement (3.4), we get two sets of final equations

$$\mathcal{J}\sigma^*\left(\frac{D\mathcal{L}}{De_i^\mu} - D_k\frac{D\mathcal{L}}{DT_{ki}^\mu}\right)=0, \tag{3.7a}$$

$$\mathcal{J}\sigma^*\left(\frac{D\mathcal{L}}{D\omega_i{}^{\mu\nu}} - \frac{D\mathcal{L}}{DT_{ji}^\mu}e_j^\sigma\eta_{\sigma\nu} + \frac{D\mathcal{L}}{DT_{ji}^\nu}e_j^\sigma\eta_{\sigma\mu} - D_k\frac{D\mathcal{L}}{DR_{ki}{}^{\mu\nu}}\right)=0, \tag{3.7b}$$

representing the actual field equations of the theory.

In particular, if we consider the purely gravitational Lagrangian

$$L = \tfrac{1}{2} e_i^{\mu} dx^i \wedge e_j^{\nu} dx^j \wedge R^{\lambda\rho} \epsilon_{\mu\nu\lambda\rho} := \mathcal{L} ds, \tag{3.8}$$

where $\mathcal{L} := \frac{1}{4} e_i^{\mu} e_j^{\nu} R_{k\ell}{}^{\lambda\rho} \epsilon^{ijkl} \epsilon_{\mu\nu\lambda\rho}$, Eqs. (3.7) yield

$$\tfrac{1}{2} e_j^{\nu} R_{kl}{}^{\sigma\lambda} \epsilon^{ijkl} \epsilon_{\mu\nu\sigma\lambda} = 0, \tag{3.9a}$$

$$-2 D_k(e_p^{\sigma}) e_q^{\lambda} \epsilon^{pqki} \epsilon_{\sigma\lambda\mu\nu} = 0, \tag{3.9b}$$

where $D_k(e_p^{\sigma}) = \partial e_p^{\sigma} / \partial x^k + \omega_k{}^{\sigma}{}_{\lambda} e_p^{\lambda}$.

As is well known, (provided that $\det(e_i^{\mu}) \neq 0$) the theory described by Eqs. (3.9) is on-shell equivalent to Einstein's theory in empty space.

Joining together the present mathematical setting with that proposed in Refs. 1 and 2, we can develop a new geometrical approach to the combined theory of gravitational and Yang–Mills fields.

To this end, let $Q \to M$ be a principal fiber bundle over space–time, with structural group a semisimple Lie group G.

Principal connections of $Q \to M$ are additional dynamical fields; the latter may be represented as sections of the affine bundle $J_1 Q/G \to M$ (the space of principal connections), referred to local coordinates x^i, a_i^A, $A = 1, \ldots, r = \dim G$ (see Refs. 1 and 2 for more details).

The extended configuration space of the theory is the fibered product $\mathcal{E} \times_M \mathcal{C} \times_M J_1 Q/G$ ($\mathcal{E} \times \mathcal{C} \times J_1 Q/G$ for short) over M.

The construction of the associated quotient space $\mathcal{J}(\mathcal{E} \times \mathcal{C} \times J_1 Q/G)$ follows the lines illustrated in Refs. 1 and 2 and in the present paper too. Then, once again referring to Refs. 1 and 2 for comments and details, we recall that we can choose the components of the curvature tensor F_{ij}^A of the connection as $\mathcal{J}$-coordinates (together with T_{ij}^{μ} and $R_{ij}{}^{\mu\nu}$) on $\mathcal{J}(\mathcal{E} \times \mathcal{C} \times J_1 Q/G)$ [More precisely, if $A_{ij}^A \left(\simeq \frac{1}{2}(\partial a_i^A / \partial x^j - \partial a_j^A / \partial x^i)\right)$ are $\mathcal{J}$-coordinates on $\mathcal{J}(\mathcal{E} \times \mathcal{C} \times J_1 Q/G)$, then we have $F_{ij}^A := 2A_{ji}^A + a_j^B a_i^C C_{CB}^A$, C_{CB}^A being the structure coefficients of the Lie algebra of the group G.]

There are r further contact two-forms on $\mathcal{J}(\mathcal{E} \times \mathcal{C} \times J_1 Q/G)$, expressed as

$$\theta^A := da_i^A \wedge dx^i + A_{ij}^A dx^i \wedge dx^j = \Phi^A - F^A,$$

where $F^A := \frac{1}{2} F_{ij}^A dx^i \wedge dx^j$, $\Phi^A := \Phi_i^A \wedge dx^i$ with $\Phi_i^A := da_i^A + \frac{1}{2} a_i^B a_j^C C_{CB}^A dx^j$.

Also, we complete the bases (2.17) and (2.18) to local bases of $T\mathcal{J}(\mathcal{E} \times \mathcal{C} \times J_1 Q/G)$ and $T^* \mathcal{J}(\mathcal{E} \times \mathcal{C} \times J_1 Q/G)$, respectively, by introducing the vectors

$$\frac{D}{Dx^k} := \frac{\partial}{\partial x^k} - \omega_k{}^{\mu}{}_{\nu} e_i^{\nu} \frac{\partial}{\partial e_i^{\mu}} - \frac{1}{2} \omega_k{}^{\mu}{}_{\lambda} T_{ij}^{\lambda} \frac{\partial}{\partial T_{ij}^{\mu}} - \frac{1}{2} \omega_k{}^{\mu}{}_{\lambda} \omega_i{}^{\lambda\nu} \frac{\partial}{\partial \omega_i{}^{\mu\nu}} + \frac{1}{4} (-\omega_k{}^{\mu}{}_{\lambda} R_{ij}{}^{\lambda\nu} + \omega_k{}^{\lambda\nu} R_{ij}{}^{\mu}{}_{\lambda}) \frac{\partial}{\partial R_{ij}{}^{\mu\nu}}$$
$$+ \frac{1}{2} a_k^B a_i^C C_{CB}^A \frac{\partial}{\partial a_i^A} - \frac{1}{2} F_{ij}^B a_k^C C_{CB}^A \frac{\partial}{\partial F_{ij}^A}, \quad \frac{D}{Da_i^A} := \frac{\partial}{\partial a_i^A}, \quad \frac{D}{DF_{ij}^A} := \frac{\partial}{\partial F_{ij}^A},$$

and the forms

$$\Phi_i^A, \quad DF_{ij}^A := dF_{ij}^A + F_{ij}^B a_k^C C_{CB}^A dx^k.$$

The latter are consistent with the definition of the covariant differential operator D, acting on tensorial forms on $\mathcal{J}(\mathcal{E} \times \mathcal{C} \times J_1 Q/G)$ as

$$D\eta^A := d\eta^A + a_k^B dx^k \wedge \eta^C C_{BC}^A,$$

$$D\eta_A := d\eta_A - a_k^B dx^k \wedge \eta_C C_{BA}^C.$$

For the present case, a Lagrangian is then a horizontal four-form on $\mathcal{J}(\mathcal{E} \times \mathcal{C} \times J_1 Q/G)$, locally expressed as

$$L = \mathcal{L}(x,e,\omega,a,T,R,F)ds.$$

The corresponding Poincaré–Cartan form is given by

$$\Theta_L = \mathcal{L}ds - \tfrac{1}{2}\theta^{\mu} \wedge P_{\mu} - \tfrac{1}{4}\theta^{\mu\nu} \wedge P_{\mu\nu} - \tfrac{1}{2}\theta^{A} \wedge P_{A},$$

where $P_A := (\partial\mathcal{L}/\partial F^A_{ij})ds_{ij}$, and the ansatz

$$\mathcal{J}\sigma * (\mathcal{J}(X) \rfloor d\Theta_L) = 0,$$

for all $\mathcal{J}$-prolongable vector fields X on $\mathcal{E}\times\mathcal{C}\times J_1Q/G$, yields field equation of the form (3.7) together with (see Refs. 1 and 2)

$$\mathcal{J}\sigma * \left(\frac{\partial\mathcal{L}}{\partial a^A_i} - D_k \frac{\partial\mathcal{L}}{\partial F^A_{ki}} \right) = 0. \tag{3.10}$$

More in detail, in the theory of interacting gravitational and free Yang–Mills fields, the Lagrangian L is the sum of the purely gravitational Lagrangian (3.8) and of the free Yang–Mills one. Therefore, in the present geometrical framework, we have explicitly

$$L = \mathcal{L}ds := (\tfrac{1}{4}e^{\mu}_i e^{\nu}_j R_{kl}{}^{\lambda\rho}\varepsilon^{ijkl}\varepsilon_{\mu\nu\lambda\rho} - \tfrac{1}{4}F^A_{ij}F^B_{pq}\gamma_{AB}\eta^{\mu\nu}e^p_{\mu}e^i_{\nu}\eta^{\lambda\sigma}e^q_{\lambda}e^j_{\sigma}e)ds, \tag{3.11}$$

where $e := \det(e^{\mu}_i)$, e^i_{μ} denotes the inverse matrix of e^{μ}_i and γ_{AB} indicates the adjoint-invariant metric of the Lie algebra $\mathfrak{G}$ of the Lie group G.

Inserting expression (3.11) in Eqs. (3.7) and (3.10) as well as taking the identities $\partial e^j_{\nu}/\partial e^{\mu}_i = -e^j_{\mu}e^i_{\nu}$ and $\partial e/\partial e^{\mu}_i = ee^i_{\mu}$ into account, we get the final equations

$$\tfrac{1}{2}e^{\nu}_j R_{kl}{}^{\sigma\lambda}\varepsilon^{ijkl}\varepsilon_{\mu\nu\sigma\lambda} = -(F^{Ai}_j F^j_{Ak}e^k_{\mu} - \tfrac{1}{4}F^A_{jk}F^{jk}_A e^i_{\mu})e, \tag{3.12a}$$

$$-2D_k(e^{\sigma}_p)e^{\lambda}_q\epsilon^{pqki}\epsilon_{\sigma\lambda\mu\nu} = 0, \tag{3.12b}$$

$$D_k(F^{ik}_A e) = 0, \tag{3.12c}$$

where $F^{ij}_A := F^B_{kh}\gamma_{BA}\eta^{\mu\nu}e^k_{\mu}e^i_{\nu}\eta^{\sigma\lambda}e^h_{\sigma}e^j_{\lambda}$ and $D_k(F^{ik}_A e) = \partial(F^{ik}_A e)/\partial x^k - a^B_k(F^{ik}_C e)C^C_{BA}$.

In the right side of Eq. (3.12a) we recover the energy-momentum tensor $T^i_{\mu} := F^{Ai}_j F^j_{Ak}e^k_{\mu} - \frac{1}{4}F^A_{jk}F^{jk}_A e^i_{\mu}$ of the Yang–Mills field.

It is worth noticing that all the restrictions about the vector fields $\mathcal{J}(X)$ in Eq. (3.4) may be removed. In fact, it is easily seen that Eq. (3.4) automatically implies

$$\mathcal{J}\sigma * (X \rfloor d\Theta_L) = 0, \quad \forall\, X \in D^1(\mathcal{J}(\mathcal{E}\times\mathcal{C}\times J_1Q/G)). \tag{3.13}$$

As pointed out in Ref. 1, this remark plays an important role in the study of the relationships between Nöther vector fields and infinitesimal dynamical symmetries. This topic will be dealt with in the next Section.

IV. SYMMETRIES AND NOETHER THEOREM

The Poincaré–Cartan representation (3.13) of the field equations turns out to be especially useful in the study of symmetries and conserved quantities. To see this point, let us introduce the following[14,15]

Definition 4.1: A vector field Z on $\mathcal{J}(\mathcal{E}\times\mathcal{C}\times J_1Q/G)$ is called a generalized infinitesimal Lagrangian symmetry *if it satisfies the requirement*

$$L_Z(\mathcal{L}ds) = d\alpha, \tag{4.1}$$

for some $(m-1)$-form α on $\mathcal{J}(\mathcal{E}\times\mathcal{C}\times J_1Q/G)$.

Definition 4.1 extends the usual notion of Lagrangian symmetry. In fact, if the vector field Z satisfies $L_Z(\mathcal{L}ds)=0$ and projects to M, then we have

$$\mathcal{L} = \det\left|\frac{\partial \chi_s^i}{\partial x^j}\right| \mathcal{L}\circ\Psi_s \quad \forall\, s,$$

(Ψ_s,χ_s) denoting the flow of Z.

Definition 4.2: A vector field Z on $\mathcal{J}(\mathcal{E}\times\mathcal{C}\times J_1Q/G)$ is called a Noether vector field *if it satisfies the following condition*

$$L_Z\Theta_L = \omega + d\alpha, \tag{4.2}$$

where ω is a m-form belonging to the ideal generated by the contact forms and α is any $(m-1)$-form on $\mathcal{J}(E)$.

As above, if Z satisfies the trivial case $L_Z\Theta_L=0$ and projects to M, then Z is an infinitesimal dynamical symmetry. Indeed, in such a circumstance, denoting again by (Ψ_s,χ_s) the flow of Z, it is a straightforward matter to see that $\Psi_s^*\circ\mathcal{J}\sigma\circ\chi_{-s}^*$ is a critical section if $\mathcal{J}\sigma$ does.

Directly from Proposition 2.4 we derive

Proposition 4.1: If a generalized infinitesimal Lagrangian symmetry Z is a $\mathcal{J}$-prolongation of some vector field (2.11) *on $\mathcal{E}\times\mathcal{C}\times J_1Q/G$, then it is a Noether vector field.*

Also, we have

Proposition 4.2: If a Noether vector field Z is a $\mathcal{J}$-prolongation of some vector field (2.11) *on $\mathcal{E}\times\mathcal{C}\times J_1Q/G$, then it is an infinitesimal dynamical symmetry*. (See Ref. 1 for proofs.)

We can associate with any Noether vector field Z a corresponding conserved current, so restating a sort of Noether theorem in the present geometrical setting. In fact, given Z satisfying Eq. (4.2) and a critical section $\sigma: M\to\mathcal{E}\times\mathcal{C}\times J_1Q/G$, Eqs. (3.13) and (4.2) imply

$$d\mathcal{J}\sigma^*(Z\rfloor\Theta_L-\alpha) = \mathcal{J}\sigma^*(\omega - Z\rfloor d\Theta_L) = 0,$$

showing that the current $\mathcal{J}\sigma^*(Z\rfloor\Theta_L-\alpha)$ is conserved on shell.

As an example, let us consider once again the Lagrangian (3.11), expressing gravity coupled with a Yang–Mills field; the associated Poincaré–Cartan form is

$$\Theta_L = \mathcal{L}ds - \tfrac{1}{4}\theta^{\mu\nu}\wedge e_i^\sigma e_j^\lambda \varepsilon^{ijpq}\varepsilon_{\sigma\lambda\mu\nu}ds_{pq} + \tfrac{1}{2}\theta^A\wedge F_A^{ij}eds_{ij}.$$

As it is well known, diffeomorphisms, Lorentz transformations (for tetrad and connection) and gauge transformations (for the Yang–Mills field) are dynamical symmetries of the theory. We want to restate these results in the newer scheme.

To start with, let $Y=\xi^i(\partial/\partial x^i)$ be the generator of a (local) one parameter group of diffeomorphisms of M. The vector field Y may be "lifted" to vector fields X on $\mathcal{E}\times\mathcal{C}\times J_1Q/G$, by setting locally

$$X = \xi^i\frac{\partial}{\partial x^i} - \frac{\partial\xi^k}{\partial x^q}e_k^\mu\frac{\partial}{\partial e_q^\mu} - \frac{1}{2}\frac{\partial\xi^k}{\partial x^q}\omega_k{}^{\mu\nu}\frac{\partial}{\partial\omega_q{}^{\mu\nu}} - \frac{\partial\xi^k}{\partial x^q}a_k^A\frac{\partial}{\partial a_q^A}. \tag{4.3}$$

We stress that the procedure is not covariant but strictly depends on the local coordinates in which we are working. In any case, we show that vector fields having a local representation (4.3) are Noether vector fields and infinitesimal dynamical symmetries.

To this end, recalling Eq. (2.11), we notice that vector fields (4.3) are $\mathcal{J}$-prolongable; in connection with this, making use of Eq. (2.12), we easily get the local expression

$$\mathcal{J}(X) = \xi^i \frac{\partial}{\partial x^i} - \frac{\partial \xi^k}{\partial x^q} e_k^\mu \frac{\partial}{\partial e_q^\mu} - \frac{1}{2} \frac{\partial \xi^k}{\partial x^q} \omega_k{}^{\mu\nu} \frac{\partial}{\partial \omega_q{}^{\mu\nu}} - \frac{\partial \xi^k}{\partial x^q} a_k^A \frac{\partial}{\partial a_q^A} + T_{jk}^\mu \frac{\partial \xi^k}{\partial x^i} \frac{\partial}{\partial T_{ij}^\mu} + \frac{1}{2} R_{jk}{}^{\mu\nu} \frac{\partial \xi^k}{\partial x^i} \frac{\partial}{\partial R_{ij}{}^{\mu\nu}} + F_{jk}^A \frac{\partial \xi^k}{\partial x^i} \frac{\partial}{\partial F_{ij}^A}, \tag{4.4}$$

for their $\mathcal{J}$-prolongations on $\mathcal{J}(\mathcal{E}\times\mathcal{C}\times J_1 Q/G)$.

We prove now that the fields $\mathcal{J}(X)$ are infinitesimal Lagrangian symmetry. To do this, it is convenient to work in new "tetrad" coordinates on $\mathcal{E}\times\mathcal{C}\times J_1 Q/G$ of the form [of course, the coordinate transformation (4.5) is thought in the invariant region of $\mathcal{E}\times\mathcal{C}\times J_1 Q/G$ in which one has $e \neq 0$]

$$x^i,\ e_i^\mu, \quad \omega_\sigma{}^{\mu\nu} := \omega_i^{\mu\nu} e_\sigma^i, \quad a_\sigma^A := a_i^A e_\sigma^i,$$

$$T_{\sigma\lambda}^\mu := T_{ij}^\mu e_\sigma^i e_\lambda^j, \quad R_{\sigma\lambda}{}^{\mu\nu} := R_{ij}{}^{\mu\nu} e_\sigma^i e_\lambda^j, \quad F_{\sigma\lambda}^A := F_{ij}^A e_\sigma^i e_\lambda^j. \tag{4.5}$$

In these coordinates the vector field $\mathcal{J}(X)$ assumes the simpler expression

$$\mathcal{J}(X) = \xi^i \frac{\partial}{\partial x^i} - \frac{\partial \xi^k}{\partial x^q} e_k^\mu \frac{\partial}{\partial e_q^\mu},$$

while the Lagrangian is locally described as

$$L = \mathcal{L}ds = (R_{\mu\nu}{}^{\mu\nu} e - \tfrac{1}{4} F_{\mu\nu}^A F_A^{\mu\nu} e) ds,$$

where $F_A^{\mu\nu} := F_{\sigma\lambda}^B \eta^{\sigma\mu} \eta^{\lambda\nu} \gamma_{BA}$.

It is then a straightforward matter to verify that

$$L_{\mathcal{J}(X)}(\mathcal{L}ds) = \mathcal{J}(X)(\mathcal{L})ds + \mathcal{L}d(\mathcal{J}(X) \rfloor ds) = -\frac{\partial \xi^k}{\partial x^k}\mathcal{L}ds + \frac{\partial \xi^k}{\partial x^k}\mathcal{L}ds = 0.$$

Therefore, from Propositions 4.1 and 4.2, we conclude that the vector fields $\mathcal{J}(X)$ are Noether vector fields and thus infinitesimal dynamical symmetries.

There are no (nontrivial) conserved quantities arising from the fields (4.4). In fact, a direct calculation shows that the inner product $\mathcal{J}(X) \rfloor \Theta_L$ consists in an exact term plus a term vanishing identically when pulled-back under critical section.

Another family of Noether vector fields and infinitesimal dynamical symmetries is given by infinitesimal gauge transformations for the Yang–Mills field.

The latter may be represented by vector fields X on $\mathcal{E}\times\mathcal{C}\times J_1 Q/G$ of the form

$$X = D_i b^A \frac{\partial}{\partial a_i^A}, \tag{4.6}$$

where $b^A = b^A(x) \in F(M)$ and $D_i b^A = \partial b^A/\partial x^i + b^C a_i^B C_{BC}^A$.

As above, vector fields (4.6) are $\mathcal{J}$-prolongable and their $\mathcal{J}$-prolongations $\mathcal{J}(X)$ on $\mathcal{E}\times\mathcal{C}\times J_1 Q/G$ are locally expressed as

$$\mathcal{J}(X) = D_i b^A \frac{\partial}{\partial a_i^A} + \frac{1}{2} b^C F_{ij}^B C_{BC}^A \frac{\partial}{\partial F_{ij}^A}. \tag{4.7}$$

The latter are infinitesimal Lagrangian symmetries, indeed one has

$$L_{\mathcal{J}(X)}(\mathcal{L}ds) = L_{\mathcal{J}(X)}(-\tfrac{1}{4} F_{ij}^A F_A^{ij} e ds) = -\tfrac{1}{2} b^B F_{ij}^C C_{CB}^A F_A^{ij} e ds = 0. \tag{4.8}$$

The vanishing of (4.8) is due to the relation $\gamma_{AB} C_{CD}^A = \gamma_{A[B} C_{CD]}^A$, consequence of the adjoint-invariance of the metric γ.

Once again, it follows that the vector fields (4.7) are Noether vector fields and infinitesimal dynamical symmetries of the theory. Moreover, if σ is a critical section, then the quantities

$$\mathcal{Q} = \mathcal{J}\sigma * (\mathcal{J}(X) \rfloor \Theta_L) = D_i b^A(x) F_A^{ij}(x) ds_j,$$

are the conserved Noether currents, associated with the fields (4.7).

To introduce the third and last example, let us consider a tensor-valued function $A^\mu{}_\nu(x) \in \mathfrak{GD}(1,3)$, $\forall x \in M$. Through any such an $A^\mu{}_\nu$, we can define the following vector field on $\mathcal{E} \times \mathcal{C} \times J_1 Q/G$

$$X = A^\gamma{}_\sigma e_q^\sigma \frac{\partial}{\partial e_q^\gamma} - \frac{1}{2} D_q A^{\mu\nu} \frac{\partial}{\partial \omega_q{}^{\mu\nu}}, \tag{4.9}$$

where $D_q A^{\mu\nu} = \partial A^{\mu\nu}/\partial x^q + \omega_q{}^\mu{}_\sigma A^{\sigma\nu} - \omega_q{}^\sigma{}_\nu A^\mu{}_\sigma$. We notice that expressions (4.9) are covariant, in the sense that, under changes of coordinates, they undergo the transformation law

$$X = \overline{A}^\gamma{}_\sigma \overline{e}_q^\sigma \frac{\partial}{\partial \overline{e}_q^\gamma} - \frac{1}{2} D_q \overline{A}^{\mu\nu} \frac{\partial}{\partial \overline{\omega}_q{}^{\mu\nu}},$$

with $\overline{A}^\nu{}_\lambda = \Lambda^\nu{}_\mu A^\mu{}_\sigma \Lambda_\lambda{}^\sigma$.

Taking Eqs. (2.11) and (2.12) into account, it is easily seen that vector fields (4.9) are $\mathcal{J}$-prolongable and their $\mathcal{J}$-prolongations are locally described as

$$\mathcal{J}(X) = A^\gamma{}_\sigma e_q^\sigma \frac{\partial}{\partial e_q^\gamma} - \frac{1}{2} D_q A^{\mu\nu} \frac{\partial}{\partial \omega_q{}^{\mu\nu}} + \frac{1}{2} A^\mu{}_\sigma T_{ij}^\sigma \frac{\partial}{\partial T_{ij}^\mu} + \frac{1}{2} A^\mu{}_\sigma R_{ij}{}^{\sigma\nu} \frac{\partial}{\partial R_{ij}{}^{\mu\nu}}. \tag{4.10}$$

As made for the previous cases, we show that vector fields (4.10) are infinitesimal Lagrangian symmetries. To do this, it is again convenient working in the coordinates (4.5), in which the fields (4.10) have local expression

$$\begin{aligned}\mathcal{J}(X) = {} & A^\gamma{}_\sigma e_q^\sigma \frac{\partial}{\partial e_q^\gamma} - \frac{1}{2}\left[D_q A^{\mu\nu} e_\sigma^q + A^\gamma{}_\sigma \omega_\gamma{}^{\mu\nu}\right] \frac{\partial}{\partial \omega_\sigma{}^{\mu\nu}} - A^\gamma{}_\mu a_\gamma^A \frac{\partial}{\partial a_\mu^A} + \frac{1}{2}\left[A^\mu{}_\sigma T_{\lambda\rho}^\sigma - 2A^\gamma{}_\lambda T_{\gamma\rho}^\mu\right] \frac{\partial}{\partial T_{\lambda\rho}^\mu} \\ & + \frac{1}{2}\left[A^\mu{}_\gamma R_{\sigma\lambda}{}^{\gamma\nu} - A^\gamma{}_\sigma R_{\gamma\lambda}{}^{\mu\nu}\right] \frac{\partial}{\partial R_{\sigma\lambda}{}^{\mu\nu}} - A^\gamma{}_\mu F_{\gamma\nu}^A \frac{\partial}{\partial F_{\mu\nu}^A}.\end{aligned}$$

Using the latter, it is a straightforward matter to verify that the identity

$$L_{\mathcal{J}(X)}(\mathcal{L} ds) = A^\mu{}_\mu \mathcal{L} ds + A^{\mu\lambda} F_{\mu\nu}^A F_{\lambda\sigma}^B \eta^{\nu\sigma} \gamma_{AB} e ds = 0$$

holds true, because of the skew-symmetry of $A^{\mu\nu}$ and the symmetry of $F_{\mu\nu}^A F_{\lambda\sigma}^B \eta^{\nu\sigma} \gamma_{AB}$.

As above, the conclusion follows that the fields (4.10) are infinitesimal dynamical symmetries and that, denoting by σ a critical section, the quantities

$$\mathcal{Q} = \mathcal{J}\sigma * (\mathcal{J}(X) \rfloor \Theta_L) = -\tfrac{1}{2} D_t A^{\alpha\beta}(x) e_i^\mu(x) e_j^\nu(x) \epsilon^{ijpt} \epsilon_{\mu\nu\alpha\beta} ds_p,$$

are the corresponding conserved Noether currents.

Hyperbolic Kac Moody algebras and Einstein billiards

Sophie de Buyl[a] and Christiane Schomblond[b]

(Received 20 July 2004; accepted 9 August 2004; published 4 November 2004)

We identify the hyperbolic Kac Moody algebras for which there exists a Lagrangian of gravity, dilatons, and p-forms which produces a billiard that can be identified with their fundamental Weyl chamber. Because of the invariance of the billiard upon toroidal dimensional reduction, the list of admissible algebras is determined by the existence of a Lagrangian in three space–time dimensions, where a systematic analysis can be carried out since only zero-forms are involved. We provide all highest dimensional parent Lagrangians with their full spectrum of p-forms and dilaton couplings. We confirm, in particular, that for the rank 10 hyperbolic algebra, $CE_{10}=A_{15}^{(2)\wedge}$, also known as the dual of $B_8^{\wedge\wedge}$, the maximally oxidized Lagrangian is nine-dimensional and involves besides gravity, 2 dilatons, a 2-form, a 1-form, and a 0-form. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1806537]

I. INTRODUCTION

It has been shown recently that the dynamics of the gravitational scale factors becomes equivalent, in the vicinity of a spacelike singularity, to that of a relativistic particle moving freely on an hyperbolic billiard and bouncing on its walls.[1–6] A criterion for the gravitational dynamics to be chaotic is that the billiard has a finite volume. This in turn stems from the remarkable property that the billiard can be identified with the fundamental Weyl chamber of an hyperbolic Kac Moody algebra. Some of these algebras are well known: in particular, the famous hyperbolic algebras [$E_{10}=E_8^{\wedge\wedge}$, $BE_{10}=B_8^{\wedge\wedge}$, $DE_{10}=D_8^{\wedge\wedge}$, $AE_n=A_{n-2}^{\wedge\wedge}$; more generally, the names here given to the algebras are taken from Refs. 12 and 13; in the table of the Dynkin diagrams given in Ref. 13, the name $D_{r+1}^{(2)}$ should be replaced by $D_{r+1}^{(2)\wedge}$] E_{10}, BE_{10}, DE_{10} (Refs. 8–10) are related to strings, supergravities, and M-theory; the $AE_n, n<10$ (Ref. 7) emerge from pure gravity in various dimensions and more generally, the algebras that are overextensions of finite dimensional simple Lie algebras[11,12]—also twisted overextensions[13]—are associated with gravitational models that reduce to G/H coset models upon toroidal dimensional reduction to $D=3$. Several other hyperbolic algebras also appear in the billiard analysis of $D=4$ and $D=5$ spatially homogeneous cosmological models.[14] This kind of analysis has attracted a lot of interest recently in connection with U-dualities[15] and hidden symmetries of M-theory.[16–21]

The purpose of this paper is twofold: first we select all hyperbolic Kac Moody algebras for which a billiard description exists and then we explicitly construct all Lagrangians describing gravity coupled to dilatons and p-forms producing these billiards.

We are able to give exhaustive results because (i) the hyperbolic algebras are all known and classified (note however six missing cases in Ref. 22, two with rank 3, two with rank 4, and two with rank 5; their Dynkin diagrams are displayed at the end of the paper),[22] and (ii) only the finite number of algebras with rank r between 3 and 10 are relevant in this context. Note that there are infinitely many hyperbolic algebras of rank two and that there exists no hyperbolic algebra of rank $r>10$. The analysis is considerably simplified because of the invariance of the billiard under

[a]Aspirant du Fonds National de la Recherche Scientifique, Belgique. Electronic mail: sdebuyl@ulb.ac.be
[b]Electronic mail: cschomb@ulb.ac.be

toroidal dimensional reduction to dimensions $D \geqslant 3$. Indeed, as explained in Ref. 12, the billiard region stays the same, but a symmetry wall in D dimensions may become an electric or magnetic p-form wall in a lower dimension. The invariance under dimensional reduction implies in particular that the selection of algebras with a billiard description can be performed by analyzing Lagrangians in $D=3$ dimensions.

Simplifications in $D=3$ occur because only 0-forms are present: indeed, via appropriate dualizations, all p-forms can be reduced to 0-forms. To be concrete, for the hyperbolic algebras of real rank r between 3 and 6, we first try to reproduce their Dynkin diagram with a set of r dominant walls comprising one symmetry wall $(\beta^2-\beta^1)$ and $(r-1)$ scalar walls. If this can be done, we still have to check that the remaining walls are subdominant i.e., that they can be written as linear combinations of the dominant ones with positive coefficients. In particular, this analysis requires that any dominant set necessarily involves one magnetic wall and $(r-2)$ electric walls. Note that our search for gravitational Lagrangians in $D=3$ is systematic although no symmetry is required. To deal with the hyperbolic algebras of ranks 7–10, it is actually not necessary to first reduce to three dimensions: the overextensions of finite simple Lie algebras have already been associated with billiards of some Lagrangians and for the remaining four algebras, the rules we have found in the previous cases allow to straightforwardly construct the Lagrangian in the maximal oxidation dimension.

We then analyze which three-dimensional system admits parents in higher dimensions and construct the Lagrangian in the maximal oxidation dimension. In order to do so, we take an algebra in the previous list and we determine successively the maximal space–time dimension, the dilaton number, the p-form content, and the dilaton couplings:

(1) One considers the Dynkin diagram of the selected algebra and looks at the length of its "A-chain" (an "A-chain" of length k is a chain of k vertices with norm squared equal to 2 and simply laced), starting with the symmetry root. Our analysis produces the following oxidation rule: if the A-chain has length k, the theory can be oxidized up to

   (a) $D_{\max}=k+2$, if the next connected root has a norm squared smaller than 2;
   (b) $D_{\max}=k+1$, if the next connected root has a norm squared greater than 2.
   This generalizes the oxidation rule by Refs. 23–26, obtained by group theoretical arguments applied to coset models.

(2) For given space dimension $d=D-1$ and rank r of the algebra, the number of dilatons is given by $N=r-d$ because the dominant walls are required to be r independent linear forms in the d scale factors $\{\beta^1,\ldots,\beta^d\}$ and the N dilatons.
(3) Because it is known how the p-form walls connect to the A-chain,[12] one can read on the Dynkin diagram which p-forms [or their dual $(d-p-1)$-forms] appear in the maximal oxidation dimension.
(4) The dilaton couplings of the p-forms are computed from the norms and scalar products of the walls which have to generate the Cartan matrix of the hyperbolic algebra. This means in particular that, even if the nature of the walls changes during the oxidation procedure, their norms and scalar products remain unchanged. Note also that in all dimensions $D>3$ the subdominant conditions are always satisfied.

As a by-product of our analysis, we note that, for each billiard identifiable as the fundamental Weyl chamber of an hyperbolic algebra, the positive linear combinations of the dominant walls representing the subdominant ones only contain integer coefficients. Hence, the dominant walls of the Lagrangian correspond to the simple roots of the hyperbolic algebra, while the subdominant ones correspond to nonsimple positive roots. The gravitational theory does not give all the positive roots; even the three-dimensional scalar Lagrangians do not describe coset spaces in general. Nevertheless, the reflections relative to the simple roots generate the Weyl group of the hyperbolic algebra; this group in turn gives an access to other positive roots and suggests that a Lagrangian capable to produce these roots via billiard walls needs more exotic fields than just p-forms.

Our analysis is linked with the important physical problem of hidden symmetries of gravita-

tional theories. Furthermore, as recalled above, the hyperbolic character of the underlying Kac Moody algebra has crucial consequences on the dynamical features of the physical systems under consideration as it is linked to chaos and the BKL behavior.[1] As these properties are discussed at length in the literature, we shall not repeat them here and refer the interested reader to Refs. 11 and 27–29 for hidden symmetries and Refs. 5 and 7 for chaotic behavior.

Our paper is organized as follows: The general framework of our analysis is outlined in the first section: the form of the searched for gravitational Lagrangians is recalled, together with the list of their walls and the metric used to build the Cartan matrix. In the next four sections, we deal with hyperbolic algebras of rank 3–6. First, in $D=3$ space–time dimensions, we compute the three-dimensional dilaton couplings needed to reproduce the Dynkin diagram and check the status of the subdominant walls. This is how we select the admissible algebras. Next, for each of them, we determine which Lagrangian can be oxidized and we produce it in the maximal oxidation dimension. The 18 hyperbolic algebras of ranks 7–10 are reviewed in the last section; as explained before, they are singled out for special treatment because 14 of them are overextensions of finite dimensional simple Lie algebras and the remaining 4 are dual to the overtextension $B_n^{\wedge\wedge}$ (with $n=5,6,7,8$). We explicitly write down the $D_{\max}=9$ Lagrangian system obtained previously in Ref. 30, the billiard of which is the fundamental Weyl chamber of the algebra CE_{10}. Among the four hyperbolic algebras of rank 10, CE_{10} is special because, unlike E_{10}, BE_{10}, and DE_{10}, it does not stem from supergravities. Finally, we close our paper with some conclusions.

II. GENERAL FRAMEWORK

The billiard analysis refers to the dynamics, in the vicinity of a spacelike singularity, of a gravitational model described by the Lagrangian (compared to the notations of Ref. 12, we have put a factor of 2 in the exponents of the dilaton couplings; this way, a factor $1/2$ will be removed in front of the dilatonic part of the p-form walls)

$$\mathcal{L}_D = {}^{(D)}R \star \mathbb{1} - \sum_\alpha \star d\phi^\alpha \wedge d\phi^\alpha - \frac{1}{2}\sum_p e^{2\lambda^{(p)}(\phi)} \star F^{(p+1)} \wedge F^{(p+1)}, \quad D \geqslant 3, \tag{2.1}$$

where $\lambda^{(p)}(\phi)=\Sigma_\alpha \lambda_\alpha^{(p)}\phi^\alpha$ and $\star\mathbb{1}=\sqrt{|{}^{(D)}g|}\, dx^0\wedge\cdots\wedge dx^{D-1}$. The dilatons are denoted by ϕ^α ($\alpha=1,\ldots,N$); their kinetic terms are normalized with a weight 1 with respect to the Ricci scalar. The Einstein metric has Lorentz signature $(-,+,\ldots,+)$; its determinant is ${}^{(D)}g$. The integer $p\geqslant 0$ labels the various p-forms $A^{(p)}$ present in the theory, with field strengths $F^{(p+1)}=dA^{(p)}$. If there are several p-form gauge fields with the same form degree p, we will use different letters $A^{(p)}, B^{(p)},\ldots$, to distinguish them.

The rules for computing the billiards have been given in details in Refs. 6, 7, and 12 to which we refer the reader. We here recall the essential tools that are used throughout the paper.

A. The walls

The walls bounding the billiard have different origins: some arise from the Einstein–Hilbert action and involve only the scale factors β^i ($i=1,\ldots,d$), introduced through the Iwasawa decomposition of the space metric. They are

(1) the symmetry walls

$$w_{ij}^S(\beta) = \beta^j - \beta^i, \quad i<j, \tag{2.2}$$

and

(2) the curvature walls

$$w^G_{i;jk}(\beta) = 2\beta^i + \sum_{\ell \neq i,j,k} \beta^\ell, \quad i \neq j, i \neq k, j \neq k. \tag{2.3}$$

The others come from the energy densities of the p-forms; they depend on the scale factors and the dilatons and are

(3) the electric walls

$$w^{E(p)}_{i_1 \cdots i_p}(\beta, \phi) = \beta^{i_1} + \cdots + \beta^{i_p} + \sum_\alpha \lambda^{(p)}_\alpha \, \phi^\alpha, \quad i_1 < \cdots < i_p \tag{2.4}$$

and

(4) the magnetic walls

$$w^{M(p)}_{i_1 \cdots i_{d-p-1}}(\beta, \phi) = \beta^{i_1} + \cdots + \beta^{i_{d-p-1}} - \sum_\alpha \lambda^{(p)}_\alpha \, \phi^\alpha, \quad i_1 < \cdots < i_{d-p-1}. \tag{2.5}$$

Notice that upon the change of ϕ^α into $-\phi^\alpha$, the electric walls of a p-form become the magnetic walls of its dual $(d-p-1)$-form and vice versa.

The region of hyperbolic space where the particle motion takes place is defined through the inequalties $w^S_{ij} \geqslant 0$, $w^G_{i;jk} \geqslant 0$, $w^{E(p)}_{i_1 \cdots i_p} \geqslant 0$, and $w^{M(p)}_{i_1 \cdots i_{d-p-1}} \geqslant 0$; in fact, these inequalities follow from a simpler subset, namely

$$\beta^1 \leqslant \beta^2 \cdots \leqslant \beta^d, \quad w^G_{1;23} \geqslant 0, \quad w^E_{1 \cdots p} \geqslant 0, \quad w^M_{1 \cdots (d-p-1)} \geqslant 0, \tag{2.6}$$

which may still be redundant. The walls forming the minimal set needed to define completely the billiard are called "dominant"; the others are referred to as subdominant. More precisely, a wall is called subdominant if it can be expressed as a linear combination with positive coefficients of the dominant ones.

B. The metric

Given two walls $w(\beta, \phi) = w_i \, \beta^i + w_\alpha \, \phi^\alpha = w_\mu \, \beta^\mu$ and $w'(\beta, \phi) = w'_i \beta^i + w'_\alpha \phi^\alpha = w'_\mu \beta^\mu$—the $\beta^\mu (\mu = 1, \ldots, d, 1+d, \ldots, N+d)$ here denote scale factors β^i $(i = 1, \ldots, d)$ and dilatons, $\beta^{\alpha+d} = \phi^\alpha$—their scalar product is defined as

$$(w|w') = G^{\mu\nu} \, w_\mu \, w'_\nu = \sum_i (w_i \, w'_i) - \frac{1}{d-1} \left(\sum_i w_i \right) \left(\sum_j w'_j \right) + \sum_\alpha (w_\alpha \, w'_\alpha). \tag{2.7}$$

The metric $G^{\mu\nu}$ is the inverse of the Lorentzian metric $G_{\mu\nu}$ defining the kinetic term of the scale factors and dilatons; as shown in (2.7), it depends explicitly on the spatial dimension d. Notice that a symmetry wall has a norm squared equal to 2. Furthermore, the p-form electric wall $w^E_{1 \cdots p}$ is orthogonal to all symmetry walls except one, namely, $w^S_{p,p+1} = \beta^{p+1} - \beta^p$; the corresponding scalar product is equal to -1.

Let $\{w_B = w_B(\beta, \phi), B = 1, \ldots, r\}$ denote a set of dominant walls. The enclosed billiard volume is finite if the scalar products are such that the $r \times r$ matrix

$$A_{BC} = 2 \frac{(w_B|w_C)}{(w_B|w_B)} \tag{2.8}$$

is the generalized Cartan matrix of an hyperbolic Kac Moody algebra of rank r.

III. RANK 3 HYPERBOLIC ALGEBRAS

A. $D=3$

In space dimension $d=2$, one has a single symmetry wall, namely,

$$\alpha_1 = \beta^2 - \beta^1 \tag{3.1}$$

and $N=r-d=3-2=1$ dilaton denoted as ϕ. It is obvious that only a 0-form magnetic wall can be connected to the symmetry wall, say

$$\alpha_2 = \beta^1 - \lambda\phi. \tag{3.2}$$

Let us show that the last dominant wall has to be an electric one denoted by

$$\alpha_3 = \lambda'\phi. \tag{3.3}$$

Indeed, had one taken for dominant the magnetic wall $\tilde{\alpha}_3=\beta^1-\lambda'\phi$ instead of (3.3), then, its corresponding electric wall, which is precisely $\alpha_3=\lambda'\phi$, would be dominant too because of the impossibility to write it as a linear combination with positive coefficients of the other three α_1, α_2, and $\tilde{\alpha}_3$.

Using the metric (2.7) adapted to $d=2$, we build the matrix

$$A_{ij} = 2\frac{(\alpha_i|\alpha_j)}{(\alpha_i|\alpha_i)} \tag{3.4}$$

and obtain

$$A = \begin{pmatrix} 2 & -1 & 0 \\ -\dfrac{2}{\lambda^2} & 2 & -2\dfrac{\lambda'}{\lambda} \\ 0 & -2\dfrac{\lambda}{\lambda'} & 2 \end{pmatrix}, \tag{3.5}$$

which has to be identified with the generalized Cartan matrix of an hyperbolic Kac Moody algebra of rank 3. Because ϕ can be changed into $-\phi$, λ and λ' can be chosen positive.

Since in such a matrix (i) the nonzero off-diagonal entries are negative integers and (ii) not any finite or affine Lie algebra of rank 2 has an off-diagonal negative integer <-4, one immediately infers from the expression of A_{21} in (3.5) that the allowed values for λ are

$$\lambda \in \{\sqrt{2}, 1, \sqrt{2/3}, 1/2\}. \tag{3.6}$$

Being a symmetry wall, α_1 has norm squared equal to 2; α_2 has norm squared $\lambda^2 \leqslant 2$, so that, if the Dynkin diagram has an arrow between α_1 and α_2, this arrow must be directed towards α_2. Once the value of λ has been fixed, one needs to find λ' such that both $2\lambda'/\lambda$ and $2\lambda/\lambda'$ are positive integers: this leaves $\lambda=\lambda'/2, \lambda', 2\lambda'$. These values are further constrained by the condition that the subdominant walls $\tilde{\alpha}_2=\lambda\phi$ and $\tilde{\alpha}_3=\beta^1-\lambda'\phi$, stay really behind the others, i.e., that there exist $k>0$ and $\ell \geqslant 0$ such that

$$\tilde{\alpha}_2 = k\alpha_3 \Rightarrow \lambda/\lambda' = k, \tag{3.7}$$

$$\tilde{\alpha}_3 = \alpha_2 + \ell\alpha_3 \Rightarrow \lambda/\lambda' = \ell + 1, \tag{3.8}$$

which implies $k=\ell+1 \geqslant 1$. Hence, the subdominant conditions require

$$\lambda' = \lambda \quad \text{or} \quad \lambda' = \lambda/2. \tag{3.9}$$

Let us summarize the 8 different possibilities for the pairs (λ, λ') that lead to Cartan matrices and draw the corresponding Dynkin diagrams:

(i) for $\lambda = \sqrt{2}$ and $\lambda' = \sqrt{2}$, the Dynkin diagram describes the overextension $A_1^{\wedge\wedge}$

3-1 
and for $\lambda = \sqrt{2}$ and $\lambda' = 1/\sqrt{2}$, the Dynkin diagram corresponds to the twisted overextension[13] $A_2^{(2)\wedge}$

3-2 
(ii) $\lambda = 1$; the two possibilities are $\lambda' = 1$ and $\lambda' = 1/2$. The Dynkin diagrams are, respectively;

3-3 
3-4 
(iii) $\lambda = \sqrt{2/3}$; the two possibilities are $\lambda' = \sqrt{2/3}$ and $\lambda' = 1/\sqrt{6}$ with Dynkin diagrams given by

3-5 
3-6 
(iv) $\lambda = 1/2$; the two possibilities are $\lambda' = 1/2$ and $\lambda' = 1/4$. The Dynkin diagrams are, respectively,

3-7 
3-8 
Comments:

(1) When $\lambda' = \lambda$, α_2 and α_3 have to be assigned to a single scalar field; when $\lambda' \neq \lambda$, two scalars are needed in the three-dimensional Lagrangian.
(2) The algebra (3-8) is missing in Table 2 of Ref. 22. The subalgebra obtained when removing the first or the last root is the affine $A_2^{(2)}$; the removal of the middle root gives $A_1 \times A_1$ so that this algebra satisfies indeed the criterion of hyperbolicity.
(3) Remark that none of the 8 algebras above is strictly hyperbolic. (A strictly hyperbolic algebra is such that upon removal of a simple root, only finite Lie algebras are left behind.) The latter are listed in Table 1 of Ref. 22.

B. $D=4$

The four-dimensional Lagrangian will have no dilaton in it since $N = r - d = 0$; hence, if such a Lagrangian exists, it cannot stem from a higher dimensional parent and $D_{\max} = 4$. When looking at the algebras of rank 3 selected above, one sees that only (3-1) and (3-2) have an A-chain of length $k = 2$ and allow, *a priori*, a second symmetry wall. One starts with

$$\alpha_1 = \beta^3 - \beta^2 \quad \text{and} \quad \alpha_2 = \beta^2 - \beta^1. \tag{3.10}$$

The third root may only contain β^1 and can be associated with

(1) The curvature wall $\alpha_3 = 2\beta^1$ in the case of four-dimensional pure gravity. The Dynkin diagram bears number (3-1) above and is the overextension $A_1^{\wedge\wedge}$.
(2) The electric/magnetic wall of a 1-form: $\alpha_3 = \beta^1$. This case leads to diagram (3-2) which belongs to the twisted overextension $A_2^{(2)\wedge}$.

One sees immediately that the regions of hyperbolic space delimited by both sets of walls coincide; the difference is entirely due to the normalization of the third wall which is thus responsible for the emergence of two distinct Cartan matrices.

IV. RANK 4 HYPERBOLIC ALGEBRAS

A. $D=3$

In order to reproduce through walls the four roots of such an algebra, besides the scale factors β^1 and β^2, one needs $N=2$ dilatons; they will be denoted as $\phi^1 = \phi, \phi^2 = \varphi$. There is one symmetry wall, i.e., $\alpha_1 = \beta^2 - \beta^1$ and, *a priori*, two choices can be made for the next three dominant walls: either (i) one takes one magnetic wall and two electric ones or (ii) one takes one electric wall and two magnetic ones. We will start with case (i) and show later how case (ii) is eliminated on account of the subdominant conditions.

1. One magnetic wall and two electric ones

The dominant walls are thus the symmetry wall

$$\alpha_1 = \beta^2 - \beta^1, \tag{4.1}$$

the magnetic wall, written as (this ansatz represents no loss of generality because starting from the more general expression $\alpha_2 = \beta^1 - \lambda\phi + \mu\varphi$, one can redefine the dilatons via an orthogonal transformation—leaving the dilaton Lagrangian invariant—to get the simpler expression used above)

$$\alpha_2 = \beta^1 - \lambda\phi \tag{4.2}$$

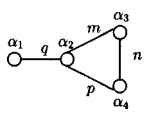
and the two electric ones

$$\alpha_3 = \lambda'\phi - \mu'\varphi, \tag{4.3}$$

respectively,

$$\alpha_4 = \lambda''\phi + \mu''\varphi. \tag{4.4}$$

As before, the signs have already been distributed to account for the negative signs of the off-diagonal Cartan matrix elements when allowing the parameters to be either all $\geqslant 0$ or all $\leqslant 0$; that they can further be chosen positive is due to the possibility to change ϕ^α into $-\phi^\alpha$. The general structure of the Dynkin diagram is therefore the following:



where we have not drawn the arrows and q, m, n, p are integers which count the number of lines joining two vertices.

What are the possible values that can be assigned to q, m, n, and p? Since this diagram has to become the Dynkin diagram of an hyperbolic algebra, the maximal value of each of these integers is 3, because there is no finite or affine algebra of rank 3 with off-diagonal Cartan matrix elements

smaller than −3. Another point is that if there were an arrow between α_1 and α_2 it necessarily points towards α_2: one has indeed $(\alpha_1,\alpha_2)=-1$, $(\alpha_1,\alpha_1)=2$ (it is a symmetry wall), $(\alpha_2,\alpha_2)=\lambda^2$ and $A_{21}=-2/\lambda^2$ can only be $-1,-2$ or -3. We may also state that if A_{ij} is neither 0 nor −1 then $A_{ji}=-1$, because this is a common property of all finite or affine algebras of rank 3. Taking all these restrictions into account, one has to consider three different situations characterized, respectively, by (i) m, n, p are all different from zero, (ii) $n=0$ and m, p are not zero, (iii) $p=0$ and n, m are not zero.

(i) If m, n, and p are all nonzero, then they must all be equal to 1 because, upon removal of the root α_1, one obtains a triangular diagram; now, in the set of the finite or affine algebras, there is only one such triangular Dynkin diagram and it is simply laced. That leaves, *a priori*, three cases labeled by the values $q=1,2,3$. The corresponding dilaton couplings are

$$\lambda=\sqrt{\frac{2}{q}};\quad \lambda'=\frac{1}{\sqrt{2q}};\quad \mu'=\sqrt{\frac{3}{2q}};\quad \lambda''=\frac{1}{\sqrt{2q}};\quad \mu''=\sqrt{\frac{3}{2q}}. \tag{4.5}$$

The Dynkin diagrams corresponding to $q=1$, 2, and 3, are respectively,

4-1 
which is the overextension $A_1^{\wedge\wedge}$ and

4-2 
4-3 
The subdominant conditions are satisfied in all cases; let us show this explicitly. With the couplings in (4.5), the dominant walls other than the symmetry wall read

$$\alpha_2=\beta^1-2\frac{\phi}{\sqrt{2q}},\quad \alpha_3=\frac{\phi}{\sqrt{2q}}-\varphi\sqrt{\frac{3}{2q}},\quad \alpha_4=\frac{\phi}{\sqrt{2q}}+\varphi\sqrt{\frac{3}{2q}}. \tag{4.6}$$

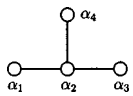
The corresponding subdominant ones are

$$\tilde{\alpha}_2=2\frac{\phi}{\sqrt{2q}},\quad \tilde{\alpha}_3=\beta^1-\frac{\phi}{\sqrt{2q}}+\varphi\sqrt{\frac{3}{2q}},\quad \tilde{\alpha}_4=\beta^1-\frac{\phi}{\sqrt{2q}}-\varphi\sqrt{\frac{3}{2q}} \tag{4.7}$$

and they obey

$$\tilde{\alpha}_2=\alpha_3+\alpha_4,\quad \tilde{\alpha}_3=\alpha_2+\alpha_4,\quad \tilde{\alpha}_4=\alpha_2+\alpha_3. \tag{4.8}$$

(ii) If $n=0$ and m, p are not zero, the structure of the Dynkin diagram is the following:



Comparison with the similar graphs of Ref. 22 impose (i) $m=p=2$, (ii) $q=1$ or $q=2$, and (iii) an arrow pointing from α_2 to α_3 and another arrow from α_2 to α_4. Accordingly, the dilaton couplings producing them are given by

$$\lambda=\sqrt{\frac{2}{q}};\quad \lambda'=\frac{1}{\sqrt{2q}};\quad \mu'=\frac{1}{\sqrt{2q}};\quad \lambda''=\frac{1}{\sqrt{2q}};\quad \mu''=\frac{1}{\sqrt{2q}}. \tag{4.9}$$

TABLE I. Possible couplings.

	λ	λ'	μ'
1	$\sqrt{2}$	$\sqrt{2}$	$\sqrt{2}$
2.a	$\sqrt{2}$	$1/\sqrt{2}$	$\sqrt{3/2}$
2.b	$\sqrt{2}$	$1/\sqrt{2}$	$1/\sqrt{2}$
2.c	$\sqrt{2}$	$1/\sqrt{2}$	$1/\sqrt{6}$
3	1	1	1
4.a	1	1/2	$\sqrt{3}/2$
4.b	1	1/2	1/2
4.c	1	1/2	$1/\sqrt{12}$
5	$\sqrt{2/3}$	$\sqrt{2/3}$	$\sqrt{2/3}$
6.a	$\sqrt{2/3}$	$1/\sqrt{6}$	$1/\sqrt{2}$
6.b	$\sqrt{2/3}$	$1/\sqrt{6}$	$1/\sqrt{6}$
6.c	$\sqrt{2/3}$	$1/\sqrt{6}$	$1/\sqrt{18}$

The Dynkin diagrams corresponding to $q=1$ and 2, are, respectively,

4-4 
4-5 
Again, the subdominant conditions are fulfilled: indeed, one gets $\tilde{\alpha}_2=\alpha_3+\alpha_4$, $\tilde{\alpha}_3=\alpha_2+\alpha_4$, $\tilde{\alpha}_4=\alpha_2+\alpha_3$.

(iii) If $p=0$ and n, m are not zero, the structure of the Dynkin diagram is the following:

The dominant walls now simplify as

$$\alpha_1=\beta^2-\beta^1, \quad \alpha_2=\beta^1-\lambda\phi, \quad \alpha_3=\lambda'\phi-\mu'\varphi, \quad \alpha_4=\mu''\varphi. \tag{4.10}$$

We want the corresponding magnetic and electric walls to be effectively subdominant: this is indeed satisfied when (1) λ and therefore λ' are positive; (2) $\lambda'/\lambda\leqslant 1$ (that is $\lambda'/\lambda=1$ or $\lambda'/\lambda=1/2$), and (3) $\mu'/\mu''\geqslant\lambda'/\lambda$. Accordingly, the remaining possibilities for λ, λ', and μ' are, *a priori*, those given in Table I.

The different values for μ' correspond to distinct admissible values for A_{32}. Finally, for the values of μ'', we again meet two cases depending on which of A_{34} or A_{43} is equal to -1. In each case, one has still to check the subdominant conditions.

(1) The two possibilities lead to a Cartan matrix: either $\mu''=2\sqrt{2}$ or $\mu''=\sqrt{2}$. The former case is ruled out because the subdominant conditions cannot be satisfied. The Dynkin diagram of the remaining case describes the twisted overextension $D_3^{(2)\wedge}$,

4-6 
(2a) Either $\mu''=\sqrt{2/3}$ or $\mu''=\sqrt{6}$; both lead to hyperbolic algebras which correspond, respectively, to the overextension $G_2^{\wedge\wedge}$,

4-7 
and to the twisted overextension $D_4^{(3)\wedge}$,

4-8 

(2b) Either $\mu''=\sqrt{1/2}$ or $\mu''=\sqrt{2}$; the Dynkin diagrams correspond respectively to the twisted overextension $A_4^{(2)\wedge}$,

4-9 
and to the overextension $C_2^{\wedge\wedge}$,

4-10 
(2c) Only the value $\mu''=2/\sqrt{6}$ is compatible with the subdominant conditions. The corresponding algebra is given by

4-11 

(3) Here again, only the value $\mu''=1$ can be retained on account of the subdominant conditions. This leads to

4-12 
(4a) Either $\mu''=\sqrt{3}$ or $\mu''=1/\sqrt{3}$; both values are admissible. They lead to

4-13 

4-14 

(4b) Either $\mu''=1/2$ or $\mu''=1$; both values are allowed and they give, respectively,

4-15 
4-16 
(4c) Does not correspond to any hyperbolic algebra.

(5) Only the value $\mu''=\sqrt{2/3}$ is compatible with the subdominant conditions but again there is no corresponding hyperbolic algebra.

(6a) Only the first of the 2 values $\mu''=\sqrt{2}$ and $\mu''=\sqrt{2}/3$ leads to an hyperbolic algebra, which is

4-17 
(6b) and (6c) do not give a hyperbolic algebra.

2. One electric wall and two magnetic ones

This case can be eliminated on account of the subdominant conditions. Indeed, without loss of generality, one may choose the parametrization of the dominant walls such that the electric wall takes a simple form, i.e., such that

$$\alpha_1 = \beta^2 - \beta^1,$$

$$\alpha_2 = \beta^1 - \lambda\phi - \mu\varphi,$$

$$\alpha_3 = \beta^1 - \lambda'\phi + \mu'\varphi,$$

$$\alpha_4 = \lambda''\phi. \tag{4.11}$$

Being assumed subdominant, the electric walls associated with α_2 and α_3, namely $\tilde{\alpha}_2 = \lambda\phi + \mu\varphi$ and $\tilde{\alpha}_3 = \lambda'\phi - \mu'\varphi$ need be proportional to α_4; this happens only when $\mu = \mu' = 0$, but then (4.11) does no longer define a rank four root system.

B. $D > 3$

Our aim is now to determine which of the 17 algebras selected in the previous section admit Lagrangians in higher space–time dimensions and to provide the maximal oxidation dimension and the p-forms content with its characteristic features. By considering each Dynkin diagram and looking at the length of the A-chain starting from the symmetry root α_1, we establish the following "empirical" oxidation rule: if the A-chain has length k one can oxidize the spatial dimension up to (i) $d = k+1$ if the norm squared of the next connected root is smaller than 2 and up (ii) to $d = k$ if the norm squared of the next connected root is greater than 2. In particular, the subdominant conditions are always satisfied. Explicitly,

(1) Diagram (4-1) is the overextension $A_2^{\wedge\wedge}$. We know from Ref. 12 that it corresponds to pure gravity in $D_{\max} = 5$.

(2) Diagrams (4-2) and (4-3) have an A-chain of length 1; the three-dimensional theory cannot be oxidized.

(3) Diagram (4-4): $D_{\max} = 4$. The walls are given by

$$\alpha_1 = \beta^3 - \beta^2, \quad \alpha_2 = \beta^2 - \beta^1, \tag{4.12}$$

$$\alpha_3 = \beta^1 - \phi/\sqrt{2}, \quad \alpha_4 = \beta^1 + \phi/\sqrt{2}. \tag{4.13}$$

The last two are the electric and magnetic dominant walls of a one-form coupled to the dilaton. One sees immediately that $\tilde{\alpha}_3 = \alpha_4$ and $\tilde{\alpha}_4 = \alpha_3$.

(4) Diagram (4-5): the three-dimensional Lagrangian has no parent in $D > 3$.

(5) Diagram (4-6) is the twisted overextension $D_3^{(2)\wedge}$. The 3D Lagrangian cannot be oxidized the reason being that $\|\alpha_3\|^2 > 2$.

(6) Diagram (4-7) is the overextension $G_2^{\wedge\wedge}$. We know from Ref. 12 that the theory can be oxidized up to $D_{\max} = 5$ where the Lagrangian is that of the Einstein–Maxwell system.

(7) Diagram (4-8) describes $D_4^{(3)\wedge}$. The A-chain has length $k = 3$ and the next connected root is longer than $\sqrt{2}$. The maximal oxidation dimension is $D_{\max} = 4$ and the dominant walls are given by

$$\alpha_1 = \beta^3 - \beta^2, \quad \alpha_2 = \beta^2 - \beta^1, \tag{4.14}$$

$$\alpha_3 = \beta^1 - \sqrt{3/2}\phi, \quad \alpha_4 = \sqrt{6}\phi. \tag{4.15}$$

The root α_3 is the electric wall of a 1-form, α_4 is the electric wall of a 0-form. One easily checks that the subdominant magnetic walls satisfy

$$\tilde{\alpha}_3 = \beta^1 + \sqrt{3/2}\phi = \alpha_3 + \alpha_4, \tag{4.16}$$

$$\tilde{\alpha}_4 = \beta^1 + \beta^2 - \sqrt{6}\phi = 2\alpha_3 + \alpha_2. \tag{4.17}$$

(8) Diagram (4-9) represents $A_4^{(2)\wedge}$. $D_{\max}=4$. Its billiard realization requires

$$\alpha_1=\beta^3-\beta^2,\quad \alpha_2=\beta^2-\beta^1, \tag{4.18}$$

$$\alpha_3=\beta^1-\sqrt{1/2}\phi,\quad \alpha_4=\sqrt{1/2}\phi. \tag{4.19}$$

The last two are again the electric walls of a 1-form and a zero-form; only the dilaton couplings differ from the previous ones. The subdominant conditions are fulfilled: indeed, one obtains $\tilde{\alpha}_3=\alpha_3+2\alpha_4$ and $\tilde{\alpha}_4=2\alpha_3+\alpha_4+\alpha_2$.

(9) Diagram (4-10) is the overextension $C_2^{\wedge\wedge}$. We know from Ref. 12 that the theory can be oxidized up to $D_{\max}=4$.

(10) Diagram (4-11) has $D_{\max}=4$ and

$$\alpha_1=\beta^3-\beta^2,\quad \alpha_2=\beta^2-\beta^1, \tag{4.20}$$

$$\alpha_3=\beta^1-\sqrt{1/6}\phi,\quad \alpha_4=\sqrt{2/3}\phi. \tag{4.21}$$

It has the same form content as (4-8) and (4-9) but the dilaton couplings are still different. Again, the subdominant conditions are fulfilled: $\tilde{\alpha}_3=\alpha_3+\alpha_4$ and $\tilde{\alpha}_4=2\alpha_3+\alpha_2$.

(11) Diagrams (4-12) to (4-17): their 3D Lagrangians cannot be oxidized because there is a unique root of norm squared equal to 2.

Comments:

(a) The subdominant conditions are indeed always fulfilled in $D>3$ and only positive integer coefficients enter the linear combinations.

(b) In case (4-4), α_3 and α_4 are the electric and magnetic walls of the same one-form. In the other cases, they are respectively assigned to a single one-form and a single zero-form. The root multiplicity being one, there is no room for various p-forms with identical couplings.

V. RANK 5 HYPERBOLIC ALGEBRAS

A. $D=3$

The three-dimensional Lagrangians need $N=r-d=3$ dilatons ($\phi^1=\phi,\phi^2=\varphi,\phi^3=\psi$); there are two scale factors and one symmetry wall $\alpha_1=\beta^2-\beta^1$. In order to reproduce the other four simple roots of the algebra in terms of dominant walls, one has *a priori* three different cases to consider: indeed, the set of dominant walls can comprise (i) one magnetic wall and three electric ones, (ii) two electric walls and two magnetic ones and (iii) one electric wall and three magnetic ones. Only the first possibility will survive because as soon as the set of dominant walls contains more than one magnetic wall, one can show that the corresponding electric walls cannot fulfill the subdominant conditions. Although the proof is a straightforward generalization of the one given in Sec. IV A, we will provide it at the end of this section.

1. One magnetic wall and three electric ones

As in the previous sections, we use the freedom to redefine dilatons through an orthogonal transformation and choose the parametrization of the dominant walls such that

$$\alpha_1=\beta^2-\beta^1, \tag{5.1}$$

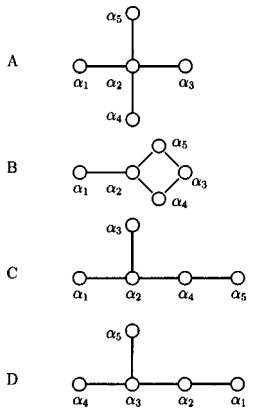
$$\alpha_2=\beta^1-\lambda\phi, \tag{5.2}$$

$$\alpha_3=\lambda'\phi-\mu'\varphi, \tag{5.3}$$

$$\alpha_4 = \lambda''\phi + \mu''\varphi - \nu''\psi, \tag{5.4}$$

$$\alpha_5 = \lambda'''\phi + \mu'''\varphi + \nu'''\psi. \tag{5.5}$$

One sees immediately that the symmetry root α_1 is only linked to the magnetic root α_2 while α_2 can further be connected to one, two or three roots. According to (Ref. 22), five different structures for the Dynkin diagrams can be encountered; we classify them below according to the total number of roots connected to α_2; this number is 4 in case A, 3 in cases B and C, 2 in cases D and E.



Note that C and D simply differ by the assignment of the symmetry root.

Case A: This case may be discarded. Indeed, there are in fact two hyperbolic algebras with a Dynkin diagram of that shape: one of them has a long and four short roots, while the other one has one short and four long roots. Either one cannot find couplings that reproduce their Cartan matrix or it is the subdominant condition that is violated. More concretely:

(A1) Consider first the case for which $\alpha_1, \alpha_2, \alpha_3, \alpha_4$ correspond to the short roots and α_5 is the long root. Then, according to (Ref. 22), one needs

$$\|\alpha_1\|^2 = \|\alpha_2\|^2 = \|\alpha_3\|^2 = \|\alpha_4\|^2 = 2, \quad \text{and} \quad \|\alpha_5\|^2 = 4. \tag{5.6}$$

These conditions are immediately translated into

$$\lambda^2 = 2, \quad \lambda'^2 + \mu'^2 = 2, \quad \lambda''^2 + \mu''^2 + \nu''^2 = 2, \quad \lambda'''^2 + \mu'''^2 + \nu'''^2 = 4. \tag{5.7}$$

Hence $\lambda = \sqrt{2}$. From the shape of the diagram or equivalently from the elements of the Cartan matrix, one infers successively

(1) $A_{23} = -1 = -\lambda\lambda'$ which gives $\lambda' = 1/\sqrt{2}$ and $\mu' = \sqrt{3/2}$;
(2) $A_{24} = -1 = -\lambda\lambda''$ and $A_{34} = 0 = \lambda'\lambda'' - \mu'\mu''$ which gives $\lambda'' = 1/\sqrt{2}$, $\mu'' = 1/\sqrt{6}$ and $\nu'' = 2/\sqrt{3}$;
(3) $A_{25} = -2 = -\lambda\lambda'''$ which gives $\lambda''' = \sqrt{2}$;
(4) $A_{35} = 0 = \lambda'\lambda''' - \mu'\mu'''$ which gives $\mu''' = \sqrt{2/3}$ and, using the norm of α_5, $\nu''' = 2/\sqrt{3}$.

Notice that the condition $A_{45} = 0 = \lambda''\lambda''' + \mu''\mu''' - \nu''\nu'''$ is identically satisfied.

In summary, in order to fit the Dynkin diagram displayed in A (with simple lines between α_2 and $\alpha_1, \alpha_3, \alpha_4$ and a double line between α_2 and α_5 oriented towards α_2), besides the symmetry wall, we need the following set of dominant walls:

$$\alpha_2 = \beta^1 - \sqrt{2}\phi, \quad \alpha_4 = \frac{\phi}{\sqrt{2}} + \frac{\varphi}{\sqrt{6}} - \frac{2\psi}{\sqrt{3}}, \tag{5.8}$$

$$\alpha_3 = \frac{\phi}{\sqrt{2}} - \sqrt{\frac{3}{2}}\varphi, \quad \alpha_5 = \sqrt{2}\phi + \sqrt{\frac{2}{3}}\varphi + \frac{2\psi}{\sqrt{3}}. \tag{5.9}$$

It is now easy to verify, for instance, that $\tilde{\alpha}_3 = \beta^1 - (\phi/\sqrt{2}) + \sqrt{\frac{3}{2}}\varphi$, cannot be written as a positive linear combination of the $\alpha_i, i = 2, \ldots, 5$. Accordingly, on account of the subdominant conditions, this case has to be rejected.

(A2) There is another possibility producing the same diagram as in (A1) above where the symmetry wall α_1 now plays the role of the long root: their norms are

$$\|\alpha_1\|^2 = 2 \quad \text{and} \quad \|\alpha_2\|^2 = \|\alpha_3\|^2 = \|\alpha_4\|^2 = \|\alpha_5\|^2 = 1, \tag{5.10}$$

but the equations giving the couplings analogous to Eq. (1)–(4) above have no solution.

(A3) In the third case, there is a short and four long roots with norms

$$\|\alpha_1\|^2 = \|\alpha_2\|^2 = \|\alpha_3\|^2 = \|\alpha_4\|^2 = 2 \quad \text{and} \quad \|\alpha_5\|^2 = 1. \tag{5.11}$$

One can solve the equations for the couplings and write the following set of billiard walls: the symmetry wall $\alpha_1 = \beta^2 - \beta^1$ and

$$\alpha_2 = \beta^1 - \sqrt{2}\phi, \quad \alpha_4 = \frac{\phi}{\sqrt{2}} + \frac{\varphi}{\sqrt{6}} - \frac{2\psi}{\sqrt{3}}, \tag{5.12}$$

$$\alpha_3 = \frac{\phi}{\sqrt{2}} - \sqrt{\frac{3}{2}}\varphi, \quad \alpha_5 = \frac{\phi}{\sqrt{2}} + \frac{\varphi}{\sqrt{6}} + \frac{\psi}{\sqrt{3}}. \tag{5.13}$$

However, like in case (A1) above, one sees immediately that $\tilde{\alpha}_3 = \beta^1 - (\phi/\sqrt{2}) + (3\varphi/\sqrt{6})$, for instance, is not subdominant; that is the reason why we discard this possibility.

Cases B: There are three hyperbolic algebras with a Dynkin diagram of this shape.

(B1) The first one admits the following couplings:

$$\lambda = \sqrt{2}; \quad \lambda' = \frac{1}{\sqrt{2}}; \quad \mu' = \sqrt{\tfrac{3}{2}};$$

$$\lambda'' = 0; \quad \mu'' = \sqrt{\tfrac{2}{3}}; \quad \nu'' = \frac{2}{\sqrt{3}}; \quad \lambda''' = \frac{1}{\sqrt{2}}; \quad \mu''' = \frac{1}{\sqrt{6}}; \quad \nu''' = \frac{2}{\sqrt{3}} \tag{5.14}$$

and is the overextension $A_3^{\wedge\wedge}$

5-1 
(B2) The second one has the following Dynkin diagram:

5-2 
and the following set of dilaton couplings:

$$\lambda = 1; \lambda' = \tfrac{1}{2}; \quad \mu' = \frac{\sqrt{3}}{2};$$

$$\lambda'' = 0; \quad \mu'' = \frac{1}{\sqrt{3}}; \quad \nu'' = \frac{\sqrt{2}}{\sqrt{3}}; \quad \lambda''' = \tfrac{1}{2}; \quad \mu''' = \frac{1}{2\sqrt{3}}; \quad \nu''' = \frac{\sqrt{2}}{\sqrt{3}}. \tag{5.15}$$

(B3) The diagram of the third one is the same as (5-2) but with the reversed arrow; this is impossible since in the present context the norms are required to satisfy $\|\alpha_1\|^2 \geqslant \|\alpha_2\|^2$.

Case C: In order to generate this kind of structure, one needs $\lambda''' = \mu''' = 0$ and $\lambda'\lambda'' = \mu'\mu''$. Next, from the subdominant condition for $\tilde{\alpha}_3$, we deduce that A_{32} can be -2 or -3 but since we want hyperbolic algebras, only the value $A_{32} = -2$ can be retained. Therefore $A_{23} = -1$ and $\lambda = \sqrt{2}$, $\lambda' = \lambda'' = 1/\sqrt{2}$, $\mu' = 1/\sqrt{2}$, $\mu'' = 1/\sqrt{2}$, and $\nu'' = 1$. *A priori*, one might still have $\nu''' = 2, 1, \sqrt{2}$ but only one value is compatible with the magnetic wall $\tilde{\alpha}_5$ being subdominant, namely $\nu''' = 1$. Accordingly, the couplings need to be defined as

$$\lambda = \sqrt{2}; \quad \lambda' = \frac{1}{\sqrt{2}}; \quad \mu' = \frac{1}{\sqrt{2}};$$

$$\lambda'' = \frac{1}{\sqrt{2}}; \quad \mu'' = \frac{1}{\sqrt{2}}; \quad \nu'' = 1; \quad \lambda''' = 0; \quad \mu''' = 0; \quad \nu''' = 1. \tag{5.16}$$

and the Dynkin diagram is the following:

5-3 
Case D: Dynkin diagrams of this shape can only be recovered with

$$\lambda'' = \lambda''' = 0 \quad \text{and either} \quad \lambda = \sqrt{2} \quad \text{or} \quad \lambda = 1. \tag{5.17}$$

(D.1) $\lambda = \sqrt{2}$.

All hyperbolic diagrams of that type have in their Cartan matrix $A_{34} = A_{43} = -1$ which means that $\|\alpha_3\|^2 = \|\alpha_4\|^2$. Two additional cases must be considered depending on which of α_2 or α_5 has a norm equal to the norm of α_3:

(1) In case (D.1.1) we assume that the norms of α_3, α_4, and α_5 are equal.
(2) In case (D.1.2) we assume that the norms of α_2, α_3, and α_4 are equal.

The subdominant conditions here simply reduce to $A_{23} = -1$.

(D.1.1) Again two hyperbolic algebras correspond to this case. For the first one, the billiard walls are built out of the following couplings:

$$\lambda = \sqrt{2}; \quad \lambda' = \frac{1}{\sqrt{2}}; \quad \mu' = \sqrt{\frac{3}{2}};$$

$$\lambda'' = 0; \quad \mu'' = \sqrt{\frac{2}{3}}; \quad \nu'' = \frac{1}{\sqrt{3}}; \quad \lambda''' = 0; \quad \mu''' = \sqrt{\frac{2}{3}}; \quad \nu''' = \frac{2}{\sqrt{3}} \tag{5.18}$$

and the Dynkin diagram is that of the overextension $B_3^{\wedge\wedge}$,

5-4 
One can produce a billiard for the second one using the same couplings as in (5.18) except for

$$\lambda'' = 0; \quad \mu'' = 2\sqrt{\frac{2}{3}}; \quad \nu'' = \frac{2}{\sqrt{3}}. \tag{5.19}$$

The Dynkin diagram here describes the twisted overextension $A_5^{(2)\wedge}$,

5-5 
(D.1.2) Here also, two hyperbolic algebras correspond to this case but one is eliminated on account of the subdominant conditions. For the remaining one, the couplings are

$$\lambda = \sqrt{2}; \quad \lambda' = \frac{1}{\sqrt{2}}; \quad \mu' = \frac{1}{\sqrt{2}};$$

$$\lambda'' = 0; \quad \mu'' = \frac{1}{\sqrt{2}}; \quad \nu'' = \frac{1}{\sqrt{2}}; \quad \lambda''' = 0; \quad \mu''' = \frac{1}{\sqrt{2}}; \quad \nu''' = \frac{1}{\sqrt{2}} \tag{5.20}$$

and the Dynkin diagram is

5-6 
(D.2) $\lambda = 1$.

In Table 2 of Ref. 22, there are two hyperbolic algebras with a Dynkin diagram of this shape. Both are admissible for our present purpose:

(D.2.1) The first one has couplings given by

$$\lambda = 1; \quad \lambda' = \frac{1}{2}; \quad \mu' = \frac{\sqrt{3}}{2};$$

$$\lambda'' = 0; \quad \mu'' = \frac{2}{\sqrt{3}}; \quad \nu'' = \sqrt{\frac{2}{3}}; \quad \lambda''' = 0; \quad \mu''' = \frac{1}{\sqrt{3}}; \quad \nu''' = \sqrt{\frac{2}{3}} \tag{5.21}$$

and corresponds to

5-7 
(D.2.2) The second one requires

$$\lambda = 1; \quad \lambda' = \frac{1}{2}; \quad \mu' = \frac{\sqrt{3}}{2};$$

$$\lambda'' = 0; \quad \mu'' = \frac{1}{\sqrt{3}}; \quad \nu'' = \frac{1}{\sqrt{6}}; \quad \lambda''' = 0; \quad \mu''' = \frac{1}{\sqrt{3}}; \quad \nu''' = \sqrt{\frac{2}{3}} \tag{5.22}$$

and has the following diagram:

5-8 
Case E: Table 2 of Ref. 22 displays two hyperbolic algebras of rank 5 which are duals of each other and have linear diagrams. Only one of these two can be associated to a billiard the walls of which correspond to (E.1) $\lambda = \sqrt{2}$, $\lambda'' = \lambda''' = \mu''' = 0$ and all other dilaton couplings equal to $1/\sqrt{2}$.

Its Dynkin diagram is the twisted overextension $A_6^{(2)\wedge}$ and is given by

5-9 
There are however two more hyperbolic algebras with such linear Dynkin diagrams; they are missing in Ref. 22 but perfectly relevant in the present context:

(E.2) the first one is the overextension $C_3^{\wedge\wedge}$,

5-10 
whose couplings are equal to the previous ones except $\nu'''=\sqrt{2}$.

(E.3) The second one is the dual of $C_3^{\wedge\wedge}$ known as the twisted overextension $D_4^{(2)\wedge}$; its Dynkin diagram corresponds to the previous one with reversed arrows

5-11 
and the dilaton couplings are such that $\lambda=\lambda'=\mu'=\mu''=\nu''=\nu'''=\sqrt{2}$ while $\lambda''=\lambda'''=\mu'''=0$.

2. Two or more magnetic walls

That these cases may be discarded will be proved on a particular case but the argument can be easily generalized. Suppose the dominant set comprises two magnetic walls and two electric ones, we can always choose the parametrization such that

$$\alpha_1=\beta^2-\beta^1,$$

$$\alpha_2=\beta^1-\lambda\phi-\mu\varphi-\nu\psi,$$

$$\alpha_3=\beta^1-\lambda'\phi-\mu'\varphi+\nu'\psi,$$

$$\alpha_4=\lambda''\phi+\mu''\varphi,$$

$$\alpha_5=\lambda'''\phi. \tag{5.23}$$

Being assumed subdominant, the electric walls $\tilde{\alpha}_2=\lambda\phi+\mu\varphi+\nu\psi$ and $\tilde{\alpha}_3=\lambda'\phi+\mu'\varphi-\nu'\psi$, independent of β^1, must be written as positive linear combinations of α_4 and α_5 only; this requires $\nu=\nu'=0$ but then (5.23) can no longer describe a rank five root system.

The same argument remains of course valid for more magnetic walls.

B. *D*>3

The empirical oxidation rule set up in the previous sections also holds for the rank 5 algebras:

(1) Diagram (5-1) is the Dynkin diagram of the overextension $A_3^{\wedge\wedge}$. The Lagrangian is that of pure gravity in $D_{\max}=6$.
(2) Diagram (5-2): the three-dimensional Lagrangian cannot be oxidized because of the norm of α_2.
(3) Diagram (5-3): The Lagrangian can be oxidized twice, up to $D_{\max}=5$. The dominant walls are the three symmetry walls $\alpha_1=\beta^4-\beta^3$, $\alpha_2=\beta^3-\beta^2$, $\alpha_3=\beta^2-\beta^1$ and the electric wall of a 1-form

$$\alpha_4=\beta^1-\sqrt{1/3}\phi \tag{5.24}$$

and its magnetic wall

$$\alpha_5=\beta^1+\beta^2+\sqrt{1/3}\phi. \tag{5.25}$$

Obviously, $\tilde{\alpha}_4=\alpha_5$ and $\tilde{\alpha}_5=\alpha_4$.

(4) Diagram (5-4) represents $B_3^{\wedge\wedge}$. The maximally oxidized Lagrangian is six-dimensional. The dominant walls are here the four symmetry walls $\alpha_1=\beta^5-\beta^4$, $\alpha_2=\beta^4-\beta^3$, $\alpha_3=\beta^3-\beta^2$, $\alpha_4=\beta^2-\beta^1$, and

$$\alpha_5=\beta^1+\beta^2, \tag{5.26}$$

which is the electric or magnetic wall of a self-dual 2-form: obviously $\tilde{\alpha}_5=\alpha_5$.

(5) Diagram (5-5) is the twisted overextension $A_5^{(2)\wedge}$. Here, $D_{\max}=4$ and besides the symmetry walls $\alpha_1=\beta^3-\beta^2$ and $\alpha_2=\beta^2-\beta^1$, one finds

$$\alpha_3=\beta^1-\sqrt{3/2}\phi, \tag{5.27}$$

$$\alpha_4=\sqrt{2/3}\phi-2/\sqrt{3}\varphi, \tag{5.28}$$

$$\alpha_5=2\sqrt{2/3}\varphi+2/\sqrt{3}\psi, \tag{5.29}$$

which are the electric walls, respectively, of a one-form and two 0-forms. One easily checks that $\tilde{\alpha}_3=\alpha_3+\alpha_4+\alpha_5$, $\tilde{\alpha}_4=\alpha_2+2\alpha_3+\alpha_5$, and $\tilde{\alpha}_5=\alpha_2+2\alpha_3+\alpha_4$.

(6) Diagram (5-6): $D_{\max}=4$ and one needs $\alpha_1=\beta^3-\beta^2$, $\alpha_2=\beta^2-\beta^1$, and

$$\alpha_3=\beta^1-\sqrt{1/2}\phi, \tag{5.30}$$

$$\alpha_4=\sqrt{1/2}\phi-\sqrt{1/2}\varphi, \tag{5.31}$$

$$\alpha_5=\sqrt{1/2}\phi+\sqrt{1/2}\varphi. \tag{5.32}$$

The form-field content is the same as the previous one but the dilaton couplings are different. Moreover: $\tilde{\alpha}_3=\alpha_3+\alpha_4+\alpha_5$, $\tilde{\alpha}_4=\alpha_2+2\alpha_3+\alpha_5$, and $\tilde{\alpha}_5=\alpha_2+2\alpha_3+\alpha_4$.

(7) Diagrams (5-7) and (5-8): their 3D Lagrangians cannot be further oxidized because of the norm of α_2.

(8) Diagram (5-9) describes $A_6^{(2)\wedge}$. Here, $D_{\max}=4$. One obtains the billiard with $\alpha_1=\beta^3-\beta^2$, $\alpha_2=\beta^2-\beta^1$, and

$$\alpha_3=\beta^1-\sqrt{1/2}\phi, \tag{5.33}$$

$$\alpha_4=\sqrt{1/2}\phi-\sqrt{1/2}\varphi, \tag{5.34}$$

$$\alpha_5=\sqrt{1/2}\varphi. \tag{5.35}$$

One draws the same conclusion as for (5-6) and (5-9) above. Here again: $\tilde{\alpha}_3=\alpha_3+\alpha_4+\alpha_5$, $\tilde{\alpha}_4=\alpha_2+2\alpha_3+\alpha_4+2\alpha_5$, and $\tilde{\alpha}_5=\alpha_2+2\alpha_3+2\alpha_4+\alpha_5$.

(9) Diagram (5-10) is the overextension $C_3^{\wedge\wedge}$; the maximal oxidation dimension is $D_{\max}=4$ and the corresponding Lagrangian can be found in Ref. 12.

(10) Diagram (5-11) is the twisted overextension $D_4^{(2)\wedge}$. No Lagrangian exists in higher dimensions.

Comment:

The results of this section show again that the subdominant conditions play an important role in three dimensions where they effectively contribute to the elimination of several Dynkin diagrams. However, once they are satisfied in three dimensions, they are always fulfilled in all dimensions where a Lagrangian exists and only integers enter the linear combinations.

VI. RANK 6 HYPERBOLIC ALGEBRAS

A. $D=3$

The number of dilatons in the three-dimensional Lagrangian is equal to $N=4$: we denote them by $\phi^1=\phi, \phi^2=\varphi, \phi^3=\psi, \phi^4=\chi$. A straightforward generalization of the argument used in the previous sections implies that a single configuration for the set of dominant walls has to be considered. It comprises one magnetic wall and four electric ones.

After allowed simplifications, the dominant walls are parametrized according to

$$\alpha_1 = \beta^2 - \beta^1, \tag{6.1}$$

$$\alpha_2 = \beta^1 - \lambda\phi, \tag{6.2}$$

$$\alpha_3 = \lambda'\phi - \mu'\varphi, \tag{6.3}$$

$$\alpha_4 = \lambda''\phi + \mu''\varphi - \nu''\psi, \tag{6.4}$$

$$\alpha_5 = \lambda'''\phi + \mu'''\varphi + \nu'''\psi - \rho'''\chi, \tag{6.5}$$

$$\alpha_6 = \lambda''''\phi + \mu''''\varphi + \nu''''\psi + \rho''''\chi. \tag{6.6}$$

The structure of the Dynkin diagrams is therefore displayed in one of the cases labeled A–E below, depending on the number of vertices connected to α_2. When necessary, further subclasses are introduced according to the number of vertices linked to α_3.

Case A: The central vertex is labeled α_2 and is connected to the five other vertices:

A 
There is a single hyperbolic algebra of this type in Ref. 22; one can solve the equations for the dilaton couplings, but the subdominant walls are not expressible as positive linear combinations of the dominant ones.

Case B: The root α_2 is connected to four vertices:

B 
There are three hyperbolic algebras with that kind of Dynkin diagram but none of them can be retained: indeed, couplings exist but the subdominant conditions cannot be fulfilled.

Case C: α_2 has three links.

One has first the loop diagram

C.1 
One hyperbolic algebra has such a Dynkin diagram, namely, the overextension $A_4^{\wedge\wedge}$. As we already know from Ref. 6, the searched for three-dimensional Lagrangian coincides with the toroidal dimensional reduction of the seven-dimensional Einstein–Hilbert Lagrangian. The dilaton couplings are given by

$$\lambda = \sqrt{2}; \quad \lambda' = \frac{1}{\sqrt{2}}; \quad \mu' = \sqrt{\frac{3}{2}}; \quad \lambda'' = 0; \quad \mu'' = \sqrt{\frac{2}{3}}; \quad \nu'' = \frac{2}{\sqrt{3}}; \quad \lambda''' = 0; \quad \mu''' = 0;$$
$$\nu''' = \frac{\sqrt{3}}{2}; \quad \rho''' = \frac{\sqrt{5}}{2}; \quad \lambda'''' = \frac{1}{\sqrt{2}}; \quad \mu'''' = \frac{1}{\sqrt{6}}; \quad \nu'''' = \frac{1}{2\sqrt{3}}; \quad \rho'''' = \frac{\sqrt{5}}{2} \tag{6.7}$$

and its Dynkin diagram is

6-1 
Next comes the tree diagram

C.2 
Two hyperbolic algebras have a Dynkin diagram of this shape; but they cannot be associated with billiards again because of the impossibility to satisfy the subdominant conditions.

One also has to allow a relabeling of the vertices according to

C.3 
There are five hyperbolic algebras of that type; but for only one of them can one fulfill all conditions. The dilaton couplings are given by

$$\lambda = \sqrt{2}; \quad \lambda' = \frac{1}{\sqrt{2}}; \quad \mu' = \sqrt{\frac{3}{2}}; \quad \lambda'' = 0; \quad \mu'' = \sqrt{\frac{2}{3}}; \quad \nu'' = \frac{1}{\sqrt{3}}; \quad \lambda''' = \frac{1}{\sqrt{2}}; \quad \mu''' = \frac{1}{\sqrt{6}};$$
$$\nu''' = \frac{1}{\sqrt{3}}; \quad \rho''' = 1; \quad \lambda'''' = 0; \quad \alpha'''' = 0; \quad \beta'''' = 0; \quad \rho'''' = 1 \tag{6.8}$$

and its Dynkin diagram is the following

6-2 
Cases D are characterized by the fact that α_2 has two links:

(D.1). Corresponds further to α_3 having four links

D.1 
Three diagrams of (Ref. 22) fit in this shape; only two of them are realized through billiards. The couplings of the first one are given by

$$\lambda = \sqrt{2}; \quad \lambda' = \frac{1}{\sqrt{2}}; \quad \mu' = \sqrt{\frac{3}{2}}; \quad \lambda'' = 0; \quad \mu'' = \sqrt{\frac{2}{3}} = \mu'''; \quad \nu'' = \frac{2}{\sqrt{3}}; \quad \lambda''' = 0;$$
$$\nu''' = \frac{1}{\sqrt{3}}; \quad \rho''' = 1; \quad \lambda'''' = 0; \quad \mu'''' = \sqrt{\frac{2}{3}}; \quad \nu'''' = \frac{1}{\sqrt{3}}; \quad \rho'''' = 1, \tag{6.9}$$

they provide the Dynkin diagram which is $D_4^{\wedge\wedge}$:

6-3 
For the second one, $\lambda = 1$ and all the other couplings are those given in (6.9) divided by $\sqrt{2}$. They lead to the following diagram:

6-4 
Case (D.2) corresponds to α_3 having three connections

D.2 
and differs from (C.3) above by the assignment of the symmetry root. There are 4 Dynkin diagrams representing hyperbolic algebras of this type and they all admit a billiard.

(D.2.1) The couplings are

$$\lambda = 1; \quad \lambda' = \frac{1}{2}; \quad \mu' = \frac{\sqrt{3}}{2}; \quad \lambda'' = 0; \quad \mu'' = \frac{1}{\sqrt{3}}; \quad \nu'' = \sqrt{\frac{2}{3}}; \quad \lambda''' = 0; \quad \mu''' = \frac{1}{\sqrt{3}};$$
$$\nu''' = \frac{1}{\sqrt{6}}; \quad \rho''' = \frac{1}{\sqrt{2}}; \quad \lambda'''' = 0; \quad \mu'''' = 0; \quad \nu'''' = 0; \quad \rho'''' = \sqrt{2}, \tag{6.10}$$

and the Dynkin diagram corresponds to

6-5 
(D.2.2) The couplings are the same as in (6.10) above except ρ'''' which reads

$$\rho'''' = 1/\sqrt{2}. \tag{6.11}$$

The Dynkin diagram is

6-6 
(D.2.3) The dilaton couplings are given by

$$\lambda = \sqrt{2}; \quad \lambda' = \frac{1}{\sqrt{2}}; \quad \mu' = \sqrt{\frac{3}{2}}; \quad \lambda'' = 0; \quad \mu'' = \sqrt{\frac{2}{3}}; \quad \nu'' = \frac{2}{\sqrt{3}}; \quad \lambda''' = 0; \quad \mu''' = \sqrt{\frac{2}{3}};$$

$$\nu''' = \frac{1}{\sqrt{3}}; \quad \rho''' = 1; \quad \lambda'''' = 0; \quad \mu'''' = 0; \quad \nu'''' = 0; \quad \rho'''' = 1 \tag{6.12}$$

they provide the Dynkin diagram of $B_4^{\wedge\wedge}$,

6-7 
(D.2.4) The couplings are the same as in (6.12) except

$$\rho'''' = 2 \tag{6.13}$$

and the algebra is $A_7^{(2)\wedge}$,

6-8 
Case D.3 describes the general structure below in which α_2 and α_3 have two links while α_4 is connected three times

D.3 
There are two hyperbolic algebras of that type but only one satisfies all billiard conditions. Its nonzero couplings are

$$\lambda = \sqrt{2} \quad \text{and} \quad \lambda' = \mu' = \mu'' = \nu'' = \nu''' = \rho''' = \rho'''' = 1/\sqrt{2}. \tag{6.14}$$

The Dynkin diagram is

6-9 
Case E: This set provides all linear diagrams. There are seven hyperbolic algebras of this kind and all of them are admissible

E 
(E.1) has the following couplings:

$$\lambda = \sqrt{2}; \quad \lambda' = \frac{1}{\sqrt{2}}; \quad \mu' = \sqrt{\frac{3}{2}}; \quad \lambda'' = 0; \quad \mu'' = \sqrt{\frac{2}{3}}; \quad \nu'' = \frac{2}{\sqrt{3}}; \quad \lambda''' = 0; \quad \mu''' = 0;$$

$$\nu''' = \sqrt{3}; \quad \rho''' = 1; \quad \lambda'''' = 0; \quad \mu'''' = 0; \quad \nu'''' = 0; \quad \rho'''' = 2, \tag{6.15}$$

and its Dynkin diagram belongs to $E_6^{(2)\wedge}$,

6-10 
(E.2) corresponds to

$$\lambda = \sqrt{2}; \quad \lambda' = \frac{1}{\sqrt{2}}; \quad \mu' = \sqrt{\frac{3}{2}}; \quad \lambda'' = 0; \quad \mu'' = \sqrt{\frac{2}{3}}; \quad \nu'' = \frac{1}{\sqrt{3}}; \quad \lambda''' = 0; \quad \mu''' = 0;$$
$$\nu''' = \frac{\sqrt{3}}{2}; \quad \rho''' = \frac{1}{2}; \quad \lambda'''' = 0; \quad \mu'''' = 0; \quad \nu'''' = 0; \quad \rho'''' = 1, \tag{6.16}$$

and its algebra is associated with

6-11 
(E.3) The walls are defined through the following set of parameters:

$$\lambda = \sqrt{2}; \quad \lambda' = \frac{1}{\sqrt{2}}; \quad \mu' = \sqrt{\frac{3}{2}}; \quad \lambda'' = 0; \quad \mu'' = \sqrt{\frac{2}{3}}; \quad \nu'' = \frac{2}{\sqrt{3}}; \quad \lambda''' = 0; \quad \mu''' = 0;$$
$$\nu''' = \frac{\sqrt{3}}{2}; \quad \rho''' = \frac{1}{2}; \quad \lambda'''' = 0; \quad \mu'''' = 0; \quad \nu'''' = 0; \quad \rho'''' = 1, \tag{6.17}$$

and the algebra is $F_4^{\wedge\wedge}$,

6-12 
(E.4) has the following couplings:

$$\lambda = \sqrt{2}; \quad \lambda' = \frac{1}{\sqrt{2}}; \quad \mu' = \frac{1}{\sqrt{2}}; \quad \lambda'' = 0; \quad \mu'' = \frac{1}{\sqrt{2}}; \quad \nu'' = \frac{1}{\sqrt{2}}; \quad \lambda''' = 0; \quad \mu''' = 0;$$
$$\nu''' = \frac{1}{\sqrt{2}}; \quad \rho''' = \frac{1}{\sqrt{2}}; \quad \lambda'''' = 0; \quad \mu'''' = 0; \quad \nu'''' = 0; \quad \rho'''' = \sqrt{2} \tag{6.18}$$

and its diagram corresponds to $C_4^{\wedge\wedge}$,

6-13 
(E.5) has the same couplings as those given in (6.18) except

$$\rho'''' = \frac{1}{\sqrt{2}}. \tag{6.19}$$

Its diagram corresponds to $A_8^{(2)\wedge}$,

6-14 
(E.6) is characterized by

$$\lambda = \sqrt{2}; \quad \lambda' = \sqrt{2}; \quad \mu' = \sqrt{2}; \quad \lambda'' = 0; \quad \mu'' = \sqrt{2}; \quad \nu'' = \sqrt{2}; \quad \lambda''' = 0; \quad \mu''' = 0;$$
$$\nu''' = \sqrt{2}; \quad \rho''' = \sqrt{2}; \quad \lambda'''' = 0; \quad \mu'''' = 0; \quad \nu'''' = 0; \quad \rho'''' = \sqrt{2} \tag{6.20}$$

and its diagram describes $D_5^{(2)\wedge}$,

6-15 
(E.7) is the last one of this rank; its couplings are

$$\lambda = 1; \quad \lambda' = \frac{1}{2}; \quad \mu' = \frac{\sqrt{3}}{2}; \quad \lambda'' = 0; \quad \mu'' = \frac{1}{\sqrt{3}}; \quad \nu'' = \sqrt{\frac{2}{3}}; \quad \lambda''' = 0; \quad \mu''' = 0;$$

$$\nu''' = \frac{\sqrt{3}}{2\sqrt{2}}; \quad \rho''' = \frac{1}{2\sqrt{2}}; \quad \lambda'''' = 0; \quad \mu'''' = 0; \quad \nu'''' = 0; \quad \rho'''' = \frac{1}{\sqrt{2}} \tag{6.21}$$

and its diagram gives $A_8^{(2)\prime\wedge}$,

6-15 
B. $D>3$

Our next task is again to study which of the 16 algebras admitting a three-dimensional billiard model allow in addition a higher dimensional Lagrangian description.

(1) Diagram (6-1) is the overextension $A_4^{\wedge\wedge}$. The maximal oxidation dimension is $D_{\max}=7$, where the Lagrangian describes pure gravity.[7]

(2) Diagram (6-2): Here, $D_{\max}=5$. The dominant walls are the symmetry walls $\alpha_1=\beta^4-\beta^3$, $\alpha_2=\beta^3-\beta^2$, $\alpha_3=\beta^2-\beta^1$, and

$$\alpha_4 = \beta^1 - 1/\sqrt{3}\phi, \tag{6.22}$$

$$\alpha_5 = \beta^1 + \beta^2 + 1/\sqrt{3}\phi - \psi, \tag{6.23}$$

$$\alpha_6 = \psi. \tag{6.24}$$

These are respectively the electric walls of a one-form, a two-form and a zero-form. One easily checks that $\tilde{\alpha}_4=\alpha_5+\alpha_6$, $\tilde{\alpha}_5=\alpha_4+\alpha_6$ and $\tilde{\alpha}_6=\alpha_2+\alpha_3+\alpha_4+\alpha_5$.

(3) Diagram (6-3) is the overextension $D_4^{\wedge\wedge}$; its 3D version can be oxidized up to $D_{\max}=6$ and the Lagrangian is written in Refs. 11 and 12.

(4) Diagrams (6-4), (6-5), and (6-6): their Lagrangians have no higher dimensional parent.

(5) Diagram (6-7) is the overextension $B_4^{\wedge\wedge}$. Remark that since the diagram has a fork one can oxidize in two different ways, both lead to $D_{\max}=6$. The Lagrangians can again be found in Refs. 11 and 12.

(6) Diagram (6-8) is the twisted overextension $A_7^{(2)\wedge}$. $D_{\max}=6$. The dominant walls are the symmetry walls $\alpha_1=\beta^5-\beta^4$, $\alpha_2=\beta^4-\beta^3$, $\alpha_3=\beta^3-\beta^2$, and $\alpha_4=\beta^2-\beta^1$, and

$$\alpha_5 = \beta^1 + \beta^2 - \phi, \tag{6.25}$$

$$\alpha_6 = 2\phi, \tag{6.26}$$

which are the electric walls of a 2-form and a zero-form. Their respective magnetic walls are subdominant; indeed one finds

$$\tilde{\alpha}_5 = \beta^1 + \beta^2 + \phi = \alpha_5 + \alpha_6, \tag{6.27}$$

$$\tilde{\alpha}_6 = \beta^1 + \beta^2 + \beta^3 + \beta^4 - 2\phi = 2\alpha_5 + \alpha_4 + 2\alpha_3 + \alpha_2. \tag{6.28}$$

(7) Diagram (6-9): $D_{\max}=4$. The wall system reads $\alpha_1=\beta^3-\beta^2$, $\alpha_2=\beta^2-\beta^1$ and

$$\alpha_3 = \beta^1 - 1/\sqrt{2}\phi, \tag{6.29}$$

$$\alpha_4 = 1/\sqrt{2}(\phi - \psi), \tag{6.30}$$

$$\alpha_5 = 1/\sqrt{2}(\psi - \chi), \tag{6.31}$$

$$\alpha_6 = 1/\sqrt{2}(\psi + \chi); \tag{6.32}$$

the last four are the electric walls of a 1-form and three zero-forms. The subdominant condition is fulfilled: indeed, one finds $\tilde{\alpha}_3 = \alpha_3 + 2\alpha_4 + \alpha_5 + \alpha_6$, $\tilde{\alpha}_4 = \alpha_2 + 2\alpha_3 + \alpha_4 + \alpha_5 + \alpha_6$, $\tilde{\alpha}_5 = \alpha_2 + 2\alpha_3 + 2\alpha_4 + \alpha_6$, $\tilde{\alpha}_6 = \alpha_2 + 2\alpha_3 + 2\alpha_4 + \alpha_5$.

(8) Diagram (6-10) is the twisted overextension $E_6^{(2)\wedge}$. The oxidation rule gives the maximal dimension $D_{\max} = 5$. The walls other than the symmetry ones are

$$\alpha_4 = \beta^1 - 2/\sqrt{3}\phi, \tag{6.33}$$

$$\alpha_5 = \sqrt{3}\phi - \varphi, \tag{6.34}$$

$$\alpha_6 = 2\varphi. \tag{6.35}$$

One checks that $\tilde{\alpha}_4 = \alpha_3 + 2\alpha_4 + 2\alpha_5 + \alpha_6$, $\tilde{\alpha}_5 = \alpha_2 + 2\alpha_3 + 3\alpha_4 + \alpha_5 + \alpha_6$, $\tilde{\alpha}_6 = \alpha_2 + 2\alpha_3 + 3\alpha_4 + 2\alpha_5$.

(9) Diagram (6-11): A Lagrangian exists in $D_{\max} = 5$ which produces besides the symmetry walls

$$\alpha_4 = \beta^1 - 1/\sqrt{3}\phi, \tag{6.36}$$

$$\alpha_5 = \sqrt{3}/2\phi - 1/2\varphi, \tag{6.37}$$

$$\alpha_6 = \varphi. \tag{6.38}$$

The subdominant conditions read $\tilde{\alpha}_4 = \alpha_3 + 2\alpha_4 + 2\alpha_5 + \alpha_6$, $\tilde{\alpha}_5 = \alpha_2 + 2\alpha_3 + 3\alpha_4 + \alpha_5 + \alpha_6$, and $\tilde{\alpha}_6 = \alpha_2 + 2\alpha_3 + 3\alpha_4 + 2\alpha_5$.

(10) Diagram (6-12) is the overextension $F_4^{\wedge\wedge}$; the maximally oxidized theory is six-dimensional and contains the metric, one dilaton, one zero-form, and a one-form.[11,12]

(11) Diagram (6-13) is the overextension $C_4^{\wedge\wedge}$.[11] This is the last one of its series: remember that the $C_n^{\wedge\wedge}$ algebras are hyperbolic only for $n \leqslant 4$. The maximal oxidation dimension is $D_{\max} = 4$; besides the symmetry walls, the other dominant ones are

$$\alpha_3 = \beta^1 - 1/\sqrt{2}\phi, \tag{6.39}$$

$$\alpha_4 = 1/\sqrt{2}(\phi - \varphi), \tag{6.40}$$

$$\alpha_5 = 1/\sqrt{2}(\varphi - \psi), \tag{6.41}$$

$$\alpha_6 = \sqrt{2}\psi. \tag{6.42}$$

The subdominant conditions are satisfied, they read $\tilde{\alpha}_3 = \alpha_3 + 2\alpha_4 + 2\alpha_5 + \alpha_6$, $\tilde{\alpha}_4 = \alpha_2 + 2\alpha_3 + \alpha_4 + 2\alpha_5 + \alpha_6$, $\tilde{\alpha}_5 = \alpha_2 + 2\alpha_3 + 2\alpha_4 + \alpha_5 + \alpha_6$, $\tilde{\alpha}_6 = \alpha_2 + 2\alpha_3 + 2\alpha_4 + 2\alpha_5$.

(12) Diagram (6-14) is the twisted overextension $A_8^{(2)\wedge}$. There is no higher dimensional theory.

(13) Diagram (6-15) represents $D_5^{(2)\wedge}$. In $D_{\max} = 4$, the dominant walls other than the symmetry ones are given by

$$\alpha_3 = \beta^1 - 1/\sqrt{2}\phi, \tag{6.43}$$

$$\alpha_4 = 1/\sqrt{2}(\phi - \varphi), \tag{6.44}$$

$$\alpha_5 = 1/\sqrt{2}(\varphi - \psi), \tag{6.45}$$

$$\alpha_6 = 1/\sqrt{2}\psi. \tag{6.46}$$

One obtains easily the following expressions $\tilde{\alpha}_3 = \alpha_3 + 2\alpha_4 + 2\alpha_5 + \alpha_6$, $\tilde{\alpha}_4 = \alpha_2 + 2\alpha_3 + \alpha_4 + 2\alpha_5 + 2\alpha_6$, $\tilde{\alpha}_5 = \alpha_2 + 2\alpha_3 + 2\alpha_4 + \alpha_5 + 2\alpha_6$, $\tilde{\alpha}_6 = \alpha_2 + 2\alpha_3 + 2\alpha_4 + 2\alpha_5 + \alpha_6$.

(14) Diagram (6-16) describes $A_8^{(2)\prime\wedge}$; it cannot be associated to a billiard in $D > 3$.

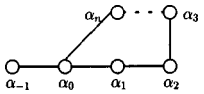
Comment:

Here again, in $D > 3$, the subdominant conditions are always satisfied; it is only in $D = 3$ that their role is crucial in the selection of the admissible algebras. Hence, they do not add any constraint in the oxidation construction.

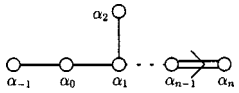
VII. RANK 7, 8, 9, AND 10 HYPERBOLIC ALGEBRAS

These hyperbolic algebras fall into two classes: the first one comprises all algebras of rank $7 \leqslant r \leqslant 10$ that are overextensions of the following finite simple Lie algebras $A_n, B_n, D_n, E_6, E_7, E_8$. They are

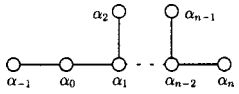
$A_n^{\wedge\wedge}$ $(n = 5,6,7)$,



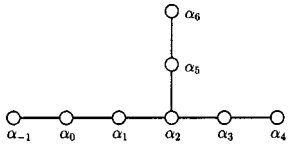
$B_n^{\wedge\wedge}$ $(n = 5,6,7,8)$,



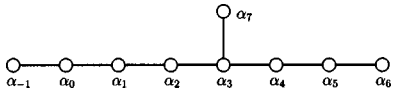
$D_n^{\wedge\wedge}$ $(n = 5,6,7,8)$,



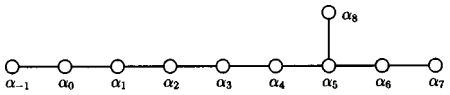
$E_6^{\wedge\wedge}$,



$E_7^{\wedge\wedge}$,

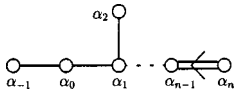


$E_8^{\wedge\wedge}$,



In the second class, one finds the four duals of the $B_n^{\wedge\wedge}$ $(n=5,6,7,8)$, i.e., the algebras known as $CE_{n+2}=A_{2n-1}^{(2)\wedge}$,

$$CE_{n+2} = A_{2n-1}^{(2)\wedge},$$



A. Overextensions of finite simple Lie algebras

The algebras of the first class have already been encountered as billiards of some three-dimensional G/H coset theories as explained in Ref. 12 to which we refer for more information. Those of rank 10, E_{10}, BE_{10}, and DE_{10} have been found[8] to describe the billiards of the seven string theories, M, IIA, IIB, I, HO, HE and the closed bosonic string in 10 dimensions. More precisely, these theories split into three separate blocks which correspond to three distinct billiards: namely, $\mathcal{B}_2=\{M, IIA, IIB\}$ leads to E_{10}, $\mathcal{B}_1=\{I, HO, HE\}$ corresponds to BE_{10}, and $\mathcal{B}_0=\{D=10$ closed bosonic string$\}$ gives DE_{10}.

For sake of completeness, we here simply recall the maximal spacetime dimensions and the specific p-forms menus producing the billiards.

(1) $A_n^{\wedge\wedge}$ $(n=5,6,7)$: the Lagrangian is that of pure gravity in $D_{\max}=n+3$.
(2) $B_n^{\wedge\wedge}$ $(n=5,6,7,8)$: the maximally oxidized Lagrangian lives in $D_{\max}=n+2$, where it comprises a dilaton, a 1-form coupled to the dilaton with coupling equal to $\lambda^{(1)}(\phi)=\phi/\sqrt{d-1}$ and a 2-form coupled to the dilaton with coupling equal to $\lambda^{(2)}(\phi)=2\phi/\sqrt{d-1}$.
(3) $D_n^{\wedge\wedge}$ $(n=5,6,7,8)$: a Lagrangian exists in $D_{\max}=n+2$ and comprises a dilaton and a 2-form coupled to the dilaton with coupling equal to $\lambda^{(2)}(\phi)=2\phi/\sqrt{d-1}$.
(4) $E_6^{\wedge\wedge}$: the maximal oxidation dimension is $D_{\max}=8$. The Lagrangian has a dilaton, a 0-form with coupling $\lambda^{(0)}(\phi)=\phi\sqrt{2}$ and a 3-form with coupling $\lambda^{(3)}(\phi)=-\phi/\sqrt{2}$.
(5) $E_7^{\wedge\wedge}$: the maximal space–time dimension is $D_{\max}=10$. The Lagrangian describes gravity and a 4-form: it is a truncation of type IIB supergravity.
(6) $E_8^{\wedge\wedge}$: $D_{\max}=11$. The Lagrangian describes gravity coupled to a 3-form; it is the bosonic sector of eleven dimensional supergravity.

B. The algebras $CE_{n+2}=A_{2n-1}^{(2)\wedge}$

The Weyl chamber of the algebras CE_{n+2} $(n=5,6,7,8)$, which are dual to $B_n^{\wedge\wedge}$, allows a billiard realization in maximal dimension $D_{\max}=n+1=d+1$. The field content of the theory is the following: there are two dilatons, ϕ and φ, a 0-form coupled to the dilatons through

$$\lambda^{(0)}(\phi) = 2\sqrt{\frac{(d-1)}{d}}\phi - \frac{2}{\sqrt{d}}\varphi, \tag{7.1}$$

a one form with dilaton couplings

$$\lambda^{(1)}(\phi) = -\sqrt{\frac{d}{(d-1)}}\ \phi \tag{7.2}$$

and a 2-form with the following couplings

$$\lambda^{(2)}(\phi) = -\frac{2}{\sqrt{d(d-1)}}\phi - \frac{2}{\sqrt{d}}\varphi. \tag{7.3}$$

In particular, the Lagrangian in $D_{\max}=9$ producing the billiard identifiable as the fundamental Weyl chamber of CE_{10} corresponds to $n=8=d$ and is explicitly given by[30]

$$\mathcal{L}_9 = {}^{(9)}R * \mathbb{1} - \star d\phi \wedge d\phi - \star d\varphi \wedge d\varphi - \tfrac{1}{2}\, e^{(2\phi\sqrt{7/2}-\varphi\sqrt{2})} \star F^{(1)} \wedge F^{(1)} - \tfrac{1}{2} e^{-4\phi\sqrt{2/7}} \star F^{(2)} \wedge F^{(2)} - \tfrac{1}{2}\, e^{-(\phi\sqrt{2/7}+\varphi\sqrt{2})} \star F^{(3)} \wedge F^{(3)}. \tag{7.4}$$

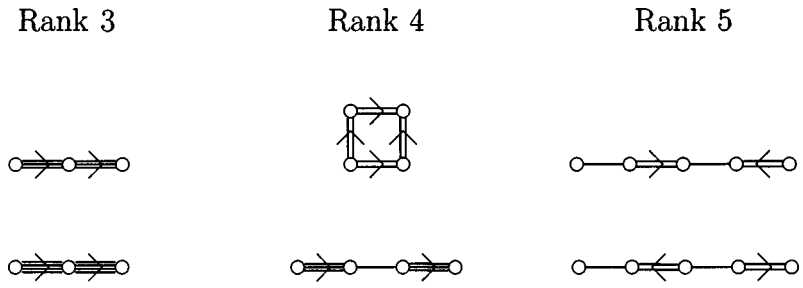
CE_{10} is the fourth hyperbolic algebra of rank 10; contrary to the other three cited above, which belong to the class of the overtextensions of finite simple Lie algebras, its Lagrangian (7.4) does not stem from string theories.

VIII. CONCLUSIONS

In this paper we have presented all Lagrangian systems in which gravity, dilatons and p-forms combine in such a way as to produce a billiard that can be identified with the Weyl chamber of a given hyperbolic Kac Moody algebra. Exhaustive results have been systematically obtained by first constructing Lagrangians in three space–time dimensions, at least for the algebras of rank $r \leqslant 6$. We insist on the fact that our three-dimensional Lagrangians are not assumed to realize a coset theory. We also have solved the oxidation problem and provided the Lagrangians in the maximal space time dimension with their p-forms content and specific dilaton couplings. It turns out that the subdominant conditions play no role in the oxidation analysis. The positive integer coefficients that appear when expressing the subdominant walls in terms of the dominant ones in the maximal oxidation dimension have been systematically worked out.

IX. MORE HYPERBOLIC ALGEBRAS

For completeness, we draw hereafter the Dynkin diagrams of 6 hyperbolic algebras missing in Ref. 22. This raises their total number to 142, in agreement with Ref. 31.



ACKNOWLEDGMENTS

We are grateful to Marc Henneaux for suggesting the problem. Thanks to Patrick Meessen for a useful reference. Lifshits tails for random smooth magnetic vortices

J. L. Borg[a] and J. V. Pulé[b]
Department of Mathematical Physics, University College Dublin (National University of Ireland, Dublin), Belfield, Dublin 4, Ireland

(Received 18 May 2004; accepted 6 August 2004; published 4 November 2004)

We study the density of states of the Pauli Hamiltonian with a Poisson random distribution of smooth finite-width vortices and we obtain classical bounds for the Lifshits tails for them. These Hamiltonians are smooth approximations to the self-adjoint extensions of the Aharonov–Bohm Hamiltonian. In this case because pairs of impurities are coupled by the magnetic field we cannot use the Laplace characteristic functional. © *2004 American Institute of Physics.*

I. INTRODUCTION

The following formal Hamiltonian may be used to represent a system of magnetic vortices distributed randomly in a two-dimensional domain:

$$H=\frac{1}{2m}\left(\mathbf{p}-\sum_{i=1}^{N}\alpha\frac{\mathbf{k}\times(\mathbf{r}-\mathbf{r}_i)}{(\mathbf{r}-\mathbf{r}_i)^2}\right)^2+\sum_{i=1}^{N}\pi\frac{\beta}{m}\delta^2(\mathbf{r}-\mathbf{r}_i). \tag{1.1}$$

It is known experimentally[1,2] that magnetic vortices may appear in two-dimensional electron gas layers on top of superconductivity materials when the external magnetic field penetrates the sample at some points in the form of isolated random flux tubes. Suppression of the Hall conductivity has been observed in these cases.

Numerical calculations using perturbation theory have been carried out in Refs. 3–5. For the operator considered in (1.1), with a repulsive delta function and the assumption that $\alpha\in\left[-\frac{1}{2},\frac{1}{2}\right]$, numerical calculations for the case $\beta=|\alpha|$, have shown that[4] if α is small, the density of states of this operator exhibits Landau oscillations, while for α close to $\frac{1}{2}$, no such oscillations are observed, indeed the density of states increases monotonically and there is a Lifshits tail at the bottom of the spectrum ($E=0$). It has been proposed[5] that this model may explain some features of the integer quantum Hall effect.

The integrated density of states and the existence of Lifshits tails for random Schrödinger operators of the type $-\Delta+V_\omega$, where V_ω is a random scalar potential, have been the object of extensive study in mathematical physics (see Refs. 6–8 for the basic theory and results). Recently there has been much interest in the study of their generalization to random Schrödinger operators with magnetic field

$$H(\mathbf{A},V_\omega)=(\mathbf{p}+\mathbf{A}_\omega)^2+V_\omega. \tag{1.2}$$

The case of nonrandom magnetic field was studied in, for example, Refs. 9–13 while other papers have proved results for Lifshits tails for operators where the magnetic field is random.[14–16]

Nakamura[14] has studied the case where $\mathbf{A}_\omega$ is random, $V_\omega=0$ and the magnetic field $\mathbf{B}_\omega=\nabla\times\mathbf{A}_\omega$ is almost surely uniformly bounded on $\mathbb{R}^d$, $d\geqslant 2$. He obtained the following result for the Lifshits tails of the integrated density of states $N(\lambda)$:

$$\limsup_{\lambda\downarrow 0}\frac{\ln(-\ln N(\lambda))}{\ln\lambda}\leqslant -\frac{d}{2}. \tag{1.3}$$

Ueki[15] considered the case when $\mathbf{A}_\omega$ and V_ω are independent, and V_ω is Gaussian. He obtained

$$\lim_{\lambda\to-\infty}\frac{\ln N(\lambda)}{\lambda^2}=-\frac{1}{2\gamma(0)}, \tag{1.4}$$

where γ is the covariance of V_ω. In Ref. 16, the operator considered is the Pauli operator $(\mathbf{p}-\mathbf{A}_\omega)^2\pm(g/2)\mathbf{k}\cdot\mathbf{B}_\omega$, where $g>2$ is the anomalous magnetic moment, and $\mathbf{k}\cdot\mathbf{B}_\omega$ is a Gaussian field. In this case

$$\lim_{\lambda\to-\infty}\frac{\ln N(\lambda)}{\lambda^2}=-\frac{2}{(g-2)^2\gamma(0)}, \tag{1.5}$$

where γ is the covariance of $\mathbf{k}\cdot\mathbf{B}_\omega$.

In this paper we study the Pauli Hamiltonian for a Poisson random distribution of smooth finite-width Aharonov–Bohm vortices. These vortices are based on smooth approximations to the self-adjoint extensions of the Aharonov–Bohm Hamiltonian analyzed in Ref. 17, with the added condition that cutoffs are introduced to ensure that the vector potential is summable.

With probability one, the spectrum of this operator is the whole real line. We obtain classical bounds for the asymptotic behavior of the integrated density of states at the bottom of the spectrum. The analysis follows the method of Ref. 6 for a random Schrödinger operator with a Poisson distributed random potential. However the expression for the potential is not simply a sum over all the atoms of the Poisson distribution, but contains also cross-terms. For this reason, we cannot use the Laplace characteristic functional and have to proceed by a direct method. The cases mentioned above for random magnetic fields are different from the present one, since in this case $\mathbf{B}_\omega$ is neither bounded nor Gaussian.

II. THE MODEL

The Aharonov–Bohm (AB) Hamiltonian[18] is formally given by

$$H^{AB}=(\mathbf{p}+\mathbf{A})^2, \tag{2.1}$$

where

$$\mathbf{A}(\mathbf{r})=\alpha\frac{\mathbf{k}\times\mathbf{r}}{r^2}.$$

This Hamiltonian is not essentially self-adjoint, but has a four-parameter family of self-adjoint extensions,[19,20] which reduces to a two-parameter family if only those self-adjoint extensions that commute with the angular momentum operator are considered.

In Ref. 17, finite-width approximations to the self-adjoint extensions of the AB Hamiltonian were studied. Let $\tilde{a}:\mathbb{R}\mapsto\mathbb{R}$ be a smooth, monotonic nondecreasing function with $\tilde{a}(r)=0$ for $r\leqslant 0$ and $\tilde{a}(r)=1$ for $r\leqslant 1$. Let $\tilde{b}(r)=(1/r)(d/dr)\tilde{a}(r)$. Then $\tilde{b}$ has support only in [0, 1], and $\int_0^\infty\tilde{b}(r)r\,dr=1$. Let $\alpha\notin\mathbb{Z}$, and write $|\alpha|=N+\delta$, where $N\in\mathbb{N}_0$ and $0<\delta<1$. We take

$$\mathbf{A}_\rho(\mathbf{r})=\alpha\frac{\hat{\mathbf{k}}\times\mathbf{r}}{r^2}\tilde{a}\left(\frac{r-\rho}{\rho^5}\right) \tag{2.2}$$

for $\rho>0$ and $\mathbf{B}_\rho=\mathrm{curl}\,\mathbf{A}_\rho$. Then

$$\hat{\mathbf{k}} \cdot \mathbf{B}_\rho(\mathbf{r}) = \alpha\left(1 - \frac{\rho}{r}\right)\rho^{-10}\tilde{b}\left(\frac{r-\rho}{\rho^5}\right). \tag{2.3}$$

Let

$$H_\rho = (i\nabla + \mathbf{A}_\rho)^2 + \frac{\beta}{\alpha}\hat{\mathbf{k}} \cdot \mathbf{B}_\rho. \tag{2.4}$$

β may be identified with $-\frac{1}{2}g\alpha$, where g is the anomalous magnetic moment. In Ref. 17 it was shown that only two one-parameter subfamilies of self-adjoint extensions of the Aharonov–Bohm Hamiltonian can be approximated as $\rho \to 0$, in the norm resolvent sense, by such Pauli operators. For the operator H_ρ in $L^2(\mathbb{R}^2)$ to be a smooth approximation an element of the one of these one-parameter families of self-adjoint extensions, β must depend on ρ, for small ρ, in one of the following ways:

$$\text{(a) } \beta(\alpha,\rho) \simeq -|\alpha|\left(1 - \frac{2\delta}{|\alpha|}\nu\rho^{2\delta}\right), \tag{2.5}$$

$$\text{(b) } \beta(\alpha,\rho) \simeq (|\alpha| - 2(N+1))\left(1 - \frac{2(1-\delta)}{2(N+1) - |\alpha|}\nu\rho^{2(1-\delta)}\right), \tag{2.6}$$

for some constant ν satisfying $-\infty < \nu \leqslant \infty$.

We note here that

(1) $\lim_{\rho\to 0} \beta \leqslant -|\alpha|$;

(2) if we suppose that $\hat{\mathbf{k}}\cdot\mathbf{B}_\rho(\mathbf{r})$ has a maximum point at r_0, then it is easy to see that for small ρ the inequality

$$\hat{\mathbf{k}} \cdot \mathbf{B}_\rho(r_0) > \frac{a(r_0)}{r_0^2}, \tag{2.7}$$

is satisfied.

Motivated by the above discussion, we shall consider the following Hamiltonian in $L^2(\mathbb{R}^2)$

$$H = (i\nabla + \mathbf{A}(\mathbf{r} - \mathbf{r}_1))^2 + \frac{\beta}{\alpha}\hat{\mathbf{k}} \cdot \mathbf{B}(\mathbf{r} - \mathbf{r}_1), \tag{2.8}$$

where

$$\mathbf{A}(\mathbf{r}) = \alpha\frac{\hat{\mathbf{k}} \times \mathbf{r}}{r^2}a(r) \text{ and } \mathbf{B} = \operatorname{curl}\mathbf{A}. \tag{2.9}$$

We shall assume that $\beta \leqslant -|\alpha|$ and that $a:\mathbb{R}\mapsto\mathbb{R}$ is of class C_0^4 with $a(r)=0$ for $r\leqslant 0$. Note that $\operatorname{div}\mathbf{A}=0$ and we have $\hat{\mathbf{k}}\cdot\mathbf{B}(\mathbf{r})=\alpha\, b(r)$ where $b(r)=(1/r)(d/dr)a(r)$. We assume also that at a maximum point r_0 of b,

$$b_0 := b(r_0) > \frac{a(r_0)}{r_0^2}. \tag{2.10}$$

So far we have considered a smooth magnetic vortex centered at $\mathbf{r}_1$. Let $\mathbf{r}_i \in \mathbb{R}^2$, where $i \in \mathbb{N}$, be distributed with a Poisson distribution in $\mathbb{R}^2$. Then the Pauli Hamiltonian H_ω in $L^2(\mathbb{R}^2)$ for an infinite set of Poisson distributed smooth vortices is as follows:

$$H_\omega = \left(i\nabla + \sum_{i=1}^{\infty} \mathbf{A}(\mathbf{r}-\mathbf{r}_i) \right)^2 + \frac{\beta}{\alpha}\hat{\mathbf{k}} \cdot \sum_{i=1}^{\infty} \mathbf{B}(\mathbf{r}-\mathbf{r}_i). \tag{2.11}$$

We can use an adaptation of the usual argument to show that with probability one the spectrum of this operator is $\mathbb{R}$. We need to show that with nonzero probability the spectrum of H_ω contains arbitrarily large negative numbers (cf. Theorem 5.34 of Ref. 6). Since $\operatorname{div} \mathbf{A}=0$,

$$\langle \psi, \mathbf{A}(\cdot - \mathbf{r}_i) \cdot \nabla \psi \rangle = -\langle \mathbf{A}(\cdot - \mathbf{r}_i) \cdot \nabla \psi, \psi \rangle. \tag{2.12}$$

Therefore if ψ is real valued

$$\langle \psi, \mathbf{A}(\cdot - \mathbf{r}_i) \cdot \nabla \psi \rangle = 0 \tag{2.13}$$

and thus

$$\langle \psi, H_\omega \psi \rangle = \langle \psi, (-\Delta + V)\psi \rangle, \tag{2.14}$$

where

$$V(\mathbf{r}) = \frac{\beta}{\alpha}\hat{\mathbf{k}} \cdot \sum_{i=1}^{\infty} \mathbf{B}(\mathbf{r}-\mathbf{r}_i) + \left| \sum_{i=1}^{\infty} \mathbf{A}(\mathbf{r}-\mathbf{r}_i) \right|^2 = \beta \sum_{i=1}^{\infty} b(|\mathbf{r}-\mathbf{r}_i|) + \alpha^2 \left| \sum_{i=1}^{\infty} \mathbf{D}(\mathbf{r}-\mathbf{r}_i) \right|^2, \tag{2.15}$$

with

$$\mathbf{D}(\mathbf{r}) = \frac{a(|\mathbf{r}|)}{|\mathbf{r}|^2}\mathbf{r}.$$

Consider what happens at the origin if n Poisson points are placed symmetrically on a circle of radius r_0 centered at the origin so that $\Sigma_{i=1}^{n}\mathbf{r}_i=0$, while all the others are located very far from the origin. Then

$$V(\mathbf{0}) = \beta \sum_{i=1}^{n} b(|\mathbf{r}_i|) + \alpha^2 \left| \sum_{i=1}^{n} \mathbf{D}(\mathbf{r}_i) \right|^2 = \beta n b(r_0) + \alpha^2 \frac{a^2(r_0)}{r_0^4} \left| \sum_{i=1}^{n} \mathbf{r}_i \right|^2 = -n|\beta| b_0. \tag{2.16}$$

Thus by this configuration we can produce an arbitrarily deep well and by varying this configuration slightly we can do this with nonzero probability.

III. LIFSHITS TAILS

In this section we prove upper and lower bounds on the integrated density of states $N(\lambda)$ as $\lambda \to -\infty$. Our result is as follows:

Theorem: *Let the Hamiltonian H_ω be as defined in Sec. II. Then,*

$$\limsup_{\lambda \to -\infty} \ln N(\lambda) \leqslant -\frac{|\lambda|}{|\beta| b_0} \ln|\lambda| \tag{3.1}$$

and

$$\liminf_{\lambda \to -\infty} \ln N(\lambda) \geqslant -\frac{|\lambda|}{c_1 |\beta| b_0} \ln|\lambda|, \tag{3.2}$$

where

$$c_1 = \frac{6}{11}\left[1 - \frac{|\alpha|}{|\beta|}\left(1 - \frac{8}{3}\frac{a(r_0)}{b_0 r_0^2} + \frac{22}{9}\frac{a^2(r_0)}{{b_0}^2 r_0^4} \right)^{1/2} \right]. \tag{3.3}$$

Proof: The upper bound is straightforward. Applying the diamagnetic inequality (see for example, Theorem 15.7 of Ref. 22), we have

$$\mathrm{Tr}(\exp(-tH_{\omega,\Lambda})) \leqslant \mathrm{Tr}(\exp(-tH'_{\omega,\Lambda})), \tag{3.4}$$

where $H'_\omega = -\Delta + \beta\Sigma_{i=1}^{\infty} b(|\mathbf{r}-\mathbf{r}_i|)$, and the operators $H_{\omega,\Lambda}$ and $H'_{\omega,\Lambda}$ are, respectively, H_ω and H'_ω restricted to some finite domain Λ with Dirichlet boundary conditions.

If $\tilde{N}$ is the Laplace transform of N then from the corresponding bounds for the nonmagnetic case we get (see, for example, Theorems 5.18 and 9.1 of Ref. 6),

$$\tilde{N}(t) \leqslant \frac{1}{4\pi t}\exp(2\pi\rho r_0 e^{|\beta|b_0 t})(1+o(1)) \tag{3.5}$$

as $t\to\infty$ and (3.1) follows by a Tauberian argument.

As mentioned earlier, because the magnetic field couples pairs of impurities, the lower bound requires much more work. From Theorem 9.5 of Ref. 6 we have the following lower bound for $\tilde{N}(t)$:

$$\tilde{N}(t) \geqslant \frac{1}{\Lambda_\psi}\mathbb{E}[\exp(-t\langle\psi, H_\omega\psi\rangle)] \tag{3.6}$$

for any ψ which has unit norm and compact support, and is in the quadratic form domain of H_ω. This simply means that it is in the form domain of the Laplacian operator. Here $\Lambda_\psi = |\mathrm{supp}\ \psi|$. If ψ is real valued, we have from (2.14)

$$\mathbb{E}[\exp(-t\langle\psi, H_\omega\psi\rangle)] = e^{-t\langle\psi,-\Delta\psi\rangle}\mathbb{E}[e^{-t\langle\psi,V\psi\rangle}]. \tag{3.7}$$

Since the first term in (2.15) is nonpositive, the problem may be treated in a similar way to that of an attractive Poisson potential.[21] The crucial difference in the subsequent discussion is that, because of the second term on the r.h.s. of (2.15), we cannot calculate the expectation of $\exp(-t\langle\psi, V\psi\rangle)$ using the Laplace characteristic functional (Sec. 1.C of Ref. 6). So proceeding in a direct fashion, since a and b have compact support:

$$\mathbb{E}[e^{-t\langle\psi,V\psi\rangle}] = e^{-\rho|\Lambda|}\sum_{N=0}^{\infty}\frac{\rho^N}{N!}I_N(\psi,t), \tag{3.8}$$

where

$$I_N(\psi,t) = \int_{\Lambda^N} \mathrm{d}^2\mathbf{r}_1\cdots\mathrm{d}^2\mathbf{r}_N \exp\left(-t\int \mathrm{d}^2\mathbf{r}\, V_N(\mathbf{r}_1-\mathbf{r},\ldots,\mathbf{r}_N-\mathbf{r};1)|\psi(\mathbf{r})|^2\right) \tag{3.9}$$

and

$$V_N(\mathbf{r}_1,\ldots\mathbf{r}_N;s) = \frac{\beta}{\alpha}\hat{\mathbf{k}}\cdot\sum_{i=1}^{N}\mathbf{B}(\mathbf{r}_i) + s\alpha^2\left|\sum_{i=1}^{N}\mathbf{D}(\mathbf{r}_i)\right|^2. \tag{3.10}$$

Without loss of generality we can take Λ to be a disk of radius L centred at the origin. From (3.6)–(3.8) we obtain

$$\tilde{N}(t) \geqslant \frac{1}{\Lambda_\psi}e^{-t\langle\psi,-\Delta\psi\rangle}e^{-\rho|\Lambda|}\sum_{N=0}^{\infty}\frac{\rho^N}{N!}I_N(\psi,t). \tag{3.11}$$

For $t>0$ let the function $\phi(\mathbf{r}) = \phi_t(r)$ be defined by

$$\phi_t(r) = \begin{cases} N_t\sigma(t)e^{-(1/2)\sigma^2(t)r^2}, & 0 \leqslant r \leqslant 1 - \dfrac{1}{\sigma(t)}, \\ N_t\sigma^2(t)\exp\left(-\dfrac{1}{2}(\sigma(t)-1)^2\right)(1-r), & 1 - \dfrac{1}{\sigma(t)} < r \leqslant 1, \\ 0, & r > 1, \end{cases} \tag{3.12}$$

where $\sigma(t) = \exp(\exp(\xi t))$ for some $\xi < c_1|\beta|b_0$ and the constants N_t are such that $\|\phi_t\|_2 = 1$. The function ϕ_t is circularly symmetric with support in the unit ball centered at the origin. We shall explain the choice of this function later. Take

$$\psi_t(\mathbf{r}) = \frac{1}{R(t)}\phi\left(\frac{\mathbf{r}}{R(t)}\right),$$

where $R(t)$ is a function of t to be determined later. We shall write ϕ, ψ, and R rather than ϕ_t, ψ_t, and $R(t)$ to make the notation less cumbersome and we shall also use the notation

$$\sigma_1^2 := \int_0^1 \phi'^2(r) r dr \text{ and } \sigma_2^2 := \int_0^1 \phi^2(r) r^3 dr. \tag{3.13}$$

We have

$$\Lambda_\psi = \pi R^2, \tag{3.14}$$

$$\langle \psi, -\Delta\psi \rangle = R^{-2}\sigma_1^2, \tag{3.15}$$

and

$$I_N(\psi,t) = \int_{\Lambda^N} \mathrm{d}^2\mathbf{r}_1 \cdots \mathrm{d}^2\mathbf{r}_N \exp\left(-t\int_{r\leqslant 1} \mathrm{d}^2\mathbf{r} V_N(\mathbf{r}_1 - R\mathbf{r}, \ldots, \mathbf{r}_N - R\mathbf{r}; 1)|\phi(\mathbf{r})|^2\right). \tag{3.16}$$

Taking one term in (3.11) we get

$$\tilde{N}(t) \geqslant \frac{e^{-\rho|\Lambda|}}{N!\,\pi R^2} e^{-\sigma_1^2 t/R^2} I_N(\psi,t). \tag{3.17}$$

As usual we shall be making R small and using the Laplace approximation theorem to estimate $I_N(\psi,t)$ for large t. Now $-V_N(\mathbf{r}_1, \ldots, \mathbf{r}_N; 1)$ has maximum equal to $|\beta|Nb_0$. This maximum is attained when b is at a maximum, and the second term in (3.10) is zero, that is when $\mathbf{r}_1, \ldots, \mathbf{r}_N$ lie on a circle of radius r_0 centered at the origin so that $\Sigma_{i=1}^N \mathbf{r}_i = \mathbf{0}$. However there are a large number of these configurations for large N and this makes the second derivative at these points singular. Because it is difficult to estimate $I_N(\psi,t)$ for large t and N we find a lower bound by taking $N = 3n$ for some $n \in \mathbb{N}$. See the remark at the end of the proof for a justification of this choice. Using

$$(x_1 + \cdots + x_r)^2 \leqslant r(x_1^2 + \cdots + x_r^2), \tag{3.18}$$

we find that

$$\begin{aligned} \left|\sum_{i=1}^{3n} \mathbf{D}(\mathbf{r}_i)\right|^2 &\leqslant (|\mathbf{D}(\mathbf{r}_1) + \mathbf{D}(\mathbf{r}_2) + \mathbf{D}(\mathbf{r}_3)| + \cdots + |\mathbf{D}(\mathbf{r}_{3n-2}) + \mathbf{D}(\mathbf{r}_{3n-1}) + \mathbf{D}(\mathbf{r}_{3n})|)^2 \\ &\leqslant n(|\mathbf{D}(\mathbf{r}_1) + \mathbf{D}(\mathbf{r}_2) + \mathbf{D}(\mathbf{r}_3)|^2 + \cdots + |\mathbf{D}(\mathbf{r}_{3n-2}) + \mathbf{D}(\mathbf{r}_{3n-1}) + \mathbf{D}(\mathbf{r}_{3n})|^2). \end{aligned} \tag{3.19}$$

Therefore

$$V_{3n}(\mathbf{r}_1 - R\mathbf{r}, \ldots, \mathbf{r}_{3n} - R\mathbf{r}; s) \leqslant \sum_{i=1}^{n} V_3(\mathbf{r}_{3i-2} - R\mathbf{r}, \mathbf{r}_{3i-1} - R\mathbf{r}, \mathbf{r}_{3i} - R\mathbf{r}; sn). \tag{3.20}$$

Substituting this into (3.16) gives

$$I_{3n}(\psi, t) \geqslant [\overline{I_3}(n, \phi, t)]^n, \tag{3.21}$$

where

$$\overline{I_3}(n, \phi, t) = \int_{\Lambda^3} \mathrm{d}^2\mathbf{r}_1 \mathrm{d}^2\mathbf{r}_2 \mathrm{d}^2\mathbf{r}_3 \exp\left(- t \int_{r \leqslant 1} \mathrm{d}^2\mathbf{r} V_3(\mathbf{r}_1 - R\mathbf{r}, \mathbf{r}_2 - R\mathbf{r}, \mathbf{r}_3 - R\mathbf{r}; n) |\phi(\mathbf{r})|^2 \right). \tag{3.22}$$

Therefore (3.17) implies that

$$\widetilde{N}(t) \geqslant \frac{e^{-\rho|\Lambda|}}{(3n)!\,\pi R^2} e^{-\sigma_1^2 t/R^2} [\overline{I_3}(n, \phi, t)]^n. \tag{3.23}$$

Now we use the Laplace approximation theorem to estimate $\overline{I_3}(n, \phi, t)$ for large t. As explained earlier, $-V_3(\mathbf{r}_1, \mathbf{r}_2, \mathbf{r}_3; n)$ attains its maximum when $\mathbf{r}_1$, $\mathbf{r}_2$, and $\mathbf{r}_3$ are equally spaced on a circle of radius r_0 centered at the origin.

Using the rotational symmetry of $V_3(\cdot; n)$ and ϕ we can integrate over the orientation of $\mathbf{r}_1$ to get

$$\overline{I_3}(n, \phi, t) = 2\pi \int_0^L r_1 \mathrm{d}r_1 \int_{\Lambda^2} \mathrm{d}^2\mathbf{r}_2 \mathrm{d}^2\mathbf{r}_3 \exp\left(- t \int_{r \leqslant 1} \mathrm{d}^2\mathbf{r} V_3(r_1\mathbf{i} - R\mathbf{r}, \mathbf{r}_2 - R\mathbf{r}, \mathbf{r}_3 - R\mathbf{r}; n) \cdot |\phi(\mathbf{r})|^2 \right). \tag{3.24}$$

$-V_3(r_1\mathbf{i}, \mathbf{r}_2, \mathbf{r}_3; n)$ is at a maximum when $r_1 = r_0$, $\mathbf{r}_2 = \tilde{\mathbf{r}}_2 := r_0(-\frac{1}{2}\mathbf{i} + \frac{1}{2}\sqrt{3}\mathbf{j})$ and $\mathbf{r}_3 = \tilde{\mathbf{r}}_3 := r_0(-\frac{1}{2}\mathbf{i} - \frac{1}{2}\sqrt{3}\mathbf{j})$. Therefore we make the transformations $r_1 \to r_0 + r_1$, $\mathbf{r}_2 \to \tilde{\mathbf{r}}_2 + \mathbf{r}_2$ and $\mathbf{r}_3 \to \tilde{\mathbf{r}}_3 + \mathbf{r}_3$ which gives

$$\overline{I_3}(n, \phi, t) = 2\pi \int_{-r_0}^{L - r_0} \mathrm{d}r_1 (r_0 + r_1) \int_{\Lambda - \tilde{\mathbf{r}}_2} \mathrm{d}^2\mathbf{r}_2 \int_{\Lambda - \tilde{\mathbf{r}}_3} \mathrm{d}^2\mathbf{r}_3 \exp\left(- t \int_{r \leqslant 1} \mathrm{d}^2\mathbf{r} V_3((r_0 + r_1)\mathbf{i} - R\mathbf{r}, \tilde{\mathbf{r}}_2 + \mathbf{r}_2 - R\mathbf{r}, \tilde{\mathbf{r}}_3 + \mathbf{r}_3 - R\mathbf{r}; n) |\phi(\mathbf{r})|^2 \right). \tag{3.25}$$

Now, from Taylor's theorem, we know that

$$f(\mathbf{x} + \mathbf{x}') = f(\mathbf{x}) + \mathbf{x}' \cdot \nabla f(\mathbf{x}) + \tfrac{1}{2}(\mathbf{x}' \cdot \nabla)^2 f(\mathbf{x}) + \tfrac{1}{6}(\mathbf{x}' \cdot \nabla)^3 f(\mathbf{x} + \zeta\mathbf{x}'), \tag{3.26}$$

where $\zeta \in (0, 1)$. Let us apply this to the function $V_3(\cdot; n)$, taking $\mathbf{x} = (r_0\mathbf{i}, \tilde{\mathbf{r}}_2, \tilde{\mathbf{r}}_3)$, and $\mathbf{x}' = (r_1\mathbf{i} - R\mathbf{r}, \mathbf{r}_2 - R\mathbf{r}, \mathbf{r}_3 - R\mathbf{r})$.

First, we have that

$$V_3(r_0\mathbf{i}, \tilde{\mathbf{r}}_2, \tilde{\mathbf{r}}_3; n) = 3\beta b_0, \tag{3.27}$$

where $b_0 = b(r_0)$ and

$$\nabla V_3(r_0\mathbf{i}, \tilde{\mathbf{r}}_2, \tilde{\mathbf{r}}_3; n) = \mathbf{0}, \tag{3.28}$$

because the function has a minimum at that point. In the next term,

$$((r_1\mathbf{i}-R\mathbf{r},\mathbf{r}_2-R\mathbf{r},\mathbf{r}_3-R\mathbf{r})\cdot\nabla)^2V_3(r_0\mathbf{i},\tilde{\mathbf{r}}_2,\tilde{\mathbf{r}}_3;n)$$
$$=\langle((r_1\mathbf{i}-R\mathbf{r},\mathbf{r}_2-R\mathbf{r},\mathbf{r}_3-R\mathbf{r}),D_{2,n}(r_0\mathbf{i},\tilde{\mathbf{r}}_2,\tilde{\mathbf{r}}_3)(r_1\mathbf{i}-R\mathbf{r},\mathbf{r}_2-R\mathbf{r},\mathbf{r}_3-R\mathbf{r})\rangle, \tag{3.29}$$

where the 6×6 matrix $D_{2,n}(r_0\mathbf{i},\tilde{\mathbf{r}}_2,\tilde{\mathbf{r}}_3)$ is given in the Appendix. We can write (3.29) as a sum of four terms:

$$\langle(r_1\mathbf{i},\mathbf{r}_2,\mathbf{r}_3),D_{2,n}(r_0\mathbf{i},\tilde{\mathbf{r}}_2,\tilde{\mathbf{r}}_3)(r_1\mathbf{i},\mathbf{r}_2,\mathbf{r}_3)\rangle+R^2\langle(\mathbf{r},\mathbf{r},\mathbf{r}),D_{2,n}(r_0\mathbf{i},\tilde{\mathbf{r}}_2,\tilde{\mathbf{r}}_3)(\mathbf{r},\mathbf{r},\mathbf{r})\rangle$$
$$+R\langle(r_1\mathbf{i},\mathbf{r}_2,\mathbf{r}_3),D_{2,n}(r_0\mathbf{i},\tilde{\mathbf{r}}_2,\tilde{\mathbf{r}}_3)(\mathbf{r},\mathbf{r},\mathbf{r})\rangle+R\langle(\mathbf{r},\mathbf{r},\mathbf{r})D_{2,n}(r_0\mathbf{i},\tilde{\mathbf{r}}_2,\tilde{\mathbf{r}}_3),(r_1\mathbf{i},\mathbf{r}_2,\mathbf{r}_3)\rangle. \tag{3.30}$$

The first term in (3.30) is independent of $\mathbf{r}$ and it is equal to

$$\langle(r_1,\mathbf{r}_2,\mathbf{r}_3),D'_{2,n}(r_0\mathbf{i},\tilde{\mathbf{r}}_2,\tilde{\mathbf{r}}_3)(r_1,\mathbf{r}_2,\mathbf{r}_3)\rangle, \tag{3.31}$$

where $D'_{2,n}(\mathbf{r}',\mathbf{r}'',\mathbf{r}''')$ is the 5×5 matrix obtained by deleting from $D_{2,n}(\mathbf{r}',\mathbf{r}'',\mathbf{r}''')$ all the terms involving derivatives with respect to the second component of $\mathbf{r}'$. This is another step needed to account for the symmetry inherent in maximizing the integrand in (3.22).

For the second term, writing $\mathbf{r}=(x,y)$ and using

$$\int_{r\leqslant1}\mathrm{d}^2\mathbf{r}\,x^2|\phi(\mathbf{r})|^2=\int_{r\leqslant1}\mathrm{d}^2\mathbf{r}\,y^2|\phi(\mathbf{r})|^2=\frac{1}{2}\sigma_2^2, \tag{3.32}$$

we have that

$$\int_{r\leqslant1}\mathrm{d}^2\mathbf{r}\langle(\mathbf{r},\mathbf{r},\mathbf{r}),D_{2,n}(r_0\mathbf{i},\tilde{\mathbf{r}}_2,\tilde{\mathbf{r}}_3)(\mathbf{r},\mathbf{r},\mathbf{r})\rangle|\phi(\mathbf{r})|^2=2C_1\sigma_2^2, \tag{3.33}$$

where

$$C_1=\frac{3}{4}b''(r_0)+\alpha^2n\left(\frac{9}{4}b_0^2-6b_0\frac{a(r_0)}{r_0^2}+\frac{11}{2}\frac{a^2(r_0)}{r_0^4}\right). \tag{3.34}$$

Note that all the terms in the integrand of (3.33) are even or odd in $\mathbf{r}$ and only the even terms give a nonzero result. The contribution from the last two terms in (3.30) is zero since, for example,

$$\int_{r\leqslant1}\mathrm{d}^2\mathbf{r}\langle(r_1\mathbf{i},\mathbf{r}_2,\mathbf{r}_3),D_{2,n}(r_0\mathbf{i},\tilde{\mathbf{r}}_2,\tilde{\mathbf{r}}_3)(\mathbf{r},\mathbf{r},\mathbf{r})\rangle|\phi(\mathbf{r})|^2 \tag{3.35}$$

vanishes because integrand is odd in $\mathbf{r}$.

For the third order term, we have that

$$|((r_1\mathbf{i}-R\mathbf{r},\mathbf{r}_2-R\mathbf{r},\mathbf{r}_3-R\mathbf{r})\cdot\nabla)^3V_3\ ((r_0\mathbf{i},\tilde{\mathbf{r}}_2,\tilde{\mathbf{r}}_3)+\zeta(r_1\mathbf{i}-R\mathbf{r},\mathbf{r}_2-R\mathbf{r},\mathbf{r}_3-R\mathbf{r}));n)|$$
$$\leqslant[\max(|r_1|,\|\mathbf{r}_2\|,\|\mathbf{r}_3\|)+R\|\mathbf{r}\|]^3|D_{3,n}((r_0\mathbf{i},\tilde{\mathbf{r}}_2,\tilde{\mathbf{r}}_3)+\zeta(r_1\mathbf{i}-R\mathbf{r},\mathbf{r}_2-R\mathbf{r},\mathbf{r}_3-R\mathbf{r}))|, \tag{3.36}$$

where

$$D_{3,n}(\mathbf{x})=\sum_{i,j,k=1}^{6}\frac{\partial^3V_3(\mathbf{x};n)}{\partial x_i\partial x_j\partial x_k},$$

and $\|\mathbf{r}\|\leqslant1$ because the integration in the exponential in (3.22) is carried out over the unit disk.

Also, the above assumptions on the functions a and b imply that their derivatives are uniformly bounded, so that

$$|D_{3,n}((r_0\mathbf{i},\tilde{\mathbf{r}}_2,\tilde{\mathbf{r}}_3)+\zeta(r_1\mathbf{i}-R\mathbf{r},\mathbf{r}_2-R\mathbf{r},\mathbf{r}_3-R\mathbf{r}))|\leqslant nC_2, \tag{3.37}$$

where the constant C_2 does not depend on n or R.

This gives

$$\overline{I_3}(n,\phi,t) \geqslant 2\pi e^{3t|\beta|b_0}\exp(-tC_1\sigma_2^2R^2)\int_{-r_0}^{L-r_0} dr_1(r_0+r_1)\int_{\Lambda-\tilde{\mathbf{r}}_2} d^2\mathbf{r}_2\int_{\Lambda-\tilde{\mathbf{r}}_3} d^2\mathbf{r}_3$$
$$\times\exp\left(-\frac{t}{2}\langle(r_1,\mathbf{r}_2,\mathbf{r}_3),D'_{2,n}(r_0\mathbf{i},\tilde{\mathbf{r}}_2,\tilde{\mathbf{r}}_3)(r_1,\mathbf{r}_2,\mathbf{r}_3)\rangle - tnC_2[\max(|r_1|,\|\mathbf{r}_2\|,\|\mathbf{r}_3\|)+R]^3\right). \tag{3.38}$$

Now we perform the following transformation

$$(\rho_1,\boldsymbol{\rho}_2,\boldsymbol{\rho}_3) = \frac{t^{1/2}}{\sqrt{2}}[D'_{2,n}(r_0\mathbf{i},\tilde{\mathbf{r}}_2,\tilde{\mathbf{r}}_3)]^{1/2}(r_1,\mathbf{r}_2,\mathbf{r}_3) \tag{3.39}$$

and afterwards restrict the domain of integration to B_η, a hypercube in 5 dimensions of side $2t^{1/2}\eta$ around 0.

Letting $D_n=\det[D'_{2,n}(r_0\mathbf{i},\tilde{\mathbf{r}}_2,\tilde{\mathbf{r}}_3)]$, after the transformation (3.39), we get

$$\overline{I_3}(n,\phi,t) \geqslant \frac{2^{7/2}\pi}{D_n^{1/2}}t^{-(5/2)}e^{3t|\beta|b_0}\exp(-tC_1\sigma_2^2R^2 - tnC_2[\sqrt{10}\eta\|[D'_{2,n}(r_0\mathbf{i},\tilde{\mathbf{r}}_2,\tilde{\mathbf{r}}_3)]^{-(1/2)}\|+R]^3)$$
$$\times\int_{B_\eta} d\rho_1 d^2\boldsymbol{\rho}_2 d^2\boldsymbol{\rho}_3(r_0+\sqrt{2}t^{-1/2}([D'_{2,n}(r_0\mathbf{i},\tilde{\mathbf{r}}_2,\tilde{\mathbf{r}}_3)]^{-(1/2)}(\rho_1,\boldsymbol{\rho}_2,\boldsymbol{\rho}_3))_1)e^{-(\rho_1,\boldsymbol{\rho}_2,\boldsymbol{\rho}_3)^2}, \tag{3.40}$$

where $(\mathbf{x})_1$ denotes the first component of $\mathbf{x}$.

The second term in the integrand in (3.40) is odd, and so its integral over a symmetric domain is zero. We further define

$$\tilde{C}_1 = |\alpha|\left(9b_0^2 - 24b_0\frac{a(r_0)}{r_0^2} + 22\frac{a^2(r_0)}{r_0^4}\right)^{1/2} \tag{3.41}$$

so that $C_1=\frac{3}{4}b''(r_0)+\frac{1}{4}\tilde{C}_1^2n$. There exist positive constants C_4, C_5, C_6, and C_7 such that

$$D_n^{-(1/2)} \geqslant C_4n^{-(5/2)}, \tag{3.42}$$

$$\sqrt{10}\|[D'_{2,n}(r_0\mathbf{i},\tilde{\mathbf{r}}_2,\tilde{\mathbf{r}}_3)]^{-(1/2)}\| \leqslant C_5n^{-(1/2)} \tag{3.43}$$

and

$$\int_{B_\eta} d\rho_1 d^2\boldsymbol{\rho}_2 d^2\boldsymbol{\rho}_3 e^{-(\rho_1,\boldsymbol{\rho}_2,\boldsymbol{\rho}_3)^2} \geqslant \pi^{5/2}(1-C_6e^{C_7t\eta^2}). \tag{3.44}$$

Putting together what we have obtained so far and substituting into (3.23), we get

$$\tilde{N}(t) \geqslant e^{-\rho|\Lambda|}\frac{K_3^nt^{-(5/2)n}}{n^{(11/2)n}R^2}(1-C_6e^{-C_7t\eta^2})^n\exp\left(\left(3|\beta|b_0n - \frac{\sigma_1^2}{R^2} - \frac{1}{4}\tilde{C}_1^2\sigma_2^2R^2n^2\right.\right.$$
$$\left.\left. - \frac{3}{4}b''(r_0)\sigma_2^2R^2n - C_2C_5n^{1/2}\right)t\right), \tag{3.45}$$

where $K_3=(8\sqrt{2}/27)\pi^{5/2}\rho^3r_0C_4$. We would like to make the term in n^2 in the exponential, $\frac{1}{4}\tilde{C}_1^2\sigma_2^2R^2n^2$, small by letting $R\to 0$. However in doing this we make the term σ_1^2/R^2 large. Therefore we minimize the sum of the two terms by taking $R=\sqrt{2/\tilde{C}_1}(\sigma_1/\sigma_2)^{1/2}n^{-(1/2)}$. Note that in the nonmagnetic case the corresponding term is of order n and not n^2. To maximize the right-hand

side of (3.45) we take n as a function of t. We shall also write R in terms of n, and hence in terms of t so that $R \to 0$ as $t \to \infty$. Therefore we write

$$n(t) = \frac{K_3^{2/11}}{e} t^{-(5/11)} (1 - C_6 e^{-C_7 t \eta^2})^{2/11} \exp\left(\frac{2t}{11} (3|\beta| b_0 - \tilde{C}_1 \sigma_1 \sigma_2) \right), \tag{3.46}$$

so that

$$R(t) = \sqrt{\frac{2e}{\tilde{C}_1}} \left(\frac{\sigma_1}{\sigma_2} \right)^{1/2} K_3^{-(1/11)} t^{5/22} (1 - C_6 e^{-C_7 t \eta^2})^{-(1/11)} \exp\left(- \frac{t}{11} (3|\beta| b_0 - \tilde{C}_1 \sigma_1 \sigma_2) \right) \tag{3.47}$$

as $t \to \infty$.

Then we have that there exists t_0 independent of ϕ such that

$$\begin{aligned} \tilde{N}(t) \geqslant \frac{e^{-\rho|\Lambda|}}{2} \tilde{C}_1 \frac{\sigma_2}{\sigma_1} \exp\Bigg(& \frac{11}{2e} \frac{K_3^{2/11}}{t^{5/11}} (1 - C_6 e^{-C_7 t \eta^2})^{2/11} \exp\left(\frac{2t}{11} (3|\beta| b_0 - \tilde{C}_1 \sigma_1 \sigma_2) \right) \\ & - \frac{C_2 C_5}{\sqrt{e}} K_3^{1/11} t^{17/22} (1 - C_6 e^{-C_7 t \eta^2})^{1/11} \exp\left(\frac{t}{11} (3|\beta| b_0 - \tilde{C}_1 \sigma_1 \sigma_2) \right) - \frac{3}{2\tilde{C}_1} b''(r_0) \sigma_1 \sigma_2 t \Bigg) \end{aligned} \tag{3.48}$$

for $t > t_0$. The last two terms are subdominant. Clearly, the above is meaningful only if

$$3|\beta| b_0 - \tilde{C}_1 \sigma_1 \sigma_2 > 0. \tag{3.49}$$

First of all, we note that by the Heisenberg Uncertainty Principle, $\sigma_1 \sigma_2$ cannot be made smaller than 1. However we have defined ϕ so that $\sigma_1 \sigma_2 \to 1$ as $t \to \infty$. This explains our choice of ϕ in (3.12). So then as $t \to \infty$,

$$\tfrac{2}{11} (3|\beta| b_0 - \tilde{C}_1 \sigma_1 \sigma_2) \to c_1 |\beta| b_0, \tag{3.50}$$

where c_1 was defined in (3.3).

Now, the fact that $|\beta| > |\alpha|$ together with assumption (2.10) which implies that

$$\frac{8}{3} \frac{a(r_0)}{b_0 r_0^2} - \frac{22}{9} \frac{a^2(r_0)}{{b_0}^2 r_0^4} > 0, \tag{3.51}$$

ensures that (3.49) is true. This gives us as $t \to \infty$

$$\tilde{N}(t) \geqslant \frac{e^{-\rho|\Lambda|}}{2} \tilde{C}_1 \frac{\sigma_2}{\sigma_1} \exp\left(\frac{11}{2e} {K_3}^{2/11} t^{-(5/11)} (1 - C_6 e^{-C_7 t \delta^2})^{2/11} \exp(c_1 |\beta| b_0 t) \right). \tag{3.52}$$

Furthermore, as $t \to \infty$,

$$\frac{\sigma_2}{\sigma_1} = \frac{1}{\sigma^2(t)} (1 + o(1)), \tag{3.53}$$

so that

$$\ln \tilde{N}(t) \geqslant \frac{11}{2e} {K_3}^{2/11} t^{-(5/11)} \exp(c_1 |\beta| b_0 t)(1 + o(1)) \tag{3.54}$$

as $t \to \infty$ or

$$\liminf_{t\to\infty} t^{5/11}\exp(-c_1|\beta|b_0 t)\ln \tilde{N}(t) \geqslant \frac{11}{2e}K_3^{2/11}. \tag{3.55}$$

From this we can use a Tauberian argument (Theorem 9.7 of Ref. 6) to obtain (3.2). □

Remark 1: In the above calculation, we have been working with the choice $N=3n$ which, after applying the inequality (3.18), leads us to work with $V_3(\cdot;n)$. This choice demands some justification.

We note first of all that working with $V_m(\mathbf{r}_1,\ldots,\mathbf{r}_m;n)$ for $m>1$ ensures that we can exploit the fact the second term in (3.10) is zero for a certain configuration of $\mathbf{r}_1,\ldots,\mathbf{r}_m$, so that the maximum value of $-V_m(\mathbf{r}_1,\ldots,\mathbf{r}_m;n)$ is $m|\beta|b_0$ (as in (3.27)).

If we apply inequality (3.18) directly to N, leading us to work with $V_1(\mathbf{r};n)$, the corresponding maximum value will be less than the expected $|\beta|b_0$, so that we get a worse lower bound.

For the case $m=2$ (i.e., choosing $N=2n$), we find that the expression corresponding to the l.h.s. of (3.49) is of the order $2|\beta|b_0-2\sqrt{2}|\alpha|b_0\sigma_1\sigma_2$. As noted earlier, the Heisenberg Uncertainty Principle forbids $\sigma_1\sigma_2<1$, so the method does not work in this case.

For $m>3$, we find that we do not get any improvement over the case $m=3$. For example, for the case $m=4$, the expression corresponding to the l.h.s. of (3.49) is

$$4|\beta|b_0-4|\alpha|b_0\sigma_1\sigma_2\left(1-\frac{2a(r_0)}{b_0 r_0^2}\right)^{1/2} \tag{3.56}$$

while for the case $m=5$, it is again of the order $5|\beta|b_0-5|\alpha|b_0\sigma_1\sigma_2$. This explains why we have chosen to work with the case $m=3$.

Remark 2: We have hitherto assumed that $\beta\leqslant-|\alpha|$. We note, however, that because of (3.51), there exists $\varepsilon>0$ such that (3.49) is true when $\beta<-|\alpha|+\varepsilon$. In this case, $c_1|\beta|b_0$ is not of order b_0 for large b_0.

APPENDIX

Let $(\mathbf{r}_1,\tilde{\mathbf{r}}_2,\tilde{\mathbf{r}}_3)=\left(r_0\mathbf{i},r_0\left(-\frac{1}{2}\mathbf{i}+\frac{1}{2}\sqrt{3}\mathbf{j}\right),r_0\left(-\frac{1}{2}\mathbf{i}-\frac{1}{2}\sqrt{3}\mathbf{j}\right)\right)$. Then $D_{2,n}(\mathbf{r}_1,\tilde{\mathbf{r}}_2,\tilde{\mathbf{r}}_3)=B+2\alpha^2 nA$, where

$$B=\begin{pmatrix} b''(r_0) & 0 & 0 & 0 & 0 & 0\\ 0 & 0 & 0 & 0 & 0 & 0\\ 0 & 0 & \frac{1}{4}b''(r_0) & \frac{\sqrt{3}}{4}b''(r_0) & 0 & 0\\ 0 & 0 & \frac{\sqrt{3}}{4}b''(r_0) & \frac{3}{4}b''(r_0) & 0 & 0\\ 0 & 0 & 0 & 0 & \frac{1}{4}b''(r_0) & -\frac{\sqrt{3}}{4}b''(r_0)\\ 0 & 0 & 0 & 0 & -\frac{\sqrt{3}}{4}b''(r_0) & \frac{3}{4}b''(r_0) \end{pmatrix} \tag{A1}$$

and the matrix A is symmetric and its entries a_{ij} are given by

$$a_{11}=\left(b_0-\frac{a(r_0)}{r_0^2}\right)^2, \tag{A2}$$

$$a_{12}=0, \tag{A3}$$

$$a_{13} = \left(b_0 - \frac{a(r_0)}{r_0^2} \right) \left(\frac{1}{4} b_0 - \frac{a(r_0)}{r_0^2} \right), \tag{A4}$$

$$a_{14} = \left(b_0 - \frac{a(r_0)}{r_0^2} \right) \left(- \frac{\sqrt{3}}{4} b_0 + \frac{\sqrt{3} a(r_0)}{2 r_0^2} \right), \tag{A5}$$

$$a_{15} = a_{13}, \tag{A6}$$

$$a_{16} = - a_{14}, \tag{A7}$$

$$a_{22} = \left(\frac{a(r_0)}{r_0^2} \right)^2, \tag{A8}$$

$$a_{23} = \frac{a(r_0)}{r_0^2} \left(- \frac{\sqrt{3}}{4} b_0 + \frac{\sqrt{3} a(r_0)}{2 r_0^2} \right), \tag{A9}$$

$$a_{24} = \frac{a(r_0)}{r_0^2} \left(\frac{3}{4} b_0 - \frac{a(r_0)}{2 r_0^2} \right), \tag{A10}$$

$$a_{25} = - a_{23}, \tag{A11}$$

$$a_{26} = - a_{24}, \tag{A12}$$

$$a_{33} = \left(\frac{1}{4} b_0 - \frac{a(r_0)}{r_0^2} \right)^2 + \left(- \frac{\sqrt{3}}{4} b_0 + \frac{\sqrt{3} a(r_0)}{2 r_0^2} \right)^2, \tag{A13}$$

$$a_{34} = \left(\frac{1}{4} b_0 - \frac{a(r_0)}{r_0^2} \right) \left(- \frac{\sqrt{3}}{4} b_0 + \frac{\sqrt{3} a(r_0)}{2 r_0^2} \right) + \left(- \frac{\sqrt{3}}{4} b_0 + \frac{\sqrt{3} a(r_0)}{2 r_0^2} \right) \left(\frac{3}{4} b_0 - \frac{a(r_0)}{2 r_0^2} \right), \tag{A14}$$

$$a_{35} = \left(\frac{1}{4} b_0 - \frac{a(r_0)}{r_0^2} \right)^2 - \left(- \frac{\sqrt{3}}{4} b_0 + \frac{\sqrt{3} a(r_0)}{2 r_0^2} \right)^2, \tag{A15}$$

$$a_{36} = \left(\frac{1}{4} b_0 - \frac{a(r_0)}{r_0^2} \right) \left(\frac{\sqrt{3}}{4} b_0 - \frac{\sqrt{3} a(r_0)}{2 r_0^2} \right) + \left(- \frac{\sqrt{3}}{4} b_0 + \frac{\sqrt{3} a(r_0)}{2 r_0^2} \right) \left(\frac{3}{4} b_0 - \frac{a(r_0)}{2 r_0^2} \right), \tag{A16}$$

$$a_{44} = \left(- \frac{\sqrt{3}}{4} b_0 + \frac{\sqrt{3} a(r_0)}{2 r_0^2} \right)^2 + \left(\frac{3}{4} b_0 - \frac{a(r_0)}{2 r_0^2} \right)^2, \tag{A17}$$

$$a_{45} = \left(\frac{1}{4} b_0 - \frac{a(r_0)}{r_0^2} \right) \left(- \frac{\sqrt{3}}{4} b_0 + \frac{\sqrt{3} a(r_0)}{2 r_0^2} \right) - \left(- \frac{\sqrt{3}}{4} b_0 + \frac{\sqrt{3} a(r_0)}{2 r_0^2} \right) \left(\frac{3}{4} b_0 - \frac{a(r_0)}{2 r_0^2} \right), \tag{A18}$$

$$a_{46} = - \left(- \frac{\sqrt{3}}{4} b_0 + \frac{\sqrt{3} a(r_0)}{2 r_0^2} \right)^2 + \left(\frac{3}{4} b_0 - \frac{a(r_0)}{2 r_0^2} \right)^2, \tag{A19}$$

$$a_{55} = a_{33}, \tag{A20}$$

$$a_{56} = -a_{34}, \tag{A21}$$

$$a_{66} = a_{44}. \tag{A22}$$

Coherent solutions for relativistic vectorial fields

Attilio Maccari
Technical Institute "G. Cardano," Piazza della Resistenza 1, 00015 Monterotondo, Rome, Italy

(Received 17 May 2004; accepted 18 August 2004; published 4 November 2004)

Approximate interacting localized solutions of a vectorial massive nonlinear equation are obtained by using the asymptotic perturbation (AP) method, based on Fourier expansion and spatio-temporal rescaling. The amplitude slow modulation of Fourier modes is described by a system of nonlinear evolution equations solvable via an appropriate change of variables. Various types of localized solutions (dromions, lumps, ring solitons, and breathers) as well as multiple soliton and instanton solutions can be explicitly constructed and their interaction is completely elastic, because they pass through each other and preserve their shape, the only change being a phase shift. © *2004 American Institute of Physics*.
[DOI: 10.1063/1.1807956]

I. INTRODUCTION

Many methods are available for obtaining nontrivial solutions of nonlinear partial differential equations. We cite, for example, the bilinear method, inverse scattering transformation, symmetry reductions, Backlund and Darboux transformations, etc.[1–3] The most important solutions are the celebrated solitons, i.e., exponentially stable localized solutions of integrable (exact solutions) or nonintegrable nonlinear equations (exact or approximate solutions) in $1+1$ dimensions. In the past 30 years, solitons have been extensively applied in many natural sciences and especially in almost all fields of physics such as plasma physics, optics, fluid mechanics, and so on.[4,5]

In $2+1$ dimensions, there are many nonlinear equations integrable by the inverse scattering method such as the Davey–Stewartson (DS) equation, Kadomtsev–Petviashvili (KP) equation. A new type of coherent (exponentially localized in all directions) solution (dromion) driven by straight line solitons has been found in some cases, for example for the so called DS-I equation.[6–11]

Moreover, it has been demonstrated that dromions exist as approximate solutions in the particular case of ion acoustic waves in an unmagnetized or magnetized plasma and electron acoustic waves.[12–14] Each dromion propagates with its own group velocity and during a collision maintains its shape, because a phase shift is the only change. They are solutions of a *C*-integrable (solvable via an appropriate change of variables) nonlinear partial differential system of equations describing N-interacting waves $(N>1)$ for modulated amplitudes $\Psi_j=\Psi_j(\xi,\eta,\tau)$, $j=1,\ldots,N$.

In this paper, we seek approximate localized solutions for the following nonlinear equation for a massive vectorial field,

$$(\partial_\mu\partial^\mu + M^2)A^\nu + a|A_\mu|^2A^\nu = 0, \tag{1.1}$$

where $A^\nu=(A^0,\underline{A})$, $\partial_\mu\partial^\mu=\partial_t^2-\nabla^2$, M and a are parameter and $|A_\mu|^2=A^\mu A^*_\mu$.

We consider the interaction and eventually the collisions among coherent solutions with different velocities that are not close to each other and use the asymptotic reduction (AP) method[15,16] based on the spatio-temporal rescaling

$$\xi^\mu = \varepsilon^2 x^\mu, \tag{1.2}$$

where

$$\xi^{\mu} = (\xi^0, \underline{\xi}), \quad x^{\mu} = (x^0, \underline{x}), \tag{1.3}$$

with $\xi^0 = \tau$ and $x^0 = t$. The small positive nondimensional parameter ε is artificially introduced to serve as bookkeeping device and will be set equal to unity in the final analysis. The reduction method focuses on a solution that is small and is close to a superposition of N several dispersive waves, with different group velocities.

In the linear limit the solution is

$$\sum_{j=1}^{N} C_j^{\nu} \exp(-is_j), \quad s_j = k_{j,\mu} x^{\mu} = \omega_j t - \underline{K}_j \,.\, \underline{x}, \quad j = 1, \ldots, N, \; N > 1, \tag{1.4}$$

where C_j^{ν} are the complex amplitudes, $\underline{K}_j \equiv (K_{1,j}, K_{2,j}, K_{3,j})$ the wave vectors and the (circular) frequency ω_j is furnished by the dispersion relation $\omega_j = \omega_j(\underline{K}_j)$. The amplitudes of these N nonresonant dispersive waves (constant in the linear limit) are slowly modulated by the non linear term of the vectorial massive nonlinear Eq. (1.1).

In Sec. II we derive a model system of equations for the slow modulation of the Fourier modes amplitudes and, subsequently, in Sec. III we show that it is *C*-integrable. The Cauchy problem is resolved, just by quadratures, and explicit nontrivial solutions are constructed. In Sec. IV, we demonstrate the existence of dromions which preserve their shape during collisions, the only change being a phase shift. Moreover, other coherent solutions (line solitons, multilump solutions, ring solitons, instanton solutions, and breathers) are derived. Conclusion and final considerations are reserved for the last section.

II. DERIVATION OF THE MODEL SYSTEM

It is well known that the linearized version of Eq. (1.1),

$$(\partial_{\mu}\partial^{\mu} + M^2) A^{\nu} = 0, \tag{2.1}$$

is satisfied by Fourier modes with constant amplitudes,

$$A_j^{\nu} \approx C_j^{\nu} \exp i(\underline{K}_j \,.\, \underline{X} - \omega_j t) = C_j^{\nu} \exp(-ik_{j,\mu} x^{\mu}), \tag{2.2}$$

if the following dispersion relation is verified:

$$\omega_j^2 = K_j^2 + M^2. \tag{2.3}$$

The group velocity $\underline{U}_j$ (the speed with which a wave packet peaked at that Fourier mode would move) is

$$\underline{U}_j = \frac{d\omega_j}{d\underline{K}_j} = \frac{\underline{K}_j}{\omega_j}. \tag{2.4}$$

In the following we consider a superposition of N dispersive waves, characterized by different values of the wave vector $\underline{K}_j$ and by group velocities not close to each other. Weak nonlinearity induces a slow variation of the amplitudes of these dispersive waves and the AP method derives the nonlinear system of equations for the Fourier modes amplitudes modulation, obviously in appropriate "slow" and "coarse-grained" variables defined by Eq. (1.2). Since the amplitude of Fourier modes are not constant, higher order harmonics appear and in order to construct an approximate solution that is small of order ε and that is close in the limit of small ε to the linear solution (2.2), we introduce the asymptotic Fourier expansion

$$A^{\nu}(x) = \sum_{\underline{n}=-\infty}^{\infty} \exp\left(i\sum_{j=1}^{N} n_j s_j \right) \varepsilon^{\gamma_{\underline{n}}} \psi_{\underline{n}}^{\nu}(\xi;\varepsilon), \tag{2.5}$$

where the index $\underline{n}$ stands for the set $\{n_j; j=1, 2, \ldots, N\}$, s_j is given in Eq. (1.4) and summation is limited only to terms with n_j odds (note that the only nonlinear term present in Eq. (1.1) is cubic). The functions, $\psi_{\underline{n}}^{\nu}(\xi, \eta, \tau, \varepsilon)$ depend parametrically on ε and we assume that their limit for $\varepsilon \to 0$ exists and is finite. We moreover assume that there hold the conditions

$$\gamma_{\underline{n}} = \gamma_{-\underline{n}}, \tag{2.6}$$

$$\gamma_{\underline{n}} = \sum_{j=1}^{N} |n_j|, \text{ otherwise}. \tag{2.7}$$

This implies that we obtain the main amplitudes if one of the indices n_j has unit modulus and all the others vanish. We use the following notations:

$$\psi_{\underline{n}}(\xi, \varepsilon \to 0) = \Psi_j(\xi), \text{ if } n_j = 1 \text{ and } n_m = 0 \text{ for } j \neq m, \tag{2.8a}$$

$$\psi_{\underline{n}}(\xi, \varepsilon \to 0) = \Phi_j(\xi), \text{ if } n_j = -1 \text{ and } n_m = 0 \text{ for } j \neq m. \tag{2.8b}$$

Taking into account (2.6) and (2.8), the Fourier expansion (2.5) can be written more explicitly in the following form:

$$\begin{aligned} A^{\nu}(x) = &\sum_{j=1}^{N} [\exp(is_j)\Psi_j(\xi) + \varepsilon^2 \exp(3is_j)\Psi_{3,j}(\xi) + \text{c.c.}] + \sum_{j=1}^{N} [\exp(-is_j)\Phi_j(\xi) \\ &+ \varepsilon^2 \exp(-3is_j)\Psi_{-3,j}(\xi) + \text{c.c.}] + O(\varepsilon^4), \end{aligned} \tag{2.9}$$

where c.c. stands for complex conjugate.

Substituting (2.9) in Eq. (1.1) and considering the different equations obtained for every harmonic and for a fixed order of approximation in ε, we obtain for $n_j=1$, $n_m=0$, if $j \neq m$, to the order of ε^3, the following system of equations for the modulated amplitudes:

$$(-2ik_{\mu}\partial^{\mu})\Psi_j^{\nu} + a\sum_{m=1}^{N} [(\Psi_{\mu,m}\Psi_m^{*\mu} + \Phi_{\mu,m}\Phi_m^{*\mu})\Psi_j^{\nu} + \Phi_m^{\nu}\Phi_m^{*\mu}\Psi_{\mu,j}] = 0, \tag{2.10}$$

and $n_j=-1$, $n_m=0$, if $j \neq m$, to the order of ε^3,

$$(2ik_{\mu}\partial^{\mu})\Phi_j^{\nu} + a\sum_{m=1}^{N} [(\Phi_{\mu,m}\Phi_m^{*\mu} + \Psi_{\mu,m}\Psi_m^{*\mu})\Phi_j^{\nu} + \Psi_m^{\nu}\Psi_m^{*\mu}\Phi_{\mu,j}] = 0. \tag{2.11}$$

The validity of the approximate solution should be expected to be restricted on bounded intervals of the τ-variable and on time-scale $t=O(1/\varepsilon^2)$. If one wishes to study solutions on intervals such that $\tau=O(1/\varepsilon)$, then the higher terms will in general affect the solution and must be included.

III. INTEGRABILITY OF THE MODEL SYSTEM OF EQUATIONS

The system of nonlinear equations (2.10) and (2.11) is *C*-integrable by means of an appropriate transformation of the dependent variables. We set

$$\Psi_j^{\nu}(\xi) = \rho_j^{\nu}(\xi)\exp[i\vartheta_j^{\nu}(\xi)], \quad \Phi_j^{\nu}(\xi) = \chi_j^{\nu}(\xi)\exp[i\varphi_j^{\nu}(\xi)], \quad j = 1, \ldots N, \tag{3.1}$$

with $\rho_j^{\nu}=\rho_j^{\nu}(\xi)$, $\chi_j^{\nu}=\chi_j^{\nu}(\xi)>0$ and $\vartheta_j^{\nu}=\vartheta_j^{\nu}(\xi)$, $\varphi_j^{\nu}=\varphi_j^{\nu}(\xi)$ real functions. Then Eqs. (2.10) and (2.11) yield

$$\rho^{\nu}_{j,\tau}(\xi) + \underline{U}_j \,.\, \nabla\, \rho^{\nu}_j(\xi) = 0, \tag{3.2}$$

$$\chi^{\nu}_{j,\tau}(\xi) + \underline{U}_j \,.\, \nabla\, \chi^{\nu}_j(\xi) = 0, \tag{3.3}$$

$$(\vartheta_{j,\tau}(\xi) + \underline{U}_j \,.\, \nabla\, \vartheta^{\nu}_j(\xi))\rho^{\nu}_j + \frac{a}{2\omega_j}\sum_{m=1}^{N}[(\rho_{\mu,m}\rho^{\mu}_m + \chi_{\mu,m}\chi^{\mu}_m)\rho^{\nu}_j + \chi^{\nu}_m\chi^{\mu}_m\rho_{\mu,j}] = 0, \tag{3.4}$$

$$(\varphi_{j,\tau} + \underline{U}_j \,.\, \nabla\, \varphi^{\nu}_j)\chi^{\nu}_j - \frac{a}{2\omega_j}\sum_{m=1}^{N}[(\chi_{\mu,m}\chi^{\mu}_m + \rho_{\mu,m}\rho^{\mu}_m)\chi^{\nu}_j + \rho^{\nu}_m\rho^{\mu}_m\chi_{\mu,j}] = 0. \tag{3.5}$$

A suitable solution for the Cauchy problem of (3.2) and (3.3) reads

$$\rho^{\nu}_j = \rho^{\nu}_j(\alpha_{\mu,j}\xi^{\mu}),\ \chi^{\nu}_j = \chi^{\nu}_j(\beta_{\mu,j}\xi^{\mu}), \tag{3.6}$$

where $\alpha^{\nu}_{\mu,j}=(\alpha^{\nu}_{0,j},\underline{\alpha}^{\nu}_j)$, $\beta^{\nu}_{\mu,j}=(\beta^{\nu}_{0,j},\underline{\beta}^{\nu}_j)$, the $8N$ real functions $\rho_j(\underline{\alpha}^{\nu}_j\cdot\underline{\xi})$, $\chi_j(\underline{\beta}^{\nu}_j\cdot\underline{\xi})$ which represent the initial shape can be chosen arbitrarily and $\alpha^{\nu}_{\mu,j},\beta^{\nu}_{\mu,j}$ are real constants which satisfy the relation

$$\alpha^{\nu}_{0,j} + \underline{\alpha}^{\nu}_j\underline{U} = 0, \quad \beta^{\nu}_{0,j} + \underline{\beta}^{\nu}_j\underline{U} = 0. \tag{3.7}$$

A suitable solution of (3.4) and (3.5) is

$$\vartheta^{\nu}_j = \delta_j(\tilde{\alpha}^{\nu}_{\mu,j}\xi^{\mu}) - \frac{a}{2\omega_j}\sum_{m=1}^{N}\int_0^{\tau}\frac{(\chi^{\nu}_m(\lambda)\chi^{\mu}_m(\lambda)\rho_{\mu,j}(\lambda))}{\rho^{\nu}_j(\lambda)}d\tilde{\tau} - \frac{a}{2\omega_j}\sum_{m=1}^{N}\int_0^{\tau}(\rho_{\mu,m}(\lambda)\rho^{\mu}_m(\lambda) + \chi_{\mu,m}(\lambda)\chi^{\mu}_m(\lambda))d\tilde{\tau}, \tag{3.8a}$$

where

$$f(\lambda) = f(\underline{\xi} - \underline{U}_j\cdot(\tau-\tilde{\tau}),\tilde{\tau}), \tag{3.8b}$$

and

$$\varphi^{\nu}_j = \tilde{\delta}_j(\tilde{\beta}^{\nu}_{\mu,j}\xi^{\mu}) + \frac{a}{2\omega_j}\sum_{m=1}^{N}\int_0^{\tau}\frac{(\rho^{\nu}_m(\lambda)\rho^{\mu}_m(\lambda)\chi_{\mu,j}(\lambda))}{\chi^{\nu}_j(\lambda)}d\tilde{\tau} + \frac{a}{2\omega_j}\sum_{m=1}^{N}\int_0^{\tau}(\chi_{\mu,m}(\lambda)\chi^{\mu}_m(\lambda) + \rho_{\mu,m}(\lambda)\rho^{\mu}_m(\lambda))d\tilde{\tau}, \tag{3.9}$$

where the $8N$ functions $\delta^{\nu}_j(\underline{\alpha}^{\nu}_j\cdot\underline{\xi})$, $\tilde{\delta}^{\nu}_j(\underline{\alpha}^{\nu}_j\cdot\underline{\xi})$ are fixed by the initial data and

$$\tilde{\alpha}^{\nu}_{0,j} + \underline{\tilde{\alpha}}^{\nu}_j\cdot\underline{U}_j = 0, \quad \tilde{\beta}^{\nu}_{0,j} + \underline{\tilde{\beta}}^{\nu}_j\cdot\underline{U}_j = 0. \tag{3.10}$$

The approximate solution for the massive vector field Eq. (1.1) is

$$A^{\nu} = 2\varepsilon\sum_{j=1}^{N}\rho^{\nu}_j\cos(\vartheta^{\nu}_j + k_{j,\mu}\xi^{\mu}) + 2\varepsilon\sum_{j=1}^{N}\chi^{\nu}_j\cos(\varphi^{\nu}_j - k_{j,\mu}\xi^{\mu}) + O(\varepsilon^3). \tag{3.11}$$

The corrections of order ε^3 to the approximate solution depend on higher harmonics and can be easily calculated from results obtained in Sec. II.

IV. EXACT SOLUTIONS FOR THE *C*-INTEGRABLE MODEL EQUATION

A. Nonlinear wave

The most simple solution of the system (2.10) and (2.11) is the plane wave

$$\chi_j^\nu = \tilde{C}_j^\nu = \text{const}, \quad \vartheta_j^\nu = -\tilde{k}_{\mu,j}^\nu \xi^\mu, \tag{4.1a}$$

$$\rho_j^\nu = C_j^\nu = \text{const}, \quad \varphi_j^\nu = -\hat{k}_{\mu,j}^\nu \xi^\mu, \tag{4.1b}$$

$$\hat{k}_{\mu,j}^\nu = (\hat{\omega}_j^\nu, \underline{K}_j), \quad \tilde{k}_{\mu,j}^\nu = (\tilde{\omega}_j^\nu, \underline{K}_j), \tag{4.1c}$$

where the amplitudes and phases are connected according to the dispersion relation

$$\tilde{\omega}_j = \underline{U}_j \cdot \underset{-}{\tilde{K}}_j + \frac{a}{2\omega_j} \sum_{m=1}^{N} \left(\frac{\tilde{C}_m^\nu \tilde{C}_m^\mu C_{\mu,j}}{C_j^\nu} + C_{\mu,m} C_m^\mu + \tilde{C}_{\mu,m} \tilde{C}_m^\mu \right), \tag{4.2a}$$

$$\hat{\omega}_j = \underline{U}_j \cdot \underset{-}{\tilde{K}}_j - \frac{a}{2\omega_j} \sum_{m=1}^{N} \left(\frac{C_m^\nu C_m^\mu \tilde{C}_{\mu,j}}{\tilde{C}_j^\nu} + \tilde{C}_{\mu,m} \tilde{C}_m^\mu + C_{\mu,m} C_m^\mu \right). \tag{4.2b}$$

B. Solitons

The *C*-integrable nature of the system (2.10) and (2.11) implies the existence of more interesting solutions. It is possible the existence of *N* solitons which interact each other preserving their shapes and propagate with the relative group velocity $\underline{U}_j$ **(**see (2.4)**)**. These *N* solitons have fixed speeds but arbitrary shapes:

$$\rho_j^\nu = \frac{2C_j^\nu}{ch(2C_j^\nu(\alpha_{\mu,j}^\nu \xi^\mu))}, \quad \chi_j^\nu = \frac{2\tilde{C}_j^\nu}{ch(2\tilde{C}_j^\nu(\beta_{\mu,j}^\nu \xi^\mu))}, \tag{4.3a}$$

$$\delta_j^\nu = 0 \text{ for } j = 1, \ldots, N, \tag{4.3b}$$

where $\alpha_{\mu,j}^\nu$, $\beta_{\mu,j}^\nu$ are given by (3.7), C_j^ν, $\tilde{C}_j^\nu$ for $j=1, \ldots, N$, are real constants of order ε, and the phases ϑ_j^ν, φ_j^ν are given by (3.8)–(3.9).

Substituting (4.3) in (3.7) we obtain the approximate solution good to the order of ε. Each soliton advances with a constant velocity (the group velocity) before and after collisions. Only the phase is changed during collisions owing to the presence of the other solitons.

For example, if for the initial conditions we choose $N=2$ and

$$A^\nu(\underline{x},0) = 4\sum_{j=1}^{2} \frac{C_j^\nu}{ch(2C_j^\nu(\underline{\alpha}_j^\nu \cdot (\underline{x} - \underline{x}_{0,j}^\nu)))} \cos(\underline{K}_j \cdot \underline{x}), \tag{4.4}$$

where the initial positions are $x_{0,1}^\nu$, $x_{0,2}^\nu$, then the approximate solution good to the order of ε is given by

$$A^\nu(\underline{x},t) = 4\sum_{j=1}^{2} \frac{C_j^\nu \cos(k_{\mu,j} x^\mu + \vartheta_j^\nu)}{ch(2C_j^\nu(\alpha_{\mu,j} \cdot (x^\mu - x_{0,j}^\mu)))}. \tag{4.5}$$

C. Dromions

It is well known that dromions have been found in many $(2+1)$-dimensional equations integrable by the inverse scattering method and usually are driven by two or more nonparallel straight-line "ghost" solitons. The localized wave packet is located at the intersection of two line-solitons of the mean field and the lump travels along the tracks. In the DS-I system dromion solutions are driven by two perpendicular line "ghost" solitons, while in the Kadomtsev–Petviashvili equation the dromion solutions are driven by nonperpendicular line "ghost" solitons. In the last case dromions exist only for some suitable potentials of the field. Recently dromions solutions driven by curved and straight-line solitons have been found for some nonlinear equations in $2+1$ dimensions.[9]

The existence of localized solutions is possible also for *C*-integrable systems, because dromion solutions are not exclusive characteristics of equations integrable by the inverse scattering method.

A particular solution of the model system (2.10) and (2.11) is given by

$$\rho_j^\nu = C_j^\nu \exp(-B_j^\nu|\underline{\xi} - \underline{U}_j\tau|), \quad \chi_j^\nu = 0,\ \varphi_j^\nu = 0, \tag{4.6}$$

$$\delta_j^\nu = 0 \text{ for } j = 1,2,\ldots,N, \tag{4.7}$$

where B_j^ν, C_j^ν are real constants (note that the functions ρ_j^ν 4.6(a) are localized) and ϑ_j^ν is given by Eq. (3.5).

Substituting the solution (4.6) in Eq. (3.7) and taking $N=2$ we obtain for two dromions with different shapes and amplitudes the approximate solution

$$A^\nu(\underline{x},t) = 2\sum_{j=1}^{2} C_j^\nu \exp(-B_j^\nu|\underline{\xi} - \underline{U}_j\tau|)\cos(k_{\mu,j}x^\mu + \vartheta_j^\nu). \tag{4.8}$$

In Fig. 1 we show a collision between two dromions: the initial condition is shown in Fig. 1(a), then the two dromions collide [Fig. 1(b)] and then separate [Fig. 1(c)]. We can see that dromions preserve their shapes but with a phase shift.

D. Lumps

It is well known that in high dimension, in addition to the dromion solutions, other interesting localized solutions, formed by rational functions, are the multiple lumps. Obviously, there are many possible choices in order to obtain multilump solutions. For instance, we take

$$\rho_j^\nu = \frac{B_j^\nu}{C_j^\nu + D_j^\nu|\underline{\xi} - \underline{U}_j\tau|^2}, \quad \chi_j^\nu = 0,\ \varphi_j^\nu = 0, \tag{4.9a}$$

$$\delta_j^\nu = 0 \text{ for } j = 1,\ldots,N, \tag{4.9b}$$

where B_j^ν, C_j^ν, and D_j^ν are arbitrary real constants and ϑ_j^ν is given by Eq. (3.5).

E. Ring solitons

The multiple ring solitons are solutions that are not equal to zero at some closed curves and decay exponentially away from the closed curves. A possible selection is

$$\rho_j^\nu = C_j^\nu \exp(-B_j^\nu f_j^\nu(R_j)), \quad \chi_j^\nu = 0,\ \varphi_j^\nu = 0, \tag{4.10a}$$

$$\delta_j^\nu = 0 \text{ for } j = 1,\ldots,N, \tag{4.10b}$$

ϑ_j^ν given by Eq. (3.5) and

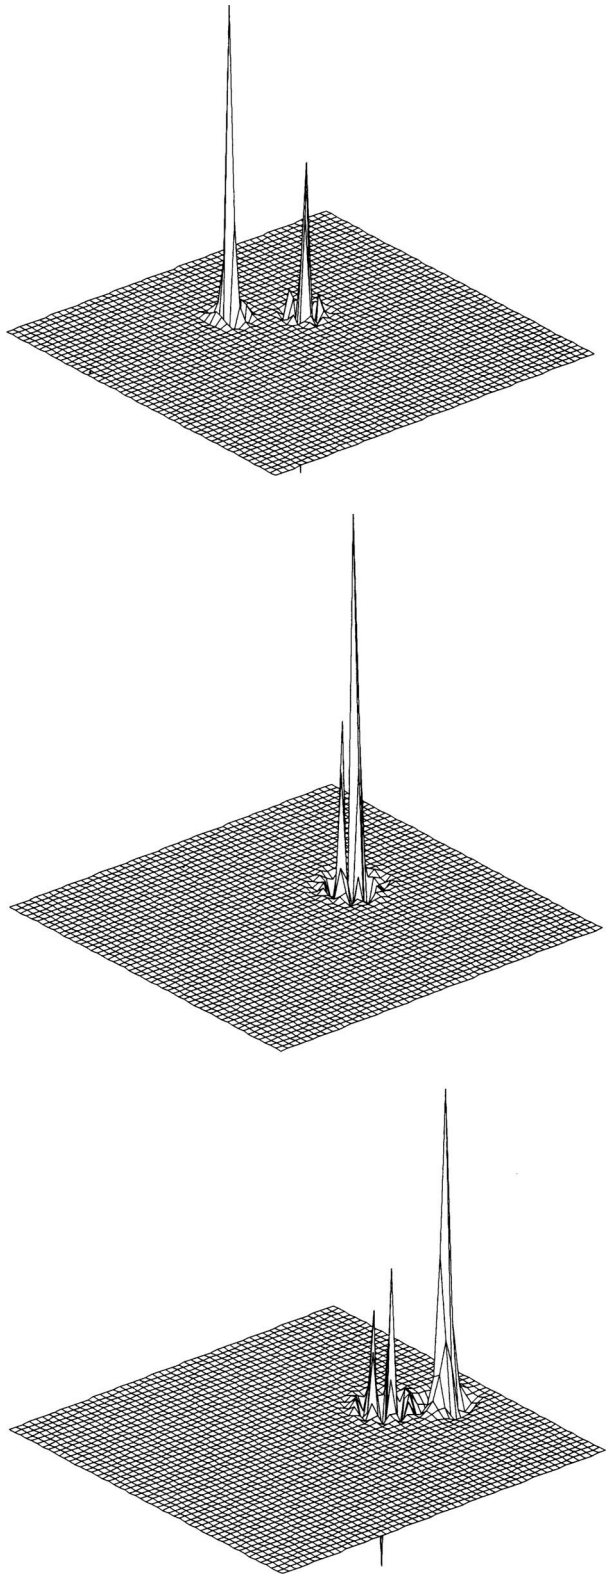

FIG. 1. Evolution plots of two dromions with different shapes and amplitudes ($A_1=2.0$, $A_2=2.5$, $B_1=0.01$, $B_2=0.01$, $K_{1,1}=1.3$, $K_{2,1}=1.2$, $K_{1,2}=0.8$, $K_{2,2}=0.7$). The initial condition is represented in (a), then the two dromions undergo a collision (b) and separate (c).

$$R_j = |\underline{\xi} - \underline{U}_j \tau|, \tag{4.10c}$$

$$f_j^\nu(R_j) = (R_j - R_{0,j}^\nu)^2, \tag{4.10d}$$

with C_j^ν, B_j^ν, and $R_{0,j}^\nu$ as arbitrary constants.

F. Instantons

If we choose a decaying function of time, we obtain also multiple instanton solutions, for example,

$$\rho_j^\nu = C_j^\nu \exp(\underline{\alpha}_j^\nu \cdot \underline{\xi} - \lambda_j^\nu \tau), \quad \chi_j^\nu = 0, \quad \varphi_j^\nu = 0, \tag{4.11a}$$

$$\delta_j^\nu = 0 \text{ for } j = 1, \ldots, N, \tag{4.11b}$$

with ϑ_j^ν given by Eq. (3.5), C_j^ν, $\underline{\alpha}_j^\nu$ arbitrary constants and

$$\lambda_j^\nu = \underline{\alpha}_j^\nu \cdot \underline{U}_j. \tag{4.11c}$$

G. Moving breatherlike structures

Finally, if we choose some types of periodic functions of time in the above mentioned solutions, then we obtain breathers. For example, we take

$$\rho_j^\nu = C_j^\nu \cos(\underline{\alpha}_j^\nu \cdot \underline{\xi} - \Omega_j^\nu t)\exp[-B_j^\nu |\underline{\xi} - \underline{U}_j \tau|], \quad \chi_j^\nu = 0, \quad \varphi_j^\nu = 0, \tag{4.12a}$$

$$\delta_j^\nu = 0 \text{ for } j = 1, \ldots, N, \tag{4.12b}$$

with ϑ_j^ν given by Eq. (3.5), B_j^ν, C_j^ν, $\underline{\alpha}_j^\nu$ arbitrary constants and

$$\Omega_j^\nu = \underline{\alpha}_j^\nu \cdot \underline{U}_j. \tag{4.12c}$$

V. CONCLUSION

We have found approximate analytical solutions for the vectorial massive nonlinear equation (1.1). Appropriately coarse-grained and slow variables have been introduced and a model system of equations for the amplitudes modulation of Fourier modes has been derived by means of the AP method.

The model system is *C*-integrable and with appropriate nontrivial initial conditions we can obtain multiple localized solutions (dromions, solitons, lumps, ring solitons, breathers, instantons) moving with different and not close to each other velocities. The richness of the solitons types is obviously a consequence of the high dimensions of the nonlinear equations.

This topic will be further investigated with the derivation of the model equation for other nonlinear waves and of the model equations for the interactions among phase resonant waves. Moreover, it will be worthy to study further the behavior of the solutions, and in particular of the dromions, beyond the leading order in the expansion parameter ε.

(Received 13 January 2004; accepted 15 July 2004; published 4 November 2004)

We propose to describe higher spins as invariant subspaces of the Casimir operators of the Poincaré Group, P^2, and the squared Pauli–Lubanski operator, W^2, in a properly chosen representation, $\psi(\mathbf{p})$ (in momentum space), of the Homogeneous Lorentz Group. The resulting equation of motion for any field with $s \neq 0$ is then just a specific combination of the respective covariant projectors. We couple minimally electromagnetism to this equation and show that the corresponding wave fronts of the classical solutions propagate causally. Furthermore, for $(s,0)\oplus(0,s)$ representations, the formalism predicts the correct gyromagnetic factor, $g_s=1/s$. The advocated method allows us to describe any higher spin without auxiliary conditions and by one covariant matrix equation alone. This master equation is only quadratic in the momenta and its dimensionality is that of $\psi(\mathbf{p})$. We prove that the suggested master equation avoids the Velo–Zwanziger problem of superluminal propagation of higher spin waves and points toward a consistent description of higher spin quantum fields. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1794843]

I. INTRODUCTION

The field theoretical description of interacting particles with spin >1 is a long standing problem. The interaction of a spin $\frac{3}{2}$ Rarita–Schwinger (RS) field minimally coupled to an external electromagnetic field was shown to be inconsistent more than 40 years ago.[1] Later on, Velo and Zwanziger observed superluminal propagation of the RS wave front in the presence of a minimally coupled electromagnetic field[2] and also studied the conditions under which the Proca field interacting with an external electromagnetic field propagates causally.[3] After these works many authors have addressed the above problem from different perspectives and for different interactions[4] and the general feeling seems to be that it is not possible to construct a consistent quantum theory for massive particles with $s>1$.

At several decades of distance in looking afresh onto the equations of motion can lead to a different understanding of this fundamental problem. Weinberg emphasizes in his textbook on quantum field theory[5] that the equation of motion satisfied by the Dirac field is nothing but the record about the way how one puts together the two irreducible representations, $(1/2,0)$, and $(0,1/2)$, of the proper orthochronous Lorentz group to form a field that transforms invariantly under parity. In a wider understanding, this means that the equations of motion satisfied by a field are just a consequence of the properties of the representations of the Homogeneous Lorentz Group (HLG) chosen by us to accommodate the field and the discrete symmetries we require to be realized in this space. Closely related arguments can be found, among others, in Refs. 6–9.

[a)]Electronic mail: mauro@fisica.ugto.mx

More recently, Refs. 10 and 11 studied covariant projectors onto invariant subspaces of the squared Pauli–Lubanski operator in the representation space of the four-vector–spinor and showed that the associated equations are free from the Velo–Zwanziger problem. The corresponding projectors for the $(s,0)\oplus(0,s)$ representation space were studied in Ref. 12 where it was shown that under minimal coupling a particle in this representation has the correct value for the spin gyromagnetic factor, $g_s=1/s$, thus proving Belinfante's conjecture[13] from 1953.

In this work we explore the projectors onto the invariant subspaces of the Poincaré Casimir operators, the squared four-momentum and the squared Pauli–Lubanski operator, for any s, and study the propagation of the corresponding wave fronts along the lines of Refs. 2 and 3. The paper is organized as follows. In the next section we recall in brief a current description of higher spins and its relation to the Poincaré group. In Sec. III we suggest describing higher spins as invariant subspaces of the Poincaré Casimirs. In Sec. IV we show that particles within this framework propagate causally in the presence of an electromagnetic field, thus avoiding the classical Velo–Zwanziger problem. In this paper we close with a brief summary.

II. CURRENT DESCRIPTION OF FIELDS AND ITS RELATION TO POINCARÉ GROUP REPRESENTATIONS

The primary classification of elementary systems is usually done by identifying them (up to form factors) with the irreducible representations (irreps) of the Poincaré group (PG). If so, then one necessarily has to consider particles as invariant spaces of the Casimir operators of this group—the squared four-momentum P^2, on the one side, and the squared Pauli–Lubanski operator W^2, on the other side and label them by their respective eigenvalues, p^2, and $-p^2s(s+1)$, as $|p^2,s(s+1)\rangle$. Further quantum numbers can be associated with the Casimir invariants of the underlying Homogeneous Lorentz Group (HLG), $SO(1,3)$, and are approached by the reduction chain $PG\supset SO(1,3)$. For finite dimensional representations, the Casimir invariants of $SO(1,3)$ are frequently expressed in terms of two $SU(2)$ Casimirs, in turn denoted by $\mathbf{S}_L^2$, and $\mathbf{S}_R^2$, of $SU(2)_L\otimes SU(2)_R$, a group that is locally isomorphic to $SL(2,C)$, the universal covering of HLG. The two additional quantum labels gained in this manner are the well known left- and right-handed "angular momenta," s_L, and s_R, respectively. Therefore, a covariant state labeling can be introduced as $|p^2,s(s+1);s_L,s_R\rangle$, with $s=|s_L-s_R|,\ldots,s_L+s_R$. In so doing one encounters essentially two types of finite dimensional HLG representations.

(1) The first ones contain just one W^2 invariant subspace, and correspond to the case when one of the s_L, s_R labels vanishes [i.e., either $(s_L,0)$, or $(0,s_R)$], and $s_R=s_L$. In such a case, $s_{L/R}(s_{L/R}+1)=s(s+1)$, equals the $[-(1/m^2)W^2]$ eigenvalue in the space under consideration [see Eq. (20)] and W^2– and $\mathbf{S}_{L/R}^2$ invariant spaces coincide. Irreps of the above type are suggestive of replacing W^2– by $SU(2)$ spin labels.

As long as the basic fields in physics are precisely of the above type [the Dirac field is $(1/2,0)\oplus(0,1/2)$, the electromagnetic field strength tensor is $(1,0)\oplus(0,1)$, and scalars are just $(0,0)$] identifying Poincaré labels with $SU(2)$ spins works out without any harm.

(2) The second ones are HLG irreps containing several W^2 invariant subspaces. In this case, both s_L and s_R are nonvanishing, and the irreps are of the type (s_L,s_R) with $s_L\neq 0$, and $s_R\neq 0$. Examples are the vector- and tensor-gauge fields, $(1/2,1/2)$ and $(1,1)$, respectively. In the rest frame, $W^2=-(1/m^2)\ \mathbf{S}^2$ hence W^2 and $\mathbf{S}^2$ invariant subspaces coincide. However, beyond the rest frame, in flight, W^2 and $\mathbf{S}^2$ invariant subspaces are no longer identical, a situation caused by the property of the boost to mix up SU(2) spins differing by one unit.

Often, Lorentz representations that contain as building blocks irreps of the second type, appear attractive for the description of higher spins, the classical examples being the totally symmetric K rank Lorentz tensors with Dirac spinor components, generically denoted by $\psi_{\mu_1\cdots\mu_K}$. They are exploited for the description of fields that have been labeled in the rest frame by the highest spin $J=K+1/2$. The separation between Lorentz and spinor indices inherent to such

tensors makes them especially appealing for the construction of covariant fermion–boson vertices. However, one has to face the problem of how to pick up the favored degrees of freedom and exclude interference with the unwanted ones. It seems inevitable to return back to the Poincaré invariants, if one wishes to distinguish all the degrees of freedom contained in $\psi_{\mu_1\cdots\mu_K}$ in a covariant and transitionally invariant fashion. Yet, for one reason or the other, this is not the path tenaciously pursued by the theory. Rather, one still prefers to stay within the elaborated scheme of substituting W^2 by $SU(2)$ labels, but, yes, modify the latter scheme to account for the new situation in introducing constraints, considered as appropriate.

To be specific, in order to select out of ψ_μ **(**a field belonging to $[(1/2,0)\oplus(0,1/2)]\otimes(1/2,1/2)$**)** the W^2 invariant subspace that relates to spin $3/2$ at rest, one requires

$$(i\partial^\mu\gamma_\mu - m)\psi_\nu = 0,$$

$$\partial^\mu\psi_\mu = 0,$$

$$\gamma^\mu\psi_\mu = 0. \tag{1}$$

Exploiting constraints (some times termed to as auxiliary, or, supplementary, conditions) in place of W^2 quantum numbers brings the advantage of remaining within the framework of equations linear in the momenta, and to work with four-dimensional Dirac spinors. However, these advantages reveal themselves as deceptive at the moment one has to face grave worries about the compatibility of constraints and dynamics. Recall that the constraints change upon gauging and one has to make sure that the modification is preserved in time by the equation of motion and the latter does not violate causality. Notice that covariance alone is indeed a necessary but not a sufficient condition for special relativity. For example, space-like intervals are doubtlessly covariant objects, but they are unacceptable for the description of *free* physical fields as they prescribe the particle to violate causality during propagation. Precisely a flaw of that very type was revealed by Velo and Zwanziger in Ref. 2 regarding the $\gamma^\mu\psi_\mu=0$ constraint onto the four-vector spinor. Velo and Zwanziger showed that the above constraint triggers acausal propagation of Rarita–Schwinger particles crossing an electromagnetic field.

In the present article we shall avoid the previous inconsistencies in developing a different view on the form and content of wave equations for higher spins. Namely, we take the position that the equation of motion for whatever free particle has to be (i) a function of P^2 and W^2, the Casimir invariants of the Poincaré group, (ii) operates immediate, i.e., without any supplementary constraints, on the HLG representation chosen to embed the field as one of its covariant sectors.[16]

Within this context, there are two primordial equations of motion to be satisfied by any field. One of them searches for P^2 invariant subspaces. It is nothing more but the Klein–Gordon equation. The other one secures in addition invariance under pseudo-rotations and pins-down W^2 invariant subspaces by means of appropriately constructed covariant projectors. It is that very latter type of equations on which we focus attention here. For the sake of self-sufficiency of the presentation, the subsequent section opens with a brief review of the basics of space–time symmetries.

III. COVARIANT WAVE EQUATIONS FOR HIGHER SPINS FROM W^2 INVARIANT SUBSPACES

A. Basics of space–time transformations

A general Poincaré transformation in space–time can be written in the factorized form

$$g(b,\Lambda) = T(b)\Lambda, \tag{2}$$

where $T(b)=g(b,E)$ (E denotes the unit matrix) is a translation and $\Lambda=g(0,\Lambda)$ is a proper Lorentz transformation. In the standard convention, the generators of the translation group in $1+3$ time–space dimensions, $\mathcal{T}_{1,3}$, are P_μ in $T(b)$, which are commuting,

$$[P_\mu, P_\nu] = 0. \tag{3}$$

The HLG transformation in coordinate space,

$$x'_\mu = \Lambda_\mu{}^\nu \quad x_\nu, \quad \Lambda_{\mu\nu} = \exp\left[-\frac{i}{2}\theta^{\mu\nu} L_{\mu\nu} \right], \quad L_{\mu\nu} = X_\mu P_\nu - X_\nu P_\mu, \tag{4}$$

induces the following transformation for a field $\psi(x)$,

$$\psi'(x) = \exp\left[-\frac{i}{2}\theta^{\mu\nu} M_{\mu\nu} \right] \psi(\Lambda^{-1} x). \tag{5}$$

Here, $\theta^{\mu\nu}$are continuous parameters, while the $n \times n$ matrices $M_{\mu\nu}$ represent a totally antisymmetric 2nd rank Lorentz tensor. They are the generators of the homogeneous Lorentz group in the representation space of interest, and satisfy the commutation relations of the associated algebra:

$$[M_{\mu\nu}, M_{\alpha\beta}] = -i(g_{\mu\alpha} M_{\nu\beta} - g_{\mu\beta} M_{\nu\alpha} + g_{\nu\beta} M_{\mu\alpha} - g_{\nu\alpha} M_{\mu\beta}). \tag{6}$$

Their commutators with the generators of the translation group read as

$$[P_\mu, M_{\alpha\beta}] = i(g_{\mu\alpha} P_\beta - g_{\mu\beta} P_\alpha), \tag{7}$$

where $g_{\mu\nu}$=diag$(1,-1,-1,-1)$ is the metric tensor. The $M_{\mu\nu}$ generators consist of

$$M_{\mu\nu} = L_{\mu\nu} + S_{\mu\nu}, \quad [L_{\mu\nu}, S_{\mu\nu}] = 0, \tag{8}$$

where $L_{\mu\nu}$ and $S_{\mu\nu}$ in turn generate rotations in external coordinate- and internal representation spaces. The generators of boosts $(\mathcal{K}_x, \mathcal{K}_y, \mathcal{K}_z)$ and rotations (J_x, J_y, J_z) are related to $M_{\mu\nu}$ via

$$\mathcal{K}_i = M_{0i}, \quad J_i = \frac{1}{2}\epsilon_{ijk} M_{jk}, \tag{9}$$

respectively.

B. Pauli Lubanski vector and associated Casimir invariant

The Pauli–Lubanski (PL) vector is now defined as

$$W_\mu = \frac{1}{2}\epsilon_{\mu\nu\alpha\beta} M^{\nu\alpha} P^\beta, \tag{10}$$

where $\epsilon_{0123}=1$. This operator can be shown to satisfy the commutators

$$[W_\alpha, M_{\mu\nu}] = i(g_{\alpha\mu} W_\nu - g_{\alpha\nu} W_\mu), \quad [W_\alpha, P_\mu] = 0, \tag{11}$$

i.e., it transforms as a four-vector under Lorentz transformations. The remarkable point is that the external coordinate part of $M_{\mu\nu}$, namely the "orbital" momentum $L_{\mu\nu}$, does not contribute to W_μ due to the anti-symmetric Levi-Civita tensor. As a result, W_μ restricts to

$$W_\mu = \frac{1}{2}\epsilon_{\mu\nu\rho\tau} S^{\nu\rho} P^\tau, \tag{12}$$

and its square (in covariant form) is calculated to be

$$W^2 = -\frac{1}{2} S_{\mu\nu} S^{\mu\nu} P^2 + G^2, \quad G_\mu := S_{\mu\nu} P^\nu. \tag{13}$$

The operators $S_{\mu\nu}$ act exclusively in the internal spin space and commute like

$$[S_{\mu\nu},S_{\alpha\beta}] = -i(g_{\mu\alpha}S_{\nu\beta} - g_{\mu\beta}S_{\nu\alpha} + g_{\nu\beta}S_{\mu\alpha} - g_{\nu\alpha}S_{\mu\beta}). \tag{14}$$

As long as Eq. (14) has same form as Eq. (6), one may view $S_{\mu\nu}$ as generators of Lorentz transformations in the intrinsic space. However, in contrast to Eq. (7), $S_{\mu\nu}$ *commute* with the operators of translations,

$$[P_\alpha,S_{\mu\nu}] = 0. \tag{15}$$

In effect, one does not find precisely Poincaré transformations in the internal space but rather a contracted form of them. Hereafter we will refer to the group generated by $S_{\mu\nu}$ as the "Internal Homogeneous Lorentz Group" ($\mathcal{I}$HLG) to distinguish it from the HLG spanned by $M_{\mu\nu}$. In summary, one can write down generators of boosts and rotations in the internal space as

$$K_i = S_{0i}, \quad S_i = \frac{1}{2}\epsilon_{ijk}S_{jk}. \tag{16}$$

The internal HLG has by itself two Casimir invariants, in turn given by $C_1 = 1/4 S_{\mu\nu}S^{\mu\nu}$, and $C_2 = S_{\mu\nu}\tilde{S}^{\mu\nu}$, with $\tilde{S}_{\mu\nu} = \epsilon_{\mu\nu\rho\tau}S^{\rho\tau}$. In terms of **K**, and **S** one finds

$$C_1 = \frac{1}{2}(\mathbf{S}^2 - \mathbf{K}^2), \quad C_2 = i\mathbf{S}\cdot\mathbf{K}. \tag{17}$$

The latter equation allows us to cast W^2 into the form

$$W^2 = -2C_1P^2 + G^2. \tag{18}$$

For irreps of the type $(s,0)\oplus(0,s)$ where $K_i = \mp iS_i$, one finds the insightful relation[11]

$$G^2 = -W^2. \tag{19}$$

The insertion of Eq. (19) into Eq. (18) amounts to

$$W^2 = -\mathbf{S}^2P^2. \tag{20}$$

The latter relation explains the privileged position of $(s,0)\oplus(0,s)$ states to carry a unique SU(2) spin both at rest [where W^2 any way reduces to $-\mathbf{S}^2\,m^2$ in accord with Eq. (20)] and in flight. However, for all the other types of Lorentz representations, $W^2 \neq G^2$ and the $[-(1/m^2)W^2]$ labels for particles in flight do not have the interpretation of ordinary $SU(2)$ spin. In the following we label W^2 invariant subspaces by s but in general without any reference to SU(2) spin.

C. Covariant projectors onto W^2 invariant subspaces

To begin with, we recall that the interpretation of elementary systems as Poincaré group irreducible representations requires any field to transform invariantly under the action of both P^2 and W^2. In the following we work with massive fields. The former invariance leads to the Klein–Gordon equation for any arbitrary field,

$$(P^2 - m^2)\psi(\mathbf{p}) = 0. \tag{21}$$

Invariance under the action of W^2 results in the new condition

$$\Pi^s(\mathbf{p})\psi(\mathbf{p}) = \psi(\mathbf{p}), \tag{22}$$

where $\Pi^s(\mathbf{p})$ stands for an appropriately constructed covariant projector onto the $(-p^2s(s+1))$ invariant subspace of W^2 in $\psi(\mathbf{p})$. To be specific, for the case of the four-vector spinor, such projectors have been presented in Ref. 10. In general, equations of the type (22) are equivalent to

$$[W^2 + P^2 s(s+1)]\psi(\mathbf{p}) = 0. \tag{23}$$

Next, it is necessary to account for the mass shell condition in Eq. (21). For this purpose, we sum up Eqs. (23) and (21), weighted by $1/s$ and $(-s)$, respectively, to obtain

$$\left[\frac{1}{s}W^2 + sP^2 + m^2\right]\psi(\mathbf{p}) = 0, \tag{24}$$

and cast the latter equation into the explicitly covariant form

$$[t_{\mu\nu}P^\mu P^\nu - m^2]\psi(\mathbf{p}) = 0. \tag{25}$$

Here $t_{\mu\nu}$ stands for

$$t_{\mu\nu} = \frac{1}{s}(2C_1 g_{\mu\nu} - S_{\alpha\nu}S^\alpha{}_\mu) - s\, g_{\mu\nu};$$

C_1 denotes the first Casimir in Eq. (17) and $S^{\beta\rho}$ are the $\mathcal{I}$HLG generators in the particular representation chosen for $\psi(\mathbf{p})$. Their construction as solutions of the algebra of the Lorentz group for the representation space under consideration is straightforward.[7,9,10]

Using now the gauge principle for electromagnetism in this equation, we obtain

$$\left[\left(\frac{1}{s}(2C_1 g_{\mu\nu} - S_{\alpha\nu}S^\alpha{}_\mu) - s\, g_{\mu\nu}\right)\pi^\mu\ \pi^\nu - m^2\right]\psi(\mathbf{p}) = 0, \tag{26}$$

with $\pi^\mu = P^\mu + eA^\mu$, and e denoting the charge of the field $\psi(\mathbf{p})$. Notice that Eq. (26) is a covariant matrix equation that operates in the vector space of the dimensionality of $\psi(\mathbf{p})$. For example, when $\psi(\mathbf{p})$ stands for the four-vector-spinor, W^2 is represented by a 16×16 matrix. For the sake of illustration, here we bring the Lagrangian density for the lowest Rarita–Schwinger representation. It reads as

$$\mathcal{L}(x) = \overline{\psi}(x)t_{\mu\nu}\ \pi^\mu\ \pi^\nu\ \psi(x) - m^2\overline{\psi}(x)\psi(x), \tag{27}$$

where $\overline{\psi}(x) = \psi^\dagger(x)(\gamma^0 \otimes g)$ where g is the matrix of the metric tensor. The definition of $\overline{\psi}(x)$ has to be performed for each representation individually. When applied to the Dirac representation $(\frac{1}{2},0)\oplus(0,\frac{1}{2})$, Eq. (26) also has the great advantage to yield the correct value of the gyromagnetic factor, $g_s = 2$. This is not fortuitous but reflects the general property of our master equation (26) to predict the correct value for the gyromagnetic ratio as $g_s = 1/s$ for fields in $(s,0)\oplus(0,s)$. Had we used instead Eq. (23) alone, we would have found the problematic case of $g_s = 1/s(s+1)$.

With respect to $(\frac{1}{2},0)\oplus(0,\frac{1}{2})$, Eq. (24) is nothing more than the Klein–Gordon equation for each field component. This is due to the fact that the squared Pauli–Lubanski vector for all $(s,0)\oplus(0,s)$ fields is just $-s(s+1)P^2\mathbf{1}_{(2s+1)\times(2s+1)}$. The W^2 Casimir invariant identifies only the spin content and remains indifferent to the discrete C, P, or, T properties of the representation of interest. Recall that one has different options to stick together, say, $(\frac{1}{2},0)$ and $(0,\frac{1}{2})$ depending on whether one wants $(\frac{1}{2},0)\oplus(0,\frac{1}{2})$ to diagonalize the parity, $\gamma^0\mathcal{R}$ or, the charge conjugation, $i\gamma_2 K$, operator. For parity eigenstates one ends up with the standard Dirac equation, while for C-parity states one finds again the Dirac equation but with a Majorana mass term, respectively. Notice however that, under gauging, this equation gives the right magnetic properties for $(s,0)\oplus(0,s)$ fields. This means that solutions to Dirac equation are solutions to Eq. (26) although the converse is not necessarily true since our equation specifies just the value of the spin.

For product representation spaces of the type $\psi_{\mu_1\mu_2\ldots\mu_K}$, the most interesting representation space for applications in hadron physics, the situation is different provided, one is tracking the highest spin. As long as the highest spins are nondegenerate, there is no confusion with parity doubling, as would be the case for the lower spins. For these reasons, Eq. (26) has its major merits

with respect to the highest spins in the representations. Next we study wave front propagation of particles described by means of Eq. (26) along the line of Refs. 2 and 3.

IV. AVOIDING SUPERLUMINAL PROPAGATION OF HIGHER SPIN WAVES

Wave propagation is associated with a hyperbolic system of partial differential equations.[14] For such a class of differential equations the initial value problem can be posed on a class of surfaces ("space-like" surfaces with respect to the equation of motion). The equations possess solutions with wave fronts traveling along rays at finite velocities. At any point on the surface, the rays form a cone that is entirely determined by the coefficients of the highest derivatives in the equation of motion.[14] The wave front can be characterized by $n^\mu=(n^0,\mathbf{n})$, the vectors normal to the characteristic surface. The system of equations is hyperbolic if n^0 is real for any $\mathbf{n}$. To find the normal vectors it is sufficient to first replace in the highest derivatives of the equation of motion P_μ by n_μ and then calculate the determinant $D(n)$ (so called "characteristic determinant"[3]) of the matrix given by the corresponding coefficients.

A. Wave front propagation of the Klein–Gordon, Dirac, and Rarita–Schwinger equations

In cases when the coupling to external fields is carried by the lower derivatives in the equation of motion, such as, say, the Klein–Gordon equation, the ray cones for interacting and free fields coincide. Indeed, in the latter case and under minimal coupling one finds

$$[\pi^\mu\pi_\mu - m^2]\psi(\mathbf{p}) = [P^\mu P_\mu + e(P^\mu A_\mu + A^\mu P_\mu) + e^2 A^\mu A_\mu - m^2]\psi(\mathbf{p}) = 0. \tag{28}$$

The vanishing of the characteristic determinant in this case yields

$$D(n) = \mathrm{Det}(n^2) = n^2 = 0, \tag{29}$$

which has real n^0 for any $\mathbf{n}$. The same is true for Dirac particles, though not as obvious. As is well known, a Dirac particle coupled minimally to the electromagnetic field is described by

$$[\gamma^\mu(P_\mu + eA_\mu) - m]\psi(\mathbf{p}) = 0. \tag{30}$$

Now, the resulting characteristic determinant is found to be the square of Eq. (29),

$$D(n) = \mathrm{Det}(\gamma^\mu n_\mu) = (n^2)^2. \tag{31}$$

The vanishing of this determinant results once again into a ray cone that coincides with the light cone.

The wave front propagation of the solution of the Rarita–Schwinger set of equations was studied in great detail in Ref. 2. To understand the essence of the latter work recall that Eqs. (1) or the analogous equation in the interacting case can be derived from a Lagrangian, a method suggested by Fierz and Pauli.[15] Within the latter framework not all the Euler–Lagrange equations appear as genuine equations of motion, meaning that some of them may not involve time derivatives, a property that qualifies them only as constraints onto the fields. Precisely this is the case for the Rarita–Schwinger framework discussed in Sec. II. As a consequence, any surface in space–time is a characteristic surface.[14] The Rarita–Schwinger system of coupled equations turns to be equivalent to a system of hyperbolic equations supplemented by constraints that are conserved in time. In this case, the wave fronts of the constrained system are no longer given by the characteristic determinant of the Euler-Lagrange equations. Rather, it is necessary to find the genuine equation of motion, i.e., the one which (i) contains all the higher order derivatives needed for the complete characterization of the system, and (ii) preserves the constraints in time. Finding such an equation in general introduces, in addition to the derivatives already present in the system of coupled equations, also new ones which as a rule spoil causal propagation, a result due to Refs. 2 and 3.

B. Wave front propagation of W^2 invariant subspaces

In the present work we suggested an alternative formalism to the Rarita–Schwinger framework. Our proposal was to pin down the degrees of freedom of interest by means of Eq. (26). This equation was build upon the covariant projector onto the W^2 invariant vector spaces in the representation under consideration, and did not invoke any supplementary conditions. In this concern, it is worth remarking that the formalism does not deal with the whole representation space but only with one of its W^2 invariant subspaces. Below we prove that equations of the latter type do not suffer the Velo–Zwanziger problem upon gauging.

First, we have to check that for all the degrees of freedom of $\psi(\mathbf{p})$, the second order time-derivatives enter Eq. (26) with nonvanishing coefficients. This can be done in full generality in momentum space where

$$t_{00} = \frac{1}{s}(2C_1 g_{00} - S_{\alpha 0} S^{\alpha}{}_{0}) - s g_{00} = \mathbf{1}. \tag{32}$$

Therefore, for all W^2 invariant subspaces, the time derivative of each field component in Eq. (26) does not vanish. This equation will be hyperbolic if the solutions n^0 to $D(n)=0$ are real for any $\mathbf{n}$. In this case we must solve

$$\mathrm{Det}\left[-\frac{1}{s} W^2(n) - s\, n^2 \right] = 0. \tag{33}$$

In order to demonstrate that (26) is a hyperbolic equation in the HLG representation space chosen for $\psi(\mathbf{p})$ here we exploit decomposition of the latter into invariant subspaces of W^2.

The most transparent representation of W^2 is obtained in the basis of $\mathbf{p}$-dependent W^2 eigenstates where W^2 is block diagonal and equal to

$$W^2(P) = -P^2\ \mathrm{Diag}[s_1(s_1+1)\mathbf{1}_{s_1}, s_2(s_2+1)\mathbf{1}_{s_2}, \ldots, s_N(s_N+1)\mathbf{1}_{s_N}]. \tag{34}$$

Here $\{s_1, s_2, \ldots, s_N\}$ label the different eigensubspaces of W^2 (one of them being s) in the representation of interest, while $\mathbf{1}_{s_j}$ denotes the unit matrix of dimensionality $(2s_j+1)\times(2s_j+1)$. Notice that the dimensionality, (d), of the representation space $\psi(\mathbf{p})$ relates to the W^2 quantum numbers via $d=\Sigma_i\, m_i(2s_i+1)$, where m_i is the multiplicity of s_i. The latter accounts for possible degeneracies of the W^2 invariant subspaces in $\psi(\mathbf{p})$ with respect to further symmetries such as, one of the discrete space–time symmetries.

The determinant (33) is calculated as

$$\mathrm{Det}\left[-\frac{1}{s} W^2(n) - s\, n^2 \right] = \prod_{k=0}^{N} \left(n^2 \left(\frac{s_k(s_k+1)}{s} - s \right) \right)^{2s_k+1}. \tag{35}$$

As long as for the integer/half-integer s under consideration, there are no positive integers and half-integers s_k satisfying

$$\frac{s_k(s_k+1)}{s} - s = 0, \tag{36}$$

the roots of the characteristic determinant are $n^2=0$. Thus the solutions have n^0 real for any $\mathbf{n}$, and Eq. (26) is a set of hyperbolic equations for the $\psi(\mathbf{p})$ components. The characteristic surfaces are the same for free and interacting particles, and the ray cone coincides with the light cone. In other words, the wave front propagation of W^2 invariant subspaces is free from the Velo–Zwanziger problem.

V. CONCLUSIONS AND PERSPECTIVES

In the present article we advocate the idea to consider higher spins as invariant subspaces of the Casimir operators of the Poincaré group, the squared four-momentum and the squared Pauli–Lubanski vector, in a properly chosen representation of the HLG, $\psi(\mathbf{p})$. In executing the idea we demonstrated that any higher spin is described in terms of one covariant matrix equation that (i) is determined exclusively by the HLG generators in $\psi(\mathbf{p})$, (ii) is of the dimensionality of $\psi(\mathbf{p})$, and (iii) is always of second order in the momenta. We gauged this equation minimally and found the resulting particle propagation to be causal, thus avoiding the classical Velo–Zwanziger problem. Moreover, for the single spin valued $(s,0)\oplus(0,s)$ representations, our master equation (26) has the great advantage to predict the correct value for the gyromagnetic ratio, $g_s=1/s$, thus proving Belinfante's conjecture[13] from 1953.

The development of a calculation scheme for interacting particles of higher spins from the perspective of the present work is underway.

Finite size effects in thermal field theory

N. F. Svaiter[a)]

(Received 24 June 2004; accepted 17 August 2004; published 5 November 2004)

We consider a neutral self-interacting massive scalar field defined in a d-dimensional Euclidean space. Assuming thermal equilibrium, we discuss the one-loop perturbative renormalization of this theory in the presence of rigid boundary surfaces (two parallel hyperplanes), which break translational symmetry. In order to identify the singular parts of the one-loop two-point and four-point Schwinger functions, we use a combination of dimensional and zeta-function analytic regularization procedures. The infinities which occur in both the regularized one-loop two-point and four-point Schwinger functions fall into two distinct classes: local divergences that could be renormalized with the introduction of the usual bulk counterterms, and surface divergences that demand counterterms concentrated on the boundaries. We present the detailed form of the surface divergences and discuss different strategies that one can assume to solve the problem of the surface divergences. We also briefly mention how to overcome the difficulties generated by infrared divergences in the case of Neumann–Neumann boundary conditions. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1808485]

I. INTRODUCTION

The Casimir effect is the manifestation of the zero-point energy of the quantized electromagnetic field, in the presence of metallic plates.[1] A very simple calculation predicts that in a four-dimensional space–time, uncharged perfectly conducting parallel plates should attract each other with a force per unit area $F(L) \propto 1/L^4$, where L is the distance between the plates. Extensive reviews of this subject can be found in Refs. 2–6. As stressed by Milloni *et al.*,[7] a brief argument showing that the zero-point energy associated with the quantized electromagnetic field must have a physical meaning was already given by Einstein and Stern.[8] These authors noted that a zero-point energy seems necessary in order to avoid a first-order quantum correction to β^{-1} in the classical limit $\beta \gg \omega$ in Planck's expression for the average energy of an oscillator in equilibrium with radiation at temperature β^{-1}.

Although the vacuum energies of different physical configurations are formally divergent, their diference can be finite. In the case of a free scalar field, interacting only with boundary surfaces, the Casimir approach can be summarized as follows: first a complete set of modes solutions of the Klein–Gordon equation satisfying appropriate boundary conditions, and their respective eigenfrequencies are presented. Next, the divergent zero-point energy is regularized by the introduction of an ultraviolet cutoff. Finally, the polar part of the regularized energy is removed using a renormalization procedure. This procedure was first discussed by Fierz[9] a long time ago, followed by Boyer[10] and also by Svaiter and Svaiter[11,12] In these two last references, an attempt to clarify the relation between the cutoff method and analytic regularization procedures in Casimir effect has been developed. In particular, in these papers an analytic regularization procedure was interpreted as a cutoff method, and using a mixed cutoff in the regularized zero-point energy, it was possible to unify these two methods both in two- and three-dimensional space–

[a)]Electronic-mail: nfuxsvai@cbpf.br

times. Further, a general proof was given that when the introduction of an exponential cutoff yields an analytic function with a pole at the origin, then the analytic regularization using the zeta function (or a generalization for the zeta function) is equivalent to the application of a cutoff with the subtraction of the singular part at the origin.[13,14] More recently, Fulling offered an interesting discussion with regard to the problems in the renormalization program devised to find the renormalized vacuum stress tensor in different field theories.[15]

It is important to point out that these results are valid at one-loop level and one is dealing with free fields only. It is clear that the formalism must be generalized to take into account the case of self-interacting fields. Although higher-loop corrections to the Casimir effect seem beyond experimental reach today, theoretically such corrections are certainly of interest. Nevertheless, with the exception for some few papers, only global issues have been discussed in the study of radiative corrections to the Casimir effect. One such exception is the discussion presented by Robaschik *et al.*[16] With this scenario in mind, it is natural to ask the important question: how to implement the perturbative renormalization algorithm, assuming the presence of rigid boundaries (hard walls), using the standard weak-coupling perturbative expansion in quantum field theory, that is, how to implement the one-loop perturbative renormalization of a self-interacting scalar theory, assuming boundary conditions which do break translational symmetry. Our aim when studying these issues is linked to the following question: does the infrared problem have a solution in theories where translational invariance is broken? Note that temperature effects can solve the infrared problem in some models in quantum field theory;[17] for a recent treatment in non-abelian gauge theories at high temperature, and the infrared problem, see for example, Ref. 18. Also, in massless scalar $\lambda\varphi^4$ theory, if thermal equilibrium with a reservoir is assumed, the infrared problem can be solved after a ressumation procedure. The standard is to use the Dyson–Schwinger equation to write a nonperturbative version of the self-energy gap equation, or to use the composite operator formalism.[19–21]

We would like to call the attention of the reader that there are some disagreements in the literature as to implementing the one-loop perturbative renormalization in finite size systems when translational invariance is broken. In the one-loop approximation, Albuquerque *et al.*[22] found that the mass counterterm depends on the size of the compact dimension in the $\lambda\varphi^4$ theory. Also, Malbouisson *et al.*[23] assumed a self-interacting scalar field confined between two infinite parallel plates, and using the techniques developed by Ananos *et al.*[21] these authors did not find any surface counterterm in the $\lambda\varphi^4$ theory at finite temperature. Furthermore, they were able to define temperature and size-dependent mass and coupling constant terms in systems where translational invariance is broken.

The purpose of this paper is to present a detailed calculation of the one-loop renormalization of the $\lambda\varphi^4$ theory at finite temperature, assuming that one of the spatial coordinates is confined to a finite interval. Since this assumption is not sufficient to explicitly breaking the translational symmetry, we will further introduce boundary surfaces where the field satisfies appropriate boundary conditions. In this situation, the breaking of the translational invariance of the theory is ensured. This paper is a natural continuation of the papers of Fosco and Svaiter[24] and also Caicedo and Svaiter.[25] Our aim is to further the understanding of the renormalization procedure in systems at finite temperature where there is a break of translational symmetry. We will discuss the Dirichlet–Dirichlet (DD) and also the Neumann–Neumann (NN) boundary conditions. For the Dirichlet–Dirichlet boundary conditions, the model is free of infrared divergences. In the Neumann–Neumann boundary conditions case, infrared divergences associated with zero modes will appear for bare massless fields. We show that there is no clear meaning for a thermal- or size-dependent mass in such situations. Consequently, a resummation procedure cannot be used to solve the infrared problem in the case of Neumann–Neumann boundary conditions.

The organization of the paper is the following: in Sec. II we sketch the general formalism of the theory, deriving the one-loop two-point and four-point functions. In Sec. III we use two different analytic regularization procedures, i.e., dimensional regularization and zeta-function analytic regularization, to identify the polar contributions that appear in the expressions of the one-loop two-point and four-point Schwinger functions. In Sec. IV we renormalize the four-point

Schwinger function and the problem for the infrared divergences is raised. In the conclusions we will discuss alternative solutions for the problem of the surfaces counterterms. In this paper we use $\hbar = c = k_B = 1$.

II. GENERAL FORMALISM AND THE FINITE TEMPERATURE GENERATING FUNCTIONAL OF SCHWINGER FUNCTIONS

The static properties of finite temperature field theory can be derived from the partition function.[26] To obtain the partition function the starting point is the Feynman, Matheus, and Salam approach.[27] Thus, let us consider the generating functional of (complete) Green's functions for a self-interacting scalar field theory defined in a flat d-dimensional Euclidean space $Z(h)$, given by

$$Z(h) = \int [\mathrm{d}\varphi] \exp\left(- S[\varphi] + \int \mathrm{d}^d x \; h(x)\varphi(x) \right), \tag{1}$$

where $[\mathrm{d}\varphi]$ is a translational invariant measure [formally given by $[\mathrm{d}\varphi] = \Pi_{x \in R^d} \mathrm{d}\varphi(x)$] and $S[\varphi]$ is the classical action associated with the scalar field. The quantity $Z(h)$ can be regarded as the functional integral representation for the imaginary time evolution operator $\langle \varphi_2 | U(t_2, t_1) | \varphi_1 \rangle$, with boundary conditions $\varphi(t_1, \vec{x}) = \varphi_1(\vec{x})$ and $\varphi(t_2, \vec{x}) = \varphi_2(\vec{x})$ which gives the transition amplitude from the initial state $|\varphi_1\rangle$ to a final state $|\varphi_2\rangle$ in the presence of some scalar source of compact support. As usual, the generating functional of the connected correlation functions shall be given by $W(h) = \ln Z(h)$. In a free scalar theory, $Z(h)$ as well as $W(h)$ can be calculated exactly. Regarding the Lagrangian density, we assume that

$$\mathcal{L}(\varphi, \partial\varphi) = \frac{1}{2}(\partial\varphi)^2 + \frac{1}{2} m_0^2 \varphi^2 + \frac{1}{4!} \lambda_0 \varphi^4, \tag{2}$$

where m_0 is the bare mass and λ_0 is the bare coupling constant of the model. We are also assuming $m_0^2 \geqslant 0$ and also $\lambda_0 > 0$. The Euclidean n-point correlation functions, i.e., the n-point Schwinger functions are given by the expectation value with respect to the weight $\exp(-S(\varphi))$, defined as

$$G^{(n)}(x_1, x_2, \ldots, x_n) = \frac{1}{Z(h)} \left. \frac{\delta^n Z(h)}{\delta h(x_1) \cdots \delta h(x_n)} \right|_{h=0}. \tag{3}$$

The n-point connected correlation functions $G_c^{(n)}(x_1, x_2, \ldots, x_n)$ are given by

$$G_c^{(n)}(x_1, x_2, \ldots, x_n) = \frac{1}{Z(h)} \left. \frac{\delta^n W(h)}{\delta h(x_1) \cdots \delta h(x_n)} \right|_{h=0}. \tag{4}$$

Finally, the generating functional of connected one-particle irreducible correlation functions (the effective action) is introduced by performing a Legendre transformation on $W(h)$,

$$\Gamma(\varphi_0) = - W(h) + \int \mathrm{d}^d x \; \varphi_0(x) h(x). \tag{5}$$

Let us define the proper vertices $\Gamma^{(n)}(x_1, \ldots, x_n)$ as

$$\Gamma^{(n)}(x_1, \ldots, x_n) = \left. \frac{\delta^n \Gamma(\varphi_0)}{\delta\varphi_0(x_1) \cdots \delta\varphi_0(x_n)} \right|_{\varphi_0 = 0}, \tag{6}$$

where the normalized vacuum expectation value of the field $\varphi_0(x)$ is given by

$$\varphi_0(x) = \frac{\delta W}{\delta h(x)}. \tag{7}$$

It is clear that in the case of a single scalar field, for a zero normalized vacuum expectation value of the field $\varphi_0(x)$, the effective action may be represented as a functional power series around the value $\varphi_0 = 0$, with the form

$$\Gamma(\varphi_0) = \sum_{n=0}^{\infty} \frac{1}{n!} \int \mathrm{d}^d x_1 \cdots \mathrm{d}^d x_n \, \Gamma^{(n)}(x_1, \ldots, x_n) \varphi_0(x_1) \cdots \varphi_0(x_n). \tag{8}$$

If the bare coupling constant vanishes, i.e., $\lambda_0 = 0$, the generating functional of all n-point Schwinger functions $Z(h)$ can be calculated exactly, since we have to evaluate only Gaussian integrals. After some manipulations we obtain that the Gaussian generating functional $Z_0(h)$ is given by

$$Z_0(h) = \exp\left(\frac{1}{2} \int \mathrm{d}^d x \int \mathrm{d}^d y \; h(x) G_0^{(2)}(x - y, m_0) h(y) \right), \tag{9}$$

where the two-point Schwinger function (the inverse kernel) satisfies

$$(-\Delta_x + m_0^2) G_0^{(2)}(x - y, m_0) = \delta^d(x - y). \tag{10}$$

In this situation, the free Euclidean field is a Gaussian random variable defined by its two-point correlation function

$$G_0^{(2)}(x - y, m_0) = \langle x | (-\Delta + m_0^2)^{-1} | y \rangle, \tag{11}$$

and the two-point Schwinger function has a well-known Fourier representation given by

$$G_0^{(2)}(x - y, m_0) = \frac{1}{(2\pi)^d} \int \mathrm{d}^d p \frac{e^{ip(x-y)}}{(p^2 + m_0^2)}. \tag{12}$$

In the next section we will show that the two-point function $G_0^{(2)}(x-y, m_0)$ can be expressed in terms of the modified Bessel function of the third kind or Macdonald's function $K_\mu(x)$. At present, we are not interested in evaluating the two-point Schwinger function, but only in the analysis of the behavior of $G_0^{(2)}(x-y, m_0)$ in a given ϵ neighborhood. Let us assume that $m|x-y| \ll 1$; in this case, for $d \geqslant 3$ we can use that $G_0^{(2)}(x-y, m_0^2) \approx G_0^{(2)}(x-y, m_0^2 = 0) = |x-y|^{-(d-2)}$. For $d=2$, the mass parameter cannot be eliminated from the denominator and we have the following short distance behavior: $G_0^{(2)}(x-y, m_0^2) \propto \ln(m|x-y|)$. It is well known that a massless two-dimensional scalar field theory is not consistent, once the model has severe infrared divergences. There are different proposals to circumvent this problem; we only mention some of them. For instance, one may violate the positivity of the state vector space; another attempt is to restrict the test functions of the theory, and finally one can introduce a cutoff in the definition of the positive and negative Wightman functions. It is clear that such cutoff procedure is equivalent to introducing a box to regulate the theory in the infrared. Later, we will discuss other strategies to solve the problem of the infrared divergences in scalar theories at finite temperature.

Coming back to the generating functional of all Schwinger functions, for $\lambda_0 \neq 0$ it is not possible to find a closed exact expression for the partition function, and a perturbative expansion is mandatory. Let us then assume the weak-coupling perturbative expansion of the theory. It is important to point out that the partition function can be defined in arbitrary geometries, and classical boundary conditions must be implemented in the two-point Schwinger function, restricting the space of functions that appear in the functional integrals. If we want to include thermal effects, and assuming thermal equilibrium, from the Feynman, Matheus, and Salam formula we have

$$\langle\varphi_b|e^{-iH(t_f-t_i)}|\varphi_a\rangle=\int_{\varphi(t_i)=\varphi_a}^{\varphi(t_f)=\varphi_b}\exp\left(i\int_{t_i}^{t_f}dt\int d^{d-1}x\ \mathcal{L}(\varphi,\partial\varphi)\right),\tag{13}$$

where we have to assume that $t_f-t_i=-i\beta$ and also set $\varphi_a=\varphi_b$, and the sum over all φ_a must be performed in order to produce the trace. The partition function $\mathrm{Tr}[e^{-\beta H}]$ is given by

$$\mathrm{Tr}[e^{-\beta H}]=\int_{\text{periodic}}[d\varphi]\exp\left(i\int_{ti}^{t_i-i\beta}dt\int d^{d-1}x\ \mathcal{L}(\varphi,\partial\varphi)\right),\tag{14}$$

where the integration over the fields satisfying $\varphi(t_i-i\beta,\vec{x})=\varphi(t,\vec{x})$. Since the time integration must range from some value t_i to $t_i-i\beta$, let $t_i=0$ and set the contour along the negative imaginary axis from 0 to $-i\beta$. Thus, $t=-i\tau$, where $0\leqslant\tau\leqslant\beta$, and we have

$$Z(h)|_{h=0}=\int_{\text{periodic}}[d\varphi]\exp\left(\int_0^{\beta}d\tau\int d^{d-1}x\ \mathcal{L}(\varphi,\partial\varphi)\right).\tag{15}$$

To generate the n-point Schwinger functions we need to couple the field with an external source. We will assume that the system is confined between two parallel hyperplates (which we call the Casimir configuration), localized at $z=0$ and $z=L$, and we are using Cartesian coordinates $x^{\mu}=(\vec{r},z)$, where $\vec{r}$ is a $(d-1)$ dimensional vector perpendicular to the $\vec{z}$ vector. Note that since we assume thermal equilibrium with a reservoir, we have periodicity in the first coordinate and $0\leqslant r_1\leqslant\beta$. See, for example, Ref. 28, or for a complete review of quantum field theory at thermal equilibrium, see for example, Ref. 29. The choice of Dirichlet–Dirichlet boundary conditions means that the scalar field satisfies

$$\varphi(\vec{r},z)|_{z=0}=\varphi(\vec{r},z)|_{z=L},\tag{16}$$

and Neumann–Neumann boundary conditions means that

$$\frac{\partial}{\partial z}\varphi(\vec{r},z)|_{z=0}=\frac{\partial}{\partial z}\varphi(\vec{r},z)|_{z=L}.\tag{17}$$

In the next section we will discuss the perturbative renormalization at the one-loop level of the field theory in the presence of rigid boundaries. The great interest of this matter is when systems contain macroscopic structures, how is it possible to implement the renormalization program? We will examine how the weak-coupling perturbative expansion and the renormalization program can be implemented. In order to identify the singular part of the one-loop two-point Schwinger function, we use a combination of dimensional and zeta-function analytic regularization procedures. We also present the detailed form of the surface divergences. Note that due to our choice (two-parallel hyperplates), the region outside the boundaries is the union of two-simple connected domains. The renormalization of the field theory in such exterior regions must be carried out along the same lines as for the interior region. For simplicity we are considering only the interior region.

III. THE REGULARIZED ONE-LOOP TWO AND FOUR-POINT SCHWINGER FUNCTIONS

The aim of this section is to reshape a well-known result, adding finite temperature effects to the problem. In order to implement the renormalization program in a scalar field theory where we assume Dirichlet–Dirichlet or Neumann–Neumann boundary conditions on rigid surfaces one must introduce surface counterterms. To write the full renormalized action for the theory with rigid boundaries we need two regulators: the first one is the usual ϵ that is introduced in the dimensional regularization procedure and the second one which we call η, represents the distance to a boundary. Accordingly we will show that the full renormalized action must be given by

$$S(\varphi)=\int_0^L \mathrm{d}z\int \mathrm{d}^{d-1}r\left(\frac{A(\epsilon)}{2}(\partial_\mu\varphi)^2+\frac{B(\epsilon)}{2}\varphi^2+\frac{C(\epsilon)}{4!}\varphi^4\right)+\int \mathrm{d}^{d-1}r(c_1(\eta)\varphi^2(\vec{r},0)+c_2(\eta)\varphi^2(\vec{r},L))$$
$$+\int \mathrm{d}^{d-1}r(c_3(\eta)\varphi^4(\vec{r},0)+c_4(\eta)\varphi^4(\vec{r},L)), \tag{18}$$

where $A(\epsilon)$, $B(\epsilon)$, and $C(\epsilon)$ are the usual coefficients for the bulk counterterms and the coefficients $c_i(\eta)$, $i=1,\ldots,4$, which depend on the boundary conditions for the field, are the coefficients for the surface counterterms. As usual, all of these coefficients must be calculated order by order in perturbation theory. Note that we are interested in systems that are invariant under translation along directions parallel to the plates, which implies that the full momentum is not conserved. For such conditions, a more convenient representation for the n-point Schwinger functions to implement the perturbative renormalization is a mixed $(\vec{p},z)$ representation. Careless one-loop perturbation theory leads to ultraviolet counterterms that depend on the distance between the plates or also to the absence of surface counterterms.[22,23]

In a straightforward way, in the Matsubara formalism all the Feynman rules are the same as in the zero temperature case, except that the momentum-space integrals over the zeroth component is replaced by a sum over discrete frequencies. For the case of boson fields we must perform the replacement

$$\int \frac{\mathrm{d}^d p}{(2\pi)^d}f(p)\to\frac{1}{\beta}\sum_n\int\frac{\mathrm{d}^{d-1}p}{(2\pi)^{d-1}}f\left(\frac{2n\pi}{\beta},\vec{p}\right), \tag{19}$$

where we are using the following notation: $(\int \mathrm{d}^{d-1}r=\int_0^\beta \mathrm{d}r_1\int \mathrm{d}^{d-2}r)$.

We begin the study of the interacting theory by building the one-loop correction $(G_1^{(2)}(\lambda_0,x,x'))$ to the bare two-point Schwinger function $G_0^{(2)}(x,x')$, for both the DD and NN boundary conditions. Using the Feynman rules we have that $G_1^{(2)}(\lambda_0,\vec{r}_1,z_1,\vec{r}_2,z_2)$ can be written as

$$G_1^{(2)}(\lambda_0,\vec{r}_1,z_1,\vec{r}_2,z_2)=\frac{\lambda_0}{2}\int \mathrm{d}^{d-1}r\int_0^L \mathrm{d}z\; G_0^{(2)}(\vec{r}_1-\vec{r},z_1,z)G_0^{(2)}(\vec{0},z)G_0^{(2)}(\vec{r}-\vec{r}_2,z,z_2). \tag{20}$$

Even though the functions $G_0^{(2)}(\vec{r}_1-\vec{r}_2,z_1,z_2)$ and $G_0^{(2)}(\vec{r}_2-\vec{r}_3,z_2,z_3)$ are singular at coincident points $(\vec{r}_1=\vec{r}_2,\ z_1=z_2)$ and $(\vec{r}_2=\vec{r}_3,\ z_2=z_3)$, the singularities are integrable for points outside the plates. It is worth mentioning that the most simple way to take into account the boundary is to implement the boundary conditions through the explicit form of the free two-point Schwinger function $G_0^{(2)}(x-y,m_0)$. A straightforward substitution yields the order λ_0 correction to the bare two-point Schwinger function in the one-loop approximation for the case of Dirichlet–Dirichlet boundary conditions. Using the Feynman rules, $G_2^{(4)}(\lambda_0,x_1,x_2,x_3,x_4)$, i.e., the $O(\lambda_0^2)$ correction to the bare one-loop four-point Schwinger function, is given by

$$G_2^{(4)}(\lambda_0,\vec{r}_1,z_1,\vec{r}_2,z_2,\vec{r}_3,z_3,\vec{r}_4,z_4)=\frac{\lambda_0^2}{2}\int \mathrm{d}^{d-1}r\int \mathrm{d}^{d-1}r'\int_0^L \mathrm{d}z\int_0^L \mathrm{d}z' G_0^{(2)}(\vec{r}_1-\vec{r},z_1,z)G_0^{(2)}(\vec{r}_2-\vec{r},z_2,z)$$
$$\times(G_0^{(2)}(\vec{r}-\vec{r}',z,z'))^2G_0^{(2)}(\vec{r}'-\vec{r}_3,z',z_3)G_0^{(2)}(\vec{r}'-\vec{r}_4,z',z_4). \tag{21}$$

Note that we supress the m_0 term in each expression. Again, all G_0's are singular at coincident points, but the singularities are integrable for points outside the plates, except for $G_0^{(2)}(\vec{r}-\vec{r}',z,z')$. Having in mind the above discussion, in this section we will study the following expressions:

$$\frac{\lambda_0}{2}\int \mathrm{d}^{d-1}r\int_0^L \mathrm{d}z(G_0^{(2)}(\vec{0},z)) \tag{22}$$

and

$$\frac{\lambda_0^2}{2}\int \mathrm{d}^{d-1}r \int \mathrm{d}^{d-1}r' \int_0^L \mathrm{d}z \int_0^L \mathrm{d}z' (G_0^{(2)}(\vec{r}-\vec{r}',z,z'))^2. \tag{23}$$

Let us first study $\frac{1}{2}G_0^{(2)}(\vec{0},z) \equiv I(z,m_0,L,\beta,d)$, and define the following quantities: $1/b=2/\beta$, $L=a$ and finally the dimensionless coupling constant $g=\mu^{4-d}\lambda_0$. Therefore, the argument in the integral defined in Eq. (22) , $I(z,m_0,a,b,d)$ can be written as

$$I(z,m_0,a,b,d) = \frac{g}{2(2\pi)^{d-2}ab}\sum_{n=-\infty}^{\infty}\sum_{n'=1}^{\infty}\sin^2\left(\frac{n'\pi z}{a}\right)\int \mathrm{d}^{d-2}p \frac{1}{\left(\vec{p}^2+\left(\frac{n'\pi}{a}\right)^2+\left(\frac{n\pi}{b}\right)^2++m_0^2\right)}. \tag{24}$$

There are two points that we would like to stress. First to perform analytic regularizations we must introduce a parameter μ with dimension of mass in order to have dimensionless quantities raised to a complex power. Second, the generalization for the case of Neumann boundary conditions is straightforward, although in this case infrared divergences associated with the $n=0$ mode will appear in the case of massless scalar field. To circumvent this situation, we must have a finite Euclidean volume to regularize the model in the infrared, or trying to implement a resummation to generate a thermal mass. We will return to this point later.

Using trigonometric identities, it is convenient to write the amputated one-loop two-point Schwinger in two parts. The first comprises the contributions that do not depend on the distance to the boundary, and the second the contributions that do depend on this distance. Therefore, the quantity $I(z,m_0,a,b,d)$ can be split in two parts $T_1(m_0,a,b,d)$ and $T_2(z,m_0,a,b,d)$, i.e.,

$$I(z,m_0,a,b,d) = T_1(m_0,a,b,d) + T_2(z,m_0,a,b,d). \tag{25}$$

The first quantity $T_1(m_0,a,b,d)$, independent on the distance to the boundaries can be expressed in the following way:

$$T_1(m_0,a,b,d) = I_0(m_0,a,b,d) + I_1(m_0,a,b,d) + I_2(m_0,a,b,d), \tag{26}$$

where each term is given, respectively, by

$$I_0(m_0,a,b,d) = -\frac{g}{16(2\pi)^{d-2}ab}\int \mathrm{d}^{d-2}p \frac{1}{(\vec{p}^2+m_0^2)}, \tag{27}$$

$$I_1(m_0,a,b,d) = \frac{g}{8(2\pi)^{d-2}ab}\sum_{n=1}^{\infty}\int \mathrm{d}^{d-2}p \frac{1}{\left(\vec{p}^2+m_0^2+\left(\frac{n\pi}{a}\right)^2\right)}, \tag{28}$$

and finally

$$I_2(m_0,a,b,d) = \frac{g}{4(2\pi)^{d-2}ab}\sum_{n,n'=1}^{\infty}\int \mathrm{d}^{d-2}p \frac{1}{\left(\vec{p}^2+\left(\frac{n\pi}{a}\right)^2+\left(\frac{n'\pi}{b}\right)^2+m_0^2\right)}. \tag{29}$$

The contribution that depends on the distance to the boundaries given by $T_2(z,m_0,a,b,d)$, can be split in the following way:

$$T_2(z,m_0,a,b,d) = I_3(z,m_0,b,d) + I_4(z,m_0,a,b,d) + I_5(z,m_0,b,d) + I_6(z,m_0,a,b,d). \tag{30}$$

Each term contributing to $T_2(z,m_0,a,b,d)$ is given, respectively, by

$$I_3(z,m_0,b,d)=\frac{g}{2b}h(d)\int_{m_0}^{\infty}\mathrm{d}v(v^2-m_0^2)^{(d-4)/2}\exp(-2vz), \tag{31}$$

$$I_4(z,m_0,a,b,d)=\frac{g}{2b}h(d)\int_{m_0}^{\infty}\mathrm{d}v(v^2-m_0^2)^{(d-4)/2}(\coth av-1)\cosh 2vz, \tag{32}$$

$$I_5(z,m_0,b,d)=\frac{g}{b}h(d)\sum_{n=1}^{\infty}\int_{m_0}^{\infty}\mathrm{d}v\left(v^2-m_0^2-\left(\frac{n\pi}{b}\right)^2\right)^{(d-4)/2}\exp(-2vz), \tag{33}$$

and finally

$$I_6(z,m_0,a,b,d)=\frac{g}{b}h(d)\sum_{n=1}^{\infty}\int_{\alpha}^{\infty}\mathrm{d}v\left(v^2-m_0^2-\left(\frac{n\pi}{b}\right)^2\right)^{(d-4)/2}(\coth av-1)\cosh 2vz. \tag{34}$$

In the above expression the quantity α is given by

$$\alpha=\left(m_0^2+\left(\frac{n\pi}{b}\right)^2\right)^{1/2}, \tag{35}$$

and $h(d)$, that appears in Eqs. (31)–(34) is an entire function given by

$$h(d)=\frac{1}{4(4\pi)^{(d-2)/2}}\frac{1}{\Gamma\left(\frac{d-2}{2}\right)}. \tag{36}$$

Let us investigate each contribution in detail. Using dimensional regularization we obtain for $I_0(m_0,d)$ the following expression:

$$I_0(m_0,a,b,d)=-\frac{g}{16ab(2\sqrt{\pi})^{d-2}}\Gamma\left(2-\frac{d}{2}\right)(m_0^2)^{(d/2)-2}. \tag{37}$$

An analytic expression for the gamma function $\Gamma(z)$, defined in the whole complex plane, can be found and in the neighborhood of a pole $z=-n$ $(n=0,1,2,\ldots)$ the gamma function has the representation

$$\Gamma(z)=\frac{(-1)^n}{n!}\frac{1}{(z+n)}+\Omega(z+n), \tag{38}$$

with regular part $\Omega(z+n)$. Using that $4-d=\epsilon$ and the duplication formula for the gamma function $\Gamma(z)$ we have

$$I_0\,(m_0,a,b,d)\big|_{d=4}=-\frac{g}{16\pi\,ab}\frac{1}{m_0^{\epsilon}}\left(\frac{1}{\epsilon}+\Omega(\epsilon)\right). \tag{39}$$

Here one may adopt different renormalization schemes. We can choose the minimal subtraction (MS) scheme, in which we eliminate only the pole term $1/\epsilon$ in the dimensionally regularized expression for the Schwinger functions. Another choice is the modified minimal subtraction (MS) scheme, where we eliminate not only the pole term $1/\epsilon$ but also the regular part around the pole. Note that in the minimal subtraction scheme the counterterms acquire the simplest expression, while the renormalized Schwinger functions have more complicated expressions. Let us analyze the second expression, given by $I_1(m_0,a,b,d)$. Using dimensional regularization it is possible to show that

$$I_1(m_0,a,b,d)=\frac{g}{8(2\sqrt{\pi})^{d-2}ab}\Gamma\left(2-\frac{d}{2}\right)\sum_{n=1}^{\infty}\frac{1}{\left(m_0^2+\left(\frac{n\pi}{a}\right)^2\right)^{2-(d/2)}}. \tag{40}$$

We note that to extract a finite result from $I_1(m_0,a,b,d)$ we still have to use the analytic extension of the Epstein–Hurwitz zeta function. A direct calculation gives

$$I_1(m_0,a,b,d)=-\frac{g}{8ab}m_0^{d-4}\frac{\sqrt{\pi}}{(2\sqrt{\pi})^{d-1}}\Gamma\left(2-\frac{d}{2}\right)+\frac{gm_0^{d-3}}{8b}\frac{1}{(2\pi)^{d-1}}$$
$$\times\left(\Gamma\left(\frac{3-d}{2}\right)+4\sum_{n=1}^{\infty}(am_0n)^{(3-d)/2}K_{(3-d)/2}(2m_0na)\right). \tag{41}$$

The first term in the above equation is a polar part and the second one is finite. Assuming the minimal subtraction scheme, $I_1(m_0,a,b,d)$ becomes finite. The next term that we must analyze is $I_2(m_0,a,b,d)$ defined by

$$I_2(m_0,a,b,d)=\frac{g}{4ab}\frac{1}{(2\pi)^{d-2}}\sum_{n,n'=1}^{\infty}\int \mathrm{d}^{d-2}p\frac{1}{\left(\vec{p}^2+\left(\frac{n\pi}{a}\right)^2+\left(\frac{n'\pi}{b}\right)^2+m_0^2\right)}. \tag{42}$$

The contribution given by the above equation is a part of the amputated one-loop two-point Schwinger function that does not depend on the distance to the boundaries, and in the renormalization procedure it will require only a usual bulk counterterm. The form of the counterterm is given by the principal part of the Laurent expansion of Eq. (42) around some d, which must be given by the analytic extension of the Epstein zeta function in the complex d plane. The structure of the divergences of the Epstein zeta function is well known in the literature.[30–33] Since the polar structure of the above equation can be found in the literature, we will focus only on the position-dependent divergent part given by $T_2(z,m_0,a,b,d)$. We are now in position to discuss the behavior of $I_3(z,m_0,b,d)$, $I_4(z,m_0,a,b,d)$, $I_5(z,m_0,b,d)$ and finally $I_6(z,m_0,a,b,d)$.

Let us first analyze $I_3(z,m_0,b,d)$. Using the following integral representation of the modified Bessel functions of third kind, or Macdonald's functions $K_\nu(x)$,[34]

$$\int_u^{\infty}(x^2-u^2)^{\nu-1}e^{-\mu x}\,\mathrm{d}x=\frac{1}{\sqrt{\pi}}\left(\frac{2u}{\mu}\right)^{(\nu-1/2)}\Gamma(\nu)K_{\nu-1/2}(u\mu), \tag{43}$$

which is valid for $u>0$, $\mathrm{Re}(\mu)>0$ and $\mathrm{Re}(\nu)>0$, we see that $I_3(z,m_0,a,b,d)$ can be written in terms of these functions. A simple substitution gives

$$I_3(z,m_0,a,b,d)=\frac{2}{b}\frac{h(d)}{(2\sqrt{\pi})^{d-1}}\left(\frac{m_0}{z}\right)^{(d-3)/2}K_{(d-3/2)}(2m_0z). \tag{44}$$

Using a asymptoptic formula for the Bessel function, $I_3(z,m_0,a,b,d)$ is given by

$$I_3(z,m_0,a,b,d)=\frac{2}{b}\frac{h(d)}{(2\sqrt{\pi})^{d-1}}\frac{\Gamma\left(\frac{d-3}{2}\right)}{z^{d-3}}. \tag{45}$$

We can see that we have a divergent behavior as $z\to 0$, which demands a surface counterterm. Let us show that the other terms also contain surface divergences, and study $I_4(z,m_0,a,b,d)$. To advance in the calculations, we must extend the binomial series for both positive or negative integral exponents, written in the form

$$(1+x)^k = \sum_{n=0}^{\infty} C_n^k x^n. \tag{46}$$

First, it is possible to show that the binomial expansion holds for any real exponent α, $|x|<1$ and $\alpha \epsilon R$, i.e.,

$$(1+x)^\alpha = \sum_{n=0}^{\infty} C_\alpha^n x^n, \tag{47}$$

where C_α^n are the generalization of the binomial coefficients. Since we are using dimensional regularization, it is possible to extend the binomial expansion when both the exponent α as well the variable x assume complex values. For this purpose we use the following theorem.

For any complex exponent α and any complex z in $|z|<1$, the binomial series

$$\sum_{n=0}^{\infty} C_\alpha^n z^n = 1 + C_\alpha^1 z + \cdots + C_\alpha^n z^n + \cdots \tag{48}$$

converges and has for sum the principal value of the power $(1+z)^\alpha$, where the principal value of the power b^a is given by the number uniquely defined by the formula $b^a = \exp(a \ln b)$, where a and b denotes any complex numbers, with $b \neq 0$ as the only condition, and $\ln b$ is given its principal value. Going back to $I_4(z,m_0,a,b,d)$, using the generalization of the binomial theorem, let us define $C^{(1)}(d,k) = \frac{1}{2} h(d)(-1)^k C_{(d-4)/2}^k$ to obtain

$$I_4(z,m_0,a,b,d) = \frac{g}{a^{d-3} b} \sum_{k=0}^{\infty} C^{(1)}(d,k)(m_0 a)^{2k} \int_{m_0 a}^{\infty} u^{d-4-2k} (\coth u - 1) \cosh\left(\frac{2uz}{a}\right). \tag{49}$$

Let us use the following integral representation of the gamma function:

$$\int_0^\infty \mathrm{d}t\, t^{\mu-1} e^{-\nu t} = \frac{1}{\nu^\mu} \Gamma(\mu), \quad \mathrm{Re}(\mu) > 0, \quad \mathrm{Re}(\nu) > 0, \tag{50}$$

and also the following integral representation of the product of the gamma function times the Hurwitz zeta function,

$$\int_0^\infty \mathrm{d}t\, t^{\mu-1} e^{-\alpha t} (\coth t - 1) = 2^{1-\mu} \Gamma(\mu) \zeta\left(\mu, \frac{\alpha}{2} + 1\right), \quad \mathrm{Re}(\alpha) > 0, \quad \mathrm{Re}(\mu) > 1, \tag{51}$$

where $\zeta(s,u)$ is the Hurwitz zeta function defined by[34]

$$\zeta(s,u) = \sum_{n=0}^{\infty} \frac{1}{(n+u)^s}, \quad \mathrm{Re}(s) > 1, \quad u \neq 0, -1, -2, \ldots. \tag{52}$$

It is not difficult to show that $I_4(z,m_0,a,b,d)$ contains surface divergences at $z=0$ and also $z=a$. For more details, see, for example, Ref. 35. The other expression that we must study is $I_5(z,m_0,a,b,d)$. Using an integral representation of the Bessel function of third kind we have

$$I_5(z,m_0,a,b,d) = \frac{1}{b} \frac{1}{(2\sqrt{\pi})^{d-1}} \sum_{n=1}^{\infty} \left(\frac{\alpha}{z}\right)^{(d-3)/2} K_{(d-3)/2}(2\alpha z). \tag{53}$$

Using an asymptotic representation of the Bessel function it is posssible to present also the singular behavior near $z=0$. Let us finally investigate $I_6(z,m_0,a,b,d)$. A simple calculation for the massless case gives

$$I6\,(z,m_0,a,b,d)|_{m=0}=\frac{1}{a^{d-3}b}\sum_{k=0}^{\infty}C^{(2)}(d,k)\left(\frac{a}{b}\right)^{2k}\sum_{n=1}^{\infty}n^{2k}\int_{n\pi a/b}^{\infty}\mathrm{d}u\;u^{d-4-2k}(\coth u-1)\cosh\left(\frac{2uz}{a}\right), \tag{54}$$

where $C^{(2)}(d,k)=h(d)(-1)^kC^k_{(d-4)/2}\pi^{2k}$ is an entire function in the complex d plane. The integral that appears in Eq. (54) cannot be evaluated explicity in terms of well-known functions. Nevertheless it is possible to write Eq. (54) in a convenient way where the structure of the divergences near the plate when $y\to b$ appear. Clearly for details see Ref. 35. In the next section we will investigate the singularities of the four-point Schwinger function.

IV. THE FOUR-POINT SCHWINGER FUNCTION IN THE ONE-LOOP APPROXIMATION

We now turn our attention to the four-point Schwinger function in the one-loop approximation. For simplicity we shall study only the zero temperature case. In this section we are following the discussion developed in Ref. 25. Introducing new variables as $u_{\pm}\equiv z\pm z'$, and also $(\vec{\rho}=\vec{r}-\vec{r}')$, the zero-temperature two-point Schwinger function in the tree-level $G_0^{(2)}(\vec{\rho},z,z')$ can be split into

$$G_0^{(2)}(\vec{\rho},z,z')=G_+^{(2)}(\vec{\rho},u_+)+G_-^{(2)}(\vec{\rho},u_-), \tag{55}$$

where we are defining $A_n(a,m_0,d,\vec{\rho})$ by

$$A_n(a,m_0,d,\vec{\rho})=\frac{1}{(2\pi)^{d-1}}\int\mathrm{d}^{d-1}p\frac{e^{i\vec{p}\cdot\vec{\rho}}}{\left(\vec{p}^2+\left(\frac{n\pi}{a}\right)^2+m_0^2\right)}, \tag{56}$$

and so $G_{\pm}^{(2)}(\vec{\rho},u_{\pm})$ can be expressed as

$$G_{\pm}^{(2)}(\vec{\rho},u_{\pm})=\mp\frac{1}{a}\sum_{n=1}^{\infty}\cos\left(\frac{n\pi u_{\pm}}{a}\right)A_n(a,m_0,d,\vec{\rho}). \tag{57}$$

Before proceeding, let us present a explicit formula for the free two-point Schwinger function $G_{\pm}^{(2)}(\rho,u_{\pm})$ in terms of Bessel functions. Let us define an analytic function $f(d)$ by

$$f(d)=\frac{1}{\sqrt{\pi}(2\pi)^{(d-1)/2}}\frac{\Gamma\left(\frac{d-2}{2}\right)}{\Gamma\left(\frac{d-3}{2}\right)}. \tag{58}$$

Strictly speaking, it is possible to show that we can write $G_{\pm}^{(2)}(\rho,u_{\pm})$ in terms of the Bessel function of the third kind. To this end, we use the standard formula

$$\frac{1}{(2\pi)^d}\int\mathrm{d}^dr\;F(r)e^{i\vec{k}\cdot\vec{r}}=\frac{1}{\sqrt{\pi}(2\pi)^{d/2}}\frac{\Gamma\left(\frac{d-1}{2}\right)}{\Gamma\left(\frac{d-2}{2}\right)}\int_0^{\infty}F(r)r^{d/2}J_{(d-3)/2}(kr)\mathrm{d}r, \tag{59}$$

which leads us to

$$G_{\pm}^{(2)}(\rho,u_{\pm})=\mp\frac{f(d)}{\rho^{(d-3)/2}a}\sum_{n=1}^{\infty}\cos\left(\frac{n\pi u_{\pm}}{a}\right)\int_0^{\infty}\mathrm{d}p\frac{p^{(d-1)/2}}{\left(p^2+\left(\frac{n\pi}{L}\right)^2+m_0^2\right)}J_{(d-3)/2}(p\rho), \tag{60}$$

where $J_{\nu}(x)$ is the Bessel function of the first kind of order ν. The integral in Eq. (60) can be calculated by using the result[34]

$$\int_0^\infty \mathrm{d}x \frac{x^{\nu+1} J_\nu(ax)}{(x^2+b^2)} = b^\nu K_\nu(ab), \tag{61}$$

implying that it is possible to write $G_\pm^{(2)}(\rho, u_\pm)$ as

$$G_\pm^{(2)}(\rho,u_\pm) = \mp \frac{f(d)}{\rho^{(d-3)/2} a} \sum_{n=1}^{\infty} \cos\left(\frac{n\pi u_\pm}{a}\right)\left(\left(\frac{n\pi}{a}\right)^2 + m_0^2\right)^{(d-3)/4} K_{(d-3)/2}\left(\rho\sqrt{m_0^2+\left(\frac{n\pi}{a}\right)^2}\right). \tag{62}$$

Using Eq. (55) and the above formula, the explicit expression for the two-point Schwinger function in a generic d-dimensional Euclidean space confined between two flat parallel hyperplanes, where we assume Dirichlet–Dirichlet boundary conditions is given. It is difficult to use the above expressions for $G_\pm^{(2)}(\rho, u_\pm)$ to investigate the analytic structure of the four-point function for both the bulk and near the boundaries. Nevertheless, it is clear that the divergences of the four-point function in the one-loop approximation appear at coincident points and therefore the singular behavior is encoded in the polar part of $M(\lambda_0, a, m, d)$ given by

$$M(\lambda_0,a,m_0,d) = g^2 \int \mathrm{d}^{d-1}r \int \mathrm{d}^{d-1}r' \int_0^a \mathrm{d}z \int_0^a \mathrm{d}z' F(\vec{r},\vec{r}',z,z')(G_0^{(2)}(\vec{r}-\vec{r}',z,z'))^2. \tag{63}$$

It is easy to show that $G_2^{(4)}(\lambda_0, a, m_0, d)_{\mathrm{amp}}$ is given by

$$G_2^{(4)}(\lambda_0,a,m_0,d)_{\mathrm{amp}} = \frac{g^2}{2(2\pi)^{2d-2}} \int \mathrm{d}^{d-1}r \int \mathrm{d}^{d-1}r' \int \mathrm{d}^{d-1}k \int \mathrm{d}^{d-1}q \times \sum_{n=1}^{\infty} \frac{e^{i\vec{\rho}\cdot(\vec{q}-\vec{k})}}{\left(\vec{q}^2+\left(\frac{n\pi}{a}\right)^2+m_0^2\right)\left(\vec{k}^2+\left(\frac{n\pi}{a}\right)^2+m_0^2\right)}, \tag{64}$$

where $F(\vec{r},\vec{r}',z,z')$ is a regular function. As with the one-loop two-point function, it is not difficult to realize that the above equation has two kinds of singularities, those coming from the bulk and those arising from the behavior near the surface. As before, the behavior in the bulk is similar to the thermal field theory case and consequently we will discuss only the singularities arising from the boundaries. This can be done studying the polar part of $\tilde{M}(\lambda_0, a, m_0, d)$ given by

$$\tilde{M}(\lambda,a,m_0,d) = \frac{g^2}{2}\int_0^a \mathrm{d}z \int_0^a \mathrm{d}z' \mathcal{F}(z,z')(G_0^{(2)}(\vec{0},z,z'))^2, \tag{65}$$

where $\mathcal{F}(z,z')$ is a regular function. Now, we recall that the form of $G_\pm^{(2)}(\rho,u_\pm)|_{\rho=0}$ is given by

$$G_\pm^{(2)}(\rho,u_\pm)|_{\rho=0} = \mp \frac{1}{(2\pi)^{d-1}a} \sum_{n=1}^{\infty} \cos\left(\frac{n\pi u_\pm}{a}\right) \int \mathrm{d}^{d-1}p \frac{1}{\left(\vec{p}^2+m_0^2+\left(\frac{n\pi}{a}\right)^2\right)}, \tag{66}$$

where it is not difficult to show that

$$G_\pm^{(2)}(\rho,u_\pm)|_{\rho=0} = \mp\left(-\frac{1}{2a}A_0(\rho,L,m_0)|_{\rho=0} + f_2\left(a,m_0,d,\frac{u_\pm}{2}\right)\right). \tag{67}$$

In the above definition we are making use of the auxiliary function $f_2(a,d,m_0,z)$ given by

$$f_2(a,m_0,d,z)=\frac{1}{2(2\pi)^{d-1}}\int \mathrm{d}^{d-1}p\,\frac{1}{\sqrt{\vec{p}^2+m_0^2}}\,\frac{\cosh((a-2z)\sqrt{\vec{p}^2+m_0^2})}{\sinh(a\sqrt{\vec{p}^2+m_0^2})}. \tag{68}$$

Note that the amputated one-loop two-point Schwinger function can be decomposed in a translational invariant part and a translational invariance breaking part, given exactly by $f_2(a,m_0,d,z)$. When we sum to find the free propagator, we end up with the following expression:

$$G_0^{(2)}(\rho,z,z')|_{\rho=0}=f_2\left(a,m_0,d,\frac{u_-}{2}\right)-f_2\left(a,m_0,d,\frac{u_+}{2}\right). \tag{69}$$

For the sake of simplicity, we will discuss only the massless case once the singularities of the massive case have the same structure as in the massless one. The function $f_2(a,m_0,d,u_+/2)$ is nonsingular in the bulk, i.e., in the interior of the interval $[0,a]$, while $f_2(a,m_0,d,u_-/2)$ has a singularity along the line $z=z'$. Indeed, closer inspection shows that for $0\leqslant z,z'\leqslant a$ the only singularities are those at $u_+=0$, $u_+=2a$ and also $u_-=0$. The former two are genuinely boundary singularities (the two conditions imply $z,z'\to 0$ or $z,z'\to a$), while the last comes from $z=z'$ in the whole domain and is just the standard bulk singularity. In fact, using the structure of the two-point function and showing just those terms from which singularities might arise, one finds that the counterterms for $\tilde{M}$ are given by

$$-\,\mathrm{pole}\int_0^a \mathrm{d}z\int_0^a \mathrm{d}z'\left[\frac{C_1}{(z+z')^{d-2}}+\frac{C_2}{(2a-z-z')^{d-2}}+\frac{C_3}{(z-z')^{d-2}}+\cdots\right]^2, \tag{70}$$

where C_i, $i=1,\ldots,3$ are regular functions that do not depend on z or z'. From this discussion it is clear that in order to render the field theory finite, we must introduce surface terms in the action. This is a general statement. For any fields that satisfy boundary conditions that break the translational invariance it suffices to introduce surface counterterms in the action, in addition to the usual bulk counterterms, to render the theory finite in the ultraviolet.[36–38] Now we are able to discuss whether in the Casimir configuration the infrared problems can be solved for the case of Neumann boundary conditions. For the case of massless $(\lambda\varphi^4)_d$ theory at finite temperature, the infrared problem can be solved after a resummation procedure.[17–20,39] The key point for the solution of the infrared problem is to use the Dyson–Schwinger equation to rewrite the self-energy gap equation. Simple inspection of Eq. (24) show us that it is not possible to implement such scheme in a situation where there is a break of translational invariance.

A different possibility to approach the infrared problem is to single out the zero mode component of the field, treating the nonzero modes perturbatively and treating the zero mode exactly. This is a standard procedure in high-temperature field theory, where by means of the dimensional reduction idea, we relate the thermal Schwinger functions in a d-dimensional Euclidean space to zero temperature Schwinger functions in a $(d-1)$ dimensional Euclidean space.[40–42] In this situation we have a dimensionally reduced effective theory. The key point in this construction is the fact that the leading infrared behavior of any field theory at high temperature in a d-dimensional Euclidean space is governed by the zero frequency Matsubara mode.

V. DISCUSSIONS AND CONCLUSIONS

In this paper we are interested in the analysis of the important questions of perturbative expansion and renormalization program in quantum field theory with boundary conditions that break translation symmetry, assuming that the system is in equilibrium with a reservoir at temperature β^{-1}. Specifically, the purpose of this paper is to study the renormalization procedure up to one-loop level in the $(\lambda\varphi^4)_d$ theory at finite temperature assuming that the scalar field satisfies Dirichlet–Dirichlet or Neumann–Neumann boundary conditions on two parallel hyperplates.

We first obtained the regularized one-loop diagrams associated with scalar field defined in the Casimir configuration in a d-dimensional Euclidean space. We obtained a well-known result concerning surface divergences that appear in the one-loop two-point and four-point Schwinger

functions as a consequence of the uncertainty principle. There are at least three different possible solutions to eliminate these divergences. The first one is to take into account that real materials have imperfect conductivity at high frequencies. As was stressed by many authors, the infinities that appear in renormalized values of local observables for the ideal conductor (or perfect mirror) represent a breakdown of the perfect-conductor approximation. A wavelength cutoff corresponding to the finite plasma frequency must be included. The second one is to substitute classical boundary conditions by classical potentials; for previous papers using this idea see, for example, Refs. 43–45. A localized boundary with some cutoff can also be used to replace the potential. Nevertheless, it is necessary to renormalize the potential.[25] The third one regards a quantum mechanical treatment of the boundary conditions. A fruitful approach to avoid surface divergences, discussed by Kennedy *et al.*[46] is to treat the boundary as a quantum mechanical object. This approach was developed by Ford and Svaiter[47] to produce finite values for the renormalized $\langle\varphi^2\rangle$ and other quantities that diverge as one approaches the classical boundary.

Consequently, we have two main distinct directions for future investigations. The first is related to the infrared divergences of our model. Infrared divergences of massless thermal field theory arise from the zero frequency Matsubara modes, so we construct an effective $(d-1)$ dimensional theory by integrating out the nonstatic modes and therefore the zero frequency Matsubara modes which are responsible for infrared divergences can be treated separately. The second direction is related to the surface divergences. In the Euclidean formalism for field theory, one may imagine that our simplified model of rigid boundaries is a good approximation only for points in the bulk; for points close to the surfaces however, our approximation is no longer acurate and a model taking into account at least thermal fluctuations of the boundaries must be developed.[48] In other words, a fundamental understanding of the perturbative renormalization algorithm in the standard weak-coupling perturbative expansion of an Euclidean field in the presence of fluctuating boundaries is desired. This interesting situation of thermal fluctuating boundaries is under the investigation by the authors.

(Received 25 June 2004; accepted 18 August 2004; published 5 November 2004)

These brief notes record our puzzles and findings surrounding Givental's recent conjecture which expresses higher genus Gromov–Witten invariants in terms of the genus-0 data. We limit our considerations to the case of a complex projective line, whose Gromov–Witten invariants are well-known and easy to compute. We make some simple checks supporting his conjecture. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1808486]

I. BRIEF SUMMARY

These notes are brief sketches of our troubles and findings surrounding a work of Givental.[5]

Let $\mathcal{F}_g$ be the generating function in the small phase space for genus-g Gromov–Witten (GW) invariants of a manifold X with a semisimple Frobenius structure on $H^*(X,\mathbb{Q})$. Then, Givental's conjecture, whose equivariant counterpart he has proved,[5] is

$$e^{\Sigma_{g\geq 2}\lambda^{g-1}\mathcal{F}_g(t)} = \left[e^{(\lambda/2)\Sigma_{k,l\geq 0}\Sigma_{i,j} V_{kl}^{ij}\sqrt{\Delta_i}\sqrt{\Delta j}\partial_{q_k^i}\partial_{q_l^j}} \prod_j \tau(\lambda\Delta_j;\{q_n^j\}) \right]\Bigg|_{q_n^j=T_n^j}, \tag{1}$$

where $i,j=1,\ldots,\dim H^*(X,\mathbb{Q})$; τ is the KdV tau-function governing the intersection theory on the Deligne–Mumford space $\overline{\mathcal{M}}_{g,n}$; and V_{kl}^{ij},Δ_j, and T_n^j are functions of the small phase space coordinates $t\in H^*(X,\mathbb{Q})$ and are defined by solutions to the flat-section equations associated with the genus-0 Frobenius structure of $H^*(X,\mathbb{Q})$.[5] This remarkable conjecture organizes the higher genus GW invariants in terms of the genus-0 data and the τ function for a point. The motivation for our work lies in verifying the conjecture for $X=\mathbb{P}^1$, which is the simplest example with a semisimple Frobenius structure on its cohomology ring and whose GW invariants can be easily computed.

We have obtained two particular solutions to the flat-section equations (5), an analytic one encoding the two-point descendant GW invariants of $\mathbb{P}^1$ and a recursive one corresponding to Givental's fundamental solution. According to Givental, both of these two solutions are supposed to yield the same data V_{kl}^{ij},Δ_j, and T_n^j. Unfortunately, we were not able to produce the desired information using our-analytic solutions, but the recursive solutions do lead to sensible quantities which we need. Combined with an expansion scheme which allows us to verify the conjecture at each order in λ, we thus use our recursive solutions to check the conjecture (1) for $\mathbb{P}^1$ up to order λ^2. Already at this order, we need to expand the differential operators in (1) up to λ^6 and need to consider up to genus-3 free energy in the τ functions, and the computations quickly become cumbersome with increasing order. We have managed to re-express the conjecture for this case into a form which resembles the Hirota-bilinear relations, but at this point, we have no insights into a general proof. It is nevertheless curious how the numbers work out, and we hope that our results would provide a humble support for Givental's master equation.

Many confusions still remain—for instance, the discrepancy between our analytic and recursive solutions. As mentioned above, Givental's conjecture for $\mathbb{P}^1$ can be rewritten in a form which resembles the Hirota-bilinear relations for the KdV hierarchies [see (32)]. It would thus be interesting to speculate a possible relation between his conjecture and the conjectural Toda hierarchy for $\mathbb{P}^1$.

We have organized our notes as follows: in Sec. II, we review the canonical coordinates for $\mathbb{P}^1$, to be followed by our solutions to the flat-section equations in Sec. III. We conclude by presenting our checks in Sec. IV.

II. CANONICAL COORDINATES FOR $\mathbb{P}^1$.

We here review the canonical coordinates $\{u_\pm\}$ for $\mathbb{P}^1$.[1,2,4] Recall that a Frobenius structure on $H^*(\mathbb{P}^1,\mathbb{Q})$ carries a flat pseudo-Riemannian metric $\langle\cdot,\cdot\rangle$ defined by the Poincaré intersection pairing. The canonical coordinates are defined by the property that they form the basis of idempotents of the quantum cup product, denoted in the present note by $\circ$. The flat metric $\langle\cdot,\cdot\rangle$ is diagonal in the canonical coordinates, and following Givental's notation, we define $\Delta_\pm := 1/\langle\partial_{u_\pm},\partial_{u_\pm}\rangle$.

Let $\{t^\alpha\}, \alpha \in \{0,1\}$ be the flat coordinates of the metric and let $\partial_\alpha := \partial/\partial t^\alpha$. The quantum cohomology of $\mathbb{P}^1$ is

$$\partial_0 \circ \partial_\alpha = \partial_\alpha \quad \text{and} \quad \partial_1 \circ \partial_1 = e^{t^1}\partial_0.$$

The eigenvalues and eigenvectors of $\partial_1\circ$ are

$$\pm e^{t^1/2} \quad \text{and } (\pm e^{t^1/4}\partial_0 + e^{-t^1/4}\partial_1),$$

respectively. So, we have

$$(\pm e^{t^1/4}\partial_0 + e^{-t^1/4}\partial_1)\circ(\pm e^{t^1/4}\partial_0 + e^{-t^1/4}\partial_1) = \pm 2\, e^{t^1/4}(\pm e^{t^1/4}\partial_0 + e^{-t^1/4}\partial_1),$$

which implies that

$$\frac{\partial}{\partial_{u_\pm}} = \frac{\partial_0 \pm e^{-t^1/2}\partial_1}{2},$$

such that

$$\partial_{u_\pm}\circ\partial_{u_\pm} = \partial_{u_\pm} \quad \text{and } \partial_{u_\pm}\circ\partial_{u_\mp} = 0.$$

We can solve for $u_\pm$ up to constants as

$$u_\pm = t^0 \pm 2\, e^{t^1/2}. \tag{2}$$

To compute $\Delta_\pm$, note that

$$\frac{1}{\Delta_\pm} := \langle\partial_{u_\pm},\partial_{u_\pm}\rangle = \pm\frac{1}{2e^{t^1/2}}.$$

The two bases are related by

$$\partial_0 = \partial_{u_+} + \partial_{u_-} \quad \text{and } \partial_1 = e^{t^1/2}(\partial_{u_+} - \partial_{u_-}).$$

Define an orthonormal basis by $f_i = \Delta_i^{1/2}\partial/\partial u_i$. Then the transition matrix Ψ from $\{\partial/\partial t_\alpha\}$ to $\{f_i\}$ is given by

$$\Psi_{\alpha}^{\ i} = \frac{1}{\sqrt{2}} \begin{pmatrix} e^{-t^1/4} & -i\, e^{-t^1/4} \\ e^{t^1/4} & i\, e^{t^1/4} \end{pmatrix} = \begin{pmatrix} \Delta_+^{-1/2} & \Delta_-^{-1/2} \\ \frac{1}{2}\Delta_+^{1/2} & \frac{1}{2}\Delta_-^{1/2} \end{pmatrix}, \tag{3}$$

such that

$$\frac{\partial}{\partial t_\alpha} = \sum_i \Psi_{\alpha}^{\ i} f_i.$$

We will also need the inverse of (3):

$$(\Psi^{-1})_i^{\ \alpha} = \frac{1}{\sqrt{2}} \begin{pmatrix} e^{t^1/4} & e^{-t^1/4} \\ i\, e^{t^1/4} & -i\, e^{-t^1/4} \end{pmatrix} = \begin{pmatrix} \frac{1}{2}\Delta_+^{1/2} & \Delta_+^{-1/2} \\ \frac{1}{2}\Delta_-^{1/2} & \Delta_-^{-1/2} \end{pmatrix}. \tag{4}$$

III. SOLUTIONS TO THE FLAT-SECTION EQUATIONS

The relevant data V_{kl}^{ij}, Δ_j, and T_n^j are extracted from the solutions to the flat-section equations of the genus-0 Frobenius structure for $H^*(\mathbb{P}^1, \mathbb{Q})$. We here find two particular solutions. The analytic solution correctly encodes the two-point descendant GW invariants, while the recursive solution is used in the next section to verify Givental's conjecture.

A. Analytic solution

The genus-0 free energy for $\mathbb{P}^1$ is

$$\mathcal{F}_0 = \tfrac{1}{2}(t^0)^2 t^1 + e^{t^1}.$$

Flat sections S_α of $TH^*(\mathbb{P}^1, \mathbb{Q})$ satisfy the equations

$$z\, \partial_\alpha S_\beta = \mathcal{F}_{\alpha\beta\mu} g^{\mu\nu} S_\nu, \tag{5}$$

where $z \neq 0$ is an arbitrary parameter and $\mathcal{F}_{\alpha\beta\mu} := \partial^3 \mathcal{F} / \partial t^\alpha \partial t^\beta \partial t^\mu$. The only nonvanishing components of $\mathcal{F}_{\alpha\beta\mu}$ are

$$\mathcal{F}_{001} = 1 \quad \text{and } \mathcal{F}_{111} = e^{t^1}.$$

Hence, we find that the general solutions to the flat-section equations (5) are

$$S_0 = e^{t^0/z}[c_1 I_0(2\, e^{t^1/2}/z) - c_2 K_0(2\, e^{t^1/2}/z)] \tag{6}$$

and

$$S_1 = e^{t^0/z} e^{t^1/2}[c_1 I_1(2e^{t^1/2}/z) + c_2 K_1(2e^{t^1/2}/z)],$$

where $I_n(x)$ and $K_n(x)$ are modified Bessel functions, and c_i are integration constants which may depend on z.

We would now like to find two particular solutions corresponding to the following Givental's expression:

$$S_{\alpha\beta}(z) = g_{\alpha\beta} + \sum_{n\geqslant 0,(n,d)\neq(0,0)} \frac{1}{n!} \left\langle \phi_\alpha \cdot \frac{\phi_\beta}{z - \psi} \cdot (t^0\phi_0 + t^1\phi_1)^n \right\rangle_d, \tag{7}$$

where $S_{\alpha\beta}$ denotes the αth component of the βth solution. Here, $\{\phi_\alpha\}$ is a homogeneous basis of $H^*(\mathbb{P}^1, \mathbb{Q})$, $g_{\alpha\beta}$ is the intersection paring $\int_{\mathbb{P}^1} \phi_\alpha \cup \phi_\beta$ and $\psi \in H^2(\overline{M}_{0,n+2}(\mathbb{P}^1, d), \mathbb{Q})$ is the first Chern class of the universal cotangent line bundle over the moduli space $\overline{M}_{0,n+2}(\mathbb{P}^1, d)$. In order to find the particular solutions, we compare our general solution (6) with the 0th components of $S_{0\beta}$

in (7) *at the origin of the phase space*. The two-point functions appearing in (7) have been computed at the origin in Ref. 6 and have the following forms:

$$S_{00}\big|_{t^\alpha=0} = -\sum_{m=1}^{\infty} \frac{1}{z^{2m+1}} \frac{2d_m}{(m!)^2}, \quad \text{where } d_m = \sum_{k=1}^{m} 1/k, \tag{8}$$

and

$$S_{01}\big|_{t^\alpha=0} = 1 + \sum_{m=1}^{\infty} \frac{1}{z^{2m}} \frac{1}{(m!)^2}. \tag{9}$$

Using the standard expansion of the modified Bessel function K_0, we can evaluate (6) at the origin of the phase space to be

$$c_1 I_0\left(\frac{2}{z}\right) - c_2 K_0\left(\frac{2}{z}\right) = c_1 I_0\left(\frac{2}{z}\right) - c_2\left[-(-\log(z) + \gamma_E) I_0\left(\frac{2}{z}\right) + \sum_{m=1} \frac{c_m}{z^{2m}(m!)^2}\right], \tag{10}$$

where γ_E is Euler's constant. Now matching (10) with (8) gives

$$c_1 = -c_2 \log(1/z) - c_2 \gamma_E \quad \text{and } c_2 = \frac{2}{z},$$

while noticing that (9) is precisely the expansion of $I_0(2/z)$ and demanding that our general solution coincides with (9) at the origin yields

$$c_1 = 1 \quad \text{and } c_2 = 0.$$

To recapitulate, we have found

$$S_{00} = -\frac{2e^{t^0/z}}{z}\left[(\gamma_E - \log(z)) I_0\left(\frac{2e^{t^1/2}}{z}\right) + K_0\left(\frac{2e^{t^1/2}}{z}\right)\right],$$

$$S_{10} = \frac{2e^{t^0/z}e^{t^1/2}}{z}\left[K_1\left(\frac{2e^{t^1/2}}{z}\right) - (\gamma_E - \log(z)) I_1\left(\frac{2e^{t^1/2}}{z}\right)\right],$$

$$S_{01} = e^{t^0/z} I_0\left(\frac{2e^{t^1/2}}{z}\right),$$

$$S_{11} = e^{t^0/z}e^{t^1/2} I_1\left(\frac{2e^{t^1/2}}{z}\right).$$

We have checked that these solutions correctly reproduce the corresponding descendant Gromov–Witten invariants obtained in Ref. 6.

If the inverse transition matrix in (4) is used to relate the matrix elements S^i_α to $S_{\alpha\beta}$ as $S^i_\alpha = S_{\alpha\beta}((\psi^{-1})^t)^\beta_j \delta^{ji}$, then we should have

$$S^\pm_\alpha = \sqrt{\pm 2} e^{t^1/4}\left(\frac{1}{2} S_{\alpha 0} \pm \frac{e^{-t^1/2}}{2} S_{\alpha 1}\right). \tag{11}$$

B. Recursive solution

In Refs. 4 and 5, Givental has shown that near a semisimple point, the flat-section equations (5) have a fundamental solution given by

$$S^i_\alpha = \Psi^j_\alpha (R_0 + zR_1 + z^2R_2 + \cdots + z^nR_n + \cdots)_{jk}[\exp(U/z)]^{ki},$$

where $R_n = (R_n)_{jk}, R_0 = \delta_{jk}$ and U is the diagonal matrix of canonical coordinates. The matrix R_1 satisfies the relations

$$\Psi^{-1}\frac{\partial \Psi}{\partial t^1} = \left[\frac{\partial U}{\partial t^1}, R_1\right] \tag{12}$$

and

$$\left[\frac{\partial R_1}{\partial t^1} + \Psi^{-1}\left(\frac{\partial \Psi}{\partial t^1}\right)R_1\right]_{\pm\pm} = 0, \tag{13}$$

which we use to find its expression. From the transition matrix given in (3) we see that

$$\Psi^{-1}\frac{\partial \Psi}{\partial t^1} = \frac{1}{4}\begin{pmatrix} 0 & i \\ -i & 0 \end{pmatrix},$$

while taking the $(+-)$ component of the relation (12) gives

$$\frac{i}{4} = \frac{\partial U_{++}}{\partial t^1}(R_1)_{+-} - (R_1)_{+-}\frac{\partial U_{--}}{\partial t^1} = 2e^{t^1/2}(R_1)_{+-},$$

where in the last step we have used the definition (2) of canonical coordinates. We therefore have

$$(R_1)_{+-} = \frac{i}{8}e^{-t^1/2},$$

and similarly considering the $(-+)$ component of (12) gives

$$(R_1)_{-+} = \frac{i}{8}e^{-t^1/2}.$$

The diagonal components of R_1 can be obtained from (13), which implies that

$$\frac{\partial (R_1)_{++}}{\partial t^1} = (R_1)_{+-}\frac{\partial U_{--}}{\partial t^1}(R_1)_{-+} - \frac{\partial U_{++}}{\partial t^1}(R_1)_{+-}(R_1)_{-+} = \frac{\exp(-t^1/2)}{32} = -\frac{\partial (R_1)_{--}}{\partial t^1}.$$

Hence, $(R_1)_{++} = -\exp(-t^1/2)/16 = -(R_1)_{--}$ and the matrix R_1 can be written as

$$(R_1)_{jk} = \frac{1}{16}e^{-t^1/2}\begin{pmatrix} -1 & 2i \\ 2i & 1 \end{pmatrix}. \tag{14}$$

In general, the matrices R_n satisfy the recursion relations[4]

$$(\mathrm{d} + \Psi^{-1}\,\mathrm{d}\Psi)R_n = [\mathrm{d}U, R_{n+1}],$$

which, for our case, imply the following set of equations:

$$\frac{\partial R_n}{\partial t^0} = 0, \tag{15}$$

$$\frac{\partial (R_n)_{++}}{\partial t^1} = -\frac{i}{4}(R_n)_{-+}, \tag{16}$$

$$(R_{n+1})_{-+} = -\frac{1}{2}e^{-t^1/2}\left[\frac{\partial (R_n)_{-+}}{\partial t^1} - \frac{i}{4}(R_n)_{++}\right], \tag{17}$$

$$\frac{\partial (R_n)_{--}}{\partial t^1} = \frac{i}{4}(R_n)_{+-}, \tag{18}$$

$$(R_{n+1})_{+-} = \frac{1}{2}e^{-t^1/2}\left[\frac{\partial (R_n)_{+-}}{\partial t^1} + \frac{i}{4}(R_n)_{--}\right]. \tag{19}$$

Lemma 3.1: *For $n \geqslant 1$, the matrices R_n in the fundamental solution are given by*

$$(R_n)_{ij} = \frac{(-1)^n}{(2n-1)}\frac{\alpha_n}{2^n}e^{-nt^1/2}\begin{pmatrix} -1 & (-1)^{n+1}2n\ i \\ 2n\ i & (-1)^{n+1} \end{pmatrix}, \tag{20}$$

where

$$\alpha_n = (-1)^n \frac{1}{8^n n!}\prod_{\ell=1}^{n}(2\ell-1)^2, \quad \alpha_0 = 1.$$

These solutions satisfy the unitarity condition,

$$\mathbf{R}(z)\mathbf{R}^t(-z) := (1 + zR_1 + z^2R_2 + \cdots + z^nR_n + \cdots)(1 - zR_1^t + z^2R_2^t + \cdots + (-1)^n z^n R_n^t + \cdots) = 1,$$

and the homogeneity condition and, thus, are unique.

Proof: For $n=1, \alpha_1=-1/8$ and (20) is equal to the correct solution (14). The proof now follows by an induction on n. Assume that (20) holds true up to and including $n=m$. Using the fact that

$$\alpha_{m+1} = -\frac{(2m+1)^2}{8(m+1)}\alpha_m,$$

we can show that R_{m+1} in (20) satisfies the relations (16)–(19) as well as (15).

To check unitarity, consider the z^k-term $P_k := \Sigma_{\ell=0}^{k}(-1)^\ell R_{k-\ell}R_\ell^t$ in $\mathbf{R}(z)\mathbf{R}^t(-z) = \Sigma_{k=0} P_k z^k$. As shown by Givental, the equations satisfied by the matrices R_n imply that the off-diagonal entries of P_k vanish. As a result, combined with the antisymmetry of P_k for odd k, we see that P_k vanishes for k odd. Hence, we only need to show that for our solution, P_k vanishes for all positive even k as well. To this end, we note that Givental has also deduced from the equation $\mathrm{d}P_k + [\Psi^{-1}\,\mathrm{d}\Psi, P_k] = [\mathrm{d}U, P_{k+1}]$ that the diagonal entries of P_k are constant. The expansion of P_{2k} is

$$P_{2k} = R_{2k} + R_{2k}^t + \cdots,$$

where the remaining terms are products of R_ℓ, for $\ell < 2k$. Now, we proceed inductively. We first note that R_1 and R_2 given in (20) satisfy the condition $P_2=0$, and assume that R_ℓ's in (20) for $\ell < 2k$ satisfy $P_\ell = 0$. Then, since the off-diagonal entries of P_n vanish for all n, the expansion of P_{2k} is of the form

$$P_{2k} = A\ e^{-2k\ t^1/2} + B,$$

where A is a constant diagonal matrix resulting from substituting our solution (20) and B is a possible diagonal matrix of integration constants for R_{2k}. But, since the diagonal entries of P_n are constant for all n, we know that $A=0$. We finally choose the integration constants to be zero so that $B=0$, yielding $P_{2k}=0$. Hence, the matrices in our solution (20) satisfy the unitarity condition and are manifestly homogeneous. It then follows by the proposition in Ref. 5 that our solutions R_n are unique. □

Let $\mathbf{R} := (R_0 + zR_1 + z^2R_2 + \cdots + z^nR_n + \cdots)$. Then, we can use the matrices R_n from Lemma 3.1 to find

$$S_0^{+} = (\mathbf{R}_{++} - i\,\mathbf{R}_{-+})\frac{\exp(u_+/z)}{\sqrt{\Delta_+}} = \left[1 + \sum_{n=1}^{\infty}\frac{\alpha_n}{2^n}\exp\left(\frac{-nt^1}{2}\right)(-z)^n\right]\frac{\exp(u_+/z)}{\sqrt{\Delta_+}}, \tag{21}$$

$$S_0^{-} = (\mathbf{R}_{--} + i\,\mathbf{R}_{+-})\frac{\exp(u_-/z)}{\sqrt{\Delta_-}} = \left[1 + \sum_{n=1}^{\infty}(-1)^n\frac{\alpha_n}{2^n}\exp\left(\frac{-nt^1}{2}\right)(-z)^n\right]\frac{\exp(u_-/z)}{\sqrt{\Delta_-}}, \tag{22}$$

$$S_1^{+} = (\mathbf{R}_{++} + i\,\mathbf{R}_{-+})\frac{\sqrt{\Delta_+}}{2}\exp(u_+/z) = \left[1 - \sum_{n=1}^{\infty}\frac{(2n+1)}{(2n-1)}\frac{\alpha_n}{2^n}\exp\left(\frac{-nt^1}{2}\right)(-z)^n\right]\frac{\sqrt{\Delta_+}}{2}\exp(u_+/z), \tag{23}$$

$$S_1^{-} = (\mathbf{R}_{--} - i\,\mathbf{R}_{+-})\frac{\sqrt{\Delta_-}}{2}\exp(u_-/z) = \left[1 - \sum_{n=1}^{\infty}(-1)^n\frac{(2n+1)}{(2n-1)}\frac{\alpha_n}{2^n}\exp\left(\frac{-nt^1}{2}\right)(-z)^n\right]\frac{\sqrt{\Delta_-}}{2}\exp(u_-/z). \tag{24}$$

Using the above expressions for $S_\alpha{}^i(z)$, we can also find $V^{ij}(z,w)$, which is given by the expression

$$V^{ij}(z,w) := \frac{1}{z+w}[S_\mu{}^i(w)]^t[g^{\mu\nu}][S_\nu{}^j(z)].$$

If we define

$$A_{p,q} := \frac{(4p\ q-1)}{(2p-1)(2q-1)}\frac{\alpha_p\alpha_q}{2^{p+q}}e^{[-(p+q)t^1/2]}$$

and

$$B_{p,q} := \frac{2(p-q)}{(2p-1)(2q-1)}\frac{\alpha_p\alpha_q}{2^{p+q}}e^{[-(p+q)t^1/2]},$$

then after some algebraic manipulations we obtain

$$V^{++}(z,w) = e^{u_+/w+u_+/z}\left\{\frac{1}{z+w} + \sum_{k,l=0}^{\infty}\left[\sum_{n=0}^{k}(-1)^n A_{l+n+1,k-n}\right](-1)^{k+l}w^k z^l\right\},$$

$$V^{--}(z,w) = e^{u_-/w+u_-/z}\left\{\frac{1}{z+w} - \sum_{k,l=0}^{\infty}\left[(-1)^{k+l}\sum_{n=0}^{k}(-1)^n A_{l+n+1,k-n}\right](-1)^{k+l}w^k z^l\right\}, \tag{25}$$

$$V^{+-}(z,w) = e^{u_+/w+u_-/z}\left\{\sum_{k,l=0}^{\infty}\left[i(-1)^l\sum_{n=0}^{k}B_{l+n+1,k-n}\right](-1)^{k+l}w^k z^l\right\},$$

$$V^{-+}(z,w) = e^{u_-/w+u_+/z}\left\{\sum_{k,l=0}^{\infty}\left[i(-1)^k\sum_{n=0}^{k}B_{l+n+1,k-n}\right](-1)^{k+l}w^k z^l\right\}. \tag{26}$$

C. A puzzle

Incidentally, we note that in the asymptotic limit $z \to 0$,

$$S_0{}^+ = \Re\left[\sqrt{\frac{2\pi}{z}}e^{t^0/z}I_0\left(\frac{2e^{t^1/2}}{z}\right)\right]$$

and

$$S_0{}^- = -i\sqrt{\frac{2}{\pi z}}e^{t^0/z}K_0\left(\frac{2e^{t^1/2}}{z}\right)$$

reproduce the expansions in (21) and (22). This is in contrast to what was expected from the discussion leading to (11). Despaired of matching the two expressions, it seems to us that the analytic correlation functions obtained in Sec. III A do not encode the right information that appear in Givental's conjecture. In the following section, we will use the recursive solutions from Sec. III B to check Givental's conjectural formula at low genera.

