where the two representations in the sum are disjoint and the sum is a direct sum of imprimitivity systems. Since $W\simeq\mathrm{ind}_N^G(\gamma_{0,-1})$, it is not restrictive to assume $\sigma=\sigma_1$, i.e., that μ_σ is concentrated in the orbit $\mathcal{O}_{\gamma_{0,-1}}=\mathbb{R}^n\times\{-1\}\cong\mathbb{R}^n$. Let T be the following unitary operator in $L^2(\mathbb{R}^n\times\mathbb{R}^n,dx\otimes d\mu_\sigma(x);\mathcal{H})$:

$$[Tf](x,h)=f(x+h,h).$$

If we define the representation $\hat{\rho}$, given by

$$[\hat{\rho}((p,t),q)f](x,h)=e^{-i(t-p\cdot x)}f(x-q,h),$$

then T intertwines $\hat{\rho}$ with ρ. Since $\hat{\rho}\simeq W\otimes I_{L^2(\mathbb{R}^n,\mu_\sigma;\mathcal{H})}$ and W is irreducible, every isometry intertwining W with $\hat{\rho}$ has the form

$$[\tilde{L}f](x,h)=f(x)\varphi(h) \quad \forall f\in L^2(\mathbb{R}^n)$$

for some $\varphi\in L^2(\mathbb{R}^n,\mu_\sigma;\mathcal{H})$ with $\|\varphi\|_{L^2}=1$. The most general isometry L intertwining W with ρ has then the form $L=T\tilde{L}$ for some choice of φ, and the corresponding observable is given by

$$\begin{aligned}\langle g\,|\,E(X)f\rangle &=\langle g\,|\,L^*P(X)Lf\rangle\\ &=\langle T\tilde{L}g\,|\,P(X)T\tilde{L}f\rangle\\ &=\int_{\mathbb{R}^{2n}}\chi_X(x)f(x+h)\overline{g(x+h)}\langle\varphi(h),\varphi(h)\rangle dx\,d\mu_\sigma(h).\end{aligned}$$

It follows that

$$[E(X)f](x)=f(x)\int_{\mathbb{R}^n}\chi_X(x-h)\|\varphi(h)\|^2 d\mu_\sigma(h)=f(x)\int_{\mathbb{R}^n}\chi_X(x-h)d\mu(h),$$

where $d\mu(h)=\|\varphi(h)\|^2 d\mu_\sigma(h)$ is a probability measure on $\mathbb{R}^n$.

APPENDIX B: SUPPLEMENT TO REMARK 2

Let $A'(a)=U(t)A(a)U(t)^*$. Then, $A'(a)\Pi_Q(X)A'(a)^*=\Pi_Q(aX)$. Denote with Π_Q^+ the restriction of Π_Q to the Borel subsets of $\mathbb{R}_+$. Then, $S_0=(A_0,\Pi_Q^+,L^2(0,+\infty))$ and $S=(A',\Pi_Q^+,L^2(0,+\infty))$ are transitive imprimitivity systems of the group $\mathbb{R}_+$ based on $\mathbb{R}_+$. Using the Mackey Imprimitivity Theorem, there exists a Hilbert space $\mathcal{K}$ such that $S=\mathrm{ind}_{\{1\}}^{\mathbb{R}_+}(I_\mathcal{K})$, where $I_\mathcal{K}$ is the trivial representation of $\{1\}$ acting in $\mathcal{K}$. Since $S_0=\mathrm{ind}_{\{1\}}^{\mathbb{R}_+}(1)$, we have the isomorphism of intertwining operators $\mathcal{C}(1,I_\mathcal{K})\simeq\mathcal{C}(S_0,S)$, and hence there exists an isometry $W_1:L^2(0,+\infty)\to L^2(0,+\infty)$ intertwining S_0 with S. In particular, $W_1\Pi_Q^+=\Pi_Q^+W_1$, and hence there exists a measurable function $\beta_1:\mathbb{R}_+\to\mathbb{T}$ such that

$$[W_1f](x)=\beta_1(x)f(x) \quad \forall f\in L^2(0,+\infty).$$

It follows that W_1 is unitary. Reasoning as above, one finds a unitary operator W_2 intertwining the restrictions of A_0 and A' to $L^2(-\infty,0)$, with

$$[W_2f](x)=\beta_2(x)f(x) \quad \forall f\in L^2(-\infty,0),$$

for some measurable function $\beta_2:\mathbb{R}_-\to\mathbb{T}$. Then, $\tilde{W}=W_1\oplus W_2$ is unitary on $L^2(-\infty,+\infty)$, and $A(a)=U(t)^*\tilde{W}A_0(a)\tilde{W}^*U(t)$ has the claimed form for all $a\in\mathbb{R}_+$.

(Received 1 March 2004; accepted 23 March 2004; published online 21 May 2004)

In the first part of this work we show that on the space of solutions of a certain class of systems of three second-order PDE's, $u_{\alpha\alpha}=\Upsilon(\alpha,\beta,u,u_\alpha,u_\beta)$, $u_{\beta\beta}=\Psi(\alpha,\beta,u,u_\alpha,u_\beta)$ and $u_{\alpha\beta}=\Omega(\alpha,\beta,u,u_\alpha,u_\beta)$, a three-dimensional definite or indefinite metric, g_{ab}, can be constructed such that the three-dimensional Hamilton–Jacobi equation, $g^{ab}u_{,a}u_{,b}=1$ holds. Furthermore, we remark that this structure is invariant under a subset of contact transformations. In the second part, we obtain analogous results for a certain class of third-order ordinary differential equation (ODE's), $u'''=\Lambda(s,u,u',u'')$. In both cases, we apply our general results to the cental force problem. © *2004 American Institute of Physics.*

I. INTRODUCTION

In the early years of the 20th century, while studying the structure and transformation properties of second- and third-order ODE's, Lie, Tresse, Wünschmann[1–4] among others, discovered that there was a rich differential geometry induced on the solution spaces of the differential equations by the equations themselves. This work was greatly developed and generalized by Cartan and Chern[5–9] in the 1930–1940s. Robert Bryant,[10] in more recent years, studied the geometry associated with fourth-order ODE's. Paul Tod[11] showed how third-order ODE's could generate three-dimensional Einstein–Weyl metrics.

With a totally different motivation and from a different point of view originating with General Relativity, Frittelli, Kozameh and Newman, in a series of papers[12–17] came to the same set of issues and problems. Rather than starting with given differential equations, the point of view of these authors began with three- and four-dimensional conformal Lorentzian manifolds, already containing a metric. They then studied families of complete solutions to the eikonal equation on these manifolds. From these solutions, by the elimination of the space–time coordinates, the differential equations of Cartan and Chern were reobtained. However, from this point of view, unwittingly, the Cartan–Chern work was generalized from ODE's to pairs of second-order PDE's whose solution spaces could be identified with any four-dimensional manifold with a conformal Lorentzian metric. In particular, they showed that the Einstein equations could be reformulated in terms of pairs of second-order PDE's.

Later, with Kamran and Nurowski,[18–22] this work was connected with the Cartan–Chern work for both the equivalence problem for differential equations under a variety of transformations and with the theory of Cartan normal conformal connections. With this consideration one saw how the differential equations (both the third-order equation and the pair of second-order equations) had to lie in a restricted class defined by the vanishing of the so-called Wünschmann (or generalized Wünschmann) equation.

An underlying unifying theme in many of the discussions was the existence of the eikonal equation and families of complete solutions. These solutions could be obtained either via the given

third-order ODE or pair of second-order PDE's or alternatively from the solutions to the eikonal equation on the given conformal background space.

In a recent work,[23] we turned to the geometry associated with a new class of second-order ODE's. The connecting link with the earlier work is that now we used the time-independent two-dimensional Hamilton–Jacobi equation rather than the eikonal equation to obtain this new class. We showed (via two different procedures) that, in the solution spaces of the ODE's, either a two-dimensional Riemannian or Lorentzian metric can be constructed in a natural way and that the metric structure associated with each differential equation is preserved when the equation is transformed by a subset of contact transformations (namely canonical transformations).

The aim of the present work is to generalize our previous result to the three-dimensional time-independent Hamilton–Jacobi equation. In Sec. II we begin with a three-dimensional manifold, $\mathcal{M}$, with no further structure and then investigate arbitrary two-parameter families of surfaces on $\mathcal{M}$ given by $u=constant=Z(x^a,\alpha,\beta)$. (The x^a are local coordinates on $\mathcal{M}$ and α and β parametrize the families and take values on $\mathcal{S}^2$, $\mathcal{S}^1\times\mathcal{R}$ or on $\mathcal{R}^2$.) More specifically, we then ask when do such families of surfaces define a three-dimensional metric, $g_{ab}(x^a)$, such that

$$g^{ab}\nabla_a Z(x^a,\alpha,\beta)\nabla_b Z(x^a,\alpha,\beta)=1. \tag{1}$$

We will show that the $u=Z(x^a,\alpha,\beta)$ must also satisfy a system of three second-order PDE's

$$\begin{aligned}\partial_{\alpha\alpha}Z&=\Upsilon(u,v,w,\alpha,\beta),\\ \partial_{\beta\beta}Z&=\Psi(u,v,w,\alpha,\beta),\\ \partial_{\alpha\beta}Z&=\Omega(u,v,w,\alpha,\beta),\end{aligned} \tag{2}$$

with

$$v\equiv\partial_\alpha Z,\quad \text{and}\quad w\equiv\partial_\beta Z,$$

and where Υ, Ψ, and Ω are restricted to satisfy certain "Wünschmann-type" conditions.

Here ∂ denotes partial derivative. Observe that in the solutions $u=Z(x^a,\alpha,\beta)$, the x^a are three constants of integration for Eqs. (2) while the "α" and "β" are two integration constants for Eq. (1).

Before proceeding we make the following important remark:

Remark 1: The time-independent Hamilton–Jacobi equation for a particle, with mass m and energy E, in a three-dimensional Riemannian space under the influence of a potential and the eikonal equation describing the evolution of the light rays in a three-dimensional isotropic optical medium characterized by its index of refraction, i.e., either of

$$\begin{aligned}g^{*ab}\nabla_a S(x^a,\alpha,\beta)\nabla_b S(x^a,\alpha,\beta)&=E-V(x^a),\\ g^{*ab}\nabla_a S(x^a,\alpha,\beta)\nabla_b S(x^a,\alpha,\beta)&=n(x^a),\end{aligned}$$

can be rewritten in the form of Eq. (1) by dividing the equations by either $E-V(x^a)$ or by $n(x^a)$ and simultaneously rescaling the metric by the same factors.

This action has the effect of changing certain properties of solutions to the Hamilton–Jacobi (H-J) equation. Normally for the three-dimensional H-J equation a complete integral contains three constants of integration, where one of them is E. In our case, after the conformal rescaling, E is hidden as a *fixed* constant in the metric g^{ab} and the solution will depend now on only two parameters, α and β. With an abuse of language, we will refer to $u=Z(x^a,\alpha,\beta)$ as a "restricted complete" integral to the H-J equation. In Sec. II we also show that any two arbitrary restricted complete integrals of the same H-J equation are connected via a special contact transformation. This result allows one to establish that if two systems of three second-order PDE's are connected

via that special contact transformation then in their spaces of solutions the same three-dimensional metric can be constructed. Finally, our result is applied to the central force problem in spherical polar coordinates.

In Sec. III we present analogous results for a certain class of third-order ODE's. That is, we begin with a three-dimensional manifold, $\mathcal{M}$, with no further structure and then investigate arbitrary one-parameter families of surfaces on $\mathcal{M}$ given by $u=constant=Z(x^a,s)$. (The x^a are local coordinates on $\mathcal{M}$ and s parametrizes the families and takes values on $\mathcal{S}^1$ or on $\mathcal{R}^1$.) More specifically, we ask when do such families of surfaces define a three-dimensional metric, $g_{ab}(x^a)$, such that

$$g^{ab}\nabla_a Z(x^a,s)\nabla_b Z(x^a,s)=1. \tag{3}$$

We will show that the $u=Z(x^a,s)$ must also satisfy a third-order ODE,

$$u'''=\Lambda(s,u,u',u''), \tag{4}$$

where Λ is restricted to satisfy a certain ''Wünschmann-type'' condition.

Here the prime denotes ''s'' derivatives. Observe that in the solutions $u=Z(x^a,s)$, which we will refer to as a one-parameter family of solutions to the Hamilton–Jacobi equation, the x^a, are three constant of integration for Eq. (4) while the ''s'' is an integration constant for Eq. (3). In this section it is also remarked that the three-metric is invariant when the third-order ODE is transformed by a subclass of contact transformations. Finally, these results are also applied to the central force problem in spherical polar coordinates.

II. THE SYSTEM OF PDE's CASE

In this section we prove that in the space of solutions of a certain class of systems of three second-order PDE's, a three-dimensional definite or indefinite metric, g_{ab}, can be constructed such that the solutions satisfy the three-dimensional H-J equation. We start with a three-dimensional manifold $\mathcal{M}$ [with local coordinates $x^a=(x^0,x^1,x^2)$] and assume we are given a two-parameter set of functions $u=Z(x^a,\alpha,\beta)$, the parameters α and β can take values on $\mathcal{S}^2$, $\mathcal{S}^1\times\mathcal{R}$ or on $\mathcal{R}^2$. We also assume that for fixed values of the parameters α and β the level surfaces

$$u=constant=Z(x^a,\alpha,\beta), \tag{5}$$

locally foliate the manifold $\mathcal{M}$ and that $u=Z(x^a,\alpha,\beta)$ satisfies the H-J equation

$$g^{ab}(x^a)\nabla_a Z(x^a,\alpha,\beta)\nabla_b Z(x^a,\alpha,\beta)=1 \tag{6}$$

for some unknown metric $g_{ab}(x^a)$.

Remark 2: If g^{ab} contains the E simply as a number or fixed parameter it will appear in the solution to the H-J equation. i.e., $u=Z(x^a,E,\alpha,\beta)$.

The basic idea now is to solve Eq. (6) for the components of the metric in terms of $\nabla_a Z(x^a,\alpha,\beta)$. To do so, we will consider a number of parameter derivatives of the condition (6), and then by manipulation of these derivatives, obtain both the three-dimensional metric and the three partial differential equations defining the surfaces plus the conditions they must satisfy. We will refer to them as the Wünschmann-type conditions.

Remark 3: The notation is as follows: there will be two types of differentiation, one is with respect to the local coordinates, x^a, of the manifold $\mathcal{M}$, denoted by ∇_a or ''comma a,'' the other is with respect to the parameters α and β, denoted by ∂_α and ∂_β.

From the assumed existence of $u=Z(x^a,\alpha,\beta)$, we define three parametrized scalars θ^i in the following way:

$$\theta^0 = u \equiv Z(x^a, \alpha, \beta),$$

$$\theta^1 = v \equiv \partial_\alpha Z(x^a, \alpha, \beta), \tag{7}$$

$$\theta^2 = w \equiv \partial_\beta Z(x^a, \alpha, \beta).$$

Remark 4: For each value of α and β Eqs. (7) can be thought of as a coordinate transformation between the x^a's and (u, v, w).

We also define the following three important scalars

$$\Upsilon^* = \partial_{\alpha\alpha} Z(x^a, \alpha, \beta),$$

$$\Psi^* = \partial_{\beta\beta} Z(x^a, \alpha, \beta), \tag{8}$$

$$\Omega^* = \partial_{\alpha\beta} Z(x^a, \alpha, \beta).$$

In what follows we will assume that Eqs. (7) can be solved for the x^a's; that is,

$$x^a = X^a(u, v, w, \alpha, \beta),$$

so that Eqs. (8) can be rewritten as

$$\partial_{\alpha\alpha} Z = \Upsilon(u, v, w, \alpha, \beta),$$

$$\partial_{\beta\beta} Z = \Psi(u, v, w, \alpha, \beta), \tag{9}$$

$$\partial_{\alpha\beta} Z = \Omega(u, v, w, \alpha, \beta).$$

This means that the two-parameter family of level surfaces, Eq. (5), can be obtained as solutions to the system of three second-order PDE's (9). Note that (Υ, Ψ, Ω) satisfy the integrability conditions, $\Upsilon_{,\beta} = \Omega_{,\alpha}$ and $\Omega_{,\beta} = \Psi_{,\alpha}$.

The solution space of Eqs. (9) is three-dimensional. This can be seen in the following way. The system of PDE's (9) is equivalent to the vanishing of the three one-forms, ω^i,

$$\omega^0 = du - v\, d\alpha - w\, d\beta,$$

$$\omega^1 = dv - \Upsilon\, d\alpha - \Omega\, d\beta, \tag{10}$$

$$\omega^2 = dw - \Omega\, d\alpha - \Psi\, d\beta.$$

A simple calculation, using the integrability conditions on (Υ, Ψ, Ω), leads to $d\omega^i = 0$ (*modulo* ω^i) from which, via the Frobenius Theorem, the solution space of Eqs. (9) is three-dimensional.

From the three scalars, θ^i, we have their associated gradient basis $\theta^i{}_{,a}$ given by

$$\theta^i{}_{,a} = \nabla_a \theta^i = \{Z_{,a}, \partial_\alpha Z_{,a}, \partial_\beta Z_{,a}\}, \tag{11}$$

and its dual vector basis $\theta_i{}^a$, so that

$$\theta_i{}^a \theta^j{}_{,a} = \delta_i{}^j, \quad \theta_i{}^a \theta^i{}_{,b} = \delta_b{}^a. \tag{12}$$

Definition 1: The total α and β derivatives of a function $F = F(u, v, w, \alpha, \beta)$ are defined by

$$D_\alpha F \equiv F_\alpha + F_u v + F_v \Upsilon + F_w \Omega,$$

$$D_\beta F \equiv F_\beta + F_u w + F_v \Omega + F_w \Psi, \tag{13}$$

respectively.

It is easier to search for the components of the three-dimensional metric in the gradient basis rather than in the original coordinate basis. Furthermore, it is preferable to use the contravariant components rather than the covariant components of the metric; that is, we want to determine

$$g^{ij}(x^a,s)=g^{ab}(x^a)\,\theta^i{}_{,a}\,\theta^j{}_{,b}\,. \tag{14}$$

The metric components and the Wünschmann-type conditions, for this case, are obtained by repeatedly operating with ∂_α and ∂_β on Eq. (6), that is, by definition, on

$$g^{00}=g^{ab}Z_{,a}Z_{,b}=1. \tag{15}$$

Applying ∂_α to Eq. (15) yields $\partial_\alpha g^{00}=2g^{ab}\partial_\alpha Z,_a Z,_b=0$, i.e.,

$$g^{10}=0. \tag{16}$$

In the same way we obtain that $\partial_\beta g^{00}=2g^{ab}\partial_\beta Z,_a Z,_b=0$ and thus,

$$g^{20}=0. \tag{17}$$

A direct computation shows that

$$\partial_{\alpha\alpha}(g^{00}/2)=g^{ab}\partial_{\alpha\alpha}Z,_a Z,_b+g^{ab}\partial_\alpha Z,_a\partial_\alpha Z,_b=g^{ab}\Upsilon,_a Z,_b+g^{11}=0. \tag{18}$$

Since, by the assumed linear independence of $(Z,_a,\partial_\alpha Z,_a,\partial_\beta Z,_a)$,

$$\Upsilon,_a=\Upsilon_u Z,_a+\Upsilon_v\partial_\alpha Z,_a+\Upsilon_w\partial_\beta Z,_a\,, \tag{19}$$

Eq. (18), using Eqs. (16), (17), and (19), is equivalent to

$$g^{11}=-\Upsilon_u\,. \tag{20}$$

In exactly the same way we find that

$$\begin{aligned}\partial_{\alpha\beta}(g^{00}/2)&=\Omega_u+g^{21}=0,\\ \partial_{\beta\beta}(g^{00}/2)&=\Psi_u+g^{22}=0.\end{aligned} \tag{21}$$

Therefore, the final result is

$$(g^{ij})=\begin{pmatrix}1 & 0 & 0\\ 0 & -\Upsilon_u & -\Omega_u\\ 0 & -\Omega_u & -\Psi_u\end{pmatrix}. \tag{22}$$

Remark 5: We require that $\det(g^{ij})=\Delta$ *be different from zero, with*

$$\Delta\equiv(\Upsilon_u\Psi_u-\Omega_u^2). \tag{23}$$

The metricity or Wünschmann-type conditions are obtained from the conditions $\partial_{\alpha\alpha\alpha}g^{00}=0$, $\partial_{\beta\alpha\alpha}g^{00}=0$, $\partial_{\beta\beta\alpha}g^{00}=0$, and $\partial_{\beta\beta\beta}g^{00}=0$. A direct computation shows that they are equivalent to

$$\begin{aligned}\Upsilon_{u\alpha}+\Upsilon_{uu}v+\Upsilon_{uv}\Upsilon+\Upsilon_{uw}\Omega&=2(\Upsilon_v\Upsilon_u+\Upsilon_w\Omega_u),\\ \Upsilon_{u\beta}+\Upsilon_{uu}w+\Upsilon_{uv}\Omega+\Upsilon_{uw}\Psi&=2(\Omega_v\Upsilon_u+\Omega_w\Omega_u),\\ \Omega_{u\beta}+\Omega_{uu}w+\Omega_{uv}\Omega+\Omega_{uw}\Psi&=\Omega_v\Omega_u+\Omega_w\Psi_u+\Psi_v\Upsilon_u+\Psi_w\Omega_u\,,\end{aligned} \tag{24}$$

$$\Psi_{u\beta}+\Psi_{uu}w+\Psi_{uv}\Omega+\Psi_{uw}\Psi=2(\Psi_v\Omega_u+\Psi_w\Psi_u).$$

Summarizing: (a) If we start from a restricted complete integral, $u=Z(x^a,\alpha,\beta)$ to the H-J equation, (6), then it satisfies the system of three second-order PDE's (9), with Υ, Ψ and Ω satisfying the Wünschmann-type conditions (24); in other words, in the solution space of Eqs. (9) there is the naturally defined metric,

$$ds^2=\left[u_{,a}u_{,b}-\frac{1}{\Delta}(\Psi_u v_{,a}v_{,b}-\Omega_u(v_{,a}w_{,b}+w_{,a}v_{,b})+\Upsilon_u w_{,a}w_{,b})\right]dx^a dx^b, \tag{25}$$

where Δ is defined by Eq. (23). (b) If we start with a system of three second-order PDE's (9), where Υ, Ψ, and Ω satisfy Eqs. (24) and the integrability conditions, then in its solution space there exist a natural three-dimensional metric given by Eq. (25). Though it might appear as if the metric components depend on the parameters (α,β), the Wünschmann-type conditions guarantees that they do not. Furthermore, the solutions $u=Z(x^a,\alpha,\beta)$ satisfy the H-J equation

$$g^{ab}\nabla_a Z(x^a,\alpha,\beta)\nabla_b Z(x^a,\alpha,\beta)=1$$

with the just determined metric, Eq. (25).

Remark 6: From the results presented above we conclude that solving the three-dimensional H-J equation is equivalent to solving a system of three second-order PDE's.

In some of the earlier work on the eikonal equation in three and four dimensional Lorentzian spaces, it was proved that the conformal Lorentzian metrics associated with third-order ODE's and pairs of second order PDE's satisfying the Wünschmann condition and generalized Wünschmann condition, is preserved when the differential equation is transformed by a contact transformation. For our present case, there is an analogous result given by the following:

Theorem 1: *Let Eqs. (9) be a system of three second-order PDE's, with* Υ, Ψ, *and* Ω *satisfying the conditions* (24) *and let*

$$\begin{aligned}
\partial_{\overline{\alpha}\overline{\alpha}}\overline{Z}&=\overline{\Upsilon}(\overline{u},\overline{v},\overline{w},\overline{\alpha},\overline{\beta}),\\
\partial_{\overline{\beta}\overline{\beta}}\overline{Z}&=\overline{\Psi}(\overline{u},\overline{v},\overline{w},\overline{\alpha},\overline{\beta}),\\
\partial_{\overline{\alpha}\overline{\beta}}\overline{Z}&=\overline{\Omega}(\overline{u},\overline{v},\overline{w},\overline{\alpha},\overline{\beta}),
\end{aligned} \tag{26}$$

be a system of three second-order PDE's locally equivalent to Eqs. (9) under the subset of contact transformations generated by the generating function

$$H(\alpha,\beta,u,\overline{\alpha},\overline{\beta},\overline{u})=\overline{u}-u-G(\alpha,\beta,\overline{\alpha},\overline{\beta}). \tag{27}$$

Then under this subset of contact transformations the metric given by Eq. (25) is preserved.

The proof of this theorem is exactly as that presented in Ref. 18 for a system of two second-order PDE's such that in its space of solutions is living a four-dimensional conformal Lorentzian metric, g^{ab}, such that $g^{ab}u_{,a}u_{,b}=0$ holds. Here we only justify the form of the generating function (27). We first review the definition of a general contact transformation.

Theorem 2: *Every contact transformation which is not a prolonged point transformation is determined in terms of a generating function* $H(\alpha,\beta,u,\overline{\alpha},\overline{\beta},\overline{u})$ *by solving the following five implicit equations for* $\overline{\alpha}$, $\overline{\beta}$, $\overline{u}$, $\overline{v}=\partial_{\overline{\alpha}}\overline{u}$, $\overline{w}=\partial_{\overline{\beta}}\overline{u}$:

$$\begin{aligned}
&H(\alpha,\beta,u,\overline{\alpha},\overline{\beta},\overline{u})=0,\\
&H_\alpha+vH_u=0,\quad H_{\overline{\alpha}}+\overline{v}H_{\overline{u}}=0,\\
&H_\beta+wH_u=0,\quad H_{\overline{\beta}}+\overline{w}H_{\overline{u}}=0.
\end{aligned} \tag{28}$$

The generating function $H(\alpha,\beta,u,\overline{\alpha},\overline{\beta},\overline{u})$ *is an arbitrary smooth function, subject only to the solubility of Eqs. (28) for* $\overline{\alpha}$, $\overline{\beta}$, $\overline{u}$, $\overline{v}$, $\overline{w}$.

For a proof of this theorem see, for example, Olver.[24]

Without loss of generality one can take

$$H=\overline{u}-\overline{V}(u,\alpha,\beta,\overline{\alpha},\overline{\beta}), \tag{29}$$

so that the contact transformation has the form

$$\begin{aligned}
\overline{u}&=\overline{V}(u,\alpha,\beta,A(\alpha,\beta,u,v,w),B(\alpha,\beta,u,v,w)),\\
\overline{\alpha}&=A(\alpha,\beta,u,v,w),\\
\overline{\beta}&=B(\alpha,\beta,u,v,w),\\
\overline{v}&=\overline{V}_{\overline{\alpha}}(u,\alpha,\beta,A(\alpha,\beta,u,v,w),B(\alpha,\beta,u,v,w)),\\
\overline{w}&=\overline{V}_{\overline{\beta}}(u,\alpha,\beta,A(\alpha,\beta,u,v,w),B(\alpha,\beta,u,v,w)),
\end{aligned} \tag{30}$$

where $A(\alpha,\beta,u,v,w)$ and $B(\alpha,\beta,u,v,w)$ are obtained by solving

$$\begin{aligned}
\overline{V}_{\alpha}+v\overline{V}_{u}&=0,\\
\overline{V}_{\beta}+w\overline{V}_{u}&=0,
\end{aligned} \tag{31}$$

for $\overline{\alpha}$ and $\overline{\beta}$ in terms of α, β u, v, and w.

As was pointed out earlier, for each value of α and β, the three-parameter family of solutions

$$u=Z(x^a,\alpha,\beta), \tag{32}$$

of (9) is also a two-parameter family of solutions of Eq. (6), i.e., are ''restricted complete'' integrals of Eq. (6). We now invoke the envelope construction to take one restricted complete integral of Eq. (6) into another such solution. Consider the function $\overline{u}=\overline{Z}(x^a,\overline{\alpha},\overline{\beta})$ defined by

$$\overline{u}=\overline{V}(u,\alpha,\beta,\overline{\alpha},\overline{\beta}), \tag{33}$$

where u is defined by Eq. (32) and α and β are defined implicitly as functions of x^a, $\overline{\alpha}$ and $\overline{\beta}$ by the envelope condition[18,25]

$$\begin{aligned}
\overline{V}_{u}v+\overline{V}_{\alpha}&=0,\\
\overline{V}_{u}w+\overline{V}_{\beta}&=0.
\end{aligned} \tag{34}$$

Note that although Eqs. (34) have the same form as Eqs. (31), they involve the variables x^a, α, and β. Using both Eqs. (33) and (34), we have that

$$\overline{u}_{,a}=\overline{V}_{u}u_{,a}\,. \tag{35}$$

By direct substitution of $\overline{u}_{,a}$ into the H-J equation, Eq. (6), we see that it is a new restricted complete integral if and only if $\overline{V}_{u}^{2}=1$. That is, $\overline{u}=\overline{V}(u,\alpha,\beta,\overline{\alpha},\overline{\beta})$ has the form $\overline{u}=\pm u+G(\alpha,\beta,\overline{\alpha},\overline{\beta})$. For simplicity, taking the positive sign, we have that if $u(x^a,\alpha,\beta)$ is a restricted complete integral of Eq. (6) then

$$\overline{u}=u+G(\alpha,\beta,\overline{\alpha},\overline{\beta}), \tag{36}$$

where α and β are defined implicitly as a function of x^a, $\overline{\alpha}$, and $\overline{\beta}$ by the envelope conditions

$$v+G_\alpha=0,$$

$$w+G_\beta=0, \tag{37}$$

is a new restricted complete integral of Eq. (6). Equations (36) and (37) define a particular subset of the contact transformations given by contact transformations

$$\overline{u}=u+G(\alpha,\beta,\overline{\alpha},\overline{\beta}), \tag{38}$$

$$v=-G_\alpha, \tag{39}$$

$$w=-G_\beta, \tag{40}$$

$$\overline{v}=G_{\overline{\alpha}}, \tag{41}$$

$$\overline{w}=G_{\overline{\beta}}. \tag{42}$$

The generating function for this set of contact transformations is given by

$$H(\alpha,\beta,u,\overline{\alpha},\overline{\beta},\overline{u})=\overline{u}-u-G(\alpha,\beta,\overline{\alpha},\overline{\beta})=0, \tag{43}$$

thus justifying our choice of the generating function, Eq. (27).

As an example we apply our results to the central force problem in spherical polar coordinates, $x^a=(r,\theta,\phi)$. For this problem the time-independent Hamilton–Jacobi equation is given by

$$\left(\frac{1}{2m(E-V)}\right)\left(u_{,r}^2+\frac{u_{,\theta}^2}{r^2}+\frac{u_{,\phi}^2}{r^2\sin^2\theta}\right)=1, \tag{44}$$

where m is the mass, $V(r)$ the potential energy, and E is the total energy of the particle, respectively. By the method of separation of variables one finds that a complete solution to Eq. (44) can be written in the following form

$$u=Z(x^a,E,\alpha,\beta)=\int\sqrt{2m(E-V)-\frac{\beta^2}{r^2}}\,dr+\int\sqrt{\beta^2-\frac{\alpha^2}{\sin^2\theta}}\,d\theta+\alpha\phi, \tag{45}$$

where α and β are two constants of separation. For this problem, α, is the magnitude of the total angular momentum and β is the value of the angular momentum about the polar axis. In this case, our restricted complete integral is obtained from Eq. (45) by fixing E. Now we obtain the system of three second-order PDE's associated with this restricted complete integral. A direct computation shows that

$$v=\partial_\alpha Z=\int\frac{-\alpha\,d\theta}{\sin^2\theta\sqrt{\beta^2-\dfrac{\alpha^2}{\sin^2\theta}}}+\phi,$$

$$w=\partial_\beta Z=\int\frac{-\beta dr}{r^2\sqrt{2m(E-V)-\dfrac{\beta^2}{r^2}}}+\int\frac{\beta\,d\theta}{\sqrt{\beta^2-\dfrac{\alpha^2}{\sin^2\theta}}}. \tag{46}$$

By using Eqs. (45) and (46), one sees that the Jacobian of the coordinate transformation, $\theta^i = \theta^i(x^a, \alpha, \beta)$, for this case, is given by

$$J = \frac{\partial(u,v,w)}{\partial(r,\theta,\phi)} = \frac{-2m(E-V)\beta}{\sqrt{\beta^2 - \dfrac{\alpha^2}{\sin^2\theta}}\sqrt{2m(E-V) - \dfrac{\beta^2}{r^2}}}. \tag{47}$$

Therefore, β cannot be zero.

Using Eqs. (46), we see that for the central force problem in spherical polar coordinates

$$\begin{aligned} \partial_{\alpha\alpha} Z &= -\beta^2 \mathcal{F}(\theta,\alpha,\beta), \\ \partial_{\beta\beta} Z &= -\mathcal{G}(r,\beta) - \alpha^2 \mathcal{F}(\theta,\alpha,\beta), \\ \partial_{\alpha\beta} Z &= \alpha\beta \mathcal{F}(\theta,\alpha,\beta), \end{aligned} \tag{48}$$

where

$$\begin{aligned} \mathcal{F}(\theta,\alpha,\beta) &= \int \frac{d\theta}{\sin^2\theta\left(\beta^2 - \dfrac{\alpha^2}{\sin^2\theta}\right)^{3/2}}, \\ \mathcal{G}(r,\beta) &= \int \frac{2m(E-V)dr}{r^2\left(2m(E-V) - \dfrac{\beta^2}{r^2}\right)^{3/2}}. \end{aligned} \tag{49}$$

On the other hand, Eqs. (45) and (46) imply that

$$\begin{aligned} r &= R(u,v,w,\alpha,\beta), \\ \theta &= \Theta(u,v,w,\alpha,\beta). \end{aligned} \tag{50}$$

Therefore, the system of three second-order PDE's for the central force problem in spherical polar coordinates is given by

$$\begin{aligned} \partial_{\alpha\alpha} Z = \Upsilon &= -\beta^2 \mathcal{F}(\Theta(u,v,w,\alpha,\beta),\alpha,\beta), \\ \partial_{\beta\beta} Z = \Psi &= -\mathcal{G}(R(u,v,w,\alpha,\beta),\beta) - \alpha^2 \mathcal{F}(\Theta(u,v,w,\alpha,\beta),\alpha,\beta), \\ \partial_{\alpha\beta} Z = \Omega &= \alpha\beta \mathcal{F}(\Theta(u,v,w,\alpha,\beta),\alpha,\beta). \end{aligned} \tag{51}$$

Since $u(x^a,\alpha,\beta)$ given by Eq. (45) with E fixed is a restricted complete integral to the H-J equation (44), then Υ, Ψ, and Ω given in Eqs. (51) satisfy Eqs. (24) and, therefore, a three-dimensional metric can be defined in the space of solutions of Eqs. (51). By comparison of Eqs. (6) and (44) it is clear what that metric should be. However, here we show the steps to explicitly obtain this metric by the procedure developed in earlier. What is remarkable is that this metric can be obtained without the evaluation of the integrals that arose in this problem. As we can see from Eq. (25), to obtain the three-dimensional metric, g_{ab}, associated with this problem, we need to compute: $\theta^i{}_{,a} = (u_{,a}, v_{,a}, w_{,a})$, Υ_u, Ψ_u, Ω_u, and Δ. By using Eqs. (45) and (46), we have that

$$u_{,a}=\left(\sqrt{2m(E-V)-\frac{\beta^2}{r^2}},\quad \sqrt{\beta^2-\frac{\alpha^2}{\sin^2\theta}},\alpha\right),$$

$$v_{,a}=\left(0,\frac{-\alpha}{\sin^2\theta\sqrt{\beta^2-\frac{\alpha^2}{\sin^2\theta}}},\quad 1\right), \tag{52}$$

$$w_{,a}=\left(\frac{-\beta}{r^2\sqrt{2m(E-V)-\frac{\beta^2}{r^2}}},\quad \frac{\beta}{\sqrt{\beta^2-\frac{\alpha^2}{\sin^2\theta}}},\quad 0\right).$$

From Eq. (47) we have that these three vectors are linearly independent when β is different from zero.

Since, for example,

$$\Psi_u=(\partial\Psi/\partial r)(\partial r/\partial u)+(\partial\Psi)/\partial\theta)(\partial\theta/\partial u),$$

then to compute Υ_u, Ψ_u, Ω_u, and Δ we need to obtain $(\partial\theta/\partial u)$ and $(\partial r/\partial u)$. From Eqs. (45) and (46), via implicit derivations, we obtain that

$$\frac{\partial r}{\partial u}=\frac{\sqrt{2m(E-V)-\frac{\beta^2}{r^2}}}{2m(E-V)},$$

$$\frac{\partial\theta}{\partial u}=\frac{\sqrt{\beta^2-\frac{\alpha^2}{\sin^2\theta}}}{2mr^2(E-V)}. \tag{53}$$

By using the definition of Δ given by Eqs. (23), (51), and (53), a direct computation shows that

$$\frac{\Upsilon_u}{\Delta}=-2mr^2(E-V)+\beta^2,$$

$$\frac{\Psi_u}{\Delta}=-2mr^2(E-V)\sin^2\theta+\alpha^2, \tag{54}$$

$$\frac{\Omega_u}{\Delta}=\frac{\alpha[2mr^2(E-V)-\beta^2]}{\beta}.$$

Finally, substituting Eqs. (52) and (54) into Eq. (25) we obtain the three-dimensional metric living in the solution space of the PDE's (51);

$$ds^2=g_{ab}dx^a dx^b=2m(E-V)(dr^2+r^2d\theta^2+r^2\sin^2\theta d\phi^2), \tag{55}$$

the desired result.

In the special case of the Kepler problem with energy equal to zero, i.e., for $V=-k/r$ and $E=0$, we have for the three PDE's.

$$\partial_{\alpha\alpha}Z=\frac{\beta\cot(\partial_\beta Z+\arccos\epsilon)}{\alpha^2-\beta^2},$$

$$\partial_{\beta\beta}Z=\frac{\alpha^2\cot(\partial_\beta Z+\arccos\epsilon)}{\beta(\alpha^2-\beta^2)}+\frac{4}{Z-\alpha\partial_\alpha Z-\beta\partial_\beta Z}, \tag{56}$$

$$\partial_{\alpha\beta}Z=\frac{\alpha\cot(\partial_\beta Z+\arccos\epsilon)}{\beta^2-\alpha^2},$$

where

$$\epsilon=\left(\frac{4\beta^2-(Z-\alpha\partial_\alpha Z-\beta\partial_\beta Z)^2}{4\beta^2+(Z-\alpha\partial_\alpha Z-\beta\partial_\beta Z)^2}\right). \tag{57}$$

III. THE THIRD-ORDER ODE's CASE

In this section we prove that in the solution space of a certain class of third-order ODE's a three-dimensional definite or indefinite metric, g_{ab}, can be constructed directly from the solutions such that the three-dimensional time-independent H-J equation holds. We begin with a three-dimensional manifold $\mathcal{M}$ (with local coordinates $x^a=(x^0,x^1,x^2)$) and assume we are given a one-parameter set of functions $u=Z(x^a,s)$; the parameter s can take values on $\mathcal{S}^1$ or on $\mathcal{R}$. We also assume that for a fixed value of the parameter s, the level surfaces

$$u=constant=Z(x^a,s), \tag{58}$$

locally foliate the manifold $\mathcal{M}$ and that $u=Z(x^a,s)$ satisfies the H-J equation

$$g^{ab}\nabla_a Z(x^a,s)\nabla_b Z(x^a,s)=1, \tag{59}$$

for some unknown metric $g_{ab}(x^a)$. That is, $u=Z(x^a,s)$, is a one-parameter family of solutions to the three-dimensional time-independent H-J equation.

The basic idea now is to solve Eq. (59) for the components of the metric in terms of $\nabla_a Z(x^a,s)$. To do so, we will consider a number of parameter derivatives of the condition (59), and then by manipulation of these derivatives, obtain both the three-dimensional metric and the ODE defining the surfaces and the Wünschmann-type condition it must satisfy.

Remark 7: The notation is as follows: as in the previous section, there will be two types of differentiation, one is with respect to the local coordinates, x^a, of the manifold $\mathcal{M}$, denoted by ∇_a or "comma a," the other is with respect to the parameter s, denoted by a prime or by ∂_s.

We first note that the one-parameter family of "level" surfaces, Eq. (58), can be obtained as solutions to the third-order ODE

$$u'''=\Lambda(u,u',u'',s) \tag{60}$$

by first calculating

$$u'''(x^a,s)\equiv\Lambda^*(x^a,s) \tag{61}$$

and then by inverting the relations

$$u=Z(x^a,s),$$

$$u'=Z'(x^a,s),$$

$$u''=Z''(x^a,s),$$

obtaining

$$x^a = X^a(u,u',u'',s). \tag{62}$$

The three x^a can be eliminated in Λ^* yielding Eq. (60).

Remark 8: Eq. (62) can be thought of as an "s" dependent coordinate transformation between x^a and (u,u',u'').

We define three parametrized scalars:

$$\theta^i = \{\theta^0,\theta^1,\theta^2\} \equiv \{u,u',u''\} = \{Z(x^a,s),Z'(x^a,s),Z''(x^a,s)\}, \tag{63}$$

which for each value of s form a coordinate system intrinsically adapted to the surfaces.

From the three scalars, θ^i, we have their associated gradient basis $\theta^i{}_{,a}$ given by

$$\theta^i{}_{,a} = \nabla_a \theta^i = \{Z_{,a},\partial Z_{,a},\partial^2 Z_{,a}\}, \tag{64}$$

and its dual vector basis $\theta_i{}^a$, so that

$$\theta_i{}^a \theta^j{}_{,a} = \delta_i^j, \quad \theta_i{}^a \theta^i{}_{,b} = \delta_b{}^a. \tag{65}$$

Definition 2: The total s derivative of a function $F = F(s,u,u',u'')$ *is defined by*

$$DF \equiv F_s + F_u u' + F_{u'} u'' + F_{u''} \Lambda. \tag{66}$$

As in the previous section, it is easier to search for the components of the three-dimensional metric in the gradient basis rather than in the original coordinate basis. Furthermore, it is preferable to use the contravariant components rather than the covariant components of the metric; that is, we are interested in

$$g^{ij}(x^a,s) = g^{ab}(x^a)\,\theta^i{}_{,a}\,\theta^j{}_{,b}\,. \tag{67}$$

The metric components and the Wünschmann-type condition, for this case, are obtained by repeatedly operating with ∂_s on Eq. (59), that is, on

$$g^{00} = g^{ab} Z_{,a} Z_{,b} = 1. \tag{68}$$

Applying ∂_s on Eq. (68) yields

$$\partial_s(g^{ab} Z_{,a} Z_{,b}) = 2 g^{ab} Z'_{,a} Z_{,b} = 2 g^{10} = 0, \tag{69}$$

where we have used that $\partial_s g^{ab} = 0$. Applying ∂_s on Eq. (69) we obtain

$$\partial_s^2(g^{00}/2) = g^{ab} Z''_{,a} Z_{,b} + g^{ab} Z'_{,a} Z'_{,b} = 0, \tag{70}$$

which is equivalent to $g^{11} = -g^{20}$. In the same manner we find that

$$\partial_s^3(g^{00}/2) = g^{ab} Z'''_{,a} Z_{,b} + 2 g^{ab} Z''_{,a} Z'_{,b} + g^{ab} Z'_{,a} Z''_{,b} = g^{ab} \Lambda_{,a} Z_{,b} + 3 g^{ab} Z''_{,a} Z'_{,b} = 0. \tag{71}$$

Since

$$\Lambda_{,a} = \Lambda_u Z_{,a} + \Lambda_{u'} Z'_{,a} + \Lambda_{u''} Z''_{,a}\,, \tag{72}$$

then Eq. (71) is equivalent to

$$g^{21} = -\tfrac{1}{3}[\Lambda_u + \Lambda_{u''} g^{20}]. \tag{73}$$

In the same way we find that

$$\partial_s^4(g^{00}/2)=D\Lambda_u-\tfrac{1}{3}\Lambda_u\Lambda_{u''}+[D\Lambda_{u''}-\tfrac{1}{3}(\Lambda_{u''})^2-3\Lambda_{u'}]g^{20}+3g^{22}=0, \tag{74}$$

$$\partial_s^5(g^{00}/2)=-W^{(1)}[\Lambda]-g^{20}W^{(2)}[\Lambda]=0, \tag{75}$$

where

$$W^{(1)}[\Lambda]\equiv-D^2\Lambda_u-\tfrac{1}{3}\Lambda_uD\Lambda_{u''}+\tfrac{7}{3}\Lambda_{u''}D\Lambda_u+4\Lambda_u\Lambda_{u'}-\tfrac{4}{9}\Lambda_u(\Lambda_{u''})^2, \tag{76}$$

$$W^{(2)}[\Lambda]\equiv-\tfrac{4}{9}(\Lambda_{u''})^3+2\Lambda_{u''}D\Lambda_{u''}-2\Lambda_{u'}\Lambda_{u''}-D^2\Lambda_{u''}+3D\Lambda_{u'}-6\Lambda_u. \tag{77}$$

Remark 9: Observe that $W^{(2)}[\Lambda]$ is the standard Wünschmann invariant for third-order ODE's, which is an invariant under a general contact transformation.

From Eq. (75) one sees that there are, at this point, four different possible cases to look at:

(a) $W^{(1)}[\Lambda]\neq0$, $W^{(2)}[\Lambda]\neq0$; in this case the three-dimensional metric can be completely reconstructed;
(b) $W^{(1)}[\Lambda]=0$, $W^{(2)}[\Lambda]\neq0$; in this case we obtain a degenerate metric, which must be excluded by the assumption of the H-J equation. See Remark 10 below, for the proof;
(c) $W^{(1)}[\Lambda]=0$, $W^{(2)}[\Lambda]=0$; in this case the metric is not completely determined. See the conjecture below;
(d) The case of $W^{(2)}[\Lambda]=0$ with nothing said about $W^{(1)}[\Lambda]$ arises not with the H-J equation but with the time dependent three-dimensional eikonal equation. It leads to a conformal metric on the solution space.[12–17] As this case has been extensively studied, nothing further will be said here about it.

We thus consider only the first case which leads to the final result

$$g^{ij}(x^a,s)=h^{ij}(x^a,s)+g_c^{ij}(x^a,s), \tag{78}$$

where

$$(h^{ij})=\begin{pmatrix}1&0&0\\0&0&-\tfrac{1}{3}\Lambda_u\\0&-\tfrac{1}{3}\Lambda_u&-\tfrac{1}{3}D\Lambda_u+\tfrac{1}{9}\Lambda_u\Lambda_{u''}\end{pmatrix}, \tag{79}$$

$$(g_c^{ij})=g^{20}\begin{pmatrix}0&0&1\\0&-1&-\tfrac{1}{3}\Lambda_{u''}\\1&-\tfrac{1}{3}\Lambda_{u''}&-\tfrac{1}{3}D\Lambda_{u''}+\tfrac{1}{9}\Lambda_{u''}^2+\Lambda_{u'}\end{pmatrix}, \tag{80}$$

with

$$g^{20}=-\left(\frac{W^{(1)}[\Lambda]}{W^{(2)}[\Lambda]}\right). \tag{81}$$

The Wünschmann-type condition, which is obtained from $\partial_s^6(g^{00}/2)=0$, is

$$D\left(\frac{W^{(1)}[\Lambda]}{W^{(2)}[\Lambda]}\right)=\left(\frac{2}{3}\right)\left(\frac{\Lambda_{u''}W^{(1)}[\Lambda]}{W^{(2)}[\Lambda]}-\Lambda_u\right). \tag{82}$$

Remark 10: When $W^{(1)}[\Lambda]=0$, using Eqs. (81) and (82), one sees from

$$\det(g^{ij}) = -\frac{\Lambda_u^2}{9} + \frac{g^{20}}{3}[D\Lambda_u - \Lambda_u\Lambda_{u''}] + \frac{(g^{20})^2}{3}\left[D\Lambda_{u''} - \frac{2}{3}(\Lambda_{u''})^2 - 3\Lambda_{u'}\right] + (g^{20})^3 \quad (83)$$

that $\det(g^{ij})=0$. *This implies a degenerate metric thus excluding this case*.

Summarizing, we conclude the following: If Λ is such that $W^{(1)}[\Lambda]\neq 0$, $W^{(2)}[\Lambda]\neq 0$ and satisfies the Wünschmann-type condition (82), then in the solution space of the ODE, $u''' = \Lambda(u,u',u'',s)$, there is defined either a three-dimensional Riemannian or Lorentzian metric given by

$$ds^2 = g_{ab}dx^a dx^b = g_{ij}\theta^i{}_{,a}\theta^j{}_{,b}dx^a dx^b, \quad (84)$$

with (g^{ij}) given by Eqs. (78)–(81). Furthermore the solution satisfies the H-J equation with this metric. One can think of the ODE and the H-J equation as dual to each other; each being satisfied by the same function but with respect to different variables.

In earlier work on the eikonal equation in three-dimensional Lorentzian spaces, it was proved that the conformal Lorentzian metric associated with a third-order ODE satisfying the Wünschmann condition, is preserved when the differential equation is transformed by a contact transformation. For our present case, there is an analogous result given by the following:

Theorem 3: *Let Eq. (60) be a third-order ODE, with* Λ *satisfying the condition* (82) *with* $W^{(1)}[\Lambda]\neq 0$, $W^{(2)}[\Lambda]\neq 0$ *and let*

$$\overline{u}''' = \overline{\Lambda}(\overline{u},\overline{u}',\overline{u}'',\overline{s}), \quad (85)$$

be a third-order ODE locally equivalent to Eq. (60) under the subset of contact transformations generated by the generating function

$$H(s,u,\overline{s},\overline{u}) = \overline{u} - u - G(s,\overline{s}). \quad (86)$$

Then under this subset of contact transformations the metric given by Eqs. (78)–(81) is preserved.

The proof of this theorem is exactly as that presented in Ref. 18 for the third-order ODE case such that a conformal Lorentzian metric, g^{ab}, lives on its space of solutions is living, such that the eikonal equation $g^{ab}u_a u_b = 0$ is satisfied. The justification of this choice of generating function (86) is the same as that given in the previous section.

We return to the example from the previous section of the central force problem but now with only one parameter, s, in the solution. We see that ODE's can be constructed from the two-parameter solution, Eq. (45), i.e., from

$$u = Z(x^a,E,\alpha,\beta) = \int \sqrt{2m(E-V) - \frac{\beta^2}{r^2}}\,dr + \int \sqrt{\beta^2 - \frac{\alpha^2}{\sin^2\theta}}\,d\theta + \alpha\phi, \quad (87)$$

by choosing α and β as functions of s. To illustrate what can occur we take three different cases:

(a) $(\alpha = s, \beta = \beta_0) \Rightarrow W^{(1)}[\Lambda]=0$ and $W^{(2)}[\Lambda]=0$;
(b) $(\alpha = \alpha_0, \beta = s) \Rightarrow W^{(1)}[\Lambda]=0$ and $W^{(2)}[\Lambda]=0$;
(c) $(\alpha = as, \beta = s), \Rightarrow W^{(1)}[\Lambda]=0$, the three vectors $\theta^i{}_{,a}$ are not linearly independent;
(d) $(\alpha = s^2, \beta = s), \Rightarrow W^{(1)}[\Lambda]\neq 0$, $W(2)[\Lambda]\neq 0$.

Conjecture: Whenever one has a third-order ODE, $u''' = \Lambda(u,u',u'',s)$, *so that* $W^{(1)}[\Lambda]=0$ *and* $W^{(2)}[\Lambda]=0$ *then the equation came from a solution where the one-parameter entered the solution as a Killing trajectory; i.e., the change in the solution as "s" evolves can be undone by dragging the metric along the Killing trajectory*.

For case (d) the metric can be found (after a lengthy calculation) from the solution

$$u(x^a,s)=\int \sqrt{2m(E-V(r))-\frac{s^2}{r^2}}\,dr+\int s\sqrt{1-s^2\csc^2\theta}\,d\theta+s^2\phi \tag{88}$$

by the following steps:

$$u'=\int \frac{-s\,dr}{r^2\sqrt{2m(E-V(r))-\frac{s^2}{r^2}}}+\int \frac{(1-2s^2\csc^2\theta)d\theta}{\sqrt{1-s^2\csc^2\theta}}+2s\phi,$$

$$u''=\int \frac{-2m(E-V)dr}{r^2\left[2m(E-V(r))-\frac{s^2}{r^2}\right]^{3/2}}+\int \frac{s\csc^2\theta(2s^2\csc^2\theta-3)d\theta}{(1-s^2\csc^2\theta)^{3/2}}+2\phi. \tag{89}$$

The ODE becomes

$$u'''=-[\mathcal{H}(r,s)+\mathcal{J}(\theta,s)], \tag{90}$$

where

$$\mathcal{H}(r,s)=\int \frac{6sm(E-V)dr}{r^4\left[2m(E-V(r))-\frac{s^2}{r^2}\right]^{5/2}},$$

$$\mathcal{J}(\theta,s)=\int \frac{3\csc^2\theta d\theta}{(1-s^2\csc^2\theta)^{5/2}}. \tag{91}$$

By inverting, we, in principle, find

$$r=R(u,u',u'',s),$$

$$\theta=\Theta(u,u',u'',s),$$

$$\phi=\Phi(u,u',u'',s), \tag{92}$$

from which

$$u'''=\Lambda=-[\mathcal{H}(R(u,u',u'',s),s)+\mathcal{J}(\Theta(u,u',u'',s),s)]. \tag{93}$$

This leads after much work to

$$\frac{W^{(1)}[\Lambda]}{W^{(2)}[\Lambda]}=\frac{-2mr^2(E-V)+s^4\csc^2\theta}{2mr^2[2mr^2(E-V)-s^2](E-V)(s^2\csc^2\theta-1)} \tag{94}$$

and finally to

$$u_{,a}=\left(\frac{\sqrt{2mr^2(E-V)-s^2}}{r},s\sqrt{1-s^2\csc^2\theta},s^2\right),$$

$$u'_{,a}=\left(\frac{-s}{r\sqrt{2mr^2(E-V)-s^2}},\frac{1-2s^2\csc^2\theta}{\sqrt{1-s^2\csc^2\theta}},2s\right), \tag{95}$$

$$u''_{,a}=\left(\frac{-2mr(E-V)}{(2mr^2(E-V)-s^2)^{3/2}},\frac{s\csc^2\theta(2s^2\csc^2\theta-3)}{(1-s^2\csc^2\theta)^{3/2}},2\right),$$

and the metric (first in tetrad components)

$$
\begin{aligned}
g^{00} &= 1, \\
g^{20} &= \frac{2mr^2(E-V) - s^4 \csc^2\theta}{2mr^2[2mr^2(E-V)-s^2](E-V)(s^2\csc^2\theta - 1)}, \\
g^{21} &= \frac{2s\sin^2\theta}{mr^2(E-V)[2s^2+\cos(2\theta)-1]^2} + \frac{s}{[2mr^2(E-V)-s^2]^2}, \\
g^{22} &= \frac{2mr^2(E-V)}{[2mr^2(E-V)-s^2]^3} + \frac{3s^2\sin^2\theta - 4\sin^4\theta}{2mr^2(E-V)[s^2-\sin^2\theta]^3},
\end{aligned}
\tag{96}
$$

and then the final form,

$$
ds^2 = g_{ab}dx^a dx^b = 2m(E-V)[dr^2 + r^2 d\theta^2 + r^2\sin^2\theta d\phi^2]. \tag{97}
$$

IV. CONCLUSIONS

In this work, we have shown that the ideas and procedures developed in our recent paper[23] on the two-dimensional time-independent H-J equation can be generalized to the three-dimensional time-independent H-J equation. The results presented in this work show that solving the three-dimensional time-independent H-J equation is equivalent to solving a system of three second-order PDE's or a third-order ODE.

We point out that, though we have used, in the present work, only the three-dimensional time-independent H-J equation, this can be generalized. In a future paper we will present the results for the four-dimensional H-J equation.

(Received 9 November 2003; accepted 10 March 2004; published online 21 May 2004)

We use sums over Bessel functions of the first kind to derive a convenient form of the Poisson summation identity relating sums over direct lattices in two dimensions to sums over reciprocal lattices. After three simple examples of the use of the identity, we consider sums over complex powers of the radial distance to lattice points, and also sums incorporating factors $\exp(4im\varphi_p)$ depending on angles of lattice points. We study the distribution of zeros of lattice sums, and show two which seemingly obey the Riemann hypothesis, and a third which does not. We provide a reflection formula for angular lattice sums, and a Macdonald function sum for the lowest order angular lattice sum. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1755861]

I. INTRODUCTION

The study of lattice sums is an old problem in physics, dating back to investigations of the Madelung constant,[1] and to the foundations of the Lorentz–Lorenz equation.[2] Such sums may be divided into various types, for example, according to dimensionality, governing equation and whether the summand is a function of distance only, or of distance and angles.

Here, we will investigate two-dimensional lattice sums, and will show the interest of combining knowledge of sums related to the Helmholtz equation with sums related to the Laplace equation. The former type of sum is naturally linked with the Bloch Theorem, and phase-modulated sums, and depends on both a wavenumber and wavevector. We will show that these extra parameters enable one to deduce interesting connections between lattice sums for the Laplace equation. These take the form of connections between sums over the direct and reciprocal lattices, and are particularly interesting when the two coincide, for example for the square lattice. These connections have been remarked before, for example, by Hardy and Titchmarsh[3] and Kober,[4] but these early investigations were hampered by lack of access to numerical and symbolic algebra tools.

We commence by showing that a sum over Bessel functions of the first kind over a lattice is equivalent to a sum of delta functions over the reciprocal lattice. This relation can be integrated over wavenumber to give a convenient form of the Poisson summation formula connecting sums over the direct lattice with sums over the reciprocal lattice. After three simple examples of this formula, we move to the consideration of complex powers of distance in the plane. This is a rich topic, connected with, but not restricted to, the Epstein zeta function. Potter and Titchmarsh[5] have speculated that the complex zeros of certain Epstein functions obey the Riemann hypothesis, while others do not. We provide an example of a lattice sum already studied by Kober,[4] which may be represented as the sum of two terms, with the original term and one of its components seemingly obeying the Riemann hypothesis, while the second component does not. We also provide a reflection formula for angular lattice sums, and a Macdonald function sum for the lowest order angular lattice sum.

a)Electronic address: ross@physics.usyd.edu.au

The main results of this paper are, firstly, a concise formula linking a general class of sums over a direct lattice with related sums over its reciprocal lattice (Sec. III). Second, we illustrate the utility of considering lattice sums incorporating a phase modulation term characterized by a Bloch factor in establishing links between unmodulated lattice sums (Secs. IV–VI). Third, we identify functions other than the zeta function which seem to obey the Riemann hypothesis (Secs. IV, VI, and the Appendix). In particular, we exhibit an example of two different functions which seemingly obey the hypothesis, while their difference does not. We also give numerical evidence bearing on the Lindelöf hypothesis for these functions.

II. THE BASIC DISTRIBUTIVE SUM

Lattice sums $S_l(k,\mathbf{k}_0)$ are defined by

$$S_l(k,\mathbf{k}_0)=\sum_{p\neq 0} H_l^{(1)}(kR_p)e^{il\varphi_p}e^{i\mathbf{k}_0\cdot\mathbf{R}_p}$$

$$=\sum_{p\neq 0} J_l(kR_p)e^{il\varphi_p}e^{i\mathbf{k}_0\cdot\mathbf{R}_p}+i\sum_{p\neq 0} Y_l(kR_p)e^{il\varphi_p}e^{i\mathbf{k}_0\cdot\mathbf{R}_p}$$

$$\overset{\text{def}}{=}S_l^J(k,\mathbf{k}_0)+iS_l^Y(k,\mathbf{k}_0). \tag{1}$$

Here $\mathbf{k}_0$ is the Bloch vector, k is a wavenumber and $\mathbf{R}_p$ is a lattice vector, written in polar form (R_p,φ_p). Note that k will be regarded as an extra parameter over which we can integrate to derive the formula in Sec. III linking sums over the direct lattice with sums over the reciprocal lattice. This will leave the Bloch vector as an essential tool in derivation of later results. In what follows, we assume the lattice to be square with lattice constant d, although our methods are applicable to other lattices.

We evaluate the sums $S_l^J(k,\mathbf{k}_0)$ as follows. First we have the Poisson summation formula

$$\sum_p e^{-i\mathbf{R}_p\cdot\mathbf{s}}=\left(\frac{2\pi}{d}\right)^2\sum_h \delta(\mathbf{s}-\mathbf{K}_h),$$

where $\mathbf{K}_h$, $h\in\mathbb{Z}^2$, are the reciprocal lattice vectors. Hence with $\mathbf{s}=\mathbf{k}-\mathbf{k}_0$ we have

$$1+\sum_{p\neq 0} e^{-i(\mathbf{k}-\mathbf{k}_0)\cdot\mathbf{R}_p}=\left(\frac{2\pi}{d}\right)^2\sum_h \delta(\mathbf{k}-\mathbf{k}_0-\mathbf{K}_h). \tag{2}$$

Next we substitute the Bessel function expansion

$$e^{-i\mathbf{R}_p\cdot\mathbf{k}}=\sum_{l=-\infty}^{\infty}(-i)^l J_l(kR_p)e^{il(\varphi_p-\theta)}$$

into Eq. (2), where $\theta=\arg\mathbf{k}$, to get

$$1+\sum_{l=-\infty}^{\infty}(-i)^l e^{-il\theta}\sum_{p\neq 0} J_l(kR_p)e^{il\varphi_p}e^{i\mathbf{k}_0\cdot\mathbf{R}_p}=\left(\frac{2\pi}{d}\right)^2\sum_h \delta(\mathbf{k}-\mathbf{k}_0-\mathbf{K}_h)$$

$$=\left(\frac{2\pi}{d}\right)^2\sum_h \frac{\delta(k-Q_h)\,\delta(\theta-\theta_h)}{k}, \tag{3}$$

where

$$Q_h=|\mathbf{k}_0+\mathbf{K}_h|,\qquad \theta_h=\arg\mathbf{Q}_h. \tag{4}$$

Multiplying both sides of Eq. (3) by $e^{in\theta}$ and integrating from 0 to 2π yields

$$\delta_{n,0}+(-i)^l S_l^J(k,\mathbf{k}_0)\,\delta_{n,l}=\frac{2\pi}{kd^2}\sum_h\ \delta(k-Q_h)e^{in\theta_h}, \tag{5}$$

so that

$$S_l^J(k,\mathbf{k}_0)=-\delta_{l,0}+\frac{2\pi i^l}{kd^2}\sum_h\ \delta(k-Q_h)e^{il\theta_h}. \tag{6}$$

For the $S_l^Y(k,\mathbf{k}_0)$ terms, we use a Green's function $G(\mathbf{r},\mathbf{r}';\omega,\mathbf{k}_0)$ which satisfies the inhomogeneous equation

$$\nabla^2 G+k^2 G=\sum_p\ \delta(\mathbf{r}-\mathbf{r}_s-\mathbf{R}_p), \tag{7}$$

from which we can derive (following Chin, Nicorovici, and McPhedran[6])

$$\begin{aligned} S_l J_l(k\xi)&=-H_0^{(1)}(k\xi)\,\delta_{l,0}-\frac{4i^{l+1}}{d^2}\sum_h\ \frac{J_l(Q_h\xi)}{Q_h^2-k^2}e^{il\theta_h}\\ &=-H_0^{(1)}(k\xi)\,\delta_{l,0}-\frac{4i^{l+1}}{d^2}\sum_h\ \frac{J_l(Q_h\xi)}{2Q_h}\left(\frac{1}{Q_h+k}+\frac{1}{Q_h-k}\right)e^{il\theta_h}, \end{aligned} \tag{8}$$

where $\xi=|\mathbf{r}-\mathbf{r}'|$. Using the Plemelj formula

$$\frac{1}{x-i0}=i\pi\delta(x)+\mathcal{P}\left(\frac{1}{x}\right), \tag{9}$$

we rewrite this equation as

$$\begin{aligned} S_l J_l(k\xi)&=-J_0(k\xi)\,\delta_{l,0}-iY_0(k\xi)\,\delta_{l,0}\\ &\quad-\frac{4i^{l+1}}{d^2}\sum_h\ \frac{J_l(Q_h\xi)}{2Q_h}\left(\frac{1}{Q_h+k}+i\pi\delta(k-Q_h)+\mathcal{P}\frac{1}{Q_h-k}\right)e^{il\theta_h}. \end{aligned} \tag{10}$$

Comparing Eqs. (10) and (6), we find

$$S_l^Y J_l(k\xi)=-Y_0(k\xi)\,\delta_{l,0}-\frac{4i^l}{d^2}\sum_h\ \frac{J_l(Q_h\xi)}{2Q_h}\left(\frac{1}{Q_h+k}+\mathcal{P}\frac{1}{Q_h-k}\right)e^{il\theta_h}. \tag{11}$$

The interpretation of Eqs. (6) and (11) is that the S_l^J are distributive lattice sums, with their distributive nature being concentrated around light lines, which are the trajectories $Q_h=k$ in the Brillouin zone. The S_l^Y are singular at light lines, exhibiting first order poles at each.

It is an elementary consequence of their definition (1) that the S_l^J all integrate to zero across the Brillouin zone. Hence,

$$\frac{1}{A_{BZ}}\int_{BZ}\sum_h\ \delta(k-Q_h)e^{il\theta_h}d^2\mathbf{k}_0=\frac{kd^2}{2\pi}\,\delta_{l,0}. \tag{12}$$

The only nonzero value of the right-hand side occurs for $l=0$, and is the density of states in free space subject to a period cell which is a square with side d. Hence, we see that S_0^J is associated with the free-space spectral density of states for the lattice.

III. A GENERAL EXPRESSION FOR LATTICE SUMS

We start with Eq. (6), which we multiply by a real or complex function of wavenumber $f(k)$:

$$\sum_{p\neq 0} f(k)J_l(kR_p)e^{il\varphi_p}e^{i\mathbf{k}_0\cdot\mathbf{R}_p} = -f(k)\,\delta_{l,0} + \frac{2\pi i^l}{d^2}\sum_h \frac{f(Q_h)}{Q_h}\,\delta(k-Q_h)e^{il\theta_h}. \tag{13}$$

Integrating this expression over k,

$$\sum_{p\neq 0}\left[\int_0^\infty f(k)J_l(kR_p)dk\right]e^{il\varphi_p}e^{i\mathbf{k}_0\cdot\mathbf{R}_p} = -\left[\int_0^\infty f(k)dk\right]\delta_{l,0} + \frac{2\pi i^l}{d^2}\sum_h \frac{f(Q_h)}{Q_h}e^{il\theta_h}, \tag{14}$$

and changing the variable in the first integration, yields

$$\sum_{p\neq 0}\left[\int_0^\infty \frac{1}{R_p}f\left(\frac{x}{R_p}\right)J_l(x)dx\right]e^{il\varphi_p}e^{i\mathbf{k}_0\cdot\mathbf{R}_p} = -\left[\int_0^\infty f(k)dk\right]\delta_{l,0} + \frac{2\pi i^l}{d^2}\sum_h \frac{f(Q_h)}{Q_h}e^{il\theta_h}. \tag{15}$$

The companion result to (12) is then

$$\frac{1}{A_{BZ}}\int_{BZ}\sum_h \frac{f(Q_h)}{Q_h}e^{il\theta_h}d^2\mathbf{k}_0 = \frac{d^2}{2\pi}\,\delta_{l,0}\left[\int_0^\infty f(k)dk\right]. \tag{16}$$

To apply Eqs. (14) or (15), we need choices of the function f for which, ideally, the two integrals are evaluable in closed form, and, certainly, for which they converge (in the normal sense, or in the sense of generalized functions). One convenient list of integrals is given in Chap. 11 of Abramowitz and Stegun.[7] As a first example, with

$$f(k) = k^{l+1}e^{-a^2k^2}, \tag{17}$$

from Eq. (11.4.29)[7] where $\mathrm{Re}(a^2)>0$, we obtain

$$\sum_{p\neq 0} R_p^l e^{-R_p^2/(4a^2)}e^{il\varphi_p}e^{i\mathbf{k}_0\cdot\mathbf{R}_p} = -\,\delta_{l,0} + \frac{2^{l+2}a^2\pi i^l}{d^2}\sum_h (a^2Q_h)^l e^{-a^2Q_h^2}e^{il\theta_h}. \tag{18}$$

This is analogous to the theta function transformation,[8] but is more general. It contains the extra distance and angle terms for $l\neq 0$, and a phase modulation present through the Bloch factor $\exp(i\mathbf{k}_0\cdot\mathbf{R}_p)$ on the left-hand side. The occurrence of $\mathbf{k}_0$ on the right-hand side is implicit via the definition of Q_h in Eq. (4). The form of (18) for $l=0$ is

$$\sum_{p\neq 0} e^{-R_p^2/(4a^2)}e^{i\mathbf{k}_0\cdot\mathbf{R}_p} = -1 + \frac{4a^2\pi}{d^2}\sum_h e^{-a^2Q_h^2}e^{il\theta_h}. \tag{19}$$

Figure 1 shows the real and imaginary parts of the right-hand side of this relation for a particular value of a. Note the sign reversal around the edge of the Brillouin zone, and the fourfold symmetry of the function consequent on the choice of the square array for study. Note also that, as is often the case with sums connected by the Poisson summation formula, the left-hand side of Eq. (18) converges rapidly when $\mathrm{Re}(1/a^2)$ is large and positive, whereas its right-hand side converges rapidly when $\mathrm{Re}(a^2)$ is large and positive. Since both series have a common region of convergence, we were able to test Eqs. (18) and (19) numerically in particular cases.

As a second example, we use Eq. (11.4.44),[7] putting

$$f(k) = \frac{k^{l+1}}{(k^2+z^2)^{\mu+1}}, \tag{20}$$

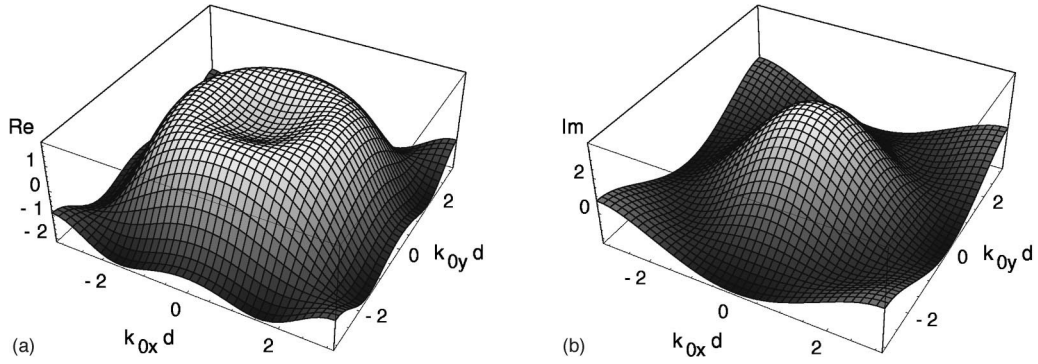

FIG. 1. Real part (left) and imaginary part (right) of Eq. (19) as a function of $k_{0x}d$ and $k_{0y}d$, for $a=0.5+0.3i$.

where $\mathrm{Re}(z)>0$, $l<2\mathrm{Re}(\mu)+3/2$, and find

$$\sum_{p\neq 0}\frac{R_p^{\mu}z^{l-\mu}}{2^{\mu}\Gamma(\mu+1)}K_{l-\mu}(R_pz)e^{il\varphi_p}e^{i\mathbf{k}_0\cdot\mathbf{R}_p}=-\frac{\delta_{l,0}}{2\mu z^{2\mu}}+\frac{2\pi i^l}{d^2}\sum_h\frac{Q_h^l e^{il\theta_h}}{(Q_h^2+z^2)^{\mu+1}}. \tag{21}$$

An example of the behavior of this sum is given in Fig. 2, for integer μ. For noninteger μ (real or complex), both sides of Eq. (21) exhibit branch-cut behavior. Note that the rapidity of the convergence of the left-hand side of Eq. (21) is governed by the magnitude of $\mathrm{Re}(z)$, while that of the right-hand side is governed by $\mathrm{Re}(2\mu)+2-l$. The nonzero value of l is reflected in the angular dependence in Fig. 2, which of course is different for real and imaginary parts.

As a third example, we choose $f(k)=J_{l-1}(kd)$ which leads to the discontinuous integral [Eq. (11.4.42)[7]]:

$$\int_0^{\infty}J_{l-1}(kd)J_l(kR_p)dk=\begin{cases}\dfrac{d^{l-1}}{R_p^l} & \text{if } R_p>d,\\[2ex] \dfrac{1}{2d} & \text{if } R_p=d,\end{cases} \tag{22}$$

for $l>0$. Hence,

$$d^l\sum_{R_p\neq 0}\frac{e^{il\varphi_p}e^{i\mathbf{k}_0\cdot\mathbf{R}_p}}{R_p^l}=\sigma_l(\mathbf{k}_0)=\frac{d^l}{2}\sum_{R_p=d}\frac{e^{il\varphi_p}e^{i\mathbf{k}_0\cdot\mathbf{R}_p}}{R_p^l}+\frac{2\pi i^l}{d}\sum_h\frac{J_{l-1}(Q_hd)e^{il\theta_h}}{Q_h}. \tag{23}$$

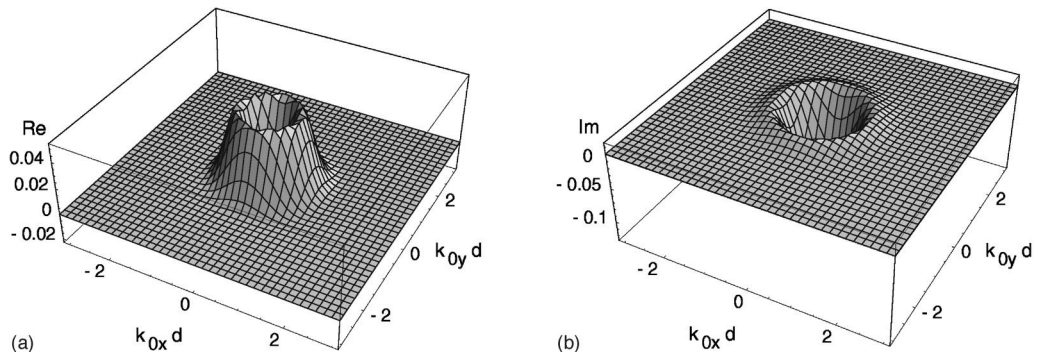

FIG. 2. Real part (left) and imaginary part (right) of Eq. (21) as a function of $k_{0x}d$ and $k_{0y}d$, for $l=2$, $\mu=5$, $z=2.18+0.82i$, $d=1$.

Here, the sums $\sigma_l(\mathbf{k}_0)$ (written here in nondimensional form) have been considered previously by McPhedran and Nicorovici,[9] who provide the following alternative expression for them:

$$\sigma_l(\mathbf{k}_0)=(2\pi i)^l\left\{\frac{1}{(2l)!!}\left[\frac{l}{\pi}\kappa^{l-2}-\kappa^l\right]+\sum_{m\geqslant 1}^{\infty}\mathcal{S}_{l-4m,4m,l}(\kappa)e^{-4im\theta_0}\right\}e^{il\theta_0}. \tag{24}$$

Here, $\kappa=k_0d/2\pi$ and

$$\mathcal{S}_{l,4m,n}(\xi)=\frac{1}{d^n}\sum_{K_h\neq 0}\frac{J_l(K_h\xi)}{K_h^n}e^{i4m\psi_h}. \tag{25}$$

McPhedran and Nicorovici[9] provide graphs of $\sigma_1,\ldots,\sigma_6$ across the first Brillouin zone. Note that, from (24), σ_1 has a first-order singularity as $k_0\to 0$.

IV. POWERS OF RADIAL DISTANCE

We now consider the applications of Eqs. (14) and (16) to complex powers s of the radial distance. The analysis is more difficult than in Sec. III, principally because of the occurrence of an undefined integral which arises in a straightforward application of (14). We will use raising and lowering operators to remove this difficulty.

We rely on results obtained using the methods of the theory of distributions from Chap. 7 of Jones,[10] and in particular

$$\int_{-\infty}^{\infty}r^{\beta}e^{-i\boldsymbol{\alpha}\cdot\mathbf{x}}d\mathbf{x}=2\pi\int_0^{\infty}r^{\beta+1}J_0(\alpha r)dr=\frac{(\frac{1}{2}\beta)!2^{\beta+2}\pi}{(-\frac{1}{2}\beta-1)!\alpha^{\beta+2}}, \tag{26}$$

valid when $\beta\neq 2m$ and $\beta\neq -2-2m$ $(m=0,1,2,\ldots)$. Hence, if $s\neq 2m-1$ or $-1-2m$,

$$\int_0^{\infty}r^sJ_0(\alpha r)dr=\frac{\Gamma(\frac{1}{2}+\frac{1}{2}s)2^s}{\Gamma(\frac{1}{2}-\frac{1}{2}s)\alpha^{1+s}}. \tag{27}$$

By differentiation under the integral sign in (27), and use of Bessel function recurrence relations, we obtain Weber's integral:

$$\int_0^{\infty}r^sJ_l(\alpha r)dr=\frac{\Gamma\left(\dfrac{1+l+s}{2}\right)2^s}{\Gamma\left(\dfrac{1+l-s}{2}\right)\alpha^{1+s}}, \tag{28}$$

provided $1+l\pm s$ is not a negative even integer.

Hence, if we put

$$f(k)=k^s \tag{29}$$

in Eq. (14), we obtain for nonzero l,

$$2^s\Gamma\left(\frac{l+1+s}{2}\right)\sum_{p\neq 0}\frac{e^{i\mathbf{k}_0\cdot\mathbf{R}_p}e^{il\varphi_p}}{R_p^{1+s}}=\frac{2\pi i^l}{d^2}\Gamma\left(\frac{l+1-s}{2}\right)\left(\frac{e^{il\theta_0}}{k_0^{1-s}}+\sum_{h\neq 0}\frac{e^{il\theta_h}}{Q_h^{1-s}}\right). \tag{30}$$

For $l=0$, we can write the result formally:

$$2^s\Gamma\left(\frac{1+s}{2}\right)\sum_{p\neq 0}\frac{e^{i\mathbf{k}_0\cdot\mathbf{R}_p}}{R_p^{1+s}}=\Gamma\left(\frac{1-s}{2}\right)\int_0^{\infty}k^sdk+\frac{2\pi}{d^2}\Gamma\left(\frac{1-s}{2}\right)\left(\frac{1}{k_0^{1-s}}+\sum_{h\neq 0}\frac{1}{Q_h^{1-s}}\right), \tag{31}$$

but the expression (31) is nugatory because of the presence of the first integral on the right-hand side. Hence, we approach the case $l=0$ by a different argument.

A. Definition of phased lattice sums

Let us extend the definition of (23) to nonintegral powers of the distance

$$\sigma_{1+s}^{m}(\mathbf{k}_0)=d^{1+s}\sum_{p\neq 0}\frac{\exp(im\varphi_p)}{R_p^{1+s}}e^{i\mathbf{k}_0\cdot\mathbf{R}_p}. \tag{32}$$

Here, the lattice sum subscript $1+s$ is taken to be real or complex, while the superscript m must be integral, if the angular factor $\exp(im\varphi_p)$ is to be continuous at $\varphi_p=2\pi$. Note that the Bloch sums $\sigma_{1+s}^{m}(\mathbf{k}_0)$ are absolutely convergent if $\mathrm{Re}(s)>1$, conditionally convergent if $\mathrm{Re}(s)=1$, and divergent otherwise. We seek their analytic continuations across the whole complex plane of s, and knowledge of their poles and zeros. Further, note that in the region of absolute convergence, $\sigma_{1+s}^{m}(\mathbf{k}_0)$ is zero for the square array unless m is a multiple of four. Also, the sums for positive and negative m are equivalent. In what follows, we will use the compact notation $\sigma_{1+s}^{(m)}$ for $\sigma_{1+s}^{m}(0)$.

We expand the phase factor in (32) in terms of its Bessel function series, and obtain

$$\sigma_{1+s}^{m}(\mathbf{k}_0)=i^m e^{im\theta_0}d^{1+s}\sum_{n}\sum_{p\neq 0}\frac{J_{m+4n}(k_0R_p)e^{4in\varphi_p}}{R_p^{1+s}}. \tag{33}$$

We re-express (33) in terms of the dimensionless lattice sums studied by Nicorovici *et al.*:[11]

$$\sigma_{1+s}^{m}(\mathbf{k}_0)=i^m(2\pi)^{1+s}e^{im\theta_0}\sum_{n}\mathcal{S}_{m+4n,4n,1+s}(\kappa)e^{4in\theta_0}, \tag{34}$$

where $\kappa=k_0d/(2\pi)$ and

$$\mathcal{S}_{m+4n,4n,1+s}(\kappa)=\sum_{h\neq 0}\frac{J_{m+4n}(\kappa K_h d)e^{4in\psi_h}}{(K_h d)^{1+s}} \tag{35}$$

is expressed as a reciprocal lattice sum.

The treatment of the sums $\mathcal{S}$ in Ref. 11 separates the sums with $n=0$ from those with $n\neq 0$. In the first case, the Weber–Schafheitlin integral[7] is used in connection with the Poisson summation formula to give

$$\mathcal{S}_{m,0,1+s}(\kappa)=\kappa^{s-1}\frac{2^{-(s+1)}\Gamma((m-s+1)/2)}{\pi\Gamma((m+s+1)/2)}+\sum_{p\neq 0}\frac{d^{m-s+1}\kappa^m\Gamma((m-s+1)/2)}{2^{s+1}\pi R_p^{m-s+1}\Gamma(m+1)\Gamma((s+1-m)/2)}$$
$$\times{}_2F_1\left(\frac{m-s+1}{2},\frac{m-s+1}{2};m+1;\frac{\kappa^2d^2}{R_p^2}\right). \tag{36}$$

Expanding the hypergeometric function, we obtain

$$\mathcal{S}_{m,0,1+s}(\kappa)=\kappa^{s-1}\frac{2^{-(s+1)}\Gamma((m-s+1)/2)}{\pi\Gamma((m+s+1)/2)}+\frac{\kappa^m\sin\pi(s+1-m)/2}{\pi^2 2^{s+1}}$$
$$\times\sum_{l=0}^{\infty}\frac{[\Gamma((m-s+1)/2+l)]^2}{(m+l)!\,l!}\kappa^{2l}\sigma_{2l+m+1-s}^{(0)}. \tag{37}$$

The conditions required in the manipulations leading to (37) were $\mathrm{Re}(m-s-1)>0$, $\mathrm{Re}(s)>-1/2$ and $\kappa<1$. As far as the last is concerned, κ does not exceed $1/\sqrt{2}$ in the Brillouin zone. As

far as the first two are concerned, we shall see that the right-hand side of the expression (37) provides an analytic continuation of the left-hand side for all integral values of m and complex values of s.

The sums $\sigma^{(0)}_{2l+m+1-s}$ were evaluated analytically by Hardy,[12–14] in a form valid throughout the complex plane

$$\sigma^{(0)}_{1+s}=d^{1+s}\sum_{p\neq 0}\frac{1}{R_p^{1+s}}=4\zeta\left(\frac{1+s}{2}\right)\beta\left(\frac{1+s}{2}\right). \tag{38}$$

Here, $\zeta(s)$ is the Riemann zeta function [Eq. (23.2.1) in Ref. 7], while

$$\beta(s)=\sum_{n=0}^{\infty}(-1)^n(2n+1)^{-s}=2^{-s}\Phi(-1,s,1/2)=\frac{1}{4^s}\left(\zeta\left(s,\frac{1}{4}\right)-\zeta\left(s,\frac{3}{4}\right)\right) \tag{39}$$

is the Catalan beta function [Eq. (23.2.21) in Ref. 7], which may be defined in terms of the Lerch phi function and the Hurwitz zeta function, respectively. We will need the following reflection formula[13]

$$\pi^{-(1+s)/2}\zeta\left(\frac{1+s}{2}\right)\beta\left(\frac{1+s}{2}\right)\Gamma\left(\frac{1+s}{2}\right)=\pi^{-(1-s)/2}\zeta\left(\frac{1-s}{2}\right)\beta\left(\frac{1-s}{2}\right)\Gamma\left(\frac{1-s}{2}\right). \tag{40}$$

We consider next the sums $\mathcal{S}$ with $n\neq 0$. The treatment from Ref. 11 again uses the Weber–Schafheitlin integral, and gives (if $s\neq l-1$)

$$\mathcal{S}_{l,4m,s+1}(\kappa)=\frac{1}{2^{s+1}\pi\Gamma(1-w+4m)\Gamma(w-4m)}\sum_{q=0}^{\infty}\frac{\Gamma(w+q)\Gamma(w-4m+q)}{q!(q+l)!}\sigma^{(4m)}_{2q+l-s+1}\kappa^{2q+l}, \tag{41}$$

where $w=2m+(l+1-s)/2$.

We now return to (34):

$$\sigma^0_{1+s}(\mathbf{k}_0)=(2\pi)^{1+s}\left[\mathcal{S}_{0,0,1+s}(\kappa)+2\sum_{n=1}^{\infty}\mathcal{S}_{4n,4n,1+s}(\kappa)\cos(4n\theta_0)\right]. \tag{42}$$

Using (37) and (41), this gives

$$\begin{aligned}\sigma^0_{1+s}(\mathbf{k}_0)=(2\pi)^{1+s}\Bigg\{&\frac{\kappa^{s-1}\Gamma((1-s)/2)}{\pi 2^{s+1}\Gamma((1+s)/2)}+\frac{\sin\pi(s+1)/2}{\pi^2 2^{s+1}}\sum_{l=0}^{\infty}\left[\frac{\Gamma((2l+1-s)/2)}{l!}\right]^2\kappa^{2l}\sigma^{(0)}_{2l+1-s}\\&+2\sum_{n=1}^{\infty}\frac{\cos 4n\theta_0}{2^{s+1}\pi\Gamma((1-s)/2)\Gamma((1+s)/2)}\\&\times\sum_{q=0}^{\infty}\frac{\Gamma(4n+q+(1-s)/2)\Gamma(q+(1-s)/2)}{q!(q+4n)!}\sigma^{(4n)}_{2q+4n-s+1}\kappa^{2q+4n}\Bigg\}.\end{aligned} \tag{43}$$

The term in κ^{s-1} in fact cancels the second term on the right-hand side of (31). This suggests the identification

$$\frac{2\pi}{d^2}\frac{\Gamma\left(\frac{1-s}{2}\right)}{2^s\Gamma\left(\frac{1+s}{2}\right)}\sum_{h\neq 0}\frac{1}{Q_h^{1-s}}=\left(\frac{2\pi}{d}\right)^{1+s}\left\{\frac{\sin\pi(s+1)/2}{\pi^2 2^{s+1}}\sum_{l=0}^{\infty}\left[\frac{\Gamma((2l+1-s)/2)}{l!}\right]^2\kappa^{2l}\sigma^{(0)}_{2l+1-s}\right.$$
$$+2\sum_{n=1}^{\infty}\frac{\cos 4n\theta_0}{2^{s+1}\pi\Gamma((1-s)/2)\Gamma((1+s)/2)}$$
$$\left.\times\sum_{q=0}^{\infty}\frac{\Gamma(4n+q+(1-s)/2)\Gamma(q+(1-s)/2)}{q!(q+4n)!}\sigma^{(4n)}_{2q+4n-s+1}\kappa^{2q+4n}\right\}. \tag{44}$$

Let us define a nondimensional lattice sum over the reciprocal lattice by analogy with (32):

$$\rho^0_{1-s}(\mathbf{k}_0)=\left(\frac{2\pi}{d}\right)^{1-s}\sum_{h\neq 0}\frac{1}{Q_h^{1-s}}. \tag{45}$$

Then, from (44),

$$\rho^0_{1-s}(\mathbf{k}_0)=\sigma^{(0)}_{1-s}+\sum_{l=1}^{\infty}\left[\frac{\Gamma((2l+1-s)/2)}{l!\Gamma((1-s)/2)}\right]^2\kappa^{2l}\sigma^{(0)}_{2l+1-s}+2\sum_{n=1}^{\infty}\frac{\cos 4n\theta_0}{(\Gamma((1-s)/2))^2}$$
$$\times\sum_{q=0}^{\infty}\frac{\Gamma(4n+q+(1-s)/2)\Gamma(q+(1-s)/2)}{q!(q+4n)!}\sigma^{(4n)}_{2q+4n-s+1}\kappa^{2q+4n}. \tag{46}$$

If we examine the various terms in (46), we see that the part independent of θ_0 is defined for all complex values of s, while in the part dependent on θ_0 convergence is limited by the term $\sigma^{(4)}_{5-s}$ to the region $\mathrm{Re}(s)<3$.

Note that Eq. (46) can be obtained directly from the definition (45). The inverse power of the distance is expanded via the expression (22.9.3) from Abramowitz and Stegun,[7] while the ultraspherical functions occurring in the expansion are expressed using (22.3.12).

B. Raising and lowering operators

We can transform the angular and radial variations in these sums using the following raising and lowering operators:

$$\mathcal{R}=\frac{-i}{d}\left(\frac{\partial}{\partial k_{0x}}+i\frac{\partial}{\partial k_{0y}}\right)=\frac{-i}{2\pi}e^{i\theta_0}\left(\frac{\partial}{\partial\kappa}+\frac{i}{\kappa}\frac{\partial}{\partial\theta_0}\right) \tag{47}$$

and

$$\mathcal{L}=\frac{-i}{d}\left(\frac{\partial}{\partial k_{0x}}-i\frac{\partial}{\partial k_{0y}}\right)=\frac{-i}{2\pi}e^{-i\theta_0}\left(\frac{\partial}{\partial\kappa}-\frac{i}{\kappa}\frac{\partial}{\partial\theta_0}\right). \tag{48}$$

Then, by direct differentiation, we find

$$\mathcal{L}\sigma^m_{1+s}(\mathbf{k}_0)=\sigma^{m-1}_s(\mathbf{k}_0),\quad \mathcal{R}\sigma^m_{1+s}(\mathbf{k}_0)=\sigma^{m+1}_s(\mathbf{k}_0). \tag{49}$$

Again by direct differentiation,

$$\mathcal{L}\rho^m_{1-s}(\mathbf{k}_0)=\frac{(m-s-1)}{2\pi i}\rho^{m-1}_{2-s}(\mathbf{k}_0),\quad \mathcal{R}\rho^m_{1-s}(\mathbf{k}_0)=\frac{-(m+1-s)}{2\pi i}\rho^{m+1}_{2-s}(\mathbf{k}_0). \tag{50}$$

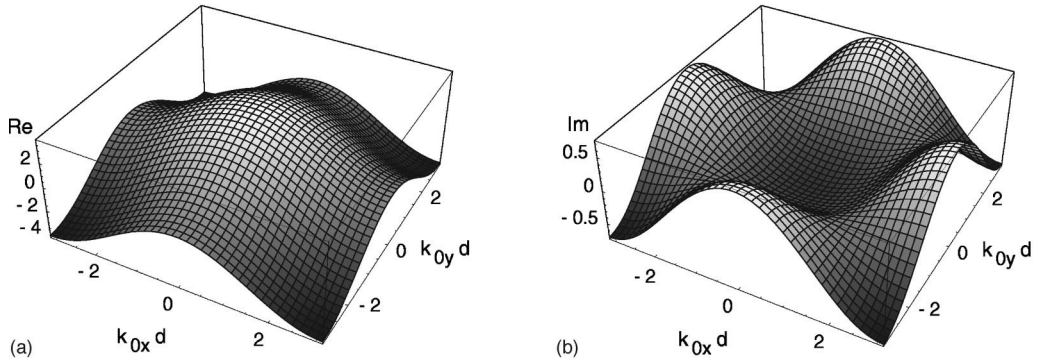

FIG. 3. Real part (left) and imaginary part (right) of $\sigma^0_{1+s}(k_{0x},k_{0y})$, for $s=4.128+5.073i$.

Let us rewrite Eq. (30):

$$2^s\Gamma((l+1+s)/2)\sigma^l_{1+s}(\mathbf{k}_0)=(2\pi)^s i^l\Gamma((l+1-s)/2)[e^{il\theta_0}\kappa^{s-1}+\rho^l_{1-s}(\mathbf{k}_0)]. \tag{51}$$

Then, we can verify using (49) and (50) that $\mathcal{L}$ transforms l in this equation to $l-1$ and s to $s-1$. If we apply $\mathcal{L}$ to (51) with $l=1$, we obtain

$$\Gamma((1+s)/2)\sigma^0_{1+s}(\mathbf{k}_0)=\pi^s\Gamma((1-s)/2)[\kappa^{s-1}+\rho^0_{1-s}(\mathbf{k}_0)]. \tag{52}$$

This is Eq. (31), with the nugatory integral replaced by zero.

Hence, if $\mathrm{Re}(s)>1$, we have in the limit as $\kappa\to 0$ in (52):

$$\begin{aligned}\Gamma((1+s)/2)\sigma^0_{1+s}(0)&=4\Gamma((1+s)/2)\beta((1+s)/2)\zeta((1+s)/2)\\&=\pi^s\Gamma((1-s)/2)\rho^0_{1-s}(0)\\&=4\pi^s\Gamma((1-s)/2)\beta((1-s)/2)\zeta((1-s)/2).\end{aligned} \tag{53}$$

The equality of the left- and right-hand sides of (53) is guaranteed by the reflection formula (40). If $\mathrm{Re}(s)<1$, we know from (46) that $\rho^0_{1-s}(\mathbf{k}_0)$ continues to behave continuously at the center of the Brillouin zone, while $\sigma^0_{1+s}(\mathbf{k}_0)$ develops a singularity there.

We give an example of the behavior of σ^0_{1+s} across the Brillouin zone in Fig. 3. The value of s chosen permits rapid direct evaluation of the sum using the definition (32). We can also use (46) and (52), with the two methods agreeing to the accuracy of the determination of the lattice sums $\sigma^{(4n)}_{2q+4n-s+1}$. For the latter, we need to use the Macdonald function series for the sums with $n=1$ derived in the Appendix. We note in Fig. 3 that the real and imaginary parts of σ^0_{1+s} are fourfold symmetric, and their normal derivatives are zero both at the edges of the Brillouin zone, and on the lines $k_{0x}=0$ and $k_{0y}=0$.

From the definition of $\sigma^m_{1+s}(\mathbf{k}_0)$, we see that

$$\int_{BZ}\sigma^m_{1+s}(\mathbf{k}_0)d^2\mathbf{k}_0=0. \tag{54}$$

Using the Laplacian operator with respect to $\mathbf{k}_0$, we note that

$$\nabla^2\sigma^m_{1+s}(\mathbf{k}_0)=-d^2\sigma^m_{s-1}(\mathbf{k}_0). \tag{55}$$

Using this, we see that the property (54) is guaranteed if the normal derivative vanishes at the edge of the Brillouin zone:

$$\int_{BZ}\sigma_{1+s}^{m}(\mathbf{k}_0)d^2\mathbf{k}_0=\frac{1}{d^2}\int_{BZ}\nabla^2\sigma_{3+s}^{m}(\mathbf{k}_0)d^2\mathbf{k}_0=\frac{1}{d^2}\int_{BBZ}\frac{\partial\sigma_{3+s}^{m}(\mathbf{k}_0)}{\partial n}dl, \tag{56}$$

with the last integral running over the boundary of the Brillouin zone, of which dl denotes an element of length, and the partial derivative is taken along the outward normal to the boundary.

We can deduce an interesting relation from (51), if we assume $\mathrm{Re}(s)>1$ and let $\kappa\to 0$:

$$\Gamma\left(\frac{4l+1+s}{2}\right)\sigma_{1+s}^{4l}(0)=\pi^s\Gamma\left(\frac{4l+1-s}{2}\right)\rho_{1-s}^{4l}(0). \tag{57}$$

This suggests the following reflection formula:

$$\frac{1}{\pi^{(4l+1+s)/2}}\Gamma\left(\frac{4l+1+s}{2}\right)\sigma_{1+s}^{(4l)}=\frac{1}{\pi^{(4l+1-s)/2}}\Gamma\left(\frac{4l+1-s}{2}\right)\sigma_{1-s}^{(4l)}, \tag{58}$$

so that, if we define the function

$$G_{4l}\left(\frac{s}{2}\right)=\frac{1}{\pi^{(4l+1+s)/2}}\Gamma\left(\frac{4l+1+s}{2}\right)\sigma_{1+s}^{(4l)}, \tag{59}$$

then G_{4l} is even in s. In the Appendix we comment on verifications of this formula for the case $l=1$.

V. LATTICE SUM IDENTITIES

We commence with (32). We evaluate the partial derivative of this with respect to k_{0x}, set $k_{0x}=\pi/d$, and put $\mathbf{R}_p=(X_p,Y_p)$. The result is, for a sum of even order,

$$\left.\frac{\partial\sigma_{1+s}^{2m}}{\partial k_{0x}}\right|_{k_{0x}=\pi/d}=id^{1+s}\sum_{p\neq 0}\frac{X_p e^{2im\varphi_p}}{R_p^{1+s}}e^{i(\pi X_p/d+k_{0y}Y_p)}. \tag{60}$$

We evaluate the contribution to this sum from four points in the lattice at equal distances from the origin: (X_p,Y_p), $(-X_p,-Y_p)$, $(-X_p,Y_p)$ and $(X_p,-Y_p)$. These collectively give

$$\frac{-4X_p\, i\, d^{1+s}}{R_p^{1+s}}e^{i\pi X_p/d}\sin(k_{0y}Y_p)\sin(2m\varphi_p). \tag{61}$$

Hence, we arrive at two lattice sum identities:

$$\left.\frac{\partial\sigma_{1+s}^{0}}{\partial k_{0x}}\right|_{k_{0x}=\pi/d}=0 \tag{62}$$

and

$$\left.\frac{\partial}{\partial k_{0x}}[\sigma_{1+s}^{2m}+\sigma_{1+s}^{-2m}]\right|_{k_{0x}=\pi/d}=0. \tag{63}$$

These identities hold for all values of k_{0y} ranging from $-\pi/d$ to π/d.

We will concentrate here on (62). We note that this guarantees that the integral of σ_{1+s}^{0} over the Brillouin zone is zero [see (55) and (56)]. Using (46) and (52), (62) becomes

$$\frac{(s-1)}{2}\kappa^{s-3}+\sum_{l=1}^{\infty} l\left[\frac{\Gamma((2l+1-s)/2)}{l!\Gamma((1-s)/2)}\right]^2\kappa^{2l-2}\sigma^{(0)}_{2l+1-s}$$
$$+2\sum_{n=1}^{\infty}\sum_{q=0}^{\infty}\frac{\Gamma((8n+2q+1-s)/2)\Gamma((2q+1-s)/2)q}{q!(q+4n)![\Gamma((1-s)/2)]^2}\sigma^{(4n)}_{2q+4n+1-s}\kappa^{2q+4n-2}\cos(4n\theta_0)$$
$$+8\sum_{n=1}^{\infty}\sum_{q=0}^{\infty}\frac{\Gamma((8n+2q+1-s)/2)\Gamma((2q+1-s)/2)n}{q!(q+4n)![\Gamma((1-s)/2)]^2}\sigma^{(4n)}_{2q+4n+1-s}\kappa^{2q+4n-1}$$
$$\times\cos((4n-1)\theta_0)=0. \tag{64}$$

This identity is to be applied for

$$\kappa^2=(\tfrac{1}{4}+\kappa_y^2),\quad \kappa\cos\theta_0=\tfrac{1}{2},\quad \kappa_y\in[-\tfrac{1}{2},\tfrac{1}{2}]. \tag{65}$$

The sums in (64) are of hypergeometric form and converge absolutely provided $\kappa<1$, where of course the largest value of κ encountered in the Brillouin zone is $1/\sqrt{2}$. However, the sums do converge more slowly and become increasingly badly conditioned numerically as $|s|$ increases, due to the gamma function ratios in them. If we put $\kappa_y=0$ in (64), we obtain

$$\sigma^{(0)}_{1-s}=\frac{\Gamma((-1-s)/2)}{2^{s-1}\Gamma((1-s)/2)}-\sum_{l=2}^{\infty}\left(\frac{\Gamma((2l-s-1)/2)}{\Gamma((1-s)/2)}\right)^2\frac{\sigma^{(0)}_{2l-1-s}}{l!(l-1)!2^{2l-2}}$$
$$-\sum_{n=1}^{\infty}\sum_{q=0}^{\infty}\frac{\Gamma((8n+2q-1-s)/2)\Gamma((2q-1-s)/2)}{(\Gamma((1-s)/2))^2q!(q+4n)!2^{2q+4n-2}}(2q+4n)\sigma^{(4n)}_{2q+4n-1-s}. \tag{66}$$

This equation is also obtainable from the symmetry property that σ^1_{1+s} is zero for $\kappa_x=1/2$ and $\kappa_y=0$.

The convergence of the series on the right-hand side of (66) may be accelerated somewhat by re-expressing nearest neighbor terms in their original form. Let us define

$$\tilde{\sigma}^{(4n)}_{2q+4n+1-s}=\sigma^{(4n)}_{2q+4n+1-s}-d^{2q+4n+1-s}\sum_{p\in\mathcal{N}}\frac{e^{4in\varphi_p}}{R_p^{2q+4n+1-s}}, \tag{67}$$

where $\mathcal{N}$ denotes a set of nearest neighbors of the origin. For $2q+4n$ large, the sums $\tilde{\sigma}^{(4n)}_{2q+4n+1-s}$ can be evaluated by direct summation:

$$\tilde{\sigma}^{(4n)}_{2q+4n+1-s}=d^{2q+4n+1-s}\sum_{p\in\bar{\mathcal{N}}}\frac{e^{4in\varphi_p}}{R_p^{2q+4n+1-s}}, \tag{68}$$

where $\bar{\mathcal{N}}$ denotes the complement of $\mathcal{N}$ in the lattice. Then (66) can be rewritten

$$\tilde{\sigma}^{(0)}_{1-s}=\frac{-1}{(s+1)2^{s-2}}-\sum_{l=2}^{\infty} l\left(\frac{\Gamma((2l-s-1)/2)}{l!\Gamma((1-s)/2)}\right)^2\frac{\tilde{\sigma}^{(0)}_{2l-1-s}}{2^{2l-2}}$$
$$-\sum_{n=1}^{\infty}\sum_{q=0}^{\infty}\frac{\Gamma((8n+2q-1-s)/2)\Gamma((2q-1-s)/2)}{(\Gamma((1-s)/2))^2q!(q+4n)!2^{2q+4n-2}}(2q+4n)\tilde{\sigma}^{(4n)}_{2q+4n-1-s}$$
$$-\frac{4}{s+1}\sum_{h\in NN}\frac{h_x+1/2}{[(h_x+1/2)^2+h_y^2]^{(1-s)/2}}. \tag{69}$$

Numerical studies has shown that (69) is numerically better-conditioned than (66). However, both become less and less useful as $\mathrm{Im}(s)$ increases in the region where $\mathrm{Re}(s)$ is close to zero, with the

summations generating larger and larger initial terms which have to be cancelled by later terms. Thus, it seems that the lattice sum identities described here have more analytic than numeric interest.

VI. PROPERTIES OF THE SUM $\sigma^{(0)}$

We start with the expansion (A3) from the Appendix, which we consider for the square array $(d_1=d_2)$, and write in symmetric form:

$$G_0(s)=f_1(s)+8\sum_{p_1,p_2=1}^{\infty}\left(\frac{p_2}{p_1}\right)^s K_s(2\pi p_1 p_2)\overset{\text{def}}{=}f_1(s)+f_2(s), \tag{70}$$

where

$$f_1(s)=2\zeta(2s+1)\frac{\Gamma(s+1/2)}{\pi^{s+1/2}}+2\zeta(2s)\frac{\Gamma(s)}{\pi^s}. \tag{71}$$

Equation (70) links three analytic functions, all of which are even functions of s, are real on $\mathrm{Re}(s)=0$ and also real on $\mathrm{Im}(s)=0$. Note that $G_0(s)$ has $s=\pm 1/2$ as its only poles, and these have residue ± 1 respectively. The same property applies to $f_1(s)$, while $f_2(s)$ is regular in the finite part of the plane. Our purpose here is to provide numerical and analytical data on the order of these three functions, and on the distribution of their zeros.

A. Lindelöf analysis

We start with the order of $\zeta(s)$ and $\beta(s)$. Writing the argument of each in the standard form $s=\sigma+it$, we wish to know their behavior as $t\to\infty$, as a function of σ. We write

$$\zeta(\sigma+it)=O(t^{\mu(\sigma)}),\quad \beta(\sigma+it)=O(t^{\nu(\sigma)}), \tag{72}$$

where we are interested in the smallest values μ and ν for which the order assignments are valid. As discussed by Titchmarsh,[15] Lindelöf's hypothesis is that

$$\mu(\sigma)=\begin{cases}\frac{1}{2}-\sigma & \text{for } \sigma\leqslant\frac{1}{2},\\ 0 & \text{for } \sigma>\frac{1}{2},\end{cases} \tag{73}$$

where $\mu(\sigma)$ is continuous, nonincreasing, convex downwards and never negative. Glasser[13] has provided order estimates for $\beta(s)$.

Our procedure will be numerical, and so we are in a position to investigate somewhat stronger statements than the order of each function—i.e., typically we will seek both powers and coefficients of the leading term. Our first investigation will be into the asymptotics of locally smoothed functions, to establish statements which we will denote

$$|\zeta(\sigma+it)|\bar{\sim}C_\zeta t^{\mu(\sigma)},\quad |\beta(\sigma+it)|\bar{\sim}C_\beta t^{\nu(\sigma)}, \tag{74}$$

using the bar over the asymptotic sign to denote a leading term on average.

To investigate numerically the order of the smoothed functions $\zeta(\sigma+it)$ and $\beta(\sigma+it)$, we plot the logarithm of the absolute value of the function in question, as a function of t, divided by t^p, for a test power p. To smooth the plot somewhat, we average the result over a significant number of neighboring points. The value of p is chosen to deliver as flat a plot as possible, and then C is obtained using a growing average over all the points on the first graph. This procedure is illustrated in Fig. 4, for $\sigma=0.3$. The results are in keeping with Lindelöf's hypothesis, and furthermore indicate that the exponents for ζ and β are equal to computational accuracy.

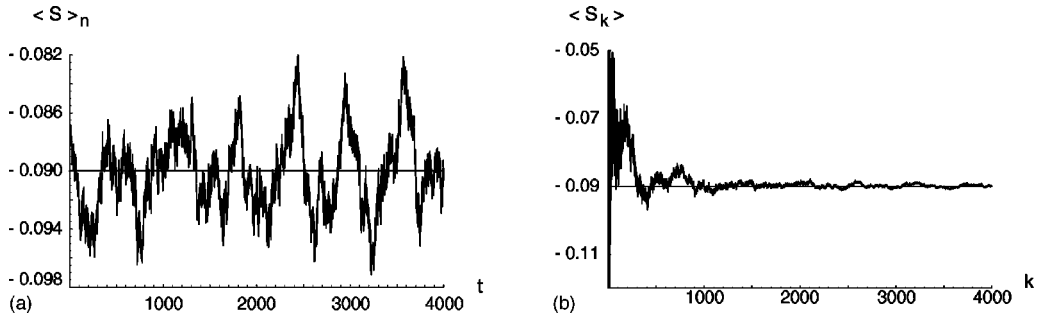

FIG. 4. Averages of the sequence $S=\{S(t)\mid t=1,\ldots,4800\}$, where $S(t)=\log(|\beta(0.3+i\,t)|)/t^{0.20}$. Left: the moving average $\langle S\rangle_n(t)=(S(t)+S(t+1)+\cdots+S(t+n))/n$, with $n=800$. Right: the averages of the sequences $S_k=\{S(t)\mid t=1,\ldots,k\}$ for $k=1,\ldots,4000$. Its values near the end of the sample give the value (-0.090) reported in Table I.

Table I shows the numerical estimates for the coefficients C, for $\sigma\leqslant 0.5$. Above this limit, the coefficients are unity to computational accuracy. The coefficients in fact bear a constant ratio (around 58.7), to the accuracy of their determination. We thus have the augmented Lindelöf hypothesis:

$$\mu(\sigma)=\nu(\sigma)=\begin{cases}\frac{1}{2}-\sigma & \text{for } \sigma\leqslant\frac{1}{2},\\ 0 & \text{for } \sigma>\frac{1}{2}.\end{cases} \tag{75}$$

Note that the truth of the Riemann hypothesis implies that of the Lindelöf hypothesis, but not the contrary.[15]

Assuming $C_\zeta=1$ and $C_\beta=1$ for $\sigma\geqslant 1/2$, we can use the reflection formulas for these functions to arrive at

$$C_\beta=\left(\frac{2}{\pi}\right)^{1/2-\sigma},\quad C_\zeta=\left(\frac{1}{\pi}\right)^{1/2-\sigma},\quad \sigma\leqslant 1/2. \tag{76}$$

This result is illustrated in Table I, where the difference between numerical results and the formulas (76) evidently illustrates the accuracy of the former.

Our second numerical procedure is to find the minimum value of the modulus of a function such as $\log(|\zeta(1/2+\delta+it)|/t^\mu)$, for t ranging over N equally spaced values between $n-1/2$ and $n+1/2$. This minimum value is plotted as a function of n, and the exponent μ chosen to yield as flat a graph as possible, for a range of values of δ. The exponent values resulting for both ζ and β are again found to be equal, and in accord with (75).

If we consider $G_0(s)$, using (75) and (76), we have

TABLE I. The coefficients of the leading terms in ζ and β.

σ	$\log C_\zeta$	(76)	$\log C_\beta$	(76)

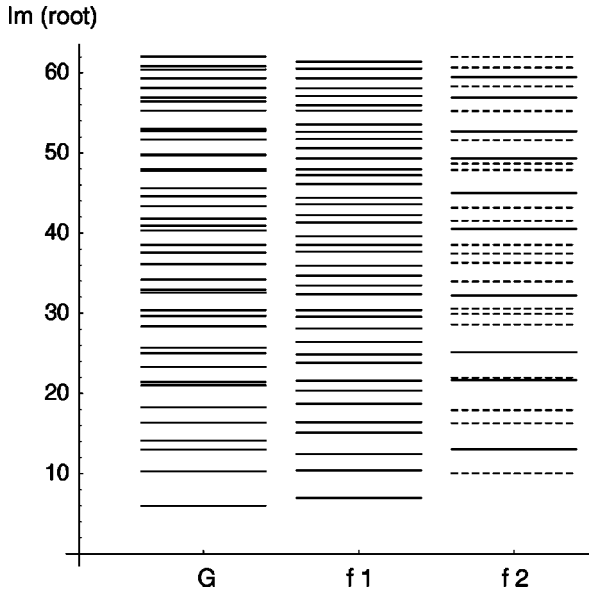

FIG. 5. Imaginary parts of the roots of $G(s)$, $f_1(s)$ and $f_2(s)$. For the first two, all roots have $\mathrm{Re}(s)=0$, while for the third function, those with this property are indicated by dashed lines, and those off the line by solid lines. Note that the roots off the critical line come in pairs, with equal imaginary parts and opposite real parts.

$$|G_0(\sigma+it)| \sim 4\left|\frac{\Gamma(1/2+\sigma+it)}{\pi^{1/2+\sigma+it}}\right| \sim 4\sqrt{2}\left(\frac{t}{\pi}\right)^{\sigma} e^{-\pi t/2}, \tag{77}$$

for $\sigma>0$ and $t>0$. Since $G_0(s)$ is even, (77) holds for with $|\sigma|$ replacing σ.

B. Distributions of zeros

We next consider the distributions of zeros of G_0, f_1, and f_2. We have numerically determined the zeros up to modulus of the argument around 60 using an algorithm based on the argument principle.[16] We have found that the zeros of G_0 and f_1 both lie on the line $\mathrm{Re}(s)=0$, while those of f_2 are mixed, with some lying on the critical line and others not. The imaginary parts of the roots found are shown in Fig. 5, while the roots of f_2 are shown in Fig. 6. Note that about half the roots of f_2 shown lie on $\mathrm{Re}(s)=0$. The roots of $G_0(s)$ are associated with those of $\beta(s+1/2)$ and $\zeta(s+1/2)$, with the former having around twice the density of roots of the latter. It is to be noted that the zeros of $f_1(s)$ occur for points where the arguments of the two zeta functions do not have $\mathrm{Re}(s)=1/2$. At these points, if we write

$$f_1(s)=f_1^+(s)+f_1^-(s), \quad f_1^+(s)=2\zeta(1+2s)\frac{\Gamma(1/2+s)}{\pi^{1/2+s}},$$

$$f_1^-(s)=2\zeta(1-2s)\frac{\Gamma(1/2-s)}{\pi^{1/2-s}}, \tag{78}$$

then we find the roots exhibited have the property that

$$\mathrm{Re}(f_1^+)=0=\mathrm{Re}(f_1^-), \quad \mathrm{Im}(f_1^+)=-\mathrm{Im}(f_1^-). \tag{79}$$

Given that the function $f_2(s)$ has zeros off the critical line, it is interesting to compare the order of this function with that of $G_0(s)$. Using the same method as described in the previous sub-section, we have verified that the function $f_2(\sigma+it)\exp(\pi t/2)$ scales as t^{σ} for large and positive σ. In Fig. 7 we compare the asymptotic order for the two functions $G_0(\sigma$

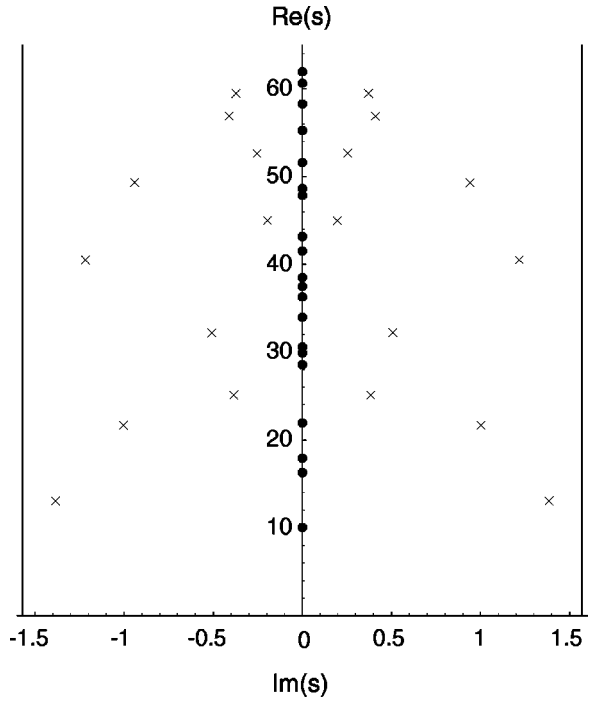

FIG. 6. Distribution of the lowest roots of $f_2(s)$ for $\mathrm{Re}(s) \in [-\pi/2, \pi/2]$ (the limits of this interval are shown by the lateral vertical lines. The roots on the imaginary axis are marked by dots.

$+it)\exp(\pi t/2)/t^{\sigma}$ or $4\sqrt{2}/\pi^{\sigma}$, from (77), and $f_2(\sigma+it)\exp(\pi t/2)/t^{\sigma}$. Note the change in the behavior of f_2 at $\sigma=1$, in contrast with the smoothly varying G_0. We can conclude that $f_2(s)$ does not behave asymptotically in the same way as $G_0(s)$, and thus that the presence of zeros of the former off the critical line is not in contradiction with the Lindelöf hypothesis.

VII. CONCLUSIONS

We have exhibited here some analytic properties of lattice sums in two dimensions, concentrating on results for the square lattice. The properties we have exhibited are interesting, and indicate that there is much yet to be understood about these sums. Their link with the Riemann hypothesis is one topic which merits further exploration. We have seen that the Catalan beta function shares many of the properties of the Riemann zeta function, and is connected to it in Hardy's formula for radial lattice sums over the square lattice. This suggests the exploration of

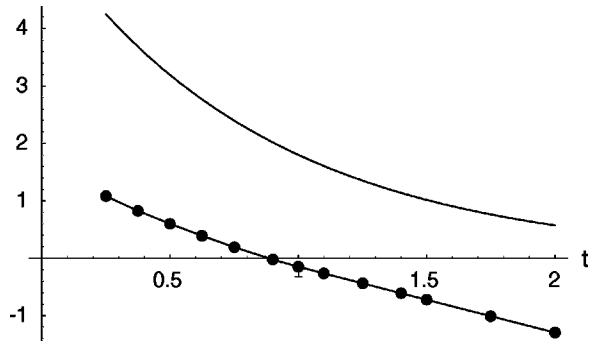

FIG. 7. Continuous line: $|G_0(\sigma+it)| \sim 4\sqrt{2}/\pi^{\sigma}$—see (77). Line with points: the asymptotic estimate for the limit of $f_2(\sigma+it)\exp(\pi t/2)/t^{\sigma}$ for large t, as a function of σ.

radial lattice sums for other arrays, and of angular lattice sums, in the light of the properties we have shown for $\sigma_{1+s}^{(4)}$. This may result in the identification of other analytic functions sharing essential characteristics with the zeta function.

We might call such functions ''complementary zeta functions.'' Characteristics required of them would be the existence of a reflection formula, reduction to a form even about the critical line, and numerical evidence for the confinement of zeros to the critical line. Evidence we have presented for the square array shows that $G_0(s)$ and $G_4(s)$ may well belong to this family, and we conjecture that, for general m, $G_{4m}(s)$ will also belong to it. Of course, it will be interesting to investigate other two-dimensional lattices to see whether similar functions occur for them.

APPENDIX: RECTANGULAR AND ANGULAR ARRAY SUMS

We now consider sums over inverse powers of the distance from the origin for the rectangular array, with periods d_1 and d_2 along the x and y axes, respectively. The result will be a rapidly convergent Macdonald function series of the type derived by Kober.[4] Given the series, by successive differentiation with respect to the periods d_1 and d_2, one can obtain Macdonald function series for angular lattice sums. We illustrate the procedure by deriving the series for $\sigma_{1+s}^{(4)}$.

We consider the nondimensionalized sum:

$$\sigma_{1+s}^{(0)}=(d_1d_2)^{(1+s)/2}\sum_{p\neq 0}\frac{1}{(p_1^2d_1^2+p_2^2d_2^2)^{(1+s)/2}}. \tag{A1}$$

The procedure we follow is based on that of Glasser.[17] We represent the inverse power of the distance as a Mellin transform, apply Jacobi's transformation from the theory of theta functions, and separate out the terms from the axes $p_1=0$ and $p_2=0$, before using Hobson's integral

$$\int_0^\infty t^{s-1}e^{-pt}e^{-q/t}dt=2\left(\frac{q}{p}\right)^{(s/2)}K_s(2\sqrt{qp}). \tag{A2}$$

The result is

$$\begin{aligned}\sigma_{1+s}^{(0)}(d_1,d_2)=&2\zeta(1+s)\left(\frac{d_1}{d_2}\right)^{(1+s)/2}+2\frac{\Gamma(s/2)}{\Gamma((s+1)/2)}\sqrt{\pi}\zeta(s)\left(\frac{d_2}{d_1}\right)^{(s-1)/2}\\&+\frac{8\pi^{(1+s)/2}}{\Gamma((1+s)/2)}\left(\frac{d_1}{d_2}\right)^{1/2}\sum_{p_1=1}^{\infty}\sum_{p_2=1}^{\infty}\left(\frac{p_2}{p_1}\right)^{s/2}K_{s/2}\left(\frac{2\pi d_1p_1p_2}{d_2}\right).\end{aligned} \tag{A3}$$

Note the apparent asymmetry between d_1 and d_2 in this formula arises from the arbitrary choice as to whether the Jacobi transform applies to p_1 or to p_2. An alternative and equivalent expression arises if d_1,p_1 and d_2,p_2 are interchanged. As a numerical example of (A2), if we choose $s=3.43+4.68i$, $d_1=1.0$, $d_2=0.73$, we can use direct summation of the left-hand side to obtain $3.300\,85+1.380\,22i$, and either form of the right-hand side to obtain as a rapidly convergent series the same value. Putting $d_1=d_2$ in (A3), we obtain Kober's result.[4]

The next step is to take the partial derivative of (A3) with respect to d_1. Using the Macdonald function recurrence relations, this gives

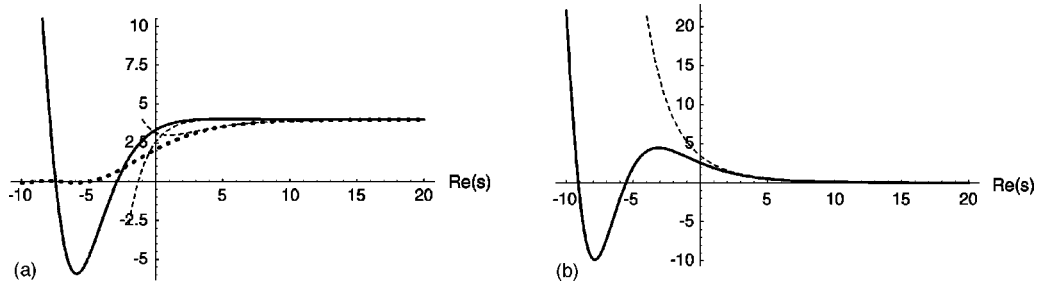

FIG. 8. Left: real part of $\sigma_{1+s}^{(4)}$ for (dotted curve) $\mathrm{Im}(s)=0$ and (solid curve) $\mathrm{Im}(s)=5$. Right: the corresponding imaginary part for $\mathrm{Im}(s)=5$. Dashed lines correspond to the nearest neighbor expansion (A7).

$$d_1^{(1+s)/2}d_2^{(1+s)/2}\sum_{p\neq 0}\frac{p_1^2}{(p_1^2d_1^2+p_2^2d_2^2)^{(1+s)/2}}$$
$$=2\frac{\Gamma(s/2)}{\Gamma((s+1)/2)}\sqrt{\pi}\zeta(s-2)\left(\frac{d_2}{d_1}\right)^{(s-1)/2}$$
$$+\frac{8\pi^{(1+s)/2}}{\Gamma((1+s)/2)}\left(\frac{d_1}{d_2}\right)^{1/2}\sum_{p_1=1}^{\infty}\sum_{p_2=1}^{\infty}\frac{p_2^{s/2}}{p_1^{s/2-2}}K_{s/2}\left(\frac{2\pi d_1p_1p_2}{d_2}\right). \tag{A4}$$

For $s=5.43+4.68i$, $d_1=1.0$, $d_2=0.73$, both the left-hand and right-hand sides of (A4) give the value $0.432\,88-0.761\,512i$. A second relation involving p_2^2 in the numerator rather than p_1^2 follows by interchanging p_1,d_1 and p_2,d_2.

We now take the partial derivative of (A3) with respect to d_2. The result is

$$d_1^{(1+s)/2}d_2^{(1+s)/2}\sum_{p\neq 0}\frac{p_1^2p_2^2}{(p_1^2d_1^2+p_2^2d_2^2)^{(1+s)/2}}$$
$$=\frac{\Gamma(s/2-1)}{\Gamma((s+1)/2)}\sqrt{\pi}\zeta(s-4)\left(\frac{d_2}{d_1}\right)^{(s-5)/2}$$
$$+\frac{4\pi^{(s-1)/2}}{\Gamma((1+s)/2)}\left(\frac{d_1^3}{d_2^3}\right)^{1/2}\sum_{p_1=1}^{\infty}\sum_{p_2=1}^{\infty}\frac{p_2^{s/2-1}}{p_1^{s/2-3}}$$
$$\times K_{s/2-1}\left(\frac{2\pi d_1p_1p_2}{d_2}\right)-\frac{8\pi^{(s+1)/2}}{\Gamma((1+s)/2)}\left(\frac{d_1^5}{d_2^5}\right)^{1/2}$$
$$\times\sum_{p_1=1}^{\infty}\sum_{p_2=1}^{\infty}\frac{p_2^{s/2}}{p_1^{s/2-4}}K_{s/2-2}\left(\frac{2\pi d_1p_1p_2}{d_2}\right). \tag{A5}$$

For $s=7.43+4.68i$, $d_1=1.0$, $d_2=0.73$, both the left-hand and right-hand sides of (A4) give the value $-0.053\,880\,1-0.146\,562i$.

The final step is to use these relations to evaluate

$$\sigma_{1+s}^{(4)}=(d_1d_2)^{(1+s)/2}\sum_{p\neq 0}\frac{e^{4i\varphi_p}}{R_p^{1+s}}=(d_1d_2)^{(1+s)/2}\sum_{p\neq 0}\frac{1}{R_p^{1+s}}-8(d_1d_2)^{(5+s)/2}\sum_{p\neq 0}\frac{p_1^2p_2^2}{R_p^{5+s}}. \tag{A6}$$

For $s=7.43+4.68i$, $d_1=1.0$, $d_2=0.73$, both the left-hand and right-hand sides of (A6) give the value $5.986\,87+4.832\,69i$. A second check on (A5) is to use it to evaluate $\sigma_4^{(4)}$, for $d_1=d_2$. The value obtained is $3.151\,200\,2$, to be compared with the value obtained by hand ($3.151\,204$) by Lord Rayleigh,[2] using hyperbolic series.