IV. CHECKS OF THE CONJECTURE AT LOW GENERA

The T_n^i that appear in Givental's formula (1) are defined by the equations[5]

$$S_0{}^\pm := \left[1 - \sum_{n=0}^{\infty} T_n^\pm (-z)^{n-1}\right]\frac{\exp(u_\pm/z)}{\sqrt{\Delta_\pm}}.$$

From the computations of $S_0{}^+$ and $S_0{}^-$ in (21) and (22), respectively, one can extract T_n^i to be

$$T_n^+ = \begin{cases} 0, & n = 0,1, \\ -\dfrac{\alpha_{n-1}}{2^{n-1}}\exp\left[\dfrac{-(n-1)t^1}{2}\right], & n \geqslant 2, \end{cases}$$

$$T_n^- = \begin{cases} 0, & n = 0,1, \\ -(-1)^{n-1}\dfrac{\alpha_{n-1}}{2^{n-1}}\exp\left[\dfrac{-(n-1)t^1}{2}\right], & n \geqslant 2. \end{cases}$$

Notice that

$$T_n^- = (-1)^{n-1}T_n^+. \tag{27}$$

The functions V_{kl}^{ij} are defined by the expansion[5]

$$V^{ij}(z,w) = e^{u^i/w + u^j/z}\left[\frac{\delta^{ij}}{z+w} + \sum_{k,l=0}^{\infty}(-1)^{k+l}V_{kl}^{ij}w^k z^l\right],$$

and from (25) and (26) we see that

$$V_{kl}^{++} = \sum_{n=0}^{k}(-1)^n A_{l+n+1,k-n} = \sum_{n=0}^{k}\frac{(-1)^n(4(l+n+1)(k-n)-1)}{(2l+2n+1)(2k-2n-1)}T_{l+n+2}^+ T_{k-n+1}^+,$$

$$V_{kl}^{+-} = i(-1)^l\sum_{n=0}^{k}B_{l+n+1,k-n} = i(-1)^l\sum_{n=0}^{k}\frac{2(l+2n+1-k)}{(2l+2n+1)(2k-2n-1)}T_{l+n+2}^+ T_{k-n+1}^+.$$

There seems to be a misprint in the original formula for V_{kl}^{ij} in Ref. 5, i.e., we believe that w and z should be exchanged, as in our expression here.

Now, the τ function for the intersection theory on the Deligne–Mumford moduli space $\overline{\mathcal{M}}_{g,n}$ of stable curves is defined by

$$\tau(\lambda;\{q_k\}) = \exp\left(\sum_{g=0}^{\infty} \lambda^{g-1}\mathcal{F}_g^{\mathrm{pt}}(\{q_k\})\right)$$

and has the following nice scaling invariance: consider the scaling of the phase-space variables q_k given by

$$q_k \mapsto s^{k-1}q_k \tag{28}$$

for some constant s. Then, since a nonvanishing intersection number $\langle \tau_{k_1}\cdots\tau_{k_n}\rangle$ must satisfy

$$\sum_{i=1}^{n}(k_i-1) = \dim(\overline{\mathcal{M}}_{g,n}) - n = 3g-3,$$

we see that under the transformation (28), the genus-g generating function $\mathcal{F}_g^{\mathrm{pt}}$ must behave as

$$\mathcal{F}_g^{\mathrm{pt}}(\{s^{k-1}q_k\}) = (s^3)^{g-1}\mathcal{F}_g^{\mathrm{pt}}(\{q_k\}).$$

Hence, upon scaling the "string coupling constant" λ to $s^{-3}\lambda$, we see that

$$\tau(s^{-3}\lambda;\{s^{k-1}q_k\}) = \tau(\lambda;\{q_k\}). \tag{29}$$

Now, consider the function

$$F(\{q_n^+\},\{q_n^-\}) := [e^{(\lambda/2)\Sigma_{k,l\geq 0}\Sigma_{i,j\in\{\pm\}}V_{kl}^{ij}\sqrt{\Delta_i}\sqrt{\Delta_j}\partial_{q_k^i}\partial_{q_l^j}}\tau(\lambda\Delta_+;\{q_n^+\})\tau(\lambda\Delta_-;\{q_n^-\})]. \tag{30}$$

Then, since the Gromov–Witten potentials of $\mathbb{P}^1$ for $g\geq 2$ all vanish, Givental's conjectural formula for $\mathbb{P}^1$ is

$$F(\{T_n^+\},\{T_n^-\}) = 1,$$

where it is understood that one sets $q_k^i = T_k^i$ after taking the derivatives with respect to q_k^i. Since T_n^+ and T_n^- are related by (27), let us rescale $q_k^- \mapsto (-1)^{k-1}q_k^-$ in (30). Then, since $\Delta_+ = -\Delta_-$, we observe from (29) that

$$F(\{T_n^+\},\{T_n^-\}) = \left\{\exp\left[\frac{\lambda}{2}\Delta_+\sum_{k,l\geq 0}\left(V_{kl}^{++}\partial_{q_k^+}\partial_{q_l^+} + i(-1)^{l-1}V_{kl}^{+-}\partial_{q_k^+}\partial_{q_l^-} + i(-1)^{k-1}V_{kl}^{-+}\partial_{q_k^-}\partial_{q_l^+}\right.\right.\right.$$
$$\left.\left.\left. - (-1)^{k+l}V_{kl}^{--}\partial_{q_k^-}\partial_{q_l^-}\right)\right]\tau(\lambda\Delta_+;\{q_n^+\})\tau(\lambda\Delta_+;\{q_n^-\})\right\}\Bigg|_{q_n^+,q_n^-=T_n^+}.$$

But, the V_{kl}^{ij} satisfy the relations $V_{kl}^{--} = -(-1)^{k+l}V_{kl}^{++}$ and $V_{kl}^{+-} = V_{lk}^{-+}$, so

$$F(\{T_n^+\},\{T_n^-\}) = \left\{\exp\left[\frac{\lambda}{2}\Delta_+\sum_{k,l\geq 0}\left(V_{kl}^{++}(\partial_{q_k^+}\partial_{q_l^+} + \partial_{q_k^-}\partial_{q_l^-})\right.\right.\right.$$
$$\left.\left.\left. + 2i(-1)^{l-1}V_{kl}^{+-}\partial_{q_k^+}\partial_{q_l^-}\right)\right]\tau(\lambda\Delta_+;\{q_n^+\})\tau(\lambda\Delta_+;\{q_n^-\})\right\}\Bigg|_{q_n^+,q_n^-=T_n^+}. \tag{31}$$

Now, consider the following transformations of the variables:

$$q_k^+ = x_k + y_k \quad \text{and } q_k^- = x_k - y_k,$$

so that

$$\partial_{q_k^+} = \tfrac{1}{2}(\partial_{x_k} + \partial_{y_k}) \quad \text{and } \partial_{q_k^-} = \tfrac{1}{2}(\partial_{x_k} - \partial_{y_k}).$$

Then, in these new coordinates, (31) becomes

$$F(\{T_n^+\},\{T_n^-\}) = G(\{T_n^+\},\{0\}),$$

where the new function $G(\{x_k\},\{y_k\})$ is defined by

$$G(\{x_n\},\{y_n\}) = \exp\left[\frac{\lambda}{4}\Delta_+ \sum_{k,l\geqslant 0}(V_{kl}\partial_{x_k}\partial_{x_l} + W_{kl}\partial_{y_k}\partial_{y_l})\right]\tau(\lambda\Delta_+;\{x_n+y_n\})\tau(\lambda\Delta_+;\{x_n-y_n\}), \quad (32)$$

where

$$V_{kl} \coloneqq V_{kl}^{++} + i(-1)^{l-1}V_{kl}^{+-},$$

$$W_{kl} \coloneqq V_{kl}^{++} - i(-1)^{l-1}V_{kl}^{+-}.$$

Here, we have simplified the expression by noting that the mixed derivative terms cancel because of the identity $V_{kl}^{+-}=(-1)^{k-1}V_{lk}^{+-}$.

Remark: The conjecture expressed in terms of (32), i.e., that $G(\{T_k^+\},\{0\})=1$, is now in a form which resembles the Hirota bilinear relations, which might be indicating some kind of an integrable hierarchy, perhaps of Toda type.

Because the tau functions are exponential functions, upon acting on them by the differential operators, we can factor them out in the expression of $G(\{x_k\},\{y_k\})$. We thus define the following.

Definition 4.1: *$P(\lambda\Delta_+,\{x_k\},\{y_k\})$ is a formal power series in the variables $\lambda\Delta_+,\{x_k\}$ and $\{y_k\}$ such that*

$$G(\{x_k\},\{y_k\}) = P(\lambda\Delta_+,\{x_k\},\{y_k\})\tau(\lambda\Delta_+,\{x_k+y_k\})\tau(\lambda\Delta_+,\{x_k-y_k\}).$$

Hence, Givental's conjecture for $\mathbb{P}^1$ can be restated as follows.

Conjecture 4.2 (Givental): *The generating function $G(\{T_k^+\},\{0\})$ is equal to one, or equivalently*

$$P(\lambda\Delta_+,\{T_k^+\},\{0\}) = \frac{1}{\tau(\lambda\Delta_+,\{T_k^+\})^2}. \quad (33)$$

This conjecture can be verified order by order in λ. This procedure is possible because when $q_0=q_1=0$, only a finite number of terms in the free energies and their derivatives are nonvanishing. In particular, the genus-0 and genus-1 free energies vanish when $q_0=q_1=0$.

Let us check (33) up to order λ^2, for which we need to consider up to λ^6 expansions in the differential operators acting on the τ functions. Let $h=\lambda\Delta_+$. The low-genus free energies for a point target space can be easily computed using the KdV hierarchy and topological axioms; they can also be verified using Faber's program.[3] The terms relevant to our computation are

$$\begin{aligned}\frac{\mathcal{F}_0^{\mathrm{pt}}}{h} + \mathcal{F}_1^{\mathrm{pt}} + h\mathcal{F}_2^{\mathrm{pt}} = \frac{1}{h}\Bigg[&\frac{(q_0)^3}{3!} + \frac{(q_0)^3q_1}{3!} + 2!\,\frac{(q_0)^3(q_1)^2}{3!\,2!} + 3!\,\frac{(q_0)^3(q_1)^3}{3!\,3!} + \frac{(q_0)^4q_2}{4!}\\ &+ 3\frac{(q_0)^4q_1q_2}{4!} + 12\frac{(q_0)^4(q_1)^2q_2}{4!\,2!} + \frac{(q_0)^5q_3}{5!} + 4\frac{(q_0)^5q_1q_3}{5!} + 6\frac{(q_0)^5(q_2)^2}{5!\,2!}\\ &+ 30\frac{(q_0)^5q_1(q_2)^2}{5!\,2!} + \frac{(q_0)^6q_4}{6!} + 10\frac{(q_0)^6q_2q_3}{6!} + 90\frac{(q_0)^6(q_2)^3}{6!\,3!} + \cdots\Bigg] + \Bigg[\frac{1}{24}q_1\\ &+ \frac{1}{24}\frac{(q_1)^2}{2!} + \frac{1}{12}\frac{(q_1)^3}{3!} + \frac{1}{4}\frac{(q_1)^4}{4!} + \frac{1}{24}q_0q_2 + \frac{1}{12}q_0q_1q_2 + \frac{1}{4}\frac{q_0(q_1)^2q_2}{2!}\\ &+ \frac{q_0(q_1)^3q_2}{3!} + \frac{1}{6}\frac{(q_0)^2(q_2)^2}{2!\,2!} + \frac{2}{3}\frac{(q_0)^2q_1(q_2)^2}{2!\,2!} + \frac{10}{3}\frac{(q_0)^2(q_1)^2(q_2)^2}{2!\,2!\,2!}\end{aligned}$$

$$+\frac{1}{24}\frac{(q_0)^2q_3}{2!}+\frac{1}{8}\frac{(q_0)^2q_1q_3}{2!}+\frac{1}{2}\frac{(q_0)^2(q_1)^2q_3}{2!\,2!}+\frac{7}{24}\frac{(q_0)^3q_2q_3}{3!}$$
$$+\frac{35}{24}\frac{(q_0)^3q_1q_2q_3}{3!}+2\frac{(q_0)^3(q_2)^3}{3!\,3!}+12\frac{(q_0)^3q_1(q_2)^3}{3!\,3!}+\frac{1}{24}\frac{(q_0)^3q_4}{3!}+\frac{1}{6}\frac{(q_0)^3q_1q_4}{3!}$$
$$+48\frac{(q_0)^4(q_2)^4}{4!\,4!}+\frac{59}{12}\frac{(q_0)^4(q_2)^2q_3}{4!\,2!}+\frac{7}{12}\frac{(q_0)^4(q_3)^2}{4!\,2!}+\frac{11}{24}\frac{(q_0)^4q_2q_4}{4!}$$
$$+\frac{1}{24}\frac{(q_0)^4q_5}{4!}+\cdots\Bigg]+h\Bigg[\frac{7}{240}\frac{(q_2)^3}{3!}+\frac{29}{5760}q_2q_3+\frac{1}{1152}q_4+\frac{7}{48}\frac{q_1(q_2)^3}{3!}$$
$$+\frac{7}{8}\frac{(q_1)^2(q_2)^3}{2!\,3!}+\frac{29}{1440}q_1q_2q_3+\frac{29}{288}\frac{(q_1)^2q_2q_3}{2!}+\frac{1}{384}q_1q_4+\frac{1}{96}\frac{(q_1)^2q_4}{2!}$$
$$+\frac{7}{12}\frac{q_0(q_2)^4}{4!}+\frac{49}{12}\frac{q_0q_1(q_2)^4}{4!}+\frac{5}{72}\frac{q_0(q_2)^2q_3}{2!}+\frac{5}{12}\frac{q_0q_1(q_2)^2q_3}{2!}$$
$$+\frac{29}{2880}\frac{q_0(q_3)^2}{2!}+\frac{29}{576}\frac{q_0q_1(q_3)^2}{2!}+\frac{11}{1440}q_0q_2q_4+\frac{11}{288}q_0q_1q_2q_4+\frac{1}{1152}q_0q_5$$
$$+\frac{1}{288}q_0q_1q_5+\frac{245}{12}\frac{(q_0)^2(q_2)^5}{2!\,5!}+\frac{11}{6}\frac{(q_0)^2(q_2)^3q_3}{2!\,3!}+\frac{109}{576}\frac{(q_0)^2q_2(q_3)^2}{2!\,2!}$$
$$+\frac{17}{960}\frac{(q_0)^2q_3q_4}{2!}+\frac{7}{48}\frac{(q_0)^2(q_2)^2q_4}{2!\,2!}+\frac{1}{90}\frac{(q_0)^2q_2q_5}{2!}+\frac{1}{1152}\frac{(q_0)^2q_6}{2!}+\cdots\Bigg].$$

This expression gives the necessary expansion of $\tau(\lambda\Delta_+;\{x_k\pm y_k\})$ for our consideration, and upon evaluating $G(\{T_k^+\},\{0\})$, we find

$$P(h,\{T_k^+\},\{0\})=1-\frac{17}{2\,359\,296}e^{-3t^1/2}h+\frac{41\,045}{695\,784\,701\,952}e^{-3t^1}h^2+\mathcal{O}(h^3). \tag{34}$$

At this order, the expansion of the right-hand side of (33) is

$$\tau(h,\{T_k^+\})^{-2}=1-2\mathcal{F}_2^{\mathrm{pt}}h+2[(\mathcal{F}_2^{\mathrm{pt}})^2-\mathcal{F}_3^{\mathrm{pt}}]h^2+\mathcal{O}(h^3).$$

At $q_n=T_n^+,\forall n$, the genus-2 free energy is precisely given by

$$\mathcal{F}_2^{\mathrm{pt}}=\frac{1}{1152}T_4+\frac{29}{5760}T_3T_2+\frac{7}{240}\frac{T_2^3}{3!}=\frac{17}{4\,718\,592}e^{-3t^1/2},$$

and the genus-3 free energy is

$$\mathcal{F}_3^{\mathrm{pt}}=\frac{1}{82\,944}T_7+\frac{77}{414\,720}T_2T_6+\frac{503}{1\,451\,520}T_3T_5+\frac{17}{11\,520}(T_2)^2T_5+\frac{607}{2\,903\,040}(T_4)^2$$
$$+\frac{1121}{241\,920}T_2T_3T_4+\frac{53}{6912}(T_2)^3T_4+\frac{583}{580\,608}(T_3)^3+\frac{205}{13\,824}(T_2)^2(T_3)^2+\frac{193}{6912}(T_2)^4T_3$$
$$+\frac{245}{20\,736}(T_2)^6=-\frac{656\,431}{22\,265\,110\,462\,464}e^{-3t^1}.$$

Thus, we have

$$\tau(h,\{T_k^+\})^{-2}=1-\frac{17}{2\,359\,296}e^{-3t^1/2}h+\frac{41\,045}{695\,784\,701\,952}e^{-3t^1}h^2+\mathcal{O}(h^3),$$

which agrees with our computation of $P(\lambda,\{T_k^+\},\{0\})$ in (34).

It would be very interesting if one could actually prove Givental's conjecture, but even our particular example remains elusive and verifying its validity to all orders seems intractable using our method.

Under certain conditions, a $(1+1)$-dimensional slice $\hat{g}$ of a spherically symmetric black hole space–time can be equivariantly embedded in $(2+1)$-dimensional Minkowski space. The embedding depends on a real parameter that corresponds physically to the surface gravity κ of the black hole horizon. Under conditions that turn out to be closely related, a real surface that possesses rotational symmetry can be equivariantly embedded in three-dimensional Euclidean space. The embedding does not obviously depend on a parameter. However, the Gaussian curvature is given by a simple formula: If the metric is written $g=\phi(r)^{-1}\,\mathrm{d}r^2+\phi(r)\mathrm{d}\theta^2$, then $K_g=-\frac{1}{2}\phi''(r)$. This note shows that metrics g and $\hat{g}$ occur in dual pairs, and that the embeddings described above are orthogonal facets of a single phenomenon. In particular, the metrics and their respective embeddings differ by a Wick rotation that preserves the ambient symmetry. Consequently, the embedding of g depends on a real parameter. The ambient space is not smooth, and κ is inversely proportional to the cone angle at the axis of rotation. Further, the Gaussian curvature of $\hat{g}$ is given by a simple formula that seems not to be widely known. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1808487]

I. INTRODUCTION

The most concrete way to study a surface is (when possible) to embed it isometrically in a flat three-dimensional space. Isometric embedding "realizes" the abstract surface, and is useful for developing geometric intuition.[1] Naturally, the signature of the surface metric is related to the signature of the ambient metric. For example, a "space–time slice" of signature $(1+1)$ cannot be isometrically embedded in $\mathbf{R}^3$; instead, one might seek an embedding into the Minkowski space $\mathbf{R}^{2+1}$.

If an abstract surface has symmetry, it is natural to seek an embedding in which the intrinsic symmetry is realized by a symmetry of the ambient space. When this occurs, the embedding is said to be *equivariant* (with respect to the actions of the abstract symmetry groups).

This paper originates with two families of equivariant isometric embeddings. The first realizes slices of certain spherically symmetric static space–times as surfaces in Minkowski space $\mathbf{R}^{2+1}$, see Refs. 7 and 10. (These papers were in turn inspired by earlier work[3,4,6,9,11,12] involving higher-dimensional embeddings into flat space.) The second is a "symplectic" description of (classical) surfaces of revolution, see Ref. 8. Each family of metrics has continuous symmetry: time translation and rotation, respectively.

These two families of metrics are equivariantly related by "Wick rotation," in a sense made precise below. The relationship is roughly analogous to the duality between conjugate minimal surfaces: For each suitable space–time slice, there is a "dual" surface of revolution, and a single equivariant embedding into $\mathbf{C}^3$ that interpolates the embeddings of the respective surfaces into flat (real) three-dimensional spaces. The resulting one-parameter family of metrics on the abstract surface interpolates metrics of different signatures, so unlike the situation for minimal surfaces, the interpolating metrics are not mutually isometric (even locally).

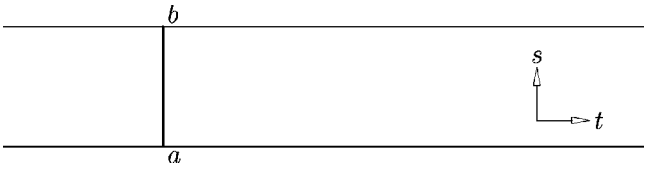

FIG. 1. The domain of an intrinsic metric.

Geometric properties of one family have consequences for the other family.

(i) The Gaussian curvature of a space–time slice is given by an extremely simple formula.
(ii) The surface gravity of a black hole horizon has a geometric interpretation as angular defect of a cone singularity. In particular, the metrics studied in Ref. 8 are instances of a one-parameter family of (possibly singular) metrics that are "smoothly embedded" in a (flat) singular ambient space.

Organization: In Sec. II we introduce the abstract surfaces under consideration; fixed points are removed for simplicity, and the intrinsic "Wick rotation" is described as a discrete symmetry. In Sec. III, we equip the ambient space $\mathbf{C}^3$ with coordinates, an action of the additive complex group, and an appropriate (flat) indefinite metric. Section IV describes the interpolating embedding, a map from $\mathbf{C}\times\mathbf{R}$ to $\mathbf{C}^3$. The equivariant embeddings of space–time slices and surfaces of revolution are the restrictions of this embedding to $i\mathbf{R}\times\mathbf{R}$ and $\mathbf{R}\times\mathbf{R}$. In Sec. V, we address "boundary" questions of smoothness and embeddability.

II. INTRINSIC METRICS

We take the mathematical point of view that a "metric" comprises a metric tensor and a parameter domain (or manifold). Thus, a metric can be two-dimensional, compact, connected, oriented, etc.

Consider an oriented two-dimensional metric that admits a free, isometric action of the additive group $\mathbf{R}$. The interpretation of the symmetry depends on the signature: In Lorentz signature, the action should be viewed as time translation of a $(1+1)$-dimensional slice of a static space–time. In Riemannian signature, the action is something like a rotation about an axis, except that fixed points have been removed and the resulting metric lifted to its universal cover.

The existence of useful coordinate systems is independent of the metric signature, so for the moment we work with a Riemannian metric g.

A. Isothermal parameters

Away from fixed points of the action, existence of isothermal parameters is elementary: Construct nets of curves by taking orbits of the action and the associated g-orthogonal family. Clearly these curves are coordinate curves in which the metric is diagonal and the group action is a coordinate translation. A change of variable in the direction transverse to the action ensures that the diagonal metric components are equal; see Ref. 8 for details.

More precisely, our metric may be regarded as living on the planar domain $D:=\mathbf{R}\times(a,b)$ with coordinates (t,s), and with $\mathbf{R}$ acting by translation in t, Fig. 1. After changing s if necessary, there exists a smooth function $\varphi:(a,b)\to\mathbf{R}$ such that

$$g=\varphi(s)(\mathrm{d}t^2+\mathrm{d}s^2). \tag{2.1}$$

B. Action-angle coordinates

An additional change of transverse coordinate expresses the metric in *action-angle* (or *symplectic*) form

$$g = \phi(r)\mathrm{d}t^2 + \frac{1}{\phi(r)}\mathrm{d}r^2. \tag{2.2}$$

Indeed, set

$$r = \int^s \varphi(\zeta)\mathrm{d}\zeta, \quad \phi(r) = \varphi(s). \tag{2.3}$$

The integral equation defines r as a function of s (up to an additive constant) on each interval where φ is nonvanishing, and the resulting coordinate is easily shown to satisfy (2.2). The additive constant amounts to translation of the interval (a,b), and is geometrically harmless.

Given a nonvanishing function $\phi:(a,b)\to\mathbf{R}$, the equations

$$s = \int^r \frac{\mathrm{d}\zeta}{\phi(\zeta)}, \quad \varphi(s) = \phi(r), \tag{2.4}$$

define a translation-invariant, isothermal metric on D that satisfies (2.1). These constructions are inverse to each other up to isometry of g and domain translation of ϕ. In other words, an isometry class of g corresponds to a function ϕ that is unique up to translation in the domain. For reasons originating in symplectic geometry, this correspondence is called the *momentum construction*, and the function ϕ is called the *momentum profile* of g.

C. Elementary metric geometry

In action-angle coordinates, the arc length element along a generator, and the area form, are

$$\mathrm{d}\sigma = \frac{\mathrm{d}r}{\sqrt{\phi(r)}}, \quad \mathrm{d}A = \mathrm{d}r\ \mathrm{d}t. \tag{2.5}$$

The second formula highlights the geometric significance of the coordinate r: In a region of surface defined by the inequalities $c_1 \leqslant t \leqslant c_2$, the change in r is proportional to the enclosed surface area. On a surface of revolution where the t-interval $[0,2\pi]$ corresponds to one full turn, $2\pi r$ measures zonal area.

The Killing field $\mathrm{d}/\mathrm{d}t$ that generates the group action has squared length $\phi(r)$. This formula is meaningful even for metrics of Lorentz signature: The symmetry is time translation. For a Riemannian metric embedded as a surface of revolution in $\mathbf{R}^3$, one full turn of the surface is a t interval of length 2π, and $\sqrt{\phi(r)}$ is the Euclidean radius of the surface at r.

D. Gaussian curvature

The interplay between action-angle and isothermal (i.e., holomorphic) coordinates on a surface of revolution leads to a remarkable formula for the Gaussian curvature, see Ref. 8,

$$K = -\tfrac{1}{2}\phi''(r).$$

On the Lorentzian side, direct calculation shows that the Gaussian curvature of a space–time slice is

$$K = \tfrac{1}{2}\phi''(r).$$

In both signatures

$$K = -\tfrac{1}{2}g_{tt}''(r). \tag{2.6}$$

From the standpoint of constructing metrics of specified (e.g., constant) curvature, action-angle coordinates have the substantial advantage that the Gaussian curvature is a *linear* function of

the profile. Further, as we shall see, metrics presented in this form are explicitly embeddable in a flat ambient space.

E. Complexification

Regard t as a *complex* coordinate. The complex-valued tensor,

$$g_{\mathbf{C}} = \phi(r)\mathrm{d}t^2 + \frac{1}{\phi(r)}\mathrm{d}r^2,$$

on $\mathbf{C}\times(a,b)$ is real valued on $\mathbf{R}\times(a,b)$, where it is positive–definite, and on $i\mathbf{R}\times(a,b)$, where it has Lorentz signature. *Intrinsic Wick rotation* is the transformation $t\mapsto it$, under which g corresponds to

$$\hat{g} = -\phi(r)\mathrm{d}t^2 + \frac{1}{\phi(r)}\mathrm{d}r^2. \tag{2.7}$$

We assume from now on that the additive group $\mathbf{C}$ acts by translation in t. Since t is determined by the group action, while r is characterized by (2.2), the duality $g\leftrightarrow\hat{g}$ (which is defined using coordinates) actually depends only on $g_{\mathbf{C}}$. The metric $\hat{g}$ is the space–time slice associated to the surface of revolution g.

F. An example

Consider the momentum profile $\phi(r)=1-r^2$ on $(-1,1)$. By (2.4),

$$s = \int_0^r \frac{\mathrm{d}\zeta}{1-\zeta^2} = \frac{1}{2}\log\left|\frac{1+r}{1-r}\right|,$$

or $r=\tanh s$ and $\varphi(s)=\operatorname{sech}^2 s$. The arc length element and function are

$$\mathrm{d}\sigma = \frac{\mathrm{d}r}{\sqrt{1-r^2}}, \quad \sigma = \arcsin r, \quad \text{or } r=\sin\sigma.$$

If this metric is embedded isometrically in $\mathbf{R}^3$, the radius at r is $\sqrt{\phi(r)}=\sqrt{1-r^2}=\cos\sigma$. As should be clear, we are looking at the round metric of unit radius on a sphere, a fact that is confirmed (at least circumstantially) by the fact that the Gaussian curvature is $-\frac{1}{2}\phi''(r)=1$. The dual space–time slice is

$$\hat{g} = \frac{\mathrm{d}r^2}{1-r^2} - (1-r^2)\mathrm{d}t^2,$$

a portion of the well-known de Sitter metric, which embeds in $\mathbf{R}^{2+1}$ as (part of) a hyperboloid of one sheet. Figure 2 depicts the images at the same scale. The coordinate curves on the hyperboloid are not those of embedding coordinates. These classic embeddings are presented here to illuminate similarity; a formal relationship is developed below.

III. THE AMBIENT SPACE

Consider the ambient space $\mathbf{C}^3=\{(T,X,Y)\}$, and write $T=T_1+iT_2$, etc. Endow $\mathbf{C}^3$ with the flat metric

$$E = \mathrm{Re}(\mathrm{d}T^2+\mathrm{d}X^2+\mathrm{d}Y^2) = (\mathrm{d}T_1^2+\mathrm{d}X_1^2+\mathrm{d}Y_1^2) - (\mathrm{d}T_2^2+\mathrm{d}X_2^2+\mathrm{d}Y_2^2).$$

Euclidean space is identified with the totally real slice $\mathbf{R}^3\subset\mathbf{C}^3$, while Minkowski space is the three-dimensional subspace $i\mathbf{R}\times\mathbf{R}^2=\mathbf{R}^{2+1}$ defined by the equations $T_1=X_2=Y_2=0$. The *ambient Wick rotation* is the map $\mathsf{W}:(T,X,Y)\mapsto(iT,X,Y)$, which carries $\mathbf{R}^3$ to $\mathbf{R}^{2+1}$.

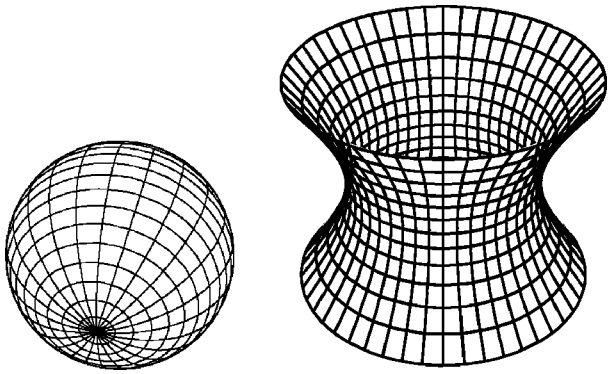

FIG. 2. Riemannian and Lorentzian embeddings of $\phi(r)=1-r^2$.

The ambient symmetry group that realizes the intrinsic symmetries of our surface metrics is the additive complex group acting as "(complex) rotation about the Y axis,"

$$\mathsf{R}_\theta(T,X,Y) = (X\sin\theta + T\cos\theta, X\cos\theta - T\sin\theta, Y). \tag{3.1}$$

A short calculation gives

$$\mathsf{W}^{-1}\mathsf{R}_{i\theta}\mathsf{W}(T,X,Y) = (X\sinh\theta + T\cosh\theta, X\cosh\theta + T\sinh\theta, Y).$$

This formula hints at the close relationship between rotations of Euclidean space and boosts of Minkowski space.

Henceforth, the ambient space is essentially $\mathbf{C}^2\times\mathbf{R}\subset\mathbf{C}^3$. In fact, the embeddings of primary interest take values in $\mathbf{C}\times\mathbf{R}\times\mathbf{R}$; only T is "really" complex. However, Eq. (3.1) shows that continuous interpolation of embeddings requires consideration of $\mathbf{C}^2=\mathbf{R}^{2,2}$.

Cylindrical coordinates: The *complex cylindrical coordinates* mappings $\Phi^\pm:\mathbf{C}^2\to\mathbf{C}^2$ are defined by

$$(T,X) = \Phi^+(\rho,\psi) = e^\rho(\sin\psi,\cos\psi),$$

$$(T,X) = \Phi^-(\rho,\psi) = ie^\rho(\cos\psi,-\sin\psi). \tag{3.2}$$

Two mappings are required to cover a dense open set in $\mathbf{C}^2$, see below. The ambient group action is coordinate translation,

$$\mathsf{R}_\theta\Phi^\pm(\rho,\psi) = \Phi^\pm(\rho,\psi+\theta).$$

The metric quadratic form $Q=t_1^2+x_1^2-t_2^2-x_2^2$ partitions $\mathbf{C}^2$ into sets of spacelike (for which Q is positive), timelike (for which Q is negative), and lightlike vectors. Each of these sets is a union of rays into the origin, so understanding these sets amounts to understanding the way each intersects the unit sphere $S^3=\{t_1^2+x_1^2+t_2^2+x_2^2=1\}$. The lightlike cone intersects the sphere in a real 2-torus whose complement consists of two linked solid tori. The real cones over these solid tori are the sets of spacelike and timelike vectors, and the mapping $(T,X)\mapsto(iX,-iT)$ (among others) involutively exchanges these sets. The image of Φ^+ is the set of spacelike vectors, so the image of Φ^- is the set of timelike vectors.

The pullback tensors $(\Phi^\pm)^*E$ express the metric E "in cylindrical coordinates,"

$$(\Phi^\pm)^*E = \pm e^{2\rho}(\mathrm{d}\psi^2+\mathrm{d}\rho^2) + \mathrm{d}Y^2. \tag{3.3}$$

It is straightforward to verify that the restrictions to the real three-dimensional ambient slices of interest satisfy

$$E^3 = e^{2\rho}(\mathrm{d}\psi^2 + \mathrm{d}\rho^2) + \mathrm{d}Y^2,$$

$$E^{2+1} = e^{2\rho}(-\mathrm{d}\psi^2 + \mathrm{d}\rho^2) + \mathrm{d}Y^2.$$

To check the second equation, it is necessary to use both cylindrical coordinate regions.

An equivariant embedding of a surface is one for which (intrinsic) t-translation is induced by ψ-translation in cylindrical coordinates.

IV. EMBEDDINGS

Fix a real constant $\kappa > 0$, let $\phi:(a,b)\to\mathbf{R}$ be a positive profile satisfying $|\phi'| \leqslant 2\kappa$, and let g be the metric on $\mathbf{C}\times(a,b)$ as in (2.2). The functions

$$T = \frac{1}{\kappa}\sqrt{\phi(r)}\sin(\kappa t), \qquad X = \frac{1}{\kappa}\sqrt{\phi(r)}\cos(\kappa t), \qquad Y = \int^r \sqrt{\frac{1}{\phi(\zeta)}\left[1 - \left(\frac{1}{2\kappa}\phi'(\zeta)\right)^2\right]}\,\mathrm{d}\zeta, \tag{4.1}$$

define a mapping $f:\mathbf{C}\times(a,b)\to\mathbf{C}^3$. (The function Y, which depends only on r, is well-defined up to an additive constant, which alters the mapping by an ambient translation.) Not incidentally, Y is real valued. To see that f is an isometric embedding of g into $(\mathbf{C}^3, E)$, use cylindrical coordinates,

$$\mathrm{d}\psi = \kappa\,\mathrm{d}t, \quad \mathrm{d}\rho = \frac{\phi'(r)}{2\phi(r)}\mathrm{d}r, \quad \mathrm{d}Y = \sqrt{\frac{1}{\phi(r)}\left[1 - \left(\frac{1}{2\kappa}\phi'(r)\right)^2\right]}\mathrm{d}r$$

so the pullback of E by f is

$$f^*E = e^{2\rho}(\mathrm{d}\psi^2 + \mathrm{d}\rho^2) + \mathrm{d}Y^2 = \frac{\phi(r)}{\kappa^2}\left(\kappa^2\mathrm{d}t^2 + \frac{\phi'(r)^2}{4\phi(r)^2}\mathrm{d}r^2\right) + \mathrm{d}Y^2 = \phi(r)\mathrm{d}t^2 + \frac{1}{\phi(r)}\mathrm{d}r^2 = g.$$

Observe that the embedding "decouples" in complex cylindrical coordinates, ψ is a function of t alone, while ρ and Y are functions of r alone. Since the ambient and intrinsic group actions are translations in ψ and t, respectively, equivariance of f is obvious.

A. Negative profiles

The embedding (4.1) was introduced under the condition that $\phi > 0$. If $\phi < 0$ on an interval, the wish that Y be real valued imposes the condition $|\phi'| \geqslant 2\kappa$. In this situation, we are led to define

$$T = \frac{1}{\kappa}\sqrt{-\phi(r)}\cos(\kappa t), \qquad X = -\frac{1}{\kappa}\sqrt{-\phi(r)}\sin(\kappa t), \qquad Y = \int^r \sqrt{\frac{1}{\phi(\zeta)}\left[1 - \left(\frac{1}{2\kappa}\phi'(\zeta)\right)^2\right]}\,\mathrm{d}\zeta. \tag{4.2}$$

The formal expression of this mapping in terms of the cylindrical coordinate mapping Φ^- is identical to that of (4.1) with respect to Φ^+. In particular, Eq. (4.2) defines an equivariant isometric embedding of the metric

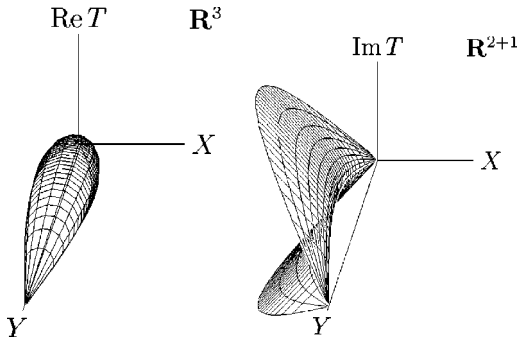

FIG. 3. A surface of revolution and the dual space–time slice.

$$g = \frac{1}{\phi(r)}\mathrm{d}r^2 + \phi(r)\mathrm{d}t^2, \quad \phi < 0,$$

into $\mathbf{C}^3$. Since $\phi<0$ but t is imaginary, the intrinsic coordinates have "switched roles," r is timelike and t is spacelike.

B. The Schwarzschild–de Sitter metric

The metrics associated to the positive portion of the profile $\phi(r)=1-(2/r)-(r^2/100)$ are depicted in Fig. 3. The X and Y axes are the real axes of the complex coordinate directions. The space–time slice that results is part of the Schwarzschild–de Sitter metric.

Each surface intersects the (X,Y) plane in the curve whose parametrization may be read off Eq. (4.1); the respective surfaces are swept out as this curve is acted on by a real or imaginary coordinate translation in ψ.

V. FIXED POINTS AND HORIZONS

In the preceding section we omitted points at which $\phi=0$, including fixed points of the group action and null lines in the ambient space. In this section, we investigate issues related to boundary conditions.

A. Riemannian signature

In the Riemannian situation, the profile is non-negative, $\sqrt{\phi(r)}$ is the length of the Killing field generating the group action, and a t interval of length $2\pi/\kappa$ corresponds to one full turn of the image surface. Consequently, the action has a fixed point at each zero of ϕ. To understand the significance of κ, we look more closely at the geometry of g near a fixed point.

Without loss of generality, we transform such that $\phi(0)=0$, and $\phi>0$ in some interval to the right of 0. The Taylor expansion is

$$\phi(r) = \phi'(0)r + o(r) \quad \text{near } r = 0.$$

Let θ be the cone angle at the vertex. Because the area element of g is $\mathrm{d}A=\mathrm{d}r\,\mathrm{d}t$, the portion of surface $0\leqslant r\leqslant\varepsilon$ has area $2\pi\varepsilon/\kappa$. The boundary curve $\{r=\varepsilon\}$ has circumference $2\pi\sqrt{\phi(\varepsilon)}/\kappa$. By elementary geometry, the cone angle is

$$\theta = \lim_{\varepsilon\to 0}\frac{\text{circumference}^2}{2\cdot\text{area}} = \frac{\pi}{\kappa}\phi'(0).$$

Since the image of the embedding is smooth at a fixed point iff $\theta=2\pi$, smoothness is equivalent to $\phi'(0)=2\kappa$. A similar argument holds if ϕ is positive to the left of 0: The embedding is smooth

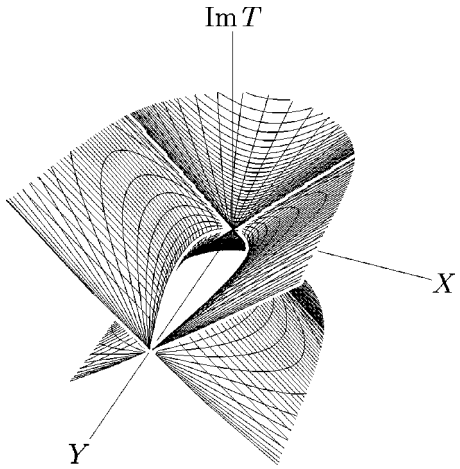

FIG. 4. Extension of the Schwarzschild–de Sitter embedding.

iff $\phi'(0)=-2\kappa$. Generally, $\phi'(0)$ is a measure of angular defect (also known as point curvature) at a fixed point.[2]

In Ref. 8, the value $\kappa=1$ was used tacitly. If $\kappa\neq 1$, it is appropriate to view the embedding (4.1) as taking values not in $\mathbf{R}^3$, but in a space that is flat away from the Y axis and has cone angle $2\pi/\kappa$ along the Y axis. If $|\phi'|=2$ at a zero of the profile, the embedding meets the Y axis perpendicularly; the intrinsic and ambient metric singularities have the same total angle.

B. Lorentz signature

Provided the radicand in the definition of Y is non-negative, the embedding of a space–time slice extends to intervals on which ϕ achieves negative values. Geometrically, a zero of the profile must map to a null line in $\mathbf{R}^{2+1}$, and the image of the embedding can cross from the spacelike portion of $\mathbf{R}^{2+1}$ to the timelike portion, see Fig. 4.

A *horizon* of an embedding is a curve in $\mathbf{R}^{2+1}$ along which the image is null. Intrinsically, a horizon comes from a zero of ϕ, where the space–time slice degenerates. A glance at (4.1) shows that the embedding is smooth at a horizon only if $|\phi'|=2\kappa$ and $\phi''<0$. There are two horizons in Fig. 4: one in the foreground (a cosmological horizon), and one containing the origin (the black hole horizon).

C. Embeddability criteria

Engman[5] studied momentum profiles and their associated surfaces of revolution, and characterized embeddability in terms of bounds on the total curvature of a disk centered at a fixed point. His bounds naturally have a space–time analogue, though a satisfactory topological interpretation is lacking due to noncompactness.

The portion of metric associated to a profile ϕ embeds iff the coordinate function Y in (4.1) is real valued. Non-negativity of the radicand is an obvious necessary condition, and is sufficient if the profile is (say) real analytic at each zero. If a metric associated to ϕ embeds, then at each point of the momentum interval one of the following conditions holds:

(i) $\phi>0$ and $|\phi'|\leqslant 2\kappa$,
(ii) $\phi<0$ and $|\phi'|\geqslant 2\kappa$,
(iii) $\phi=0$, $|\phi'|=2\kappa$.

In the Riemannian situation, the profile must be non-negative, and the metric embeds iff $|\phi'| \leqslant 2\kappa$. To obtain bounds on the total curvature of a disk, assume without loss of generality that $\kappa = 1$ (so that the ambient space is smooth), $\phi(0) = 0$, and $\phi'(0) = 2$. For $r_1 > 0$, the total curvature of the disk $D = \{0 \leqslant r \leqslant r_1\}$ is

$$\int_D K \, \mathrm{d}A = -\pi \int_0^{r_1} \phi''(r) \mathrm{d}r = \pi(2 - \phi'(r_1)).$$

We read off at once that the metric embeds iff the total curvature of an arbitrary disk (centered at the fixed point) is between 0 and 4π. A similar analysis holds for profiles that are positive to the left of a zero.

The upper bound is topologically significant: By the Gauss–Bonnet theorem, a surface of revolution generated by a profile that vanishes twice has total curvature 4π, even if the surface is not smooth at a fixed point. There are two ways the upper bound can be achieved by a profile satisfying $\phi(0) = 0$ and $\phi'(0) = 2$: The profile can become too steep (downward), or vanish at some $r_1 > 0$. In either case, ϕ no longer defines an embedding.

The space–time situation is analogous to an extent: There is an embeddability criterion in terms of total curvature, which has the expected sign change from the Riemannian case. Because the symmetry group is noncompact, we must speak of curvature *per unit time*. Further, it is meaningful to speak of embeddings defined by negative profiles, so there are two cases to consider. As above, we assume ϕ is a profile satisfying $\phi(0) = 0$ and $\phi'(0) = \pm 2\kappa$, and that ϕ is nonvanishing between 0 and r_1 for some $r_1 > 0$.

If $\phi > 0$, embeddability is equivalent to the pointwise inequality $|\phi'| \leqslant 2\kappa$. Integrating the curvature form $K \, \mathrm{d}A$ over a t interval of length 1 and the r interval $[0, r_1]$, we find that the total curvature per unit time is nonpositive, but no less than -4π, in every neighborhood of the horizon $r = 0$.

If $\phi < 0$, embeddability is equivalent to the bounds $|\phi'| \geqslant 2\kappa$. By an entirely analogous argument, the total curvature over $[0, r_1]$ is either $\geqslant 2\pi$ or is nonpositive. However, total curvature is a continuous function of r_1, and since the total curvature vanishes in the limit as $r_1 \to 0$, the first bound cannot hold for arbitrary r_1.

We conclude that embeddability of a piece of space–time metric associated to a negative profile implies that the metric has nonpositive total curvature in every neighborhood of the horizon, regardless of the sign of the profile. In an interval where the profile is positive, the total curvature is no smaller than -4π, while if the profile is negative, there is no *a priori* lower bound on the total curvature.

Nonpositivity of the total curvature implies the observation made in Ref. 7, if $\phi'(0) = 2\kappa \neq 0$ then the metric embeds in a neighborhood of the horizon if $\phi'' < 0$.

(Received 8 June 2004; accepted 22 August 2004; published 5 November 2004)

We consider the resolvent of a second order differential operator with a regular singularity, admitting a family of self-adjoint extensions. We find that the asymptotic expansion for the resolvent in the general case presents unusual powers of λ which depend on the singularity. The consequences for the pole structure of the ζ function, and for the small-t asymptotic expansion of the heat kernel, are also discussed. © *2004 American Institute of Physics*. [DOI: 10.1063/1.1809257]

I. INTRODUCTION

It is well known that in quantum field theory under external conditions, quantities like vacuum energies and effective actions, which describe the influence of boundaries or external fields on the physical system, are generically divergent and require a renormalization to get a physical meaning.

In this context, a powerful and elegant regularization scheme to deal with these problems is based on the use of the ζ function[1,2] or the heat kernel (for recent reviews see, for example, Refs. 3–7) associated to the relevant differential operators appearing in the quadratic part of the actions. In this way, ground state energies, heat-kernel coefficients, functional determinants, and partition functions for quantum fields can be given in terms of the corresponding ζ function, where the ultraviolet divergent pieces of the one-loop contributions are encoded as poles of its holomorphic extension.

Thus, it is of major interest in Physics to determine the singularity structure of ζ functions associated with these physical models.

In particular,[8] for an elliptic boundary value problem in a ν-dimensional compact manifold with boundary, described by a differential operator A of order ω, with smooth coefficients and a ray of minimal growth, defined on a domain of functions subject to local boundary conditions, the ζ function

$$\zeta_A(s) := \mathrm{Tr}\{A^{-s}\} \tag{1.1}$$

has a meromorphic extension to the complex s plane whose singularities are isolated simple poles at $s=(\nu-j)/\omega$, with $j=0,1,2,\ldots$.

In the case of positive definite operators, the ζ function is related, via Mellin transform, to the trace of the heat kernel of the problem, and the pole structure of $\zeta_A(s)$ determines the small-t asymptotic expansion of this trace,[8,9]

$$\mathrm{Tr}\{e^{-tA}\} \sim \sum_{j=0}^{\infty} a_j(A) t^{(j-\nu)/\omega}, \tag{1.2}$$

where the coefficients are related to the residues by

$$a_j(A) = \mathrm{Res}|_{s=(\nu-j)/\omega}\, \Gamma(s)\zeta_A(s). \tag{1.3}$$

For operators of the form $-\partial_x^2+V(x)$ with a singular potential $V(x)$ asymptotic to κ/x^2 as $x\to 0$, this expansion is substantially different. If $\kappa \geqslant 3/4$, the operator is essentially self-adjoint. This case has been treated in Refs. 10–12, where log terms are found, as well as terms with coefficients which are distributions concentrated at the singular point $x=0$. For the case $\kappa > -1/4$, the Friedrichs extension has been treated in Ref. 13 for operators in $\mathbf{L_2}(0,1)$, and in Ref. 14 for operators in $\mathbf{L_2}(\mathbf{R}^+)$, making use of the scale invariance of the operator domain and explicit representations of the resolvent. Moreover, as a particular case of a manifold with an isolated conic singularity, Ref. 15 gave a description of the boundary behavior of the Friedrichs heat kernel which does not make use of the resolvent, and showed via boundary maps how it can be used to construct the heat kernel for other self-adjoint extensions of these operators, showing explicitly the first two terms in the asymptotic expansion of the trace of their difference.

On the other hand, Ref. 16 gave the pole structure of the ζ function of a second order differential operator defined on the (noncompact) half-line $\mathbf{R}^+$, having a singular zeroth order term $V(x)=\kappa\, x^{-2}+x^2$. It showed that, for a certain range of real values of κ, this operator admits nontrivial self-adjoint extensions in $\mathbf{L_2}(\mathbf{R}^+)$, for which the associated ζ function (given by an integral representation) presents isolated simple poles which (in general) do not lie at $s=(1-j)/2$ for $j=0,1,\ldots$ [as would be the case for a regular $V(x)$], and can even take irrational values.

A similar structure has been noticed in Ref. 17 for the singularities of the ζ and η functions of a system of first order differential operators with a singular zeroth order term $\sim g\, x^{-1}$, which also admits a family of self-adjoint extensions for real g taking values in a certain range. It has been shown that, in the general case, the asymptotic expansion of the resolvent contains g-dependent powers of λ which make the ζ and η functions to present poles lying at points which depend on the singularity, with residues depending on the self-adjoint extension.

Let us mention that singular potentials $\sim 1/x^2$ have been considered in the description of several physical systems, like the Calogero model,[16,18–20] conformal invariant quantum mechanical models[21–23] and, more recently, the dynamics of quantum particles in the asymptotic near-horizon region of black-holes.[24–28] The self-adjoint extensions of these operators have also been considered in Ref. 29. Moreover, singular superpotentials has been considered as possible agents of supersymmetry breaking in models of supersymmetric quantum mechanics.[30–32]

It is the aim of the present paper to analyze the behavior of the resolvent, the ζ function and the trace of the heat kernel of a second order differential operator with a regular singularity in a compact segment, $D_x=-\partial_x^2+g(g-1)x^{-2}$, for those values of g for which it admits a family of self-adjoint extensions.

Following the scheme developed in Ref. 17, we will show that the asymptotic expansion for the resolvent in the general case presents powers of λ which depend on the singularity, and can even take irrational values. The consequence of this behavior on the corresponding ζ function is the presence of simple poles lying at points which also depend on the singularity, with residues depending on the self-adjoint extension considered.

We first construct the resolvents for two particular extensions, for which the boundary condition at the singular point $x=0$ is invariant under the scaling $x\to c\,x$. The resolvent expansion for these special extensions displays the usual powers, leading to the usual poles for the ζ function (and the usual structure for the asymptotic expansion of the heat-kernel trace).

The resolvents of the remaining extensions are convex linear combinations of these special extensions, but the coefficients in the convex combination depend on the eigenvalue parameter λ. This dependence leads to unusual powers in the resolvent expansion, and hence to unusual poles for the zeta function (and unusual powers in the asymptotic expansion of the heat-kernel trace).

These self-adjoint extensions are not invariant under the scaling $x \to c\,x$. As $c \to 0$ they tend (at least formally) to one of the invariant extensions, and as $c \to \infty$ they tend to the other. As $c \to 0$ the residues at the anomalous poles tend to zero, whereas as $c \to \infty$ these residues become infinite. The way these residues depend on the boundary condition is explained by a scaling argument in Sec. VII.

The structure of the paper is as follows: In Sec. II we define the operator and determine its self-adjoint extensions for $\frac{1}{2} < g < \frac{3}{2}$, and in Sec. III we study their spectra. In Sec. IV we construct the resolvent for a general extension as a linear combination of the resolvent of two limiting cases, and in Sec. V we consider the traces of these operators. The asymptotic expansions of these traces, evaluated in Sec. VI, are used in Sec. VII to construct the associated ζ function and study its singularities, as well as the small-t asymptotic expansion of the heat-kernel trace. The special case $g = \frac{1}{2}$ is considered in Appendix A.

II. THE OPERATOR AND ITS SELF-ADJOINT EXTENSIONS

Let us consider the differential operator,

$$D_x = -\frac{d^2}{dx^2} + \frac{g(g-1)}{x^2}, \tag{2.1}$$

with $g \in \mathbb{R}$, defined on a domain of smooth functions with compact support in a segment, $\mathcal{D}(D) = C_0^\infty(0,1)$. It can be easily seen that D_x so defined is symmetric.

The adjoint operator D_x^*, which is the maximal extension of D_x, is defined on the domain $\mathcal{D}(D_x^*)$ of functions $\phi(x) \in \mathbf{L_2}(0,1)$, having a locally sumable second derivative and such that

$$D_x\phi(x) = -\phi''(x) + \frac{g(g-1)}{x^2}\phi(x) = f(x) \in \mathbf{L_2}(0,1). \tag{2.2}$$

Lemma 2.1: If $\phi(x) \in \mathcal{D}(D_x^*)$ *and* $\frac{1}{2} < g < \frac{3}{2}$, *then* (the case $g = \frac{1}{2}$ will be considered separately, in Appendix A)

$$\left| \phi(x) - \left(\frac{C_1[\phi]x^g + C_2[\phi]x^{1-g}}{\sqrt{2g-1}} \right) \right| \leqslant \frac{\|D_x\phi(x)\|}{(3/2-g)\sqrt{2g+1}} x^{3/2} \tag{2.3}$$

and

$$\left| \phi'(x) - \left(\frac{gC_1[\phi]x^{g-1} + (1-g)C_2[\phi]x^{-g}}{\sqrt{2g-1}} \right) \right| \leqslant \frac{3/2\|D_x\phi(x)\|}{(3/2-g)\sqrt{2g+1}} x^{1/2} \tag{2.4}$$

for some constants $C_1[\phi]$ *and* $C_2[\phi]$, *where* $\|\cdot\|$ *is the* $\mathbf{L_2}$ *norm.*

Proof: Let us write $\phi(x) = x^g u(x)$. Then, Eq. (2.2) implies

$$u'(x) = K_2 x^{-2g} - x^{-2g}\int_0^x y^g f(y)\mathrm{d}y,$$

$$u(x) = K_1 + \frac{K_2}{1-2g}x^{1-2g} - \int_0^x y^{-2g}\int_0^y z^g f(z)\mathrm{d}z\ \mathrm{d}y, \tag{2.5}$$

for some constants K_1 and K_2. Now, taking into account that

$$\left| \int_0^x y^g f(y) dy \right| \leqslant \frac{x^{g+1/2}}{\sqrt{2g+1}} \|f\|,$$

$$\left| \int_0^x y^{-2g} \int_0^y z^g f(z) \mathrm{dz}\ \mathrm{dy} \right| \leqslant \frac{x^{3/2-g}}{(3/2-g)\sqrt{2g+1}} \|f\|, \tag{2.6}$$

we immediately get Eqs. (2.3) and (2.4).

Lemma 2.2: Let $\phi(x), \psi(x) \in \mathcal{D}(D^*)$ *and* $\frac{1}{2} < g < \frac{3}{2}$. *Then*

$$(D_x\psi, \phi) - (\psi, D_x\phi) = \{C_1[\psi]^* C_2[\phi] - C_2[\psi]^* C_1[\phi]\} + \{\psi(1)^* \phi'(1) - \psi'(1)^* \phi(1)\}. \tag{2.7}$$

Proof: From Eq. (2.2) one easily obtains

$$(D_x\psi, \phi) - (\psi, D_x\phi) = \lim_{\varepsilon \to 0^+} \int_\varepsilon^1 \partial_x \{\psi(x)^* \phi'(x) - \psi'(x)^* \phi(x)\} \mathrm{dx}, \tag{2.8}$$

from which, taking into account the results in Lemma 2.1, Eq. (2.7) follows directly.

Now, if $\psi(x)$ in Eq. (2.7) belongs to the domain of the closure of D_x, $\overline{D_x} = (D_x^*)^*$,

$$\psi(x) \in \mathcal{D}(\overline{D_x}) \subset \mathcal{D}(D_x^*), \tag{2.9}$$

then the right-hand side of Eq. (2.7) must vanish for any $\phi(x) \in \mathcal{D}(D_x^*)$. Therefore

$$C_1[\psi] = C_2[\psi] = \psi(1) = \psi'(1) = 0. \tag{2.10}$$

On the other hand, if $\psi(x), \phi(x)$ belong to the domain of a symmetric extension of D_x [contained in $\mathcal{D}(D_x^*)$], the right-hand side of Eq. (2.7) must also vanish.

Thus, the closed extensions of D_x correspond to the subspaces of $\mathbb{C}^4$ under the map $\Phi \to (C_1[\Phi], C_2[\Phi], \phi(1), \phi'(1))$, and the self-adjoint extensions correspond to those subspaces $S \subset \mathbb{C}^4$ such that $S = S^\perp$, with the orthogonal complement taken in the sense of the symplectic form on the right-hand side of Eq. (2.7).

For definiteness, in the following we will consider self-adjoint extensions satisfying the local boundary condition:

$$\phi(1) = 0. \tag{2.11}$$

Each such extension is determined by a condition of the form

$$\alpha C_1[\Phi] + \beta C_2[\Phi] = 0, \tag{2.12}$$

with $\alpha, \beta \in \mathbb{R}$, and $\alpha^2 + \beta^2 = 1$. We denote this extension by $D_x^{(\alpha,\beta)}$.

III. THE SPECTRUM

In order to determine the spectrum of the self-adjoint extensions of D_x for $\frac{1}{2} < g < \frac{3}{2}$, we need the solutions of

$$(D_x - \lambda)\phi_\lambda(x) = 0, \tag{3.1}$$

satisfying the boundary conditions in Eqs. (2.11) and (2.12).

The general solution of the homogeneous equation for $\lambda = 0$ is

$$\phi_0(x) = \frac{1}{\sqrt{2g-1}} (C_1 x^g + C_2 x^{1-g}), \tag{3.2}$$

and the boundary conditions in Eqs. (2.11) and (2.12) imply that

$$C_1 + C_2 = 0, \quad \alpha C_1 + \beta C_2 = 0. \tag{3.3}$$

Consequently, there are no zero modes except for the self-adjoint extension characterized by $\alpha = \beta = 1/\sqrt{2}$.

For $\lambda \neq 0$, the solutions of Eq. (3.1) are of the form

$$\phi(x) = \frac{C_1}{\sqrt{2g-1}} \frac{\Gamma(\frac{1}{2}+g)}{2^{1/2-g}\mu^{g-1/2}} \sqrt{x} J_{g-1/2}(\mu x) + \frac{C_2}{\sqrt{2g-1}} \frac{\Gamma(\frac{3}{2}-g)}{2^{g-1/2}\mu^{1/2-g}} \sqrt{x} J_{1/2-g}(\mu x), \tag{3.4}$$

where $\mu = +\sqrt{\lambda}$, and the μ-dependent coefficients have been introduced for later convenience.

Taking into account that

$$J_\nu(z) = z^\nu \left\{ \frac{1}{2^\nu \Gamma(1+\nu)} + O(z^2) \right\}, \tag{3.5}$$

we get from Eqs. (2.3) and (2.12),

$$\alpha\, C_1 + \beta\, C_2 = 0. \tag{3.6}$$

On the other hand, the condition in Eq. (2.11) implies

$$\phi(1) = \frac{C_1}{\sqrt{2g-1}} \frac{\Gamma(\frac{1}{2}+g)}{2^{1/2-g}\mu^{g-1/2}} J_{g-1/2}(\mu) + \frac{C_2}{\sqrt{2g-1}} \frac{\Gamma(\frac{3}{2}-g)}{2^{g-1/2}\mu^{1/2-g}} J_{1/2-g}(\mu) = 0. \tag{3.7}$$

For $\alpha = 0$, Eq. (3.6) implies $C_2 = 0$ (Dirichlet boundary conditions at the origin). Therefore, $\phi(1) = 0 \Rightarrow J_{g-1/2}(\mu) = 0$. Thus, the spectrum of this self-adjoint extension is positive and nondegenerate, with the eigenvalues of $D_x^D := D_x^{(0,1)}$ given by

$$\lambda_n = j_{g-1/2,n}^2, \quad n = 1, 2, \ldots, \tag{3.8}$$

where $j_{\nu,n}$ is the nth positive zero of the Bessel function $J_\nu(z)$. [Let us recall that large zeros of $j_{\nu,}(\lambda)$ have the asymptotic expansion

$$j_{\nu,n} \simeq \gamma - \frac{4\nu^2 - 1}{8\gamma} + O\left(\frac{1}{\gamma}\right)^3, \tag{3.9}$$

with $\gamma = \left[n + (\nu/2) - \frac{1}{4}\right]\pi$.]

For $\alpha \neq 0$, from Eqs. (3.6) and (3.7) we easily get the following transcendental equation for the eigenvalues of $D_x^{(\alpha,\beta)}$:

$$F(\mu) := \mu^{2g-1} \frac{J_{1/2-g}(\mu)}{J_{g-1/2}(\mu)} = \rho(\alpha, \beta), \tag{3.10}$$

where we have defined

$$\rho(\alpha, \beta) := \frac{\beta}{\alpha} \frac{2^{2g-1}\Gamma(\frac{1}{2}+g)}{\Gamma(\frac{3}{2}-g)}. \tag{3.11}$$

For the positive eigenvalues $\lambda = \mu^2$, both sides in Eq. (3.10) have been plotted in Fig. 1, for particular values of $\rho(\alpha, \beta)$ and g.

Moreover, if $\beta/\alpha > 1 \Rightarrow \rho(\alpha, \beta) > \rho(\alpha, \alpha)$, and the extension $D_x^{(\alpha,\beta)}$ has a negative eigenvalue. Indeed, if $\lambda_- = (i\mu)^2 < 0$, then

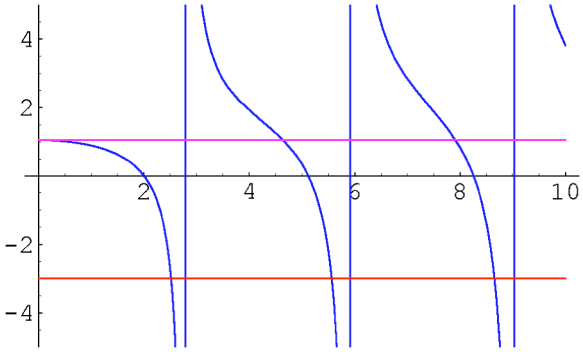

FIG. 1. Plot for $F(\mu)$, $\rho(\alpha,\beta)=-3$ and $\rho(\alpha,\alpha)$, with $g=3/4$.

$$F(i\mu)=\mu^{2g-1}\frac{I_{1/2-g}(\mu)}{I_{g-1/2}(\mu)}=2^{2g-1}\frac{\Gamma(\frac{1}{2}+g)}{\Gamma(\frac{3}{2}-g)}\left\{1+\frac{(2g-1)\mu^2}{(3-2g)(1+2g)}+O(\mu^4)\right\}, \tag{3.12}$$

where $I_\nu(\mu)$ is the modified Bessel function. For a plot, see Fig. 2. (It can be seen that this negative eigenvalue goes to $-\infty$ as $\alpha\to 0$, while the corresponding eigenfunction tends to concentrate tends to concentrate on the singularity at $x=0$. See also Ref. 33.)

Notice that the spectrum is always nondegenerate, and there is a positive eigenvalue between each pair of consecutive squared zeros of $J_{g-1/2}(\lambda)$. Therefore, from Eq. (3.9) we get $\lambda_n=\pi^2\, n^2+O(n)$.

In particular, for the $\beta=0$ extension (which we call the "N-extension"), $D_x^N:=D_x^{(1,0)}$, it can be seen from Eq. (3.10) that the eigenvalues are given by

$$\lambda_n=j_{1/2-g,n}^2, \quad n=1,2,\ldots, \tag{3.13}$$

where $j_{1/2-g,n}^2$ are the positive zeros of $J_{1/2-g}(\mu)$.

IV. THE RESOLVENT

In this section we will construct the resolvent of D_x,

$$G(\lambda)=(D_x-\lambda)^{-1}, \tag{4.1}$$

for its different self-adjoint extensions when $\frac{1}{2}<g<\frac{3}{2}$.

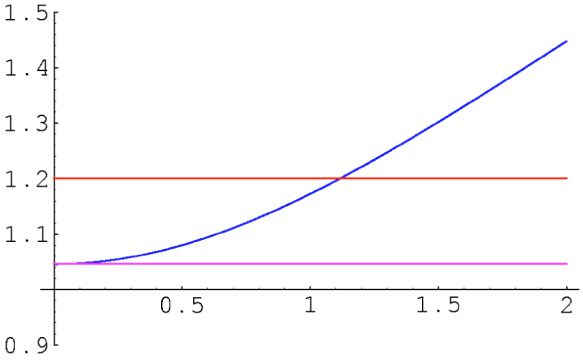

FIG. 2. Plot for $F(i\,\mu)$, $\rho(\alpha,\beta)=1.2$ and $\rho(\alpha,\alpha)$, with $g=3/4$.

We will first consider the two limiting cases in Eq. (2.12), namely the "*D*-extension," for which $\alpha=0\Rightarrow C_2[\phi]=0$, and the "*N*-extension," with $\beta=0\Rightarrow C_1[\phi]=0$. The resolvent for a general self-adjoint extension will be later evaluated as a linear combination of those obtained for these two limiting cases.

For the kernel of the resolvent we have

$$(D_x-\mu^2)G(x,y;\mu^2)=\delta(x-y), \tag{4.2}$$

where $\mu^2=\lambda$, with $-\pi/2<\arg(\mu)\leqslant\pi/2$.

To proceed, we need some particular solutions of the homogeneous equation (3.1). Then, let us define

$$L^D(x,\mu)=\sqrt{x}J_{g-1/2}(\mu x),$$

$$L^N(x,\mu)=\sqrt{x}J_{1/2-g}(\mu x),$$

$$R(x,\mu)=\sqrt{x}(J_{1/2-g}(\mu)J_{g-1/2}(\mu x)-J_{g-1/2}(\mu)J_{1/2-g}(\mu x)). \tag{4.3}$$

Notice that $R(1,\mu)=0$.

We will also need the Wronskians,

$$W[L^D(x,\mu),R(x,\mu)]=\frac{2\cos(g\pi)}{\pi}J_{g-1/2}(\mu)=\frac{1}{\gamma_D(\mu)},$$

$$W[L^N(x,\mu),R(x,\mu)]=\frac{2\cos(g\pi)}{\pi}J_{1/2-g}(\mu)=\frac{1}{\gamma_N(\mu)}, \tag{4.4}$$

which vanish only at the zeros of $J_\nu(\mu)$, for $\nu=\pm\left(g-\frac{1}{2}\right)$.

A. The resolvent for the *D*-extension

In this case, the function

$$\phi(x)=\int_0^1 G_D(x,y;\mu^2)f(y)\mathrm{d}y \tag{4.5}$$

must satisfy $\phi(1)=0$ and $C_2[\phi]=0$, for any function $f(x)\in\mathbf{L_2}(0,1)$.

This requires that

$$G_D(x,y;\mu^2)=\gamma_D(\mu)\times\begin{cases}L^D(x,\mu)R(y,\mu) & \text{for } x\leqslant y,\\ R(x,\mu)L^D(y,\mu) & \text{for } x\geqslant y.\end{cases} \tag{4.6}$$

The fact that the boundary conditions are satisfied, as well as $(D_x-\mu^2)\phi(x)=f(x)$, can be straightforwardly verified from Eqs. (4.3) and (4.4).

Indeed, from Eqs. (4.5), (4.6), (4.3), and (4.4), one gets

$$\phi(x)=\frac{C_1^D[\phi]}{\sqrt{2g-1}}x^g+O(x^{3/2}), \tag{4.7}$$

with

$$C_1^D[\phi]=\frac{\pi\mu^{g-1/2}\sqrt{2g-1}}{2^{1/2+g}\cos(g\pi)J_{g-1/2}(\mu)\Gamma(\frac{1}{2}+g)}\int_0^1 R(y,\mu)f(y)\mathrm{d}y, \tag{4.8}$$

for μ not a zero of $J_{g-1/2}(\mu)$.

Notice that $C_1^D[\phi] \neq 0$ if the integral on the right-hand side of Eq. (4.8) is nonvanishing.

B. The resolvent for the *N*-extension

In this case, the function

$$\phi(x) = \int_0^1 G_N(x,y;\mu^2) f(y) \mathrm{d}y \tag{4.9}$$

must satisfy $\phi(1)=0$ and $C_1[\phi]=0$, for any function $f(x) \in \mathbf{L_2}(0,1)$.

This requires that

$$G_N(x,y;\mu^2) = \gamma_N(\mu) \times \begin{cases} L^N(x,\mu) R(y,\mu) & \text{for } x \leqslant y, \\ R(x,\mu) L^N(y,\mu) & \text{for } x \geqslant y. \end{cases} \tag{4.10}$$

These boundary conditions, as well as the fact that $(D_x - \mu^2)\phi(x) = f(x)$, can be straightforwardly verified from Eqs. (4.3) and (4.4).

In this case, from Eqs. (4.9), (4.10), (4.3), and (4.4), one gets

$$\phi(x) = \frac{C_2^N[\phi]}{\sqrt{2g-1}} x^{1-g} + O(x^{3/2}), \tag{4.11}$$

with

$$C_2^N[\phi] = \frac{\pi \mu^{1/2-g} \sqrt{2g-1}}{2^{3/2-g} \cos(g\pi) J_{1/2-g}(\mu) \Gamma(\frac{3}{2}-g)} \int_0^1 R(y,\mu) f(y) \mathrm{d}y, \tag{4.12}$$

for μ not a zero of $J_{1/2-g}(\mu)$.

Notice that $C_2^N[\phi] \neq 0$ if the integral on the right-hand side of Eq. (4.12) [the same integral as the one appearing in the *D*-extension, Eq. (4.8)] is nonvanishing.

C. The resolvent for a general self-adjoint extension of D_x

For the general case, we can adjust the boundary conditions

$$\phi(1) = 0, \quad \alpha C_1[\phi] + \beta C_2[\phi] = 0, \quad \alpha, \beta \neq 0, \tag{4.13}$$

for

$$\phi(x) = \int_0^1 G(x,y;\lambda) f(y) \mathrm{d}y, \tag{4.14}$$

for any $f(x) \in \mathbf{L_2}(0,1)$, by taking a linear combination of the resolvent for the limiting cases,

$$G(x,y;\lambda) = [1 - \tau(\lambda)] G_D(x,y;\lambda) + \tau(\lambda) G_N(x,y;\lambda). \tag{4.15}$$

Since the boundary condition at $x=1$ is automatically fulfilled, one must just impose

$$\alpha[1 - \tau(\lambda)] C_1^D[\phi] + \beta \tau(\lambda) C_2^N[\phi] = 0. \tag{4.16}$$

Notice that, in view of Eqs. (4.8), (4.12), and (3.10),

$$\alpha C_1^D[\phi] - \beta C_2^N[\phi] = 0, \tag{4.17}$$

precisely when $\lambda = \mu^2$ is an eigenvalue of $D_x^{(\alpha,\beta)}$. Therefore, from Eq. (4.16) we get the resolvent of $D_x^{(\alpha,\beta)}$ by setting

$$\tau(\mu^2)=\frac{\alpha C_1^D[\phi]}{\alpha C_1^D[\phi]-\beta C_2^N[\phi]}=\frac{1}{1-\rho(\alpha,\beta)\mu^{1-2g}\dfrac{J_{g-1/2}(\mu)}{J_{1/2-g}(\mu)}}, \tag{4.18}$$

for μ not a zero of $J_{1/2-g}(\mu)$.

V. THE TRACE OF THE RESOLVENT

It follows from Eq. (4.15) that the resolvent of a general self-adjoint extension of D_x can be expressed in terms of the resolvents of the two limiting cases, $G_D(\lambda)$ and $G_N(\lambda)$. Moreover, since the eigenvalues of any extension grow as n^2 (see Sec. III), these resolvents are trace class operators.

Then, we have

$$\mathrm{Tr}\{G(\lambda)\}=\mathrm{Tr}\{G_D(\lambda)\}-\tau(\lambda)[\mathrm{Tr}\{G_D(\lambda)\}-\mathrm{Tr}\{G_N(\lambda)\}]. \tag{5.1}$$

From Eqs. (4.6) and (4.10) we straightforwardly get (see Appendix B for the details)

$$\mathrm{Tr}\{G_D(\mu^2)\}=\int_0^1 \mathrm{tr}\{G_D(x,x;\mu^2)\}\mathrm{d}x=\frac{J_{1/2+g}(\mu)}{2\mu J_{g-1/2}(\mu)}=\frac{2g-1}{4\mu^2}-\frac{J'_{g-1/2}(\mu)}{2\mu J_{g-1/2}(\mu)} \tag{5.2}$$

and

$$\mathrm{Tr}\{G_N(\mu^2)\}=\int_0^1 \mathrm{tr}\{G_N(x,x;\mu^2)\}\mathrm{d}x=\frac{J_{3/2-g}(\mu)}{2\mu J_{1/2-g}(\mu)}=-\frac{2g-1}{4\mu^2}-\frac{J'_{1/2-g}(\mu)}{2\mu J_{1/2-g}(\mu)}, \tag{5.3}$$

where we have taken into account that

$$J_{\nu+1}(z)=\frac{\nu}{z}J_\nu(z)-J'_\nu(z). \tag{5.4}$$

Finally, we get

$$\mathrm{Tr}\{G(\mu^2)\}=\left\{\frac{2g-1}{4\mu^2}-\frac{J'_{g-1/2}(\mu)}{2\mu J_{g-1/2}(\mu)}\right\}-\tau(\mu^2)\left\{\frac{2g-1}{2\mu^2}-\frac{1}{2\mu}\left(\frac{J'_{g-1/2}(\mu)}{J_{g-1/2}(\mu)}-\frac{J'_{1/2-g}(\mu)}{J_{1/2-g}(\mu)}\right)\right\}. \tag{5.5}$$

VI. ASYMPTOTIC EXPANSION FOR THE TRACE OF THE RESOLVENT

Using the Hankel asymptotic expansion for Bessel functions[34] (see Appendix C), we get for the first term on the right-hand side of Eq. (5.5),

$$\mathrm{Tr}\{G_D(\mu^2)\}\sim\sum_{k=1}^{\infty}\frac{A_k(g,\sigma)}{\mu^k}=\frac{i\sigma}{2\mu}+\frac{g}{2\mu^2}-\frac{i\sigma g(g-1)}{4\mu^3}+\frac{g(g-1)}{4\mu^4}+O(\mu^{-5}), \tag{6.1}$$

where $\sigma=1$ for $\Im(\mu)>0$, and $\sigma=-1$ for $\Im(\mu)<0$. The coefficients in this series can be straightforwardly evaluated from Eqs. (C8) and (C19). Notice that $A_k(g,-1)=A_k(g,1)^*$, since $A_{2k}(g,1)$ is real and $A_{2k+1}(g,1)$ is pure imaginary.

Similarly, from (C22) we simply get for the second factor in the second term on the right-hand side of Eq. (5.5),

$$\mathrm{Tr}\{G_D(\mu^2)-G_N(\mu^2)\}\sim\frac{2g-1}{2\mu^2}. \tag{6.2}$$

Finally, taking into account Eq. (C12), we have

$$\tau(\mu^2) \sim \frac{1}{1 - e^{\sigma i\pi(g-1/2)}\rho(\alpha,\beta)\mu^{1-2g}} \sim \sum_{k=0}^{\infty} (e^{\sigma i\pi(g-1/2)}\rho(\alpha,\beta)\mu^{1-2g})^k, \tag{6.3}$$

where $\sigma=1$ ($\sigma=-1$) corresponds to $\Im(\mu)>0$ ($\Im(\mu)<0$).

Notice the appearance of g-dependent powers of μ in this asymptotic expansion.

VII. THE ζ FUNCTION AND THE TRACE OF THE HEAT KERNEL

The ζ function for a general self-adjoint extension of D_x is defined, for $\Re(s)>1/2$, as

$$\zeta(s) = -\frac{1}{2\pi i}\oint_C \lambda^{-s}\,\mathrm{Tr}\{\mathrm{G}(\lambda)\}\mathrm{d}\lambda, \tag{7.1}$$

where the curve $\mathcal{C}$ encircles counterclockwise the spectrum of the operator, keeping to the left of the origin. According to Eq. (5.1), we have

$$\zeta(s) = \zeta^D(s) + \frac{1}{2\pi i}\oint_C \lambda^{-s}\tau(\lambda)\mathrm{Tr}\{\mathrm{G}_D(\lambda) - G_N(\lambda)\}\mathrm{d}\lambda, \tag{7.2}$$

where $\zeta^D(s)$ is the ζ function for the D-extension.

Since, according to the discussion in Sec. III, D_x^D has a positive spectrum, and the self-adjoint extension $D_x^{(\alpha,\beta)}$ has at most one negative eigenvalue, we can write

$$\zeta^{(\alpha,\beta)}(s) = \zeta^D(s) + \Theta(s) - \frac{1}{2\pi i}\int_{-i\infty+0}^{i\infty+0} \lambda^{-s}\tau(\lambda)\mathrm{Tr}\{G_D(\lambda) - G_N(\lambda)\}\mathrm{d}\lambda, \tag{7.3}$$

where $\Theta(s)=\lambda_-^{-s}$ if there is a negative eigenvalue, and vanishes otherwise.

We can also write

$$\zeta^{(\alpha,\beta)}(s) = \frac{e^{-i(\pi/2)s}}{\pi}\int_1^{\infty} \mu^{1-2s}\,\mathrm{Tr}\{G((e^{i(\pi/4)}\mu)^2)\}\mathrm{d}\mu + \frac{e^{i(\pi/2)s}}{\pi}\int_1^{\infty} \mu^{1-2s}\,\mathrm{Tr}\{G((e^{-i(\pi/4)}\mu)^2)\}\mathrm{d}\mu + h_1(s), \tag{7.4}$$

where $h_1(s)$ is an entire function. [The cut of the complex plane has been chosen to lie on the left half-plane. So, a negative real number can be written as $\lambda_-=e^{i\theta}|\lambda_-|$, where θ can take the value $+\pi$ or $-\pi$, depending on the position of the cut. In any case, $\Theta(s)=\lambda_-^{-s}=e^{-is\theta}|\lambda_-|^{-s}$ is an entire function, and the value of θ has no effects on the singular part of the ζ function.] Therefore, in order to determine the poles of $\zeta^{(\alpha,\beta)}(s)$, we can subtract and add a partial sum of the asymptotic expansion obtained in the preceding section to $\mathrm{Tr}\{G(\lambda)\}$ in the integrands on the right-hand side of Eq. (7.4).

In so doing, we get for the D-extension and for a real $s>1/2$,

$$\begin{aligned}\zeta^D(s) &= \frac{1}{\pi}\sum_{\sigma=\pm1}\int_1^{\infty} e^{-i\sigma(\pi/2)s}\mu^{1-2s}\left\{\sum_{k=1}^{N} e^{-i\sigma(\pi/4)k}A_k(g,\sigma)\mu^{-k}\right\}\mathrm{d}\mu + h_2(s)\\ &= \frac{1}{\pi}\sum_{k=1}^{N}\frac{\Re\{e^{-i(\pi/2)(s+k/2)}A_k(g,1)\}}{s-(1-k/2)} + h_2(s),\end{aligned} \tag{7.5}$$

where $h_2(s)$ is holomorphic in the open half-plane $\Re(s)>(1-N)/2$.

Consequently, the meromorphic extension of $\zeta^D(s)$ presents simple poles at

$$s = 1 - k/2 \quad \text{for } k = 1,2,3,\ldots, \tag{7.6}$$

with residues

$$\text{Res } \zeta^D(s)_{s=1-k/2} = -\frac{1}{\pi}\Re\{iA_k(g,1)\}, \tag{7.7}$$

where the coefficients $A_k(g,1)$ are given in Eq. (6.1). Notice that these residues vanish for even k.

In particular, for $s=1/2$ ($k=1$) one gets

$$\text{Res } \zeta^D(s)\,|_{s=1/2} = -\frac{1}{\pi}\Re\{iA_1(g,1)\} = \frac{1}{2\pi}. \tag{7.8}$$

This is the unique pole present in $\zeta^D(s)$ for the $g=1$ case, where there is no singularity in the 0th order coefficient of D_x.

For a general self-adjoint extension $D_x^{(\alpha,\beta)}$, we must also consider the singularities coming from the asymptotic expansion of $\tau(\lambda)\text{Tr}\{G_D(\lambda)-G_N(\lambda)\}$ in Eq. (5.1), given in Eqs. (6.2) and (6.3).

From Eq. (7.3), and taking into account Eq. (7.4), for real $s>1/2$ we can write

$$\zeta^{(\alpha,\beta)}(s)-\zeta^D(s) = h_3(s) - \frac{2g-1}{2\pi}\sum_{\sigma=\pm1} e^{-i\sigma(\pi/2)(s+1)}\int_1^\infty \mu^{-1-2s}\left\{\sum_{k=0}^{N}(e^{i\sigma(\pi/2)(g-1/2)}\rho(\alpha,\beta)\mu^{1-2g})^k\right\}\mathrm{d}\mu$$

$$= -\left(\frac{2g-1}{2\pi}\right)\sum_{k=0}^{N}\frac{1}{s-(\frac{1}{2}-g)k}\Re\{e^{i(\pi/2)((g-1/2)k-s-1)}\rho(\alpha,\beta)^k\} + h_3(s), \tag{7.9}$$

where $h_3(s)$ is holomorphic for $\Re(s)>(\frac{1}{2}-g)(N+1)$.

Therefore, $(\zeta^{(\alpha,\beta)}(s)-\zeta^D(s))$ has a meromorphic extension which presents simple poles located at negative g-dependent positions,

$$s = -(g-\tfrac{1}{2})k \quad \text{for } k=1,2,\ldots, \tag{7.10}$$

with residues which depend on the self-adjoint extension given by

$$\text{Res}\{\zeta^{(\alpha,\beta)}(s)-\zeta^D(s)\}\,|_{s=(1/2-g)k} = -\left(\frac{2g-1}{2\pi}\right)\rho(\alpha,\beta)^k\sin\left[\frac{\pi}{2}(2g-1)k\right]. \tag{7.11}$$

Notice that these poles are irrational for irrational values of g. Moreover, the residues vanish for the "N-extension" ($\rho(\alpha,0)=0$), and have a singular limit for $\alpha\to0$.

In particular, these poles for the $g=1$ case (for which there are no singularity in the zeroth order term of D_x) are negative half-integers, since in this case the residues vanish for even k.

It is interesting to notice that the poles in Eq. (7.10) are also poles of the ζ function of the corresponding self-adjoint extension of the operator $-\partial_x^2+g(g-1)x^{-2}+x^2$ in $\mathbf{L}_2(\mathbb{R}^+)$ considered in Ref. 16, with exactly the same residues, as can be easily verified.

Let us remark that when $\alpha\neq0$ the residue of $\zeta^{(\alpha,\beta)}$ at $s=-(g-\frac{1}{2})k$ is a constant times $(\beta/\alpha)^k$. This is consistent with the behavior of D_x under the scaling isometry $Tu(x)=c^{1/2}u(cx)$ taking $\mathbf{L_2}(0,1)\to\mathbf{L_2}(0,1/c)$. The extension $D_x^{(\alpha,\beta)}$ is unitarily equivalent to the operator $(1/c^2)\dot{D}_x^{(\alpha',\beta')}$ similarly defined on $\mathbf{L_2}(0,1/c)$, with $\alpha'=c^{-g}\alpha$ and $\beta'=c^{g-1}\beta$,

$$T\,D_x^{(\alpha,\beta)} = \frac{1}{c^2}\dot{D}_x^{(\alpha',\beta')}\,T. \tag{7.12}$$

Notice that only for the extensions with $\alpha=0$ or $\beta=0$ the boundary condition at the singular point $x=0$, Eq. (2.12), is left invariant by this scaling.

Therefore, we have for the ζ function of the scaled problem

$$\dot{\zeta}^{(\alpha',\beta')}(s) = c^{-2s}\zeta^{(\alpha,\beta)}(s), \tag{7.13}$$

and for the residues

$$\text{Res}\,\{\zeta^{(\alpha',\beta')}(s)\}\,|_{s=(1/2-g)k} = c^{(2g-1)k}\,\text{Res}\,\{\zeta^{(\alpha,\beta)}(s)\}\,|_{s=(1/2-g)k}. \tag{7.14}$$

The factor $c^{(2\,g-1)k}$ exactly cancels the effect the change in the boundary condition at the singularity has on $\rho(\alpha,\beta)$,

$$\rho(\alpha,\beta)^k = c^{(1-2g)k}\rho(\alpha',\beta')^k. \tag{7.15}$$

Then, the difference between the intervals $(0,1)$ and $(0,1/c)$ has no effect on the structure of these residues, which presumably are determined locally in a neighborhood of $x=0$.

In this way we conclude that, for a general self-adjoint extension, the presence of poles in the ζ function located at g-dependent positions is a consequence of the singular behavior ($\sim x^{-2}$) of the zeroth order term in D_x near the origin, together with a scaling noninvariant boundary condition at the singularity.

Finally, let us remark that the relation between the ζ function and the trace of the heat kernel of $D_x^{(\alpha,\beta)}$,

$$\zeta^{(\alpha,\beta)}(s) = \frac{1}{\Gamma(s)}\int_0^1 t^{s-1}\,\text{Tr}\{e^{-tD_x^{(\alpha,\beta)}}\}\,dt + H(s), \tag{7.16}$$

where $H(s)$ is an entire function, straightforwardly lead to the following small-t asymptotic expansion:

$$\text{Tr}\{e^{-tD_x^{(\alpha,\beta)}} - e^{-tD_x^{D}}\} \sim \left(g-\frac{1}{2}\right) - \sum_{k=1}^{\infty}\left\{\Gamma\left(\left[\frac{1}{2}-g\right]k\right)\frac{2g-1}{2\pi}\rho(\alpha,\beta)^k \sin\left[\frac{\pi}{2}(2g-1)k\right]\right\}t^{(g-1/2)k}. \tag{7.17}$$

The first term on the right-hand side, coming from Eq. (6.2) and the first term in the asymptotic expansion of $\tau(\lambda)$ in Eq. (6.3), coincides with the result reported in Ref. 15. Notice also the g-dependent powers of t appearing in the asymptotic series on the right-hand side of Eq. (7.17) for any general self-adjoint extension [except for the "N-extension," for which $\rho(\alpha,0)=0$]. In particular, the first term in this series reduces to

$$-\frac{\beta}{\alpha}\frac{2^{2g-1}}{\Gamma(\frac{1}{2}-g)}t^{g-1/2}. \tag{7.18}$$

This power of t also coincides with the result quoted in Ref. 15, but we find a different coefficient.

APPENDIX A: THE CASE $g=1/2$

The case $g=1/2$, for which the differential operator D_x takes the form

$$D_x = -\frac{d^2}{dx^2} - \frac{1}{4\,x^2}, \tag{A1}$$

requires a separate consideration which we briefly present in this appendix.

Along the same lines as in the proof of Lemma 2.1, it is straightforward to show that, if $\phi(x) \in \mathcal{D}(D_x^*)$, then

$$|\phi(x) - (C_1[\phi]\sqrt{x} + C_2[\phi]\sqrt{x}\,\log x)| \leqslant \frac{\|D_x\phi(x)\|}{\sqrt{2}}x^{3/2} \tag{A2}$$

and

$$\left|\phi'(x) - \left[\frac{1}{2}C_1[\phi]x^{-1/2} + C_2[\phi]\left(x^{-1/2} + \frac{1}{2}x^{-1/2}\,\log x\right)\right]\right| \leqslant \frac{3}{2\sqrt{2}}\|D_x\phi(x)\|x^{1/2} \tag{A3}$$

for some constants $C_1[\phi]$ and $C_2[\phi]$, where $\|\cdot\|$ stands for the $\mathbf{L_2}$ norm.

Therefore, it is easy to see that Eq. (2.7) is also valid in the present case, and the self-adjoint extensions of D_x correspond again to those subspaces $S\subset\mathbb{C}^4$ such that $S=S^{\perp}$, with the orthogonal complement taken in the sense of the symplectic form on the right-hand side of Eq. (2.7).

If, in addition, we select the Dirichlet condition at $x=1$, $\phi(1)=0$, the remaining self-adjoint extensions of D_x correspond to a one-parameter family characterized by Eq. (2.12), $D_x^{(\alpha,\beta)}$.

There exists a particular self-adjoint extension for which $C_2[\phi]=0$, namely $D_x^D := D_x^{(0,1)}$, such that the functions in its domain behave near the origin as

$$\phi(x) = C_1[\phi]\sqrt{x} + O(x^{3/2}). \tag{A4}$$

The eigenfunction of D_x^D corresponding to the eigenvalue λ is given by

$$\phi(x) = C_1[\phi]\sqrt{x}J_0(\mu x), \tag{A5}$$

where $\lambda=\mu^2$ and μ is a (positive) zero of $J_0(\mu)$.

For an arbitrary self-adjoint extension $D_x^{(\alpha,\beta)}$ with $\alpha\neq 0$, the eigenfunction corresponding to the eigenvalue $\lambda=\mu^2$ is given by

$$\phi(x) = \{C_1[\phi] - C_2[\phi](\log\,\mu - \log\,2 + \gamma)\}\sqrt{x}J_0(\mu x) + \frac{\pi}{2}C_2[\phi]\sqrt{x}N_0(\mu x), \tag{A6}$$

where $C_1[\phi]$, $C_2[\phi]$ are constrained by Eq. (2.12). The condition $\phi(1)=0$ leads to the equation

$$(\theta - \log\,\mu)J_0(\mu) + \frac{\pi}{2}N_0(\mu) = 0, \tag{A7}$$

where $\theta=-\beta/\alpha+\log 2-\gamma$, which determines the spectrum of $D_x^{(\alpha,\beta)}$. Notice that there are no negative eigenvalues.

In order to determine the kernels of the resolvents $\mathcal{G}^D(\mu^2) := (D_x^D-\mu^2)^{-1}$ and $\mathcal{G}^{(\alpha,\beta)}(\mu^2) := (D_x^{(\alpha,\beta)}-\mu^2)^{-1}$, we define

$$\mathcal{L}^D(x;\mu) = \sqrt{x}J_0(\mu x),$$

$$\mathcal{L}^{(\alpha,\beta)}(x;\mu) = \sqrt{x}\left\{(\theta - \log\,\mu)J_0(\mu x) + \frac{\pi}{2}N_0(\mu x)\right\},$$

$$\mathcal{R}(x;\mu) = \sqrt{x}\{N_0(\mu)J_0(\mu x) - J_0(\mu)N_0(\mu x)\}, \tag{A8}$$

to get

$$\mathcal{G}^D(x,y;\mu^2) = \frac{1}{W[\mathcal{L}^D(x;\mu),\mathcal{R}(x;\mu)]}\times\begin{cases}\mathcal{L}^D(x;\mu)\mathcal{R}(y;\mu), & x\leqslant y,\\ \mathcal{L}^D(y;\mu)\mathcal{R}(x;\mu), & x\geqslant y,\end{cases} \tag{A9}$$

and

$$\mathcal{G}^{(\alpha,\beta)}(x,y;\mu^2)=\frac{1}{W[\mathcal{L}^{(\alpha,\beta)}(x;\mu),\mathcal{R}(x;\mu)]}\times\begin{cases}\mathcal{L}^{(\alpha,\beta)}(x;\mu)\mathcal{R}(y;\mu), & x\leqslant y,\\ \mathcal{L}^{(\alpha,\beta)}(y;\mu)\mathcal{R}(x;\mu), & x\geqslant y,\end{cases} \tag{A10}$$

where the Wronskians can be easily computed from (A8),

$$W[\mathcal{L}^{D}(x;\mu),\mathcal{R}(x;\mu)]=\frac{2}{\pi}J_0(\mu),$$

$$W[\mathcal{L}^{(\alpha,\beta)}(x;\mu),\mathcal{R}(x;\mu)]=\frac{2}{\pi}(\theta-\log\,\mu)J_0(\mu)+N_0(\mu). \tag{A11}$$

From Eq. (3.9), it can be seen that both $\mathcal{G}^{D}(\lambda)$ and $\mathcal{G}^{(\alpha,\beta)}(\lambda)$ are trace class operators.

Now, taking into account that[34,35]

$$\int x\,Z_1(0,x)Z_2(0,x)\mathrm{d}x=\frac{x^2}{2}\{Z_1(0,x)Z_2(0,x)+Z_1(1,x)Z_2(1,x)\}, \tag{A12}$$

where $Z_{1,2}(\nu,x)=J_\nu(x)$ or $N_\nu(x)$, the traces of the resolvents can be readily computed to get

$$\mathrm{Tr}\{\mathcal{G}^{D}(\mu^2)\}=\int_0^1\mathcal{G}^{D}(x,x;\mu^2)\mathrm{d}x=\frac{1}{2\mu}\frac{J_1(\mu)}{J_0(\mu)},$$

$$\mathrm{Tr}(\mathcal{G}^{(\alpha,\beta)(\mu^2)})=\int_0^1\mathcal{G}^{(\alpha,\beta)}(x,x;\mu^2)\mathrm{d}x=\frac{1}{2\mu}\frac{\frac{2}{\pi}(\theta-\log\,\mu)J_1(\mu)+N_1(\mu)}{\frac{2}{\pi}(\theta-\log\,\mu)J_0(\mu)+N_0(\mu)}. \tag{A13}$$

From Eqs. (C6) and (C7) one straightforwardly gets the same asymptotic expansion for these two traces,

$$\begin{aligned}\mathrm{Tr}\{\mathcal{G}^{D}(\mu^2)\}&\sim\frac{e^{i\sigma(\pi/2)}}{2\mu}\left(\frac{P(1,\mu)-i\sigma\,Q(1,\mu)}{P(0,\mu)-i\sigma\,Q(0,\mu)}\right)\\&\sim\mathrm{Tr}(\mathcal{G}^{(\alpha,\beta)}(\mu^2))\sim\sum_{k=1}^{\infty}\frac{A_k(1/2,\sigma)}{\mu^k}=\frac{i\,\sigma}{2\mu}+\frac{1}{4\,\mu^2}+\frac{i\,\sigma}{16\mu^3}-\frac{1}{16\,\mu^4}+O(\mu^{-5}),\end{aligned} \tag{A14}$$

where $\sigma=+1\ (-1)$ for $\Im(\mu)>0\ (\Im(\mu)<0)$.

Notice that the asymptotic series in Eq. (A14) coincides with the right-hand side of Eq. (6.1) evaluated at $g=1/2$. Therefore, from Eq. (7.5) one concludes that, in the present case, $\zeta^{(\alpha,\beta)}(s)$ has simple poles only at $s=1-k/2$, for $k=1,2,3,\ldots$, with residues given by

$$\mathrm{Res}\ \zeta^{D}(s)\,|_{s=1-k/2}=-\frac{1}{\pi}\Re\{iA_k(1/2,1)\} \tag{A15}$$

(vanishing for even k) for all the self-adjoint extensions of D_x.

So, in contrast to the case of $1/2<g<3/2$, the pole structure of the ζ function for $g=1/2$ is independent of the self-adjoint extension considered and does not differ from the usual one.

APPENDIX B: EVALUATION OF THE TRACES OF THE RESOLVENTS

In this appendix we briefly describe the evaluation of the traces appearing in Sec. V.

From Eq. (4.6) we get for the kernel of $G_D(\lambda)$ on the diagonal

$$G_D(x,x;\mu^2) = \gamma_D x\{J_{1/2-g}(\mu)J_{g-1/2}(\mu\, x)^2 - J_{g-1/2}(\mu)J_{g-1/2}(\mu\, x)J_{1/2-g}(\mu)\}. \tag{B1}$$

Therefore, in order to evaluate its trace it is sufficient to know the primitives[35,36]

$$\int xJ_\nu^2(\mu\, x)\mathrm{d}x = \frac{x^2}{2}\{J_\nu(x\,\mu)^2 - J_{\nu-1}(x\,\mu)J_{\nu+1}(x\,\mu)\} \tag{B2}$$

and

$$\int xJ_\nu(\mu\, x)J_{-\nu}(\mu\, x)\mathrm{d}x = \frac{-\nu^2}{\mu^2\Gamma(1-\nu)\Gamma(1+\nu)}\left[{}_1F_2(\{-1/2\},\{-\nu,\nu\},-x^2\mu^2) - 1\right], \tag{B3}$$

where

$$\begin{aligned}{}_1F_2(\{-1/2\},\{-\nu,\nu\},-x^2\mu^2) = -\frac{\pi x^2\mu^2\csc(\pi\nu)}{4\nu}&\{J_{-1-\nu}(x\,\mu)J_{-1+\nu}(x\,\mu) + 2\,J_{-\nu}(x\,\mu)J_\nu(x\,\mu)\\ &+ J_{1-\nu}(x\,\mu)J_{1+\nu}(x\,\mu)\}.\end{aligned} \tag{B4}$$

These primitives, together with the relation

$$J_{\nu-1}(z) + J_{\nu+1}(z) = \frac{2\nu}{z}J_\nu(z), \tag{B5}$$

necessary to simplify the intermediate results, straightforwardly lead to Eq. (5.2).

Similarly, for the kernel of $G_N(\lambda)$ on the diagonal we have

$$G_N(x,x;\mu^2) = \gamma_N\, x\{-J_{g-1/2}(\mu)J_{1/2-g}(\mu\, x)^2 + J_{1/2-g}(\mu)J_{1/2-g}(\mu\, x)J_{g-1/2}(\mu\, x)\}. \tag{B6}$$

The same argument as before leads to Eq. (5.3).

APPENDIX C: THE HANKEL EXPANSION

To develop an asymptotic expansion for the trace of the resolvent we employ the Hankel asymptotic expansion for the Bessel functions which, for completeness, we briefly describe in this appendix.

For $|z|\to\infty$, with ν fixed and $|\arg z| < \pi$, we have[34]

$$J_\nu(z) \sim \left(\frac{2}{\pi\, z}\right)^{1/2}\{P(\nu,z)\cos\,\chi(\nu,z) - Q(\nu,z)\sin\,\chi(\nu,z)\} \tag{C1}$$

and

$$N_\nu(z) \sim \left(\frac{2}{\pi\, z}\right)^{1/2}\{P(\nu,z)\sin\,\chi(\nu,z) + Q(\nu,z)\cos\,\chi(\nu,z)\}, \tag{C2}$$

where

$$\chi(\nu,z) = z - \left(\frac{\nu}{2} + \frac{1}{4}\right)\pi, \tag{C3}$$

$$P(\nu,z) \sim \sum_{k=0}^{\infty}\frac{(-1)^k\,\Gamma(\frac{1}{2}+\nu+2k)}{(2k)!\,\Gamma(\frac{1}{2}+\nu-2k)}\frac{1}{(2z)^{2k}}, \tag{C4}$$

and

$$Q(\nu,z) \sim \sum_{k=0}^{\infty} \frac{(-1)^k \Gamma(\frac{1}{2}+\nu+2k+1)}{(2k+1)!\,\Gamma(\frac{1}{2}+\nu-2k-1)} \frac{1}{(2z)^{2k+1}}. \tag{C5}$$

Moreover, $P(-\nu,z)=P(\nu,z)$ and $Q(-\nu,z)=Q(\nu,z)$, since these functions depend only on ν^2 (see Ref. 34, p. 364).

Therefore,

$$J_\nu(z) \sim \frac{e^{-i\sigma z}\, e^{i\sigma\pi[(\nu/2)+1/4]}}{\sqrt{2\pi z}} \{P(\nu,z) - i\sigma\, Q(\nu,z)\}, \tag{C6}$$

where $\sigma=1$ for z in the upper open half-plane and $\sigma=-1$ for z in the lower open half-plane.

Similarly,

$$N_\nu(z) \sim i\sigma \frac{e^{-i\sigma z}\, e^{i\sigma\pi[(\nu/2)+1/4]}}{\sqrt{2\pi z}} \{P(\nu,z) - i\sigma\, Q(\nu,z)\}, \tag{C7}$$

with $\sigma=1$ if $\Im(z)>0$ and $\sigma=-1$ for $\Im(z)<0$.

In these equations,

$$P(\nu,z) - i\sigma\, Q(\nu,z) \sim \sum_{k=0}^{\infty} \langle \nu,k\rangle \left(\frac{-i\sigma}{2z}\right)^k, \tag{C8}$$

where the coefficients

$$\langle \nu,k\rangle = \frac{\Gamma(\frac{1}{2}+\nu+k)}{k!\,\Gamma(\frac{1}{2}+\nu-k)} = \langle -\nu,k\rangle \tag{C9}$$

are the Hankel symbols.

For the quotient of two Bessel functions we have

$$\frac{J_{\nu_1}(z)}{J_{\nu_2}(z)} \sim e^{i\sigma(\pi/2)(\nu_1-\nu_2)} \frac{P(\nu_1,z) - i\sigma\, Q(\nu_1,z)}{P(\nu_2,z) - i\sigma\, Q(\nu_2,z)}, \tag{C10}$$

where $\sigma=1$ for $\Im(z)>0$ and $\sigma=-1$ for $\Im(z)<0$. The coefficients of this asymptotic expansion can be easily obtained, to any order, from Eq. (C8),

$$\frac{P(\nu_1,z) \pm i\, Q(\nu_1,z)}{P(\nu_2,z) \pm i\, Q(\nu_2,z)} \sim 1 + (\langle \nu_1,1\rangle - \langle \nu_2,1\rangle)\left(\frac{\pm i}{2z}\right) + O\left(\frac{1}{z^2}\right). \tag{C11}$$

In particular,

$$\frac{J_{1/2-g}(z)}{J_{g-1/2}(z)} \sim e^{i\sigma\pi(1/2-g)} \frac{P(\frac{1}{2}-g,z) - i\sigma\, Q(\frac{1}{2}-g,z)}{P(g-\frac{1}{2},z) - i\sigma\, Q(g-\frac{1}{2},z)} = e^{i\sigma\pi(1/2-g)}, \tag{C12}$$

since $P(\nu,z)$ and $Q(\nu,z)$ are even in ν.

Similarly, the derivative of the Bessel function has the following asymptotic expansion[34] for $|\arg z|<\pi$:

$$J'_\nu(z) \sim -\frac{2}{\sqrt{2\pi z}} \{R(\nu,z)\sin\,\chi(\nu,z) + S(\nu,z)\cos\,\chi(\nu,z)\} \tag{C13}$$

and

$$N'_\nu(z) \sim \frac{2}{\sqrt{2\pi z}}\{R(\nu,z)\cos\,\chi(\nu,z) - S(\nu,z)\sin\,\chi(\nu,z)\}, \tag{C14}$$

where

$$R(\nu,z) \sim \sum_{k=0}^{\infty}(-1)^k \frac{\nu^2+(2k)^2-1/4}{\nu^2-(2k-1/2)^2}\frac{\langle \nu,2k\rangle}{(2z)^{2k}} \tag{C15}$$

and

$$S(\nu,z) \sim \sum_{k=0}^{\infty}(-1)^k \frac{\nu^2+(2k+1)^2-1/4}{\nu^2-(2k+1-1/2)^2}\frac{\langle \nu,2k+1\rangle}{(2z)^{2k+1}}. \tag{C16}$$

Then,

$$J'_\nu(z) \sim \mp i\frac{e^{\mp iz}\,e^{\pm i\pi[(\nu/2)+1/4]}}{\sqrt{2\pi z}}\{R(\nu,z) \mp i\,S(\nu,z)\}, \tag{C17}$$

where the upper sign is valid for $\Im(\lambda)>0$, and the lower one for $\Im(\lambda)<0$. We have also

$$R(\nu,z) \pm i\,S(\nu,z) = P(\nu,z) \pm i\,Q(\nu,z) + T_\pm(\nu,z), \tag{C18}$$

with

$$T_\pm(\nu,z) \sim \sum_{k=1}^{\infty}(2k-1)\langle \nu,k-1\rangle\left(\frac{\pm i}{2z}\right)^k. \tag{C19}$$

Therefore, we get

$$\frac{J'_\nu(z)}{J_\nu(z)} \sim \mp i\left\{1+\frac{T_\mp(\nu,z)}{P(\nu,z)\mp iQ(\nu,z)}\right\}, \tag{C20}$$

where the upper sign is valid for $\Im(\lambda)>0$, and the lower one for $\Im(\lambda)<0$. The coefficients of the asymptotic expansion on the right-hand side of Eq. (C20) can be easily obtained from Eqs. (C8) and (C19),

$$\frac{T_\pm(\nu,z)}{P(\nu,z)\pm iQ(\nu,z)} = \left(\frac{\pm i}{2z}\right) + O\left(\frac{1}{z^2}\right). \tag{C21}$$

Finally, since the Hankel symbols are even in ν [see Eq. (C9)], from Eqs. (C8), (C19), and (C20) we have

$$\frac{J'_\nu(z)}{J_\nu(z)} \sim \frac{J'_{-\nu}(z)}{J_{-\nu}(z)}. \tag{C22}$$

Deformations of loop algebras and integrable systems: hierarchies of integrable equations

T. Skrypnyk[a)]

(Received 3 June 2003; accepted 5 August 2004; published 5 November 2004)

Using special quasigraded Lie algebras, that could be viewed as deformations of loop algebras, we obtain new hierarchies of integrable nonlinear equations admitting zero-curvature representations. In particular, we obtain integrable hierarchies that generalize the Heisenberg magnet, Landau–Lifshitz, and anisotropic chiral field hierarchies. We also obtain a new type of $so(3)$ anisotropic chiral field equation along with its higher rank generalization. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1804229]

I. INTRODUCTION

It is known that integrability of equations of $1+1$ field theory and condensed matter physics is based on the possibility to represent them in the form of the so-called zero-curvature equations:[1–3]

$$\frac{\partial U(x,t,\lambda)}{\partial t} - \frac{\partial V(x,t,\lambda)}{\partial x} + [U(x,t,\lambda), V(x,t,\lambda)] = 0, \tag{1}$$

where U, V are the matrix-valued functions, depending on the dynamical variables (fields), their derivatives with respect to the "space" coordinate x and an additional complex parameter λ usually called "spectral."

The most convenient interpretation of zero-curvature equations, that has arisen independently in Refs. 4 and 5 for the case of the rational dependence of $U-V$ pair on λ, is to consider them as a consistency condition for a set of a commuting Hamiltonian flows on the dual space to some infinite-dimensional Lie algebra $\tilde{\mathfrak{g}}$ of matrix-valued function of λ written in the Euler–Arnold (generalized Lax) form

$$\frac{\partial L(\lambda)}{\partial t_l} = ad^*_{\nabla I_l(L(\lambda))} L(\lambda), \quad \frac{\partial L(\lambda)}{\partial t_k} = ad^*_{\nabla I_k(L(\lambda))} L(\lambda), \tag{2}$$

where $L(\lambda) \in \tilde{\mathfrak{g}}^*$ is the generic element of the dual space, $\nabla I_k(L(\lambda)) \in \tilde{\mathfrak{g}}$ is the algebra-valued gradient of $I_k(L(\lambda))$, and the "Hamiltonians" $I_k(L(\lambda)), I_l(L(\lambda))$ belong to the set of mutually commuting with respect to the natural Lie–Poisson bracket functions on $\tilde{\mathfrak{g}}^*$. Consistency condition of Eqs. (2) coincides with Eq. (1), where $U \equiv \nabla I_k$, $V \equiv \nabla I_l$, $x \equiv t_k$, $t \equiv t_l$ for some fixed indices k and l. Requiring Eq. (1) to be true for all degrees of spectral parameter λ we obtain a self-consistent system of differential equations in the dynamical variables—coordinate functions on $\tilde{\mathfrak{g}}^*$. In this way we obtain a lot of equations in partial derivatives that are labeled by the two commuting Hamiltonians I_k and I_l. The set of such equations with different l and fixed k (i.e., with fixed space variable $x \equiv t_k$) constitutes so-called *integrable hierarchy*.[3]

Hence, in order to construct integrable hierarchies in the framework of the described earlier approach it is necessary to construct infinite family of commuting Hamiltonians on the dual space

[a)]Electronic mail: tskrypnyk@imath.kiev.ua

to some infinite-dimensional Lie algebra $\tilde{\mathfrak{g}}$ of the algebra-valued functions of one complex variable λ. From the fact that not for arbitrary dependence of U, V on λ corresponding Eq. (1) have nontrivial solutions,[6] it follows that not for all algebras $\tilde{\mathfrak{g}}$ this program could be realized. That is why very special Lie algebras $\tilde{\mathfrak{g}}$ admitting some algorithm of construction of infinite set of mutually commuting functions on $\tilde{\mathfrak{g}}^*$ are required in this approach. The most powerful of such algorithms is the famous Kostant–Adler scheme.[7,8] In particular, it is known[2,4,5,9] that applying it to the graded loop algebras $L(\mathfrak{g})=\mathfrak{g}\otimes Pol(\lambda,\lambda^{-1})$ it is possible to obtain almost all known integrable equations.

The main purpose of the present paper is to extend applications of the approach of Refs. 4 and 5 to construction of integrable differential equations in order to obtain new hierarchies of integrable differential equations in partial derivatives. For this purpose we construct a new class of infinite-dimensional Lie algebras to which the Kostant–Adler scheme may be applied. Contrary to the loop algebras they are not graded but possess a weaker property of a *quasigradation*. Constructed quasigraded Lie algebras are *continuous multiparametric deformations* of the graded loop algebras $L(\mathfrak{g})$. Matrix elements of a certain matrice A serve for the parameters of the deformation. We denote the corresponding infinite-dimensional Lie algebras by $\tilde{\mathfrak{g}}_A$. We study the properties of the obtained algebras $\tilde{\mathfrak{g}}_A$ in detail. We construct their coadjoint representations and infinite sets of coadjoint invariants $\{I_k^m\}$. Restricting these invariants onto subspaces $(\tilde{\mathfrak{g}}_A^{\pm})^*$, where $\tilde{\mathfrak{g}}_A=\tilde{\mathfrak{g}}_A^+ + \tilde{\mathfrak{g}}_A^-$, we obtain two infinite sets of polynomial functions $\{I_k^{m\pm}\}$. From the framework of the Kostant–Adler scheme it follows that the functions $\{I_k^{m\pm}\}$ mutually commute inside each set: $\{I_k^{m\pm}, I_l^{n\pm}\}=0$, where $\{,\}$ is the standard Lie–Poisson bracket on $\tilde{\mathfrak{g}}_A$. In such a way we obtain two sets of integrable equations: the first set is generated by pairs of the Hamiltonians $\{I_k^{m+}\}$ and $\{I_l^{n+}\}$ and associated with the Lie algebra $\tilde{\mathfrak{g}}_A^+$ and the second set is associated with the Lie algebra $\tilde{\mathfrak{g}}_A^-$ and pairs of the Hamiltonians $\{I_k^{m-}\}$ and $\{I_l^{n-}\}$. Besides, like in the case of the ordinary loop algebras,[2] the scope of the Kostant–Adler (K–A) scheme can be extended, proving that $\{I_k^{m\pm}, I_l^{n\mp}\}=0$. This fact permits us to consider the third type of integrable equations generated by the Hamiltonians $\{I_k^{m\pm}\}$ and $\{I_l^{n\mp}\}$ and associated with the whole Lie algebra $\tilde{\mathfrak{g}}_A$. Although this set of equations contains in itself sets of equations connected with $\tilde{\mathfrak{g}}_A^{\pm}$, the last two are completely self-contained and could be considered separately. Hence, in the result, using the triple $(\tilde{\mathfrak{g}}_A, \tilde{\mathfrak{g}}_A^-, \tilde{\mathfrak{g}}_A^+)$ we obtain three types of integrable hierarchies: two "small" hierachies associated with $\tilde{\mathfrak{g}}_A^{\pm}$ and "large" hierarchy associated with $\tilde{\mathfrak{g}}_A$.

We show that for all the types of hierarchies their structure depends on the matrix of deformation A which play the role of the anisotropy tensor. There are two substantially different cases. The first case is connected with the nondegenerate matrices A. In this case the hierarchies connected with the algebras $\tilde{\mathfrak{g}}_A^+$ and $\tilde{\mathfrak{g}}_A^-$ are equivalent and yield integrable hierarchies that could be viewed as an "anisotropic deformation" of the generalized Heisenberg magnet hierarchy or a matrix generalization of the Landau–Lifshitz hierarchy. Large hierarchy connected with the whole algebra $\tilde{\mathfrak{g}}_A$ gives in case of the nondegenerate matrices A a new type of anisotropic chiral field equation. The second case is connected with the degenerated matrices A. In this case the hierarchies corresponding to the algebras $\tilde{\mathfrak{g}}_A^{\pm}$ cease to be equivalent. Moreover in the case of hierarchies associated with the algebras $\tilde{\mathfrak{g}}_A^+$ an additional reduction appears. Multiparametric character of the algebra $\tilde{\mathfrak{g}}_A$ gives us a new possibility to perform reduction procedure. Manipulating by these parameters (matrix elements of the matrix A) we can, in some cases, substantially simplify corresponding U-operator and reduce the number of its independent components. In the present paper we illustrate this by the simplest example of the minimally degenerated matrices A. In this case the integrable hierarchy, that corresponds to the algebra $\tilde{\mathfrak{g}}_A^+$ and $\mathfrak{g}=so(n)$, is a vector generalization of the Landau–Lifshitz hierarchy. Ordinary Landau–Lifshitz hierarchy corresponds to the case $\mathfrak{g}=so(4)$, $A=\mathrm{diag}(a_1,a_2,a_3,0)$. The large hierarchy connected with the whole algebra $\tilde{\mathfrak{g}}_A$ gives us in this degenerated case "coupled" generalized Landau–Lifshitz and generalized anisotropic chiral field hierarchies.

The structure of the present paper is the following: in the second section we introduce algebras $\tilde{\mathfrak{g}}_A$ and describe their properties, in the third section we describe infinite-dimensional Hamiltonian

systems on the algebras $\tilde{\mathfrak{g}}_A^{\pm}$ and $\tilde{\mathfrak{g}}_A$ possessing infinite sets of mutually commuting integrals. In the fourth section we consider the corresponding hierarchies of integrable equations admitting zero-curvature representations.

II. K–A ADMISSIBLE QUASIGRADED LIE ALGEBRAS

In this section we describe a new class of infinite-dimensional Lie algebras $\tilde{\mathfrak{g}}$ that could be used to generate classical integrable systems. These algebras satisfy the following integrability requirements (IR):

- (IR1) they possess an infinite number of algebraically independent invariants of coadjoint representation;
- (IR2) they are decomposable into the direct sum of two subalgebras: $\tilde{\mathfrak{g}}=\tilde{\mathfrak{g}}^{-}+\tilde{\mathfrak{g}}^{+}$; and
- (IR3) subalgebras $\tilde{\mathfrak{g}}^{+}$, $\tilde{\mathfrak{g}}^{-}$ possess infinite set of embedded ideals $\mathcal{J}_{\pm n}$ of finite codimensions.

A. General construction

Definition 1: Infinite-dimensional Lie algebra $\tilde{\mathfrak{g}}$ *is called* $\mathbb{Z}$*-quasigraded of type* (p,q)[10] *if it admits the decomposition*

$$\tilde{\mathfrak{g}}=\sum_{j\in\mathbb{Z}}\mathfrak{g}_j, \quad \textit{such that } [\mathfrak{g}_i,\mathfrak{g}_j]\subset\sum_{k=-p}^{q}\mathfrak{g}_{i+j+k}.$$

The following proposition holds true.[16]

Proposition 1: Let $\tilde{\mathfrak{g}}$ *be* $\mathbb{Z}$*-quasi graded of type* $(0,1)$, *or* $(1,0)$. *Then* $\tilde{\mathfrak{g}}$ *satisfies conditions* (*IR2*) *and* (*IR3*).

So our aim in this section will be a construction of $\mathbb{Z}$-quasi graded algebras of type $(0,1)$. For this purpose we will deform Lie algebraic structure in loop algebras. We will introduce into $L(\mathfrak{g})=\mathfrak{g}\otimes Pol(\lambda,\lambda^{-1})$ new Lie bracket

$$[X\otimes p(\lambda),Y\otimes q(\lambda)]_F=[X,Y]\otimes p(\lambda)q(\lambda)-F(X,Y)\otimes\lambda p(\lambda)q(\lambda), \tag{3}$$

where $X,Y\in\mathfrak{g}$, $p(\lambda),q(\lambda)\in Pol(\lambda,\lambda^{-1})$, $[,]$ in the right-hand side of this identity denotes ordinary Lie bracket in $\mathfrak{g}$ and map $F:\mathfrak{g}\times\mathfrak{g}\to\mathfrak{g}$ is skew. It is evident by the very construction that the Lie algebras with the so defined bracket are $\mathbb{Z}$-quasi graded Lie algebras of type $(0,1)$ with the quasigrading being defined in the standard way by degrees of the spectral parameter λ.

The following propositions answer the question when bracket (3) satisfies the Jacobi identity.

Proposition 2: For bracket (3) to satisfy the Jacobi identities the cochain F should satisfy the following two requirements:

$$(J1)\quad \sum_{c.p.\{i,j,k\}}([F(X_i,X_j),X_k]+[F(X_i,X_j),X_k])=0,$$

$$(J2)\quad \sum_{c.p.\{i,j,k\}}F(F(X_i,X_j),X_k)=0.$$

In the case of classical matrix Lie algebras it is possible to give an explicit construction of large (multiparametric) family of cochains F, that satisfy conditions $(J1)-(J2)$. Let $\mathfrak{g}$ be hereafter a classical matrix Lie algebra of the type $gl(n)$, $so(n)$, and $sp(n)$ over the field of the complex or real numbers. We will realize algebra $so(n)$ as algebra of skew-symmetric matrices: $so(n)=\{X\in gl(n)|X=-X^{\mathsf{T}}\}$ and algebra $sp(n)$ as the following matrix algebra: $sp(n)=\{X\in gl(n)|X=sX^{\mathsf{T}}s\}$, where n is an even number, $s\in so(n)$ and $s^2=-1$.

The following proposition holds true.

Proposition 3: Let $\mathfrak{g}$ *be a classical matrix Lie algebra over the field* $\mathbb{K}$ *of complex or real numbers. Let us define the numerical* ($\mathbb{K}$*-valued*) $n\times n$ *matrix A of the following type*:

(1) *A is arbitrary for $\mathfrak{g}=gl(n)$;*
(2) *$A=A^{\mathsf{T}}$ for $\mathfrak{g}=so(n)$;* and
(3) *$A=-sA^{\mathsf{T}}s$ for $\mathfrak{g}=sp(n)$.*

Then maps $F_A:\mathfrak{g}\times\mathfrak{g}\to\mathfrak{g}$ of the form $F_A(X,Y)=XAY-YAX$ are correctly defined skew symmetric maps that satisfy conditions (J1)–(J2).

Remark 1: Cocycle F_A defines a second Lie bracket in the finite dimensional Lie algebras $\mathfrak{g}$, that is compatible with the standard one. This fact was noticed in Ref. 11 and was used to construct compatible Poisson brackets on the finite-dimensional Lie algebras $\mathfrak{g}$. The idea to use the same cocycle to generate infinite-dimensional Lie algebras with Kostant–Adler decomposition was proposed in Ref. 12 as a natural generalization of semi-geometric construction of Refs. 13–16 of special quasigraded Lie algebras on the higher genus curves.

Definition 2: We will denote Lie bracket in the space $\mathfrak{g}$, defined by the cocycle F_A by $[,]_A$ and the corresponding finite-dimensional Lie algebra by $\mathfrak{g}_A$. We will denote infinite-dimensional space $\mathfrak{g}\otimes Pol(\lambda,\lambda^{-1})$ with the Lie bracket given by (3) *and cocycle F_A by $\widetilde{\mathfrak{g}}_A$.*

Lie bracket in the algebra $\widetilde{\mathfrak{g}}_A$ will have the following form:

$$[X(\lambda),Y(\lambda)]_{F_A}=[X(\lambda),Y(\lambda)]-\lambda[X(\lambda),Y(\lambda)]_A, \tag{4}$$

where $X(\lambda),Y(\lambda)\in L(\mathfrak{g})=\mathfrak{g}\otimes Pol(\lambda,\lambda^{-1})$, $A(\lambda)\equiv 1-\lambda A$, and we extend brackets $[,]$ and $[,]_A$ from Lie algebra $\mathfrak{g}$ to Lie algebra of $\mathfrak{g}$-valued functions $L(\mathfrak{g})$ in a natural way. This bracket can be also written in the more compact form as follows:

$$[X(\lambda),Y(\lambda)]_{F_A}\equiv[X(\lambda),Y(\lambda)]_{A(\lambda)}=X(\lambda)A(\lambda)Y(\lambda)-Y(\lambda)A(\lambda)X(\lambda). \tag{5}$$

Now we can introduce the convenient bases in the algebras $\widetilde{\mathfrak{g}}_A$. Due to the fact that we are dealing with matrix Lie algebras $\mathfrak{g}$, we will denote their basic elements as X_{ij}. For example, for the case $\mathfrak{g}=gl(n)$ we will have that $X_{ij}=I_{ij}$, where $(I_{ij})_{ab}=\delta_{ai}\delta_{bj}$ for the case $\mathfrak{g}=so(n)$ we will have that $X_{ij}=I_{ij}-I_{ji}$ etc. Let $X_{ij}^m\equiv X_{ij}\otimes\lambda^m$ be the natural basis in $\widetilde{\mathfrak{g}}_A$. Commutation relations (4) in this basis have the following form:

$$[X_{ij}^r,X_{kl}^m]_{F_A}=\sum_{p,q}C_{ij,kl}^{pq}X_{pq}^{r+m}-\sum_{p,q}C_{ij,kl}^{pq}(A)X_{pq}^{r+m+1}, \tag{6}$$

where $C_{ij,kl}^{pq}$ and $C_{ij,kl}^{pq}(A)$ are the structure constants of the Lie algebras $\mathfrak{g}$ and $\mathfrak{g}_A$, respectively.

Remark 2: Algebras $\widetilde{\mathfrak{g}}_A$ can be realized also in the space of special matrix valued functions of λ with an ordinary Lie bracket $[,]$. In particular in the case of the diagonal matrices A they can be realized as the special quasigraded Lie algebras on the higher genus curves (see Refs. 13–16). They can be also realized as *special quasigraded subalgebras* of $gl(n)$-loop algebras, which contrary to the graded subalgebras of loop algebras are not isomorphic to the corresponding loop algebras. Nevertheless we consider realization in the space $\mathfrak{g}\otimes Pol(\lambda,\lambda^{-1})$ with the "deformed" bracket to be the most convenient.

Remark 3: Contrary to the case of loop algebras our algebras $\widetilde{\mathfrak{g}}_A$ admit only one type of decomposition $\widetilde{\mathfrak{g}}_A=\widetilde{\mathfrak{g}}_A^+ + \widetilde{\mathfrak{g}}_A^-$ compatible with quasigrading, where the subalgebras $\widetilde{\mathfrak{g}}_A^{\pm}$ are defined in the natural way

$$\widetilde{\mathfrak{g}}_A^+=\mathrm{Span}_{\mathbb{K}}\{X_{ij}^m|m\geqslant 0\},\quad \widetilde{\mathfrak{g}}_A^-=\mathrm{Span}_{\mathbb{K}}\{X_{ij}^m|m<0\}. \tag{7}$$

The following proposition holds true.

Proposition 4: Let $\det A\neq 0$ then the algebra $\widetilde{\mathfrak{g}}_{A^{-1}}^-$ is isomorphic to the algebra $\widetilde{\mathfrak{g}}_A^+$.

Proof: This follows from the substitution of variables in the algebra $\widetilde{\mathfrak{g}}_A$: $\widetilde{X^{-n}}=A^{-1/2}X^{n-1}A^{-1/2}$, which maps generators of $\widetilde{\mathfrak{g}}_A^+$ into the generators of $\widetilde{\mathfrak{g}}_{A^{-1}}^-$.

Let us consider several examples of the algebra $\widetilde{\mathfrak{g}}_A$:

Example 1: Let $\mathfrak{g}=so(4)$ and matrix A be diagonal: $A=\mathrm{diag}(a_1,a_2,a_3,a_4)$. In this case commutation relations will be more simple if we introduce standard basis in $so(4)$ algebra. Putting

$X_k^n \equiv \epsilon_{ijk} X_{ij}^n$, $Y_k^m \equiv X_{i4}^m$ where $i,j,k \in 1,3$ we obtain the following commutation relations for the $\widetilde{so(4)_A}$:

$$[X_i^r, X_j^s] = \epsilon_{ijk} X_k^{r+s} - \epsilon_{ijk} a_k X_k^{r+s+1}, \tag{8a}$$

$$[X_i^r, Y_j^r] = \epsilon_{ijk} Y_k^{r+s} - \epsilon_{ijk} a_j Y_k^{r+s+1}, \tag{8b}$$

$$[Y_i^r, Y_j^s] = \epsilon_{ijk} X_k^{r+s} - a_4 \epsilon_{ijk} X_k^{r+s+1}. \tag{8c}$$

In the case when $a_4 = 0$ this algebra coincides with anisotropic affine algebra discovered in Ref. 17 (see also Ref. 18) in the connection with the integrability of Landau–Lifshitz equations.

B. Coadjoint representation and its invariants

In this subsection we define dual spaces, coadjoint representations and their invariants for the Lie algebras $\tilde{\mathfrak{g}}_A$. Let us at first explicitly describe the dual space $\tilde{\mathfrak{g}}_A^*$ of $\tilde{\mathfrak{g}}_A$. For this purpose we will define the pairing between $\tilde{\mathfrak{g}}_A$ and $\tilde{\mathfrak{g}}_A^*$ in the following standard way:

$$\langle X, L \rangle = \mathrm{res}_{\lambda=0} \mathrm{Tr}\,(X(\lambda) L(\lambda)). \tag{9}$$

The generic element of the dual space $L(\lambda) \in \tilde{\mathfrak{g}}_A^*$ is written as follows:

$$L(\lambda) = \sum_{k \in Z} \sum_{i,j=1,n} l_{ij}^{(k)} \lambda^{-(k+1)} X_{ij}^*. \tag{10}$$

The following proposition holds true:[12]

Proposition 5: The coadjoint action of the algebra $\tilde{\mathfrak{g}}_A$ on the dual space $\tilde{\mathfrak{g}}_A^*$ has the form

$$ad^*_{X(\lambda)} \circ L(\lambda) = A(\lambda) X(\lambda) L(\lambda) - L(\lambda) X(\lambda) A(\lambda), \tag{11}$$

where $X(\lambda), Y(\lambda) \in \tilde{\mathfrak{g}}_A$, $L(\lambda) \in \tilde{\mathfrak{g}}_A^*$.

Remark 4: Note that linear spaces $\tilde{\mathfrak{g}}_A$ and $\tilde{\mathfrak{g}}_A^*$ do not coincide as $\tilde{\mathfrak{g}}_A$-modules. Moreover, rigorously speaking, they also do not coincide as linear spaces because $\tilde{\mathfrak{g}}_A^*$ contains formal power series, and $\tilde{\mathfrak{g}}_A$, by the very definition, consists of the Loran polynomials.

Proposition 5 has the following important corollary.

Corollary 1: Let $L(\lambda)$ be the generic element of $\tilde{\mathfrak{g}}_A^*$. Then the functions

$$I_k^m(L(\lambda)) = \frac{1}{m} \mathrm{res}_{\lambda=0} \lambda^{-(k+1)} \mathrm{Tr}\,(L(\lambda) A(\lambda)^{-1})^m \tag{12}$$

are invariants of the coadjoint representation of $\tilde{\mathfrak{g}}_A$.

Remark 5: Matrix $A(\lambda)^{-1} \equiv (1 - \lambda A)^{-1}$ has to be understood as a power series in λ in the neighborhood of 0 or ∞: $A(\lambda)^{-1} = (1 + A\lambda + A^2\lambda^2 + \cdots)$ or $A(\lambda)^{-1} = -(A^{-1}\lambda^{-1} + A^{-2}\lambda^{-2} + \cdots)$.

Remark 6: We will also use invariants of the Lie algebras $\widetilde{so(2n)_A}$ of the form

$$P_k(L(\lambda)) = \mathrm{res}_{\lambda=0} \lambda^{-(k+1)} Pf(L(\lambda)). \tag{13}$$

They can be expressed as functions of the invariants introduced in corollary 1.

C. Lie–Poisson structure

Let us define the Poisson structures in the space $\tilde{\mathfrak{g}}_A^*$ using the defined earlier pairing $\langle , \rangle$. It defines Lie–Poisson (Kirillov–Kostant) bracket on $P(\tilde{\mathfrak{g}}_A^*)$ in the following standard way:

$$\{F(L(\lambda)), G(L(\lambda))\} = \langle L(\lambda), [\nabla F(L(\lambda)), \nabla G(L(\lambda))]_{A(\lambda)} \rangle, \tag{14}$$

where $\nabla F(L(\lambda)) = \Sigma_{k \in Z} \Sigma_{i,j=1}^n [\partial F / \partial l_{ij}^{(k)}] X_{ij}^k$, $\nabla G(L) = \Sigma_{m \in Z} \Sigma_{k,l=1}^n [\partial G(\lambda) / \partial l_{kl}^{(m)}] X_{kl}^m$.

From corollary 1 and standard arguments follows the next statement.

Proposition 6: Functions $I_k^m(L(\lambda))$ are central for the Lie–Poisson bracket (14).

Let us explicitly calculate Poisson bracket (14). It is easy to show that for the coordinate functions $l_{ij}^{(m)}$ these brackets will have the following form:

$$\{l_{ij}^{(n)}, l_{kl}^{(m)}\} = \sum_{p,q} C_{ij,kl}^{pq} l_{pq}^{(n+m)} - \sum_{p,q} C_{ij,kl}^{pq}(A) l_{pq}^{(n+m+1)}. \tag{15}$$

It is evident that this bracket determines in the space of linear functions $\{l_{ij}^{(n)}\}$ a structure of the Lie algebra isomorphic to $\tilde{\mathfrak{g}}_A$. That is why the corresponding Poisson algebra possesses decomposition into direct sum of two Poisson subalgebras or, in other words, subspaces $(\tilde{\mathfrak{g}}_A^{\pm})^*$ are Poisson.

III. INFINITE-DIMENSIONAL HAMILTONIAN SYSTEMS VIA K–A ADMISSIBLE LIE ALGEBRAS

In the previous section we have constructed infinite-dimensional Lie algebras $\tilde{\mathfrak{g}}_A$ that have a decomposition into direct sum of two subalgebras and possess an infinite set of invariants of coadjoint representation, i.e., admit so-called the Kostant–Adler scheme. In this section we apply the Kostant–Adler scheme and its extension to $\tilde{\mathfrak{g}}_A$ in order to construct an infinite set of mutually commuting (with respect to the natural Lie–Poisson bracket) functions on $\tilde{\mathfrak{g}}_A^{\pm}$ and $\tilde{\mathfrak{g}}_A$ and obtain a "deformed" Lax representation for the corresponding Hamiltonian equations.

A. Integrable Hamiltonian systems connected with algebras $\tilde{\mathfrak{g}}_A^{\pm}$

Let $L^{\mp}(\lambda) \equiv \Sigma_{i,j=1,n} L_{ij}^{\mp}(\lambda) X_{ji} = \Sigma_{k \in \mathbb{Z}_{\pm}} \Sigma_{i,j=1,n} l_{ij}^{(k)} \lambda^{-(k+1)} X_{ji}$ be the generic elements of the spaces $(\tilde{\mathfrak{g}}_A^{\pm})^*$. Let us consider restriction of the invariant functions $\{I_k^m(L(\lambda))\}$ onto these subspaces. Note, that although Poisson subspaces $(\tilde{\mathfrak{g}}_A^{\pm})^*$ are infinite dimensional, all functions $\{I_k^m(L^{\pm}(\lambda))\}$ are polynomials, i.e., after restriction to $(\tilde{\mathfrak{g}}_A^{\pm})^*$ no infinite sums appear in their explicit expressions. Corresponding Hamiltonian equations are written as

$$\frac{\partial L_{ij}^{\mp}(\lambda)}{\partial t_k^m} = \{L_{ij}^{\mp}(\lambda), I_k^m(L^{\mp}(\lambda))\}. \tag{16}$$

The following important theorem holds true.

Theorem 1: (*i*) *Time flows defined by Eq. (16) mutually commute.* (*ii*) *Euler–Arnold equations (16) are written in the deformed Lax form*

$$\frac{\partial L^{\mp}(\lambda)}{\partial t_k^m} = A(\lambda) M_k^m(\lambda) L^{\mp}(\lambda) - L^{\mp}(\lambda) M_k^m(\lambda) A(\lambda), \tag{17}$$

where $M_k^m(\lambda) = \nabla I_k^m(L^{\mp}(\lambda)) \equiv \Sigma_{s \in \mathbb{Z}_{\pm}} \Sigma_{i,j=1}^n [\partial I_k^m / \partial l_{ij}^{(s)}] X_{ij}^s$ *is an algebra-valued gradient of* $I_k^m(L^{\mp}(\lambda))$. (*iii*) *Functions* $I_l^n(L^{\pm})$ *are constant along all times* $t_k^{m\pm}$: $[\partial I_l^n(L^{\pm}) / \partial t_k^{m\pm}] = 0$.

Proof of the theorem follows from the general framework of the Kostant–Adler scheme.[8]

Remark 7: Using earlier mentioned realizations of $\tilde{\mathfrak{g}}_A$ deformed Lax equations could be rewritten in the forms of the standard Lax equations, but in this case corresponding $L-M$ pairs will be more complicated and we prefer to work with the Lax equations in the "deformed" form (17).

B. Integrable Hamiltonian systems connected with algebras $\tilde{\mathfrak{g}}_A$

Let us now extend our phase space from $(\tilde{\mathfrak{g}}_A^{\pm})^*$ to the whole space $\tilde{\mathfrak{g}}_A^*$ and extend corresponding Hamiltonian flows. In other words, let us consider the same Hamiltonians as functions on the extended phase space. Corresponding Hamiltonian equations are written in the standard way

$$\frac{\partial L_{ij}(\lambda)}{\partial_k^{m\mp} t} = \{L_{ij}(\lambda), I_k^m(L^{\mp}(\lambda))\}. \tag{18}$$

Note, that on the extended phase space there are two types of the Hamiltonian flows: "positive" flows defined by the Hamiltonians $I_k^m(L^+(\lambda))$ and "negative" flows defined by the Hamiltonians $I_l^n(L^-(\lambda))$. A remarkable fact is positive time flows commute with negative ones. The following analog of theorem 1 holds true.

Theorem 2: *The time flows defined by Eq. (18) commute for all times* t_k^{m+}, t_l^{n-}.

(*ii*) *Euler–Arnold equations (18) could be written in the deformed Lax form*

$$\frac{\partial L(\lambda)}{\partial t_k^{m\mp}} = A(\lambda) M_k^{m\mp}(\lambda) L(\lambda) - L(\lambda) M_k^{m\mp}(\lambda) A(\lambda), \tag{19}$$

where $M_k^{m\mp}(\lambda) = \nabla I_k^m(L^{\mp}(\lambda)) \equiv \Sigma_{s\in\mathbb{Z}_\pm} \Sigma_{i,j=1}^n [\partial I_k^m / \partial l_{ij}^{(s)}] X_{ij}^s$.

(*iii*) *The functions* $I_q^p(L^{\pm})$ *are constant along all times* $t_k^{m\pm}$ *and* $t_l^{n\mp}$.

Proof of this theorem is analogous to the proof of the corresponding theorem for the case of the loop algebras (see Ref. 4, and references therein).

Remark 8: Note that theorem 2 does not follow directly from the Kostant–Adler scheme[8] because commutativity of the time flows (18) implies commutativity of the corresponding Hamiltonians $I_k^m(L^{\pm}(\lambda)), I_l^n(L^{\mp}(\lambda))$ with respect to the initial Lie–Poisson bracket on $\tilde{\mathfrak{g}}_A^*$ (commutativity of these functions with respect to the r-matrix bracket $\{,\}_0$ (see Ref. 8) follows trivially from theorem 1).

In this section we have obtained Hamiltonian systems of the Euler–Arnold type on the special infinite-dimensional Lie algebras posessing infinite number of the commuting integrals of motion. These Hamiltonian systems, despite being infinite-dimensional are "mechanical" because they are described by ordinary differential equations. Nevertheless we can consider our dynamical variables $l_{ij}^{(p)}$ to be functions of all time variables $t_k^{m\pm}$ and using the commutativity of all time flows obtain differential identities on functions $l_{ij}^{(p)}(t_k^{m\pm})$, that coincide with the wanted integrable equations in partial derivatives. For this purpose in the next section we will derive an analog of zero-curvature equations.

IV. DEFORMED ZERO CURVATURE EQUATIONS

In this section we will obtain zero curvature-type equations as compatibility conditions for the set of the commutative Hamiltonian flows constructed in the previous section.

The following theorem holds true.

Theorem 3: *Let infinite-dimensional Lie algebras* $\tilde{\mathfrak{g}}_A$, $\tilde{\mathfrak{g}}_A^{\pm}$, *their dual spaces and polynomial Hamiltonians* $I_k^m(L^{\pm}(\lambda))$, $I_l^n(L^{\pm}(\lambda))$ *on them be defined as in previous sections. Then algebra-valued gradients of these functions satisfy the deformed zero-curvature equations*

$$\frac{\partial \nabla I_k^m(L^{\pm}(\lambda))}{\partial t_l^{n\pm}} - \frac{\partial \nabla I_l^n(L^{\pm}(\lambda))}{\partial t_k^{m\pm}} + [\nabla I_k^m(L^{\pm}(\lambda)), \nabla I_l^n(L^{\pm}(\lambda))]_{A(\lambda)} = 0, \tag{20}$$

$$\frac{\partial \nabla I_k^m(L^{\pm}(\lambda))}{\partial t_l^{n\mp}} - \frac{\partial \nabla I_l^n(L^{\mp}(\lambda))}{\partial t_k^{m\pm}} + [\nabla I_k^m(L^{\pm}(\lambda)), \nabla I_l^n(L^{\mp}(\lambda))]_{A(\lambda)} = 0. \tag{21}$$

Proof of this theorem is analogous to the proof of the analogous theorem of Ref. 16.

Remark 9: Using earlier mentioned realizations of $\tilde{\mathfrak{g}}_A$ deformed zero-curvature equations can be rewritten in the form of the standard zero-curvature equations, but in this case corresponding $U-V$ pairs will be more complicated and we will work with zero-curvature equations in the deformed form (20) and (21).

Theorem 3 provides us with an infinite number of $\tilde{\mathfrak{g}}_A^{\pm}$-valued $U-V$ pairs that satisfy zero curvature-type equations. The latter are nonlinear equations in the partial derivatives on the dynamical variables—matrix elements of the matrices $L^{\pm}(\lambda)$. In the terminology of Ref. 3 equations

generated by the infinite set of $U-V$ pairs are called "integrable in the kinematic sense." In the next subsections we will consider the simplest examples of such integrable equations and their hierarchies. We distinguish three types of hierarchies connected with the algebras $\tilde{\mathfrak{g}}_A^{\pm}$ and $\tilde{\mathfrak{g}}_A$. For the case of integrable hierarchies connected with $\tilde{\mathfrak{g}}_A^{\pm}$ we should consider only Eq. (20) while considering hierarchies connected with $\tilde{\mathfrak{g}}_A$ we should consider both Eqs. (20) and (21), which reflects the fact, that we have in this case both positive and negative flows.

Now we will explain in more detail the technique of obtaining integrable equations in partial derivatives starting from zero-curvature equations. Let us at first note that in the described approach no space variable x is *a priori* singled out: all times $t_k^{m\pm}$ are equivalent. Fixation of the space flow is equivalent to the fixation of integrable hierarchy. For this purpose one should fix Hamiltonians that generate x-flow. For the case of integrable systems, connected with algebras $\tilde{\mathfrak{g}}_A^*$ this choice yields fixation of dynamical variables. In more detail, for the dynamical variables in this case serve the matrix elements of $U \equiv \nabla I_k^m(L^{\mp}(\lambda))$, where Hamiltonian $I_k^m(L^{\mp}(\lambda))$ is chosen to generate an x-flow. Using zero-curvature conditions one can express matrix elements of all other matrix gradients $\nabla I_l^n(L^{\mp}(\lambda))$ via these dynamical variables and their derivatives with respect to the space coordinate. Substituting these expressions back to zero-curvature condition we obtain the wanted equation in partial derivatives on the matrix elements of $\nabla I_k^m(L^{\mp}(\lambda))$.

For the case of integrable systems associated with the whole algebras $\tilde{\mathfrak{g}}_A$ there are two types of Hamiltonians and two types of flows. That is why in this case the number of independent dynamical variables may be doubled: their role is played by matrix elements of $\nabla I_k^m(L^+(\lambda))$and $\nabla I_l^n(L^-(\lambda))$ that generate evolution with respect to x_+ and x_- correspondingly.

V. INTEGRABLE HIERARCHIES ASSOCIATED WITH ALGEBRAS $\tilde{\mathfrak{g}}_A^-$

In this section we will obtain integrable hierarchies of differential equations in partial derivatives, admitting a zero curvature type representation (20) with the values in $\tilde{\mathfrak{g}}_A^-$.

Let us consider dual space $(\tilde{\mathfrak{g}}_A^-)^*$. Its generic element has the following form:

$$L^+(\lambda) = \sum_{k<0} \sum_{i,j=1,n} l_{ij}^{(k)} \lambda^{-(k+1)} X_{ji} = L^{(-1)} + L^{(-2)} + \lambda^2 L^{(-3)} + \lambda^3 L^{(-4)} + \cdots, \tag{22}$$

where $L^{(-k)} \equiv \Sigma_{i,j=1,n} l_{ij}^{(-k)} X_{ji}$. Let us now calculate the Hamiltonians $I_k^m(L^+(\lambda))$. In order for the Hamiltonians $I_k^m(L^+(\lambda))$ to be polynomials we have to expand expression $A(\lambda)^{-1}$ in the power series in the neighborhood of zero: $A(\lambda)^{-1} = 1 + A\lambda + A^2\lambda^2 + \cdots$. From the results of the previous section it follows that the matrix gradients of Hamiltonians $I_k^m(L^+(\lambda))$ satisfy deformed zero-curvature Eq. (20). We will be interested in the two simplest Hamiltonians of the set $I_k^2(L^+(\lambda))$. By the direct calculations we obtain for them the following expressions:

$$I_0^2(L^+(\lambda)) = 1/2 \operatorname{Tr}(L^{(-1)})^2, \quad I_1^2(L^+(\lambda)) = \operatorname{Tr}(A(L^{(-1)})^2) + \operatorname{Tr}(L^{(-1)}L^{(-2)}). \tag{23}$$

The corresponding matrix gradients are

$$\nabla I_0^2(L^+(\lambda)) = L^{(-1)}\lambda^{-1}, \quad \nabla I_1^2(L^+(\lambda)) = L^{(-1)}\lambda^{-2} + ((AL^{(-1)} + L^{(-1)}A) + L^{(-2)})\lambda^{-1}. \tag{24}$$

As it follows from the earlier work, in order to fix integrable hierarchy we should choose the Hamiltonian, that generates x-flow. We will take for such the Hamiltonian function $I_0^2(L^+(\lambda))$, putting $t_0^{2+} \equiv x$, $\nabla I_0^2(L^+(\lambda)) \equiv U(x,\lambda)$, $\nabla I_k^m(L^+(\lambda)) \equiv V_k^m(x,\lambda), m,k>0$ as the basic $U-V$ pairs that generate this hierarchy. In this case the role of the dynamical variables is played by the matrix elements of the matrix $L^{(-1)}$.

A. Matrix generalization of the Landau–Lifshitz equation

In this subsection we will obtain an explicit form of the simplest equation of the earlier described hierarchy. For this purpose we have to choose a Hamiltonian that generates "time" flow

in the simplest possible way. We take for such Hamiltonian the function $I_1^2(L^+(\lambda))$, i.e., $t \equiv t_1^{2+}$. In the result we obtain that zero-curvature Eq. (20) is equivalent to the following λ-independent equations:

$$\frac{\partial L}{\partial t} - \frac{\partial M}{\partial x} = [L, M]_A, \tag{25a}$$

$$\frac{\partial L}{\partial x} = [L, M], \tag{25b}$$

where $L \equiv L^{(-1)}, M \equiv L^{(-2)} + (AL^{(-1)} + L^{(-1)}A)$.

In order to obtain equations in partial derivatives on the dynamical variables—matrix elements of the matrix L it is necessary to solve Eq. (25b), i.e., to express M via L and L_x and then substitute this expression into Eq. (25a). We will illustrate this procedure on the simplest, but most interesting example and show that corresponding equation coincides with matrix generalization of the Landau–Lifshitz equation.

Let $\mathfrak{g} = gl(n)$, $so(2n)$, or $sp(n)$. In this case in order to solve Eq. (25b), i.e., in order to obtain instead of two Eqs. (25a) and (25b) one matrix equation in partial derivatives it is necessary to impose additional constraint on the matrix L[15] (a similar situation holds for the Heisenberg magnet hierarchies associated with the higher rank algebras[19,20]). We will chose the simplest G-invariant form of such matrix constraint

$$L^2 = -\tfrac{1}{4}E, \tag{26}$$

where E is a unit matrix. This constraint means that L belongs to the degenerated coadjoint orbits of G of the following type: $Gl(n)/GL(p) \times GL(q)$, $SO(2n)/Gl(n)$, or $SP(n)/GL(n)$.

On this orbit we may solve Eq. (25b) in the next way

$$M = -\left[L, \frac{\partial L}{\partial x}\right] + M', \text{ where } M' \in \ker ad_L.$$

Ambiguity connected with the existence of $\ker ad_L$ is removed by the requirement that the constraint (26) is consistent with Eqs. (25a) and (25b). The following proposition is true.

Proposition 7: Let $M' = 1/2(AL + LA)$. *Then the constraint (26) is consistent with Eqs. (25a) and (25b), i.e.,* $(\partial L^2/\partial x)|_{L^2=-(1/4)E} = 0$ *and* $(\partial L^2/\partial t)_{L^2=-(1/4)E} = 0$.

Proposition is proved by direct verification.

The resulting equation acquires the following form:

$$\frac{\partial L}{\partial t} = -\left[L, \frac{\partial^2 L}{\partial x^2}\right] + \frac{1}{2}\frac{\partial}{\partial x}(AL + LA) - \left[L, \left[L, \frac{\partial L}{\partial x}\right]\right]_A + \frac{1}{2}[L, AL + LA]_A, \tag{27}$$

where $L^2 = -\frac{1}{4}E$. This equation is an "anisotropic" generalization of the Heisenberg magnet equation. Let us also show that it coincides with matrix generalization of the Landau–Lifshitz equation. In order to do this we will consider the following example.

Example 2: Let $\mathfrak{g} = so(4)$, $\mathrm{Tr}\, A = 0$ and matrix L satisfy G-invariant constraint (26). In this case it is easy to show that matrix S can be written in the form

$$L = \begin{pmatrix} 0 & -s_3 & s_2 & s_1 \\ s_3 & 0 & -s_1 & s_2 \\ -s_2 & s_1 & 0 & s_3 \\ -s_1 & -s_2 & -s_3 & 0 \end{pmatrix},$$

where three-component vector $\boldsymbol{s}$ belongs to $S^2 = SO(3)/SO(2) = SO(4)/SO(3) \times SO(2)$:

$$\langle \boldsymbol{s},\boldsymbol{s}\rangle = 1/4.$$

As a result of the special form of matrix L, the second and third items of the right-hand side of Eq. (27) conceal and it could be rewritten as equation for the vector $\boldsymbol{s}$ as follows:

$$\frac{\partial \boldsymbol{s}}{\partial t} = \left[\boldsymbol{s} \times \frac{\partial^2 \boldsymbol{s}}{\partial x^2}\right] + [\boldsymbol{s} \times J(\boldsymbol{s})],$$

where $J=1/4(\hat{A}^2-2a_4\hat{A})$, $\hat{A}=\mathrm{diag}(a_1,a_2,a_3)$. This is the famous Landau–Lifshitz equation.

In such a way we have obtained that the case $\mathfrak{g}=so(4)$ in Eq. (27) corresponds to the Landau–Lifshitz equation. Hence, Eq. (27) could be indeed considered as a direct matrix generalization of the Landau–Lifshitz equation.

B. Other equations from the hierarchy. Anisotropic chiral field equations

In this subsection we will show that the hierarchy of differential equations associated with $\widetilde{\mathfrak{g}}_A^-$ include [except Eqs. (25a) and (25b)] other interesting equations. In order to obtain such equations we have to choose other Hamiltonians that generate time flows. For this purpose, we will consider also Hamiltonians $P(L^+(\lambda))$. We will be interested in the simplest Hamiltonian of this power series, namely in $P_0(L^+(\lambda))$. Direct calculation gives

$$P_0(L^+(\lambda)) = P(L^{(-1)}), \tag{28}$$

where $P(L)\equiv\det(L)$ if $\mathfrak{g}=gl(n)$ or $\mathfrak{g}=sp(n)$, $P(L)\equiv\mathrm{Pf}(L)$ if $\mathfrak{g}=so(n)$ and n is even. Its matrix gradient has the following form:

$$\nabla P_0(L^+(\lambda)) = \sum_{i,j=1}^{n} \frac{\partial P(L^{(-1)})}{\partial l_{ij}^{(-1)}} X_{ij}\lambda^{-1}. \tag{29}$$

The corresponding zero-curvature condition yields the following λ-independent equation:

$$\frac{\partial L}{\partial \tau} - \frac{\partial M}{\partial x} = -[L,M]_A, \tag{30}$$

where $L\equiv L^{(-1)}$, $M\equiv\nabla P$ and we have used that $[L,M]=0$ due to the G-invariance of P. Equation (30) is, in some sense, the higher rank generalization of the ordinary $so(3)$-anisotropic chiral field equation. In order to show this we consider the following example.

Example 3: Let $\mathfrak{g}=so(4)$. The corresponding Lax operator $L\in so(4)$ has the form

$$L = \sum_{1\leqslant i<j\leqslant 3} l_{ij}X_{ij} + \sum_{1\leqslant i\leqslant 3} l_{ij}X_{i4} \equiv \sum_{1\leqslant k\leqslant 3} l_k^+ X_k + \sum_{1\leqslant k\leqslant 3} l_k^- Y_k,$$

where $X_k\equiv\epsilon_{ijk}X_{ij}$, $Y_k\equiv X_{k4}$, $l_k^+\equiv\epsilon_{ijk}l_{ij}$, $l_k^-\equiv l_{k4}$. Introducing the vectors $l^+=\Sigma_{1\leqslant k\leqslant 3}l_k^+X_k$, $l^-=\Sigma_{1\leqslant k\leqslant 3}l_k^-Y_k$, $L\equiv l^++l^-$ we obtain for our Hamiltonians the following expressions:

$$I_0^2(L) = 1/2((l^+,l^+)+(l^-,l^-)), \quad P_0^2(L) = (l^+,l^-).$$

The corresponding matrix gradients are easily calculated to be the following:

$$\nabla I_0^2(L) \equiv \lambda^{-1}L, \quad \nabla P_0^2(L) \equiv \lambda^{-1}M = \lambda^{-1}\left(\sum_{1\leqslant k\leqslant 3} l_k^- X_k + \sum_{1\leqslant k\leqslant 3} l_k^+ Y_k\right). \tag{31}$$

Let us hereafter assume that matrix $A\in\mathrm{Symm}(4)$ is diagonal: $A=\mathrm{diag}(a_1,a_2,a_3,a_4)$. By direct calculation, using commutation relations

$$[X_i,X_j]_A = \epsilon_{ijk}a_kX_k, \quad [X_i,Y_j]_A = \epsilon_{ijk}a_jY_k, \quad [Y_i,Y_j]_A = a_4\epsilon_{ijk}X_k, \tag{32}$$

we obtain the following differential equations for components of vectors $l^\pm$:

$$\frac{\partial l_i^+}{\partial \tau} - \frac{\partial l_i^-}{\partial x} = a_i \epsilon_{ijk} l_j^+ l_k^- + a_4 \epsilon_{ijk} l_j^+ l_k^-, \quad \frac{\partial l_i^-}{\partial \tau} - \frac{\partial l_i^+}{\partial x} = \epsilon_{ijk} l_j^+ a_k l_k^+ - \epsilon_{ijk} l_j^- a_k l_k^-. \tag{33}$$

Introducing vectors u, v with the components $u_i = l_i^+ + l_i^-$, $v_i = l_i^+ - l_i^-$ and new "light-cone" coordinates $\xi \equiv \tau - x$, $\eta \equiv \tau + x$ we can rewrite Eqs. (33) in the following form:

$$\frac{\partial u_i}{\partial \xi} = 1/2(-a_i \epsilon_{ijk} u_j v_k - a_4 \epsilon_{ijk} u_j v_k + \epsilon_{ijk} u_j a_k v_k + \epsilon_{ijk} v_j a_k u_k),$$

$$\frac{\partial v_i}{\partial \eta} = 1/2(-a_i \epsilon_{ijk} u_j v_k - a_4 \epsilon_{ijk} u_j v_k - \epsilon_{ijk} u_j a_k v_k - \epsilon_{ijk} v_j a_k u_k).$$

Taking into account that $\epsilon_{ijk}(a_i + a_j + a_k) \equiv (a_1 + a_2 + a_3)\epsilon_{ijk}$ and putting for simplicity $\mathrm{Tr}\, A \equiv a_1 + a_2 + a_3 + a_4 = 0$ we obtain that the last equations are written as follows:

$$\frac{\partial u_i}{\partial \xi} = \epsilon_{ijk} u_j a_k v_k, \quad \frac{\partial v_i}{\partial \eta} = \epsilon_{ijk} a_j u_j v_k \tag{34}$$

or, introducing matrix $\hat{A} = \mathrm{diag}(a_1, a_2, a_3)$ we can rewrite Eqs. (24) in vector form

$$\frac{\partial u}{\partial \xi} = [u \times \hat{A}(v)], \quad \frac{\partial v}{\partial \eta} = [\hat{A}(u) \times v]. \tag{35}$$

Equations (35) are the standard anisotropic $so(3)$-chiral field equations[21] (see also Refs. 18 and 22, and references therein). They satisfy two second order constraints

$$(\boldsymbol{u}, \boldsymbol{u}) = c_1, \quad (\boldsymbol{v}, \boldsymbol{v}) = c_2. \tag{36}$$

that follow from the constancy of the Hamiltonians $I_0^2(L)$ and $P_0^2(L)$ along all time flows.

Remark 10: Considered earlier $so(4)$-example is very special. Resulting decomposition of Eq. (30) in a pair of Eqs. (35) is a consequence of the fact that the algebra $so(4)$ is decomposed into the direct sum of two $so(3)$ subalgebras. That is why, in the general case, Eq. (30) could not be transformed into the simple form of Eqs. (35).

VI. INTEGRABLE HIERARCHIES ASSOCIATED WITH ALGEBRAS $\widetilde{\mathfrak{g}}_A^+$

In this section we consider integrable hierarchies admitting the deformed zero-curvature representation with $U-V$ pairs taking the value in the algebra $\widetilde{\mathfrak{g}}_A^+$. The generic element of the dual space $(\widetilde{\mathfrak{g}}_A^+)^*$ has the following form:

$$L^-(\lambda) = \sum_{k \geqslant 0} \sum_{i,j=1,n} l_{ij}^{(k)} \lambda^{-(k+1)} X_{ji} = \lambda^{-1} L^{(0)} + \lambda^{-2} L^{(1)} + \lambda^{-3} L^{(2)} + \cdots, \tag{37}$$

where $L^{(k)} \equiv \Sigma_{i,j=1,n} l_{ij}^{(k)} X_{ji}$. Contrary to the case of the algebra $\widetilde{\mathfrak{g}}_A^-$ the structure of the hierarchy will strongly depend on the form of the matrix A. There will be two essentially different cases: the case that corresponds to the nondegenerated matrices A and the case that corresponds to the degenerated matrices A. We begin with the first case.

A. Hierarchies connected with the nondegenerated matrices *A*

Let us consider Hamiltonians $I_k^m(L^-(\lambda))$ in case $\det A \neq 0$. In order for these Hamiltonians to be well-defined we have to expand expression $A(\lambda)^{-1}$ in the power series in the neighborhood of infinity: $A(\lambda)^{-1} = -(A^{-1}\lambda^{-1} + A^{-2}\lambda^{-2} + A^{-3}\lambda^{-3} + \cdots)$. In this case all functions $I_k^m(L^-(\lambda))$ are polynomials in the dynamical variables $l_{ij}^{(k)}$. Hence, as it follows from the results of the previous sections,

their matrix gradients satisfy deformed zero-curvature Eq. (20). Let us consider corresponding Hamiltonians. For the first two Hamiltonians of the set $I_k^2(L^-(\lambda))$ we obtain the following expressions:

$$I_{-4}^2(L^-(\lambda)) = \tfrac{1}{2}\,\mathrm{Tr}\,(A^{-1}L^{(0)})^2, \quad I_{-5}^2(L^+(\lambda)) = \mathrm{Tr}\,(A^{-1}(A^{-1}L^{(0)})^2) + \mathrm{Tr}\,(A^{-1}L^{(0)}A^{-1}L^{(1)}).$$

Their matrix gradients are

$$\nabla I_{-4}^2(L^-(\lambda)) = A^{-1}L^{(0)}A^{-1}, \quad \nabla I_{-5}^2(L^-(\lambda)) = A^{-1}(L^{(0)}\lambda + ((A^{-1}L^{(0)} + L^{(0)}A^{-1}) + L^{(1)}))A^{-1}. \quad (38)$$

By direct calculation it is easy to show that corresponding zero-curvature Eq. (20) after substitution: $L^{(-1)}=A^{-1/2}L^{(0)}A^{-1/2}$, $M=A^{-1/2}(L^{(1)}+(A^{-1}L^{(0)}+L^{(0)}A^{-1}))A^{-1/2}$ coincide with Eqs. (25) with matrix A replaced by the matrix A^{-1}. Hence, $U-V$ pair (38) gives differential equations equivalent to Eqs. (25). Corresponding hierarchies will also be equivalent. This equivalence is a consequence of the fact that in the case of the nondegenerated matrices A algebras $\tilde{\mathfrak{g}}_A^+$ and $\tilde{\mathfrak{g}}_{A^{-1}}^-$ are isomorphic. We will use these Lax pairs and the corresponding Hamiltonians in the next subsections, in particular, considering integrable equations connected with the whole algebra $\tilde{\mathfrak{g}}_A$.

B. Hierarchies connected with the degenerated matrices *A*

In this subsection we will consider integrable hierarchy connected with the algebras $\tilde{\mathfrak{g}}_A^+$ and degenerated matrices A. We will restrict ourselves to the consideration of the case of the "minimal" degeneracy of A, i.e., when rank $A=n-1$ and the case of the algebras $\mathfrak{g}=so(n)$. We will show that simplest of the corresponding hierarchies coincide with the vector generalization of the Landau–Lifshitz hierarchy.

Let us now consider the corresponding hierachies in details. Without the loss of the generosity we will put $A=\mathrm{diag}(A',0)$, where $A'\in \mathrm{Symm}(n-1)$. Let us consider commuting second order integrals (Hamiltonians), that generate our hierarchies. For this purpose we will consider block-diagonal nondegenerate matrices $\mathcal{A}$ of the type: $\mathcal{A}=A+aI$, where A is the earlier described matrix, $I=\mathrm{diag}(0,0,\ldots,0,1)$. By the very definition $A=\lim_{a\to 0}\mathcal{A}$. We will consider commuting integrals of the systems connected with $\tilde{\mathfrak{g}}_A^+$ and obtain the corresponding commuting integrals on $\tilde{\mathfrak{g}}_A^+$ as a limiting case of the commuting integrals on $\tilde{\mathfrak{g}}_{\mathcal{A}}^+$. Commuting integrals of the series $I^r(L^-(\lambda))$ contain expression $\mathcal{A}^{-1}$ and in the limit $a\to 0$ should be regularized in the appropriate way. For example, in order to regularize the simplest integral of the series $I^2(L^-(\lambda))$ we have to multiply it by a. Taking into account that $\mathcal{A}^{-1}=A^{-1}+a^{-1}I$ we obtain its explicit form

$$I_{-4}^{2'}(L^-(\lambda)) = \lim_{a\to 0} aI_{-4}^2(L^-(\lambda)) = 1/2\ \mathrm{Tr}\,(IL^{(0)}A^{-1}L^{(0)}).$$

Here, without abuse of notation we introduce the following: $A^{-1}\equiv \mathrm{diag}((A')^{-1},0)$.

Matrix gradient of $I_{-4}^{2'}$ has the form $\nabla I_{-4}^{2'}=-(IL^{(0)}A^{-1}+A^{-1}L^{(0)}I)$. As it was explained above fixation of the integrable hierarchy is equivalent to fixation of the U operator that generate space flow. We will take matrix $\nabla I_{-4}^{2'}$ for such the U-operator. This is the simplest possible choice that provides integrable hierarchy with the minimal number of dynamical variables equal to $(n-1)$. In the next subsections we will show that this hierarchy coincides with the generalized Landau–Lifshitz hierarchy.

C. Simplest equation of the generalized Landau–Lifshitz hierarchy

In order to choose one of the equations from the fixed hierarchy, i.e., when U operator is fixed we have to choose second operator in $U-V$ pair that generates time flow. In this subsection we consider the case when $V\equiv \nabla I_{-5}^{2'}$, where the "regularized" Hamiltonian $I_{-5}^{2'}$ is defined as follows:

$$I_{-5}^{2'}(L^-(\lambda)) = \lim_{a\to 0}(aI_{-5}^2(L^-(\lambda)) - 2I_{-4}^2(L^-(\lambda))).$$

Direct calculation gives its following explicit form:

$$I_{-5}^{2'}(L^-(\lambda)) = -(\mathrm{Tr}(IL^{(1)}A^{-1}L^{(0)}) + \mathrm{Tr}(IL^{(0)}A^{-1}L^{(1)})) + 1/2\ \mathrm{Tr}\,(A^{-1}L^{(0)}A^{-1}L^{(0)}) - \mathrm{Tr}(A^{-2}L^{(0)}IL^{(0)}).$$

In the case of the diagonal matrices $A' = \mathrm{diag}(a_1, a_2, \ldots, a_{n-1})$ Hamiltonians $I_{-4}^{2'}$ and $I_{-5}^{2'}$ acquire the following coordinate form:

$$I_{-4}^{2'}(L^-(\lambda)) = \sum_{i<n}\frac{(l_{in}^{(0)})^2}{a_i}, \quad I_{-5}^{2'}(L^-(\lambda)) = \sum_{i<n}\left(2\frac{l_{in}^{(1)}l_{in}^{(0)}}{a_i} + \frac{(l_{in}^{(0)})^2}{a_i^2}\right) - \sum_{0<i<j<n}\frac{(l_{ij}^{(0)})^2}{a_ia_j}.$$

Corresponding matrix gradients are written as follows:

$$\nabla I_{-4}^{2'} = 2\sum_{i<n}\frac{l_{in}^{(0)}}{a_i}X_{in}, \quad \nabla I_{-5}^{2'} = 2\lambda\sum_{i<n}\frac{l_{in}^{(0)}}{a_i}X_{in} - 2\sum_{i<j<n}\frac{l_{ij}^{(0)}}{a_ia_j}X_{ij} + 2\sum_{i<n}\left(\frac{l_{in}^{(1)}}{a_i} + \frac{l_{in}^{(0)}}{a_i^2}\right)X_{in}.$$

Dividing both matrix gradients by two (it is equivalent to the rescaling of the corresponding time variables) and introducing the following notations: $m_i^{(1)} = l_{in}^{(1)} + [l_{in}^{(0)}/a_i]$, we obtain that for the chosen $U-V$ pair deformed zero-curvature equation is equivalent to the following system of differential equations:

$$\frac{\partial l_{in}^{(0)}}{\partial t} - \frac{\partial m_i^{(1)}}{\partial x} = \sum_{k=1}^{n-1}\frac{l_{ik}^{(0)}l_{kn}^{(0)}}{a_k^2}, \tag{39}$$

$$\frac{\partial l_{in}^{(0)}}{\partial x} = \sum_{k=1}^{n-1}\frac{l_{ik}^{(0)}l_{kn}^{(0)}}{a_k}, \tag{40}$$

$$\frac{\partial l_{ij}^{(0)}}{\partial x} = m_i^{(1)}l_{jn}^{(0)} - m_j^{(1)}l_{in}^{(0)}. \tag{41}$$

In order to obtain differential equation in partial derivatives in the dynamical variables $l_{jn}^{(0)}$ we have to express $m_i^{(1)}$ and $l_{ij}^{(0)}$ via $l_{jn}^{(0)}$ and their derivatives. Using this and Eq. (40) it is easy to deduce that

$$l_{ij}^{(0)} = \frac{\partial l_{in}^{(0)}}{\partial x}l_{jn}^{(0)} - \frac{\partial l_{jn}^{(0)}}{\partial x}l_{in}^{(0)}, \tag{42}$$

$$m_i^{(1)} = \frac{\partial^2 l_{in}^{(0)}}{\partial x^2} + c_2(L^{(0)})l_{in}^{(0)}, \tag{43}$$

where $c_2(L^{(0)})$ is some scalar function of the dynamical variables $l_{in}^{(0)}$. In order to determine its explicit form we will use that Hamiltonians $I_{-4}^{2'}$ and $I_{-5}^{2'}$ are constant along all the flows. For convenience we will hereafter put $I_{-4}^{2'} = \mathrm{const}_1 = 1$, $I_{-5}^{2'} = \mathrm{const}_2 = 0$. Introducing the vector $(\boldsymbol{l})_i = l_{in}^{(0)}/a_i$ we obtain $c_2(\boldsymbol{l}) = 1/2(\boldsymbol{l},\boldsymbol{l}) + 3/2((\partial\boldsymbol{l}/\partial x), A'(\partial\boldsymbol{l}/\partial x))$. Using Eq. (42) it is easy to deduce that:

$$\sum_{k=1}^{n-1}[l_{ik}^{(0)}l_{kn}^{(0)}/a_ia_k^2] = -1/2[\partial(\boldsymbol{l},\boldsymbol{l})/\partial x](\boldsymbol{l})_i + (\boldsymbol{l},\boldsymbol{l})[\partial(\boldsymbol{l})_i/\partial x].$$

In the result we obtain the following differential equation in partial derivatives:

$$\frac{\partial \boldsymbol{l}}{\partial t}=\frac{\partial}{\partial x}\left(\frac{\partial^2 \boldsymbol{l}}{\partial x^2}+3/2\left(\frac{\partial \boldsymbol{l}}{\partial x},A'\frac{\partial \boldsymbol{l}}{\partial x}\right)\boldsymbol{l}\right)+3/2(\boldsymbol{l},\boldsymbol{l})\frac{\partial \boldsymbol{l}}{\partial x}. \tag{44}$$

In new notations: $\boldsymbol{s}=(A')^{1/2}\boldsymbol{l}$, $J\equiv(A')^{-1}$ we obtain that constraint $(\boldsymbol{l},A'\boldsymbol{l})=1$ passes to the standard constraint $(\boldsymbol{s},\boldsymbol{s})=1$ and Eq. (44) passes to the higher Landau–Lifshitz equation

$$\frac{\partial \boldsymbol{s}}{\partial t}=\frac{\partial}{\partial x}\left(\frac{\partial^2 \boldsymbol{s}}{\partial x^2}+3/2\left(\frac{\partial \boldsymbol{s}}{\partial x},\frac{\partial \boldsymbol{s}}{\partial x}\right)\boldsymbol{s}\right)+3/2(\boldsymbol{s},J\boldsymbol{s})\frac{\partial \boldsymbol{s}}{\partial x}. \tag{45}$$

In the case $n=4$ this equation is the higher equation of the Landau–Lifshitz hierarchy.[18] For $n>4$ this equation was obtained also in Ref. 23 using the technique of "dressing" and the embedding of a special realization of the algebra $\widetilde{so(n)}_A^+$ into algebra $so(n)((\lambda))$ of formal power series.

D. Landau–Lifshitz equation

In this subsection we will consider another equation from the earlier introduced generalized Landau–Lifshitz hierarchy. In such a way we will obtain the ordinary Landau–Lifshitz equation and show that although there is direct vector generalization of the Landau–Lifshitz hierarchy, but it does not contain vector generalization of the Landau–Lifshitz (L–L) equation.

In order to obtain a precise analog of L−L equation we have to find out Hamiltonian that generates a "correct" time flow. This will be the simplest Hamiltonian of the series

$$P(L^-(\lambda))\equiv Pf(\lambda^{-1}L^{(0)}+\lambda^{-2}L^{(1)}+\lambda^{-3}L^{(3)}+\cdots). \tag{46}$$

Due to the fact that pfaffian exists only for the orthogonal matrices in the spaces of even dimensions there arise the natural condition $n=2N$. By direct calculation we obtain: $P_{-N}(L^-(\lambda))\equiv Pf(L^{(0)})$. Its matrix gradient is written as follows:

$$\nabla P_{-N}(L^-(\lambda))=\sum_{i<n}\frac{\partial Pf(L^{(0)})}{\partial l_{in}^{(0)}}X_{in}+\sum_{i,j<n}\frac{\partial Pf(L^{(0)})}{\partial l_{ij}^{(0)}}X_{ij}. \tag{47}$$

Let us consider the corresponding zero-curvature equations

$$\frac{\partial\,\nabla I_{-4}^{2'}(L^-(\lambda))}{\partial\tau}-\frac{\partial\,\nabla P_{-N}(L^-(\lambda))}{\partial x}+[\nabla I_{-4}'^{2}(L^-(\lambda)),\ \nabla P_{-N}(L^-(\lambda))]_{A(\lambda)}=0.$$

Taking into account, that $[X_{in},X_{jn}]_A=0$, and $\Sigma_{i=1}^{n-1}[\partial P_{-N}(L^-(\lambda))/\partial l_{ij}^{(0)}]l_{in}^{(0)}=0$, we obtain that $[\nabla I_{-4}^{2'}(L^-(\lambda)),\nabla P_{-N}(L^-(\lambda))]_A=0$ and the corresponding zero-curvature type equation is reduced to the spectral parameter-independent form

$$\frac{\partial\,\nabla I_{-4}^{2'}(L^{(0)})}{\partial\tau}-\frac{\partial\,\nabla P_{-N}(L^{(0)})}{\partial x}+[\nabla I_{-4}^{2'}(L^{(0)}),\ \nabla P_{-N}(L^{(0)})]=0. \tag{48}$$

Before making a more detailed analysis of Eq. (48) in the case of general n, we will consider $n=4$ example in order to obtain the ordinary Landau–Lifshitz equation.

Example 4: Let $\mathfrak{g}=so(4)$. Taking into account Z_2 grading of $so(4)$: $so(4)=so(3)+\mathbb{R}^3$ and denoting projection of $\nabla P_{-N}(L^-(\lambda))$ onto subalgebra $so(3)\subset so(4)$ by $\nabla_+P_{-N}(L^-(\lambda))$ and projection onto subspace $\mathbb{R}^3\subset so(4)$ by $\nabla_-P_{-N}(L^-(\lambda))$ we obtain that Eq. (48) is rewritten as follows:

$$\frac{\partial\,\nabla I_{-4}^{2'}(L^{(0)})}{\partial\tau}=-[\nabla I_{-4}^{2'}(L^{(0)}),\quad \nabla_+P_{-4}(L^{(0)})]+\frac{\partial\nabla_-P_{-4}(L^{(0)})}{\partial x}, \tag{49}$$

$$\frac{\partial \nabla_+ P_{-4}(L^{(0)})}{\partial x} = [\nabla I^{2'}_{-4}(L^{(0)}), \nabla_- P_{-4}(L^{(0)})]. \tag{50}$$

Introducing notations: $l_i = l^{(0)}_{i4}$, $m_i = \epsilon_{ijk} l^{(0)}_{jk}$, $Y_i = X_{i4}$, $X_k = \epsilon_{ijk} X_{jk}$ $(i,j,k<4)$ we obtain

$$\nabla I^{2'}_{-4}(L^{(0)}) = \sum_{i=1}^{3} a_i^{-1} l_i Y_i, \quad \nabla_+ P_{-4}(L^{(0)}) = \sum_{i=1}^{3} l_i X_i, \quad \nabla_- P_{-4}(L^{(0)}) = \sum_{i=1}^{3} m_i Y_i.$$

Substituting this expression into Eqs. (49) and introducing in the evident manner vectors $\boldsymbol{l}$, $\boldsymbol{m}$, and matrix $J \equiv \mathrm{diag}(a_1^{-1}, a_2^{-1}, a_3^{-1})$ we obtain the following equations:

$$J\frac{\partial \boldsymbol{l}}{\partial \tau} = -[J\boldsymbol{l} \times \boldsymbol{l}] + \frac{\partial \boldsymbol{m}}{\partial x}, \tag{51a}$$

$$\frac{\partial \boldsymbol{l}}{\partial x} = [J\boldsymbol{l}, \boldsymbol{m}]. \tag{51b}$$

Due to the fact that all Hamiltonians are constant along all time flows, vectors $\boldsymbol{m}$ and $\boldsymbol{l}$ are subjected to the conditions: $I^{2'}_{-4} = (J\boldsymbol{l}, \boldsymbol{l}) = c_2$, $P_{-4} = (\boldsymbol{m}, \boldsymbol{l}) = c_1$. For the sake of simplicity we will hereafter put $c_2 = 1$, $c_1 = 0$. Using these constraints and Eq. (51b) we obtain for the vector $\boldsymbol{m}$ the explicit expression: $\boldsymbol{m} = -[\boldsymbol{l}, (\partial \boldsymbol{l}/\partial x)]$. Substituting this expression into Eq. (51a) we obtain the following equation:

$$J\frac{\partial \boldsymbol{l}}{\partial \tau} = -\left[\boldsymbol{l}, \frac{\partial^2 \boldsymbol{l}}{\partial x^2}\right] - [J\boldsymbol{l} \times \boldsymbol{l}]. \tag{52}$$

Introducing variables: $\boldsymbol{s} = J^{1/2}\boldsymbol{l}$, $t = -(\det J)^{1/2}\tau$ we can write Eq. (52) as follows:

$$\frac{\partial \boldsymbol{s}}{\partial t} = \left[\boldsymbol{s}, \frac{\partial^2 \boldsymbol{s}}{\partial x^2}\right] + [J\boldsymbol{s} \times \boldsymbol{s}], \text{where } (\boldsymbol{s}, \boldsymbol{s}) = 1. \tag{53}$$

It is easy to see, that Eq. (53) coincides with the standard *Landau–Lifshitz equation*.

Let us now consider Eq. (48) in the case of $n>4$. The next theorem is true.

Theorem 4: *In the case $n>4$ hierarchy of the vector Eq. (45) contains no nontrivial analog of the Landau–Lifshitz equation.*

Proof: Let us show, that the Hamiltonian flows that generate time flow of L–L equations are trivial for the case $n>4$. In order to do this it is enough to show that the V operator (i.e., matrix gradient of the corresponding Hamiltonian) is trivial. But this follows from the definition of the pfaffian: $P_{-N}(L^{(0)}) = \Sigma_{i_1, i_2, \ldots, i_{2N} \leqslant n} \epsilon_{i_1 i_2 i_3 \cdots i_{2N}} l^{(0)}_{i_1 i_2} l^{(0)}_{i_3 i_4} \cdots l^{(0)}_{i_{2N-1} i_{2N}}$ and Eq. (42). Indeed, substituting expression $l^{(0)}_{ij} = [\partial l^{(0)}_{in}/\partial x] l^{(0)}_{jn} - [\partial l^{(0)}_{jn}/\partial x] l^{(0)}_{in}$ in the explicit expression of $\nabla P_{-N}(L^{(0)})$ and taking into account skew symmetry of the tensor $\epsilon_{i_1 i_2 i_3 \cdots i_{2N}}$, we obtain that for the case when $\nabla P_{-N}(L^{(0)})$ is a polynomial in $L^{(0)}$ of the degree exceeding one, i.e., when $n = 2N > 4$, $\nabla P_{-N}(L^{(0)})$ turns identically zero.

The theorem is proved.

VII. INTEGRABLE HIERARCHIES ASSOCIATED WITH ALGEBRAS $\widetilde{\mathfrak{g}}_A$

In this section we will obtain the simplest equations of integrable hierarchies associated with algebras $\widetilde{\mathfrak{g}}_A$. We will again distinguish two types of hierarchies—those connected with degenerated and those connected with nondegenerated matrices A.

A. Hierarchy connected with nondegenerated matrices *A*

Let us consider the second order Hamiltonians $I^2_k(L^+(\lambda))$and $I^2_l(L^-(\lambda))$. For the first Hamiltonians of these sets we have (see previous sections) the following expressions:

$$I_0^2(L^+(\lambda)) = 1/2\ \mathrm{Tr}\,(L^{(-1)})^2, \quad I_{-4}^2(L^-(\lambda)) = 1/2\ \mathrm{Tr}\,(A^{-1}L^{(0)}A^{-1}L^{(0)}). \tag{54}$$

The corresponding matrix gradients are

$$\nabla I_0^2(L^+(\lambda)) = L^{(-1)}\lambda^{-1}, \quad \nabla I_{-4}^2(L^-(\lambda)) = A^{-1}L^{(0)}A^{-1}. \tag{55}$$

As it follows from the results of Sec. III B Hamiltonians $I_k^2(L^+(\lambda))$ and $I_l^2(L^-(\lambda))$, considered as functions on $\widetilde{\mathfrak{g}}_A^*$ commute with respect to the usual Lie-Poisson bracket on $\widetilde{\mathfrak{g}}_A^*$. Hence, their matrix gradients satisfy deformed zero-curvature equations

$$\frac{\partial\ \nabla I_0^2(L^+(\lambda))}{\partial x_-} - \frac{\partial\ \nabla I_{-4}^2(L^-(\lambda))}{\partial x_+} + [\nabla I_0^2(L^+(\lambda)),\ \nabla I_{-4}^2(L^-(\lambda))]_{A(\lambda)} = 0. \tag{56}$$

A direct calculation gives us λ independent form of Eqs. (56):

$$\frac{\partial U}{\partial x_+} = [U,V]_A, \quad \frac{\partial V}{\partial x_-} = [U,V], \tag{57}$$

where $V \equiv L^{(-1)}$, $U \equiv A^{-1}L^{(0)}A^{-1}$. We consider Eqs. (57) to be the new examples of *anisotropic chiral field equations*. They go together with natural constraints

$$\mathrm{Tr}(UA)^r = \mathrm{const}_r^-, \quad \mathrm{Tr}(V)^r = \mathrm{const}_r^+, r \in \overline{1,n} \tag{58}$$

that follows from the fact that Hamiltonians $I_0^r(L^+(\lambda))$ and $I_{-r-2}^r(L^-(\lambda))$ are constant along all time flows: $I_0^r(L^+(\lambda)) = \mathrm{const}_r^+$, $I_{-r-2}^r(L^-(\lambda)) = \mathrm{const}_r^-$.

Remark 11: Note, that in order to obtain usual "isotropic"chiral field equations we have to put $A_{ij} \to a\delta_{ij}$ not $A_{ij} \to 0$. This is explained by the fact that a standard Lax pair generating isotropic chiral field equations depends not on $\lambda^{\pm 1}$ but on $(\lambda \pm a)^{-1}$.

Example 5: Let $\mathfrak{g} = so(3)$, $A = \mathrm{diag}(a_1, a_2, a_3)$. In this case we can consider elements of $U, V \in g^* \simeq so(3)$ as vectors $\boldsymbol{u}, \boldsymbol{v} \in \mathbb{R}^3$ and rewrite Eqs. (57) in the following form:

$$\frac{\partial \boldsymbol{u}}{\partial x_+} = A([\boldsymbol{u} \times \boldsymbol{v}]), \quad \frac{\partial \boldsymbol{v}}{\partial x_-} = [\boldsymbol{u} \times \boldsymbol{v}], \tag{59}$$

where matrix A acts on $\boldsymbol{u} = \Sigma_{i=1,3} u_k X_k$ as on a vector in $\mathbb{R}^3$: $A(\boldsymbol{u}) = \Sigma_{i=1,3} a_k u_k X_k$. Constraints (58) that correspond to the two second order Hamiltonians $I_0^2(L^+(\lambda))$ are written as follows: $(\boldsymbol{u}, A^{-1}\boldsymbol{u}) = \mathrm{const}^-$, $(\boldsymbol{v}, \boldsymbol{v}) = \mathrm{const}^+$.

Using Eqs. (59) it is easy to deduce that there exists vector-potential $\boldsymbol{\phi}$ such that $\boldsymbol{u} = A(\partial\boldsymbol{\phi}/\partial x_-), \boldsymbol{v} = (\partial\boldsymbol{\phi}/\partial x_+)$. In the result we obtain that Eqs. (59) are equivalent to the following equation:

$$\frac{\partial^2 \boldsymbol{\phi}}{\partial x_+ \partial x_-} = -\left[\frac{\partial \boldsymbol{\phi}}{\partial x_+} \times A\left(\frac{\partial \boldsymbol{\phi}}{\partial x_-}\right)\right]. \tag{60}$$

B. Hierarchies connected with the degenerated matrices *A*

Let us consider the simplest equation of the hierarchy associated with the degenerated matrices A. In this case, like in the case of hierarchies associated with Lie algebras $\widetilde{\mathfrak{g}}_A^+$ degeneration of A will lead to the "reduction" i.e., decreasing the number of independent "fields" in the corresponding system of equations in partial derivatives. We will again restrict ourselves to the simplest case of rank $A = n-1$.

Let us consider the second order Hamiltonians $I_0^2(L^+(\lambda))$ and $I_{-4}^{2'}(L^-(\lambda))$. They have (see previous sections) the following form:

$$I_0^2(L^+(\lambda)) = 1/2\ \mathrm{Tr}\,(L^{(-1)})^2, \quad I_{-4}^{2'}(L^-(\lambda)) = -\,\mathrm{Tr}\,(IL^{(0)}A^{-1}L^{(0)}). \tag{61}$$

The corresponding matrix gradients are

$$\nabla I_0^2(L^+(\lambda)) = L^{(-1)}\lambda^{-1}, \quad \nabla I_{-4}^{2'}(L^-(\lambda)) = -\,(IL^{(0)}A^{-1} + A^{-1}L^{(0)}I). \tag{62}$$

Here, as in the previous section, without abuse of notation we introduce the following: $A^{-1} = \mathrm{diag}((A')^{-1}, 0)$ where $A = \mathrm{diag}(A', 0)$ and matrix A' is nondegenerate.

The Hamiltonians $I_0^2(L^+(\lambda))$ and $I_{-4}^{2'}(L^-(\lambda))$, considered as functions on $\tilde{\mathfrak{g}}_A^*$ commute with respect to the usual Lie–Poison bracket on $\tilde{\mathfrak{g}}_A^*$. Corresponding zero-curvature condition

$$\frac{\partial\, \nabla I_0^2(L^+(\lambda))}{\partial x_-} - \frac{\partial\, \nabla I_{-4}^{2'}(L^-(\lambda))}{\partial x_+} + [\nabla I_0^2(L^+(\lambda)),\ \nabla I_{-4}^{2'}(L^-(\lambda))]_{A(\lambda)} = 0$$

yields the following λ-independent equations:

$$\frac{\partial V}{\partial x_-} = [U_-, V], \quad \frac{\partial U_-}{\partial x_+} = [U_-, V]_A, \tag{63}$$

where $U_- \equiv (IL^{(0)}A^{-1} + A^{-1}L^{(0)}I)$, $V \equiv L^{(-1)}$. Note, that although Eqs. (63) look very similar to Eqs. (57) they do not coincide: matrix-valued functions U and U_- have a different number of independent components.

Let us now consider the most interesting case $\mathfrak{g} = so(n)$ and rewrite Eqs. (63) in a more simple way. Let us take into consideration the following Z_2 grading of $so(n)$: $so(n) = so(n)_0 + so(n)_1 \equiv so(n-1) + \mathbb{R}^{n-1}$. We will denote the part of the matrix valued function V, that belongs to the subalgebra $so(n-1)$ of the earlier decomposition by V_+ and the part that belongs to $\mathbb{R}^{n-1}$ by V_- (note that by the definition U_- belong to $\mathbb{R}^{n-1}$). In the result we obtain that Eqs. (63) are equivalent to the following three equations:

$$\frac{\partial V_+}{\partial x_-} = [U_-, V_-], \quad \frac{\partial V_-}{\partial x_-} = [U_-, V_+], \quad \frac{\partial U_-}{\partial x_+} = [U_-, V_+]_A. \tag{64}$$

Introducing in the evident manner vectors $\boldsymbol{u}_-$ and $\boldsymbol{v}_-$ that correspond to the matrices U_- and V_- we may rewrite these equations as follows:

$$\frac{\partial V_+}{\partial x_-} = \boldsymbol{u}_- \wedge \boldsymbol{v}_-, \quad \frac{\partial \boldsymbol{v}_-}{\partial x_-} = -\,V_+(\boldsymbol{u}_-), \quad \frac{\partial \boldsymbol{u}}{\partial x_+} = -\,V_+A'(\boldsymbol{u}_-). \tag{65}$$

This is a system of differential equations in partial derivatives on the $n(n-1)/2 + (n-1)$ independent functions—components of vectors $\boldsymbol{u}_-$ and $\boldsymbol{v}_-$ and matrix V_+. Comparing with Eqs. (56) we see that we have reduced our system on $(n-1)(n-2)/2$ functional degrees of freedom. In the case $n=4$ system (64) admit further reduction.

Example 6: Let $\mathfrak{g} = so(4)$. In this case, introducing instead of $so(3)$-valued matrix V_+ vector $\boldsymbol{v}_+ \in \mathbb{R}^3$ we may rewrite all Eqs. (64) in the vector form:

$$\frac{\partial \boldsymbol{v}_+}{\partial x_-} = [\boldsymbol{u}_- \times \boldsymbol{v}_-], \quad \frac{\partial \boldsymbol{v}_-}{\partial x_-} = [\boldsymbol{u}_- \times \boldsymbol{v}_+], \tag{66}$$

$$\frac{\partial \boldsymbol{u}_-}{\partial x_+} = [A'(\boldsymbol{u}_-) \times \boldsymbol{v}_+], \tag{67}$$

where $\boldsymbol{u} \times \boldsymbol{v}$ denote ordinary vector product of two vectors $\boldsymbol{u}$, $\boldsymbol{v}$. These equations satisfy three second order constraints

$$(\boldsymbol{u}_-, A'\boldsymbol{u}_-) = \text{const}^-, \quad (\boldsymbol{v}_+, \boldsymbol{v}_-) = \text{const}_1^+, \quad (\boldsymbol{v}_+, \boldsymbol{v}_+) + (\boldsymbol{v}_-, \boldsymbol{v}_-) = \text{const}_2^+, \tag{68}$$

that follows from the constancy of functions $I_{-4}^{2'}(L^-(\lambda))$, $P_0(L^+(\lambda))$, $I_0^2(L^+(\lambda))$ along all flows.

Taking into account definition of the vectors $\boldsymbol{v}_+$ and explicit form of the isomorphism $so(4) \simeq so(3)+so(3)$ we may put $\boldsymbol{v}_+ = \pm \boldsymbol{v}_-$ [evidently such reduction is well agreed with Eqs. (66)]. In the result we obtain the system of two vector equations that after replacement of variables $\boldsymbol{u} = A'^{1/2}(\boldsymbol{u}_-)$, $\boldsymbol{v} \equiv \boldsymbol{v}_-$ pass to the standard anisotropic chiral field Eqs. (35).

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 45, NUMBER 12 DECEMBER 2004

Moduli of quantum Riemannian geometries on ⩽4 points

S. Majid[a] and E. Raineri
Queen Mary University of London, School of Mathematical Sciences, London E1 4NS, United Kingdom

(Received 13 July 2004; accepted 2 August 2004; published 5 November 2004)

We classify parallelizable noncommutative manifold structures on finite sets of small size in the general formalism of framed quantum manifolds and vielbeins introduced previously [S. Majid, Commun. Math. Phys. **225**, 131 (2002)]. The full moduli space is found for ⩽3 points, and a restricted moduli space for 4 points. Generalized Levi–Cività connections and their curvatures are found for a variety of models including models of a discrete torus. The topological part of the moduli space is found for ⩽9 points based on the known atlas of regular graphs. We also remark on aspects of quantum gravity in this approach. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1804231]

I. INTRODUCTION

There has been a lot of interest over the years[1–8] in the specific application of noncommutative geometry[9] to the commutative algebra of functions on a finite set Σ (usually a finite group) in which the differential forms do not commute with functions. This provides a systematic way of handling geometry on finite lattices which, at the level of cohomology, electromagnetism, and Yang–Mills theory has already proven interesting and computable. Notably, Ref. 8 contains the moduli of $U(1)$-Yang–Mills on the permutation group S_3 while Ref. 7 quantizes $U(1)$-Yang–Mills theory on the finite group $\mathbb{Z}_2\times\mathbb{Z}_2$.

In this paper we want systematically to extend this theory to the gravitational case. Some first steps are in Ref. 10, to which the present paper is a sequel. It was shown there that finite groups have indeed a natural Riemannian geometry in a vielbein and frame-bundle formalism[11] which was worked out in detail for S_3 (it turns out to have Ricci essentially proportional to the metric, i.e., an "Einstein manifold"). Similarly, the alternating group A_4 was considered in Ref. 12 and has an essentially unique invariant metric with 4-bein and an associated spin connection with nonzero curvature but with Ricci=0, i.e., solves the vacuum Einstein equations. Hence the system of equations for a framed quantum Riemannian manifold is already known to have interesting nontrivial solutions. However, for quantum gravity (or classical but finite gravity) we need a better understanding of the moduli spaces of *all* metrics, connections, etc. and this is what we study now on small sets. Once one has this, one can in principle begin to quantize this moduli space in a path integral approach, i.e., quantum gravity.

Section II starts with a brief account of the formalism for algebras which we then rapidly specialize to the case $\mathbb{C}(\Sigma)$, the algebra of functions in a finite set. That the theory is a specialization of a functorial construction that is formulated for general algebras ensures that it is not *ad hoc* (indeed, this same theory can be specialized to classical geometry and to q-deformed geometry for other choices of algebra[13]). Following Ref. 10, we find that for finite sets Σ the classification of "differential forms" or exterior algebras of parallelizable type reduces to the classification of finite regular graphs with vertices Σ and a fixed number n arrows from every vertex. New results are Theorem 2.1 showing in detail that the calculus is then inner, and Theorem 2.2 for the construction of two-forms. Both are needed in the paper. Further ingredients in the formalism are

[a]Electronic mail: s.majid@qmul.ac.uk

a choice of n-beins and a frame group G (in our case a finite group) acting on the vector space spanned by them. This gives the moduli of "quantum framed manifold" structures on Σ. After this, one may look for a compatible connection ∇, find the Riemann curvature and from this the Ricci tensor and Ricci scalar. In this way we set up the theory that we are going to explore for small numbers of points.

In Sec. III A we analyze the case $\Sigma=\{x,y\}$ of two points and frame groups S_2,S_3 acting on an einbein e_1 parametrized by a function Θ. We find that for each einbein there is a natural generalized Levi–Cività connection

$$\nabla(fe_1)=\mathrm{d}f\otimes e_1+2f\langle\Theta\rangle e_1\otimes e_1$$

for any function f, where $\langle\ \rangle$ is the average value over the two points. This has zero Riemannian curvature, which emerges as a typical feature on two points. In our spin connection approach we find also the moduli of spin connections; for S_2 framing we have a unique spin connection underlying ∇. For S_3 we find a larger moduli of spin connections, with gauge curvature, underlying the Riemannian geometry itself (all giving the same ∇).

In Sec. III B we similarly cover the case $\Sigma=\{x,y,z\}$ of three points and frame groups S_2,S_3 acting on a zweibein. The zweibein moduli space is itself nontrivial as an algebraic variety but we show how to put a generic point into a canonical form, and then study spin connections for a fixed zweibein. A general feature for three points emerges, namely that in all our models the Ricci scalar vanishes, but the Riemann and Ricci tensors themselves generically do not. For S_2 we have a linear constraint on the zweibein to admit a connection, after which there is a one-parameter family of connections. For S_3 there is no constraint on the zweibein and an eight-dimensional moduli of connections.

The canonical form for the vielbeins obtained in our analysis of 2 and 3 points in Sec. III is one where (after linear transformations), one may restrict to vielbeins which have only a scalar Θ_a associated to each edge. In Sec. IV we proceed to restrict attention to this canonical form, now for four point sets. Physically, the modulus of the vielbein assigns a "length" to each edge, while the natural connectivity for 4 points is that of $\mathbb{Z}_2\times\mathbb{Z}_2$ (interpreted as a discrete model of a torus), which we consider in Secs. IV A–IV C; we consider various frame groups, among them an interesting choice (Sec. IV B) is a frame group $\mathbb{Z}_4$ of "quarter rotations" again as a discrete model of a torus; we find the most general connection, its Riemann and Ricci curvatures, etc. This model has the feature (Theorem 4.4) that a fully metric compatible spin connection is determined uniquely by the zweibein, but with the latter further constrained. By contrast, our weaker "skew metric compatible" or cotorsion free condition admits further parameters a,b with the zweibein relatively unconstrained. We also see what happens if one takes too big a calculus on the frame group, namely additional unphysical modes emerge which do not, however, enter into the covariant derivative. This seems to us an important lesson for finite manifold-building by these methods. Section IV D completes the picture by covering the alternative connectivity of 4 points joined in a tetrahedron, which is more like a sphere. Here with $\mathbb{Z}_3$ frame group of "one-third" rotations we find an unusual but interesting calculus, moduli, etc., without classical analogue.

Later, in Sec. V we make some first remarks on the quantum theory, including a look at the discrete torus model on $\mathbb{Z}_2\times\mathbb{Z}_2$. Mainly, we find what we show on this model to be a reasonable unitarity or *-structure on the system which is needed to reduce the functional integrals to real variables. We do not try to do the integrals themselves, which would be beyond the scope of our current analysis.

Finally, Sec. VI return to a more qualitative account of all bidirectional framed geometries up to 9 points, deduced from the known atlas of graphs.[14] This covers the connectivity or topological aspect of the vielbein moduli space. At this level a vielbein amounts to a coloring of the graph into n-colors. For each such vielbein, there are further continuous degrees of freedom for matrices e_a labeled according to the coloring a (as seen in detail in Sec. III). If we ignore these then we have in principle a "combinatorial quantum gravity" in which one sums over all such colorings.

Let us note that "geometry" on finite sets in some form or other has a long pedigree. Common to all approaches is the basic data of "differentials" as defined by directed edges between vertices

(a "digraph" or quiver). Such objects are used in representation theory for quivers formed on Dynkin diagrams. One also considers in that context some kind of "vector bundles" with vector spaces over each vertex albeit of varying dimension. Similarly in physics as well as in simplicial cohomology one may "approximate" a manifold by a finite triangulation and work on that. From the algebraic point of view one does not actually need bidirectional edges, e.g., every poset defines a connectivity graph and differential calculus with $x\to y$ if $x<y$ (albeit not a parallelizable one if it is finite). This would be relevant to modeling Lorentzian manifolds[15] with $x\to y$ modeling a time-like path from x to y. Hence the deeper notions of vielbeins and Riemannian geometry that we develop on such data potentially have several applications.

II. PRELIMINARIES: FORMALISM OF QUANTUM RIEMANNIAN MANIFOLDS

Here we briefly recall the formalism of Ref. 10. To tie in with the general theory we start with a brief recap over general algebras in Sec. II A. Then in Sec. II B we specialize to the finite set case in more detail than outlined in Ref. 10. We cover here only the parallelizable case where the frame bundle algebra has a trivial tensor product form. There is a still more general theory where the bundle is nontrivial, see Ref. 10, but this needs much more machinery and we do not cover it here. It would be needed for finite posets, for example.

A. Over general algebras

Let M be a unital algebra. We equip M with a differential structure in the sense $(\Omega^1(M),\mathrm{d})$, where $\Omega^1(M)$ is an $M-M$ bimodule, and $\mathrm{d}:M\to\Omega^1(M)$. This is a notion common to all approaches to noncommutative geometry including Ref. 9. We also need $\Omega^2(M)$ or (in principle) higher $\Omega^k(M)$ with $\mathrm{d}^2=0$, for which we can take the maximal prolongation of $\Omega^1(M)$ or any of its quotients.

In this context we define a (left) *vielbein* or V-bein as a collection $\{e_a\}$ forming an M-basis of one-forms $e_a\in\Omega^1(M)$, i.e., $\Omega^1(M)\cong M\otimes V$ where $V=\mathrm{span}\{e_a\}$. One can also think equivalently of the V-bein as a map $e:V\to\Omega^1(M)$ as in Ref. 10 if we regard V as a fixed abstract vector space. Given a vielbein we deduce operators $\rho_a^b,\partial^a:M\to M$ where

$$e_a f=\sum_b \rho_a^b(f)e_b,\quad \mathrm{d}f=\sum_a(\partial^a f)e_a,\quad \forall\, f\in M \tag{1}$$

as an expression of the bimodule and exterior derivative structure.

Next, we assume that we actually have an A-vielbein, i.e., we require V to be an A-comodule under a Hopf algebra A. There is also a more general theory with A merely a coalgebra, i.e., this is not a critical assumption. We fix a left-covariant differential structure $\Omega^1(A)$ on the fiber of the frame bundle. Like Lie groups, quantum groups are always parallelizable and hence $\Omega^1(A)=A\otimes\Lambda^1$ for some space of invariant one-forms Λ^1. This is a quotient of the augmentation ideal A_+ of A (classically it means the functions that vanish at the group identity), i.e., $\Lambda^1=A_+/Q_A$ for some left ideal $Q_A\subseteq A_+$. We call $\Lambda^{1*}\subset H_+$ the associated "quantum tangent space," where we suppose Λ^1 is finite dimensional and H a Hopf algebra dually paired with A (it plays the role classically of the enveloping algebra of the Lie algebra of the frame group). We will be interested only in the bicovariant case as in Ref. 10 where one knows from the Woronowicz theory[16] that Λ^1 is Ad-stable or that Λ^{1*} inherits Ad as a "quantum Lie bracket." When A is coquasitriangular one knows that Λ^{1*} is in fact a braided-Lie algebra.[17] However, neither assumption is critical for the geometry.

We let $\{f^i\}$ be a basis of Λ^{1*} and we denote by $\triangleright$ its left action inherited from the left action of H on V corresponding to the coaction of A. It is only this action which is needed in the formulas below. In this basis a spin connection means a collection of one-forms $\{A_i\}$. Its torsion tensor corresponds to

$$\mathrm{d}e_a + \sum_i A_i \wedge f^i \triangleright e_a \tag{2}$$

and we are interested in torsion-free connections. We also (optionally) impose a regularity or "differentiability" condition linking $\Omega^2(M)$ and $\Omega^1(A)$, namely

$$\sum_{ij} A_i \wedge A_j \langle f^i f^j, q\rangle = 0 \quad \forall\, q \in Q_A. \tag{3}$$

This ensures that the component two-forms $\{F_i\}$ of the curvature of the spin connection, namely

$$F_i = \mathrm{d}A_i + \sum_{jk} c_i^{jk} A_j \wedge A_k \tag{4}$$

have a proper geometrical interpretation as a curvature two-form with values in Λ^{1*}. Here $c_i^{jk} = \langle e_i, f^j f^k\rangle$ are structure constants of the product of H projected to Λ^{1*} (where $\{e_i\}$ is a dual basis of Λ^1).

For metrics we specialize to the case $g = \Sigma_{a,b}\ \eta^{ab} e_a \otimes_M e_b$ where $\eta \in V \otimes V$ is a nondegenerate H-invariant "local metric." This is not the most general setup up in Refs. 11 and 10, where one can consider g an arbitrary (but nondegenerate) two-form. In our case the cotorsion-free condition, which is the natural generalization of Levi–Cività metric compatibility in Refs. 11 and 10, is vanishing of

$$\mathrm{d}e_a + \sum_i S^{-1}(f^i) \triangleright e_a \wedge A_i \tag{5}$$

where S denotes the antipode of H.

Finally, we specialize to the case of $\Omega^2(M)$ constructed from an H-equivariant projection $\pi: V \otimes V \to V \otimes V$ according to the scheme indicated in Ref. 10. From the above, we know that $\Omega^1(M) \otimes_M \Omega^1(M) \cong M \otimes V \otimes V$ allowing us to define surjections

$$\Omega^1(M) \underset{M}{\otimes} \Omega^1(M) \to \Omega^2(M),$$

where we quotient out $M \otimes \ker \pi$. In fact we define Λ as a quadratic algebra on V with relations $\ker \pi$, and $\Omega(M) \cong M \otimes \Lambda$. Such a scheme imposes constraints on π. In this setting there is a canonical lift

$$i: \Omega^2(M) \hookrightarrow \Omega^1(M) \underset{M}{\otimes} \Omega^1(M), \quad i(e_a \wedge e_b) = \pi(e_a \otimes e_b). \tag{6}$$

Finally, we let $i(F_i) = \Sigma_{a,b}\ i(F_i)^{ab} e_a \otimes_M e_b$ define the components in the V-bein basis of the lifted F_i. Then

$$\mathrm{Ricci} = \sum_{i,a,b} i(F_i)^{ab} e_b \underset{M}{\otimes} f^i \triangleright e_a. \tag{7}$$

The full Riemann curvature of the connection and the covariant derivative acting on one-forms are

$$\mathrm{Riemann}(\alpha) = \sum_{i,a} \alpha^a F_i \underset{M}{\otimes} f^i \triangleright e_a, \quad \nabla\, \alpha = \sum_a \mathrm{d}\alpha^a \underset{M}{\otimes} e_a - \sum_{i,a} \alpha^a A_i \underset{M}{\otimes} f^i \triangleright e_a \tag{8}$$

where $\alpha = \Sigma_a\ \alpha^a e_a$. The derivation of these local formulas from a more abstract theory is in Ref. 10, in an equivalent comodule notation.

B. Over finite sets

We now specialize the above to the case $M = \mathbb{C}(\Sigma)$ where Σ is a finite set and $H = \mathbb{C}(G)$ where G is a finite group. In this case the possible $\Omega^1(\Sigma)$ are given by subsets

$$E \subset \Sigma \times \Sigma - \text{diagonal}$$

of "allowed directions." This is already known from Ref. 9 and E is the same as the structure of a quiver or digraph with vertex set Σ and the notation $x \to y$ whenever $(x,y) \in E$. In the geometrical examples we typically expect E symmetric or "bidirectional," i.e., for every edge $x \to y$ there is an edge $x \leftarrow y$, but we do not assume this in general. Explicitly,

$$\Omega^1(\Sigma) = \text{span}\{\, \delta_x \otimes \delta y | x \to y\}, \quad \mathrm{d}f = \sum_{y \in F_x} (f(y) - f(x)) \delta_x \otimes \delta_y; \quad F_x = \{\, y | x \to y\}.$$

Note also that the k-fold product

$$\Omega^1(\Sigma) \underset{M}{\otimes} \cdots \underset{M}{\otimes} \Omega^1(\Sigma) = \text{span}\{\, \delta_x \otimes \delta_{x_1} \otimes \cdots \otimes \delta_{x_k} | x \to x_1 \to x_2 \to \cdots \to x_k\},$$

i.e., the linear span of the set of k-arcs. The bimodule structures are the pointwise ones for products from the extreme left and right.

As explained in Ref. 10 a vielbein in this setting is possible *iff* E fibers over Σ, i.e., F_x have cardinality n (say), independent of x. In this case an n-bein is the specification of invertible $n \times n$ matrices $e_{\cdot x,\cdot}$ for each $x \in \Sigma$. Here e_{axy} has indices $a \in 1, \ldots, n$ and $y \in F_x$. We write the inverses as e_a^{-1xy} with

$$\sum_{y \in F_x} e_a^{-1xy} e_{bxy} = \delta_{a,b}, \quad \sum_a e_a^{-1xy} e_{axy'} = \delta^y_{y'}. \tag{9}$$

In this case the operators (1) are

$$\rho^b_a(f)(x) = \sum_{y \in F_x} e_b^{-1xy} f(y) e_{axy}, \quad (\partial^a f)(x) = \sum_{y \in F_x} (f(y) - f(x)) e_a^{-1xy}. \tag{10}$$

A calculus on an algebra M is inner if there is a one-form θ with $\mathrm{d}f = [\theta, f]$ for $f \in M$.

Theorem 2.1: *cf. Ref. 10. A finite set calculus equipped with a vielbein is inner,*

$$\theta = \sum_a \Theta_a e_a, \quad \Theta_a(x) = \sum_{y \in F_x} e_a^{-1xy}.$$

Moreover, the maximal prolongation exterior algebra $\Omega(\Sigma)$ *has likewise* $\mathrm{d} = [\theta, \}$ (*graded anticommutator) and is generated by* $\mathbb{C}(\Sigma)$ *and the quadratic algebra on the* $\{e_a\}$ *with relations*

$$\sum_{y \in F_{x,z}} \sum_{a,b} e_a^{-1xy} e_b^{-1yz} e_a \wedge e_b = 0, \quad \forall\, (x,z) \notin E \cup \text{diag}; \quad F_{x,z} = \{\, y | x \to y \to z\}.$$

Proof: We define θ as stated. Then the explicit formulas (10) allow one to verify that $\mathrm{d}f = [\theta, f]$ for any function f, as required. The maximal prolongation of the Ω^1 is defined as the tensor algebra over $M = \mathbb{C}(\Sigma)$ modulo the relations in degree 2 imposed by extending d as a superderivation with $\mathrm{d}^2 = 0$. More precisely, we lift any one-form to the universal differential calculus over $\mathbb{C}(\Sigma)$, apply the universal exterior derivative there, and then project down to Ω^2. That this should be well-defined defines the minimal relations in degree 2 (which are the only ones imposed in the maximal prolongation). In our case a basis of the kernel of the projection to Ω^1 is given by $\delta_x \mathrm{d} \delta_z = 0$ whenever $(x,z) \notin E \cup \text{diag}$, so we require for each such (x,z) the relation

$$\mathrm{d}\delta_x \wedge \mathrm{d}\delta_z = 0.$$

We compute

$$\mathrm{d}\delta_x = \sum_a \sum_{y\in F_\cdot} (\delta_x(y) - \delta_x) e_a^{-1\cdot y} e_a = \sum_a (e_a^{-1\cdot x} - \delta_x \Theta_a(x)) e_a,$$

where $\cdot$ denotes a functional dependence on points in Σ and we adopt the convention that $e_a^{-1wx} = 0 = e_{awx}$ if $x \notin F_w$. Note also that

$$\sum_a e_a^{-1\cdot x} \rho_a^c(f) = \sum_{y\in F_\cdot} \sum_a e_a^{-1\cdot x} e_c^{-1\cdot y} f(y) e_{\cdot y} = f(x) e_c^{-1\cdot x}$$

by (10) and (9). The latter also implies that $\Sigma_a \Theta_a(x) e_{axy} = 1$ if $y \in F_x$. Hence

$$\begin{aligned}
\mathrm{d}\delta_x \wedge \mathrm{d}\delta_z &= \sum_{a,b,c} e_a^{-1\cdot x} \rho_a^c(e_b^{-1\cdot z}) e_c \wedge e_b - \sum_{a,b,c} e_a^{-1\cdot x} \Theta_b(z) \rho_a^c(\delta_z) e_c \wedge e_b - \sum_{a,b,c} \delta_x \Theta_a(x) \rho_a^c(e_b^{-1\cdot z}) e_c \wedge e_b \\
&\quad + \sum_{a,b,c} \delta_x \Theta_a(x) \Theta_b(z) \rho_a^c(\delta_z) e_c \wedge e_b \\
&= \sum_{b,c} e_c^{-1\cdot x} e_b^{-1xz} e_c \wedge e_b - \sum_{b,c} \delta_z(x) \Theta_b(z) e_c^{-1\cdot z} e_c \wedge e_b - \delta_x \sum_{b,c} \sum_{y\in F_x} e_c^{-1xy} e_b^{-1yz} e_c \wedge e_b \\
&\quad + \delta_x \sum_{a,b,c} \Theta_a(x) \Theta_b(z) e_{axz} e_c^{-1xz} e_c \wedge e_b.
\end{aligned}$$

The first and last terms vanish for $(x,z) \notin E$ and the second term for $x \neq z$. Hence in this case we obtain precisely the relation stated from the remaining third term. This completes the proof of the result mentioned in Ref. 10.

It is then a computation to write

$$e_a = \sum_{(x,y)\in E} e_{axy} \delta_x \mathrm{d}\delta_y = \sum_{y\in F_\cdot} e_{a\cdot y} \mathrm{d}\delta_y$$

and obtain $\mathrm{d}e_a = \theta e_a + e_a \theta$. Note that the compatibility of d with the relations (1) for all f more or less requires this relation since applying d to (1) gives $(\mathrm{d}e_a - \{\theta, e_a\}) f = \rho_a^b(f)(\mathrm{d}e_b - \{\theta, e_b\})$ after using (1) and that the calculus is inner. □

We note in passing that by similar computations the maximal prolongation has

$$\begin{aligned}
\theta \wedge \theta = \sum_{a,b} \Theta_a e_a \Theta_b e_b &= \sum_{a,b,c} \Theta_a \sum_{y\in F_\cdot} e_c^{-1\cdot y} \Theta_b(y) e_{a\cdot y} e_c \wedge e_b \\
&= \sum_{b,c} \sum_{y\in F_\cdot} e_c^{-1\cdot y} \Theta_b(y) e_c \wedge e_b = \sum_{a,b} \sum_{\cdot\to y\to z} e_a^{-1\cdot y} e_b^{-1yz} e_a \wedge e_b
\end{aligned}$$

which [in view of the relations for $\Omega^2(\Sigma)$] has contributions only from $z = \cdot$ and $\cdot \to z$. This is not necessarily zero, i.e., θ is not necessarily closed [rather, $\mathrm{d}\theta = 2\theta \wedge \theta$ so that $\alpha = -2\theta$ is always a zero curvature $U(1)$ connection].

We also require for a G-covariant vielbein that $V = \mathrm{span}\{e_a\}$ is a G module. The above constructions are all G-covariant under these local transformations of V. To define more general exterior algebras $\Omega(\Sigma)$ we let $\pi: V \otimes V \to V \otimes V$ be a G-equivariant projection operator, with components defined by $\pi_x(e_a \otimes e_b) = \Sigma_{c,d} \pi_{ab}^{cd} e_c \otimes e_d$. We define operators

$$\pi_{x,z}: \mathbb{C}F_{x,z} \to \mathbb{C}F_{x,z}, \quad \pi_{x,z}{}^{y}{}_{y'} = \sum_{a,b,c,d} \pi_{ab}^{cd} e_a^{-1xy} e_b^{-1yz} e_{cxy'} e_{dy'z} \tag{11}$$

on the space spanned by 2-arcs with fixed endpoints x, z.

Theorem 2.2: *π defines an exterior algebra with $\mathrm{d}^2 = 0$ as a quotient of the tensor algebra on V by the quadratic relations*

$$\ker \pi = 0$$

iff

$$\text{(i)}\quad \sum_{a,b,c,d} \pi_{ab}^{cd} e_a^{-1xy} e_b^{-1yz} e_{cxy'} e_{dy'z'} = 0, \quad \forall\, z \neq z';\quad y \in F_{x,z},\quad y' \in F_{x,z'}$$

$$\text{(ii)}\quad \sum_{y \in F_{x,z}} \pi_{x,z}{}^{y}{}_{y'} = 0, \quad \forall\, (x,z) \notin E \cup \mathrm{diag},\quad y' \in F_{x,z}.$$

Proof: We identify $\Omega^1(\Sigma) \otimes_M \Omega^1(\Sigma)$ with $\mathbb{C}(\Sigma) \otimes V \otimes V$ via the vielbein so that π induces left-module projection operators on this. These are, therefore, given by projection matrices π_x on the space spanned by the 2-arcs from x, for each x. Their components are

$$\pi^{yz}_{x_{y'z'}} = \sum_{a,b,c,d} \pi_{ab}^{cd} e_a^{-1xy} e_b^{-1yz} e_{cxy'} e_{dy'z'}.$$

We require that these are also right module maps, which is the condition (i) stated. It means that $\pi^{yz}_{x_{y'z'}} = \pi_{x,z}{}^{y}{}_{y'} \delta_z^{z'}$ for a family of projections $\pi_{x,z}$ for each fixed x, z. These are the operators (11). As explained in Ref. 10 there is then a condition on the family of projectors to ensure that the quotient $\Omega^1(\Sigma) \otimes_M \Omega^1(\Sigma) \to \Omega^2(\Sigma)$ factors through the maximal prolongation, namely the condition (ii). This is necessary and sufficient for the relations in $\Omega^2(\Sigma)$ defined by $\ker \pi$ to be compatible with the extension of d to two-forms via the graded Leibniz rule. □

The maximal prolongation in Theorem 2.1 can be viewed as given by a generalization of this construction in which the projection π is allowed to vary from point to point. The more specific construction in Theorem 2.2 is necessarily a quotient of it by further relations.

Finally, we fix an Ad-stable subset $\mathcal{C} \subset G$ with $e \notin \mathcal{C}$ (e here the group identity), e.g., a nontrivial conjugacy class. These describe the bicovariant calculi $\Omega^1(G)$ in the Woronowicz theory.[16] The space of invariant forms Λ^1 in $\Omega^1(G)$ has basis $\{e_i \,|\, i \in \mathcal{C}\}$. The dual basis of Λ^{1*} is $\{f^i\}$ with $f^i = i - e$. The torsion and cotorsion equations then have the same forms (2) and (5), with $Si = i^{-1}$ the group algebra antipode. The regularity condition now reads

$$\sum_{ij=q} A_i \wedge A_j = 0, \quad \forall\, q \notin \mathcal{C} \cup \{e\}. \tag{12}$$

This is empty if we chose the universal calculus on G (where $\mathcal{C} = G - \{e\}$), but in general it is a quadratic constraint. The curvature form is then

$$F_i = \mathrm{d}A_i + \sum_{jk=i} A_j \wedge A_k - \left\{ A_i, \sum_j A_j \right\}. \tag{13}$$

The formulas for the Ricci and Riemann tensors and ∇ have the same form (8).

III. MODULI OF GEOMETRIES ON TWO OR THREE POINTS

In this section we describe the moduli space of possible vielbeins and metrics on two or three points, and moduli of spin connections and their curvature for some points in the moduli of vielbeins with respect to frame group S_2 or S_3.

More precisely, the moduli of possible vielbeins is in the first place labeled by two natural numbers $m = |\Sigma|$ and n a fixed number of arcs from each point. For each m, n, the combinatorial part of the moduli space consists of determining all possible quiver structures with no self-arcs, i.e., all $E \subseteq \Sigma \times \Sigma - \mathrm{diag}$ with F_x of cardinality n at each $x \in \Sigma$. We interpret it as finding all possible parallelizable $\Omega^1(\Sigma)$ with n-dimensional cotangent space. Note that $\overline{E}$ where we flip the entries of E defines another calculus $\overline{\Omega^1}(\Sigma)$ and in the asymmetric case one could (although we do not do it here) demand this to also be parallelizable, with an associated number $\overline{n}$. There is a corresponding moduli of geometries built on this arrow-reversed calculus.

For $m = 2$ or $\Sigma = \{x, y\}$ there is only one possibility, namely $n = 1$ and the quiver

$$x \leftrightarrow y$$

up to relabelings. This is the universal calculus on Σ where E is as large as possible.

For $m=3$ or $\Sigma=\{x,y,z\}$ there are two cases for $n=1$, namely

$$\begin{array}{ccc} x & \to & y \\ & \searrow\ \swarrow & \\ & z & \end{array}, \quad x \leftrightarrow y \leftarrow z$$

up to relabelings. These are asymmetric. For $n=2$ there is only one possibility, the universal calculus on Σ again, which is always symmetric. It is given by

$$\begin{array}{ccc} x & \leftrightarrow & y \\ & \searrow\ \swarrow & \\ & z & \end{array}.$$

Next, for our projection matrix π to define $\Omega^2(\Sigma)$ we make the "naïve" choice

$$\pi = \tfrac{1}{2}(\mathrm{id} - \tau), \tag{14}$$

where τ is the usual "flip" operator on the tensor product, i.e., we assume the basic one-forms anticommute. This seems to give reasonable results for $n=2$ and a small number of points (in general it would be too restrictive). For $n=1$ we choose $\pi=1$ (the choice $\pi=0$ is also allowed but not very interesting). More generally, we should determine all possible equivariant $\pi: V\otimes V\to V\otimes V$ for choice of frame group G and a representation V of dimension n. The representation theory of G then dictates the possible equivariant projection matrices $\pi: V\otimes V\to V\otimes V$. This is the representation theoretic part of the moduli space. In our case, we take symmetric groups S_2, S_3 appropriate to a our small number of points. For $n=1$, V has to be trivial (we denote this by $\mathbb{C}$) or the sign representation given by $(-1)^{l(g)}$ where l is the length function. For $n=2$ we have $V=\mathbb{C}\oplus\mathrm{sign}$, $V=\mathrm{sign}\oplus\mathrm{sign}$ or, in the case of S_3 also its two-dimensional representation. In all three cases $V\otimes V=\mathbb{C}\oplus\mathrm{sign}\oplus V$ and the "naïve" π (14) projects out all but the sign representation here (cf. in classical geometry the top form transforms by the determinant under a linear transformation). The invariant local metric η up to a normalization is also classified by representation theory and we take it as the generator of the natural trivial representation in the decomposition of $V\otimes V$.

Fixing all the above quasi-combinatorial data, we have a moduli space

$$\mathrm{Vielbeins}_{m,n,E,\pi} = \{e_{a,x,y}\}/\mathrm{GL}_n \tag{15}$$

consisting of m $n\times n$ invertible matrices subject to the constraints in Theorem 2.2. We divide by an overall GL_n acting on the left and corresponding to a change of basis of V. We arrive at a certain algebraic variety which we shall describe first.

Finally, for a fixed vielbein and the above data, we look at the moduli of spin connections for η. This last part requires us to fix a differential structure on G. For S_2 the only choice is the universal calculus $\Omega^1(S_2)$. For S_3 there is the universal calculus and the calculus corresponding to the two-cycles conjugacy class. The remaining conjugacy class does not give a reasonable geometry of S_3 (it is not connected) and does not appear to give interesting results, so we omit it. In all cases we assume that the action of G on V is not trivial when restricted to the braided-Lie algebra generators f^i. Otherwise, they would act as zero, the Riemann curvature would be automatically zero and ∇ would be just given by d for any spin connection. So we omit this uninteresting case in our analysis.

The case $\pi=0$ is trivial and we deal with it here. In this case $\Omega^1(\Sigma)$ is the top degree so that there is no constraint on the $\{e_{axy}\}$ other than being invertible, i.e.,

$$\mathrm{Vielbeins}_{m,n,E,0} = (GL_n)^{m-1}.$$

Similarly the torsion, cotorsion and regularity conditions are empty and any collection of one-forms $\{A_i\}$ are trivially a spin connection, with zero curvature.

A. Two points

For $\Sigma=\{x,y\}$ the only choice is the universal calculus as explained above, which has $n=1$, i.e., we look for a 1-bein e_1. We write

$$e_1=\alpha\delta_x\otimes\delta_y+\beta\delta_y\otimes\delta_x;\quad e_{1xy}=\alpha,\quad e_{1yx}=\beta,\quad \alpha,\beta\neq 0.$$

The partial derivatives and commutation relations are

$$e_1 f=\overline{f}e_1,\quad \partial^1 f=(\overline{f}-f)\Theta;\quad \Theta(x)=\alpha^{-1},\quad \Theta(y)=\beta^{-1};$$

$$\overline{f}(x)=f(y),\quad \overline{f}(y)=f(x).$$

The generating one-form and exterior derivative are

$$\theta=\Theta e_1,\quad \mathrm{d}f=(\overline{f}-f)\theta.$$

For $\Omega^2(\Sigma)$ we have only one nontrivial possibility, namely $\pi=1$, which gives the maximal prolongation with no relations in the exterior algebra (it is the universal exterior algebra on Σ). The conditions in Theorem 2.2 are empty as the assumptions are never satisfied. Here $\Lambda=\mathbb{C}[e_1]$ and each $\Omega^k(\Sigma)$ is one-dimensional over $\mathbb{C}(\Sigma)$. The exterior derivatives are defined by the graded-Leibniz rule and

$$\mathrm{d}e_1=(\Theta+\overline{\Theta})e_1^2.$$

Proposition 3.1: For any Θ *the dimensions* p_i of H^i *are* $1:0:0:\ldots$. *Here*

$$H^0=\mathbb{C}.1,\quad H^i=\{0\};\quad i\geqslant 1.$$

Proof: First of all we show explicitly that, in accordance with Theorem 2.2, $\mathrm{d}^2=0$.

$$\mathrm{d}(\mathrm{d}f)=\mathrm{d}(\Theta(\overline{f}-f)e_1)=(\Theta\overline{\Theta}(f-\overline{f})+\Theta\overline{\Theta}(\overline{f}-f))e_1^2=0.$$

The functions f such that $df=0$ are the constant ones so the nullspace of d acting on $\mathbb{C}(\Sigma)$ is one-dimensional (and therefore, $p_0=1$). Since the dimension of $\Omega^1(\Sigma)=2$ this means that the image of d in $\Omega^1(\Sigma)$ is one-dimensional. If $\omega=fe_1$ is a one-form, $\mathrm{d}\omega=0$ if and only if $f\overline{\Theta}+f\overline{\Theta}=0$, or $f=\Theta(\delta_x-\delta_y)$ which implies that the nullspace of d contained in $\Omega^1(\Sigma)$ is one-dimensional. Then, $p_1=1-1=0$. In turn, the image of d in $\Omega^2(\Sigma)$ is one-dimensional, and so $p_2=1-1=0$ and so forth. □

Since we are working modulo an overall change of basis including normalization, only $\alpha^{-1}\beta$ is significant, so

$$\mathrm{Vielbeins}_{2,1,\mathrm{univ},1}=\mathbb{C}^*.$$

Next we look at spin connections. For group G we assume a symmetric group acting in the only nontrivial possibility, the sign representation on e_1. Thus $f^i\triangleright e_1=0$ if the permutation i is even and $f^i\triangleright e_1=-2e_1$ if i is odd. For S_2 we have only the universal calculus, hence only one f^i where $i=(12)$. We write $A=ae_1$ for a function a. Then the torsion-free condition becomes

$$\Theta+\overline{\Theta}-2a=0,$$

which is also the cotorsion-free condition, while the regularity condition is empty. Hence for each one-bein there is a unique spin connection

$$a = \frac{\alpha + \beta}{2\alpha\beta} = \frac{\Theta + \overline{\Theta}}{2},$$

which is a constant function. Its curvature is

$$F = \mathrm{d}A - 2A^2 = 0,$$

which means that the Riemann tensor is also zero. The covariant derivative is

$$\nabla(fe_1) = \mathrm{d}f \otimes e_1 + f(\Theta + \overline{\Theta})e_1 \otimes e_1. \tag{16}$$

For S_3 with its three-dimensional (two-cycles) calculus we have $f^i \triangleright e_1 = -2e_1$ and writing the three components functions a_1, a_2, a_3 of the spin connections in directions (12), (23), and (13), the torsion and cotorsion conditions for any fixed one-bein become

$$\Theta + \overline{\Theta} - 2(a_1 + a_2 + a_3) = 0$$

while the regularity (which does not depend on the representation) is

$$a_1\overline{a_2} + a_2\overline{a_3} + a_3\overline{a_1} = 0.$$

There are different classes of solutions including a two-dimensional part of the moduli space of spin connections for a generic one-bein. The curvature is

$$F_i = (a_i - \overline{a_i})(\overline{\Theta} - \Theta)e_1 \wedge e_1$$

and is typically nonzero if the factor $(\overline{\Theta} - \Theta)(x) = (\alpha - \beta/)\alpha\beta$ is nonzero. On the other hand, we find (16) again, with zero Riemann curvature.

For S_3 with its five-dimensional (universal) calculus, a spin connection consists of components b_1, b_2 in the three-cycles directions which are unconstrained, and a_1, a_2, a_3 in the two-cycles directions, with the single linear equation

$$\Theta + \overline{\Theta} - 2(a_1 + a_2 + a_3) = 0$$

for vanishing of torsion and cotorsion. The regularity condition is empty. So here the moduli space of connections is linear for each vielbein. There is typically curvature at the frame bundle level but again the Riemann curvature vanishes since ∇ is still given by (16).

We conclude for 2 points that increasing the frame braided Lie algebra allows more spin connections but these do not enter into the Riemannian geometry itself. Instead, we find a unique generalized Levi–Cività type covariant derivative (16) for each einbein, and it has zero Riemannian curvature.

B. Three points

For $\Sigma = \{x, y, z\}$ there are two fibrations for $n=1$ and one for $n=2$ as explained above.

For $n=1$ a vielbein means three invertible numbers $\{e_{\cdot x}\}, \{e_{\cdot y}\}, \{e_{\cdot z}\}$. However, both types of fibrations for $n=1$ imply $\pi=0$ as the only solution. This is forced by the conditions in Theorem 2.2 as follows. For the triangular fibration the 2-arcs are

$$x \to y \to z, \quad y \to z \to x, \quad z \to x \to y$$

but then condition (ii) requires $\pi_{x,z}{}^{y}{}_{y'} = 0$, which implies $\pi = 0$. For the case of the other fibration the two-arcs are

$$z \to x \to y, \quad x \to y \to x, \quad y \to x \to y.$$

In this case condition (ii) requires $\pi_{z,y}{}^{x}{}_{x'} = 0$ and hence $\pi = 0$. Hence for $n=1$ only the trivial case $\pi = 0$ already covered in general above is allowed.

For $n=2$ we have only one fibration, which is the universal $\Omega^1(\Sigma)$. Then a vielbein means in the first place three invertible matrices

$$e_{\cdot x\cdot}=X,\quad e_{\cdot y\cdot}=Y,\quad e_{\cdot z\cdot}=Z.$$

Because of the cyclic nature of the graph, we label the columns of X as y,z, of Y as z,x and of Z as x,y. There are two types of two-arcs, namely

$$x\to y\to z,\quad x\to z\to y,\quad y\to x\to z,\quad y\to z\to x,\quad z\to x\to y,\quad z\to y\to x$$

or

$$x\to y\to x,\quad x\to z\to x,\quad y\to x\to y,\quad y\to z\to y,\quad z\to x\to y,\quad z\to y\to x.$$

Finally, we take the "naive" form (14) for π. The condition (ii) in Theorem 2.2 is empty because $\Omega^1(\Sigma)$ is universal. Condition (i) gives equations of the form

$$0=\pi^{xyz}_{xy'z'}=\tfrac{1}{2}(e_1^{-1xy}e_2^{-1yz}-e_2^{-1xy}e_1^{-1yz})(e_{1xy'}e_{2y'z'}-e_{2xy'}e_{1y'z'})$$

for $z'\neq z$ and $x\to y'\to z'$. Similarly for other 2-arcs in place of $x\to y\to z$. The allowed cases are vanishing of

$$\pi^{xyz}_{xzy},\quad \pi^{xyz}_{xyx},\quad \pi^{xyx}_{xzy},\quad \pi^{xzx}_{xyz},\quad \pi^{xzx}_{xzy},\quad \pi^{xzy}_{xyz},\quad \pi^{xyx}_{xyz},\quad \pi^{xzy}_{xyx},\quad \pi^{xyz}_{xzx},\quad \pi^{xzy}_{xzx}$$

and the cyclic rotations of (xyz). Finally, keeping in mind the factorization in the formula for π, we define

$$f(x,y,z)=X_{1y}Y_{2z}-X_{2y}Y_{1z}=X_{11}Y_{21}-X_{21}Y_{11},$$

$$f(x,y,x)=X_{1y}Y_{2x}-X_{2y}Y_{1x}=X_{11}Y_{22}-X_{21}Y_{12},$$

etc. Here the first two entries of f determine the matrices used, while the second two entries of f label the indices on the matrices. Similarly, we define $\overline{f}(x,y,z)$, etc. in the same way but with X^{-t}, Y^{-t}, Z^{-t} the inverse-transposed matrices. With these notations we see that

$$\mathrm{Vielbeins}_{3,2,\mathrm{univ,flip}}$$

is the variety consisting of three invertible matrices X,Y,Z subject to the relations

$$0=\overline{f}(x,y,z)f(x,z,y),\quad 0=\overline{f}(x,y,z)f(x,y,x),\quad 0=\overline{f}(x,y,x)f(x,z,y),$$

$$0=\overline{f}(x,z,x)f(x,y,z),\quad 0=\overline{f}(x,z,x)f(x,z,y),\quad 0=f(x,y,z)\overline{f}(x,z,y),$$

$$0=f(x,y,z)\overline{f}(x,y,x),\quad 0=f(x,y,x)\overline{f}(x,z,y),$$

$$0=f(x,z,x)\overline{f}(x,y,z),\quad 0=f(x,z,x)(x,z,y),$$

and their cyclic rotations of (xyz), and modulo an overall GL_2.

In principle this could have several cases depending on which factor vanishes in each case. One special case is

$$f(x,y,z)=0,\quad f(x,z,y)=0,\quad \overline{f}(x,y,z)=0,\quad \overline{f}(x,z,y)=0,$$

and its cyclic rotations. These equations reduce to

$$X_{21}Y_{11}=X_{11}Y_{21},\quad Y_{12}X_{22}=X_{12}Y_{22},\quad X_{11}Z_{21}=Z_{11}X_{21},\quad X_{22}Z_{12}=X_{12}Z_{22}.$$

Up to an overall GL_2, this component of the moduli space of vielbeins has the general solution

$$X=\begin{pmatrix}\alpha_1 & 0\\ 0 & \alpha_2\end{pmatrix},\quad Y=\begin{pmatrix}\beta_1 & 0\\ 0 & \beta_2\end{pmatrix},\quad Z=\begin{pmatrix}\gamma_1 & 0\\ 0 & \gamma_2\end{pmatrix}$$

modulo a remaining $\mathbb{C}^*\times\mathbb{C}^*$ (e.g., up to GL_n one can assume $\alpha_1=\alpha_2=1$). We have

$$\Theta_a(x)=\alpha_a^{-1},\quad \Theta_a(y)=\beta_a^{-1},\quad \Theta_a(z)=\gamma_a^{-1}$$

and

$$e_a f=R_a(f)e_a,\quad \partial^a f=(R_a(f)-f)\Theta_a,$$

where we identify Σ with $\mathbb{Z}_3$ and use its addition law according to the conventions above to define $R_a(f)=f(()+a)$. For the exterior algebra, by our choice of π, the exterior algebra relations are $e_1\wedge e_2=-e_2\wedge e_1$ and $e_1^2=e_2^2=0$. We are finally ready to look at compatible spin connections, which we do for groups S_2 and then S_3, with their natural nontrivial representations and calculi. Note that since we have already chosen a diagonal form of the vielbein moduli space, different actions are not all equivalent.

Proposition 3.2: For any values of Θ_1,Θ_2 the dimensions p_i of H^i are $1:2:1$. *Here*

$$H^0=\mathbb{C}.1,\quad H^1=\mathbb{C}.\langle-\Theta_1\delta_y e_1+\Theta_2\delta_z e_2,-\Theta_1\delta_x e_1+\Theta_2\delta_y e_2\rangle,\quad H^2=\mathbb{C}.e_1\wedge e_2.$$

Proof: Since in this case $R_2=R_1^{-1}$ we have

$$\mathrm{d}(\mathrm{d}f)=(\Theta_1R_1\Theta_2-\Theta_2R_2\Theta_1)(R_1R_2f-f)=0,\ \forall\ f\in\mathbb{C}[\Sigma]$$

and d is cohomological. By observing that $\mathrm{d}f=0$ if and only if f is constant, we have $p_0=1$ and the dimension of the image of d in $\Omega^1(\Sigma)$ (which is itself of dimension 6) is 2. If $\omega=fe_1+ge_2$ is a one form, then $\mathrm{d}\omega=0$ if and only if $(-\Theta_2\overline{\partial^2}f+f\overline{\partial^1}\Theta_2+\Theta_1\overline{\partial^1}g-g\overline{\partial^2}\Theta_1)=0$. This equation admits a four-dimensional space of solutions, therefore $p_1=4-2=2$. Moreover the image of d in the two-forms is of dimension 2, and given that d sends every two-form to zero, one obtains $p_2=3-2=1$. H^1 is spanned by $\langle-\Theta_1\delta_y e_1+\Theta_2\delta_z e_2,-\Theta_1\delta_x e_1+\Theta_2\delta_y e_2\rangle$, and $H^2=\mathbb{C}.e_1\wedge e_2$. □

For S_2 with its universal calculus, we choose the natural action of $i=(12)$ of $V=\mathrm{span}\{e_1,e_2\}$ that flips the basis vectors (hence by orientation reversal of the frame). The invariant metric here is

$$\eta=e_1\otimes e_1+e_2\otimes e_2$$

and the action of the braided-Lie algebra generator of S_2 is $f^i\triangleright e_1=e_2-e_1$ and $f^i\triangleright e_2=e_1-e_2$. Let us denote by $\overline{\partial^i}\equiv R_i-\mathrm{id}$ the usual finite difference on the group $\mathbb{Z}_3$, and $\langle\ \rangle$ denotes the average value over the three points.

Proposition 3.3: For 3 points, two-dimensional cotangent space and S_2 frame group, existence of a torsion free cotorsion free connection requires the zweibein to obey

$$\Theta_1+R_1\Theta_2=\langle\Theta_1+\Theta_2\rangle.$$

In this case there is a one-parameter family of connections of the form

$$A=(\Theta_1-\lambda)e_1+(-R_2\Theta_1+\lambda)e_2$$

for an arbitrary constant λ. *The covariant derivative is*

$$\nabla e_1=-\nabla e_2=((\Theta_1-\lambda)e_1+(-R_2\Theta_1+\lambda)e_2)\otimes(e_1-e_2).$$

Its Riemannian and Ricci curvatures are

$$\text{Riemann}(e_1) = -\text{Riemann}(e_2) = \rho e_1 \wedge e_2 \otimes (e_2 - e_1), \quad \text{Ricci} = \frac{\rho}{2}(e_1 + e_2) \otimes (e_1 - e_2),$$

where

$$\rho = (2\lambda - \langle \Theta_1 + \Theta_2 \rangle)\overline{\partial}^2 \Theta_1.$$

The Ricci scalar vanishes identically.

Proof: Writing a spin connection $A = ae_1 + be_2$, the torsion and cotorsion equations reduce to

$$\overline{\partial}^1 \Theta_2 = \overline{\partial}^2 \Theta_1 = -(a + b) = R_2(a) + R_1(b)$$

and there is no regularity condition since the calculus on S_2 is universal. The third of these equations has solution $b = -R_2(a)$ since $(\mathrm{id} + R_1)$ is invertible on $\mathbb{Z}_3$. The full system for a vielbein and spin connection then reduces to invertibility of the Θ_i values, the stated constraint on the zweibein, and

$$a = \Theta_1 - \lambda, \quad b = -R_2\Theta_1 + \lambda$$

for an arbitrary constant λ. A straightforward computation then gives the curvature as

$$F = \mathrm{d}A - A^2 = \rho e_1 \wedge e_2$$

for ρ as stated, which Riemann curvature as the action of F. One may also compute this directly from the covariant derivative stated. Finally, for the antisymmetrization projector that we use, the lifting map i is

$$i(e_1 \wedge e_2) = \tfrac{1}{2}(e_1 \otimes e_2 - e_2 \otimes e_1). \tag{17}$$

Using this to lift the two-form values of the Riemann tensor and contracting as in (7) we obtain the Ricci tensor as stated. Its further contraction by the inverse metric is then zero. □

We see among other things that Θ_2 is determined up to a constant from Θ_1, i.e., not every zweibein is allowed. On the other hand, for a generic allowed zweibein we have zero full curvature for a unique spin connection in the family, given by $\lambda = \frac{1}{2}\langle \Theta_1 + \Theta_2 \rangle$. Otherwise the curvatures are nonzero.

For S_3 with its standard two-dimensional irreducible representation and 2-cycles calculus, we have now $i = (12), (23), (13)$ (as i ranges 1,2,3) with the above flip action of (12) extended to a permutation of $e_1, e_2, e_3 \equiv -e_1 - e_2$. The invariant metric is

$$\eta = e_1 \otimes e_1 + e_2 \otimes e_2 + \tfrac{1}{2}(e_1 \otimes e_2 + e_2 \otimes e_1)$$

and the action of S_3 on the vielbein is

$$f^1 \triangleright e_1 = e_2 - e_1, \quad f^2 \triangleright e_1 = 0, \quad f^3 \triangleright e_1 = -2e_1 - e_2,$$

$$f^1 \triangleright e_2 = e_1 - e_2, \quad f^2 \triangleright e_2 = -e_1 - 2e_2, \quad f^3 \triangleright e_2 = 0.$$

Proposition 3.4: For 3 points, two-dimensional cotangent space and S_3 frame group, the zweibein is unconstrained and the torsion free cotorsion free connections are of the form

$$A_i = a_i e_1 + b_i e_2; \quad a_1 = a, \quad b_1 = b,$$

$$a_2 = \tfrac{1}{2}(\overline{\Theta}_1 - a), \quad b_2 = R_2\overline{\Theta}_1 + b, \quad a_3 = R_1\overline{\Theta}_2 + a, \quad b_3 = \tfrac{1}{2}(\overline{\Theta}_2 - b)$$

for arbitrary functions a, b and constants λ, μ. Here $\overline{\Theta}_1 \equiv \Theta_1 - \lambda$ and $\overline{\Theta}_2 \equiv \Theta_2 - \mu$ are notations. For a regular connection we would need in addition:

$$aR_1b_2 - bR_2a_2 + a_3R_1b - b_3R_2a + a_2R_1b_3 - b_2R_2a_3 = 0,$$

$$a_2R_1b - b_2R_2a + aR_1b_3 - bR_2a_3 + a_3R_1b_2 - b_3R_2a = 0.$$

The covariant derivative for the connection is

$$\nabla e_1 = (3a + 2R_1\overline{\Theta}_2)e_1 \otimes e_1 + R_1\overline{\Theta}_2 e_1 \otimes e_2 + \overline{\Theta}_2 e_2 \otimes e_1 + \tfrac{1}{2}(\overline{\Theta}_2 - 3b)e_2 \otimes e_2,$$

$$\nabla e_2 = \tfrac{1}{2}(\overline{\Theta}_1 - 3a)e_1 \otimes e_1 + \overline{\Theta}_2 e_1 \otimes e_2 + R_2\overline{\Theta}_1 e_2 \otimes e_1 + (3b + 2R_2\overline{\Theta}_1)e_2 \otimes e_2.$$

Proof: The torsion equations for a spin connection with components a_i, b_i are

$$\overline{\partial}^1\Theta_2 + a_1 + b_1 + 2b_3 - a_3 = 0, \quad -\overline{\partial}^2\Theta_1 - a_1 - b_1 + b_2 - 2a_2 = 0$$

and the cotorsion equations

$$\overline{\partial}^1\Theta_2 - (R_2a_1 + R_1b_1 - R_2a_3 + 2R_1b_3) = 0,$$

$$-\overline{\partial}^2\Theta_1 + R_1b_1 + R_2a_1 - R_1b_2 + 2R_2a_2 = 0.$$

By combining these equations and using similar methods as in the previous S_2 examples, one finds that their general solution is of the form:

$$\Theta_1 = 2a_2 + a_1 + \lambda, \quad R_1(\Theta_2) = a_3 - a_1 + \mu,$$

$$b_1 + 2b_3 = R_2(a_3 - a_1), \quad 2b_3 + b_2 = R_2(2a_2 + a_3)$$

for some constants λ, μ. This means that for a fixed vielbein and constants μ, λ the equations for a connection are solved as stated. One then writes out the covariant derivative and the optional regularity condition. □

We can see here (and also in our previous examples) why full metric compatibility $\nabla\eta = 0$ is too strong in finite noncommutative geometry (which is why we need our weaker cotorsion-free condition):

Proposition 3.5: The covariant derivatives above do not fully preserve the metric unless $a = b = 0$ *and* $\Theta_1 = \lambda, \Theta_2 = \mu$ *are constant.*

Proof: We compute

$$\begin{aligned}\nabla\eta = {} & \left(\frac{9}{2}a + 4R_1\overline{\Theta}_2 + \frac{\overline{\Theta}_1}{2}\right)e_1 \otimes e_1 \otimes e_1 + (2R_1\overline{\Theta}_2 + \overline{\Theta}_1)e_1 \otimes e_1 \otimes e_2 + (2R_1\overline{\Theta}_2 + \overline{\Theta}_1)e_1 \otimes e_2 \otimes e_1 \\ & + (2\overline{\Theta}_2 + R_2\overline{\Theta}_1)e_2 \otimes e_1 \otimes e_1 + (2\overline{\Theta}_1 + R_1\overline{\Theta}_2)e_1 \otimes e_2 \otimes e_2 + (\overline{\Theta}_2 + 2R_2\overline{\Theta}_1)e_2 \otimes e_1 \otimes e_2 + (\overline{\Theta}_2 \\ & + 2R_2\overline{\Theta}_1)e_2 \otimes e_2 \otimes e_1 + \left(\frac{9}{2}b + 4R_2\overline{\Theta}_1 + \frac{\overline{\Theta}_2}{2}\right)e_2 \otimes e_2 \otimes e_2.\end{aligned}$$

For this to be zero forces $a = b = \overline{\Theta}_1 = \overline{\Theta}_2 = 0$ which translates as stated since λ, μ are arbitrary. □

One may proceed to compute the curvatures, etc., for a general solution. Here we present the results for the special case where the zweibein is constant with $\Theta_1 = \lambda$, $\Theta_2 = \mu$ say, but the a, b are artibrary, i.e., the flat background but not flat spin connection case.

Proposition 3.6: For constant zweibein but a, b *arbitrary, the Riemann and Ricci curvatures take the form*

$$\text{Riemann}(e_1) = (3\partial^2 a - \partial^1 b)e_1 \wedge e_2 \otimes e_1 - 2\partial^1 b e_1 \wedge e_2 \otimes e_2,$$

$$\text{Riemann}(e_2) = -\partial^2 a e_1 \wedge e_2 \otimes e_1 + 3\partial^1 b e_1 \wedge e_2 \otimes e_2,$$

$$\text{Ricci} = -\tfrac{3}{4}\partial^2 a e_1 \otimes e_1 + \tfrac{3}{2}\partial^1 b e_1 \otimes e_2 - \tfrac{1}{2}(3\partial^2 a - \partial^1 b)e_2 \otimes e_1 + \partial^1 b e_2 \otimes e_2.$$

The Ricci scalar vanishes identically. The regularity condition is

$$aR_1(b) = 0.$$

Proof: We compute the gauge curvature of the spin connection as

$$F_1 = (\mu\overline{\partial}^2 a + \lambda\overline{\partial}^1 b)e_1 \wedge e_2,$$

$$F_2 = -\left(\frac{1}{2}\mu\overline{\partial}^2 a - \lambda\overline{\partial}^1 b\right)e_1 \wedge e_2,$$

$$F_3 = -(-\mu\overline{\partial}^2 a + \lambda\overline{\partial}^1 b)e_1 \wedge e_2.$$

Its action on the zweibein then determines the Riemann curvature as stated, using (8). We recall that $\partial^i = \Theta_i\overline{\partial}^i$ is the geometrical partial derivative defined by d and we revert to this. We use the same lifting map as in Proposition 3.1 and (7) to find

$$\text{Ricci} = \frac{1}{2}\begin{pmatrix} F_2 - F_1 & F_1 + 2F_2 \\ -F_1 - 2F_3 & F_1 - F_3 \end{pmatrix}$$

in the e_i basis. This gives the result stated. Finally, note that the inverse of the matrix in η is

$$\eta^{-1} = \frac{4}{3}\begin{pmatrix} 1 & -\frac{1}{2} \\ -\frac{1}{2} & 1 \end{pmatrix}$$

in the dual basis and it is this which we use to contract against the Ricci tensor to obtain the Ricci scalar. Independently of the details of F_i, we have this as $\frac{2}{3}(F_2 - F_1 + F_1 - F_3 - \frac{1}{2}(F_1 + 2F_2 - F_1 - 2F_3)) = 0$, i.e., vanishes identically. □

The general case may be worked out in the same way: The formulas for the F_i are rather more complicated functions of the $a, b, \lambda, \mu, \Theta_i$, but the other steps follow the same pattern. In particular, the Ricci tensor has the same asymmetric form and the Ricci scalar vanishes in general. We see that with 3 points, the conditions with frame group S_2 are a little strong and constrain the zweibein, while with S_3 there are an abundance of spin connections compatible with any zweibein, namely a, b arbitrary (and two further parameters which one might fix, for example, by $\lambda = \langle\Theta_1\rangle$ and $\mu = \langle\Theta_2\rangle$) and that in all cases with three points, the Ricci scalar vanishes. Note that we have not covered it here, but one has a similar picture for S_3 with its universal calculus; then there are five one-forms A_i for the spin connection with linear equations for the torsion and cotorsion that prescribe the derivatives of Θ_1, Θ_2 in terms of the fields, and an empty equation for regularity.

IV. GEOMETRIES ON FOUR POINTS

For four points we will not be fully general as above but restrict to the more interesting class of models featuring already in our analysis for 2,3 points. First of all, we shall focus on the case of all arrows bidirectional, i.e., a symmetric subset E to define the calculus. This means for four points that we have (a) the square connectivity which is a two-dimensional calculus or (b) the universal or three-dimensional calculus. We look mainly at the former since it has a clear geometrical interpretation as the connectivity of a torus, namely in Secs. IV A–IV C. Indeed, this is

the natural calculus for the group $\mathbb{Z}_2\times\mathbb{Z}_2$ viewed as a discrete model of a torus. Section IV D covers the alternative of the universal calculus on the basis which has the connectivity of a tetrahedron or discrete model of a sphere.

Next, rather than the full analysis, we shall restrict attention to the diagonal vielbeins given by scalars attached to the edges as we deduced up to equivalence for the 3 points case above. These scalars are our remaining continuous degrees of freedom and allow our square to "pulse" by stretching or contracting edges. Such a restricted class is interesting for any fixed combinatorics. On the other hand, we will have more choices for the frame group and its calculus, still giving several models.

A. Discrete torus as base space

Thus, in this section, and the next two, we write the vertices as $\Sigma=\{(0,0),(1,0),(0,1),(1,1)\}$, using an additive group notation.

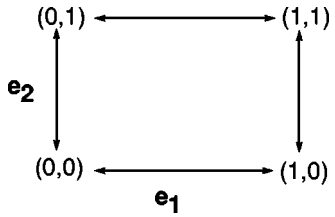
Over each point we have a fiber

$$F_{(0,0)}=\{(1,0),(0,1)\},\quad F_{(1,0)}=\{(0,0),(1,1)\},\quad F_{(0,1)}=\{(0,0),(1,1)\},\quad F_{(1,1)}=\{(1,0),(0,1)\}$$

of order 2. We fix the connectivity by identifying these fibers by vielbeins of the diagonal form

$$e_{1,x,y}=\Theta_1^{-1}(x)\delta_{y-x,(1,0)},\quad e_{2,x,y}=\Theta_2^{-1}(x)\delta_{y-x,(0,1)}$$

for any two points $x,y\in\Sigma$. This is the natural vielbeinon $\mathbb{Z}_2\times\mathbb{Z}_2$ with additional continuous nowhere-zero functional parameters Θ_i. We have the picture



From each point in the lattice it is possible to move in two directions, which correspond to the vectors e_1 and e_2. Here e_1 translates adding the element $(1,0)$ of $\mathbb{Z}_2\times\mathbb{Z}_2$, and e_2 corresponds to moving by adding $(0,1)$. We define the translation operators acting on the functions f as

$$(R_1f)(x)=f(x+(1,0)),\quad (R_2f)(x)=f(x+(0,1))$$

and obtain the partial derivatives

$$\partial^1 f(x)=(f(x+(1,0))-f(x))\Theta_1,\quad \partial^2 f(x)=(f(x+(0,1))-f(x))\Theta_2$$

and commutation relations [which define the right multiplication on $\Omega^1(\Sigma)$, left multiplication being the obvious one] as:

$$e_1f=R_1(f)e_1,\quad e_2f=R_2(f)e_2$$

for all functions f. This has the same form as we found up to GL_2 for three points in the preceding section and completes our description of Ω^1 and its $\mathbb{C}(\mathbb{Z}_2\times\mathbb{Z}_2)$-basis $\{e_1,e_2\}$.

Next we fix the projector π as the naive antisymmetrizer (14) on the e_a basis, again as we took in Sec. III B for three points. We check that for four points it obeys the condition needed in Theorem 2.2 to define the two-forms Ω^2. Thus, labeling the points as x,y,z,t where we start at $(0,0)$ and go around the square clockwise, we have the possible 2 arcs of two different forms:

$$x\to y\to z,\quad y\to z\to t,$$

$$x\to t\to z,\quad y\to x\to t,$$

$$z \to t \to x, \quad t \to x \to y,$$

$$z \to y \to x, \quad t \to z \to y,$$

or

$$x \to y \to x, \quad y \to z \to y,$$

$$z \to y \to z, \quad x \to t \to x,$$

$$y \to x \to y, \quad z \to t \to z,$$

$$t \to x \to t, \quad t \to z \to t.$$

To check out condition (i) in Theorem 2.2 we will consider the two-arcs leaving from x, the starting point being irrelevant in the reasoning which follows. This implies that we have to verify the vanishing of $\pi^{yx}_{xyz}, \pi^{tx}_{xyz}, \pi^{yz}_{xyx}, \pi^{yz}_{xtx}$. Now, in general

$$\pi^{yz}_{x_{y'z'}} = (e_1^{-1xy} e_2^{-1yz} - e_2^{-1xy} e_1^{-1yz})(e_{1xy'} e_{2y'z} - e_{2xy'} e_{1y'z'})$$

and replacing in this expression the actual form of the arc, we establish that

$$\pi^{yx}_{xyz}, \quad \pi^{tx}_{xyz}, \quad \pi^{yz}_{xyx}, \quad \pi^{yz}_{xtx}$$

are zero. (We obtain a similar result swapping upper and lower indices.) The second constraint of Theorem 2.2 is not trivially satisfied in this case. The conditions $\pi_{x,z}{}^{y}{}_{t} + \pi_{x,z}{}^{t}{}_{t} = 0$ and $\pi_{x,z}{}^{y}{}_{y} + \pi_{x,z}{}^{t}{}_{y} = 0$ both give

$$\Theta_1 R_1 \Theta_2 = \Theta_2 R_2 \Theta_1, \quad \text{i.e.,} \quad \partial_1 \Theta_2 - \partial_2 \Theta_1 = 0. \tag{18}$$

Finally, we will take as a metric the element $\eta = e_1 \otimes e_1 + e_2 \otimes e_2$ and we will take the lifting (17) which is the natural choice for the antisymmetrizer projector. The exterior differentials of the base elements are

$$\mathrm{d}e_1 = \overline{\partial}^1 \Theta_2 e_1 \wedge e_2, \quad \mathrm{d}e_2 = -\overline{\partial}^2 \Theta_1 e_1 \wedge e_2,$$

where we recall that $\overline{\partial^a} = \Theta_a^{-1} \partial^a = R_a - \mathrm{id}$ are the usual group finite differences.

Proposition 4.1: For generic values of Θ_1, Θ_2 the dimensions p_i of H^i are 1:2:1. Here

$$H^0 = \mathbb{C}.1, H^1 = \langle (\Theta_2(y)\delta_t + \Theta_2(z)\delta_z)e_1, (\Theta_2(z)\delta_x + \Theta_2(y)\delta_t)e_2 \rangle, \quad H^2 = \mathbb{C}\,.\, e_1 \wedge e_2.$$

Proof:

$$\mathrm{d}(\mathrm{d}f) = (\Theta_1 R_1 \Theta_2 - \Theta_2 R_2 \Theta_1)(R_1 R_2 f - f) e_1 \wedge e_2 = 0, \ \forall\, f \in \mathbb{C}[\Sigma]$$

which is zero due to the constraint we imposed on the Θs. In the usual way, $p_0 = 1$, and the dimension of the image of d in $\Omega^1(\Sigma)$ (itself of dimension 8) is 3. A one form $fe_1 + ge_2$ is in the nullspace of d if and only if it satisfies $(-\Theta_2 \overline{\partial^2} f + f \overline{\partial^1} \Theta_2 + \Theta_1 \overline{\partial^1} g - g \overline{\partial^2} \Theta_1) = 0$; it is easy to find that the solution space of this equation has, for generic values of Θ_i satisfying (18), dimension 5 (and therefore, $p_1 = 5 - 3 = 2$). This, in turn, implies the image of d inside $\Omega^2(\Sigma)$ is three-dimensional. Then, $p_2 = 4 - 3 = 1$. For generic values of Θ, $e_1 \wedge e_2$ is not in the image of d, and gives a representative for H^2. □

For the remaining aspects of the geometry we fix the frame group and its calculus. Then we can solve for the connections, curvature, etc. Even with all of the above choices, we have several models.

B. Torus model with $\mathbb{Z}_4 \subset SO(2)$ frame group

Here we think of the additive group $\mathbb{Z}_4=\{\overline{0},\overline{1},\overline{2},\overline{3}\}$ as a discrete model of SO(2), i.e., 90-degree notations. This is in keeping with our discrete model of a torus. We have on $\mathbb{Z}_4$ either the three-dimensional universal calculus or the natural two-dimensional calculus given by a square.

1. 3D calculus on $\mathbb{Z}_4$

We choose the three-dimensional (universal) calculus defined on Z_4 by $\{\overline{1},\overline{2},\overline{3}\}$. This corresponds to $f^{\overline{1}},f^{\overline{2}},f^{\overline{3}}$ acting as the corresponding rotation of the vielbein vectors e_1 and e_2, minus the identity, that is

$$f^{\overline{1}} \triangleright e_1 = e_2 - e_1, \quad f^{\overline{1}} \triangleright e_2 = -e_1 - e_2,$$

$$f^{\overline{2}} \triangleright e_1 = -2e_1, \quad f^{\overline{2}} \triangleright e_2 = -2e_2,$$

$$f^{\overline{3}} \triangleright e_1 = -e_1 - e_2, \quad f^{\overline{3}} \triangleright e_2 = e_1 - e_2.$$

Proposition 4.2: The moduli space of torsion free cotorsion free connections on the quantum Riemannian manifold above is given by

$$A_1 = \alpha e_1 + \beta e_2,$$

$$A_2 = \frac{1}{2}(-\alpha+\beta-\gamma-\delta-\overline{\partial}^2\Theta_1)e_1 + \frac{1}{2}(-\alpha-\beta+\gamma-\delta-\overline{\partial}^1\Theta_2)e_2,$$

$$A_3 = \gamma e_1 + \delta e_2$$

for four functions $\alpha,\beta,\gamma,\delta$ subject to the linear constraint

$$(R_1+R_2)a = 0, \quad (R_1+R_2)b = 0,$$

where $a=\gamma-\alpha$ and $b=\beta-\delta$. The corresponding covariant derivative is

$$\nabla e_1 = (b-\overline{\partial}^2\Theta_1)e_1\otimes e_1 + ae_1\otimes e_2 + (a-\overline{\partial}^1\Theta_2)e_2\otimes e_1 - be_2\otimes e_2,$$

$$\nabla e_2 = -ae_1\otimes e_1 + (b-\overline{\partial}^2\Theta_1)e_1\otimes e_2 + be_2\otimes e_1 + (a-\overline{\partial}^1\Theta_2)e_2\otimes e_2.$$

Proof: We want the connection to be torsion free, i.e., it has to satisfy the following two linear equations:

$$A_1^1 + A_1^2 + 2A_2^2 - A_3^1 + A_3^2 = -\overline{\partial}^1\Theta_2,$$

$$-A_1^1 + A_1^2 - 2A_2^1 - A_3^1 - A_3^2 = \overline{\partial}^2\Theta_1,$$

from which we obtain the general solution above, without constraints on $\alpha,\beta,\gamma,\delta$. In conformity to what we have done so far, we also demand that the cotorsion of the connection be zero. Notice that, differently from the previous cases investigated in this paper, the elements of the fiber group $\mathbb{Z}_4$ are not of order 2, which implies that the action of S on the f^is is not trivial; we have in fact $S^{-1}(f^1)=f^3, S^{-1}(f^2)=f^2, S^{-1}(f^3)=f^1$, and the zero-cotorsion condition can be put down as

$$-R_1A_1^2 + R_2A_1^1 - 2R_1A_2^2 - R_2A_3^1 - R_1A_3^2 = -\overline{\partial}^1\Theta_2,$$

$$R_1A_1^2 + R_2A_1^1 + 2R_2A_2^1 - R_1A_3^2 + R_2A_3^1 = \overline{\partial}^2\Theta_1.$$

The requirement on the cotorsion translates into the constraint $(R_1+R_2)a=(R_1+R_2)b=0$, where a,b are defined in the statement of the proposition. The regularity condition is empty, because the calculus on $\mathbb{Z}_4$ is the universal one. We then compute the covariant derivative using (8). □

Note that the covariant derivative depends only on a,b so these parametrize the "physical" or effective moduli space, which is, therefore, four-dimensional: Two functions on $\mathbb{Z}_2\times\mathbb{Z}_2$ modulo the linear constraint. One may check that the torsion is indeed zero, which is to say $\nabla\wedge e_1=\mathrm{d}e_1$ and $\nabla\wedge e_2=\mathrm{d}e_2$. The cotorsion condition means that ∇ respects η in a skew sense, as one may also directly verify evaluating the cotorsion of the metric (when the torsion is null)

$$\Gamma\eta = (\nabla\wedge\mathrm{id} - \mathrm{id}\wedge\nabla)(e_1\otimes e_1 + e_2\otimes e_2) = 0,$$

where

$$(\nabla\wedge\mathrm{id})\eta = \overline{\partial}^1\Theta_2 e_1\wedge e_2\otimes e_1 - \overline{\partial}^2\Theta_1 e_1\wedge e_2\otimes e_2$$

and

$$(\mathrm{id}\wedge\nabla)\eta = (-(R_1+R_2)a + \overline{\partial}^1\Theta_2)e_1\wedge e_2\otimes e_1 - ((R_1+R_2)b + \overline{\partial}^2\Theta_1)e_1\wedge e_2\otimes e_2$$

(later on we will consider $\nabla\eta=0$ in the usual full sense).

Proposition 4.3: The Ricci scalar for the covariant derivative above is

$$R = \partial^2 a + \overline{\partial}^1\Theta_2 R_2 a - 2aR_2 a + \partial^1 b + \overline{\partial}^2\Theta_1 R_1 b - 2bR_1 b$$

Proof: From the action of the f^i we can then compute the Riemann curvature using the general theory in Sec. II, finding now

$$\mathrm{Riemann}(e_1) = (-F_1 - 2F_2 - F_3)\otimes e_1 + (F_1 - F_3)\otimes e_2,$$

$$\mathrm{Riemann}(e_2) = (-F_1 + F_3)\otimes e_1 + (-F_1 - 2F_2 - F_3)\otimes e_2.$$

In the same way the Ricci tensor is

$$\mathrm{Ricci} = \tfrac{1}{2}((F_1 - F_3)e_1\otimes e_1 + (F_1 + 2F_2 + F_3)e_1\otimes e_2 - (F_1 + 2F_2 + F_3)e_2\otimes e_1 + (F_1 - F_3)e_2\otimes e_2),$$

where we identify the two-forms F_i with their scalar coefficients as multiples of the top form $e_1\wedge e_2$. Taking the trace in a standard way, the Ricci scalar is $R=F_1-F_3$ (this and the other component $F_1+2F_2+F_3$ occur also in the Riemann tensor so we see that the Ricci tensor vanishes if and only if the entire Riemann tensor does). We can compute F_1,F_2,F_3 by means of

$$F_1 = \mathrm{d}A_1 + A_2\wedge A_3 + A_3\wedge A_2 - 2A_1\wedge A_1 - A_2\wedge A_1 - A_1\wedge A_2 - A_3\wedge A_1 - A_1\wedge A_3,$$

$$F_2 = \mathrm{d}A_2 + A_1\wedge A_1 + A_3\wedge A_3 - A_1\wedge A_2 - A_2\wedge A_1 - 2A_2\wedge A_2 - A_3\wedge A_2 - A_2\wedge A_3,$$

$$F_3 = \mathrm{d}A_3 + A_2\wedge A_1 + A_1\wedge A_2 - A_3\wedge A_1 - A_1\wedge A_3 - A_3\wedge A_2 - A_2\wedge A_3 - 2A_3\wedge A_3,$$

as inferred from (13) where

$$\mathrm{d}A_1 = (-\Theta_2\overline{\partial}^2\alpha + \alpha\overline{\partial}^1\Theta_2 + \Theta_1\overline{\partial}^1\beta - \beta\overline{\partial}^2\Theta_1)e_1\wedge e_2,$$

$$\mathrm{d}A_2 = \frac{1}{2}(\Theta_1\overline{\partial}^1(-\alpha-\beta+\gamma-\delta) + \Theta_2\overline{\partial}^2(\alpha-\beta+\gamma+\delta) + \overline{\partial}^1\Theta_2(-\alpha+\beta-\gamma-\delta+2\Theta_1) + \overline{\partial}^2\Theta_1(\alpha + \beta-\gamma+\delta-2\Theta_2))e_1\wedge e_2,$$

$$\mathrm{d}A_3 = (-\Theta_2\overline{\partial}^2\gamma + \gamma\overline{\partial}^1\Theta_2 + \Theta_1\overline{\partial}^1\delta - \delta\overline{\partial}^2\Theta_1)e_1\wedge e_2,$$

and

$$A_1\wedge A_1 = \alpha R_1\beta - \beta R_2\alpha,$$

$$A_1\wedge A_2 = \frac{\alpha}{2}(-R_1\alpha - R_1\beta + R_1\gamma - R_1\delta + \overline{\partial}^1\Theta_2) + \frac{\beta}{2}(R_2\alpha - R_2\beta + R_2\gamma + R_2\delta - \overline{\partial}^2\Theta_1),$$

etc. The detailed form of the curvature two-form is

$$\begin{aligned}F_1 = {}& -\partial^2\alpha + \partial^1\beta + \alpha\left(-R_1\beta - R_1\delta - R_2\alpha + R_2\gamma + \frac{\overline{\partial}^1\Theta_2}{2}\right) + \beta\left(R_2\alpha + R_2\gamma + R_2\beta - R_2\delta - \frac{\overline{\partial}^2\Theta_1}{2}\right)\\ &+ \gamma\left(-R_1\delta - R_1\beta - R_1\alpha + R_1\gamma + \frac{\overline{\partial}^1\Theta_2}{2}\right) + \delta\left(R_1\beta - R_1\delta + R_2\gamma + R_2\alpha - \frac{\overline{\partial}^2\Theta_1}{2}\right) + \frac{\overline{\partial}^2\Theta_1}{2}R_1(\beta\\ &- \delta) - \frac{\overline{\partial}^1\Theta_2}{2}R_2(\alpha - \gamma),\end{aligned}$$

$$\begin{aligned}F_2 = {}& \frac{1}{2}\partial^1(-\alpha - \beta + \gamma - \delta) + \frac{1}{2}\partial^2(\alpha - \beta + \gamma + \delta) + \frac{\overline{\partial}^1\Theta_2}{2}(-R_2(\beta - \delta) - \alpha + \beta - \gamma - \delta)\\ &+ \frac{\overline{\partial}^2\Theta_1}{2}(-R_1(\alpha - \gamma) + \alpha + \beta - \gamma + \delta) + \frac{\alpha}{2}(3R_1\beta - R_2(\beta - \delta) - \overline{\partial}^2\Theta_1 + R_1\delta) + \frac{\beta}{2}(-3R_2\alpha\\ &+ R_1(\alpha - \gamma) - \overline{\partial}^1\Theta_2 - R_2\gamma) + \frac{\gamma}{2}(3R_1\delta + R_2(\beta - \delta) + \overline{\partial}^2\Theta_1 + R_1\beta) + \frac{\delta}{2}(-3R_2\gamma - R_1a\\ &+ \overline{\partial}^1\Theta_2 - R_2\alpha),\end{aligned}$$

$$\begin{aligned}F_3 = {}& -\partial^2\gamma + \partial^1\delta + \frac{\overline{\partial}^1\Theta_2}{2}R_2(\alpha - \gamma) - \frac{\overline{\partial}^2\Theta_1}{2}R_1(\beta - \delta) + \alpha\left(-R_1\delta - R_1\alpha + R_1\gamma - R_1\beta + \frac{\overline{\partial}^1\Theta_2}{2}\right)\\ &+ \beta\left(R_2\alpha + R_2\gamma + R_1\beta - R_1\delta - \frac{\overline{\partial}^2\Theta_1}{2}\right) + \gamma\left(-R_1\delta + R_1\alpha - R_1\gamma + \frac{\overline{\partial}^1\Theta_2}{2} - R_1\beta\right)\\ &+ \delta\left(R_2\gamma + R_2\alpha + R_2\beta - R_2\delta - \frac{\overline{\partial}^2\Theta_1}{2}\right),\end{aligned}$$

from which we compute the Ricci curvature, etc. as above, and write in terms of a, b. □

It is useful to observe that it is not mandatory to compute the curvature two-form in order to get hold of the Riemann tensor. One could also[10] use the formula $\mathrm{Riemann}(e_1) = ((\mathrm{id}\wedge\nabla) - (\mathrm{d}\otimes\mathrm{id}))\circ\nabla(e_1)$ and similarly for e_2, which provides a useful check. Either way, the Riemann tensor turns out to have the form

$$\mathrm{Riemann}(e_1) = \rho e_1\wedge e_2\otimes e_1 + Re_1\wedge e_2\otimes e_2, \quad \mathrm{Riemann}(e_2) = -Re_1\wedge e_2\otimes e_1 + \rho e_1\wedge e_2\otimes e_2$$

with

$$\rho = \partial^2 b - \partial^1 a + 2bR_1a - 2aR_2b - \overline{\partial}^2\Theta_1R_1a + \overline{\partial}^1\Theta_2R_2b$$

and R the Ricci scalar computed above. We see in particular that $a=b=0$ is a natural point in the effective moduli space where the Ricci tensor (and the entire curvature) is zero.

Next we consider full metric compatibility as opposed to the weaker cotorsion condition.

Theorem 4.4: *The metric η satisfies the equation $\nabla\eta=0$, if and only if*

$$a=\overline{\partial}^1\Theta_2,\quad b=\overline{\partial}^2\Theta_1,\quad \overline{\partial}^2(\overline{\partial}^1\Theta_2)=0,\quad \overline{\partial}^1(\overline{\partial}^2\Theta_1)=0.$$

The Ricci scalar is given by

$$R=-(\overline{\partial}^1\Theta_2)^2-(\overline{\partial}^2\Theta_1)^2.$$

Proof: We only need to state explicitly the equality $\nabla\eta=0$, as in

$$\nabla(e_1\otimes e_1+e_2\otimes e_2)=2((b-\overline{\partial}^2\Theta_1)e_1\otimes e_1\otimes e_1+(a-\overline{\partial}^1\Theta_2)e_2\otimes e_1\otimes e_1+(b-\overline{\partial}^2\Theta_1)e_1\otimes e_2\otimes e_2+(a-\overline{\partial}^1\Theta_2)e_2\otimes e_2\otimes e_2)=0$$

the solution to the above equation is $a=\overline{\partial^1}\Theta_2$, $b=\overline{\partial^2}\Theta_1$. The kernel constraint on a,b then requires the constraint on the vielbein. □

We see that not every vielbein admits a strictly metric compatible condition—in general we need our weaker cotorsion-free condition. However, when it does so, the covariant derivative is uniquely determined as in classical Riemannian geometry.

2. 2D calculus on $\mathbb{Z}_4$

We also consider the two-dimensional (2D) calculus on $\mathbb{Z}_4$, defined by $\{\overline{1},\overline{3}\}$ with $f^{\overline{1}}$ and $f^{\overline{3}}$, acting as before. Our interesting result is that the geometric content is the same as the universal calculus above except that some redundant modes in the universal case are not present, but replaced by a quadratic regularity condition.

Proposition 4.5: With the above specification for the action, the moduli space of torsion free, cotorsion free connections is given by

$$A_1=\left(-\alpha-\frac{\overline{\partial}^2\Theta_1}{2}\right)e_1+\left(\beta-\frac{\overline{\partial}^1\Theta_2}{2}\right)e_2,$$

$$A_3=\left(\beta-\frac{\overline{\partial}^2\Theta_1}{2}\right)e_1+\left(\alpha-\frac{\overline{\partial}^1\Theta_2}{2}\right)e_2,$$

with the conditions

$$(R_1+R_2)a=0,\quad (R_1+R_2)b=0,$$

where $a=\alpha+\beta$ and $b=\beta-\alpha$. In terms of a,b the covariant derivative ∇ is as before, in Proposition 4.1, and the regularity condition reads

$$\overline{\partial}^2\Theta_1\overline{\partial}^2a-\overline{\partial}^1\Theta_2\overline{\partial}^1b=0.$$

Proof: Here the parameters α,β are not the same as in the previous section (but related to them). We solve the zero torsion condition

$$A_1^1+A_1^2-A_3^1+A_3^2=-\overline{\partial}^1\Theta_2,$$

$$-A_1^1+A_1^2-A_3^1-A_3^2=\overline{\partial}^2\Theta_1,$$

which gives the solution above in terms of α,β or the combinations a,b, but free of any constraint on the a,b. Next we require the connection to have zero cotorsion:

$$-R_1A_1^2-R_1A_3^2-R_2A_1^1+R_2A_3^1=-\overline{\partial}^1\Theta_2,$$

$$-R_1A_1^2+R_1A_3^2+R_2A_1^1+R_2A_3^1=\overline{\partial}^2\Theta_1,$$

and obtain the constraint $(R_1+R_2)a=(R_1+R_2)b=0$. We then compute the covariant derivative using the action of f^1, f^3. The regularity condition in this case is given by

$$A_1\wedge A_1+A_3\wedge A_3=0.$$

□

Corollary 4.6: The Riemann and Ricci tensors corresponding to the connection above have the form (in terms of a and b) as in Proposition 4.2.

Proof: This follows since the Riemann and Ricci tensors are determined by ∇ which has the same form. It is also instructive (but a different computation) to compute them directly; as usual from the definition of the curvature

$$F_1=\mathrm{d}A_1-2A_1\wedge A_1-A_3\wedge A_1-A_1\wedge A_3,$$

$$F_3=\mathrm{d}A_3-A_1\wedge A_3-A_3\wedge A_1-2A_3\wedge A_3,$$

we compute the expression for the Riemann tensor:

$$\mathrm{Riemann}(e_1)=(-F_1-F_3)\otimes e_1+(F_1-F_3)\otimes e_2,$$

$$\mathrm{Riemann}(e_2)=(-F_1+F_3)\otimes e_1+(-F_1-F_3)\otimes e_2,$$

inserting the actual form of F_1 and F_3 and the regularity condition.

The Ricci tensor is

$$\mathrm{Ricci}=\frac{1}{2}((F_1-F_3)e_1\otimes e_1+(F_1+F_3)e_1\otimes e_2+(-F_1-F_3)e_2\otimes e_1+(F_1-F_3)e_2\otimes e_2).$$

□

If we want Ricci flatness, we must force $F_1=F_3=0$. Note that if the Ricci is null, so is the Riemann tensor.

The condition for the metric compatibility is the same as in Theorem 4.4.

Proposition 4.7: The metric η satisfies the equation $\nabla\eta=0$, if and only if

$$a=\overline{\partial}^1\Theta_2,\quad b=\overline{\partial}^2\Theta_1,\quad \overline{\partial}^2(\overline{\partial}^1\Theta_2)=0,\quad \overline{\partial}^1(\overline{\partial}^2\Theta_1)=0.$$

The regularity condition holds and the Riemann and Ricci tensors are as in Theorem 4.4.

Proof: We impose the condition $\nabla\eta=0$, which has the same shape as in the previous case. We then check that the regularity condition in Proposition 4.1 indeed holds for these a, b. □

We conclude that moving to the 2D calculus on $\mathbb{Z}_4$ gives essentially the same Riemannian geometry as using the universal (3D) calculus but without some of the superfluous modes that we found there. Instead, these are replaced by a regularity condition. This gives us some insight into the "correct" choice of calculus for the frame group and what happens if one chooses one that is too big.

C. Torus model with translations $\mathbb{Z}_2\times\mathbb{Z}_2$ as frame group

We take now the frame group to be $\mathbb{Z}_2\times\mathbb{Z}_2$ acting by "translation" on our base space which we recall is also the group $\mathbb{Z}_2\times\mathbb{Z}_2$. We write the frame group elements as $\overline{00},\overline{01},\overline{10},\overline{11}$, say. As before, we have two choices for the calculus on the frame group.

1. 3D calculus on $\mathbb{Z}_2\times\mathbb{Z}_2$

This is the universal calculus defined by $\{\overline{10},\overline{10},\overline{11}\}$. The corresponding f's act by

$$f^{\overline{10}}\triangleright e_1=-2e_1,\quad f^{\overline{10}}\triangleright e_2=0,$$

$$f^{\overline{01}}\triangleright e_1=0,\quad f^{\overline{01}}\triangleright e_2=-2e_2,$$

$$f^{\overline{11}}\triangleright e_1=-2e_1,\quad f^{\overline{11}}\triangleright e_2=-2e_2.$$

Proposition 4.8: The moduli space of torsion free, cotorsion free connections is given by

$$A_{10}=\alpha e_1-\left(\delta+\frac{\overline{\partial}^1\Theta_2}{2}\right)e_2,$$

$$A_{01}=-\left(\gamma+\frac{\overline{\partial}^2\Theta_1}{2}\right)e_1+\beta e_2,$$

$$A_{11}=\gamma e_1+\delta e_2.$$

We set $a=\alpha+\gamma$, $b=\beta+\delta$. The covariant derivative corresponding to this connection is

$$\nabla e_1=2ae_1\otimes e_1-\overline{\partial}^1\Theta_2 e_2\otimes e_1,\quad \nabla e_2=-\overline{\partial}^2\Theta_1 e_1\otimes e_2+2be_2\otimes e_2.$$

Proof: We solve the torsion condition

$$2A_{10}^2+2A_{11}^2=-\overline{\partial}^1\Theta_2,\quad -2A_{01}^1-2A_{11}^1=\overline{\partial}^2\Theta_1$$

and the zero cotorsion condition

$$-2R_1A_{10}^2-2R_1A_{11}^2=-\overline{\partial}^1\Theta_2,\quad 2R_2A_{01}^1+2R_2A_{11}^1=\overline{\partial}^2\Theta_1;$$

then we work out the covariant derivative using (8). □

There is no regularity condition for the universal calculus on the frame group (because there is no element different from the identity which lies outside the subset defining the calculus).

Proposition 4.9: The Riemann and Ricci tensors corresponding to the above connection are

$$\text{Riemann}(e_1)=-2\left(-\partial^2 a+\overline{\partial}^1\Theta_2(\Theta_1-R_2a)+\frac{\overline{\partial}^1\Theta_2\overline{\partial}^2\Theta_1}{2}\right)e_1\wedge e_2\otimes e_1,$$

$$\text{Riemann}(e_2)=-2\left(\overline{\partial}^2\Theta_1(R_1b-\Theta_2)+\partial^1 b-\frac{\overline{\partial}^2\Theta_1\overline{\partial}^1\Theta_2}{2}\right)e_1\wedge e_2\otimes e_2,$$

$$\text{Ricci}=\left(-\partial^2 a+\overline{\partial}^1\Theta_2(\Theta_1-R_2a)+\frac{\overline{\partial}^1\Theta_2\overline{\partial}^2\Theta_1}{2}\right)e_1\otimes e_2$$
$$-\left(\overline{\partial}^2\Theta_1(R_1b-\Theta_2)+\partial^1 b-\frac{\overline{\partial}^2\Theta_1\overline{\partial}^1\Theta_2}{2}\right)e_2\otimes e_1.$$

Proof: We have

$$F_{10}=\mathrm{d}A_{10}+A_{01}\wedge A_{11}+A_{11}\wedge A_{01}-2A_{10}\wedge A_{10}-A_{10}\wedge A_{01}-A_{01}\wedge A_{10}-A_{10}\wedge A_{11}-A_{11}\wedge A_{10},$$

$$F_{01}=\mathrm{d}A_{01}+A_{10}\wedge A_{11}+A_{11}\wedge A_{10}-A_{10}\wedge A_{01}-A_{01}\wedge A_{10}-2A_{01}\wedge A_{01}-A_{01}\wedge A_{11}-A_{11}\wedge A_{01},$$

$$F_{11} = \mathrm{d}A_{11} + A_{10}\wedge A_{01} + A_{01}\wedge A_{10} - A_{11}\wedge A_{10} - A_{10}\wedge A_{11} - A_{11}\wedge A_{01} - A_{01}\wedge A_{11},$$

and

$$\mathrm{Riemann}(e_1) = -2(F_{10}+F_{11})\otimes e_1, \quad \mathrm{Riemann}(e_2) = -2(F_{01}+F_{11})\otimes e_2.$$

The same result is obtained by $\mathrm{Riemann}(e_a) = ((\mathrm{id}\wedge\nabla) - (\mathrm{d}\otimes\mathrm{id}))\circ\nabla(e_a)$. □

Proposition 4.10: The condition $\nabla\eta = 0$ is satisfied if and only if $\alpha = -\gamma$ and $\beta = -\delta$ and $\overline{\partial^1}\Theta_2 = \overline{\partial^2}\Theta_1 = 0$. In this case, both the Riemann and the Ricci tensor are zero.

Proof: The first part of the proposition is easily proved by computing

$$\nabla(e_1\otimes e_1 + e_2\otimes e_2) = 4ae_1\otimes e_1\otimes e_1 - 2\overline{\partial^1}\Theta_2 e_2\otimes e_1\otimes e_1 - 2\overline{\partial^2}\Theta_1 e_1\otimes e_2\otimes e_2 + 4be_2\otimes e_2\otimes e_2$$
$$= 0$$

which means $a = b = \overline{\partial^1}\Theta_2 = \overline{\partial^2}\Theta_1 = 0$ have; this implies that the Riemann and the Ricci tensor are both zero. □

2. 2D calculus on $\mathbb{Z}_2\times\mathbb{Z}_2$

The calculus on the fiber will be defined now by $\{\overline{10}, \overline{01}\}$

Proposition 4.11: The moduli space of torsion free, cotorsion free connections is given by

$$A_{10} = \alpha e_1 - \frac{\partial^1\Theta_2}{2}e_2,$$

$$A_{01} = -\frac{\partial^2\Theta_1}{2}e_1 + \beta e_2.$$

We set $a = \alpha$, $b = \beta$ (as in the case before but with $\gamma = \delta = 0$), then the covariant derivative has the same form as in Proposition 4.8. The regularity condition is

$$a\overline{\partial^1}b - b\overline{\partial^2}a = 0.$$

Proof: We solve the torsion equations

$$2A^2_{10} = -\overline{\partial^1}\Theta_2, \quad -2A^1_{01} = \overline{\partial^2}\Theta_1$$

and the cotorsion equations

$$-2R_1A^2_{10} = -\overline{\partial^1}\Theta_2, \quad 2R_2A^1_{01} = \overline{\partial^2}\Theta_1.$$

The regularity condition is, in this case, $A_{10}\wedge A_{01} + A_{01}\wedge A_{10} = 0$, which comes out as $aR_1b - bR_2a = 0$, which can be written as stated. □

Corollary 4.12: The Riemann and Ricci tensors are (as functions of a, b) as in Proposition 4.9.

Proof: This follows from ∇ but can also be computed directly as useful check; the curvature two form corresponding to the regular connection above, is given by

$$F_{10} = \left(-\Theta_2\overline{\partial^2}a + \overline{\partial^1}\Theta_2(\Theta_1 - R_2a) + \frac{\overline{\partial^1}\Theta_2\overline{\partial^2}\Theta_1}{2}\right)e_1\wedge e_2,$$

$$F_{01} = \left(\overline{\partial^2}\Theta_1(R_1b - \Theta_2) + \Theta_1\overline{\partial^1}b - \frac{\overline{\partial^2}\Theta_1\overline{\partial^1}\Theta_2}{2}\right)e_1\wedge e_2,$$

computed from the expression for F (regularity condition applied)

$$F_{10} = \mathrm{d}A_{10} - 2A_{10} \wedge A_{10},$$

$$F_{01} = \mathrm{d}A_{01} - 2A_{01} \wedge A_{01},$$

the Ricci tensor is $F_{01}e_1 \otimes e_2 - F_{10}e_2 \otimes e_1$, Riemann is given by $\mathrm{Riemann}(e_1) = -2F_{10} \otimes e_1$, $\mathrm{Riemann}(e_2) = -2F_{01} \otimes e_2$. □

Finally, the only connection fulfilling the condition

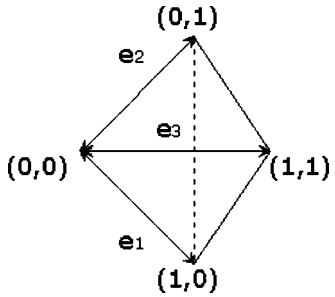
$$\nabla\eta = \nabla(e_1 \otimes e_1 + e_2 \otimes e_2) = -4ae_1 \otimes e_1 \otimes e_1 + 2be_2 \otimes e_2 \otimes e_2 + \overline{\partial}^1\Theta_2(e_1 \otimes e_2 \otimes e_1 + e_1 \otimes e_1 \otimes e_2) - 2\overline{\partial}^2\Theta_1 e_1 \otimes e_2 \otimes e_2 = 0$$

is, in this case, the null connection.

We see again the same phenomenon as in Sec. IV B; working with the "correct" 2D calculus rather than the universal 3D eliminates redundant fields that do not enter into the Riemannian geometry, trading them for an optional regularity condition.

D. Discrete sphere base with $\mathbb{Z}_3 \subset \mathbf{SO(2)}$ frame group

As the main alternative to the above models, we look at the case of the universal calculus on the 4 points of our base space, which has the connectivity of a tetrahedron or discrete model of a sphere:



Our results are rather unusual, probably due to the small number of points in the model. As a projector we are led to π defined by

$$\pi(e_a \otimes e_b) = i(e_a \wedge e_b) = \begin{cases} 0 & a \neq b \\ \frac{1}{3}(e_1 \otimes e_1 + e_2 \otimes e_2 \otimes e_3 \otimes e_3) & a = b. \end{cases}$$

This means that Ω^2 has the relations

$$e_1^2 = e_2^2 = e_3^2 \equiv \mathrm{Top}, \quad e_a \wedge e_b = 0, \quad \forall\, a \neq b.$$

This projector obeys the compatibility condition (i) of Theorem 2.2 as follows. We are required to list all the two-arcs contained in the graph. Naming the vertices as x, y, z, t (starting from (0,0) and going clockwise) the possible two arcs from x are

$$x \to y \to x, \quad x \to y \to z, \quad x \to y \to t,$$

$$x \to z \to x, \quad x \to z \to y, \quad x \to z \to t,$$

$$x \to t \to x, \quad x \to t \to y, \quad x \to t \to z.$$

Now we have to make sure all the possible expression of the form

$$\pi^{yz}_{xyx}, \pi^{yt}_{xyx}, \pi^{zy}_{xyx}, \pi^{zt}_{xyx}, \ldots$$

(60 of them in total) vanish, which happens to be the case. Note that we just considered the two arcs departing from x, since the choice of "start point" is immaterial here due to the symmetry of the graph. The second condition of Theorem 2.2 is empty in the case, because the calculus on Σ is the universal one. $\Omega^2(\Sigma)$ The action of the external derivative on the vielbein elements e_a is computed from Theorem 2.1 and is

$$\mathrm{d}e_1 = (\Theta_1 + R_1\Theta_1)\mathrm{Top} \equiv \tilde{\Theta}_1\mathrm{Top}, \quad \mathrm{d}e_2 = (\Theta_2 + R_2\Theta_2)\mathrm{Top} \equiv \tilde{\Theta}_2\mathrm{Top},$$

$$\mathrm{d}e_3 = (\Theta_3 + R_3\Theta_3)\mathrm{Top} \equiv \tilde{\Theta}_3\mathrm{Top}.$$

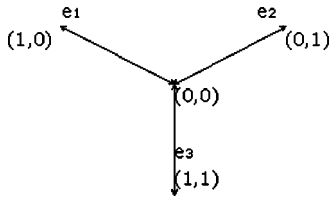
Next, we take $\mathbb{Z}_3=\{\overline{0},\overline{1},\overline{2}\}$ as a frame group, with calculus defined by $\{\overline{1},\overline{2}\}$. $\overline{f^1},\overline{f^2}$ will act on e_1,e_2,e_3 as $e_1\to e_3\to e_2\to e_1$ (notice that the definition of the projector is invariant under this action), or

$$\overline{f^1}\triangleright e_1 = e_3 - e_1, \quad \overline{f^2}\triangleright e_1 = e_2 - e_1,$$

$$\overline{f^1}\triangleright e_2 = e_1 - e_2, \quad \overline{f^2}\triangleright e_2 = e_3 - e_2,$$

$$\overline{f^1}\triangleright e_3 = e_2 - e_3, \quad \overline{f^2}\triangleright e_3 = e_1 - e_3$$

[it is an anticlockwise rotation in the picture below, which is the tetrahedron from the viewpoint of the vertex $(0,0)$]



Proposition 4.13: The moduli space of torsion free connections is 16-dimensional, given by 6 functional parameters $\alpha_1,\ldots,\alpha_3,\beta_1,\ldots,\beta_3$ with two independent equations given by

$$\tilde{\Theta}_1 + \alpha_3 - \alpha_1 - \beta_1 + \beta_2 = 0$$

and cyclic permutations. The additional conditions for zero-cotorsion are the two independent equations given by

$$\overline{\partial^1}(\alpha_1 + \beta_1) - \overline{\partial^2}\alpha_2 - \overline{\partial^3}\beta_3 - \alpha_2 + \alpha_3 + \beta_2 - \beta_3 = 0$$

and cyclic permutations.

Proof: Firstly, we write down the zero torsion conditions, but with a notation of the form

$$A^1_1 = \alpha_1, \quad A^2_1 = \alpha_2, \quad A^3_1 = \alpha_3, \quad A^1_2 = \beta_1, \quad A^2_2 = \beta_2, \quad A^3_2 = \beta_3$$

to underline a symmetry of the theory with respect to cyclical permutations in the upper indexes of the A^j_i (as usual, the lower index refers to the frame group directions). The vanishing of the cotorsion corresponds to

$$\tilde{\Theta}_1 + R_2\alpha_2 - R_1\alpha_1 + R_3\beta_3 - R_1\beta_1 = 0$$

and cyclic permutations. Combining the torsion and cotorsion equations we obtain the equations as stated. □

The covariant derivative shows the same rotational symmetry. In fact,

$$\nabla e_1 = (\omega + \tilde{\omega}) \otimes e_1 - \omega \otimes e_2 - \tilde{\omega} \otimes e_3,$$

$$\omega = \sum_a \alpha_a e_a, \quad \tilde{\omega} = \sum_a \beta_a e_a$$

and ∇e_2 and ∇e_3 can be found by cyclical rotations of ∇e_1.

Proposition 4.14: The Riemann tensor corresponding to the connection above is

$$\mathrm{Riemann}(e_1) = -(\rho + \tilde{\rho})\,\mathrm{Top} \otimes e_1 + \tilde{\rho}\,\mathrm{Top} \otimes e_2 + \rho \mathrm{Top} \otimes e_3$$

[$\mathrm{Riemann}(e_2), \mathrm{Riemann}(e_3)$ *can be found by cyclical rotation] where*

$$\rho = \partial^1 \alpha_1 + \alpha_1 \tilde{\Theta}_1 + \beta_1 R_1(\beta_1 - \alpha_1) - \alpha_1 R_1(2\alpha_1 + \beta_1) + cycl\,.\,,$$

$$\tilde{\rho} = \partial^1 \beta_1 + \beta_1 \tilde{\Theta}_1 + \alpha_1 R_1(\alpha_1 - \beta_1) - \beta_1 R_1(2\beta_1 + \alpha_1) + cycl\,.\,,$$

and the Ricci scalar, $R = -(\rho + \tilde{\rho})$.

Proof: Riemann tensor is obtained in the usual way from the curvature components F_i; the expression for Ricci then comes out as

$$\mathrm{Ricci} = \frac{1}{3}[-(F_1 + F_2)e_1 \otimes e_1 + F_2 e_1 \otimes e_2 + F_1 e_1 \otimes e_3 + F_1 e_2 \otimes e_1 - (F_1 + F_2)e_2 \otimes e_2 + F_2 e_2 \otimes e_3$$
$$+ F_2 e_3 \otimes e_1 + F_1 e_3 \otimes e_2 - (F_1 + F_2)e_3 \otimes e_3]$$

[from which the Ricci scalar $R = -(F_1 + F_2)$]. The curvature two-form is

$$F_1 = \mathrm{d}A_1 + A_2 \wedge A_2 - 2A_1 \wedge A_1 - A_2 \wedge A_1 - A_1 \wedge A_2,$$

$$F_2 = \mathrm{d}A_2 + A_1 \wedge A_1 - A_1 \wedge A_2 - A_2 \wedge A_1 - 2A_2 \wedge A_2$$

and similarly for the other components. □

We know that the moduli space of connections has two functional parameters, which we see here is reflected in the two physical curvature parameters $\rho, \tilde{\rho}$. This model is obviously far from classical, but we see that it has several reasonable features including a cyclic symmetry and a degree 2 top form, i.e., a nonclassical "surface."

V. REMARKS ON THE QUANTUM THEORY

So far we have solved only the classical geometry, which could form the basis for classical equations of motion for gravity and matter in a classical background. For quantum theory at least in a path integral approach one must integrate over all such moduli with respect to an action weighting. Here quantum gravity, in particular, diverges badly. The advantage of working only on a finite number of points as we have done above is that now such functional integrals become finite dimensional integrals, which may still diverge but which are surely much more tractable. Such integrals for gauge theory on S_3 are discussed in Ref. 8 and carried to fruition for Yang–Mills on $\mathbb{Z}_2 \times \mathbb{Z}_2$ in Ref. 7, where the theory was found to be divergent but renormalizable. Here we make some first remarks about how to extend this in principle to the gravitational case. The new ingredient, not yet covered, is the correct "unitarity" or reality condition on the spin connection, which we now propose.

Thus, until now we could have worked above over a generic field, but now we work over $\mathbb{C}$ and specify reality or "unitarity" conditions which should be expected for a physical interpretation. This cuts down our moduli still further and also reduces us to integration over real variables in our finite setting. To do this, we note that $\mathbb{C}(\Sigma)$ is a *-algebra with * given by pointwise complex

conjugation. We extend this to inner calculi with the assumption $\theta^*=\theta$ so that * anticommutes with d (other conventions are also possible). For models based on groups and conjugacy classes with elements of order 2 this is naturally implemented by $e_a^*=e_a$ (more generally, $e_{a^{-1}}$), as in Refs. 6–8. For the models based on $\mathbb{Z}_2\times\mathbb{Z}_2$ connectivity in Sec. IV we take $e_a^*=e_a$. We likewise, and more importantly, take

$$\theta^* = \theta,$$

which ensures that $\mathrm{d}=[\theta,\ \}$ behaves as usual for a * structure in the differential graded algebra (so d graded-commutes with *). In terms of field components this translates to

$$\overline{\Theta_a(x)} = R_a\Theta_a(x).$$

This is consistent with our model in Sec. IV, for example, where the condition (18) on Θ in Sec. VI A for a two-form projector is invariant under *.

Next, we consider the spin connection components. For a unitary action for the braided-Lie algebra generators f^i we would take $A_i^*=A_i$. What is a unitary action is motivated from Hopf algebra theory where for the action of a Hopf *-algebra one would require $(f^i\triangleright e_a)^*=S^{-1}(f^{i^*})\triangleright e_a^*$, where in our case $Sf^i=f^{i^{-1}}$ is inversion in the frame group algebra. The *-structure on the braided-Lie algebra generators is not so clear, but if we assumed that $f^{i*}=f^{i^{-1}}$ as for elements in a group algebra, these two inverses cancel and we would be led to require $(f^i\triangleright e_a)^*=f^i\triangleright e_a$. This indeed holds for the actions in the present paper, particularly those in Sec. IV, since these are obtained from permutations. Next, if the generators are unitary in this sense, we want the frame group connection to be "antihermitian" so we propose here

$$A_i^* = A_{i^{-1}}$$

for the component one-forms. This has the reasonable consequence that applying * to the torsion equations gives the cotorsion equations, i.e., these are related by complex conjugation in the unitary version of the theory. This is desirable as it suggests that imposing the unitarity condition on the moduli space of torison and cotorsion free connections is not so likely to give no solutions. This too is borne out when we look closely at the moduli of connections on our $\mathbb{Z}_2\times\mathbb{Z}_2$ in Proposition 4.2 or 4.5. We concentrate on the second of these as the more physical model with modes a,b.

Proposition 5.1: The reality condition in the moduli of torsion free and cotorsion free connections on the discrete torus in Proposition 4.5 is $\overline{a}=R_2a$, $\overline{b}=R_1b$. *The regularity condition is invariant under conjugation and the Ricci scalar in Proposition 4.5 is real up to a "total divergence" given by* $\overline{\partial^1},\overline{\partial^2}$.

Proof: From the above, we deduce from Proposition 4.5 and the reality condition on the Θ_a that $\overline{\alpha}=-R_1\beta$, $\overline{\beta}=R_2\alpha$ which translates as stated given that the functions a,b reverse sign under R_1R_2. The latter also means that $R_1(\overline{\partial^2}a)=\overline{\partial^2}(-R_2a)=\overline{\partial^2}a$, and similarly $\overline{\partial^1}b$ is R_2-invariant. Since $(\overline{\partial^2}\Theta_1)^*=R_1(\overline{\partial^2}\Theta_1)$, and similarly with R_2 for $\overline{\partial^1}\Theta_2$, we see that the regularity condition is invariant under *. We then compute

$$\begin{aligned}\overline{R} &= R_1(\partial^1 b+\overline{\partial}^2\Theta_1R_1b)+R_2(\partial^1a+\overline{\partial}^1\Theta_2R_2a)-2bR_1b-2aR_2a\\ &= R+\overline{\partial}^1(\partial^1b+\overline{\partial}^2\Theta_1R_1b)+\overline{\partial}^2(\partial^2a+\overline{\partial}^1\Theta_2R_2a),\end{aligned}$$

where $(\partial^1b)^*=(R_1\Theta_1)\partial^1R_1b=R_1(\partial^1b)$, and similarly for ∂^2a. □

The reduced moduli space with full metric compatibility in Proposition 4.7 is also consistent with this *-structure, i.e., our reality condition holds for a,b given by Θ_a as stated there. Moreover, the stated condition on the Θ_a required for this reduces simply to a,b real.

After that, for quantum gravity one should presumably take as action $S=\Sigma_{x\in\Sigma}R(x)$ using the Ricci scalar curvature; we are not in a position to deduce field equations by a variational principle, so this is an assumption of one way to make sense of the quantum theory. To see how this works

we again look at our discrete torus model on 4 points. We already know from Sec. III that for 2 or 3 points the Ricci scalar vanishes in all our models, so this model would be the first with nontrivial Ricci scalar. From the above Propostition 5.1 we see that the action S is real. Moreover, our fields a,b, etc. are functions on the four points but so highly constrained as to be fully determined each by a single complex number, which we denote A,B. Here

$$A = a(0,0) = -a(0,0), \quad \overline{A} = a(0,1) = -a(1,0),$$

$$B = b(0,0) = -b(1,1), \quad \overline{B} = b(1,0) = -b(0,1).$$

Note that the Ricci scalar splits up into two terms

$$R = R_B + R_A; \quad R_B = \partial^1 b + \overline{\partial}^2 \theta_1 R_1 b - 2bR_1 b = R_2 \theta_1 \overline{b} - \theta_1 b - 2b\overline{b}$$

and the similar expression for R_A with $1,2$ interchanged. Writing

$$\Theta = \Theta_1(0,0), \quad \overline{\Theta} = \Theta_1(1,0), \quad \tilde{\Theta} = \Theta_1(0,1), \quad \overline{\tilde{\Theta}} = \Theta_1(1,1)$$

we find

$$S = S_B + S_A; \quad S_B = -8B\overline{B} + 2B(\overline{\tilde{\Theta}} - \Theta) + 2\overline{B}(\tilde{\Theta} - \overline{\Theta}),$$

where we compute R_B at the four points in terms of our new variables and add up. Similarly for the A field and Θ_2. If we restrict to the full metric compatibility in Theorem 4.4 then the action is just $S_B = -4B^2$ and the dynamical variables are $\Theta, \tilde{\Theta}$ constrained such that $B = \tilde{\Theta} - \overline{\Theta}$ is real. Again similarly for the A system.

Finally, we make a polar decomposition of the fields as

$$B = \lambda e^{\imath\phi}, \quad \Theta = \mu e^{\imath\psi}, \quad \tilde{\Theta} = \tilde{\mu} e^{i\tilde{\psi}}$$

in terms of real positive $\lambda, \mu, \tilde{\mu}$ and angles $\phi, \psi, \tilde{\psi}$. In terms of these, we find

$$S_B = -8\lambda^2 + 4\lambda\tilde{\mu}\cos(\phi - \tilde{\psi}) - 4\lambda\mu\cos(\phi + \psi)$$

with similar results for the A system. Then "quantum gravity" is reduced to integrals over these real variables. There remains the constraint (18) as well as the optional regularity condition to be imposed on the moduli in Proposition 4.5. These both cross-couple the A and B systems making even this simplest model nontrivial.

It is not our scope to consider the quantum theory in detail here, particularly since the geometries in this paper are low dimensonal, where one does not expect very dynamical quantum gravity; for a compact surface in two-dimensions the integral of the classical Ricci scalar is a constant by the Gauss–Bonnet theorem. For a classical torus this should be zero, so we see that the discrete torus model already exhibits nonstandard behavior, the meaning of which remains to be understood. It also remains to identify physical observables to be computed by such functional integral methods. However, our low-dimensional example does indicate the possibility of reasonable unitarity constraints and illustrate how a quantum gravity theory might proceed in principle.