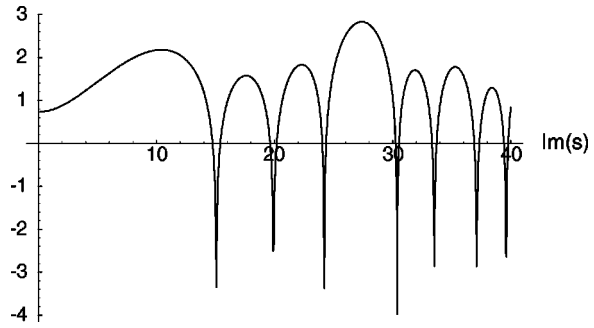

FIG. 9. The logarithm of the absolute value of $\sigma_{1+s}^{(4)}$ on the critical line $\mathrm{Re}(s)=0$, for $d_1=d_2$.

Figure 8 shows the behavior of $\sigma_{1+s}^{(4)}$, with $d_1=d_2$, as a function of the real part of its argument, for two constant values of the imaginary part. For $\mathrm{Im}(s)=0$, this sum has zeros at $\mathrm{Re}(s)=-5,-7,-9,\ldots$, corresponding to the poles of the factor $\Gamma((5+s)/2)$ present in the denominator of the second term in (A5), which coincide with the later poles of the factor $\Gamma((1+s)/2)$ in the first term. Note from Fig. 8 how the value of the sum tends towards the nearest-neighbor contribution (4) as $\mathrm{Re}(s)$ increases. The first three terms in its nearest-neighbor expansion, useful when $\mathrm{Re}(s)$ is sufficiently positive (say greater than 5), are

$$\sigma_{1+s}^{(4)}(d_1,d_1)=4\left(1-\frac{1}{2^{(1+s)/2}}+\frac{1}{2^{1+s}}+\cdots\right). \tag{A7}$$

Figure 9 shows the behavior of the logarithm of the absolute value of $\sigma_{1+s}^{(4)}$ along the critical line $\mathrm{Re}(s)=0$. The first seven zeros of this function are evident. Note that the sum is not real on the critical line. However, numerical investigations have verified that the function $G_4(s)$ of (59) is an even function of s, in keeping with (58), and is real on $\mathrm{Re}(s)=0$. It is also real on $\mathrm{Im}(s)=0$, but has no zeros on this line.

This function plays the same role for $\sigma_{1+s}^{(4)}(d_1,d_1)$ as does the function

$$G_0\left(\frac{s}{2}\right)=\frac{\sigma_{1+s}^{(0)}(d_1,d_1)\Gamma((1+s)/2)}{\pi^{(1+s)/2}}=4\,\frac{\zeta((1+s)/2)\beta((1+s)/2)\Gamma((1+s)/2)}{\pi^{(1+s)/2}} \tag{A8}$$

for the radial sum $\sigma_{1+s}^{(0)}$.

(Received 17 December 2003; accepted 19 March 2004;
published online 27 May 2004)

We prove the existence of the Bogoliubov $S(g)$ operator for the $(:\phi^4:)_2$ quantum field theory for coupling functions g of compact support in space and time. The construction is nonperturbative and relies on a theorem of Kisyński. It implies almost automatically the properties of unitarity and causality for disjoint supports in the time variable. © *2004 American Institute of Physics.*

I. INTRODUCTION AND SUMMARY

Recent progress in perturbative quantum field theory for the Stückelberg–Bogoliubov–Epstein–Glaser $S(g)$ operator[1,2] in non-Abelian gauge theories[3] (see also Ref. 4), revived interest in a long-standing problem: is it possible to construct $S(g)$ *nonperturbatively* in quantum field theory? This question is of obvious relevance to theories where the (dimensionless) coupling constant is large ($\gtrsim 1$), e.g., strong interactions, for which perturbation theory is not expected to be asymptotic.

For certain super-renormalizable theories—the $(:P(\phi):)_2$ theories—there exists, for weak coupling, a construction of the true (LSZ–Haag–Ruelle) scattering operator, due to Osterwalder and Séneor[5] and Eckmann, Epstein, and Fröhlich,[6] one of the crowning achievements of constructive quantum field theory which started with the pioneering work on the particle structure of weakly coupled $P(\phi)_2$ model by Glimm, Jaffe, and Spencer.[7] The method of proof was, however, perturbative: the perturbation series for the scattering operator was shown to be asymptotic.

In contrast to the true scattering operator, $S(g)$ is, in perturbation theory, the generating functional for the time-ordered products of Wick polinomials. However, on the basis of Ref. 8 one might expect that, in the present massive case, defining

$$g_\varepsilon(x) \equiv g(\varepsilon x), \quad g \in \mathcal{S}(\mathbb{R}^2)$$

the (adiabatic) limit

$$S\Psi \equiv \lim_{\varepsilon \to 0} \; S(g_\varepsilon)\Psi \tag{1.1}$$

exists, $\forall \quad \Psi \in \mathcal{D}$, where $\mathcal{D}$ is a Poincaré-invariant dense set in Fock space $\mathcal{F}$. Thus we expect that the physical S-matrix elements are obtainable as

$$(\Phi, S\Psi) \equiv \lim_{\varepsilon \to 0} \quad (\Phi, S(g_\varepsilon)\Psi), \tag{1.2}$$

[b]Electronic mail: lmanzoni@fma.if.usp.br
[c]Present address: Department of Mathematics, University of California, Davis, CA 95616-8633; electronic mail: oscar@math.ucdavis.edu

with $\Phi \in \mathcal{F}$, $\Psi \in \mathcal{D}$, where $g(0)>0$ should be identified with the coupling constant. In Ref. 4 an algebraic construction of the adiabatic limit was performed for perturbative QED.

A natural nonperturbative approach to construct $S(g)$ for the $(:\phi^4:)_2$ theory (and hopefully for any super-renormalizable QFT) consists in proving the existence of a (unique) solution of the evolution (propagator) equation ($\hbar=1$),

$$i\frac{\partial U(t,s)}{\partial t}\Psi=\tilde{H}(t)U(t,s)\Psi, \tag{1.3}$$

with

$$\tilde{H}(t)\equiv H_g(t)+M\mathbf{1}, \tag{1.4}$$

where M is a constant introduced in order to make $\tilde{H}(t)$ a positive operator (see Sec. II) and

$$H_g(t)\equiv H_0+V_g(t). \tag{1.5}$$

In (1.3) $U(t,s)$ is a two-parameter family of unitary operators on (symmetric) Fock space $\mathcal{F}$. H_0 is the free field Hamiltonian corresponding to a zero-time scalar field $\phi(x,0)$ of mass m,[9,10] and, formally, for

$$g\in\mathcal{D}(\mathbb{R}^2), \quad g\geqslant 0, \tag{1.6}$$

let

$$V_g(t)=\int \mathrm{d}x\, g(x,t):\phi^4(x,0):. \tag{1.7}$$

Above, $\mathcal{D}$ denotes the Schwartz space of infinitely differentiable functions of compact support. The operators in (1.3) are expected to satisfy the propagator conditions:

$$U(t,s)U(s,r)=U(t,r), \quad -\infty<r\leqslant s\leqslant t<\infty,$$

$$U(t,t)=\mathbf{1}, \quad \forall \quad t\in\mathbb{R}. \tag{1.8}$$

The vector Ψ is supposed to belong to the domain $D(\tilde{H}(s))$ (dense in $\mathcal{F}$) such that

$$U(t,s)D(\tilde{H}(s))\subset D(\tilde{H}(t)). \tag{1.9}$$

Above and elsewhere in this paper $D(A)$ denotes the domain of an operator A.

Under assumptions (1.3) and (1.9), defining the ''Dirac (or interaction) picture propagator'' by

$$U^D(t,s)\equiv e^{i(H_0+M)t}U(t,s)e^{-i(H_0+M)s}, \tag{1.10}$$

it follows that

$$i\frac{\partial U^D(t,s)}{\partial t}\Psi=H_g^D(t)U^D(t,s)\Psi, \tag{1.11}$$

for $\Psi\in e^{i(H_0+M)s}D(H_g(s))$, which is a dense set in $\mathcal{F}$ for every s, where

$$H_g^D(t)\equiv e^{iH_0t}V_g(t)e^{-iH_0t}. \tag{1.12}$$

One may then define

$$S(g)\equiv s-\lim_{\substack{t\to+\infty\\ s\to-\infty}} U^D(t,s), \tag{1.13}$$

if the above limit exists; $S(g)$ is expected to satisfy

(i) $S(g)^{-1}=S(g)^*$ (*unitarity);*
(ii) $S(g_1+g_2)=S(g_1)S(g_2)$ if
$(ii.a)$ supp $g_1>$supp g_2 and/or
$(ii.b)$ supp $g_1\sim$supp g_2 (*causality),*
where "$\sim$" means "spacelike to," i.e., $(x-y)^2=(t_1-t_2)^2-(x_1-x_2)^2<0$, $\forall\ (t_1,x_1)\in$supp g_1 and $\forall\ (t_2,x_2)\in$supp g_2;
(iii) there exists a unitary representation $U(a,\Lambda)$ of the Poincaré group on $\mathcal{F}$—the scalar field representation of mass m—such that

$$U(a,\Lambda)S(g)U(a,\Lambda)^{-1}=S(\{a,\Lambda\}g),$$

where

$$(\{a,\Lambda\}g)(x)=g(\Lambda^{-1}(x-a))$$

(*Lorentz covariance*).

The main difficulty to proving (1.3)–(1.9) is that $D(H_g(t))$ is, for each $g\in\mathcal{D}(\mathbb{R}^2)$, time-dependent. In Sec. II we state the basic existence theorem we employ, which is due to Kisyński[11] (see also Ref. 12). In Sec. III we prove our central existence theorem for $S(g)$, as well as properties (i) and $(ii.a)$. In Sec. IV we provide a brief summary of the remarkable results of Ref. 11, establishing a concrete link between them and our conditions in Sec. III. We leave the conclusion and open problems to Sec. V. The Appendix summarizes some of the basics elements of the construction of Refs. 11 and 13 for the convenience of the reader.

II. THE BASIC EXISTENCE THEOREM

The Hamiltonian of the $(:\phi^4:)_2$ theory[14] is given by (1.5), where

$$H_0=\int \omega(k)a^*(k)a(k)\mathrm{d}k, \tag{2.1}$$

with

$$\omega(k)=(k^2+m^2)^{1/2}, \tag{2.2}$$

is the free field Hamiltonian on symmetric Fock space $\mathcal{F}$, with

$$[a(k),a^*(k')]=\delta(k-k'). \tag{2.3}$$

The self-interaction V_g is given by (1.7), with the $t=0$ scalar free field of mass m:

$$\phi(x)=\frac{1}{(4\pi)^{1/2}}\int e^{-ikx}[a^*(k)+a(-k)]\omega(k)^{-1/2}\mathrm{d}k. \tag{2.4}$$

Thus V_g may be written[14]

$$V_g(t)=\sum_{j=0}^{4}\binom{4}{j}\int a^*(k_1)\cdots a^*(k_j)a(-k_{j+1})\cdots a(-k_4)\tilde{g}\left(\sum_{i=1}^{4}k_i,t\right)\prod_{i=1}^{4}\omega(k_i)^{-1/2}\mathrm{d}k_i, \tag{2.5}$$

where

$$\tilde{g}(k,t)\equiv\int \mathrm{d}x\, e^{ikx}g(x,t). \tag{2.6}$$

The number operator N is defined by

$$N=\int \mathrm{d}k\, a^*(k)a(k). \tag{2.7}$$

By (Ref. 14 Lemma 2.2)

$$\|(N+\mathbf{1})^{-j/2}\ \ V_g(t)\ \ (N+\mathbf{1})^{-(4-j)/2}\|\leqslant\ \text{const}\ \ \|W\|_{L^2},\quad |j|\leqslant 4, \tag{2.8}$$

where

$$W(k,t)\equiv\tilde{g}\left(\sum_{i=1}^{4}k_i,t\right)\prod_{i=1}^{4}\omega(k_i)^{-1/2}. \tag{2.9}$$

The above-mentioned lemma just uses the Fock space definitions of the creation and annihilation operators and the Schwartz inequality. We need two theorems due to Glimm and Jaffe, which we state as adapted to our case:

Theorem II.1 (Ref. 14): (**a**) *$H(t)$ is self-adjoint on the domain*

$$D(H(t))=D(H_0)\cap D(V_g(t)), \tag{2.10}$$

where $D(V_g(t))$ is the domain of the unique self-adjoint closure of $V_g(t)$ on the domain

$$D_0=\bigcap_{n=0}^{\infty}D(H_0^n). \tag{2.11}$$

(**b**) *$H(t)$ is essentially self-adjoint on D_0.*

Theorem II.2 (Ref. 10): *For each $g\in\mathcal{D}(\mathbb{R}^2)$, there exists $0<M_g<\infty$ such that*

$$H_g(t)\geqslant -M_g\mathbf{1} \tag{2.12}$$

as a bilinear form on $D_0\times D_0$.

By Theorem II.2 and (**b**) of Theorem II.1, $H(t)$ is a semi-bounded self-adjoint operator, and thus defining

$$M=M_g+c, \tag{2.13}$$

for some $c>0$, then

$$\tilde{H}(t)=H_g(t)+M\mathbf{1}\geqslant c\mathbf{1} \tag{2.14}$$

is a positive self-adjoint operator. Let $\mathcal{F}_{+2}=D(H_0)$ endowed with the Hilbert space structure given by

$$f_{+2}(x,y)=\langle(H_0+1)x,(H_0+1)y\rangle \tag{2.15}$$

and denote $\sqrt{f_{+2}(x,x)}$ by $\|x\|_{+2}$. By the Riesz lemma we may associate $\mathcal{F}_{+2}$ and the space $\mathcal{F}_{-2}$ of continuous conjugate linear functions on $\mathcal{F}_{+2}$. While we consider $\mathcal{F}$ isomorphic to its conjugate dual space $\mathcal{F}^*$, the isomorphism being the identity, the isomorphism of $\mathcal{F}_{+2}$ with $\mathcal{F}_{-2}$ is given by the operator $(H_0+1)^2$, because

$$\|v\|_{-2}=\sup\{|\langle w,v\rangle|\ :\ \|w\|_{+2}\leqslant 1\}.$$

Since $f_{+2}(x,y)=\langle x,(H_0+1)^2y\rangle$, we have

$$\|(H_0+1)^2y\|_{-2}=\sup\{|\langle w,(H_0+1)^2y\rangle| : \|w\|_{+2}=\sqrt{\langle w,(H_0+1)^2w\rangle}\leqslant 1\}=\|(H_0+1)y\|=\|y\|_{+2},$$

from which we also have, for $y\in\mathcal{F}$,

$$\|y\|_{-2}=\|(H_0+1)^{-1}y\|, \tag{2.16}$$

which explains the notation $\mathcal{F}_{-2}$. Clearly $\|x\|\leqslant\|x\|_{+2}$ for $x\in\mathcal{F}_{+2}$, and by (2.16), $\|y\|_{-2}\geqslant\|y\|$ for $y\in\mathcal{F}$. Thus, under the above conditions:

$$\mathcal{F}_{+2}\subset\mathcal{F}\subset\mathcal{F}_{-2}. \tag{2.17}$$

A bounded operator $\mathbf{B}$ from $\mathcal{F}_{+2}$ to $\mathcal{F}_{-2}$ is thus such that, for some constant c,

$$\|\mathbf{B}\psi\|_{-2}\leqslant c\|\psi\|_{+2}, \quad \psi\in\mathcal{F}_{+2}, \tag{2.18}$$

or, by (2.15) and (2.16),

$$\|(H_0+1)^{-1}\mathbf{B}\psi\|\leqslant c\|(H_0+1)\psi\|, \quad \psi\in\mathcal{F}_{+2}, \tag{2.19}$$

or

$$\|(H_0+1)^{-1}\mathbf{B}(H_0+1)^{-1}\phi\|\leqslant c\|\phi\|, \quad \phi\in\mathcal{F}. \tag{2.20}$$

Now, by (2.14), we may define $\tilde{H}(t)^{1/2}$, and, by (2.8) for $x\in\mathcal{F}_{+2}$, the closed sesquilinear form

$$S(x,y)=\langle\tilde{H}(t)^{1/2}x,\tilde{H}(t)^{1/2}y\rangle, \tag{2.21}$$

which is, by the form representation theorem,[15] the form of the operator $\tilde{H}(t)$. In Sec. III we show the explicit connection of (2.21) to the basic theorem of Kisyński,[11] which we state in the form of Theorems II.23 and II.24 of Ref. 12, with slight changes.

In the theorem stated below, $\mathcal{F}_{\pm2}$ have been defined in (2.15)–(2.17).

Theorem II.3: *Let (2.17) hold and $\tilde{H}(t)$ $(-T\leqslant t\leqslant S)$ be a one-parameter family of strictly positive [i.e., satisfying (2.14)] self-adjoint operators on $\mathcal{F}$. Suppose that $\tilde{H}(t):\mathcal{F}_{+2}\to\mathcal{F}_{-2}$ are bounded and twice differentiable, with a continuous second derivative, in the $\|\cdot\|_{-2,2}$-norm (2.18). Then there exists a two-parameter family $U(t,s)$ of unitary propagators satisfying (1.3), (1.8), and (1.9).*

III. THE CENTRAL EXISTENCE THEOREM

We now use Theorem II.3 in order to prove our main

Theorem III.1: *The $(:\phi^4:)_2$ theory, as defined by (1.5), (1.6), (1.7), (2.1), and (2.2), satisfies a stronger condition than the hypothesis of Theorem II.3: $H_g(\cdot)$ is infinitely differentiable as an operator from $\mathcal{F}_{+2}$ to $\mathcal{F}_{-2}$.*

In order to prove Theorem III.1 we first show a useful auxiliary result.

Lemma III.1: Let W be defined by (2.9). Then there exists $r>1$ such that

$$\|W(\cdot,t)\|_2\leqslant\text{const}\ \ \|g(\cdot,t)\|_r, \tag{3.1}$$

where

$$\|g(\cdot,t)\|_r=\left(\int_{-\infty}^{+\infty}\mathrm{d}k|\tilde{g}(k,t)|^r\right)^{1/r}. \tag{3.2}$$

Proof: We have

$$\|W(\cdot,t)\|_2^2=\int_{-\infty}^{+\infty}\mathrm{d}k_1\omega(k_1)^{-1}\cdot\int_{-\infty}^{+\infty}\mathrm{d}k_2\omega(k_2)^{-1}\cdot\int_{-\infty}^{+\infty}\mathrm{d}k_3\omega(k_3)^{-1}$$
$$\cdot\int_{-\infty}^{+\infty}\mathrm{d}k'|\tilde{g}(k',t)|^2\omega\left(k'-\sum_{i=1}^{3}k_i\right)^{-1} \tag{3.3}$$

by the change of variable $k'=\Sigma_{i=1}^{3}k_i$. Introducing further the variables K_1,K_2,K_3 such that

$$K_1=k_1+k_2+k_3,$$

$$K_2=k_1+k_2,$$

$$K_3=k_1,$$

so that $k_3=K_1-K_2$ and $k_2=K_2-K_3$, we write (3.3) as

$$\|W(\cdot,t)\|_2^2=(\omega^{-1}*(\omega^{-1}*(\omega^{-1}*(\omega^{-1}*|\tilde{g}|^2))))(0), \tag{3.4}$$

where the convolution is defined as usual by

$$(f*g)(k)=\int_{-\infty}^{+\infty}\mathrm{d}k_1 f(k-k_1)g(k_1).$$

Consider, now, the quantity associated to the right-hand side of (3.3):

$$I(q,t)\equiv\int_{-\infty}^{+\infty}\mathrm{d}k_1\ \ \omega(k_1-q)^{-1}\cdot\int_{-\infty}^{+\infty}\mathrm{d}k_2\ \ \omega(k_2)^{-1}\cdot\int_{-\infty}^{+\infty}\mathrm{d}k_3\ \ \omega(k_3)^{-1}$$
$$\cdot\int_{-\infty}^{+\infty}\mathrm{d}k'\ \ |\tilde{g}(k',t)|^2\omega\left(k'-\sum_{i=1}^{3}k_i\right)^{-1}. \tag{3.5}$$

Since $g\in\mathcal{D}(\mathbb{R})$ this function is differentiable, hence continuous, in q for any compact subset containing the origin, which implies that $I(0,t)\leqslant\|I(\cdot,t)\|_\infty$ (where $\|\cdot\|_\infty$-norm is with respect to the q-variable).

We now apply Young's inequality[16]

$$\|f*g\|_r\leqslant C_{rpq}\|f\|_p\|g\|_q$$

with C_{rpq} a constant and

$$\frac{1}{p}+\frac{1}{q}=1+\frac{1}{r}$$

to (3.4), starting with $r=\infty$. Above,

$$\|f\|_p=\left(\int_{-\infty}^{+\infty}\mathrm{d}k|f(k)|^p\right)^{1/p}.$$

We thus obtain

$$\|W(\cdot,t)\|_2^2\leqslant C_{2r_1r_2}\|\omega^{-1}\|_{r_1}\ \ \|(\omega^{-1}*(\omega^{-1}*(\omega^{-1}*|\tilde{g}|^2)))\|_{r_2}$$

with $r_1^{-1}+r_2^{-1}=1$, and so on, up to (indicating all the constants resulting from the Young's inequality by C')

$$\|W(\cdot,t)\|_2^2 \leqslant C' \|\omega^{-1}\|_{r_1} \ \|\omega^{-1}\|_{r_3} \ \|\omega^{-1}\|_{r_5} \ \|\omega^{-1}\|_{r_7} \ \||\tilde{g}|^2\|_{r_8} \tag{3.6}$$

with $r_3^{-1}+r_4^{-1}=1+r_2^{-1}$, $r_5^{-1}+r_6^{-1}=1+r_4^{-1}$, $r_7^{-1}+r_8^{-1}=1+r_6^{-1}$. We require $r_i>1$, for $i=1,3,5,7$, so that $\|\omega^{-1}\|_{r_i}<\infty$, the choice $r_1=r_2=2$, $r_3=r_4=\frac{4}{3}$, $r_5=r_6=\frac{8}{7}$, $r_7=r_8=\frac{16}{15}$ is, for instance, possible. By (3.6)

$$\|W(\cdot,t)\|_2^2 \leqslant C \||\tilde{g}|^2\|_r \tag{3.7}$$

with

$$r>1. \tag{3.8}$$

Above

$$\| \ |\tilde{g}|^2 \ \|_r = \left(\int_{-\infty}^{+\infty} \mathrm{d}k |\tilde{g}(k,t)|^{2r} \right)^{1/r}. \tag{3.9}$$

obtaining finally, (3.7). □

Proof of III.1: By (2.8),

$$\|(N+\mathbf{1})^{-1} V_g(t) (N+\mathbf{1})^{-1}\| \leqslant \text{const} \|W\|_{L^2} \tag{3.10}$$

and, by (2.2), $\omega(k) \geqslant m\mathbf{1}$; hence

$$\|(H_0+\mathbf{1})^{-1}(N+\mathbf{1})\| \leqslant d_1, \quad \|(N+\mathbf{1})(H_0+\mathbf{1})^{-1}\| \leqslant d_2,$$

for constants d_1 and d_2. Hence, by (3.10) and (3.1),

$$\|(H_0+\mathbf{1})^{-1} V_g(t) (H_0+\mathbf{1})^{-1}\| \leqslant \text{const} \|g(\cdot,t)\|_r \tag{3.11}$$

with $r>1$: *a fortiori* this holds for $H_g(\cdot)$ by (1.5), hence

$$\|(H_0+\mathbf{1})^{-1} H_g(t) (H_0+\mathbf{1})^{-1}\| \leqslant \text{const} \|g(\cdot,t)\|_r. \tag{3.12}$$

By (2.20) and Theorem II.3 we only need to prove that the left-hand side of (3.12) is three times differentiable. We shall prove that

$$\left\| (H_0+\mathbf{1})^{-1} \left(\frac{H_g(t+h)-H_g(t)}{h} - H_g'(t) \right) (H_0+\mathbf{1})^{-1} \right\| \to 0 \qquad \text{as} \qquad h \to 0, \tag{3.13}$$

where

$$H_g'(t) = H_0 + V_{g'}(t) \tag{3.14}$$

with

$$V_{g'}(t) = \int \mathrm{d}x : \phi^4(x,0) : g'(x,t) \tag{3.15}$$

and

$$g'(x,t) \equiv \frac{\partial g(x,t)}{\partial t}.$$

We now prove (3.13). By (3.12)

$$J \equiv \left\| (H_0+\mathbf{1})^{-1}\left(\frac{H_g(t+h)-H_g(t)}{h}-H_g'(t)\right)(H_0+\mathbf{1})^{-1}\right\|$$
$$\leqslant \text{const}\left[\int_{-\infty}^{\infty} \mathrm{d}k \left| \int \mathrm{d}x\, e^{-ikx}\left(\frac{g(x,t+h)-g(x,t)}{h}-g'(x,t)\right)\right|^r\right]^{1/r}. \tag{3.16}$$

We now write the integral on the right-hand side of (3.16) as

$$\int_{-\infty}^{\infty} \mathrm{d}k\{\cdots\} = \int_{-\infty}^{1} \mathrm{d}k\{\cdots\} + \int_{-1}^{1} \mathrm{d}k\{\cdots\} + \int_{1}^{\infty} \mathrm{d}k\{\cdots\}$$

and estimate the last integral above

$$J_+ \equiv \int_1^{\infty} \mathrm{d}k \left| \int \mathrm{d}x\, e^{-ikx}\left(\frac{g(x,t+h)-g(x,t)}{h}-g'(x,t)\right)\right|^r$$
$$\leqslant \int_1^{\infty} \frac{\mathrm{d}k}{k^{2r}} \left| \int \mathrm{d}x\, e^{-ikx}\left(\frac{\partial_x^2 g(x,t+h)-\partial_x^2 g(x,t)}{h}-\partial_x^2 g'(x,t)\right)\right|^r, \tag{3.17}$$

where we have used two partial integrations and $\partial_x \equiv \partial/\partial x$. Let now

$$V(x,t) \equiv \partial_x^2 g(x,t). \tag{3.18}$$

Now V is also an infinitely differentiable function of compact support and

$$V(x,t+h) = V(x,t) + hV'(x,t) + \frac{h^2}{2!}V''(x,t+t_h^*(x)) \tag{3.19}$$

by Taylor's formula with remainder, where $0<t_h^*(x)<h$. Putting (3.19) into (3.17) we get

$$J_+ \leqslant c_r' h^r \left(\int_{-\infty}^{\infty} \mathrm{d}x |V''(x,t+t_h^*(x))|\right)^r \leqslant c_r \quad h^r (\sup_{x,t} |V''(x,t)|)^r,$$

where c_r' and c_r are constants depending on r. The estimate of $J_- \equiv \int_{-\infty}^{-1}\{\cdots\}$ is similar. The estimate of $J_1 \equiv \int_{-1}^{1}\{\cdots\}$ follows along the same lines, but in this case we should not introduce the partial integrations in order to avoid divergences at $k=0$. Then, we obtain

$$J \leqslant \text{const}\, h[A_r(\sup_{x,t}|g''(x,t)|)^r + B_r(\sup_{x,t}|V''(x,t)|)^r]^{1/r}$$

with A_r and B_r constants depending on r. Then we have (3.13).

We now notice that the bounds (3.12) *continue to hold* for $H_g'(t)$ with $\|g(\cdot,t)\|_r$ replaced by $\|g'(\cdot,t)\|_r$ on the right-hand side of (3.12). Thus the same proof applies to $H_g'(t)$, $H_g''(t)$, ... and in fact $H_g(t)$ is infinitely differentiable as an operator from $\mathcal{F}_{+2}$ to $\mathcal{F}_{-2}$. □

Proposition III.1: The $S(g)$ matrix for the $(:\phi^4)_2$ theory, as defined in (1.13), is unitary and it satisfies the causality condition for disjoint supports [condition $(ii.a)$—Sec. I].

Proof: The unitarity follows directly from the existence theorems. For the proof of causality it is convenient to explicitly dispose of the dependence of the propagators on the function g. Let $\text{supp}_t g_1 > \text{supp}_t g_2$ and suppose $\text{supp}_t g_1 \subset (r,+\infty)$ and $\text{supp}_t g_2 \subset (-\infty,r)$, where supp_t stands for the support in the time variable. Then, for $t>r>s$ we have

$$U^D_{(g_1+g_2)}(t,s) = U^D_{(g_1+g_2)}(t,r)\,U^D_{(g_1+g_2)}(r,s) \tag{3.20}$$

but

$$i\frac{\partial}{\partial t}U^D_{(g_1+g_2)}(t,r)\Psi = H^D_{(g_1+g_2)}(t)U^D_{(g_1+g_2)}(t,r)\Psi = H^D_{g_1}(t)U^D_{(g_1+g_2)}(t,r)\Psi$$

and, by the uniqueness of the solutions of the above equation, we have $U^D_{(g_1+g_2)}(t,r) = U^D_{g_1}(t,r)$. Analogously, we have $U^D_{(g_1+g_2)}(r,s) = U^D_{g_2}(r,s)$. This, together with (3.20) imply that

$$U^D_{(g_1+g_2)}(t,s) = U^D_{g_1}(t,r)U^D_{g_2}(r,s)$$

from this equation and the fact that $U^D_{g_1}(t,s) = U^D_{g_1}(t,r)$ and $U^D_{g_2}(r,s) = U^D_{g_2}(t,s)$ due to the support properties of g_1 and g_2, we finally have

$$U^D_{(g_1+g_2)}(t,s) = U^D_{g_1}(t,s)U^D_{g_2}(t,s). \tag{3.21}$$

Then, by (3.21) and the definition (1.13), we obtain

$$S(g_1+g_2) = S(g_1)S(g_2).$$

□

IV. THE RELATION BETWEEN KISYŃSKI'S THEORY AND THEOREM III.1

Let us now briefly summarize (without proof) some steps in Kisyński's proof of Theorem II.3. First of all, we will state a crucial auxiliary theorem. Let X be a Banach space with the norm $\|\cdot\|$ and $A(t)$, $t\in[-T_1,T_2]$ $(T_1,T_2>0)$, a family of linear operators in X. Consider the following conditions:

(a) there exists a family $\|\cdot\|_t$, $t\in[-T_1,T_2]$, of norms in X equivalent to $\|\cdot\|$ such that $|\,\|\Psi\|_t - \|\Psi\|_s\,| \leqslant k\,\|\Psi\|_s\,|t-s|$ with $k=\text{const}$, $-T_1\leqslant s,t\leqslant T_2$ and $\Psi\in X$;
(b) for all $t\in[-T_1,T_2]$ the set $D(A(t))$ is dense in X;
(c) there exists a constant $\lambda_0\geqslant 0$ such that $R(\lambda-\epsilon A(t))=X$ and $\|(\lambda-\epsilon A(t))\Psi\|_t \geqslant (\lambda-\lambda_0)\|\Psi\|_t$ for $\epsilon=\pm 1$, $\lambda>\lambda_0$, $t\in[-T_1,T_2]$ and $\Psi\in D(A(t))$;
(d) there exists a family $R(t)$, $t\in[-T_1,T_2]$, of invertible bounded linear operators in X, such that $R(t)$ is twice weakly continuously differentiable in $[-T_1,T_2]$ and $(R(t))^{-1}D(A(t)) = Y = \text{const}\ \forall t\in[-T_1,T_2]$;
(e) $(R(t))^{-1}A(t)R(t)$ is weakly continuously differentiable.

Above $R(A)$ stands for the range of the operator A. Then we have:

Theorem IV.1 (Ref. 11, Theorem 4.4): *Let the conditions* (a)–(e) *be satisfied. Then there exists a two-parameter family of propagators* $U(t,s)$, $-T_1\leqslant s,t\leqslant T_2$, *such that*

$$\Psi(t)\equiv U(t,s)\Psi(s), \quad \Psi(s)\in D(A(s)),$$

is the unique solution of the problem

$$\frac{\mathrm{d}}{\mathrm{d}t}\Psi(t) = A(t)\Psi(t) \tag{4.1}$$

with initial data $\Psi(s)$. *The bounded propagators* $U(t,s)$ *are strongly continuous on* $-T_1\leqslant s,t\leqslant T_2$ *and satisfy*

$$U(t,t)=1\ , \quad \forall\ \ t\in[-T_1,T_2], \tag{4.2}$$

$$U(t,s)U(s,r)=U(t,r), \quad \text{for} -T_1\leqslant r,s,t\leqslant T_2, \tag{4.3}$$

$$U(t,s)D(A(s))=D(A(t)), \quad \text{for} -T_1\leqslant s,t\leqslant T_2, \tag{4.4}$$

besides, $\forall\ s\in[-T_1,T_2]$ *and* $\Psi\in D(A(s))$ *the function* $U(t,s)\Psi$ *is continuously differentiable (in the sense of the norm) in* X*, satisfying*

$$\frac{\mathrm{d}}{\mathrm{d}t}U(t,s)\Psi=A(t)U(t,s)\Psi. \tag{4.5}$$

The method of proof of this theorem is to reduce the problem to the case where we have an operator with constant domain by making use of the properties of $R(t)$ [for an outline of Kisyński's solution of the problem (4.1) with $D(A(t))=\text{const}$ see the Appendix].

Let us now consider Kisyński's approach to the abstract Schrödinger equation

$$\frac{\mathrm{d}}{\mathrm{d}t}\Psi(t)=-iA(t)\Psi(t),\quad -T_1\leqslant t\leqslant T_2, \tag{4.6}$$

where $\Psi\in\mathcal{H}$, with $\mathcal{H}$ a Hilbert space and $A(t)$ an operator in $\mathcal{H}$ defined as follows. Consider the condition:

(i) Let $\mathcal{H}$ be a Hilbert space, $\mathcal{H}_+$ a dense subset of $\mathcal{H}$ and, $\forall\ t\in[-T_1,T_2]$, let $\langle\cdot,\cdot\rangle_t^+$ be a scalar product defined on $\mathcal{H}_+$ which makes it a Hilbert space $\mathcal{H}_+^t$ algebraically and topologically contained in $\mathcal{H}$. Assume that $\langle\cdot,\cdot\rangle_t^+$ is n times $(n\geqslant 1)$ continuously differentiable on $[-T_1,T_2]$.

If condition (i) is satisfied we have

Lemma IV.1 (Ref. 11, Lemma 7.2): *The equality*

$$\langle\Phi,\Psi\rangle_t^+=\langle\Phi,Q(t)\Psi\rangle_{-T_1}^+,\quad \Phi,\Psi\in\mathcal{H}_+,\quad t\in[-T_1,T_2] \tag{4.7}$$

defines a bounded n *times weakly continuously differentiable operator* $Q(t)$ *on* $\mathcal{H}_+^{-T_1}$*. For all fixed* $t\in[-T_1,T_2]$*,* $Q(t)$ *is Hermitian with* $\inf Q(t)>0$ *in* $\mathcal{H}_+^{-T_1}$*.*

Another consequence of condition (i) is that we can define an operator $J_{-T_1}(t)$ by means of the equality (Ref. 11, Lemma 7.4)

$$\langle\Phi,\Psi\rangle=\langle\Phi,J_{-T_1}(t)\Psi\rangle_t^+,\quad \Phi\in\mathcal{H}_+,\quad \Psi\in\mathcal{H} \tag{4.8}$$

with $J_{-T_1}(t)$ a positive Hermitian operator in $\mathcal{L}(\mathcal{H})$ such that $J_{-T_1}(t)\mathcal{H}_+$ is a dense subset of $\mathcal{H}_+^t$. Then, defining

$$\|\Psi\|_t^-\equiv\|J_{-T_1}(t)\Psi\|_t^+,\quad \Psi\in\mathcal{H}, \tag{4.9}$$

it follows that the completion $\mathcal{H}_-^t=\mathcal{H}_-^{-T_1}\equiv\mathcal{H}_-$ of $\mathcal{H}$ in the norm $\|\cdot\|_t^-$ contains $\mathcal{H}$ algebraically and topologically (Ref. 11, Lemma 7.5).

Finally, we can define an operator $A(t)$ by means of the form $\langle\cdot,\cdot\rangle_t^+$ according to the following lemma:

Lemma IV.2 (Ref. 11, Lemma 7.7): *For all* $t\in[-T_1,T_2]$*,*

$$D(A(t))=\left\{\Psi\in\mathcal{H}_+:\ \sup_{\Phi\in\mathcal{H}_+,\,\|\Phi\|\leqslant 1}\{|\langle\Phi,\Psi\rangle_t^+|\}<+\infty\right\}, \tag{4.10}$$

$$\langle\Phi,A(t)\Psi\rangle\equiv\langle\Phi,\Psi\rangle_t^+,\quad \Psi\in D(A(t)) \tag{4.11}$$

define an inversible self-adjoint positive operator $A(t)$ *in* $\mathcal{H}$*, with*

$$D(A(t))=(Q(t))^{-1}D(A(-T_1)) \tag{4.12}$$

and

$$A(t)=(J_{-T_1}(t))^{-1}=A(-T_1)Q(t). \tag{4.13}$$

Then the operator $A(t)$ is shown to satisfy the Schrödinger equation (4.6) and the propagators of problem (4.6) satisfy the properties enumerated in Theorem II.3 (Ref. 11, Theorem 8.1). In order to prove his Theorem 8.1 for the operator $A(t)$, as defined above, Kisyński made use of Theorem IV.1 identifying $R(t)=(Q(t))^{-1}$. Let us now show that the $(:\phi^4:)_2$ theory satisfies the necessary conditions for Theorem II.3. In fact, all we need to show is that condition (i) is satisfied. However for the benefit of clarity we will explicitly display the main operators introduced in Kisyński's proof and some of its properties.

The Hilbert space $\mathcal{H}$ in (i) should be identified with the symmetric Fock space $\mathcal{F}$ (as defined in Sec. II) and $\mathcal{F}_{+2}=D(H_0)$ is a dense subset of $\mathcal{F}$. Then, taking the closure $\mathcal{F}^t_{+2}$ of $\mathcal{F}_{+2}$ in the norm induced by the scalar product $\langle\cdot,\cdot\rangle^+_t$, which is related to the operator $\tilde{H}(t)$ [see Eq. (2.14)] by means of the form (2.21), i.e.,

$$\langle\Phi,\Psi\rangle^+_t\equiv S(\Phi,\Psi)=\langle\tilde{H}(t)^{1/2}\Phi,\tilde{H}(t)^{1/2}\Psi\rangle, \tag{4.14}$$

we can show the following:

Proposition IV.1: $\mathcal{F}^t_{+2}$ is a Hilbert space such that

$$\mathcal{F}^t_{+2}\subset\mathcal{F} \tag{4.15}$$

algebraically and topologically.

Proof: That $\mathcal{F}^t_{+2}$ is a Hilbert space follows immediately from the fact that the form defined in (4.14) is closed (see, e.g., Ref. 15). The property that $\mathcal{F}^t_{+2}\subset\mathcal{F}$ algebraically is trivial. So, it remains to show that (4.15) holds topologically. This is achieved by showing that for $\{f_n\}_{n=1}^{\infty}\in\mathcal{F}_{+2}$ and $f\in\mathcal{F}_{+2}$ such that

$$\|f_n-f\|\to 0 \tag{4.16}$$

we have

$$\|f_n-f\|^+_t\to 0.$$

To show this, set

$$\begin{aligned}(\|f_n-f\|^+_t)^2&=\langle(f_n-f),(f_n-f)\rangle^+_t=\langle(f_n-f),\tilde{H}(t)(f_n-f)\rangle\\&=\langle(H_0+\mathbf{1})(f_n-f),(H_0+\mathbf{1})^{-1}\tilde{H}(t)(H_0+\mathbf{1})^{-1}(H_0+\mathbf{1})(f_n-f)\rangle.\end{aligned}$$

The Schwarz inequality applied to the last term above yields

$$\|f_n-f\|^+_t\leqslant\|(H_0+\mathbf{1})^{-1}\tilde{H}(t)(H_0+\mathbf{1})^{-1}\|\ \ \|(H_0+\mathbf{1})(f_n-f)\|^2.$$

The first term on the right-hand side is bounded due to (3.12). The second term on the right-hand side converges since $H_0+\mathbf{1}$ is a self-adjoint operator (hence closed) and, by hypothesis, (4.16) holds. Then the proof of the proposition is complete. □

In addition, it follows straightforwardly from (4.14) and Theorem III.1 that $\langle\cdot,\cdot\rangle^+_t$ is n times (infinitely, in fact) continuously differentiable. Then it is proved that condition (i) is satisfied and Theorem II.3 follows as proved in Ref. 11 and summarized above.

Now we turn to explicitly show the properties of $Q(t)$ in our case. From (4.14) and the definition

$$\langle\Phi,\Psi\rangle^+_t\equiv\langle\Phi,Q(t)\Psi\rangle^+_{-T_1}$$

we obtain that $Q(t)$ is the operator

$$Q(t)=(\tilde{H}(-T_1))^{-1}\tilde{H}(t). \tag{4.17}$$

Proposition IV.2: $Q(t)$, as defined in (4.17), is a (strictly) positive Hermitian operator in $\mathcal{F}_{+2}$ and it is infinitely weakly differentiable.

Proof: It follows directly from the properties of the scalar product $\langle\cdot,\cdot\rangle_t^+$ that $Q(t)$ is infinitely weakly differentiable.

For Φ, $\Psi\in\mathcal{F}_{+2}$, we have

$$(\langle\Phi,Q(t)\Psi\rangle_{-T_1}^+)^*=\langle Q(t)\Psi,\Phi\rangle_{-T_1}^+=\langle\tilde{H}(-T_1)^{-1}\tilde{H}(t)\Psi,\tilde{H}(-T_1)\Phi\rangle=\langle\tilde{H}(t)\Psi,\Phi\rangle, \tag{4.18}$$

where we have used (4.17). We then have that

$$\begin{aligned}(\langle\Phi,Q(t)\Psi\rangle_{-T_1}^+)^*&=\langle\Psi,\tilde{H}(-T_1)(\tilde{H}(-T_1))^{-1}\tilde{H}(t)\Phi\rangle\\&=\langle\Psi,\tilde{H}(-T_1)Q(t)\Phi\rangle=\langle\Psi,Q(t)\Phi\rangle_{-T_1}^+,\end{aligned} \tag{4.19}$$

which proves that $Q(t)$ is Hermitian.

In order to prove that $Q(t)$ is strictly positive on $\mathcal{F}_{+2}$, we must remember that, since $\mathcal{F}_{+2}^t\subset\mathcal{F}_{+2}$ $\forall$ t algebraically and topologically, it follows that the norms $\|\cdot\|_{-T_1}^+$ and $\|\cdot\|_t^+$ are equivalent, i.e., there exists $a_t\geqslant 1$ such that $a_t^{-1}\|\cdot\|_{-T_1}^+\leqslant\|\cdot\|_t^+\leqslant a_t\|\cdot\|_{-T_1}^+$. Then, for $\Psi\in\mathcal{F}_{+2}$,

$$\langle\Psi,Q(t)\Psi\rangle_{-T_1}^+=(\|\Psi\|_t^+)^2\geqslant a_t^{-2}(\|\Psi\|_{-T_1}^+)^2, \tag{4.20}$$

from which it follows that $\inf Q(t)>0$ and the proof is complete. □

V. CONCLUSION: OPEN PROBLEMS

The problem of the nonperturbative construction of $S(g)$ for the $(:\phi^4:)_2$ quantum field theory was addressed in Ref. 17 using Yosida's approach, which requires that the domain of $H_g(t)$ be time-independent. For test functions $g(x,t)=h_1(x)\cdot f_1(t)$, i.e., of the product form, this condition is satisfied, but already for a sum of two products, e.g., $g(x,t)=h_1(x)\cdot f_1(t)+h_2(x)\cdot f_2(t)$, with f_1 and f_2 having disjoint supports, this is no longer true, and thus the results of Ref. 17 are incomplete. The present approach does not suffer from this inconvenience, and g is allowed to be an arbitrary infinitely differentiable function of compact support. Moreover, the use of a scale of spaces makes the theory very flexible, being applicable to more singular super-renormalizable theories, as well as to four-dimensional theories with an ultraviolet cutoff. It is a very challenging problem to discover a possibility of ''renormalization'' of the exponentials of the type (A7) in the latter, in analogy to the interesting approach of Barata[18] and Gentile[19] to the study of certain two-level systems.

There are, however, open problems even to finish this program for the present $(:\phi^4:)_2$ theory: proof of causality for space-like supports $(ii.b)$ and proof of Lorentz covariance (iii). For this purpose, the method outlined in Ref. 17 seems natural: the above properties would follow from a proof of Faris's product formula[20] under the assumptions of Theorem IV 1. We shall return to this problem in the future.

ACKNOWLEDGMENTS

W.F.W. thanks Professor K. Hepp for posing this problem in 1971 and W.F.W. and L.A.M. thank Professor K. Fredenhagen for fruitful discussions. W.F.W. was supported in part by CNPq. APPENDIX

Let us consider the problem (4.1) for the case in which $D(A(t))=\text{const}$. The notation is as in the first part of Sec. IV.

Consider the following conditions (in what follows $t\in[-T_1,T_2]$, unless otherwise specified):

(i) there exists a family $\|\cdot\|_t$, of norms in X such that $a^{-1}\|\Psi\|\leqslant\|\Psi\|_t\leqslant\|\Psi\|_s\leqslant a\|\Psi\|$, $a\geqslant 1$, for $-T_1\leqslant s\leqslant t\leqslant T_2$ and $\Psi\in X$;
(ii) Y is a dense subset of X with $D(A(t))=Y$;
(iii) for all $\lambda>0$ and $\Psi\in Y$ we have $R(\lambda-A(t))=X$ and $\|(\lambda-A(t))\Psi\|_t\geqslant\lambda\|\Psi\|_t$;
(iv) $A(t)$ is weakly continuously differentiable.

Theorem A.1 (Ref. 11, Theorem 3.0): *Let the conditions (i)–(iv) be satisfied. Then, there exists a unique solution of the problem (4.1) and the corresponding propagator $U(t,s)$ is strongly continuous in $-T_1\leqslant s\leqslant t\leqslant T_2$ and satisfies the properties (4.2), (4.3), (4.4), and (4.5).*

Now we shall explain some aspects of Kisyński's proof of this theorem. Consider the family of equations

$$\frac{\mathrm{d}}{\mathrm{d}t}\Phi(t)=A_n(t)\Phi(t),\quad \Phi(0)=\Phi_0,\quad n=1,2,\ldots, \tag{A1}$$

with

$$A_n(t)=nA(t)(n-A(t))^{-1}. \tag{A2}$$

The set Y supplied with the norm $\|\|\cdot\|\|_t=\|((1-A(t))\cdot\|$ is a Banach space algebraically and topologically contained in X. Then, from (i) and (iv), it follows that $A(t)\in\mathcal{L}(Y,X)$ is a weakly continuously differentiable operator, which, by the Banach–Steinhaus theorem, implies $\|A(t)\Phi\|\leqslant C\|\|\Phi\|\|_0$ for $\Phi\in Y$ and some constant C (the equivalence of the norms $\|\|\cdot\|\|_t$ was used). So, by using (i) and (iii), it follows that

$$\|\Phi-n(n-A(t))^{-1}\Phi\|=\frac{1}{n}\|(1-A(t)/n)^{-1}(A(t)\Phi)\|\leqslant\frac{Ca^2}{n}\|\|\Phi\|\|_0, \tag{A3}$$

which implies that $n(n-A(t))^{-1}$ converges strongly and uniformly to 1. Therefore, the sequence of bounded operators $A_n(t)$ converges strongly to $A(t)$. The operators $A_n(t)$ are weakly continuously differentiable, therefore they satisfy a Lipschitz condition in the sense of the norm. Hence, it follows that $A_n(t)$ is continuous in the sense of the norm and Yosida's method[13] guarantees the existence and the uniqueness of the evolution operators $U_n(t,s)$ of Eq. (A1) satisfying the properties equivalent to (4.2)–(4.5). Besides, $U_n(t,s)$ satisfy[11]

$$\|U_n(t,s)\|\leqslant M. \tag{A4}$$

Before proceeding we will consider Eq. (A1) perturbed by the bounded (in X) weakly continuous operator

$$B(t)=-\frac{\mathrm{d}A(t)}{\mathrm{d}t}(1-A(t))^{-1},$$

that is,

$$\frac{\mathrm{d}}{\mathrm{d}t}\Phi(t)=(A_n(t)+B(t))\Phi(t),\quad \Phi(0)=\Phi_0. \tag{A5}$$

The evolution operator of (A5), denoted $H_n(t,s)$, is given by

$$H_n(t,s)=(1-A(t))U_n(t,s)(1-A(s))^{-1}.$$

Then, it follows that $H_n(t,s)\in\mathcal{L}(X)$ is weakly continuously differentiable in $-T_1\leqslant s,t\leqslant T_2$, satisfying

$$\|H_n(t,s)\|\leqslant D. \tag{A6}$$

Next we subdivide the segment $[-T_1,T_2]$ into K equal intervals. Then, the conditions ($T\equiv T_1+T_2$)

$$U_{nK}(t,s)=\exp\left\{(t-s)A_n\left(-T_1+\frac{i-1}{K}T\right)\right\}, \tag{A7}$$

$-T_1+((i-1)/K)\,T\leqslant s,t\leqslant -T_1+(i/K)\,T,\ i=1,\ldots,K,$ and

$$U_{nK}(t,s)U_{nK}(s,r)=U_{nK}(t,s),\quad -T_1\leqslant r,s,t\leqslant T_2, \tag{A8}$$

define a unique family of operators $U_{nK}(t,s)\in\mathcal{L}(X)$ continuous in the sense of the norm such that

$$\|U_{nK}(t,s)\|\leqslant a^2. \tag{A9}$$

The operators $U_{nK}(t,s)$ satisfy

$$\frac{\partial}{\partial s}U_{nK}(t,s)=-U_{nK}(t,s)A_n\left(-T_1+\frac{T}{K}\left[\frac{Ks}{T}\right]\right),$$

where $[(Ks)/T]$ stands for the integer part of $(Ks)/T$. Besides, for fixed K, $U_{nK}(t,s)$, $n=1,2,\ldots$, is a sequence uniformly strongly convergent in $-T_1\leqslant s\leqslant t\leqslant T_2$.

Then, by integrating $(\partial/\partial\tau)\,U_{nK}(t,\tau)U_n(\tau,s)$ we obtain

$$U_n(t,s)-U_{nK}(t,s)=\int_s^t U_{nK}(t,\tau)\left(A_n(\tau)-A_n\left(-T_1+\frac{T}{K}\left[\frac{K\tau}{T}\right]\right)\right)U_n(\tau,s)\,\mathrm{d}\tau. \tag{A10}$$

We have[11]

$$\left\|A_n(\tau)\Phi-A_n\left(-T_1+\frac{T}{K}\left[\frac{K\tau}{T}\right]\right)\Phi\right\|\leqslant\frac{\text{const}}{K}\||\Phi|\|_0. \tag{A11}$$

Then, since

$$U_n(t,s)=(1-A(t))^{-1}H_n(t,s)(1-A(s))$$

and $(1-A(s))\in\mathcal{L}(Y,X)$ and $(1-A(t))^{-1}\in\mathcal{L}(X,Y)$ are weakly differentiable, we obtain, by using (A6),

$$\||U_n(t,s)\Phi|\|_0\leqslant\text{const}\||\Phi|\|_0, \tag{A12}$$

for $\Phi\in Y$ and $-T_1\leqslant s\leqslant t\leqslant T_2$. Then, from (A9), (A10), (A11), and (A12), it follows that

$$\|U_n(t,s)\Phi-U_{nK}(t,s)\Phi\|\leqslant\frac{\mathrm{L}}{K}\||\Phi|\|_0, \tag{A13}$$

with $L=\text{const}$.

Now, for $\Phi\in Y$ we have

$$\begin{aligned}\|U_n(t,s)\Phi - U_m(t,s)\Phi\| &\leqslant \|U_n(t,s)\Phi - U_{nK}(t,s)\Phi\| + \|U_{mK}(t,s)\Phi - U_m(t,s)\Phi\| \\ &\quad + \|U_{nK}(t,s)\Phi - U_{mK}(t,s)\Phi\| \\ &\leqslant 2\frac{L}{K}\|\|\Phi\|\|_0 + \|U_{nK}(t,s)\Phi - U_{mK}(t,s)\Phi\|. \end{aligned} \tag{A14}$$

The first term on the right-hand side may be made arbitrarily small for large K. After this, one chooses n and m so large that the second term becomes arbitrarily small for all $-T_1 \leqslant s \leqslant t \leqslant T_2$, since the sequence $U_{nK}(t,s)$ is uniformly strongly convergent. Since Y is dense in X, and from (A4), (A14) implies that the convergence is in all of X, in the triangle $-T_1 \leqslant s \leqslant t \leqslant T_2$. Then, it follows directly from the properties of $U_n(t,s)$ that $U(t,s) = s - \lim_{n\to\infty} U_n(t,s)$ is the evolution operator of (4.1) for constant domain.[11]

Remark: The proof outlined above is valid for $-T_1 \leqslant s \leqslant t \leqslant T_2$. However, by substituting the conditions (i) and (iii) above by the conditions (a) and (c) in Theorem IV.1 the proof can be extended for the square $-T_1 \leqslant s,t \leqslant T_2$.

Killing initial data revisited

Daniel Maerten[a)]
Institut de Mathématiques et de Modélisation de Montpellier, UMR 5149 CNRS, Place Eugène Bataillon, 34095 Montpellier, France

(Received 21 January 2004; accepted 26 March 2004; published online 27 May 2004)

Considering the Killing vector fields on a Lorentzian manifold in terms of their lapse and shift along a space-like hypersurface, we give a new definition of the Killing Initial Data (KID) of Beig and Chruściel [Class. Quantum Grav. **14-1A**, A83 (1996)]. We define, on these new KID's, the bracket operation induced by the usual Lie bracket of Killing vector fields on the Lorentzian manifold, and study the conditions for our new KID's to form a Lie algebra. The interesting fact is that these conditions only depend on data along the hypersurface. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1755862]

I. INTRODUCTION AND NOTATIONS

The starting point of this work is the paper of Beig and Chruściel, Killing Initial Data,[1] where they studied properties of Killing vector fields on a Lorentzian manifold $(\overline{M},\overline{g})$ of dimension $n+1$. Let (M,g,k) be a space-like hypersurface, with induced metric g and second fundamental form k. Then they raised the following issue: If we decompose any vector field $\overline{X}$ in terms of a lapse function N and a shift vector X, that is to say, $\overline{X}=X+N\partial_t$, where ∂_t denotes the unit normal to M, how can we deduce that $\overline{X}$ is Killing only thanks to information along (M,g,k)?

For convenience, we are going to consider a tubular neighborhood $]-\epsilon,+\epsilon[\times M$ of M, $\epsilon>0$, and write $\overline{g}$ in Gaussian normal coordinates, that is to say,

$$\overline{g}=-dt^2+g_t,$$

where g_{t_0} is the Riemannian metric on the slice of equation $\{t=t_0\}$ induced by $\overline{g}$. Such coordinates will be chosen so that $M=\{t=0\}$, and then the Killing equations for $\overline{X}=X+N\partial_t$ are

$$\mathcal{L}_X g=-2Nk, \tag{1}$$

$$\partial_t N=0, \tag{2}$$

$$\partial_t X=\nabla N, \tag{3}$$

where $\mathcal{L}$ is the Lie derivative. Taking ∂_t of (1) we find

$$\mathcal{L}_X k+HessN=N(Ric+(trk)k-2(k\circ k))-N\overline{Ric}_{|TM\otimes TM}, \tag{4}$$

where $\circ$ is the composition of 2-tensors:

$$(k\circ k)_{ij}=k_{ip}k_{rj}g^{rp}.$$

In order to define "candidate Killing vector fields" they decided to call Killing Initial Data (KID), any couple $(N,X)\in C^\infty(M)\times\Gamma(TM)$ satisfying (1) and (4). Then, noticing that the space

a)Electronic mail: maerten@darboux.math.univ-montp2.fr

of Killing fields on $\overline{M}$ was closed under the usual bracket on $\overline{M}$, they wondered whether they could define a bracket {,} on the space of KID's with the same stability property.

Still reasoning from the decomposition of Killing fields in terms of lapse and shift, they gave a natural bracket {,} on the space of KID's, constructed from the usual bracket of Killing vector fields on $\overline{M}$. The important fact is that the conditions, in order to make KID's closed under {,}, involve a geometric quantity which is distinct from the constraints [part of Ricci curvature of $\overline{g}$ which is solely determined by the data (M,g,k)].

As a matter of fact, from a Cauchy point of view, a slightly different definition of KID's (that we will call new KID's) is more natural that the one used in Ref. 1. Both coincide in the vacuum and cosmological cases but they are not identical in general. The present work singles out the necessary and sufficient conditions under which the new KID's form a Lie algebra. The result obtained here is much more satisfactory, as the resulting conditions for the Lie algebra structure only involve objects naturally defined by a initial data set: The energy density and the momentum density.

Let us denote by G the Einstein tensor, and let us focus on the vacuum $(G=0)$ or cosmological $(G=\Lambda\overline{g},\ \Lambda$ constant) cases for a moment. If we call $L^\star$ the adjoint of the linearized constraints map, then being a KID exactly means belonging to Ker$L^\star$. More precisely, according to Ref. 2, it is possible to give an explicite correspondence between KID's and solutions of $L^\star=0$:

$$(N,X) \quad \text{KID} \Leftrightarrow L^\star(N,X^\flat)=0,$$

where $^\flat$ is the canonical isomorphism from TM to $T^\star M$ with respect to g. We will use the symbol $^\sharp$ to denote its inverse.

As a consequence, it leads us to adopt, in general, that is to say for *any Einstein tensor* G, the following:

Definition: Our new "candidate Killing vector fields" are the $(N,X)\in C^\infty(M)\times\Gamma(TM)$ *such as*

$$L^\star(N,X^\flat)=0.$$

Thus, using the same bracket as in Ref. 1, we study the conditions so that the space of our ''new KID's'' is a Lie algebra.

We will adopt the following definitions and conventions.[3,4] The Einstein tensor G of $\overline{g}$, is by definition

$$G=\overline{Ric}-\tfrac{1}{2}\overline{Scal}\,\overline{g}, \tag{5}$$

where $\overline{Ric}$ and $\overline{Scal}$ are the Ricci curvature and the scalar curvature of $\overline{g}$.

Let us define the constraint map as

$$\Phi(g,k)=\begin{pmatrix} Scal+(trk)^2-|k|^2 \\ -2(\delta k+dtrk)\end{pmatrix}, \quad (g,k)\in\mathcal{M}\times\Gamma(S^2T^\star M),$$

where $\mathcal{M}$ denotes the space of Riemannian metrics on M, *Scal* is the scalar curvature of g, norm and trace have to be taken with respect to g, and δ is the divergence operator acting on symmetric tensors, that is to say,

$$\delta S=-\sum_{i=1}^{n} D_{e_i}S(e_i,.,\ldots,.),$$

where D is the Levi-Civita connexion of (M,g), $(e_i)_{i=1}^n$ is any orthonormal basis at the point, and S is any symmetric tensor. We also define the adjoint of δ denoted by $\delta^\star$ which is

$$\delta^\star\beta(X,Y)=\tfrac{1}{2}(D_X\beta(Y)+D_Y\beta(X)),$$

for any 1-form β. For later use we define the Hessian and the Laplacian of a function f as follows:

$$Hess(f)=Ddf, \quad \Delta f=\delta df=-tr_g Hess(f).$$

If we denote at $t=0$

$$2G_{|TM\otimes TM}=\tau, \quad 2G(\partial_t,\partial_t)=\psi, \quad 2G(\partial_t,.)=\omega,$$

then the following equations, known as the constraints equations, are satisfied on M:

$$\begin{pmatrix} Scal+(trk)^2-|k|^2 \\ -2(\delta k+dtrk) \end{pmatrix}=\begin{pmatrix} \psi \\ \omega \end{pmatrix}.$$

If one defines

$$E(f,\alpha)=Hess(f)-f(Ric+2(trk)k-2(k\circ k))+\mathcal{L}_{\alpha^\sharp}k+(\delta\alpha)k,$$

then the expression of $L^\star$ is

$$\begin{pmatrix} L_1^\star(f,\alpha) \\ L_2^\star(f,\alpha) \end{pmatrix}=\begin{pmatrix} E(f,\alpha)-tr(E(f,\alpha))g-(\frac{1}{2}\langle L_2^\star(f,\alpha),k\rangle+\frac{1}{2}\langle\alpha,\omega\rangle+f\psi)g \\ -2(\delta^\star\alpha+fk)+2tr(\delta^\star\alpha+2fk)g \end{pmatrix},$$

where $(f,\alpha)\in C^\infty(M)\times\Gamma(T^\star M)$ are the dual infinitesimal deformations for Φ at the point (g,k) and $\langle,\rangle$ denotes the scalar product extended to all tensors.

Finally a direct computation leads us to

$$L^\star(f,\alpha)=0\Leftrightarrow\begin{cases} \mathcal{L}_X k+HessN=N(Ric+(trk)k-2(k\circ k))+\dfrac{1}{2(1-n)}(\omega(X)+2N\psi)g \\ \mathcal{L}_X g+2Nk=0, \end{cases}$$

if we denote $f=N$, $\alpha=X^\flat$. These relations, and the equivalence above will be used implicitly throughout the text, so that we can write elements of $\mathrm{Ker}L^\star$ in terms of (N,X) or in terms of (f,α).

II. LIE ALGEBRA STRUCTURE OF Ker$L^\star$

The motivation for the definition of the bracket lies on the Lie structure of the Killing fields on the Lorentzian manifold $\overline{M}$. Let us take two Killing fields $\overline{X_i}=X_i+N_i\partial_t$ $(i=1,2)$, their bracket, using (2)–(4), is

$$[\overline{X_1},\overline{X_2}]=[X_1,X_2]+N_1\nabla N_2-N_2\nabla N_1+(\mathcal{L}_{X_1}N_2-\mathcal{L}_{X_2}N_1)\partial_t.$$

Definition: We define $\{,\}$ *on* $C^\infty(M)\times\Gamma(TM)$ *as*

$$\{(N_1,X_1),(N_2,X_2)\}:=(\mathcal{L}_{X_1}N_2-\mathcal{L}_{X_2}N_1,[X_1,X_2]+N_1\nabla N_2-N_2\nabla N_1).$$

Proposition: $\{,\}$ *satisfies the Jacobi identity on* $KerL_2^\star\subset C^\infty(M)\times\Gamma(TM)$.

Proof: It relies on computations which are the same as in Ref. 1.