VI. COMBINATORICS OF GEOMETRIES UP TO NINE POINTS

For higher numbers of points we do not attempt a detailed classification but rather we overview the range of possibilities with a view to picking out the most interesting ones.

In the first place, we now limit ourselves to the more interesting case of symmetric ("bidirectional") differential calculi. These are just graphs with no self-edges and no more than one edge between vertices. For a fibration with fiber size n, these are the so-called n-regular graphs. There is no classification theory for n-regular graphs (e.g., any n-regular simplicial approximation of a

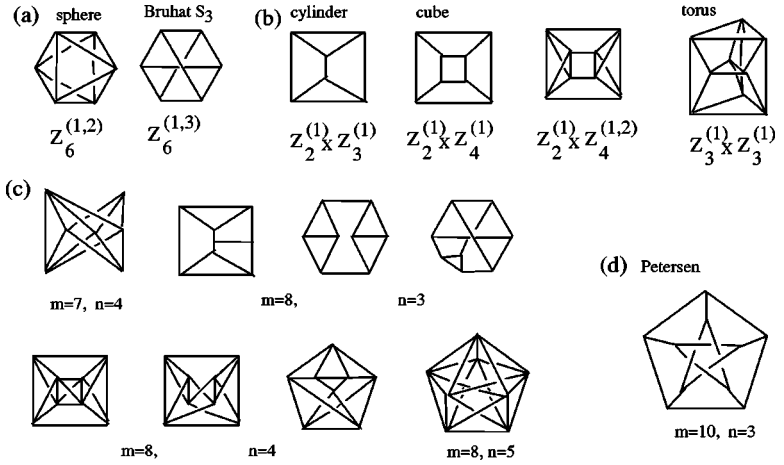


FIG. 1. (a) Examples of circulant graphs; (b) all products of circulants up to $m=9$; (c) graphs up to $m=8$ not circulants or products of them; (d) Petersen graph at $m=10$.

manifold gives one) but small ones are listed in Ref. 14. From there we see that there is a reasonable number for $m\leqslant 8$ after which the number grows rapidly. We deal only with connected graphs.

Note also for any m that here are none for $n=1$ (except $m=2$). For $n=2$ there is just the m-gon for all m. This is the differential calculus on $\mathbb{Z}_m$ with $\mathcal{C}=\{-1,1\}$. For $n=m-1$ there is exactly the universal calculus or totally connected graph. We observe that the m-gon and universal calculi are members of a "circulant graph" family $\mathbb{Z}_m^{1,p,q,\cdots}$ where $p,q,\ldots$ are distinct integers modulo m. They correspond to the calculus on $\mathbb{Z}_m$ with $\mathcal{C}=\{\pm 1,\pm p,\pm q,\ldots\}$ where we only have p if $2p=0$ mod m, etc. The direct product of circulants with $\mathcal{C}_1,\mathcal{C}_2$ means with $\mathcal{C}=(\mathcal{C}_1,0)\cup(0,\mathcal{C}_2)$ (as for the product of any groups equipped with differential structures, see Ref. 10). An example of a circulant is in Fig. 1. Note also the "handshaking lemma" in graph theory that nm has to be even. Then we have the following list of connected graphs which is complete up to $m=8$:

For $m=2$ we have only the universal calculus at $n=1$.

For $m=3$ we have only the universal calculus which equals the 3-gon calculus at $n=2$.

For $m=4$ we have only the 4-gon at $n=2$, which can also be viewed as $\mathbb{Z}_2^{(1)}\times\mathbb{Z}_2^{(1)}$ (i.e., with the direct product calculus where $\mathcal{C}=\{(0,1),(1,0)\}$), and the universal calculus at $n=3$.

For $m=5$ we have only the 5-gon at $n=2$ and the universal at $n=4$.

For $m=6$ we have only the 6-gon at $n=2$ and two choices at $n=3$. These are the circulant $\mathbb{Z}_6^{(1,3)}$, which is also the graph for the S_3 calculus with its two-cycles conjugacy class, and the circulant $\mathbb{Z}_2^{(1)}\times\mathbb{Z}_3^{(1)}$. At $n=4$ we have only the circulant $\mathbb{Z}_6^{(1,2)}$, which is a triangulation of the sphere and is also the graph for S_3 with a left-covariant calculus. See Figs. 1(a) and 1(b). At $n=5$ we just have the universal one. Note that the three-cycles calculus on S_3 is not connected so does not appear in this list.

For $m=7$ we have only the 7-gon at $n=2$, none at $n=3,5$ and two choices at $n=4$. One is the circulant $\mathbb{Z}_7^{(1,2)}$ and the other is shown in Fig. 1(c). At $n=6$ we just have the universal one.

For $m=8$ we have the 8-gon at $n=2$ and five at $n=3$. One of these is the cube, which is $\mathbb{Z}_2^{(1)}\times\mathbb{Z}_2^{(1)}\times\mathbb{Z}_2^{(1)}$. It can also be viewed as $\mathbb{Z}_2^{(1)}\times\mathbb{Z}_4^{(1)}$. Another is the circulant $\mathbb{Z}_8^{(1,4)}$. See Fig. 1(b). The remaining three are as in Fig. 1(c). At $n=4$ there are six, namely the circulants $\mathbb{Z}_8^{(1,2)}$ and $\mathbb{Z}_8^{(1,3)}$, and $\mathbb{Z}_2^{(1)}\times\mathbb{Z}_4^{(1,2)}$ and the remaining three in Fig. 1(c). At $n=5$ there are three, namely the circulants $\mathbb{Z}_8^{(1,2,4)}$ and $\mathbb{Z}_8^{(1,3,4)}$ and the remaining one in Fig. 1(c). At $n=6$ we have only the circulant $\mathbb{Z}_8^{(1,2,3)}$. At $n=7$ we just have the universal calculus.

For $m=9$ there is the 9-gon at $n=2$, none at $n=3$ and already sixteen at $n=4$, of which three are groups, namely the circulants $\mathbb{Z}_9^{(1,3)}$, $\mathbb{Z}_9^{(1,4)}$ and a simplicial torus [see Fig. 1(b)], which is $\mathbb{Z}_3^{(1)}\times\mathbb{Z}_3^{(1)}$. There are none at $n=5$ and three at $n=6$ of which two are circulants on $\mathbb{Z}_9$, and so forth.

Figure 1(d) also shows an important $m=10$ graph with $n=3$ which is a $\mathbb{Z}_2$ quotient of the dodecahedron and can be thought of as a discrete $\mathbb{RP}^2$.

At the qualitative or "topological" level of this section, we can immediately present a discrete moduli space of combinatorial solutions for vielbeins. Namely, for any E that fibers over Σ with $|F_x|=n$, an n-bein is provided by any choice of bijections $s_x:\{1,\dots,n\}\to F_x$ by

$$e_{axy}=\delta_{s_x(a),y}=e_a^{-1xy},\quad e_a=\sum_x \delta_x \mathrm{d}\delta_{s_x(a)} \tag{19}$$

giving

$$e_a f=f(s_\cdot(b))e_a,\quad (\partial^a f)(x)=f(s_x(a))-f(x). \tag{20}$$

Here $s_\cdot(a)$ is a function on Σ (with $\cdot$ denoting the functional dependence). Pictorially, we label all one-arcs arbitrarily by $\{1,\dots,n\}$ and $s_x(a)$ is the endpoint of the arc labeled a from x. The element θ and the relations of the maximal prolongation are

$$\theta=\sum_a e_a,\quad \sum_{\substack{a\ b\\ x\to\to z}} e_a\wedge e_b=0,\quad \forall\, x\neq z, x\not\to z. \tag{21}$$

The corresponding projectors are

$$\pi(e_a\otimes e_b)=e_a\otimes e_b-\sum_x \frac{\delta_x}{|F_{x,z}|}\sum_{\substack{c\ d\\ x\to\to z}} e_c\otimes e_d;\quad \text{where } x\overset{a\ \ b}{\to\to} z \tag{22}$$

and have a functional dependence. Since the wedge product is given by setting to zero the elements of the tensor product which are in the kernel of this projector, we have the lift $i:\Omega^2\to\Omega^1\otimes\Omega^1$ given by the same formula. These formulas are for general left-parallelizable calculi. In our bidirectional case each arc really means two arrows since we can move along it in either direction. In this case the combinatorial data $\{s_x(a)\}$ for this class of vielbeins is a bicoloring of the graph, with two colors $a\in\{1,\dots,n\}$ for each arc, namely one for each arrow. Moveover, we can follow the colored arrows from vertex to vertex and in this way the doubled-up graph (in which each arc is a pair of arrows going in opposite directions) is decomposed into colored loops. The loops of each color need not be connected.

For the framed geometry one must also choose a frame group G acting on the vector space V spanned by the vielbeins, a calculus on the group given by an Ad-stable subset, and projectors π. For the combinatorial solutions above it is natural to take $G=S_n$ acting by permuting the colors, i.e., $g\triangleright e_a=e_{g(a)}$ for a permutation g. We can then take (for example) the universal differential calculus on S_n where $i\in S_n-\{e\}$ so that there is no regularity condition to solve when we use the braided-Lie algebra with basis $\{f^i\}$. Then the torsion and cotorsion equations for A_i are linear and hence determined by linear algebra. More generally, our choice of frame group and associated structures have to be chosen according to what geometry we want to model. I.e., for each choice of regular graph for the "topology" of the finite set, we have further choices for the actual geometry we want to model. We have already seen how this goes for a small number of points; there are progressively more choices as the number of points increases.

Finally, putting together all the considerations in the paper, we arrive at a first impression of "quantum gravity" in our finite geometry approach. Let us discuss this in a fixed n dimensions, say. As in our examples in Sec. IV, we focus for the sake of discussion on the case of bidirectional graphs and vielbein of the form

$$e_{axy}=\Theta_a(x)^{-1}\delta_{s_x(a),y},$$

where we are allowed to vary each edge in the combinatorial vielbein discussed above by continuous degree of freedom Θ_a. Then for the partition function of this part of quantum gravity one should sum over all remaining topological variables, i.e., all numbers m of points, all n-regular

graphs (so the cotangent bundle is n-dimensional) with the variable m vertices, and all colorings s_a of them into loops (see above); then for each of those (and associated choices of frame group) we integrate over the moduli spaces for the continuous degrees of freedom Θ_a of the vielbein and the spin connection, weighted with some action such as the Einstein–Hilbert one. For example we have at this point the real integrals $\mathrm{d}\lambda, \mathrm{d}\phi, \mathrm{d}\mu, \mathrm{d}\tilde{\mu}, \mathrm{d}\psi, \mathrm{d}\tilde{\psi}$ with the action in Sec. V as a small piece of such a quantum gravity in two-dimensions, in the sector consisting of 4 points with square connectivity and coloring according to $\mathbb{Z}_2^{(1)} \times \mathbb{Z}_2^{(1)}$. Note carefully that our approach is intrinsically a quantum gravity theory in which differential structures (which go into the graph) are summed over as well as more familiar modes.

We are now ready to observe a new kind of duality which is suggested by our sketch of quantum gravity: The sum over all n-regular graphs (n fixed) with variable numbers m of points, which is the main combinatorial part of our theory in n-dimensions, is the same as in the Feynman diagram rules for a scalar theory in flat space with Φ^n-interaction terms. There the graph edges correspond to propagating fields and each vertex is an interaction, i.e., the interpretation is entirely different. The weights for each graph are also somewhat different, but in the Feynman rules one again identifies the loops in the graph (each contributes a momentum integral). One could, therefore, speculate that some flat space quantum field theory with Feynman rules could be equivalent to finite quantum gravity with some action, which would be a novel and somewhat unexpected duality between gravity and elementary particles. These remarks are of course speculative at the moment but may be an interesting direction for further study.

We study the integrability of nonlinear lattices with nonhomogeneous polynomial potentials. We prove a nonintegrability theorem for these dynamical systems. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1806260]

I. INTRODUCTION

The integrability or nonintegrability of a given Hamiltonian system is one of the most fundamental and important issues in characterizing the dynamics of its solutions. Ziglin's theorem[1,2] provides a powerful method to prove the nonintegrability of a given Hamiltonian system. In addition to Ziglin's original example, the Ziglin's theorem has been successfully applied to several Hamiltonian systems with a small number of degrees of freedom to prove the nonexistence of an additional first integral: some homogeneous potential systems,[3] the three-particle Fermi–Pasta–Ulam (FPU) lattice,[4] and the Hénon–Heiles system.[5,6]

Nonlinear lattices are simple Hamiltonian systems with a large number of degrees of freedom, which have been of great physical interest in connection with the dynamical foundation of the statistical mechanics. Their dynamical behavior has been extensively studied since the numerical experiments by Fermi, Pasta, and Ulam on the relaxation process toward equilibrium in one-dimensional nonlinear lattices.[7] It has been believed that nonlinear lattice models are in general nonintegrable, except for some integrable models such as the Toda lattice.[8] However, there are only a few nonlinear lattice models that have been proved to be nonintegrable: homogeneous interaction potential lattices with the fixed-end boundary condition[9,10] and the FPU-β lattice, which has quadratic and quartic interaction potentials, with the fixed-end boundary condition.[11] For these lattice models, the nonintegrability has been proved in a strong sense that no additional analytic first integral exists in the complex phase space.

In the present paper, we consider a more general class of nonlinear lattice models described by the Hamiltonian

$$H = \frac{1}{2}\sum_{i=1}^{N} p_i^2 + \sum_{i=1}^{N} [U(q_i) + V(q_i - q_{i-1})], \tag{1}$$

which is defined on the complex symplectic manifold $\mathcal{M} = \mathbf{C}^{2N} = \{(q_1, \ldots, q_N, p_1, \ldots, p_N)\}$. We assume the periodic boundary condition, i.e., $q_0 = q_N$. The on-site potential U and the nearest neighbor interaction potential V are of the forms

$$U(X) = \sum_{k=2}^{2m} \frac{\mu_k}{k} X^k, \tag{2}$$

$$V(X) = \sum_{k=2}^{2m} \frac{\kappa_k}{k} X^k, \tag{3}$$

where $\mu_k \in \mathbf{R}$ and $\kappa_k \in \mathbf{R}$ are the real constants. We assume $\mu_k = 0$ for odd k so that the on-site potential $U(X)$ may have the symmetry $U(X) = U(-X)$. The purpose of the present paper is to give rigorous results on the nonintegrability of the nonlinear lattices described by Eq. (1). For this purpose, we derive a reduced Hamiltonian system for the system (1), which describes the dynamics on a low-dimensional invariant manifold, and apply a version of the Ziglin's theorem derived by Yoshida[12] to the reduced system. We prove a nonintegrability theorem for the nonlinear lattices described by Eq. (1).

The present paper is organized as follows. In Sec. II, we review the Ziglin's theorem in the case of generic two-dimensional systems. In Sec. III, we review known results on the application of Ziglin's theorem to nonhomogeneous potential systems. In Sec. IV, we relate the nonintegrability of the reduced system with that of the original full system. The reduced Hamiltonian system of (1) is derived and the main theorem is given in Sec. V.

II. ZIGLIN'S THEOREM

The aim of this section is to give a brief review of Ziglin's theorem.[1] Consider the two-dimensional Hamiltonian system

$$H = \tfrac{1}{2}(p_x^2 + p_y^2) + \Phi(x,y) \tag{4}$$

with an analytic potential function $\Phi(x,y)$ in the complex phase space $\mathbf{C}^4 = \{(x,y,p_x,p_y)\}$. The solutions of this system are functions of complex time $t \in \mathbf{C}$. Assume that there exists a straight-line solution of the form

$$x(t) = 0, \quad y(t) = \varphi(t). \tag{5}$$

The solution $\varphi(t)$ satisfies the differential equation

$$\frac{\mathrm{d}^2\varphi}{\mathrm{d}t^2} + \Phi_y(0,\varphi) = 0, \tag{6}$$

where $\Phi_y = \partial\Phi/\partial y$. This equation has the integral

$$\frac{1}{2}\left(\frac{\mathrm{d}\varphi}{\mathrm{d}t}\right)^2 + \Phi(0,\varphi) = h, \tag{7}$$

where $h \in \mathbf{R}$ is a constant corresponding to the energy. The function $\varphi(t)$ is determined as the inverse function of

$$t = \int_{\varphi_0}^{\varphi} \mathrm{d}w/\sqrt{P(w)}, \tag{8}$$

with

$$P(w) = 2[h - \Phi(0,w)], \tag{9}$$

where the integral (8) is taken along a path of integration starting from an initial point φ_0 to the end point φ in the w plane. The value φ determined as a function of t gives the solution $\varphi(t)$.

The function $z=\sqrt{P(w)}$ defines a Riemann surface $\mathcal{R}$ and the roots of $P(w)=0$ give the branch points. Let γ be an arbitrary closed path encircling some of the branch points. The value T_γ of integral (8) given by

$$T_\gamma = \oint_\gamma \mathrm{d}w/\sqrt{P(w)} \tag{10}$$

does not vanish in general and T_γ gives a period of the function $\varphi(t)$. The period T_γ depends only on the homotopy class $[\gamma]$ of γ on $\mathcal{R}$.

Now we consider variational equations along the solution $\varphi(t)$. The variational equations for x and y directions are decoupled because the existence of solution (5) implies that $\Phi_{xy}(0,\varphi(t))=0$ holds identically. Let ξ be the variation in the x direction. The equation for ξ is called the normal variational equation (NVE) and given by

$$\frac{\mathrm{d}^2\xi}{\mathrm{d}t^2} + \Phi_{xx}(0,\varphi(t))\xi = 0. \tag{11}$$

Let us consider a set $\{\gamma\}$ of closed paths, which share a common base point $w_0=\varphi(t_0)$ on $\mathcal{R}$. Since $\mathcal{R}$ is parametrized by $t\in\mathbf{C}$, a closed path γ corresponds to a path in the t plane. In what follows, the analytic continuation along a closed path γ in $\mathcal{R}$ is considered as the analytic continuation along the corresponding path in the t plane. A 2×2 symplectic matrix $g(\gamma)\in \mathrm{SL}(2,\mathbf{C})$ called a monodromy matrix is defined for each closed path γ. The monodromy matrix $g(\gamma)$ describes the time evolution of a system of fundamental solutions of Eq. (11) along γ, i.e., $g(\gamma)$ is defined as the matrix such that

$$(\xi_1(t+T_\gamma),\xi_2(t+T_\gamma)) = (\xi_1(t),\xi_2(t))\cdot g(\gamma), \tag{12}$$

where $\{\xi_1,\xi_2\}$ is a system of fundamental solutions of the NVE. The monodromy matrix $g(\gamma)$ depends only on the homotopy class $[\gamma]$ of γ on $\mathcal{R}$. The set of all monodromy matrices forms a group G called the monodromy group.

Definition: A monodromy matrix $g\in G$ is said to be nonresonant if the eigenvalues $\{\rho,\rho^{-1}\}$ of g satisfy that $\rho^n\neq 1$ for any nonzero integer n.

Let $H^{-1}(h)$ be the energy surface defined by $H^{-1}(h)=\{(x,y,p_x,p_y)\in\mathbf{C}^4 \,|\, H(x,y,p_x,p_y)=h\}$. We define a point set Γ_h by $\Gamma_h=\{(0,\varphi(t),0,\dot{\varphi}(t))\in H^{-1}(h)\,|\,t\in\mathbf{C}\}$. Ziglin's theorem[1] can be stated as follows in our situation.

Theorem 1: *Suppose that system (4) has an integral $f(x,y,p_x,p_y)=$const, which is analytic in a neighborhood of Γ_h and functionally independent of H. If there exists a nonresonant monodromy matrix $g_1\in G$, then any monodromy matrix $g_2\in G$ satisfies that either (i) g_2 commutes with g_1, or (ii)* $\mathrm{tr}\, g_2=0$.

III. APPLICATION OF ZIGLIN'S THEOREM TO POLYNOMIAL POTENTIAL SYSTEMS

A. Monodromy group for homogeneous potential systems

We briefly review some known results on the monodromy matrices of NVE for a homogeneous potential system (for detail, see Ref. 3). Consider the Hamiltonian system (4) with a homogeneous potential of degree $2m\geqslant 4$, which has the straight-line solution of the form (5). The equation for $\varphi(t)$ and the NVE can be written as

$$\frac{\mathrm{d}^2\varphi}{\mathrm{d}t^2} + \alpha_{2m}\varphi^{2m-1} = 0 \tag{13}$$

and

$$\frac{d^2\xi}{dt^2} + \beta_{2m}\varphi(t)^{2m-2}\xi = 0, \tag{14}$$

where α_{2m} and β_{2m} are real constants and we assume $\alpha_{2m} > 0$. We define a parameter λ_{2m} as

$$\lambda_{2m} = \frac{\beta_{2m}}{\alpha_{2m}}. \tag{15}$$

In this case, the function $P(w)$ in Eq. (8) is given by

$$P(w) = 2\left[h - \left(\frac{\alpha_{2m}}{2m}\right)w^{2m}\right], \tag{16}$$

and the branch points $\hat{s}_k$, $k=0,1,\ldots,2m-1$ in the Riemann surface $\mathcal{R}$ defined by $z=\sqrt{P(w)}$ are located at

$$\hat{s}_k = \left(\frac{2mh}{\alpha_{2m}}\right)^{1/2m} \exp\left[i\frac{\pi k}{m}\right]. \tag{17}$$

We define two closed paths $\hat{\gamma}_1$ and $\hat{\gamma}_2$ in $\mathcal{R}$ as follows: $\hat{\gamma}_1$ is a counterclockwise circuit encircling two branch points $\hat{s}_0$ and $\hat{s}_m$, which defines the real period; $\hat{\gamma}_2$ is a counter-clockwise circuit encircling $\hat{s}_1$ and $\hat{s}_{m+1}$. A common base point w_0 is taken between $w=0$ and $\hat{s}_0$ on the real w axis. It is known that the NVE (14) is transformed into the Gauss hypergeometric equation by the change of the independent variable from t to $z=(\alpha_{2mh}/2mh)[\varphi(t)]^{2m}$.[3] This fact enables us to obtain explicit expressions for the two monodromy matrices $\hat{g}_1$ and $\hat{g}_2$, which associate with $\hat{\gamma}_1$ and $\hat{\gamma}_2$, respectively, as follows:[12]

$$\hat{g}_1 = \begin{pmatrix} -1 & -BC \\ A & ABC-1 \end{pmatrix}^2, \tag{18}$$

$$\hat{g}_2 = \begin{pmatrix} -1-\Omega AB & -B(ABC+\Omega AB+\Omega^{-1}C) \\ \Omega A & ABC+\Omega AB-1 \end{pmatrix}^2, \tag{19}$$

where

$$A = 1-\Omega^{-1}e^{-i2\pi a}, \quad B = 1-\Omega^{-1}e^{-i2\pi b}, \quad C = 2\Omega/(\Omega-1), \tag{20}$$

and

$$\Omega = e^{i\pi/m}, \quad a+b = 1/2-1/2m, \quad ab = -\lambda_{2m}/4m. \tag{21}$$

In the homogeneous potential case, the monodromy matrices do not depend on the energy h as seen in Eqs. (18) and (19). A simple computation shows that

$$\mathrm{tr}\,\hat{g}_1 = \mathrm{tr}\,\hat{g}_2 = F_{2m}(\lambda_{2m}), \tag{22}$$

where the function $F_{2m}(\lambda_{2m})$ is defined by

$$F_{2m}(\lambda_{2m}) = \frac{4}{\sin^2(\pi/2m)}\cos^2\left[(\pi/2m)\sqrt{(m-1)^2+4m\lambda_{2m}}\right] - 2. \tag{23}$$

It can be confirmed that $\hat{g}_1$ and $\hat{g}_2$ commute, i.e., the commutator $[\hat{g}_1,\hat{g}_2]=0$, if and only if λ_{2m} has values such that $F_{2m}(\lambda_{2m})=\pm 2$. In addition, we can show that $F_{2m}(\lambda_{2m})>2$ when λ_{2m} is in the region S_{2m} defined by

$$S_{2m} = \{\lambda \in \mathbf{R} | \lambda < 0 \text{ or } 1 < \lambda < 2m-1 \text{ or } 2m+2 < \lambda < 6m-2 \text{ or } \cdots \text{ or } j(j-1)m + j < \lambda < j(j+1)m - j \text{ or } \cdots\}. \tag{24}$$

B. Nonintegrability theorem for nonhomogeneous potential systems

Consider the nonhomogeneous Hamiltonian system

$$H = \frac{1}{2}(p_x^2 + p_y^2) + \sum_{k=2}^{2m} \Phi_k(x,y), \tag{25}$$

where $\Phi_k(x,y)$ is the homogeneous part of degree k, and assume that the system has the straight-line solution of the form (5). The equation for $\varphi(t)$ can be written in the form

$$\frac{d^2\varphi}{dt^2} + W'(\varphi) = 0, \tag{26}$$

where we introduced an effective potential function $W(X)$ defined by

$$W(X) = \sum_{k=2}^{2m} \frac{\alpha_k}{k} X^k. \tag{27}$$

The NVE can be written in the form

$$\frac{d^2\xi}{dt^2} + \left[\sum_{k=2}^{2m} \beta_k \varphi(t)^{k-2}\right]\xi = 0. \tag{28}$$

In Eqs. (27) and (28), α_k and β_k represent the real constants, and we assume that $\alpha_2 > 0$ and $\alpha_{2m} > 0$.

The function $P(w)$ in Eq. (8) is given by

$$P(w) = 2[h - W(w)]. \tag{29}$$

There are h-dependent branch points s_k, $k=0,1,\ldots,2m-1$ in the Riemann surface $\mathcal{R}$ such that $s_k/\hat{s}_k \to 1$ in the limit $h \to \infty$, where $\hat{s}_k$ is the branch point of the homogeneous system given by Eq. (17). In what follows, we assume that the branch points $s_0, s_1, \ldots, s_{2m-1}$ differ from each other for any $h > 0$, i.e., the algebraic equation $W(X) - h = 0$ has $2m$ distinct roots for any $h > 0$. Since any branch point s_k does not collide with the others as h varies under this assumption, we can define the following two closed paths $\gamma_1(h)$ and $\gamma_2(h)$, which deform continuously as h varies: $\gamma_1(h)$ is a counterclockwise circuit encircling only two branch points s_0 and s_m on the real w axis; $\gamma_2(h)$ is a counterclockwise circuit encircling only s_1 and s_{m+1}. A common base point w_0 is taken between $w=0$ and s_0 on the real w axis.

Let $g_1(h)$ and $g_2(h)$ be the two monodromy matrices associated with $\gamma_1(h)$ and $\gamma_2(h)$, respectively. These monodromy matrices depend on h. The elements of $g_1(h)$ and $g_2(h)$ are analytic functions of h in the interval $(0,\infty)$, since s_k, $k=0,1,\ldots,2m-1$ are analytic functions of h due to the assumption that $W(X)-h=0$ has $2m$ distinct roots for any $h>0$. When the potential is nonhomogeneous, there is no analytical method to calculate the monodromy matrices. However, Yoshida pointed out in Ref. 12 that they can be evaluated in the limits $h \to 0$ and $h \to \infty$.

In the limit $h \to \infty$, the highest order terms of φ become dominant in Eqs. (26) and (28). Therefore, $g_1(h)$ and $g_2(h)$ converges to the monodromy matrices $\hat{g}_1$ and $\hat{g}_2$ of the homogeneous system of degree $2m$, respectively, which are given by Eqs. (18) and (19). We have

$$\lim_{h\to\infty} \operatorname{tr} g_1(h) = \lim_{h\to\infty} \operatorname{tr} g_2(h) = F_{2m}(\lambda_{2m}) \tag{30}$$

and

$$\lim_{h\to\infty}[g_1(h),g_2(h)]=[\hat{g}_1,\hat{g}_2]. \tag{31}$$

In the opposite limit $h\to 0$, the lowest order terms of φ become dominant in Eqs. (26) and (28): the NVE (28) tends to that of the homogeneous system of degree 2. The assumption on the roots of $W(X)-h=0$ implies that only two branch points s_0 and s_m are real numbers for any $h>0$. These two real branch points approach those of the homogeneous system of degree 2, which are given by $w=\pm(2h/\alpha_2)^{1/2}$, in the limit $h\to 0$. Therefore, $g_1(h)$ converges to the monodromy matrix of the homogeneous system of degree 2 that corresponds to the real period and we have

$$\lim_{h\to 0}\operatorname{tr} g_1(h)=2\cos[2\pi\sqrt{\lambda_2}], \tag{32}$$

where $\lambda_2=\beta_2/\alpha_2$.

Based on the above arguments, Yoshida obtained the following useful theorem.[12] To state the theorem, we define a point set of a straight line solution $\Gamma_h=\{(0,\varphi(t),0,\dot{\varphi}(t))\in H^{-1}(h)\,|\,t\in\mathbf{C}\}$ and a family of the straight line solutions $\{\Gamma_h\}_{h_0,\varepsilon}=\{\Gamma_h\in\mathbf{C}^4\,|\,h\in U_\varepsilon(h_0)=(h_0-\varepsilon,h_0+\varepsilon)\}$, where $h_0\in(0,\infty)$ is an arbitrary fixed energy value and ε is a small positive real number.

Theorem 2: *Suppose that* $m\geqslant 2$, $\alpha_2>0$, $\alpha_{2m}>0$, *and the algebraic equation* $W(X)-h=0$ *has* $2m$ *distinct roots for any* $h>0$. *If* $\lambda_{2m}=\beta_{2m}/\alpha_{2m}$ *is a value such that* $F_{2m}(\lambda_{2m})\notin\{0,\pm 2,2\cos[2\pi\sqrt{\lambda_2}]\}$, *then for any* $h_0>0$ *and any* $\varepsilon>0$ *the system (25) cannot have an additional integral, which is analytic and functionally independent of H in a connected neighborhood of* $\{\Gamma_h\}_{h_0,\varepsilon}$.

Proof: We consider the monodromy matrices $g_1(h)$ and $g_2(h)$ defined in the above. The components of $g_1(h)$ and $g_2(h)$ are analytic functions of h in the whole interval $(0,\infty)$. From Eqs. (30) and (32), in the limits $h\to 0$ and $h\to\infty$, we know $\operatorname{tr} g_1(0)=2\cos[2\pi\sqrt{\lambda_2}]$ and $\operatorname{tr} g_1(\infty)=\operatorname{tr} g_2(\infty)=F_{2m}(\lambda_{2m})$.

Since $g_1(h)$ is an analytic function of h in the whole interval $(0,\infty)$, the condition $F_{2m}(\lambda_{2m})\neq 2\cos[2\pi\sqrt{\lambda_2}]$ implies that $\operatorname{tr} g_1(h)$ actually changes as h varies. Therefore, there exists a dense subset S of the interval $(0,\infty)$ such that $g_1(h)$ is nonresonant for any $h\in S$. Assume that there exists an additional integral in a neighborhood of $\{\Gamma_h\}_{h_0,\varepsilon}$. It follows from Theorem 1 that either $[g_1(h),g_2(h)]=0$ or $\operatorname{tr} g_2(h)=0$ holds for any fixed $h\in S\cap U_\varepsilon(h_0)$.

Assume that $[g_1(\bar{h}),g_2(\bar{h})]\neq 0$ for some $\bar{h}\in S\cap U_\varepsilon(h_0)$. Because of the continuity of $[g_1(h),g_2(h)]$ with respect to h, $[g_1(h),g_2(h)]\neq 0$ holds in some neighborhood $U'(\bar{h})\subseteq U_\varepsilon(h_0)$ of $\bar{h}$. Thus, $\operatorname{tr} g_2(h)=0$ holds for any $h\in S'$, where S' is defined by $S'=S\cap U'(\bar{h})$. Since $\operatorname{tr} g_2(h)$ is an analytic function of h and $\operatorname{tr} g_2(h)=0$ holds in the dense subset S' of $U'(\bar{h})$, it follows that $\operatorname{tr} g_2(h)=0$ holds identically over the whole interval $(0,\infty)$. This contradicts the assumption $\operatorname{tr} g_2(\infty)=F_{2m}(\lambda_{2m})\neq 0$. On the other hand, if we assume that $\operatorname{tr} g_2(\bar{h})\neq 0$ for some $\bar{h}\in S\cap U_\varepsilon(h_0)$, then it follows that $[g_1(h),g_2(h)]=0$ holds for any $h\in S''$, where S'' is a dense subset of some neighborhood of $\bar{h}$, by a similar argument to the above. Since $[g_1(h),g_2(h)]$ is an analytic function of h and $[g_1(h),g_2(h)]=0$ holds in the dense subset S'', it follows that $[g_1(h),g_2(h)]=0$ holds identically over the whole interval $(0,\infty)$. Thus, we have $\lim_{h\to\infty}[g_1(h),g_2(h)]=0$. The commutator is given by $[\hat{g}_1,\hat{g}_2]$ in the limit $h\to\infty$ from Eq. (31). Therefore, $F_{2m}(\lambda_{2m})=\pm 2$ follows from $\lim_{h\to\infty}[g_1(h),g_2(h)]=0$. This contradicts the assumption $F_{2m}(\lambda_{2m})\neq\pm 2$. From the above arguments, the nonexistence of an additional integral, which is analytic and functionally independent of H in a connected neighborhood of $\{\Gamma_h\}_{h_0,\varepsilon}$, has been proven. ■

Remark: A condition to guarantee the analyticity of $g_1(h)$ and $g_2(h)$ was not included in the original statement of this theorem in Ref. 12. As a sufficient condition, we added the nondegeneracy condition on the roots of $W(X)-h=0$.

IV. REDUCED HAMILTONIAN SYSTEM ON LOW-DIMENSIONAL INVARIANT MANIFOLD AND NONINTEGRABILITY

In this section we give a lemma, which relates the nonintegrability of a reduced system on a low-dimensional invariant manifold and that of the full system. Consider the Hamiltonian system of $n+2$ degrees of freedom,

$$H(q_1,\ldots,q_{n+2},p_1,\ldots,p_{n+2}), \tag{33}$$

which is defined on the complex symplectic manifold $\mathcal{N}=\mathbf{C}^{2(n+2)}$. Suppose that the Hamiltonian system (33) has a four-dimensional invariant manifold $\mathcal{I}$ defined by

$$\mathcal{I}=\{(q_1,\ldots,q_{n+2},p_1,\ldots,p_{n+2})\in \mathbf{C}^{2(n+2)} | q_i=p_i=0, i=1,2,\ldots,n\}, \tag{34}$$

and the vector field restricted to $\mathcal{I}$ is associated with the Hamiltonian $\tilde{H}(q_{n+1},q_{n+2},p_{n+1},p_{n+2})$, which we call the *reduced Hamiltonian*. The reduced Hamiltonian $\tilde{H}$ is related to the original Hamiltonian H as

$$\tilde{H}(q_{n+1},q_{n+2},p_{n+1},p_{n+2})=H(0,\ldots,0,q_{n+1},q_{n+2},0,\ldots,0,p_{n+1},p_{n+2}). \tag{35}$$

Let Γ_h be a straight line solution of the reduced Hamiltonian system. We denote its family by $\{\Gamma_h\}$. Then, we have the following lemma.

Lemma 1: Suppose that the reduced Hamiltonian system (35) is nonintegrable, in the sense that there does not exist an additional integral which is analytic and functionally independent of $\tilde{H}$ in a connected neighborhood of $\{\Gamma_h\}$ in $\mathcal{I}$. Then, the full Hamiltonian system (33) cannot have a set of $n+2$ analytic integrals $f_1=H,f_2,\ldots,f_{n+2}$ defined in a connected neighborhood U of $\{\Gamma_h\}$ in $\mathcal{N}$, such that

(C1) The 1-forms $\mathrm{d}f_i, i=1,2,\ldots,n+2$ are linearly independent over a dense open set $D\subseteq U$ such that $D\cap\mathcal{I}\neq\phi$.

(C2) They form an involutive set: the Poisson brackets for any pair of f_i and f_j vanish, i.e., $\{f_i,f_j\}=0, i,j=1,2,\ldots,n+2$.

Proof: Suppose that there exists a set of $n+2$ integrals satisfying the conditions (C1) and (C2). Let $\tilde{f}_i$ defined by $\tilde{f}_i(q_{n+1},q_{n+2},p_{n+1},p_{n+2})=f_i(0,\ldots,0,q_{n+1},q_{n+2},0,\ldots,0,p_{n+1},p_{n+2})$. Since $\mathcal{I}$ is the invariant manifold, each $\tilde{f}_i$ is an integral of the reduced system (35) in $\mathcal{I}\cap U$. The nonexistence of an additional integral, which is functionally independent of $\tilde{H}$ in $\mathcal{I}\cap U$, implies that $\tilde{f}_i$ and $\tilde{H}$ are functionally dependent in $\mathcal{I}\cap U$. Then, $\tilde{f}_i$ is a function of $\tilde{H}$ only, i.e., $\tilde{f}_i=\Psi_i(\tilde{H})$ with some analytic function Ψ_i. Therefore, except for the Hamiltonian $f_1=H$, we can assume that $f_i=0$ over $\mathcal{I}\cap U$ for $i=2,3,\ldots,n+2$. In fact, if $\tilde{f}_i\neq 0$, then we can use $f_i-\Psi_i(H)$ as an integral instead of f_i.

There is a point $x\in D\cap\mathcal{I}$ such that $\mathrm{d}f_i$, $i=1,2,\ldots,N$ are linearly independent at x. Let U_x be a neighborhood of x in $\mathcal{N}$. Since f_i is an analytic function of $(q_1,\ldots,q_{n+2},p_1,\ldots,p_{n+2})$, we can expand f_i for $i=2,3,\ldots,n+2$ in U_x as

$$f_i=\sum_{|\boldsymbol{\nu}|=1}^{\infty} f_{\boldsymbol{\nu}}^{(i)}(q_{n+1},q_{n+2},p_{n+1},p_{n+2})q_1^{\nu_1}\cdots q_n^{\nu_n}p_1^{\nu_{n+1}}\cdots p_n^{\nu_{2n}}, \tag{36}$$

where ν_j, $j=1,\ldots,2n$ are non-negative integers, $\boldsymbol{\nu}$ is the multi-index $\boldsymbol{\nu}=(\nu_1,\ldots,\nu_{2n}), |\boldsymbol{\nu}|=\nu_1+\nu_2+\cdots+\nu_{2n}$, and $f_{\boldsymbol{\nu}}^{(i)}$ is an analytic function of $(q_{n+1},q_{n+2},p_{n+1},p_{n+2})$, and we used the fact $\tilde{f}_i=0$.

A simple calculation using Eq. (36) shows that the 1-form $\mathrm{d}f_i$ at x is of the form

$$\mathrm{d}f_i=\sum_{j=1}^{n}[a_j^{(i)}(x)\mathrm{d}q_j+a_{n+j}^{(i)}(x)\mathrm{d}p_j], \tag{37}$$

for $i=2,3,\ldots,n+2$. In Eq. (37), $a_j^{(i)}$ is given by $f_{\boldsymbol{\nu}}^{(i)}$ with the multi-index $\boldsymbol{\nu}$ such that its kth component is $\nu_k=\delta_{jk}$, where δ_{jk} is the Kronecker's delta. Note that $\mathrm{d}f_i$ does not include the terms

of $\mathrm{d}q_i$ and $\mathrm{d}p_i$, $i=n+1,n+2$. Let L_x be a subspace of the tangent space $T_x\mathcal{N}$ at the point x defined by $L_x=\mathrm{span}\{\partial/\partial q_1,\ldots,\partial/\partial q_n,\partial/\partial p_1,\ldots,\partial/\partial p_n\}$ and L_x^* be the dual space of L_x defined by $L_x^*=\mathrm{span}\{\mathrm{d}q_1,\ldots,\mathrm{d}q_n,\mathrm{d}p_1,\ldots,\mathrm{d}p_n\}$. Equation (37) shows that $\mathrm{d}f_i\in L_x^*$ for $i=2,3,\ldots,n+2$. In addition, we define a subspace $L_{f,x}=\{v\in L_x|\mathrm{d}f_i(v)=0,\ i=2,3,\ldots,n+2\}\subseteq L_x$. Since the 1-forms $\mathrm{d}f_i$, $i=2,3,\ldots,n+2$ are linearly independent at x, the dimension of $L_{f,x}$ is obtained as $\dim L_{f,x}=\dim L_x-(n+1)=n-1$.

Let I be the isomorphism between the cotangent bundle $T^*\mathcal{N}$ and the tangent bundle $T\mathcal{N}$, which maps a 1-form to the associated Hamiltonian vector field. From Eq. (36), the Hamiltonian vector fields $I\,\mathrm{d}f_i$, $i=2,3,\ldots,n+2$ associated with the Hamiltonian f_i are obtained at x as follows:

$$I\,\mathrm{d}f_i=\sum_{j=1}^{n}\left[b_j^{(i)}(x)\frac{\partial}{\partial q_j}+b_{n+j}^{(i)}(x)\frac{\partial}{\partial p_j}\right], \tag{38}$$

where $b_j^{(i)}=a_{n+j}^{(i)}$, $b_{n+j}^{(i)}=-a_j^{(i)}$, $j=1,2,\ldots,n$. The condition (C2) implies that $\mathrm{d}f_i(I\,\mathrm{d}f_j)=0$, $i,j,=2,3,\ldots,n+2$ and thus $I\,\mathrm{d}f_j\in L_{f,x}$, $j,=2,3,\ldots,n+2$. Since the map I is nondegenerate, the $n+1$ vectors $I\,\mathrm{d}f_j$, $j=2,3,\ldots,n+2$ are linearly independent. This implies $\dim L_{f,x}\geqslant n+1$ and we get a contradiction. Therefore, there cannot exist a set of $n+2$ integrals satisfying the two conditions (C1) and (C2). ■

V. NONINTEGRABILITY THEOREM FOR NONLINEAR LATTICES

A. Invariant manifold and reduced Hamiltonian

Consider the lattice Hamiltonian (1) with the polynomial potential functions (2) and (3) in $\mathcal{M}=\mathbf{C}^{2N}$. Suppose that the on-site potential $U(X)$ has the symmetry $U(X)=U(-X)$, that is, $\mu_k=0$ for odd k. In the following arguments, we employ the periodic boundary condition and assume the lattice size N to be a multiple of four, i.e.,

$$q_0=q_N,\quad q_{N+1}=q_1,\quad N=4n\ (n\in\mathbf{N}). \tag{39}$$

The equations of motion read

$$\frac{\mathrm{d}^2q_i}{\mathrm{d}t^2}+U'(q_i)-V'(q_{i+1}-q_i)+V'(q_i-q_{i-1})=0,\quad i=1,2,\ldots,N. \tag{40}$$

We define the canonical transformation $(q_1,\ldots,q_N,p_1\ldots,p_N)\mapsto(Q_0,\ldots,Q_{N-1},P_0,\ldots,P_{N-1})$ as follows:

$$q_i=\sum_{k=0}^{N-1}Q_k\left[\sin\left(\frac{2\pi k}{N}i\right)+\cos\left(\frac{2\pi k}{N}i\right)\right], \tag{41}$$

$$p_i=\frac{1}{N}\sum_{k=0}^{N-1}P_k\left[\sin\left(\frac{2\pi k}{N}i\right)+\cos\left(\frac{2\pi k}{N}i\right)\right], \tag{42}$$

where $i=1,2,\ldots,N$. This new variables Q_k and P_k are called the normal mode coordinates. Then, as for the invariant manifold, we have the following.

Proposition 1: Suppose that $U(X)$ has the symmetry $U(X)=U(-X)$ and $N=4n$ $(n\in\mathbf{N})$. *Nonlinear lattice* (1) *with the periodic boundary condition has the four-dimensional invariant manifold* $\mathcal{I}_1$ *defined by*

$$\mathcal{I}_1=\{(Q_0,\ldots,Q_{N-1},P_0,\ldots,P_{N-1})\in\mathbf{C}^{2N}|Q_k=P_k=0,\ k\neq N/4,N/2\}. \tag{43}$$

Moreover, the reduced Hamiltonian $\tilde{H}_1$, *which determines the vector field on* $\mathcal{I}_1$, *is given by*

$$\tilde{H}_1 = \frac{1}{2N}(p_x^2 + p_y^2) + \frac{N}{2}[U(x-y) + U(x+y)] + \frac{N}{4}[V(2(x+y)) + V(2(y-x)) + 2V(-2y)], \quad (44)$$

where $(x, y, p_x, p_y) = (Q_{N/4}, Q_{N/2}, P_{N/4}, P_{N/2})$.

Proof: From Eqs. (41) and (42), any point in $\mathcal{I}_1$ is expressed in the original $(\mathbf{q}, \mathbf{p})$ coordinates as follows:

$$\begin{aligned} q_{4k+1} &= -q_{4k+2} = Q_{N/4} - Q_{N/2}, \quad p_{4k+1} = -p_{4k+2} = \frac{1}{N}(P_{N/4} - P_{N/2}), \\ -q_{4k+3} &= q_{4k+4} = Q_{N/4} + Q_{N/2}, \quad -p_{4k+3} = p_{4k+4} = \frac{1}{N}(P_{N/4} + P_{N/2}), \end{aligned} \quad (45)$$

where $k = 0, 1, \ldots, N/4 - 1$. Let $\mathcal{I}_1'$ be the submanifold of $\mathcal{M}$ defined by

$$\begin{aligned} \mathcal{I}_1' = \{(q_1, \ldots, q_N, p_1, \ldots, p_N) \in \mathbf{C}^{2N} | & q_{4k+1} = -q_{4k+2} = q_1, \quad q_{4k+3} = -q_{4k+4} = q_3, \\ & p_{4k+1} = -p_{4k+2} = p_1, \quad p_{4k+3} = -p_{4k+4} = p_3, \quad k = 0, 1, \ldots, N/4 - 1\}. \end{aligned} \quad (46)$$

The submanifold $\mathcal{I}_1'$ is identical with $\mathcal{I}_1$. Then, in order to show that $\mathcal{I}_1$ is an invariant manifold, it is enough to show that $\mathcal{I}_1'$ is invariant under the flow associated with Hamiltonian (1). Since $U(X) = U(-X)$, it can be easily checked that for any initial point on $\mathcal{I}_1'$ the solution to Eqs. (40) with the periodic boundary condition is of the form

$$q_{4k+1}(t) = -q_{4k+2}(t) = \psi_1(t), \quad q_{4k+3}(t) = -q_{4k+4}(t) = \psi_2(t), \quad k = 0, 1, \ldots, N/4 - 1, \quad (47)$$

where ψ_1 and ψ_2 are the solutions of the set of differential equations

$$\frac{\mathrm{d}^2\psi_1}{\mathrm{d}t^2} + U'(\psi_1) - V'(-2\psi_1) + V'(\psi_1 + \psi_2) = 0, \quad (48)$$

$$\frac{\mathrm{d}^2\psi_2}{\mathrm{d}t^2} + U'(\psi_2) - V'(-2\psi_2) + V'(\psi_1 + \psi_2) = 0. \quad (49)$$

Since the solution (47) is contained in $\mathcal{I}_1'$ for any t, $\mathcal{I}_1'$, or $\mathcal{I}_1$ is an invariant manifold. The reduced Hamiltonian (44) is obtained by substituting Eq. (45) into the original Hamiltonian (1) and rewriting $(Q_{N/4}, Q_{N/2}, P_{N/4}, P_{N/2})$ by (x, y, p_x, p_y). ■

Remark: It is not assumed that the potential functions $U(X)$ and $V(X)$ are polynomials in the proof of Proposition 1.

The reduced Hamiltonian system (44) with the potentials (2) and (3) has a straight line solution of the form $x(t) = 0$, $y(t) = \varphi(t)$. The solution φ satisfies the differential equation

$$\frac{\mathrm{d}^2\varphi}{\mathrm{d}t^2} + \sum_{r=1}^{m} (\mu_{2r} + 2^{2r}\kappa_{2r})\varphi^{2r-1} = 0, \quad (50)$$

with the integral

$$\frac{1}{2}\left(\frac{\mathrm{d}\varphi}{\mathrm{d}t}\right)^2 + W_1(\varphi) = h, \quad (51)$$

where the effective potential function $W_1(X)$ is defined by

$$W_1(X) = \sum_{r=1}^{m} \frac{1}{2r}(\mu_{2r} + 2^{2r}\kappa_{2r})X^{2r}. \tag{52}$$

In Eq. (51), h can be regarded as the single particle energy and is related to the energy H of the whole system (1) as $h=H/N$. As for the NVE, we have

$$\frac{\mathrm{d}^2\xi}{\mathrm{d}t^2} + \left[\sum_{k=2}^{2m}(k-1)(\mu_k + 2^{k-1}\kappa_k)\varphi(t)^{k-2}\right]\xi = 0. \tag{53}$$

From Eqs. (50) and (53), parameters λ_2 and λ_{2m} are determined as

$$\lambda_2 = \frac{\mu_2 + 2\kappa_2}{\mu_2 + 4\kappa_2}, \quad \lambda_{2m} = (2m-1)\frac{\mu_{2m} + 2^{2m-1}\kappa_{2m}}{\mu_{2m} + 2^{2m}\kappa_{2m}}. \tag{54}$$

B. Main theorem

The straight line solution φ defines a point set $\Gamma_{1,h}=\{(q_1,\ldots,q_N,p_1,\ldots,p_N)\in H^{-1}(Nh)\,|\,q_i=(-1)^i\varphi(t),\ p_i=(-1)^i\dot{\varphi}(t),\ t\in\mathbf{C},\ i=1,2,\ldots,N\}\subseteq\mathcal{M}=\mathbf{C}^{2N}$. In addition, we define a family of $\Gamma_{1,h}$ by $\{\Gamma_{1,h}\}_{h_0,\varepsilon}=\{\Gamma_{1,h}\in\mathcal{M}\,|\,h\in(h_0-\varepsilon,h_0+\varepsilon)\}$, where $h_0\in(0,\infty)$ and ε is a small positive real number. Then, our theorem is stated as follows.

Theorem 3: *Suppose that $m\geqslant 2$ and $N=4n$ ($n\in\mathbf{N}$). Further, suppose that parameters in the potentials μ_k, κ_k, $k=2,3,\ldots,2m$ have values such that (i) $\mu_k=0$ for odd k, (ii) the inequalities $\min\{\mu_2+2\kappa_2,\mu_2+4\kappa_2\}>0$, $\mu_{2m}\geqslant 0$, and $\kappa_{2m}>0$ hold, and (iii) the algebraic equation $W_1(X)-h=0$ has $2m$ distinct roots for any $h>0$. Then, for any $h_0>0$ and any $\varepsilon>0$, reduced system (44) cannot have an additional integral, which is analytic and functionally independent of $\tilde{H}_1$, in a connected neighborhood of $\{\Gamma_{1,h}\}_{h_0,\varepsilon}$ in $\mathcal{I}_1$. Moreover, periodic nonlinear lattice (1) with potential functions (2) and (3) is nonintegrable in the following sense: for any $h_0>0$ and any $\varepsilon>0$, in a connected neighborhood $U_{\mathcal{M}}$ of $\{\Gamma_{1,h}\}_{h_0,\varepsilon}$ in $\mathcal{M}$, there does not exist an involutive set of N analytic integrals $f_1=H,f_2,\ldots,f_N$ such that there is a point in $U_{\mathcal{M}}\cap\mathcal{I}_1$ at which $\mathrm{d}f_i$, $i=1,\ldots,N$ are linearly independent.*

Proof: Consider the invariant manifold $\mathcal{I}_1$ and the reduced Hamiltonian system $\tilde{H}_1$. Equation (50) shows that $\alpha_2=\mu_2+4\kappa_2$ and $\alpha_{2m}=\mu_{2m}+2^{2m}\kappa_{2m}$. It follows from the assumptions in (ii) that $\alpha_2>0$ and $\alpha_{2m}>0$. From Eq. (54), the parameter λ_{2m} is rewritten as

$$\lambda_{2m} = (2m-1)\left[1 - \frac{2^{2m-1}}{(\mu_{2m}/\kappa_{2m}) + 2^{2m}}\right]. \tag{55}$$

Since $m\geqslant 2$ and $\mu_{2m}/\kappa_{2m}\geqslant 0$, we see that $1<(2m-1)/2\leqslant\lambda_{2m}<2m-1$ and thus λ_{2m} is in the region S_{2m} defined by Eq. (24). This implies $F_{2m}(\lambda_{2m})>2$. It follows from the assumption $\min\{\mu_2+2\kappa_2,\mu_2+4\kappa_2\}>0$ that $\lambda_2>0$ and $2\cos[2\pi\sqrt{\lambda_2}]\leqslant 2$. Therefore, $F_{2m}(\lambda_{2m})\notin\{0,\pm 2,2\cos[2\pi\sqrt{\lambda_2}]\}$. From Theorem 2, the reduced Hamiltonian system (44) cannot have an additional integral, which is analytic and functionally independent of $\tilde{H}_1$ in a connected neighborhood of $\{\Gamma_{1,h}\}_{h_0,\varepsilon}$ in $\mathcal{I}_1$. Then, the hypotheses of Lemma 1 are satisfied and hence Theorem 3 has been proven. ■

C. Application to small *m* cases

We apply Theorem 3 to some cases of small m. For these cases, we can give explicit conditions on the parameters μ_k and κ_k such that $W_1(X)-h=0$ has $2m$ distinct roots for any $h>0$. If we introduce a new variable $Y=X^2$, we have the algebraic equation

$$\mathcal{F}_m(Y) = \sum_{r=1}^{m} A_r Y^r - h = 0, \tag{56}$$

instead of the equation $W_1(X)-h=0$, where A_r is defined by

$$A_r = \frac{1}{2r}(\mu_{2r} + 2^{2r}\kappa_{2r}). \tag{57}$$

The equation $W_1(X)-h=0$ has $2m$ distinct roots for any $h>0$ if and only if $\mathcal{F}_m(Y)=0$ has m distinct roots for any $h>0$. In what follows, we consider the cases of $m=2$, 3, and 4.

Corollary 1: Suppose that $m=2$ and $N=4n$ $(n \in \mathbf{N})$. If parameters μ_k, κ_k, $k=2,3,4$ satisfy that $\min\{\mu_2+2\kappa_2, \mu_2+4\kappa_2\}>0$, $\mu_4 \geqslant 0$, $\kappa_4>0$, and $\mu_3=0$, then periodic nonlinear lattice (1) with potential functions (2) and (3) is nonintegrable in the sense of Theorem 3.

Proof: The discriminant $D(\mathcal{F}_2)$ of the polynomial $\mathcal{F}_2$ is calculated as

$$D(\mathcal{F}_2) = A_1^{\,2} + 4A_2 h. \tag{58}$$

Since $A_1>0$ and $A_2>0$, $D(\mathcal{F}_2)>0$ holds for any $h>0$. This implies that $\mathcal{F}_2(Y)=0$ has two distinct roots for any $h>0$. Therefore, the hypotheses of Theorem 3 are satisfied and the corollary has been proven. ■

The FPU lattice corresponds to the case of $\mu_2=\mu_3=\mu_4=0$. Corollary 1 shows that if $\kappa_2, \kappa_4>0$ then the FPU lattice is nonintegrable.

Corollary 2: Suppose that $m=3$ and $N=4n$ $(n \in \mathbf{N})$. If parameters μ_k, κ_k, $k=2,3,\ldots,6$ satisfy that $\min\{\mu_2+2\kappa_2, \mu_2+4\kappa_2\}>0$, $\mu_6 \geqslant 0$, $\kappa_6>0$, $\mu_3=\mu_5=0$, and $-\sqrt{3A_1A_3}<A_2\leqslant 2\sqrt{A_1A_3}$, then periodic nonlinear lattice (1) with potential functions (2) and (3) is nonintegrable in the sense of Theorem 3.

Proof: The discriminant $D(\mathcal{F}_3)$ is calculated as

$$D(\mathcal{F}_3) = -27A_3^{\,2}h^2 + 2A_2(2A_2^{\,2} - 9A_1A_3)h + A_1^{\,2}(A_2^{\,2} - 4A_1A_3). \tag{59}$$

If $D(\mathcal{F}_3)\neq 0$ holds for any $h>0$, then $\mathcal{F}_3(Y)=0$ has three distinct roots for any $h>0$. The discriminant $D(\mathcal{F}_3)$ is simply a quadratic function of h. In Eq. (59), $A_1>0$ and $A_3>0$ because of the assumptions $\mu_2+4\kappa_2>0$, $\mu_6\geqslant 0$, and $\kappa_6>0$. It is easily confirmed that $D(\mathcal{F}_3)<0$ holds for any $h>0$ if $A_1, A_3>0$ and $-\sqrt{3A_1A_3}<A_2\leqslant 2\sqrt{A_1A_3}$. Then, the hypotheses of Theorem 3 are satisfied and the Corollary has been proven. ■

Corollary 3: Suppose that $m=4$ and $N=4n$ $(n \in \mathbf{N})$. If parameters μ_k, κ_k, $k=2,3,\ldots,8$ satisfy that $\min\{\mu_2+2\kappa_2, \mu_2+4\kappa_2\}>0$, $\mu_8\geqslant 0$, $\kappa_8>0$, $\mu_3=\mu_5=\mu_7=0$, and $108A_1^{\,2}A_4^{\,2}+27(A_3^{\,2} - 4A_2A_4)A_1A_3+(32A_2A_4-9A_3^{\,2})A_2^{\,2}>0$, then periodic nonlinear lattice (1) with potential functions (2) and (3) is nonintegrable in the sense of Theorem 3.

Proof: Since $\mathcal{F}_4(Y)$ is a quartic function with $A_1, A_4>0$, it has two distinct real roots and a pair of two complex conjugate roots for $h>0$ if $\mathcal{F}_4(Y)$ is a unimodal function on the real Y axis for $h=0$, i.e., if $\mathrm{d}\mathcal{F}_4(Y)/\mathrm{d}Y=0$ has only one real root. The derivative $\mathrm{d}\mathcal{F}_4(Y)/\mathrm{d}Y$ is a cubic function and the discriminant of $\mathrm{d}\mathcal{F}_4(Y)/\mathrm{d}Y$ is given by

$$D(\mathrm{d}\mathcal{F}_4/\mathrm{d}Y) = -4[108A_1^{\,2}A_4^{\,2} + 27(A_3^{\,2} - 4A_2A_4)A_1A_3 + (32A_2A_4 - 9A_3^{\,2})A_2^{\,2}]. \tag{60}$$

The equation $\mathrm{d}\mathcal{F}_4(Y)/\mathrm{d}Y=0$ has only one real root when $D(\mathrm{d}\mathcal{F}_4/\mathrm{d}Y)<0$. Since $D(\mathrm{d}\mathcal{F}_4/\mathrm{d}Y)<0$ holds from the assumption, it follows that $\mathcal{F}_4(Y)=0$ has four distinct roots for any $h>0$. Then, the hypotheses of Theorem 3 are satisfied and the corollary has been proven. ■

(Received 30 April 2004; accepted 27 May 2004; published 15 November 2004)

It is shown that the algebra of diffeomorphism-invariant charges of the Nambu–Goto string cannot be quantized in the framework of canonical quantization. The argument is shown to be independent of the dimension of the underlying Minkowski space. © *2004 American Institute of Physics.*

I. INTRODUCTION

The action of the Nambu–Goto string is a generalization of the reparametrization-invariant action of the relativistic particle in d-dimensional Minkowski space, where instead of a point-particle, a one-dimensional extended object (a string) is considered. Correspondingly, the solutions of the equations of motion are surfaces swept out by the string in space–time (called world-sheets) which are extremal with respect to the Minkowski metric. The parametrization of these surfaces is not fixed by the equations of motion, and, hence, a change of the parametrization corresponds to a symmetry transformation which does not change the physical state of the system. Therefore, the Nambu–Goto string is a system with gauge group given by the diffeomorphisms of a surface. As such, it provides an interesting model to study the fundamental problem of quantizing a system with gauge freedom given by the diffeomorphism group.

For closed strings, the world-sheet is tube-shaped. It was shown especially in this case that the Nambu–Goto string can be treated as an integrable system and that its integrals of motion can be constructed from a suitably defined monodromy.[1] These integrals of motion are functionals on the world-sheet which are invariant under arbitrary reparametrizations (gauge transformations) and as such are observable quantities. They form a graded Poisson algebra,[2,3] the Poisson algebra of invariant charges, and were shown to be complete in the sense that, up to translations in the direction of its total energy-momentum vector, the string can be reconstructed from the knowledge of the invariant charges and the infinitesimal generators of boosts.[4] In this scheme, the constraints which are present in the system enter as a condition on the representation of the algebra, and—along with conditions regarding Hermiticity and positivity of the energy—distinguish its physically meaningful representations.

The algebra of invariant charges provides the starting point of the algebraic quantization of the Nambu–Goto string.[1] This scheme is based on the idea that the correspondence principle should be applied to physically meaningful quantities only, which in a theory with gauge freedom means that it is applicable only to gauge-invariant observables. In this spirit, the graded Poisson algebra of invariant charges of the Nambu–Goto string is quantized by application of the correspondence principle, replacing the Poisson brackets by commutators and allowing for particular (observable) quantum corrections which are restricted by demanding structural similarity of the classical and the quantum algebra. So far, it does not seem at all likely that in this scheme an obstruction regarding the dimension d of the underlying Minkowski space should appear (other than $d>2$). In contrast to this, the canonical quantization of the Nambu–Goto string is consistent only in certain critical dimensions. Here, the correspondence principle is assumed to hold for the Fourier modes

a)Electronic mail: bahns@mail.desy.de

of some particular parametrization, i.e., for quantities which are not observable. It leads to the well-known construction of Fock space which contains the physically relevant states as a subspace.

In this paper, which is an exposition of results gained some years ago,[5] it is shown that canonical quantization does not yield a representation of the algebra of invariant charges. After a short exposition of known results regarding the algebraic approach to the quantization of the Nambu–Goto string[2,3,6] in the following two sections, the fourth section contains an investigation of the canonical quantization and its application to the algebra of invariant charges. It is shown that unobservable anomalies arise in the defining relations of the algebra in $3+1$ dimensions. In Sec. V it is then shown that the problem cannot be cured by adjusting the dimension of the underlying Minkowski space.

II. THE POISSON ALGEBRA OF INVARIANTS

In the Hamiltonian formalism, the fact that the world-sheet is independent of the particular parametrization chosen to describe it becomes manifest in the appearance of two primary constraints which are the infinitesimal generators of gauge transformations (reparametrizations). The canonical momenta p_μ and positions x_μ, $\mu=0,\ldots,d-1$ are not independent of each other, and the canonical Hamilton function vanishes. Following Dirac's treatment of systems with constraints, a total Hamiltonian H_T is introduced which is a linear combination of the two primary constraints with two Lagrangian multipliers α and β. Here, we specialize to the case where α and β do not depend on the original degrees of freedom x_μ and p_μ. The dynamics of the string is thus governed by the gauge freedom only, and fixing the two Lagrangian multipliers corresponds to fixing a gauge. It follows that integrals of motion of H_T are gauge-invariant quantities, i.e., invariant charges which do not depend on the parametrization. In Ref. 1 it was shown that by treating the string as an integrable system, such invariant charges arise as (symmetric polynomials of) the eigenvalues of a monodromy matrix of a system of linear differential equations whose compatibility condition (a "zero curvature condition") is equivalent to the equations of motion of the string.

It is convenient to express the equations of motion as well as the constraints in terms of left and right movers $u^\pm_\mu(\tau,\sigma)=p_\mu(\tau,\sigma)\pm(1/2\pi\alpha')\partial_\sigma x_\mu(\tau,\sigma)$, $\mu=0,\ldots,d-1$, where $1/2\pi\alpha'$ is the string tension. Here, a foliation is chosen such that $\partial_\tau x_\mu(\tau,\sigma)$ is a timelike vector and $\partial_\sigma x_\mu(\tau,\sigma)$ is spacelike, $\sigma\in[0,\omega(\tau))$, where $\omega(\tau)$ is the period of the string's parametrization (as a function of σ at fixed τ). The constraints are then equivalent to demanding that $u^\pm$ be lightlike. With left and right movers, an invariant charge is given by the following explicit expression,

$$\begin{aligned}\mathcal{Z}^\pm_{\mu_1\cdots\mu_N}(\tau,\sigma) &\overset{\text{def}}{=} \mathcal{R}^\pm_{\mu_1\cdots\mu_N}(\tau,\sigma)+\mathcal{R}^\pm_{\mu_2\cdots\mu_N\mu_1}(\tau,\sigma)+\cdots+\mathcal{R}^\pm_{\mu_N\mu_1\cdots\mu_{N-1}}(\tau,\sigma)\\ &=\int_\sigma^{\sigma+\omega(\tau)} d\sigma' u^\pm_{\mu_1}(\tau,\sigma')\mathcal{R}^\pm_{\mu_2\cdots\mu_N}(\tau,\sigma'),\end{aligned}\tag{1}$$

where

$$\mathcal{R}^\pm_{\mu_1\cdots\mu_N}(\tau,\sigma)=\int_\sigma^{\sigma+\omega(\tau)} d\sigma_1\mu^\pm_{\mu_1}(\tau,\sigma_1)\int_\sigma^{\sigma_1} d\sigma_2 u^\pm_{\mu_2}(\tau,\sigma_2)\cdots\int_\sigma^{\sigma_{N-1}} d\sigma_N u^\pm_{\mu_N}(\tau,\sigma_N).\tag{2}$$

From the equations of motion of the monodromy matrices (see Ref. 3), one finds

$$\partial_\sigma\mathcal{R}^\pm_{\mu_1\cdots\mu_N}(\tau,\sigma)=u^\pm_{\mu_1}(\tau,\sigma)\mathcal{R}^\pm_{\mu_2\cdots\mu_N}(\tau,\sigma)-\mathcal{R}^\pm_{\mu_1\cdots\mu_{N-1}}(\tau,\sigma)u^\pm_{\mu_N}(\tau,\sigma),$$

$$\partial_\tau\mathcal{R}^\pm_{\mu_1\cdots\mu_N}(\tau,\sigma)=(\alpha\pm\beta)(\tau,\sigma)\partial_\sigma\mathcal{R}^\pm_{\mu_1\cdots\mu_N}(\tau,\sigma),\tag{3}$$

such that, indeed,

$$\partial_\sigma \mathcal{Z}^{\pm}_{\mu_1\cdots\mu_N}(\tau,\sigma) = \partial_\tau \mathcal{Z}^{\pm}_{\mu_1\cdots\mu_N}(\tau,\sigma) = 0. \tag{4}$$

Another way to express the fact that the functionals $\mathcal{Z}$ are gauge invariant is that they Poisson-commute with the total Hamiltonian, $\{\mathcal{Z}^{\pm}_{\mu_1\cdots\mu_N}, H_T\}_0 = 0$. Here, the Poisson bracket is derived from the canonical Poisson bracket $\{x_\mu, p_\nu\}_0$, such that (for fixed τ, where w.l.o.g. $\omega(\tau) = 2\pi$ and with the periodic δ-distribution $\delta_{2\pi}$),

$$\{u^{\pm}_\mu(\tau,\sigma), u^{\pm}_\nu(\tau,\sigma')\}_0 = \pm\frac{1}{2\pi\alpha'} 2\eta_{\mu\nu}\partial_\sigma\delta_{2\pi}(\sigma-\sigma'), \quad \text{all others } 0. \tag{5}$$

The invariant charges form a Poisson algebra with respect to this bracket.[2,3] From the knowledge of the invariants, together with the generators of boosts, the string can be reconstructed up to translations in the direction of its total energy-momentum vector and, in this sense, the invariant charges are complete.[4] (The ambiguity is due to the fact that the construction of the $\mathcal{Z}$ relies only on $\partial_\sigma x$, not on x itself. If the string splits into different parts or if two strings collide,[7] an absolute position, the splitting or meeting point, enters.)

Let us now turn to an exposition of the structure of the Poisson algebra of invariant charges.[6] An invariant charge $\mathcal{Z}_{\mu_1\cdots\mu_N}$ can be split into a sum of so-called homogeneous invariants $\mathcal{Z}^{(K)}_{\mu_1\cdots\mu_N}$ of order $K=1,\ldots,N$, which arise from powers of the logarithm of the monodromy matrices[2,3] and are themselves invariant under arbitrary reparametrizations,

$$\mathcal{Z}^{\pm}_{\mu_1\cdots\mu_N} = \sum_{K=1}^{N} \mathcal{Z}^{\pm(K)}_{\mu_1\cdots\mu_N}.$$

The only invariant charge of order $K=1$ is the total momentum, $\mathcal{Z}^{-(1)}_\mu = \mathcal{Z}^{+(1)}_\mu = \oint d\sigma_1 u^{\pm}_\mu(\tau,\sigma_1) = \mathcal{P}_\mu$. It is the only invariant charge which is an element of both the algebra built from left movers and the one built from right movers, and it Poisson-commutes with all (homogeneous) invariant charges. In what follows, only massive strings will be considered, where $\mathcal{P}^2 = \mathfrak{m}^2$, and we pass to the rest frame of the string where $\mathcal{P}_\mu = (\mathfrak{m},0,\ldots,0)$, $\mathfrak{m}>0$. By (5), the algebra built from left movers and the one built from right movers Poisson-commute with one another, and their structure constants differ only by signs. It is therefore sufficient to analyze the right mover part (referred to as $\mathfrak{h}$) only. Analogous results then hold also for the left mover part. The algebra $\mathfrak{h}$ is graded under the action of the Poisson bracket $\{\cdot,\cdot\}$ which, compared to the canonical one, is rescaled by a factor $2\pi\alpha'$,

$$\mathfrak{h} = \bigoplus_{\ell=0}^{\infty} \mathfrak{V}^\ell(\mathfrak{h}), \quad \{\mathfrak{V}^{\ell_1},\mathfrak{V}^{\ell_2}\} \subset \mathfrak{V}^{\ell_1+\ell_2}, \quad \mathfrak{V}^{\ell_1}\cdot\mathfrak{V}^{\ell_2} \subset \mathfrak{V}^{\ell_1+\ell_2+1}, \quad \ell = N-K-1, \tag{6}$$

where each $\mathfrak{V}^\ell$ is finite dimensional as a vector space. A parity operator is defined on $\mathfrak{h}$ which assigns positive (negative) parity to an invariant which contains an even (odd) number of spacelike indices. Each $\mathfrak{V}^\ell$ splits up into a direct sum of a space with even ($\mathfrak{V}^\ell_+$) or odd ($\mathfrak{V}^\ell_-$) parity (one of which may be trivial). The vector space $\mathfrak{V}^0$ is $(d-1)$-dimensional and forms a subalgebra isomorphic to the Lie algebra $\mathrm{so}(d-1)$, the Lie algebra of the stabilizer group of $\mathcal{P}_\mu$. All vector spaces $\mathfrak{V}^\ell_\pm$ are invariant under the Poisson action of $\mathfrak{V}^0$, and, therefore, each of them carries a linear representation of $\mathrm{so}(d-1)$ and can be decomposed into a direct sum of isotypical components (corresponding to different spins and parities).

By a well-scrutinized conjecture, which has been proved for $d=3$ up to degree $\ell=7$, any invariant charge can be expressed as a polynomial in certain standard invariants, and the number of standard invariants in each level $\mathfrak{V}^\ell$ is known. It was shown, however, in Refs. 2 and 3 that some invariant charges, the so-called exceptional elements, cannot be expressed in terms of *Poisson brackets* of standard invariants of lower degrees. Moreover, a major complication in the investigation of $\mathfrak{h}$ is that taking a Poisson bracket of two standard invariants, one in general obtains not only a standard invariant, but, additionally, a linear combination of *products* of other standard invariants, whence the standard invariants do not form a Lie algebra. In fact, it was

shown that there is no algebraic basis which would render $\mathfrak{h}$ as the enveloping algebra of a *Lie* algebra.[2,3] Instead, it is necessary to generate $\mathfrak{h}$ by (multiple) Poisson brackets *as well as* by products of a set of generating invariant charges. The generating invariant charges do not freely generate $\mathfrak{h}$, and relations (other than those given by antisymmetry and the Jacobi identity) between (multiple) Poisson brackets and products persist. Their number at given degree ℓ is equal to $m_\ell - n_\ell$, where n_ℓ is the number of standard invariants in $\mathfrak{V}^\ell$ and m_ℓ is the number of Hall-basis elements in $\mathfrak{V}^\ell$ which can be built from standard invariants of lower degree than ℓ, see Ref. 6. (A Hall-basis contains only such Poisson brackets as cannot be transformed into each other by antisymmetry or by the Jacobi identity.)

In what follows, $d=4$ spacetime dimensions are considered and some of the structural insight gained in Ref. 6 is reproduced. The set of generating invariants in $d=4$ is given by $3+14$ invariants from $\mathfrak{V}^0$ and $\mathfrak{V}^1$, respectively, which generate a subalgebra $\mathfrak{U}$ of $\mathfrak{h}$, together with the (modified) exceptional elements $B_0^{(\ell)}$, $\ell=1,3,5,\ldots$, which form an Abelian subalgebra of $\mathfrak{h}$, and act semidirectly on $\mathfrak{U}$. In the present investigation only $\ell\leqslant 2$ will be considered, where these claims were proved rigorously. Employing an angular momentum (or rather a spin) basis $\{e_0, e_\pm=(1/\sqrt{2})(e_1\pm ie_2), e_3\}$ in $\mathbb{R}^4$, we obtain the following generating invariants for the vector space basis of $\mathfrak{V}^0$:

$$J_{1,1}=\frac{-1}{4\mathfrak{m}}(i\mathcal{Z}^{(2)}_{0+3}-i\mathcal{Z}^{(2)}_{03+}),\quad J_{1,0}=\frac{-1}{4\mathfrak{m}}(i\mathcal{Z}^{(2)}_{0+-}-i\mathcal{Z}^{(2)}_{0-+}),\quad J_{1,-1}=\frac{-1}{4\mathfrak{m}}(i\mathcal{Z}^{(2)}_{0-3}-i\mathcal{Z}^{(2)}_{03-}).$$

As a vector space, $\mathfrak{V}^1$ is spanned by

$$(J_1^2)_0,\ B_0^{(1)},\ S_1 \text{ and } (J_1^2)_2,\ T_2,\ S_2,$$

which are multiplets of so(3) with spin $J=0$, 1, and 2, respectively, with the 14 generating invariants given by

$$B_0^{(1)}=\mathcal{Z}^{(2)}_{0-0+}+\frac{1}{2}\mathcal{Z}^{(2)}_{0303},$$

$$T_2=\{T_{2,m}|m=-2,\ldots,2\} \text{ with } T_{2,-2}=\frac{1}{2}\mathcal{Z}^{(2)}_{00--},$$

$$S_2=\{S_{2,m}|m=-2,\ldots,2\} \text{ with } S_{2,-2}=i\mathcal{Z}^{(2)}_{03--}, \tag{7}$$

$$S_1=\{S_{1,m}|m=-1,\ldots,1\} \text{ with } S_{1,-1}=\mathcal{Z}^{(2)}_{0+--}-\mathcal{Z}^{(2)}_{0-33},$$

$$\text{with } i\{J_{1,\pm1},X_{j,m}\}=\pm\frac{1}{\sqrt{2}}\sqrt{(j\pm m+1)(j\mp m)}X_{j,m\pm1},$$

and where

$$(X_{j_1}\cdot Y_{j_2})_{j,m}=\underbrace{\sum_{m_1=-j_1}^{j_1}\sum_{m_2=-j_2}^{j_2}}_{m_1+m_2=m}\langle j,m|j_1,m_1;j_2,m_2\rangle X_{j_1,m_1}\cdot Y_{j_2,m_2}.$$

Here, the Clebsch–Gordan coefficients $\langle j,m|j_1,m_1;j_2,m_2\rangle$ are defined with conventions of Condon and Shortley. The action of $J_{1,1}$ respects the parity, the tensor rank N, as well as the order K, and, hence, the basis elements with higher magnetic numbers than $m=-J$ are indeed again invariants of the same parity, tensor rank $N=4$ and order $K=2$, whose explicit form can be calculated

using (5) (or the closed formulas for Poisson brackets of invariant charges given in Refs. 2 and 3). Complex conjugation yields an involution on the algebra, and the phases of the generating invariants are chosen such that for $m=0$ they are real, $X^*_{j,m}=(-1)^m X_{j,-m}$.

The vector space basis of $\mathfrak{V}^2$ is again given by products and Poisson brackets of the above generating invariant charges. By (6), such Poisson brackets can only be single brackets built from elements of $\mathfrak{V}^1$. The number of standard invariants in $\mathfrak{V}^1$ being 14, $\frac{1}{2}\cdot 14\cdot 13=91$ such brackets can be formed, if the antisymmetry of the bracket is taken into account (no dependences from the Jacobi identity arise, since no multiple brackets appear). The number of standard invariants in $\mathfrak{V}^2$ being 40, 51 algebraic relations between these brackets persist, which by the above remarks will also involve products of generators. They were given in Ref. 6 and are reproduced in Appendix A. The relations, which are real, are organized in nine multiplets, and it follows that only nine relations are truly independent, while the others can be produced by the action of $\mathfrak{V}^0$.

III. ALGEBRAIC QUANTIZATION BY CORRESPONDENCE

The basic idea of the algebraic approach is that the correspondence principle is physically meaningful only for *observable* (i.e., gauge-invariant) quantities. Since it provides an alternative to the canonical quantization scheme of the Nambu–Goto string, the general idea is reproduced here, cf. Ref. 6. The classical Poisson algebra with commutative multiplication is to be deformed into an associative algebra, where Poisson brackets are replaced by commutators and certain quantum corrections are admitted, which are restricted by demanding structural similarity of the classical and the quantum algebra (see below). In particular, it is required that the number of independent relations should not be changed. In principle, this quantization scheme is applicable in arbitrary dimensions, but the calculations used in this paper have been performed in $1+3$ dimensions. In a first step, it is assumed that (dimensionless) quantum generators $\hat{\mathfrak{Y}}_1$, $\hat{\mathfrak{T}}_2$, $\hat{\mathfrak{S}}_2$, $\hat{\mathfrak{S}}_1$, $\hat{\mathfrak{B}}_0{}^{(\ell)}$, $\ell=1,3,\ldots$, exist which correspond to the classical ones (when scaled by factors $(\hbar/2\pi\alpha')^{\ell+1}$). The quantum version of a classical relation at order ℓ is then obtained as follows:

(i) Replace each rescaled Poisson bracket by a commutator $[\cdot,\cdot]$ (multiplied with a factor $2\pi\alpha'/i\hbar$) without changing the order of the bracket's entries. The action of $\mathfrak{V}^0$ on higher levels $\mathfrak{V}^\ell$ remaining the same, this replacement can be done for the full multiplet. Replace the multiplication by anticommutators $\{\cdot,\cdot\}$ (multiplied with a factor $\frac{1}{2}$).

(ii) By construction, the resulting relation consists of (anti-)commutators of the dimensionless generators, multiplied by a global factor $(\hbar/2\pi\alpha')^{(\ell+1)}$. Now quantum corrections are admitted which have the same spin and parity as the relation under consideration but are of lower degree. They enter the relation multiplied by an appropriate positive power of $\hbar$ as well as with parameters which respect the reality property of the relation and are restricted by the structural similarity conditions (see below).

As an example, we consider the classical relation with $J^P=1^-$ involving $B_0^{(1)}$,

$$\{B_0^{(1)},S_1\}_1=-i6\sqrt{\frac{2}{5}}\{T_2,S_2\}_1+2\sqrt{\frac{3}{5}}\{T_2,S_1\}_1-24\sqrt{\frac{3}{5}}(J_1\cdot S_2)_1+i12\sqrt{2}(J_1\cdot S_1)_1,$$

where Poisson brackets and products are multiplets of spin $J=1$ as given in formulas (A1) and (A2) in Appendix A. This relation is replaced by

$$[\hat{\mathfrak{B}}_0^{(1)},\hat{\mathfrak{S}}_1]_1=-i6\sqrt{\frac{2}{5}}[\hat{\mathfrak{T}}_2,\hat{\mathfrak{S}}_2]_1+2\sqrt{\frac{3}{5}}[\hat{\mathfrak{T}}_2,\hat{\mathfrak{S}}_1]_1-i12\sqrt{\frac{3}{5}}\{\hat{\mathfrak{Y}}_1,\hat{\mathfrak{S}}_2\}_1-6\sqrt{2}\{\hat{\mathfrak{Y}}_1,\hat{\mathfrak{S}}_1\}_1+id\hat{\mathfrak{S}}_1$$

with a real (in fact, rational) parameter d and multiplets of (anti-)commutators with spin $J=1$. Note that in quantum relations, $\{\cdot,\cdot\}$ denotes the anticommutator, not the Poisson bracket. Let us now consider the requirement of structural similarity of the classical and the quantized algebra which puts restrictions on these parameters. In order to compare two relations, they have to be brought into some standard form, and the multiplication now being noncommutative, it is clear

that in doing so, one may pick up correction terms of lower order, for instance (see Ref. 6),

$$\{\{A_{j_1},B_{j_2}\}_j,C_{j_3}\}_J=\sum_k(-)^{k+j_2+j_3}\sqrt{(2j+1)(2k+1)}\cdot\left((-)^{j+1}\begin{Bmatrix}j_2 & j_1 & j\\ j_3 & J & k\end{Bmatrix}[[\mathbf{A_{j_1}},\mathbf{C_{j_3}}]_\mathbf{k},\mathbf{B_{j_2}}]_\mathbf{J}\right.$$
$$\left.+\begin{Bmatrix}j_1 & j_2 & j\\ j_3 & J & k\end{Bmatrix}\{\{B_{j_2},C_{j_3}\}_k,A_{j_1}\}_J\right)$$

with $6j$-symbols $\{:::\}$ (the correction term is printed in boldface letters). By this mechanism, new dependences between these lower order correction terms may arise, which do not possess a classical analog. It has been shown explicitly up to the fifth degree[6,8] that these dependences can be trivially fulfilled or can be reduced to old dependences by fixing the parameters in the quantum relations in a suitable way. In $\ell=2$, all but one (which appears in the relation with $J^P=1^+$) have been shown to be trivial. The elements of the quantized algebra are again referred to as observables.

In Refs. 9 and 10 it was shown that a quantization which is consistent with the relations found so far is possible to all orders ℓ, provided that certain hypotheses concerning the classical algebra (as sketched in the preceding section) are true. There, an *a posteriori* approach was pursued, namely to use an explicit infinite dimensional embedding Lie algebra whose elements are not necessarily invariant under reparametrizations, but which is distinguished by the fact that, restricted to its reparametrization invariant elements, it provides a concrete realization of the quantum algebra of observables found in Ref. 6.

IV. CANONICAL QUANTIZATION

The canonical quantization of the Nambu–Goto string is by far more popular than the approach described above. Its virtue is that it is much simpler. On the other hand, it has some undesirable features, for instance, to name but two, the appearance of a critical dimension and the impossibility to fully implement the constraints. While the general theory of strings has by now evolved into an elaborate theory in its own right and has moved away from the original Nambu–Goto action, it is still worthwhile to consider the fundamental question whether, in the presence of the alternative approach of algebraic quantization, the canonical quantization scheme is apt to capture the reparametrization invariance of the Nambu–Goto string. It is the aim of the following sections to show that the Fourier modes of an arbitrary parametrization do not provide a suitable starting point for the quantization of the algebra of invariant charges.

A. Classical Fourier modes

In order to fix the notation, the well-known decomposition of left and right movers $u_\mu^\pm$, $\mu=0,\ldots,d-1$, into Fourier modes is reproduced here,

$$u_\mu^-(\tau,\sigma)=p_\mu(\tau,\sigma)-\frac{1}{2\pi\alpha'}\partial_\sigma x_\mu(\tau,\sigma)=\frac{\mathcal{P}_\mu}{2\pi}+\frac{\mathfrak{m}}{2\pi}\sum_{n>0}(\alpha_\mu^n(\tau)e^{in\sigma}+\alpha_\mu^{-n}(\tau)e^{-in\sigma})$$
$$u_\mu^+(\tau,\sigma)=p_\mu(\tau,\sigma)+\frac{1}{2\pi\alpha'}\partial_\sigma x_\mu(\tau,\sigma)=\frac{\mathcal{P}_\mu}{2\pi}+\frac{\mathfrak{m}}{2\pi}\sum_{n>0}(\beta_\mu^n(\tau)e^{-in\sigma}+\beta_\mu^{-n}(\tau)e^{in\sigma}), \tag{8}$$

with $(\alpha_\mu^{-n})^*=\alpha_\mu^n$ and $(\beta_\mu^{-n})^*=\beta_\mu^n$. The zero modes α_μ^0 and β_μ^0 are equal to $\mathcal{P}_\mu/\mathfrak{m}$, since the positions' zero mode is independent of σ and hence vanishes in $\partial_\sigma x$. Note that in the conformal gauge, where $2\pi\alpha' p(\tau,\sigma)=\partial_\tau x(\tau,\sigma)$, the components' dependence on τ is given as follows:

$$\alpha_\mu^{\pm n}(\tau)=\alpha_\mu^{\pm n}e^{\mp in\tau}\text{ and }\beta_\mu^{\pm n}(\tau)=\beta_\mu^{\pm n}e^{\mp in\tau}. \tag{9}$$

In what follows, the dependence on τ is suppressed, and we write $\alpha_\mu^{\pm n}$ for $\alpha_\mu^{\pm n}(\tau)$. With conventions as above, we find the following (un-rescaled) Poisson brackets,

$$\{\alpha_\mu^m, \alpha_\nu^{-n}\}_0 = -\frac{4\pi}{2\pi\alpha'\mathfrak{m}^2} in\,\eta_{\mu\nu}\delta_{m,n} \quad \text{and} \quad \{\beta_\mu^m, \beta_\nu^{-n}\}_0 = -\frac{4\pi}{2\pi\alpha'\mathfrak{m}^2} in\,\eta_{\mu\nu}\delta_{m,n}, \tag{10}$$

all others 0. It is important to bear in mind that, apart from the zero mode $\mathcal{P}_\mu/\mathfrak{m}$, the Fourier coefficients depend on the chosen parametrization. Nonetheless, it is of course possible that certain polynomials in the coefficients are independent of the parametrization. Prominent examples are the generators of the Poincaré group. Moreover, as was analyzed in Ref. 4 and further elaborated in Ref. 11, the *classical* invariant charges $\mathcal{Z}$ can be expressed as polynomials of Fourier modes: Inserting the decomposition (8) in (1), we find (for the left mover part of the algebra, and likewise for the right mover part)

$$\begin{aligned}\mathcal{Z}_{\mu_1\cdots\mu_N} &= \frac{\mathfrak{m}^N}{(2\pi)^N}\sum_{n_1=-\infty}^{\infty}\cdots\sum_{n_N=-\infty}^{\infty}\alpha_{\mu_1}^{n_1}\cdots\alpha_{\mu_N}^{n_N}\oint d\sigma_1 e^{in_1\sigma_1}\int_{\sigma_1}^{\sigma_1+2\pi} d\sigma_2 e^{in_2\sigma_2}\cdots\int_{\sigma_1}^{\sigma_{N-1}} d\sigma_N e^{in_N\sigma_N}\\ &= \frac{\mathfrak{m}^N}{(2\pi)^N}\sum_{n_1=-\infty}^{\infty}\cdots\sum_{n_N=-\infty}^{\infty}\alpha_{\mu_1}^{n_1}\cdots\alpha_{\mu_N}^{n_N}\sum_{K=1}^{N}\frac{(2\pi)^K}{(K-1)!}\left(\frac{1}{i}\right)^{N-K} C^{[K,N]}_{n_1\cdots n_N},\end{aligned}$$

where, by (4), the starting point of the last integration is irrelevant, and where, without loss of generality, $\omega(\tau)=2\pi$. Following Ref. 11, the iterated integrals are replaced by a sum over combinatorial factors $C^{[K,N]}_{n_1\cdots n_N}$ with the following properties:

(i) cyclic symmetry in $n_1,\ldots,n_N$

(ii) recursion relation:

$$C^{[K,N]}_{n_1\cdots n_N} = \frac{1}{n_N}\left(C^{[K,N-1]}_{n_1\cdots n_{N-2}n_{N-1}+n_N} - C^{[K,N-1]}_{n_1+n_N n_2\cdots n_{N-1}}\right) \text{ for } n_N\neq 0,$$

(iii)

$$C^{[N,N]}_{n_1\cdots n_N} = \delta_{n_1,0}\cdots\delta_{n_N,0} \text{ and } C^{[K,N]}_{0\cdots 0} = \delta_{K,N}.$$

Due to the recursion relation, the combinatorial coefficients are in general linear combinations of products of Kronecker symbols (with rational coefficients). It follows from the definitions that the Fourier decomposition of homogeneous invariants is given as follows,

$$\mathcal{Z}^{(K)}_{\mu_1\cdots\mu_N} = \frac{\mathfrak{m}^N}{(2\pi)^{N-K}}\frac{1}{(K-1)!}\left(\frac{1}{i}\right)^{N-K}\sum_{n_1=-\infty}^{\infty}\cdots\sum_{n_N=-\infty}^{\infty}\alpha_{\mu_1}^{n_1}\cdots\alpha_{\mu_N}^{n_N}C^{[K,N]}_{n_1\cdots n_N}. \tag{11}$$

It is important to note that the degree $\ell=N-K-1$ of the homogeneous invariant can be determined only by the inverse power of the factor 2π (minus 1), while its tensor rank N is encoded in the power of the mass $\mathfrak{m}$. The rest system is implemented by requesting that $\alpha_\mu^{n=0}=\delta_{\mu,0}$.

The reader is assumed to be familiar with the canonical approach and hence it is only mentioned that the decomposition of left and right movers into Fourier modes leads to the following decomposition of the constraints:

$$0\approx\pi\alpha'(u^-)^2 =: \sum_{n=-\infty}^{\infty}\overline{L^n}e^{in\sigma}, \quad 0\approx\pi\alpha'(u^+)^2 =: \sum_{n=-\infty}^{\infty}L^{-n}e^{in\sigma},$$

where L^n and $\overline{L^n}$ are generators of (two copies of) the Witt algebra.

B. Normal ordering of the invariant charges

In the canonical quantization procedure, the correspondence principle is applied to the (nonobservable) Fourier modes. They are replaced by operators on Fock space, with positive modes corresponding to annihilation operators, and negative modes corresponding to creation operators (such that in the conformal gauge, $e^{-in\tau}$, $n>0$, belongs to an annihilation operator). Zero modes correspond to multiples of the identity and normal ordering is used to define monomials of operators. The Poisson brackets (10) are replaced by commutators $(1/i\hbar)[\cdot,\cdot]$, such that

$$[\alpha_\mu^m,\alpha_\nu^{-n}]=\hbar\frac{4\pi}{2\pi\alpha'\mathfrak{m}^2}n\,\eta_{\mu\nu}\delta_{m,n}\quad\text{and}\quad[\beta_\mu^m,\beta_\nu^{-n}]=\hbar\frac{4\pi}{2\pi\alpha'\mathfrak{m}^2}n\,\eta_{\mu\nu}\delta_{m,n},\tag{12}$$

all others 0. The consequences of this quantization procedure for the Witt algebra are well known. It yields a *nontrivial* central extension of it, the so-called Virasoro algebra, and, due to the appearance of the central charge, it is not possible to define the physical subspace of the Fock space as the kernel of all generators $:L^n:$ and $:\overline{L^n}:$, but only of those with $n\geqslant -1$ (alternatively of those with $n\leqslant 1$). For later use, the explicit form of a generator with $n>0$ is reproduced here,

$$:\overline{L^n}:=\frac{\alpha'}{2}\mathfrak{m}\mathcal{P}\cdot\alpha^n+\frac{\alpha'}{4}\mathfrak{m}^2\sum_{m=1}^{n-1}\alpha^m\cdot\alpha^{n-m}+\frac{\alpha'}{2}\mathfrak{m}^2\sum_{m=1}^{\infty}\alpha^{-m}\cdot\alpha^{n+m},\tag{13}$$

the dot $\cdot$ denoting Lorentz products. Application of the canonical quantization procedure to a homogeneous invariant charge $\mathcal{Z}^{(K)}_{\mu_1\cdots\mu_N}$ as in (11) renders a normally ordered counterpart

$$:\mathcal{Z}^{(K)}_{\mu_1\cdots\mu_N}:=\frac{\mathfrak{m}^N}{(2\pi)^{N-K}}\frac{(-i)^{N-K}}{(K-1)!}\sum_{n_1=-\infty}^{\infty}\cdots\sum_{n_N=-\infty}^{\infty}:\alpha_{\mu_1}^{n_1}\cdots\alpha_{\mu_N}^{n_N}C^{[K,N]}_{n_1\cdots n_N}:.\tag{14}$$

The combinatorial factors are to be calculated in such a manner that after evaluation of the Kronecker symbols no indices with relative signs (for instance, n_1-n_2 with n_1, $n_2>0$) arise in order to simplify the distinction between positive, negative and zero modes, and lengthy calculations then yield homogeneous invariant charges expressed in terms of annihilation and creation operators (for those needed in what follows, see Appendix B).

In this section, the dimension of the underlying space–time has so far been arbitrary. For an attempt to quantize the algebra of observables canonically, let us again specialize to $1+3$ dimensions and proceed as follows: in a first step, the normally ordered quantum analogs of the classical generators J_1, T_2, S_2, S_1 and $B_0^{(\ell)}$ are calculated by application of formula (14). Next, we consider the zeroth level $\mathfrak{V}^0$ as well as the action of $\mathfrak{V}^0$ on the other levels $\mathfrak{V}^\ell$, where the rescaled Poisson brackets are replaced by commutators multiplied by $2\pi\alpha'/i\hbar$. By Appendix B, we find for the generators of $\mathfrak{V}^0$:

$$:J_{1,-1}:=-\frac{\mathfrak{m}^2}{4\pi}\sum_{n=1}^{\infty}\frac{1}{n}(\alpha_-^{-n}\alpha_3^n-\alpha_3^{-n}\alpha_-^n),\quad:J_{1,0}:=-\frac{\mathfrak{m}^2}{4\pi}\sum_{n=1}^{\infty}\frac{1}{n}(\alpha_+^{-n}\alpha_-^n-\alpha_-^{-n}\alpha_+^n),$$

$$:J_{1,+1}:=-\frac{\mathfrak{m}^2}{4\pi}\sum_{n=1}^{\infty}\frac{1}{n}(\alpha_+^{-n}\alpha_3^n-\alpha_3^{-n}\alpha_+^n).$$

Obviously, commutators of the form

$$[\alpha_\mu^{-n}\alpha_\nu^n,\ \text{:polynomial in }\alpha\text{'s:}],\quad n>0,$$

can only yield normally ordered terms, and we may conclude that the action of $J_{1,m}$ remains unchanged. Therefore, $\mathfrak{V}^0$ as well as the multiplet structure of $\mathfrak{V}^\ell$ is not affected by the quantization prescription. Regarding the quantum relations in higher degrees ℓ, one now proceeds as follows. Write all terms of the classical relation (in terms of the appropriate multiplets) on the left

hand side of an equation. Replace all generators by their normally ordered counterparts, and the rescaled Poisson brackets and products as described in Sec. III. The commutators are then evaluated by application of the derivation rule. Finally, all resulting terms are brought into normal order. From the classical relation it follows that in leading order the result is 0, but from the process of reordering, quantum corrections may arise.

Explicitly, the relations which form the starting point of the calculations are the following:

$$J^P=4^-: \quad \frac{2\pi\alpha'}{\hbar}[:T_2:,:S_2:]_4 = 0 + \text{anomalies},$$

$$J^P=3^+\ (i): \quad \frac{2\pi\alpha'}{\hbar}[:T_2:,:T_2:]_3 + i\frac{2\pi\alpha'}{\hbar}[:S_2:,:S_1:]_3 + 16(:J_1:^3)_3 = 0 + \text{anomalies},$$

$$(ii): \quad \frac{2\pi\alpha'}{\hbar}[:S_2:,:S_2:]_3 - i2\frac{2\pi\alpha'}{\hbar}[:S_2:,:S_1:]_3 - 4\{:J_1:,:T_2:\}_3 - 48(:J_1:^3)_3 = 0 + \text{anomalies},$$

$$J^P=3^-: \quad \frac{2\pi\alpha'}{\hbar}[:T_2:,:S_2:]_3 - i\frac{2\pi\alpha'}{\hbar}[:T_2:,:S_1:]_3 + 4\{:J_1:,:S_2:\}_3 = 0 + \text{anomalies},$$

$$J^P=2^-: \quad \frac{2\pi\alpha'}{\hbar}[:T_2:,:S_2:]_2 + \frac{i}{3}\sqrt{\frac{7}{2}}\frac{2\pi\alpha'}{\hbar}[:T_2:,:S_1:]_2 - \frac{2}{3}\sqrt{14}\{:J_1:,:S_2:\}_2 = 0 + \text{anomalies},$$

$$J^P=1^+: \quad \frac{2\pi\alpha'}{\hbar}[:S_2:,:S_2:]_1 + i\sqrt{\frac{2}{3}}\frac{2\pi\alpha'}{\hbar}[:S_2:,:S_1:]_1 + \frac{1}{6}\sqrt{5}\frac{2\pi\alpha'}{\hbar}[:S_1:,:S_1:]_1 - 8\sqrt{\frac{2}{3}}\{:J_1:,:T_2:\}_1$$
$$- 16\sqrt{\frac{2}{15}}\{:J_1:,(:J_1:^2)_0\}_1 + \frac{\hbar^2}{(2\pi\alpha')^2}\, f\,\sqrt{10}:J_1: = 0 + \text{anomalies},$$

and for the action of $:B_0^{(1)}:$,

$$J^P=2^+: \quad \frac{2\pi\alpha'}{\hbar}[:B_0^{(1)}:,:T_2:]_2 - i\sqrt{6}\frac{2\pi\alpha'}{\hbar}[:S_2:,:S_1:]_2 = 0 + \text{anomalies},$$

$$J^P=1^-: \quad \frac{2\pi\alpha'}{\hbar}[:B_0^{(1)}:,:S_1:]_1 + i6\sqrt{\frac{2}{5}}\frac{2\pi\alpha'}{\hbar}[:T_2:,:S_2:]_1 - 2\sqrt{\frac{3}{5}}\frac{2\pi\alpha'}{\hbar}[:T_2:,:S_1:]_1$$
$$+ 12i\sqrt{\frac{3}{5}}\{:J_1:,:S_2:\}_1 + 6\sqrt{2}\{:J_1:,:S_1:\}_1 = 0 + \text{anomalies},$$

$$J^P=2^-: \quad \frac{2\pi\alpha'}{\hbar}[:B_0^{(1)}:,:S_2:]_2 + i2\sqrt{\frac{2}{3}}\frac{2\pi\alpha'}{\hbar}[:T_2:,:S_1:]_2 - i2\sqrt{\frac{2}{3}}\{:J_1:,:S_2:\}_2 - i6\{:J_1:,:S_1:\}_2$$
$$= 0 + \text{anomalies}.$$

Note that (as in the case of algebraic quantization) there is no need to use an anticommutator if the coupling to spin J in a product $(:J_1:^n)_J$ is unique.

The *observable* quantum correction $+(\hbar^2/(2\pi\alpha')^2)f\sqrt{10}:J_1:$, found in Ref. 6 for the relation with $J^P=1^+$, was added to the left hand side of the equation (in normally ordered form) in order to simplify the comparison with the algebraically quantized relations: if they were reproduced in the canonical approach, all right hand sides would be identically 0 (with the parameter f fixed). However, as we shall see below, we will find anomalies which destroy the algebraic structure of the algebra $\mathfrak{h}$. What is worse, the anomalies neither possess reparametrization-invariant classical counterparts, nor can they be written in terms of Virasoro generators.

C. Anomalies for $\ell=2$

Let us start with some general considerations as to which anomalies are to be expected in the relations in $\mathfrak{V}^2$. First we note that commutators $[:\mathcal{Z}^{(2)}_{\mu_1\ldots\mu_4}:,:\mathcal{Z}^{(2)}_{\nu_1\ldots\nu_4}:]$ yield at most $2+2-1$

annihilation operators and as many creation operators. Likewise, we find at most three annihilation and three creation operators in products $\mathfrak{m}^{-1}{:}\mathcal{Z}^{(2)}_{0\mu_1\mu_2}{::}\mathcal{Z}^{(2)}_{\nu_1\ldots\nu_4}{:}$ and $\mathfrak{m}^{-3}{:}\mathcal{Z}^{(2)}_{0\mu_1\mu_2}{::}\mathcal{Z}^{(2)}_{0\nu_1\nu_2}{::}\mathcal{Z}^{(2)}_{0\rho_1\rho_2}{:}$, respectively (see Appendix B). Now, reordering terms with at most three annihilation and three creation operators, we derive a quantum correction consisting of at most two annihilation and two creation operators, and reordering such terms finally yields quantum corrections consisting of at most one annihilation and one creation operator. The expressions possess the following physical units:

Order	Units ($\ell=2$)
leading (=0)	$\dfrac{2\pi\alpha'}{\hbar}\dfrac{\mathfrak{m}^8}{(2\pi)^4}\dfrac{\hbar 2\pi}{2\pi\alpha'\mathfrak{m}^2}=\dfrac{\mathfrak{m}^6}{(2\pi)^3}$
first reordering	$\dfrac{\mathfrak{m}^6}{(2\pi)^3}\dfrac{\hbar 2\pi}{2\pi\alpha'\mathfrak{m}^2}=\dfrac{\mathfrak{m}^4}{(2\pi)^2}\dfrac{\hbar}{2\pi\alpha'}$
second reordering	$\dfrac{\mathfrak{m}^4}{(2\pi)^2}\dfrac{\hbar}{2\pi\alpha'}\dfrac{\hbar 2\pi}{2\pi\alpha'\mathfrak{m}^2}=\dfrac{\mathfrak{m}^2}{2\pi}\dfrac{\hbar^2}{(2\pi\alpha')^2}$

which makes sense as $\mathfrak{m}^4/(2\pi)^2$ is the unit of an element of $\mathfrak{V}^1$, and $\mathfrak{m}^2/(2\pi)$ is that of an element of $\mathfrak{V}^0$. By the canoncial commutation relations (12), either two spacelike or two timelike indices are contracted, whence the parity is unchanged by reorderings. The anomalies will again arise as multiplets of so(3), such that it suffices to calculate the anomalies for fixed magnetic quantum number $m=-J$. In fact, the possible anomalies for each relation can be predicted. For example, the only possible quantum correction with $m=-4$ would be $\alpha_-^{(\cdot)}\alpha_-^{(\cdot)}\alpha_-^{(\cdot)}\alpha_-^{(\cdot)}$, which, however, has positive parity P and hence cannot appear in the relation with $J^P=4^-$. While many of the possible anomalies arise somewhere in the course of the calculation, most of them cancel and only some remain in the end.

The calculations are performed for fixed but arbitrary summation indices and, at intermediate steps, involve several thousand terms. (The convergence problem of the infinite series of operators is ignored, since the sole purpose of this investigation is the comparison with the ordinary canonical approach, where these questions likewise do not play a role.) It is therefore necessary to use computer algebra, and the program package MATHEMATICA was employed (for an explanation of the devised routines, see Ref. 5). In the course of the calculation, some simplifications have to be done by hand, such as

$$-\sum_{n_1,n_2>0}\frac{3}{n_1n_2}\alpha_\mu^{-n_1-n_2}\alpha_\nu^{n_1}\alpha_\nu^{n_2}+\sum_{n_1,n_2>0}\frac{4}{n_1(n_1+n_2)}\alpha_\mu^{-n_1-n_2}\alpha_\nu^{n_1}\alpha_\nu^{n_2}+\sum_{n_1,n_2>0}\frac{2}{n_2(n_1+n_2)}\alpha_\mu^{-n_1-n_2}\alpha_\nu^{n_1}\alpha_\nu^{n_2}$$
$$=\sum_{n_1,n_2>0}\frac{-n_1+n_2}{n_1n_2(n_1+n_2)}\alpha_\mu^{-n_1-n_2}\alpha_\nu^{n_1}\alpha_\nu^{n_2}=0,$$

or

$$\sum_{n_1,n_2>0}\frac{1}{n_1n_2}\alpha_\mu^{-n_1-n_2}\alpha_\nu^{n_1}\alpha_\nu^{n_2}=\sum_{n_1,n_2>0}\frac{2}{n_1(n_1+n_2)}\alpha_\mu^{-n_1-n_2}\alpha_\nu^{n_1}\alpha_\nu^{n_2}.$$

In order to check the manipulations, it was calculated that indeed, the leading order terms in the relations yield 0. The results of the calculation are

J^P	Anomalies for $m=-J$
4^-	0
3^+ (i)	$\frac{\hbar}{2\pi\alpha'}\frac{\mathfrak{m}^4}{(2\pi)^2}\sum_{n,m>0}\frac{-8}{nm}(\alpha_-^{-n}\alpha_-^{-m}\alpha_-^m\alpha_3^n-\alpha_3^{-n}\alpha_-^{-m}\alpha_-^m\alpha_-^n)$
(ii)	$\frac{\hbar}{2\pi\alpha'}\frac{\mathfrak{m}^4}{(2\pi)^2}\sum_{n,m>0}\frac{20}{nm}(\alpha_-^{-n}\alpha_-^{-m}\alpha_-^m\alpha_3^n-\alpha_3^{-n}\alpha_-^{-m}\alpha_-^m\alpha_-^n)$
3^-	$\frac{\hbar}{2\pi\alpha'}\frac{\mathfrak{m}^4}{(2\pi)^2}\sum_{n,m>0}\frac{4i}{nm}(2\alpha_0^{-n}\alpha_-^{-m}\alpha_-^m\alpha_-^n-2\alpha_-^{-n}\alpha_-^{-m}\alpha_-^m\alpha_0^n+\alpha_-^{-n}\alpha_-^{-m}\alpha_-^{n+m}-\alpha_-^{-n-m}\alpha_-^n\alpha_-^m)$
2^-	0
1^+	$\frac{\hbar}{2\pi\alpha'}\frac{\mathfrak{m}^4}{(2\pi)^2}\frac{1}{\sqrt{10}}\frac{80}{3}\left(\sum_{n>0}\frac{1}{n^2}(\alpha_3^{-n}\alpha_-^n-\alpha_-^{-n}\alpha_3^n)+\sum_{n,m>0}\frac{1}{(n+m)^2}(\alpha_3^{-n-m}\alpha_-^{n+m}-\alpha_-^{-n-m}\alpha_3^{n+m})\right)$

and similar results were found for the relations involving $B_0^{(1)}$ (see Appendix C). In addition to the anomalies given above, the following term appeared in the relation with $J^P=1^+$ for $m=-1$,

$$\frac{\hbar^2}{(2\pi\alpha')^2}\frac{\mathfrak{m}^2}{2\pi}\frac{1}{\sqrt{10}}\frac{64}{3}\sum_{n>0}\frac{1}{n}(\alpha_3^{-n}\alpha_-^n-\alpha_-^{-n}\alpha_3^n),$$

whence we deduce that $f=-128/30$. Note that this is not consistent with the result found later by the method presented in Ref. 10.

The anomalies in the relation with $J^P=1^+$ can be rewritten in the following way. Since there are $n-1$ possibilities to write $\mathbb{N}\ni n>0$ as a sum of two natural numbers $n_i>0$, the following identity holds:

$$\sum_{n_1,n_2>0}\frac{1}{(n_1+n_2)^2}X_{(n_1+n_2)}=\sum_{n>0}\frac{n-1}{n^2}X_n,$$

and the anomalies for $J^P=1^+$ can be simplified to yield

$$\begin{aligned}&\frac{\hbar}{2\pi\alpha'}\frac{\mathfrak{m}^4}{(2\pi)^2}\left(\sum_{n>0}\frac{1}{n^2}(\alpha_3^{-n}\alpha_-^n-\alpha_-^{-n}\alpha_3^n)+\sum_{n>0}\left(\frac{1}{n}-\frac{1}{n^2}\right)(\alpha_3^{-n}\alpha_-^n-\alpha_-^{-n}\alpha_3^n)\right)\\&\quad=\frac{\hbar}{2\pi\alpha'}\frac{\mathfrak{m}^4}{(2\pi)^2}\sum_{n>0}\frac{1}{n}(\alpha_3^{-n}\alpha_-^n-\alpha_-^{-n}\alpha_3^n)=\frac{\hbar}{2\pi\alpha'}\frac{\mathfrak{m}^4}{\pi}:J_{1,-1}:.\end{aligned}\tag{15}$$

At first sight, this is surprising, since after once reordering an expression in $\mathfrak{V}^2$ we would not expect an element of $\mathfrak{V}^0$ to arise (but rather one of $\mathfrak{V}^1$). However, as was remarked in Sec. IV A, the tensor rank of an expression in terms of annihilation and creation operators (or Fourier components) is given by the power of $\mathfrak{m}$ in the expression, while the corresponding degree ℓ is given only by the negative power of 2π in the expression minus 1 (which is correctly given here by $\ell=2-1$). We should therefore not think of the above expression as an element of $\mathfrak{V}^0$, but rather as

an anomaly with $\ell=1$, accidentally having a similar form as $J_{1,-1}\in\mathfrak{V}^0$. It is illustrative to explicitly retrace how this term arises.

Remark 1: The term (15) is part of the following commutator:

$$\frac{2\pi\alpha'}{\hbar}[:\mathcal{Z}^{(2)}_{0-++}:,:\mathcal{Z}^{(2)}_{03--}:], \tag{16}$$

which appears in the relation with $J^P=1^+$, $m=-1$.

Proof: First note that by (7) this commutator appears in $[S_2,S_1]_{1,-1}$ and, hence, is indeed part of the relation under consideration. Now, in the homogeneous invariants $:\mathcal{Z}^{(2)}_{\mu_1\cdots\mu_4}:$, terms of the following form appear,

$$\frac{\mathfrak{m}^4}{(2\pi)^2}\delta_{\mu_1,0}\sum_{n_1>0}\sum_{n_2>0}\frac{1}{n_1(n_1+n_2)}(\alpha^{-n_1-n_2}_{\mu_2}\alpha^{n_1}_{\mu_4}\alpha^{n_2}_{\mu_3}+\alpha^{-n_1}_{\mu_4}\alpha^{-n_2}_{\mu_3}\alpha^{n_1+n_2}_{\mu_2}),$$

such that a commutator $(2\pi\alpha'/\hbar)[:\mathcal{Z}^{(2)}_{\mu_1\cdots\mu_4}:,:\mathcal{Z}^{(2)}_{\nu_1\cdots\nu_4}:]$ yields (among other terms)

$$\frac{\mathfrak{m}^8}{(2\pi)^4}\frac{2\pi\alpha'}{\hbar}\sum_{n_1,n_2>0}\sum_{m_1,m_2>0}\frac{1}{n_1(n_1+n_2)m_1(m_1+m_2)}\alpha^{-n_1-n_2}_{\mu_2}\alpha^{n_1}_{\mu_4}[\alpha^{n_2}_{\mu_3},\alpha^{-m_1}_{\nu_4}]\alpha^{-m_2}_{\nu_3}\alpha^{m_1+m_2}_{\nu_2}$$

$$=\frac{2\mathfrak{m}^6}{(2\pi)^3}\sum_{n_1,n_2>0}\sum_{m_2>0}\frac{\eta_{\mu_3\nu_4}}{n_1(n_1+n_2)(n_2+m_2)}\alpha^{-n_1-n_2}_{\mu_2}\alpha^{n_1}_{\mu_4}\alpha^{-m_2}_{\nu_3}\alpha^{n_2+m_2}_{\nu_2}.$$

Hence from (16) we find the contribution

$$-\frac{\mathfrak{m}^6}{4\pi^3}\sum_{n_1,n_2,m_2>0}\frac{1}{n_1(n_1+n_2)(n_2+m_2)}\alpha^{-n_1-n_2}_{-}\alpha^{n_1}_{+}\alpha^{-m_2}_{-}\alpha^{n_2+m_2}_{3},$$

which by normal ordering yields the anomaly

$$-\frac{\mathfrak{m}^6}{4\pi^3}\sum_{n_1,n_2,m_2>0}\frac{1}{n_1(n_1+n_2)(n_2+m_2)}[\alpha^{n_1}_{+},\alpha^{-m_2}_{-}]\alpha^{-n_1-n_2}_{-}\alpha^{n_2+m_2}_{3}$$

$$=\frac{\hbar}{2\pi\alpha'}\frac{\mathfrak{m}^4}{\pi^2}\sum_{n_1,n_2>0}\frac{1}{(n_1+n_2)^2}\alpha^{-n_1-n_2}_{-}\alpha^{n_1+n_2}_{3}$$

and in the same manner we find

$$-\frac{\hbar}{2\pi\alpha'}\frac{\mathfrak{m}^4}{\pi^2}\sum_{n_1,n_2>0}\frac{1}{(n_1+n_2)^2}\alpha^{-n_1-n_2}_{3}\alpha^{n_1+n_2}_{-}.$$

■

Let us now turn to an interpretation of the anomalies.

D. Unobservability of the anomalies

First we note that in the conformal gauge (9) the anomalies are independent of τ. However, no invariant charges $\mathcal{Z}_{\ldots}$ correspond to the anomalies, and it can even be shown directly that the anomalies do not in general correspond to classical functionals on the world-sheet which are

invariant under changes of the parametrization. To see this, we rewrite the anomalies in a more compact manner as multiplets of so(3). To that end, the following operators are defined:

$$(i)\ :R_1: = \{:R_{1,-1}:,:R_{1,0}:,:R_{1,1}:\} \overset{\text{def}}{=} \{:R_{0-}:,:R_{03}:,-:R_{0+}:\},\ \text{with}$$

$$\mathcal{M}_{\mu\nu} = x_\mu \mathcal{P}_\nu - x_\nu \mathcal{P}_\mu + \frac{2\pi\alpha'}{2i} \underbrace{\frac{\mathfrak{m}^2}{2\pi} \sum_{n>0} \frac{1}{n} (\alpha_\mu^{-n}\alpha_\nu^n - \alpha_\nu^{-n}\alpha_\mu^n}_{:R_{\mu\nu}:} + \beta_\mu^{-n}\beta_\nu^n - \beta_\nu^{-n}\beta_\mu^n).$$

$$(ii)\ :A_{2,m}: = \frac{\mathfrak{m}^2}{2\pi} \sum_{n>0} \frac{1}{n} (\alpha_1^{-n}\alpha_1^n)_{2,m} = \frac{\mathfrak{m}^2}{2\pi} \sum_{n>0} \frac{1}{n} \underbrace{\sum_{m_1,m_2=-1}^{1}}_{m_1+m_2=m} \langle 2,m|1,m_1;1,m_2\rangle \alpha_{1,m_1}^{-n}\alpha_{1,m_2}^n$$

$$\text{with } \alpha_{1,-1}^{\pm n} = \alpha_-^{\pm n},\ \alpha_{1,0}^{\pm n} = \alpha_3^{\pm n} \text{ and } \alpha_{1,1}^{\pm n} = -\alpha_+^{\pm n}.$$

$:A_{2,m}:$ is symmetric in the coordinate indices, since for the Clebsch–Gordan coefficients we have $\langle 2,\pm 1|1,\pm 1;1,0\rangle = \langle 2,\pm 1|1,0;1,\pm 1\rangle$ and $\langle 2,0|1,-1;1,1\rangle = \langle 2,0|1,1;1,-1\rangle$.

An elementary calculation now shows that the anomalies can be written as follows:

J^P	Anomalies
4^-	0
3^- (i)	$\frac{\hbar}{2\pi\alpha'} 8\{:J_1:,:A_2:\}_3$
(ii)	$-\frac{\hbar}{2\pi\alpha'} 20\{:J_1:,:A_2:\}_3$
3^-	$\frac{\hbar}{2\pi\alpha'} 4i\{:R_1:,:A_2:\}_3 +$ "more"
2^-	0
1^+	$\frac{\hbar}{2\pi\alpha'} \frac{1}{\sqrt{10}} \frac{80}{3} \frac{\mathfrak{m}^2}{\pi} :J_1:$

with anticommutators $\{\cdot,\cdot\}_{j,m}$ again coupled to spin j and magnetic quantum number m, and where (still) $f=-128/30$. Here, the term "more" in a relation indicates that further anomalous terms appear which involve mixed summation indices such as $n+m$ and for which no further simplification has been found. Similarly, for the relations involving $B_0^{(1)}$,

J^P	Anomalies
2^+	$-\frac{\hbar}{2\pi\alpha'}4\sqrt{6}\{:J_1:,:A_2:\}_2$
2^-	$-\frac{\hbar}{2\pi\alpha'}2\sqrt{6}\mathrm{i}\{:R_1:,:A_2:\}_2+$ "more"
1^-	$-\frac{\hbar}{2\pi\alpha'}12\sqrt{\frac{3}{5}}\{:R_1:,:A_2:\}_1+$ "more" $+\frac{\hbar^2}{(2\pi\alpha')^2}12:R_1:$

where the anomaly of second order in the relation with $J^P=1^-$ appears when the normally ordered anomaly term is written as the anticommutator $\{:R_1:,:A_2:\}_1$.

We are now prepared to state the main result of the present investigation.

Remark 2: The classical symmetric monomials $A_{2,m}$ which correspond to the products $:A_{2,m}:$ are not observable.

Proof: Consider a left mover u_μ which is written in terms of classical Fourier modes (8) and split it into its negative, positive, and null modes,

$$u_\mu(\sigma)=\frac{\mathfrak{m}}{2\pi}\sum_{n>0}\alpha_\mu^n e^{in\sigma}+\frac{\mathfrak{m}}{2\pi}\sum_{n>0}\alpha_\mu^{-n}e^{-in\sigma}+\frac{\mathfrak{m}}{2\pi}\alpha_\mu^0=:u_\mu^p(\sigma)+u_\mu^n(\sigma)+u_\mu^0,$$

and calculate the following integral, which is symmetrized in the coordinate indices μ and ν,

$$\begin{aligned}I(\mu,\nu)&=\int_0^{2\pi}d\sigma_1 u_{(\mu}(\sigma_1)\int_0^{\sigma_1}d\sigma_2(u_{\nu)}^p(\sigma_2)-u_{\nu)}^n(\sigma_2))\\&=\frac{\mathfrak{m}^2}{4\pi^2}\int_0^{2\pi}d\sigma_1\sum_{n_1=-\infty}^{\infty}e^{in_1\sigma_1}\alpha_{(\mu}^{n_1}\left(\sum_{n_2>0}\alpha_{\nu)}^{n_2}\frac{e^{in_2\sigma_1}-1}{in_2}-\sum_{n_2>0}\alpha_{\nu)}^{-n_2}\frac{e^{-in_2\sigma_1}-1}{-in_2}\right)\\&=\frac{\mathfrak{m}^2}{4\pi^2}\sum_{n_1=-\infty}^{\infty}\sum_{n_2>0}\alpha_{(\mu}^{n_1}\alpha_{\nu)}^{n_2}\frac{1}{in_2}2\pi(\delta_{n_1+n_2,0}-\delta_{n_1,0})\\&\quad+\frac{\mathfrak{m}^2}{4\pi^2}\sum_{n_1=-\infty}^{\infty}\sum_{n_2>0}\alpha_{(\mu}^{n_1}\alpha_{\nu)}^{-n_2}\frac{1}{in_2}2\pi(\delta_{n_1-n_2,0}-\delta_{n_1,0})\\&=\frac{\mathfrak{m}^2}{2\pi}\frac{2}{i}\sum_{n_2>0}\frac{1}{n_2}\alpha_{(\mu}^{-n_2}\alpha_{\nu)}^{n_2}-\underbrace{\frac{\mathfrak{m}^2}{4\pi^2}\frac{2\pi}{i}\sum_{n_2>0}\frac{1}{n_2}(\alpha_{(\mu}^0\alpha_{\nu)}^{n_2}+\alpha_{(\mu}^0\alpha_{\nu)}^{-n_2})}_{\circledast}.\end{aligned}$$

For μ and ν spacelike, the term $\circledast$ vanishes in the rest system and, hence, the products $:A_{2,m}:$ (which contain spacelike indices only) are linear combinations of integrals of the form $I(\mu,\nu)$. Now consider a change of parametrization $\sigma\to\hat{\sigma}$. Then the integral over u_ν is invariant:

$$\int_{\sigma_0}^{\sigma} d\sigma_1[u_\nu^p(\sigma_1)+u_\nu^n(\sigma_1)+u_\nu^0]=\int_{\sigma_0}^{\sigma} d\sigma_1 u_\nu(\sigma_1)=\int_{\hat\sigma_0}^{\hat\sigma} d\hat\sigma_1\hat u_\nu(\hat\sigma_1)=\int_{\hat\sigma_0}^{\hat\sigma} d\hat\sigma_1[\hat u_\nu^p(\hat\sigma_1)+\hat u_\nu^n(\hat\sigma_1)+u_\nu^0].$$

Here, we have used that the zero modes α_ν^0 are independent of the parametrization. Note that the splitting of $\hat u$ into positive and negative modes has to be done with respect to the new parametrization. In contrast to this, the difference of positive and negative modes does not in general possess the correct behavior under reparametrizations,

$$\int_{\sigma_0}^{\sigma} d\sigma_1[u_\nu^p(\sigma_1)-u_\nu^n(\sigma_1)]\overset{\text{i.g.}}{\neq}\int_{\hat\sigma_0}^{\hat\sigma} d\hat\sigma_1[\hat u_\nu^p(\hat\sigma_1)-\hat u_\nu^n(\hat\sigma_1)]. \tag{17}$$

To see this, consider the following counter example. Given a left mover with

$$u_0(\sigma)=1,\ \text{hence}\ u_0^p(\sigma)=u_0^n(\sigma)=0,$$

the left hand side of (17) is zero, while this is not true in general for the right hand side. Consider the reparametrization $\sigma\to\hat\sigma$ with $\sigma=f(\hat\sigma)$, where

$$e^{i\sigma}=\frac{e^{i\hat\sigma}-w}{\overline{w}e^{i\hat\sigma}-1}\ \text{with fixed}\ w,\ |w|<1,\ w=|w|e^{i\chi}.$$

In more technical terms, consider the unit disk $\subset\mathbb{C}$, whose boundary corresponds to the string. Then the above defines an automorphism of the disk which maps the boundary of the disk to itself, while respecting its orientation. Therefore, it does indeed define a parametrization. Obviously, we have

$$d\sigma=(1-|w|^2)\frac{d\hat\sigma}{(1-\overline{w}e^{i\hat\sigma})(1-we^{-i\hat\sigma})},$$

and, hence, the transformed $\hat u_0(\hat\sigma)$ is given as

$$\hat u_0(\hat\sigma)=u_0(f(\hat\sigma))\frac{df(\hat\sigma)}{d\hat\sigma}=\frac{1-|w|^2}{(1-\overline{w}e^{i\hat\sigma})(1-we^{-i\hat\sigma})}.$$

In particular, the zero mode $\hat u_0^0(\hat\sigma)=u_0^0(\sigma)=1$ is invariant, while for positive and negative modes an explicit calculation yields

$$\hat u_0^p(\hat\sigma)=(1-|w|^2)\sum_{l\geqslant 1}\left(\sum_{n\geqslant 0}|w|^{2n}\right)|w|^l e^{-il\chi}e^{il\hat\sigma},$$

$$\hat u_0^n(\hat\sigma)=(1-|w|^2)\sum_{l\leqslant -1}\left(\sum_{n\geqslant |l|}|w|^{2n}\right)|w|^l e^{-il\chi}e^{il\hat\sigma}.$$

We may thus conclude that while the left hand side of (17) is zero, the right hand side yields

$$\int_{\hat\sigma_0}^{\hat\sigma} d\hat\sigma_1[\hat u_0^p(\hat\sigma_1)-\hat u_0^n(\hat\sigma_1)]=(1-|w|^2)\sum_{l\geqslant 1}\left(\sum_{n\geqslant 0}|w|^{2n}|w|^l e^{-il\chi}\frac{e^{il\hat\sigma}-e^{il\hat\sigma_0}}{il}\right.$$
$$\left.-\sum_{n\geqslant l}|w|^{2n}|w|^{-l}e^{il\chi}\frac{e^{-il\hat\sigma}-e^{-il\hat\sigma_0}}{-il}\right)\neq 0$$

for general $\hat\sigma\neq\hat\sigma_0+2\pi$. Therefore, the products $A_{2,m}$ are not invariant under general reparametrizations. ■

An alternative proof of the above remark is to show that the *classical* monomial corresponding to an anomaly does not Poisson-commute with the generators of the Witt algebra. For instance, for the Poisson bracket of $A_{2,-2}=(\mathfrak{m}^2/2\pi)\Sigma(1/n)\alpha_-^{-n}\alpha_-^n$ and $\overline{L^l}$, $l\geqslant 2$, we find the following term,

$$-\sum_{m=1}^{l-1}\alpha_-^m\alpha_-^{l-m},$$

and similarly for $l\leqslant -2$. Since the anomalies cannot be written as functions of the constraints, they do not even vanish weakly (on the physical subspace) and we may conclude that not even in this sense, the invariant charges in $3+1$ dimensions can be represented as a subalgebra of the polynomial algebra of normally ordered annihilation and creation operators.

To conclude, it is emphasized that the anomalies are not multiples of the identity, and, therefore, canonical quantization does not merely yield a central extension of the algebra of invariant charges.

V. ANOMALIES APPEAR IN ANY DIMENSION

The calculations in the preceding section were performed in a $d=3+1$ dimensional background. A natural objection would be to claim that in some critical dimension, the problem could be absent. This, however, is not the case.

From the relation in $d=3+1$ with $J^P=2^+$ involving the exceptional element $B_0^{(1)}$, we can deduce that in arbitrary dimensions d, commutators of normally ordered invariant charges will in general yield anomalies which do not correspond to classical reparametrization-invariant quantities. This follows directly from the fact that the relation under consideration for, say, $m=-2$ can also be read independently of the dimension d as follows:

$$\tfrac{1}{2}[:\mathcal{Z}^{(2)}_{0-0+}:+\tfrac{1}{2}:\mathcal{Z}^{(2)}_{0303}:,:\mathcal{Z}^{(2)}_{00--}:]-[:\mathcal{Z}^{(2)}_{0-33}:,:\mathcal{Z}^{(2)}_{0+--}:]+[:\mathcal{Z}^{(2)}_{0+--}:,:\mathcal{Z}^{(2)}_{0-33}:]-2[:\mathcal{Z}^{(2)}_{03--}:,:\mathcal{Z}^{(2)}_{0-3+}:]$$

$$=-\frac{\hbar}{2\pi\alpha'}8\left(\frac{\sqrt{2}}{4m}\{i:\mathcal{Z}^{(2)}_{0-3}:-i:\mathcal{Z}^{(2)}_{03-}:,X\}-\frac{1}{2m}\{i:\mathcal{Z}^{(2)}_{0+-}:-i:\mathcal{Z}^{(2)}_{0-+}:,Y\}\right),$$

with

$$X=\frac{\mathfrak{m}^2}{2\pi}\frac{1}{\sqrt{2}}\sum_{n>0}\frac{1}{n}(\alpha_-^{-n}\alpha_3^n+\alpha_3^{-n}\alpha_-^n),\quad Y=\frac{\mathfrak{m}^2}{2\pi}\sum_{n>0}\frac{1}{n}\alpha_-^{-n}\alpha_-^n,$$

and where the basis e_0, $e_\pm=(1/\sqrt{2})(e_1\pm ie_2)$, $e_3,\ldots,e_{d-1}$ is chosen in d-dimensional Minkowski space.

Although the above may not be one of the defining relations in d dimensions, its classical counterpart (where the commutators are again replaced by Poisson brackets and the right hand side is set to 0) is an identity in the Poisson algebra of invariant charges for arbitrary dimension d. The proof of Remark 2 being independent of the dimension of the underlying space, we deduce that the right hand side of the above still is not observable. Neither is it a function of the Virasoro generators, and hence the algebra of normally ordered invariant charges is no subalgebra of the normally ordered polynomials in annhihilation and creation operators, not even on the physical subspace and independently of the dimension d.

It is instructive to consider this result also from the following different point of view.

Remark 3: Consider the commutator of a normally ordered invariant charge $:\mathcal{Z}^{(2)}_{\mu_1\cdots\mu_4}:$ with a Virasoro generator $:\overline{L^n}:$, $n>0$. Then from the terms in $:\overline{L^n}:$ which involve two annihilation operators, we find anomalies of the following form:

$$A(i_1,i_2,i_3,i_4)=\eta_{\mu_{i_1}\mu_{i_2}}\sum_{n_1=1}^{n-1}(\alpha^{n-n_1}_{\mu_{i_3}}\alpha^{n_1}_{\mu_{i_4}}+\alpha^{n_1}_{\mu_{i_3}}\alpha^{n-n_1}_{\mu_{i_4}}),\tag{18}$$

$$A(i_1,i_2,i_3)=\eta_{\mu_{i_1}\mu_{i_2}}\frac{n}{2}(n-1)\alpha^n_{\mu_{i_3}}.\tag{19}$$

Proof: The claim follows from Appendix B by simple calculations. Anomalies of the form (18) arise from normal ordering expressions such as

$$\sum_{m_1,m_2>0}\frac{1}{m_1m_2}\sum_{n_1=1}^{n-1}\sum_{\nu=0}^{d-1}[\alpha_\nu^{n-n_1},\alpha_{\mu_{i_1}}^{-m_1}]\alpha^{n_1\nu}\alpha_{\mu_{i_2}}^{-m_2}\alpha_{\mu_{i_3}}^{m_2}\alpha_{\mu_{i_4}}^{m_1}$$

$$+\sum_{m_1,m_2>0}\frac{1}{m_1m_2}\sum_{n_1=1}^{n-1}\sum_{\nu=0}^{d-1}[\alpha_\nu^{n-n_1},\alpha_{\mu_{i_2}}^{-m_2}]\alpha^{n_1\nu}\alpha_{\mu_{i_1}}^{-m_1}\alpha_{\mu_{i_3}}^{m_2}\alpha_{\mu_{i_4}}^{m_1}.$$

Likewise, anomalies of the form (19) arise from normal ordering of expressions

$$\sum_{m_1,m_2>0}\frac{1}{m_1(m_1+m_2)}\sum_{n_1=1}^{n-1}\sum_{\nu=0}^{d-1}\alpha^{n_1\nu}[\alpha_\nu^{n-n_1},\alpha_{\mu_{i_1}}^{-m_1}\alpha_{\mu_{i_2}}^{-m_2}]\alpha_{\mu_{i_3}}^{m_1+m_2}$$

as well as

$$\sum_{m_1,m_2>0}\frac{1}{m_1m_2}\sum_{n_1=1}^{n-1}\sum_{\nu=0}^{d-1}\alpha^{n_1\nu}[\alpha_\nu^{n-n_1},\alpha_{\mu_{i_1}}^{-m_1}\alpha_{\mu_{i_2}}^{-m_2}]\alpha_{\mu_{i_3}}^{m_1+m_2}.$$

Here, the anomalies turn out to be independent of n_1 such that the sum $\Sigma_{n_1=1}^{n-1}$ yields the factor $\frac{1}{2}n(n-1)$. ■

No other anomalies appear, since one needs at least three operators which are not multiples of the identity and at least two creation operators in order to find nontrivial contributions. The leading order of the commutator is 0, as it corresponds to the classical result (the invariant charges Poisson-commute with the generators of the Witt algebra). From Appendix B one calculates that the complete set of anomalies is given by

$$A(1,2,3,4)-A(1,3,4,2)-A(1,3,2,4)+A(1,4,3,2)+A(2,3,4,1)$$

$$-A(2,4,3,1)-A(2,4,1,3)+A(3,4,1,2)$$

and

$$-(\delta_{\mu_1,0}A(2,3,4)+\delta_{\mu_1,0}A(4,3,2)+\delta_{\mu_2,0}A(3,4,1)+\delta_{\mu_2,0}A(1,4,3)+\delta_{\mu_3,0}A(4,1,2)$$

$$+\delta_{\mu_3,0}A(2,1,4)+\delta_{\mu_4,0}A(1,2,3)+\delta_{\mu_4,0}A(3,2,1))$$

$$+(\delta_{\mu_1,0}A(2,4,3)+\delta_{\mu_2,0}A(1,3,4)+\delta_{\mu_3,0}A(2,4,1)+\delta_{\mu_4,0}A(1,3,2)).$$

These anomalies do not vanish in any particular dimension of the underlying Minkowski space. Neither are they functions of the Virasoro generators and hence they do not vanish on the physical subspace. To see that they furthermore do not in general correspond to classical observables, we consider the following example in d dimensions with canonical basis $e_0,\ldots,e_{d-1}$:

$$[:\overline{L}^m:,:\mathcal{Z}_{0011}:],\ m\geqslant 2.$$

Here, a simple calculation shows that the anomalies are proportional to

$$2\sum_{n=1}^{m-1}(\alpha_1^{m-n}\alpha_1^n-\alpha_0^{m-n}\alpha_0^n) \text{ and } m(m-1)(\alpha_0^m-\alpha_1^m), \tag{20}$$

such that the Poisson bracket of $\overline{L^l}$ with the *classical* momomials corresponding to (20) yields terms of the form

$$2\sum_{n=1}^{m-1}((m-n)(\alpha_1^n\alpha_1^{l+m-n}-\alpha_0^n\alpha_0^{l+m-n})+n(\alpha_1^{m-n}\alpha_1^{l+m}-\alpha_0^{m-n}\alpha_0^{l+m}))$$

and

$$-m^2(m-1)(\alpha_1^{l+m}-\alpha_0^{l+m}).$$

It follows that the normally ordered invariants do not commute with the generators of the Virasoro algebra, and that, again, the anomalies which arise are neither themselves invariant nor do they vanish on the physical subspace. Again, they are not simply multiples of the identity, and, in fact, for invariants of higher tensor rank may even be polynomials in annihilation and creation operators of arbitrary rank. Hence, the question of whether canonical quantization encodes the geometric content of the Nambu–Goto string has to be answered in the negative.

Similar problems occur when the gauge is fixed to the light-cone gauge. One of the reasons for the necessity of a critical dimension in the canonical approach is that in this gauge, the generators of the Poincaré group only close as a Lie algebra (at least weakly) in $d=26$. Calculating the action of these generators on invariant charges we also find anomalies which, however, contrary to those arising in a commutator of two generators, do not vanish in some critical dimension. Hence, the canonically quantized invariant charges no longer transform covariantly in this approach. For details, see Ref. 5.

The results presented here show that the canonical approach and the algebraic quantization are inequivalent. This means, in particular, that the usual Fock space does not yield a suitable representation of the algebra of invariant charges. Lately, a representation providing an alternative to the Fock space construction was proposed in Ref. 12.

To conclude, some comments on the relation between the algebra of the invariant charges and the so-called DDF operators[13] seem to be appropriate. Since the latter commute with all Virasoro generators (in the conformal gauge), they are sometimes considered to provide a "canonical algebra of invariant quantities." However, the crucial point is that the *construction rules* for a genuine invariant quantity must be gauge-independent. This requirement is met by the algebra of invariant charges: regardless of whether one starts from a conformal or from some other parametrization, the rules for the construction of the algebra of invariant charges are the same (and the charges are invariant under arbitrary reparametrizations). In contrast to this, the construction of the DDF operators relies on choosing the conformal gauge, and, hence, by the above criterion, the DDF operators are not genuinely invariant.

Note added. In the meantime, a construction of classical DDF-like operators independent of a particular gauge has been given and it was shown that the classical invariant charges can be written as functionals of these operators.[14] One main difficulty in using these operators as a starting point for quantization is to show that Lorentz symmetry can be kept after quantization.

ACKNOWLEDGMENT

I would like to thank K. Pohlmeyer, who provided the idea for this investigation and supervised my thesis on the subject. His critical comments on this manuscript are also gratefully acknowledged.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 45, NUMBER 12 DECEMBER 2004

A technique to identify solvable dynamical systems, and another solvable extension of the goldfish many-body problem

Francesco Calogero[a)]

(Received 11 May 2004; accepted 24 August 2004; published 15 November 2004)

We take advantage of the simple approach, recently discussed, which associates to (solvable) matrix equations (solvable) dynamical systems interpretable as (interesting) many-body problems, possibly involving auxiliary dependent variables in addition to those identifying the positions of the moving particles. Starting from a solvable matrix evolution equation, we obtain the corresponding many-body model and note that in one case the auxiliary variables can be altogether eliminated, obtaining thereby an (also Hamiltonian) extension of the "goldfish" model. The solvability of this novel model, and of its *isochronous* variant, is exhibited. A related, as well *solvable*, model, is also introduced, as well as its *isochronous* variant. Finally, the small oscillations of the *isochronous* models around their equilibrium configurations are investigated, and from their isochronicity certain diophantine relations are evinced. © *2004 American Institute of Physics.*
[DOI: 10.1063/1.1809256]

I. INTRODUCTION AND SOME RESULTS

Recently we discussed a simple approach which associates to (solvable) matrix equations (solvable) dynamical systems, generally interpretable as (interesting) many-body problems, possibly involving auxiliary dependent variables in addition to those identifying the positions of the moving particles.[16,17] In this paper we apply the same approach to a new (namely, not previously considered in this context), but again *solvable*, matrix evolution equation, and we thereby obtain a novel class of *solvable* many-body models, generally involving auxiliary variables.[16] We then note that in one case the auxiliary variables can be altogether eliminated, obtaining thereby a novel *solvable* extension, see (7) and its *isochronous* variant (10), of the "goldfish" many-body problem.[13,8,14,15] In this section we outline the main findings concerning these models, and in Sec. II we prove them. In Sec. III we introduce an alternative approach, which leads to the identification of another *solvable* model, also endowed with an *isochronous* variant. In Sec. IV we focus on the (obviously *isochronous*) behavior of these two *isochronous* models around their equilibrium configurations, and we thereby obtain, as a purely mathematical by-product, certain *diophantine* results (including a conjecture that we test numerically but we have been so far unable to prove). Since the equilibrium configuration of the first *isochronous* model—the one which provides a generalized version of the goldfish N-body problem—turns out to coincide with the (complex) zeros x_n of the generalized Laguerre polynomial $L_N^{(-2N-1)}(x)$ the first class of *diophantine* relations involves these zeros. The second class involves less exotic numbers. Some additional remarks are proffered in Sec. V. A more detailed analysis of the behavior of this extended "goldfish" model, including the explicit display of its solution in the three cases with only one, only two and only three particles, will be presented in a separate paper.[19]

[a)]Electronic mail: francesco.calogero@roma1.infn.it

The starting point of the treatment is the *solvable* matrix evolution equation

$$\ddot{U} = a(\dot{U}U + U\dot{U}). \tag{1}$$

Here the $N \otimes N$ matrix $U \equiv U(t)$ is the dependent variable, the independent variable t ("time") is *real* and superimposed dots indicate derivatives with respect to it; a indicates a *scalar* constant, which might of course be eliminated by a trivial rescaling of the dependent or independent variables, although we prefer not to do so in order to keep track of the contributions coming from the (nonlinear) right-hand side of this matrix evolution equation, (1), and also to maintain open the option to set a to zero, going thereby back to the standard goldfish many-body problem and related results.[16,17,13]

It is easily seen that the *general* solution of this matrix evolution equation, (1), reads

$$U(t) = a^{-1}[\cos(At) - BA^{-1}\sin(At)]^{-1}[A\sin(At) + B\cos(At)], \tag{2a}$$

where A and B are two arbitrary *constant* $N \otimes N$ matrices. In terms of the initial-value problem for the matrix evolution equation (1) clearly (2a) entails

$$U(0) = a^{-1}B, \quad \dot{U}(0) = a^{-1}(A^2 + B^2), \tag{2b}$$

and these two matrix equations can be inverted to yield

$$A^2 = -a^2[U(0)]^2 + a\dot{U}(0), \quad B = aU(0). \tag{2c}$$

Note that the explicit expression (2a) entails that the matrix $U(t)$ is actually a function of the matrix A^2 rather than A.

As shown in Sec. II, the *solvable* many-body problem related to the *solvable* matrix evolution equation (1) is characterized by the following Newtonian equations of motion:

$$\ddot{z}_n = 2a\dot{z}_n z_n - 2\sum_{m=1, m\neq n}^{N} (z_n - z_m)M_{nm}M_{mn}, \tag{3a}$$

$$(z_n - z_m)\dot{M}_{nm} + 2(\dot{z}_n - \dot{z}_m)M_{nm} = a(z_n^2 - z_m^2)M_{nm} + \sum_{\ell=1;\ell\neq n,m}^{N} (z_n + z_m - 2z_\ell)M_{n\ell}M_{\ell m} - (z_n - z_m)M_{nm}(F_n - F_m), \quad n \neq m. \tag{3b}$$

The N coordinates $z_n \equiv z_n(t)$ denote the positions of the N moving particles, the $N(N-1)$ "auxiliary variables" $M_{nm} \equiv M_{nm}(t)$ evolve according to the system of $N(N-1)$ first-order ODEs (3b), and the N "source terms" F_n can be assigned as arbitrary functions of time, or even of the other dependent variables z_m and $M_{m\ell}$ without spoiling the solvable character of the model. Here and throughout indices like n, m, ℓ range from 1 to N unless otherwise indicated.

An interesting redefinition of the auxiliary variables obtains by setting

$$M_{nm} = (z_n - z_m)^{-1}(\dot{z}_n\dot{z}_m)^{1/2}u_{nm} \tag{4}$$

(as already mentioned in Ref. 16 this assignment is suggested by the form of the Lax matrix introduced in Ref. 7). The equations of motion (3) of the many-body model take thereby the form

$$\ddot{z}_n = 2a\dot{z}_n z_n + 2\sum_{m=1, m\neq n}^{N} \frac{\dot{z}_n\dot{z}_m}{z_n - z_m}u_{nm}u_{mn}, \tag{5a}$$

$$\dot{u}_{nm} + \frac{\dot{z}_n - \dot{z}_m}{z_n - z_m} u_{nm}(1 - u_{nm}u_{mn}) = -\sum_{\ell=1;\ell\neq n,m}^{N} \dot{z}_\ell \left[\frac{u_{n\ell}(u_{\ell m} + u_{nm}u_{\ell n})}{z_n - z_\ell} + \frac{u_{\ell m}(u_{n\ell} + u_{nm}u_{m\ell})}{z_m - z_\ell} \right]$$

$$- u_{nm}(F_n - F_m), \quad n \neq m. \tag{5b}$$

Here the auxiliary variables are of course the $N(N-1)$ quantities $u_{nm}(t)$; and note that, while the (Newtonian) equations of motion (5a) that characterize the evolution of the "particle coordinates" $z_n(t)$ follow straightforwardly from (3a) via (4), to obtain the equations (5b) that characterize the evolution of the auxiliary variables $u_{nm}(t)$ from (5b) one must use, in addition to (4), the equations of motion (5a). It is now clear that, for $F_n=0$ (or, equivalently, for $F_n=F$), the $N(N-1)$ evolution equations (5b) admit the (special) solution

$$u_{nm} = -1, \quad n \neq m, \tag{6}$$

entailing that the Newtonian equations of motion (5a) become then

$$\ddot{z}_n = 2a\dot{z}_n z_n + 2\sum_{m=1,m\neq n}^{N} \frac{\dot{z}_n \dot{z}_m}{z_n - z_m}. \tag{7}$$

For $a=0$ these equations of motion coincide with those of the standard "goldfish" model (see Refs. 13, 8, 14, 15, and 17 and the literature quoted there); for $a\neq 0$ they characterize a novel *solvable* extension of the goldfish many-body problem.

Before discussing the solvability of this model, (7), let us note its Hamiltonian character (see Ref. 14 and the literature quoted there). Indeed the Hamiltonian

$$H = \sum_{n=1}^{N} \left\{ -\frac{a}{s} z_n^2 + \exp(sp_n) \prod_{m=1,m\neq n}^{N} (z_n - z_m)^{-1} \right\}, \tag{8a}$$

where s is an arbitrary (nonvanishing) constant, yields the Hamiltonian equations

$$\dot{z}_n = \frac{\partial H}{\partial p_n} = s\exp(sp_n) \prod_{m=1,m\neq n}^{N} (z_n - z_m)^{-1}, \tag{8b}$$

$$\dot{p}_n = -\frac{\partial H}{\partial z_n} = \frac{1}{s}\left\{ 2az_n + \sum_{m=1,m\neq n}^{N} \frac{\dot{z}_n + \dot{z}_m}{z_n - z_m} \right\}. \tag{8c}$$

Note that to write more neatly the second set of these Hamiltonian equations, (8c), we used the first, (8b). It is then obvious that t-differentiation of (the logarithm of) the first set of Hamiltonian equations (8b), yields, via the second set (8c), just the Newtonian equations of motion (7), demonstrating thereby their Hamiltonian character.

The solution of the initial-value problem for this many-body model, (7), is given by the following result (proven in Sec. II): the coordinates $z_n(t)$ are the N eigenvalues of the $N\otimes N$ matrix (2a) with

$$(A^2)_{nm} = -\delta_{nm}a^2 z_n^2(0) + a[\dot{z}_n(0)\dot{z}_m(0)]^{1/2}, \quad B_{nm} = \delta_{nm}az_n(0). \tag{9}$$

Here δ_{nm} is the standard Kronecker symbol, $\delta_{nm}=1$ if $n=m$, $\delta_{nm}=0$ if $n\neq m$. These formulas indicate that the $N\otimes N$ matrix B is diagonal, while the $N\otimes N$ matrix A^2 is the sum of a diagonal matrix and a dyadic matrix.

Via the standard trick (outlined at the end of this section; for more detailed and general treatments see, for instance, Refs. 10, 12, and 14) the following variant of the model (7) is obtained:

$$\ddot{z}_n - 3i\omega\dot{z}_n - 2\omega^2 z_n = 2a(\dot{z}_n - i\omega z_n)z_n + 2\sum_{m=1,m\neq n}^{N} \frac{\dot{z}_n\dot{z}_m - i\omega(\dot{z}_n z_m + \dot{z}_m z_n) - \omega^2 z_n z_m}{z_n - z_m}. \tag{10}$$

Here and throughout ω is a *real* (for definiteness, *positive*) constant, and because of the way this ω-modified system is obtained from (7) *all* its nonsingular solutions are completely periodic with period,

$$T = \frac{2\pi}{\omega}, \tag{11}$$

or with an integer multiple of this basic period. Indeed the solutions $z_n(t)$ of these equations of motion, (10), are the N eigenvalues of the ω-modified matrix $\tilde{U}(t)$ defined as follows:

$$\tilde{U}(t) = \exp(i\omega t)U(\tau), \quad \tau = \frac{\exp(i\omega t) - 1}{i\omega}, \tag{12a}$$

where the matrix $U(\tau)$ is defined by (2a) (of course with t replaced by τ), but now with

$$\tilde{U}(0) = a^{-1}B, \quad \dot{\tilde{U}}(0) = a^{-1}(A^2 + B^2) + i\omega\tilde{U}(0), \tag{12b}$$

entailing

$$A^2 = -a^2[\tilde{U}(0)]^2 + a\dot{\tilde{U}}(0) - ia\omega\tilde{U}(0), \quad B = a\tilde{U}(0). \tag{12c}$$

In terms of the initial-value data for the model (10) these expressions read

$$(A^2)_{nm} = -\delta_{nm}a^2 z_n^2(0) + a\{[\dot{z}_n(0) - i\omega z_n(0)][\dot{z}_m(0) - i\omega z_m(0)]\}^{1/2},$$

$$B_{nm} = \delta_{nm}a z_n(0). \tag{12d}$$

Note that the assertion made above about the complete periodicity of *all* the nonsingular solutions of the system (10) is implied by the assertion made now about the solution of this system, since it is clear that the matrix $\tilde{U}$ is periodic in the time variable t with period T, see (11), (12a), and (2a). This incidentally allows to consider this generalized goldfish model, (10), as describing an assembly of "nonlinear harmonic oscillators."[18] The behavior of this system in the neighborhood of its equilibrium configuration is discussed in Sec. IV.

Finally let us emphasize that the solutions $z_n(t)$ of the generalized goldfish model (10) are necessarily *complex* (for *positive* ω, $\omega > 0$) and that these equations of motion can be reformulated as *real* and *covariant* equations describing the motion in the (horizontal) plane of N particles the positions of which there are identified by the *real* two-vectors $\vec{r}_n$ related to the *complex* numbers z_n by the standard[11,12,16] relations

$$z_n = x_n + iy_n, \quad a = a_x - ia_y, \tag{13a}$$

$$\vec{r}_n = (x_n, y_n, 0), \quad \vec{a} = (a_x, a_y, 0), \quad \hat{k} = (0,0,1), \tag{13b}$$

which entail that the equations of motion (10) read then as follows:

$$\ddot{\vec{r}}_n - 3\omega\hat{k}\wedge\dot{\vec{r}}_n - 2\omega^2\vec{r}_n = 2[\dot{\vec{r}}_n(\vec{a}\cdot\vec{r}_n) + \vec{r}_n(\vec{a}\cdot\dot{\vec{r}}_n) - \vec{a}(\dot{\vec{r}}_n\cdot\vec{r}_n)] - 2\omega\hat{k}\wedge[2\vec{r}_n(\vec{a}\cdot\vec{r}_n) - \vec{a}r_n^2]$$
$$+ 2\sum_{m=1,m\neq n}^{N} r_{nm}^{-2}\{\dot{\vec{r}}_n(\dot{\vec{r}}_m\cdot\vec{r}_{nm}) + \dot{\vec{r}}_m(\dot{\vec{r}}_n\cdot\vec{r}_{nm}) - \vec{r}_{nm}(\dot{\vec{r}}_n\cdot\dot{\vec{r}}_m) - \omega\hat{k}\wedge[\dot{\vec{r}}_n(\vec{r}_m\cdot\vec{r}_{nm})$$
$$+ \dot{\vec{r}}_m(\vec{r}_n\cdot\vec{r}_{nm}) - \vec{r}_n([\dot{\vec{r}}_n+\dot{\vec{r}}_m]\cdot\vec{r}_m) + \vec{r}_m([\dot{\vec{r}}_n+\dot{\vec{r}}_m]\cdot\vec{r}_m)] + \omega^2[\vec{r}_n r_m^2 - \vec{r}_m r_n^2]\}, \tag{13c}$$

where we use the short-hand notation $\vec{r}_{nm}\equiv\vec{r}_n-\vec{r}_m$ entailing $r_{nm}^2=r_n^2+r_m^2-2\vec{r}_n\cdot\vec{r}_m$. This equation is covariant [thanks to the definition (13) of a; note the minus sign there], but it is not rotation-invariant because the constant two-vector $\vec{a}$ identifies a preferred direction in the plane.

Before closing this section let us, for completeness, outline how the *isochronous* model (10) is obtained from (7), which to this end we rewrite here in the following (merely notationally) modified guise:

$$\zeta_n'' = 2a\zeta_n'\zeta_n + 2\sum_{m=1,m\neq n}^{N}\frac{\zeta_n'\zeta_m'}{\zeta_n-\zeta_m}, \tag{14}$$

where $\zeta_n\equiv\zeta_n(\tau)$ and appended primes indicate of course differentiations with respect to the (*complex*, see immediately below) independent variable τ. We then set

$$z_n(t) = \exp(i\omega t)\zeta_n(\tau),\quad \tau = \frac{\exp(i\omega t)}{i\omega}. \tag{15}$$

And it is then easily verified that (14) implies (10).

II. SOLUTION TECHNIQUE

The point of departure of our treatment is the $N\otimes N$ matrix equation (1). We then introduce the parametrization of the $N\otimes N$ matrix $U(t)$ in terms of its N eigenvalues $z_n(t)$ and of its diagonalizing $N\otimes N$ matrix $R(t)$,

$$U = RZR^{-1}, \tag{16a}$$

$$Z = \mathrm{diag}[z_n]. \tag{16b}$$

But before proceeding to obtain the evolution equations implied by (1) for the diagonal matrix $Z(t)$ and for the diagonalizing matrix $R(t)$, or rather (see below) for the matrix $M(t)$ defined in terms of $R(t)$ by the formula

$$M = R^{-1}\dot{R}, \tag{17}$$

let us note that the formulas (16) define the matrix R only up to multiplication from the right by an *arbitrary* diagonal matrix, say

$$D = \mathrm{diag}[d_n], \tag{18}$$

since replacing in (16a) R with

$$\tilde{R} = RD \tag{19}$$

is clearly of no consequence. The corresponding "gauge transformation" of the matrix M,

$$\tilde{M} = \tilde{R}^{-1}\dot{\tilde{R}} = D^{-1}MD + D^{-1}\dot{D}, \tag{20a}$$

namely

$$\tilde{M}_{nn} = M_{nn} + \frac{\dot{d}_n}{d_n}, \tag{20b}$$

$$\tilde{M}_{nm} = d_n^{-1} M_{nm} d_m, \quad n \neq m, \tag{20c}$$

entails that in our parametrization of the $N \otimes N$ matrix $U(t)$ [via (16) with (17)] the N^2 matrix elements of this matrix get replaced by the N elements $z_n(t)$ of the diagonal matrix $Z(t)$ [namely by the N eigenvalues of the matrix $U(t)$: see (16)] and by the $N(N-1)$ off-diagonal elements $M_{nm}(t)$ (with $n \neq m$) of the $N \otimes N$ matrix $M(t)$, while the N diagonal elements $M_{nn}(t)$ can be arbitrarily adjusted by choosing appropriately the elements $d_n(t)$ of the diagonal matrix $D(t)$, see (20b) [of course, up to a corresponding adjustment of the corresponding off-diagonal elements, see (20c)].

Differentiation of (16a) with respect to the independent variable t yields, using (17),

$$\dot{U} = R\{\dot{Z} + [M,Z]\}R^{-1}, \tag{21a}$$

$$\ddot{U} = R\{\ddot{Z} + [\dot{M},Z] + 2[M,\dot{Z}] + [M,[M,Z]]\}R^{-1}. \tag{21b}$$

Here and throughout we use of course the standard notation $[X,Y] \equiv XY - YX$ for the commutator of two matrices.

The treatment in this section has been up to now identical to that of Ref. 16 (it is reported here to make this paper self-contained). We now insert these formulas, (16) and (21), in the matrix evolution equation (1) and we thereby obtain the $N \otimes N$ matrix evolution equation,

$$\ddot{Z} + [\dot{M},Z] + 2[M,\dot{Z}] + [M,[M,Z]] = a\{(\dot{Z} + [M,Z])Z + Z(\dot{Z} + [M,Z])\}, \tag{22}$$

namely, by separating the diagonal and off-diagonal terms, precisely the system (3), where we made the notational assignment

$$M_{nn} \equiv F_n \tag{23}$$

and, consistently with the observation made above, we retain the freedom to assign arbitrarily these N quantities F_n.

All the other findings reported in Sec. I follow sufficiently straightforwardly not to require additional elaboration here.

Of course alternative assignments, different from (4), could be made.[16] For instance the introduction of the new auxiliary variables $g_{nm}(t)$ in place of $M_{nm}(t)$ via the natural position[16]

$$M_{nm} = (z_n - z_m)^{-2} g_{nm}, \quad n \neq m, \tag{24}$$

transforms the equations of motion (3) into

$$\ddot{z}_n = 2a\dot{z}_n z_n - 2\sum_{m=1, m\neq n}^{N} \frac{g_{nm}g_{mn}}{(z_n - z_m)^3}, \tag{25a}$$

$$\dot{g}_{nm} - a(z_n + z_m)g_{nm} = -\sum_{\ell=1;\ell\neq n,m}^{N} g_{n\ell}g_{\ell m}[(z_n - z_\ell)^{-2} - (z_m - z_\ell)^{-2}] - g_{nm}(F_n - F_m), \quad n \neq m. \tag{25b}$$

But, for $a \neq 0$, there is no choice of the arbitrarily assignable quantities F_n that is consistent with getting rid of the auxiliary variables g_{nm} (in the sense of making them time independent).

Before ending this section we like to reiterate[16] that the approach presented here is not altogether new, see, for instance, the following papers: Refs. 4, 25, 20, 26–29, 23, 5, 6, 22, 24, 3, 2, and 17.

III. AN ALTERNATIVE APPROACH

In this section we describe an alternative approach (see, for instance, Sec. 2.3 of Ref. 14). Let $\psi(z,t)$ be a monic polynomial of degree N in the (complex) variable z, and let us denote with $c_m(t)$ its coefficients and with $z_n(t)$ its zeros [which will be eventually identified with the coordinates of the particles evolving according to the Newtonian equations of motion (7)]:

$$\psi(z,t)=\prod_{n=1}^{N}[z-z_n(t)]=z^N+\sum_{m=1}^{N}c_m(t)z^{N-m}. \tag{26}$$

Note that this formula implies the relation

$$c_1(t)=-\sum_{n=1}^{N}z_n(t). \tag{27}$$

We now recall the relations [that obtain by logarithmic differentiation of the representation of $\psi(z,t)$ via its zeros, see (26); or see the Eqs. (2.3.2–8, 11) of Ref. 14],

$$\psi_t(z,t)=-\psi(z,t)\sum_{n=1}^{N}[z-z_n(t)]^{-1}\dot{z}_n(t), \tag{28}$$

that clearly implies [via (27)]

$$z\psi_t(z,t)-\dot{c}_1(t)\psi(z,t)=\psi(z,t)\sum_{n=1}^{N}[z-z_n(t)]^{-1}\{-z_n(t)\dot{z}_n(t)\} \tag{29a}$$

and

$$\psi_{tt}(z,t)=\psi(z,t)\sum_{n=1}^{N}[z-z_n(t)]^{-1}\left\{-\ddot{z}_n(t)+2\sum_{m=1,m\neq n}^{N}\frac{\dot{z}_n(t)\dot{z}_m(t)}{z_n(t)-z_m(t)}\right\}. \tag{29b}$$

Here and below subscripted variables denote of course partial differentiations.

It is clear from these formulas, (29), that the equations of motion (7) imply that the polynomial (26) satisfy the PDE

$$\psi_{tt}(z,t)-2a[z\psi_t(z,t)-\dot{c}_1(t)\psi(z,t)]=0, \tag{30}$$

and clearly this PDE, via the (second) relation (26), entails the system of ODEs,

$$\ddot{c}_m-2a\dot{c}_{m+1}+2a\dot{c}_1c_m=0, \tag{31a}$$

supplemented with the "boundary conditions"

$$c_0=1,\ \ c_{N+1}=0. \tag{31b}$$

Note that (31a) is trivially satisfied for $m=0$ [see (31b)], and that it can be integrated once for $m=1$ yielding

$$c_2=\frac{1}{2}c_1^2+\frac{1}{2a}(\dot{c}_1+C), \tag{32}$$

where C is an integration constant. Insertion of this expression of c_2 in (31a) with $m=2$ yields

$$\dot{c}_3 = \left(\frac{1}{2a}\right)^2 \dddot{c}_1 + \frac{\ddot{c}_1 c_1 + 2\dot{c}_1^2 + C\dot{c}_1}{2a} + \frac{1}{2}\dot{c}_1 c_1^2, \tag{33}$$

the right-hand side of which is however not an exact differential. Alternatively one could start from $m=N$ [which yields, see (34), the Schrödinger-type linear equation

$$\ddot{c}_N + 2a\dot{c}_1 c_N = 0, \tag{34}$$

with $c_N(t)$ playing the role of eigenfunction and $\dot{c}_1(t)$ playing the role of "potential"] and work all the way down by solving sequentially (but only formally) the series of second-order, nonhomogeneous, linear ODEs for $c_m(t)$ with $m=N-1, N-2, \ldots$, arriving in the end, for $m=1$, to a highly nonlinear (integrodifferential) equation for $c_1(t)$.

Clearly the fact that the system (31) is *solvable* is far from trivial. It is obviously implied by the results described above, since the coefficients $c_m(t)$ can be explicitly written in terms of the zeros $z_n(t)$ (see, for instance, Sec. 2.3.1 of Ref. 14); in particular (26) and (16) clearly entail the relations

$$c_1(t) = -\,\mathrm{trace}[U(t)], \quad c_N(t) = (-)^N \det[U(t)] \tag{35}$$

with the $N \otimes N$ matrix $U(t)$ evolving according to (2a).

The *isochronous* variant of this system, (31), can be obtained by first rewriting it in the following guise:

$$\gamma_m'' - 2a\gamma_{m+1}' + 2a\gamma_1'\gamma_m = 0, \quad \gamma_0 = 1, \quad \gamma_{N+1} = 0 \tag{36}$$

with $\gamma_m \equiv \gamma_m(\tau)$, and by then setting

$$c_m(t) = \exp(im\omega t)\,\gamma_m(\tau), \quad \tau = \frac{\exp(i\omega t) - 1}{i\omega}. \tag{37}$$

It reads

$$\ddot{c}_m - i(2m+1)\omega\dot{c}_m - m(m+1)\omega^2 c_m - 2a[\dot{c}_{m+1} - i(m+1)\omega c_{m+1}] + 2a[\dot{c}_1 - i\omega c_1]c_m = 0,$$

$$c_0 = 1, \quad c_{N+1} = 0. \tag{38}$$

Again, the *isochronous* character of the *general* solution of this system, implied by our treatment, is a nontrivial finding (up to the observation that all true mathematical results are indeed trivial).

A detailed discussion of the behavior of these *solvable* systems of ODEs, (31) and (38), as well as (7) and (10), for small values of N is postponed to a separate paper.[19] In the next section we consider the behavior of the *isochronous* models, (10) and (38), in the neighborhood of their equilibrium configurations.

IV. EQUILIBRIUM CONFIGURATIONS OF THE ISOCHRONOUS MODELS, SMALL OSCILLATIONS AND DIOPHANTINE RELATIONS

In this section we discuss the equilibrium configuration of the two (clearly related) *isochronous* models characterized by the equations of motion (10) and (38), as well as the behavior of these systems in the neighborhood of their equilibrium configurations. In this manner we also obtain some results for "remarkable matrices," following an approach already employed in the past in analogous contexts, see for instance Refs. 1, 9, and 14 and the references cited there.

The equilibrium configuration

$$z_n(t) = \overline{z_n},\ \ \dot{z}_n(t) = 0 \tag{39a}$$

of the system (10) is clearly characterized by the following system of N algebraic equations which determine (up to permutations) the N unknowns $\overline{z_n}$:

$$1 = i\left(\frac{a}{\omega}\right)\overline{z_n} + \sum_{m=1,m\neq n}^{N} \frac{\overline{z_m}}{\overline{z_n} - \overline{z_m}}. \tag{39b}$$

This suggests setting

$$\overline{z_n} = \left(\frac{i\omega}{2a}\right)x_n. \tag{40}$$

This notation is convenient to make contact with other results; the reader should of course note that the numbers x_n introduced here have nothing to do with the real parts of the quantities z_n, see (13). Indeed these N numbers x_n need not be real; they satisfy the N algebraic equations

$$x_n = -2 + 2\sum_{m=1,m\neq n}^{N} \frac{x_m}{x_n - x_m}, \tag{41a}$$

or equivalently

$$x_n = -2N + 2\sum_{m=1,m\neq n}^{N} \frac{x_n}{x_n - x_m}, \tag{41b}$$

and can therefore be identified as the N zeros of the generalized Laguerre polynomial $L_N^{(-2N-1)}(x)$,

$$L_N^{(-2N-1)}(x_n) = 0. \tag{41c}$$

[Let us provide, for completeness, a proof of this result (not new, see Refs. 1 and 9 and the literature quoted there). The (conveniently normalized) generalized Laguerre polynomial

$$(-)^N N! L_N^{(-2N-1)}(x) \equiv \chi(x) = \sum_{m=0}^{N} \frac{(N+m)!x^{N-m}}{(N-m)!m!} \tag{42}$$

is characterized by the ODE

$$x\chi''(x) - (x+2N)\chi'(x) + N\chi(x) = 0, \tag{43}$$

while its representation via its zeros,

$$\chi(x) = \prod_{n=1}^{N}(x - x_n) \tag{44a}$$

entails clearly [by logarithmic differentiation; or see the Eqs. (7), (12), and (13) of Sec. 2.3.2 of Ref. 14]

$$\chi'(x) = \chi(x)\sum_{n=1}^{N}(x - x_n)^{-1}, \tag{44b}$$

$$x\chi'(x) - N\chi(x) = \chi(x)\sum_{n=1}^{N}(x - x_n)^{-1}x_n, \tag{44c}$$

$$x\chi''(x) = \chi(x)\sum_{n=1}^{N}(x-x_n)^{-1}2\sum_{m=1,m\neq n}^{N}(x_n-x_m)^{-1}x_n, \tag{44d}$$

where the appended primes denote of course differentiations. It is then clear that the insertion of these three formulas in (43) entails (41b).

Let us now consider the behavior of our *isochronous* system (10) in the neighborhood of its equilibrium configuration. To this end we set

$$z_n(t) = \overline{z_n} + \varepsilon w_n(t), \tag{45}$$

and we then insert this assignment in the equations of motion (10) treating ε as a small parameter. We thus get the *linearized* equations of motion

$$\ddot{w}_n - 3i\omega\dot{w}_n - 2\omega^2 w_n = 2a\overline{z_n}(\dot{w}_n - 2i\omega w_n) + 2\sum_{m=1,m\neq n}^{N}\left[\frac{-i\omega(\overline{z_m}\dot{w}_n + \overline{z_n}\dot{w}_m)}{\overline{z_n}-\overline{z_m}} + \frac{\omega^2(\overline{z_m^2}w_n - \overline{z_n^2}w_m)}{(\overline{z_n}-\overline{z_m})^2}\right], \tag{46a}$$

namely

$$\underline{\ddot{w}} + i\omega\underline{\Gamma}\underline{\dot{w}} + \omega^2\underline{\Lambda}\underline{w} = 0. \tag{46b}$$

Here and throughout this section, to underline the vector and matrix character of our formulas, N-vectors are denoted by *lower* case *underlined* letters, hence $\underline{w} \equiv \underline{w}(t)$ denotes the N-vector of components $w_n \equiv w_n(t)$, and likewise $N \otimes N$ matrices are denoted by *upper* case *underlined* letters. In particular the two (constant) matrices $\underline{\Gamma}$ and $\underline{\Lambda}$ are defined (componentwise) as follows, via (40), in terms of the N zeros x_n of the generalized Laguerre polynomial $L_N^{(-2N-1)}(x)$:

$$\Gamma_{nm} = -\delta_{nm} + (1-\delta_{nm})\frac{2x_n}{x_n - x_m}, \tag{47a}$$

$$\Lambda_{nm} = -\delta_{nm}2\left[1 + x_n + \sum_{\ell=1,\ell\neq n}^{N}\frac{x_\ell^2}{(x_n - x_\ell)^2}\right] + (1-\delta_{nm})\frac{2x_n^2}{(x_n - x_m)^2}. \tag{47b}$$

Note that to simplify the expression of the diagonal part of the matrix $\underline{\Gamma}$ we used (41a). For an analogous simplification of the expression of the diagonal part of the matrix $\underline{\Lambda}$ see, in the Appendix, (A8) with (A2).

The *general* solution of the linear evolution equations (46), is provided by the formula

$$\underline{w}(t) = \sum_{k=1}^{2N} a_k \exp(i\lambda_k\omega t)\underline{v}^{(k)}, \tag{48}$$

where the $2N$ constants a_k are arbitrary [to be determined, in the context of the initial-value problem, from the $2N$ initial data $w_n(0)$ and $\dot{w}_n(0)$], while the $2N$ numbers λ_k, respectively, the corresponding N-vectors $\underline{v}^{(k)}$, are the eigenvalues, respectively, the eigenvectors, of the following (generalized) N-vector eigenvalue equation [see (46b)]:

$$-\lambda_k^2\underline{v}^{(k)} - \lambda_k\underline{\Gamma}\underline{v}^{(k)} + \underline{\Lambda}\underline{v}^{(k)} = 0, \quad k = 1, \ldots, 2N. \tag{49}$$

Hence the numbers λ_k are the $2N$ roots of the following equation (polynomial of degree $2N$) in λ:

$$\det[\lambda^2\underline{1} + \lambda\underline{\Gamma} - \underline{\Lambda}] = 0. \tag{50}$$

Here and throughout $\underline{1}$ denotes of course the $N \otimes N$ unit matrix, $(\underline{1})_{nm} = \delta_{nm}$.

But we already know, from our previous treatment, that the solutions of the *isochronous* model (10) are *completely periodic* with period T, see (11). [Actually solutions with a (larger)

period which is an integer multiple of T can also emerge, due to the exchange of the identity of the eigenvalues of the matrix $U(t)$, see (12), through the motion; and some exceptional singular solutions also exist, in which two or more particles collide at some finite time; but neither one of these two phenomena can occur for the *small* oscillations around the equilibrium configuration considered here.] The same periodicity property must therefore characterize the behavior (48) in the neighborhood of the equilibrium configuration of this system. We thus arrive at the following *diophantine* finding: *the* $2N$ *numbers* λ_k *are all integers*. In fact, motivated by this finding and by some numerical checks, we make the following conjecture.

Conjecture: *Let the two* $N \otimes N$ *matrices* $\underline{\Gamma}$ *and* $\underline{\Lambda}$ *be defined by (47), in terms of the* N *zeros* x_n *of the generalized Laguerre polynomial* $L_N^{(-2N-1)}(x)$, *namely the polynomial of degree* N *characterized by the ODE (43); then*

$$\det[\lambda^2 \underline{1} + \lambda \underline{\Gamma} - \underline{\Lambda}] = \prod_{k=1}^{N} [(\lambda - 2k)(\lambda + 2k - 1)]. \tag{51}$$

It stands to reason that a route to prove this result emerge from the approach (based on generalized Lagrangean interpolation and yielding finite-dimensional representations of the differential operator[14]) employed in Refs. 1 and 9 to obtain analogous results; an outline of this approach, which seems to indicate some progress in this direction, is provided in the Appendix, but unfortunately it does not quite allow to prove the above conjecture, of the validity of which we are nevertheless quite certain, on the basis of numerical checks, see below.

Indeed a related *diophantine* conjecture—more explicit hence more suitable for numerical checks—is provided below, in the context of the investigation of the behavior of the *isochronous* system (38) in the neighborhood of its equilibrium configuration,

$$c_m(t) = \overline{c_m} = \left(\frac{i\omega}{2a}\right)^m \frac{(N+m)!}{(N-m)!m!}. \tag{52}$$

The fact that this formula provides a time-independent solution of (38) can be easily verified, as well as its consistency with (42) and (40).

To study the behavior of the system (38) in the neighborhood of this equilibrium configuration, (52), we now set

$$c_m(t) = \overline{c_m} + \varepsilon \left(\frac{i\omega}{2a}\right)^m \eta_m(t), \tag{53}$$

and by treating ε as a small parameter we obtain the following *linearized* system for the time evolution of the quantities $\eta_m(t)$:

$$\ddot{\eta}_m - i(2m+1)\omega \dot{\eta}_m + [N(N+1) - m(m+1)]\omega^2 \eta_m - i\omega \dot{\eta}_{m+1}$$
$$- (m+1)\omega^2 \eta_{m+1} + \frac{(N+m)!}{(N-m)!m!}[i\omega \dot{\eta}_1 + \omega^2 \eta_1] = 0,$$

$$\eta_0 = 0, \ \eta_{N+1} = 0, \tag{54a}$$

namely

$$\ddot{\underline{\eta}} + i\omega \underline{C}\, \dot{\underline{\eta}} + \omega^2 \underline{L}\, \underline{\eta} = 0, \tag{54b}$$

where the two matrices $\underline{C}$ and $\underline{L}$ are defined (componentwise) as follows:

$$C_{nm} = -\delta_{nm}(2n+1) - \delta_{n+1,m} + \delta_{1m}\frac{(N+n)!}{(N-n)!n!}, \tag{55a}$$

$$L_{nm} = \delta_{nm}[N(N+1) - n(n+1)] - \delta_{n+1,m}(n+1) + \delta_{1m}\frac{(N+n)!}{(N-n)!n!}. \tag{55b}$$

The *general* solution of this system of linear equations reads

$$\underline{\eta}(t) = \sum_{k=1}^{2N} b_k \exp(i\lambda_k \omega t)\underline{w}^{(k)}, \tag{56}$$

where the $2N$ constants b_k are arbitrary [to be determined, in the context of the initial-value problem, from the $2N$ initial data $\eta_n(0)$ and $\dot{\eta}_n(0)$], while the $2N$ numbers λ_k, respectively, the corresponding N-vectors $\underline{w}^{(k)}$, are the eigenvalues, respectively, the eigenvectors, of the following (generalized) matrix eigenvalue equation [see (54b)]:

$$-\lambda_k^2 \underline{w}^{(k)} - \lambda_k \underline{C}\,\underline{w}^{(k)} + \underline{L}\,\underline{w}^{(k)} = 0, \quad k = 1, \ldots, 2N. \tag{57}$$

Hence the numbers λ_k are the $2N$ roots of the following equation (polynomial of degree $2N$) in λ:

$$\det[\lambda^2 \underline{1} + \lambda \underline{C} - \underline{L}] = 0. \tag{58}$$

But obviously these numbers coincide with those defined above, see (50). We may therefore assert with certainty that they are *all* integers, and the Conjecture made above can now be reformulated to read

$$\det[\lambda^2 \underline{1} + \lambda \underline{C} - \underline{L}] = \prod_{k=1}^{N} [(\lambda - 2k)(\lambda + 2k - 1)]. \tag{59}$$

An even more explicit reformulation of this *diophantine* assertion can be made by taking advantage of the expressions (55) and noting that they entail that $\lambda = 2$ is certainly a root of (58) because the first line of the determinant of order N in the left-hand side of (58) and (59) is proportional to $\lambda - 2$. It reads [after factoring out the $(\lambda - 2)$ factor]

$$\begin{vmatrix} \lambda - 1 + N(N+1) & -1 & 0 & 0 & 0 & 0 & 0 & 0 \\ g_2 & f_2 & h_2 & 0 & 0 & 0 & 0 & 0 \\ g_3 & 0 & f_3 & h_3 & 0 & 0 & 0 & 0 \\ \vdots & \mathbf{0} & \mathbf{0} & \ddots & \ddots & \mathbf{0} & \mathbf{0} & \mathbf{0} \\ g_n & 0 & 0 & 0 & f_n & h_n & 0 & 0 \\ \vdots & \mathbf{0} & \mathbf{0} & \mathbf{0} & \mathbf{0} & \ddots & \ddots & \mathbf{0} \\ g_{N-1} & 0 & 0 & 0 & 0 & 0 & f_{N-1} & h_{N-1} \\ g_N & 0 & 0 & 0 & 0 & 0 & 0 & f_N \end{vmatrix} = \left[\prod_{k=2}^{N} (\lambda - 2k)\right]\left[\prod_{j=1}^{N} (\lambda + 2j - 1)\right] \tag{60a}$$

where

$$f_n = (\lambda - n + N)(\lambda - n - N - 1), \tag{60b}$$

$$g_n = \frac{(N+n)!}{(N-n)!n!}(\lambda - 1), \tag{60c}$$

$$h_n = n + 1 - \lambda. \tag{60d}$$

Examples of the (true) *diophantine* relations entailed, for increasing values of N, by this formula follow:

$$\begin{vmatrix} \lambda+5 & -1 \\ 12(\lambda-1) & \lambda(\lambda-5) \end{vmatrix} = (\lambda-4)(\lambda+1)(\lambda+3) = \lambda^3 - 13\lambda - 12, \tag{61}$$

$$\begin{vmatrix} \lambda+11 & -1 & 0 \\ 60(\lambda-1) & (\lambda+1)(\lambda-6) & 3-\lambda \\ 120(\lambda-1) & 0 & \lambda(\lambda-7) \end{vmatrix}$$
$$= (\lambda-4)(\lambda-6)(\lambda+1)(\lambda+3)(\lambda+5)$$
$$= (\lambda-7)(\lambda-6)\lambda(\lambda+1)(\lambda+11) + 60(\lambda-1)[(\lambda-7)\lambda + 2(\lambda-3)]$$
$$= (\lambda-7)(\lambda-6)\lambda(\lambda+1)(\lambda+11) + 60(\lambda-6)(\lambda-1)(\lambda+1)$$
$$= 120(\lambda-3)(\lambda-1) + (\lambda-7)\lambda[(\lambda-6)(\lambda+1)(\lambda+11) + 60(\lambda-1)]$$
$$= \lambda^5 - \lambda^4 - 43\lambda^3 + \lambda^2 + 402\lambda + 360, \tag{62}$$

$$\begin{vmatrix} \lambda+19 & -1 & 0 & 0 \\ 180(\lambda-1) & (\lambda+2)(\lambda-7) & 3-\lambda & 0 \\ 840(\lambda-1) & 0 & (\lambda+1)(\lambda-8) & 4-\lambda \\ 1680(\lambda-1) & 0 & 0 & \lambda(\lambda-9) \end{vmatrix}$$
$$= (\lambda-4)(\lambda-6)(\lambda-8)(\lambda+1)(\lambda+3)(\lambda+5)(\lambda+7)$$
$$= (\lambda-8)(\lambda+1)[(\lambda-9)(\lambda-7)\lambda(\lambda+2)(\lambda+19) - 60(\lambda-1)(3\lambda^2 - 13\lambda - 42)]$$
$$= (\lambda-4)[1680(\lambda-3)(\lambda-1) + (\lambda-9)\lambda(\lambda^4 + 11\lambda^3 + 9\lambda^2 - 179\lambda - 1522)]$$
$$= \lambda^7 - 2\lambda^6 - 98\lambda^5 + 100\lambda^4 + 2809\lambda^3 - 98\lambda^2 - 22\,872\lambda - 20\,160, \tag{63}$$

$$\begin{vmatrix} \lambda+29 & -1 & 0 & 0 & 0 \\ 420(\lambda-1) & (\lambda+3)(\lambda-8) & 3-\lambda & 0 & 0 \\ 3360(\lambda-1) & 0 & (\lambda+2)(\lambda-9) & 4-\lambda & 0 \\ 15\,120(\lambda-1) & 0 & 0 & (\lambda+1)(\lambda-10) & 5-\lambda \\ 30\,240(\lambda-1) & 0 & 0 & 0 & \lambda(\lambda-11) \end{vmatrix}$$
$$= (\lambda-4)(\lambda-6)(\lambda-8)(\lambda-10)(\lambda+1)(\lambda+3)(\lambda+5)(\lambda+7)(\lambda+9)$$
$$= (\lambda-10)(\lambda-8)(\lambda+1)(\lambda+3)[(\lambda-11)(\lambda-9)(\lambda+2)(\lambda+29) - 420(\lambda-1)\lambda(\lambda^2 - 5\lambda - 18)]$$
$$= (\lambda-4)[-30\,240(\lambda-5)(\lambda-3)(\lambda-1)$$
$$+ (\lambda-11)\lambda(\lambda^6 + 12\lambda^5 - 50\lambda^4 - 900\lambda^3 + 229\lambda^2 + 888\lambda + 120\,780)]$$
$$= \lambda^9 - 3\lambda^8 - 186\lambda^7 + 378\lambda^6 + 11\,529\lambda^5$$
$$- 11\,907\lambda^4 - 275\,584\lambda^3 + 11\,532\lambda^2 + 2\,078\,640\lambda + 1\,814\,400. \tag{64}$$

In these equations we also reported the expressions that are obtained when the determinants are computed by expanding via the first, or the last, line, which only contain two nonvanishing terms and yield relations that also have a nontrivial diophantine character.

The determinant appearing in the left-hand side of (60a) can be somewhat simplified, without changing its value, by performing the similarity transformation that corresponds to multiplying its element in the line n and the column m by the factor g_m/g_n, see (60c). Thereby (60) gets replaced by

$$\begin{vmatrix} \lambda-1+N(N+1) & -\frac{(N+2)(N-1)}{2} & 0 & 0 & 0 & 0 & 0 & 0 \\ N(N+1)(\lambda-1) & f_2 & \tilde{h}_2 & 0 & 0 & 0 & 0 & 0 \\ N(N+1)(\lambda-1) & 0 & f_3 & \tilde{h}_3 & 0 & 0 & 0 & 0 \\ \vdots & \mathbf{0} & \mathbf{0} & \ddots & \ddots & \mathbf{0} & \mathbf{0} & \mathbf{0} \\ N(N+1)(\lambda-1) & 0 & 0 & 0 & f_n & \tilde{h}_n & 0 & 0 \\ \vdots & \mathbf{0} & \mathbf{0} & \mathbf{0} & \mathbf{0} & \ddots & \ddots & \mathbf{0} \\ N(N+1)(\lambda-1) & 0 & 0 & 0 & 0 & 0 & f_{N-1} & \tilde{h}_{N-1} \\ N(N+1)(\lambda-1) & 0 & 0 & 0 & 0 & 0 & 0 & f_N \end{vmatrix} = \left[\prod_{k=2}^{N}(\lambda-2k)\right]\left[\prod_{j=1}^{N}(\lambda+2j-1)\right], \tag{65a}$$

where f_n is of course always defined by (60b) and

$$\tilde{h}_n = \frac{(N+n+1)(N-n)(n+1-\lambda)}{n+1}. \tag{65b}$$

Another version of this formula is obtained by subtracting, in the determinant which appears in the left-hand side of (65a), from every line (except the first two) the line above it,

$$\begin{vmatrix} \lambda-1+N(N+1) & -\frac{(N+2)(N-1)}{2} & 0 & 0 & 0 & 0 & 0 & 0 \\ N(N+1)(\lambda-1) & f_2 & \tilde{h}_2 & 0 & 0 & 0 & 0 & 0 \\ 0 & -f_2 & \tilde{f}_3 & \tilde{h}_3 & 0 & 0 & 0 & 0 \\ \mathbf{0} & \mathbf{0} & \ddots & \ddots & \ddots & \mathbf{0} & \mathbf{0} & \mathbf{0} \\ 0 & 0 & 0 & -f_{n-1} & \tilde{f}_n & \tilde{h}_n & 0 & 0 \\ \mathbf{0} & \mathbf{0} & \mathbf{0} & \mathbf{0} & \ddots & \ddots & \ddots & \mathbf{0} \\ 0 & 0 & 0 & 0 & 0 & -f_{N-2} & \tilde{f}_{N-1} & \tilde{h}_{N-1} \\ 0 & 0 & 0 & 0 & 0 & 0 & -f_{N-1} & \tilde{f}_N \end{vmatrix} = \left[\prod_{k=2}^{N}(\lambda-2k)\right]\left[\prod_{j=1}^{N}(\lambda+2j-1)\right], \tag{66a}$$

where f_n, respectively, $\tilde{h}_n$ continues of course to be defined by (60b), respectively, (65b) while

$$\tilde{f}_n = f_n - \tilde{h}_{n-1} = (\lambda-2n)\left(\lambda-n+\frac{N(N+1)}{n}\right). \tag{66b}$$

Since clearly [see (60b) and (66b)]

$$f_{N-1} = \tilde{f}_N = (\lambda+1)(\lambda-2N), \tag{66c}$$

we identify from this formulation, (66), two additional roots of the original determinant [in addition to $\lambda=2$, see (59)], namely $\lambda=-1$ and $\lambda=2N$, since the last line of the determinant in the left-hand side of (66a) vanishes for these values of λ, see (66c).

As example, let us exhibit (66) for $N=5$,

$$\begin{vmatrix} \lambda+29 & -14 & 0 & 0 & 0 \\ 30(\lambda-1) & (\lambda-8)(\lambda+3) & -8(\lambda-3) & 0 & 0 \\ 0 & -(\lambda-8)(\lambda+3) & (\lambda-6)(\lambda+7) & -\frac{9}{2}(\lambda-4) & 0 \\ 0 & 0 & -(\lambda-9)(\lambda+2) & (\lambda-8)\left(\lambda+\frac{7}{2}\right) & -2(\lambda-5) \\ 0 & 0 & 0 & -1 & 1 \end{vmatrix}$$
$$= (\lambda-4)(\lambda-6)(\lambda-8)(\lambda+3)(\lambda+5)(\lambda+7)(\lambda+9), \tag{67}$$

where we eliminated from the last line, and of course from the right-hand side, the factor $(\lambda-10)(\lambda+1)$.

Let us end this section by mentioning that an analogous discussion could be made for the *nonisochronous* cases (7) [namely, (10) with $\omega=0$] and (31) [namely, (38) with $\omega=0$]. In those cases *any* configuration is an equilibrium one, since particles with vanishing initial velocities do not move. But the mathematical implications of the behavior of these models near their equilibrium configuration are not so interesting: indeed a treatment analogous to that made above leads merely to the rather trivial identity

$$\begin{vmatrix} z+c_1 & -1 & 0 & 0 & 0 & 0 & 0 & 0 \\ c_2 & z & -1 & 0 & 0 & 0 & 0 & 0 \\ c_3 & 0 & z & -1 & 0 & 0 & 0 & 0 \\ \vdots & \mathbf{0} & \ddots & \ddots & \ddots & \mathbf{0} & \mathbf{0} & \mathbf{0} \\ c_n & 0 & 0 & 0 & z & -1 & 0 & 0 \\ \vdots & \mathbf{0} & \mathbf{0} & \mathbf{0} & \ddots & \ddots & \ddots & 0 \\ c_{N-1} & 0 & 0 & 0 & 0 & 0 & z & -1 \\ c_N & 0 & 0 & 0 & 0 & 0 & 0 & z \end{vmatrix} = z^N + \sum_{m=1}^{N} c_m z^{N-m}, \tag{68}$$

valid for any arbitrary set of N numbers c_n.

V. OUTLOOK

Recently, via an approach analogous to that described in Sec. III, a model remarkably similar to that considered in this paper has been investigated by Gomez-Ullate, Hone, and Sommacal.[21] The equations of motions of their model, in its "many-body problem" formulation, read

$$\ddot{z}_n = 2(1-N)z_n^3 + 2\sum_{m=1,m\neq n}^{N} \frac{\dot{z}_n\dot{z}_m + z_n^4}{z_n - z_m}, \tag{69}$$

and those of the model related to it via the approach of Sec. III read

$$\ddot{c}_m + (m+1)(m+2)c_{m+2} - 2c_2c_m = 0, \tag{70a}$$

with the "boundary conditions"

$$c_0 = 1, \quad c_{N+1} = 0. \tag{70b}$$

Via the simple change of dependent variables,

$$z_n = b\tilde{z}_n, \; b = \left(\frac{a}{1-N}\right)^{1/2}, \tag{71}$$

the equations of motion (69) can be recast in the form

$$\ddot{\tilde{z}}_n = 2a\tilde{z}_n^3 + 2\sum_{m=1,m\neq n}^{N} \frac{\dot{\tilde{z}}_n\dot{\tilde{z}}_m + b^2\tilde{z}_n^4}{\tilde{z}_n - \tilde{z}_m}, \tag{72}$$

demonstrating that they are indeed rather similar to (7). Likewise, via the simple change of dependent variables,

$$c_{2m} = \frac{(-a)^m \tilde{c}_m}{(2m)!}, \tag{73}$$

the evolution equations (70a) (with even m; note that they are decoupled from those for odd m) become

$$\ddot{\tilde{c}}_m - 2a\tilde{c}_{m+1} + 2a\tilde{c}_1\tilde{c}_m = 0, \tag{74}$$

which are remarkably similar to the evolution equations (31a). However, in contrast to the systems treated in this paper, (7) and (31), which are *solvable*, as explained above, for *all* values of the positive integer N, the systems (69) and (70), or equivalently (72) and (74), have been shown to be *solvable* only for $N<4$; moreover, for $N=3$ their solution generally involves transcendental (more precisely, elliptic) functions of the time variable, as well as algebraic functions of such elliptic functions (typically roots of N-degree polynomials the coefficients of which evolve in time as elliptic functions), in contrast to the solution of the models treated in this paper, which clearly only involve, for all values of N, algebraic functions of elementary (more precisely, exponential, or equivalently trigonometric) functions of the time variable [again, typically, via roots of N-degree polynomials the coefficients of which evolve exponentially, or equivalently trigonometrically, in the time variable, see (2a)].

APPENDIX

Let the two $N\otimes N$ matrices $\underline{X}$ and $\underline{D}$ be defined, in terms of the N, *a priori* arbitrary, numbers x_n, as follows:

$$\underline{X} = \mathrm{diag}[x_n],\ X_{nm} = \delta_{nm}x_n, \tag{A1}$$

$$D_{nm} = \delta_{nm}d_n + (1-\delta_{nm})(x_n - x_m)^{-1}, \tag{A2a}$$

$$d_n = \sum_{\ell=1,\ell\neq n}^{N} (x_n - x_\ell)^{-1}. \tag{A2b}$$

[Beware, this nondiagonal matrix $\underline{D}$ has nothing to do with the diagonal matrix D of Sec. II, see (18)–(20).] It is then known [see Eq. (2.4.1–5d) of Ref. 14] that

$$(\underline{D}^2)_{nm} = \delta_{nm}\left[d_n^2 - \sum_{\ell=1,\ell\neq n}^{N} (x_n - x_\ell)^{-2}\right] + (1-\delta_{nm})2[d_n(x_n - x_m)^{-1} - (x_n - x_m)^{-2}], \tag{A3}$$

and that the following result (Corollary 2.4.1–3 of Ref. 14) holds: *if for the differential operator*

$$\hat{A} = \sum_k a_k(x)\left(\frac{d}{dx}\right)^k \tag{A4a}$$

there holds the equation

$$\hat{A}f(x) = 0 \tag{A4b}$$

with $f(x)$ a polynomial in x of degree less than N, then the $N\otimes N$ matrix

$$\underline{A} = \sum_k a_k(\underline{X})\underline{D}^k \tag{A5a}$$

has vanishing determinant,

$$\det[\underline{A}] = 0. \tag{A5b}$$

Assume now that the N numbers x_n coincide with the N zeros of the generalized Laguerre polynomial $L_N^{(-2N-1)}(x)$. There holds then the following relations:

$$d_n = \frac{1}{2} + \frac{N}{x_n}, \tag{A6a}$$

$$x_n^2 \sum_{\ell=1,\ell\neq n}^{N} (x_n - x_\ell)^{-2} = -\frac{1}{12}(x_n^2 + 4N^2 - 8N), \tag{A6b}$$

$$\sum_{\ell=1,\ell\neq n}^{N} x_\ell^2 (x_n - x_\ell)^{-2} = -\frac{1}{12}(x_n^2 + 12x_n + 4N^2 + 4N + 12) \tag{A6c}$$

[the first coincides with (41b) via (A2b), the second and third can be easily obtained from the first, or, more directly, from Eq. (4.2c) of Ref. 1, via (41a) and (41b)].

Using these formulas we see [from (47a), via (A1), (A2), and (A6a)] that

$$\underline{\Gamma} = 2\underline{X}\underline{D} - \underline{X} - (1+2N)\underline{1}, \tag{A7}$$

and likewise [from (47b), via (A1), (A2), and (A6)] that

$$\underline{\Lambda} = -\underline{X}^2\underline{D}^2 + (\underline{X} + 2N)\underline{X}\underline{D} - N\underline{X}. \tag{A8}$$

Hence (50) reads now

$$\det\{\underline{X}^2\underline{D}^2 - [\underline{X} + 2(N-\lambda)]\underline{X}\underline{D} + (N-\lambda)\underline{X} + [\lambda^2 - (1+2N)\lambda]\underline{1}\} = 0. \tag{A9}$$

Therefore if, for some value of λ, the ODE

$$x^2 f''(x) - [x + 2(N-\lambda)]xf'(x) + [(N-\lambda)x + \lambda^2 - (1+2N)\lambda]f(x) = 0 \tag{A10}$$

were satisfied by a polynomial in x of degree less than N, we could assert that that same value of λ satisfies the determinantal equation (A9). But unfortunately, as it can be easily shown, for no value of λ this ODE is satisfied by a polynomial of degree less than N [for certain values of λ it is satisfied by a polynomial $f(x)$ of degree no less than N; for instance for $N=1$ and $\lambda=0$ this equation is satisfied by the polynomial $f(x)=x+2$ of degree 1]. We must therefore conclude (much to our surprise) that this approach does not (seem to) allow us to prove the conjecture proffered above.

(Received 5 March 2004; accepted 19 July 2004; published 15 November 2004)

This paper aims at presenting the first steps towards a formulation of the Exact Renormalization Group Equation in the Hopf algebra setting of Connes and Kreimer. It mostly deals with some algebraic preliminaries allowing us to formulate perturbative renormalization within the theory of differential equations. The relation between renormalization, formulated as a change of boundary condition for a differential equation, and an algebraic Birkhoff decomposition for rooted trees is explicited. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1794366]

I. INTRODUCTION

During the last five decades, renormalization group theory has proven to be a major discovery in theoretical physics whose applications range from high energy physics, its original birthplace,[19] to statistical physics and dynamical systems, thanks to the work of Wilson.[16] Originally proposed as a computational device in quantum field theory allowing to compare physical theories defined at different energy scales, it finally turned out to have a deep conceptual significance. Indeed, it is known since more than twenty years that renormalization group arguments allow to define the theory in the sense that one can construct a finite renormalized quantum field theory by asking it to fulfil a differential equation known as the Exact Renormalization Group Equation.[20]

On the other side, renormalization recently triggered a couple of mathematical works[4] that focused on algebraic aspects of the subtraction procedure and of the resulting renormalization group invariance. While these works mostly focus on the BPHZ procedure formulated within the minimal subtraction procedure in dimensional regularization (see, for instance, Ref. 17 for an application to the renormalization of the wave function), it is obvious that the framework proposed by Connes and Kreimer is versatile enough to encompass the ERGE.

This paper aims at presenting the first steps towards a formulation of the ERGE in the Hopf algebra setting. It mostly deals with some algebraic preliminaries allowing to formulate perturbative renormalization within the theory of differential equations.

In the first part, we present some general results on rooted trees and their interpretation as a coefficients of formal power series of nonlinear operators, in analogy with the theory developed in numerical analysis under the name of B-series.[2,10] In the second part, we explicit the relation between renormalization, formulated as a change of boundary condition for a differential equation, and an algebraic Birkhoff decomposition for rooted trees.

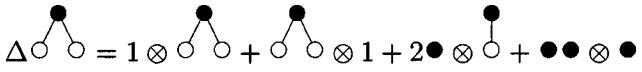

FIG. 1. Example of coproduct.

While this paper mostly presents some elementary facts, a more thorough survey involving the precise relation between trees and Feynman diagrams and their use as computational tools for effective actions will be the subject of a forthcoming publication.

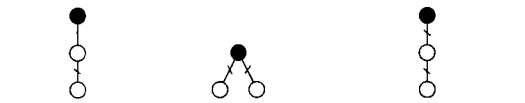
II. TREES AND POWER SERIES OF NONLINEAR OPERATORS

This section presents the algebraic tools for the interpretation of the continuous renormalization group in term of Birkhoff decomposition. We introduce the well-known Hopf algebra H of rooted trees to generate formal power series of (nonlinear) operators. Recalling the isomorphism between the group of characters of H and series with nonzero constant term, we focus on two particular series: The geometrical series $f_{\phi_1}[X]$ and the exponential series $f_{\phi_e}[X]$.

A. The Hopf algebra of rooted trees

Most of the material is detailed in Refs. 9 and 7 and refers to the original work Ref. 4. A rooted tree is a distinguished vertex, the *root*, together with a set of vertices and nonintersecting oriented lines. Any vertex has one and only one incoming line, except the root which has only outgoing lines. The *fertility* of a vertex is the number of its outgoing lines, its *length* is the number of lines of the (unique) path that joins it to the root. Two rooted trees are isomorphic if the number of vertices with given length and fertility is the same for all possible choices of lengths and fertilities. Symbols T, one for each isomorphism class, together with a unit 1 corresponding to the empty tree generate a complex commutative algebra H with disjoint union as a product.

A *simple cut* c of a tree T is a (nonempty) subset of its lines (selected for deletions) such that the path from the root to any other vertex includes at most one line of c. Deleting the cut lines produces $\mathrm{Card}(c)+1$ subtrees: The *trunk* $R_c(T)$ which contains the original root and the set $P_c(T)$ of the pruned branches. The set of simple cuts of T is written $C(T)$.



Definition II.1: H is a Hopf algebra with counit $\epsilon=0$ *except* $\epsilon(1)=1$, *the antipode*

$$S: \quad \bullet \mapsto \quad -\bullet$$

$$T \mapsto \quad -T - \sum_{c\in C(T)} - S(P_c(T))R_c(T) \tag{1}$$

and the coproduct

$$\Delta(T) = T\otimes 1 + 1\otimes T + \sum_{c\in C(T)} P_c(T)\otimes R_c(T), \quad \Delta(1) = 1\otimes 1. \tag{2}$$

(See Fig. 1.)

Among the common quantities associated to a tree T, we use the *symmetry factor* S_T which is the number of isomorphic trees that can be generated by permutation of the branches, the number of vertices $|T|$ (including the root) and the *depth* which is the maximum length of the vertices of T. The number of vertices is a natural graduation which makes H a graded connected Hopf algebra.[15]

The dual H^* (i.e., the set of linear applications from an Hopf algebra H to $\mathbb{C}$) is an algebra with the convolution product $*$

$$f * g(a) \doteq \langle f \otimes g, \Delta a \rangle, \tag{3}$$

for $f, g \in H^*, a \in H$ and $\langle , \rangle$ the duality pairing. For those f in H^* for which the transposition of the multiplication m of H takes its values in $H^* \otimes H^*$, one writes $\Delta(f) \doteq {}^t m(f)$, i.e.,

$$\Delta f(a \otimes b) = f(ab) \; \forall \; a, b \in H. \tag{4}$$

A *derivation* is an element δ of H^* satisfying

$$\Delta \delta = \delta \otimes \epsilon + \epsilon \otimes \delta. \tag{5}$$

The algebra generated by the derivations and ϵ is an Hopf algebra[15] H_* for the product (3) and coproduct (4) (antipode, unit and counit are obtained by transposition of antipode and unit of H). A *character* ϕ (algebra morphism from H to $\mathbb{C}$) is a grouplike element of H_*

$$\Delta \phi = \phi \otimes \phi. \tag{6}$$

Characters with product (3) and unity ϵ form a group G. The inverse is given by the antipode

$$\phi^{-1} = \phi \circ S. \tag{7}$$

When H is graded, with degree $|.|$, derivations are called *infinitesimal characters* because

$$e^{\delta} \doteq \sum_{n=0}^{+\infty} \frac{\delta^n}{n!} \tag{8}$$

(well defined since $\delta^n(a)$ vanishes as soon as $n > |a|$) is grouplike.[9] The correspondence between characters and infinitesimal characters is one to one:

$$\ln \phi \doteq \sum_{n=1}^{+\infty} \frac{(-1)^{n-1}}{n} (\phi - \epsilon)^n, \phi \in G, \tag{9}$$

is a derivation satisfying $e^{\ln \phi} = \phi$. [Identify

$$\Delta(\ln \phi) = \sum_{n=1,p=0}^{n=+\infty,p=n} \frac{(-1)^{p+1}}{n} C_p^n \phi^p \otimes \phi^p \quad \text{to } \ln xy = \sum_{n=1,p=0}^{n=+\infty,p=n} \frac{(-1)^{p+1}}{n} C_p^n x^p y^p, \quad x, y \in \mathbb{R},$$

$$\ln \phi \otimes \epsilon + \epsilon \otimes \ln \phi = \sum_{n=1}^{+\infty} \frac{(-1)^{n-1}}{n} (\phi^n \otimes \epsilon + \epsilon \otimes \phi^n) \quad \text{to } \ln x + \ln y = \sum_{n=1}^{+\infty} \frac{(-1)^{n-1}}{n} (x^n + y^n).$$

Developing $e^{\ln \phi}(a)$ in $\tilde{\phi} \doteq \phi - \epsilon$, terms in $\tilde{\phi}^p$ cancel by combinatoric for $2 \leqslant p \leqslant |a|$. For $p > |a|, \tilde{\phi}^p(a)$ vanishes because for graded connected Hopf algebra[9] $\Delta(a) = a \otimes 1 + 1 \otimes a + \Sigma a' \otimes a''$ with $|a'|, |a''| < |a|$.] Similarly $\ln e^{\delta}$ coincides with δ. The set of infinitesimal characters is linearly spanned by derivations Z^T that cancel everywhere but on a given generator

$$Z^T(T') \doteq 0 \text{ for any } T' \neq T, \quad Z^T(T) \doteq 1, \quad Z^T(1) = 0. \tag{10}$$

B. Power series of operators

Let $\mathcal{E}$ be a Banach vector space with norm $\|.\|, \mathcal{S}(\mathcal{E})$ the set of smooth applications from $\mathcal{E}$ to $\mathcal{E}$ and $\mathcal{L}_n^s(\mathcal{E})$ the set of n-linear symmetric applications from $\mathcal{E}^n$ to $\mathcal{E}$. Take $X \in \mathcal{S}(\mathcal{E})$. For any $x \in \mathcal{E}$, there exists an infinite sequence of smooth

$$X_x^{[n]} \in \mathcal{L}_n^s(\mathcal{E}), \tag{11}$$

such that for any y in the neighborhood of x

$$X(x+y) = X(x) + X'_x(y) + \cdots + \frac{1}{n!}X_x^{[n]}(y,\ldots,y) + \mathcal{O}(\|y\|^{n+1}). \tag{12}$$

For instance when the norm is associated to real coordinates over a base e_μ, X is a collection of smooth functions X^μ with derivatives $X^\mu_{,\nu\ldots}$ and (summing on repeated indices)

$$X'_x(y) = X^\mu_{,\nu}(x)y^\nu e_\mu, \quad X''_x(y_1,y_2) \doteq X^\mu_{,\nu\rho}(x)y_1^\nu y_2^\rho e_\mu. \tag{13}$$

Here we intend to work with a coordinate free notation and we view $X^{[n]}$ as an element of $\mathcal{L}_n^s(\mathcal{S}(\mathcal{E}))$

$$X^{[n]}(X_1,X_2,\ldots,X_n): \quad \mathcal{E} \to \mathcal{E} \tag{14}$$

$$x \mapsto X_x^{[n]}(X_1(x),X_2(x),\ldots,X_n(x)). \tag{15}$$

One defines a formal power series in $\hbar$ by Taylor expanding X around the identity

$$X(x+\hbar Y(x)) = X(x) + \hbar X'(Y)(x) + \frac{\hbar^2}{2}X''(Y,Y)(x) + \cdots, \tag{16}$$

with $Y \in \mathcal{S}(\mathcal{E})$. When $Y=X$, (16) can be written in a nice graphic way by using rooted trees. Explicitly one defines

$$X^{\bullet} \doteq X \quad , \quad X^{\overset{\bullet}{\circ}} \doteq X'(X) \tag{17}$$

$$X^{\overset{\bullet}{\circ}\circ} \doteq \frac{1}{2}X''(X,X) \quad , \quad X^{\overset{\bullet}{\circ}\circ\circ} \doteq \frac{1}{3!}X'''(X,X,X) \tag{18}$$

so that (16) writes

$$X(\mathbb{I}+\hbar X) = X^{\bullet} + \hbar X^{\overset{\bullet}{\circ}} + \hbar^2 X^{\overset{\bullet}{\circ}\circ} + \hbar^3 X^{\overset{\bullet}{\circ}\circ\circ} + \ldots \tag{19}$$

Formally there is no reason to limit to trees of depth 1 and one associates to any T the operator recursively defined by

$$X^T \doteq \frac{1}{\prod \theta_i!}X^{[n]}(\underbrace{X^{T_1},X^{T_1},\ldots}_{\theta_1 \text{ times}},\underbrace{X^{T_2},\ldots}_{\theta_2 \text{ times}},\ldots,\underbrace{X^{T_m},\ldots}_{\theta_m \text{ times}}). \tag{20}$$

$$X^1 = \mathbb{I} \tag{21}$$

where the T_i's are the subtrees of T obtained by promoting as roots the vertices of T of length 1 and $n=\Sigma_{i=1}^m \theta_i$ is the fertility of the root of T. For instance

$$X^{\overset{\bullet}{\circ}\overset{\bullet}{\circ}\circ} = \frac{1}{8}X''(X'(X''(X,X)),X'(X''(X,X))). \tag{22}$$

Note that the numerical factor in X^T is $1/S_T$. In the following, we use the shorthand notation

$$X^T = \frac{1}{\prod \theta_i!} X^{[n]}(X_i^{\theta_i}). \tag{23}$$

When X is a linear operator, $X^T=0$ as soon as $n>1$. The following construction, inspired from the theory of Butcher group,[10] is mostly interesting for nonlinear operators and provide a generalization of Taylor expansion (19) by associating to any smooth X a formal power serie $f[X]$

$$f[X] \doteq \sum_T f_T X^T \hbar^{|T|}, \tag{24}$$

where f_T are complex numbers and the sum runs over all generators (including unit 1).

The set $\mathcal{G}$ of series with $f_1=1$ is in one to one correspondence with the characters of H. Moreover $\mathcal{G}$ with the composition of series

$$f \circ g[X] = \sum_T f_T X^T \left(\sum_{T'} g_{T'} X^{T'} \hbar^{|T'|} \right) \hbar^{|T|}, \tag{25}$$

is a group, isomorphic to G^{op}, the opposite of the group of characters of H. That $\mathcal{G}$ is a group is known from the theory of Butcher group. However, by using the Hopf algebraic structure of trees we present a proof of the isomorphism

$$G^{op} \sim \mathcal{G}, \tag{26}$$

that does not require to compute explicitly the coefficients of the product series (25), as this is done in Ref. 10 for instance. The main tool for our proof is a slight adaptation to our component free notation of Caley's relation[3] between differentials and trees. It appears indeed that the differentials of the X^T's are easily computed in a graphic way. In the simplest cases this is immediate from definition (20), for instance

$$X^{\bullet\prime}(X^{\curlywedge}) = X^{\curlyvee} \text{ and } X^{\bullet\prime\prime}(X^{\curlywedge}, X^{\curlywedge}) = 2X^{\curlywedge\!\curlywedge}. \tag{27}$$

The differentiation process consists in grafting on a tree as many trees as the order of derivation, with a suitable numerical ponderation reflecting the symmetry of the argument.

Lemma II.2: For any trees $T, T_1, \ldots, T_l$ and integers $\beta_1, \ldots \beta_l$

$$X^{T[k]}(\underbrace{X^{T_1}, X^{T_1}, \ldots}_{\beta_1 \text{ times}}, \ldots, \underbrace{X^{T_l}, X^{T_l}, \ldots}_{\beta_l \text{ times}}) = \prod \beta_i ! \sum_{\tilde{T}} n(\tilde{T}; T, \prod T_i^{\beta_i}) X^{\tilde{T}}, \tag{28}$$

where $k \doteq \Sigma_{i=1}^l \beta_i$ and $n(\tilde{T}; T, \Pi T_i^{\beta_i})$ is the number of simple cut c of $\tilde{T}$ such that

$$R_c(\tilde{T}) = T \text{ and } P_c(\tilde{T}) = \Pi T_i^{\beta_i}. \tag{29}$$

Proof: Let $X \in \mathcal{S}(\mathcal{E}), x \in \mathcal{E}$ and $y \doteq y_1 + \ldots + y_J$ in a neighborhood of x. For any collection $\{z_i\}_{i \in [1,n]}$ of elements of $\mathcal{E}$,

$$X_{x+y}^{[n]}(z_i) = \sum_{\beta=0}^{+\infty} \sum_{[\beta_j]=\beta} \frac{1}{\prod \beta_j!} X_x^{[n+\beta]}(y_j^{\beta_j}, z_i), \tag{30}$$

where the second sum runs on all the configurations of the β_j's such that $\Sigma_{i=1}^J \beta_j = \beta$ and we use notation similar as (23). This formula can be obtained by comparing

$$X(x+y+z) = X(x+y) + \sum_{n=1}^{+\infty} \sum_{[\alpha_i]=n} \frac{1}{\prod \alpha_i!} X^{[n]}_{x+y}(z_i^{\alpha_i}), \tag{31}$$

where $z=z_1+\cdots+z_n$ is in a neighborhood of $x+y$, to

$$X(x+y+z) = X(x) + \sum_{n=1}^{+\infty} \sum_{[\beta_j,\alpha_i]=n} \frac{1}{\prod \beta_j ! \prod \alpha_i!} X^{[n]}_{x}(y_j^{\beta_j}, z_i^{\alpha_i}). \tag{32}$$

Choosing all $\alpha_i=1$, the term $X^{[n]}_{x+y}(z_i)$ in (30) is identified to the sum of terms of (31) that are linear in each z_i. For instance

$$X'_{x+y_1+y_2}(z_1) = X'_x(z_1) + X''_x(z_1,y_1) + X''_x(z_1,y_2) + X'''_x(z_1,y_1,y_2) + \tfrac{1}{2}X'''_x(z_1,y_1,y_1) + \tfrac{1}{2}X'''_x(z_1,y_2,y_2) + \cdots.$$

Then

$$X^T(x+y) = \frac{1}{\prod \theta_i!} X^{[n]}_{x+y}(X_i^{\theta_i}(x+y)) \tag{33}$$

$$= \frac{1}{\prod \theta_i!} \sum_{\beta=0}^{+\infty} \sum_{[\beta_j]=\beta} \frac{1}{\prod \beta_j!} X^{[n+\beta]}_{x}(y_j^{\beta_j}, X_i^{\theta_i}(x+y)). \tag{34}$$

Inserting

$$X_i(x+y) = X_i(x) + \sum_{r=1}^{+\infty} \sum_{[\beta'_j]=r} \frac{1}{\prod \beta'_j!} X^{[r]}_{ix}(y_j^{\beta'_j}), \tag{35}$$

and choosing $\{y_j\}$ of cardinality $J=k$, one identifies $X_x^{T[k]}(y_j)$ as the terms of (34) linear in each y_j, namely those appearing with either β_j or $\beta'_j=1$. Explicitly, for a tree T with depth 1,

$$X^{T'}(X^{\tilde{T}_1}) = \frac{1}{n!} X^{[n+1]}_x(X^{\tilde{T}_1}, X^n) + \frac{1}{(n-1)!} X^{[n]}_x(X'(X^{\tilde{T}_1}), X^{n-1}) = \sum_{\tilde{T}} n(\tilde{T}; T, \tilde{T}_1) X^{\tilde{T}},$$

for any $\tilde{T}_1$. For instance, with notations (13)

$$X^{\bullet\!\!\diagup\!\!\diagdown'}(X^\bullet) = \tfrac{1}{2}(X^\mu_{,\nu\rho} X^\nu X^\rho)_{,\delta} X^\delta e_\mu = \tfrac{1}{2} X^\mu_{,\nu\rho\delta} X^\nu X^\rho X^\delta e_\mu + \tfrac{1}{2} X^\mu_{,\nu\rho} X^\nu_{,\delta} X^\rho X^\delta e_\mu + \tfrac{1}{2} X^\mu_{,\nu\rho} X^\nu X^\rho_{,\delta} X^\delta e_\mu \tag{36}$$

$$= 3X^{\bullet\!\!\diagup\!\!\diagdown} + X^{\bullet\!\!\diagup\!\!\diagdown\!\!\diagup} \tag{37}$$

Similarly for any k and distinct T_j's one obtains

$$X^{T[k]}(X^{\tilde{T}_1}, \ldots, X^{\tilde{T}_k}) = \sum_{\tilde{T}} n(\tilde{T}; T, \Pi\tilde{T}_j) X^{\tilde{T}}. \tag{38}$$

When some of the $\tilde{T}_j$'s are identic, the extra factor $1/\beta_j!$ is absorbed by the definition of $\tilde{T}$ but such terms have to be identified as part of

$$\frac{1}{\beta_j!} X^{T[\beta_j]}(\tilde{X}_j^{\beta_j}). \tag{39}$$

Hence the lemma for any T of depth 1. The final result is obtained recursively on the depth of T.■

Proposition II.3: $\mathcal{G}$ is a group, isomorphic to G^{op}.

Proof: Since $\mathcal{G}$ is in bijection with G, we just have to show that

$$\sum_T \phi(T) X^T \left(\sum_{T'} \psi(T') X^{T'} \hbar^{|T'|} \right) \hbar^{|T|} = \sum_T (\psi * \phi)(T) X^T \hbar^{|T|}, \tag{40}$$

for any $\phi, \psi \in G$. In the l.h.s. ϕ is evaluated on generators only. By (2) and (3) one checks that the same is true for the r.h.s. Moreover both sides are linear in ϕ so this is enough to work with the infinitesimal character

$$\phi = Z^{T_0}, \tag{41}$$

for a fixed T_0. Note that a similar simplification is not available for ψ since $P_c(T)$ may not be a single generator. Then r.h.s. of (40) reduces to

$$X^{T_0} \hbar^{|T_0|} + \sum_T \sum_{c \in \tilde{C}(T)} \psi(P_c(T)) X^T \hbar^{|T|}, \tag{42}$$

where $\tilde{C}(T)$ is the set of simple cuts of T such that $R_c(T) = T_0$. The l.h.s. of (40) developed thanks to (19) writes

$$X^{T_0} \hbar^{|T_0|} + \sum_{T_1} \psi(T_1) X^{T_0{}'}(X^{T_1}) \hbar^{|T_0|+|T_1|} + \cdots + \sum_{\{T_i^{\beta_i}\}} \frac{\Pi \psi(T_i)^{\beta_i}}{\Pi \beta_i!} X^{T_0{}^{[n]}}(T_i^{\beta_i}) \hbar^{\Sigma_i |T_i|} + \cdots, \tag{43}$$

where sums run over generators distinct from 1 and we use a similar notation as in (23). Thanks to lemma II.2, (43) = (42). ■

Thanks to this isomorphism one can easily compute some interesting series. Let us write

$$f_\phi[X], \tag{44}$$

the formal power series associated to a character ϕ by the isomorphism II.3. We define the *exponential series* as the one corresponding to the character

$$\phi_e \doteq e^{Z \bullet}, \tag{45}$$

defined by (8) and (10). Since (see Ref. 4 for the definition of the factorial $T!$ of a tree)

$$\phi_e(T) = \frac{1}{T!}, \tag{46}$$

the exponential series writes

$$f_{\phi_e}[X] = \sum_T \frac{1}{T!} \hbar^{|T|} X^T. \tag{47}$$

Another nice example is the *geometrical series*

$$(\mathbb{I} - \hbar X)^{-1} = f_{\phi_1}[X] = \sum_T \hbar^{|T|} X^T, \tag{48}$$

obtained by noting that the constant character

$$\phi_1 : T \mapsto 1 \quad \forall\, T, \tag{49}$$

is the inverse of the character $T \mapsto 0$ except $1 \mapsto 1, \bullet \mapsto -1$.

III. FIXED POINT EQUATION AND ALGEBRAIC BIRKHOFF DECOMPOSITION

The geometrical and exponential series (47) and (48) are interesting to solve a fixed point equation. In particular if we view a fixed point equation as the integral form of a differential

equation then the change of initial condition (corresponding to the change of the constant in the fixed point equation) is coded into the group G_2 of characters of the Hopf algebra of decorated rooted trees. Namely if $\phi \in G_2$ represents the solution for initial condition x_0 and $\phi_+ \in G_2$ corresponds to the solution for initial condition x_1, then the decomposition

$$\phi_+ = \phi_- * \phi, \tag{50}$$

turns out to define an *algebraic Birkhoff decomposition* (see definition III.1) similar as the one introduced by Connes and Kreimer in their seminal paper Ref. 4.

Using trees to solve fixed point and differential equations is at the heart of the theory of *B*-series (see Ref. 1 for a nice overview of such applications). However, to the knowledge of the authors, the interpretation in terms of Birkhoff decomposition is not found in the literature.

A. Change of initial conditions in fixed point equations

Let us start by the fixed point equation

$$x = x_0 + \hbar X(x), \tag{51}$$

where $X \in \mathcal{S}(\mathcal{E})$, $\hbar$ is small and $x_0 \in \mathcal{E}$. (51) is formally solved by writing

$$x = (\mathbb{I} - \hbar X)^{-1}(x_0), \tag{52}$$

that is to say, thanks to (48)

$$x = f_{\phi_1}[X](x_0) = \sum_T \hbar^{|T|} X^T(x_0). \tag{53}$$

This is the same series as the one found by recursively developing $x = x_0 + \hbar X(x_0 + \hbar X(X_0 + \cdots))$.

Consider now a curve $x : \mathbb{R} \to \mathcal{E}$ given by

$$x(t) = x_0 + \hbar \int_{t_0}^{t} X(x(u))du, \tag{54}$$

for some $X \in \mathcal{S}(\mathcal{E})$. This is the integral form of the differential equation

$$\frac{dx}{dt} = \hbar X(x), \quad x(t_0) = x_0. \tag{55}$$

By recursively developing

$$x(t) = x_0 + \hbar \int_{t_0}^{t} X\left(x_0 + \hbar \int_{t_0}^{t_1} X\left(x_0 + \int_{t_0}^{t_2} \cdots\right) dt_2\right) dt_1, \tag{56}$$

one finds[1]

$$x(t) = \sum_T \frac{1}{T!}(t - t_0)^{|T|} \hbar^{|T|} X^T(x_0), \tag{57}$$

that is to say, according to (47)

$$x(t) = f_{\phi_e}[X_0](x_0), \tag{58}$$

where

$$X_0 \doteq (t - t_0)X. \tag{59}$$

One may be tempted to solve (55) formally by writing

$$x(t) = e^{\hbar X_0}(x_0). \tag{60}$$

The genuine definition of the exponential of an operator ($\exp(X) = \mathbb{I} + X + (1/2)X \circ X + \cdots$) is not compatible with (58). However, *defining*

$$e^{\hbar X_0} \doteq f_{\phi_e}[X_0], \tag{61}$$

ensures that (58) equals (60). In other terms rooted trees provide a definition of the exponential of a (nonlinear) operator which is compatible with the resolution of fixed point equations.

The same differential equation can be directly solved in its integral form (54) by considering the Banach vector space $\mathcal{E}'$ of curves in $\mathcal{E}$ and the operator $\chi \in \mathcal{S}(\mathcal{E}')$ defined by

$$\chi(x):t \mapsto \int_{t_0}^{t} X(x(u))du. \tag{62}$$

Considering x_0 as the curve $t \mapsto x_0$, (54) reads as the fixed point equation

$$x = x_0 + \hbar\chi(x), \tag{63}$$

whose formal solution is given by (53)

$$x = (\mathbb{I} - \hbar\chi)^{-1}(x_0) = f_{\phi_1}[\chi](x_0). \tag{64}$$

Trees are especially useful to deal with change of initial condition. Let us fix

$$x(t_1) = x_1, \tag{65}$$

for a given $x_1 \in \mathcal{E}$ and $t_1 \neq t$. Solution (58) becomes

$$x(t) = f_{\phi_e}[X_1](x_1), \tag{66}$$

where

$$X_1 \doteq (t - t_1)X. \tag{67}$$

In order to keep a trace of the solution with an initial condition at t_0, let us write (66) for $t = t_0$,

$$x_0 = f_{\phi_e}[X_1 - X_0](x_1), \tag{68}$$

which, inserted into (58)

$$x(t) = f_{\phi_e}[X_0] \circ f_{\phi_e}[X_1 - X_0](x_1), \tag{69}$$

and compared to (66) yields

$$f_{\phi_e}[X_1] = f_{\phi_e}[X_0] \circ f_{\phi_e}[X_1 - X_0]. \tag{70}$$

A similar decomposition can be found for the integral form (54) of the differential equation. The solution for initial condition (67) is

$$x = f_{\phi_1}[\zeta](x_1), \tag{71}$$

with

$$\zeta(x):t \mapsto \int_{t_1}^{t} X(x(u))du. \tag{72}$$

Factorizing

$$(\mathbb{I} - \hbar\zeta)^{-1} = (\mathbb{I} - \hbar\chi)^{-1} \circ (\mathbb{I} - \hbar\xi)^{-1} \tag{73}$$

where we define

$$\hbar\xi \doteq \mathbb{I} - (\mathbb{I} - \hbar\zeta) \circ (\mathbb{I} - \hbar\chi)^{-1}, \tag{74}$$

yields by (48)

$$f_{\phi_1}[\zeta] = f_{\phi_1}[\chi] \circ f_{\phi_1}[\xi]. \tag{75}$$

Both (70) and (75) involves a unique character ϕ_1 or ϕ_e and three distinct operators χ, ζ, ξ, or $X_0, X_1, X_1 - X_0$. To fix notations we now focus on the decomposition of geometrical series (75) but the following is also true for exponential series. In order to take advantage of the isomorphism (26) one needs a series involving the same operator. This can be obtained by considering the group G_2 of characters of the Hopf algebra H_2 of *decorated rooted trees*, i.e., trees whose vertices carry a decoration chosen in a set of cardinality two, in our case of interest either a bullet or a square. To any generator $\mathcal{T}$ of H_2, one associates $Y^{\mathcal{T}} \in \mathcal{S}(\mathcal{E}')$ defined in a similar manner as in (20) with the extra rule that bullets are associated to ξ and squares to ζ. For instance

$$Y^{\blacksquare} = \zeta, \quad Y^{\bullet} = \xi, \tag{76}$$

$$Y^{\begin{smallmatrix}\blacksquare\\ \diagup\ \diagdown\\ \bullet\quad\bullet\end{smallmatrix}} = \zeta''(\xi, \xi). \tag{77}$$

Let $\mathcal{G}_2$ be the group of power series $\mathbb{I} + \Sigma_{\mathcal{T}} f_{\mathcal{T}} Y^{\mathcal{T}}$. A straightforward adaptation of proposition II.3 shows that

$$\mathcal{G}_2 \, G_2^{op}. \tag{78}$$

Let us define two characters of H_2

$$\phi_-(\mathcal{T}) \doteq \begin{cases} \phi_1(\mathcal{T}) \text{ if } \mathcal{T} \in H_{\bullet} \\ 0 \text{ if } \mathcal{T} \notin H_{\bullet}, \end{cases} \qquad \phi_+(\mathcal{T}) \doteq \begin{cases} \phi_1(\mathcal{T}) \text{ if } \mathcal{T} \in H_{\blacksquare} \\ 0 \text{ if } \mathcal{T} \notin H_{\blacksquare}, \end{cases} \tag{79}$$

where $H_{\bullet}$ is the set of trees decorated with bullets only and $H_{\blacksquare}$ those decorated by square only. Then

$$f_{\phi_1}[\zeta] = f_{\phi_+}[Y], \quad f_{\phi_1}[\xi] = f_{\phi_-}[Y], \tag{80}$$

are both elements of G_2^{op}. By (75) and (78)

$$f_{\phi_1}[\chi] = f_{\phi}[Y], \tag{81}$$

for the character $\phi \in G_2$ given by (remembering (49), ϕ_-^{-1} vanishes on all generators of H_2 except $\phi_-^{-1}(1) = 1, \phi_-^{-1}(\bullet) = -1$; by (3) one obtains

$$\phi(\mathcal{T}) = \begin{cases} 1 & \text{for } \mathcal{T} \in H_{\blacksquare} \\ -1 & \text{for } \mathcal{T} = \bullet \\ -n_{\mathcal{T}} & \text{otherwise,} \end{cases} \tag{82}$$

where $n_{\mathcal{T}} = 1$ if there is a simple cut such that $R_c(\mathcal{T}) \in H_{\blacksquare}$ and $P_c(\mathcal{T}) = \bullet, n_{\mathcal{T}} = 0$ otherwise)

$$\phi = \phi_-^{-1} * \phi_+. \tag{83}$$

(75) can be written with a unique operator Y and three characters

$$f_{\phi_+}[Y] = f_\phi \circ f_{\phi_-}[Y]. \tag{84}$$

(70) can be written as well, by associating bullet to $X_1 - X_0$, square to X_1 and defining $\phi_\pm$ according to ϕ_e instead of ϕ_1.

(83) is the announced equation (50), establishing that the change of initial condition in a fixed point equation is coded into the group of characters of the algebra of decorated rooted trees. In next section, we show that (83) [or equivalently (84) by identifying characters and series] allows to define a so-called algebraic Birkhoff decomposition.

B. Algebraic Birkhoff decomposition

A decomposition of the same kind as (83) appears in renormalization of quantum field theory with minimal subtraction scheme and dimensional regularization.[4] The bare theory gives rise to a loop

$$\gamma(z) \in G_F, \quad z \in \mathcal{C}, \tag{85}$$

where $\mathcal{C} \in \mathbb{C}$ is a small circle around the dimension D of space time and G_F is the group of characters of the Hopf algebra of Feynman diagrams H_F. The renormalized theory is the evaluation at $z=D$ of the holomorphic part γ_+ of the *Birkhoff decomposition* of γ. To give a similar interpretation to our decomposition (83), we need to adapt to rooted trees some of the tools of Ref. 4 initially developed for Feynman diagrams.

An important feature is the commutative algebra $\mathcal{A}$ of smooth functions meromorphic inside $\mathcal{C}$ with pole only at D. Also important are the subalgebras $\mathcal{A}_+ \subset \mathcal{A}$ of functions holomorphic inside $\mathcal{C}$, and $\mathcal{A}_- \subset \mathcal{A}$ the subalgebra of polynomial in $1/(z-D)$ without constant term. There exists a projection

$$p_-: \mathcal{A} \to \mathcal{A}_-, \tag{86}$$

parallel to $\mathcal{A}_+$, i.e.

$$\text{Ker } p_- = \mathcal{A}_+. \tag{87}$$

Feynman rules (ponderated by a suitable mass factor) yields an algebra homomorphism

$$U: H_F \to \mathcal{A}. \tag{88}$$

The counterterms are given by the algebra homomorphism

$$C(X) \doteq -p_-\Big(U(X) + \sum C(X')U(X'')\Big), \tag{89}$$

where

$$\Delta(X) = X \otimes 1 + 1 \otimes X + \sum X' \otimes X'', \quad X \in \tilde{H}_F \doteq \text{Ker } \epsilon, \tag{90}$$

while the renormalized theory is given by the homomorphism

$$R(X) = (C * U)(X). \tag{91}$$

One checks that

$$C(\tilde{H}_F) \subset \mathcal{A}_-, \quad R(\tilde{H}_F) \subset \mathcal{A}_+. \tag{92}$$

Equation (91) viewed as an equality between algebra homomorphisms

$$C * U = R, \tag{93}$$

is called the *algebraic Birkhoff decomposition* of U. Such a terminology is justified by considering the G_F-valued loops

$$\gamma(z) \doteq \chi_z \circ U, \quad \gamma_-(z) = \chi_z \circ C, \quad \gamma_+(z) = \chi_z \circ R, \tag{94}$$

where

$$\chi_z(f) \doteq f(z) \quad \forall f \in \mathcal{A}. \tag{95}$$

Indeed (91) indicates that

$$\gamma_+(z) = \gamma_-(z)\gamma(z) \quad \forall z \in \mathcal{C}, \tag{96}$$

for the pointwise product in G. One then shows that (96) is precisely the Birkhoff decomposition of γ. Namely, viewing $\mathcal{C}$ as a subset of the Riemann sphere $\mathbb{C}P_1$, γ_- extends to a G_F-valued holomorphic maps on $\mathcal{C}_-$ (the component of the complement of $\mathcal{C}$ containing ∞) with $\gamma_-(\infty)=0$ while γ_+ extends to G_F-valued holomorphic maps on $\mathcal{C}_+$ (the other component of the complement of $\mathcal{C}$). The reader is invited to consult Ref. 4 for a precise definition of the Birkhoff decomposition and its link to the Riemann–Hilbert problem. Let us simply recall that the replacement of γ by γ_+ is a natural principle to extract a finite value from the singular expression $\gamma(z)$.

The use of the algebra of meromorphic functions on $\mathcal{C}$ is intimately linked to dimensional regularization scheme. In the framework of the continuous renormalization group, there is no pole given by the dimension of space–time. However, given a decomposition of algebra homomorphisms such as (93), satisfying conditions (92), it still makes sense to talk of Birkhoff decomposition, but in the following algebraic sense (taken from Refs. 15 or 12).

Definition III.1: Let H be a commutative Hopf algebra, $\mathcal{A}$ a commutative algebra with a projection p_- on a subalgebra $\mathcal{A}_-$. An algebra homomorphism $\gamma: H \to \mathcal{A}$ has an algebraic Birkhoff decomposition if there exists two algebras homomorphisms γ_+, γ_- from H to $\mathcal{A}$ such that

$$\gamma_+ = \gamma_- * \gamma, \tag{97}$$

where $*$ is the convolution product (3) *and*

$$p_+\gamma_+ = \gamma_+, \quad p_-\gamma_- = \gamma_-, \tag{98}$$

where p_+ is the projection on

$$\mathcal{A}_+ = \mathrm{Ker}\, p_-. \tag{99}$$

To interpret (83) and (84) as an algebraic Birkhoff decomposition one may be first tempted to consider the algebra of polynomials in $Y^{\mathcal{T}}$ as the equivalent in the continuous renormalization framework of the meromorphic functions. As well characters may be understood as the equivalent of the homomorphisms defined by Feynman rules: In the same way that U, C, R map a Feynman diagram to a meromorphic function, characters map a decorated rooted tree to a monomial in $Y^{\mathcal{T}}$,

$$\Phi(\mathcal{T}) \doteq \phi(\mathcal{T})Y^{\mathcal{T}}, \quad \Phi_\pm(\mathcal{T}) \doteq \phi_\pm(\mathcal{T})Y^{\mathcal{T}}. \tag{100}$$

Unfortunately $\Phi, \Phi_\pm$ do not define an algebraic Birkhoff decomposition. For instance (see the proof of proposition III.2 for the computation of ϕ)

$$\Phi_+(\ \bullet^{\,1}\ ) \ = \ 0 \tag{101}$$

$$(\Phi_- * \Phi)(\ \blacksquare\!\!\circ\ ) \ = \ \langle \Phi_- \otimes \Phi, 1 \otimes \ \blacksquare\!\!\circ\ + \ \blacksquare\!\!\circ\ \otimes 1 + \bullet \otimes \blacksquare \rangle \tag{102}$$

$$= \ -Y \ \blacksquare\!\!\circ\ + Y^{\circ} Y^{\blacksquare}. \tag{103}$$

A solution would be to define the product of monomials so that (103) vanishes,

$$Y^{\blacksquare} Y^{\circ} = Y \ \blacksquare\!\!\circ \tag{104}$$

but such a product would not be commutative. However, by considering the (commutative) formal product of decorations, it appears that the sum (ponderated by the numerical coefficient) of the products of decorations in (103) vanishes (i.e., $-\circ\blacksquare+\circ\blacksquare=0$). Consequently we propose a Birkhoff decomposition with value on the the algebra $\mathcal{A}$ of decorations, that is to say the free unital algebra generated by square and bullet

$$\mathcal{A} = \overline{\{1, \bullet, \blacksquare\}}. \tag{105}$$

For $\mathcal{A}_-$ we choose the unital subalgebra of $\mathcal{A}$ generated by the bullet

$$\mathcal{A}_- = \overline{\{1, \bullet\}}. \tag{106}$$

We note p_- the projection $\mathcal{A} \to \mathcal{A}_-$

$$p_-(1) = 1, \quad p_-(\bullet) = \bullet, \quad p_-(\blacksquare) = 0, \tag{107}$$

extended to all $\mathcal{A}$ by algebra homomorphism

$$p_-(\bullet^n \blacksquare^m + \bullet^{n'} \blacksquare^{m'}) = \bullet^n + \bullet^{n'}. \tag{108}$$

$\mathcal{A}_+$ and p_+ are defined by (99). Let Γ be the algebra homorphism $H_2 \to \mathcal{A}$

$$\Gamma(1) = 1, \quad \Gamma(\mathcal{T}) = \bullet^{|\mathcal{T}|_\circ} \blacksquare^{|\mathcal{T}|_\square} \tag{109}$$

where $|\mathcal{T}|_\circ$ is the number of bullets of $\mathcal{T}$ and $|\mathcal{T}|_\square$ is the number of squares. Γ just "counts the decorations," for instance

$$\Gamma(\ \blacksquare\!\!\circ\!\!\circ\ ) = \bullet^3 \blacksquare. \tag{110}$$

Finally we define three algebra homomorphisms from H_2 to $\mathcal{A}$,

$$\gamma(\mathcal{T}) = \phi(T)\Gamma(T), \quad \gamma_\pm(\mathcal{T}) = \phi_\pm(T)\Gamma(T). \tag{111}$$

Proposition III.2: $\gamma_+ = \gamma_- * \gamma$ is an algebraic Birkhoff decomposition.

Proof: Let $\overline{H_\bullet}$ be the algebra of trees with bullets only (and similarly $\overline{H_\blacksquare}$). Then

$$\gamma_-(\mathcal{T}) = \begin{cases} \bullet^{|\mathcal{T}|_\circ} & \text{for } \mathcal{T} \in \overline{H_\bullet} \\ 0 & \text{otherwise}, \end{cases} \qquad \gamma_+(\mathcal{T}) = \begin{cases} \blacksquare^{|\mathcal{T}|_\square} & \text{for } \mathcal{T} \in \overline{H_\blacksquare} \\ 0 & \text{otherwise}, \end{cases} \tag{112}$$

so that (98) is satisfied, as well as (99) by construction. By algebra homomorphism, (97) has to be checked only on generators. Let us first note that

$$\gamma(\mathcal{T}) = \begin{cases} \blacksquare^{|\mathcal{T}|_\square} & \text{for } \mathcal{T} \in H_\blacksquare \\ -\bullet & \text{for } \mathcal{T} = \bullet \\ -n_{\mathcal{T}} \bullet^{|\mathcal{T}|_\circ} \blacksquare^{|\mathcal{T}|_\square} & \text{otherwise} \end{cases} \tag{113}$$

where $n_{\mathcal{T}}$ is defined in (82). Second, for any $\mathcal{T} \neq 1$

$$(\gamma_- * \gamma)(\mathcal{T}) = \gamma(\mathcal{T}) + \gamma_-(\mathcal{T}) + \sum_{c \in C(\mathcal{T})} \gamma_-(P_c(\mathcal{T}))\,\gamma(R_c(\mathcal{T})). \tag{114}$$

This is then not difficult to check (97) for $\mathcal{T} \in H_\bullet$ or $\mathcal{T} \in H_\blacksquare$.

For $\mathcal{T} \notin H_\bullet \cup H_\blacksquare$,

$$(\gamma_- * \gamma)(\mathcal{T}) = -\,n_{\mathcal{T}}\,\bullet^{|\mathcal{T}|_\bullet}\blacksquare^{|\mathcal{T}|_\square} + \sum_{c \in C(\mathcal{T})} \gamma_-(P_c(\mathcal{T}))\,\gamma(R_c(\mathcal{T})). \tag{115}$$

Assume $n_{\mathcal{T}}=0$. Then (115) is nonzero only if there is at least either a simple cut c such that

$$P_c(\mathcal{T}) \in \overline{H_\bullet} \text{ and } R_c(\mathcal{T}) \in H_\blacksquare, \tag{116}$$

or a simple cut $\tilde{c}$ with

$$P_{\tilde{c}}(\mathcal{T}) \in \overline{H_\bullet} \text{ and } n_{R_{\tilde{c}}(\mathcal{T})} \neq 0. \tag{117}$$

Assume there exists a simple cut c for which $P_c(\mathcal{T})$ is a single tree. Then there exist a $\tilde{c}$ in which $R_{\tilde{c}}(\mathcal{T})$ is the subtree of $\mathcal{T}$ consisting in $R_c(\mathcal{T})$ and the root of $P_c(\mathcal{T})$ while $P_{\tilde{c}}(\mathcal{T})$ is the union of all the subtrees of $P_c(\mathcal{T})$ obtained by promoting as roots the vertices of length 1 ($P_{\tilde{c}}(\mathcal{T}) \neq \emptyset$ because $n_{\mathcal{T}}=0$). The simple cut c contributes to (115) with a factor

$$\bullet^{|P_c(\mathcal{T})|}\blacksquare^{|R_c(\mathcal{T})|}, \tag{118}$$

whereas $\tilde{c}$ contributes with a factor

$$\bullet^{|P_{\tilde{c}}(\mathcal{T})|}(-\bullet\blacksquare^{|R_{\tilde{c}}(\mathcal{T})|_\square}). \tag{119}$$

This is easy to observe that (118) $=-$ (119). The same is true if $P_c(\mathcal{T})$ is a product of m trees, the only difference being that the contribution of c is canceled by the sum of the contributions of the m $\tilde{c}$ obtained by grafting alternatively to $R_c(\mathcal{T})$ each of the roots of $P_c(\mathcal{T})$. Also, starting from a $\tilde{c}$, one would similarly notice that its contribution is canceled by a c so that, finally, (115) vanishes for any $\mathcal{T} \notin H_\blacksquare \cup H_\bullet$ with $n_{\mathcal{T}}=0$. Hence (97).

The same procedure applies when $n_{\mathcal{T}} \neq 0$. The term of (115) in $\gamma(\mathcal{T})$ is cancelled by the sum of the $n_{\mathcal{T}}$ terms corresponding to the simple cuts with $P_c(\mathcal{T})=\bullet$. ■

As announced in (50), we have shown that the change of initial condition in a fixed point equation does correspond to the algebraic Birkhoff decomposition of the algebra morphisms associated by (111) to the characters encoding the solutions. By convention we say that γ_+ is the positive part of the algebraic $\mathcal{A}$-valued Birkhoff decomposition of γ.

C. Continuous renormalization group

Birkhoff decomposition has been introduced in renormalization of quantum field theory by Connes and Kreimer in the framework of minimal subtraction scheme and dimensional regularization. Our algebraic Birkhoff decomposition (83) has an interpretation in the framework of the continuous renormalization group of Wilson[23] (see also Ref. 18 for a nice introduction). The latest describes the evolution of the parameters of a quantum field theory under a change of the observation scale. When the rescaling is parametrized by a continuous quantity, say the energy, the evolution is governed by flow equation

$$\Lambda \frac{\partial}{\partial \Lambda} S = \beta(\Lambda, S), \tag{120}$$

in which $\Lambda \in \mathbb{R}^{*+}$ is the scale and $S=S(\Lambda)$ implements the parameters (mainly S is a functional of the fields and their coupling constants). The initial conditions are encoded by the knowledge of $S_0 \doteq S(\Lambda_0)$ at a given scale Λ_0. A typical example of continuous renormalization group equations (120) are Polchinski's equations[20] which gives $\beta(\Lambda, S)$ for a theory with an infrared (IR) cutoff.

Let us consider the most general context by simply assuming that the theory is described by a smooth operator S

$$S{:}\Lambda \mapsto S(\Lambda) \in \mathcal{E},$$

where $\mathcal{E} \doteq \mathcal{S}(\mathcal{H})$ and $\mathcal{H}$ is the (infinite dimensional) vector space spanned by vectors labeled with the parameters of the theory. A scale transformation

$$\Lambda \to \Lambda^s,$$

with $s \in \mathbb{R}^{*+}$ induces the transformation[14]

$$S(\Lambda) \to S(\Lambda^s) = s^{\Delta} S(\Lambda)$$

where $\Delta \in \mathcal{E}$ is the diagonal matrix whose coefficients are the dimensions of the parameters. We define the dimensionless quantities $x(\Lambda) \in \mathcal{E}$ and $t \in \mathbb{R}$,

$$S(\Lambda) = \Lambda^{\Delta} x(\Lambda), \quad t \doteq \ln\left(\frac{\Delta}{\mu}\right),$$

where μ is a parameter of the theory with same dimension as Λ. Then (120) yields

$$\Lambda \frac{\partial x}{\partial \Lambda} = -\Delta x + \Lambda^{-\Delta} \beta(\Lambda, \Lambda^{\Delta} x). \tag{121}$$

By dimensional analysis, β is transforming homogeneously under change of scale,

$$\beta(\Lambda, \Lambda^{\Delta} x) = \Lambda^{\Delta} \beta(1, x), \tag{122}$$

so that, writing $\hbar X(x) \doteq \beta(1, x)$ and $D = -\Delta$,

$$\frac{\partial x}{\partial t} = Dx + \hbar X(x), \tag{123}$$

whose integral form, with initial condition $x_0 = \Lambda_0^D S_0$, is

$$x(t) = e^{(t-t_0)D} x_0 + \hbar \int_{t_0}^{t} e^{(t-u)D} X(x(u)) du. \tag{124}$$

Viewing x as an element of $\mathcal{E}'$, Banach vector space of applications from $\mathbb{R}^{*+}$ to $\mathcal{E}$, we define

$$\tilde{x}_0 \in \mathcal{E}' : t \mapsto e^{(t-t_0)D} x_0, \tag{125}$$

and $\chi \in \mathcal{S}(\mathcal{E}')$,

$$\chi(x) : t \mapsto \int_{t_0}^{t} e^{(t-u)D} X(x(u)) du \quad \forall\, x \in \mathcal{E}' \tag{126}$$

so that (124) reads as the fixed point equation

$$x = \tilde{x}_0 + \hbar \chi(x). \tag{127}$$

In the context of Wilson's continuous renormalization group, Λ_0 is interpreted as an ultraviolet (UV) cutoff and one is interested in the limits of very high energy scale, i.e., $t_0 \to +\infty$. However $\tilde{x}_0$ is already ill-defined since

$$e^{(t-t_0)D}x_0 \begin{cases} \text{converges on } \mathcal{H}^+ \\ \text{is constantly zero on } \mathcal{H}^0 \\ \text{diverges on } \mathcal{H}^-, \end{cases} \quad \text{as } t_0 \to +\infty \tag{128}$$

where $\mathcal{H}^+, \mathcal{H}^0, \mathcal{H}^- \subset \mathcal{H}$ are the proper subspaces of D corresponding to positive, zero and negative eigenvalues (the corresponding parameters are called *relevant, marginal* and *irrelevant*). χ as well is ill defined, even in the relevant sector. A solution to ensure the finiteness of $x(t)$ at high scale consists in fixing the initial conditions for the irrelevant sector at scale t_1 (equivalently: At scale Λ_1) distinct from t_0. Namely one imposes the mixed boundary conditions

$$x_R \doteq P\tilde{x}_1 + (\mathbb{I} - P)\tilde{x}_0, \tag{129}$$

where P is the orthogonal projection from $\mathcal{H}$ to $\mathcal{H}^-$ and

$$\tilde{x}_1 \in \mathcal{E}' : t \mapsto e^{(t-t_1)D}x_1. \tag{130}$$

Defining

$$\rho(x) : t \mapsto \int_{t_1}^{t} e^{(t-u)D}X(x(u))du \tag{131}$$

and

$$\zeta \doteq P\rho + (\mathbb{I} - P)\chi, \tag{132}$$

allows us to write (127) with initial condition x_R

$$x(t) = x_R + \hbar\zeta(x). \tag{133}$$

This is a well-known result that $x(t)$ computed with mixed boundary condition, namely

$$x(t) = f_{\phi_1}[\zeta](x_R) \tag{134}$$

remains finite at high energy scale and does not depend on x_0. Trees have already been used to prove this result (see Refs. 11, 8, and 21, for instance). To be complete we propose here a simple proof taking advantage of the Hopf algebraic structure.

Proposition III.3: $\lim_{t_0 \to +\infty} f_{\phi_1}[\zeta](x_R)$ *is finite order by order and does not depend on* x_0.

Proof: The idea is to use decorated trees in a similar way as (76) except that the rule now is

$$Y^{\bullet} = \zeta_1 \doteq P_\rho, \quad Y^{\blacksquare} = \zeta_2 \doteq (\mathbb{I} - P)\chi. \tag{135}$$

Then

$$\zeta \; \overset{\bullet}{\circ} \; = \; (\zeta_1 + \zeta_2)'(\zeta_1 + \zeta_2) \tag{136}$$

$$= (\zeta_1)'(\zeta_1) + (\zeta_1)'(\zeta_2) + (\zeta_2)'(\zeta_1) + (\zeta_2)'(\zeta_2) \tag{137}$$

$$= \; Y \; \overset{\bullet}{\circ} \; + Y \; \overset{\bullet}{\square} \; + Y \; \overset{\blacksquare}{\circ} \; + Y \; \overset{\blacksquare}{\square} \tag{138}$$

$$= \sum_{\mathcal{T} \in \left\{ \begin{array}{c} \bullet \\ \circ \end{array} \right\}_2} Y^{\mathcal{T}} \tag{139}$$

where $\{T\}_2$ is the set of all decorated trees obtained by decoration of the vertices of $T \in H$, e.g.,

$$\{\bullet\}_2 = \{\bullet, \blacksquare\}. \tag{140}$$

It is not difficult to check that the same is true for any $T \in H$,

$$\zeta^T = \sum_{\mathcal{T} \in \{T\}_2} Y^{\mathcal{T}}. \tag{141}$$

Thus

$$f_{\phi_1}[\zeta] = \sum_{\mathcal{T} \in H_2} Y^{\mathcal{T}}. \tag{142}$$

Since

$$\lim_{t_0 \to +\infty} Y^1(x_R) = \lim_{t_0 \to +\infty} x_R = \tilde{x}_1, \tag{143}$$

and $Y^{\bullet}$ does not depend on t_0 then

$$\lim_{t_0 \to +\infty} Y^{\bullet}(x_R) = Y^{\bullet}(\tilde{x}_1). \tag{144}$$

Similarly for any $\mathcal{T} \in H_{\bullet}$, $\lim_{t_0 \to +\infty} Y^{\mathcal{T}}(x_R)$ is both x_0 and t_0 independent. In the same way

$$\lim_{t_0 \to +\infty} Y^{\blacksquare}(x_R) = \lim_{t_0 \to +\infty} (\mathbb{I} - P) \int_{t_0}^{t} e^{(t-u)D} X(\tilde{x}_1(u)) du, \tag{145}$$

is finite because X is smooth. Similarly for any $\mathcal{T} \in H_{\blacksquare}$. For $\mathcal{T}$ decorated with both bullets and squares, combination of (144) and (145) ensures that $Y^{\mathcal{T}}$ is finite and x_0 independent. ■

Now, using decorated rooted trees with the rule (76), one identifies $f_{\phi_1}[\zeta](x_R) = f_{\phi_+}[Y](x_R)$ as the renormalized theory, $f_{\phi_1}[\chi](x_R) = f_{\phi}[Y](x_R)$ as the bare theory and the counterterms are given by $f_{\phi_-}[Y](x_R)$. By proposition III.2 one finally obtains the main result of this paper:

The bare and renormalized theories define two algebra morphisms γ and γ_+ between the Hopf algebra of decorated rooted trees and the free algebra $\mathcal{A}$ of decorations. γ_+ is the positive part of the algebraic $\mathcal{A}$-valued Birkhoff decomposition of γ.

IV. OUTLOOK AND CONCLUSION

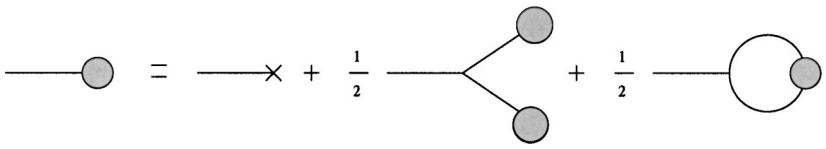
As a nice application for the tools developed above in the resolution of fixed point equation, let us mention Schwinger–Dyson equations. The latest (see Ref. 13 as well as Ref. 5 for a pedagogical account) form a system of nonlinear implicit functional differential equations analogous to the exact renormalization group equation in many respects. They are best formulated as an equation for the functional derivative of the connected generating functional $W[j]$

$$\left((\Box_x + m^2) \frac{\delta}{\delta J(x)} - V' \left(\frac{\delta}{\delta J(x)} \right) + J(x) \right) e^{W[J]} = 0, \tag{146}$$

for a Euclidian scalar field theory with interacting potential $V(\phi)$. In the simplest case of a $\lambda \phi^3$ theory, the equation reads

$$\frac{\delta W}{\delta J(x)} = \int dy\ K(x,y)J(y) + \frac{\lambda}{2}\int dy\ K(x,y)\left(\frac{\delta W}{\delta J(y)}\right)^2 + \frac{\lambda}{2}\int dy\ K(x,y)\frac{\delta^2 W}{\delta J(y)^2}, \qquad (147)$$

where $K(x,y)$ is the kernel of the free propagator. They are best captured by a diagrammatic expression,



that can be used recursively to generate the full Feynamn diagram expansion. Beyond ordinary convention of QFT, note that the cross stands for an insertion of the source J.

For our purpose, it is rewritten as a fixed point equation for the classical field $\phi(x) = \delta W / \delta J(x)$

$$\phi = \phi_0 + \lambda\ F_1(\phi) + \lambda\ F_2(\phi), \qquad (148)$$

where ϕ_0 is the classical field in the absence of interaction. The functions F_i are in one-to-one correspondence with the diagrams appearing above. This equation can be solved perturbatively in powers of λ by a recursive procedure. The order n term can be easily expressed as a sum over trees with n vertices which are decorated with the 2 diagrams of (147). These are trees that are drawn on the Feynman diagram and that retrace the ways a given Feynman diagram can be obtained through an iteration of the Schwinger–Dyson equations.

While the correspondence between Feynman diagrams and trees is in general complicated, if one restricts to the classical level, the Schwinger–Dyson degenerates because only F_1 survives. Accordingly, they reduce to the classical equation of motion so that the previous tree expansion is nothing but the tree level Feynman diagram expansion. Finally, a Legendre transformation from $W[j]$ to $\Gamma[\phi]$ allows to formulate an equation for $\delta\Gamma / \delta\phi(x)$.

A more precise treatment of Schwinger–Dyson equations within the Hopf algebraic framework of rooted trees will be developped in some future work. As a (temporary) conclusion, let us recall that we have presented the first algebraic steps towards an adaption of Connes–Kreimer work to the ERGE. As in the BPHZ procedure with minimal subtraction scheme in dimensional regularization, renormalized and bare theories are linked inside a Birkhoff decomposition. In the BPHZ framework, renormalization corresponds to the projection of meromorphic functions (with pole only at dimension of space time) on their holomorphic part. Continuous renormalization appears as a projection on one decoration. Whether the algebra of decorations is an artefact—hiding deeper connection with the Rieman–Hilbert problem—or is truly meaningful is not perfectly clear at the moment. Hopefully this might be clarified by revisiting our algebraic Birkhoff decomposition within the more general framework of Rota–Baxter equation (see Ref. 6 for nice and recent development on this topic).

Finally, it appears that the Birkhoff decomposition, which plays a major role in the theory of integrable systems, provides a relation between the latter and renormalization theory.[22] This could have important consequences for actual computations in renormalization by using the full power of complete integrability.

(Received 23 March 2004; accepted 2 September 2004; published 15 November 2004)

The exact computation of asymptotic quasinormal frequencies is a technical problem which involves the analytic continuation of a Schrödinger-type equation to the complex plane and then performing a method of monodromy matching at several poles in the plane. While this method was successfully used in asymptotically flat space–time, as applied to both the Schwarzschild and Reissner–Nordstrøm solutions, its extension to nonasymptotically flat space–times has not been achieved yet. In this work it is shown how to extend the method to this case, with the explicit analysis of Schwarzschild–de Sitter and large Schwarzschild–anti–de Sitter black holes, both in four dimensions. We obtain, for the first time, analytic expressions for the asymptotic quasinormal frequencies of these black hole space–times, and our results match previous numerical calculations with great accuracy. We also list some results concerning the general classification of asymptotic quasinormal frequencies in *d*-dimensional space–times. © *2004 American Institute of Physics.*

I. INTRODUCTION

A long time has passed since research first focused on analyzing the linear stability of four dimensional black hole solutions in general relativity.[1,2] However, it was not until very recent times that this stability problem was addressed within a *d*-dimensional setting.[3–5] These papers tried to be as exhaustive as possible, studying in detail the perturbation theory of spherically symmetric black holes in *d* dimensions and allowing for the possibilities of both charge and a background cosmological constant. Having thus acquired a list of stable black hole solutions, the next question to address within this problem are quasinormal modes—the damped oscillations which describe the return to the initial configuration, after the onset of a linear perturbation (see Refs. 6 and 7 for reviews).

Besides their natural role in the perturbation theory of general relativity, quasinormal modes have recently been the focus of much attention following suggestions that they could have a role to play in the quest for a theory of quantum gravity.[8,9] The idea is to look at those special modes

[a)]Electronic mail: vcardoso@fisica.ist.utl.pt
[b)]Electronic mail: jnatar@math.ist.utl.pt
[c)]Electronic mail: schiappa@math.ist.utl.pt

which are infinitely damped, and thus do not radiate. It was suggested in Ref. 8 that an application of Bohr's correspondence principle to these asymptotic quasinormal frequencies could yield new information about quantum gravity, in particular on the quantization of area at a black hole event horizon. It was further suggested in Ref. 9 that asymptotic quasinormal frequencies could help fix certain parameters in loop quantum gravity. Both these suggestions lie deeply on the fact that the real part of the asymptotic quasinormal frequencies is given by the logarithm of an integer number, a fact that was analytically shown to be true, for Schwarzschild black holes in d-dimensional space–time, in Refs. 10 and 11. A question of particular relevance that immediately follows is whether the suggestions in Refs. 8 and 9 are universal or are only applicable to the Schwarzschild solution. Given the mentioned analysis of Refs. 3 and 5, one has at hand all the required information to address this problem and compute asymptotic quasinormal frequencies of d-dimensional black holes. A preliminary clue is already present in Ref. 11, where the analysis of the four-dimensional Reissner–Nordstrøm solution yielded a negative answer: the asymptotic quasinormal frequencies obeyed a complicated relation which did not seem to have the required form. While extending this result to both the d-dimensional and the extremal Reissner–Nordstrøm solutions did not pose great obstacles,[12] an extension of the analytical techniques in Ref. 11 to nonasymptotically flat space–times proves to be a greater challenge. It is the goal of this paper to carry out an extension of the techniques in Ref. 11 to nonasymptotically flat space–times, with the explicit analysis of Schwarzschild–de Sitter and large Schwarzschild–anti–de Sitter black holes, both in four dimensions. The detailed study of these solutions in d-dimensions will appear elsewhere,[12] including charged solutions in asymptotically de Sitter and asymptotically anti–de Sitter space–times, as well as an analysis of the implications of our results on what concerns the proposals of Refs. 8 and 9, dealing with the application of quasinormal modes to quantum gravity.

It is important to stress that even if the ideas in Refs. 8 and 9 turn out not to be universal, it is still the case that quasinormal frequencies will most likely have a role to play in the quest for a theory of quantum gravity. Indeed, quasinormal frequencies can also be regarded as the poles in the black hole greybody factors which play a pivotal role in the study of Hawking radiation. Furthermore, the monodromy technique introduced in Ref. 11 to analytically compute asymptotic quasinormal frequencies was later extended, in Ref. 13, so that it can also be used in the computation of asymptotic greybody factors. It was first suggested in Ref. 13 that the results obtained for these asymptotic greybody factors could be of helpin identifying the dual conformal field theory which microscopically describes the black hole, and these ideas have been taken one step forward with the recent work of Ref. 14. It remains to be seen how much asymptotic quasinormal modes and greybody factors can help in understanding quantum gravity.

Let us conclude this introduction with some generics concerning quasinormal frequencies (we refer the reader to the upcoming[12] for a full list of conventions and details). Later, in Sec. II, we shall compute asymptotic quasinormal frequencies for a Schwarzschild–de Sitter black hole in four-dimensional space–time. Our results will also be shown to match earlier numerical computations with great accuracy. In Sec. III, we shall study large Schwarzschild–anti–de Sitter black holes in four dimensions, and analytically compute their asymptotic quasinormal frequencies. Again, our results match earlier numerical computations to great accuracy. We end with some comments concerning the general classification of asymptotic quasinormal frequencies in d-dimensional space–times.[12]

For a four-dimensional Schwarzschild black hole, one has the asymptotic quasinormal frequencies

$$\lim_{n\to+\infty}\omega_n \sim [\text{offset}] + in[\text{gap}] + \mathcal{O}\left(\frac{1}{\sqrt{n}}\right),$$

where the real part of the offset is the frequency of the emitted radiation, and the gap are the quantized increments in the inverse relaxation time. Here, the gap is given by the surface gravity. One can try to extend this analysis to more general situations and also include space–times with two horizons, but then generic results become much harder to obtain.[15–18] We shall take the time

dependence for the perturbation to be $e^{i\omega t}$, so that $\mathbb{I}\mathrm{m}(\omega)>0$ for stable solutions. There is also a reflection symmetry $\omega\leftrightarrow-\overline{\omega}$ which changes the sign of $\mathbb{R}\mathrm{e}(\omega)$. In this case, our quasinormal mode conventions are the following (see Ref. 12 for a full list of conventions in d dimensions). The perturbation master equations of Refs. 3 and 5 can be cast in a Schrödinger-type form as

$$-\frac{\mathrm{d}^2\Phi_\omega}{\mathrm{d}x^2}(x)+V(x)\Phi_\omega(x)=\omega^2\Phi_\omega(x), \tag{1.1}$$

where the potential will vary according to the specific case at hand. The boundary conditions are the usual: incoming waves at the black hole horizon and outgoing waves at infinity (or at the cosmological horizon, for the asymptotically de Sitter case). (For the asymptotically anti–de Sitter situation things will be different.) These can be written as

$$\Phi_\omega(x)\sim e^{i\omega x} \text{ as } x\to-\infty,$$

$$\Phi_\omega(x)\sim e^{-i\omega x} \text{ as } x\to+\infty,$$

where x is the tortoise coordinate. Indeed, if the metric is chosen as $g=-f(r)\mathrm{d}t\otimes\mathrm{d}t+f(r)^{-1}\,\mathrm{d}r\otimes\mathrm{d}r+r^2\,\mathrm{d}\Omega_2^2$, with parameters $M=\boldsymbol{\mu}$ for the black hole mass and $\Lambda=3\boldsymbol{\lambda}$ for the background cosmological constant, then at any (event or cosmological) horizon, $f(R_H)=0$. One can expand near the horizon $f(r)\simeq(r-R_H)f'(R_H)+\cdots$, and it follows for the tortoise,

$$x\equiv\int\frac{\mathrm{d}r}{f(r)}\simeq\int\frac{\mathrm{d}r}{(r-R_H)f'(R_H)}=\frac{1}{f'(R_H)}\log(r-R_H)\equiv\frac{1}{2k_H}\log(r-R_H)\equiv\frac{1}{4\pi T_H}\log(r-R_H),$$

locally near the chosen horizon. Here k_H is the surface gravity and T_H is the Hawking temperature.

II. ASYMPTOTICALLY DE SITTER SPACE–TIMES

Reference 5 discusses the stability of black holes in asymptotically de Sitter (dS) space–times to tensor, vector, and scalar-type perturbations of the metric and the electromagnetic field. For black holes without charge, which is the case we shall focus on, tensor and vector-type perturbations are stable in any dimension. Scalar-type perturbations are stable up to dimension six but there is no proof of stability in dimension $d\geqslant 7$. As we shall work in four dimensions, we are guaranteed a stable solution. Quantization in dS space was first addressed in Ref. 19. These authors found that the cosmological event horizon is stable, but also that there is an isotropic background of thermal radiation. Analysis of the wave equation in dS space also led to the natural boundary conditions on quasinormal modes: incoming waves at the black hole horizon and outgoing waves at the cosmological horizon. The Schwarzschild dS solution in dimension $d=4$ has parameters $\boldsymbol{\mu}$ and $\boldsymbol{\lambda}>0$, with metric

$$f(r)=1-\frac{2\boldsymbol{\mu}}{r}-\boldsymbol{\lambda}r^2.$$

The potentials to be used in the master equation (1.1), describing the evolution of scalar, electromagnetic and gravitational fields, can be followed through the Klein–Gordon, Maxwell, and Einstein equations, respectively. They will necessarily depend on the specific field under consideration and are as follows. For scalar perturbations[20]

$$V_s(r)=f(r)\left(\frac{\ell(\ell+1)}{r^2}+\frac{2\boldsymbol{\mu}}{r^3}-2\boldsymbol{\lambda}\right), \tag{2.1}$$

while for electromagnetic perturbations[21]

$$V_{\mathrm{em}}(r) = f(r)\left(\frac{\ell(\ell+1)}{r^2}\right). \tag{2.2}$$

The gravitational perturbations decompose into two sets, the odd and the even parity one.[21] For the odd parity perturbations one has (these are the vector-type gravitational perturbations)

$$V_{\mathrm{odd}}(r) = f(r)\left(\frac{\ell(\ell+1)}{r^2} - \frac{6\boldsymbol{\mu}}{r^3}\right), \tag{2.3}$$

while for the even parity perturbations (these are the scalar-type gravitational perturbations),

$$V_{\mathrm{even}}(r) = \frac{2f(r)}{r^3}\frac{9\boldsymbol{\mu}^3 + 3a^2\boldsymbol{\mu}r^2 + a^2(1+a)r^3 + 3\boldsymbol{\mu}^2(3ar - 3\boldsymbol{\lambda}r^3)}{(3\boldsymbol{\mu} + ar)^2}, \tag{2.4}$$

where $a=\frac{1}{2}(\ell(\ell+1)-2)$. In all cases, we have denoted by ℓ the angular momentum quantum number, which yields the multipolarity of the field. These are the potentials we shall use in the following.

To simplify the calculation, we choose the radius of the black hole to be our length unit. The radius of the cosmological horizon will then be an adimensional quantity $R>1$. In this case, it is easily seen that the warp factor must be of the form

$$f(r) = 1 - \frac{2\boldsymbol{\mu}}{r} - \boldsymbol{\lambda}r^2 = -\frac{\boldsymbol{\lambda}(r-1)(r-R)(r+R+1)}{r},$$

and consequently the black hole's parameters will be given in our units by

$$\boldsymbol{\lambda} = \frac{1}{R^2+R+1},$$

$$\boldsymbol{\mu} = \frac{R^2+R}{2(R^2+R+1)}.$$

The (complex) tortoise coordinate which vanishes at the origin is

$$x = \int \frac{\mathrm{d}r}{f(r)} = \frac{1}{2k_H}\log(1-r) + \frac{1}{2k_C}\log\left(1-\frac{r}{R}\right) + \frac{1}{2k_F}\log\left(1+\frac{r}{R+1}\right),$$

where

$$k_H = \frac{1}{2}f'(1) = \frac{(R-1)(R+2)}{2(R^2+R+1)},$$

$$k_C = \frac{1}{2}f'(R) = -\frac{(R-1)(2R+1)}{2R(R^2+R+1)},$$

$$k_F = \frac{1}{2}f'(-R-1) = \frac{(R+2)(2R+1)}{2(R+1)(R^2+R+1)},$$

are the surface gravities at the black hole horizon $r=1$, the cosmological horizon $r=R$, and the fictitious horizon $r=-R-1$. Notice that we take the surface gravity at the cosmological horizon to be negative.

As in Ref. 11, we notice that although x has a ramification point at each horizon, $\mathbb{R}\mathrm{e}(x)$ is well defined and we can look at the Stokes line $\mathbb{R}\mathrm{e}(x)=0$. Since $x(0)=0$, this curve contains the origin and its singular points are given by

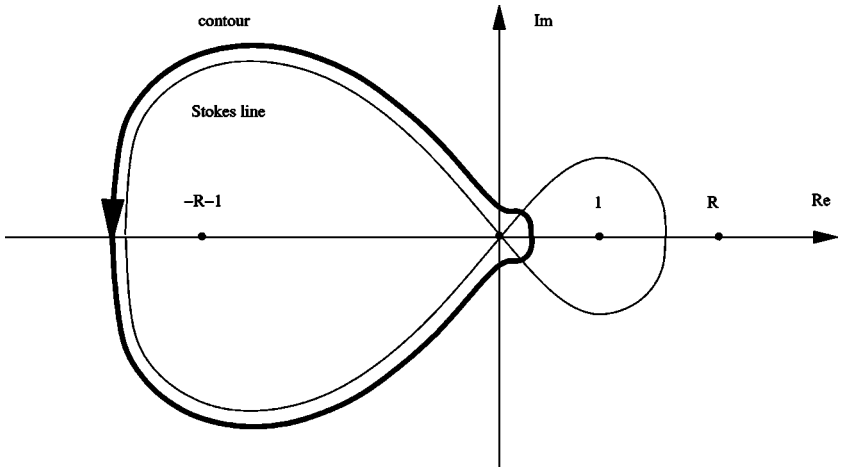

FIG. 1. Stokes line for the Schwarzschild dS black hole, along with the chosen contour for monodromy matching.

$$\frac{dx}{dr} = 0 \;\Leftrightarrow\; \frac{1}{f(r)} = 0 \Leftrightarrow r = 0.$$

For $r \sim 0$ one has $f(r) \sim (-2\mu/r)$ and hence

$$x \sim -\int \frac{r\,dr}{2\mu} = -\frac{r^2}{4\mu}.$$

Consequently the Stokes line is given by $r = \rho e^{\pm(i\pi/4)}$, $\rho \in \mathbb{R}$ in a neighborhood of the origin. On the other hand, for $r \sim \infty$ one has $f(r) \sim -\Lambda r^2$, and thus

$$x \sim -\int \frac{dr}{\Lambda r^2} = x_0 + \frac{1}{\Lambda r}.$$

Notice that in particular x has no monodromy at infinity, and hence

$$\frac{1}{k_H} + \frac{1}{k_C} + \frac{1}{k_F} = 0.$$

Thus we can choose the three ramification lines of x to cancel each other off, and x_0 is well defined. Using the expression for x with an appropriate choice of ramification line in each logarithm, one can compute the real part of x_0, which is not zero. Therefore the Stokes line cannot extend all the way to infinity and the four lines starting out at the origin must thus connect among themselves. Studying the behavior of $\mathbb{R}\mathrm{e}(x)$ near the horizons, it is not hard to guess that the Stokes line is as indicated in Fig. 1. This guess is moreover verified by a numerical computation of the same Stokes line, indicated in Fig. 2.

Since for $r \sim 0$ the presence of the cosmological constant is irrelevant, we expect the potential to behave as in the Schwarzschild black hole, and this is indeed the case,

$$V \sim \frac{j^2 - 1}{4x^2},$$

where $j = 0$ for scalar fields and scalar-type gravitational perturbations, $j = 1$ for electromagnetic perturbations, and $j = 2$ for vector-type gravitational perturbations. Correspondingly, for $x \sim 0$ the complexified solution of the Schrödinger-type equation is of the form

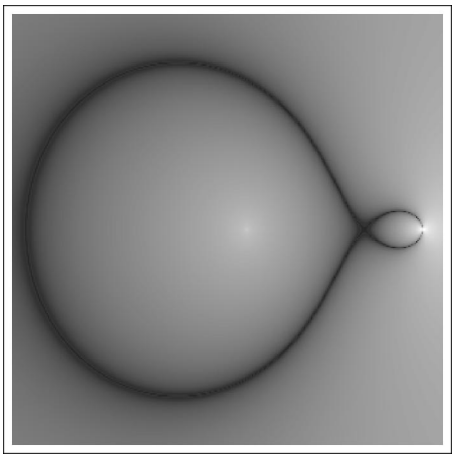

FIG. 2. Numerical calculation of the Stokes line for the Schwarzschild dS black hole.

$$\Phi(x) \sim A_+\sqrt{2\pi\omega x}J_{j/2}(\omega x) + A_-\sqrt{2\pi\omega x}J_{-j/2}(\omega x),$$

where J_ν represents a Bessel function of the first kind and $A_\pm$ are (complex) integration constants.

For the asymptotic quasinormal modes one has $\mathbb{I}\mathrm{m}(\omega) \gg \mathbb{R}\mathrm{e}(\omega)$, and hence ω is approximately purely imaginary. Consequently in a neighborhood of the origin one has $\omega x \in \mathbb{R}^+$ for $r=\rho e^{i\pi/4}$, $\rho \in \mathbb{R}$, and $\omega x \in \mathbb{R}^-$ for $r=\rho e^{-i\pi/4}$, $\rho \in \mathbb{R}$. From the asymptotic expansion

$$J_\nu(z) = \sqrt{\frac{2}{\pi z}}\cos\left(z - \frac{\nu\pi}{2} - \frac{\pi}{4}\right),\ z \gg 1,$$

we see that

$$\Phi(x) \sim 2A_+\cos(\omega x - \alpha_+) + 2A_-\cos(\omega x - \alpha_-) = (A_+e^{-i\alpha_+} + A_-e^{-i\alpha_-})e^{i\omega x} + (A_+e^{i\alpha_+} + A_-e^{i\alpha_-})e^{-i\omega x},$$

for $r=\rho e^{i\pi/4}$, $\rho \in \mathbb{R}^-$, where

$$\alpha_\pm = \frac{\pi}{4}(1 \pm j).$$

For $z \sim 0$ one has the expansion

$$J_\nu(z) = z^\nu w(z),$$

where $w(z)$ is an even holomorphic function. Consequently, as one rotates from $r=\rho e^{i\pi/4}$, $\rho \in \mathbb{R}^-$ to $r=\rho e^{-i\pi/4}$, $\rho \in \mathbb{R}^-$, one has

$$\sqrt{2\pi e^{3\pi i}\omega x}J_{\pm j/2}(e^{3\pi i}\omega x) = e^{(3\pi i/2)(1\pm j)}\sqrt{2\pi\omega x}J_{\pm j/2}(\omega x) \sim 2e^{6i\alpha_\pm}\cos(\omega x - \alpha_\pm)$$

and hence

$$\begin{aligned}\Phi(x) &\sim 2A_+e^{6i\alpha_+}\cos(-\omega x - \alpha_+) + 2A_-e^{6i\alpha_-}\cos(-\omega x - \alpha_-)\\ &= (A_+e^{7i\alpha_+} + A_-e^{7i\alpha_-})e^{i\omega x} + (A_+e^{5i\alpha_+} + A_-e^{5i\alpha_-})e^{-i\omega x},\end{aligned}$$

for $r=\rho e^{-i\pi/4}$, $\rho \in \mathbb{R}^-$. As one would expect, this completely parallels the computation for the Schwarzschild solution in Ref. 11. Next we compute the monodromy of the solution at infinity. For $r \sim \infty$ we have

$$V_s \sim 2\boldsymbol{\lambda}^2 r^2 \sim \frac{2}{(x-x_0)^2} = \frac{3^2-1}{4(x-x_0)^2},$$

$$V_{\text{em}} \sim V_{\text{odd}} \sim -\boldsymbol{\lambda}\ell(\ell+1),$$

$$V_{\text{even}} \sim -\boldsymbol{\lambda}\left[\ell(\ell+1) - \frac{18\boldsymbol{\mu}^2\boldsymbol{\lambda}}{a^2}\right].$$

Consequently, either

$$\Phi(x) \sim B_+\sqrt{2\pi\omega(x-x_0)}J_{3/2}(\omega(x-x_0)) + B_-\sqrt{2\pi\omega(x-x_0)}J_{-3/2}(\omega(x-x_0))$$

or (here $\tilde{\omega}^2=\omega^2+\boldsymbol{\lambda}\ell(\ell+1)$ for the electromagnetic and odd parity perturbations, and $\tilde{\omega}^2=\omega^2+\boldsymbol{\lambda}[\ell(\ell+1)-18\mu^2\lambda/a^2]$ for the even parity perturbations)

$$\Phi(x) \sim B_+e^{i\tilde{\omega}(x-x_0)} + B_-e^{-i\tilde{\omega}(x-x_0)}$$

for $r\sim\infty$; in any case, Φ is holomorphic and hence the monodromy of Φ at infinity is equal to one. If Φ corresponds to a quasinormal mode, its monodromy around $r=1$ must be the same as the monodromy of $e^{i\omega x}$, that is, $e^{i\omega(2\pi i/2k_H)}=e^{-\pi\omega/k_H}$. Similarly, its monodromy around $r=R$ must be the same as the monodromy of $e^{-i\omega x}$, that is, $e^{\pi\omega/k_C}$. Since the only other singularities of Φ are at the origin and at $r=-R-1$, it is then clear that the monodromy of Φ around the contour depicted in the figure must be

$$\frac{1}{e^{-(\pi\omega/k_H)+(\pi\omega/k_C)}} = e^{(\pi\omega/k_H)-(\pi\omega/k_C)}.$$

The monodromy of $e^{\pm i\omega}$ around the contour is $e^{\pm i\omega(2\pi i/2k_F)}=e^{\mp\pi\omega/k_F}$. As one goes around the contour the coefficient of $e^{i\omega x}$ in the asymptotic expansion of Φ gets multiplied by

$$\frac{A_+e^{7i\alpha_+}+A_-e^{7i\alpha_-}}{A_+e^{-i\alpha_+}+A_-e^{-i\alpha_-}}.$$

For this term to have the required monodromy we must impose

$$\frac{A_+e^{7i\alpha_+}+A_-e^{7i\alpha_-}}{A_+e^{-i\alpha_+}+A_-e^{-i\alpha_-}}e^{-\pi\omega/k_F} = e^{(\pi\omega/k_H)-(\pi\omega/k_C)} \Leftrightarrow \frac{A_+e^{7i\alpha_+}+A_-e^{7i\alpha_-}}{A_+e^{-i\alpha+}+A_-e^{-i\alpha_-}} = e^{-2\pi\omega/k_C}.$$

Similarly, for the term in $e^{-i\omega x}$ we get the condition

$$\frac{A_+e^{5i\alpha_+}+A_-e^{5i\alpha_-}}{A_+e^{i\alpha_+}+A_-e^{i\alpha_-}}e^{-\pi\omega/k_F} = e^{(\pi\omega/k_H)-(\pi\omega/k_C)} \Leftrightarrow \frac{A_+e^{5i\alpha_+}+A_-e^{5i\alpha_-}}{A_+e^{i\alpha_+}+A_-e^{i\alpha_-}} = e^{2\pi\omega/k_H}.$$

The condition for these equations to have nontrivial solutions (A_+,A_-) is then

$$\begin{vmatrix} e^{7i\alpha_+}-e^{-2\pi\omega/k_C}e^{-i\alpha_+} & e^{7i\alpha_-}-e^{-2\pi\omega/k_C}e^{-i\alpha_-} \\ e^{5i\alpha_+}-e^{2\pi\omega/k_H}e^{i\alpha_+} & e^{5i\alpha_-}-e^{2\pi\omega/k_H}e^{i\alpha_-} \end{vmatrix} = 0 \Leftrightarrow \begin{vmatrix} \sin\left(4\alpha_+-\frac{i\pi\omega}{k_C}\right) & \sin\left(4\alpha_--\frac{i\pi\omega}{k_C}\right) \\ \sin\left(2\alpha_++\frac{i\pi\omega}{k_H}\right) & \sin\left(2\alpha_-+\frac{i\pi\omega}{k_H}\right) \end{vmatrix} = 0.$$

As in the Schwarzschild case, this equation is automatically satisfied for $j=0$. This is to be expected, as for $j=0$ the Bessel functions $J_{\pm j/2}$ coincide and do not form a basis for the space of solutions of the Schrödinger-type equation near the origin. As in Ref. 11, we consider this equation for j nonzero and take the limit as $j\to 0$. This amounts to writing the equation as a power series in j and equating to zero the first nonvanishing coefficient, which in this case is the coefficient of the linear part. Thus, we just have to require that the derivative of the determinant above with respect to j be zero for $j=0$. This amounts to

$$\begin{vmatrix} \pi\cos\left(\pi-\frac{i\pi\omega}{k_C}\right) & -\pi\cos\left(\pi-\frac{i\pi\omega}{k_C}\right) \\ \sin\left(\frac{\pi}{2}+\frac{i\pi\omega}{k_H}\right) & \sin\left(\frac{\pi}{2}+\frac{i\pi\omega}{k_H}\right) \end{vmatrix} + \begin{vmatrix} \sin\left(\pi-\frac{i\pi\omega}{k_C}\right) & \sin\left(\pi-\frac{i\pi\omega}{k_C}\right) \\ \frac{\pi}{2}\cos\left(\frac{\pi}{2}+\frac{i\pi\omega}{k_H}\right) & -\frac{\pi}{2}\cos\left(\frac{\pi}{2}+\frac{i\pi\omega}{k_H}\right) \end{vmatrix} = 0,$$

from where we obtain our final result as

$$\cosh\left(\frac{\pi\omega}{k_H}-\frac{\pi\omega}{k_C}\right)+3\cosh\left(\frac{\pi\omega}{k_H}+\frac{\pi\omega}{k_C}\right)=0. \tag{2.5}$$

Notice that if ω is a solution of this equation then so is $-\overline{\omega}$, as must be the case with quasinormal modes.

To recover the Schwarzschild quasinormal frequencies we first write out the equation as

$$e^{(\pi\omega/k_H)-(\pi\omega/k_C)}+e^{-(\pi\omega/k_H)+(\pi\omega/k_C)}+3e^{(\pi\omega/k_H)+(\pi\omega/k_C)}+3e^{-(\pi\omega/k_H)-(\pi\omega/k_C)}=0,$$

and next take the limit as $R\to\infty$, in which $k_H\to\frac{1}{2}$ and $k_C\to 0^-$. If we assume that $\mathbb{R}\mathrm{e}(\omega)>0$, we see that the two middle terms are exponentially small, and hence the equation reduces to

$$e^{\pi\omega/k_H}+3e^{-\pi\omega/k_H}=0\Leftrightarrow e^{4\pi\omega}=-3,$$

which is exactly the equation obtained in Refs. 10 and 11. Therefore, the Schwarzschild black hole is not a singular limit of the Schwarzschild dS black hole as far as the quasinormal modes are concerned, unlike what happens with the Reissner–Nordstrøm black hole solution. The reason for this is clear from the monodromy calculation: whereas the structure of the tortoise near the singularity $r=0$ in the Reissner–Nordstrøm solution depends crucially on whether the charge is zero or not, in the Schwarzschild dS case it does not depend on $\boldsymbol{\lambda}$. Thus, as $R\to+\infty$, the cosmological horizon approaches the point at infinity and the contour approaches the contour used in Ref. 11.

For $j=1$ one has $\alpha_+=\pi/2$, $\alpha_-=0$ and hence the condition for the quasinormal frequencies is

$$\begin{vmatrix} -\sin\left(\frac{i\pi\omega}{k_C}\right) & -\sin\left(\frac{i\pi\omega}{k_C}\right) \\ -\sin\left(\frac{i\pi\omega}{k_H}\right) & \sin\left(\frac{i\pi\omega}{k_H}\right) \end{vmatrix} = 0\Leftrightarrow \sin\left(\frac{i\pi\omega}{k_C}\right)\sin\left(\frac{i\pi\omega}{k_H}\right)=0,$$

with the solutions

$$\omega=ink_H \quad \text{or} \quad \omega=ink_C \quad (n\in\mathbb{N}).$$

Again, as $R\to\infty$ one obtains the Schwarzschild result, $\omega=ni/2$. Finally, for $j=2$ one has $2\alpha_\pm=(\pi/2)\pm\pi$, $4\alpha_\pm=\pi\pm 2\pi$, and consequently the quasinormal frequencies are the same as in the $j=0$ case, for which $2\alpha_\pm=\pi/2$, $4\alpha_\pm=\pi$.

Let us now review the literature concerning asymptotic quasinormal frequencies in the Schwarzschild dS space–time, so that we can compare our results to what has been previously accomplished on this subject. First of all, it is possible to prove, without computing explicitly the quasinormal frequencies, that $j=0$ and $j=2$ perturbations must have the same quasinormal spectra,[22] and so this is a consistency check on our results. For Schwarzschild dS, early results on quasinormal modes were studied in Ref. 23, without great emphasis on the asymptotic case. The first analytical results in $d=4$ were derived in the near-extremal situation, where event and cosmological horizons are nearly coincident,[24] but the approximation used therein is not expected to hold in the asymptotic limit, at least on what concerns the real part of the asymptotic frequencies. Further approximations were studied in Ref. 25, in a limit where the black hole mass is much smaller than the space–time radius of curvature, but focusing explicitly on the time *dependent* transient situation. An attempt at an analytic solution for the asymptotic quasinormal frequencies,

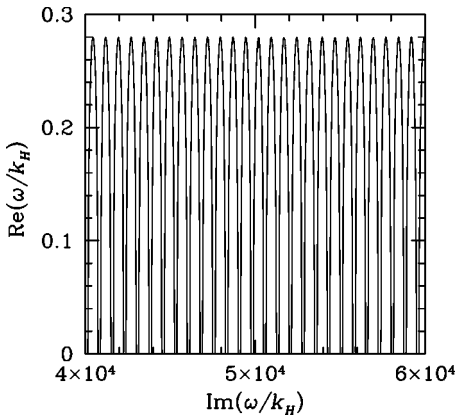

FIG. 3. Real versus imaginary part of quasinormal frequencies for the nearly extremal Schwarzschild dS solution.

using the monodromy technique of Ref. 11, was done in Ref. 26. However, an erroneous identification of the relevant contours led these authors to an incorrect result (see also Ref. 27, where other arguments were given trying to explain the failure of Ref. 26 to reproduce available numerical data). Perhaps the most thorough analytical work on Schwarzschild dS asymptotic quasinormal frequencies to date is the one in Ref. 18. These authors find that because there are two different surface gravities, there are also two sets of solutions for $\mathbb{I}\mathrm{m}(\omega)$ when the horizons are *widely* spaced, namely $\mathbb{I}\mathrm{m}(\omega)$ equally spaced with spacing equal to k_H or $\mathbb{I}\mathrm{m}(\omega)$ equally spaced with spacing equal to k_C. It was further claimed in Ref. 18 that this lack of consensus on quasinormal frequencies was due to the fact that there is no global definition of temperature in this space–time. Our results appear to confirm this expectation: in the limit where the cosmological radius goes to infinity, and one recovers the Schwarzschild modes, we found the spacing to be equal to k_H. In the limit where the black hole radius is very small, (2.5) yields modes with spacing equal to k_C (notice that this formula does not depend on the choice of units).

Besides the mentioned works, there are also numerical results available, and this is where our comparisons prove to be most conclusive. In Ref. 28 the asymptotic quasinormal frequencies for electromagnetic and gravitational perturbations of nearly extremal Schwarzschild dS space–times were studied. It turned out that, for gravitational perturbations, the real part of the asymptotic quasinormal frequencies has an oscillatory behavior as plotted against its imaginary part. We plot the same figure as in Ref. 28, using our final result (2.5), in Fig. 3. This figure corresponds to the roots of (2.5) for a near extremal black hole with $k_H = 10^{-3}$, and should be compared to Fig. 4 in Ref. 28 which refers to the same value of k_H. One immediately observes agreement to large accuracy: first, the oscillation period is exactly the same. Second, the value of $\max(\mathbb{R}\mathrm{e}(\omega))$ in Ref. 28 is of the same order as our maximum, but always larger than it, as it must be since our value refers to the asymptotic regime only. Moreover, and on what concerns $j=1$ electromagnetic perturbations, the numerical data in Ref. 28 is very clear and indicates that the real part of the asymptotic quasinormal frequencies should vanish, and this is precisely what we have obtained. Further numerical results have recently been obtained in Ref. 29, this time around without any near extremality constraints. Again, for the gravitational perturbations, the real part of the asymptotic quasinormal frequencies was found to have an oscillatory behavior. Also, for electromagnetic perturbations, the real part of the asymptotic quasinormal frequencies was found to vanish. Our analytical results still agree very well with the numerics: we are able to reproduce the basic features of Fig. 2 in Ref. 29, with the exception that we also find modes with a zero real part. This should not be cause for concern as it is known to be highly difficult to numerically obtain modes with a vanishing real part. On what concerns the $j=1$ perturbations of Ref. 29, we obtain exactly what they have found.

III. ASYMPTOTICALLY ANTI–DE SITTER SPACE–TIMES

Reference 5 discusses the stability of black holes in asymptotically anti–de Sitter (AdS) space–times to tensor, vector and scalar perturbations of the metric and the electromagnetic field. For black holes without charge, which is the case we shall focus on, tensor and vector perturbations are stable in any dimension. Scalar perturbations are stable in dimension four but there is no proof of stability in dimension $d \geqslant 5$. As we shall work in four dimensions, we are guaranteed a stable solution. Quantization of scalar field in AdS was first addressed in Ref. 30. An important theme concerned boundary conditions: because AdS light rays can reach spatial infinity and return to the origin in finite time, as measured by the observer at the origin, one could expect for reflecting boundary conditions at the AdS walls. However, these walls are at timelike spatial infinity. As it turns out, the sensible boundary conditions to impose on quasinormal modes include the usual incoming waves at the black hole horizon and then vanishing of the fields at infinity (i.e., at the boundary of AdS). The Schwarzschild AdS solution in dimension $d=4$ has parameters $\boldsymbol{\mu}$ and $\boldsymbol{\lambda} < 0$, with metric

$$f(r) = 1 - \frac{2\boldsymbol{\mu}}{r} - \boldsymbol{\lambda} r^2 = 1 - \frac{2\boldsymbol{\mu}}{r} + |\boldsymbol{\lambda}| r^2.$$

The potentials to be used in the master equation (1.1) are the same as before. Also, in the following we shall focus on scalar field perturbations.

Again, to simplify the calculation we choose the radius of the black hole to be our length unit. The length scale determined by the cosmological constant will then be an adimensional quantity R, with $\boldsymbol{\lambda} = -1/R^2$. It is then easily seen that the warp factor must be of the form

$$f(r) = 1 - \frac{2\boldsymbol{\mu}}{r} - \boldsymbol{\lambda} r^2 = \frac{(r-1)(r^2 + r + 1 + R^2)}{R^2 r}$$

and consequently the black hole mass will be given in our units by

$$\boldsymbol{\mu} = \frac{1 + R^2}{2R^2}.$$

Moreover, one can compute

$$f(r) = \frac{(r-1)(r-\gamma)(r-\overline{\gamma})}{R^2 r},$$

where

$$\gamma = -\frac{1}{2} + \frac{i}{2}\sqrt{4R^2 + 3}.$$

For simplicity, we shall consider quasinormal modes for large black holes only, in which $R \ll 1$. This serves our purpose of illustrating how the techniques in Ref. 11 are generalized for asymptotically AdS space–times, whereas the full case is carefully analyzed in Ref. 12. For these large black holes we have, approximately,

$$\gamma = e^{i(2\pi/3)} = \sqrt[3]{1}, \quad \overline{\gamma} = \gamma^2,$$

and consequently

$$\frac{1}{f(r)} = \frac{R^2}{3}\left(\frac{1}{r-1} + \frac{\overline{\gamma}}{r-\gamma} + \frac{\gamma}{r-\overline{\gamma}}\right).$$

The (complex) tortoise coordinate which vanishes at the origin is therefore

$$x = \int \frac{\mathrm{d}r}{f(r)} = \frac{R^2}{3}(\log(1-r) + \overline{\gamma}\log(1-\overline{\gamma}r) + \gamma\log(1-\gamma r)).$$

We now wish to examine the Stokes line, i.e., the curve $\mathbb{I}\mathrm{m}(\omega x)=0$. However, this time around, the expression of the tortoise makes it clear that $\mathbb{I}\mathrm{m}(\omega x)$ is a multivalued function. To bypass this problem, we choose a particular branch and simply trace out the curve shifting the ramification lines so that it never hits them. Note that the behavior of $e^{\pm i\omega x}$ will still be oscillatory along the curve. Again the Stokes line has a unique singular point at the origin, where four lines meet, as

$$\omega x \sim -\int \frac{\omega r\,\mathrm{d}r}{2\boldsymbol{\mu}} = -\frac{\omega r^2}{4\boldsymbol{\mu}}$$

for $r\sim 0$. To understand its behavior near the singularities, we notice that following our procedure, the curve

$$\mathbb{I}\mathrm{m}(\alpha\log(z)) = 0$$

is the curve

$$\alpha\log(z) = \rho \;\Leftrightarrow\; z = e^{\xi\rho}e^{i\eta\rho}$$

[with $\alpha=1/(\xi+i\eta)$ and $\rho\in\mathbb{R}$ a parameter]. This is a spiral that approaches the singularity $z=0$, except in the case where $\xi=0$, i.e., when α is purely imaginary. Therefore, generically one expects the Stokes line to hit all three singularities, and hence the fourth line starting out at the origin must extend all the way to infinity. For $r\sim\infty$ we have

$$x \sim \int \frac{R^2\,\mathrm{d}r}{r^2} = x_0 - \frac{R^2}{r}.$$

In particular, x has no monodromy at infinity, as can also be seen from its expression and the fact that

$$1+\gamma+\gamma^2 = 0.$$

We can therefore choose the three ramification lines of x to cancel each other off, making x_0 well defined. (There are however three nonequivalent ways of doing this, leading to three possible values of x at infinity: x_0, $\overline{x_0}$, and $-|x_0|$. The second choice leads to the quasinormal frequencies $-\overline{\omega}$, where ω are the quasinormal frequencies obtained by choosing x_0; the third choice leads to no solutions.) Using the expression for x with appropriate choice of ramification line in each logarithm, one then obtains

$$x_0 = \frac{2\pi\sqrt{3}R^2}{9}e^{-i\pi/3}.$$

Therefore we must have

$$\omega x_0 \in \mathbb{R} \;\Leftrightarrow\; \omega = \zeta e^{i\pi/3}\ (\zeta\in\mathbb{R}^+).$$

For such a value of ω and our choice of ramification lines, it is easily seen that ωx is real for $r=\rho e^{i\pi/3}$, $\rho\in(-1,+\infty)$. On the other hand, near the origin the Stokes line is given by

$$\mathbb{I}\mathrm{m}(-e^{i\pi/3}r^2) = 0 \;\Leftrightarrow\; r = \rho e^{-i\pi/6} \quad \text{or} \quad r = \rho e^{i\pi/3}\ (\rho\in\mathbb{R}).$$

Consequently, it is not hard to guess that the Stokes line is as depicted in Fig. 4. We have verified this guess with a numerical computation of the same Stokes line, and this is indicated in Fig. 5. It should be noted that due to the ramification lines (which can be readily identified in the figure) the spirals at the singularities are not so clearly depicted in the numerical result.

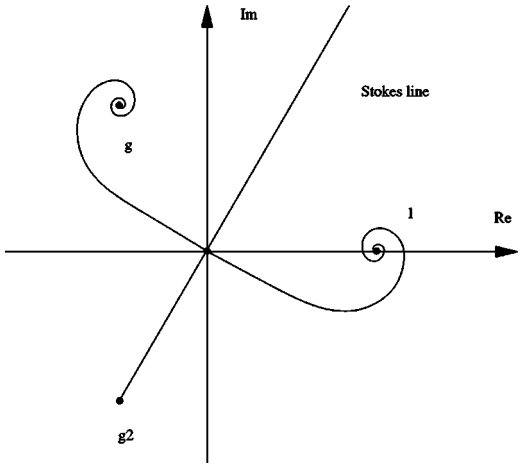

FIG. 4. Stokes line for the Schwarzschild AdS black hole.

Now, for $r\sim\infty$ we have

$$V_s \sim 2\lambda^2 r^2 \sim \frac{2}{(x-x_0)^2} = \frac{3^2-1}{4(x-x_0)^2}.$$

Consequently,

$$\Phi(x) \sim B_+\sqrt{2\pi\omega(x-x_0)}\; J_{3/2}(\omega(x-x_0)) + B_-\sqrt{2\pi\omega(x-x_0)}\; J_{-3/2}(\omega(x-x_0))$$

for $r\sim\infty$. The boundary condition $\Phi=0$ at $r=\infty$ requires that $B_-=0$. Hence,

$$\Phi(x) \sim B_+\sqrt{2\pi\omega(x-x_0)}\; J_{3/2}(\omega(x-x_0)),$$

for $r\sim\infty$. Now, and as in the Schwarzschild dS case, for $r\sim 0$ the presence of the cosmological constant is irrelevant, and the potential behaves as in the Schwarzschild black hole,

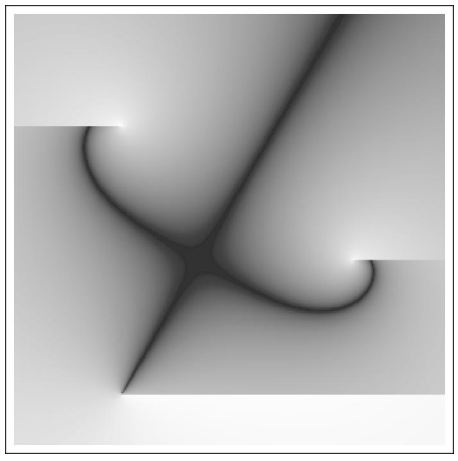

FIG. 5. Numerical calculation of the Stokes line for the Schwarzschild AdS black hole.

$$V_s \sim \frac{j^2-1}{4x^2},$$

where $j=0$ for scalar field perturbations. Correspondingly, for $x\sim 0$ the complexified solution of the Schrödinger-type equation is of the form

$$\Phi(x) \sim A_+\sqrt{2\pi\omega x}\, J_{j/2}(\omega x) + A_-\sqrt{2\pi\omega x}\, J_{-j/2}(\omega x),$$

where $A_\pm$ are (complex) integration constants. One has $\omega x \in \mathbb{R}^+$ for $r=\rho e^{i\pi/3}$, $\rho\in\mathbb{R}$, and $\omega x\in\mathbb{R}^-$ for $r=\rho e^{-i\pi/6}$, $\rho\in\mathbb{R}$. From the asymptotic expansion for $J_\nu(z)$, with $z\gg 1$, we see that

$$\begin{aligned}\Phi(x) &\sim 2A_+\cos(\omega x-\alpha_+) + 2A_-\cos(\omega x-\alpha_-)\\ &= (A_+e^{-i\alpha_+}+A_-e^{-i\alpha_-})e^{i\omega x} + (A_+e^{i\alpha_+}+A_-e^{i\alpha_-})e^{-i\omega x},\end{aligned}$$

for $r=\rho e^{i\pi/3}$, $\rho\in\mathbb{R}^+$, where

$$\alpha_\pm = \frac{\pi}{4}(1\pm j).$$

The same expansion yields

$$\Phi(x) \sim B_+e^{-i\beta_+}e^{i\omega(x-x_0)} + B_+e^{i\beta_+}e^{-i\omega(x-x_0)} = -B_+e^{-i\omega x_0}e^{i\omega x} - B_+e^{i\omega x_0}e^{-i\omega x}$$

in the same limit, since

$$\beta_+ = \frac{\pi}{4}(1+3) = \pi.$$

We conclude that A_+, A_- must satisfy

$$(A_+e^{-i\alpha_+}+A_-e^{-i\alpha_-})e^{i\omega x_0} = (A_+e^{i\alpha_+}+A_-e^{i\alpha_-})e^{-i\omega x_0}.$$

Again for $z\sim 0$, one has the expansion

$$J_\nu(z) = z^\nu w(z),$$

where $w(z)$ is an even holomorphic function. Consequently, as one rotates from $r=\rho e^{i\pi/3}$, $\rho\in\mathbb{R}^-$ to $r=\rho e^{-i\pi/6}$, $\rho\in\mathbb{R}^+$ one has

$$\sqrt{2\pi e^{-\pi i}\omega x}\, J_{\pm j/2}(e^{-\pi i}\omega x) = e^{(-\pi i/2)(1\pm j)}\sqrt{2\pi\omega x}\, J_{\pm j/2}(\omega x) \sim 2e^{-2i\alpha_\pm}\cos(\omega x-\alpha_\pm)$$

and hence

$$\begin{aligned}\Phi(x) &\sim 2A_+e^{-2i\alpha_+}\cos(-\omega x-\alpha_+) + 2A_-e^{-2i\alpha_-}\cos(-\omega x-\alpha_-)\\ &= (A_+e^{-i\alpha_+}+A_-e^{-i\alpha_-})e^{i\omega x} + (A_+e^{-3i\alpha_+}+A_-e^{-3i\alpha_-})e^{-i\omega x},\end{aligned}$$

for $r=\rho e^{-i\pi/6}$, $\rho\in\mathbb{R}^+$. This form of the solution can be propagated along the corresponding branch of the Stokes line which approaches the event horizon, and where we know that $\Phi(x)$ must behave as $e^{i\omega x}$. Consequently we obtain the second condition on A_+, A_- as

$$A_+e^{-3i\alpha_+} + A_-e^{-3i\alpha_-} = 0.$$

The two conditions on these coefficients can only have nontrivial solutions if and only if

$$\begin{vmatrix} e^{-3i\alpha_+} & e^{-3i\alpha_-} \\ e^{-i\alpha_+}e^{i\omega x_0} - e^{i\alpha_+}e^{-i\omega x_0} & e^{-i\alpha_-}e^{i\omega x_0} - e^{i\alpha_-}e^{-i\omega x_0}\end{vmatrix} = 0 \quad\Leftrightarrow\quad \begin{vmatrix} e^{-3i\alpha_+} & e^{-3i\alpha_-} \\ \sin(\alpha_+-\omega x_0) & \sin(\alpha_--\omega x_0)\end{vmatrix} = 0.$$

Again, this equation is automatically satisfied for $j=0$. We must thus consider j nonzero and then take the limit as $j\to 0$. This amounts to writing the equation as a power series in j and equating to

zero the first nonvanishing coefficient, which in this case is the coefficient of the linear part. Thus we just have to require that the derivative of the determinant above with respect to j be zero for $j=0$. This is

$$\begin{vmatrix} -\frac{3i\pi}{4}e^{-3i\pi/4} & \frac{3i\pi}{4}e^{-3i\pi/4} \\ \sin\left(\frac{\pi}{4}-\omega x_0\right) & \sin\left(\frac{\pi}{4}-\omega x_0\right) \end{vmatrix} + \begin{vmatrix} e^{-3i\pi/4} & e^{-3i\pi/4} \\ \frac{\pi}{4}\cos\left(\frac{\pi}{4}-\omega x_0\right) & -\frac{\pi}{4}\cos\left(\frac{\pi}{4}-\omega x_0\right) \end{vmatrix} = 0$$

from where we obtain our final result as

$$\tan\left(\frac{\pi}{4}-\omega x_0\right)=\frac{i}{3} \quad \Leftrightarrow \quad \omega x_0=\frac{\pi}{4}-\arctan\left(\frac{i}{3}\right)+n\pi (n\in\mathbb{N}). \tag{3.1}$$

If one makes use of the notation $\omega=[\text{offset}]+n[\text{gap}]$ (which is slightly different from the one in the Introduction), it is simple to obtain the numerical values

$$[\text{offset}]=\frac{\frac{\pi}{4}-\arctan\left(\frac{i}{3}\right)}{R^2\left(\frac{\sqrt{3}\pi}{9}-\frac{i\pi}{3}\right)}=\frac{1}{R^2}(0.572\,975+0.419\,193i)$$

and

$$[\text{gap}]=\frac{9}{4\sqrt{3}R^2}+\frac{9i}{4R^2}=\frac{1}{R^2}(1.299\,04+2.25i),$$

in complete agreement with available numerical results, as we shall see in the following (recall that we have taken the radius of the black hole horizon as our length unit).