From now on, $\odot$ will denote the symmetric product of 1-forms, that is to say,

$$\theta_1\odot\theta_2(U,V)=\tfrac{1}{2}(\theta_1(U)\theta_2(V)+\theta_1(V)\theta_2(U)),$$

for any 1-forms θ_i, $i=1,2$. The main result of this note is then:

Theorem: *The* $\mathbb{R}$*-vector space* $KerL^\star \subset C^\infty(M) \times \Gamma(TM)$ *with the bracket* $\{,\}$*, is a Lie algebra if and only if the following conditions are satisfied:*

$$\text{(i)} \quad N_1\omega(X_2) = N_2\omega(X_1),$$

$$\text{(ii)} \quad \omega \odot (N_2 \mathrm{d}N_1 - N_1 \mathrm{d}N_2) = 0,$$

$$\text{(iii)} \quad \mathrm{d}\omega(X_1, X_2) + \mathrm{d}\psi(N_2X_1 - N_1X_2) = 0,$$

$\forall (N_1X_1), (N_2X_2) \in KerL^\star$, along (M, g, k, ω, ψ).

Remark: We have to underline that the existence of nontrivial solutions of $L^\star = 0$ prevents the level-sets of the constraints map from being manifolds. So it could appear important to be able to give information about Ker$L^\star$ only depending on the constraints which caracterize the level-sets. This provides another interest for this new definition of KID's.

Corollary: If $\psi = constant$ *and* $\omega = 0$*, then* $(KerL^\star, \{,\})$ *is a Lie algebra.*

Applications of the Corollary: The first remark concerns the vacuum and cosmological cases. The corollary points out a result that was already known thanks to the KID's. This is a consequence of the simple fact that, in both cases, being a KID in the sense of Ref. 1, is equivalent to be a solution of the equation $L^\star = 0$.

Second, we can hope, thanks to the following example, that this theorem could have good applications. Indeed let us consider the case of perfect fluid-pure matter for the stress-energy tensor. Then

$$T = (\rho + p)\xi \otimes \xi + p\overline{g},$$

where $v = \xi^\flat$ is the unitary and time-like speed vector of fluid particule. If we assume moreover that $\xi = dt$, so that

$$T = \rho dt^2 + p g_t .$$

If we make the assumption that ρ only depends on t, the conditions of our theorem are satisfied, whereas the conditions for the KID's are not if we do not make any assumption on the function p. This shows that the conditions of our theorem are adapted to the geometric constraints (ψ and ω), whereas the conditions of Ref. 1 are less, because of the role of τ in their expression.

III. PROOF OF THE THEOREM

(i) Let us take 2 couples $(N_1X_1), (N_2X_2)$ satisfying $L^\star(N_i, X_i^\flat) = 0$ $(i = 1,2)$. Then one finds

$$\begin{aligned} &\mathcal{L}_{[X_1,X_2]+N_1\nabla N_2 - N_2\nabla N_1} g + 2(\mathcal{L}_{X_1}N_2 - \mathcal{L}_{X_2}N_1)k \\ &\quad = 2N_1(\mathcal{L}_{X_2}k + Hess N_2) - 2N_2(\mathcal{L}_{X_1}k + Hess N_1) \\ &\quad = \frac{1}{(1-n)}(N_1\omega(X_2) - N_2\omega(X_1)), \end{aligned}$$

and the first condition follows.

(ii) Still in order to make Ker$L^\star$ closed under $\{,\}$, the following equation has to hold:

$$\begin{aligned} 0 = {} & \mathcal{L}_{N_1\nabla N_2 - N_2\nabla N_1}k + [Hess, \mathcal{L}_{X_1}]N_2 - [Hess, \mathcal{L}_{X_2}]N_1 + (N_2\mathcal{L}_{X_1} - N_1\mathcal{L}_{X_2})(Ric + (trk)k \\ & - 2(k \circ k)) + \frac{1}{(1-n)}(N_2\mathcal{L}_{X_1} - N_1\mathcal{L}_{X_2})(\psi g) + \frac{1}{2(1-n)}(\mathcal{L}_{X_1}(\omega(X_2)g) - \mathcal{L}_{X_2}(\omega(X_1)g)) \\ & - \frac{1}{2(1-n)}\omega([X_1, X_2] + N_1\nabla N_2 - N_2\nabla N_1)g = \mathrm{I} + \mathrm{II} + \mathrm{III} + \mathrm{IV} + \mathrm{V} + \mathrm{VI}. \end{aligned} \tag{6}$$

From this point, we will assume that condition (i) holds. For convenience, we are going to compute this expression in several steps. We will use the notation $\{(N_1,X_1)\leftrightarrow(N_2,X_2)\}$ which means that we rewrite the beginning of the expression replacing (N_1,X_1) by (N_2,X_2).

$$\mathrm{I}=D_{N_1\nabla N_2}k+2\mathrm{d}N_1\odot i_{\nabla N_2}k+N_1(k\circ HessN_2+HessN_2\circ k)-\{(N_1,X_1)\leftrightarrow(N_2,X_2)\},$$

$$\mathrm{II}=2N_2\delta^\star(i_{\nabla N_1}k)+2\mathrm{d}N_2\odot i_{\nabla N_1}k-D_{N_2\nabla N_1}k-N_2(HessN_1\circ k+k\circ HessN_1)$$
$$-\{(N_1,X_1)\leftrightarrow(N_2,X_2)\}.$$

Three terms are involved in III:
First of all:

$$(N_2\mathcal{L}_{X_1}-N_1\mathcal{L}_{X_2})(Ric)=-N_2\Delta N_1k+2N_2D_{\nabla N_1}k-2N_2\delta^\star(i_{\nabla N_1}k)$$
$$-(N_2trk)\mathcal{L}_{X_1}k-\omega\odot(N_2\mathrm{d}N_1)-\{(N_1,X_1)\leftrightarrow(N_2,X_2)\}.$$

Second:

$$(N_2\mathcal{L}_{X_1}-N_1\mathcal{L}_{X_2})(k\circ k)=N_2(k\circ\mathcal{L}_{X_1}k+\mathcal{L}_{X_1}k\circ k)-\{(N_1,X_1)\leftrightarrow(N_2,X_2)\}.$$

And finally, taking the trace of $L_1^\star(f,\alpha)=0$, we find

$$\mathcal{L}_{X_i}(trk)+2\langle k,\delta^\star X_i^\flat\rangle-\Delta N_i=N_i(Scal+(trk)^2-2|k|^2)+[n/2(1-n)](\omega(X_i)+2N_i\psi),$$

but reminding that $\langle k,\delta^\star X_i^\flat\rangle=\langle k,\delta^\star\alpha_i\rangle=-f_i|k|^2=-N_i|k|^2$, this equation is equivalent to

$$\mathcal{L}_{X_i}(trk)=\Delta N_i+N_i\left(Scal+(trk)^2+\frac{n}{(1-n)}\psi\right)+\frac{n}{2(1-n)}\omega(X_i).$$

We use this information in order to compute the last term of III:

$$(N_2\mathcal{L}_{X_1}-N_1\mathcal{L}_{X_2})((trk)k)=trk(N_2\mathcal{L}_{X_1}-N_1\mathcal{L}_{X_2})k+(N_2\Delta N_1-N_1\Delta N_2)k.$$

Thus it follows:

$$\mathrm{III}=2N_2(D_{\nabla N_1}k-\delta^\star(i_{\nabla N_1}k)-k\circ\mathcal{L}_{X_1}k-\mathcal{L}_{X_1}k\circ k-\tfrac{1}{2}\omega\odot\mathrm{d}N_1)-\{(N_1,X_1)\leftrightarrow(N_2,X_2)\}.$$

Finally, we have a look at the terms involving ψ and ω in the expression of (6). After some easy computations, the remainig terms are

$$(1-n)\mathrm{IV}=\mathrm{d}\psi(N_2X_1-N_1X_2)g+\psi(N_2\mathcal{L}_{X_1}g-N_1\mathcal{L}_{X_2}g)=\mathrm{d}\psi(N_2X_1-N_1X_2)g,$$

$$2(1-n)\mathrm{V}=((D_{X_1}\omega)(X_2)-(D_{X_2}\omega)(X_1)+\omega([X_1,X_2]))g+2(N_2\omega(X_1)-N_1\omega(X_2))k$$
$$=(2\mathrm{d}\omega(X_1,X_2)+\omega([X_1,X_2]))g.$$

Finally, when we add all terms of (6) together, still assuming that condition (i) holds, (6) becomes

$$0=-\omega\odot(N_2\mathrm{d}N_1-N_1\mathrm{d}N_2)$$
$$+\frac{1}{(1-n)}\left(\mathrm{d}\omega(X_1,X_2)+\mathrm{d}\psi(N_2X_1-N_1X_2)+\frac{1}{2}\omega(N_2\nabla N_1-N_1\nabla N_2)\right)g. \qquad (7)$$

Now, taking the trace of (7), it follows:

$$\omega(N_2\nabla N_1 - N_1\nabla N_2) = \frac{2n}{(2-3n)}(\mathrm{d}\omega(X_1,X_2) + \mathrm{d}\psi(N_2X_1 - N_1X_2)). \tag{8}$$

And finally we obtain

$$\omega\odot(N_2\mathrm{d}N_1 - N_1\mathrm{d}N_2) = \frac{2}{(2-3n)}(\mathrm{d}\omega(X_1,X_2) + \mathrm{d}\psi(N_2X_1 - N_1X_2))g. \tag{9}$$

And the proof is complete: The fact that the rank of the left member of (9) is 2 whereas the rank of the right one is $n \geqslant 3$, entails that both vanish. The corollary is straightforward since the conditions of our theorem are clearly satisfied. □

We consider the problem of correcting the errors incurred from sending quantum information through a noisy quantum environment by using classical information obtained from a measurement on the environment. For discrete time Markovian evolutions, in the case of fixed measurement on the environment, we give criteria for quantum information to be perfectly corrigible and characterize the related feedback. Then we analyze the case when perfect correction is not possible and, in the qubit case, we find optimal feedback maximizing the channel fidelity. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1758320]

I. INTRODUCTION

Error correction is a key problem in quantum information processing. Without it, decoherence would easily destroy all hopes for quantum computation and quantum cryptography.

Two important approaches have been devoloped to combat decoherence. The usual theory of quantum error-correction[1,2] redundantly encodes the original quantum information in a larger quantum system by a unitary operation which maps the initial Hilbert space into the code space, a subspace of the Hilbert space associated to this larger system. After encoding, the larger system is subjected to noise and then a measurement is performed on the system to diagnose the type of error which occurred. Finally, on the basis of the outcome, a restoring operation is performed to return the system to the original state in the code space.

Another approach,[3–7] based on feedback control, has been developed for systems which are continuously monitored during their noisy evolution.[8] It employs the result of this continuous measurement to determine the errors occurred and, on this basis, perform corrections in real time to protect states which are known to lie initially within a certain code space. The continuous measurement can be performed introducing an additional interaction to the evolution of the system or preferably by simply observing the environment after its interaction with the system. Up to now there is no general theory for quantum feedback control, but some correction schemes have been considered and have dealt only with Hamiltonian feedback.

Taking from feedback control the idea of a correction scheme based on a measurement performed not on the system but on the environment, we have analyzed in an earlier publication[9] the different possible behaviors of a channel with respect to the existence of a measurement allowing perfect correction of information, quantum or classical. No code space is introduced and, for every initial state, the aim is to find proper measurement and restoring operations, not necessarily unitary, to recover the initial information or at least optimally restore it.

Here we develop the analysis in Ref. 9 to evolutions composed of many time steps. We consider quantum information carried by a system undergoing a discrete time Markovian evolution (multistep channel $T=T^{(n)}\circ\cdots\circ T^{(1)}$) and allow correction operations between any two sub-

sequent steps: every time we perform a measurement on the environment and a restoring operation on the system. We take the measurments on the environment as given and we look for the best restoring operations choosen on the basis of all the outcomes observed so far. First we give conditions for quantum information to be perfectly corrigible and characterize the related feedback. It turns out that classical feedback is not useful because perfect correction of quantum information is possible only if a unique correction at the end would suffice. Then we analyze the case when perfect correction is not possible and, in the qubit case, we find optimal feedback maximizing the channel fidelity. Similarly to the case of perfect correction, but more surprisingly, classical feedback is still useless if quantum information is carried by one qubit because again a unique restoring operation performed at the end of the evolution guarantees the same performance of correction. Anyway classical feedback is shown to be helpful when the quantum carrier has a higher dimensional Hilbert space.

Every section of the paper considers first the case of quantum information sent through a single-step channel, so that it is possible only one correction after this noisy evolution just as in Ref. 9, and then the case of a multistep channel, so that classical feedback is possible during the noisy evolution. In Sec. II, we set up the framework and the basic correction scheme. In Sec. III, for a given channel and given measurements on the environment, we prove the basic criteria for the existence of a scheme perfectly correcting quantum information, and we characterize the related feedback. In Sec. IV we look for optimal correction scheme when it is not be possible to achieve a complete correction of errors. In Sec. V we briefly discuss the transposition of this approach to continuous time and the difficulties which arise in this case.

II. THE CORRECTION SCHEME

We consider quantum information carried by a quantum system with finite dimensional Hilbert space $\mathcal{H}$. We work in the Schrödinger picture, so the action of the noisy *channel*, which corrupts the information transforming each input density operator ρ on $\mathcal{H}$ to a different output density operator $T(\rho)$ on $\mathcal{H}$, is given by a completly positive, trace preserving, linear map $T:\mathcal{L}(\mathcal{H})\to\mathcal{L}(\mathcal{H})$, where $\mathcal{L}(\mathcal{H})$ denotes the space of all linear operators on $\mathcal{H}$. A channel T is not physically reversible, i.e., there is no channel R such that $R\circ T=\mathrm{id}$, unless T is a unitary channel $T(\rho)=u\,\rho\,u^*$, with $u\in\mathcal{U}(\mathcal{H})$, the group of unitary operators on $\mathcal{H}$.

A. Single-step channel

Every channel can be described as the result of a unitary coupling to an environment, followed by the discard of the environment after the interaction. Nevertheless, the initial information carried by $\mathcal{H}$ is then shared with the environment and indeed, if we controlled perfectly the combined system, then we could recover the initial quantum information simply by reversing the global evolution, so restoring perfectly the input state ρ. We do not hypothesize this, but we assume that our control on the environment is good enough to have its initial state pure and to be able to perform any measurement on it after the interaction with $\mathcal{H}$. The measurement of an observable X on the environment decomposes the channel T into an *instrument*, a family of completely positive maps T_x giving the (non-normalized) output states $T_x(\rho)$ of the subensembles of systems selected according to the result "x" of this measurement: the probability of observing x is $\mathbb{P}(X=x)=\mathrm{tr}T_x(\rho)$, the normalized output state for the corresponding subensemble is $T_x(\rho)/\mathrm{tr}T_x(\rho)$, and the expectation in that subensemble of a self-adjoint $A\in\mathcal{L}(\mathcal{H})$ is $\mathrm{tr}(T_x(\rho)A)/\mathrm{tr}T_x(\rho)$. Ignoring the result of the measurement one recovers the original channel

$$T=\sum_x T_x. \tag{1}$$

Of course, the result x of the measurement gives classical information about the environment after the interaction, and hence also about $\mathcal{H}$ before the interaction. The idea for the correction scheme is to employ this information to select a proper restoring channel: we introduce a family of channels $R^{(x)}:\mathcal{L}(\mathcal{H})\to\mathcal{L}(\mathcal{H})$, where $R^{(x)}$ can depend in an arbitrary way on x. After correction,

the state of the subensemble for which the measurement has given the result x, will be $R^{(x)}(T_x(\rho))$ up to the normalization factor $\mathrm{tr}(T_x(\rho))$. The overall corrected channel is built from these conditional operations by ignoring the intermediate information x, and is the sum of these contributions:

$$T_{\mathrm{corr}}=\sum_x R^{(x)}\circ T_x. \tag{2}$$

The goodness of the scheme in restoring quantum information depends on how T_{corr} can be brought close to the ideal channel on $\mathcal{H}$, i.e., id.

Whether or not we can find a good correction scheme in principle depends not only on the noisy channel T, but also on the set of decompositions (1) obtainable by a measurment on the environment, which usually depends on the particular coupling which induces the noisy evolution T. Anyway the assumption of a pure environment overcomes this problem because it guarantees that every decomposition of T into c.p. summands T_x can be realized by a measurement on the environment. Moreover, in order to correct quantum information, the preferable docompositions are the finest ones, those for which no proper refinement is possible. Therefore we shall consider the non refinable decompositions given by the Kraus representations of T:

$$T(\rho)=\sum_x t_x\,\rho\,t_x^*, \quad \text{where } \sum_x t_x^* t_x=\mathbb{1}. \tag{3}$$

In the following we shall assume that a decomposition (3) is given, that it is associated to the measurement of an observable X, and for it we shall consider the problem of perfectly correcting quantum information or, if this is not possible, optimally restoring it.

B. Multistep channel

We are especially interested in multistep channels, where the noisy evolution T is given by n Markovian steps:

$$T=T^{(n)}\circ\cdots\circ T^{(1)}, \tag{4}$$

where $T^{(k)}:\mathcal{L}(\mathcal{H})\to\mathcal{L}(\mathcal{H})$ are n possibly different channels. In this case we assume to be able to perform a measurement at each step, so that every $T^{(k)}$ is decomposed into

$$T^{(k)}(\rho)=\sum_{x_k} t_{x_k}^{(k)}\,\rho\,t_{x_k}^{(k)*}, \quad \text{where } \sum_{x_k} t_{x_k}^{(k)*} t_{x_k}^{(k)}=\mathbb{1}, \tag{5}$$

the channel T is decomposed into

$$T(\rho)=\sum_{x_1,\ldots,x_n} t_{x_n}^{(n)}\cdots t_{x_1}^{(1)}\,\rho\,t_{x_1}^{(1)*}\cdots t_{x_n}^{(n)*}, \tag{6}$$

and the probability of observing $(x_1,\ldots,x_n)$ is $\mathbb{P}(X_1=x_1,\ldots,X_n=x_n)=\mathrm{tr}\,t_{x_n}^{(n)}\cdots t_{x_1}^{(1)}\,\rho\,t_{x_1}^{(1)*}\cdots t_{x_n}^{(n)*}$.

We also assume to be able to interfere in the evolution of the system after each step by appling a restoring channel selected according to the whole information gathered so far. For every $k=1,\ldots,n$, we introduce a family of channels $R^{(x_1,\ldots,x_k)}:\mathcal{L}(\mathcal{H})\to\mathcal{L}(\mathcal{H})$, where $R^{(x_1,\ldots,x_k)}$ can depend in an arbitrary way on $(x_1,\ldots,x_k)$ and it is applied after the measurement of X_k so that the overall corrected channel turns out to be

$$T_{\mathrm{corr}}(\rho)=\sum_{x_1,\ldots,x_n} R^{(x_1,\ldots,x_n)}(t_{x_n}^{(n)}\cdots R^{(x_1)}(t_{x_1}^{(1)}\,\rho\,t_{x_1}^{(1)*})\cdots t_{x_n}^{(n)*}). \tag{7}$$

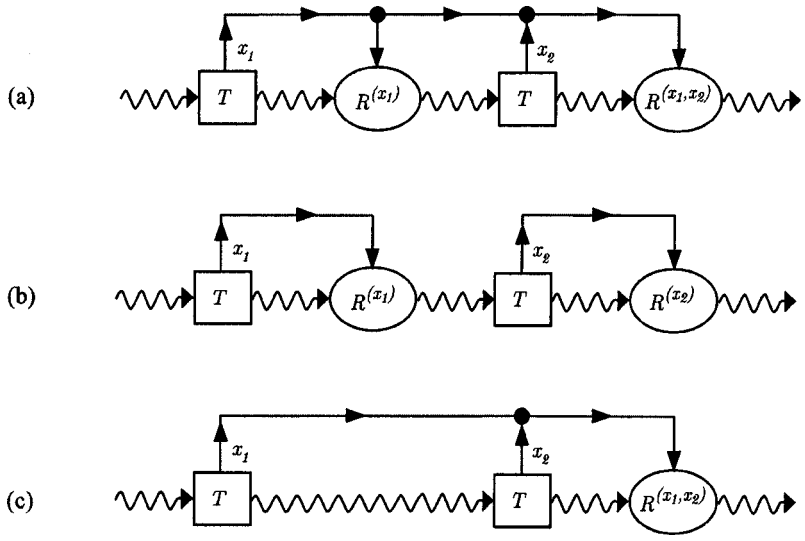

FIG. 1. Different error correction schemes for multiple channels. (a) represents the most general case. In (b) only the information from the immediately preceding step is used. In (c) only one correction is done at the end.

So the classical information obtained by the measurement process on the environment is fedback to modify the evolution of the system $\mathcal{H}$. Notice that this general scheme includes the special cases (compare Fig. 1):

(b) $R^{(x_1,\ldots,x_k)}=R^{(x_k)}$ for every $k=1,\ldots,n$, i.e., every restoring channel is selected according only to the last observation x_k;

(c) $R^{(x_1,\ldots,x_k)}=\mathrm{id}$ for every $k=1,\ldots,n-1$, i.e., the information given by the measurement on the environment is gathered during the evolution, but every correction is deferred after it.

In the following we shall assume that a decomposition (6) is fixed, that it is associated with a measurement process, and, given this, we shall consider the problem of perfect or optimal correction of quantum information.

III. PERFECT CORRECTION OF QUANTUM INFORMATION

Given a channel T with a fixed decomposition (3) or (6), our scheme can perfectly correct quantum information if one can find restoring channels R such that

$$T_{\mathrm{corr}}=\mathrm{id}\,.$$

A. Single-step channel

Let us improve the criterion given in Ref. 9.

Propostion 1: Let $T:\mathcal{L}(\mathcal{H})\to\mathcal{L}(\mathcal{H})$ be a channel over a finite dimensional Hilbert space $\mathcal{H}$. Given a Kraus decomposition $T(\rho)=\Sigma_x t_x\,\rho\,t_x^*$, the following are equivalent:

(a) there exists a family of channels $R^{(x)}:\mathcal{L}(\mathcal{H})\to\mathcal{L}(\mathcal{H})$ perfectly restoring quantum information;

(b) $t_x^* t_x=p_x\mathbb{1}$ for all x, with $p_x\geqslant 0$, $\Sigma_x p_x=1$;

(b′) $t_x=\sqrt{p_x}\,u_x$ for all x, with $u_x\in\mathcal{U}(\mathcal{H})$, $p_x\geqslant 0$, $\Sigma_x p_x=1$;

(b″) $T(\rho)=\Sigma_x p_x\,u_x\,\rho\,u_x^*$ is a convex combination of unitary channels;

(c) $\mathbb{P}(X=x)=\mathrm{tr}\,t_x\,\rho\,t_x^*$ is independent of the input state ρ.

When these conditions hold, then the restoring channels in (a) have to be

$$R^{(x)}(\rho)=u_x^*\,\rho\,u_x\,, \tag{8}$$

and the probability law of the outcome is

$$\mathbb{P}(X=x)=p_x\,. \tag{9}$$

Proof: (a)⇒(b). Let $R^{(x)}$ be channels such that $\Sigma_x R^{(x)}(t_x\,\rho\,t_x^*)=\rho$ for every state ρ. Then for every x, by the ''No information without perturbation'' Theorem, $R^{(x)}(t_x\,\rho\,t_x^*)=p_x\,\rho$, for some $p_x\geqslant 0$, $\Sigma_x p_x=1$. Therefore $\mathrm{tr}t_x^*t_x\,\rho=\mathrm{tr}t_x\,\rho\,t_x^*=\mathrm{tr}R^{(x)}(\mathrm{tr}t_x\,\rho\,t_x^*)=p_x$ for all ρ, and so $t_x^*t_x=p_x\,\mathbb{1}$.

(b)⇔(b′)⇔(b″). These conditions are clearly all equivalent because $\dim\mathcal{H}<\infty$.

(b′)⇒(c). $\mathbb{P}(X=x)=\mathrm{tr}t_x\,\rho\,t_x^*=\mathrm{tr}\sqrt{p_x}\,u_x^*\,\rho\,\sqrt{p_x}\,u_x=p_x$ for every ρ, so (b′) implies (c), and Eq. (9), too.

(c)⇒(a). $\mathrm{tr}\,t_x^*t_x\,\rho=\mathrm{tr}\,t_x\,\rho\,t_x^*=\mathbb{P}(X=x)$ which does not depend on ρ and so $t_x^*t_x=\mathbb{P}(X=x)\,\mathbb{1}$. Then $t_x=\sqrt{\mathbb{P}(X=x)}\,u_x$, where u_x is unitary because $\dim\mathcal{H}<\infty$, and the channels $R^{(x)}(\rho)=u_x^*\,\rho\,u_x$ perfectly restore quantum information.

Now we have to show that conditions (a), (b), and (c) imply (8). Consider a family of channels $R^{(x)}$ restoring quantum information, with $R^{(x)}(\rho)=\Sigma_j r_j^{(x)}\,\rho\,r_j^{(x)*}$ and $\Sigma_j r_j^{(x)*}r_j^{(x)}=\mathbb{1}$. Then

$$\sum_{x,j} r_j^{(x)}\,t_x\,\rho\,t_x^*\,r_j^{(x)*}=\rho\,,\quad \forall\ \rho\,,$$

and using again the ''No information without perturbation'' Theorem we have

$$r_j^{(x)}\,t_x=\sqrt{p_{x,j}}\,\mathrm{e}^{\mathrm{i}\theta(x,j)}\,\mathbb{1}\,,\quad \forall\ x,j,$$

for some probability law $p_{x,j}$ and some real function θ. Using (b′), we get

$$r_j^{(x)}=\sqrt{\frac{p_{x,j}}{p_x}}\,\mathrm{e}^{\mathrm{i}\theta(x,j)}\,u_x^*\propto u_x^*\quad \forall\ j,$$

i.e., fixed $R^{(x)}$, all the Kraus oprators $r_j^{(x)}$ have to be proportional to the same unitary operator u_x^*, and (8) holds. □

Let us remark that condition (b) gives a simple criterion for the existence of channels R perfectly restoring quantum information based directly on the Kraus operators of T. Moreover it clarifies the structure of channels which allow perfect correction with our scheme: the measurement on the environment has to decompose T into a convex combination of unitary channels, so that the overall evolution can be seen as an average of reversible evolutions $\rho\mapsto u_x\,\rho\,u_x^*$, which occur randomly with probability p_x; the measurement detects the transformation occurred and $R^{(x)}(\rho')=u_x^*\,\rho'\,u_x$ restores the initial state ρ. This means also, by condition (c), that the measurement on the environment is completely uninformative about the system $\mathcal{H}$: the output x can be interpreted as classical information about ''what happened'' to the system $\mathcal{H}$, but it gives no information about the input system because it is independent of its state. And the uninformative character of the observation, if associated to a Kraus decomposition of T, is sufficient for perfect correction. Moreover, if perfect correction is possible, the restoring channels R have to be unitary.

Here every channel T with a decomposition satisfying condition (b) will be called *corrigible*.

Just to show how useful can be a suitable measurement on the environment, let us remark that our scheme can perfectly correct quantum information sent through a depolarizing channel, which is known to destroy all quantum information and for which no ordinary quantum error correcting code works (it has zero quantum and classical capacity). Indeed, set $N=\dim\mathcal{H}$, the depolarizing channel $T(\rho)=(1/N)\mathbb{1}$ admits the Kraus representation

$$T(\rho)=\sum_{x,y=1}^{N} t_{x,y}\,\rho\,t_{x,y}^*\,,\quad t_{x,y}=\frac{1}{N}\sum_{z=1}^{N}\mathrm{e}^{(2\pi\mathrm{i}/N)\,zy}\,|z+x\rangle\langle z|=\frac{1}{N}u_{x,y}\,,$$

with unitary operators $u_{x,y}$, where $\{|z\rangle\}_{z\in\mathbb{Z}_N}$ denotes a basis labeled cyclically so that addition in $|z+x\rangle$ is modulo N.

B. Multistep channel

Let us consider now perfect correction for multistep channels.

Propostion 2: Let $T=T^{(n)}\circ\cdots\circ T^{(1)}$, *with every* $T^{(k)}:\mathcal{L}(\mathcal{H})\to\mathcal{L}(\mathcal{H})$, *be a multistep channel over a finite dimensional Hilbert space* $\mathcal{H}$. *Given the Kraus decompositions* $T^{(k)}(\rho)=\Sigma_{x_k}t^{(k)}_{x_k}\rho\, t^{(k)*}_{x_k}$, *T.F.A.E.*

(a) there exists a family of channels $R^{(x_1)},R^{(x_1,x_2)},\ldots,R^{(x_1,\ldots,x_n)}$ *perfectly restoring quantum information*;

(b) every channel $T^{(k)}(\rho)=\Sigma_{x_k}t^{(k)}_{x_k}\rho\, t^{(k)*}_{x_k}$ *is corrigible, i.e., for all* x_k *we have* $t^{(k)}_{x_k}=\sqrt{p^{(k)}_{x_k}}\,u^{(k)}_{x_k}$, *with* $u^{(k)}_{x_k}\in\mathcal{U}(\mathcal{H})$, $p^{(k)}_{x_k}\geqslant 0$, $\Sigma_{x_k}p^{(k)}_{x_k}=1$;

(c) $\mathbb{P}(X_1=x_1,\ldots,X_n=x_n)=\mathrm{tr}\,t^{(n)}_{x_n}\cdots t^{(1)}_{x_1}\rho\, t^{(1)*}_{x_1}\cdots t^{(n)*}_{x_n}$ *is independent of the input state* ρ.

When these conditions hold, then for every $k=1,\ldots,n$ *the restoring channels in (a) have to be*

$$R^{(x_1,\ldots,x_k)}(\rho)=v^{(x_1,\ldots,x_k)}\rho\, v^{(x_1,\ldots,x_k)*},\quad v^{(x_1,\ldots,x_k)}\in\mathcal{U}(\mathcal{H}),\tag{10}$$

with

$$v^{(x_1,\ldots,x_n)}=u^{(1)*}_{x_1}v^{(x_1)*}\cdots v^{(x_1,\ldots,x_{n-1})*}u^{(n)*}_{x_n},\tag{11}$$

and the probability law of the outcome process is always

$$\mathrm{tr}\,R^{(x_1,\ldots,x_n)}(t^{(n)}_{x_n}\cdots R^{(x_1)}(t^{(1)}_{x_1}\rho\, t^{(1)*}_{x_1})\cdots t^{(n)*}_{x_n})=\prod_{k=1}^{n}p^{(k)}_{x_k}.\tag{12}$$

Therefore, as long as we are interested in perfect correction of quantum information, the multistep structure of the channel and the possibility of applying feedback during the evolution do not help: perfect correction is possible if and only if every step is corrigible and, in this case, it is enough to make a unique correction at the end. Indeed only unitary corrections are allowed, otherwise the original information would be corrupted by the feedback itself, and then the first $n-1$ unitaries $v^{(x_1,\ldots,x_k)}$ can be chosen arbitrarly, also $v^{(x_1,\ldots,x_k)}=\mathbb{1}$, provided that the whole evolution is reversed by the last one (Eq. (11)). Again, the channel is corrigible if and only if the measured process is uninformative; moreover its probabilistic law, which cannot be modified by the unitary feedback, is that of a sequence of independent random variables.

The proof of Proposition 2 goes via a more general result about the composition of n channels when each channel is decomposed according to a measurement and, not only each channel itself, but also its decomposition, may depend on the previous observations. Therefore, denoted by x_k the outcomes of the measurement at the kth step, we want to consider the evolution of a quantum system sent through a sequence of channels on $\mathcal{L}(\mathcal{H})$,

$$T^{(x_1,\ldots,x_{k-1})}(\rho)=\sum_{x_k}t^{(x_1,\ldots,x_{k-1})}_{x_k}\rho\, t^{(x_1,\ldots,x_{k-1})*}_{x_k},\quad \sum_{x_k}t^{(x_1,\ldots,x_{k-1})*}_{x_k}t^{(x_1,\ldots,x_{k-1})}_{x_k}=\mathbb{1},\tag{13}$$

where for the first step, $k=1$, we denote by "0" the empty string of prior results, so we write

$$T^{(0)}(\rho)=\sum_{x_1}t^{(0)}_{x_1}\rho\, t^{(0)*}_{x_1},\quad \sum_{x_1}t^{(0)*}_{x_1}t^{(0)}_{x_1}=\mathbb{1}.$$

Then the total evolution is

$$T(\rho)=\sum_{x_1,\ldots,x_n}t^{(x_1,\ldots,x_{n-1})}_{x_n}\cdots t^{(0)}_{x_1}\rho\, t^{(0)*}_{x_1}\cdots t^{(x_1,\ldots,x_{n-1})*}_{x_n},\tag{14}$$

and the next Proposition holds.

Propostion 3: Given a finite dimensional Hilbert space $\mathcal{H}$, let $T:\mathcal{L}(\mathcal{H})\to\mathcal{L}(\mathcal{H})$ be a channel (14) resulting from the application of n decomposed channels $T^{(x_1,\ldots,x_{k-1})}$ (13). If $T=\mathrm{id}$, then

(a) every channel $T^{(x_1,\ldots,x_{k-1})}(\rho)=\Sigma_{x_k}t_{x_k}^{(x_1,\ldots,x_{k-1})}\,\rho\,t_{x_k}^{(x_1,\ldots,x_{k-1})^*}$ is corrigible;

*(b) a channel $T^{(x_1,\ldots,x_{k-1})}$ is unitary if later channels and their decomositions do not depend on the value x_k observed at the k*th *step.*

Proof: If $T=\mathrm{id}$, then

$$t_{x_n}^{(x_1,\ldots,x_{n-1})}\cdots t_{x_1}^{(0)}=\sqrt{p(x_1,\ldots,x_n)}\,\mathrm{e}^{\mathrm{i}\theta(x_1,\ldots,x_n)}\,\mathbb{1},\quad\forall\ x_1,\ldots,x_n, \tag{15}$$

where p is the joint probability law of the outcomes, independent of ρ, and θ is a real function.

(a) Using the normalization property of Kraus operators, we can immediately show that $T^{(0)}$ is corrigible:

$$\begin{aligned}t_{x_1}^{(0)^*}t_{x_1}^{(0)}&=\sum_{x_2,\ldots,x_n}t_{x_1}^{(0)^*}t_{x_2}^{(x_1)^*}\cdots t_{x_n}^{(x_1,\ldots,x_{n-1})^*}t_{x_n}^{(x_1,\ldots,x_{n-1})}\cdots t_{x_2}^{(x_1)}t_{x_1}^{(0)}\\&=\sum_{x_2,\ldots,x_n}p(x_1,\ldots,x_n)\,\mathbb{1}=p(x_1)\,\mathbb{1},\end{aligned}$$

where $p(x_1)$ is the probability of observing x_1 at the first step. Now, since $t_{x_1}^{(0)}=\sqrt{p(x_1)}\,u_{x_1}^{(0)}$ for some unitary $u_{x_1}^{(0)}$, we can fix x_1 and find that $T^{(x_1)}$ is corrigible:

$$\begin{aligned}t_{x_2}^{(x_1)^*}t_{x_2}^{(x_1)}&=\frac{1}{p(x_1)}u_{x_1}^{(0)}t_{x_1}^{(0)^*}t_{x_2}^{(x_1)^*}t_{x_2}^{(x_1)}t_{x_1}^{(0)}u_{x_1}^{(0)^*}\\&=\frac{1}{p(x_1)}u_{x_1}^{(0)}\sum_{x_3,\ldots,x_n}t_{x_1}^{(0)^*}t_{x_2}^{(x_1)^*}\cdots t_{x_n}^{(x_1,\ldots,x_{n-1})^*}t_{x_n}^{(x_1,\ldots,x_{n-1})}\cdots t_{x_2}^{(x_1)}t_{x_1}^{(0)}u_{x_1}^{(0)^*}\\&=\frac{1}{p(x_1)}\sum_{x_3,\ldots,x_n}p(x_1,\ldots,x_n)\,\mathbb{1}=p(x_2|x_1)\,\mathbb{1},\end{aligned}$$

where $p(x_2|x_1)$ is the probability of observing x_2 at the second step conditioned upon the observation of x_1 at the first step. Again we have $t_{x_2}^{(x_1)}=\sqrt{p(x_2|x_1)}\,u_{x_2}^{(x_1)}$ for some unitary $u_{x_2}^{(x_1)}$ and, repeating the same argument, we find for every k

$$t_{x_k}^{(x_1,\ldots,x_{k-1})}=\sqrt{p(x_k|x_1,\ldots,x_{k-1})}\,u_{x_k}^{(x_1,\ldots,x_{k-1})},\quad u_{x_k}^{(x_1,\ldots,x_{k-1})}\in\mathcal{U}(\mathcal{H}), \tag{16}$$

where $p(x_k|x_1,\ldots,x_{k-1})$ is the probability of observing x_k at the kth step conditioned upon the observation of $(x_1,\ldots,x_{k-1})$ during the previous steps. Equation (16) gives the polar decomposition of $t_{x_k}^{(x_1,\ldots,x_{k-1})}$, which in this case is unique.

(b) Combining Eqs. (15) and (16) we get

$$t_{x_k}^{(x_1,\ldots,x_{k-1})}=\sqrt{p(x_k|x_1,\ldots,x_{k-1})}\,\mathrm{e}^{\mathrm{i}\theta(x_1,\ldots,x_n)}\,u_{x_{k+1}}^{(x_1,\ldots,x_k)^*}\cdots u_{x_n}^{(x_1,\ldots,x_{n-1})^*}\,u_{x_1}^{(0)^*}\cdots u_{x_{k-1}}^{(x_1,\ldots,x_{k-2})^*},$$

where, because of the uniqueness of the polar decomposition of $t_{x_k}^{(x_1,\ldots,x_{k-1})}$,

$$\mathrm{e}^{\mathrm{i}\theta(x_1,\ldots,x_n)}\,u_{x_{k+1}}^{(x_1,\ldots,x_k)^*}\cdots u_{x_n}^{(x_1,\ldots,x_{n-1})^*}\,u_{x_1}^{(0)^*}\cdots u_{x_{k-1}}^{(x_1,\ldots,x_{k-2})^*}=u_{x_k}^{(x_1,\ldots,x_{k-1})},$$

which therefore has to be independent of $x_{k+1},\ldots,x_n$. If moreover $(x_1,\ldots,x_{k-1})$ is such that for all $m>k$ the operators $t_{x_m}^{(x_1,\ldots,x_{m-1})}$ do not depend on x_k, then the same is true for the unitary

operator $u_{x_{k+1}}^{(x_1,\ldots,x_k)^*}\cdots u_{x_n}^{(x_1,\ldots,x_{n-1})^*}\,u_{x_1}^{(0)^*}\cdots u_{x_{k-1}}^{(x_1,\ldots,x_{k-2})^*}$ and so the Kraus operators $t_{x_k}^{(x_1,\ldots,x_{k-1})}$ are all proportional to a same unitary operator $u^{(x_1,\ldots,x_{k-1})}$ and $T^{(x_1,\ldots,x_{k-1})}(\rho)=u^{(x_1,\ldots,x_{k-1})}\,\rho\,u^{(x_1,\ldots,x_{k-1})^*}$.

Proof of Proposition 2:

(a)⇒(b). Let $R^{(x_1,\ldots,x_{k-1})}(\rho)=\Sigma_{j_k} r_{j_k}^{(x_1,\ldots,x_{k-1})}\,\rho\,r_{j_k}^{(x_1,\ldots,x_{k-1})^*}$, where $\Sigma_{j_k} r_{j_k}^{(x_1,\ldots,x_{k-1})^*} r_{j_k}^{(x_1,\ldots,x_{k-1})}=\mathbb{1}$.

If $\Sigma_{\substack{x_1,\ldots,x_n\\ j_1,\ldots,j_n}} r_{j_n}^{(x_1,\ldots,x_n)}\,t_{x_n}^{(n)}\cdots r_{j_1}^{(x_1)}\,t_{x_1}^{(1)}\,\rho\,t_{x_1}^{(1)^*}\,r_{j_1}^{(x_1)^*}\cdots t_{x_n}^{(n)^*}\,r_{j_n}^{(x_1,\ldots,x_n)^*}=\rho$ for every ρ, then this decomposition of the ideal channel is associated to a probability measure $p(x_1,j_1,\ldots,x_n,j_n)$ and Proposition 3 directly implies $t_{x_k}^{(k)}=\sqrt{p(x_k|x_1,j_1,\ldots,x_{k-1},j_{k-1})}\,u_{x_k}^{(x_1,j_1,\ldots,x_{k-1},j_{k-1})}$, where $u_{x_k}^{(x_1,j_1,\ldots,x_{k-1},j_{k-1})}$ is unitary and where $p(x_k|x_1,j_1,\ldots,x_{k-1},j_{k-1})=p_{x_k}^{(k)}$ and $u_{x_k}^{(x_1,j_1,\ldots,x_{k-1},j_{k-1})}=u_{x_k}^{(k)}$ because $t_{x_k}^{(k)}$ does not depend on $(x_1,j_1,\ldots,x_{k-1},j_{k-1})$.

(b)⇒(c). If $t_{x_k}^{(k)}=\sqrt{p_{x_k}^{(k)}}\,u_{x_k}^{(k)}$, with $u_{x_k}^{(k)}\in\mathcal{U}(\mathcal{H})$, $p_{x_k}^{(k)}\geqslant 0$, $\Sigma_{x_k}p_{x_k}^{(k)}=1$, then for every ρ

$$\mathbb{P}(X_1=x_1,\ldots,X_n=x_n)=\operatorname{tr} t_{x_n}^{(n)}\cdots t_{x_1}^{(1)}\,\rho\,t_{x_1}^{(1)^*}\cdots t_{x_n}^{(n)^*}=\prod_{k=1}^{n} p_{x_k}^{(k)}.$$

(c)⇒(a). According to (c), $\operatorname{tr} t_{x_1}^{(1)^*}\cdots t_{x_n}^{(n)^*}t_{x_n}^{(n)}\cdots t_{x_1}^{(1)}\,\rho=\operatorname{tr} t_{x_n}^{(n)}\cdots t_{x_1}^{(1)}\,\rho\,t_{x_1}^{(1)^*}\cdots t_{x_n}^{(n)^*}$ $=\mathbb{P}(X_1=x_1,\ldots,X_n=x_n)$ does not depend on ρ and so one gets $t_{x_1}^{(1)^*}\cdots t_{x_n}^{(n)^*}t_{x_n}^{(n)}\cdots t_{x_1}^{(1)}$ $=\mathbb{P}(X_1=x_1,\ldots,X_n=x_n)\,\mathbb{1}$. Then, with the same argument used in the proof of property (a) of Proposition 3,

$$t_{x_k}^{(k)}=\sqrt{\mathbb{P}(X_k=x_k|X_1=x_1,\ldots,X_{k-1}=x_{k-1})}\,u_{x_k}^{(x_1,\ldots,x_{k-1})},$$

where $u_{x_k}^{(x_1,\ldots,x_{k-1})}$ is unitary, and where actually $\mathbb{P}(X_k=x_k|X_1=x_1,\ldots,X_{k-1}=x_{k-1})$ $=\mathbb{P}(X_k=x_k)$ and $u_{x_k}^{(x_1,\ldots,x_{k-1})}=u_{x_k}^{(k)}$ because $t_{x_k}^{(k)}$ is independent of $(x_1,\ldots,x_{k-1})$. Then the channels $R^{(x_1,\ldots,x_k)}(\rho)=u_{x_k}^{(k)^*}\,\rho\,u_{x_k}^{(k)}$ perfectly restore quantum information.

When (a), (b), and (c) hold, all the restoring channels R in (a) satisfy (10) by Proposition 3, and of course for every choice of $v^{(x_1,\ldots,x_k)}$, $k=1,\ldots,k-1$, the channel $R^{(x_1,\ldots,x_n)}$ defined by (11) can perfectly restore quantum information. Finally Eq. (12) directly follows from condition (b) and Eq. (10). □

IV. OPTIMAL RECOVERY OF QUANTUM INFORMATION

When perfect correction of quantum information is not possible, we would like the restoring channels R which bring the corrected channel T_{corr} as close as possible to id, in some sense. We look for channels R which maximize the *channel fidelity* of the corrected channel, $\mathcal{F}(T_{\text{corr}})$. For a channel $T:\mathcal{L}(\mathcal{H})\to\mathcal{L}(\mathcal{H})$, $T(\rho)=\Sigma_x t_x\,\rho\,t_x^*$, $\dim\mathcal{H}=N$, denoted by Ω a maximally entangled unit vector in $\mathcal{H}\otimes\mathcal{H}$, the channel fidelity

$$\mathcal{F}(T)=\langle\Omega,T\otimes\mathrm{id}(|\Omega\rangle\langle\Omega|)\,\Omega\rangle=\frac{1}{N^2}\sum_x |\operatorname{tr} t_x|^2$$

measures how well T preserves quantum information, reaching 1 if and only if $T=\mathrm{id}$.

A. Single-step channel

Let us recall what was found in Ref. 9 for the single-step case. Given T, chosen a Kraus decomposition (3) and the restoring channels $R^{(x)}$,

$$R^{(x)}(\rho)=\sum_j r_j^{(x)}\,\rho\,r_j^{(x)*},\quad \sum_j r_j^{(x)*}r_j^{(x)}=\mathbb{1},$$

we are interested in

$$\mathcal{F}(T_{\mathrm{corr}})=\frac{1}{N^2}\sum_{x,j}|\mathrm{tr}\,r_j^{(x)}\,t_x|^2, \tag{17}$$

and we want to maximize it with respect to all possible families $\{R^{(x)}\}$.

Propostion 4: Let $T:\mathcal{L}(\mathcal{H})\to\mathcal{L}(\mathcal{H})$ be a channel over a finite dimensional Hilbert space $\mathcal{H}$. Fixed a Kraus decomposition $T(\rho)=\Sigma_x t_x\,\rho\,t_x^*$, for every family of channels $R^{(x)}:\mathcal{L}(\mathcal{H})\to\mathcal{L}(\mathcal{H})$ let T_{corr} be the corresponding overall corrected channel (2). Then

$$\mathcal{F}(T_{\mathrm{corr}})\leqslant\frac{1}{N^2}\sum_x(\mathrm{tr}|t_x|)^2. \tag{18}$$

Moreover equality holds if and only if

$$T_{\mathrm{corr}}(\rho)=\sum_x|t_x|\,\rho\,|t_x|, \tag{19}$$

and it can always be attained choosing

$$R^{(x)}(\rho)=u_x^*\,\rho\,u_x, \tag{20}$$

where u_x is a unitary operator in the polar decomposition $t_x=u_x|t_x|$.

Proof: Inequality (18) follows from (17) because the Cauchy–Schwarz inequality for the Hilbert–Schmidt inner product gives

$$\begin{aligned}\sum_j|\mathrm{tr}\,r_j^{(x)}\,t_x|^2&=\sum_j|\mathrm{tr}(r_j^{(x)}\,u_x|t_x|^{1/2}|t_x|^{1/2})|^2\\&\leqslant\sum_j\mathrm{tr}(|t_x|^{1/2}u_x^*r_j^{(x)*}r_j^{(x)}u_x|t_x|^{1/2})\,\mathrm{tr}|t_x|=(\mathrm{tr}|t_x|)^2.\end{aligned} \tag{21}$$

Equality holds in (18) if and only if equality holds in (21) for every x, which occurs if and only if $r_j^{(x)}\,u_x|t_x|^{1/2}=\lambda_{xj}|t_x|^{1/2}$, $\lambda_{xj}\in\mathbb{C}$, for every x and j. Then $r_j^{(x)}\,t_x=\lambda_{xj}|t_x|$ and (19) holds. The opposite implication is obvious.

Finally, if $R^{(x)}$ are chosen according to (20), then T_{corr} is given by (19) and equality holds in (18). □

The structure of the optimal restoring channels (20) obtained by maximizing $\mathcal{F}(T_{\mathrm{corr}})$, is just what one could expect. When a measurement on the environment has given the result x, we deal with a subensemble of systems undergone the state transformation $\rho\mapsto t_x\,\rho\,t_x^*=u_x|t_x|\,\rho\,|t_x|u_x^*$, which can be seen as a composition of $\rho\mapsto|t_x|\,\rho\,|t_x|$ followed by $\rho\mapsto u_x\,\rho\,u_x^*$. Unless we are in the trivial case $|t_x|\propto\mathbb{1}$, only the second transformation is physically reversible, and this is just what the channel (20) does. Therefore $\mathcal{F}(T_{\mathrm{corr}})$ can be maximized considering only unitary feedback, even if sometimes non unitary feedback could work as well (for example, every time the polar decomposition of t_x is not unique).

B. Multistep channel

Given a multistep channel T, decomposed according to (6), we allow corrections also before the evolution stops and so we want to maximize the channel fidelity of T_{corr} over all possible families $R^{(x_1)},R^{(x_1,x_2)},\ldots,R^{(x_1,\ldots,x_n)}$ in (7). We are interested in the optimal feedback, of course, and we want to compare the maximum attainable fidelity with

(1) the maximum fidelity obtainable only with a unique correction at the end, which is, by Proposition 4,

$$\mathcal{F}(T'_{\mathrm{corr}}) = \frac{1}{N^2} \sum_{x_1,\ldots,x_n} (\mathrm{tr}|t^{(n)}_{x_n} \cdots t^{(1)}_{x_1}|)^2 , \tag{22}$$

where T'_{corr} denotes the corrected channel

$$T'_{\mathrm{corr}}(\rho) = |t^{(n)}_{x_n} \cdots t^{(1)}_{x_1}| \, \rho \, |t^{(n)}_{x_n} \cdots t^{(1)}_{x_1}| ;$$

(2) the fidelity obtainable applying step by step the feedback suggested by Proposition 4, chosen on the basis of the whole avaible information; the corrected evolution associated to the observation of $(x_1,\ldots,x_n)$ would be

$$\rho \mapsto t^{(1)}_{x_1} \rho \, t^{(1)*}_{x_1} \mapsto |t^{(1)}_{x_1}| \, \rho \, |t^{(1)}_{x_1}| \mapsto t^{(2)}_{x_2} |t^{(1)}_{x_1}| \, \rho \, |t^{(1)}_{x_1}| \, t^{(2)*}_{x_2} \mapsto |t^{(2)}_{x_2} |t^{(1)}_{x_1}|| \, \rho \, |t^{(2)}_{x_2} |t^{(1)}_{x_1}|| \mapsto \cdots$$

$$\mapsto |t^{(n)}_{x_n} \cdots |t^{(2)}_{x_2}| t^{(1)}_{x_1}||| \, \rho \, |t^{(n)}_{x_n} \cdots |t^{(2)}_{x_2}| t^{(1)}_{x_1}||| := T''_{\mathrm{corr}}(\rho) , \tag{23}$$

with fidelity

$$\mathcal{F}(T''_{\mathrm{corr}}) = \frac{1}{N^2} \sum_{x_1,\ldots,x_n} (\mathrm{tr}|t^{(n)}_{x_n} \cdots |t^{(2)}_{x_2}| t^{(1)}_{x_1}|||)^2 . \tag{24}$$

Quite surprisingly, these two strategies are equivalent, and optimal, in the qubit case ($\dim \mathcal{H} = 2$), but in the general case ($\dim \mathcal{H} \geqslant 3$) there is no relationship between them, and neither of them gives the optimal correction.

1. Qubit multistep channels

Propostion 5: Let $\dim \mathcal{H} = 2$ *and* $T = T^{(n)} \circ \cdots \circ T^{(1)}$ *be a multistep channel, with every* $T^{(k)} : \mathcal{L}(\mathcal{H}) \to \mathcal{L}(\mathcal{H})$. *Fixed the Kraus decompositions* $T^{(k)}(\rho) = \Sigma_{x_k} t^{(k)}_{x_k} \rho \, t^{(k)*}_{x_k}$, *for every family of channels* $R^{(x_1)}, R^{(x_1,x_2)}, \ldots, R^{(x_1,\ldots,x_n)}$, *let* T_{corr} *be the corresponding overall corrected channel (7). Then*

$$\mathcal{F}(T_{\mathrm{corr}}) \leqslant \frac{1}{4} \sum_{x_1,\ldots,x_n} (\mathrm{tr}|t^{(n)}_{x_n} \cdots t^{(1)}_{x_1}|)^2 . \tag{25}$$

Moreover equality can always be attained choosing

$$R^{(x_1,\ldots,x_k)}(\rho) = v^{(x_1,\ldots,x_k)} \rho \, v^{(x_1,\ldots,x_k)*} , \quad v^{(x_1,\ldots,x_k)} \in \mathcal{U}(\mathcal{H}) , \quad \forall \;\; k = 1,\ldots,n , \tag{26}$$

with $v^{(x_1,\ldots,x_n)} = w^{(x_1,\ldots,x_n)*}$, *where* $w^{(x_1,\ldots,x_n)}$ *is a unitary operator in the polar decomposition* $t^{(n)}_{x_n} v^{(x_1,\ldots,x_{n-1})} \cdots v^{(x_1)} t^{(1)}_{x_1} = w^{(x_1,\ldots,x_n)} |t^{(n)}_{x_n} v^{(x_1,\ldots,x_{n-1})} \cdots v^{(x_1)} t^{(1)}_{x_1}|$.

Proof: The key property in a two-dimensional Hilbert space is that for every operator A

$$(\mathrm{tr}|A|)^2 = \mathrm{tr}(|A|^2) + 2 \det|A| , \quad \text{where} \quad \det|A| = |\det A| \leqslant \tfrac{1}{2} \mathrm{tr}(|A|^2) .$$

Then, for every family of channels $R^{(x_1,\ldots,x_{k-1})}(\rho) = \Sigma_{j_k} r^{(x_1,\ldots,x_{k-1})}_{j_k} \rho \, r^{(x_1,\ldots,x_{k-1})*}_{j_k}$, $\Sigma_{j_k} r^{(x_1,\ldots,x_{k-1})*}_{j_k} r^{(x_1,\ldots,x_{k-1})}_{j_k} = \mathbb{I}$,

$$\begin{aligned}
\mathcal{F}(T_{\mathrm{corr}}) &= \frac{1}{4}\sum_{\substack{x_1,\dots,x_n\\ j_1,\dots,j_n}} |\operatorname{tr} r_{j_n}^{(x_1,\dots,x_n)}\, t_{x_n}^{(n)}\cdots r_{j_1}^{(x_1)}\, t_{x_1}^{(1)}|^2 \\
&\leqslant \frac{1}{4}\sum_{\substack{x_1,\dots,x_n\\ j_1,\dots,j_{n-1}}} (\operatorname{tr}|t_{x_n}^{(n)}\, r_{j_{n-1}}^{(x_1,\dots,x_{n-1})}\cdots r_{j_1}^{(x_1)}\, t_{x_1}^{(1)}|)^2 \\
&= \frac{1}{2}+\frac{1}{2}\sum_{\substack{x_1,\dots,x_n\\ j_1,\dots,j_{n-1}}} |\det t_{x_n}^{(n)}\cdots t_{x_1}^{(1)}|\cdot|\det r_{j_{n-1}}^{(x_1,\dots,x_{n-1})}|\cdot|\det r_{j_1}^{(x_1)}| \\
&\leqslant \frac{1}{2}+\frac{1}{2}\sum_{x_1,\dots,x_n} |\det t_{x_n}^{(n)}\cdots t_{x_1}^{(1)}| \\
&= \frac{1}{4}\sum_{x_1,\dots,x_n} (\operatorname{tr}|t_{x_n}^{(n)}\cdots t_{x_1}^{(1)}|)^2 .
\end{aligned}$$

Analogously for every family of unitary channels $R^{(x_1,\dots,x_k)}(\rho)=v^{(x_1,\dots,x_k)}\,\rho\, v^{(x_1,\dots,x_k)*}$, with $v^{(x_1,\dots,x_n)}=w^{(x_1,\dots,x_n)*}$,

$$\begin{aligned}
\mathcal{F}(T_{\mathrm{corr}}) &= \frac{1}{4}\sum_{x_1,\dots,x_n} (\operatorname{tr}|t_{x_n}^{(n)}\, v^{(x_1,\dots,x_{n-1})}\cdots v^{(x_1)}\, t_{x_1}^{(1)}|)^2 \\
&= \frac{1}{2}+\frac{1}{2}\sum_{x_1,\dots,x_n} |\det t_{x_n}^{(n)}\, v^{(x_1,\dots,x_{n-1})}\cdots v^{(x_1)}\, t_{x_1}^{(1)}| \\
&= \frac{1}{2}+\frac{1}{2}\sum_{x_1,\dots,x_n} |\det t_{x_n}^{(n)}\cdots t_{x_1}^{(1)}| = \frac{1}{4}\sum_{x_1,\dots,x_n} (\operatorname{tr}|t_{x_n}^{(n)}\cdots t_{x_1}^{(1)}|)^2 .
\end{aligned}$$

□

2. Higher dimensional two-step channels

When $\dim\mathcal{H}\geqslant 3$ there is no general relationship between the two fidelities (22) and (24). Consider on $\mathbb{C}^3$ the multistep channels $T=T^{(2)}\circ T^{(1)}$ and $S=S^{(2)}\circ S^{(1)}$, where

$$T^{(1)}(\rho)=T^{(2)}(\rho)=\sum_{x=1}^{2} t_x\,\rho\, t_x^*, \quad S^{(1)}(\rho)=S^{(2)}(\rho)=\sum_{x=1}^{2} s_x\,\rho\, s_x^*,$$

$$|t_1|^2=|s_1|^2=\begin{pmatrix} 1/6 & 0 & 0\\ 0 & 1/3 & 0\\ 0 & 0 & 1/2\end{pmatrix}, \quad |t_2|^2=|s_2|^2=\begin{pmatrix} 5/6 & 0 & 0\\ 0 & 2/3 & 0\\ 0 & 0 & 1/2\end{pmatrix},$$

$$t_1=u\,|t_1|, \quad t_2=|t_2|, \quad s_1=v\,|s_1|, \quad s_1=u\,|s_1|,$$

where

$$u=\begin{pmatrix} 0 & 1 & 0\\ 1 & 0 & 0\\ 0 & 0 & 1\end{pmatrix}, \quad \text{and} \quad v=\frac{1}{\sqrt{3}}\begin{pmatrix} e^{2i\pi/3} & e^{-2i\pi/3} & 1\\ e^{-2i\pi/3} & e^{2i\pi/3} & 1\\ 1 & 1 & 1\end{pmatrix}.$$

Then since the absolute values of the Kraus operators coincide, the single-step corrected versions of T and S are the same. Moreover, since these absolute values commute, the iterated absolute values factorize, i.e.,

$$|t_{x_n}^{(n)}\cdots|t_{x_2}^{(2)}\,|t_{x_1}^{(1)}|||=|t_{x_n}^{(n)}|\cdots|t_{x_2}^{(2)}|\cdot|t_{x_1}^{(1)}|. \tag{27}$$

Hence the greedy strategy of correcting for maximal fidelity at every step, using all available information, gives the same result for these channels as the product of the single-step corrected channels. In particular, S and T are equivalent in this respect, and $\mathcal{F}(T''_{\mathrm{corr}})=\mathcal{F}(S''_{\mathrm{corr}})$ (see last line in the table below).

On the other hand, we can leave the system undisturbed, and only make an optimal correction at the end, again using all available information. Finally, we may optimize fidelity over all correction schemes. Numerically this achieved by an iteration, developed in Ref. 10, which efficiently determines the maximum of a general positive linear functional on channels. In the case at hand this is the overall channel fidelity as a function of the correcting channels R. Since we can correct the unitaries u and v immediately in every step, it is clear that the channels S and T once again give the same corrected fidelities. The results are summarized in the following:

Channel fidelities	T	S
Optimal correction	0.9584	0.9584
Final correction only	0.9556	0.9576
	$<$	$>$
Optimal correction at each step	0.9570	0.9570

Hence, in contrast to the case of perfect corrigibility, it may help to perform corrections on the way, rather than a single correction at the end (column T). Perhaps surprisingly, the optimal correction at the intermediate steps requires some foresight, and depends on what is to follow: otherwise the strategy of correcting for highest fidelity using all available information, which is clearly optimal in the last step, would also have to be optimal in the intermediate steps (compare first and last line). Even leaving out the intermediate correction altogether may be better (column S).

3. Higher dimensional many-step channels

We noted that in the previous example the correction scheme for T''_{corr} is equivalent to multiplying the one-step corrected channels. That is, whether this correction step may use all available information or just the information from the last step, leads to the same corrected channel. We showed this by noting that the absolute values of all Kraus operators involved commute. This will be true in any dimension if there are only two Kraus operators, as in the example. Here we just note that this equality is not a general fact. In fact using random channels one quickly finds examples (3 Hilbert space dimensions, 3 Kraus operators, and 4 time steps), in which using all information or just information from the last step give different results. Surprisingly, once again the comparison may be either way: sometimes using only one-step information is *better* than using all information. Of course, this is only possible because the greedy strategy is not optimal in the first place.

V. OUTLOOK

We would like to spend some words about the quantum error-correction in *continuous* time. Our aim would be to generalize this correction scheme for quantum information corrupted by a noisy Markovian evolution assigned by a Quantum Dynamical Semigroup. The present analysis for a multistep channel $T=(T^{(1)})^n$ would provide the intervalwise treatment, but it is not easy to take the limit to continuous time. The well established theory of continuous measurements[11] gives the possible decompositions (unravelings) of the channel according to the observed trajectoies, but a continuous time formulation of general non-Hamiltonian feedback is missing. There is no general description of the evolution conditioned on the observed process if a feedback depending on the whole measurement record is added. And also if the feedback is supposed to depend only on the present observation, the measured current, still there is no general description for non-Hamiltonian feedback. A theory exists only for Hamiltonian feedback simply proportional to the measured currents.[12] Anyway a preliminary study of perfect correction in this framework leads to the same conclusions of Proposition 2: perfect correction is possible if and only if the measured

process is uninformative and in this case a unique correction at the end suffices. It is also possible to characterize the Linblad generator of semigroups allowing such perfect correction and, as pointed out by Luc Bouten, these semigroups are just the ones admitting an essentially commutative dilation.[13]

We consider the inverse scattering problem for the Schrödinger operator with optical potential introduced in nuclear physics to study the scattering of nucleons by nuclei. We show that the corresponding spin–orbit interaction and the complex matrix potential can be uniquely reconstructed from the scattering amplitude at fixed energy. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1753665]

I. INTRODUCTION

The optical model is an operator phenomenologically or empirically introduced in nuclear physics to study the scattering of nucleons by nuclei. The model corresponds to the Schrödinger operator with a complex potential and it was first effectively used by Feshbach, Porter, and Weisskopf[9] to reproduce with great success the experimental results on the scattering of neutrons. Since then this optical model has been improved and accepted as a fundamental tool in nuclear physics. Usually the spin–orbit interaction is included and the following form of the Hamiltonian is adopted:

$$\begin{gathered} H=-\Delta+V, \\ V=W(x)+a(x)\sigma\cdot(x\times p)+U_c(x), \quad p=-i\nabla_x, \\ W(x)=c_1F(r;R_1,\alpha_1)+i\left\{c_2F(r;R_2,\alpha_2)-c_3\frac{\mathrm{d}}{\mathrm{d}r}F(r;R_2,\alpha_2)\right\}, \\ a(x)=c_4\frac{1}{r}\frac{\mathrm{d}}{\mathrm{d}r}F(r;R_3,\alpha_3), \end{gathered} \tag{1.1}$$

where $F(r;R,\alpha)$ is the so-called Woods–Saxon potential having the following form:

$$F(r;R,\alpha)=\left(1+\exp\left(\frac{r-R}{\alpha}\right)\right)^{-1},$$

and $U_c(x)$ is the Coulomb interaction. Here $\sigma\cdot x=\Sigma_{i=1}^3\sigma_i x_i$ and $\sigma=(\sigma_1,\sigma_2,\sigma_3)$ is the vector of Pauli spin matrices, that is, they are the 2×2 Hermitian matrices satisfying the following commutation relations:

a)Electronic mail: isozakih@math.tsukuba.ac.jp
b)Electronic mail: nakazawa@pf.it-chiba.ac.jp
c)Electronic mail: gunther@math.washington.edu

$$\sigma_1\sigma_2 = i\sigma_3, \quad \sigma_2\sigma_3 = i\sigma_1, \quad \sigma_3\sigma_1 = i\sigma_2. \tag{1.2}$$

A standard representation of the Pauli matrices is

$$\sigma_1 = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \quad \sigma_2 = \begin{pmatrix} 0 & -i \\ i & 0 \end{pmatrix}, \quad \sigma_3 = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}. \tag{1.3}$$

The original problem of scattering nucleons should be dealt with by the N body Schrödinger operator, in which many scattering channels appear. Usually the elastic process is dominant, and in order to ignore the inelastic processes, physicists introduced the complex two-body potential so that these inelastic scattering processes are regarded to be absorbed into the background. This is the origin of the terminology *optical* in analogy to the scattering and absorption of light by materials. By suitably adjusting constants c_i (which are usually energy-dependent) and R_i, α_i, the cross section calculated by this model is known to reproduce very well the experimental data (see, e.g., Feshbach[8] or Roy and Nigam[18]).

Let us consider the operator (1.1) in $(L^2(\mathbf{R}^3))^2$, where

$$V = a(x)\sigma\cdot(x\times p) + W(x), \tag{1.4}$$

and $a(x)$, $W(x)$ satisfy the following assumptions:

(A.1) $a(x)$ is a complex-valued C^∞-function on $\mathbf{R}^3$ such that for some $\delta_0 > 0$,

$$|\partial_x^\alpha \ a(x)| \leqslant C_\alpha e^{-\delta_0|x|} \quad \forall\, \alpha.$$

(A.2) $W(x)$ is a 2×2-matrix valued function on $\mathbf{R}^3$ with complex entries such that for some $\delta_0 > 0$,

$$|W(x)| \leqslant Ce^{-\delta_0|x|}.$$

In Sec. II, we shall show that under these assumptions, there is a discrete set $\mathcal{E}_0$ in a neighborhood of $(0,\infty)$ such that for $E \in (0,\infty)\backslash\mathcal{E}_0$, there exists a solution $\psi(x,E,\omega)$, $\omega \in S^2$, of the Schrödinger equation

$$(-\Delta + V)\psi(x,E,\omega) = E\psi(x,E,\omega)$$

having the following asymptotic expansion:

$$\psi(x,E,\omega) \sim e^{i\sqrt{E}\omega\cdot x} + \frac{e^{i\sqrt{E}r}}{r} f(E;\theta,\omega), \quad \theta = x/r, \quad r = |x| \to \infty.$$

The 2×2-matrix valued function $f(E;\theta,\omega)$ of $\theta,\omega \in S^2$ is the scattering amplitude. The main theorem of this paper is the following one.

Theorem 1.1: *For each fixed energy $E \in (0,\infty)\backslash\mathcal{E}_0$, one can uniquely reconstruct the perturbations $a(x), W(x)$ from the scattering amplitude $f(E;\theta,\omega)$.*

The Born approximation at high energies is not valid in the case considered in this paper since the perturbation is energy dependent so that it is natural to consider the fixed energy problem.

There has been considerable works in recent years in studying inverse scattering problem at fixed energy for the case of the Schrödinger equation associated to a potential, that is the two-body problem. To solve this problem one can use Faddeev's Green function[7] and the direction dependent Faddeev's Green's function (see Ref. 12 for a review and references) or the method of constructing complex geometrical optics solutions initiated by Calderón[3] and the connection to the Dirichlet-to-Neumann map (see Ref. 22 for a review and references). The problem considered here is more closely related to the case of the Schrödinger equation in the presence of a magnetic field studied in Ref. 5 or 16. An important ingredient in those articles is the reduction to the case of a lower order perturbation of the Laplacian by exponentiating with a pseudodifferential operator. We

use a similar method to deal with the main difficulty in the optical model, which is the reconstruction of the spin–orbit interaction $a(x)\sigma\cdot(x\times p)$. Namely by making semi-classical analysis type arguments (Lemma 5.1) and using the commutation relations of the Pauli spin matrices, we reconstruct $a(x)$ using the complex Born approximation of the scattering amplitude. We shall also use the gauge invariance of the scattering amplitude and introduce an auxiliary magnetic field to reconstruct the complex potential $W(x)$.

For earlier results on the scattering theory for non-self-adjoint Schrödinger operators see, e.g., Refs. 15, 19, 14, and 4 from the mathematical side, and Refs. 2 and 21 from the physical side.

Some remarks on the notations. For two Banach spaces X and Y, $\mathbf{B}(X;Y)$ denotes the set of all bounded operators from X to Y. For $x\in\mathbf{R}^3$, $\langle x\rangle=(1+|x|^2)^{1/2}$. C's denote various constants.

II. RESOLVENT ESTIMATES AND THE SCATTERING AMPLITUDE

We shall derive in this section the analytic continuation of the resolvent of $-\Delta+V$ and introduce the scattering amplitude.

A. Resolvent estimates

Let $H_0=-\Delta$ in $(L^2(\mathbf{R}^3))^2$. For $a\in\mathbf{R}$, we define

$$f\in\mathcal{H}_a\Leftrightarrow\|f\|_{\mathcal{H}_a}=\|e^{a|x|}f(x)\|_{L^2(\mathbf{R}^3)}<\infty. \tag{2.1}$$

Then, by passing to the Fourier transformation and by shifting the path of $|\xi|$-integration, for any $\delta>0$ $R_0(z)=(H_0-z)^{-1}$ defined for $\mathrm{Im}\,z>0$ has an analytic continuation across $(0,\infty)$ into the region

$$\Omega_\delta=\{z;\mathrm{Im}\ \ z>0\}\cup\{z;\mathrm{Re}\,\sqrt{z}>0,\ \ 0\geqslant\mathrm{Im}\ \ \sqrt{z}>-\delta\} \tag{2.2}$$

as a $\mathbf{B}(\mathcal{H}_\delta;\mathcal{H}_{-\delta})$-valued function. We denote this operator by $R_0^{(+)}(z)$. This is actually the integral operator with kernel $e^{i\sqrt{z}|x-y|}/(4\pi|x-y|)$.

For a technical reason, which will be explained in Sec. VI, we include also a magnetic field $b(x)$. Let $H=H_0+V$, where

$$V=V(-i\nabla_x), \tag{2.3}$$

$$V(\xi)=(2b(x)\cdot\xi-i\,\mathrm{div}\,b(x)+|b(x)|^2)I+a(x)\sigma\cdot(x\times\xi)+W(x), \tag{2.4}$$

I being the 2×2 identity matrix. We shall assume that

(A.1) $a(x)\in C^\infty(\mathbf{R}^3;\mathbf{C}),b(x)\in C^\infty(\mathbf{R}^3;\mathbf{R}^3)$ *and for some* $\delta_0>0$

$$|\partial_x^\alpha a(x)|+|\partial_x^\alpha b(x)|\leqslant C_\alpha e^{-\delta_0|x|},\quad\forall\alpha.$$

(A.2) $W(x)$ *is a* $M_2(\mathbf{C})$*-valued function such that for some* $\delta_0>0$,

$$|W(x)|\leqslant Ce^{-\delta_0|x|}.$$

These assumptions imply that for $0<\delta<\delta_0/2$, $R_0^{(+)}(z)V$ is a $\mathbf{B}(\mathcal{H}_{-\delta};\mathcal{H}_{-\delta})$-valued analytic function on Ω_δ and is compact for each z. We define $\mathcal{E}_0$ to be the set

$$\mathcal{E}_0=\{z\in\Omega_\delta;-1\in\mathrm{spec}_p(R_0^{(+)}(z)V)\}. \tag{2.5}$$

Here $\mathrm{spec}_p(A)$ denotes the point spectrum of the operator A.

Lemma 2.1: (1) There exists $C>0$ *such that*

$$\mathcal{E}_0\cap\{i\tau;\tau>C\}=\varnothing.$$

(2) $\mathcal{E}_0$ *is discrete in* Ω_δ.

Proof: Suppose $i\tau \in \mathcal{E}_0$ and let u be the associated eigenvector. Since $R_0^{(+)}(i\tau) \in \mathbf{B}(L^2;H^2)$, we have $u \in H^2$. Since $(-\Delta + V - i\tau)u = 0$, we then have

$$\|u\|_{H^1}^2 = ((1-\Delta)u,u) \leqslant C(\|u\|_{H^{1/2}}^2 + \tau\|u\|_{L^2}^2),$$

which implies $\|u\|_{H^1} \leqslant C\sqrt{\tau}\|u\|_{L^2}$. Using the equation $u = -R_0^{(+)}(i\tau)Vu$, we then have

$$\|u\|_{L^2} \leqslant \frac{C}{\tau}\|u\|_{H^1} \leqslant \frac{C}{\sqrt{\tau}}\|u\|_{L^2}.$$

Therefore $u = 0$ for large $\tau > 0$. This proves (1). Assertion (2) follows from the analytic Fredholm theorem (Ref. 17, p. 204). □

We define

$$R(z) = (1 + R_0^{(+)}(z)V)^{-1}R_0^{(+)}(z), \quad z \in \Omega_\delta \backslash \mathcal{E}_0. \tag{2.6}$$

The following theorem is easily proved.

Theorem 2.2: *(1) $R(z)$ is a $\mathbf{B}(\mathcal{H}_\delta;\mathcal{H}_{-\delta})$-valued analytic function on $\Omega_\delta \backslash \mathcal{E}_0$.*
(2) $R(z) = (H-z)^{-1}$ for $z \in \{z;\mathrm{Im}\ z > 0\} \cap (\Omega_\delta \backslash \mathcal{E}_0)$.
(3) For $z \in \Omega_\delta \backslash \mathcal{E}_0$,

$$R(z) = R_0^{(+)}(z) - R_0^{(+)}(z)VR(z). \tag{2.7}$$

For $s \in \mathbf{R}$, $L^{2,s}$ is defined by

$$u \in L^{2,s} \Leftrightarrow \|u\|_s = \|(1+|x|)^s u(x)\|_{L^2(\mathbf{R}^3)} < \infty.$$

Since $R_0^{(+)}(E) = (-\Delta - E - i0)^{-1} \in \mathbf{B}(L^{2,s};L^{2,-s})$ for $s > 1/2$ and $E > 0$ (see, e.g., Ref. 19), it follows from (2.6) that

$$R(E) \in \mathbf{B}(L^{2,s};L^{2,-s}), \quad s > 1/2, \quad E \in (0,\infty) \backslash \mathcal{E}_0. \tag{2.8}$$

In fact, let A_1 and A_2 be $R_0^{(+)}(E)V$ acting on $\mathcal{H}_{-\delta}$ and $L^{2,-s}$, respectively. Then it is easy to see that

$$-1 \in \mathrm{spec}_p(A_1) \Leftrightarrow -1 \in \mathrm{spec}_p(A_2). \tag{2.9}$$

B. Scattering amplitudes

Theorem 2.3: *For $E \in (0,\infty) \backslash \mathcal{E}_0$ and $\omega \in S^2$, there exists a unique solution ψ of the equation*

$$(-\Delta + V - E)\psi = 0$$

such that $u = \psi - e^{i\sqrt{E}\omega \cdot x}$ satisfies the radiation condition

$$\left(\frac{\partial}{\partial r} - i\sqrt{E}\right)u \in L^{2,-\alpha}, \quad 0 < \alpha < 1/2.$$

Such ψ is represented as

$$\psi(x,E,\omega) = e^{i\sqrt{E}\omega \cdot x} - R(E)Ve^{i\sqrt{E}\omega \cdot x}. \tag{2.10}$$

Proof: To show existence, we have only to put ψ as in (2.9). To show the uniqueness, we note that the difference of two such solutions satisfies

$$(-\Delta-E)u=-Vu,\quad \left(\frac{\partial}{\partial r}-i\sqrt{E}\right)u\in L^{2,-\alpha}.$$

Then $u=-R_0^{(+)}(E)Vu$. Hence if $u\neq 0$, $-1\in \mathrm{spec}_p(A_1)$. □

Using the resolvent equation (2.7), we have

$$\psi(x,E,\omega)\sim e^{i\sqrt{E}\omega\cdot x}+\frac{e^{i\sqrt{E}r}}{r}f(E;\theta,\omega),\quad \theta=x/r \tag{2.11}$$

as $r=|x|\to\infty$, where

$$f(E;\theta,\omega)=-\frac{1}{4\pi}\int_{\mathbf{R}^3}e^{-i\sqrt{E}\theta\cdot x}Ve^{i\sqrt{E}\omega\cdot x}\mathrm{d}x+\frac{1}{4\pi}\int_{\mathbf{R}^3}e^{-i\sqrt{E}\theta\cdot x}VR(E)Ve^{i\sqrt{E}\omega\cdot x}\mathrm{d}x. \tag{2.12}$$

We introduce the following notation for 2×2-matrices $f(x),g(x)$:

$$\langle f,g\rangle=\int_{\mathbf{R}^3}f(x)^*g(x)\mathrm{d}x. \tag{2.13}$$

Then $f(E;\theta,\omega)$ is written as

$$f(E;\theta,\omega)=-\frac{1}{4\pi}\int_{\mathbf{R}^3}e^{-i\sqrt{E}(\theta-\omega)\cdot x}V(\sqrt{E}\omega)\mathrm{d}x+\frac{1}{4\pi}\langle V^*(\sqrt{E}\theta)e^{i\sqrt{E}\theta\cdot x},R(E)V(\sqrt{E}\omega)e^{i\sqrt{E}\omega\cdot x})\rangle, \tag{2.14}$$

where

$$V^*(\xi)=2b(x)\cdot\xi+\overline{a(x)}\sigma\cdot(x\times\xi)-i\sigma\cdot(x\times\overline{\nabla a(x)})+|b(x)|^2+W(x)^*. \tag{2.15}$$

III. DIRECTION DEPENDENT GREEN OPERATORS

The aim of this section is to construct Green operators for $-\Delta+V$ depending on a direction $\gamma\in S^2$.

A. Unperturbed operator

For $\epsilon>0$, we let

$$D_\epsilon=\{z\in\mathbf{C};\mathrm{Im}\,z>0,|\mathrm{Re}\,z|<\epsilon/2\}. \tag{3.1}$$

We fix an arbitrary direction $\gamma\in S^2$.

Theorem 3.1: *(1) For any $\delta>0$ and $E>0$, there exists an $\epsilon>0$ and a $\mathbf{B}(\mathcal{H}_\delta;\mathcal{H}_{-\delta})$-valued analytic function $U_{\gamma,0}(E,z)$ defined on D_ϵ such that*

$$(-\Delta-2iz\gamma\cdot\nabla+z^2-E)U_{\gamma,0}(E,z)=I.$$

(2) When $z\to t\in(-\epsilon/2,\epsilon/2)$, $U_{\gamma,0}(E,z)$ has a boundary value $U_{\gamma,0}(E,t)$. Moreover

$$U_{\gamma,0}(E,t)\in\mathbf{B}(L^{2,s};L^{2,-s}),\quad s>1/2.$$

(3) For $\tau>0$,

$$U_{\gamma,0}(E,i\tau)f(x)=(2\pi)^{-3/2}\int_{\mathbf{R}^3}\frac{e^{ix\cdot\xi}\hat{f}(\xi)}{(\xi+i\tau\gamma)^2-E}\mathrm{d}\xi,$$

$\hat{f}$ being the Fourier transform of f. If f is rapidly decreasing, the integral is absolutely convergent.

(4) For $0<s<1$, $U_{\gamma,0}(E,i\tau)\in\mathbf{B}(L^{2,s};L^{2,s-1})$, *and*

$$\|U_{\gamma,0}(E,i\tau)\|_{\mathbf{B}(L^{2,s};L^{2,s-1})}\leqslant C_s/\tau,\quad \tau>1.$$

Proof: For the proof see Ref. 13, Theorem 2.10. The last assertion (4) is proved in the same way as in Sylvester–Uhlmann,[20] Lemma 3.1. □

We next observe a relation between this direction dependent Green operator and the $\bar{\partial}$-operator. For $\zeta\in\mathbf{C}^3$, Im $\zeta\neq 0$, let

$$\tilde{G}(\zeta)f(x)=(2\pi)^{-3/2}\int_{\mathbf{R}^3}\frac{e^{ix\cdot\xi}\hat{f}(\xi)}{\xi^2+2\zeta\cdot\xi}\mathrm{d}\xi. \tag{3.2}$$

For $\eta\in S^2$ such that $\eta\cdot\gamma=0$, let $p(\tau)=\sqrt{E+\tau^2}\,\eta$ and $\zeta(\tau)=p(\tau)+i\tau\gamma$. Then

$$e^{-ip(\tau)\cdot x}U_{\gamma,0}(E,i\tau)e^{ip(\tau)\cdot x}=\tilde{G}(\zeta(\tau)). \tag{3.3}$$

We also define

$$M_\gamma(\tau)=\tau\tilde{G}(\zeta(\tau)), \tag{3.4}$$

$$N_\gamma f=(2\pi)^{-3/2}\int_{\mathbf{R}^3}\frac{e^{ix\cdot\xi}\hat{f}(\xi)}{2\xi\cdot(\eta+i\gamma)}\mathrm{d}\xi. \tag{3.5}$$

Lemma 3.2: (1) For $0<s<1$ *and* $\tau>0$,

$$M_\gamma(\tau)\in\mathbf{B}(L^{2,s};L^{2,s-1}).$$

(2) For $f\in L^{2,s}$, $0<s<1$,

$$M_\gamma(\tau)f\to N_\gamma f$$

in $L^{2,s-1}$ *as* $\tau\to\infty$.

The proof is the same as the one in Ref. 20, Proposition 3.6 and Ref. 13, Theorem 4.6.

B. Perturbed operator

Let $p=-i\nabla_x$. For $\zeta\in\mathbf{C}^3$, we let

$$H_0(\zeta)=(p+\zeta)^2, \tag{3.6}$$

and

$$H(\zeta)=(p+b(x)+\zeta)^2+a(x)\sigma\cdot(x\times(p+\zeta))+W(x)=H_0(\zeta)+V(p+\zeta), \tag{3.7}$$

where V is defined by (2.4).

Our aim is to construct a direction dependent Green operator for $H(z\gamma)-E$. The main difficulty comes from the term $2b(x)\cdot(p+z\gamma)+a(x)\sigma\cdot(x\times(p+z\gamma))$, which we are going to eliminate by introducing a suitable pseudodifferential operator (ΨDO). Namely by using the identity

$$(H(z\gamma)-E)SU_{\gamma,0}(E,z)S^{-1}=1+([H_0(z\gamma),S]+V(p+z\gamma)S)U_{\gamma,0}(E,z)S^{-1},$$

we seek S in such a way that the right-hand side is invertible.

Before entering into the technical details, we explain the idea in the background. Let us suppose for the sake of simplicity that $b(x)=0$. If S is a ΨDO belonging to $\mathcal{S}^0$ to be introduced below, the natural choice is to assume that the symbol $S(x,\xi)$ of S satisfies

$$2(\xi+z\gamma)\cdot\nabla_x S(x,\xi)+ia(x)\sigma\cdot(x\times(\xi+z\gamma))S(x,\xi)=0.$$

In general when one considers inverse scattering problems at a fixed energy for systems of partial differential equations, one often encounters the equation $\zeta\cdot\nabla_x S=B(x,\zeta)S$, where ζ is a complex vector satisfying some conditions and $B(x,\zeta)$ is a matrix coming from the lower part of the equation. This sort of Cauchy-Riemann type equation is difficult to solve for systems (see Ref. 6 for a recent review). It is trivial to solve for scalar equations like in the case of the Schrödinger equation in the presence of a magnetic field. However, in our case it is sufficient to solve the equation

$$2(\xi+z\gamma)\cdot\nabla_x\psi+ia(x)=0,$$

and put $S=e^C$, $C=\psi(x,D_x)\sigma\cdot(x\times(D_x+z\gamma))$, $D_x=-i\nabla_x$. This is due to the fact that at the level of symbols, C solves

$$2i(\xi+z\gamma)\cdot\nabla_x C=a(x)\sigma\cdot(x\times(\xi+z\gamma))=:B(x,\xi+z\gamma),$$

and the symbol of C commutes with $B(x,\xi+z\gamma)$. (See Lemma 3.3 below.) Now the above equation for ψ is just the one we encounter in considering the inverse scattering problem for the scalar Schrödinger operator in a magnetic field, and the solution plays a significant role only near the zeros of $(\xi+z\gamma)^2-E$. With these remarks in mind, let us return to the construction of the perturbed direction dependent Green operator.

For a sufficiently small $\epsilon>0$, let $\chi_0(t)\in C^\infty(\mathbf{R})$ be such that $\chi_0(t)=1$ if $|t|<\epsilon/2$, $\chi_0(t)=0$ if $|t|>\epsilon$ and let

$$\chi(\xi+i\tau\gamma)=\chi_0\left(\frac{|(\xi+i\tau\gamma)^2-E|^2}{E+\tau^2+|\xi|^2}\right). \tag{3.8}$$

Note that on the support of $\chi(\xi+i\tau\gamma)$,

$$|\xi^2+2i\tau\gamma\cdot\xi-\tau^2-E|\leqslant\epsilon(E+\tau^2+|\xi|^2). \tag{3.9}$$

Let us put

$$\varphi(x,\xi+i\tau\gamma)=-(2\pi)^{-3/2}\chi(\xi+i\tau\gamma)\int_{\mathbf{R}^3}e^{ix\cdot k}\frac{\hat{b}(k)\cdot(\xi+i\tau\gamma)}{k\cdot(\xi+i\tau\gamma)}\mathrm{d}k, \tag{3.10}$$

$$\psi(x,\xi+i\tau\gamma)=-(2\pi)^{-3/2}\chi(\xi+i\tau\gamma)\int_{\mathbf{R}^3}e^{ix\cdot k}\frac{\hat{a}(k)}{2k\cdot(\xi+i\tau\gamma)}\mathrm{d}k. \tag{3.11}$$

For $m\in\mathbf{R}$, let $\mathcal{S}^m$ be the class of ΨDO's with symbol $p(x,\xi;\tau)$ satisfying

$$|\partial_x^\alpha\partial_\xi^\beta\ p(x,\xi;\tau)|\leqslant C_{\alpha\beta}\langle x\rangle^{-1}(\tau+|\xi|)^{m-|\beta|}\quad\forall\alpha,\beta,\quad\tau>1.$$

We use the same notation $\mathcal{S}^m$ to denote the associated class of symbols.

Lemma 3.3: (1) $\varphi(x,\xi+i\tau\gamma)\in\mathcal{S}^0,\psi(x,\xi+i\tau\gamma)\in\mathcal{S}^{-1}$.

(2) We have

$$2i(\xi+i\tau\gamma)\cdot\nabla_x\varphi(x,\xi+i\tau\gamma)=2\chi(\xi+i\tau\gamma)b(x)\cdot(\xi+i\tau\gamma),$$

$$2i(\xi+i\tau\gamma)\cdot\nabla_x[\psi(x,\xi+i\tau\gamma)\sigma\cdot(x\times(\xi+i\tau\gamma))]=\chi(\xi+i\tau\gamma)a(x)\quad\sigma\cdot(x\times(\xi+i\tau\gamma)).$$

The assertion (2) follows from a direct computation. The assertion (1) is proved in the Appendix.

Let $\varphi_0(\tau),\psi_0(\tau)$ be ΨDO's with symbol $\varphi(x,\xi+i\tau\gamma),\psi(x,\xi+i\tau\gamma)$ and let

$$A(\tau)=\varphi_0(\tau)+\psi_0(\tau)\sigma\cdot(x\times(p+i\tau\gamma)),\quad S(\tau)=e^{A(\tau)}. \tag{3.12}$$

Lemma 3.4: Let

$$K(\tau)=([H_0(i\tau\gamma),S(\tau)]+V(p+i\tau\gamma)S(\tau))U_{\gamma,0}(E,i\tau)S(\tau)^{-1}. \tag{3.13}$$

Then for $1/2<s<1$ *and large* $\tau>0$,

$$\|K(\tau)\|_{\mathbf{B}(L^{2,s};L^{2,s})}\leqslant C_s/\tau.$$

Proof: For two operators $P_1(\tau)$ and $P_2(\tau)$ we write

$$P_1(\tau)\sim P_2(\tau), \tag{3.14}$$

if they satisfy for large $\tau>0$,

$$\|P_1(\tau)-P_2(\tau)\|_{\mathbf{B}(L^{2,s};L^{2,s})}\leqslant C_s/\tau. \tag{3.15}$$

Let $L>\sup_{-1/2<s<1,1<\tau}\|A(\tau)\|_{\mathbf{B}(L^{2,s};L^{2,s})}$. Then we have

$$e^{A(\tau)}=\frac{1}{2\pi i}\int_{|z|=L}e^z(z-A(\tau))^{-1}\mathrm{d}z. \tag{3.16}$$

Therefore we have

$$[H_0(i\tau\gamma),e^{A(\tau)}]=\frac{1}{2\pi i}\int_{|z|=L}e^z(z-A(\tau))^{-1}[H_0(i\tau\gamma),A(\tau)](z-A(\tau))^{-1}\mathrm{d}z. \tag{3.17}$$

Since $A(\tau)\in S^0$ by Lemma 3.3 (1), by the symbolic calculus we have

$$[H_0(i\tau\gamma),A(\tau)]=P_1(\tau)+P_2(\tau), \tag{3.18}$$

where $\|P_2(\tau)\|_{\mathbf{B}(L^{2,s-1};L^{2,s})}\leqslant C_s$, and $P_1(\tau)$ is the ΨDO with symbol

$$-2\chi(\xi+i\tau\gamma)b(x)\cdot(\xi+i\tau\gamma)-\chi(\xi+i\tau\gamma)a(x)\sigma\cdot(x\times(\xi+i\tau\gamma)). \tag{3.19}$$

Let $Q(\tau)$ be the ΨDO with symbol $\chi(\xi+i\tau\gamma)$. By (3.18) and (3.19), we have

$$[H_0(i\tau\gamma),A(\tau)]=-Q(\tau)R(\tau)+P_3(\tau), \tag{3.20}$$

where $\|P_3(\tau)\|_{\mathbf{B}(L^{2,s-1};L^{2,s})}\leqslant C_s$, and

$$R(\tau)=2b(x)\cdot(p+i\tau\gamma)+a(x)\sigma\cdot(x\times(p+i\tau\gamma)). \tag{3.21}$$

Let us note that

$$[Q(\tau),A(\tau)]\in\mathcal{S}^{-1}, \tag{3.22}$$

$$[R(\tau),A(\tau)]\in\mathcal{S}^0, \tag{3.23}$$

$$\|(1-Q(\tau))U_{\gamma,0}(E,i\tau)\|_{\mathbf{B}(L^{2,s};L^{2,s})}\leqslant C_s/\tau^2. \tag{3.24}$$

The estimate (3.24) follows from Theorem 3.1 (3). Then in view of Theorem 3.1 (4), we have

$$[H_0(i\tau\gamma),S(\tau)]U_{\gamma,0}(E,i\tau)\sim-\frac{1}{2\pi i}\int_{|z|=L}e^z(z-A(\tau))^{-1}R(\tau)Q(\tau)(z-A(\tau))^{-1}\mathrm{d}zU_{\gamma,0}(E,i\tau)$$

$$\sim-R(\tau)\frac{1}{2\pi i}\int_{|z|=L}e^z(z-A(\tau))^{-2}\mathrm{d}zU_{\gamma,0}(E,i\tau)$$

$$=-R(\tau)e^{A(\tau)}U_{\gamma,0}(E,i\tau).$$

It then follows that

$$K(\tau)\sim(-R(\tau)+V(p+i\tau\gamma))S(\tau)U_{\gamma,0}(E,i\tau)S(\tau)^{-1}\sim 0. \tag{3.25}$$

This proves the lemma. □

With the aid of Lemma 3.4, we define the modified direction dependent Green operator for large $\tau>0$ by

$$L_\gamma(\tau)=S(\tau)U_{\gamma,0}(E,i\tau)S(\tau)^{-1}(1+K(\tau))^{-1}. \tag{3.26}$$

By definition it satisfies

$$(H(i\tau\gamma)-E)L_\gamma(\tau)=I. \tag{3.27}$$

We define $\mathcal{E}_\gamma(E)$ to be the set of $z\in\overline{D_\epsilon}$ such that

$$-1\in\mathrm{spec}_p(U_{\gamma,0}(E,z)V(p+z\gamma)).$$

Lemma 3.5: (1) $\mathcal{E}_\gamma(E)\cap\{z;\mathrm{Im}\,z>0\}$ *is discrete.*
(2) $\mathcal{E}_\gamma(E)\cap\mathbf{R}$ *is a closed set of measure zero.*
(3) There exists a constant $C>0$ *such that*

$$i\tau\notin\mathcal{E}_\gamma(E)\quad\text{if}\quad\tau>C.$$

Proof: We have only to show the last assertion. The assertions (1) and (2) follow from the analytic Fredholm theorem and the well-known Riesz' theorem on boundary values of analytic functions (see, e.g., Ref. 11, p. 52). Let $K_1(\tau)=U_{\gamma,0}(E,i\tau)V(p+i\tau\gamma)$. Since $K_1(\tau)$ is compact, we have only to show that $\mathrm{Ran}(1+K_1(\tau))$ is dense in $L^{2,-s},1/2<s<1$ for large $\tau>0$. For $f\in C_0^\infty(\mathbf{R}^3)$, let $u=L_\gamma(\tau)(H_0(i\tau\gamma)-E)f$. Then we have $(H_0(i\tau\gamma)-E)(u-f+K_1(\tau)u)=0$. Since $u-f+K_1(\tau)u\in L^{2,-s},1/2<s<1$, we have $u-f+K_1(\tau)u=0$ by virtue of Theorem 2.2 of Agmon–Hörmander.[1] □

Let us define for $z\notin\mathcal{E}_\gamma(E)$,

$$U_\gamma(E,z)=(1+U_{\gamma,0}(E,z)V(p+z\gamma))^{-1}U_{\gamma,0}(E,z). \tag{3.28}$$

Theorem 3.6. *(1) As a* $\mathbf{B}(\mathcal{H}_\delta;\mathcal{H}_{-\delta})$*-valued function,* $U_\gamma(E,z)$ *is meromorphic on* D_ϵ.
(2) When $z\to t\in(-\epsilon/2,\epsilon/2)\backslash\mathcal{E}_\gamma(E)$, $U_\gamma(E,z)$ *converges to* $U_\gamma(E,t)$ *and*

$$U_\gamma(E,t)\in\mathbf{B}(L^{2,s};L^{2,-s})\quad s>1/2.$$

(3) For large $\tau>0$,

$$U_\gamma(E,i\tau)=L_\gamma(\tau).$$

Proof: We show the last assertion. We have only to show that the equation $(H(i\tau\gamma)-E)u=0,u\in L^{2,-s}$, has only a trivial solution for large $\tau>0$. Since $(H_0(i\tau\gamma)-E)u=-V(p+i\tau\gamma)u\in L^{2,s}$, we have by the uniqueness theorem of Agmon–Hörmander, $u=-U_{\gamma,0}(E,i\tau)V(p+i\tau\gamma)u$. Therefore $u=0$ by using Lemma 3.5 (3). □

IV. FADDEEV SCATTERING AMPLITUDE

The Faddeev theory, which we have rewritten in Ref. 12, is transferred without any essential change to the non-self-adjoint case. For $E>0$, let

$$\mathcal{F}_0(E)f(\omega)=(2\pi)^{-3/2}(E/4)^{1/4}\int_{\mathbf{R}^3}e^{-i\sqrt{E}\omega\cdot x}f(x)\mathrm{d}x. \tag{4.1}$$

As is well known $\mathcal{F}_0(E)\in\mathbf{B}(L^{2,s};L^2(S^2))$ if $s>1/2$. Then for $E\notin\mathcal{E}_0$, the scattering amplitude is written as, up to a constant depending only on E,

$$A(E)=\mathcal{F}_0(E)(V-VR(E)V)\mathcal{F}_0(E)^*. \tag{4.2}$$

The scattering amplitude $f(E;\theta,\omega)$ from (2.12) is the integral kernel of $A(E)$. Let for $t\in(-\epsilon/2,\epsilon/2)\backslash\mathcal{E}_\gamma(E)$,

$$R_\gamma(E,t)=e^{it\gamma\cdot x}U_\gamma(E,t)e^{-it\gamma\cdot x}. \tag{4.3}$$

Then the Faddeev scattering amplitude is defined by

$$A_\gamma(E,t)=\mathcal{F}_0(E)(V-VR_\gamma(E,t)V)\mathcal{F}_0(E)^*. \tag{4.4}$$

The following two theorems are proved in the same way as in Theorems 7.1 and 7.3 of Ref. 12.

Theorem 4.1: *Let $F_\gamma(E,t)$ be the operator of multiplication by the characteristic function of the set $\{\omega\in S^2;\gamma\cdot\omega\geqslant t/\sqrt{E}\}$. Then*

$$A_\gamma(E,t)=A(E)+2\pi iA(E)F_\gamma(E,t)A_\gamma(E,t).$$

Theorem 4.2: *Let $K=2\pi iA(E)F_\gamma(E,t)$. Then*

$$t\in\mathcal{E}_\gamma(E)\Leftrightarrow 1\in\mathrm{spec}_p(K).$$

Let us give a brief sketch of the proof of the above theorems. Let

$$T_\gamma=2\pi i\mathcal{F}_0(E)^*F_\gamma(E,t)\mathcal{F}_0(E). \tag{4.5}$$

Then we have (Ref. 12, Lemma 6.4)

$$R_\gamma=R-(1-RV)T_\gamma(1-VR_\gamma), \tag{4.6}$$

where $R_\gamma=R_\gamma(E,t),R=R(E)$. The eigenoperator $\mathcal{F}(E)$ and the Faddeev eigenoperator $\mathcal{F}_\gamma(E,t)$ are defined by

$$\mathcal{F}(E)=\mathcal{F}_0(E)(1-V^*R(E)^*), \tag{4.7}$$

$$\mathcal{F}_\gamma(E,t)=\mathcal{F}_0(E)(1-V^*R_\gamma(E,t)^*). \tag{4.8}$$

Then by the resolvent equation (4.6) we have

$$\mathcal{F}_\gamma(E,t)^*=\mathcal{F}(E)^*+(1-RV)T_\gamma V\mathcal{F}_\gamma(E,t)^*.$$

Using (4.5) we get

$$\mathcal{F}_\gamma(E,t)^*=\mathcal{F}(E)^*+2\pi i\mathcal{F}(E)^*F_\gamma(E,t)A_\gamma(E,t).$$

Multiplying this by $\mathcal{F}_0(E)V$, we obtain Theorem 4.1.

To prove Theorem 4.2 we note the following operator equation:

$$1+R_{\gamma,0}(E,t)V=(1+R_0(E+i0)V)(1-\tilde{K}), \tag{4.9}$$

$$\tilde{K}=(1-R(E)V)T_\gamma V, \tag{4.10}$$

where $R_0(z)=(-\Delta-z)^{-1}$, $R_{\gamma,0}(E,t)=e^{it\gamma\cdot x}U_{\gamma,0}(E,t)e^{-it\gamma\cdot x}$. In fact, this follows from the formula

$$R_{\gamma,0}(E,t)=R_0(E+i0)-T_\gamma$$

(Ref. 12, Lemma 6.3) and the resolvent equation.

Since $E\notin\mathcal{E}_0$, $1+R_0(E+i0)V$ is invertible. Therefore

$$t\in\mathcal{E}_\gamma(E)\Leftrightarrow 1\in \mathrm{spec}_p(\tilde{K}). \tag{4.11}$$

Letting

$$S_1=2\pi i(1-R(E)V)\mathcal{F}_0(E)^*F_\gamma(E,t),$$

$$S_2=\mathcal{F}_0(E)V,$$

we have

$$\tilde{K}=S_1S_2,\quad K=S_2S_1.$$

Therefore

$$1\in\mathrm{spec}_p(\tilde{K})\Leftrightarrow 1\in\mathrm{spec}_p(K). \tag{4.12}$$

This proves Theorem 4.2.

It follows from Theorems 4.1 and 4.2 that for $t\in(-\epsilon/2,\epsilon/2)\backslash\mathcal{E}_\gamma(E)$,

$$A_\gamma(E,t)=(1-K)^{-1}A(E). \tag{4.13}$$

We have thus constructed the Faddeev scattering amplitude $A_\gamma(E,t)$ from the scattering amplitude $A(E)$. The kernel of $A_\gamma(E,t)$ is written as, up to a constant depending only on E,

$$A_\gamma(E,t;\theta',\theta)=\int_{\mathbf{R}^3}e^{-i\sqrt{E}(\theta'-\theta)\cdot x}V(\sqrt{E}\,\theta)\mathrm{d}x-\langle V^*(\sqrt{E}\,\theta')e^{i\sqrt{E}\theta'\cdot x},R_\gamma(E,t)V(\sqrt{E}\,\theta)e^{i\sqrt{E}\theta\cdot x}\rangle, \tag{4.14}$$

where $V^*(\xi)$ is defined by (2.15). We now put

$$\sqrt{E}\,\theta=\sqrt{E-t^2}\,\omega+t\gamma,\quad \sqrt{E}\,\theta'=\sqrt{E-t^2}\,\omega'+t\gamma, \tag{4.15}$$

where $\omega,\omega'\in S^2,\omega\cdot\gamma=\omega'\cdot\gamma=0$. Then the above kernel is rewritten as

$$\int_{\mathbf{R}^3}e^{-i\sqrt{E-t^2}(\omega'-\omega)\cdot x}V(\sqrt{E}\,\theta)\mathrm{d}x-\langle V^*(\sqrt{E}\,\theta')e^{i\sqrt{E-t^2}\omega'\cdot x},U_\gamma(E,t)V(\sqrt{E}\,\theta)e^{i\sqrt{E-t^2}\omega\cdot x}\rangle, \tag{4.16}$$

which we denote by $B_\gamma(\omega',\omega;t)$. Since $U_\gamma(E,t)$ is a boundary value of a meromorphic function, $B_\gamma(\omega',\omega;t)$ is uniquely extended to a meromorphic function on D_ϵ.

V. RECONSTRUCTION OF THE SPIN–ORBIT INTERACTION

In this section we reconstruct the spin–orbit term from $B_\gamma(\omega',\omega;t)$ defined by (4.16). Our intention is to consider the case without magnetic field $b(x)$. However, since we shall use an auxiliary magnetic field in the next section, we include $b(x)$ until Lemma 5.5.

As has been noted above, $B_\gamma(\omega',\omega;t)$ is meromorphically extended to D_ϵ. By Theorem 3.6 (3), for large $\tau>0$, $B_\gamma(\omega',\omega;i\tau)$ has the following expression:

$$B_\gamma(\omega',\omega;i\tau)=\int e^{-i\sqrt{E+\tau^2}(\omega'-\omega)\cdot x}V(\sqrt{E}\,\theta)\mathrm{d}x - \langle V^*(\sqrt{E}\,\theta')e^{i\sqrt{E+\tau^2}\omega'\cdot x},L_\gamma(\tau)V(\sqrt{E}\,\theta)e^{i\sqrt{E+\tau^2}\omega\cdot x}\rangle, \tag{5.1}$$

where

$$\sqrt{E}\,\theta=\sqrt{E+\tau^2}\,\omega+i\tau\gamma,\quad \sqrt{E}\,\theta'=\sqrt{E+\tau^2}\,\omega'+i\tau\gamma.$$

For $\xi\in\mathbf{R}^3$, we take $\gamma,\eta\in S^2$ such that $\xi\cdot\gamma=\xi\cdot\eta=\eta\cdot\gamma=0$, and put

$$\omega=\omega(\tau)=\left(1-\frac{|\xi|^2}{4\tau^2}\right)^{1/2}\eta-\frac{\xi}{2\tau},\quad \omega'=\omega(\tau)'=\left(1-\frac{|\xi|^2}{4\tau^2}\right)^{1/2}\eta+\frac{\xi}{2\tau},$$

$$p(\tau)=\sqrt{E+\tau^2}\,\omega(\tau),\quad p(\tau)'=\sqrt{E+\tau^2}\,\omega(\tau)',$$

$$\zeta(\tau)=p(\tau)+i\tau\gamma,\quad \zeta(\tau)'=p(\tau)'+i\tau\gamma.$$

We split $B_\gamma(\omega(\tau)',\omega(\tau);i\tau)$ into two parts:

$$B_\gamma(\omega(\tau)',\omega(\tau);i\tau)=B_\gamma^{(1)}(\tau)+B_\gamma^{(2)}(\tau), \tag{5.2}$$

$$B_\gamma^{(1)}(\tau)=\int e^{-i(p(\tau)'-p(\tau))\cdot x}V(\zeta(\tau))\mathrm{d}x, \tag{5.3}$$

$$B_\gamma^{(2)}(\tau)=-\langle V^*(\zeta(\tau)')e^{ip(\tau)'\cdot x},L_\gamma(\tau)V(\zeta(\tau))e^{ip(\tau)\cdot x}\rangle. \tag{5.4}$$

Noting that

$$p(\tau)'-p(\tau)=\xi+O(\tau^{-1}),$$

$$\zeta(\tau)/\tau=\eta+i\gamma+O(\tau^{-1}),$$

we have by (2.4)

$$\lim_{\tau\to\infty}B_\gamma^{(1)}(\tau)/\tau=\int e^{-ix\cdot\xi}\{2b(x)\cdot(\eta+i\gamma)+a(x)\sigma\cdot(x\times(\eta+i\gamma))\}\mathrm{d}x. \tag{5.5}$$

To compute $B_\gamma^{(2)}(\tau)$, we rewrite it as follows:

$$B_\gamma^{(2)}(\tau)=-\langle V^*(\zeta(\tau)')e^{i(p(\tau)'-p(\tau))\cdot x},U(\tau)^{-1}L_\gamma(\tau)U(\tau)V(\zeta(\tau))\rangle, \tag{5.6}$$

where

$$U(\tau)=e^{ip(\tau)\cdot x}. \tag{5.7}$$

By (3.3) and (3.26), the term $U(\tau)^{-1}L_\gamma(\tau)U(\tau)$ is rewritten as

$$U(\tau)^{-1}L_\gamma(\tau)U(\tau)=U(\tau)^{-1}S(\tau)U(\tau)\cdot\tilde{G}(\zeta(\tau))\cdot U(\tau)^{-1}S(\tau)^{-1}(1+K(\tau))^{-1}U(\tau).$$

Let $A(\tau)$ be from (3.12) and put

$$B(\tau)=U(\tau)^{-1}A(\tau)U(\tau). \tag{5.8}$$

Then we have by virtue of (3.12)

$$U(\tau)^{-1}S(\tau)^{-1}U(\tau)=e^{-B(\tau)}. \tag{5.9}$$

Lemma 5.1: Let

$$\Psi(x,\xi+\zeta(\tau))=\varphi(x,\xi+\zeta(\tau))+\psi(x,\xi+\zeta(\tau))\sigma\cdot(x\times(\xi+\zeta(\tau))),$$

and let $P(\tau)$ be the ΨDO with symbol $e^{-\Psi(x,\xi+\zeta(\tau))}$. Then

$$e^{-B(\tau)}-P(\tau)\in\mathcal{S}^{-1}.$$

Proof: Modulo $\mathcal{S}^{-1}$, $B(\tau)$ is a ΨDO with symbol $\Psi(x,\xi+\zeta(\tau))$. Therefore for large $|z|$, $(z-B(\tau))^{-1}$ is a ΨDO with symbol $(z-\Psi(x,\xi+\zeta(\tau)))^{-1}$ modulo $\mathcal{S}^{-1}$. Since for large M,

$$e^{-B(\tau)}=\frac{1}{2\pi i}\int_{|z|=M}e^{-z}(z-B(\tau))^{-1}\mathrm{d}z,$$

$e^{-B(\tau)}$ is a ΨDO with symbol $e^{-\Psi(x,\xi+\zeta(\tau))}$, modulo $\mathcal{S}^{-1}$. □

We put

$$\eta=e_1,\quad \gamma=e_2,\quad \eta\times\gamma=e_3, \tag{5.10}$$

$$\Psi_\infty(x)=f+g\sigma\cdot(x\times(e_1+ie_2)), \tag{5.11}$$

$$f=-(2\pi)^{-3/2}\int_{\mathbf{R}^3}e^{ix\cdot k}\frac{\hat{b}(k)\cdot(e_1+ie_2)}{k_1+ik_2}\mathrm{d}k, \tag{5.12}$$

$$g=-(2\pi)^{-3/2}\int_{\mathbf{R}^3}e^{ix\cdot k}\frac{\hat{a}(k)}{2(k_1+ik_2)}\mathrm{d}k, \tag{5.13}$$

where $k_j=k\cdot e_j, x_j=x\cdot e_j$ and $\tilde{a}(\xi_1,\xi_2,x_3)$ is the partial Fourier transform with respect to x_1,x_2 of $a(x)$. We also let

$$f_0(x)=2b(x)\cdot(e_1+ie_2)+a(x)\sigma\cdot(x\times(e_1+ie_2)). \tag{5.14}$$

Lemma 5.2:

$$\lim_{\tau\to\infty}\frac{1}{\tau}B_\gamma^{(2)}(\tau)=-\int_{\mathbf{R}^3}e^{-ix\cdot\xi}f_0e^{\Psi_\infty}N_\gamma(e^{-\Psi_\infty}f_0)\mathrm{d}x.$$

Proof: First we note

$$U(\tau)^{-1}(1+K(\tau))^{-1}U(\tau)V(\zeta(\tau))/\tau\to f_0(x). \tag{5.15}$$

Let

$$\chi_1(\xi+i\tau\gamma)=\chi_0\left(\frac{2|(\xi+i\tau\gamma)^2-E|}{E+\tau^2+|\xi|^2}\right),\quad \chi_2(\xi+i\tau\gamma)=1-\chi_1(\xi+i\tau\gamma),$$

$\chi_0(t)$ being as in (3.8), and let Q_j be the ΨDO with symbol $\chi_j(\xi+i\tau\gamma)$. On the support of $\chi_2(\xi+i\tau\gamma)$, we have

$$|(\xi+i\tau\gamma)^2-E|\geqslant\frac{\epsilon}{4}(E+\tau^2+|\xi|^2).$$

So we have

$$\|U_{\gamma,0}(E,i\tau)Q_2\|_{\mathbf{B}(L^2;L^2)}\leqslant C/\tau^2.$$

Therefore as an operator in $\mathbf{B}(L^{2,s};L^{2,s-1})$,$0<s<1$,

$$U_{\gamma,0}(E,i\tau)=U_{\gamma,0}(E,i\tau)Q_1+O(\tau^{-2}). \tag{5.16}$$

On the other hand, by Lemma 5.1, we have

$$\tilde{Q}_1U(\tau)^{-1}S(\tau)^{-1}U(\tau)=\tilde{Q}_1e^{-B(\tau)}\sim\tilde{Q}_1P(\tau), \tag{5.17}$$

and $\tilde{Q}_1P(\tau)$ converges strongly to $e^{-\Phi_\infty(x)}$.

Similarly $U(\tau)^{-1}S(\tau)U(\tau)$ converges strongly to $e^{\Psi_\infty(x)}$. Furthermore by Lemma 3.2,

$$\tau\tilde{G}(\zeta(\tau))\to N_\gamma.$$

These facts prove Lemma 5.2. □

Our next aim is to compute $N_\gamma(e^{-\Psi_\infty}f_0)$. Let us note that putting $\bar{\partial}=\frac{1}{2}(e_1+ie_2)\cdot\nabla_x$, we have

$$4i\bar{\partial}\Psi_\infty=f_0. \tag{5.18}$$

Since $\bar{\partial}\Psi_\infty$ and Ψ_∞ commute, we also have

$$\bar{\partial}e^{\Psi_\infty}=(\bar{\partial}\Psi_\infty)e^{\Psi_\infty}. \tag{5.19}$$

Lemma 5.3:

$$\int_{\mathbf{R}^3}e^{-ix\cdot\xi}f_0e^{\Psi_\infty}N_\gamma e^{-\Psi_\infty}f_0\mathrm{d}x=4i\int_{\mathbf{R}^3}e^{-ix\cdot\xi}(\bar{\partial}e^{\Psi_\infty})(e^{-\Psi_\infty}-1)\mathrm{d}x.$$

Proof: The left-hand side is equal to

$$\int_{\mathbf{R}^3}e^{-ix\cdot\xi}4i(\bar{\partial}\Psi_\infty)e^{\Psi_\infty}N_\gamma e^{-\Psi_\infty}4i(\bar{\partial}\Psi_\infty)\mathrm{d}x=16\int_{\mathbf{R}^3}e^{-ix\cdot\xi}(\bar{\partial}e^{\Psi_\infty})N_\gamma(\bar{\partial}e^{-\Psi_\infty})\mathrm{d}x.$$

Using

$$N_\gamma\bar{\partial}e^{-\Psi_\infty}=\frac{i}{4}(e^{-\Psi_\infty}-1),$$

which follows from Liouville's theorem, we get the lemma. □

Lemma 5.4:

$$\int_{\mathbf{R}^3}e^{-ix\cdot\xi}f_0e^{\Psi_\infty}N_\gamma e^{-\Psi_\infty}f_0\mathrm{d}x=0.$$

Proof: By integration by parts, we have

$$\int_{x_1^2+x_2^2<r^2} e^{-ix\cdot\xi}(\overline{\partial}e^{\Psi_\infty})(e^{-\Psi_\infty}-1)\mathrm{d}x_1\,\mathrm{d}x_2$$

$$=\frac{1}{2}\int_{x_1^2+x_2^2=r^2} e^{-ix\cdot\xi}(x_1+ix_2)(1-e^{\Psi_\infty})\mathrm{d}\theta-\int_{x_1^2+x_2^2<r^2} e^{-ix\cdot\xi}e^{\Psi_\infty}\overline{\partial}e^{-\Psi_\infty}\mathrm{d}x_1\,\mathrm{d}x_2\equiv(I)-(II).$$

The second term is written as

$$(II)=-\int_{x_1^2+x_2^2<r^2} e^{-ix\cdot\xi}\overline{\partial}\Psi_\infty\mathrm{d}x_1\,\mathrm{d}x_2=-\frac{1}{2}\int_{x_1^2+x_2^2=r^2} e^{-ix\cdot\xi}(x_1+ix_2)\Psi_\infty\mathrm{d}\theta.$$

On the other hand, $e^{\Psi_\infty}=1+\Psi_\infty+O(|x|^{-2})$. Therefore

$$(I)\sim-\frac{1}{2}\int_{x_1^2+x_2^2=r^2} e^{-ix\cdot\xi}(x_1+ix_2)\Psi_\infty\mathrm{d}\theta.$$

□

Using (5.5) and Lemmas 5.2, 5.4, one can compute

$$\int_{\mathbf{R}^3} e^{-ix\cdot\xi}\{2b(x)\cdot(\eta+i\gamma)+a(x)\sigma\cdot(x\times(\eta+i\gamma))\}\mathrm{d}x \tag{5.20}$$

form the scattering amplitude.

Here let us recall the following formulas for spin matrices, which are proved by using the commutation relations:

$$(\sigma\cdot\xi)(\sigma\cdot\eta)=\xi\cdot\eta+i\sigma\cdot(\xi\times\eta), \tag{5.21}$$

$$[\sigma\cdot(x\times(e_1+ie_2)),\sigma\cdot e_3]=2ix_3\sigma\cdot(e_1+ie_2). \tag{5.22}$$

We now reconstruct $a(x)$. We take $b(x)\equiv 0$. Then by (5.20) and (5.22), one can recover

$$\int e^{-ix\cdot\xi}a(x)x_3\mathrm{d}x.$$

Since $\xi=(0,0,\xi_3)$, one can recover

$$\int_{\mathbf{R}^3} a(x_1,x_2,x_3)\mathrm{d}x_1\,\mathrm{d}x_2.$$

Choosing the direction of ξ arbitrarily, one can reconstruct $a(x)$ by the inversion formula of the Radon transform (see, e.g., Ref. 10).

VI. RECONSTRUCTION OF THE COMPLEX POTENTIAL

A. Gauge invariance

In the previous section we constructed the spin–orbit term $a(x)\sigma\cdot(x\times p)$ from the scattering amplitude of the operator

$$-\Delta+V(p),\quad V(p)=a(x)\sigma\cdot(x\times p)+W(x).$$

To reconstruct $W(x)$ we shall make use of the gauge invariance.

Let $\psi(x)$ be the solution of

$$(-\Delta+V(p)-E)\psi=0 \tag{6.1}$$

having the asymptotic expansion

$$\psi \sim e^{i\sqrt{E}\omega\cdot x} + \frac{e^{i\sqrt{E}r}}{r} f(E;\theta,\omega), \quad \theta = x/r, \quad r = |x| \to \infty. \tag{6.2}$$

Let $c(x) = \exp(-|x|^2)$ and $\psi_\lambda(x) = e^{i\lambda c(x)}\psi(x)$, λ being a large parameter. Then ψ_λ satisfies

$$((p-b_\lambda)^2 + V(p-b_\lambda) - E)\psi_\lambda = 0 \tag{6.3}$$

with $b_\lambda(x) = \lambda\nabla c(x)$. Since $c(x)$ is exponentially decreasing, ψ_λ has the same asymptotic expansion as in (6.2). This means that the family of operators $\{(p-b_\lambda)^2 + V(p-b_\lambda); \lambda > 0\}$ has the same scattering amplitude. One should also note that due to the unitary equivalence, the sets of exceptional points $\mathcal{E}_0$ and $\mathcal{E}_\gamma(E)$ are independent of $\lambda > 0$.

B. Reconstruction of the complex potential

We use the same notation as in Sec. V with b replaced by $b_\lambda = \lambda\nabla c(x)$. Let

$$V_1(\xi) = 2b_\lambda\cdot\xi + a\sigma\cdot(x\times\xi),$$

$$V_2 = -i\,\mathrm{div}\, b_\lambda - |b_\lambda|^2 - a\sigma\cdot(x\times b_\lambda) + W.$$

Then

$$V(\zeta(\tau) - b_\lambda) \simeq \tau V_1(\eta + i\gamma) - V_1(\xi/2) + V_2,$$

$$V^*(\zeta(\tau)' - b_\lambda) \simeq \tau V_1^*(\eta - i\gamma) + V_1^*(\xi/2) + V_2^*.$$

Recall that we already know $a(x)$ and $b_\lambda(x)$.

We first show that up to known terms

$$B_\gamma^{(1)}(\tau) + B_\gamma^{(2)}(\tau) \simeq \int_{\mathbf{R}^3} e^{-ix\cdot\xi} W(x)\mathrm{d}x - \langle e^{-ix\cdot\xi} V_1^*(\eta - i\gamma), e^{\Psi_\infty} N_\gamma e^{-\Psi_\infty}(-V_1(\xi/2) + V_2)\rangle$$
$$- \langle e^{-ix\cdot\xi}(V_1^*(\xi/2) + V_2), e^{\Psi_\infty} N_\gamma e^{-\Psi_\infty} V_1(\eta + i\gamma)\rangle.$$

In fact,

$$B_\gamma^{(1)}(\tau) \simeq \tau\int_{\mathbf{R}^3} e^{-ix\cdot\xi} V_1(\eta + i\gamma)\mathrm{d}x - \int_{\mathbf{R}^3} e^{-ix\cdot\xi} V_1(\xi/2)\mathrm{d}x + \int_{\mathbf{R}^3} e^{-ix\cdot\xi} V_2 \mathrm{d}x.$$

Up to a known term, this is equal to $\int e^{-ix\cdot\xi} W(x)\mathrm{d}x$.

Next we note that

$$B_\gamma^{(2)}(\tau) \sim -\tau^2\langle V_1^*(\eta - i\gamma)e^{ip(\tau)'x}, L_\gamma(\tau) V_1(\eta + i\gamma)e^{ip(\tau)x}\rangle - \tau\langle V_1^*(\eta - i\gamma)e^{ip(\tau)'x}, L_\gamma(\tau)$$
$$\times(-V_1(\xi/2) + V_2)e^{ip(\tau)x}\rangle - \tau\langle (V_1^*(\xi/2) + V_2^*)e^{ip(\tau)'x}, L_\gamma(\tau) V_1(\eta + i\gamma)e^{ip(\tau)x}\rangle.$$

Since

$$L_\gamma(\tau) = S(\tau) U_{\gamma,0}(E, i\tau) S(\tau)^{-1}(1 - K(\tau)) + O(\tau^{-3}),$$

the first term is a known term. Applying

$$L_\gamma(\tau) = S(\tau) U_{\gamma,0}(E, i\tau) S(\tau)^{-1} + O(\tau^{-2}),$$

and arguing in the same way as in the proof of Lemma 5.2, we get

$$B_\gamma^{(2)}(\tau)\simeq -\langle e^{-ix\cdot\xi}V_1^*(\eta-i\gamma),e^{\Psi_\infty}N_\gamma e^{-\Psi_\infty}(-V_1(\xi/)+V_2)\rangle-\langle e^{-ix\cdot\xi}(V_1^*(\xi/2)+V_2^*),e^{\Psi_\infty}N_\gamma e^{-\Psi_\infty}V_1(\eta+i\gamma)\rangle.$$

The right-hand side is equal to

$$-\int e^{ix\cdot\xi}(\overline{\partial}e^{\Psi_\infty})N_\gamma e^{-\Psi_\infty}(-V_1(\xi/2)+V_2)\mathrm{d}x+\int e^{ix\cdot\xi}(V_1(\xi/2)+V_2)e^{\Psi_\infty}N_\gamma(\overline{\partial}e^{-\Psi_\infty})\mathrm{d}x$$

$$=\int e^{ix\cdot\xi}(N_\gamma\overline{\partial}e^{\Psi_\infty})e^{-\Psi_\infty}(-V_1(\xi/2)+V_2)\mathrm{d}x+\int e^{ix\cdot\xi}(V_1(\xi/2)+V_2)e^{\Psi_\infty}(N_\gamma\overline{\partial}e^{-\Psi_\infty})\mathrm{d}x,$$

where we have used (7.6). Since

$$N_\gamma e^{\pm i\Psi_\infty}=\frac{i}{4}(e^{\pm i\Psi_\infty}-1),$$

this is equal to

$$\frac{i}{4}\int e^{ix\cdot\xi}(1-e^{\Psi_{-\infty}})(-V_1(\xi/2)+V_2)\mathrm{d}x+\frac{i}{4}\int e^{ix\cdot\xi}(V_1(\xi/2)+V_2)(1-e^{\Psi_\infty})\mathrm{d}x.$$

Since $\Psi_\infty=-i\lambda c(x)+g$, by the stationary phase method, the term containing $e^{\pm i\Psi_\infty}$ vanishes as $\lambda\to\infty$. Here one must note that $b_\lambda(0)=0$. What remains is

$$\frac{i}{2}\int e^{ix\cdot\xi}V_2\mathrm{d}x.$$

Up to a known term this is equal to $i/2\int e^{ix\cdot\xi}W\,\mathrm{d}x$. We have thus reconstructed $\hat{W}(\xi)$.

APPENDIX

We summarize here basic properties of the $\overline{\partial}$-operator used in this paper. Note that we define $\overline{\partial}=(\partial/\partial x_1+i\partial/\partial x_2)/2$.

Theorem 7.1: *If* $|f(z)|\leqslant C(1+|z|)^{-1-\epsilon}$ *for some* $C,\epsilon>0$, *the solution of the equation* $\overline{\partial}u=f$ *satisfying* $u(z)\to 0$ *as* $|z|\to\infty$ *is unique and is given by*

$$u(z)=\frac{1}{2\pi i}\int_{\mathbf{C}}\frac{f(\zeta)}{\zeta-z}\mathrm{d}\zeta\wedge\mathrm{d}\overline{\zeta}=\frac{1}{\pi}\int_{\mathbf{R}^2}\frac{f(x_1-y_1,x_2-y_2)}{y_1+iy_2}\mathrm{d}y_1\mathrm{d}y_2.$$

Using the identity

$$\frac{1}{\zeta-z}=-\frac{1}{z}\sum_{k=0}^{n}\left(\frac{\zeta}{z}\right)^k+\frac{1}{\zeta-z}\left(\frac{\zeta}{z}\right)^{n+1}$$

we have if $(1+|z|)^n f(z)\in L^1(\mathbf{C})$,

$$u(z)=-\frac{1}{2\pi i}\sum_{k=0}^{n}z^{-k-1}\int_{\mathbf{C}}\zeta^k f(\zeta)\mathrm{d}\zeta\wedge\mathrm{d}\overline{\zeta}+\frac{1}{2\pi i}z^{-n-1}\int_{\mathbf{C}}\frac{\zeta^{n+1}f(\zeta)}{\zeta-z}\mathrm{d}\zeta\wedge\mathrm{d}\overline{\zeta}.$$

In particular we have

Theorem 7.2. *If* $|f(z)| \leqslant C(1+|z|)^{-3-\epsilon}$, *the above solution satisfies*

$$(x_1+ix_2)u(z)=\frac{1}{\pi}\int_{\mathbf{R}^2} f(y_1,y_2)\mathrm{d}y_1\mathrm{d}y_2+O(|x|^{-1}).$$

From this theorem it follows that

$$u(x)=(2\pi)^{-1}\int_{\mathbf{R}^2}\frac{e^{ix\cdot k}\hat{f}(k)}{k_1+ik_2}\mathrm{d}k \tag{A1}$$

satisfies

$$(x_1+ix_2)u(x)=\frac{i}{2\pi}\int_{\mathbf{R}^2} f(y)\mathrm{d}y+O(|x|^{-1}), \tag{A2}$$

if $|f(y)| \leqslant C(1+|y|)^{-3-\epsilon}$.