We now need to review the literature concerning the calculation of asymptotic quasinormal frequencies in the Schwarzschild AdS space–time, in order to compare our results to earlier work done on this subject. Quasinormal modes of Schwarzschild AdS black holes were addressed in Refs. 31, 20, and 32, having a direct interpretation in terms of the dual conformal field theory, as large static AdS black holes correspond to conformal field theory thermal states. However, for what concerns us in this paper, only the first modes were computed in Refs. 31 and 20. Due to the AdS/CFT correspondence, this work sparked a series of investigations on AdS asymptotic quasinormal frequencies, which naturally concentrated on the five-dimensional case (see, e.g., Refs. 33–36). For the case that concerns us in here, $d=4$, the first numerical results for the asymptotic quasinormal frequencies were published in Ref. 37. These authors found that scalar perturbations are isospectral with both odd and even parity gravitational perturbations, and they also found the existence of modes with purely imaginary frequency. Later, an extensive study of asymptotic quasinormal frequencies for Schwarzschild AdS black holes in $d=4$ was done in Ref. 38, and numerically produced a number which exactly matches our analytical prediction. While the authors of Ref. 38 found that the real part of the frequency mode increases with the overtone number, n, in what seems to be a characteristic particular to AdS space, they also found that, for the large black holes which we have studied in the present paper, the offset is

$$[\text{offset}]=\frac{1}{R^2}(0.578+0.420i),$$

and the gap is

$$[\text{gap}] = \frac{1}{R^2}(1.299 + 2.250i),$$

in complete and precise agreement with our analytical results.

IV. FUTURE DIRECTIONS

Having opened the way for an extension of the monodromy technique introduced in Ref. 11 to the case of nonasymptotically flat space–times, and having at hand the full list of potentials for both gravitational and electromagnetic perturbations of d-dimensional black holes,[3,5] one can now proceed and compute asymptotic quasinormal modes for d-dimensional black holes. This is done in Ref. 12. The relevance of this calculation towards quantum gravity is dual: on the one hand, one would like to test if the ideas in Refs. 8 and 9 are universal. A positive answer would have great consequences in the theoretical development of both loop quantum gravity and string theory. On the other hand, the computation of these asymptotic quasinormal frequencies will open the way to the calculation of asymptotic greybody factors for d-dimensional black holes which, as we have alluded at previously, may have a deeper role to play on the road to quantum gravity than the quasinormal frequencies. Indeed, it is expected that these greybody factors may yield clues on dual string theoretic microscopic descriptions of black holes, at high energies.[13,14] These are themes to which we shall return in future publications.

For the moment, let us conclude with some comments on the upcoming results.[12] Besides generalizing the present results to d dimensions (and removing the large black hole constraint in the AdS case), we also show how to include charge in this nonasymptotically flat situation. In what respects the charged solutions, we have also generalized the computation of asymptotic quasinormal frequencies in the four-dimensional Reissner–Nordstrøm solution of Ref. 11, to d dimensions, with the following result:

$$e^{\beta_H^+\omega} + (1 + 2\cos(\pi j)) + (2 + 2\cos(\pi j))e^{-\beta_H^-\omega} = 0,$$

where the $\beta_H^\pm$ are the inverse temperatures at the outer and the inner horizons, and

$$j = \frac{d-3}{2d-5}.$$

This formula is valid in any dimension and for any type of gravitational or electromagnetic perturbation. In the case of the extremal Reissner–Nordstrøm solution, where mass equals charge, we have found that the asymptotic frequencies are solutions of the expression

$$\omega = \frac{d-3}{d-2}\left(\frac{d-3}{4\pi R_H}\right)\log\left(\frac{\sin\left(\frac{5\pi j}{2}\right)}{\sin\left(\frac{\pi j}{2}\right)}\right),$$

where R_H is the radius of the extremal horizon and j is as before. We have also found solutions for normal modes in d-dimensional pure AdS space, and solutions for quasinormal modes in pure dS space, for particular values of the dimension. A complete list of all these results will appear in Ref. 12.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 45, NUMBER 12 DECEMBER 2004

Composite systems and the role of the complex numbers in quantum mechanics

Gerd Niestegge
Zillertalstrasse 39, D-81373 Muenchen, Germany

(Received 8 June 2004; accepted 23 August 2004; published 15 November 2004)

An axiomatic approach to the mathematical formalism of quantum mechanics, based upon a certain concept of conditional probability, has been proposed in two recent papers by the author. It leads to Jordan operator algebras and thus comes rather close to the standard Hilbert space model of quantum mechanics, but still includes the so-called exceptional Jordan algebras, for which a Hilbert space representation does not exist. This approach is now extended by defining a mathematical model of composite systems. Such a model is required for the study of the joint distribution of two quantum observables. A very general type of observables (not only the real-valued observables corresponding to the self-adjoint operators) is considered. The joint distribution is defined, using the concept of conditional probability, and exhibits a certain dependence on the succession of the observations which is different from the classical case and unknown so far in quantum mechanics. Finally, it turns out that, at least in the finite-dimensional case, a really satisfying model of the composite system exists only if each single system is modeled by a complex Jordan matrix algebra (or a direct sum), and the model then becomes the tensor product. This provides some reasoning why the exceptional Jordan algebras can be ruled out, why quantum mechanics needs the complex numbers and the complex Hilbert space, and why the tensor product is the right choice for the model of a composite system.
[DOI: 10.1063/1.1811371]

I. INTRODUCTION

An axiomatic approach to the mathematical formalism of quantum mechanics, based upon a certain concept of conditional probability and some interpretable postulates concerning these conditional probabilities, has recently been presented by the author.[10,11] It leads to Jordan operator algebras and thus comes rather close to the standard Hilbert space model of quantum mechanics, but still includes the so-called exceptional Jordan algebras, for which a Hilbert space representation does not exist.

This approach is extended by proposing a mathematical model of composite systems. The combination of two systems to a single one is equally important for modeling physical as well as stochastic systems, e.g., for the definition of a joint distribution of two random variables. For this purpose, classical probability theory contains the concept of product σ-algebras, and quantum mechanics uses the Hilbert space tensor product.

The proposed model renders possible the study of joint distributions of a very general type of quantum observables (usually, only real-valued observables corresponding to self-adjoint operators are considered). The joint distributions are defined using the concept of the conditional probabilities, thus differ from those considered by other authors,[5,12,13] and exhibit a certain dependence on the succession of the observations which is different from the classical case and unknown so far in quantum mechanics. The goal to become able to define a unique joint distribution for a pair of quantum observables satisfying a certain compatibility criterion is the major motiva-

tion for the proposed model of a composite system, which thus differs from the algebraic concepts[6,16] and from other concepts[1,8,9] where only product distributions are considered and the uniqueness of the joint distribution is not addressed.

Finally, it turns out that, at least in the finite-dimensional case, a model of the composite system that satisfies all the postulates from Refs. 10 and 11 exists only if each single system is modeled by a complex Jordan matrix algebra (or a direct sum), and the model then becomes the tensor product. This rules out not only the exceptional octonion, but also the real and quaternion Jordan matrix algebras and may be a reason why quantum mechanics needs the complex numbers and the complex Hilbert space. Moreover, this provides some reasoning why the tensor product is the right choice for modeling composite systems.

Beyond that, this may have some impact on quantum information and quantum computing where a certain phenomenon of composite quantum systems, the so-called *entanglement*, plays a major role, but this is out of the scope of the present paper.

Section II of the paper provides a brief survey of the author's recently presented approach,[10,11] which is then extended in Sec. III by defining the postulates for a mathematical model of a composite system. After studying the joint distributions in Sec. IV, the paper addresses the questions whether and when the postulates can be fulfilled and whether they determine a unique mathematical model (Secs. V and VI); currently, only the finite-dimensional case can be resolved and, for this purpose, Jordan matrix algebras are considered. Some still open issues are summarized in the conclusions.

II. NON-BOOLEAN PROBABILITIES

An *orthospace*[10] is a set $\mathcal{E}$ with distinguished elements 0 and $\mathbb{I}$, an orthogonality relation $\perp$, and a partial binary operation + such that for $D,E,F\in\mathcal{E}$:

(OS1) $E\perp F\Rightarrow F\perp E$,
(OS2) $E+F$ is defined for $E\perp F$, and $E+F=F+E$,
(OS3) $D\perp E, D\perp F, E\perp F\Rightarrow D\perp E+F, F\perp D+E$ and $D+(E+F)=(D+E)+F$,
(OS4) $0\perp E$ and $E+0=E$ for all $E\in\mathcal{E}$,
(OS5) For every $E\in\mathcal{E}$ there exists a unique $E'\in\mathcal{E}$ such that $E\perp E'$ and $E+E'=\mathbb{I}$,
(OS6) $E\perp F'\Leftrightarrow$ There exists a $D\in\mathcal{E}$ such that $E\perp D$ and $E+D=F$.

Then $0'=\mathbb{I}$ and $E''=E$ for $E\in\mathcal{E}$. A further relation $\prec$ is defined on $\mathcal{E}$ via $E\prec F:\Leftrightarrow E\perp F'\Leftrightarrow\mathcal{E}$ containing an element D such that $D\perp E$ and $F=E+D(E,F\in\mathcal{E})$. A *state* is a map $\mu:\mathcal{E}\rightarrow[0,1]$ such that $\mu(\mathbb{I})=1$ and $\mu(E+F)=\mu(E)+\mu(F)$ for all orthogonal pairs $E,F\in\mathcal{E}$. Then $\mu(0)=0$, and μ is additive for each finite family of pairwise orthogonal elements in $\mathcal{E}$. (OS6) ensures that $\mu(E)\leqslant\mu(F)$ for $E\prec F$. If μ is a state and $E\in\mathcal{E}$ with $\mu(E)>0$ and if ν is another state such that $\nu(F)=\mu(F)/\mu(E)$ holds for all $F\in\mathcal{E}$ with $F\prec E$, then ν is called a *conditional probability* of μ under E.

A *σ-orthospace* is an orthospace $\mathcal{E}$ such that $\Sigma_{n=1}^{\infty}E_n$ is defined in $\mathcal{E}$ for every sequence of mutually orthogonal events E_n, and a state μ is *σ-additive* if $\mu(\Sigma_{n=1}^{\infty}E_n)=\Sigma_{n=1}^{\infty}\mu(E_n)$. A σ-UCP *space* is a σ-orthospace $\mathcal{E}$ satisfying the following two axioms:[11]

(UC1) *If $E,F\in\mathcal{E}$ and $E\neq F$, then there is a σ-additive state μ with $\mu(E)\neq\mu(F)$.*
(UC2) *For each σ-additive state μ and $E\in\mathcal{E}$ with $\mu(E)>0$, there exists one and only one σ-additive conditional probability μ_E of μ under E.*

With a σ-UCP space $\mathcal{E}$, there is a σ-additive state μ with $\mu(E)=1$ for each element $E\neq 0,D$ in (OS6) becomes unique, the relation $\prec$ is antisymmetric (but still not an order relation), and we have $E\perp E\Leftrightarrow E\perp\mathbb{I}\Leftrightarrow E=0(E\in\mathcal{E})$.

The elements $E\in\mathcal{E}$ are interpreted as *events* and will be called so in the following. The (only partially defined) operation + is interpreted as the *or* connection of mutually exclusive events, E' is the *negation* of E. For a σ-additive state μ, the interpretation of the real number $\mu(E)$ is that of the *probability* of the event E in the state μ, and $\mu_E(F)$ is the probability of the event F in the state

μ after the event E has been observed. Using the same terminology as in mathematical probability theory, we will also write $\mu(F|E)$ for $\mu_E(F)$ in the sequel. If $\mu(E)=1$, then $\mu_E=\mu$ and $\mu(F|E)=\mu(F)$ for all $F\in\mathcal{E}$.

If $\mu(F|E)$ does not depend on μ for two events E,F with $E\neq 0$, we say that F is *statistically predictable* under E and denote the state-independent conditional probability by $\mathbb{P}(F|E)$. We then have that F is statistically predictable under E with $\mathbb{P}(F|E)=\lambda$ if and only if $\mu(F)=\lambda$ holds for every σ-additive state μ with $\mu(E)=1$. Cases with $0<\mathbb{P}(F|E)<1$ are a particular non-Boolean phenomenon playing a major role within quantum measurement.[10]

An *observable* is a σ-homomorphism X from another σ-orthospace $\mathcal{F}$ to $\mathcal{E}$. If μ is a σ-additive state on $\mathcal{E}$, a σ-additive state μ^X is defined on $\mathcal{F}$ via $\mu^X(F):=\mu(X(F))$; μ^X is called the distribution of X under μ.

The classical σ-algebras and particularly the system $\mathcal{B}$ of Borel-measurable sets in $\mathbb{R}$ are σ-orthospaces. If $\mathcal{F}=\mathcal{B}$, the observable $X:\mathcal{B}\to\mathcal{E}$ is called a *real-valued* or $\mathbb{R}$*-valued* observable on $\mathcal{E}$, although it is a map from $\mathcal{B}$ to $\mathcal{E}$. The reason is that we want to keep the notation in line with what is called a real-valued classical random variable. The *expectation value* of a real-valued observable X in a σ-additive state μ on $\mathcal{E}$ is defined as $\mathrm{Exp}_\mu(X):=\int t\,\mathrm{d}\mu^X$, and X is *bounded* if

$$\|X\|:=\inf\{r\geqslant 0|X([-r,r])=\mathbb{I}\}$$

is finite ($\inf\varnothing=\infty$). Now let $O_b(\mathcal{E},\mathbb{R})$ denote the set of all bounded $\mathbb{R}$-valued observables on $\mathcal{E}$. An observable $\chi_E\in O_b(\mathcal{E},\mathbb{R})$ is allocated to each $E\in\mathcal{E}$ via ($B\in\mathcal{B}$),

$$\chi_E(B):=\begin{cases} E & \text{for } 1\in B \text{ and } 0\notin B,\\ E' & \text{for } 1\notin B \text{ and } 0\in B,\\ 0 & \text{for } 1\notin B \text{ and } 0\notin B,\\ \mathbb{I} & \text{for } 1\in B \text{ and } 0\in B.\end{cases}$$

With a real-valued observable X and a measurable function $f:\mathbb{R}\to\mathbb{R}$, another real-valued observable Y is defined via $Y(B):=X(f^{-1}(B))$ for $B\in\mathcal{B}$; Y is denoted by $f(X)$ in the sequel. Then $\chi_{X(B)}=I_B(X)$, where B is any Borel set and I_B is the indicator function with $I_B(t)=1$ for $t\in B$ and $I_B(t)=0$ for $t\notin B$.

$O_b(\mathcal{E},\mathbb{R})$ forms a pre-JB algebra (i.e., its completion is a JB algebra[7]) if the following three axioms hold in the σ-UCP space $\mathcal{E}$:[11]

(A1) $\mu(E|F)\mu(F)+\mu(E'|F')\mu(F')=\mu(F|E)\mu(E)+\mu(F'|E')\mu(E')$ *for all events* E *and* F *and all* σ*-additive states* μ *on* $\mathcal{E}$.

(A2) *For each pair of events* E *and* F *there is a bounded real-valued observable* $U_E(F)$ *such that* $\mu(F|E)\mu(E)=\mathrm{Exp}_\mu(U_E(F))$ *for every* σ*-additive state* μ *on* $\mathcal{E}$.

(A3) *For each pair of bounded real-valued observables* X *and* Y *there is one and only one bounded real-valued observable* $X+Y$ *such that* $\mathrm{Exp}_\mu(X+Y)=\mathrm{Exp}_\mu(X)+\mathrm{Exp}_\mu(Y)$ *for every* σ*-additive state* μ *on* $\mathcal{E}$.

The addition operation on $O_b(\mathcal{E},\mathbb{R})$ is given by (A3), the generally nonassociative multiplication operation $\circ$ can be derived from (A1) and (A2). The relation $\prec$ then becomes an order relation and coincides with the usual order relation $\leqslant$ on JB algebras if, as it is often done later on, $E\in\mathcal{E}$ and $\chi_E\in O_b(\mathcal{E},\mathbb{R})$ are identified with each other.

III. POSTULATES FOR A MODEL OF A COMPOSITE SYSTEM

A model of a composite system consisting of two single systems each modeled by the σ-UCP spaces $\mathcal{E}$ and $\mathcal{F}$, respectively, should be a σ-UCP space $\mathcal{C}$ with at least the following property:

(C1) There is a map $\otimes:\mathcal{E}\times\mathcal{F}\to\mathcal{C}$ such that $0\otimes F=E\otimes 0=0$ for all $E\in\mathcal{E}$ and $F\in\mathcal{F}$, $\mathbb{I}\otimes\mathbb{I}=\mathbb{I}$, and $E_1\otimes F_1\perp E_2\otimes F_2$ whenever $E_1\perp E_2$ or $F_1\perp F_2$ ($E_1,E_2\in\mathcal{E}$ and $F_1,F_2\in\mathcal{F}$). Moreover,

$\Sigma(E_k \otimes F) = (\Sigma E_k) \otimes F$ for every sequence of mutually orthogonal events E_k in $\mathcal{E}$ and every event F in $\mathcal{F}$, and $\Sigma(E \otimes F_k) = E \otimes (\Sigma F_k)$ for every sequence of mutually orthogonal events F_k in $\mathcal{F}$ and every event E in $\mathcal{E}$.

A particular role is played by the state-independent conditional probabilities, and we shall now see that they are multiplicative on $\mathcal{C}$.

Proposition 3.1: Assume that $\mathcal{E}$ and $\mathcal{F}$ are σ-UCP spaces and that $\mathcal{C}$ is a σ-UCP space such that (C1) holds. If $E \in \mathcal{E}$ is statistically predictable under $D (0 \neq D \in \mathcal{E})$ and $F \in \mathcal{F}$ is statistically predictable under $G (0 \neq G \in \mathcal{F})$, then $E \otimes F$ is statistically predictable under $D \otimes G$ with $\mathbb{P}(E \otimes F | D \otimes G) = \mathbb{P}(E|D)\mathbb{P}(F|G)$.

Proof: Let ρ be a σ-additive state on $\mathcal{C}$ with $\rho(D \otimes G) = 1$. Then $\rho(D \otimes \mathbb{I}) = 1 = \rho(\mathbb{I} \otimes G)$. We now define σ-additive states μ_1 and μ_2 on $\mathcal{E}$ via $\mu_1(C) := \rho(C \otimes G)$ and $\mu_2(C) := \rho(C \otimes \mathbb{I})$ for $C \in \mathcal{E}$. Since $\mu_1(D) = 1 = \mu_2(D)$ and since E is statistically predictable under D, we get $\mathbb{P}(E|D) = \mu_1(E) = \rho(E \otimes G) = \mu_2(E) = \rho(E \otimes \mathbb{I})$ and $\mathbb{P}(E'|D) = \mu_1(E') = \rho(E' \otimes G) = \mu_2(E') = \rho(E' \otimes \mathbb{I})$.

If $\mathbb{P}(E|D) > 0$, we define a σ-additive state ν on $\mathcal{F}$ via $\nu(H) := \rho(E \otimes H)/\mathbb{P}(E|D)$ for $H \in \mathcal{F}$. Then $\nu(G) = 1$ and $\mathbb{P}(F|G) = \nu(F) = \rho(E \otimes F)/\mathbb{P}(E|D)$.

If $\mathbb{P}(E|D) = 0$, then $\mathbb{P}(E'|D) = 1$ and we consider the σ-additive states ν_1 and ν_2 on $\mathcal{F}$ defined via $\nu_1(H) := \rho(E' \otimes H)$ and $\nu_2(H) := \rho(\mathbb{I} \otimes H)$ for $H \in \mathcal{F}$. Thus $\nu_1(G) = 1 = \nu_2(G)$ and $\mathbb{P}(F|G) = \nu_1(F) = \rho(E' \otimes F) = \nu_2(F) = \rho(\mathbb{I} \otimes F)$. Hence $\rho(E \otimes F) = \rho(\mathbb{I} \otimes F) - \rho(E' \otimes F) = 0$.

We thus get that $E \otimes F$ is statistically predictable under $D \otimes G$ with $\mathbb{P}(E \otimes F | D \otimes G) = \mathbb{P}(E|D)\mathbb{P}(F|G)$. □

With a further σ-UCP space $\mathcal{D}$ and two observables $X: \mathcal{E} \to \mathcal{D}$ and $Y: \mathcal{F} \to \mathcal{D}$, a σ-additive state ν on $\mathcal{C}$ is called a *joint distribution* of (X, Y) under the σ-additive state μ on $\mathcal{D}$, if

$$\nu(E \otimes F) = \mu(X(E))\mu(Y(F)|X(E))$$

for all $E \in \mathcal{E}$ and $F \in \mathcal{F}$. This definition of a joint distribution is rather naturally based upon the concept of conditional probabilities and differs from the joint distributions considered by other authors.[5,12,13] Gudder[5] defines a joint distribution via $\mu(X(E) \wedge Y(F))$, which coincides with the above one when the lattice operation $\wedge$ exists and $X(E)$ and $Y(F)$ commute for all E, F.

Generally, the right-hand side of the above equation is additive only in F, but not in E, and a necessary condition for the existence of the joint distribution is that it is additive in E as well. We shall discuss this later on. Moreover, beyond that, the existence and the uniqueness of the joint distribution require the following second postulate on $\mathcal{C}$:

(C2) For every σ-additive bistate ρ on $\mathcal{E} \times \mathcal{F}$, there exists one and only one σ-additive state ω on $\mathcal{C}$ with $\rho(E, F) = \omega(E \otimes F)$ for $E \in \mathcal{E}$ and $F \in \mathcal{F}$.

Here, a *bistate* is a map $\rho: \mathcal{E} \times \mathcal{F} \to [0, 1]$ with $\rho(\mathbb{I}, \mathbb{I}) = 1, \rho(E_1 + E_2, F) = \rho(E_1, F) + \rho(E_2, F)$ and $\rho(E, F_1 + F_2) = \rho(E, F_1) + \rho(E, F_2)$ for all $E, E_1, E_2 \in \mathcal{E}$ with $E_1 \perp E_2$ and $F, F_1, F_2 \in \mathcal{F}$ with $F_1 \perp F_2$. A bistate is σ-additive if it is σ-additive in each component with the other component fixed.

A *stochastically independent coupling* $\mu \otimes \nu$ of the σ-additive states μ on $\mathcal{E}$ and ν on $\mathcal{F}$ is a σ-additive state $\mu \otimes \nu$ on $\mathcal{C}$ with $(\mu \otimes \nu)(E \otimes F) = \mu(E)\nu(F)$ for $E \in \mathcal{E}$ and $F \in \mathcal{F}$. It immediately follows from (C2) that a unique stochastically independent coupling $\mu \otimes \nu$ exists by applying (C2) to the bistate $\rho(E, F) := \mu(E)\nu(F)$ for $E \in \mathcal{E}$ and $F \in \mathcal{F}$. Other authors,[1,8,9] when defining a model for a composite system, consider only these product states and no bistates and do not address the uniqueness of the coupled state.

When (C2) holds, the following proposition now provides the reverse of Proposition 3.1. Note that $E \otimes F$ is statistically predictable under $D \otimes G$ with $\mathbb{P}(E \otimes F | D \otimes G) = 0$ for any F and G in $\mathcal{F}$ if E and D are orthogonal in $\mathcal{E}$ (and for any D and E in $\mathcal{E}$ if F and G are orthogonal in $\mathcal{F}$).

Proposition 3.2: Assume that $\mathcal{E}$ and $\mathcal{F}$ are σ-UCP spaces and that $\mathcal{C}$ is a σ-UCP space such that (C1) and (C2) hold. Let $E \otimes F$ be statistically predictable under $D \otimes G$ for the events $D, E \in \mathcal{E}$ and $F, G \in \mathcal{F} (D \neq 0, G \neq 0)$.

If $\mathbb{P}(E \otimes F | D \otimes G) > 0$, then E is statistically predictable under D and F is statistically predictable under G with $\mathbb{P}(E \otimes F | D \otimes G) = \mathbb{P}(E|D)\mathbb{P}(F|G)$.

If $\mathbb{P}(E\otimes F|D\otimes G)=0$, *then* E *is statistically predictable under* D *with* $\mathbb{P}(E|D)=0$ *or* F *is statistically predictable under* G *with* $\mathbb{P}(F|G)=0$.

Proof: Let μ be any σ-additive state on $\mathcal{E}$ with $\mu(D)=1$ and ν any σ-additive state on $\mathcal{F}$ with $\nu(G)=1$. Then $(\mu\otimes\nu)(D\otimes G)=1$ and $\lambda:=\mathbb{P}(E\otimes F|D\otimes G)=(\mu\otimes\nu)(E\otimes F)=\mu(E)\nu(F)$.

$\lambda>0$: Then $\mu(E)\neq 0\neq\nu(F)$. Since $\mu(E)=\lambda/\nu(F)$ holds for all σ-additive states μ on $\mathcal{E}$ with $\mu(D)=1$ and ν fixed, we get that E is statistically predictable under D with $\mathbb{P}(E|D)=\lambda/\nu(F)\neq 0$. Now $\nu(F)=\lambda/\mathbb{P}(E|D)$ for all σ-additive states ν on $\mathcal{F}$ with $\nu(G)=1$. Thus F is statistically predictable under G with $\mathbb{P}(F|G)=\lambda/\mathbb{P}(E|D)$.

$\lambda=0$: If $\mu(E)=0=\nu(F)$ for all μ,ν with $\mu(D)=1=\nu(G)$, then $\mathbb{P}(E|D)=0=\mathbb{P}(F|G)$. If $\mu(E)>0$ for some μ with $\mu(D)=1$, then $\nu(F)=0$ for all ν with $\nu(G)=1$, i.e., $\mathbb{P}(F|G)=0$. If $\nu(F)>0$ for some ν with $\nu(G)=1$, then $\mu(E)=0$ for all μ with $\mu(D)=1$, i.e., $\mathbb{P}(E|D)=0$. □

An event $D\neq 0$ in a σ-UCP space $\mathcal{E}$ is called an *atom* if $0<E<D$ for an event E in $\mathcal{E}$ implies that either $E=0$ or $E=D$. Then all events in $\mathcal{E}$ are statistically predictable under D. Vice versa, if all events in $\mathcal{E}$ are statistically predictable under an event D, D must be an atom. To see this, assume that an event $0<E<D$ exists with $0\neq E\neq D$. Then there is an event $F\neq 0$ with $E\perp F$ and $D=E+F$, and there are σ-additive states μ and ν with $\mu(E)=1$ and $\nu(F)=1$. Hence $\mu(E|D)=1$ and $\nu(E|D)=0$ such that E cannot be statistically predictable under D.

Proposition 3.3: Assume that $\mathcal{E}$ *and* $\mathcal{F}$ *are* σ*-UCP spaces and that* $\mathcal{C}$ *is a* σ*-UCP space such that (C1) and (C2) hold. If* $D\in\mathcal{E}$ *and* $G\in\mathcal{F}$ *are atoms, then* $D\otimes G$ *is an atom in* $\mathcal{C}$.

Proof: Let $D\in\mathcal{E}$ and $G\in\mathcal{F}$ be atoms. From Proposition 3.1 we get that $E\otimes F$ is statistically predictable under $D\otimes G$ for every $E\in\mathcal{E}$ and $F\in\mathcal{F}$. A σ-additive bistate ρ on $\mathcal{E}\times\mathcal{F}$ is defined via $\rho(E,F):=\mathbb{P}(E\otimes F|D\otimes G)$, and there is a unique σ-additive state ω on $\mathcal{C}$ with $\omega(E\otimes F)=\rho(E,F)$ for $E\in\mathcal{E}$ and $F\in\mathcal{F}$.

Now let μ be a σ-additive state on $\mathcal{C}$ with $\mu(D\otimes G)=1$. Then $\mu(E\otimes F)=\mathbb{P}(E\otimes F|D\otimes G)=\rho(E,F)$ for all $E\in\mathcal{E}$ and $F\in\mathcal{F}$. Therefore $\mu=\omega$, and every event C in $\mathcal{C}$ is statistically predictable under $D\otimes G$ with $\mathbb{P}(C|D\otimes G)=\omega(C)$. Thus $D\otimes G$ is an atom in $\mathcal{C}$. □

IV. JOINT DISTRIBUTIONS OF QUANTUM OBSERVABLES

Note that the product σ-algebra $\mathcal{C}=\mathcal{B}\otimes\mathcal{B}$ which is identical with the Borel measurable subsets of $\mathbb{R}^2$ satisfies (C1) and (C2) for $\mathcal{E}=\mathcal{F}=\mathcal{B}$. Therefore, the joint distribution of two real-valued observables, if it exists, is a probability distribution on $\mathbb{R}^2$.

In classical probability theory, a joint distribution of a family of random variables always exists. In the σ-UCP space model, however, many different cases are possible, and the joint distribution of (X,Y) may exist while the one of (Y,X) does not.

Let $\mathcal{E},\mathcal{F},\mathcal{C}$ be σ-UCP spaces such that $\mathcal{C}$ satisfies (C1) and (C2) for $\mathcal{E}$ and $\mathcal{F}$. With a fourth σ-UCP space $\mathcal{D}$ and two observables $X:\mathcal{E}\to\mathcal{D}$ and $Y:\mathcal{F}\to\mathcal{D}$, we write

$$X\underset{\mu}{\to}Y,\quad \text{if the joint distribution } \mu^{(X,Y)} \text{ of } (X,Y) \text{ under the } \sigma\text{-additive state } \mu \text{ on } \mathcal{D} \text{ exists on } \mathcal{C},$$

$$X\underset{\mu}{\leftrightarrow}Y,\quad \text{if } X\underset{\mu}{\to}Y \text{ as well as } Y\underset{\mu}{\to}X \ (X \text{ and } Y \text{ are then called } \textit{compatible under } \mu),$$

$$X\to Y,\quad \text{if } X\underset{\mu}{\to}Y \text{ holds for all states } \mu \text{ on } \mathcal{D}, \text{ and}$$

$$X\leftrightarrow Y,\quad \text{if } X\to Y \text{ as well as } Y\to X \ (X \text{ and } Y \text{ are then called } \textit{compatible}).$$

We have

$$X\underset{\mu}{\to}Y\Rightarrow\chi_{X(E)}\underset{\mu}{\to}\chi_{Y(F)} \text{ for all } E\in\mathcal{E} \text{ and } F\in\mathcal{F},$$

and with two events E and F in the σ-UCP space $\mathcal{D}$, we have

$$\chi_E \underset{\mu}{\rightarrow} \chi_F \Leftrightarrow \mu(F) = \mu(F|E)\mu(E) + \mu(F|E')\mu(E')$$

(μ a σ-additive state on $\mathcal{D}$). Two events E and F are said to be compatible (compatible under μ), if χ_E and χ_F are compatible (compatible under μ).

In classical probability theory, the joint distributions $\mu^{(X,Y)}$ and $\mu^{(Y,X)}$ are connected via $\mu^{(X,Y)}(E\otimes F)=\mu^{(Y,X)}(F\otimes E)$, which is equivalent to $\mu(X(E))\mu(Y(F)|X(E))=\mu(Y(F))\times\mu(X(E)|Y(F))$. It is axiom (A1) that ensures this property for the σ-UCP spaces as well.

Lemma 4.1: Let E and F be events in a σ-UCP space $\mathcal{D}$ that satisfies (A1). They are equivalent for a σ-additive state μ on $\mathcal{D}$:

(i) *E and F are compatible under* μ,
(ii) $\mu(E)\mu(F|E)=\mu(F)\mu(E|F)$, $\mu(E)\mu(F'|E)=\mu(F')\mu(E|F')$, *and* $\mu(E')\mu(F|E')=\mu(F)\mu(E'|F)$.

Proof: First we assume (ii). Then $\mu(F|E)\mu(E)+\mu(F|E')\mu(E')=\mu(E|F)\mu(F)+\mu(E'|F)\mu(F)=\mu(F)$ and $\mu(E|F)\mu(F)+\mu(E|F')\mu(F')=\mu(F|E)\mu(E)+\mu(F'|E)\mu(E)=\mu(E)$. Note that (A1) is not needed here for the proof of the implication (ii) $\Rightarrow$ (i).

We now assume (i). Then $\mu(E)=\mu(E|F)\mu(F)+\mu(E|F')\mu(F')$ and $\mu(F)=\mu(F|E)\mu(E)+\mu(F|E')\mu(E')$. Hence

$$\begin{aligned}\mu(E'|F')\mu(F') &= (1-\mu(E|F'))\mu(F')\\ &= \mu(F')-\mu(E)+\mu(E|F)\mu(F) = 1-\mu(F)-\mu(E)+\mu(E|F)\mu(F)\end{aligned}$$

and

$$\begin{aligned}\mu(F'|E')\mu(E') &= (1-\mu(F|E'))\mu(E')\\ &= \mu(E')-\mu(F)+\mu(F|E)\mu(E) = 1-\mu(E)-\mu(F)+\mu(F|E)\mu(E).\end{aligned}$$

Thus, by forming the difference of these two identities and then by (A1),

$$\mu(E|F)\mu(F)-\mu(F|E)\mu(E)=\mu(E'|F')\mu(F')-\mu(F'|E')\mu(E')=\mu(F|E)\mu(E)-\mu(E|F)\mu(F),$$

i.e.,

$$\mu(E)\mu(F|E)=\mu(F)\mu(E|F).$$

Since the compatibility of E and F under μ implies the one of E and F' as well as of E' and F, the other two equations of (ii) follow in the same way. □

Theorem 4.2: *Let $\mathcal{E},\mathcal{F},\mathcal{C}$ be σ-UCP spaces such that $\mathcal{C}$ satisfies (C1) and (C2) for $\mathcal{E}$ and $\mathcal{F}$. Let $\mathcal{D}$ be a fourth σ-UCP space where (A1) holds, μ a σ-additive state on $\mathcal{D}$ and let $X:\mathcal{E}\rightarrow\mathcal{D}$ and $Y:\mathcal{F}\rightarrow\mathcal{D}$ be observables. If $X(E)$ and $Y(F)$ are compatible under μ for all $E\in\mathcal{E}$ and $F\in\mathcal{F}$, then the joint distributions $\mu^{(X,Y)}$ on $\mathcal{C}$ and $\mu^{(Y,X)}$ on $\overline{\mathcal{C}}$ (which is similar to $\mathcal{C}$, but with exchanged roles of $\mathcal{E}$ and $\mathcal{F}$) exist and satisfy $\mu^{(X,Y)}(E\otimes F)=\mu^{(Y,X)}(F\otimes E)$.*

Proof: From Lemma 4.1 we get that $\mu(X(E)|Y(F))\mu(Y(F))=\mu(Y(F)|X(E))\mu(X(E))$ for $E\in\mathcal{E}$ and $F\in\mathcal{F}$. This then implies (1) the σ-additivity in E with F fixed as well as in F with E fixed, (2) the existence of both the joint distributions, and (3) the identity $\mu^{(X,Y)}(E\otimes F)=\mu^{(Y,X)}(F\otimes E)$. □

We now assume that $\mathcal{E}=\mathcal{F}=\mathcal{B}$ ($\mathcal{B}$ is the system of the Borel sets in $\mathbb{R}$) and that $\mathcal{D}$ is a standard quantum logic, i.e., the system of the closed linear subspaces of a Hilbert space $\mathcal{H}$ or, equivalently, the system of the orthogonal projectors on $\mathcal{H}$. Then $\mu(E|F)=\mathrm{Exp}_\mu(FEF)/\mu(F)$ for $E,F\in\mathcal{D}$.[10]

Therefore, $F\rightarrow E$ holds if and only if $E=FEF+F'EF'$, which is equivalent to $EF=FE$. Thus, $F\rightarrow E, E\rightarrow F$ and $E\leftrightarrow F$ are equivalent to each other and to the standard quantum-mechanical concept of compatibility in this case. Moreover, $X\rightarrow Y, Y\rightarrow X, X\leftrightarrow Y$, and $[X,Y]=0$ become

equivalent for real-valued observables X and Y. Here the observable which is a spectral measure is identified with the corresponding operator, and the observables χ_E, χ_F are identified with the events E, F.

However, the situation is different when the joint distribution exists only under a single σ-additive state μ. We have $F \underset{\mu}{\rightarrow} E$ if and only if

$$\mu(E) = \mathrm{Exp}_\mu(FEF + F'EF') = \mathrm{Exp}_\mu(2FEF + E - EF - FE)$$

or, equivalently,

$$\mathrm{Exp}_\mu(FEF) = \mathrm{Exp}_\mu(EF + FE)/2,$$

which is not symmetrical in E and F. An example can easily be constructed by using two nonorthogonal vectors $\eta, \xi \in \mathcal{H}$ with $\|\eta\| = 1 = \|\xi\|$ and choosing $E = |\eta\rangle\langle\eta|, F = |\xi\rangle\langle\xi|$, and $\mu(D) = \langle\eta|D\eta\rangle$; then $E \underset{\mu}{\rightarrow} F$, but not $F \underset{\mu}{\rightarrow} E$. Moreover, the above equivalence immediately implies that all pairs of events are compatible under the trace state if $\mathcal{H}$ has a finite dimension, which distinguishes the trace among other states.

If X and Y are real-valued observables, $\mu^{(X,Y)}$ is the joint distribution of two subsequent observations (measurements) of X and Y, where X is observed (measured) first and Y second. That $\mu^{(X,Y)}$ may exist while $\mu^{(Y,X)}$ does not exist, shows that the time order of observations (measurements) plays a more significant role with the non-Boolean probabilities than with the classical probabilities. Quantum probabilities are non-Boolean, which is the origin of many typical quantum phenomena.[10]

The classical concept of stochastic independence can now be extended to the general case of observables $X: \mathcal{E} \rightarrow \mathcal{D}$ and $Y: \mathcal{F} \rightarrow \mathcal{D}$ ($\mathcal{E}, \mathcal{F}, \mathcal{D}$ σ-UCP spaces) in the following obvious way: X and Y are *independent under* μ if $\mu(X(E)) = \mu(X(E)|Y(F))$ holds for $\mu(Y(F)) > 0$ and $\mu(Y(F)) = \mu(Y(F)|X(E))$ holds for $\mu(X(E)) > 0$ ($E \in \mathcal{E}$ and $F \in \mathcal{F}$). Note that this implies $X(E) \underset{\mu}{\leftrightarrow} Y(F)$ for $E \in \mathcal{E}, F \in \mathcal{F}$ and, if the assumptions of Theorem 4.2 hold, the joint distributions exist with

$$\mu^{(X,Y)}(E \otimes F) = \mu^X(E)\mu^Y(F) = \mu^{(Y,X)}(F \otimes E).$$

When (A1), (A2), and (A3) hold, two events E and F in $\mathcal{E}$ are independent under μ if and only if they are compatible under μ and the identity $\mathrm{Exp}_\mu(E \circ F) = \mu(E)\mu(F)$ holds for the product $E \circ F$ in $O_b(\mathcal{E}, \mathbb{R})$. For two independent real-valued observables we then get $\mathrm{Exp}_\mu(X \circ Y) = \mathrm{Exp}_\mu(X)\mathrm{Exp}_\mu(Y)$ and $\mathrm{Var}_\mu(X+Y) = \mathrm{Var}_\mu(X) + \mathrm{Var}_\mu(Y)$. The first equation follows since the bounded real-valued observables can be approximated by linear combinations of events in $O_b(\mathcal{E}, \mathbb{R})$; the second equation follows from the first one. Using the Chebychev inequality, the weak *law of large numbers* can now be proved under the same assumptions and in the same way as with classical probabilities, but only for the bounded observables.

In classical probability theory, the law of large numbers provides the link between probabilities and relative frequencies as well as between expectation values and statistical averages. In quantum theory, the law of large numbers gets an additional significance since the convergence towards a constant observable also means that large systems become asymptotically classical.

V. JORDAN MATRIX ALGEBRAS

We shall now study the question whether a σ-UCP space $\mathcal{C}$ satisfying (C1) and (C2) exists for given σ-UCP spaces $\mathcal{E}$ and $\mathcal{F}$. Unfortunately, a general answer cannot be given at present, and we have to restrict to the case when $\mathcal{E}, \mathcal{F}$ as well as $\mathcal{C}$ satisfy (A1), (A2), and (A3) and $O_b(\mathcal{E}, \mathbb{R})$ as well as $O_b(\mathcal{F}, \mathbb{R})$ are finite dimensional. Then $O_b(\mathcal{E}, \mathbb{R}), O_b(\mathcal{F}, \mathbb{R})$ and, as we shall see later on, $O_b(\mathcal{C}, \mathbb{R})$ as well are finite-dimensional formally real Jordan algebras and are direct sums of real, complex, quaternion or octonion Jordan matrix algebras.[7]

Let $\mathbb{H}$ denote the noncommutative field of quaternions and $\mathbb{O}$ the noncommutative and nonassociative field of octonions (Cayley numbers). For $K = \mathbb{R}, \mathbb{C}, \mathbb{H}$ or $\mathbb{O}$, $M_n(K)$ is the algebra of $n \times n$-matrices over K and $H_n(K)$ the algebra of the Hermitian elements of $M_n(K)$ equipped with the Jordan product. Then $H_n(K)$ with $K = \mathbb{R}, \mathbb{C}, \mathbb{H}$ is a Jordan algebra for all positive integers n, $H_n(\mathbb{O})$

is a Jordan algebra if and only if $n \leqslant 3$ (Ref. 7). These are the real, complex, quaternion, and octonion Jordan matrix algebras. The real dimension of $H_n(K)$ is $n+kn(n-1)/2$ where k is the real dimension of K, i.e., $k=1$ for $K=\mathbb{R}, k=2$ for $K=\mathbb{C}, k=4$ for $K=\mathbb{H}$, and $k=8$ for $K=\mathbb{O}$.

Let $J_n(K)$ denote the system of idempotent elements in $H_n(K); J_n(K)$ with $n \neq 2$ and $K \neq \mathbb{O}$ as well as $J_3(\mathbb{O})$ are UCP spaces[10] and satisfy (A1), (A2), and (A3). Note that σ-additivity need not be distinguished from finite additivity, due to the finite dimension, and that $\mathcal{O}_b(J_n(K), \mathbb{R}) = H_n(K)$ by identifying the Hermitian matrices with their spectral measures.

Theorem 5.1: *Assume $\mathcal{E}=J_n(K)$ and $\mathcal{F}=J_m(K)$ with $K=\mathbb{R}, \mathbb{C}, \mathbb{H}$ and $m, n \geqslant 3$, or with $K=\mathbb{O}$ and $m=n=3$. Then a σ-UCP space $\mathcal{C}$ satisfying (C1) and (C2) as well as (A1), (A2), and (A3) exists if and only if $K=\mathbb{C}$.*

I*n this case, (C1) and (C2) are fulfilled with $\mathcal{C}=J_{mn}(\mathbb{C})$ and $E \otimes F \in J_{mn}(\mathbb{C})$ being the Kronecker product of $E \in J_n(\mathbb{C})$ and $F \in J_m(\mathbb{C})$.*

The proof of Theorem 5.1 will be broken into a series of lemmas. First note that the tensor product $M_n(\mathbb{C}) \otimes M_m(\mathbb{C})$ can be identified with $M_{mn}(\mathbb{C})$ via the Kronecker product,

$$X \otimes Y = \begin{pmatrix} x_{11}Y & \cdots & x_{1n}Y \\ \vdots & \ddots & \vdots \\ x_{n1}Y & \cdots & x_{nn}Y \end{pmatrix},$$

for $X \in M_n(\mathbb{C})$ and $Y \in M_m(\mathbb{C})$. Then $E \otimes F \in J_{mn}(\mathbb{C})$ for $E \in J_n(\mathbb{C}), F \in J_m(\mathbb{C})$.

The real-linear spaces $H_n(\mathbb{C}) \otimes H_m(\mathbb{C})$ and $H_{mn}(\mathbb{C})$ coincide, and $H_{mn}(\mathbb{C})$ is the real-linear hull of the $E \otimes F \in J_{mn}(\mathbb{C})$ with $E \in J_n(\mathbb{C})$ and $F \in J_m(\mathbb{C})$. Note that this does not hold for the real Jordan matrix algebras.

Lemma 5.2: $\mathcal{C}=J_{mn}(\mathbb{C})$ with $E \otimes F$ being the Kronecker product fulfills (C1) and (C2) for $\mathcal{E} = J_n(\mathbb{C})$ and $\mathcal{F}=J_m(\mathbb{C}), n, m \geqslant 3$.

Proof: (C1) is obviously fulfilled, and we prove (C2). Let ρ be a bistate on $J_n(\mathbb{C}) \times J_m(\mathbb{C})$. By Gleason's theorem,[4] there is one and only one positive matrix $T_F \in H_n(\mathbb{C})$ for every $F \in J_m(\mathbb{C})$ such that $\rho(E,F)=\mathrm{tr}(ET_F)$ for all $E \in J_n(\mathbb{C})$. The map $F \to T_F$ is then orthogonally additive in F and, for each positive matrix $X \in H_n(\mathbb{C})$, we again apply Gleason's theorem, this time to the map $F \to \mathrm{tr}(XT_F)$ on $J_m(\mathbb{C})$, such that there is one and only one positive matrix $S_X \in H_m(\mathbb{C})$ with $\mathrm{tr}(XT_F))=\mathrm{tr}(S_XF)$. Since every matrix in $H_n(\mathbb{C})$ is the difference of two positive matrices, we can assume that an $S_X \in H_m(\mathbb{C})$ with $\mathrm{tr}(XT_F))=\mathrm{tr}(S_XF)$ exists for every $X \in H_n(\mathbb{C})$. The map $X \to S_X$ is real-linear, and the map $H_n(\mathbb{C}) \times H_m(\mathbb{C}) \ni (X,Y) \to \mathrm{tr}(S_XY)$ is a bilinear extension of ρ. Therefore, there exists a real-linear functional ω on the real-linear tensor product $H_n(\mathbb{C}) \otimes H_m(\mathbb{C}) = H_{mn}(\mathbb{C})$ such that $\omega(X \otimes Y)=\mathrm{tr}(S_XY)$ for $X \in H_n(\mathbb{C})$ and $Y \in H_m(\mathbb{C})$. Hence $\rho(E,F)=\omega(E \otimes F)$, and ω is positive as well as uniquely determined since $H_{mn}(\mathbb{C})$ is the real-linear hull of the $E \otimes F \in J_{mn}(\mathbb{C})$ with $E \in J_n(\mathbb{C})$ and $F \in J_m(\mathbb{C})$. The restriction of ω to $\mathcal{C}=J_{mn}(\mathbb{C})$ provides the desired state. □

We now assume that $\mathcal{E}, \mathcal{F}, \mathcal{C}$ are σ-UCP spaces where (A1), (A2), and (A3) hold, that $\mathcal{O}_b(\mathcal{E}, \mathbb{R})$ and $\mathcal{O}_b(\mathcal{F}, \mathbb{R})$ are finite-dimensional and that $\mathcal{C}$ satisfies (C1) and (C2) for $\mathcal{E}$ and $\mathcal{F}$. Note that χ_E and E as well as $\chi_{E \otimes F}$ and $E \otimes F$ are not distinguished in the sequel.

On $\mathcal{O}_b(\mathcal{C}, \mathbb{R})$, we consider the weak topology induced by those linear functionals φ which have the shape $\varphi(X)=s\,\mathrm{Exp}_\mu(X) - t\,\mathrm{Exp}_\nu(X)$ with σ-additive states μ, ν on $\mathcal{C}, s, t \in \mathbb{R}$.

Lemma 5.3: $\mathcal{O}_b(\mathcal{C}, \mathbb{R})$ is the weakly closed linear hull of $\{E \otimes F : E \in \mathcal{E}, F \in \mathcal{F}\}$.

Proof: We assume that the weakly closed linear hull of $\{E \otimes F : E \in \mathcal{E}, F \in \mathcal{F}\}$ does not coincide with $\mathcal{O}_b(\mathcal{C}, \mathbb{R})$. Then there is a linear functional $\varphi \neq 0$ on $\mathcal{O}_b(\mathcal{C}, \mathbb{R})$, having the above shape with σ-additive states μ, ν on $\mathcal{C}, s, t \in \mathbb{R}$, such that $\varphi(E \otimes F)=0$ for $E \in \mathcal{E}, F \in \mathcal{F}$. Then $s=t \neq 0$, since $\varphi(\mathbb{I} \otimes \mathbb{I})=0$ and $\varphi \neq 0$. Since the restrictions of μ and ν to $\{E \otimes F : E \in \mathcal{E}, F \in \mathcal{F}\}$ provide identical bistates on $\mathcal{E} \times \mathcal{F}$, μ and ν must coincide on $\mathcal{C}$, contradicting $\varphi \neq 0$. Note that $\mathcal{O}_b(\mathcal{C}, \mathbb{R})$ is the linear hull of $\mathcal{C}$.[11] □

Lemma 5.4: For every bistate ρ on $\mathcal{E} \times \mathcal{F}$, there is a unique linear functional φ_ρ on the linear tensor product $\mathcal{O}_b(\mathcal{E}, \mathbb{R}) \otimes \mathcal{O}_b(\mathcal{F}, \mathbb{R})$ such that $\rho(E,F)=\varphi_\rho(E \otimes F)$ for $E \in \mathcal{E}, F \in \mathcal{F}$.

Proof: For $E \in \mathcal{E}$ with $\rho(E, \mathbb{I}) > 0$ define a state ρ_E on $\mathcal{F}$ via $\rho_E(F) := \rho(E,F)/\rho(E, \mathbb{I})$. Let $\hat{\rho}_E$ be

its linear extension to $\mathcal{O}_b(\mathcal{F},\mathbb{R})$, i.e., $\hat{\rho}_E(Y)$ is the expectation value of the observable X in the state $\hat{\rho}_E$. Define $\hat{\rho}_E := 0$ for $\rho(E,\mathbb{I})=0$. Since $\mathcal{O}_b(\mathcal{E},\mathbb{R})$ is the linear hull of $\mathcal{E}$,[11] we can choose a basis $E_1,\ldots,E_n$ of $\mathcal{O}_b(\mathcal{E},\mathbb{R})$ such that $E_1,\ldots,E_n \in \mathcal{E}$. Every $X \in \mathcal{O}_b(\mathcal{E},\mathbb{R})$ then has the shape $X=t_1E_1 + \cdots + t_nE_n$ with unique numbers $t_1,\ldots,t_n \in \mathbb{R}$, and we define a bilinear functional φ_0 via

$$\varphi_0(X,Y) := \sum_{k=1}^{n} t_k \rho(E_k,\mathbb{I})\hat{\rho}_{E_k}(Y)$$

for $X \in \mathcal{O}_b(\mathcal{E},\mathbb{R})$ and $Y \in \mathcal{O}_b(\mathcal{F},\mathbb{R})$. Hence, there is a linear functional φ_ρ on $\mathcal{O}_b(\mathcal{E},\mathbb{R}) \otimes \mathcal{O}_b(\mathcal{F},\mathbb{R})$ with $\varphi_\rho(X\otimes Y)=\varphi_0(X,Y)$. Then $\varphi_\rho(E_k\otimes F)=\rho(E_k,F)$ for $F \in \mathcal{F}$.

For $F \in \mathcal{F}$ with $\rho(\mathbb{I},F)>0$ define a state ρ^F on $\mathcal{E}$ via $\rho^F(E) := \rho(E,F)/\rho(\mathbb{I},F)$. Let $\hat{\rho}^F$ be its linear extension to $\mathcal{O}_b(\mathcal{E},\mathbb{R})$. Define $\hat{\rho}^F := 0$ for $\rho(\mathbb{I},F)=0$. The maps $X \to \rho(\mathbb{I},F)\hat{\rho}^F(X)$ and $X \to \varphi_\rho(X\otimes F)$ are linear functionals on $\mathcal{O}_b(\mathcal{E},\mathbb{R})$ coinciding on the basis $E_1,\ldots,E_n$ and therefore being identical. Hence $\varphi_\rho(E\otimes F)=\rho(E,F)$ for all $E \in \mathcal{E}$ and $F \in \mathcal{F}$.

Since $\mathcal{O}_b(\mathcal{E},\mathbb{R})$ is the linear hull of $\mathcal{E}$ and $\mathcal{O}_b(\mathcal{F},\mathbb{R})$ is the linear hull of $\mathcal{F}$, $\mathcal{O}_b(\mathcal{E},\mathbb{R}) \otimes \mathcal{O}_b(\mathcal{F},\mathbb{R})$ is generated by $\{E\otimes F : E \in \mathcal{E}, F \in \mathcal{F}\}$, which implies the uniqueness of φ_ρ. □

Lemma 5.5: Every linear functional ρ on the linear tensor product $\mathcal{O}_b(\mathcal{E},\mathbb{R})\otimes\mathcal{O}_b(\mathcal{F},\mathbb{R})$ has the shape $\rho=\alpha\rho_+ - \beta\rho_-$ with $\alpha,\beta \geqslant 0$ such that the maps $\mathcal{E}\times\mathcal{F} \ni (E,F) \to \rho_\pm(E\otimes F)$ are bistates.

Proof: For $X,Y \in \mathcal{O}_b(\mathcal{E},\mathbb{R})\otimes\mathcal{O}_b(\mathcal{F},\mathbb{R})$, we define $X \leqslant Y :\Leftrightarrow (\varphi\otimes\psi)(X) \leqslant (\varphi\otimes\psi)(Y)$ for all positive linear functionals φ on $\mathcal{O}_b(\mathcal{E},\mathbb{R})$ and ψ on $\mathcal{O}_b(\mathcal{F},\mathbb{R})$.

Since every linear functional on $\mathcal{O}_b(\mathcal{E},\mathbb{R})$ or $\mathcal{O}_b(\mathcal{F},\mathbb{R})$ is the difference of two positive functionals, the dual space of $\mathcal{O}_b(\mathcal{E},\mathbb{R})\otimes\mathcal{O}_b(\mathcal{F},\mathbb{R})$ is generated by the $\varphi\otimes\psi$ with positive functionals φ on $\mathcal{O}_b(\mathcal{E},\mathbb{R})$ and ψ on $\mathcal{O}_b(\mathcal{F},\mathbb{R})$. Therefore, $X \leqslant 0$ and $0 \leqslant X$ holds if and only if $X=0$ such that $\leqslant$ becomes an order relation.

Now let $X \in \mathcal{O}_b(\mathcal{E},\mathbb{R})\otimes\mathcal{O}_b(\mathcal{F},\mathbb{R})$. Then X has the shape

$$X = \sum_{k=1}^{n} t_k E_k \otimes F_k$$

with $k \in \mathbb{N}, E_1,\ldots,E_n \in \mathcal{E}, F_1,\ldots,F_n \in \mathcal{F}$ and $t_1,\ldots,t_n \in \mathbb{R}$. Hence $|(\varphi\otimes\psi)(X)| \leqslant \Sigma|t_k|(\varphi\otimes\psi)(\mathbb{I}\otimes\mathbb{I})$ for positive functionals φ on $\mathcal{O}_b(\mathcal{E},\mathbb{R})$ and ψ on $\mathcal{O}_b(\mathcal{F},\mathbb{R})$, i.e., $-\Sigma|t_k|\mathbb{I}\otimes\mathbb{I} \leqslant X \leqslant \Sigma|t_k|\mathbb{I}\otimes\mathbb{I}$. Obviously, $\mathcal{O}_b(\mathcal{E},\mathbb{R})\otimes\mathcal{O}_b(\mathcal{F},\mathbb{R})$ is Archimedian and thus an order unit space[7] with the order unit $\mathbb{I}\otimes\mathbb{I}$.

Therefore,[7] every linear functional ρ on $\mathcal{O}_b(\mathcal{E},\mathbb{R})\otimes\mathcal{O}_b(\mathcal{F},\mathbb{R})$ has the shape $\rho=\rho_+-\rho_-$ with positive linear functionals ρ_+ and ρ_-. Then, either $\rho_\pm=0$ or the maps $\mathcal{E}\times\mathcal{F} \ni (E,F) \to \rho_\pm(E\otimes F)/\rho_\pm(\mathbb{I}\otimes\mathbb{I})$ are bistates. □

Lemma 5.6: $\dim \mathcal{O}_b(\mathcal{C},\mathbb{R}) = \dim \mathcal{O}_b(\mathcal{E},\mathbb{R}) \dim \mathcal{O}_b(\mathcal{F},\mathbb{R})$.

Proof: We prove that there is a linear bijection Φ from the linear tensor product $\mathcal{O}_b(\mathcal{E},\mathbb{R}) \otimes \mathcal{O}_b(\mathcal{F},\mathbb{R})$ onto $\mathcal{O}_b(\mathcal{C},\mathbb{R})$. Every element Z of $\mathcal{O}_b(\mathcal{E},\mathbb{R})\otimes\mathcal{O}_b(\mathcal{F},\mathbb{R})$ has the shape

$$\sum_{k=1}^{n} t_k E_k \otimes F_k$$

with $E_1,\ldots,E_n \in \mathcal{E}, F_1,\ldots,F_n \in \mathcal{F}$ and $t_k \in \mathbb{R}$, and we allocate to Z the element $\Phi(Z)$ of $\mathcal{O}_b(\mathcal{C},\mathbb{R})$, having the same shape in $\mathcal{O}_b(\mathcal{C},\mathbb{R})$. Note that the same notation $E\otimes F$ is used here for two different objects, one lying in $\mathcal{O}_b(\mathcal{E},\mathbb{R})\otimes\mathcal{O}_b(\mathcal{F},\mathbb{R})$ and the other one in $\mathcal{C}\subseteq\mathcal{O}_b(\mathcal{C},\mathbb{R})$. In $\mathcal{O}_b(\mathcal{E},\mathbb{R})\otimes\mathcal{O}_b(\mathcal{F},\mathbb{R})$,

$$\sum_{k=1}^{n} t_k E_k \otimes F_k = 0$$

holds if and only if (use Lemma 5.4 and Lemma 5.5)

$$\sum_{k=1}^{n} t_k \rho(E_k, F_k) = 0$$

for every bistate ρ on $\mathcal{E}\times\mathcal{F}$. By (C2), this is equivalent to

$$\sum_{k=1}^{n} t_k \mu(E_k \otimes F_k) = 0$$

for every σ-additive state μ on $\mathcal{C}$, i.e., to

$$\sum_{k=1}^{n} t_k E_k \otimes F_k = 0$$

in $\mathcal{O}_b(\mathcal{C},\mathbb{R})$. Therefore $\Phi:\mathcal{O}_b(\mathcal{E},\mathbb{R})\otimes\mathcal{O}_b(\mathcal{F},\mathbb{R})\to\mathcal{O}_b(\mathcal{C},\mathbb{R})$ is a well-defined and injective linear map. The range of Φ has a finite dimension, is closed then and thus, by Lemma 5.3, Φ is surjective as well. □

The *center* of a Jordan algebra $\mathcal{A}$ is the set of those elements of $\mathcal{A}$ that operator-commute with every element of $\mathcal{A}$, and $\mathcal{A}$ is called a *factor* if its center consists of the scalar multiples of the identity $\mathbb{I}$ alone. The finite-dimensional JB factors are the Jordan matrix algebras over $\mathbb{R},\mathbb{C},\mathbb{H}$ or $\mathbb{O}$.

In the sequel, we shall need the so-called *Jordan triple product*[7] $\{\ ,\ ,\ \}$, which is defined as follows for three elements X,Y,Z in a Jordan algebra: $\{X,Y,Z\} := X\circ(Y\circ Z) - Y\circ(Z\circ X) + Z\circ(X\circ Y)$.

If E and F are atoms in a finite-dimensional JB factor $\mathcal{A}$, there is an atom D which is orthogonal neither with E nor with F. If E and F are not orthogonal, choose $D=E$ or $D=F$. If E and F are orthogonal, they must be *strongly connected* and hence $\{E,\mathcal{A},F\}\neq\{0\}$.[7] Since $\mathcal{A}$ is generated by its atoms, there is an atom D with $0\neq\{E,D,F\}=E\circ(F\circ D)-D\circ(E\circ F)+F\circ(E\circ D)$ $=E\circ(F\circ D)+F\circ(E\circ D)$, and since E and F operator-commute, $E\circ(F\circ D)=F\circ(E\circ D)$, such that $F\circ D\neq 0\neq E\circ D$.

Lemma 5.7: If $\mathcal{O}_b(\mathcal{E},\mathbb{R})$ and $\mathcal{O}_b(\mathcal{F},\mathbb{R})$ are factors, then $\mathcal{O}_b(\mathcal{C},\mathbb{R})$ is a factor.

Proof: $\mathcal{O}_b(\mathcal{C},\mathbb{R})$ is a factor if and only if 0 and $\mathbb{I}\otimes\mathbb{I}$ are the only idempotent elements in its center. Assume that H is an idempotent element in the center, and let $E\in\mathcal{E}$ and $F\in\mathcal{F}$ be atoms. Then (see Ref.7)

$$E\otimes F = \{H,E\otimes F,H\} + \{H',E\otimes F,H'\}$$

and $\{H,E\otimes F,H\}$ as well as $\{H',E\otimes F,H'\}$ are idempotent ($H'=\mathbb{I}\otimes\mathbb{I}-H$). Since $E\otimes F$ is an atom (Proposition 3.3), one of these two idempotent elements must equal 0 and the other one must equal $E\otimes F$, i.e., either $E\otimes F\leqslant H$ or $E\otimes F\leqslant H'$. Both cases are symmetric, and we assume $E\otimes F\leqslant H$.

Now let $D_o\in\mathcal{E}$ and $G_o\in\mathcal{F}$ be atoms such that $\mathbb{P}(E|D_o)\neq 0$ and $\mathbb{P}(F|G_o)\neq 0$. Then again either $D_o\otimes G_o\leqslant H$ or $D_o\otimes G_o\leqslant H'$. From Proposition 3.1 we get $\mathbb{P}(E\otimes F|D_o\otimes G_o)\neq 0$, i.e., $\{D_o\otimes G_o,E\otimes F,D_o\otimes G_o\}\neq 0$, which excludes $D_o\otimes G_o\leqslant H'$ such that $D_o\otimes G_o\leqslant H$.

Now let $D\in\mathcal{E}$ and $G\in\mathcal{F}$ be any atoms. Then there exists an atom $D_o\in\mathcal{E}$ which is orthogonal with neither E nor D, and there is an atom $G_o\in\mathcal{F}$ which is orthogonal with neither F nor G. Then $\mathbb{P}(E|D_o)\neq 0\neq\mathbb{P}(D_o|D)$ and $\mathbb{P}(F|G_o)\neq 0\neq\mathbb{P}(G_o|G)$. Applying the above, we get first $D_o\otimes G_o\leqslant H$ and then $D\otimes G\leqslant H$ (by exchanging E,F with D_o,G_o and D_o,G_o with D,G).

Now let $D_1,\ldots,D_n\in\mathcal{E}$ and $G_1,\ldots,G_m\in\mathcal{F}$ be pairwise orthogonal atoms in $\mathcal{E}$ and $\mathcal{F}$, respectively, with $\mathbb{I}=\Sigma D_j$ and $\mathbb{I}=\Sigma G_k$. Then $\mathbb{I}\otimes\mathbb{I}=\Sigma\Sigma D_j\otimes G_k\leqslant H$ and therefore $\mathbb{I}\otimes\mathbb{I}=H$. □

Proof of Theorem 5.1: $\mathcal{E}=J_n(K)$ and $\mathcal{F}=J_m(K)$ with $K=\mathbb{R},\mathbb{C},\mathbb{H}$, or $\mathbb{O}, m,n\geqslant 3$, and $m=n=3$ if $K=\mathbb{O}$. Assume that a UCP space $\mathcal{C}$ satisfying (C1) and (C2) as well as (A1), (A2), and (A3) exists with $\mathcal{O}_b(\mathcal{C},\mathbb{R})$ being finite-dimensional. By Lemmas 5.6, 5.7 and Proposition 3.3, $\mathcal{O}_b(\mathcal{C},\mathbb{R})$ is a JB factor with $\dim\mathcal{O}_b(\mathcal{C},\mathbb{R})=\dim H_n(K)\dim H_m(K)$ and the identity in $\mathcal{O}_b(\mathcal{C},\mathbb{R})$ is the sum of the mn pairwise orthogonal atoms $E_j\otimes F_k$, where $E_1,\ldots,E_n$ are orthogonal atoms in $\mathcal{E}$ the sum of which is $\mathbb{I}$, and $F_1,\ldots,F_m$ are orthogonal atoms in $\mathcal{F}$ the sum of which is $\mathbb{I}$. Therefore $\mathcal{O}_b(\mathcal{C},\mathbb{R})$

$=H_{mn}(K_0)$ with $K_0=\mathbb{R},\mathbb{C}$ or $\mathbb{H}$; $K_0=\mathbb{O}$ is not possible since $mn\geqslant 9$ and $H_{mn}(\mathbb{O})$ is a Jordan algebra only if $mn=3$.

Case 1: $K=\mathbb{R}$. Then $\dim \mathcal{O}_b(\mathcal{C},\mathbb{R})=\dim H_n(\mathbb{R})\dim H_m(\mathbb{R})=m(m+1)n(n+1)/4$. On the other hand, $\dim \mathcal{O}_b(\mathcal{C},\mathbb{R})$ must equal $\dim H_{mn}(K_0)$ which is $mn(mn+1)/2$ for $K_0=\mathbb{R}, m^2n^2$ for $K_0=\mathbb{C}$, and $mn(2mn-1)$ for $K_0=\mathbb{H}$, i.e., $(m+1)(n+1)=2(mn+1), 4mn$, or $8mn-4$, but all these three cases are impossible since $(m+1)(n+1)<2(mn+1)\leqslant 4mn\leqslant 8mn-4$ for $m,n\geqslant 3$.

Case 2: $K=\mathbb{C}$. See Lemma 3.2.

Case 3: $K=\mathbb{H}$. Then $\dim \mathcal{O}_b(\mathcal{C},\mathbb{R})=m(2m-1)n(2n-1)$ which must equal $mn(mn+1)/2$ for $K_0=\mathbb{R}, m^2n^2$ for $K_0=\mathbb{C}$, and $mn(2mn-1)$ for $K_0=\mathbb{H}$, i.e., $(2m-1)(2n-1)=(mn+1)/2, mn$ or $2mn-1$, which is impossible since $(2m-1)(2n-1)>2mn-1\geqslant mn\geqslant (mn+1)/2$.

Case 4: $K=\mathbb{O}$. Then $\mathcal{E}=\mathcal{F}=J_3(\mathbb{O})$, $\dim \mathcal{O}_b(\mathcal{C},\mathbb{R})=27^2\neq 45,81,153$ which are the dimensions of $H_9(\mathbb{R}), H_9(\mathbb{C}), H_9(\mathbb{H})$. □

VI. NONUNIQUENESS OF THE MODEL

We now turn to the question whether the postulates for a model of a composite system uniquely determine such a model, and we first define with mathematical rigor what uniqueness here means.

Let $\mathcal{E}$ and $\mathcal{F}$ be two σ-UCP spaces, and let $\mathcal{C}_1,\otimes_1$ and $\mathcal{C}_2,\otimes_2$ be two models for a composite system consisting of $\mathcal{E}$ and $\mathcal{F}$ such that the axioms (C1) and (C2) are fulfilled. The two models are isomorphic if there is an isomorphism Π between the two σ-UCP spaces $\mathcal{C}_1$ and $\mathcal{C}_2$ with $\Pi(E\otimes_1 F)=\Pi(E)\otimes_2\Pi(F)$ for all $E\in\mathcal{E}$ and $F\in\mathcal{F}$.

We shall now see that there are two nonisomorphic models for $\mathcal{E}=J_n(\mathbb{C})$ and $\mathcal{F}=J_m(\mathbb{C}), n,m\geqslant 3$. The first one is $\mathcal{C}_1:=J_{mn}(\mathbb{C})$ with $\otimes_1$ being the Kronecker product (Lemma 5.2). The second one $\mathcal{C}_2:=\mathcal{C}_1=J_{mn}(\mathbb{C})$, but $\otimes_2$ is now defined differently from $\otimes_1$ in the following way: $E\otimes_2 F:=E\otimes_1 F^t$, where F^t is the transposed matrix of the matrix F.

The second model $\mathcal{C}_2,\otimes_2$ satisfies the axioms (C1) and (C2) as well; (C1) follows from the fact that the map $F\to F^t$ is an isomorphism of $\mathcal{F}=J_m(\mathbb{C})$, and (C2) can be seen in the following way. If ρ is a bistate on $\mathcal{E}\times\mathcal{F}$, define another bistate ρ' by $\rho'(E,F):=\rho(E,F^t)$. From Lemma 5.2 we get that there is a state ω' on $J_{mn}(\mathbb{C})$ with $\omega'(E\otimes_1 F)=\rho'(E,F)$ for all $E\in\mathcal{E}$ and $F\in\mathcal{F}$. Then $\rho(E,F)=\rho'(E,F^t)=\omega'(E\otimes_1 F^t)=\omega'(E\otimes_2 F)$ such that ω' is the desired state extending ρ on $\mathcal{C}_2$ with $\otimes_2$. It is unique since $H_{mn}(\mathbb{C})$ is the real-linear hull of the $E\otimes_2 F\in J_{mn}(\mathbb{C})$ with $E\in J_n(\mathbb{C})$ and $F\in J_m(\mathbb{C})$.

If $\mathcal{C}_1$ with $\otimes_1$ and $\mathcal{C}_2$ with $\otimes_2$ were isomorphic, there would be an automorphism Π of $J_{mn}(\mathbb{C})$ with $\Pi(E\otimes_1 F)=\Pi(E)\otimes_2\Pi(F)=\Pi(E)\otimes_1(\Pi(F))^t$ for all $E\in\mathcal{E}$ and $F\in\mathcal{F}$. Then, Π would have a unique extension to an automorphism of $H_{mn}(\mathbb{C})$ which would have a unique complex-linear extension Π' to $M_{mn}(\mathbb{C})$. The latter extension would be either multiplicative or antimultiplicative,[7] i.e., either $\Pi'(AB)=\Pi'(A)\Pi'(B)$ for all matrices A,B in $M_{mn}(\mathbb{C})$ or $\Pi'(AB)=\Pi'(B)\Pi'(A)$ for all A,B in $M_{mn}(\mathbb{C})$. However, both cases are impossible since the restriction of Π' to $M_n(\mathbb{C})\otimes\mathbb{I}$ is the identity map and is multiplicative while the restriction of Π' to $\mathbb{I}\otimes M_m(\mathbb{C})$ is the matrix transposition which is antimultiplicative.

Therefore, the two models $\mathcal{C}_1$ with $\otimes_1$ and $\mathcal{C}_2$ with $\otimes_2$ are not isomorphic. The same kind of nonuniqueness occurs with those tensor products that have been considered by other authors.[1,8,9]

VII. CONCLUSIONS

The conditional probabilities considered in the σ-UCP space model take us directly to the definition of joint distributions in Sec. III. The Hilbert space formalism of quantum mechanics itself does not give such a clear answer to the question what a joint distribution could be, and different solutions, all distinct from the above one, have therefore been proposed (e.g., by Urbanik[12,13] or Gudder[5,12]). A new phenomenon of the joint distributions defined in Sec. III is that the joint distribution of (X,Y) under a given state may exist while the one of (Y,X) does not. Time order of observations (measurements) plays a more significant role here than in classical probability theory.

Moreover, the consideration of joint distributions not only for real-valued observables, but for a very general type of observables has immediately provided the postulates for a mathematical model of a composite quantum system. This model is in line with product σ-algebras used in classical probability theory as well as with the Hilbert space tensor product used in quantum-mechanics—at least in the finite-dimensional case.

The UCP space modeling the combined system [e.g., $J_{mn}(\mathbb{C})$ for the single systems $J_m(\mathbb{C})$ and $J_n(\mathbb{C})$] contains atoms that do not have the shape $E \otimes F$ with atoms E and F in the UCP spaces modeling the single systems. This means that maximum information on the combined system is not the same as maximum information on each single system, which is a well-known and widely discussed quantum feature called *entanglement*.[14] It originates from the underlying non-Boolean event structure and distinguishes quantum mechanics from classical physics and classical probability theory, both using Boolean event structures. Quantum entanglement has been regaining interest during the past 10 years because of its role in the theories of quantum information and quantum computing.

Theorem 5.2 distinguishes the complex Jordan matrix algebras not only from the exceptional octonion one, but also from the real and quaternion ones. This might be a reason why quantum mechanics needs the complex numbers and the complex Hilbert space. There are other ways of distinguishing the complex case from the real one and the other cases by features either of the underlying state space[2,3] or of the underlying orthomodular space.[15] Such features can mathematically be described, but are physically or statistically less plausible.

Theorem 5.2 covers the finite-dimensional case. The infinite-dimensional case, including the type II and type III JBW factors,[7] still needs further study. If it turns out that the existence of a satisfactory model of a composite system requires the complex numbers in the infinite-dimensional cases as well, we would get a complete axiomatic characterization of the quantum mechanical standard model which uses only the complex Hilbert space.

Furthermore, the combination of only two single systems to a composite system has been regarded. The extension to a finite number of systems is straightforward, but an extension to an arbitrary number of systems may be required. Note that product σ-algebras of an infinite (countable as well as noncountable) number of σ-algebras are used in mathematical probability theory for the study of stochastic processes.

Another open issue is the question whether σ-UCP spaces exist that do not stem from Jordan operator algebras; so far all known examples do, and thus satisfy the axioms (A1), (A2), and (A3). Or are these axioms automatically fulfilled by every σ-UCP space and redundant therefore? Finite UCP spaces are the finite Boolean algebras, but do UCP spaces exist that contain only a finite number of events and at least one pair of incompatible events?

(Received 15 October 2003; accepted 17 August 2004; published 15 November 2004)

A family of spherically symmetric solutions in the model with m-component multicomponent anisotropic fluid is considered. The metric of the solution depends on parameters $q_s>0$, $s=1,\ldots,m$, relating radial pressures and the densities and contains $(n-1)m$ parameters corresponding to Ricci-flat "internal space" metrics and obeying certain $m(m-1)/2$ ("orthogonality") relations. For $q_s=1$ (for all s) and certain equations of state ($p_i^s=\pm\rho^s$) the metric coincides with the metric of intersecting black brane solution in the model with antisymmetric forms. A family of solutions with (regular) horizon corresponding to natural numbers $q_s=1,2,\ldots$ is singled out. Certain examples of "generalized simulation" of intersecting M-branes in $D=11$ supergravity are considered. The post-Newtonian parameters β and γ corresponding to the four-dimensional section of the metric are calculated. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1812357]

I. INTRODUCTION

This paper is devoted to spherically symmetric solutions with a horizon in the multidimensional model with multicomponent anisotropic fluid defined on product manifolds $\mathbf{R}\times M_0\times\cdots\times M_n$. These solutions in certain cases may simulate black brane solutions[1–3] (for a review on p-brane solutions see Ref. 4 and references therein).

We remind that p-brane solutions (e.g., black brane ones) usually appear in the models with antisymmetric forms and scalar fields (see also Refs. 5–15). Cosmological and spherically symmetric solutions with p-branes are usually obtained by the reduction of the field equations to the Lagrange equations corresponding to Toda-type systems.[14] An analogous reduction for the models with multicomponent "perfect" fluid was done earlier in Refs. 16 and 17.

For cosmological models with antisymmetric forms without scalar fields any p-brane is equivalent to a multicomponent anisotropic perfect fluid with the equations of state:

$$p_i=-\rho, \quad \text{or } p_i=\rho, \tag{1.1}$$

when the manifold M_i belongs or does not belong to the brane world-volume, respectively (here p_i is the pressure in M_i and ρ is the density, see Sec. II).

In this paper we find a new family of exact spherically symmetric solutions in the model with m-component anisotropic fluid for the following equations of state (see Appendix for more familiar form of equations of state):

a)Electronic mail: heinz.dehnen@uni-konstanz.de
b)Electronic mail: ivas@rgs.phys.msu.su

$$p_r^s = -\rho^s(2q_s-1)^{-1}, \quad p_0^s = \rho^s(2q_s-1)^{-1}, \tag{1.2}$$

and

$$p_i^s = \left(1-\frac{2U_i^s}{d_i}\right)\rho^s \Big/ (2q_s-1), \tag{1.3}$$

$i>1$, $s=1,\dots,m$, where for sth component: ρ^s is a density, p_r^s is a radial pressure, p_i^s is a pressure in M_i, $i=2,\dots,n$. Here parameters U_i^s $(i>1)$ and the parameters $q_s=U_1^s>0$ obey the following "orthogonality" relations (see also Sec. II below)

$$B_{sl}=0, \quad s\neq l, \tag{1.4}$$

where

$$B_{sl} \equiv \sum_{i=1}^{n}\frac{U_i^s U_i^l}{d_i} + \frac{1}{2-D}\left(\sum_{i=1}^{n} U_i^s\right)\left(\sum_{j=1}^{n} U_j^l\right), \tag{1.5}$$

$q_s\neq 1/2$; and $s,l=1,\dots,m$. The manifold M_0 is d_0-dimensional sphere in our case and p_0^s is the pressure in the tangent direction.

The one-component case was considered earlier in Ref. 1. For the special case with $q_s=1$ see Refs. 2 and 3 (for one-component and multicomponent case, respectively).

The paper is organized as follows. In Sec. II the model with multicomponent (anisotropic or "perfect") fluid is formulated. In Sec. III a subclass of spherically symmetric solutions (generalizing solutions from Ref. 3) is presented and solutions with (regular) horizon corresponding to integer q_s are singled out. Section IV deals with certain examples of two-component solutions in dimension $D=11$ containing for $q_s=1$ intersecting $M2\cap M2$, $M2\cap M5$, and $M5\cap M5$ black brane metrics. In Sec. V the post-Newtonian parameters for the four-dimensional section of the metric are calculated. In the Appendix a class of general spherically symmetric solutions in the model under consideration is presented.

II. THE MODEL

Here, we consider a family of spherically symmetric solutions to Einstein equations with a multicomponent anisotropic fluid matter source

$$R_N^M - \tfrac{1}{2}\delta_N^M R = kT_N^M \tag{2.1}$$

defined on the manifold

$$M = \underset{\text{radial variables}}{\mathbf{R}} \times \underset{\text{spherical variables}}{(M_0=S^{d_0})} \times \underset{\text{time}}{(M_1=\mathbf{R})} \times M_2 \times \cdots \times M_n, \tag{2.2}$$

with the block-diagonal metrics

$$ds^2 = e^{2\gamma(u)}\,du^2 + \sum_{i=0}^{n} e^{2X^i(u)} h^{(i)}_{m_i n_i}\,dy^{m_i}\,dy^{n_i}. \tag{2.3}$$

Here $\mathbf{R}=(a,b)$ is interval. The manifold M_i with the metric $h^{(i)}$, $i=1,2,\dots,n$, is the Ricci-fiat space of dimension d_i:

$$R_{m_i n_i}[h^{(i)}]=0, \tag{2.4}$$

and $h^{(0)}$ is standard metric on the unit sphere S^{d_0},

$$R_{m_0 n_0}[h^{(0)}] = (d_0-1)h^{(0)}_{m_0 n_0}, \tag{2.5}$$

u is radial variable, κ is the multidimensional gravitational constant, $d_1=1$ and $h^{(1)}=-dt\otimes dt$.

The energy-momentum tensor is adopted in the following form:

$$T_N^M = \sum_{s=1}^{m} T_N^{(s)M}, \tag{2.6}$$

where

$$T_N^{(s)M} = \mathrm{diag}(-(2q_s-1)^{-1}\rho^s, (2q_s-1)^{-1}\rho^s \delta_{k_0}^{m_0}, -\rho^s, p_2^s \delta_{k_2}^{m_2}, \ldots, p_n^s \delta_{k_n}^{m_n}), \tag{2.7}$$

$q_s > 0$ and $q_s \neq 1/2$. The pressures p_i^s and the density ρ^s obey the relations (1.3) with constants U_i^s, $i > 1$.

The "conservation law" equations

$$\nabla_M T_N^{(s)M} = 0 \tag{2.8}$$

are assumed to be valid for all s.

In what follows we set $\kappa = 1$ for simplicity.

III. EXACT SOLUTIONS

Let us define

$$1°, \quad U_0^s = 0, \tag{3.1}$$

$$2°, \quad U_1^s = q_s, \tag{3.2}$$

$$3°, \quad (U^s, U^l) = U_i^s G^{ij} U_j^l, \tag{3.3}$$

where $U^s = (U_i^s)$ is $(n+1)$-dimensional vector and

$$G^{ij} = \frac{\delta^{ij}}{d_i} + \frac{1}{2-D} \tag{3.4}$$

are components of the matrix inverse to the matrix of the minisuperspace metric[18,19]

$$(G_{ij}) = (\mathrm{d}_i \delta_{ij} - \mathrm{d}_i \mathrm{d}_j), \tag{3.5}$$

$i, j = 0, \ldots, n$, and $D = 1 + \Sigma_{i=0}^n d_i$ is the total dimension.

In our case the scalar products (3.3) are given by relations

$$(U^s, U^l) = B_{kl} \tag{3.6}$$

with B_{kl} from (1.5) and hence due to (1.4) vectors U^s are mutually orthogonal, i.e.,

$$(U^s, U^l) = 0, \quad s \neq l. \tag{3.7}$$

It is proved in the Appendix that the relation 1° implies

$$(U^s, U^s) > 0, \tag{3.8}$$

for all s.

For the equations of state (1.2) and (1.3) with parameters obeying (1.4) we have obtained the following spherically symmetric solutions to the Einstein equations (2.1) (see Appendix),

$$\mathrm{d}s^2 = J_0 \left(\frac{\mathrm{d}r^2}{1 - \dfrac{2\mu}{r^d}} + r^2 \, \mathrm{d}\Omega_{d_0}^2 \right) - J_1 \left(1 - \frac{2\mu}{r^d} \right) \mathrm{d}t^2 + \sum_{i=2}^{n} J_i h_{m_i n_i}^{(i)} \, \mathrm{d}y^{m_i} \, \mathrm{d}y^{n_i}, \tag{3.9}$$

$$\rho^s = \frac{(2q_s-1)(\mathrm{d}q_s)^2 P_s(P_s+2\mu)(1-2\mu r^{-d})^{q_s-1}}{2(U^s,U^s)\left(\prod_{s=1}^{m} H_s\right)^2 J_0 r^{2d_0}}, \tag{3.10}$$

by methods similar to obtaining p-brane solutions.[14] Here $d=d_0-1$, $\mathrm{d}\Omega_{d_0}^2=h^{(0)}_{m_0n_0}\,\mathrm{d}y^{m_0}\,\mathrm{d}y^{n_0}$ is spherical element, the metric factors

$$J_i = \prod_{s=1}^{m} H_s^{-2U^{si}/(U^s,U^s)}, \tag{3.11}$$

$$H_s = 1 + \frac{P_s}{2\mu}\left[1-\left(1-\frac{2\mu}{r^d}\right)^{q_s}\right]; \tag{3.12}$$

$P>0$, $\mu>0$ are constants and

$$U^{si} = G^{ij}U_j^s = \frac{U_i^s}{d_i} + \frac{1}{2-D}\sum_{j=0}^{n} U_j^s. \tag{3.13}$$

Using (3.13) and $U_0^s=0$ we get

$$U^{s0} = \frac{1}{2-D}\sum_{j=0}^{n} U_j^s \tag{3.14}$$

and hence one can rewrite (3.9) as follows:

$$\mathrm{d}s^2 = J_0\left[\frac{\mathrm{d}r^2}{1-\dfrac{2\mu}{r^d}} + r^2\,\mathrm{d}\Omega_{d_0}^2 - \left(\prod_{s=1}^{m} H_s^{-2q_s/(U^s,U^s)}\right)\left(1-\frac{2\mu}{r^d}\right)\mathrm{d}t^2 + \sum_{i=2}^{n}\left(\prod_{s=1}^{m} H_s^{-2U_i^s/(d_i(U^s,U^s))}\right)h^{(i)}_{m_in_i}\,\mathrm{d}y^{m_i}\,\mathrm{d}y^{n_i}\right]. \tag{3.15}$$

These solutions are the special case of general solutions spherically symmetric solutions obtained in the Appendix by the method suggested in Ref. 17.

Black holes for natural q_s: For natural

$$q_s = 1,2,\ldots, \tag{3.16}$$

the metric has a horizon at $r^d=2\mu=r_h^2$. Indeed, for these values of q_s the functions $H_s(r)>0$ are smooth in the interval $(r_*,+\infty)$ for some $r_*<r_h$. For odd $q_s=2m_s+1$ (for all s) one gets $r_*=0$.

A global structure of the black hole solutions corresponding to these values of q_s will be a subject of a separate publication.

It was shown in Ref. 1 that in the one-component case for $2U^{s0}\neq -1$ and $0<q_s<1$ one obtains singularity at $r^d\to 2\mu$.

Remark: For noninteger $q_s>1$ the function $H_s(r)$ have a nonanalytical behavior in the vicinity of $r^d=2\mu$. In this case one may conject that the limit $r^d\to 2\mu$ corresponds to the singularity (in the general case) but here a separate investigation is needed.

IV. EXAMPLES: GENERALIZED SIMULATION OF INTERSECTING BLACK BRANES

The solutions with a horizon from the preceding section allows us to simulate the intersecting black brane solutions[4] in the model with antisymmetric form without scalar fields[2] when all $q_s=1$.

These solutions may also be generalized to the case of general natural $q_s \in \mathbf{N}$. In this case the parameters U_i^s and the pressures have the following form:

$$U_i^s = q_s d_i, \quad p_i^s = -\rho^s, \quad i \in I_s,$$

$$0, \quad (2q_s - 1)^{-1}\rho^s, \quad i \notin I_s. \tag{4.1}$$

Here $I_s=\{i_1,\ldots,i_k\} \in \{1,\ldots n\}$ is the index set[4] corresponding to the "brane" submanifold $M_{i_1} \times \cdots \times M_{i_k}$.

The "orthogonality" relations (1.4) lead us to the following dimension of intersection of brane submanifolds:[4]

$$d(I_s \cap I_l) = \frac{d(I_s)d(I_l)}{D-2}, \quad s \neq l, \tag{4.2}$$

where $d(I_s)=\Sigma_{i\in I_s} d_i$ is dimension of p-brane world volume.

Remark: The set of Diophantus equations (4.2) was solved explicitly in Ref. 20 for so-called "flower" Ansatz from Ref. 21. The solution in this case takes place for infinite number of dimensions $D=6,10,11,14,18,20,26,27,\ldots$, etc.

As an example, here we consider a "generalized simulation" of intersecting $M2\cap M5$, $M2\cap M2$ and $M5\cap M5$ black branes in $D=11$ supergravity. In what follows functions H_s, $s=1,2$, are defined in (3.12).

(a) For an analog of intersecting $M2\cap M5$ branes the metric reads

$$\mathrm{d}s^2 = H_1^{1/(3q_1)} H_2^{2/(3q_2)} \left[\frac{\mathrm{d}r^2}{1-2\mu/r^d} + r^2 \mathrm{d}\Omega_{d_0}^2 - H_1^{-1/q_1} H_2^{-1/q_2} \left\{ \left(1 - \frac{2\mu}{r^d}\right) \mathrm{d}t^2 + \mathrm{d}y^{m_2}\, \mathrm{d}y^{m_2} \right\} \right.$$
$$\left. + H_2^{-1/q_2} h^{(3)}_{m_3 n_3}\, \mathrm{d}y^{m_3}\, \mathrm{d}y^{n_3} + H_1^{-1/q_1}\, \mathrm{d}y^{m_4}\, \mathrm{d}y^{m_4} + h^{(5)}_{m_5 n_5}\, \mathrm{d}y^{m_5}\, \mathrm{d}y^{n_5} \right], \tag{4.3}$$

where $M2$-brane includes three one-dimensional: M_2, M_4 and the time manifold M_1; and $M5$-brane includes M_1, M_2, $M_3 (d_3=4)$.

(b) An analog of two electrical $M2$ branes intersecting on the time manifold has the following metric

$$\mathrm{d}s^2 = H_1^{1/(3q_1)} H_2^{1/(3q_2)} \left[\frac{\mathrm{d}r^2}{1-2\mu/r^d} + r^2\, \mathrm{d}\Omega_{d_0}^2 - H_1^{-1/q_1} H_2^{-1/q_2} \left(1 - \frac{2\mu}{r^d}\right) \mathrm{d}t^2 + H_1^{-1/q_1} h^{(2)}_{m_2 n_2}\, \mathrm{d}y^{m_2}\, \mathrm{d}y^{n_2} \right.$$
$$\left. + H_2^{-1/q_2} h^{(3)}_{m_3 n_3}\, \mathrm{d}y^{m_3}\, \mathrm{d}y^{n_3} + h^{(4)}_{m_4 n_4}\, \mathrm{d}y^{m_4} \mathrm{d}y^{n_4} \right], \tag{4.4}$$

where $d_2=d_3=2$.

(c) For an analog of two intersecting $M5$ branes the dimension of intersection is 4 and the metric reads

$$\mathrm{d}s^2 = H_1^{2/(3q_1)} H_2^{2/(3q_2)} \left[\frac{\mathrm{d}r^2}{1-2\mu/r} + r^2\, \mathrm{d}\Omega_2^2 - H_1^{-1/q_1} H_2^{-1/q_2} \left\{ \left(1 - \frac{2\mu}{r}\right) \mathrm{d}t^2 + h^{(2)}_{m_2 n_2}\, \mathrm{d}y^{m_2}\, \mathrm{d}y^{n_2} \right\} \right.$$
$$\left. + H_1^{-1/q_1} h^{(3)}_{m_3 n_3}\, \mathrm{d}y^{m_3}\, \mathrm{d}y^{n_3} + H_2^{-1/q_2} h^{(4)}_{m_4 n_4}\, \mathrm{d}y^{m_4}\, \mathrm{d}y^{n_4} \right]. \tag{4.5}$$

Here $d_0=d_3=d_4=2$ and $d_2=3$.

For the density of the sth component we get in any of these three cases

$$\rho^s = \frac{(2q_s - 1)\mathrm{d}^2 P_s (P_s + 2\mu)(1 - 2\mu r^{-d})^{q_s^{-1}}}{4(H_1 H_2)^2 J_0 r^{2d_0}}, \tag{4.6}$$

where

$$J_0 = \prod_{s=1}^{2} H_s^{d(I_s)/(9q_s)} \tag{4.7}$$

and $d(I_s) = 3, 6$ for $M2$, $M5$ branes, respectively.

V. PHYSICAL PARAMETERS

A. Gravitational mass and PPN parameters

Here we set $d_0 = 2$ ($d = 1$). Let us consider the four-dimensional space–time section of the metric (3.15). Introducing a new radial variable by the relation

$$r = R\left(1 + \frac{\mu}{2R}\right)^2, \tag{5.1}$$

we rewrite the 4-section in the following form:

$$\mathrm{d}s^2_{(4)} = \left(\prod_{s=1}^{m} H^{-2U^{s0}/(U^s, U^s)}\right)\left[-\left(\prod_{s=1}^{m} H_s^{-2q_s/(U^s, U^s)}\right)\left(\frac{1 - \dfrac{\mu}{2R}}{1 + \dfrac{\mu}{2R}}\right)^2 \mathrm{d}t^2 + \left(1 + \frac{\mu}{2R}\right)^4 \delta_{ij}\, \mathrm{d}x^i\, \mathrm{d}x^j\right], \tag{5.2}$$

$i, j = 1, 2, 3$. Here $R^2 = \delta_{ij} x^i x^j$.

The parametrized post-Newtonian (Eddington) parameters are defined by the well-known relations

$$g_{00}^{(4)} = -(1 - 2V + 2\beta V^2) + O(V^3), \tag{5.3}$$

$$g_{ij}^{(4)} = \delta_{ij}(1 + 2\gamma V) + O(V^2), \tag{5.4}$$

$i, j = 1, 2, 3$. Here

$$V = \frac{GM}{R} \tag{5.5}$$

is the Newtonian potential, M is the gravitational mass and G is the gravitational constant.

From (5.2)–(5.4) we obtain

$$GM = \mu + \sum_{s=1}^{m} \frac{P_s q_s (q_s + U^{s0})}{(U^s, U^s)} \tag{5.6}$$

and

$$\beta - 1 = \sum_{s=1}^{m} \frac{|A_s|}{(GM)^2}(q_s + 2U^{s0}), \tag{5.7}$$

$$\gamma - 1 = -\sum_{s=1}^{m} \frac{P_s q_s}{(U^s, U^s) GM} (q_s + U^{s0}), \tag{5.8}$$

where

$$|A_s| = \tfrac{1}{2} q_s^2 P_s (P_s + 2\mu)/(U^s, U^s) \tag{5.9}$$

(see Appendix) or, equivalently,

$$P_s = -\mu + \sqrt{\mu^2 + 2|A_s|(U^s, U^s) q_s^{-2}} > 0. \tag{5.10}$$

For fixed U_i^s the parameter $\beta - 1$ is proportional to the ratio of two quantities: the weighted sum of multicomponent anisotropic fluid density parameters $|A_s|$ and the gravitational radius squared $(GM)^2$.

B. Hawking temperature

The Hawking temperature of the black hole may be calculated using the well-known relation[22]

$$T_H = \frac{1}{4\pi\sqrt{-g_{tt} g_{rr}}} \frac{d(-g_{tt})}{\mathrm{d}r}_{\text{horizon}}. \tag{5.11}$$

We get

$$T_H = \frac{d}{4\pi (2\mu)^{1/d}} \prod_{s=1}^{m} \left(1 + \frac{P_s}{2\mu}\right)^{-q_s/(U^s, U^s)}. \tag{5.12}$$

Here all q_s are natural numbers.

For any of $D = 11$ metrics from Sec. IV the Hawking temperature reads

$$T_H = \frac{d}{4\pi (2\mu)^{1/d}} \prod_{s=1}^{2} \left(1 + \frac{P_s}{2\mu}\right)^{-1/(2q_s)}.$$

.

VI. CONCLUSIONS

In this paper, using the methods developed earlier for obtaining perfect fluid and p-brane solutions, we have considered a family of spherically symmetric solutions in the model with m-component anisotropic fluid when the equations of state (1.2)–(1.4) are imposed. The metric of any solution contains $(n-1)$ Ricci-flat "internal" space metrics and depends upon a set of parameters U_i^s, $i > 1$.

For $q_s = 1$ (for all s) and certain equations of state (with $p_i^s = \pm \rho^s$) the metric of the solution coincides with that of intersecting black brane solution in the model with antisymmetric forms without dilatons.[3] For natural numbers $q_s = 1, 2, \ldots$, we have obtained a family of solutions with regular horizon.

Here we have considered three examples of solutions with horizon, that simulate (by fluids) binary intersecting $M2$ and $M5$ black branes in $D = 11$ supergravity.

We have also calculated (for possible estimations of observable effects of extra dimensions) the post-Newtonian parameters β and γ corresponding to the four-dimensional section of the metric and the Hawking temperature as well.

APPENDIX A: LAGRANGE REPRESENTATION

It is more convenient for finding of exact solutions, to write the stress-energy tensor in cosmological-type form,

$$(T_N^{(s)M}) = \mathrm{diag}(-\hat{\rho}^s, \hat{p}_0^s \delta_{k_0}^{m_0}, \hat{p}_1^s \delta_{k_1}^{m_1}, \ldots, \hat{p}_n^s \delta_{k_n}^{m_n}), \tag{A1}$$

where $\hat{\rho}^s$ and $\hat{p}_i^s$ are "effective" density and pressures of sth component, respectively, depending upon the radial variable u and the physical density ρ^s and pressures p_i^s are related to the effective ("hat") ones by formulas

$$\rho^s = -\hat{p}_1^s, \quad p_r^s = -\hat{\rho}^s, \quad p_i^s = \hat{p}_i^s \quad (i \neq 1), \tag{A2}$$

$s = 1, \ldots, m$.

The equations of state may be written in the following form:

$$\hat{p}_i = \left(1 - \frac{2U_i^s}{d_i}\right)\hat{\rho}^s, \tag{A3}$$

where U_i^s are constants, $i = 0, 1, \ldots, n$. It follows from (A2) and (A3), and $U_1^s = q_s$ that

$$\rho^s = (2q_s - 1)\hat{\rho}^s. \tag{A4}$$

The "conservation law" equations $\nabla_M T_N^{(s)M} = 0$ may be written, due to relations (2.3) and (A1) in the following form:

$$\dot{\hat{\rho}}^s + \sum_{i=0}^{n} \mathrm{d}_i \dot{X}^i (\hat{\rho}^s + \hat{p}_i^s) = 0. \tag{A5}$$

Using the equation of state (A3) we get

$$\hat{\rho}^s = -A_s e^{2U_i^s X^i - 2\gamma_0}, \tag{A6}$$

where $\gamma_0(X) = \Sigma_{i=0}^n \mathrm{d}_i X^i$ and A_s are constants.

The Einstein equations (2.1) with the relations (A3) and (A6) imposed are equivalent to the Lagrange equations for the Lagrangian,

$$L = \tfrac{1}{2} e^{-\gamma + \gamma_0(X)} G_{ij} \dot{X}^i \dot{X}^j - e^{\gamma - \gamma_0(X)} V, \tag{A7}$$

where

$$V = \tfrac{1}{2} d_0 (d_0 - 1) \exp(2U_i^0 X^i) + A_s \exp(2U_i^s X^i) \tag{A8}$$

is the potential and the components of the minisupermetric G_{ij} are defined in (3.5),

$$U_i^0 X^i = -X^0 + \gamma_0(X), \quad U_i^0 = \delta_i^0 + d_i, \tag{A9}$$

$i = 0, \ldots, n$ (for the cosmological case see Refs. 16 and 17).

For $\gamma = \gamma_0(X)$, i.e., when the harmonic time gauge is considered, we get the set of Lagrange equations for the Lagrangian,

$$L = \tfrac{1}{2} G_{ij} \dot{X}^i \dot{X}^j - V, \tag{A10}$$

with the zero-energy constraint imposed,

$$E = \tfrac{1}{2} G_{ij} \dot{X}^i \dot{X}^j + V = 0. \tag{A11}$$

It follows from the restriction $U_0^s = 0$ that

$$(U^0, U^s) \equiv U_i^0 G^{ij} U_j^s = 0. \tag{A12}$$

Indeed, the contravariant components $U^{0i} = G^{ij} U_j^0$ are the following ones:

$$U^{0i} = -\frac{\delta_0^i}{d_0}. \tag{A13}$$

Then we get $(U^0, U^s) = U^{0i} U_i^s = -U_0^s / d_0 = 0$. In what follows we also use the formula

$$(U^0, U^0) = \frac{1}{d_0} - 1 < 0 \tag{A14}$$

for $d_0 > 1$.

Now we prove that $(U^s, U^s) > 0$ for all $s > 0$. Indeed, minisupermetric has the signature $(-, +, \ldots, +)$,[18,19] vector U^0 is timelike and orthogonal to any vector $U^s \neq 0$. Hence any vector U^s is spacelike.

APPENDIX B: GENERAL SPHERICALLY SYMMETRIC SOLUTIONS

When the orthogonality relations (A12) and (3.7) are satisfied the Euler–Lagrange equations for the Lagrangian (A10) with the potential (A8) have the following solutions (see relations from Ref. 17 adopted for our case):

$$X^i(u) = -\sum_{\alpha=0}^{m} \frac{U^{\alpha i}}{(U^\alpha, U^\alpha)} \ln |f_\alpha(u - u_\alpha)| + c^i u + \overline{c}^i, \tag{B1}$$

where u_α are integration constants; and vectors $c = (c^i)$ and $\overline{c} = (\overline{c}^i)$ are dually orthogonal to covectors $U^\alpha = (U_i^\alpha)$, i.e., they satisfy the linear constraint relations

$$U^0(c) = U_i^0 c^i = -c^0 + \sum_{j=0}^{n} \mathrm{d}_j c^j = 0, \tag{B2}$$

$$U^0(\overline{c}) = U_i^0 \overline{c}^i = -\overline{c}^0 + \sum_{j=0}^{n} \mathrm{d}_j \overline{c}^j = 0, \tag{B3}$$

$$U^s(c) = U_i^s c^i = 0, \tag{B4}$$

$$U^s(\overline{c}) = U_i^s \overline{c}^i = 0. \tag{B5}$$

Here

$$f_\alpha(\tau) = R_\alpha \frac{\sinh(\sqrt{C_\alpha}\tau)}{\sqrt{C_\alpha}}, \quad C_\alpha > 0, \quad \eta_\alpha = +1,$$

$$R_\alpha \frac{\cosh(\sqrt{C_\alpha}\tau)}{\sqrt{C_\alpha}}, \quad C_\alpha > 0, \quad \eta_\alpha = -1,$$

$$R_\alpha \frac{\sin(\sqrt{|C_\alpha|}\tau)}{\sqrt{|C_\alpha|}}, \quad C_\alpha < 0, \quad \eta_\alpha = +1,$$

$$R_\alpha \tau, \quad C_\alpha = 0, \quad \eta_\alpha = +1, \tag{B6}$$

$\alpha = 0, \ldots, m$; where $R_0 = d_0 - 1$, $\eta_0 = 1$, $R_s = \sqrt{2|A_s|(U^s, U^s)}$, $\eta_s = -\text{sign } A_s$ $(s = 1, \ldots, m)$.

The zero-energy constraint, corresponding to the solution (B1) reads

$$E = \frac{1}{2}\sum_{\alpha=0}^{m} \frac{C_\alpha}{(U^\alpha, U^\alpha)} + \frac{1}{2} G_{ij} c^i c^j = 0. \tag{B7}$$

Special solutions: The (weak) horizon condition (i.e., infinite time of propagation of light for $u \to +\infty$) leads us to the following integration constants:

$$\overline{c^i} = 0, \tag{B8}$$

$$c^i = \overline{\mu} \sum_{\alpha=0}^{m} \frac{U_1^\alpha U^{\alpha i}}{(U^\alpha, U^\alpha)} - \overline{\mu}\delta_1^i, \tag{B9}$$

$$C_\alpha = (U_1^\alpha)^2 \overline{\mu}^2, \tag{B10}$$

where $\overline{\mu} > 0$, $\alpha = 0, \ldots, m$. For analogous choice of parameters in the p-brane case see Refs. 13, 14, and 4.

We also introduce a new radial variable $r = r(u)$ by relations

$$\exp(-2\overline{\mu} u) = 1 - \frac{2\mu}{r^d}, \quad \mu = \overline{\mu} d > 0, \quad d = d_0 - 1, \tag{B11}$$

and set $u_s < 0$ and $A_s < 0$ for all s and also $u_0 = 0$.

The relations of the Appendix imply the formulas (3.9) and (3.10) for the solution from Sec. III with

$$H_s = \exp(-\overline{\mu} q_s u) f_s(u - u_s), \quad A_s = -\frac{(dq_s)^2}{2(U^s, U^s)} P_s(P_s + 2\mu), \tag{B12}$$

$P_s > 0$.

(Received 12 July 2004; accepted 2 August 2004; published 22 November 2004)

According to a theorem of Treves, the conserved functionals of the Ablowitz, Kaup, Newell, and Segur (AKNS) equation vanish on all pairs of formal Laurent series $(\tilde{q},\tilde{r})$ of a specified form, both of them with a pole of the first order. We propose a new and very simple proof for this statement, based on the theory of Bäcklund transformations; using the same method, we prove that the AKNS conserved functionals vanish on other pairs of Laurent series. The spirit is the same as in our previous paper on the Treves theorem for the Korteweg–de Vries hierarchy, with some nontrivial technical differences. © *2004 American Institute of Physics.*
[DOI: 10.1063/1.1805730]

I. INTRODUCTION AND PRELIMINARIES

Some recent works of Treves (see Refs. 10 and 11, and references therein) have introduced, in the words of Dickey,[2] a "fresh idea" in the sector of integrable evolutionary PDEs [Korteweg–de Vries (KdV), nonlinear Schrödinger, etc.]. The discovery of Treves is that all the conserved functionals of these equations vanish when they are evaluated on certain formal Laurent series (intending the integrals which appear in the functionals as loop integrals in $\mathbb{C}$ around zero).

To be more specific, let us consider the KdV equation $q_t = q_{xxx} - 12qq_x$, and the functionals $h = h(q)$ which are integrals of polynomials in q and its x derivatives; for any such functional to be conserved by the KdV equation, it is necessary and sufficient[10] that $h(\tilde{q}) = 0$ for all formal Laurent series with complex coefficients of the form $\tilde{q} = 1/x^2 + \tilde{q}_0 + \Sigma_{k=2}^{+\infty} \tilde{q}_k x^k$. Now, let us pass to the coupled equations

$$q_t = \tfrac{1}{2} q_{xx} - q^2 r, \quad r_t = -\tfrac{1}{2} r_{xx} + q r^2, \tag{1.1}$$

which have been considered in Ref. 11; as well known, these become the nonlinear Schrödinger equation $iq_\tau = (1/2)q_{xx} - |q|^2 q$ if r is the complex conjugate of q and $\tau := it$; if q, r are regarded as independent, the pair (1.1) is usually called the AKNS equation after Ablowitz, Kaup, Newell, and Segur (see Ref. 8, and references therein), a terminology which we also use in this paper.

Let us consider the functionals $h(q,r)$ which are integrals of polynomials in q, r and their x derivatives; for any such functional to be conserved by Eq. (1.1), it is necessary[11] that $h(\tilde{q},\tilde{r}) = 0$ for all pairs of Laurent series $\tilde{q} = e^{\varphi}(1/x + \alpha + \beta x + \Sigma_{k=2}^{+\infty} \tilde{\chi}_k x^k)$, $\tilde{r} = e^{-\varphi}(1/x - \alpha + \beta x + \Sigma_{k=2}^{+\infty} \tilde{\rho}_k x^k)$ (with $\varphi, \alpha, \beta, \tilde{\chi}_k, \tilde{\rho}_k \in \mathbb{C}$); differently from the KdV case, the sufficiency of this condition has been conjectured but not proved in Ref. 11.

[a)]Electronic mail: carmor@mate.polimi.it
[b)]Electronic mail: livio.pizzocchero@mat.unimi.it

The proofs in the original papers of Treves are based on a long and highly technical analysis, where a central role is played by the recurrence relations for some standard basis of conserved functionals. A simple alternative proof of the necessary condition for the KdV, and an analogue of this result for the Boussinesq equation, were obtained by Dickey[2] using the dressing method for the Lax operator. Another proof of necessity for the KdV was proposed in a paper of ours,[7] where we employed the invariance of the KdV conserved functionals under the (auto)-Bäcklund transformation. The relation between Refs. 2 and 7 has been very recently discussed in Ref. 3, where the extension of the Bäcklund method to the Boussinesq and the other GD hierarchies has also been sketched.

In the present paper the Bäcklund invariance of the conserved functionals will be used in relation to the AKNS, to get a new proof of the Treves theorem for this equation. Using this idea we will show that the AKNS conserved functionals vanish on other nontrivial pairs of Laurent series, in particular for those of the form $\tilde{q}=e^{\varphi}(2/x^2+\alpha+\beta x+\Sigma_{k=2}^{+\infty}\tilde{\chi}_k x^k)$, $\tilde{r}=e^{-\varphi}(1+\beta x^3+\Sigma_{k=4}^{+\infty}\tilde{\rho}_k x^k)$.

Both for the pairs $(\tilde{q},\tilde{r})$ considered by Treves and for the ones in the above variant, our proof is very simple and conceptually similar to the argument of Ref. 7 for the KdV: in fact, we show that any $(\tilde{q},\tilde{r})$ as before is the Bäcklund transform of a pair (q,r) of holomorphic series (with no negative powers of x), on which every functional of polynomial type is zero for trivial reasons.

In comparison with our previous analysis of the KdV case, the AKNS is a bit more difficult regarding the precise definition of the Bäcklund transformation; in fact, even though this transformation for the AKNS is known in the literature,[1,9] its usual formulation involves rational maps that would cause some troubles in the present framework; for this reason, in this paper we give a different presentation which is more implicit but involves only polynomial mappings.

Let us describe the organization of the paper. In the rest of this Introduction, we generalize for our present needs the language of differential algebras and formal variational calculus already employed in Ref. 7; the AKNS equation and the space of its conserved functionals are described formally within this framework. In Sec. II we state precisely the Treves theorem for the AKNS (Proposition 2.1) and our variant of it mentioned before (Proposition 2.2). In Sec. III we introduce the Bäcklund transformation and state the invariance under it of the AKNS conserved functionals, in a way suitable for our purposes; in Sec. IV we use it to prove Propositions 2.1 and 2.2.

Two Appendixes have been added to review the matrix Lax formalism *à la* Drinfeld–Sokolov, and its relation to Bäcklund transformations, for certain classes of integrable systems and especially for the AKNS; the aim is, essentially, to justify the slightly nonstandard presentation of the Bäcklund machinery employed in this work.

All vector spaces considered in this paper are over $\mathbb{C}$. As anticipated, hereafter we summarize some concepts from differential algebra and from the formal variational calculus of Gelfand–Dickey,[4] including their applications to the AKNS theory.

Differential algebras: By a differential algebra, we mean an associative algebra (commutative or not) equipped with a derivation, i.e., with a linear map of the algebra into itself having the Leibnitz property with respect to the product. We do not require the algebra to possess a unity; if this exists, one easily proves that it is annihilated by the derivation. A morphism of differential algebras is an algebraic morphism respecting the derivations.

A differential algebra is typically written as $(\mathcal{Q},\partial_x)$; the subscript x attached to the derivation is also used to denote its action on the elements q of the algebra, so $\partial_x\colon \mathcal{Q}\to\mathcal{Q}$, $q\mapsto q_x$.

We write $\mathcal{Q}_x$ for the image of ∂_x; if $q,p\in\mathcal{Q}$ and $p=q_x$, sometimes we say that q is a primitive of p. The quotient vector space

$$\int \mathcal{Q} := \mathcal{Q}/\mathcal{Q}_x = \{q+\mathcal{Q}_x | q\in\mathcal{Q}\} \tag{1.2}$$

is called the *space of integrals* of $\mathcal{Q}$. The corresponding quotient map is denoted with

$$\int : \mathcal{Q} \to \int \mathcal{Q}, \quad q \mapsto \int q := q + \mathcal{Q}_x, \tag{1.3}$$

and we call $\int q$ the integral of q; of course $\int q_x = 0$ for each q. Let $\mathcal{S}$ be any subset of $\mathcal{Q}$; we write

$$\int \mathcal{S} := \{s + \mathcal{Q}_x | s \in \mathcal{S}\} \subset \int \mathcal{Q}, \tag{1.4}$$

and note that the restriction of (1.3) is a map $\mathcal{S} \to \int \mathcal{S}, s \mapsto \int s$.

Sometimes, it is necessary to specify the dependence from the differential algebra $\mathcal{Q}$ of the previous operations of integration: in this case we write $\int^{\mathcal{Q}}$ for the map (1.3) or its restriction to $\mathcal{S}$, and $\int^{>\mathcal{Q}} \mathcal{S}$ for the set (1.4).

A differential subalgebra of a differential algebra $(\mathcal{Q}, \partial_x)$ is a subalgebra $\mathcal{P} \subset \mathcal{Q}$ closed under ∂_x; of course, the differential subalgebra $\mathcal{P}$ with the restricted map $\partial_x \restriction \mathcal{P} \equiv \partial_x$ is itself a differential algebra. In this situation, one must distinguish between two kinds of integration, the first one intrinsic for the differential algebra $(\mathcal{P}, \partial_x)$, and the second one relative to $\mathcal{Q}$. In the first case, we introduce as usual the quotient space and the quotient map

$$\int \mathcal{P} := \mathcal{P}/\mathcal{P}_x, \quad \int : \mathcal{P} \mapsto \int \mathcal{P}, \quad p \mapsto \int p := p + \mathcal{P}_x; \tag{1.5}$$

in the second case, we consider the space and the map

$$\int^{\mathcal{Q}} \mathcal{P} := \{p + \mathcal{Q}_x | p \in \mathcal{P}\} \subset \int \mathcal{Q}, \quad \int^{\mathcal{Q}} : \mathcal{P} \mapsto \int^{\mathcal{Q}} \mathcal{P}, \quad p \mapsto \int^{\mathcal{Q}} p := p + \mathcal{Q}_x. \tag{1.6}$$

One easily checks the existence of a unique map

$$\psi: \int \mathcal{P} \to \int^{\mathcal{Q}} \mathcal{P} \text{ such that } \psi\left(\int p\right) = \int^{\mathcal{Q}} p \quad \forall\, p \in \mathcal{P}. \tag{1.7}$$

The map ψ is linear and furthermore, it is injective if and only if

$$\mathcal{P} \cap \mathcal{Q}_x = \mathcal{P}_x. \tag{1.8}$$

If condition (1.8) holds, we will say that $\mathcal{P}$ is a *strict differential subalgebra* of $\mathcal{Q}$. [Of course, for any differential subalgebra $\mathcal{P}$ it is $\mathcal{P} \cap \mathcal{Q}_x \supset P_x$; Eq. (1.8) means that any element of $\mathcal{P}$ with a primitive in $\mathcal{Q}$ also has a primitive in $\mathcal{P}$.]

Throughout the paper, the term *ideal* is employed with the usual sense; a *differential ideal* of a differential algebra is an ideal closed under the derivation.

Gelfand–Dickey differential algebra in any number γ of generators: This is the commutative differential algebra

$$\mathfrak{F} := \mathbb{C}[\xi_1, \ldots \xi_\gamma, \xi_{1,x}, \ldots, \xi_{\gamma,x}, \ldots]_0, \tag{1.9}$$

made of complex polynomials in infinitely many indeterminates $\xi_s, \xi_{s,x}, \xi_{s,xx}, \ldots$ $(s = 1, \ldots, \gamma)$, without free term (the absence of this is indicated by the subscript 0); $\mathfrak{F}$ is equipped with the unique derivation $\partial_x \equiv \cdot_x$ such that

$$(\xi_s)_x = \xi_{s,x}, \quad (\xi_{s,x})_x = \xi_{s,xx}, \quad \ldots\ . \tag{1.10}$$

We write F, G, etc., for the elements of $\mathfrak{F}$. (For example, $F := \xi_{1,x}^2 \xi_{2,xx}$, $G := 3\xi_{1,x}\xi_2 \in \mathfrak{F}$; $FG = 3\xi_{1,x}^3 \xi_2 \xi_{2,xx}$.)

For the elements of $\int \mathfrak{F} = \mathfrak{F}/\mathfrak{F}_x$, which have the form $f = \int F$ $(F \in \mathfrak{F})$, the general denomination of "integrals" is of course available; however, in this case the name *functionals* is more standard.

The Gelfand–Dickey algebra $\mathfrak{F}$ can be represented in terms of transformations on any commutative differential algebra $(\mathcal{Q},\partial_x)$, in the following way. Let us consider the Cartesian product $\times^\gamma\mathcal{Q}\equiv\mathcal{Q}^\gamma$; then, any $F\in\mathfrak{F}$ induces a map

$$F(\,)\colon\ \mathcal{Q}^\gamma\to\mathcal{Q},\ \ (q_1,\ldots,q_\gamma)\mapsto F(q_1,\ldots,q_\gamma), \tag{1.11}$$

where $F(q_1,\ldots,q_\gamma)$ is obtained from the expression of the polynomial F replacing ξ_s with q_s, $\xi_{s,x}$ with $q_{s,x}$, etc.

It is important to distinguish the elements of $\mathfrak{F}$ from the maps on $\mathcal{Q}^\gamma$: this is the reason why the symbol of the map in (1.11) contains parentheses. (In Ref. 7, for the same reason we used bold symbols for the elements of $\mathfrak{F}$, and nonbold notations for the maps on $\mathcal{Q}$; in the present framework, the proliferation of bold symbols would be excessive.) We note that

$$F(\,)\in\mathrm{Pol}(\mathcal{Q}^\gamma,\mathcal{Q}), \tag{1.12}$$

where $\mathrm{Pol}(\mathcal{X},\mathcal{Y})$ are the polynomial maps[7] between any two vector spaces $\mathcal{X},\mathcal{Y}$ and $\mathcal{Q}^\gamma$ is regarded as a vector space with the product structure. $\mathrm{Pol}(\mathcal{Q}^\gamma,\mathcal{Q})$ is a commutative algebra with the pointwise product, and a differential algebra with the unique derivation $\partial_x\colon\ P(\,)\mapsto P_x(\,)$ such that $P_x(q):=P(q)_x$ for all $P(\,)$. The correspondence

$$\mathfrak{F}\to\mathrm{Pol}(\mathcal{Q}^\gamma,\mathcal{Q}),\ \ F\mapsto F(\,) \tag{1.13}$$

is a morphism of differential algebras. It also induces a linear map

$$\int\mathfrak{F}\to\mathrm{Pol}\left(\mathcal{Q}^\gamma,\int\mathcal{Q}\right),\ \ f\mapsto f(\,) \tag{1.14}$$

in the following way: if $f=\int F$, then

$$f(\,)\colon\ \mathcal{Q}^\gamma\to\int\mathcal{Q},\ \ (q_1,\ldots,q_\gamma)\mapsto f(q_1,\ldots,q_\gamma):=\int F(q_1,\ldots,q_\gamma). \tag{1.15}$$

The maps (1.11) and (1.15) will be called the *representations* on $\mathcal{Q}$ of F and f, respectively.

Vector fields and Lie derivatives: We consider again the Gelfand–Dickey differential algebra (1.9). In this framework, by a vector field we simply mean a family

$$X=(X_1,\ldots,X_\gamma)\in\mathfrak{F}^\gamma \tag{1.16}$$

[this is represented as map $X(\,)=(X_1(\,),\ldots,X_\gamma(\,))\in\mathrm{Pol}(\mathcal{Q}^\gamma,\mathcal{Q}^\gamma)$ on any commutative differential algebra $\mathcal{Q}$]. The Lie derivative on $\mathfrak{F}$ induced by X is the unique derivation

$$\mathcal{L}_X\colon\ \mathfrak{F}\to\mathfrak{F}\ \text{ such that }\mathcal{L}_X\partial_x=\partial_x\mathcal{L}_X,\ \ \mathcal{L}_X\xi_s=X_s\ \ (s=1,\ldots,\gamma); \tag{1.17}$$

the corresponding Lie derivative on $\int\mathfrak{F}$ is the unique map

$$\mathcal{L}_X\colon\ \int\mathfrak{F}\to\int\mathfrak{F}\ \text{ such that }\ \mathcal{L}_X\int\ =\int\mathcal{L}_X; \tag{1.18}$$

of course this map is linear. The set of *conserved functionals* of a vector field X is

$$\mathfrak{I}_X:=\left\{h\in\int\mathfrak{F}\,|\,\mathcal{L}_Xh=0\right\}; \tag{1.19}$$

this is a vector subspace of $\int\mathfrak{F}$.

The AKNS theory and its conserved functionals (Ref. 8): This is a theory in $\gamma=2$ components. For our purposes, it is necessary to formulate it in the language of formal variational calculus; so, we introduce the Gelfand–Dickey algebra

$$\mathfrak{F} := \mathbb{C}[\xi, \eta, \xi_x, \eta_x, \dots]_0 \tag{1.20}$$

with generators $\xi_1 \equiv \xi, \xi_2 \equiv \eta$. The AKNS vector field is

$$X_{\mathrm{AKNS}} \equiv X := (\tfrac{1}{2}\xi_{xx} - \xi^2\eta, -\tfrac{1}{2}\eta_{xx} + \xi\eta^2) \in \mathfrak{F}^2. \tag{1.21}$$

The space of conserved functionals

$$\mathfrak{Z}_{X_{\mathrm{AKNS}}} \equiv \mathfrak{Z} \tag{1.22}$$

is known to be of infinite dimension, a remarkable property placing this vector field within the realm of integrable systems. In the Appendixes A and B we will review the Lax formalism to obtain the conserved functionals of this vector field and of similar systems. This approach gives a basis $(h_i)_{i=1,2,\dots}$ for $\mathfrak{Z}$, derived from the "fundamental invariants" of the Lax operator: the first elements are

$$h_1 := \tfrac{1}{2}\int \xi\eta, \quad h_2 := \tfrac{1}{4}\int \xi_x\eta, \quad h_3 := -\tfrac{1}{8}\int (\xi^2\eta^2 + \xi_x\eta_x), \quad h_4 := \tfrac{1}{16}\int (-3\eta^2\xi\xi_x + \xi_x\eta_{xx}). \tag{1.23}$$

II. THE TREVES THEOREM (AND SOME VARIANT OF IT) FOR THE AKNS

As in the case of the KdV,[10] this theorem concerns the representation of an integrable system on a peculiar differential algebra. This is the commutative differential algebra of formal Laurent series in one indeterminate x and complex coefficients, i.e.,

$$\mathcal{Q} := \left\{ q = \sum_{k=k_{\min}}^{+\infty} q_k x^k \,|\, q_k \in \mathbb{C} \ \ \forall\, k, k_{\min} = k_{\min}(q) \in \mathbb{Z} \right\}; \tag{2.1}$$

the product is the usual Cauchy product of series, and the derivation is

$$\partial_x \colon \mathcal{Q} \to \mathcal{Q}_x, \quad q \mapsto q_x := \sum_{k=k_{\min}}^{+\infty} k q_k x^{k-1}. \tag{2.2}$$

Clearly, we have

$$\mathcal{Q}_x = \{q \in \mathcal{Q} \,|\, q_{-1} = 0\} \tag{2.3}$$

and the map $\int \mathcal{Q} \to \mathbb{C}$, $\int q \mapsto q_{-1}$ is a linear isomorphism. For this reason, from now on we make the identifications

$$\int \mathcal{Q} \simeq \mathbb{C}, \quad \int q \simeq q_{-1} \quad \forall\, q \in \mathcal{Q} \tag{2.4}$$

(in Ref. 7, this was presented for simplicity as the very *definition* of $\int$). Of course, the above description of $\int q$ as the "residue" q_{-1} suggests to interpret it as a loop integral in $\mathbb{C}$ around zero.

We come to the Treves theorem for $\mathfrak{Z}_{\mathrm{AKNS}} \equiv \mathfrak{Z}$ and for the differential algebra (2.1) and (2.2). In our notations, this reads as follows.

Proposition 2.1 (Ref. 11): Let $h \in \mathfrak{Z} \subset \int\mathfrak{F}$, and consider its representation $h(\,)\colon \mathcal{Q}^2 \to \mathbb{C}$. Then

$$h(\tilde{q},\tilde{r}) = 0 \quad \forall\, \tilde{q} = e^{\varphi}\left(\frac{1}{x} + \alpha + \beta x + \sum_{k=2}^{+\infty} \tilde{\chi}_k x^k\right), \ \tilde{r} = e^{-\varphi}\left(\frac{1}{x} - \alpha + \beta x + \sum_{k=2}^{+\infty} \tilde{\rho}_k x^k\right) \tag{2.5}$$

$(\varphi, \alpha, \beta, \tilde{\chi}_k, \tilde{\rho}_k \in \mathbb{C})$.

As anticipated, our aim in this paper is to give a new proof of this result, based on the Bäcklund transformations. This technique will allow us to prove the following variant of the previous result.

Proposition 2.2: Let $h \in \mathfrak{Z}$; *then*

$$h(\tilde{q},\tilde{r}) = 0 \quad \forall\, \tilde{q} = e^{\varphi}\left(\frac{2}{x^2} + \alpha + \beta x + \sum_{k=2}^{+\infty} \tilde{\chi}_k x^k\right),\ \tilde{r} = e^{-\varphi}\left(1 + \beta x^3 + \sum_{k=4}^{+\infty} \tilde{\rho}_k x^k\right) \tag{2.6}$$

$(\varphi, \alpha, \beta, \tilde{\chi}_k, \tilde{\rho}_k \in \mathbb{C})$.

Both Propositions 2.1 and 2.2 are proved in Sec. IV. Hereafter, as a preliminary step we discuss the AKNS Bäcklund transformation, in a formulation suitable for our purposes.

III. BÄCKLUND TRANSFORMATION FOR THE AKNS THEORY

Essentially, this is a transformation leaving invariant the AKNS conserved functionals. However, its description in the language of formal variational calculus requires some technical subtleties introduced hereafter. To this purpose, we consider besides $\mathfrak{F} := \mathbb{C}[\xi, \eta, \xi_x, \eta_x, \dots]_0$ a "copy" of it, say

$$\tilde{\mathfrak{F}} := \mathbb{C}[\tilde{\xi}, \tilde{\eta}, \tilde{\xi}_x, \tilde{\eta}_x, \dots]_0, \tag{3.1}$$

with the derivation such that $(\tilde{\xi})_x = \tilde{\xi}_x$, etc. Of course, there is a unique differential-algebraic isomorphism $\tilde{\cdot}: \mathfrak{F} \to \tilde{\mathfrak{F}}$, $F \mapsto \tilde{F}$ sending ξ, η into $\tilde{\xi}, \tilde{\eta}$. This also induces a linear isomorphism

$$\tilde{}: \int \mathfrak{F} \to \int \tilde{\mathfrak{F}},\ f = \int F \mapsto \tilde{f} := \int \tilde{F}. \tag{3.2}$$

We interpret $\mathfrak{F}$, $\tilde{\mathfrak{F}}$ as describing the "initial" and "final variables" for the "transformation" to be introduced. The latter is in fact defined implicitly in terms of an "auxiliary variable" ν; its description mixes together the initial auxiliary and final variables, so we introduce a third differential algebra

$$\mathfrak{M} := \mathbb{C}[\xi, \eta, \nu, \tilde{\xi}, \tilde{\eta}, \xi_x, \eta_x, \nu_x, \tilde{\xi}_x, \tilde{\eta}_x \dots]_0, \tag{3.3}$$

writing again ∂_x for its derivation. Up to trivial identifications, we have

$$\mathfrak{F}, \tilde{\mathfrak{F}} \subset \mathfrak{M}; \tag{3.4}$$

both $\mathfrak{F}$ and $\tilde{\mathfrak{F}}$ are strict differential subalgebras of $\mathfrak{M}$ [in the sense of (1.8)], so

$$\int \mathfrak{F} \simeq \int^{\mathfrak{M}} \mathfrak{F},\quad \int \tilde{\mathfrak{F}} \simeq \int^{\mathfrak{M}} \tilde{\mathfrak{F}} \subset \int \mathfrak{M}. \tag{3.5}$$

Definition 3.1: The AKNS Bäcklund ideal $\mathcal{I}_{\mathrm{AKNS}} \equiv \mathcal{I} \subset \mathfrak{M}$ *is the ideal of* $\mathfrak{M}$ *generated by the elements*

$$I_1 := \xi_x - \tilde{\xi}_x + \nu(\xi + \tilde{\xi}),\ I_2 := \eta_x - \tilde{\eta}_x + \nu(\eta + \tilde{\eta}),\ I_3 := \nu_x + \xi\eta - \tilde{\xi}\tilde{\eta}. \tag{3.6}$$

From standard commutative algebra,

$$\mathcal{I} = \left\{ \sum_{j=1}^{3} F_j I_j \,\middle|\, F_j \in \mathfrak{M}\ \forall\, j \right\}. \tag{3.7}$$

In the language of formal variational calculus, the Bäcklund invariance of the AKNS conserved functionals can be expressed as follows.

Proposition 3.2: Let $h \in \mathfrak{Z}_{\mathrm{AKNS}} \equiv \mathfrak{Z} \subset \mathfrak{F}$, *and define* $\tilde{h}$ *following* (3.2). *Then*

$$\tilde{h} - h \in \int \mathcal{I} \quad \left(\int \equiv \int^{\mathfrak{M}} \right). \tag{3.8}$$

The above proposition is essentially known in the literature, even though it is not usually formulated in the language of formal variational calculus. In any case, to make the paper self-contained we propose a proof in Appendix B.

In order to exemplify Eq. (3.8), let us consider the functionals h_i in Eq. (1.23) $(i=1,2,3,4)$ and their tilded images $\tilde{h}_1 = \int \tilde{\xi}\tilde{\eta}, \ldots$; it turns out that

$$\tilde{h}_1 - h_1 = -\frac{1}{2}\int I_3, \quad \tilde{h}_2 - h_2 = \frac{1}{4}\int (-\eta I_1 + \tilde{\xi} I_2 + \nu I_3),$$

$$\tilde{h}_3 - h_3 = \frac{1}{8}\int ((-\tilde{\eta}\nu + \tilde{\eta}_x) I_1 + (\xi\nu + \xi_x) I_2 + (\xi\eta + \tilde{\xi}\tilde{\eta} - \nu^2) I_3), \tag{3.9}$$

$$\tilde{h}_4 - h_4 = \frac{1}{16}\int ((\xi\eta^2 - \tilde{\xi}\eta^2 - \xi\eta\tilde{\eta} + 2\tilde{\xi}\eta\tilde{\eta} + \tilde{\xi}\tilde{\eta}^2 - \eta\nu^2 + \nu\tilde{\eta}_x - \tilde{\eta}_{xx}) I_1 + (-\xi\tilde{\xi}\eta + \tilde{\xi}^2\eta - 2\tilde{\xi}^2\tilde{\eta} + \tilde{\xi}\nu^2$$
$$+ \nu\xi_x + \xi\nu_x + \tilde{\xi}\nu_x + \xi_{xx}) I_2 + (-\xi\eta\nu + \tilde{\xi}\eta\nu + \xi\tilde{\eta}\nu - \tilde{\xi}\tilde{\eta}\nu + \nu^3 + \eta\xi_x + \tilde{\eta}\xi_x - \xi\eta_x - \tilde{\xi}\eta_x) I_3),$$

We now present the consequences of the previous statements in terms of concrete differential algebras. From now on $(\mathcal{Q}, \partial_x)$ is a commutative differential algebra; so, the generators I_j in Eq. (3.6) induce maps

$$I_j(\,)\colon \mathcal{Q}^5 \to \mathcal{Q}, \quad (q,r,v,\tilde{q},\tilde{r}) \mapsto I_j(q,r,v,\tilde{q},\tilde{r}),$$
$$I_1(q,\ldots,\tilde{r}) := q_x - \tilde{q}_x + v(q+\tilde{q}), \quad I_2(q,\ldots,\tilde{r}) := r_x - \tilde{r}_x + v(r+\tilde{r}), \quad I_3(q,\ldots,\tilde{r}) := v_x + qr - \tilde{q}\tilde{r} \tag{3.10}$$

(here and in the sequel $\tilde{q}$, $\tilde{r}$ are simply names for certain elements of $\mathcal{Q}$, employed for obvious reasons).

Definition 3.3: Let $\mathcal{Q}^2 := \mathcal{Q} \times \mathcal{Q}$ *and consider the set* $2^{\mathcal{Q}^2}$ *of all subsets of* $\mathcal{Q}^2$. *The AKNS Bäcklund transformation for* $\mathcal{Q}$ *is the map*

$$B_{\mathrm{AKNS}}(\,) \equiv B(\,)\colon \mathcal{Q}^2 \to 2^{\mathcal{Q}^2}, \quad (q,r) \mapsto B(q,r),$$
$$B(q,r) := \{(\tilde{q},\tilde{r}) \in \mathcal{Q}^2 \mid \exists\, v \in \mathcal{Q} \text{ s.t. } I_j(q,r,v,\tilde{q},\tilde{r}) = 0 \text{ for } j = 1,2,3\}. \tag{3.11}$$

Proposition 3.4: Let $h \in \mathfrak{Z}$ *and consider its representation* $h(\,)\colon \mathcal{Q}^2 \to \mathbb{C}$. *For all* $(q,r) \in \mathcal{Q}^2$ *and* $(\tilde{q},\tilde{r}) \in B(q,r)$, *it is*

$$h(\tilde{q},\tilde{r}) = h(q,r). \tag{3.12}$$

Proof: From Proposition 3.2 we know that $\tilde{h} - h = \int I$ for some I in the Bäcklund ideal $\mathcal{I}$. So, using the representation $I(\,)\colon \mathcal{Q}^5 \to \mathcal{Q}$ we find

$$h(\tilde{q},\tilde{r}) - h(q,r) = \int I(q,r,v,\tilde{q},\tilde{r}) \quad \forall\, (q,r,v,\tilde{q},\tilde{r}) \in \mathcal{Q}^5. \tag{3.13}$$

On the other hand, by comparison with (3.7) we have

$$I(\,) = \sum_{j=1}^{3} F_j(\,) I_j(\,), \tag{3.14}$$

where $F_j(\,)\colon \mathcal{Q}^5 \to \mathcal{Q}$ are certain polynomial maps. In particular, let $\tilde{q},\tilde{r} \in B(q,r)$; if v is as in (3.11), we have $I_j(q,r,v,\tilde{q},\tilde{r}) = 0$ implying $I(q,r,v,\tilde{q},\tilde{r}) = 0$, and Eq. (3.13) gives $h(\tilde{q},\tilde{r}) - h(q,r) = 0$. ■

IV. PROOFS OF PROPOSITIONS 2.1 AND 2.2

From now on, $(\mathcal{Q}, \cdot_x, \int)$ is the differential algebra of formal Laurent series described in Sec. II. For convenience, we consider therein the differential subalgebra of "holomorphic series,"

$$\mathcal{Z} := \left\{ q \in \mathcal{Q} | q = \sum_{k=0}^{+\infty} q_k x^k \right\}. \tag{4.1}$$

Trivially, we have

Lemma 4.1: Consider any $h \in \int\mathfrak{F}$ and its representation $h(\,)\colon \mathcal{Q}^2 \to \mathbb{C}$; then

$$h(\,) \restriction \mathcal{Z}^2 = 0. \tag{4.2}$$

Proof: Write $h = \int H$. If $q,r \in \mathcal{Z}$, it is also $H(q,r) \in \mathcal{Z}^2$, because this is a polynomial in q,r and their derivatives. Thus, the residue $h(q,r) = \int H(q,r)$ is zero. ■

We consider the AKNS Bäcklund transformation $B(\,)\colon \mathcal{Q}^2 \to 2^{\mathcal{Q}^2}$ (see Definition 3.3); then, combining the previous lemma with the Bäcklund invariance of all the AKNS conserved functionals (Proposition 3.4) we obtain the following.

Proposition 4.2: Let $h \in \mathfrak{Z}_{\mathrm{AKNS}} \equiv \mathfrak{Z}$; then

$$h(\,) \restriction B(\mathcal{Z}^2) = 0, \quad B(\mathcal{Z}^2) := \bigcup_{(q,r)\in\mathcal{Z}^2} B(q,r). \tag{4.3}$$

We now fix the attention on the set of Laurent series appearing in the Treves theorem 2.1, i.e.,

$$\mathcal{T} := \left\{ \tilde{q},\tilde{r} \in \mathcal{Q}^2 | \tilde{q} = e^{\varphi}\left(\frac{1}{x} + \alpha + \beta x + \sum_{k=2}^{+\infty} \tilde{\chi}_k x^k\right), \right.$$

$$\left. \tilde{r} = e^{-\varphi} \left(\frac{1}{x} - \alpha + \beta x + \sum_{k=2}^{+\infty} \tilde{\rho}_k x^k\right) \ (\varphi,\alpha,\beta,\tilde{\chi}_k,\tilde{\rho}_k \in \mathbb{C}) \right\}. \tag{4.4}$$

Lemma 4.3: (i) Let $\tilde{q},\tilde{r}$ be as in Eq. (4.4). Then, there are uniquely determined series of the form

$$q = e^{\varphi}\left(-\alpha + \sum_{k=2}^{+\infty} \chi_k x^k\right), \quad r = e^{-\varphi}\left(\alpha + \sum_{k=2}^{+\infty} \rho_k x^k\right), \quad v = -\frac{1}{x} + 2\beta x + \sum_{k=2}^{+\infty} v_k x^k, \tag{4.5}$$

such that

$$I_j(q,r,v,\tilde{q},\tilde{r}) = 0 \quad (j = 1,2,3). \tag{4.6}$$

(ii) Statement (i) implies

$$\mathcal{T} \subset B(\mathcal{Z}^2). \tag{4.7}$$

Proof: (i) Let $q,\ldots,\tilde{r}$ be as in Eqs. (4.4) and (4.5), and set for brevity $I_j \equiv I_j(q,r,v,\tilde{q},\tilde{r})$. Direct computation gives

$$I_1 = e^{\varphi}\sum_{k=1}^{+\infty} J_{1k}x^k,\ \ I_2 = e^{-\varphi}\sum_{k=1}^{+\infty} J_{2k}x^k,\ \ I_3 = \sum_{k=1}^{+\infty} I_{3k}x^k, \tag{4.8}$$

$$J_{11} := \chi_2 - 3\tilde{\chi}_2 + v_2,\ \ J_{12} := 2\chi_3 - 4\tilde{\chi}_3 + 2\beta^2 + v_3,\ \ J_{13} := 3\chi_4 - 5\tilde{\chi}_4 + \beta(2\chi_2 + 2\tilde{\chi}_2 + v_2) + v_4,$$
$$J_{1k} := k\chi_{k+1} - (k+2)\tilde{\chi}_{k+1} + \beta(2\chi_{k-1} + 2\tilde{\chi}_{k-1} + v_{k-1}) + v_{k+1} + \sum_{\ell=2}^{k-2} v_{k-\ell}(\chi_\ell + \tilde{\chi}_\ell)\ \ (k \geqslant 4), \tag{4.9}$$

$$J_{21} := \rho_2 - 3\tilde{\rho}_2 + v_2,\ \ J_{22} := 2\rho_3 - 4\tilde{\rho}_3 + 2\beta^2 + v_3,\ \ J_{23} := 3\rho_4 - 5\tilde{\rho}_4 + \beta(2\rho_2 + 2\tilde{\rho}_2 + v_2) + v_4,$$
$$J_{2k} := k\rho_{k+1} - (k+2)\tilde{\rho}_{k+1} + \beta(2\rho_{k-1} + 2\tilde{\rho}_{k-1} + v_{k-1}) + v_{k+1} + \sum_{\ell=2}^{k-2} v_{k-\ell}(\rho_\ell + \tilde{\rho}_\ell)\ \ (k \geqslant 4), \tag{4.10}$$

$$I_{31} := 2v_2 - \tilde{\rho}_2 - \tilde{\chi}_2,\ I_{32} := 3v_3 - \alpha(\rho_2 - \chi_2 + \tilde{\rho}_2 - \tilde{\chi}_2) - \tilde{\rho}_3 - \tilde{\chi}_3 - \beta^2,$$
$$I_{33} := 4v_4 - \alpha(\rho_3 - \chi_3 + \tilde{\rho}_3 - \tilde{\chi}_3) - \tilde{\rho}_4 - \tilde{\chi}_4 - \beta(\tilde{\rho}_2 + \tilde{\chi}_2), \tag{4.11}$$

$$I_{3k} := (k+1)v_{k+1} - \alpha(\rho_k - \chi_k + \tilde{\rho}_k - \tilde{\chi}_k) - \tilde{\rho}_{k+1} - \tilde{\chi}_{k+1} - \beta(\tilde{\rho}_{k-1} + \tilde{\chi}_{k-1})$$
$$+ \sum_{\ell=2}^{k-2} (\chi_{k-\ell}\rho_\ell - \tilde{\chi}_{k-\ell}\tilde{\rho}_\ell)(k \geqslant 4).$$

We must show that the equations $J_{1k}=0$, $J_{2k}=0$, $I_{3k}=0$ for all $k\geqslant 1$ have uniquely determined solutions for the coefficients χ_k, ρ_k, v_k $(k\geqslant 2)$.

The proof is recursive; for $k=1,2,3,\ldots$, the equation $I_{3k}=0$ determines v_{k+1}, and inserting the result into $J_{2k}=0$, $J_{1k}=0$ one determines, respectively, ρ_{k+1} and χ_{k+1}.

(ii) Let $(\tilde{q},\tilde{r}) \in \mathcal{T}$, and q,r,v as in (i). It is clear that $(q,r) \in \mathcal{Z}^2$; Eq. (4.6) means $(\tilde{q},\tilde{r}) \in B(q,r)$. ■

Proof of the Treves theorem (Proposition 2.1): Set together Eqs. (4.3) and (4.7). ■

In a similar way we now prove Proposition 2.2, that concerns the set

$$\mathcal{S} := \left\{ \tilde{q},\tilde{r} \in \mathcal{Q}^2 | \tilde{q} = e^{\varphi}\left(\frac{2}{x^2} + \alpha + \beta x + \sum_{k=2}^{+\infty} \tilde{\chi}_k x^k\right), \right.$$
$$\left. \tilde{r} = e^{-\varphi}\ \left(1 + \beta x^3 + \sum_{k=4}^{+\infty} \tilde{\rho}_k x^k\right),\ (\varphi,\alpha,\beta,\tilde{\chi}_k,\tilde{\rho}_k \in \mathbb{C})\right\}; \tag{4.12}$$

everything relies on the following.

Lemma 4.4: (i) Let $\tilde{q},\tilde{r}$ be as in Eq. (4.12). Then, there are uniquely determined series of the form

$$q = e^{\varphi}\sum_{k=2}^{+\infty} \chi_k x^k,\ \ r = e^{-\varphi}\left(-1 + \sum_{k=3}^{+\infty} \rho_k x^k\right),\ \ v = -\frac{2}{x} + \alpha x + \sum_{k=2}^{+\infty} v_k x^k \tag{4.13}$$

such that $I_j(q,r,v,\tilde{q},\tilde{r})=0$ for $j=1,2,3$.

(ii) Statement (i) implies

$$\mathcal{S} \subset B(\mathcal{Z}^2). \tag{4.14}$$

Proof: (i) Let $q,\dots,\tilde{r}$ be as in Eqs. (4.12) and (4.13), and $I_j \equiv I_j(q,r,v,\tilde{q},\tilde{r})$. Then

$$I_1 = e^{\varphi}\sum_{k=0}^{+\infty} J_{1k}x^k,\ \ I_2 = e^{-\varphi}\sum_{k=2}^{+\infty} J_{2k}x^k,\ \ I_3 = x\sum_{k=0}^{+\infty} J_{3k}x^k, \tag{4.15}$$

$$J_{10} := 2v_2 - 3\beta,\ \ J_{11} := 2v_3 - 4\tilde{\chi}_2 + \alpha^2,\ \ J_{12} := \chi_3 + 2v_4 + \alpha v_2 - 5\tilde{\chi}_3 + \alpha\beta,$$

$$J_{13} := 2\chi_4 + 2v_5 + \alpha v_3 + \beta v_2 - 6\tilde{\chi}_4 + \alpha(\chi_2 + \tilde{\chi}_2), \tag{4.16}$$

$$J_{1k} := (k-1)\chi_{k+1} + 2v_{k+2} - (k+3)\tilde{\chi}_{k+1} + \alpha v_k + \beta v_{k-1} + \alpha(\chi_{k-1} + \tilde{\chi}_{k-1}) + \sum_{\ell=2}^{k-2} v_{k-\ell}(\chi_\ell + \tilde{\chi}_\ell)\ \ (k \geqslant 4),$$

$$J_{22} := \rho_3 - 5\beta,\ \ J_{23} := 2\rho_4 - 6\tilde{\rho}_4,\ \ J_{24} := 3\rho_5 + \alpha(\rho_3 + \beta) - 7\tilde{\rho}_5,$$

$$J_{25} := 4\rho_6 + v_2\rho_3 + \beta v_2 - 8\tilde{\rho}_6 + \alpha(\rho_4 + \tilde{\rho}_4), \tag{4.17}$$

$$J_{2k} := (k-1)\rho_{k+1} - (k+3)\tilde{\rho}_{k+1} + \beta v_{k-3} + \alpha(\rho_{k-1} + \tilde{\rho}_{k-1}) + \sum_{\ell=3}^{k-2} v_{k-\ell}\rho_\ell + \sum_{\ell=4}^{k-2} v_{k-\ell}\tilde{\rho}_\ell\ \ (k \geqslant 6),$$

$$J_{30} := 2v_2 - 3\beta,\ \ J_{31} := 3v_3 - \chi_2 - \tilde{\chi}_2 - 2\tilde{\rho}_4,\ \ J_{32} := 4v_4 - \chi_3 - \tilde{\chi}_3 - 2\tilde{\rho}_5 - \alpha\beta,$$

$$J_{33} := 5v_5 - \chi_4 - \tilde{\chi}_4 - 2\tilde{\rho}_6 - \alpha\tilde{\rho}_4 - \beta^2,\ \ J_{34} := 6v_6 - \chi_5 - \tilde{\chi}_5 - 2\tilde{\rho}_7 - \alpha\tilde{\rho}_5 - \beta\tilde{\rho}_4 + \chi_2\rho_3 - \tilde{\chi}_2\beta, \tag{4.18}$$

$$J_{3k} := (k+2)v_{k+2} - \chi_{k+1} - \tilde{\chi}_{k+1} - 2\tilde{\rho}_{k+3} - \alpha\tilde{\rho}_{k+1} - \beta\tilde{\chi}_{k-2} - \beta\tilde{\rho}_k + \sum_{\ell=3}^{k-1} \chi_{k+1-\ell}\rho_\ell - \sum_{\ell=4}^{k-1} \tilde{\chi}_{k+1-\ell}\tilde{\rho}_\ell\ \ (k \geqslant 5).$$

Again, we must show that the equations $J_{1k}=0$, $J_{2k}=0$, $J_{3k}=0$ for all k have uniquely determined solutions for the coefficients χ_k,ρ_k,v_k.

In fact, from $J_{10}=0$ and $J_{11}=0$ one uniquely determines v_2, v_3; now, the equation $J_{30}=0$ is automatically fulfilled, and $J_{31}=0$ gives χ_2. At this point, we must determine v_{k+2}, ρ_{k+1}, and χ_{k+1} for $k \geqslant 2$, which is performed recursively in the following way. From $J_{1k}=0$ and $J_{3k}=0$ one computes v_{k+2} and χ_{k+1}; to find them, one must solve a linear system whose matrix $\left(\begin{smallmatrix} 2 & k-1 \\ k+2 & -1 \end{smallmatrix}\right)$ has determinant $-k(k+1) \neq 0$. Finally, from $J_{2k}=0$ one gets ρ_{k+1}.

(ii) Let $(\tilde{q},\tilde{r}) \in \mathcal{S}$, and q,r,v as in (i). Then $(q,r) \in \mathcal{Z}^2$, and statement (i) means $(\tilde{q},\tilde{r}) \in B(q,r)$. ■

Proof of Proposition 2.2: Set together Eqs. (4.3) and (4.14). ■

Remark: In any case, the following holds:

$$(\tilde{q},\tilde{r}) \in B(\mathcal{Z}^2),\ \ \tilde{q} = \sum_{k=a}^{+\infty} \tilde{q}_k x^k,\ \tilde{q}_a \neq 0,\ \ \tilde{r} = \sum_{k=b}^{+\infty} \tilde{r}_k x^k,\ \tilde{r}_b \neq 0,\ \ \min(a,b) < 0 \Rightarrow a + b = -2,$$

$$\tilde{q}_a\tilde{r}_b = -\min(a,b). \tag{4.19}$$

In fact, we are assuming $I_j \equiv I_j(q,r,v,\tilde{q},\tilde{r}) = 0$ for some holomorphic $q,r \in \mathcal{Z}$ and $v \in \mathcal{Q}$. To fix the ideas, let us assume $\min(a,b)=a$; then, from $I_1=0$ we easily infer $v = \sum_{k=-1}^{+\infty} v_k x^k$ with $v_{-1}=a$.

Inserting these facts into $I_3=0$, we obtain $a+b=-2$ and $\tilde{q}_a\tilde{r}_b=-a$. If $\min(a,b)=b$ we proceed similarly, using the equations $I_2=0$ and $I_3=0$.

Of course, if $(\tilde{q},\tilde{r})$ are in the subsets $\mathcal{T}$ or $\mathcal{S}$ we have, respectively, $a=b=-1$ or $a=-2$, $b=0$.

APPENDIX A: MATRIX LAX OPERATORS: THE DRINFELD–SOKOLOV FORMULATION

Some more algebra: Consider any differential algebra $(\mathcal{U},\partial_x\equiv\cdot_x)$, possibly noncommutative. Then, the algebra of *differential operators with coefficients* in $\mathcal{U}$ is the associative (and noncommutative) algebra $\mathrm{Diff}(\mathcal{U})$ with generators

$$\partial_x,\ U\ (U\in\mathcal{U}) \tag{A1}$$

and defining relations

$$\underbrace{UV}_{\text{product in Diff}(\mathcal{U})} = \underbrace{UV}_{\text{product in }\mathcal{U}}\ ,\qquad \underbrace{\partial_x U}_{\text{product in Diff}(\mathcal{U})} = U\partial_x + U_x \qquad (U,V\in\mathcal{U}). \tag{A2}$$

Any $D\in\mathrm{Diff}(\mathcal{U})$ has a representation

$$D=\sum_{k=0}^{d} D_k\partial_x^k\ (d\in\mathbb{N},D_k\in\mathcal{U}\ \forall\, k), \tag{A3}$$

which is unique under the condition $D_d\neq 0$ if $d\neq 0$; the unique integer d determined in this way is called the *order* of the differential operator D. $\mathcal{U}$ can be identified with the subalgebra of $\mathrm{Diff}(\mathcal{U})$ made of zero order operators; if $\mathcal{U}$ has unity 1, this is also the unity of $\mathrm{Diff}(\mathcal{U})$ (so, the invertible zero order operators are just the invertible elements of $\mathcal{U}$).

For any vector space $\mathcal{V}$, we introduce the vector space of $n\times n$ matrices

$$\mathrm{Mat}_n(\mathcal{V})=\{\mathsf{V}=(V_{ab})_{a,b=1,\ldots,n}|V_{ab}\in\mathcal{V}\ \forall\, a,b\}; \tag{A4}$$

we often consider therein the supplementary subspaces $\mathrm{Diag}_n(\mathcal{V})$, $\mathrm{Off}_n(\mathcal{V})$ made, respectively, by the diagonal and off-diagonal matrices.

If $(\mathcal{V},\partial_x)$ is a differential algebra, $\mathrm{Mat}_n(\mathcal{V})$ is a differential algebra when equipped with the usual "row by column" product and with the "term by term" derivation $\mathsf{V}\mapsto\mathsf{V}_x:=(V_{ab,x})$. Up to trivial identifications, we have $\int\mathrm{Mat}_n(\mathcal{V})=\mathrm{Mat}_n(\int\mathcal{V})$ and $\int\mathsf{V}=(\int V_{ab})$. Of course, $\mathrm{Diag}_n(\mathcal{V})$ is a differential subalgebra of $\mathrm{Mat}_n(\mathcal{V})$. If $\mathcal{I}$ is an ideal, or a differential (∂_x-closed) ideal in $\mathcal{V}$, the same occurs for $\mathrm{Mat}_n(\mathcal{I})$ in $\mathrm{Mat}_n(\mathcal{V})$.

Consider again a vector space, now denoted for convenience with $\mathcal{W}$. We can build from it the vector space of formal series in one indeterminate λ,

$$\mathcal{W}(\lambda):=\left\{W=\sum_{i=i_{min}}^{+\infty} W_i\lambda^{-i}|i_{\min}=i_{\min}(W)\in\mathbb{Z},W_i\in\mathcal{W}\,\forall\, i\right\}; \tag{A5}$$

we will often fix the attention on the subspaces,

$$\mathcal{W}(\lambda)_{\leqslant}:=\left\{\sum_{i=0}^{+\infty} W_i\lambda^{-i}\right\},\quad \mathcal{W}(\lambda)_{<}:=\left\{\sum_{i=1}^{+\infty} W_i\lambda^{-i}\right\}. \tag{A6}$$

If $\mathcal{W}$ is a differential algebra with derivation $\partial_x\equiv\cdot_x$, then $\mathcal{W}(\lambda)$ is a differential algebra, with the usual Cauchy product of series and the derivation $\partial_x\colon\ W\mapsto W_x:=\Sigma_i W_{i,x}\lambda^{-i}$. Of course, $\mathcal{W}$ can be identified with the differential subalgebra of $\mathcal{W}(\lambda)$ made of series W with $W_i=0$ for $i\neq 0$; $\mathcal{W}(\lambda)_{\leqslant}$, $\mathcal{W}(\lambda)_{<}$ are also differential subalgebras. If $\mathcal{W}$ has unity 1, this is also the unity of $\mathcal{W}(\lambda)$; the subset

$$1 + \mathcal{W}(\lambda)_< = \left\{ 1 + \sum_{i=1}^{+\infty} W_i \lambda^{-i} \right\} \tag{A7}$$

is a group with respect to the Cauchy product.

To conclude these preliminaries we point out that the notation [,], employed in the sequel for matrices or differential operators, stands for the usual commutator.

Drinfeld–Sokolov theory: Let us consider a commutative differential algebra $(\mathcal{F}, \partial_x)$; to fix the ideas, one can think $\mathcal{F}$ to be the algebra (1.9) with generators ξ_s $(s=1, \ldots, \gamma)$, but for the moment this is not necessary. For a given n, we construct from it the matrix differential algebra $\mathrm{Mat}_n(\mathcal{F})$. In the sequel, elements of $\int\mathcal{F}$ and $\mathrm{Mat}_n(\int\mathcal{F})$ will be called, respectively, the *scalar* and the $n \times n$ *matrix integrals, or functionals* of $\mathcal{F}$.

For technical reasons appearing in the sequel, we need the direct sum of this algebra and the $n \times n$ matrices with complex entries, i.e.,

$$\mathrm{Mat}_n(\mathcal{F}) \oplus \mathrm{Mat}_n(\mathbb{C}), \tag{A8}$$

which is in an obvious way an associative algebra [the product beween elements of $\mathrm{Mat}_n(\mathcal{F})$ and $\mathrm{Mat}_n(\mathbb{C})$ is defined again row by column]; this algebra contains $\mathrm{Mat}_n(\mathcal{F})$ as an ideal. The derivation ∂_x of $\mathrm{Mat}_n(\mathcal{F})$ is extended to the previous direct sum, prescribing that it annihilates $\mathrm{Mat}_n(\mathbb{C})$; in this way, (A8) is a differential algebra and $\mathrm{Mat}_n(\mathcal{F})$ a differential ideal of it. Of course the unity of (A8) is $\mathsf{1} := \mathrm{diag}_n(1, \ldots, 1)$.

The next step is to form the differential algebra of formal series

$$(\mathrm{Mat}_n(\mathcal{F}) \oplus \mathrm{Mat}_n(\mathbb{C}))(\lambda) := \left\{ \mathsf{N} = \sum_{i=i_{\min}}^{+\infty} \mathsf{N}_i \lambda^{-i} \,|\, i_{\min} \in \mathbb{Z}, \mathsf{N}_i \in \mathrm{Mat}_n(\mathcal{F}) \oplus \mathrm{Mat}_n(\mathbb{C}) \ \forall\, i \right\} \tag{A9}$$

[which of course contains the differential ideal $\mathrm{Mat}_n(\mathcal{F})(\lambda)$, made of series as above with coefficients $\mathsf{N}_i \in \mathrm{Mat}_n(\mathcal{F})$]. The ultimate step is the algebra

$$\mathfrak{D}_n(\mathcal{F}) := \mathrm{Diff}((\mathrm{Mat}_n(\mathcal{F}) \oplus \mathrm{Mat}_n(\mathbb{C}))(\lambda)), \tag{A10}$$

made of differential operators with coefficients in the algebra (A9).

Definition A.1: A first order, $n \times n$ Lax operator is a differential operator of the form

$$\mathsf{L} \equiv \mathsf{L}_{\mathsf{A},\mathsf{S}} := \partial_x - \lambda \mathsf{A} - \mathsf{S} \in \mathfrak{D}_n(\mathcal{F}),$$
$$\mathsf{S} \in \mathrm{Mat}_n(\mathcal{F}), \ \mathsf{A} = \mathrm{diag}(a_1, \ldots, a_n) \in \mathrm{Diag}_n(\mathbb{C}), \ a_i \neq 0 \text{ for all } i, a_i \neq a_j \text{ for } i \neq j. \tag{A.11}$$

We will write $\mathfrak{L}_n(\mathcal{F})$ for the set of these operators.

The first result in the Drinfeld–Sokolov theory is a diagonalization theorem for these operators.

Proposition A.2: Consider an operator $\mathsf{L} = \mathsf{L}_{\mathsf{A},\mathsf{S}} \in \mathfrak{L}_n(\mathcal{F})$. Then, there is a pair of objects

$$\mathsf{U} = 1 + \sum_{i=1}^{+\infty} \mathsf{U}_i \lambda^{-i} \in 1 + \mathrm{Mat}_n(\mathcal{F})(\lambda)_<, \tag{A12}$$

$$\mathsf{H} = \sum_{i=0}^{+\infty} \mathsf{H}_i \lambda^{-i} \in \mathrm{Diag}_n(\mathcal{F})(\lambda)_\leqslant, \tag{A13}$$

such that

$$\mathsf{L} = \mathsf{U}(\partial_x - \lambda \mathsf{A} - \mathsf{H})\mathsf{U}^{-1}; \tag{A14}$$

moreover, the matrix functionals

$$\mathsf{h}_{\mathsf{L},i} \equiv \mathsf{h}_i := \int \mathsf{H}_i \quad (i = 0,1,2,\dots) \tag{A15}$$

are uniquely determined by L.

Proof: See Sec. I of Ref. 5. The main point is that Eq. (A14) is equivalent to $\mathsf{LU}=\mathsf{U}(\partial_x - \lambda\mathsf{A}-\mathsf{H})$, and that the expansion in powers of λ of both sides in this equality gives rise to recursion equations for the sequences (H_i), (U_i). ■

Definition A.3: Any pair (U,H) *as in Proposition A.2 will be called a diagonalizing pair for* L. *The matrix functionals* $\mathsf{h}_{\mathsf{L},i}$ *will be called the fundamental invariants of* L.

Remark: Suppose $(\mathcal{F},\partial_x)$ is a strict differential subalgebra of a commutative differential algebra $(\mathcal{M},\partial_x)$ [Eq. (1.8); recall that $\int\mathcal{F}\simeq\int^{\mathcal{M}}\mathcal{F}\subset\int\mathcal{M}$]. Then, by the uniqueness statement of the previous proposition, the diagonalizations of L as an element of $\mathfrak{L}_n(\mathcal{F})$, or as an element of $\mathfrak{L}_n(\mathcal{M})$, give rise to the same fundamental invariants which belong in any case to $\mathrm{Diag}_n(\int\mathcal{F})$.

The forthcoming proposition considers a situation of this kind; the result stated therein clarifies the origin of the term "invariant" for the functionals h_i.

Proposition A.4: Let $(\mathcal{M},\partial_x)$ *be a commutative differential algebra containing* $\mathcal{F}$ *as a strict differential subalgebra; further, let* $\widetilde{\mathcal{F}}$ *denote another strict differential subalgebra of* $\mathcal{M}$.

Consider two operators

$$\mathsf{L} = \mathsf{L}_{\mathsf{A},\mathsf{S}} \in \mathfrak{L}_n(\mathcal{F}),\ \widetilde{\mathsf{L}} = \mathsf{L}_{\mathsf{A},\widetilde{\mathsf{S}}} \in \mathfrak{L}_n(\widetilde{\mathcal{F}}) \tag{A16}$$

(*with the same* A) *and their fundamental invariants* $\mathsf{h}_{\mathsf{L},i}\equiv\mathsf{h}_i \in \mathrm{Diag}_n(\int\mathcal{F})$, $\mathsf{h}_{\widetilde{\mathsf{L}},i}\equiv\widetilde{\mathsf{h}}_i \in \mathrm{Diag}_n(\int\widetilde{\mathcal{F}})$.

Let $\mathcal{I}$ *denote an ideal of* $\mathcal{M}$, *and assume there is*

$$\mathsf{V} = 1 + \sum_{i=1}^{+\infty} \mathsf{V}_i\lambda^{-i} \in 1 + \mathrm{Mat}_n(\mathcal{M})(\lambda)_< \tag{A17}$$

such that

$$\widetilde{\mathsf{L}} - \mathsf{VLV}^{-1} \in \mathrm{Mat}_n(\mathcal{I})(\lambda)_{\leqslant}. \tag{A18}$$

Then

$$\widetilde{\mathsf{h}}_i - \mathsf{h}_i \in \mathrm{Diag}_n\left(\int\mathcal{I}\right) \quad (i = 0,1,2,\dots) \tag{A19}$$

(*where, in the last equation,* $\int\equiv\int^{\mathcal{M}}$).

In a few words, if $\mathsf{L},\widetilde{\mathsf{L}}$ are similar up to a series with coefficients in the ideal $\mathrm{Mat}_n(\mathcal{I})$, their fundamental invariants coincide up to elements of $\mathrm{Diag}_n(\int\mathcal{I})$. This result is essential for our purposes; since our language is slightly different from the one of Ref. 5, it is convenient to report the following.

Proof of Proposition A.4: We choose a diagonalizing pair (U,H) for L, so as to fulfill Eqs. (A12)–(A14), and proceed in three steps.

Step 1: There are

$$\mathsf{W} \in 1 + \mathrm{Mat}_n(\mathcal{M})(\lambda)_<,\ \mathsf{J} \in \mathrm{Mat}_n(\mathcal{I})(\lambda)_{\leqslant}\ \textit{such that}\ \widetilde{\mathsf{L}} = \mathsf{W}(\partial_x - \lambda\mathsf{A} - \mathsf{H} - \mathsf{J})\mathsf{W}^{-1}. \tag{A20}$$

In fact, assumption (A18) means $\widetilde{\mathsf{L}}=\mathsf{VLV}^{-1}+\mathsf{F}$, where $\mathsf{F}\in\mathrm{Mat}_n(\mathcal{I})(\lambda)_{\leqslant}$; from here and (A14) we get

$$\widetilde{\mathsf{L}} = \mathsf{VU}(\partial_x - \lambda\mathsf{A} - \mathsf{H})\mathsf{U}^{-1}\mathsf{V}^{-1} + \mathsf{F} = \mathsf{VU}(\partial_x - \lambda\mathsf{A} - \mathsf{H} + \mathsf{U}^{-1}\mathsf{V}^{-1}\mathsf{FVU})\mathsf{U}^{-1}\mathsf{V}^{-1}; \tag{A21}$$

this gives the thesis (A20), with $\mathsf{W}:=\mathsf{VU}$ and $\mathsf{J}:=-\mathsf{U}^{-1}\mathsf{FVU}$ [the relations $\mathsf{W}\in 1+\mathrm{Mat}_n(\mathcal{M})\times(\lambda)_<$, $\mathsf{J}\in\mathrm{Mat}_n(\mathcal{I})(\lambda)_{\leqslant}$ are easily checked from the previous definitions recalling that 1

$+\mathrm{Mat}_n(\mathcal{M})(\lambda)_<$ is a group, $\mathrm{Mat}_n(\mathcal{M})(\lambda)_\leqslant$ a subalgebra and $\mathrm{Mat}_n(\mathcal{I})$ an ideal].

Step 2: Consider the differential ideal $\mathcal{G}$ of $\mathcal{M}$ generated by $\mathcal{I}$ (i.e., the smallest differential ideal containing $\mathcal{I}$). Then $\tilde{\mathsf{L}}$, as an element of $\mathfrak{L}_n(\mathcal{M})$, admits a diagonalizing pair $(\tilde{\mathsf{U}},\tilde{\mathsf{H}})$ with $\tilde{\mathsf{H}}$ of the form

$$\tilde{\mathsf{H}} = \mathsf{H} + \mathsf{G},\ \ \mathsf{G} \in \mathrm{Diag}_n(\mathcal{G})(\lambda)_\leqslant. \tag{A22}$$

To prove this, we write

$$\tilde{\mathsf{U}} = \mathsf{W}\mathsf{Z},\ \ \mathsf{W} \text{ as in step 1, } \mathsf{Z} = 1 + \sum_{i=1}^{+\infty} \mathsf{Z}_i \lambda^{-i} \in 1 + \mathrm{Off}_n(\mathcal{G})(\lambda)_< \text{ to be found,} \tag{A23}$$

$$\tilde{\mathsf{H}} = \mathsf{H} + \mathsf{G} = \sum_{i=0}^{+\infty} (\mathsf{H}_i + \mathsf{G}_i)\lambda^{-i},\ \ \mathsf{G}_i \in \mathrm{Diag}_n(\mathcal{G}) \text{ to be found} \tag{A24}$$

(recall that Off_n stands for the the off-diagonal $n\times n$ matrices). Due to these representations and to Eq. (A20) for $\tilde{\mathsf{L}}$, the diagonalizing condition $\tilde{\mathsf{L}} = \tilde{\mathsf{U}}(\partial_x - \lambda\mathsf{A} - \tilde{\mathsf{H}})\tilde{\mathsf{U}}^{-1}$ is fulfilled if

$$(\partial_x - \lambda\mathsf{A} - \mathsf{H} - \mathsf{J})\mathsf{Z} = \mathsf{Z}(\partial_x - \lambda\mathsf{A} - \mathsf{H} - \mathsf{G}). \tag{A25}$$

Recalling that $\partial_x \mathsf{Z} = \mathsf{Z}\partial_x + \mathsf{Z}_x$ and expanding the last equation in powers of λ, we see that (A25) is fulfilled if

$$-\mathsf{G}_i + [\mathsf{A},\mathsf{Z}_{i+1}] = \mathsf{Z}_{i,x} - \mathsf{J}_i + \sum_{k=1}^{i} ([\mathsf{Z}_k,\mathsf{H}_{i-k}] + \mathsf{Z}_k\mathsf{G}_{i-k} - \mathsf{J}_{i-k}\mathsf{Z}_k)\ \ (i = 0,1,2,\dots) \tag{A26}$$

[intending $\mathsf{Z}_{0,x} := (1)_x = 0$ and $\Sigma_{k=1}^{0} := 0$]. We will show that the system (A26) can be solved recursively. To this purpose, we introduce the projections $\mathcal{D}_n, \mathcal{O}_n$ of $\mathrm{Mat}_n(\mathcal{M})$ onto the supplementary subspaces $\mathrm{Diag}_n(\mathcal{M})$, $\mathrm{Off}_n(\mathcal{M})$; furthermore, recalling that A is diagonal with nonzero and all different eigenvalues, we infer that $\mathrm{ad}_\mathsf{A} := [\mathsf{A},\cdot]$: $\mathrm{Off}_n(\mathcal{M}) \to \mathrm{Off}_n(\mathcal{M})$ is a linear isomorphism. These remarks yield for (A26) the solution

$$\mathsf{G}_i = \mathcal{D}_n\left(\mathsf{J}_i - \sum_{k=1}^{i} (\mathsf{Z}_k\mathsf{G}_{i-k} - \mathsf{J}_{i-k}\mathsf{Z}_k)\right), \tag{A27}$$

$$\mathsf{Z}_{i+1} = ad_\mathsf{A}^{-1}\left(\mathsf{Z}_{ix} - \mathcal{O}_n(\mathsf{J}_i) + \sum_{k=1}^{i} [\mathsf{Z}_k,\mathsf{H}_{i-k}] + \sum_{k=1}^{i} \mathcal{O}_n(\mathsf{Z}_k\mathsf{G}_{i-k} - \mathsf{J}_{i-k}\mathsf{Z}_k)\right)\ (i = 0,1,2,\dots)$$

(note that $[\mathsf{Z}_k,\mathsf{H}_{i-k}]$ is purely off-diagonal). From these equations, with $i=0$, one gets $\mathsf{G}_0 = \mathcal{D}_n(\mathsf{J}_0)$, $\mathsf{Z}_1 = -\mathrm{ad}_\mathsf{A}^{-1}\mathcal{O}_n(\mathsf{J}_0)$; subsequently, one uses recursively Eqs. (A27) to determine at each step $\mathsf{G}_i, \mathsf{Z}_{i+1}$. The fact that $\mathrm{Mat}_n(\mathcal{G})$ is a differential ideal and the structure of the above equations also make evident that $\mathsf{G}_i, \mathsf{Z}_{i+1}$ belong to $\mathrm{Mat}_n(\mathcal{G})$ for all i; by construction these matrices are, respectively, diagonal and off-diagonal as required.

Step 3: Conclusion of the proof. Let us intend $\int \equiv \int^{\mathcal{M}}$ (recalling the remark on $\int\mathcal{F}$ just before the statement of this proposition, and the analogous one for $\int\tilde{\mathcal{F}}$). Equation (A22) implies

$$\tilde{\mathsf{h}}_i - \mathsf{h}_i = \int \tilde{\mathsf{H}}_i - \int \mathsf{H}_i = \int \mathsf{G}_i \in \mathrm{Diag}_n\left(\int \mathcal{G}\right); \tag{A28}$$

the thesis (A19) follows from here, and from the remark that

$$\int \mathcal{G} = \int \mathcal{I}. \tag{A29}$$

To prove Eq. (A29), we note that any element of the differential ideal $\mathcal{G}$ has the form

$$G = \sum_{\ell \in \Lambda} F_\ell I_\ell^{(\sigma_\ell)} \ (\Lambda \text{ a finite set}, \ F_\ell \in \mathcal{M}, I_\ell \in \mathcal{I}, \sigma_\ell \in \mathbb{N} \ \ \forall\, \ell \in \Lambda), \tag{A30}$$

where $\cdot^{(\sigma_\ell)}$ indicates the σ_ℓth power of the derivation $\cdot_x$. Now, standard integration by parts gives

$$\int G = \int I, \ \ I := \sum_{\ell \in \Lambda} (-1)^{\sigma_\ell} F_\ell^{(\sigma_\ell)} I_\ell \in \mathcal{I}. \tag{A31}$$

■

We now review some known relations between Lax operators, their diagonalization and evolutionary problems. From now on, we work with the Gelfand–Dickey differential algebra,

$$\mathfrak{F} = \mathbb{C}[\xi_1, \dots, \xi_\gamma, \xi_{1,x}, \dots, \xi_{\gamma,x}, \dots]_0 \tag{A32}$$

[see Eq. (1.9)]. Also, we are given a vector field $X = (X_1, \dots, X_\gamma) \in \mathfrak{F}^\gamma$; as explained in Sec. I, there are Lie derivative operators $\mathcal{L}_X: \mathfrak{F} \to \mathfrak{F}$ and $\mathcal{L}_X: \int\mathfrak{F} \to \int\mathfrak{F}$ [see Eqs. (1.17) and (1.18)]; these induce "componentwisely" maps $\mathcal{L}_X$ of $\mathrm{Mat}_n(\mathfrak{F})$ or $\mathrm{Mat}_n(\int\mathfrak{F})$ into itself. Trivially, $\mathcal{L}_X$ can be extended to a map of $\mathrm{Mat}_n(\mathfrak{F}) \oplus \mathrm{Mat}_n(\mathbb{C})$ into itself, defining it to be zero on $\mathrm{Mat}_n(\mathbb{C})$.

Again trivially, we extend the Lie derivative to a map $\mathcal{L}_X$ of $[\mathrm{Mat}_n(\mathfrak{F}) \oplus \mathrm{Mat}_n(\mathbb{C})](\lambda)$ into itself, setting $\mathcal{L}_X(\Sigma_i \mathsf{N}_i \lambda^{-i}) := \Sigma_i (\mathcal{L}_X \mathsf{N}_i)\lambda^{-i}$; we finally define $\mathcal{L}_X: \mathfrak{D}_n(\mathfrak{F}) \to \mathsf{D}_n(F)$ by $\mathcal{L}_X(\Sigma_k \mathsf{D}_k \partial_x^k) := \Sigma_k (\mathcal{L}_X \mathsf{D}_k)\partial_x^k$.

Definition A.5: X is said to admit an $n \times n$ Lax formulation if there are an operator $\mathsf{L} = \mathsf{L}_{\mathsf{A},\mathsf{S}} \in \mathfrak{L}_n(\mathfrak{F}) \subset \mathfrak{D}_n(\mathfrak{F})$ and a zero-order operator $\mathsf{C} \in \mathrm{Mat}_n(\mathfrak{F})(\lambda) \subset \mathfrak{D}_n(\mathfrak{F})$ such that

$$\mathcal{L}_X \mathsf{L} = [\mathsf{L}, \mathsf{C}]. \tag{A33}$$

Proposition A.6: If X is admits a Lax formulation as above, the fundamental invariants $\mathsf{h}_{\mathsf{L},i} \equiv \mathsf{h}_i$ $(i = 0, 1, 2, \dots)$ are conserved matrix functionals for X,

$$\mathcal{L}_X \mathsf{h}_i = 0. \tag{A34}$$

Proof: Reference 5, Sec. I. ■

Of course, from here we get conserved scalar functionals taking all matrix elements $h_{i,ab} \in \int\mathfrak{F}$.

APPENDIX B: LAX FORMALISM AND BÄCKLUND TRANSFORMATIONS FOR THE AKNS THEORY

As in Sec. III, we consider the differential algebra,

$$\mathfrak{F} = \mathbb{C}[\xi, \eta, \xi_x, \eta_x, \dots], \tag{B1}$$

with two generators ξ, η, and the vector field $X_{\mathrm{AKNS}} \equiv X$. This is known to admit a Lax formulation of the type (A33), with $n = 2$; the matrices S, A of L, and the matrix C are given by

$$\mathsf{S} := \begin{pmatrix} 0 & \xi \\ \eta & 0 \end{pmatrix}, \ \ \mathsf{A} := \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}, \ \ \mathsf{C} := \frac{1}{2}\begin{pmatrix} -\xi\eta & \xi_x \\ -\eta_x & \xi\eta \end{pmatrix} + \lambda \mathsf{S} + \lambda^2 \mathsf{A}. \tag{B2}$$

This operator has a diagonalizing pair $\mathsf{U} = 1 + \mathsf{U}_1/\lambda + \mathsf{U}_2/\lambda^2 + \mathsf{U}_3/\lambda^3 + \cdots$, $\mathsf{H} = \mathsf{H}_0 + \mathsf{H}_1/\lambda + \mathsf{H}_2/\lambda^2 + \mathsf{H}_3/\lambda^3 + \cdots$, where

$$\mathsf{U}_1 = \frac{1}{2}\begin{pmatrix} 0 & -\xi \\ \eta & 0 \end{pmatrix}, \ \ \mathsf{U}_2 = \frac{1}{4}\begin{pmatrix} 0 & -\xi_x \\ -\eta_x & 0 \end{pmatrix}, \tag{B3}$$

$$\mathsf{U}_3 = \frac{1}{8}\begin{pmatrix} 0 & -\xi_{xx} + \xi^2\eta \\ \eta_{xx} - \xi\eta^2 & 0 \end{pmatrix} \cdots,$$

$$\mathsf{H}_0 = 0,\ \mathsf{H}_1 = \frac{1}{2}\begin{pmatrix} \xi\eta & 0 \\ 0 & -\xi\eta \end{pmatrix},\ \mathsf{H}_2 = -\frac{1}{4}\begin{pmatrix} \xi\eta_x & 0 \\ 0 & \eta\xi_x \end{pmatrix},\ \mathsf{H}_3 = \frac{1}{8}\begin{pmatrix} \xi\eta_{xx} - \xi^2\eta^2 & 0 \\ 0 & -\eta\xi_{xx} + \xi^2\eta^2 \end{pmatrix},$$

$$\mathsf{H}_4 := \frac{1}{16}\begin{pmatrix} -\xi\eta_{xxx} + \xi\xi_x\eta^2 + 4\xi^2\eta\eta_x & 0 \\ 0 & -\eta\xi_{xxx} + \eta\eta_x\xi^2 + 4\eta^2\xi\xi_x \end{pmatrix}, \ldots. \tag{B4}$$

The fundamental invariants $\mathsf{h}_i := \int \mathsf{H}_i$ are conserved functionals for X; for all i, the diagonal elements of H_i are opposite up to total derivatives, so that

$$\mathsf{h}_i \equiv \mathsf{h}_{\mathrm{L},i} = \begin{pmatrix} h_i & 0 \\ 0 & -h_i \end{pmatrix}. \tag{B5}$$

For $i=1,2,3,4$, the conserved scalar functionals $h_i \in \int\mathfrak{F}$ are the ones appearing in Eq. (1.23).

Up to a rescaling of each element by a suitable constant, the sequence $(h_i)_{i=1,2,\ldots}$ can be identified with the basis of $\mathfrak{Z}_{\mathrm{AKNS}} \equiv \mathfrak{Z}$ considered in Ref. 11. [The basis in Ref. 11 is not defined via the Lax formalism but, rather, by a precise formulation of the known bi-Hamiltonian recursion scheme for the AKNS;[6] the fact that the functionals (h_i) fulfill this recursion scheme reflect a general feature of the Drinfeld–Sokolov approach: see again Ref. 5, Sec. I where a general construction is given for the bi-Hamiltonian structure of the evolution equations arising from matrix first order Lax operators.]

We come to the Bäcklund transformation. Let us recall the formalism of Sec. III; this involves the "initial variables" ξ,η generating $\mathfrak{F}$, the "final variables" $\tilde{\xi},\tilde{\eta}$ generating $\tilde{\mathfrak{F}}$, and the "auxiliary variable" ν generating with all of the previous ones in differential algebra $\mathfrak{M}$ [see Eq. (3.3)]. Of course, the "tilde" map $\tilde{}: \mathfrak{F} \to \tilde{\mathfrak{F}}$ induces componentwise a tilde map $\tilde{}: \mathrm{Mat}_n(\mathfrak{F}) \to \mathrm{Mat}_n(\tilde{\mathfrak{F}})$; the inclusions $\mathfrak{F}, \tilde{\mathfrak{F}} \subset \mathfrak{M}$ induce inclusions of the corresponding spaces of matrices, formal series in λ and differential operators. In particular, we fix the attention on the Lax operators,

$$\mathsf{L}_{\mathsf{A},\mathsf{S}} \equiv \mathsf{L} \in \mathfrak{D}_2(\mathfrak{F}) \subset \mathfrak{D}_2(\mathfrak{M}),\ \mathsf{L}_{\mathsf{A},\tilde{\mathsf{S}}} \equiv \tilde{\mathsf{L}} \in \mathfrak{D}_2(\tilde{\mathfrak{F}}) \subset \mathfrak{D}_2(\mathfrak{M}) \tag{B6}$$

[A,S as in Eq. (B2); as stipulated before, $\tilde{\mathsf{S}}$ means $\left(\begin{smallmatrix} 0 & \tilde{\xi} \\ \tilde{\eta} & 0 \end{smallmatrix}\right)$].

Lemma B.1: Let

$$\mathsf{V} := 1 + \frac{1}{2\lambda}\begin{pmatrix} \nu & \xi - \tilde{\xi} \\ \tilde{\eta} - \eta & -\nu \end{pmatrix}. \tag{B7}$$

Then

$$\tilde{\mathsf{L}} - \mathsf{V}\mathsf{L}\mathsf{V}^{-1} \in \mathrm{Mat}_2(\mathcal{I})(\lambda)_<, \tag{B8}$$

where $\mathcal{I}$ is the Bäcklund ideal of Definition 3.1.

Proof: One finds by direct computation that

$$\tilde{\mathsf{L}}\mathsf{V} - \mathsf{V}\mathsf{L} = \mathsf{V}_x - \tilde{\mathsf{S}}\mathsf{V} + \mathsf{V}\mathsf{S} - \lambda[\mathsf{A},\mathsf{V}] = \mathsf{I},\ \mathsf{I} := \frac{1}{2\lambda}\begin{pmatrix} I_3 & I_1 \\ -I_2 & -I_3 \end{pmatrix}, \tag{B9}$$

where I_j $(j=1,2,3)$ are the generators (3.6) of the Bäcklund ideal. This implies $\tilde{\mathsf{L}} - \mathsf{V}\mathsf{L}\mathsf{V}^{-1} = \mathsf{F}$, where $\mathsf{F} := \mathsf{I}\mathsf{V}^{-1} \in \mathrm{Mat}_2(\mathcal{I})(\lambda)_<$. ■

The previous lemma allows to give the following.

Proof of Proposition 3.2: The vector space $\mathfrak{Z}$ is generated by the sequence (h_i), so it suffices to prove that

$$\tilde{h}_i - h_i \in \int \mathcal{I} \quad (i = 1,2,3, \ldots). \tag{B10}$$

From Eq. (B5) and its tilded analogue, we know that

$$\begin{pmatrix} h_i & 0 \\ 0 & -h_i \end{pmatrix}, \quad \begin{pmatrix} \tilde{h}_i & 0 \\ 0 & -\tilde{h}_i \end{pmatrix} \tag{B11}$$

are the invariant matrix functionals of L and $\tilde{\mathsf{L}}$, respectively; by Proposition A.4 and Lemma B.1, these differ by elements of $\mathrm{Diag}_2(\int \mathcal{I})$, yielding the thesis. ■

As an example, in Eq. (3.9) we have given explicit representations of $\tilde{h}_i - h_i$ as integrals of elements of $\mathcal{I}$, for $i=1,2,3,4$; these representations have been computed specializing to this case the general argument employed to prove Proposition (A4). In particular, this has required the application of the recursion relations (A27) up to $i=4$.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 45, NUMBER 12 DECEMBER 2004

Angular intricacies in hot gauge field theories

T. Grandou[a)]
Institut Non Linéaire de Nice UMR CNRS 6618; 1361, Route des Lucioles, 06560 Valbonne, France

(Received 1 October 2003; accepted 9 September 2004; published 22 November 2004)

It is argued that in hot quantum field theories, "hard thermal loops" leading order calculations call for a definite sequence of angular averages and discontinuity (or imaginary part prescription) operations, and run otherwise into incorrect results. The 10 years old collinear singularity problem of hot QCD provides a dramatic illustration of that fate. © *2004 American Institute of Physics.*

I. INTRODUCTION

The intrinsic nonperturbative nature of nonzero temperature quantum field theories has long been recognized.[1] Naive thermal perturbation theory can nevertheless be devised, both in imaginary and real time formalisms,[2] but then, it promptly appears that, under certain circumstances, the original perturbative series must be reorganized. Such an example of reorganization is provided by the so-called *resummation program*.[3] This program, RP for short, is a resummation scheme of the leading order thermal fluctuations which, in the literature, are known under the spell of hard thermal loops. Whenever one is calculating a physical process related to thermal Green's functions whose external/internal legs are *soft*, it is mandatory to trade the naive thermal perturbation theory for the RP. The softness alluded to above, refers to momenta on the order of the soft scale gT, where T, the temperature, stands for the hard scale and g for any relevant (bare/renormalized) and small enough coupling constant.

The RP which has been set up in order to remedy an obvious lack of completeness of the naive thermal perturbation theory, has produced interesting results, but has also met serious obstructions in the infrared regime of the theories.[4,5] Within the resummation program itself, the solutions proposed so far,[5–7] however interesting in their own respect, can hardly be organized in a systematic way and display too much dependences on the process under consideration.

In this paper, we point out some overlooked aspects concerning "the historical derivations" of the famous RP *collinear singularity problem of hot* QCD.[5] The matter of the present paper has to do with the proper sequence of two operations that are of the utmost importance in the calculational context of hot quantum field theories. These operations are an angular average, on the one hand, and a discontinuity or imaginary part prescription, on the other hand. Though illustrated on the famous problem alluded to above, the point made here is relevant of a most universal property of hot quantum fields, because at $n \geqslant 3$, the hot gauge fields effective vertices are all defined by angular averages. As several of our previous and ongoing calculations have displayed, in effect, the pertinence of the advocated "proper sequence" extends far beyond the historical derivations to be recalled shortly.

The paper is organized as follows. Section II is a short reminder of the collinear singularity problem met in hot QCD, a more detailed introduction to the matter being given in Sec. II of Ref. 8. In Sec. III, we demonstrate that illicit mathematical steps have been taken, plaguing either of the

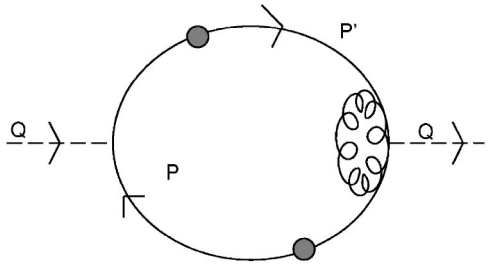

FIG. 1. A graph denoted by ($\star$, $\star$; 1) in the text, with two internal effective propagators ${}^{\star}S_{\alpha}(P(P'))$, of Eq. (2.2), depicted with a blob, and one HTL vertex correction $\Gamma_{\mu}^{\mathrm{HTL}}$ of Eq. (2.5), the other bare, γ_{μ}.

two distinct collinear problem historical derivations. Our conclusions are summarized in Sec. IV, whereas an appendix gathers the important calculational details of Sec. III.

Throughout the paper, we will be using the convention of upper case letters for quadrimomenta and lower case ones for their components, writing, for example, $P=(p_0,\vec{p})$. Our conventions for labelling internal and external momenta can be read off Fig. 1.

II. THE COLLINEAR SINGULARITY PROBLEM OF HOT QCD

This 10 years old issue is the following. The soft real photon emission rate out of a quark-gluon plasma in thermal equilibrium involves, in particular, the calculation of the quantity

$$\Pi_R(Q) = i\int \frac{\mathrm{d}^4P}{(2\pi)^4}(1-2n_F(p_0))\mathrm{disc}_P\mathrm{Tr}\left\{{}^{\star}S_R(P){}^{\star}\Gamma_{\mu}(P_R,Q_R,-P'_A){}^{\star}S_R(P'){}^{\star}\Gamma^{\mu}(P_R,Q_R,-P'_A)\right\}. \tag{2.1}$$

The discontinuity is to be taken in the energy variable p_0, by forming the difference of R and A-indiced P-dependent quantities, and within standard notations, fermionic high-temperature limit (HTL) self-energies, effective propagators, and vertices are, respectively, given by

$${}^{\star}S_{\alpha}(P) = \frac{i}{\not{P} - \Sigma_{\alpha}(P) + i\epsilon_{\alpha}p_0}, \quad \alpha = R,A, \quad \epsilon_R = -\epsilon_A = \epsilon, \tag{2.2}$$

$$\Sigma_{\alpha}(P) = m^2\int \frac{\mathrm{d}\hat{K}}{4\pi}\frac{\hat{\not{K}}}{\hat{K}\cdot P + i\epsilon_{\alpha}}, \quad m^2 = C_F\frac{g^2T^2}{8}, \tag{2.3}$$

$${}^{\star}\Gamma_{\mu}(P_{\alpha},Q_{\beta},P'_{\delta}) = -ie(\gamma_{\mu} + \Gamma_{\mu}^{\mathrm{HTL}}(P_{\alpha},Q_{\beta},P'_{\delta})), \tag{2.4}$$

$$\Gamma_{\mu}^{\mathrm{HTL}}(P_{\alpha},Q_{\beta},P'_{\delta}) = m^2\int \frac{\mathrm{d}\hat{K}}{4\pi}\frac{\hat{k}_{\mu}\hat{\not{K}}}{(\hat{K}\cdot P + i\epsilon_{\alpha})(\hat{K}\cdot P' + i\epsilon_{\delta})}, \tag{2.5}$$

where $\hat{K}$ is the lightlike four vector $(1,\hat{k})$. As (2.4) is plugged into (2.1), four terms come about, three of them proportional to a collinear singularity. These singular terms are the two terms with one bare vertex γ_{μ}, the other $\Gamma_{\mu}^{\mathrm{HTL}}$, plus the term including two HTL vertices, $\Gamma_{\mu}^{\mathrm{HTL}}$. Thanks to an Abelian Ward identity peculiar to the high temperature limit, a partial cancellation of these collinear singularities occurs, but out of the term including two $\Gamma_{\mu}^{\mathrm{HTL}}$ vertices, a collinear singularity remains,

$$-2i\frac{e^2m^2}{q^2}\left(\int\frac{\mathrm{d}\hat{K}}{4\pi}\frac{1}{\hat{Q}\cdot\hat{K}+i\epsilon}\right)\int\frac{\mathrm{d}^4P}{(2\pi)^3}\delta(P\cdot\hat{Q})(1-2n_F(p_0))[\mathrm{Tr}(^\star S_A(P)\hat{\not{Q}})-\mathrm{Tr}(^\star S_R(P')\hat{\not{Q}})], \tag{2.6}$$

where, the soft photon being real, Q is the lightlike 4-vector $Q=q\hat{Q}=q(1,\hat{q})$, with q a real and positive number. In the literature, this result is ordinarily written in the form

$$\frac{C^{st}}{\varepsilon}\int\frac{d^4P}{(2\pi)^4}\delta(\hat{Q}\cdot P)(1-2n_F(p_0))\sum_{s=\pm1,V=P,P'}\pi\left(1-s\frac{v_0}{v}\right)\beta_s(V), \tag{2.7}$$

where the overall $1/\varepsilon$ comes from a dimensionally regularized evaluation of the factored out angular integration appearing in (2.6), and where $\beta_s(V)$ is related to the effective fermionic propagator usual parametrization,[2]

$$^\star S_\alpha(P)=\frac{i}{2}\sum_{s=\pm1}\hat{\not{P}}_s{}^\star\Delta^s(p_0+i\epsilon_\alpha,p) \tag{2.8}$$

with $\hat{P}_s=(1,s\hat{p})$, the label s referring to the two dressed fermion propagating modes. One has then

$$^\star\Delta^s(p_0+i\epsilon_\alpha,p)\equiv{}^\star\Delta^s_\alpha(p_0,p)=\alpha_s(p_0,p)-i\pi\epsilon(\epsilon_\alpha)\beta_s(p_0,p), \tag{2.9}$$

where $\epsilon(x)$ is the distribution "sign of x."

III. IMPROPER TRADITIONAL DERIVATIONS

The historical derivation just reminded above, however, is plagued with erroneous manipulations, which, following Ref. 5, are most easily described on the two simpler diagrams including one bare vertex γ_μ, the other $\Gamma^{\mathrm{HTL}}_\mu$. The R/A real time formalism conveys us to the expression

$$\Pi^{(\star,\star;1)}_R(Q)=-ie^2m^2\int\frac{\mathrm{d}^4P}{(2\pi)^4}(1-2n_F(p_0))\times\mathrm{disc}_{p_0}\int\frac{\mathrm{d}\hat{K}}{4\pi}\frac{\mathrm{Tr}(^\star S_R(P)\hat{\not{K}}{}^\star S_R(P')\hat{\not{K}})}{(\hat{K}\cdot P+i\epsilon)(\hat{K}\cdot P'+i\epsilon)}, \tag{3.1}$$

where the superscript $(\star,\star;1)$ on the left-hand side refers to a self-energy diagram involving two effective propagators and one vertex HTL correction, as depicted in Fig. 1. The steps leading to the collinear singularity of (3.1) are as follows. In consistency with the R/A formalism, and the standard mathematical definition of a discontinuity (ϵ is an infinitesimal parameter to be taken to zero in the end[9]), the discontinuity in the energy variable p_0 is taken by writing

$$\mathrm{disc}_{p_0}\frac{\mathrm{Tr}(^\star S_R(P)\hat{\not{K}}{}^\star S_R(P')\hat{\not{K}})}{(\hat{K}\cdot P+i\epsilon)(\hat{K}\cdot P'+i\epsilon)}=\frac{\mathrm{Tr}(^\star S_R(P)\hat{\not{K}}{}^\star S_R(P')\hat{\not{K}})}{(\hat{K}\cdot P+i\epsilon)(\hat{K}\cdot P'+i\epsilon)}-\frac{\mathrm{Tr}(^\star S_A(P)\hat{\not{K}}{}^\star S_R(P')\hat{\not{K}})}{(\hat{K}\cdot P-i\epsilon)(\hat{K}\cdot P'+i\epsilon)}. \tag{3.2}$$

Closing the p_0 integration contour in the upper half complex p_0 plane, one selects a pole term contribution to $\Pi^{(\star,\star;1)}_R(Q)$, which comes from the vertex $\Gamma^{\mathrm{HTL}}_\mu$ and reads

$$-ie^2m^2\int\frac{\mathrm{d}^4P}{(2\pi)^4}(1-2n_F(p_0))\times\int\frac{\mathrm{d}\hat{K}}{4\pi}\frac{-2i\pi\delta(\hat{K}\cdot P)}{\hat{K}\cdot P'+i\epsilon}\mathrm{Tr}(^\star S_A(P)\hat{\not{K}}{}^\star S_R(P')\hat{\not{K}}). \tag{3.3}$$

Since $P'=P+Q$, we have indeed, as a building block of (3.3), the expression

$$\int\frac{\mathrm{d}\hat{K}}{4\pi}\frac{-2i\pi\delta(\hat{K}\cdot P)}{\hat{K}\cdot Q+i\epsilon}\mathrm{Tr}(^\star S_A(P)\hat{\not{K}}{}^\star S_R(P')\hat{\not{K}}). \tag{3.4}$$

Here, it is traditionally claimed that the angular average develops a collinear singularity in a

neighborhood of $\hat{K}=\hat{Q}$, not balanced by the numerator, and whose "*residue*" is obtained by replacing everywhere $\hat{K}$ by $\hat{Q}$, except for the denominator. The result is then,

$$\frac{C^{st}}{\varepsilon}\frac{\delta(\hat{Q}\cdot P)}{q}\,\mathrm{Tr}(\overset{\star}{S}_A(P)\hat{\not{Q}}\overset{\star}{S}_R(P')\hat{\not{Q}}), \tag{3.5}$$

where the first factor, singular at $\varepsilon=0$, is obtained by using a dimensional regularization of the angular integral, and where the constant, C^{st}, is independent of P. Up to regular contributions that we do not consider here, this singular piece of (3.4) translates, for $\Pi_R^{(\star,\star;1)}(Q)$, into a singular result of

$$-\frac{C^{(st)}}{\varepsilon}\frac{e^2m^2}{q}\int\frac{\mathrm{d}^4P}{(2\pi)^3}(1-2n_F(p_0))\times\delta(\hat{Q}\cdot P)\mathrm{Tr}(\overset{\star}{S}_A(P)\hat{\not{Q}}\overset{\star}{S}_R(P')\hat{\not{Q}}). \tag{3.6}$$

The contribution of (3.6) to the soft photon emission rate being proportional to its imaginary part, the emission rate is plagued with a collinear singularity [as recalled in Sec. II, this very contribution cancels against a similar one in $\Pi_R^{(\star,\star;2)}(Q)$; but an uncancelled singular piece remains which, *mutatis mutandis*, is derived along the very same steps as taken here, in the simpler and more illustrative case of $\Pi_R^{(\star,\star;1)}(Q)$].

The RP is known to be ill defined in the infrared sector of hot gauge theories, and the above famous divergent result is one of the most compelling arguments in favor of this widespread opinion. Several solutions have been proposed ever since, which, however, do not meet with a general consensus. They display, in effect, too much dependences on the physical process under consideration, so that it seems reasonable to think of this, as an indication that things have not reached a satisfying enough state. Some decades ago, one may have written "*Our task as mathematicians (…) is to assist physicists in their work by throwing mathematical light if things grow too unsystematic or too complicated.*"[10] This is why it matters to stress that this 10 years old divergent and important result is incorrect, being derived on the basis of illicit mathematical steps. This can be seen as follows:

(i) Getting back to the building block expression (3.4), one can rewrite the trace as

$$\mathrm{Tr}(\overset{\star}{S}_A(P)\hat{\not{K}}\overset{\star}{S}_R(P')\hat{\not{K}})=\mathrm{Tr}(\overset{\star}{S}_A(P)\hat{\not{K}}\overset{\star}{S}_R(P')\hat{\not{K}})-\mathrm{Tr}(\overset{\star}{S}_A(P)\hat{\not{Q}}\overset{\star}{S}_R(P')\hat{\not{Q}})+\mathrm{Tr}(\overset{\star}{S}_A(P)\hat{\not{Q}}\overset{\star}{S}_R(P')\hat{\not{Q}}). \tag{3.7}$$

On the right-hand side of (3.7), the difference of the first two terms can be expressed as

$$\sum_{s,s'=\pm1}\overset{\star}{\Delta}{}_A^{s'}(P')\overset{\star}{\Delta}{}_R^{s}(P)\;(\hat{K}\cdot\hat{P}'_{s'}[\hat{P}_s\cdot(\hat{K}-\hat{Q})]+\hat{Q}\cdot\hat{P}_s[\hat{P}'_{s'}\cdot(\hat{K}-\hat{Q})]), \tag{3.8}$$

where the effective propagators representations (2.8) have been used. In this form, it is clear that these two terms pose no problem under the remaining angular integration of (3.4), and that the only potential trouble could come from the third term of (3.7), that is, from

$$\mathrm{Tr}(\overset{\star}{S}_A(P)\hat{\not{Q}}\overset{\star}{S}_R(P')\hat{\not{Q}})\times\int\frac{\mathrm{d}\hat{K}}{4\pi}\frac{-2i\pi\delta(\hat{K}\cdot P)}{\hat{K}\cdot Q+i\epsilon}. \tag{3.9}$$

As advertised after (3.4), a potentially singular behavior develops at $\hat{K}=\hat{Q}$. It has been taken care of by performing the angular integration at $D=3+2\varepsilon$ spatial dimensions,[5] and the so far admitted singular counterpart of (3.4) is then obtained under the form (3.5).

As shown in the Appendix, though, a direct evaluation of (3.9) is doable, and makes it clear that the traditional result (3.5) is incorrect. In view of (A4), we have in effect

$$\int \frac{d\hat{K}}{4\pi}\frac{-2i\pi\delta(\hat{K}\cdot P)}{\hat{K}\cdot Q+i\epsilon}=\frac{-i\Theta(-P^2)}{2qp}\int_0^{2\pi}\frac{d\varphi}{a+b\sin\varphi}=\frac{-i\Theta(-P^2)}{2qp}\times 4a\int_0^{\pi/2}\frac{d\varphi}{a^2-b^2\sin^2\varphi} \tag{3.10}$$

and the integral appearing on the right-hand side of (3.10) is dependent on the relative magnitude of coefficients a^2 and b^2. Corresponding to the condition $a^2=b^2$, that is to $\hat{Q}\cdot P=0$, a singularity is obtained, with, for (3.9), the resulting expression [see (A12)],

$$\mathrm{Tr}(^\star S_A(P)\hat{\not{Q}}^\star S_R(P')\hat{\not{Q}})\times\frac{-i\delta(\hat{Q}\cdot P)}{2q}\frac{-4p^2}{P^2-i\epsilon}\times\cot\eta_{|_{\eta=0^+}}, \tag{3.11}$$

where $\Theta(x)$ stands for the usual Heaviside step function.

Compared to the standard historical result (3.5), (3.11) presents a most interesting similarity, since, like the ε^{-1} logarithmic singularity of (3.5), a singular piece of $\cot\eta$, as $\eta\to 0$, factors out, in total independence of the remaining integrations to be performed on p_0 and $\vec{p}$.

However, as emphasized in the appendix, it appears that the terms which accompany these singularities are not the same, and, most importantly, that the singularities themselves are not the same since, in particular, the logarithmic nature of (3.5) is not recovered.

(ii) The traditional result (3.5) is also relevant of another, more important error, as being a systematic one, rather peculiar to the context of hot gauge field theories. Passing from (3.1) to (3.2) in effect, the prescription of discontinuity in p_0 is permuted with the angular integration on $\hat{K}$. Now, this permutation is an illicit mathematical step because, whatever the formalism in use, real or imaginary time, the discontinuity of the integral is in order, and not the integral of the discontinuity. Since a discontinuity is defined through a limiting procedure, it is long known that its permutability with an integration cannot be supposed to hold in general.

For the sake of a simpler and clear-cut illustration of our claim, we will focus on the "efficient" piece of (3.1), the expression

$$\mathrm{disc}_{p_0}\int\frac{d\hat{K}}{4\pi}\frac{1}{\hat{K}\cdot P+i\epsilon}\frac{1}{\hat{K}\cdot P'+i\epsilon}. \tag{3.12}$$

That this "efficient" piece be relevant to the problem under consideration, and in particular the one to be compared to the improper sequence expression (3.4), is shown in the Appendix. Let us begin with recalling that the improper sequence of discontinuity and integral operations has produced the corrected, still singular result,

$$\int\frac{d\hat{K}}{4\pi}\mathrm{disc}_{p_0}\frac{1}{\hat{K}\cdot P+i\epsilon}\frac{1}{\hat{K}\cdot P'+i\epsilon}=\frac{2i\delta(\hat{Q}\cdot P)}{q}\frac{p^2}{P^2-i\epsilon}\cot\eta_{|_{\eta=0^+}}. \tag{3.13}$$

On the other hand, we have[8]

$$\int\frac{d\hat{K}}{4\pi}\frac{1}{\hat{K}\cdot P+i\epsilon}\frac{1}{\hat{K}\cdot P'+i\epsilon}=\frac{1}{2Q\cdot P+i\epsilon q}\ln\frac{P'^2+i\epsilon p_0'}{P^2+i\epsilon p_0}. \tag{3.14}$$

Since $2Q\cdot P=P'^2-P^2$, this result is symmetric under the exchange $P\leftrightarrow P'$, as it should, and allows to calculate the proper sequence of the discontinuity and integration operations. One finds,

$$\mathrm{disc}_{p_0}\int\frac{d\hat{K}}{4\pi}\frac{1}{\hat{K}\cdot P+i\epsilon}\frac{1}{\hat{K}\cdot P'+i\epsilon}=\frac{i\pi\epsilon(p_0)\Theta(-P^2)}{Q\cdot P+i\epsilon q}. \tag{3.15}$$

The differences between the (corrected) improper sequence result (3.13) and the above proper sequence one, (3.15), are of utmost importance in the calculational context of hot quantum field

theories, because salient features emerge which reveal to be sound and general features, extending, beyond the present illustration, to any of the higher number of points HTL- vertices and related calculations.

(1) Staring at (3.14), one can observe how the angular average is able to reproduce all of the correct internal/external legs R/A specifications, the $i\epsilon q$, $i\epsilon p_0$, and $i\epsilon p_0'$, which are not manifest on the left-hand side. The same property can be observed on the angular identites (4.9)–(4.11) derived elsewhere.[8] A first important difference is therefore that the relevant $i\epsilon$ prescriptions of internal/external lines are preserved within the proper sequence, not along the reversed improper one. In calculations, it has been stressed that this drawback can only result into violent, structural inconsistencies.[11]

(2) A second essential difference is the sign distribution $\epsilon(p_0)$. In all of the real or imaginary time formalisms, and any possible resummation scheme,[8] sign distributions have long been noticed to be of paramount importance so as to preserve *integrable* and *nonintegrable* infrared singularity compensations.[12] As observed here again, correct sign distributions are a natural outcome of the calculational operations proper sequence (3.15), not of the improper one, (3.13), (A7), and (A8). That is, the proper sequence of angular average and discontinuity operations complies with the required, exact sign distributions and internal/external line prescriptions which, otherwise, are violated.

(3) The above two properties are not restricted to the soft photon emission rate problem, however important it is. Now, focusing on that problem again, the following summary may be in order. As displayed through Eqs. (A7)–(A9), the improper sequence result is not a systematically singular result. When the result comes out regular, at $a^2>b^2$ that is at $(\hat{Q}\cdot P)^2>0$, it still differs the proper sequence one, the shortcomings described above. At $\hat{Q}\cdot P=0$, the improper sequence result comes out effectively plagued with a divergence which factors out any possible calculation it is involved in, in total independence of the remaining integrations to be performed on p_0, $\vec{p}$. At variance with its original version, though, this divergence does not come out logarithmic, at least in a canonically devised dimensional regularization scheme, set up at $D=3+2\varepsilon$ spatial dimensions.

At this stage, it is worth noticing that when the proper sequence result (3.15) is plugged into the $\Pi_R^{(\star,\star;1)}(Q)$ calculation, then, the resulting contribution to the soft photon emission rate comes out regular (Ref. 14). In the same vein, it is interesting to stress also that the same property of regularity has been derived in Ref. 8, concerning any $\Pi_R^{(N,N';1)}(Q)$ and $\Pi_R^{(N,N';2)}(Q)$ contribution, where $N(N')$ are the numbers of HTL self-energy insertions (2.3) along the $P(P')$ internal lines. The proper sequence of discontinuity and angular average was followed throughout, whereas, again, the same overall factoring out mass singularity as (3.11), could be shown to appear along the improper, inverted sequence.

That makes the singularity so derived, definitely appear a fate of the improper sequence of discontinuity and angular average operations.

IV. CONCLUSION

Mathematically, the fact that the proper sequence of angular average and discontinuity operations are inverted by the so far conventional use, accounts for a substantial difference because a discontinuity is defined by a limiting procedure. The possibility of its permutation with an integration, should accordingly never be taken for granted *a priori*. In this respect, it is worth noticing that the authors of Ref. 5 (published version), while inverting the proper sequence of operations, were conscious of the risks this manipulation possibly entailed.

Though technically more involved of a step, we conclude that the angular averages inherent to the context of hot gauge field theories must definitely be performed in the first place, and in particular, before that any discontinuity and/or imaginary part prescriptions be actually taken. This sets in, we think, the general character and related importance of the point made in the present paper.

It is true that in the hot quantum field theories context, this is more of a trap as the formalisms in use are rather fuzzy about the distinction between discontinuity and imaginary part prescriptions which, then, can usually be permuted with integrations. Up to a trivial factor of 2, in effect, the one is generally mistaken for the other, whereas their difference, and in particular the prevalence of the discontinuity aspect over the imaginary part one, had been advocated in Ref. 13.

Ignoring that proper sequence may lead (and has led) to incorrect derivations and/or results. Not only have the infrared singularity cancellation patterns long revealed to be particularly sensitive to the angular averages and discontinuity operations proper sequence, but, as noticed in the Appendix, regular terms also, are the more endangered by an improper sequence calculation as the latter develops singularities.

Our point has been illustrated on the basis of the hot QCD collinear singularity problem, and it seems reasonable to think that this 10 years old and important issue should now be totally revisited within the proper sequence. Because of the complexity of the angular integrations inherent to the contribution of $\Pi_R^{(\star,\star;2)}(Q)$ (Ref. 8) it is a somewhat complicated task which could be deferred to a further publication.

However, it is certainly worth mentioning here, that we have been able to prove that the so far reputed singular contributions of type $\Pi_R^{(\star,\star;1)}(Q)$, come out regular, when taken within the correct, proper sequence of angular integration and discontinuity operations.[14]

ACKNOWLEDGMENT

It is a pleasure to thank B. Candelpergher for an intersting discussion about the integrals of the Appendix.

APPENDIX

On Eq. (3.10)

We proceed here to the direct calculation of (3.9), as alluded to in the main text, that is

$$\int \frac{\mathrm{d}\hat{K}}{4\pi}\mathrm{disc}_{p_0}\frac{1}{\hat{K}\cdot P+i\epsilon}\,\frac{1}{\hat{K}\cdot P'+i\epsilon}=\int\frac{\mathrm{d}\hat{K}}{4\pi}\frac{-2i\pi\delta(\hat{K}\cdot P)}{\hat{K}\cdot Q+i\epsilon}. \tag{A1}$$

If $\hat{p}\neq\hat{q}$, the calculation is most easily carried out in the orthonormal basis of vectors

$$\left\{\frac{\hat{p}\wedge\hat{q}}{\sin\alpha},\frac{\hat{p}\cos\alpha-\hat{q}}{\sin\alpha},\hat{p}\right\},\quad \cos\alpha=\hat{p}\cdot\hat{q}. \tag{A2}$$

We have then for (A1),

$$\begin{aligned}&\frac{-i}{2qp}\int_0^{2\pi}\mathrm{d}\varphi\int_{-1}^{+1}\mathrm{d}\cos\theta\,\frac{\delta(p_0/p-\cos\theta)}{1-\cos\theta\cos\alpha+\sin\theta\sin\alpha\sin\varphi+i\epsilon}\\&\quad=\frac{-i\Theta(-P^2)}{2qp}\int_0^{2\pi}\frac{\mathrm{d}\varphi}{1-\dfrac{p_0}{p}\cos\alpha+\sin\left[\arccos\left(\dfrac{p_0}{p}\right)\right]\sin\alpha\sin\varphi+i\epsilon}.\end{aligned} \tag{A3}$$

This integral reads

$$\frac{-i\Theta(-P^2)}{2qp}\int_0^{2\pi}\frac{\mathrm{d}\varphi}{a+b\sin\varphi} \tag{A4}$$

at

$$a = 1 - \left(\frac{p_0}{p}\right)\hat{p}\cdot\hat{q} + i\epsilon,\ \ b = \eta\sqrt{-\frac{P^2}{p^2}}\,\eta'\sqrt{1-(\hat{p}\cdot\hat{q})^2},\ \ \eta,\eta' = \pm 1. \tag{A5}$$

Note that because of the constraint $\Theta(-P^2)$, we have $\mathrm{Re}(a)\geqslant 0$.

Three cases are now to be considered.

(i) $a^2 > b^2$. The result is then

$$\int_0^{2\pi}\frac{\mathrm{d}\varphi}{a+b\sin\varphi} = \frac{2\pi\epsilon(a)}{\sqrt{a^2-b^2}} \tag{A6}$$

as given[15] by formula 3.6151, and (A1) reads in this case as

$$(\mathrm{A1}) = \frac{-i\pi\Theta(-P^2)}{\sqrt{(Q\cdot P)^2 + i\epsilon}}. \tag{A7}$$

Note that, relevant of this case, is also the situation where no such basis as (A2) can be devised because $\hat{p}=\hat{q}$. Now, a direct evaluation of (A1) is then straightforward,

$$\int\frac{\mathrm{d}\hat{K}}{4\pi}\frac{-2i\pi\delta(\hat{K}\cdot P)}{\hat{K}\cdot Q + i\epsilon} = \frac{i\pi\Theta(-P^2)}{q(p_0-p-i\epsilon)} = \frac{i\pi\Theta(-P^2)}{Q\cdot P - i\epsilon|_{\hat{p}=\hat{q}}} \tag{A8}$$

which results also from (A7) in the limit $\hat{p}=\hat{q}$.

(ii) $a^2 < b^2$. The integral would be undefined at $\sin^2\varphi = a^2/b^2$, and would be given the meaning of

$$4a\lim_{\eta=0}\left\{\int_0^{\arcsin(a/|b|)-\eta} + \int_{\arcsin(a/|b|)+\eta}^{\pi/2}\right\}\frac{\mathrm{d}\varphi}{a^2-b^2\sin\varphi}.$$

The result would then read

$$4a\lim_{\eta=0}\frac{\epsilon(a^2)}{\sqrt{a^2(b^2-a^2)}}\left\{\mathrm{Arth}\left(1-\frac{b^2}{\sqrt{a^2(b^2-a^2)}}\eta+\mathcal{O}(\eta^2)\right)\right.$$
$$\left.-\mathrm{Arcth}\left(1+\frac{b^2}{\sqrt{a^2(b^2-a^2)}}\eta+\mathcal{O}(\eta^2)\right)\right\} = 0 \tag{A9}$$

as given[15] by formula 2.5621. This case however, is not really to be considered in the present situation where we have $a^2-b^2=(\hat{Q}\cdot P)^2/p^2+i\epsilon$, that is, $\mathcal{R}e(a^2-b^2)\geqslant 0$.

(iii) $a^2=b^2$. This condition corresponds to $\hat{Q}\cdot P=0$, and we have

$$\int_0^{2\pi}\frac{\mathrm{d}\varphi}{a+b\sin\varphi} = \frac{4}{a}\int_0^{\pi/2}\frac{\mathrm{d}\varphi}{1-\sin^2\varphi} = -4\frac{p^2}{P^2-i\epsilon}\int_0^{\pi/2}\frac{\mathrm{d}\varphi}{1-\sin^2\varphi}. \tag{A10}$$

The integral does not exist, and it is noteworthy that, had we introduced a dimensional regularization at $D=3+2\varepsilon$ spatial dimensions,[5] then (A4) was multiplied by an overall factor of $(-P^2/p^2)^{\varepsilon}$, and the measure $\mathrm{d}\varphi$, by a factor of $\sin^{2\varepsilon}\varphi$.[16] The integral was then turned into

$$\int_0^{\pi/2}\mathrm{d}\varphi\frac{\sin^{2\epsilon}}{1-\sin^2\varphi} \tag{A11}$$

making it clear that, contrarily to the results obtained,[5] the dimensional regularization so introduced is not able to take care of the divergence developing in a neighbourhood of $\varphi=\pi/2$. A cutoff, $\eta=0^+$, may be introduced so as to supply the above integral with enough regularization, and one gets for (A10) the result

$$\frac{-4p^2}{P^2-i\epsilon}\lim_{\eta=0^+}\int_0^{\pi/2-\eta}\frac{\mathrm{d}\varphi}{1-\sin^2\varphi}=\frac{-4p^2}{P^2-i\epsilon}\lim_{\eta=0^+}\cot\eta. \tag{A12}$$

Clearly, a canonically devised dimensional scheme, is not able to reproduce the historical logarithmic divergence.

On expression (3.12)

The expression (3.12) is "efficient" in the sense of relevance for the problem under consideration, but this is obscured by the fact that an improper sequence of operations has been followed throughout the two historical derivations of the hot QCD collinear problem. Still, it is rather straightforward to see that (3.12) is the pertinent counterpart of the required comparison.

Relying again on the representations (2.8), we have

$$\mathrm{disc}_{p_0}\int\frac{\mathrm{d}\hat{K}}{4\pi}\frac{\mathrm{Tr}\left({}^\star S_A(P)\hat{K}\,{}^\star S_R(P')\hat{K}\right)}{(\hat{K}\cdot P+i\epsilon)(\hat{K}\cdot P'+i\epsilon)}=8\sum_{s,s'}{}^\star\Delta_R^{s'}(P')\left\{{}^\star\rho_R^s(P)\int\frac{\mathrm{d}\hat{K}}{4\pi}\frac{\hat{K}\cdot\hat{P}_s}{\hat{K}\cdot\hat{P}+i\epsilon}\frac{\hat{K}\cdot\hat{P}'_{s'}}{\hat{K}\cdot\hat{P}'+i\epsilon}\right.$$
$$\left.+{}^\star\Delta_R^s(P)\mathrm{disc}_{p_0}\int\frac{\mathrm{d}\hat{K}}{4\pi}\frac{\hat{K}\cdot\hat{P}_s}{\hat{K}\cdot\hat{P}+i\epsilon}\frac{\hat{K}\cdot\hat{P}'_{s'}}{\hat{K}\cdot\hat{P}'+i\epsilon}\right\}, \tag{A13}$$

where, within standard notations,[2]

$${}^\star\rho_R^s(P)=\mathrm{disc}_{p_0}{}^\star\Delta_R^s(P).$$

On the right-hand side of (A13), it appears clearly that it is the second term, entailing the proper sequence of discontinuity and integration, which compares with the improper sequence derivation (3.2) to (3.6). This second term can further be developed as

$$8\sum_{s,s'}{}^\star\Delta_R^{s'}(P'){}^\star\Delta_R^s(P)\mathrm{disc}_{p_0}\int\frac{\mathrm{d}\hat{K}}{4\pi}\left\{\frac{ss'}{pp'}+\frac{s'}{p'}\left(1-s\frac{p_0}{p}\right)\frac{1}{\hat{K}\cdot\hat{P}+i\epsilon}+\frac{s}{p}\left(1-s'\frac{p'_0}{p'}\right)\frac{1}{\hat{K}\cdot\hat{P}'+i\epsilon}\right.$$
$$\left.+\left(1-s\frac{p_0}{p}\right)\left(1-s'\frac{p'_0}{p'}\right)\frac{1}{(\hat{K}\cdot\hat{P}+i\epsilon)(\hat{K}\cdot\hat{P}'+i\epsilon)}\right\} \tag{A14}$$

whence the focus put on (3.12) as the "efficient" and simpler piece of the needed comparison with expression (3.13), since, starting from it and permuting the discontinuity with the integration, it is elementary to recover a result equivalent (not equal) to (3.5).

Equivalent but nonequal, because of the incorrect steps plaguing the traditional derivations, as in particular the factorization of a factor like $\mathrm{Tr}({}^\star S_A(P)\hat{Q}\,{}^\star S_R(P')\hat{Q})$. This simple, byproduct remark is enough of an argument to pin up the fact that not only the singular, but also the regular structure of the calculation is endangered by the improper sequence (this is of course so, because the improper sequence calculation generates an undefined integration).

For time dependent black hole space–times the event horizon cannot be described by a Killing horizon. In the case when the space–time admits a timelike conformal Killing field, which becomes null on a boundary called the conformal stationary limit surface, one can locally describe the expanding event horizon by using this boundary, provided that it is a null geodesic hypersurface. In this case the boundary is called a conformal Killing horizon and is shown to be null and geodesic if and only if the twist of the conformal Killing trajectories on the hypersurface vanishes. Moreover if the space–time is conformally related to a stationary asymptotically flat black hole space–time, it is shown that this hypersurface is globally equivalent to the event horizon, provided that the conformal factor goes to a constant at null infinity. When the conformal stationary limit surface does not coincide with the conformal Killing horizon, a generalization of the weak rigidity theorem which establishes the conformal Killing property of the event horizon and the rigidity of its rotation is obtained. A physical definition of surface gravity for conformal Killing horizons is given, which is then used to formulate a generalized zeroth law of black hole physics. © *2004 American Institute of Physics.*

I. INTRODUCTION

For more than 30 years, black hole physics has been one of the most active areas of research in both classical and quantum gravity. However almost all the research has been limited to isolated black holes, represented in general by the Kerr–Newman solution,[1] of which the Schwarzschild, Reissner-Nordström, and Kerr solutions are special cases. All these exact solutions share two basic characteristics: namely asymptotic flatness, and time independence which implies the existence of a global timelike Killing vector field, K, satisfying

$$\mathcal{L}_K \mathbf{g} = 0, \tag{1}$$

where $\mathcal{L}$ denotes the Lie derivative in the direction K and g is the metric of the space–time. While these black holes have been very useful for studying the physical effects like the classical tests and the quantum effects like black hole evaporation, they do not represent a realistic model.

In a realistic situation, the black hole is embedded in a cosmological background or surrounded by a local mass distribution and so it may cease to be time independent. Moreover the space–time becomes cosmological and nonflat at large distances from the black hole. One expects

[b)]Electronic mail: dyer@astro.utoronto.ca

significant differences in the structure and properties of these black holes from the well-known isolated black holes, where even the passage from the Schwarzschild black hole to the Kerr black hole brings profound changes. In accordance with the strong rigidity theorem[2] the event horizon of a static or stationary asymptotically flat black hole is represented by the Killing horizon,[3] provided that the space–time is analytic, the fundamental matter fields obey well behaved hyperbolic equations and the stress-energy tensor satisfies the weak energy condition. The Killing horizon is defined as the union $H[K]=\cup H_i[K]$, where $H_i[K]$ is a connected component of the set of points forming a null hypersurface on which a Killing field K is null and not identically vanishing. The horizon Killing field K either coincides with the stationary Killing field, in which case the Killing horizon coincides with the static limit surface $(K|K)=0$, or the space–time admits at least one axial Killing field M such that[4] $[K,M]=0$. The latter case corresponds to a rotating asymptotically flat black hole in which the Killing horizon $H[\tilde{K}]$ is generated by

$$\tilde{K}=K+\Omega_H M, \tag{2}$$

where Ω_H is the angular velocity of the Killing horizon which is constant on $H[\tilde{K}]$. Moreover,[5] the Killing trajectories associated with the Killing field $\tilde{K}$ are null geodesics on $H[\tilde{K}]$ and coincide with the generators of the horizon.

According to the strong rigidity theorem in the case of a time dependent black hole space–time the event horizon cannot be defined as a Killing horizon and hence an alternative definition of a black hole must be found. Once a definition of an event horizon is found, one can then try to obtain exact solutions that describe dynamical black hole space–times. In the next section we address this problem by using the concepts of conformally stationary limit surfaces and conformal Killing horizons.[6]

If a space–time $(M,\mathbf{g})$ admits a conformal Killing vector field K satisfying

$$\mathcal{L}_K\mathbf{g}=2\phi\,\mathbf{g}, \tag{3}$$

where ϕ is related to the divergence of K by, $4\phi=-\mathrm{d}^\dagger K$, one can define a *conformal stationary limit surface* as the hypersurface Σ_0 on which K is null, i.e., the norm $N\equiv(K|K)=0$. To see the physical significance of this hypersurface it is first necessary to define a *conformal Killing observer* in the regions where K is timelike. This observer travels along a conformal Killing trajectory with a four velocity $u=e^{-\psi}K$, where $e^{2\psi}=N$, such that $(u|u)=1$ in a signature of -2. The function ϕ appearing in (3) is then equal to $(K|\mathrm{d}\psi)$, and hence is a measure of the rate of change of the scale along the conformal Killing trajectory. In the case of a Killing trajectory this function is zero implying that N remains constant along the trajectory. As the conformal Killing observer moves along the conformal Killing trajectory, he experiences a pure conformal change in the metric $\mathbf{g}$, in the sense that the metric can be written as $\mathbf{g}=f\mathbf{h}$, where f is related to ϕ, and is a function of space–time position and $\mathbf{h}$ is a function of position which is constant on any conformal Killing trajectory.[7] When the conformal Killing congruence of timelike curves is irrotational, i.e., the rotation or twist $\omega=\frac{1}{2}*(K\wedge\mathrm{d}K)$ vanishes, the observer concludes that the space–time is *conformally static*. Otherwise in the case of a nonzero ω, the space–time is seen as *conformally stationary*. In the regions where the conformal Killing field turns from timelike to spacelike such an observer cannot be defined. This leads to the boundary Σ_0 for the existence of such observers, where the conformal Killing field is null. Thus the name "conformal stationary limit surface."

For conformal Killing observers and sources the hypersurface Σ_0 is an infinite frequency shift surface. This can be seen by considering a conformal Killing source at S say, emitting photons at frequency μ_s, and a conformal Killing observer O receiving the photons at a frequency μ_0. If the photons from S to O travel along the null geodesic Γ with tangent vector k, then the frequency measured at O is proportional to $(u|k)$, where u is the four velocity of the observer. Also since Γ is a null geodesic, $(K|k)$ is constant along Γ, and hence it follows that the frequency shift obeys

$$\frac{\mu_s}{\mu_0} = \sqrt{\frac{N_0}{N_s}}. \tag{4}$$

So it is clear from (4) that when S lies on Σ_0 the observed frequency is zero, while when O lies on Σ_0 the observed frequency is infinite for finite emitted frequency μ_s. This explains why $N=0$ is a surface of infinite frequency shift for the conformal Killing observers and sources.

If the conformal stationary limit surface Σ_0 is itself a null surface then it is called a *conformal Killing horizon*. Dyer and Honig[6] proved that the hypersurface $N=0$ is a null surface, if and only if the rotation of the conformal Killing congruence has vanishing norm on the hypersurface, i.e., $(\omega|\omega)=0$. Moreover it was also shown that the conformal Killing trajectories are null pregeodesics on Σ_0 and therefore coincide with its null generators. Being a null geodesic hypersurface the conformal Killing horizon acts as a one-way membrane, i.e., the future null cone lies entirely on one side of the null surface such that future directed timelike directions cross the null surface in the same sense. In this way Σ_0 satisfies the local conditions for it to constitute the event horizon of a dynamical black hole space–time.

Time-dependent space–times admitting conformal Killing horizons can be obtained by applying a conformal transformation, $\tilde{\mathbf{g}}=\Omega^2\mathbf{g}$, to a stationary, asymptotically flat black hole space–time $(M,\mathbf{g})$ which admits a Killing horizon, Σ_0, generated by the Killing field K. Under a conformal transformation the Killing field K is mapped to a conformal Killing field, provided that $(K|\mathrm{d}\Omega)\neq 0$. Also since conformal transformations preserve causal structure as well as null geodesics, the hypersurface Σ_0 in the manifold $(M,\tilde{\mathbf{g}})$, is still a null surface whose null geodesic generators now coincide with the conformal Killing trajectories of K, i.e., it is a null geodesic hypersurface and therefore a conformal Killing horizon. In this way the conformal stationary limit surface and conformal Killing horizon in $(M,\tilde{\mathbf{g}})$, are the images of the corresponding stationary limit surface and Killing horizon in the space–time $(M,\mathbf{g})$. Such space–times are asymptotically conformally flat. However in general, there can be other space–times which are not asymptotically conformally flat, and which admit a timelike conformal field that generates a conformal Killing horizon.

In the next section we prove that the nullity of the conformal stationary limit surface requires a stronger necessary and sufficient condition than the one obtained earlier by Dyer and Honig[6] Moreover, in the case when the time dependent black hole space–time arises as a result of a conformal transformation on a stationary asymptotically flat space–time containing a Killing horizon, we prove that the conformal Killing horizon is globally equivalent to the event horizon, provided that the conformal factor goes to a constant at null infinity. This is an extension of the strong rigidity theorem[2] which establishes the conformal Killing property of the event horizon for such dynamic black hole space–times.

As discussed previously there are cases when the conformal stationary limit surface is a null surface and hence coincides with the conformal Killing horizon. These kind of space–times are conformally static. However there may be other cases where the conformal stationary limit surface is not a null surface. In this case one must assume the existence of another conformal Killing field which can be used with the above conformal Killing field K to construct a "mixed" conformal Killing field $\tilde{K}$ which has vanishing twist on the hypersurface $\tilde{\Sigma}_0, (\tilde{K}|\tilde{K})=0$. In this case the conformal stationary limit surface Σ_0 and the conformal Killing horizon $\tilde{\Sigma}_0$ do not coincide. This situation is analogous to the "mixed" Killing vector introduced in the Kerr space–time by Vishveshwara[8] and Carter,[3] where the stationary limit surface and the Killing horizon are separated by the ergosphere. This suggests that the so-called "weak rigidity theorem"[9] which establishes the Killing property of the horizon and the rigidity of its rotation for circular space–times, could be extended to conformal Killing horizons. This is done in Sec. III.

In the last section a physical definition of surface gravity for conformal Killing horizons similar to that for Killing horizons is given. This is then used to formulate a generalized zeroth law of black hole physics.

II. CONFORMAL KILLING TRAJECTORIES

The necessary and sufficient condition for a conformal stationary limit surface to be a null surface is given by the following theorem. Its proof is obtained in the framework of exterior calculus in order to make it easier and shorter. A concise introduction to the subject of exterior differential forms is given in Willmore.[10] We use the same symbol K to denote the conformal Killing field and its associated one form $\mathbf{g}(K)$.

Before proving the theorem we prove the following lemma.

Lemma 1: Let K be an arbitrary conformal Killing field with associated norm N and twist ω. Then

$$-\mathrm{d}K = \frac{1}{N}[2*(K\wedge\omega)+K\wedge\mathrm{d}N], \tag{5}$$

and

$$N(\mathrm{d}K|\mathrm{d}K) = (\mathrm{d}N|\mathrm{d}N) - 4(\omega|\omega) - 4\phi^2 N, \tag{6}$$

where $\phi=-\frac{1}{4}\mathrm{d}^{\dagger}K$.

Proof: Using the definition of the twist ω of the conformal Killing field K we have

$$-2*(K\wedge\omega) = 2i_K*\omega = i_K(K\wedge\mathrm{d}K).$$

Now

$$i_K(K\wedge\mathrm{d}K) = i_K K\wedge\mathrm{d}K - K\wedge i_K\,\mathrm{d}K = N\,\mathrm{d}K - K\wedge i_K\,\mathrm{d}K,$$

where

$$i_K\,\mathrm{d}K = -\mathrm{d}i_K\,K + \mathcal{L}_K K = -\mathrm{d}N + 2\phi K.$$

Hence

$$-2*(K\wedge\omega) = N\,\mathrm{d}K + K\wedge\mathrm{d}N,$$

which then gives the first identity

$$-\mathrm{d}K = \frac{1}{N}[2*(K\wedge\omega)+K\wedge\mathrm{d}N].$$

Then using the above identity we can write

$$N(\mathrm{d}K|\mathrm{d}K) = \frac{1}{N}[4(*(K\wedge\omega)|*(K\wedge\omega)) + 4(K\wedge\mathrm{d}N|*(K\wedge\omega)) + (K\wedge\mathrm{d}N|K\wedge\mathrm{d}N)].$$

Now

$$(*(K\wedge\omega)|*(K\wedge\omega)) = -(K\wedge\omega|K\wedge\omega) = -N(\omega|\omega),$$

because $(K|\omega)=0$. Moreover the cross term $(K\wedge\mathrm{d}N|*(K\wedge\omega))=0$ since it is proportional to $K\wedge K$. Finally

$$(K\wedge\mathrm{d}N|K\wedge\mathrm{d}N) = (K|K)(\mathrm{d}N|\mathrm{d}N) - (K|\mathrm{d}N)(K|\mathrm{d}N) = N(\mathrm{d}N|\mathrm{d}N) - 4\phi^2N^2,$$

since for a conformal Killing field $(K|\mathrm{d}N)=\mathcal{L}_K N=2\phi N$. Hence this gives

$$N(\mathrm{d}K|\mathrm{d}K) = \frac{1}{N}[-4N(\omega|\omega) + N(\mathrm{d}N|\mathrm{d}N) - 4\phi^2N^2],$$

from which we get the second identity

$$N(\mathrm{d}K|\mathrm{d}K) = (\mathrm{d}N|\mathrm{d}N) - 4(\omega|\omega) - 4\phi^2 N.$$

Theorem 1 (condition for CSLS to be a CKH): *If a space–time* $(M,\mathbf{g})$ *admits a timelike conformal Killing field* K *and* Σ_0 *denotes the surface* $\{N\equiv(K|K)=0\}$, *then the surface* Σ_0 *is a null surface (i.e., a conformal Killing horizon) if and only if*[11]

$$\omega = 0, \quad i_K\, \mathrm{d}K - 2\phi K \neq 0 \quad \textit{on } \Sigma_0, \tag{7}$$

where ω *denotes the rotation (twist) associated with the conformal Killing trajectories, and* ϕ *is the scalar function defined in (3).*

Proof: Let Σ_0 be a null surface such that $\mathrm{d}N$ is null on Σ_0. Then the orthogonality of $\mathrm{d}N$ and K on Σ_0 is evident from

$$(K|\mathrm{d}N) = \mathcal{L}_K N = (\mathcal{L}_K \mathbf{g})(K,K) + 2(K|[K,K]) = 0,$$

where the Leibnitz rule for the Lie derivative has been used together with the fact that the Lie bracket $[K,K]=\mathcal{L}_K K=0$, and $\mathcal{L}_K \mathbf{g}=2\phi\,\mathbf{g}$ for the CKV K. Since two orthogonal null vectors are proportional one must also have $K\wedge \mathrm{d}N=0$. Therefore from (5) which can be written in the form

$$2\,{}^*(K\wedge\omega) = -(N\,\mathrm{d}K + K\wedge \mathrm{d}N),$$

where $N=0$, it follows that $\omega=0$ on Σ_0. In addition

$$i_K\,\mathrm{d}K = \mathcal{L}_K K - \mathrm{d}i_K K = 2\phi K - \mathrm{d}N,$$

and so $\mathrm{d}N\neq 0$ implies $i_K\,\mathrm{d}K - 2\phi K \neq 0$.

Conversely let $\omega=0$, $i_K\,\mathrm{d}K - 2\phi K\neq 0$ on Σ_0. Then using (6), it follows that

$$(\mathrm{d}N|\mathrm{d}N) = N(\mathrm{d}K|\mathrm{d}K) - 4\phi^2 N = 0 \quad \text{on } \Sigma_0.$$

Then the assumption $i_K\,\mathrm{d}K - 2\phi K = -\mathrm{d}N \neq 0$ on Σ_0, implies that $\mathrm{d}N$ is null on Σ_0, which is therefore a null surface.

Having obtained the condition for the conformal stationary limit surface to be a conformal Killing horizon, one can easily show that the conformal Killing trajectories are null pregeodesics on the conformal Killing horizon. This property can be proved if one takes into account that the conformal Killing horizon by definition is a null surface, and hence its generators are null geodesics. As mentioned in the above proof the conformal Killing field K is tangent on Σ_0 to the generators, and so it follows that the conformal Killing trajectories on the conformal Killing horizon coincide with its generators and are therefore nonaffinely parametrized null geodesics. For this reason the conformal Killing horizon is sometimes referred to as a geodesic null hypersurface.

In the case when the time dependent black hole space–time admitting a conformal Killing horizon is conformally related to a static or stationary asymptotically flat black hole space–time, as described in the introduction, then one can say more about the role played by conformal Killing horizons. We will show in the next theorem that in this case the conformal Killing horizon, besides satisfying the local conditions for it to constitute an event horizon, is also globally equivalent to an event horizon $\mathcal{H}^+=\partial J^-(\mathcal{J}^+)\cap M$ of the black hole $\mathcal{B}=M-J^-(\mathcal{J}^+)$, provided that the conformal factor tends to a constant at null infinity.

Theorem 2 (extension of the strong rigidity theorem): *Consider a space–time* $(M,\tilde{\mathbf{g}})$ *which is conformally related to an analytic black hole space–time* $(M,\mathbf{g})$ *admitting a Killing horizon* Σ_0, *such that the conformal factor in* $\tilde{\mathbf{g}}=\Omega^2\mathbf{g}$ *goes to a constant at null infinity. Then the conformal Killing horizon* Σ_0 *in* $(M,\tilde{\mathbf{g}})$ *is globally equivalent to the event horizon, provided that the stress-energy tensor satisfies the weak energy condition.*

Proof: The proof of this theorem follows easily from the global definition of the event horizon and the properties of conformal transformations. The event horizon by definition is the boundary of the set $J^-(\mathcal{J}^+)$, which in turn is a union of terminal indecomposable past sets (TIPs). A TIP[12] is defined as the chronological past, $I^-(\gamma)$, of a future endless (or future inextendible, i.e., having no future end point[13]) causal curve γ. The TIPs are represented by the points on $\mathcal{J}^+$.[12] Each TIP being

a past-set[14] is unchanged if the metric is altered by the introduction of a finite conformal factor, and hence the global definition of an event horizon is conformally invariant, provided that the conformal factor tends to a constant such that the structure of conformal infinity in $(M,\tilde{\mathbf{g}})$ is preserved. This implies that in the manifold $(M,\mathbf{g})$, the event horizon $\partial J^-(\mathcal{J}^+)$ is a Killing horizon, while in the conformal manifold $(M,\tilde{\mathbf{g}})$ it is a conformal Killing horizon.

The case when the conformal factor goes to infinity on some surface S outside the Killing horizon Σ_0, needs special attention. At first it seems that since in this case the surface S is blown up to infinity in the conformal manifold $(M,\tilde{\mathbf{g}})$, the global definition $\partial J^-(\mathcal{J}^+)$ of the event horizon cannot be used. However one can show that in this situation the usual definition of event horizon is still applicable and hence the event horizon is a conformal Killing horizon as in the case of a finite conformal transformation. This can be shown by considering one of the TIPS, $I^-[\gamma]$ represented by the point p on $\mathcal{J}^+$, and generated by the null geodesic γ which intersects the surface S at a finite affine parameter λ_S in the manifold $(M,\mathbf{g})$. By the properties of conformal transformations, γ is still a null geodesic in $(M,\tilde{\mathbf{g}})$ with an affine parameter $\tilde{\lambda}$ related to λ by

$$\frac{d\tilde{\lambda}}{d\lambda} = c\Omega^2,$$

where c is a constant. From this it can be seen that the parameter λ_S in $(M,\mathbf{g})$ corresponds to $\tilde{\lambda}_S=\infty$ in $(M,\tilde{\mathbf{g}})$. This solves the problem for the case when Ω goes to infinity on some surface outside the Killing horizon.

III. ROTATING CONFORMAL KILLING HORIZONS

As discussed in the Introduction, there may be space–times where the conformal stationary limit surface $\{N\equiv(K|K)=0\}$ is not a null surface and hence does not coincide with the conformal Killing horizon. In this case besides the timelike conformal Killing field K, we consider another spacelike conformal Killing field M which commutes with K and which can be used in combination with it to construct a conformal Killing field $\tilde{K}$ that generates the conformal Killing horizon. This leads to a generalization of the weak rigidity theorem[9] which establishes the conformal Killing property of the event horizon for rotating black hole space–times, and the rigidity of its rotation. This is stated and proved after the following proposition.

Proposition 1: If K and M are two commuting conformal Killing fields with twist ω_K and ω_M, respectively, and $\tilde{K}$ and Ω are defined as

$$\tilde{K} = K + \Omega M, \quad \Omega = -\frac{W}{X},$$

where $X=(M|M)$ and $W=(K|M)$, then the twist of the vector field $\tilde{K}$ is given by

$$\omega_{\tilde{K}} = [(M|\omega_K) - \Omega(K|\omega_M)]\frac{M}{X}. \tag{8}$$

Proof: From the definition of $\tilde{K}$ it follows that

$$\tilde{K}\wedge d\tilde{K} = K\wedge dK + \Omega^2(M\wedge dM) + \Omega(K\wedge dM + M\wedge dK) - K\wedge M\wedge d\Omega.$$

Now since the two conformal Killing fields commute, $[M,K]=\mathcal{L}_M K=0$, one gets

$$dW = di_M K = -i_M\, dK + \mathcal{L}_M K = 2\phi_M K - i_M\, dK,$$

and

$$\mathrm{d}X = \mathrm{d}i_M\, M = -\, i_M\, \mathrm{d}M + \mathcal{L}_M M = 2\phi_M M - i_M\, \mathrm{d}M,$$

where ϕ_M is the scalar function associated with the conformal Killing field M and defined in (3). Therefore

$$\mathrm{d}\Omega = -\frac{1}{X}\left(\mathrm{d}W - \frac{W}{X}\mathrm{d}X\right) = \frac{1}{X}\left[i_M\left(\mathrm{d}K - \frac{W}{X}\mathrm{d}M\right) - 2\phi_M\left(K - \frac{W}{X}M\right)\right]. \tag{9}$$

Substituting for $\mathrm{d}\Omega$ in the expression for $\tilde{K}\wedge\mathrm{d}\tilde{K}$, gives

$$\begin{aligned}\tilde{K}\wedge\mathrm{d}\tilde{K} &= \frac{1}{X}[X(K\wedge\mathrm{d}K) - W(M\wedge\mathrm{d}K) - K\wedge M\wedge i_M\,\mathrm{d}K] + \frac{W}{X^2}[W(M\wedge\mathrm{d}M) - X(K\wedge\mathrm{d}M)\\ &\quad + K\wedge M\wedge i_M\,\mathrm{d}M]\\ &= \frac{1}{X} i_M\left[(M\wedge K\wedge\mathrm{d}K) + \frac{W}{X}(K\wedge M\wedge\mathrm{d}M)\right].\end{aligned} \tag{10}$$

Using the definitions of ω_M and ω_K, which represent the twist associated with M and K, respectively, and the fact that $*1=\eta$, where η is the volume form, we get

$$M\wedge K\wedge\mathrm{d}K = 2(M|\omega_K) * 1, \quad K\wedge M\wedge\mathrm{d}M = 2(K|\omega_M) * 1.$$

After substituting these in (10) and using $i_M * 1 = *M$, the identity in (8) is obtained by taking the dual of both sides of (10).

As in the case of the weak rigidity theorem[9] it is assumed that our space–time is circular or in other words orthogonally transitive. This means that the surfaces of transitivity are orthogonal to a family of surfaces of conjugate dimension. By Frobenius theorem[15] this requires that

$$\mathrm{d}K = \alpha_1\wedge K + \alpha_2\wedge M \tag{11}$$

and

$$\mathrm{d}M = \alpha_3\wedge K + \alpha_4\wedge M, \tag{12}$$

where α_i $(i=1,2,3,4)$, are arbitrary one-forms in $\Lambda^1 T^*$. Then the above two equations imply that

$$\mathrm{d}K\wedge K\wedge M = \mathrm{d}M\wedge M\wedge K = 0.$$

But $M\wedge K\wedge\mathrm{d}K = 2(M|\omega_K)\,\eta$ and similarly $K\wedge M\wedge\mathrm{d}M = 2(K|\omega_M)\,\eta$. This gives

$$(M|\omega_K) = (K|\omega_M) = 0.$$

Therefore as a corollary to the above proposition we can say that for a circular space–time admitting commuting, timelike, and spacelike conformal Killing fields K and M, respectively, the vector field $\tilde{K}$ defined by

$$\tilde{K} = K - \frac{(K|M)}{(M|M)}M,$$

is hypersurface orthogonal, i.e., $\omega_{\tilde{K}}=0$.

Theorem 3 (generalized weak rigidity theorem): *Consider a circular space–time admitting commuting timelike and spacelike conformal Killing fields K and M respectively, and let* $\tilde{\Sigma}_0$ *be the surface* $\{(\tilde{K}|\tilde{K})=0\}$, *where* $\tilde{K}=K+\Omega M$ *with* $\Omega=-W/X=-(K|M)/(M|M)$. *Then* Ω *is constant on* $\tilde{\Sigma}_0$, $\tilde{K}$ *is a conformal Killing field on* $\tilde{\Sigma}_0$, *and* $\tilde{\Sigma}_0$ *is a geodesic null hypersurface provided that the surface* $\tilde{\Sigma}_0$ *is regular.*

Proof: Using the commutativity of the conformal Killing fields, $\mathcal{L}_K M=[K,M]=0$, we can write

$$dW = di_K M = -i_K\, dM + \mathcal{L}_K M = *(K \wedge *\, dM) + 2\phi_K M,$$

$$dX = di_M M = -i_M\, dM + \mathcal{L}_M M = *(M \wedge *\, dM) + 2\phi_M M,$$

where now ϕ_K is the scalar field associated with K and defined by (3). Substituting this expression in (9) gives

$$d\Omega = -\frac{1}{X}[*(K \wedge *\, dM) + \Omega * (M \wedge *\, dM)] - \frac{2}{X}(\phi_K + \Omega\phi_M)M.$$

Taking the Hodge dual of both sides gives

$$*d\Omega = -\frac{1}{X}[\tilde{K} \wedge *\, dM] - \frac{2}{X}(\phi_K + \Omega\phi_M) * M. \tag{13}$$

From the above definition of $\tilde{K}$ it is easy to see that $(\tilde{K}|M)=0$ and $(\tilde{K}|\tilde{K})=(\tilde{K}|K)$. Applying i_M to (13) we have

$$i_M * d\Omega = \frac{1}{X}[\tilde{K} \wedge 2\omega_M] - \frac{2}{X}(\phi_K + \Omega\phi_M) i_M * M = \frac{1}{X}[\tilde{K} \wedge 2\omega_M],$$

since $i_M * M = 0$. Applying now i_K to the above expression, we get

$$i_K i_M * d\Omega = \frac{1}{X}[i_K\tilde{K} \wedge 2\omega_M - \tilde{K} \wedge 2i_K\omega_M] = \frac{2}{X}[(\tilde{K}|\tilde{K})\omega_M - (K|\omega_M)\tilde{K}].$$

But $(\tilde{K}|\tilde{K})=0$ on $\tilde{\Sigma}_0$ and by the circularity condition $(K|\omega_M)=0$. Therefore it follows that $i_K i_M * d\Omega = 0$ on $\tilde{\Sigma}_0$, and hence it is clear that $d\Omega$ can be expressed as a combination of the conformal Killing fields K and M on $\tilde{\Sigma}_0$, i.e., $d\Omega = aK + bM$, where a and b are two scalar fields. So for any vector field Y orthogonal to the conformal Killing fields one has $\mathcal{L}_Y\Omega = i_Y\, d\Omega = a(Y|K) + b(Y|M) = 0$ on $\tilde{\Sigma}_0$.

Moreover we can show using the definition of Ω that $\mathcal{L}_K\Omega = \mathcal{L}_M\Omega = 0$. For example,

$$\mathcal{L}_K\Omega = -\frac{\mathcal{L}_K W}{X} + \frac{W}{X^2}\mathcal{L}_K X. \tag{14}$$

But

$$\mathcal{L}_K W = \mathcal{L}_K(K|M) = (\mathcal{L}_K\mathbf{g})(K,M) + (K|[K,M]) = 2\phi_K(K|M),$$

and

$$\mathcal{L}_K X = \mathcal{L}_K(M|M) = (\mathcal{L}_K\mathbf{g})(M,M) + 2(M|[M,M]) = 2\phi_K(M|M).$$

Substituting these in (14) gives $\mathcal{L}_K\Omega = 0$. Similarly one can show that $\mathcal{L}_M\Omega = 0$. From this we conclude that Ω is constant on $\tilde{\Sigma}_0$, and thus the vector field $\tilde{K}$ is a conformal Killing field on $\tilde{\Sigma}_0$. As was shown above this field has vanishing twist on $\tilde{\Sigma}_0$, and hence since we assume that the surface $\tilde{\Sigma}_0$ is regular, i.e., $d(\tilde{K}|\tilde{K}) \neq 0$, theorem 1 implies that $\tilde{\Sigma}_0$ is a null geodesic hypersurface.

The space between the conformal stationary limit surface and the conformal Killing horizon provides a generalization of Penrose's ergosphere.

IV. SURFACE GRAVITY

We define the surface gravity, κ, for a space–time that admits a conformal Killing horizon Σ_0 generated by a conformal Killing field K, by the equation

$$\nabla_K K = \kappa K, \tag{15}$$

where the equality in the above equation applies only on Σ_0. In this way the surface gravity measures the extent to which the parametrization of the null geodesic congruence, represented by the conformal Killing trajectories on Σ_0, is not affine. This is regarded as the proper definition of surface gravity, because besides being a natural generalization of the surface gravity on Killing horizons, it also gives a physical interpretation to κ. Using the conformal Killing equations (3) which can be written in the form

$$\mathrm{d}N = -2\nabla_K K + 4\phi K, \tag{16}$$

we can write an alternative expression for the surface gravity by substituting (15) in the above equation, such that

$$\mathrm{d}N = -2\kappa K + 4\phi K = -2(\kappa - 2\phi)K. \tag{17}$$

When $\phi=0$ the above expression reduces to the well-known expression for surface gravity on Killing horizons which relates the one-form $\mathrm{d}N$ with the Killing field K, both of which are perpendicular to the Killing horizon.

An important difference between the properties of surface gravity on Killing horizons and the surface gravity on conformal Killing horizons, is that in the former case, the surface gravity along each Killing trajectory on the Killing horizon is constant, while in the latter case it scales up or down with ϕ along the conformal Killing trajectories generating the conformal Killing horizon. This can be shown by applying the Lie operator to both sides of (17), such that

$$\mathcal{L}_K \mathrm{d}N = -2\mathcal{L}_K[(\kappa - 2\phi)K]. \tag{18}$$

The left-hand side (LHS) of the above equation can be written as

$$\mathcal{L}_K\, \mathrm{d}N = \mathrm{d}\mathcal{L}_K N = 2\mathrm{d}(\phi N) = 2N\, \mathrm{d}\phi + 2\phi\, \mathrm{d}N,$$

where we have used the commutativity of the Lie derivative and exterior derivative when applied on scalars, together with the fact that $\mathcal{L}_K N = 2\phi N$ for a conformal Killing field K. Considering the right-hand side (RHS) and using $\mathcal{L}_K K = 2\phi K$, we have

$$\mathcal{L}_K[(\kappa - 2\phi)K] = 2\phi(\kappa - 2\phi)K + K\mathcal{L}_K[(\kappa - 2\phi)].$$

Therefore (18) becomes

$$2N\, \mathrm{d}\phi + 2\phi\, \mathrm{d}N = -4\phi(\kappa - 2\phi)K - 2K\mathcal{L}_K[(\kappa - 2\phi)].$$

On the conformal Killing horizon Σ_0, $N=0$ and from (17) $\mathrm{d}N = -2(\kappa - 2\phi)K$. So

$$\mathcal{L}_K(\kappa - 2\phi) = 0. \tag{19}$$

From this we conclude that in the conformal Killing case it is the combination, $\kappa - 2\phi$, which is constant along the null geodesic generators of the conformal Killing horizon Σ_0. In the case when K is a homothetic Killing field, i.e., ϕ is a constant, the situation is the same as in the Killing case, i.e., the surface gravity is constant along the homothetic Killing trajectories on the horizon. One would also like to consider the variation of $\kappa - 2\phi$ from one generator of Σ_0 to another in analogy to the generalized Hawking–Lichnerowicz theorem in the case of Killing horizons, which is also known as the zeroth law of black hole physics,[16] and which states that the surface gravity κ is constant over any connected component of the Killing horizon. This is discussed later on after we obtain an explicit expression for the surface gravity on conformal Killing horizons.

At this point we should remark that our definition of surface gravity on conformal Killing horizons is different than the one proposed earlier by Jacobson and Kang.[17] They suggested a conformally invariant definition of surface gravity κ_1 defined by

$$\mathrm{d}N = -2\kappa_1 K. \tag{20}$$

Unlike our definition this conformally invariant definition of surface gravity has no physical meaning attached to it. In our case the surface gravity as defined in (15) is not conformally invariant. To see this let us consider a conformal transformation $\tilde{\mathbf{g}}=\Omega^2\mathbf{g}$. Then in the conformal manifold $(M,\tilde{\mathbf{g}})$, (17) is written as

$$\mathrm{d}\tilde{N} = -2(\tilde{\kappa} - 2\tilde{\phi})\tilde{K}. \tag{21}$$

But $\tilde{N}=\Omega^2 N$ and hence on Σ_0

$$\mathrm{d}\tilde{N} = \Omega^2\ \mathrm{d}N + N\ \mathrm{d}\Omega^2 = \Omega^2\ \mathrm{d}N.$$

Also $\tilde{K}=\Omega^2 K$ and from the definition of the scalar function $\phi\left(\phi=\frac{1}{4}\nabla_c K^c\right)$, it follows that

$$\tilde{\phi} = \phi + \Omega^{-1}(K|\mathrm{d}\Omega).$$

Hence (21) gives

$$\mathrm{d}N = -2[\tilde{\kappa} - 2\phi - 2\Omega^{-1}(K|\mathrm{d}\Omega)]K.$$

Comparing this with the definition (17) we have

$$\tilde{\kappa} = \kappa + 2\Omega^{-1}(K|\mathrm{d}\Omega), \tag{22}$$

and hence unless Ω is a constant, the two surface gravities are different.

We now obtain an explicit expression for surface gravity on the conformal Killing horizon Σ_0 by using the fact that the twist ω associated with the conformal Killing field K vanishes on Σ_0. For this we use the identity,

$$(\mathrm{d}K|\mathrm{d}K) * K = i_K(\mathrm{d}K \wedge * \mathrm{d}K) = i_K\ \mathrm{d}K \wedge * \mathrm{d}K + \mathrm{d}K \wedge i_K * \mathrm{d}K. \tag{23}$$

The first part of this identity follows from the fact that

$$(\mathrm{d}K|\mathrm{d}K) = -\ *(\mathrm{d}K \wedge * \mathrm{d}K),$$

which implies that

$$(\mathrm{d}K|\mathrm{d}K)K = -K \wedge *(\mathrm{d}K \wedge * \mathrm{d}K),$$

such that

$$(\mathrm{d}K|\mathrm{d}K) * K = -\ *(K \wedge *(\mathrm{d}K \wedge * \mathrm{d}K)) = i_K(\mathrm{d}K \wedge * \mathrm{d}K).$$

Now using the definitions of N and ω, we have

$$i_K\ \mathrm{d}K = \mathcal{L}_K K - \mathrm{d}i_K\ K = 2\phi K - \mathrm{d}N \tag{24}$$

and

$$i_K * \mathrm{d}K = *(\mathrm{d}K \wedge K) = 2\omega, \tag{25}$$

such that (23) becomes

$$(\mathrm{d}K|\mathrm{d}K) * K = 2\phi K \wedge * \mathrm{d}K - \mathrm{d}N \wedge * \mathrm{d}K + 2\ \mathrm{d}K \wedge \omega.$$

Then using (17) and the fact that $\omega=0$ on Σ_0, this leads to

$$(\mathrm{d}K|\mathrm{d}K) * K = 2(\kappa - \phi)K \wedge * \mathrm{d}K,$$

which by (24) can also be written as

$$(\mathrm{d}K|\mathrm{d}K) * K = -2(\kappa-\phi) * i_K\, \mathrm{d}K = -2(\kappa-\phi)(2\phi * K - * \mathrm{d}N).$$

Finally using (17) we can write

$$(\mathrm{d}K|\mathrm{d}K) * K = -4(\kappa-\phi)^2 * K,$$

i.e.,

$$(\kappa-\phi)^2 = [-\tfrac{1}{4}(\mathrm{d}K|\mathrm{d}K)]_{\Sigma_0}. \tag{26}$$

After having shown that the combination $(\kappa-2\phi)$ is constant along the null generators of the conformal Killing horizon Σ_0, we now show that under certain assumptions this function is constant everywhere on Σ_0. In order to do this we first show that the quantity $(\kappa-2\phi)$ is conformally invariant under a general conformal transformation $\tilde{\mathbf{g}}=\Omega^2\mathbf{g}$, which maps the conformal Killing horizon Σ_0 in $(M,\mathbf{g})$, to another conformal Killing horizon in $(M,\tilde{\mathbf{g}})$. Thus letting $h=\kappa-2\phi$, Eq. (17) gives

$$-2\tilde{h}\tilde{K} = \mathrm{d}\tilde{N} = N\,\mathrm{d}\Omega^2 + \Omega^2\,\mathrm{d}N.$$

But $N=0$ on Σ_0 and hence

$$-2\tilde{h}\tilde{K} = \Omega^2\,\mathrm{d}N = -2h\Omega^2 K = -2h\tilde{K}.$$

Hence $h=\tilde{h}$.

The conformal invariance of h implies that if we start with a space–time $(M,\mathbf{g})$, admitting a Killing horizon on which h reduces to the surface gravity κ, then by the zeroth law of black hole physics together with the conformal invariance of h, we conclude that $\kappa-2\phi$ is constant on the conformal Killing horizon Σ_0 in the space–time $(M,\tilde{\mathbf{g}})$, provided that Einstein's equations hold with matter satisfying the dominant energy condition. Therefore in analogy to the Killing case, $\kappa-2\phi$ is not only constant along the null generators of Σ_0, but is constant over any connected component of Σ_0. Moreover by introducing another assumption, we now show that the constancy of $\kappa-2\phi$ on conformal Killing horizons is not only restricted to those cases in which the space–time admitting the conformal Killing horizon is obtained via a conformal transformation of a space–time with a Killing horizon.

So considering a space–time $(V,\mathbf{g})$ admitting a conformal Killing field K that generates a conformal Killing horizon H, we attempt to answer the following question: when does there exist at least locally on H, a conformally related metric $\tilde{\mathbf{g}}=\Omega^2\mathbf{g}$ such that K is a Killing field with respect to $\tilde{\mathbf{g}}$. It is not difficult to show that this requires finding a function Ω satisfying

$$(K|\mathrm{d}(\ln\Omega)) + \phi = 0, \tag{27}$$

or in coordinate form

$$K^c(\ln\Omega)_{,c} + \phi = 0,$$

where ϕ is the scalar function defined in (3) and a comma denotes partial differentiation. Clearly this is always possible at points $p\in H$ where the conformal Killing field K does not vanish. The problems in solving (27) occur at homothetic fixed points[18] of K on H, i.e., points $p\in H$ where $K=0$, but $\phi\neq 0$. A similar but more general question involving the algebra of conformal Killing fields $\mathcal{C}(\mathbf{g})$ on the entire space–time $(M,\mathbf{g})$ rather than a single conformal Killing field on a submanifold H of M, was considered first by Bilyalov[19] and Defrise-Carter[20] and recently by Hall and Steele.[21] Later Capocci[22] considered the case of a single conformal Killing field K in $(M,\mathbf{g})$ with a zero at $p\in M$ and gave sufficient conditions, for the existence of a conformally related metric defined on a neighborhood of p, with respect to which K is a Killing field. Hence returning to our case, in order to achieve the Killing property of K on H we can either apply the conditions stated by Capocci on H or, maybe easier, assume that there are no fixed points on H. In each case

the conformal Killing horizon H is mapped to a Killing horizon in $(V,\tilde{\mathbf{g}})$ on which the surface gravity is constant. Then the conformal invariance of h guarantees again that the quantity $\kappa-2\phi$ is constant on the conformal Killing horizon H in $(V,\mathbf{g})$. We have thus proved the following generalized version of the zeroth law of black hole physics.

Theorem 4 (generalized zeroth law): *If a space–time admits a conformal Killing horizon Σ_0 generated by a conformal vector field with no homothetic fixed points on Σ_0, then the quantity $\kappa-2\phi$ is constant everywhere on Σ_0, provided that Einstein's equations hold with matter satisfying the dominant energy condition.*

When $\phi=0$ it is clear that this theorem reduces to the well known zeroth law for Killing horizons.

V. CONCLUSION

In this work we have shown that conformal Killing horizons in time dependent black hole space–times can be used in general to describe locally the event horizon, both in the nonrotating case and in the rotating case. In the former case the conformally static limit surface coincides with the conformal Killing horizon, thus satisfying the necessary and sufficient conditions presented in theorem 1. In the latter case we have shown by generalizing the weak rigidity theorem, that the conformal stationary limit surface and the conformal Killing horizon are two distinct surfaces, with the space between them providing a generalization of Penrose's ergosphere. In the particular case when the black hole space–time admitting a conformal Killing horizon is the image of a conformal transformation applied to a stationary isolated black hole space–time, we have shown that the conformal Killing horizon is globally equivalent to the event horizon, provided that the conformal factor goes to a constant at null infinity. This is an extension of the strong rigidity theorem.

A physical definition of surface gravity, κ, on conformal Killing horizons was also given and later used to obtain a generalization of the zeroth law. The constancy of $\kappa-2\phi$ on the conformal Killing horizon, suggests that in general it is $\kappa-2\phi$, and not κ, to which the Hawking temperature is proportional, i.e., $T=(\kappa-2\phi)/2\pi$. This relation reduces to the usual one, $T=\kappa/2\pi$, for stationary asymptotically flat black holes, where the event horizon is a Killing horizon.

The Poincaré equation, a second-order partial differential equation describing wave motions in a rotating spheroid of arbitrary eccentricity satisfying a certain set of the boundary condition, is studied. A new polynomial as the general solution of the Poincaré equation in spheroidal geometry is found for the first time. The paper focuses on some unusual and intriguing mathematical properties of the new Poincaré polynomial. The possible completeness of the set of eigenfunctions of the Poincaré equation in the form of the new polynomial is also discussed. The new Poincaré polynomial would provide a powerful basis for the mathematical analysis in many important geophysical and astrophysical problems. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1811786]

I. INTRODUCTION

Many geophysical and astrophysical problems are concerned with the following classical mechanic problem: Wave motions in an incompressible and inviscid fluid contained in an oblate spheroidal cavity rotating with constant angular velocity Ω (for example, Poincaré, 1885; Chandrasekhar, 1961; Greenspan, 1968; Zhang and Schubert, 2000). The spheroidal geometry of a planet or a star is mainly caused by its rapid rotation. The envelope of the spheroidal cavity, shown in Fig. 1, is usually described by the equation

$$s^2 + \frac{z^2}{1-\epsilon^2} = 1, \tag{1.1}$$

where (s,ϕ,z) are cylindrical polar coordinates with the unit vectors $(\mathbf{e}_s,\mathbf{e}_\phi,\mathbf{e}_z)$, $s=0$ represents the axis of rotation and ϵ is the eccentricity of the oblate spheroid, $0<\epsilon<1$. The limit $\epsilon\to 0$ corresponds to a special case for a sphere and the limit $\epsilon\to 1$ gives a flatted spheroidal disk.

The effect of rapid rotation results in fluid motions in the form of azimuthally traveling waves or oscillations in an oblate spheroidal cavity. The pressure of the wave motion and oscillations is governed by the well-known Poincaré equation (Lyttleton, 1953; Greenspan, 1968; Zhang *et al.*, 2001) which was derived more than a century ago by Poincaré (1885). Bryan (1889) discussed an implicit solution of the Poincaré equation using modified oblate spheroidal coordinates. It was first

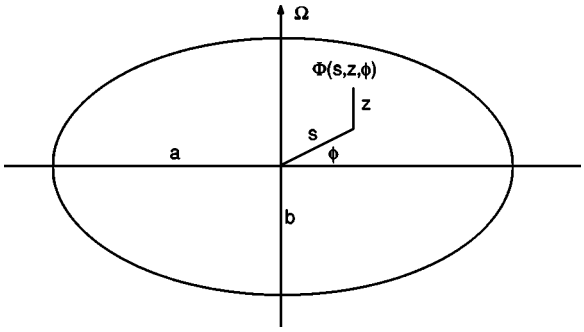

FIG. 1. Geometry of an oblate spheroid and cylindrical polar coordinates (s,z,ϕ). The major and minor axes of the oblate spheroid are $a=1$ and $b=\sqrt{1-\epsilon^2}$, respectively, with $0<\epsilon<1$. The pressure of wave motions is denoted by Φ.

recognized by Greenspan (1968) that the general solution for the Poincaré equation in spherical or spheroidal geometry is a double polynomial in terms of s and z. However, the explicit analytical expression for the double polynomial has not been found.

This paper presents the first explicit expression for the double polynomial as the general solution of the Poincaré equation in a spheroid of arbitrary eccentricity. The paper focuses on some unusual and intriguing mathematical properties of the new Poincaré polynomial, and the possible completeness of the set of eigenfunctions of the Poincaré equation in the form of the Poincaré polynomial.

II. THE NEW POINCARÉ POLYNOMIAL

In the following analysis, we shall use both cylindrical polar coordinates (s,ϕ,z) and spheroidal polar coordinates (η,ϕ,τ) which are related by

$$s^2=(\epsilon^2+\eta^2)(1-\tau^2),\quad z^2=\eta^2\tau^2. \tag{2.1}$$

The envelope of a spheroidal cavity in spheroidal polar coordinates is simply given by

$$\eta=\sqrt{1-\epsilon^2}. \tag{2.2}$$

Either the pressure Φ or the flow velocity $\mathbf{V}$ can be employed to describe the Poincaré problem in an oblate spheroid (Greenspan, 1968). The relationship between $\mathbf{V}$ and Φ is given by

$$\mathbf{V}=\frac{1}{2(1-\sigma^2)}\mathbf{e}_z\times\nabla\Phi-\frac{\hat{i}\sigma}{2(1-\sigma^2)}\nabla\Phi+\frac{\hat{i}}{2\sigma(1-\sigma^2)}(\mathbf{e}_z\cdot\nabla\Phi)\mathbf{e}_z, \tag{2.3}$$

where $\hat{i}=\sqrt{-1}$ and σ is the half frequency of a wave or an oscillation mode in a spheroid. Both the pressure Φ and the velocity $\mathbf{V}$ can be expressed as

$$\Phi=\Phi(\eta,\tau)e^{\hat{i}(2\sigma t+m\phi)},\quad \text{or}\quad \Phi=\Phi(s,z)e^{\hat{i}(2\sigma t+m\phi)}, \tag{2.4}$$

$$\mathbf{V}=\mathbf{V}(\eta,\tau)e^{\hat{i}(2\sigma t+m\phi)},\quad \text{or}\quad \mathbf{V}=\mathbf{V}(s,z)e^{\hat{i}(2\sigma t+m\phi)}, \tag{2.5}$$

where m is the azimuthal wave number of a wave. In cylindrical polar coordinates (s,ϕ,z), the pressure Φ is governed by the Poincaré equation in the form (Greenspan, 1968)

$$\left(\frac{1}{s}\frac{\partial\Phi}{\partial s}+\frac{\partial^2\Phi}{\partial s^2}-\frac{m^2}{s^2}\Phi\right)+\frac{(\sigma^2-1)}{\sigma^2}\frac{\partial^2\Phi}{\partial z^2}=0 \tag{2.6}$$

subject to the boundary condition

$$(1-\sigma^2)z\frac{\partial\Phi}{\partial z}-\sigma^2\left(\sqrt{1-\frac{z^2}{1-\epsilon^2}}\right)(1-\epsilon^2)\frac{\partial^2\Phi}{\partial s^2}-(1-\epsilon^2)m\sigma\Phi=0 \tag{2.7}$$

on the envelope of the spheroidal cavity give by (1.1). In spheroidal polar coordinates (η,ϕ,τ), the Poincaré equation has the more complicated form

$$C_{\tau\tau}\frac{\partial^2\Phi}{\partial\tau^2}+C_{\eta\eta}\frac{\partial^2\Phi}{\partial\eta^2}+C_\tau\frac{\partial\Phi}{\partial\tau}+C_\eta\frac{\partial\Phi}{\partial\eta}+C_{\tau\eta}\frac{\partial^2\Phi}{\partial\tau\,\partial\eta}+C_0\Phi=0, \tag{2.8}$$

where

$$C_{\tau\tau}=\frac{v^2}{w^4}\left(\tau^2u^2+\frac{(\sigma^2-1)}{\sigma^2}\eta^2v^2\right),$$

$$C_{\eta\eta}=\frac{u^2}{w^4}\left(\eta^2v^2+\frac{(\sigma^2-1)}{\sigma^2}\tau^2u^2\right),$$

$$C_\tau=\frac{\tau}{w^6}[-2w^4+u^2v^2(3\eta^2-\tau^2\epsilon^2)]+\frac{(\sigma^2-1)}{\sigma^2}\left(\frac{v^2}{\tau w^6}\right)[w^4-\eta^2w^2(1+\tau^2)-2\eta^2\tau^2(u^2+\epsilon^2v^2)],$$

$$C_\eta=\frac{\eta}{w^6}[2w^4+u^2v^2(3\tau^2\epsilon^2-\eta^2)]+\frac{(\sigma^2-1)}{\sigma^2}\left(\frac{u^2}{\eta w^6}\right)[w^4-\tau^2w^2(\epsilon^2-\eta^2)-2\eta^2\tau^2(u^2+\epsilon^2v^2)],$$

$$C_{\tau\eta}=-\frac{2\tau\eta u^2v^2}{\sigma^2w^4},$$

$$C_0=-\frac{m^2}{u^2v^2},$$

where

$$u=\sqrt{\eta^2+\epsilon^2},\quad v=\sqrt{1-\tau^2},\quad w=\sqrt{\eta^2+\epsilon^2\tau^2}.$$

The above equation is subject to the boundary condition

$$e_\eta\cdot\mathbf{V}=0\quad\text{at}\quad\eta=\sqrt{1-\epsilon^2}, \tag{2.9}$$

where $(\mathbf{e}_\eta,\mathbf{e}_\phi,\mathbf{e}_\tau)$ are the unit vectors for spheroidal polar coordinates. After solving the Poincaré equation for the pressure Φ, the flow velocity $\mathbf{V}$ can be readily obtained from (2.4).

There exist two different parities of solutions with respect to the equatorial plane, $\tau=0$ (or $z=0$), in a rotating spheroid. An equatorially symmetric solution (an even polynomial) is characterized by the symmetry property

$$(V_\tau,V_\phi,V_\eta,\Phi)(\tau,\phi,\eta)=(-V_\tau,V_\phi,V_\eta,\Phi)(-\tau,\phi,\eta), \tag{2.10}$$

or

$$(V_z,V_\phi,V_s,\Phi)(z,\phi,s)=(-V_z,V_\phi,V_s,\Phi)(-z,\phi,s), \tag{2.11}$$

while an equatorially antisymmetric solution (an odd polynomial) satisfies

$$(V_\tau,V_\phi,V_\eta,\Phi)(\tau,\phi,\eta)=(V_\tau,-V_\phi,-V_\eta,-\Phi)(-\tau,\phi,\eta), \tag{2.12}$$

or

$$(V_z, V_\phi, V_s, \Phi)(z, \phi, s) = (V_z, -V_\phi, -V_s, -\Phi)(-z, \phi, s). \tag{2.13}$$

Since the mathematical analyses for both the parities are nearly identical, we shall focus on the equatorially symmetric (even) polynomial.

The Poincaré equation (2.6) [or (2.8)] together with the boundary condition (2.7) [or (2.9)] defines an eigenvalue problem in spheroidal geometry. We find that the general explicit solution for (2.6) in cylindrical coordinates can be written as

$$\Phi(s,z) = \sum_{i=0}^{N} \sum_{j=0}^{N-i} C_{ijmN} \sigma^{2i} (1-\sigma^2)^j s^{m+2j} z^{2i+\delta}; \tag{2.14}$$

while in spheroidal polar coordinates the general solution is given by

$$\Phi(\eta, \tau) = \sum_{i=0}^{N} \sum_{j=0}^{N-i} C_{ijmN} \sigma^{2i} (1-\sigma^2)^j (uv)^{m+2j} (\eta\tau)^{2i+\delta}, \tag{2.15}$$

where C_{ijmN} is defined by

$$C_{ijmN} = \left[\frac{-1}{(1-\sigma^2\epsilon^2)}\right]^{i+j} \frac{[2(m+N+i+j+\delta)-1]!!}{2^{j+1}[2(i+\delta)-1]!!\,(N-i-j)!\,i!\,j!\,(m+j)!},$$

where the even polynomials are given by $\delta=0$, the odd polynomials correspond to $\delta=1$, and N is zero or a positive integer taking

$$N = (1-\delta), (2-\delta), (3-\delta), \ldots,$$

which characterizes the spatial complexity of a polynomial. The polynomial given by (2.14) or (2.15) represents the first explicit general solution for the Poincaré equation in a spheroid of arbitrary eccentricity.

The validity of polynomial (2.14) as solutions for the Poincaré equation can be verified by a direct substitution of (2.14) into (2.6). For example, in the case of the even polynomials, we obtain after shifting indices i and j by 1 in the resulting expression,

$$\begin{aligned}\left(\frac{1}{s}\frac{\partial\Phi}{\partial s} + \frac{\partial^2\Phi}{\partial s^2} - \frac{m^2}{s^2}\Phi\right) + \frac{(\sigma^2-1)}{\sigma^2}\frac{\partial^2\Phi}{\partial z^2} &= \sum_{i=0}^{N-1}\sum_{j=0}^{N-i-1} [4(j+1)(j+m+1)C_{i(j+1)mN} \\ &\quad - C_{(i+1)jmN}(2i+1)(2i+2)]F_{ij} \\ &= \sum_{i=0}^{N-1}\sum_{j=0}^{N-i-1}\left[\frac{(-1)^{i+j+1}[2(m+N+i+j)+1]!!}{2^j(N-i-j-1)!\,(1-\sigma^2\epsilon^2)^{(i+j)}}\right] \\ &\quad \times F_{ij}\left[\frac{(j+1)(j+m+1)}{(2i-1)!!\,i!\,(j+1)!\,(m+j+1)!}\right. \\ &\quad \left. - \frac{(2i+1)(i+1)}{(2i+1)!!\,(i+1)!\,j!\,(m+j)!}\right] \equiv 0\end{aligned} \tag{2.16}$$

for all values of N, m and σ, where F_{ij} is a function of m, σ, s and z.

Three components of the velocity $\mathbf{V}$ can be readily derived from (2.3). In cylindrical coordinates with $\mathbf{V}=(V_s, V_\phi, V_z)$, we obtain

$$V_s = \frac{-\hat{i}}{2}\sum_{i=0}^{N}\sum_{j=0}^{N-i} C_{ijmN}\sigma^{2i}(1-\sigma^2)^{j-1}(2j\sigma + m\sigma + m)s^{m+2j-1}z^{2i+\delta}, \tag{2.17}$$

$$V_\phi = \frac{1}{2}\sum_{i=0}^{N}\sum_{j=0}^{N-i} C_{ijmN}\sigma^{2i}(1-\sigma^2)^{j-1}(2j+m+m\sigma)s^{m+2j-1}z^{2i+\delta}, \tag{2.18}$$

$$V_z = \frac{\hat{i}}{2}\sum_{i=0}^{N}\sum_{j=0}^{N-i} C_{ijmN}\sigma^{2i-1}(1-\sigma^2)^{j}(2i+\delta)s^{m+2j}z^{2i-1+\delta}. \tag{2.19}$$

In spheroidal polar coordinates with $\mathbf{V}=(V_\eta, V_\phi, V_\tau)$, we obtain

$$V_\eta = \frac{\hat{i}}{2w}\sum_{i=0}^{N}\sum_{j=0}^{N-i} C_{ijmN}\sigma^{2i-1}(1-\sigma^2)^{j-1}u^{m+2j-1}v^{m+2j}\eta^{2i-1}\tau^{2i+\delta} \times[-\eta^2\sigma(2j\sigma+m\sigma+m)+(2i+\delta)u^2(1-\sigma^2)], \tag{2.20}$$

$$V_\phi = \frac{1}{2}\sum_{i=0}^{N}\sum_{j=0}^{N-i} C_{ijmN}\sigma^{2i}(1-\sigma^2)^{j-1}(2j+m+m\sigma)(uv)^{m+2j-1}(\eta\tau)^{2i+\delta}, \tag{2.21}$$

$$V_\tau = \frac{\hat{i}}{2w}\sum_{i=0}^{N}\sum_{j=0}^{N-i} C_{ijmN}\sigma^{2i-1}(1-\sigma^2)^{j-1}u^{m+2j}v^{m+2j-1}\eta^{2i}\tau^{2i-1+\delta} \times[\tau^2\sigma(2j\sigma+m\sigma+m)+(2i+\delta)v^2(1-\sigma^2)]. \tag{2.22}$$

We shall refer to polynomials given by (2.17)–(2.19) or (2.20)–(2.22) as the Poincaré polynomial, which represents the first general explicit solution for the flow velocity in a rotating spheroid of arbitrary eccentricity.

The eigenvalue σ (the half-frequency of a wave or an oscillation mode) can be determined by substituting (2.14) into (2.7), which yields

$$\sum_{n=0} F_N(\sigma)\mathcal{C}_n z^{2n+\delta} = 0, \tag{2.23}$$

where $\mathcal{C}_n$ are nonzero coefficients and $F_N(\sigma)$ is a polynomial of σ. Equation (2.23) implies that $F_N(\sigma)=0$, i.e.,

$$F_N(\sigma) = \left\{\frac{(-1)^N[2(N+m)]!\,(1-\delta)\sigma(1-\epsilon^2)(1-\sigma^2\epsilon^2)^N}{N!\,(N+m)!}\right\} - \sum_{j=0}^{N-1+\delta}(-1)^j\frac{[2(2N+m-j+\delta)]!}{[2(N-j)+\delta]!\,j!\,(2N+m-j+\delta)!}[(1-\epsilon^2)\sigma^2]^{N-j}(1-\sigma^2\epsilon^2)^j \times\{(1-\sigma)[2(N-j)+\delta]-m\sigma(1-\epsilon^2)\}=0. \tag{2.24}$$

For a given ϵ, m and N, there exist $(2N+\delta)$ different eigenvalues or $(2N+\delta)$ different polynomials. At this stage, it is convenient to introduce a triple index notation for the polynomial (eigenfunction) and the eigenvalue by denoting

$$\Phi \to \Phi_{Nnm}, \quad \mathbf{V} \to \mathbf{V}_{Nnm}, \quad \sigma \to \sigma_{Nnm}.$$

While $0 \leqslant N < \infty$ and $0 \leqslant m < \infty$, n has a finite range $n=1,2,3,\ldots,(2N+\delta)$ (which is the number of the roots in (2.24) for a given N). For example, when $N=1$ and $\delta=0$ (even polynomials), (2.24) gives

$$[(2m+3)(m+2)-2m(m+1)\epsilon^2]\sigma_{1nm}^2 - 2(2m+3)\sigma_{1nm} - m = 0. \tag{2.25}$$

For each nonzero wave number m and ϵ, there exist two different eigenvalues

$$\sigma_{11m} = \frac{(2m+3)}{(m+2)(2m+3) - 2m(m+1)\epsilon^2}\left\{1 - \left[\frac{(m+2)^2-1}{(2m+3)} - \frac{2m^2(m+1)\epsilon^2}{(2m+3)^2}\right]^{1/2}\right\}, \quad (2.26)$$

$$\sigma_{12m} = \frac{(2m+3)}{(m+2)(2m+3) - 2m(m+1)\epsilon^2}\left\{1 + \left[\frac{(m+2)^2-1}{(2m+3)} - \frac{2m^2(m+1)\epsilon^2}{(2m+3)^2}\right]^{1/2}\right\}. \quad (2.27)$$

The corresponding eigenvectors are given by (2.17)–(2.19) or (2.20)–(2.22). Several more examples for σ_{Nnm} with $m=2$ are presented in Tables I and II.

III. UNUSUAL PROPERTIES OF THE POINCARÉ POLYNOMIAL

There are a number of well-known general properties of the the Poincaré equation which were discussed in detail by Greenspan (1968). The most important are that (i) the eigenvalue σ_{Nmn} is real and satisfies

$$-1 < \sigma_{Nmn} < 1, \quad (3.1)$$

and (ii) any eigenvector-eigenvalue pairs, $(\sigma_{Nmn}, \mathbf{V}_{Nmn})$ and $(\sigma_{N'm'n'}, \mathbf{V}_{N'm'n'})$, are orthogonal, i.e.,

$$\int_V \mathbf{V}^+_{Nmn} \cdot \mathbf{V}_{N'm'n'} dV = 0, \quad \text{if} \quad \sigma_{Nmn} \neq \sigma_{N'm'n'}, \quad (3.2)$$

where $\int_V$ denotes the integral over the volume of the solution domain and $\mathbf{V}^+_{Nmn}$ is the complex conjugate of $\mathbf{V}_{Nmn}$. It is of primary importance to note that the properties (3.1) and (3.2) are

TABLE II. Several examples of σ_{Nmn} for the even polynomials with $m=2$ at two different eccentricities.

derived directly from the basic equations without reference to particular geometry of the problem or the detailed structure of an eigenfunction.

In the nonlinear theory of the wave problem, the following integral

$$\int_V \mathbf{V}^+_{Nmn} \cdot \nabla^2 \mathbf{V}_{Nmn} dV \tag{3.3}$$

plays a key role in the higher-order problem. It can be readily shown that the integral (3.3) is always nonzero and negative in the geometries of an infinitely extended plane layer or a box or a cylinder or an annulus for which the eigenfunctions are not in the form of a polynomial. In spheroidal geometry, however, we have discovered an intriguing, unusual property of the Poincaré polynomial that

$$\int_V \mathbf{V}^+_{Nmn} \cdot \nabla^2 \mathbf{V}_{Nmn} dV \equiv 0, \tag{3.4}$$

for all values of ϵ, m, N, and σ. It should be emphasized that (3.4) holds only for spheroidal geometry in which its eigenfunction is in the form of a polynomial. The mathematical proof for (3.4) is rather complicated and lengthy, requiring the detailed structure of the Poincaré polynomial. Hence we focus on the case of the even (equatorially symmetric) polynomials since the proof for the odd polynomials is similar.

On the basis of explicit expressions (2.17)–(2.19) for the even polynomial ($\delta=0$), it is straightforward to carry out the relevant integration over the volume of the spheroid, which yields

$$\int_V \mathbf{V}^+_{Nmn} \cdot \nabla^2 \mathbf{V}_{Nmn} dV = D_1(\sigma)\mathcal{S}_1 + D_2(\sigma)\mathcal{S}_2 + D_3(\sigma)\mathcal{S}_3, \tag{3.5}$$

where $D_j(\sigma)$, $j=1,2,3$ are a nonzero function of σ and

$$\mathcal{S}_1 = \sum_{i=0}^{N}\sum_{k=1}^{N}\sum_{j=0}^{N-i}\sum_{l=0}^{N-k}(-1)^{i+j+k+l}\Delta^{2(i+k)}(1-\Delta^2)^{j+l} \times\frac{[2(m+N+i+j)-1]!!}{[2(l+k+i+j+m)-1]!!} \times\frac{[2(m+N+k+l)-1]!![2m(m+l+j)+4jl]}{(2i-1)!!\,(N-i-j)!\,i!\,j!\,(m+j)!} \times\frac{(2i+2k-3)!!\,(l+j+m-1)!}{(k-1)!\,l!\,(2k-3)!!\,(l+m)!\,(N-k-l)!}, \tag{3.6}$$

$$\mathcal{S}_2 = \sum_{i=0}^{N}\sum_{k=1}^{N}\sum_{j=0}^{N-i}\sum_{l=0}^{N-k}(-1)^{i+j+k+l}\Delta^{2(i+k)}(1-\Delta^2)^{j+l} \times\frac{[2(m+N+i+j)-1]!!}{[2(l+k+i+j+m)-1]!!} \times\frac{[2(m+N+k+l)-1]!!}{(2i-1)!!\,(N-i-j)!\,i!\,j!\,(m+j)!} \times\frac{(2i+2k-3)!!\,(l+j+m)!}{(k-1)!\,l!\,(2k-3)!!\,(l+m)!\,(N-k-l)!}, \tag{3.7}$$

$$\mathcal{S}_3 = \sum_{i=1}^{N}\sum_{k=2}^{N}\sum_{j=0}^{N-i}\sum_{l=0}^{N-k}(-1)^{i+j+k+l}\Delta^{2(i+k)}(1-\Delta^2)^{j+l} \times\frac{[2(m+N+i+j)-1]!!}{[2(l+k+i+j+m)-1]!!} \times\frac{[2(m+N+k+l)-1]!!}{(2i-1)!!\,(N-i-j)!\,(i-1)!\,j!\,(m+j)!} \times\frac{(2i+2k-5)!!\,(l+j+m)!}{(k-2)!\,l!\,(2k-3)!!\,(l+m)!\,(N-k-l)!}, \tag{3.8}$$

where

$$\Delta^2 = \frac{\sigma^2(1-\epsilon^2)}{(1-\sigma^2\epsilon^2)}.$$

We need to prove that

$$\mathcal{S}_1 = \mathcal{S}_2 = \mathcal{S}_3 \equiv 0$$

for all possible values of ϵ, m, σ and $N>1$. For $N=0$ and $N=1$, we can easily carry out the direct calculation. We shall only present the general proof for $\mathcal{S}_3\equiv 0$ because the proofs for $\mathcal{S}_1\equiv 0$ and $\mathcal{S}_2\equiv 0$ are rather similar.

First, we note that four indices (i,j,k,l) in (3.8) are intimately entangled. In consequence, a direct summation of (3.8) is generally impossible. An essential step in establishing $\mathcal{S}_3\equiv 0$ for all N is to introduce two additional indices, say α and β, by considering a new summation with six indices

$$\mathcal{P}_N^M = \sum_{\alpha=0}^{M}\sum_{\beta=0}^{M-\alpha} Z_{\alpha,\beta}^M \sum_{i=1}^{N-M}\sum_{k=2}^{N-M}\sum_{j=0}^{N-i-M}\sum_{l=0}^{N-k-M} (-1)^{i+j+k+l}\Delta^{2(i+k+2\alpha)}(1-\Delta^2)^{j+l+2\beta}$$
$$\times\frac{[2(m+N+i+j+\alpha+\beta)-1]!!}{[2(i+\alpha)-1)!!\,(N-i-j-M)!\,(i-1)!\,j!\,(m+j+\beta)!}$$
$$\times\frac{[2(m+N+k+l+\alpha+\beta)-1]!!}{[2(k+\alpha)-3)!!\,(N-k-l-M)!\,(k-2)!\,l!\,(m+l+\beta)!}$$
$$\times\frac{(m+j+l+\beta)!\,[2(i+k+\alpha)-5)!!}{[2(m+i+j+k+l+\alpha+\beta+M)-1]!!}, \tag{3.9}$$

where coefficients $Z_{i,j}$ are generally nonzero and defined as

$$Z_{0,0}^0 = 1;$$

$$Z_{i,0}^{M+1} = (-1)^{M+1-i}\frac{(M+1)!}{(M+1-i)!\,i!}2^{M+1};$$

$$Z_{0,i}^{M+1} = (-2)^{M+1-i}\frac{(M+1)!}{(M+1-i)!\,i!}; \tag{3.10}$$

$$Z_{i,M+1-i}^{M+1} = 2^i\frac{(M+1)!}{(M+1-i)!\,i!};$$

$$Z_{i,j}^{M+1} = -2Z_{i,j}^M + 2Z_{i-1,j}^M + Z_{i,j-1}^M; \quad 1\leqslant i\leqslant(M-1), \quad 1\leqslant j\leqslant(M-i).$$

The precise values for the coefficients $Z_{i,j}^M$ are in fact not required in the mathematical proof. Clearly $\mathcal{S}_3$ and $\mathcal{P}_N^M$ are related by

$$\mathcal{S}_3 = \mathcal{P}_N^0.$$

In order to decouple the entangled indices, we first establish an important recurrence relation in the form

$$\mathcal{P}_N^0 = \frac{1}{(N-1)}\mathcal{P}_N^1 = \frac{1}{(N-1)(N-2)}\mathcal{P}_N^2 = \cdots. \tag{3.11}$$

Note that the expression (3.9) can be decomposed into the three different summations

$$\mathcal{P}_N^M = \mathcal{Q}_1 + \mathcal{Q}_2 + \mathcal{Q}_3, \tag{3.12}$$

where

$$\mathcal{Q}_1 = \frac{-1}{N-1-M}\sum_{\alpha=0}^{M}\sum_{\beta=0}^{M-\alpha} Z_{\alpha,\beta}^M \sum_{i=1}^{N-M-1}\sum_{j=0}^{N-i-M-1}\sum_{k=2}^{N-M}\sum_{l=0}^{N-k-M} (-1)^{i+j+k+l}\Delta^{2(i+k+2\alpha+1)}(1-\Delta^2)^{j+l+2\beta}$$
$$\times\frac{[2(m+N+i+j+\alpha+\beta)+1]!!}{[2(i+\alpha)+1)!!\,(N-i-j-M-1)!\,(i-1)!\,j!\,(m+j+\beta)!}$$
$$\times\frac{[2(m+N+k+l+\alpha+\beta)-1]!!}{[2(k+\alpha)-3)!!\,(N-k-l-M)!\,(k-2)!\,l!\,(m+l+\beta)!}$$

$$\times\frac{(m+j+l+\beta)\,![2(i+k+\alpha)-3]!!}{[2(m+i+j+k+l+\alpha+\beta+M)+1]!!}, \tag{3.13}$$

$$\begin{aligned}\mathcal{Q}_2=&\frac{1}{N-1-M}\sum_{\alpha=0}^{M}\sum_{\beta=0}^{M-\alpha}Z_{\alpha,\beta}^{M}\sum_{i=1}^{N-M-1}\sum_{j=0}^{N-i-M-1}\sum_{k=2}^{N-M}\sum_{l=0}^{N-k-M}(-1)^{i+j+k+l}\Delta^{2(i+k+2\alpha)}(1-\Delta^2)^{j+l+2\beta}\\&\times\frac{[2(m+N+i+j+\alpha+\beta)-1]!!}{[2(i+\alpha)-1)\,!!\,(N-i-j-M-1)\,!\,(i-1)\,!\,j\,!\,(m+j+\beta)!}\\&\times\frac{[2(m+N+k+l+\alpha+\beta)-1]!!}{[2(k+\alpha)-3)\,!!\,(N-k-l-M)\,!\,(k-2)\,!\,l\,!\,(m+l+\beta)!}\\&\times\frac{(m+j+l+\beta)\,![2(i+k+\alpha)-5]!!}{[2(m+i+j+k+l+\alpha+\beta+M)-1]!!},\end{aligned} \tag{3.14}$$

$$\begin{aligned}\mathcal{Q}_3=&\frac{-1}{N-1-M}\sum_{\alpha=0}^{M}\sum_{\beta=0}^{M-\alpha}Z_{\alpha,\beta}^{M}\sum_{i=1}^{N-M-1}\sum_{j=0}^{N-i-M-1}\sum_{k=2}^{N-M}\sum_{l=0}^{N-k-M}(-1)^{i+j+k+l}\Delta^{2(i+k+2\alpha)}(1-\Delta^2)^{j+l+2\beta+1}\\&\times\frac{[2(m+N+i+j+\alpha+\beta)+1]!!}{[2(i+\alpha)-1)\,!!\,(N-i-j-M-1)\,!\,(i-1)\,!\,j\,!\,(m+j+\beta+1)!}\\&\times\frac{[2(m+N+k+l+\alpha+\beta)-1]!!}{[2(k+\alpha)-3)\,!!\,(N-k-l-M)\,!\,(k-2)\,!\,l\,!\,(m+l+\beta)!}\\&\times\frac{(m+j+l+\beta+1)\,![2(i+k+\alpha)-5]!!}{[2(m+i+j+k+l+\alpha+\beta+M)+1]!!}.\end{aligned} \tag{3.15}$$

For the recurrence relation, we require the further rearrangement of the summation so that the index $(M+1)$ appears in each term. After splitting $\mathcal{Q}_3$ into two parts and combining them with various terms in (3.13)–(3.15), $\mathcal{P}_N^M$ can be expressed in terms of the following three sums

$$\mathcal{P}_N^M=\mathcal{R}_1+\mathcal{R}_2+\mathcal{R}_3, \tag{3.16}$$

where

$$\begin{aligned}\mathcal{R}_1=&\frac{1}{N-1-M}\sum_{\alpha=0}^{M}\sum_{\beta=0}^{M-\alpha}Z_{\alpha,\beta}^{M}\sum_{i=1}^{N-(M+1)}\sum_{j=0}^{N-i-(M+1)}\sum_{k=2}^{N-(M+1)}\sum_{l=0}^{N-k-(M+1)}(-1)^{i+j+k+l}\Delta^{2(i+k+2\alpha)}(1-\Delta^2)^{j+l+2\beta}\Delta^4\\&\times\frac{2[2(m+N+i+j+\alpha+\beta)+1]!!}{[2(i+\alpha)+1)\,!!\,[N-i-j-(M+1)]\,!\,(i-1)\,!\,j\,!\,(m+j+\beta)!}\\&\times\frac{[2(m+N+k+l+\alpha+\beta)+1]!!}{[2(k+\alpha)-1)\,!!\,[N-k-l-(M+1)]\,!\,(k-2)\,!\,l\,!\,(m+l+\beta)!}\\&\times\frac{(m+j+l+\beta)\,![2(i+k+\alpha)-3]!!}{[2(m+i+j+k+l+\alpha+\beta+M+1)+1]!!},\end{aligned} \tag{3.17}$$

$$\mathcal{R}_2=\frac{1}{N-1-M}\sum_{\alpha=0}^{M}\sum_{\beta=0}^{M-\alpha}Z_{\alpha,\beta}^{M}\sum_{i=1}^{N-(M+1)}\sum_{j=0}^{N-i-(M+1)}\sum_{k=2}^{N-(M+1)}\sum_{l=0}^{N-k-(M+1)}(-1)^{i+j+k+l}\Delta^{2(i+k+2\alpha)}(1-\Delta^2)^{j+l+2(\beta+1)}$$
$$\times\frac{[2(m+N+i+j+\alpha+\beta)+1]!!}{[2(i+\alpha)-1)!!\,[N-i-j-(M+1)]!\,(i-1)!\,j!\,(m+j+\beta)!}$$
$$\times\frac{[2(m+N+k+l+\alpha+\beta)+1]!!}{[2(k+\alpha)-3)!!\,[N-k-l-(M+1)]!\,(k-2)!\,l!\,(m+l+\beta+1)!}$$
$$\times\frac{(m+j+l+\beta+1)!\,[2(i+k+\alpha)-5]!!}{[2(m+i+j+k+l+\alpha+\beta+M+1)+1]!!},\tag{3.18}$$

$$\mathcal{R}_3=\frac{-1}{N-1-M}\sum_{\alpha=0}^{M}\sum_{\beta=0}^{M-\alpha}Z_{\alpha,\beta}^{M}\sum_{i=1}^{N-(M+1)}\sum_{j=0}^{N-i-(M+1)}\sum_{k=2}^{N-(M+1)}\sum_{l=0}^{N-k-(M+1)}(-1)^{i+j+k+l}\Delta^{2(i+k+2\alpha)}(1-\Delta^2)^{j+l+2\beta}$$
$$\times\frac{2[2(m+N+i+j+\alpha+\beta)-1]!!}{[2(i+\alpha)-1)!!\,[N-i-j-(M+1)]!\,(i-1)!\,j!\,(m+j+\beta)!}$$
$$\times\frac{[2(m+N+k+l+\alpha+\beta)-1]!!}{[2(k+\alpha)-3)!!\,[N-k-l-(M+1)]!\,(k-2)!\,l!\,(m+l+\beta)!}$$
$$\times\frac{(m+j+l+\beta)!\,[2(i+k+\alpha)-5]!!}{[2(m+i+j+k+l+\alpha+\beta+M+1)-1]!!}.\tag{3.19}$$

Evidently, by shifting α in $\mathcal{R}_1$ by 1, and shifting β in $\mathcal{R}_2$ by 1, combining the resulting three summations with the definition of (3.10), we obtain

$$\mathcal{P}_N^M=\frac{1}{N-(M+1)}\sum_{\alpha=0}^{M+1}\sum_{\beta=0}^{M+1-\alpha}Z_{\alpha,\beta}^{M+1}$$
$$\times\sum_{i=1}^{N-(M+1)}\sum_{k=2}^{N-(M+1)}\sum_{j=0}^{N-i-(M+1)}\sum_{l=0}^{N-k-(M+1)}(-1)^{i+j+k+l}\Delta^{2(i+k+2\alpha)}(1-\Delta^2)^{j+l+2\beta}$$
$$\times\frac{[2(m+N+i+j+\alpha+\beta)-1]!!}{[2(i+\alpha)-1)!!\,[N-i-j-(M+1)]!\,(i-1)!\,j!\,(m+j+\beta)!}$$
$$\times\frac{[2(m+N+k+l+\alpha+\beta)-1]!!}{[2(k+\alpha)-3)!!\,[N-k-l-(M+1)]!\,(k-2)!\,l!\,(m+l+\beta)!}$$
$$\times\frac{(m+j+l+\beta)!\,[2(i+k+\alpha)-5)!!}{[2(m+i+j+k+l+\alpha+\beta+M+1)-1]!!}.\tag{3.20}$$

Comparing (3.20) to (3.9), we have found the relationship between $\mathcal{P}_N^M$ and $\mathcal{P}_N^{M+1}$

$$\mathcal{P}_N^{M+1}=[N-(M+1)]\mathcal{P}_N^M.\tag{3.21}$$

In other words, we have proved that

$$\mathcal{S}_3=\mathcal{P}_N^0=\frac{1}{(N-1)}\mathcal{P}_N^1=\frac{1}{(N-1)(N-2)}\mathcal{P}_N^2=\ldots=\frac{1}{(N-1)!}\mathcal{P}_N^{N-2}.\tag{3.22}$$

A remarkable property of the summation (3.20) is that, when $M=N-2$, the indices (i,j) and the indices (α,β) become decoupled and, more significantly, the indices (k,l) are eliminated in the summation. It follows that the summation (3.20) at $M=N-2$ can be carried out explicitly

$$\mathcal{P}_N^{N-2} = \left\{ \sum_{\alpha=0}^{N-2} \sum_{\beta=0}^{N-2-\alpha} Z_{\alpha,\beta}^{N-2} \Delta^{4(\alpha+1)} (1-\Delta^2)^{2\beta} \frac{[2(m+N+\alpha+\beta)+3]!!}{(2\alpha+1)!!\,(m+\beta)!} \right\} \times \left\{ \sum_{i=1}^{2} \sum_{j=0}^{2-i} \Delta^{2i} (1-\Delta^2)^j \left[\frac{(-1)^{i+j}}{(i-1)!\,j!\,(2-i-j)!} \right] \right\}.$$

For any given parameters, $\mathcal{P}_N^{N-2}$ is identically zero because

$$\sum_{i=1}^{2} \sum_{j=0}^{2-i} \left[\frac{\sigma^{2i}(1-\sigma^2)^j (1-\epsilon^2)^i}{(1-\sigma^2\epsilon^2)^{i+j}} \right] \left[\frac{(-1)^{i+j}}{(i-1)!\,j!\,(2-i-j)!} \right] \equiv 0.$$

This implies, by the recurrence relation (3.22), that $\mathcal{S}_3 \equiv 0$.

IV. COMPLETENESS OF THE POINCARÉ EIGENFUNCTION

A fundamental mathematical question is completeness of the set of eigenfunctions of the Poincaré equation given by the new Poincaré polynomials (2.17)–(2.19). If the Poincaré eigenfunction is complete, it would revolutionize the mathematical analysis in many geophysical and astrophysical problems in which the effect of rotation is critically important and the relevant geometry is spheroidal.

Nearly all the existing analyses for geophysical and astrophysical fluid dynamical problems in rotating spherical or spheroidal systems employ the Legendre polynomial (for example, Chandrasekhar, 1961; Zhang, 1992). A major disadvantage in using the Legendre polynomial is that the rotational effect couples all the orders of the Legendre polynomial together. This makes the mathematical analysis using the Legendre polynomial in rotating systems rather complicated. The undesirable coupling comes from the fact that the Legendre polynomial is not associated with the differential operator in rotating systems. The Poincaré polynomials such as (2.17)–(2.19) would replace the Legendre polynomial to provide an extremely powerful basis for the mathematical analysis in rotating spherical or spheroidal systems.

It is unfortunate, however, that we find the mathematical proof for the completeness of the set of eigenfunctions of the Poincaré equation given by the new Poincaré polynomial (2.17)–(2.19) is too complicated to be tractable. We, therefore, look for numerical evidence indicating that the new Poincaré eigenfunction given by (2.17)–(2.19) is complete and can be used to expand an arbitrary velocity distribution in rotating spheroidal systems. We consider the problem of fluid motions in a rotating spheroid driven by an external force **F**, which is governed by the following two equations (Greenspan, 1968)

$$\frac{\partial \mathbf{V}}{\partial t} + 2\mathbf{e}_z \times \mathbf{V} + \nabla \Phi = \mathbf{F}, \tag{4.1}$$

$$\nabla \cdot \mathbf{V} = 0, \tag{4.2}$$

subject to the boundary condition

$$\mathbf{e}_\eta \cdot \mathbf{V} = 0 \quad \text{at } \eta = \sqrt{1-\epsilon^2}. \tag{4.3}$$

Generally speaking, it is a difficult task to solve (4.1)–(4.3) because of spheroidal geometry. However, assuming that the Poincaré eigenfunction given by (2.17)–(2.19) is complete, we can express solutions for (4.1) and (4.2) in the form

$$\mathbf{V} = \sum_{m,N,n} Z_{Nmn} \mathbf{V}_{Nmn} e^{\hat{i}m\phi}, \tag{4.4}$$

where the eigenvector $\mathbf{V}_{Nmn}$ are normalized such that

TABLE III. Numerical evidence for the completeness of the Poincaré polynomial. N_m denotes the largest N used in expansion (4.4), $l=3$ ($l=4$) uses the odd (even) Poincaré polynomial in the expansion.

N_m	$E(l=3)$	$E(l=4)$
5	0.0859	0.1594
6	0.0334	0.0572
7	0.0133	0.0192
8	0.0075	0.0105
9	0.0027	0.0031

$$\int_V |\mathbf{V}_{Nmn}|^2 dV = 1. \tag{4.5}$$

It follows that solutions of the problem defined by (4.1)–(4.3) in a spheroid is simply

$$\mathbf{V} = \sum_{m,N,n} \frac{\hat{i}}{2\sigma_{Nmn}} \left(\int_V \mathbf{F} \cdot \mathbf{V}^+_{Nmn} dV \right) \mathbf{V}_{Nmn} e^{\hat{i} m \phi}. \tag{4.6}$$

There are no difficulties to carry out the integral in (4.6) by using the explicit Poincaré polynomial found in this paper. The discovery of the explicit Poincaré polynomial thus offers a highly effective and efficient way to solve this rather difficult problem in a rotating spheroid of arbitrary eccentricity.

To test the completeness and the convergence of expansion (4.5), we consider a special case for a rotating fluid sphere ($\epsilon=0$) in which the flow motion is driven by

$$\mathbf{F} = \mathbf{e}_z \times \left[\nabla \frac{\partial (r\Psi)}{\partial r} - \mathbf{r} \nabla^2 \Psi \right], \tag{4.7}$$

where $\mathbf{r}$ is the position vector and

$$\Psi = r^l \sin(n\pi r) P_l^m(\cos\theta) e^{im\phi},$$

where $P_l^m(\cos\theta)$ is the standard Legendre polynomial. In this case, the exact solution for (4.1)–(4.3) with $\mathbf{F}$ given by (4.7) can be easily found and can be used to check the convergence of expansion (4.4). Our extensive calculations for various different cases strongly indicate that expansion (4.4) always converges to the exact solution. Two typical examples with $m=2$ and $n=2$ using the even and odd Poincaré polynomials are shown in Table III, in which the error E is defined by

$$E = \frac{1}{V} \int_V |\mathbf{V} - \mathbf{V}_{\text{exact}}| dV, \tag{4.8}$$

where $\mathbf{V}$ is given by the truncated expansion (4.4). There is clear numerical evidence suggesting the set of eigenfunctions given by the explicit Poincaré polynomial reported in this paper is complete.

V. SUMMARY

We have presented three significant new results on the classical Poincaré problem in this paper. First, an explicit polynomial as the general solution for the classical Poincaré problem in a spheroid of arbitrary eccentricity is found for the first time. Second, we have uncovered an intriguing integral property (3.4) that has important implications for the nonlinear wave theory in a rotating spheroid. It may also have important mathematical significance in connection with why an extremely complicated summation such as (3.20) vanishes identically and whether there exists

a simpler mathematical proof for (3.4). Thirdly, the possible completeness of the set of eigenfunctions given by the Poincaré polynomial opens an exciting new line in the research of many astrophysical fluid dynamical problems in a rotating spheroid. We are able to provide numerical evidence indicating that the Poincaré eigenfunction given by the Poincaré polynomials (2.17)–(2.19) is complete and can be used to expand an arbitrary velocity distribution in rotating spheroidal systems. However, a mathematical proof for the completeness of the Poincaré eigenfunction remains to be a challenging task.

An approach to nonstandard quantum mechanics

A. Raab[a)]
St.-Ilgener-Str. 2, 69190 Walldorf, Federal Republic of Germany

(Received 1 December 2003; accepted 3 September 2004; published 22 November 2004)

We use nonstandard analysis to formulate quantum mechanics in hyperfinite-dimensional spaces. Self-adjoint operators on hyperfinite-dimensional spaces have complete eigensets, and bound states and continuum states of a Hamiltonian can thus be treated on an equal footing. We show that the formalism extends the standard formulation of quantum mechanics. To this end we develop the Loeb-function calculus in nonstandard hulls. The idea is to perform calculations in a hyperfinite-dimensional space, but to interpret expectation values in the corresponding nonstandard hull. We further apply the framework to nonrelativistic quantum scattering theory. For time-dependent scattering theory, we identify the starting time and the finishing time of a scattering experiment, and we obtain a natural separation of time scales on which the preparation process, the interaction process, and the detection process take place. For time-independent scattering theory, we derive rigorously explicit formulas for the Møller wave operators and the S-matrix. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1812358]

I. INTRODUCTION

Quantum mechanics is conventionally formulated in a complex Hilbert space, $\mathcal{H}$. The possible states of a quantum system are associated with unit vectors in $\mathcal{H}$, and the observables are associated with self-adjoint linear operators on $\mathcal{H}$. A central role plays the Hamiltonian of the quantum system. The eigenvalues of the Hamiltonian are commonly interpreted as the energies of bound states of the system. Moreover, the values of the continuous part of the Hamiltonians spectrum are interpreted as the energies of "continuum" or scattering states. The interpretation is physically motivated, and we use the term "continuum state" in a physical sense in the following. While bound states can be identified with eigenvectors of the Hamiltonian, appropriate vectors do not exist in $\mathcal{H}$ for continuum states. Continuum states can be treated in the conventional Hilbert-space framework only approximately.[1]

The probably most prominent approach to solve this problem is the rigged-Hilbert-space formalism.[2–4] Within the rigged Hilbert-space formalism, continuum states are associated with linear functionals on a dense subspace $\mathcal{M}$ of $\mathcal{H}$. The linear functionals belong to the dual space $\mathcal{M}'$ of $\mathcal{M}$, which is a locally convex space and not a Hilbert space. In particular, we do not have a scalar product at hand. The rigged-Hilbert-space formalism is thus more complicated than the Hilbert-space formalism, and more efforts are required in mathematically rigorous applications. There exist further similar approaches to model continuum states, e.g., approaches that introduce lattices of Hilbert spaces or partial-inner-product spaces. These two approaches together with the rigged-Hilbert-space approach can be classified as "super-Hilbert-space" formalisms.[2] The main idea in common is to use linear functionals on (dense) subspaces of $\mathcal{H}$, and the mathematical complications are consequently of the same nature. If we look for an appropriate formalism, which includes a scalar product, we still face a mathematical-modelling problem.

[a)]Electronic mail: andreas.raab.mail@web.de

This paper suggests an approach to nonstandard quantum mechanics. This means that we use nonstandard analysis (NSA) to construct a framework where quantum mechanics can be formulated without the drawbacks mentioned above. Work in this direction is done in Ref. 5. However, this paper presents another approach that focuses more on eigenvector expansions. Eigenvector expansions are of great importance in practical applications since they simplify calculations. Within the approach, we are able to treat bound and continuum states on the same footing without losing the scalar product. However, we require a basic knowledge of NSA for the construction as it is presented in Ref. 6 (Ref. 7), for example. Nevertheless, a few remarks on NSA are made in the following.

NSA has its origin in logics and provides an astonishing rich formalism. The author of this paper believes that we should rather speak of nonstandard methods than of NSA since NSA suggests an application of nonstandard methods to analysis, but the term NSA is commonly used in the literature in a general sense. In this sense, NSA can be applied to a wide range of mathematical areas, e.g., real analysis, topology, measure theory, functional analysis, etc. NSA introduces rigorously many interesting objects like infinitesimals, infinitely large numbers, and functions that behave like Dirac's delta distribution. The author of this paper believes that these objects — which are not available in standard mathematics — make NSA rather attractive for physical applications.

The basic tool of NSA is the transfer principle. The transfer principle enables us to transfer sets and formulas from standard to nonstandard frameworks. Roughly speaking, every formula in a standard framework is true if, and only if, the corresponding transferred formula is true in the nonstandard framework. For the application of the transfer principle we however have to formulate formulas in a rather formal way marked by logics. The formal language appears laborious from the viewpoint of the concrete application, but we need the language to ensure rigorous results.

The paper is organized as follows. In Sec. II, the basic framework is introduced, and we start discussing its relationship to the standard framework used in quantum mechanics. We continue the discussion in Sec. III where we derive the required nonstandard function calculus. We establish then the final form of the approach to nonstandard quantum mechanics in Sec. IV. In Sec. V, we apply the framework to nonrelativistic scattering theory. We discuss first the impact of the approach on time-dependent scattering theory, and derive then explicit formulas within time-independent scattering theory. Finally, we summarize the results and conclude in Sec. VI.

II. NONSTANDARD EXTENSIONS

A. Spatial and operational extensions

NSA basically introduces extensions of superstructures that contain for a given context all mathematical objects of interest. Superstructures usually contain real numbers, complex numbers, functions, etc. The extension of a superstructure $\mathcal{V}$ is actually an injective mapping of $\mathcal{V}$ onto another superstructure $\mathcal{W}$. We note that there exist different types of extensions, but for applications of NSA polysaturated extensions are probably most convenient. For this reason, we assume a polysaturated extension ${}^\star:\mathcal{V}\to\mathcal{W}$ of a superstructure $\mathcal{V}$ that contains every standard mathematical object we will consider in this paper. Roughly speaking, the extension allows us to switch from the "standard world" $\mathcal{V}$ to the "nonstandard world" $\mathcal{W}$, in which we can use our standard mathematical objects of interest more conveniently, as we will see. In particular, $\mathcal{V}$ contains a complex Hilbert space $\mathcal{H}$ and linear operators on $\mathcal{H}$, which implies that appropriate counterparts are available in the "nonstandard world" $\mathcal{W}$. Moreover, for the sake of convenience we follow the common practice and drop the prefix * from many nonstandard objects when there is no ambiguity. For example, we write $r+s$ instead of $r^\star+s$ for $r,s\in{}^\star\mathbb{R}$. We obtain for our example a sensible simplification of notation since two hyper-real numbers can be added in the same manner as two real numbers.

As a consequence of polysaturation, there exists a hyperfinite-dimensional space H which externally contains $\mathcal{H}$,[8] i.e., $\{{}^\star x:x\in\mathcal{H}\}\subset H$. For the sake of convenience we simply write

$\mathcal{H} \subset H \subset {}^\star\mathcal{H}$. We use this result as an avenue to a nonstandard framework for quantum mechanics. Beside the well-known advantages of NSA, which are sketched in Sec. I, this approach has another important advantage: The transfer principle allows us to apply the results of linear algebra in finite-dimensional spaces to the hyperfinite-dimensional space H. We note that this idea is already known in the literature for a long time.[9,10]

The main goal in the following is to show that the formulation of quantum mechanics in an appropriate hyperfinite-dimensional space yields an extension of the standard formulation of quantum mechanics. We choose however a more general setting than outlined above, and assume only a dense subspace $\mathcal{M}$ of $\mathcal{H}$. We will see in Sec. IV B that this approach is quite convenient when we construct the hyperfinite dimensional space H in an example. However, by polysaturation there exists a hyperfinite-dimensional space H which externally contains $\mathcal{M}$, i.e., $\mathcal{M} \subset H \subset {}^\star\mathcal{M} \subset {}^\star\mathcal{H}$.

Proposition 1: Let $H \subset {}^\star\mathcal{H}$ be an internal Hilbert space that externally contains a dense subspace $\mathcal{M}$ of $\mathcal{H}$, and let O denote the projection of ${}^\star\mathcal{H}$ onto H, then ${}^\star x \approx O^\star x$ for all $x \in \mathcal{H}$.

Proof: Assume $x \in \mathcal{H}$. Since $\mathcal{M}$ is dense in $\mathcal{H}$ the internal statement $(\exists y \in H)\|{}^\star x - y\| < 1/n$ is true for all $n \in \mathbb{N}$. By the overflow principle there exists an infinite $m \in {}^\star\mathbb{N}$ for which $(\exists y \in H)\|{}^\star x - y\| < 1/m$ holds. Moreover, the (transferred) projection theorem states that $\|{}^\star x - O^\star x\| \leqslant \|{}^\star x - y\| < 1/m$.[1] □

Let us proceed with our discussion. As in proposition 1, let O denote the projection of ${}^\star\mathcal{H}$ onto H. O can be defined (as usual) by an orthonormal basis of H, as we show in the appendix. Moreover, let A be a self-adjoint operator with domain $\mathcal{D}(A)$, for which $\mathcal{M} \subset \mathcal{D}(A) \subset \mathcal{H}$ holds. Using the transfer principle we define the restriction of ${}^\star A$ to H by $B = O^\star A O$, and $B^\star x = O^\star(Ax) \approx {}^\star(Ax)$ for all $x \in \mathcal{M}$. B can thus be seen as a nonstandard extension of the restriction of A to $\mathcal{M}$. As shown in the Appendix, B is an internal hyperfinite-rank operator, and there exists an eigensystem $\{(\lambda_i, x_i)\}_{i=1}^h$ for B, which yields the representation

$$(\forall x, y \in H) \quad \langle x, By \rangle = \sum_{i=1}^{h} \lambda_i \langle x, x_i \rangle \langle x_i, y \rangle.$$

We note that h is the (nonstandard) dimension of H.

Our construction shows that there exist self-adjoint hyperfinite-rank operators, which yield extensions of standard self-adjoint operators in a certain sense. The relation is however rather weak at the moment since we do not know how the spectra and the function calculus of these operators are related. In particular, we may ask if nonstandard eigenvalues and nonstandard eigenvectors can be interpreted in a sensible way. To discuss these questions more thoroughly we introduce nonstandard hulls, which are important tools in NSA.[8] From a physical point of view, the introduction of nonstandard hulls is motivated by the assumption that infinitesimally different states cannot be distinguished in a measurement.

The definition of the nonstandard hull ${}^oH$ of the hyperfinite-dimensional space H introduces an equivalence relation on the set of finite nonstandard vectors, $\mathrm{fin}(H) = \{x \in H : \|x\| \in \mathrm{fin}({}^\star\mathbb{R})\}$. We note that $\mathrm{fin}({}^\star\mathbb{R})$ is the set of finite hyper-reals. Two vectors are equivalent if their difference has infinitesimal norm. The nonstandard hull ${}^oH$ of the space H is given as the quotient

$${}^oH = \mathrm{fin}(H)/H_0, \quad H_0 = \{x \in H : \|x\| \approx 0\},$$

$$\|{}^o x\| = \mathrm{st}(\|x\|), \quad \langle {}^o x, {}^o y \rangle = \mathrm{st}(\langle x, y \rangle). \tag{1}$$

${}^oH$ is a Hilbert space, and $\mathcal{H}$ is a closed subspace of ${}^oH$ by proposition 1. Especially, reconsidering our example above the equation $B^\star x = O^\star(Ax) \approx {}^\star(Ax)$ yields $Ax = {}^o(Bx)$ for all $x \in \mathcal{M}$. We note that we adopt the notation ${}^oH$ for the nonstandard hull of H as it is used in Refs. 9 and 10, instead of the notation $\hat{H}$ that seems to be more common.[6] The author of this paper believes that we gain a more uniform notation since, for example, for the standard part ${}^o r = \mathrm{st}(r)$ of $r \in \mathrm{fin}({}^\star\mathbb{R})$ we could also write $\hat{r}$, meaning an element of the nonstandard hull of ${}^\star\mathbb{R}$.

Furthermore, nonstandard hulls are defined also for finitely bounded nonstandard linear operators. If A is a bounded operator on $\mathcal{H}$, then $B=O^{\star}AO$ is finitely bounded and its nonstandard hull is defined as

$$
\begin{aligned}
{}^{o}B\,{}^{o}x &= {}^{o}(Bx) \quad \forall\, x \in \mathrm{fin}(H), \\
\|{}^{o}B\| &= \mathrm{st}(\|B\|).
\end{aligned}
\tag{2}
$$

Since A is bounded we obtain ${}^{\star}(Ax)\approx O^{\star}AO^{\star}x$ for $x\in\mathcal{H}$. Thus, ${}^{o}B$ is a self-adjoint bounded operator on ${}^{o}H$, which extends A, i.e., ${}^{o}Bx={}^{o}(B^{\star}x)=Ax$ for all $x\in\mathcal{H}$. We note that operational nonstandard extensions of this type are already discussed in Ref. 10. In particular, the relationship between the spectral resolution of bounded self-adjoint operators and their nonstandard extension is investigated. However, we come back to these results in Sec. II B.

B. Spectral properties of operator extensions

Hyperfinite-rank operators have convenient spectral properties, which are determined by linear algebra. If we consider a nonstandard extension B of a self-adjoint operator A as constructed in Sec. II A then we may naturally ask how the eigenvalues and eigenvectors of the hyperfinite-rank operator B are related to the spectral resolution of A. Let us focus first on the eigenvalues.

Lemma 1: Let B be a normal hyperfinite-rank operator, and let $\lambda\in\mathbb{C}$. Assume that for each $n\in\mathbb{N}$ there exists an $x_n\in H$ for which $\|x_n\|\approx 1$ and $\|\lambda x_n - Bx_n\|<1/n$ holds, then there exists a $\lambda'\in\sigma(B)$, and $\lambda\approx\lambda'$.

Proof: As shown in the Appendix, B has an eigensystem $\{(\lambda_i,x_i)\}_{i=1}^{h}$. Fix $\epsilon\in\mathbb{R}_+$, $\epsilon<1$, then

$$
(\forall\, n\in\mathbb{N})(\exists x\in H)\left(\|x\|>(1-\epsilon)\wedge\|\lambda x - Bx\|\leqslant\frac{1}{n}\right).
$$

By the overspill principle there exists an infinite $m\in{}^{\star}\mathbb{N}$ for which

$$
(\exists x_0\in H)\left(\|x_0\|>(1-\epsilon)\wedge\|\lambda x_0 - Bx_0\|\leqslant\frac{1}{m}\right)
$$

is true. Assume that there exists an $\epsilon'\in\mathbb{R}_+$ for which $|\lambda-\lambda'|\geqslant\epsilon'$ holds for all $\lambda'\in\sigma(B)$. Then,

$$
\|Bx_0-\lambda x_0\|^2=\sum_{i=1}^{h}|\lambda-\lambda_i|^2|\langle x_i,x_0\rangle|^2\geqslant(\epsilon')^2\sum_{i=1}^{h}|\langle x_i,x_0\rangle|^2=(\epsilon')^2\,\|x_0\|^2>(\epsilon')^2(1-\epsilon)^2
$$

and we obtain the contradiction $\|Bx_0-\lambda x_0\|>\epsilon'(1-\epsilon)>1/m$. There thus exists a $\lambda'\in\sigma(B)$ for which $\lambda\approx\lambda'$ holds. □

Proposition 2:

(1) Let B be a nonstandard extension of a self-adjoint operator A as constructed in Sec. II A, then for each $\lambda\in\sigma(A)$ there exists a $\lambda'\in\sigma(B)$ for which $\lambda\approx\lambda'$ holds, i.e., $\sigma(A)\subset{}^{o}NS(\sigma(B))$.
(2) Let B be a finitely bounded normal hyperfinite-rank operator, then $\sigma({}^{o}B)={}^{o}\sigma(B)$.

Proof:

(1) Let $\lambda\in\sigma(A)$, then for each $n\in\mathbb{N}$ there exists an $x_n\in\mathcal{M}$ for which $\|x_n\|=1$ and $\|(\lambda-A)x_n\|<1/n$ holds. Since $\mathcal{M}$ is externally contained in H, we obtain $\|(\lambda-B)^{\star}x_n\|\leqslant 1/n$ for each $n\in\mathbb{N}$, and by lemma 1 there exists a $\lambda'\in\sigma(B)$ with $\lambda\approx\lambda'$.
(2) We note that this statement can be proved also with the help of lemma 1. However, the statement is proved in a more general form in Ref. 8, and therefore we omit the proof. □

The first part of proposition 2 shows that the spectrum of A is approximated well by the eigenvalues of its nonstandard extension B. We can draw from this result a remarkable conclusion.

Let $\lambda \in \sigma(A)$, then there exists an eigenvalue $\lambda' \approx \lambda$ of B. Since B has a complete set of (normed) eigenvectors, there exists an $x \in H$ for which $Bx = \lambda' x$ holds. For each $y \in \mathcal{M}$ we obtain thus

$$\langle {}^o x, Ay \rangle = {}^o\langle x, B^\star y \rangle = st(\lambda')\,{}^o\langle x, {}^\star y \rangle = \lambda \langle {}^o x, y \rangle. \tag{3}$$

Equations of this type can usually be formulated only as eigenfunctional equations in super-Hilbert-space formalisms. The treatment of continuum states is therefore more complicated than the treatment of bound states in these frameworks. In a hyperfinite-dimensional space we can however treat both types of states on an equal footing. We note that work in this direction is also presented in Ref. 5 where the concept of ultraeigenvectors is introduced. The concept leads to similar equations, but ultraeigenvectors are not necessarily eigenvectors of a nonstandard extension. In particular, we generally do not obtain an eigenvector basis, which is simpler to use in applications as compared to projection-valued measures.

Moreover, if the operator A is bounded in proposition 2 then the nonstandard hull ${}^oB$ of B is a bounded self-adjoint operator on ${}^oH$. This case is extensively studied in Refs. 9 and 10. In particular, the operator A is then the restriction of ${}^oB$ to $\mathcal{H}$, and the projection-valued measure associated with A can be retrieved with the help of the eigenvectors of B. Unfortunately, most of the self-adjoint operators occurring in applications are unbounded. Also, we do not know how the function calculus of A is related to the function calculus of B, especially when we consider noncontinuous functions. We therefore use a more general approach that is related to nonstandard integration theory.

III. LOEB-FUNCTION CALCULUS

In our approach to nonstandard function calculus we introduce first projection-valued Loeb measures that are closely related to Loeb measures. The relationship is analogous to the relationship of standard projection-valued measures to finite Borel measures. We use projection-valued Loeb measures to prove a nonstandard spectral theorem and to establish the Loeb-function calculus. Finally, we use the results to introduce generalized nonstandard hulls, which we use in Sec. IV for the further discussion.

A. Projection-valued Loeb measures

Let $\mathcal{B}$ denote the set of Borel subsets of $\mathbb{R}$, and let P be a finite probability measure on $\mathcal{B}$. The associated probability space $(\mathbb{R}, \mathcal{B}, P)$ transfers to a finitely additive internal probability space, $({}^\star\mathbb{R}, {}^\star\mathcal{B}, {}^\star P)$. To be more general, we replace ${}^\star P$ by a finitely additive internal probability function μ, and consider the probability space $({}^\star\mathbb{R}, {}^\star\mathcal{B}, \mu)$. An important result of nonstandard measure theory is the construction of a Loeb (probability) space out of $({}^\star\mathbb{R}, {}^\star\mathcal{B}, \mu)$,[11] i.e., there exists a standard (σ-additive) probability space $({}^\star\mathbb{R}, {}^\star\mathcal{B}_L, \mu_L)$ such that

(1) ${}^\star\mathcal{B}_L$ is a σ-algebra with ${}^\star\mathcal{B} \subset {}^\star\mathcal{B}_L \subset \mathcal{P}({}^\star\mathbb{R})$,
(2) ${}^o\mu = \mu_L$ on ${}^\star\mathcal{B}$.

The sets $\Omega \in {}^\star\mathcal{B}_L$ are called Loeb measurable, and μ_L is called a Loeb measure. The σ-algebra ${}^\star\mathcal{B}_L$ is however related to the finitely additive internal probability function μ, i.e., we should rather write ${}^\star\mathcal{B}_L(\mu)$. To obtain a more general setting we introduce a smaller σ-algebra. Let Λ denote the set of finitely additive internal probability functions on ${}^\star\mathcal{B}$. The intersection $\mathcal{A} = \cap_{\mu \in \Lambda} {}^\star\mathcal{B}_L(\mu)$ is a σ-algebra, and contains the universally Loeb-measurable sets. For each $\mu \in \Lambda$ the space $({}^\star\mathbb{R}, \mathcal{A}, \mu_L)$ is a standard probability space. Moreover, ${}^\star\mathcal{B} \subset \mathcal{A}$ and ${}^o\mu = \mu_L$ on ${}^\star\mathcal{B}$.

Let χ_Ω denote the characteristic function of a set $\Omega \in {}^\star\mathcal{B}$. We may, for example, use the eigensystem of a normal hyperfinite-rank operator B to define a finitely additive internal projection-valued probability function:

$$E_\Omega = \chi_\Omega(B) = \sum_{\lambda_i \in \Omega} |x_i\rangle\langle x_i| = \sum_{i=1}^{h} \chi_\Omega(\lambda_i)|x_i\rangle\langle x_i| \quad (\Omega \in {}^\star\mathcal{B}). \tag{4}$$

We note that $\{E_\Omega\}$ is the projection-valued * measure of B. Generally, if we assume a finitely additive internal projection-valued probability function $\{E_\Omega\}_{\Omega \in {}^\star\mathcal{B}}$, e.g., a projection-valued * measure that is associated with an internal normal operator, then we can define for each normed vector $x \in H$, $\|x\|=1$, a probability function $\mu^{(x)}$ on ${}^\star\mathcal{B}$:

$$\mu^{(x)}(\Omega) = \|E_\Omega x\|^2 = \langle x, E_\Omega x\rangle \quad (\Omega \in {}^\star\mathcal{B}). \tag{5}$$

We denote the associated Loeb measure by $\mu_L^{(x)}$. Moreover, we introduce complex-valued Loeb measures. For $x,y \in \mathrm{fin}(H)$ let

$$\mu^{(x,y)}(\Omega) = \langle x, E_\Omega y\rangle \quad (\Omega \in {}^\star\mathcal{B}). \tag{6}$$

Since E_Ω is a projection, $\mu^{(x,y)}$ can be decomposed into four finitely additive positive internal functions on ${}^\star\mathcal{B}$ by polarization,[1]

$$\mu^{(x,y)} = \sum_{k=1}^{4} a_k \nu^{(k)}, \quad a_k \in {}^\star\mathbb{C}.$$

If $\nu^{(k)} \neq 0$ we can use the normalization $\nu^{(k)}({}^\star\mathbb{R})=1$ without any restriction. Each nonzero $\nu^{(k)}$ can be extended to an ordinary Loeb measure $\nu_L^{(k)}$. If $\mu^{(x,y)} \neq 0$ we can thus construct a finite complex-valued Loeb measure, $\mu_L^{(x,y)}$, that is the sum of up to four ordinary Loeb measures multiplied by appropriate complex factors. For the sake of completeness we define further $\mu_L^{(x,y)}=0$ if $\mu^{(x,y)}=0$.

The family of nonstandard hulls $\{{}^oE_\Omega\}_{\Omega \in {}^\star\mathcal{B}}$ is a family of projections on ${}^oH$, and $\mu_L^{(x,y)}(\Omega) = \langle {}^ox, {}^oE_\Omega {}^oy\rangle$ for all $x,y \in \mathrm{fin}(H)$, $\Omega \in {}^\star\mathcal{B}$. This result motivates us to extend the definition of ${}^oE_\Omega$ to all sets $\Omega \in \mathcal{A}$. For $\Omega \in {}^\star\mathcal{B}$ we denote the range of ${}^oE_\Omega$ by $R(\Omega)$, which is a closed subspace. For $\Omega \in \mathcal{A}$ let ${}^\star\mathcal{B}_\Omega = \{\Omega' \in {}^\star\mathcal{B} : \Omega' \subset \Omega\}$. We extend $R(\Omega)$ to $\mathcal{A}$ by

$$R(\Omega) = \mathrm{cl}\left(\bigcup_{\Omega' \in {}^\star\mathcal{B}_\Omega} R(\Omega') \right), \tag{7}$$

and define ${}^oE_\Omega$ as the projection of ${}^oH$ onto $R(\Omega)$. Using a statement in Ref. 12 on families of projections we conclude for $x \in H$, $\|x\|=1$,

$$\langle {}^ox, {}^oE_\Omega {}^ox\rangle = \sup_{\Omega' \in {}^\star\mathcal{B}_\Omega} \langle {}^ox, {}^oE_{\Omega'} {}^ox\rangle = \sup_{\Omega' \in {}^\star\mathcal{B}_\Omega} \mu_L^{(x)}(\Omega') = \mu_L^{(x)}(\Omega). \tag{8}$$

Theorem 2: Let $\{E_\Omega\}_{\Omega \in {}^\star\mathcal{B}}$ be a finitely additive internal projection-valued probability function, then $\{{}^oE_\Omega\}_{\Omega \in \mathcal{A}}$ defines a projection-valued Loeb measure.

Proof: We show that the family $\{{}^oE_\Omega\}_{\Omega \in \mathcal{A}}$ has the properties of a projection-valued measure.

(a) Assume $\Omega_1, \Omega_2 \in \mathcal{A}$, and $\Omega_1 \cap \Omega_2 = \emptyset$, then $\Omega_1' \cap \Omega_2' = \emptyset$ and $R(\Omega_1') \perp R(\Omega_2')$ for all $\Omega_1' \in {}^\star\mathcal{B}_{\Omega_1}$, $\Omega_2' \in {}^\star\mathcal{B}_{\Omega_2}$. Thus, $R(\Omega_1') \perp R(\Omega_2)$ for all $\Omega_1' \in {}^\star\mathcal{B}_{\Omega_1}$, $R(\Omega_1) \perp R(\Omega_2)$, and ${}^oE_{\Omega_1} {}^oE_{\Omega_2} = {}^oE_{\Omega_2} {}^oE_{\Omega_1} = 0$.

(b) Assume $\Omega_1, \Omega_2 \in \mathcal{A}$, and $\Omega_1 \subset \Omega_2$, then $R(\Omega_1) \subset R(\Omega_2)$, and ${}^oE_{\Omega_1} {}^oE_{\Omega_2} = {}^oE_{\Omega_2} {}^oE_{\Omega_1} = {}^oE_{\Omega_1}$.[12]

(c) Assume $\Omega_n \in \mathcal{A}$, $n \in \mathbb{N}$, and $\Omega_n \cap \Omega_m = \emptyset$ if $n \neq m$. Let $\Omega = \cup_n \Omega_n$, and let $P_N = \Sigma_{n=1}^N {}^oE_{\Omega_n}$. P_N is a projection since P_N is self-adjoint and $P_N^2 = P_N$ by (a).[1] For $x \in H$, $\|x\|=1$, we obtain by (b),

$$\|({}^oE_\Omega - P_N){}^ox\|^2 = \langle {}^ox, ({}^oE_\Omega - P_N){}^ox\rangle = \mu_L^{(x)}(\Omega) - \sum_{n=1}^{N} \mu_L^{(x)}(\Omega_n),$$

$$\lim_{N\to\infty}\|({}^oE_\Omega - P_N)^o x\|^2 = 0.$$

(d) Assume $\Omega_1,\Omega_2 \in \mathcal{A}$. Using (c) we obtain ${}^oE_{\Omega_1\cap\Omega_2} + {}^oE_{\Omega_1\setminus\Omega_2} = {}^oE_{\Omega_1}$, and using (a), (b) we obtain ${}^oE_{\Omega_1}{}^oE_{\Omega_2} = ({}^oE_{\Omega_1\cap\Omega_2} + {}^oE_{\Omega_1\setminus\Omega_2}){}^oE_{\Omega_2} = {}^oE_{\Omega_1\cap\Omega_2} = {}^oE_{\Omega_2}({}^oE_{\Omega_1\cap\Omega_2} + {}^oE_{\Omega_1\setminus\Omega_2}) = {}^oE_{\Omega_2}{}^oE_{\Omega_1}$.

B. Spectral theorem

We have seen in Sec. III A that a projection-valued ★ measure extends to a projection-valued Loeb measure $\{{}^oE_\Omega\}_{\Omega\in\mathcal{A}}$ on ${}^oH$. We now use this result to formulate a nonstandard spectral theorem. We note that the theorem is obtained not by transfer of a standard spectral theorem. It is rather an analog associated with Loeb integration theory.

We call a complex-valued function $f: {}^\star\mathbb{R}\to\mathbb{C}$ $\mathcal{A}$-measurable or Loeb measurable if $f^{-1}(\Omega) \in \mathcal{A}$ for each Borel set $\Omega\subset\mathbb{C}$. We note that st$(\cdot)$ is $\mathcal{A}$-measurable.[11]

Theorem 3: Let B be an internal self-adjoint operator on an internal Hilbert space H, let $\{{}^oE_\Omega\}_{\Omega\in\mathcal{A}}$ be the projection-valued Loeb measure associated with the projection-valued ★ measure of B, and let f be a complex-valued $\mathcal{A}$-measurable function, then $f(B)=\int f\ \mathrm{d}\,{}^oE$ is a normal operator on ${}^oH$, and $\sigma(f(B))\subset \mathrm{cl}(f(\sigma(B)))$.

Proof: First we note that if two vectors $x,y\in \mathrm{fin}(H)$ are approximately equal, $x\approx y$, then the associated Loeb measures are equal, $\mu_L^{(x)}=\mu_L^{(y)}$. Consequently, for $x,y\in{}^oH$ the Loeb measure $\langle x,{}^oE_\Omega y\rangle$ $(\Omega\in\mathcal{A})$ is well defined, and we use the notation $\mu_L^{(x,y)}=\langle x,{}^oE_\Omega y\rangle$ in this proof. The domain of f is given by

$$D(f(B)) = \left\{ x\in {}^oH: \int |f|^2\ \mathrm{d}\mu_L^{(x)} < \infty \right\}. \tag{9}$$

For $n\in\mathbb{N}$ let $\Omega_n=\{r\in{}^\star\mathbb{R}: |f(r)|\leqslant n\}$. Each Ω_n is measurable, $\Omega_n\in\mathcal{A}$. Let $x\in{}^oH$, and let $x_n = {}^oE_{\Omega_n}x$, then $x_n\in D(f(B))$ for all $n\in\mathbb{N}$, and $x=\lim_n x_n$. Hence, $\mathrm{cl}(D(f(B))={}^oH$. Let $f(B)^\dagger$ denote the adjoint of $f(B)$, and let z^* denote the complex conjugate of $z\in\mathbb{C}$. For $x\in D(f(B))$, $y\in D(f(B)^\dagger)$ we obtain

$$\langle x, f(B)^\dagger y\rangle = \langle f(B)x, y\rangle = \langle y, f(B)x\rangle^* = \left(\int f\ \mathrm{d}\mu_L^{(y,x)}\right)^* = \int f^*\ \mathrm{d}\mu_L^{(x,y)} = \langle x, f^*(B)y\rangle, \tag{10}$$

i.e., $f(B)^\dagger = f^*(B)$, $D(f(B)^\dagger)=D(f(B))$, and $f(B)$ is normal.

Let $\lambda\in\sigma(f(B))$, and let $\epsilon > o$. Since $f(B)$ is normal there exists an $x\in{}^oH$ for which $\|x\|=1$ and

$$\|(f(B)-\lambda)x\|^2 = \int |f-\lambda|^2\ \mathrm{d}\mu_L^{(x)} < \epsilon^2$$

holds. Let $\Omega_\epsilon=\{r\in{}^\star\mathbb{R}: |f(r)-\lambda|<\epsilon\} = f^{-1}(\{r\in\mathbb{R}: |r-\lambda|<\epsilon\})$, then $\mu_L^{(x)}(\Omega_\epsilon)>0$, and thus ${}^oE_{\Omega_\epsilon}\neq 0$. Moreover, there exists an $\Omega'_\epsilon\in{}^\star\mathcal{B}_{\Omega_\epsilon}$ for which $\mu_L^{(x)}(\Omega'_\epsilon)>0$ holds. Thus, $E_{\Omega'_\epsilon}\neq 0$ and $\Omega'_\epsilon\cap\sigma(B)\neq\emptyset$. Choose $\omega_\epsilon\in\Omega'_\epsilon\cap\sigma(B)$, then $|f(\omega_\epsilon)-\lambda|<\epsilon$, and thus $\lambda\in\mathrm{cl}(f(\sigma(B)))$. □

Corollary 1: Assume the conditions of theorem 3. If B is additionally a hyperfinite-rank operator, then

(1) $\sigma(f(B))=\mathrm{cl}(f(\sigma(B)))$,
(2) $\sigma({}^og(B))={}^og(\sigma(B))$ for finitely bounded $g\in{}^\star\mathcal{B}(\mathbb{R})$.

Proof:

(1) Let $\lambda\in\sigma(B)$, and let x be a corresponding eigenvector, then ${}^oE_{\{\lambda\}}{}^ox = {}^ox$, $f(B)^ox = f(\lambda)^ox$, and $f(\lambda)\in\sigma(f(B))$. Since $\sigma(f(B))$ is closed we obtain $\mathrm{cl}(f(\sigma(B)))\subset\sigma(f(B))$. The assertion follows now from theorem 3.

(2) Let $g \in {}^\star\mathcal{B}(\mathbb{R})$ be finitely bounded. Since B is a hyperfinite-rank operator we obtain $\sigma(g(B))=g(\sigma(B))$. Thus, $\sigma({}^o g(B))={}^o\sigma(g(B))={}^o g(\sigma(B))$ by proposition 2. □

If we consider in theorem 3 a real-valued function f, then we obtain a self-adjoint operator $f(B)$. For this operator, the standard spectral theorem yields the standard spectral representation. Since theorem 3 states an alternative nonstandard representation of $f(B)$ we clarify now the relationship between both representations.

Theorem 4: Let B be an internal self-adjoint operator on an internal Hilbert space H, let f be a real-valued $\mathcal{A}$-measurable function, and let g be a Borel function, then $g(f(B))=(g\circ f)(B)$.

Proof: For a Borel set $\Omega \in \mathcal{B}$ let $F_\Omega = {}^oE_{f^{-1}(\Omega)}$. F_Ω defines a projection-valued measure, and for $x \in \mathrm{fin}(H)$ we obtain

$$\mu_{f,L}^{(x)}(\Omega) = \mu_L^{(x)}(f^{-1}(\Omega)) = \langle {}^o x, {}^oE_{f^{-1}(\Omega)}\, {}^o x\rangle = \langle {}^o x, F_\Omega\, {}^o x\rangle.$$

Let us assume first that g is bounded, then we obtain for $\Omega \in \mathcal{B}$,

$$\int_\Omega g \, \mathrm{d}\mu_{f,L}^{(x)} = \int_{f^{-1}(\Omega)} g\circ f \, \mathrm{d}\mu_L^{(x)}.$$

We conclude that $\int g\, \mathrm{d}F = \int g\circ f \, \mathrm{d}\, {}^oE$. If we apply pointwise-convergence arguments the latter equation is valid for any Borel function g. In particular, for $g=i\mathrm{d}$ we obtain $f(B)=\int \omega \, \mathrm{d}F_\omega$, which is just the standard spectral representation. Since $\int g\, \mathrm{d}F = g(\int \omega \, \mathrm{d}F_\omega) = g(f(B))$ we obtain the statement of the theorem. □

We note that theorem 4 reveals the relationship between the standard and the nonstandard spectral representation of the self-adjoint operator $f(B)$: For each Borel set Ω we obtain $F_\Omega := \chi_\Omega(f(B)) = \int \chi_\Omega \circ f \, \mathrm{d}\, {}^oE = {}^oE_{f^{-1}(\Omega)}$, and $f(B)=\int \omega \, \mathrm{d}F_\omega$.

C. Nonstandard hulls

As pointed out in Sec. II operational nonstandard hulls are well known for finitely bounded internal operators. For infinite internal operators, however, ambiguities occur if we consider standard parts: Let B be a hyperfinite-rank operator that has an infinite eigenvalue λ, let x be the corresponding normed eigenvector, and let $y=x/\lambda$, then ${}^o y = 0$ but ${}^o(By) = {}^o x \neq 0$. We see by this example that for infinite internal operators an equation like ${}^oB\, {}^o x = {}^o(Bx)$ can generally not be true. The definition of nonstandard hulls for infinite internal operators is thus not straightforward. Nevertheless, if we consider self-adjoint internal operators then we can use the Loeb-function calculus for a sensible definition. The principal idea is to project those vectors out that cause the ambiguities. To arrive at a sensible definition we consider first finitely bounded internal operators. Moreover, let $\mathcal{B}(\mathbb{R})$ be the set of complex-valued Borel functions on $\mathbb{R}$.

Proposition 3: Let B be an internal self-adjoint operator on an internal Hilbert space H, let $\{{}^oE_\Omega\}_{\Omega\in A}$ be the projection-valued Loeb measure associated with the projection-valued * measure of B, and let $f \in {}^\star\mathcal{B}(\mathbb{R})$ be finitely bounded, then

$$\langle {}^o x, {}^o f(B)\, {}^o y\rangle = \mathrm{st}\left(\int f(\omega)\mathrm{d}\langle x, E_\omega y\rangle\right) = \int {}^o f \mathrm{d}\mu_L^{(x,y)} \quad (x,y \in \mathrm{fin}(H)). \tag{11}$$

Proof: We assume first that f is real valued. The generalization to complex-valued functions f is straightforward.

For $n \in {}^\star\mathbb{N}$, $k \in {}^\star\mathbb{Z}$ let $S_{k,n}=\{r \in {}^\star\mathbb{R} : k/n \leqslant f(r) < (k+1)/n\}$, and let $I_n=\{k \in {}^\star\mathbb{Z} : S_{k,n} \neq \emptyset\}$. Since f is finitely bounded I_n is hyperfinite. Moreover, ${}^\star\mathbb{R} = \cup_{k\in I_n} S_{k,n}$. Define $f_n = \Sigma_{k\in I_n} (k/n)\, \chi_{S_{k,n}}$, then $f_n \uparrow f$, and $|f_n(r)-f(r)| < 1/n$ for all $r \in {}^\star\mathbb{R}$. Moreover, ${}^o f_n \uparrow {}^o f (n \in \mathbb{N}))$, and

$$\int {}^o f d\mu_L^{(x,y)} = \lim_{n\in\mathbb{N}} \int {}^o f_n \mathrm{d}\mu_L^{(x,y)} \quad (x,y \in \mathrm{fin}(H))$$

$$= \lim_{n\in\mathbb{N}} \sum_{k\in I_n} \frac{k}{n} \mu_L^{(x,y)}(S_{k,n})$$

$$= \lim_{n\in\mathbb{N}}{}^{o}\sum_{k\in I_n} \int \frac{k}{n} \chi S_{k,n}(\omega) \mathrm{d}\langle x, E_\omega y\rangle$$

$$= {}^{o}\int f_n(\omega) \mathrm{d}\langle x, E_\omega y\rangle \quad (n \in {}^{\star}\mathbb{N}\setminus\mathbb{N})$$

$$= {}^{o}\int f(\omega) \mathrm{d}\langle x, E_\omega y\rangle$$

$$= {}^{o}\langle x, f(B) y\rangle = \left\langle {}^{o}x, {}^{o}f(B)\, {}^{o}y\right\rangle.$$

We note that we use $f_n(r) \approx f(r)$ for $n \in {}^{\star}\mathbb{N}\setminus\mathbb{N}$in the calculation. □

We note that if the operator B is finitely bounded in proposition 3 then the spectrum of B consists only of near-standard points, $\sigma(B) \subset \mathrm{fin}({}^{\star}\mathbb{R})$, and thus ${}^{o}B = \int_{\mathrm{fin}({}^{\star}\mathbb{R})} \mathrm{st}\ \mathrm{d}\,{}^{o}E$. Moreover, the last equation provides a correct approach for an extended definition of nonstandard hulls.

Definition 1: Let B be an internal self-adjoint operator on an internal Hilbert space H, and let $\{{}^{o}E_\Omega\}_{\Omega\in\mathcal{A}}$ be the projection-valued Loeb measure associated with the projection-valued * measure of B. The nonstandard hull of B is given by

$${}^{o}B = \int_{\mathrm{fin}\left({}^{\star}\mathbb{R}\right)} \mathrm{st}\ \mathrm{d}\,{}^{o}E.$$

This definition avoids the ambiguities mentioned above since the critical vectors, i.e., the vectors belonging to the range of ${}^{o}E_{\mathrm{fin}({}^{\star}\mathbb{N}\setminus{}^{\star}\mathbb{N})}$, are projected out. In particular, if x is an eigenvector of B in definition 1, then ${}^{0}B^{0}x = 0$ if x belongs to an infinite eigenvalue. We note that the statement $(\forall x \in \mathrm{fin}(H))\ {}^{0}B^{0}x = {}^{0}(Bx)$ holds for finitely bounded operators but not for infinite operators in definition 1. Generally, we obtain for $x, Bx \in \mathrm{fin}(H)$ rather

$${}^{0}B\,{}^{o}x = {}^{o}E_{\mathrm{fin}\left({}^{\star}\mathbb{R}\right)}\,{}^{o}(Bx). \tag{12}$$

IV. NONSTANDARD QUANTUM MECHANICS

A. Operational extensions

We continue now our discussion started in Sec. II. In particular, we consider a dense subset $\mathcal{M}$ of a Hilbert space $\mathcal{H}$, which is externally contained in a hyperfinite dimensional space H, and for which $\mathcal{M} \subset H \subset {}^{\star}\mathcal{M} \subset {}^{\star}\mathcal{H}$ holds. We note that $\mathcal{H} \subset {}^{o}H$ by proposition 1. We have seen in Sec. II that each bounded linear operator on $\mathcal{H}$ can be extended by a finitely bounded hyperfinite-rank operator on H, and that the extension is based on nonstandard hulls. In Sec. III we have worked out the connection of nonstandard hulls to the Loeb-function calculus. In particular, we have introduced nonstandard hulls for infinite self-adjoint internal operators. Now we use these results to generally establish the extension of standard self-adjoint operators to self-adjoint hyperfinite-rank operators.

Let A be a self-adjoint operator on $\mathcal{H}$, then $A' = \tan^{-1}(A)$ is a bounded self-adjoint operator on H. The hyperfinite-rank operator $B' = O\ {}^{\star}A' O$ is a nonstandard extension of A', i.e., ${}^{o}B'|_{\mathcal{H}} = A'$. We note that O denotes the projection of ${}^{\star}\mathcal{H}$ onto H. Moreover, we note that $\chi_{(-\pi/2,\pi/2)}(A')$

$=\chi_{\mathbb{R}}(A)=1$ and that $A=\tan(A')$. For $r\in\mathbb{R}$ let $\mathrm{tg}(r)=\tan(r\cdot\chi_{(-\pi/2,\pi/2)}(r))$. Since ${}^oB'|_{\mathcal{H}}=A'$ we obtain $\mathrm{tg}(A')=\mathrm{tg}({}^oB')|_{\mathcal{D}(\mathrm{tg}(A'))}$. Since $\mathrm{st}\circ\mathrm{tg}=\mathrm{tg}\circ\mathrm{st}$ on $\mathrm{fin}({}^\star\mathbb{R})$ we get further $\mathrm{tg}({}^oB')={}^o\mathrm{tg}(B')$ by proposition 3 and theorem 4, and thus $A=\mathrm{tg}(A')={}^o(\mathrm{tg}(B'))|_{\mathcal{D}(A)}$.

Our construction shows that for any standard self-adjoint operator A there exists a self-adjoint hyperfinite-rank operator B whose nonstandard hull extends A, i.e., $A={}^oB|_{\mathcal{D}(A)}$. In particular, we obtain $\sigma(A)\subset\sigma({}^oB)=\mathrm{cl}({}^o\mathrm{NS}(\sigma(B))$ by corollary 1. For each $\lambda\in\sigma(A)$ there exists thus a $\lambda'\in\sigma(B)$ for which $\lambda\approx\lambda'$ holds (cf. Sec. II B).

Definition 2: Let A be a self-adjoint operator on a Hilbert space $\mathcal{H}$. Let H be an internal Hilbert space for which $\mathcal{H}\subset{}^oH$ holds and let B be an internal self-adjoint operator on H. B is called a nonstandard extension of A if $A={}^oB|_{\mathcal{D}(A)}$.

We note that the nonstandard extension of A is not unique. We discuss now how the function calculus of A is related to the function calculus of its nonstandard extensions.

Proposition 4: Let A be a standard self-adjoint operator and let B be a nonstandard extension of A. Then, for each real-valued Borel function g there exists an internal function f for which $g(A)x={}^o(f(B)^\star x)={}^of(B)x$ holds for all $x\in\mathcal{D}(g(A))$. In particular, $f(B)$ is a nonstandard extension of $g(A)$.

Proof: Let g be a real-valued Borel function and let $\{{}^oE_\Omega\}_{\Omega\in A}$ be the projection-valued Loeb measure associated with the projection-valued * measure of B. Since $g(A)=g({}^oB)|_{\mathcal{D}(g(A))}$ we conclude from theorem 4 that $g(A)x=\int_{\mathrm{fin}({}^\star\mathbb{R})}(g\circ\mathrm{st})\mathrm{d}{}^oEx$ $(x\in\mathcal{D}(g(A)))$. Moreover, for $x\in\mathcal{D}(g(A))$ let $\mu_L^{(x)}$ be the Loeb measure for which $\langle x,{}^oE_\Omega x\rangle=\mu_L^{(x)}(\Omega)$ $(\Omega\in\mathcal{A})$ holds. For each Loeb measure $\mu_L^{(x)}$ there exists an internal function f_x for which ${}^of_x=g\circ\mathrm{st}$ holds $\mu_L^{(x)}$ almost everywhere,[11] i.e., $\int_{\mathrm{fin}({}^\star\mathbb{R})}({}^of_x-g\circ\mathrm{st}^o)^2\mathrm{d}\|{}^oEx\|^2=0$. For $n\in\mathbb{N}$ let

$$f_{x,n}(\lambda):=\begin{cases}f_x(\lambda), & |f_x(\lambda)|\leqslant n,\\ 0, & \text{else},\end{cases}$$

then each $f_{x,n}$ is a finite internal function and $g(A)x=g({}^oB)x=\lim_n{}^of_{x,n}(B)x=\lim_n{}^o(f_{x,n}(B)^\star x)$. Hence, the internal sets

$$\Omega_{x,n}=\left\{f\in{}^\star(\mathbb{C}^{\mathbb{R}}):\left\|{}^\star(g(A)x)-f(B)^\star x\right\|<1/n\right\}$$

are nonempty for each $x\in\mathcal{D}(g(A))$, $n\in\mathbb{N}$. We note that $\Omega_{x,n}\subset\Omega_{x,m}$ for $n>m$. Moreover, for $x_1,\ldots,x_m\in\mathcal{D}(g(A))$ we consider the Loeb measure $\nu_L=\mu_L^{(x_1)}+\cdots+\mu_L^{(x_m)}$. For ν_L there exists also an internal function f for which ${}^of=g\circ\mathrm{st}$ holds ν_L almost everywhere.[11] In particular, ${}^of=g\circ\mathrm{st}$ holds $\mu_L^{(x_k)}$ almost everywhere for each $1\leqslant k\leqslant m$. If we define f_n with the help of f analogously as we have defined $f_{x,n}$ with the help of f_x then $g(A)x=g({}^oB)x_k=\lim_n{}^of_n(B)x_k=\lim_n{}^o(f_n(B)^\star x_k)$ for each $1\leqslant k\leqslant m$, and thus $\Omega_{x_1,n}\cap\cdots\cap\Omega_{x_m,n}\neq\emptyset$. The collection of internal sets $(\Omega_{x,n})_{x\in\mathcal{D}(g(A)),n\in\mathbb{N}}$ has thus the finite-intersection property, and by polysaturation there exists an internal $f\in\cap_{x\in\mathcal{D}(g(A)),n\in\mathbb{N}}\Omega_{x,n}$. In particular, we obtain $g(A)x={}^o(f(B)^\star x)$ for all $x\in\mathcal{D}(g(A))$.

Assume $x\in\mathcal{D}(g^2(A))$ and let $y=g(A)x$, then ${}^\star y\approx f(B)^\star x$ and ${}^\star(g^2(A)x)={}^\star(g(A)y)\approx f(B)^\star y$. Since $f(B)^\star y$ is finite we obtain $y=Py$ for the projection $P={}^o\chi_{\mathrm{fin}({}^\star\mathbb{R})}(f(B))$. Thus, $y={}^o(f(B)^\star x)=P{}^o(f(B)^\star x)={}^of(B)x$. Since $g(A)$ is essentially self-adjoint on $\mathcal{D}(g^2(A))$ we obtain $g(A)={}^of(B)|_{\mathcal{D}(g(A))}$. □

We note that the internal function in proposition 4 is not uniquely determined. In fact, if B is of hyperfinite rank we can even choose a * polynomial p for which $p(\lambda)=f(\lambda)$ holds for all eigenvalues λ of B, i.e., $f(B)=p(B)$. We can also restrict f to be a * continuous function or a * Borel function in proposition 4. We note also that if in proposition 4 the function g is bounded and continuous ($\mu_L^{(x)}$ almost everywhere for all $x\in\mathcal{H}$) then we may simply choose $f={}^\star g$.

Proposition 5: Let A be a standard self-adjoint operator and let B be a nonstandard extension of A. Let $(F_\Omega)_{\Omega\in\mathcal{B}}$ be the projection-valued measure associated with A and let $(E_\Omega)_{\Omega\in{}^\star\mathcal{B}}$ be the projection-valued * measure associated with B, then for each $\Omega\in\mathcal{B}$ there exists an $\Omega'\in{}^\star\mathcal{B}$ for which $F_\Omega x={}^oE_{\Omega'}x$ holds for all $x\in\mathcal{H}$.

Proof: Let $x\in\mathcal{D}(A)$, then $F_\Omega x=\chi_\Omega(A)x=\chi_\Omega({}^oB)x={}^oE_{\mathrm{st}^{-1}(\Omega)}x$ by theorem 4. Let $\mu_L^{(x)}$ be the

Loeb measure associated with $\langle x, {}^oE'_\Omega x\rangle$ ($\Omega' \in {}^\star\mathcal{B}$). There exists an $\Omega'_x \in {}^\star\mathcal{B}$ for which $\mu_L^{(x)}(\mathrm{st}^{-1}(\Omega)\Delta\Omega'_x)=0$ holds[11] ($\Omega\Delta\Omega' = (\Omega\setminus\Omega')\cup(\Omega'\setminus\Omega)$). We get in particular ${}^oE_{\Omega'_x}x = {}^oE_{\mathrm{st}^{-1}(\Omega)}x$. Let

$$\Gamma_{x,n} = \{\Omega' \in {}^\star\mathcal{B} : \|(E_{\Omega'} - E_{\Omega'_x})^\star x\| < 1/n\}.$$

The sets $\Gamma_{x,n}$ are internal and $\Gamma_{x,n} \subset \Gamma_{x,m}$ if $n > m$. Moreover, for $x_1, \ldots, x_m \in \mathcal{D}(A)$ we consider the Loeb measure $\nu_L = \mu_L^{(x_1)} + \cdots + \mu_L^{(x_m)}$. For ν_L there exists also an $\Omega' \in {}^\star\mathcal{B}$ for which $\nu_L(\mathrm{st}^{-1}(\Omega)\Delta\Omega')=0$ holds, i.e., ${}^oE_{\Omega'}x_k = {}^oE_{\mathrm{st}^{-1}(\Omega)}x_k$ for $1 \leqslant k \leqslant m$. The collection of internal sets $(\Gamma_{x,n})_{x\in\mathcal{D}(A),n\in\mathbb{N}}$ has thus the finite-intersection property, and by polysaturation there exists an $\Omega' \in \cap_{x\in\mathcal{D}(A),n\in\mathbb{N}}\Gamma_{x,n}$. In particular, ${}^oE_{\Omega'}x = {}^oE_{\mathrm{st}^{-1}(\Omega)}x$ for all $x \in \mathcal{D}(A)$, which proves the assertion. □

Let us come back to the discussion at the beginning of this section. We have seen that for any self-adjoint operator A on $\mathcal{H}$ there exist self-adjoint hyperfinite-rank operators on H that extend A in the sense of definition 2. Proposition 4 and proposition 5 provide further results that we discuss now from a physical point of view.

(1) If we want to model a standard measurement process we usually use a probability space $(\mathbb{R}, \mathcal{B}, \mu)$. The measure μ is related to a projection-valued measure of a self-adjoint operator A and a normalized state vector $x \in \mathcal{H}$. Proposition 5 suggests that we could also use a * probability space $(\mathbb{R}, {}^\star\mathcal{B}, \mu)$ to model the measurement process. The * measure μ is then related to the projection-valued * measure of a self-adjoint hyperfinite-rank extension B of A and the normalized vector $y = O^\star x/\|O^\star x\|$. We note that O denotes the projection of ${}^\star\mathcal{H}$ onto H and that $O^\star x \approx {}^\star x$.

(2) Proposition 4 tells us that the set of * Borel functions contains all functions that we need to retrieve standard results. We note that we may restrict ourselves to any set that contains the * polynomials, i.e., the * continuous functions, for example. In particular, for the time evolution we simply obtain $\exp(-iAt)x = {}^o(\exp(-iBt)y) = {}^o\exp(-iBt)x$ ($t \in \mathbb{R}$). We note that we use A, B, x, and y as in 1.

Following these two arguments we may formulate quantum mechanics in a hyperfinite-dimensional Hilbert space H, which extends the standard formulation in a Hilbert space $\mathcal{H}$. However, our results have a rather general nature so far. To demonstrate how a concrete formulation can be achieved we discuss Schrödinger representations as an example in Sec. IV B.

B. Schrödinger operators

The conventional Schrödinger representation of one-particle quantum mechanics is formulated in $\mathcal{H} = \mathcal{L}^2(\mathbb{R})$. The momentum operator p and the position operator q are the closures of $i^{-1}\mathrm{d}/\mathrm{d}x$ and multiplication by x on $S(\mathbb{R})$. $S(\mathbb{R})$ is the space of functions of rapid decrease on $\mathbb{R}$, which is a domain of essential self-adjointness for p and q. Moreover, Schrödinger Hamiltonians are given by $A = p^2 + V(q)$, for which $V(\cdot)$ denotes a Borel function. We note that we restrict ourselves to the one-dimensional case and that the generalization to multidimensions is straightforward, as we will see.

Let $\{u_n\}_{n=o}^\infty$ be the basis of Hermite functions, let $h \in {}^\star\mathbb{N}\setminus\mathbb{N}$ be a fixed hypernatural number, and let H be the hyperfinite-dimensional space that has the basis $\{{}^\star u_n\}_{n=o}^h$. H externally contains the space $\mathcal{M}$ of finite linear combinations of $\{u_n\}_{n=0}^\infty$, which is dense in $\mathcal{H}$, and $H \subset {}^\star\mathcal{M}$. The triple $(\mathcal{M}, \mathcal{H}, H)$ thus realizes the setting described in Sec. II A.

We derive now explicit nonstandard extensions of several self-adjoint operators on $\mathcal{H}$. For example, let $O = \Sigma_{n=0}^h |{}^\star u_n\rangle\langle {}^\star u_n|$ be the projection from ${}^\star\mathcal{H}$ onto H associated with the Hermite-function basis $\{{}^\star u_n\}_{n=0}^h$, then the hyperfinite-rank operator $P = O^\star pO$ has a well-known simple representation, and for $x \in \mathcal{M}$ we obtain ${}^\star(px) = P^\star x$. Let $(E_\Omega)_{\Omega\in{}^\star\mathcal{B}}$ be the projection-valued

* measure associated with P. Since $P^{2\star}x$ is finite we obtain $px={}^o(P^\star x)={}^oE_{\mathrm{fin}(\mathbb{R})}{}^o(P^\star x)={}^oPx$ for $x\in\mathcal{M}$. In order to show that P is a nonstandard extension of p we prove that $p|_{\mathcal{M}}$ is essentially self-adjoint.

Let $x\in\mathcal{S}$ then there exists a sequence (x_n) in $\mathcal{M}$ that converges to x with respect to the topology of $\mathcal{S}$.[1] In particular, $\lim_n\|x-x_n\|=0$ and $\lim_n\|p(x-x_n)\|=0$. Let $\Gamma(p|_{\mathcal{M}})$ denote the graph of p restricted to $\mathcal{M}$. (px,x) is thus contained in the closure of $\Gamma(p|_{\mathcal{M}})$, i.e., $\Gamma(p|_S)\subset\mathrm{cl}(\Gamma(p|_{\mathcal{M}}))=\mathrm{cl}(\Gamma(p|_S))$. Since $p|_S$ is essentially self-adjoint we conclude that $p|_{\mathcal{M}}$ is also essentially self-adjoint and that $p={}^oP|_{\mathcal{D}(p)}$. P is thus a nonstandard extension of p. The following lemma generalizes our result.

Lemma 2: Let H be an internal Hilbert space and let $\mathcal{M}$ be a dense subset of a standard Hilbert space $\mathcal{H}$ for which $\mathcal{M}\subset H\subset{}^\star\mathcal{M}\subset{}^\star\mathcal{H}$ holds. Let A be a self-adjoint operator on $\mathcal{H}$, which is essentially self-adjoint on $\mathcal{M}$, and let O be the projection of ${}^\star\mathcal{H}$ onto H. Then, $B=O^\star AO$ is a nonstandard extension of A.

Proof: Let $(F_\Omega)_{\Omega\in{}^\star\mathcal{B}}$ be the projection-valued * measure associated with B. Since

$$\|B^\star x\|^2=\int_{{}^\star\mathbb{R}}\omega^2\mathrm{d}\langle{}^\star x,F_\omega{}^\star x\rangle$$

is finite for $x\in\mathcal{M}$ we conclude that

$$\int_{|\omega|>n}|\omega|\mathrm{d}\langle{}^\star x,F_\omega{}^\star x\rangle<\epsilon$$

for any standard $\epsilon>o$ and any $n\in{}^\star\mathbb{N}\backslash\mathbb{N}$. For a fixed standard $\epsilon>o$ there exists by the underflow principle an $n\in\mathbb{N}$ for which

$$\int_{|\omega|>n}|\omega|\mathrm{d}\langle{}^\star x,F_\omega{}^\star x\rangle<\epsilon$$

holds, and thus

$$\langle x,{}^o(B^\star x)\rangle=\mathrm{st}\left(\int_{{}^\star\mathbb{R}}\omega\mathrm{d}\langle{}^\star x,F_\omega{}^\star x\rangle\right)=\lim_{n\to\infty}\mathrm{st}\left(\int_{|\omega|\leqslant n}\omega\mathrm{d}\langle{}^\star x,F_\omega{}^\star x\rangle\right)=\langle x,{}^oBx\rangle\quad(x\in\mathcal{M}).$$

Moreover, by polarization we obtain $\langle y,{}^o(B^\star x)\rangle=\langle y,{}^oBx\rangle$ for $x,y\in\mathcal{M}$. Since ${}^o(B^\star x)=Ax\in\mathcal{H}$ we get

$$\left\|{}^o(B^\star x)\right\|=\sup_{y\in\mathcal{M}_1}|\langle y,{}^o(B^\star x)\rangle|=\sup_{y\in\mathcal{M}_1}|\langle y,{}^oBx\rangle|\leqslant\left\|{}^oBx\right\|,$$

using $\mathcal{M}_1=\{y\in\mathcal{M}:\|y\|=1\}$. Since

$$\|{}^o(B^\star x)\|=\|{}^oBx\|+\|{}^oF_{{}^\star\mathbb{R}\backslash\mathrm{fin}({}^\star\mathbb{R})}(B^\star x)\|$$

we obtain ${}^oF_{{}^\star\mathbb{R}\backslash\mathrm{fin}({}^\star\mathbb{R})}(B^\star x)=0$ and $Ax={}^o(B^\star x)={}^oBx$ for $x\in\mathcal{M}$. Since $A|_{\mathcal{M}}$ is essentially self-adjoint we obtain $A={}^oB|_{\mathcal{D}(A)}$. □

With the help of lemma 2 we gain explicit nonstandard extensions of many self-adjoint operators on $\mathcal{H}$. For example, since $q^n|_S$ and $p^n|_S(n\in\mathbb{N})$ are essentially self-adjoint we conclude in the same manner as for p that $Q^{(n)}=O^\star q^nO$ and $P^{(n)}=O^\star p^nO$ are nonstandard extensions, respectively. Also, if for a real Borel function V the operator $V(q)|_{\mathcal{M}}$ is essentially self-adjoint, which is for example true if V is bounded, then $W=O^\star V(q)O$ is a nonstandard extension of $V(q)$. We note that the matrix elements of W are given by explicit analytic expressions. Moreover, let us assume that the Schrödinger operator $A=p^2+V(q)$ is essentially self-adjoint on $\mathcal{M}$ and that $\mathcal{M}\subset\mathcal{D}(V(q))$. This requirement is fulfilled, for example, if V is a bounded Borel function (cf. Wüst's theorem[13]). Using lemma 2 we conclude that $B=O({}^\star p^2+{}^\star V(q))O=P^{(2)}+W$ is a nonstandard extension of A.

Without giving an explicit proof we note that we may even choose $V \in \mathcal{L}^2 + \mathcal{L}^\infty$ as in theorem X.15 of Ref. 13. Moreover, we note that in this example we simply may add the nonstandard extensions of p^2 and $V(q)$ to obtain a nonstandard extension of A. However, this is generally not valid since for two internal self-adjoint operators B_1 and B_2 the sum ${}^oB_1 + {}^oB_2$ is not necessarily defined although ${}^o(B_1 + B_2)$ is always defined.

V. APPLICATION IN SCATTERING THEORY

We apply in this section our nonstandard framework to nonrelativistic quantum scattering theory. First, we shortly review the concepts of conventional time-dependent scattering theory as it is presented in Ref. 14. We show then how the concepts fit into the framework, and discuss the physical impact. We finally derive explicit expressions for the Møller wave operators and the S-matrix.

A. Time-dependent scattering theory

In quantum scattering theory the Hamiltonian of the quantum system is the sum of a "free" Hamiltonian and an interaction potential, $A = A_0 + V$. If we consider a state x that was prepared in the remote past then the corresponding free state x_+ is given by $x = W^+ x_+ = \lim_{t \to -\infty} e^{iAt} e^{-iA_0 t} x_+$. W^+ is a Møller wave operator. Prerequisite is however that $\lim_{t \to -\infty} e^{iAt} e^{-iA_0 t} x_+$ exists. Analogously, the free state x_- that looks like x when it is detected in the far future is given by $x = W^- x_- = \lim_{t \to \infty} e^{iAt} e^{-iA_0 t} x_-$. We note that we use the convention of time-independent scattering theory that $t \to \mp\infty$ refers to $W^\pm$ (cf. Sec. 5.2, Ref. 14). The quantum system is complete if $W^+(\mathcal{H}) = W^-(\mathcal{H}) = \mathcal{H}_{ac}$. $\mathcal{H}_{ac}$ is the subspace of $\mathcal{H}$ that is connected to the absolutely continuous part of the spectrum of A.

Let us assume now an internal Hilbert space H, and self-adjoint hyperfinite-rank operators B and B_0 on H. We associate B_0 with the free Hamiltonian of the quantum system. Analogous to the conventional theory we are interested in the limits $W^\pm x = \lim_{t \to \pm\infty} ({}^o e^{iBt})({}^o e^{-iB_0 t}) x$ $(x \in {}^o H)$. Since we use NSA we can however give the terms "remote past" and "far future" a quantitative meaning. Let $Y_t = e^{iBt} e^{-iB_0 t}$ and let $L^\pm = \{x \in \mathrm{fin}(H) : \lim_{t \to \mp\infty} {}^o(Y_t x) \text{exists}\}$. We note that the spaces ${}^oL^\pm$ are closed subspaces of ${}^oH$ on which the Møller operators $W^\pm$ are defined. We assume in the following that the system is "reasonably" complete, i.e., that $W^+(L^+) \cap W^-(L^-)$ is a sensible set of physical states. This assumption is justified if we consider the nonstandard extension of a complete standard quantum system.

Lemma 3: $x \in L^\pm$ iff there exist infinite hyper-reals $T_{\pm,x}$ for which $W^{\pm o} x = {}^o(Y_t x)$ holds if t is infinite and $0 < (\mp t) \leqslant T_{\pm,x}$.

Proof: We carry out only the proof for L^-, since the proof for L^+ is analogous. Let $x \in \mathrm{fin}(H)$ and assume that there exists an infinite $T_{-,x}$ for which $W^{-o} x = {}^o(Y_t x)$ holds if t is infinite and $0 < t \leqslant T_{-,x}$. Since ${}^o(Y_t x) \in {}^oH$ there exists a $y \in \mathrm{fin}(H)$ for which ${}^o y = {}^o(Y_t x)$ holds. For a (standard) $\epsilon > 0$ let

$$\Gamma_\epsilon = \{T \in [0, T_{-,x}] : (\forall\, t \in [T, T_{-,x}]) \| y - Y_t x \| < \epsilon\}.$$

Since $T \in \Gamma_\epsilon$ if T is infinite and $T_{-,x} \geqslant T > 0$, and since Γ_ϵ is internal and nonempty there exists a finite $T_\epsilon \in \Gamma_\epsilon$. Hence, $(\forall\, t > {}^o T_\epsilon) \| W^{-o} x - {}^o(Y_t x) \| \leqslant \epsilon$, and thus $W^{-o} x = \lim_{t \to \infty} {}^o(Y_t x)$.

Now assume $W^{-o} x = \lim_{t \to \infty} {}^o(Y_t x)$. Since $W^{-o} x \in {}^oH$ there exists a $y \in \mathrm{fin}(H)$ for which ${}^o y = W^{-o} x$ holds. For each (standard) $\epsilon > 0$ there exists a T_ϵ for which $(\forall\, t > T_\epsilon) \| W^{-o} x - {}^o(Y_t x) \| < \epsilon$ holds. Let $T'_\epsilon = \max\{T_\epsilon, 1/\epsilon\}$, and let $F_t = \{s \in {}^\star\mathbb{R} : s \geqslant t\}$ for $t \in {}^\star\mathbb{R}$. The set

$$G_{\epsilon,x} = \{T \in F_{T'_\epsilon} : (\forall\, t \in [T'_\epsilon, T]) \| y - Y_t x \| < \epsilon\}$$

is nonempty and internal. By the overflow principle $G_{\epsilon,x}$ contains an infinite $T_{\epsilon,x}$, and by polysaturation the set

$$G_x = \bigcap_{\epsilon>0} [T'_\epsilon, T_{\epsilon,x}]$$

is nonempty, i.e., we can choose a $T_{-,x} \in G_x$. $T_{-,x}$ is infinite since $T_{-,x} > T'_\epsilon \geqslant 1/\epsilon$ for all $\epsilon > 0$. Moreover, if t is infinite and $t \leqslant T_{-,x}$ we obtain $(\forall \epsilon > 0) t \in [T'_\epsilon, T_{\epsilon,x}]$, and thus ${}^o y = W^- {}^o x = {}^o(Y_t x)$.□

Theorem 5: Assume that ${}^oH$ contains a standard Hilbert space $\mathcal{H}$, then there exist infinite hyper-reals $T_\pm$ for which $W^\pm {}^o x = {}^o(Y_t x)$ holds if t is infinite, $0 < (\mp t) \leqslant T_\pm$, $x \in L^\pm$, and ${}^o x \in \mathcal{H}$.

Proof: Again, we carry out only the proof for L^-, since the proof for L^+ is analogous. Let $x \in L^-$ and let $T_{-,x}$ be the infinite hyper-real determined by lemma 3. Since Y_t is finitely bounded for each $t \in {}^\star\mathbb{R}$ we obtain ${}^o(Y_t x) = {}^o(Y_t y)$ for all $y \approx x$. Thus, if t is infinite and $0 < t < T_{-,x}$ then $W^- {}^o y = {}^o(Y_t y)$ for all $y \approx x$. For $z \in \mathcal{H} \cap {}^o L^-$ we choose a representative $x \in L^-$ for which ${}^o x = z$ holds, and set $T'_{-,z} = T_{-,x}$. For $y \in L^-$ we obtain then $W^- z = {}^o(Y_t y)$ if t is infinite, $0 < t < T'_{-,z}$, and ${}^o y = z$. Let $G_{n,z} = [n, T'_{-,z}]$, then there exists an infinite $T_- \in \cap_{n \in \mathbb{N}, z \in \mathcal{H}} G_{n,z}$ by polysaturation. Since $T_- \leqslant T'_{-,z}$ for all $z \in \mathcal{H}$ we obtain the assertion. □

We note that theorem 5 is valid also if we replace $\mathcal{H}$ by any set of standard elements. The crucial point is that we use the properties of polysaturation in our proof, which limits the size of subsets of $L^\pm$ for which common hyper-reals $T_\pm$ can be determined. However, if we accept that we observe only a standard set of states in a scattering experiment, then theorem 5 yields an interesting result. Motivated by theorem 5, we may identify three phases of a scattering experiment: The preparation of the system is done in the remote past at infinite times t for which $-T_+ \leqslant t < 0$ holds. The scattering happens at finite times t, and the detection takes place in the far future at times t for which $0 < t \leqslant T_-$ holds. $-T_+$ and T_- may be interpreted as starting time and as finishing time of the experiment, respectively.

Moreover, we naturally obtain a separation of time scales within our nonstandard model: We observe the interacting system on a large time scale that is defined by the infinite time interval $[-T_+, T_-]$, whereas the interaction takes place on a small time scale that is defined by finite times, $t \in \mathrm{fin}({}^\star\mathbb{R})$. The separation of time scales, which cannot be done in standard models in the same manner, is a nice example of the strength of NSA. We note however that our result does not state that the preparation and the detection take place on the same time scale since the fraction T_-/T_+ is not necessarily finite.

B. Time-independent scattering theory

We discuss time-independent scattering theory in the following on the basis of our results for time-dependent scattering theory. In particular, we assume in this section the setting of theorem 5 and that H is hyperfinite-dimensional. As outlined in the discussion of theorem 5, we may assume especially two infinite hyper-reals $T_\pm$ that mark the starting and the finishing times of a scattering experiment. We introduce first a set of infinitesimals that is closely related to $T_\pm$. Let $T = \min\{T_-, T_+\}$, and let $\Gamma = \{t \approx 0 : t > 0 \text{ and } tT \text{ infinite}\}$. Γ is nonempty since, for example, $\{t/\sqrt{T} : {}^o t > 0 \text{ and } t \in \mathrm{fin}({}^\star\mathbb{R}_+)\} \subset \Gamma$. We note that Γ is a set of infinitesimals that depends only on $T_\pm$, and that is thus fundamentally related to the scattering system. We assume for the rest of the section that $\epsilon \in \Gamma$, i.e., $\epsilon \approx 0$, $\epsilon > 0$, and ϵt is infinite for $t \geqslant \min\{T_-, T_+\}$. Moreover, we use in the following transferred integration theory.

Lemma 4: Let $Y^\pm = Y_{\mp T_\pm/2}$, then

$$Y^\pm u \approx \int_0^{{}^\star\infty} \mathrm{d}s \; \epsilon e^{-\epsilon s} Y_{\mp s} u \tag{13}$$

if $u \in L^\pm$ and ${}^o u \in \mathcal{H}$.

Proof: Let $0 < {}^o\alpha < 1$, let $T_1 = 1/\sqrt{\epsilon}$, and let $T_2 = \alpha \min\{T_+, T_-\}$. Since $\|Y_s\| = 1$ for all $s \in {}^\star\mathbb{R}$ we obtain

$$\left\| \int_0^{{}^\star T_1} \mathrm{d}s \; \epsilon e^{-\epsilon s} Y_{\mp s} \right\| \leqslant \int_0^{{}^\star\sqrt{\epsilon}} \mathrm{d}s \; e^{-s} = 1 - e^{-\sqrt{\epsilon}} \approx 0,$$

$$\left\| \int_{T_2}^{\star\infty} \mathrm{d}s\ \epsilon e^{-\epsilon s} Y_{\mp s} \right\| \leqslant e^{-\epsilon T_2} \approx 0,$$

$$\int_{T_1}^{\star T_2} \mathrm{d}s\ \epsilon e^{-\epsilon s} Y_{\mp s} \approx \int_0^{\star\infty} \mathrm{d}s\ \epsilon e^{-\epsilon s} Y_{\mp s}.$$

Assume $u \in L^{\pm}$ and ${}^o u \in \mathcal{H}$. By theorem 5, $Y_{\mp s}\, u \approx Y^{\pm} u$ for $s \in [T_1, T_2]$, and thus

$$\int_{T_1}^{\star T_2} \mathrm{d}s\ \epsilon e^{-\epsilon s} Y_{\mp s} u \approx (e^{-\sqrt{\epsilon}} - e^{-\epsilon T_2}) Y^{\pm} u \approx Y^{\pm} u.$$

□

Lemma 4 enables us to deduce an explicit formula for the operators $W^{\pm} = {}^o Y^{\pm}$. Let $\{\lambda_j, x_j\}_{j=1}^h$ be an eigensystem of the free Hamiltonian B_0. If $u \in L^{\pm}$ and ${}^o u \in \mathcal{H}$ we obtain

$$\begin{aligned} Y^{\pm} u &\approx \int_0^{\star\infty} \mathrm{d}t\ \epsilon e^{-\epsilon t} Y_{\mp t} u = u \mp i \int_0^{\star\infty} \mathrm{d}t\ e^{-\epsilon t} e^{\mp iBt} V e^{\pm iB_0 t} u \quad (V = B - B_0) \\ &= u \mp i \sum_{j=1}^{h} u_j \int_0^{\star\infty} \mathrm{d}t\ e^{-\epsilon t} e^{\mp i(B-\lambda_j)t} V x_j \quad (u_j = \langle x_j, u \rangle) \\ &= u \pm i \sum_{j=1}^{h} u_j \frac{1}{\mp i(B - \lambda_j) - \epsilon} V x_j = \sum_{j=1}^{h} u_j \left(1 + \frac{1}{\lambda_j - B \pm i\epsilon} V \right) x_j. \end{aligned}$$

Theorem 6:

$$W^{\pm o} u = {}^o(Y^{\pm} u) = {}^o \sum_{j=1}^{h} u_j \left(1 + \frac{1}{\lambda_j - B \pm i\epsilon} V \right) x_j \tag{14}$$

if $u \in L^{\pm}$ and ${}^o u \in \mathcal{H}$.

Let $[Y^+, B_0] = Y^+ B_0 - B_0 Y^+$, and let $T_t = e^{iB_0 t}[Y^+, B_0] e^{-iB_0 t}$. We consider now the S-matrix, $S = (Y^-)^{\dagger} Y^+$, for which $\langle W^{-o} u, W^{+\ o} v \rangle = {}^o\langle u, Sv \rangle$ holds if $u \in L^-$, $v \in L^+$, and ${}^o u, {}^o v \in \mathcal{H}$.

Lemma 5:

$$\langle u, (S-1)v \rangle \approx -i \int_{-\star\infty}^{\star\infty} \mathrm{d}t\ e^{-\epsilon|t} \langle u, T_t v \rangle \tag{15}$$

if $u \in L^- \cap L^+$, $v \in L^+$, and ${}^o u, {}^o v \in \mathcal{H}$.

Proof: If $u \in L^- \cap L^+$, $v \in L^+$, and ${}^o u, {}^o v \in \mathcal{H}$ we obtain by lemma 4,

$$\langle u, (S-1)v \rangle = \langle u, (Y^- - Y^+)^{\dagger} Y^+ v \rangle \approx \int_0^{\star\infty} \epsilon e^{-\epsilon s} \langle u, (Y_t - Y_{-t})^{\dagger} Y^+ v \rangle.$$

Let $0 < {}^o\alpha < 1/2$, let $T_1 = 1/\sqrt{\epsilon}$, and let $T_2 = \alpha \min\{T_+, T_-\}$, then

$$\int_0^{\star\infty} \mathrm{d}t\ \epsilon e^{-\epsilon t} \langle u, (Y_t - Y_{-t})^{\dagger} Y^+ v \rangle \approx \int_{T_1}^{\star T_2} \mathrm{d}t\ \epsilon e^{-\epsilon t} \langle u, (Y_t - Y_{-t})^{\dagger} Y^+ v \rangle.$$

By theorem 5, we obtain for $t \in [T_1, T_2]$,

$$(Y_t)^{\dagger} Y^+ v \approx e^{iB_0 t} e^{-iBt} e^{-iB(T_+/2 - t)} e^{iB_0 (T_+/2 - t)} v = e^{iB_0 t} e^{-iBT_+/2} e^{iB_0 T_+/2} e^{-iB_0 t} v = e^{iB_0 t} Y^+ e^{-iB_0 t} v.$$

Analogously,

$$(Y_{-t})^{\dagger}Y^{+}v \approx e^{-iB_0t}e^{iBt}e^{-iB(T_+/2+t)}e^{iB_0(T_+/2+t)}v = e^{-iB_0t}e^{-iBT_+/2}e^{iB_0T_+/2}e^{iB_0t}v = e^{-iB_0t}Y^{+}e^{iB_0t}v.$$

Let $Z_t = e^{iB_0t}Y^{+}e^{-iB_0t}$, then

$$\int_{T_1}^{\star T_2} \mathrm{d}t\ \epsilon e^{-\epsilon t}\langle u,(Y_t - Y_{-t})^{\dagger}Y^{+}v\rangle \approx \int_{T_1}^{\star T_2} \mathrm{d}t\ \epsilon e^{-\epsilon t}\langle u,(Z_t - Z_{-t})v\rangle \approx \int_{0}^{\star \infty} \mathrm{d}t\ \epsilon e^{-\epsilon t}\langle u,(Z_t - Z_{-t})v\rangle.$$

We recognize that $^{\star}(\mathrm{d}/\mathrm{d}t)Z_t = -iT_t$, and obtain by partial integration

$$\int_{0}^{\star \infty} \mathrm{d}t\ \epsilon e^{-\epsilon t}\langle u,(Z_t - Z_{-t})v\rangle = -i\int_{0}^{\star \infty} \mathrm{d}t\ e^{-\epsilon t}\langle u,(T_t + T_{-t})v\rangle = -i\int_{-\star \infty}^{\star \infty} \mathrm{d}t\ e^{-\epsilon|t}\langle u,T_t v\rangle.$$

□

Let $T_{j,k} = \langle x_j,[Y^{+},B_0]x_k\rangle$ (the T-matrix). For $u \in L^{-} \cap L^{+}$, $v \in L^{+}$, and ${}^{o}u, {}^{o}v \in \mathcal{H}$ we obtain

$$\begin{aligned}
\langle u,(S-1)v\rangle &\approx -i\int_{-\star \infty}^{\star \infty} \mathrm{d}t\ e^{-\epsilon|t}\langle u,T_t v\rangle \\
&= -i\sum_{j,k=1}^{h} u_j^{*}v_k T_{j,k}\int_{-\star \infty}^{\star \infty} \mathrm{d}t\ e^{-\epsilon|t}e^{i(\lambda_j-\lambda_k)} \quad (u_j^{*} = \langle u,x_j\rangle, \quad v_k = \langle x_k,v\rangle) \\
&= -i\sum_{j,k=1}^{h} u_j^{*}v_k T_{j,k}\left(\frac{1}{i(\lambda_j-\lambda_k)+\epsilon} - \frac{1}{i(\lambda_j-\lambda_k)-\epsilon}\right) \\
&= -i\sum_{j,k=1}^{h} u_j^{*}v_k T_{j,k}\frac{-2\epsilon}{-(\lambda_j-\lambda_k)^2-\epsilon^2} = -2\pi i\sum_{j,k=1}^{h} u_j^{*}v_k\delta_{\epsilon}(\lambda_j-\lambda_k)T_{j,k}.
\end{aligned}$$

We note that since ϵ is a positive infinitesimal the function

$$\delta_{\epsilon}(x) = \frac{1}{\pi}\frac{\epsilon}{x^2+\epsilon^2} \tag{16}$$

behaves like Dirac's delta distribution. [5]

Theorem 7:

$$\left\langle {}^{o}u, {}^{o}S^{o}v\right\rangle = {}^{o}\sum_{j,k=1}^{h} (\delta_{j,k} - 2\pi i\,\delta_{\epsilon}(\lambda_j-\lambda_k)T_{j,k})u_j^{*}v_k \tag{17}$$

if $u \in L^{-} \cap L^{+}$, $v \in L^{+}$, and ${}^{o}u, {}^{o}v \in \mathcal{H}$.

VI. SUMMARY AND CONCLUSIONS

We have formulated in this paper an approach to nonstandard quantum mechanics, i.e., we have introduced a mathematical framework that is based on NSA, and that can be appropriately applied to quantum mechanics. The principal step is the embedding of a dense subset of a standard complex Hilbert space $\mathcal{H}$ into a hyperfinite-dimensional space H. We have focused then on self-adjoint operators on $\mathcal{H}$, and have constructed appropriate extensions to self-adjoint hyperfinite-rank operators on H. To obtain a sensible interpretation of expectation values we have introduced further nonstandard hulls. We have defined the nonstandard hull ${}^{o}H$ of the hyperfinite-dimensional space H, which is a complex Hilbert space, and the nonstandard hulls of hyperfinite-rank operators on H. The idea is to perform calculations in H, and to interpret expectation values in the nonstandard hull ${}^{o}H$. To this end, we have developed the function calculus with respect to Loeb-measurable functions by introducing projection-valued Loeb measures. Using projection-valued Loeb measures we have proved then a nonstandard spectral theorem. With the help of the

spectral theorem we have shown how our nonstandard framework extends the standard framework used for quantum mechanics. As an example, we have applied our general results to Schrödinger representations of quantum mechanics.

Beside the mathematical results, which are rather interesting for their own, two important advantages are obtained by this approach. First, we can use nonstandard objects like infinitesimals, infinite numbers, or functions that behave like delta distributions in our framework. The availability of these objects is a general advantage of NSA as compared to standard mathematics. Second, since we perform calculations in a hyperfinite-dimensional space we can apply the transferred rules of linear algebra. In particular, self-adjoint hyperfinite-rank operators have complete sets of eigenvalues and eigenvectors. If we use this result to model the Hamiltonian of a quantum system we treat bound states and continuum states on the same footing. We note that this is also a feature of super-Hilbert space formalisms,[2,3] but the present approach seems to be more convenient for physical applications.

Moreover, we have applied the approach to nonrelativistic scattering theory. First we have extended standard time-dependent scattering theory to our framework. If we observe a standard set of states in a scattering experiment, as stated in theorem 5, then the extension yields two fundamental times of a scattering experiment that can be interpreted as the starting time, $-T_+$, and the finishing time, T_-, of the experiment. These times occur as infinite hyper-reals, and are not available in standard theories. Moreover, this result yields a natural separation of time scales: We observe the interacting system on a large time scale that is defined by the infinite time interval $[-T_+, T_-]$, whereas the interaction takes place on a small time scale that is defined by finite times, $t \in \mathrm{fin}({}^\star\mathbb{R})$. In particular, the preparation of the system is done in the remote past at infinite times t for which $-T_+ \leqslant t < 0$ holds, and the detection takes place in the far future at infinite times t for which $0 < t \leqslant T_-$ holds. We note however that this result does not state that the preparation and the detection processes take place on the same time scale since the fraction T_-/T_+ is not necessarily finite. Furthermore, we have applied our results to time-independent scattering theory. For time-independent scattering theory we have shown how concrete calculations work in the framework, and we have derived explicit formulas for the Møller wave operators and for the S-matrix. These formulas, which are well-known from standard physical text books, are proved rigorously.

From the author's point of view, the application of nonstandard methods to nonrelativistic scattering theory is rather fruitful. In particular, this example demonstrates the main advantages of the formalism mentioned above.

APPENDIX

The linear algebra in finite-dimensional subspaces of $\mathcal{H}$ is well known from standard textbooks. We need the results however to obtain the linear algebra in hyperfinite-dimensional subspaces of ${}^\star\mathcal{H}$ in the following. For this purpose, we formulate the standard results in a way that enables us to easily apply the transfer principle. However, although a presentation of nonstandard linear algebra should be available elsewhere, the author was not able to find an appropriate reference in the literature.

1. Linear algebra in finite-dimensional subspaces

Let $\mathcal{F}$ be the set of finite-dimensional subspaces of $\mathcal{H}$. For $F \in \mathcal{F}$ let $\mathrm{ONB}(F)$ be the set of orthonormal bases in F. The dimension d of F is the unique number of elements of each $B \in \mathrm{ONB}(F)$, i.e.,

$$(\exists d \in \mathbb{N})(\forall B \in \mathrm{ONB}(F)), \quad |B| = \mathrm{d}. \tag{A1}$$

We use here ONB as a function on $\mathcal{F}$. Let $\delta: \mathcal{H} \times \mathcal{H} \to \{0,1\}$ be the function defined by

$$\delta(x,y) = \begin{cases} 1, & x = y, \\ 0, & \text{else.} \end{cases}$$

The orthonormality of the bases can be expressed then as

$$(\forall B \in \mathrm{ONB}(F))(\forall x,y \in B), \quad \langle x,y\rangle = \delta(x,y),$$

and basis-set expansions are given by

$$(\forall B \in \mathrm{ONB}(F))(\forall x \in F), \quad x = \sum_{y\in B} \langle y,x\rangle y.$$

We denote the set of finite-rank operators on $\mathcal{H}$ by

$$\mathrm{LF} = \{f \in \mathcal{H}^{\mathcal{H}} : f \text{ is linear and } R(f) \in \mathcal{F}\}. \tag{A2}$$

$R(f)$ denotes the range of the function f. A finite-rank operator A on $\mathcal{H}$ is called normal if $A^\dagger A = AA^\dagger$, and we denote the set of normal finite-rank operators on $\mathcal{H}$ by

$$\mathrm{LFN} = \{A \in \mathrm{LF} : A^\dagger A = AA^\dagger\}. \tag{A3}$$

For $A \in \mathrm{LF}$ and $B \in \mathrm{ONB}(R(A))$ we can express the action of A on $R(A)$ as follows:

$$(\forall x \in R(A)), \quad Ax = \sum_{y\in B} \langle y,Ax\rangle y = \sum_{y,y'\in B} \langle y,Ay'\rangle\langle y',x\rangle y.$$

If A is normal, then $(\langle y,Ay'\rangle)_{y,y'\in B}$ is a normal matrix. Hence, there exists an eigensystem that can be used to express the action of A on $R(A)$, and we obtain

$$(\forall A \in \mathrm{LFN})(\exists B \in \mathrm{ONB}(R(A)))(\exists f \in \mathbb{C}^{\mathcal{H}})(\forall x \in R(A)),$$

$$Ax = \sum_{y\in B} f(y)\langle y,x\rangle y. \tag{A4}$$

The set $\{f(y)\}_{y\in B}$ is the set of eigenvalues of the restriction of A to $R(A)$.

2. Linear algebra in hyperfinite-dimensional subspaces

We assume in the sequel a polysaturated extension of the basic superstructure. Then, ${}^\star\mathcal{F}$ is the set of hyperfinite-dimensional subspaces of ${}^\star\mathcal{H}$. The transferred relation ${}^\star\mathrm{ONB}$ acts on ${}^\star\mathcal{F}$, and by the transfer principle we obtain for $F \in {}^\star\mathcal{F}$,

$$(\exists d \in {}^\star\mathbb{N})(\forall B \in {}^\star\mathrm{ONB}(F)), \quad |B| = d. \tag{A5}$$

We note that the dimension d of F is now a hypernatural number, which may be infinite. The orthonormality of the nonstandard bases is expressed by

$$(\forall B \in {}^\star\mathrm{ONB}(F))(\forall x,y \in B), \quad {}^\star\langle x,y\rangle = {}^\star\delta(x,y),$$

and the nonstandard basis-set expansions are given by

$$(\forall B \in {}^\star\mathrm{ONB}(F))(\forall x \in F), \quad x = \sum_{y\in B} {}^\star\langle y,x\rangle y.$$

Note that ${}^\star\langle\cdot,\cdot\rangle$ is the transferred scalar product, and that $\Sigma_{y\in B}$ may be a hyperfinite sum. The internal hyperfinite-rank operators on ${}^\star\mathcal{H}$ are given by the set

$$^{\star}\mathrm{LF} = \{f \in {}^{\star}(\mathcal{H}^{\mathcal{H}}) : f \text{ is linear and } R(f) \in {}^{\star}\mathcal{F}\}. \tag{A6}$$

A normal linear operator A on $^{\star}\mathcal{H}$ fulfills the condition $A^{\dagger}A = AA^{\dagger}$, and the set of normal hyperfinite-rank operators on $^{\star}\mathcal{H}$ is

$$^{\star}\mathrm{LFN} = \{A \in {}^{\star}\mathrm{LF} : A^{\dagger}A = AA^{\dagger}\}. \tag{A7}$$

For each $A \in {}^{\star}\mathrm{LFN}$ there exists an eigensystem, and we obtain

$$(\forall A \in {}^{\star}\mathrm{LFN})(\exists B \in {}^{\star}\mathrm{ONB}(R(A)))(\exists f \in {}^{\star}(\mathbb{C}^{\mathcal{H}}))(\forall x \in R(A)),$$

$$Ax = \sum_{y \in B} f(y)\,{}^{\star}\langle y, x\rangle y. \tag{A8}$$

Since each $A \in {}^{\star}\mathrm{LFN}$ is internal, the range of A, $R(A)$, is internal, $^{\star}\mathrm{ONB}(R(A))$ is internal, and each $B \in {}^{\star}\mathrm{ONB}(R(A))$ is internal. Moreover, $f \in {}^{\star}(\mathbb{C}^{\mathcal{H}})$ is internal, and the set of eigenvalues, $f(B)$, is thus internal too.

If we consider a standard eigensystem E then it is convenient to enumerate the elements, $E = \{(\lambda_1, x_1), \ldots, (\lambda_d, x_d)\}$, and $\mathrm{d} \in \mathbb{N}$ is the dimension. In the same manner we can denote a nonstandard eigensystem, assuming $\mathrm{d} \in {}^{\star}\mathbb{N}$.

(Received 8 July 2004; accepted 24 July 2004; published 24 November 2004)

If a state is passive for uniformly accelerated observers in n-dimensional ($n \geqslant 2$) anti–de Sitter (Ads) space–time (i.e., cannot be used by them to operate a *perpetuum mobile*), they will (a) register a universal value of the Unruh temperature, (b) discover a PCT symmetry, and (c) find that observables in complementary wedge-shaped regions necessarily commute with each other in this state. The stability properties of such a passive state induce a "geodesic causal structure" on AdS and concommitant locality relations. It is shown that observables in these complementary wedge-shaped regions fulfill strong additional independence conditions. In two-dimensional AdS these even suffice to enable the derivation of a nontrivial, local, covariant net indexed by bounded space–time regions. All these results are model-independent and hold in any theory which is compatible with a weak notion of space–time localization. Examples are provided of models satisfying the hypotheses of these theorems. © *2004 American Institute of Physics.*

I. INTRODUCTION AND BASIC ASSUMPTIONS

Quantum field theory in anti–de Sitter space–time (AdS) has been studied for almost 40 years (see, e.g., Refs. 1 and 20), primarily because it was found that AdS occurs as the ground state geometry in certain supergravity theories with gauged internal symmetry.[6,35] But it has become the object of an extraordinary amount of attention since the AdS–CFT correspondence has emerged. (We refer the interested reader to the SPIRES database, where a comprehensive list of articles on this topic can be retrieved.) There is therefore motivation to clarify in a model-independent setting and in a mathematically rigorous manner the universal properties of such theories, as implied by generally accepted and physically meaningful assumptions. This investigation has lead us to results which apparently have not been remarked in any form in the literature before.

AdS is a maximally symmetric and globally static solution of the vacuum Einstein equations. We consider here AdS of any dimension $n \geqslant 2$, except when explicitly stated otherwise. It can conveniently be described in terms of Cartesian coordinates in the ambient space $\mathbb{R}^{n+1}$ as the quadric surface

$$\mathrm{AdS}^n = \{ x \in \mathbb{R}^{n+1} | x^2 \doteq x_0^2 - x_1^2 - \cdots - x_{n-1}^2 + x_n^2 = R^2 \} \tag{1.1}$$

with metric $g = \mathrm{diag}(1,-1,\ldots,-1,1)$ in diagonal form. As the value of the radius R is not relevant for the results of this paper, we shall set it equal to 1 for convenience. The AdS^n isometry group is $\mathrm{O}(2,n-1)$ whose identity component will be denoted by $\mathrm{SO}_0(2,n-1)$. AdS^n is a homogeneous space of the group $\mathrm{SO}(2,n-1)$. It is not globally hyperbolic; indeed, it has closed timelike curves

[a)] Dedicated to Jacques Bros on the occasion of his seventieth birthday.

[c)] Electronic mail: sjs@math.ufl.edu

and has a timelike boundary at spatial infinity through which physical data can propagate. Although the covering space of AdS^n eliminates the closed timelike curves, it still has a timelike boundary at spatial infinity. We shall find some notable differences between the properties of quantum field theories on AdS^n and those of theories on the covering space.

As some of our basic assumptions are motivated by physical considerations concerning certain families of observables, we must collect some basic facts about observers in AdS. Let $x_O \in \mathrm{AdS}^n$ be any point and let $\lambda(t)$, $t \in \mathbb{R}$, be any one-parameter subgroup of $\mathrm{SO}_0(2,n-1)$ such that $t \mapsto \lambda(t)x_O$ is an orthochronous curve. (Note that AdS is time orientable.) We interpret this curve as the worldline of some observer. Among these observers will be those moving along a geodesic (henceforth, geodesic observers) and those experiencing a constant acceleration (uniformly accelerated observers). Points in a neighborhood of x_O will, in general, also give rise to orthochronous curves under the action of the chosen subgroup of $\mathrm{SO}_0(2,n-1)$, and we denote by W the connected neighborhood of x_O in AdS^n consisting of all such curves. Typically, W is the causal completion of the originally specified worldline. We view the region W as the maximal possible localization for any laboratory within the purview of the given observer. The associated dynamics are given by $e^{itM} \doteq U(\lambda(t))$ with suitable generator M. Since we are choosing a fixed parametrization of the pertinent subgroups of $\mathrm{SO}_0(2,n-1)$, the proper time of the observer is obtained by rescaling t with $((\dot{\lambda}(0)x_O)^2)^{1/2}$.

To become more precise, the geodesics of AdS^n are conic sections by two-planes containing the origin of the ambient space $\mathbb{R}^{n+1}$. So, one-parameter subgroups [see Appendix A for our notation concerning $\mathrm{SO}_0(2,n-1)$] $\lambda(t)$, $t \in \mathbb{R}$, of $\mathrm{SO}_0(2,n-1)$ of the form $\lambda\lambda_{0n}(t)\lambda^{-1}$, $t \in \mathbb{R}$, for some $\lambda \in \mathrm{SO}_0(2,n-1)$ generate admissible geodesic worldlines in the sense just indicated. These worldlines are closed, timelike curves, whose causal completion is the entire space AdS^n. Hence, the maximal laboratory localization region W for such geodesic observers must be the entire space–time, AdS^n. For uniformly accelerated observers, the corresponding one-parameter subgroups are of the form $\lambda\lambda_{01}(t)\lambda^{-1}$, $t \in \mathbb{R}$, for some $\lambda \in \mathrm{SO}_0(2,n-1)$. Their laboratory regions, called AdS wedges, are described immediately below. The algebras $\mathcal{A}(W)$ corresponding to any such wedge region as well as to $W = \mathrm{AdS}^n$ are taken to be weakly closed.

We define a "wedge" in AdS^n to be the causal completion of the worldline of a uniformly accelerated observer in AdS^n. To be concrete and in order to simplify the necessary computations, we consider the particular choice of region

$$W_R = \{ x \in \mathrm{AdS}^n | x_1 > |x_0|, x_n > 0 \}, \tag{1.2}$$

on which the one-parameter subgroup of boosts $\lambda_{01}(t)$, $t \in \mathbb{R}$, in the $0-1$ plane acts in an orthochronous manner. For any $x_O \in W_R$, the curve $t \mapsto \lambda_{01}(t)x_O$ is the worldline of a uniformly accelerated observer for which the causal completion is precisely W_R. By the assumed $\mathrm{SO}_0(2,n-1)$ covariance, all results concerning this wedge have natural extensions to all images of W_R under $\mathrm{SO}_0(2,n-1)$. We therefore define the set of AdS^n wedges to be

$$\mathcal{W} \doteq \{ \lambda W_R | \lambda \in \mathrm{SO}_0(2,n-1) \}. \tag{1.3}$$

These are maximal laboratory localizations for the uniformly accelerated observers.

We can now describe the four standing assumptions of this paper. A discussion of their physical motivation is given in Ref. 12, so we shall only expand upon the less familiar ones.

(i) There exists a strongly continuous, unitary, nontrivial representation U of the symmetry group $\mathrm{SO}_0(2,n-1)$ acting on a separable Hilbert space $\mathcal{H}$. (It is sufficient here to consider the subspace of "bosonic" states, so we shall not need to proceed to the covering group of the space–time symmetry group.)

(ii) On $\mathcal{H}$ act the global von Neumann algebra of observables $\mathcal{A} = \mathcal{A}(\mathrm{AdS}^n)$, which contains any observable measurable in AdS^n, and an isotonous family of von Neumann algebras $\{\mathcal{A}(W)\}_{W \in \mathcal{W}}$ associated with the wedges $\mathcal{W}$. Furthermore, one has

$$\bigvee_{W\in\mathcal{W}} \mathcal{A}(W) = \mathcal{A}. \tag{1.4}$$

(iii) For each wedge $W \in \mathcal{W}$ and $\lambda \in \mathrm{SO}_0(2,n-1)$, one has the equality

$$U(\lambda)\mathcal{A}(W)U(\lambda)^{-1} = \mathcal{A}(\lambda W). \tag{1.5}$$

The weak additivity condition (1.4) is a generalization of the natural idea that all observables are constructed out of local ones. But in contrast to Ref. 12, we do not assume that all observables can be constructed out of observables with arbitrarily small localization region. This is because there are nets of physical interest on curved space–times for which the condition (v) specified below holds but the algebras $\mathcal{A}(\mathcal{O})$ associated with all bounded open regions $\mathcal{O}$ are trivial.[13,31] Also, there exist examples in which the algebra $\mathcal{A}(\mathcal{O})$ is nontrivial only for sufficiently large bounded regions $\mathcal{O}$.[13] In both of these cases the assumption made in Ref. 12 is violated. We have therefore eliminated all assumptions referring to bounded regions.

We emphasize that we do not postulate from the outset any local commutation relations of the observables. For, in contrast to the case of globally hyperbolic space–times, the principle of Einstein causality does not provide any clues as to which observables in AdS should commute with each other. Instead, we shall *derive* such commutation relations from stability properties of the vacuum, which we now specify.

We shall assume that the state ω determined by Ω is passive (cf. Ref. 29 and Sec. 5.4.4 in Ref. 5) for the dynamical system $(\mathcal{A}(W), \mathrm{ad}U(\lambda(t)))$, for all geodesic and all uniformly accelerated observers described earlier. We recall that passivity is an expression of the Second Law of Thermodynamics. Since the vacuum is the most elementary system, all order parameters should have sharp values in this state. This is expressed by the weak mixing property

$$\lim_{T\to\infty} \frac{1}{T}\int_0^T \left(\omega(A(t)B) - \omega(A(t))\omega(B)\right)\, dt = 0, \tag{1.6}$$

for all $A, B \in \mathcal{A}$, where $A(t) \doteq e^{itM}Ae^{-itM}$. The restriction of the state ω to $\mathcal{A}(W)$ is said to be central if $\omega(AB) = \omega(BA)$, for all $A, B \in \mathcal{A}(W)$. If this holds, then either Ω is annihilated by most of the observables in $\mathcal{A}(W)$ or $\mathcal{A}(W)$ is a finite algebra (cf. Sec. 8.1 in Ref. 26). In quantum field theory this is a physically pathological circumstance, which we shall exclude from consideration.

These basic features of the vacuum can be summarized as follows.

(iv) The vacuum vector Ω is cyclic for $\mathcal{A}$ and determines a passive, weakly mixing and noncentral state ω for all geodesic and all uniformly accelerated observers.

The standing assumptions (i)–(iv) are model-independent and physically natural. In this paper we shall show that these assumptions entail that for geodesic observers the vacuum ω is a ground state; uniformly accelerated observers in AdS will register a universal value of the Unruh temperature; they will discover a PCT symmetry; and they will find that observables localized in complementary wedge-shaped regions must commute in the vacuum state. Not only do such observables commute in this sense, but the corresponding algebras manifest strong properties of statistical independence, the nature of which will be studied in detail. We shall also see that these assumptions imply that quantum theories on AdS obey a geodesic causal structure.

Related results appeared in Ref. 12, and we revisit some of those arguments here in more detail than in that announcement. But our research in the intervening time has led not only to further results and a weakening of the assumptions, but also to a shift in our point of view, which now places emphasis on the locality and independence properties which can be derived from our assumptions. We establish independence properties going far beyond those announced in Ref. 12, and we prove an additional locality property of such theories on proper AdS^n which was not observed in Ref. 12. Moreover, we show that in two dimensions these suffice to construct a nontrivial, local, covariant net indexed by bounded space–time regions. We also explain how known examples of quantum fields on AdS fit into our scheme.

The primary lesson to be drawn from this paper is the observation that covariance and passivity properties of states induce strong algebraic relations between the observables, which may be interpreted as manifestations of Einstein causality. In our research program, the theories on AdS treated here serve as a theoretical laboratory to test this striking feature. But the insight gained in this analysis goes beyond this class of field theoretical models to quantum fields on other space–times. Further, it seems to be of relevance in the discussion of causality problems appearing in nonlocal theories, such as string theory and quantum field theory on noncommutative space–times.

II. UNRUH EFFECT, PCT SYMMETRY, AND WEAK LOCALITY

We now enter into the analysis of the implications of our standing assumptions (i)–(iv) by appealing to a deep result of Pusz and Woronowicz for general quantum dynamical systems.[29] In the present context this result says that the vacuum vector Ω is, as a consequence of its passivity and mixing properties, invariant under the dynamics of any of the observers discussed earlier (Ref. 29, Theorem 1.1). In particular, this entails that $M_{01}\Omega=0$ (and hence, by Lemma A.3, Ω is invariant under the entire group $U(\mathrm{SO}_0(2,n-1))$), and ω is either (Ref. 29, Theorem 1.3) a ground state for M_{01} (which is excluded by Lemma A.1), or satisfies, for some *a priori* unknown $\beta\geqslant 0$, the Kubo–Martin–Schwinger (KMS) condition. In fact, our assumptions exclude the possibility of $\beta=0$. In the proof of Lemma 4.1 in Ref. 29 it is shown that if $\beta=0$, then either ω is a trace state on $\mathcal{A}(W_R)$ or $M_{01}=0$. In the second case, one would have the triviality of the representation of the boost group and thus the triviality of $U(\mathrm{SO}_0(2,n-1))$, which is excluded by (i). The first case is excluded by assumption (iv). Therefore, for any pair of operators $A,B\in\mathcal{A}(W_R)$ there exists an analytic function F in the strip $\{z\in\mathbb{C}|0<\mathrm{Im}(z)<\beta\}$ with continuous boundary values at $\mathrm{Im}(z)=0$ and $\mathrm{Im}(z)=\beta$, which are given by

$$F(t)=\omega(AB(t)),\quad F(t+i\beta)=\omega(B(t)A), \tag{2.1}$$

respectively, for all $t\in\mathbb{R}$ and with $B(t)\doteq e^{itM_{01}}Be^{-itM_{01}}$. By the $\mathrm{SO}_0(2,n-1)$-covariance the same assertions are valid for the action of the groups $e^{itM_{0j}}$, $j=2,\ldots,n-1$, on the suitable wedge algebras.

In Appendix C it is proven that this analyticity entails that the theories we are considering here satisfy the Reeh–Schlieder property (cf. Lemma C.1). So the vacuum vector Ω is cyclic for the algebra $\mathcal{A}(W)$, given any $W\in\mathcal{W}$, and, by the KMS property, it is also separating for $\mathcal{A}(W)$ (Ref. 5, Corollary 5.3.9). Hence, the Tomita–Takesaki modular theory is applicable to $(\mathcal{A}(W),\Omega)$, for every $W\in\mathcal{W}$ (cf. Refs. 4 and 26). Let J_{W_R} denote the modular conjugation and $\Delta_{W_R}^{it}$ the modular unitaries associated to the pair $(\mathcal{A}(W_R),\Omega)$. Since the adjoint action of the strongly continuous unitary group $e^{itM_{01}}$, $t\in\mathbb{R}$, leaves the algebra $\mathcal{A}(W_R)$ invariant and satisfies the KMS condition, we must have $\Delta_{W_R}^{it}=e^{-\beta tM_{01}}$, for all $t\in\mathbb{R}$ (Ref. 26, Theorem 9.2.16). Hence, J_{W_R} is determined by the equation

$$J_{W_R}A\Omega=e^{-(\beta/2)M_{01}}A^*\Omega,\quad A\in\mathcal{A}(W_R). \tag{2.2}$$

A. Unruh temperature

The main task of this subsection is to determine the Unruh temperature β^{-1} and specific properties of the operator J_{W_R}. To this end we shall adapt methods employed in Ref. 3.

We show in Lemma B.1 that there exists a wedge $W_0\in\mathcal{W}$ such that $\lambda W_0\subset W_R$ for all λ in a neighborhood of the identity in $\mathrm{SO}_0(2,n-1)$. Therefore, for any $j=2,\ldots,n-1$ one has $\lambda_{0j}(s)W_0\subset W_R$ for the boosts $\lambda_{0j}(s)$ in the $0-j$ plane for all sufficiently small parameters s. From Eq. (A10) in Appendix A we have

$$e^{itM_{01}}e^{isM_{0j}}=e^{is(\cosh(t)M_{0j}+\sinh(t)M_{1j})}e^{itM_{01}}. \tag{2.3}$$

Thus we get for any vector $\Phi\in\mathcal{H}$ and operator $A^*\in\mathcal{A}(W_0)$:

$$\langle \Phi, e^{itM_{01}} e^{isM_{0j}} A^* e^{-isM_{0j}} \Omega \rangle = \langle \Phi, e^{is(\cosh(t)M_{0j} + \sinh(t)M_{1j})} e^{itM_{01}} A^* \Omega \rangle. \tag{2.4}$$

We are now in the position of employing the argument given in Ref. 12 to yield the equalities

$$J_{W_R} e^{isM_{0j}} = e^{is(\cos(\beta/2)M_{0j} + i \sin(\beta/2)M_{1j})} J_{W_R}. \tag{2.5}$$

As pointed out in Ref. 12, the operator on the left-hand side of this equation is antiunitary, which entails that β is an *integer* multiple of 2π, for otherwise the operator appearing in the exponential function on the right-hand side would not be skew-adjoint. By using the proof of Theorem 6.2 in Ref. 3 with $\mathcal{A}(\mathcal{O})$ replaced by $\mathcal{A}(W_0)$, one sees that its only possible value is $\beta = 2\pi$. Proceeding to the proper time scale of the observer, we conclude that he is exposed to the Unruh temperature $(1/2\pi)((\dot{\lambda}_{01}(0)x_O)^2)^{-1/2}$, in accordance with the value found in computations for some particular models[17,25] and also by more general considerations.[7]

For geodesic observers, Lemma A.1 is not applicable. In fact, ω cannot be a KMS state for $e^{itM_{0n}}$ on $\mathcal{A}$, the laboratory observable algebra for geodesic observers. Indeed, since the covariance assumption (iii) implies $U(\lambda)\mathcal{A}U(\lambda)^{-1} = \mathcal{A}$, for all $\lambda \in \mathrm{SO}_0(2, n-1)$, if $e^{itM_{0n}}$ were the modular group for Ω on $\mathcal{A}$, then modular theory would necessitate $U(\lambda)e^{itM_{0n}} = e^{itM_{0n}}U(\lambda)$, for all $\lambda \in \mathrm{SO}_0(2, n-1)$ (cf. Theorem 3.2.18 in Ref. 4). But this would only be possible if the representation $U(\mathrm{SO}_0(2, n-1))$ were trivial, which is excluded by assumption (i). So ω must be a ground state for $e^{itM_{0n}}$.

We have therefore established the following general facts:

Theorem 2.1: *Let standing assumptions (i)–(iv) hold. Then Ω is invariant under the action of $U(\mathrm{SO}_0(2, n-1))$ and each uniformly accelerated observer testing Ω in AdS^n finds a universal value $(1/2\pi)((\dot{\lambda}_{01}(0)x_O)^2)^{-1/2}$ of the Unruh temperature which depends only on his particular orbit. For geodesic observers ω is a ground state; in particular, M_{0n} is a positive operator.*

This result is a consequence of the passivity of ω, and this vacuum state is the only normal state on $\mathcal{A}$ which is passive for all observers. In light of Theorem 2.1, it is physically justified to identify the operator M_{0n} with the global energy operator.

The result $\beta = 2\pi$ and (Ref. 26, Theorem 9.2.16) permit us to completely determine the modular unitaries corresponding to the pair $(\mathcal{A}(W), \Omega)$, for all $W \in \mathcal{W}$.

Corollary 2.2: Given the standing assumptions (i)–(iv), the modular unitaries for the pair $(\mathcal{A}(W_R), \Omega)$ are given by

$$\Delta_{W_R}^{it} = e^{-i2\pi t M_{01}}, \quad t \in \mathbb{R}. \tag{2.6}$$

Covariance and the uniqueness of the modular objects yield similar results for Δ_W^{it}, for all $W \in \mathcal{W}$.

B. PCT symmetry

Having computed the modular unitaries and the value of the inverse temperature β seen by the uniformly accelerated observers, let us return now to the analysis of J_{W_R} and clarify its relation to space–time reflections. Plugging $\beta = 2\pi$ into Eq. (2.5), we see that for small s:

$$J_{W_R} e^{isM_{0j}} = e^{-isM_{0j}} J_{W_R}, \quad j = 2, \ldots, n-1. \tag{2.7}$$

This relation can be extended to arbitrary s by iteration, if one decomposes $e^{isM_{0j}}$ into an m-fold product $(e^{i(s/m)M_{0j}})^m$ for sufficiently large m. A similar argument with λ_{0j} replaced by λ_{0n} and Eq. (A10) replaced by Eq. (A8) yields

$$J_{W_R} e^{isM_{0n}} = e^{-isM_{0n}} J_{W_R}. \tag{2.8}$$

On the other hand, modular theory yields

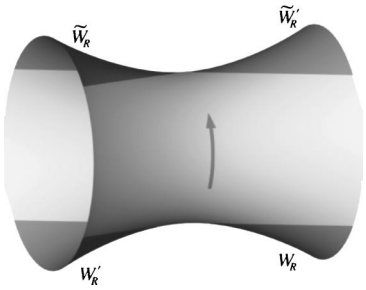

FIG. 1. Conjugate wedges in anti–de Sitter space and arrow of time.

$$J_{W_R} e^{isM_{01}} = e^{isM_{01}} J_{W_R}. \tag{2.9}$$

Since these one-parameter subgroups generate $\mathrm{SO}_0(2,n-1)$, the intertwining properties of J_{W_R} with all unitaries $U(\lambda) \in U(\mathrm{SO}_0(2,n-1))$ are determined.

Lemma 2.3: Given standing assumptions (i)–(iv), one has

$$J_{W_R} U(\lambda) = U(\theta_{01}\lambda\theta_{01}) J_{W_R}, \tag{2.10}$$

for all $\lambda \in \mathrm{SO}_0(2,n-1)$, *where* $\theta_{01} = \mathrm{diag}(-1,-1,1,\ldots,1)$ *is the reflection which changes the sign of the* $0-1$*-coordinates of the points in* AdS^n *(the reflection about the edge of the wedge* W_R*).*

Hence, if we define $U(\theta_{01}\lambda) \doteq J_{W_R} U(\lambda)$, for any $\lambda \in \mathrm{SO}_0(2,n-1)$, the following partial analog of the PCT-theorem can be proven.

Theorem 2.4: *If standing assumptions (i)–(iv) hold, then the unitary representation* U *of* $\mathrm{SO}_0(2,n-1)$ *extends to a representation of* $\mathrm{SO}(2,n-1)$ *in which the reflection* θ_{01} *is implemented by the antiunitary involution* J_{W_R}.

Proof: Note that $\mathrm{SO}(2,n-1)$ is the disjoint union of $\theta_{01}\mathrm{SO}_0(2,n-1)$ and $\mathrm{SO}_0(2,n-1)$. Since

$$U(\theta_{01}\lambda_1 \cdot \lambda_2) = J_{W_R} U(\lambda_1\lambda_2) = J_{W_R} U(\lambda_1) U(\lambda_2) = U(\theta_{01}\lambda_1) U(\lambda_2) \tag{2.11}$$

and

$$U(\theta_{01}\lambda_1 \cdot \theta_{01}\lambda_2) = U(\theta_{01}\lambda_1\theta_{01}) U(\lambda_2) = J_{W_R} U(\lambda_1) J_{W_R} U(\lambda_2) = U(\theta_{01}\lambda_1) U(\theta_{01}\lambda_2), \tag{2.12}$$

for all $\lambda_1, \lambda_2 \in \mathrm{SO}_0(2,n-1)$, the assertion follows.

Theorem 2.4 is a purely group-theoretic statement which does not yet say anything about the adjoint action of J_{W_R} on the observables. Results of that type require an additional assumption and will appear in a later publication.

C. Weak locality

In order to gain insight into the locality properties of the net, we consider the observables which are localized in the region

$$W_R' \doteq \{x \in \mathrm{AdS}^n \,|\, -x_1 > |x_0|, x_n > 0\}. \tag{2.13}$$

Throughout this subsection we shall only consider AdS^n of dimension $n \geq 3$. Since the regions W_R and W_R' are each one-half (on the same "side" of AdS^n—see Fig. 1 above) of the regions obtained by intersecting opposite wedge-shaped regions in the ambient space $\mathbb{R}^{n+1}$ with AdS^n, we call them opposite wedges. In general, if $W = \lambda W_R$, for some $\lambda \in \mathrm{SO}_0(2,n-1)$, then $W' = \lambda W_R'$.

In Ref. 12 it was shown that for $n \geq 3$ the earlier results entail that observables which are localized in complementary wedges are weakly local in the vacuum state. So we can state:

Theorem 2.5: *Under the assumptions (i)–(iv) and for* $n \geq 3$, *observables which are localized in opposite wedges of* AdS^n *are weakly local with respect to each other. Explicitly, for any* λ

$\in \mathrm{SO}_0(2,n-1)$ *and any* $A' \in \mathcal{A}(\lambda W_R')$, $B \in \mathcal{A}(\lambda W_R)$, *one has* $\langle \Omega, A'B\Omega\rangle = \langle \Omega, BA'\Omega\rangle$.

This result is also valid for theories in the covering space of AdS^n which satisfy (i)–(iv). A similar result was proven in Ref. 7 for two-point functions of quantum fields on the covering space of AdS^n satisfying a different set of assumptions in the Wightman framework.

The uniqueness of the modular objects and the covariance assumption (iii) give us a relation we shall use repeatedly in the following:

$$U(\lambda) J_W U(\lambda)^{-1} = J_{\lambda W}, \tag{2.14}$$

for all $W \in \mathcal{W}$ and all $\lambda \in \mathrm{SO}_0(2,n-1)$. Hence, since $\mathcal{A}(W_R') = e^{i\pi M_{12}} \mathcal{A}(W_R) e^{-i\pi M_{12}}$, Eq. (2.14) and the observations made above imply

$$J_{W_R'} = e^{i\pi M_{12}} J_{W_R} e^{-i\pi M_{12}} = J_{W_R} e^{-i2\pi M_{12}} = J_{W_R}. \tag{2.15}$$

Thus, the $\mathrm{SO}_0(2,n-1)$-covariance of the net entails

$$J_{W'} = J_W, \quad \text{for every } W \in \mathcal{W}. \tag{2.16}$$

If the algebras $\mathcal{A}(W)$ and $\mathcal{A}(W')$ commuted strongly with each other, it can be shown that (2.16) follows from modular theory. It is therefore of interest that (2.16) obtains when the algebras only weakly commute.

We continue with some further locality results, which distinguish theories on proper AdS from those on the covering space. We have chosen our wedge regions $W \in \mathcal{W}$ to be connected for physical reasons, as previously explained. But the intersection of the (connected) wedge $\mathbf{W}$ in the ambient space

$$\mathbf{W} = \{ x \in \mathbb{R}^{n+1} | x_1 > |x_0| \} \tag{2.17}$$

with AdS^n has two connected components, one of which is W_R and the other is the conjugate wedge

$$\widetilde{W}_R' = \{ x \in \mathrm{AdS}^n | x_1 > |x_0|, -x_n > 0 \}. \tag{2.18}$$

One has the geometric relations

$$\widetilde{W}_R = \theta_{01} \widetilde{W}_R' = -W_R \quad \text{and} \quad W_R' = -\widetilde{W}_R'. \tag{2.19}$$

Moreover, it is easy to see that

$$e^{i\pi M_{0n}} \mathcal{A}(W_R) e^{-i\pi M_{0n}} = \mathcal{A}(\widetilde{W}_R') \quad \text{and} \quad e^{i\pi M_{0n}} \mathcal{A}(W_R') e^{-i\pi M_{0n}} = \mathcal{A}(\widetilde{W}_R). \tag{2.20}$$

The rotation in the 0-n plane by π also reverses the orientation of the world lines $\lambda_{01}(t) x_O$ (cf. Eq. (A5)), so that the world lines in $\widetilde{W}_R'$ run in the same direction as those of W_R', while those in $\widetilde{W}_R$ have the same orientation as those in W_R. Explicitly, Corollary 2.2 implies that the modular unitaries for the pair $(\mathcal{A}(W_R'), \Omega)$ are given by

$$\Delta_{W_R'}^{it} = e^{i2\pi t M_{01}}, \quad t \in \mathbb{R}. \tag{2.21}$$

Hence, for all $t \in \mathbb{R}$, one has

$$\Delta_{\widetilde{W}_R}^{it} = e^{i\pi M_{0n}} \Delta_{W_R'}^{it} e^{-i\pi M_{0n}} = e^{i\pi M_{0n}} e^{i2\pi t M_{01}} e^{-i\pi M_{0n}} = e^{-i2\pi t M_{01}} = \Delta_{W_R}^{it}, \tag{2.22}$$

by (A5). So, $\{e^{-i2\pi t M_{01}}\}_{t \in \mathbb{R}}$ is the group of modular unitaries for $(\mathcal{A}(\widetilde{W}_R), \Omega)$, and we have the relation

$$J_{\tilde{W}_R} A\Omega = e^{-\pi M_{01}} A^* \Omega, \quad \text{for} \quad A \in \mathcal{A}(\tilde{W}_R). \tag{2.23}$$

Moreover, we may appeal to (2.16) and the modular theory to find

$$J_{\tilde{W}_R} A'\Omega = e^{\pi M_{01}} A'^* \Omega, \quad \text{for} \quad A' \in \mathcal{A}(\tilde{W}'_R). \tag{2.24}$$

From Eqs. (2.14) and (2.8) follow the equalities:

$$J_{\tilde{W}'_R} = e^{i\pi M_{0n}} J_{W_R} e^{-i\pi M_{0n}} = e^{i2\pi M_{0n}} J_{W_R} = J_{W_R}, \tag{2.25}$$

where we have used $e^{i2\pi M_{0n}} = 1$, valid in proper AdS but not in its covering space. Thus, by (2.16) we have for $n \geqslant 3$:

$$J_{W'_R} = J_{W_R} = J_{\tilde{W}_R} = J_{\tilde{W}'_R}. \tag{2.26}$$

We can now prove that $\mathcal{A}(\tilde{W}'_R)$ and $\mathcal{A}(W_R)$ are weakly local with respect to each other.

Theorem 2.6: *Under the assumptions (i)–(iv) and for $n \geqslant 3$, observables which are localized in W_R are weakly local with respect to observables localized in $\tilde{W}'_R$. Explicitly, for any $\lambda \in \mathrm{SO}_0(2, n-1)$ and any $A' \in \mathcal{A}(\lambda \tilde{W}'_R)$, $B \in \mathcal{A}(\lambda W_R)$, one has $\langle \Omega, A'B\Omega \rangle = \langle \Omega, BA'\Omega \rangle$.*

Proof: With the earlier preparations, one sees that for any $A' \in \mathcal{A}(\tilde{W}'_R)$ and $B \in \mathcal{A}(W_R)$, one has

$$\langle \Omega, A'^* B\Omega \rangle = \overline{\langle \Omega, B^* A'\Omega \rangle} = \overline{\langle \Omega, B^* J_{W_R} J_{W_R} A'\Omega \rangle} = \langle \Omega, Be^{-\pi M_{01}} e^{\pi M_{01}} A'^* \Omega \rangle = \langle \Omega, BA'^* \Omega \rangle. \tag{2.27}$$

Theorem 2.6 does not hold in the covering space of AdS^n, since, in general, $e^{i\pi M_{0n}}$ and J_{W_R} will not commute in such theories. Indeed, in Refs. 7 and 21 can be found examples of a free field theory on the covering space of AdS^n for which it can be shown that assumptions (i)–(iv) are satisfied, but the elements of $\mathcal{A}(W_R)$ and $\mathcal{A}(\tilde{W}'_R)$ do not commute in the vacuum state—see Appendix E for further discussion. However, for theories on proper AdS, Theorem 2.6 is consistent with a property of two-point functions observed in Ref. 7 and arrived at there by very different means and assumptions.

In Theorems 2.5 and 2.6 we see that the passivity of the vacuum state and the group relations in $\mathrm{SO}_0(2, n-1)$ have determined which regions in AdS^n are to have (weakly) commensurable observables. In theories on AdS where the basic fields satisfy standard *c*-number commutation relations, it follows from this result that such observables actually commute in the usual (operator) sense.[33] Indeed, it follows then that

$$\mathcal{A}(W'_R) \subset \mathcal{A}(W_R)' \quad \text{and} \quad \mathcal{A}(W_R) \subset \mathcal{A}(\tilde{W}'_R)'. \tag{2.28}$$

But assumptions (i)–(iv) do not imply the strong locality relations (2.28) in general. Indeed, consider a tempered Hermitian Fermi-type field ϕ with anticommutator

$$\phi(x)\phi(y) + \phi(y)\phi(x) = (W(x,y) + W(y,x)) \cdot 1, \tag{2.29}$$

where $W(x,y)$ is taken to be any $\mathrm{SO}_0(2, n-1)$-invariant two-point function satisfying the spectrum condition. [Specific examples are provided by two-point functions given in Ref. 21, Eq. (4.9).] This anticommutator does not vanish when x and y are in complementary wedges. The field ϕ generates a CAR-algebra with a quasifree state fixed by the two-point function

$$\omega(\phi(x)\phi(y)) = W(x,y). \tag{2.30}$$

Proceeding to the GNS representation with cyclic vector Ω, we conclude from Refs. 7 and 21 that this example satisfies all of our standing assumptions. Since $W(x,y)$ is symmetric when x, y are in complementary wedges, the weak locality is explicit.

As explained in Ref. 12, if (2.28) holds there are grounds to expect that the theory generically cannot have interaction. Theories which are weakly local but not strongly local escape that argument. In the following sections we shall therefore continue to explore consequences of standing assumptions (i)–(iv) when (2.28) does not hold, beginning with the nature of the independence of the algebras $\mathcal{A}(W_1)$, $\mathcal{A}(W_2)$ associated with suitable spacelike separated wedges. But, first, we make some further observations.

Assumptions (i)–(iv) entail that each wedge algebra $\mathcal{A}(W)$ is a factor (cf. the proof of Theorem 4.3). If wedge locality (2.28) held, then it would follow that $\mathcal{A}(W)\cap\mathcal{A}(W')=\mathbb{C}1$, i.e., no nontrivial observable can be localized in both W and W'. It is therefore of physical interest that this fact also follows directly from (i)–(iv) in the absence of (2.28).

Proposition 2.7: Let standing assumptions (i)–(iv) hold and let $n\geqslant 3$. *Then for any* $W\in\mathcal{W}$, *one has* $\mathcal{A}(W)\cap\mathcal{A}(W')=\mathbb{C}1$ *and* $\mathcal{A}(W)\vee\mathcal{A}(W')=B(\mathcal{H})$.

Proof: By covariance, it suffices to prove the assertion for $W=W_R$. Let $A\in\mathcal{A}(W_R)\cap\mathcal{A}(W_R')$ and $\mathcal{H}_0$ be the closure in $\mathcal{H}$ of $(\mathcal{A}(W_R)\cap\mathcal{A}(W_R'))\Omega$. Since $e^{i2t\pi M_{01}}$, respectively, $e^{-i2t\pi M_{01}}$, are the modular unitaries corresponding to $(\mathcal{A}(W_R),\Omega)$, respectively, $(\mathcal{A}(W_R'),\Omega)$, then with $\Delta=e^{2\pi M_{01}}$ one has

$$J_{W_R}\Delta^{1/2}A\Omega=A^*\Omega,\quad J_{W_R'}\Delta^{-1/2}A\Omega=A^*\Omega. \tag{2.31}$$

Hence, Eq. (2.26) entails that $\Delta^{1/2}=\Delta^{-1/2}$ on $\mathcal{H}_0$. Therefore, $\Delta A\Omega=A\Omega$, which yields $A\Omega=\Delta^{it}A\Omega=e^{i2t\pi M_{01}}A\Omega$, for all $t\in\mathbb{R}$. Hence, the mean ergodic theorem (see, e.g., Ref. 27) entails that $A\Omega=F_0A\Omega$, where F_0 is the projection onto the subspace of vectors in $\mathcal{H}$ each left invariant under $U(\mathrm{SO}_0(2,n-1))$, using Lemma A.3. Since the mixing property in condition (iii) entails that the rank of F_0 is 1 and since Ω is separating for $\mathcal{A}(W_R)$, it follows that A is a multiple of the identity. But this entails

$$\mathbb{C}1=J_W(\mathcal{A}(W)\cap\mathcal{A}(W'))J_W=J_W\mathcal{A}(W)J_W\cap J_W\mathcal{A}(W')J_W=\mathcal{A}(W)'\cap\mathcal{A}(W')', \tag{2.32}$$

using (2.26), so that $\mathcal{A}(W)\vee\mathcal{A}(W')=\mathcal{B}(\mathcal{H})$, for every $W\in\mathcal{W}$. □

Before we close this section, we have a final proposition to prove.

Proposition 2.8: Let standing assumptions (i)–(iv) hold, $n\geqslant 3$ *and* $W_1,W_2\in\mathcal{W}$. *If* $W_2\neq\pm W_1$, *then* $\mathcal{A}(W_1)\neq\mathcal{A}(W_2)$.

Proof: Since two unequal wedges $W_1,W_2\in\mathcal{W}$ have unequal reflections about their edges, unless W_2 coincides with W_1', $\widetilde{W}_1$ or $\widetilde{W}_1'$, Lemma 2.3 entails $J_{W_1}\neq J_{W_2}$ and, thus, $\mathcal{A}(W_1)\neq\mathcal{A}(W_2)$.

If $\mathcal{A}(W_1)\subset\mathcal{A}(W_1')$, then Theorem 2.5 entails that the restriction of ω to $\mathcal{R}(W_1)$ is a trace, which is excluded by assumptions (i) and (iii). Similarly Theorem 2.6 yields $\mathcal{A}(W_1)\neq\mathcal{A}(\widetilde{W}_1')$. □

III. THE SCHLIEDER PROPERTY

Many versions of the notion of independence of algebras of observables in spacelike separated regions have emerged in algebraic quantum theory (see Ref. 34 for a review), and most are logically independent of the usual notion of commensurability, which is that the algebras commute with each other elementwise. In this section we shall prove that algebras associated with properly spacelike separated wedges W_1,W_2 satisfy an extended form of the algebraic independence condition known as the Schlieder property, namely that $A_1\in\mathcal{A}(W_1),A_2\in\mathcal{A}(W_2)$ and $A_1A_2=0$ imply either $A_1=0$ or $A_2=0$. We shall say that two wedges W_1,W_2 are properly spacelike separated if $\lambda W_1\subset W_2'$ for all λ in some neighborhood of the identity in $\mathrm{SO}(2,n-1)$. Note that W and W' are not properly spacelike separated. Although in de Sitter and Minkowski spaces of dimension $n\geqslant 3$ such properly spacelike separated wedges do not exist, we show in Appendix B that they are plentiful in AdS.

The proof of an extended Schlieder property in AdS^n, $n\geqslant 3$, will be carried out in a series of steps.

Lemma 3.1: Let $W_1,W_2\in\mathcal{W}$ *be properly spacelike separated and let* $A_{1,k}\in\mathcal{A}(W_1)$, $A_{2,k}$

$\in \mathcal{A}(W_2), k=1,\ldots,n$. *If* $B \in \mathcal{B}(\mathcal{H})$ *is such that*

$$\sum_{k=1}^{n} A_{1,k} U(\lambda) B U(\lambda)^{-1} A_{2,k} = 0, \tag{3.1}$$

for all λ *in some neighborhood* $\mathcal{N} \subset \mathrm{SO}_0(2,n-1)$ *of the identity, then this equality holds for all* $\lambda \in \mathrm{SO}_0(2,n-1)$.

Proof: Choosing a smaller neighborhood $\mathcal{N}$, if necessary, it may be assumed that there exists a $W \in \mathcal{W}$ such that $W_1 \subset \lambda_0\lambda_1 W$ and $W_2 \subset \lambda_0\lambda_1 W'$ for $\lambda_0, \lambda_1 \in \mathcal{N}$. Let $s \mapsto \lambda_W(s)$ be the group of boosts inducing a positive timelike flow on the wedge W (and hence a negative timelike flow on W'). Setting $\lambda_1(s) \doteq \lambda_1 \lambda_W(s) \lambda_1^{-1}$ for $\lambda_1 \in \mathcal{N}$, it will first be shown that $B_s \doteq U(\lambda_1(s)) B U(\lambda_1(s))^{-1}$, $s \in \mathbb{R}$, satisfies the hypothesis of the lemma as well. Putting $\lambda(s) \doteq \lambda_0 \lambda_1 \lambda_W(s) \lambda_1^{-1} \lambda_0^{-1}$, $\lambda_0 \in N$, and picking arbitrary elements X_1, X_2 in $\mathcal{A}(W_1)$, $\mathcal{A}(W_2)$, respectively, one has

$$\begin{aligned} &\sum_{k=1}^{n} \langle \Omega, X_1 A_{1,k} U(\lambda_0) B_s U(\lambda_0)^{-1} A_{2,k} X_2 \Omega \rangle \\ &\quad = \sum_{k=1}^{n} \langle \Omega, X_1 A_{1,k} U(\lambda(s)) U(\lambda_0) B U(\lambda_0)^{-1} U(\lambda(s))^{-1} A_{2,k} X_2 \Omega \rangle = 0 \end{aligned} \tag{3.2}$$

for sufficiently small $|s|$. Now $s \mapsto U(\lambda(s))$ is, after rescaling s, the modular group corresponding to $(\mathcal{A}(\lambda_0\lambda_1 W), \Omega)$ and, similarly, $s \mapsto U(\lambda(s))^{-1}$ is the modular group corresponding to $(\mathcal{A}(\lambda_0\lambda_1 W'), \Omega)$. Since $\mathcal{A}(W_1) \subset \mathcal{A}(\lambda_0\lambda_1 W)$ and $\mathcal{A}(W_2) \subset \mathcal{A}(\lambda_0\lambda_1 W')$, it follows that

$$s \mapsto \langle \Omega, X_1 A_{1,k} U(\lambda(s)) U(\lambda_0) B U(\lambda_0)^{-1} U(\lambda(s))^{-1} A_{2,k} X_2 \Omega \rangle \tag{3.3}$$

extends to an analytic function on a strip of the upper complex half plane for each $k=1,\ldots,n$. By the preceding result, the corresponding sum of functions thus has to vanish for all $s \in \mathbb{R}$. As X_1, X_2 were arbitrary within the above limitations and Ω is cyclic for $\mathcal{A}(W_1)$ and $\mathcal{A}(W_2)$, respectively, one concludes that $\Sigma_{k=1}^{n} A_{1,k} U(\lambda_0) B_s U(\lambda_0)^{-1} A_{2,k} = 0$, $s \in \mathbb{R}$ and $\lambda_0 \in \mathcal{N}$.

Next, let $\lambda_1, \ldots, \lambda_m \in \mathcal{N}$. Setting $\lambda_i(s) \doteq \lambda_i \lambda_W(s) \lambda_i^{-1}$, $i=1,\ldots,m$, one deduces by induction on m that also

$$B_{s_1,\ldots,s_m} \doteq U(\lambda_m(s_m)) \cdots U(\lambda_1(s_1)) B U(\lambda_1(s_1))^{-1} \cdots U(\lambda_m(s_m))^{-1} \tag{3.4}$$

satisfies the hypothesis of the lemma for $s_1, \ldots, s_m \in \mathbb{R}$. Indeed, the case $m=1$ has just been proven. By the induction hypothesis and the group property of U, the assertion follows for $s_1, \ldots, s_{m-1} \in \mathbb{R}$ and small $|s_m|$. The argument presented in the preceding paragraph then entails that the assertion holds for all $s_m \in \mathbb{R}$.

But, according to Lemma A.2, the closure of the group generated by $\lambda_0 \lambda_W(s) \lambda_0^{-1}$, $\lambda_0 \in \mathcal{N}$, $s \in \mathbb{R}$, is $\mathrm{SO}_0(2,n-1)$. Hence, taking into account that U is a continuous representation, it follows by (weak operator) continuity of $\lambda \mapsto U(\lambda) B U(\lambda)^{-1}$ that these operators satisfy the hypothesis of the lemma as well, thereby completing its proof.

In the following, we shall say that the wedge W_1 is properly contained in the wedge W_2 and shall write $W_1 \Subset W_2$ if there exists a neighborhood $\mathcal{N}$ of the origin in $\mathrm{SO}_0(2,n-1)$ such that $\lambda W_1 \subset W_2$, for all $\lambda \in \mathcal{N}$. Again, note that in de Sitter space and Minkowski space of dimension $n \geqslant 3$ such pairs of wedges do not exist, but in AdS they are abundant (see Appendix B).

Lemma 3.2: Let W_1, W_2 *be properly spacelike separated, let* W *be any wedge such that* W_1, W_2 *are properly contained in* W *and* W', *respectively. If* $A_{1,k}$, $A_{2,k}, k=1,\ldots,n$, *are elements of* $\mathcal{A}(W_1)$ *and* $\mathcal{A}(W_2)$, *respectively, such that* $\Sigma_{k=1}^{n} A_{1,k} A_{2,k} = 0$, *one has*

$$\sum_{k=1}^{n} A_{1,k} U(\lambda_1) B_1 U(\lambda_1)^{-1} \cdots U(\lambda_m) B_m U(\lambda_m)^{-1} A_{2,k} = 0, \tag{3.5}$$

for $m \in \mathbb{N}$ *and* $B_i \in \mathcal{A}(W)'$, $\lambda_i \in \mathrm{SO}_0(2,n-1), i=1,\ldots,m$.

Proof: The proof of the lemma proceeds by induction on m. Let $\mathcal{N}$ be a neighborhood of the identity in $\mathrm{SO}_0(2,n-1)$ such that $\lambda_0^{-1}W_1 \subset W$ for $\lambda_0 \in \mathcal{N}$. Then

$$U(\lambda_0)^{-1}A_{1,k}U(\lambda_0) \in \mathcal{A}(\lambda_0^{-1}W_1) \subset \mathcal{A}(W) = (J_W\mathcal{A}(W)J_W)'. \tag{3.6}$$

So $A_{1,k}$ and $U(\lambda_0)B_0U(\lambda_0)^{-1}$ commute for any $B_0 \in J_W\mathcal{A}(W)J_W$ and consequently

$$0 = U(\lambda_0)B_0U(\lambda_0)^{-1}\sum_{k=1}^{n} A_{1,k}A_{2,k} = \sum_{k=1}^{n} A_{1,k}U(\lambda_0)B_0U(\lambda_0)^{-1}A_{2,k}. \tag{3.7}$$

By the preceding lemma, this equality extends to all $\lambda_0 \in \mathrm{SO}_0(2,n-1)$. Assuming now that the statement holds for m, one has with the same choices of B_0 and λ_0 as in the preceding step

$$\begin{aligned} 0 &= \sum_{k=1}^{n} U(\lambda_0)B_0U(\lambda_0)^{-1}A_{1,k}U(\lambda_1)B_1U(\lambda_1)^{-1}\cdots U(\lambda_m)B_mU(\lambda_m)^{-1}A_{2,k} \\ &= \sum_{k=1}^{n} A_{1,k}U(\lambda_0)B_0U(\lambda_0)^{-1}U(\lambda_1)B_1U(\lambda_1)^{-1}\cdots U(\lambda_m)B_mU(\lambda_m)^{-1}A_{2,k}, \end{aligned} \tag{3.8}$$

for $B_i \in J_W\mathcal{A}(W)J_W$, $\lambda_i \in \mathrm{SO}_0(2,n-1), i=1,\ldots,m$. Taking into account that U is a representation of $\mathrm{SO}_0(2,n-1)$, this implies (after an obvious redefinition of $\lambda_1,\ldots,\lambda_m$):

$$\sum_{k=1}^{n} A_{1,k}U(\lambda_0)(B_0U(\lambda_1)B_1U(\lambda_1)^{-1}\cdots U(\lambda_m)B_mU(\lambda_m)^{-1})U(\lambda_0)^{-1}A_{2,k} = 0. \tag{3.9}$$

Applying once more the preceding lemma, one concludes that

$$\sum_{k=1}^{n} A_{1,k}U(\lambda_0)B_0U(\lambda_0)^{-1}U(\lambda_1)B_1U(\lambda_1)^{-1}\cdots U(\lambda_m)B_mU(\lambda_m)^{-1}A_{2,k} = 0, \tag{3.10}$$

for $B_i \in J\mathcal{A}(W)J$, $\lambda_i \in \mathrm{SO}_0(2,n-1), i=0,1,\ldots,m$, completing the proof.

In the next step of our argument we make use of the relation $J_WU(\lambda)J_W = U(\theta\lambda\theta)$, where θ is the reflection about the edge of W (cf. Lemma 2.3). Because of weak additivity, Proposition 2.7 and the preceding relation we have

$$\bigvee_{\lambda} U(\lambda)J_W\mathcal{A}(W)J_WU(\lambda)^{-1} = J_W\Big(\bigvee_{\lambda} U(\lambda)\mathcal{A}(W)U(\lambda)^{-1}\Big)J_W = J_W\mathcal{B}(\mathcal{H})J_W = \mathcal{B}(\mathcal{H}), \tag{3.11}$$

showing that $\mathcal{B}(\mathcal{H})$ is the weak operator closure of the algebra generated by the operators $U(\lambda)J_WBJ_WU(\lambda)^{-1}$, $B \in \mathcal{A}(W)$, $\lambda \in \mathrm{SO}_0(2,n-1)$. It therefore follows that for any collection of operators $A_{1,k}$, $A_{2,k}$ as in the preceding lemma one has

$$\sum_{k=1}^{n} A_{1,k}BA_{2,k} = 0, \quad B \in \mathcal{B}(\mathcal{H}). \tag{3.12}$$

Taking into account that $\mathcal{B}(\mathcal{H})$ contains in particular all operators of rank 1, we conclude that for any normal state $\tilde{\omega}$ on $\mathcal{B}(\mathcal{H})$ we have

$$\sum_{k=1}^{n} \tilde{\omega}(A_{1,k})A_{2,k} = 0 = \sum_{k=1}^{n} A_{1,k}\tilde{\omega}(A_{2,k}). \tag{3.13}$$

So we have established that properly spacelike separated wedge algebras manifest a strong form of algebraic independence which implies the Schlieder property.

Proposition 3.3: Let standing assumptions (i)–(iv) hold and let W_1 *and* W_2 *be properly space-*

like separated wedges. For any $A_{1,k} \in \mathcal{A}(W_1)$ *and* $A_{2,k} \in \mathcal{A}(W_2), k=1,\ldots,n$, *such that* $\Sigma_{k=1}^{n} A_{1,k}A_{2,k}=0$, *relation (3.13) must hold for all normal states* $\tilde{\omega}$ *on* $\mathcal{B}(\mathcal{H})$. *In particular, if* $A_1A_2=0$, *then either* $A_1=0$ *or* $A_2=0$.

If the algebras $\mathcal{A}(W_1)$ and $\mathcal{A}(W_2)$ were mutually commuting, then the Schlieder property is equivalent to C^*-independence.[32] However, in the noncommuting case, the Schlieder condition is strictly weaker than C^*-independence,[24] and it is an open question in our setting whether C^*-independence holds if $\mathcal{A}(W_1)$ and $\mathcal{A}(W_2)$ do not commute.

IV. THE SPLIT PROPERTY

We shall next show that if W_1 is properly contained in W_2, then there exists a type I factor $\mathcal{M}$ such that $\mathcal{A}(W_1) \subset \mathcal{M} \subset \mathcal{A}(W_2)$, as long as the multiplicity of the eigenvalues of M_{0n} does not grow too fast. Hence, with this additional assumption, the algebras $\mathcal{A}(W_1)$ and $\mathcal{A}(W_2)'$ manifest a particularly strong form of statistical independence.

Since AdS^n is periodic in the time variable and M_{0n} is a positive operator, the spectrum of M_{0n} is a subset of $\mathbb{N}_0=\{0\}\cup\mathbb{N}$. If the multiplicities of the eigenvalues of M_{0n} do not increase too rapidly, then $e^{-\gamma M_{0n}}$ is a trace class operator for any $\gamma>0$. In Appendix D we exhibit simple examples, constructed from irreducible unitary positive energy representations of $\mathrm{SO}_0(2,n-1)$, where this situation obtains. We formulate this assumption explicitly as condition (NC).

(NC). There exist constants $c_0>0$ and $0<k_0<1$ such that the spectral multiplicities $\boldsymbol{\mu}_m$ of the eigenvalues m of M_{0n} are bounded by $\boldsymbol{\mu}_m \leqslant e^{c_0 m^{k_0}}$, $m \in \mathbb{N}_0$.

It is particularly straightforward to establish the "split property" in the presence of condition (NC). In fact, in Ref. 16, Theorem 3.2 it was shown that in conformally invariant theories a trace-class condition on the exponentiated conformal Hamiltonian entails that suitable inclusions are split. We indicate here a somewhat different and more explicit argument. To this end, we recall the following lemma (Ref. 10, Lemma 2.3).

Lemma 4.1: Let $U(t)=e^{itH}$, $t \in \mathbb{R}$, *determine a strongly continuous one-parameter group of unitary operators with positive generator H and invariant unit vector* $\Omega \in \mathcal{H}$. *Moreover, let* $\mathcal{A}$ *and* $\mathcal{B}$ *be von Neumann algebras satisfying*

$$U(t)\mathcal{A}U(t)^{-1} \subset \mathcal{B}, \tag{4.1}$$

for all $|t|<\delta$ *and some* $\delta>0$. *Then there exists a continuous function* $f:\mathbb{R}\to\mathbb{R}$ *which decreases almost exponentially, i.e.,* $\sup_\omega |f(\omega)|e^{|\omega|^k}<\infty$, *for any* $0<k<1$, *such that*

$$\langle \Omega, AB'\Omega\rangle = \langle \Omega, Af(H)B'\Omega\rangle + \langle \Omega, B'f(H)\Omega\rangle, \tag{4.2}$$

for all $A \in \mathcal{A}$ *and* $B' \in \mathcal{B}'$.

We use this to establish the following general result.

Proposition 4.2: Let $U(t)=e^{itH}$, $t \in \mathbb{R}$, *be a strongly continuous one-parameter group of unitary operators with an (up to a phase) unique invariant unit vector* $\Omega \in \mathcal{H}$ *and with a generator H having spectrum in* $\mathbb{N}_0$ *and spectral multiplicities bounded by* $\boldsymbol{\mu}_m \leqslant e^{c_0 m^{k_0}}$, $m \in \mathbb{N}_0$, *for fixed* $c_0>0$ *and* $0<k_0<1$. *Moreover, let* $\mathcal{A}$ *and* $\mathcal{B}$ *be type III factors with* Ω *cyclic and separating for both and satisfying*

$$U(t)\mathcal{A}U(t)^{-1} \subset \mathcal{B}, \tag{4.3}$$

for all $|t|<\delta$ *and some* $\delta>0$. *Then there exists a type I factor* $\mathcal{M}$ *such that* $\mathcal{A} \subset \mathcal{M} \subset \mathcal{B}$.

Proof: Consider the algebraic tensor product $\mathcal{A}\odot\mathcal{B}'$ and two of its representations

(a) $(\pi, \mathcal{H}, \Omega)$ with $\pi(A\odot B') \doteq AB'$,
(b) $(\pi_p, \mathcal{H}\otimes\mathcal{H}, \Omega\otimes\Omega)$ with $\pi_p(A\odot B') \doteq A\otimes B'$

in an obvious notation. By the preceding lemma, one has

$$\langle \Omega, \pi(A \odot B')\Omega \rangle = \langle \Omega, AB'\Omega \rangle = \langle \Omega, Af(H)B'\Omega \rangle + \langle \Omega, B'f(H)\Omega \rangle. \tag{4.4}$$

Let P_Ω be the projection onto $\mathbb{C}\Omega \subset \mathcal{H}$ and let V be the unitary flip on $\mathcal{H} \otimes \mathcal{H}$:

$$V\Phi \otimes \Psi \doteq \Psi \otimes \Phi, \quad \Phi, \Psi \in \mathcal{H}. \tag{4.5}$$

Taking into account that $f(H)$ is a trace class operator on $\mathcal{H}$, because of the assumptions on the spectrum of H and the rapid decay of f, one may conclude from (4.4) that

$$\langle \Omega, \pi(A \odot B')\Omega \rangle = tr_{\mathcal{H}\otimes\mathcal{H}}([V(f(H) \otimes P_\Omega) + (P_\Omega \otimes f(H))V]A \otimes B'), \tag{4.6}$$

where the operator in square brackets is of trace class on $\mathcal{H} \otimes \mathcal{H}$. Thus

$$\langle \Omega, \pi(A \odot B')\Omega \rangle = \omega_p(\pi_p(A \odot B')), \tag{4.7}$$

where ω_p is some normal functional with respect to the representation π_p. Since the left-hand side defines a state on $A \odot \mathcal{B}'$, so does the right-hand side; hence, ω_p is, in fact, a state on $\pi_p(\mathcal{A} \odot \mathcal{B}')^- = \mathcal{A} \overline{\otimes} \mathcal{B}'$. Since $\mathcal{A}, \mathcal{B}'$ are type III factors, so is their tensor product. Moreover, $\Omega \otimes \Omega$ is a cyclic and separating vector for $\mathcal{A} \overline{\otimes} \mathcal{B}'$, since Ω is cyclic and separating for $\mathcal{A}$ and $\mathcal{B}'$. Hence ω_p is represented by a vector $\Omega_p \in \mathcal{H} \otimes \mathcal{H}$, and one has

$$\langle \Omega, \pi(A \odot B')\Omega \rangle = \langle \Omega_p, \pi_p(A \odot B')\Omega_p \rangle, \quad A \in \mathcal{A}, B' \in \mathcal{B}'. \tag{4.8}$$

Since Ω is cyclic for $\pi(\mathcal{A} \otimes \mathcal{B}')$, one concludes that π is unitarily equivalent to some subrepresentation of π_p. But, due to the fact that $\pi_p(\mathcal{A} \otimes \mathcal{B}')$ is a factor of type III, any subrepresentation of π_p is equivalent to π_p; hence, π and π_p are unitarily equivalent.

So let $W: \mathcal{H} \otimes \mathcal{H} \to \mathcal{H}$ be a unitary such that

$$AB' = \pi(A \odot B') = W\pi_p(A \odot B')W^{-1} = WA \otimes B'W^{-1}. \tag{4.9}$$

Since $\mathcal{A} \otimes 1 \subset \mathcal{B}(\mathcal{H}) \otimes 1 \subset (1 \otimes \mathcal{B}')'$, one concludes, after applying the adjoint action of W to this chain of inclusions,

$$\mathcal{A} \subset W(\mathcal{B}(\mathcal{H}) \otimes 1)W^{-1} \subset \mathcal{B}'' = \mathcal{B}, \tag{4.10}$$

where $\mathcal{M} \doteq W(\mathcal{B}(\mathcal{H}) \otimes 1)W^{-1}$ is a type I factor. □

We can now prove the following theorem for our immediate purposes.

Theorem 4.3: *Let the assumptions (i)–(iv) and (NC) hold. Then for any wedges W_1 and W_2 such that*

$$e^{itM_{0n}}\mathcal{A}(W_1)e^{-itM_{0n}} \subset \mathcal{A}(W_2), \tag{4.11}$$

for all sufficiently small $t \in \mathbb{R}$, there exists a type I_∞ factor $\mathcal{M}$ such that $\mathcal{A}(W_1) \subset \mathcal{M} \subset \mathcal{A}(W_2)$.

Remark: Of course, if $W_1 \Subset W_2$, then (4.11) holds.

Proof: Our passivity and mixing assumptions entail that $\mathcal{A}(W)$ is a type III_1 factor, for all $W \in \mathcal{W}$ (Ref. 29, Theorem 4.3). The theorem then follows at once from Proposition 4.2.

Note that in de Sitter space and Minkowski space of dimension $n \geqslant 3$ no inclusions of wedge algebras can be split. For Minkowski space this was observed in Ref. 8; in de Sitter space $W_1 \subset W_2$ entails $W_1 = W_2$.

The earlier results hold only for theories on proper AdS. If the covering space of AdS is considered, then condition (NC) must be replaced by the condition that the map

$$\mathcal{A}(W) \ni A \mapsto e^{-\gamma M_{0n}}A\Omega, \tag{4.12}$$

is nuclear, for all $\gamma > 0$.[9] The proof presented in Ref. 9 is formulated in terms of double cone algebras in Minkowski space but carries over to the present situation without difficulty.

V. LOCAL NETS ON TWO-DIMENSIONAL AdS

In this section we prove that standing assumptions (i)–(iv) and the spectral condition (NC) entail the existence of a nontrivial, covariant and local subnet in two-dimensional AdS. It is noteworthy that locality properties can be derived in these circumstances, and it would be of interest to see whether the same is also true in higher-dimensional AdS.

In two-dimensional AdS, the set of all wedge-shaped regions consists of two disconnected pieces $\{\lambda W_R|\lambda \in \mathrm{SO}_0(2,n-1)\}$ and $\{\lambda W_L|\lambda \in \mathrm{SO}_0(2,n-1)\}$, where $W_L = W_R'$. The former (respectively, latter) will be denoted by $\mathcal{W}_R(\mathcal{W}_L)$ and called the class of right wedges (left wedges). Note that $W \in \mathcal{W}_R$ if and only if $W' \in \mathcal{W}_L$. We assume as before that

$$\mathcal{A} = \bigvee_{W \in \mathcal{W}_R} \mathcal{A}(W), \tag{5.1}$$

and that Ω is cyclic for $\mathcal{A}$. Hence, once again, Proposition C.1 yields the cyclicity of Ω for every $\mathcal{A}(W)$, $W \in \mathcal{W}_R$.

In AdS^2 the edge of a wedge is a single point. For each point $a \in \mathrm{AdS}^2$ we shall denote by W_a the unique element of $\mathcal{W}_R$ whose edge is a. Then W_a' is the unique element of $\mathcal{W}_L$ whose edge is a. For $a,b \in \mathrm{AdS}^2$ such that $W_b \Subset W_a$ we define the open sets (double cones) $\mathcal{O}_{a,b} = W_a \cap W_b'$. Corresponding to $\mathcal{O}_{a,b}$ we define the von Neumann algebra

$$\mathcal{B}(\mathcal{O}_{a,b}) = \mathcal{A}(W_a) \cap \mathcal{A}(W_b)'. \tag{5.2}$$

Note that $\mathcal{O}_{a,b} \subset \mathcal{O}_{c,d}$ if and only if $W_a \subset W_c$ and $W_d \subset W_b$. The isotony of the original net of wedge algebras then implies

$$\mathcal{B}(\mathcal{O}_{a,b}) \subset \mathcal{B}(\mathcal{O}_{c,d}), \tag{5.3}$$

i.e., the isotony of the net $\{\mathcal{B}(\mathcal{O}_{a,b})|a,b \in \mathrm{AdS}^2\}$. The covariance of the original net of wedge algebras entails

$$U(\lambda)\mathcal{B}(\mathcal{O}_{a,b})U(\lambda)^{-1} = U(\lambda)(\mathcal{A}(W_a) \cap \mathcal{A}(W_b)')U(\lambda)^{-1} = \mathcal{A}(\lambda W_a) \cap \mathcal{A}(\lambda W_b)' = \mathcal{B}(\lambda \mathcal{O}_{a,b}) \tag{5.4}$$

for all $\lambda \in \mathrm{SO}(2,n-1)$.

In general, there is no reason for such relative commutants of wedge algebras to be nontrivial. But in our setting they turn out to be very large algebras, having a dense G_δ set of cyclic vectors.

Proposition 5.1: If conditions (i)–(iv) and (NC) hold in a theory on two-dimensional AdS and $W_b \Subset W_a$, *then* $\mathcal{B}(\mathcal{O}_{a,b})$ *is a type* III_1 *factor*.

Proof: If W_b is properly contained in W_a, then from Theorem 4.3 one has the existence of a type I factor $\mathcal{M}$ such that $\mathcal{A}(W_b) \subset \mathcal{M} \subset \mathcal{A}(W_a)$. From the proof of Theorem 2.1 in Ref. 18 there exists a unitary mapping $\mathcal{H} \to \mathcal{H} \otimes \mathcal{H}$ such that $U\mathcal{A}(W_b)U^{-1} = \mathcal{A}(W_b) \otimes 1$ and $U\mathcal{A}(W_a)U^{-1} = \mathcal{B}(\mathcal{H}) \otimes \mathcal{A}(W_a)$. Using Takesaki's commutant theorem for tensor products (cf. Ref. 26, Theorem 11.2.16) one therefore sees that

$$\mathcal{B}(\mathcal{O}_{a,b}) = \mathcal{A}(W_a) \cap \mathcal{A}(W_b)' = U^{-1}((\mathcal{B}(\mathcal{H}) \otimes \mathcal{A}(W_a)) \cap (\mathcal{A}(W_b)' \otimes \mathcal{B}(\mathcal{H})))U = U^{-1}\mathcal{A}(W_b)' \otimes \mathcal{A}(W_a)U. \tag{5.5}$$

Since $\mathcal{A}(W_a)$ and $\mathcal{A}(W_b)$ are type III_1 factors (cf. proof of Theorem 4.3), the algebra $\mathcal{A}(W_b)' \otimes \mathcal{A}(W_a)$ and, thus, also $\mathcal{B}(\mathcal{O}_{a,b})$ is a type III_1 factor (cf. Ref. 26, Corollary 11.2.17 and Ref. 15, Theorems 1.3.4 and 3.4.1).

We have seen previously that assumptions (i)–(iv) prescribe the sense in which "spacelike separated" is to be understood in AdS^n. Hence, the region $\mathcal{O}_{a,b}$ is spacelike separated from $\mathcal{O}_{c,d}$ if there exists a wedge W such that $\mathcal{O}_{a,b} \subset W$ and $\mathcal{O}_{c,d} \subset W'$. Without loss of generality, we may assume for concreteness that $W \in \mathcal{W}_R$, so that $W_a \subset W \subset W_d$. Then one finds that the local algebras satisfy locality

$$\mathcal{B}(\mathcal{O}_{a,b}) = \mathcal{A}(W_a) \cap \mathcal{A}(W_b)' \subset \mathcal{A}(W) \subset \mathcal{A}(W_c)' \vee \mathcal{A}(W_d) = \mathcal{B}(\mathcal{O}_{c,d})'. \tag{5.6}$$

We summarize these findings in the following theorem.

Theorem 5.2: If conditions (i)–(iv), (NC) and (5.1) hold in a theory on two-dimensional AdS, then the above construction yields a nontrivial, covariant and local net $\mathcal{O} \mapsto \mathcal{B}(\mathcal{O})$ *based on double cones* $\mathcal{O} \subset AdS^2$, *in which each algebra* $\mathcal{B}(\mathcal{O})$ *is a factor of type* III_1.

One can similarly define a second nontrivial, covariant, and local net from a given net of wedge algebras based upon the wedges in $\mathcal{W}_L$. These two local nets coincide if the initial nets of wedge algebras are local with respect to each other, $\mathcal{A}(W') \subset \mathcal{A}(W)'$.

We wish to sketch some consequences of this construction. The weakly local, but quite nonlocal net fixed by the field ϕ given in Eq. (2.29) is also well-defined in two-dimensional AdS, as long as the two-point function $W(x,y)$ is suitably chosen. The preceding construction yields many nontrivial observables localized in precompact subsets of AdS^2 and associated with this field. In terms of the original, simply expressed field, these local observables are quite complicated objects. This suggests the possibility of constructing complex local objects from relatively simple nonlocal fields.

In Ref. 14 the existence of split inclusions of wedge algebras was replaced by a modular nuclearity condition to employ the above construction in theories on two-dimensional Minkowski space. This modular nuclearity condition has been verified[28] in a factorizing S-matrix model with S-matrix not equal to the identity. The basic field in that model has algebraic relations similar to those of our field ϕ. Since in some suitable sense quantum theories on AdS become close to theories on Minkowski space as the AdS radius becomes sufficiently large, one may expect that the model on AdS^2 determined by ϕ also describes physics which goes beyond that of generalized free fields. These matters shall be further investigated elsewhere.

VI. CONCLUSIONS AND FURTHER REMARKS

We have thus shown that stability properties of a state carrying the interpretation of a "vacuum" imply a PCT theorem, the uniqueness of the Unruh temperature, as well as commensurability and independence properties of the observables in any quantum field theory on AdS. Such implications exist also in other space–times, but they are of particular interest in the case of AdS, where the causal structure is such that it is not clear *a priori* how to define "mutually spacelike regions," and therefore it is not clear which locality relations are physically meaningful. Nor is it sufficient to sidestep the issue by appealing to theories on the covering space of AdS^n. In fact, we have seen that observables in opposite wedges W and W' or in conjugate wedges W and $\widetilde{W}'$ necessarily commute with each other, either weakly or strongly. The former fact can seem natural from the point of view of the covering space of AdS^n, but the latter can certainly not be observed in theories on the covering space. It is remarkable that locality properties can be determined by stability assumptions. Indeed, we showed that in two-dimensional AdS these stability assumptions and a weak growth condition on the eigenvalues of M_{02} entail the existence of a nontrivial, covariant, local net indexed by bounded regions in AdS. It would be of interest to determine if the same is true of theories on higher dimensional AdS.

It was conjectured by Bros, Epstein, and Moschella in Ref. 7 that the assumptions made in that paper should follow from our standing assumptions. This would be an interesting matter to settle, since it would allow one to derive more detailed information about the analyticity properties of the two-point function of quantum fields on AdS.

support by the Deutsche Forschungsgemeinschaft (DFG). The authors have benefited from discussions with J. Bros. They also acknowledge conversations with M. Florig at an early stage of these investigations.

APPENDIX A: UNITARY REPRESENTATIONS OF THE AdS GROUP

The algebraic properties of the strongly continuous unitary representation of $\mathrm{SO}_0(2,n-1)$ assumed to exist in (i) are of crucial importance to us. As a convenience to the reader, we collect the relevant properties here. Many of the arguments in this section are adapted from Ref. 3. Given any such representation U and a coordinate system on AdS^n, we denote by $M_{\mu\nu}, \mu,\nu = 0,1,\ldots,n$, the corresponding self-adjoint generators. On a dense, invariant domain of analytic vectors in $\mathcal{H}$, they fulfill the following Lie-algebraic relations:

$$[M_{\mu\nu},M_{\rho\sigma}] = -ig_{\mu\rho}M_{\nu\sigma} + ig_{\mu\sigma}M_{\nu\rho} - ig_{\nu\sigma}M_{\mu\rho} + ig_{\nu\rho}M_{\mu\sigma}, \tag{A1}$$

where $g=\mathrm{diag}(1,-1,\ldots,-1,1)$, $\mu,\nu=0,1,\ldots,n$. In particular, the operator M_{01} generates the action of the boosts λ_{01}:

$$U(\lambda_{01}(t)) = e^{itM_{01}}, \quad t \in \mathbb{R}, \tag{A2}$$

and similarly for the operators $M_{0j}, j=2,\ldots,n-1$. M_{0n} is the generator of the time translations. Any of the operators $M_{0j}, j=1,\ldots,n$, may be taken to be the operator M discussed in the Introduction (see Sec. I). If $n\geqslant 3$, the operators $M_{jk}, j,k=1,\ldots,n-1$, are the generators of spatial rotations, whereas $M_{jn}, j=2,\ldots,n-1$ generate other subgroups of boosts obtained from the first-mentioned by temporal rotation. If $n=2$, then M_{01} and M_{12} are generators of boosts and there are no spatial rotations.

The Lie-algebraic relations (A1) yield the equality

$$e^{isM_{0n}}M_{01}e^{-isM_{0n}} = \cos(s)M_{01} - \sin(s)M_{1n}, \tag{A3}$$

which implies

$$e^{i\pi M_{0n}}M_{01}e^{-i\pi M_{0n}} = -M_{01}. \tag{A4}$$

Hence, M_{01} cannot be a positive operator on $\mathcal{H}$. Since the representation $U(\mathrm{SO}_0(2,n-1))$ is nontrivial, we may conclude the following lemma from the assumed $\mathrm{SO}_0(2,n-1)$-covariance.

Lemma A.1: The operators $M_{0j}, j=1,\ldots,n-1$, cannot be positive on $\mathcal{H}$ and thus Ω cannot be a ground state for the group $e^{itM_{0j}}$.

The Lie-algebraic relations (A1) also imply the following group relations:

$$e^{isM_{0n}}e^{itM_{01}}e^{-isM_{0n}} = e^{it(\cos(s)M_{01}-\sin(s)M_{1n})}; \tag{A5}$$

$$e^{isM_{0j}}e^{itM_{01}}e^{-isM_{0j}} = e^{it(\cosh(s)M_{01}-\sinh(s)M_{1j})}, \quad j=2,\ldots,n-1; \tag{A6}$$

$$e^{isM_{j1}}e^{itM_{01}}e^{-isM_{j1}} = e^{it(\cos(s)M_{01}-\sin(s)M_{j0})}, \quad j=2,\ldots,n-1; \tag{A7}$$

$$e^{isM_{01}}e^{itM_{0n}}e^{-isM_{01}} = e^{it(\cosh(s)M_{0n}-\sinh(s)M_{1n})}. \tag{A8}$$

Of course, Eqs. (A6) and (A7) are vacuous if $n=2$. We shall establish a few necessary tools.

Lemma A.2: Let $\mathcal{N}\subset \mathrm{SO}_0(2,n-1)$ be any neighborhood of the identity in $\mathrm{SO}_0(2,n-1)$. Then the closure $\mathcal{U}_\mathcal{N}$ in the strong operator topology of the group generated by the unitaries $U(\lambda\lambda_{01}(t)\lambda^{-1})$, $t\in\mathbb{R}$, $\lambda\in\mathcal{N}$, contains $U(\mathrm{SO}_0(2,n-1))$.

Proof: Consider first $n\geqslant 3$. From (A6) it follows that for all sufficiently small $|s|$ and for all $t\in\mathbb{R}$, $\mathcal{U}_\mathcal{N}$ contains the operator $e^{it(\cosh(s)M_{01}-\sinh(s)M_{1j})}$ for $j=2,\ldots,n-1$. With fixed s, the Trotter product formula[30] applied to the product of the one–parameter groups $e^{it(\cosh(s)M_{01}-\sinh(s)M_{1j})}$ and $e^{it\,\cosh(s)M_{01}}\in\mathcal{U}_\mathcal{N}$ implies that the rotations $e^{-it\,\sinh(s)M_{1j}}$, $j=2,\ldots,n-1$, are also contained in $\mathcal{U}_\mathcal{N}$.

Similarly, Eqs. (A5) and (A7) entail that the operators $e^{itM_{1n}}$ and $e^{itM_{j0}}$, $j=2,\ldots,n-1$, $t\in\mathbb{R}$, are contained in $\mathcal{U}_{\mathcal{N}}$. Since the group $U(\mathrm{SO}_0(2,n-1))$ is generated by these subgroups, the proof is complete for $n\geqslant 3$.

If $n=2$, then the same argument applied to (A5) entails that the group $e^{itM_{12}}$, $t\in\mathbb{R}$, is contained in $\mathcal{U}_{\mathcal{N}}$. One may then apply the same reasoning to the equality

$$e^{isM_{12}}e^{itM_{01}}e^{-isM_{12}}=e^{it(\cosh(s)M_{01}-\sinh(s)M_{02})} \tag{A9}$$

to conclude that also the group $e^{itM_{02}}$, $t\in\mathbb{R}$, is contained in $\mathcal{U}_{\mathcal{N}}$. The assertion now follows for $n=2$.

Lemma A.3: Let $\Psi\in\mathcal{H}$ satisfy $U(\lambda_{01}(t))\Psi=\Psi$, for all $t\in\mathbb{R}$. Then $U(\lambda)\Psi=\Psi$, for all $\lambda\in\mathrm{SO}_0(2,n-1)$.

Proof: Consider first $n\geqslant 3$. Using the equation

$$e^{isM_{01}}e^{itM_{0j}}e^{-isM_{01}}=e^{it(\cosh(s)M_{0j}+\sinh(s)M_{1j})},\quad j=2,\ldots,n-1, \tag{A10}$$

and setting $t=2re^{-|s|}$, the continuity of the representation $U(\mathrm{SO}_0(2,n-1))$ implies that

$$\lim_{s\to\pm\infty}e^{isM_{01}}e^{i2re^{-|s|}M_{0j}}e^{-isM_{01}}=e^{ir(M_{0j}\pm M_{1j})}, \tag{A11}$$

for $j=2,\ldots,n-1$, where the limit is the strong operator limit on $\mathcal{H}$. But then, by hypothesis, one has

$$\lim_{s\to\pm\infty}\left\|e^{isM_{01}}e^{i2re^{-|s|}M_{0j}}e^{-isM_{01}}\Psi-\Psi\right\|=\lim_{s\to\pm\infty}\left\|e^{i2re^{-|s|}M_{0j}}\Psi-\Psi\right\|=0, \tag{A12}$$

since $e^{i2re^{-|s|}M_{0j}}$ converges strongly to the identity 1 on $\mathcal{H}$ as $s\to\pm\infty$. These two equations then imply

$$e^{ir(M_{0j}\pm M_{1j})}\Psi=\Psi, \tag{A13}$$

for all $r\in\mathbb{R}$ and $j=2,\ldots,n-1$. Similarly, the equation

$$e^{isM_{01}}e^{itM_{1n}}e^{-isM_{01}}=e^{it(\cosh(s)M_{1n}+\sinh(s)M_{0n})} \tag{A14}$$

yields

$$e^{ir(M_{1n}\pm M_{0n})}\Psi=\Psi, \tag{A15}$$

for all $r\in\mathbb{R}$. By using the Trotter product formula again and taking suitable limits, it is clear that $M_{0j}\Psi=0=M_{1j}\Psi$, for all $j=0,\ldots,n$. Equation (A1) then implies that Ψ is annihilated by all of the generators $M_{\mu\nu}$, which yields the assertion for $n\geqslant 3$.

If $n=2$, Eq. (A14) yields

$$e^{ir(M_{12}\pm M_{02})}\Psi=\Psi, \tag{A16}$$

for all $r\in\mathbb{R}$, and thus $M_{12}\Psi=0=M_{02}\Psi$. The assertion then follows for $n=2$.

We mention that Lemma A.3 is also stated (without explicit proof) as Lemma 5.4 in Ref. 7.

APPENDIX B: WEDGE INCLUSIONS IN AdS

Here we give the proof of some useful geometric properties of the subregions of AdS^n which we have identified as the correct choice of wedges in AdS^n. Indeed, we wish to show that for any wedge $W\in\mathcal{W}$ there exist wedges $W_0\in\mathcal{W}$ which are properly contained in W, $W_0\Subset W$, respectively, such that W_0' is properly spacelike separated from W, $W\Subset W_0$. In fact, such wedges are quite abundant. These results are to be contrasted with the situation in de Sitter space, where de Sitter

wedges satisfy $W_1 \subset W_2$ if and only if $W_1 = W_2$.[11] In Minkowski space of dimension $n \geq 3$, two wedges form an inclusion $W_1 \subset W_2$ only if W_1 is a suitable translation of W_2. Hence, also in the latter case there do not exist properly spacelike separated wedges.

It is convenient to use the following description of W_R:

$$W_R = \{x \in \mathrm{AdS}^n | e_\pm \cdot x < 0, x \cdot e_4 > 0\}, \tag{B1}$$

where $e_\pm = (\pm 1, 1, 0, \ldots, 0)$ and $e_4 = (0, \ldots, 0, 1)$. Consider the lightlike vectors $f_\pm = (\pm 1, c, 0, \ldots, 0, s)$, where $s > 0$ and $c^2 = 1 + s^2$, and the wedge they determine

$$W_0 \doteq \{x \in \mathrm{AdS}^n | x \cdot f_\pm < 0, x \cdot e_4 > 0\}. \tag{B2}$$

The edge of this wedge is the spacelike submanifold

$$\mathcal{E}_1 \doteq \{(0, s(1+\boldsymbol{\sigma}^2)^{1/2}, \boldsymbol{\sigma}, c(1+\boldsymbol{\sigma}^2)^{1/2}) | \boldsymbol{\sigma} \in \mathbb{R}^{n-2}\}, \tag{B3}$$

which is contained in W_R.

Lemma B.1: With the earlier definitions, for any $t \in \mathbb{R}$ there exists a neighborhood $\mathcal{N}$ of the identity in $\mathrm{SO}_0(2, n-1)$ such that $\lambda \lambda_{01}(t) W_0 \subset W_R$ for all $\lambda \in \mathcal{N}$. Hence, for any wedge $W_2 \in \mathcal{W}$ there exist wedges $W_1, W_3 \in \mathcal{W}$ such that $W_1 \Subset W_2$ and W_2 and W_3 are properly spacelike separated.

Proof: In order to show that $\lambda \lambda_{01}(t) \overline{W_0} \subset W_R$ for λ in a neighborhood of the identity, it suffices to show that the characteristic boundary of $\lambda \lambda_{01}(t) \overline{W_0}$ is contained in W_R: $\lambda \lambda_{01}(t)(\mathcal{E}_1 + \mathbb{R}_+ f_\pm) \subset W_R$, i.e., $\lambda \lambda_{01}(t)(x + l f_\pm) \in W_R$, for all $l \geq 0$, $x \in \mathcal{E}_1$. Since λ is to be in a neighborhood of the identity 1, consider $\lambda = 1 + M$, where $\|M\| < \varepsilon$ and $\|\cdot\|$ is the norm on the $(n+1) \times (n+1)$ matrices with real entries. Then one has

$$\begin{aligned} \lambda \lambda_{01}(t)(x + l f_+) \cdot e_\pm &= (\pm \sinh(t) - \cosh(t)) s (1+\boldsymbol{\sigma}^2)^{1/2} + l(\pm \cosh(t) \pm c \sinh(t) - \sinh(t) - c \cosh(t)) \\ &\quad + M \lambda_{01}(t) x \cdot e_\pm + l M \lambda_{01}(t) f_+ \cdot e_\pm \leq (\pm \sinh(t) - \cosh(t)) s (1+\boldsymbol{\sigma}^2)^{1/2} + \|M\| \|e_\pm\| \\ &\quad \times \{\|\lambda_{01}(t) x\| + l \|\lambda_{01}(t) f_+\|\}, \end{aligned} \tag{B4}$$

where use was made of the fact that

$$\pm \cosh(t) \pm c \sinh(t) - \sinh(t) - c \cosh(t) = (\mp 1 + c)(\pm \sinh(t) - \cosh(t)) < 0. \tag{B5}$$

But $\|\lambda_{01}(t) f_\pm\| \leq 2 \cosh(t)$, $\|\lambda_{01}(t) x\| \leq \cosh(t)(1 + c^2 + 2s^2)^{1/2}(1 + \boldsymbol{\sigma}^2)^{1/2}$ and $\|e_\pm\| = \sqrt{2}$. In addition, $\pm \sinh(t) - \cosh(t) < 0$, for all $t \in \mathbb{R}_+$. Hence, if ε is sufficiently small, there exists a $\delta < 0$ (depending on t) such that

$$\lambda \lambda_{01}(t)(x + l f_+) \cdot e_\pm \leq \delta < 0, \quad x \in \mathcal{E}_1, l \geq 0. \tag{B6}$$

Similarly, one shows that

$$\lambda \lambda_{01}(t)(x + l f_-) \cdot e_\pm \leq \delta < 0, \quad x \in \mathcal{E}_1, l \geq 0, \tag{B7}$$

for suitably small ε.

Since $(\lambda W)' = \lambda W'$, for all $\lambda \in \mathrm{SO}_0(2, n-1)$ and $W \in \mathcal{W}$, it is clear that W_2 and W_3' are properly spacelike separated if and only if $W_2 \Subset W_3$. Thus, since $\mathcal{W} = \{\lambda W_R | \lambda \in \mathrm{SO}_0(2, n-1)\}$, the remaining assertions follow at once. □

It is of interest to note that in AdS^n, $n \geq 3$, there exists a wedge $W_2 \in \mathcal{W}$ such that $\overline{W_2} \subset W_R$, but in any neighborhood of the identity of $\mathrm{SO}_0(2, n-1)$ there exists some λ such that $\lambda W_2 \not\subset W_R$.

APPENDIX C: THE REEH–SCHLIEDER PROPERTY

We prove that the theories we are considering here must satisfy the Reeh–Schlieder property for the wedge algebras. Let $W \in \mathcal{W}$ be a wedge, and let $\mathcal{B}(W)$ denote the *–algebra consisting of

all $B \in \mathcal{A}(W)$ for which there exists a neighborhood $\mathcal{N}(B)$ of the identity in $\mathrm{SO}_0(2,n-1)$ such that $B(\lambda) \doteq U(\lambda)BU(\lambda)^{-1} \in \mathcal{A}(W)$, for all $\lambda \in \mathcal{N}(B)$. Note that Lemma B.1 entails that there exists a wedge $W_0 \in \mathcal{W}$ such that $\mathcal{A}(W_0) \subset \mathcal{B}(W)$.

Proposition C.1: Let assumptions (i)–(iv) obtain. Then Ω *is cyclic for* $\mathcal{A}(W)$*, given any* $W \in \mathcal{W}$.

Proof: (This proof is a straightforward adaptation of an argument given in Ref. 3.) Let $W, W_0 \in \mathcal{W}$ and $\mathcal{B}(W)$ be as described earlier and let $\mathcal{N}$ be a neighborhood of the identity in $\mathrm{SO}_0(2,n-1)$ such that $\lambda^{-1}W_0 \subset W$, for all $\lambda \in \mathcal{N}$. By the covariance assumption (iii), it suffices to consider $W = W_R$. Further, let $\Psi \in \mathcal{H}$ be orthogonal to the set of vectors $\mathcal{A}(W)\Omega$.

Since $\mathcal{B}(W) \subset \mathcal{A}(W)$, Ψ is also orthogonal to $\mathcal{B}(W)\Omega$. From the definition of $\mathcal{B}(W)$ and the continuity of the representation U, it is clear that for any $B \in \mathcal{B}(W)$ and $\lambda \in \mathcal{N}$ as described above there exists an $\varepsilon > 0$ such that $B(\lambda\lambda_{01}(t)\lambda^{-1}) \in \mathcal{B}(W)$, for all $|t| < \varepsilon$. Therefore, one has

$$\langle \Psi, B(\lambda\lambda_{01}(t)\lambda^{-1})\Omega \rangle = 0, \tag{C1}$$

for $|t| < \varepsilon$. Since $\lambda\lambda_{01}(t)\lambda^{-1}W_0 \subset \lambda W$, one also has $B(\lambda\lambda_{01}(t)\lambda^{-1}) \in \mathcal{A}(\lambda W)$, for all $t \in \mathbb{R}$. Hence, by the KMS property of the restriction of ω to $\mathcal{A}(\lambda W)$, the function

$$t \mapsto B(\lambda\lambda_{01}(t)\lambda^{-1})\Omega, \quad t \in \mathbb{R}, \tag{C2}$$

extends analytically to a vector-valued function in the strip $\{z \in \mathbb{C} | 0 < \mathrm{Im}(z) < \beta/2\}$ with continuous boundary values. Therefore, one must have

$$\langle U(\lambda\lambda_{01}(t)\lambda^{-1})^{-1}\Psi, B\Omega \rangle = \langle \Psi, B(\lambda\lambda_{01}(t)\lambda^{-1})\Omega \rangle = 0, \tag{C3}$$

for all $t \in \mathbb{R}$ and $B \in \mathcal{B}(W)$. By iterating this argument, it follows that for $\lambda_1, \ldots, \lambda_k \in \mathcal{N}$ and $t_1, \ldots, t_k \in \mathbb{R}$,

$$\langle U(\lambda_1\lambda_{01}(t_1)\lambda_1^{-1})^{-1} \cdots U(\lambda_k\lambda_{01}(t_k)\lambda_k^{-1})^{-1}\Psi, B\Omega \rangle = 0. \tag{C4}$$

Lemma A.2 then implies that $U(\lambda)\Psi$ is orthogonal to $\mathcal{B}(W)\Omega$, for any $\lambda \in \mathrm{SO}_0(2,n-1)$, and hence Ψ is orthogonal to $U(\lambda)^{-1}\mathcal{B}(W)\Omega = \mathcal{B}(\lambda^{-1}W)\Omega$.

Moreover, since $\mathcal{B}(W)$ is a *-algebra, $B^*U(\lambda)\Psi$ is orthogonal to $\mathcal{B}(W)\Omega$, for any $B \in \mathcal{B}(W)$ and $\lambda \in \mathrm{SO}_0(2,n-1)$. Hence, by induction, for any $\lambda_1, \ldots, \lambda_k \in \mathrm{SO}_0(2,n-1)$ and $B_1, \ldots, B_k \in \mathcal{B}(W)$ one has

$$\langle \Psi, B_1(\lambda_1) \cdots B_k(\lambda_k)\Omega \rangle = 0. \tag{C5}$$

Putting these results together, it now follows that Ψ is orthogonal to $(\cup_{\lambda \in \mathrm{SO}_0(2,n-1)} U(\lambda)\mathcal{B}(W)U(\lambda)^{-1})\Omega$. And since $\mathcal{A}(W_0) \subset \mathcal{B}(W)$, one observes

$$\Big(\bigvee_{\lambda \in \mathrm{SO}_0(2,n-1)} \mathcal{B}(\lambda W) \Big)\Omega \supset \Big(\bigvee_{\lambda \in \mathrm{SO}_0(2,n-1)} \mathcal{A}(\lambda W_0) \Big)\Omega = \mathcal{A}\Omega, \tag{C6}$$

by the assumption of weak additivity (1.4). Thus, Ψ is orthogonal to $\mathcal{A}\Omega$. As Ω is cyclic for $\mathcal{A}$, the assertion is proven.

APPENDIX D: MULTIPLICITY OF ENERGY LEVELS AND NUCLEARITY

In this appendix we wish to prove that given any irreducible unitary positive energy representation U_1 of the anti–de Sitter group $\mathrm{SO}_0(2,n-1)$ on a Hilbert space $\mathcal{H}_1$, then the corresponding unitary representation U obtained by "second quantization" on the bosonic or fermionic Fock space $\mathcal{H}$ based upon $\mathcal{H}_1$ satisfies condition (NC). Hence the free field examples discussed in the main text and Appendix E satisfy (NC). To verify this, we shall have need of some basic results about unitary representations of $\mathrm{SO}_0(2,n-1)$. We merely recall these and refer the reader to Refs. 19–21 for details and proofs. We shall present the case $n=4$; the situation is similar for the other cases.

Let $SO(2)\otimes SO(3)\subset \mathrm{SO}_0(2,3)$ be the maximal compact subgroup consisting of the "time rotations" around AdS^4 and the spatial rotations. Restricting U_1 to this compact group, the Hilbert space $\mathcal{H}_1$ decomposes into a direct sum of corresponding irreducible subspaces which are labeled by the energy $n\in\mathbb{N}$ and angular momentum $l\in\mathbb{N}_0$. It has been shown in Ref. 19 that in this decomposition there appear only representations where $l<n$. Moreover, for given (n,l), the number of these representations is bounded by $l+1$. Taking these facts into account, the multiplicity μ_n of the eigenvalue n of the generator of the time rotations on $\mathcal{H}_1$ can be estimated by $\mu_n \leqslant \Sigma_{l=0}^{n-1}(2l+1)(l+1)\leqslant 2n^3$, $n\in\mathbb{N}$.

Next, let M_{04} be the generator of the time rotations on the Fock space $\mathcal{H}$. The bound given earlier entails by standard arguments in statistical mechanics that in the bosonic case the corresponding partition function satisfies, for any $\gamma>0$:

$$\begin{aligned}\ln \operatorname{tr} e^{-\gamma M_{04}} &= -\sum_n \mu_n \ln(1-e^{-\gamma n})\\ &\leqslant \sum_n 2n^3 \frac{e^{-\gamma n}}{1-e^{-\gamma}} = \frac{2}{1-e^{-\gamma}}(-\partial_\gamma)^3 \frac{1}{1-e^{-\gamma}}\\ &\leqslant \frac{12e^{-\gamma}}{(1-e^{-\gamma})^5} \leqslant \frac{12\cdot 5^5}{\gamma^5}. \end{aligned} \tag{D1}$$

Denoting by $\boldsymbol{\mu}_n$ the multiplicity of the eigenvalue n of M_{04}, $n\in\mathbb{N}_0$, we obtain the estimate

$$\operatorname{tr} e^{-\gamma M_{04}} = \sum_n \boldsymbol{\mu}_n e^{-\gamma n} \leqslant e^{12\cdot 5^5/\gamma^5}, \tag{D2}$$

which implies

$$\boldsymbol{\mu}_n \leqslant e^{\gamma n + 12\cdot 5^5/\gamma^5}, \tag{D3}$$

for all $n\in\mathbb{N}_0$ and $\gamma>0$. With the choice $\gamma=5n^{-1/6}$, we conclude that

$$\boldsymbol{\mu}_n \leqslant e^{17n^{5/6}}, \quad n\in\mathbb{N}_0. \tag{D4}$$

A similar argument applies also to the fermionic case and in any number of space–time dimensions. Hence we have the following result.

Proposition D.1: In any free boson or fermion model based upon an irreducible positive energy representation of the anti–de Sitter group, condition (NC) holds.

APPENDIX E: EXAMPLES

In this appendix we shall discuss some examples of nets and states which fulfill standing assumptions (i)–(iv), as well as the condition (NC). Because AdS is not globally hyperbolic, the standard means of obtaining examples do not suffice. Free field models on AdS have been discussed in a series of papers by Fronsdal[20–23] and by Avis, Isham, and Storey.[1] More recently, the Wightman functions of quantum field models on AdS satisfying certain general conditions have been treated rigorously in Ref. 7. In addition, models of quantum field theories on AdS can also be obtained *via* holography[31] (see also Ref. 2). We begin our discussion with the latter.

In an elegant paper[31] Rehren has given rigorous mathematical meaning to the notion of holography, namely the correspondence between theories on AdS^n and conformally invariant theories on the boundary CM_{n-1} of AdS^n, compactified $(n-1)$-dimensional Minkowski space. He shows that between the set of wedges W in AdS and the set of (conformal images of) double cones C in the boundary there exists a canonical bijection α which preserves inclusions and causal complements, and intertwines the actions of the anti–de Sitter group and of the conformal group (which are isomorphic groups):

$$\alpha(\lambda(W)) = \tilde{\lambda}(\alpha(W)), \quad \alpha^{-1}(\tilde{\lambda}(C)) = \lambda(\alpha^{-1}(C)), \tag{E1}$$

where $\tilde{\lambda}$ is the restriction of the action of $\lambda \in \mathrm{SO}_0(2,n-1)$ to the boundary. The double cone $C = \alpha(W)$ is defined to be the intersection of W with the boundary. Hence, given a net $\{\tilde{\mathcal{A}}(\alpha(W))\}$ associated with a (for example) free quantum field on CM_{n-1} and a vacuum state $\tilde{\omega}$ on this net, one can define a net $\{\mathcal{A}(W)\}$ and state ω on AdS^n by

$$\mathcal{A}(W) \doteq \tilde{\mathcal{A}}(\alpha(W)), \quad \omega(A) \doteq \tilde{\omega}(A), \tag{E2}$$

for every $A \in \mathcal{A}(W) = \tilde{\mathcal{A}}(\alpha(W))$. From the results in Ref. 31 it is easy to show that the resulting theory on AdS^n fulfills our assumptions (i)–(iv), provided the underlying net on CM_{n-1} complies with the standard assumptions of conformal Minkowski space theories. In such theories one also has the equality $\mathcal{A}(W) = \mathcal{A}(-W)$, for every $W \in \mathcal{W}$. The CGMA and the modular stability condition, formulated in Ref. 11, both obtain in these models.

Using an irreducible representation of $\mathrm{SO}_0(2,3)$, Fronsdal[21] defines Hermitian free fields on the covering space of AdS^4; only if the energy spectrum of the theory is contained in $\mathbb{N}_0$ does his field restrict to AdS proper. In this latter case, Fronsdal's model satisfies assumptions (i)–(iv), as well as (NC)—see later and Appendix D. Moreover, the elements of $\mathcal{A}(W)$ commute weakly with those of $\mathcal{A}(\tilde{W}')$. Yet if the energy spectrum is not a subset of $\mathbb{N}_0$, this feature is no longer present, confirming our expectation that Theorem 2.6 cannot hold in general for fields not manifesting the periodicity in time required to enable them to be defined on AdS. We note that since in his examples the fields are invariant under the map $x \mapsto -x$, one has $\mathcal{A}(\tilde{W}') = \mathcal{A}(W') = \mathcal{A}(W)'$.

In Ref. 1 Avis, Isham, and Storey use an embedding of (the covering space of) AdS into the static Einstein universe to construct a free quantum field on AdS. Since the static Einstein universe is globally hyperbolic, one can rigorously construct free fields and the associated nets of local algebras in (subsets of) that space–time. And since the covering space of AdS can be conformally embedded into the Einstein universe, one can define free massless, i.e., conformally invariant, fields on AdS. However, the matter is complicated by the fact that one must find suitable boundary conditions at spacelike infinity in AdS—we must refer the reader to Ref. 1 for details. Since the resultant fields manifest the necessary periodicity in the time variable, they may be understood to be defined on AdS. Inspection of the resulting representations then led them to construct analogous representations of "conformally coupled massive" free fields on AdS. From the construction of their examples and the results in Ref. 7 it follows that standing assumptions (i)–(iv) hold. All of their examples are consistent with Theorem 2.6.

In Ref. 7 an axiomatic study is made of quantum fields on the covering space of AdS from the point of view of a suitable modification of the Wightman function approach to quantum field theory on Minkowski space. Explicit examples of two-point functions satisfying their assumptions are given there, which include Fronsdal's examples. A subclass of those two-point functions restrict to AdS; it is of interest to note that such two-point functions are characterized by a certain uniformity property—cf. Sec.6 in Ref. 7. Using the results of Refs. 7 and 29 it is easy to show that free fields built upon those two-point functions satisfy our assumptions (i)–(iv); the elements of a subclass also satisfy assumption (NC). The authors of Ref. 7 also observe that the locality property proven in Theorem 2.6 obtains only in those free field models which restrict to AdS proper (Ref. 7, p. 509).

(Received 20 February 2004; accepted 27 July 2004; published 24 November 2004)

We study the problem of constructing a probability density in $2N$-dimensional phase space which reproduces a given collection of n joint probability distributions as marginals. Only distributions authorized by quantum mechanics, i.e., depending on a (complete) commuting set of N variables, are considered. A diagrammatic or graph theoretic formulation of the problem is developed. We then exactly determine the set of "admissible" data, i.e., those types of data for which the problem always admits solutions. This is done in the case where the joint distributions originate from quantum mechanics as well as in the case where this constraint is not imposed. In particular, it is shown that a necessary (but not sufficient) condition for the existence of solutions is $n \leqslant N+1$. When the data are admissible and the quantum constraint is not imposed, the general solution for the phase space density is determined explicitly. For admissible data of a quantum origin, the general solution is given in certain (but not all) cases. In the remaining cases, only a subset of solutions is obtained. © *2004 American Institute of Physics.*

I. INTRODUCTION

In quantum theory, we usually assume that probability densities for eigenvalues of two noncommuting observables cannot be measured by the same experimental setup. A related theoretical question is: Does there exist a joint probability distribution of the eigenvalues of two such observables A and B which correctly reproduces the individual probabilities for A and for B as marginals (i.e., on integration over the eigenvalues of the other observable). Perhaps surprisingly, the answer to this question is yes. More generally, for a system with N configuration space variables $q_1, q_2, \ldots, q_N$, consider complete commuting sets (CCS) $S_1, S_2, \ldots, S_n$ of observables, each S_i consisting of some coordinate and some momentum variables (where S_i and S_j must contain some mutually noncommuting observables to be considered distinct CCS). Is there a joint probability density $\rho(q_1, \ldots, q_N, p_1, \ldots, p_N)$ whose marginals reproduce the quantum probability

densities of the different CCS, $S_1, S_2, \ldots, S_n$? We shall prove that a necessary condition for this to be possible for arbitrary quantum states is $n \leqslant N+1$; this result is a precise no go theorem for simultaneous realization of more than $(N+1)$ quantum marginals.

Actually, this no go theorem also has applications to the classical arena of joint time-frequency distributions in signal processing and joint position-wave number distributions in image processing. It is therefore useful to state the problem in a general setting encompassing both classical and quantum mechanics.

Consider the general problem of reconstructing a probability density over $\mathbb{R}^M$, given a set of n associated joint probability distributions over subspaces of $\mathbb{R}^M$. In this general setting the problem can be stated as follows. Suppose first that a probability density $\rho(y_1, \ldots, y_M)$ is given and define the marginal distributions

$$\sigma_\alpha(Y_\alpha) = \int dY'_\alpha \rho(y_1, \ldots, y_M) \quad (\alpha = 1, \ldots, n), \tag{1.1}$$

where $Y_\alpha \cup Y'_\alpha$ is, for each α, a partition of $\{y_1, \ldots, y_M\}$. These joint distributions obey a set of compatibility conditions. Indeed, let $Y_{\alpha\beta}$ be the set of variables that $\sigma_\alpha(Y_\alpha)$ and $\sigma_\beta(Y_\beta)$ have in common and introduce the partitions $Y_\alpha = Y_{\alpha\beta} \cup Y'_{\alpha\beta}$ and $Y_\beta = Y_{\alpha\beta} \cup Y''_{\alpha\beta}$. Then Eq. (1.1) implies

$$\int dY'_{\alpha\beta} \sigma_\alpha(Y_{\alpha\beta}, Y'_{\alpha\beta}) = \int dY''_{\alpha\beta} \sigma_\beta(Y_{\alpha\beta}, Y''_{\alpha\beta}). \tag{1.2}$$

Conversely, suppose that a set $\{\sigma_1, \ldots, \sigma_n\}$ of joint probability distributions is given, which satisfies the compatibility conditions (1.2). Is it always possible to find some probability density ρ which reproduces them as marginals, in accordance with Eq. (1.1)? In the affirmative, how can we "reconstruct" such ρ's? It turns out that Eq. (1.2) is in general only necessary conditions for the existence of a positive density ρ, and our problem is precisely to solve the questions of existence, multiplicity, and explicit determination of the ρ's (if any).

Actually, we address these questions not in such a general setting, but in the case where $\mathbb{R}^M = \mathbb{R}^{2N}$ is the phase space of some physical system with coordinates y_j identified with conjugate canonical variables $\{q_j, p_j\}_{j=1}^N$ and where all distributions σ_α depend on exactly N variables $x_1, \ldots, x_N$ restricted by the condition $x_i = q_i$ or p_i $(i = 1, \ldots, N)$. The reason for this choice lies in the motivation of the problem within the context of quantum mechanics. Indeed, the functions σ_α just introduced can then be understood as quantum probability distributions associated with n complete commuting sets of observables (CCS), selected among 2^N possible choices (the 2^N possible assignments of the variables x_i). By "*quantum* probability distributions" is meant here a set of functions $\sigma_\alpha(x_1, \ldots, x_N)$ derived from a common wave function $\langle q_1, \ldots, q_N | \psi \rangle$ (in the Schrödinger representation), in accordance with the formula

$$\sigma_\alpha(x_1, \ldots, x_N) = |\langle x_1, \ldots, x_N \rangle \psi|^2 \quad (\alpha = 1, \ldots, n), \tag{1.3}$$

or more generally, for a mixed quantum state described by the density operator $\hat{\rho}$,

$$\sigma_\alpha(x_1, \ldots, x_N) = \langle x_1, \ldots, x_N | \hat{\rho} | x_1, \ldots, x_N \rangle \quad (\alpha = 1, \ldots, n). \tag{1.4}$$

The problem in this physical framework is directly related to the construction of "maximally realistic quantum mechanics," a program initiated by Roy and Singh in 1995 (Ref. 1) and intensively pursued since then.[2–4] Without entering a detailed discussion of this relationship from the viewpoint of quantum physics (for which we refer the reader to Refs. 1–4), let us recall the main results gained so far. In Ref. 2 it was shown that for any $N \geqslant 2$, a set of $n = N+1$ quantum probability distributions of the special form

$$\{\sigma_1(q_1, q_2, \ldots, q_N), \sigma_2(p_1, q_2, \ldots, q_N), \sigma_3(p_1, p_2, q_3, \ldots, q_N), \ldots, \sigma_{N+1}(p_1, p_2, \ldots, p_N)\} \tag{1.5}$$

can be realized as a set of marginals of a common phase space probability density $\rho(q_1, \ldots, q_N, p_1, \ldots, p_N)$. Further the "no go" conjecture was made that for $n \geqslant N+2$ (and for any

choice of n distinct CCS), there exist sets $\{\sigma_1,\ldots,\sigma_n\}$ of quantum probability distributions which cannot be recovered as marginals of some ρ. The determination of the most general density ρ reproducing the set (1.5), as well as the status of sets of CCS-distributions different from (1.5) and not necessarily of a quantum origin (i.e., mutually compatible but not necessarily construed according to Eq. (1.4)), were left as open questions. In Ref. 4, hereafter denoted by (I), complete answers to these questions were given in the special case $N=2$ (see also Ref. 3 for a brief summary). In particular, the general positive solution ρ of the equations

$$\begin{cases} \int dp_1 dp_2 \rho(q_1,q_2,p_1,p_2) = \sigma_1(q_1,q_2), \\ \int dq_1 dp_2 \rho(q_1,q_2,p_1,p_2) = \sigma_2(p_1,q_2), \\ \int dq_1 dq_2 \rho(q_1,q_2,p_1,p_2) = \sigma_3(p_1,p_2), \end{cases} \tag{1.6}$$

was worked out for an arbitrary set $\{\sigma_1,\sigma_2,\sigma_3\}$ (quantum or not) and the "no go" conjecture stated above was proved for $N=2$. In fact, it was shown that a necessary and sufficient condition for $n(\leqslant 4)$ arbitrarily given compatible σ_α's to be marginals of a probability density in four-dimensional phase space is $n\leqslant 3$ ("Three marginal theorem"). These results were obtained by first deriving certain correlation inequalities between the σ_α's from the mere existence of a positive and normalized ρ. Such inequalities, which are the analogs in phase space of the standard Bell inequalities for spin variables,[5] turn out to have an interest of their own in the context of quantum physics, as discussed in Refs. 3 and 4.

The generalization of the study performed in (I) to the case of an arbitrary number n of CCS-distributions of any species in a phase space of arbitrary dimension $2N$, which is precisely the aim of the present work, is not a straightforward task. It will be accomplished by means of two main tools: the Bell-type inequalities just mentioned (it turns out that no new correlation inequalities, proper to the $2N$-dimensional case, are needed for the present purpose) and a specific diagrammatic formulation of the problem which appears essential both for a concise exposition of our final statements and for their proof. In this way, we shall be able to treat the problem exhaustively and to give, in the general case, definite answers to the questions previously posed, in the form of a clear-cut theorem. This theorem will be stated at once in Sec. II (Theorem 1), after having introduced a set of appropriate definitions. As a by-product, the theorem affords a proof of the "no go" conjecture for any N (Theorem 2). On the positive side, it considerably extends early results of Cohen and Zaparovanny[6] for two marginals with non intersecting sets of variables by simultaneous realizability of $N+1$ marginals which have intersecting sets of variables as well. The rest of the paper (Secs. III–V) is almost entirely devoted to the (quite long!) proof of Theorem 1, and is therefore mainly technical. Our concluding comments are presented in Sec. VI.

II. DEFINITIONS AND RESULTS

In order to give our results a precise and unambiguous form, we introduce the following definitions:

(1) A CCS-distribution (CCS for Complete Commuting Set) in N dimensions is a probability distribution [Here and in the following, probability distributions are understood as positive normalized measures, with an absolutely continuous part and (possibly) Dirac measures.] $\sigma(x_1,\ldots,x_N)$, with $x_j=q_j$ or p_j for each index j.

The CCS-distributions can occur in 2^N different types, each type corresponding to one choice of the N-tuple of arguments.

(2) An n-chain is a set $\{\sigma_1,\ldots,\sigma_n\}$ of *mutually compatible* CCS-distributions of distinct types. Here, the mutual compatibility conditions (1.2) read, for any pair $\{\sigma_\alpha(Y_\alpha),\sigma_\beta(Y_\beta)\}$, where

$Y_\alpha=\{y_1,\ldots,y_r,Y\}$, $Y_\beta=\{y'_1,\ldots,y'_r,Y\}$ and y'_j is the conjugate of y_j ($y'_j=q_j$ or p_j according as $y_j=p_j$ or q_j),

$$\int dy_1\cdots dy_r\sigma_\alpha(y_1,\ldots,y_r,Y)=\int dy'_1\cdots dy'_r\sigma_\beta(y'_1,\ldots,y'_r,Y). \tag{2.1}$$

Thus, an n-chain is a possible candidate for a set of n marginals, i.e., joint probability distributions obtained from some phase space probability distribution [we shall use sometimes the notation $\rho(\mathbf{q},\mathbf{p})$] $\rho(q_1,\ldots,q_N,p_1,\ldots,p_N)$ by integrating over some of the arguments.

The type of an n-chain is defined by the types of its elements.

(3) An n-chain is admissible if there exists at least one phase space probability distribution ρ reproducing all the CCS distributions of the n-chain, namely such that

$$\sigma_\alpha(x_1,\ldots,x_N)=\int dx'_1\cdots dx'_N\rho(q_1,\ldots,q_N,p_1,\ldots,p_N)\ \ (\alpha=1,\ldots,n), \tag{2.2}$$

where x'_i is the conjugate of x_i. Equation (2.2) imply (2.1). Using the notation $Z_\alpha=\{x_1,\ldots,x_N\}$, $Z'_\alpha=\{x'_1,\ldots,x'_N\}$, and $d^NZ'_\alpha=dx'_1\cdots dx'_N$, (2.2) can be rewritten as

$$\sigma_\alpha(Z_\alpha)=\int d^NZ'_\alpha\rho(\mathbf{q},\mathbf{p})\ \ (\alpha=1,\ldots,n).$$

(4) An n-chain is a quantum n-chain if there exists at least one quantum state described by the density operator $\hat{\rho}$ such that Eq. (1.4) holds.

Note that in that case the compatibility conditions (2.1) are automatically satisfied.

(5) Two CCS-distributions σ_α and σ_β are contiguous if they differ by the assignment of only one variable x_i (to q_i and p_i), namely

$$\sigma_\alpha(x_1,\ldots,x_{i-1},q_i,x_{i+1},\ldots,x_N)\text{ and }\sigma_\beta(x_1,\ldots,x_{i-1},p_i,x_{i+1},\ldots,x_N).$$

We call i the index of the pair $\{\sigma_\alpha,\sigma_\beta\}$.

(6) To each n-chain we associate a graph which is constructed as follows:

(a) To every CCS-distribution of the chain, associate a vertex characterized by the collection of the variables of this distribution;

(b) Connect two vertices by a link if they correspond to contiguous CCS-distributions. We call index of the link the index of the pair of contiguous CCS-distributions, and we say that the two vertices are contiguous.

As usual, there are connected and disconnected graphs, tree graphs and graphs with loops. A graph G completely determines the type of the associated n-chain, so that we can speak of a chain of type G.

(7) An n-chain and its associated graph are said to be proper if no two links have the same index.

Since there are at most N possible indices, a proper graph has at most N links, and thus, if it is connected, at most $(N+1)$ vertices. Furthermore, a graph with a loop cannot be proper. Therefore, a connected proper graph is necessarily a tree graph with at most $(N+1)$ vertices.

(8) A graph G is fully admissible if all n-chains of type G are admissible.

A graph G is quantum admissible if all quantum n-chains of type G are admissible.
Full admissibility entails quantum admissibility.
A graph G is nonadmissible if it is not quantum (and *a fortiori* not fully) admissible.

(9) Let a nonconnected graph G be subgraph of a connected graph G_c. We call insertions the vertices of G_c which are not vertices of G. G_c is called G-simple if all its insertions have only two legs.

In the following, in order to shorten the writing, particularly when drawing graphs, we often replace the variables q_j and p_j by the indices j and j', respectively. For example, to a CCS-distribution $\sigma(q_1,p_2,q_3)$ we associate the vertex $\boxed{12'3}$ in a rectangle box. As for the inserted vertices, we use instead round boxes, e.g., (12′3).

We are now in a position to give a complete characterization of the graphs, or equivalently of the types of n-chains, according to their (full, quantum or non) admissibility.

Theorem 1:

(1) If a graph G is proper and connected, then it is fully admissible.
(2) If G is proper but nonconnected, then

(a) if G is subgraph of a proper connected graph G_c, then

(i) if G_c is G-simple, G is fully admissible,
(ii) if G_c is not G-simple, G is quantum, but not fully, admissible,

(b) *if G is not subgraph of a proper connected graph G_c, then it is nonadmissible.*

(3) *If G is nonproper, then it is nonadmissible.*

This theorem is complemented by the explicit construction of all the phase space distributions ρ reproducing a given chain of type G, a construction which is completed only in the case of full admissibility, that is to say when G is either connected and proper, or subgraph of a connected, proper and G-simple graph G_c (see Sec. IV B). In the case of quantum admissibility, when the connected graph G_c is proper but not G-simple, the situation is not as favorable and the general expression of ρ is not known (see Sec. V B 2).

Remarks:

(1) Given a graph G, a proper G_c, when there is one (case 2a), is in general not unique. It is a consequence of the theorem that either all the proper G_c's are G-simple, or none of them is.

Notice that this is a pure graph theoretic statement.

(2) For $N=2$, the main result of Sec. IV of (I), which was derived from Bell-type correlation inequalities, is the following: both in the classical and quantum cases, there exist 4-chains $\sigma_1(q_1,q_2)$, $\sigma_2(p_1,q_2)$, $\sigma_3(q_1,p_2)$, and $\sigma_4(p_1,p_2)$ which cannot be reproduced as marginals of any probability distribution $\rho(\mathbf{q},\mathbf{p})$. In the language of the present paper, this can be rephrased as:

The nonproper graph  *is non admissible.*

This is the simplest case of part 3 of the above theorem, and actually it is the clue of its proof.

An immediate corollary of Theorem 1 is

Theorem 2 ($N+1$ Marginal Theorem):

A necessary condition for all quantum n-chains of a given type to be admissible is $n \leqslant N+1$.

It suffices to use parts 2b and 3 of Theorem 1 and to note that G cannot have more vertices than G_c, and that a proper G_c has at most $N+1$ vertices (see the remark after the above definition 7 of *proper* n-chains and graphs).

Notice that, in contradistinction with the *three* marginal theorem of (I), the above theorem gives only a necessary condition. This is because only proper connected graphs G_c are involved when $N=2$ and $n \leqslant N+1$, whereas nonproper connected G_c's do appear as soon as $N \geqslant 3$. Of course, for proper connected graphs G for which n must be $\leqslant N+1$, part 1 of Theorem 1 guarantees admissibility for $N \geqslant 3$ also.

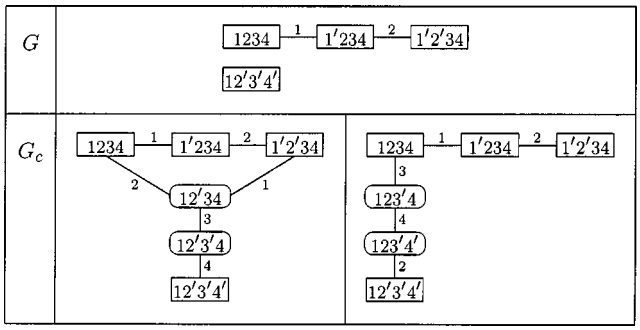

FIG. 1. A nonconnected proper graph G which is not subgraph of any proper connected graph G_c: G is nonadmissible. Two possible (nonproper) G_c's are shown: one with a loop, the other one a tree graph.

Theorem 1 will be proved in Secs. III–V. In order to help understanding its content, we give in Figs. 1 and 2 examples of the various cases encountered.

III. NONPROPER GRAPHS

Consider a nonproper graph G. By definition, there exist at least two links with the same index (say 1) connecting a first pair of vertices (V, V') and a second pair (W, W'). Then there necessarily exists a second index (say 2) such that the variables x_1 and x_2 have in the four vertices V, V', W, and W' the assignments as shown in Fig. 3.

Quite generally, in a graph G (proper or not), a set of four vertices where a pair of variables takes the four possible assignments will be called a *critical quartet*.

We now prove

Lemma 1: A graph G containing a critical quartet is nonadmissible.

Given an n-chain $\{\sigma_\alpha\}_{\alpha=1,\ldots,n}$ of type G in N dimensions and a partition of the set of indices $\{1,\ldots,N\}=J\cup K$, let us introduce the distributions

$$\tilde{\sigma}_\alpha(X_J)=\int \prod_{k\in K} dx_k \sigma_\alpha(X_J,X_K).$$

Some of these $\tilde{\sigma}_\alpha$'s may coincide. We call *J-reduced n′-chain* the maximal set of n' distinct $\tilde{\sigma}_\alpha$'s $(n'\leqslant n)$. Obviously, a necessary condition for the n-chain to be admissible is that the associated J-reduced n'-chain be admissible. Now, consider a quantum n-chain constructed with a factorized wave function of the form

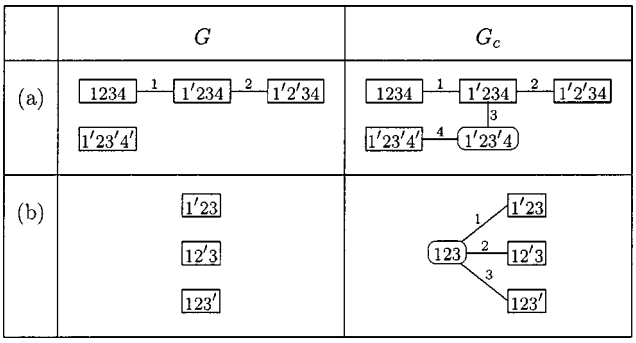

FIG. 2. (a) A nonconnected proper graph G which is subgraph of a proper connected G-simple graph G_c: G is fully admissible. (b) A nonconnected proper graph G which is subgraph of a proper connected non G-simple graph G_c: G is quantum but not fully admissible.

FIG. 3. Critical quartet in a nonproper graph.

$$\Psi(q_1, \ldots, q_N) = \Psi_1(Q_J)\Psi_2(Q_K). \tag{3.1}$$

Choosing then $J=\{1,2\}$, to be the indices of a critical quartet, our results in (I) (see Remark 2 after Theorem 1) immediately imply the nonadmissibility of the J-reduced 4-chain. Hence, the nonadmissibility of the n-chain σ_α itself, and Lemma 1 follows.

This establishes part 3 of Theorem 1, namely that a nonproper graph G is nonadmissible.

IV. CONNECTED PROPER GRAPHS

Let G be a connected proper graph. We establish part 1 of Theorem 1 by associating to any chain of type G a particular phase space distribution ρ_0 reproducing this chain. The explicit construction of such a ρ_0 is described in Sec. IV A. In Sec. IV B, we derive the expression of the most general phase space distribution reproducing the given chain.

A. Particular solution

Let $\mathcal{C}_n=\{\sigma_1, \ldots, \sigma_n\}$ be an n-chain of type G. Since G is a proper tree graph with $(n-1)$ links, there are exactly $(N-n+1)$ variables which have the same assignments in all the distributions σ_α. After a possible renumbering of the indices of the x_i's, we can therefore assume that in $\sigma_\alpha(x_1, \ldots, x_{n-1}, x_n, \ldots, x_N)$ the assignment of each of the variables $x_n, \ldots, x_N$ is independent of α. These variables, which will play a purely passive role, are henceforth denoted collectively by T, whereas T' will stand for the set of conjugate variables $\{x'_n, \ldots, x'_N\}$.

The solution $\rho_0(q_1, \ldots, q_N, p_1, \ldots, p_N)$ of Eq. (2.2) is constructed as the product of "vertex functions," "propagators" and an arbitrary positive function of T'. The former elements are defined by the following "Feynman rules:"

1) to each vertex $\boxed{x_1, \ldots, x_N}$ of G, we associate the vertex function $\sigma_\alpha(x_1, \ldots, x_N)$ of the chain $\mathcal{C}_n$,

2) for each link l_i of G carrying the index i, by using the compatibility condition (2.1) for the pair $\{\sigma_{\alpha i}, \sigma_{\beta i}\}$ of contiguous CCS-distributions attached to this link, we define the integrated distribution

$$\sigma_{\alpha_i\beta_i}(x_1, \ldots, x_{i-1}, x_{i+1}, \ldots, x_N) = \int dq_i \sigma_{\alpha_i}(x_1, \ldots, x_{i-1}, q_i, x_{i+1}, \ldots, x_N)$$
$$= \int dp_i \sigma_{\beta_i}(x_1, \ldots, x_{i-1}, p_i, x_{i+1}, \ldots, x_N). \tag{4.1}$$

Then, to the link l_i we associate the propagator

$$\varpi_i(x_1, \ldots, x_{i-1}, x_{i+1}, \ldots, x_N) \equiv \begin{cases} \dfrac{1}{\sigma_{\alpha_i\beta_i}(x_1, \ldots, x_{i-1}, x_{i+1}, \ldots, x_N)} & \text{if } (x_1, \ldots, x_{i-1}, x_{i+1}, \ldots, x_N) \in S_{\alpha_i\beta_i}, \\ 0 \quad \text{otherwise}, \end{cases} \tag{4.2}$$

where $\mathcal{S}_{\alpha_i\beta_i}$ is the (essential) support of $\sigma_{\alpha_i\beta_i}$.

The support properties of the σ_α's, $\sigma_{\alpha\beta}$'s, and ρ_0, and the relations between them (due to compatibility and positivity) are not innocent in the forthcoming considerations, and we should pay attention to them. However, doing so leads to cumbersome technicalities which are in fact

straightforward generalizations of those developed in the rigorous proof of Theorem 1 in (I) for the case $N=2$. Thus, in this Sec. IV, we shall ignore such inessential complications.

The function ρ_0 is then written as

$$\rho_0 = \left(\prod_{\alpha=1}^{n} \sigma_\alpha \prod_{i=1}^{n-1} \varpi_i \right) \zeta, \tag{4.3}$$

where $\zeta(T')$ is an arbitrary non-negative function in $L^1(\mathbb{R}^{N-n+1}, d^{N-n+1}T')$ with normalization

$$\int d^{N-n+1}T'\, \zeta(T') = 1. \tag{4.4}$$

That the expression (4.3) for ρ_0 solves Eq. (2.2) results from the following property:

Let $\hat{V}=\boxed{x_1,\ldots,x_N}$ be a one-leg vertex of the proper tree graph G and i be the index of the link $\hat{l}$ attached to it. Let $\hat{\sigma}(x_1,\ldots,x_N)$ be the corresponding element of the chain $\mathcal{C}_n$. Then

$$\int dq_i \rho_0^{(n)}(\mathbf{q},\mathbf{p}) = \rho_0^{(n-1)}(q_1,\ldots,q_{i-1},q_{i+1},\ldots,q_N,p_1,\ldots,p_N) \text{ if } x_i = q_i,$$

$$\int dq_i \rho_0^{(n)}(\mathbf{q},\mathbf{p}) = \rho_0^{(n-1)}(q_1,\ldots,q_N,p_1,\ldots,p_{i-1},p_{i+1},\ldots,p_N) \text{ if } x_i = p_i, \tag{4.5}$$

where $\rho_0^{(n)}$ is the above defined ρ_0 associated with the n-chain $\mathcal{C}_n$, and $\rho_0^{(n-1)}$ is the ρ_0 similarly associated with the $(n-1)$-chain $\mathcal{C}_{n-1}$ obtained from $\mathcal{C}_n$ by removing the CCS-distribution $\hat{\sigma}$. Notice that the reduced chain $\mathcal{C}_{n-1}$ corresponds to the reduced graph $G^{(n-1)}$ obtained from G by removing the one-leg vertex $\hat{V}$ and the link $\hat{l}$. Hence $\rho_0^{(n-1)}=\rho_0/(\hat{\sigma}\overline{\omega_i})$.

Equation (5.5) holds because: (*i*) in $\rho_0^{(n)}$ the variable x_i appears only in the factor $\hat{\sigma}$, (*ii*) the propagator of the link $\hat{l}$ is precisely the inverse of the integral of $\hat{\sigma}$ over x_i.

Now, given any σ_α in the chain $\mathcal{C}_n$, corresponding to the vertex V_α of G, one can start the reduction $G^{(n)} \to G^{(n-1)}$ of the tree graph $G^{(n)} \equiv G$ at some arbitrarily chosen one-leg vertex $\hat{V} \neq V_\alpha$, and repeat it $(n-1)$ times in such a way that one is left with the graph $G^{(1)}$ consisting solely of the vertex V_α. To this "peeling process" $G^{(n)} \to G^{(n-1)} \to \cdots \to G^{(1)}$ of tree graphs is naturally associated, via Eqs. (4.5), a reduction $\rho_0 \equiv \rho_0^{(n)} \to \rho_0^{(n-1)} \to \cdots \to \rho_0^{(1)}$ of functions $\rho_0^{(m)}$, which eventually produces

$$\rho_0^{(1)}(x_1,\ldots,x_{n-1},T,T') = \int dx_1' \cdots dx_{n-1}' \rho_0 = \sigma_\alpha(x_1,\ldots,x_{n-1},T)\zeta(T'), \tag{4.6}$$

and hence, by integrating over T':

$$\int dx_1' \cdots dx_N' \rho_0 = \sigma_\alpha(x_1,\ldots,x_N). \tag{4.7}$$

Notice that, although the order of the repeated integrations over the x_i''s is imposed by the steps of the peeling process, this order becomes obviously irrelevant in the above equation: Eq. (2.2) is valid for $\rho=\rho_0$ indeed.

Finally, to illustrate our Feynman rules, let us take as an example the graph $G^{(5)}$ of Fig. 4. The distribution ρ_0 associated with any 5-chain of type $G^{(5)}$ is

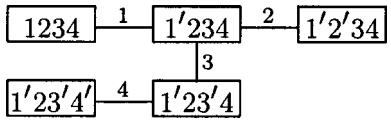

FIG. 4. A proper connected graph with $N=4$ and $N=5$.

$$\rho_0(\mathbf{q},\mathbf{p}) = \sigma_1(q_1q_2q_3q_4)\frac{1}{\sigma_{12}(q_2q_3q_4)}\sigma_2(p_1q_2q_3q_4)\frac{1}{\sigma_{23}(p_1q_3q_4)}\sigma_3(p_1p_2q_3q_4)\frac{1}{\sigma_{24}(p_1q_2q_4)}$$
$$\times\sigma_4(p_1q_2p_3q_4)\frac{1}{\sigma_{45}(p_1q_2p_3)}\sigma_5(p_1q_2p_3p_4).$$

Here and in the sequel, we keep writing the propagators as $1/\sigma_{\alpha\beta}$, although they are strictly given by Eq. (4.2).

B. General solution

Let us define the n following positive measures, each one associated to a particular component σ_α of the n-chain $\mathcal{C}_n$:

$$d\mu_\alpha = \begin{cases} \dfrac{\rho_0(\mathbf{q},\mathbf{p})}{\sigma_\alpha(Z_\alpha)}d^NZ'_\alpha & \text{if } Z_\alpha=(x_1,\ldots,x_N)\in\mathcal{S}_\alpha, \\ 0 \quad \text{otherwise}, \end{cases} \tag{4.8}$$

where $\mathcal{S}_\alpha$ denotes the (essential) support of σ_α. Due to Eq. (4.7) these $(x_1,\ldots,x_N)$-dependent measures [notice also that the $d\mu_\alpha$'s are continuous linear mappings of $L^1(\mathbb{R}^{2N},\rho_0d^Nqd^Np)$ into itself] are normalized for all $(x_1,\ldots,x_N)\in\mathcal{S}_\alpha$.

It is convenient to write the general solution ρ we are looking for in the form

$$\rho=\rho_0(1+\lambda h). \tag{4.9}$$

Here, the function $h(\mathbf{q},\mathbf{p})$ will be chosen as to ensure Eq. (2.2), which results in the linear equations

$$\int d^NZ'_\alpha\rho_0(\mathbf{q},\mathbf{p})h(\mathbf{q},\mathbf{p})=0 \quad (\alpha=1,\ldots,n), \tag{4.10}$$

whereas the real constant λ is a normalization factor which will be useful to control the positivity of ρ. Thanks to definitions (4.8), Eq. (4.10) is equivalent to

$$\int d\mu_\alpha h=0 \quad (\alpha=1,\ldots,n). \tag{4.11}$$

We then observe that, for any α and any function g in $L^1(\mathbb{R}^{2N},\rho_0d^Nqd^Np)$

$$\int d\mu_\alpha\left(\int d\mu_\alpha g\right)=\int d\mu_\alpha g, \tag{4.12}$$

since $\int d\mu_\alpha g$ does not depend any longer on the integration variables $(x'_1,\ldots,x'_N)$ and $d\mu_\alpha$ is normalized. That is, the linear operators $P_\alpha: L^1(\mathbb{R}^{2N},\rho_0d^Nqd^Np)\to L^1(\mathbb{R}^{2N},\rho_0d^Nqd^Np)$ defined by $P_\alpha g=\int d\mu_\alpha g$ are projectors,

$$P_\alpha^2=P_\alpha \quad (\alpha=1,\ldots,n). \tag{4.13}$$

The set $\{P_\alpha\}$ enjoys certain algebraic properties which are crucial for the construction of the general solution h of Eq. (4.11).

Lemma 2:

(a) The projectors P_α and P_β associated with any pair $\{V_\alpha, V_\beta\}$ of contiguous vertices commute

$$[P_\alpha, P_\beta] = 0. \tag{4.14}$$

(b) If V_α, V_β, and V_γ, are three vertices of the connected proper (tree) graph G such that V_α belongs to the (unique) path connecting V_β to V_γ, and is contiguous to at least one of these two vertices, then

$$P_\gamma P_\alpha P_\beta = P_\gamma P_\beta. \tag{4.15}$$

The proof is given in Appendix A. We stress that the contiguity of V_α with V_β or V_γ is essential for the validity of Eq. (4.15).

Let us now introduce the central object of our construction, namely the operator

$$\Pi = 1 - \sum_{\alpha=1}^{n} P_\alpha + \sum_{i=1}^{n-1} P_{\alpha_i} P_{\beta_i}, \tag{4.16}$$

where P_{α_i} and P_{β_i} denote the operators P associated with the two (contiguous) vertices V_{α_i} and V_{β_i} attached to the link with index i. Thanks to Lemma 2, it is readily shown that Π is annihilated by all the projectors P_α:

$$P_\gamma \Pi = 0 \quad (\gamma = 1, \ldots, n). \tag{4.17}$$

Indeed

$$P_\gamma \Pi = P_\gamma - \sum_{\alpha=1}^{n} P_\gamma P_\alpha + \sum_{i=1}^{n-1} P_\gamma P_{\alpha_i} P_{\beta_i} = - P_\gamma \sum_{\substack{\alpha=1 \\ \alpha \neq \gamma}}^{n} P_\alpha + \sum_{i=1}^{n-1} P_\gamma P_{\alpha_i} P_{\beta_i}. \tag{4.18}$$

But, according to Eq. (4.15):

$$P_\gamma P_{\alpha_i} P_{\beta_i} = P_\gamma P_{\delta_i}, \tag{4.19}$$

where $\delta_i = \beta_i$ (resp. α_i) if V_{α_i} (resp. V_{β_i}) belongs to the path connecting V_γ to V_{β_i} (resp. V_{α_i}). Hence

$$\sum_{i=1}^{n-1} P_\gamma P_{\alpha_i} P_{\beta_i} = P_\gamma \sum_{\substack{\alpha=1 \\ \alpha \neq \gamma}}^{n} P_\alpha, \tag{4.20}$$

which entails Eq. (4.17) (the property $\Pi P_\gamma = 0$ $(\gamma = 1, \ldots, n)$, which also holds as a consequence of Eq. (4.15), will not be used here). Note that Eq. (4.20) would not be valid if the graph G were not connected.

Furthermore, Π is itself a projector:

$$\Pi^2 = \Pi, \tag{4.21}$$

as immediately deduced from

$$\Pi^2 = \left(1 - \sum_{\alpha=1}^{n} P_\alpha + \sum_{i=1}^{n-1} P_{\alpha_i} P_{\beta_i} \right) \Pi$$

and Eq. (4.17). This operator allows us to write down at once the general solution of Eq. (4.11), i.e.,

$$P_\alpha h = 0 \quad (\alpha = 1, \ldots, n), \tag{4.22}$$

as

$$h = \Pi f, \tag{4.23}$$

where f is an arbitrary function in $L^1(\mathbb{R}^{2N}, d^N q d^N p)$. That Eq. (4.23) implies Eq. (4.22) is trivial due to Eq. (4.17). Conversely, any function h satisfying Eq. (4.22) assumes the form (4.23): since then $h = \Pi h$, it suffices to take $f = h$.

We now have to give the representation formula for h resulting from Eqs. (4.23) and (4.16) an explicit form in terms of the data of the problem, namely, the elements of the chain $\mathcal{C}_n$. For this purpose, it is necessary to use appropriate notations. First, we denote by Z_α the collection of arguments of the vertex function σ_α, and Z'_α the collection of the conjugate arguments (a notation already used in the definition (4.8)). Then

$$(P_\alpha f)(Z_\alpha) = \frac{1}{\sigma_\alpha(Z_\alpha)} \int d^N Z'_\alpha \rho_0(\mathbf{q},\mathbf{p}) f(\mathbf{q},\mathbf{p}). \tag{4.24}$$

Second, we denote by $\sigma_{\alpha_i}(X_i, x_i)$ and $\sigma_{\beta_i}(X_i, x'_i)$ the vertex functions of the vertices V_{α_i} and V_{β_i}, where $X_i = \{x_1, \ldots, x_{i-1}, x_{i+1}, \ldots, x_N\}$. Accordingly, we write $\rho_0(X_i, X'_i, x_i, x'_i)$ for $\rho_0(\mathbf{q},\mathbf{p})$, where $X'_i = \{x'_1, \ldots, x'_{i-1}, x'_{i+1}, \ldots, x'_N\}$, and so on. With these notations

$$(P_{\alpha_i} P_{\beta_i} f)(X_i) = \int d^{N-1} X'_i dx'_i \frac{\rho_0(X_i, X'_i, x_i, x'_i)}{\sigma_{\alpha_i}(X_i, x_i)} (P_{\beta_i} f)(X_i, x'_i), \tag{4.25}$$

and

$$(P_{\beta_i} f)(X_i, x'_i) = \int d^{N-1} X'_i dx_i \frac{\rho_0(X_i, X'_i, x_i, x'_i)}{\sigma_{\beta_i}(X_i, x'_i)} f(X_i, X'_i, x_i, x'_i). \tag{4.26}$$

In the r.h.s. of Eq. (4.25), one observes that the integral $\int d^{N-1} X'_i \rho_0$ can be performed explicitly by means of the "peeling process" described in Sec. IV A,

$$\int d^{N-1} X'_i \rho_0(X_i, X'_i, x_i, x'_i) = \frac{\sigma_{\alpha_i}(X_i, x_i) \sigma_{\beta_i}(X_i, x'_i)}{\sigma_{\alpha_i \alpha_i}(X_i)}. \tag{4.27}$$

This equation obtains by stopping the peeling process at the reduced graph made of the two vertices V_{α_i}, V_{β_i} and the link between them. Here appears the propagator $1/\sigma_{\alpha_i \beta_i}$ with

$$\sigma_{\alpha_i \beta_i}(X_i) = \int dx_i \sigma_{\alpha_i}(X_i, x_i) = \int dx'_i \sigma_{\beta_i}(X_i, x'_i). \tag{4.28}$$

Then, inserting Eqs. (4.26) and (4.27) in Eq. (4.25), one gets, after simplifications,

$$(P_{\alpha_i} P_{\beta_i} f)(X_i) = \int d^{N-1} X'_i dx_i dx'_i \frac{\rho_0(X_i, X'_i, x_i, x'_i)}{\sigma_{\alpha_i \beta_i}(X_i)} f(X_i, X'_i, x_i, x'_i). \tag{4.29}$$

Finally, collecting Eqs. (4.23), (4.16), (4.24), and (4.29), we obtain the expression of the function h we were looking for

$$h(\mathbf{q},\mathbf{p}) = f(\mathbf{q},\mathbf{p}) - \sum_{\alpha=1}^{n} \frac{1}{\sigma_\alpha(Z_\alpha)} \int d^N Z'_\alpha \rho_0(\mathbf{q},\mathbf{p}) f(\mathbf{q},\mathbf{p}) + \sum_{i=1}^{n-1} \frac{1}{\sigma_{\alpha_i \beta_i}(X_i)} \int d^{N-1} X'_i dx_i dx'_i \rho_0(\mathbf{q},\mathbf{p}) f(\mathbf{q},\mathbf{p}). \tag{4.30}$$

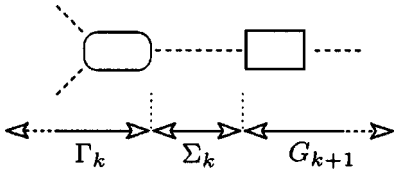

FIG. 5. The diagram Γ_{k+1}.

Equations (4.9) and (4.30) provide us with the general solution ρ of the linear system (2.2). It remains to enforce the positivity of this solution. Let us denote by m_+ (resp. $-m_-$) the (essential) supremum (resp. infimum) of h. Because of Eq. (4.10), m_+ and m_- are strictly positive when h does not vanish identically. Then, from Eq. (4.9), the condition $\rho \geqslant 0$ is equivalent to the condition on the parameter λ

$$-\frac{1}{m_+} \leqslant \lambda \leqslant \frac{1}{m_-}. \tag{4.31}$$

We stress that the allowed interval $[-(1/m_+),(1/m_-)]$ is not zero as soon as the range of the arbitrary function f is (essentially) bounded. Indeed, assuming that $A \leqslant f \leqslant B$ (almost) everywhere, one finds from Eq. (4.30) that $m_\pm \leqslant n(B-A)$.

Equations (4.9), (4.30), and (4.31) for ρ constitute the generalization of the results in Sec. V of (I) (see Eqs. (5.8)–(5.10) there) to phase spaces of arbitrary dimension, in one case of full admissibility (connected proper graphs).

V. NONCONNECTED PROPER GRAPHS

Throughout this section, devoted to the proof of part 2 of Theorem 1, a vertex (or insertion) with only two legs will be called *simple vertex*.

A. Nonproper G_c

Our purpose here is to establish part 2b of Theorem 1. To this end we first construct a particular connected graph G_c such that the proper graph G is subgraph of G_c. By hypothesis G_c is not proper. We then show that this implies the existence of at least one critical quartet in the graph G. According to Lemma 1, the statement 2b immediately follows.

Let $G=\cup_k G_k$ be the decomposition of a proper graph G into connected components G_k's. Each G_k is a proper graph, hence a tree. We connectify G recursively according to the following scheme. Assume we have already connectified the components $G_1,\ldots,G_k$ into a connected *diagram* Γ_k. We define Γ_{k+1} as follows. Let us call segment a linear chain of inserted simple vertices and links, and define its length by the number of its links. We choose one of the shortest segments which connect Γ_k to the component G_r $(r=k+1,\ldots)$. Among the G_r's we select one, say G_{k+1}, which minimizes the length of the attached segment. We call Σ_k this segment. The diagram Γ_{k+1} is defined by $\Gamma_{k+1}=\Gamma_k \cup G_{k+1} \cup \Sigma_k$.

Note that:

(1) In the above construction, two contiguous vertices of a Γ are not necessarily linked, so that the *diagrams* Γ are not always *graphs* as defined in Sec. II. The advantage of this construction is that the Γ_k's are trees.
(2) The segment Σ_k is attached to G_{k+1} through a vertex of G and attached to Γ_k through either a vertex of G or an inserted vertex of Γ_k (as represented in Fig. 5). In the latter case, this inserted vertex becomes nonsimple (if it was simple before).
(3) There is in general some arbitrariness in the construction of the Γ_k's. First, the recursive process has to be initialized by the choice of one component as Γ_1. Next, in the subsequent steps of the process, there is a possible arbitrariness in the choice of G_{k+1} and its attached segment.

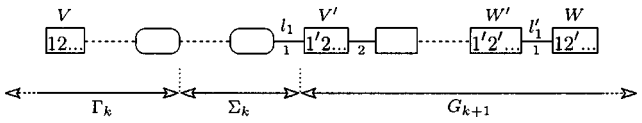

FIG. 6. Case a.

Once this connectification process is completed, we end up with a connected tree diagram Γ_c which contains all the components of G. If Γ_c is not a graph, we obtain a graph G_c by adding links between all pairs of contiguous vertices which are still not linked in Γ_c.

G_c and Γ_c may coincide or not. In the latter case, it is important to notice that G_c and Γ_c are still either both proper or both nonproper. This follows from the fact that (i) when going from Γ_c to G_c, a loop of G_c is created each time one adds a link, (ii) a loop contains at least two pairs of links carrying the same index.

Let us define the diagrams Ω_k by

$$\Omega_k = \Gamma_k \cup G_{k+1} \cup G_{k+2} \cup \cdots$$

which satisfy the inclusion relations

$$\Omega_1 \equiv G \subset \Omega_2 \subset \cdots \subset \Omega_c \equiv \Gamma_c \subset G_c.$$

Now, by hypothesis G_c, and thus also $\Omega_c = \Gamma_c$, are nonproper, whereas $\Omega_1 = G$ is proper. This implies the existence of an integer k such that $\Omega_k \subset \Omega_{k+1}$ with Ω_k proper and Ω_{k+1} nonproper. From the observation that

$$\Omega_{k+1} = \Omega_k \cup \Sigma_k,$$

we deduce that there exists at least one index, say 1, which is carried by just two links, one l_1 in Σ_k and a second one l_1' in Ω_k. The link l_1' may appear either in Γ_k or in the components $G_{k+1}, \ldots$ of G, which leads us to distinguish three cases:

(a) $l_1' \subset G_{k+1}$,
(b) $l_1' \subset \Gamma_k$,
(c) $l_1' \subset G_{k+2}$ or G_{k+3} or ….

We now proceed with a few remarks which will be useful in the forthcoming argument, although not always explicitly refered to thereby:

(1) All the end points (one leg vertices) of the Γ_k's belong to G.
(2) Any link of a Γ_k belongs to at least one linear chain with end vertices belonging to G.
(3) On a segment, the indices of the links can be reordered at our convenience. This should be kept in mind when constructing the Γ_k's.
(4) Two links carrying the same index cannot be attached to a common vertex.

As a consequence of these last two remarks, since all the Σ_k's are shortest connecting chains.
(5) All segments Σ_k are proper.
(6) On a connected tree Γ_k, the (unique) path joining two links carrying the same index contains either two vertices of G, or one vertex of G and one inserted nonsimple vertex, or two inserted nonsimple vertices.

Case a:

Let V be any vertex of Γ_k belonging to G, and V' be the vertex of G_{k+1} where the segment Σ_k attaches. Figure 6 exhibits the relevant part of Ω_{k+1}, namely the linear chain joining the vertices V and V', and the linear chain from V' to the link l_1' in G_{k+1}. Moreover, in accordance with Remark 3, we have attached the link l_1 to V'. We have also called 2 the index of the other link attached to V'.

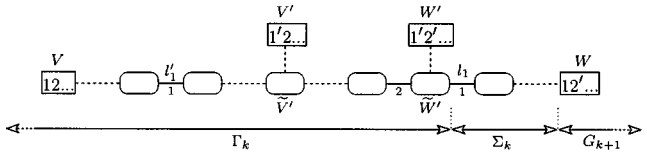

FIG. 7. Case b.

According to Remarks 3 and 4, there is no link with index 2 in Σ_k. Furthermore, since $\Gamma_k \cup G_{k+1}$ is proper, no new link of index 1 or 2 can appear in the linear chain connecting V to W. As a consequence, the vertices V, V', W, and W' constitute a critical quartet.

Case b:

The relevant part of Ω_{k+1} is displayed in Fig. 7. Here, V is a vertex of Γ_k belonging to G, such that the (unique) path joining it to Σ_k contains the link l_1'.

The existence of the nonsimple vertices $\widetilde{V}'$ and $\widetilde{W}'$ results from Remark 6. They may possibly coincide with respectively the vertices V' and W' of G. As previously, no new index 1 or 2 can appear in the chain displayed in Fig. 7, which implies that the vertices V, V', W, and W' constitute a critical quartet.

Case c:

In that case, the relevant part of Ω_{k+1} is made of two disconnected parts, as displayed in Fig. 8. As previously, the nonsimple inserted vertex $\widetilde{V}$ may possibly coincide with V.

Let us denote by I the set of indices appearing (each only once) in the links between V and $\widetilde{V}$, by J the set of indices appearing in the segment Σ_k but the index 1, and by K all the remaining indices. We can assume $I \cap J = \emptyset$ (otherwise the configuration would also enter the case b). We further split the sets I, J, and K as $I = I_1 \cup I_2$, $J = J_1 \cup J_2$, $K = K_1 \cup K_2$. Here, I_1 and I_2 are introduced to separate the variables which have the same or different assignments in the vertices V on the one hand and in the vertices W and W' on the other hand, and similarly for the splitting of J and K. Then $\{1, I_1, I_2, J_1, J_2, K_1, K_2\}$ is a partition of $\{1, 2, \ldots, N\}$, and the assignments of the variables in the vertices V, V', W, and W' of G, and $\widetilde{V}$ take the form

$$\begin{cases} V = \{1\mathcal{I}_1\mathcal{I}_2\mathcal{J}_1\mathcal{J}_2\mathcal{K}_1\mathcal{K}_2\}, \\ \widetilde{V} = \{1\mathcal{I}_1'\mathcal{I}_2'\mathcal{J}_1\mathcal{J}_2\mathcal{K}_1\mathcal{K}_2\}, \\ V' = \{1'\mathcal{I}_1'\mathcal{I}_2'\mathcal{J}_1'\mathcal{J}_2'\mathcal{K}_1\mathcal{K}_2\}, \\ W = \{1\mathcal{I}_1\mathcal{I}_2'\mathcal{J}_1\mathcal{J}_2'\mathcal{K}_1\mathcal{K}_2'\}, \\ W' = \{1'\mathcal{I}_1\mathcal{I}_2'\mathcal{J}_1\mathcal{J}_2'\mathcal{K}_1\mathcal{K}_2'\}. \end{cases} \tag{5.1}$$

In these formulas, $\mathcal{I}_1, \mathcal{I}_2, \ldots$ represent collections of variables q and p. In accordance with our convention (see Sec. II), $\mathcal{I}_1$ is written as a set of indices, namely those of I_1 but each one being primed or not. As for $\mathcal{I}_1'$, it is written as a set of the same indices, nonprimed (resp. primed) if primed (resp. nonprimed) in $\mathcal{I}_1$. Similarly for the other sets $\mathcal{I}_2, \mathcal{I}_2', \ldots$.

Let us define the distance $d(U, U')$ between two vertices U and U' as the number of variables with different assignments in U and U'. Inspecting Eq. (5.1), one readily obtains

$$\begin{cases} d(\widetilde{V}, V') = 1 + j_1 + j_2, \\ d(\widetilde{V}, W) = i_1 + j_2 + k_2, \end{cases} \tag{5.2}$$

where $j_1 = \text{card } J_1$, and so on. Since Σ_k is one of the shortest segments connecting Γ_k to one of the components $G_{k+1}, G_{k+2}, \ldots$, one must have $d(\widetilde{V}, V') \leqslant d(\widetilde{V}, W)$, which entails

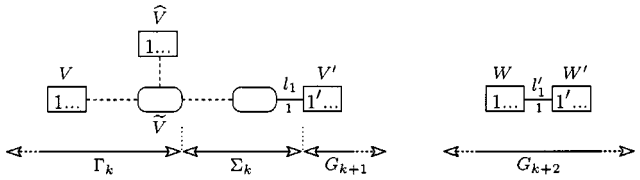

FIG. 8. Case c.

$$i_1 + k_2 \geqslant 1.$$

This means that the sets I_1 and K_2 cannot be both empty. If $K_2 \neq \emptyset$, we choose the index 2 in K_2, so that the vertices V, V', W, and W' constitute a critical quartet. If $K_2 = \emptyset$, I_1 is not empty, $\tilde{V}$ does not coincide with V, and thus $\tilde{V}$ is a nonsimple inserted vertex, necessarily linked in Γ_k to a vertex $\hat{V}$ of G as displayed in Fig. 8. Choosing now the index 2 in I_1, one finds that the vertices $\hat{V}$, V', W, and W' constitute a critical quartet.

B. Proper G_c

When G is subgraph of a *proper* connected graph G_c, the latter is a tree graph which can be decomposed into the connected components G_i of G and connecting segments Σ_k, even when G_c does not coincide with the specific graph G_c constructed in the previous Sec. V A. One needs to distinguish two cases:

(a) All the segments Σ_k's are disjoint. Then all insertions are simple and G_c is G-simple.
(b) At least two segments have one common vertex. This vertex is not a simple insertion and thus G_c is not G-simple.

1. G-simple G_c

Here, as in Sec. IV, we establish part 2.a.i of Theorem 1 by associating to any chain $\mathcal{C}$ of type G a particular phase space distribution ρ_0 reproducing this chain. We also give the general form of the ρ's reproducing the chain.

The construction of ρ_0 proceeds through the "Feynman rules" of Sec. IV A, complemented with propagators associated with the segments of G_c. Let Σ be such a segment connecting the vertices V_α and V_β of G, and let r be its length. Let $\sigma_\alpha(X,Y)$ and $\sigma_\beta(X,Y')$ be the corresponding vertex functions of $\mathcal{C}$, where X (resp. Y) denote the set of variables which have the same (resp. a different) assignment in σ_α and σ_β. The compatibility of σ_α and σ_β allows us to define

$$\sigma_{\alpha\beta}(X) \equiv \int d^r Y \sigma_\alpha(X,Y) = \int d^r Y' \sigma_\beta(X,Y'). \tag{5.3}$$

For different segments Σ_l labelled by the index l, we use the notation $\sigma_{\alpha_l\beta_l}(X_l)$.

To the segment Σ_l we now associate the propagator

$$\varpi_l(X_l) = \begin{cases} \dfrac{1}{\sigma_{\alpha_l\beta_l}(X_l)} & \text{if } X_l \in \mathcal{S}_{\alpha_l\beta_l}, \\ 0 \quad \text{otherwise}, \end{cases} \tag{5.4}$$

where $\mathcal{S}_{\alpha_l\beta_l}$ is the support of $\sigma_{\alpha_l\beta_l}$. This amounts to consider Σ_l as a new kind of link (in the graph G_c) which we call *composite link*. Then the function ρ_0 reads

$$\rho_0(\mathbf{q},\mathbf{p}) = \left(\prod_{\alpha=1}^{n} \sigma_\alpha(Z_\alpha)\right)\left(\prod_{l=1}^{n-1} \varpi_l(X_l)\right)\zeta(T'), \tag{5.5}$$

where the second product in the r.h.s. is performed on all links, namely the links of G and the composite links of G_c. Note that, since G_c is a connected tree, the total number of links is $(n-1)$. As for the function $\zeta(T')$, which is arbitrary but non-negative and normalized, it takes care of the "passive" variables $T=\{x_n, x_{n+1}, \ldots, x_N\}$ and their conjugate T', as in Eq. (4.3).

The proof that the ρ_0 of Eq. (5.5) solves Eq. (2.2) relies on the "peeling process" described in Sec. IV A. Here, this process has to be extended to the case where the one-leg vertex $\hat{V}$ introduced there is attached to a composite link. Let $\hat{\sigma}(X,Y)$ be the vertex function of $\mathcal{C}$ associated to $\hat{V}$, where X (resp. Y) is the set of variables whose assignment does not change (resp. changes) through the composite link. Then Eqs. (4.5) become

$$\int d^r Y \rho_0^{(m)}(\mathbf{q},\mathbf{p}) = \rho_0^{(m-1)}(X,X',Y'), \tag{5.6}$$

and the rest of the proof is completely similar to that given in Sec. IV A.

The determination of the general solution ρ of Eq. (2.2) is also carried out along the lines followed in Sec. IV B, by using this time the extended peeling process. The definitions of the measures $d\mu_\alpha$ and of the projectors P_α (which now involve the function ρ_0 of Eq. (5.5)) are unchanged. The Lemma 2 still holds, though with an extended acceptation of "contiguity": two vertices V_{α_l} and V_{β_l} of G connected by a composite link Σ_l of G_c are declared contiguous. Actually, only minor changes are needed to generalize the proof given in Appendix A (essentially the substitution $x_i \to Y$). The operator Π is now defined as

$$\Pi = 1 - \sum_{\alpha=1}^{n} P_\alpha + \sum_{l=1}^{n-1} P_{\alpha_l} P_{\beta_l}, \tag{5.7}$$

where the last sum in the r.h.s. is a sum over all links of G_c, composite or not. Its properties (4.17) and (4.21) remain true and, with ρ written as in Eq. (4.9), one finds that the general solution for h is given again by Eq. (4.23). A change then occurs in Eq. (4.27) when the two vertices V_{α_i} and V_{β_i} there become two vertices V_{α_l} and V_{β_l} connected by a composite link. In this case Eq. (4.27) becomes

$$\int d^{N-r_l} X_l' \rho_0(X_l, X_l', Y_l, Y_l') = \frac{\sigma_{\alpha_l}(X_l, Y_l)\sigma_{\beta_l}(X_l, Y_l')}{\sigma_{\alpha_l\beta_l}(X_l)}. \tag{5.8}$$

One ends up with the following expression of h, generalizing the representation formula (4.30)

$$h(\mathbf{q},\mathbf{p}) = f(\mathbf{q},\mathbf{p}) - \sum_{\alpha=1}^{n} \frac{1}{\sigma_\alpha(Z_\alpha)} \int d^N Z_\alpha' \rho_0(\mathbf{q},\mathbf{p}) f(\mathbf{q},\mathbf{p}) + \sum_{l=1}^{n-1} \frac{1}{\sigma_{\alpha_l\beta_l}(X_l)} \int d^{N-r_l} X_l' d^{r_l} Y_l d^{r_l} Y_l' \rho_0(\mathbf{q},\mathbf{p}) f(\mathbf{q},\mathbf{p}). \tag{5.9}$$

We remind the reader that, in this formula:

(i) f is an arbitrary function in $L^1(\mathbb{R}^{2N}, \rho_0 d^N q d^N p)$;
(ii) the first sum in the r.h.s. is over all vertices V_α of G; Z_α denotes the collection of arguments of the vertex function σ_α and Z_α' the collection of conjugate arguments;

(iii) the second sum is over all links (of length r_l), that is the simple links of G and the composite links of G_c; the definition of the functions $\sigma_{\alpha_l\beta_l}$ occurring in the sum, as well as the meaning of the collections of variables X_l, X'_l, Y_l, and Y'_l, are provided by Eq. (5.3), which reduces to Eq. (4.28) in the case of a simple link of index i.

2. Non G-simple G_c

Part 2.a.ii of Theorem 1 remains to be proven.

Consider first an arbitrary *quantum* chain $\mathcal{C}$ of type G. The CCS-distributions of $\mathcal{C}$ are then expressed in terms of some density operator $\hat{\rho}$, in accordance with Eq. (1.4). But, in this case, a set of CCS-distributions associated with the insertions of G_c can also be computed through these equations. One thus obtains an extended chain $\mathcal{C}_c$ of compatible CCS-distributions associated with all the vertices of G_c. Since G_c is proper, the chain $\mathcal{C}_c$ admissible (irrespective of the fact that G_c is not G-simple), which implies the admissibility of $\mathcal{C}$. Hence the quantum admissibility of the graph G.

To prove that G is not fully admissible, we show that there are (nonquantum) chains of type G which are not admissible.

By assumption G_c contains at least one insertion V with $k \geqslant 3$ legs, say the vertex $\boxed{12\ldots N}$ with legs carrying the indices $j=1,2,\ldots,k$. These legs connect V to k subgraphs $G_c^{(j)}$ of G_c which are proper connected trees, but mutually disconnected (otherwise G_c would contain loops). By removing all the insertions, together with their legs, from each of the $G_c^{(j)}$'s, we obtain k subgraphs $G^{(j)}$ of G which are proper (not necessarily connected) trees. The vertices $V_l^{(j)}$ of each $G^{(j)}$ are of the form $\boxed{1,2,\ldots,j-1,j',j+1,\ldots,k,\mathcal{J}_l^{(j)}}$, where $\mathcal{J}_l^{(j)}$ represents a set $\{k+1,k+2,\ldots,N\}$ of indices, each one being primed or not.

We now use the following lemma, the proof of which is given in Appendix B.

Lemma 3:

In a $2k$*-dimensional phase space with* $k \geqslant 3$, *there exist k-chains of compatible distributions* $\{\tau_1(p_1,q_2,q_3,\ldots,q_k),\ \tau_2(q_1,p_2,q_3,\ldots,q_k),\ \ldots,\ \tau_k(q_1,q_2,\ldots,q_{k-1},p_k)\}$ *which are not admissible.*

Let us construct a chain $\mathcal{C}$ of type G by assigning to each vertex $V_l^{(j)}$ of $G^{(j)}$ $(j=1,\ldots,k)$ the CCS-distributions

$$\sigma_l^{(j)}(q_1,\ldots,q_{j-1},p_j,q_{j+1},\ldots,q_k,X_l^{(j)}) = \tau_j(q_1,\ldots,q_{j-1},p_j,q_{j+1},\ldots,q_k)\tilde{\sigma}_l^{(j)}(X_l^{(j)}), \tag{5.10}$$

where $X_l^{(j)}$ denotes the set of variables x_i corresponding to $\mathcal{J}_l^{(j)}$ and the $\tilde{\sigma}_l^{(j)}$'s are arbitrary probability distributions depending on these variables, only subjected to the opposite compatibility conditions. (That such $\tilde{\sigma}_l^{(j)}$'s always exist is easy to see, e.g., by choosing completely factorized forms for them.) The elements of the chain $\mathcal{C}=\{\sigma_l^{(j)}\}_{j=1,\ldots,k;l}$ are evidently compatible CCS-distributions. Let us pretend that these distributions are marginals of some phase space density ρ. Then, by defining the reduced density

$$\tilde{\rho}(q_1,\ldots,q_k,p_1,\ldots,p_k) = \int dq_{k+1}dp_{k+1}\cdots dq_N dp_N \rho(\mathbf{q},\mathbf{p}) \tag{5.11}$$

in a $2k$-dimensional phase space, one finds that

$$\tau_j = \int d^{N-k}X_l^{(j)}\sigma_l^{(j)} \text{ (any } l),$$

$$= \int dp_1\cdots dp_{j-1}dq_j dp_{j+1}\cdots dp_k\tilde{\rho} \ (j=1,\ldots,k). \tag{5.12}$$

This would mean that the reduced k-chain $\tilde{\mathcal{C}}=\{\tau_j\}_{j=1,\ldots,k}$ is always admissible, in contradistinction with Lemma 3. We conclude that there exist chains of type G which are not admissible.

The two statements in part 2.a.ii of Theorem 1 are now established and the proof of this theorem is complete.

Finally, we would like to obtain an explicit expression of all the phase space densities ρ solving Eq. (2.2) for a given quantum chain $\mathcal{C}$ of type G, by following again the method of Sec. IV. However, serious complications crop up in the final step of the procedure.

First, a particular solution ρ_0 is obtained by applying formula (4.3) *to the extended chain* $\mathcal{C}_c$. Alternatively, one can determine other particular solutions ρ_0' by using, instead of $\mathcal{C}_c$, the chains $\mathcal{C}_c'$ obtained from $\mathcal{C}_c$ by removing all or some of the *simple* insertions of G_c and applying the procedure of Sec. V B 1 involving composite links and their associated propagators. Whatever ρ_0 is chosen, we keep writing the general solution in the form $\rho=\rho_0(1+\lambda h)$, as in Eq. (4.9).

Then a change appears in the determination of the function h, because one does not have to require the density ρ to reproduce all the CCS-distributions of the chain $\mathcal{C}_c$ (or $\mathcal{C}_c'$), but only those of the given chain $\mathcal{C}$. This means that h should satisfy Eq. (4.22), where the index α now refers to the only elements of the *initial chain* $\mathcal{C}$. As a consequence, the form (4.16) of the appropriate operator Π (to be used in Eq. (4.23)) is no longer valid, since the properties (4.17) and (4.21) hold only if the underlying graph is *connected*. Notice that a similar difficulty already appeared when dealing with G-simple graphs G_c in the previous subsection. There, it was overcome by introducing composite links which eventually allowed us to remove the insertions of G_c. Unfortunately, no such device presents itself for non G-simple G_c's, and constructing the "good" projector Π in this case seems to be quite a difficult problem, which we leave unsolved here.

Of course, the projector Π_c associated with the chain $\mathcal{C}_c$ already provides us with a large class of solutions, but certainly not all the solutions.

VI. CONCLUSIONS

We have investigated the extent to which it is possible to reproduce a given set of joint probability distributions $\sigma_\alpha(x_1,x_2,\ldots,x_N)$ with $x_i=q_i$ or p_i, in arbitrary number n and with arbitrary position-momentum assignments of the x_i's, as marginals of some probability density $\rho(\mathbf{q},\mathbf{p})$ in $2N$-dimensional phase space. We have been able to give a complete characterization of those sets which can always be reproduced by a $\rho(\mathbf{q},\mathbf{p})$ (admissible sets), irrespective of the functional form of the σ_α's provided they are compatible, and both for quantum probability distributions σ_α and for more general (classical) ones. This has been achieved by introducing a specific, powerful diagrammatic method and by relying on previous results[3,4] obtained in the case $N=2$ by means of Bell-type inequalities in phase space.

When both classical and quantum sets $\{\sigma_\alpha\}_{\alpha=1,\ldots,n}$ are admissible, we have constructed the general solution $\rho(\mathbf{q},\mathbf{p})$ of the problem. When only quantum sets are admissible, we have the explicit expression of a large class of solutions, which however is not exhaustive. Concerning the dynamical aspect which is completely ignored in this paper, our results in the quantum case motivate the construction of realistic quantum mechanics reproducing $(N+1)$ marginals at all times t and thus considerably improving on the de Broglie–Bohm mechanics,[7] which reproduces only one σ_α (the position probability distribution $\sigma(\mathbf{q},t)$).

On the other hand, all cases of nonadmissibility have been identified. For quantum σ_α's again, this may be viewed as a general contextuality theorem of the Gleason–Kochen–Specker-type,[8] which also extends a previous result of this type due to Martin and Roy.[9] At the same time, this provides a proof of a long-standing conjecture, the "$(N+1)$ marginal theorem."

From the mathematical standpoint, the parts of our main theorem (Theorem 1), pertaining to the quantum case are essentially new statements concerning multidimensional Fourier transforms in $L^2(\mathbb{R}^{2N},d^Nqd^Np)$. These statements vastly extend the results of Cohen and Zaparovanny[6] for two nonintersecting marginals to the case of $N+1$ marginals containing overlapping variables.

In classical image processing previous constructions of joint probability densities for position and wave number vectors which reproduce just two marginals (the position vector probability density and the wave number vector probability density) can now be extended to reproduce $N+1$ marginals whenever the admissibility conditions are obeyed. This has potential for new applications in classical signal and image processing.[10]

In the quantum arena the $N+1$ marginal theorem proved here makes precise the extent to which noncommuting CCS can be simultaneously realized extending the $N=2$ results of (I). Our results completely settle, at a formal level, the question of "maximal reality" raised and already investigated in special cases.[1–4] Their possible relevance for related fundamental problems of quantum theory (in particular for helping towards a clarification of the still controversial problem of measurement) remains to be explored.

At a practical level, the theorem is intimately related to quantum entanglement. The impossibility of reproducing more than $N+1$ marginals stems from allowing the most general entangled states. This indicates a direction in which the present work can be extended and applied to quantum information theory. For example, for partially separable quantum states, one may obtain theorems allowing positive phase space densities with more than $N+1$ marginals agreeing with quantum probabilities. To make this point forcefully suppose that $q_1, q_2, \ldots, q_N$ are coordinates of N particles and the quantum state $\hat{\rho}$ is separable (i.e., completely separable),

$$\hat{\rho} = \sum_r \mu_r \bigotimes_{i=1}^{N} \hat{\rho}_r^{(i)}, \tag{6.1}$$

where $\mu_r > 0$, $\Sigma_r \mu_r = 1$, and $\hat{\rho}_r^{(i)}$ is a density operator for the ith particle. We demonstrate now that the 2^N quantum probability densities

$$\sigma(x_1, x_2, \ldots, x_N) = \langle x_1, \ldots, x_N | \hat{\rho} | x_1, \ldots, x_N \rangle = \sum_r \mu_r \prod_{i=1}^{N} \langle x_i | \hat{\rho}_r^{(i)} | x_i \rangle \tag{6.2}$$

obtained by choosing $x_i = q_i$ or p_i, can all be reproduced as marginals of a single positive phase space density,

$$\rho(\mathbf{q}, \mathbf{p}) = \sum_r \mu_r \prod_{i=1}^{N} \langle q_i | \hat{\rho}_r^{(i)} | q_i \rangle \langle p_i | \hat{\rho}_r^{(i)} | p_i \rangle. \tag{6.3}$$

As before, denoting by x_i' the variable conjugate to x_i we obtain the 2^N equations

$$\int dx_1' \cdots dx_N' \rho(\mathbf{q}, \mathbf{p}) = \sum_r \mu_r \prod_{i=1}^{N} \langle x_i | \hat{\rho}_r^{(i)} | x_i \rangle = \sigma(x_1, x_2, \ldots, x_N), \tag{6.4}$$

which are the desired marginal conditions. We have used the normalization conditions

$$\int dx_i' \langle x_i' | \hat{\rho}_r^{(i)} | x_i' \rangle = 1. \tag{6.5}$$

We therefore expect that partial separability will allow a number of marginals intermediate between $N+1$ and 2^N to agree with quantum probabilities. We also expect that future work will demonstrate and exploit phase space Bell inequalities for general N following from hypotheses of marginal conditions or of quantum separability.

APPENDIX A: PROOF OF LEMMA 2

1. Commutation relation (4.14)

Consider two contiguous vertices V_α and V_β of G connected by a link l_i with index i, and denote by $\sigma_\alpha(x_i, X, T)$ and $\sigma_\beta(x_i', X, T)$ the corresponding distributions of the chain $\mathcal{C}_n$, where $X = \{x_1, \ldots, x_{i-1}, x_{i+1}, \ldots, x_{n-1}\}$. By removing the link l_i, the proper tree graph G is broken in two

connected components G_α and G_β: $G=G_\alpha \cup l_i \cup G_\beta$. To this splitting clearly corresponds a partition $\{X_\alpha, X_\beta\}$ of the variables X such that, among X and their conjugate X', all the variables $\{X_\alpha, X'_\alpha, X_\beta\}$ and only them appear in the vertices of G_α, whereas all the variables $\{X_\alpha, X_\beta, X'_\beta\}$ and only them appear in the vertices of G_β. In parallel, the particular solution ρ_0 given in Eq. (4.3) factorizes as

$$\rho_0 = \frac{\rho_\alpha \rho_\beta}{\sigma_{\alpha\beta}} \zeta, \tag{A1}$$

where the function ρ_α (the "ρ_0/ζ" of the subchain of $\mathcal{C}_n$ of type G_α) depends only on $(x_i, X_\alpha, X'_\alpha, X_\beta)$, the function ρ_β depends only on $(x'_i, X_\alpha, X_\beta, X'_\beta)$, and

$$\sigma_{\alpha\beta}(X,T) = \int dx_i \sigma_\alpha(x_i, X, T) = \int dx'_i \sigma_\beta(x'_i, X, T).$$

The measures $d\mu_\alpha$ and $d\mu_\beta$ as defined by Eq. (4.8) now take the form

$$\begin{cases} d\mu_\alpha = \dfrac{\rho_\alpha}{\sigma_\alpha} dX'_\alpha \dfrac{1}{\sigma_{\alpha\beta}} \rho_\beta dX'_\beta dx'_i \zeta dT', \\ d\mu_\beta = \rho_\alpha dX'_\alpha \dfrac{1}{\sigma_{\alpha\beta}} \dfrac{\rho_\beta}{\sigma_\beta} dX'_\beta dx_i \zeta dT'. \end{cases} \tag{A2}$$

Hence, for any $g(\mathbf{q},\mathbf{p}) \in L^1(\mathbb{R}^{2N}, \rho_0 d^N q d^N p)$:

$$P_\alpha P_\beta g = \frac{1}{\sigma_{\alpha\beta}} \int dx'_i \int dX'_\alpha \frac{\rho_\alpha}{\sigma_\alpha} \int dX'_\beta \rho_\beta \int dT' \zeta (P_\beta g).$$

The integrations over X'_α, X'_β, and T' can be performed explicitly since $P_\beta g$ does not depend on these variables. Noticing that

$$\int dX'_\alpha \rho_\alpha = \sigma_\alpha, \quad \int dX'_\beta \rho_\beta = \sigma_\beta, \tag{A3}$$

and taking account of Eq. (4.4), we get

$$P_\alpha P_\beta g = \frac{1}{\sigma_{\alpha\beta}} \int dx'_i \sigma_\beta (P_\beta g), \tag{A4}$$

$$= \frac{1}{\sigma_{\alpha\beta}} \int dx'_i \sigma_\beta \frac{1}{\sigma_{\alpha\beta}} \int dx_i dX'_\alpha dX'_\beta dT' \rho_\alpha \frac{\rho_\beta}{\sigma_\beta} \zeta g. \tag{A5}$$

Since σ_β does not depend on x_i, X'_α, and X'_β, the factors σ_β and $1/\sigma_\beta$ in Eq. (A5) cancel each other. This gives

$$P_\alpha P_\beta g = \frac{1}{(\sigma_{\alpha\beta})^2} \int dx_i dx'_i dX'_\alpha dX'_\beta dT' \rho_\alpha \rho_\beta \zeta g. \tag{A6}$$

The r.h.s. of this equation is symmetric in $\alpha \leftrightarrow \beta$, which establishes Eq. (4.14).

2. Relation (4.15)

Let V_α, V_β, and V_γ be now three vertices of G such that V_α belongs to the path connecting V_γ to V_β and is contiguous to V_β. Consider again the connected subgraphs G_α and G_β defined in Appendix A1 above, together with the partition $\{X_\alpha, X_\beta\}$ of the variables X, and distinguish in G_α the linear subgraph $G_{\alpha\gamma}$ made of the vertices V_α, V_γ and the path connecting them. Denote by I_{α_1}

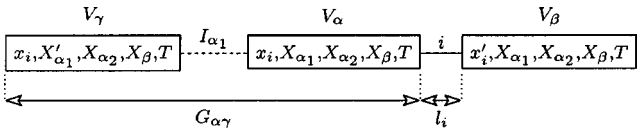

FIG. 9. The path between V_γ and V_β in G.

the set of indices of the links of $G_{\alpha\gamma}$ and by I_{α_2} the set of indices of the remaining links in G_α. To this splitting corresponds a further partition $\{X_{\alpha_1}, X_{\alpha_2}\}$ of the variables X_α, as indicated in Fig. 9.

With a factorization of the measure $d\mu_\gamma$ analogous to those of Eq. (A2), we can write

$$P_\gamma P_\alpha P_\beta g = \int dX_{\alpha_1} dX'_{\alpha_2} dX'_\beta dx'_i dT' \frac{\rho_\alpha}{\sigma_\gamma} \frac{1}{\sigma_{\alpha\beta}} \rho_\beta \zeta (P_\alpha P_\beta g). \tag{A7}$$

Here, we can perform explicitly the integrations over x'_i, X'_β, X'_{α_2}, and T', for $P_\alpha P_\beta g$ does not depend on these variables. First

$$\int dx'_i dX'_\beta \rho_\beta = \int dx'_i \sigma_\beta = \sigma_{\alpha\beta}. \tag{A8}$$

The left equality in Eq. (A8) results, as in Eq. (A3), from the "peeling process" (described in Sec. IV A) corresponding to the reduction of the graph G_β to the vertex V_β. Similarly, the (partial) peeling process corresponding to the reduction $G_\alpha \to G_{\alpha\gamma}$ yields

$$\int dX'_{\alpha_2} \rho_\alpha = \rho_{\alpha\gamma}, \tag{A9}$$

where $\rho_{\alpha\gamma}$ is the "ρ_0/ζ" of the subchain of type $G_{\alpha\gamma}$. Thanks to Eqs. (A8), (A9), and (4.7), Eq. (A7) boils down to

$$P_\gamma P_\alpha P_\beta g = \int dX_{\alpha_1} \frac{\rho_{\alpha\gamma}}{\sigma_\gamma} (P_\alpha P_\beta g)$$

or, by inserting the expression (A4) of $P_\alpha P_\beta g$:

$$P_\gamma P_\alpha P_\beta g = \int dX_{\alpha_1} \frac{\rho_{\alpha\gamma}}{\sigma_\gamma} \int dx'_i \frac{\sigma_\beta}{\sigma_{\alpha\beta}} (P_\beta g). \tag{A10}$$

On the other hand,

$$P_\gamma P_\beta g = \int dX_{\alpha_1} dX'_{\alpha_2} dX'_\beta dx'_i dT' \frac{\rho_0}{\sigma_\gamma} \zeta (P_\beta g), \tag{A11}$$

where the integrations over X'_β, X'_{α_2}, and T' can be performed explicitly since $P_\beta g$ does not depend on these variables. The integration over X'_β first produces, through the partial peeling process corresponding to $G \to (G_\alpha \cup l_i \cup V_\beta)$:

$$\int dX'_\beta \rho_0 = \rho_\alpha \frac{1}{\sigma_{\alpha\beta}} \sigma_\beta. \tag{A12}$$

Then Eqs. (A9) and (4.4) are used again for the integrations over X'_{α_2} and T', respectively. Altogether, this reduces the expression (A11) to the r.h.s. of Eq. (A10). Therefore $P_\gamma P_\alpha P_\beta g = P_\gamma P_\beta g$, which establishes Eq. (4.15) in the case where V_α is contiguous to V_β.

The proof of Eq. (4.15) in the case where V_α is contiguous to V_γ is completely similar.

Q.E.D.

APPENDIX B: PROOF OF LEMMA 3

We construct a particular k-chain of compatible distributions τ_j and we prove that there is no positive phase space density ρ reproducing these distributions as marginals. We take τ_j of the form:

$$\tau_j(q_1,\ldots,q_{j-1},p_j,q_{j+1},\ldots,q_k)=\gamma_j(p_j)\overline{\tau_j}(q_1,\ldots,q_{j-1},q_{j+1},\ldots,q_k)\ (j=1,\ldots,k),$$

where $\{\overline{\tau_1},\ldots,\overline{\tau_k}\}$ is a k-chain of compatible, reduced distributions and the $\gamma_j(p_j)$'s are arbitrary, normalized one variable distributions.

Let us look for a phase space density ρ reproducing the τ_j's. The $\overline{\tau_j}$'s are given in terms of the configuration space density

$$\overline{\rho}(q_1,\ldots,q_k)\equiv\int d^k p\rho(q_1,\ldots,q_k,p_1,\ldots,p_k) \tag{B1}$$

as

$$\overline{\tau_j}(q_1,\ldots,q_{j-1},q_{j+1},\ldots,q_k)=\int dq_j\overline{\rho}(q_1,\ldots,q_k). \tag{B2}$$

We now choose the $\overline{\tau_j}$'s as follows:

$$\begin{cases}\overline{\tau_1}(q_2,\ldots,q_k)=\displaystyle\prod_{r=2}^{k}T_r-\prod_{r=2}^{k}U_r,\\ \overline{\tau_j}(q_1,\ldots,q_{j-1},q_{j+1},\ldots,q_k)=\displaystyle\prod_{\substack{r=1\\ r\neq j}}^{k}T_r+\prod_{\substack{r=1\\ r\neq j}}^{k}U_r,\quad (j=2,\ldots,k),\end{cases} \tag{B3}$$

where

$$\begin{cases}T_r=\frac{1}{2}[\delta(q_r-1)+\delta(q_r+1)],\\ U_r=\frac{1}{2}[\delta(q_r-1)-\delta(q_r+1)],\end{cases}\quad (r=1,\ldots,k).$$

The $\overline{\tau_j}$'s, which appear as sums of 2^{k-2} monomials of the form

$$\frac{1}{2^{k-2}}\prod_{\substack{r=1\\ r\neq j}}^{k}\delta(q_r-\varepsilon_r)\quad \varepsilon_r=\pm 1,$$

are obviously positive and normalized. Furthermore,

$$\int dq_i\overline{\tau_j}(q_1,\ldots,q_{j-1},q_{j+1},\ldots,q_k)=\prod_{\substack{r=1\\ r\neq i,j}}^{k}T_r\quad (i\neq j).$$

The r.h.s. of this equation is symmetric in $i\leftrightarrow j$, which entails the compatibility of the $\overline{\tau_j}$'s.

Clearly, the most general *positive* $\overline{\rho}$ obeying Eqs. (B2) is the sum of 2^k terms proportional to $\Pi_{r=1}^{k}\delta(q_r-\varepsilon_r)$. Equivalently, $\overline{\rho}$ can be written as a homogeneous polynomial $P(\{T_r\},\{U_r\})$ of degree k which, for each index r, is linear in T_r and U_r. Then, since $\int dq_jT_j=1$ and $\int dq_jU_j=0$, we can express $\int dq_j\overline{\rho}$ as $\partial P/\partial T_j$, so that Eqs. (B2) and (B3) yield

$$\begin{cases} \dfrac{\partial P}{\partial T_1} = \displaystyle\prod_{r=2}^{k} T_r - \prod_{r=2}^{k} U_r, \\ \dfrac{\partial P}{\partial T_j} = \displaystyle\prod_{\substack{r=1 \\ r\neq j}}^{k} T_r + \prod_{\substack{r=1 \\ r\neq j}}^{k} U_r \ (j = 2, \ldots, k). \end{cases}$$

The general solution of these equations is

$$P = \prod_{r=1}^{k} T_r - T_1 \prod_{r=2}^{k} U_r + \sum_{j=2}^{k} T_j \prod_{\substack{r=1 \\ r\neq j}}^{k} U_r + \lambda \prod_{r=1}^{k} U_r, \tag{B4}$$

where λ is an arbitrary real parameter.

Now, whatever the value of λ is, P, and thus ρ, are not positive. To show this, it is sufficient to look at the coefficients of the two monomials

$$\delta(q_1 + 1) \prod_{r=2}^{k} \delta(q_r - 1) \text{ and } \delta(q_1 - 1)\delta(q_2 + 1)\delta(q_3 + 1) \prod_{r=4}^{k} \delta(q_r - 1)$$

which appear in Eq. (B4) if $k \geqslant 3$. One finds $-(k-1+\lambda)/2^k$ and $(k-5+\lambda)/2^k$, respectively, the sum of which is independent of λ and negative. Q.E.D.

(Received 31 October 2003; accepted 21 July 2004; published 24 November 2004)

We study the invariant theory of trilinear forms over a three-dimensional complex vector space, and apply it to investigate the behavior of pure entangled three-partite qutrit states and their normal forms under local filtering operations (SLOCC). We describe the orbit space of the SLOCC group $\mathrm{SL}(3,\mathbb{C})^{\times 3}$ both in its affine and projective versions in terms of a very symmetric normal form parametrized by three complex numbers. The parameters of the possible normal forms of a given state are roots of an algebraic equation, which is proved to be solvable by radicals. The structure of the sets of equivalent normal forms is related to the geometry of certain regular complex polytopes. © *2004 American Institute of Physics.*

I. INTRODUCTION

The invariant theory of trilinear forms over a three-dimensional complex vector space is an old subject with a long history, which, as we shall see, appears even longer if we take into account certain indirect but highly relevant contributions.[1–4] This question has been recently revived in the field of Quantum Information Theory as the problem of classifying entanglement patterns of three-qutrit states.

Indeed, since the advent of quantum computation and quantum cryptography, entanglement has been promoted to a resource that allows quantum physics to perform tasks that are classically impossible. Quantum cryptography[5,6] proved that this gap even exists with small systems of two entangled qubits. Furthermore, it is expected that the study of higher dimensional systems and of multipartite (e.g., 3-partite) states would lead to more applications. A seminal example is the so-called 3-qutrit Aharonov-state, which "*is so elegant it had to be useful*":[7] Fitzi, Gisin, and Maurer[7] found out that the classically impossible Byzantine agreement problem[8] can be solved using 3-partite qutrit states. From a more fundamental point a view, the Aharonov state led to nontrivial counterexamples of the conjectures on additivity of the relative entropy of entanglement[9] and of the output purity of quantum channels.[10] Obviously, these results provide a strong motivation for studying 3-partite qutrit states. Furthermore, interesting families of higher-dimensional states are perfectly suited to address questions concerning local realism and Bell inequalities (see, e.g., Ref. 11 for a study of three-qutrit correlations).

It is therefore of interest to find some classification scheme for three-qutrit states. A possible direction is to look for classes of equivalent states, in the sense that they are equivalent up to local unitary transformations[12–14] or local filtering operations (also called SLOCC operations).[14–19] In the case of three qubits, especially the last classification proved to yield a lot of insights (the

[d]Electronic mail: frank.verstraete@mpq.mpg.de

classification up to local unitaries has too many parameters left); the reason for that is that in the closure of each generic orbit induced by SLOCC operations, there is a unique state (up to local unitary transformations) with maximal entanglement.[14,17]

In Ref. 19, a numerical method converging to such a maximally entangled state has been described. It has been experimentally observed that, when applied to a three-qutrit state, this method converged to a very special normal form. We shall provide a formal proof of this property, and then study in some detail the geometry of those normal forms. Precise statements of the results are summarized in the forthcoming section.

II. RESULTS

Let $V=\mathbb{C}^3$ and $\mathcal{H}=V\otimes V\otimes V$ regarded as a representation of the group $G=\mathrm{SL}(3,\mathbb{C})^{\times 3}$. The elements of $\mathcal{H}$ will be interpreted either as three-qutrit states

$$|\psi\rangle = \sum_{i,j,k=0}^{2} A_{ijk}|i,j,k\rangle \tag{1}$$

or as trilinear forms

$$f = f(\mathbf{x},\mathbf{y},\mathbf{z}) = \sum_{i,j,k=0}^{2} A_{ijk}x_i y_j z_k, \tag{2}$$

that is, we identify the basis state $|ijk\rangle$ with the monomial $x_i y_j z_k$. If $g=(g^{(1)},g^{(2)},g^{(3)})\in G$ is a triple of matrices, we define $x'_i=\Sigma_p g^{(1)}_{ip}x_p$, $y'_j=\Sigma_q\, g^{(2)}_{jq}y_q$, $z'_k=\Sigma_r\, g^{(3)}_{kr}z_r$, and the coefficients A'_{ijk} by the condition

$$\sum A'_{ijk}x'_i y'_j z'_k = \sum A_{ijk}x_i y_j z_k, \tag{3}$$

the action of G on $\mathcal{H}$ being defined by

$$g\cdot A = \sum A'_{ijk}x_i y_j z_k, \tag{4}$$

It has been shown by Vinberg[20] that a generic state can be reduced to the normal form

$$A'_{ijk} = u\,\delta_{ijk} + \frac{w-v}{2}\epsilon_{ijk} + \frac{w+v}{2}|\epsilon_{ijk}| \tag{5}$$

(where δ_{ijk} is the Kronecker symbol and ϵ_{ijk} the completely antisymmetric tensor) by an appropriate choice of $g\in G$.

Our first result is as follows.

Theorem II.1: *When applied to a generic 3-qutrit state (1) the numerical algorithm of Ref. 19 converges to a state which is a Vinberg normal form, generically in the same G-orbit as* $|\psi\rangle$.

As proved in Refs. 14 and 19, the normal form $|\psi'\rangle$ is unique up to local unitary transformations. More precisely, we have the following.

Theorem II.2: *A generic state has exactly* 648 *different normal forms. For special states, this number can be reduced to* 216, 72, 27 *or* 1. *Moreover, the coefficients u, v, w of the normal form can be computed algebraically.*

Theorem II.3: *The coefficients of the normal forms are determined, up to a sign, by an algebraic equation of degree* 1296, *which is explicitly solvable by radicals.*

To form this equation, we need some notions of invariant theory.

A polynomial $P(A)$ in the coefficients A_{ijk} is an *invariant* of the action of G on $\mathcal{H}$ if $P(A')=P(A)$ for all $g\in G$. These invariants form a graded algebra R (any invariant P is a sum of homogeneous invariants) and the first issue is to determine the dimension of the space R_d of homogeneous invariants of degree d. The Hilbert series

$$h(t) = \sum_{d \geqslant 0} \dim R_d t^d \tag{6}$$

is known[20]

$$h(t) = \frac{1}{(1-t^6)(1-t^9)(1-t^{12})} \tag{7}$$

and in fact, one can prove that R is a polynomial algebra generated by three algebraically independent invariants of respective degree 6, 9, and 12.

The modern way to prove this result is due to Vinberg, who obtained it from his notion of Weyl group of a graded Lie algebra, applied to a Z_3-grading of the exceptional Lie algebra E_6.[21]

In Sec. III, we shall explain how it can be deduced from the work of Chanler.[22] We prove that certain invariants I_6, I_9, and I_{12} introduced in Ref. 22 are indeed algebraic generators of R and explain how to compute them from the numerical values of the coefficients A_{ijk}, by expressing them in terms of *transvectants*, that is, by means of certain differential polynomials in the form f, rather than in terms of the classical symbolic notation. Given the values of the invariants for a particular state, we show how to form and solve the system of algebraic equations determining the coefficients, u, v, w of the normal form.

Let $a=I_6$, $b=I_{12}$, and $c=I_{18}$ (a certain polynomial in the fundamental invariants). Then, the symmetric functions of u^3, v^3, and w^3

$$\psi = u^3 + v^3 + w^3, \quad \chi = u^3v^3 + u^3w^3 + v^3w^3, \quad \lambda = 216u^3v^3w^3 \tag{8}$$

satisfy

$$\psi^2 - 12\chi - a = 0,$$

$$\psi^4 + \lambda\psi - b = 0,$$

$$\psi^6 - \tfrac{5}{2}\lambda\psi^3 - \tfrac{1}{8}\lambda^2 - c = 0. \tag{9}$$

Theorem II.4: *The system (9) has generically* 1296 *solutions* (u,v,w)*, which can be obtained by solving a chain of algebraic equations of degree at most* 4*. Only* 648 *of them give the correct sign for* I_9*. The number of solutions (with the correct sign for* I_9*) can be reduced only to* 216, 72, 27 *or* 1*. Moreover, the isotropy groups of these degenerate orbits can be determined, and the configuration of the points* (u,v,w) *in* $\mathbb{C}^3$ *can be interpreted in terms of the geometry of regular complex polyhedra.*

The details are given in Sec. VII.

III. THE FUNDAMENTAL INVARIANTS

In this section, we describe the fundamental invariants, as well as the other concomitants obtained by Chanler,[22] in a form suitable for calculations, in particular for their numerical evaluation (see also Refs. 23 and 24).

As already mentioned, we shall identify a three-qutrit state $|\psi\rangle \in \mathcal{H}$ with a trilinear form

$$f(\mathbf{x},\mathbf{y},\mathbf{z}) = \sum_{1 \leqslant i,j,k \leqslant 3} A_{ijk} x_i y_j z_k \tag{10}$$

in three ternary variables. To construct its fundamental invariants, we shall need the notion of a transvectant, which is defined by means of Cayley's omega process (see, e.g., Ref. 25).

Let f_1, f_2, and f_3 be three forms in a ternary variable $\mathbf{x}=(x_1,x_2,x_3)$. Their tensor product $f_1 \otimes f_2 \otimes f_3$ is identified with the polynomial $f_1(\mathbf{x}^{(1)})f_2(\mathbf{x}^{(2)})f_3(\mathbf{x}^{(3)})$ in the three independent ternary variables $\mathbf{x}^{(1)}$, $\mathbf{x}^{(2)}$ and $\mathbf{x}^{(3)}$. We use the "trace" notation of Olver[26] to denote the multiplication map $f_1 \otimes f_2 \otimes f_3 \to f_1 f_2 f_3$, that is,

$$\operatorname{tr} f_1(\mathbf{x}^{(1)})f_2(\mathbf{x}^{(2)})f_3(\mathbf{x}^{(3)}) = f_1(\mathbf{x})f_2(\mathbf{x})f_3(\mathbf{x}). \tag{11}$$

Cayley's operator $\Omega_{\mathbf{x}}$ is the differential operator

$$\Omega_{\mathbf{x}} = \begin{vmatrix} \frac{\partial}{\partial x_1^{(1)}} & \frac{\partial}{\partial x_1^{(2)}} & \frac{\partial}{\partial x_1^{(3)}} \\ \frac{\partial}{\partial x_2^{(1)}} & \frac{\partial}{\partial x_2^{(2)}} & \frac{\partial}{\partial x_2^{(3)}} \\ \frac{\partial}{\partial x_3^{(1)}} & \frac{\partial}{\partial x_3^{(2)}} & \frac{\partial}{\partial x_3^{(3)}} \end{vmatrix}. \tag{12}$$

Now, we consider three independent ternary variables $\mathbf{x}$, $\mathbf{y}$, and $\mathbf{z}$ together with the associated dual (contravariant) variables $\xi=(\xi_1,\xi_2,\xi_3)$, $\eta=(\eta_1,\eta_2,\eta_3)$, $\zeta=(\zeta_1,\zeta_2,\zeta_3)$ [that is, ξ_i is the linear form on the $\mathbf{x}$ space such that $\xi_i(x_j)=\delta_{ij}$].

A *concomitant* of f is, by definition, a polynomial F in the A_{ijk}, $\mathbf{x}$, $\mathbf{y}$, $\mathbf{z}$, ξ, η, ζ, such that if $g=(g_1,g_2,g_3)\in \mathrm{SL}(3,\mathbb{C})^3$, then, with A', $\mathbf{x}'$, etc., as above,

$$F(A';\mathbf{x}',\mathbf{y}',\mathbf{z}';\xi',\eta',\zeta') = F(A;\mathbf{x},\mathbf{y},\mathbf{z};\xi,\eta,\zeta). \tag{13}$$

The algebra of concomitants admits only one generator of degree 1 in the A_{ijk}, which is the form f itself. Other concomitants can be deduced from f and the three absolute invariants $P_\alpha=\Sigma\xi_i x_i$, $P_\beta=\Sigma\eta_j y_j$, and $P_\gamma=\Sigma\zeta_k z_k$, using transvectants. If F_1, F_2, and F_3 are three 6-tuple forms in the independent ternary variables $\mathbf{x}$, $\mathbf{y}$, $\mathbf{z}$, ξ, η, and ζ, one defines for any $(n_1,n_2,n_3)\times(m_1,m_2,m_3)\in\mathbb{N}^3\times\mathbb{N}^3$ the multiple transvectant of F_1, F_2, and F_3 by

$$(F_1,F_2,F_3)^{n_1n_2n_3}_{m_1m_2m_3} = \operatorname{tr}\quad \Omega_{\mathbf{x}}^{n_1}\Omega_{\mathbf{y}}^{n_2}\Omega_{\mathbf{z}}^{n_3}\Omega_{\xi}^{m_1}\Omega_{\eta}^{m_2}\Omega_{\zeta}^{m_3}\prod_{i=1}^{3} F_i(\mathbf{x}^{(i)},\mathbf{y}^{(i)},\mathbf{z}^{(i)};\xi^{(i)},\eta^{(i)},\zeta^{(i)}). \tag{14}$$

For convenience, we will set $(F_1,F_2,F_3)^{n_1n_2n_3}=(F_1,F_2,F_3)^{n_1n_2n_3}_{000}$. The concomitants of degree 2 given by Chanler[22] can be obtained using these operations,

$$Q_\alpha = (f,f,P_\beta P_\gamma)^{011}, \tag{15}$$

$$Q_\beta = (f,f,P_\alpha P_\gamma)^{101}, \tag{16}$$

$$Q_\gamma = (f,f,P_\alpha P_\beta)^{110}. \tag{17}$$

The invariant I_6 is then

$$I_6 = \tfrac{1}{96}(Q_\alpha,Q_\alpha,Q_\alpha)^{200}_{011} = \tfrac{1}{96}(Q_\beta,Q_\beta,Q_\beta)^{020}_{101} = \tfrac{1}{96}(Q_\gamma,Q_\gamma,Q_\gamma)^{002}_{110}. \tag{18}$$

There is an alternative expression using only the ground form f,

$$I_6 = \frac{1}{1152}(f^2,f^2,f^2)^{222}. \tag{19}$$

Now, in degree 3 the covariants B_α, B_β, and B_γ of Ref. 22 are

$$B_\alpha = (f,f,f)^{011}, \tag{20}$$

$$B_\beta = (f,f,f)^{101}, \tag{21}$$

$$B_\gamma = (f,f,f)^{110}. \tag{22}$$

The other concomitants found by Chanler can be written in a similar way,

$$C_{\alpha\beta} = \tfrac{1}{4}(f, f, fP_\beta)^{110}, \tag{23}$$

$$C_{\beta\alpha} = \tfrac{1}{4}(f, f, fP_\alpha)^{110}, \tag{24}$$

$$C_{\alpha\gamma} = \tfrac{1}{4}(f, f, fP_\gamma)^{101}, \tag{25}$$

$$C_{\gamma\alpha} = \tfrac{1}{4}(f, f, fP_\alpha)^{101}, \tag{26}$$

$$C_{\beta\gamma} = \tfrac{1}{4}(f, f, fP_\gamma)^{011}, \tag{27}$$

$$C_{\gamma\beta} = \tfrac{1}{4}(f, f, fP_\beta)^{011}, \tag{28}$$

$$D_\alpha = -2(fP_\beta, fP_\gamma, f)^{111}, \tag{29}$$

$$D_\beta = 2(fP_\alpha, fP_\gamma, f)^{111}, \tag{30}$$

$$D_\gamma = -2(fP_\alpha, fP_\beta, f)^{111}, \tag{31}$$

$$E_\alpha = (Q_\alpha, f, P_\alpha)^{100}, \tag{32}$$

$$E_\beta = (Q_\beta, f, P_\beta)^{010}, \tag{33}$$

$$E_\gamma = (Q_\gamma, f, P_\gamma)^{001}, \tag{34}$$

$$G_\alpha = -\tfrac{3}{8}(fP_\beta, fP_\gamma, f)^{011} + \tfrac{5}{16}(fP_\beta P_\gamma, f, f)^{011}, \tag{35}$$

$$G_\beta = -\tfrac{3}{8}(fP_\alpha, fP_\gamma, f)^{101} + \tfrac{5}{16}(fP_\alpha P_\gamma, f, f)^{101}, \tag{36}$$

$$G_\gamma = -\tfrac{3}{8}(fP_\alpha, fP_\beta, f)^{110} + \tfrac{5}{16}(fP_\alpha P_\beta, f, f)^{110}, \tag{37}$$

$$H = \tfrac{1}{2}(fP_\alpha, fP_\beta, fP_\gamma)^{111}. \tag{38}$$

Here, we have combined the concomitants of degrees 0, 1, and 2 into independent concomitants of degree 3. Next, we have chosen the scalar factors so that the syzygies given by Chanler[22] hold in the form

$$H + E_\alpha - E_\gamma + D_\beta P_\beta = 0, \tag{39}$$

$$H + E_\beta - E_\alpha + D_\gamma P_\gamma = 0, \tag{40}$$

$$H + E_\gamma - E_\beta + D_\alpha P_\alpha = 0, \tag{41}$$

$$3C_{\alpha\beta} - B_\gamma P_\beta = 0, \tag{42}$$

$$3C_{\beta\alpha} - B_\gamma P_\alpha = 0, \tag{43}$$

$$3C_{\alpha\gamma} - B_\beta P_\gamma = 0, \tag{44}$$

$$3C_{\gamma\alpha} - B_\beta P_\alpha = 0, \tag{45}$$

$$3C_{\beta\gamma} - B_\alpha P_\gamma = 0, \tag{46}$$

$$3C_{\gamma\beta} - B_\alpha P_\beta = 0, \tag{47}$$

$$6G_\alpha - 3Q_\alpha f + B_\alpha P_\beta P_\gamma = 0, \tag{48}$$

$$6G_\beta - 3Q_\beta f + B_\beta P_\alpha P_\gamma = 0, \tag{49}$$

$$6G_\gamma - 3Q_\gamma f + B_\gamma P_\alpha P_\beta = 0. \tag{50}$$

One can remark that a basis of the space of the concomitants of degree 3 found by Chanler can be constructed using only transvections and products from smaller degrees,

$$f^3, Q_\alpha f, Q_\beta f, Q_\gamma f, B_\alpha, B_\beta, B_\gamma, D_\alpha, D_\beta, D_\gamma, E_\alpha. \tag{51}$$

The knowledge of these concomitants allows one to construct the invariants I_9 and I_{12},

$$I_9 = \tfrac{1}{576}(E_\alpha, E_\beta, E_\beta)^{111}_{111}, \tag{52}$$

$$I_{12} = \frac{1}{124\,416}(B_\alpha f, B_\alpha f, B_\alpha f)^{411}. \tag{53}$$

These expressions, which can be easily implemented in any computer algebra system, will prove convenient to compute the specializations discussed in the sequel.

IV. NORMAL FORM AND INVARIANTS

It will now be shown that a generic state can be reduced to the normal form

$$A_{ijk} = u\,\delta_{ijk} + \frac{w-v}{2}\epsilon_{ijk} + \frac{w+v}{2}|\epsilon_{ijk}|, \tag{54}$$

where ϵ_{ijk} is the alternating tensor, or, otherwise said, that the generic trilinear form $f(\mathbf{x},\mathbf{y},\mathbf{z})$ is equivalent to some

$$\begin{aligned} N_{uvw}(\mathbf{x},\mathbf{y},\mathbf{z}) = {} & u(x_1y_1z_1 + x_2y_2z_2 + x_3y_3z_3) + v(x_1y_3z_2 + x_2y_1z_3 + x_3y_2z_1) \\ & + w(x_1y_2z_3 + x_2y_3z_1 + x_3y_1z_2). \end{aligned} \tag{55}$$

For such a state, the local density operators are all proportional to the identity. This property is automatically satistfied by the limiting state obtained from the numerical method of Ref. 19, and implies maximal entanglement as well. Since this algorithm amounts to an infinite sequence of invertible local filtering operations, the genericity of Vinberg's normal form, together with the previously mentioned properties, implies convergence to a Vinberg normal form for a generic input state, that is, our Theorem II.1 (see also Refs. 27 and 28).

This normal form is in general not unique, and the relations between the various N_{uvw} in a given orbit is an interesting question, which will be addressed in the sequel.

Although, the validity of this normal form follows from Vinberg's theory,[21] it can also be proved in other ways, some of them being particularly instructive. We shall detail one of these possibilities, which will give us the opportunity to introduce some important polynomials, playing a role in the algebraic calculation of the normal form and in the geometric discussion of the orbits.

The shortest possibility, although not the most elementary, relies on the results of Ref. 22, and starts with computing the invariants of N_{uvw}. We then use a few results of algebraic geometry, which can be found in Ref. 29. Let us denote by $C_k \equiv C_k(u,v,w)$ $(k=6,9,12)$ the values of the I_k on N_{uvw}. Direct calculation gives, denoting by m_{pqr} the monomial symmetric functions of u,v,w (sum of all distinct permutations of the monomial $u^p v^q w^r$),

$$C_6 = m_{(6)} - 10m_{(3,3)}, \tag{56}$$

$$C_9 = (u^3 - v^3)(u^3 - w^3)(v^3 - w^3), \tag{57}$$

$$C_{12} = m_{(12)} + 4m_{(9,3)} + 6m_{(6,6)} + 228m_{(6,3,3)}. \tag{58}$$

It is easily checked by direct calculation that the Jacobian of these three functions is nonzero for generic values of (u,v,w). Actually, its zero set consists of 12 planes, whose geometric significance will be discussed below.

Let us denote by $\varphi: \mathcal{H} \xrightarrow{(I_6,I_9,I_{12})} \mathbb{C}^3$, the map sending a trilinear form to its three invariants, so that $(C_6,C_9,C_{12}) = \varphi(N_{uvw})$. Let $S = \{N_{uvw} | (u,v,w) \in \mathbb{C}^3\}$ be the three-dimensional space of normal forms. The nonvanishing of the Jacobian proves that φ induces a dominant mapping from S to $\mathbb{C}^3$ (that is, the direct image of any nonempty open subset of S contains a nonempty open subset of $\mathbb{C}^3$). Note that the independence of C_6,C_9,C_{12} implies the independence of I_6,I_9,I_{12}. Now, Chanler[22] has shown that I_6,I_9,I_{12} separate the orbits in general position. This proves that the field of rational invariants of G is freely generated by I_6,I_9,I_{12} (Ref. 29, Lemma 2.1). As a consequence, φ is a *rational quotient* (Ref. 29, Sec. 2.4) for the action of G on $\mathcal{H}$ (actually, this also implies that φ is a categorical quotient, by Ref. 29, Proposition 2.5 and Theorem 4.12, using that $\varphi_{|S}$ is surjective, whence also φ).

There exists a nonempty open subset Y_0 of $\mathbb{C}^3$ such that the fiber of φ over each of its points is the closure of an orbit (Ref. 29, Proposition 2.5). Let then $U_0 = \varphi^{-1}(Y_0)$. This set cuts S since $\varphi_{|S}$ is dominant. Let U_1 be the union of all orbits having maximal dimension (a nonempty open set, the function *dimension of the orbit* being lower semicontinuous). It is easy to see that U_1 intersects S (for instance at $u=1$, $v=1$, $w=-1$, whose orbit has dimension $24 = \dim G$, as may be checked by direct calculation). Let $S_0 = U_1 \cap S$, a dense open subset of S. The set $\varphi^{-1}\varphi(S_0)$ thus contains a dense open subset U_2 of $\mathcal{H}$. One then checks that $U_0 \cap U_1 \cap U_2$ (a dense open subset, as an intersection of dense open subsets of an irreducible space) is contained in GS. This proves $\overline{GS} = \mathcal{H}$, that is, the normal form N_{uvw} is generic.

Let us remark that the above discussion also proves, thanks to Igusa's theorem (Ref. 29, Theorem 4.12) that $\mathbb{C}[\mathcal{H}]^G = \mathbb{C}[I_6,I_9,I_{12}]$, that is, the algebra of invariants is freely generated by Chanler's invariants.

Is is also possible to give a direct proof of the normal form by using the same technique as in Ref. 22. Chanler's method relies on the geometry of plane cubics, which will play a prominent role in the sequel.

V. THE FUNDAMENTAL CUBICS

The trilinear form $f(\mathbf{x},\mathbf{y},\mathbf{z})$ can be encoded in three ways by a 3×3 matrix of linear forms $M_x(\mathbf{x})$, $M_y(\mathbf{y})$, and $M_z(\mathbf{z})$, defined by

$$f(\mathbf{x},\mathbf{y},\mathbf{z}) = {}^t\mathbf{y} M_x(\mathbf{x})\mathbf{z} = {}^t\mathbf{x} M_y(\mathbf{y})\mathbf{z} = {}^t\mathbf{x} M_z(\mathbf{z})\mathbf{y} \tag{59}$$

and the classification of trilinear forms amounts to the classification of one of these matrices, say $M_x(\mathbf{x})$ up to left and right multiplication by elements of $\mathrm{SL}(3,\mathbb{C})$ and action of $\mathrm{SL}(3,\mathbb{C})$ on the variable $\mathbf{x}$.

The most immediate covariants of f are the determinants of these matrices

$$X(\mathbf{x}) = \det M_x(\mathbf{x}) = \tfrac{1}{6}B_\alpha, \tag{60}$$

$$Y(\mathbf{y}) = \det M_y(\mathbf{y}) = \tfrac{1}{6}B_\beta, \tag{61}$$

$$Z(\mathbf{z}) = \det M_z(\mathbf{z}) = \tfrac{1}{6}B_\gamma. \tag{62}$$

These are ternary cubic forms, and for generic f the equations $X(\mathbf{x})=0$, etc., will define nonsingular cubics (elliptic curves) in $\mathbb{P}^2$. It is shown in Ref. 24 that whenever one of these curves is elliptic, so are the other two ones, and moreover, all three are projectively equivalent. Actually, one can check by direct calculation that they have the same invariants. When $f=N_{uvw}$, these three cubics have even the same equation and are in the Hesse canonical form[30]

$$X(\mathbf{x}) = -\phi(x_1^3 + x_2^3 + x_3^3) + \psi x_1 x_2 x_3 = Y(\mathbf{x}) = Z(\mathbf{x}), \tag{63}$$

where we introduced, following the notation of Ref. 2,

$$\phi = uvw, \quad \psi = u^3 + v^3 + w^3. \tag{64}$$

The Aronhold invariants of the cubics (63) are given by

$$6^4 S = -\phi(\psi^3 + (6\phi)^3), \tag{65}$$

$$6^6 T = (6\phi)^6 + 20(6\phi^3)\psi^3 - 8\psi^6. \tag{66}$$

These are of course invariants of f. We recognize that $6^4S=-C_{12}$, and we introduce an invariant I_{18} such that $C_{18}=I_{18}(N_{uvw})=6^6T$. The three cubics have the same discriminant $64S^3+T^2$, known to be proportional to the hyperdeterminant of f (see Refs. 31 and 32), which we normalize as

$$\Delta = 27(64S^3 + T^2). \tag{67}$$

Then $\Delta = C'^3_{12}$, where C'_{12} is the product of 12 linear forms

$$\begin{aligned} C'_{12} = {} & uvw(u+v+w)(\varepsilon u+v+w)(u+\varepsilon v+w)(\varepsilon^2 u+\varepsilon v+w)(u+\varepsilon^2 v+w) \\ & \times (\varepsilon u+\varepsilon v+w)(\varepsilon^2 u+v+w)(\varepsilon u+\varepsilon^2 v+w)(\varepsilon^2 u+\varepsilon^2 v+w), \end{aligned} \tag{68}$$

where $\varepsilon = e^{2i\pi/3}$, so that $C'_{12}=0$ is the equation in $\mathbb{P}^2$ of the twelve lines containing 3×3 the nine inflection points of the pencil of cubics,

$$u^3 + v^3 + w^3 + 6m\, uvw = 0, \tag{69}$$

obtained from X, Y, Z by treating the original variables as parameters. We note also that the Jacobian of C_6, C_9, C_{12} is proportional to C'^2_{12}.

VI. SYMMETRIES OF THE NORMAL FORMS

In this section, we will prove Theorem II.2. That is, a generic f has 648 different normal forms [the points (u,v,w) for which this number is reduced will be studied in Sec. VII].

To prove the theorem, we remark that the Hilbert series (7) is also the one of the ring of invariants of G_{25}, the group number 25 in the classification of irreducible complex reflection groups of Shephard and Todd.[4] This group, which we will denote for short by K, has order 648. It is one of the groups considered by Maschke[2] in his determination of the invariants of the symmetry group of the 27 lines of a general cubic surface in $\mathbb{P}^3$ (a group with 51 840 elements, which is related to the exceptional root system E_6). To define K, we first have to introduce Maschke's group H, a group of order 1296, which is generated by the matrices of the linear transformations on $\mathbb{C}^3$ given in Table I.

TABLE I. The generators of H.

	A	B	C	D	E
u'	v	u	u	u	$1/i\sqrt{3}(u+v+w)$
v'	w	w	εv	εv	$1/i\sqrt{3}(u+\varepsilon v+\varepsilon^2 w)$
w'	u	v	$\varepsilon^2 w$	εw	$1/i\sqrt{3}(u+\varepsilon^2 v+\varepsilon w)$

This group contains in particular the permutation matrices, and simultaneous multiplication by $\pm\varepsilon^k$, since $E^2=-B$. The subgroup K is the one in which odd permutations can appear only with a minus sign. It is generated by A,C,D,E.