For $f \in \mathcal{S}(\mathbf{R}^3)$, let

$$Nf(x)=(2\pi)^{-3/2}\int_{\mathbf{R}^3}\frac{e^{ix\cdot\xi}\hat{f}(\xi)}{2(\xi_1+i\xi_2)}\mathrm{d}\xi. \tag{A3}$$

Then we have

$$\frac{1}{2}\left(\frac{\partial}{\partial x_1}+i\frac{\partial}{\partial x_2}\right)Nf=\frac{i}{4}f, \tag{A4}$$

$$Nf(x)=\frac{i}{4\pi}\int_{\mathbf{R}^2}\frac{f(y_1,y_2,x_3)}{x_1-y_1+i(x_2-y_2)}\mathrm{d}y, \tag{A5}$$

$$\int_{\mathbf{R}^3}(Nf(x))g(x)\mathrm{d}x=-\int_{\mathbf{R}^3} f(x)(Ng(x))\mathrm{d}x. \tag{A6}$$

Let us prove Lemma 3.3 (1). We first note that $|\xi^2+2i\tau\gamma\cdot\xi-\tau^2-E| \leqslant \epsilon(E+\tau^2+|\xi|^2)$ implies there exists a constant $C>0$ such that

$$C^{-1}\tau \leqslant |\xi| \leqslant C\tau, \quad |\gamma\cdot\frac{\xi}{|\xi|}| \leqslant C\epsilon, \tag{A7}$$

for large $\tau>0$. Therefore we have only to show the following lemma.

Lemma 7.3: Let $m \in \mathbf{R}$. *Suppose* $f(x,\xi;\tau)$ *satisfies*

$$|\partial_x^\alpha\partial_\xi^\beta f(x,\xi;\tau)| \leqslant C_{\alpha\beta}\langle x\rangle^{-3-|\alpha|}(\tau+|\xi|)^{m-|\beta|} \quad \forall\alpha,\beta$$

for ξ, τ *satisfying the condition (7.7). Then*

$$g(x,\xi;\tau)=(2\pi)^{-3/2}\int_{\mathbf{R}^3} e^{ix\cdot k}\frac{\hat{f}(k,\xi;\tau)}{k\cdot(\xi+i\tau\gamma)}\mathrm{d}k$$

satisfies

$$|\partial_x^\alpha\partial_\xi^\beta g(x,\xi;\tau)| \leqslant C_{\alpha\beta}\langle x\rangle^{-1}(\tau+|\xi|)^{m-1-|\beta|} \quad \forall\alpha,\beta,$$

for ξ, τ *satisfying the condition (7.7).*

Proof: We make the linear change of variables $p=Ak$, where

$$p_1=\frac{\xi}{\tau}\cdot k,\ p_2=\gamma\cdot k, p_3=\left(\frac{\xi}{\tau}\times\gamma\right)\cdot k.$$

Then letting $f_A(x,\xi;\tau)=f({}^tAx,\xi;\tau)$, we have

$$g({}^tAx,\xi;\tau)=\frac{i}{2\pi\tau}\int_{\mathbf{R}^2}\frac{f_A(x_1-y_1,x_2-y_2,x_3,\xi;\tau)}{y_1+iy_2}\mathrm{d}y,$$

whose derivative is estimated as follows:

$$|\partial_x^\alpha\partial_\xi^\beta g({}^tAx,\xi;\tau)|\leqslant C_{\alpha\beta}(\tau+|\xi|)^{m-1-|\beta|}\int_{\mathbf{R}^2}\frac{(1+|x'-y|+|x_3|)^{-3}}{|y|}\mathrm{d}y,$$

where $x'=(x_1,x_2)$. The integral over the region $\{|y|<|x'|/2\}$ is estimated as

$$\int_{|y|<|x'|/2}\frac{(1+|x'-y|+|x_3|)^{-3}}{|y|}\mathrm{d}y\leqslant C(1+|x|)^{-2}.$$

The integral over the region $\{|y|>|x'|/2\}$ is estimated as

$$\int_{|y|>|x'|/2}\frac{(1+|x'-y|+|x_3|)^{-3}}{|y|}\mathrm{d}y\leqslant\frac{C}{|x'|}\int_{\mathbf{R}^2}(1+|y|+|x_3|)^{-3}\mathrm{d}y\leqslant\frac{C}{|x'|(1+|x^3|)}.$$

If $|x'|>1$, this is dominated from above by $C(1+|x|)^{-1}$. If $|x'|\leqslant 1$, we estimate in the following manner:

$$\int_{|x'|/2<|y|<1}\frac{(1+|x'-y|+|x_3|)^{-3}}{|y|}\mathrm{d}y\leqslant C(1+|x_3|)^{-3}\int_{|y|<1}\frac{\mathrm{d}y}{|y|}\leqslant C(1+|x_3|)^{-3}\leqslant C(1+|x|)^{-3},$$

$$\int_{|y|>1}\frac{(1+|x'-y|+|x_3|)^{-3}}{|y|}\mathrm{d}y\leqslant C\int_{|y|<1}(1+|x'-y|+|x_3|)^{-3}\mathrm{d}y$$
$$\leqslant C(1+|x_3|)^{-1}\leqslant C(1+|x|)^{-1}.$$

We have thus proven

$$|\partial_x^\alpha\partial_\xi^\beta g({}^tAx,\xi;\tau)|\leqslant C_{\alpha\beta}\langle x\rangle^{-1}(\tau+|\xi|)^{m-1-|\beta|}.$$

From this we can conclude the lemma. □

(Received 8 January 2004; accepted 29 March 2004; published online 1 June 2004)

In this paper we study a new hierarchy of equations derived from the system of isentropic gas dynamics equations where the pressure is a nonlocal function of the density. We show that the hierarchy of equations is integrable. We construct the two compatible Hamiltonian structures and show that the first structure has three distinct Casimirs while the second has one. The existence of Casimirs allows us to extend the flows to local ones. We construct an infinite series of commuting local Hamiltonians as well as three infinite series (related to the three Casimirs) of nonlocal charges. We discuss the zero curvature formulation of the system where we obtain a simple expression for the nonlocal conserved charges, which also clarifies the existence of the three series from a Lie algebraic point of view. We point out that the nonlocal hierarchy of Hunter–Zheng equations can be obtained from our nonlocal flows when the dynamical variables are properly constrained. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1756699]

I. INTRODUCTION

The dynamics of a gas are described by the equations[1]

$$\begin{aligned} &u_t+uu_x+\frac{1}{\rho}P_x=0,\\ &\rho_t+(\rho u)_x=0,\\ &s_t+us_x=0, \end{aligned} \tag{1}$$

where u,ρ,s denote, respectively, the velocity, density, and entropy while P represents the pressure. Here the pressure, in general, can have a functional dependence of the form

$$P=P(\rho^{(n)},s^{(n)}),$$

where $n\in\mathbb{Z}$ and

$$\rho^{(n)}=(\partial^n\rho),\quad s^{(n)}=(\partial^n s).$$

For an isentropic gas (s constant), the equations in (1) take the forms

$$\begin{aligned} &u_t+uu_x+\frac{1}{\rho}P=0,\\ &\rho_t+(\rho u)_x=0, \end{aligned} \tag{2}$$

and have been well studied in the literature for the cases where the pressure is a local monomial of the density, i.e., it has the simple form $P=P(\rho^{(0)})$. For example, for $P=\rho^{\gamma}$, $\gamma\neq 0,1$, Eq. (1) is known as the polytropic gas equations, and for the choice $P=-1/\rho$, the system is called the Chaplygin gas. This class of systems are known to be Hamiltonian systems of hydrodynamic type[2] and are integrable. Various properties associated with such systems have been derived in the past several years.[3–5]

In this paper, we will study a new class of Hamiltonian equations derived from the isentropic gas dynamics system (2) where the pressure is a nonlocal function of the density. In particular, we will choose for the pressure $P(v^{(-1)})=-\frac{1}{2}(\partial^{-1}v)^2$, where $v\equiv\rho$ (we make this identification to be consistent with the conventional choice in the literature), leading to the dynamical equations

$$\begin{aligned} u_t&=-uu_x+(\partial^{-1}v),\\ v_t&=-(uv)_x. \end{aligned} \tag{3}$$

As we will show later, this system of equations is Hamiltonian (in fact, bi-Hamiltonian). In fact, let us note here that the simple first order action

$$S=\int \mathrm{d}t\,\mathrm{d}x\left[(\partial^{-1}u)v_t-\frac{1}{2}u^2v-\frac{1}{2}(\partial^{-1}v)^2\right], \tag{4}$$

generates the dynamical equations in (3) as Euler–Lagrange equations and leads to one of the Hamiltonian structures to be discussed in the next section. In this first order representation, the dynamical equations have a nonlocal form.

One can, of course, take the time derivative of the first equation in (3) to obtain a local representation of the form

$$\begin{aligned} u_{tt}&=-(uu_x)_t+uv,\\ v_t&=-(uv)_x. \end{aligned} \tag{5}$$

This is a second order representation involving only the second time derivative of u and cannot be given a Hamiltonian description. In fact, even a Lagrangian description for this system is not easily obtained. One can, of course, make the system of equations completely second order in which case a Lagrangian formulation is possible. However, since the properties of integrability are best discussed within the Hamiltonian formulation, we will not pursue a Lagrangian description. Sometimes a redefinition of variables can also convert a nonlocal equation into a local one. Indeed, with the identification $z=(\partial^{-1}v)$, the set of equations (3) take the local form

$$u_t=-uu_x+z,\quad z_t=-uz_x, \tag{6}$$

and can be described by a simple first order action of the form

$$S=\int \mathrm{d}t\,\mathrm{d}x\left[zu_t-\frac{1}{2}(u^2z_x+z^2)\right], \tag{7}$$

which shows that the system is Hamiltonian. (The Hamiltonian structure in these new variables can be easily seen to be the canonical one.) However, description of the system in these variables makes the connection with the gas dynamics less transparent.

Although the system of equations in (3), (5), and (6) are equivalent, since we are interested in the integrability properties within the Hamiltonian description, we will study the system in detail in the form described in (3) keeping in mind the mapping to the Hunter–Zheng equation that we will discuss later in the paper. We will show that the hierarchy of equations associated with this system is integrable. The system (3) is bi-Hamiltonian[6,7] (possesses two compatible Hamiltonian

structures) and the infinite set of (nonlocal) charges can be constructed recursively. The two Hamiltonian structures of the system possess nontrivial Casimirs (distinguished functionals) leading to three distinct infinite series of nonlocal charges and allowing us to extend the flows to local ones.[8,9] As a result, we can also construct recursively an infinite set of local conserved charges associated with the system which are in involution. The zero curvature formulation for both the local and the nonlocal equations of the hierarchy can be given in terms of the Lie algebra valued potentials belonging to $SL(2)\otimes U(1)$ (Ref. 10) and generate the nonlocal charges in a compact form. However, we have not yet succeeded in finding a scalar Lax description for the local equations and, consequently, the relation between the local conserved charges and a Lax operator remains an open question. Finally, we show that the hierarchy of equations associated with (3) reduce to the nonlocal hierarchy of Hunter–Zheng equations[11] when properly constrained, whereas the local equations become trivial (they do not go over to the hierarchy of Harry Dym equations[12]). We note that even though we do not yet know of a physical system corresponding to Eqs. (3) or (6), the nice integrability properties that emerge make it worth studying it in its own right. Furthermore, from its relation with the Hunter–Zheng equation, it is quite likely that such a system of equations would find application in a physical problem.

This paper is organized as follows. In Sec. II, we show that the system is bi-Hamiltonian. We obtain the two Hamiltonian structures associated with the Hamiltonian description of Eq. (3). We prove Jacobi identity as well as the compatibility of the two structures using the method of prolongation. We comment on the relation between these structures and the known Lie algebras. The bi-Hamiltonian nature of the system is sufficient to guarantee the integrability of the system. We construct the recursion operator and obtain the first few charges recursively. We show that the two Hamiltonian structures have nontrivial Casimirs which allows us to construct three distinct series of nonlocal charges associated with the three different Casimirs of the first Hamiltonian structure. The Casimir of the second Hamiltonian structure, on the other hand, allows us to extend the flows to local ones. In this case, the recursion operator can be inverted and allows us to construct the infinite set of local charges associated with the system recursively. By construction these charges are in involution. We also describe briefly the matrix Lax description for the system. In Sec. III, we present the zero curvature description of both the local as well as the nonlocal hierarchies of equations based on the Lie algebra $SL(2)\otimes U(1)$. We obtain the nonlocal charges associated with the system from the zero curvature which also clarifies from a different perspective why there are three distinct series of nonlocal charges. In Sec. IV, we summarize our results as well as present some open problems. In particular, we point out how the nonlocal hierarchy of equations associated with (3) reduce to the nonlocal hierarchy of Hunter–Zheng equations. In spite of having a zero curvature formulation of the system, we have not succeeded in obtaining a scalar Lax description for the local equations which remains an interesting open problem.

II. BI-HAMILTONIAN STRUCTURE

In this section, we will show that Eq. (3) is a bi-Hamiltonian system with an infinite number of conserved charges. From the structure of the equations, it is easy to construct the first few conserved charges of the system which take the forms

$$H_1=\int \mathrm{d}x\, v,$$

$$H_2=\int \mathrm{d}x\, uv, \tag{8}$$

$$H_3=\int \mathrm{d}x \left[\frac{1}{2}u^2v+\frac{1}{2}(\partial^{-1}v)^2\right].$$

From the structure of the conserved charges in (8), we see that Eq. (3) can be written in the Hamiltonian forms as

$$\begin{pmatrix} u \\ v \end{pmatrix}_t = \mathcal{D}_1 \begin{pmatrix} \delta H_3/\delta u \\ \delta H_3/\delta v \end{pmatrix} = \mathcal{D}_2 \begin{pmatrix} \delta H_2/\delta u \\ \delta H_2/\delta v \end{pmatrix},$$

where we have defined

$$\mathcal{D}_1 = \begin{pmatrix} 0 & -\partial \\ -\partial & 0 \end{pmatrix}, \quad \mathcal{D}_2 = \begin{pmatrix} \partial^{-1} & -u_x \\ u_x & -(v\,\partial + \partial v) \end{pmatrix}. \tag{9}$$

The skew symmetry of these Hamiltonian structures is manifest. The proof of the Jacobi identity for these structures as well as their compatibility can be shown through the standard method of prolongation[7] which we describe briefly. Introducing the matrix univector

$$\vec{\theta} = \begin{pmatrix} \theta_1 \\ \theta_2 \end{pmatrix},$$

we can construct the two bivectors associated with the two structures $\mathcal{D}_1$ and $\mathcal{D}_2$ as

$$\Theta_{\mathcal{D}_1} = \frac{1}{2}\int dx\,\{\vec{\theta}^{\,T} \wedge \mathcal{D}_1 \vec{\theta}\} = -\int dx\; \theta_1 \wedge \theta_{2x},$$

$$\Theta_{\mathcal{D}_2} = \frac{1}{2}\int dx\,\{\vec{\theta}^{\,T} \wedge \mathcal{D}_2 \vec{\theta}\} = \frac{1}{2}\int dx\,[\,\theta_1 \wedge (\partial^{-1}\theta_1) - 2v\;\theta_2 \wedge \theta_{2x} - 2u_x\,\theta_1 \wedge \theta_2].$$

Using the prolongation relations for any vector field $\tilde{\mathbf{v}}$,

$$\begin{aligned} \mathbf{pr}\,\tilde{\mathbf{v}}_{\mathcal{D}_1\vec{\theta}}(u) &= -\theta_{2x}, \\ \mathbf{pr}\,\tilde{\mathbf{v}}_{\mathcal{D}_1\vec{\theta}}(v) &= -\theta_{1x}, \\ \mathbf{pr}\,\tilde{\mathbf{v}}_{\mathcal{D}_2\vec{\theta}}(u) &= (\partial^{-1}\theta_1) - u_x\,\theta_2, \\ \mathbf{pr}\,\tilde{\mathbf{v}}_{\mathcal{D}_2\vec{\theta}}(v) &= u_x\,\theta_1 - v\;\theta_{2x} - (v\;\theta_2)_x, \end{aligned} \tag{10}$$

it is straightforward to show that the prolongations of the bivectors $\Theta_{\mathcal{D}_1}$ and $\Theta_{\mathcal{D}_2}$ vanish,

$$\mathbf{pr}\,\tilde{\mathbf{v}}_{\mathcal{D}_2\vec{\theta}}(\Theta_{\mathcal{D}_1}) = \mathbf{pr}\,\tilde{\mathbf{v}}_{\mathcal{D}_2\vec{\theta}}(\Theta_{\mathcal{D}_2}) = 0,$$

implying that $\mathcal{D}_1$ and $\mathcal{D}_2$ satisfy Jacobi identity. Furthermore, using (10), it also follows that

$$\mathbf{pr}\,\tilde{\mathbf{v}}_{\mathcal{D}_1\vec{\theta}}(\Theta_{\mathcal{D}_2}) + \mathbf{pr}\,\tilde{\mathbf{v}}_{\mathcal{D}_2\vec{\theta}}(\Theta_{\mathcal{D}_1}) = 0.$$

This shows that $\mathcal{D}_1$ and $\mathcal{D}_2$ are compatible, namely, not only are $\mathcal{D}_1$ and $\mathcal{D}_2$ genuine Hamiltonian structures, any arbitrary linear combination of them is as well. As a result, the dynamical equations in (3) correspond to a bi-Hamiltonian system and, consequently, are integrable.[6,7]

It is worth making a few remarks about these Hamiltonian structures. We note that the first Hamiltonian structure is the standard structure that arises in systems of hydrodynamic type (for example, in polytropic gas dynamics[4,5]). It is the second Hamiltonian structure which normally has some interesting connection with Lie algebras. The Lie algebra structure of $\mathcal{D}_2$ is not quite manifest in the form given in (9). However, with a change of basis

$$\tilde{u} = u_x, \quad \tilde{v} = v - \tfrac{1}{2}u_x^2 = v - \tfrac{1}{2}\tilde{u}^2,$$

it follows that the second structure can be written as

$$\tilde{\mathcal{D}}_2=\begin{pmatrix} -\partial & 0 \\ 0 & -(\tilde{v}\partial+\partial\tilde{v}) \end{pmatrix}.$$

We recognize this to be the Lie algebra of $\mathrm{SL}(2)\otimes\mathrm{U}(1)$ without the central charge [for SL(2)]. This is similar to the algebra in the case of the two boson hierarchy where there is a central charge present in the SL(2) algebra.[10] It is also clear from this analysis that we can naturally assign the scaling dimensions $[\tilde{v}]=[v]=2$, $[\tilde{u}]=[u]+1=1$, $[x]=-1$ (with these assignments $[t]=-1$ for nonlocal equations and $[t]=0$ for local ones as will be clear later), which will be useful later in connection with the zero curvature formulation of the system. For completeness, we also note that in this new basis, the first Hamiltonian structure takes the form

$$\tilde{\mathcal{D}}_1=\begin{pmatrix} 0 & -\partial^2 \\ \partial^2 & -(\tilde{u}_x\partial+\partial\tilde{u}_x) \end{pmatrix}.$$

We will, however, continue to use, for simplicity, the variables u,v which are conventional in the study of such systems.

For the bi-Hamiltonian system such as in (3), we can naturally define an associated hierarchy of commuting flows through the relation

$$\begin{pmatrix} u \\ v \end{pmatrix}_t=\mathcal{D}_1\begin{pmatrix} \delta H_{n+1}/\delta u \\ \delta H_{n+1}/\delta v \end{pmatrix}=\mathcal{D}_2\begin{pmatrix} \delta H_n/\delta u \\ \delta H_n/\delta v \end{pmatrix}, \quad n=1,2,\ldots .$$

The gradients of the successive Hamiltonians in the hierarchy can be related through the recursion operator as

$$\begin{pmatrix} \delta H_{n+1}/\delta u \\ \delta H_{n+1}/\delta v \end{pmatrix}=R^{\dagger}\begin{pmatrix} \delta H_n/\delta u \\ \delta H_n/\delta v \end{pmatrix}, \tag{11}$$

where we have defined

$$R=\mathcal{D}_2\mathcal{D}_1^{-1}=\begin{pmatrix} u_x\partial^{-1} & -\partial^{-2} \\ 2v+v_x\partial^{-1} & -u_x\partial^{-1} \end{pmatrix}. \tag{12}$$

It is interesting to note that, in this case, we can invert the recursion operator to write

$$R^{-1}=\begin{pmatrix} -\frac{1}{2}\partial z\partial^{-1}zu_x\partial & \frac{1}{2}\partial z\partial^{-1}z \\ -\partial^2-\frac{1}{2}\partial^2 zu_x\partial^{-1}u_xz\partial & \frac{1}{2}\partial^2u_xz\partial^{-1}z \end{pmatrix}, \tag{13}$$

where we have defined

$$z=(v-\tfrac{1}{2}u_x^2)^{-1/2}.$$

This will be useful later in the construction of the local flows associated with the system. Using Eqs. (11) and (12), we can write the relations for the gradients explicitly as

$$\frac{\delta H_{n+1}}{\delta u}=-\partial^{-1}u_x\frac{\delta H_n}{\delta u}+(2v-\partial^{-1}v_x)\frac{\delta H_n}{\delta v},$$

$$\frac{\delta H_{n+1}}{\delta v}=-\partial^{-2}\frac{\delta H_n}{\delta u}+\partial^{-1}u_x\frac{\delta H_n}{\delta v}, \quad n=1,2,\ldots . \tag{14}$$

These can be explicitly integrated to give the infinite set of (nonlocal) Hamiltonians

$$H_1=\int \mathrm{d}x\, v,$$

$$H_2=\int \mathrm{d}x\, uv,$$

$$H_3=\int \mathrm{d}x\left[\frac{1}{2}u^2v+\frac{1}{2}(\partial^{-1}v)^2\right],$$

$$H_4=\int \mathrm{d}x\left[\frac{1}{6}u^3v-uv\,(\partial^{-2}v)-\frac{1}{2}u\,(\partial^{-1}v)^2\right],$$

$$H_5=\int \mathrm{d}x\left[\frac{1}{24}u^4v+\frac{1}{2}u^2\left(-v\,(\partial^{-2}v)-\frac{1}{2}(\partial^{-1}v)^2\right)-\frac{1}{2}(\partial^{-1}v)^2(\partial^{-2}v)\right.$$
$$\left.+\frac{1}{2}(\partial^{-1}(u_x(\partial^{-1}v)))^2\right],\quad \ldots. \tag{15}$$

The corresponding flows (the first few) have the forms

$$u_{t_1}=-u_x,\quad v_{t_1}=-v_x,$$

$$u_{t_2}=-uu_x+(\partial^{-1}v),\quad v_{t_2}=-(uv)_x, \tag{16}$$

$$u_{t_3}=-\tfrac{1}{2}u^2u_x+u(\partial^{-1}v)+\partial^{-1}(u_{xx}(\partial^{-2}v)),$$

$$v_{t_3}=-uvu_x-\tfrac{1}{2}u^2v_x+2v(\partial^{-1}v)+v_x(\partial^{-2}v),\ldots.$$

We note that, with the dimensionalities of the variables described earlier, all the conserved charges in (15) have the same canonical dimension of 1 and by construction they are all in involution.

To further understand the properties of this hierarchy, let us note that the first Hamiltonian structure in (9) has three Casimirs

$$H_1=\int \mathrm{d}x\, v,$$

$$H_1^{(1)}=-\int \mathrm{d}x\, u_x\to 0,$$

$$H_1^{(2)}=\int \mathrm{d}x\, u,$$

such that

$$\mathcal{D}_1\begin{pmatrix}\delta H_1/\delta u\\ \delta H_1/\delta v\end{pmatrix}=\mathcal{D}_1\begin{pmatrix}\delta H_1^{(1)}/\delta u\\ \delta H_1^{(1)}/\delta v\end{pmatrix}=\mathcal{D}_1\begin{pmatrix}\delta H_1^{(2)}/\delta u\\ \delta H_1^{(2)}/\delta v\end{pmatrix}=0. \tag{17}$$

We remark here that the Casimir $H_1^{(1)}$ is trivial much like in the case of the Hunter–Zheng equation.[11] The existence of Casimirs would normally imply that the series of recursive flows cannot be extended to negative values of n. However, in the present case, it is not very hard to check that the second Hamiltonian structure $\mathcal{D}_2$ also has a Casimir of the form

$$H_{-1}=2\int \mathrm{d}x\left(v-\frac{1}{2}u_x^2\right)^{1/2},$$

such that

$$\mathcal{D}_2\begin{pmatrix}\delta H_{-1}/\delta u\\ \delta H_{-1}/\delta v\end{pmatrix}=0. \tag{18}$$

As a consequence, the hierarchy of flows in (16) can be extended to negative values of n.[8] We note that the Casimir in (18) is conserved under the flows of (16).

For negative values of n, the gradients of the Hamiltonians will satisfy a recursion relation involving R^{-1} given in (13), and take the explicit forms

$$\begin{aligned}\frac{\delta H_n}{\delta v}&=\frac{1}{2}\left(v-\frac{1}{2}u_x^2\right)^{-1/2}\partial^{-1}\left(v-\frac{1}{2}u_x^2\right)^{-1/2}\left(\partial\frac{\delta H_{n+1}}{\delta u}-u_x\partial^2\frac{\delta H_{n+1}}{\delta v}\right),\\ \frac{\delta H_n}{\delta u}&=\frac{1}{2}\partial u_x\left(v-\frac{1}{2}u_x^2\right)^{-1/2}\partial^{-1}\left(v-\frac{1}{2}u_x^2\right)^{-1/2}\left(\partial\frac{\delta H_{n+1}}{\delta u}-u_x\partial^2\frac{\delta H_{n+1}}{\delta v}\right)-\partial^2\frac{\delta H_{n+1}}{\delta v}\\ &=\partial u_x\frac{\delta H_n}{\delta v}-\partial^2\frac{\delta H_{n+1}}{\delta v},\quad n=-2,-3,\ \ldots\quad .\end{aligned} \tag{19}$$

The corresponding conserved charges can now be recursively constructed and have the forms

$$\begin{aligned}H_{-1}&=2\int \mathrm{d}x\left(v-\frac{1}{2}u_x^2\right)^{1/2},\\ H_{-2}&=-\int \mathrm{d}x\,u_{xx}\left(v-\frac{1}{2}u_x^2\right)^{-1/2},\\ H_{-3}&=-\frac{1}{12}\int \mathrm{d}x\,(v_{xx}+2u_{xx}^2-u_xu_{xxx})\left(v-\frac{1}{2}u_x^2\right)^{-3/2},\\ H_{-4}&=-\frac{1}{8}\int \mathrm{d}x\,(v_{xx}u_{xx}-v_xu_{xxx})\left(v-\frac{1}{2}u_x^2\right)^{-5/2},\\ H_{-5}&=-\int \mathrm{d}x\left[\frac{5}{64}\left(u_{xx}^2+\left(v-\frac{1}{2}u_x^2\right)_{xx}\right)^2-\frac{1}{24}\left(\left(v-\frac{1}{2}u_x^2\right)_{xx}\right)^2-\frac{5}{192}(v_x-u_xu_{xx})\left(v-\frac{1}{2}u_x^2\right)_{xxx}\right.\\ &\quad\left.-\frac{1}{8}u_{xx}u_{xxxx}\left(v-\frac{1}{2}u_x^2\right)\right]\left(v-\frac{1}{2}u_x^2\right)^{-7/2},\quad \ldots .\end{aligned} \tag{20}$$

The dynamical equations following from these (the first few) take the forms

$$\begin{aligned}u_{t_{-1}}&=-[(v-\tfrac{1}{2}u_x^2)^{-1/2}]_x,\quad v_{t_{-1}}=-[u_x(v-\tfrac{1}{2}u_x^2)^{-1/2}]_{xx},\\ u_{t_{-2}}&=-\tfrac{1}{2}[u_{xx}(v-\tfrac{1}{2}u_x^2)^{-3/2}]_x,\qquad v_{t_{-2}}=-\tfrac{1}{2}[v_x(v-\tfrac{1}{2}u_x^2)^{-3/2}]_{xx},\quad \ldots .\end{aligned} \tag{21}$$

We note that these flows and the Hamiltonians for negative n are completely local. The Hamiltonians involve increasing number of derivatives of the variables, unlike the conserved charges in the polytropic gas where they are pure polynomials of the dynamical variables. Similarly, the local dynamical equations become increasingly more nonlinearly dispersive as n becomes more nega-

tive. Thus, this hierarchy of equations is very different from the usual polytropic gas systems.[4,5] Nonetheless, all these local charges are in involution (having been constructed from compatible Hamiltonian structures). We note here that, with the dimensionalities for the variables described earlier, all the local charges in (20) have the scaling dimension 0.

The three Casimirs in (17) can be easily checked to be conserved under the flows (21). In fact, we can also construct nonlocal charges from $H_1^{(1)}$ recursively and they take the forms

$$\begin{aligned} H_1^{(1)} &= -\int \mathrm{d}x\, u_x \to 0, \\ H_2^{(1)} &= -\int \mathrm{d}x\, (\partial^{-1} v), \\ H_3^{(1)} &= \int \mathrm{d}x\ \partial^{-1}(u_x(\partial^{-1} v)), \\ H_4^{(1)} &= \int \mathrm{d}x\ \partial^{-1}\left[-\frac{1}{2}(\partial^{-1} v)^2 - u_x\, \partial^{-1}(u_x(\partial^{-1} v))\right], \quad \ldots . \end{aligned} \tag{22}$$

All these charges have the dimensionality 0 and are in involution. [Note that we can obtain $H_2^{(1)}$ from the trivial Casimir $H_1^{(1)}$ using the recursion relation (14) with the prescription $(\partial^{-1} 0) = -1$, for more details see Ref. 8 and references therein.] Similarly, $H_1^{(2)}$ also leads to the following series of nonlocal charges which are related recursively:

$$\begin{aligned} H_1^{(2)} &= \int \mathrm{d}x\, u, \\ H_2^{(2)} &= -\int \mathrm{d}x \left[\frac{1}{2}u^2 + (\partial^{-2} v)\right], \\ H_3^{(2)} &= \int \mathrm{d}x \left[\frac{1}{6}u^3 + \partial^{-2}(u_x(\partial^{-1} v)) + v\,(\partial^{-2} u)\right], \\ H_4^{(2)} &= \int \mathrm{d}x \left[-\frac{1}{24}u^4 - \frac{1}{2}(\partial^{-2} v)^2 - \frac{1}{2}\partial^{-2}(\partial^{-1} v)^2 - \frac{1}{2}v(\partial^{-2} u^2) + v\ \partial^{-1}(u_x(\partial^{-2} u))\right. \\ &\quad \left. - \partial^{-2}(u_x \partial^{-1}(u_x(\partial^{-1} v)))\right], \end{aligned} \tag{23}$$

The scaling dimensions for this set of charges turn out to be -1. They are all conserved under the local flows of (21) and are in involution. The meaning of the three series of nonlocal charges is quite clear from the point of view of the existence of three Casimirs. However, in the next section, we will see within the context of the zero curvature formulation that the three series are related to the fact that the Lie algebra of SL(2) (related to the second Hamiltonian structure of the system) has three generators. We remark here that nonlocal flows can also be derived from the set of charges in (22) and (23), but we do not get into that.

To close this section, we note that a bi-Hamiltonian system of evolution equations,

$$\begin{pmatrix} u \\ v \end{pmatrix}_t = K_n[u,v],$$

is known[13,14] to have a natural Lax description of the form

$$\frac{\partial \mathbb{M}}{\partial t}=[\mathbb{M},\mathbb{B}],$$

where, we can identify

$$\mathbb{M}\equiv R,$$

$$\mathbb{B}\equiv \mathbb{K}_n'.$$

Here $\mathbb{K}_n'$ represents the matrix Fréchet derivative of K_n, defined by

$$\mathbb{K}_n'\begin{pmatrix} w_1 \\ w_2 \end{pmatrix}=\frac{\mathrm{d}}{\mathrm{d}\epsilon}K_n[u+\epsilon w_1, v+\epsilon w_2]\Big|_{\epsilon=0}.$$

In this way, we can obtain a matrix Lax description ($\mathbb{M}$,$\mathbb{B}$ are matrix operators) for the nonlocal as well as the local equations. However, such a Lax description is not very useful since it does not directly lead to conserved charges. Therefore, we do not give details of this and study the zero curvature formulation for this system in the next section.

III. ZERO CURVATURE

To construct the zero curvature for the local as well as the nonlocal equations, let us recall some of the features of our system of equations. We note that the second Hamiltonian structure corresponds to the Lie algebra of $\mathrm{SL}(2)\otimes\mathrm{U}(1)$ so that the zero curvature condition can be based on this algebra. Furthermore, the canonical dimensions of the variables are given by $[u]=0$, $[v]=2$, $[x]=-1$, $[t]=0$ (for local flows). Since the canonical dimension of t is zero, for a zero curvature condition of the form

$$\partial_t \mathbb{A}_1-\partial_x \mathbb{A}_0-[\mathbb{A}_0,\mathbb{A}_1]=0, \tag{24}$$

we note that multiplication with the matrix $\mathbb{A}_0$ must preserve the canonical dimensions of the elements of any matrix and, therefore, will have the unique form

$$\mathbb{A}_0=\begin{pmatrix} [\ ]=0 & [\ ]=-1 \\ [\ ]=1 & [\ ]=0 \end{pmatrix}, \tag{25}$$

where [ ] represents the dimensionality of the matrix element. It follows from (24) that the matrix $\mathbb{A}_1$ will have the form (since $[\partial]=1$)

$$\mathbb{A}_1=\begin{pmatrix} [\ ]=1 & [\ ]=0 \\ [\ ]=2 & [\ ]=1 \end{pmatrix}. \tag{26}$$

Following the procedure in Ref. 10 which describes the general construction of zero curvature based on $\mathrm{SL}(2)\otimes\mathrm{U}(1)$, and recalling the dimensionalities of our matrices in (25) and (26), let us choose

$$\mathbb{A}_0=\begin{pmatrix} -\lambda B_x+\frac{\lambda^2}{2}(-(\partial^{-1}A)+2u_xB) & -B \\ \frac{\lambda^3}{2}(-A+\lambda Bv) & -\frac{\lambda^2}{2}(\partial^{-1}A) \end{pmatrix},$$

$$\mathbb{A}_1=\begin{pmatrix} \lambda u_x & -\dfrac{1}{\lambda} \\ \dfrac{\lambda^3}{2}v & 0 \end{pmatrix}, \tag{27}$$

where λ represents a dimensionless spectral parameter and A,B are arbitrary functions of the dynamical variables as well as the spectral parameter. The zero curvature condition (24), in this case, leads to the dynamical equations

$$u_t=\lambda(-(\partial^{-1}A)+u_xB)-B_x,$$

$$v_t=\lambda(-u_xA+(v\partial+\partial v)B)-A_x. \tag{28}$$

Since the dynamical variables are independent of the spectral parameter, it is clear that the functions A,B must depend on λ for this equation to be meaningful. Let us make a Taylor expansion in λ of the form (recall that for the local flows n is negative)

$$A=\sum_{j=-1}^{-|n|}\lambda^{j+|n|}A_j, \quad B=\sum_{j=-1}^{-|n|}\lambda^{j+|n|}B_j, \tag{29}$$

with

$$A_{-1}=(u_x(v-\tfrac{1}{2}u_x^2)^{-1/2})_x, \quad B_{-1}=(v-\tfrac{1}{2}u_x^2)^{-1/2}. \tag{30}$$

Substituting (29) and (30) into (28), we obtain

$$\begin{gathered}\mathcal{D}_2\begin{pmatrix}A_j\\B_j\end{pmatrix}=\mathcal{D}_1\begin{pmatrix}A_{j+1}\\B_{j+1}\end{pmatrix}, \quad j=-1,-2,\ldots,-|n|+1, \\ \begin{pmatrix}u_t\\v_t\end{pmatrix}=\mathcal{D}_1\begin{pmatrix}A_{n+1}\\B_{n+1}\end{pmatrix}.\end{gathered} \tag{31}$$

It is clear now that if we identify

$$A_j=\frac{\delta H_j}{\delta u}, \quad B_j=\frac{\delta H_j}{\delta v}, \tag{32}$$

then (31) gives the dynamical equations of the hierarchy (for any n), the two Hamiltonian structures of the system as well as the recursion relations between the conserved charges given in (19). The first local flow for $n=-1$, for example, takes the form

$$u_t=-[(v-\tfrac{1}{2}u_x^2)^{-1/2}]_x,$$

$$v_t=-[u_x(v-\tfrac{1}{2}u_x^2)^{-1/2}]_{xx},$$

which coincides with the first flow in (21).

For the nonlocal equations (n positive) let us choose

$$\mathbb{A}_0=\begin{pmatrix} -B_x+\dfrac{1}{2\lambda}(-(\partial^{-1}A)+2u_xB) & -B \\ \dfrac{1}{2\lambda}\left(-A+\dfrac{1}{\lambda}vB\right) & -\dfrac{1}{2\lambda}(\partial^{-1}A) \end{pmatrix},$$

$$\mathbb{A}_1=\begin{pmatrix} \frac{1}{\lambda}u_x & -1 \\ \frac{1}{2\lambda^2}v & 0 \end{pmatrix}.$$

The zero curvature condition (24), in this case, gives

$$u_t=(-(\partial^{-1}A)+u_xB)-\lambda B_x,$$

$$v_t=(-u_xA+(v\partial+\partial v)B)-\lambda A_x.$$

Using a Taylor expansion of the type in (29) (here n is positive), namely,

$$A=\sum_{j=1}^{n}\lambda^{n-j}A_j, \quad B=\sum_{j=1}^{n}\lambda^{n-j}B_j,$$

with

$$A_1=0, \quad B_1=1,$$

we obtain

$$\mathcal{D}_1\begin{pmatrix}A_{j+1}\\ B_{j+1}\end{pmatrix}=\mathcal{D}_2\begin{pmatrix}A_j\\ B_j\end{pmatrix}, \quad j=1,2,\ldots,n-1,$$

$$\begin{pmatrix}u_t\\ v_t\end{pmatrix}=\mathcal{D}_2\begin{pmatrix}A_n\\ B_n\end{pmatrix}.$$

Once again, with the identification in (32), it is easy to see that this leads to the dynamical nonlocal equations of the hierarchy. For $n=1$, for example, it gives the chiral boson equation of (16).

As we have seen, the zero curvature formulation is quite nice in that it not only gives the dynamical equations, but also leads to the two Hamiltonian structures of the system as well as the recursion relation for the conserved charges. It can also give the nonlocal charges (if present) of the system.[15] For example, let us consider the matrix $\mathbb{A}_1$ in (27). Then, it is straightforward to show that as a result of the zero curvature condition (24),

$$Z=P(e^{-\int_{-\infty}^{\infty}dx\,\mathbb{A}_1}),$$

is conserved. Here "P" stands for path ordering of the exponential. This path ordered exponential can be expanded as

$$Z=-\int_{-\infty}^{\infty}dx\,\mathbb{A}_1+\int_{-\infty}^{\infty}dx\,\mathbb{A}_1(\partial^{-1}\mathbb{A}_1)-\int_{-\infty}^{\infty}dx\,\mathbb{A}_1(\partial^{-1}(\mathbb{A}_1(\partial^{-1}\mathbb{A}_1))+\cdots,$$

and each term of the expansion will be individually conserved. (Actually, the coefficient of each independent power of λ would be conserved. However, as we will see below, each term in the expansion leads to different powers of λ for the matrix elements, as a result of which each term in the expansion is individually conserved.) We can work out explicitly the first few terms in the expansion to see that

$$\int_{-\infty}^{\infty} dx\, \mathbb{A}_1 = \begin{pmatrix} \lambda \int_{-\infty}^{\infty} dx\, u_x & -\frac{1}{\lambda}\int_{-\infty}^{\infty} dx \\ \frac{\lambda^3}{2}\int_{-\infty}^{\infty} dx\, v & 0 \end{pmatrix} = \begin{pmatrix} 0 & c \\ \frac{\lambda^3}{2}\int_{-\infty}^{\infty} dx\, v & 0 \end{pmatrix},$$

$$\int_{-\infty}^{\infty} dx\, \mathbb{A}_1(\partial^{-1}\mathbb{A}_1) = \begin{pmatrix} \lambda^2 \int_{-\infty}^{\infty} dx \left(u_x(\partial^{-1}u_x) - \frac{1}{2}\left(\partial^{-1}\left(v - \frac{1}{2}u_x^2\right)\right)\right) & -\int_{-\infty}^{\infty} dx\, u_x(\partial^{-1}1) \\ \frac{\lambda^4}{2}\int_{-\infty}^{\infty} dx\, v(\partial^{-1}u_x) & -\frac{\lambda^2}{2}\int_{-\infty}^{\infty} dx\, v(\partial^{-1}1) \end{pmatrix}$$

$$= \begin{pmatrix} -\frac{\lambda^2}{2}\int_{-\infty}^{\infty} dx(\partial^{-1}v) & \int_{-\infty}^{\infty} dx\, u \\ \frac{\lambda^4}{2}\int_{-\infty}^{\infty} dx\, uv & \frac{\lambda^2}{2}\int_{-\infty}^{\infty} dx\, (\partial^{-1}v) \end{pmatrix},$$

$$\int_{-\infty}^{\infty} dx\, \mathbb{A}_1(\partial^{-1}(\mathbb{A}_1(\partial^{-1}\mathbb{A}_1)))$$

$$= -\int_{-\infty}^{\infty} dx\, (\partial^{-1}\mathbb{A}_1)(\mathbb{A}_1(\partial^{-1}\mathbb{A}_1))$$

$$= -\begin{pmatrix} -\frac{\lambda^3}{2}\int_{-\infty}^{\infty} dx\, \partial^{-1}(u_x(\partial^{-1}v)) & \lambda\int_{-\infty}^{\infty} dx\left[\frac{1}{2}u^2 + (\partial^{-2}v)\right] \\ -\frac{\lambda^5}{2}\int_{-\infty}^{\infty} dx\left[\frac{1}{2}u^2 v + \frac{1}{2}(\partial^{-1}v)^2\right] & \frac{\lambda^3}{2}\int_{-\infty}^{\infty} dx\, \partial^{-1}(u_x(\partial^{-1}v)) \end{pmatrix}.$$

These are indeed the three series of nonlocal charges for our system (up to multiplicative constants). The origin of the three infinite series of charges can be understood in this approach in the following manner. We note that our zero curvature condition is based on the Lie algebra SL(2) $\otimes$U(1) and that the potential $\mathbb{A}_1$ belongs to this algebra. However, the Abelian (U(1)) part of the potential is not subjected to path ordering and, consequently, does not contribute to nonlocal charges. On the other hand, SL(2) has three generators and the charges projected along any of the generators must be conserved. Consequently, the system possesses three infinite series of nonlocal charges.

IV. CONCLUSION

In this paper, we have studied a new system of equations derived from a gas dynamics with the pressure given by a nonlocal function of the density and have shown that the hierarchy of equations is integrable. We have shown that the system possesses two compatible Hamiltonian structures and have constructed an infinite number of (nonlocal) conserved charges recursively. The second Hamiltonian structure of this system corresponds to the centerless SL(2)$\otimes$U(1) algebra. We have shown that the first Hamiltonian structure of the system possesses three nontrivial Casimirs while the second Hamiltonian structure has one. This allows us to extend the nonlocal flows into local ones corresponding to negative flows of the hierarchy. We have constructed an infinite series of commuting local charges associated with the system recursively. This local system of equations possesses three infinite series of nonlocal charges and we have constructed them from the three Casimirs of the first Hamiltonian structure recursively. We have given the zero curvature formulation for the system of local as well as nonlocal equations based on the Lie algebra SL(2)$\otimes$U(1). This brings out naturally the two Hamiltonian structures of the system

as well as the recursion relations between the conserved charges. The zero curvature formulation also leads to the three infinite series of conserved nonlocal charges of the system in a simple manner and relates their existence to the fact that the Lie algebra of SL(2) has three generators.

There are some other interesting features of this system that we would like to discuss briefly. We note that the nonlocal hierarchy of flows associated with the Hunter–Zheng equation can be obtained from (16) when the dynamical variables are constrained as

$$u=(\partial^{-2}w), \quad v=\tfrac{1}{2}(\partial^{-1}w)^2=\tfrac{1}{2}u_x^2. \tag{33}$$

Under this reduction, the three series of nonlocal charges go over to the ones associated with the Hunter–Zheng equation. However, under this reduction, the local flows of the hierarchy become trivial and do not go over to the Harry Dym equation.

Another interesting issue that remains open is the construction of a scalar Lax representation for the system of local equations. (We do not expect to find a scalar Lax representation for the nonlocal flows.) It is well known that given the zero curvature formulation of a system, one can easily go over to a scalar Lax description and vice versa.[16,17] In this case, however, in spite of the fact that we have a zero curvature formulation, we have not been able to find a scalar Lax description for this system. We have discussed the standard matrix Lax description, but finding a scalar Lax operator remains an open question that deserves further study.

We study the deformed Harry Dym and Hunter–Zheng equations with two arbitrary deformation parameters. These reduce to various other known models in appropriate limits. We show that both these systems are bi-Hamiltonian with the same Hamiltonian structures. They are integrable and belong to the same hierarchy corresponding to positive and negative flows. We present the Lax pair description for both the systems and construct the conserved charges of negative order from the Lax operator. For the deformed Harry Dym equation, we construct the nonstandard Lax representation for two special classes of values of the deformation parameters. In general, we argue that a nonstandard description will involve a pseudodifferential operator of infinite order. © *2004 American Institute of Physics.*

I. INTRODUCTION

The search for exactly solvable equations has acquired enormous importance since the nonlinear Kortweg–de Vries equation was shown to be integrable.[1,2] Exactly solvable equations, linear or nonlinear, constitute a very special class of dynamical systems with many interesting properties. The significance of determining new integrable systems, as well as studying their properties and solutions, can not be overestimated. The structure of integrable systems (or partial differential equations) is highly restrictive and, in general does not allow for deformations. In particular, the presence of arbitrary constant parameters (which cannot be transformed away by some symmetry) is quite rare. One notable exception is the two boson equation,[3] which has an arbitrary constant parameter present, is known to be integrable. Different values of this parameter reduce the model to other known soluble models. In this paper, we propose a new system of equations, with two arbitrary constant parameters, that is exactly soluble and reduces to various other known physical models in different limits of these parameters.

Let us recall that the Harry Dym (HD) equation,[4,5]

$$u_t = (u_{xx}^{-1/2})_x, \tag{1}$$

and the Hunter–Zheng (HZ) equation,[6]

$$(u_t + u u_x)_x = \tfrac{1}{2} u_x^2, \tag{2}$$

are known to be integrable and, in fact, belong to the same hierarchy corresponding to negative and positive order flows, respectively.[7] The HD equation has interest in the study of the Saffman–Taylor problem which describes the motion of a two-dimensional interface between a viscous and

a nonviscous fluid.[8] The HZ equation, on the other hand, arises in the study of massive nematic liquid crystals and in the study of shallow water waves.[6] In this paper we will show that the following system of two equations,

$$u_t=\sqrt{2}\left(\frac{1-\lambda u_{xx}}{\sqrt{2u_{xx}-\alpha-\lambda u_{xx}^2}}\right)_x \tag{3}$$

and

$$u_{xxt}=\alpha u_x-2u_xu_{xx}-uu_{xxx}+\frac{\lambda}{6}(u_x^3)_{xx}, \tag{4}$$

are integrable for arbitrary values of the constant parameters α,λ. Furthermore, they belong to the same hierarchy corresponding to the negative and positive flows respectively, much like the HD and the HZ equations. It is interesting to note from (4) that when $\alpha\neq 0$, it can be scaled to unity through the scaling $x\to x/\alpha$, $u\to u/\alpha$. Therefore, looking at (4) alone, it would appear that there are only two meaningful values for α, namely, $\alpha=0,1$. Similarly, under a scaling $t\to t/\alpha^{3/2}$, $x\to x/\alpha$, $u\to u/\alpha$, the parameter α in the dHD equation (3) can be scaled to unity when it is not zero. However, there is no scaling which will scale α to unity (when it is nonzero) simultaneously in both the equations and, consequently, if the two systems belong to the same hierarchy, α has to be thought of as an arbitrary parameter.

We note that, for $\alpha=\lambda=0$, Eqs. (3) and (4) reduce, respectively, to the HD equation (1) and the HZ equation (2). For lack of a better name, we will refer to (3) as the deformed Harry Dym equation (dHD) and (4) as the deformed Hunter–Zheng equation (dHZ). (The name ''generalized Harry Dym'' equation has already been used earlier in the context of a multicomponent Harry Dym equation.[9]) For $\alpha\neq 0$ and $\lambda=0$ equation (4) was studied by Alber *et al.*[10] and its solutions contain solitons of the type known as umbilic solitons. Equation (4) with $\alpha=1$ and $\lambda\neq 0$ has appeared more recently in the literature[11] as describing short capillary-gravity waves and its solutions are known to become multivalued in a finite amount of time. While a matrix Lax pair for this system was provided in Ref. 11 and solubility of the model was argued based on a map to the sine-Gordon equation, interesting properties, such as the bi-Hamiltonian structure, the infinite number of conserved charges were not discussed at all. Our results clarify these aspects and provide direct support for the integrability of this new system. The deformed equation (3) for arbitrary α and $\lambda\neq 0$ is truly a new integrable system (which to the best of our knowledge has not been studied in the literature) and leads to the above mentioned models in different limits. This can, therefore, be considered as a very rich system, much like the two boson hierarchy.

Our paper is organized as follows: In Sec. II, we obtain the first Hamiltonian structure of the dHD and dHZ equations. In Sec. III, a second Hamiltonian structure, compatible with the first one, is obtained. We show that both the dHD and dHZ equations are bi-Hamiltonian and, therefore, integrable and belong to the same hierarchy corresponding to negative and positive flows. In Sec. IV, we present a Lax pair description of both the system of equations and construct the conserved charges of negative order from the Lax operator. We obtain a nonstandard Lax description for the dHD equation for the special values of the deformation parameters $\lambda=0,\lambda=-3/\alpha$. We argue that, for general values of the parameters, a nonstandard Lax description will involve a pseudodifferential operator of infinite order. In Sec. V we present our conclusions.

II. dHZ AND dHD AS HAMILTONIAN SYSTEMS

To describe the dHD and the dHZ equations in a compact manner, let us introduce the following notation. Let us define

$$F_{(\alpha,\lambda)}^2\equiv 2u_{xx}-\alpha-\lambda u_{xx}^2,\quad A\equiv\frac{1-\lambda u_{xx}}{F}. \tag{5}$$

Then, it follows from the definitions in (5) that

$$\kappa \equiv (1-\alpha\lambda) = \lambda F^2 + (1-\lambda u_{xx})^2 = (\lambda + A^2)F^2,$$

$$\frac{F_x}{F^3} = -\frac{1}{\kappa} A A_x, \tag{6}$$

$$\frac{u_{xxx}}{F^3} = -\frac{1}{\kappa} A_x.$$

These and other relations following from these prove very useful in the analysis of the two systems.

Given the dHZ equation (4), we obtain from the definition in (5) that

$$F_t = -\left[F\left(u - \frac{\lambda}{2} u_x^2 \right) \right]_x. \tag{7}$$

Similarly, in terms of the new variables in (5), the dHD equation (3) can be written as

$$u_t = \sqrt{2}\, A_x, \tag{8}$$

and it follows that, under the evolution of dHD,

$$\begin{aligned} F_t &= \sqrt{2}\, A\, A_{xxx}, \\ A_t &= -\sqrt{2}\, \kappa \frac{A_{xxx}}{F^3}. \end{aligned} \tag{9}$$

It is now straightforward to note from Eqs. (7) and (9) that

$$H_{-1} = \sqrt{2} \int dx\, F \tag{10}$$

is conserved under both the dHD and dHZ flows.

The dHZ equation can be obtained from a variational principle, $\delta \int dt dx\, \mathcal{L}$, with the Lagrangian density

$$\mathcal{L} = \frac{1}{2} u_x u_t + \frac{\alpha}{2} u^2 + \frac{1}{2} u u_x^2 - \frac{\lambda}{24} u_x^4. \tag{11}$$

This is a first order Lagrangian density and, consequently, the Hamiltonian structure can be readily read out, or we can use, for example, Dirac's theory of constraints[12] to obtain the Hamiltonian and the Hamiltonian operator associated with (11). The Lagrangian is degenerate and the primary constraint is obtained to be

$$\Phi = \pi - \tfrac{1}{2} u_x, \tag{12}$$

where $\pi = \partial \mathcal{L} / \partial u_t$ is the canonical momentum. The total Hamiltonian can be written as

$$H_T = \int dx (\pi u_t - \mathcal{L} + \beta \Phi) = \int dx \left[-\frac{\alpha}{2} u^2 - \frac{1}{2} u u_x^2 + \frac{\lambda}{24} u_x^4 + \beta \left(\pi - \frac{1}{2} u_x \right) \right], \tag{13}$$

where β is a Lagrange multiplier field. Using the canonical Poisson bracket relation

$$\{ u(x), \pi(y) \} = \delta(x-y), \tag{14}$$

with all others vanishing, it follows that the requirement of the primary constraint to be stationary under time evolution,

$$\{\Phi(x),H_T\}=0,$$

determines the Lagrange multiplier field β in (13) and the system has no further constraints.

Using the canonical Poisson bracket relations (14), we can now calculate

$$K(x,y)\equiv\{\Phi(x),\Phi(y)\}=\tfrac{1}{2}\partial_y\delta(x-y)-\tfrac{1}{2}\partial_x\delta(x-y). \tag{15}$$

This shows that the constraint (12) is second class and that the Dirac bracket between the basic variables has the form

$$\{u(x),u(y)\}_D=\{u(x),u(y)\}-\int dz\,dz'\{u(x),\Phi(z)\}J(z,z')\{\Phi(z'),u(y)\}=J(x,y),$$

where J is the inverse of the Poisson bracket of the constraint (15),

$$\int dz\,K(x,z)J(z,y)=\delta(x-y)\,.$$

This last relation determines

$$\partial_x J(x,y)=\delta(x-y),$$

or

$$J(x,y)=\mathcal{D}_1\delta(x-y),$$

where

$$\mathcal{D}_1=\partial^{-1}, \tag{16}$$

and can be thought of as the alternating step function in the coordinate space. We can now set the constraint (12) strongly to zero in (13) to obtain

$$H_2\equiv -H_T=\int dx\left(\frac{\alpha}{2}u^2+\frac{1}{2}uu_x^2-\frac{\lambda}{24}u_x^4\right). \tag{17}$$

Therefore, the dHZ equation can be written in the Hamiltonian form

$$u_t=\mathcal{D}_1\frac{\delta H_2}{\delta u},$$

with $\mathcal{D}_1$ and H_2 given by (16) and (17), respectively.

From the results in Ref. 7 we know that the HD and HZ equations belong to the same hierarchy of equations. Here, too, we will see that both the dHD and the dHZ equations belong to the same hierarchy. In particular, we note that

$$u_t=\mathcal{D}_1\frac{\delta H_{-1}}{\delta u},$$

with H_{-1}, given by (10), yields the deformed Harry Dym equation (8). As a result, the dHD equation also is Hamiltonian with the same Hamiltonian structure of the dHZ equation in (16) and, consequently, has a Lagrangian description given by

$$\mathcal{L}=\tfrac{1}{2}u_x u_t-\sqrt{2}\,F.$$

The reader can easily check that H_2 is also conserved by both the dHD and dHZ equations, much like H_{-1}. Note that for $\alpha=\lambda=0$, these two charges reduce to the corresponding ones in the HD and HZ systems.

III. dHD AND dHZ AS BI-HAMILTONIAN SYSTEMS

It is well known that a system can be shown to be integrable if it is bi-Hamiltonian.[13,14] This corresponds to the system having a Hamiltonian description with two distinct Hamiltonian structures that are compatible. Therefore, we try to see if the dHD and the dHZ equations can be described as bi-Hamiltonian systems. For this, we have to find a second Hamiltonian description for the two systems.

In order to determine a second Hamiltonian structure for the two systems, we recall[7] that, when $\alpha=\lambda=0$, the corresponding H_{-1} is a Casimir of the second Hamiltonian structure for the HD and HZ systems, namely,

$$\mathcal{D}_2^{(\alpha=\lambda=0)}=\partial^{-2}u_{xx}\,\partial^{-1}+\partial^{-1}u_{xx}\,\partial^{-2} \tag{18}$$

satisfies

$$\mathcal{D}_2^{(\alpha=\lambda=0)}\frac{\delta H_{-1}^{(\alpha=\lambda=0)}}{\delta u}=0.$$

Since we know H_{-1} for the deformed systems which is a generalization of $H_{-1}^{(\alpha=\lambda=0)}$, we look for a Hamiltonian structure for which it is a Casimir. With some work, it can be determined that H_{-1} given in (10) is a Casimir of

$$\mathcal{D}_2\equiv\mathcal{D}_2^{(\alpha,\lambda)}=\tfrac{1}{2}(\partial^{-2}F^2\,\partial^{-1}+\partial^{-1}F^2\,\partial^{-2})+\lambda\,\partial^{-2}u_{xxx}\,\partial^{-1}u_{xxx}\partial^{-2}. \tag{19}$$

Note that this structure reduces to (18) when $\alpha=\lambda=0$. The skew symmetry of this Hamiltonian structure is manifest. The proof of the Jacobi identity for this structure as well as its compatibility with $\mathcal{D}_1$ in (16) can be determined through the standard method of prolongation described in Ref. 14, which we discuss briefly.

Performing the change of variables

$$w=u_{xx},$$

the Hamiltonian structures (16) and (19) assume the forms

$$\mathcal{D}_1=\partial^3,$$

$$\mathcal{D}_2=\tfrac{1}{2}(F^2\partial+\partial F^2)+\lambda w_x\,\partial^{-1}w_x.$$

We can construct the two bivectors associated with the two structures as

$$\Theta_{\mathcal{D}_1}=\frac{1}{2}\int dx\,\{\theta\wedge\mathcal{D}_1\theta\}=\frac{1}{2}\int dx\;\theta\wedge\theta_{xxx},$$

$$\Theta_{\mathcal{D}_2}=\frac{1}{2}\int dx\,\{\theta\wedge\mathcal{D}_2\theta\}=\frac{1}{2}\int dx\,\{-\alpha\;\theta\wedge\theta_x+2w\;\theta\wedge\theta_x-\lambda\;w^2\theta\wedge\theta_x+\lambda\;w_x\;\theta\wedge(\partial^{-1}w_x\;\theta)\}.$$

Using the prolongation relations,

$$\begin{aligned}
&\mathbf{pr}\,\mathbf{v}_{\mathcal{D}_1\theta}(w)=\theta_{xxx},\\
&\mathbf{pr}\,\mathbf{v}_{\mathcal{D}_1\theta}(w^2)=2w\,\mathbf{pr}\,\mathbf{v}_{\mathcal{D}_1\theta}(w),\\
&\mathbf{pr}\,\mathbf{v}_{\mathcal{D}_1\theta}(w_x)=(\,\mathbf{pr}\,\mathbf{v}_{\mathcal{D}_1\theta}(w))_x,\\
&\mathbf{pr}\,\mathbf{v}_{\mathcal{D}_2\theta}(w)=-\alpha\,\theta_x+2w\,\theta_x-\lambda\,w^2\theta_x+w_x\,\theta-\lambda\,ww_x\,\theta+\lambda w_x(\partial^{-1}w_x\,\theta),\\
&\mathbf{pr}\,\mathbf{v}_{\mathcal{D}_2\theta}(w^2)=2w\;\,\mathbf{pr}\,\mathbf{v}_{\mathcal{D}_2\theta}(w),\\
&\mathbf{pr}\,\mathbf{v}_{\mathcal{D}_2\theta}(w_x)=(\,\mathbf{pr}\,\mathbf{v}_{\mathcal{D}_2\theta}(w))_x,
\end{aligned}\tag{20}$$

it is straightforward to show that the prolongation of the bivector $\Theta_{\mathcal{D}_2}$ vanishes,

$$\mathbf{pr}\,\mathbf{v}_{\mathcal{D}_2\theta}(\Theta_{\mathcal{D}_2})=0,$$

implying that $\mathcal{D}_2$ satisfies Jacobi identity. Using (20), it also follows that

$$\mathbf{pr}\,\mathbf{v}_{\mathcal{D}_1\theta}(\Theta_{\mathcal{D}_2})+\mathbf{pr}\,\mathbf{v}_{\mathcal{D}_2\theta}(\Theta_{\mathcal{D}_1})=0,$$

showing that $\mathcal{D}_1$ and $\mathcal{D}_2$ are compatible. Namely, not only are $\mathcal{D}_1,\mathcal{D}_2$ genuine Hamiltonian structures, any arbitrary linear combination of them is as well. Any physical system that is Hamiltonian with respect to these two structures, therefore, defines a pencil system and is integrable. It is worth pointing out here that when $\alpha=\lambda=0$, the second Hamiltonian structure (18) represents the centerless Virasoro algebra[15] (with dimension zero operators). The structure in (19) appears to be a highly nonlocal generalization of this algebra, but we are not familiar with any study of such an algebra in the literature.

To show that the dHD and dHZ are bi-Hamiltonian systems, we note that the charges

$$H_1=\int dx\,u_x^2, \tag{21}$$

$$H_{-2}=\frac{1}{2\kappa}\int dx\,FA_x^2 \tag{22}$$

are also conserved by both the dHZ and dHD equations. While the charge in (21) is the unmodified charge of the HD and HZ systems (this seems to be a simple coincidence), the charge in (22) is a true generalization of the corresponding charge of the HD and HZ systems. With these charges, it is easy to see that the dHZ equation can be written in a truly bi-Hamiltonian form

$$u_t=\mathcal{D}_1\frac{\delta H_2}{\delta u}=\mathcal{D}_2\frac{\delta H_1}{\delta u}.$$

Similarly, the dHD equation can also be written in the bi-Hamiltonian form

$$u_t=\mathcal{D}_1\frac{\delta H_{-1}}{\delta u}=\mathcal{D}_2\frac{\delta H_{-2}}{\delta u}.$$

Thus, we see that both the dHD as well as dHZ systems are bi-Hamiltonian with the same two compatible Hamiltonian structures and are, therefore, integrable.