Then, as proved by Maschke, the algebra of invariants of K in $\mathbb{C}[u,v,w]$ is precisely $\mathbb{C}[C_6,C_9,C_{12}]$.

Hence, we can conclude that K is the symmetry group of the normal forms N_{uvw}. There was another, equally natural possibility leading to the same Hilbert series. The symmetry group L of the equianharmonic cubic surface $\Sigma: z_0^3+z_1^3+z_2^3+z_3^3=0$ acting on the homogeneous coordinate ring $\mathbb{C}[\Sigma]$ has as fundamental invariants the elementary symmetric functions of the z_i^3, the first one being 0 by definition, so that the Hilbert series of $\mathbb{C}[\Sigma]^L$ coincides with (7). Moreover, L is also of order 648, but it is known that it is not isomorphic to K.

Taking into account the results of Sec. IV, we see that

$$S=\{N_{uvw}|(u,v,w)\in\mathbb{C}^3\} \tag{70}$$

is what is usually called a Chevalley section of the action of G on $\mathcal{H}$, with Weyl group K (see Ref. 29, p. 174).

VII. THE FORM PROBLEM

This section contains the proofs of Theorems II.3 and II.4. Klein (see Ref. 33) has introduced and investigated the notion of "Formenproblem" associated to a finite group action. This is the following: given the numerical values of the invariants, compute the coordinates of a point of the corresponding orbit.

In our case, we shall see that the problem of finding the parameters (u,v,w) of the normal form of a given generic f, given the values of the invariants, can be reduced to a chain of algebraic equations of degree at most 4, hence sovable by radicals.

Let $a=I_6$, $b=I_{12}$ and $c=I_{18}$ (we start with I_{18}, because C_{18} is a symmetric function of u^3,v^3,w^3, and at the end of the calculation, select the solutions which give the correct sign for C_9, which is alternating).

What we have to do is to determine the elementary symmetric functions $e_1=\psi, e_2=\chi, e_3=\phi^3$ of u^3,v^3,w^3. Let $\lambda=216\phi^3$. Then,

$$\psi^4+\lambda\psi-b=0, \tag{71}$$

$$\psi^6-\tfrac{5}{2}\lambda\psi^3-\tfrac{1}{8}\lambda^2-c=0. \tag{72}$$

Eliminating λ from these equations, we get a quartic equation for ψ^2,

$$27\psi^8-18b\psi^4-8c\psi^2-b^2=0. \tag{73}$$

The discriminant (with respect to ψ) of this polynomial is proportional to $D=b^2(b^3-c^2)^4$. When it is nonzero, we get eight values for e_1, each of which determines univocally e_2 and e_3. Hence, we obtain eight cubic equations whose roots are the possible values of u^3,v^3,w^3. This gives eight sets, whence $8\times6=48$ triples, each of which providing generically 27 values of (u,v,w), in all $48\times27=1296$ triples corresponding to the given values of a,b,c, among which exactly $1296/2=648$ give the correct sign for I_9. The common discriminant of the eight cubics is $\delta=a^3-3ab$

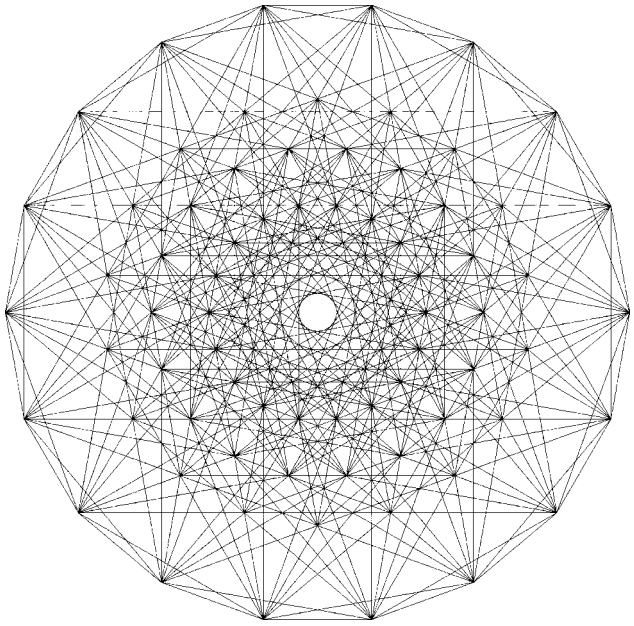

FIG. 1. The polyhedron 2{4}3{3}3.

$+2c$. Clearly, when $\delta \neq 0$, we will have 648 triples. If $\delta = 0$, one can check that the cubics cannot have a triple root, and that no root is zero. Hence, in this case, we obtain again 648 triples.

If $D=0$, we can have $b^3=c^2$ or $b=0$. In the first case, setting $b=q^2, c=q^3$, the equation becomes

$$(\psi^2 - q)^3(\psi^2 + 2q)^3 = 0. \tag{74}$$

In this case, we get only four quartics for ψ^2. If $C_9 \neq 0$, we obtain 216 triples. If $C_9=0$ and $b=a^2/4$, $c=-a^3/8$ we obtain again 216 triples which form the centers of the edges of a complex polyhedron of type 2{4}3{3}3 in $\mathbb{C}^3$ (see Fig. 1), in the notation of Ref. 34. The vertices of this polyhedron are the vertices of two reciprocal Hessian polyhedra (see Fig. 2) and its edges join each vertex of one Hessian polyhedron to the eight closest vertices of the other one. In Fig. 2, the edges of the Hessian polyhedron, which are complex lines, are represented by real equilateral triangles, so that the figure can as well be interpreted as a two-dimensional projection of a six-dimensional Gosset polytope 2_{21}. If $C_9=0$ and $b=a^2$, $c=a^3$, we obtain only 72 triples which

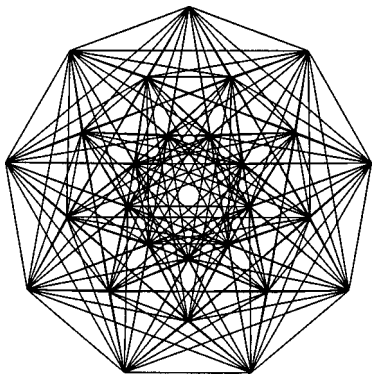

FIG. 2. The Hessian polyhedron.

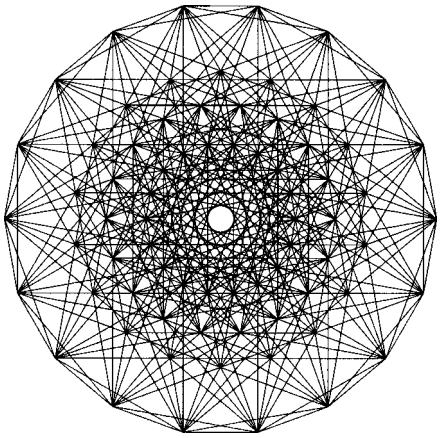

FIG. 3. The polyhedron 3{3}3{4}2.

are the centers of the edges of a Hessian polyhedron and the vertices of a complex polytope of type 3{3}3{4}2 (see Fig. 3).

In the case where $b=0$, we have to distinguish between the cases $c\neq 0$ and $c=0$. If $c\neq 0$, we find 648 triples, whatever the value of a. If $c=0$, we obtain 27 triples if $a\neq 0$, and only one if $a=0$.

Indeed, for $b=c=0$, the ψ-equation reduces to $\psi^8=0$, and all the cubics collapse to $12U^3-aU=0$. For $a\neq 0$ we obtain precisely 27 triples (u,v,w) which form the vertices of a Hessian polyhedron in $\mathbb{C}^3$ (see Ref. 1).

From the results of Ref. 3 about the arrangement of 12 planes formed by the mirrors of the pseudoreflections of $K=G_{25}$, we can determine the structure of the stabilizers of the normal forms. The only nontrivial cases are as follows:

(i) the orbits with 216 elements, for which the stabilizer is the cyclic group C_3;
(ii) the orbits with 72 elements, for which it is $C_3\times C_3$;
(iii) the Hessian orbits with 27 elements, for which it is the group G_4 of the Shephard–Todd classification.

These results can be regarded as a complete description of the moduli space of three-qutrit states. To see what this means, let us recall some definitions from geometric invariant theory.

It is well known that it in general, the orbits of a group action on an algebraic variety cannot be regarded as the points of an algebraic variety. To remedy this situation, one has to discard certain degenerate orbits. It is then possible to construct a *categorical quotient* and a *moduli space*, which describe the geometry of sufficiently generic orbits, respectively, in the affine and projective situation.

The *categorical quotient* $Y=\mathcal{H}//G$ is defined as the affine variety whose affine coordinate ring is the ring of polynomial invariants $R=\mathbb{C}[\mathcal{H}]^G$. The moduli space is the projective variety $\mathcal{M}=\mathrm{Proj}(R)$ of which R is the homogeneous coordinate ring. It is the quotient of the set $\mathbb{P}(\mathcal{H})^{\mathrm{ss}}$ of *semistable* points by the action of G (by definition, a point is semistable iff at least one of its algebraic invariants is nonzero, see Ref. 29).

Now, since in our case the algebra of invariants is a polynomial algebra, we see that the categorical quotient is just the affine space $\mathbb{C}^3$.

The moduli space is more interesting. The projective variety whose homogeneous coordinate ring is a polynomial algebra over generators of respective degrees $d_1,\ldots,d_m$ is called a *weighted projective space* $\mathbb{P}(d_1,\ldots,d_m)$. Hence, by definition, our moduli space $\mathcal{M}$ is the weighted projective space $\mathbb{P}(6,9,12)\simeq\mathbb{P}(2,3,4)$. It is known that this space is isomorphic to $\mathbb{P}(1,2,3)$,[35] which in turn can be embedded as a sextic surface in $\mathbb{P}^6$, the so-called *del Pezzo surface* F^6 (see Ref. 36). The del Pezzo surfaces are very interesting objects, known to be related to the exceptional root systems (see, e.g., Ref. 37).

The above results can then be interpreted as a description of the singularities of $\mathcal{M}$, since one can view it as the quotient of the projective plane $\mathbb{P}^2$ of the parameters $(u:v:w)$ under the projective action of G_{25}. We have described this quotient as a 648-fold ramified covering $\mathbb{P}^2 \to \mathcal{M}$, and analyzed its ramification locus.

VIII. CONCLUSION

A problem of current interest in Quantum Information Theory has been connected to various important mathematical works, scattered on a period of more than one century from Ref. 2 in 1889 to Ref. 27 in 2000, in general independent of each other and apparently discussing different subjects. Relying on all these works, we have described the geometry of the normal forms of semistable orbits of three-qutrit states under the action of $\mathrm{SL}(3,\mathbb{C})^{\times 3}$, the group of local filtering (SLOCC) operations. From a physical point of view, our results can be expected to provide a good starting point for studying the richness of the entanglement of three qutrits and its differences with that of the simpler qubit systems. From a mathematical point of view, we have worked out an interesting example of a problem in invariant theory, using both classical algebraic and modern geometric methods, found a surprising connection with the geometry of complex polytopes, and applied Klein's vision of Galois theory to the explicit solution of an algebraic equation of degree 648.

Also, this example provides a good illustration of the ideas presented in Refs. 14 and 17.

(Received 8 June 2004; accepted 3 August 2004; published 24 November 2004)

Fundamental properties for the Tsallis relative entropy in both classical and quantum systems are studied. As one of our main results, we give the parametric extension of the trace inequality between the quantum relative entropy and the minus of the trace of the relative operator entropy given by Hiai and Petz. The monotonicity of the quantum Tsallis relative entropy for the trace preserving completely positive linear map is also shown without the assumption that the density operators are invertible. The generalized Tsallis relative entropy is defined and its subadditivity is shown by its joint convexity. Moreover, the generalized Peierls–Bogoliubov inequality is also proven. © *2004 American Institute of Physics.*

I. INTRODUCTION

In the field of the statistical physics, Tsallis entropy was defined in Ref. 28 by $S_q(X)=-\Sigma_x p(x)^q \ln_q p(x)$ with one parameter q as an extension of Shannon entropy, where q-logarithm is defined by $\ln_q(x)\equiv(x^{1-q}-1)/(1-q)$ for any non-negative real number q and x, and $p(x)\equiv p(X=x)$ is the probability distribution of the given random variable X. We easily find that the Tsallis entropy $S_q(X)$ converges to the Shannon entropy $-\Sigma_x p(x)\log p(x)$ as $q\to 1$, since q-logarithm uniformly converges to natural logarithm as $q\to 1$. Tsallis entropy plays an essential role in nonextensive statistics, which is often called Tsallis statistics, so that many important results have been published from the various points of view.[29] As a matter of course, the Tsallis entropy and its related topics are mainly studied in the field of statisitical physics. However the concept of entropy is important not only in thermodynamical physics and statistical physics but also in information theory and analytical mathematics such as operator theory and probability theory. Recently, information theory has been in progress as quantum information theory[19] with the help of the operator theory[5,12] and the quantum entropy theory.[20] To study a certain entropic quantity is important for the development of information theory and the mathematical interest itself. In particular, the relative entropy is fundamental in the sense that it produces the entropy and the mutual information as special cases. Therefore in the present paper, we study properties of the Tsallis relative entropy in both the classical and quantum systems.

In the rest of this section, we will review several fundamental properties of the Tsallis relative entropy, as giving short proofs for the convenience of the readers. See Refs. 7, 27, and 26, for the pioneering works of the Tsallis relative entropy and their applications in the classical system.

Definition 1.1: We suppose a_j and b_j are probability distributions satisfying $a_j\geqslant 0$, $b_j\geqslant 0$, and

[a)]Electronic mail: furuichi@ed.yama.tus.ac.jp
[b)]Electronic mail: yanagi@yamaguchi-u.ac.jp
[c)]Electronic mail: kuriyama@yamaguchi-u.ac.jp

$\Sigma_{j=1}^{n} a_j = \Sigma_{j=1}^{n} b_j = 1$. Then we define the Tsallis relative entropy between $A=\{a_j\}$ and $B=\{b_j\}$, for any $q \geqslant 0$ as

$$D_q(A|B) \equiv -\sum_{j=1}^{n} a_j \ln_q \frac{b_j}{a_j}, \tag{1}$$

where q-logarithm function is defined by $\ln_q(x) \equiv (x^{1-q}-1)/(1-q)$ for non-negative real number x and q, and we make a convention $0 \ln_q \infty \equiv 0$.

Note that $\lim_{q\to 1} D_q(A|B) = D_1(A|B) \equiv \Sigma_{j=1} a_j \log(a_j/b_j)$, which is known as relative entropy (which is often called Kullback–Leibler information, divergence or cross entropy). For the Tsallis relative entropy, the following proposition is known.

Proposition 1.2:

(1) (Non-negativity) $D_q(A|B) \geqslant 0$.
(2) (Symmetry) $D_q(a_{\pi(1)}, \ldots, a_{\pi(n)} | b_{\pi(1)}, \ldots, b_{\pi(n)}) = D_q(a_1, \ldots, a_n | b_1, \ldots, b_n)$.
(3) (Possibility of extention) $D_q(a_1, \ldots, a_n, 0 | b_1, \ldots, b_n, 0) = D_q(a_1, \ldots, a_n | b_1, \ldots, b_n)$.
(4) (Pseudoadditivity)

$$D_q(A^{(1)} \times A^{(2)} | B^{(1)} \times B^{(2)}) = D_q(A^{(1)}|B^{(1)}) + D_q(A^{(2)}|B^{(2)}) + (q-1) D_q(A^{(1)}|B^{(1)}) D_q(A^{(2)}|B^{(2)}),$$

where

$$A^{(1)} \times A^{(2)} = \{a_j^{(1)} a_j^{(2)} | a_j^{(1)} \in A^{(1)}, a_j^{(2)} \in A^{(2)}\},$$

$$B^{(1)} \times B^{(2)} = \{b_j^{(1)} b_j^{(2)} | b_j^{(1)} \in B^{(1)}, b_j^{(2)} \in B^{(2)}\}.$$

(5) (Joint convexity) For $0 \leqslant \lambda \leqslant 1$, any $q \geqslant 0$ and the probability distributions $A^{(i)} = \{a_j^{(i)}\}$, $B^{(i)} = \{b_j^{(i)}\}$ $(i=1,2)$, we have

$$D_q(\lambda A^{(1)} + (1-\lambda) A^{(2)} | \lambda B^{(1)} + (1-\lambda) B^{(2)}) \leqslant \lambda D_q(A^{(1)}|B^{(1)}) + (1-\lambda) D_q(A^{(2)}|B^{(2)}).$$

(6) (Strong additivity)

$$\begin{aligned} &D_q(a_1, \ldots, a_{i-1}, a_{i_1}, a_{i_2}, a_{i+1}, \ldots, a_n | b_1, \ldots, b_{i-1}, b_{i_1}, b_{i_2}, b_{i+1}, \ldots, b_n) \\ &= D_q(a_1, \ldots, a_n | b_1, \ldots, b_n) + b_i^{1-q} a_i^q D_q\left(\frac{a_{i_1}}{a_i}, \frac{a_{i_2}}{a_i} \middle| \frac{b_{i_1}}{b_i}, \frac{b_{i_2}}{b_i} \right), \end{aligned}$$

where $a_i = a_{i_1} + a_{i_2}$, $b_i = b_{i_1} + b_{i_2}$.

Proof: (1) follows from the convexity of the function $-\ln_q(x)$:

$$D_q(A|B) \equiv -\sum_{j=1}^{n} a_j \ln_q \frac{b_j}{a_j} \geqslant -\ln_q\left(\sum_{j=1}^{n} a_j \frac{b_j}{a_j} \right) = 0.$$

(2) and (3) are trivial. (4) follows by the direct calculation. (5) follows from the generalized log-sum inequality:[7]

$$\sum_{i=1}^{n} \alpha_i \ln_q\left(\frac{\beta_i}{\alpha_i} \right) \leqslant \left(\sum_{i=1}^{n} \alpha_i \right) \ln_q\left(\frac{\sum_{i=1}^{n} \beta_i}{\sum_{i=1}^{n} \alpha_i} \right), \tag{2}$$

for non-negative numbers α_i, β_i $(i=1,2,\ldots,n)$ and any $q \geqslant 0$. We define the function L_q for $q \geqslant 0$ to prove (6) as

$$L_q(x,y) \equiv -x \ln_q \frac{y}{x}$$

and

$$a_{i_1} = a_i(1-s), \quad b_{i_1} = b_i(1-t),$$

$$a_{i_2} = a_i s, \quad b_{i_2} = b_i t.$$

Then we have

$$L_q(x_1x_2,y_1y_2) = x_2L_q(x_1,y_1) + x_1L_q(x_2,y_2) + (q-1)L_q(x_1,y_1)L_q(x_2,y_2),$$

which implies the claim with easy calculations. ■

Remark 1.3: 1. (1) of Proposition 1.2 implies

$$S_q(A) \leqslant \ln_q n,$$

since we have

$$D_q(A|U) = -n^{q-1}(S_q(A) - \ln_q n),$$

for any $q \geqslant 0$ and two probability distributions $A=\{a_j\}$ and $U=\{u_j\}$, where $u_j = 1/n$, $(^\forall j)$, where the Tsallis entropy is represented by

$$S_q(A) \equiv -\sum_{j=1}^{n} a_j^q \ln_q a_j.$$

2. (4) of Proposition 1.2 is reduced to the pseudoadditivity for the Tsallis entropy:

$$S_q(A^{(1)} \times A^{(2)}) = S_q(A^{(1)}) + S_q(A^{(2)}) + (1-q)S_q(A^{(1)})S_q(A^{(2)}). \tag{3}$$

3. (5) of Proposition 1.2 recover the concavity for the Tsallis entropy, by setting $B^{(1)} = \{1,0,\ldots,0\}$, $B^{(2)} = \{1,0,\ldots,0\}$.

4. (6) of Proposition 1.2 is reduced to the strong additivity for the Tsallis entropy:

$$S_q(a_1,\ldots,a_{i-1},a_{i_1},a_{i_2},a_{i+1},\ldots,a_n) = S_q(a_1,\ldots,a_{i-1},a_i,a_{i+1},\ldots,a_n) + a_i^q S_q\left(\frac{a_{i1}}{a_i},\frac{a_{i2}}{a_i}\right).$$

We finally show the monotonicity for the Tsallis relative entropy. To this end, we introduce some notations. We consider the transition probability matrix W: $\mathcal{A} \to \mathcal{B}$, which can be identified to the matrix having the conditional probability W_{ji} as elements, where $\mathcal{A}$ and $\mathcal{B}$ are alphabet sets (finite sets) and $\Sigma_{j=1}^m W_{ji} = 1$ for all $i=1,\ldots,n$. By $A=\{a_i^{(\mathrm{in})}\}$ and $B=\{b_i^{(\mathrm{in})}\}$, two distinct probability distributions in the input system $\mathcal{A}$ are denoted. Then the probability distributions in the output system $\mathcal{B}$ are represented by $WA=\{a_j^{(\mathrm{out})}\}$, $WB=\{b_j^{(\mathrm{out})}\}$, where $a_j^{(\mathrm{out})} = \Sigma_{i=1}^n a_i^{(\mathrm{in})} W_{ji}$, $b_j^{(\mathrm{out})} = \Sigma_{i=1}^n b_i^{(\mathrm{in})} W_{ji}$, in terms of $W=\{W_{ji}\}$ $(i=1,\ldots,n; j=1,\ldots,m)$. Then we have the following.

Proposition 1.4: In the above notation, for any $q \geqslant 0$, we have

$$D_q(WA|WB) \leqslant D_q(A|B).$$

Proof: Applying the generalized log-sum inequality Eq. (2), we have

$$D_q(WA|WB) = -\sum_{j=1}^{m} a_j^{(\mathrm{out})} \ln_q \frac{b_j^{(\mathrm{out})}}{a_j^{(\mathrm{out})}} = -\sum_{j=1}^{m}\sum_{i=1}^{n} a_i^{(\mathrm{in})} W_{ji} \ln_q \frac{\sum_{i=1}^{n} b_i^{(\mathrm{in})} W_{ji}}{\sum_{i=1}^{n} a_i^{(\mathrm{in})} W_{ji}} \leqslant$$

$$-\sum_{j=1}^{m}\sum_{i=1}^{n} a_i^{(\mathrm{in})} W_{ji} \ln_q \frac{b_i^{(\mathrm{in})} W_{ji}}{a_i^{(\mathrm{in})} W_{ji}} = -\sum_{i=1}^{n} a_i^{(\mathrm{in})} \ln_q \frac{b_i^{(\mathrm{in})}}{a_i^{(\mathrm{in})}} = D_q(A|B).$$

■

We note that the above proposition is a special case of the monotonicity of f divergence[9] for the convex function f. Closing the introduction, we should also note here that the Tsallis entropy can be derived by a simple transformation from Rényi entropy which was used before the Tsallis one in the mathematical literature. See Ref. 4 on the details of Rényi entropy, in particular see pp. 184–191 of Ref. 4 for the relation to the structural a-entropy[14] [or called the entropy of type β (Ref. 10)], which is one of the nonextensive entropies including the Tsallis entropy.

II. QUANTUM TSALLIS RELATIVE ENTROPY AND ITS PROPERTIES

In Refs. 1 and 2, the quantum Tsallis relative entropy was defined by

$$D_q(\rho|\sigma) \equiv \frac{1 - \mathrm{Tr}[\rho^q \sigma^{1-q}]}{1-q} \tag{4}$$

for two density operators ρ and σ and $0 \leqslant q < 1$, as one parameter extension of the definition of the quantum relative entropy by Umegaki[30]

$$U(\rho|\sigma) \equiv \mathrm{Tr}[\rho(\log \rho - \log \sigma)]. \tag{5}$$

See Chap. II written by Rajagopal in Ref. 29, for the quantum version of Tsallis entropies and their applications.

For the quantum Tsallis relative entropy $D_q(\rho|\sigma)$ and the quantum relative entropy $U(\rho|\sigma)$, the following relations are known.

Proposition 2.1 [Ruskai–Stillinger[24] (see also Ref. 21)]: For the strictly positive operators with a unit trace ρ and σ, we have

(1) $D_q(\rho|\sigma) \leqslant U(\rho|\sigma) \leqslant D_{2-q}(\rho|\sigma)$ for $0 \leqslant q < 1$.
(2) $D_{2-q}(\rho|\sigma) \leqslant U(\rho|\sigma) \leqslant D_q(\rho|\sigma)$ for $1 < q \leqslant 2$.

Note that both sides in both inequalities converge to $U(\rho|\sigma)$ as $q \to 1$. We must extend this definition of the Tsallis relative entropy Eq. (4) for $0 \leqslant q \leqslant 2$ and impose the invertibility on the density operators of $D_{2-q}(\rho|\sigma)$ for $0 \leqslant q < 1$ and of $D_q(\rho|\sigma)$ for $1 < q \leqslant 2$.

Proof: Since we have for any $x > 0$ and $t > 0$,

$$\frac{1 - x^{-t}}{t} \leqslant \log x \leqslant \frac{x^t - 1}{t},$$

the following inequalities hold for any $a, b, t > 0$:

$$a\left(\frac{1 - a^{-t} b^t}{t}\right) \leqslant a \log \frac{a}{b} \leqslant a\left(\frac{a^t b^{-t} - 1}{t}\right). \tag{6}$$

Let $\rho = \Sigma_i \lambda_i P_i$ and $\sigma = \Sigma_j \mu_j Q_j$ be the spectral decompositions. Since $\Sigma_i P_i = \Sigma_j Q_j = I$, then we have

$$\mathrm{Tr}\left[\frac{\rho^{1+t}\sigma^{-t}-\rho}{t}-\rho(\log\rho-\log\sigma)\right]=\sum_{i,j}\mathrm{Tr}\left[P_i\left\{\frac{\rho^{1+t}\sigma^{-t}-\rho}{t}-\rho(\log\rho-\log\sigma)\right\}Q_j\right]$$
$$=\sum_{i,j}\mathrm{Tr}\left[P_i\left(\frac{1}{t}\lambda_i^{1+t}\mu_j^{-t}-\frac{1}{t}\lambda_i-\lambda_i\log\lambda_i+\lambda_i\log\mu_j\right)Q_j\right]$$
$$=\sum_{i,j}\left(\frac{1}{t}\lambda_i^{1+t}\mu_j^{-t}-\frac{1}{t}\lambda_i-\lambda_i\log\lambda_i+\lambda_i\log\mu_j\right)\mathrm{Tr}[P_iQ_j]\geqslant 0.$$

The last inequality in the above is due to the inequality of the right-hand side of Eq. (6). Thus we have

$$\mathrm{Tr}[\rho(\log\rho-\log\sigma)]\leqslant\frac{1}{t}\mathrm{Tr}[\rho^{1+t}\sigma^{-t}-\rho].$$

The left-hand side inequality is proven by a similar way. Thus setting $1-q=t(>0)$ in the above, we have (1) in Proposition 2.1. Also we have (2) in Proposition 2.1, by setting $q-1=t(>0)$. ■

We next consider another relation on the quantum Tsallis relative entropy. In Ref. 11, the relative operator entropy was defined by

$$S(\rho|\sigma)\equiv\rho^{1/2}\log(\rho^{-1/2}\sigma\rho^{-1/2})\rho^{1/2},$$

for two strictly positive operators ρ and σ. If ρ and σ are commutative, then we have $U(\rho|\sigma)=-\mathrm{Tr}[S(\rho|\sigma)]$. For this relative operator entropy and the quantum relative entropy $U(\rho|\sigma)$, Hiai and Petz proved the following relation:

$$U(\rho|\sigma)\leqslant-\mathrm{Tr}[S(\rho|\sigma)],\tag{7}$$

in Ref. 15 (see also Ref. 16).

In our previous papers,[32] we introduced the Tsallis relative operator entropy $T_q(\rho|\sigma)$ as a parametric extension of the relative operator entropy $S(\rho|\sigma)$ such as

$$T_q(\rho|\sigma)\equiv\frac{\rho^{1/2}(\rho^{-1/2}\sigma\rho^{-1/2})^{1-q}\rho^{1/2}-\rho}{1-q},$$

for $0\leqslant q<1$ and strictly positive operators ρ and σ, in the sense that

$$\lim_{q\to1}T_q(\rho|\sigma)=S(\rho|\sigma).\tag{8}$$

Actually we should note that there is a slight difference between the two parameters q in the present paper and λ in the previous paper,[32] which is an extension of Ref. 13. If ρ and σ are commutative, then we have $D_q(\rho|\sigma)=-\mathrm{Tr}[T_q(\rho|\sigma)]$. Also we now have that

$$\lim_{q\to1}D_q(\rho|\sigma)=U(\rho|\sigma).\tag{9}$$

These relations, Eq. (7), Eq. (8), and Eq. (9) naturally lead us to show the following theorem as a parametric extension of Eq. (7).

Theorem 2.2: For $0\leqslant q<1$ and any strictly positive operators with unit trace ρ and σ, we have

$$D_q(\rho|\sigma)\leqslant-\mathrm{Tr}[T_q(\rho|\sigma)].\tag{10}$$

Proof: We denote the α-power mean $\sharp_\alpha$ by $A\sharp_\alpha B\equiv A^{1/2}(A^{-1/2}BA^{-1/2})^\alpha A^{1/2}$. From Theorem 3.4 of Ref. 16, we have

$$\mathrm{Tr}[e^A \sharp_\alpha e^B] \leqslant \mathrm{Tr}[e^{(1-\alpha)A+\alpha B}]$$

for any $\alpha \in [0,1]$. Setting $A=\log \rho$ and $B=\log \sigma$, we have

$$\mathrm{Tr}[\rho \sharp_\alpha \sigma] \leqslant \mathrm{Tr}[e^{\log \rho^{1-\alpha}+\log \sigma^\alpha}].$$

Since the Golden–Thompson inequality $\mathrm{Tr}[e^{A+B}] \leqslant \mathrm{Tr}[e^A e^B]$ holds for any Hermitian operators A and B, we have

$$\mathrm{Tr}[e^{\log \rho^{1-\alpha}+\log \sigma^\alpha}] \leqslant \mathrm{Tr}[e^{\log \rho^{1-\alpha}} e^{\log \sigma^\alpha}] = \mathrm{Tr}[\rho^{1-\alpha}\sigma^\alpha].$$

Therefore

$$\mathrm{Tr}[\rho^{1/2}(\rho^{-1/2}\sigma\rho^{-1/2})^\alpha \rho^{1/2}] \leqslant \mathrm{Tr}[\rho^{1-\alpha}\sigma^\alpha]$$

which implies the theorem by taking $\alpha=1-q$. ■

Corollary 2.3 (Hiai–Petz[15,16]): For any strictly positive operators with unit trace ρ and σ, we have

$$\mathrm{Tr}[\rho(\log \rho - \log \sigma)] \leqslant \mathrm{Tr}[\rho \log(\rho^{1/2}\sigma^{-1}\rho^{1/2})]. \tag{11}$$

Proof: It follows by taking the limit as $q \to 1$ in both sides of Eq. (10). ■

Thus the result proved by Hiai and Petz in Refs. 15 and 16 is recovered as a special case of Theorem 2.2.

For the quantum Tsallis relative entropy $D_q(\rho|\sigma)$, (i) pseudoadditivity and (ii) non-negativity are shown in Ref. 1, moreover (iii) joint convexity and (iv) monotonicity for projective mesurements, are shown in Ref. 2 Here we show the unitary invariance of $D_q(\rho|\sigma)$ and the monotonicity of that for the trace-preserving completely positive linear map.

Proposition 2.4: For $0 \leqslant q < 1$ and any density operators ρ and σ, the quantum relative entropy $D_q(\rho|\sigma)$ has the following properties.

(1) (Non-negativity) $D_q(\rho|\sigma) \geqslant 0$.
(2) (Pseudoadditivity) $D_q(\rho_1 \otimes \rho_2|\sigma_1 \otimes \sigma_2) = D_q(\rho_1|\sigma_1) + D_q(\rho_2|\sigma_2) + (q-1)D_q(\rho_1|\sigma_1)D_q(\rho_2|\sigma_2)$.
(3) (Joint convexity) $D_q(\Sigma_j \lambda_j \rho_j | \Sigma_j \lambda_j \sigma_j) \leqslant \Sigma_j \lambda_j D_q(\rho_j|\sigma_j)$.
(4) The quantum Tsallis relative entropy is invariant under the unitary transformation U:

$$D_q(U\rho U^* | U\sigma U^*) = D_q(\rho|\sigma).$$

Proof: Since it holds that $f(q,x,y) \equiv (x - x^q y^{1-q})/(1-q) - (x-y) \geqslant 0$ for $x \geqslant 0$, $y \geqslant 0$, and $0 \leqslant q < 1$, we have $D_q(\rho|\sigma) \geqslant \mathrm{Tr}[\rho - \sigma]$, which implies (1), since ρ and σ are density operators. (See Proposition 3.16 of Ref. 21 on the so-called Klein inequality.)

(2) follows by the direct calculation.

(3) follows from the Lieb's theorem that for any operator Z and and $0 \leqslant t \leqslant 1$, the functional $f(A,B) \equiv \mathrm{Tr}[Z^* A^t Z B^{1-t}]$ is joint concave with respect to two positive operators A and B.

(4) is obvious by the use of Stone–Weierstrass approximation theorem. (It also can be shown by the application of Theorem 2.5.) ■

(1) of the above proposition follows from the generalized Peierls–Bogoliubov inequality which will be shown in the next section.

In Ref. 22, the monotonicity for more generalized relative entropy was shown under the assumption of the invertibility of the density operators. Here we show the monotonicity for the quantum Tsallis relative entropy in the case of $0 \leqslant q < 1$ without the assumption of the invertibility of the density operators.

Theorem 2.5: For any trace-preserving completely positive linear map Φ, any density operators ρ and σ and $0 \leqslant q < 1$, we have

$$D_q(\Phi(\rho)|\Phi(\sigma)) \leqslant D_q(\rho|\sigma).$$

Proof: We prove this theorem in a similar way as Ref. 18. To this end, we first prove the monotonicity of $D_q(\rho|\sigma)$ for the partial trace Tr_B in the composite sysytem AB. Let ρ^{AB} and σ^{AB} be density operators in the composite system AB. From Refs. 20 and 31, there exists unitary operators U_j and the probability p_j such that

$$\rho^A \otimes \frac{I}{n} = \sum_j p_j (I \otimes U_j)\rho^{AB}(I \otimes U_j)^* ,$$

where n and I present the dimension and identity operator of the system B, $\rho^A = \mathrm{Tr}_B[\rho^{AB}]$ and $\sigma^A = \mathrm{Tr}_B[\sigma^{AB}]$. By the help of the joint concavity and the unitary invariance of the Tsallis relative entropy, we thus have

$$\begin{aligned} D_q\left(\rho^A \otimes \frac{I}{n} \middle| \sigma^A \otimes \frac{I}{n}\right) &\leqslant \sum_j p_j D_q((I \otimes U_j)\rho^{AB}(I \otimes U_j)^* | (I \otimes U_j)\sigma^{AB}(I \otimes U_j)^*) \\ &= \sum_j p_j D_q(\rho^{AB}|\sigma^{AB}) = D_q(\rho^{AB}|\sigma^{AB}). \end{aligned}$$

Since

$$D_q\left(\rho^A \otimes \frac{I}{n} \middle| \sigma^A \otimes \frac{I}{n}\right) = D_q(\rho^A|\sigma^A),$$

we thus have

$$D_q(\mathrm{Tr}_B(\rho^{AB})|\mathrm{Tr}_B(\sigma^{AB})) \leqslant D_q(\rho^{AB}|\sigma^{AB}). \tag{12}$$

It is known[25] (see also Refs. 8, 18, and 19) that every trace-preserving completely positive linear map Φ has the following representation with some unitary operator U^{AB} on the total system AB and the projection (pure state) P^B on the subsystem B,

$$\Phi(\rho^A) = \mathrm{Tr}_B\, U^{AB}(\rho^A \otimes P^B)U^{AB*}.$$

Therefore we have the following result, by the result of Eq. (12) and the unitary invariance of $D_q(\rho|\sigma)$ again,

$$D_q(\Phi(\rho^A)|\Phi(\sigma^A)) \leqslant D_q(U^{AB}(\rho^A \otimes P^B)U^{AB*}|U^{AB}(\sigma^A \otimes P^B)U^{AB*}) = D_q(\rho^A \otimes P^B|\sigma^A \otimes P^B)$$

which implies our claim, since $D_q(\rho^A \otimes P^B|\sigma^A \otimes P^B) = D_q(\rho^A|\sigma^A)$. ■

Setting $\sigma = (1/n)I$ in Theorem 2.5, we have the following corollary.

Corollary 2.6: For any trace-preserving completely positive linear unital map Φ, any density operator ρ and $0 \leqslant q < 1$, we have

$$H_q(\Phi(\rho)) \geqslant H_q(\rho),$$

where $H_q(X) = (\mathrm{Tr}[X^q] - 1)/(1-q)$ represents the Tsallis entropy for density operator X, which is often called the quantum Tsallis entropy.

We note that Theorem 2.5 for the fixed σ, namely the monotonicity of the quantum Tsallis relative entropy in the case of $\Phi(\sigma) = \sigma$, was proved in Ref. 3 to establish Clausius' inequality.

Remark 2.7: It is known[19] (see also Ref. 23) that there is an equivalent relation between the monotonicity for the quantum relative entropy and the strong subadditivity for the quantum entropy. However in our case, we have not yet found such a relation. Because the pseudoadditivity of the q-logarithm function,

$$\ln_q xy = \ln_q x + \ln_q y + (1-q)\ln_q x \ln_q y,$$

disturbs us to derive the beautiful relation such as

$$D_q(p(x,y)|p(x)p(y)) = S_q(p(x)) + S_q(p(y)) - S_q(p(x,y))$$

for the Tsallis relative entropy $D_q(p(x,y)|p(x)p(y))$, the Tsallis entropy $S_q(p(x))$, $S_q(p(y))$, and the Tsallis joint entropy $S_q(p(x,y))$, even if our stage is in the classical system.

III. GENERALIZED TSALLIS RELATIVE ENTROPY

For any two positive operators A, B and any real number $q \in [0,1)$, we can define the generalized Tsallis relative entropy.

Definition 3.1:

$$D_q(A\|B) \equiv \frac{\mathrm{Tr}[A] - \mathrm{Tr}[A^q B^{1-q}]}{1-q}.$$

To avoid the confusions of readers, we use the different symbol $D_q(\cdot\|\cdot)$ for the generalized Tsallis relative entropy.

Since Lieb's concavity theorem is available for any positive operators A and B, the generalized Tsallis relative entropy has a joint convexity,

$$D_q\left(\sum_j \lambda_j A_j \middle\| \sum_j \lambda_j B\right) \leqslant \sum_j \lambda_j D_q(A_j\|B_j), \tag{13}$$

for the positive number λ_j satisfying $\Sigma_j \lambda_j = 1$ and any positive operators A_j and B_j. Then we have the subadditivity of the generalized Tsallis relative entropy between A_1+A_2 and B_1+B_2.

Theorem 3.2: For any positive operators A_1, A_2, B_1, and B_2, and $0 \leqslant q < 1$, we have the subadditivity

$$D_q(A_1 + A_2\|B_1 + B_2) \leqslant D_q(A_1\|B_1) + D_q(A_2\|B_2). \tag{14}$$

Proof: First we note that we have the following relation for any numbers α and β, and two positive operators A and B,

$$D_q(\alpha A\|\beta B) = \alpha D_q(A\|B) - \alpha \ln_q \frac{\beta}{\alpha} \mathrm{Tr}[A^q B^{1-q}]. \tag{15}$$

Now from Eq. (13), we have

$$D_q(\lambda_1 X_1 + \lambda_2 X_2\|\lambda_1 Y_1 + \lambda_2 Y_2) \leqslant \lambda_1 D_q(X_1\|Y_1) + \lambda_2 D_q(X_2\|Y_2)$$

for any positive operators X_1, X_2, Y_1, and Y_2, and λ_1, λ_2 ($\lambda_1+\lambda_2=1$). Setting $A_i = \lambda_i X_i$ and $B_i = \lambda_i Y_i$ for $i=1,2$ in the above inequality, we have

$$D_q(A_1 + A_2\|B_1 + B_2) \leqslant \lambda_1 D_q\left(\frac{A_1}{\lambda_1}\middle\|\frac{B_1}{\lambda_1}\right) + \lambda_2 D_q\left(\frac{A_2}{\lambda_2}\middle\|\frac{B_2}{\lambda_2}\right).$$

Thus we have our claim due to Eq. (15). ■

As a famous inequality in statistical physics, the Peierls–Bogoliubov inequality[17,6] is known. Finally, we prove the generalized Peierls–Bogoliubov inequality for the generalized Tsallis relative entropy in the following.

Theorem 3.3: For any positive operators A and B, $0 \leqslant q < 1$,

$$D_q(A\|B) \geqslant \frac{\mathrm{Tr}[A] - (\mathrm{Tr}[A])^q (\mathrm{Tr}[B])^{1-q}}{1-q}.$$

Proof: In general, we have the following Hölder's inequality:

$$|\mathrm{Tr}[XY]| \leqslant \mathrm{Tr}[|X|^s]^{1/s}\,\mathrm{Tr}[|Y|^t]^{1/t}, \tag{16}$$

for any bounded linear operators X and Y satisfying $\mathrm{Tr}[|X|^s]<\infty$ and $\mathrm{Tr}[|Y|^t]<\infty$ and for any $1<s<\infty$ and $1<t<\infty$ satisfying $(1/s)+(1/t)=1$. By setting $X=A^q$, $Y=B^{1-q}$, and $s=1/q$, $t=1/(1-q)$ in Eq. (16), we have

$$\mathrm{Tr}[A^qB^{1-q}] \leqslant (\mathrm{Tr}[A])^q(\mathrm{Tr}[B])^{1-q},$$

which implies our claim. ■

Note that Theorem 3.3 can be considered a noncommutative version of Eq. (2). If A and B are density operators, then the non-negativity of the quantum Tsallis relative entropy follows from Theorem 3.3.

IV. CONCLUSION

As we have seen, the monotonicity of the quantum Tsallis relative entropy for the trace-preserving completely positive map was shown. Also the trace inequality between the Tsallis quantum relative entropy and the Tsallis relative operator entropy was shown. It is remarkable that our inequality recovers the famous inequality shown by Hiai–Petz as $q\to 1$.

In this paper, we give a realization of crystal bases of the fundamental representations over $U_q(C_n^{(1)})$ in terms of Young diagrams k introduced by Premat. Further, we give a generalized Lascoux–Leclerc–Thibon algorithm for computing the global bases. © *2004 American Institute of Physics*. [DOI: 10.1063/1.1811791]

I. INTRODUCTION

In Refs. 11, 12, and 17, the *crystal basis* theory or *canonical basis* theory for the integrable modules over quantum groups $U_q(\mathfrak{g})$ was developed by Kashiwara and Lusztig, independently. Roughly speaking, crystal bases are the bases of representations of $U_q(\mathfrak{g})$ as the parameter q tends to zero, and they give a structure of colored oriented graphs, called the *crystal graphs*, which reflect the combinatorial structure of integrable modules. Hence one of the important problems in the crystal basis theory is to give explicit realization of crystals.

The Fock space representations of affine Lie algebras play an important role in the soliton theory. In Ref. 5, Hayashi gave the Fock space representation of $U_q(A_n^{(1)})$ and realized the fundamental representations. From Hayashi's results, Misra and Miwa gave an explicit characterization of the crystal basis for the basic representations of $U_q(A_n^{(1)})$ using colored Young diagrams.[18] In Ref. 4, this construction was generalized to all irreducible hight weight representations $V(\lambda)$ with a dominant integral weight λ of $U_q(A_n^{(1)})$. In Ref. 10, Kang, Misra, and Miwa gave the Fock space representation of $U_q(C_n^{(1)})$, $U_q(A_{2n}^{(2)})$, and $U_q(D_{n+1}^{(2)})$. Moreover, they realized all level one representations $V(\Lambda_k)$ for $U_q(C_n^{(1)})$, and they realized the level two representations $V(2\Lambda_0)$, $V(\Lambda_1), \ldots, V(\Lambda_n)$ [resp., $V(\Lambda_n)$] for $U_q(A_{2n}^{(2)})$ [resp., $U_q(D_{n+1}^{(2)})$].

In Ref. 6, Kang constructed the crystal graphs $B(\lambda)$ of the basic representations using *reduced proper Young walls* for the classical quantum affine algebras except $U_q(C_n^{(1)})$. The $C_n^{(1)}$ case was more difficult to deal with because the level 1 perfect crystal for this type is intrinsically of level 2. In Ref. 3, using the notion of *splitting block*, Hong, Kang and Lee overcame this difficulty. But, this realization is so complex and so difficult to deal with. In Ref. 19, Premat constructed the Fock space representation $\mathcal{F}(\Lambda_k)$ over $U_q(C_n^{(1)})$ using, two-dimensional object, colored Young diagrams and she showed that the connected component $\mathcal{Y}(\Lambda_k)$ in $\mathcal{F}(\Lambda_k)$ containing the maximal vector ϕ_k of weight Λ_k is isomorphic to $B(\Lambda_k)$. One of the main results in this paper is to give a characterization of $\mathcal{Y}(\Lambda_k)$.

On the other hand, from crystal graphs, Kashiwara recovered the true bases of $U_q(\mathfrak{g})$-modules which are called *global bases* in a canonical way.[12] But, in general, it is difficult to find global bases. In Ref. 13, Lascoux, Leclerc, and Thibon gave an algorithm, called LLT algorithm, for computing the global bases of the basic representations over $U_q(A_n^{(1)})$. Moreover, they gave a conjecture that there is a connection between the representation theory of the quantum affine

[a]Electronic mail: jakim@kias.re.kr
[b]Electronic mail: shindong@kias.re.kr

algebras and the Hecke algebras. This conjecture was proved by Ariki.[1] There are several variants of LLT algorithm using Young diagrams for the classical Lie algebras and Young walls for affine types $A^{(2)}_{2n-1}$, $B^{(1)}_n$, $D^{(1)}_n$, $D^{(2)}_{n+1}$, and $C^{(1)}_2$.[7–9,14–16] In this paper, we give a generalized LLT algorithm using colored Young diagrams introduced by Kang, Misra, Miwa,[10] and Premat.[19]

II. THE FOCK SPACE REPRESENTATION FOR $U_q(C^{(1)}_n)$

The basic concepts on quantum groups and crystal bases may be found in many articles and books (for example Refs. 2, 11, and 12). We refer the readers to these references. In this section, we mostly explain the Fock space representation for $U_q(C^{(1)}_n)$ constructed by Premat.[19]

Let $U_q(\mathfrak{g})=U_q(C^{(1)}_n)$ be the quantum affine algebra of type $C^{(1)}_n$ and $I=\{0,1,\ldots,n\}$ be the index set for simple roots of $U_q(\mathfrak{g})$. Let $P^\vee=(\oplus_{i\in I}\mathbb{Z}h_i)\oplus\mathbb{Z}d$ and $P=(\oplus_{i\in I}\mathbb{Z}\Lambda_i)\oplus\mathbb{Z}\delta$ be the dual weight lattice and the weight lattice, respectively. Moreover, α_i $(i\in I)$, δ, Λ_i $(i\in I)$ are the simple roots, null root, fundamental weights, respectively, and e_i, f_i, K_i, q^d are the generators of $U_q(C^{(1)}_n)$. Further, $P^+=(\oplus_{i\in I}\mathbb{Z}_{\geqslant 0}\Lambda_i)\oplus\mathbb{Z}\delta$ is the set of dominant weights, and $\tilde{e}_i$, $\tilde{f}_i$ are the Kashiwara operators.

A *Young diagram* Y $k\in I$ is a sequence $\{y_l\}_{l\in\mathbb{N}}$ of integers such that

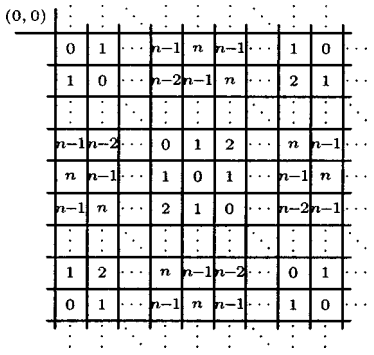
$$\text{(i) } y_l\leqslant y_{l+1} \text{ for all } l\in\mathbb{N},\quad \text{(ii) } y_l=k \text{ for all } l\gg 0,$$

where $\mathbb{N}$ is the set of positive integers. The empty Young diagram $\{k,k,\ldots\}$ k will be denoted by ϕ_k and we denote by $\mathcal{Z}(\Lambda_k)$ the set of all Young diagrams k. Define the *Fock space* of weight Λ_k by

$$\mathcal{F}(\Lambda_k)=\bigoplus_{Y\in\mathcal{Z}(\Lambda_k)}\mathbb{Q}(q)Y,$$

where $\mathbb{Q}$ is the set of rational numbers.

The Young diagram $Y=\{y_l\}_{l\in\mathbb{N}}$ k is represented by the region $\{(x,y)\,|\,x\in\mathbb{N},y\geqslant y_x\}$ in the following colored xy-plane



All Young diagrams of charge k contain the region $\{(x,y)\,|\,x\in\mathbb{N},y\geqslant k\}$ corresponding to ϕ_k. Hence for simplicity, when we represent a Young diagram, we remove this region ϕ_k, and so the empty Young diagram ϕ_k is meaningful. We also define the map wt: $\mathcal{F}(\Lambda_k)\to P$ by

$$\mathrm{wt}(Y)=\Lambda_k-\sum_{i\in I}k_i\alpha_i,$$

where k_i is the number of i-colored boxes in Y that have been added to the ϕ_k.

Example 1.1: For $n=2$, a Young diagram $Y=\{-3,-3,-2,0,1,1,\ldots\}$ 1 is represented as follows:

$Y =$  $=$  .

Further, we have

$$\mathrm{wt}(Y) = \Lambda_1 - (3\alpha_0 + 6\alpha_1 + 3\alpha_2).$$

Let $Y=\{y_l\}_{l\in\mathbb{N}} \in \mathcal{Z}(\Lambda_k)$. If $y_l \neq y_{l+1}$ for some $l \in \mathbb{N}$, the site (l, y_{l+1}) [resp., $(l+1, y_{l+1}-1)$] is called a *concave* (resp., *addable*) *corner* of Y, and the site (l, y_l) is called a *convex* or *removable corner* of Y. Moreover, the site $(0, y_1)$ [resp., $(1, y_1-1)$] is also called a *concave* (resp., *addable*) *corner*. Moreover, the site (l, y) with coloring i is called an *i-colored corner*. Note that the definition of addable (resp., convex) corner of Young diagram Y k is similar to that of admissible slot (resp., removable block) in Young walls.[6]

Example 1.2: The Young diagram Y in Example 1.1 has a 0-colored addable corner $(3,-3)$, and 1-colored addable corners $(1,-4)$, $(4,-1)$, and (5, 0). Moreover, it has a 0-colored convex (removable) corner (4, 0), 1-colored convex (removable) corners $(2,-3)$ and $(3,-2)$.

Now, following Refs. 10 and 19, we define an action of $U_q(\mathfrak{g})$ on $\mathcal{F}(\Lambda_k)$. For $(x,y) \in \mathbb{N}\times\mathbb{Z}$, we define $E_{(x,y)}$, $F_{(x,y)}$, $T^{\pm}_{(x,y)}: \mathcal{F}(\Lambda_k) \to \mathcal{F}(\Lambda_k)$ as follows:

$$E_{(x,y)}(Y) = \begin{cases} Y \nearrow (x,y) & \text{if } (x,y) \text{ is a convex corner,} \\ 0 & \text{otherwise,} \end{cases}$$

$$F_{(x,y)}(Y) = \begin{cases} Y \swarrow (x,y) & \text{if } (x,y) \text{ is an addable corner,} \\ 0 & \text{otherwise,} \end{cases}$$

$$T^{\pm}_{(x,y)}(Y) = \begin{cases} q_i^{\pm} Y & \text{if } (x,y) \text{ is a } i\text{-colored concave corner,} \\ q_i^{\mp} Y & \text{if } (x,y) \text{ is a } i\text{-colored convex corner,} \\ Y & \text{otherwise.} \end{cases}$$

Here, $Y \nearrow (x,y)$ (resp., $Y \swarrow (x,y)$) is the Young diagram k obtained by removing (resp., adding) the site (x,y) from Y (resp., to Y).

Define the order $>$ on $\mathbb{N}\times\mathbb{Z}$ as follows: $(x,y) > (x',y')$ if and only if $x+y > x'+y'$. We define linear operators E_i, F_i, $T_i^{\pm}$ $(i \in I)$ and $T_d: \mathcal{F}(\Lambda_k) \to \mathcal{F}(\Lambda_k)$ as follows:

$$E_i = \sum_{(x,y)\in\mathbb{N}\times\mathbb{Z}} \left(\prod_{(x',y')<(x,y)} T^{-}_{(x',y')} \right) E_{(x,y)},$$

$$F_i = \sum_{(x,y)\in\mathbb{N}\times\mathbb{Z}} \left(\prod_{(x',y')>(x,y)} T^{+}_{(x',y')} \right) F_{(x,y)},$$

$$T_i^{\pm} = \prod_{(x,y)\in\mathbb{N}\times\mathbb{Z}} T^{\pm}_{(x,y)},$$

and for $Y \in \mathcal{Z}(\Lambda_k)$, $T_d(Y) = q^{-(\text{the number of 0-colored corners in } Y)}$. Here, the sites (x,y) and (x',y') are i-colored corners.

Then we have

Theorem 1.3 (Refs. 10 and 19): (a) *The Fock space* $\mathcal{F}(\Lambda_k)$ $(k \in I)$ *is a* $U_q(\mathfrak{g})$*-module under the action of* e_i, f_i, q^{h_i} *and* q^d *is given by that of* E_i, F_i, T_i *and* T_d, *respectively*.

(b) *The* $U_q(\mathfrak{g})$*-module* $\mathcal{F}(\Lambda_k)$ *lies in the category* $\mathcal{O}_{\text{int}}$, *where* $\mathcal{O}_{\text{int}}$ *is the category of integrable modules in* Refs. 2, 11, and 12.

Corollary 1.4 (Refs. 10 and 19): There is a $U_q(\mathfrak{g})$*-module isomorphism from* $U_q(\mathfrak{g})\phi_k$ *to the irreducible highest weight module* $V(\Lambda_k)$ *with the highest weight* Λ_k.

Let $\mathbf{A}_0=\{f/g \in \mathbb{Q}(q) \mid f,g \in \mathbb{Q}[q], g(0) \neq 0\}$ be the localization of $\mathbb{Q}[q]$ at $q=0$.

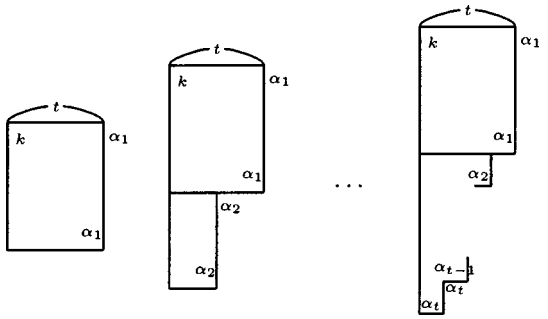
Theorem 1.5 (Refs. 10 and 19): *Let* $L(\mathcal{F}(\Lambda_k))=\Sigma_{Y \in \mathcal{F}(\Lambda_k)}\mathbf{A}_0 Y$ *and* $B(\mathcal{F}(\Lambda_k))=\{Y+qL(\mathcal{F}(\Lambda_k)) \mid Y \in \mathcal{Z}(\Lambda_k)\}$. *Then* $(L(\mathcal{F}(\Lambda_k)), B(\mathcal{F}(\Lambda_k)))$ *is a crystal base for the integrable* $U_q(\mathfrak{g})$*-module* $\mathcal{F}(\Lambda_k)$.

Now, we give a crystal structure on $\mathcal{Z}(\Lambda_k)$. Let $Y \in \mathcal{Z}(\Lambda_k)$ and $(x_1,y_1)>(x_2,y_2)>\cdots>(x_i,y_i)$ be the i-colored convex or addable corners of Y. At first, to each i-colored convex or addable corner (x_j,y_j) $(j=1,\ldots,l)$, we assign its i-signature $sgn(x_j,y_j)$ as $-$ (resp., $+$) if it is a convex (resp., addable) corner. From the sequence $(sgn(x_1,y_1),\ldots,sgn(x_l,y_l))$ of $+$'s and $-$'s, cancel out every $(+,-)$-pair to obtain a sequence of $-$'s followed by $+$'s, reading from left to right. This sequence is called the *i-signature* of Y.

We define $\tilde{f}_i Y$ to be the Young diagram k obtained from Y by adding the i-colored box to the i-colored addible corner corresponding to the left-most $+$ in the i-signature of Y. We define $\tilde{f}_i Y=0$ if there is no $+$ in the i-signature of Y. We define $\tilde{e}_i Y$ to be the Young diagram k obtained from Y by removing the i-colored convex corner corresponding to the right-most $-$ in the i-signature of Y. We define $\tilde{e}_i Y=0$ if there is no $-$ in the i-signature of Y.

Theorem 1.6 (Ref. 19): *The operators* $\tilde{e}_i$ *and* $\tilde{f}_i$ *defined above coincide with the Kashiwara operators*.

Using Theorem 1.3 and Theorem 1.6, it is easy to find all maximal vectors in $\mathcal{Z}(\Lambda_k)$. That is, if the rightmost convex corner C_v of a maximal vector Y is a α-colored corner, by the definition of Kashiwara operators, there should exist a α-colored addable corner in the right hand side of C_v which must be the rightmost addable corner. Applying this argument to other convex corners, we can obtain a maximal vector. The following are maximal vectors consisting of t columns $(t \geqslant 1)$:



(1.1)

In particular, consider the case $\mathfrak{g}=C_2^{(1)}$. Let $a(m)$ be the number of partitions of m on the set $\frac{1}{2}\mathbb{Z}_{>0}=\{\frac{1}{2},1,\frac{3}{2},\ldots,\}$, and $b(m)$ be the number of partitions of $m+\frac{1}{2}$ on the set $\frac{1}{2}\mathbb{Z}_{>0}$. Let $c(m)$ be the number of partitions of m on the set $\{1,3,5,\ldots\}\cup\{1',2',3',\ldots\}$ such that $2k-1=(2k-1)'$ $(k \geqslant 1)$. For instance, since

$$3'=3=2'+1'=2'+1=1'+1'+1'=1'+1'+1=1'+1+1=1+1+1,$$

we have $c(3)=8$.

Proposition 1.7: Let $\mathfrak{g}=C_2^{(1)}$ *and let* Λ_k $(k=0,1,2)$ *be a dominant integral weight. Then we have*

$$\mathcal{F}(\Lambda_k)=\begin{cases}(\oplus_{m\geqslant 0}V(\Lambda_k-m\delta)^{\oplus a(m)})\oplus(\oplus_{m\geqslant 0}V(\Lambda_k-m\delta-\alpha_k-\alpha_1)^{\oplus b(m)}) & \text{if } k=0,2,\\ \oplus_{m\geqslant 0}V(\Lambda_k-m\delta)^{\oplus c(m)} & \text{if } k=1.\end{cases}$$

Proof: Since the proof is similar, we only check the $\mathcal{F}(\Lambda_1)$-case. By (1.1), the maximal vectors M_t $(t\geqslant 1)$ with the least number of boxes among the maximal vectors consisting of t columns are as follows:

$$M_1=\begin{array}{|c|}\hline 1\\\hline 2\\\hline 1\\\hline 0\\\hline\end{array},\qquad M_2=\begin{array}{|c|c|}\hline 1&0\\\hline 2&1\\\hline\end{array},\qquad M_3=\begin{array}{|c|c|c|}\hline 1&0&1\\\hline 2&1&0\\\hline 1&2&1\\\hline 0&1&2\\\hline\end{array},\qquad M_4=\begin{array}{|c|c|c|c|}\hline 1&0&1&2\\\hline 2&1&0&1\\\hline\end{array},\qquad \cdots$$

Let Y be a maximal vector which is not the empty diagram ϕ_1. Then Y is obtained by attaching some maximal vectors $M_{t_1},\ldots,M_{t_2}$. For instance, the maximal vector

$$M=\begin{array}{|c|c|c|c|}\hline 1&0&1&2\\\hline 2&1&0&1\\\hline\end{array}\\\begin{array}{|c|c|}\hline 1&2\\\hline 0&1\\\hline\end{array}\\\begin{array}{|c|}\hline 1\\\hline 2\\\hline 1\\\hline 0\\\hline\end{array}$$

is obtained by attaching M_1, M_2, and M_4. We associate p_j's for M_{t_j} as follows:

$$p_j=\begin{cases}t_j & \text{if } t_j \text{ is odd},\\ \left(\dfrac{t_j}{2}\right)' & \text{if } t_j \text{ is even}.\end{cases}$$

Then $(p_j)_{j=1}^s$ forms a partition on $\{1,3,5,\ldots\}\cup\{1',2',3',\ldots\}$ and $\mathrm{wt}(Y)=\Lambda_1-(\Sigma_{j=1}^s p_j)\delta$. Therefore, it is easy to see that the number of maximal vectors with weight $\Lambda_1-m\delta$ is $c(m)$. Conversely, for a given partition $(p_j)_{j=1}^s$ of m on $\{1,3,5,\ldots\}\cup\{1',2',3',\ldots\}$, we can find a unique Young diagram $Y\in\mathcal{Z}(\Lambda_1)$ 1 with $\mathrm{wt}(Y)=\Lambda_1-m\delta$, which is obtained by attaching maximal vectors M_{t_j}'s, where

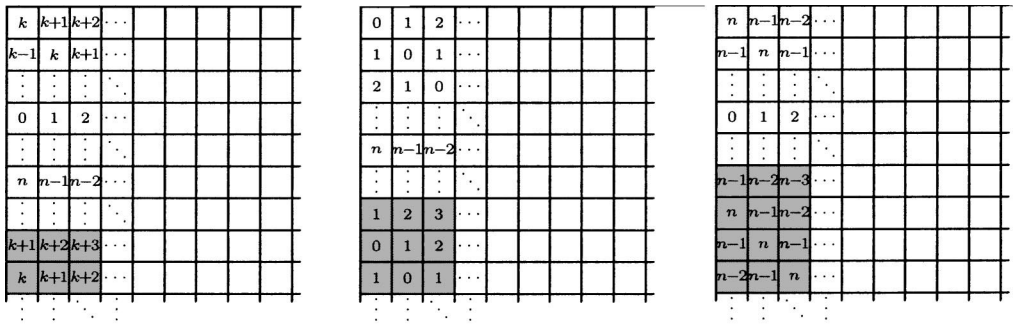
$$t_j=\begin{cases}p_j & \text{if } p_j\in\{1,3,5,\ldots\},\\ 2q_j & \text{if } p_j\in\{1',2',3'\ldots\} \text{ and } p_j=q_j'.\end{cases}$$

□

Until now, we described the Fock space representation $\mathcal{F}(\Lambda_k)$ and the crystal structure on $\mathcal{Z}(\Lambda_k)$ given by Premat. But, she did not give explicit description of the crystal basis $\mathcal{Y}(\Lambda_k)$ of the fundamental representation $U_q(\mathfrak{g})\phi_k=V(\Lambda_k)$. In next section, we deal with it.

III. CHARACTERIZATION OF THE CRYSTAL BASIS $\mathcal{Y}(\Lambda_k)$

Let Y be a Young diagram k. It is represented by some region in the following xy-planes with coloring.



$(k \neq 0, n)$ $(k = 0)$ $(k = n)$

In the above xy-planes, we denote by C_i^+ the ith column of xy-plane and we can find regions in C_{i-1}^+ with the same coloring as C_i^+. Among these, we denote by C_{i-1}^- the largest region. The shaded parts in above xy-planes represent C_1^-, C_2^-, and C_3^-.

Now, consider 0-colored or n-colored corners in the first row. We write these sites $(x_i, k-1)$ with $i \geqslant 1$ from left to right. Then $(x_i+1, k-1)$ and $(x_i, k-2)$ are the sites of the same coloring. For example, in Figs. 1 and 2, the third site and the seventh site in the first row are n-colored and 0-colored corners, respectively. That is, $x_1=3$ and $x_2=7$. Also, both the fourth site in the first row and the third site in the second row are 3-colored corners, and both the eighth site in the first row and the seventh site in the second row are 1-colored corners, and so on. Let U_i $(i \geqslant 1)$ be the area consisting of sites (x,y) such that $x+y \geqslant x_i+k$. Then it is easy to see that there is an area which is symmetric to U_i with respect to the line $l_i=\{(x,y)|x+y=x_i+k-1\}$. That is, $\{(x,y)|x \geqslant x_i, x+y<x_i+k-1\}$. We denote by L_i this region. For $k \neq 0$, n, we denote by U_0 (resp., L_0) the area consisting of corners (x,y) such that $x+y>k$ (resp., $x+y<-k$). For $k=0$, n, we also denote by U_0 (resp., L_0) the area consisting of corners (x,y) such that $x+y>k$ (resp., $x+y<k$). Notice that if we set

$$l_0 = \begin{cases} \{(x,y)|x+y=0\} & \text{if } k \neq n, \\ \{(x,y)|x+y=n\} & \text{if } k=n, \end{cases}$$

then U_0 and L_0 are symmetric to each other with respect to the line l_0. Note that for $k=0$, n, U_1 (resp., L_1) is equal to U_0 (resp., L_0). For instance, the shaded parts in Fig. 1 represent U_0, L_0, and in Fig. 2, the shaded parts represent U_1 and L_1 for the Young diagram 2 of $C_4^{(1)}$.

Now, for each $Y \in \mathcal{Z}(\lambda)$, we denote by $Y \cap U_i$ (resp., $Y \cap L_i$) for $i=0,1,\ldots,n$ the set of all common sites in Y and U_i (resp., L_i) and denote by $|Y \cap L_i|$ the diagram obtained by reflecting $Y \cap L_i$ with respect to the line l_i. Finally, for the sites $(x,y) \in U_i$ and $(x',y') \in L_i$, we say that (x,y) corresponds to (x',y') if (x,y) is symmetric to (x',y') with respect to l_i.

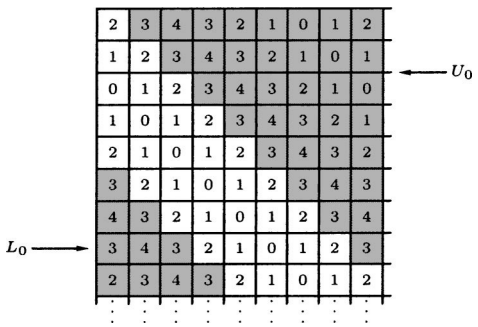


FIG. 1. U_0 and L_0.

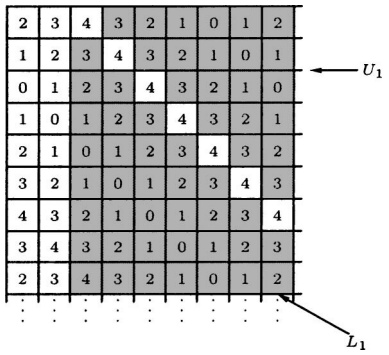

FIG. 2. U_1 and L_1.

Example 2.1: Let $\mathfrak{g}=C_4^{(1)}$ and let

$$Y = \begin{array}{|c|c|c|c|}\hline 0&1&2&3\\\hline 1&0\\\cline{1-2} 2&1\\\cline{1-2} 3\\\cline{1-1}\end{array}$$

be a Young diagram 0. Then

$$Y\cap U_1=\begin{array}{|c|c|c|}\hline 1&2&3\\\hline\end{array},\quad Y\cap L_1=\begin{array}{|c|c|}\hline 1\\\hline 2&1\\\hline 3\\\cline{1-1}\end{array},\quad \text{and}\quad |Y\cap L_1|=\begin{array}{|c|c|c|}\hline 1&2&3\\\hline 1\\\cline{1-1}\end{array}.$$

Now, we introduce some configuration conditions.

Definition 2.2: (a) Assume that $Y\in\mathcal{Z}(\Lambda_k)$ has i-convex corners $(x_1,y_1)\in U_j$ and $(x_2,y_2)\in L_j$ corresponding to each other for some $j=0,1,2,\ldots$. If there is no i-concave corner between (x_1,y_1) and (x_2,y_2), we say that Y satisfies the *configuration condition* (**C1**).

(b) Assume that $Y\in\mathcal{Z}(\Lambda_k)$ has an i-convex corner $(x_1,y_1)\in U_j$ and an i-addable corner $(x_2,y_2)\in L_j$ corresponding to each other for some $j=0,1,2,\ldots$. We say that Y satisfies the *configuration condition* (**C2**) unless there is another i-addable corner between (x_1,y_1) and (x_2,y_2), and the i-signature of the diagram $\{(x,y)\in Y\,|\,x_2+y_2<x+y<x_1+y_1\}$ does not have $+$'s, i.e., $\emptyset=(\cdot)$ or $(-,-,-,\ldots)$.

(c) Assume that $Y\in\mathcal{Z}(\Lambda_k)$ has i-addable corners $(x_1,y_1)\in U_j$ and $(x_2,y_2)\in L_j$ corresponding to each other for some $j=0,1,2,\ldots$. We say that Y satisfies the *configuration condition* (**C3**) unless there is another i-addable corner between (x_1,y_1) and (x_2,y_2), and the i-signature of the diagram $\{(x,y)\in Y\,|\,x_2+y_2<x+y<x_1+y_1\}$ is $\emptyset=(\cdot)$.

From now on, for simplicity, we call the i-signature of the diagram $\{(x,y)\in Y\,|\,x_2+y_2<x+y<x_1+y_1\}$ the i-signature between (x_1,y_1) and (x_2,y_2).

Example 2.3: Let $\mathfrak{g}=C_3^{(1)}$ and let

$$Y = \begin{array}{|c|c|c|c|c|}\hline 0&1&2&3&2\\\hline 1&0&1&2\\\cline{1-4} 2\\\cline{1-1} 3\\\cline{1-1} 2\\\cline{1-1}\end{array}\quad.$$

be a Young diagram 0. The shaded parts $(1,-5)$ and $(5,-1)$ represent the 2-colored convex corners corresponding to each other. Since there is a 2-colored addable corner $(4,-2)$ between these convex corners, Y does not satisfy the configuration condition (**C1**).

Let $Y \in \mathcal{Z}(\Lambda_k)$ be a Young diagram k. Let C_v be the maximal convex corner in Y with respect to the order $>$ on $\mathbb{N}\times\mathbb{Z}$ and assume that C_v is a α-colored corner. Then we denote by C_a the maximal α-addable corner. Now, we define $\hat{Y}$ to be the Young diagram k obtained from Y by removing all α-colored convex corners between C_v and C_a in Y.

Example 2.4: (a) For $\mathfrak{g}=C_3^{(1)}$ and $\lambda=\Lambda_0$, let

$$Y = \begin{array}{|c|c|c|c|c|}\hline 0&1&2&3&2\\\hline 1\\\cline{1-1} 2\\\cline{1-1}\end{array} \in \mathcal{Z}(\lambda),$$

where the shaded corner represents the maximal convex corner C_v. In this case, there is no 2-addable corner and so $\hat{Y}$ is the Young diagram 0 obtained by removing all 2-colored convex corners. That is,

$$\hat{Y} = \begin{array}{|c|c|c|c|}\hline 0&1&2&3\\\hline 1\\\cline{1-1}\end{array}$$

(b) For $\mathfrak{g}=C_3^{(1)}$ and $\lambda=\Lambda_1$, let

$$Y = \begin{array}{|c|c|c|c|c|}\hline 1&2&3&2&1\\\hline 0&1&2&3&2\\\hline 1&0&1\\\cline{1-3} 2\\\cline{1-1}\end{array} \in \mathcal{Z}(\lambda),$$

where the shaded corner represents the maximal convex corner C_v. Since there exists C_a in Y, $\hat{Y}$ is the Young diagram 1 obtained by removing the 2-colored convex corner C_v. That is,

$$\hat{Y} = \begin{array}{|c|c|c|c|c|}\hline 1&2&3&2&1\\\hline 0&1&2&3\\\cline{1-4} 1&0&1\\\cline{1-3} 2\\\cline{1-1}\end{array}$$

Now, we are ready to give an explicit description of the crystal graph $\mathcal{Y}(\Lambda_k)$.

Theorem 5: *The crystal basis $\mathcal{Y}(\Lambda_k)$ of $V(\Lambda_k)=U_q(\mathfrak{g})\phi_k$ is realized as the set of Young diagrams $Y \in \mathcal{Z}(\Lambda_k)$ k satisfying the following conditions*:

(I) *for each* $i=2,3,\ldots$, $Y\cap C_{i-1}^{-}\subset Y\cap C_i^{+}$,
(II) *for each* $i=0,1,2,\ldots$, $|Y\cap L_i|\subset Y\cap U_i$,
(III) *if we set* $Y_0=Y$, $Y_1=\hat{Y}$ *and* $Y_k=\widehat{Y_{k-1}}$, *every* Y_k *satisfies configuration conditions* (**C1**), (**C2**), *and* (**C3**).

Remark 2.6: (a) In Theorem 2.5 (I), we regard $Y\cap C_{i-1}^{-}$ and $Y\cap C_i^{+}$ as only diagrams without coordinates, that is, (I) means that if we put $Y\cap C_{i-1}^{-}$ and $Y\cap C_i^{+}$ on the xy-plane left-top adjusted, then $Y\cap C_{i-1}^{-}$ is a subdiagram of $Y\cap C_i^{+}$.

(b) If $Y \in \mathcal{Y}(\Lambda_k)$ is a Young diagram k, then $\hat{Y}$ also belongs to $\mathcal{Y}(\Lambda_k)$.

Example 2.7: (a) Let $\mathfrak{g}=C_2^{(1)}$ and let

$$Y = \begin{array}{|c|c|c|c|}\hline 1&2&1&0\\\hline 0&1&2\\\cline{1-3} 1&0&1\\\cline{1-3} 2&1&0\\\cline{1-3} 1&2&1\\\cline{1-3} 0\\\cline{1-1}\end{array} .$$

Then we have

$$Y \cap C_2^+ = \begin{array}{|c|}\hline 2\\\hline 1\\\hline 0\\\hline 1\\\hline 2\\\hline\end{array}, \quad Y \cap C_3^+ = \begin{array}{|c|}\hline 1\\\hline 2\\\hline 1\\\hline 0\\\hline 1\\\hline\end{array}, \quad Y \cap C_4^+ = \begin{array}{|c|}\hline 0\\\hline\end{array},$$

$$Y \cap C_1^- = \begin{array}{|c|}\hline 2\\\hline 1\\\hline 0\\\hline\end{array}, \quad Y \cap C_2^- = \begin{array}{|c|}\hline 1\\\hline 2\\\hline\end{array}, \quad \text{and} \quad Y \cap C_3^- = \begin{array}{|c|}\hline 0\\\hline 1\\\hline\end{array}.$$

Therefore,

$$Y \cap U_1 = \subseteq Y \cap C_2^+,\ Y \cap C_2^- \subseteq Y \cap C_3^+, \text{ and } Y \cap C_3^- \nsubseteq Y \cap C_4^+.$$

(b) In Example 2.1, we have

$$Y \cap U_1 = \begin{array}{|c|c|c|}\hline 1&2&3\\\hline\end{array}, \quad Y \cap L_1 = \begin{array}{|c|c|}\hline 1&\multicolumn{1}{c}{}\\\hline 2&1\\\hline 3&\multicolumn{1}{c}{}\\\cline{1-1}\end{array}, \quad \text{and} \quad |Y \cap L_1| = \begin{array}{|c|c|c|}\hline 1&2&3\\\hline 1&\multicolumn{2}{c}{}\\\cline{1-1}\end{array}.$$

Therefore, $Y \cap U_1 \ngeq |Y \cap L_1|$ and so Y does not belong to $\mathcal{Y}(\Lambda_0)$.

(c) Let $\mathfrak{g} = C_4^{(1)}$ and let

$$Y = \begin{array}{|c|c|c|c|c|c|c|}\hline 0&1&2&3&4&3&2\\\hline 1&0&1&2&3&\multicolumn{2}{c}{}\\\cline{1-5} 2&1&0&1&2&\multicolumn{2}{c}{}\\\cline{1-5} 3&2&\multicolumn{5}{c}{}\\\cline{1-2} 4&\multicolumn{6}{c}{}\\\cline{1-1} 3&\multicolumn{6}{c}{}\\\cline{1-1} 2&\multicolumn{6}{c}{}\\\cline{1-1}\end{array}.$$

be a Young diagram 0. Then Y does not satisfy the configuration condition (**C2**), which implies $Y \notin \mathcal{Y}(\Lambda_0)$.

IV. GENERALIZED LLT ALGORITHM

In this section, we give a generalized LLT algorithm, which is an algorithm for constructing the global basis $\mathcal{G}(\Lambda_k)$ of the irreducible highest weight module $V(\Lambda_k)$ of level 1 over $U_q(\mathfrak{g})$. More precisely, for a Young diagram Y k in $\mathcal{Y}(\Lambda_k)$, we give an algorithm of computing the corresponding global basis element $G(Y)$ as a linear combination of Young diagrams k in $\mathcal{Z}(\Lambda_k)$.

We recall the notion of global basis. Consider a $\mathbb{Q}$-algebra involution–of $U_q(\mathfrak{g})$ defined by

$$\overline{e_i} = e_i,\ \overline{f_i} = f_i,\ \overline{q^h} = q^{-h},\ \overline{q} = q^{-1} \text{ for } i \in I,\ h \in P^\vee.$$

Then we have a $\mathbb{Q}$-linear automorphism of $V(\lambda)$ given by

$$Pv_\lambda \mapsto \overline{P}v_\lambda \text{ for } P \in U_q(\mathfrak{g})$$

with the highest weight vector v_λ of $V(\lambda)$. Let $\mathbf{A} = \mathbb{Q}[q, q^{-1}]$. Let $U_{\mathbf{A}}^-$ be the $\mathbf{A}$-subalgebra of $U_q(\mathfrak{g})$ generated by $f_i^{(n)}$ $(i \in I, n \in \mathbb{Z}_{\geqslant 0})$ and set $V(\lambda)_{\mathbf{A}} = U_{\mathbf{A}}^- v_\lambda$. Let $(L(\lambda), B(\lambda))$ be a crystal basis of the irreducible highest weight $U_q(\mathfrak{g})$-module $V(\lambda)$ with a dominant integral weight λ. Then there is a unique $\mathbf{A}$-basis $\mathcal{G}(\lambda) = \{G(b) \in V(\lambda)_{\mathbf{A}} \cap L(\lambda) \,|\, b \in B(\lambda)\}$ of $V(\lambda)_{\mathbf{A}}$ such that

$$\overline{G(b)} = G(b),\ G(b) \equiv b \bmod qL(\lambda) \text{ for all } b \in B(\lambda).$$

The basis $\{G(b)\}$ is called the *global basis* of $V(\lambda)$ corresponding to the crystal basis $B(\lambda)$ (Ref. 12).

Now, we are ready to describe the generalized LLT algorithm. At first, we consider the action of divided powers $f_i^{(r)}$ on the Young diagrams k.

Lemma 3.1: Let Y be a Young diagram k, and write

$$f_i^{(r)}Y = \sum_{\substack{Z\in Z(\Lambda_k)\\ wt(Z)=wt(Y)-r\alpha_i}} Q_{Y,Z}(q)Z,$$

where $Q_{Y,Z}(q)\in\mathbb{Q}(q)$. Then we have $Q_{Y,Z}(q)\in\mathbb{Z}[q,q^{-1}]$.

Proof: If $Z\in\mathcal{Z}(\Lambda_k)$ satisfies $Q_{Y,Z}(q)\neq 0$, we can find a unique sequence of Young diagrams k, $Y=Y_0,Y_1,\ldots,Y_r=Z$ such that

(i) $Y_{k+1}=Y_k\swarrow(x_{k+1},y_{k+1})$ for an i-colored addable corner (x_{k+1},y_{k+1}),
(ii) the site (x_{k+1},y_{k+1}) is smaller than the site (x_k,y_k).

For each k, let $Q_{Y_k,Y_{k+1}}(q)$ be the coefficient of Y_{k+1} in f_iY_k and let

$$Q^{\circ}_{Y,Z}(q)=\prod_{k=0}^{r-1}Q_{Y_k,Y_{k+1}}(q)\in\mathbb{Z}[q,q^{-1}].$$

Then by induction on r, we can see that

$$Q_{Y,Z}(q)=Q^{\circ}_{Y,Z}(q)q_i^{r(r-1)/2}\in\mathbb{Z}[q,q^{-1}]. \tag{3.1}$$

□

For Y in $\mathcal{Z}(\Lambda_k)$, we associate a sequence $\|Y\|=(\ldots,y_{-1},y_0,y_1,\ldots)$, where y_i is the number of sites (x,y) in Y such that $x+y=i$. For Y and Z in $\mathcal{Z}(\Lambda_k)$, consider the associated sequences $\|Y\|=(\ldots,y_{-1},y_0,y_1,\ldots)$ and $\|Z\|=(\ldots,z_{-1},z_0,z_1,\ldots)$. We define $Y>Z$ if and only if there exists p such that $y_i=z_i$ for all $i>p$ and $y_p>z_p$. Then we have

Proposition 3.2: Let $Y\in\mathcal{Y}(\Lambda_k)$ be a Young diagram k. Suppose that $wt(\hat{Y})=wt(Y)+r\alpha_i$. Then

$$f_i^{(r)}\hat{Y}=Y+\sum_{\substack{wt(Z)=wt(Y)\\ Y>Z}}Q_{\hat{Y},Z}(q)Z,$$

where $Q_{\hat{Y},Z}(q)\in\mathbb{Z}[q,q^{-1}]$.

Proof: Recall that $\hat{Y}$ is obtained from Y by removing i-colored convex corners between maximal convex corner C_v and the maximal i-colored addable corner C_a. Then it is easy to see that $Q_{\hat{Y},Z}(q)=0$ unless $Y\geqslant Z$ and $wt(Y)=wt(Z)$. Further, there is a unique sequence of Young diagrams k, $\hat{Y}=Y_0,Y_1,\ldots,Y_r=Y$ such that

(i) $Y_{k+1}=Y_k\swarrow(x_{k+1},y_{k+1})$ for some i-colored addable corner (x_{k+1},y_{k+1}),
(ii) there is no addable corner located above the site (x_k,y_k) with respect to the ordering $>$ on $\mathbb{N}\times\mathbb{Z}$.

In this case, it is easy to see that $Q_{Y_k,Y_{k+1}}(q)=q_i^{-k}$ and so

$$Q^{\circ}_{\hat{Y},Y}(q)=\prod_{k=0}^{r-1}Q_{Y_k,Y_{k+1}}(q)=q_i^{-r(r-1)/2}.$$

Therefore, by (3.1) $Q_{\hat{Y},Y}(q)=1$. □

Definition 3.3: Let $Y \in \mathcal{Y}(\Lambda_k)$ be a Young diagram k. Then we have the unique sequence of Young diagrams k in $\mathcal{Y}(\Lambda_k)$ such that $Y=Y_0$, $Y_1=\hat{Y}_0, \ldots, Y_{k+1}=\hat{Y}_k, \ldots, Y_N=\hat{Y}_{N-1}=\phi_k$. Suppose that $Y_k=\hat{Y}_{k-1}$ is obtained by removing r_k-many i_k-colored convex corners from Y_{k-1}. We define

$$A(Y) = f_{i_1}^{(r_1)} \cdots f_{i_N}^{(r_N)} \phi_k \in V(\Lambda_k)_{\mathbf{A}}. \tag{3.2}$$

By definition, $\overline{A(Y)}=A(Y)$. We write

$$A(Y) = \sum_{Z \in Z(\Lambda_k)} A_{Y,Z}(q) Z,$$

where $A_{Y,Z}(q) \in \mathbb{Q}(q)$. Then we have

Proposition 3.4: Let $Y \in \mathcal{Y}(\Lambda_k)$ *be a Young diagram* k. *Then for a Young diagram* $Z \in \mathcal{Z}(\Lambda_k)$ k, *we have*

$$A(Y) = Y + \sum_{\substack{wt(Z)=wt(Y) \\ Y>Z}} A_{Y,Z}(q) Z,$$

where $A_{Y,Z}(q) \in \mathbb{Z}|q, q^{-1}|$.

Proof: By Lemma 3.1 and Proposition 3.2, it is clear that $A_{Y,Z}(q) \in \mathbb{Z}|q, q^{-1}|$ and $A_{Y,Y}(q)=1$. Therefore, it suffices to show that $A_{Y,Z}(q)=0$ unless $Y \geqslant Z$ and $wt(Y)=wt(Z)$. Now, we use the induction on N. If $N=1$, it is just the Proposition 3.2. Suppose that

$$f_{i_{j+1}}^{(r_{j+1})} \cdots f_{i_N}^{(r_N)} \phi_k = Y_{j+1} + \sum_{Y_{j+1}>Z} A_{Y_{j+1},Z}(q) Z.$$

Then

$$\begin{aligned} f_{i_j}^{(r_j)} f_{i_{j+1}}^{(r_{j+1})} \cdots f_{i_N}^{(r_N)} \phi_k &= f_{i_j}^{(r_j)} Y_{j+1} + \sum_{Y_{j+1}>Z} A_{Y_{j+1},Z}(q) f_{i_j}^{(r_{i_j})} Z \\ &= Y_j + \sum_{Y_j>W} Q_{Y_j,W}(q) W + \sum_{Y_{j+1}>Z} A_{Y_{j+1},Z}(q) \sum_W Q_{Z,W}(q) W. \end{aligned}$$

Let $\|Y_{j+1}\|=(\ldots, y_{-1}, y_0, y_1, \ldots)$ and $\|Z\|=(\ldots, z_{-1}, z_0, z_1, \ldots)$ and let p be the largest integer such that $y_p > z_p$ and $y_q=z_q$ $(q>p)$. Let α be the coloring of (x,y) such that $x+y=p$. If i_j is not α, it is easy to see that $Y_j > W$. If i_j is α, by definition of Y, we can see that Y_j and W are obtained by adding i_j-many α's to the addable corners (x,y) such that $x+y>p$. Hence $Y_j > W$. □

Let $\mathcal{G}(\Lambda_k)=\{G(Y) \mid Y \in \mathcal{Y}(\Lambda_k)\}$ be a global basis of $V(\Lambda_k)_A$. For $Y \in \mathcal{Y}(\Lambda_k)$, let us write

$$G(Y) = \sum_{Z \in \mathcal{Z}(\Lambda_k)} G_{Y,Z}(q) Z \in V(\Lambda_k)_{\mathbf{A}} \cap \mathcal{L}(\Lambda_k),$$

where $G_{Y,Z}(q) \in \mathbf{A}_0$. Since $\mathcal{G}(\Lambda_k)$ is a $\mathbf{A}$-basis of $V(\Lambda_k)_{\mathbf{A}}$, it is easy to see that $G_{Y,Z}(q) \in \mathbb{Q}[q, q^{-1}]$. Further, $G(Y) \equiv Y \bmod q\mathcal{L}(\mathcal{F}(\Lambda_k))$ implies (i) $G_{Y,Z}(q) \in \mathbb{Q}[q]$, (ii) $G_{Y,Z}(q) \in q\mathbb{Q}[q]$ unless $Y=Z$, (iii) $G_{Y,Y}(q)=1$.

On the other hand, since $\mathcal{G}(\Lambda_k)$ and $\mathcal{A}(\Lambda_k)$ are both $\mathbb{Q}(q)$-basis of $V(\Lambda_k)$, there is a matrix $H=(H_{Y,W}(q))_{Y,W \in \mathcal{Y}(\Lambda_k)}$ such that

$$G(Y) = \sum_{W \in \mathcal{Y}(\Lambda_k)} H_{Y,W}(q) A(W).$$

Since $\overline{G(Y)}=G(Y)$ and $\overline{A(W)}=A(W)$, $H_{Y,W}(q)=H_{Y,W}(q^{-1})$.

Proposition 3.5 (cf. Ref. 8):

(a) *$H_{Y,W}(q)$ satisfies the following properties*:

(i) $H_{Y,W}(q) \in \mathbb{Q}[q,q^{-1}]$,
(ii) $H_{Y,W}(q)=0$ *unless* $Y \geqslant W$ *and* $wt(Y)=wt(W)$,
(iii) $H_{Y,Y}(q)=1$.

(b) $A(\Lambda_k)=\{A(Y)\,|\,Y \in \mathcal{Y}(\Lambda_k)\}$ *is an* **A**-*basis of* $V(\Lambda_k)_A$.

Proof: The proof is the same as that of Proposition 7.12 in Ref. 17. □

By above proposition, for each $Y \in \mathcal{Y}(\Lambda_k)_\lambda$ $(\lambda \leqslant \Lambda_k)$, we have

$$A(Y) = G(Y) + \sum_{\substack{Z \in \mathcal{Y}(\Lambda_k)_\lambda \\ Y>Z}} \gamma_{Y,Z}(q)G(Z), \tag{3.3}$$

where $\gamma_{Y,Z}(q) \in \mathbb{Q}[q,q^{-1}]$ and $\gamma_{Y,Z}(q)=\gamma_{Y,Z}(q^{-1})$. If Y is the minimal element in $\mathcal{Y}(\Lambda_k)_\lambda$, then $G(Y)=A(Y)$. Suppose that Y is not minimal and $G(Y')$ are given for $Y' \in \mathcal{Y}(\Lambda_k)_\lambda$ such that $Y' < Y$. Then $\gamma_{Y,Y'}(q)$ are completely determined as follows:

(1) if Y' is the maximal one such that $Y > Y'$ and $A_{Y,Y'}(q)=\Sigma_{i=-r'}^{r} a_i q^i$, then $\gamma_{Y,Y'}(q)=\Sigma_{i=1}^{r'} a_i(q^i + q^{-i}) + a_0$;
(2) if the coefficient of Y' in $A(Y) - \Sigma_{Y>Z>Y'} \gamma_{Y,Z}(q)G(Z)$ is $\Sigma_{i=-r'}^{r} a_i q^{-i}$, then $\gamma_{Y,Y'}(q)=\Sigma_{i=1}^{r'} a_i(q^i + q^{-i}) + a_0$.

From the description of the algorithm, we have

Theorem 3.6: *For a Young diagram $Y \in \mathcal{Y}(\Lambda_k)_\lambda$ $(\lambda \leqslant \Lambda_k)$ k, the corresponding global basis element $G(Y)$ is of the following form*

$$G(Y) = Y + \sum_{\substack{Z \in \mathcal{Z}(\Lambda_k)_\lambda \\ Y>Z}} G_{Y,Z}(q)Z, \tag{3.4}$$

where $G_{Y,Z}(q) \in q\mathbb{Z}[q]$ for $Y \neq Z$.

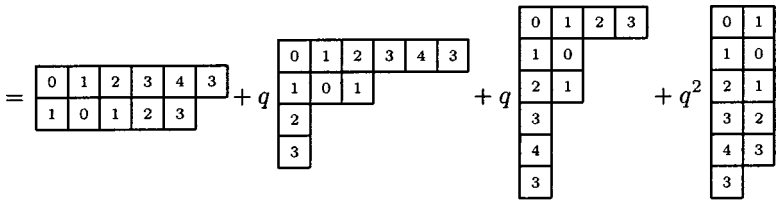
Example 3.7: Let $g=C_4^{(1)}$. In this case, $q_0=q_4=q^2$ and $q_1=q_2=q_3=q$. The following are the all Young diagrams 0 with the weight $\Lambda_0-(2\alpha_0+3\alpha_1+2\alpha_2+3\alpha_3+\alpha_4)$.

$$Y_1 = \begin{array}{|c|c|c|c|c|c|}\hline 0&1&2&3&4&3\\\hline 1&0&1&2&3\\\cline{1-5}\end{array} \quad \text{and} \quad Y_2 = \begin{array}{|c|c|c|c|c|c|}\hline 0&1&2&3&4&3\\\hline 1&0&1\\\cline{1-3} 2\\\cline{1-1} 3\\\cline{1-1}\end{array}\ .$$

Now, $Y_1 > Y_2$ and

$$= \begin{array}{|c|c|c|c|c|c|}\hline 0&1&2&3&4&3\\\hline 1&0&1\\\cline{1-3} 2\\\cline{1-1} 3\\\cline{1-1}\end{array} + q \begin{array}{|c|c|c|c|}\hline 0&1&2&3\\\hline 1&0&1\\\cline{1-3} 2\\\cline{1-1} 3\\\cline{1-1} 4\\\cline{1-1} 3\\\cline{1-1}\end{array} + q \begin{array}{|c|c|c|c|c|c|}\hline 0&1&2&3&4&3\\\hline 1&0\\\cline{1-2} 2&1\\\cline{1-2} 3\\\cline{1-1}\end{array} + q^2 \begin{array}{|c|c|c|c|}\hline 0&1&2&3\\\hline 1&0\\\cline{1-2} 2&1\\\cline{1-2} 3\\\cline{1-1} 4\\\cline{1-1} 3\\\cline{1-1}\end{array}\ .$$

Moreover,



and so $A(Y_1)=Y_1+q\mathcal{L}(\Lambda_0)$. Therefore, $G(Y_1)=A(Y_1)$.

Remark 3.8: Indeed, we have a Young diagram $Y\in\mathcal{Z}(\lambda)$ such that $A(Y)\neq G(Y)$. But, in general, it is composed of a lot of colored boxes.

V. THE PROOF OF THE MAIN THEOREM

In this section, we give a proof of our main theorem. Let $\mathcal{Y}(\Lambda_k)$ be the set of Young diagrams k satisfying the conditions of the Theorem 2.5.

By Corollary 1.4 and Theorem 1.5, it suffices to prove the following statements:

(1) For all $i\in I$ we have $\tilde{e}_i\mathcal{Y}(\Lambda_k)\subset\mathcal{Y}(\Lambda_k)\cup\{0\}$, $\tilde{f}_i\mathcal{Y}(\Lambda_k)\subset\mathcal{Y}(\Lambda_k)\cup\{0\}$.
(2) If $Y\in\mathcal{Y}(\Lambda_k)$ and $\tilde{e}_iY=0$ for all $i\in I$, then $Y=\phi_k$.

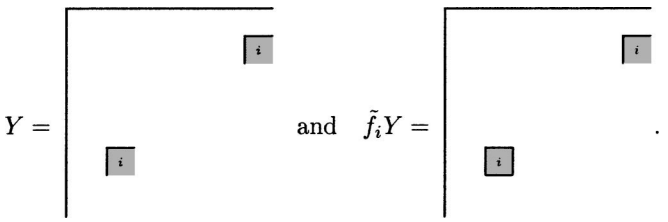
But, thanks to (1.1), it is easy to see that all maximal Young diagrams k except ϕ_k does not satisfy the condition (II). Hence (2) is proved. For (1), let $y\in\mathcal{Y}(\Lambda_k)$ be a Young diagram k. Suppose that $\tilde{f}_iY$ does not belong to $\mathcal{Y}(\Lambda_k)$. It means that $\tilde{f}_iY$ violates at least one of the conditions (I)–(III).

Case I. suppose that $\tilde{f}_iY$ does not satisfy the condition (I). Then there exists an i-colored convex corner in C_k^- for some k, where i-colored box can be added to get $\tilde{f}_iY$ such that

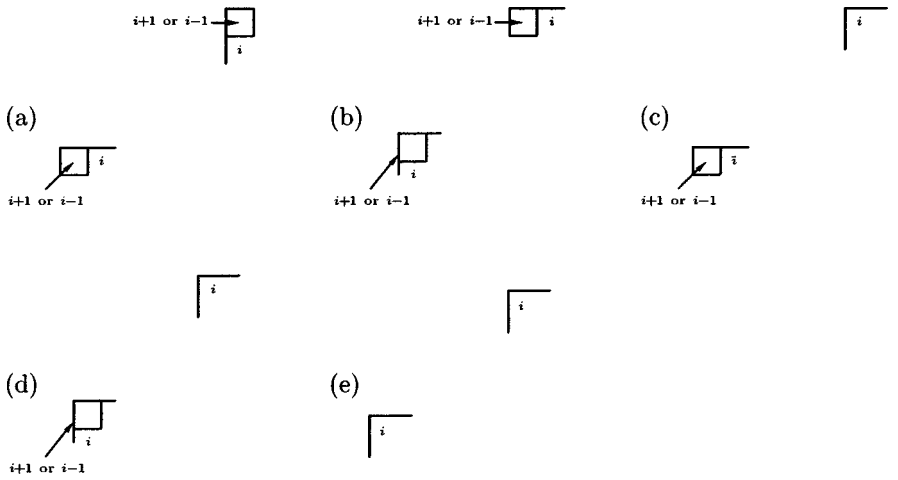
$$\tilde{f}_iY\cap C_k^-\not\subseteq\tilde{f}_iY\cap C_{k+1}^+.$$

Moreover, since Y satisfies the condition (I), there should exist the i-colored addable corner in C_{k+1}^+ of $\tilde{f}_iY$, which implies that Y has i-colored addable corners in both C_k^- and C_{k+1}^+. But, by the definition of Kashiwara operators, it is a contradiction.

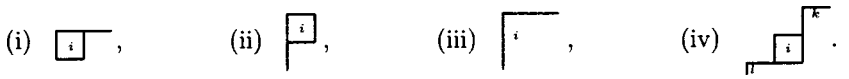
Case II. Suppose that $\tilde{f}_iY$ does not satisfy the condition (II). Then Y has i-colored addable corners (x,y) and (x',y') corresponding to each other, and Y and $\tilde{f}_iY$ have the following form:



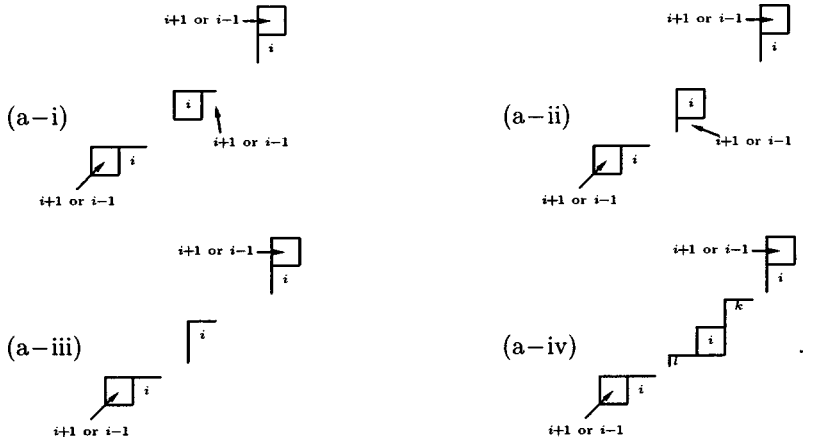
By the condition (II), we have the following possibilities for Y:



By the definition of Kashiwara operator $\tilde{f}_i$, there should be a convex i-colored corner between (x,y) and (x',y') in Y. Hence, one of the following diagrams appears between the corners (x,y) and (x',y').



Consider the case (a). Then we have the following four cases:



For the case (a-i) and (a-ii), if Y has $(i+1)$-colored [resp., $(i-1)$-colored] convex corner and $(i+1)$-colored [resp., $(i-1)$-colored] addable corner, it contradicts to the configuration condition (**C1**). If Y has $(i+1)$-colored [resp., $(i-1)$-colored] convex corner and $(i-1)$-colored [$(i+1)$-colored] addable corner, then we can check that Y_t for some $t \geqslant 0$ cannot satisfy the configuration condition (**C1**) for the $(i-1)$-color [$(i+1)$-color]. In case (a-iii), it is easy to see that Y does not satisfy the configuration condition (**C1**). In case (a-iv), thanks to the pattern of coloring in xy-plane, we can check that Y_t for some t cannot satisfy the configuration condition (**C1**). For the remaining cases, we can give a proof by the similar method.

Case III. Suppose that $\tilde{f}_i Y$ does not satisfy the condition (III). Then there is a Young diagram $(\tilde{f}_i Y)_l$ which does not satisfy one of the configuration conditions (**C1**), (**C2**), (**C3**). At first, consider the case $l=0$. That is, suppose that $\tilde{f}_i Y$ does not satisfy one of the configuration conditions

(**C1**), (**C2**) and (**C3**). At first, suppose that $\tilde{f}_i Y$ violates the configuration condition (**C1**). If C_v of $\tilde{f}_i Y$ is a i-colored convex corner, then Y and $\tilde{f}_i Y$ have the following form:

$Y =$  and $\tilde{f}_i Y =$  .

By the definition of Kashiwara operator $\tilde{f}_i$, it is easy to see that the i-signature between i-colored convex corner C_v and i-colored addable corner corresponding to C_v in Y is $\emptyset=(\cdot)$ or $(-, -, -, \ldots)$. Since Y satisfies the configuration condition (**C2**), it is a contradiction. If C_v of $\tilde{f}_i Y$ is a $(i+1)$-colored or $(i-1)$-colored convex corner, then Y and $\tilde{f}_i Y$ have the following possibilities:

(a) $Y =$  and $\tilde{f}_i Y =$  ,

(b) $Y =$  and $\tilde{f}_i Y =$  .

Here, the left hand side or the upside of C_v is i-colored. In any case, by the pattern of coloring in xy-plane and the condition (II) which Y should satisfy, Y_t for some t can not satisfy the configuration condition (**C1**). It is a contradiction. Similarly, for the remaining cases, we can see that it contradicts to the fact that $Y \in \mathcal{Y}(\Lambda_k)$.

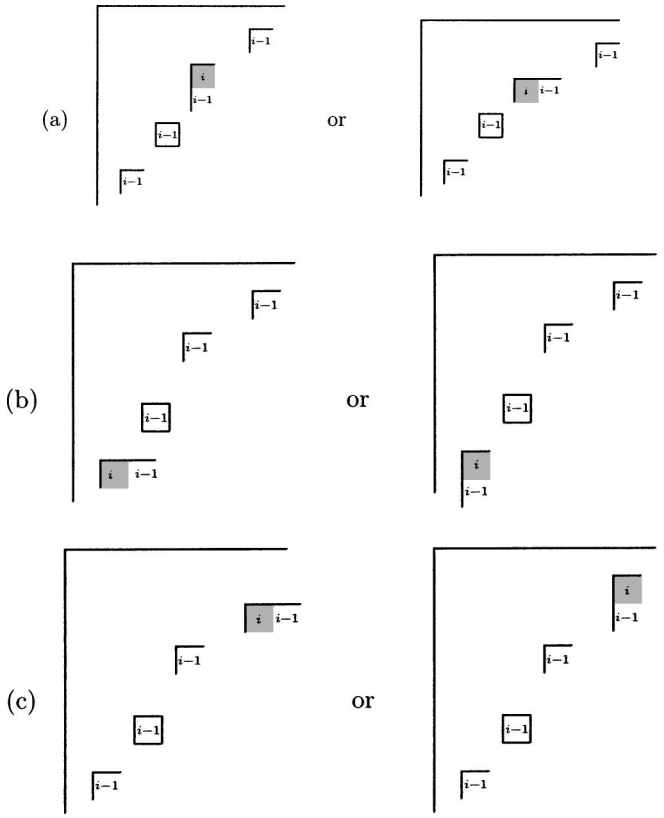
By the similar argument, if $\tilde{f}_i Y$ violates the configuration condition (**C2**), we can show that Y does not satisfy the configuration condition (**C2**) or (**C3**).

Finally, suppose that $\tilde{f}_i Y$ violates the configuration condition (**C3**). If the addable corners of $\tilde{f}_i Y$ which violate (**C3**) are i-colored corners, then Y and $\tilde{f}_i Y$ have the following form:

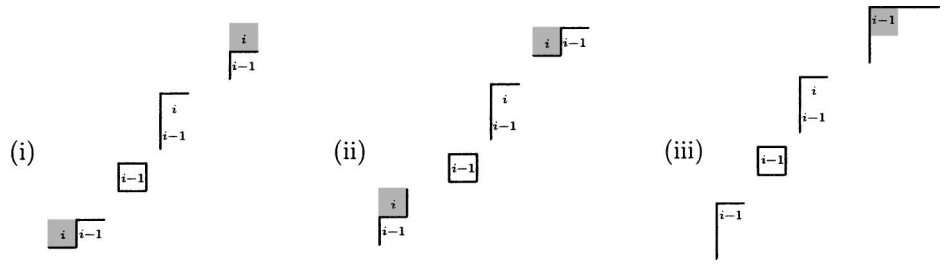
$Y =$  and $\tilde{f}_i Y =$  .

Note that i-signature of Y between above two i-addable corners is $(+)$. Hence, by the definition of Kashiwara operator $\tilde{f}_i$, it is impossible.

If the addable corners of $\tilde{f}_i Y$ which violate (**C3**) are $(i-1)$-colored corners, then Y should be one of the following forms:

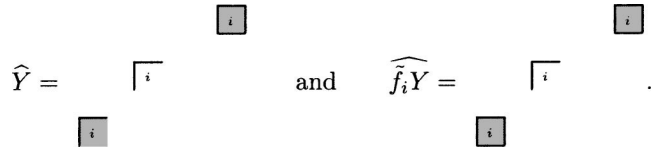


Here, the shaded parts represent the sites where i-colored box will be added in $\tilde{f}_i Y$. Consider the first case of (a). Then we have the following cases:

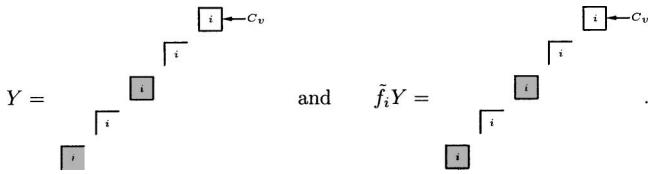


The cases (i) and (ii) violate the configuration condition (**C1**). Further, for the case (iii), we can see that Y_t for some t has the form of (i) and (ii). It is a contradiction. The case (b) is also proved by the similar argument. Moreover, the case (c) cannot appear by the condition (I).

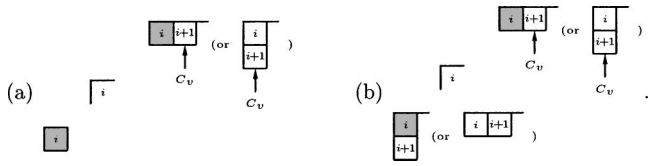
Now, suppose that $(\tilde{f}_i Y)_{l>0}$ does not satisfy one of the configuration conditions (**C1**), (**C2**), (**C3**). Consider the case (**C1**). Using Remark 2.6 (b) and induction argument, we may assume that $\widehat{\tilde{f}_i Y}$ violates the configuration condition (**C1**). If C_v is a α-colored $(\alpha \neq i, i \pm 1)$ corner, $\hat{Y}$ and $\widehat{\tilde{f}_i Y}$ have the following forms:



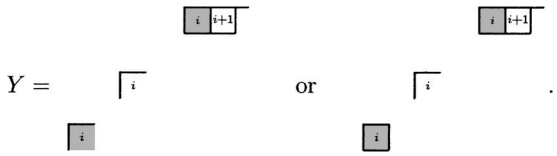
In this case, since $\alpha \neq i, i\pm 1$, it is straightforward to see $\tilde{f}_i\hat{Y} = \widehat{\tilde{f}_i Y}$. Moreover, it means that $\hat{Y}$ violates the configuration condition (**C1**), which is a contradiction. Secondly, if C_v is a i-colored corner, then Y and $\tilde{f}_i Y$ are the following forms:



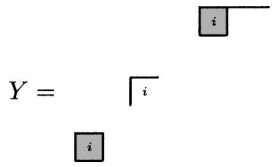
But, in this case, $\tilde{f}_i Y$ does not satisfy the configuration condition (**C1**), which is a contradiction. Finally, if C_v is a $(i+1)$ or $(i-1)$-colored corner, $\tilde{f}_i Y$ is one of the following forms:



In case (a), we have



Then $\hat{Y}$ violates the configuration condition (**C1**) or (**C2**), which is a contradiction. For the case (b), we have



Moreover, Y does not satisfy the configuration condition (**C1**), which is a contradiction.

By the similar argument, we can see that $(\tilde{f}_i Y)_l$ for all l satisfy the configuration conditions (**C2**) and (**C3**). Therefore, $\tilde{f}_i Y$ satisfies the condition (III).

Similarly, we can see that $\tilde{e}_i Y$ belongs to $\mathcal{Y}(\Lambda_k) \cup \{0\}$. □

(Received 24 June 2004; accepted 18 August 2004; published 24 November 2004; publisher error corrected 21 December 2004)

To analyze linear field equations on a locally homogeneous space–time by means of separation of variables, it is necessary to set up appropriate harmonics according to its symmetry group. In this paper, the harmonics are presented for a spatially compactified Bianchi II cosmological model—the *nilgeometric model*. Based on the group structure of the Bianchi II group (also known as the Heisenberg group) and the compactified spatial topology, the irreducible differential regular representations and the multiplicity of each irreducible representation, as well as the explicit form of the harmonics are all completely determined. They are also extended to vector harmonics. It is demonstrated that the Klein–Gordon and Maxwell equations actually reduce to systems of ODEs, with an asymptotic solution for a special case. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1811373]

I. INTRODUCTION

A basic strategy to analyze linear field equations on a given space–time, like linear perturbation equations of Einstein's equation, is to separate the equations using appropriate harmonics. The harmonics for a given manifold are in general determined by the underlying symmetry group (isometry group) and the topology of the manifold. The simplest example is that of a commutative group acting on a flat manifold. If the manifold is compactified to, e.g., a torus, then functions on the manifold are expanded in the form of usual Fourier series. When the group is noncommutative, however, the harmonics become much more complicated. The most familiar example in homogeneous cosmology is the SU(2) (Bianchi IX) case,[2,6,8] where one needs to use the spherical harmonics (and their generalization to vector and tensor harmonics if necessary) to separate field variables. A notable nontrivial example is the $H^2\times\mathbf{R}$ (Bianchi III) case[17,13] with compactified three-dimensional manifold. Since such a manifold is a direct product of two submanifolds, a closed hyperbolic plane and a circle, the harmonics are simply given by making products of those for the two lower dimensional manifolds. Note that the Bianchi III belongs to Class B.[4] Separations of variables regarding locally rotationally symmetric (LRS) Class A Bianchi types (and gravitational perturbations) were discussed in Refs. 3 and 9 without compactification.

In this paper we consider the *generic* (i.e., non-LRS) Bianchi II model *with* compactification. The Bianchi II type is one of the class A types. The underlying symmetry group is the three-dimensional Heisenberg group H_1, which we refer to as the Bianchi II group G_{II}. The Bianchi II homogeneous manifolds correspond to Thurston's nilgeometry.[20] We will refer to spatially compactified Bianchi II space–times (i.e., ones obtained from Bianchi II spatially homogeneous space–times by compactifying the homogeneous spatial sections) as *nilgeometric cosmological models* (to distinguish from the conventional open models).

By considering a compactified (spatial) manifold we have the following merits: (1) a compact Cauchy surface makes it natural to view the field equations as an initial value problem in cosmo-

a)Electronic mail: masayuki.tanimoto@aei.mpg.de

logical context, (2) a finite spatial volume is physically reasonable, and (3) functional analysis on a compact manifold is much easier and tractable than one on an open manifold, since we can avoid many complexities involved in continuous spectra and those for the convergence of integrals (remember the contrast between Fourier series analysis on the "compactified space" $S^1=\mathbf{R}^1/\mathbf{Z}$ and Fourier analysis on the open space $\mathbf{R}$).

We also mention that a motivation of considering compactified manifolds also comes from recent evidence that the spatial topology and global dynamical properties of solutions of Einstein's equation are related in some ways. In particular, recent results[1,5] suggest a very general picture of how an appropriately conformally transformed spatial manifold evolves in time by the vacuum Einstein equation, depending upon its topology. This picture motivates us to study linear perturbation equations for locally homogeneous solutions which have various spatial topologies.

Fortunately, although it is not as trivial as the torus compactification of a flat manifold, the compactification of Bianchi II manifolds (or Bianchi II type space–times) is not very difficult. We will describe our compactification following Refs. 10, 15, and 16.

In this paper we explore detailed properties for the scalar and vector harmonics. We also demonstrate separation of variables for the Klein–Gordon scalar field equation and the source-free Maxwell equation. Although generalization to tensor harmonics is straightforward we leave their explicit presentation to a subsequent paper as well as a study of linear perturbations. This paper is intended to lay a solid basis for exploring those more complicated problems, or to be useful for many applications on the nilgeometric space–time model like quantum field analysis.

Some of the mathematical background assumed in this paper and some related results obtained are the following. As well known (e.g., Ref. 32), the harmonics on a manifold M on which a transformation group G acts are naturally obtained through irreducible decomposition of a representation T, called the *regular representation*, of G on $L^2(M)$. Let $g\in G$ and let $f(x)\in L^2(M)$. The (right) regular representation $(T,L^2(M))$ is given by the homomorphism $T:g\to T_g$, where T_g is the right translation map $T_g:f(x)\to f(xg)$.[22] In fact, letting $g,g'\in G$, we can see $T_gT_{g'}f(x)=(T_{g'}f)(xg)=f(xgg')=T_{gg'}f(x)$, showing T is a representation (homomorphism), $T_gT_{g'}=T_{gg'}$. This representation is however *not* irreducible in general. The appropriate harmonics on M are naturally obtained through an irreducible decomposition of $(T,L^2(M))$.

In our context, the transformation group G is the Bianchi II group G_{II}, which acts on $\tilde{M}=\mathbf{R}^3$ from the left simply transitively, i.e., for arbitrary $p,q\in\tilde{M}$ there exists a unique element $g\in G$ such that $gp=q$. Thanks to this property, choosing an arbitrary fixed point $o\in\tilde{M}$, e.g., the coordinate origin, one can identify the group G_{II} and the manifold $\tilde{M}$, $G_{\mathrm{II}}=\tilde{M}$, by associating go with g. With this identification, the manifold $\tilde{M}$ is also the group G_{II}, and therefore the right action of G_{II} on $\tilde{M}$ is also naturally defined. We make $\tilde{M}$ compact by identifying points by left action of a discrete subgroup $A\subset G_{\mathrm{II}}$, $M=A\backslash\tilde{M}$. The (right) regular representation $(T,L^2(A\backslash\tilde{M}))$ on this space is indeed well defined, since keeping in mind the fact that we can identify an arbitrary function on $A\backslash\tilde{M}$ with an "automorphic function" $f(x)$ on $\tilde{M}$ such that $f(x)=f(Ax)$, we can confirm the consistency $T_gf(Ax)=f(Axg)=f(xg)=T_gf(x)$. This shows the consistency of the fact that we choose the "right" regular representation, i.e., since we want to define the (Killing) symmetry of the manifold with respect to the left action, and make a quotient by the left one, the regular representation on the quotient should be the right one for commutativity. The universal covering manifold $(\tilde{M},\tilde{q}^{(0)})$ with a standard left invariant metric $\tilde{q}^{(0)}$ naturally defines a left invariant measure $\mathrm{d}\mu_0\equiv\mathrm{d}\mu_L$ on $\tilde{M}$, for which we can define the natural inner product on $L^2(\tilde{M})$. Since for the Bianchi II group this measure is also right invariant $\mathrm{d}\mu_L\propto\mathrm{d}\mu_R$, i.e., G_{II} is unimodular, the right regular representation $(T,L^2(A\backslash\tilde{M}))$ with the inner product is unitary; $\int_M|f(xg)|^2\,\mathrm{d}\mu_0=\int_M|f(x)|^2\mathrm{d}\mu_0$.

Our mode functions on M will be denoted as ϕ_{l,m,n_0} (or φ_{l,m,n_0} on the space–time $M\times\mathbf{R}$) for generic modes with $m\neq0$. The index m labels inequivalent irreducible representations, while the index n_0 labels ones in equivalent representations. For fixed m and n_0, the functions $\{\phi_l\}_{l=0}^{\infty}$ work

as a set of basis functions for the irreducible representation space specified by m and n_0. Each single ϕ_l spans the eigenspace of an operator denoted as L^2, which is like a total angular momentum operator.

For the purpose of separation of variables, the most important relations are those for the differential representation, which is a linear transformation acting on the representation space spanned by mode functions. Those relations are written in terms of group-invariant differential operators denoted as χ_I $(I=1-3)$. [See Eqs. (4.14) and (7.9).] Indeed, since group-invariant field equations like the Klein–Gordon equation can be written with no explicit coordinate dependences if it is written with the invariant operators, these relations are found to provide the key to separate the equations.

The formulas for the differential representation however do not provide complete information about the representation. For example, they do not tell whether the representation specified by m does exist in $(T,L^2(M))$, or how many equivalent copies of a representation exist in $(T,L^2(M))$. To see how the representation $(T,L^2(M))$ is decomposed to irreducible representations we need to find all the appropriate mode functions on M. In this paper, the universal covering manifold $\tilde{M}$ (with a group invariant standard metric) is compactified to a circle bundle over the torus. The regular representation $(T,L^2(M))$ is completely reducible, and as a result of finding of the mode functions on the given topology of M we find the following.

Theorem 1.1: *Let M be the circle bundle over the torus with Euler class $e=1$ [see Eq. (2.15) for its fundamental group], and let $(T,L^2(M))$ be the regular representation of the Bianchi II group G_{II}. Then, it holds that*

$$T=\Big(\bigoplus_{m\in\mathbf{Z}\setminus\{0\}}|m|T_m\Big)\oplus\Big(\bigoplus_{k_1,k_2\in\mathbf{Z}}\mathbf{1}_{k_1,k_2}\Big), \tag{1.1}$$

where T_m is an infinite dimensional irreducible representation, $\mathbf{1}_{k_1,k_2}$ is a one-dimensional irreducible representation, and the coefficient $|m|$ stands for the multiplicity in T_m. $\mathbf{Z}\setminus\{0\}$ represents nonzero integers.

(See Ref. 30, Secs. X and XI and references therein for some related mathematical works.) This decomposition expresses the completeness of the harmonics we construct. In particular, this decomposition does not depend on the Teichmüller (or moduli) parameters of M. From the Stone–von Neumann theorem,[19,30] T_m is equivalent to a corresponding Schrödinger representation.

Construction of vector (or tensor) harmonics is not difficult on the one hand. However the important point is to divide each irreducible space of vectors into subspaces such that each subspace is invariant under the action of the operator L^2. This feature is necessary to obtain decoupled systems of ODEs when the background space–time has an additional symmetry. We define three kinds of vector harmonics, two of which have this property.

The plan of the paper is as follows. In the next section we describe the background solution and also account for some basic facts. Section III sets up some basic eigenvalues used to label mode functions, based on the compactification of the spatial manifold. In Sec. IV we make algebraic discussions to derive the χ relations. Section V is devoted to construction of the mode functions on the spatial manifold. In Sec. VI the mode functions constructed on the spatial manifold are generalized to those on the space–time. While Secs. IV–VI deal with the generic modes, Sec. VII deals with the exceptional modes, the U(1)-symmetric modes, which complete all possible (scalar) modes. The results so far are applied to the Klein–Gordon equation and the reduced ODEs are explicitly given, with an asymptotic solution for a special case, in Sec. VIII. In Sec. IX we develop the vector harmonics. Section X is devoted to an application to Maxwell's equation. The final section is devoted to the conclusion.

This paper is a full account, with much generalizations and development, of the subject outlined in Sec. III of Ref. 13. Although most notations remain the same, one of the changes is that a quotient by the left action is now written $A\backslash\tilde{M}$ instead of $\tilde{M}/A$ to make clear which action is used. We employ the abstract index notation[21] and use leading italic letters $a,b,\ldots$ to denote abstract indices for vectors and tensors in Secs. VIII–X. In the other sections however we write them without abstract indices. We often drop the tensor product symbol and write, e.g., $(\sigma^1)^2$

instead of $\sigma^1 \otimes \sigma^1$. Beware that since vectors are also used as differential operators, products of them like $(\chi_1)^2$ can stand for second order derivatives like $\chi_1\chi_1$ or tensor products like $\chi_1 \otimes \chi_1$, depending upon the quantity considered.

II. THE BACKGROUND SOLUTION

Our background solution is specified by the following: (1) it is a solution of the vacuum Einstein equation, (2) it is spatially locally homogeneous of Bianchi II type, and (3) its spatial manifold is compact without boundary, in other words, *closed*. (An explicit topology will be chosen later.)

A Bianchi type II solution is characterized by the fact that the solution (or the universal cover of it) is invariant under the action of the *Bianchi II group* G_{II}, which is a three-dimensional nilpotent (e.g., Ref. 19) Lie group. The group multiplication is given by

$$(a,b,c)(a',b',c') = (a + a', b + b', c + c' + ab'), \tag{2.1}$$

for $(a,b,c),(a',b',c') \in G_{\mathrm{II}}$. (Note: To save space we try to express components of group elements in a row form as above, but a column form is also equally used when it is more convenient.)

Let $\tilde{M} = \mathbf{R}^3$ be the simply connected open manifold with coordinates (x,y,z). We can define the group action on this manifold identifying the group manifold G_{II} with $\tilde{M}$. The left action is therefore expressed as

$$(a,b,c)(x,y,z) = (a + x, b + y, c + z + ay), \tag{2.2}$$

where $\mathbf{a} = (a,b,c) \in G_{\mathrm{II}}$, and $\mathbf{x} = (x,y,z) \in \tilde{M} (\simeq G_{\mathrm{II}})$. Let ξ_I $(I = 1,2,3)$ be the generators of the one-parameter subgroups $(a,0,0)$, $(0,b,0)$, and $(0,0,c) \in G_{\mathrm{II}}$. It is easy to find that they are expressed

$$\xi_1 = \frac{\partial}{\partial x} + y\frac{\partial}{\partial z}, \quad \xi_2 = \frac{\partial}{\partial y}, \quad \xi_3 = \frac{\partial}{\partial z}. \tag{2.3}$$

Similarly, the generators of the right actions and their dual one-forms are given by

$$\chi_1 = \frac{\partial}{\partial x}, \quad \chi_2 = \frac{\partial}{\partial y} + x\frac{\partial}{\partial z}, \quad \chi_3 = \frac{\partial}{\partial z},$$

$$\sigma^1 = \mathrm{d}x, \quad \sigma^2 = \mathrm{d}y, \quad \sigma^3 = \mathrm{d}z - x\,\mathrm{d}y. \tag{2.4}$$

These vectors χ_I and one-forms σ^I $(I = 1-3)$ are called the *invariant vectors or one-forms* of G_{II}, since they are left invariant;

$$\mathcal{L}_{\xi_I}\chi_J = [\xi_I, \chi_J] = 0 = \mathcal{L}_{\xi_I}\sigma^J, \quad I,J = 1-3, \tag{2.5}$$

where $\mathcal{L}_{\xi_I}$ is the Lie derivative with respect to ξ_I. The invariant vectors satisfy the following commutation relations:

$$[\chi_1,\chi_2] = \chi_3, \quad [\chi_2,\chi_3] = 0, \quad [\chi_3,\chi_1] = 0. \tag{2.6}$$

The vectors ξ_I $(I = 1,2,3)$ are *Killing vectors* for the metric of the form $\tilde{q} = \tilde{q}_{IJ}\sigma^I \otimes \sigma^J$ with the components $\tilde{q}_{IJ}$ being constants. Riemannian manifold $(\tilde{M},\tilde{q})$ is called *homogeneous*, since G_{II} acts transitively on it as its isometry group.

A homogeneous metric is called *locally rotationally symmetric (LRS)* if it has a fourth independent Killing vector ξ_4. Bianchi type II LRS metrics are given by the metrics of the form $\tilde{q}^{(\mathrm{LRS})} = \tilde{q}_{11}((\sigma^1)^2 + (\sigma^2)^2) + \tilde{q}_{33}(\sigma^3)^2$, since such a metric has an additional Killing vector, given by

$$\xi_4 = -y\frac{\partial}{\partial x} + x\frac{\partial}{\partial y} + \frac{1}{2}(x^2 - y^2)\frac{\partial}{\partial z}. \tag{2.7}$$

This Killing vector generates the following one-parameter isometries $s_\theta = e^{\theta\xi_4}$ for the metric $\tilde{q}^{(\mathrm{LRS})}$:

$$s_\theta : \begin{pmatrix} x \\ y \\ z \end{pmatrix} \to \begin{pmatrix} R_\theta \begin{pmatrix} x \\ y \end{pmatrix} \\ z + \zeta_\theta(x,y) \end{pmatrix}, \tag{2.8}$$

where $(x,y,z) \in \tilde{M}$, R_θ is the rotation matrix $R_\theta = \left(\begin{smallmatrix} \cos\theta & -\sin\theta \\ \sin\theta & \cos\theta \end{smallmatrix}\right)$, and

$$\zeta_\theta(x,y) \equiv \tfrac{1}{2}((x^2 - y^2)\cos\theta - 2xy\sin\theta)\sin\theta. \tag{2.9}$$

An LRS manifold $X = (\tilde{M}, \tilde{q}^{(\mathrm{LRS})})$ has as a result a four-dimensional isometry group Isom X. Let $\mathrm{Isom}_0 X$ be its identity component, i.e., the component connected to the identity. An element $\alpha \in \mathrm{Isom}_0 X$ can be uniquely expressed as the composite $(\alpha_1, \alpha_2, \alpha_3) \circ s_\theta$ for a choice of $(\alpha_1, \alpha_2, \alpha_3) \in G_{\mathrm{II}}$ and s_θ.

The one-parameter diffeomorphism s_θ plays an important role even when the metric is not LRS. It forms a one-parameter subgroup of the automorphism group of G_{II}, which induces on the cotangent space a rotation of the invariant one-forms,

$$s_{\theta *} : \begin{pmatrix} \sigma^1 \\ \sigma^2 \\ \sigma^3 \end{pmatrix} \to \begin{pmatrix} R_\theta \begin{pmatrix} \sigma^1 \\ \sigma^2 \end{pmatrix} \\ \sigma^3 \end{pmatrix}. \tag{2.10}$$

The induced map s_θ^* on the tangent space acts on the invariant vectors χ_I the same way with replacement $R_\theta \to R_{-\theta}$ above. The significance of the automorphisms of Bianchi groups was first fully recognized by Jantzen.[7] Maps $s_{\theta *}$ or s_θ^* will be used in this paper in several contexts.

We can obtain the space–time metric for the conventional Bianchi cosmology assuming that all the components with respect to the invariant frame $(\mathrm{d}t, \sigma^I)$ formed by the invariant one-forms and the timelike basis dt are functions of time t only. The vacuum Bianchi II solution $\tilde{g}$ was first obtained by Taub.[18] We write that metric in the following form using our invariant one-forms (2.4):

$$\tilde{g} = -N^2(t)\mathrm{d}t^2 + q_1(t)(\sigma^1)^2 + q_2(t)(\sigma^2)^2 + q_3(t)(\sigma^3)^2, \tag{2.11}$$

where

$$N^2 = 1 + \beta^2 t^{4p_3}, \quad q_1 = t^{2p_1}N^2, \quad q_2 = t^{2p_2}N^2, \quad q_3 = 16p_3^2\beta^2 t^{2p_3}/N^2. \tag{2.12}$$

Parameters p_i $(i = 1,2,3)$ and β are constants such that $\beta > 0$, $p_3 \neq 0$, and

$$\Sigma p_i = \Sigma p_i^2 = 1. \tag{2.13}$$

When $p_1 = p_2$, the solution is LRS. Although there exist two possible such cases $(p_1, p_2, p_3) = (0,0,1)$ (case I LRS) and $(2/3, 2/3, -1/3)$ (case II LRS), these two solutions represent equivalent one-parameter solutions. In fact, we can check that the case I LRS solution with $\beta = \beta_{\mathrm{I}}$ is isometric to the case II LRS solution with $\beta = \beta_{\mathrm{II}} = 3^{-2/3}\beta_{\mathrm{I}}^{-1/3}$. When we are interested in an LRS solution, the case II LRS solution may be preferable, since the time coordinate t in this solution approaches the proper time τ at future infinity. This will make comparisons with other models like the Bianchi type III[17,13] more straightforward.

It is also worth pointing out that a solution $\tilde{g}$ with (p_1, p_2, p_3) is isometric to another solution $\tilde{g}'$ with p_1 and p_2 swapped. In fact, it is at once using Eq. (2.10) to see that $\tilde{g}'$ is the metric induced by $s_{\pi/2}$; $\tilde{g}' = s_{\pi/2 *}\tilde{g}$. We can therefore without loss of generality assume, e.g., $p_1 \leqslant p_2$.

We denote the conventional solution described so far as $(\tilde{M} \times \mathbf{R}, \tilde{g})$, and call it the *universal*

covering solution. On the other hand, our spatially closed solution, denoted $(M\times\mathbf{R},g)$, is obtained introducing a spatial compactification with it. We express the solution as

$$(M\times\mathbf{R},g)=\Gamma\backslash(\tilde{M}\times\mathbf{R},\tilde{g}), \tag{2.14}$$

using an appropriate discrete subgroup Γ of G_{II} which acts spatially from the left on the solution. The metric g here is the one induced from $\tilde{g}$. (g and $\tilde{g}$ are therefore locally isometric to each other.) While there are infinitely many possible compactifications (i.e., spatial topologies), we for definiteness specify the spatial manifold M to be "the circle bundle over the 2-torus with Euler class $e=1$." (See, e.g., Refs. 12 and 31. In general, a closed Bianchi II manifold is a *Seifert fiber space* over a Euclidean orbifold.) The fundamental group can be represented in the standard notation as

$$\pi_1(M)=\langle g_1,g_2,g_3;[g_1,g_2]=g_3,[g_1,g_3]=1,[g_2,g_3]=1\rangle, \tag{2.15}$$

where the brackets stand for group commutators, $[a,b]\equiv aba^{-1}b^{-1}$. The procedure for the actual compactification is described in the next section. The resulting spatially compactified generalization was first constructed and discussed in Ref. 15. Note that as a result of the compactification the spatial manifold specified by $t=$constant is now *locally homogeneous* (e.g., Ref. 12), and the space–time solution is said to be *spatially locally homogeneous*.

As shown in Ref. 15, Γ contains four free parameters [see Eq. (6.1)]. Our spatially closed solution (2.14) therefore forms a *six* parameter solution (since the universal cover has as we have seen *two* independent parameters, β and, e.g., p_3).

III. COMPACTIFICATION AND EIGENVALUES

To proceed, we need to describe the compactification of the spatial manifold and thereby define some eigenvalues.

Let us first describe a canonical way of expressing the Bianchi type II locally homogeneous manifold (M,q). Let $\tilde{q}^{(0)}$ be the standard metric given by

$$\tilde{q}^{(0)}=(\sigma^1)^2+(\sigma^2)^2+(\sigma^3)^2 \tag{3.1}$$

and let

$$\mathcal{N}\equiv(\tilde{M},e^{2\alpha}\tilde{q}^{(0)}) \tag{3.2}$$

be the *standard conformal manifold*, with $e^{2\alpha}$ being a constant conformal factor. Then,[10] the manifold (M,q_{ab}) can be expressed as a quotient of the standard conformal manifold (with an appropriate choice of the factor $e^{2\alpha}$),

$$(M,q)=A\backslash\mathcal{N}, \tag{3.3}$$

where A is an appropriate discrete subgroup of the isometry group of $\mathcal{N}$, $A\subset\mathrm{Isom}\,\mathcal{N}$.

The subgroup A must be isomorphic to the fundamental group $\pi_1(M)$ given by (2.15). (In fact, M is a Haken manifold.[31]) This means that A must be an embedding of $\pi_1(M)$ into the isometry group Isom $\mathcal{N}$. Let $\mathbf{a}_i\in\mathrm{Isom}\,\mathcal{N}$ $(i=1,2,3)$ be the image of π_1-generator g_i by such an embedding. Following the procedure shown in Ref. 10, we find that it is possible to parametrize them in the following way:[23]

$$\mathbf{a}_1=(u,\delta,0),\quad \mathbf{a}_2=(0,2\pi v,0),\quad \mathbf{a}_3=(0,0,2\pi uv). \tag{3.4}$$

Here, $\mathbf{a}_i\in G_{\mathrm{II}}\subset\mathrm{Isom}\,\mathcal{N}$.[24] We denote $A=\{\mathbf{a}_1,\mathbf{a}_2,\mathbf{a}_3\}$. The three real parameters u, v, and δ are called the *Teichmüller parameters of geometric structure* for the locally homogeneous 3-manifold (M,q).

We construct the harmonics on (M,q) by two steps; first we do a construction on a covering manifold, denoted $(\overline{M},\overline{q})$, and then superpose appropriate subset of the harmonics to obtain those on (M,q). The *auxiliary manifold* $(\overline{M},\overline{q})$ is simply defined by removing $\mathbf{a}_1$ from A, i.e., $(\overline{M},\overline{q})$

$=\overline{A}\backslash\mathcal{N}$, where $\overline{A}=\{\mathbf{a}_2,\mathbf{a}_3\}$. $\overline{A}$ is a commutative subgroup of A, and therefore $\overline{M}$ is homeomorphic to the much tractable manifold $T^2\times\mathbf{R}$. In fact, we can easily see that it is each $x=$constant plane in $\mathcal{N}$ that is compactified to a 2-torus.

Now, let us introduce some important operators. We define the "total angular momentumlike" operator

$$\mathsf{L}^2 \equiv (\mathcal{L}_{\chi_1})^2 + (\mathcal{L}_{\chi_2})^2, \tag{3.5}$$

using the Lie derivatives $\mathcal{L}_{\chi_1}$ and $\mathcal{L}_{\chi_2}$. Note that when acting on a scalar, it becomes a simple form

$$\mathsf{L}^2 = (\chi_1)^2 + (\chi_2)^2, \tag{3.6}$$

which also coincides with the Laplacian Δ_0 with respect to the standard metric $\tilde{q}^{(0)}$, up to square of χ_3,

$$\Delta_0 = \mathsf{L}^2 + (\chi_3)^2, \tag{3.7}$$

when acting on a scalar. Here, χ_I $(I=1,2,3)$ are regarded as differential operators. It is quite important to recognize that operators χ_I are well defined not only on the universal cover $\tilde{M}$ but also on the compactified manifold $M=A\backslash\tilde{M}$. In other words, the induced vector fields $\pi^*\chi_I$ on M for the covering map $\pi:\tilde{M}\to M=A\backslash\tilde{M}$ is well defined because of the invariance of χ_I under the action of $A\subset G_{\mathrm{II}}$. (For simplicity we do not explicitly write π^*, and identify $\pi^*\chi_I$ and χ_I.) Since $\overline{A}$ is also a subgroup of G_{II}, χ_I are well defined on $\overline{M}$, also. The globally defined invariant operators χ_I work as the fundamental derivative operators, since any group-invariant field equations become independent of coordinates when they are written with χ_I. This coordinate-free property of the field equations is necessary to be able to reduce the field equation to ordinary differential equations.

The operator χ_3, called the *fiber generator*, has a special importance, since it commutes with all the invariant operators χ_I. In other words, χ_3 is the *center* of the Bianchi II algebra. As a direct consequence of Schur's lemma, such an operator must be diagonalized to obtain an irreducible representation of the regular representation mentioned in the Introduction.

The operator $\mathsf{L}^2=(\chi_1)^2+(\chi_2)^2$ commutes with χ_3, since χ_3 is the center. We may therefore be able to diagonalize our mode functions with respect to both χ_3 and L^2. Also, consider another operator $\xi_2=\partial/\partial y$, which we can find commutes with both L^2 and χ_3, so we may diagonalize the mode functions with respect to ξ_2, also. This operator however is *not* well defined on M, but on $\overline{M}$. This is the reason we consider the auxiliary manifold $\overline{M}$. The existence of ξ_2 is important to make it possible to perform separation of variables for the eigenvalue equation for L^2 (see below).

Let $i\mu$ and $i\nu$ be eigenvalues for the operators χ_3 and ξ_2,

$$\chi_3\overline{\phi}=i\mu\overline{\phi}, \quad \xi_2\overline{\phi}=i\nu\overline{\phi}. \tag{3.8}$$

The function $\overline{\phi}$ is supposed to be an appropriate mode function on $\overline{M}$. Also, we define λ by $\mathsf{L}^2\overline{\phi}=-\lambda^2\overline{\phi}$. The solution of these equations is given by

$$\overline{\phi}=X(x)e^{i\mu z}e^{i\nu y}, \tag{3.9}$$

where the function $X(x)$ is a solution of the following "harmonic oscillator Schrödinger equation":

$$\frac{\mathrm{d}^2X}{\mathrm{d}x^2}+(\lambda^2-(\mu x+\nu)^2)X=0. \tag{3.10}$$

For $\overline{\phi}$ to be well defined on $\overline{M}$, it must be an automorphic function such that $\overline{\phi}(\overline{A}\mathbf{x})=\overline{\phi}(\mathbf{x})$.[25] From this condition we find

$$\mu = \mu(m) = m/(uv), \quad m \in \mathbf{Z},$$

$$\nu = \nu(n) = n/v, \quad n \in \mathbf{Z}. \tag{3.11}$$

We call μ, m, ν, and n, respectively, the *fiber eigenvalue*, *fiber index*, *auxiliary eigenvalue*, and *auxiliary index*. We call λ^2 the *total eigenvalue*. The spectrum of λ^2 is determined in the next section.

IV. IRREDUCIBLE DIFFERENTIAL REPRESENTATIONS

It is not difficult to determine the irreducible representations of the regular representation in their differential form, i.e., the differential representations of the Bianchi II algebra. In fact, it will be found that this procedure is similar to the one in determining quantum states of the harmonic oscillator, since L^2 (or the scalar Laplacian Δ_0) has essentially the same algebraic structure as that of the Hamiltonian of the oscillator.

As mentioned in the preceding section since the fiber generator χ_3 must be a constant when acting on an irreducible subspace, the fiber index $m \in \mathbf{Z}$ is constant in this space. We therefore assume that m is fixed throughout this section. It may be helpful to bear in mind that as for the correspondence to quantum mechanics, the fiber eigenvalue $\mu = m/uv$ corresponds to the Planck constant h, while χ_1 and χ_2 correspond, respectively, to the position x and momentum p operators, as in $[x,p]=ih \Leftrightarrow [\chi_1,\chi_2]=\chi_3=i\mu$. Remember however that our representation space is $L^2(M)$ instead of $L^2(\mathbf{R})$.

In this section we deal with the generic $m \neq 0$ case. The exceptional $m=0$ case will be discussed in Sec. VII.

Let ϕ be an eigenfunction on M for the operators χ_3 and L^2, i.e., $\chi_3\phi = i\mu\phi$, and $\mathsf{L}^2\phi = -\lambda^2\phi$. It is helpful to introduce a symbol signifying the sign of the fiber eigenvalue, which allows us to discuss both $m \gtrless 0$ cases simultaneously; we define

$$\varsigma \equiv \mathrm{sign}(m) = \mathrm{sign}(\mu) \quad (m \neq 0). \tag{4.1}$$

Let us then define

$$\mathcal{A}_1 \equiv \frac{1}{\sqrt{2}}(\chi_1 + \varsigma i\chi_2), \quad \mathcal{A}_2 \equiv \frac{1}{\sqrt{2}}(\chi_1 - \varsigma i\chi_2), \quad \mathcal{A}_3 \equiv -\varsigma i\chi_3. \tag{4.2}$$

Then, we immediately find the following commutation relations:

$$[\mathsf{L}^2, \mathcal{A}_1] = \varsigma 2i\mathcal{A}_1\chi_3, \quad [\mathsf{L}^2, \mathcal{A}_2] = -\varsigma 2i\mathcal{A}_2\chi_3. \tag{4.3}$$

This means that $\mathcal{A}_1$ and $\mathcal{A}_2$ are, respectively, a *raising and lowering operator* for the total eigenvalue λ^2. In fact, since

$$\mathsf{L}^2\mathcal{A}_1\phi = ([\mathsf{L}^2, \mathcal{A}_1] + \mathcal{A}_1\mathsf{L}^2)\phi = (\varsigma 2i\mathcal{A}_1\chi_3 + \mathcal{A}_1\mathsf{L}^2)\phi = -(2|\mu| + \lambda^2)\mathcal{A}_1\phi, \tag{4.4}$$

$\mathcal{A}_1\phi$ is an eigenfunction for $\lambda'^2 = \lambda^2 + 2|\mu|$. Similarly, $\mathcal{A}_2\phi$ is an eigenfunction for $\lambda'^2 = \lambda^2 - 2|\mu|$.

Taking into account the fact that $\mathcal{A}_1$ and $\mathcal{A}_2$ change the eigenvalue λ^2 by $\pm 2|\mu(m)|$, we can without loss of generality assume the form of spectrum as

$$\lambda^2 = |\mu|(2l + c_m), \tag{4.5}$$

where

$$l = 0, 1, \ldots . \tag{4.6}$$

The value for $l=0$, $\lambda^2 = \lambda_0^2 \equiv |\mu| c_m$, corresponds to the smallest one for given m, which must exist because minus the Laplacian $-\Delta_0 = -\mathsf{L}^2 - (\chi_3)^2 = -(\mathsf{L}^2 + \mu^2)$ can have only non-negative eigenvalues. We call l the *spin index*.

At this point we know the eigenmode is specified by the pair of integers (l,m), so the corresponding eigenfunction can be expressed with these labels $\phi_{l,m}$. As we remarked since the value of m does not change in an irreducible space, we drop m and write ϕ_l for simplicity.

Let us write down the whole relations we have as

$$\begin{aligned} \mathsf{L}^2\phi_l &= -|\mu|(2l+c_m)\phi_l, \\ \mathcal{A}_3\phi_l &= |\mu|\phi_l, \\ \mathcal{A}_1\phi_l &= \alpha_l\phi_{l+1}, \\ \mathcal{A}_2\phi_l &= \beta_l\phi_{l-1}, \end{aligned} \tag{4.7}$$

where we have introduced unknown constants α_l and β_l, which possibly depend on l.

Note the following identity that can be easily checked by a direct computation:

$$\mathsf{L}^2 = 2\mathcal{A}_1\mathcal{A}_2 - \mathcal{A}_3. \tag{4.8}$$

Using Eqs. (4.7), this implies $-|\mu|(2l+c_m)=2\alpha_{l-1}\beta_l-|\mu|$, i.e.,

$$\alpha_{l-1}\beta_l = -|\mu|\left(l+\frac{c_m-1}{2}\right). \tag{4.9}$$

Because of the arbitrariness of constant multipliers for the eigenfunctions ϕ_l, we may set α_l or β_l arbitrarily, but once it is set, the other is constrained from this relation. We take[26]

$$\alpha_l = -\sqrt{|\mu|}, \quad \beta_l = \sqrt{|\mu|}\left(l+\frac{c_m-1}{2}\right). \tag{4.10}$$

These do satisfy Eq. (4.9). Then, since we defined l so that $l=0$ gives, for given $m\neq 0$, the smallest eigenvalue of $-\mathsf{L}^2$, we should have

$$\mathcal{A}_2\phi_0 = \beta_0\phi_{-1} = \sqrt{|\mu|}\left(\frac{c_m-1}{2}\right)\phi_{-1} = 0, \tag{4.11}$$

implying

$$c_m = 1. \tag{4.12}$$

So, now we have

$$\alpha_l = -\sqrt{|\mu|}, \quad \beta_l = \sqrt{|\mu|}\, l. \tag{4.13}$$

Gathering Eqs. (4.2), (4.7), and (4.13), we arrive at the following set of relations:

$$\begin{aligned} \chi_1\phi_l &= -\sqrt{\frac{|\mu|}{2}}(\phi_{l+1}-l\phi_{l-1}), \\ \chi_2\phi_l &= \varsigma i\sqrt{\frac{|\mu|}{2}}(\phi_{l+1}+l\phi_{l-1}), \\ \chi_3\phi_l &= i\mu\phi_l, \\ l &= 0,1,\ldots. \end{aligned} \tag{4.14}$$

In particular,

$$\mathsf{L}^2\phi_l = -\lambda_l^2\phi_l, \quad \lambda_l^2 \equiv |\mu|(2l+1). \tag{4.15}$$

Now, we have found the following. A "ground state" ϕ_0 is determined as a solution for the two equations

$$\mathcal{A}_3\phi_0 = |\mu|\phi_0, \quad \mathcal{A}_2\phi_0 = 0. \tag{4.16}$$

Note that the function ϕ_0 obtained this way is automatically an eigenfunction of L^2 as seen from the identity (4.8). The excited states ϕ_l are determined by successively multiplying the raising operator $(-1/\sqrt{|\mu|})\mathcal{A}_1$, i.e.,

$$\phi_l = \left(-\frac{\mathcal{A}_1}{\sqrt{|\mu|}}\right)^l \phi_0. \tag{4.17}$$

The space spanned by these functions, $L_m^2(M) \equiv \{\Sigma_{l=0}^{\infty} a_l\phi_l | a_l \in \mathbf{C}\} \cap L^2(M)$, gives an irreducible subspace of $L^2(M)$. In other words, the restriction of the regular representation T to $L_m^2(M)$, denoted as $(T_m, L_m^2(M))$, gives an irreducible representation. The differential representation $(\mathrm{d}T_m, L_m^2(M))$ is given by Eqs. (4.14), which will be repeatedly used to separate the field equations. For convenience, we call these relations the χ *relations*.

V. MODE FUNCTIONS ON THE COMPACTIFIED MANIFOLD

In this section we solve the eigenvalue equations for the mode functions ϕ_l under the appropriate automorphic conditions. As a result we find how many equivalent copies of the irreducible representation T_m are contained in T, in other words, the multiplicity of T_m is determined. The explicit form of ϕ_l itself is also of great interest. In this section we continue to assume $m \neq 0$.

One of the possible procedures to find the explicit form of ϕ_l is to solve the equations (4.16) to find ϕ_0 and compute successive differential operations in Eq. (4.17) to find general ϕ_l. Another procedure is to directly solve the eigenvalue equation $\mathsf{L}^2\phi_l = -\lambda^2\phi_l$ for general spin index l. While both ways are possible, we take the latter, which provides a quicker way of identifying the solutions with known functions.

As remarked in Sec. III, let us find the mode functions on $\overline{M}$ first. Note that Eq. (3.10) becomes (attaching index l to X)

$$\frac{\mathrm{d}^2X_l}{\mathrm{d}\zeta^2} + \left(l + \frac{1}{2} - \frac{\zeta^2}{4}\right)X_l = 0, \tag{5.1}$$

if we define

$$\zeta = \mathfrak{s}\sqrt{\frac{2}{|\mu|}}(\mu x + \nu). \tag{5.2}$$

Independent solutions to the above equation are given by $D_l(\zeta)$ and $D_{-l-1}(i\zeta)$, where $D_l(\zeta)$ is the Weber parabolic cylinder function. When l is zero or a positive integer, $D_l(\zeta)$ can be expressed using the Hermite polynomial $H_l(\zeta)$,

$$D_l(\zeta) = e^{-(1/4)\zeta^2}H_l(\zeta). \tag{5.3}$$

Our convention for the Hermite polynomial is $H_l(\zeta) = (-1)^l e^{(1/2)\zeta^2}(\mathrm{d}^l/\mathrm{d}\zeta^l)e^{-(1/2)\zeta^2}$.

Since ϕ_0 must be annihilated by $\mathcal{A}_2$ the appropriate choice is found to be $D_l(\zeta)$, i.e., we must take $X_l = \mathrm{const} \times D_l(\zeta)$. In fact, the equation $\mathcal{A}_2\overline{\phi_0} = 0$ together with the separation form $\overline{\phi_l} = X_l(x)e^{i\nu y}e^{i\mu z}$, implies $(\mathrm{d}/\mathrm{d}\zeta + (1/2)\zeta)X_0 = 0$, with the solution being $X_0 = \mathrm{const} \times e^{-(1/4)\zeta^2}$. This coincides with the one claimed for $l=0$. [Conversely, as we will see, functions ϕ_l constructed using these X_l can satisfy the desired relations (4.14) for all l, which justifies our choice.]

The mode functions on $\overline{M}$ are therefore, attaching indices m and n, given by

$$\overline{\phi}_{l,m,n}(\mathbf{x}) = C_l D_l\left(\pm\sqrt{\frac{2}{|\mu|}}(\mu x+\nu)\right)e^{i\mu z}e^{i\nu y}, \tag{5.4}$$

where C_l are constants and μ and ν are defined in Eqs. (3.11).

The constants C_l are determined by requiring that the functions $\overline{\phi}_{l,m,n}(\mathbf{x})$ obey the χ relations (4.14). Using the widely known formulas

$$D_l'(\zeta) = -\tfrac{1}{2}(D_{l+1}(\zeta) - lD_{l-1}(\zeta)),$$

$$\zeta D_l(\zeta) = D_{l+1}(\zeta) + lD_{l-1}(\zeta), \tag{5.5}$$

we can easily find $C_{l+1}=C_l$, i.e., they are constants that do not depend on l;

$$C_l = C. \tag{5.6}$$

[Actually, this is the reason we choose Eqs. (4.13).] The constant C may be determined by a normalization of the square integral on M. (See below.)

The mode functions on M are, as mentioned, expressed as an infinite sum of these eigenfunctions on $\overline{M}$. Remember that they must be invariant under the action of $A=\{\mathbf{a}_1,\mathbf{a}_2,\mathbf{a}_3\}$, and the functions $\overline{\phi}_{l,m,n}$ are already invariant under $\overline{A}=\{\mathbf{a}_2,\mathbf{a}_3\}$. We therefore want to make a linear combination of $\overline{\phi}_{l,m,n}$ so that it is invariant under $\mathbf{a}_1$. Recalling the multiplication rule (2.2), we find the following transformation law [cf. Ref. 13, Eq. (3.15)]:

$$\overline{\phi}_{l,m,n}(\mathbf{a}_1\mathbf{x}) = e^{i(\delta/v)n}\overline{\phi}_{l,m,n+m}(\mathbf{x}). \tag{5.7}$$

From this we can see that the following function ϕ_{l,m,n_0}, defined as an infinite sum, is actually invariant under the action of $\mathbf{a}_1$ (cf. Ref. 13, Theorem 3.1), i.e., $\phi_{l,m,n_0}(\mathbf{a}_1\mathbf{x})=\phi_{l,m,n_0}(\mathbf{x})$ for

$$\phi_{l,m,n_0}(\mathbf{x}) = \sum_{k=-\infty}^{\infty} e^{i\delta\{n_0k+m[k(k-1)/2]\}}\overline{\phi}_{l,m,n_0+mk}(\mathbf{x}), \tag{5.8}$$

where $l=0,1,\ldots,\infty$, $|m|=1,2,\ldots,\infty$, $n_0=0,1,\ldots,|m|-1$. The sum is convergent at any point $\mathbf{x}$. It is easy to see that since the functions $\overline{\phi}_{l,m,n}(\mathbf{x})$ satisfy the relations (4.14), so do $\phi_{l,m,n_0}(\mathbf{x})$. These functions are therefore the right mode functions on $M=A\backslash\tilde{M}$.

As a result of the compactification, the index n_0 for the mode functions on M is now bounded by $|m|$. $|m|$ is the *multiplicity* of the modes specified by the same l and m. Since for each n_0 the functions $\phi_{l,m}$ span an irreducible subspace of $L^2(M)$, $|m|$ is also the multiplicity of the irreducible representation T_m contained in T.

We can summarize the results as follows.

Theorem 5.1: *There exist $|m|$ different sets of mode functions $\{\phi_l(\mathbf{x})\}_{l=0}^{\infty}$ that satisfy the relations (4.14) on the compactified manifold $(M,q_{ab})=A\backslash\mathcal{N}$ (with M being the S^1-bundle over the 2-torus with Euler class $e=1$).*

Let us discuss how the mode functions can be normalized. We define the inner product in $L^2(M)$ as

$$(f,g) \equiv \int_M fg^*\,\mathrm{d}\mu_0, \tag{5.9}$$

where g^* is the complex conjugate of g, $\mathrm{d}\mu_0=\sigma^1\wedge\sigma^2\wedge\sigma^3=\mathrm{d}x\,\mathrm{d}y\,\mathrm{d}z$ is the standard invariant measure. We want to determine the square norm

$$N_l \equiv (\phi_l,\phi_l). \tag{5.10}$$

We first observe the following.

Lemma 5.2: The invariant operators χ_I $(I=1-3)$ *in* $L^2(M)$ *are anti-self-adjoint,* $\chi_I^\dagger=-\chi_I$.
Proof: Since

$$(\chi_I f,g)=\int_M (\chi_I(fg^*)-f\chi_I g^*)\mathrm{d}\mu_0=\mathcal{I}_I-(f,\chi_I g), \tag{5.11}$$

we need to show $\mathcal{I}_I\equiv\int_M \chi_I(fg^*)\mathrm{d}\mu_0=0$. In fact, when, e.g., $I=1$, we can show $\mathcal{I}_1=\int_M \chi_1(fg^*)\sigma^1\wedge\sigma^2\wedge\sigma^3=\int_M \mathrm{d}(fg^*\sigma^2\wedge\sigma^3)$, which is from Stoke's theorem $\int_{\partial M} fg^*\sigma^2\wedge\sigma^3=0$. Here, we have used the identity

$$\mathrm{d}f=(\chi_1 f)\sigma^1+(\chi_2 f)\sigma^2+(\chi_3 f)\sigma^3, \tag{5.12}$$

which is valid for an arbitrary function f on M, and also used the relation $\mathrm{d}(\sigma^2\wedge\sigma^3)=0$, which is confirmed from the definition (2.4). The other cases $I=2,3$ are the same, since $\mathrm{d}(\sigma^1\wedge\sigma^3)=\mathrm{d}(\sigma^1\wedge\sigma^2)=0$. ■

Remark: Operators $(1/i)\chi_I$ $(I=1-3)$ are self-adjoint.

Corollary 5.3: In $L^2(M)$, $\mathcal{A}_1^\dagger=-\mathcal{A}_2$.

Proof: $\mathcal{A}_1^\dagger=2^{-1/2}(\chi_1+\mathfrak{s}i\chi_2)^\dagger=2^{-1/2}(\chi_1^\dagger-\mathfrak{s}i\chi_2^\dagger)=-2^{-1/2}(\chi_1-\mathfrak{s}i\chi_2)=-\mathcal{A}_2$. ■

Returning to the issue of N_l, consider $N_{l+1}=(\phi_{l+1},\phi_{l+1})$. When $m\neq 0$, from Eqs. (4.7) and Corollary 5.3 we have

$$\mathcal{N}_{l+1}=\frac{1}{\alpha_l\alpha_l^*}(\mathcal{A}_1\phi_l,\mathcal{A}_1\phi_l)=\frac{1}{\alpha_l\alpha_l^*}(\phi_l,\mathcal{A}_1^\dagger\mathcal{A}_1\phi_l)=\frac{-1}{\alpha_l\alpha_l^*}(\phi_l,\mathcal{A}_2\mathcal{A}_1\phi_l)=\frac{-1}{\alpha_l\alpha_l^*}(\phi_l,\beta_{l+1}\alpha_l\phi_l)=\frac{-\beta_{l+1}^*}{\alpha_l}N_l. \tag{5.13}$$

Substituting our choice (4.13) of α_l and β_l we have

$$N_{l+1}=(l+1)N_l. \tag{5.14}$$

Taking $N_0=1$ we conclude

$$N_l=l!\,. \tag{5.15}$$

Now, we have the following.

Theorem 5.4: *Suppose that* ϕ_l *are mode functions on* $(M,q_{ab})=A\backslash\mathcal{N}$ *such that they satisfy the relations (4.14). Multiplying the same constant normalization factor* C *to all* ϕ_l, $\phi_l\to C\phi_l$, *does not change those relations. By choosing* C *appropriately, we can make the normalization*

$$(\phi_{l,m,n_0},\phi_{l',m',n_0'})=l!\,\delta_{ll'}\delta_{mm'}\delta_{n_0n_0'} \tag{5.16}$$

hold.

Proof: The orthogonality for m and m' is apparent from the fact that $\mu(m)$ is the eigenvalue of the self-adjoint operator $(1/i)\underline{\chi}_3$. The orthogonality for n_0 and n_0' comes from the orthogonality among the mode functions on $\bar{M}$:

$$(\bar{\phi}_{l,m,n},\bar{\phi}_{l,m,n'})_{\bar{M}}\equiv\int_{\bar{M}}\bar{\phi}_{l,m,n}\bar{\phi}_{l,m,n'}^*\,\mathrm{d}\mu_0=0\quad(n\neq n'), \tag{5.17}$$

which is also apparent from the fact that the operator $(1/i)\xi_2$, of which eigenvalues are $\nu(n)$, is self-adjoint on $L^2(\bar{M})$. Observing that when $n_0\neq n_0'$, ϕ_{l,m,n_0}, and $\phi_{l,m,n_0'}$ are linear combinations in different sets $\{\bar{\phi}_{l,m,n}\}_{n\in\mathcal{N}_1}$ and $\{\bar{\phi}_{l,m,n}\}_{n\in\mathcal{N}_2}$, $\mathcal{N}_1\cap\mathcal{N}_2=\varnothing$, we can easily see

$$\int_{\bar{M}} \phi_{l,m,n_0} \phi^*_{l,m,n_0'} \, \mathrm{d}\mu_0 = 0 \quad (n_0 \neq n_0'), \tag{5.18}$$

which in turn implies the orthogonality for n_0 and n_0' in $L^2(M)$. The other part has already been proven. ■

Remark: The constant C does not depend on l, but can depend on m and n_0, so we may write $C = C_{m,n_0}$.

Apparently, if we define

$$\phi^{(\mathrm{n})}_{l,m,n_0} \equiv \frac{1}{\sqrt{l!}} \phi_{l,m,n_0}, \tag{5.19}$$

they become orthonormal to each other,

$$(\phi^{(\mathrm{n})}_{l,m,n_0}, \phi^{(\mathrm{n})}_{l',m',n_0'}) = \delta_{ll'} \delta_{mm'} \delta_{n_0 n_0'}. \tag{5.20}$$

As seen from Eqs. (5.13) and (4.9) this corresponds to choosing

$$\alpha^{(\mathrm{n})}_l = e^{i\Theta_l} \sqrt{|\mu|(l+1)}, \quad \beta^{(\mathrm{n})}_l = -e^{-i\Theta_l} \sqrt{|\mu| l}, \tag{5.21}$$

where Θ_l is an arbitrary phase factor, which we may want to take zero, $\Theta_l = 0$. Substituting $\alpha_l = \alpha^{(\mathrm{n})}_l$ and $\beta_l = \beta^{(\mathrm{n})}_l$ into Eqs. (4.7) we have another version of χ relations for $\phi^{(\mathrm{n})}_{l,m,n_0}$, which have the most direct correspondence to the usual relations between the quantum states of the harmonic oscillator. As mentioned however we employ the unnormalized ϕ_l in this paper for the convenience of computation.

VI. FURTHER TRANSFORMATION

The mode functions $\phi_{l,m,n_0}(\mathbf{x})$ shown in the preceding section are *not* well defined on the general space–time solution $(M \times \mathbf{R}, g) = \Gamma \backslash (\tilde{M} \times \mathbf{R}, \tilde{g})$, because of the fact $A \neq \Gamma$. Remember that $\Gamma \subset G_{\mathrm{II}}$ is a four-parameter embedding, while A is a three-parameter one. This incompatibility means that we cannot identify the coordinates $\mathbf{x}$ in $\mathcal{N}$ with the spatial coordinates $\mathbf{x}$ in $(\tilde{M} \times \mathbf{R}, \tilde{g})$.[27] Although it is expected that an appropriate diffeomorphism can make the mode functions well defined on the space–time, such a diffeomorphism can affect the χ relations. In the following, we show by explicit computations that this is the case but a further renormalization makes the mode functions retain the original χ relations.

As shown in Ref. 15, the covering group Γ can be parametrized as

$$\Gamma = \{\gamma_1, \gamma_2, \gamma_3\} = \left\{ \begin{pmatrix} R_{-\theta} \begin{pmatrix} u \\ \delta \end{pmatrix} \\ 0 \end{pmatrix}, \begin{pmatrix} R_{-\theta} \begin{pmatrix} 0 \\ 2\pi v \end{pmatrix} \\ 0 \end{pmatrix}, \begin{pmatrix} 0 \\ 0 \\ 2\pi u v \end{pmatrix} \right\}, \tag{6.1}$$

where $\gamma_i \in G_{\mathrm{II}}$, and θ, u, δ, and v are real parameters.[28,29] Let $(M, q) = \Gamma \backslash (\tilde{M}, \tilde{q}_{ab})$ be the *spatial section* of the solution, where $\tilde{q}$ is the spatial part of $\tilde{g}$. For convenience of considering diffeomorphisms between the spatial universal cover $(\tilde{M}, \tilde{q}_{ab})$ and the standard conformal manifold $\mathcal{N} = (\tilde{M}, e^{2\alpha} \tilde{q}^{(0)})$, let us distinguish the latter manifold (without metric structure) by denoting $\tilde{M}'$. This distinction is meant to be helpful just to keep track of the direction of the diffeomorphisms we consider.

Let ψ be a diffeomorphism,

$$\psi : \tilde{M} \to \tilde{M}' \tag{6.2}$$

such that

$$\Gamma = \psi^{-1} \circ A \circ \psi. \tag{6.3}$$

Then, the induced function of $\phi_{l,m,n_0}(\mathbf{x})$ will be invariant under Γ, since so is $\phi_{l,m,n_0}(\mathbf{x})$ under A.

We can find ψ in Isom $\mathcal{N}$, which is explicitly given by

$$\psi = \mathbf{b} \circ s_\theta, \tag{6.4}$$

where $\mathbf{b} \in G_{\mathrm{II}}$ is

$$\mathbf{b} = (\pi v \cos\theta \sin\theta, u^{-1}(-\zeta_{-\theta}(u,\delta) + \pi\delta v \sin\theta \cos\theta), 0). \tag{6.5}$$

We have, for simplicity, chosen the third component of $\mathbf{b}$ as zero, though it can be an arbitrary constant. The induced vectors $\psi^* \chi_I$ on $\tilde{M}'$ becomes a linear transformation of χ_I, due to the property that elements in Isom $\mathcal{N}$ are automorphisms of G_{II}. Note that when acting on the vectors χ_I, the induced map $\psi^* = \mathbf{b}^* \circ s_\theta^*$ becomes the same as s_θ^*, since χ_I are by definition invariant under the induced map $\mathbf{b}^*$ for $\mathbf{b} \in G_{\mathrm{II}}$. Therefore from (the vector version of) Eq. (2.10), we have

$$\psi^* : \begin{pmatrix} \chi_1 \\ \chi_2 \\ \chi_3 \end{pmatrix} \to \begin{pmatrix} \psi^*\chi_1 \\ \psi^*\chi_2 \\ \psi^*\chi_3 \end{pmatrix} = \begin{pmatrix} R_{-\theta}\begin{pmatrix} \chi_1 \\ \chi_2 \end{pmatrix} \\ \chi_3 \end{pmatrix}. \tag{6.6}$$

Let $\phi_l^{(\mathrm{ss})}(\mathbf{x}) \equiv (\psi_* \phi_l)(\mathbf{x}) = \phi_l \circ \psi(\mathbf{x})$, where $\mathbf{x} \in \tilde{M}$. [Superscript (ss) stands for "spatial section."] Then,

$$\chi_1 \phi_l^{(\mathrm{ss})} = \chi_1(\psi_* \phi_l) = (\psi^* \chi_1)\phi_l \circ \psi = (\cos\theta \chi_1 + \sin\theta \chi_2)\phi_l \circ \psi = \sqrt{\frac{|\mu|}{2}}(-e^{-i\theta}\phi_{l+1} + e^{i\theta} l \phi_{l-1}) \circ \psi$$

$$= \sqrt{\frac{|\mu|}{2}}(-e^{-i\theta}\phi_{l+1}^{(\mathrm{ss})} + e^{i\theta} l \phi_{l-1}^{(\mathrm{ss})}), \tag{6.7}$$

where we have used the relations (4.14). Similarly, we obtain

$$\chi_2 \phi_l^{(\mathrm{ss})} = \mathrm{s}i \sqrt{\frac{|\mu|}{2}}(e^{-i\theta}\phi_{l+1}^{(\mathrm{ss})} + e^{i\theta} l \phi_{l-1}^{(\mathrm{ss})}), \tag{6.8}$$

and $\chi_3 \phi_l^{(\mathrm{ss})} = i\mu \phi_l^{(\mathrm{ss})}$. These relations are different from the original χ relations (4.14) unless θ is a multiple of 2π.

However, it is possible to renormalize $\phi_l^{(\mathrm{ss})}$ so that the original χ relations are recovered. It is straightforward to check that

$$\varphi_l = e^{i\theta l} \phi_l^{(\mathrm{ss})} \tag{6.9}$$

gives such a renormalized function. Thus, we have found that the functions $\varphi_l = e^{i\theta l}\phi_l \circ \psi$ with ϕ_l given by Eq. (5.8) and ψ being Eq. (6.4), are served as the right mode functions on the spatial section (and therefore on the space–time) that satisfy the relations (4.14). This provides a direct proof of the following.

Theorem 6.1: *There exist $|m|$ different sets of time-independent mode functions $\{\varphi_{l,m}(\mathbf{x})\}_{l=0}^{\infty}$ on the spatially closed Bianchi II solution $(M \times \mathbf{R}, g) = \Gamma \backslash (\tilde{M} \times \mathbf{R}, \tilde{g})$ such that they satisfy the relations (4.14).*

VII. U(1)-SYMMETRIC MODES

Let us, for completeness, consider the modes with the fiber index m being zero. We call these modes U(1)-*symmetric*, since they are constant along the U(1) ($\simeq S^1$) fibers.

Let ϕ be an eigenfunction for $m=0$, i.e., $\chi_3 \phi = (\partial\phi/\partial z) = 0$. This in turn implies that χ_1 and χ_2 are commutative when acting on ϕ,

$$[\chi_1,\chi_2]\phi=0, \tag{7.1}$$

since $[\chi_1,\chi_2]=\chi_3$. Due to this property, the harmonics describing the $m=0$ subspace of $L^2(M)$ become the usual Fourier expansion on a torus. (Thus, together with the results for the generic modes we obtain Theorem 1.1.) In the following we explicitly determine the spectrum of the eigenvalues for the operators χ_1 and χ_2 in terms of the space–time moduli parameters u, δ, v, and θ.

Let us first work on the 3-manifold $A\backslash\mathcal{N}$ (not on the space–time manifold) as we did for the generic $(m\neq 0)$ case. Taking the form of A into account, we label the mode functions with the following equations:

$$(u\chi_1+\delta\chi_2)\phi=2\pi i k_1\phi,$$

$$v\chi_2\phi=ik_2\phi, \tag{7.2}$$

where the eigenvalues k_1 and k_2 are to be used as labels. Let us therefore write the solution of these equations as $\phi=\phi^{(0)}_{k_1,k_2}(\mathbf{x})=\phi^{(0)}_{k_1,k_2}(x,y)$, which is given by

$$\phi^{(0)}_{k_1,k_2}=\text{const}\times e^{(i/u)[2\pi k_1 x+(k_2/v)(-\delta x+uy)]}. \tag{7.3}$$

Since, recalling the rule (2.2),

$$\phi^{(0)}_{k_1,k_2}(\mathbf{a}_1\mathbf{x})=\phi^{(0)}_{k_1,k_2}(x+u,y+\delta)=\phi^{(0)}_{k_1,k_2}(\mathbf{x})e^{2\pi i k_1},$$

$$\phi^{(0)}_{k_1,k_2}(\mathbf{a}_2\mathbf{x})=\phi^{(0)}_{k_1,k_2}(x,y+2\pi v)=\phi^{(0)}_{k_1,k_2}(\mathbf{x})e^{2\pi i k_2}, \tag{7.4}$$

we find

$$k_1\in\mathbf{Z},\quad k_2\in\mathbf{Z}, \tag{7.5}$$

for $\phi^{(0)}_{k_1,k_2}$ to be well defined on $M=A\backslash\tilde{M}$. The remaining condition $\phi^{(0)}_{k_1,k_2}(\mathbf{a}_3\mathbf{x})=\phi^{(0)}_{k_1,k_2}(\mathbf{x})$ is trivial.

Therefore from Eqs. (7.2) the χ relations for the U(1)-symmetric modes are

$$\chi_1\phi^{(0)}_{k_1,k_2}=iK_1(k_1,k_2)\phi^{(0)}_{k_1,k_2},$$

$$\chi_2\phi^{(0)}_{k_1,k_2}=iK_2(k_2)\phi^{(0)}_{k_1,k_2}, \tag{7.6}$$

$$\chi_3\phi^{(0)}_{k_1,k_2}=0,$$

where

$$K_1(k_1,k_2)\equiv\frac{1}{u}\left(2\pi k_1-\frac{\delta}{v}k_2\right),$$

$$K_2(k_2)\equiv\frac{k_2}{v}. \tag{7.7}$$

To extend the mode functions on the space–time manifold $\Gamma\backslash(\tilde{M}\times\mathbf{R},\tilde{g})$, we need to apply the diffeomorphism ψ defined in Eq. (6.4) again, and as a result the spectrum of the eigenvalues are altered. (Contrary to the generic case, any renormalizations of the resulting mode functions do not affect the χ relations.)

As in the preceding section, let us define $\varphi^{(0)}_{k_1,k_2}\equiv\phi^{(0)}_{k_1,k_2}\circ\psi$. Then, from Eq. (6.6), we have, e.g.,

$$\chi_1\varphi^{(0)}_{k_1,k_2} = (\psi^*\chi_1)\phi^{(0)}_{k_1,k_2}\circ\psi = (\cos\ \theta\chi_1 + \sin\ \theta\chi_2)\phi^{(0)}_{k_1,k_2}\circ\psi = i(\cos\ \theta K_1 + \sin\ \theta K_2)\varphi^{(0)}_{k_1,k_2}. \quad (7.8)$$

A similar result is also obtained for $\chi_2\varphi^{(0)}_{k_1,k_2}$. We write the final form of the relations as follows:

$$\chi_1\varphi^{(0)}_{k_1,k_2} = i\kappa_1(k_1,k_2)\varphi^{(0)}_{k_1,k_2},$$

$$\chi_2\varphi^{(0)}_{k_1,k_2} = i\kappa_2(k_1,k_2)\varphi^{(0)}_{k_1,k_2}, \quad (7.9)$$

$$\chi_3\varphi^{(0)}_{k_1,k_2} = 0, \quad k_1 \in \mathbf{Z}, \quad k_2 \in \mathbf{Z},$$

where

$$\kappa_1(k_1,k_2) \equiv \cos\ \theta K_1(k_1,k_2) + \sin\ \theta K_2(k_2),$$

$$\kappa_2(k_1,k_2) \equiv -\sin\ \theta K_1(k_1,k_2) + \cos\ \theta K_2(k_2). \quad (7.10)$$

Now, we have the following.

Theorem 7.1: *There exist time-independent mode functions* $\varphi^{(0)}_{k_1,k_2}(\mathbf{x})$, $k_1,k_2 \in \mathbf{Z}$, *on the spatially closed Bianchi II solution* $(M\times\mathbf{R},g)=\Gamma\backslash(\tilde{M}\times\mathbf{R},\tilde{g})$ *such that they satisfy the relations (7.9).*

VIII. APPLICATION TO THE KLEIN–GORDON EQUATION

As an example, let us consider the Klein–Gordon equation

$$(g^{ab}\nabla_a\nabla_b - m_\Phi^2)\Phi = 0, \quad (8.1)$$

where $m_\Phi \geqslant 0$ is the mass of the field Φ. ∇_a is the covariant derivative operator associated with the space–time metric g_{ab}. It is straightforward to see that this equation on our background can be expressed, using the invariant operators χ_I, as

$$\left(\frac{-1}{\sqrt{-g}}\frac{\partial}{\partial t}\left(\sqrt{-g}N^{-2}\frac{\partial}{\partial t}\right) + \Delta_q - m_\Phi^2\right)\Phi = 0, \quad (8.2)$$

where Δ_q is the Laplacian with respect to the spatial metric q_{ab},

$$\Delta_q = q_1^{-1}(\chi_1)^2 + q_2^{-1}(\chi_2)^2 + q_3^{-1}(\chi_3)^2, \quad (8.3)$$

and $\sqrt{-g} \equiv \sqrt{-\det\ g_{ab}} = 4|p_3|\beta t N^2$.

Let us consider a generic irreducible component of Φ, i.e., $\Phi = \Phi_{m,n_0}$, $m \neq 0$. We can expand this component as

$$\Phi(t,\mathbf{x}) = \sum_{l=0}^{\infty} a_l(t)\varphi_l(\mathbf{x}), \quad (8.4)$$

where $\varphi_l = \varphi_{l,m,n_0}$ are the mode functions mentioned in Theorem 6.1.

From the relations (4.14), we have

$$(\chi_1)^2\varphi_l = \frac{|\mu|}{2}(\varphi_{l+2} - (2l+1)\varphi_l + l(l-1)\varphi_{l-2}),$$

$$(\chi_2)^2\varphi_l = -\frac{|\mu|}{2}(\varphi_{l+2} + (2l+1)\varphi_l + l(l-1)\varphi_{l-2}), \quad (8.5)$$

$$(\chi_3)^2\varphi_l = -\mu^2\varphi_l,$$

from which we immediately obtain the following wave equations for $a_l(t)$:

$$\ddot{a}_l + \frac{1}{t}\dot{a}_l + Z(t)a_l = I(t;a_{l-2},a_{l+2}), \tag{8.6}$$

where

$$Z(t) \equiv \frac{\mu^2}{16(p_3)^2\beta^2}(1+\beta^2t^{4p_3})^2t^{-2p_3} + m_\Phi^2(1+\beta^2t^{4p_3}) + \frac{2l+1}{2}|\mu|(t^{-2p_1}+t^{-2p_2}), \tag{8.7}$$

with the inhomogeneous term I being

$$I(t;a_{l-2},a_{l+2}) \equiv \frac{|\mu|}{2}(t^{-2p_1}-t^{-2p_2})(a_{l-2}+(l+2)(l+1)a_{l+2}). \tag{8.8}$$

[In $I(t;a_{l-2},a_{l+2})$, a_{l-2} should be regarded zero when $l=0$ and 1.]

Note that the inhomogeneous term I introduces couplings with the next neighboring modes with $l\pm2$. The Eqs. (8.6) therefore comprise two systems of infinite number of equations, the one with $l=$even and the one with $l=$odd, unless the background is LRS. When on the other hand the background is LRS, each equation (8.6) for a given l becomes closed itself, due to the vanishing of the inhomogeneous term I.

When the background is LRS, we can find future ($t\to\infty$) asymptotic solutions.

Proposition 8.1: On the LRS Bianchi II vacuum solution with $p_1=p_2=2/3$ and $p_3=-1/3$, the scalar field equation (8.6) for a generic mode has the following fundamental solutions as $t\to\infty$:

$$y_l^{\pm}(t) = t^{-2/3}e^{\pm i\mu T_{\mathrm{KG}}(t)}(1+o(1)), \tag{8.9}$$

where

$$T_{\mathrm{KG}}(t) \equiv \frac{9}{16\beta}t^{4/3} + \frac{\beta m_\Phi^2}{\mu^2}t^{2/3} + \left(\frac{3\beta}{4} - \frac{8\beta^3m_\Phi^4}{27\mu^4}\right)\log t. \tag{8.10}$$

The symbol $o(1)$ stands for a function such that $\lim_{t\to\infty} o(1)=0$.

Proof: This result is a generalization of Theorem 3.4, Ref. 13, with finite mass m_Φ. As emphasized there, it is an appropriate choice of new time variable that is essential to obtain an asymptotic solution. In the present case an appropriate choice $T(t)$ is given by

$$\frac{\mathrm{d}T}{\mathrm{d}t} = \frac{3}{4\beta}t^{1/3} + \frac{2\beta m_\Phi^2}{3\mu^2}t^{-1/3} + \left(\frac{3\beta}{4} - \frac{8\beta^3m_\Phi^4}{27\mu^4}\right)\frac{1}{t}. \tag{8.11}$$

Following the procedure shown in the reference, one obtains the asymptotic solution (8.9). ■

It is worth noticing that the asymptotic solution only depends on the fiber index m and the other index l does not affect them. See the final section for more discussion.

IX. VECTOR HARMONICS

Let us discuss how we can construct the vector harmonics.

Fortunately, this is on the one hand a trivial issue as the invariant frame $\{\sigma^I,\chi_I\}$ is well defined on the compactified manifold M (and on the space–time manifold $M\times\mathbf{R}$). This means we can define the components $T_{I\cdots}{}^{J\cdots}$ of any type of tensor $T_{a\cdots}{}^{b\cdots}$ with respect to this invariant frame,

$$T_{I\cdots}{}^{J\cdots} = T_{a\cdots}{}^{b\cdots}\chi_I{}^a\cdots\sigma_b{}^J\cdots. \tag{9.1}$$

All we must do is expand these components with respect to the scalar harmonics ϕ_{l,m,n_0} and $\phi^{(0)}_{k_1,k_2}$. This procedure corresponds to using the set of one-forms $\{\phi_l\sigma_a{}^1,\phi_l\sigma_a{}^2,\phi_l\sigma_a{}^3\}_{l=0}^{\infty}$ as vector har-

monics for given $m\neq 0$ and n_0. (As for $m=0$, ϕ_l should of course be replaced by $\phi^{(0)}_{k_1,k_2}$.) On the space–time manifold, we also need the timelike mode vectors, as well as the replacement $\phi_{l,m,n_0} \to \varphi_{l,m,n_0}$. We therefore can define the following harmonics (basis mode vectors):

$$(V'^0_l)_a \equiv \varphi_l(\mathrm{d}t)_a, \quad (V'^1_l)_a \equiv \varphi_l\sigma^1_a, \quad (V'^2_l)_a \equiv \varphi_l\sigma^2_a, \quad (V'^3_l)_a \equiv \varphi_l\sigma^3_a \tag{9.2}$$

(or the one with $\varphi^{(0)}_{k_1,k_2}$ instead of φ_l for $m=0$). We call them the *simple vector harmonics*.

The advantage of considering these harmonics is that they are apparently complete (since the scalar harmonics used are complete). However, this choice of harmonics does not reflect very well the group structure regarding the rotational automorphisms (2.10). A more natural and convenient choice can be obtained by using the "spherical bases"[9] $\mathcal{A}_I$ ($I=1-3$) defined in Eqs. (4.2), or their duals such that $\mathcal{A}_I{}^a\varrho_a{}^J=\delta^J_I$;

$$\varrho^1 \equiv \frac{1}{\sqrt{2}}(\sigma^1 - \varsigma i\sigma^2), \quad \varrho^2 \equiv \frac{1}{\sqrt{2}}(\sigma^1 + \varsigma i\sigma^2), \quad \varrho^3 \equiv \varsigma i\sigma^3. \tag{9.3}$$

Using these we can set up new harmonics as

$$(V^0_l)_a \equiv \varphi_l(\mathrm{d}t)_a, \quad (V^1_l)_a \equiv \varphi_{l+1}\varrho_a{}^1, \quad (V^2_l)_a \equiv \varphi_{l-1}\varrho_a{}^2, \quad (V^3_l)_a \equiv \varphi_l\varrho_a{}^3. \tag{9.4}$$

(When $m=0$ we just use the same harmonics as the simple harmonics.) Beware that $\varphi_{l\pm1}$ are used to define $(V^1_l)_a$ and $(V^2_l)_a$. The reason will become clear below. Because of this index correspondence, we should think that the harmonics $\{(V^I_l)_a\}^3_{I=0}$ are defined for $l\geqslant -1$ (not for $l\geqslant 0$). The basis $(V^I_{-1})_a$ for $l=-1$ is nonzero only for $I=1$, and the others should simply be regarded as zero. We call these harmonics the *polarized vector harmonics* or the *standard vector harmonics*.

We can confirm that for given m, the simple harmonics and the polarized harmonics span the same space of vector fields. This ensures the completeness of the polarized vector harmonics.

Theorem 9.1: *For given fiber index $m\in\mathbf{Z}$ (and given auxiliary index n_0), the linear span of the simple harmonics*

$$\mathrm{Span}(V'^m) \equiv \left\{ \sum_{l=0}^{\infty}\sum_{I=0}^{3} c_{I,l}(V'^I_l)_a \,\middle|\, c_{I,l}\in\mathbf{C} \right\} \quad (m\neq 0) \tag{9.5}$$

(*the $m=0$ case is defined similarly) and that of the polarized harmonics*

$$\mathrm{Span}(V^m) \equiv \left\{ \sum_{l=-1}^{\infty}\sum_{I=0}^{3} c_{I,l}(V^I_l)_a \,\middle|\, c_{I,l}\in\mathbf{C} \right\} \quad (m\neq 0) \tag{9.6}$$

(*the $m=0$ case is defined similarly) are the same*,

$$\mathrm{Span}(V'^m) = \mathrm{Span}(V^m). \tag{9.7}$$

Proof: This is trivial for the $m=0$ case, since in this case the two kinds of harmonics are the same. So, we can assume $m\neq 0$. From the definition (9.4), it is apparent that each basis one-form V^I_l of the polarized harmonics for given m can be expressed as a linear combination of the simple harmonics belonging to the same m. Conversely, each basis one-form V'^I_l of the simple harmonics for given m can be expressed as a linear combination of the polarized harmonics with the same m as

$$V'^0_l = V^0_l,$$

$$V'^1_l = \frac{1}{\sqrt{2}}(V^1_{l-1} + V^2_{l+1}), \tag{9.8}$$

$$V_l'^2 = \frac{si}{\sqrt{2}}(V_{l-1}^1 - V_{l+1}^2),$$

$$V_l'^3 = V_l^3.$$

Therefore the two sets are related by a regular linear transformation, which proves the identity of the two spans. ■

The significance of the polarized harmonics is that for given l (and as usual, given m and n_0), the space spanned by them

$$\mathrm{Span}(V_l) \equiv \left\{ \sum_{I=0}^{3} c_I (V_l^I)_a \,\middle|\, c_I \in \mathbf{C} \right\} \tag{9.9}$$

is invariant under the operation of L^2. To show this, let us start with observing the commutation relations

$$[\mathcal{A}_1, \mathcal{A}_2] = \mathcal{A}_3, \quad [\mathcal{A}_1, \mathcal{A}_3] = 0, \quad [\mathcal{A}_2, \mathcal{A}_3] = 0, \tag{9.10}$$

from which one can immediately have

$$\mathcal{L}_{\mathcal{A}_I} \mathcal{A}_J = [\mathcal{A}_I, \mathcal{A}_J] = \epsilon_{IJ3} \mathcal{A}_3, \tag{9.11}$$

where ϵ_{IJK} is the unit skew symmetric symbol; $\epsilon_{123} = +1$, $\epsilon_{IJK} = \epsilon_{[IJK]}$. Then, noting the duality $A_J^{\ a} \varrho_a^{\ K} = \delta_J^K$, it is also easy to see

$$\mathcal{L}_{\mathcal{A}_I} \varrho^J = -\delta_3^J \epsilon_{IK3} \varrho^K. \tag{9.12}$$

From this equation and the χ relations, as well as the identity

$$\mathsf{L}^2 = \mathcal{L}_{\mathcal{A}_1} \mathcal{L}_{\mathcal{A}_2} + \mathcal{L}_{\mathcal{A}_2} \mathcal{L}_{\mathcal{A}_1}, \tag{9.13}$$

one obtains

$$\mathsf{L}^2(\varphi_l \varrho^I) = -\lambda_l^2 \varphi_l \varrho^I - 2\sqrt{|\mu|}\,\delta_3^I (\varphi_{l+1} \varrho^1 + l \varphi_{l-1} \varrho^2). \tag{9.14}$$

This equation happens to be valid when $I = 0$, as well. Converting to our bases (9.4), we obtain the following statement.

Lemma 9.2: Let V_l^I $(I = 0-3)$ *be the basis mode one-forms defined in Eqs. (9.4), and let* L^2 *be the second order Lie derivative operator defined in Eq. (3.5) . Then, it holds that*

$$\begin{aligned} \mathsf{L}^2 V_l^0 &= -\lambda_l^2 V_l^0, \\ \mathsf{L}^2 V_l^1 &= -\lambda_{l+1}^2 V_l^1, \\ \mathsf{L}^2 V_l^2 &= -\lambda_{l-1}^2 V_l^2, \\ \mathsf{L}^2 V_l^3 &= -\lambda_l^2 V_l^3 - 2\sqrt{|\mu|}(V_l^1 + IV_l^2), \end{aligned} \tag{9.15}$$

where $-\lambda_l^2$ *is the eigenvalue of* L^2 *with respect to the mode function* φ_l*, defined in Eq. (4.15).*

Note that the right-hand sides of Eqs. (9.15) are linear combinations of $\{V_l^I\}_{I=0}^3$ belonging to given l. This proves the invariance we claimed.

Theorem 9.3: *The linear span* $\mathrm{Span}(V_l)$*, defined in Eq. (9.9), of the harmonics* $\{V_l^I\}_{I=0}^3$ *is invariant under the operation of* L^2,

$$\mathsf{L}^2\ \mathrm{Span}(V_l) \subset \mathrm{Span}(V_l). \tag{9.16}$$

Thanks to this property, if the background space–time is LRS and the field equation is invariant under the LRS-action induced by s_θ as well as the usual group action, the ODEs reduced from the field equation become all independent from the others. In other words, "each l" decouples from the others in case of LRS. (This property does not occur for the simple harmonics, since the linear span of them for a given l is *not* L^2 invariant.)

Before ending this section let us mention the approach taken in Ref. 13, Sec. III, which was based on the analogy of the spherically symmetric case[11] or the Bianchi III hyperbolically symmetric case.[17] Let us denote the harmonics used in the reference with double primes like $(V_l''^I)_a$. $V_l''^0$ and $V_l''^3$ are defined in the same way (up to constant multiplication factor) as the polarized ones,

$$V_l''^0 = V_l^0, \quad V_l''^3 = \varsigma\mu V_l^3. \tag{9.17}$$

$V_l''^0$ is called the *timelike basis one-form*, while $V_l''^3$ is called the *fiber basis one-form*. Let us then consider the "plane field" spanned by χ_1 and χ_2, which is horizontal to the base manifold. This horizontal plane field is invariant under the natural actions of the fibers generated by χ_3. We define the "area two-form" ε of this field by $\varepsilon_{ab}=2\sigma^1{}_{[a}\sigma^2_{b]}$ (although the plane field is not integrable). We define the *horizontal gradient (HG) basis one-form* (corresponding to the "even" one-form[11,17]) by taking gradient of the scalar harmonics and subtracting the fiber part,

$$(V_l''^1)_a = \partial_a\varphi_l - (V_l''^3)_a = (\chi_1\varphi_l)\sigma_a{}^1 + (\chi_2\varphi_l)\sigma_a{}^2 = \sqrt{\frac{|\mu|}{2}}(-(\varphi_{l+1} - l\varphi_{l-1})\sigma_a{}^1 + \varsigma i(\varphi_{l+1} + l\varphi_{l-1})\sigma_a{}^2). \tag{9.18}$$

And, we define the *dual horizontal gradient (DHG) basis one-form* (corresponding to the "odd" one-form) by taking the dual gradient associated with ε,

$$(V_l''^2)_a = i\varepsilon_a{}^b\partial_b\varphi_l = i((\chi_2\varphi_l)\sigma_a{}^1 - (\chi_1\varphi_l)\sigma_a{}^2) = \sqrt{\frac{|\mu|}{2}}(-\varsigma(\varphi_{l+1} + l\varphi_{l-1})\sigma_a{}^1 + i(\varphi_{l+1} - l\varphi_{l-1})\sigma_a{}^2). \tag{9.19}$$

To raise an index for ε_{ab} we use the (inverse of the) standard Bianchi II metric $h^{(0)ab}=\chi_1{}^a\chi_1{}^b + \chi_2{}^a\chi_2{}^b + \chi_3{}^a\chi_3{}^b$. It is clear that the harmonics $V_l'' \equiv \{(V_l''^I)_a\}_{I=0}^3$ are equivalent (i.e., their span is the same) to the polarized harmonics $V_l \equiv \{(V_l^I)_a\}_{I=0}^3$ *for each* l, since they are merely related to each other by a regular linear transformation, as seen from the relations

$$V_l''^1 = -\sqrt{|\mu|}(V_l^1 - IV_l^2), \quad V_l''^2 = -\varsigma\sqrt{|\mu|}(V_l^1 + IV_l^2), \tag{9.20}$$

as well as (9.17). We call these harmonics the *mixed vector harmonics*. This choice is particularly convenient for Maxwell's equation, since the U(1)-gauge transformation, $A_a \to A_a + \partial_a f$, does not affect the component for the DHG basis one-form (9.19). (As a result, this component itself becomes gauge invariant. See the next section.)

X. APPLICATION TO MAXWELL'S EQUATION

As an application let us consider the source-free Maxwell equation $\nabla^a F_{ab} = 0$. Since the electromagnetic field F_{ab} is given by (twice) the exterior derivative of the vector potential A_a; $F_{ab} = \partial_a A_b - \partial_b A_a$, this equation can be dealt with by vector harmonics.

Let us consider the irreducible component belonging to given $m \neq 0$ and n_0. For this component we can expand the vector potential as follows:

$$A_a = \sum_{l=-1}^{\infty} \sum_{I=0}^{3} \gamma_I^{(l)}(t)(V_l''^I)_a, \tag{10.1}$$

where $(V_l''^I)_a$ are the mixed vector harmonics. The four kinds of functions of time $\gamma_I^{(l)}(t)$ ($I = 0-3$) serve as the field variables.

The quantities we are interested in are the U(1)-gauge invariant variables, which can be easily found by inspecting components of the field strength $F_{ab} = \partial_a A_b - \partial_b A_a$. We obtain the following four independent U(1)-invariant variables:

$$Q_1^{(l)} = \gamma_1^{(l)} - \gamma_3^{(l)}, \quad Q_2^{(l)} = \gamma_2^{(l)}, \quad P_1^{(l)} = \dot{\gamma}_1^{(l)} - \gamma_0^{(l)}, \quad P_2^{(l)} = \dot{\gamma}_2^{(l)}. \tag{10.2}$$

Although function $P_3 \equiv \dot{\gamma}_3 - \gamma_0$ is also invariant, it is found that it can be (consistently) solved with the others, due to the constraint part of Maxwell's equation $0 = (\partial_t)^a \nabla^b F_{ab}$, which can be written, using the invariant operator, as

$$0 = N^{-1}(q_1^{-1}\chi_1 \dot{A}_1 + q_2^{-1}\chi_2 \dot{A}_2 + q_3^{-1}\chi_3 \dot{A}_3) - \Delta_q A_0, \tag{10.3}$$

where $A_0 \equiv N^{-1}(\partial_t)^a A_a$ and $A_I \equiv \chi_I^a A_a$ ($I = 1-3$). Laplacian Δ_q is given in Eq. (8.3). The evolution equations $0 = \chi_I^a \nabla^b F_{ab}$ ($I = 1-3$) can similarly be written

$$\begin{aligned} 0 = &- N^{-1}\dot{F}_{0I} + q_1^{-1}\chi_1 F_{1I} + q_2^{-1}\chi_2 F_{2I} + q_3^{-1}\chi_3 F_{3I} + N^{-1}q_I^{-1}\dot{q}_I F_{0I} - (2N)^{-1}(q_1^{-1}\dot{q}_1 + q_2^{-1}\dot{q}_2 + q_3^{-1}\dot{q}_3)F_{0I} \\ &+ (q_1 q_2)^{-1} q_3 \delta_I^3 F_{12} \end{aligned} \tag{10.4}$$

(no sum for repeated indices), where $F_{0I} \equiv N^{-1}(\partial_t)^a \chi_I^{\ b} F_{ab}$ and $F_{IJ} \equiv \chi_I^{\ a}\chi_J^{\ b} F_{ab}$. After a rather lengthy computation they become the following:

$$\begin{aligned} \dot{Q}_1^{(l)} &= P_1^{(l)} + \frac{(q_1^{-1} + q_2^{-1})q_3}{2|\mu|}((2l+1)P_1^{(l)} + \varsigma P_2^{(l)}) + I_{Q_1}, \\ \dot{Q}_2^{(l)} &= P_2^{(l)}, \\ \dot{P}_1^{(l)} &= \left(\frac{\dot{N}}{N} - \frac{1}{2}\frac{\dot{q}_3}{q_3}\right)P_1^{(l)} - \mu^2 \frac{N^2}{q_3} Q_1^{(l)} + I_{P_1}, \\ \dot{P}_2^{(l)} &= \left(\frac{\dot{N}}{N} - \frac{1}{2}\frac{\dot{q}_3}{q_3}\right)P_2^{(l)} - \mu^2 \frac{N^2}{q_3} Q_2^{(l)} - \frac{\mu}{2} N^2 (q_1^{-1} + q_2^{-1})(Q_1^{(l)} + \varsigma(2l+1)Q_2^{(l)}) + I_{P_2}, \end{aligned} \tag{10.5}$$

where the inhomogeneous terms are

$$I_{Q_1} \equiv -\frac{(q_1^{-1}-q_2^{-1})q_3}{2|\mu|}\{(l+2)(l+1)(P_1^{(l+2)}-\varsigma P_2^{(l+2)})+(P_1^{(l-2)}+\varsigma P_2^{(l-2)})\},$$

$$I_{P_1} \equiv \frac{N^2}{4}(q_1^{-1}-q_2^{-1})|\mu|\{(l+2)(Q_1^{(l+2)}+\varsigma(2l+5)Q_2^{(l+2)})-l^{-1}(Q_1^{(l-2)}+\varsigma(2l-3)Q_2^{(l-2)})\}$$
$$-\frac{1}{4}\left(\frac{\dot q_1}{q_1}-\frac{\dot q_2}{q_2}\right)\{(l+2)(P_1^{(l+2)}-\varsigma P_2^{(l+2)})+l^{-1}(P_1^{(l-2)}+\varsigma P_2^{(l-2)})\}, \tag{10.6}$$

$$I_{P_2} \equiv \frac{N^2}{4}(q_1^{-1}-q_2^{-1})|\mu|\{(l+2)(\varsigma Q_1^{(l+2)}+(2l+5)Q_2^{(l+2)})+l^{-1}(\varsigma Q_1^{(l-2)}+(2l-3)Q_2^{(l-2)})\}$$
$$-\frac{1}{4}\left(\frac{\dot q_1}{q_1}-\frac{\dot q_2}{q_2}\right)\{(l+2)(\varsigma P_1^{(l+2)}-P_2^{(l+2)})-l^{-1}(\varsigma P_1^{(l-2)}+P_2^{(l-2)})\}.$$

Again, we can see the same qualitative features in the Klein–Gordon equations; we have two systems of infinite number of equations, the one with $l=$even and the one with $l=$odd, unless the background is LRS. When the background is LRS, the couplings between mode l and the next neighbors $l\pm2$ are cut off due to the vanishing of the inhomogeneous terms I_{Q_1}, I_{P_1} and I_{P_2} and this makes each system of four first-order equations (10.5) for given l closed itself. This is of course a result of the invariance described in Theorem 9.3.

XI. CONCLUSION

There are three main results about basic properties for the nilgeometric harmonics obtained in this paper. They are (i) the irreducible decomposition of the regular representation (Theorem 1.1), (ii) the explicit form of the mode functions, and (iii) the differential representation formula, the χ relations [see Eqs. (4.14) and (7.6)]. The decomposition (i) represents the completeness of our harmonics. As for the point (ii), remember that we have two kinds of formula, the one for the canonical manifold and the one for the space–time manifold. The former is given in Eqs. (5.8) and (7.3), while the latter is obtained by the transformations explicitly given in Secs. VI and VII. Remember also that the χ relations are the most important for the purpose of separation of variables. We also have generalized the (scalar) harmonics to vector harmonics, and demonstrated separation of variables for a scalar equation (the Klein–Gordon equation) and a vector equation (the Maxwell equation).

As we have seen, when the fiber index m is nonzero the ODEs reduced from a field equation, e.g., the ones from the KG equation, become systems of *infinite number of* simultaneous equations. In this sense, infinite number of different modes are coupled to each other. This is a result of the fact that the corresponding irreducible representation is infinite dimensional. When the background is LRS however, the couplings between the modes are cut off and as a result, each single reduced KG equation becomes closed itself. Although the Maxwell equations give rise to much more complicated reduced equations because of the multiple components of the field variable, it has the same feature that the couplings between modes disappear when the background is LRS. It is also apparent that the linear perturbation equations will have the same feature if we choose the tensor harmonics so as to possess the invariance under L^2 like the vector harmonics do (cf. Theorem 9.3).

An interesting fact is that as shown in Sec. VIII, the future asymptotic solution of the LRS KG wave equation depends only on the fiber index m and does not depend on the spin index l. This fact seems to indicate a clue for analyzing the generic non-LRS cases, since it suggests that the couplings between the modes asymptotically disappear even when the background is non-LRS, at least if the background is close enough to the LRS one. See Ref. 14 for the same ("fiber term

dominated") behavior of other models (Bianchi VIII and III). Detailed studies of the non-LRS cases, as well as linear perturbations of the nilgeometric model, will be reported elsewhere, on the basis of this work.

ACKNOWLEDGMENTS

The author wishes to thank Vincent Moncrief for helpful discussions, especially at an early stage of this work. The author is also grateful to the organizers, including Akio Hosoya and Tatsuhiko Koike, and the participants of the *5th Workshop on Singularity, Spacetime and Related Physics* held at Keio University, Yokohama, December 19–21, 2003, for the kind invitation and many beneficial comments.

[22] The "left" regular representation can also be defined similarly. We take the "right" one for the reason explained below.
[23] In Refs. 10, 15, and 16, the second component of $\mathbf{a}_1$ was taken zero instead of the first component of $\mathbf{a}_2$. It is however not difficult to see that those two choices are equivalent (*conjugate*) to each other following the procedure shown in the same references. The present parametrization will be proved more convenient for our purpose.
[24] While Isom $\mathcal{N}$ is four-dimensional, the extra isometries are not necessary for us to represent $\mathbf{a}_i$, resulting in $\mathbf{a}_i \in G_{\mathrm{II}}$ here. Remark however that to obtain this representation the fourth-dimensional isometries play an essential role, especially to delete the first component of $\mathbf{a}_2$.
[25] Like this, we consider any functions on M or $\overline{M}$ as functions on the universal cover $\tilde{M}=\mathbf{R}^3$. If $f(Ax)=f(x)$ holds we regard $f(x)$ as a function on $M=A\backslash\tilde{M}$. Similarly, If $f(\overline{A}x)=f(x)$ holds, $f(x)$ is a function on $\overline{M}=\overline{A}\backslash\tilde{M}$. Those functions are called *automorphic functions*.
[26] We could impose a unitary condition on $\mathcal{A}_i$ $(i=1,2)$ to make the choice of α_l and β_l unique, although there is no strong reason to do so for our purpose. On the other hand, our present choice (4.10) makes the final formula [see Eqs. (4.14)] to some extent simpler, with less square roots appearing in the formula than in the one obtained requiring the unitary condition. It is however easy to convert the resulting mode functions into those for unitary $\mathcal{A}_i$. See the last paragraph of Sec. V.
[27] We are assuming that the action of A on the space–time manifold $\tilde{M}\times\mathbf{R}$ is defined by $A\circ(\mathbf{x},t)=(A\circ\mathbf{x},t)$, $(\mathbf{x},t)\in\tilde{M}\times\mathbf{R}$. (Apparently, the same equality for Γ defines its action on $\tilde{M}$.)
[28] The parametrization among the free parameters has been rearranged from Ref. 15 so that it is convenient for our purpose.

[29] Although we use, for convenience, the same symbols θ, u, δ, and v as in A here, it is worth emphasizing that their meaning is distinctly different; those in Γ are moduli parameters of *space–time*, while those in A are the Teichmüller (or moduli) parameters of *space*, which are functions of time in space–time (Refs. 15 and 16). The space–time moduli parameters parametrize the admissible initial values and velocities of the Teichmüller parameters.

(Received 1 October 2003; accepted 7 September 2004;
published 24 November 2004)

The Hughston–Jozsa–Wootters theorem shows that any finite ensemble of quantum states can be prepared "at a distance," and it has been used to demonstrate the insecurity of all bit commitment protocols based on finite quantum systems without superselection rules. In this paper, we prove a generalized HJW theorem for arbitrary ensembles of states on a C^*-algebra. We then use this result to demonstrate the insecurity of bit commitment protocols based on infinite quantum systems, and quantum systems with Abelian superselection rules. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1812827]

I. INTRODUCTION

Recent work in quantum cryptography has focused on questions of which sorts of information-transfer protocols are secure from attempts at cheating by an intruder or by one of the participants. As early as 1984, the question was raised whether quantum theory would permit a secure bit commitment protocol, i.e., a protocol in which a bit of information is committed by one party Alice to another party Bob, such that Alice cannot change her commitment, and such that Bob cannot determine Alice's commitment until given further information by Alice. An initial protocol using pairs of polarized photons was proposed by Bennett and Brassard;[2] however, Bennett and Brassard showed that this protocol can be cheated by exploiting the nonlocal correlations of the EPR-Bohm state.

A number of other quantum bit commitment protocols have been proposed in the intervening years (see Refs. 3, 4, and 6 for reviews). Most of these protocols rely on the fact that a non-pure-density operator corresponds to more than one ensemble of quantum states. In particular, two different ensembles on a composite system can induce the same density operator on a local system. Thus, if Alice encodes her bits into these two ensembles, then Bob cannot possibly determine Alice's commitment until she provides further information about the composite system.

However, Lo and Chau[15] and Mayers[16,17] show that, as a consequence of the Hughston–Jozsa–Wootters (HJW) theorem, if a bit commitment protocol is concealing against Bob, then it is not binding against Alice. (Kent's[12] relativistic bit commitment protocol does not rely on the existence of alternative decompositions of a density operator, and so its security is not challenged by the Mayers–Lo–Chau result.) That is, if the ensembles prepared in the protocol are indistinguishable to Bob (i.e., correspond to approximately the same local density operator), then Alice can "steer" between these ensembles after the Commit stage of the protocol.

HJW Theorem:[10] *Let $\mathcal{H}_A$ and $\mathcal{H}_B$ be finite-dimensional Hilbert spaces, let $\{D_i\}_{i=1}^n$ be density operators on $\mathcal{H}_B$, and let x be a unit vector in $\mathcal{H}_A \otimes \mathcal{H}_B$ such that $\mathrm{Tr}_A(P_x) = \Sigma_{i=1}^n \lambda_i D_i$. Then there are positive operators $\{A_i\}_{i=1}^n$ in $\mathcal{B}(\mathcal{H}_A) \otimes I$ such that*

$$\langle A_i^{1/2} x | B A_i^{1/2} x \rangle = \lambda_i \mathrm{Tr}(D_i B), \tag{1}$$

[a)]Electronic mail: hhalvors@princeton.edu

for all $B \in I \otimes \mathcal{B}(\mathcal{H}_B)$.

Thus, the HJW theorem shows that any *finite* decomposition of $\mathrm{Tr}_A(P_x)$ can be prepared from the state P_x by a measurement operation on $\mathcal{H}_A$. However, all nonpure density operators have countably infinite convex decompositions, as well as uncountably infinite integral decompositions. For the case of countably infinite decompositions, Cassinelli *et al.*[7] have proved a generalized HJW theorem, but their results do not cover the case of integral decompositions. What is more, the HJW theorem and its generalization by Cassinelli *et al.* apply only to a very narrow class of quantum systems—namely those whose observables are represented by type I von Neumann factors. Thus, these results do not directly establish the insecurity of bit commitment protocols that employ systems with nontrivial superselection rules (represented by direct sums of type I von Neumann factors), or bit commitment protocols that employ infinite quantum systems (represented by type II or type III von Neumann algebras).

In this paper, we prove a generalized HJW theorem for arbitrary ensembles of states on a C^*-algebra. We show first (in Sec. II) that each measure on the state space of a C^*-algebra $\mathcal{B}$ gives rise to a positive-operator-valued measure with range in the commutant $\mathcal{B}'$ of $\mathcal{B}$. (This first result is completely general, and does not impose any restrictions on the C^*-algebra $\mathcal{B}$.) We then show that when $\mathcal{B}'$ is a hyperfinite von Neumann algebra, there is a completely positive instrument that prepares the relevant ensemble of states on $\mathcal{B}$. In Sec. III we apply our results to the question of the security of bit commitment protocols.

II. GENERALIZED HJW THEOREM

Our first result (Theorem 1) shows that for any C^*-algebra $\mathcal{B}$ of operators acting on a Hilbert space $\mathcal{H}$, a measure on the state space of $\mathcal{B}$ gives rise to a corresponding POV measure with values in the commutant $\mathcal{B}' = \{A \in \mathcal{B}(\mathcal{H}) : [A,B] = 0 \text{ for all } B \in \mathcal{B}\}$. For the case that $\mathcal{B} = I \otimes \mathcal{M}_n$, where $\mathcal{M}_n$ is the C^*-algebra of $n \times n$ matrices over $\mathbb{C}$, our result yields an alternate proof of the original HJW theorem.

Let K denote the compact convex set of states of $\mathcal{B}$ with the weak* topology. [A net $\{\omega_a\}_{a \in \mathbb{A}}$ of states of $\mathcal{B}$ converges in the weak* topology to a state ω just in case, for each $B \in \mathcal{B}, \lim_a \omega_a(B) = \omega(B)$. If $\mathcal{B} = \mathcal{M}_n$, then the weak* topology on states is equivalent to the standard topology on density operators.] In this paper, we consider positive regular measures on (K, Σ), where Σ is the Borel σ-algebra of K. When we say that μ is a measure, it can be assumed that μ is positive and regular.

Definition (Ref. 1, p. 12): If μ is a measure on the state space K, then the state

$$\rho_\mu = \mu(K)^{-1} \int x \, d\mu(x), \tag{2}$$

is called the *barycenter* of μ. Measures μ and ν on K are said to be *equivalent* if they have the same barycenter.

Let K be the convex set of density operators on $\mathbb{C}^n$. If ρ is a density operator and μ is a finitely supported measure on K with barycenter ρ, then Hughston *et al.* call μ a *ρ-ensemble*. So, the set of ρ-ensembles consists of those measures on K that have barycenter ρ, and that are supported on a finite set. In this paper, we consider all measures with barycenter ρ, and not just those with finite support.

Notation: If x is a vector in $\mathcal{H}$, we let $\omega_x(A) = \langle x | Ax \rangle$, for all $A \in \mathcal{B}(\mathcal{H})$. If $\mathcal{B}$ is a set of operators on $\mathcal{H}$, we let $\mathcal{B}x = \{Bx : B \in \mathcal{B}\}$, and we let $[\mathcal{B}x]$ denote the closed linear span of $\mathcal{B}x$.

Lemma 1 (Ref. 11, Proposition. 7.3.5): If $\mathcal{B}$ is a C^*-algebra of operators acting on the Hilbert space $\mathcal{H}$ and ρ is a positive linear functional on $\mathcal{B}$ such that $\rho \leqslant \omega_x|_{\mathcal{B}}$ for some vector x in $\mathcal{H}$, then there is a positive operator H in the unit ball of $\mathcal{B}'$ such that $\rho(A) = \omega_x(HA) = \omega_{H^{1/2}x}(A)$, for all $A \in \mathcal{B}$.

Proof: Define a conjugate-bilinear functional φ on $\mathcal{B}x$ by setting $\varphi(Ax, Bx) = \rho(A^*B)$. Then,

$$|\varphi(Ax,Bx)|^2 = |\rho(A^*B)|^2 \leq \rho(A^*A)\rho(B^*B) \leq \|Ax\|^2\|Bx\|^2. \tag{3}$$

The first inequality follows from the Cauchy–Schwartz inequality for the inner product $\langle A|B\rangle_\rho = \rho(A^*B)$ on $\mathcal{B}$. Thus φ is positive and bounded by 1. It follows that φ has a unique extension to the subspace $[\mathcal{B}x]$. Moreover, the Riesz representation theorem entails that there is a positive operator H on $[\mathcal{B}x]$ such that $\|H\| \leq 1$ and $\varphi(Ax,Bx) = \langle Ax|HBx\rangle$. In particular, $\rho(A) = \langle x|HAx\rangle = \omega_x(HA)$ for all $A \in \mathcal{B}$. Extend H to the entire Hilbert space $\mathcal{H}$ by setting it to zero on $\mathcal{H} \ominus [\mathcal{B}x]$. Since

$$\langle Ax|HCBx\rangle = \rho(A^*CB) = \rho((C^*A)^*B) \tag{4}$$

$$= \langle C^*Ax|HBx\rangle = \langle Ax|CHBx\rangle \tag{5}$$

for all C in $\mathcal{B}$, it follows that $[H,C]=0$ on $[\mathcal{B}x]$. Since $[H,C]=0$ on $\mathcal{H} \ominus [\mathcal{B}x]$, it follows that $[H,C]=0$ on the entire Hilbert space. Therefore, $H \in \mathcal{B}'$. □

The following result is a special case of a theorem proved by Tomita[25] in 1956 (compare with Ref. 5, Lemma 4.1.21, Proposition 4.1.22).

Theorem 1: *Let $\mathcal{B}$ be a C^*-algebra acting on the Hilbert space $\mathcal{H}$, and let μ be a probability measure on the state space of $\mathcal{B}$. If there is a unit vector x in $\mathcal{H}$ such that $\omega_x|_{\mathcal{B}}$ is the barycenter of μ, then there is a POV measure* **A** *with range in $\mathcal{B}'$ such that*

$$\langle A(S)^{1/2}x|BA(S)^{1/2}x\rangle = \int_S \omega(B)d\mu(\omega), \tag{6}$$

for all $S \in \Sigma$ and $B \in \mathcal{B}$.

Proof: Let S be a Borel subset of the state space of $\mathcal{B}$, and let $\rho_S = \int_S \omega d\mu(\omega)$. Then ρ_S is a positive linear functional on $\mathcal{B}$ with $\rho_S \leq \omega_x|_{\mathcal{B}}$. By Lemma 1, there is a positive operator $A(S)$ in the unit ball of $\mathcal{B}'$ such that $\rho_S(B) = \omega_x(A(S)B)$ for all $B \in \mathcal{B}$, and $A(S)=0$ on $\mathcal{H} \ominus [\mathcal{B}x]$. In order to verify that $S \mapsto A(S)$ is countably additive, suppose that $\{S_i : i \in \mathbb{N}\}$ are disjoint Borel subsets, and let $S = \cup_{i=1}^{\infty} S_n$. Then for fixed $B \in \mathcal{B}$,

$$\sum_{i=1}^{\infty} \chi_{S_i}(\omega) \cdot \omega(B) = \chi_S(\omega) \cdot \omega(B), \tag{7}$$

and so the monotone convergence theorem entails that

$$\sum_{i=1}^{\infty} \left(\int_{S_i} \omega(B)d\mu(\omega) \right) = \int_S \omega(B)d\mu(\omega) = \langle x|A(S)Bx\rangle. \tag{8}$$

Furthermore, countable additivity of the map $Z \mapsto \langle x|ZBx\rangle$ entails that

$$\left\langle x \middle| \left(\sum_{i=1}^{\infty} A(S_i) \right) Bx \right\rangle = \sum_{i=1}^{\infty} \langle x|A(S_i)Bx\rangle. \tag{9}$$

Replacing B with B^*C, where $B,C \in \mathcal{B}$, we have

$$\left\langle Bx \middle| \sum_{i=1}^{\infty} A(S_i)Cx \right\rangle = \langle Bx|A(S)Cx\rangle, \tag{10}$$

and therefore $(\Sigma_{i=1}^{\infty} A(S_i))y = A(S)y$, for all $y \in [\mathcal{B}x]$. Since $A(S)=0$ on $\mathcal{H} \ominus [\mathcal{B}x]$, it follows that $\Sigma_{i=1}^{\infty} A(S_i) = A(S)$. □

Thus, if μ is a measure on the state space of Bob's algebra $\mathcal{B}$, Alice's algebra $\mathcal{A}=\mathcal{B}'$ contains the range of a POV measure $\mathbf{A}$ satisfying Eq. (6). But this does not yet yield the conclusion that Alice can prepare the ensemble μ on Bob's system—for that, we need to show that Alice has an "instrument" corresponding to the POV measure $\mathbf{A}$.

Definition:[9,19] Let (X,Σ) be a Borel space. A *completely positive (CP) instrument* on $\mathcal{B}(\mathcal{H})$ is a map $\mathcal{E}:\Sigma\times\mathcal{B}(\mathcal{H})\to\mathcal{B}(\mathcal{H})$ such that

(1) for fixed $B\in\mathcal{B}(\mathcal{H})$, $\mathcal{E}[\cdot](B)$ is σ-additive in the weak-operator topology;
(2) for fixed $S\in\Sigma$, $\mathcal{E}[S](\cdot)$ is a completely positive linear map such that $\mathcal{E}[S](I)\leqslant I$.

Since the map $\mathcal{E}[S](\cdot),(S\in\Sigma)$, is positive, it is automatically norm-continuous. If, in addition, each such map is weak-operator continuous on bounded sets, then $\mathcal{E}$ is said to be *normal*. [A net $\{A_a\}_{a\in\mathbb{A}}$ of bounded operators on $\mathcal{H}$ converges in the weak-operator topology to an operator A just in case $\lim_a\langle x|A_a y\rangle=\langle x|Ay\rangle$ for all vectors x,y in $\mathcal{H}$.] However, we do not require instruments to be normal, because continuous PV measures give rise to non-normal instruments,[9,23] and a continuous ensemble of states on $\mathcal{B}$ will give rise to a continuous PV measure in $\mathcal{B}'$.

Each instrument $\mathcal{E}$ determines a unique POV measure $\mathbf{A}$ via the formula

$$A(S)\equiv\mathcal{E}[S](I)\quad(S\in\Sigma). \tag{11}$$

If Eq. (11) holds for an instrument $\mathcal{E}$ and a POV measure $\mathbf{A}$, then $\mathcal{E}$ and $\mathbf{A}$ are said to be *compatible*. For any given POV measure $\mathbf{A}$, there are many instruments that are compatible with $\mathbf{A}$. In fact, if Φ is a CP projection of $\mathcal{B}(\mathcal{H})$ with $\mathrm{ran}(\Phi)\subseteq\mathrm{ran}(\mathbf{A})'$, then

$$\mathcal{E}[S](B)=A(S)\Phi(B)\quad(S\in\Sigma,B\in\mathcal{B}(\mathcal{H})) \tag{12}$$

is compatible with $\mathbf{A}$. In particular, if ρ is a state on $\mathcal{B}(\mathcal{H})$, then

$$\mathcal{E}[S](B)=A(S)\rho(B)\quad(S\in\Sigma,B\in\mathcal{B}(\mathcal{H})) \tag{13}$$

is compatible with $\mathbf{A}$.

Thus, given a POV measure $\mathbf{A}$ with range in Alice's algebra $\mathcal{A}=\mathcal{B}'$, we can easily find an instrument $\mathcal{E}$ that is compatible with $\mathbf{A}$. However, it does not follow that Alice can in any sense measure $\mathbf{A}$ with the instrument $\mathcal{E}$, because $\mathcal{E}$ may not be "local" to Alice's system. In particular, an instrument that is local to Alice's system should not disturb the statistics of measurements of observables in Bob's algebra $\mathcal{B}=\mathcal{A}'$. In other words, for any state ρ on $\mathcal{B}$, the equation

$$\rho(\mathcal{E}[X](B))=\rho(B) \tag{14}$$

should hold for all $B\in\mathcal{B}$. But Eq. (14) holds for all states ρ on $\mathcal{B}$ iff the CP map $\mathcal{E}[X](\cdot)$ is the identity on $\mathcal{B}$. Thus, we capture the locality requirement with the following definition.

Definition: An instrument $\mathcal{E}$ is *local* to an algebra $\mathcal{A}$ just in case $\mathcal{E}[S](B)=\mathcal{E}[S](I)B$, for all $B\in\mathcal{A}'$ and $S\in\Sigma$.

Of course, if $\mathbf{A}$ is a POV measure on $\mathbb{N}$, there is a canonical instrument $\mathcal{E}^{\mathbf{A}}$ that is compatible with $\mathbf{A}$ and local to any algebra containing $\mathrm{ran}(\mathbf{A})$:

$$\mathcal{E}^{\mathbf{A}}[S](B)=\sum_{n\in S}A_n^{1/2}BA_n^{1/2}\quad(S\subseteq\mathbb{N},B\in\mathcal{B}(\mathcal{H})). \tag{15}$$

We wish to extend this result to show that for each POV measure $\mathbf{A}$ with range in a C^*-algebra $\mathcal{A}$, there is a CP instrument $\mathcal{E}^{\mathbf{A}}$ that is compatible with $\mathbf{A}$ and local to $\mathcal{A}$. In this paper, we prove this result for finite quantum systems (Theorem 2), and for infinite quantum systems that can be approximated, in an appropriate sense, by finite quantum systems (Theorem 3). While our proof for the finite case uses only elementary linear algebra, our proof for the infinite case is nonconstructive (i.e., invokes the axiom of choice in the form of the Tychonoff product theorem), and uses tools from the theory of operator algebras.

We first show that if Alice has a finite quantum system, then she can perform a "maximally disturbing" local operation—i.e., an operation that maps all her states to the maximally mixed state.

Lemma 2: If $\mathcal{A}$ is finite-dimensional C^*-algebra on the Hilbert space $\mathcal{H}$, then there is a completely positive projection Φ from $\mathcal{B}(\mathcal{H})$ onto $\mathcal{A}'$. In particular, Φ maps $\mathcal{A}$ onto $\mathbb{C}I$.

Proof (Compare with Ref. 11, Proposition 8.3.11, and Ref. 22): Since $\mathcal{A}$ is finite-dimensional, $\mathcal{A}=\bigoplus_{i=1}^{m}\mathcal{M}_{n(i)}$ for some positive integers $n(1),\ldots,n(m)$. Consider the following statement:

(†) There is a projective unitary representation $g\mapsto W(g)$ of a finite group G in $\mathcal{A}$ such that $\{W(g):g\in G\}$ spans $\mathcal{A}$.

We first show that (†) holds when $\mathcal{A}=\mathcal{M}_n$. Let $\{|0\rangle,\ldots,|n-1\rangle\}$ be a basis for $\mathbb{C}^n$, and for each $g\in\mathbb{Z}_n\times\mathbb{Z}_n$ let $W(g)$ be the unitary operator on $\mathbb{C}^n$ defined by

$$W(g)|a\rangle = e^{ig_1a}|a+g_2\rangle \quad (a=1,\ldots,n). \tag{16}$$

Then $g\mapsto W(g)$ is a projective representation of $\mathbb{Z}_n\times\mathbb{Z}_n$ with bicharacter $\xi(g,h)=e^{ig_1h_2}$; i.e., $W(g)W(h)=e^{ig_1h_2}W(g+h)$. Furthermore, $\{W(g):g\in\mathbb{Z}_n\times\mathbb{Z}_n\}$ is an orthonormal basis for $\mathcal{M}_n$ relative to the inner product $\langle A|B\rangle_2=\mathrm{Tr}(A^*B)$. Thus, we have established (†) for the case that $\mathcal{A}=\mathcal{M}_n$. We now show that (†) holds when $\mathcal{A}=\bigoplus_{i=1}^{m}\mathcal{M}_{n(i)}$. Indeed, let

$$G=\bigoplus_{i=1}^{m}[\mathbb{Z}_{n(i)}\times\mathbb{Z}_{n(i)}], \tag{17}$$

and take the direct sum of the corresponding projective representations.

We now show that if (†) holds, then there is a CP projection from $\mathcal{B}(\mathcal{H})$ onto $\mathcal{A}'$. For each $g\in G$, define an automorphism α_g of $\mathcal{B}(\mathcal{H})$ by

$$\alpha_g(A)=W(g)^*AW(g) \quad (B\in\mathcal{B}(\mathcal{H})). \tag{18}$$

Then $\mathcal{G}=\{\alpha_g:g\in G\}$ is a finite group of automorphisms of $\mathcal{B}(\mathcal{H})$. If $\alpha(A)=A$ for all $\alpha\in\mathcal{G}$, then $AW(g)=W(g)A$ for all $g\in G$, and $A\in\mathcal{A}'$. Thus,

$$\Phi(A)=|\mathcal{G}|^{-1}\sum_{\alpha\in\mathcal{G}}\alpha(A) \quad (A\in\mathcal{B}(\mathcal{H})) \tag{19}$$

is a CP projection from $\mathcal{B}(\mathcal{H})$ onto $\mathcal{A}'$. □

We are now prepared to prove a generalized HJW theorem, valid for all finite quantum systems (i.e., systems whose algebra of observables is finite-dimensional). In particular, if the C^*-algebra $\mathcal{B}'$ is finite-dimensional, then the product $\Phi\otimes\mathbf{A}$ of the maximally disturbing operation Φ (from Lemma 2) and the POV measure $\mathbf{A}$ (from Theorem 1) yields an instrument that prepares the ensemble μ on system $\mathcal{B}$.

Theorem 2 (Generalized HJW Theorem): *Let $\mathcal{B}$ be a C^*-algebra acting on the Hilbert space $\mathcal{H}$, let x be a unit vector in $\mathcal{H}$, and let μ be a measure on the state space of $\mathcal{B}$ such that $\omega_x|_{\mathcal{B}}$ is the barycenter of μ. If $\mathcal{B}'$ is finite-dimensional, then there is a CP instrument $\mathcal{E}$ on $\mathcal{B}(\mathcal{H})$ that is local to $\mathcal{B}'$ and*

$$\langle x|\mathcal{E}[S](B)x\rangle=\int_S\omega(B)d\mu(\omega), \tag{20}$$

for all $S\in\Sigma$ and $B\in\mathcal{B}$.

Proof: By Lemma 2, there is a CP projection Φ from $\mathcal{B}(\mathcal{H})$ onto $\mathcal{A}'$. Let $\mathcal{E}=\Phi\otimes\mathbf{A}$, where $\mathbf{A}$ is the POV measure defined in Theorem 1. That is,

$$\mathcal{E}[S](B)=\Phi(B)A(S), \tag{21}$$

for all $S\in\Sigma$ and $B\in\mathcal{B}(\mathcal{H})$. □

This generalized HJW theorem applies to bit commitment protocols that employ continuous ensembles on finite quantum systems (e.g., continuous measures on the Bloch sphere), and to finite quantum systems with Abelian superselection rules (direct sums of matrix algebras). However, this first result leaves open the possibility of secure bit commitment protocols that employ infinite quantum systems. So, in the following subsection, we prove a more general HJW theorem that also applies to infinite quantum systems.

A. HJW theorem for hyperfinite algebras

Definition: A von Neumann algebra $\mathcal{R}$ is said to be *hyperfinite* just in case there is an upward directed family $\{\mathcal{R}_a\}_{a\in\mathbb{A}}$ of finite-dimensional C^*-algebras such that $\mathcal{R}$ is the weak-operator closure of $\cup_{a\in\mathbb{A}}\mathcal{R}_a$.

As in the finite case, an observer with a hyperfinite von Neumann algebra can perform a maximally disturbing measurement operation.

Lemma 3: If $\mathcal{R}$ is a hyperfinite von Neumann algebra acting on the Hilbert space $\mathcal{H}$, then there is a completely positive projection Φ from $\mathcal{B}(\mathcal{H})$ onto $\mathcal{R}'$. In particular, Φ maps $\mathcal{R}$ onto $\mathbb{C}I$.

Notation: For an arbitrary operator B in $\mathcal{B}(\mathcal{H})$ we write $\mathrm{co}_{\mathcal{R}}(B)^-$ for the weak-operator closed convex hull of $\{UBU^*: U\in\mathcal{R}, U \text{ unitary}\}$.

Proof (Compare with Ref. 11, Proposition. 8.3.11; Exercise 8.7.24, and Ref. 22): Let $\{\mathcal{R}_a: a\in\mathbb{A}\}$ be an increasing net of finite-dimensional C^*-algebras on $\mathcal{H}$ such that

$$\left(\cup_{a\in\mathbb{A}}\mathcal{R}_a\right)^- = \mathcal{R}, \tag{22}$$

where $\mathcal{X}^-$ denotes the weak-operator closure of $\mathcal{X}$. By Lemma 2, for each $a\in\mathbb{A}$ there is a CP projection Φ_a from $\mathcal{B}(\mathcal{H})$ onto $\mathcal{R}_a'$. Let

$$X = \prod_{B\in\mathcal{B}(\mathcal{H})} \mathrm{co}_{\mathcal{R}}(B)^- \tag{23}$$

be the product topological space, where each factor is equipped with the weak-operator topology. For fixed $B\in\mathcal{B}(\mathcal{H})$, $\mathrm{co}_{\mathcal{R}}(B)^-$ is weak-operator closed and bounded, and is therefore weak-operator compact (Ref. 11, Theorem 5.1.3). Thus, the Tychonoff product theorem entails that X is compact. Let $\mathcal{M}$ be the subset of X consisting of mappings Φ that are positive, linear, normalized, and such that

$$\Phi(R_1'BR_2') = R_1'\Phi(B)R_2', \tag{24}$$

for all $R_1', R_2'\in\mathcal{R}'$ and for all $B\in\mathcal{B}(\mathcal{H})$. Since $\mathcal{M}$ is closed in X, $\mathcal{M}$ is compact, and $\{\Phi_a: a\in\mathbb{A}\}$ has a limit point $\Phi\in\mathcal{M}$. Note that $\lim_a\Phi_a=\Phi$ iff, for each fixed $B\in\mathcal{B}(\mathcal{H})$, $\text{w-lim}_a\Phi_a(B)=\Phi(B)$. We claim that $\Phi(B)\in\mathcal{R}'$ for each $B\in\mathcal{B}(\mathcal{H})$. Let $A\in\cup_{a\in\mathbb{A}}\mathcal{R}_a$; that is, there is an $m\in\mathbb{A}$ such that $A\in\mathcal{R}_m$. Then, $A\Phi_a(B)=\Phi_a(B)A$, for all $a\geqslant m$. Since the maps $Z\mapsto AZ$ and $Z\mapsto ZA$ are weak-operator continuous,

$$A\left[\text{w-}\lim_{a\geqslant m}\Phi_a(B)\right] = \text{w-}\lim_{a\geqslant m}[A\Phi_a(B)] = \text{w-}\lim_{a\geqslant m}[\Phi_a(B)A] \tag{25}$$

$$=\left[\text{w-}\lim_{a\geqslant m}\Phi_a(B)\right]A. \tag{26}$$

Since $\Phi(B)=\text{w-}\lim_a\Phi_a(B)=\text{w-}\lim_{a\geqslant m}\Phi_a(B)$, it follows that $A\Phi(B)=\Phi(B)A$. Since A was an arbitrary element of $\cup_{a\in\mathbb{A}}\mathcal{R}_a$, $\Phi(B)\in(\cup_{a\in\mathbb{A}}\mathcal{R}_a)'=\mathcal{R}'$. Therefore $\mathrm{ran}(\Phi)=\mathcal{R}'$. Finally, since Φ is an $\mathcal{R}'$-bimodule mapping [i.e., Eq. (24) holds], Φ is idempotent and completely positive (Ref. 24, Corollary 3.4). □

Again, a maximally disturbing operation Φ can be tensored with the POV measure **A** to yield an instrument that prepares the ensemble μ on Bob's system.

Theorem 3 (Generalized HJW Theorem): *Let $\mathcal{B}$ be a C^*-algebra acting on the Hilbert space $\mathcal{H}$, let x be a unit vector in $\mathcal{H}$, and let μ be a measure on the state space of $\mathcal{B}$ such that $\omega_x|_{\mathcal{B}}$*

is the barycenter of μ. If $\mathcal{B}'$ is hyperfinite, then there is a CP instrument $\mathcal{E}$ on $\mathcal{B}(\mathcal{H})$ that is local to $\mathcal{B}'$ and

$$\langle x|\mathcal{E}[S](B)x\rangle = \int_S \omega(B)d\mu(\omega), \tag{27}$$

for all $S \in \Sigma$ and $B \in \mathcal{B}$.

Proof: The proof is identical to the proof of Theorem 2, with Lemma 3 replacing Lemma 2.□

III. APPLICATION TO BIT COMMITMENT

The Mayers–Lo–Chau theorem shows that when $\mathcal{A}=\mathcal{M}_n\otimes I$ and $\mathcal{B}=\mathcal{A}'$, and when bits are encoded in finite ensembles, then $(\mathcal{A},\mathcal{B})$ cannot be used to implement a secure bit commitment protocol. The generalized HJW theorem allows us to extend this result to the case where $\mathcal{A}(=\mathcal{B}')$ is an arbitrary hyperfinite von Neumann algebra, and to encodings that employ arbitrary ensembles of states on $\mathcal{B}$. In particular, the generalized HJW theorem entails that there can be no secure bit commitment protocol using infinite (hyperfinite) quantum systems, or quantum systems with Abelian superselection rules.

A. Bit commitment with infinite quantum systems

The quantum bit commitment protocols that have been proposed to date employ finite quantum systems. In this subsection, we describe a bit commitment protocol that employs continuous ensembles of states on infinite qubit lattices. Since this protocol does not fall within the range of validity of the HJW theorem, it is immune to current no-go theorems against bit commitment. However, we show that this protocol can be cheated by exploiting the nonlocal correlations of an "infinitely entangled" EPR state (see Ref. 13).

Let $|0,0\rangle$ and $|0,1\rangle$ be orthogonal unit eigenvectors of σ_x, and let $|1,0\rangle$ and $|1,1\rangle$ be orthogonal unit eigenvectors of σ_y. Then, heuristically, the states of a one-dimensional infinite qubit lattice include vectors of the form

$$\|b,s\rangle\rangle =_{\text{def}} \otimes_{i=1}^{\infty}|b,s(i)\rangle \quad (s \in (\mathbb{Z}_2)^{\omega}), \tag{28}$$

with $b=0$ or $b=1$. (We provide a rigorous definition of these states below.)

During the Commit stage of the protocol, Alice performs operations on a composite $(\mathcal{A},\mathcal{B})$ consisting of two lattice systems $\mathcal{A}$ and $\mathcal{B}$, and she then sends system $\mathcal{B}$ to Bob. During the Unveil stage, Alice makes measurements on $\mathcal{A}$, and sends classical information to Bob, who then makes measurements on $\mathcal{B}$.

Commit: For $b=0,1$, Alice chooses a random sequence $s \in (\mathbb{Z}_2)^{\omega}$, and prepares the state

$$\|b,s\rangle\rangle_A \otimes \|b,s\rangle\rangle_B.$$

Alice holds part A, and sends part B to Bob. (So, the ensemble Bob receives is an equal mixture over $\|b,s\rangle\rangle$, for $s \in (\mathbb{Z}_2)^{\omega}$.)

Unveil: Alice measures the observable

$$A_b = \sum_{i=1}^{\infty} \frac{2}{3^i} P_b^{(i)},$$

on her systems, where $P_b=\frac{1}{2}(I+\sigma_b)$ and

$$P_b^{(i)} = I \otimes \cdots I \otimes P_b \otimes I \otimes \cdots.$$

(Each state $\|b,s\rangle\rangle$ is an eigenstate of A_b, and when $s_1 \neq s_2$, $\|b,s_1\rangle\rangle$ and $\|b,s_2\rangle\rangle$ assign different values to A_b.) Alice sends the results of her measurements (a list of numbers in the Cantor set) to Bob. Bob measures A_b on his systems and compares his numbers with Alice's. Bob accepts if the two lists agree, and rejects if the two lists disagree.

Let ρ_b be the state that Bob receives. It is intuitively clear that if Alice follows the protocol honestly, then $\rho_0=\rho_1$, and so Bob cannot cheat. (We prove this fact below.)

We now tighten up the mathematical description of the systems involved in the protocol. The observables of a one-dimensional qubit lattice are represented by the C^*-algebraic infinite direct product

$$\mathcal{A} = \bigotimes_{i\in\mathbb{N}} \mathcal{M}_{n(i)}, \tag{29}$$

where $n(i)=2$ for each $i\in\mathbb{N}$. For each $i\in\mathbb{N}$ and $A\in\mathcal{M}_2$, let

$$A^{(i)} = I\otimes\cdots\otimes I\otimes A\otimes I\cdots, \tag{30}$$

where A is in the ith position. If for each $i\in\mathbb{N}, \omega_i$ is a state of $\mathcal{M}_2$, then there is a unique state $\otimes_{i=1}^{\infty}\omega_i$ of $\mathcal{A}$ defined by

$$(\otimes_{i=1}^{\infty}\omega_i)(A^{(j)}) = \omega_j(A). \tag{31}$$

Furthermore, $\otimes_{i=1}^{\infty}\omega_i$ is pure iff each ω_i is pure, and is a trace iff each ω_i is a trace (Ref. 11, Proposition 11.4.7). Thus, if $\{|i\rangle : i\in\mathbb{N}\}$ are unit vectors in $\mathbb{C}^2$, then $\otimes_{i=1}^{\infty}|i\rangle$ can be used to denote the corresponding pure state of $\mathcal{A}$. In particular, for any $s\in(\mathbb{Z}_2)^{\omega}$, $\|b,\ s\rangle\rangle$ does in fact correspond to a pure state of $\mathcal{A}$.

Let $\mathcal{B}$ be an isomorphic copy of $\mathcal{A}$. Since $\mathcal{A}$ is a uniform limit of an increasing sequence of finite-dimensional algebras, it is nuclear; i.e., there is a unique norm on the algebraic tensor product $\mathcal{A}\odot\mathcal{B}$ whose completion is a C^*-algebra. We denote this C^*-algebra by $\mathcal{A}\otimes\mathcal{B}$. We now establish the existence of the ensembles described in the protocol, and we show that they give rise to the same quantum state (namely, the "maximally mixed" tracial state) on system $\mathcal{B}$.

Proposition 4: If μ is the normalized Haar measure on $(\mathbb{Z}_2)^{\omega}$, then there is a probability measure μ_b on the state space of $\mathcal{A}\otimes\mathcal{B}$ such that

$$\mu_b(\{\|b,s\rangle\rangle_A\otimes\|b,s\rangle\rangle_B : s\in S\}) = \mu(S), \tag{32}$$

for every Borel subset S of $(\mathbb{Z}_2)^{\omega}$. Furthermore, if ρ_b is the barycenter of μ_b, then $\rho_b|_{I\otimes\mathcal{B}}$ is the tracial state.

To establish the first part of Proposition 4, it will suffice to show that

$$s \overset{\varphi}{\mapsto} \|b,s\rangle\rangle_A\otimes\|b,s\rangle\rangle_B \tag{33}$$

is a continuous mapping of $(\mathbb{Z}_2)^{\omega}$ into the state space of $\mathcal{A}\otimes\mathcal{B}$ (with the weak* topology), for then the induced measure $\mu_b=\mu\circ\varphi^{-1}$ will satisfy Eq. (32).

Let $G=\Sigma_{i\in\mathbb{N}}(\mathbb{Z}_2\oplus\mathbb{Z}_2)_i$ be the direct sum of a countable number of copies of $\mathbb{Z}_2\oplus\mathbb{Z}_2$. Elements of G are sequences with values in $\mathbb{Z}_2\oplus\mathbb{Z}_2$ that differ from the identity (0, 0) in only finitely many positions. Let $V_{(0,0)}=I$, $V_{(0,1)}=\sigma_x, V_{(1,0)}=\sigma_y$, and $V_{(1,1)}=\sigma_z$, and, for any $s\in G$, let

$$U(s) =_{\text{def}} V_{s(1)}\otimes V_{s(2)}\otimes V_{s(3)}\otimes\cdots\in\mathcal{A}. \tag{34}$$

Then the set $\{U(s) : s\in G\}$ is linearly dense in $\mathcal{A}$. Let H_b denote the subgroup of G generated by those sequences s with the property that $s(i)=(0,0)$ or $s(i)=(b,b\oplus 1)$ for all $i\in\mathbb{N}$. Then, $\{U(s) : s\in H_b\}$ generates an Abelian subalgebra of $\mathcal{A}$, namely, the algebra generated by the spin operator $V_{(b,b\oplus 1)}$ at each lattice site.

Lemma 5: If $\mathcal{C}$ is the Abelian subalgebra of $\mathcal{A}$ generated by $\{U(s): s \in H_b\}$, then the pure state space of $\mathcal{C}$ is homeomorphic to $(\mathbb{Z}_2)^\omega$.

Proof: The Abelian C^*-algebra $\mathcal{C}$ is isomorphic to the C^*-algebra $C(X)$ of continuous complex-valued functions on X, where X is the pure state space of $\mathcal{C}$ equipped with the weak* topology. Furthermore, if $C(X)$ and $C(Y)$ are isomorphic, then X and Y are homeomorphic. Thus, if $\mathcal{C} \simeq C(Y)$, then the space of pure states of $\mathcal{C}$ is homeomorphic to Y. Now, $\mathcal{C} \simeq \bigotimes_{i=1}^{\infty} \mathcal{N}_i$, where $\mathcal{N}_i$ is the Abelian algebra generated by σ_b. Since $\mathcal{N}_i$ is isomorphic to $C(\mathbb{Z}_2)$,

$$\bigotimes_{i=1}^{\infty} \mathcal{N}_i \simeq \bigotimes_{i=1}^{\infty} C(\mathbb{Z}_2) \simeq C((\mathbb{Z}_2)^\omega), \tag{35}$$

where $(\mathbb{Z}_2)^\omega$ is equipped with the product topology (see Ref. 11, pp. 910–911; Proposition 11.4.3). Therefore the pure state space of $\mathcal{C}$ is homeomorphic to $(\mathbb{Z}_2)^\omega$. □

Since $\mathcal{C}$ is isomorphic to $C((\mathbb{Z}_2)^\omega)$, there is (by the Riesz representation theorem) a one-to-one correspondence between positive normalized measures on $(\mathbb{Z}_2)^\omega$ and states on $\mathcal{C}$.

Lemma 6: If μ is the Haar measure on $(\mathbb{Z}_2)^\omega$, then the barycenter of μ is $\tau|_{\mathcal{C}}$, where τ is the trace on $\mathcal{A}$.

Proof: Let $\sigma(\mathcal{C})$ denote the pure state space of $\mathcal{C}$, and let $\rho = \int_{\sigma(\mathcal{C})} \omega d\mu(\omega)$ be the barycenter of μ. To show that $\rho = \tau$, it will suffice to show that $\rho(U(s)) = 0$ whenever $s \in H_b - \{e\}$. Indeed, if $s \neq e$, then there is an $i \in \mathbb{N}$ such that $s(i) = (b, b \oplus 1)$. Let s' be the element of $\oplus_{i=1}^{\infty}(\mathbb{Z}_2 \oplus \mathbb{Z}_2)_i$ such that $s'(j) = s(j)$ when $j \neq i$, and $s'(i) = (b \oplus 1, b)$. Then $U(s')^* U(s) U(s') = -U(s)$. Since μ is translation-invariant, $\rho(U(s)) = -\rho(U(s))$. Therefore $\rho(U(s)) = 0$. □

Lemma 7: There is a completely positive projection Φ from $\mathcal{A}$ onto $\mathcal{C}$ such that $\tau(\Phi(A)) = \tau(A)$ for all A in $\mathcal{A}$.

Proof: For each $t \in \mathbb{R}$, define an automorphism α_t of $\mathcal{A}$ by

$$\alpha_t(B) = e^{-itA_b} B e^{itA_b} \quad (B \in \mathcal{A}). \tag{36}$$

Since A_b is bounded, the map $t \mapsto \alpha_t(B)$ is norm-continuous. If ν is an invariant mean on $\mathbb{R}$, then

$$\Phi(B) = \int_{\mathbb{R}} \alpha_t(B) d\nu(t) \quad (B \in \mathcal{A}) \tag{37}$$

is a positive linear map on $\mathcal{A}$ (Ref. 20, Lemma 7.4.4). (To show that Φ is completely positive, it will suffice to show that the range of Φ is Abelian.) Clearly $\Phi(C_1 B C_2) = C_1 \Phi(B) C_2$ for all $C_1, C_2 \in \mathcal{C}$, and $B \in \mathcal{A}$. In particular, $\Phi(C) = C$ for all $C \in \mathcal{C}$. To see that the image of Φ lies in $\mathcal{C}$, let s be an element of $G = \Sigma_{i \in \mathbb{N}}(\mathbb{Z}_2 \oplus \mathbb{Z}_2)_i$. If $s \in H_b$, then $U(s) \in \mathcal{C}$ and $\Phi(U(s)) = U(s)$. Suppose then that $s \notin H_b$; that is, there is an $i \in \mathbb{N}$ such that either $s(i) = (b \oplus 1, b)$ or $s(i) = (1, 1)$. (It will suffice to consider the first case; the second case follows by symmetry.) Then

$$U(s) = V_{s(1)} \otimes \cdots \otimes V_{s(i-1)} \otimes V_{s(i)} \otimes V_{s(i+1)} \otimes \cdots, \tag{38}$$

and

$$\Phi(U(s)) = V_{s(1)} \otimes \cdots \otimes V_{s(i-1)} \otimes B_i \otimes V_{s(i+1)} \otimes \cdots, \tag{39}$$

where

$$B_i = \int_{\mathbb{R}} e^{-itP_b} [V_{(b \oplus 1, b)}] e^{itP_b} d\nu(t) = 0. \tag{40}$$

Thus, $\Phi(U(s)) = 0$. Since $\{U(s): s \in G\}$ spans $\mathcal{A}$, it follows that $\mathrm{ran}(\Phi) = \mathcal{C}$. To see that $\tau = \tau \circ \Phi$, note that every nonidentity element of $\{U(s): s \in G\}$ is trace-free. If $s \in H_b$, then $\Phi(U(s)) = U(s)$ and therefore $\tau(\Phi(U(s))) = \tau(U(s))$. If $s \notin H_b$, then $\Phi(U(s)) = 0$ and $\tau(U(s)) = 0$. Since τ and $\tau \circ \Phi$ are continuous linear functionals, $\tau = \tau \circ \Phi$. □

The mapping $\Psi=\Phi\otimes\Phi$ is a CP projection from $\mathcal{A}\otimes\mathcal{B}$ onto $\mathcal{C}\otimes\mathcal{C}$, and its adjoint Ψ^* is a weak* continuous mapping from the state space of $\mathcal{C}\otimes\mathcal{C}$ into the state space of $\mathcal{A}\otimes\mathcal{B}$. Let $\sigma(\mathcal{C}\otimes\mathcal{C})$ denote the pure state space of $\mathcal{C}\otimes\mathcal{C}$, and let $\sigma(\mathcal{A}\otimes\mathcal{B})$ denote the pure state space of $\mathcal{A}\otimes\mathcal{B}$. Using Ψ^* again to denote the restriction of Ψ^* to $\sigma(\mathcal{C}\otimes\mathcal{C})$, and identifying $\sigma(\mathcal{C}\otimes\mathcal{C})$ with $(\mathbb{Z}_2)^\omega\times(\mathbb{Z}_2)^\omega$, it follows that Ψ^* is a continuous injection of $(\mathbb{Z}_2)^\omega\times(\mathbb{Z}_2)^\omega$ into $\sigma(\mathcal{A}\otimes\mathcal{B})$. Note that

$$\Psi^*[(s,s)] = \|b,s\rangle\rangle_A \otimes \|b,s\rangle\rangle_B \tag{41}$$

and so the mapping

$$s \overset{\varphi}{\mapsto} \|b,s\rangle\rangle_A \otimes \|b,s\rangle\rangle_B = (\Psi^* \circ \Delta)(s), \tag{42}$$

where $\Delta(s)=(s,s)$, is continuous, which establishes the first part of Proposition 4.

Now let ρ_b denote the barycenter of μ_b, and let $\nu_b =_{\text{def}} \mu\circ(\Phi^*)^{-1}$ denote the measure on $\sigma(\mathcal{B})$ induced by Φ^* from the measure μ on $\sigma(\mathcal{C})$. Then for any $B\in\mathcal{B}$,

$$\rho_b(I\otimes B) = \int_{\sigma(\mathcal{A}\otimes\mathcal{B})} \omega(I\otimes B)\,d\mu_b(\omega) = \int_{\sigma(\mathcal{B})} \omega(B)\,d\nu_b(\omega) \tag{43}$$

$$= \int_{\sigma(\mathcal{C})} \omega(\Phi(B))\,d\mu(\omega) = \tau(\Phi(B)) = \tau(B). \tag{44}$$

This establishes the second part of Proposition 4. Thus, μ_0 and μ_1 are the ensembles prepared by Alice if she follows the protocol honestly.

Finally, we show that Alice can cheat by preparing an entangled state during the Commit stage rather than μ_0 or μ_1. In particular, if for each $i\in\mathbb{N}$, $\psi_i=\psi$ is the Bohm-EPR state of $\mathcal{M}_2\otimes\mathcal{M}_2$, then $\omega=_{\text{def}}\otimes_{i=1}^{\infty}\psi_i$ is a pure state of $\bigotimes_{i=1}^{\infty}(\mathcal{M}_{n(i)}\otimes\mathcal{M}_{n(i)})=\mathcal{A}\otimes\mathcal{B}$.[13] It is not difficult to see, then, that if Alice performs a nonselective measurement of A_b [represented by the CP map in Eq. (36)] when $\mathcal{A}\otimes\mathcal{B}$ is in state ω, then the posterior state is the ensemble μ_b. Therefore, if Alice prepares ω during the Commit stage, then she can unveil either 0 or 1.

B. Bit commitment and superselection rules

It has recently been argued by Mayers, Kitaev, and Preskill,[14,18] in response to a question raised by Popescu,[21] that the no-go theorem for bit commitment extends to the case of quantum systems with superselection rules. The generalized HJW theorem provides another route to this result, at least for systems whose superselection rules are Abelian. In the case of Abelian superselection rules, $\mathcal{A}=\mathcal{B}'$; that is, Alice can perform any operation that commutes with Bob's measurement operations. And the generalized HJW theorem shows that an observer with algebra $\mathcal{B}'$ can steer system $\mathcal{B}$ into any ensemble consistent with $\omega_x|_{\mathcal{B}}$. Thus, a bit commitment protocol is perfectly concealing against Bob only if it is not binding against Alice. However, the generalized HJW theorem has nothing to say (directly) about Alice's ability to cheat when both systems are governed by non-Abelian superselection rules (in which case $\mathcal{A}\subset\mathcal{B}'$).

Mayers *et al.*[14] claim that—HJW theorem aside—Alice can always steer Bob's system into the state of her choice by adding, if necessary, an appropriate ancilla to her system. Their argument is based on a more general claim that restrictions imposed by superselection rules on a local system can always be effectively removed by embedding the local system in a larger system (in particular, by adding an ancilla).

The formalism of elementary quantum mechanics imposes no restriction on adding ancillae. However, in the setting of algebraic quantum field theory, an observer can measure only those observables that correspond to her space–time region. As a result, adding ancillae is not permitted—at least if "adding an ancilla" is interpreted to mean that Alice can measure observables that are not in her local observable algebra $\mathcal{R}(O_A)$. Thus, in this richer theoretical framework, Alice is subject to further constraints on her ability to simulate any operation that commutes

with Bob's measurement operations, and these constraints could—it seems theoretically possible—prevent Alice from cheating in a bit commitment protocol. (It would be interesting to explore connections between the formal condition $\mathcal{A}\subset\mathcal{B}'$ and relativistic constraints of the sort exploited by Kent's[12] bit commitment protocol.)

C. Limitations on the generalized HJW theorem

Let us say that a bit commitment protocol employs a *quantum encoding* just in case Alice encodes her choice of a bit 0 or 1 in two ensembles μ_0 or μ_1 of quantum states. Then, even in the case of bit commitment schemes that employ quantum encodings, there is one further assumption of the generalized HJW theorem that is not *prima facie* guaranteed to hold in any bit commitment protocol: the assumption that the barycenter of μ_b is a *vector* state. (Let us call this latter assumption the *vector state assumption*.)

First, it is not difficult to find pairs of C^*-algebras $(\mathcal{A},\mathcal{B})$, and measures μ_b on the state space of $\mathcal{B}$ such that the vector state assumption does not hold: e.g., let $\mathcal{B}=\mathcal{M}_2$, and let μ_b be the measure on the state space of $\mathcal{B}$ that assigns $\frac{1}{2}$ to each of $\frac{1}{2}(I+\sigma_b)$ and $\frac{1}{2}(I-\sigma_b)$. (Of course, this trivial example could not be used to construct a secure bit commitment protocol, since Alice could not perform any nontrivial measurements to verify her commitment to Bob.) However, the vector state assumption does hold when $\mathcal{B}$ has a separating vector in $\mathcal{H}$.

Definition: A vector x in the Hilbert space $\mathcal{H}$ is said to be *separating* for the C^*-algebra $\mathcal{B}$ just in case $Bx=0$ only if $B=0$ for all $B\in\mathcal{B}$.

Proposition 8 (Ref. 11, Theorem 7.3.8): If $\mathcal{B}$ is a C^*-algebra acting on the Hilbert space $\mathcal{H}$ and if $\mathcal{B}$ has a separating vector x in $\mathcal{H}$, then each state of $\mathcal{B}$ is implemented by some vector in $\mathcal{H}$.

Thus, if $\mathcal{B}$ has a separating vector in the Hilbert space $\mathcal{H}$ (and if $\mathcal{A}=\mathcal{B}'$), then any ensemble of states on $\mathcal{B}$ corresponds to a state $\omega_x|_{\mathcal{B}}$ induced by a vector x in $\mathcal{H}$, and the generalized HJW theorem entails that any two equivalent ensembles can be prepared at a distance (from a common state). For example, $\mathcal{B}=I_A\otimes\mathcal{B}(\mathcal{H}_B)$ has a separating vector in $\mathcal{H}_A\otimes\mathcal{H}_B$ if and only if $\dim(\mathcal{H}_B)\leqslant\dim(\mathcal{H}_A)$.[8] So, in the case of elementary quantum systems, by adding an ancilla, Alice can "make her Hilbert space as large as Bob's," which ensures that their joint Hilbert space $\mathcal{H}=(\mathcal{H}_{A'}\otimes\mathcal{H}_A)\otimes\mathcal{H}_B$ contains a vector representative of each of Bob's states.

Nonetheless, there are C^*-algebras that do not have—and could not have, in any faithful representation—a separating vector, e.g., C^*-algebras which contain an uncountable family of mutually orthogonal projection operators. But if $\mathcal{B}$ does not have a separating vector, then the HJW theorem does not show that an observer with algebra $\mathcal{B}'$ could perform operations that prepare any one of two equivalent measures on the state space of $\mathcal{B}$ (from a common ancestor state). Until the HJW theorem is generalized to cover such cases, there remains a small, but theoretically crucial, loophole in current proofs of the impossibility of secure bit commitment.

IV. CONCLUSION

We have shown, subject to a mild constraint (viz., that the systems involved are "hyperfinite"), that any two equivalent measures on the state space of a C^*-algebra can be prepared "at a distance." This result generalizes the Hughston–Jozsa–Wootters theorem, and so can be used to extend the Mayers–Lo–Chau argument against the security of quantum bit commitment protocols.

However, the results proved to date—including the results in this paper—are not yet sufficient to rule out the security of any conceivable quantum bit commitment protocol. First, it remains an open question whether an analog of the HJW theorem holds for any system whose observables can be represented by self-adjoint operators in some abstract (not necessarily nuclear) C^*-algebra. Second, in order to invoke the HJW theorem in an argument against bit commitment, one must make further physical assumptions—e.g., that the states on Bob's system correspond to vector states of some larger system S, and that Alice can perform any operation on S that commutes with Bob's measurement operations—that have yet to be justified in a fully general context.

Chaos in the case of two fixed black holes

G. Contopoulos and M. Harsoula
Academy of Athens, Center for Astronomy, 10673 Athens, Greece

(Received 17 February 2004; accepted 4 May 2004; published 24 November 2004)

We study the structure of chaos in the relativistic problem of particles moving in the field of two fixed black holes M_1 and M_2 by considering the asymptotic curves of some simple unstable periodic orbits on a surface of section. These curves consist of infinite arcs reaching the two black holes. Most orbits starting along these curves (asymptotic orbits) escape, i.e., they fall into the black holes M_1 (type I orbits) and M_2 (type II orbits). The number of the remaining orbits after n iterations (intersections with the surface of section) decreases exponentially with n. The asymptotic curves intersect at infinite homoclinic and heteroclinic points. We study in detail the forms of the asymptotic orbits with emphasis on the homoclinic and heteroclinic orbits. The homoclinic and heteroclinic intersections are confined in certain intervals along the asymptotic curves. Every homoclinic and heteroclinic orbit is the limit of infinite more homoclinic and heteroclinic orbits. Between an asymptotic orbit falling on the black hole M_1 and another orbit falling on the black hole M_2 there are infinite homoclinic and heteroclinic orbits and infinite transitions between type I and type II orbits. Therefore the orbits of type I and II form fractal sets. The nonasymptotic curves falling on the black holes M_1 and M_2 also form fractal sets. The black holes act as attractors and the areas on the surface of section are not conserved despite the fact that the system is conservative. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1782672]

I. INTRODUCTION

The relativistic system of two fixed black holes is important because it has a large degree of chaos, while the corresponding classical problem is completely ordered (integrable) and does not have any chaos at all.[1,2] In the case of orbits of photons (null geodesics) and of particles (timelike geodesics) with hyperbolic or parabolic energy almost all orbits either escape to infinity, or fall on a black hole, while in the case of particles with elliptic energy many orbits fall on one of the two black holes.

In the present paper we explore the structure of chaos by studying the forms of the asymptotic curves and of the corresponding asymptotic orbits. We study in detail a case with particular values of the energy and masses of the black holes, but this case is typical of most other cases.

The basic characteristic feature of chaos is the existence of asymptotic manifolds intersecting along homoclinic and heteroclinic orbits. On a surface of section $x=0$ (with $\dot{x}>0$) there are asymptotic curves intersecting along homoclinic and heteroclinic points. The asymptotic curves are composed of infinite disjoint arcs reaching the black holes. The structure of these arcs is discussed in Sec. II.

Section III describes the main simple periodic orbits (i.e., periodic orbits of period 1) and the main homoclinic intersections of their asymptotic curves. Then Sec. IV describes in detail the forms of the orbits starting on an asymptotic curve, i.e., the asymptotic orbits. Of special interest are the homoclinic and heteroclinic orbits connecting various periodic orbits to each other. There are infinite homoclinic and heteroclinic points along an asymptotic curve. However, the homoclinic and heteroclinic points are confined in certain domains of the phase space, leaving most of the phase space without any such points.

As a consequence of the existence of heteroclinic orbits connecting periodic orbits around M_1 and M_2 the sets of points along an asymptotic curve leading to one or the other black hole are fractal.

In Sec. V we find the basins of attraction of nonperiodic and nonasymptotic orbits, leading to the black holes M_1 and M_2. These basins consist of compact domains and of infinite filaments mixed in a fractal way.

In Sec. VI we consider briefly what happens for other values of the masses of the black holes and in Sec. VII we summarize our conclusions.

Finally, in an Appendix we consider theoretically the orbits very close to a black hole and explain the forms of the asymptotic curves when they reach the black holes.

II. ASYMPTOTIC CURVES AND ASYMPTOTIC ORBITS

Our study consists mainly of an exhaustive numerical exploration of orbits of particles (timelike geodesics) in a number of cases, with a representative value of the energy $E=\sqrt{0.5}$. We use standard numerical integration methods (fourth order Runge–Kutta), as in our previous papers (Refs. 1 and 2) and we checked the accuracy by requiring that any error in the energy conservation should be less than 10^{-10}. The energy we use is of the elliptic type ($0<E<1$), therefore there are no escapes to infinity. The mass of the black hole M_2 is always taken equal to $M_2=1$, while M_1 takes various values. In particular for $M_1=1.1$, there are two simple (almost circular) orbits around M_1 (orbits of types a, a'), two simple orbits around M_2 (orbits of types b, b') and an orbit like a hyperbolic arc [orbit of type h, intersecting the z axis and reaching the curve of zero velocity (CZV) at two symmetric points].[2]

These are the only simple periodic orbits, i.e., orbits intersecting the z axis at only one point perpendicularly (with $x=\dot{z}=0$ and $\dot{x}>0$).

In most cases all simple periodic orbits are unstable. However, there is a small interval of values of M_1 (around $M_1=1.324$), where the orbit a' is stable, and another small interval of values of M_1 (around $M_1=0.908$) where the orbit b' is stable.[2]

We study now in detail the asymptotic curves and the corresponding asymptotic orbits from the inner unstable periodic orbit of type a in the case $M_1=1.1$. This orbit (O) has $z_0=2.504\,568\,37$, $\dot{z}_0=0$.

The eigenvalue of the inner orbit a is $\lambda=32.330\,01$, the direction of the unstable eigenvector is $d\dot{z}/dz=0.0983$ and the direction of the stable eigenvector is -0.0983.

We have calculated 2×10^4 asymptotic orbits along the (upper) unstable eigenvector with a step $\Delta x=10^{-8}$. All these orbits approach asymptotically the periodic orbit O for negative time tending to $-\infty$, while for positive time they deviate further and further from O. The whole set of initial conditions has a length $\Delta x=2\times10^{-4}$. In this interval the deviations of the eigenvector from the corresponding asymptotic curve are very small, namely smaller than 2×10^{-7}. The deviations of the nth images of the 2×10^4 points from the asymptotic curves are even smaller, by a factor λ^n.

The first iterations of the original points reach a distance of order $2\times10^4\lambda\approx6.5\times10^{-3}$ and the second iterations reach a distance of order $2\times10^{-4}\lambda^2\approx0.2$. But the third iterations reach a large distance and are appreciably curved (Fig. 1). The numbers m along the asymptotic curve mark the third iterations of the initial points with distance $m\times10^{-8}$ from the periodic orbit, where m varies from 1 up to 20 000.

In Fig. 1 we see three arcs of the asymptotic curve. The first arc (1) starts at the periodic orbit (O) towards larger z with $\dot{z}$ small positive. This curve is continued with $\dot{z}<0$, and z reaches a maximum near $z=4$. Then it turns to smaller z until it reaches the black hole $z=1$, with $\dot{z}=-0.75$ (point M_1^-). The point marked 6722 is the third intersection of an orbit with initial distance $m\times10^{-8}$, along the unstable asymptotic curve from O, with $m=6722$. The orbits $m=6723-9051$ do not have a third image in Fig. 1, because these orbits fall into the black hole $z=1$ before their third intersection with the z axis with $\dot{x}>0$. The same points in Fig. 2 are the fourth iterations of the original points with $m=(6723/\lambda)-(9051/\lambda)\approx208-279$. The orbits with initial conditions $m=9052-11\,014$ in Fig. 1 ($m=280-340$ in Fig. 2) form the second arc (2). This

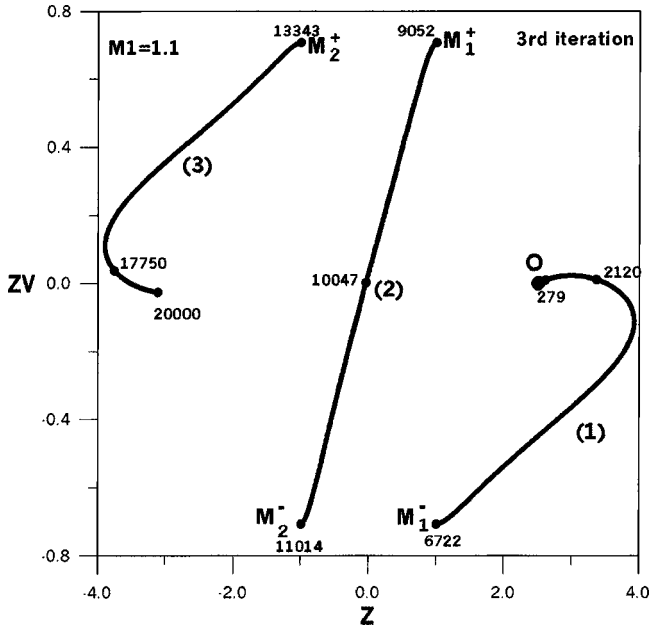

FIG. 1. An unstable asymptotic curve from the unstable periodic orbit O ($z_0=2.504\,568\,37$, $\dot{z}_0=0$) on a surface of section $(z,\dot{z})$ for $M_1=1.1$, $M_2=1$, $E=\sqrt{0.5}$. The numbers (m) indicate the third intersections of the z axis (with $\dot{x}>0$) by asymptotic orbits starting close to O (at distances $m\times10^{-8}$ along the asymptotic curve). The first part of this curve (1) starts at O and reaches the black hole $z=1$. The second part (2) starts at $z=1$ and reaches the second black hole $z=-1$. The third part (3) starts at $z=-1$ and continues beyond at $m=20\,000$.

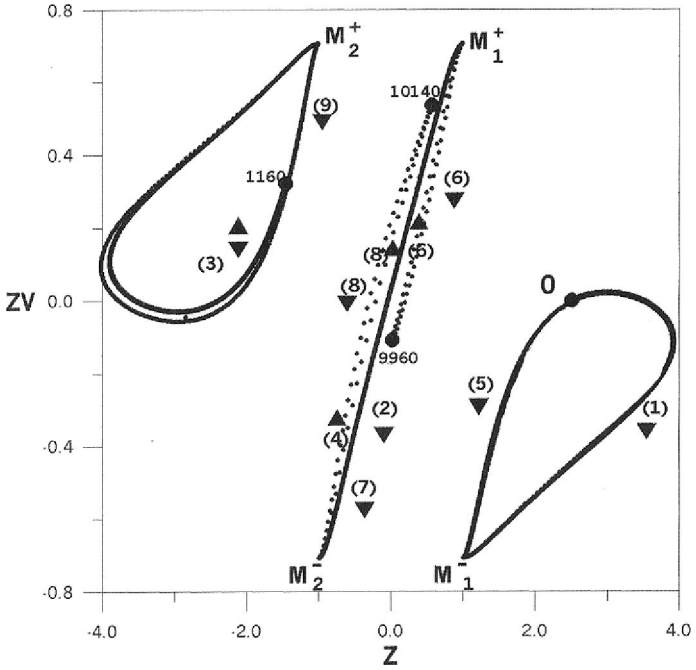

FIG. 2. The fourth iterations of orbits starting close to the unstable periodic orbit O along the unstable asymptotic curve at distances $m\times10^{-8}$. This curve consists of various arcs (1), (2),…,(9). The first arc starts at the periodic orbit O and ends at the black hole $z=1$. The other arcs start and end at a black hole. The numbers mark the turning points of the arcs (3), (6), and (8).

arc starts at the point M_1^+ ($z=1$, $\dot{z}=0.75$) and terminates at the point M_2^- ($z=-1$, $\dot{z}=-0.75$). The orbits of this arc have again a third intersection with the z axis ($\dot{x}>0$) before falling into a black hole. This third intersection is between the black holes M_1 and M_2.

The orbits with initial conditions $m=11\,015-13\,342$ in Fig. 1 (or $m=340-412$ in Fig. 2) do not have a third intersection; all these orbits fall into the black hole $z=-1$ before a third intersection with the z axis ($\dot{x}>0$). Finally, the orbits with initial conditions $m=13\,343-20\,000$ have third iterates with $z<-1$, i.e., below the black hole M_2 [third arc (3)].

The asymptotic curve continues beyond the third iteration of the point with $m=20\,000$ marked in Fig. 1. The third iteration of the initial point with $m=20\,000$ has the same position on the phase space with the fourth iteration of an initial point with $m=20\,000/\lambda\approx 615$. Thus, the points of Fig. 2 with $m<615$ belong to the arcs given in Fig. 1, and the points with $m>615$ belong to the continuation of the unstable asymptotic curve.

Figure 2 contains nine successive arcs of the asymptotic curve from the periodic orbit O, composed of the fourth iterations of the point m (with initial distance $m\times 10^{-8}$ along the asymptotic curve close to O). These arcs are separated by gaps in m, containing orbits that do not have fourth iterations. These arcs and gaps are as follows:

Arc (1) from $m=0$(O) to $m=207$ (point M_1^-),

Gap from $m=208$ to $m=279$,

Arc (2) from $m=280$ (point M_1^+) to $m=340$ (M_2^-),

Gap from $m=341$ to $m=412$,

Arc (3) from $m=413$ (point M_2^+) to $m=2054$ (M_2^+),

Gap from $m=2055$ to $m=2120$,

Arc (4) from $m=2121$ (point M_2^-) to $m=2175$ (M_1^+),

Gap from $m=2175$ to $m=2240$,

Arc (5) from $m=2241$ (point M_1^-) to $m=2748$ (M_1^-),

Gap from $m=2749$ to $m=9917$,

Arc (6) from $m=9918$ (point M_1^+) to $m=9986$ (M_1^+),

Gap from $m=9987$ to $m=10\,047$,

Arc (7) from $m=10\,048$ (point M_1^+) to $m=10\,052$ (M_2^-),

Gap from $m=10\,053$ to $m=10\,107$,

Arc (8) from $m=10\,108$ (point M_2^-) to $m=10\,185$ (M_2^-),

Gap from $m=10\,186$ to $m=17\,750$,

Arc (9) from $m=17\,751$ (point M_2^+) to $m=18\,276$ (M_2^+).

We give this detailed information in order to show the various types of arcs. After the arc (1) that starts at O and terminates at M_1 all other arcs start and terminate at M_1 or M_2.

There are three types of arcs: (a) arcs starting at M_1^- and terminating at the same point [arc (5)], (b) arcs starting at M_2^+ and terminating at the same point [arcs (3) and (9)], and (c) arcs close to the diagonal M_1^+, M_2^-. These orbits are of four subtypes: (c1) starting at M_1^+ and terminating at M_2^- [arcs (2) and (7)], (c2) starting at M_2^- and terminating at M_1^+ [arc (4)], (c3) starting at M_1^+ and terminating at the same point [arc (6)], or (c4) starting at M_2^- and terminating at the same point [arc (8)].

TABLE I. Intervals of escaping orbits.

m	Δm	Into
	(1) Escape-3 intervals (escaping before the third iteration)	
6723–9051	2328	M_1
11 015–13 342	2327	M_2
	(2) Escape-4 intervals (escaping before the fourth iteration)	
208–279	71	M_1
341–412	72	M_2
2055–2120	65	M_2
2176–2240	64	M_1
2749–9917	7168	M_1 (including the escape-3)
9987–10047	60	M_1
10 053–10 107	54	M_2
10 186–17 750	7564	M_2 (including the escape-3)
18 277–18 330	53	M_2
18 380–18 440	60	M_1
19 080–20 000+	920+	M_1

We notice also that certain intervals of m along arcs, or intervals in gaps (intervals of escape) are rather short while other intervals are quite long. The escape intervals up to $m=20\,000$ are given in Table I.

Before the third iteration a total interval $\Sigma\Delta m \approx 4660$ escape, and before the fourth iteration a total interval $\Sigma\Delta m = 16\,150$ escape up to $m=20\,000$. There remains 77% of the original set of points m after the third iteration and 19% after the fourth iteration.

After the fourth iteration only intervals summing up to less than $\Sigma\Delta m = 4000$ remain. Further intervals escape before the fifth, sixth, etc., iterations. After the fifth iteration there remains only a total interval $\Sigma\Delta m = 462$, i.e., 2.3% and after the sixth iteration a total interval $\Sigma\Delta m = 52$, i.e., 0.26%. As the order of iteration increases, the remaining intervals become very small.

The remaining total interval after the nth iteration follows approximately the relation

$$\ln(\Sigma\Delta m) = a - bn \tag{1}$$

with $a=16.2758$ and $b=2.080\,58$, i.e., $\Sigma\Delta m$ is reduced exponentially with n.

The splitting of the asymptotic curve into pieces separated by sets of orbits that fall into one of the two black holes is remarkable. It reminds us of the splitting of the asymptotic curves in a potential with escapes, by sets of orbits that escape to infinity.[3] In that case the separate arcs of the asymptotic curves do not terminate abruptly but after infinite rotations around an "escape domain." However, in the present case the arcs of the asymptotic curve terminate abruptly at the black holes ($z=\pm 1$, $\dot{z}=\pm 0.75$). A theoretical explanation of this effect is given in the Appendix.

Now the question arises whether there is a continuity between the orbits that fall into the black holes in Figs. 1 and 2 before and after a third or a fourth iteration.

This question is easy to answer. Consider two orbits marked $m=6722$ and $m=9052$ in Fig. 3. The orbit $m=6722$ has a third intersection with the z axis ($\dot{x}>0$) a little above $z=1$, while the orbit $m=6723$ does not have a third intersection. The two orbits are so close that they cannot be separated in Fig. 3. Both orbits make a small angle with the z axis above $z=1$ as they reach the black hole M_1 (small positive, i.e., clockwise from the upper z axis for $m=6722$ and small negative, i.e., counterclockwise for $m=6723$). The orbit $m=6723$ is slightly below the orbit $m=6722$ near the black hole $z=1$ and reaches the black hole from the left of the z axis without a third intersection with the z axis. Thus, the continuity between the orbits $m=6722$ and $m=6723$

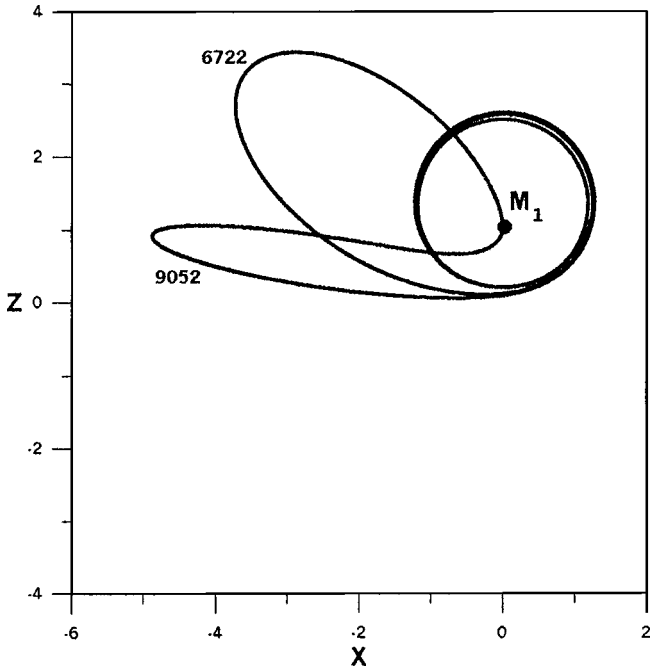

FIG. 3. The orbits with $m=6722$ and $m=9052$ reach the black hole M_1. The first orbit intersects the z axis ($\dot{x}=0$) for a third time above and very close to M_1, while the second orbit intersects this axis below and very close to M_1. The orbits with $6723<m<9051$ reach M_1 from the left, without intersecting for a third time the z axis.

close to the black hole is obvious. As m increases from $m=6722$ to $m=9052$ the orbits reach the black hole $z=1$ from the left of the z axis making larger and larger negative angles with the z axis until they reach an angle very close to $-180°$. The orbit $m=9051$ does not have a third intersection with the z axis, while the orbit $z=9052$ has a third intersection just below $z=1$. Again the continuity between these orbits is obvious.

Similar results refer to the fourth and higher order intersections. The orbits between $m=208$ and $m=279$ in Fig. 2 do not have a fourth intersection with the z axis ($\dot{x}>0$). These orbits correspond to the orbits $m=6723$ ($=208\lambda$) and $m=9051$ ($=279\lambda$) that do not have third intersections. In Fig. 4 the orbit $m=279$ does not have a fourth intersection with the z axis (with $\dot{x}>0$) but the orbit $m=280$ does have such a fourth intersection just below $z=1$, and there is an obvious continuity between the orbits $m=279$ and $m=280$.

The orbit $m=341$ of Fig. 4 corresponds to the orbit with $m=11\,015$ in Fig. 1. This orbit does not have a fourth intersection with the z axis ($\dot{x}>0$), but reaches the black hole $z=-1$ before the fourth intersection. But the orbit with $m=340$ does have a fourth intersection with the z axis just above the black hole $z=-1$. The continuity between the orbits $m=340$ and $m=341$ is again obvious.

III. PERIODIC ORBITS: HOMOCLINIC AND HETEROCLINIC INTERSECTIONS

The periodic orbits in a system of two fixed black holes have been studied by Contopoulos[1,2] and by Contopoulos and Papadaki.[4]

In the present case we consider the most simple periodic orbits in the case ($M_1=1.1$, $M_2=1$, $E=\sqrt{0.5}$). There are two periodic orbits of period 1 around M_1 [inner orbit (a) and outer orbit (a')], two periodic orbits around M_2 [inner orbit (b) and outer orbit (b')], and the orbit (h), which is like an arc of a hyperbola. The main periodic orbits starting at the points ($z, x=0, \dot{z}=0$) are given in Table II, together with their absolutely larger eigenvalues λ (Fig. 5). The orbits (a), (a') and (b), (b') can be described also in the opposite direction of rotation and then they are called ($\overline{a}, \overline{a'}, \overline{b}, \overline{b'}$).

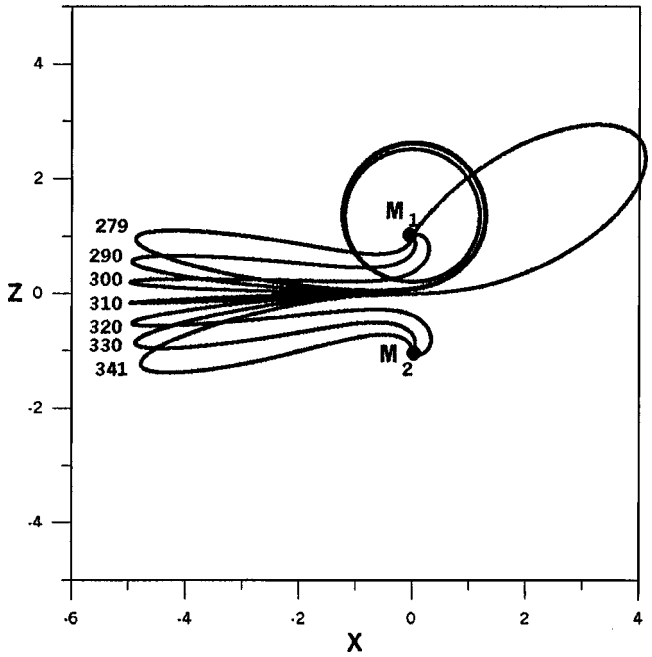

FIG. 4. The orbits with $m=279$, 290, 300 fall into M_1 after a loop to the left and have $\dot{z}>0$ at their minimum x. The orbits with $m=320$, 330, 341 fall into M_2 after a loop to the left and have $\dot{z}<0$ at their minimum x. The orbit $m=310$ has $\dot{z}<0$ at its minimum x, but reaches M_1.

The most important periodic orbits are the orbits (a), $(\overline{a})$ and (b), $(\overline{b})$ because all orbits crossing them inwards fall into the black holes M_1 and M_2, respectively.[1]

The above periodic orbits have multiplicity 1, i.e., they have only one intersection with the z axis and $\dot{x}>0$. The characteristic curve of the periodic orbit h is given in Fig. 6. This curve gives z as a function of M_1 for $M_2=1$ and $E=\sqrt{0.5}$. For $M_1<1$ the orbit h has $z>0$ and it is curved upwards, and for $M_1\to 0$ it tends to a straight line along the z axis above M_1. For $M_1>1$ the orbit h has $z<0$ and it is curved downwards. As $M_1\to\infty$ this orbit tends to a straight line along the z axis below M_2. The characteristics of the orbits (a,a',b,b') are given by Contopoulos.[2]

Besides the most simple periodic orbits above, there are several types of orbits of higher multiplicity. Such orbits are shown in Figs. 7(a)–7(c). The orbit of Fig. 7(a) makes a rotation around M_1 and reaches the curve of zero velocity (CZV) with $\dot{z}=0$ at two symmetric points with respect to the z axis.

The orbits of Fig. 7(b) are of type (8). The upper one makes a rotation around M_1 and then it is elongated symmetrically to the left and to the right, without reaching the CZV. Similarly the lower orbit makes a rotation around M_2 and has two symmetric extensions to the left and to the right above M_2 without reaching the CZV.

TABLE II. Positions and eigenvalues of simple periodic orbits.

	$z(\dot{x}>0)$	$z(\dot{x}<0)$	λ
(inner orbit a)	2.504 568 37	0.207 983 90	32.330 01
(outer orbit a')	3.445 740 37	0.147 178 12	−34.642 86
(inner orbit b)	−2.161 083 40	−0.306 298 55	47.561 40
(outer orbit b')	−3.762 971 63	−0.206 429 38	−60.913 58
(orbit h)	−0.044 139 73	−0.044 139 73	10 384.373

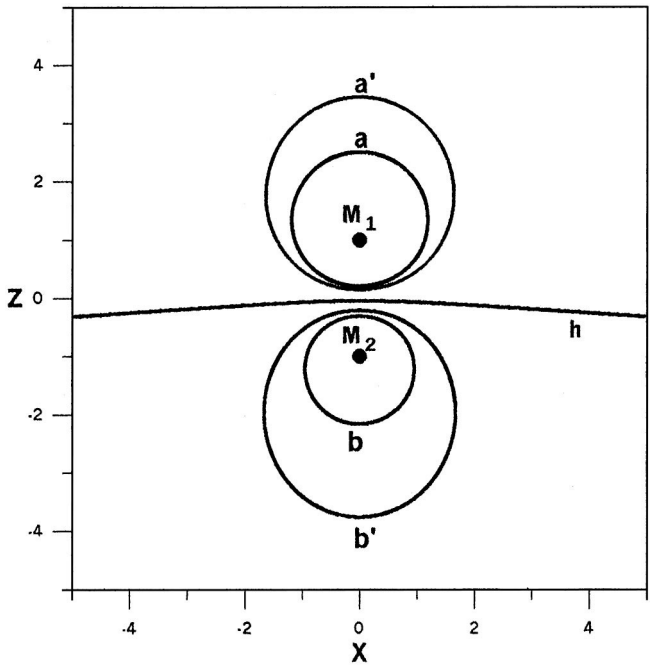

FIG. 5. The inner and outer periodic orbits (a), (a'), (b), and (b') and the hyperbolic type periodic orbit (h). In all cases $M_1=1.1$, $M_2=1$, $E=\sqrt{0.5}$.

Finally, the orbit of Fig. 7(c) makes two rotations, one around M_1 and one around M_2, and has two symmetric extensions to the left and to the right without reaching the CZV.

There are further periodic orbits that have more than one extension to the left and to the right, orbits that make two, or more, rotations around M_1, and/or M_2, and even more complicated periodic orbits.[1,2,4]

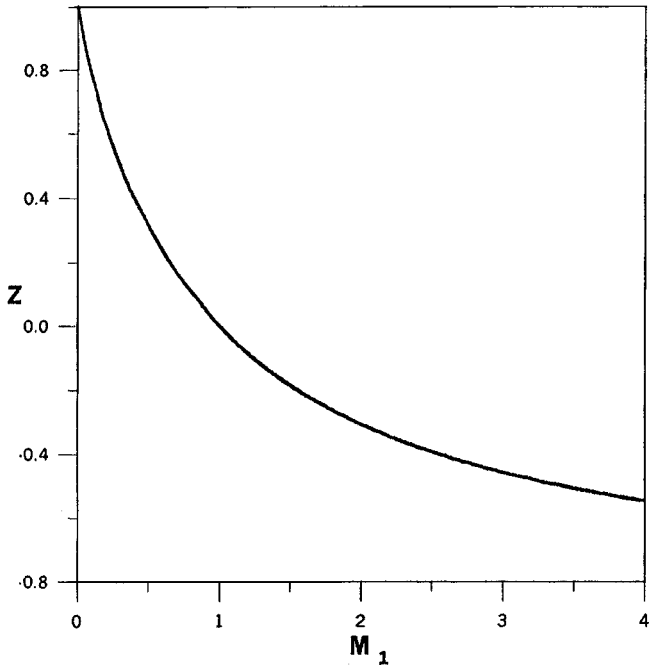

FIG. 6. The characteristic of the orbit h for $M_2=1$, $E=\sqrt{0.5}$, while M_1 varies for 0 to $M_1=4$.

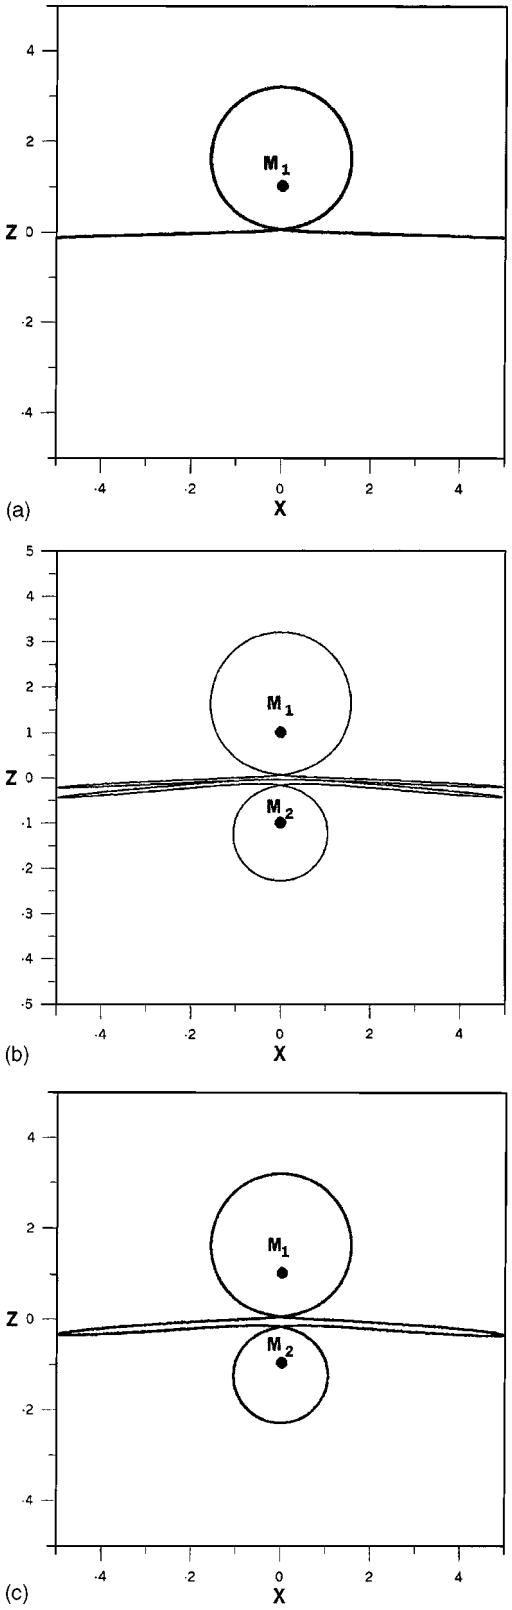

FIG. 7. (a), (b), (c). Various periodic orbits that make a rotation around M_1 and/or M_2.

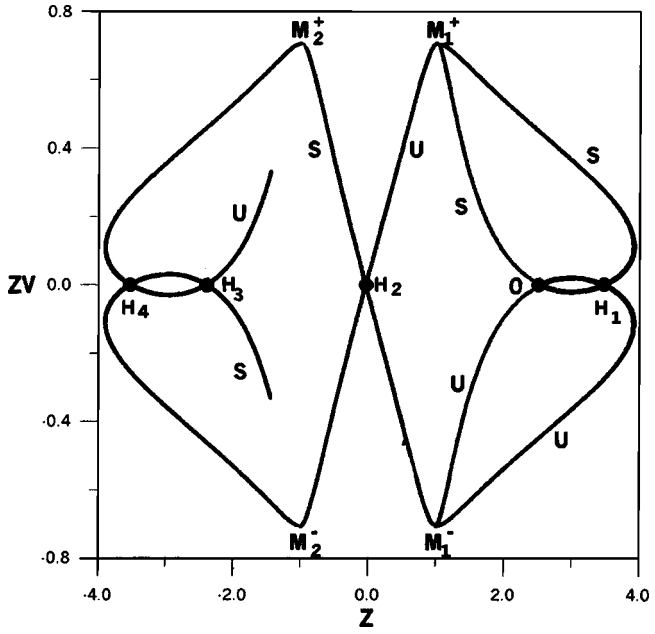

FIG. 8. The stable and unstable asymptotic curves of the orbit O [inner orbit (a) for $M_1=1.1$, $M_2=1$, $E=\sqrt{0.5}$] intersect at an infinity of homoclinic points like H_1, H_2, H_3, H_4.

We study now, the asymptotic curves of some of the main periodic orbits above and find their homoclinic and heteroclinic intersections.

In Fig. 8 we give the stable and unstable asymptotic curves of the (unstable) inner periodic orbit (a), marked O. We mark four main homoclinic points H_1, H_2, H_3, H_4, but there are infinitely more homoclinic points. The points H_1, H_2, H_3, H_4 are close to the periodic orbits a', h, b, and b', respectively. Namely they all have $\dot{z}=0$ and (m,z) given in Table III.

The points H_1, H_2, H_3, H_4 exist already in the arcs of the third iterations, given in Fig. 1, but their values m in Table III correspond to their fourth iterations.

In Fig. 9 we give one unstable asymptotic curve of the inner orbit (a) [the curve starting upwards and to the right from the point (a)] and the stable asymptotic curve of the orbit (h). The unstable asymptotic curves of the orbits (a) and (h) are close to each other, but they do not intersect themselves or each other. In the same way the stable asymptotic curves of the orbits (a) and (h) do not intersect themselves or each other. But the unstable asymptotic curve of (a) intersects the stable asymptotic curve of (h) at infinite heteroclinic points. Thus, we have an infinity of heteroclinic orbits near the point $m=311$. These heteroclinic points are confined in the interval between $m^*=307.643\,390$ and $m^{**}=314.384\,627$ (defined in the next section). In this interval we find infinite homoclinic orbits and heteroclinic orbits connecting (a) with other simple periodic orbits.

In a similar way we have infinite homoclinic and heteroclinic points between the asymptotic

TABLE III. Positions of homoclinic points and of nearby periodic orbits.

$m(H_1)=75$	$z(H_1)=3.500\,48$	$z(a')=3.445\,74$
$m(H_2)=311$	$z(H_2)=-0.041\,66$	$z(h)=-0.044\,14$
$m(H_3)=713$	$z(H_3)=-2.3947$	$z(b)=-2.161\,08$
$m(H_4)=576$	$z(H_4)=-3.5195$	$z(b')=-3.762\,97$

curves of the orbits (a), (a'), (b), (b') and so on. The homoclinic and heteroclinic points are confined in some regions in an extended neighborhoods of the points O, H_1, H_2, H_3, H_4 of Fig. 8. We will describe now the corresponding orbits in some detail.

IV. THE FORMS OF ORBITS STARTING ALONG AN ASYMPTOTIC CURVE

We consider now the changes of the forms of the orbits as we vary the initial point m along the unstable asymptotic curve of the periodic orbit (a). In Fig. 4 we see orbits that fall into M_1 (type I orbits) like $m=279$, and orbits that fall into M_2 (type II orbits), like $m=341$. All the orbits of Fig. 4 start very close to each other forming three almost circular rotations clockwise around M_1 and then an oscillation to the left. Only the last oscillation to the left is substantially different for different orbits. As m increases from $m=279$ this last oscillation becomes thinner. Similarly as m decreases from $m=341$ the last oscillation also becomes thinner. The orbits of type I in Fig. 4 up to $m=300$ have $\dot{z}>0$ at their minimum x along this last oscillation while the orbits $m=320-341$ in this figure are of type II and have $\dot{z}<0$ at their minimum x. On the other hand, the orbit $m=310$ is of type I but it has $\dot{z}<0$ at its minimum x and after this minimum it has an oscillation to the right before reaching M_1.

Between the orbits $m=300$ and $m=320$ there are many transitions between various types of orbits. As m increases beyond $m=300$ the oscillation to the left becomes very thin and for $m=m^*\approx 307.643\,390$ it becomes infinitely thin, i.e., the orbit is reflected along the same path, having $\dot{z}=0$ at its minimum z. This orbit reaches the inverse periodic orbit $(\overline{a})$ after infinite rotations counterclockwise around M_1 (Fig. 10). Therefore this critical orbit is heteroclinic between the orbit (a) and the inverse orbit $(\overline{a})$. We call it "first heteroclinic orbit." The orbits close to m^* with $m<m^*$ have $\dot{z}>0$ at their minimum x while the orbits with $m>m^*$ have $\dot{z}<0$ at this minimum. All the orbits with $74.94<m<m^*$ are of type I, i.e., they fall into the black hole M_1.

The critical value $m=m^*=307.643\,390$ is found as follows. All orbits having m in the interval $280<m<306.7$ fall into M_1 after a fourth intersection of the z axis with $\dot{x}>0$ but before a fifth intersection. The orbit $m=306.8$ makes first three clockwise rotations around M_1, then goes to the left reaching a minimum x near the CZV and then returns and makes a complete turn counterclockwise around M_1 and is the first orbit with this accuracy (i.e., with so many decimals) that has a fifth intersection with the z axis just below M_1.

The orbit with $m_0=307.613$ makes two counterclockwise rotations (six intersections in total), $m_1=307.642\,411\,0$ makes three counterclockwise rotations (seven intersections in total), $m_2=307.643\,360\,1$ makes four counterclockwise rotations (eight intersections in total), $m_3=307.643\,389\,5$ makes five counterclockwise rotations (nine intersections in total). The last orbit (Fig. 10) is very close to the "first" heteroclinic orbit.

The intervals between these successive orbits are equal to $\Delta m_1=0.029\,41$, $\Delta m_2=0.000\,949$, $\Delta m_3=0.000\,0294$. Each successive interval is smaller by a factor close to the eigenvalue $\lambda=32.33$ of the periodic orbit $(\overline{a})$.

The reason is the following. The successive intersections of the $(z,\dot{z})$ plane by the heteroclinic orbit m^* connecting the orbits (a) and $(\overline{a})$ approach the orbit $(\overline{a})$ by a factor λ at each iteration, where λ is the (larger) eigenvalue of the orbit $(\overline{a})$. An orbit starting at m close to m^* with $m<m^*$, has six, seven, etc., intersections with the $(z,\dot{z})$ plane close to the corresponding intersections of the heteroclinic orbit m^* at distances $d_6(m)$, $d_7(m)$, etc., increasing by a factor λ at each iteration. If now the initial differences $|m_i-m^*|$ decrease by factors λ ($|m_i-m^*|\approx|m_0-m^*|/\lambda^i$), the corresponding distances at the sixth intersection $d_6(m_i)$ decrease approximately by the same factors $[d_6(m_i)=d_6(m_0)/\lambda^i]$. Then as the distances $d_7(m_i)$, $d_8(m_i)$ increase by λ at each iteration we reach the initial distance $d_6(m_0)$ at the $(6+i)$ iteration $[d_{6+i}(m_i)\approx d_6(m_0)]$. If now the m_0 orbit escapes to the black hole after its sixth intersection, the orbit m_i escapes after its $(6+i)$ intersection.

As the successive intervals $|m_i-m^*|$ decrease by a factor λ, the intervals $|m_i-m_{i-1}|$ also decrease by the same factor. Thus we can calculate m^* as the limit of an infinite series beyond $m_2=307.643\,360\,1$ by adding to m_2 the sum

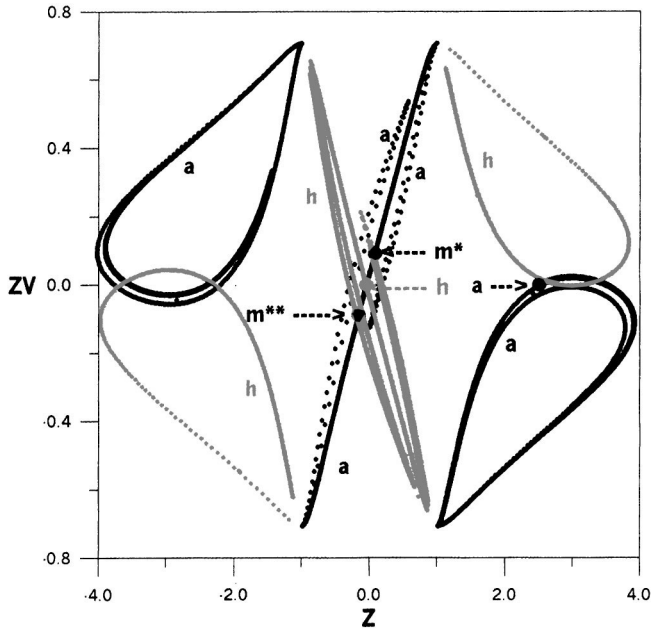

FIG. 9. The unstable asymptotic curve of the orbit (a) (black) and the stable asymptotic curve of the orbit (h) (gray) intersect at an infinity of heteroclinic points close to H_2 ($m=311$), but also close to O and some other points of this figure. The main homoclinic and heteroclinic points along the arc (2) of the unstable asymptotic curve of the orbit (a) are confined between the points $m*$ and $m**$.

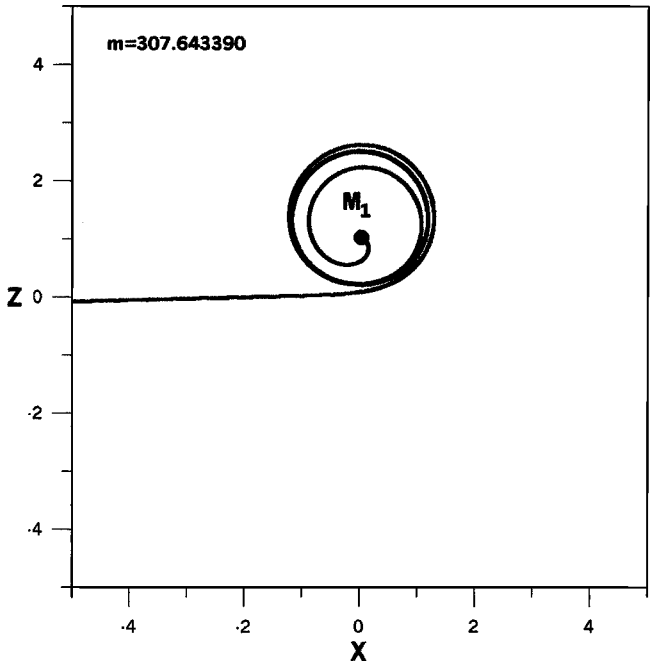

FIG. 10. The orbit $m=307.643\,390$ is very close to a heteroclinic orbit joining the periodic orbits (a) and ($\overline{a}$). The heteroclinic orbit is the limit of orbits starting above the periodic orbit (a) and intersecting the z axis n times with $\dot{x}>0$ where $n=5,6,7,8,9$, etc. This orbit has $\dot{z}=0$ at its minimum x.

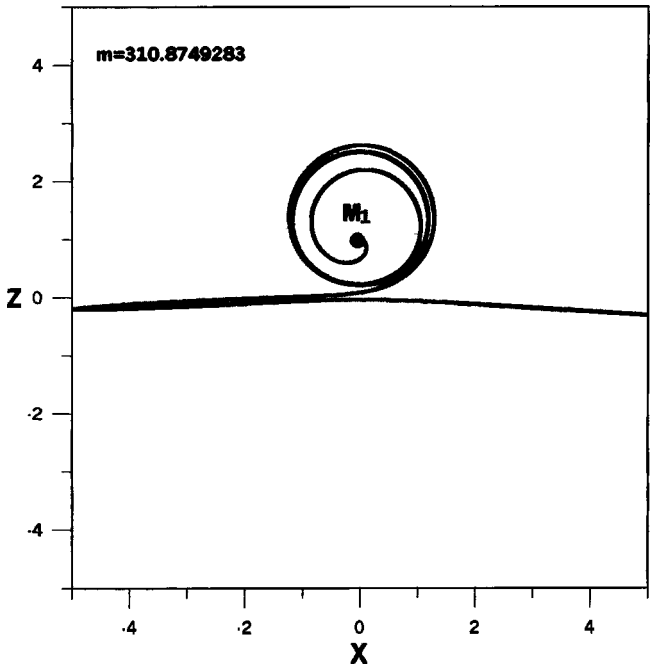

FIG. 11. The orbit $m=310.874\,928\,3$ is very close to a heteroclinic orbit joining (a) and $(\overline{a})$ that has $(\dot{z}=0)$ at its maximum x. This heteroclinic orbit is the limit of orbits having $n=6,7,8,\ldots$ intersections with the z axis with $\dot{x}>0$. These orbits have $\dot{z}<0$ at their minimum x.

$$\Sigma\Delta m=\frac{0.000\,029\,4}{1-\dfrac{1}{32.33}}=0.000\,030\,3, \tag{2}$$

hence the limiting value of m is $m^*=307.643\,360\,1+0.000\,030\,3=307.643\,390\,4$. All other homoclinic and heteroclinic orbits have been calculated in the same way.

If we proceed beyond $m=m^*$ we have orbits with $\dot{z}<0$ at their minimum x. The orbits a little beyond $m=310$ (Fig. 4) have also an oscillation to the right with $\dot{z}>0$ at the maximum x. As m increases beyond $m=310$ this oscillation becomes thinner and for m very close to $\overline{m}=310.874\,928\,3$ (Fig. 11) the orbit has $\dot{z}=0$ at its maximum x. The orbit returns along the same path and approaches the orbit $(\overline{a})$ after reaching a minimum x, following the maximum x with $\dot{z}=0$, and then making infinite counterclockwise rotations around M_1. This orbit is a second heteroclinic orbit $(a\rightarrow\overline{a})$ but of different form from the first heteroclinic orbit.

Between the first and the second heteroclinic orbits there are infinite heteroclinic orbits connecting the periodic orbit (a) with its opposite orbit $(\overline{a})$. In fact, close to the first heteroclinic orbit but with m larger than m^*, there are orbits that make one rotation counterclockwise around M_1 after their minimum x and then make an oscillation to the right. An orbit very close to $m=307.797\,852\,2$ after a counterclockwise rotation around M_1 reaches a maximum x with $\dot{z}=0$ and returns along the same path making infinite counterclockwise rotations around M_1. Therefore it is again a heteroclinic orbit connecting the orbits (a) and $(\overline{a})$.

Even closer to the first heteroclinic orbit there are orbits with two or more counterclockwise rotations around M_1 after their minimum x, that have also an oscillation to the right reaching a maximum x with $\dot{z}=0$. All these orbits are heteroclinic between (a) and $(\overline{a})$. The limit of these heteroclinic orbits is the original heteroclinic orbit m^*.

Close to the second heteroclinic orbit $\overline{m}$, but with smaller m, there are orbits that make some

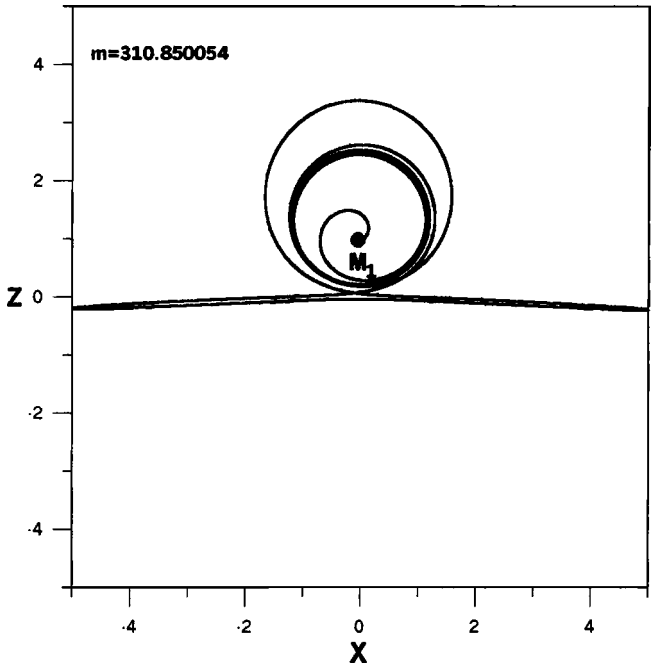

FIG. 12. The orbit $m=310.850\,054$ is very close to a homoclinic orbit for the periodic orbit (a). It is the limit of orbits having an oscillation to the left with $\dot{z}<0$ at their minimum x, then an oscillation to the right with $\dot{z}>0$ at their maximum x and then make $n=1,2,3,4\ldots$ rotations clockwise around M_1.

clockwise rotations around M_1 before reaching M_1. In particular an orbit close to $m_a=310.850\,054$ (Fig. 12) makes infinite clockwise rotations before reaching M_1. This orbit is homoclinic to the periodic orbit (a).

All the orbits between the homoclinic orbit near $m_a=310.850\,054$ (Fig. 12) and the heteroclinic orbit near $\overline{m}=310.874\,928\,3$ (Fig. 11) fall into M_1. The progression of such orbits is seen in Fig. 13. The number of clockwise rotations around M_1 is infinite for the homoclinic orbit m_a, but as m increases beyond m_a the number of rotations decreases. The orbits of Fig. 13 make first three clockwise rotations around M_1 and then they extend to the left and later to the right after a fourth intersection with the z axis. After reaching a maximum x the orbit $m=310.851$ makes one and one-half clockwise rotations around M_1 and then falls into M_1. The orbit $m=310.860$ after its maximum x makes about one clockwise rotation before falling into M_1. The orbits $m=310.868$, $m=310.873$ both have only one extension to the left, after their maximum x, but the latter starts to form a counterclockwise rotation around M_1, as it approaches M_1, and has one more intersection with the z axis. As m increases further and approaches $\overline{m}$ the number of counterclockwise rotations around M_1 increases and tends to infinity.

Close to the heteroclinic orbits joining (a) and $(\overline{a})$, with extra rotations around M_1 before the oscillation to the right with $\dot{z}=0$ at their maximum x, there are further homoclinic orbits from the orbit (a) to the same orbit (a) for slightly smaller m. For example, there is a homoclinic orbit making an oscillation to the left with $\dot{z}<0$ at its minimum x, then a counterclockwise rotation around M_1 and an oscillation to the right with $\dot{z}>0$ at its maximum x, and then infinite clockwise rotations around M_1. There is an infinity of homoclinic orbits with n counterclockwise rotations around M_1 after an oscillation to the left and before an oscillation to the right. The value of m for these homoclinic orbits decreases with increasing n, and as n tends to infinity $m\rightarrow m^*$. The calculation of these higher order orbits is difficult, because we reach the limit of double precision accuracy.

There are more heteroclinic orbits, connecting (a) with $(\overline{a})$, (a'), $(\overline{a'})$, (h), (b), (b'), $(\overline{b})$, and $(\overline{b'})$.

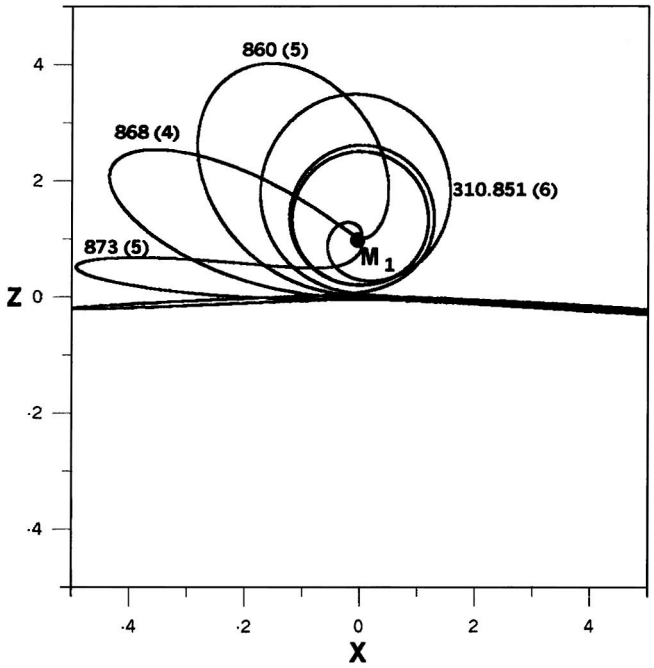

FIG. 13. All the orbits between the homoclinic orbit close to $m_1=310.850\,054$ and the heteroclinic orbit close to $m_2=310.874\,828\,3$ fall into M_1. Their total number of intersections with the z axis (with $\dot{x}>0$) is shown in parentheses.

The most important among these heteroclinic orbits is the orbit $m=m^{**}=314.384\,627$, that connects (a) with the inverse orbit $(\bar{b})$, around M_2 (Fig. 14). This is the last heteroclinic orbit in an interval of values of m around $m=311$, because all the orbits with $m>m^{**}$ up to $m=559$ reach the black hole M_2.

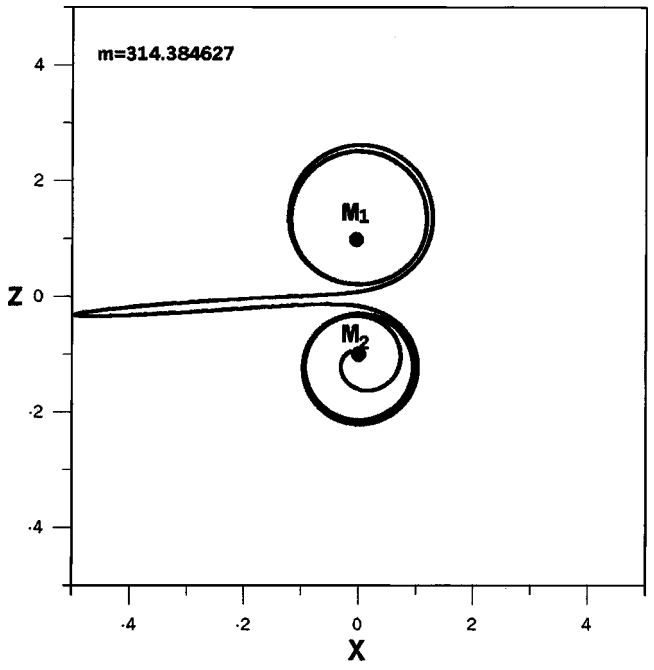

FIG. 14. The orbit $m=314.384\,627$ is very close to a heteroclinic orbit connecting (a) with (b).

In the inner neighborhood of m^{**}, i.e., for small negative $(m-m^{**})$, there are infinite heteroclinic and homoclinic orbits and transitions from orbits falling into M_1 (type I) and orbits falling into M_2 (type II). Such orbits make a number of clockwise rotations around M_2 close to the periodic orbit $(\overline{b})$ after reaching their minimum x, and then recede outwards from the orbit $(\overline{b})$ in various directions. If we try to find accurately the transitions between these orbits we have problems with accuracy, because we must go to decimal places beyond those secured by double precision.

However, if we calculate orbits with even smaller m then the main transitions are clearly defined.

As we have seen in Fig. 13 an interval $\Delta m=\overline{m}-m_a$ of orbits falling into M_1 is terminated on the one side by an homoclinic orbit and on the other side by an orbit heteroclinic with the inverse orbit $(\overline{a})$. All the orbits between them are of type I.

In general an interval Δm of orbits of type I is terminated by a homoclinic orbit $(a\rightarrow a)$ and a heteroclinic orbit $(a\rightarrow\overline{a})$, while an interval Δm of orbits of type II is terminated by two heteroclinic orbits $(a\rightarrow b)$ and $(a\rightarrow\overline{b})$. However there are also cases where the orbits at the ends of such an interval Δm are of the same type, e.g., $(a\rightarrow\overline{a})$ and $(a\rightarrow\overline{a})$. In this case the heteroclinic orbits $(a\rightarrow\overline{a})$ at the ends of the interval Δm are different in form, although they approach the same orbit $(\overline{a})$.

Transitions between orbits of type I and type II occur near every homoclinic and heteroclinic orbit. For example, while all the orbits close to $m^*=307.643\,390$ (Fig. 10) with $m<m^*$ fall into M_1 after a number of clockwise rotations around M_1, the orbits with $m>m^*$ may fall either into M_1, or M_2. Such orbits with $m>m^*$ have $\dot{z}<0$ at their minimum x, but then they form a number of rotations counterclockwise around M_1, close to the orbit $(\overline{a})$, and later they recede away from this orbit. Some of them make a number of rotations around M_2 and finally they fall into M_1, or M_2. Therefore the sets of orbits falling into M_1 and M_2 are fractal.

In Fig. 9 we see that along the diagonal part of the asymptotic curve [arc (2)], there is only a relatively small part, between m^* and m^{**}, that contains infinite heteroclinic and homoclinic orbits and correspondingly infinite intervals of orbits of types I and II. On the other hand, all orbits on the diagonal above m^* are of type I and all orbits below m^{**} are of type II.

In Fig. 8 we see the heteroclinic points H_1, H_2, H_3, H_4 which have initial conditions given in Table III. Up to now we have considered in detail the region close to H_2 $(m\approx 311)$. A characteristic feature of the orbits in this region is an oscillation to the left (Figs. 10–14) with $\dot{z}$ equal to zero or to a small negative near the minimum x.

If we come now to the orbits near $m=559$ we see that they do not have this oscillation to the left. In Fig. 15 we show two orbits close to the heteroclinic orbit from (a) to (b). These orbits start asymptotically at the orbit (a) for $t\rightarrow-\infty$. After the initial time $t=0$ they make three clockwise rotations around M_1, and four counterclockwise rotations around M_2. The first rotation around M_2 is close to the orbit (b') and the following three rotations are very close to the orbit (b). Then the orbit $m=559.1297$ makes one more rotation around M_2 and falls into M_2, while the orbit $m=559.1298$ makes one rotation clockwise around M_1 and falls into M_1. The orbit $m=m^{***}=559.1297$ is very close to the heteroclinic orbit that reaches the orbit (b) after infinite oscillations around M_2 as t tends to infinity.

All the orbits with m between $m^{**}=314.384\,627$ to $m^{***}=559.1297$ are of type II, i.e., they fall into M_2 (Fig. 16). It is remarkable that the orbits in this interval change fast only for m close to m^{**} or m^{***} while far from these limiting values they change slowly. Then there is an interval of values of m up to $m^{****}\approx 576$ with several transitions between orbits of type I and of type II, followed by a large interval of orbits of type I, up to about $m\approx 726$, and so on.

In general we find the following:

(1) Between an asymptotic orbit of type I (falling into M_1) and an orbit of type II (falling into M_2) there is always a homoclinic (or heteroclinic) orbit. The original point of this orbit on the phase space is at the intersection of the asymptotic curves of the original periodic orbit

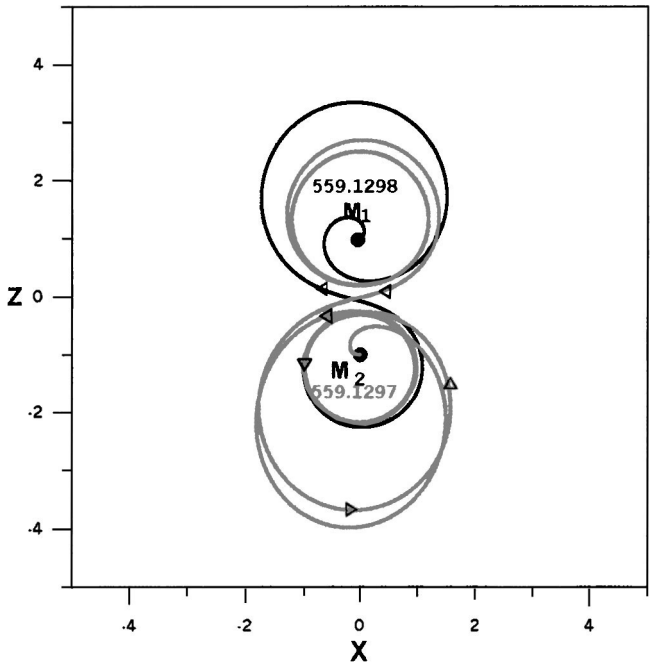

FIG. 15. The orbit $m=m^{***}=559.1297$ is close to a heteroclinic orbit connecting (a) and (b). All orbits in the large interval $m^{**}=314.3846\ldots<m<m^{***}$ are of type II. But orbits with $m>m^{***}$ are either of type I ($m=559.1298$) or of type II.

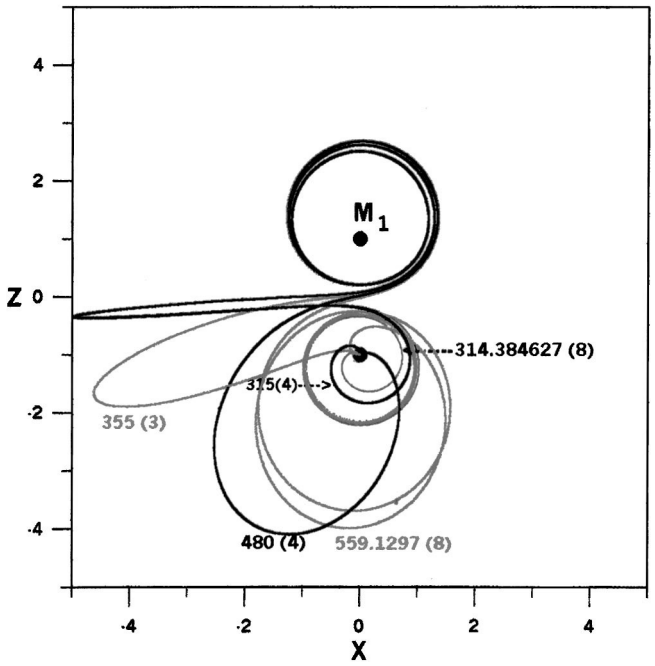

FIG. 16. All the orbits between $m^{**}=314.384\,628$ [heteroclinic to ($\bar{b}$)], and $m^{***}=559.1297$ [heteroclinic to (b)] are of type II. In parentheses we give the total numbers of intersections of the z axis (with $\dot{x}>0$) after the initial points.

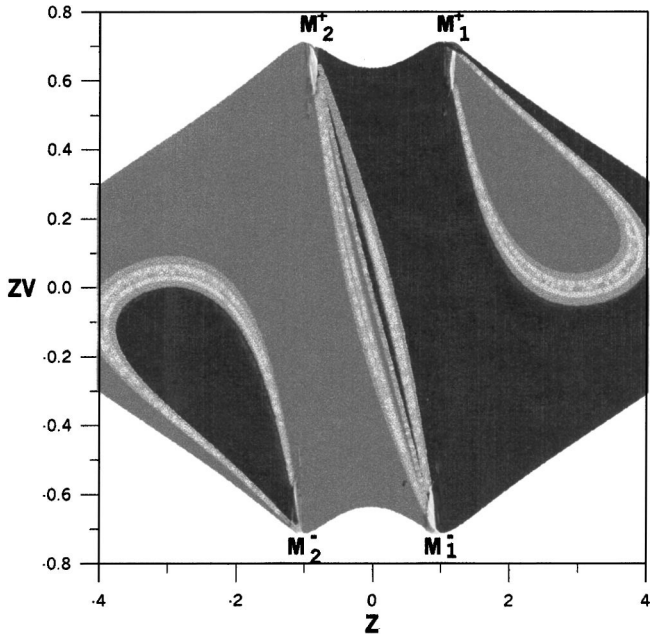

FIG. 17. Basins of attraction of the black holes M_1 and M_2. We distinguish the orbits that fall into M_1 (black), or M_2 (gray) before an intersection with the z axis, (with $\dot{x}>0$) or after only one intersection. The white regions represent orbits that fall into M_1, or M_2 after more than one intersection.

(a) and of the same, or another, periodic orbit. This orbit is homoclinic in the first case and heteroclinic in the second case.

(2) Near every homoclinic or heteroclinic orbit there are infinite intervals of orbits of types I and II. The intervals of type I are terminated by homoclinic orbit ($a\to a$) and heteroclinic orbits ($a\to\overline{a}$). The intervals of type II are terminated by two heteroclinic orbits of types ($a\to b$) and ($a\to\overline{b}$).

If we reduce m by a factor λ we find the same orbits as above after one more iteration (orbits of types I and II, and homoclinic and heteroclinic orbits). For example, the orbits close to $m=311$ considered above near their fourth intersection, are also represented by orbits near $m=311/\lambda\approx 9.5$ at their fifth intersection. Similar results appear for m equal to m/λ^2, m/λ^3, etc., after two, three, etc., more intersections with the z axis. Therefore very close to the periodic orbit O, along its unstable asymptotic curve, there are infinite transitions of types I and II orbits and infinite homoclinic and heteroclinic orbits connecting the orbit (a) with itself, or with the periodic orbits ($\overline{a}$), (a'), ($\overline{a'}$), (h), (b), (b'), ($\overline{b}$), ($\overline{b'}$).

V. BASINS OF ATTRACTION AND CHAOS

If we exclude the periodic orbits and the small islands of stability around stable periodic orbits, all other orbits fall into the black holes M_1 and M_2. The basins of attraction of the two black holes on the surface of section are shown in Fig. 17. The black regions fall into M_1 and the gray regions fall into M_2. Each basin consists of large compact regions of initial conditions falling into one black hole, and of thin filaments that have a fractal structure.

The largest regions are called 0-iterations, because they fall into M_1 or M_2, before any intersection with the z axis (with $\dot{x}>0$). These regions are surrounded by elongated regions that fall into M_1 or M_2, after one intersection with the z axis. Furthermore, there are thin filaments of 0, 1, 2 iterations, etc.

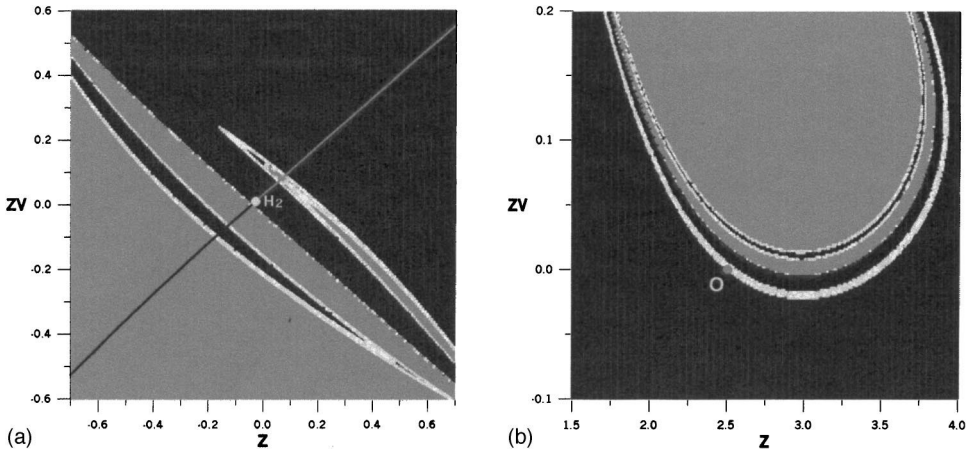

FIG. 18. (a), (b). Details of Fig. 17: Orbits that fall into M_1 (black), or M_2 (gray), before a second intersection. The orbits in the white regions fall into one of the black holes after the second iteration. The line in (a) is the arc (2) of the unstable asymptotic curve of the orbit O, marked in (b).

In Figs. 18(a) and 18(b) we see some of the regions of 0 iteration and 1 iteration, in greater detail. Near the homoclinic and heteroclinic, orbits pass thin filaments of arbitrarily high order. These filaments form fractal sets in the same way as the initial conditions of the asymptotic curves that lead to M_1 or M_2, close to the homoclinic and heteroclinic orbits.

The fact that many orbits fall into M_1 or M_2, produces a nonpreservation of areas on the surface of the section. In Fig. 19 we see the successive images of a small circle of radius $R=0.001$ around the periodic orbit O. The first iteration produces an elongated ribbon like an ellipse with the same area as the circle [Fig. 19(a)]. (This ribbon is so thin that its thickness is not apparent in this figure.) The second, third, and fourth iterations [Fig. 19(b)] produce thinner regions with the same area. However the fifth iteration produces a much longer ribbon that consists of three parts and reaches the black holes M_1 and M_2 [Fig. 19(c)]. This ribbon has an area smaller than the original circle. Therefore, the surface of section is not a "Poincaré surface of section," in which the areas are preserved.

The loss of areas and the very existence of basins of attraction characterizes dissipative systems. This seems strange because our problem is conservative. However, the existence of singularities along the orbits of most initial conditions relaxes the consequences of the conservative character of our system. The problem of two fixed black holes has many characteristics of a chaotic scattering system. But in general chaotic scattering systems lead to escapes to infinity, while here most motions are led to the points M_1 and M_2 at a finite distance.

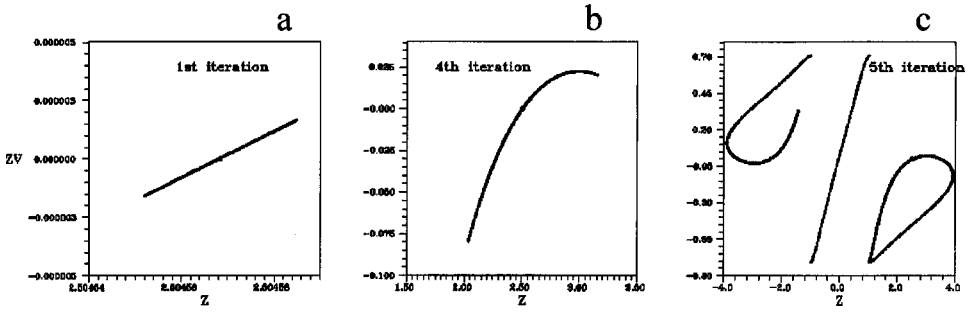

FIG. 19. (a), (b), (c). The images of a circle of radius $R=0.001$ around O on the surface of section $(z,\dot{z})$ at (*a*) the first iteration, (*b*) the fourth iteration, and (*c*) the fifth iteration.

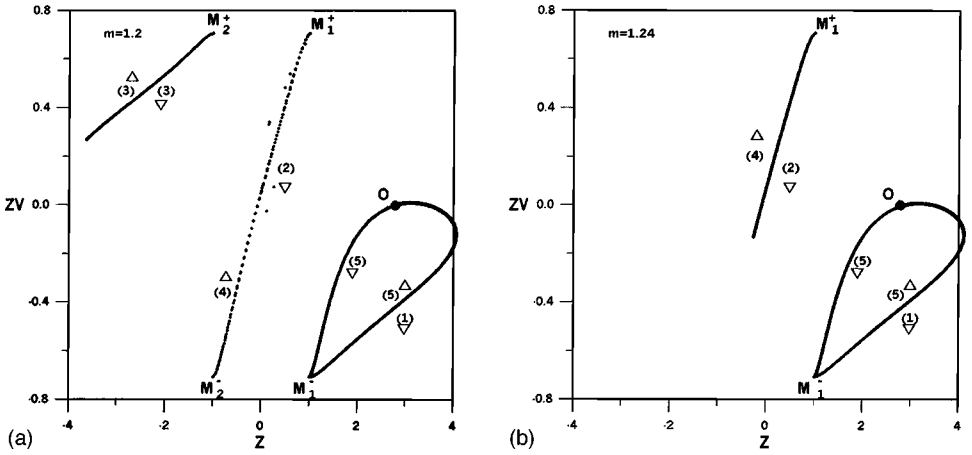

FIG. 20. The unstable asymptotic curve of the orbit O in the cases (a) $M_1=1.2$ and (b) $M_1=1.24$.

At this point we should emphasize a difference between the relativistic problem of two fixed black holes and the corresponding classical problem of two fixed centers. In the second case the phase space extends to infinity along the velocity axis ($\dot{z}$), Therefore although we do not have escapes in coordinate space, we do have escapes in velocity space. But in the relativistic problem with elliptic energy we do not have escapes to infinity, neither in the coordinates nor in the velocities.

We conclude that when the orbits in a conservative system are attracted to one or more singular points, the system does not have some of the usual properties of generic conservative systems, but has some (not all) of the properties of dissipative systems.

VI. OTHER CASES

If we vary the mass M_1 while keeping $M_2=1$ and the energy constant ($E=\sqrt{0.5}$) the positions of the periodic orbits and of the asymptotic curves change. As M_1 increases the orbits (a) and (a') approach each other and for $M_1=M_{1\,\max}=1.3257$ they join and disappear.

For M_1 close to the maximum $M_{1\,\max}$ the orbit (a') is stable.[2] The asymptotic curves of the orbit (a) starting at the point O surround the island of stability. The homoclinic point H_1, beyond the island, also approaches the orbit O.

As M_1 increases beyond $M_1=1.1$ the part (3) of the (upper) asymptotic curve of the orbit (a) (Fig. 2) becomes shorter [Fig. 20(a)] and disappears for some value of M_1 larger than $M_1=1.2$. For still larger M_1 the branches (2) and (4) join each other and they no longer reach the point M_2^- of Fig. 2 [Fig. 20(b)]. As M_1 increases further the branches (2)–(4) disappear, and for even larger M_1 the branches (1) and (5) join each other and they do not reach the point M_1^- [Fig. 21(a)].

The point H_1 is the first homoclinic point on the right of the orbit O with $\dot{z}=0$. At this point the curve U from O crosses the curve S outwards. The first image of H_1 is the homoclinic point H'_1, and between H_1 and H'_1 the curve U crosses the curve S inwards at the point H_1^-. The branches (1) and (5) in the case of Fig. 21(a) form an elongated lobe U on the right of O, reaching a point with maximum distance from O and terminating at the point H_1^-. Between O and H_1 there is the unstable periodic point a'.

For still larger M_1 [Fig. 21(b)] the lobe becomes smaller. In this case between the periodic orbit O and the homoclinic point H_1 there is an island of stability surrounding the periodic orbit a' which is stable in this case. This island consists of a set of closed invariant curves, surrounded by four small secondary islands. As M_1 increases further the points O and H_1 approach each other and the periodic orbits, the islands, and the asymptotic curves disappear for $M_1>1.3257$.

The evolution of the lobe from H_1 to H'_1 along the unstable asymptotic curve from the periodic orbit O can be described as follows. For relatively large M_1 [$M_1=1.325$; Fig. 21(b)] this

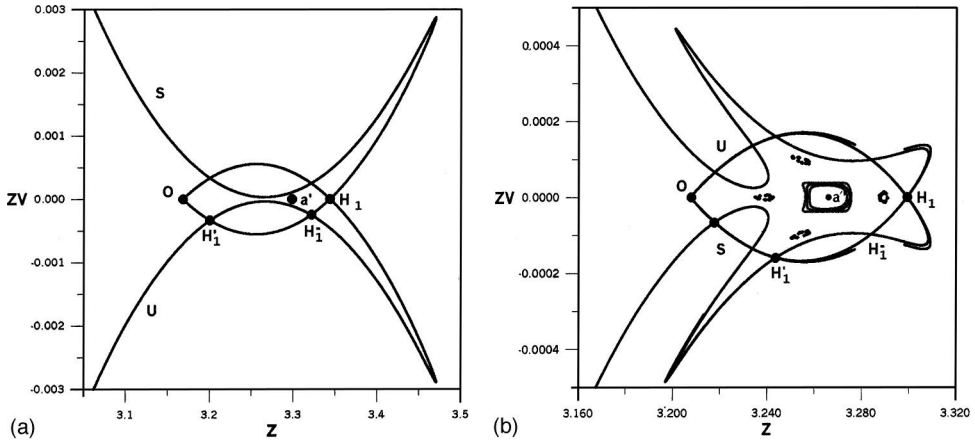

FIG. 21. The unstable and stable asymptotic curves close to the orbit O for (a) $M_1=1.322$ and (b) $M_1=1.325$. Some of the main homoclinic points are marked. In the second case some stable islands appear between O and H_1. The orbit (a') is unstable for $M_1=1.322$ and stable for $M_1=1.325$.

lobe is rather short, but it becomes longer as M_1 decreases [Fig. 21(a)]. For smaller M_1 this lobe is very long and reaches the black hole M_1 at the point M_1^-. For even smaller values of M_1 there is a second (separated) part of this lobe starting and ending at the point M_1^+ [Fig. 20(b)] and reaching a maximum distance from M_1 close to the diagonal $M_1^+ M_2^-$. For smaller M_1 this part of the lobe terminates at the point M_2^- and for still smaller M_1 there is a third (separated) part of the same lobe starting at the point M_2^+ and reaching a maximum distance from M_2^+ along the average asymptotic curve [average between the two arcs of the branch (3)] [Figs. 20(a) and 2].

When $M_1 > M_{1\,\max}$ there are no orbits (a) and (a'). In these cases the orbits (b) and (b') in some sense take the place of the orbits (a) and (a'). Namely when both orbits (a) and (b) are present the asymptotic curves of the orbit (b) (stable and unstable) are close to the asymptotic curves of the orbit (a) and when the asymptotic curves of the orbit (a) disappear they are replaced by the asymptotic curves of the orbit (b). An example is given in Fig. 22 for $M_1=1.326$. This value of M_1 is a little above the maximum value of M_1 ($M_{1\,\max}=1.3257$) beyond which the orbits (a) and (a') do not exist. This curve is qualitatively similar to the unstable asymptotic curve of the orbit (a) for $M_1=1.1$ (Fig. 2) although there are quantitative differences. Because of this similarity the overall structure of the phase space giving the basins of attraction does not change appreciably from Fig. 17.

VII. CONCLUSIONS

The main results of the present study are the following.

(1) The asymptotic curves of the main unstable periodic orbits in the case of two fixed black holes are composed of discontinuous arcs reaching one or two black holes. Some arcs join one black hole with the other, but there are also many arcs that start and terminate at the same black hole. The limiting forms of these arcs close to the black hole are explained theoretically in the Appendix.

(2) The orbits with initial conditions on the asymptotic curves are asymptotic orbits, i.e., they tend to the periodic orbit (a) as $t\to-\infty$. Most of these orbits fall into one or the other black hole. However, there are infinite doubly asymptotic orbits that tend to the same periodic orbit (homoclinic orbits) or to another periodic orbit (heteroclinic orbits) as $t\to\infty$.

(3) There is a continuity of the orbits falling into a black hole before and after n iterations (n intersections with a surface of section $x=0$ with $\dot{x}>0$).

(4) The asymptotic orbits are defined along an unstable asymptotic curve by their distances $m\times10^{-8}$ from the periodic orbit (in our calculations m varies from 1 to 20 000). At every itera-

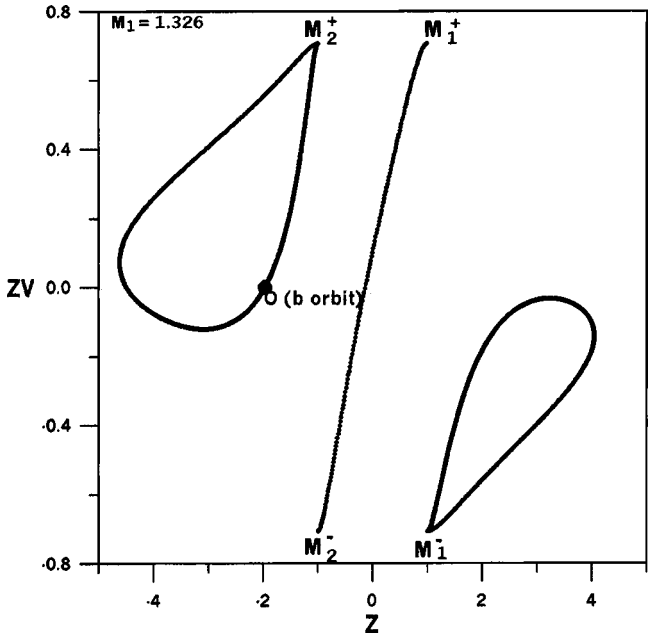

FIG. 22. Parts of the unstable asymptotic curve of the orbit (b) for $M_1=1.326$ ($M_2=1, E=\sqrt{0.5}$). This value of M_1 is just above the maximum $M_{1\,\max}$ for the existence of the orbits (a) and (a').

tion the distance $m\times 10^{-8}$ increases by a factor $\approx\lambda$, where λ is the larger (absolutely) eigenvalue of the periodic orbit. The measure $\Sigma\Delta m$ of orbits that have not reached a black hole after n iterations decreases exponentially with n.

(5) There are five types of simple periodic orbits (orbits of period 1). Two of them surround the black hole $M_1(a,a')$, two surround the black hole $M_2(b,b')$, and one (h) is like an arc of a hyperbola between the orbits (a), (a') and (b), (b'). The orbits (a,a',b,b') can be described also in the inverse direction $(\overline{a},\overline{a'},\overline{b},\overline{b'})$, while the orbit h is the same with its inverse. The sets of orbits falling into one black hole (M_1 or M_2) as $t\to\infty$, are limited by homoclinic or heteroclinic orbits asymptotic to the smaller periodic orbits around M_1 [orbits (a), $(\overline{a})$] and around M_2 [orbits (b), $(\overline{b})$].

(6) The distances Δm between asymptotic orbits falling into M_1 (or M_2 after $n=1,2$, etc., rotations around M_1 (or M_2) decrease by a factor $\approx\lambda$, where λ is the eigenvalue of the orbit (a) or (a') in the first case, and of the orbit (b) or (b') in the second case. The limit of such orbits is the homoclinic orbit connecting (a) with (a) or a heteroclinic orbit connecting (a) with (a'), (b), (b'), or the inverse orbits $(\overline{a})$, $(\overline{a'})$, $(\overline{b})$, $(\overline{b'})$.

(7) There are infinite intervals Δm of orbits of type I (falling into M_1) and of type II (falling into M_2) close to every homoclinic or heteroclinic orbit. These intervals are limited by homoclinic or heteroclinic orbits between the inner periodic orbits around M_1 and M_2. The limiting orbits are of types $a\to a$, $a\to\overline{a}$ for intervals of type I and of types $a\to b$, $a\to\overline{b}$ for intervals of type II. Therefore the sets of orbits of types I and II are fractal.

(8) The homoclinic and heteroclinic orbits are confined in relatively small intervals along an asymptotic curve. Such an interval containing infinite homoclinic and heteroclinic orbits in Fig. 10 [arc (2)] is confined between $m^*\approx 307.64$ and $m^{**}\approx 314.38$. On the other hand, all orbits in a large interval $74.94<m<m^*$ fall into M_1 and all orbits in the interval $m^{**}<m<559.12$ fall into M_2.

(9) Similar intervals containing infinite homoclinic and heteroclinic orbits appear in other arcs of the asymptotic curve. In particular if we take an interval $(m^*/\lambda, m^{**}/\lambda)$ close to the periodic

orbit O we have the same transitions after one more iteration. Similar orbits appear in the intervals $(m*/\lambda^2, m**/\lambda^2)$ and so on. Therefore close to O there are infinite sets of homoclinic and heteroclinic orbits.

(10) An exploration of the whole phase space gives the domains of escape into the black holes M_1 and M_2 after some iterations beyond the initial points. There are large domains of orbits that escape immediately into M_1 and M_2 and fractal regions with escapes into M_1 or M_2, after any number of iterations (0,1,2…). As most orbits fall into the black holes after a finite time one cannot calculate a Lyapunov characteristic number. Nevertheless the fractal mixing of the various domains of escape gives another way to establish the chaotic behavior of the system of two black holes.

(11) The areas on a surface of section are not preserved. Therefore the surface of section $x=0$ ($\dot{x}>0$) is not a "Poincaré surface of section." The black holes act as attractors despite the fact that the system is conservative. Therefore the system of two fixed black holes has certain properties of dissipative systems.

The last conclusion, together with the fact that the sets of orbits falling on the two black holes are fractal, are the main results of the present study.

APPENDIX: ORBITS VERY CLOSE TO A BLACK HOLE

The equations of motion in the case of two black holes are[5,1]

$$\frac{\mathrm{d}}{\mathrm{d}s}(U^2Q^2\dot{\psi}^2) = E^2\dot{\psi}\frac{\partial}{\partial\psi}\left[U^2Q\left(U^2-\frac{\delta_1}{E^2}\right)\right],$$
$$\frac{\mathrm{d}}{\mathrm{d}s}(U^2Q^2\dot{\theta}^2) = E^2\dot{\theta}\frac{\partial}{\partial\theta}\left[U^2Q\left(U^2-\frac{\delta_1}{E^2}\right)\right], \tag{A1}$$

where ψ and θ are prolate spheroidal coordinates in the case of particles moving on a meridian plane of a potential U with

$$U=\frac{1+[(\mathrm{M}_1+\mathrm{M}_2)\cosh\psi+(\mathrm{M}_1-\mathrm{M}_2)\cos\theta]}{Q} \tag{A2}$$

and

$$Q=\sinh^2\psi+\sin^2\theta>0, \tag{A3}$$

E is the value of the energy, which is assumed of the elliptic type, i.e., $0<E<1$, and s is the proper time, while the dot means a derivative with respect to s; $\delta_1=0$ for photons and $\delta_1=1$ for particles.

The coordinates x and z are

$$x=\sinh\psi\sin\theta,\quad z=\cosh\psi\cos\theta, \tag{A4}$$

and at the black hole M_1 we have $\psi=\theta=0$. Along the z axis, above M_1, we have $\theta=0$, and below M_1 we have $\psi=0$.

We consider now motions close to the black hole M_1. Then ψ and θ are small quantities, and to second order

$$x=\psi\theta,$$

$$z - 1 = \tfrac{1}{2}(\psi^2 - \theta^2). \tag{A5}$$

The largest term of U is

$$U = \frac{2M_1}{\psi^2 + \theta^2}. \tag{A6}$$

The largest terms of the equations of motion (A1) are

$$\begin{aligned} \frac{d}{ds}\left(\frac{\dot{\psi}}{\psi^2 + \theta^2}\right) &= -\frac{3E^2\psi}{(\psi^2 + \theta^2)^3}, \\ \frac{d}{ds}\left(\frac{\dot{\theta}}{\psi^2 + \theta^2}\right) &= -\frac{3E^2\theta}{(\psi^2 + \theta^2)^3}. \end{aligned} \tag{A7}$$

Multiplying the first equation by θ and the second equation by ψ and substracting we find

$$(\psi^2 + \theta^2)(\theta\ddot{\psi} - \psi\ddot{\theta}) - 2(\theta\dot{\psi} - \psi\dot{\theta})(\psi\dot{\psi} + \theta\dot{\theta}) = 0 \tag{A8}$$

and if we write

$$J = \theta\dot{\psi} - \psi\dot{\theta} \tag{A9}$$

we derive

$$Q\dot{J} - J\dot{Q} = 0. \tag{A10}$$

Therefore,

$$\frac{J}{Q} = c \ \text{(constant)}. \tag{A11}$$

This relation is written

$$\frac{\dfrac{d}{ds}\left(\dfrac{\psi}{\theta}\right)}{1 + \left(\dfrac{\psi}{\theta}\right)^2} = \frac{d}{ds}\tan^{-1}\left(\frac{\psi}{\theta}\right) = c \tag{A12}$$

and integrating we derive

$$\tan^{-1}(\psi/\theta) = cs + c' \tag{A13}$$

or

$$\psi = \theta\tan(cs + c') = \theta q, \tag{A14}$$

where s is zero when a particle hits the black hole.

In order to complete the integration close to the black hole we take the second equation (A7) and find

$$\ddot{\theta} - \frac{2\dot{\theta}^2}{\theta} - 2\dot{\theta}qc = -\frac{3E^2}{\theta^3(1 + q^2)^2}. \tag{A15}$$

The second member is large if θ is close to zero. Assuming

$$\theta = \alpha s^m \tag{A16}$$

we find that the second member is $-3E^2 s^{-3m}/a^3(1+q^2)^2$, while the most important terms of the first member are $as^{m-2}[m(m-1)-2m^2]$. The first and second members are of the same order iff $m=0.5$. Then we find

$$a^4 = \frac{4E^2}{(1+q^2)^2} \tag{A17}$$

and

$$z-1 = \frac{1}{2}\theta^2(q^2-1) = \frac{1}{2}a^2 s(q^2-1) = \pm E\left(\frac{q^2-1}{q^2+1}\right)s \tag{A18}$$

while

$$x = \theta^2 q. \tag{A19}$$

Thus the angle between the orbit and the z axis has a tangent equal to

$$\frac{x}{(z-1)} = \frac{2q}{q^2-1}. \tag{A20}$$

When the asymptotic curve reaches the black hole $z=1$ [e.g., at the third intersection in Fig. 1 for m near $m=6722$ (Fig. 3)], the tangent of the angle $x/(z-1)$ tends to zero, i.e., q tends to zero. Therefore, from Eq. (A18) we derive $\dot{z}=\pm E$ (and $\ddot{z}=0$). This is verified numerically for $E=\sqrt{0.5}$ in Fig. 1 where the value of $\dot{z}$ at $m=6722$ is $\ddot{z}=-0.71$ and very close to it the asymptotic curve is horizontal, i.e., $\ddot{z}=0$. The same happens near $m=9052$, where the tangent of the angle between the orbit and the z axis is close to 180°, i.e., $x/|z-1|$ again tends to zero, hence $q\to 0$ and $\dot{z}=\pm E$, $\ddot{z}=0$.

(Received 5 February 2004; accepted 20 September 2004; published 24 November 2004)

We study the combinatorics of the contributions to the form factor of the group $U(N)$ in the large N limit. This relates to questions about semiclassical contributions to the form factor of quantum systems described by the unitary ensemble.
 [DOI: 10.1063/1.1814419]

I. INTRODUCTION

The *form factor* associated to a self-adjoint operator H is a real-valued function describing statistical properties of its spectrum. For sake of simplicity we assume that H acts on finite-dimensional Hilbert space and thus has eigenvalues $E_1,\ldots,E_N\in\mathbb{R}$. Then we consider the Fourier transform of the measure

$$\mu:=\frac{1}{N}\sum_{j,k=1}^{N}\delta_{E_j-E_k}$$

and obtain the form factor

$$K(t):=\int_{\mathbb{R}}\exp(-itE)\mathrm{d}\mu(E)=\frac{1}{N}|\mathrm{tr}(U(t))|^2,$$

with the unitary time evolution $U(t):=\exp(-iHt)$ generated by H.

It is an empirical fact and a physical conjecture (see Bohigas, Giannoni, and Schmit[8] and also Ref. 15) that most form factors encountered in physical quantum systems resemble the form factor associated to a so-called random matrix ensemble (see Mehta[18]).

The simplest of these is the so-called *unitary ensemble* on which we shall concentrate below. This is given by the unitary group $U(N)$ equipped with Haar probability measure μ_N. Its form factor is defined as

$$K_N(t):=\frac{1}{N}\langle|\mathrm{tr}(U^t)|^2\rangle_N\quad(t\in\mathbb{Z}),\tag{1.1}$$

with the expectation $\langle f\rangle\equiv\langle f\rangle_N:=\int_{U(N)}f\mathrm{d}\mu_N$ of a continuous function $f:U(N)\to\mathbb{C}$.

As the map $U\mapsto\mathrm{tr}(U^t)$ is a class function on the unitary group, we can apply Weyl's integration formula

a)Electronic mail: desposti@dm.unibo.it
b)Electronic mail: knauf@mi.uni-erlangen.de

$$\int_{\mathrm{U}(N)} f \mathrm{d}\mu_N = \frac{1}{N!} \int_{\mathbb{T}^N} f \Delta^2 \mathrm{d}\nu_N \tag{1.2}$$

to evaluate (1.1). In (1.2) $f: \mathrm{U}(N) \to \mathbb{C}$ is assumed to be a class function. $\mathbb{T}^N \subseteq \mathrm{U}(N)$ is a maximal torus and may be identified with the subgroup of diagonal matrices. $\mathrm{d}\nu_N$ denotes Haar measure on $\mathbb{T}^N$. Finally for $h := \mathrm{diag}(h_1, \ldots, h_N) \in \mathbb{T}^n \subseteq \mathrm{U}(N)$

$$\Delta(h) := \sum_{1 \leqslant j < k \leqslant N} |h_j - h_k|$$

is the modulus of Vandermonde's determinant for $h_1, \ldots, h_N$. The combinatorial factor $N!$ is the order of the symmetric group S_N making its appearance as the Weyl group, see, e.g., Fulton and Harris.[13]

With these data, the form factor is evaluated,

$$K_N(t) = \begin{cases} N, & t = 0, \\ |t|/N, & 0 < |t| \leqslant N \quad (t \in \mathbb{Z}), \\ 1, & N < |t|. \end{cases} \tag{1.3}$$

This calculation is based on the eigenvalues $h_1, \ldots, h_N$ of the unitary matrix. [As the N eigenvalues of $U \in \mathrm{U}(N)$ have mean distance $2\pi/N$, note that the natural argument of the form factor would be t/N instead of t. However, in order to simplify notation, we use the parameter $t \in \mathbb{Z}$.]

In Ref. 6, Berry proposed a semiclassical evaluation of the form factor for quantum systems, based on the periodic orbits of the principal symbol (Hamiltonian function) of the Hamiltonian operator. For the different random matrix ensembles he derived in the range $0 < t \ll N$ the leading order of $K_N(t)$, which is linear in t/N.

More precisely, semiclassical theory based on the Gutzwiller trace formula provides a link between spectral quantities of the quantum Hamiltonian and properties of the chaotic dynamics of the corresponding classical system. In this approach the spectral two-point correlation function and its Fourier transform, namely the form factor, are calculated by approximating the density of states using the trace formula. This formula expresses them by sums over contributions from pairs of classical periodic trajectories.

If one includes only pairs of equal or time-reversed orbits (the so-called "diagonal approximation") then the form factor agrees with random matrix theory, asymptotically close to the origin (long-range correlations).

A more systematic approach will require a complete control of all the other contributions. A first step towards an understanding of the "off-diagonal" contributions have been achieved in Ref. 7. But only recently, beginning with the article by Sieber and Richter,[23] contributions involving pairs of periodic orbits were systematically considered in order to explain higher order terms in t/N.

In particular, for the geodesic flow on constant negative curvature, a particular family of pairs of periodic orbits have been presented in Refs. 23 and 22, which turned out to be relevant for the first correction to the diagonal approximation for the spectral form factor. These orbits pairs are given by trajectories which exhibit self-intersection with small intersection angles. This result has been generalized recently to more general uniformly hyperbolic dynamical systems.[24]

The combinatorics, however, turned out to be highly nontrivial. These combinatorial difficulties in handling high order corrections to the semiclassical expression of the form factor persist also in the context of quantum graphs, Refs. 16 and 17, where these off-diagonal contributions have been explored up to the third order.[3–5]

In our opinion the complex combinatorics should first be studied in the simplest situation possible, that is, on the group level. Here the unitary ensemble is the simplest one, since the case of the orthogonal or symplectic ensemble involves additional elements like the Brauer algebra, see Ref. 12.

Now we collect the main points of the paper.

We want to compare the form factor $K_N(t)$ with the diagonal contribution

$$\frac{t}{N}\Delta_N^{\max}(t) \quad \text{with} \quad \Delta_N^{\max}(t) := \sum_{i_1,\ldots,i_k=1}^{N} \left\langle \prod_{k=1}^{t} |U_{i_k i_{k+1}}|^2 \right\rangle_N \tag{1.4}$$

(note that only sum over *one* t-tuple of indices in $\Delta_N^{\max}$, hence the name *diagonal contribution*).

The expectation values of products of matrix entries in (1.4) and (1.1) can be evaluated using the well-known formula (2.1), that is, by summing class functions on the symmetric group S_t.

So in Sec. II we introduce some notation concerning the symmetric group.

In Sec. III we discuss the relation between the class functions V and $\mathcal{N}$ on S_t used in (2.1). As stated in Proposition 3.3 they are mutual inverses in the group algebra of S_t.

As a simple by-product, this leads to a rederivation of Eq. (1.2) in the linear regime $|t| \leqslant N$ (Remarks 3.6).

In Sec. IV we study the relation between a natural metric on S_t and the joint operation on the associated partition lattice $\mathcal{P}_t$ (Proposition 4.1).

Section V starts by a (partial) justification of our above definition (1.4), and an estimate of its contributions in terms of formula (2.1). Here the interplay between the partition lattice and cyclic permutation becomes essential (Proposition 5.4). Although Proposition 5.4 is a statement about the $N \to \infty$ limit, we present evidence for our conjecture 5.8 which is a uniform in $N \geqslant t$ version of Proposition 5.4.

In Sec. VI we first prove that only derangements (that is, fixed point free permutations) are involved in the diagonal approximation (Proposition 6.2). Then we estimate the number of contributions to $\Delta_N^{\max}$ with a given power of N (Proposition 6.3).

This leads us to our main result in Sec. VII: Assuming Conjecture 5.8, there exists a subinterval $I := [\varepsilon, C-\varepsilon] \subset [0,1]$ such that the diagonal approximation converges uniformly to the form factor if $t/N \in I$ (Theorem 7.1).

II. GENERALITIES ON THE SYMMETRIC GROUP

As already mentioned in the Introduction, the symmetric group S_t of permutations of the set $[t] := \{1, \ldots, t\}$ plays an important role in the analysis of the unitary ensemble.

We begin by introducing some notation, see Ref. 20 for more information. For $\sigma \in S_t$ the *cycle length* of $i \in [t]$ is the smallest $n \in \mathbb{N}$ with $\sigma^n(i) = i$. i is a *fixed point* of σ if $n = 1$. The *cycle* of i is given by $(i, \sigma(i), \ldots, \sigma^{n-1}(i))$, and can be interpreted as the group element of S_t which permutes the $\sigma^k(i)$ in the prescribed order, leaving the other elements of $[t]$ fixed.

$e \in S_t$ denotes the identity element.

Writing a group element $\sigma \in S_t \backslash \{e\}$ as a product of disjoint cycles $\sigma = \sigma^{(1)}, \ldots, \sigma^{(k)}$, we sometimes omit the fixed points.

Two lattices are associated with the symmetric group S_t:

(i) The *partition lattice* $\mathcal{P}_t$ of *set partitions* $p = \{a_1, \ldots, a_k\}$, with *atoms* or *blocks* $a_l \subseteq [t]$ ($a_l \cap a_m = \emptyset$ for $l \neq m$, $a_l \neq \emptyset$ and $\cup_{l=1}^k a_l = [t]$). $p \in \mathcal{P}_t$ is called *finer* than $q \in \mathcal{P}_t$ (and q *coarser* than p, denoted by $p \leqslant q$) if every block of p is contained in a block of q. The meet $p \vee q$ of $p, q \in \mathcal{P}_t$ is the unique finest element coarser than p and q. We define the rank $|p|$ of the partition $p = \{a_1, \ldots, a_k\} \in \mathcal{P}_t$ by $|p| := k$ (note that this is called the corank in Ref. 1).

(ii) The *dominance order* $\mathcal{D}_t$ of *number partitions* $\lambda = (\lambda_1, \ldots, \lambda_k) \in \mathcal{D}_t$ of $t \in \mathbb{N}$ (with $\lambda_l \in \mathbb{N}, \lambda_{l+1} \leqslant \lambda_l$ and $\Sigma_{l=1}^k \lambda_l = t$). The map

$$\mathcal{P}_t \to \mathcal{D}_t, \quad \{a_1, \ldots, a_k\} \mapsto (|a_1|, \ldots, |a_k|)$$

induces an order relation and a rank function on $\mathcal{D}_t$.

See Ref. 1 for more information.

Each permutation $\sigma \in S_t$ partitions $[t]$ into atoms belonging to the same cycle of σ. Thus we have a map

$$S_t \to \mathcal{P}_t, \quad \sigma \mapsto \hat{\sigma}.$$

If the context is clear, we omit the hat. In particular $|\sigma| := k$ if $\sigma = \sigma^{(1)}, \ldots, \sigma^{(k)}$ is the disjoint cycle decomposition of σ (including fixed points).

Examples 2.1: (1) $\sigma = (124)(3) \in S_4$ and $\rho = (142)(3) \in S_4$ have the set partition $\hat{\sigma} = \hat{\rho} = \{\{1,2,4\},\{3\}\} \in \mathcal{P}_4$ and number partition $[\sigma] = [\rho] = (3,1) \in \mathcal{D}_4$ (here $[\sigma] := \{\alpha^{-1}\sigma\alpha \,|\, \alpha \in S_t\}$ denotes the conjugacy class of $\sigma \in S_t$).

(2) $\sigma = (12)(34) \in S_4$ and $\rho = (13)(24) \in S_4$ have rank $|\sigma| = |\rho| = 2$, whereas $|\sigma \vee \rho| = |\{\{1,2,3,4\}\}| = 1$.

The importance of the dominance order $\mathcal{D}_t$ for the symmetric group is obvious, as the elements of $\mathcal{D}_t$ naturally enumerate the conjugacy classes of S_t. Thus they also enumerate the irreducible representations and their characters,

$$\chi_\lambda : S_t \to \mathbb{R} \quad (\lambda \in \mathcal{D}_t).$$

In the present context the importance of the partition lattice $\mathcal{P}_t$ comes from the following identity.

Lemma 2.2: For all $t, N, k \in \mathbb{N}$ and $\pi_1, \ldots, \pi_k \in S_t$,

$$\sum_{(i_1,\ldots,i_t)\in[N]^t} \prod_{l=1}^{k} \left(\prod_{j=1}^{t} \delta_{i_j}^{i_{\pi_l(j)}} \right) = N^{|\pi_1 \vee \ldots \vee \pi_k|}.$$

From now on our standing assumption relating the groups S_t and $\mathrm{U}(N)$ is $t \leqslant N$. Then the following important formula can be found in Ref. 21, see also Ref. 10,

$$\langle U_{a_1 b_1} \cdots U_{a_s b_s} \overline{U}_{\alpha_1 \beta_1} \cdots \overline{U}_{\alpha_t \beta_t} \rangle_N = \delta_t^s \sum_{\sigma,\pi \in S_t} V_N(\sigma^{-1}\pi) \prod_{k=1}^{t} \delta_{a_k}^{\alpha_{\sigma(k)}} \delta_{b_k}^{\beta_{\pi(k)}}, \tag{2.1}$$

where for $N \geqslant t$ the class function $V \equiv V_N : S_t \to \mathbb{R}$ is given by

$$V_N := \sum_{\lambda \in \mathcal{D}_t} \frac{\chi_\lambda(e)}{t!\, f_\lambda(N)} \chi_\lambda. \tag{2.2}$$

f_λ is a polynomial in N of order t vanishing at certain integers,

$$f_\lambda(N) := \sum_{\sigma \in S_t} \frac{\chi_\lambda(\sigma) N^{|\sigma|}}{\chi_\lambda(e)} = \prod_{i=1}^{k} \frac{(N + \lambda_i - i)!}{(N-i)!} \quad (\lambda \in \mathcal{D}_t) \tag{2.3}$$

(see Appendix A of Ref. 21).

Recalling the correspondence between irreducible representations of S_t and conjugacy classes of S_t, i.e., ordered number partitions $\lambda = (\lambda_1, \ldots, \lambda_k) \in \mathcal{D}_t$, $\lambda_1 \geqslant \cdots \geqslant \lambda_k$, of t, by evaluating Frobenius' formula the dimension $\chi_\lambda(e)$ of the representation appearing in (2.2) equals

$$\chi_\lambda(e) = t! \, \frac{\prod_{i<j} (\lambda_i - \lambda_j + j - i)}{\prod_i (\lambda_i + k - i)!} \quad (\lambda \in \mathcal{D}_t),$$

see Ref. 13, Eq. (4.11).

III. THE LINEAR REGIME OF THE FORM FACTOR

Next we decompose the form factor $K_N(t)$ into a sum of products of the class functions V_N and $\mathcal{N} : \sigma \mapsto N^{|\sigma|}$ on S_t. This will allow us to compare it with the diagonal contribution to be introduced in Sec. V.

As a side effect, we will rederive its concrete form (1.3) for $|t| \leqslant N$. Since $K_N(0) = N^{-1}(\mathrm{tr}(\mathbb{1}_N))^2 = N$ and $K_N(-t) = K_N(t)$, we effectively only need to consider the regime $0 < t \leqslant N$ where K_N is linear.

Evaluating $\mathrm{tr}(U^t)$ as $\Sigma_{i\in[N]^t}\Pi_{k=1}^{t} U_{i_k i_{k+1}}$ in (1.1), we get a cyclic ordering of the subindices, given by the circular permutation

$$\tau := (1,2,\ldots,t) \in S_t.$$

Conjugation of $\sigma \in S_t$ by τ will be denoted by $\sigma_+ := \tau^{-1}\sigma\tau$.

Given $t \in \mathbb{N}$ and the permutation group S_t, we denote by

$$\mathcal{C}_t := \{\sigma \in S_t \,|\, |\sigma| = 1\}$$

the set of *circular permutations*. This subset is of cardinality

$$|\mathcal{C}_t| = (t-1)!\,,$$

and every $\sigma \in \mathcal{C}_t$ can be written in the form $\sigma = \pi^{-1}\tau\pi,\ \pi \in S_t$.

Lemma 3.1: The sets

$$M(\phi,\phi') := \{(\pi,\sigma) \in S_t \times S_t \,|\, \phi = \pi^{-1}\sigma_+, \phi' = \pi^{-1}\sigma\} \quad (\phi,\phi' \in S_t)$$

are of size

$$|M(\phi,\phi')| = \begin{cases} t, & \phi'\tau\phi^{-1} \in \mathcal{C}_t, \\ 0, & \text{otherwise}, \end{cases}$$

and form a partition of $S_t \times S_t$.

Proof:

(1) By definition of $M(\phi,\phi')$ any given pair $(\pi,\sigma) \in S_t \times S_t$ lies in exactly one subset $M(\phi,\phi') \subseteq S_t \times S_t$, namely in $M(\pi^{-1}\sigma_+, \pi^{-1}\sigma)$.

(2) If $(\pi,\sigma) \in M(\phi,\phi')$ then $\phi'\tau\phi^{-1} = \pi^{-1}\tau\pi \in \mathcal{C}_t$. Then the t different

$$(\tau^l\pi, \tau^l\sigma) \in S_t \times S_t \quad (l = 0,\ldots,t-1)$$

are in $M(\phi,\phi')$, too. As thus there are exactly $\mathcal{C}_t \times S_t = (t-1)! \times t!$ pairs $(\phi,\phi') \in S_t \times S_t$ with cardinality of the corresponding atoms $|M(\phi,\phi')| \geqslant t$, but $S_t \times S_t = t! \times t!$, their cardinality must be exactly t. □

Proposition 3.2: For all $t \leqslant N \in \mathbb{N}$, *the form factor* (1.1) *equals*

$$K_N(t) = \frac{t}{N} \cdot \sum_{\substack{\phi,\phi' \in S_t \\ \phi'\tau\phi^{-1} \in \mathcal{C}_t}} V_N(\phi') N^{|\phi|} \tag{3.1}$$

$$= \frac{t}{N} \cdot \sum_{\gamma \in \mathcal{C}_t} \sum_{\phi \in S_t} V_N(\gamma\phi\tau^{-1}) N^{|\phi|}. \tag{3.2}$$

Proof: Using subindices (mod t),

$$\langle|\mathrm{tr}(U^t)|^2\rangle_N = \sum_{\substack{i_1,\ldots,i_t\\ j_1,\ldots,j_t}} \langle U_{i_1 i_2}\cdots U_{i_t i_1}\overline{U}_{j_1 j_2}\cdots\overline{U}_{j_t j_1}\rangle_N$$

$$= \sum_{\pi,\sigma\in S_t} V_N(\pi^{-1}\sigma)\cdot \sum_{\substack{i_1,\ldots,i_t\\ j_1,\ldots,j_t}} \prod_{k=1}^{t} \delta^{j_{\pi(k)}}_{i_k}\cdot\delta^{j_{\sigma(k+1)}}_{i_{k+1}} = \sum_{\pi,\sigma\in S_t} V_N(\pi^{-1}\sigma)\cdot N^{|\pi^{-1}\sigma_+|}, \qquad (3.3)$$

since

$$\sum_{\substack{i_1,\ldots,i_t\\ j_1,\ldots,j_t}} \prod_{k=1}^{t} \delta^{j_{\pi(k)}}_{i_k}\cdot\delta^{j_{\sigma(k+1)}}_{i_{k+1}} = \sum_{\substack{i_1,\ldots,i_t\\ j_1,\ldots,j_t}} \prod_{k=1}^{t} \delta^{j_{\pi(k)}}_{i_k}\cdot\delta^{j_{\sigma\tau(k)}}_{i_{\tau(k)}}$$

$$= \sum_{\substack{i_1,\ldots,i_t\\ j_1,\ldots,j_t}} \prod_{k=1}^{t} \delta^{j_{\pi(k)}}_{i_k}\cdot\delta^{j_{\sigma_+(k)}}_{i_k} = \sum_{\substack{i_1,\ldots,i_t\\ j_1,\ldots,j_t}} \prod_{k=1}^{t} \delta^{j_{\pi(k)}}_{i_k}\cdot\delta^{j_{\pi^{-1}\sigma_+(k)}}_{j_k} = \sum_{j_1,\ldots,j_t} \prod_{k=1}^{t} \delta^{j_{\pi^{-1}\sigma_+(k)}}_{j_k}.$$

In the last step of (3.3) we used Lemma 2.2. Equation (3.1) now follows from Lemma 3.1. In (3.1) we can write $\phi' = \phi\tau^{-1}\gamma$ for a unique $\gamma\in\mathcal{C}_t$, This implies the second equation. □

To further evaluate these expressions for the form factor, we remind the reader of some general group theoretical notions.

Let G be a finite group with normalized counting measure, that is, the inner product

$$\langle f_1, f_2\rangle := \frac{1}{|G|}\sum_{g\in G}\overline{f_1(g)}f_2(g) \quad (f_1, f_2\in L^2(G)). \qquad (3.4)$$

The characters of the irreducible representations are orthonormal with respect to this inner product and form a basis of the subspace of class functions.

On $L^2(G)$ we have the unitary operators of left and right translations, given by

$$R_h f(g) := f(gh), \quad L_h f(g) := f(hg) \quad (g,h\in G).$$

For irreducible characters $\chi_\mu, \chi_\lambda : G\to\mathbb{C}$ one has

$$\langle\chi_\lambda, L_g\chi_\mu\rangle = \langle\chi_\lambda, R_g\chi_\mu\rangle = \delta_{\lambda\mu}\frac{\chi_\lambda(g)}{\chi_\lambda(e)} \quad (g\in G), \qquad (3.5)$$

see Ref. 11, Eq. (31.16).

We now consider the group algebra $K[S_t]$ of the symmetric group, K denoting a field, i.e., the K-vector space $\{f: S_t\to K\}$, with multiplication of $f, g\in K[S_t]$ given by

$$f * g(\alpha) := \sum_{\sigma\in S_t} f(\sigma)g(\sigma^{-1}\alpha) = \sum_{\sigma\in S_t} f(\alpha\sigma^{-1})g(\sigma) \quad (\alpha\in S_t)$$

and neutral element $\mathbb{1}_e\in K[S_t]$.

More specifically we use the field $K := \mathbb{C}(N)$ of rational functions and denote by $\mathcal{N}\in K[S_t]$ the monomial-valued function

$$\mathcal{N}(\alpha) := N^{|\alpha|} \quad (\alpha\in S_t)$$

(which, like $\mathbb{1}_e$, is a class function).

Proposition 3.3: $V=\mathcal{N}^{-1}$.

Proof: We have, using Eq. (2.3),

$$V(\phi)=\sum_{\lambda\in\mathcal{D}_t}\frac{\chi_\lambda(\phi)\chi_\lambda(e)}{t!\,f_\lambda(N)}=\frac{1}{t!}\sum_{\lambda\in\mathcal{D}_t}\frac{\chi_\lambda(\phi)(\chi_\lambda(e))^2}{\sum_{\sigma\in S_t}\chi_\lambda(\sigma)N^{|\sigma|}}.$$

Thus (as $|\sigma^{-1}|=|\sigma|$) we must prove that

$$\sum_{\lambda\in\mathcal{D}_t}\frac{\sum_{\omega\in S_t}\chi_\lambda(\alpha\omega)N^{|\omega|}}{\sum_{\sigma\in S_t}\chi_\lambda(\sigma)N^{|\sigma|}}(\chi_\lambda(e))^2=t!\,\mathbb{1}_e(\alpha). \tag{3.6}$$

In order to show that the left-hand side (lhs) is in fact independent of N (if $N\geqslant t$ so that the denominator does not vanish), for $\sigma\in S_t$ we sum over the conjugacy class $[\sigma]\subseteq S_t$ of σ, using that $|\rho\sigma\rho^{-1}|=|\sigma|$.

More specifically we claim the existence of a constant $C_\lambda(\alpha)$ such that for all $\sigma\in S_t$,

$$\sum_{\tilde\sigma\in[\sigma]}\chi_\lambda(\alpha\tilde\sigma)=C_\lambda(\alpha)\sum_{\tilde\sigma\in[\sigma]}\chi_\lambda(\tilde\sigma). \tag{3.7}$$

Equivalently we show that

$$\mathcal{L}_\lambda(\sigma)\equiv\mathcal{L}_\lambda(\alpha,\sigma):=\sum_{\rho\in S_t}\chi_\lambda(\alpha\rho\sigma\rho^{-1})$$

equals $C_\lambda(\alpha)\cdot r_\lambda(\sigma)$ with $r_\lambda(\sigma):=\Sigma_{\rho\in S_t}\chi_\lambda(\rho\sigma\rho^{-1})=t!\,\chi_\lambda(\sigma)$.

Now for $\alpha\in S_t$,

$$\mathcal{L}_\lambda(\sigma)=\sum_{\rho\in S_t}\chi_\lambda((\rho^{-1}\alpha\rho)\sigma)=\frac{|S_t|}{|[\alpha]|}\sum_{\pi\in[\alpha]}\chi_\lambda(\pi\sigma)=\frac{t!}{|[\alpha]|}\sum_{\pi\in[\alpha]}L_\pi\chi_\lambda(\sigma).$$

$\mathcal{L}_\lambda$ being a class function, we write it in the form

$$\mathcal{L}_\lambda=\sum_{\mu\in\mathcal{D}_t}\mathrm{d}_\mu\chi_\mu \tag{3.8}$$

and determine the coefficients d_μ using the orthonormality relation $\langle\chi_\lambda,\chi_\mu\rangle=\delta_{\lambda\mu}$. By Eq. (3.5),

$$\langle L_\pi\chi_\lambda,\chi_\mu\rangle=\delta_{\lambda\mu}\frac{\chi_\lambda(\pi)}{\chi_\lambda(e)}$$

which leads to

$$\mathrm{d}_\mu=\delta_{\lambda\mu}\frac{t!}{|[\alpha]|\chi_\lambda(e)}\sum_{\pi\in[\alpha]}\chi_\lambda(\pi).$$

Inserting this into (3.8) we see that $C_\lambda(\alpha)$ in (3.7) equals

$$C_\lambda(\alpha)=\frac{1}{|[\alpha]|\chi_\lambda(e)}\sum_{\pi\in[\alpha]}\chi_\lambda(\pi).$$

Using

$$\sum_{\sigma\in S_t}\chi_\lambda(\alpha\sigma)N^{|\sigma|}=C_\lambda(\alpha)\sum_{\sigma\in S_t}\chi_\lambda(\sigma)N^{|\sigma|},$$

the lhs of (3.6) equals

$$\frac{1}{|[\alpha]|}\sum_{\lambda\in\mathcal{D}_t}\sum_{\pi\in[\alpha]}\chi_\lambda(\pi)\chi_\lambda(e)=\frac{1}{|[\alpha]|}\sum_{\pi\in[\alpha]}\sum_{\lambda\in\mathcal{D}_t}\chi_\lambda(\pi)\chi_\lambda(e)$$

$$=\frac{1}{|[\alpha]|}\sum_{\pi\in[\alpha]}\mathbb{1}_e(\pi)\sum_{\lambda\in\mathcal{D}_t}(\chi_\lambda(e))^2=\frac{1}{|[\alpha]|}\mathbb{1}_e(\alpha)t!=\mathbb{1}_e(\alpha)t!, \quad (3.9)$$

using the identity

$$\sum_{\lambda\in\mathcal{D}_t}\chi_\lambda(e)^2=t!$$

in (3.9), see Chap. 5.2 in Ref. 20 and 19. This proves (3.6). □

We redefine the inner product (3.4) on $\mathbb{C}[S_t]$ omitting the factor $1/|S_t|=1/t!$,

$$\langle f_1,f_2\rangle:=\sum_{\sigma\in S_t}\overline{f_1(\sigma)}f_2(\sigma)(f_1,f_2:S_t\to\mathbb{C}). \quad (3.10)$$

So the irreducible characters are now of norm $t!$. Anyhow we are now more interested in the following sets of functions.

Instead of considering the field $\mathbb{C}(N)$ of rational functions in the variable N we will now specialize the value $N\in\mathbb{N}$, $N\geqslant t$.

Define for $\sigma\in S_t$ the translates of $\mathcal{N}$,

$$\hat{q}_\sigma\in\mathbb{C}[S_t],\quad \hat{q}_\alpha(\sigma):=N^{|\sigma^{-1}\alpha|}\quad(\alpha\in S_t).$$

Similarly we define the translates

$$V_\sigma\in\mathbb{C}[S_t],\quad V_\alpha(\sigma):=V_N(\sigma^{-1}\alpha)\quad(\alpha\in S_t)$$

of V_N.

Lemma 3.4: For $N\geqslant t$ the $\hat{q}_\sigma$, $\sigma\in S_t$ form a basis of the vector space $\mathbb{C}[S_t]$, with dual basis V_σ, $\sigma\in S_t$.

Proof: Considered as rational functions, for $\alpha,\beta\in S_t$ the inner product equals

$$\langle V_\alpha,\hat{q}_\beta\rangle=\sum_{\sigma\in S_t}V_N(\sigma^{-1}\alpha)N^{|\sigma^{-1}\beta|}=\sum_{\sigma\in S_t}V_N(\alpha^{-1}\sigma)N^{|\sigma^{-1}\beta|}=\sum_{\rho\in S_t}V_N(\rho)N^{|\rho^{-1}(\alpha^{-1}\beta)|}=V*\mathcal{N}(\alpha^{-1}\beta)=\delta_\alpha^\beta.$$

Specializing the value of N, this duality relation is true as long as the rational functions are defined. By inspection of the definition (2.2) of V_N [in particular of the f_λ defined in (2.3)] this is the case as long as $N\geqslant t$. As the number of the V_α and of the $\hat{q}_\beta$ both equals $\dim(\mathbb{C}[S_t])=t!$, these are indeed bases. □

Corollary 5: For $t\leqslant N$

$$\sum_{\sigma\in S_t}V_N(\alpha\sigma^{-1})N^{|\sigma|}=\mathbb{1}_e(\alpha)\quad(\alpha\in S_t).$$

Remarks 3.6: (1) Corollary 3.5 allows us to regain formula (1.3), i.e.,

$$K_N(t)=\frac{t}{N}\quad\text{for}\quad 0<t\leqslant N.$$

Using Proposition 3.2 we have

$$K_N(t)=\frac{t}{N}\sum_{\gamma\in C_t}\sum_{\phi\in S_t}V_N(\gamma\phi\tau^{-1})N^{|\phi|}=\frac{t}{N}\sum_{\gamma\in C_t}\sum_{\sigma\in S_t}V_N(\sigma)N^{|\gamma^{-1}\sigma\tau|}=\frac{t}{N}\sum_{\gamma\in C_t}\mathbb{1}_\gamma(\tau)=\frac{t}{N}.$$

(2) As $V_N:S_t\to\mathbb{R}$ is a class function, we can also use the notation

$$V_N:\mathcal{D}_t \to \mathbb{R}, \quad V_N([\sigma]) := V_N(\sigma).$$

Then we can calculate V_N using Proposition 3.3. Some examples,

(i) for $t=1$ we have $V_N(1)=1/N$;
(ii) for $t=2$ and denominator $D_2 := N(N^2-1)$ we have

$$V_N(1,1) = \frac{N}{D_2}, \quad V_N(2) = -\frac{1}{D_2},$$

(iii) for $t=3$ and $D_3 := N^3(N^2-1)(N^2-4)$ we have

$$V_N(1,1,1) = \frac{N^4-2N^2}{D_3}, \quad V_N(2,1) = -\frac{N^3}{D_3} \quad \text{and} \quad V_N(3) = \frac{2N^2}{D_3}.$$

(3) The large N asymptotics of $V_N:\mathcal{D}_t \to \mathbb{R}$ for $\lambda=(\lambda_1,\ldots,\lambda_k)$ is given by

$$V_N(\lambda) \sim (-1)^{t-k} N^{k-2t} \prod_{l=1}^{k} C_{\lambda_l} \quad (N \to \infty) \tag{3.11}$$

with the Catalan number $C_l := \binom{2l-2}{l-1}/l$, see Ref. 21.

IV. THE RANK FUNCTION AND THE JOIN OF PARTITIONS

It is useful to give a geometric meaning to our estimates. For this purpose we equip the symmetric group S_t with the metric

$$d:S_t \times S_t \to \{0,1,\ldots,t\}, \quad d(\sigma,\gamma) = t - |\sigma\gamma^{-1}|.$$

The easiest way to visualize this metric is to consider the $\binom{t}{2}$-regular *Cayley graph* (S_t,E_t) having the symmetric group as its vertex set, and edge set

$$E_t := \{(\rho,\rho') \in S_t \times S_t | \rho^{-1}\rho' \text{ is a transposition}\}.$$

Proposition 4.1: (1) *$d(\sigma,\gamma)$ is the distance between the vertices σ and γ on the Cayley graph (S_t,E_t). So in particular the metric d is invariant under the left and right self-actions of S_t.*

(2) $|\pi\vee\sigma| = \min\{|\pi\mu^{-1}| \,|\, \mu \leqslant \sigma\} \quad (\pi,\sigma \in S_t)$.

So in particular

$$d(\pi,\sigma) \leqslant t - |\pi\vee\sigma|.$$

(3) $d(\rho,\rho') \geqslant ||\rho\vee\sigma| - |\rho'\vee\sigma|| \quad (\rho,\rho',\sigma \in S_t)$.

Proof:

(1) For $\rho := \sigma\gamma^{-1}$ with disjoint cycle decomposition $\rho=\rho_1,\ldots,\rho_k$ we have $d(\sigma,\gamma)=d(\rho,e)=t-k=\Sigma_{i=1}^{k}(l_i-1)$, l_i being the length of ρ_i. Exactly $l-1$ transpositions are needed to form a cycle of length l.
(2) Let $(c_1,\ldots,c_m)$, $c_k \subseteq \{1,\ldots,t\}$ be the partition corresponding to the cycles of π. We consider the graph (V,E) with vertex set $V := \{c_1,\ldots,c_m\}$ and edges $\{c_i,c_j\} \in E$ for which there are elements $e_i \in c_i$, $e_j \in c_j$ which belong to the same cycle of σ. Choose for each connected component of (V,E) a spanning tree and representatives $\{e_i,e_j\}$ of its edges. Then by construction the product μ_0 of the transpositions (e_i,e_j) meets $\mu_0 \leqslant \sigma$, and $|\pi\mu_0^{-1}| = |\pi\vee\sigma|$. Any $\mu \leqslant \sigma$ can be written in the form $\mu=\rho\mu_0$ with $\rho \leqslant \sigma$. As no cycles of $\pi\mu_0^{-1}$ can be joined by right multiplication with $\rho^{-1} \leqslant \sigma$, the statement follows.
(3) By symmetry of the metric d we assume $|\rho\vee\sigma| \geqslant |\rho'\vee\sigma|$ and choose $\mu_0 \leqslant \sigma$ so that $|\rho'\vee\sigma| = |\rho'\mu_0^{-1}|$. Then, again by part (2) of the proposition

$$0 \leqslant |\rho \vee \sigma| - |\rho' \vee \sigma| \leqslant |\rho\mu_0^{-1}| - |\rho'\mu_0^{-1}|.$$

By part (1) of the proposition

$$|\rho\mu_0^{-1}| - |\rho'\mu_0^{-1}| \leqslant d(\rho\mu_0^{-1}, \rho'\mu_0^{-1}) = d(\rho, \rho')$$

since multiplication by a transposition changes the number of cycles by one, and since d is invariant under right multiplication. □

Remark 4.2: As the elements $\rho = \sigma = (12)(34)$, $\rho' = (13)(24)$ of S_4 show, in general the inequality $||\rho \vee \sigma| - |\rho' \vee \sigma|| \leqslant ||\rho| - |\rho'||$ does **not** hold. The reverse inequality is wrong.

V. THE DIAGONAL CONTRIBUTION

We now define and study the *diagonal approximation* for the unitary ensemble.

Setting $[N] := \{1, \ldots, N\}$, the diagonal contribution is defined by

$$\Delta_N(t) := \sum_{i \in [N]^t} \mathrm{per}(i) \left\langle \prod_{k=0}^{t-1} |U_{i_k i_{k+1}}|^2 \right\rangle, \tag{5.1}$$

where $\mathrm{per}(i)$ denotes the period of i. In fact [see (2.1)], only those terms of the form factor

$$K_N(t) = \sum_{i,j \in [N]^t} \left\langle \prod_{k=0}^{t-1} U_{i_k i_{k+1}} \overline{U}_{j_k j_{k+1}} \right\rangle$$

can be nonzero for which the sets

$$m_i(r) := \{k \in [t] | i_k = r\}$$

have equal multiplicity $[|m_i(r)| = m_i(r)$ for all $r \in [N]]$.

In this case, if only multiplicities $|m_i(r)| \leqslant 1$ occur for i, there is a unique permutation σ with $j_{\sigma(k)} = i_k$ (and $\pi := \tau\sigma\tau^{-1}$ with $j_{\pi(k)+1} = i_{k+1}$), but in general we have

$$K_N(t) = \sum_{i,j \in [N]^t} \sum_{\kappa^{(1)}, \kappa^{(2)} \in S(m;(1)) \times \cdots \times S(m;(N))} V((\sigma\kappa^{(1)})^{-1} \pi \kappa^{(2)}).$$

As the dominant (in N) contributions are the ones with $V(e)$, i.e., $\sigma = \tau^l$ for some l, we call the sum

$$\Delta_N(t) = \sum_{i,j \in [N]^t \exists l \text{ with } j_{k+l} = i_k} \left\langle \prod_{k=0}^{t-1} U_{i_k i_{k+1}} \overline{U}_{j_k j_{k+1}} \right\rangle \tag{5.2}$$

$$= \sum_{i \in [N]^t} \mathrm{per}(i) \left\langle \prod_{k=0}^{t-1} |U_{i_k i_{k+1}}|^2 \right\rangle \tag{5.3}$$

the *diagonal contribution*.

If $|m_i(r)| \leqslant 1$, then only terms $V(e)$ occur in $\langle \Pi_{k=0}^{t-1} |U_{i_k i_{k+1}}|^2 \rangle$.

The number of all terms in $\Sigma_{i_1, \ldots, i_t}$ being N^t, for $k | t$,

$$I_k := \{(i_1, \ldots, i_t) | i_{l+k} = i_l\}$$

is the set of terms with $\mathrm{per}(i_1, \ldots, i_t) | k$. So the number of terms with $\mathrm{per}(i) < t$ equals

$$\sum_{r>1,r|t} |I_{t/r}|\mu(r),$$

with the Möbius μ function. As $|I_k|=N^k$, this is only of order $N^{t/2}\log(t)$ and thus negligible compared to $|I_t|=N^t$ as $N\to\infty$.

For these reasons, we just define and study a function similar to (5.1) but replacing the period by its maximal value t. In fact for simplicity of notation we use the constant one instead,

$$\Delta_N^{\max}(t) := \sum_{i_1,\ldots,i_t} \left\langle \prod_{k=0}^{t-1} |U_{i_k i_{k+1}}|^2 \right\rangle.$$

A basic manipulation yields the following.

Proposition 5.1:

$$\Delta_N^{\max}(t) = \sum_{\pi,\sigma\in S_t} V_N(\pi^{-1}\sigma) N^{|\pi\vee\sigma_+|}. \tag{5.4}$$

Proof: Using (2.1),

$$\Delta_N^{\max}(t) = \sum_{i\in[N]^t} \sum_{\pi,\sigma\in S_t} V_N(\pi^{-1}\sigma)\cdot \prod_{k=0}^{t-1} \delta_{i_k}^{i_{\pi(k)}}\cdot\delta_{i_{k+1}}^{i_{\sigma(k+1)}} = \sum_{i\in[N]^t} \sum_{\pi,\sigma\in S_t} V_N(\pi^{-1}\sigma)\cdot \prod_{k=0}^{t-1} \delta_{i_k}^{i_{\pi(k)}}\cdot\delta_{i_k}^{i_{\tau^{-1}\sigma\tau(k)}}. \tag{5.5}$$

Lemma (2.2) now gives the result. □

A first easy observation is that for *bounded* t,

$$\Delta_N^{\max}(t) = 1 + \mathcal{O}(1/N^2).$$

This follows by inserting (3.11) into (5.4).

Remark 5.2: In general for $0<t\leqslant N$ **neither** $K_N(t)=(1/N)\Delta_N(t)$ **nor** $K_N(t)=(t/N)\Delta_N^{\max}(t)$, although both equations hold for $N=1$ and $N=2$. Already for $t=3\leqslant N$,

$$\Delta_N(3) = \frac{3N^3}{D_3}(N^4-7N^2+4N+2) \neq 3 = NK_N(3)$$

and

$$\Delta_N^{\max}(3) = \frac{N^3}{D_3}(N^4-3N^2-6N+8) \neq 1 = N\frac{K_N(3)}{3},$$

with denominator $D_3=N^3(N^2-1)(N^2-4)$.

So the diagonal approximation is not exact.

Remark 5.3: Note that we can also write[25]

$$\Delta_N^{\max}(t) = \mathrm{tr}\langle M^t\rangle_N,$$

where M is the doubly stochastic matrix with elements $M_{i,j} := |U_{i,j}|^2$. In Ref. 2 it has been shown that if $\lambda_1=1,\lambda_2,\ldots,\lambda_N$ are the eigenvalues of M ($|\lambda_1|\geqslant|\lambda_2|\geqslant\cdots\geqslant|\lambda_N|$), then

$$\langle|\lambda_j|\rangle_N \to 0, \quad j=2,\ldots,N.$$

Moreover, the expectation of the second eigenvalue $\langle|\lambda_2|\rangle$ is of order $1/\sqrt{N}$. This upper bound is not helpful to show convergence of the trace to 1, namely this does not allow to bound expectations of positive powers $\langle|\lambda_j|^t\rangle$. [For a generic random variable X with values in [0,1], like $X := |\lambda_2|$ the lower, respectively, upper bounds

$$\mathbb{E}(X)^t \leqslant \mathbb{E}(X^t) \leqslant \mathbb{E}(X) \quad (t \in \mathbb{N}),$$

following from Jensen's inequality (applied to the convex function $x \mapsto x^t$), respectively, convolution inequality are optimal in general. This can be seen [for $c = \mathbb{E}(X) \in [0,1]$] by considering the cases of X distributions δ_c, respectively $(1-c)\delta_0 + c\delta_1$. Even for an ac distribution like in our case the falloff in t is not exponential.]

This last remark forces us to investigate more carefully each single contribution to the diagonal contribution. In particular, as we will see in the rest of the paper, the combinatorics become essential in order to bound uniformly the difference of the diagonal approximation to the form factor. This difference becomes large above the regime $t=N$. According to (3.11) the terms in the sum (5.4) have fluctuating sign,

$$\operatorname{sign}(V_N(\pi^{-1}\sigma)) = (-1)^{d(\pi,\sigma)}.$$

This makes it advisable to perform a partial summation before estimating terms in absolute value. We thus rewrite the sum over π in (5.4) in the form of an inner product,

$$\Delta_N^{\max}(t) = \sum_{\sigma \in S_t} \langle V_N, \hat{p}_\sigma \rangle \quad \text{with} \quad \hat{p}_\sigma(\alpha) := N^{|\sigma\alpha^{-1} \vee \sigma_+|}. \tag{5.6}$$

Proposition 5.4: There exists a function $C_t : S_t \to \{0,1\}$ such that

$$\langle V_N, \hat{p}_\sigma \rangle_N = N^{|\sigma \vee \sigma_+| - t}(C_t(\sigma) + \mathcal{O}(1/N)) \quad (\sigma \in S_t).$$

Proof: For $\sigma \in S_t$ the symmetric group is partitioned into the sets

$$B_n := \{\alpha \in S_t \,|\, |\alpha \vee \sigma_+| = |\sigma_+| - n \quad (n = 0, \ldots, |\sigma| - 1).$$

The metric d on S_t is then used to introduce for $\gamma \in B_n$,

$$B(\gamma) := \left\{ \alpha \in \bigcup_{k=0}^{n} B_k \,\middle|\, |\alpha \vee \sigma_+| - |\gamma \vee \sigma_+| = d(\alpha, \gamma) \right\}.$$

Observe that by part (3) of Lemma 4.1 we always have

$$0 \leqslant |\alpha \vee \sigma_+| - |\gamma \vee \sigma_+| \leqslant d(\alpha, \gamma). \tag{5.7}$$

In particular γ is the only element in $B(\gamma) \cap B(n)$. This enables us to define for $n = 0, \ldots, |\sigma| - 1$,

$$C_t(\gamma) := 1 - \sum_{\alpha \in B(\gamma) \setminus \{\gamma\}} C_t(\alpha) \quad (\gamma \in B_n), \tag{5.8}$$

and the approximants

$$\tilde{p}_\sigma : S_t \to \mathbb{R}, \quad \tilde{p}_\sigma := \sum_{\gamma \in S_t} C_t(\gamma) N^{|\gamma \vee \sigma_+| - t} \hat{q}_{\gamma^{-1}\sigma} \quad (\sigma \in S_t)$$

of the functions $\hat{p}_\sigma$.

(i) Next we prove that C_t only takes the values 0 and 1. This follows from the definition (5.8), if we can show that each γ has exactly one *predecessor* in

$$P := \{\alpha \in S_t \,|\, C_t(\alpha) = 1\},$$

that is, $|B(\gamma) \cap P| = 1$. This is done by induction in n, with

$$\gamma \in P \cap B_n \quad (n = 0, \ldots, |\sigma| - 1)$$

and noting that $P \cap B_0 = B_0$ [the $\gamma \in B_0$ are their own predecessors so that $C_t(\gamma) = 1$].

(ii) For the induction step we use the directed graph (S_t, E) with vertex set S_t and edges

$$(\alpha,\beta)\in E \Leftrightarrow d(\alpha,\beta)=1 \text{ and } \alpha\in B_n,\beta\in B_{n-1} \text{ for some } n\in\{1,\ldots,|\sigma|-1\}.$$

By the triangle inequality for $\gamma\in B(n)$ the set $B(\gamma)$ contains all $\alpha\in B_k, 0\leqslant k\leqslant n$ for which there exists a directed chain

$$\gamma=c_n,c_{n-1},\ldots,c_k=\alpha \text{ from } \gamma \text{ to } \alpha \text{ with } c_l\in B_l \text{ and } (c_l,c_{l-1})\in E \quad (l=k+1,\ldots,n).$$

Conversely all $\alpha\in B(\gamma)$ are of that form. Namely for $\alpha\in B(\gamma)\cap B_k$ we know that $d(\alpha,\gamma)=n-k$ so that there exist $c_n,\ldots,c_k\in S_t$ with $c_k=\gamma, c_k=\alpha$ and $d(c_{l-1},c_l)=1$. As $||c_{l-1}\vee\sigma_+|-|c_l\vee\sigma_+||\leqslant d(c_{l-1},c_l)=1$ and $|c_n\vee\sigma_+|=n, |c_k\vee\sigma_+|=k$, we conclude $|c_l\vee\sigma_+|=l$ so that $(c_l,c_{l-1})\in E$.

(iii) This shows that $\alpha\in P$ if there does not exist an edge $(\alpha,\beta)\in E$, and thus $|B(\gamma)\cap P|\geqslant 1$ (as every directed chain starting at γ ends somewhere). To prove that $|B(\gamma)\cap P|=1$, we need a more precise characterization of the predecessors $\alpha\in P$. As there does not exist an edge of the form (α,β) in E, for all neighbors $\beta\in S_+$ of α [i.e., $d(\alpha,\beta)=1$] we have $|\beta\vee\sigma_+|\leqslant|\alpha\vee\sigma_+|$. In other words if β differs from α by a transposition, and if two blocks of $\hat{\sigma}_+\in P_t$ belong to the same block of $\alpha\vee\sigma_+$, then they belong to the same block of $\beta\vee\sigma_+$.

(iv) We model this by considering for given $\sigma\in S_t$ the directed multigraph

$$G_\alpha=(V_\alpha,\mathcal{E}_\alpha)$$

associated to $\alpha\in S_t$. The vertex set of $G(\alpha)$ equals $V_\alpha:=\{\hat{\sigma}_{+,1},\ldots,\hat{\sigma}_{+,m}\}$, with $\hat{\sigma}_{+,1},\ldots,\hat{\sigma}_{+,m}\subseteq[N]$ the blocks of the set partition $\hat{\sigma}_+\in P_t$. The multiplicity of the directed edge $(\hat{\sigma}_{+,i},\hat{\sigma}_{+,j})\in V_\alpha\times V_\alpha$ is given by

$$\mathcal{E}_\alpha: V_\alpha\times V_\alpha\setminus\Delta\to\mathbb{N}_0, \mathcal{E}_\alpha(\hat{\sigma}_{+,i},\hat{\sigma}_{+,j}):=|\{(u,v)\in\hat{\sigma}_{+,i}\times\hat{\sigma}_{+,j}|\alpha(u)=v\}.$$

The in and out degrees of the blocks $\hat{\sigma}_{+,i}$ coincide, that is $\mathcal{E}^+_\alpha(\hat{\sigma}_{+,i})=\mathcal{E}^-_\alpha(\hat{\sigma}_{+,i})$ for

$$\mathcal{E}^+_\alpha(\hat{\sigma}_{+,i}):=\sum_{\hat{\sigma}_{+,j}}\mathcal{E}_\alpha(\hat{\sigma}_{+,i},\hat{\sigma}_{+,j}), \quad \mathcal{E}^-_\alpha(\hat{\sigma}_{+,i}):=\sum_{\hat{\sigma}_{+,j}}\mathcal{E}_\alpha(\hat{\sigma}_{+,i},\hat{\sigma}_{+,j}).$$

Henceforth we omit the superscripts $\pm$ and simply refer to the *degree* $\mathcal{E}_\alpha(\hat{\sigma}_{+,i})=\mathcal{E}^\pm_\alpha(\hat{\sigma}_{+,i})$ of the block.

(v) All ancestors $\alpha\in P$ have multigraphs G_α which have two-connected components, that is, the number of connected components cannot be increased by reducing a single degree $\mathcal{E}(\hat{\sigma}_{+,i})$ by one. This can be seen by noticing that for every $\alpha\in S_t$ the number of connected components of G_α equals $|\alpha\vee\sigma_+|$, and using that the $\alpha\in P$ do not have neighbors β with $|\beta\vee\sigma_+|=|\alpha\vee\sigma_+|+1$.

(vi) To prove $|B(\gamma)\cap P|=1$, we assume that $\alpha^{(1)},\alpha^{(2)}\in B(\gamma)\cap P$. So there exist directed chains $\gamma=c^{(i)}_n,c^{(i)}_{n-1},\ldots,c^{(i)}_{k^{(i)}}=\alpha^{(i)}$ [with $(c^{(i)}_l,c^{(i)}_{l-1})\in E$] from γ to $\alpha^{(i)}, i=1,2$, and we are to show that $\alpha^{(1)}=\alpha^{(2)}$. In each step the number $|c^{(1)}_l\vee\sigma_+|=|c^{(2)}_l\vee\sigma_+|=l$ of connected components of the multigraphs $G_{c^{(i)}_l}$ is reduced by one. That is, all connected components of the multigraph G_γ are broken into their two-connected subcomponents,

$$\mathcal{E}_{\alpha^{(i)}}\leqslant\mathcal{E}_\gamma \quad \text{and} \quad \mathcal{E}_{\alpha^{(i)}}(\hat{\sigma}_{+,j})\neq 1 \quad (i=1,2,\ j=1,\ldots,m).$$

In fact this shows that $\mathcal{E}_{\alpha^{(1)}}=\mathcal{E}_{\alpha^{(2)}}$ so that the multigraphs of $\alpha^{(1)}$ and $\alpha^{(2)}$ coincide.
The multiplicity $\mathcal{E}_\gamma(\hat{\sigma}_{+,i}\hat{\sigma}_{+,j})$ of a directed edge of G_α is reduced only if $\mathcal{E}_\gamma(\hat{\sigma}_{+,i},\hat{\sigma}_{+,j})=1$. So not only $\mathcal{E}_{\alpha^{(1)}}(\hat{\sigma}_{+,i},\hat{\sigma}_{+,j})=\mathcal{E}_{\alpha^{(2)}}(\hat{\sigma}_{+,i},\hat{\sigma}_{+,j})$ but the chains connecting γ with $\alpha^{(1)}=\alpha^{(2)}$.

(vii) We now know that $C_t(\alpha)$ only takes the values 0 and 1, and that $\tilde{p}_\sigma=\Sigma_{\gamma\in P}N^{|\gamma\vee\sigma_+|-t}\hat{q}_{\gamma^{-1}\sigma}$. This implies

$$\langle V_N,\tilde{p}_\sigma\rangle_N=\sum_{\gamma\in P}N^{|\gamma\vee\sigma_+|-t}\langle V_N,\hat{q}_{\gamma^{-1}\sigma}\rangle_N=C_t(\sigma)N^{|\sigma\vee\sigma_+|-t}.$$

It remains to show that

$$\langle V_N, \hat{p}_\sigma \rangle_N = \langle V_N, \tilde{p}_\sigma \rangle_N + \mathcal{O}(N^{|\sigma \vee \sigma_+| - t - 1}).$$

But, denoting the unique predecessor of $\beta \in S_t$ by $P(\beta)$ [that is $\{P(\beta)\} = B(\beta) \cap P$], we have

$$\tilde{p}_\sigma(\beta^{-1}\sigma) = \sum_{\gamma \in P} N^{|\gamma \vee \sigma_+| - d(\gamma,\beta)} = N^{|P(\beta) \vee \sigma_+| - d(P(\beta),\beta)} + \sum_{\substack{\gamma \in P \\ \gamma \neq P(\beta)}} N^{|\gamma \vee \sigma_+| - d(\gamma,\beta)}.$$

By definition of $B(\gamma)$ the exponent of the first term equals

$$|P(\beta) \vee \sigma_+| - d(P(\beta), \beta) = |\beta \vee \sigma_+|,$$

whereas the exponents of the second term are smaller:

$$|\gamma \vee \sigma_+| - d(\gamma, \beta) < |\beta \vee \sigma_+|$$

on the other hand,

$$\hat{p}_\sigma(\beta^{-1}\sigma) = N^{|\beta \vee \sigma_+|},$$

proving the claim. □

If $\sigma \in S_t$ consists of a single nontrivial cycle, the estimate of Proposition 5.4 can be replaced by an identity (Proposition. 5.6 below).

We prepare this by a sum rule for the class function $\mathcal{N}$.

Lemma 5.5: For all $k \in \mathbb{N}$,

$$\sum_{\sigma \in S_k} N^{|\sigma|} = \prod_{l=0}^{k-1} (N + l). \tag{5.9}$$

Proof: For $k=1$ both sides equal N. So assume the formula to hold for $k-1$, so that

$$\sum_{\tilde{\sigma} \in S_k, \tilde{\sigma}(k)=k} N^{|\tilde{\sigma}|} = N \prod_{l=0}^{k-2} (N + l). \tag{5.10}$$

The group elements $\sigma \in S_k$ either have k as a fixed point s or can uniquely be written in the form

$$\sigma = (l,k)\tilde{\sigma}$$

with $l \in \{1, \ldots, k-1\}$ and $\tilde{\sigma}(k) = k$. As in the second case $|\sigma| = |\tilde{\sigma}| - 1$,

$$\sum_{l=1}^{k-1} \sum_{\tilde{\sigma} \in S_k, \tilde{\sigma}(k)=k} N^{|\tilde{\sigma}|} = (k-1) \prod_{l=0}^{k-2} (N + l). \tag{5.11}$$

Adding the contributions (5.10) and (5.11) yields (5.9). □

We now decompose $\hat{p}_\sigma$ in the form

$$\hat{p}_\sigma = \sum_{\gamma \in S_t} c_\gamma \hat{q}_\gamma \quad \text{with} \quad c_\gamma := \langle V_\gamma, \hat{p}_\sigma \rangle.$$

Proposition 5.6: For a cycle $\sigma = (i_1 + 1, \ldots, i_k + 1) \in S_t$ [and $\sigma_+ = (i_1, \ldots, i_k)$]

$$\hat{p}_\sigma = \left(\prod_{l=1}^{k-1} (N + l) \right)^{-1} \sum_{\gamma' \preccurlyeq \sigma_+} \hat{q}_{\gamma' \sigma}. \tag{5.12}$$

Proof: (i) We evaluate both sides on $\tilde{\alpha} \in S_t$ and write $\tilde{\alpha}$ as $\tilde{\alpha} = \alpha\sigma$ to simplify expressions. Then

$$\hat{p}_\sigma(\alpha\sigma) = N^{|\alpha^{-1}\vee\sigma_+|} \quad \text{and} \quad \hat{q}_{\gamma'\sigma}(\alpha\sigma) = N^{|\alpha^{-1}\gamma'|}. \tag{5.13}$$

(ii) Next we write α as a product of disjoint cycles z_j and note that

$$|z_j\alpha^{-1}\vee\sigma_+| - |z_j\alpha^{-1}\gamma'| = |\alpha^{-1}\vee\sigma_+| - |\alpha^{-1}\gamma'|$$

if z_j and σ_+ are disjoint. We thus can reduce α to a product of cycles intersecting σ_+.

(iii) So we assume that all cycles z_j of α intersect $\sigma_+=(i_1,\ldots,i_k)$,

$$z_j = (i_{\pi(1)},\tilde{z}_1,\ldots,\tilde{z}_2,i_{\pi(2)},\tilde{z}_3,\ldots,\tilde{z}_{2s-2},i_{\pi(s)},\tilde{z}_{2s-1},\ldots,\tilde{z}_{2s})$$

with $\tilde{z}_n \in \{1,\ldots,t\}\backslash\{i_1,\ldots,i_k\}$. Then

$$(i_{\pi(s)},i_{\pi(s-1)},\ldots,i_{\pi(1)})z_j = (i_{\pi(1)},\tilde{z}_1,\ldots,\tilde{z}_2)(i_{\pi(2)},\tilde{z}_3,\ldots,\tilde{z}_4)\cdots(i_{\pi(s)},\tilde{z}_{2s-1},\ldots,\tilde{z}_{2s})$$

is a product of disjoint cycles intersecting the cycle σ_+ only at $i_{\pi(n)}$. Furthermore,

$$(i_{\pi(s)},i_{\pi(s-1)},\ldots,i_{\pi(1)}) \leqslant \sigma_+$$

so that the map

$$\gamma' \mapsto (i_{\pi(s)},i_{\pi(s-1)},\ldots,i_{\pi(1)})\gamma'$$

simply permutes the γ' in $\Sigma_{\gamma'\leqslant\sigma_+}\hat{q}_{\gamma'\sigma}$. This allows to reduce to the case of simple intersections.

(iv) We thus assume that the cycles z_j in the decomposition of α intersect σ_+ exactly in one point, say i_j. Under this assumption, by Lemma 5.5 and (5.13)

$$\left(\prod_{l=1}^{k-1}(N+l)\right)^{-1}\sum_{\gamma'\leqslant\sigma_+}\hat{q}_{\gamma'\sigma}(\alpha\sigma) = \left(\prod_{l=1}^{k-1}(N+l)\right)^{-1}N^{|\alpha^{-1}|-k}\sum_{\gamma\in S_k}N^{|\gamma|} = N^{|\alpha^{-1}|-k+1} = N^{|\alpha^{-1}\vee\sigma_+|} = \hat{p}_\sigma(\alpha\sigma),$$

proving the assertion. □

Corollary 5.7: For a cycle $\sigma=(i_1,\ldots,i_k)\in S_t$ of length k

$$\langle V_N,\hat{p}_\sigma\rangle = \begin{cases} 1, & k=1 \text{ that is } \sigma=e,\\ 0, & 1<k<t\\ \left(\prod_{l=1}^{t-1}(N+l)\right)^{-1}, & k=t. \end{cases} \tag{5.14}$$

Proof: This follows from Proposition 5.6 with $\langle V_N,\hat{q}_\sigma\rangle=\delta_{e,\sigma}$ (Lemma 3.4), remarking that only for $k=1$ or $k=t$ there is a $\gamma'\leqslant\sigma_+$ with $\gamma'\sigma=e$. □

This result and numerical experiments support the following conjecture (compare with Proposition 5.4).

Conjecture 5.8: There exists a constant $C_1\geqslant 1$ such that for all $t\leqslant N\in\mathbb{N}$,

$$|\langle V_N,\hat{p}_\sigma\rangle_N| \leqslant C_1N^{|\sigma\vee\sigma_+|-t} \quad (\sigma\in S_t).$$

VI. DERANGEMENTS AND CIRCULAR ORDER

We now show that, apart from the identity, only the *derangements*, that is the fixed-point free permutations

$$D_t := \{\sigma\in S_t | \sigma(k)\neq k \quad \text{for all} \quad k\in\{1,\ldots,t\}\}$$

contribute in the sum (5.6).

This will follow from a statement of independent interest.

Proposition 6.1: For $k=1,\ldots,t+1$ denote by $S_t^{(k)}$ the subgroup

$$S_t^{(k)} := \{\sigma \in S_{t+1} | \sigma(k) = k\},$$

and by $I_k : S_t \to S_t^{(k)}$ *the isomorphism induced by the injection*

$$\tilde{I}_k : \{1, \ldots, t\} \hookrightarrow \{1, \ldots, t+1\}, \quad \tilde{I}_k(i) = \begin{cases} i, & 1 \leqslant i < k, \\ i+1, & i \geqslant k. \end{cases}$$

Then for $\sigma = I_{k+1}(\tilde{\sigma})$ *and*

$$\hat{p}_{\tilde{\sigma}} = \sum_{\tilde{\gamma} \in S_t} c_{\tilde{\gamma}}\, \hat{q}_{\tilde{\gamma}\tilde{\sigma}},$$

we have

$$\hat{p}_\sigma = \sum_{\tilde{\gamma} \in S_t} c_{\tilde{\gamma}}\, \hat{q}_{I_k(\tilde{\gamma})\sigma}.$$

Proof: (i) For $\beta \in S_t^{(k)} \subset S_{t+1}$, that is $\beta = I_k(\tilde{\beta})$ with $\tilde{\beta} \in S_t$,

$$\hat{p}_\sigma(\beta\sigma) = N^{|I_k(\tilde{\beta}) \vee \sigma_+|} = N^{|I_k(\tilde{\beta}) \vee (I_{k+1}(\tilde{\sigma}))_+|} = N^{|I_k(\tilde{\beta}) \vee I_k(\tilde{\sigma}_+)|} = N^{|\tilde{\beta} \vee \tilde{\sigma}_+| + 1} = N \hat{p}_{\tilde{\sigma}}(\tilde{\beta}\tilde{\sigma})$$

and similarly

$$\hat{q}_{I_k(\tilde{\gamma})\sigma}(\beta\sigma) = N^{|I_k(\tilde{\gamma})(I_k(\tilde{\beta}))^{-1}|} = N^{|I_k(\tilde{\gamma}\tilde{\beta}^{-1})|} = N^{|\tilde{\gamma}\tilde{\beta}^{-1}| + 1} = N \hat{q}_{\tilde{\gamma}\tilde{\sigma}}(\tilde{\beta}\tilde{\sigma}).$$

(ii) The other elements of S_{t+1} can be uniquely written as a product of a transposition $(l,k) \in S_{t+1}$ and $\beta = I_k(\tilde{\beta}) \in S_t^{(k)}$. In that case a similar argument leads to

$$\hat{p}_\sigma(\beta\sigma) = \hat{p}_{\tilde{\sigma}}(\tilde{\beta}\tilde{\sigma}) \quad \text{and} \quad \hat{q}_{I_k(\tilde{\gamma})\sigma}(\beta\sigma) = \hat{q}_{\tilde{\gamma}\tilde{\sigma}}(\tilde{\beta}\tilde{\sigma}).$$

(iii) So in any case the proportionality factor does not depend on $\tilde{\gamma}$. □

Proposition 6.2: For all $t \leqslant N \in \mathbb{N}$,

$$\langle V_N, \hat{p}_\sigma \rangle = 0 \quad \textit{for } \sigma \in S_t \setminus D_t,\ \sigma \neq e. \tag{6.1}$$

Proof: Lemma 3.4 implies the formula

$$\langle V_N, \hat{q}_\sigma \rangle = \delta_e^\sigma.$$

So (6.1) is equivalent to show that for these σ in the base decomposition

$$\hat{p}_\sigma = \sum_{\gamma \in S_t} c_\gamma \hat{q}_{\gamma\sigma}$$

of $\hat{p}_\sigma$ the coefficient $c_{\sigma^{-1}}$ equals zero. These σ have a fixed point $k+1 \pmod t$ which has the additional property that $k \pmod t$ is *not* a fixed point. So $\sigma = I_{k+1}(\tilde{\sigma})$ with $\tilde{\sigma} \in S_{t-1}, \tilde{\sigma}(k) \neq k$. The base decomposition $\hat{p}_{\tilde{\sigma}} = \Sigma_{\tilde{\gamma} \in S_{t-1}}\, c_{\tilde{\gamma}} \hat{q}_{\tilde{\gamma}\tilde{\sigma}}$ leads to $\hat{p}_\sigma = \Sigma_{\tilde{\gamma} \in S_{t-1}}\, c_{\tilde{\gamma}} \hat{q}_{I_k(\tilde{\gamma})\sigma}$, see Propostion 6.1.

Thus if the $\tilde{\gamma} \in S_{t-1}$ term in (6.1) would be nonzero, it would be of the form $\langle V_N, \hat{p}_\sigma \rangle = c_{\tilde{\gamma}}$ for $\tilde{\gamma} \in S_{t-1}$ with $I_k(\tilde{\gamma}) = \sigma^{-1} = I_{k+1}(\tilde{\sigma}^{-1})$ or $I_{k+1}(\tilde{\sigma}) = I_k(\tilde{\gamma}^{-1})$. But this would imply $\tilde{\sigma}(k) = k$, contradicting the assumption. □

It is known that

$$|D_t| \sim \frac{|S_t|}{e} \quad \text{as} \quad t \to \infty.$$

So it could seem that we would only gain an unimportant factor $1/e$ by restricting the summation in (5.6) to the derangements (and the identity).

This is not so, since we can use the structure of the derangements under the τ action in our estimation.

For that purpose we now partition the derangements D_t by setting

$$D_t(k) := \{\sigma \in D_t \,|\, |\sigma \vee \sigma_+| = k \quad (k = 1, \ldots, t).$$

So $D_t(k) = \emptyset$ for $k > t/2$, and we estimate the cardinalities of these sets.

Proposition 6.3: There exists a $C_2 \geq 1$ such that for all $t \in \mathbb{N}$

$$|D_t(k)| \leq k C_2^k (t - k + 1)! \quad (k = 1, \ldots, \lfloor t/2 \rfloor).$$

Proof: Remark that the statement becomes trivial for $k = 1$ so that in the proof we assume $k \geq 2$.

(i) Each $\sigma \in D_t(k)$ induces a set partition

$$B(\sigma) \equiv B = (B_1, \ldots, B_k)$$

of $\{1, \ldots, t\}$ into the blocks of $\sigma \vee \sigma_+$ which is unique if you assume $|B_{l+1}| \geq |B_l|$ and $\min(B_l) \leq \min(B_{l+1})$ if $|B_{l+1}| = |B_l|$. As each B_l contains at least one cycle of σ (or rather the block corresponding to the cycle in the partition of σ), we have $|B_l| \geq 2$.

(ii) Next we consider the intersections

$$C_{l,m} := B_l \cap B_m^+ \quad (l, m \in \{1, \ldots, k\})$$

with the atoms $B_m^+ := \tau(B_m) = \{j + 1 \,|\, j \in B_m\}$ of the shifted set partition B^+. We thus get a set partition

$$C(\sigma) \equiv C = (C_{1,1}, \ldots, C_{k,k})$$

of $\{1, \ldots, t\}$ which is finer than B and B^+ but may contain empty atoms $C_{l,m}$. However, as σ is a derangement, we know that if $C_{l,m}(\sigma)$ is nonempty, it is a union of cycles of σ so that in any case $|C_{l,m}(\sigma)| \neq 1$.

(iii) We now estimate $|D_t(k)|$ by

$$|D_t(k)| \leq \sum_{b=(b_1,\ldots,b_k)} Y(b),$$

where $2 \leq b_1 \leq \cdots \leq b_k, \Sigma_{l=1}^k b_l = t$, and

$$Y(b) := |\{\sigma \in D_t \,|\, |B_l(\sigma)| = b_l, l = 1, \ldots, k\}.$$

(iv) This quantity, in turn is estimated by

$$Y(b) \leq \sum_{c=(c_{1,1},\ldots,c_{k,k})} X(c) \prod_{l,m=1}^{k} c_{l,m}!, \tag{6.2}$$

where now $c_{l,m} \in \{0, \ldots, b_l\} \setminus \{1\}$ with $\Sigma_{m=1}^k c_{l,m} = b_l$ and

$$X(c) = |\{B = (B_1, \ldots, B_k) \,||C_{l,m}| = c_{l,m}\}.$$

Here $\{B_1, \ldots, B_k\}$ is an arbitrary set partition of $\{1, \ldots, t\}$ with enumeration fixed by demanding $2 \leq |B_1| \leq \ldots \leq |B_k|$ and, again, $\min(B_l) \leq \min(B_{l+1})$ if $|B_l| = |B_{l+1}|$. Denoting as before by $C_{l,m}$ the intersection $B_l \cap B_m^+$ formula (6.2) follows by our above remark that all $\sigma \in D_t$ with $C_{l,m}(\sigma) = C_{l,m}$ have a cycle partition finer than $C = (C_{1,1}, \ldots, C_{k,k})$ and there are $c_{l,m}!$ ways to permute the set $C_{l,m}$.

We bound $X(c)$ by considering the directed multigraph $G = G(c)$ with vertex set $V := \{1, \ldots, k\}$ and $c_{l,m}$ unlabeled directed edges from vertex l to m. Then

$$X(c) \leqslant X_G(c), \tag{6.3}$$

where $X_G(c)$ is the number of closed Euler trails on G. This can be seen as follows:

(1) The length of any closed Euler trail equals $\Sigma_{l,m=1}^{k} c_{l,m} = t$.
(2) Any closed directed Euler trail on G (shortly called *trail* from now on) is uniquely characterized by the sequence $(v_1, \ldots, v_t)$ of vertices $v_j \in V$ it visits. This is due to our assumptions that the edges from l to m are unlabeled, and that the beginning of the closed trail is marked.
(3) A set partition $B = (B_1, \ldots, B_k)$ of $\{1, \ldots, t\}$ gives rise to a sequence $(v_1, \ldots, v_t)$ of vertices $v_i \in V$, where $v_i := j$ if $i \in B_j$. Using a t-periodic notation with $v_{t+1} = v_1$, we have

$$\left|\{i \in \{1, \ldots, t\} | (v_i, v_{i+1}) = (l,m)\}\right| = c_{l,m} \quad (l,m \in \{1, \ldots, k\}).$$

Thus B gives rise to a trail in $G(c)$ rooted at $v_1 \in V$.

It may be remarked that we have equality in (6.3) if the vertices of the directed multigraph $G(c)$ can be discerned by their outdegree, that is $b_1 < \cdots < b_k$. Then, given a Euler trail with sequence $(v_1, \ldots, v_t)$, we define the partition $(B_1, \ldots, B_k)$ by setting $B_j := \{i \in \{1, \ldots, t\} | v_i = j\}$.

(i) To get an upper bound on $X_G(c)$ we select a root vertex $j \in V$ and consider the Euler trails in $G(c)$ beginning at j. By the BEST formula their number equals

$$b_j^R T_j(c) \cdot \frac{\prod_{l=1}^{k} (b_l - 1)!}{\prod_{l,m=1}^{k} c_{l,m}!}, \tag{6.4}$$

where $T_j(c)$ is the number of directed spanning trees rooted at j. Equation (6.4) is derived from Theorem 13 in Chap. I of Ref. 9 by noting that, unlike here, Bollobas considers directed multigraphs with labeled edges. Here the *reduced out degree*

$$b_l^R := \sum_{m=1}^{k} c_{l,m}^R \text{ with } c_{l,m}^R := 1 \text{ if } c_{l,m} > 0 \text{ and } c_{l,m}^R := 0 \text{ otherwise}.$$

(ii) The number of directed spanning trees rooted at j equals the $(k-1) \times (k-1)$ minor of the $k \times k$ degree matrix,

$$\mathrm{diag}(b_1^R, \ldots, b_k^R) - (c_{l,m}^R)_{l,m=1}^{k}$$

obtained by deleting the jth row and the jth column. This number is known to be independent of j, and we call it $\Delta(c^R)$.
By this remark and (6.4),

$$X_G(c) \leqslant t\Delta(c^R) \frac{\prod_{l=1}^{k} (b_l - 1)!}{\prod_{l,m=1}^{k} c_{l,m}!}, \tag{6.5}$$

since $\Sigma_{j=1}^{k} b_j^R \leqslant \Sigma_{j=1}^{k} b_j = t$.
(iii) From (6.2) and (6.5) we obtain the estimate

$$Y(b) \leqslant t\prod_{l=1}^{k}(b_l-1)!\sum_{c=(c_{1,1},\ldots,c_{k,k})}\Delta(c^R). \tag{6.6}$$

A bound on $\Delta(c^R)$ only depending on the reduced out degrees $b_1^R,\ldots,b_k^R$ can be found in Ref. 14. We use it in the slightly weakened version,

$$\Delta(c^R) \leqslant \frac{1}{2}\prod_{l=1}^{k} b_l^R,$$

and thus get from (6.6)

$$Y(b) \leqslant \frac{t}{2}\prod_{l=1}^{k}[b_l^R(b_l-1)!]\cdot\sum_c 1. \tag{6.7}$$

(iv) The cardinality $\Sigma_c\,1$ of number partitions $c=(c_{1,1},\ldots,c_{k,k})$ compatible with the number partition $(b_1,\ldots,b_k)$ of t is calculated as follows:

$$\sum_c 1 = \prod_{l=1}^{k}\left|\left\{(c_{l,1},\ldots,c_{l,k})\,|\,c_{l,m}\neq 1 \text{ and}\sum_{m=1}^{k} c_{l,m}=b_l\right\}\right|.$$

But

$$\begin{aligned}
&\left|\left\{(c_{l,1},\ldots,c_{l,k})\,|\,c_{l,m}\neq 1 \text{ and}\sum_{m=1}^{k} c_{l,m}=b_l\right\}\right| \\
&\quad=\sum_{U\subseteq\{1,\ldots,k\}}\left|\left\{(c_{l,1},\ldots,c_{l,k})\,|\,c_{l,m}\geqslant 2 \text{ if } m\right.\right. \\
&\quad\left.\left.\in U \text{ and } c_{l,m}=0 \text{ otherwise}, \sum_{m\in U} c_{l,m}=b_l\right\}\right| \\
&\quad=\sum_{r=1}^{\min(k,\lfloor b_l/2\rfloor)}\sum_{|U|=r}\binom{b_l-r-1}{r-1} \\
&\quad=\sum_{r=1}^{\min(k,\lfloor b_l/2\rfloor)}\binom{b_l-r-1}{r-1}\binom{k}{r},
\end{aligned}$$

so that (6.7) reduces to

$$Y(b)\leqslant\frac{t}{2}\prod_{l=1}^{k}\left[b_l^R(b_l-1)!\sum_{r=1}^{\min(k,\lfloor b_l/2\rfloor)}\binom{b_l-r-1}{r-1}\binom{k}{r}\right]. \tag{6.8}$$

(v) We bound the sums appearing in (6.8), depending on the relative size of k and b_l. Remember our assumption $k\geqslant 2$.

We set $\hat{b}:=\lfloor b/2\rfloor$.

(1) For all $k,b\geqslant 2$ we have the estimate

$$\sum_{r=1}^{\min(k,\hat{b})}\binom{b-r-1}{r-1}\binom{k}{r}\leqslant\sum_{r=1}^{\min(k,b-1)}\binom{b-r-1}{r-1}\binom{k}{r}\leqslant\sum_{r=1}^{\min(k,b-1)}\binom{b-2}{r-1}\binom{k}{k-r}=\binom{k+b-2}{k-1}. \tag{6.9}$$

(2) For all $k\geqslant b\geqslant 2$ and $r\leqslant\hat{b}$ we use the inequality $\binom{k}{r}\leqslant\binom{k}{\hat{b}}\leqslant\binom{k}{\lfloor k/2\rfloor}$ to show

$$\sum_{r=1}^{\min(k,\hat{b})}\binom{b-r-1}{r-1}\binom{k}{r}\leqslant\left(\sum_{r=1}^{\hat{b}}\binom{b-r-1}{r-1}\right)\binom{k}{\hat{b}}=\frac{g^{b-1}-\left(\frac{-1}{g}\right)^{b-1}}{\sqrt{5}}\binom{k}{\hat{b}}\qquad(6.10)$$

with the golden mean $g:=(1+\sqrt{5})/2$, since the sum of the binomials equals the Fibonacci numbers.

(vi) The reduced out degree b_l^R is bounded by

$$b_l^R=\sum_{m=1}^{k}c_{l,m}^R\leqslant\min(k,\hat{b}_l)\leqslant\frac{2k\hat{b}_l}{k+\hat{b}_l}.\qquad(6.11)$$

Instead of summing (6.8) over the ensemble of $b=(b_1,\ldots,b_k)$ with $2\leqslant b_1\leqslant\cdots\leqslant b_k$ and $\Sigma_{l=1}^k b_l=t$, we shift the b_l by 2 and set for $\tilde{k}\leqslant k$,

$$Y_k(b_1,\ldots,b_{\tilde{k}};t):=\frac{t}{2}k^{k-\tilde{k}}\prod_{l=1}^{\tilde{k}}b_l^R(b_l+1)!\sum_{r=1}^{\min(k,\hat{b}_l)}\binom{b_l-r+1}{r-1}\binom{k}{r},$$

with $\hat{b}_l:=\lfloor b_l/2\rfloor+1$ and b_l^R is redefined as $\min(k,\hat{b}_l)$. Then for $b_l\geqslant 0$

$$Y_G(b_1+2,\ldots,b_k+2)\leqslant Y_k(b_1,\ldots,b_k;t)\qquad(6.12)$$

and our aim is to find a $C\geqslant 1$, independent of k and t, such that the recursion

$$\sum_{\substack{0\leqslant b_1\leqslant\cdots\leqslant b_{\tilde{k}+1}\\ \mathrm{P}_{l=1}^{\tilde{k}+1}b_l=t-2k}}(b_1,\ldots,b_{\tilde{k}+1};t)\leqslant C\sum_{\substack{0\leqslant b_1\leqslant\cdots\leqslant b_{\tilde{k}}\\ \mathrm{P}_{l=1}^{\tilde{k}}b_l=t-2k}}Y_k(b_1,\ldots,b_{\tilde{k}};t)\qquad(6.13)$$

in $\tilde{k}$ holds true. Assuming (6.13), we obtain from (6.12),

$$\sum_{\substack{2\leqslant b_1\leqslant\cdots\leqslant b_k\\ \mathrm{P}_{l=1}^{k}b_l=t}}Y_G(b_1,\ldots,b_k)\leqslant ke(ce)^{k-1}(t-k+1)!,$$

since

$$\begin{aligned}Y_k(t-2k;t)&\leqslant\frac{t}{2}k^{k-1}\min\left(k,\left\lfloor\frac{t}{2}-k\right\rfloor+1\right)(t-2k+1)!\binom{k+t-2k}{k-1}\\&=\frac{t}{2}\frac{k^k}{k!}\min\left(k\left\lfloor\frac{t}{2}-k\right\rfloor+1\right)(t-k)!\leqslant ke^k(t-k+1)!.\end{aligned}$$

Using (6.9) and (6.13) follows from the recursion

$$\begin{aligned}&\sum_{l=0}^{\hat{b}-1}\hat{l}(l+1)!\left(\sum_{r=1}^{\min(k,\hat{l})}\binom{l-r+1}{r-1}\binom{k}{r}\right)b\hat{}\,l(b-l+1)!\binom{k+b-l}{k-1}\\&\quad\leqslant C\cdot k(\hat{b})(b+1)!\binom{k+b}{k-1},\end{aligned}$$

with $\hat{l}=\lfloor l/2\rfloor+1$. This is equivalent to the claim

$$\sum_{l=0}^{\hat{b}-1} \hat{l}(l+1)! \left(\sum_{r=1}^{\min(k,\hat{l})} \binom{l-r+1}{r-1} \binom{k}{r} \right) b \hat{-} l \prod_{r=1}^{l} \frac{1}{k+b-r+1} \leqslant Ck\hat{b}. \tag{6.14}$$

Depending on the relative size of k and b, we estimate the lhs of (6.14) in two ways.

(i) Using (6.9), we get the uppper bound for the lhs of (6.14),

$$\sum_{l=0}^{\hat{b}-1} \hat{l}(l+1)! \binom{k+l}{k-1} b \hat{-} l \prod_{r=1}^{l} \frac{1}{k+b-r+1} = k \sum_{l=0}^{\hat{b}-1} \hat{l} b \hat{-} l \prod_{r=1}^{l} \frac{k+r}{k+b-r+1}. \tag{6.15}$$

We write the product in (6.15) in the form

$$\prod_{r=1}^{l} \frac{k+r}{k+b-r+1} = \exp\left(\sum_{r=1}^{l} g(r) \right) \quad \text{with} \quad g(r) := \ln\left(\frac{k+r}{k+b-r+1} \right).$$

For $r \leqslant l \leqslant b \hat{-} 1$ not only $g(r) \leqslant 0$ and $g(r) \geqslant g(r-1)$ but also (for all real such r)

$$g''(r) = \frac{1}{(k+b-r+1)^2} - \frac{1}{(k+r)^2} \leqslant 0.$$

So $\Sigma_{r=1}^{l} g(r) \leqslant lg[(1+l)/2] \leqslant lg(\hat{b}/2)$ or

$$\prod_{r=1}^{l} \frac{k+r}{k+b-r+1} \leqslant \lambda^l \quad \text{with} \quad \lambda := \frac{k+\frac{\hat{b}}{2}}{k+b-\frac{\hat{b}}{2}+1}. \tag{6.16}$$

For $k \leqslant b$ we have the uniform bound $\lambda \leqslant \frac{3}{4}$.
Inserting (6.16) in (6.15) and noting that $b \hat{-} l \leqslant \hat{b}$ and $\hat{l} \leqslant (l/2)+1$, we get (6.14) with

$$C := \sum_{l=0}^{\infty} \left(\frac{l}{2} + 1 \right) \left(\frac{3}{4} \right)^l = 10.$$

(ii) For $k \geqslant b$ we insert (6.10) in the lhs of (6.14) which is thus bounded by

$$\sum_{l=0}^{\hat{b}-1} \hat{l}(l+1)! \, g^l \binom{k}{\hat{l}-1} b \hat{-} l \prod_{r=1}^{l} \frac{1}{k+b-r+1} = \sum_{l=0}^{\hat{b}-1} \hat{l} b \hat{-} l g^l \binom{k}{\hat{l}-1} \prod_{r=1}^{l} \frac{r+1}{k+b-r+1}.$$

By an argument similar to the one leading to (6.16),

$$\begin{aligned}
\sum_{l=0}^{\hat{b}-1} \hat{l} b \hat{-} l g^l \binom{k}{\hat{l}-1} \prod_{r=1}^{l} \frac{r+1}{k+b-r+1} &= \sum_{l=0}^{\hat{b}-1} \hat{l}^2 b \hat{-} l \prod_{r=1}^{\lfloor l/2 \rfloor} \frac{g^2(r+\hat{l})}{(k+b-r+1)(k+b-r-\lfloor l/2 \rfloor+1)} \\
&\leqslant \sum_{l=0}^{\hat{b}-1} \hat{l}^2 b \hat{-} l \prod_{r=1}^{\lfloor l/2 \rfloor} \frac{g^2}{k+b-r+1} \leqslant \hat{b} \sum_{l=0}^{\hat{b}-1} \hat{l}^2 \left(\frac{g}{2} \right)^l \\
&\leqslant \hat{b} \sum_{l=0}^{\infty} \left(\frac{l^2}{4} + l + 1 \right) \left(\frac{g}{2} \right)^l \\
&= \frac{1}{4}(161 + 71\sqrt{5}) < 80,
\end{aligned}$$

assuming $k \geqslant 4$ and treating $k=2$ and $k=3$ separately. □

VII. THE ASYMPTOTIC ESTIMATE

Now we are ready to present our asymptotic result.

Theorem 7.1: *Under the assumption of Conjecture 5.8 the form factor K_N is approximated by the diagonal contribution in the following sense.*

For all $\varepsilon > 0$ uniformly in $t/N \in [\varepsilon, (e/C_2)(1-\varepsilon)]$

$$\left| K_N(t) - \frac{t}{N}\Delta_N^{\max}(t) \right| \to 0 \quad (N \to \infty).$$

Proof: As $K_N(t) = t/N$ for the t-values under consideration,

$$\Delta_N^{\max}(t) = \sum_{\sigma \in S_t} \langle V_N, \hat{p}_\sigma \rangle$$

[Eq. (5.6)], and $\langle V_N, \hat{p}_e \rangle = 1$ (Corollary 5.7), we need to show that

$$\sum_{\sigma \in S_t \setminus \{e\}} \langle V_N, \hat{p}_\sigma \rangle \to 0 \quad (N \to \infty).$$

Using Proposition 6.2 this amounts to show

$$\sum_{\sigma \in D_t} \langle V_N, \hat{p}_\sigma \rangle \to 0 \quad (N \to \infty),$$

which is implied by the asymptotic vanishing of

$$\sum_{k=1}^{\lfloor t/2 \rfloor} \sum_{\sigma \in D_t(k)} |\langle V_N, \hat{p}_\sigma \rangle| \leqslant C_1 \sum_{k=1}^{\lfloor t/2 \rfloor} k C_2^k (t-k+1)!\, N^{k-t},$$

using Conjecture 5.8 and Proposition 6.3. Under our assumptions for t/N,

$$\sum_{k=1}^{\lfloor t/2 \rfloor} k C_2^k (t-k+1)!\, N^{k-t} \leqslant tN \sum_{k=1}^{\lfloor t/2 \rfloor} C_2^k \left(\frac{t-k+1}{N^e} \right)^{t-k+1} \leqslant N^2 \sum_{k=1}^{\lfloor t/2 \rfloor} C_2^k \left(\frac{1-\varepsilon}{C_2} \right)^{t-k+1} \leqslant N^2 C_2^{-1} \sum_{k=1}^{\lfloor t/2 \rfloor} (1-\varepsilon)^{t-k+1}$$

$$\leqslant \frac{N^2}{C_2 \varepsilon} \cdot (1-\varepsilon)^{\lceil t/2 \rceil + 1} \leqslant \frac{N^2}{C_2 \varepsilon} (1-\varepsilon)^{\varepsilon N/2} \to 0,$$

proving the theorem.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 45, NUMBER 12 DECEMBER 2004

Description of noncommutative theories and matrix models by Wightman functions

William Gordon Ritter
Department of Physics, Harvard University, Cambridge, Massachusetts 02138

(Received 28 January 2004; accepted 19 May 2004; published 30 November 2004)

One of the main open problems of mathematical physics is to consistently quantize Yang–Mills gauge theory. If such a consistent quantization were to exist, it is reasonable to expect a "Wightman reconstruction theorem," by which a Hilbert space and quantum field operators are recovered from *n*-point functions. However, the original version of the Wightman theorem is not equipped to deal with gauge fields or fields taking values in a noncommutative space. This paper explores a generalization of the Wightman construction which allows the fundamental fields to take values in an arbitrary topological *-algebra. In particular, the construction applies to fields valued in a Lie algebra representation, of the type required by Yang–Mills theory. This appears to be the correct framework for a generalized reconstruction theorem amenable to modern quantum theories such as gauge theories and matrix models. We obtain the interesting result that a large class of quantum theories are expected to arise as limits of matrix models, which may be related to the well-known conjecture of Kazakov. Further, by considering deformations of the associative algebra structure in the noncommutative target space, we define certain one-parameter families of quantum field theories and conjecture a relationship with deformation quantization. © *2004 American Institute of Physics.*

I. INTRODUCTION

The Wightman axioms were formulated by Gårding and Wightman in the early 1950s, but no nontrivial examples existed at that time, and consequently the axioms were not published until 1964,[1] at which time their publication had been motivated by the Haag–Ruelle scattering theory. The axioms are thoroughly discussed and many consequences are derived in the two excellent books (Refs. 2 and 3). We will also formulate the axioms below in Sec. I B by way of introduction.

It is known that the Wightman axioms, in their original and unmodified form, describe only a small subset of the mathematical models used in elementary particle physics. Thus, many authors have considered modifications of the axioms which allow newer and more exotic physical theories to be formulated as rigorous mathematics. If we wish to perturb the axioms slightly, one obvious change with clear-cut physical implications is to relax the requirement that the test function space be $\mathcal{S}(\mathbb{R}^4)$. A large class of alternative test function spaces which still allow a formulation of the microscopic causality condition were proposed and developed by Jaffe.[4] The results of the present paper are a more radical modification, in which the test functions in $\mathcal{S}(\mathbb{R}^4)$ are replaced by functions into a noncommuting *-algebra.

There are at least two types of equivalent reformulations of the Wightman axioms. One is due to Wightman, who wrote down a set of conditions governing a sequence of tempered distributions

$$\mathcal{W}_n \in \mathcal{S}(\mathbb{R}^{4n}), \quad n = 0, 1, \ldots,$$

and proved that, under these conditions, the distributions $\mathcal{W}_n$ arise as vacuum expectation values of a unique quantum field theory satisfying the Wightman axioms, and conversely that the postulates hold in any Wightman field theory. This is what is known as the *Wightman reconstruction*

theorem, and first appeared in the seminal paper.[5] The part of this construction relevant to representation theory is known in functional analysis as the *GNS construction*. A second reformulation in terms of the Schwinger functions, not directly used in the present work, was given by Osterwalder and Schrader.[6]

Borchers reformulated Wightman's reconstruction theorem in several important papers,[7,8] with the result that a scalar boson quantum field theory is known to be characterized by a topological *-algebra A (with unit element 1_A) and a continuous positive form ω on A, satisfying

$$\omega(aa^*) \geqslant 0, \quad \omega(1_A) = 1, \quad a \in A. \tag{1}$$

A functional satisfying (1) is called a state.

Realistic models are generally described by tensor algebras, and the action of the state ω is computed from vacuum expectation values of products of fields. Although there is reason to believe the framework of states on tensor algebras could apply in general to a large class of quantum field theories, previous formulations of the Wightman reconstruction theorem have focused on scalar boson quantum field theories.

The Borchers formulation has proven very useful for analysis of bosonic field theory on a nontrivial manifold. Consider ω a state on the Borchers algebra built from test functions on a manifold M, and let ϕ_ω be the corresponding field. If ϕ_ω satisfies the Klein–Gordon equation and

$$[\phi_\omega(f), \phi_\omega(g)] = E(f \otimes g),$$

where E is the difference between the fundamental solutions of the Klein–Gordon operator, one calls ω a *state of the Klein–Gordon field over M*. It turns out that only certain states, called *Hadamard states*, are compatible with the semiclassical Einstein equation. For further details, we refer the reader to Ref. 9 and the monograph.[10]

There are by now many known examples of a low-energy limit or compactification of string theory which are equivalent to a gauge theory with compact gauge group. It is also known that exact quantum string amplitudes can be computed from various flavors of matrix models. If a mathematically rigorous description using constructive field theory is possible for these problems coming from string theory, then a consistent generalization of the Wightman reconstruction theorem which incorporates the structure of gauge theory and matrix models seems a useful framework in which to formulate the result.

The purpose of the present paper is to extend the work of Wightman and Borchers to include matrix-valued fields of the type required by gauge theory and matrix models. We first develop the mathematics, and then make contact with physical applications. The remainder of this introduction reviews the well-known Wightman procedure for commuting scalar fields; this serves to fix notation and set the context for the later sections. Section II presents the main new idea of the paper, a generalization of the Borchers construction, and considers some simple examples. Section III is concerned with the application of these ideas to two-dimensional Yang–Mills theory. In Sec. IV we recall important recent work which applies matrix models to high energy physics and then show that, in the same sense in which scalar quantum field theories are Wightman states, matrix models are described by *finite order states*, and thus are special cases of the construction in Sec. II. Moreover, finite order states form a dense subset of the space of all states, and hence arbitrary field theories are given as limits of matrix models. The conclusion is that traditional constructive quantum field theory, gauge theories, matrix models and certain hypothetical generalizations of these may all be described within a unified algebraic framework.

A. The Borchers construction

Let $\mathcal{S}(\mathbb{R}^d)$ denote the set of infinitely differentiable complex functions $f(x)$ on $\mathbb{R}^d$ for which

$$\|f\|_{\alpha,\beta} \equiv \sup_{x \in \mathbb{R}^d} |x^\alpha D^\beta f(x)| < \infty \quad \text{for all } \alpha, \beta,$$

where D^β is the usual multi-index derivative. Let us also define the spaces

$$\mathcal{S}_0 = \mathbb{C}, \quad \mathcal{S}_n = \mathcal{S}(\mathbb{R}^{dn}), \quad \text{and } \underline{\mathcal{S}} = \bigoplus_{n=0}^{\infty} \mathcal{S}_n.$$

The latter is a complete nuclear space under the direct sum topology. There is a natural map $\iota: \otimes^k \mathcal{S}(\mathbb{R}^n) \to \mathcal{S}(\mathbb{R}^{kn})$ given by $\iota(f_1 \otimes \cdots \otimes f_k) = \Pi_{j=1}^k f_j(x_j)$, where each $x_j \in \mathbb{R}^d$, and the image of ι is dense.

Endow $\underline{\mathcal{S}}$ with the noncommutative multiplication

$$(f \times g)_l = \sum_{i+h=l} f_i \times g_h,$$

$$f_i \times g_h(x_1, \ldots, x_{i+h}) = f_i(x_1, \ldots, x_i) g_h(x_{i+1}, \ldots, x_{i+h}), \tag{2}$$

and the involution $f^* = (f_0^*, f_1^*, \ldots)$, where $f_0^* = \overline{f_0}$ and for $i \geqslant 1$,

$$f_i^*(x_1, \ldots, x_i) = \overline{f_i(x_i, x_{i-1}, \ldots, x_1)}. \tag{3}$$

The multiplication $\times$ and the unit $\mathbf{1} = (1, 0, 0, \ldots)$ make $\underline{\mathcal{S}}$ into a unital *-algebra with no zero divisors. The center of $\underline{\mathcal{S}}$ is $\{\lambda \mathbf{1} : \lambda \in \mathbb{C}\}$, $\mathbf{1}$ is the only nonzero idempotent, and the set of invertible elements equals the center. This implies the triviality of the radical

$$\text{rad}(\underline{\mathcal{S}}) = \{g \in \underline{\mathcal{S}} : 1 + f \times g \text{ has inverse } \forall\, f\}.$$

An element $g \in \underline{\mathcal{S}}$ is called *positive* if $\exists f_i$ such that $g = \Sigma_i f_i^* \times f_i$. This induces a positive cone $\underline{\mathcal{S}}^+$ and a semiordering. We define the set of Hermitian elements,

$$\underline{\mathcal{S}}_h = \{f \in \underline{\mathcal{S}} : f^* = f\}, \tag{4}$$

which is a real vector space and we have $\underline{\mathcal{S}} = \underline{\mathcal{S}}_h + i\underline{\mathcal{S}}_h$. Also, $\underline{\mathcal{S}}^+$ is a convex cone with $\underline{\mathcal{S}}^+ \cap (-\underline{\mathcal{S}}^+) = \{0\}$. Moreover, we have $\underline{\mathcal{S}}_h = \underline{\mathcal{S}}^+ - \underline{\mathcal{S}}^+$, which follows by polarization.

B. The Wightman axioms

Let $\mathcal{S}$ denote an appropriate space of test functions, often taken to be $\mathcal{S}(\mathbb{R}^d)$.

Axiom 1: There exists a Hilbert space $\mathcal{H}$ and a dense domain $D \subset \mathcal{H}$ such that for every $f \in \mathcal{S}$, an operator $\varphi(f)$ exists, such that $D \subset \text{dom}(\varphi(f))$, $\varphi(f)D \subset D$,

$$(\psi, \varphi(f)\chi) = (\varphi(\overline{f})\psi, \chi) \quad \textit{for all } \psi, \chi \in D$$

and $f \to (\psi, \varphi(f)\chi)$ is a continuous linear functional on $\mathcal{S}$.

Axiom 2: Let $f_a(x) = f(x-a)$. There exists a strongly continuous unitary representation $\mathcal{U}$ of the translation group $\mathcal{G}$, such that for all $a \in \mathcal{G}$, $U(a)D \subset D$ and

$$\mathcal{U}(a)\varphi(f)\mathcal{U}^{-1}(a)\psi = \varphi(f_a)\psi$$

for all $f \in \mathcal{S}, \psi \in D$.

In standard constructive quantum field theory models, there is a canonical action of the proper orthochronous Poincaré group $P_+^\uparrow$ on $\mathcal{S}_n$ for all n, in other words, a representation $\alpha: P_+^\uparrow \to \text{Aut}(\underline{\mathcal{S}})$. We mention the representation α because even in the generalized models to be introduced in Sec. II, invariance under a symmetry group is expressed in terms of representations similar to α. See also Sec. II C.

Axiom 3: There exists $\Omega \in D$ such that $\mathcal{U}(a)\Omega = \Omega$ for all $a \in \mathcal{G}$, and the set of vectors of the form $\{\Omega, \varphi(f)\Omega, \varphi(f_1)\varphi(f_2)\Omega, \ldots\}$ spans $\mathcal{H}$.

Further Wightman axioms will be discussed in Sec. I G.

C. States, the GNS construction, and axiom 1

Let $\underline{\mathcal{S}}'$ be the space of continuous linear functionals $T:\underline{\mathcal{S}}\to\mathbb{C}$. For $f\in\underline{\mathcal{S}}$, denote the action of T by (T,f). The space $\underline{\mathcal{S}}'$ also has a natural involution; define T^* by

$$(T^*,f):=\overline{(T,f^*)}.$$

We say a functional is *real* if $T=T^*$, and *positive* if $(T,p)\geqslant 0$ for all $p\in\underline{\mathcal{S}}^+$. The corresponding spaces are denoted $\underline{\mathcal{S}}'_h$ and $\underline{\mathcal{S}}'^+$.

The *set of states* is

$$E(\underline{\mathcal{S}})=\{T\in\underline{\mathcal{S}}'^+:(T,1)=1\}.$$

The *left-kernel* of a state T is defined to be

$$L(T):=\{f\in\underline{\mathcal{S}}:(T,f^*\times f)=0\}. \tag{5}$$

The left-kernel is so named because it is a left ideal in the Borchers algebra. The *right-kernel* $R(T)$, defined by the analogous relation $(T,f\times f^*)=0$, is a right ideal. These kernels arise in the quantization procedure discussed later; choice of the left-kernel amounts to the convention that a sesquilinear form is conjugate-linear in the first variable.

Theorem 1: *Each state $T\in E(\underline{\mathcal{S}})$ canonically defines a representation A_T of $\underline{\mathcal{S}}$ in a Hilbert space $\mathcal{H}_T$ such that the restriction $A_T|_{\mathcal{S}_1}$ satisfies axiom 1. Conversely, if $\{\phi(f)\}$ are a set of fields satisfying axiom 1, then every $\Omega\in D$ defines a continuous linear functional T_Ω, by*

$$(T_\Omega,f_1\times f_2\times\cdots\times f_n)=(\Omega,\phi(f_1)\phi(f_2)\cdots\phi(f_n)\Omega),\quad f_i\in\mathcal{S}_1.$$

If $\|\Omega\|=1$, then T_Ω is a state. The field A_{T_Ω} is unitarily equivalent to $\{A_\Omega,D_\Omega,\mathcal{H}_\Omega\}$ where

$$D_\Omega=\text{Linear Span of }\Omega,\ \phi(f)\Omega,\ \phi(f_1)\phi(f_2)\Omega,\ \text{etc.},$$

$\mathcal{H}_\Omega$ is the closure of D_Ω, and $A_\Omega(f)=\phi(f)|_{D_\Omega}$.

Proof: As a full proof can be found elsewhere,[2,7] we merely recall the central idea for convenience, as it is used later. T defines a nondegenerate positive definite sesquilinear form on $\underline{\mathcal{S}}/L(T)$ by the relation

$$([f],[g])=(T,f^*\times g),[f],[g]\in\underline{\mathcal{S}}/L(T).$$

Define $\mathcal{H}_T$ to be the completion of the pre-Hilbert space $\underline{\mathcal{S}}/L(T)$, and define a representation of $\underline{\mathcal{S}}$ on $\mathcal{H}_T$ by $A_T(f)[g]=[f\times g]$ for $f\in\mathcal{S}_1$ and $g\in\underline{\mathcal{S}}$. The rest of the proof is straightforward. □

D. Translation invariant states satisfy axioms 1–3

Let $a\in\mathbb{R}^d$. The map α_a defined by

$$\alpha_a f_i(x_1,\ldots,x_i)=f_i(x_1-a,\ldots,x_i-a)$$

is an element of $\mathrm{Aut}(\underline{\mathcal{S}})$. A state T is *translation-invariant* if $(T,\alpha_a f)=(T,f)$ holds for all $f\in\underline{\mathcal{S}}$, and for all $a\in\mathbb{R}^d$.

Theorem 2: *Let T be a translation invariant state. Then $A_T(f)$ satisfies axioms* 1–3. *Conversely, if the system $\{A(f),D,\Omega\in D\}$ satisfies axioms* 1–3, *then T_Ω defined by $(T_\Omega,f)=(\Omega,A(f)\Omega)$ is translation invariant.*

E. Tensor products of states

Given two states $T_1,T_2\in E(\underline{\mathcal{S}})$, let $\{A_i(f),\mathcal{H}_i,D_i,\Omega_i\}$ be the associated GNS representations. Then the triple

$$\{A_1(f)\otimes I_2 + I_1\otimes A_2(f), \mathcal{H}_1\otimes\mathcal{H}_2, D_1\times D_2\}$$

satisfies axiom 1, and hence it corresponds to a new state, $T_1\otimes_s T_2$ which is the same as the vector state T_Ω with $\Omega=\Omega_1\times\Omega_2$. Let $P_{n,m}$ denote the set of all ordered splittings of $n+m$ elements into two subsets, of respective sizes n and m. Let $T_n\in\underline{\mathcal{S}}'_n$, $S_m\in\underline{\mathcal{S}}'_m$, then $T_n\otimes_\jmath S_m$ is given by

$$(T_n\otimes_\jmath S_m)(x_1,\ldots,x_{n+m}) = \sum_{P_{n,m}} T_n(x_{i_1},\ldots,x_{i_n})S_m(x_{j_1},\ldots,x_{j_m}).$$

For $T,S\in\underline{\mathcal{S}}'$, we define $(T\otimes_\jmath S)_n=\Sigma_{i+k=n}\ T_i\otimes_\jmath S_k$. This coincides with our previous definition of the $\otimes_\jmath$-product. It is clearly associative and Abelian.

F. Real scalar fields

Before discussing more complicated generalizations, we briefly indicate how the above construction can describe the salient properties of the quantum theory of a one-component real scalar field. Since $\otimes^k\mathcal{S}(\mathbb{R}^n)$ is dense in $\mathcal{S}(\mathbb{R}^{kn})$, every continuous form on the subspace has a unique continuous extension. By the classic Schwartz nuclear theorem, if $B(f_1,\ldots,f_k)$ is a separately continuous k-linear functional on $\mathcal{S}(\mathbb{R}^{n_1})\times\cdots\times\mathcal{S}(\mathbb{R}^{n_k})$, there exists $T\in\mathcal{S}'(\mathbb{R}^N)$ with

$$B(f_1,\ldots,f_k) = T(f_1\otimes\cdots\otimes f_k),$$

where $N=\Sigma_i\, n_i$. As a consequence, every state ω on the Borchers algebra is represented by a family of distributions $W_n\in\mathcal{S}'(\mathbb{R}^{dn})$, in the sense that

$$\omega(f_1\times\cdots\times f_n) = \int W_n(x_1,\ldots,x_n)f_1(x_1)\cdots f_n(x_n)\mathrm{d}^dx_1\cdots\mathrm{d}^dx_n. \tag{6}$$

A rigorous proof is known that a scalar quantum field theory, when it exists, is completely determined by its Wightman functions. By relation (6), a state ω on the Borchers algebra contains the same information as a complete specification of the n-point functions for all values of n. If ω obeys the Wightman axioms, then we have a quantum field theory and W_n are related to vacuum expectation values of products of fields. They calculate observable quantities such as cross sections and decay rates.

G. Spectral condition, locality, and uniqueness of the vacuum

The remaining two essential properties of a quantum field theory (spectral condition and locality) are equivalent to ker ω containing certain ideals. Let $\mathcal{S}_1(CV^+)$ denote the set of functions in $\mathcal{S}_1$ that vanish on the forward light cone V^+, and let $\mathcal{F}$ denote the Fourier transform. The spectral condition is the statement that ker $\omega\supset I_1$, where

$$I_1 = \left\{\int \mathrm{d}^daF(a)\alpha_a f : f\in\underline{\mathcal{S}}, f_0=0, F(a)\in\mathcal{F}[\mathcal{S}_1(CV^+)]\right\}.$$

Space–time locality is the statement that ker $\omega\supset I_2$, where I_2 is the smallest closed two-sided ideal in $\underline{\mathcal{S}}$ containing all elements of the form $f\times g-g\times f$ where f and g have spacelike-separated supports.

Uniqueness of the vacuum also has a simple interpretation in terms of Wightman functionals. A field theory is said to be *reducible* if the algebra of field operators acts reducibly on the Hilbert space. A Wightman state ω is said to be *decomposable* if there exists a positive number $\lambda<1$ such that

$$\omega = \lambda\omega^{(1)} + (1-\lambda)\omega^{(2)} \tag{7}$$

with Wightman states $\omega^{(1)}$ and $\omega^{(2)}$ different from ω. Indecomposability of the Wightman functional is equivalent to uniqueness of the vacuum in an irreducible field theory.

In Sec. II we will generalize the Wightman state ω, and it is of interest to know whether (7) also leads to uniqueness of the vacuum in the general case.

II. NONCOMMUTATIVE TARGET SPACE PERSPECTIVE

The field algebra with multiplication and involution given by (2)–(3) admits a natural generalization to the noncommutative setting. This generalization has many applications in physics, all of which come from interpreting elements of the Borchers algebra as gauge fields on a d-dimensional space–time. For $d \leqslant 1$, this gives rise to matrix models and matrix quantum mechanics. For $d \geqslant 2$, it is Yang–Mills theory. Of course, gauge symmetry is not essential for the construction to work; it applies equally well to matrix-valued scalar field theory of the type considered by Kazakov.[11] This framework is also suggestive of quantum field theory in which the target manifold is a noncommutative space in the sense of Connes.

A. Test functions valued in a noncommutative algebra

First we wish to argue that a correct description of gauge quantum field theory is possible in terms of test functions valued in a noncommutative algebra. Consider a pure gauge theory with gauge group G and Lie algebra $\mathfrak{g}=\mathrm{Lie}(G)$. In a classical pure gauge theory, the fundamental fields are $\mathfrak{g}$-valued one-forms, each determining a connection on a principal G-bundle. In a quantum version of the same gauge theory, these classical fields would be promoted to operator-valued distributions with the same algebraic structure.

For concreteness, let $\mathcal{S}(\mathbb{R}^4)$ denote the Schwartz space of rapidly decreasing functions on $\mathbb{R}^4$. An operator-valued distribution is a continuous map

$$\mathcal{S}(\mathbb{R}^4) \to \mathrm{Op}(\mathcal{H}),$$

where we consider $\mathcal{S}(\mathbb{R}^4)$ to be endowed with the Schwartz topology, $\mathcal{H}$ is a Hilbert space, and $\mathrm{Op}(\mathcal{H})$ denotes a suitable space of unbounded operators on $\mathcal{H}$. In the example of a free real scalar boson, $\mathcal{H}$ is the usual bosonic Fock space, and $\mathrm{Op}(\mathcal{H})$ would be a class of operators large enough to include all operators of the form $\phi(f)$, where ϕ is a quantum field and f is any test function. The operators $\mathrm{Op}(\mathcal{H})$, in this example, have a common core including all smooth, compactly supported Fock states with finite particle number.

Let $\rho:\mathfrak{g}\to\mathfrak{g}l(V)$ be a representation of $\mathfrak{g}$ on the representation space V. Let $\mathcal{H}^V$ denote the space of all continuous linear functionals

$$\phi:\mathcal{S}(\mathbb{R}^4) \to \mathrm{Op}(\mathcal{H}) \otimes V. \tag{8}$$

Elements of $\mathcal{H}^V$ are operator-valued distributions that transform in the representation V. The representation ρ on V naturally defines a representation $\overline{\rho}$ of $\mathfrak{g}$ on $\mathcal{H}^V$ by expanding

$$\phi(f) = \sum_{i=1}^{n} A_i^f \otimes v_i^f$$

for $A_i^f \in \mathrm{Op}(\mathcal{H}), v_i^f \in V$, and defining

$$(\overline{\rho}(g)\phi)(f) = \sum_i A_i^f \otimes (\rho(g)v_i^f), \quad g \in \mathfrak{g}.$$

One very useful choice for V is the adjoint representation, because field strength variables $F_{\mu\nu}(x)$ in Yang–-Mills theory transform in the adjoint. Other representations typically arise as direct summands of tensor powers of the adjoint and its complex conjugate representation. In all of these examples, it is useful to view the representation space V as living in some matrix algebra.

There is a natural transformation of categories by which the space $\mathcal{H}^V$ defined above is naturally isomorphic to the space $\mathcal{H}_{V^*}$ of continuous maps

$$\mathcal{S}(\mathbb{R}^4) \otimes V^* \to \mathrm{Op}(\mathcal{H}). \tag{9}$$

Let us exhibit the isomorphism between (8) and (9) explicitly. For concreteness, we will fix our attention on the special case of $V=\mathfrak{g}$, the adjoint, but we stress that no part of the discussion depends on this in an essential way.

In terms of ϕ we may define a new map

$$\tilde{\phi}:\mathcal{S}(\mathbb{R}^4) \times \mathfrak{g}^* \to \mathrm{Op}(\mathcal{H}) \tag{10}$$

by the formula

$$\tilde{\phi}(f,y) \equiv \sum_{i=1}^{n} y(v_i^f) A_i^f, \quad y \in \mathfrak{g}^*. \tag{11}$$

Equivalently, if T^a is a basis for $\mathfrak{g}$, and $\phi(f)=\phi(f)_a T^a$, then for $y \in \mathfrak{g}^*$, $\tilde{\phi}(f,y^a)=\phi(f)_a y^a$.

The map $\tilde{\phi}$ is multilinear, and therefore factors through to a map on the tensor product $\mathcal{S}(\mathbb{R}^4)\otimes\mathfrak{g}^*$. We have proved that $\phi \to \tilde{\phi}$ gives an explicit isomorphism $\mathcal{H}^V \cong \mathcal{H}_{V^*}$ between the two spaces (8) and (9).

Quantum field theory with test functions taking values in $\mathfrak{g}^*$ is most naturally described by a noncommutative version of the Borchers construction, and the latter mathematical structure will occupy us for the rest of this section and, in some form or other, for the rest of the paper. We summarize the results of the preceding paragraphs in a lemma.

Lemma 1: The following structures are equivalent.

(1) *An operator-valued distribution which transforms in the adjoint representation of a Lie algebra* $\mathfrak{g}$ *(i.e., a quantized Yang–Mills field).*
(2) *An operator-valued distribution which acts on* $\mathfrak{g}^*$*-valued test functions*.

Let us see how this isomorphism works in practice. Suppose that $F_{\mu\nu}(x)$ is an operator-valued distribution which transforms as a Lie algebra-valued two-form. An example of such an object is a quantized Yang–Mills field strength. The above construction tells us that from $F_{\mu\nu}(x)$, we can construct a single operator-valued distribution $\tilde{F}_{\mu\nu}$ which acts on test functions $f(x)$ valued in the dual of the Lie algebra. The duality between $\mathfrak{g}$ and $\mathfrak{g}^*$ is given explicitly by the Killing form $K(a,b)=\mathrm{tr}(ab)$, where the trace is taken in the adjoint representation. Therefore, the correct definition is

$$\tilde{F}_{\mu\nu}(f) = \mathrm{tr}(f \cdot F_{\mu\nu}) = \int K(f(x),F_{\mu\nu}(x))\ \mathrm{d}x, \tag{12}$$

where $f\cdot F_{\mu\nu}$ is defined by

$$[f \cdot F_{\mu\nu}]_{ij} \equiv \sum_k \int f(x)_{ik} (F_{\mu\nu}(x))_{kj}\ \mathrm{d}x.$$

The notation of (12) is the same as (10). This shows explicitly how operator-valued distributions act on $\mathfrak{g}^*$-valued test functions.

Remark 1: This duality transformation transfers the dependence on the Lie algebra to the test functions; however, if the original field also transforms as a section of an additional vector bundle E, as is the case for the two-form $F_{\mu\nu}(x)$ which is a section of $E=\wedge^2(\mathbb{R}^d)$, the quantized field operator (12) transforms in the tensor product $E\otimes\mathcal{O}_{\mathcal{H}}$, where $\mathcal{O}_{\mathcal{H}}$ is a trivial bundle with fiber $\mathrm{Op}(\mathcal{H})$. Additional complications to the theory presented above arise in the case of a nontrivial fiber bundle, in which the connection can be only locally described as a $\mathfrak{g}$-valued one-form. The gauge fields in the present paper are all assumed to be sections of globally trivial principal bundles.

Remark 2: One could imagine exotic quantum field theories in which the fields take values in

the algebra of functions over a noncommutative geometry in the sense of Connes. The present constructions define such a theory mathematically, but we do not know a direct physical interpretation.

For any manifold Σ, let

$$\mathcal{A} = \mathcal{A}(\Sigma, \mathcal{B}) \tag{13}$$

denote a vector space of test functions from Σ to a possibly noncommutative star-algebra $\mathcal{B}$ with product $\cdot$. For the quantum theories we construct, elements of $\mathcal{A}$ will play the role of test functions. Invariance of the Schwartz space under the Fourier transform implies that tempered distributions can grow at most polynomially in momentum space. Thus, the choice of the test function space has important physical consequences.

If $\mathcal{B}$ is a normed algebra and Σ is equipped with an appropriate metric, then we may consider $\mathcal{A}(\Sigma, \mathcal{B})$ to be the Schwartz space of rapidly decreasing functions. For example, one could consider a space–time which has nontrivial topology within some compact region K, and outside that region it is covered by a single chart c which is an isometry onto $\mathbb{R}^d$ minus a compact set. On such a space–time, one can demand that the $\mathfrak{B}$-norm of the function and of all its derivatives, expressed in chart c, fall off faster than any power of the *modulus function*, which measures the distance of a point from K in the ambient metric.

Alternatively, if Σ is any manifold, one can obtain the necessary analytic regularity by consideration of continuous functions with compact support. For manifolds there is the additional complication that one should integrate *densities* rather than functions, and so the test function space should properly be $C_0^\infty(\Sigma, \Omega^1)$, the space of smooth compactly supported sections of the line bundle Ω^1 of densities of order one. In this generalized situation, the terminology *test density* is more appropriate. In what follows, we will generally assume the existence of a Riemannian metric, under which conditions a function on Σ determines a density. The constructions which follow are already interesting for $\Sigma = \mathbb{R}^d$. In the application of these ideas to two-dimensional gauge theory, Σ will denote a compact Riemann surface.

Since certain gauge theories are known to possess ultraviolet behavior which is more singular than that of, say, scalar theory in $d = 2, 3$, it is of importance to recall a construction of Jaffe.[4] Given a function $g(t), t \in \mathbb{R}$, such that $g(t^2)$ is entire and positive, Jaffe defines $\tilde{S}_g$ to be the space of all functions on $\mathbb{R}^d$ which are infinitely differentiable and for which all the norms

$$\|f(p)\|_n = \sup_{p;|\alpha|\leqslant n} g(n\|p\|^2)|D^\alpha f(p)|, \quad n = 1, 2, \ldots, \tag{14}$$

are finite. Here α is a multi-index, and $\|p\|$ is an arbitrary Euclidean norm on $\mathbb{R}^d$. Finiteness of the norms (14) means that test functions and all its derivatives decay at infinity faster than $1/g(n\|p\|^2)$ for any positive n. $\tilde{S}_g$ does not depend on the choice of the Euclidean norm, but it does depend on the rate of growth of $g(t^2)$ at infinity. Define the topology on $\tilde{S}_g$ to be that generated by the countable family of norms (14). It is easy to see that $\tilde{S}_g$ is Lorenz invariant. In addition, if g satisfies

$$\frac{g(n\|p\|^2)}{g(n'\|p\|^2)} \quad \textit{is an integrable function for all } n \textit{ and sufficiently large } n', \tag{15}$$

then the nuclear theorem holds.

Let us denote the Fourier transform of $\tilde{S}_g$ by S_g. We think of $\tilde{S}_g$ as the space of test functions in momentum space, so S_g is the space of test functions in x space. The spaces S_g can be used to define quantum field theories whose ultraviolet behavior is more singular than the traditional Wightman field theories; see Ref. 4 for further details.

For our purposes, the important point is that for test functions valued in a normed star-algebra $\mathcal{B}$, a completely analogous construction exists. We modify (14) so that the complex modulus

$|D^\alpha f(p)|$ is replaced by the $\mathcal{B}$-norm of the same expression, $\|D^\alpha f(p)\|_{\mathcal{B}}$. This defines test function spaces $\widetilde{S}_g{}^{\mathcal{B}}$ which can be used in the constructions which follow, and may be important for theories which are singular in the UV.

B. Generalizing the Borchers construction

We assume for convenience that the base field of $\mathcal{B}$ is $F=\mathbb{R}$ or $\mathbb{C}$. $\mathcal{A}$ is then naturally a left and right module over $\mathcal{B}$, and of course also over F. Define

$$\mathcal{A}_n = \mathcal{A}^{\otimes n}, \quad \underline{\mathcal{A}} = \mathbb{C} \oplus \overset{\infty}{\underset{n=1}{\oplus}} \mathcal{A}_n \tag{16}$$

to be the free tensor algebra over $\mathcal{A}$. Note that

$$\mathcal{A}_n \cong \mathcal{A}(\Sigma^n, \mathcal{B}^{\otimes n}), \tag{17}$$

an isomorphism of complete topological vector spaces, where Σ^n denotes the n-fold Cartesian product. As $\mathcal{B}$ is defined to be an involutive algebra, we denote the involution by

$$\tau_*: \mathcal{B} \to \mathcal{B}.$$

This extends to give an involution on $\mathcal{A}_n$, defined by

$$f^*(x_1, \ldots, x_n) := \tau_*^{\otimes n} f(x_n, \ldots, x_1). \tag{18}$$

Also define a binary operation $\times$ on $\underline{\mathcal{A}}$ as follows:

$$(\underline{f} \times \underline{g})_n = \sum_{i+j=n} f_i \otimes g_j, \quad \underline{f} = (f_0, f_1, \ldots), \quad \underline{g} = (g_0, g_1, \ldots) \in \underline{\mathcal{A}}. \tag{19}$$

The operations (18) and (19) give $\underline{\mathcal{A}}$ the structure of a unital involutive algebra, with unit given by $\mathbf{1}=(1,0,0,\ldots)$. In analogy with the case for scalar fields, $\underline{\mathcal{A}}$ also has a cone $\underline{\mathcal{A}}^+$ of positive elements, and a subset $\underline{\mathcal{A}}_h$ of Hermitian elements.

One could imagine an analogous construction in which the tensor product in (19) is replaced with multiplication in $\mathcal{B}$. In such a framework, $\mathcal{A}_n$ would be replaced by $\mathcal{A}(\Sigma^n, \mathcal{B})$, in contrast with (17). Interestingly, *this modification is incompatible with the cluster property* for a large class of gauge theories, including all $O(N)$ gauge theories with $N \geqslant 4$. In fact, replacement of the tensor product (19) with the $\mathcal{B}$-multiplication leads to a number of problems, all of which render the theory unphysical. So when considering the Wightman construction for gauge theories, it is *essential* to use the tensor product in (19) rather than the matrix product. (The author would like to thank H. Gottschalk for explaining this crucial point.)

The cross product provides a mapping from the state space $E(\underline{\mathcal{A}})$ to the bilinear forms that arise in quantum physics. Explicitly, any state ω on $\underline{\mathcal{A}}$ determines a sesquilinear from $\langle , \rangle_\omega$ by the relation

$$\langle f, g \rangle_\omega = \omega(f^* \times g), \quad f, g \in \underline{\mathcal{A}} \tag{20}$$

and the sesquilinear forms (20) are of the type that arise in the construction of the Fock–Hilbert space for a quantum field theory. The left-kernel $L(\omega)$ of the state ω is precisely the set of all $f \in \underline{\mathcal{A}}$ such that $\langle f, f \rangle_\omega = 0$, and so the sesquilinear form (20) is positive semidefinite. It is a positive definite inner product on $\underline{\mathcal{A}}/L(\omega)$, and the completion

$$\overline{\underline{\mathcal{A}}/L(\omega)}$$

forms the physical Hilbert space $\mathcal{H}_{\text{phys}}$.

Following the well-known GNS construction, a representation of $\mathcal{A}$ on $\mathcal{H}_{\text{phys}}$ may now be defined by

$$\varphi(f)[g] = [f \times g], \quad f \in \mathcal{A}, \quad g \in \underline{\mathcal{A}}, \tag{21}$$

where $[g]$ denotes the image of g under the series of maps $\underline{\mathcal{A}} \to \underline{\mathcal{A}}/L(\omega) \to \mathcal{H}_{\text{phys}}$.

For any vector space V, we let $V' = \text{Hom}\,(V, \mathbb{C})$ denote the dual. Note that $(V^{\otimes n})' \cong (V')^{\otimes n}$ for a large class of vector spaces including all nuclear spaces. The Wightman functions are elements

$$W_n \in \mathcal{A}_n' \cong \mathcal{A}'(\Sigma^n, \mathbb{C}) \otimes \mathcal{B}'^{\otimes n}.$$

To clarify this structure, and to make contact with physics notation, it is useful to expand the relevant objects in a basis, and to assume the presence of a nondegenerate inner product on $\mathcal{B}$, so that $\mathcal{B}' \cong \mathcal{B}$.

Accordingly, let (e_a) denote a basis for $\mathcal{B}$. For $f \in \mathcal{A}_n$,

$$W_n(f) = \sum_{\substack{a_1 \cdots a_n \\ b_1 \cdots b_n}} \left(\prod_{i=1}^{n} g_{a_i b_i} \right) W_{n;a_1,\ldots,a_n}(f_{b_1,\ldots,b_n}), \tag{22}$$

where $g_{ab} = \langle e_a, e_b \rangle$, and $f_{b_1,\ldots,b_n} \in \mathcal{A}(\Sigma^n, \mathbb{C})$ are components of f with respect to the basis $e_{b_1} \otimes \cdots \otimes e_{b_n}$ of $\mathcal{B}^{\otimes n}$. If the basis is orthonormal, the formula simplifies and we have

$$W_n(f) = \sum_{a_1 \cdots a_n} W_{n;a_1 \cdots a_n}(f_{a_1 \cdots a_n}). \tag{23}$$

A Yang–Mills field is a $\mathfrak{g}$-valued one-form, and the associated field strength is a 2-form. However, the above formalism is most easily applied to the case of an algebra-valued scalar field. Fortunately, there do exist examples of great relevance to modern physics in which it suffices to consider zero-forms. In Secs. III and IV, we present two such examples in detail, in each case providing a self-contained introduction for the reader's convenience.

It is useful to see how (22) and (23) make contact with traditional physics notation. For 2D $SU(N)$ Yang–Mills theory on a genus g Riemann surface, explicit formulas are known. Nunes and Schnitzer calculate via path integral techniques that

$$W_{2;a,b}(x,y) \propto \sum_{l \in \text{irreps}} \frac{\dim(l)^{2-2g}}{\exp\left(\frac{1}{2}\lambda^2 A C_2(l)\right)} \left[\frac{(\rho,\rho)\,\delta^{ab}}{N^2} \delta_{x,y}^2 - (p^{ab}(l+\rho)^2 + m^{ab} n^2) \right],$$

where $A = \text{Area}\,(\Sigma)$, λ is a coupling constant, l is the highest weight of an irrep, ρ is the half-sum of positive roots, n=size of the Young tableau, and ρ^{ab}, m^{ab} are rational functions of N.

Let us also illustrate the above formalism for the matrix model case, in which Σ is a single point, and $\mathcal{A} = \mathcal{B} = \mathfrak{gl}_n\mathbb{C}$. Choose the orthonormal basis e_{ij}, $i, j = 1, \ldots, n$, where e_{ij} is a matrix with 1 in the (i,j) position and zeros elsewhere. In our previous notation, $a = (i,j)$, $b = (i',j')$, etc. The simplest nontrivial case involves two matrices, in which case the Wightman function is

$$W_{2;a,b} = W_{2;i,j,i',j'} = \int [d^{n^2}M] M_{ij} M_{i'j'} e^{-n\text{Tr}\ S(M)}.$$

Let $f \in \mathcal{A}_2 = (\mathfrak{gl}_n\mathbb{C})^{\otimes 2}$. Since Wightman functionals are linear, we lose no generality in assuming that f is homogeneous, and thus write $f = A \otimes B$, for $A, B \in \mathfrak{gl}_n\mathbb{C}$. The Wightman functional evaluated on f gives

$$W_2(f) = \sum_{i,j,i',j'} \left(A_{ij} B_{i'j'} \int [d^{n^2}M] M_{ij} M_{i'j'} e^{-n\text{Tr}\ S(M)} \right).$$

C. Global symmetry and unitary implementation

In this picture, a *symmetry* of the quantum theory is defined to be an ω-invariant representation

$$\alpha: \mathcal{G} \to \mathrm{Aut}(\underline{\mathcal{A}}). \tag{24}$$

Here, ω-invariance means that for all $\underline{f} \in \underline{\mathcal{A}}$, we have $\omega(\alpha_g \underline{f}) = \omega(\underline{f})$. This implies that $\alpha_g(L(\omega)) \subseteq L(\omega)$, as is easily checked. Thus for each g, α_g is a well-defined automorphism of the quotient algebra $\underline{\mathcal{A}}/L(\omega)$ and extends naturally to the completion $\mathcal{H}_{\text{phys}}$.

Any such symmetry is unitarily implementable. In fact,

$$(\alpha_g \underline{f}, \alpha_g \underline{h}) = \omega(\alpha_g(\underline{f})^* \times \alpha_g(\underline{h})) = \omega(\alpha_g(\underline{f}^* \times \underline{h})) = \omega(\underline{f}^* \times \underline{h}) = (\underline{f}, \underline{h}).$$

We infer that for any $g \in \mathcal{G}$, α_g defines a unitary operator on $\mathcal{H}_{\text{phys}}$, and denote this operator by $U(g)$. Representations of the form (24) arise often in physics; Lorentz symmetry is an example.

If the field takes values in a normed *-algebra $\mathcal{B}$, as we have assumed throughout the present paper, then any group representation T on $\mathcal{B}$ naturally lifts to a representation on $\underline{\mathcal{A}}$. If $\mathcal{B}$ is a Lie algebra, one may consider, for example, the Adjoint representation of the corresponding Lie group. In this case, $U(g)$ is the quotient by $L(\omega)$ of $\oplus_n T(g)^{\otimes n}$, and the field satisfies a simple covariance relation under conjugation by the unitary group:

$$U(g)\varphi(f)U(g)^* = \varphi(T(g)f), \tag{25}$$

as one may verify by applying each operator to an equivalence class $[\underline{h}] \in \underline{\mathcal{A}}/L(\omega)$, and using the property that $U(g)^* = U(g)^{-1} = U(g^{-1})$. Interestingly, $U(g)$ can be trivial even when α_g is not. If $\alpha_g(\underline{f}) - \underline{f} = \underline{h}^* \times \underline{h}$ for some $\underline{h} \in \underline{\mathcal{A}}$, then $\underline{h} \in L(\omega) \Rightarrow [\underline{h}] = 0$ in $\mathcal{H}_{\text{phys}}$. It follows that $U(g)$ is the identity.

It is clear that the quantum mechanical ground state remains invariant under $U(g)$; thus, the above discussion applies to unbroken symmetry of the quantum theory. As such, it cannot apply to spontaneously broken symmetry.

D. Representations of the canonical commutation relations

Let $\mathcal{A}$ denote the space of Schwartz functions form $\mathbb{R}^d$ to a (noncommutative) untial normed algebra $(\mathcal{B}, \star)$. Analogous constructions may be carried out for $\mathcal{A} = C_0^\infty(\mathbb{R}^d, \mathcal{B})$. Choose a continuous, nondegenerate $\mathcal{B}$-valued bilinear form C on $\mathcal{A} \times \mathcal{A}$. If we assume that $\mathcal{B}$ is a *-algebra, then it has a natural positive cone. In this situation, one may formulate the appropriate positivity property for C. This property entails that (f, Cf) lies in the positive cone of $\mathcal{B}$, for all f. If $\mathcal{B}$ is a matrix algebra, one could consider the massive free covariance $C = (-\Delta + m^2)^{-1}$ acting componentwise on the matrices, but this is by no means the only imortant example.

Let $\mathcal{C}(\mathcal{A}')$ be a suitable space of well-behaved functions on the dual space $\mathcal{A}'$. We define a linear functional $\langle \cdot \rangle$ from $\mathcal{C}(\mathcal{A}')$ to $\mathcal{B}$. By analogy with the standard Gaussian measures of bosonic field theory, which are denoted $d\phi_C$, we denote our functional by

$$\langle \cdot \rangle \equiv \int \cdot \widetilde{d\phi_C}.$$

The functional is defined by the recursion relation for Gaussian integrals (also known as Wick's theorem)

$$\langle \phi(f_1) \cdots \phi(f_n) \rangle = \sum_{\pi \in P_2(n)} \prod_{\{i,j\} \in \pi} \langle \phi(f_i)\phi(f_j) \rangle,$$

where $P_2(n)$ denotes the set of all partitions of $(1, \ldots, n)$ into two-element subsets. To complete the definition, we specify the two-point function

$$\int \phi(f)\phi(g)\widetilde{d\phi}_C = (f, C_g).$$

We are now in a position to specify fields which satisfy the canonical commutation relations.

Definition 1: For any $f \in \mathcal{A}$ and $\phi \in \mathcal{A}'$, $\phi(f)$ may be considered as a linear coordinate function of the variable $\phi \in \mathcal{A}'$ (according to the natural identification of $\mathcal{A}$ with its double-dual). This coordinate function defines an associated multiplication operator $\Phi(f)$ acting on $\mathcal{C}(\mathcal{A}')$. Explicitly, $(\Phi(f)A)(\phi) \equiv \phi(f)A(\phi)$.

The functional derivative is defined as

$$(D_\psi A)(\phi) = \lim_{\epsilon \to 0} \frac{A(\phi + \epsilon\psi) - A(\phi)}{\epsilon}.$$

The case in which ψ is a delta function arises so often in field theory that it has a special notation:

$$\frac{\delta}{\delta\phi(x)} A(\phi) = D_{\delta(x)} A(\phi).$$

Definition 2: The following map is called the *canonically conjugate field operator*:

$$\Pi(g) = -i\left\langle g, \frac{\delta}{\delta\phi} \right\rangle \equiv -i \int_{\mathbb{R}^d} g(x) \frac{\delta}{\delta\phi(x)} dx, \quad g \in \mathcal{A}. \tag{26}$$

The notation in (26) means that when $\Pi(g)$ is applied to a functional $A(\phi)$, the functional derivative $\delta A(\phi)/\delta\phi(x)$ is computed *before* the integral with respect to x.

Consider the Hilbert space

$$\mathcal{H} = L^2(\mathcal{A}', \mathcal{B}; \widetilde{d\phi}_C)$$

generated by taking the completion of a space of functions $A: \mathcal{A}' \to \mathcal{B}$ satisfying

$$\int_{\mathcal{A}'} \|A(\phi)\|^2 \widetilde{d\phi}_C < \infty.$$

Denote by $\mathcal{D}$ the vector subspace of $\mathcal{H}$ generated by arbitrary polynomials in the field. It is clear that $\mathcal{D}$ is dense in $\mathcal{H}$, and for all $f \in \mathcal{A}, \Phi(f)$ and $\Pi(f)$ are defined on $\mathcal{D}$. Further, it holds that $\Phi(f)\mathcal{D} \subset \mathcal{D}$ and $\Pi(f)\mathcal{D} \subset \mathcal{D}$.

The following theorem is relevant to all quantum field theories with $\mathcal{B}$-valued test functions.

Theorem 3: *Definitions 1 and 2 specify operator-valued distributions* $\Phi(f)$ *and* $\Pi(g)$ *which are defined on a common dense domain* $\mathcal{D}$ *in the Hilbert space* $\mathcal{H} = L^2(\mathcal{A}', \mathcal{B}; \widetilde{d\phi}_C)$, *and which satisfy the canonical commutation relations*

$$[\Phi(f), \Pi(g)] = i(g, f)I$$

on the domain $\mathcal{D}$, *for all* $f, g \in \mathcal{A}$.

Proof: Since $\mathcal{B}$ is an algebra, there is an exponential map

$$\exp: \mathcal{B} \to \mathcal{B}[\![z]\!],$$

where $\mathcal{B}[\![z]\!]$ is the ring of formal power series with coefficients in $\mathcal{B}$. This map is such that

$$a \to \exp(za) \equiv 1_{\mathcal{B}} + az + \tfrac{1}{2}(a \star a)z^2 + \cdots. \tag{27}$$

In particular, e^{ia} is a well-defined formal power series for any $a \in \mathcal{B}$. In fact, since $\mathcal{B}$ is a normed algebra, the power series (27) is absolutely convergent in the norm topology, although we will not make use of this.

For a test function $h \in \mathcal{A}$, we calculate

$$\Pi(g)e^{i\phi(h)} = -i\int_{\mathbb{R}^d} g(x)\frac{\delta}{\delta\phi(x)}e^{i\phi(h)}dx = (g,h)e^{i\phi(h)}.$$

Also,

$$\Pi(g)\Phi(f)e^{i\phi(h)} = (-i(g,f) + \Phi(f)(g,h))e^{i\phi(h)}.$$

Therefore,

$$[\Phi(f),\Pi(g)]e^{i\phi(h)} = i(g,f)e^{i\phi(h)}. \tag{28}$$

Relation (28) implies directly that the operator equation

$$[\Phi(f),\Pi(g)] = i(g,f)I \tag{29}$$

holds when applied to powers of the field $A(\phi) = \phi(f)^n$. This, together with the polarization identity

$$x_1\cdots x_n = \frac{1}{2^n n!}\sum_{\epsilon_j=\pm 1}\epsilon_1\cdots\epsilon_n(\epsilon_1 x_1 + \cdots + \epsilon_n x_n)^n,$$

implies that (29) holds on the space generated by polynomials in the ϕ-field. □

We conclude that (29) defines a representation of the canonical commutation relations with all the desired properties.

E. Axioms for nonpositive theories

A number of quantum field theory models are known which do not satisfy positivity. The general properties of these models are summarized in the modified Wightman axioms of indefinite metric QFT.[12] In particular, there are two replacements of the positivity axiom which immediately generalize to the noncommutative algebraic framework outlined in the present work.

Albeverio *et al.*[13] investigated Euclidean random fields as generalized white noise and remarked that the Wightman functionals belonging to those fields do not generally satisfy positivity. Those nonpositive Wightman functionals satisfy the following weaker condition, known as the Hilbert space structure condition.[14]

Axiom (Hilbert space structure condition): There exist seminorms p_n on $\mathcal{S}_n$ such that

$$|W_{n+m}(f_n^* \otimes g_m)| \leqslant p_n(f_n)p_m(g_m) \quad \textit{for all } f_n \in \mathcal{S}_n,\ g_m \in \mathcal{S}_m. \tag{30}$$

This axiom needs no modification in order to apply to the general Borchers construction of Sec. II B; the p_n are simply reinterpreted as seminorms on the subspaces $\mathcal{A}_n$ arising in the grading of the universal enveloping algebra.

A related condition known as the Krein structure condition[15] is satisfied by the physically important Gupta–Bleuler formalism for free QED, and has many attractive features from a mathematical standpoint.

Axiom (Krein positivity): There exists a dense unital subalgebra $\mathcal{A}_0$ of the Borchers algebra, and a mapping $\alpha: \mathcal{A}_0 \to \mathcal{A}_0$, such that for all $f, g \in \mathcal{A}_0$,

(1) $\omega(\alpha^2(f)^* \times g) = \omega(f^* \times g)$;
(2) $\omega(\alpha(f)^* \times f) \geqslant 0$;
(3) $\omega(\alpha(f)^* \times g) = \omega(f^* \times \alpha(g))$; *and*
(4) $p_\alpha(f) \equiv \omega(\alpha(f)^* \times f)^{1/2}$ *is continuous in the topology of the Borchers algebra.*

In the original paper,[15] it is shown that the Krein positivity condition is stronger than the Hilbert space structure condition, is satisfied by free QED, and guarantees the existence of a majorizing Krein-type Hilbert space structure associated to the Wightman functions.

It is easily seen that the Krein positivity condition may be applied to the generalized Borchers algebra of Sec. II B, and a state ω on that algebra, simply by interpreting the terminology within the new context.

III. CORRELATORS IN GAUGE THEORY

We would like to use the structure developed above to express quantities of interest in gauge theory. The difficulty with this outlook is that there are different possible choices for complete sets of observables. It is known that Wilson loop functionals are a complete set of observables for Yang–Mills theory in any dimension, but as functionals on the loop space, they cannot be directly used to generate a state on the generalized Borchers algebra. Fortunately, in some cases, a complete set of gauge-invariant correlation functions is available, and they possess a mathematical structure which is convenient for our viewpoint in this paper.

A. Complete sets of observables

In any number of dimensions, the Yang–Mills field strength is a Lie algebra valued two-form; a special feature of two dimensions is that in this case the field strength is mapped to a $\mathfrak{g}$-valued scalar field by the Hodge star. This field is denoted $\xi(x)$, and defined by the relation

$$F_{\mu\nu}(x) = \xi(x)\sqrt{g(x)}\varepsilon_{\mu\nu}.$$

The Yang–Mills action in two dimensions is

$$S = \frac{1}{8\pi^2\varepsilon}\int_{\Sigma} \mathrm{Tr}\, F \wedge {*F}, \tag{31}$$

with the trace taken in the fundamental representation for $\mathfrak{g}$. In our convention, the gauge field A is anti-Hermitian. In terms of ξ the pure Yang–Mills action takes the form

$$\int_{\Sigma} \mathrm{d}\mu\ \mathrm{Tr}(\xi^2)$$

with the appropriate coupling constant inserted. Here $\mathrm{d}\mu = \sqrt{g(x)}\ \mathrm{d}^2x$ is the Riemannian volume measure on Σ.

Field strength correlators are linear combinations of objects of the form

$$\langle \xi^a(x_1)\xi^b(x_2)\xi^c(x_3)\cdots\xi^d(x_n)\rangle. \tag{32}$$

Here $\xi(x)$ is a Lie algebra valued scalar field, and ξ^a, ξ^b, etc., come from expanding the field with respect to some fixed basis of the Lie algebra. For example, one could take the Gell-mann matrices $\mathbf{t}_a$ as a basis of SU(3) and write $\xi(x) = \xi^a(x)\mathbf{t}_a$. Thus, (32) is not a gauge-invariant correlator. It becomes gauge invariant only after inserting $\mathbf{t}_a, \mathbf{t}_b, \mathbf{t}_c$, etc., summing over repeated indices, and taking the trace. The rest of this section will be devoted to describing a second type of correlator, which are sometimes called *ϕ-field correlators*.

In two dimensions there are no propagating degrees of freedom (i.e., no gluons) so the only degrees of freedom come from the topology of space–time or Wilson loops. Since there are so few degrees of freedom, there is a very large group of local symmetries. YM_2 is invariant under the group $\mathrm{SDiff}(\Sigma)$ of area preserving diffeomorphisms, which is a larger symmetry group than local gauge invariance.

The following equivalent action is called the "first-order formalism" because Gaussian integration over ϕ gives back the original action (31),

$$Z_\Sigma(\varepsilon) = \int DA \exp\left(\frac{1}{8\pi^2\varepsilon}\int_\Sigma \mathrm{Tr}F \wedge *F\right) = \int DA\, D\phi\, e^{-S(A,\phi)},$$

where

$$S(A,\phi) = -\frac{i}{4\pi^2}\int_\Sigma \mathrm{Tr}(\phi F) - \frac{\varepsilon}{8\pi^2}\int_\Sigma \mathrm{d}\mu\ \mathrm{Tr}\ \phi^2. \tag{33}$$

Here ϕ is a Lie-algebra valued 0-form; (33) gives rise to the natural generalization,

$$I = \int_\Sigma [i\ \mathrm{tr}(\phi F) + \mathcal{V}(\phi)\mathrm{d}\mu], \tag{34}$$

where $\mathcal{V}$ is any invariant function on the Lie algebra $\mathfrak{g}$. Thus, ordinary YM_2 is one example of a general class of theories parametrized by invariant functions on $\mathfrak{g}$. It is natural to restrict to the ring of invariant polynomials on $\mathfrak{g}$. For $G=\mathrm{SU}(N)$, this ring is generated by $\mathrm{tr}\ \phi^k$, so we may describe the general theory by coordinates t_k, in terms of which

$$\mathcal{V} = \sum t_k \prod_j (\mathrm{tr}\ \phi^j)^{k_j}.$$

The generalized Borchers formulation applies equally well to the general case (34) with arbitrary $\mathcal{V}(\phi)$.

A complete set of physical observables for Yang–Mills theory in any dimension are Wilson loops. These are, in particular, interesting observables for Yang–Mills theory in $d=2$. However, gauge invariant polynomials of the field ϕ form another complete set of observables naturally suited to evaluation of the partition function. These observables include products of $\mathrm{Tr}\ \phi^2(x_i)$ at various points x_i, and more generally, traces of any homogeneous invariant polynomial defined on the Lie algebra $\mathfrak{g}$. We will adopt this terminology, and refer to expectations of products of $\mathrm{Tr}\ \phi^2(x_i)$ as *ϕ-field correlators*. This is in marked contrast to $d=4$ Yang–Mills where the only dimension four gauge invariant operators are $\mathrm{tr}(F\wedge *F)$ and $\mathrm{tr}(F^2)$, with the latter a topological term.

The most important property of expectation values of gauge-invariant observables in two dimensions is that they are almost topological. A sample calculation shows that

$$d\left\langle \frac{1}{8\pi^2}\mathrm{Tr}\phi^2(x)\right\rangle_\varepsilon = \left\langle \frac{1}{4\pi^2}\mathrm{Tr}\ \phi(x)\mathrm{d}_A\phi(x)\right\rangle_\varepsilon = 0. \tag{35}$$

The action

$$S_{\mathrm{top}} = -\frac{1}{2}\int i\ \mathrm{tr}(\phi F)$$

describes a true topological field theory whose path integral is concentrated on flat connections $F=0$. The field ϕ is sometimes denoted by B, in which case the Lagrangian is proportional to $\mathrm{Tr}(BF)$, and the terminology *BF theory* was introduced. In the small area limit (or the $\mathcal{V}\to 0$ limit) YM_2 reproduces the results of this topological field theory.

B. The Hilbert space of YM_2

We consider quantization of YM_2 on the cylinder with periodic spatial coordinate of period L. This model is well understood and we will make no attempt at exposition since several excellent references exist in the literature.[16–19] Our purpose here is to point out an unexpected mathematical relationship having to do with the space of class functions on a Lie group that is predicted by the generalized Wightman construction introduced earlier in the paper.

The Hilbert space of this model is known to be the space of L^2 class functions on G with inner product

$$\langle f_1|f_2\rangle = \int_G \mathrm{d}U\, f_1^*(U) f_2(U), \tag{36}$$

where $\mathrm{d}U$ is the Haar measure normalized to give volume one. For compact gauge groups, the Peter–Weyl theorem implies the decomposition of $L^2(G)$ into unitary irreps,

$$L^2(G) = \oplus_R R \otimes \overline{R}.$$

Consequently a natural basis for the Hilbert space of states is provided by the characters in the irreducible unitary representations. This is known as the representation basis. The states $|R\rangle$ have wave functions $\chi_R(U)$ defined by

$$\langle U|R\rangle \equiv \chi_R(U) \equiv \mathrm{Tr}_R(U). \tag{37}$$

While Eqs. (36) and (37) provide two different expressions for the inner product of YM_2, a third expression for the same inner product can be derived from the generalized Borchers construction, in the special case of constant Wightman functions. The sesquilinear form is given by (28), and the inner product of YM_2 therefore comes from (20) after taking the quotient by zero-norm states, and subsequently, taking the completion.

C. The correlators of YM_2

The correlators of YM_2 are determined by representation–theoretic invariants of the gauge group such as Casimir operators, and by the integration measure defined by the Riemannian metric on the Riemann surface Σ. Explicit expressions have been found by Nunes and Schnitzer,[20] using the Abelianization technique for path integrals developed by Blau and Thompson. In a particular gauge, the two-point function for 2D SU(N) Yang–Mills theory on a Riemann surface is

$$\langle \xi^a(x)\xi^b(y)\rangle = \frac{e^4}{Z_{\Sigma_g}} \sum_l \dim(l)^{2-2g} \exp\left(-\frac{e^2}{2} A C_2(l)\right)\left[\frac{(\rho,\rho)\delta^{ab}}{N^2}\delta^2_{x,y} - (p^{ab}(l+\rho)^2 + m^{ab}n^2)\right], \tag{38}$$

where l is the highest weight which labels the irreducible representation of SU(N), n is the total number of boxes in the Young tableau defined by l, $\dim(l)$ and $C_2(l)$ denote, respectively, the dimension and quadratic Casimir, ρ is the half-sum of the positive roots, A is the area of Σ, and

$$p^{ab} = \begin{cases} \dfrac{-1}{N(N-1)} & \text{if } a \neq b, \\ \dfrac{1}{N} & \text{if } a = b, \end{cases} \qquad m^{ab} = \begin{cases} \dfrac{1}{N(N-1)} & \text{if } a \neq b, \\ 0 & \text{if } a = b. \end{cases}$$

Note that the dependence of (38) on the choice of gauge goes away after inserting the Lie algebra generators and taking the trace.

In general, it is known that the gauge-invariant $(2p)$-point function $\langle \mathrm{Tr}\ \xi^{2p}(x)\rangle$ on a Riemann surface of genus g takes the x-independent form

$$\frac{e^{4p}}{Z_{\Sigma_g}} \sum_\ell \dim(\ell)^{2-2g} \exp\left(-\frac{e^2}{2} A C_2(\ell)\right) \sum_{i=1}^{p} f_i(\rho) C_{2i}(\ell),$$

where f_i are rational functions of (ρ,ρ).

Remark 3: The physical Hilbert space of this quantum theory is a well-defined object, and we now in principle know two ways to calculate it. As discussed previously, the Hilbert space of this

model is known to be the space of L^2 class functions on G with inner product (36). However, we expect to also recover the Hilbert space inner product from the state on the generalized Borchers algebra that is determined by (38) and all higher-order correlators. Of course, the physical Hilbert space is recovered only after taking the quotient by the left kernel of this state, which presents a difficulty. How can one see that $\underline{\mathcal{A}}/L(\omega) \cong L^2(G)$?

IV. MATRIX MODELS AND FINITE ORDER STATES

Section IV A gives the definition of matrix states and finite order states. In Secs. IV B and IV C we recall the matrix models which have come to play a prominent role in high energy physics in the last few years. Section IV D shows that, in the same sense in which scalar quantum field theories are Wightman states, matrix models are finite order states. Finally, Sec. IV E points out that an argument due to Borchers generalizes to the noncommutative case, showing that arbitrary states on the field algebra, which describe nontrivial quantum field theories, are limits of matrix states.

A. Matrix states and finite order states

Let $T \in E(\underline{\mathcal{A}})$ be a state, and denote by $I(T)$ the maximal two-sided ideal contained in the left-kernel $L(T)$.

Definition 3: T is said to be of finite order *if the family of operators* $\{A_T(f) : f \in \mathcal{A}\}$ *contains exactly N linearly independent elements for* $N < \infty$, *or equivalently if*

$$\dim(\mathcal{A}/I(T) \cap \mathcal{A}) = N.$$

In this situation, N is called the order of the state.

Definition 4: T is called a matrix state *if* $\underline{\mathcal{A}}/I(T)$ *is a finite-dimensional algebra.*

Clearly, a matrix state is of finite order, but the converse may not hold. The terminology comes from the fact that any finite-dimensional *-algebra with unit is isomorphic to a star-closed subalgebra of the algebra of $n \times n$ matrices, for some finite n. Let $\mathfrak{h}_n$ denote the *-algebra of $n \times n$ Hermitian matrices.

B. Hermitian matrix models

A Hermitian one-matrix integral (see Refs. 21 and 22 for a review) takes the form

$$Z = \int [\mathrm{d}^{n^2} M] \exp(n \ \mathrm{Tr} \ S(M)), \tag{39}$$

where $S(M)$ is an arbitrary function. The model is said to be *solvable* if the integral can be performed explicitly, at least in the large n limit. We briefly indicate how this can be done in the simplest case. Diagonalize M via the transformation $M = \mathcal{O}^+ x \mathcal{O}$ where x is diagonal and $\mathcal{O} \in U(n)$. The corresponding measure can be written as

$$\mathrm{d}^{n^2} M = \mathrm{d}[\mathcal{O}]_{U(n)} \ \Delta^2(x) \prod \mathrm{d}x_k,$$

where $\Delta(x) = \Pi_{i>j}(x_i - x_j)$ is the Vandermonde determinant. The integrand does not depend on $\mathcal{O}$, so integration over $\mathcal{O}$ produces a group volume factor. The remaining integral over the eigenvalues is $Z = \int [\Pi_{k=1}^n \mathrm{d}x_k] \exp(nS(x_k)) \Delta^2(x)$. In the large n limit the corresponding saddle point equation takes the form

$$\frac{1}{n} \frac{\partial S}{\partial x_k} = S'(x_k) + \frac{1}{n} \sum_{j \neq k} \frac{1}{x_k - x_j} = 0.$$

C. Dijkgraaf–Vafa matrix models

For simplicity, we examine an $U(N)$ gauge theory with an adjoint Higgs supermultiplet Φ and tree-level single-trace superpotential

$$W_{\text{tree}}(\Phi) = \sum_{k=1}^{p+1} \frac{1}{k} g_k \ \text{Tr}\ \Phi^k. \tag{40}$$

Dijkgraaf and Vafa [23] have proposed a very simple recipe to calculate the exact quantum effective superpotential $W(S)$ for the glueball superfield,

$$S = -\frac{\text{tr}\ \mathcal{W}^\alpha \mathcal{W}_\alpha}{16N\pi^2},$$

in the confining vacua of a large class of $\mathcal{N}=1$ supersymmetric Yang–Mills theories, where $\mathcal{W}_\alpha$ is the gauge field strength of the $U(N)$ vector superfield. The superpotential $W(S)$ contains highly nontrivial information about the nonperturbative dynamics of the theory. For example, it can be used to derive dynamical chiral symmetry breaking and calculate the tension of the associated domain walls.

The theory (40) is geometrically engineered on the (local) Calabi–Yau three-manifold,

$$\{u^2 + v^2 + y^2 + W'_{\text{tree}}(x)^2 = f_{p-1}(x)\} \subset \mathbb{C}^4, \tag{41}$$

where $f_{p-1}(x)$, an order $(p-1)$ polynomial, is a complex deformation parameter, and as is well known, the Seiberg–Witten curve is the same as the spectral curve of the associated matrix model.

Dijkgraaf and Vafa have conjectured[23] that the superpotential $W(S)$ is the sum of zero momentum planar diagrams of the $\mathcal{N}=1$ theory under consideration. In our case, their ansatz for the $U(N)$ theory is a holomorphic integral over $n\times n$ complex matrices ϕ,

$$\exp(n^2\mathcal{F}/S^2) = \int_{\text{planar}} \text{d}^{n^2}(\phi/\Lambda)\exp\left[-\frac{n}{S}W_{\text{tree}}(\phi, g_p)\right], \tag{42}$$

from which the superpotential can be deduced,

$$W(S, \Lambda^2, g_p) = -N\partial_S \mathcal{F}(S, g_p). \tag{43}$$

Here, Λ is the complex mass scale governing the one-loop running of the gauge coupling constant (see Ref. 24). For SU(N) gauge theory, the integral (42) must be restricted to traceless matrices, or equivalently one must treat g_1 as a Lagrange multiplier.

The parameter n is introduced so that the planar diagrams can be extracted by taking the $n \to \infty$ limit. The N dependence of the superpotential is then given explicitly by (43). The integral (42) involves complex matrices and couplings g_p, but the calculation is the same as for Hermitian matrices and real couplings. There is no ambiguity in the analytic continuation because we restrict to planar diagrams. This implies that standard matrix model techniques[21] do apply. A nice mathematical description of holomorphic matrix integrals was given by Lazaroiu.[25]

D. Matrix models as finite order Wightman states

The interesting point we wish to make in this section is that the aforementioned matrix models (arising in string theory, condensed matter, and other branches of physics) are well described by the noncommutative Borchers construction with a finite order state, in the sense of Definition 1. A mathematician might define the term *matrix model* to be a finite order state on the Borchers algebra $\underline{\mathcal{A}}$ constructed from a zero-dimensional space–time Σ and target $\mathcal{B}$ given by some matrix algebra.

In what follows, we consider a one-matrix model defined by an action S. If Σ is zero-dimensional, compact and connected, it is a single point, $\Sigma=\{\text{pt}\}$. From this we infer that

$$\mathcal{A} = \mathrm{Map}(\Sigma, \mathcal{B}) \cong \mathcal{B} = \mathfrak{gl}_n\mathbb{C}, \tag{44}$$

and

$$\mathcal{A}_m = (\mathfrak{gl}_n\mathbb{C})^{\otimes m}, \quad m \geqslant 1.$$

To avoid confusion with the field theory case, we will denote a finite order state by $\mathfrak{w}$. For $A, B \in \mathcal{A}$ we may compute the inner product on the Borchers algebra (before taking the quotient by the left-kernel) to be

$$\langle A, B\rangle = \mathfrak{w}(A^* \times B) = \sum_{i,j,k,l} \overline{A_{ji}} B_{kl} F(i,j,k,l), \tag{45}$$

where

$$F(i,j,k,l) = \int [d^{n^2}M] M_{ij} M_{kl} e^{-n\mathrm{Tr}\ S(M)}$$

is the analog of a correlation function for the matrix model. The matrix model is said to be *solvable* if the integrals of the form $\int [d^{n^2}M]$ may be computed, at least in the large n limit where saddle point techniques apply.

Recall the definition of the Hermitian subspace of a *-algebra, Eq. (4). Clearly in the current example, $\mathcal{A}_h$ is given by $\mathfrak{h}_n$, the space of $n \times n$ Hermitian matrices. The Wightman procedure constructs an operator formulation for Hermitian matrix models, in which $\mathcal{H}_{\mathrm{phys}}$ is the completion of

$$\underline{\mathcal{A}}_h / L(\mathfrak{w}) \cap \underline{\mathcal{A}}_h.$$

The generalized Wightman construction, in some sense, contains within it a master field formulation for matrix models.

Definition 5 (Master Field): A *master field formulation* of a matrix model is a choice of quantum mechanical Hilbert space $\mathcal{H}$ and a GNS representation on $\mathcal{H}$ such that, for arbitrary k, the gauge-invariant matrix model correlator

$$\langle \mathrm{Tr}(M^k)\rangle \equiv \int [DM] \mathrm{Tr}(M^k) e^{-n\mathrm{Tr}\ S(M)}$$

may be calculated in terms of vacuum expectation values of products of field operators on $\mathcal{H}$.

The definition is sufficiently general that there can be no question about existence of a master field formulation for any matrix model; however, to discover one that is simple and useful remains a subtle art. We will consider the natural basis e_{ij} for the space V of $n \times n$ matrices; e_{ij} is a matrix with 1 in the i,jth position and zeros elsewhere. For compactness, we will label a pair of indices by $a = (i,j)$. Let

$$\mathcal{T} = \{(i,j), (j,i) | i,j = 1, \ldots, n\}.$$

Define $f \in \mathcal{A}_2$ by the formula

$$f = f_{ab} e_a \otimes e_b, \quad f_{ab} = \begin{cases} 1, & (a,b) \in \mathcal{T} \\ 0, & \text{otherwise}, \end{cases}$$

where we use the convention that repeated indices are summed over. Then

$$\mathfrak{w}(f) = \sum_{(a,b)\in\mathcal{T}} \mathfrak{w}(e_a \otimes e_b) = \int [DM]\mathrm{Tr}(M^2)e^{-n\mathrm{TrS}(M)}.$$

Consider the Hilbert space formalism defined above, and let ϕ_a be the operator on $\mathcal{H}=\mathcal{H}_{\mathrm{phys}}$, which creates e_a out of the vacuum. Define $\Phi_{ab}=(\phi_a)^\dagger\phi_b$. It follows that

$$\mathfrak{w}(f) = \sum_{(a,b)\in\mathcal{T}} \langle e_a, e_b\rangle_{\mathcal{H}} = \sum_{(a,b)\in\mathcal{T}} \langle \Phi_{ab}\rangle_{\mathcal{H}}.$$

This gives the following relation between the matrix model gauge-invariant correlator and VEVs in the Hilbert space picture:

$$\langle \mathrm{Tr}(M^2)\rangle = \sum_{\mathcal{T}} \langle \Phi_{ab}\rangle_{\mathcal{H}}. \tag{46}$$

By generalizing this procedure, it is clear that vacuum expectations of certain products of field operators in $\mathcal{H}$ give rise to all possible gauge-invariant expectations in the matrix model.

E. Limits of matrix states

The classic result of Borchers[7] that matrix states are dense in the space of all states on the Borchers algebra generalizes to the noncommutative setting. The proof proceeds in two steps, first showing that matrix states are dense in the states of finite order, and then showing that the latter are dense in the set of all states. As the results of this section are of a topological nature, we assume throughout that $\mathcal{B}$ is a normed *-algebra and that the space $\mathcal{A}=\mathcal{A}(\Sigma,\mathcal{B})$ introduced in Eq. (13) is a Schwartz space of rapidly decreasing functions. The generalized Borchers algebra is consequently endowed with the Schwartz topology.

Given a sequence of Wightman distributions defined for fields valued in a noncommutative space, and a state on $\mathcal{B}$, Sec. II defines a state, which we now call T, on the generalized Borchers algebra. The Hilbert space $\mathcal{H}_T$, field operator A_T, and cyclic vector Ω_T are then defined, as usual, by the GNS construction.

Theorem 4: *Any finite-order state T on the generalized Borchers algebra $\underline{\mathcal{A}}$ is a limit of matrix states*.

Proof: Let $\{\mathcal{H},\varphi,\Omega\}$ be the Hilbert space, field operator, and cyclic vector given by the GNS-type construction described in Sec. II. It is clear that if T is of order N, there exist N distributions $t^i\in A'$ and N operators A^i on $\mathcal{H}$ such that

$$\varphi(f) = \sum_{i=1}^{N} (t^i, f)A^i$$

for all $f\in\mathcal{A}$. (Note that this N no longer has anything to do with the gauge group.) Let $\mathcal{H}_n$ be the vector space spanned by all vectors

$$\{A^{i_1}\cdots A^{i_n}\Omega : i_j = 1,\ldots,N, r = 0,\ldots,n\},$$

$\mathcal{H}_n$ is finite dimensional, so $\mathcal{H}_n$ is closed and $A^i|_{\mathcal{H}_n}$ is bounded. Let $E^n:\mathcal{H}\to\mathcal{H}_n$ be the associated orthogonal projection. Also define β_n as follows:

$$f \xrightarrow{\beta_n} \sum_{i=1}^{N} (t^i, f)E^nA^iE^n.$$

Thus β_n is a continuous homomorphism of $\mathcal{A}$ into a finite-dimensional matrix algebra, which is an algebra of $d(n)\times d(n)$ matrices, where $d(n)=\dim\mathcal{H}_n$. We remark that generically, $d(n)$ will be an increasing function of n, and the $n\to\infty$ limit resembles a "large n limit" of matrix models. Define approximate states $T^{(n)}$ by

$$(T^{(n)},g) = \langle \beta_n(g) \rangle_\Omega$$

for any $g \in \underline{\mathcal{A}}$. By definition, a matrix state is an expectation in some fixed vector of a homomorphism into a finite-dimensional matrix algebra, so clearly $T^{(n)}$ are matrix states. Recall that $\mathcal{A}_k$ was defined to be the image of $\mathcal{A}^{\otimes k}$ in the universal enveloping algebra $\underline{\mathcal{A}}$. Note that $T^{(n)}$ coincides with T on the spaces $\mathcal{A}_k$ for $k \leqslant n$, so $T = \lim_{n\to\infty} T^{(n)}$ and the proof is complete. □

Theorem 5: *States of finite order are dense in the set of all states on the generalized Borchers algebra.*

Proof: Let T be any state, and let $\{\mathcal{H}, \varphi, \Omega\}$ be the Hilbert space, field operator, and cyclic vector given by the GNS-type construction described in Sec. II. Choose N arbitrary elements $f_j \in \mathcal{A}$ and let $\mathcal{A}^N$ denote the subspace of $\mathcal{A}$ generated by the f_j. For arbitrary $g \in \mathcal{A}^N$, we have

$$\varphi(g) = \sum_{j=1}^{M} F_j(g)\varphi(f_j),$$

where $\{\varphi(f_j)\}_{j=1,\ldots,M}$ is a minimal basis of the span of $\{\varphi(f_i)\}_{i=1,\ldots,N}$ and the F_j are M continuous linear functionals on $\mathcal{A}^N$. By the Hahn–Banach theorem, extend each F_j to a functional t^j defined on all of $\mathcal{A}$. Define

$$\varphi'(g) = \sum_{i=1}^{M} (t^i, g)\varphi(f_j) \quad \text{and} \quad T[f_1, \ldots, f_N](g) = \langle \varphi'(g) \rangle_\Omega.$$

It is now clear that each $T[f_1, \ldots, f_N]$ is a state of order M. This process defines a Cauchy net $T[\cdots]$ of finite-order states converging to T. □

If an explicit functional $S(a)$ is known so that a finite order state $\mathfrak{w}$ is given by Eq. (45), then we say $\mathfrak{w}$ is defined by its *action* S, and call the associated quantum theory a *matrix model*.

Given a quantum theory (possibly with noncommutative target) defined in terms of its Wightman state, theorems 3–4 construct a sequence of matrix states which converge to the given state. As remarked in the proof of theorem 3, the $n \to \infty$ limit considered in that theorem resembles, at the level of dimensions of the relevant algebras, a large n limit of matrix models. It would be extremely interesting if there were a generic way to reformulate each of these matrix states as a matrix model with action S. Such a formulation would allow us to choose our favorite gauge theory, and immediately write it as a limit of matrix models.

In fact, Kazakov in a famous paper[11] completed a very similar construction. Kazakov considers the multicomponent scalar field theory in four dimensions,

$$S = N \int \mathrm{d}^4x \ \mathrm{tr}((\partial_\mu \phi)^2 + V(\phi)), \tag{47}$$

with ϕ a Hermitian $N \times N$ matrix-valued field, and showed that the four-dimensional (4D) field theory at finite N is equivalent perturbatively, graph by graph of any topology, to a one-matrix model in the large n limit. The latter was conjectured to provide a nonperturbative definition of the 4D field theory. The noncommutative Wightman construction presented in this paper is naturally suited to deal with matrix-valued field theories such as Kazakov's (47), and theorems 3–4 imply that if (47) can be defined as a field theory (meaning that it determines a well-defined state on the generalized Borchers algebra) then it is given by a limit for large n of a sequence of $n \times n$ matrix models.

V. CONCLUSIONS AND OPEN QUESTIONS

A classic result of mathematical physics is the reconstruction of the Hilbert space, vacuum vector, and field operators of a quantum field theory from a given set of distributions satisfying the Wightman axioms.[5] In the preceding sections, we have described the extension of Wightman's construction to theories with gauge symmetry, including non-Abelian pure Yang–Mills models and matrix models, and more generally to theories with fields or test functions valued in a noncom-

mutative algebra. Yang–Mills theory with an adjoint-valued Higgs field also fits within the same framework. In every case involving quantized Yang–Mills fields, the Lie algebra dependence of the fundamental fields can be transferred to the test function space.

In Sec. II C, we discuss the role of symmetry in the generalized Borchers construction. In this framework, it is straightforward to see that space–time and global symmetries are unitarily implementable. The role of the additional ambiguities arising from local gauge symmetry remains a mystery. In path integral quantization, this ambiguity is resolved through use of the Faddeev–Popov determinant, but in the Borchers framework a similarly elegant handling of local gauge symmetry is an unresolved issue. In an effort to shed light on this question, we have considered two simple examples in which the space–time dependence of the fields plays a small role: 2D Yang–Mills theories and matrix models.

This construction provides a unified algebraic framework for formulating properties of a broad class of quantum field theories. Yang–Mills theory (including matrix models) and constructive field theory models[26] possess the following common structure:

(1) A normed *-algebra $\mathcal{B}$ (not necessarily commutative), with the generalized Borchers algebra $\underline{\mathcal{A}}$ of functions into $\mathcal{B}$.
(2) A functional $\omega \in \underline{\mathcal{A}}'$, which is defined in terms of a sequence of n-point functions and which satisfies $\omega(f^* \times f) \geqslant 0 (\forall f)$ in theories with no gauge symmetry, or in gauge theories expected to possess a positive–definite inner product. For nonpositive models such as Gupta–Bleuler QED, the functional ω is postulated to satisfy axioms described in Sec. II E.
(3) A symmetry group $\mathcal{G}$ and a representation $\alpha: \mathcal{G} \to \mathrm{Aut}(\underline{\mathcal{A}})$, which is ω-*invariant* in the sense that $\omega(\alpha_g(f)) = \omega(f)$ for all $f \in \underline{\mathcal{A}}$ and $g \in \mathcal{G}$.
(4) A collection of ideals $I_1, \ldots, I_n$ of the algebra $\underline{\mathcal{A}}$ which are required to lie in the kernel of ω. (Each ideal represents a physical property satisfied by the n-point functions; in Wightman QFT, $n=2$ and the two ideals represent locality and the positive light-cone spectral condition.)
(5) A Hilbert space $\mathcal{H}_{\mathrm{phys}}$ defined to be the completion of $\underline{\mathcal{A}}/L(\omega)$, with inner product $\omega(f^* \times g)$ and vacuum vector Ω.
(6) Field operators defined by the GNS construction, with vacuum expectation values equal to the Wightman functions used to define the state ω.

The discussion following theorem 5 outlines a new research direction, concerned with the question of how quantum field theories can be written as limits of matrix models. It would be very interesting to have a deeper understanding of the issue raised by remark (3). Moreover, this construction could be studied for fields which are sections of nontrivial principal fiber bundles, as suggested by remark (1).

A very interesting analytic question is to study carefully the UV divergences of various gauge theories, and to determine whether they can be correctly described by a noncommutative Borchers construction based on the noncommutative generalization of the Jaffe test function space $\widetilde{S}_g^{\mathcal{B}}$ discussed following (14).

There are possible connections between this work and deformation theory, which we elaborate on briefly here. If we consider continuous deformations of the product $\cdot_{\mathcal{B}}$ in the noncommutative target space $\mathcal{B}$, with respect to a parameter ε, then the constructions in this paper define continuous families of Wightman functionals ω_ε on algebras $\underline{\mathcal{A}}_\varepsilon$ and associated quantum field theories with Hilbert space inner products $\langle , \rangle_\varepsilon$. Consider the quotient of $\underline{\mathcal{A}}_\epsilon$ by the ideal generated by all elements $f \otimes g - g \otimes f - [f,g]$, for $f, g \in \mathcal{A}_\epsilon$. This is the universal enveloping algebra, which we denote $\mathcal{U}(\epsilon)$. If the Wightman state ω_ϵ is well-defined on the quotient, define a new Hilbert space as the completion of $\mathcal{U}(\epsilon)/(L(\omega_\epsilon) \cap \mathcal{U}(\epsilon))$. Consider the deformation which multiplies the associative algebra product (and hence the Lie bracket) in $\mathcal{B}$ by ϵ. The Poincaré–Birkhoff–Witt theorem implies an isomorphism $\mathcal{U}(\epsilon) \simeq S\mathcal{A}_\epsilon$, where $S\mathcal{A}_\epsilon$ is the symmetric tensor algebra over $\mathcal{A}_\epsilon$. This isomorphism defines a family of multiplications on $S\mathcal{A}_\epsilon$, which take the form

$$f *_\varepsilon g = fg + \frac{1}{2}\varepsilon\{f,g\} + \sum_{k\geqslant 2} \varepsilon^k B_k(f,g) \tag{48}$$

for some bilinear forms B_k. This well-known construction is called deformation quantization in the direction of the Poisson bracket.

In general, given a quantum field theory into a noncommutative algebra $\mathcal{B}$, one could consider deforming the multiplication on $\mathcal{B}$, and in certain cases, we expect that the ε dependence might factor out of the Wightman functions and the Hilbert space inner product will scale in some simple way with respect to the deformation parameter ε.

ACKNOWLEDGMENTS

The author wishes to thank his graduate advisor, Arthur Jaffe, for continuous support and encouragement, and to thank Daniel Jafferis for many useful discussions, especially on matrix models. The author would like to thank H. Gottschalk for pointing out an error in an early preprint of this paper, and for other helpful discussions.

Centre de Physique Théorique, Unité Mixte de Recherche[d] du CNRS et des Universites Aix-Marseille I, Aix-Marseille II et de l'Université du Sud Foulon-Var, CNRS-Luminy, Case 907, 13288, Marseille Cedex 9 France

(Received 18 June 2004; accepted 26 August 2004; published 2 December 2004)

We classify all irreducible, almost commutative geometries whose spectral action is dynamically nondegenerate. Heavy use is made of Krajewski's diagrammatic language. The motivation for our definition of dynamical nondegeneracy stems from particle physics where the fermion masses are nondegenerate. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1811372]

I. INTRODUCTION

Within noncommutative geometry pioneered by Connes,[3–6] the almost commutative ones play an interesting role. They are defined by spectral triples $(\mathcal{A},\mathcal{H},\mathcal{D})$ where the algebra $\mathcal{A}_t$ has the form $\mathcal{A}_t=C^\infty(M)\otimes\mathcal{A}$ with $\mathcal{A}$ a direct sum of matrix algebras and M a (compact Euclidean) space–time. For instance in the standard model of particle physics, $\mathcal{A}=\mathbb{H}\oplus\mathbb{C}\oplus M_3(\mathbb{C})$. It is important to classify the almost commutative triples because of their applications to physics. Let us sketch some of them.

Einstein's derivation of general relativity from Riemannian geometry goes in two steps. The first step sets up the kinematics: the equivalence principle uses general coordinate transformations and starts from the flat metric of special relativity to guess curved metrics. The second step constructs a dynamics for the set of all metrics by imposing covariance under general coordinate transformations.

Connes generalizes Einstein's derivation to noncommutative geometry.[3,6] In this new setting the metric is encoded in a Dirac operator and a coherent definition of the equivalence principle becomes available: the fluctuations of the Dirac operator by algebra automorphisms properly lifted to the Hilbert space of spinors. Indeed in Riemannian geometry, the algebra is the commutative algebra of functions on spacetime, the automorphisms are precisely the general coordinate transformations and fluctuating the flat Dirac operator leads to Dirac operators with curvature and torsion. The second step is the spectral action which in the commutative i.e., Riemannian case reproduces the Einstein-Hilbert action plus a positive cosmological constant and a curvature squared term. The Euclidean spectral action is positive definite and its ground states can be interpreted as a regularization of the initial singularity.

A noncommutative space or geometry is defined by a spectral triple consisting of an algebra $\mathcal{A}$, a Hilbert space $\mathcal{H}$ and a Dirac operator $\mathcal{D}$. One important property of noncommutative geometry is that it contains discrete spaces, commutative or not. They have finite dimensional algebras and Hilbert spaces. An almost commutative geometry is a tensor product of the infinite dimensional commutative algebra consisting of space–time functions with a finite dimensional noncommutative algebra, the internal space. The internal Dirac operator is simply an initial fermionic mass matrix and the internal algebra automorphisms of the tensor product are gauge transforma-

tions. The internal fluctuations produce gauge bosons and Higgs scalars and the spectral action of an almost commutative geometry produces—besides the gravitational action—the complete Yang–Mills–Higgs action. The Higgs scalar is therefore the internal metric and its dynamics is the Higgs potential. The initial fermionic mass matrix in general is not a solution of the internal dynamics, the internal Einstein equation. These solutions are the minima of the Higgs potential which induces the spontaneous symmetry breaking. They yield the true fermionic mass matrix and we have to compute it. Let us remark that in the prior approach of noncommutative Yang–Mills theories without gravity,[7] the Dirac operator was not a dynamical variable. Consequently there was no nuance between initial and true fermion masses.

Although only a small subset of all Yang–Mills–Higgs models can be described as an almost commutative geometry this subset is still infinite and difficult to assess. We propose to reduce it using two constraints. The first is inspired by grand unified theories, in particular SO(10): the gauge group of the standard model of electromagnetic, weak and strong forces is embedded into a simple group and the representation of one generation of quarks and leptons is embedded into an irreducible representation. Therefore our first constraint is the following: take the internal algebra simple and its spectral triple irreducible. As we will see the resulting fermion masses in the ground state are degenerate in flagrant contradiction to experiment. We therefore analyze internal algebras with two and three simple summands and their irreducible spectral triples. Again, in most cases the fermion masses come out degenerate with a few exceptions. Our aim is to list these exceptions. In other words, our second constraint is to impose a nondegenerate fermionic mass spectrum in the ground state, namely to restrict the analysis to dynamically nondegenerate spectral triples. The mathematical definitions of these constraints are given in Secs. II and IV.

II. IRREDUCIBILITY

A spectral triple is given by $(\mathcal{A},\mathcal{H},\mathcal{D})$ such that the real *-algebra $\mathcal{A}$ acts on the complex Hilbert space $\mathcal{H}$, the Dirac operator $\mathcal{D}$ on $\mathcal{H}$ is selfadjoint and *a priori* unbounded. These three items satisfy certain constraints of geometrical significance.[4–6] The commutative examples come from the triple $[\mathcal{A}=\mathcal{C}^\infty(M),\ \mathcal{H}=\mathcal{L}^2(M,\mathcal{S}),\ \mathcal{D}=i\gamma^\mu\partial_\mu]$ associated to a compact Riemannian spin manifold M. As the resolvent of $\mathcal{D}$ is compact, $(\mathcal{A},\mathcal{H},\mathcal{D}=0)$ is never a spectral triple for infinite dimensional $\mathcal{H}$. However, this degenerate situation can occur in finite cases, but is excluded from our definition of irreducible spectral triples.

Definition 2.1:

(i) A spectral triple $(\mathcal{A},\mathcal{H},\mathcal{D})$ is *degenerate* if the kernel of $\mathcal{D}$ contains a nontrivial subspace of the complex Hilbert space $\mathcal{H}$ invariant under the representation ρ on $\mathcal{H}$ of the real algebra $\mathcal{A}$.

(ii) A nondegenerate spectral triple $(\mathcal{A},\mathcal{H},\mathcal{D})$ is *reducible* if there is a proper subspace $\mathcal{H}_0\subset\mathcal{H}$ invariant under the algebra $\rho(\mathcal{A})$ such that $(\mathcal{A},\mathcal{H}_0,\mathcal{D}|_{\mathcal{H}_0})$ is a nondegenerate spectral triple. If the triple is real, S^0-real and even, we require the subspace $\mathcal{H}_0$ to be also invariant under the real structure J, the S^0-real structure ϵ and under the chirality χ such that the triple $(\mathcal{A},\mathcal{H}_0,\mathcal{D}|_{\mathcal{H}_0})$ is again real, S^0-real and even.

Remark 2.2:

(i) $(\mathcal{A}=\mathcal{C}^\infty(M),\ \mathcal{H}=\mathcal{L}^2(M,\mathcal{S}),\ \mathcal{D}=i\gamma^\mu\partial_\mu)$ is never degenerate.

(ii) If $(\mathcal{A}_i,\mathcal{H}_i,\mathcal{D}_i)$ are two spectral triples then $(\mathcal{A}_1\otimes\mathcal{A}_2,\ \mathcal{H}_1\otimes\mathcal{H}_2,\ \mathcal{D}_1\otimes 1)$ is a spectral triple whose kernel of $\mathcal{D}_1\otimes 1$ is infinite dimensional when $\mathcal{H}_2$ is of infinite dimension.

(iii) A finite dimensional commutative triple is a collection of points. It is nondegenerate if all points have finite distances. The converse is wrong, $\mathcal{A}=\mathbb{C}\oplus\mathbb{C}\oplus\mathbb{C}$ with the triple given by diagram 15 is a counterexample.

(iv) A reducible triple is not necessarily decomposable into a direct sum. For example,

$$\mathcal{A} = \mathbb{C} \oplus \mathbb{C} \ni (a,b), \quad \rho(a,b) = \begin{pmatrix} \begin{pmatrix} a & 0 \\ 0 & \overline{a} \end{pmatrix} & 0 & 0 & 0 \\ 0 & b & 0 & 0 \\ 0 & 0 & \begin{pmatrix} \overline{a} & 0 \\ 0 & \overline{a} \end{pmatrix} & 0 \\ 0 & 0 & 0 & \overline{a} \end{pmatrix}, \tag{2.1}$$

$$\mathcal{D} = \begin{pmatrix} 0 & \mathcal{M} & 0 & 0 \\ \mathcal{M}^* & 0 & 0 & 0 \\ 0 & 0 & 0 & \overline{\mathcal{M}} \\ 0 & 0 & \overline{\mathcal{M}}^* & 0 \end{pmatrix}, \quad \mathcal{M} = \begin{pmatrix} 1 \\ 0 \end{pmatrix}. \tag{2.2}$$

Here and throughout, overbars and asterisks mean complex conjugation and adjoint.

(v) Our definition of irreducibility differs from the one in our favorite book.[8] Indeed every spectral triple coming from a Riemannian spin manifold is irreducible in our case, even if the manifold is not connected, that is when the commutative spectral triple is a direct sum.

(vi) In our definition of reducibility, the Dirac operator is not supposed to leave the subspace $\mathcal{H}_0$ invariant. Our definition is adapted to the use we will make of spectral triples: the fluctuations under algebra automorphisms properly lifted to the Hilbert space promote the Dirac operator to a dynamical variable and we are interested in its dynamics, the spectral action.[3]

Since we are mainly interested in finite or 0-dimensional triples, we only recall the definition for this case and also restricting ourselves to the real and S^0-real triples.[5,6]

Definition 2.3: A real, S^0-real, finite spectral triple is given by $(\mathcal{A},\mathcal{H},D,J,\epsilon,\chi)$ with a finite dimensional real algebra $\mathcal{A}$, a faithful representation ρ of $\mathcal{A}$ on a finite dimensional complex Hilbert space $\mathcal{H}$. Four additional operators are defined on $\mathcal{H}$: the Dirac operator $\mathcal{D}$ is self-adjoint, the real structure J is antiunitary, and the S^0-real structure ϵ and the chirality χ are both unitary involutions. These operators satisfy

(i)

$$J^2 = 1, \quad [J,\mathcal{D}] = [J,\chi] = [\epsilon,\chi] = [\epsilon,\mathcal{D}] = 0, \quad \epsilon J = -J\epsilon, \quad \mathcal{D}\chi = -\chi\mathcal{D},$$

$$[\chi,\rho(a)] = [\epsilon,\rho(a)] = [\rho(a),J\rho(b)J^{-1}] = [[\mathcal{D},\rho(a)],J\rho(b)J^{-1}] = 0, \quad \forall\, a,b \in \mathcal{A}.$$

(ii) The chirality can be written as a finite sum $\chi = \Sigma_i \rho(a_i) J \rho(b_i) J^{-1}$. This condition is called orientability.

(iii) The intersection form $\cap_{ij} := \mathrm{tr}(\chi\rho(p_i)J\rho(p_j)J^{-1})$ is nondegenerate, $\det \cap \neq 0$. The p_i are minimal rank projections in $\mathcal{A}$. This condition is called *Poincaré duality*.

With the help of the projectors $(1\pm\chi)/2$ and $(1\pm\epsilon)/2$, the Hilbert space is decomposed as

$$\mathcal{H} = \mathcal{H}_L \oplus \mathcal{H}_R \oplus \mathcal{H}_L^c \oplus \mathcal{H}_R^c. \tag{2.3}$$

The first two components correspond in physics to particles, $\epsilon = 1$, the last two correspond to antiparticles, $\epsilon = -1$. We use the convention where left-handed spinors have negative and right-handed spinors have positive chirality.

If we denote by ρ_L the restriction of ρ to $\mathcal{H}_L$, etc., and by ρ_R^c the restriction to $\mathcal{H}_R^c$, we will always write the representation in the following form:

$$\rho := \begin{pmatrix} \rho_L & 0 & 0 & 0 \\ 0 & \rho_R & 0 & 0 \\ 0 & 0 & \overline{\rho_L^c} & 0 \\ 0 & 0 & 0 & \overline{\rho_R^c} \end{pmatrix}. \tag{2.4}$$

With respect to the decomposition (2.3) of $\mathcal{H}$, $\mathcal{D}$ has the form

$$\mathcal{D} = \begin{pmatrix} 0 & \mathcal{M} & 0 & 0 \\ \mathcal{M}^* & 0 & 0 & 0 \\ 0 & 0 & 0 & \overline{\mathcal{M}} \\ 0 & 0 & \overline{\mathcal{M}}^* & 0 \end{pmatrix}. \tag{2.5}$$

Note that the S^0-reality of internal spaces is equivalent to the absence of Majorana–Weyl spinors. These are possible in 0-dimensional spaces, but impossible in 4- and $(1+3)$-dimensional spaces M.

III. KRAJEWSKI DIAGRAMS

Krajewski, Paschke and Sitarz have classified all finite, thus 0-dimensional, real spectral triples.[10,14] Let us summarize this classification for the S^0-real case using Krajewski's diagrammatic language.

A. Conventions and multiplicity matrices

(i) The algebra: it is a finite sum of N simple algebras, $\mathcal{A} = \oplus_{i=1}^N M_{n_{-i}}(\mathbb{K}_i)$ and $\mathbb{K}_i = \mathbb{R}, \mathbb{C}, \mathbb{H}$ where $\mathbb{H}$ denotes the quaternions.

(ii) The representation: let us start with the easy case, $\mathbb{K} = \mathbb{R}, \mathbb{H}$ in all components of the algebra. The algebras $M_n(\mathbb{R})$ and $M_n(\mathbb{H})$ only have one irreducible representation, the fundamental one on $\mathbb{C}^{(n)}$, where $(n) = n$ for $\mathbb{K} = \mathbb{R}$ and $(n) = 2n$ for $\mathbb{K} = \mathbb{H}$. Therefore ρ is of the form

$$\rho(\oplus_{i=1}^N a_i) := (\oplus_{i,j=1}^N a_i \otimes 1_{m_{ji}} \otimes 1_{(n_j)}) \oplus (\oplus_{i,j=1}^N 1_{(n_i)} \otimes 1_{m_{ji}} \otimes \overline{a_j}). \tag{3.1}$$

The multiplicities m_{ij} are non-negative integers and we denote by 1_n the $n \times n$ identity matrix and set by convention $1_0 := 0$. At the same time the real structure J permutes the two main summands and complex conjugates them, while the S^0-real structure and the chirality read

$$\epsilon = (\oplus_{i,j=1}^N 1_{(n_i)} \otimes 1_{m_{ij}} \otimes 1_{(n_j)}) \oplus (\oplus_{i,j=1}^N 1_{(n_i)} \otimes (-1) 1_{m_{ji}} \otimes 1_{(n_j)}), \tag{3.2}$$

$$\chi = (\oplus_{i,j=1}^N 1_{(n_i)} \otimes \chi_{ji} 1_{m_{ji}} \otimes 1_{(n_j)}) \oplus (\oplus_{i,j=1}^N 1_{(n_i)} \otimes \chi_{ji} 1_{m_{ji}} \otimes 1_{(n_j)}), \tag{3.3}$$

where $\chi_{ij} = \pm 1$ according to our previous convention on left- (right-) handed spinors.

We define the *multiplicity matrix* $\mu \in M_N(\mathbb{Z})$ such that $\mu_{ij} := \chi_{ij} m_{ij}$. There are N minimal projectors in $\mathcal{A}$, each of the form $p_i = 0 \oplus \cdots \oplus 0 \oplus \mathrm{diag}(1_{(1)}, 0, \ldots, 0) \oplus 0 \oplus \cdots \oplus 0$. With respect to the basis $p_i/(1)$, the matrix of the intersection form is $\mu + \mu^T$.

If the algebra has summands with $\mathbb{K} = \mathbb{C}$, things get more complicated. Indeed $M_n(\mathbb{C})$ has two nonequivalent irreducible representations, the fundamental one and its complex conjugate, so we change (3.1) into

$$\rho(\oplus_{i=1}^{N} a_i) := (\oplus_{i,j=1;\alpha_i,\alpha_j}^{N} a_{i\alpha_i} \otimes 1_{m_{j\alpha_j i\alpha_i}} \otimes 1_{(n_j)}) \oplus (\oplus_{i,j=1}^{N} 1_{(n_i)} \otimes 1_{m_{j\alpha_j i\alpha_i}} \otimes \overline{a_{j\alpha_j}}), \tag{3.4}$$

where $\alpha_i = 1$ when $a_i \in M_{n_i}(\mathbb{K})$, $\mathbb{K} = \mathbb{R}, \mathbb{H}$ and $\alpha_i = 1,2$ when $a_i \in M_{n_i}(\mathbb{C})$, and $a_{i1} := a_i$, $a_{i2} := \overline{a_i}$.

Therefore the multiplicity matrix is an integer valued square matrix of size equal to the number of summands with $\mathbb{K} = \mathbb{R}$ and $\mathbb{H}$ plus two times the number of summands with $\mathbb{K} = \mathbb{C}$ and decomposes into N^2 submatrices of size 1×1, 2×2, 1×2, and 2×1. For example $\mathcal{A} = M_n(\mathbb{C}) \oplus M_m(\mathbb{C}) \oplus M_q(\mathbb{R}) \ni (a,b,c)$ has a 5×5 multiplicity matrix. Let us label its rows and columns with algebra elements:

$$\mu = \begin{pmatrix} \mu_{aa} & \mu_{ab} & \mu_{ac} \\ \mu_{ba} & \mu_{bb} & \mu_{bc} \\ \mu_{ca} & \mu_{cb} & \mu_{cc} \end{pmatrix} \begin{matrix} \frac{a}{a} \\ \frac{b}{b} \\ c \end{matrix} .$$
$$\begin{matrix} a\overline{a} & b\overline{b} & c \end{matrix}$$

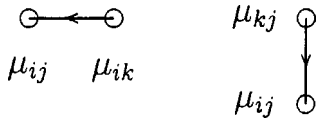
If both entries μ_{ij} and μ_{ji} of the multiplicity matrix are nonzero, then they must have the same sign.

The nonvanishing entries within each submatrix 1×2 or 2×1, like μ_{ca} or μ_{ac}, must have the same sign, while the signs of the nonvanishing entries in each 2×2 submatrix, e.g., μ_{aa} or μ_{ab} must be checkerboardlike, $\left(\begin{smallmatrix} + & - \\ - & + \end{smallmatrix}\right)$ or $\left(\begin{smallmatrix} - & + \\ + & - \end{smallmatrix}\right)$.

The *contracted multiplicity matrix* $\hat{\mu}$ is the $N \times N$ matrix constructed from μ by replacing each of the previous submatrices in μ by the sum of the entries of the submatrix.

(i) Poincaré duality: The last condition to be satisfied by the multiplicity matrix reflects the Poincaré duality. With respect to the basis $p_i/(1)$ introduced above, $(1) = 1$ for $\mathbb{K} = \mathbb{R}$ and $\mathbb{C}$, $(1) = 2$ for $\mathbb{K} = \mathbb{H}$, the matrix of the intersection form is $\hat{\mu} + \hat{\mu}^T$. Therefore we must have $\det(\hat{\mu} + \hat{\mu}^T) \neq 0$.

(ii) The Dirac operator: The components of the (internal) Dirac operator are represented by horizontal or vertical lines connecting two nonvanishing entries of opposite signs in the multiplicity matrix μ and we will orient them from plus to minus. Each arrow represents a nonvanishing, complex submatrix in the Dirac operator: For instance μ_{ij} can be linked to μ_{ik} or μ_{kj} by



and these arrows represent, respectively, submatrices of $\mathcal{M}$ in $\mathcal{D}$ of type $M \otimes 1_{(n_i)}$ with M a complex $(n_j) \times (n_k)$ matrix and $1_{(n_j)} \otimes M$ with M a complex $(n_i) \times (n_k)$ matrix.

The requirement of nondegeneracy of a spectral triple means that every nonvanishing entry in the multiplicity matrix μ is touched by at least one arrow.

Convention for the diagrams: We will see that (for sums of up to three simple algebras) irreducibility implies that most entries of μ have an absolute value less than or equal to 2. So we will use a *simple arrow* to connect plus 1 to minus 1 and *double arrows* to connect plus 1 to minus 2 or plus 1 to minus 1 (Fig. 1).

Our arrows always point from plus, that is right chirality, to minus, that is left chirality. For a given algebra, every spectral triple is encoded in its multiplicity matrix which itself is encoded in its Krajewski diagram, a field of arrows. In our conventions, for particles, $\epsilon = 1$, the column label

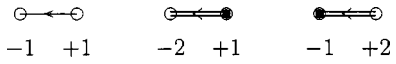


FIG. 1. Types of arrows.

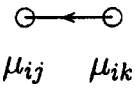
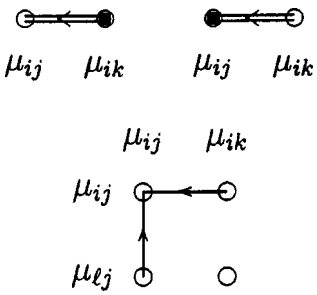
of the multiplicity matrix indicates the representation, the row label indicates the multiplicity. For antiparticles, the row label of the multiplicity matrix indicates the representation, the column label indicates the multiplicity.

Every arrow comes with three algebras: Two algebras that localize its end points, let us call them *right and left algebras* and a third algebra that localizes the arrow, let us call it *color algebra*. For example, for the arrow



the left algebra is $\mathcal{A}_j$, the right algebra is $\mathcal{A}_k$ and the color algebra is $\mathcal{A}_i$.

The *circles* in the diagrams only intend to guide the eye. A black disk on a double arrow indicates that the coefficient of the multiplicity matrix is plus or minus one at this location, "the two arrows are joined at this location." For example the the following arrows



represent respectively submatrices of $\mathcal{M}$ of type

$$\begin{pmatrix} M_1 \\ M_2 \end{pmatrix} \otimes 1_{(n_i)} \quad \text{and} \quad (M_1 \quad M_2) \otimes 1_{(n_i)}$$

with M_1, M_2 of size $(n_j)\times(n_k)$ or in the third case, a matrix of type $(M_1 \otimes 1_{(n_i)} \quad 1_{(n_j)} \otimes M_2)$ where M_1 and M_2 are of size $(n_j)\times(n_k)$ and $(n_i)\times(n_\ell)$.

According to these rules, we can omit the number ± 1, ± 2 under the arrows like in Fig. 2, since they are now redundant.

Let us give a few examples of the explicit form of the spectral triple associated to a given Krajewski diagram.

Take the algebra $\mathcal{A}=\mathbb{H}\oplus M_3(\mathbb{C})\ni(a,b)$ with the first diagram of Fig. 2. Then the multiplicity matrix and its contraction are

$$\mu=\begin{pmatrix} -1 & 1 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}, \quad \hat{\mu}=\begin{pmatrix} -1 & 1 \\ 0 & 0 \end{pmatrix}.$$

Using (2.4), its representation is, up to unitary equivalence

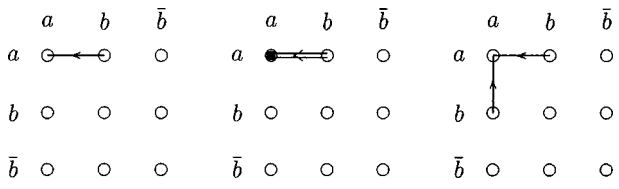


FIG. 2. Diagrams with complex conjugation.

$$\rho_L(a,b) = a \otimes 1_2, \quad \rho_R(a,b) = b \otimes 1_2, \quad \rho_L^c(a,b) = 1_2 \otimes a, \quad \rho_R^c(a,b) = 1_3 \otimes a.$$

The Hilbert space is

$$\mathcal{H} = \mathbb{C}^4 \oplus \mathbb{C}^6 \oplus \mathbb{C}^4 \oplus \mathbb{C}^6.$$

In its Dirac operator (2.5), $\mathcal{M} = M \otimes 1_2$, where M is a nonvanishing complex 2×3 matrix.

Real structure, S^0-real structure and chirality are given by (c.c. stands for complex conjugation)

$$J = \begin{pmatrix} 0 & 1_{10} \\ 1_{10} & 0 \end{pmatrix} \circ \text{c.c.}, \quad \epsilon = \begin{pmatrix} 1_{10} & 0 \\ 0 & -1_{10} \end{pmatrix}, \quad \chi = \begin{pmatrix} -1_4 & 0 & 0 & 0 \\ 0 & 1_6 & 0 & 0 \\ 0 & 0 & -1_4 & 0 \\ 0 & 0 & 0 & 1_6 \end{pmatrix}.$$

The first tensor factor in $a \otimes 1_2$ concerns particles, the second concerns antiparticles denoted by $\cdot^c$. The antiparticle representation is read from the transposed multiplicity matrix.

The second diagram of Fig. 2 yields

$$\mu = \begin{pmatrix} -1 & 2 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}, \quad \hat{\mu} = \begin{pmatrix} -1 & 2 \\ 0 & 0 \end{pmatrix},$$

and its spectral triple reads

$$\rho_L(a,b) = a \otimes 1_2, \quad \rho_R(a,b) = \begin{pmatrix} b & 0 \\ 0 & b \end{pmatrix} \otimes 1_2,$$

$$\rho_L^c(a,b) = 1_2 \otimes a, \quad \rho_R^c(a,b) = \begin{pmatrix} 1_3 & 0 \\ 0 & 1_3 \end{pmatrix} \otimes a,$$

$$\mathcal{M} = (M_1 \quad M_2) \otimes 1_2, \; M_1 \text{ and } M_2 \text{ of size } 2 \times 3,$$

$$J = \begin{pmatrix} 0 & 1_{16} \\ 1_{16} & 0 \end{pmatrix} \circ \text{c.c.}, \quad \epsilon = \begin{pmatrix} 1_{16} & 0 \\ 0 & -1_{16} \end{pmatrix}, \quad \chi = \begin{pmatrix} -1_4 & 0 & 0 & 0 \\ 0 & 1_{12} & 0 & 0 \\ 0 & 0 & -1_4 & 0 \\ 0 & 0 & 0 & 1_{12} \end{pmatrix}.$$

In Krajewski's notations, Eq. (3.1), we would have written $\rho_R(a,b) = b \otimes 1_2 \otimes 1_2$, the middle factor showing the entry of multiplicity matrix μ.

Finally, still for the same algebra, let us consider the third diagram of Fig. 2. It gives

$$\mu = \begin{pmatrix} -1 & 1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}, \quad \hat{\mu} = \begin{pmatrix} -1 & 1 \\ 1 & 0 \end{pmatrix},$$

$$\rho_L(a,b) = a \otimes 1_2, \quad \rho_R(a,b) = \begin{pmatrix} b \otimes 1_2 & 0 \\ 0 & a \otimes 1_3 \end{pmatrix},$$

$$\rho_L^c(a,b) = 1_2 \otimes a, \quad \rho_R^c(a,b) = \begin{pmatrix} 1_3 \otimes a & 0 \\ 0 & 1_2 \otimes b \end{pmatrix},$$

$$\mathcal{M} = (M_1 \otimes 1_2 \quad 1_2 \otimes M_2), \quad M_1 \text{ and } M_2 \text{ of size } 2 \times 3.$$

In the three above examples all arrows have left algebra $\mathbb{H}$, right algebra $M_3(\mathbb{C})$, and color algebra $\mathbb{H}$. The numerous examples below should allow the reader to get familiar with the translation between diagrams and triples.

B. Multiplicity matrix and irreducibility

Our work is based on the following lemma indicating that a classification of irreducible spectral triples is possible.

Lemma 3.1:

(i) The direct sum of multiplicity matrices is again a multiplicity matrix describing the direct sum of spectral triples.

(ii) For a given algebra there is only a finite list of multiplicity matrices describing irreducible triples.

Proof:

(i) is obvious.

(ii) Given an algebra $\mathcal{A}$, denote by $\mathcal{S}$ the set of multiplicity matrices $\mu \in M_n(\mathbb{Z})$ (n is determined by $\mathcal{A}$) associated to irreducible spectral triples. Define a partial order in $M_n(\mathbb{Z})$ by $\mu \geqslant \nu$ when μ_{ij} and ν_{ij} have the same sign and $|\mu_{ij}| \geqslant |\nu_{ij}|$ for all $i,j=1,\ldots,n$. The interest of this order is that for two different multiplicity matrices μ, ν such that $\mu \geqslant \nu$ and $\nu \in \mathcal{S}$, μ corresponds to a reducible triple.

To prove that card $(\mathcal{S}) < \infty$, we first identify $M_n(\mathbb{Z})$ with $\mathbb{Z}^{n^2}$. We denote by $\{e_i\}_{i \in \{1,\ldots,n^2\}}$ the canonical basis of $\mathbb{Z}^{n^2}$ and $\mathcal{S}^+ := \mathcal{S} \cap \mathbb{N}^{n^2}$. We now prove that card $(\mathcal{S}^+) < \infty$, which is sufficient.

Assume card $(\mathcal{S}^+) = \infty$. Then there exists at least one direction (say along e_1) such that $\sup\{(\mu)_1 \,|\, \mu \in \mathcal{S}^+\} = \infty$. Suppose now that in each hyperplane defined by me_1, $m \in \mathbb{N}$, all points $\mu \in \mathcal{S}^+$ remain uniformly bounded, $\mu_i < B$, $i=2,\ldots,n^2$. This means that there exists an infinite family of points in an hypertube parallel to e_1. Necessarily, there exists an infinite subfamily $\{\mu_k\}_{k \in \mathbb{N}} \subset \mathcal{S}^+$ of points in the hypertube which are aligned: $(\mu_k)_i = (\mu_{k+1})_i$, $\forall i \neq 1$ and $(\mu_k)_1 < (\mu_{k+1})_1$. But this is impossible since $\mu_k \leqslant \mu_{k+1}$ cannot happen. As a consequence, there exists a second direction (say along e_2 after renumbering) where the intersection of successive hyperplanes along e_1 and e_2 contain an infinite family of points of $\mathcal{S}^+$. By induction, the same reasoning in each direction e_i implies that there exists an infinite family $\{\mu_k\}_k$ of points in $\mathcal{S}^+$ with increasing vectors: $(\mu_k)_i < (\mu_{k+1})_i$, $\forall i$. Again this yields the contradiction $\mu_k \leqslant \mu_{k+1}$ and $\mu_{k+1} \notin \mathcal{S}^+$. □

IV. FLUCTUATIONS AND DYNAMICAL NONDEGENERACY

The aim of this work is twofold. First, we work out all irreducible real, S^0-real diagrams for algebras with one, two, and three simple summands. Second, we give all associated spectral triples that are dynamically nondegenerate. By this we mean the following. The spectrum of the (internal) Dirac operator $\mathcal{D}$ is always degenerate: all nonvanishing eigenvalues come in pairs of opposite sign due to the chirality that anticommutes with $\mathcal{D}$. All eigenvalues appear twice due to the real structure that commutes with $\mathcal{D}$. There is a further degeneracy, twofold in the example above, $\mathcal{M} = M \otimes 1_2$, that comes from the first order axiom. Let us call it *color degeneracy*. It is absent if and only if the color algebras of all arrows are commutative. Of course, these three degeneracies survive the fluctuations of the Dirac operator and the minimization of the Higgs potential. By dynamical nondegenerate we mean (see precise definition below) that no minimum of the Higgs potential has degeneracies other than the above three. The first two degeneracies survive *quantum fluctuations* as well. We also want the color degeneracies to be protected from quantum fluctua-

tions. A natural protection is unbroken gauge invariance, a requirement that we will include into the definition of dynamical nondegeneracy.

Except for complex conjugation in $M_n(\mathbb{C})$ and permutations of identical summands in the algebra $\mathcal{A}=\mathcal{A}_1\oplus\mathcal{A}_2\oplus\ldots\oplus\mathcal{A}_N$, every algebra automorphism σ is inner, $\sigma(a)=uau^{-1}$ for a unitary $u\in U(\mathcal{A})$. Therefore the connected component of the automorphism group is $\mathrm{Aut}(\mathcal{A})^e = U(\mathcal{A})/(U(\mathcal{A})\cap\mathrm{Center}(\mathcal{A}))$. Its lift to the Hilbert space[5]

$$L(\sigma)=\rho(u)J\rho(u)J^{-1}$$

is multivalued.

The *fluctuation* ${}^f\mathcal{D}$ of the Dirac operator $\mathcal{D}$ is given by a finite collection f of real numbers r_j and algebra automorphisms $\sigma_j\in\mathrm{Aut}(\mathcal{A})^e$ such that

$${}^f\mathcal{D}:=\sum_j r_j L(\sigma_j)\mathcal{D}\,L(\sigma_j)^{-1},\quad r_j\in\mathbb{R},\quad \sigma_j\in\mathrm{Aut}(\mathcal{A})^e.$$

The fluctuated Dirac operator ${}^f\mathcal{D}$ is often denoted by φ, the Higgs scalar, in the physics literature. We consider only fluctuations with real coefficients since ${}^f\mathcal{D}$ must remain self-adjoint.

To avoid the multivaluedness in the fluctuations, we allow the entire unitary group viewed as a (maximal) central extension of the automorphism group. We will come back to minimal central extensions in another work.

An almost commutative geometry is the tensor product of a finite noncommutative triple with an infinite, commutative spectral triple. By Connes' reconstruction theorem [6] we know that the latter comes from a Riemannian spin manifold, which we will take to be any four-dimensional, compact, flat manifold like the flat 4-torus. The spectral action of this almost commutative spectral triple reduced to the finite part is a functional on the vector space of all fluctuated, finite Dirac operators,

$$V({}^f\mathcal{D})=\lambda\ \mathrm{tr}[({}^f\mathcal{D})^4]-\frac{\mu^2}{2}\mathrm{tr}[({}^f\mathcal{D})^2],$$

where λ and μ are positive constants.[3,11] The spectral action is invariant under lifted automorphisms and even under the unitary group $U(\mathcal{A})\ni u$,

$$V([\rho(u)J\rho(u)J^{-1}]{}^f\mathcal{D}[\rho(u)J\rho(u)J^{-1}]^{-1})=V({}^f\mathcal{D}),$$

and it is bounded from below. Our task is to find the minima $\hat{}^f\mathcal{D}$ of this action, their spectra and their *little groups*

$$G_\ell:=\{\,u\in U(\mathcal{A})),[\rho(u)J\rho(u)J^{-1}]\hat{}^f\mathcal{D}[\rho(u)J\rho(u)J^{-1}]^{-1}=\hat{}^f\mathcal{D}\}.$$

Definition 4.1: The irreducible spectral triple $(\mathcal{A},\mathcal{H},\mathcal{D})$ is *dynamically nondegenerate* if all minima $\hat{}^f\mathcal{D}$ of the action $V({}^f\mathcal{D})$ define a nondegenerate spectral triple $(\mathcal{A},\mathcal{H},\hat{}^f\mathcal{D})$ and if the spectra of all minima have no degeneracies other than the three kinematical degeneracies: left–right, particle–antiparticle, and color. Of course in the massless case there is no left–right degeneracy. We also suppose that the color degeneracies are protected by the little group. By this we mean that all eigenvectors of $\hat{}^f\mathcal{D}$ corresponding to the same eigenvalue are in a common orbit of the little group (and scalar multiplication and charge conjugation).

In physicists' language this last requirement means noncommutative color groups are unbroken. It ensures that the corresponding mass degeneracies are protected from quantum corrections.

V. STATEMENT OF THE RESULT

The main result of this work is the following:

Theorem 5.1: *The sum of simple algebras,* $\mathcal{A}=\oplus_{i=1}^N\mathcal{A}_i$ *with* $N=1,2,3$ *admits a finite, real,*

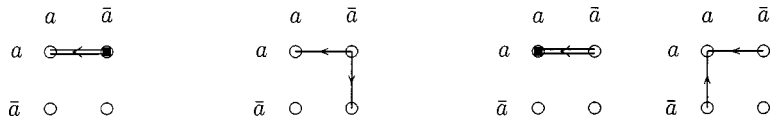

FIG. 3. One algebra: all irreducible diagrams.

S^0-real, irreducible and dynamically nondegenerate spectral triple if and only if it is in this list, up to a reordering of the summands:

$N=1$	$N=2$	$N=3$
	$\mathbf{1}\oplus\mathbf{1}$	$\mathbf{1}\oplus\mathbf{1}\oplus\mathcal{C}$
void		$\mathbf{1}\oplus\mathbf{1}\oplus\mathbf{1}$
		$\mathbf{2}\oplus\mathbf{1}\oplus\mathcal{C}$
	$\mathbf{2}\oplus\mathbf{1}$	$\mathbf{2}\oplus\mathbf{1}\oplus\mathbf{1}$

Here **1** *is a shorthand for* $\mathbb{R}$ *or* $\mathbb{C}$ *and* **2** *for* $M_2(\mathbb{R})$, $M_2(\mathbb{C})$, *or* $\mathbb{H}$.
The color algebra $\mathcal{C}$ *is any simple algebra and has two important constraints*:

(i) *Its representations on corresponding left- and right-handed subspaces of* $\mathcal{H}$ *are identical (up to possibly different multiplicities).*
(ii) *The Dirac operator* $\mathcal{D}$ *is invariant under* $U(\mathcal{C})$,

$$\rho(1,1,w)\mathcal{D}\rho(1,1,w)^{-1}=\mathcal{D}, \quad \text{for all } w\in U(\mathcal{C}).$$

This implies that the unitaries of $\mathcal{C}$ *do not participate in the fluctuations and are therefore unbroken, i.e., elements of the little group.*

Let us emphasize that although the four-dimensional space–time manifold M used to define the almost commutative geometry does not show up in this result, it is an important ingredient of the spectral action and its asymptotic behavior. In particular the dimension of M is linked to the order of the polynomial V. Therefore our classification indeed concerns four-dimensional, almost commutative geometries.

We give in Sec. IX A an example of a reducible triple which is dynamically nondegenerate and whose algebra is not in the above list.

VI. ONE SIMPLE ALGEBRA

From the classification,[10,14] we know that $\mathcal{A}=M_n(\mathbb{C})$ are the only simple algebras to admit real spectral triples. Up to permutation of a and $\overline{a}$ (complex conjugation in $\mathcal{A}$), up to permutation of particles and antiparticles (reflection of the diagram with respect to the main diagonal) and up to permutation of left- and right-handed particles (changing the direction of all arrows), all real S^0-real and irreducible triples have Krajewski diagrams indicated in Fig. 3.

Indeed, a Krajewski diagram must contain at least one arrow which can be put into the position $\mu=\left(\begin{smallmatrix}-1 & +1\\ 0 & 0\end{smallmatrix}\right)$ by use of the three above permutations. However, alone this arrow does not fulfill Poincaré duality, $\hat{\mu}+\hat{\mu}^T=0$. There are four ways to add a second arrow. But Poincaré duality can only be satisfied if the two arrows are joined in one point. Adding a third arrow makes the corresponding spectral triples reducible.

The first diagram yields

$$\rho_L(a)=\begin{pmatrix}a & 0\\ 0 & a\end{pmatrix}\otimes 1_n, \quad \rho_R(a)=\overline{a}\otimes 1_n, \quad \rho_L^c(a)=1_n\otimes\begin{pmatrix}a & 0\\ 0 & a\end{pmatrix}, \quad \rho_R^c(a)=1_n\otimes a,$$

$$\mathcal{M} := M \otimes 1_n := \begin{pmatrix} M_1 \\ M_2 \end{pmatrix} \otimes 1_n, \quad M_1, M_2 \in M_n(\mathbb{C}). \tag{6.1}$$

Real structure, S^0-real structure and chirality are

$$J = \begin{pmatrix} 0 & 1_{3n^2} \\ 1_{3n^2} & 0 \end{pmatrix} \circ \text{c.c.}, \quad \epsilon = \begin{pmatrix} 1_{3n^2} & 0 \\ 0 & -1_{3n^2} \end{pmatrix}, \quad \chi = \begin{pmatrix} -1_{2n^2} & 0 & 0 & 0 \\ 0 & +1_{n^2} & 0 & 0 \\ 0 & 0 & -1_{2n^2} & 0 \\ 0 & 0 & 0 & +1_{n^2} \end{pmatrix}.$$

Let us write the fluctuations of $\mathcal{D}$ as

$${}^f\mathcal{D} := \begin{pmatrix} 0 & {}^f\mathcal{M} & 0 & 0 \\ {}^f\mathcal{M}^* & 0 & 0 & 0 \\ 0 & 0 & 0 & {}^f\overline{\mathcal{M}} \\ 0 & 0 & {}^f\overline{\mathcal{M}}^* & 0 \end{pmatrix}. \tag{6.2}$$

Here

$${}^f\mathcal{M} = {}^fM \otimes 1_n = \begin{pmatrix} {}^fM_1 \\ {}^fM_1 \end{pmatrix} \otimes 1_n.$$

Then

$${}^fM_1 = \sum_j r_j u_j M_1 u_j^T, \quad {}^fM_2 = \sum_j r_j u_j M_2 u_j^T, \quad \text{so} \quad {}^fM = \sum_j r_j \begin{pmatrix} u_j & 0 \\ 0 & u_j \end{pmatrix} \begin{pmatrix} M_1 \\ M_2 \end{pmatrix} u_j^T \tag{6.3}$$

and

$$V({}^f\mathcal{D}) = \lambda \ \mathrm{tr}[{}^f\mathcal{D}^4] - \frac{\mu^2}{2}\mathrm{tr}[{}^f\mathcal{D}^2] = 4n\left(\lambda \ \mathrm{tr}[({}^fM * {}^fM)^2] - \frac{\mu^2}{2}\mathrm{tr}[{}^fM * {}^fM]\right).$$

The matrix ${}^fM$ is of size $2n \times n$. Therefore the fluctuation ${}^f\mathcal{D}$ has at least n vanishing eigenvalues each still coming with its n-fold color degeneracy and all triples with $n \geqslant 2$ are dynamically degenerate since ${}^fM {}^fM^* \in M_{2n}(\mathbb{C})$ has at least n zero eigenvalues.

For $n=1$, all minima of the action V are of the form $|\hat{}^fM_1|^2 + |\hat{}^fM_2|^2 = \mu^2/4\lambda$. But the corresponding fluctuated Dirac operator has a nontrivial invariant subspace in its kernel and the triple is degenerate. To make the subspace explicit apply a unitary change of basis to set ${}^fM_2$ to zero. In every minimum the little group is $\mathbb{Z}_2$.

At this point, an overkill is instructive. We will show that the case $n \geqslant 2$ also features dynamical degeneracy in the nonzero eigenvalues.

In general, the set of all possible fluctuations ${}^f\mathcal{D}$, i.e., the image under the fluctuations (6.3), is difficult to describe. However, the action V only depends on the positive $n \times n$ matrix $C := {}^fM^* {}^fM$ and is a sum of n^2 polynomials of fourth order in the matrix elements of C,

$$V(C) = 4n\left[\sum_{i=1}^{n}\left(\lambda C_{ii}^2 - \frac{\mu^2}{2}C_{ii}\right) + \sum_{i \neq j}\lambda |C_{ij}|^2\right]. \tag{6.4}$$

If $C = (\mu^2/4\lambda)/1_n$ is in this image then it is the unique minimum in terms of the variable C.

To compute the minima of the action, we now distinguish cases.

Case 1: At least one diagonal element of one of the two matrices is nonzero.

After a suitable renumbering of the basis of the Hilbert space $\mathcal{H}$, we may assume $(M_1)_{11} \neq 0$. With a first fluctuation,

$$r_1=\frac{1}{2},\quad r_2=\frac{1}{2},\quad u_1=1_n,\quad u_2=\begin{pmatrix}1 & 0\\ 0 & -1_{n-1}\end{pmatrix},$$

we obtain for ${}^fM$ a block diagonal matrix with 2×2 blocks. By means of the fluctuation

$$r_1=\frac{1}{2},\quad r_2=\frac{1}{2},\quad u_1=1_n,\quad u_2=\begin{pmatrix}1 & 0\\ 0 & i1_{n-1}\end{pmatrix},$$

we isolate the (1,1) elements of M_1 and M_2 and with $r_1=r_2=\cdots=r_n=1$, $u_1=1_n$,

$$u_2=\begin{pmatrix}0 & 1 & 0\\ 1 & 0 & 0\\ 0 & 0 & 1_{n-2}\end{pmatrix},\quad u_3=\begin{pmatrix}0 & 0 & 1 & 0\\ 0 & 1 & 0 & 0\\ 1 & 0 & 0 & 0\\ 0 & 0 & 0 & 1_{n-3}\end{pmatrix},\quad u_4=\begin{pmatrix}0 & 0 & 0 & 1 & 0\\ 0 & 1 & 0 & 0 & 0\\ 0 & 0 & 1 & 0 & 0\\ 1 & 0 & 0 & 0 & 0\\ 0 & 0 & 0 & 0 & 1_{n-4}\end{pmatrix},\quad \ldots$$

we distribute them over the entire diagonal obtaining

$${}^fM=\begin{pmatrix}(M_1)_{11}1_n\\ (M_2)_{11}1_n\end{pmatrix}.$$

Then C is a nonvanishing multiple of the identity and a suitable multiple of the above ${}^fM$ is a minimum. The spectrum of this minimum $\hat{}^f\mathcal{D}$ has an additional dynamical degeneracy and up to the sign, $\hat{}^f\mathcal{D}$ has one single eigenvalue. The little group is $G_\ell=O(n)$. Note also that $\hat{}^fM_1$ and $\hat{}^fM_2$ are proportional, $\hat{}^fM_1=\alpha\hat{}^fM_2$, $\alpha\in\mathbb{C}$, so there is a unitary change of basis in the Hilbert space $\mathcal{H}$ such that $\hat{}^fM_2=0$ in the new basis and the spectral triple $(M_n(\mathbb{C}),\mathcal{H},\hat{}^f\mathcal{D})$ is degenerate.

Case 2: All diagonal elements of M_1 and M_2 vanish but M_1 and M_2 are not both skewsymmetric.

After a suitable renumbering, we may assume $(M_1)_{12}=\beta-\gamma$, $(M_1)_{21}=\beta+\gamma$, $(M_1)_{11}=(M_1)_{22}=0$, with $\beta\neq 0$. As in case 1 we can isolate this block. Fluctuating with

$$r_1=1,\quad u_1=\begin{pmatrix}1/\sqrt{2} & -1/\sqrt{2} & 0\\ 1/\sqrt{2} & 1/\sqrt{2} & 0\\ 0 & 0 & 1_{n-2}\end{pmatrix},$$

we obtain $({}^fM_1)_{11}=-\beta$ and conclude as in case 1.

Case 3: M_1 and M_2 are skewsymmetric and linearly dependent.

Thus M can be written as $M=M_1\otimes\binom{1}{\alpha}$, $\alpha\in\mathbb{C}$ and by a unitary change of basis, we may assume $\alpha=0$ that is $M_2=0$ without changing the representation (6.1). Then the spectral triple is degenerate. Let us nevertheless finish this case. By another unitary change of basis (or fluctuation), cf. Appendix A1, we set

$$M_1=\begin{pmatrix}\begin{pmatrix}0 & -\lambda_1\\ \lambda_1 & 0\end{pmatrix} & & & \\ & \begin{pmatrix}0 & -\lambda_2\\ \lambda_2 & 0\end{pmatrix} & & \\ & & \ddots & \\ & & & 0\end{pmatrix},$$

where the zero in the lower right corner concerns the case n odd. Let us suppose that λ_1 is not zero. By isolating the upper left block and by distributing it over the entire diagonal we obtain a ${}^fM_{1i}=\lambda_1$ for all i. If n is even, we then have the minimum $\hat{C}=(\mu^2/4\lambda)/1_n$ for $V(C)$. Its spectrum

is again completely degenerate with little group $G_\ell = \mathrm{USp}(n/2)$. If n is odd the spectrum of ${}^{\hat{f}}\mathcal{D}$ contains four vanishing eigenvalues, all others being of the same absolute value and $G_\ell = \mathrm{USp}[(n-1)/2] \times \mathrm{U}(1)$.

Case 4: M_1 and M_2 are skewsymmetric and linearly independent:

Then ${}^fM_1$ and ${}^fM_2$ vary independently over all skewsymmetric matrices (cf. Lemma 11.10). For $n=3$ the minimization can be done by direct calculation. All minima are gauge equivalent to

$$ {}^{\hat{f}}M = \frac{\mu}{\sqrt{6\lambda}} \begin{pmatrix} 0 & 1 & 0 \\ -1 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 1 \\ 0 & 0 & 0 \\ -1 & 0 & 0 \end{pmatrix}, \quad \hat{C} := {}^{\hat{f}}M^{*\hat{f}}M = \frac{\mu^2}{6\lambda} \begin{pmatrix} 2 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}. $$

Although the spectrum has a twofold dynamical degeneracy the little group is only $G_\ell = U(1) \ni \mathrm{diag}(e^{i\theta}, e^{-i\theta}, e^{-i\theta})$. For general n, we were unable to compute a minimum explicitly, but we will show that its spectrum is dynamically degenerate. To alleviate notations let us rescale variables, ${}^f\mathcal{D} \to (\mu\sqrt{2\mu})/{}^f\mathcal{D}$. Then the spectral action reads for $C_i := {}^fM_i^{*f}M_i$,

$$ V({}^fM_1, {}^fM_2) = \frac{n\mu^4}{\lambda}(\mathrm{tr}[C_1^2] - \mathrm{tr}[C_1] + \mathrm{tr}[C_2^2] - \mathrm{tr}[C_2] + 2\mathrm{tr}[C_1C_2]). $$

All minima of this fourth order polynomial have vanishing partial derivatives with respect to ${}^fM_1^*$ and ${}^fM_2^*$. These equations read

$$ {}^{\hat{f}}M_1 = 2{}^{\hat{f}}M_1{}^{\hat{f}}M_1{}^{*\hat{f}}M_1 + {}^{\hat{f}}M_1{}^{\hat{f}}M_2{}^{*\hat{f}}M_2 + {}^{\hat{f}}M_2{}^{\hat{f}}M_2{}^{*\hat{f}}M_1, \tag{6.5} $$

$$ {}^{\hat{f}}M_2 = 2{}^{\hat{f}}M_2{}^{\hat{f}}M_2{}^{*\hat{f}}M_2 + {}^{\hat{f}}M_2{}^{\hat{f}}M_1{}^{*\hat{f}}M_1 + {}^{\hat{f}}M_1{}^{\hat{f}}M_1{}^{*\hat{f}}M_2. \tag{6.6} $$

Let us set $X := \hat{C}_1$, $Y := \hat{C}_2$, and $Z := {}^{\hat{f}}M_1{}^{*\hat{f}}M_2$. We multiply Eq. (6.5) from the left by ${}^{\hat{f}}M_1$ and likewise for (6.6) to get

$$ X = 2X^2 + XY + ZZ^*, \tag{6.7} $$

$$ Y = 2Y^2 + XY + Z^*Z. \tag{6.8} $$

Subtracting (6.7) from its Hermitian conjugate, we have that X and Y commute and subtracting (6.8) and (6.7) we get

$$ 2(X-Y)(X+Y-\tfrac{1}{2}1_n) = [Z^*, Z]. \tag{6.9} $$

Multiplying (6.6) from the left with ${}^{\hat{f}}M_1{}^*$ and multiplying the Hermitian conjugate of (6.5) from the right with ${}^{\hat{f}}M_2$, we have

$$ Z = 2ZY + ZX + XZ, $$

$$ Z = 2XZ + YZ + ZY. \tag{6.10} $$

Taking the difference, we find that Z commutes with $X+Y$.

We are to show that the spectrum of $\hat{C} = {}^{\hat{f}}M^{*\hat{f}}M = X+Y$ is degenerate: Let us suppose that it is nondegenerate. Take an orthonormal basis of eigenvectors of $\hat{C}$. Then it is also an eigenbasis of Z implying that $[Z, Z^*] = 0$ and by (6.9) the eigenvalues x_j and y_j of X and Y corresponding to the jth

basis vector satisfy at least one of the equations $x_j=y_j$, $x_j+y_j=1/2$. But as $\hat{}^f M_1$ and $\hat{}^f M_2$ are skewsymmetric, each eigenvalue of X and Y is doubly degenerate with the exception of one vanishing eigenvalue if n is odd. This contradicts the nondegeneracy of $X+Y$.

The triple of the second diagram of Fig. 3 differs from the first only with respect to representation and Dirac operator

$$\rho_L(a)=\begin{pmatrix} a & 0 \\ 0 & \overline{a} \end{pmatrix}\otimes 1_n, \quad \rho_R(a)=\overline{a}\otimes 1_n, \quad \rho_L^c(a)=1_n\otimes\begin{pmatrix} a & 0 \\ 0 & \overline{a} \end{pmatrix}, \quad \rho_R^c(a)=1_n\otimes a,$$

$$\mathcal{M}=\begin{pmatrix} M_1\otimes 1_n \\ 1_n\otimes M_2 \end{pmatrix}, \quad M_1,M_2\in M_n(\mathbb{C}).$$

Again, nondegeneracy of the zero eigenvalue requires $n=1$ and all minima, $|\hat{}^f M_1|^2+|\hat{}^f M_2|^2=\mu^2/4\lambda$, have little group $\mathbb{Z}_2$. But now all minima of the action V are not gauge equivalent. Indeed when $\hat{}^f M_1=\mu(4\lambda)^{-1/2}$, $\hat{}^f M_2=0$ and $\mathrm{Ker}(\mathcal{D})=\mathrm{Span}\{\mathcal{H}_{L2},\mathcal{H}_{L2}^c\}$. Thus the eigenvector in the image of $(1/2)(1-\epsilon)$ associated to the zero eigenvalue of the fluctuated Dirac operator, which is in $\mathcal{H}_{L2}$, transforms under $\rho(u)J\rho(u)J^{-1}$ as multiplication by u^{-2}, while it transforms as multiplication by u^2 when $\hat{}^f M_2=\mu(4\lambda)^{-1/2}$. According to our definition the triple is dynamically degenerate because in both cases, the eigenvectors define a one-dimensional complex subspace invariant under $\mathcal{A}$ and contained in the kernel of the fluctuated Dirac operator $\hat{}^f\mathcal{D}$.

The last two diagrams of Fig. 3 are treated as the first two and yield the same conclusions.

VII. TWO SIMPLE ALGEBRAS

Again our starting point is the list, Fig. 4, all irreducible Krajewski diagrams up to the three mentioned types of permutations and up to permutations of the two algebras and disregarding any direct sum of two diagrams from Fig. 3.

Let k and ℓ be the size of the matrices of $\mathcal{A}_1=M_n(\mathbb{K})\ni a$ and $\mathcal{A}_2=M_m(\mathbb{K})\ni b$. For example, $k=n$ for $\mathcal{A}_1=M_n(\mathbb{R})$ or $M_n(\mathbb{C})$ and $k=2n$ for $\mathcal{A}_1=M_n(\mathbb{H})$. The first diagram of Fig. 4 yields

$$\rho_L(a,b)=a\otimes 1_k, \quad \rho_R(a,b)=b\otimes 1_k, \quad \rho_L^c(a,b)=1_k\otimes a, \quad \rho_R^c(a,b)=1_\ell\otimes a,$$

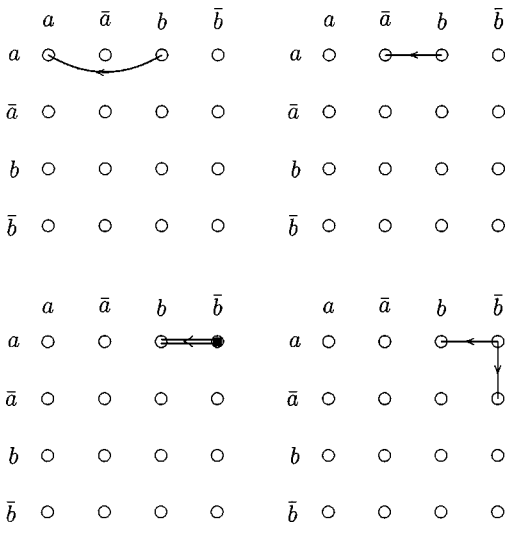

FIG. 4. Two algebras: all irreducible diagrams.

$$\mathcal{M} = M \otimes 1_k, \quad M \in M_{k\times\ell}(\mathbb{C}).$$

M is nonzero and we may assume $M_{11} \neq 0$. Except for the k-fold color degeneracy, we accept at most one zero eigenvalue of M^*M. Therefore we must have $k=\ell$ or $k=\ell\pm 1$. We assume $\ell \leqslant k$. Let in (6.2)

$$^f\mathcal{M} = {}^fM \otimes 1_k, \quad {}^fM = \sum_j r_j u_j M v_j^{-1}, \quad u_j \in U(\mathcal{A}_1), \quad v_j \in U(\mathcal{A}_2).$$

If $k \geqslant 2$, $\ell > 2$ or $k > 2$, $\ell \geqslant 2$, we may isolate the upper 2×2 block by fluctuations: With the first fluctuation,

$$r_1 = \frac{1}{2}, \quad r_2 = \frac{1}{2}, \quad u_1 = 1_k, \quad v_1 = 1_\ell, \quad u_2 \begin{pmatrix} 1_2 & 0 \\ 0 & -1_{k-2} \end{pmatrix}, \quad v_2 \begin{pmatrix} 1_2 & 0 \\ 0 & -1_{\ell-2} \end{pmatrix},$$

we obtain for M a block diagonal type matrix. By means of the fluctuation

$$r_1 = \frac{1}{2}, \quad r_2 = \frac{1}{2}, \quad u_1 = 1_k, \quad v_1 = 1_\ell, \quad u_2 = 1_k, \quad v_2 = \begin{pmatrix} 1_2 & 0 \\ 0 & -1_{\ell-2} \end{pmatrix}$$

we isolate the upper block. If $k=\ell=2$ this step is empty.

Now we may distinguish cases.

Case 1: $\mathcal{A}_1 = M_n(\mathbb{R})$ or $M_n(\mathbb{C})$, $\mathcal{A}_2 = M_m(\mathbb{R})$ or $M_m(\mathbb{C})$: like above, we isolate M_{11} and as in case 1 for one algebra we distribute M_{11} over the entire diagonal, obtaining thus ${}^fM^*{}^fM$ proportional to the identity. The spectrum of the fluctuated Dirac operator ${}^f\mathcal{D}$ minimizing the action V has an ℓ-fold dynamical degeneracy.

Case 2: $\mathcal{A}_1 = M_n(\mathbb{H})$, $\mathcal{A}_2 = M_m(\mathbb{H})$, define the fluctuation

$$r_1 = \frac{1}{2}, \quad r_2 = \frac{1}{4}, \quad r_3 = \frac{1}{4}, \quad u_1 = 1_k, \quad v_1 = 1_\ell, \quad u_2 = \begin{pmatrix} \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix} & 0 \\ 0 & 1_{k-2} \end{pmatrix},$$

$$v_2 = \begin{pmatrix} \pm\begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix} & 0 \\ 0 & 1_{\ell-2} \end{pmatrix}, \quad u_3 = \begin{pmatrix} \begin{pmatrix} 0 & i \\ i & 0 \end{pmatrix} & 0 \\ 0 & 1_{k-2} \end{pmatrix}, \quad v_3 = \begin{pmatrix} \pm\begin{pmatrix} 0 & i \\ i & 0 \end{pmatrix} & 0 \\ 0 & 1_{\ell-2} \end{pmatrix},$$

the upper block is proportional to 1_2. The plus signs in $\pm$ are used if $M_{11} = M_{22}$. We distribute the block over the diagonal and get an ℓ-fold dynamical degeneracy (recall that $\ell \leqslant k$).

Case 3: $\mathcal{A}_1 = M_n(\mathbb{R})$ or $M_n(\mathbb{C})$, $\mathcal{A}_2 = M_m(\mathbb{H})$. If $M_{12}=0$ we fluctuate with

$$r_1 = r_2 = \frac{1}{4}, \quad r_3 = \frac{1}{2}, \quad u_1 = 1_k, \quad v_1 = 1_\ell, \quad u_2 = \begin{pmatrix} \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix} & 0 \\ 0 & 1_{k-2} \end{pmatrix}, \quad v_2 = 1_\ell,$$

$$u_3 = \begin{pmatrix} \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} & 0 \\ 0 & 1_{k-2} \end{pmatrix}, \quad v_3 = \begin{pmatrix} -\begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix} & 0 \\ 0 & 1_{\ell-2} \end{pmatrix},$$

and obtain

$$ {}^fM = \begin{pmatrix} \begin{pmatrix} M_{11} & 0 \\ 0 & -M_{11} \end{pmatrix} & 0 \\ 0 & 0 \end{pmatrix}. $$

If $M_{12} \neq 0$ we fluctuate with

$$ r_1 = r_2 = \frac{1}{4}, \quad r_3 = \frac{1}{2}, \quad u_1 = 1_k, \quad v_1 = 1_\ell, \quad u_2 = \begin{pmatrix} 1_2 & 0 \\ 0 & -1_{k-2} \end{pmatrix}, \quad v_2 = 1_\ell, $$

$$ u_3 = 1_k, \quad v_3 = \begin{pmatrix} \begin{pmatrix} e^{-i\theta} & 0 \\ 0 & e^{i\theta} \end{pmatrix} & 0 \\ 0 & -1_{\ell-2} \end{pmatrix}, $$

with $\theta := \frac{1}{2}(\mathrm{Arg}(M_{11}) - \mathrm{Arg}(M_{12}))$ and obtain

$$ f_M = \begin{pmatrix} \begin{pmatrix} e^{i\theta}M_{11} & e^{-i\theta}M_{12} \\ 0 & 0 \end{pmatrix} & 0 \\ 0 & 0 \end{pmatrix}. $$

In both cases, we distribute the 2×2 block over the diagonal and achieve ${}^fM^{*fM}$ proportional to the identity.

In all three cases, ℓ must be one to avoid dynamical degeneracy.

The second diagram of Fig. 4 is treated in the same fashion. The last two diagrams of Fig. 4 have no letter changing arrow, an arrow connecting an a to a b. They are treated as the triples with one simple algebra: *Counting neutrinos*, that is requiring at most one zero eigenvalue (up to a possible color degeneracy) yields $\mathcal{A} = \mathbb{C} \oplus \mathbb{C}$ and degeneracy.

Finally using the permutations we get the list of all irreducible, dynamically nondegenerate triples with two algebras:

There are the commutative triples, that is the two-point spaces, $\mathcal{A} = \mathbb{C} \oplus \mathbb{C} \ni (a, b)$,

$$ \rho(a,b) = \begin{pmatrix} a & 0 & 0 & 0 \\ 0 & b & 0 & 0 \\ 0 & 0 & \overline{a} & 0 \\ 0 & 0 & 0 & \overline{a} \end{pmatrix}, \quad \text{and in } \mathcal{D},\ \mathcal{M} \in \mathbb{C}. \tag{7.1} $$

There is a second one with the same algebra,

$$ \rho(a,b) = \begin{pmatrix} \overline{a} & 0 & 0 & 0 \\ 0 & b & 0 & 0 \\ 0 & 0 & \overline{a} & 0 \\ 0 & 0 & 0 & \overline{a} \end{pmatrix}. \tag{7.2} $$

And there are the real versions, $\mathcal{A} = \mathbb{C} \oplus \mathbb{R}$, $\mathbb{R} \oplus \mathbb{C}$, and $\mathbb{R} \oplus \mathbb{R}$.

The noncommutative triples have $\mathcal{A} = M_2(\mathbb{C}) \oplus \mathbb{C} \ni (a, b)$ with four irreducible triples,

$$ \rho(a,b) = \begin{pmatrix} a \otimes 1_2 & 0 & 0 & 0 \\ 0 & b1_2 & 0 & 0 \\ 0 & 0 & 1_2 \otimes \overline{a} & 0 \\ 0 & 0 & 0 & \overline{a} \end{pmatrix}, \quad \mathcal{M} = \begin{pmatrix} 0 \\ m \end{pmatrix} \otimes 1_2, \quad m \in \mathbb{C}, \tag{7.3} $$

$$\rho(a,b)=\begin{pmatrix} \overline{a}\otimes 1_2 & 0 & 0 & 0\\ 0 & b1_2 & 0 & 0\\ 0 & 0 & 1_2\otimes\overline{a} & 0\\ 0 & 0 & 0 & \overline{a}\end{pmatrix},\quad \mathcal{M}=\begin{pmatrix}0\\ m\end{pmatrix}\otimes 1_2, \tag{7.4}$$

$$\rho(a,b)=\begin{pmatrix} a & 0 & 0 & 0\\ 0 & b & 0 & 0\\ 0 & 0 & \overline{b}1_2 & 0\\ 0 & 0 & 0 & \overline{b}\end{pmatrix},\quad \mathcal{M}=\begin{pmatrix}0\\ m\end{pmatrix}, \tag{7.5}$$

$$\rho(a,b)=\begin{pmatrix} a & 0 & 0 & 0\\ 0 & \overline{b} & 0 & 0\\ 0 & 0 & \overline{b}1_2 & 0\\ 0 & 0 & 0 & \overline{b}\end{pmatrix},\quad \mathcal{M}=\begin{pmatrix}0\\ m\end{pmatrix}, \tag{7.6}$$

In all four cases, all minima $\hat{f}\mathcal{D}$ are gauge equivalent to the Dirac operator $\mathcal{D}$ with the absolute value of m fixed in terms of λ and μ and the little groups are

$$G_\ell=\mathrm{U}(1)\times\mathrm{U}(1)\ni\left(\begin{pmatrix}e^{i\alpha} & 0\\ 0 & e^{-i\beta}\end{pmatrix},e^{i\beta}\right).$$

In the two triples (7.3) and (7.4), the unitaries of the color algebra, $M_2(\mathbb{C})$, are spontaneously broken, they do not leave any minimum invariant, $\mathrm{U}(2)\not\subset G_\ell$. According to our definition these two triples are dynamically degenerate.

Then there are diverse real versions: replace the complex 2×2 matrices $M_2(\mathbb{C})$ by quaternions $\mathbb{H}$ or by real matrices $M_2(\mathbb{R})$ and/or replace $\mathbb{C}$ by $\mathbb{R}$. For the real forms, of course, we have no complex conjugations in the representations. We summarize the little groups (arrows mean group homomorphisms):

$$\begin{array}{lll}
\mathbb{C}\oplus\mathbb{C} & \supset \mathrm{U}(1)\times\mathrm{U}(1) & \to \mathrm{U}(1),\\
\mathbb{C}\oplus\mathbb{R} & \supset \mathrm{U}(1)\times\mathbb{Z}_2 & \to \mathrm{U}(1),\\
\mathbb{R}\oplus\mathbb{R} & \supset \mathbb{Z}_2\times\mathbb{Z}_2 & \to \mathbb{Z}_2,\\
M_2(\mathbb{C})\oplus\mathbb{C} & \supset \mathrm{U}(2)\times\mathrm{U}(1) & \to \mathrm{U}(1)\times\mathrm{U}(1),\\
M_2(\mathbb{C})\oplus\mathbb{R} & \supset \mathrm{U}(2)\times\mathbb{Z}_2 & \to \mathrm{U}(1)\times\mathbb{Z}_2,\\
\mathbb{H}\oplus\mathbb{C} & \supset \mathrm{SU}(2)\times\mathrm{U}(1) & \to \mathrm{U}(1),\\
\mathbb{H}\oplus\mathbb{R} & \supset \mathrm{SU}(2)\times\mathbb{Z}_2 & \to \mathbb{Z}_2,\\
M_2(\mathbb{R})\oplus\mathbb{C} & \supset \mathrm{O}(2)\times\mathrm{U}(1) & \to \mathbb{Z}_2\times\mathbb{Z}_2,\\
M_2(\mathbb{R})\oplus\mathbb{R} & \supset \mathrm{O}(2)\times\mathbb{Z}_2 & \to \mathbb{Z}_2\times\mathbb{Z}_2.
\end{array} \tag{7.7}$$

The triples (7.3) or its commutative version (7.1) and (7.4) or its commutative version (7.2), (7.5), and (7.6) are represented by the four diagrams of Fig. 5.

VIII. THREE SIMPLE ALGEBRAS

A. Proof for $N=3$

So far, we found that all irreducible dynamically nondegenerate triples were associated to diagrams with letter changing arrows only, i.e., arrows connecting two different algebras. These

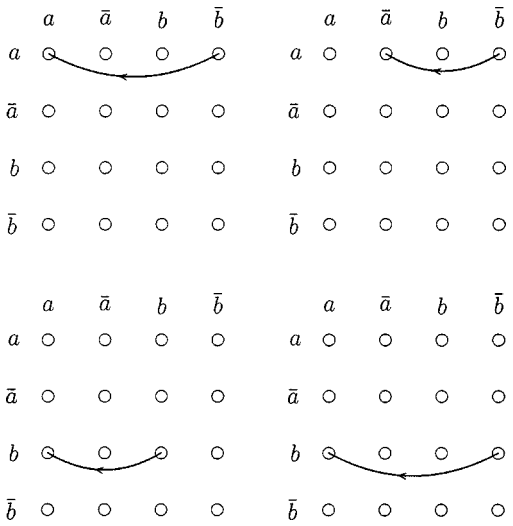

FIG. 5. Two algebras: all diagrams with nondegenerate triples.

arrows are stable under contraction of the multiplicity matrix. Therefore we start by constructing all irreducible contracted diagrams, Fig. 6. In other words we neglect the complex conjugate representations.

This list becomes exhaustive upon permutations of the three algebras $\mathcal{A}_1=M_n(\mathbb{K})\ni a$, $\mathcal{A}_2=M_m(\mathbb{K})\ni b$, $\mathcal{A}_3=M_q(\mathbb{K})\ni c$, upon permuting left and right, i.e., changing the directions of all two or three arrows simultaneously, and upon permutations of particles and antiparticles independently in every connected component of the diagram.

Let k, ℓ, p be the sizes of the matrices a,b,c.

Diagram 1 yields the following:

$$\rho_L(a,b,c)=\begin{pmatrix} a\otimes 1_k & 0 \\ 0 & b\otimes 1_\ell \end{pmatrix},\quad \rho_R(a,b,c)=\begin{pmatrix} b\otimes 1_k & 0 \\ 0 & c\otimes 1_\ell \end{pmatrix},$$

$$\rho_L^c(a,b,c)=\begin{pmatrix} 1_k\otimes a & 0 \\ 0 & 1_\ell\otimes b \end{pmatrix},\quad \rho_R^c(a,b,c)=\begin{pmatrix} 1_\ell\otimes a & 0 \\ 0 & 1_p\otimes b \end{pmatrix},$$

and

$$\mathcal{M}=\begin{pmatrix} M_1\otimes 1_k & 0 \\ 0 & M_2\otimes 1_\ell \end{pmatrix},\quad M_1\in M_{k\times\ell}(\mathbb{C}),\quad M_2\in M_{\ell\times p}(\mathbb{C}).$$

The fluctuations,

$${}^fM_1=\sum_j r_j u_j M_1 v_j^{-1},\quad u_j\in U(\mathcal{A}_1),\quad v_j\in U(\mathcal{A}_2),$$

$${}^fM_2=\sum_j r_j v_j M_2 w_j^{-1},\quad w_j\in U(\mathcal{A}_3),$$

produce two *decoupled* fields ${}^fM_1$ and ${}^fM_2$ as can be seen by applying the fluctuation, $r_1=1/2$, $u_1=1_k$, $v_1=1_\ell$, $w_1=1_p$, $r_2=1/2$, $u_2=1_k$, $v_2=1_\ell$, $w_2=-1_p$.

Since the arrows M_1 and M_2 are disconnected, the action is a sum of an action in ${}^fM_1$ and of an action in ${}^fM_2$. Proceeding as in the preceding section we find that a minimum $\hat{{}^fM_1}$ has $\min\{k,\ell\}$

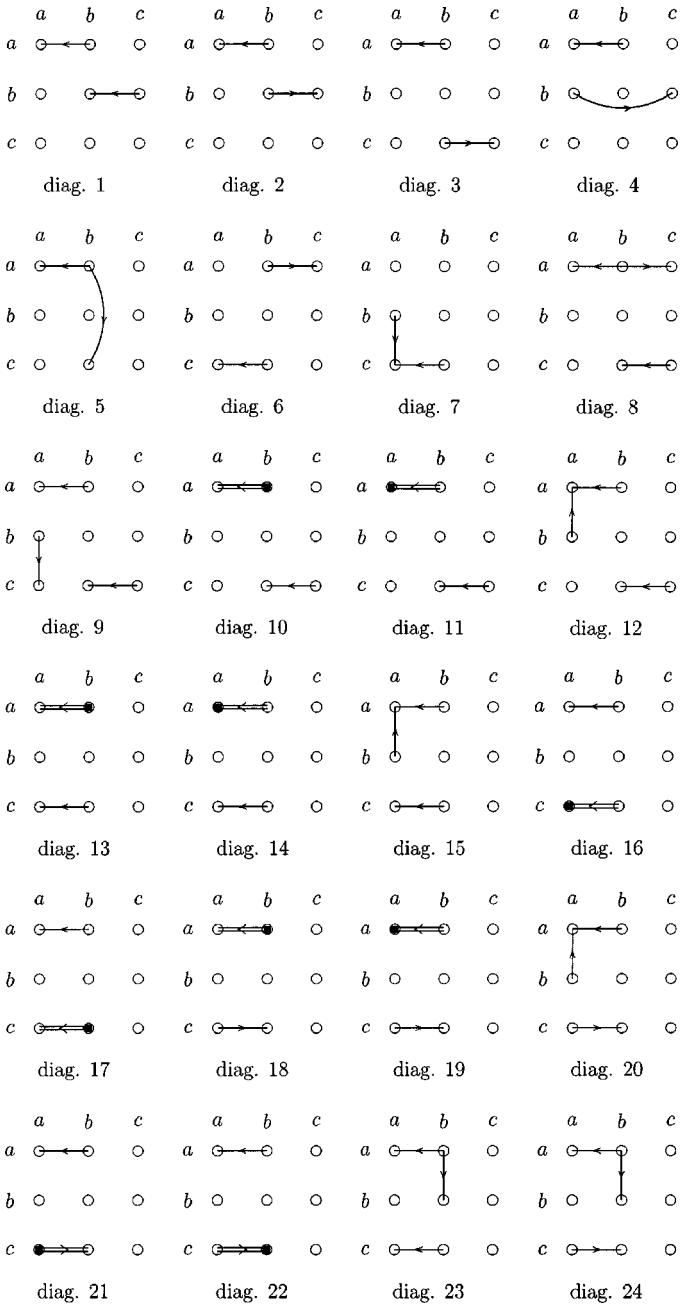

FIG. 6. Three algebras: all irreducible diagrams before blow up.

eigenvalues $\mu(4\lambda)^{-1/2}$ and $|k-\ell|$ eigenvalues zero $\hat{}^{f}M_2$ has $\min\{\ell,p\}$ eigenvalues $\mu(4\lambda)^{-1/2}$ and $|\ell-p|$ eigenvalues zero. All triples associated to the first diagram and therefore dynamically degenerate.

For the same reason, we can discard diagrams 2, 3, 4, 6, because they also have two disconnected horizontal arrows not vertically aligned.

Diagram 5 yields the following:

$$\rho_L(a,b,c)=\begin{pmatrix} a\otimes 1_k & 0 \\ 0 & b\otimes 1_p \end{pmatrix}, \quad \rho_R(a,b,c)=b\otimes 1_k,$$

$$\rho_L^c(a,b,c)=\begin{pmatrix}1_k\otimes a & 0\\ 0 & 1_\ell\otimes c\end{pmatrix},\quad \rho_R^c(a,b,c)=1_\ell\otimes a,$$

$$\mathcal{M}=\begin{pmatrix}M_1\otimes 1_k\\ 1_\ell\otimes M_2\end{pmatrix},\quad M_1\in M_{k\times\ell}(\mathbb{C}),\quad M_2\in M_{p\times k}(\mathbb{C}).$$

Again the fluctuations,

$${}^fM_1=\sum_j r_j u_j M_1 v_j^{-1},\quad u_j\in U(\mathcal{A}_1),\quad v_j\in U(\mathcal{A}_2),$$

$${}^fM_2=\sum_j r_j w_j M_2 u_j^{-1},\quad w_j\in U(\mathcal{A}_3),$$

produce two decoupled fields ${}^fM_1$ and ${}^fM_2$ but now the arrows are connected and consequently, the action does not decouple,

$$V(C_1,C_2)=4k[\lambda\ \mathrm{tr}(C_1^2)-\tfrac{1}{2}u^2\ \mathrm{tr}(C_1)]+4\ell[\lambda\ \mathrm{tr}(C_2^2)-\tfrac{1}{2}\mu^2\ \mathrm{tr}(C_2)]+8\lambda\ \mathrm{tr}(C_1)\mathrm{tr}(C_2),$$

where $C_i:={}^fM_i^{*}{}^fM_i$. Let $x_1,x_2,\ldots,x_\ell$ be the eigenvalues of C_1 and $y_1,y_2\ldots,y_k$ be the eigenvalues of C_2. The action only depends on these variables and in its minimum all x_i are equal or vanish and all y_i are equal or vanish. The spectrum of the minimal Dirac operator ${}^{\hat{f}}\mathcal{D}$ contains at most three nonvanishing numbers, $\sqrt{x}$, $\sqrt{y}$, $\sqrt{x+y}$ implying that k and ℓ are less than or equal to 2. The fermionic mass matrix $\mathcal{M}$ is of size $(k^2+\ell p)\times(k\ell)$. To get at most one zero eigenvalue we must require $|k^2+\ell p-k\ell|\leqslant 1$ implying $k=p=1$. For $\ell=1$ the minimum is at $|{}^{\hat{f}}M_1|^2+|{}^{\hat{f}}M_2|^2=\mu^2/4\lambda$, for $\ell=2$ the minimum is at ${}^{\hat{f}}M_1=0$, $|{}^{\hat{f}}M_2|^2=\mu^2/4\lambda$. In both cases, ${}^{\hat{f}}M_1=0$, the triple is degenerate in the sense that the Dirac operator has an invariant subspace in the kernel.

Diagram 7 falls in the same way.

Diagram 8 yields the representations

$$\rho_L(a,b,c)=\begin{pmatrix}a\otimes 1_k & 0 & 0\\ 0 & c\otimes 1_k & 0\\ 0 & 0 & b\otimes 1_p\end{pmatrix},\quad \rho_R(a,b,c)=\begin{pmatrix}b\otimes 1_k & 0\\ 0 & c\otimes 1_p\end{pmatrix},$$

$$\rho_L^c(a,b,c)=\begin{pmatrix}1_k\otimes a & 0 & 0\\ 0 & 1_p\otimes a & 0\\ 0 & 0 & 1_\ell\otimes c\end{pmatrix},\quad \rho_R^c(a,b,c)=\begin{pmatrix}1_\ell\otimes a & 0\\ 0 & 1_p\otimes c\end{pmatrix}.$$

The possible complex conjugations in the representation will not be important in this diagram. The mass matrix is

$$\mathcal{M}=\begin{pmatrix}M_1\otimes 1_k & 0\\ M_2\otimes 1_k & 0\\ 0 & M_3^{*}\otimes 1_p\end{pmatrix},\quad M_1\in M_{k\times\ell}(\mathbb{C}),\quad M_2,M_3\in M_{p\times\ell}(\mathbb{C}).$$

The fluctuations are

$$ {}^fM_1 = \sum_j r_j u_j M_1 v_j^{-1}, \quad u_j \in U(\mathcal{A}_1), \quad v_j \in U(\mathcal{A}_2), $$

$$ {}^fM_2 = \sum_j r_j w_j M_2 v_j^{-1}, \quad w_j \in U(\mathcal{A}_3), $$

$$ {}^fM_3 = \sum_j r_j w_j M_3 v_j^{-1}, $$

and the action is, with $C_i := {}^fM_i^{*\,f}M_i$,

$$ V(C_1,C_2,C_3) = 4k\left[\lambda\ \mathrm{tr}(C_1+C_2)^2 - \tfrac{1}{2}u^2\ \mathrm{tr}(C_1+C_2)\right] + 4p\left[\lambda\ \mathrm{tr}(C_3)^2 - \tfrac{1}{2}\mu^2\ \mathrm{tr}(C_3)\right]. $$

Requiring at most one zero eigenvalue (up to a possible color degeneracy) implies $k=1$, $\ell = p+1$ or $k=1$, $\ell = p$. In both cases ${}^fM_1$ and ${}^fM_2$ vary independently. The color group consists of the u's and w's. As they are spontaneously broken we must have $k=p=1$, leaving $\ell=1$ and $\ell=2$. In the commutative case with no complex conjugations in the representation, ${}^fM_3 = \beta\,{}^fM_2$ for a complex constant $\beta \neq 0$. If $|\beta| \geqslant 1$ the minimum is given by

$$ \left|\hat{f}M_1\right|^2 = \frac{(1-|\beta|^{-2})\mu^2}{4\lambda}, \quad \left|\hat{f}M_2\right|^2 = \frac{|\beta|^{-2}\mu^2}{4\lambda}, \quad \text{and } \left|\hat{f}M_3\right|^2 = \frac{\mu^2}{4\lambda}. $$

Its mass spectrum $\{0, \mu/4\lambda, \mu/4\lambda\}$ is dynamically degenerate. If $|\beta| \leqslant 1$ the minimum is given by

$$ \left|\hat{f}M_1\right|^2 = 0, \quad \left|\hat{f}M_2\right|^2 = \frac{1+|\beta|^2}{1+|\beta|^4}\frac{\mu^2}{4\lambda}, \quad \text{and } \left|\hat{f}M_3\right|^2 = \frac{|\beta|^2(1+|\beta|^2)}{1+|\beta|^4}\frac{\mu^2}{4\lambda}. $$

The triple is degenerate because of the invariant subspace in the kernel of the Dirac operator. With additional complex conjugations in the representation, ${}^{\hat{f}}M_3$ may decouple from ${}^{\hat{f}}M_2$ and the triple becomes dynamically degenerate as in diagram 1.

In the noncommutative case $k=1$, $\ell=2$, $p=1$, M_1 and M_2 must be linearly independent. To get a nondegenerate triple for any choice of $\mathcal{A}_1$ and $\mathcal{A}_3 = \mathbb{R}$ or $\mathbb{C}$ and $\mathcal{A}_2 = M_2(\mathbb{R})$, $M_2(\mathbb{C})$ or $\mathbb{H}$ it is sufficient to take the example $M_1 = (m_1, 0)$, $M_2 = (0, m_2)$, $M_3 = \beta M_2$. The minimum is given by ${}^{\hat{f}}M_1\,{}^{\hat{f}}M_2^* = 0$ and

$$ \left|\hat{f}M_1\right|^2 = \frac{\mu^2}{4\lambda}, \quad \left|\hat{f}M_2\right|^2 = \frac{1+|\beta|^2}{1+|\beta|^4}\frac{\mu^2}{4\lambda}, \quad \text{and } \left|\hat{f}M_3\right|^2 = |\beta|^2\frac{1+|\beta|^2}{1+|\beta|^4}\frac{\mu^2}{4\lambda}, $$

dynamically nondegenerate for $\beta \neq 0$ and $|\beta| \neq 1$.

Let us note a new phenomenon: the three eigenvalues of a minimum ${}^{\hat{f}}\mathcal{D}$ are tied together by a *mass relation*. Its origin is clear, when we add more and more irreducible components to the Hilbert space the number of possible fluctuations does not change, the number of components in the Dirac operator increases. This phenomenon does not only occur for the particular choice of the mass matrices M_1, M_2, and M_3 above, but is generic for diagram 8. The little groups are the same as the last six in (7.7).

Diagram 9 yields the representations

$$ \rho_L(a,b,c) = \begin{pmatrix} a\otimes 1_k & 0 & 0 \\ 0 & a\otimes 1_p & 0 \\ 0 & 0 & b\otimes 1_p \end{pmatrix}, \quad \rho_R(a,b,c) = \begin{pmatrix} b\otimes 1_k & 0 & 0 \\ 0 & a\otimes 1_\ell & 0 \\ 0 & 0 & c\otimes 1_p \end{pmatrix}, $$

$$\rho_L^c(a,b,c)=\begin{pmatrix}1_k\otimes a & 0 & 0\\ 0 & 1_k\otimes c & 0\\ 0 & 0 & 1_\ell\otimes c\end{pmatrix},\quad \rho_R^c(a,b,c)=\begin{pmatrix}1_\ell\otimes a & 0 & 0\\ 0 & 1_k\otimes b & 0\\ 0 & 0 & 1_p\otimes c\end{pmatrix},$$

with possible complex conjugations. The mass matrix is

$$\mathcal{M}=\begin{pmatrix}M_1\otimes 1_k & 0 & 0\\ 0 & 1_k\otimes M_2^* & 0\\ 0 & 0 & M_3\otimes 1_p\end{pmatrix},\quad M_1\in M_{k\times\ell}(\mathbb{C}),\quad M_2,M_3\in M_{\ell\times p}(\mathbb{C}).$$

The fluctuations are

$$^fM_1=\sum_j r_j u_j M_1 v_j^{-1},\quad u_j\in U(\mathcal{A}_1),\quad v_j\in U(\mathcal{A}_2),$$

$$^fM_2=\sum_j r_j u_j M_2 w_j^{-1},\quad w_j\in U(\mathcal{A}_3),$$

$$^fM_3=\sum_j r_j v_j M_3 w_j^{-1},$$

and the action $V(C_1,C_2,C_3)$ is equal to

$$4k[\lambda\ \mathrm{tr}(C_1)^2-\tfrac{1}{2}\mu^2\ \mathrm{tr}(C_1)]+4k[\lambda\ \mathrm{tr}(C_2)^2-\tfrac{1}{2}\mu^2\ \mathrm{tr}(C_2)]+4p[\lambda\ \mathrm{tr}(C_3)^2-\tfrac{1}{2}\mu^2\ \mathrm{tr}(C_3)].$$

Counting neutrinos and imposing broken color to be commutative leaves only one case, $k=\ell=p=1$. We choose $M_3=\beta M_2$ and get the minima at

$$\left|\hat{f}_{M_1}\right|^2=\frac{\mu^2}{4\lambda},\quad \left|\hat{f}_{M_2}\right|^2=\frac{1+|\beta|^2}{1+|\beta|^4}\frac{\mu^2}{4\lambda},\quad \left|\hat{f}_{M_3}\right|^2=|\beta|^2\frac{1+|\beta|^2}{1+|\beta|^4}\frac{\mu^2}{4\lambda},$$

so it is dynamically nondegenerate for $\beta\neq 0$ and $|\beta|\neq 1$.

Diagram 10 yields the representations

$$\rho_L(a,b,c)=\begin{pmatrix}a\otimes 1_k & 0 & 0\\ 0 & a\otimes 1_k & 0\\ 0 & 0 & b\otimes 1_p\end{pmatrix},\quad \rho_R(a,b,c)=\begin{pmatrix}b\otimes 1_k & 0\\ 0 & c\otimes 1_p\end{pmatrix},$$

$$\rho_L^c(a,b,c)=\begin{pmatrix}1_k\otimes a & 0 & 0\\ 0 & 1_k\otimes a & 0\\ 0 & 0 & 1_\ell\otimes c\end{pmatrix},\quad \rho_R^c(a,b,c)=\begin{pmatrix}1_\ell\otimes a & 0\\ 0 & 1_p\otimes c\end{pmatrix},$$

with possible complex conjugations. The mass matrix is

$$\mathcal{M}=\begin{pmatrix}M_1\otimes 1_k & 0\\ M_2\otimes 1_k & 0\\ 0 & M_3\otimes 1_p\end{pmatrix},\quad M_1,M_2\in M_{k\times\ell}(\mathbb{C}),\quad M_3\in M_{\ell\times p}(\mathbb{C}).$$

The fluctuations are

$$^fM_1 = \sum_j r_j u_j M_1 v_j^{-1}, \quad u_j \in U(\mathcal{A}_1), \quad v_j \in U(\mathcal{A}_2),$$

$$^fM_2 = \sum_j r_j u_j M_2 v_j^{-1},$$

$$^fM_3 = \sum_j r_j v_j M_3 w_j^{-1}, \quad w_j \in U(\mathcal{A}_3),$$

and the action is

$$V(C_1,C_2,C_3) = 4k[\lambda\ \mathrm{tr}(C_1+C_2)^2 - \tfrac{1}{2}u^2\ \mathrm{tr}(C_1+C_2)] + 4p\left[\lambda\ \mathrm{tr}(C_3)^2 - \frac{1}{2}\mu^2\ \mathrm{tr}(C_3)\right].$$

Neutrino counting implies $k=1$, $\ell=2$, $p=1$ or $k=\ell=p=1$. In both cases $^fM_3$ varies independently of $^fM_1$ and $^fM_2$.