IV. THE LAX REPRESENTATION

When a system is bi-Hamiltonian, we can naturally define a hierarchy of commuting flows through the relation

$$u_t = K_n[u] = \mathcal{D}_1 \frac{\delta H_{n+1}}{\delta u} = \mathcal{D}_2 \frac{\delta H_n}{\delta u}, \quad n = 0,1,2,\ldots . \tag{23}$$

In the present case, both the Hamiltonian structures have Casimirs. We have already seen that H_{-1} is a Casimir of $\mathcal{D}_2$ and it can be checked that the trivial Hamiltonian

$$H_0 = \int dx\, u_{xx} \tag{24}$$

formally defines the Casimir of $\mathcal{D}_1$ (namely, if we write formally $\delta H_0 / \delta u = \partial^2$, it is annihilated by $\mathcal{D}_1$). As a result, the system of flows can be extended to both positive and negative integer values for n. In this way, we see that much like in the HD and HZ systems,[7] the dHD and dHZ systems also belong to the same hierarchy corresponding to the negative and positive flows.

Let us introduce the recursion operator following from the two Hamiltonian structures as

$$R = \mathcal{D}_2 \mathcal{D}_1^{-1}.$$

Then, it follows from (23) that

$$K_{n+1} = R\, K_n,$$

and

$$\frac{\delta H_{n+1}}{\delta u} = R^{\dagger} \frac{\delta H_n}{\delta u}, \tag{25}$$

where

$$R^{\dagger} = \partial^{-1} u_{xx}\, \partial^{-1} + (-\alpha + u_{xx})\, \partial^{-2} - \lambda\, u_{xx}\, \partial^{-1} u_{xx}\, \partial^{-1} \tag{26}$$

is the adjoint of R. The conserved charges for the hierarchy can, of course, be determined in principle recursively from (25). However, in practice, integrating the recursion relation is highly nontrivial. Therefore, we look for a Lax representation for the system of dHD and dHZ equations which will allow us to construct the conserved charges directly.

It is well known[16,17] that for a bi-Hamiltonian system of evolution equations, $u_t = K_n[u]$, a natural Lax description

$$\frac{\partial M}{\partial t} = [M, B],$$

is easily obtained where, we can identify

$$M \equiv R^{\dagger},$$

$$B \equiv K_n'.$$

Here K_n' represents the Fréchet derivative of K_n, defined by

$$K_n'[u]\, v = \frac{d}{d\epsilon} K_n[u + \epsilon v]\bigg|_{\epsilon = 0}.$$

For the dHD and dHZ system of equations in (3) and (4), respectively, we have

$$B^{\mathrm{dHD}} \equiv K_{-2} = \sqrt{2}\, \kappa\, \partial^2 F^{-3} \partial,$$

$$B^{\mathrm{dHZ}} \equiv K_1 = (-\alpha + u_{xx})\,\partial^{-1} + \partial\left(u - \frac{\lambda}{2}u_x^2\right).$$

The two systems have the same $M = R^{\dagger}$ given in (26). It can now be checked that

$$\frac{\partial M}{\partial t} = [M, B^{\mathrm{dHD}}],$$

$$\frac{\partial M}{\partial t} = [M, B^{\mathrm{dHZ}}], \tag{27}$$

do indeed generate the dHD and the dHZ equations and, thereby, provide a Lax pair for the system.

One of the advantages of a Lax representation is that they directly give the conserved charges of the system. From the structure of (27), it follows that $\mathrm{Tr}\, M^{(2n+1)/2}$ are conserved, where "Tr" represents Adler's trace.[18] We note that

$$\mathrm{Tr}\, M^{(2n+1)/2} = 0, \quad n \geqslant 1,$$

$$\mathrm{Tr}\, M^{1/2} = \int dx\, F,$$

$$\mathrm{Tr}\, M^{-(1/2)} = -\frac{1}{2\kappa}\int dx\, F A_x^2, \tag{28}$$

$$\mathrm{Tr}\, M^{-(3/2)} = \frac{3}{\kappa}\int dx \left(4\frac{A_{xx}^2}{F} + \frac{1}{\kappa}F A_x^4\right),$$

$$\vdots.$$

The first two nontrivial charges correspond respectively to H_{-1}, H_{-2} given in Eqs. (10) and (22), constructed earlier by brute force. In fact, all H_{-n-1} with positive $n \geqslant 0$ can be constructed from $\mathrm{Tr}\, M^{-[(2n-1)/2]}$ and by construction (namely, because of the nature of (27)), they are conserved under both the dHD and dHZ flows. Unfortunately, as is clear from (28), this procedure does not yield the charges H_n with positive integer values. These are, in general, nonlocal and even in the HD and HZ case, construction of these charges relies primarily on the recursion relation (25). It remains an interesting question to construct these charges in a more direct manner.

The Harry Dym equation has a Gelfand–Dikii representation for the Lax pair, while the HZ equation does not. We will now discuss the existence of such a Lax representation for the dHD equation. A spectral problem associated with the dHD equations can be obtained from the recursion relation (25) (see Ref. 19, and references therein) as follows. Introducing a spectral parameter μ and defining

$$\psi^2(x,t,\mu) = \sum_{n=0}^{\infty} \mu^n \frac{\delta H_n}{\delta u},$$

we note that the recursion relation (25) can be written compactly as (recall that H_0 is a Casimir of $\mathcal{D}_1$)

$$(\mathcal{D}_1 - \mu\mathcal{D}_2)\,\psi^2 = 0,$$

or

$$(1-\mu R^{\dagger})\,\psi^2=0, \tag{29}$$

which defines an eigenvalue problem for the eigenfunction ψ^2 with eigenvalue $1/\mu$. A linear eigenvalue problem can be derived from this if we can factorize the operator $(1-\mu R^{\dagger})$.

Let us note that the operator $R^{\dagger}$ in (26) can be rewritten in the form

$$R^{\dagger}=\tfrac{1}{2}[\partial^{-1}(F^2_{(\alpha,\lambda)}+X)\partial^{-1}+(F^2_{(\alpha,\lambda)}+X)\partial^{-2}], \tag{30}$$

where

$$X=\sum_{n=1} X_n\partial^{-n},$$

and the coefficients X_n can be determined recursively to be

$$X_1=0,$$

$$X_2=\frac{\lambda}{4}u^2_{xxx},$$

$$X_3=-\tfrac{1}{2}X_{2,x},$$

$$\vdots.$$

When $\lambda=0$, it follows that $X=0$ and that $F^2_{(\alpha,\lambda=0)}$ is a simple function. In this case, the eigenvalue problem (29) can be factorized as

$$(1-R^{\dagger})\,\psi^2=2\,\partial^{-1}\phi^{-2}\,\partial\,\phi^3\left(\partial^2-\frac{\mu}{4}F^2_{(\alpha,\lambda=0)}\right)\phi=0,$$

where we have identified

$$\phi^2=(\partial^{-2}\psi^2).$$

This shows that if the linear equation

$$\left(\partial^2-\frac{\mu}{4}F^2_{(\alpha,\lambda=0)}\right)\phi=0$$

is satisfied, then (29) will hold and this identifies the Lax operator for the system to be

$$L=\frac{1}{F^2_{(\alpha,\lambda=0)}}\,\partial^2.$$

In fact, it can be readily checked that when $\lambda=0$, the hierarchy of dHD equations can be obtained from the non-standard Lax equation

$$\frac{\partial L}{\partial t_n}=4\sqrt{2}[L,(L^{(2n-1)/2})_{\geqslant 2}].$$

The conserved quantities for this system can be obtained from $\mathrm{Tr}\,L^{(2n-1)/2}$, $n=0,1,2,\ldots$.

On the other hand, when $\lambda\neq 0$, the coefficients X_n are nontrivial and X represents a pseudo-differential operator. The factorization, in such a case, is not so simple and, in principle would involve an infinite series of terms. For arbitrary values of κ, the terms in the series can possibly be determined recursively. However, this is not very interesting. We simply note here that for the

special value $\kappa=4$, the infinite series of terms seems to have a simpler compact form and the Lax operator, in such a case, has the form

$$L_{\kappa=4}=\frac{1}{F}\partial\frac{1}{F}\partial-\frac{1}{4}A_x\partial^{-1}A_x\partial,$$

and, in this case, the hierarchy of dHD equations can be obtained from the nonstandard Lax representation

$$\frac{\partial L_{\kappa=4}}{\partial t_n}=4\sqrt{2}[L_{\kappa=4},(L_{\kappa=4}^{(2n-1)/2})_{\geqslant 2}].$$

The conserved quantities, in this case, also follow from $\mathrm{Tr}\,L_{\kappa=4}^{(2n-1)/2}$ and up to multiplicative factors, they have the forms given in (28) with $\kappa=4$. A simple Lax description for arbitrary λ, however, remains an open question.

V. CONCLUSION

In this paper, we have studied the general system of dHD and dHZ equations. We have shown that both these systems are bi-Hamiltonian and, therefore, integrable and belong to the same hierarchy corresponding to negative and positive flows. The Lax pair for the two system of equations have been derived and conserved charges corresponding to negative integer values follow from the Lax operator. A simple construction of the charges for positive integer values remains an open question. For $\lambda=0$, we have constructed a nonstandard Lax representation for the dHD equation, which involves a purely differential Lax operator. For arbitrary values of λ, we have argued that a nonstandard Lax representation will necessarily involve a Lax operator which is a pseudodifferential operator of infinite order. For the particular case of $\kappa=4$, however, this takes a simpler compact form.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 45, NUMBER 7 JULY 2004

Expansion around half-integer values, binomial sums, and inverse binomial sums

Stefan Weinzierl[a)]
Max-Planck-Institut für Physik (Werner-Heisenberg-Institut), Föhringer Ring 6, D-80805 München, Germany

(Received 13 February 2004; accepted 1 April 2004; published online 8 June 2004)

I consider the expansion of transcendental functions in a small parameter around rational numbers. This includes in particular the expansion around half-integer values. I present algorithms which are suitable for an implementation within a symbolic computer algebra system. The method is an extension of the technique of nested sums. The algorithms allow in addition the evaluation of binomial sums, inverse binomial sums and generalizations thereof. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1758319]

I. INTRODUCTION

The expansion of higher transcendental functions[1,2] occurs frequently in many areas of science. In particular, one encounters these functions in the calculation of higher order corrections to scattering processes in particle physics. In a previous publication we considered the expansion of transcendental functions in a small parameter around integer values.[3,4] The restriction to integer values is in general sufficient for the evaluation of loop integrals arising in massless quantum field theories. However, the inclusion of particle masses in loop integrals[5–13] or the evaluation of phase space integrals[14–20] can lead to half-integer values. It is therefore desirable to extend the algorithm of Refs. 3, 4 to include at least half-integer values. Here I report on algorithms for the expansion of transcendental functions around rational number p/q, where p and q are integers. In particular this includes the half-integer case.

Each term in the expansion is expressed through multiple polylogarithms.[21,22] Compared to the pure integer case, the extension to rational numbers p/q introduces naturally the qth roots of unity in the arguments of the polylogarithms. All algorithms are based on manipulations of a special form of nested sums. These nested sums are generalizations of Euler–Zagier sums[23,24] or harmonic sums.[25–29] The algorithms presented here can be implemented into a symbolic computer algebra system like Form[27,30] or GiNaC.[31]

As a spin-off, the methods presented here allow the evaluation of binomial sums,[5,6] inverse binomial sums[5,7–9,32,33] and generalizations thereof. Inverse binomial sums are sometimes evaluated with the help of log-sine integrals.[10,11] In the Appendix, I compare the log-sine approach with the one presented here.

This paper is organized as follows: Sec. II recalls the definition and main properties of nested sums and multiple polylogarithms. It is a brief summary of Ref. 3. Section III introduces roots of unity and gives the basic algorithms for the expansion around rational numbers. Section IV treats binomial sums and generalizations thereof. Section V deals with inverse binomial sums and generalizations thereof. Section VI gives some simple applications to massive loop integrals and phase space integrals. Finally, Section VII contains a summary and the conclusions. The Appendix compares this approach to log-sine integrals and collects some important relations for polylogarithms of low weight.

II. A SUMMARY OF KNOWN PROPERTIES OF NESTED SUMS

In this section I shortly review properties of particular forms of nested sums, which are called Z-sums and S-sums. Details can be found in Ref. 3. Z-sums are defined by

$$Z(n;m_1,\ldots,m_k;x_1,\ldots,x_k)=\sum_{n\geqslant i_1>i_2>\cdots>i_k>0}\frac{x_1^{i_1}}{i_1^{m_1}}\cdots\frac{x_k^{i_k}}{i_k^{m_k}} \tag{1}$$

and form a Hopf algebra. If the sums go to infinity ($n=\infty$) the Z-sums are identical to multiple polylogarithms (note that we use here the reversed notation for multiple polylogs and multiple zeta values as compared to Refs. 3, 21):[21]

$$Z(\infty;m_1,\ldots,m_k;x_1,\ldots,x_k)=\mathrm{Li}_{m_1,\ldots,m_k}(x_1,\ldots,x_k). \tag{2}$$

For $x_1=\cdots=x_k=1$ the definition reduces to the Euler–Zagier sums:[23,24]

$$Z(n;m_1,\ldots,m_k;1,\ldots,1)=Z_{m_1,\ldots,m_k}(n). \tag{3}$$

For $n=\infty$ and $x_1=\cdots=x_k=1$ the sum is a multiple ζ-value:[22]

$$Z(\infty;m_1,\ldots,m_k;1,\ldots,1)=\zeta_{m_1,\ldots,m_k}. \tag{4}$$

The multiple polylogarithms contain as the notation already suggests as subsets the classical polylogarithms $\mathrm{Li}_n(x)$,[34] as well as Nielsen's generalized polylogarithms[35]

$$S_{n,p}(x)=\mathrm{Li}_{n+1,1,\ldots,1}(x,\underbrace{1,\ldots,1}_{p-1}), \tag{5}$$

the harmonic polylogarithms[36]

$$H_{m_1,\ldots,m_k}(x)=\mathrm{Li}_{m_1,\ldots,m_k}(x,\underbrace{1,\ldots,1}_{k-1}) \tag{6}$$

and two-dimensional harmonic polylogarithms.[37] The usefulness of the Z-sums lies in the fact, that they interpolate between multiple polylogarithms and Euler–Zagier sums. In addition, the interpolation is compatible with the algebra structure.

In addition to Z-sums, it is sometimes useful to introduce as well S-sums. S-sums are defined by

$$S(n;m_1,\ldots,m_k;x_1,\ldots,x_k)=\sum_{n\geqslant i_1\geqslant i_2\geqslant\cdots\geqslant i_k\geqslant 1}\frac{x_1^{i_1}}{i_1^{m_1}}\cdots\frac{x_k^{i_k}}{i_k^{m_k}} \tag{7}$$

and form an algebra. The S-sums reduce for $x_1=\cdots=x_k=1$ (and positive m_i) to harmonic sums:[27]

$$S(n;m_1,\ldots,m_k;1,\ldots,1)=S_{m_1,\ldots,m_k}(n). \tag{8}$$

The S-sums are closely related to the Z-sums, the difference being the upper summation boundary for the nested sums: $(i-1)$ for Z-sums, i for S-sums. It is advantageous to introduce both Z-sums and S-sums, since some properties are more naturally expressed in terms of Z-sums while others are more naturally expressed in terms of S-sums. One can easily convert from one notation to the other.

Basic manipulations involving nested sums are:
Conversion:

$$Z(n;\ldots)\to S(n;\ldots),$$

$$S(n;\ldots)\to Z(n;\ldots). \tag{9}$$

Multiplication:

$$\begin{aligned} Z(n;\ldots)Z(n;\ldots)&\to Z(n;\ldots),\\ S(n;\ldots)S(n;\ldots)&\to S(n;\ldots). \end{aligned} \tag{10}$$

Convolution:

$$\sum_{i=1}^{n-1} \frac{x^i}{i^m} Z(i-1;\ldots) \frac{y^{n-i}}{(n-i)^{m'}} Z(n-i-1;\ldots)\to Z(n-1;\ldots). \tag{11}$$

Conjugation:

$$-\sum_{i=1}^{n} \binom{n}{i} (-1)^i \frac{x^i}{i^m} S(i;\ldots)\to S(n;\ldots). \tag{12}$$

Conjugation and convolution:

$$-\sum_{i=1}^{n-1} \binom{n}{i} (-1)^i \frac{x^i}{i^m} S(i;\ldots) \frac{y^{n-i}}{(n-i)^{m'}} S(n-i;\ldots)\to S(n-1;\ldots). \tag{13}$$

These algorithms are described in Ref. 3. It is worth to recall some technical steps to evaluate the conjugation in Eq. (12), since the same pattern of steps will be used in Sec. IV. To evaluate the conjugation it is convenient to introduce yet another type of sum as follows:

$$B(n;N;m_1,\ldots,m_k;x_1,\ldots,x_k)=\sum_{i_1=n+1}^{N} \sum_{i_2=i_1+1}^{N} \cdots \sum_{i_k=i_{k-1}+1}^{N} \frac{x_1^{i_1}}{i_1^{m_1}} \frac{x_2^{i_2}}{i_2^{m_2}} \cdots \frac{x_k^{i_k}}{i_k^{m_k}}. \tag{14}$$

These B-sums can be used to express S-sums with upper summation limit n in terms of S-sums with upper summation limit N:

$$\begin{aligned} S(n;m_1,\ldots,m_k;x_1,\ldots,x_k)=&S(N;m_1,\ldots,m_k;x_1,\ldots,x_k)\\ &-S(N;m_2,\ldots,m_k;x_2,\ldots,x_k)B(n;N;m_1;x_1)\\ &+S(N;m_3,\ldots,m_k;x_3,\ldots,x_k)B(n;N;m_1,m_2;x_1,x_2)\\ &-\cdots+(-1)^k B(n;N;m_1,\ldots,m_k;x_1,\ldots,x_k). \end{aligned} \tag{15}$$

Equation (15) also allows us to express a B-sum recursively in terms of S-sums $S(N;\ldots)$ and $S(n;\ldots)$:

$$\begin{aligned} B(n;N;m_1,\ldots,m_k;x_1,\ldots,x_k)=&(-1)^k S(n;m_1,\ldots m_k;x_1,\ldots,x_k)\\ &-(-1)^k S(N;m_1,\ldots m_k;x_1,\ldots,x_k)\\ &+(-1)^k S(N;m_2,\ldots m_k;x_2,\ldots,x_k)B(n;N;m_1;x_1)-\cdots\\ &+(-1)^k S(N;m_k;x_k)B(n;N;m_1,\ldots,m_{k-1};x_1,\ldots,x_{k-1}). \end{aligned} \tag{16}$$

Finally, it is convenient to introduce raising and lowering operators as follows:

$$(\mathbf{x}^+)^m \cdot 1 = \frac{1}{m!}\ln^m(x),$$

$$\mathbf{x}^+ \cdot f(x) = \int_0^x \frac{dx'}{x'} f(x'), \tag{17}$$

$$\mathbf{x}^- \cdot f(x) = x\frac{d}{dx} f(x).$$

It is understood that in the second line only functions which are integrable at $x=0$ are considered. With the help of raising operators a B-sum $B(n;\infty;\dots)$ may be expressed as follows:

$$B(n;\infty;m_1,\dots,m_k;x_1,\dots,x_k)$$

$$= (\mathbf{x_k}^+)^{m_k}(\mathbf{x_{k-1}}^+)^{m_{k-1}}\cdots(\mathbf{x_1}^+)^{m_1}\frac{x_k}{1-x_k}\frac{x_{k-1}x_k}{1-x_{k-1}x_k}\cdots\frac{x_1\dots x_k}{1-x_1\dots x_k}(x_1\cdots x_k)^n. \tag{18}$$

Some important integrals related to the raising operators are

$$\mathbf{x_1}^+[1-(1-x_1x_2)^n] = \sum_{i=1}^{n}\frac{1}{i}[1-(1-x_1x_2)^i],$$

$$\mathbf{x_1}^+\frac{x_1x_2}{1-x_1x_2}[1-(1-x_0x_1x_2)^n]$$

$$= -(1-x_0)^n\sum_{i=1}^{n}\frac{1}{i}\left(\frac{1}{1-x_0}\right)^i[1-(1-x_0x_1x_2)^i]$$

$$+(1-(1-x_0)^n)\sum_{i=1}^{N}\frac{(x_1x_2)^i}{i}+\mathbf{x_1}^+\frac{x_1x_2}{1-x_1x_2}(x_1x_2)^N(1-(1-x_0)^n). \tag{19}$$

To evaluate the conjugation in Eq. (12) one first converts the S-sum to B-sums and introduces then the raising operators. This allows to perform all sums explicitly and one is left with the integrals corresponding to the raising operators. With the help of Eq. (19) one can systematically perform these integrals and convert them back into nested sums.

The basic manipulations in Eqs. (9)–(13) are the building blocks to reduce the following two generic types of sums to single Z-sums:
Type A:

$$\sum_{i=1}^{n}\frac{x^i}{(i+c)^m}\frac{\Gamma(i+a_1+b_1\varepsilon)}{\Gamma(i+c_1+d_1\varepsilon)}\cdots\frac{\Gamma(i+a_k+b_k\varepsilon)}{\Gamma(i+c_k+d_k\varepsilon)}Z(i+o-1,m_1,\dots,m_l,x_1,\dots,x_l); \tag{20}$$

Type B:

$$\sum_{i=1}^{n-1}\frac{x^i}{(i+c)^m}\frac{\Gamma(i+a_1+b_1\varepsilon)}{\Gamma(i+c_1+d_1\varepsilon)}\cdots\frac{\Gamma(i+a_k+b_k\varepsilon)}{\Gamma(i+c_k+d_k\varepsilon)}Z(i+o-1,m_1,\dots,m_l,x_1,\dots,x_l)$$

$$\times\frac{y^{n-i}}{(n-i+c')^{m'}}\frac{\Gamma(n-i+a_1'+b_1'\varepsilon)}{\Gamma(n-i+c_1'+d_1'\varepsilon)}\cdots\frac{\Gamma(n-i+a_{k'}'+b_{k'}'\varepsilon)}{\Gamma(n-i+c_{k'}'+d_{k'}'\varepsilon)}$$

$$\times Z(n-i+o'-1,m_1',\dots,m_{l'}',x_1',\dots,x_{l'}'). \tag{21}$$

Here, all a_j, a'_j, c_j, and c'_j are integers, c,c', are non-negative integers, and o,o' are integers. For sums of type A the upper summation limit n may extend to Infinity. In the rest of the paper I relax the condition on a_j, a'_j, c_j and c'_j to allow for rational numbers. Reference 3 contains in addition two generic types (labeled type C and D in Ref. 3) involving a conjugation. These types do not allow an extension to rational numbers along the lines of this paper. The conjugation is however related to two other important types of sums, which are generalizations of binomial and inverse binomial sums. They are treated in Secs. IV and V of this paper.

III. ALGORITHMS FOR THE EXPANSION AROUND RATIONAL NUMBERS

In this section I extend the algorithms for the expansion of transcendental functions towards the expansion around rational numbers. Sec. III A introduces roots of unity. Roots of unity are useful for the refinement algorithm in Sec. III B, which allows us to express an S-sum $S(n;\ldots)$ as a combination of S-sums, whose upper summation limit is an integer multiple of n. Section III C treats the expansion of Euler's Gamma function around rational numbers. Finally, in Sec. III D all pieces are assembled and the algorithms for the expansion of functions of type A and B around rational numbers are given. A restriction on these algorithms is given by the fact, that rational numbers have to appear in the same place in the numerator and in the denominator. This restriction is relaxed in Sec. IV (a rational number only in the numerator) and Sec. V (a rational number only in the denominator).

A. Roots of unity

We define a short-hand notation for the roots of unity:

$$r_q^p = \exp\left(\frac{2\pi i p}{q}\right). \tag{22}$$

Here, q is a positive integer and p is a non-negative integer. We will need a few properties of the qth roots of unity. Powers of the qth roots of unity are periodic modulo q:

$$(r_q^p)^{j+q} = (r_q^p)^j. \tag{23}$$

Sums of powers of the qth roots of unity yield

$$\sum_{p=0}^{q-1} (r_q^p)^m = \begin{cases} q, & m = 0 \bmod q, \\ 0, & m \neq 0 \bmod q. \end{cases} \tag{24}$$

If $m = 0 \bmod q$, the proof of the relation is trivial. In the case $m \neq 0 \mod q$ we may assume that $0 < m < q$ (due to the periodicity). Then $r_q^m \neq 1$ and we have

$$\sum_{p=0}^{q-1} (r_q^p)^m = \sum_{p=0}^{q-1} (r_q^m)^p = \frac{1-(r_q^m)^q}{1-r_q^m} = 0. \tag{25}$$

From Eq. (24) we obtain immediately

$$\frac{1}{q}\sum_{l=0}^{q-1} (r_q^l)^{m+p} = \begin{cases} 1, & \text{for} \quad m = nq-p, \\ 0, & \text{otherwise.} \end{cases} \tag{26}$$

Since this sum occurs frequently, we introduce the notation

$$\delta_{p,q}(m) = \frac{1}{q}\sum_{l=0}^{q-1} (r_q^l)^{m+p}. \tag{27}$$

Equation (26) will be useful to convert sums with upper summation limit n to sums with upper summation limit $(q\cdot n)$. Note that $\delta_{p,q}(m)$ is idempotent:

$$\delta_{p,q}(m)\cdot\delta_{p,q}(m)=\delta_{p,q}(m) \qquad \text{for all integer } m. \tag{28}$$

Some examples for the half-integer case are

$$\begin{aligned}\delta_{0,2}(n)&=\tfrac{1}{2}[1+(-1)^n],\\ \delta_{1,2}(n)&=\tfrac{1}{2}[1-(-1)^n].\end{aligned} \tag{29}$$

B. Refinements of *S*-sums

An S-sum $S(n;m_1,\ldots;x_1,\ldots)$ with upper summation limit n can be expressed as a combination of S-sums with upper summation limit $(q\cdot n)$, where q is a positive integer. The algorithm proceeds recursively in the depth of the S-sum. For the empty sum one has

$$S(n)=S(q\cdot n). \tag{30}$$

For a S-sum of the form

$$S(n;m_1,m_2,\ldots;x_1,x_2,\ldots)=\sum_{i=1}^{n}\frac{x_1^i}{i^{m_1}}S(i;m_2,\ldots;x_2,\ldots) \tag{31}$$

the algorithm converts first the subsum $S(i;m_2,\ldots;x_2,\ldots)$ to a combination of subsums $S(q\cdot i;\ldots)$. Finally, the outermost sum is converted according to

$$\begin{aligned}\sum_{i=1}^{n}\frac{x^i}{i^m}S(q\cdot i;\ldots)&=q^m\sum_{i=1}^{q\cdot n}\delta_{0,q}(i)\frac{1}{i^m}(x^{1/q})^iS(i;\ldots)\\ &=q^{m-1}\sum_{p=0}^{q-1}\sum_{i=1}^{q\cdot n}\frac{1}{i^m}(r_q^px^{1/q})^iS(i;\ldots).\end{aligned} \tag{32}$$

This completes the algorithm for the conversion of S-sums $S(n;\ldots)$ to $S(q\cdot n;\ldots)$. As an example we have

$$\begin{aligned}S(n;1,1;x_1,x_2)=&S(2n;1,1;\sqrt{x_1},\sqrt{x_2})+S(2n;1,1;\sqrt{x_1},-\sqrt{x_2})\\ &+S(2n;1,1;-\sqrt{x_1},\sqrt{x_2})+S(2n;1,1;-\sqrt{x_1},-\sqrt{x_2}).\end{aligned} \tag{33}$$

Note that as a consequence of the refinement algorithm one obtains relations like

$$\mathrm{Li}_m(x^2)=2^{m-1}[\mathrm{Li}_m(x)+\mathrm{Li}_m(-x)]. \tag{34}$$

C. Expansion of the gamma function

For the expansion of the gamma function around positive integer values one has the well-known formula

$$\frac{\Gamma(n+1+\varepsilon)}{\Gamma(1+\varepsilon)}=\Gamma(n+1)\exp\left(-\sum_{k=1}^{\infty}\varepsilon^k\frac{(-1)^k}{k}S_k(n)\right). \tag{35}$$

For the expansion around rational numbers one finds

$$\frac{\Gamma\left(n+1-\frac{p}{q}+\varepsilon\right)}{\Gamma\left(1-\frac{p}{q}+\varepsilon\right)} = \frac{\Gamma\left(n+1-\frac{p}{q}\right)}{\Gamma\left(1-\frac{p}{q}\right)} \exp\left(-\sum_{k=1}^{\infty} \varepsilon^k \frac{(-q)^k}{k} \sum_{j=1}^{qn} \frac{\delta_{p,q}(j)}{j^k}\right)$$

$$= \frac{\Gamma\left(n+1-\frac{p}{q}\right)}{\Gamma\left(1-\frac{p}{q}\right)} \exp\left(-\frac{1}{q}\sum_{l=0}^{q-1} (r_q^l)^p \sum_{k=1}^{\infty} \varepsilon^k \frac{(-q)^k}{k} S(q\cdot n;k;r_q^l)\right). \quad (36)$$

Here, n and q are positive integers and p is an integer with $0 \leqslant p < q$ and $\gcd(p,q)=1$. For the case $p=0$ and $q=1$ this reduces to the formula Eq. (35). Equation (36) is derived as follows: One starts from the expansion of the logarithm of the Gamma function:

$$\ln\Gamma\left(n+1-\frac{p}{q}+\varepsilon\right) = \ln\Gamma\left(n+1-\frac{p}{q}\right) + \sum_{k=1}^{\infty} \frac{\varepsilon^k}{k!} \psi^{(k-1)}\left(n+1-\frac{p}{q}\right). \quad (37)$$

Here $\psi^{(k-1)}(x)$ is the polygamma function defined as

$$\psi^{(k-1)}(x) = \frac{d^k}{dx^k} \ln\Gamma(x). \quad (38)$$

From the recurrence formula for the polygamma function

$$\psi^{(k-1)}(x+1) - \psi^{(k-1)}(x) = -\Gamma(k)\left(-\frac{1}{x}\right)^k \quad (39)$$

one obtains

$$\psi^{(k-1)}\left(n+1-\frac{p}{q}\right) = \psi^{(k-1)}\left(1-\frac{p}{q}\right) - \Gamma(k)(-1)^k \sum_{i=1}^{n} \left(\frac{1}{i-\frac{p}{q}}\right)^k. \quad (40)$$

The sum in the last term of Eq. (40) is then rewritten in terms of S-sums with upper summation limit $(q\cdot n)$ with the help of Eq. (26).

D. Expansion around rational numbers

In this section we generalize the algorithms A and B, which expand the transcendental sums in Eqs. (20) and (21) around integers to algorithms for the expansion around rational numbers. In the following we will always assume that q_j is a positive integer and that p_j is an integer with $0 \leqslant p_j < q_j$ and $\gcd(p_j,q_j)=1$. We restrict ourselves here to ratios of Gamma function of the form

$$\frac{\Gamma\left(n+a_j-\frac{p_j}{q_j}+b_j\varepsilon\right)}{\Gamma\left(n+c_j-\frac{p_j}{q_j}+d_j\varepsilon\right)}, \quad (41)$$

where n, a_j, and b_j are integers. Here the same fraction p_j/q_j occurs in the numerator and the denominator. In products of these ratios, different fractions are allowed, like, for example, in

$$\frac{\Gamma(n+a_1-\frac{1}{2}+b_1\varepsilon)}{\Gamma(n+c_1-\frac{1}{2}+d_1\varepsilon)}\frac{\Gamma(n+a_2-\frac{2}{3}+b_2\varepsilon)}{\Gamma(n+c_2-\frac{2}{3}+d_2\varepsilon)}. \tag{42}$$

The restriction to ratios of the form (41) ensures that the prefactors $\Gamma(n+1-p/q)$ from the expansion of the Gamma function in Eq. (36) cancel between the numerator and the denominator. The restriction in Eq. (41) will be relaxed in Secs. IV and V. We now consider sums of the type A and B, where we allow the substitutions

$$\begin{aligned} a_j &\to a_j-\frac{p_j}{q_j}, \quad c_j \to c_j-\frac{p_j}{q_j}, \\ a_j' &\to a_j'-\frac{p_j'}{q_j'}, \quad c_j' \to c_j'-\frac{p_j'}{q_j'}, \\ c &\to c-\frac{p_0}{q_0}, \quad c' \to c'-\frac{p_0'}{q_0'}, \end{aligned} \tag{43}$$

in Eqs. (20) and (21). For example, a sum of type A involving rational numbers is of the form

$$\sum_{i=1}^{n}\frac{x^i}{\left(i+c-\frac{p_0}{q_0}\right)^m}\frac{\Gamma\left(i+a_1-\frac{p_1}{q_1}+b_1\varepsilon\right)}{\Gamma\left(i+c_1-\frac{p_1}{q_1}+d_1\varepsilon\right)}\cdots\frac{\Gamma\left(i+a_k-\frac{p_k}{q_k}+b_k\varepsilon\right)}{\Gamma\left(i+c_k-\frac{p_k}{q_k}+d_k\varepsilon\right)}S(i+o,m_1,\ldots,x_1,\ldots), \tag{44}$$

where c_0 is a non-negative integer, o and all a_j, c_j are integers. When dealing with rational numbers it is more convenient to work with S-sums instead of Z-sums and we replaced the Z-sum in Eq. (20) by a S-sum in Eq. (44). Due to the conversion algorithm the two formulations are equivalent.

The algorithms for the expansion in ε of these sums starts by reducing the offsets o and o' in the subsums $S(i+o;m_1,\ldots;x_1,\ldots)$ and $S(n-i+o';m_1',\ldots;x_1',\ldots)$ to zero. Then, using the identity

$$\Gamma(x+1)=x\Gamma(x) \tag{45}$$

for the gamma function, the ratios of the gamma functions are brought to the form

$$\frac{\Gamma\left(i+1-\frac{p_j}{q_j}+b_j\varepsilon\right)}{\Gamma\left(i+1-\frac{p_j}{q_j}+d_j\varepsilon\right)} \quad \text{or} \quad \frac{\Gamma\left(n-i+1-\frac{p_j'}{q_j'}+b_j'\varepsilon\right)}{\Gamma\left(n-i+1-\frac{p_j'}{q_j'}+d_j'\varepsilon\right)}. \tag{46}$$

They are then expanded in ε, using Eq. (36). This yields S-sums with upper summation limit $(q_j\cdot i)$ or $(q_j'\cdot(n-i))$. Now, let $q=\mathrm{lcm}(q_0,q_1,\ldots,q_k)$ be the least common multiple of q_0, $q_1,\ldots,q_k$ and let $q'=\mathrm{lcm}(q_0',q_1',\ldots,q_k')$ be the least common multiple of $q_0',q_1',\ldots,q_k'$ Using the refinement algorithm we can convert any occuring S-sum $S(q_j i;\ldots)$ to S-sums with upper summation limit $(q\cdot i)$. Similar any S-sum $S(q_j'(n-i);\ldots)$ is converted to S-sums $S(q'(n-i);\ldots)$. Products of S-sums are then converted into single S-sums with the help of the multiplication algorithm. After partial fractioning one arrives at the following forms:

$$\text{Type A:} \quad \sum_{i=1}^{n} \frac{x^i}{\left(i+c-\frac{p_0}{q_0}\right)^m} S(qi;\dots),$$
$$\text{Type B:} \quad \sum_{i=1}^{n-1} \frac{x^i}{\left(i+c-\frac{p_0}{q_0}\right)^m} S(qi;\dots)S(q'(n-i);\dots), \tag{47}$$

where q_0 divides q. For sums of type A one then reduces the offset c to zero and one arrives at sums of the form

$$\sum_{i=1}^{n} \frac{x^i}{\left(i-\frac{p_0}{q_0}\right)^m} S(qi,\dots). \tag{48}$$

Using Eq. (26) this sum can be written as

$$\sum_{i=1}^{n} \frac{x^i}{\left(i-\frac{p_0}{q_0}\right)^m} S(qi,\dots) = q^m x^{p/q} \sum_{i=1}^{qn} \delta_{p,q}(i) \frac{(x^{1/q})^i}{i^m} S(i+p;\dots)$$
$$= q^{m-1} \sum_{l=0}^{q-1} (r_q^l x^{1/q})^p \sum_{i=1}^{qn} \frac{(r_q^l x^{1/q})^i}{i^m} S(i+p;\dots), \tag{49}$$

where $p=p_0 q/q_0$ is an integer with $0 \leqslant p < q$. Finally, reducing the offset p of the subsum $S(i+p;\dots)$ to zero, one arrives at S-sums with upper summation limit (qn).

For sums of type B one first refines the subsums $S(qi;\dots)$ and $S(q'(n-i);\dots)$ to $S(\hat{q}i;\dots)$ and $S(\hat{q}(n-i);\dots)$, respectively. Here $\hat{q}=\mathrm{lcm}(q,q')$ is the least common multiple of q and q'. The next step consists in rewriting

$$\sum_{i=1}^{n-1} \frac{x^i}{\left(i+c-\frac{p_0}{q_0}\right)^m} S(qi;\dots)S(q(n-i);\dots)$$
$$= q^m x^{p/q} \sum_{i=1}^{qn-q} \delta_{p,q}(i) \frac{(x^{1/q})^i}{(i+qc)^m} S(i+p;\dots)S(qn-i-p;\dots), \tag{50}$$

which brings us back to the integer case.

This completes the necessary modifications for the extension towards the expansion around rational numbers for the algorithm A and B.

IV. BINOMIAL SUMS AND GENERALIZATIONS

Here we study sums of the form

$$\frac{1}{\Gamma\left(1-\frac{p}{q}\right)} \sum_{n=1}^{\infty} \frac{\Gamma\left(n+1-\frac{p}{q}\right)}{\Gamma(n+1)} \frac{x_0^n}{n^{m_0}} S(n;m_1,\dots,m_k;x_1,\dots,x_k). \tag{51}$$

This relaxes the condition (41) and allows one unbalanced fraction

$$\frac{\Gamma\left(n+1-\frac{p}{q}\right)}{\Gamma(n+1)}. \tag{52}$$

A special case of the form in Eq. (51) are binomial sums

$$\sum_{n=1}^{\infty}\binom{2n}{n}\frac{z^n}{n^{m_0}}S(n;m_1,\ldots,m_k;x_1,\ldots,x_k), \tag{53}$$

which are obtained by setting $p=1$, $q=2$, $x_0=4z$ in Eq. (51) and by noting the identity

$$\binom{2n}{n}=4^n\frac{\Gamma(n+\frac{1}{2})}{\Gamma(\frac{1}{2})\Gamma(n+1)}. \tag{54}$$

Binomial sums have been studied in Refs. 5 and 6. The evaluation of the sums in Eq. (51) follows the same pattern of steps as the evaluation of the conjugation in Eq. (12), as given in Ref. 3. Due to Eq. (15) we may replace in Eq. (51) the S-sum $S(n;\ldots)$ with S-sums $S(\infty;\ldots)$ and B-sums $B(n;\infty;\ldots)$ and it is sufficient to study sums of the form

$$\begin{aligned}&\frac{1}{\Gamma\left(1-\frac{p}{q}\right)}\sum_{n=1}^{\infty}\frac{\Gamma\left(n+1-\frac{p}{q}\right)}{\Gamma(n+1)}\frac{x_0^n}{n^{m_0}}B(n;\infty;m_1,\ldots,m_k;x_1,\ldots,x_k)\\&\quad=-(\mathbf{x_k}^+)^{m_k}(\mathbf{x_{k-1}}^+)^{m_{k-1}}\cdots(\mathbf{x_1}^+)^{m_1}(\mathbf{x_0}^+)^{m_0}\frac{x_k}{1-x_k}\frac{x_{k-1}x_k}{1-x_{k-1}x_k}\cdots\frac{x_1\cdots x_k}{1-x_1\cdots x_k}\\&\qquad\times[1-(1-x_0x_1\cdots x_k)^{-(1-(p/q))}].\end{aligned} \tag{55}$$

To derive the r.h.s. of Eq. (55) we first introduced the raising operators $\mathbf{x}_+$, then performed explicitly all geometric sums from $B(n;\infty;0,\ldots,0;x_1,\ldots,x_k)$ and finally performed the remaining sum with the help of the hypergeometric summation formula

$$\frac{1}{\Gamma\left(1-\frac{p}{q}\right)}\sum_{n=1}^{\infty}\frac{\Gamma\left(n+1-\frac{p}{q}\right)}{\Gamma(n+1)}x^n=-[1-(1-x)^{-(1-p/q)}]. \tag{56}$$

We then perform succesivly the integrations corresponding to the raising operators. Due to the appearance of rational numbers in the exponent, the set in Eq. (19) is no longer sufficient and has to be supplemented with additional equations. Nevertheless, the principle stays the same: Each integration preserves the structure, such that multiple integrations can be performed iteratively. To reduce m_0 we have

$$\mathbf{x_0}^+[1-(1-x_0x_1)^{-(1-p/q)}]=q\sum_{n=1}^{\infty}\frac{1}{n}[\delta_{0,q}(n)-\delta_{q-p,q}(n)][1-(1-x_0x_1)^{n/q}],$$

$$\mathbf{x_0^+}\,\delta_{q-p,q}(n)[1-(1-x_0x_1)^{n/q}]$$

$$=q\,\delta_{q-p,q}(n)\sum_{i=1}^{\infty}\frac{1}{i}[\,\delta_{0,q}(i)-\delta_{q-p,q}(i)][1-(1-x_0x_1)^{i/q}]$$

$$+q\,\delta_{q-p,q}(n)\sum_{i=1}^{n}\frac{1}{i}\,\delta_{q-p,q}(i)[1-(1-x_0x_1)^{i/q}]. \tag{57}$$

To reduce $m_1,m_2,\ldots,m_k$ we have in the general case $x_0\neq 1$:

$$\mathbf{x_1^+}\frac{x_1x_2}{1-x_1x_2}[1-(1-x_0x_1x_2)^{-(1-p/q)}]$$

$$=-q(1-x_0)^{-(1-(p/q))}\left\{\sum_{n=1}^{\infty}\frac{1}{n}[\,\delta_{0,q}(n)-\delta_{q-p,q}(n)]\left(\frac{1}{1-x_0}\right)^{n/q}[1-(1-x_0x_1x_2)^{n/q}]\right\}$$

$$+[1-(1-x_0)^{-(1-(p/q))}]\sum_{n=1}^{N}\frac{1}{n}(x_1x_2)^n$$

$$+\mathbf{x_1^+}\frac{x_1x_2}{1-x_1x_2}(x_1x_2)^N[1-(1-x_0)^{-(1-(p/q))}], \tag{58}$$

$$\mathbf{x_1^+}\,\delta_{q-p,q}(n)\frac{x_1x_2}{1-x_1x_2}[1-(1-x_0x_1x_2)^{n/q}]$$

$$=-q(1-x_0)^{n/q}\delta_{q-p,q}(n)\left\{\sum_{i=1}^{\infty}\frac{1}{i}[\,\delta_{0,q}(i)-\delta_{q-p,q}(i)]\left(\frac{1}{1-x_0}\right)^{i/q}[1-(1-x_0x_1x_2)^{i/q}]\right.$$

$$\left.+\sum_{i=1}^{n}\frac{1}{i}\,\delta_{q-p,q}(i)\left(\frac{1}{1-x_0}\right)^{i/q}[1-(1-x_0x_1x_2)^{i/q}]\right\}$$

$$+\,\delta_{q-p,q}(n)[1-(1-x_0)^{n/q}]\sum_{i=1}^{N}\frac{1}{i}(x_1x_2)^i+\delta_{q-p,q}(n)\mathbf{x_1^+}\frac{x_1x_2}{1-x_1x_2}(x_1x_2)^N[1-(1-x_0)^{n/q}].$$

In the special case $x_0=1$ we have instead

$$\mathbf{x_1^+}\frac{x_1x_2}{1-x_1x_2}[1-(1-x_1x_2)^{-(1-(p/q))}]$$

$$=\frac{1}{1-\dfrac{p}{q}}[1-(1-x_1x_2)^{-(1-(p/q))}]+\sum_{n=1}^{N}\frac{1}{n}(x_1x_2)^n+\mathbf{x_1^+}\frac{x_1x_2}{1-x_1x_2}(x_1x_2)^N, \tag{59}$$

$$\mathbf{x_1^+}\frac{x_1x_2}{1-x_1x_2}[1-(1-x_1x_2)^{n/q}]=-\frac{q}{n}[1-(1-x_1x_2)^{n/q}]+\sum_{i=1}^{N}\frac{1}{i}(x_1x_2)^i+\mathbf{x_1^+}\frac{x_1x_2}{1-x_1x_2}(x_1x_2)^N.$$

Equations (58) and (59) introduce an arbitrary integer N. It is worth noting that Eqs. (58) and (59) hold for any integer N. We will take the limit $N\to\infty$ in the end. It is clear that in this limit terms of the form

$$(\mathbf{x}^+)^m\frac{x}{1-x}x^N=\sum_{i=N+1}^{\infty}\frac{x^i}{i^m} \tag{60}$$

can be neglected. Some examples are

$$\frac{1}{\Gamma(\frac{1}{2})}\sum_{n=1}^{\infty}\frac{\Gamma(n+\frac{1}{2})}{\Gamma(n+1)}\frac{x^n}{n}=2\ln 2-2\ln(1+\sqrt{1-x}),$$

$$\frac{1}{\Gamma(\frac{1}{2})}\sum_{n=1}^{\infty}\frac{\Gamma(n+\frac{1}{2})}{\Gamma(n+1)}\frac{x^n}{n^2}=2[\ln 2\ln(1+\sqrt{1-x})+\ln 2\ln(1-\sqrt{1-x})-\mathrm{Li}_{11}(-\sqrt{1-x},1)$$
$$-\mathrm{Li}_{11}(\sqrt{1-x},-1)-\mathrm{Li}_2(-1)-(\ln 2)^2],$$

$$\frac{1}{\Gamma(\frac{1}{2})}\sum_{n=1}^{\infty}\sum_{j=1}^{n}\frac{\Gamma(n+\frac{1}{2})}{\Gamma(n+1)}\frac{x^n}{n}\frac{y^j}{j}$$
$$=2\ \mathrm{Li}_{11}\left(\sqrt{1-x},-\sqrt{\frac{1-xy}{1-x}}\right)+2\ \mathrm{Li}_{11}\left(-\sqrt{1-x},\sqrt{\frac{1-xy}{1-x}}\right)$$
$$-2\ \mathrm{Li}_{11}\left(\sqrt{1-x},-\frac{1}{\sqrt{1-x}}\right)-2\ \mathrm{Li}_{11}\left(-\sqrt{1-x},\frac{1}{\sqrt{1-x}}\right)$$
$$+4\ \mathrm{Li}_2(-\sqrt{1-xy})-4\ \mathrm{Li}_2(-1)+2\ln\frac{1+\sqrt{1-x}}{1-\sqrt{1-x}}\ln\frac{1+\sqrt{\frac{1-xy}{1-x}}}{1+\frac{1}{\sqrt{1-x}}}. \tag{61}$$

V. INVERSE BINOMIAL SUMS AND GENERALIZATIONS

In this section I consider sums with one unbalanced rational number in the denominator. Examples of these type are sums of the form

$$\Gamma\left(1-\frac{p}{q}\right)\sum_{n_1=1}^{\infty}\frac{\Gamma(n_1+a)}{\Gamma\left(n_1+b-\frac{p}{q}\right)}x_1^{n_1}$$
$$\times\sum_{n_2=1}^{n_1-1}\frac{x_2^{n_2}}{(n_1-n_2)^{m_1}}\cdots\sum_{n_{k-1}=1}^{n_{k-2}-1}\frac{x_{k-1}^{n_{k-1}}}{(n_{k-2}-n_{k-1})^{m_{k-2}}}\sum_{n_k=1}^{n_{k-1}-1}\frac{x_k^{n_k}}{(n_{k-1}-n_k)^{m_{k-1}}n_k^{m_k}}. \tag{62}$$

Note the slightly different structure of $(n_{l+1}-n_l)$ in the denominators of the subsums. Only in the innermost sum a factor n_k appears in the denominator. Changing the summation variables according to

$$n_1=j_1+j_2+\cdots+j_k,\qquad n_2=j_2+\cdots+j_k,\qquad\ldots,\qquad n_k=j_k, \tag{63}$$

this sum is equivalent to

$$\Gamma\left(1-\frac{p}{q}\right)\sum_{j_1=1}^{\infty}\cdots\sum_{j_k=1}^{\infty}\frac{\Gamma(j_1+\cdots+j_k+a)}{\Gamma\left(j_1+\cdots+j_k+b-\frac{p}{q}\right)}\frac{x_1^{j_1}}{j_1^{m_1}}\frac{(x_1x_2)^{j_2}}{j_2^{m_2}}\cdots\frac{(x_1\cdots x_k)^{j_k}}{j_k^{m_k}}. \tag{64}$$

A special case of this form are inverse binomial sums

$$\sum_{n=1}^{\infty} \frac{1}{\binom{2n}{n}} \frac{z^n}{n^{m_1}}, \tag{65}$$

which are obtained by setting $p=1$, $q=2$, $a=b=1$, $k=1$ and $x_1=z/4$ in Eq. (64). Inverse binomial sums have been studied in Refs. 5, 7–9, 32, and 33 and have been related in the literature to log-sine integrals.[10,11] Here I follow a different path for the evaluation of inverse binomial sums. The method presented here is closely connected to the transformation

$$x' = \frac{-x}{1-x}, \tag{66}$$

whose inverse transformation is again given by

$$x = \frac{-x'}{1-x'}. \tag{67}$$

To start with the evaluation of sums of type (64) one replaces all factors $1/j$ by

$$\frac{1}{j} = \lim_{\lambda \to 0} \frac{\Gamma(j+\lambda)}{\Gamma(j+1+\lambda)}. \tag{68}$$

The original sum is recovered as the $\lambda \to 0$ limit of the regularized sum. The introduction of the regularization in λ allows us to extend the lower summation boundary of all sums from 1 to 0. This can be done recursively according to

$$\sum_{j=1}^{\infty} f(j) = -f(0) + \sum_{j=0}^{\infty} f(j). \tag{69}$$

$f(0)$ corresponds to a sum of lower depth. We therefore deal with sums of the type

$$\Gamma\left(1-\frac{p}{q}\right) \sum_{j_1=0}^{\infty} \cdots \sum_{j_k=0}^{\infty} \frac{\Gamma(j_1+\cdots+j_k+a)}{\Gamma\left(j_1+\cdots+j_k+b-\frac{p}{q}\right)} x_1^{j_1} (x_1 x_2)^{j_2} \cdots (x_1 \cdots x_k)^{j_k}$$

$$\times \left[\frac{\Gamma(j_1+\lambda)}{\Gamma(j_1+1+\lambda)}\right]^{m_1} \cdots \left[\frac{\Gamma(j_k+\lambda)}{\Gamma(j_k+1+\lambda)}\right]^{m_k}. \tag{70}$$

For these sums we have the following integral representation:

$$\frac{\Gamma\left(1-\frac{p}{q}\right)}{\Gamma\left(b-a-\frac{p}{q}\right)} \int_0^1 du u^{a-1} (1-u)^{b-a-(p/q)-1} \int_0^1 dt_1 t_1^{\lambda-1} \cdots \int_0^1 dt_{i_k} t_{i_k}^{\lambda-1} (1-u t_1 \cdots t_{i_1} x_1)^{-1}$$

$$\times (1-u t_{i_1+1} \cdots t_{i_2} x_1 x_2)^{-1} \cdots (1-u t_{i_{k-1}+1} \cdots t_{i_k} x_1 \cdots x_k)^{-1}, \tag{71}$$

where

$$i_1 = m_1, \qquad i_2 = m_1+m_2, \qquad \ldots, \qquad i_k = m_1+\cdots+m_k. \tag{72}$$

For the integration variable u we now perform the substitution

$$u \to 1-u, \tag{73}$$

and we obtain for Eq. (71),

$$\begin{aligned}
&\frac{\Gamma\left(1-\frac{p}{q}\right)\Gamma(a)}{\Gamma\left(b-a-\frac{p}{q}\right)} \sum_{j_1=0}^{\infty} \cdots \sum_{j_k=0}^{\infty} \frac{\Gamma\left(j_1+\cdots+j_k+b-a-\frac{p}{q}\right)}{\Gamma\left(j_1+\cdots+j_k+b-\frac{p}{q}\right)} \int_0^1 dt_1 t_1^{\lambda-1} \cdots \int_0^1 dt_{i_k} t_{i_k}^{\lambda-1} \\
&\quad \times (-t_1 \cdots t_{i_1} x_1)^{j_1} (1-t_1 \cdots t_{i_1} x_1)^{-j_1-1} \cdots (-t_{i_{k-1}+1} \cdots t_{i_k} x_1 \cdots x_k)^{j_k} \\
&\quad \times (1-t_{i_{k-1}+1} \cdots t_{i_k} x_1 \cdots x_k)^{-j_k-1} \\
&= \frac{\Gamma\left(1-\frac{p}{q}\right)\Gamma(a)}{\Gamma\left(b-a-\frac{p}{q}\right)} \sum_{n_1=0}^{\infty} \cdots \sum_{n_k=0}^{n_{k-1}} \frac{\Gamma\left(n_1+b-a-\frac{p}{q}\right)}{\Gamma\left(n_1+b-\frac{p}{q}\right)} \int_0^1 dt_1 t_1^{\lambda-1} \cdots \int_0^1 dt_{i_k} t_{i_k}^{\lambda-1} \\
&\quad \times (-t_1 \cdots t_{i_1} x_1)^{n_1-n_2} (1-t_1 \cdots t_{i_1} x_1)^{-n_1+n_2-1} \cdots (-t_{i_{k-2}+1} \cdots t_{i_{k-1}} x_1 \cdots x_{k-1})^{n_{k-1}-n_k} \\
&\quad \times (1-t_{i_{k-2}+1} \cdots t_{i_{k-1}} x_1 \cdots x_{k-1})^{-n_{k-1}+n_k-1} (-t_{i_{k-1}+1} \cdots t_{i_k} x_1 \cdots x_k)^{n_k} \\
&\quad \times (1-t_{i_{k-1}+1} \cdots t_{i_k} x_1 \cdots x_k)^{-n_k-1}.
\end{aligned} \tag{74}$$

Note that the substitution Eq. (73) induces the transformation $x \to -x/(1-x)$ as follows:

$$[1-(1-u)x]^{-c} = (1-x)^{-c}\left[1-\left(\frac{-x}{1-x}\right)u\right]^{-c}. \tag{75}$$

As a sideremark it is worth noting that as a special case one obtains by this procedure the transformation of the hypergeoemetric function

$${}_2F_1(a,b;c;x) = (1-x)^{-a}\,{}_2F_1\left(a,c-b;c;\frac{-x}{1-x}\right) = (1-x)^{-b}\,{}_2F_1\left(c-a,b;c;\frac{-x}{1-x}\right).$$

The purpose of the substitution in Eq. (73) is to change the ratio of gamma functions from

$$\frac{\Gamma(j_1+\cdots+j_k+a)}{\Gamma\left(j_1+\cdots+j_k+b-\frac{p}{q}\right)} \quad \text{to} \quad \frac{\Gamma\left(j_1+\cdots+j_k+b-a-\frac{p}{q}\right)}{\Gamma\left(j_1+\cdots+j_k+b-\frac{p}{q}\right)}. \tag{76}$$

In the last form, the rational number p/q appears both in the numerator and the denominator and can therefore be treated with the methods discussed in Sec. III. It remains to perform the integration over $t_1, \ldots, t_{i_k}$. These integration are recursively done according to the formula

$$\int_0^1 dt_1 t_1^{a-1} (-t_0 t_1 x)^n (1-t_0 t_1 x)^{-n-c} = \frac{\Gamma(n+a)}{\Gamma(n+c)} \sum_{k=n}^{\infty} \frac{\Gamma(k+c)}{\Gamma(k+1+a)} (-t_0 x)^k (1-t_0 x)^{-k-c}.$$

As a net result we obtain a rooted tree with side-branches, which can be expanded in λ and converted to nested sums with the help of the algorithms discussed in Ref. 3 and in Sec. III. In the final result all poles in λ cancel and one can extract the λ^0-term, which yields the evaluation of the inverse binomial sum Eq. (62). Some examples are

$$\Gamma\left(\frac{1}{2}\right)\sum_{n=1}^{\infty}\frac{\Gamma(n+1)}{\Gamma(n+\frac{1}{2})}\frac{x^n}{n}=\chi\ln\frac{1-\chi}{1+\chi},$$

$$\Gamma\left(\frac{1}{2}\right)\sum_{n=1}^{\infty}\frac{\Gamma(n+1)}{\Gamma(n+\frac{1}{2})}\frac{x^n}{n^2}=-\mathrm{Li}_{11}(\chi,1)+\mathrm{Li}_{11}(\chi,-1)-\mathrm{Li}_{11}(-\chi,1)+\mathrm{Li}_{11}(-\chi,-1),$$

$$\begin{aligned}\Gamma\left(\frac{1}{2}\right)\sum_{n=1}^{\infty}\sum_{j=1}^{n}\frac{\Gamma(n+1)}{\Gamma(n+\frac{1}{2})}\frac{x^n}{n}\frac{y^j}{j}=&-\mathrm{Li}_{11}(v,1)-\mathrm{Li}_{11}(-v,1)+\mathrm{Li}_{11}(v,-1)+\mathrm{Li}_{11}(-v,-1)\\&-\chi\left[\mathrm{Li}_{11}\left(\chi,\frac{v}{\chi}\right)+\mathrm{Li}_{11}\left(\chi,-\frac{v}{\chi}\right)-\mathrm{Li}_{11}\left(-\chi,\frac{v}{\chi}\right)\right.\\&\left.-\mathrm{Li}_{11}\left(-\chi,-\frac{v}{\chi}\right)\right]-\chi\ln(1-xy)\ln\frac{1-\chi}{1+\chi},\end{aligned}\tag{77}$$

where $\chi=\sqrt{-x/(1-x)}$ and $v=\sqrt{-xy/(1-xy)}$.

VI. APPLICATIONS

In this section I give some applications of the techniques described in the previous sections relevant to the calculation of Feynman loop integrals with massive particles or to phase space integrals. The first example concerns a one-loop triangle with a uniform internal mass $m_1=m_2=m_3=m$ and two vanishing external momenta $p_1^2=p_2^2=0$. The third external momentum $p_3^2=p^2$ is kept arbitrary. Such diagrams are for example relevant to Higgs physics. Specific examples are Higgs production via $gg\to H$ or Higgs decay into two photons $H\to\gamma\gamma$. In both cases the interaction proceeds via an internal top quark loop. It is well known that the corresponding integral in dimensional regularization is proportional to[7,38]

$${}_3F_2\left(1,1,1+\varepsilon;\ \frac{3}{2},2;\ \frac{p^2}{4m_{top}^2}\right).\tag{78}$$

Here $\varepsilon=(4-D)/2$ denotes the deviation from four space–time dimensions. The expansion of the hypergeometric function to sufficient high order in ε is a nontrivial task.[7,9] The expansion can be accomplished systematically with the methods presented here. First one notices that there is one unbalanced half-integer number in the denominator. With the results of Sec. V one can show that

$$\begin{aligned}&{}_3F_2\left(1+a_1\varepsilon,1+a_2\varepsilon,1+a_3\varepsilon;\ \frac{3}{2}+b\varepsilon,C+c\varepsilon;\ z\right)\\&=(1-z)^{-1-a_1\varepsilon}\frac{\Gamma(\frac{3}{2}+b\varepsilon)\Gamma(C+c\varepsilon)}{\Gamma(1+a_1\varepsilon)\Gamma(1+a_3\varepsilon)\Gamma(\frac{1}{2}+(b-a_2)\varepsilon)\Gamma(C-1+(c-a_3)\varepsilon)}\\&\quad\times\sum_{n=0}^{\infty}\frac{\Gamma(n+1+a_1\varepsilon)}{\Gamma(n+C+c\varepsilon)}\left(\frac{-z}{1-z}\right)^n\sum_{j=0}^{n}\\&\quad\times\frac{\Gamma(j+1+a_3\varepsilon)}{\Gamma(j+1)}\frac{\Gamma(j+\frac{1}{2}+(b-a_2)\varepsilon)}{\Gamma(j+\frac{3}{2}+b\varepsilon)}\frac{\Gamma(n-j+C-1+(c-a_3)\varepsilon)}{\Gamma(n-j+1)}.\end{aligned}\tag{79}$$

This yields a nested sum where all half-integer numbers are balanced in the numerator and in the denominator. This expression can now be expanded systematically in ε with the algorithms described in Sec. III. For the example mentioned above one finds

$$
\begin{aligned}
{}_3F_2\left(1,1,1+\varepsilon;\ \frac{3}{2},2;\ z\right) = &-\frac{1}{2z}(1-z)^{-\varepsilon}\Bigg\{\mathrm{Li}_{11}\left(\sqrt{\frac{-z}{1-z}},1\right)+\mathrm{Li}_{11}\left(-\sqrt{\frac{-z}{1-z}},1\right)\\
&-\mathrm{Li}_{11}\left(\sqrt{\frac{-z}{1-z}},-1\right)-\mathrm{Li}_{11}\left(-\sqrt{\frac{-z}{1-z}},-1\right)\\
&+2\varepsilon\Bigg[\mathrm{Li}_{111}\left(\sqrt{\frac{-z}{1-z}},1,1\right)+\mathrm{Li}_{111}\left(-\sqrt{\frac{-z}{1-z}},1,1\right)\\
&-\mathrm{Li}_{111}\left(\sqrt{\frac{-z}{1-z}},-1,-1\right)-\mathrm{Li}_{111}\left(-\sqrt{\frac{-z}{1-z}},-1,-1\right)\Bigg]+O(\varepsilon^2)\Bigg\}.
\end{aligned}
\tag{80}
$$

As a second example I discuss briefly phase space integrals. Analytic results for phase space integrals are needed for example in the calculation of higher order corrections for jet observables as integrals over approximation terms within the subtraction method.[14,17,18,39] An example is the integral over a subtraction term, which approximates the emission of a soft gluon from a heavy quark pair. This integral is given by[14]

$$
\begin{aligned}
V_{QQ}(r_0,\varepsilon) = &\left(\frac{r_0}{2}\right)^{-2\varepsilon}\int_0^1 dr\, r^{-2\varepsilon-1}(1-r)^{-\varepsilon}(1-r_0 r)^{-1}\int_{-1}^1 ds(1-s^2)^{-\varepsilon}[(2(1-r_0 r)-(1-r_0))\\
&\times(1-s_0 s)^{-1}-(1-r_0)(1-s_0 s)^{-2}],
\end{aligned}
\tag{81}
$$

where

$$
s_0 = \sqrt{\frac{r_0(1-r)}{1-r_0 r}}. \tag{82}
$$

This integral corresponds to the following triple sum:

$$
\begin{aligned}
V_{QQ}(r_0,\varepsilon) = &\frac{\Gamma(1-\varepsilon)}{\Gamma(\varepsilon)}\left(\frac{r_0}{2}\right)^{-2\varepsilon}\sum_{i=0}^{\infty}\sum_{j=0}^{\infty}\sum_{k=0}^{\infty}(-1)^i\\
&\times(1+(-1)^j)r_0^{k+j/2}\frac{\Gamma(i+j+1)}{\Gamma(i+j+2-\varepsilon)}\frac{\Gamma(i+\varepsilon)}{\Gamma(i+1)}\frac{\Gamma(k-2\varepsilon)\Gamma(j/2+1-\varepsilon)\Gamma(k+j/2)}{\Gamma(k+1)\Gamma(j/2)\Gamma(k+j/2+1-3\varepsilon)}\\
&\times\left[2-(1-r_0)(2+j)\frac{j+2k}{j}\right].
\end{aligned}
\tag{83}
$$

Using the methods of Sec. III this sum can be expanded systematically in ε. The result is

$$
\begin{aligned}
V_{QQ}(r_0,\varepsilon) = &\frac{1}{\varepsilon}\left(1-\frac{1}{2}\frac{1+r_0}{\sqrt{r_0}}\ln\frac{1+\sqrt{r_0}}{1-\sqrt{r_0}}\right)-2\ln r_0-\ln^2\left(\frac{1+\sqrt{r_0}}{1-\sqrt{r_0}}\right)+\frac{1}{\sqrt{r_0}}\ln\left(\frac{1+\sqrt{r_0}}{1-\sqrt{r_0}}\right)\\
&-\frac{1+r_0}{2\sqrt{r_0}}\Bigg[\mathrm{Li}_2(\sqrt{r_0})-\mathrm{Li}_2(-\sqrt{r_0})+2\ \mathrm{Li}_2\left(\frac{1+\sqrt{r_0}}{2}\right)-2\ \mathrm{Li}_2\left(\frac{1-\sqrt{r_0}}{2}\right)\\
&+\mathrm{Li}_2\left(\frac{\sqrt{r_0}-1}{2\sqrt{r_0}}\right)-\mathrm{Li}_2\left(\frac{\sqrt{r_0}-1}{\sqrt{r_0}}\right)+\mathrm{Li}_2\left(\frac{1}{1+\sqrt{r_0}}\right)-\mathrm{Li}_2\left(\frac{1-\sqrt{r_0}}{1+\sqrt{r_0}}\right)\\
&-2\ln r_0\ln\left(\frac{1+\sqrt{r_0}}{1-\sqrt{r_0}}\right)+\frac{1}{2}\ln^2 2+\ln 2\ln\frac{\sqrt{r_0}}{1+\sqrt{r_0}}+\ln(1-\sqrt{r_0})\ln\left(\frac{1+\sqrt{r_0}}{\sqrt{r_0}}\right)
\end{aligned}
$$

$$+\frac{1}{2}\ln^2(1+\sqrt{r_0})-\frac{1}{2}\ln^2(1-\sqrt{r_0})\Bigg]+O(\varepsilon). \tag{84}$$

VII. SUMMARY AND CONCLUSIONS

In this paper I reported on algorithms which allow the expansion of certain transcendental functions in a small parameter around rational values. These algorithms extend the ones for the expansion around integer values and are based on the manipulation of specific forms of nested sums. Of particular importance is the case of the expansion around half-integer values. This case occurs frequently in the calculation of radiative corrections in quantum field theories with massive particles. The methods presented in this paper allow a systematic approach for the calculation of these integrals.