The commutative case has always $|\hat{}^fM_1|^2+|\hat{}^fM_2|^2=|\hat{}^fM_3|^2=\mu^2(4\lambda)^{-1}$ and is dynamically degenerate.

In the noncommutative case $k=1$, $\ell=2$, $p=1$, M_1 and M_2 must be linearly independent. For $\mathcal{A}_1\oplus\mathcal{A}_2=\mathbb{R}\oplus M_2(\mathbb{C})$, $\mathbb{C}\oplus M_2(\mathbb{R})$, and $\mathbb{C}\oplus M_2(\mathbb{C})$, lemma 11.6 decouples $^fM_1$ and $^fM_2$ and the triples are dynamically degenerate, $\hat{}^fM_1=(\mu(4\lambda)^{-1/2},0)$, $\hat{}^fM_2=(0,\mu(4\lambda)^{-1/2})$, $\hat{}^fM_3=(0,\mu(4\lambda)^{-1/2})^T$. For $\mathcal{A}_1\oplus\mathcal{A}_2=\mathbb{R}\oplus\mathbb{H}$ and $\mathbb{C}\oplus\mathbb{H}$ we choose

$$\rho_L(a,b,c) = \begin{pmatrix} a\otimes 1_k & 0 & 0 \\ 0 & \overline{a}\otimes 1_k & 0 \\ 0 & 0 & b\otimes 1_p \end{pmatrix}, \quad M_1=(m_1,0), \quad M_2=(0,\alpha m_1).$$

Its minimum has the nondegenerate spectrum $\{(1+|\alpha|^2)/(1+|\alpha|^4),[|\alpha|^2(1+|\alpha|^2)/(1+|\alpha|^4)],1,0\}$ in units of $\mu^2/4\lambda$ with one mass relation. Finally for $\mathcal{A}_1\oplus\mathcal{A}_2=\mathbb{R}\oplus M_2(\mathbb{C})$ we choose $M_1=(i,1)$ and $M_2=(1,0)$ to obtain the nondegenerate spectrum $\{(2\pm\sqrt{2})/3,1,0\}$ in units of $\mu^2/4\lambda$.

Diagram 11 yields the representations

$$\rho_L(a,b,c) = \begin{pmatrix} a\otimes 1_k & 0 \\ 0 & b\otimes 1_p \end{pmatrix}, \quad \rho_R(a,b,c) = \begin{pmatrix} b\otimes 1_k & 0 & 0 \\ 0 & b\otimes 1_k & 0 \\ 0 & 0 & c\otimes 1_p \end{pmatrix},$$

$$\rho_L^c(a,b,c) = \begin{pmatrix} 1_k\otimes a & 0 \\ 0 & 1_\ell\otimes c \end{pmatrix}, \quad \rho_R^c(a,b,c) = \begin{pmatrix} 1_\ell\otimes a & 0 & 0 \\ 0 & 1_\ell\otimes a & 0 \\ 0 & 0 & 1_p\otimes c \end{pmatrix},$$

with possible complex conjugations. The mass matrix is

$$\mathcal{M}=\begin{pmatrix} M_1\otimes 1_k & M_2\otimes 1_k & 0\\ 0 & 0 & M_3\otimes 1_p\end{pmatrix},\quad M_1,M_2\in M_{k\times\ell}(\mathbb{C}),\quad M_3\in M_{\ell\times p}(\mathbb{C}).$$

The fluctuations are

$$^fM_1=\sum_j r_j u_j M_1 v_j^{-1},\quad u_j\in U(\mathcal{A}_1),\quad v_j\in U(\mathcal{A}_2),$$

$$^fM_2=\sum_j r_j u_j M_2 v_j^{-1},$$

$$^fM_3=\sum_j r_j u_j M_3 w_j^{-1},\quad w_j\in U(\mathcal{A}_3),$$

and then action is

$$V(C_1,C_2,C_3)=4k[\lambda\ \mathrm{tr}(C_1+C_2)^2-\tfrac{1}{2}u^2\ \mathrm{tr}(C_1+C_2)]+4p[\lambda\ \mathrm{tr}(C_3)^2-\tfrac{1}{2}\mu^2\ \mathrm{tr}(C_3)].$$

Neutrino counting and imposing broken color to be commutative leaves only one possibility, $k=\ell=p=1$, which is treated as the case $k=\ell=p=1$ of diagram 10 with the same conclusion, degeneracy.

Diagram 12 yields the representations

$$\rho_L(a,b,c)=\begin{pmatrix} a\otimes 1_k & 0\\ 0 & b\otimes 1_p\end{pmatrix},\quad \rho_R(a,b,c)=\begin{pmatrix} b\otimes 1_k & 0 & 0\\ 0 & a\otimes 1_\ell & 0\\ 0 & 0 & c\otimes 1_p\end{pmatrix},$$

$$\rho_L^c(a,b,c)=\begin{pmatrix} 1_k\otimes a & 0\\ 0 & 1_\ell\otimes c\end{pmatrix},\quad \rho_R^c(a,b,c)=\begin{pmatrix} 1_\ell\otimes a & 0 & 0\\ 0 & 1_k\otimes b & 0\\ 0 & 0 & 1_\ell\otimes c\end{pmatrix},$$

with possible complex conjugations. The mass matrix is

$$\mathcal{M}=\begin{pmatrix} M_1\otimes 1_k & 1_k\otimes M_2 & 0\\ 0 & 0 & M_3\otimes 1_p\end{pmatrix},\quad M_1,M_2\in M_{k\times\ell}(\mathbb{C}),\quad M_3\in M_{\ell\times p}(\mathbb{C}).$$

The fluctuations are

$$^fM_1=\sum_j r_j u_j M_1 v_j^{-1},\quad u_j\in \mathrm{U}(\mathcal{A}_1),\quad v_j\in \mathrm{U}(\mathcal{A}_2),$$

$$^fM_2=\sum_j r_j u_j M_2 v_j^{-1},$$

$$^fM_3=\sum_j r_j v_j M_3 w_j^{-1},\quad w_j\in \mathrm{U}(\mathcal{A}_3).$$

The action $V(C_1,C_2,C_3)$ equals

$$4k[\lambda\ \mathrm{tr}(C_1)^2-\tfrac{1}{2}\mu^2\ \mathrm{tr}(C_1)]+4k[\lambda\ \mathrm{tr}(C_2)^2-\tfrac{1}{2}\mu^2\ \mathrm{tr}(C_2)]+8\lambda\ \mathrm{tr}(C_1)\mathrm{tr}(C_2)+4p[\lambda\ \mathrm{tr}(C_3)^2-\tfrac{1}{2}\mu^2\ \mathrm{tr}(C_3)].$$

Since the neutrino count and imposing broken color to be commutative implies $k=\ell=p=1$. Then $M_2=\alpha M_1$ and we must distinguish two cases, $^fM_2=\alpha\,^fM_1$ or $^fM_1$ and $^fM_2$ independent. Both

possibilities have a dynamically degenerate minimum, $|\hat{}^f M_1|^2+|\hat{}^f M_2|^2=|\hat{}^f M_3|^2=\mu^2/4\lambda$.

Diagram 13 has a *ladder form*, i.e., it consists of horizontal arrows, vertically aligned. Its representations are

$$\rho_L(a,b,c)=\begin{pmatrix} a\otimes 1_k & 0 & 0\\ 0 & a\otimes 1_k & 0\\ 0 & 0 & a\otimes 1_p\end{pmatrix},\quad \rho_R(a,b,c)=\begin{pmatrix} b\otimes 1_k & 0\\ 0 & b\otimes 1_p\end{pmatrix},$$

$$\rho_L^c(a,b,c)=\begin{pmatrix} 1_k\otimes a & 0 & 0\\ 0 & 1_k\otimes a & 0\\ 0 & 0 & 1_k\otimes c\end{pmatrix},\quad \rho_R^c(a,b,c)=\begin{pmatrix} 1_\ell\otimes a & 0\\ 0 & 1_\ell\otimes c\end{pmatrix},$$

with possible complex conjugations here and there. The mass matrix is

$$\mathcal{M}=\begin{pmatrix} M_1\otimes 1_k & 0\\ M_2\otimes 1_k & 0\\ 0 & M_3\otimes 1_p\end{pmatrix},\quad M_1,M_2,M_3\in M_{k\times\ell}(\mathbb{C}).$$

The fluctuations are

$$^fM_1=\sum_j r_j u_j M_1 v_j^{-1},\quad u_j\in \mathrm{U}(\mathcal{A}_1),\quad v_j\in \mathrm{U}(\mathcal{A}_2),$$

$$^fM_2=\sum_j r_j u_j M_2 v_j^{-1},$$

$$^fM_3=\sum_j r_j u_j M_3 v_j^{-1},$$

and the action is

$$V(C_1,C_2,C_3)=4k[\lambda\ \mathrm{tr}(C_1+C_2)^2-\tfrac{1}{2}\mu^2\ \mathrm{tr}(C_1+C_2)]+4p[\lambda\ \mathrm{tr}(C_3)^2-\tfrac{1}{2}\mu^2\ \mathrm{tr}(C_3)].$$

The neutrino count implies $k=1,\ell=2$ or $k=\ell=1$.

The case $k=\ell=1$ has the following possibilities.

Case 1: $\mathbb{R}\oplus\mathbb{R}\oplus\mathcal{C}$, where $\mathcal{C}$ is any simple color algebra. All possible triples are degenerate in the sense that the Dirac operator has an invariant subspace in its kernel.

Case 2: $\mathbb{R}\oplus\mathbb{C}\oplus\mathcal{C}$, all possible triples are degenerate.

Case 3: $\mathbb{C}\oplus\mathbb{R}\oplus\mathcal{C}\ni(a,b,c)$. The nondegenerate triples have

$$\rho_L(a,b,c)=\begin{pmatrix} a & 0 & 0\\ 0 & \overline{a} & 0\\ 0 & 0 & \overline{a}\otimes 1_p\end{pmatrix},\quad \rho_R(a,b,c)=\begin{pmatrix} b & 0\\ 0 & b\otimes 1_p\end{pmatrix}.$$

The fluctuations respect the mass ratios: $|M_1|:|M_2|:|M_3|=\underline{|}^fM_1\underline{|}:|^fM_2|:|^fM_3|$. If M_1 and M_2 are different from zero, the kernel of the Dirac operator, $\mathbb{C}(-M_2,M_1,01,0;-M_2,M_1,0,0,0)^T$, is not invariant under $a\in\mathbb{C}$. If $|M_3|^2\neq|M_1|^2+|M_2|^2$, the triple is dynamically nondegenerate.

Case 4: $\mathbb{C}\oplus\mathbb{C}\oplus\mathcal{C}\ni(a,b,c)$. The only not obviously degenerate triples have the representations

$$\rho_L(a,b,c)=\begin{pmatrix} a & 0 & 0 \\ 0 & \overline{a} & 0 \\ 0 & 0 & \overline{a}\otimes 1_p \end{pmatrix},\quad \rho_R(a,b,c)=\begin{pmatrix} b & 0 \\ 0 & b\otimes 1_p \end{pmatrix}. \tag{8.1}$$

and

$$\rho_L(a,b,c)=\begin{pmatrix} a & 0 & 0 \\ 0 & \overline{a} & 0 \\ 0 & 0 & \overline{a}\otimes 1_p \end{pmatrix},\quad \rho_R(a,b,c)=\begin{pmatrix} b & 0 \\ 0 & \overline{b}\otimes 1_p \end{pmatrix}. \tag{8.2}$$

The fluctuations do not respect all mass ratios, in fact ${}^fM_1$ and ${}^fM_2$ are independent variables and only the ratio $M_2/M_3={}^fM_2/{}^fM_3=:1/\beta$ is invariant under fluctuations via (8.1). If $|\beta|\geqslant 1$ the minima are given by

$$\left|\hat{f}M_1\right|^2=\frac{(1-|\beta|^{-2})\mu^2}{4\lambda},\quad \left|\hat{f}M_2\right|^2=\frac{\mu^2}{|\beta|^2 4\lambda},\quad \text{and}\quad \left|\hat{f}M_3\right|^2=\frac{\mu^2}{4\lambda}.$$

Its mass spectrum $\{0,\mu/2\sqrt{\lambda},\mu/2\sqrt{\lambda}\ p\ \text{times}\}$ is dynamically degenerate. If $|\beta|\leqslant 1$ the minima are given by

$$\left|\hat{f}M_1\right|^2=0,\quad \left|\hat{f}M_2\right|^2=\frac{1+p|\beta|^2}{1+p|\beta|^4}\,\frac{\mu^2}{4\lambda},\quad \text{and}\quad \left|\hat{f}M_3\right|^2=\frac{|\beta|^2(1+p|\beta|^2)}{1+p|\beta|^4}\frac{\mu^2}{4\lambda}.$$

The triple is degenerate since there is an invariant subspace in the kernel of the Dirac operator. For the representation (8.2) the computational are identical to the case above, (8.1), after permuting M_1 and M_2 and after replacing M_3 by $\overline{M_3}$.

In the case $k=1$, $\ell=2$, the three submatrices M_1, M_2, M_3 are linearly dependent over $\mathbb{C}$. If M_1 is proportional to M_2 then both M_3 and $\binom{M_1}{M_2}$ have a zero eigenvalue. Therefore M_1 and M_2 are linearly independent over $\mathbb{C}$ and $M_3=:\alpha M_1+\beta M_2$ with complex coefficients α and β.

Case 5: $\mathbb{C}\oplus M_2(\mathbb{C})\oplus\mathcal{C}\ni(a,b,c)$. By lemma 11.6, ${}^fM_1$ and ${}^fM_2$ vary independently in $\mathbb{C}^2$. For the representations with

$$\rho_L(a,b,c)=\begin{pmatrix} a & 0 & 0 \\ 0 & a & 0 \\ 0 & 0 & a\otimes 1_p \end{pmatrix},\quad \rho_R(a,b,c)=\begin{pmatrix} b & 0 \\ 0 & b\otimes 1_p \end{pmatrix}, \tag{8.3}$$

we get ${}^fM_3=:\alpha{}^fM_1+\beta{}^fM_2$. For instance for $\alpha=0$ we get $\hat{f}M_1\hat{f}M_2=0$ as for diagram 8 and a similar mass relation,

$$\left|\hat{f}M_1\right|^2=\frac{\mu^2}{4\lambda},\quad \left|\hat{f}M_2\right|^2=\frac{(1+p|\beta|^2)}{1+p|\beta|^4}\,\frac{\mu^2}{4\lambda},\quad \left|\hat{f}M_3\right|^2=|\beta|^2\frac{1+p|\beta|^2}{1+p|\beta|^4}\frac{\mu^2}{4\lambda}. \tag{8.4}$$

For general α, we get the same relations with $|\beta|^2$ replaced by $|\alpha|^2+|\beta|^2$. For the representations with

$$\rho_L(a,b,c)=\begin{pmatrix} a & 0 & 0 \\ 0 & \overline{a} & 0 \\ 0 & 0 & \overline{a}\otimes 1_p \end{pmatrix},\quad \rho_R(a,b,c)=\begin{pmatrix} b & 0 \\ 0 & b\otimes 1_p \end{pmatrix},$$

and $\alpha\neq 0$, all three doublets, ${}^fM_1$, ${}^fM_2$, and ${}^fM_3$ vary independently. The minima, $|\hat{f}M_1|^2+|\hat{f}M_2|^2=|\hat{f}M_3|^2=\mu^2/4\lambda$ produce a dynamical degeneracy in this case. The other case, $\alpha=0$ is dynamically nondegenerate with the same mass relations as above, equations (8.4). All other representations of this algebra are treated the same way and they either have a mass relation or are

dynamically degenerate, which means a particularly simple mass relations.

Case 6: $\mathbb{R}\oplus M_2(\mathbb{C})\oplus\mathcal{C}$. This case is identical to case 5 with representation (8.3)

Case 7: $\mathbb{C}\oplus\mathbb{H}\oplus\mathcal{C}\ni(a,b,c)$. For example, all triples with

$$\rho_L(a,b,c)=\begin{pmatrix} a & 0 & 0\\ 0 & \overline{a} & 0\\ 0 & 0 & \overline{a}\otimes 1_p\end{pmatrix},\quad \rho_R(a,b,c)=\begin{pmatrix} b & 0\\ 0 & b\otimes 1_p\end{pmatrix},$$

$M_1=(m_1,0)$, $M_2=(0,m_2)$, and $M_3=(0,m_3)$ have no mass relation. Indeed like in case 3, the mass ratios are stable under fluctuations: $|M_1|:|M_2|:|M_3|=|{}^fM_1|:|{}^fM_2|:|{}^fM_3|$. Other triples behave like in case 5.

Case 8: $\mathbb{R}\oplus\mathbb{H}\oplus\mathcal{C}$ has the same examples without mass relations as in case 7.

Case 9: $\mathbb{C}\oplus M_2(\mathbb{R})\oplus\mathcal{C}$. For representations (8.3) and $\alpha=0$, we get minima with mass relation (8.4).

Case 10: $\mathbb{R}\oplus M_2(\mathbb{R})\oplus\mathcal{C}$. Here we take a representation (8.3) with $M_1=(m_1,0)$, $M_2=(0,m_2)$, and $M_3=(0,\beta m_2)$ and get again the mass relation (8.4).

Up to different multiplicities, we have the same conclusion for the diagrams 18, 17, 22. After permuting $\mathcal{A}_1$ and $\mathcal{A}_2$ we also have the same results for the other four ladders, diagrams 14, 19, 16, 21.

Diagram 15 yields the representations

$$\rho_L(a,b,c)=\begin{pmatrix} a\otimes 1_k & 0\\ 0 & a\otimes 1_p\end{pmatrix},\quad \rho_R(a,b,c)=\begin{pmatrix} b\otimes 1_k & 0 & 0\\ 0 & a\otimes 1_\ell & 0\\ 0 & 0 & b\otimes 1_p\end{pmatrix},$$

$$\rho_L^c(a,b,c)=\begin{pmatrix} 1_k\otimes a & 0\\ 0 & 1_k\otimes c\end{pmatrix},\quad \rho_R^c(a,b,c)=\begin{pmatrix} 1_\ell\otimes a & 0 & 0\\ 0 & 1_k\otimes b & 0\\ 0 & 0 & 1_\ell\otimes c\end{pmatrix},$$

with possible complex conjugations. The mass matrix is

$$\mathcal{M}=\begin{pmatrix} M_1\otimes 1_k & 1_k\otimes M_2 & 0\\ 0 & 0 & M_3\otimes 1_p\end{pmatrix},\quad M_1,M_2,M_3\in M_{k\times\ell}(\mathbb{C}).$$

The fluctuations are

$${}^fM_1=\sum_j r_j u_j M_1 v_j^{-1},\quad u_j\in \mathrm{U}(\mathcal{A}_1),\quad v_j\in \mathrm{U}(\mathcal{A}_2),$$

$${}^fM_2=\sum_j r_j u_j M_2 v_j^{-1},$$

$${}^fM_3=\sum_j r_j u_j M_3 v_j^{-1}.$$

Neutrino counting and imposing broken color to be commutative implies $k=\ell=1$. This case with $\mathcal{A}_1$ and $\mathcal{A}_2=\mathbb{R}$ or $\mathbb{C}$ is treated as in diagram 13, case 3 yielding a nondegenerate triple without mass relation. After replacing M_3^* by M_3, diagram 20 has identical computations.

Diagram 23 yields the representations

$$\rho_L(a,b,c)=\begin{pmatrix} a\otimes 1_k & 0 & 0\\ 0 & b\otimes 1_\ell & 0\\ 0 & 0 & b\otimes 1_p\end{pmatrix},\quad \rho_R(a,b,c)=\begin{pmatrix} b\otimes 1_k & 0\\ 0 & a\otimes 1_p\end{pmatrix},$$

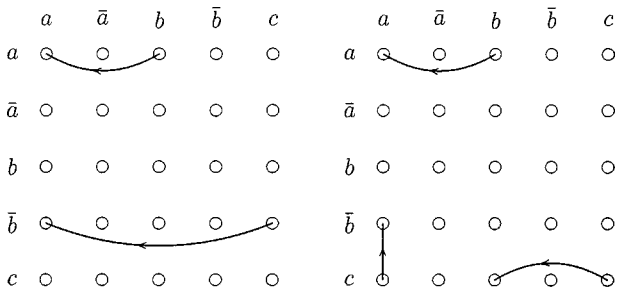

FIG. 7. Two blow ups, letter changing arrows only.

$$\rho_L^c(a,b,c)=\begin{pmatrix} 1_k\otimes a & 0 & 0\\ 0 & 1_\ell\otimes b & 0\\ 0 & 0 & 1_\ell\otimes c\end{pmatrix},\quad \rho_R^c(a,b,c)=\begin{pmatrix} 1_\ell\otimes a & 0\\ 0 & 1_k\otimes c\end{pmatrix},$$

with possible complex conjugations. The mass matrix is

$$\mathcal{M}=\begin{pmatrix} M_1\otimes 1_k & 0\\ 1_\ell\otimes M_2^* & 0\\ 0 & M_3^*\otimes 1_p\end{pmatrix},\quad M_1,M_2,M_3\in M_{k\times\ell}(\mathbb{C}).$$

The fluctuations are

$$^fM_1=\sum_j r_j u_j M_1 v_j^{-1},\quad u_j\in \mathrm{U}(\mathcal{A}_1),\quad v_j\in \mathrm{U}(\mathcal{A}_2),$$

$$^fM_2=\sum_j r_j u_j M_2 v_j^{-1},$$

$$^fM_3=\sum_j r_j u_j M_3 v_j^{-1}.$$

Neutrino counting implies $k=\ell=1$. This model with $\mathcal{A}_1$ and $\mathcal{A}_2=\mathbb{R}$ or $\mathbb{C}$ is treated as in diagram 13, case 3 yielding a nondegenerate triple without mass relation. After replacing M_3^* by M_3, diagram 24 has identical computations.

We must now extend our analysis to include the possibility of complex conjugate representations. As in the case of two algebras, one shows that any diagram containing a connected component consisting of only letter unchanging arrows leads to degenerate spectra. Therefore within the class of irreducible and dynamically nondegenerate triples the leitmotiv of a Krajewski diagram is still carried by its letter changing arrows. For three algebras there are two additional diagrams, diagrams 25, 26, Fig. 7, that involve only letter changing arrows. Their contracted diagrams resemble diagrams 4 and 9 of Fig. 6 except for the change of chirality in one arrow and the computation of their triples is similar.

Note that without the presence of conjugate representations, this change violates the condition that nonvanishing entries of the multiplicity matrix and its transposed must have the same signs. Figure 8 lists the contractions of all irreducible diagrams whose letter unchanging arrows are connected to at least one letter changing arrow. The blow up of the new symbols is given in Fig. 9.

All triples attached to the 11 diagrams of Fig. 8 are degenerate or dynamically degenerate.

Diagram 27 with the first blow up yields

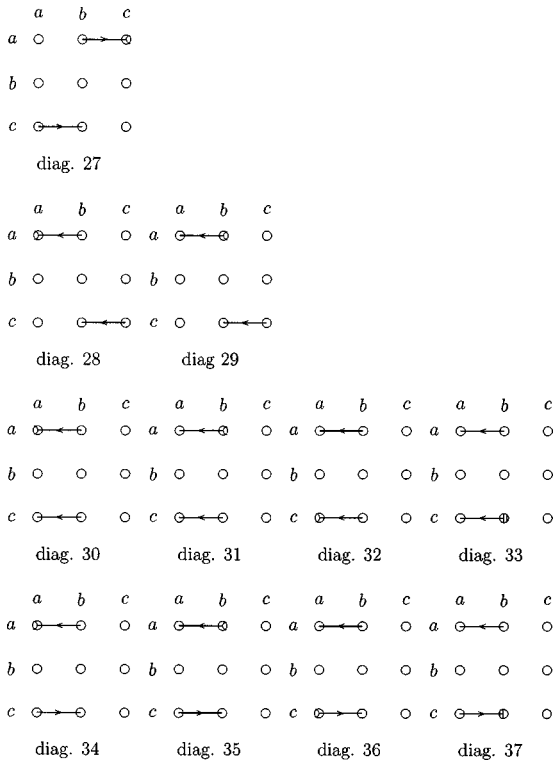

FIG. 8. Irreducible diagrams with letter unchanging arrows.

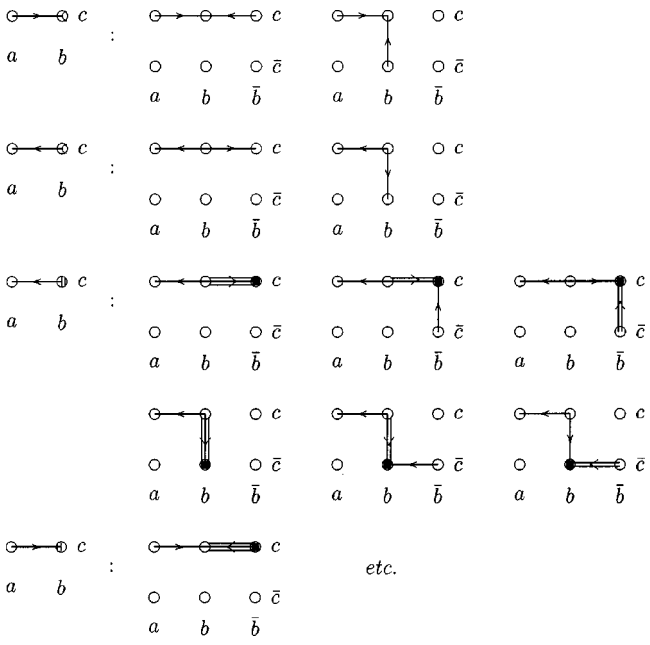

FIG. 9. Blow ups with letter unchanging arrows.

$$\rho_L(a,b,c)=\begin{pmatrix} c\otimes 1_k & 0 \\ 0 & b\otimes 1_p \end{pmatrix},\quad \rho_R(a,b,c)=\begin{pmatrix} b\otimes 1_k & 0 & 0 \\ 0 & \overline{c}\otimes 1_k & 0 \\ 0 & 0 & a\otimes 1_p \end{pmatrix},$$

$$\mathcal{M}=\begin{pmatrix} M_1\otimes 1_k & M_2\otimes 1_k & 0 \\ 0 & 0 & M_3\otimes 1_p \end{pmatrix},$$

$M_1\in M_{p\times\ell}(\mathbb{C})$, $M_2\in M_{p\times p}(\mathbb{C})$, $M_3\in M_{\ell\times k}(\mathbb{C})$. Counting neutrinos leads to $k=\ell=1$. To get a handle on p we repeat the overkill from Sec. IV. in the worst case M_2 and consequently ${}^fM_2$ is skewsymmetric and p is odd. By fluctuations we can obtain

$${}^fM_2=\begin{pmatrix} \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix} & & & \\ & \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix} & & \\ & & \ddots & \\ & & & 0 \end{pmatrix}=:\begin{pmatrix} A & 0 \\ 0 & 0 \end{pmatrix}.$$

Now ${}^fM_1$ fluctuates independently and we may obtain for its transpose ${}^fM_1^T=(0,\cdots,0,1)$. We get $({}^fM_1,{}^fM_2)({}^fM_1,{}^fM_2)^*=1_p$ and the minimum of the action is dynamically degenerate if $p\geqslant 1$. The commutative case $k=\ell=p=1$ is obviously degenerate. For the second blow up the computations are similar with ${}^fM_2$ now proportional to 1_p from the start.

Diagram 28 is treated as diagram 27.

Diagram 29 has $k=\ell=p=1$ by neutrino count and admits only degenerate triples.

Diagrams 30, 31, 32, 34, 35, 36 have $k=\ell=1$ by neutrino count. As in the commutative case of diagram 8, all their triples are degenerate.

Diagram 33 with the first of the six possible blow ups yields

$$\rho_L(a,b,c)=\begin{pmatrix} a\otimes 1_k & 0 & 0 \\ 0 & a\otimes 1_p & 0 \\ 0 & 0 & \overline{b}\otimes 1_p \end{pmatrix},$$

$$\rho_R(a,b,c)=\begin{pmatrix} b\otimes 1_k & 0 & 0 & 0 \\ 0 & b\otimes 1_p & 0 & 0 \\ 0 & 0 & b\otimes 1_p & 0 \\ 0 & 0 & 0 & b\otimes 1_p \end{pmatrix},$$

$$\rho_L^c(a,b,c)=\begin{pmatrix} 1_k\otimes a & 0 & 0 \\ 0 & 1_k\otimes c & 0 \\ 0 & 0 & 1_\ell\otimes c \end{pmatrix},$$

$$\rho_R^c(a,b,c)=\begin{pmatrix} 1_\ell\otimes a & 0 & 0 & 0 \\ 0 & 1_\ell\otimes c & 0 & 0 \\ 0 & 0 & 1_\ell\otimes c & 0 \\ 0 & 0 & 0 & 1_\ell\otimes c \end{pmatrix},$$

$$\mathcal{M}=\begin{pmatrix} M_1\otimes 1_k & 0 & 0 & 0 \\ 0 & M_2\otimes 1_p & 0 & 0 \\ 0 & M_3\otimes 1_p & M_4\otimes 1_p & M_5\otimes 1_p \end{pmatrix},$$

$M_1, M_2 \in M_{k\times\ell}(\mathbb{C})$, $M_3, M_4, M_5 \in M_{\ell\times\ell}(\mathbb{C})$. Counting neutrinos and imposing broken color to be commutative gives $k=\ell=1$. This case is degenerate: the kernel of the Dirac operator contains the invariant subspace with elements $(0,0,0,0,0,M_5v,-M_4v;0,0,0,0,0,\overline{M_5}w,-\overline{M_4}w)^T$, $v, w\in\mathbb{C}^p$.

With the second blow up diagram 33 yields

$$\rho_L(a,b,c)=\begin{pmatrix} a\otimes 1_k & 0 & 0 \\ 0 & a\otimes 1_p & 0 \\ 0 & 0 & \overline{b}\otimes 1_p \end{pmatrix},$$

$$\rho_R(a,b,c)=\begin{pmatrix} b\otimes 1_k & 0 & 0 & 0 \\ 0 & b\otimes 1_p & 0 & 0 \\ 0 & 0 & b\otimes 1_p & 0 \\ 0 & 0 & 0 & \overline{b}\otimes 1_p \end{pmatrix},$$

$$\rho_L^c(a,b,c)=\begin{pmatrix} 1_k\otimes a & 0 & 0 \\ 0 & 1_k\otimes c & 0 \\ 0 & 0 & 1_\ell\otimes c \end{pmatrix},$$

$$\rho_R^c(a,b,c)=\begin{pmatrix} 1_\ell\otimes a & 0 & 0 & 0 \\ 0 & 1_\ell\otimes c & 0 & 0 \\ 0 & 0 & 1_\ell\otimes c & 0 \\ 0 & 0 & 0 & 1_\ell\otimes \overline{c} \end{pmatrix},$$

$$\mathcal{M}=\begin{pmatrix} M_1\otimes 1_k & 0 & 0 & 0 \\ 0 & M_2\otimes 1_p & 0 & 0 \\ 0 & M_3\otimes 1_p & M_4\otimes 1_p & 1_k\otimes M_5 \end{pmatrix},$$

$M_1, M_2 \in M_{k\times\ell}(\mathbb{C})$, $M_3, M_4 \in M_{\ell\times\ell}(\mathbb{C})$, $M_5 \in M_{p\times p}(\mathbb{C})$. Counting neutrinos and imposing broken color to be commutative gives $k=\ell=p=1$. In the notations of Corollary 11.4, the action reads

$$V(a,b,c)=4\lambda[|M_1ab|^4+|M_2ab|^4+2|M_2ab|^2|M_3b^2|^2+(|M_3b^2|^2+|M_4b^2|^2+|M_5c^2|^2)^2]$$
$$-2\mu^2[|M_1ab|^2+|M_2ab|^2+(|M_3b^2|^2+|M_4b^2|^2+|M_5c^2|^2)].$$

Its minimum is degenerate, $\hat{b}=0$.

The other blow ups as well as diagram 37 lead to the same conclusion, degeneracy. This completes the proof of the theorem. □

We summarize the possible algebras with $N=3$ and the corresponding Krajewski diagrams of all their irreducible, dynamically nondegenerate triplets in a table.

Algebra	Diagrams
$\mathbb{C}\oplus\mathbb{R}\oplus(\mathcal{C}=\mathbf{1})$	14,16,19,21
$\mathbb{C}\oplus\mathbb{R}\oplus\mathcal{C}$	13,17,18,22
$\mathbf{1}\oplus\mathbf{1}\oplus\mathcal{C}$	15,20,23,24
$\mathbf{2}\oplus\mathbf{1}\oplus(\mathcal{C}=\mathbf{1})$	14,16,19,21
$\mathbf{2}\oplus\mathbf{1}\oplus\mathcal{C}$	13,17,18,22
$\mathbb{C}\oplus\mathbb{C}\oplus\mathbf{1}$	26
$\mathbf{1}\oplus\mathbf{1}\oplus\mathbf{1}$	9
$M_2(\mathbb{R})\oplus\mathbb{R}\oplus\mathbf{1}$	10
$\mathbb{H}\oplus\mathbf{1}\oplus\mathbf{1}$	10
$\mathbf{2}\oplus\mathbf{1}\oplus\mathbf{1}$	8

Note that relaxing the hypothesis of unbroken noncommutative color does not add any algebra to the list with $N=1$ and 2. It adds only few algebras to the list with $N=3$ coming from diagrams. 8, 9, and 11. We were unable to treat some of their triples, in particular quaternionic ones.

B. The standard model of electroweak and strong forces

Let us close this section by remarking that diagram 17 of Fig. 6 with flipped chirality and with algebra $\mathcal{A}=\mathbb{C}\oplus\mathbb{H}\oplus M_3(\mathbb{C})\ni(b,a,c)$, with representation

$$\rho_L(a)=\begin{pmatrix} a\otimes 1_3 & 0\\ 0 & a\end{pmatrix},\quad \rho_R(b)=\begin{pmatrix} b1_3 & 0 & 0\\ 0 & \overline{b}1_3 & 0\\ 0 & 0 & \overline{b}\end{pmatrix},$$

$$\rho_L^c(b,c)=\begin{pmatrix} 1_2\otimes c & 0\\ 0 & \overline{b}1_2\end{pmatrix},\quad \rho_R^c(b,c)=\begin{pmatrix} c & 0 & 0\\ 0 & c & 0\\ 0 & 0 & \overline{b}\end{pmatrix},$$

and with mass matrix

$$\mathcal{M}=\begin{pmatrix} \begin{pmatrix} m_u\\ 0\end{pmatrix}\otimes 1_3 & \begin{pmatrix} 0\\ m_d\end{pmatrix}\oplus 1_3 & 0\\ 0 & 0 & \begin{pmatrix} 0\\ m_e\end{pmatrix}\end{pmatrix}$$

produce the standard model of electromagnetic, weak and strong forces with one generation of quarks and leptons, u, d, ν, and e. The neutrino is a massless Weyl spinor. The intersection form written with respect to the basis of projectors

$$p_1=(0,1_2,0),\quad p_2=(1,0,0),\quad p_3=\left(0,0\begin{pmatrix}1&0&0\\0&0&0\\0&0&0\end{pmatrix}\right)$$

is

$$\cap = -2\begin{pmatrix} 0 & 1 & 1 \\ 1 & -1 & -1 \\ 1 & -1 & 0 \end{pmatrix},$$

and nondegenerate. The color group U(3) is unbroken and its representations on corresponding left- and right-handed fermions are identical. In physicists' language this means that gluons are massless and couple vertorially. Further details on the standard model as an almost commutative geometry can be found in Refs. 2 and 13.

IX. BEYOND IRREDUCIBLE TRIPLES

For the standard model, allowing reducible triples has two important physical consequences.

(i) Suppose we want to render the neutrino massive. Majorana masses are incompatible with the axiom that the Dirac operator anticommutes with the chirality. Therefore we must increase the Hilbert space by adding a right-handed neutrino. Then the triple becomes reducible, but worse Poincaré duality breaks down: the intersection form becomes

$$\cap = -2\begin{pmatrix} 0 & 1 & 1 \\ 1 & -2 & -1 \\ 1 & -1 & 0 \end{pmatrix},$$

degenerate.

(ii) We may add more generations of quarks and leptons. Then the Cabibbo–Kobayashi–Maskawa matrix makes its appearance. Now we may add right-handed neutrinos in some but no in all generations and give Dirac massses to the corresponding neutrinos without violating Poincaré duality.

So far we have no clue to why the standard model comes with three colors, with three generations of quarks and with three generations of leptons. Note however that anomaly cancellations[1] imply further constraints that are satisfied with three colors and with a number of quark generations equal to the number of lepton generations.

A. A reducible triple with nondegenerate spectrum

The criterion of dynamical degeneracy loses its meaning in presence of reducible triples as illustrated by the following example: $\mathcal{A}=M_3(\mathbb{C})\oplus M_2(\mathbb{C})\ni(a,b)$,

$$\rho(a,b,c)=\begin{pmatrix} a\otimes 1_2\otimes 1_3 & 0 & 0 & 0 \\ 0 & b\otimes 1_3\otimes 1_3 & 0 & 0 \\ 0 & 0 & 1_3\otimes 1_2\otimes \overline{a} & 0 \\ 0 & 0 & 0 & 1_2\otimes 1_3\otimes \overline{a} \end{pmatrix},$$

$$\mathcal{M} = m \begin{pmatrix} \begin{pmatrix} \sqrt{\frac{5}{17}} & 0 \\ 0 & \frac{1}{\sqrt{5}} \\ 0 & 0 \end{pmatrix} & \begin{pmatrix} 0 & 0 \\ 0 & 0 \\ 0 & 0 \end{pmatrix} & \begin{pmatrix} 0 & 0 \\ 0 & -\frac{2}{\sqrt{5}} \\ 1 & 0 \end{pmatrix} \\ \begin{pmatrix} 0 & 0 \\ 0 & 0 \\ 0 & \frac{2}{\sqrt{5}} \end{pmatrix} & \begin{pmatrix} 2\sqrt{\frac{5}{17}} & 0 \\ 0 & \frac{2}{\sqrt{5}} \\ 0 & 0 \end{pmatrix} & \begin{pmatrix} 0 & 0 \\ 0 & 0 \\ 0 & 0 \end{pmatrix} \end{pmatrix} \otimes 1_3.$$

The fluctuations of the Dirac operator generate an 18-dimensional complex vector space in which the spectral action $V({}^f\mathcal{D})$ must be minimized. We used a steepest descend method of Mathematica for this task and found an absolute minimum at ${}^{\hat{f}}\mathcal{D}=\mathcal{D}$ with $m=\mu/\sqrt{4\lambda}$ and $V({}^{\hat{f}}\mathcal{D})=-(431/340)\times(\mu^4/\lambda)$. The spectrum of this minimum ${}^{\hat{f}}\mathcal{D}$ is nondegenerate: in units of $\mu/\sqrt{4\lambda}$ we have $\{1,4/5,5/17,20/17,(9+\sqrt{17})/10\}$. All six values of course appear six times with a positive and six times with a negative sign in the spectrum of ${}^{\hat{f}}\mathcal{D}$. The little group of this minimum is $G_\ell = \mathrm{U}(1)\subset \mathrm{U}(3)\times\mathrm{U}(2)$ with generic element $(e^{i\alpha}1_3, e^{i\alpha}1_2)$. The spectrum of the minimum appears completely rigid, i.e., there are many mass relations. Note however that the threefold color degeneracy is not protected by the little group in this example.

X. CONCLUSION

Suppose we want to apply conventional, perturbative quantum field theory to the Yang–Mills–Higgs models coming from almost commutative geometries. Then after renormalization, fermion masses are functions of energy and the color degeneracy is compatible with this energy dependence only if all noncommutative color groups are unbroken. Furthermore the renormalization of fermion masses is incompatible with mass relations, in particular with the completely rigid reducible spectral triple of Sec. IX. In irreducible spectral triples, mass relations other than degeneracies only appear starting with $N=3$. All triples without such mass relations come from ladder diagrams and have algebras $\mathbf{1}\oplus\mathbf{1}\oplus\mathcal{C}$ or $\mathbb{H}\oplus\mathbf{1}\oplus\mathcal{C}$.

Let us suppose that also for $N\geqslant 4$ the irreducible triples without mass relations have contracted multiplicity matrices of ladder type,

$$\hat{\mu} = \begin{pmatrix} \alpha & \beta & 0 & 0 \\ \gamma & \delta & 0 & 0 \\ \rho & \sigma & 0 & 0 \\ \theta & \xi & 0 & 0 \end{pmatrix}, \quad N=4.$$

Then $\det(\hat{\mu}+\hat{\mu}^T)=(\rho\xi-\sigma\theta)^2$ and irreducibility implies $\alpha=\beta=\gamma=\delta=0$. For $N\geqslant 5$, all contracted multiplicity matrices $\hat{\mu}$ of ladder type have $\det(\hat{\mu}+\hat{\mu}^T)=0$ leading us to the following.

Conjecture 10.1. The sum of N simple algebras, $\mathcal{A}=\mathcal{A}_1\oplus\mathcal{A}_2\oplus\cdots\oplus\mathcal{A}_N$ admits a finite, real, S^0-real, irreducible and dynamically nondegenerate spectral triple free of mass relations if and only if it is in the list, up to a reordering of the summands:

$N=1$	$N=2$	$N=3$	$N=4$	$N\geqslant 5$
	$\mathbb{R}\oplus\mathbb{R}$	$\mathbb{R}\oplus\mathbb{R}\oplus\mathcal{C}$	$\mathbb{R}\oplus\mathbb{R}\oplus\mathcal{C}_1\oplus\mathcal{C}_2$	
	$\mathbb{R}\oplus\mathbb{C}$	$\mathbb{R}\oplus\mathbb{C}\oplus\mathcal{C}$	$\mathbb{R}\oplus\mathbb{C}\oplus\mathcal{C}_1\oplus\mathcal{C}_2$	
	$\mathbb{C}\oplus\mathbb{C}$	$\mathbb{C}\oplus\mathbb{C}\oplus\mathcal{C}$	$\mathbb{C}\oplus\mathbb{C}\oplus\mathcal{C}_1\oplus\mathcal{C}_2$	
	$M_2(\mathbb{R})\oplus\mathbb{R}$			
void	$M_2(\mathbb{R})\oplus\mathbb{C}$			void
	$M_2(\mathbb{C})\oplus\mathbb{R}$			
	$M_2\mathbb{C}\oplus\mathbb{C}$			
	$\mathbb{H}\oplus\mathbb{R}$	$\mathbb{H}\oplus\mathbb{R}\oplus\mathcal{C}$	$\mathbb{H}\oplus\mathbb{R}\oplus\mathcal{C}_1\oplus\mathcal{C}_2$	
	$\mathbb{H}\oplus\mathbb{C}$	$\mathbb{H}\oplus\mathbb{C}\oplus\mathcal{C}$	$\mathbb{H}\oplus\mathbb{C}\oplus\mathcal{C}_1\oplus\mathcal{C}_2$	

Here $\mathcal{C}$, $\mathcal{C}_1$, and $\mathcal{C}_2$ are three arbitrary simple algebras. The color algebras $\mathcal{C}$ for $N=3$ and $\mathcal{C}_1\oplus\mathcal{C}_2$ for $N=4$ have two constraints.

(i) *Their representations on corresponding left and right-handed subspaces of $\mathcal{H}$ are identical (up to possibly different multiplicities).*

(ii) *The Dirac operator $\mathcal{D}$ is invariant under* $\mathrm{U}(\mathcal{C})$ *or* $\mathrm{U}(\mathcal{C}_1\oplus\mathcal{C}_2)$,

$$\rho(1,1,w)\mathcal{D}\,\rho(1,1,w)^{-1}=\mathcal{D},\quad \text{for all } w\in \mathrm{U}(\mathcal{C}) \text{ or } \mathrm{U}(\mathcal{C}_1\oplus\mathcal{C}_2).$$

This implies that the unitaries of $\mathcal{C}$ or $\mathcal{C}_1\oplus\mathcal{C}_2$ do not participate in the fluctuations and are therefore unbroken, i.e., elements of the little group.

We must admit that our brute force proof by exhaustion is not suitable for $N=4$ and it seems already a formidable task to write down the list of all contracted irreducible diagrams.

Besides renormalizability, there are two other important items on the physicist's shopping list, which will further constrain the model building kit.

(i) The electric charge of a massless particle must be zero.
(ii) The representation of the little group on the Hilbert space of fermions must be complex.

Recall that a unitary representation is called real if it is equal to its complex conjugate and pseudoreal if it is unitarily equivalent to its complex conjugate. Otherwise the representation is complex. For example, the fundamental representation of SU(2) is pseudoreal. An irreducible, unitary representation of U(1) is complex if and only if its charge is nonzero.

Before we can examine these two criteria in the irreducible context, we must compute the minimal central extensions[12,15] that allow the lift of algebra automorphisms to the Hilbert space of fermions to have at most a finite number of values. This calculation is under way.

APPENDIX

Since this paper deals with matrices, let us briefly recall two standard results, one on the singular value decomposition of rectangular matrices and the second on the standard form of skewsymmetric matrices.

We write $\mathrm{O}(n):=\mathrm{U}(M_n(\mathbb{R}))$, $\mathrm{U}(n):=\mathrm{U}(M_n(\mathbb{C}))$ and $\mathrm{Usp}(n):=\mathrm{U}(M_n(\mathbb{H}))$.

Lemma 11.1:

(i) Let $M \in M_{n\times m}(\mathbb{C})$. *Then there exist* $U \in U(n)$, $V \in U(m)$ *such that* $M=UDV$ *where* $D \in M_{n\times m}(\mathbb{R})$ *satisfies* $D_{ij}=0$ *for* $i \neq j$ *and* $D_{11} \geqslant D_{22} \geqslant D_{kk} > D_{k+1,k+1} = \cdots = D_{qq} = 0$ *where* $k = \mathrm{rank}(M)$ *and* $q=\min(n,m)$. *The* D_{ii}^2 *are the eigenvalues of* M^*M, *the columns of* U *(respectively,* V*) are the eigenvectors of* MM^* *(respectively,* M^*M*) arranged in the same order as the eigenvalues* D_{ii}^2. *In particular, when* $M \in M_{n\times m}(\mathbb{R})$, *we may assume* $U \in O(n)$, $V \in O(m)$ *(Ref. 9, 7.3.5).*

(ii) Let $M \in M_n(\mathbb{C})$ *be a skewsymmetric matrix. Then, there exists* $U \in U(n)$ *such that*

$$UMU^T = \left(\overset{p}{\underset{i=1}{\oplus}} m_i x\right) \oplus 0 \cdots \oplus 0 \quad \text{where} \quad x = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}, \quad m_i \in \mathbb{C}^* \tag{A1}$$

and the numbers of zeros equals $n-2p$ (*Ref.* 9 *4.4, Problem 26).*

For our purpose, M is the *complex* fermionic mass matrix. Then, in (i), the diagonal elements D_{jj} are the Dirac masses and the unitaries U and V are related to the Cabibbo–Kobayashi–Maskawa matrix.

Definition 11.2: Let $M \in M_{(n)\times(m)}(\mathbb{C})$ and

$$f \in \mathcal{F}_{\mathbb{K},\mathbb{K}'} := \{(r_j,u_j,v_j)_{j\in J} \in \mathbb{R} \times \mathrm{U}(M_{(n)}(\mathbb{K})) \times \mathrm{U}(M_{(m)}(\mathbb{K}'))|J \text{ finite}\},$$

where $\mathbb{K}$, $\mathbb{K}'$ are $\mathbb{R}$, $\mathbb{C}$, or $\mathbb{H}$ where $(n)=n$ for $\mathbb{K}=\mathbb{R},\mathbb{C}$ and $(n)=qn$ for $\mathbb{K}=\mathbb{H}$. The *fluctuation* of M is defined by

$${}^fM := \sum_j r_j u_j M v_j.$$

In the case that $\mathbb{C}$ and $\mathbb{H}$ are involved, we assume of course that $\mathbb{C}\subset\mathbb{H}$.

Note that for a given M,

$$\{{}^fM|f \in \mathcal{F}_{\mathbb{R},\mathbb{C}}\} = \{{}^fM|f \in \mathcal{F}_{\mathbb{C},\mathbb{R}}\} = \{{}^fM|f \in \mathcal{F}_{\mathbb{C},\mathbb{C}}\}.$$

Lemma 11.3: Let $\mathrm{Span}_{\mathbb{R}}(E)$ *be the real vector space spanned by the set* E. *Then,*

(i) $\mathrm{Span}_{\mathbb{R}}(\mathrm{O}(n))=M_n(\mathbb{R})$.
(ii) $\mathrm{Span}_{\mathbb{R}}(\mathrm{U}(n))=M_n(\mathbb{C})$.
(iii) $\mathrm{Span}_{\mathbb{R}}(\mathrm{USp}(n))=M_n(\mathbb{H})$.

Proof:

(i) It is sufficient to prove that any $a=\pm a^T \in M_n(\mathbb{R})$ is in $\mathrm{Span}_{\mathbb{R}}(\mathrm{O}(n))$.

When $a=a^T$, there exists $v \in \mathrm{O}(n)$ such that $a=vdv^T$ where d is a real diagonal matrix. Since

$$d = \sum_{i=1}^{n} \frac{d_{ii}}{2}(2p_i - 1_n) + \frac{d_{ii}}{2}1_n,$$

where p_i is the projection on the ith vector basis, so d is in $\mathrm{Span}_{\mathbb{R}}(\mathrm{O}(n))$ and so is a.

When $a=-a^T$, there exist $v \in \mathrm{O}(n)$ and a family $r_k \in \mathbb{R}$, $k \leqslant n/2$ such that

$$a = v\ \mathrm{diag}(0,\ldots,0,r_1 b,\ldots,r_k b)v^T,$$

where $b=\left(\begin{smallmatrix} 0 & 1 \\ -1 & 0 \end{smallmatrix}\right)$. Thus for $r=\Sigma_i r_i$,

$$v^T a v = b_1\ \mathrm{diag}(1,\ldots,1,b,1_2\ldots,1_2) + r_2\ \mathrm{diag}(1,\ldots,1,1_2,b,1_2\ldots,1_2) + \cdots$$
$$+ r_k(1,\ldots,1,1_2,\ldots,1_2,b) - \mathrm{diag}(r,\ldots,r,(r-r_1)1_2,\ldots,(r-r_k)1_2)$$

is a real linear combination of matrices in $\mathrm{O}(n)$ by (i). So $a \in \mathrm{Span}_{\mathbb{R}}(\mathrm{O}(n))$.

(ii) This follows by (i) since $\mathrm{O}(n)$ and $i\mathrm{O}(n)$ are included in $\mathrm{U}(n)$.

(iii) Let $1, e_1, e_2, e_3$ be the canonical basis of $\mathbb{H}$ such that $e_ie_j=\delta_{ij}1-\epsilon_{ijk}e_k$ and $1e_i=e_i1=e_i$. Since $M_n(\mathbb{H})$ is an $\mathbb{H}$-vector space, $M_n(\mathbb{H})=1M_n(\mathbb{R})+e_1M_n(\mathbb{R})+e_2M_n(\mathbb{R})+e_3M_n(\mathbb{R})$ and the result follows from $e_i\mathrm{O}(n)\subset\mathrm{USp}(n)$. □

Corollary 11.4: $\{{}^fM|f\in\mathcal{F}_{\mathbb{K},\mathbb{K}'}\}=\{\Sigma_i a_iM\ b_i|a_i\in M_n(\mathbb{K}),b_i\in M_m(\mathbb{K}')\}$.

Remark 11.5: If $\mathbb{K}=\mathbb{K}'$, then for any $0\neq M\in M_{n\times m}(\mathbb{K})$,

$$\{{}^fM|f\in\mathcal{F}_{\mathbb{K},\mathbb{K}}\}=M_{n\times m}(\mathbb{K}).$$

Nevertheless, we have *a priori*

$$\{{}^fM|f\in\mathcal{F}_{\mathbb{K},\mathbb{K}'}\}\not\subset\{a\ M\ b|a\in M_n(\mathbb{K}),b\in M_m(\mathbb{K}')\},$$

while the converse inclusion is true by the previous corollary. Actually, for $n=m=2$ and $\mathbb{K}=\mathbb{K}'=\mathbb{C}$, if $M=\left(\begin{smallmatrix}1&0\\0&0\end{smallmatrix}\right)$, Rank $(aMb)\leqslant 1$ for any a and b in $M_n(\mathbb{C})$, but for the fluctuation

$$f=\{r_1=r_2=1,u_1=v_1=1_2,u_2=v_2=\left(\begin{smallmatrix}0&1\\1&0\end{smallmatrix}\right)\},\ ({}^fM)=\mathrm{Rank}(1_2)=2$$

.

Lemma 11.6: Given a family of k $\mathbb{R}$-linearly independent matrices $M_i\in M_{n\times m}(\mathbb{R})$, $i=1,\ldots,k$, there exists a fluctuation $f\in\mathcal{F}_{\mathbb{R},\mathbb{R}}$ such that ${}^fM_i=0$ for all $i\neq 1$ and ${}^fM_1\neq 0$.

Proof: Let $\{c_i\}_{i\in\{1,\ldots,p\}}$ be the canonical basis of column vectors in $\mathbb{R}^p$. (We use abusively the same notation for different p's.) Remark first that the fluctuation defined for given $r_1,r_2\in\mathbb{R}, i,k\in\{1,\ldots,n\}$ and $j,l\in\{1,\ldots,m\}$ by

$${}^fM:=r_1M+r_2c_ic_k^TM\ c_lc_j^T=r_1M+r_2M_{kl}c_ic_j^T$$

satisfies $({}^fM)_{pq}=r_1M_{pq}$ for all $p\neq i$ and $q\neq j$ and $({}^fM)_{ij}=r_1M_{ij}+r_2M_{kl}$.

For any $M\in M_{n\times m}(\mathbb{R})$ let

$$W(M):=\begin{pmatrix}M_{11}\\ \vdots\\ M_{1m}\\ M_{21}\\ \vdots\\ M_{nm}\end{pmatrix}\in\mathbb{R}^{nm}.$$

Given a family of matrices $M_1,\ldots,M_k\in M_{n\times m}(\mathbb{R})$, let N be the matrix in $M_{nm\times k}(\mathbb{R})$ defined by the columns $W(M_i)$,

$$N:=(W(M_1)|W(M_2)|\cdots|W(M_k)).$$

Thus, if a fluctuation $f\in\mathcal{F}_{\mathbb{R},\mathbb{R}}$ is defined simultaneously on all M_i's, N is transformed in $f(N):=(W({}^fM_1)|W({}^fM_2)|\cdots|W({}^fM_k))$. By the previous remark, adding a multiple of a line of N to a multiple of another one correspond precisely to a fluctuation. Using Gauss method, if the M_i's are linearly independent (thus $k\leqslant nm$), so are the $W(M_i)$'s and there exists a fluctuation f such that

$$f(N)=\begin{pmatrix}1_{k\times k}\\ 0_{(nm-k)\times k}\end{pmatrix}$$

since the rank of N is k. This means that a second fluctuation given by ${}^gM:=c_1c_1^TMc_1c_1^T$ will give ${}^{gf}M_1={}^fM_1\neq 0$ while ${}^{gf}M_i=0$ for all $i\neq 1$. □

Remark 11.7: This lemma is false when the matrices have complex entries: Let $M_1=\left(\begin{smallmatrix}i\\1\end{smallmatrix}\right)$ and $M_2\left(\begin{smallmatrix}1\\0\end{smallmatrix}\right)$. Then M_1 and M_2 are $\mathbb{R}$- and $\mathbb{C}$-linearly independent. Nevertheless, ${}^fM_1=0$ always yields ${}^fM_2=\mathrm{Im}\ ({}^fM_1)=0$. There only remains the following.

Lemma 11.8: Let $M_1\in M_{n\times m}(\mathbb{C}), i=1,\ldots,k$ be k matrices such that their real and imaginary

parts are $2k$ $\mathbb{R}$*-linearly independent matrices. Then there exists a fluctuation* $f \in \mathcal{F}_{\mathbb{R},\mathbb{R}}$ *such that* ${}^{f}M_i \neq 0$ *and* ${}^{f}M_1 = 0$ *for all* $i \neq 1$.

Proof: According to the previous lemma, there exists a fluctuation $f \in \mathcal{F}_{\mathbb{R},\mathbb{R}}$ such that $\mathrm{Re}({}^{f}M_1) \neq 0$ while $\mathrm{Im}({}^{f}M_1) = \mathrm{Re}({}^{f}M_i) = \mathrm{Im}({}^{f}M_i) = 0$ for all $i \neq 1$, yielding the conclusion since real and imaginary extractions commute with fluctuations. □

Among the fluctuations, there are the symmetric ones in the following sense.

Definition 11.9: Let $\mathcal{F}^{T}_{\mathbb{C},\mathbb{C}} := \{(r_j, u_j)_{j\in J} \in \mathbb{R} \times \mathrm{U}(n) | J \text{ finite}\}$ and define fluctuations $f^T \in \mathcal{F}_{\mathbb{C},\mathbb{C}^T}$ on $n \times n$ square matrices by

$$f^T M := \sum_j r_j u_j M u_j^T.$$

Lemma 11.10: Let M_1, M_2 *be two skewsymmetric matrices* in $M_n(\mathbb{C})$. *Then,*

(i) *If the constraints* ${}^{f^T}M_1 = 0$ *for* $f \in \mathcal{F}_{\mathbb{C},\mathbb{C}^T}$ *always implies* ${}^{f^T}M_2 = 0$, *then* M_2 *is* $\mathbb{C}$*-colinear to* M_1.

(ii) *If* M_2 *is not colinear to* M_1, *then there exists a fluctuation* $f^T \in \mathcal{F}_{\mathbb{C},\mathbb{C}^T}$ *such that* ${}^{f^T}M_1 = 0$ *and* ${}^{f^T}M_2 \neq 0$.

Proof: Note that (ii) is a consequence of (i).

To prove (i), we may assume that M_1 has the form as in (A1).

$s := \left(\begin{smallmatrix} 0 & 1 \\ 1 & 0 \end{smallmatrix}\right)$ and $t := \left(\begin{smallmatrix} 1 & 0 \\ 0 & -1 \end{smallmatrix}\right)$ are two unitaries satisfying $wxw^T = -x$ for $w = s, t$. Define $u = v \oplus 1 \oplus \cdots \oplus 1 \in \mathrm{U}(n)$ with $v = \oplus_{i=1}^{p} v_i \in U(2p)$ where $v_1 \in \{s, t\}$. Then $M_1 + uM_1u^T = 0$, so if M_2 has the form $\left(\begin{smallmatrix} A & B \\ C & D \end{smallmatrix}\right)$, with $A \in M_{2p}(\mathbb{C})$, $B \in M_{2p,n-2p}(\mathbb{C})$, $C \in M_{n-2p,2p}(\mathbb{C})$, $D \in M_{n-2p,n-2p}(\mathbb{C})$, then $0 = M_2 + uM_2u^T$. We deduce $0 = A + vAv^T = B + vB = C + Cv^T = D + D$. Thus choosing $V_s = \oplus_{i=1}^{p} s$ and $v_t = \oplus_{i=1}^{p} t$, we have $(1_{2p} + v_s)B + (1_{2p} + v_t)B = 0$, so $B = 0$ since $2\, 1_{2p} + v_s + v_t$ is invertible. Similarly, $C = D = 0$.

If A_{kl} is the partition of A in 2×2 matrices, the constraint $A + vAv^T = 0$ implies $0 = A_{kl} + u_k A_{kl} u_l^T$. When $k \neq l$, A_{kl} is necessarily zero since we may choose independently u_k and u_l in $\{s, t\}$. When $k = l$, $A_{kk} = \left(\begin{smallmatrix} \alpha_k & \gamma_k \\ -\gamma_k & \beta_k \end{smallmatrix}\right)$ where α, β, and γ are complex numbers, since A is skewsymmetric. If $u_k = t$, $0 = A_{kk} + u_k A_{kk} u_k = 2\left(\begin{smallmatrix} \alpha_k & 0 \\ 0 & \beta_k \end{smallmatrix}\right)$ and $A_{kk} = \gamma_k x$. Thus $M_2 = \oplus_{k=1}^{p} \gamma_k x \oplus 0 \oplus \cdots \oplus 0$ and it remains to prove that $\gamma_k = c\, m_k$ for some constant c.

Define

$$u_k := s \oplus 1_2 \oplus \cdots \oplus 1_2 \oplus 1 \oplus \cdots \oplus 1,$$

$$v_k := 1_2 \oplus \cdots \oplus s \oplus \cdots \oplus 1_2 \oplus 1 \oplus \cdots \oplus 1,$$

$$w_k := \begin{pmatrix} 0 & 0 & \cdots & 0 & 1_2 \\ 0 & 1_2 & & & 0 \\ \vdots & & \ddots & & \vdots \\ 0 & & & 1_2 & 0 \\ 1_2 & 0 & \cdots & 0 & 0 \end{pmatrix} \oplus 1_2 \oplus \cdots \oplus 1_2 \oplus 1 \oplus \cdots \oplus 1,$$

three unitaries where the perturbation in v_k is set at the kth entry. Then

$$0 = (2m_1)^{-1}(M_1 - uM_1u^T) - (2m_k)^{-1} wk(M_1 - v_k M_1 v_k^T) w_k^T$$

and the same relation for M_2 yields $0 = 2(\gamma_1 m_1^{-1} - \gamma_k m_k^{-1})$, so $\gamma_k = \gamma_1 m_1^{-1} m_k$ and $M_2 = (\gamma_1 m_1^{-1}) M_1$. □

(Received 23 February 2004; accepted 27 July 2004; published 2 December 2004)

We provide a rigorous analysis of the fluctuations of localized eigenstates in a generalized Harper equation with golden mean flux and with next-nearest-neighbor interactions. For next-nearest-neighbor interaction above a critical threshold, these self-similar fluctuations are characterized by orbits of a renormalization operator on a universal strange attractor, whose projection was dubbed the "orchid" by Ketoja and Satija [Phys. Rev. Lett. **75**, 2762 (1995)]. We show that the attractor is given essentially by an embedding of a subshift of finite type, and give a description of its periodic orbits. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1797532]

I. INTRODUCTION

The discrete one-dimensional Schrödinger equation,

$$\psi_{i+1} + \psi_{i-1} + 2\lambda \cos(2\pi(i\omega + \phi))\psi_i = E\psi_i, \tag{1.1}$$

known as the Harper (or almost Mathieu) equation is a valuable tight binding model for the Hamiltonian of an electron in a one-dimensional lattice in a commensurate ($\omega \in \mathbb{Q}$) or incommensurate ($\omega \notin \mathbb{Q}$) potential. It may also be derived[10] as the tight binding model for an electron in a two-dimensional lattice in a transverse magnetic field in the limits of strong (weak) potential and weak (resp., strong) field. In this setting the parameters ω, ϕ, and λ represent, respectively, the magnetic flux per unit cell, the wave-number of the plane wave in the transverse direction, and the ratio of the length of the unit cell in the direction of the vector potential and its length in the transverse direction.

Much is known concerning the spectrum of (1.1). The pioneering work of Aubry and André[1] tells us much about the transition from extended to localized states, with precise versions of these results and a summary appearing in Ref. 12. What concerns us here is that for Diophantine ω there is, for almost all ϕ, a localized regime $\lambda > 1$ with a pure point spectrum with exponentially decaying eigenfunctions. (See Ref. 12 for a precise sufficient condition on ϕ.) For a recent general review of these and many other results on Schrödinger operators see Ref. 29.

At the critical point $\lambda = 1$ there is self-similarity of the spectrum eigenfunctions which has been investigated from a renormalization standpoint by Ostlund and Pandit[27] and several other groups (Refs. 6, 15, 16, 21, 22, 28, and 31). See Ref. 30 for a review. This critical behavior is reflected in the localized regime $\lambda > 1$. In the case when the flux $\omega = (\sqrt{5}-1)/2$, the golden mean, it has been observed that the exponentially decaying eigenfunctions possess universal self-similar fluctuations[17] determined by the strong-coupling limit $\lambda \to \infty$. In Ref. 17, Ketoja and Satija explain this phenomenon in terms of a universal fixed point of a renormalization operator derived from

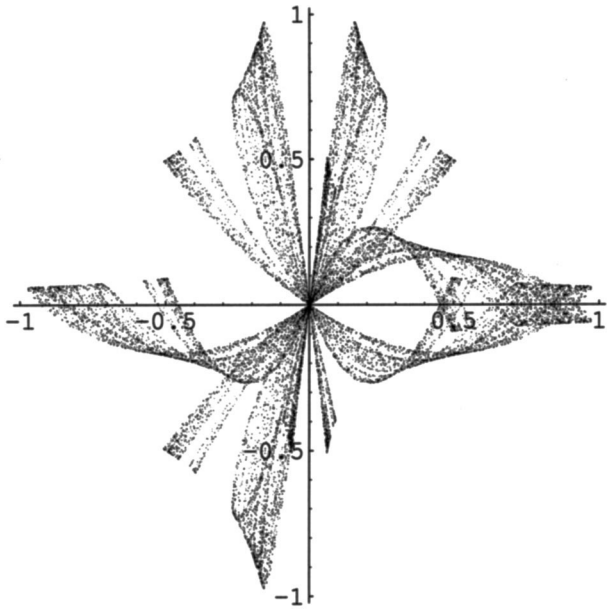

FIG. 1. The orchid.

their decimation scheme.[15,16] We have recently put their observations on a firm footing by explicitly constructing a fixed point of the appropriate renormalization operator.[24]

In this paper we consider the generalized Harper equation,[9]

$$(1+\alpha\cos(2\pi(\omega(i+1/2)+\phi)))\psi_{i+1}+(1+\alpha\cos(2\pi(\omega(i-1/2)+\phi)))\psi_{i-1}$$
$$+2\lambda\cos(2\pi(i\omega+\phi))\psi_i=E\psi_i, \tag{1.2}$$

in which, in terms of the two-dimensional system, the additional parameter α measures the next-nearest-neighbor interaction strength. (For earlier studies of the spectrum of this model see Refs. 4, 11, and 32.)

Han *et al.*[9] give the phase diagram for this model, and in Ref. 20 an investigation of the critical self-similarity that occurs when $\alpha\geqslant 1$ and $\alpha\geqslant\lambda$ is made using the decimation scheme. The conclusion is that the scaling in the "fat" critical phase appears to be governed by a strange attractor of a renormalization operator. As in the Harper equation itself, this critical behavior is mirrored in the localized phase, $\lambda\geqslant 1$ and $\lambda\geqslant\alpha$, where there again appear to be self-similar fluctuations in the exponentially decaying eigenfunctions. Ketoja and Satija[17] report two types of behavior under decimation. First, for $0\leqslant\alpha<1$ the system appears to be in the universality class of the original Harper equation ($\alpha=0$), renormalizing to the fixed point. More intriguingly, when $\alpha\geqslant 1$ the decimation/renormalization scheme appears to send the system to a universal strange attractor again determined by the strong-coupling limit $\lambda\to\infty$. A projection of this attractor has been dubbed an "orchid" in Ref. 17. Figure 1 shows the orchid. (It is a reflection in the origin of that shown in Ref. 17, as we have adopted a different sign convention.)

For certain values of the parameter α the asymptotic orbit under renormalization is a periodic orbit, but generally orbits asymptotically appear to be dense on the attractor. It is this strange attractor that we specifically analyze in this paper. (A study of the generalized Harper equation with anisotropic next-nearest-neighbor interaction[18] reveals that this richness is destroyed by anisotropy.) Our analysis combines subshifts of finite type together with dynamics of sign pairs and gives a complete mathematical description of the strange set.

The outline of this paper is as follows. In Sec. II we review the decimation approach of Ketoja and Satija which leads to the key functional recurrence,

$$t_{n+1}(x) = t_n(-\omega x)t_{n-1}(\omega^2 x + \omega), \tag{1.3}$$

that is the mathematical interest of this paper. [Here $\omega=(\sqrt{5}-1)/2$.] We also recall our earlier work[24] on the strong-coupling fixed point of this equation, and establish some preliminary renormalization results. The zeros of the initial conditions for this recurrence are crucial in our analysis. In particular, the key to our understanding is their evolution under a simple piecewise-linear interval map. The symmetry of the cosine potential in the generalized Harper equation leads to symmetry of these zeros, and in Sec. III we introduce "codes" which give a symbolic description of the dynamics of the zeros and establish a "partnering" criterion which enables us to incorporate the symmetry. In Sec. IV we construct the orchid in terms of the codes and pairs of signs, assuming the existence of a map $\mathcal{E}$ that embeds the code space into a space of function pairs. The main analytic work is in Sec. V, in which the existence of the map $\mathcal{E}$ is established. We also construct an abstract model space for a fundamental set, three copies of which comprise the orchid. Having constructed the orchid, in Sec. VI we establish its attracting nature and its "strangeness," while in Sec. VII we prove that all periodic orbits have period a multiple of three, thereby proving a conjecture formulated in Ref. 17. Section VIII contains our concluding remarks.

II. RENORMALIZATION ANALYSIS

A. Golden mean decimation

For completeness, in this section we recall the decimation approach to quasiperiodic systems as developed by Ketoja and Satija (Refs. 14–20).

We restrict our attention to the portion of the localized phase, $\lambda \geqslant 1$, $\lambda \geqslant \alpha$, for which $\alpha \geqslant 1$, where by the result of Han *et al.*,[9] the exponential decay of the eigenfunction is measured by the characteristic exponent,

$$\gamma = \log\left(\frac{\lambda}{\alpha} + \sqrt{\left(\frac{\lambda}{\alpha}\right)^2 - 1}\right). \tag{2.1}$$

Writing

$$\psi_i = e^{-\gamma|i|}\eta_i, \tag{2.2}$$

our generalized Harper equation (1.2) becomes, for $i>0$,

$$\begin{aligned} &e^{-2\gamma}(1+\alpha\cos(2\pi(\omega(i+1/2)+\phi)))\eta_{i+1} + (1+\alpha\cos(2\pi(\omega(i-1/2)+\phi)))\eta_{i-1} \\ &\quad + 2e^{-\gamma}\lambda\cos(2\pi(i\omega+\phi))\eta_i = e^{-\gamma}E\eta_i. \end{aligned} \tag{2.3}$$

We consider only the case when the flux $\omega=(\sqrt{5}-1)/2$, the golden mean. In the decimation scheme in this case, we consider only sites with indices separated by a Fibonacci number F_n, where we define $F_0=0$, $F_1=1$, and $F_n=F_{n-1}+F_{n-2}$ for $n>1$. In other words, we consider the *decimation* of (2.3) of the form

$$s_n(i)\,\eta_{i+F_{n+1}} = \eta_{i+F_n} - t_n(i)\,\eta_i. \tag{2.4}$$

By writing (2.4) with n replaced by $n-1$ and $n+1$ and in each of the resulting expressions replacing i by $i+F_n$ (and by using the defining property of the Fibonacci numbers), the functions t_n and s_n may be seen to obey the explicit recursions,

$$s_{n+1}(i) = \frac{s_{n-1}(i+F_n)s_n(i+F_n)}{1 - s_n(i)(t_{n-1}(i+F_n) + s_{n-1}(i+F_n)t_n(i+F_n))}, \tag{2.5}$$

$$t_{n+1}(i) = \frac{t_n(i)(t_{n-1}(i+F_n) + s_{n-1}(i+F_n)t_n(i+F_n))}{1 - s_n(i)(t_{n-1}(i+F_n) + s_{n-1}(i+F_n)t_n(i+F_n))}, \tag{2.6}$$

for $n>1$. The initial conditions for these recursions are

$$s_1(i) = 1, \tag{2.7}$$

$$t_1(i) = 0, \tag{2.8}$$

$$s_2(i) = \frac{e^{-\gamma}(1 + \alpha\cos(2\pi((i+3/2)\omega + \phi)))}{E - 2\lambda\cos(2\pi((i+1)\omega + \phi))}, \tag{2.9}$$

$$t_2(i) = \frac{1 + \alpha\cos(2\pi((i+1/2)\omega + \phi))}{e^{-\gamma}(E - 2\lambda\cos(2\pi((i+1)\omega + \phi)))}; \tag{2.10}$$

given by Eq. (2.4) with $n=1$ and $n=2$, respectively, referring to (2.3).

We now consider the strong-coupling limit $\lambda\to\infty$. We see from (2.1) that $\gamma\to\infty$ and $\lambda e^{-\gamma}\to\alpha/2$. We set $\varepsilon=\lim E/\lambda$ and see that $s_2(i)$, $s_3(i)$, $s_n(i)\to 0$, while

$$t_2(i) \to \frac{1 + \alpha\cos(2\pi((i+1/2)\omega + \phi))}{\alpha(\varepsilon/2 - \cos(2\pi((i+1)\omega + \phi)))}, \tag{2.11}$$

$$t_3(i) \to t_2(i)t_2(i+F_2), \tag{2.12}$$

$$t_{n+1}(i) \to t_n(i)t_{n-1}(i+F_n), \tag{2.13}$$

for $n\geqslant 3$. We thus have a single recurrence as our strong-coupling problem:

$$t_1(i) = 0, \tag{2.14}$$

$$t_2(i) = \frac{1 + \alpha\cos(2\pi((i+1/2)\omega + \phi))}{\alpha(\varepsilon/2 - \cos(2\pi((i+1)\omega + \phi)))}, \tag{2.15}$$

$$t_3(i) = t_2(i)t_2(i+F_2), \tag{2.16}$$

$$t_{n+1}(i) = t_n(i)t_{n-1}(i+F_n), \tag{2.17}$$

for $n\geqslant 3$.

To analyze the scaling we now replace the discrete lattice index i by the continuous variable $x=(-\omega)^{-n}\{i\omega\}$ where $\{\cdot\}$ denotes the fractional part. Care must be taken when doing this as the definition of x depends on the index n of the function. The result is that our recursion becomes

$$t_{n+1}(x) = t_n(-\omega x)t_{n-1}(\omega^2 x + \omega), \tag{2.18}$$

for $n\geqslant 3$, with initial conditions

$$t_2(x) = \frac{1 + \alpha\cos(2\pi(\omega^2 x + \omega/2 + \phi))}{\alpha(\varepsilon/2 - \cos(2\pi(\omega^2 x + \omega + \phi)))}, \tag{2.19}$$

$$t_3(x) = t_2(-\omega x)t_2(-\omega x - 1). \tag{2.20}$$

We remark that t_2 is "normalized" in the sense that it satisfies the constraint

$$\int_{-\omega^{-1}}^{1} \log|t_2(x)|dx = 0, \tag{2.21}$$

the significance of which will be made clear in Sec. VI A.

Henceforth, in all that follows, we shall consider these limiting equations at the "upper band edge," at which $\varepsilon/2=+1$, and the phase $\phi=0$. (The lower band edge $\varepsilon/2=-1$, $\phi=1/2$ may be treated similarly.)

As in Refs. 27 and 17, writing $u_n(x)=t_{n-1}(-\omega x)$, we obtain a first order iteration on pairs of functions (u_n,t_n):

$$u_{n+1}(x) = t_n(-\omega x), \quad t_{n+1}(x) = t_n(-\omega x)u_n(-\omega x - 1). \tag{2.22}$$

We may thus express the recursion (2.18) in terms of a renormalization operator on pairs (u,t):

$$(u_{n+1},t_{n+1}) = R(u_n,t_n), \tag{2.23}$$

where

$$R(u_n,t_n)(x) = (t_n(\theta_0(x)),t_n(\theta_0(x))u_n(\theta_1(x))), \tag{2.24}$$

and θ_0, θ_1 are the linear contractions,

$$\theta_0(x) = -\omega x, \quad \theta_1(x) = -\omega x - 1. \tag{2.25}$$

The initial conditions become

$$u_2(x) = t_2(x) = \frac{1+\alpha\cos(2\pi(\omega^2 x+\omega/2))}{\alpha(1-\cos(2\pi(\omega^2 x+\omega)))}. \tag{2.26}$$

The two linear maps θ_0, θ_1 will be important in the theory which follows. They form an iterated function system which we shall describe briefly in Sec. II D.

Associated with the multiplicative renormalization operator R there is an additive linear operator R_a defined on function pairs (U,T) by

$$R_a(U,T)(x) = (T(-\omega x),T(-\omega x) + U(-\omega x - 1)). \tag{2.27}$$

The spectrum of this operator on a function space of analytic functions has been investigated in Ref. 24. We shall study further this operator below. In loose terms, R_a is the logarithm of the multiplicative renormalization operator R, although the presence of zeros of the function pair (u,t) is an obstacle to this correspondence.

Note that the same renormalization equation, (2.18), appears in the analysis by Kuznetsov *et al.*[23] of the onset of a strange nonchaotic attractor in quasiperiodically forced nonlinear systems, and in the study by Feudel *et al.*[7] of correlations on a strange nonchaotic attractor. We have recently considered the problem of correlations in some detail.[25] In this case piecewise-constant orbits of the recurrence are desired, as they are in an analysis of correlations in a barrier billiard.[3] Similarly, piecewise-constant orbits of the additive recurrence arise in the study of the self-similarity of the autocorrelation of a quasiperiodically forced two-level system.[8] We have given a detailed analysis of such orbits in Ref. 26.

B. Function pair conventions

In what follows we shall be dealing extensively with pairs of functions (u,t). We therefore make the convention that operations on function pairs act coordinatewise. For example, we may multiply two pairs $(u_1,t_1)(u_2,t_2)=(u_1u_2,t_1t_2)$, and evaluate at a point (x,x'): $(u,t)(x,x')=(u(x),u(x'))$. It will also be convenient for the convention to apply to functions, for example, $\exp(U,T)=(\exp(U),\exp(T))$, and $|(U,T)|=(|U|,|T|)$. Note that this is not the norm $\|(U,T)\|$ of the pair (U,T), but rather the function pair with values $(|U(x)|,|T(x')|)$ at a point (x,x').

We make one further convention that will simplify notation. In general, u and t will not have the same domains, but it will nevertheless be convenient to write expressions using the same variable x. Thus we may write $|(U,T)|(x)=(|U(x)|,|T(x)|)$, it being understood implicitly that the variable x is not the same for the two functions. These conventions should not cause confusion, and we shall use them freely in what follows.

C. The strong-coupling fixed point

In Ref. 17 the case $\alpha=0$, i.e., the original Harper equation (1.1), for which the Lyapunov exponent $\gamma=\log|\lambda|$, has the initial condition

$$u_2(x)=t_2(x)=\frac{1}{2(1-\cos(2\pi(\omega^2x+\omega)))}. \tag{2.28}$$

This initial condition has a single pole of order two at $x=1$ and the iteration of R leads to a fixed point of R, the so-called *strong-coupling fixed point*, as we shall prove in Sec. VI B. The strong-coupling fixed point and its properties were studied in Ref. 24. It is given by $u(x)=t(\theta_0(x))$, $t(x)=t_*(x)^{-2}$, where t_* is the unique, real analytic, entire function satisfying the equation

$$t_*(x)=t_*(-\omega x)t_*(\omega^2x+\omega), \tag{2.29}$$

for all $x\in\mathbb{C}$ and such that (i) $t_*(1)=0$; (ii) $t_*'(1)\neq 0$; and (iii) $t_*(x)>0$ for $x\in(-\omega^{-1},1)$. We refer the reader to Ref. 24 for the proof of the existence of t_* and of its properties.

The strong-coupling fixed point is relevant to the study of the orchid because of the denominator in the initial condition (2.26). Its role is, however, simply to change the scale of the orchid which we construct in Sec. IV below.

D. The iterated function system

For $c\in\{0,1\}$, as in (2.25) above, let θ_c denote the affine function

$$\theta_c(x)=-\omega x-c. \tag{2.30}$$

Then we may view θ_c as either a map of $\mathbb{R}$ or $\mathbb{C}$ depending on the context. [Note that the notation $\theta_0(x)=-\omega x$, $\theta_1(x)=-\omega x-1$ differs from that used in Ref. 24.]

The pair of maps θ_0, θ_1 forms an iterated function system (IFS) on $\mathbb{R}$ or $\mathbb{C}$ with unique compact invariant set the interval $I=[-\omega^{-1},1]$. We have $\theta_0(I)=[-\omega,1]$ and $\theta_1(I)=[-\omega^{-1},0]$ so that $I=\theta_0(I)\cup\theta_1(I)$.

The IFS θ_0, θ_1 considered here is related to the IFS ϕ_1, ϕ_2 considered in Refs. 24 and 25, where $\phi_1(x)=-\omega x$, $\phi_2(x)=\omega^2x+\omega$ and the invariant set is the interval $[-\omega,1]$. In fact $\phi_1=\theta_0$ and $\phi_2=\theta_0\circ\theta_1$. We note the following facts about the IFS θ_0, θ_1.

(i) θ_0 and θ_1 are both linear contractions on $\mathbb{C}$ with fixed points 0 and $-\omega$, respectively.
(ii) The interval I is an attractor for the IFS. In particular, given any compact subset $K\subseteq\mathbb{C}$ and any open neighborhood U of I in $\mathbb{C}$ there exists $N\in\mathbb{N}$ such that for any $k\geqslant N$ and any choice $i_1,\ldots,i_k\in\{0,1\}$ we have $\theta_{i_1}\circ\cdots\circ\theta_{i_k}(x)\in U$ for any $x\in K$.

Let us write $I_1=[-\omega^{-1},-\omega)$ and $I_0=(-\omega,1]$. Then we may define a map G by $G(x)=\theta_c^{-1}(x)=-\omega^{-1}x-c\omega^{-1}$ for $x\in I_c$, i.e.,

$$G(x)=\begin{cases}-\omega^{-1}x-\omega^{-1}, & -\omega^{-1}\leqslant x<-\omega;\\ -\omega^{-1}x, & -\omega<x\leqslant 1.\end{cases} \tag{2.31}$$

We do not define the value of G at the point $-\omega$, but note that $G(-\omega-)=-\omega$, $G(-\omega+)=1$. The function G is illustrated in Fig. 2.

We remark that the function $F:[-\omega,1]\to[-\omega,1]$ considered in Ref. 25, defined by

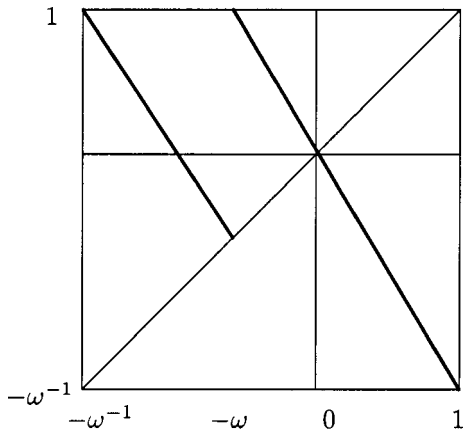

FIG. 2. The function G on the interval I.

$$F(x)=\begin{cases}\phi_1^{-1}(x), & x\in[-\omega,\omega^2];\\ \phi_2^{-1}(x), & x\in[\omega^2,1],\end{cases} \tag{2.32}$$

satisfies $F=G$ on $[-\omega,\omega^2]$ and $F=G^2$ on $(\omega^2,1]$, where $F(-\omega)=G(-\omega+)$.

We shall see that, asymptotically, the orbit of t_2 under the recursion (2.18) is determined solely by the orbits of the zeros of t_2 in I under the map G, apart from a choice of sign.

The function G is discontinuous on I. However, by identifying the points $-\omega^{-1}$, $-\omega$ and 1 in I we obtain a continuous map on the quotient topological space consisting of two circles joined at a single common point.

E. The multiplicative structure of *R*

In Ref. 25 the iteration (2.18) was studied for the case of piecewise constant functions t_n taking values ±1, and the periodic orbits were classified completely. This situation arises in the renormalization of the correlation function of strange nonchaotic attractors with a golden mean rotation number. These periodic orbits of (2.18) are determined by the periodic orbits of the map F given by (2.32) above. This is essentially because the dynamics of piecewise constant functions are governed by their discontinuity points, and the multiplicative nature of (2.18) relates any discontinuity of t_{n+1} at x with a discontinuity of t_n at $-\omega x$ or a discontinuity of t_{n-1} at $\omega^2x+\omega$. We refer the reader to Ref. 25 for details. However, such considerations apply also to the zeros of t_n and also to other singularities such as poles. In terms of the first-order renormalization R it is the map G (2.31) on I which is relevant. Indeed the following result is an immediate consequence of the definition of R and of the map G.

Proposition 2.1: Let $(u_{n+1},t_{n+1})=R(u_n,t_n)$ *where* u_n *is defined on* $[-\omega^{-1},-\omega]$ *and* t_n *is defined on* $[-\omega,1]$. *Then, defining* $G_0(x)=-\omega^{-1}x$ *and* $G_1(x)=-\omega^{-1}x-\omega^{-1}$,

(i) $u_{n+1}(x)=0$ *if and only if* $x=G_0(y)$ *where* $y\in[-\omega,1]$ *such that* $t_n(y)=0$;
(ii) $t_{n+1}(x)=0$ *if and only if* $x=G_0(y)$ *where* $y\in[-\omega,1]$ *such that* $t_n(y)=0$ *or* $x=G_1(y)$ *where* $y\in[-\omega^{-1},-\omega]$ *such that* $u_n(y)=0$.

Thus under iteration of R, the zeros evolve under iteration of the maps G_0, G_1, which, apart, from the point $x=-\omega$ correspond to the map G above.

The renormalization operator R has the following multiplicative property which is the analog of the linearity of the operator R_a. Let (u_1,t_1), (u_2,t_2) be function pairs. Then, using our convention that binary operations are defined coordinatewise, we have

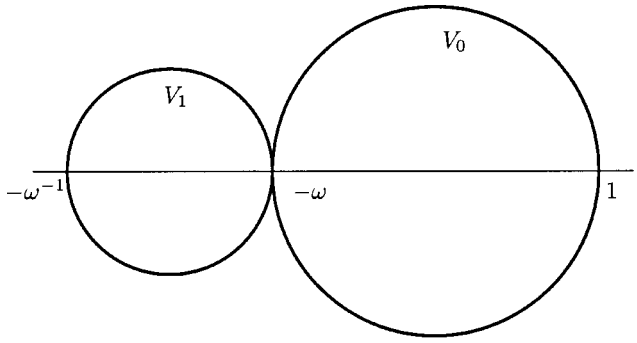

FIG. 3. The domains V_0 and V_1.

$$R((u_1,t_1)(u_2,t_2)) = R(u_1,t_1)R(u_2,t_2), \tag{2.33}$$

so that R respects the multiplication of function pairs. An analogous property holds for function pair division. We shall use this property extensively in what follows.

F. Properties of R and R_a

In this section we describe properties of the multiplicative renormalization operator R and its additive version R_a. We shall construct projections P and P_a which commute with R and R_a, respectively, and which "kill off" the unstable eigenvectors. We shall thus obtain operators RP and R_aP_a with spectral radius less than 1.

Recall that the multiplicative renormalization operator R on a pair of functions (u,t) is given by

$$R(u,t)(x) = (t(\theta_0(x)), t(\theta_0(x))u(\theta_1(x))), \tag{2.34}$$

where $\theta_0(x) = -\omega x$ and $\theta_1(x) = -\omega x - 1$. The additive version R_a of this operator is given by

$$R_a(U,T)(x) = (T(\theta_0(x)), T(\theta_0(x)) + U(\theta_1(x))). \tag{2.35}$$

We shall adopt the convention that the multiplicative operator R operates on lower-case function pairs (u,t), while the additive operator R_a operates on upper-case function pairs (U,T).

For $c \in \mathbb{C}$ and $r > 0$ let $D(c,r) = \{z \in \mathbb{C} : |z-c| < r\}$ denote the open disk with center c and radius r. Let $V_1 = D(c_1,r_1)$, $V_0 = D(c_0,r_0)$ be the disks in $\mathbb{C}$ specified by

$$c_0 = \omega^2/2, \quad r_0 = \omega^{-1}/2, \quad c_1 = -(\omega + 1/2), \quad r_1 = 1/2, \tag{2.36}$$

as illustrated in Fig. 3.

We have

$$[-\omega^{-1}, -\omega] \subseteq \overline{V_1}, \quad [-\omega, 1] \subseteq \overline{V_0}, \quad \theta_0(V_1) \subseteq V_0, \quad \theta_0(V_0) \subseteq V_0, \quad \theta_1(V_0) \subseteq V_1. \tag{2.37}$$

The convention we adopt is that the functions u and U are defined on V_1 and the functions t and T are defined on V_0. Moreover we shall assume that u and t are analytic on their respective domains, and that U and T are analytic on V_1 and V_0, respectively, or, at worst, have logarithmic singularities. For $i = 0,1$ let $\mathcal{B}_i$ be the real Banach space of real-analytic functions on V_i given by the Taylor series

$$f(z) = \sum_{k=0}^{\infty} f_k \frac{(z-c_i)^k}{r_i^k}, \tag{2.38}$$

with l_1-norm

$$\|f\|_{i,1} = \sum_{k=0}^{\infty} |f_k| < \infty. \tag{2.39}$$

Let $\mathcal{F}=\mathcal{B}_1 \times \mathcal{B}_0$ be the space of pairs (u,t) with $u \in \mathcal{B}_1$ and $t \in \mathcal{B}_0$. We equip $\mathcal{F}$ with the norm

$$\|(u,t)\| = \max\{\|u\|_{1,1}, \|t\|_{0,1}\}. \tag{2.40}$$

Then $\mathcal{F}$ is a real Banach space of pairs of analytic functions. We note that, in view of (2.37), the renormalization operators R and R_a are both well defined on $\mathcal{F}$. Indeed, R_a is a linear operator on $\mathcal{F}$, and we now discuss its functional analytic properties.

The following result is similar to Theorem 3 of Ref. 24.

Proposition 2.2: The additive renormalization operator R_a is a bounded linear operator on $\mathcal{F}$, which preserves, for each $n \geqslant 0$, the subspaces of polynomial pairs of degree at most n. The spectrum restricted to the subspace of polynomial pairs consists of the simple eigenvalues ω^{-1}, $-1, \pm\omega, \pm\omega^2, \ldots$.

The proof is straightforward and is similar to those given in Ref. 24.

Of particular note is that the eigenvalues corresponding to linear function pairs are ω^{-1}, -1, $-\omega$, and ω^2. Indeed, the eigenfunction pairs corresponding to eigenvalues ω^{-1} and -1 are, respectively,

$$\mathbf{v}_0 = \frac{1}{\sqrt{5}}(\omega, 1), \quad \mathbf{v}_1 = \frac{1}{\sqrt{5}}(\omega x - \omega, x + \omega), \tag{2.41}$$

as can readily be checked by direct computation: $R_a\mathbf{v}_0 = \omega^{-1}\mathbf{v}_0$, $R_a\mathbf{v}_1 = -\mathbf{v}_1$.

In Ref. 24 the strong-coupling fixed point was constructed using a singular function and a linear operator that is a contraction to zero, i.e., its spectrum is contained inside the unit circle in $\mathbb{C}$. Our approach to the construction of the orchid will be similar; it is therefore essential to "kill off" the noncontracting eigenfunction pairs of the operator R_a. We do this by projecting down to the stable manifold of the origin, i.e., the codimension-2 subspace of $\mathcal{F}$ spanned by the contracting eigenfunction pairs and the spectral subspace of 0. The construction of this projection P_a uses the family of linear functionals of $\mathcal{F}$ defined as follows.

Definition: For $n \geqslant 0$, let $\Delta_n : \mathcal{F} \to \mathbb{R}$ be defined by

$$\Delta_n(U,T) = \int_{-\omega^{-1}}^{-\omega} U^{(n)}(x)dx + \int_{-\omega}^{1} T^{(n)}(x)dx. \tag{2.42}$$

We note that for $n=1$,

$$\Delta_1(U,T) = U(-\omega) - U(-\omega^{-1}) + T(1) - T(-\omega), \tag{2.43}$$

and for $n=0$,

$$\Delta_0(U,T) = \int_{-\omega^{-1}}^{-\omega} U(x)dx + \int_{-\omega}^{1} T(x)dx. \tag{2.44}$$

Moreover, we remark that the linear functionals Δ_n may be defined for function pairs (U,T) with singularities in $V_1 \times V_0$. Indeed this is certainly the case for Δ_0 when U and T have logarithmic singularities on I.

The significance of the linear functionals Δ_n is that they are eigenvectors of the adjoint operator R_a^* on the dual space $\mathcal{F}^*$. Indeed we have the following.

Proposition 2.3:

$$\Delta_n(R_a(U,T)) = (-1)^n \omega^{n-1} \Delta_n(U,T). \tag{2.45}$$

Proof: The proof is a straightforward calculation:

$$\Delta_n(R_a(U,T)) = \int_{-\omega^{-1}}^{-\omega} \frac{d^n}{dx^n} T(\theta_0(x))dx + \int_{-\omega}^{1} \frac{d^n}{dx^n}(T(\theta_0(x)) + U(\theta_1(x)))dx$$

$$= (-\omega)^n \int_{-\omega^{-1}}^{-\omega} T^{(n)}(\theta_0(x))dx + (-\omega)^n \int_{-\omega}^{1} T^{(n)}(\theta_0(x)) + U^{(n)}(\theta_1(x))dx$$

$$= (-\omega)^{n-1} \int_{1}^{\omega^2} T^{(n)}(y)dy + (-\omega)^{n-1} \int_{\omega^2}^{-\omega} T^{(n)}(y)dy$$

$$+ (-\omega)^{n-1} \int_{-\omega}^{-\omega^{-1}} U^{(n)}(y')dy'$$

$$= -(-\omega)^{n-1}\left(\int_{-\omega}^{1} T^{(n)}(y)dy + \int_{-\omega^{-1}}^{-\omega} U^{(n)}(y')dy' \right)$$

$$= (-1)^n \omega^{n-1} \Delta_n(U,T), \tag{2.46}$$

as required. [In the above integrals we have changed variables: $y = \theta_0(x)$, $y' = \theta_1(x)$.] □

Direct calculation also gives the following properties:

$$\Delta_0(\mathbf{v}_0) = 1, \quad \Delta_0(\mathbf{v}_1) = 0, \quad \Delta_1(\mathbf{v}_0) = 0, \quad \Delta_1(\mathbf{v}_1) = 1. \tag{2.47}$$

Definition: The operator P_a is defined by

$$P_a(U,T) = (U,T) - \mathrm{Re}(\Delta_0(U,T))\mathbf{v}_0 - \mathrm{Re}(\Delta_1(U,T))\mathbf{v}_1. \tag{2.48}$$

We note that if $(U,T) \in \mathcal{F}$, then $\Delta_0(U,T)$, $\Delta_1(U,T) \in \mathbb{R}$.

The following results are straightforward to verify.

Proposition 2.4: The operator P_a has the following properties:

(i) $\mathrm{Re}(\Delta_0(P_a(U,T))) = \mathrm{Re}(\Delta_1(P_a(U,T))) = 0$;
(ii) $P_a^2 = P_a$;
(iii) $P_a R_a = R_a P_a$;
(iv) $P_a \mathbf{v}_0 = P_a \mathbf{v}_1 = 0$, *and* $\langle \mathbf{v}_0, \mathbf{v}_1 \rangle$ *is the null space of* P_a.

From this proposition we may conclude that P_a is a projection which commutes with R_a, and which "kills off" the noncontracting eigenfunction pairs $\mathbf{v}_0$ and $\mathbf{v}_1$.

Propositions 2.2 and 2.4 now give us the following result on the spectrum of $R_a P_a$.

Proposition 2.5: The operator $R_a P_a$ is a bounded operator, preserving, for each $n \geqslant 0$, the subspaces of polynomial pairs of degree at most n. The spectrum restricted to these subspaces of polynomial pairs consists of the simple eigenvalues $\pm\omega, \pm\omega^2, \ldots$.

We remark that, in particular, the spectral radius of $R_a P_a$ on the 4-dimensional space of linear function pairs is ω.

G. The multiplicative projection *P*

We now return to the multiplicative renormalization operator R and define a projection P that is analogous to P_a.

With the convention of Sec. II B, we note that for $(U,T) \in \mathcal{F}$ we have $R(\exp(U,T)) = \exp(R_a(U,T))$. Moreover, provided $u \neq 0$ on $\overline{V_1}$ and $t \neq 0$ on $\overline{V_0}$ and $u(x)$, $t(x) > 0$ for real x in their respective domains, we have that the principal branch of the logarithm $\log(U,T)$ is well defined and real for real argument, and $R_a(\log(u,t)) = \log R(u,t)$. Thus it is the possibility of the functions u and t changing sign that prevents a direct translation from R to R_a.

If $\log(u,t)$ exists we may define the projection $P(u,t)=\exp(P_a(\log(u,t)))$. However, in any event we may define P as follows.

Definition: The operator $P:\mathcal{F}\to\mathcal{F}$ is defined by

$$P(u,t) = (u,t)\exp(-\Delta_0(\log|(u,t)|)\mathbf{v}_0 - \Delta_1(\log|(u,t)|)\mathbf{v}_1). \tag{2.49}$$

We note that $P(u,t)=\exp(P_a(\log(u,t)))$.

It is straightforward to show that P has the properties of a projection operator.

Proposition 2.6: The operator $P:\mathcal{F}\to\mathcal{F}$ satisfies

(i) $P^2=P$;
(ii) $PR=RP$;
(iii) $P((u_1,t_1)(u_2,t_2))=P(u_1,t_1)P(u_2,t_2)$ *for* (u_1,t_1), $(u_2,t_2)\in\mathcal{F}$;
(iv) $P\exp(U,T)=\exp P_a(U,T)$ *for* $(U,T)\in\mathcal{F}$.

We remark that the operator RP may be used to construct the orchid numerically, although care must be taken to preserve the symmetry of the zero set.

H. Convergence of orbits with the same zero set

We are now in a position to prove that it is indeed the zero set of an initial condition (u_0,t_0) together with a choice of sign $(s_0^u,s_0^t)\in\{-1,+1\}^2$ which completely determines the asymptotic future of $P(u_0,t_0)$ under R. Specifically we prove the following.

Proposition 2.7: Let $(u_0,t_0)\in\mathcal{F}$ satisfy

(i) $u_0\neq 0$ *on* $\overline{V_1}$;
(ii) $t_0\neq 0$ *on* $\overline{V_0}$;
(iii) $u_0(x)>0$ *for* $x\in\overline{V_1}\cap\mathbb{R}$;
(iv) $t_0(x)>0$ *for* $x\in\overline{V_0}\cap\mathbb{R}$;
(v) $(d^2/dx^2)\log(u_0,t_0)(x)\in\mathcal{F}$.

Then

$$(\hat{u}_n,\hat{t}_n) = R^nP(u_0,t_0)\to(1,1), \quad \text{as } n\to\infty. \tag{2.50}$$

Sketch Proof: From the above we may write $(\hat{U}_0,\hat{T}_0)=P_a\log(u_0,t_0)$ with $(\hat{U}_0,\hat{T}_0)\in\mathcal{F}$. Moreover, it can be shown that $(\hat{U}_n,\hat{T}_n)=R_a^n(\hat{U}_0,\hat{T}_0)\to(0,0)$ as $n\to\infty$. Then

$$(\hat{u}_n,\hat{t}_n) = R^nP(u_0,t_0) = R^n\exp(P_a\log(u_0,t_0)) = \exp(R_a^nP_a\log(u_0,t_0)) = \exp(\hat{U}_n,\hat{T}_n)\to(1,1),$$
$$\text{as } n\to\infty. \tag{2.51}$$

This completes the proof. □

From this result we may immediately deduce that the future of (u_0,t_0) under R is determined by the zero sets of u_0, t_0 together with a choice of sign. For if (u_0^1,t_0^1), (u_0^2,t_0^2) have the same zero sets in V_1 and V_0, then we may find a choice of signs $(s_0^u,s_0^t)\in\{-1,+1\}^2$ such that

$$(s_0^u,s_0^t)(u_0^1,t_0^1)/(u_0^2,t_0^2) = \left(s_0^u\frac{u_0^1}{u_0^2},s_0^t\frac{t_0^1}{t_0^2}\right) \tag{2.52}$$

(once the removable singularities have been removed) satisfies the proposition above so that

$$\frac{R^nP(u_0^1,t_0^1)R^n(s_0^u,s_0^t)}{R^nP(u_0^2,t_0^2)}\to(1,1), \quad \text{as } n\to\infty, \tag{2.53}$$

and so

$$\frac{|R^n P(u_0^1, t_0^1)|}{|R^n P(u_0^2, t_0^2)|} \to (1,1), \quad \text{as } n \to \infty. \tag{2.54}$$

III. SHIFT SPACES AND PARTNERS

A. Shift spaces

Let X be a metric space with metric d. We write $X^{\mathbb{Z}}$ for the set of bi-infinite sequences $\mathbf{x}=(x_k)_{k\in\mathbb{Z}}$ with $x_k \in X$. We denote by $\sigma: X^{\mathbb{Z}} \to X^{\mathbb{Z}}$ the shift map defined for $\mathbf{x}=(x_k)_{k\in\mathbb{Z}} \in X^{\mathbb{Z}}$ by $\sigma(\mathbf{x})_k = x_{k+1}$. If X is bounded then we may define a metric on $X^{\mathbb{Z}}$ as follows:

$$d(\mathbf{x}, \mathbf{x}') = \sum_{k=-\infty}^{\infty} d(x_k, x_k') 2^{-|k|}. \tag{3.1}$$

With respect to this metric the shift map σ is a homeomorphism of $X^{\mathbb{Z}}$. Of particular importance for us will be the case when $X=\{0,1\}$ with the metric $d(x,x')=|x-x'|$ with $x, x' \in \{0,1\}$. We note that the space $\{0,1\}^{\mathbb{Z}}$, which is the full two-sided/bi-infinite shift space on the two symbols 0, 1, is homeomorphic to a Cantor set.

We now denote by $\hat{\Sigma}$ the *subshift of finite type* consisting of bi-infinite sequences $\mathbf{c}=(c_k)_{k\in\mathbb{Z}}$ satisfying $c_k c_{k+1}=0$, i.e., sequences for which no two consecutive terms of the sequence have digit 1. Then $\hat{\Sigma}$ inherits a topology from $\{0,1\}^{\mathbb{Z}}$ and moreover the shift map σ restricts to a homeomorphism $\sigma: \hat{\Sigma} \to \hat{\Sigma}$. We shall henceforth refer to bi-infinite sequences in $\hat{\Sigma}$ as *codes*.

Let Σ be the subset of $\hat{\Sigma}$ obtained by removing all codes $\mathbf{c}$ which terminate in either all 0s or the block 01 repeated infinitely often. Then Σ is invariant under σ, but is not closed in $\hat{\Sigma}$.

B. The evaluation map

Definition: For $n \in \mathbb{Z}$, we define the *evaluation map* at index n, $e_n: \hat{\Sigma} \to I$, to be the base $-\omega$ expansion,

$$e_n(\mathbf{c}) = -\sum_{k=n}^{\infty} c_k (-\omega)^{k-n}. \tag{3.2}$$

The evaluation map satisfies

$$e_n(\sigma(\mathbf{c})) = -\sum_{k=n}^{\infty} c_{k+1}(-\omega)^{k-n} = -\sum_{k'=n+1}^{\infty} c_{k'}(-\omega)^{k'-(n+1)} = e_{n+1}(\mathbf{c}). \tag{3.3}$$

Writing $\mathbf{e}$ for the map of sequence spaces $\mathbf{e}: \hat{\Sigma} \to I^{\mathbb{Z}}$ given by $\mathbf{e}(\mathbf{c})_n = e_n(\mathbf{c})$, the relation (3.3) becomes

$$\mathbf{e}(\sigma(\mathbf{c})) = \sigma(\mathbf{e}(\mathbf{c})). \tag{3.4}$$

For each $n \in \mathbb{Z}$, e_n is continuous and thus so is $\mathbf{e}$. We note that the codes that have been deleted from $\hat{\Sigma}$ to form Σ are those for which $e_n(\mathbf{c})=0$ or 1 for some $n \in \mathbb{Z}$.

Of particular interest to us is the fact that the image $\mathbf{e}(\Sigma)$ is precisely the set of full orbits of the map G which never take the values 0 or 1. Indeed,

$$e_n(\sigma(\mathbf{c})) = e_{n+1}(\mathbf{c}) = -\sum_{k=n+1}^{\infty} c_k(-\omega)^{k-(n+1)}$$
$$= -\omega^{-1}\left(-\sum_{k=n+1}^{\infty} c_k(-\omega)^{k-n}\right) = -\omega^{-1}\left(-\sum_{k=n}^{\infty} c_k(-\omega)^{k-n} + c_n\right)$$
$$= -\omega^{-1}e_n(\mathbf{c}) - \omega^{-1}c_n = G(e_n(\mathbf{c})), \tag{3.5}$$

since $c_n = c$ if and only if $e_n(\mathbf{c}) \in I_c$.

C. Partners

We now define a symmetry operation on bi-infinite codes $\mathbf{c} \in \Sigma$ which we call "partnering." The partnering operation will be important in the construction of the orchid below.

The definition of the operation will be eased by introducing the symbols A, B, C where $A = 010$, $B = 00$, $C = 01$ are groups of digits in the code $\mathbf{c}$. We can write any code $\mathbf{c} \in \Sigma$ uniquely in terms of the symbols A, B, C as given by the following lemma.

Lemma 3.1: Let $\mathbf{c} \in \Sigma$. *Then* $\mathbf{c}$ *may be written uniquely in terms of the symbols* A, B, C. *Conversely, any bi-infinite sequence of symbols* A, B, C *corresponds to a unique* $\mathbf{c} \in \Sigma$ *once the location of* $k = 0$ (*which need not be the first digit of* A, B, C) *is known.*

Proof: It is clear that any symbol sequence of A, B, C gives a unique code $\mathbf{c} \in \Sigma$ provided the origin $k = 0$ is known. It remains to show that any code $\mathbf{c} \in \Sigma$ may be written in terms of A, B, C.

Let $\mathbf{c} \in \Sigma$. We first of all consider the case when $\mathbf{c}$ does not begin in only zeros. Since no two consecutive 1s occur in the code we may write $\mathbf{c}$ in terms of blocks of digits beginning with 01. Such a block will be one of two forms: (i) $010(00)^m$; or (ii) $01(00)^m$. Here $m \geqslant 0$ is an integer, and, for a group of digits D, D^m means repeat the group D m times. In case (i) we write the block as AB^m. In case (ii) we write CB^m. In the case when $\mathbf{c}$ begins in all zeros then $\mathbf{c}$ may be written as $B^\infty A\ldots$ or $B^\infty C\ldots$. It is clear that the representation in terms of the symbols A, B, C is unique. □

As an example we illustrate with the code

$$\ldots\underbrace{010}_{A}\,\underbrace{0\dot{1}000}_{AB}\,\underbrace{010000}_{CB^2}\,\underbrace{01}_{C}\,01\ldots, \tag{3.6}$$

in which the "dot" above a digit indicates the location of the origin $k = 0$.

We are now able to define the partner operation via the following substitution rule on the symbols A, B, C:

$$A \to A, \quad B \to C, \quad C \to B. \tag{3.7}$$

We denote the resulting partner of a code $\mathbf{c} = (c_k)_{k\in\mathbb{Z}}$ by $\tilde{\mathbf{c}} = (\tilde{c}_k)_{k\in\mathbb{Z}}$. So, for example, the code considered above

$$\mathbf{c} = \ldots\underbrace{010}_{A}\,\underbrace{0\dot{1}000}_{AB}\,\underbrace{010000}_{CB^2}\,\underbrace{01}_{C}\,01\ldots \tag{3.8}$$

has partner

$$\tilde{\mathbf{c}} = \ldots\underbrace{010}_{A}\,\underbrace{0\dot{1}001}_{AC}\,\underbrace{000101}_{BC^2}\,\underbrace{00}_{B}\ldots. \tag{3.9}$$

It is clear from the rule (3.7) that the partner operation is an involution: $\tilde{\tilde{\mathbf{c}}} = \mathbf{c}$. Moreover it is also clear that it commutes with the shift $\sigma: \Sigma \to \Sigma$: $\sigma(\tilde{\mathbf{c}}) = \widetilde{\sigma(\mathbf{c})}$. This is because the location of $k = 0$ is preserved under partnering.

The code $\mathbf{c}$ corresponds to a full orbit $\mathbf{y} = (y_n)_{n\in\mathbb{Z}}$ of the map G by the evaluation map $\mathbf{e}$, i.e., $\mathbf{y} = \mathbf{e}(\mathbf{c})$, where $y_n = e_n(\mathbf{c})$.We may now ask how the orbits $\mathbf{y} = \mathbf{e}(\mathbf{c})$ and $\tilde{\mathbf{y}} = \mathbf{e}(\tilde{\mathbf{c}})$ are related. In order

to give the answer we define the following "sum map" $\mathbf{S}:\Sigma\to\{-\omega^{-1},-\omega,1\}^{\mathbb{Z}}$, the space of bi-infinite sequences taking values in $\{-\omega^{-1},-\omega,1\}$. We define $\mathbf{S}$ on a code $\mathbf{c}\in\Sigma$ by defining its action on the symbols A, B, C:

$$\mathbf{S}(A)=1(-\omega^{-1})(-\omega),\quad \mathbf{S}(B)=\mathbf{S}(C)=1(-\omega^{-1}). \tag{3.10}$$

We then define $\mathbf{S}$ on the whole code $\mathbf{c}$ by writing $\mathbf{c}$ in terms of A, B, C as in Lemma 3.1 and applying $\mathbf{S}$ to each of the symbols A, B, C separately. We note that since $\mathbf{S}$ preserves the number of symbols it commutes with σ:

$$\mathbf{S}(\sigma(\mathbf{c}))=\sigma(\mathbf{S}(\mathbf{c})). \tag{3.11}$$

Furthermore, comparing (3.10) with (3.7) we see that the map $\mathbf{S}$ is invariant under the partner map: $\mathbf{S}(\tilde{\mathbf{c}})=\mathbf{S}(\mathbf{c})$ for all $\mathbf{c}\in\Sigma$.

We have the following result which specifies precisely how $\mathbf{y}=\mathbf{e}(\mathbf{c})$ and $\tilde{\mathbf{y}}=\mathbf{e}(\tilde{\mathbf{c}})$ are related, and explains our terminology "sum map."

Proposition 3.1: Let $\mathbf{y}=\mathbf{e}(\mathbf{c})$ *and* $\tilde{\mathbf{y}}=\mathbf{e}(\tilde{\mathbf{c}})$. *Then* $\mathbf{y}+\tilde{\mathbf{y}}=\mathbf{S}(\mathbf{c})$, *where the sum is to be calculated termwise.*

Proof: For $n\in\mathbb{Z}$ let $S_n=y_n+\tilde{y}_n$. We write the codes of $\mathbf{c}$ and $\tilde{\mathbf{c}}$ in terms of the symbols A, B, C. We note that

$$y_n=-\sum_{k=n}^{\infty}c_k(-\omega)^{k-n},\quad \tilde{y}_n=-\sum_{k=n}^{\infty}\tilde{c}_k(-\omega)^{k-n}, \tag{3.12}$$

and that $y_n,\tilde{y}_n\in[-\omega^{-1},1]$ for all $n\in\mathbb{Z}$. In particular they are bounded.

Let us first of all consider the case when c_n starts a symbol A, B, or C. Then we have two cases.

(i) Both c_n and $\tilde{c}_n$ start an $A=010$. Then

$$\begin{aligned}S_n=y_n+\tilde{y}_n&=-(-\omega)-(-\omega)^3\sum_{k=n+3}^{\infty}c_k(-\omega)^{k-(n+3)}-(-\omega)-(-\omega)^3\sum_{k=n+3}^{\infty}\tilde{c}_k(-\omega)^{k-(n+3)}\\&=2\omega-\omega^3S_{n+3}.\end{aligned} \tag{3.13}$$

(ii) One of c_n, $\tilde{c}_n$ starts a $B=00$ and the other starts a $C=01$. Then we obtain

$$S_n=\omega+\omega^2S_{n+2}. \tag{3.14}$$

Now let

$$\kappa_2(x)=\omega+\omega^2x,\quad \kappa_3(x)=2\omega-\omega^3x. \tag{3.15}$$

Both of these maps are contractions with fixed point 1, and we have

$$S_n=\kappa_{i_1}\circ\cdots\circ\kappa_{i_\ell}(S_{n+i_1+\cdots+i_\ell}), \tag{3.16}$$

where $i_1,\ldots,i_\ell\in\{2,3\}$ according to the sequence of A, B, C in the codes $\mathbf{c}$, $\tilde{\mathbf{c}}$ starting at n. Now

$$|S_n-1|=\omega^{i_1+\cdots+i_\ell}|S_{n+i_1+\cdots+i_\ell}-1|, \tag{3.17}$$

and, since S_k is bounded for all $k\in\mathbb{Z}$, it follows, taking $\ell\to\infty$, that $S_n=1$.

We have therefore proved that $y_n+\tilde{y}_n=1$ provided n is at the start of a symbol A, B, or C.

Next we consider the case where c_n (and therefore $\tilde{c}_n$) is the digit 1 of $A=010$. Then we see that

$$S_n = -2 + \omega^2 S_{n+2}, \tag{3.18}$$

where c_{n+2} starts an A, B, or C in $\mathbf{c}$ and $\tilde{\mathbf{c}}$. Thus $S_{n+2}=1$ and so $S_n=-2+\omega^2=-\omega^{-1}$.

When c_n (and again therefore $\tilde{c}_n$) is the second digit 0 of $A=010$ we have that $S_n=-\omega S_{n+1}=-\omega$, since $S_{n+1}=1$.

These last two cases show that the sums for a symbol $A=010$ are $1(-\omega^{-1})(-\omega)$ as in the definition of the map $\mathbf{S}$ (3.10).

Finally, we consider the case when c_n (respectively, $\tilde{c}_n$) is the second digit of a B or C (respectively, C or B). We have $S_n=-1-\omega S_{n+1}=-1-\omega=-\omega^{-1}$. Thus, from this and the first case considered, the sums for the symbols $B=00$ and $C=01$ are both $1(-\omega^{-1})$ as in the definition of the map $\mathbf{S}$ (3.10), and the lemma is proved. □

For future use, we remark that (3.10) indicates that if $y_0+\tilde{y}_0=1$ then c_0 can only be at the beginning of a symbol A, B or C.

We illustrate this result with an example. Let

$$\mathbf{c} = \ldots \underbrace{\dot{0}1000}_{AB}\underbrace{01000}_{AB}\ldots \tag{3.19}$$

be the bi-infinite sequence of AB repeated which has the partner

$$\tilde{\mathbf{c}} = \ldots \underbrace{\dot{0}1001}_{AC}\underbrace{01001}_{AC}\ldots \ . \tag{3.20}$$

Then $\mathbf{y}$ and $\tilde{\mathbf{y}}$ are the period-5 orbits of G:

$$\mathbf{y} = \ldots, \frac{\omega}{1+\omega^5}, \frac{-1}{1+\omega^5}, \frac{-\omega^4}{1+\omega^5}, \frac{\omega^3}{1+\omega^5}, \frac{-\omega^2}{1+\omega^5}, \ldots, \tag{3.21}$$

$$\tilde{\mathbf{y}} = \ldots, \frac{\omega-\omega^4}{1+\omega^5}, \frac{\omega^3-1}{1+\omega^5}, \frac{-(\omega^2+\omega^4)}{1+\omega^5}, \frac{\omega+\omega^3}{1+\omega^5}, \frac{-(1+\omega^2)}{1+\omega^5}, \ldots, \tag{3.22}$$

with period-5 sum

$$\mathbf{S}(\mathbf{c}) = \mathbf{S}(\tilde{\mathbf{c}}) = \ldots, 1, -\omega^{-1}, -\omega, 1, -\omega^{-1}, \ldots, \tag{3.23}$$

as can easily be verified.

IV. CONSTRUCTION OF THE ORCHID

In this section we describe the construction of the Ketoja–Satija orchid $\mathcal{O}$. By the orchid we mean the whole set in function-pair space, not just the projection onto the plane by an evaluation at the origin of the function pair as in Fig. 1. We shall see that an uncountable dense subset of the orchid consists essentially of three copies of the sequence space Σ and, together with a map that acts on the signs of the functions, the shift map σ on Σ provides a dynamical model for the action of R on this dense subset of $\mathcal{O}$.

To construct the orchid we first define a map $\mathcal{E}:\Sigma\to\mathcal{F}$ which essentially conjugates R to the shift map σ on Σ. For $c\in\{0,1\}$, let us define a map on sign pairs $\kappa_c:\{-1,+1\}^2\to\{-1,+1\}^2$ by

$$\kappa_c(s^u,s^t) = (-s^t, -(-1)^c s^u s^t). \tag{4.1}$$

The map $\mathcal{E}:\Sigma\to\mathcal{F}$ is given by the following proposition.

Proposition 4.1: There exists a continuous map $\mathcal{E}:\Sigma\to\mathcal{F}$ such that for $\mathbf{c}\in\Sigma$, $\mathcal{E}(\mathbf{c})$ is a pair $(u,t)\in\mathcal{F}$ such that

(i) *if $c_{-1}=0$ then $u(x)=(y_0-x)u^1(x)$, $t(x)=(y_0-x)t^1(x)$; otherwise*
(ii) *if $c_{-1}=1$ then $u(x)=u^1(x)$, $t(x)=(y_0-x)t^1(x)$,*

where $y_0=e_0(\mathbf{c})$, and u^1, t^1 are functions analytic on V_1 and V_0, respectively, satisfying $u^1(x)>0$

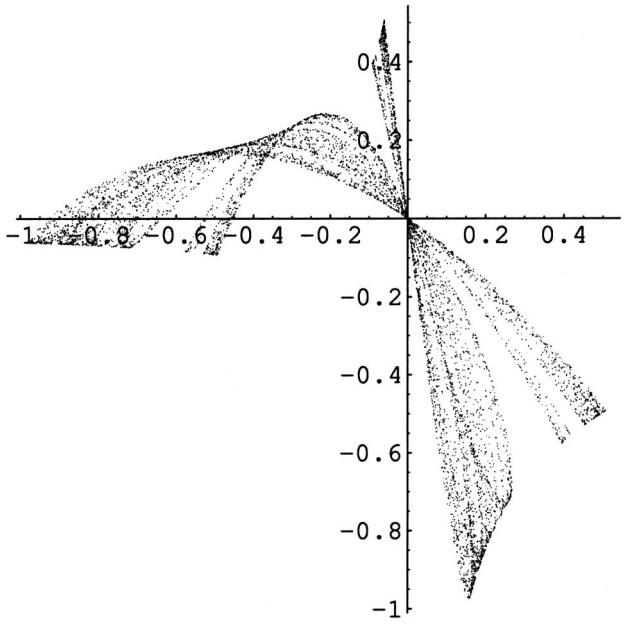

FIG. 4. A projection of the fundamental set cl($\beta(\Sigma)$).

on $(-\omega^{-1},-\omega)$ *and* $t^1(x)>0$ *on* $(-\omega,1)$. *Furthermore, let* $(s^u,s^t)\in\{-1,+1\}^2$ *be a choice of signs. Then, using our convention that multiplication of pairs is defined coordinatewise, we have that for* $\mathbf{c}\in\Sigma$,

$$R((s^u,s^t)\mathcal{E}(\mathbf{c}))=\kappa_{c_0}(s^u,s^t)\mathcal{E}(\sigma(\mathbf{c})). \tag{4.2}$$

In essence the proposition says that the action of R on a pair $(u,t)=(s^u,s^t)\mathcal{E}(\mathbf{c})$ is the map κ_{c_0} on the pair of signs (s^u,s^t) together with the shift map on the code $\mathbf{c}$.

The proof of this proposition is in Sec. V.

We now return to the construction of the orchid itself. The orchid is constructed from a code $\mathbf{c}$ and its partner $\tilde{\mathbf{c}}$. Indeed we may use the map $\mathcal{E}$ to define one of the three fundamental sets that make up the orchid.

Definition: The map $\beta:\Sigma\to\mathcal{F}$ is defined for $\mathbf{c}\in\Sigma$ by

$$\beta(\mathbf{c})=\mathcal{E}(\mathbf{c})\mathcal{E}(\tilde{\mathbf{c}}), \tag{4.3}$$

where $\tilde{\mathbf{c}}$ is the partner of $\mathbf{c}$.

A projection to the plane of the closure of the image of β is shown in Fig. 4.

We now define a new map on the sign pairs as follows.

Definition: For $b\in\{0,1\}$ let $L_b:\{-1,+1\}^2\to\{-1,+1\}^2$ be defined by

$$L_b(s^u,s^t)=(s^t,(-1)^b s^u s^t). \tag{4.4}$$

It is easy to check that the map L_b is invertible with inverse $L_b^{-1}(s^u,s^t)=((-1)^b s^u s^t,s^u)$.

We then have the following theorem.

Theorem 4.1: *The map* $\beta:\Sigma\to\mathcal{F}$ *satisfies the equation*

$$R((s^u,s^t)\beta(\mathbf{c}))=L_{b_0}(s^u,s^t)\beta(\sigma(\mathbf{c})), \tag{4.5}$$

where $b_0=c_0+\tilde{c}_0 \bmod 2$. *The map* β *is continuous and two-to-one from* Σ *to its image* $\beta(\Sigma)\subseteq\mathcal{F}$.

Equation (4.5) follows immediately from (4.2), and we prove the other properties of β in Sec. V D. We now proceed to use the theorem to construct the orchid. The orchid $\mathcal{O}$ is made up of three copies of the fundamental set $\beta(\Sigma)$ as follows. Let $\mathbf{c}$, $\tilde{\mathbf{c}}$ be partners and let $\mathbf{b}=\mathbf{c}+\tilde{\mathbf{c}} \bmod 2$ be the

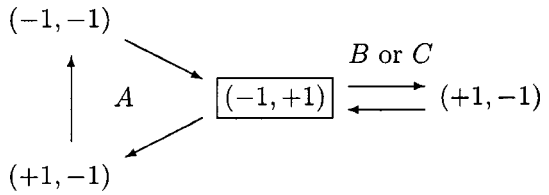

FIG. 5. The fundamental transition diagram.

bi-infinite sequence giving the parities of the sum $\mathbf{c}+\tilde{\mathbf{c}}$. Recall from Sec. III C that the partner code $\tilde{\mathbf{c}}$ is obtained from $\mathbf{c}$ by writing $\mathbf{c}$ uniquely in terms of the letters *A*, *B*, *C*. We shall need the set of indices which begin an *A*, *B*, *C* in the code of $\mathbf{c}$.

Definition: We define $S=\{k\in\mathbb{Z}$: the code of $\mathbf{c}$ begins an *A*, *B*, *C* at index $k\}$.

The set S is important and we shall have to restrict the signs (s^u,s^t) at indices $k\in S$. For $\mathbf{c}\in\Sigma$ and $(s_0^u,s_0^t)\in\{-1,+1\}^2$ we define, for $n\in\mathbb{Z}$, $(s_n^u,s_n^t)=(s_n^u(\mathbf{c}),s_n^t(\mathbf{c}))$ by the condition

$$L_{b_n}(s_n^u,s_n^t)=(s_{n+1}^u,s_{n+1}^t), \tag{4.6}$$

for all $n\in\mathbb{Z}$, where, as before $\mathbf{b}=\mathbf{c}+\tilde{\mathbf{c}}$ mod 2.

Definition (Ketoja–Satija orchid): The Ketoja–Satija orchid $\mathcal{O}$ is defined as

$$\mathcal{O}=\mathrm{cl}\{(s_0^u,s_0^t)\beta(\mathbf{c}):\mathbf{c}\in\Sigma \text{ and } (s_n^u(\mathbf{c}),s_n^t(\mathbf{c}))\in\{(+1,+1),(+1,-1),(-1,-1)\} \text{ for all } n\in S\}. \tag{4.7}$$

A projection of $\mathcal{O}$ is shown in Fig. 1, obtained by evaluating $\beta(\mathbf{c})$ at the origin. Thus the orchid is given by the closure of the image of Σ under the map β together with a restricted choice of signs so that at the start of each block $\mathbf{(}s_n^u(\mathbf{c}),s_n^t(\mathbf{c})\mathbf{)}$ lies in the "permitted set" $\{(+1,+1),(+1,-1),(-1,-1)\}$. In fact the choice of signs in the definition of $\mathcal{O}$ is not so restrictive as can be seen from the following lemma.

Lemma 4.1: Let $n\in S$ and let $n'\in S$ be the smallest integer in S greater than n. Then $\mathbf{(}s_n^u(\mathbf{c}),s_n^t(\mathbf{c})\mathbf{)}\in\{(+1,+1),(+1,-1),(-1,-1)\}$ *if and only if* $\mathbf{(}s_{n'}^u(\mathbf{c}),s_{n'}^t(\mathbf{c})\mathbf{)}\in\{(+1,+1),(+1,-1),(-1,-1)\}$.

The set S is the set of indices that start a block consisting of an *A*, *B*, or *C*. Thus Lemma 4.1 states that if the sign pair $\mathbf{(}s_n^u(\mathbf{c}),s_n^t(\mathbf{c})\mathbf{)}$ is in the permitted set $\{(+1,+1),(+1,-1),(-1,-1)\}$ for index n, the start of an *A*, *B*, or *C*, then $\mathbf{(}s_{n'}^u(\mathbf{c}),s_{n'}^t(\mathbf{c})\mathbf{)}$ will also be in the permitted set for index n', the start of the next block, and vice versa. It follows that condition (4.7) need only be satisfied at the start of a single block, i.e., a single index $n\in S$, for it to hold throughout S.

Proof of Lemma 4.1: Let $n\in S$ and suppose $\mathbf{(}s_n^u(\mathbf{c}),s_n^t(\mathbf{c})\mathbf{)}=(-1,+1)$, i.e., not in the permitted set at the start of a block and index n. The block may be an *A* or a *B*/*C* and we consider the two cases separately.

Block *A*. Then $n'=n+3$, and $b_n=a_n+\tilde{a}_n=0$, $b_{n+1}=0$, $b_{n+2}=0$, and (omitting the explicit dependence on $\mathbf{c}$) we have $(s_{n+1}^u,s_{n+1}^t)=(+1,-1)$, $(s_{n+2}^u,s_{n+2}^t)=(-1,-1)$, $(s_{n+3}^u,s_{n+3}^t)=(-1,+1)$, as required.

Block *B*/*C*. Then $n'=n+2$, and $b_n=a_n+\tilde{a}_n=0$, $b_{n+1}=1$, so, in this case, we have $(s_{n+1}^u,s_{n+1}^t)=(+1,-1)$, $(s_{n+2}^u,s_{n+2}^t)=(-1,+1)$, as required.

The converse statement that $\mathbf{(}s_{n'}^u(\mathbf{c}),s_{n'}^t(\mathbf{c})\mathbf{)}=(-1,+1)$ implies $\mathbf{(}s_n^u(\mathbf{c}),s_n^t(\mathbf{c})\mathbf{)}=(-1,+1)$ follows immediately from the invertibility of the maps L_b on $\{-1,+1\}^2$. The lemma follows. □

The action of the blocks *A*, *B*/*C* on the sign pair $\mathbf{(}s_n^u(\mathbf{c}),s_n^t(\mathbf{c})\mathbf{)}$ is illustrated in Figs. 5 and 6.

Figure 5 represents the action of the maps L_b on the sign pair $(-1,+1)$ as a block *A* or *B*/*C* is traversed. The sign pair $(-1,+1)$ is at the start of a block which we indicate by enclosing the pair in a box. Although other sign pairs occur as the blocks are traversed, the sign pair returns to $(-1,+1)$ at the start of each block.

The transition diagram in Fig. 5 represents the fundamental set $\beta(\Sigma)\subseteq\mathcal{F}$.

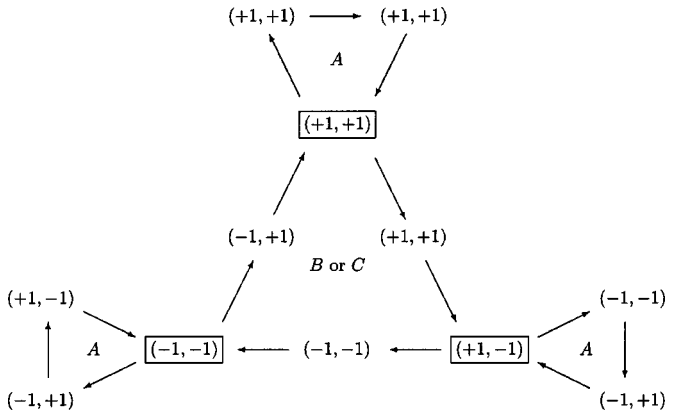

FIG. 6. The orchid transition diagram.

The orchid transition diagram is illustrated in Fig. 6. Again, the sign pairs occurring at the start of blocks are enclosed in boxes. Note that the sign pair $(-1,+1)$ that gives only the fundamental set $\beta(\Sigma)$ occurs as an intermediary as the blocks are traversed.

We thus have the following theorem.

Theorem 4.2: *The set $\mathcal{O}$ is an invariant set for R, i.e., $R(\mathcal{O})=\mathcal{O}$. The action of R on $\mathcal{O}$ is given by*

$$R((s_0^u,s_0^t)\beta(\mathbf{c})) = L_{b_0}(s_0^u,s_0^t)\beta(\sigma(\mathbf{c})), \tag{4.8}$$

for $\mathbf{c}\in\Sigma$ and $(s_0^u,s_0^t)\in\{-1,+1\}^2$.

This theorem gives a description of the dynamics on $\mathcal{O}$ in terms of the dynamics on Σ. In Sec. VI we study the properties of $\mathcal{O}$. First, however, we must complete the construction of the map $\mathcal{E}$.

V. CONSTRUCTION OF THE MAP $\mathcal{E}$

In this section we use the results of Sec. III above to construct the map $\mathcal{E}:\Sigma\to\mathcal{F}$ as given by Proposition 4.1.

Let $\mathbf{c}\in\Sigma$. Our method for constructing $\mathcal{E}(\mathbf{c})$ is as follows. We first consider the twice-differentiated additive operator R_2 given by

$$R_2(U,T) = (\omega^2 T\theta_0, \omega^2 T\theta_0 + \omega^2 U\theta_1), \tag{5.1}$$

and construct a function pair $E_2(\mathbf{c})$ such that

$$R_2(E_2(\mathbf{c})) = E_2(\sigma(\mathbf{c})). \tag{5.2}$$

The relationship between R_2 and R_a is the following:

$$R_a(U,T)'' = R_2(U'',T''), \tag{5.3}$$

so that R_2 is the map induced by R_a on the second derivative pair (U'',T''). Having constructed $E_2(\mathbf{c})$, we then obtain a function pair $\mathcal{E}(\mathbf{c})$ satisfying the relation

$$R(\mathcal{E}(\mathbf{c})) = \kappa_{c_0}(+1,+1)\mathcal{E}(\sigma(\mathbf{c})), \tag{5.4}$$

where, as in (4.1),

$$\kappa_{c_0}(+1,+1) = (-1,-(-1)^{c_0}). \tag{5.5}$$

The construction of $\mathcal{E}(\mathbf{c})$ from $E_2(\mathbf{c})$ is somewhat involved, as indeed is the construction of $E_2(\mathbf{c})$ itself.

A. Convergence proof preliminaries

Let $\mathbf{c} \in \Sigma$. For $k \in \mathbb{N}_0$ define $y_{-k} = e_{-k}(\mathbf{c})$, and $\delta_{-k} = y_{-k} + \omega$. We note that $\delta_{-k} \neq 0$ for all $\mathbf{c} \in \Sigma$. It may, however, be arbitrarily small, thereby creating a "small divisor" problem that must be controlled. We shall use the following lemma, which is fundamental to the convergence proof.

Lemma 5.1:

$$\sum_{k \geqslant 1} \frac{\omega^k}{|\delta_{-k}|} < +\infty. \tag{5.6}$$

$$\sum_{k \geqslant 1} \frac{k\omega^k}{|\delta_{-k}|} < +\infty. \tag{5.7}$$

$$\sum_{k \geqslant 1} \omega^k |\log|\delta_{-k}|| < +\infty. \tag{5.8}$$

Proof: We prove (5.6); the proofs of the other inequalities are similar. Let $0 < k_1 < k_2 < \cdots < k_i < \cdots$ be the values of k such that $|\delta_{-k}| < 1/2$. Let us consider k_i. We deal with the two cases $\delta_{-k_i} > 0$ and $\delta_{-k_i} < 0$ separately. If $\delta_{-k_i} > 0$, then for $1 \leqslant j < (\log|\delta_{-k_i}| - \log 1/2)/\log \omega$, we have

$$\min\{|y_{-k_i+j} - 1|, |y_{-k_i+j} + \omega^{-1}|\} < 1/2, \tag{5.9}$$

so that $k_i - k_{i-1} \geqslant (\log|\delta_{-k_i}| - \log 1/2)/\log \omega$. On the other hand, if $\delta_{-k_i} < 0$, then it is possible that $k_{i-1} + 1 = k_i$, and then for $2 \leqslant j < (\log|\delta_{-k_i}| - \log 1/2)/\log \omega$ we have

$$\min\{|y_{-k_i+j} - 1|, |y_{-k_i+j} + \omega^{-1}|\} < 1/2, \tag{5.10}$$

so that $k_i - k_{i-2} \geqslant (\log|\delta_{-k_i}| - \log 1/2)/\log \omega$. Otherwise $k_i - k_{i-1} \geqslant (\log|\delta_{-k_i}| - \log 1/2)/\log \omega$, as before. Anyway, we certainly have $k_i - k_{i-2} \geqslant (\log|\delta_{-k_i}| - \log 1/2)/\log \omega$ for all i, so that

$$\frac{\omega^{k_i}}{|\delta_{-k_i}|} \leqslant 2\omega^{k_{i-2}}. \tag{5.11}$$

Now we estimate

$$\sum_{k \geqslant 1} \frac{\omega^k}{|\delta_{-k}|} \leqslant \sum_{j \neq k_i} \frac{\omega^j}{1/2} + \frac{\omega^{k_1}}{|\delta_{-k_1}|} + \frac{\omega^{k_2}}{|\delta_{-k_2}|} + \sum_{i \geqslant 3} 2\omega^{k_{i-2}} < +\infty, \tag{5.12}$$

as required. □

B. Construction of the function pair $E_2(\mathbf{c})$

We now proceed to construct the map E_2 outlined above. Let $\mathbf{c} \in \Sigma$, let $k \in \mathbb{N}_0$ and let $H_2^{k,0}$ be defined as

$$H_2^{k,0}(x) = \begin{cases} ((y_{-k} - x)^{-2}, (y_{-k} - x)^{-2}), & c_{-(k+1)} = 0; \\ (0, (y_{-k} - x)^{-2}), & c_{-(k+1)} = 1. \end{cases} \tag{5.13}$$

Then a straightward calculation shows that for $k \geqslant 1$,

$$R_2 H_2^{k,0} = H_2^{k-1,0} + H_2^{k,1}, \tag{5.14}$$

where

$$H_2^{k,1}(x)=\begin{cases}(0,\omega^2(y_{-k}-\theta_1(x))^{-2}), & c_{-(k+1)}=0, c_{-k}=0;\\ (\omega^2(y_{-k}-\theta_0(x))^{-2},\omega^2(y_{-k}-\theta_0(x))^{-2}), & c_{-(k+1)}=0, c_{-k}=1;\\ (0,0), & c_{-(k+1)}=1, c_{-k}=0.\end{cases} \tag{5.15}$$

The idea here is that the singular part of $R_2H_2^{k,0}$ is contained in $H_2^{k-1,0}$, while $H_2^{k,1}$ is nonsingular on $\overline{V_1}\times\overline{V_0}$.

Let us now define

$$H_2^{k,k}=R_2^{k-1}H_2^{k,1}. \tag{5.16}$$

Then a formal calculation from (5.14) gives

$$R_2^kH_2^{k,0}=\sum_{j=0}^{k}H_2^{j,j}. \tag{5.17}$$

We wish to show that the series $\Sigma_{j=1}^{k}H_2^{j,j}$ converges in $\mathcal{F}$. To do this we shall show that

$$\|H_2^{k,k}\|\leqslant\frac{K\omega^k}{|\delta_{-k}|}, \tag{5.18}$$

for some constant K, and then invoke Lemma 5.1.

Let us introduce the following convention. For a finite sequence of indices $i_1,\ldots,i_k$ we shall implicitly assume that $i_j\in\{0,1\}$, $j=1,\ldots,k$, and that $i_ji_{j+1}=0$, $j=1,\ldots,k-1$, so that no two consecutive 1s appear in the sequence. It is now straightforward to verify the following formula for the kth iterate of R_a:

$$R_a^k(U,T)=\left(\sum_{\substack{i_1,\ldots,i_k\\ i_1=1,i_k=0}}U\theta_{i_1}\cdots\theta_{i_k}+\sum_{\substack{i_1,\ldots,i_k\\ i_k=0,i_k=0}}T\theta_{i_1}\cdots\theta_{i_k},\sum_{\substack{i_1,\ldots,i_k\\ i_1=1}}U\theta_{i_1}\cdots\theta_{i_k}+\sum_{\substack{i_1,\ldots,i_k\\ i_1=0}}T\theta_{i_1}\cdots\theta_{i_k}\right). \tag{5.19}$$

Similarly, for R_2 we have

$$R_2^k(U,T)=\omega^{2k}R_a^k(U,T). \tag{5.20}$$

Thus, combining (5.15) and (5.19), we have

$$\begin{aligned}H_2^{k,k}(x)&=(R_2^{k-1}H_2^{k,1})(x)\\ &=\begin{cases}\left(\displaystyle\sum_{\substack{i_1,\ldots,i_{k-1}\\ i_1=0,i_{k-1}=0}}\omega^{2k}(y_{-k}-\theta_1\theta_{i_1}\cdots\theta_{i_{k-1}}(x))^{-2}\right.\ ,\\ \left.\displaystyle\sum_{\substack{i_1,\ldots,i_{k-1}\\ i_1=0}}\omega^{2k}(y_{-k}-\theta_1\theta_{i_1}\cdots\theta_{i_{k-1}}(x))^{-2}\right), & c_{-(k+1)}=0\ c_{-k}=0;\\ \left(\displaystyle\sum_{\substack{i_1,\ldots,i_{k-1}\\ i_{k-1}=0}}\omega^{2k}(y_{-k}-\theta_0\theta_{i_1}\cdots\theta_{i_{k-1}}(x))^{-2},\right.\\ \left.\displaystyle\sum_{i_1,\ldots,i_{k-1}}\omega^{2k}(y_{-k}-\theta_0\theta_{i_1}\cdots\theta_{i_{k-1}}(x))^{-2}\right), & c_{-(k+1)}=0\ c_{-k}=1;\\ (0,0), & c_{-(k+1)}=1\ c_{-k}=0.\end{cases}\end{aligned} \tag{5.21}$$

Using the identity

$$\omega^{2k}(y_{-k}-\theta_{i_0}\cdots\theta_{i_{k-1}}(x))^{-2}=(\theta_{i_{k-1}}^{-1}\cdots\theta_{i_0}^{-1}(y_{-k})-x)^{-2}, \tag{5.22}$$

we may rewrite this as

$$H_2^{k,k}(x)=\begin{cases}\left(\displaystyle\sum_{\substack{j_1,\ldots,j_k\\ j_1=\overline{c}_{-k},j_k=0}}(\theta_{j_k}^{-1}\cdots\theta_{j_1}^{-1}(y_{-k})-x)^{-2},\ \sum_{\substack{j_1,\ldots,j_k\\ j_1=\overline{c}_{-k}}}(\theta_{j_k}^{-1}\cdots\theta_{j_1}^{-1}(y_{-k})-x)^{-2}\right), & c_{-(k+1)}=0;\\ (0,0), & c_{-(k+1)}=1,\end{cases} \tag{5.23}$$

where we have used the notation

$$\overline{c}=\begin{cases}1, & c=0;\\ 0, & c=1.\end{cases} \tag{5.24}$$

We now wish to bound the norm of $H_2^{k,k}$ and to do so we make use of the following elementary norm estimate.

Lemma 5.2: Let $y\in\mathbb{C}$. The l_1-norm of the function $f(x)=(y-x)^{-2}$ on the domain $D(c,r)$ is

$$\|f\|_1=(|y-c|-r)^{-2}<+\infty, \tag{5.25}$$

provided $r<|y-c|$.

Proof: We have

$$f(x)=(y-x)^{-2}=(y-c-r(x-c)/r)^{-2}=\frac{1}{(y-c)^2}\sum_{i=0}^{\infty}\left(\frac{r}{y-c}\right)^i(i+1)\left(\frac{x-c}{r}\right)^i, \tag{5.26}$$

so that

$$\|f\|_1=\frac{1}{|y-c|^2}\sum_{i=0}^{\infty}\left(\frac{r}{|y-c|}\right)^i(i+1)=(|y-c|-r)^{-2}<+\infty, \tag{5.27}$$

provided $r<|y-c|$. □

As a consequence of this estimate, we have the following lemma.

Lemma 5.3:

(i) *$H_2^{k,1}\in\mathcal{F}$, so that the function pair $H_2^{k,1}$ is analytic on $V_1\times V_0$ with bounded norm $\|H_2^{k,1}\|<+\infty$;*

(ii) *For $k\geqslant 1$,*

$$\|H_2^{k,k}\|\leqslant\begin{cases}\max\left\{\displaystyle\sum_{\substack{j_1,\ldots,j_k\\ j_1=\overline{c}_{-k},j_k=0}}(|\theta_{j_k}^{-1}\cdots\theta_{j_1}^{-1}(y_{-k})-c_1|-r_1)^{-2},\right.\\ \left.\displaystyle\sum_{\substack{j_1,\ldots,j_k\\ j_1=\overline{c}_{-k}}}(|\theta_{j_k}^{-1}\cdots\theta_{j_1}^{-1}(y_{-k})-c_0|-r_0)^{-2}\right\}, & c_{-(k+1)}=0;\\ 0, & c_{-(k+1)}=1.\end{cases} \tag{5.28}$$

Proof:

(i) It is trivial in the third case of (5.15) that $H_2^{k,1}\in\mathcal{F}$. In the first case ($c_{-(k+1)}=0$, $c_{-k}=0$), we have $y_{-k}\in(-\omega,1)$. Thus $\theta_1^{-1}(y_{-k})\in(-2/\omega,-\omega)$, which does not intersect $\overline{V_0}$. Thus $(\theta_1^{-1}(y_{-k})-x)^{-2}$ is analytic on V_0, and thus has a bounded l_1-norm. It follows that $\|H_2^{k,1}\|<+\infty$ and $H_2^{k,1}\in\mathcal{F}$.

Similarly, in the second case ($c_{-(k+1)}=0$, $c_{-k}=1$), we have $y_{-k}\in(-\omega^{-1},-\omega)$. Thus $\theta_0^{-1}(y_{-k})\in(1,2/\omega)$, which does not intersect $\overline{V_0}\cup\overline{V_1}$, so that $H_2^{k,1}$ is analytic on $\overline{V_1}\times\overline{V_0}$ and $\|H_2^{k,1}\|<+\infty$.

(ii) Since $R_2\mathcal{F}\subseteq\mathcal{F}$, all singularities of $H_2^{k,k}=R_2^{k-1}H_2^{k,1}$ lie outside $\overline{V_0}\cup\overline{V_1}$ so the estimate for $\|H_2^{k,k}\|$ follows from Lemma 5.2 and (5.23).

Lemma 5.3 gives us a bound on $\|H_2^{k,k}\|$, but we still need to bound the sums on the right-hand sides of (5.28).

In what follows we shall make use of the following lemma whose proof is elementary.

Lemma 5.4: Let a, $b>0$. Then

$$\sum_{i=0}^{\infty}\frac{1}{(a+bi)^2}\leqslant\frac{a+b}{a^2b}. \tag{5.29}$$

Our fundamental estimate is the following.

Lemma 5.5: There exists a constant $K>0$ such that

$$\|H_2^{k,k}\|\leqslant\frac{K\omega^k}{|\delta_{-k}|}. \tag{5.30}$$

Corollary 5.1: The series $\Sigma_{k\geqslant 1}H_2^{k,k}$ converges in $\mathcal{F}$.

Proof: This follows immediately from Lemmas 5.5 and 5.1. □

In order to prove Lemma 5.5, we need to identify more precisely the singularities of $H_2^{k,k}$. In particular, we have the following result, which follows from the properties of the golden mean. Its proof is straightforward if somewhat lengthy, and is omitted.

Lemma 5.6: Let

$$A=\{\theta_{j_k}^{-1}\cdots\theta_{j_1}^{-1}(y_{-k}):j_1=\overline{c_{-k}}\}, \tag{5.31}$$

$$B=\{\theta_{j_k}^{-1}\cdots\theta_{j_1}^{-1}(y_{-k}):j_1=\overline{c_{-k}},j_k=0\}. \tag{5.32}$$

Then we have the following cases.

Case (i) $c_{-k}=1$ ($\delta_{-k}<0$); when $k\geqslant 1$ is odd,

$$A=-\omega^{-k}\delta_{-k}+\{1\}\cup\{\lceil i/\omega\rceil+i\omega:i=1,\ldots,F_{k+1}-1\}, \tag{5.33}$$

$$B=-\omega^{-k}\delta_{-k}+\{\lceil i/\omega\rceil+i\omega:i=\lfloor|j/\omega|\rfloor,j=1,\ldots,F_k-1\}\cup\{\lceil i/\omega\rceil-1+i\omega-\omega:i=\lfloor F_k/\omega\rfloor\}. \tag{5.34}$$

When $k\geqslant 1$ is even,

$$A=\omega^{-k}\delta_{-k}+\{\lceil i/\omega\rceil+i\omega:i=1-F_{k+1},\ldots,-1\}\cup\{\lceil i/\omega\rceil+1+i\omega:i=-F_{k+1}\}, \tag{5.35}$$

$$B=\omega^{-k}\delta_{-k}+\{\lceil i/\omega\rceil+i\omega:i=\lceil j/\omega\rceil,j=1-F_k,\ldots,-1\}\cup\{-1-\omega\}. \tag{5.36}$$

Case (ii) $c_{-k}=0$ ($\delta_{-k}>0$); when $k\geqslant 1$ is odd,

$$A=-\omega^{-k}\delta_{-k}+\{\lceil i/\omega\rceil+i\omega:i=1-F_k,\ldots,-1\}\cup\{\lceil i/\omega\rceil+1+i\omega:i=-F_k\}, \tag{5.37}$$

$$B=-\omega^{-k}\delta_{-k}+\{\lceil i/\omega\rceil+i\omega:i=\lceil j/\omega\rceil,j=1-F_{k-1},\ldots,-1\}\cup\{-1-\omega\}. \tag{5.38}$$

When $k\geqslant 1$ is even,

$$A=\omega^{-k}\delta_{-k}+\{1\}\cup\{\lceil i/\omega\rceil+i\omega:i=1,\ldots,F_k-1\}, \tag{5.39}$$

$$B = \omega^{-k}\delta_{-k} + \{\lceil i/\omega\rceil + i\omega : i = \lfloor j/\omega\rfloor, j = 1, \ldots, F_{k-1} - 1\} \cup \{\lceil i/\omega\rceil - 1 + i\omega - \omega : i = \lfloor F_{k-1}/\omega\rfloor\}. \tag{5.40}$$

Proof of Lemma 5.5: Referring to Lemma 5.6, we see that for each k, the sets A and B have the same overall structure while differing in detail. In particular, we have that the elements grow linearly. To be more specific, we make the following observation. Writing $A=\{x_0^0, \ldots, x_{N_k^0}^0\}$, $B=\{x_0^1, \ldots, x_{N_k^1}^1\}$, for N_k^0, $N_k^1 \in N$ with $|x_0^0| < |x_1^0| < \cdots < |x_{N_k^0}^0|$, $|x_0^1| < |x_1^1| < \cdots < |x_{N_k^1}^1|$, we have that there exists a constant $C>0$ (independent of k) such that, for $i=0$, 1, $x_j^i \geqslant 1 + Cj + (-\omega)^{-k}\delta_{-k}$, $j=0, \ldots, N_k^i$ for $(-1)^k\delta_{-k} > 0$, while $x_j^i \leqslant -\omega^{-1} - Cj + (-\omega)^{-k}\delta_{-k}$, $j=0, \ldots, N_k^i$ for $(-1)^k\delta_{-k} < 0$.

We now refer to (5.28) and observe that the sums are taken over the sets B and A, respectively, and each term in the sum is of the form $(|x_j^i - c_i| - r_i)^{-2}$, and, since $-\omega^{-1} \leqslant c_1 - r_1 \leqslant c_1 + r_1 = c_0 - r_0 \leqslant c_0 + r_0 \leqslant 1$, we have that each sum in (5.28) is majorized by

$$\sum_{j=0}^{\infty} (\omega^{-k}|\delta_{-k}| + Cj)^{-2} \leqslant \frac{C + \omega^{-k}|\delta_{-k}|}{\omega^{-2k}|\delta_{-k}|^2 C} \quad \text{by Lemma 5.4} \tag{5.41}$$

$$= \frac{\omega^k}{C|\delta_{-k}|} + \frac{\omega^{2k}}{|\delta_{-k}|^2} \tag{5.42}$$

$$\leqslant K\frac{\omega^k}{|\delta_{-k}|}, \tag{5.43}$$

for some $K>0$ (depending on $\mathbf{c}$) since $\Sigma_{k=1}^{\infty}\, \omega^k/|\delta_{-k}| < +\infty$. □

We are therefore able to define

$$E_2(\mathbf{c}) = \lim_{k\to\infty} R_2^k H_2^{k,0} = H_2^{0,0} + G_2(\mathbf{c}), \quad \text{where } G_2(\mathbf{c}) = \sum_{j\geqslant 1} H_2^{j,j}. \tag{5.44}$$

The first part of $E_2(\mathbf{c})$, i.e., $H_2^{0,0}$, may contain singularities on $\overline{V_1} \times \overline{V_0}$. These singularities are all poles. We note that, by definition, $H_2^{k,0}(\mathbf{c}) = H_2^{k+1,0}(\sigma(\mathbf{c}))$, so that

$$H_2^{k,1}(\mathbf{c}) = H_2^{k+1,1}(\sigma(\mathbf{c})) \tag{5.45}$$

and

$$R_2(H_2^{k,k}(\mathbf{c})) = R_2(R_2^{k-1}H_2^{k,1}(\mathbf{c})) = R_2^k H_2^{k+1,1}(\sigma(\mathbf{c})) = H_2^{k+1,k+1}(\sigma(\mathbf{c})). \tag{5.46}$$

Hence, by continuity of R_2,

$$R_2 G_2(\mathbf{c}) = R_2\left(\sum_{j\geqslant 1} H_2^{j,j}(\mathbf{c})\right) = \sum_{j\geqslant 1} H_2^{j+1,j+1}(\sigma(\mathbf{c})) = G_2(\sigma(\mathbf{c})) - H_2^{0,1}(\mathbf{c}). \tag{5.47}$$

Allowing for singularities we have

$$R_2(E_2(\mathbf{c})) = R_2 H^{0,0}(\mathbf{c}) + R_2 G_2(\mathbf{c}) = H_2^{0,0}(\sigma(\mathbf{c})) + G_2(\sigma(\mathbf{c})) = E_2(\sigma(\mathbf{c})), \tag{5.48}$$

which is (5.2) as desired.

C. Definition and outline construction of the function pair $\mathcal{E}(\mathbf{c})$

The construction of the map $\mathcal{E}$ from E_2 is somewhat involved, and we only give an outline here. To obtain $\mathcal{E}(\mathbf{c})$ from $E_2(\mathbf{c})$ one essentially has to integrate twice and then project onto the complement of the subspace spanned by the linear eigenfunction pairs $\mathbf{u}_0$, $\mathbf{u}_1$, $\mathbf{v}_0$, $\mathbf{v}_1$ given below.

However, technical obstacles have prevented the direct implementation of this approach. It is to be hoped that a simpler method can be found in the future. Our approach here is to obtain $\mathcal{E}(\mathbf{c}) = h^0(\mathbf{c})\exp(K^1(\mathbf{c}))$, where $\log h^0(\mathbf{c}) \notin \mathcal{F}$, but $K^1(\mathbf{c}) \in \mathcal{F}$.

$K^1(\mathbf{c})$ is then constructed by the same method of forward iteration of initial conditions defined for negative time as was used in the construction of $E_2(\mathbf{c})$, but making use of the spectral properties of R_a restricted to $\mathrm{span}\{\mathbf{u}_0, \mathbf{u}_1, \mathbf{v}_0, \mathbf{v}_1\}$.

Let $\mathbf{u}_0$, $\mathbf{u}_1$, $\mathbf{v}_0$, $\mathbf{v}_1$ be eigenfunction pairs of R_a such that

$$R_a(\mathbf{u}_0) = -\omega\mathbf{u}_0, \quad R_a(\mathbf{u}_1) = \omega^2\mathbf{u}_1, \quad R_a(\mathbf{v}_0) = \omega^{-1}\mathbf{v}_0, \quad R_a(\mathbf{v}_1) = -\mathbf{v}_1. \tag{5.49}$$

Here

$$\mathbf{u}_0 = (1, -\omega), \quad \mathbf{u}_1 = (1 + 2\omega x, \omega^2 - 2\omega^2 x), \tag{5.50}$$

and $\mathbf{v}_0$, $\mathbf{v}_1$ are as defined above in Eq. (2.41). We define the integral operator $\mathcal{I}$ by

$$\mathcal{I}(U_2, T_2) = \left(\int_{c_1}^{z} \int_{c_1}^{z'} U_2(z')dz'dz, \int_{c_0}^{z} \int_{c_0}^{z'} T_2(z')dz'dz \right). \tag{5.51}$$

We denote by D the differentiation operator. Then we have $D^2\mathcal{I} = \mathrm{id}$.

We define the function pairs $h^0(\mathbf{c})$, $H^0(\mathbf{c})$, and $H_2^0(\mathbf{c})$ by $H^0(\mathbf{c}) = \log h^0(\mathbf{c})$, $H_2^0(\mathbf{c}) = D^2H^0(\mathbf{c})$ where $h^0(\mathbf{c}) \in \mathcal{F}$ is defined by

$$h^0(\mathbf{c})(x) = \begin{cases} (y_0 - x, y_0 - x), & c_{-1} = 0; \\ (1, y_0 - x), & c_{-1} = 1. \end{cases} \tag{5.52}$$

We note that $H_2^0(\mathbf{c}) = H_2^{0,1}(\mathbf{c})$ as given in Sec. IV.B.

We now define $h^1(\mathbf{c})$ by the equation

$$R(h^0)(\mathbf{c}) = \kappa_{c_0}(+1, +1)h^0(\sigma(\mathbf{c}))h^1(\mathbf{c}). \tag{5.53}$$

The function pair $h^1(\mathbf{c})$ is readily calculated as follows. We have three cases.

Case (i): $c_{-1} = 0$ and $c_0 = 0$. Then

$$\begin{aligned} R(h^0)(\mathbf{c})(x) &= (y_0 - \theta_0(x), (y_0 - \theta_0(x))(y_0 - \theta_1(x))) \\ &= (-1, -1)(y_1 - x, y_1 - x)(\omega, \omega(y_0 - \theta_1(x))) \\ &= \kappa_{c_0}(+1, +1)h^0(\sigma(\mathbf{c}))(x)h^1(\mathbf{c})(x), \end{aligned} \tag{5.54}$$

where $h^1(\mathbf{c})(x) = (\omega, \omega(y_0 - \theta_1(x)))$. In this calculation we have used the fact that if $c_0 = 0$ then $y_0 - \theta_0(x) = \theta_0(y_1) - \theta_0(x) = -\omega(y_1 - x)$.

Similar calculations give, for the other cases, the following.

Case (ii): $c_{-1} = 0$ and $c_0 = 1$: $h^1(\mathbf{c})(x) = (\theta_0(x) - y_0, \omega(\theta_0(x) - y_0))$.

Case (iii): $c_{-1} = 1$ and $c_0 = 0$: $h^1(\mathbf{c})(x) = (\omega, \omega)$.

We note the following result.

Lemma 5.7: Let us write $h^1(\mathbf{c}) = (u^1, t^1)$. *Then we have* $u^1(x) \geq 0$ *for* $x \in [-\omega^{-1}, -\omega] = \overline{V_1} \cap \mathbb{R}$ *and* $t^1(x) > 0$ for $x \in [-\omega, 1] = \overline{V_0} \cap \mathbb{R}$. *Moreover* $u^1(x) \neq 0$ *for* $x \in \overline{V_1}$, *and* $t^1(x) \neq 0$ *for* $x \in \overline{V_0}$.

Proof: We consider separately the three cases in the definition of h^1 above. Case (iii) is clear. Let us consider case (i). Then $u^1(x) = \omega > 0$ and for $x \in [-\omega, 1]$, $t^1(x) = \omega(y_0 - \theta_1(x)) > 0$ since $y_0 \in (-\omega, 1)$ and $\theta_1(x) \in [-\omega^{-1}, -\omega)$. In case (ii) for $x \in [-\omega^{-1}, -\omega]$ we have $u^1(x) = \theta_0(x) - y_0 > 0$ since $y_0 \in (-\omega^{-1}, -\omega)$ and $\theta_0(x) \in [\omega^2, 1]$, while for $x \in [-\omega, 1]$ we have $t^1(x) = \omega(\theta_0(x) - y_0) > 0$ since $y_0 \in (-\omega^{-1}, -\omega)$ and $\theta_0(x) \in [-\omega, \omega^2]$. The second statement in the lemma follows from the fact that both u^1 and t^1 are linear with real roots. □

The importance of this lemma is that it implies that the logarithm of $h^1(\mathbf{c})$ is a function in $\mathcal{F}$. Indeed, we may define $H^1(\mathbf{c}) = \log h^1(\mathbf{c})$ and $H_2^1(\mathbf{c}) = D^2H^1(\mathbf{c})$ and, we have, analogously to the above results,

$$R_a H^0(\mathbf{c}) = H^0(\sigma(\mathbf{c})) + H^1(\mathbf{c}), \quad R_2 H_2^0(\mathbf{c}) = H_2^0(\sigma(\mathbf{c})) + H_2^1(\mathbf{c}). \tag{5.55}$$

Clearly, $H^1(\mathbf{c})$, $H_2^1(\mathbf{c}) \in \mathcal{F}$.

We now define $\mathcal{E}: \Sigma \to \mathcal{F}$ by

$$\mathcal{E}(\mathbf{c}) = h^0(\mathbf{c}) \exp(K^1(\mathbf{c})), \tag{5.56}$$

demanding that K^1 satisfies $H^1(\mathbf{c}) + R_a K^1(\mathbf{c}) = K^1(\sigma(\mathbf{c}))$.

In Sec. II we constructed a function pair $G_2(\mathbf{c}) \in \mathcal{F}$ with $R_2 G_2(\mathbf{c}) = G_2(\sigma(\mathbf{c})) - H_2^0(\mathbf{c})$. Our task is to construct $K^1(\mathbf{c})$ from $G_2(\mathbf{c})$. Let us define, for $k \geqslant 0$,

$$L^k(\mathbf{c}) = R_a^k P_a (H^0(\sigma^{-k}(\mathbf{c})) - \mathcal{I} G_2(\sigma^{-k}(\mathbf{c}))) - H^0(\mathbf{c}). \tag{5.57}$$

Then $L^k(\mathbf{c}) \in \mathcal{F}$ since the singularities of $R_a^k P_a H^0(\sigma^{-k}(\mathbf{c}))$ and $-H^0(\mathbf{c})$ cancel.

The proof that $L^k(\mathbf{c})$ converges in $\mathcal{F}$ depends on the following three technical lemmas, the proofs of which we omit.

Lemma 5.8: $L^{k+1}(\mathbf{c}) - L^k(\mathbf{c}) \in \ker D^2$.

Lemma 5.9: $R_a H^0(\sigma^{-(k+1)}(\mathbf{c})) - H^0(\sigma^{-k}(\mathbf{c})) - R_a \mathcal{I} G_2(\sigma^{-(k+1)}(\mathbf{c})) + \mathcal{I} G_2(\sigma^{-k}(\mathbf{c}))$ *has a norm bounded by* $K_1 |\log|\delta_{-k}|| + K_2(\|G_2(\sigma^{-k}(c))\| + \|G_2(\sigma^{-(k+1)}(\mathbf{c}))\|)$ *for suitable constants* $K_1, K_2 > 0$.

Lemma 5.10:

$$\sum_{\ell \geqslant 1} \omega^\ell \|G_2(\sigma^{-\ell}(\mathbf{c}))\| < +\infty. \tag{5.58}$$

We now indicate how these results imply the convergence of $L^k(\mathbf{c})$ to a function pair $K^1(\mathbf{c}) \in \mathcal{F}$ satisfying the required functional equation.

Since $D^2(L^{k+1}(\mathbf{c}) - L^k(\mathbf{c})) = 0$ we have that $L^{k+1}(\mathbf{c}) - L^k(\mathbf{c})$ is in the span of the eigenfunction pairs $\mathbf{u}_0$, $\mathbf{u}_1$, $\mathbf{v}_0$, $\mathbf{v}_1$ which span the four-dimensional kernel of D^2 in $\mathcal{F}$. Now $P_a(\mathbf{v}_0) = P_a(\mathbf{v}_1) = 0$, so that for $\mathbf{H} \in \text{span}\{\mathbf{u}_0, \mathbf{u}_1, \mathbf{v}_0, \mathbf{v}_1\}$, we have $P_a(\mathbf{H}) \in \text{span}\{\mathbf{u}_0, \mathbf{u}_1\}$. Now R_a has spectrum $\{-\omega, \omega^2\}$ on $\text{span}\{\mathbf{u}_0, \mathbf{u}_1\}$. Since $\text{span}\{\mathbf{u}_0, \mathbf{u}_1\}$ is two-dimensional there exists a constant $K_3 > 0$ such that $\|R_a^k P_a\| \leqslant K_3 \omega^k$ on the space $\text{span}\{\mathbf{u}_0, \mathbf{u}_1, \mathbf{v}_0, \mathbf{v}_1\}$. Let $\varepsilon > 0$. We now estimate as follows. For $m > n$,

$$\begin{aligned} \|L^m(\mathbf{c}) - L^n(\mathbf{c})\| &\leqslant \sum_{k=n}^{m-1} \|L^{k+1}(\mathbf{c}) - L^k(\mathbf{c})\| \\ &\leqslant \sum_{k=n}^{m-1} K_3 \omega^k (K_1 |\log|\delta_{-k}|| + K_2 \|G_2(\sigma^{-k}(\mathbf{c}))\| + K_2 \|G_2(\sigma^{-(k+1)}(\mathbf{c}))\|) \leqslant \varepsilon, \end{aligned} \tag{5.59}$$

for m, n sufficiently large by Lemmas 5.1 and 5.10. We conclude that $(L^k(\mathbf{c}))$ is a Cauchy sequence and converges in $\mathcal{F}$ to a function pair $K^1(\mathbf{c})$.

We must now show that $K^1(\mathbf{c})$ satisfies the required functional equation:

$$R_a K^1(\mathbf{c}) + H^1(\mathbf{c}) - K^1(\sigma(\mathbf{c})) = 0. \tag{5.60}$$

Defining

$$F^k(\mathbf{c}) = R_a L^k(\mathbf{c}) + H^1(\mathbf{c}) - L^k(\sigma(\mathbf{c})), \tag{5.61}$$

we have that $F^k(\mathbf{c}) \to 0$ in $\mathcal{F}$, since

$$F^k(\mathbf{c}) = R_a^k P_a (R_a(-\mathcal{I} G_2(\sigma^{-k}(\mathbf{c})) + H^0(\sigma^{-k}(\mathbf{c}))) + \mathcal{I} G_2(\sigma^{-(k-1)}(\mathbf{c})) - H^0(\sigma^{-(k-1)}(\mathbf{c}))),$$

$$R_a(-\mathcal{I} G_2(\sigma^{-k}(\mathbf{c})) + H^0(\sigma^{-k}(\mathbf{c}))) + \mathcal{I} G_2(\sigma^{-(k-1)}(\mathbf{c})) - H^0(\sigma^{-(k-1)}(\mathbf{c})) \in \ker D^2 \tag{5.62}$$

and

$$\|R_a(-\mathcal{I}G_2(\sigma^{-k}(\mathbf{c}))+H^0(\sigma^{-k}(\mathbf{c})))+\mathcal{I}G_2(\sigma^{-(k-1)}(\mathbf{c}))-H^0(\sigma^{-(k-1)}(\mathbf{c}))\|\leqslant K_4|\log|\delta_{-k}||$$
$$+K_5\|G_2(\sigma^{-k}(\mathbf{c}))\|+K_5\|G_2(\sigma^{-(k-1)}(\mathbf{c}))\|, \tag{5.63}$$

so that $\|F^k(\mathbf{c})\|\to 0$ by the same argument as above. Thus $K^1(\mathbf{c})$ satisfies (5.60).

D. Properties of the maps $\mathcal{E}$, β

In this section we consider briefly the properties of the maps $\mathcal{E}$, β. The following results may be readily proved.

Lemma 5.11: Let $\mathbf{c}$, $\mathbf{c}'\in\Sigma$. *Then* $\mathcal{E}(\mathbf{c})=\mathcal{E}(\mathbf{c}')$, *if, and only if,* $\mathbf{c}'=\mathbf{c}$. *Furthermore,* $\beta(\mathbf{c})=\beta(\mathbf{c}')$, *if, and only if,* $\mathbf{c}'=\mathbf{c}$ *or* $\tilde{\mathbf{c}}$.

Lemma 5.12: The maps $\mathcal{E}$, β *are continuous.*

Proof: These results follow from the continuity of the evaluation maps $e_n(\mathbf{c})$. Indeed, let $\mathbf{c}\in\Sigma$. We first of all show that G_2 is continuous at $\mathbf{c}$. We have

$$G_2(\mathbf{c})=\sum_{j\geqslant 1}H_2^{j,j}(\mathbf{c}). \tag{5.64}$$

Let $\varepsilon>0$ be given. Referring to the proof of Lemma 5.1, we have for $\mathbf{c}'$ close to $\mathbf{c}$ that k_1 and k_2 equal their values for $\mathbf{c}$. Now let $N>k_2$ be such that

$$\sum_{k>N}\frac{K\omega^k}{|\delta_{-k}|}<\varepsilon/4, \tag{5.65}$$

where K is given in Lemma 5.5. Then

$$\left\|\sum_{j\geqslant 1}H_2^{j,j}(\mathbf{c}')-\sum_{j\geqslant 1}H_2^{j,j}(\mathbf{c})\right\|\leqslant\sum_{j=1}^{N}\|H_2^{j,j}(\mathbf{c}')-H_2^{j,j}(\mathbf{c})\|+\sum_{j>N}\|H_2^{j,j}(\mathbf{c}')\|+\sum_{j>N}\|H_2^{j,j}(\mathbf{c})\| \tag{5.66}$$

$$<\sum_{j=1}^{N}\|H_2^{j,j}(\mathbf{c}')-H_2^{j,j}(\mathbf{c})\|+\varepsilon/4+\varepsilon/4 \tag{5.67}$$

$$<\varepsilon, \tag{5.68}$$

provided $\mathbf{c}'$ is taken sufficiently close to $\mathbf{c}$ so that the first sum is less than $\varepsilon/2$.

Hence G_2 is continuous at $\mathbf{c}$, and it follows immediately that $\mathcal{E}$ is continuous at $\mathbf{c}$. □

In fact, more can be said. For if for a sequence of codes $\mathbf{c}^k$, we have $\mathcal{E}(\mathbf{c}^k)\to\mathcal{E}(\mathbf{c})$ for some $\mathbf{c}\in\Sigma$, then $\mathbf{c}^k\to\mathbf{c}$. To prove this, suppose the contrary. Then there is a sequence $\mathbf{c}^k$ and $\mathbf{c}$ with $d(\mathbf{c}^k,\mathbf{c})\geqslant\varepsilon$ for some $\varepsilon>0$ but with $\mathcal{E}(\mathbf{c}^k)\to\mathcal{E}(\mathbf{c})$. Then there is $n\in\mathbb{Z}$ for which $\sigma^n(\mathbf{c}^k)$ and $\sigma^n(\mathbf{c})$ are in different intervals I_0 and I_1 for k sufficiently large. Then, since $\mathcal{E}(\mathbf{c}^k)\to\mathcal{E}(\mathbf{c})$, we have $\mathcal{E}(\mathbf{c}^k)/\mathcal{E}(\mathbf{c})\to(1,1)$, and thus, from the invertibility of R at $(1,1)$ and Eq. (4.2), we have $e_n(\mathbf{c}^k)_n\to e_n(\mathbf{c})$ as $k\to\infty$, so that $e_n(\mathbf{c})=-\omega$, contradicting the fact that $\mathbf{c}\in\Sigma$.

Furthermore, we have the following lemma.

Lemma 5.13: The maps $\mathcal{E}$, $\beta:\Sigma\to\mathcal{F}$ *satisfy* $P\mathcal{E}=\mathcal{E}$, $P\beta=\beta$.

Proof: Clearly, we need only prove that $P\mathcal{E}=\mathcal{E}$. By definition we have $\mathcal{E}(\mathbf{c})=h^0(\mathbf{c})\exp(K^1(\mathbf{c}))$ and

$$P(\mathcal{E}(\mathbf{c}))=P(h^0(\mathbf{c}))\exp(P_aK^1(\mathbf{c}))=h^0(\mathbf{c})\exp(-\Delta_0(\log|h^0(\mathbf{c})|)\mathbf{v}_0-\Delta_1(\log|h^0(\mathbf{c})|)\mathbf{v}_1)\exp(P_aK^1(\mathbf{c})), \tag{5.69}$$

so we need to show that

$$P_a K^1(\mathbf{c}) - \Delta_0(\log|h^0(\mathbf{c})|)\mathbf{v}_0 - \Delta_1(\log|h^0(\mathbf{c})|)\mathbf{v}_1 = K^1(\mathbf{c}). \tag{5.70}$$

Now

$$\begin{aligned} P_a K^1(\mathbf{c}) &= \lim_{k\to\infty} P_a L^k(\mathbf{c}) = \lim_{k\to\infty} P_a(R_a^k P_a(H^0(\sigma^{-k}(\mathbf{c}) - \mathcal{I}G_2(\sigma^{-k}(\mathbf{c}))) - H^0(\mathbf{c})) \\ &= \lim_{k\to\infty} R_a^k P_a(H^0(\sigma^{-k}(\mathbf{c})) - \mathcal{I}G_2(\sigma^{-k}(\mathbf{c})) - P_a H^0(\mathbf{c}) \\ &= \lim_{k\to\infty} L^k(\mathbf{c}) + H^0(\mathbf{c}) - P_a H^0(\mathbf{c}) = K^1(\mathbf{c}) + H^0(\mathbf{c}) - P_a H^0(\mathbf{c}). \end{aligned} \tag{5.71}$$

However, by definition, we have that

$$H^0(\mathbf{c}) - P_a H^0(\mathbf{c}) = \mathrm{Re}(\Delta_0 H^0(\mathbf{c}))\mathbf{v}_0 + \mathrm{Re}(\Delta_1 H^0(\mathbf{c}))\mathbf{v}_1, \tag{5.72}$$

and, since $\mathrm{Re}(H^0(\mathbf{c})) = \log|h^0(\mathbf{c})|$, we are done. □

E. Construction of a model space for the fundamental set

In this section we outline the construction of a model space for the fundamental set $\overline{\beta(\Sigma)}$. The space is obtained by quotienting Σ by the partnering operation $\sim$, and then completing in a pull-back metric.

The map $\beta:\Sigma\to\mathcal{F}$ is continuous but not injective. Indeed, recall from Lemma 5.11 that $\beta(\mathbf{c}) = \beta(\mathbf{c}')$, if, and only if, $\mathbf{c}' = \mathbf{c}$ or $\tilde{\mathbf{c}}$, so that β is invariant under the partnering operation. If we now define Σ' to be the topological quotient of Σ with respect to the continuous involution $\sim$, i.e., in which we identify $\mathbf{c}$ with its partner $\tilde{\mathbf{c}}$ to make a new topological space, then β induces a map on Σ' which we also denote by β. The map $\beta:\Sigma'\to\mathcal{F}$ is continuous and one-to-one onto its image inside $\mathcal{F}$. Indeed, the map $\beta:\Sigma'\to\beta(\Sigma')$ is a homeomorphism.

The metric d on Σ induces a metric on Σ' which we may also denote by d. Since Σ is not closed in $\hat{\Sigma}$, the metric d on Σ is not complete and so neither is d on Σ'. Indeed there are obstructions to extending $\mathcal{E}$, and hence β, to the whole of $\hat{\Sigma}$. The space Σ' is therefore a model of only a dense subset of the fundamental set $\overline{\beta(\Sigma)}$.

However, by pulling back the metric on $\mathcal{F}$ to Σ', we may complete Σ' in this new metric and obtain a model space for the whole of $\overline{\beta(\Sigma)}$. We define a metric on Σ' by pulling back the metric on $\mathcal{F}$ (given by the Banach space structure), rather than by projecting down the metric on Σ to the quotient. This results in the same topology on Σ', but a different metric structure.

The space Σ' is not complete as a metric space, but we may complete it in the standard manner to obtain $\hat{\Sigma}'$. The homeomorphism β (which is now trivially, by construction, an isometry) extends to an isometry $\beta:\hat{\Sigma}'\to\widehat{\beta(\Sigma')} = \overline{\beta(\Sigma')}$, the closure of the image $\beta(\Sigma')$ in $\mathcal{F}$.

Now, since $\sigma:\Sigma\to\Sigma$ is a homeomorphism commuting with the partnering operation, then induced map $\sigma:\Sigma'\to\Sigma'$ is also a homeomorphism. Moreover, we may extend the function $b_0(\mathbf{c})$ to $\hat{\Sigma}'$ so that we have the equation

$$R(\beta(\mathbf{c})) = L_{b_0}(+1, +1)\beta(\sigma(\mathbf{c})), \tag{5.73}$$

for $\mathbf{c}\in\hat{\Sigma}'$, where, as earlier, $b_0 = c_0 + \tilde{c}_0 \bmod 2$.

VI. PROPERTIES OF THE ORCHID

In this section we discuss the properties of the orchid constructed in Sec. IV. In particular we wish to show that (restricting to a codimension-2 stable manifold) it is a strange attractor, and that the function pair given by the generalized Harper equation (1.2) does indeed lie on the stable manifold of the orchid. In fact, this is not strictly the case (as we shall see) for the presence of the denominator in (2.26) leads to a scaled version of the orchid $\mathcal{O}$. Of further interest is the periodic orbit structure of $\mathcal{O}$ which we shall discuss in the next section.

The precise definition of a "strange attractor" is still not firmly established despite the familiarity of the whole scientific community with the basic concept. However central ingredients are as follows:

(i) the attractor should be closed;
(ii) the attractor should be indecomposable—this means that there should be a dense orbit in forward, or both forward and backward time;
(iii) the periodic points should be dense in the attractor;
(iv) the attractor should exhibit "sensitive dependence on initial conditions."

We shall show that the orchid does indeed possess these four characteristics, although it is not an attractor for all function pairs in $\mathcal{F}$.

We first of all discuss the initial conditions (2.26) given by the generalized Harper equation.

A. The generalized Harper equation orchid

We now prove that the initial condition derived from the generalized Harper equation is attracted to the orchid under iteration of R. Let u_2, t_2 be initial conditions for the operator R given by (2.26). Let us separate the numerator and denominator of (2.26) as follows, writing

$$u_2^1(x) = t_2^1(x) = \frac{1 + \alpha \cos(2\pi(\omega^2 x + \omega/2))}{\alpha/2}, \tag{6.1}$$

$$u_2^2(x) = t_2^2(x) = \frac{1}{2(1 - \cos(2\pi(\omega^2 x + \omega)))}. \tag{6.2}$$

Then from the multiplicative property (2.33) of R we have

$$(u_n, t_n) = R^{n-2}(u_2, t_2) = R^{n-2}(u_2^1, t_2^1) R^{n-2}(u_2^2, t_2^2), \tag{6.3}$$

for $n \geqslant 3$. We shall analyze the dynamics of $(u_n^1, t_n^1) = R^{n-2}(u_2^1, t_2^1)$ and $(u_n^2, t_n^2) = R^{n-2}(u_2^2, t_2^2)$ separately. We first prove the following lemma.

Lemma 6.1: $P(u_2^1, t_2^1) = (u_2^1, t_2^1)$, $P(u_2^2, t_2^2) = (u_2^2, t_2^2)$.

Proof: Recall the definition of P in Eq. (2.49). We prove the lemma by direct calculation using (2.43) and (2.44).

We first of all show that $\Delta_0(\log|(u_2^j, t_2^j)|) = 0$ for $j = 1, 2$. Using the integral identity

$$\int_a^{a+2\pi/c} \log|1 + b \cos(cx + d)| dx = \frac{2\pi}{c} \log(|b|/2), \tag{6.4}$$

for $a, b, c, d \in \mathbb{R}$ with $|b| \geqslant 1$, $c > 0$, we have, setting $a = -\omega^{-1}$, $b = -1$, $c = 2\pi\omega^2$, $d = 2\pi\omega$,

$$\Delta_0(\log|(u_2^2, t_2^2)|) = \int_{-\omega^{-1}}^{1} -\log 2 - \log|1 - \cos(2\pi(\omega^2 x + \omega))| dx = -\omega^{-2} \log 2 - \omega^{-2} \log(1/2) = 0, \tag{6.5}$$

and, setting $a = -\omega^{-1}$, $b = \alpha$, $c = 2\pi\omega^2$, $d = 2\pi\omega^2/2$, we have

$$\begin{aligned} \Delta_0(\log|(u_2^1, t_2^1)|) &= \int_{-\omega^{-1}}^{1} -\log(\alpha/2) + \log|1 + \alpha \cos(2\pi(\omega^2 x + \omega/2))| dx \\ &= -\omega^{-2} \log(\alpha/2) + \omega^{-2} \log(\alpha/2) = 0. \end{aligned} \tag{6.6}$$

Second, we note that

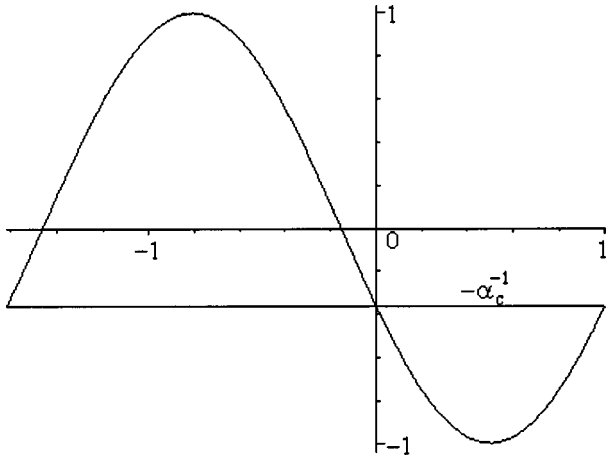

FIG. 7. The graph of $\cos(2\pi(\omega^2 x+\omega/2))$ in the range $-\omega^{-1}\leqslant x\leqslant 1$.

$$\Delta_1(\log|(u_2^j,t_2^j)|)=\int_{-\omega^{-1}}^{1}\frac{d}{dx}\log|t_2^j(x)|dx=0, \tag{6.7}$$

for $j=1, 2$, since t_2^j is periodic with period ω^{-2}. This calculation is complicated by the presence of logarithmic singularities both within the interval $(-\omega^{-1},1)$ and at the endpoints $-\omega^{-1}$ and 1. □

We note that the constraint (2.21) is simply the condition $\Delta_0(\log|(u_2,t_2)|)=0$.

B. Convergence to a scaled orchid

We now study the zero set of the function pair (u_2^1,t_2^1). The pattern of its zeros is the essential ingredient that gives the fundamental set $\overline{\beta(\Sigma)}$, three copies of which make up the orchid.

Looking at (6.1), we see that the zeros of t_2^1 are given by the solutions of the equation

$$-\alpha^{-1}=\cos(2\pi(\omega^2 x+\omega/2)). \tag{6.8}$$

The graph of $\cos(2\pi(\omega^2 x+\omega/2))$ in the range $-\omega^{-1}\leqslant x\leqslant 1$ is shown in Fig. 7.

For $\alpha\geqslant 1$ the locations of the solutions of (6.8) are determined by whether (a) $1\leqslant\alpha<\alpha_c$, (b) $\alpha_c<\alpha$, or (c) $\alpha=\alpha_c$, where

$$\alpha_c=\frac{-1}{\cos(\pi\omega)}\simeq 2.759. \tag{6.9}$$

We shall see that [apart from a countable set of values of the parameter α corresponding to zeros with codes not in Σ, i.e., ending $(00)^\infty$ or $(01)^\infty$] each initial condition (u_2^1,t_2^1) is asymptotic to the orbit of a point in the orchid $\mathcal{O}$ given by $(+1,+1)\beta(\mathbf{c})$ for some $\mathbf{c}\in\Sigma$.

We have three cases, which we deal with in turn.

Case (a): $1\leqslant\alpha<\alpha_c$. There are two zeros of t_2^1 which we denote x_L, $x_U\in[0,1]$ with $x_L+x_U=1$ by the symmetry about 1/2. We write $t_2^1(x)=(x_L-x)(x_U-x)g(x)$, where $g(x)>0$ for $x\in[-\omega^{-1},1]$. Then, except for countably many x_L, there exists $\mathbf{c}\in\Sigma$ with $c_{-1}=\tilde{c}_{-1}=0$ and $e_0(\mathbf{c})=x_L$ and therefore $(+1,+1)\beta(\mathbf{c})/(u_2^1,t_2^1)$ satisfies the hypotheses of Proposition 2.7. Moreover, since $x_L+x_U=1$, we have that $0\in S$, where S is the set defined in Sec. IV (see Proposition 3.1), and hence that $(+1,+1)\beta(\mathbf{c})\in\mathcal{O}$ for some choice of $\mathbf{c}$ with $(+1,+1)\beta(\mathbf{c})/(u_2^1,t_2^1)$ satisfying the hypotheses of Proposition 2.7.

Case (b): $\alpha_c<\alpha$. In this case t_2^1 has a zero, x_L, in the interval $[-\omega/4,0)$ and another, $x_{U'}$, in $(-\omega^{-1},-\omega^{-1}+\omega/4]$. By the symmetry of the graph about $-\omega^{-1}/2$ we have that $x_L+x_{U'}=-\omega^{-1}$. We now have $t_2^1(x)=(x_L-x)(x_{U'}-x)g(x)$, where $g(x)>0$ for $x\in[-\omega^{-1},1]$. Again, except for countably many x_L, there exists $\mathbf{c}\in\Sigma$ with $e_0(\mathbf{c})=x_L$ and $c_{-1}=\tilde{c}_{-1}=0$, and so that $(+1,+1)\beta(\mathbf{c})/(u_2^1,t_2^1)$

satisfies the hypotheses of Proposition 2.7. Now, since $x_L + x_{U'} = -\omega^{-1}$, we have, from Proposition 3.1, that index 0 is the second digit of an *A*, *B* or *C*. However, since $c_0 = 0$, the cases *A* and *C* are not possible so that index 0 is the second digit of a *B*. Thus $1 \in S$. Moreover, recalling from Sec. IV that $\mathbf{b} = \mathbf{c} + \tilde{\mathbf{c}}$ mod 2, as in Sec. IV, we have $b_0 = 1$ and thus $L_{b_0}(+1,+1) = L_1(1,1) = (+1,-1)$, and $1 \in S$, so referring back to Eq. (4.7) and Lemma 4.1, we see that $(+1,+1)\beta(\mathbf{c}) \in \mathcal{O}$.

Case (c): $\alpha = \alpha_c$. In this case t_2^1 has three zeros on $[-\omega^{-1}, 1]$, viz., $-\omega^{-1}$, 0, 1, but these points have codes ending in $(00)^\infty$ or $(01)^\infty$ which have been excluded.

In summary, for all but a countable number of $\alpha \geqslant 1$, there exists $\mathbf{c} \in \Sigma$ such that $(+1,+1)\beta(\mathbf{c})/(u_2^1, t_2^1)$ satisfies the hypotheses of Proposition 2.7 and such that $(+1,+1)\beta(\mathbf{c}) \in \mathcal{O}$.

Let us now briefly consider the function pair (u_2^2, t_2^2). We note that u_2^2 and t_2^2 have double poles at $-\omega^{-1}$ and 1 and that both satisfy $u_2^2(x), t_2^2(x) > 0$ on $(-\omega^{-1}, 1)$. From the above considerations we may conclude the following result which proves that a scaled version of the orchid $\mathcal{O}$ is the limit of the initial conditions (2.26). We denote by (u_{sc}, t_{sc}) the strong-coupling fixed point $(u_*, t_*)^{-2}$.

Proposition 6.1: The following limits hold as $n \to \infty$:

(i) $R^{n-2}(u_2^1, t_2^1) \to \mathcal{O}$, *the orchid defined in (4.7);*
(ii) $R^{n-2}(u_2^2, t_2^2) \to (u_{sc}, t_{sc})$;
(iii) $R^{n-2}(u_2, t_2) \to (u_{sc}, t_{sc})\mathcal{O}$.

C. Strangeness of $\mathcal{O}$

We now address the strangeness of the orchid $\mathcal{O}$. In particular we wish to show that the characteristics (i)–(iv) above hold. Let us briefly discuss the notion of the "sensitive dependence on initial conditions." This notion is one of the most varied in the literature. Indeed, it is sometimes taken to mean that given any point *p* in the attractor the orbits of *p* and those of all nearby points separate at a geometric rate. However a much weaker notion is also used, viz., that given any point *p* the orbit of *p* and that of at least one other point in every neighborhood of *p* separate, not necessarily geometrically. In our case it is the latter notion which we adopt. For it is clear that any two points $(s_0^u, s_0^t)\beta(\mathbf{c})$ and $(s_0^u, s_0^t)\beta(\mathbf{c}')$ on the orchid for which $e_0(\mathbf{c}) = e_0(\mathbf{c}')$ and $c_{-1} = c'_{-1}$ the ratio $(s_0^u, s_0^t)\beta(\mathbf{c})/((s_0^u, s_0^t)\beta(\mathbf{c}'))$ satisfies the hypotheses of Proposition 2.7 and thus $(s_0^u, s_0^t)\beta(\mathbf{c})$ and $(s_0^u, s_0^t)\beta(\mathbf{c}')$ converge under the iteration of *R*. Indeed, arbitrarily close to a point $(s_0^u, s_0^t)\beta(\mathbf{c}) \in \mathcal{O}$ there are such points $(s_0^u, s_0^t)\beta(\mathbf{c}')$ and so the stronger definition given above cannot hold. However, close by to $(s_0^u, s_0^t)\beta(\mathbf{c})$ and $(s_0^u, s_0^t)\beta(\mathbf{c}')$ there will be points which diverge under iteration. In fact we have the following proposition.

Proposition 6.2: The orchid $\mathcal{O}$ *satisfies the following:*

(i) $\mathcal{O}$ *is closed;*
(ii) *There is a dense forward orbit in* $\mathcal{O}$;
(iii) *The periodic points of R are dense in* $\mathcal{O}$;
(iv) $\mathcal{O}$ *has sensitive dependence on initial conditions in the following sense. There exists* $\delta > 0$ *such that for all function pairs* h_1, $h_2 \in \mathcal{O}$ *and all* $\varepsilon > 0$ *there exists* h_1', $h_2' \in \mathcal{O}$ *with* $\|h_1' - h_1\| < \varepsilon$, $\|h_2' - h_2\| < \varepsilon$ *and* $n > 0$ *such that* $\|R^n(h_1') - R^n(h_2')\| > \delta$.

Proof:

(i) The orchid $\mathcal{O}$ is closed by definition.
(ii) The construction of a dense orbit for a shift space is a standard procedure. One simply concatenates all finite permitted sequences in both forward and backward time (with appropriate interpolation between sequences to ensure that the constructed sequence is itself permitted). The adaptation of this method to the orchid is straightforward. We construct a function with a dense orbit (in both forward and backward time) by concatenating three copies of each finite permitted sequence in Σ with appropriate interpolations between each sequence to ensure first that the resulting bi-infinite sequence is a sequence in Σ, and, second, that each of the three parts of the orchid is visited for each of the finite sequences. This can be achieved by ensuring that each of the three finite sequences corresponds to a

different permitted sign-pair choice at the start of the A, B, or C immediately preceding the sequence. So constructed, the sequence $\mathbf{c}$ will give a function pair $\beta(\mathbf{c})$ with a dense orbit in the orchid under R.

(iii) Similarly, it is straightforward to show that the periodic points are dense in the orchid. For given $(s^u,s^t)\beta(\mathbf{c})$ in the orchid, one may approximate $\mathbf{c}$ arbitrarily closely by a periodic orbit, by truncating $\mathbf{c}$ in both forward and backward time at the start/end of an A, B, or C, and then repeating the truncated string in forward and backward time to obtain a periodic orbit in Σ with the same structure as $\mathbf{c}$ in the truncated part. By choosing the sign pair to correspond to that of $\mathbf{c}$ one obtains a periodic orbit in the orchid that is arbitrarily close to $(s^u,s^t)\beta(\mathbf{c})$.

(iv) Choose $\mathbf{c}_0\in\Sigma$ such that 0 starts an A, B, C and let $0<\delta<\min\{\|\beta(\mathbf{c}_0)-(-1,-1)\beta(\mathbf{c}_0)\|,\ \|\beta(\mathbf{c}_0)-(+1,-1)\beta(\mathbf{c}_0)\|,\|(+1,-1)\beta(\mathbf{c}_0)-(-1,-1)\beta(\mathbf{c}_0)\|\}/3$. Let h_1, $h_2\in\mathcal{O}$ and let $\varepsilon>0$ be given. Our aim is to construct h_1', h_2' as in the statement of the proposition. First, let $\hat{h}_1=(s_0^{u,1},s_0^{t,1})\beta(\mathbf{c}_1)$, $\hat{h}_2=(s_0^{u,2},s_0^{t,2})\beta(\mathbf{c}_2)$ be points of $\mathcal{O}$ such that $\|\hat{h}_1-h_1\|<\varepsilon$ and $\|\hat{h}_2-h_2\|<\varepsilon$. (This step is necessary since h_1, h_2 may be in the closure of $\beta(\Sigma)$. Now let $\delta_1>0$ be such that for all $\mathbf{c}\in\Sigma$,

(a) $d(\mathbf{c},\mathbf{c}_1)<\delta_1$ implies $\|(s_0^{u,1},s_0^{t,1})\beta(\mathbf{c})-h_1\|<\varepsilon$;
(b) $d(\mathbf{c},\mathbf{c}_2)<\delta_1$ implies $\|(s_0^{u,2},s_0^{t,2})\beta(\mathbf{c})-h_2\|<\varepsilon$;
(c) $d(\mathbf{c},\mathbf{c}_0)<\delta_1$ implies $\|\beta(\mathbf{c})-\beta(\mathbf{c}_0)\|<\delta$.

Such a δ_1 exists by the continuity of the map β.

Let $m>0$ be chosen sufficiently large so that for all codes $\mathbf{c}$, $\mathbf{d}\in\Sigma$, $c_i=d_i$ for $i=-m,\ldots,m$ implies $d(\mathbf{c},\mathbf{d})<\delta_1$. We now construct $\mathbf{c}_1'$, $\mathbf{c}_2'$ with the following properties:

(a) $d(\mathbf{c}_1',\mathbf{c}_1)<\delta_1$, $d(\mathbf{c}_2',\mathbf{c}_2)<\delta_1$;
(b) $d(\sigma^{3m}(\mathbf{c}_1'),\mathbf{c}_0)<\delta_1$, $d(\sigma^{3m}(\mathbf{c}_2'),\mathbf{c}_0)<\delta_1$;
(c) Defining $(s_i^{u,1},s_i^{t,1})$, $(s_i^{u,2},s_i^{t,2})$ by Eq. (4.6) we require $(s_{3m}^{u,1},s_{3m}^{t,1})\neq(s_{3m}^{u,2},s_{3m}^{t,2})$.

It is clear that we can achieve these properties by defining $(\mathbf{c}_1')_i=(\mathbf{c}_1)_i$, $(\mathbf{c}_2')_i=(\mathbf{c}_2)_i$, $i=-m,\ldots,m$ and $(\mathbf{c}_1')_i=(\mathbf{c}_0)_i$, $(\mathbf{c}_2')_i=(\mathbf{c}_0)_i$, $i=2m,\ldots,4m$ and interpolating in the range $m+1\leqslant i\leqslant 2m-1$ so that (c) is satisfied.

It is now clear that $h_1'=(s_0^{u,1},s_0^{t,1})\beta(\mathbf{c}_1')$, $h_2'=(s_0^{u,2},s_0^{t,2})\beta(\mathbf{c}_2')$ satisfy $\|R^{3m}(h_1')-(s_{3m}^{u,1},s_{3m}^{t,1})\beta(\mathbf{c}_0)\|<\delta$, $\|R^{3m}(h_2')-(s_{3m}^{u,2},s_{3m}^{t,2})\beta(\mathbf{c}_0)\|<\delta$, so that, from the definition of δ, $\|R^{3m}(h_1')-R^{3m}(h_2')\|>\delta$ as required. □

VII. PERIODIC ORBITS

In this section we discuss the periodic points in the orchid, focusing on the periods that are permitted. In Ref. 17 the periods of several periodic orbits for the parameter value,

$$\alpha=\frac{1}{|\cos(2\pi r)|},\tag{7.1}$$

with rational r are calculated and the conjecture is made that such orbits are all periodic with period a multiple of three. Here we prove this fact, and, indeed, prove that *all* periodic orbits of R on the orchid have period a multiple of three.

The periodic orbits of Σ under the shift map σ are simply the periodic sequences $\mathbf{c}\in\Sigma$. Such periodic sequences in code 0 1 are clearly also periodic with the same period when written in terms of the symbols A, B, C and vice versa. By choosing the start of the periodic code we may, without loss of generality, assume that index 0 starts an A, B, or C. In terms of the symbols A, B, C any periodic code is permitted other than the period-1 codes ${}^{\infty}BB^{\infty}$, ${}^{\infty}CC^{\infty}$ and it is therefore clear that any period greater than 2 can be achieved by suitable choice of A, B, C.

Now let $\mathbf{c}$ be a periodic code of period $\ell\geqslant 1$. We note that the sequence $\ldots,\mathcal{E}(\mathbf{c}),\mathcal{E}(\sigma(\mathbf{c})),\ldots$, is also of period ℓ and vice versa. This is because the zero sets of $\mathcal{E}(\mathbf{c})$ are given by $e_0(\mathbf{c})$, and the

sequence $\ldots, e_0(\mathbf{c}), e_0(\sigma(\mathbf{c})), \ldots$, has the same period ℓ. However, the sequence $\ldots, \beta(\mathbf{c}), \beta(\sigma(\mathbf{c})), \ldots$ may have period less than ℓ. $\beta(\mathbf{c}) = \mathcal{E}(\mathbf{c})\mathcal{E}(\tilde{\mathbf{c}})$, so if for some $k < \ell$ it should occur that $\sigma^k(\mathbf{c}) = \tilde{\mathbf{c}}$ and $\sigma^k(\tilde{\mathbf{c}}) = \mathbf{c}$ we have $\beta(\sigma^k(\mathbf{c})) = \beta(\mathbf{c})$. If this does occur we clearly have $\sigma^{2k}(\mathbf{c}) = \mathbf{c}$ so that, since $\mathbf{c}$ has period ℓ, we have $k = \ell/2$ and so ℓ is even. Indeed this phenomenon occurs precisely when the sequence $c_0, \ldots, c_{\ell-1}$ is of the form $c_0, \ldots, c_{k-1}, \tilde{c}_0, \ldots, \tilde{c}_{k-1}$. For example, the periodic sequence 0100001001 of period 10 when written in terms of A, B, C is $ABAC = AB\tilde{A}\tilde{B}$ giving period 5 for the sequence $\ldots, \beta(\mathbf{c}), \beta(\sigma(\mathbf{c})), \ldots$. We shall refer to the reduction in the period due to this symmetry in the code as *period halving*.

We now consider a periodic point p on the orchid $\mathcal{O}$. Let $p = (s_0^u, s_0^t)\beta(\mathbf{c})$ for some $\mathbf{c} \in \Sigma$. Clearly, from Eq. (4.5) a necessary condition for p to be periodic for R is that $\mathbf{c}$ is periodic for σ on Σ. Let ℓ be the period of $\mathbf{c}$. Then, as we saw above, the period k of the sequence $\ldots, \beta(\mathbf{c}), \beta(\sigma(\mathbf{c})), \ldots$ is either $k = \ell$, or $k = \ell/2$ in the case of period halving. Recall from Sec. IV that under a symbol A the sign pair (s^u, s^t) is the same after as before, while after a B or C the transitions $(+1, +1) \to (+1, -1) \to (-1, -1) \to (+1, +1)$ occur. Thus we have two possibilities.

(a) The number of B and C (added together) in the sequence $c_0, \ldots, c_{k-1}$ is divisible by 3. Then we have $(s_k^u, s_k^t) = (s_0^u, s_0^t)$ and the period of p is precisely k. We note that in this case k is a multiple of 3 since the symbol A consists of 3 digits.

(b) The number of B and C (added together) in the sequence $c_0, \ldots, c_{k-1}$ is not divisible by 3. Then after the end of the sequence $c_0, \ldots, c_{k-1}$ the sign pair $(s_k^u, s_k^t) \neq (s_0^u, s_0^t)$, and, because of the period-3 nature of the sign pair evolution we have $(s_{2k}^u, s_{2k}^t) \neq (s_0^u, s_0^t)$, but $(s_{3k}^u, s_{3k}^t) = (s_0^u, s_0^t)$. Then $R^{3k}(p) = (s_{3k}^u, s_{3k}^t)\beta(\sigma^{3k}(\mathbf{c})) = p$. We have therefore proved the following result.

Theorem 7.1: *Let $p = (s_0^u, s_0^t)\beta(\mathbf{c}) \in \mathcal{O}$. Then p is periodic of period m for R if and only if $\mathbf{c}$ is periodic for σ of period ℓ. The relationship between m and ℓ is as follows. If period halving occurs set $k = \ell/2$, otherwise set $k = \ell$. If the number of B* and *C (added together) in the sequence $a_0, \ldots, a_{k-1}$ is divisible by 3 then $m = k$, otherwise $m = 3k$.*

The conjecture concerning the periodic orbits in Ref. 17 is incorporated in the following immediate consequence of this result.

Corollary 7.1: The periods of all periodic orbits in $\mathcal{O}$ are multiples of three.

As an illustration of these results we give the following examples.

(1) In the period-10 example $\overline{0100001001}$ above we have $\ell = 10$, $k = 5$ and $c_0, \ldots, c_4 = 01000 = AB$. Since the number of B and C in this sequence is 1 we have that $m = 3 \times 5 = 15$. Thus we have a period-15 orbit.

(2) Let $\mathbf{c} = 000001 = \overline{BBC}$. Then $\ell = 6$, $k = 6$, and since the number of B and C is 3 we have $m = 6$. Thus we have a period-6 orbit.

VIII. DISCUSSION

In this paper we have constructed a model space in terms of bi-infinite codes for the fundamental set (Fig. 4), three copies of which constitute the Ketoja–Satija orchid. We have shown that the initial conditions for the generalized Harper equation converge to a scaled orchid (Fig. 1) under the golden mean renormalization transformation. The intriguing three-fold symmetry of the orchid has been shown to stem from the dynamics on the sign pairs, as given by the transition diagram (Fig. 6). Finally, we have analyzed the periods of the periodic orbits in the orchid.

The structure of the orchid depends crucially on the symmetries of the generalized Harper equation (1.2), and in particular on those of the cosine function. It is these symmetries that lead to the partnering operation on codes and the relation given by Proposition 3.1 on the zeros of the function pairs $\beta(\mathbf{c})$. If one destroys the symmetries, then, likewise, the orchid is destroyed and is replaced by a different strange set. Indeed, when calculating the orchid numerically, care must be taken with round-off error in the zeros of the function pairs. Since the chaotic map G governs the dynamics of these zeros, round off error grows quickly leading to the violation of Proposition 3.1 and nonconvergence to the orchid. Thus the universality class for the orchid is restricted to those

quantum models displaying the same symmetries as the generalized Harper equation model (1.2). Moreover, the existence of nonstable eigendirections for the operator R_a implies further conditions on a function pair (u,t) to converge to $\mathcal{O}$. These conditions are satisfied for the initial conditions derived from the generalized Harper equation model, but it is clearly a moot point to what extent one should refer to the orchid as a renormalization strange "attractor."

The ideas and techniques in this paper are likely to find application in other problems in the field. As first pointed out by Bondeson *et al.*,[2] there is an equivalence between the transition to the localized state in quasiperiodic Schrödinger equations and the onset of a strange nonchaotic attractor in quasiperiodically forced nonlinear systems. See also Ref. 19. Kuznetsov *et al.*[23] have given a renormalization analysis of the onset of a strange nonchaotic attractor. We anticipate that our work in this paper will shed considerable light on this related problem, and in particular we expect that the numerical results in Ref. 23 can be generalized and put on a rigorous foundation. Rigorous renormalization analyses of correlations in strange nonchaotic attractors[7] and in a quasiperiodically forced two-level system[8] have recently been completed.[25,26]

The existence of a strong coupling fixed point for the Harper equation in the case of flux $\omega=(\sqrt{a^2+4}-a)/2$ satisfying $\omega^2+a\omega=1$ (i.e., in continued fraction notation $\omega=[a,a,\ldots]$), has recently been established,[5] generalizing the results in Ref. 24. Preliminary work shows that for each such ω there exists an orchid, similar to that analyzed in this article, governing the fluctuations. The case of more general irrational ω is the subject of current investigation.

(Received 24 March 2004; accepted 24 August 2004; published 2 December 2004)

We describe the qualitative features of the joint spectrum of the quantum 1:1:2 resonant swing spring. The monodromy of the classical analogue of this problem is studied in Dullin *et al.* [Physica D **190**, 15–37 (2004)]. Using symmetry arguments and numerical calculations we compute its three-dimensional (3D) lattice of quantum states and show that it possesses a codimension 2 defect characterized by a nontrivial 3D-monodromy matrix. The form of the monodromy matrix is obtained from the lattice of quantum states and depends on the choice of an elementary cell of the lattice. We compute the quantum monodromy matrix, that is the inverse transpose of the classical monodromy matrix. Finally we show that the lattice of quantum states for the 1:1:2 quantum swing spring can be obtained—preserving the symmetries—from the regular 3D-cubic lattice by means of three "elementary monodromy cuts." © *2004 American Institute of Physics.*

I. INTRODUCTION

The swing spring is a simple mechanical system consisting of a spring of length ℓ and spring constant k with one end attached at a fixed point (the origin of a Cartesian system) and with a weight of mass m attached at the other end. This system admits a Hamiltonian formulation in which the phase space is $\mathbb{R}^6$ with coordinates x,y,z,p_x,p_y,p_z and symplectic form $\mathrm{d}x\wedge\mathrm{d}p_x+\mathrm{d}y\wedge\mathrm{d}p_y+\mathrm{d}z\wedge\mathrm{d}p_z$. The Hamiltonian function H is

$$(x,y,z,p_x,p_y,p_z)\mapsto\frac{1}{2m}(p_x^2+p_y^2+p_z^2)+mgz+\frac{k}{2}(\ell-\sqrt{x^2+y^2+z^2})^2. \tag{1}$$

Note that ℓ is the same as ℓ_0 in Refs. 11 and 17.

When the physical parameters are chosen so that $3gm=k\ell$, which is equivalent to requiring that the frequencies of small oscillations of the swing spring near the stable equilibrium are in a 1:1:2 resonance (the only resonance with cubic secular terms), the swing spring has some remarkable features: energy exchange and precession of the swing plane.[11,17] These characteristics have been widely studied (see Ref. 17 for a comprehensive bibliography), but the information hidden in this classical mechanical system has not been exhausted by these investigations. In fact, the resonant swing spring is a model for molecules such as CO_2 (a textbook example of a 1:1:2 Fermi resonance between stretching and doubly degenerate bending vibration states[4,13]), HCP,[18] and a whole class of CHX_3 molecules which possess a Fermi resonance between the CH stretching and bending vibrational states.[19]

We define the integrable approximation of the swing spring system and discuss the range of energies in which our approximating Hamiltonian gives data that can be considered reliable for the original system. After explaining the origin of the continuous and discrete symmetries of our approximation, we define the quantum analogue of the system and proceed to analyze its quantum spectrum. As the classical swing spring is a three degree of freedom system, its spectrum is represented by a three-dimensional (3D) lattice of points in the space of the values of quantized actions and energy. The main purpose of this work is to show how the nontrivial monodromy of the classical system[2,3,5] manifests itself (1) as a defect of this lattice and (2) in the distribution of quantum states with respect to quantum numbers which can be predicted from the theorem of Duistermaat–Heckman.[10]

Fixing a global quantum number associated to the momentum corresponding to a circle symmetry, we first analyze the quantum lattice of two-dimensional (2D) slices of the swing spring quantum spectrum and find that the monodromy computed in such slices gives insufficient information to determine the monodromy of the full 3D quantum spectrum. We proceed with the investigation of the 3D quantum lattice by giving two methods to compute the quantum monodromy matrix. The first method, presented in Ref. 26, requires the introduction of quantum defects in the regular $\mathbb{Z}^3$ lattice. In order to preserve the discrete symmetries of the system, one must use three elementary defects to obtain the quantum lattice. The second method obtains the quantum monodromy matrix directly by moving an elementary cell in the three-dimensional quantum lattice.

II. CLASSICAL AND QUANTUM 1:1:2 SWING SPRING

The swing spring is a Hamiltonian system on $(\mathbb{R}^6, dx\wedge dp_x+dy\wedge dp_y+dz\wedge dp_z)$ with Hamiltonian H given by (1). Despite it being a chaotic dynamical system,[16] the motions of the swing spring near the stable equilibrium located at $p_0=(0,0,-\ell-mg/k,0,0,0)$ have a clear quasiperiodic behavior when the parameters are chosen so that the characteristic oscillations of the system are tuned in 1:1:2 resonance.

To study this behavior we will begin by considering the Taylor expansion of H around p_0. The quadratic part of the Taylor expansion of H at p_0 is

$$H_2=\frac{1}{2m}(p_x^2+p_y^2+p_z^2)+\frac{k}{2}\left(\frac{gm}{k\ell+gm}x^2+\frac{gm}{k\ell+gm}y^2+z^2\right).$$

To have a 1:1:2 harmonic oscillator as dominant term, the physical coefficients in H_2 must satisfy the condition $3gm=k\ell$. Assuming this and making the change of coordinates

$$x\mapsto\sqrt[4]{\frac{4}{km}}\xi,\ \ y\mapsto\sqrt[4]{\frac{4}{km}}\eta,\ \ z\mapsto\sqrt[4]{\frac{1}{km}}\zeta,\ \ p_x\mapsto\sqrt[4]{\frac{km}{4}}p_\xi,\ \ p_y\mapsto\sqrt[4]{\frac{km}{4}}p_\eta,\ \ p_z\mapsto\sqrt[4]{km}p_\zeta,$$

we find that

$$H_2=\tfrac{1}{2}\hbar(\xi^2+p_\xi^2+\eta^2+p_\eta^2+2\zeta^2+2p_\zeta^2)$$

and the Taylor expansion of H (1) about p_0 up to sixth order terms becomes

$$\begin{aligned}H_{\text{trunc}}=H_2&-\tfrac{3}{8}\hbar^{3/2}\zeta(\eta^2+\xi^2)+\tfrac{3}{64}\hbar^2(\eta^2+\xi^2)(-2\zeta^2+\eta^2+\xi^2)-\tfrac{3}{256}\hbar^{5/2}\zeta(\eta^2+\xi^2)(2\zeta^2-3(\eta^2+\xi^2))\\&-\tfrac{3}{1024}\hbar^3(\eta^2+\xi^2)(2\zeta^4-6\zeta^2(\eta^2+\xi^2)+(\eta^2+\xi^2)^2),\end{aligned}\tag{2}$$

where $\hbar=\sqrt{k^3/(g^4m^5)}$. To obtain (2) we have rescaled H_{trunc} to remove the factor $g^2m^2/(2k)$ and dropped an additive constant. The original Hamiltonian H (1), and thus the Hamiltonian H_{trunc} (2), has an SO(2) axial symmetry

$$(\xi,\eta,\zeta,p_\xi,p_\eta,p_\zeta)\mapsto\left(R_t\begin{pmatrix}\xi\\ \eta\\ \zeta\end{pmatrix},R_t\begin{pmatrix}p_\xi\\ p_\eta\\ p_\zeta\end{pmatrix}\right).$$

Here

$$R_t=\begin{pmatrix}\cos t & -\sin t & 0\\ \sin t & \cos t & 0\\ 0 & 0 & 1\end{pmatrix}$$

is a rotation about the ζ axis lifted to the full phase space $\mathbb{R}^6$. The momentum of this symmetry is the function $L=\xi p_\eta-\eta p_\xi$.

It is convenient to perform another coordinate change, namely

$$\xi\mapsto\frac{1}{\sqrt{2}}(p_2+q_1),\quad \eta\mapsto\frac{1}{\sqrt{2}}(p_1+q_2),\quad \zeta\mapsto q_3,\quad p_\xi\mapsto\frac{1}{\sqrt{2}}(p_1-q_2),\quad p_\eta\mapsto\frac{1}{\sqrt{2}}(p_2-q_1),\quad p_\zeta\mapsto p_3.$$

This brings the momentum L into diagonal form $\frac{1}{2}(q_2^2+p_2^2-q_1^2-p_1^2)$ and does not change the quadratic part H_2 of the Hamiltonian H_{trunc}.

Bringing H_{trunc} into normal form with respect to H_2 up to order 6, one obtains the Hamiltonian $H_{\text{nf}}^{(6)}$. This is the polynomial Hamiltonian (as well as its truncation $H_{\text{nf}}^{(3)}$ to third order) whose quantum spectrum we analyze in Secs. III–V.

A. Lie symmetry of classical and quantum system

The sixth order normalized Hamiltonian $H_{\text{nf}}^{(6)}$ defines a three degree of freedom system with two integrals of motion: L, the momentum associated to the axial symmetry and N, the quadratic part H_2 of the normalized Hamiltonian, which is the same as the quadratic part of the original Hamiltonian H. The flows of the Hamiltonian vector fields associated to these integrals commute and define a 2-torus action that preserves $H_{\text{nf}}^{(6)}$. Thus L and N together with the Hamiltonian $H_{\text{nf}}^{(6)}$ form a completely integrable system.

Being $S^1\times\text{SO}(2)$-invariant, the normalized Hamiltonian $H_{\text{nf}}^{(6)}$ can be written as a polynomial in the generators of the ring of $S^1\times\text{SO}(2)$-invariant functions. The Molien generating function[20] (A7) indicates that this ring is generated by five invariants, three quadratic and two cubic, see Appendix A 1. These invariants can be chosen to be

$$N=\tfrac{1}{2}(q_1^2+p_1^2+q_2^2+p_2^2+2q_3^2+2p_3^2),\tag{3a}$$

$$R=\tfrac{1}{2}(q_1^2+p_1^2+q_2^2+p_2^2),\tag{3b}$$

$$L=\tfrac{1}{2}(-q_1^2-p_1^2+q_2^2+p_2^2),\tag{3c}$$

$$S=(q_1p_2+q_2p_1)q_3-(q_1q_2-p_1p_2)p_3,\tag{3d}$$

$$T=(q_1q_2-p_1p_2)q_3+(q_1p_2+q_2p_1)p_3,\tag{3e}$$

and they are subject to the relations (A9).

B. Normalized system and its analysis

The normalized Hamiltonian H_{trunc} (2) written in terms of the invariants (3) is

$$H_{\mathrm{nf}}^{(6)} = \hbar N - \tfrac{3}{16}\hbar^{3/2}S - \tfrac{57}{1024}\hbar^2 NR + \tfrac{177}{2048}\hbar^2 R^2 - \tfrac{39}{2048}\hbar^2 L^2 - \tfrac{819}{65\,536}\hbar^{5/2}NS + \tfrac{2151}{65\,536}\hbar^{5/2}RS - \tfrac{8025}{4\,194\,304}\hbar^3 N^2 R + \tfrac{7623}{2\,097\,152}\hbar^3 NR^2 + \tfrac{6879}{2\,097\,152}\hbar^3 R^3 - \tfrac{6555}{2\,097\,152}\hbar^3 NL^2 + \tfrac{4803}{4\,194\,304}\hbar^3 RL^2 - \tfrac{1089}{262\,144}\hbar^3 S^2. \tag{4}$$

Note that powers of T higher than 1 should not appear in (4) since the invariants satisfy the relation (A9). Furthermore, (4) does not include any power of N higher than 1 because the swing spring (1) contains a two degree of freedom harmonic oscillator as subsystem. Other special features of $H_{\mathrm{nf}}^{(6)}$ are related to the discrete symmetries described below.

In most of what follows, we describe the quantum spectrum of the Hamiltonian S instead of that of $H_{\mathrm{nf}}^{(6)}$. Of course, (S,L,N) is also a completely integrable system. At first order the difference between the Hamiltonian S and (4) is given by $H \mapsto -(16/3\hbar^{3/2})(H-\hbar N)$. This means that to first order for any given value of N the quantum spectra of H and S coincide up to a translation and dilation.

The energy-momentum map

$$\mathcal{EM}\colon \mathbb{R}^6 \to \mathbb{R}^3 \quad (q,p) \to (S(q,p),L(q,p),N(q,p))$$

is widely used in our analysis. Its image $U \subset \mathbb{R}^3$ and the corresponding bifurcation diagram is described in Ref. 11 and Appendix A 3. $U_{\mathrm{reg}} \subset U$ is the set of regular values which represent regular tori $\mathbb{T}^3$. Points of the boundary ∂U represent equilibria relative to the $\mathbb{T}^2 = S^1 \times \mathrm{SO}(2)$ action. The main feature to note is that $U \backslash U_{\mathrm{reg}}$ also contains a thread of singular values inside U, which represent a special singular 3D fiber described in Appendix A 3.

It can be shown that the system $(H_{\mathrm{nf}}^{(6)},L,N)$ is qualitatively the same as (S,L,N) for sufficiently small values of N. In particular it has qualitatively the same energy-momentum map and corresponding 3D quantum lattice. The concrete estimate of the upper limit for N can be obtained from the analysis of the slope of $S(R)$ at $R=L=0$ of $H_{\mathrm{nf}}=\mathrm{const}$. Specifically, $|\mathrm{d}S/\mathrm{d}R|$ should be smaller than the slope at the conical singular point of the reduced space, see Appendix A 2. In particular considering the terms of order $\hbar^2$ we obtain $N < 2^{12}19^{-2}\hbar^{-1}$.

C. Discrete symmetries and a pseudosymmetry

The normalized Hamiltonian $H_{\mathrm{nf}}^{(6)}$ (4) is not a generic $S^1 \times \mathrm{SO}(2)$-symmetric polynomial in the invariants, because (4) does not contain terms of odd degree in L or any power of T. The reason for this is that the original Hamiltonian (1) has a $\mathbb{Z}_2 \times \mathbb{Z}_2$ discrete symmetry group generated by

$$\mathcal{T}\colon (x,y,z,p_x,p_y,p_z) \mapsto (x,y,z,-p_x,-p_y,-p_z),$$

$$\mathcal{T}_s\colon (x,y,z,p_x,p_y,p_z) \mapsto (y,x,z,-p_y,-p_x,-p_z),$$

$$\sigma_v\colon (x,y,z,p_x,p_y,p_z) \mapsto (y,x,z,p_y,p_x,p_z).$$

Note that $\mathcal{T}_s = \mathcal{T} \circ \sigma_v = \sigma_v \circ \mathcal{T}$ and that the square of each generator is the identity. This discrete symmetry survives truncation and normalization. It induces the following transformations on the invariants:

$$\mathcal{T}\colon (N,R,L,S,T) \mapsto (N,R,-L,S,-T), \tag{5a}$$

$$\mathcal{T}_s\colon (N,R,L,S,T) \mapsto (N,R,L,S,-T), \tag{5b}$$

$$\sigma_v\colon (N,R,L,S,T) \mapsto (N,R,-L,S,T). \tag{5c}$$

From (5) we see that the functions T and L are not invariant of the $\mathbb{Z}_2 \times \mathbb{Z}_2$ action. This explains the absence of odd powers of L and T in (4).

To analyze the model system (S,L,N) we also consider the involution

$$(\xi,\eta,\zeta,p_\xi,p_\eta,p_\zeta)\mapsto(-\xi,-\eta,-\zeta,-p_\xi,-p_\eta,-p_\zeta), \tag{6a}$$

which acts on the invariants as

$$(N,R,L,S,T)\mapsto(N,R,L,-S,-T). \tag{6b}$$

As the transformation (6a) maps S to $-S$, we call it a pseudosymmetry. We will exploit this pseudosymmetry below. In particular the image of the energy-momentum map of (S,L,N) is symmetric with respect to (6b). Similarly, the corresponding 3D quantum lattice is symmetric with respect to the plane $S=0$.

D. Classical integrals, quantum numbers, and joint quantum spectrum

Each of the functions in the integrable system (S,L,N) can be quantized according to the rules discussed in Appendix B. The corresponding three quantum operators $\hat{N}$, $\hat{L}$, and $\hat{S}$ are self-adjoint and commute. Hence they can be simultaneously diagonalized. In Appendix B we give the details of the calculation of the joint quantum spectrum of $(\hat{S},\hat{L},\hat{N})$ and of the quantum analogue of $H^{(6)}_{\mathrm{nf}}$. We also explain the decomposition of the domain of the quantum operators that allows us to numerically compute the quantum spectrum. To every common eigenspace one can associate a triple of real numbers and plot these triples in $\mathbb{R}^3$, generating a lattice of quantum states represented as points in 3-space. This 3D lattice of points fits in the image of the classical energy-momentum map $\mathcal{EM}$ of the integrable system (S,L,N), a description of which is in Appendix A 3. Similarly the quantum lattice for the swing spring $(H^{(6)}_{\mathrm{nf}},L,N)$ fits inside the respective $\mathcal{EM}$ image.

Definition 1: The lattice of quantum states of $(\hat{H},\hat{L},\hat{N})$ superimposed to the image of the $\mathcal{EM}$ map of the corresponding classical completely integrable system (H,L,N) is called the *quantum diagram*. A *polyad quantum number* is an injective integer labeling of the eigenvalues of the quantum operator $\hat{N}$. A *local quantum number* is an injective integer labeling of the eigenspaces of a quantum operator associated to a local action variable for the completely integrable quantum system $(\hat{H},\hat{L},\hat{N})$. A *local action variable* is a function locally defined on phase space whose Hamiltonian vector field has a 2π-periodic flow and Poisson commutes with the classical Hamiltonian H and the momenta N and L.

The notion of polyad quantum number is well established in the theoretical chemistry and molecular physics community.[24] Both polyad and local quantum numbers label eigenspaces with large dimension, that is, eigenvalues with high multiplicity. A choice of labeling of the points of the quantum spectrum corresponding to the quantum numbers of a global action will be referred to as *global quantum number*. The definition of global quantum numbers, as opposed to the choice of a quantum number, which is just a labeling of eigenspaces of a quantum spectrum, is at the heart of the presentation to follow.

Since the systems with Hamiltonian $H=S$ and $H=H^{(6)}_{\mathrm{nf}}$ are qualitatively the same, we will use $H=S$ which is easier to study analytically.

Lemma 1: The eigenstates of the quantum system $(\hat{S},\hat{L},\hat{N})$ can be labeled by three quantum numbers related to the three commuting operators $\hat{S}$, $\hat{N}$, and $\hat{L}$:

(i) The global quantum number $n_N=0,1,2,\ldots$ can be chosen to be the eigenvalue of the operator $\hat{N}$ and is the total number of quanta for the 1:1:2 resonance oscillator or the *polyad* quantum number. The total number of quantum states within one n_N-polyad equals

$$\mathcal{N}(n_N)=\begin{cases}\left(\frac{1}{2}n_N+1\right)^2 & \text{if } n_N \text{ is even},\\ \left(\frac{1}{2}n_N+1\right)^2-\frac{1}{4} & \text{if } n_N \text{ is odd}.\end{cases}$$

(ii) The global quantum number n_L can be chosen to be the eigenvalue of the operator $\hat{L}$ and is the projection of the angular momentum on the axis of symmetry. For each n_N, the quantum number n_L takes (n_N+1) different values

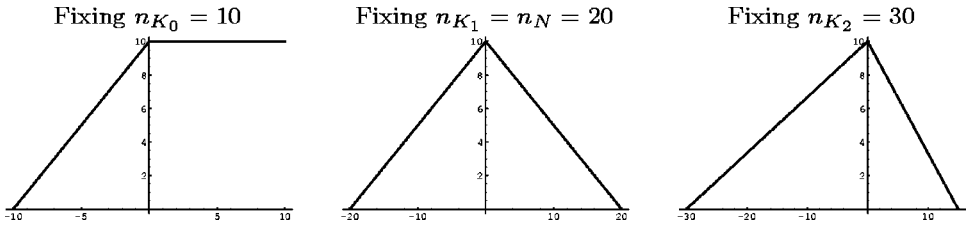

FIG. 1. The plot of the number of states in the slice having a fixed n_{K_m} quantum number as a function of the quantum number n_L.

$$n_L = n_N, n_N - 2, \ldots, -n_N + 2, -n_N.$$

The total number of states for each fixed value of n_N and n_L equals

$$\mathcal{N}(n_N, n_L) = \tfrac{1}{2}(n_N - |n_L|) + 1.$$

(iii) A quantum number n_S labels the eigenspaces within the set of states with the same n_L and n_N according to the energy of the system.

Instead of using the natural momenta N and L, one could use the momentum

$$K_m = (m+1)N + (m-1)L \tag{7}$$

together with L. The number of states in a fixed quantum level of the operator $\hat{K}_m$ can be thought as a function of n_L. A computation shows that this function assigns to every n_L in $[-n_{K_m}, 0]$ the natural number $(n_L + n_{K_m})/(m+1)$ and to every n_L in $[0, n_{K_m}/m]$ the natural number $(-n_L m + n_{K_m})/(m+1)$. The cases corresponding to $m=0,1,2$ are plotted in Fig. 1.

A classical formula states that the number of quantum states of a given quantum system is $\hbar$-proportional to the symplectic area of the phase space in which the system is defined. Hence, the graphs in Fig. 1 can also be obtained by first reducing $\mathbb{R}^6$ with respect to the circle action with momentum K_m, which defines the manifold M_k, and then by plotting the L-dependent symplectic volume of the manifold M_k reduced with respect to the circle action with momentum L. These volumes can be computed directly from the theorem of Duistermaat and Heckman, see Refs. 10 and 15. In Ref. 14 this theorem was applied to the analysis of a three-dimensional quantum problem with monodromy.

The theorem of Duistermaat and Heckman states that the cohomology class of the symplectic form of a symplectically T^n-reduced space varies piecewise linearly with the values of the momentum map. To be more precise denote by M_x the symplectic manifold obtained by symplectically reducing a manifold M with respect to the T^n-action above the value x in $\mathfrak{t}^*$. Let a be a regular value of the momentum map, let b be an element in $\mathfrak{t}^*$, and let t be a small real number. The manifold M_{a+tb} is diffeomorphic to M_a. Both manifolds are base spaces of diffeomorphic principal T^n bundles. The symplectic forms of M_a and M_{a+tb} define cohomology classes that differ by the class $t\langle b, c\rangle$, where c is the Chern class of the torus bundle over M_a, that is, an element of $H^2(M_a) \otimes \mathfrak{t}$, and $\langle , \rangle$ is the pairing between the Lie algebra $\mathfrak{t}$ and its dual $\mathfrak{t}^*$. Observe that $t\langle b, c\rangle$ is a function linear in t. Crossing the set of critical values of the T^n-momentum map, the Chern class, and hence the slope of the linear function changes into $\langle b, c'\rangle$. Since the volume form of a symplectic manifold is an appropriate power of the symplectic form, it changes polynomially in t.

In our case we are given a T^2 action having the tuple (N, L) for momentum map. The momentum polytope is the convex solid wedge with boundaries $0 \leqslant N = L$ and $0 \leqslant N = -L$. In addition to this boundary, the set of critical values of the T^2-momentum map also contains the line $L = 0$. The fiber of the T^2-momentum map over values in the set $E^+ = \{L > 0, L < N\}$ is a 2-torus bundle over a 2-sphere with Chern class $(\omega\xi_N + \omega\xi_L)/2$; while that above values in the set

$E^-=\{L<0, L>-N\}$ is a 2-torus bundle over a 2-sphere with Chern class $(\omega\xi_N-\omega\xi_L)/2$. Here ω is the standard volume form on the 2-sphere and ξ_N, ξ_L are the elements of $\mathfrak{t}$ whose infinitesimal action is X_N and X_L, respectively.

Starting from the symplectic manifold $\mathbb{R}^6$ one can reduce with respect to the momentum K_m to obtain the manifold $M_k=K_m^{-1}(k)/S^1$. On M_k there is a (residual) circle action with momentum L. The image of the (residual) momentum map is the intersection of the line $L_m=\{(m+1)N+(m-1)L=k\}$ with the image of the momentum map of the T^2 action.

We can now use the Duistermaat–Heckman theorem to compute the change in the (cohomology class of the) symplectic structure of the L-reduced manifolds $M_{k,l}=L^{-1}(l)/S^1$, and plot it as a function of l. The line L_m is spanned by the element $b=\xi_N^*-(m+1)/(m-1)\xi_L^*$. The cohomology class $\langle b, c\rangle$ is $\omega/(m+1)$ in the segment $L_m\cap E^+$ and $-m\omega/(m+1)$ in the segment $L_m\cap E^-$. This gives, as expected, the graphs in Fig. 1.

III. QUANTUM SPECTRUM: LATTICE OF QUANTUM STATES

Given a 3D quantum diagram, an important problem is to "smoothly" map it to the lattice $\mathbb{Z}^3$ in $\mathbb{R}^3$. This can always be done locally by means of independent local quantum numbers. In systems with nontrivial monodromy a global labeling of the eigenstates is impossible. To be more precise, a global labeling of the quantum states with three suitable global quantum numbers is the quantum analogue of the classical problem of defining global action functions for a completely integrable system. This problem has been shown to have no solution in systems with monodromy.[21] The quantum numbers n_N and n_L are *a priori* global, because they correspond to global classical actions. On the other hand, because of the nontrivial classical monodromy of the swing spring system, the quantum number n_S can be only locally defined. In this section we show that this last quantum number cannot be defined globally, and we analyze this phenomenon.

Informally speaking, we try to construct a third global quantum number for the quantum swing spring, which is independent of n_L and n_N. Having three global quantum numbers corresponds to defining a bijection of the given lattice to the standard $\mathbb{Z}^3$. Of course, many such bijections exist, but none of them can have the property of "$\hbar$-smoothness," which we define in Sec. III B. We begin by describing the quantum lattice of the quantum swing spring and then apply the idea of $\hbar$-smoothness.

A. Qualitative and quantitative description of the quantum lattice

One way of describing the 3D lattice of the quantum swing spring is to look at its planar slices, that is, the slices obtained by fixing a quantum number (n_N or n_{K_m} in our case). These plane slices intersect the thread of classical singular values (see Appendix A 3) in one point, which we refer to as a *singularity* of the quantum lattice.

To start with, we use the symmetries and the number of states discussed in Lemma 1 to deduce the qualitative aspects of the quantum spectrum of the swing spring. At the end of this section we give numerically computed pictures of the plane slices obtained by fixing the value of the polyad number n_N.

Let us now fix the polyad number n_N and then compute the joint spectrum of the operators $\hat{L}$ and $\hat{S}$. We recall that the quantum spectrum one computes in this way is that of the classical system obtained from the original one by reducing it with respect to the circle action having momentum N at the value n_N+2.

Lemma 2: For fixed polyad number n_N, the structure of the joint spectrum for the operators $\hat{L}$ and $\hat{S}$ is invariant under the symmetries $n_L\to -n_L$ and $n_S\to -n_S$ and it consists of four possible arrangements in a neighborhood of the intersection of the symmetry axes. These arrangements have a modulo 4 periodicity, $n_N\equiv n_N' \bmod 4$, see Fig. 2.

From the symmetry σ_v and the pseudosymmetry discussed in Sec. II C, it follows that if (n_N, n_L, n_S) is a point of the quantum diagram, then also the points $(n_N, \pm n_L, \pm n_S)$ belong to the quantum spectrum.

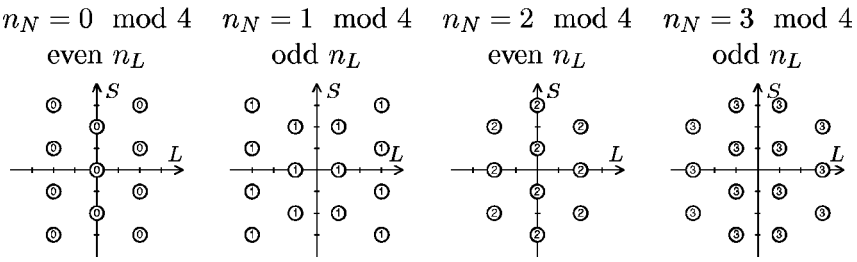

FIG. 2. Joint eigenvalues of the operators $\hat{L}$ and $\hat{S}$ near the origin.

Let us make the generic assumption that the spectrum of $\hat{S}$ at fixed n_L has no degeneracies, that is, the spectrum of $\hat{S}$ at fixed polyad numbers n_N and quantum number n_L is simple, and that the distances of consecutive $\hat{S}$-eigenvalues varies monotonically and slowly. In the rest of our argument we simply fix such distance to be some positive constant, say 2, as we did in the pictures in Fig. 2.

By Lemma 1, the quantum numbers n_N and n_L are both even or both odd, and when n_N is fixed n_L changes in steps of two. For even n_N, we have one central string of lattice points at $n_L=0$ with the maximum number of states $\mathcal{N}(n_N,n_L)=\frac{1}{2}n_N+1$ for given n_N. This string is symmetric under $S\to -S$. For $n_N=0 \bmod 4$ it has the central node at (0,0) because $\mathcal{N}(0 \bmod 4,0)$ is odd. For $n_N=0 \bmod 2$ the closest to (0,0) is a pair of nodes $(0,\pm 1)$ symmetric under $S\to -S$. Patterns for the other values of n_N are deduced by a similar argument. The other symmetric distributions are not admissible because they do not give the right rate of change of the number of quantum states as a function of n_L.

Corollary 1: For sufficiently small polyad numbers n_N, the quantum spectrum of the N-reduced normalized swing spring $(\hat{H}^{(6)}_{\rm nf},\hat{L})$ is qualitatively the same as the quantum spectrum of $(\hat{S},\hat{L})$ in Lemma 2. Hence, the quantum diagrams of such systems are qualitatively the same as those in Fig. 2.

Figure 3 and, respectively, Fig. 4 display the joint spectrum of the operators $\hat{L}$ and the Hamiltonian $\hat{H}^{(6)}_{\rm nf}$, respectively, $\hat{H}^{(3)}_{\rm nf}$, computed numerically for fixed polyad number n_N, and,

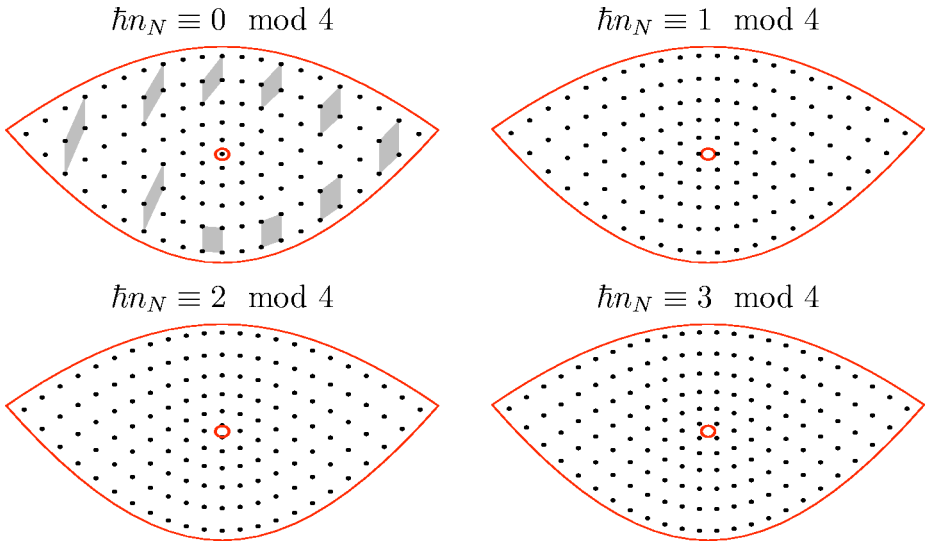

FIG. 3. Consecutive slices with fixed n_N polyad number for the normalized swing spring $(\hat{H}^{(6)}_{\rm nf},\hat{N},\hat{L})$. The polyad quantum number $n_N/\hbar$ is chosen to be about 1. Here $\hbar$ is $1/20$.

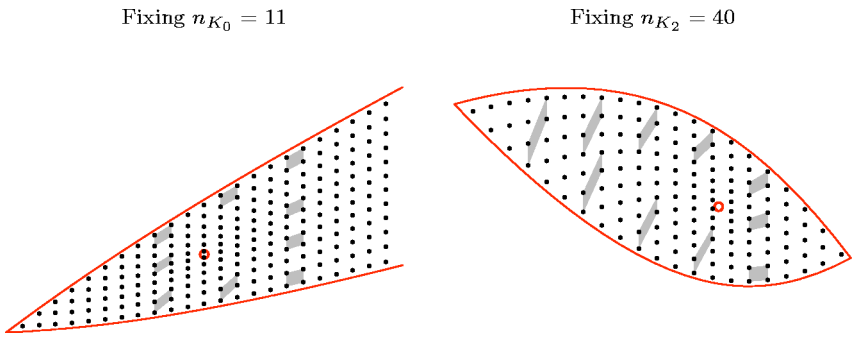

FIG. 4. Quantum diagrams obtained by fixing the quantum number n_{K_m} and plotting the quantum spectrum of the operators $\hat{L}$ and $\hat{H}^{(3)}_{\text{nf}}$.

respectively, n_{K_0} and n_{K_2}. Note that, to preserve the qualitative structure of the approximating normalized system, one must choose a polyad number of the order of unity. With such a low polyad number there are too few quantum states to perform the analysis we are presenting here. A standard technique to increase the number of points in the quantum lattice (that is, states of the quantum system) at a fixed energy level is to scale the variables by the number $\sqrt{\hbar}$, where $\hbar$ is the inverse of a natural number. This is equivalent to considering a Hilbert space of quantum states of the form $|n_1,n_2,n_3\rangle$ where n_i is a $\hbar$-multiple of a natural number.

In Sec. II D we gave a formula for the dependence on n_L of the number of quantum states having a fixed n_{K_m} quantum number. The results shown in Figs. 3 and 4 confirm the predictions made in Fig. 1 and used in Lemma 1.

B. Local mapping to the regular lattice

The effect of monodromy: Having described the plane slices and their relative position in 3-space, we can proceed with a tentative definition of the missing quantum number. Let us do this for the planar slices in Fig. 3. For every choice of quantum numbers n_N and n_L, that is, fixing the eigenspace associated to the quantum numbers n_N and n_L, one can assign a third quantum number by enumerating the quantum states of the operator $\hat{S}$ in the joint eigenspace (n_N,n_L), beginning with 0. Though this seems to be a global choice of third quantum number, we can easily show that it is not the case. As first suggested in Ref. 25, we can choose an elementary cell of the lattice and transport it around the classical singularity, see Fig. 3 (top left). After one tour around the singularity, we will come back with a different cell. This signifies that the third quantum number cannot be globally chosen.

Furthermore, when one fixes n_N and n_L and draws the curves having fixed the third quantum number proposed above, see Fig. 5, it is quite obvious that the curves above the classical singularity have a nonsmooth behavior, unlike those below. The closer $\hbar$ is to zero, the more obvious

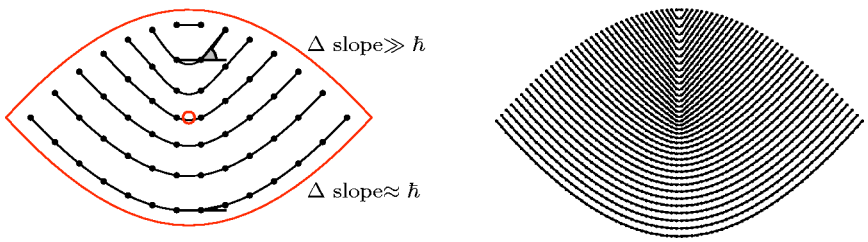

FIG. 5. Numbering the eigenstates with fixed n_L in the natural way within one n_N polyad of the system (S,L,N). The curves connecting the eigenstates with the same label are not $\hbar$-smooth at $n_L=0$ and $S>0$. The classical singularity at $L=S=0$ is shown by an empty circle.

the discontinuity (or "kink") in the tangent to the level curve becomes. Of course if one starts numbering from the top, one observes a nonsmooth behavior in the lines below the singularity. For this reason we introduce the following.

Definition 2: For a planar diagram, the choice of quantum numbers is *$\hbar$-smooth* if the discrete directional derivatives of the level curves obtained by fixing one quantum number are continuous of order $\hbar$. By *continuous of order $\hbar$* we mean that the difference of the discrete directional derivatives computed at two consecutive points must be of order of $\hbar$. An *$\hbar$-smooth chart* is a choice of $\hbar$-smooth quantum numbers. An *$\hbar$-smooth atlas* is a family of *$\hbar$-smooth* charts that cover $U_{\mathrm{reg}} \subset U \subset \mathbb{R}^3$, the set of regular values in the image of the energy-momentum map.

The above definitions are void for a choice of $\hbar$ of order 1. In fact, such a choice gives a quantum diagram with very few points, which makes every choice of quantum numbers $\hbar$-smooth. On the other hand, the nonexistence of global action variables implies that somewhere the level curves have a nonsmooth behavior of order one, which becomes visible when $\hbar$ is sufficiently small, see Fig. 5.

The problem in numbering the quantum states is a consequence of a well-known obstruction to existence of classical global action variables known as *monodromy*.[9] Monodromy is due to the nontriviality of the covering of U_{reg} defined by the period lattices. When the fundamental group of U_{reg} is $\mathbb{Z}$, the monodromy can be written as a matrix, which is called *monodromy matrix*. The inverse transpose of the monodromy matrix can be effectively computed by analyzing the quantum spectrum corresponding to the classical completely integrable system.[12,23] The way we propose to do this is to use $\hbar$-smooth charts as follows. Let us cover the quantum lattice in U_{reg} (see Fig. 5) with two overlapping $\hbar$-smooth charts: one obtained by numbering the points in the columns starting from the bottom and the other obtained by numbering the points in the columns starting from the top. Let us choose in the first chart an *elementary cell*, which is a quadrangle that does not contain any lattice point in its interior or on its sides, with a distinguished vertex and an ordering of the sides adjacent to that vertex. Let us finally move the elementary cell in the first chart of the atlas following the level lines of the $\hbar$-smooth variables. Choosing a path that winds around the singular point and transporting our elementary cell along this path, one is forced, once the first region of chart overlap is reached, to identify the elementary cell with its corresponding representation in the second chart. Then one continues with the transport in the second chart. Reaching the second region of chart overlap, the elementary cell is identified with its representation in the first chart and then is compared with the initial cell. This final cell is *different* from the original one.

Definition 3: Given a n-dimensional quantum diagram admitting an $\hbar$-smooth atlas, an initial elementary cell defines a frame. The matrix expressing the change of frame from the initial elementary cell and the final elementary cell is the *quantum monodromy matrix*. A quantum monodromy matrix always belongs to $\mathrm{SL}(n,\mathbb{Z})$.

In our example in Fig. 3, the sides of the final elementary cell, written with respect to the sides of the initial elementary cell as *columns*, define the quantum monodromy matrix $\left(\begin{smallmatrix}1 & 0\\ 2 & 1\end{smallmatrix}\right)$.

In the same way, we can also compute the quantum monodromy matrix for other slices of the 3D lattice. For the K_0 and K_2 slices in Fig. 4 we obtain the matrices $\left(\begin{smallmatrix}1 & 0\\ 1 & 1\end{smallmatrix}\right)$ and $\left(\begin{smallmatrix}1 & 0\\ 3 & 1\end{smallmatrix}\right)$, respectively. This shows that the 2D monodromy depends on the choice of the slices, and therefore we must study directly the 3D monodromy by transporting a 3D elementary cell.

In the problem under investigation, the mod 4 periodicity allows one to project four subsequent constant N slices of the lattice on the same plane, creating the regular grid in Fig. 6 (left). In this projected lattice we can draw elementary cells and move them around the singularity at the origin. Choosing the initial cell as in Fig. 6 (right) and moving it around the origin of the projected lattice, being careful to move every vertex of the cell by the same number of steps, we find that the full monodromy matrix for the 3D lattice with that choice of initial elementary cell is

$$\begin{pmatrix} 1 & 0 & 0 \\ 2 & 1 & -1 \\ 0 & 0 & 1 \end{pmatrix}.$$

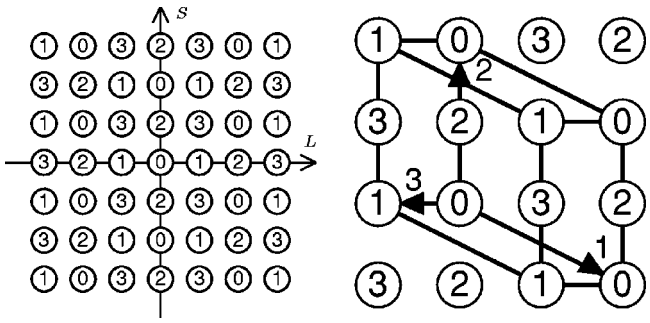

FIG. 6. Four n_N slices can be projected to the same plane, making it possible to draw and move an elementary cell. On the right, the choice of one such elementary cell. The numbers refer to the order of the sides.

IV. HOW TO OBTAIN THE 1:1:2 QUANTUM LATTICE FROM THE SIMPLE CUBIC LATTICE

A. 2D lemma and applications

Rather than using an $\hbar$-smooth atlas to compute the monodromy, one can introduce defects in regular lattices. The treatment we give here is inspired by Ref. 26.

Definition 4: Let (I_1,I_2) be coordinate functions on $\mathbb{R}^2$. Let k be an integer. Consider the set $\mathcal{C}(kI_1:I_2)=\{(I_1,I_2)\in\mathbb{R}^2|kI_1>2|I_2|\}$, which we call a *wedge*. The set of points $\mathcal{D}(kI_1:I_2)$ in the complement of the wedge $\mathcal{C}(kI_1:I_2)$, after identifying the points with integral coordinates among those of the form $(n,nk/2)=(n,-nk/2)$ where $n\in\mathbb{Z}_{\geqslant 0}$, is called a *defect diagram.*

The above prescription can be easily adapted to the wedge $\mathcal{C}(kI_2:I_1)=\{(I_1,I_2)\in\mathbb{R}^2|kI_2>2|I_1|\}$.

Given a defect diagram associated to a wedge, the lattice obtained by vertically sliding the columns of lattice points, thus physically performing the identification, is called *a reconstructed diagram*, which we denote by $\mathcal{R}(kI_1:I_2)$. The process of taking a given lattice, introducing a cut and inserting or removing a wedge, is called *deconstruction of a diagram*. The vertex of the wedge is called a *defect point*. The defect point can be in any point of the $\{I_1,I_2\}$ plane.

Computing monodromy using a deconstructed diagram is straightforward. If we pick a square elementary cell below a wedge (assuming that k is positive) and translate it above the wedge, we end up with a parallelogram whose two sides remain orthogonal to the symmetry axis of the wedge, whereas the two other sides, initially parallel to the symmetry axis, have now slope k. This proves the following.

Lemma 3: The reconstructed diagram $\mathcal{R}(kI_1:I_2)$ has nontrivial monodromy. Its quantum monodromy matrix computed along a path winding counterclockwise around the origin, with respect to the elementary cell with vertex in $(0,-n)$ and with an ordered pair of sides $s_1=[(0,-n),(1,-n)]$, $s_2=[(0,-n),(0,-n+1)]$ is $\left(\begin{smallmatrix}1&0\\k&1\end{smallmatrix}\right)$.

Remark 1: The monodromy matrix associated to a defect diagram depends solely on the type and position of the defect introduced and on the choice of the ordered sides of the elementary cell. It does not depend either on the path Γ one uses, or on the initial position of the vertex, nor on the point where Γ crosses the wedge. Also, the expression of the monodromy matrix M with respect to an arbitrary choice of elementary cell, whose defining frame $\{a_1,a_2\}$ gives the matrix $A\in\mathrm{GL}(2,\mathbb{Z})$ with columns a_1 and a_2, corresponds to the matrix $A^{-1}MA$.

It is straightforward to check that a clockwise rotation around the defect point changes the sign of k in the monodromy matrix while the monodromy matrix associated to the defect $\mathcal{R}(kI_2:I_1)$ is the matrix $\left(\begin{smallmatrix}1&-k\\0&1\end{smallmatrix}\right)$.

Lemma 4: Suppose that the path Γ crosses a finite number of removed wedges in the order $\mathcal{C}_1,\ldots,\mathcal{C}_n$. Then the monodromy matrix associated to this defect diagram computed along Γ is the matrix $M=M_{\mathcal{C}_n}\cdots M_{\mathcal{C}_1}$.

Proof: Choose the initial elementary cell. After crossing the first elementary wedge $\mathcal{C}_1$, we

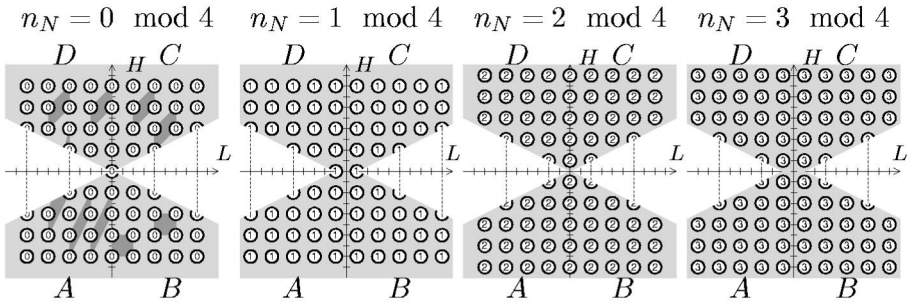

FIG. 7. Deconstruction of the diagrams obtained for constant n_N slices of the swing spring quantum diagram. Gluing the pictures along the dashed vertical lines one obtains the diagrams in Fig. 3.

obtain a cell which is formed by applying the matrix M_1 to the frame defining the initial elementary cell. By remark 1, crossing the second wedge $\mathcal{C}_2$ produces a cell whose sides are identified by the columns of the matrix M_2M_1. This argument is repeated until the last wedge has been passed and the lemma follows. □

It is now time to apply the ideas above to the planar quantum diagrams in Figs. 3 and 4. The quantum diagrams in Fig. 3 have a nontrivial singularity at $(n_L, n_H) = (0,0)$. Each of them can be deconstructed by introducing the two wedges $\mathcal{C}(L:H)$ and $\mathcal{C}(-L:H)$ as shown in Fig. 7. To keep the mod 4 period symmetries, one must choose a regular lattice with a step of 2 in the L direction and with order 2 period in the H direction. This is equivalent to placing the defect point not at the origin of a regular lattice. The monodromy matrix computed using Lemma 3 is precisely the one obtained using $\hbar$-smooth charts in Figs. 3 and 4.

The two planar quantum diagrams in Fig. 4 can be treated in a similar way and give the deconstructed diagrams in Fig. 8. From these diagrams we find that the quantum monodromy matrix for slices with constant quantum number n_{K_m} is $\left(\begin{smallmatrix} 1 & 0 \\ m+1 & 1 \end{smallmatrix}\right)$.

B. 3D lemma and applications

We now extend the idea of a defect diagram in order to deconstruct the 3D quantum diagram of the swing spring. It is natural to define a defect of a three-dimensional regular lattice by extending a defect of a two-dimensional lattice trivially in one direction.

Definition 5: Let (I_1, I_2, I_3) be coordinate functions on $\mathbb{R}^3$. A two-dimensional wedge $\mathcal{C}(kI_1:I_2)$ can be trivially extended along the direction I_3, meaning that all constant I_3 slices intersect this extension in the same wedge. Such a 3D wedge is *trivial in the* I_3 *direction* and is denoted by $\mathcal{C}(kI_1:I_2:I_3)$.

The boundary of the 3D wedge $\mathcal{C}(kI_1:I_2:I_3)$ consists of a roof made up of two half-planes joined along the I_3 axis, which is a "roof top." The roof top is a singularity of the 3D quantum diagram called *defect line*.

Lemma 5: The reconstructed diagram $\mathcal{R}(kI_1:I_2:I_3)$ has nontrivial monodromy. Its quantum monodromy matrix computed along a path winding counterclockwise in the $\{I_1, I_2\}$ plane around the positively oriented defect line, the I_3 axis, with respect to the elementary cell with vertex in

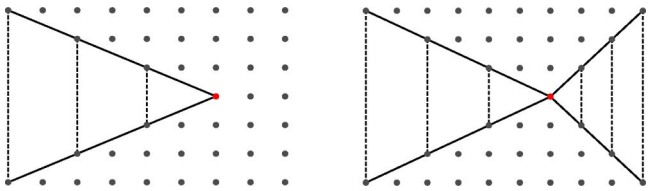

FIG. 8. Deconstructed n_{K_0} and n_{K_2} slices.

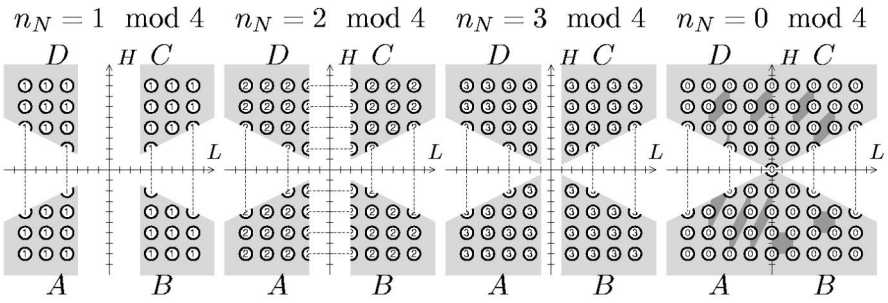

FIG. 9. Defect for constant n_N slices of the joint spectrum of the quantum swing spring. The slices with nonzero $n_N \bmod 4$ are obtained from the $n_N = 0 \bmod 4$ lattice by cutting out an additional region along the vertical axis. Dashed vertical lines show identification of points on the border of the cutout regions.

$(0,-n,0)$ and with sides $s_1=[(0,-n,0),(1,-n,0)]$, $s_2=[(0,-n,0),(0,-n+1,0)]$, $s_3=[(0,-n,0),(0,-n,1)]$ is the matrix

$$\begin{pmatrix} 1 & 0 & 0 \\ k & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}.$$

When a path crosses a family of 3D wedges, the monodromy matrix along the path is obtained as in Lemma 4.

Again, one must be careful when treating a defect with a different orientation. Let us choose, say $\mathcal{D}(kI_3{:}I_1{:}I_2)$. A path winding counterclockwise in the $\{I_3,I_1\}$ plane is a path which begins at the positive I_3 axis and moves towards the positive I_1 axis. The monodromy matrix for the elementary cell in lemma 5 along such path is the matrix

$$\begin{pmatrix} 1 & 0 & k \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}.$$

.

The diagrams in Fig. 7, which are obtained for fixed polyad number n_N, can be modified by introducing auxiliary spacings along the vertical axis S as shown in Fig. 9. Though inessential in the planar figures, this modification helps to deconstruct the 3D lattice of the quantum swing spring up to any fixed polyad number $N_{\max}$ into a regular cubic lattice with three 3D wedges removed, namely, $\mathcal{C}(L{:}H{:}N)$, $\mathcal{C}(-L{:}H{:}N)$, and $\mathcal{C}(-N{:}L{:}H)_{(0,0,N_{\max})}$, see Fig. 10. The roof tops of the first two 3D wedges lie on the N axis, which is the singular thread of the energy momentum

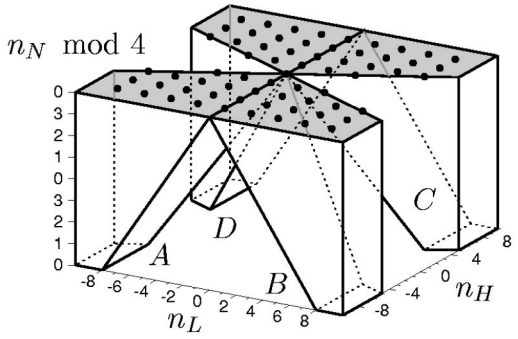

FIG. 10. Three-dimensional model of the deconstructed joint spectrum of the quantum swing spring.

map $\mathcal{EM}$ of the classical swing spring. The roof top of the last 3D wedge lies on the line $\{L=0, N=N_{\max}\}$. This last singular line should be pushed at infinity to obtain the quantum diagram of the swing spring.

The pictures in Fig. 7 account for the 2D wedges of the 3D wedge $\mathcal{C}(\pm L:H:N)$; the cut along the H axis shown in Fig. 9 corresponds to the 3D wedge $\mathcal{C}(-N:L:H)_{(0,0,N_{\max})}$. The deconstruction of the swing spring quantum lattice resembles a table with four legs, labeled by $A\subset\{n_H<0, n_L<0\}$, $B\subset\{n_H<0, n_L>0\}$, $C\subset\{n_H>0, n_L>0\}$, and $D\subset\{n_H>0, n_L<0\}$ as shown in Fig. 10.

V. CALCULATION OF MONODROMY USING SIMPLE CUBIC LATTICE WITH CUTS

In this section we use the deconstructed 3D quantum lattice of the swing spring in the preceding section to calculate the monodromy matrix associated to a path winding around the defect line situated on the vertical N axis.

Let us start the path in the component A of Fig. 10 and move counterclockwise around the defect line. Passing from A to B, we cross the elementary wedge $\mathcal{C}(-N:L:H)_{(0,0,N_{\max})}$. In passing from B to C we cross the elementary wedge $\mathcal{C}(L:H:N)$. In passing from C to D we cross again the elementary wedge $\mathcal{C}(-N:L:H)_{(0,0,N_{\max})}$. Returning to the component A we cross the elementary wedge $\mathcal{C}(-L:H:N)$. From Lemma 5 it follows that the quantum monodromy matrix of the quantum swing spring along the given path is

$$M=\begin{pmatrix}1&0&0\\1&1&0\\0&0&1\end{pmatrix}\begin{pmatrix}1&0&1\\0&1&0\\0&0&1\end{pmatrix}\begin{pmatrix}1&0&0\\1&1&0\\0&0&1\end{pmatrix}\begin{pmatrix}1&0&1\\0&1&0\\0&0&1\end{pmatrix}^{-1}=\begin{pmatrix}1&0&0\\2&1&-1\\0&0&1\end{pmatrix}.$$

The matrix M above is expressed with respect to a frame determined by the initial unitary cubic elementary cell. This implies that with a different choice of elementary cell one would obtain a new quantum monodromy matrix related to M by conjugation in $\mathrm{SL}(3,\mathbb{Z})$.

It is therefore natural to try to determine an initial elementary cell for which the monodromy matrix assumes its simplest form. In the discussion above we choose an initial cell, labeled α in Table I, and then we compute the monodromy associated to this cell. We now take five different cells in quadrant A of the lattice, namely, $\alpha,\beta,\gamma,\delta$, and κ, as shown in Table I. We denote by $\{a_1,a_2,a_3\}$ the frame associated to the cell α, the frames associated to the cells β,γ,δ, and κ, are $\{b_1,b_2,b_3\}$, $\{c_1,c_2,c_3\}$, $\{d_1,d_2,d_3\}$, and $\{k_1,k_2,k_3\}$, respectively. They are related to the frame defining α by the matrix given in the second column of Table I.

Once we have embedded each elementary cell in the component A of the deconstructed diagram of Fig. 10 or in the projected diagram of Fig. 9, we can move it around the vertical defect corresponding to the singular thread of the energy momentum map of the classical swing spring, and compute the quantum monodromy matrix. From Table I we see that the monodromy matrix of the quantum diagram of the swing spring system takes the simplest possible form of a unipotent matrix with only one nonzero off-diagonal entry equal to 1, when κ is chosen as initial elementary cell.

Observe that for 3D quantum diagrams the sign is not an invariant as it is for the 2D quantum diagrams, see Ref. 7. More specifically, the monodromy matrix of all 2D quantum diagrams, associated to a two degree of freedom completely integrable Hamiltonian system with a circle symmetry, have the form $\left(\begin{smallmatrix}1&0\\k&1\end{smallmatrix}\right)$ with $k>0$. Such matrices can be obtained by introducing the 2D defects we gave above. Another 2D defect obtained by *adding* a solid wedge instead of subtracting it produces a minus sign in the monodromy matrix $\left(\begin{smallmatrix}1&0\\-k&1\end{smallmatrix}\right)$. The two matrices are *not* conjugate in $\mathrm{SL}(2,\mathbb{Z})$. At the same time, when the dimension is bigger than 2 such sign can be changed by conjugation in $\mathrm{SL}(3,\mathbb{Z})$. So, while the construction of defects by removing and adding solid wedges still exists in 3D, the monodromy matrix cannot distinguish them.

TABLE I. Possible choices of elementary cells in the unit cell basis of the reconstructed $\mathcal{EM}$ lattice of quantum swing spring.

Cell	A	Shape	Shape[a]	$A^{-1}MA$
α	$\begin{pmatrix}1&0&0\\0&1&0\\0&0&1\end{pmatrix}$			$\begin{pmatrix}1&0&0\\2&1&-1\\0&0&1\end{pmatrix}=M$
β	$\begin{pmatrix}1&0&1\\0&1&1\\0&0&1\end{pmatrix}$			$\begin{pmatrix}1&0&0\\2&1&1\\0&0&1\end{pmatrix}$
γ	$\begin{pmatrix}1&1&0\\0&1&0\\0&0&1\end{pmatrix}$			$\begin{pmatrix}-1&-2&1\\2&3&-1\\0&0&1\end{pmatrix}$

VI. COMPARISON OF CLASSICAL AND QUANTUM CALCULATIONS OF MONODROMY

We now recall how the classical monodromy matrix of the swing spring was computed in Ref. 11. Define the momenta $N_1=(N+L)/2$ and $N_2=(N-L)/2$. Fixing the values of the momenta and of the energy, one specifies a 3-torus. It is possible to define a basis of the fundamental group of this torus by means of three paths generated as follows: $\gamma_{N_1}=\exp(tX_{N_1})$, $\gamma_{N_2}=\exp(tX_{N_2})$, and

$$\gamma_H=\exp\frac{t}{2\pi}(TX_H-\Theta_1X_{N_1}-\Theta_2X_{N_2}).$$

Here Θ_1 and Θ_2 are the rotation numbers of the flow of X_H on the given 3-torus and T is its fully reduced period, see Ref. 11. Considering the initial choice of three paths as a frame, and then moving the paths around the singular thread with a continuous homotopy (imposed by the functions T,Θ_1,Θ_2) one ends up with three final paths, or final frame. The matrix of change of frames is the classical monodromy matrix of the swing spring and is

$$\begin{pmatrix}1&0&0\\0&1&0\\1&-1&1\end{pmatrix}.$$

Observe that K_m (7) and L are not the momenta of an effective 2-torus action. In fact L is the momentum of the $-1:1:0$ oscillator; while K_m is the momentum of the $1:m:m+1$ oscillator. Thus the momentum K_m+L is that of the $0:m+1:m+1$ oscillator, whose flow is $2\pi/(m+1)$ periodic. Despite this noneffectiveness, one can show that the classical monodromy matrix with respect to the frame $\gamma_L=-\gamma_{N_1}+\gamma_{N_2}$, $\gamma_{K_m}=\gamma_{N_1}+m\gamma_{N_2}$, and γ_H is

$$\begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 1 \\ 0 & 0 & 1 \end{pmatrix}.$$

Reducing with respect to the circle action with momentum K_m one obtains a 2D system whose monodromy is represented by the matrix $\left(\begin{smallmatrix} 1 & 1 \\ 0 & 1 \end{smallmatrix}\right)$. At first sight this does not seem to be in agreement with the quantum results computed when n_{K_m} is held constant. However, one observes that the noneffectiveness of the T^2 action generated by the flows of X_{K_m} and X_L implies that a basis of cycles in the 2-tori of the K_m-reduced space are not the cycles $\tilde{\gamma}_L$ and $\tilde{\gamma}_H$, where the tildes represent the projection of γ_L and γ_N on the reduced space, but the cycles $\tilde{\gamma}_L/(m+1)$ and $\tilde{\gamma}_H$. With respect to these cycles the monodromy matrix is the matrix $\left(\begin{smallmatrix} 1 & m+1 \\ 0 & 1 \end{smallmatrix}\right)$, which confirms our quantum calculations.

Another interesting aspect of the 2D system, highlighted by reduction of the symmetry associated to the K_m momentum, is that the singular fiber of the energy momentum map of the reduced completely integrable system is always a singly pinched torus. This does not contradict the monodromy theorem in Refs. 6 and 27. In fact, the phase space of the 2D system obtained by K_m reduction is *not* smooth, being singular precisely at the pinch point of the singular fiber of its energy momentum mapping. Consequently, this pinch point is not a focus–focus critical point.

To find the relation between the quantum monodromy matrices and the classical monodromy matrix we follow Appendix A 2 in Ref. 12 and choose the elementary cell whose sides in the space with coordinates (N_1,N_2,H) are given by the vectors $e_1=(1,0,\Theta_1/T)$, $e_2=(0,1,\Theta_2/T)$, and $e_3=(0,1/T,0)$, where $\Theta=(\Theta_1+\Theta_2)/2$. Mapped onto (L,H,N)-space these vectors become $f_1=(1,\Theta_1/T,1)$, $f_2=(-1,\Theta_2/T,1)$, and $f_3=(0,1/T,0)$. Computing the values Θ_1 and Θ_2 after completing a circuit, one finds that the cell is precisely the one called γ in Table I (up to exchanging e_2 and e_3). The quantum matrix associated to this cell is

$$\begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 1 & -1 & 1 \end{pmatrix},$$

which is precisely the inverse transpose of the classical monodromy matrix.

VII. CONCLUSIONS

In this paper, we have analyzed the qualitative features of a model quantum system with 3 degrees of freedom whose classical limit corresponds to an integrable approximation of a swing spring in 1:1:2 resonance.

Quantum monodromy is manifested in the joint spectrum of three commuting observables. Locally, this joint quantum spectrum can almost everywhere be interpreted as a regular lattice of quantum states. This reflects the existence of local action variables in the corresponding classical system. Equivalently, the joint spectrum can be described globally as a regular lattice of quantum states with defects. Thus it is clear that quantum and classical monodromy are directly related. The atlas formed by different $\hbar$-smooth local charts covers almost all the quantum lattice with the exception of regions containing nonregular values of the classical energy momentum map. Quantum monodromy can be directly read from the joint spectrum by looking at the evolution of an elementary cell of the quantum lattice along a closed path lying in $\hbar$-smooth charts of an $\hbar$-smooth atlas of the lattice.

Globally the 3D quantum lattice is interpreted as a regular lattice with 1D defects. The construction of 1D defects for 3D lattices, which are characterized by the elementary monodromy matrix, follows the recipe formulated for 2D lattices with point defects which are obtained by cutting out a wedge from the regular lattice and gluing together the boundaries which have been created. For the 1:1:2 swing spring we have shown that the lattice of quantum states can be reconstructed from a regular cubic lattice by removing three solid wedges, two of which create a line defect in the physical region while the third creates a line defect, which lies in a nonphysical region at infinity. The representation of the 3D quantum lattice of the swing spring by a simple cubic lattice with wedges removed allows us to visualize clearly the transport of the elementary cell over the lattice. It also allows us to calculate the matrix of quantum monodromy for any choice of initial elementary cell in the lattice.

An important additional consequence of our analysis of the quantum swing spring is the clear demonstration that 1D defects in the 3D lattice (or equivalently 1D subspaces of critical values of the 3D classical energy-momentum map) should be characterized by the complete 3D quantum/classical monodromy matrix. The analysis of two-dimensional slices is *insufficient* to uncover the singularities of the full 3D quantum lattice. Therefore it is important to be able to understand the geometry of lattices of any dimension and be able to compute its quantum monodromy as a transformation of an elementary cell along a close path. Deconstruction/reconstruction of lattices seems to be an essential tool in the analysis of quantum lattices and in the computation of their quantum monodromy. It is an open question whether 3D quantum lattices exist whose monodromy cannot be reproduced via the introduction of elementary defects. In 2D we know how to decompose any quantum monodromy matrix into a product of elementary matrices. Therefore every defect of a 2D quantum lattice arises from a known set of elementary defects, see Ref. 8.

Monodromy of n-dimensional lattices is defined up to conjugation in $\mathrm{SL}(n,\mathbb{Z})$. In particular, it cannot distinguish between two different defects obtained by removing or adding the same angular part in a regular lattice. Whether the defect corresponding to adding a wedgelike region to a regular lattice can be realized by an integrable Hamiltonian system is an open question. The 1D lattice defects in 3D systems introduced here straightforwardly generalize to codimension 2 defects in integrable Hamiltonian systems with arbitrary number of degrees of freedom. Codimension 1 defects which correspond to fractional monodromy[22] can also be treated with the same approach. It is worth noting that the whole 3D quantum lattice of the quantum swing spring, has a defect of codimension 2 which corresponds to integer monodromy, even though the 1:1:2 system studied in this paper has a 1:2 resonant subsystem with a fractional defect.[1] In order to see codimension 1 defects and fractional monodromy for 3D quantum lattices, we need to study more complicated examples of integrable Hamiltonian systems with higher order resonances.

APPENDIX A: REDUCTION OF RESONANT OSCILLATOR SYSTEMS IN THREE DIMENSIONS WITH SO(2) SYMMETRY

Consider an $m':m':m''$ resonant 3-oscillator system with zero order Hamiltonian

$$H_0 = m'\tfrac{1}{2}(z_1\overline{z_1}) + m'\tfrac{1}{2}(z_2\overline{z_2}) + m''\tfrac{1}{2}(z_3\overline{z_3}) \tag{A1}$$

and whose higher order terms Poisson commute with H_0. Here the positive integer numbers m' and m'' are such that $\gcd(m',m'')=1$, and $(z,\overline{z})$ are complex symplectic coordinates of the form $(q\pm ip)$. The flow of H_0 generates an oscillator symmetry S^1 whose action on the six dynamical variables $(z_1,z_2,z_3,\overline{z_1},\overline{z_2},\overline{z_3})$ is given by the 6×6 diagonal matrix,

$$U_t = \mathrm{diag}(e^{im't}, e^{im't}, e^{im''t}, e^{-im't}, e^{-im't}, e^{-im''t}) = \mathrm{diag}(\theta^{m'}, \theta^{m'}, \theta^{m''}, \theta^{-m'}, \theta^{-m'}, \theta^{-m''}). \quad \text{(A2)}$$

Suppose that this system is invariant with respect to the additional Lie symmetry group SO(2) of rotations in the plane (z_1, z_2), whose action is represented by the matrix

$$U_s = \mathrm{diag}\left[\begin{pmatrix} \cos s & \sin s \\ -\sin s & \cos s \end{pmatrix}, 1, \begin{pmatrix} \cos s & \sin s \\ -\sin s & \cos s \end{pmatrix}, 1\right]. \quad \text{(A3)}$$

It can be seen that the two actions (A3) and (A2) commute, and that the full symmetry group of such system is therefore a torus $T^2 = S^1 \times \mathrm{SO}(2)$.

We study the case where $m' : m''$ is 1:2. The indices 1,2,3 of our coordinates here correspond to ξ, η, ζ in Sec. II A. In this appendix we give details of the reduction of the $S^1 \times \mathrm{SO}(2)$ symmetry of this system. It can be considered as a two-stage reduction. For example, first we reduce the 3-oscillator symmetry and then the SO(2) symmetry. We will do the two stages at once. Since the T^2 action is not free, we use *singular reduction*.[3]

We also consider certain discrete symmetries. It can be verified easily that the spatial symmetry of the spherical pendulum as well as that of the swing spring system[11] is not just the plain SO(2) but the group $\mathrm{SO}(2) \rtimes C_s$. Here $C_s = \{1, \sigma_v\}$ is the group of reflections in a plane containing the SO(2) symmetry axis. Explicitly

$$\sigma_v\colon (q_1, q_2, q_3, p_1, p_2, p_3) \mapsto (q_2, q_1, q_3, p_2, p_1, p_3), \quad \text{(A4a)}$$

where by convention we take q_3 as the symmetry axis.

The Schönflis notation for such group is $C_{\infty v}$. The total symmetry group of these systems is $\mathrm{SO}(2) \rtimes C_s \times \mathcal{T}$ and combines the above spatial group with the antisymplectic momentum reversal symmetry,

$$\mathcal{T}\colon (q, p, z) \to (q, -p, \overline{z}), \quad \text{(A4b)}$$

which is present in many other physical systems and is often called *time reversal*. So we will consider an additional discrete group of order four

$$\{1, \sigma_v, \mathcal{T}, \mathcal{T}_s = \mathcal{T} \circ \sigma_v\}$$

which is isomorphic as an abstract group to $\mathbb{Z}_2 \times \mathbb{Z}_2$.

1. Generating function and integrity basis

By Molien's theorem,[20] the generating function for the invariants of the $S^1 \times \mathrm{SO}(2)$ action is given by the double integral,

$$g(\lambda) = \frac{1}{2\pi}\int_0^{2\pi} \frac{1}{2\pi}\int_0^{2\pi} \frac{1}{\det(1 - \lambda U_t U_s)}\,dt\,ds. \quad \text{(A5)}$$

Here the formal variable λ represents any of the dynamical variables $(z, \overline{z})$ or, equivalently, (q, p). In the complex unimodular variables

$$\theta = \exp(it) \text{ and } \varphi = \exp(is)$$

the determinant in (A5) can be expressed as

$$\det(1 - \lambda U_t U_s) = (\lambda - \theta^2)\left(\lambda - \frac{1}{\theta^2}\right)(\lambda - \theta\varphi)\left(\lambda - \frac{1}{\varphi\theta}\right)\left(\lambda - \frac{\theta}{\varphi}\right)\left(\lambda - \frac{\varphi}{\theta}\right).$$

The generating function (A5) can now be computed as a double Cauchy integral,

$$g(\lambda) = \frac{1}{2\pi i}\oint_{|\theta|=1} \frac{1}{2\pi i}\oint_{|\varphi|=1} \frac{\lambda^2\theta^3\varphi \, d\theta d\varphi}{D(\theta,\varphi;\lambda)}, \tag{A6}$$

where

$$D(\theta,\varphi;\lambda) = (\lambda - \theta^2)\left(\theta^2 - \frac{1}{\lambda}\right)(\lambda - \theta\varphi)\left(\varphi\theta - \frac{1}{\lambda}\right)(\lambda\varphi - \theta)(\lambda\theta - \varphi).$$

Since the formal variable λ is used to Taylor expand $g(\lambda)$ at $\lambda = 0$, it can be arbitrarily small. This means that when we integrate (A6) on θ we should consider only four poles,

$$\theta = \pm\sqrt{\lambda}, \quad \theta = \frac{\lambda}{\varphi}, \quad \theta = \lambda\varphi,$$

which lie inside the unit circle $|\theta| = 1$. Applying the Cauchy integral formula for each pole and then integrating the result on φ in the similar way gives the Molien generating function,

$$g(\lambda) = \frac{1 + \lambda^3}{(1 - \lambda^2)^3(1 - \lambda^3)}. \tag{A7}$$

The function (A7) indicates not only the fact that the space of invariant polynomials is generated by *five* polynomials, three quadratic and two cubic, but also that this ring is not freely generated and that the integrity basis of this ring has four principal (denominator) invariants and one cubic auxiliary (numerator) invariant. From (A2) we see that all invariants of the 1:1:2 oscillator action are built from monomials $z_1\overline{z_1}$, $z_2\overline{z_2}$, $z_3\overline{z_3}$, $z_1\overline{z_2}$, $z_1^2\overline{z_3}$, $z_2^2\overline{z_3}$, $z_1z_2\overline{z_3}$ and their conjugates which should be further symmetrized with respect to the SO(2) action in (A3). The explicit choice of invariants is

$$N = \tfrac{1}{2}(z_1\overline{z_1} + z_2\overline{z_2} + 2z_3\overline{z_3}), \quad R = \tfrac{1}{2}(z_1\overline{z_1} + z_2\overline{z_2}), \quad L = \Im(\overline{z_1}z_2),$$

$$S = \tfrac{1}{2}\Re(z_3(\overline{z_1^2} + \overline{z_2^2})), \quad T = \tfrac{1}{2}\Im(z_3(\overline{z_1^2} + \overline{z_2^2})).$$

In the rotated coordinates q_1, q_2, q_3, p_1, p_2, p_3 of Sec. II A these invariants equal those in (3). Comparing with Ref. 11 we find that

$$N = \tfrac{1}{2}\rho_1 + \tfrac{1}{2}\rho_2 + \rho_3, \quad R = \tfrac{1}{2}\rho_1 + \tfrac{1}{2}\rho_2, \quad S = -\rho_4, \quad T = \rho_5.$$

Note that coordinates ξ, η, ζ in Ref. 11 correspond to our rotated coordinates q_1, q_2, q_3 in Sec. II A. Choosing T to be the auxiliary invariant, we can represent the structure of the ring as

$$\mathbb{R}[N,R,L,S] \bullet \{1,T\} = \mathbb{R}[N,R,L,S] \oplus \mathbb{R}[N,R,L,S]T, \tag{A8}$$

where the ring $\mathbb{R}[N,R,L,S]$ is freely generated by (N,R,L,S).

A different way to reflect the structure of the ring (A8) is by specifying the relations (*sygyzies*) between its generators. Rewriting the function (A7) in the Hilbert form,

$$g(\lambda) = \frac{1 - \lambda^6}{(1 - \lambda^2)^3(1 - \lambda^3)^2}, \tag{A7a}$$

we see that there is one such relation of degree 6. From our choice of invariants (3) we find

$$2\Phi_{n,l}^{1:1:2} = T^2 + S^2 - (R - L)(R + L)(N - R) = 0, \tag{A9a}$$

and we can also verify that

$$N \geqslant R \geqslant |L| \geqslant 0. \tag{A9b}$$

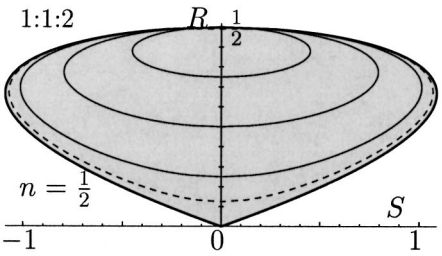

FIG. 11. Reduced phase space $P^{1:1:2}_{n,l}$ of the 1:1:2 resonant oscillator system with SO(2) symmetry. Shaded area bounded by a bold line shows the projection of the singular space $P^{1:1:2}_{n,0}$ on the plane $\{T=0\}$; other lines show boundaries of similar projections for $l=\frac{1}{8}n$ (dashed line), $\frac{1}{4}n$, $\frac{1}{2}n$, and $\frac{3}{4}n$; note that $l_{\max}=n$.

2. Reduced space and Hamiltonian

From the preceding section it is obvious that the T^2-reduced system (the doubly reduced system in Ref. 11) can be described in terms of invariants (R,S,T). The space $L^{-1}(l)\cap N^{-1}(n)$ is to be reduced by the T^2-action generated by the flows of X_L and X_N. Equation (A9a) defines the reduced phase space $P^{1:1:2}_{n,l}$, which is a surface of revolution about the R axis in the ambient 3-space with coordinate functions (R,S,T). The projection of $P^{1:1:2}_{n,l}$ on the $\{T=0\}$ plane is shown in Fig. 11.

When $n=l=0$ or when $|l|=n$ the space $P^{1:1:2}_{n,l}$ degenerates to a point; for all $n>|l|\neq 0$ it is diffeomorphic to a 2-sphere. When $l=0$ and $n>0$ the space $P^{1:1:2}_{n,0}$ is a sphere with one singular point at $R=S=T=0$ (a "turnip"). Since near this point $\rho^2=T^2+S^2\approx nR^2$, the singularity is conical (as in the case of the 1:2 resonance).[1]

The reconstruction of the T^2 orbit map $L^{-1}(l)\cap N^{-1}(n)\subset T\mathbb{R}^3\mapsto P^{1:1:2}_{n,l}$ can be described as follows. The two points $l=\pm n$ lift to two relative equilibria which correspond to pure (and fast) rotation about axis q_3 without swinging nor springing; of course the spring is stretched and the pendulum is somewhat bent. All points of $P^{1:1:2}_{n,l}$ with $0<|l|<n$ lift to the regular $\mathbb{T}^2$ orbits of the $S^1\times \mathrm{SO}(2)$ group with periods 2π in both directions. Same is true for all regular points of $P^{1:1:2}_{n,0}$, that is, all points with $R\neq 0$. The singular point of this space (with $S=R=0$) goes to a special periodic orbit in $L^{-1}(0)\cap N^{-1}(n)$ of period π. It corresponds to pure swinging along the q_3 axis.

The triple of Hamiltonian functions (R,S,T) generates the Poisson algebra of the (second) reduced system which defines the Poisson structure on $P^{1:1:2}_{n,l}$. Using the functions defined in (3), we compute this Poisson structure first in the original phase space TR^3 (note that $\{z,\overline{z}\}=2i$), take (A9a) into account and restrict to $P^{1:1:2}_{n,l}$. This gives the structure

$$\{R,S\}=2T,\ \ \{T,R\}=2S,\ \ \{S,T\}=3R^2-2nR-l^2. \tag{A10a}$$

The function (A9a) is the Casimir of this algebra and we can also see that

$$\{\psi_a,\psi_b\}=\sum_c \varepsilon_{abc}\frac{\partial \Phi^{1:1:2}_{n,l}}{\partial \psi_c},\ \ \text{where } \psi=(\psi_1,\psi_2,\psi_3)=(R,S,T). \tag{A10b}$$

Introducing a new set of functions

$$\mathfrak{N}=\tfrac{1}{4}(N-|L|),\ \ \mathfrak{N}_1=\tfrac{1}{2}R-\tfrac{1}{4}(N+|L|),\ \ \mathfrak{N}_2=S\chi^{-1},\quad \mathfrak{N}_3=T\chi^{-1}, \tag{A11a}$$

where

$$\chi=2\sqrt{R+|L|}\ \text{ and }\ \mathfrak{N}^2=\mathfrak{N}_1^2+\mathfrak{N}_2^2+\mathfrak{N}_3^2, \tag{A11b}$$

deforms the Poisson algebra (A10) into a standard so(3) algebra with generators $(\mathfrak{N}_1,\mathfrak{N}_2,\mathfrak{N}_3)$ and Casimir $\mathfrak{N}$. It follows that the singular map (A11) sends every reduced phase space $P^{1:1:2}_{n,l}$ to a smooth sphere S^2 of radius $\mathfrak{N}$ (which is maximal when $l=0$ and zero when $|l|=l_{\max}=n$). The conelike singularity of $P^{1:1:2}_{n,0}$ at $n>0$ is removed due to the singularity of this map at $R=L=0$.

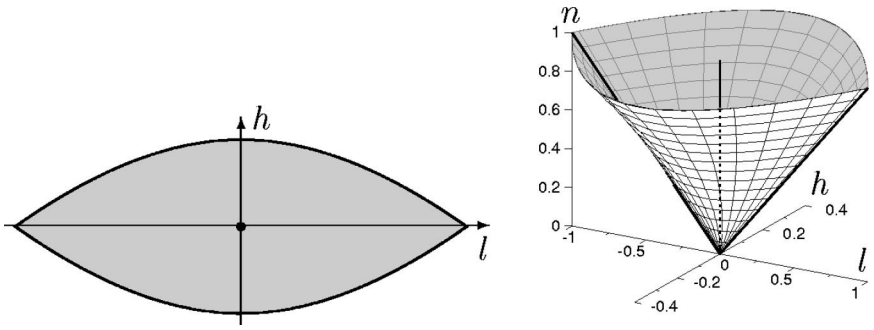

FIG. 12. Constant $n>0$ slice (left) of the image of the energy-momentum map (right) of the 1:1:2 resonant oscillator system with Hamiltonian $H_{n,l}=S$.

The doubly reduced system has one degree of freedom. Trajectories of this system can be found as intersections $\{H_{n,l}=h\}\cap P_{n,l}$ of the constant h-level sets of the reduced Hamiltonian $H_{n,l}$ and the phase space $P_{n,l}$. It is simpler to work on the space $V_{n,l}=P_{n,l}/(\mathbb{Z}_2\times\mathbb{Z}_2)$ obtained by reducing the discrete symmetries. This space is defined by

$$\tau+S^2=(R-l^2)(n-R),\ \text{where } n\geqslant R\geqslant |l|\geqslant 0 \text{ and } \tau=T^2\geqslant 0$$

with boundary $\partial V_{n,l}$ given by

$$S^2=(R^2-l^2)(n-R),\ \ n\geqslant R\geqslant |l|\geqslant 0$$

and study $\{H_{n,l}(R,S)=h\}\cap V_{n,l}$.

The lowest order approximation studied in Ref. 11 is sufficient for a qualitative description. As usual, we use the rescaled and shifted energy function $H_{n,l}(R,S)=S$.

Lemma A.1: The intersections $\{S=h\}\cap V_{n,l}$ are of three kinds:

(i) one regular point of $\partial V_{n,l}$;
(ii) a closed interval, whose endpoints are regular points of $\partial V_{n,l}$, that is, any point except point $(R,S)=0$ of $V_{n,0}$;
(iii) a closed interval whose one endpoint is a regular point of $\partial V_{n,0}$ and the other is the singular point $(R,S)=0$.

Every sufficiently small generic deformation of the Hamiltonian function S has three types of level sets on $V_{n,l}$.

Proof: The level sets of the Hamiltonian function S are straight vertical lines in the plane with coordinates (R,S). From (A9a) which defines $\partial V_{n,l}$ when $T=0$ we can see that these lines touch $\partial V_{n,l}$ at the points

$$R_c=\tfrac{1}{3}(n+\sqrt{n^2+3l^2}),\ \ S_c=\pm\sqrt{(n-R_c)(R_c^2-l^2)}, \tag{A12}$$

where S reaches its maximum and minimum value. □

3. Energy-momentum map

The image U of the energy-momentum map,

$$\mathcal{EM}\colon T\mathbb{R}^3\to U\subset\mathbb{R}^3\colon (q,p)\to (L(q,p),H(q,p),N(q,p)),$$

is a three-dimensional domain in $\mathbb{R}^3$ with coordinates (l,h,n). In the first approximation with $H=S$, Eqs. (A12) and inequalities $n\geqslant 0$, $|l|\leqslant n$ define the boundary ∂U. It can be seen that $U\cap\{n=0\}$ is the point (0,0,0), while for any $n>0$ the constant n slice of U has the same topology of a closed disc with two singular points on the boundary and one isolated singular point inside, see Fig. 12 (left).

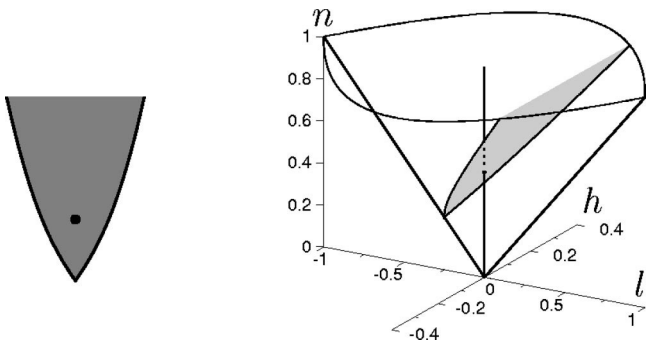

FIG. 13. Constant $n+l$ slice of the image of the energy-momentum map of the 1:1:2 resonant oscillator system with Hamiltonian $H_{n,l}=S$.

It can be seen that the whole domain U is a solid cone which has three curves of distinguished singular values: one is a thread inside U, the n axis, the other two are lines that lie on the boundary ∂U (the lines $l=\pm n$, $h=0$), see Fig. 12 (right).

Note that different slices of U can be considered, see for example, the slice with constant $n+l$ in Fig. 13. All such slices have a topology of half-plane with one isolated singular point inside and one singular point on the boundary.

The fibers of the energy momentum map reconstruct as follows. The regular values shown as shaded area in Fig. 12 lift to regular 3-tori. The points in the smooth part of the boundary with $S\neq 0$, $N>0$ lift to relative equilibria $\mathbb{T}^2$, while singular points of the boundary with $S=0$, $N>0$ lift to relative equilibria S^1. The points in the singular thread with $N>0$ and $S=L=0$ correspond to a special singular 3D fiber $\mathfrak{T}_n$ whose topology can be best represented using two partial reduction maps, one with respect to the SO(2) symmetry, the other with respect to the oscillator symmetry S^1. As illustrated in Fig. 14 the former gives a curled torus while the latter gives a pinched torus.

APPENDIX B: DETAILS OF THE QUANTUM DESCRIPTION

Our quantum-mechanical investigation deals with the quantum system associated to the classical system whose Hamiltonian is the swing spring Hamiltonian normalized to third or sixth order. We use the quantum expression of the Hamiltonian expanded up to sixth order when discussing the range of energy levels at which our analysis is reasonable for applications, and its truncation at third order for the description of the 3D quantum lattice. In this section we explicitly write the expression of the operators associated to the four invariants appearing in the expansion of the Hamiltonian in a basis in which the operators $\hat{N}$ and $\hat{L}$ are diagonal.

In quantum mechanics one associates to a classical (polynomial) Hamiltonian H its quantized operator $\hat{H}$. The rule to obtain $\hat{H}$ follows straightforwardly from the following ansatz (here stated for 1D systems): the domain of the operator is the Hilbert space with basis $|n\rangle$ ($n\in\mathbb{N}$); the

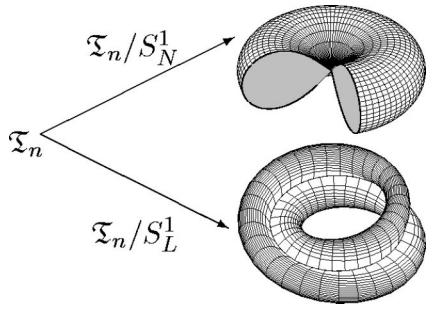

FIG. 14. Partial reduction of the singular 3D fiber.

operators $a=(1/\sqrt{2})(\hat{q}+i\hat{p})$ and $a^\dagger=(1/\sqrt{2})(\hat{q}-i\hat{p})$ act on the basis vectors as follows: $a|n\rangle = \sqrt{n}|n-1\rangle$ and $a^\dagger|n\rangle=\sqrt{n+1}|n+1\rangle$. In this treatment, we express every polynomial in p, q using the variables $(1/\sqrt{2})(q+ip)$ and $(1/\sqrt{2})(q-ip)$ and hence we define its associated quantum operator by replacing such variables with the operators a and $a^\dagger$, being careful to symmetrize the expressions (the variables of a polynomial commute, a and $a^\dagger$ do *not*).

In our 3D case, the basis elements of the Hilbert space are denoted by $|n_1,n_2,n_3\rangle$, while the basic operators are called a_1, $a_1^\dagger$, a_2, $a_2^\dagger$, a_3, $a_3^\dagger$. With these notations, the classical polynomial $\frac{1}{2}(q_1^2+p_1^2)$ becomes the quantum operator $\frac{1}{2}(a_1a_1^\dagger+a_1^\dagger a_1)$. This operator associates to the basis vector $|n_1,n_2,n_3\rangle$ the vector $(n_1+1/2)|n_1,n_2,n_3\rangle$.

It follows that the quantizations of the functions playing a role in the completely integrable system $(H_{\mathrm{nf}}^{(6)},L,N)$ are

$$\hat{N}=\tfrac{1}{2}(a_1a_1^\dagger+a_1^\dagger a_1+a_2a_2^\dagger+a_2^\dagger a_2+2a_3a_3^\dagger+2a_3^\dagger a_3),\ \ \hat{S}=\sqrt{2}i(a_1^\dagger a_2^\dagger a_3-a_1a_2a_3^\dagger),$$

$$\hat{R}=\tfrac{1}{2}(a_1a_1^\dagger+a_1^\dagger a_1+a_2a_2^\dagger+a_2^\dagger a_2),\ \ \hat{L}=\tfrac{1}{2}(-a_1a_1^\dagger-a_1^\dagger a_1+a_2a_2^\dagger+a_2^\dagger a_2).$$

The action of these operators on the generic vector $v=|n_1,n_2,n_3\rangle$ is

$$\hat{N}v=(n_1+n_2+2n_3+2)v,\ \ \hat{L}v=(n_1-n_2)v,\ \ \hat{R}v=(n_1+n_2+1)v,$$

$$\hat{S}v=i\sqrt{2(n_1+1)(n_2+1)n_3}v^+-i\sqrt{2n_1n_2(n_3+1)}v^-,$$

where $v^-=|n_1-1,n_2-1,n_3+1\rangle$ and $v^+=|n_1+1,n_2+1,n_3-1\rangle$.

To plot the two-dimensional quantum diagrams in Fig. 3, we fix an eigenspace for the operator $\hat{N}$, that is, we fix a *polyad number*, and then compute the joint spectrum of the operators $\hat{L}$ and $\hat{H}_{\mathrm{nf}}^{(6)}$ in that eigenspace. The eigenspace associated to the eigenvalue $m+2$ is generated by all the vectors $|n_1,n_2,n_3\rangle$ such that $n_1+n_2+2n_3=m$. Observe that there are essentially two cases, depending on the parity of m. If m is even, the $\hat{N}$-eigenspace associated to the eigenvalue $m+2$ decomposes in the direct sum of eigenspaces for $\hat{L}$, $V_h=\mathbb{R}\{v_{h,k}=\big|k,h+k,\frac{1}{2}(m-h-2k)\big\rangle\,|\,k=0,\ldots,\frac{1}{2}(m-h)\}$, where h, the $\hat{L}$-eigenvalue associated to V_h, runs over all even numbers from $-m$ to m. Here $\mathbb{R}\{v_{h,k}\}$ stands for real span of the vectors $v_{h,k}$. The dimension of V_h is $\frac{1}{2}(m-h)+1$. On each subspace V_h the operator $\hat{L}$ is the scalar multiplication by h while $\hat{S}$ acts as the tridiagonal matrix

$$\hat{S}v_{h,k}=i\sqrt{(k+1)(h+k+1)(m-h-2k)}v_{h,k+1}-i\sqrt{k(h+k)(m-h-2k+2)}v_{h,k-1}. \qquad \text{(B1)}$$

If m is odd, the $\hat{N}$ eigenspace associated to the eigenvalue $m+2$ decomposes into $\hat{L}$ eigenspaces $V_h=\mathbb{R}\{\big|k,h+k,\frac{1}{2}(m-h-2k)\big\rangle\,|\,k=0,\ldots,\frac{1}{2}(m-h)\}$ indexed by all odd numbers from $-m$ to m. The dimension of V_h is $\frac{1}{2}(m-h)+1$. The operator $\hat{H}$ acts on V_h according to (B1). These operators have been used to plot the quantum diagram of the swing spring.

To quantize the Hamiltonian $H_{\mathrm{nf}}^{(6)}$ (4) and model the swing spring system for higher energy levels one can push further the process described above. Since the operators $\hat{N}$ and $\hat{L}$ commute with all the other operators, there is no difficulty in defining the operators $\widehat{NR}$, $\widehat{L^2}$, $\widehat{R^2}$, $\widehat{NR^2}$, $\widehat{NS}$, and $\widehat{S^2}$. The only two noncommuting operators are $\hat{R}$ and $\hat{S}$, for this reason $\widehat{RS}$ acts on the vectors as $\frac{1}{2}(\hat{R}\hat{S}+\hat{S}\hat{R})$. The matrix of the quantum analog of the Hamiltonian $\hat{H}_{\mathrm{nf}}^{(6)}$ on the vector space V_h with respect to the basis $v_{h,k}$ is pentadiagonal and depend on the physical variable $\hbar$, but we will not write here its expressions.

Another quantum diagram, displayed in Fig. 4, can be obtained by slicing the 3D quantum diagram by means of different momenta coming from the T^2 symmetry. To work with momenta that define an effective torus action, the authors of Ref. 11 use the functions $N_1=\frac{1}{2}(N-L)$, $N_2=\frac{1}{2}(N+L)$. In q_i, p_i variables

$$N_1 = \tfrac{1}{2}(q_1^2 + p_1^2 + q_3^2 + p_3^2),\ \ N_2 = \tfrac{1}{2}(q_2^2 + p_2^2 + q_3^2 + p_3^2),\ \ H_{\mathrm{nf}}^{(3)} = \hbar(N_1 + N_2) - \tfrac{3}{16}\hbar^{3/2}S.$$

The quantization of the functions N_1 and N_2 is

$$\hat{N}_1 = \tfrac{1}{2}(a_1 a_1^\dagger + a_1^\dagger a_1 + a_3 a_3^\dagger + a_3^\dagger a_3),\ \ \hat{N}_2 = \tfrac{1}{2}(a_2 a_2^\dagger + a_2^\dagger a_2 + a_3 a_3^\dagger + a_3^\dagger a_3).$$

Again, one can restrict the analysis to the eigenspaces of the operator $\hat{N}_1$ corresponding to the eigenvalue $m+1$. In this case, the eigenspace of $\hat{N}_1$ is not finite dimensional, but it still can be decomposed into direct sum of subspaces,

$$W_h = \begin{cases} \mathbb{R}\{|m,h,0\rangle, |m-1,h-1,1\rangle, \ldots, |m-h,0,h\rangle\}, & \text{when } h < m, \\ \mathbb{R}\{|m,h,0\rangle, |m-1,h-1,1\rangle, \ldots, |0,h-m,m\rangle\}, & \text{when } h \geqslant m. \end{cases}$$

Note that $\dim W_h = \begin{cases} h+1, & \text{when } h<m \\ m+1, & \text{when } h \geqslant m \end{cases}$. On each space W_h, the operator $\hat{N}_2$ acts as the multiplication by $h+1$; whereas the operator $\hat{H}_{\mathrm{nf}}^{(3)}$ acts as the tridiagonal matrix

$$\begin{aligned} \hat{H}_{\mathrm{nf}}^{(3)} v_{h,k} = {} & \tfrac{3}{16}\hbar^{3/2} i \sqrt{2(m-k)(h-k)(k+1)}\, v_{h,k+1} + \hbar(m+h+2) v_{h,k} \\ & - \tfrac{3}{16}\hbar^{3/2} i \sqrt{2(m-k+1)(h-k+1)k}\, v_{h,k-1}. \end{aligned} \tag{B2}$$

Here $v_{h,k}$ is the vector $|m-k, h-k, k\rangle$. These operators are the ones used to numerically plot Fig. 4 (right). The technique to obtain the slices with fixed quantum numbers n_{K_m} is very similar to the ones described above.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 45, NUMBER 12 DECEMBER 2004

Erratum: Semiclassical asymptotics for the Maxwell–Dirac system [J. Math. Phys. 44, 4555 (2003)]

C. Sparber[a] and P. Markowich[b]
Wolfgang Pauli Institute Vienna and Department of Mathematics, University of Vienna, Nordbergstraße 15, A-1090 Vienna, Austria

(Received 6 August 2004; accepted 9 August 2004; published 2 December 2004)

[DOI: 10.1063/1.1807957]

Due to a computational mistake the polarization conditions (3.18), (3.19), for $u_{0,\pm}$ (or equivalently $u_{0,\pm 1}$) are incorrect. Indeed the correct relations are obtained by choosing $\phi=\phi_-$, i.e., ϕ satisfies

$$\partial_t \phi = \sqrt{|\nabla \phi|^2 + 1}.$$

Then Eq. (3.18) is correct (and formally the same but with this new choice of ϕ) whereas (3.19) has to be replaced by

$$(\Pi_+(-\nabla \phi)u_{0,-1})(t,x) = 0 \Leftrightarrow (\Pi_-(-\nabla \phi)u_{0,-1})(t,x) = u_{0,-1}(t,x).$$

This is then consistent with the corresponding negative phase factor $\exp(-i\phi/\varepsilon)$ used throughout the paper, i.e., instead of (3.20) we get

$$u_0(t,x,\phi(t,x)/\varepsilon) := u_{0,+1}e^{i\phi/\varepsilon} + u_{0,-1}e^{-i\phi/\varepsilon}, \quad u_{0,\pm 1} = \Pi_\pm(\pm \nabla \phi)u_{0,\pm 1}.$$

Also we get that $\omega_-(\nabla\phi)$ has to be replaced everywhere by $\omega_-(-\nabla\phi)$ [which indeed happens to be equal to $\omega_+(\nabla\phi)$]. The only point where this flaw causes problems is where we have used the orthogonality of $u_{0,-}$ and $u_{0,+}$, which clearly is no longer valid. This implies that on the r.h.s. of (4.1) we get two additional mixed terms of the form

$$\langle u_{0,\pm}(t,x), u_{0,\mp}(t,x)\rangle e^{\mp i2\phi(t,x)/\varepsilon}.$$

However, these terms can then be easily dealt with by using the same argument as given in Lemma 4.1 for the zitterbewegung Z_k. The electric-potential V^ε then also becomes an asymptotic expansion similar to the one given for the magnetic potential A^ε in (4.20) and (4.21). With these modifications all other results remain valid.

We also want to correct two cumbersome typos: In (4.12) the factor ± should be canceled whereas an additional factor $\frac{1}{4}$ has to be included [similarly on the r.h.s. of (4.18)]. Also the second expression in (2.18) is not as it should be, but rather has to be replaced by $\mathbb{I}_4 - \Pi_\pm(\xi) = \Pi_\mp(\xi)$.

Finally we want to add one sentence of explanation the reader might consider helpful. In Remark 3.3, after (3.17): This clearly implies that we have to assume either $u_{0,-}(0,x)$ or $u_{0,+}(0,x)$ to be identically zero, in order to proceed with an analogous *one-phase ansatz* (a fact which has already been noted earlier).