APPENDIX A: LOG-SINE INTEGRALS

Inverse binomial sums are often expressed in terms of log-sine integrals. In this appendix I briefly summarize the results from the literature. The following inverse binomial sum can be evaluated with elementary functions as follows:

$$\Gamma\left(\frac{1}{2}\right)\sum_{n=1}^{\infty}\frac{\Gamma(n+1)}{\Gamma\left(n+\frac{1}{2}\right)}\frac{x^n}{n}=\frac{2\sqrt{x}\arcsin(\sqrt{x})}{\sqrt{1-x}}. \tag{A1}$$

This result agrees with the one given in Eq. (77). In the literature, evaluations of inverse binomial sums of higher weights are given in terms of log-sine functions:[5,7–11,32,33]

$$\Gamma\left(\frac{1}{2}\right)\sum_{n=1}^{\infty}\frac{\Gamma(n+1)}{\Gamma\left(n+\frac{1}{2}\right)}\frac{z^n}{n^m}=-\sum_{j=0}^{m-2}\frac{(-2)^j}{j!(m-2-j)!}(\ln 4z)^{m-2-j}\mathrm{Ls}_{j+2}^{(1)}(\theta), \tag{A2}$$

where $\theta=2\arcsin\sqrt{z}$ and the log-sine functions are defined by

$$\mathrm{Ls}_j^{(k)}(\theta)=-\int_0^{\theta}d\theta'(\theta')^k\ln^{j-k-1}\left|2\sin\frac{\theta'}{2}\right|. \tag{A3}$$

By analytic continuation the log-sine functions are then related to polylogarithms.[9] A simple example is given by

$$\mathrm{Ls}_2^{(0)}(\theta)=\mathrm{Cl}_2(\theta), \tag{A4}$$

involving the Clausen function Cl_2. The Clausen functions Cl_n are given in terms of polylogarithms by

$$\mathrm{Cl}_n(\theta)=\begin{cases}\dfrac{1}{2i}[\mathrm{Li}_n(e^{i\theta})-\mathrm{Li}_n(e^{-i\theta})], & n \text{ even},\\ \dfrac{1}{2}[\mathrm{Li}_n(e^{i\theta})+\mathrm{Li}_n(e^{-i\theta})], & n \text{ odd}.\end{cases} \tag{A5}$$

APPENDIX B: RELATIONS FOR POLYLOGARITHMS

Multiple polylogarithms of low weight can be expressed in terms of ordinary logarithms and polylogarithms. Relations relevant to the examples in this paper are

$$\mathrm{Li}_1(x) = -\ln(1-x),$$

$$\mathrm{Li}_{11}(x,1) = \tfrac{1}{2}\ln^2(1-x),$$

$$\mathrm{Li}_{11}(x,-1) = \frac{1}{2}\zeta_2 - \frac{1}{2}\ln^2 2 - \ln(1-x)\ln(1+x) + \ln 2\,\ln(1+x) - \mathrm{Li}_2\left(\frac{1+x}{2}\right),$$

$$\mathrm{Li}_{11}(x,y) = \ln(1-x)\ln(1-y) + \mathrm{Li}_2\left(\frac{-y}{1-y}\right) - \mathrm{Li}_2\left(\frac{-y(1-x)}{1-y}\right),$$

$$\mathrm{Li}_{111}(x,1,1) = -\tfrac{1}{6}\ln^3(1-x),$$

$$\mathrm{Li}_{111}(x,-1,-1) = \tfrac{1}{2}\zeta_2\ln 2 - \tfrac{7}{8}\zeta_3 - \tfrac{1}{6}\ln^3 2 - \tfrac{1}{2}\ln(1-x)\ln^2(1+x) + \tfrac{1}{2}\ln 2\,\ln^2(1+x) - \ln(1+x)\mathrm{Li}_2\left(\frac{1+x}{2}\right) + \mathrm{Li}_3\left(\frac{1+x}{2}\right). \tag{B1}$$

More relations can be found in Refs. 37 and 40.

(Received 17 January 2004; accepted 18 April 2004; published online 8 June 2004)

The use of the so(2,1) algebra for the study of the two-electron atoms is suggested. The radial part of the two-electron function is expanded into the products of the one-electron functions. These one-electron functions form complete, entirely discrete set and are identified as the eigenfunctions of one of the generators of the so(2,1) algebra. By applying this algebra we are able to express all the matrix elements in analytic and numericaly stable form. For matrix elements of the two-electron interaction this is done in three steps, all of them completely novel from the methodological point of view. First, repulsion integrals over four radial functions are written as a linear combination of the integrals over two radial functions and the coefficients of the linear combination are given in terms of hypergeometric functions. Second, combining algebraic technique with the integration by parts we derive recurrence relations for the repulsion integrals over two radial functions. Third, the derived recurrence relations are solved analytically in terms of the hypergeometric functions. Thus we succeed in expressing the repulsion integrals as rational functions of the hypergeometric functions. In this way we resolve the problem of the numerical stability of calculation of the repulsion integrals. Finally, as an illustration, the configuration interaction calculation of the lowest lying states of the He atom is discussed. © *2004 American Institute of Physics.*

I. INTRODUCTION

Two-electron atoms (like He, H^-, Li^+) are of great importance for their relative simplicity. There are primarily three interesting problems to be studied on the two-electron atoms. First, since the nonrelativistic Schrödinger equation can be solved very accurately for the ground as well as low excited states,[1–13] the relativistic and QED effects can be taken into account[13–18] and compared to the experiment.[19–22] This yields together with the study of the hydrogenlike atoms precise test of QED as a fundamental theory of the interaction of the electrically charged particles.[23–25] The second interesting point is the study of resonances.[26–28] This was stimulated by the experimental discovery of the strong correlation effects in the doubly excited states of helium[29] and led to new theoretical concepts, like approximate quantum numbers[30–32] and others. For an excellent review of these methods, see Ref. 33. Third, if the many-electron wave function is searched for in the form of expansion of a properly symmetrized product of the one-electron functions all the necessary matrix elements can be reduced either to one- or two-electron matrix elements whatever the number of the electrons involved. Therefore, if we find an effective method of calculating these matrix elements for the two-electron atoms, this method can be directly applied to *all* atoms and to the simplest molecules where it is physically reasonable to use orbitals localized at one center.

For low lying states of the two-electron atoms with low nuclear charge, the best approach is the one based on the use of the explicitly correlated functions.[1–11,13] This method consists of considering the interelectronic distance r_{12} as one of the coordinates. For example, for the S-states

of helium, the two electron wave function is considered as a function of three variables r_1, r_2, and r_{12}, $\psi=\psi(r_1,r_2,r_{12})$. However, the disadvantage of this method is that transition to the three-electron atoms is very difficult[34] and increasing the number of the electrons further the method quickly loses its attractivity. Therefore, the method is not generally considered as a suitable tool for solving the many-electron problem.

The most accurate available method applicable for many electron problems is the configuration interaction method (CI) (see e.g., Refs. 35, 36). This method has been applied on the two-electron atoms either for finding some general trends of behavior of correlation energy like its angular dependence, optimization of the screening constant, and so on[37–44] or in combination with the complex scaling method (see, e.g., Ref. 45) for a description of resonances.[26–28,31,32]

However, the problem is when one wants to perform very large scale CI calculation to get very accurate results. Then one encounters what is usually refered to as the effect of linear dependence of the basis set. Due to numerical errors, for large basis sets the linear independence of the basis functions is lost. Thus, from some point the inclusion of more basis functions does not improve the variational results. To avoid this, one should keep the basis functions orthogonal. However, this requirement causes the highly excited functions to have large number of nodes and to change their sign frequently. That leads to the numerical instability of the calculation of the repulsion integrals.

This effect is quite general and appears also in the case of the explicitely correlated functions. However, here the convergence of the method is so fast that very accurate results are obtained before the problem appears.

To ensure numerical stability for the large scale CI calculations nonanalytic types of the basis functions like B-splines[12] or piecewise polynomials[41] or analytic types with many parameters[28] were invoked.

The aim of this paper is to suggest an efficient analytic method for calculating the one- and two-electron matrix elements applicable to all atoms and with numerical stability under control.

In this paper, a great deal of attention is devoted to the calculation of the repulsion integrals and the numerical stability of such a procedure. We expand the two-electron wave function into the symmetrized product of the complete, entirely discrete one-electron basis set. This basis set is in literature often refered to as a Sturmian one and its use goes back to the classical paper of Hylleraas.[46] However, in contrast to the usual treatment we identify these basis functions as the eigenfunction of one of the generators of the so(2,1) algebra.[47–52] This algebra is used for the calculation of the radial integrals appearing in the multipole expansion. We first introduce an analog to the Wigner–Eckart theorem for the so(2,1) algebra, i.e., we write the product of two radial functions as a linear combination of the radial functions. The coefficients of the linear combination can be expressed in terms of the hypergeometric functions. In this way we reduce the two-dimensional integration over four radial functions to the two-dimensional integration over two radial functions. Combining commutations relations of the so(2,1) algebra and analytic integration by parts we derive the reccurence relations for the integrals over two radial functions. In this way we reduce all the integrals to the integrals over nodeless functions. These integrals are calculated analytically. Finally, the derived reccurence relations are solved analytically in terms of the hypergeometric functions. Thus, we are able to express all the repulsion integrals as rational functions of the hypergeometric functions. Succeeding in this, this paper represents the solution of the problem of the numerical instability for the large scale CI calculations.

The problem considered in this paper was already tackled in Ref. 53. For the following reasons we believe that our solution is better suited for the computational purposes than that given in Ref. 53. First, when writing the products of the Laguerre polynomials as a linear combination of the Laguerre polynomials we succeded in expressing the coefficients of the linear combination in terms of the hypergeometric functions. Second, our recurrence relations for the integrals are much more simpler than that derived in Ref. 53. Third, we were able to solve them in terms of the hypergeometric functions. In this way all possible numerical instabilities are localized into the calculation of the well-known hypergeometric functions. These functions were thoroughly investigated by mathematicians and are known for long time. Once the values of these functions are

calculated, the computation can be run in the double presicion arithmetics. In Ref. 53, the numerically unstable parts of the calculation had to be performed in integer arithmetics. On the other hand, at the present stage, the method described in this paper is less general than that given in Ref. 53. Possible generalizations of our method are indicated in the conclusions and will be described in detail in the forthcoming paper.

The paper is organized as follows: First, the algebraic solution of the hydrogen atom by means of the so(2,1) Lie algebra is described. Second, the problem of the helium atom is put into the form suitable for the use of so(2,1) algebra. Then we turn to the calculation of the repulsion integrals. Relying on the usual multipole expansion and integrating out the angular degrees of freedom in the usual manner, we concentrate on the calculation of the radial integrals. The two methods for calculation of the radial integrals are described. The first one consists of the expansion of the radial functions into the Slater-type orbitals, i.e., into the products of the exponential function and power of r. It is shown that this method is numerically unstable and reason of the instability is clarified. The second, ''quasialgebraic'' method is that described above. Finally, as an illustration, the CI calculation for the lowest lying states of helium atom is made and the optimization of the screening constant is discussed.

We would like to stress that we are not going to compete with the techniques using explicitly correlated functions. We apply the method for the states where CI is known to be converging very slowly to see numerical stability of our computation of the integrals. It is reasonable to expect that for other states the performance of the method will be better.

II. ALGEBRAIC TREATMENT OF THE HYDROGEN ATOM

In this section we introduce the so(2,1) algebra and show its use for the solution of the Schrödinger equation for hydrogen atom. For more detailed discussion see, e.g., Ref. 47. We adopt the same notation as that in Refs. 47 and 48.

Let us consider the Schrödinger equation for the hydrogen atom in atomic units

$$\left[-\frac{\nabla^2}{2}-\frac{1}{r}\right]\psi=E\psi. \tag{1}$$

The key idea for solving this equation algebraically is to transform this equation into the equation for the eigenvalues n of the operator T_3

$$T_3|l,n\rangle=n|l,n\rangle, \tag{2}$$

where the operator T_3 equals

$$T_3=\frac{1}{2}\left(rp_r^2+\frac{l(l+1)}{r}+r\right). \tag{3}$$

Here p_r is the conjugated radial momentum

$$p_r=-i\left(\frac{d}{dr}+\frac{1}{r}\right), \tag{4}$$

$l(l+1)$ is the eigenvalue of L^2, the square of the angular momentum and n is the principal quantum number (see below).

Equation (1) can be transformed to Eq. (2) as follows. Using the expression for the Laplace operator in the spherical coordinates

$$\nabla^2=p_r^2+\frac{L^2}{r^2}, \tag{5}$$

multiplying Eq. (1) by r and making the scaling transformation $r\rightarrow nr$ we get

$$\left[\frac{1}{2}r\left(p_r^2+\frac{L^2}{r^2}\right)-n^2Er\right]\psi=n\psi. \tag{6}$$

We separate the angular and radial degrees of freedom

$$\langle \mathbf{x}|\psi\rangle=\langle r|l,n\rangle\langle \mathbf{n}|l,m\rangle, \tag{7}$$

where $\mathbf{n}$ is a unit vector pointing in arbitrary direction and $\langle \mathbf{n}|l,m\rangle$ are spherical harmonics, the eigenfunctions of the square and the third component of the angular momentum, L^2 and L_3, respectively. Setting

$$E=-\frac{1}{2n^2}, \tag{8}$$

Eqs. (2) and (6) are the same.

The advantage of this reformulation of the problem of the hydrogen atom is that first, as we show below, the problem of the eigenvalues of the operator T_3 can be solved purely algebraically, second, the spectrum of the operator T_3 is purely discrete. Therefore, this operator is much more advantageous for description of bound atomic states than the usual operator in Eq. (1).

The eigenvalues of the operator T_3 can be obtained by observation that T_3 and the operators

$$T_1=\frac{1}{2}\left(rp_r^2+\frac{l(l+1)}{r}-r\right) \tag{9}$$

and

$$T_2=rp_r \tag{10}$$

are closed under the commutation and form the so-called so(2,1) Lie algebra

$$[T_1,T_2]=-iT_3, \tag{11}$$

$$[T_2,T_3]=iT_1, \tag{12}$$

and

$$[T_3,T_1]=iT_2. \tag{13}$$

Proceeding in analogy with the usual treatment of the so(3) algebra of the components of the angular momentum we introduce the ladder operators

$$T_\pm=T_1\pm iT_2. \tag{14}$$

From the commutation relations (12) and (13) we get

$$[T_3,T_\pm]=\pm T_\pm. \tag{15}$$

Applying the last equation to the eigenvectors $|l,n\rangle$ we get after some manipulation

$$T_3(T_\pm|l,n\rangle)=(n\pm1)(T_\pm|l,n\rangle). \tag{16}$$

It is clear from the last equation that the vectors $T_\pm|l,n\rangle$ are the eigenvectors of the operator T_3 with the eigenvalues corresponding to $n\pm1$. Therefore, we can write

$$T_\pm|l,n\rangle=\alpha^\pm(l,n)|l,n\pm1\rangle, \tag{17}$$

where $\alpha^{\pm}(l,n)$ are numbers specified as follows. From Eqs. (14), (11), (9), (10), and (3) we get successively

$$T_+T_-=T_1^2+T_2^2+i[T_2,T_1]=T_1^2+T_2^2-T_3=T_3^2-l(l+1)-T_3. \tag{18}$$

Applying the last equation to the eigenvectors $|l,n\rangle$ we get from Eqs. (2) and (17)

$$\alpha^+(l,n-1)\alpha^-(l,n)=n^2-n-l(l+1)=(n+l)(n-l-1). \tag{19}$$

Requiring that the spectrum of the operator T_3 is bounded from below, i.e., there exists some $n_{\min}$ such that

$$T_-|l,n_{\min}\rangle=0, \tag{20}$$

we get from Eq. (19) that $\alpha^-(l,n_{\min})=0$. This implies

$$n_{\min}=l+1. \tag{21}$$

Therefore, the eigenvalue spectrum of the operator T_3 starts at $n=l+1$ and then increases by 1 up to the infinity. Since the energy E is given by Eq. (8) we identify n with the usual principal quantum number.

To determine the numbers $\alpha^{\pm}(l,n)$ uniquely we require that the eigenvectors $|l,n\rangle$ are normalized ($\langle l,n|l,n\rangle=1$). It leads to the following solution of Eq. (19):[48]

$$\alpha^+(l,n-1)=\alpha^-(l,n)=\sqrt{(n+l)(n-l-1)}. \tag{22}$$

For further considerations, let us show how the matrix elements of the radial coordinate r can be obtained. The radial coordinate r can be expressed as the difference of the operators T_3 and T_1 [see Eq. (3) and (9)]. From Eqs. (14), (17), and (22) we get that the operator r acts on the states $|l,n\rangle$ as follows (see, e.g., Ref. 48)

$$r|l,n\rangle=-\tfrac{1}{2}\sqrt{(n+l)(n-l-1)}|l,n-1\rangle+n|l,n\rangle-\tfrac{1}{2}\sqrt{(n+l+1)(n-l)}|l,n+1\rangle. \tag{23}$$

III. ALGEBRAIC TREATMENT OF THE HELIUM ATOM

In this section we first transform the Schrödinger equation into the form suitable for the use of the so(2,1) algebra. Next we turn our attention to the symmetry adaptation of the wave function. Relying on the multipole expansion, we separate angular and radial degrees of freedom in the conventional manner. We note that one of the alternatives to such an approach was recently suggested in Ref. 57. Finally, we integrate out the angular part and derive the expression for the radial integrals.

A. Schrödinger equation

The Schrödinger equation for the two-electron atoms in atomic units takes the form

$$\left[-\frac{\nabla_{(1)}^2}{2}-\frac{\nabla_{(2)}^2}{2}-\frac{Z}{r_1}-\frac{Z}{r_2}+\frac{1}{r_{12}}\right]\psi=E\psi, \tag{24}$$

where Z is the charge of the nucleus and r_{12} denotes the interelectronic distance.

By scaling the coordinates of the electrons $\mathbf{x}^{(i)}\to\eta Z^{-1}\mathbf{x}^{(i)}$, $i=1,2$, we get an equivalent equation

$$\left[-\frac{\nabla_{(1)}^2}{2}-\frac{\nabla_{(2)}^2}{2}-\frac{\eta}{r_1}-\frac{\eta}{r_2}+\frac{\eta}{Z}\frac{1}{r_{12}}\right]\psi=\frac{\eta^2}{Z^2}E\psi. \tag{25}$$

Here, η is an arbitrary scaling parameter that can be subject to further optimization. Multiplying Eq. (25) by $r_1 r_2$, writing the energy E as

$$E = -\frac{Z^2}{\eta^2} + \Delta E \tag{26}$$

and using Eqs. (3) and (5) we rewrite Eq. (25) into the form

$$\left[r_1 (T_3^{(2)} - \eta) + r_2 (T_3^{(1)} - \eta) + \frac{\eta}{Z} r_1 r_2 r_{12}^{-1} \right] \psi = \frac{\eta^2}{Z^2} \Delta E r_1 r_2 \psi. \tag{27}$$

Since the matrix elements of the one-electron operators r_i and $T_3^{(i)}$ can be calculated from Eqs. (23) and (2), respectively, the only remaining matrix elements to be calculated are the matrix elements of the operator $r_1 r_2 r_{12}^{-1}$, i.e., the repulsion integrals. Before doing so, we turn our attention to the construction of the wave function.

B. Construction of the wave function

The two electron wave function $|\psi\rangle$ has to be antisymmetric with respect to the interchange of the electrons. In this paper we restrict ourselves to the calculation of the ground state energy. Since the spin part of the ground state wave function of the helium atom is antisymmetric, the space part has to be symmetric. Further, because of the spherical symmetry of the problem, the components and the square of the total angular momentum $\mathbf{L} = \mathbf{L}^{(1)} + \mathbf{L}^{(2)}$ commute with the Hamiltonian. It means that the Hamiltonian has the block structure and the states with different eigenvalues of L_3 and L^2 do not mutually interact. The ground state is the singlet state with $L = 0$, where $L(L+1)$ is the eigenvalue of the operator L^2. Therefore, the angular part of the wave function equals

$$|(l,l)0\rangle = \sum_{m=-l}^{l} (l,m,l,-m|0,0)|l,m\rangle^{(1)}|l,-m\rangle^{(2)}. \tag{28}$$

Here, $(\,|\,)$ denotes the Clebsch–Gordan (CG) coefficients. It follows from the properties of CG coefficients that Eq. (28) is the only nonzero combination of the products of one-electron angular states yielding the state with $L = 0$. It means that to characterize the angular part of the total wave function we need just one quantum number l. It also follows from the properties of CG coefficients that the linear combination is symmetric with respect to the interchange of the electrons. Therefore, we expand the exact wave function into the unperturbed wave functions as follows:

$$|\psi\rangle = \sum_{i=0}^{\infty} f_i |i\rangle, \tag{29}$$

where

$$|i\rangle = 2^{-(1+\delta_{n_{i1},n_{i2}})/2} (|l_i, n_{i1}\rangle^{(1)}|l_i, n_{i2}\rangle^{(2)} + |l_i, n_{i2}\rangle^{(1)}|l_i, n_{i1}\rangle^{(2)})|(l_i, l_i)0\rangle. \tag{30}$$

Here, the states $|l,n\rangle$ are the eigenstates of the operator T_3 given by Eq. (2). The coefficients f_i will be determined from the diagonalization of Eq. (27).

C. Matrix elements

Now we describe how the matrix elements of the operator $r_1 r_2 r_{12}^{-1}$ among the functions (30) are calculated.

Projecting the states $|l,n\rangle$ onto the coordinate basis we get the radial functions $R_{n,l}(r) = \langle r|l,n\rangle$. Introducing the inner product

$$\langle l_1,n_1|l_2,n_2\rangle=\int_0^\infty dr\, r\, R_{n_1,l_1}(r)R_{n_2,l_2}(r) \tag{31}$$

the functions $R_{n,l}(r)$ are orthonormal for $l_1=l_2$, $\langle l_1,n_1|l_1,n_2\rangle=\delta_{n_1,n_2}$. We note that this inner product differs from the usual one by the factor r^{-1} in the integrand (see, e.g., Refs. 47, 48).

To separate the angular and radial degrees of freedom we expand r_{12}^{-1} in the multipole expansion

$$r_{12}^{-1}=\frac{1}{r_>}\sum_{l=0}^{\infty}\left(\frac{r_<}{r_>}\right)^l P_l(\mathbf{n}_1\cdot\mathbf{n}_2), \tag{32}$$

where $r_<=r_1$, $r_>=r_2$ if $r_1<r_2$ and $r_<=r_2$, $r_>=r_1$ if $r_1>r_2$. Here, the $P_l(x)$ denotes the Legendre polynomials. With the definition of the inner product (31) and multipole expansion (32) the matrix elements of $r_1r_2r_{12}^{-1}$ can be written as

$$\langle i|r_1r_2r_{12}^{-1}|j\rangle=2^{-(\delta_{n_{i1},n_{i2}}+\delta_{n_{j1},n_{j2}})/2}\sum_{l=|l_i-l_j|}^{l_i+l_j}\theta_{l_i,l_j,l}[X^{l_i,l_j,l}_{n_{i1},n_{i2},n_{j1},n_{j2}}+X^{l_i,l_j,l}_{n_{i1},n_{i2},n_{j2},n_{j1}}], \tag{33}$$

where l in the summation increases by 2.

Here, the angular part $\theta_{l_i,l_j,l}$ corresponds to the calculation of the matrix elements of the Legendre polynomials between the coupled states (28)

$$\theta_{l_i,l_j,l}=\langle(l_i,l_i)0|P_l(\mathbf{n}_1\cdot\mathbf{n}_2)|(l_j,l_j)0\rangle=(-1)^{l_i+l_j}\frac{[(2l_i+1)(2l_j+1)]^{1/2}}{2l+1}(l_i,0,l_j,0|l,0)^2. \tag{34}$$

This result is obtained with help of the algebraic angular-momentum methods (see e.g., Refs. 54–56). It follows from the properties of the CG coefficients that $\theta_{l_i,l_j,l}$ is zero unless $|l_i-l_j|\leqslant l\leqslant l_i+l_j$ and l_i+l_j+l is even. Therefore, the sum in Eq. (33) is not infinite and in fact contains only a few terms.

The radial part of the integration reads

$$\begin{aligned}X^{l_i,l_j,l}_{n_{i1},n_{i2},n_{j1},n_{j2}}&=\int_0^\infty dr_1\int_0^\infty dr_2 r_1^2r_2^2R_{n_{i1},l_i}(r_1)R_{n_{i2},l_i}(r_2)\frac{r_<^l}{r_>^{l+1}}R_{n_{j1},l_j}(r_1)R_{n_{j2},l_j}(r_2)\\&=\int_0^\infty dr_1R_{n_{i1},l_i}(r_1)R_{n_{j1},l_j}(r_1)r_1^{l+2}\int_{r_1}^\infty dr_2R_{n_{i2},l_i}(r_2)R_{n_{j2},l_j}(r_2)r_2^{-l+1}\\&\quad+\int_0^\infty dr_1R_{n_{i1},l_i}(r_1)R_{n_{j1},l_j}(r_1)r_1^{-l+1}\int_0^{r_1}dr_2R_{n_{i2},l_i}(r_2)R_{n_{j2},l_j}(r_2)r_2^{l+2}.\end{aligned} \tag{35}$$

The following section is devoted to the calculation of these integrals.

IV. CALCULATION OF THE RADIAL INTEGRALS

In this section that is the main part of the paper, two methods of the calculations of the radial integrals (35) are described. The first method is given in the Sec. IV A and is based on the reduction of the integrals to the integrals over the Slater-type orbitals. This method is essentially the same as that used in Ref. 37. This method is shown to be numerically unstable. The second method is described in the remaining three subsections. In the Sec. IV B the integrals over four radial functions are transformed to the integrals over two radial functions with help of the analog

of Wigner–Eckart theorem for so(2,1) algebra. In Sec. IV C the recurrence relations for the remaining integrals over two radial functions are derived. In Sec. IV D these recurrence relations are solved analytically.

A. Expansion into the Slater-type orbitals

The expansion of the integrals into the Slater-type orbitals is based on the explicit form of the radial functions

$$R_{n,l}(r)=2\sqrt{\frac{(n-l-1)!}{(n+l)!}}e^{-r}(2r)^l L_{n-l-1}^{2l+1}(2r), \tag{36}$$

where $L_{n-l-1}^{2l+1}(2r)$ are generalized Laguerre polynomials (see, e.g., Refs. 59–61).

Using the explicit form of the Laguerre polynomials we can rewrite the radial functions $R_{n,l}(r)$ as the linear combination of the Slater-type orbitals, i.e., as the products of the exponential function and power of r

$$R_{n,l}(r)=2\sum_{q=0}^{n-l-1} d_{n,l,q}e^{-r}r^{q+l}, \tag{37}$$

where the coefficients $d_{n,l,q}$ equal

$$d_{n,l,q}=\sqrt{\frac{(n-l-1)!}{(n+l)!}}\frac{(n+l)!}{(n-l-1-q)!q!(2l+1+q)!}(-1)^q 2^{q+l}. \tag{38}$$

Inserting this expansion into the integrals (35) we obtain after some manipulation

$$X_{n_{i1},n_{i2},n_{j1},n_{j2}}^{l_i,l_j,l}=\sum_{q_{i1}=0}^{n_{i1}-l_i-1} d_{n_{i1},l_i,q_{i1}}\sum_{q_{i2}=0}^{n_{i2}-l_i-1} d_{n_{i2},l_i,q_{i2}}\sum_{q_{j1}=0}^{n_{j1}-l_j-1} d_{n_{j1},l_j,q_{j1}}\sum_{q_{j2}=0}^{n_{j2}-l_j-1} d_{n_{j2},l_j,q_{j2}}$$
$$\times[I_{q_{i1}+q_{j1}+l_i+l_j+1,q_{i2}+q_{j2}+l_i+l_j+1}^{l}+I_{q_{i2}+q_{j2}+l_i+l_j+1,q_{i1}+q_{j1}+l_i+l_j+1}^{l}], \tag{39}$$

where

$$\begin{aligned}I_{a,b}^{l}&=2^4\int_0^\infty dr_1 e^{-2r_1}r_1^{a-l}\int_0^{r_1}dr_2 e^{-2r_2}r_2^{b+l+1}\\&=2^4\int_0^\infty dr_1 e^{-2r_1}r_1^{b+l+1}\int_{r_1}^\infty dr_2 e^{-2r_2}r_2^{a-l}\\&=(a-l)!2^{-1-2b-l-a}\sum_{q=0}^{a-l}\frac{(b+l+q+1)!}{q!}2^{-q}.\end{aligned} \tag{40}$$

This way of calculation of the integrals (35) suffers by numerical instability. For example, running the formula (39) between the states with $n_{i1}=21$, $n_{i2}=19$, $l_i=3$ and $n_{j1}=17$, $n_{j2}=23$, $l_j=1$ in the double precision arithmetics yields the totally meaningless result 10^{20} for both $l=2$ and $l=4$. The reason for the instability is the changing sign of the $d_{n,l,q}$ coefficients, Eq. (38), that causes cancellation errors (see also discussion in Ref. 53). These changes are related to the orthogonality of the Laguerre polynomials. There is, of course, possibility to relax the requirement of having the orthonormal system of the functions and to consider the radial wave functions in the form $\tilde{R}_{n,l}(r)=\tilde{U}_{n,l}e^{-r}r^{n-1}$. This system is complete as well as the system (36). The pertinent radial integrals (35) can then be calculated according to the formula (40) and the matrix elements of the operators in Eq. (27) are calculated easily as well. The problem of doing this is

that the numerical instability is just moved from the calculation of the integrals (35) to the generalized eigenvalue problem (27). In the case of the nonorthogonal basis the matrix $r_1 r_2$ on the right-hand side of Eq. (27) is not just quasitridiagonal, but full.

Therefore, we will solve the problem of the numerical stability on the level of calculation of the integrals (35).

B. "Wigner–Eckart theorem" for so(2,1) algebra

Looking at Eq. (35) we observe that there are always the products of the wave functions of the same variable (like $R_{n_{i1},l_i}(r_1)R_{n_{j1},l_j}(r_1)$) that enter into the integration. Therefore, in the first step we try to write the product of two radial functions as a linear combination of the radial functions. Here, we proceed analogously to the angular integration. This trick of writing the product of two spherical harmonics as a linear combination of the spherical harmonics is a special case of much more general theorem called Wigner–Eckart theorem (see e.g., Refs. 54–58). We found its analog for so(2,1) algebra to be

$$rR_{n_i,l_i}(r)R_{n_j,l_j}(r)=A^{l_i,l_j}_{n_i,n_j}\sum_{n=-1}^{n_i+n_j-l_i-l_j-2} c^{l_i,l_j}_{n_i,n_j,n}\sqrt{\frac{(n_i+n_j-n-1+l_i+l_j)!}{(n_i+n_j-n-l_i-l_j-2)!}}R_{n_i+n_j-n-1,l_i+l_j}(2r), \tag{41}$$

where the multiplicative factor $A^{l_i,l_j}_{n_i,n_j}$ equals

$$A^{l_i,l_j}_{n_i,n_j}=\frac{2^{1-n_i-n_j}(n_i+n_j-l_i-l_j-2)!(n_i+l_i+n_j+l_j)!}{(n_i-l_i-1)!(n_j-l_j-1)!}\sqrt{\frac{(n_i-l_i-1)!}{(n_i+l_i)!}}\sqrt{\frac{(n_j-l_j-1)!}{(n_j+l_j)!}}. \tag{42}$$

The coefficients $c^{l_i,l_j}_{n_i,n_j,n}$ of the linear combination read

$$c^{l_i,l_j}_{n_i,n_j,n}=C^{l_i,l_j}_{n_i,n_j,n}-(n_i+n_j-l_i-l_j-2-n)C^{l_i,l_j}_{n_i,n_j,n+1}, \tag{43}$$

where the coefficients $C^{l_i,l_j}_{n_i,n_j,n}$ are given as

$$C^{l_i,l_j}_{n_i,n_j,n}=\frac{F(-n_i+l_i+1,-n;-n_i-n_j+l_i+l_j+2;2)\,F(-n_i-l_i,-n;-n_i-n_j-l_i-l_j;2)}{(n_i+l_i+n_j+l_j-n-1)!n!} \tag{44}$$

for $n\geqslant 0$ and equal zero otherwise. Here, $F(\alpha,\beta;\gamma;z)$ denotes the hypergeometric function (see e.g., Refs. 59–61).

The formula (41) was derived from the identities for the Laguerre polynomials found in Ref. 59, namely Eq. (5) of Sec. 8.6.4 and Eq. (11) of Sec. 5.5.2.

It is evident from the orthonormality of the radial functions for $l_i=l_j$ that an expression like (41) has to exist. What is new here is the explicit form of the coefficients $c^{l_i,l_j}_{n_i,n_j,n}$.

Using Eq. (41) in the radial integrals (35) we rewrite them into the form

$$\begin{aligned}X^{l_i,l_j,l}_{n_{i1},n_{i2},n_{j1},n_{j2}}=&A^{l_i,l_j}_{n_{i1},n_{j1}}A^{l_i,l_j}_{n_{i2},n_{j2}}\sum_{n_1=-1}^{n_{i1}+n_{j1}-l_i-l_j-2} c^{l_i,l_j}_{n_{i1},n_{j1},n_1}\sum_{n_2=-1}^{n_{i2}+n_{j2}-l_i-l_j-2} c^{l_i,l_j}_{n_{i2},n_{j2},n_2}\\ &\times\sqrt{\frac{(n_{i1}+n_{j1}-n_1-1+l_i+l_j)!}{(n_{i1}+n_{j1}-n_1-l_i-l_j-2)!}}\sqrt{\frac{(n_{i2}+n_{j2}-n_2-1+l_i+l_j)!}{(n_{i2}+n_{j2}-n_2-l_i-l_j-2)!}}\\ &\times Q^{l_i+l_j,l}_{n_{i1}+n_{j1}-1-n_1,n_{i2}+n_{j2}-1-n_2},\end{aligned} \tag{45}$$

where $Q^{L,l}_{N_1,N_2}$ denotes the integrals over two radial functions

$$Q^{L,l}_{N_1,N_2}=Q^{+,L,l}_{N_1,N_2}+Q^{-,L,l}_{N_1,N_2}. \tag{46}$$

Here,

$$Q^{+,L,l}_{N_1,N_2}=\int_0^\infty dr_1 R_{N_1,L}(2r_1)r_1^{l+1}\int_{r_1}^\infty dr_2 R_{N_2,L}(2r_2)r_2^{-l} \tag{47}$$

and

$$Q^{-,L,l}_{N_1,N_2}=\int_0^\infty dr_1 R_{N_1,L}(2r_1)r_1^{-l}\int_0^{r_1} dr_2 R_{N_2,L}(2r_2)r_2^{l+1}. \tag{48}$$

Before proceeding further let us point out that once the values of the hypergeometric functions and factorials are calculated, Eq. (43) is numerically stable. Therefore, this step of the calculation, the reduction of the integrals over four radial functions to the integrals over two radial functions, is numerically stable. The next step is to find the stable way of calculation of the integrals (46)–(48).

C. Derivation of the reccurrence relations for the integrals

In this subsection, we derive the recurrence relations for the integrals (47) and (48).

To motivate our further considerations we note that when we expand the radial functions in the integrals (47) and (48) into the powers of r, Eq. (37), the numerical instabilities appear again. Obviously, to achieve numerical stabilization we have to treat the functions $R_{n,l}(2r)$ as one indivisible object. The functions $R_{n,l}(2r)$ are treated in this way, when applying algebraic approach. The ladder operators $T_\pm$ change the whole function $R_{n,l}(2r)$ into the other functions $R_{n\pm1,l}(2r)$. Therefore, in the following we try to apply these ladder operators to the radial functions. To do so, we have to combine this algebraic technique with the analytic integration by parts.

1. Elementary example

For the sake of transparency, let us first consider the integral

$$\int_0^{r_1} dr_2\, R_{N_2,L}(2r_2). \tag{49}$$

After we show the numerically stable way how to calculate this integral, we extend it to the integrals (47) and (48).

First, let us show that

$$\int_0^{r_1} dr_2\, r_2\left(\frac{d}{dr_2}+\frac{1}{r_2}\right)[R_{N_2,L}(2r_2)]=r_1 R_{N_2,L}(2r_1). \tag{50}$$

The proof is elementary. Expanding the brackets on the left hand side we get

$$\int_0^{r_1} dr_2\, r_2\left(\frac{d}{dr_2}+\frac{1}{r_2}\right)[R_{N_2,L}(2r_2)]=\int_0^{r_1} dr_2\, R_{N_2,L}(2r_2)+\int_0^{r_1} dr_2\, r_2\frac{d}{dr_2}[R_{N_2,L}(2r_2)]. \tag{51}$$

Integrating the second term by parts

$$\int_0^{r_1} dr_2\, r_2\frac{d}{dr_2}[R_{N_2,L}(2r_2)]=[r_2 R_{N_2,L}(2r_2)]_0^{r_1}-\int_0^{r_1} dr_2\, R_{N_2,L}(2r_2) \tag{52}$$

and inserting this term into Eq. (51) we get Eq. (50).

Second, we observe that the operator $r((d/dr)+(1/r))$ is up to the imaginary unit equal to the operator T_2, Eq. (10) and the operator T_2 can be expressed as the difference of the creation and annihilation operators T_+ and T_-, Eq. (14)

$$r\left(\frac{d}{dr}+\frac{1}{r}\right)=irp_r=iT_2=\frac{1}{2}(T_+-T_-). \tag{53}$$

Thus, from the algebraic side we see that the operator (53) acts on the radial functions as

$$r\left(\frac{d}{dr}+\frac{1}{r}\right)[R_{N_2,L}(2r)]=\frac{1}{2}\sqrt{(N_2+L+1)(N_2-L)}R_{N_2+1,L}(2r) - \frac{1}{2}\sqrt{(N_2+L)(N_2-L-1)}R_{N_2-1,L}(2r), \tag{54}$$

where Eq. (17) was used.

Finally, combining the analytic result (50) with the algebraic one (54) we get the recurrence relation for the integrals (49)

$$\frac{1}{2}\sqrt{(N_2+L+1)(N_2-L)}\int_0^{r_1}dr_2\,R_{N_2+1,L}(2r_2)-\frac{1}{2}\sqrt{(N_2+L)(N_2-L-1)}\int_0^{r_1}dr_2\,R_{N_2-1,L}(2r_2) =r_1R_{N_2,L}(2r_1). \tag{55}$$

With this reccurence relation we reduce the quantum number N_2 to $L+1$. The integral over nodeless function $R_{L+1,L}(2r_2)$ is calculated analytically according to Eq. (40). The advantage of the recurrence relation (55) is that calculating integral over $R_{N_2+1,L}(2r_2)$ from the integral over $R_{N_2-1,L}(2r_2)$ contains the sum of positive numbers and not the difference of two numbers. Therefore, it is numerically stable.

2. Recurrence relations for $Q^{-;L,l}_{N_1;N_2}$ connecting different values of N_2

Now, we extend the described procedure to the calculation of the integrals appearing in Eq. (48)

$$\int_0^{r_1}dr_2\,r_2^{l+1}R_{N_2,L}(2r_2). \tag{56}$$

The analytic aspect is the same. By the same calculation as for Eq. (50) we get

$$\int_0^{r_1}dr_2\,r_2\left(\frac{d}{dr_2}+\frac{1}{r_2}\right)[R_{N_2,L}(2r_2)r_2^{l+1}]=r_1^{l+2}R_{N_2,L}(2r_1). \tag{57}$$

From the algebraic side we can deal with the extra term r^{l+1} using the commutation relation[47]

$$[r^k,irp_r]=-kr^k \tag{58}$$

that holds for every integer $k>0$. Applying this operator identity for $k=l+1$ to the radial functions $R_{N_2,L}(2r)$ we get

$$\int_0^{r_1} dr_2\, ir_2 p_{r_2}[R_{N_2,L}(2r_2) r_2^{l+1}] = \int_0^{r_1} dr_2\, r_2^{l+1} ir_2 p_{r_2}[R_{N_2,L}(2r_2)] + (l+1)\int_0^{r_1} dr_2\, r_2^{l+1} R_{N_2,L}(2r_2). \tag{59}$$

Combining again the analytical result (57) with the algebraic results (54) and (59) we get

$$r_1^{l+2} R_{N_2,L}(2r_1) = \frac{1}{2}\sqrt{(N_2+L+1)(N_2-L)}\int_0^{r_1} R_{N_2+1,L}(2r_2) r_2^{l+1} dr_2 - \frac{1}{2}\sqrt{(N_2+L)(N_2-L-1)}\int_0^{r_1} R_{N_2-1,L}(2r_2) r_2^{l+1} dr_2 + (l+1)\int_0^{r_1} R_{N_2,L}(2r_2) r_2^{l+1}. \tag{60}$$

Finally, multiplying the last equation by $r_1^{-l} R_{N_1,L}(2r_1)$ and integrating from zero to infinity we obtain

$$\tfrac{1}{8}\langle L, N_1 | r | L, N_2\rangle = \tfrac{1}{2}\sqrt{(N_2+L+1)(N_2-L)}\, Q^{-,L,l}_{N_1,N_2+1} - \tfrac{1}{2}\sqrt{(N_2+L)(N_2-L-1)}\, Q^{-,L,l}_{N_1,N_2-1} + (l+1) Q^{-,L,l}_{N_1,N_2}, \tag{61}$$

where we used Eqs. (31) and (48). Matrix elements of r are calculated from Eq. (23).

3. Recurrence relations for $Q^{-,L,l}_{N_1,N_2}$ connecting different values of N_1

To derive recurrence relations for $Q^{-,L,l}_{N_1,N_2}$ connecting the different values of N_1 we will need a slight modification of Eq. (57)

$$\int_0^{\infty} dr_1\, r_1\left(\frac{d}{dr_1}+\frac{1}{r_1}\right)[r_1^{-l} R_{N_1,L}(2r_1)]\int_0^{r_1} dr_2\, R_{N_2,L}(2r_2) r_2^{l+1} = -\int_0^{\infty} dr_1\, r_1^2 R_{N_1,L}(2r_1) R_{N_2,L}(2r_1). \tag{62}$$

This equation can be derived as follows. We expand the bracket on the left-hand side

$$\int_0^{\infty} dr_1\, r_1\left(\frac{d}{dr_1}+\frac{1}{r_1}\right)[r_1^{-l} R_{N_1,L}(2r_1)]\int_0^{r_1} dr_2\, R_{N_2,L}(2r_2) r_2^{l+1} = \int_0^{\infty} dr_1\, r_1^{-l} R_{N_1,L}(2r_1)\int_0^{r_1} dr_2\, R_{N_2,L}(2r_2) r_2^{l+1} + \int_0^{\infty} dr_1\, r_1 \frac{d}{dr_1}[r_1^{-l} R_{N_1,L}(2r_1)]\int_0^{r_1} dr_2\, R_{N_2,L}(2r_2) r_2^{l+1} \tag{63}$$

and integrate the second term by parts

$$\int_0^\infty dr_1\, r_1 \frac{d}{dr_1}[r_1^{-l} R_{N_1,L}(2r_1)] \int_0^{r_1} dr_2\, R_{N_2,L}(2r_2) r_2^{l+1}$$
$$= \left[r_1^{-l+1} R_{N_1,L}(2r_1) \int_0^{r_1} dr_2\, R_{N_2,L}(2r_2) r_2^{l+1} \right]_0^\infty - \int_0^\infty dr_1\, r_1^{-l} R_{N_1,L}(2r_1) \int_0^{r_1} dr_2$$
$$\times R_{N_2,L}(2r_2) r_2^{l+1} - \int_0^\infty dr_1\, r_1^2 R_{N_1,L}(2r_1) R_{N_2,L}(2r_1), \tag{64}$$

where we used the Newton formula for differentiation of the integral with respect to the upper bound. Since the boundary term vanishes, by inserting Eq. (64) into Eq. (63) we get Eq. (62).

Also the algebraic side of the calculation requires only slight modification of the previous case. Instead of the commutation relation (58) we use the commutation relation

$$[r^{-k}, irp_r] = -kr^{-k} \tag{65}$$

that is obtained from Eq. (58) by multiplying both sides by r^{-k}. Applying this operator identity to the radial functions $R_{N_1,L}(2r_1)$ for $k=l$ leads to

$$ir_1 p_{r_1}[r_1^{-l} R_{N_1,L}(2r_1)] = r_1^{-l} ir_1 p_{r_1}[R_{N_1,L}(2r_1)] - lr_1^{-l} R_{N_1,L}(2r_1). \tag{66}$$

We use the last equation in the integrand on the left hand side of Eq. (62), then apply Eq. (54), where we just replace N_2 by N_1. After some manipulation we get the sought reccurence relation

$$-\tfrac{1}{8}\langle L, N_1|r|L, N_2\rangle = \tfrac{1}{2}\sqrt{(N_1+L+1)(N_1-L)}\, Q^{-,L,l}_{N_1+1,N_2}$$
$$- \tfrac{1}{2}\sqrt{(N_1+L)(N_1-L-1)}\, Q^{-,L,l}_{N_1-1,N_2} - l Q^{-,L,l}_{N_1,N_2}. \tag{67}$$

4. Recurrence relations for the integrals $Q^{+,L,l}_{N_1,N_2}$

No new ideas are required to derive the recurrence relations for the integrals $Q^{+,L,l}_{N_1,N_2}$. Proceeding in analogy with the previous cases we derive recurrence relations connecting the integrals with different values of N_2,

$$-\tfrac{1}{8}\langle L, N_1|r|L, N_2\rangle = \tfrac{1}{2}\sqrt{(N_2+L+1)(N_2-L)}\, Q^{+,L,l}_{N_1,N_2+1}$$
$$- \tfrac{1}{2}\sqrt{(N_2+L)(N_2-L-1)}\, Q^{+,L,l}_{N_1,N_2-1} - l Q^{+,L,l}_{N_1,N_2} \tag{68}$$

and the recurrence relations connecting the integrals with different values of N_1,

$$\tfrac{1}{8}\langle L, N_1|r|L, N_2\rangle = \tfrac{1}{2}\sqrt{(N_1+L+1)(N_1-L)}\, Q^{+,L,l}_{N_1+1,N_2}$$
$$- \tfrac{1}{2}\sqrt{(N_1+L)(N_1-L-1)}\, Q^{+,L,l}_{N_1-1,N_2} + (l+1) Q^{+,L,l}_{N_1,N_2}. \tag{69}$$

It is immediately seen from Eqs. (61), (67), (68), and (69) that

$$Q^{+,L,l}_{N_1,N_2} = Q^{-,L,l}_{N_2,N_1}. \tag{70}$$

Through the derived recurrence relations all the needed integrals are reduced to the calculation of the integrals $Q^{+,L,l}_{L+1,L+1}$. These integrals can be calculated from Eq. (40),

$$Q^{+,L,l}_{L+1,L+1}=\frac{2^{-2+4L}}{(2L+1)!}I^{l}_{L,L}=2^{-1}(2L+1)!\,F(1,-L+l;-2L-1;2). \tag{71}$$

D. Solution of recurrence relations

To solve recurrence relations derived in the previous section it is advantageous to eliminate the irrational factors by introducing the unnormalized integrals

$$\tilde{Q}^{\pm,L,l}_{N_1,N_2}=4\sqrt{\frac{(N_1+L)!}{(N_1-L-1)!}}\sqrt{\frac{(N_2+L)!}{(N_2-L-1)!}}\,Q^{\pm,L,l}_{N_1,N_2}. \tag{72}$$

Then the recurrence relations take the form

$$\begin{aligned}&-\sqrt{\frac{(N_1+L)!}{(N_1-L-1)!}}\sqrt{\frac{(N_2+L)!}{(N_2-L-1)!}}\langle L,N_1|r|L,N_2\rangle\\&\quad=(N_2-L)\tilde{Q}^{+,L,l}_{N_1,N_2+1}-(N_2+L)\tilde{Q}^{+,L,l}_{N_1,N_2-1}-2l\tilde{Q}^{+,L,l}_{N_1,N_2}\end{aligned} \tag{73}$$

and

$$\begin{aligned}&\sqrt{\frac{(N_1+L)!}{(N_1-L-1)!}}\sqrt{\frac{(N_2+L)!}{(N_2-L-1)!}}\langle L,N_1|r|L,N_2\rangle\\&\quad=(N_1-L)\tilde{Q}^{+,L,l}_{N_1+1,N_2}-(N_1+L)\tilde{Q}^{+,L,l}_{N_1-1,N_2}+2(l+1)\tilde{Q}^{+,L,l}_{N_1,N_2}.\end{aligned} \tag{74}$$

The recurrence relations for $\tilde{Q}^{-,L,l}_{N_1,N_2}$ are obtained using Eq. (70).

1. Solution in the variable N_1

Because of Eq. (70) we can restrict our attention to the case $N_1\geqslant N_2$. We note that the matrix elements $\langle L,N_1|r|L,N_2\rangle$ vanish whenever $|N_2-N_1|>1$, see Eq. (23). That means that for $N_1>N_2+1$ the recurrence relation (74) is homogenous. Since it is the three-term recursion relation we need two initial values of $\tilde{Q}^{+,L,l}_{N_1,N_2}$, namely $\tilde{Q}^{+,L,l}_{N_2+2,N_2}$ and $\tilde{Q}^{+,L,l}_{N_2+1,N_2}$ to determine the solution uniquely.

General solution of homogenous Eq. (74) is

$$\begin{aligned}\tilde{Q}^{+,L,l}_{N_1,N_2}&=g_1(N_2)F(N_1-L,-L+l+1;-2L;2)\\&\quad+g_2(N_2)(-1)^{N_1-L-1}F(N_1-L,-L-l-1;-2L;2).\end{aligned} \tag{75}$$

We found this solution by realizing that the recurrence relation (74) can be transformed to the one of the relations between contigous hypergeometric functions (see, e.g., Ref. 61). This solution holds for all $N_1>N_2$ including the cases $N_1=N_2+2$ and $N_1=N_2+1$, that can be viewed as the initial conditions. In principle we could determine the functions $g_1(N_2)$ and $g_2(N_2)$ by considering Eq. (75) for $N_1=N_2+1$ and $N_1=N_2+2$. However, it is more advantageous to proceed in different way; to insert directly solution (75) into Eq. (73). This is done in the following paragraph.

2. Solution in the variable N_2

If we consider Eq. (73) for $N_1=N_2+2$ we obtain

$$(N_2-L)\tilde{Q}^{+,L,l}_{N_2+2,N_2+1}-2l\tilde{Q}^{+,L,l}_{N_2+2,N_2}-(N_2+L)\tilde{Q}^{+,L,l}_{N_2+2,N_2-1}=0. \tag{76}$$

Further, considering Eq. (73) for $N_1=N_2+3$ we get

$$(N_2-L)\tilde{Q}^{+,L,l}_{N_2+3,N_2+1}-2l\tilde{Q}^{+,L,l}_{N_2+3,N_2}-(N_2+L)\tilde{Q}^{+,L,l}_{N_2+3,N_2-1}=0, \tag{77}$$

and so on. It seen from these equations that the values of $\tilde{Q}^{+,L,l}_{N_1,N_2}$ for $N_2=N_1+1$ can be calculated from Eq. (76), the values of $\tilde{Q}^{+,L,l}_{N_1,N_2}$ for $N_2=N_1+2$ can be calculated from Eq. (77), and so on. Therefore, all the values of $\tilde{Q}^{+,L,l}_{N_1,N_2}$ for $N_1>N_2$ including the values $N_1=N_2+1$ and $N_1=N_2+2$ can be calculated from *homogenous* Eq. (73).

By inserting solution (75) into the homogenous equation (73) we get

$$\begin{aligned}&F(N_1-L,-L+l+1;-2L;2)[(N_2-L)g_1(N_2+1)-(N_2+L)g_1(N_2-1)-2lg_1(N_2)]\\&\quad+(-1)^{N_1-L-1}F(N_1-L,-L-l-1;-2L;2)[(N_2-L)g_2(N_2+1)\\&\quad-(N_2+L)g_2(N_2-1)-2lg_2(N_2)]=0.\end{aligned} \tag{78}$$

Requiring that this equation is satisfied for $N_1=N_2+1$ and $N_1=N_2+2$ the expression in the brackets have to vanish. It is the three-term recursion relation having the solution

$$\begin{aligned}g_i(N_2)=&g_i^{(1)}(-1)^{N_2-L-1}F(N_2-L,-L+l;-2L;2)\\&+g_i^{(2)}F(N_2-L,-L-l;-2L;2),\quad i=1,2.\end{aligned} \tag{79}$$

Thus, Eqs. (75) and (79) represent a general solution for $\tilde{Q}^{+,L,l}_{N_1,N_2}$ for all $N_1>N_2$. Four constants $g_i^{(j)}$, $i,j=1,2$ are determined from four values $\tilde{Q}^{+,L,l}_{L+i+j,L+j}$, $i,j=1,2$.

The solution for $\tilde{Q}^{-,L,l}_{N_1,N_2}$ is obtained by reversing the role of N_1 and N_2 in Eqs. (75) and (79). The constants $g_i^{(j)}$, $i,j=1,2$ are determined as in the previous case.

3. Final result

Proceeding in the way described above we arrive to the explicit solution for the integrals $\tilde{Q}^{\pm,L,l}_{N_1,N_2}$,

$$\begin{aligned}\tilde{Q}^{+,L,l}_{N_1,N_2}=&K(L,l)F(N_1-L,-L+l+1;-2L;2)[(-1)^{N_2+1-L}\\&\times F(N_2-L,-L+l;-2L;2)+F(N_2-L,-L-l;-2L;2)]\end{aligned} \tag{80}$$

and

$$\begin{aligned}\tilde{Q}^{-,L,l}_{N_1,N_2}=&K(L,l)(-1)^{N_1-L-1}F(N_1-L,-L+l;-2L;2)\times[(-1)^{N_2+1-L}F(N_2-L,-L-l-1;\\&-2L;2)+F(N_2-L,-L+l+1;-2L;2)].\end{aligned} \tag{81}$$

The constant $K(L,l)$ is in both cases the same and equals

$$K(L,l)=\frac{(2L+1)!}{F(2,-L+l+1;-2L;2)}\,\frac{L+1-(l+1)F(1,-L+l;-2L-1;2)}{F(1,-L+l;-2L;2)+F(1,-L-l;-2L;2)}. \tag{82}$$

These solutions hold for all $N_1>N_2$ and for all $L>l$. The solution for $L=l$ has very simple form

$$\tilde{Q}^{+,L,L}_{N_1,N_2}=0 \tag{83}$$

and

$$\tilde{Q}^{-,L,L}_{N_1,N_2}=(-1)^{N_2-N_1}\frac{(N_2+L)!}{(N_2-L-1)!}. \tag{84}$$

TABLE I. Labeling of the basis sets. States are ordered in accordance with the increasing unperturbed energies, i.e., in accordance with the sum of principal quantum numbers $n_{12}(i)=n_{i1}+n_{i2}$.

i	n_{i1}	n_{i2}	l_i	n_{12}
1	1	1	0	2
2	1	2	0	3
3	1	3	0	4
4	2	2	0	4
5	2	2	1	4
6	1	4	0	5
7	2	3	0	5
8	2	3	1	5

The solutions for $N_1=N_2$ for $N_1>L+1$ are obtained by considering Eq. (73) for $N_2=N_1-1$.

The explicit solution of reccurence relations given in this subsection finishes our way to the stable calculation of the radial integrals. The final solution of numerical stable calculation of the radial integrals is the use of Eq. (45), where the integrals $Q^{L,l}_{N_1,N_2}$ are calculated from Eqs. (46), (72), (80), (81), (83), and (84). Running these equations in the double precision arithmetics for $n_{i1}=21$, $n_{i2}=19$, $n_{j1}=17$, and $n_{j2}=23$ for different values of l_i, l_j, and l yields the relative error in the worst cases of the order 10^{-14}.

Finally, we would like to emphasize that all the hypergeometric functions appearing in Eqs. (44), (80), (81), and (82) are in fact polynomials, so the question of convergence of the corresponding series in their computation does not arise.

V. CONFIGURATION INTERACTION

As an illustration, we solve Eq. (27) variationally for the helium atom, i.e., for $Z=2$. It is well-known that the ground state of helium is one of the most difficult cases of calculation of the electron–electron correlation (see below), so we give this example to see the performance of the method under unfavorable circumstances. We label the basis vectors $|i\rangle$ in the way indicated in Table I. The states are ordered in such a way that the unperturbed energies increase, i.e., according to the sum of the hydrogen principal quantum numbers $n_{i1}+n_{i2}$. The truncated basis sets are characterized by the number n_{12} that denotes the maximum of the sums $n_{i1}+n_{i2}$ of the states included in the truncated basis sets. For example, the basis set characterized by $n_{12}=2$ includes all the states with $2\geqslant n_{i1}+n_{i2}$. This basis set is one-dimensional $\{|0,1\rangle^{(1)}|0,1\rangle^{(2)}|(0,0)0\rangle\}$. The basis set characterized by $n_{12}=3$ is two-dimensional: $\{|0,1\rangle^{(1)}|0,1\rangle^{(2)}|(0,0)0\rangle, 2^{-1/2}(|0,1\rangle^{(1)}|0,2\rangle^{(2)}+|0,2\rangle^{(1)}|0,1\rangle^{(2)})|(0,0)0\rangle\}$. Similarly, the basis set characterized by $n_{12}=4$ is five-dimensional, by $n_{12}=5$ eight-dimensional, and so on.

We note that our variational calculation corresponds to what is usually called the full CI with the successivelly increasing basis set.

The parameter η in Eq. (27) was optimized numerically by calculating the values of the energy for some discrete values of η and looking for the minimum of these discrete values. Results are shown in Table II.

We found that the parameter η with increasing basis set decreases, see Table II. This can be intuitively understood as follows. We have to build the atomic orbitals in such a way to describe the motion of the electrons properly, i.e., to obtain high probability of their appearence in the places where they ''really'' are. As we enlarge the basis sets the maximum of this probability is moving to the places more distant from the nucleus. Therefore, to get it to the proper place, close to the nucleus, the screening constant η has to decrease. Numerical analysis shows that the optimal screening constant η goes to zero roughly like n_{12}^{-1}. However, this analysis is not very reliable since the optimal screening constant η is determined with lower accuracy than the variational

TABLE II. energy $E(\eta)$. The reason is that with the increasing basis set the second derivative of the function $E(\eta)$ in minimum goes to zero, see Ref. 37. Therefore small variations of η around the minimum yield energies that differ negligibly.

It is seen from Table II that convergence of the variational energy levels towards the exact one is rapid at the beginning but rather slow afterwards. It is quite remarkable that we can get ''chemical accuracy'' -2.903, i.e., error about 1 kcal/mol just with 55 basis functions considering the simplicity of the wave function used. However, it is seen from Table II that to go beyond this ''chemical accuracy'' it is very difficult. This slow convergence can be partially removed by extrapolating the results for finite basis sets to the infinite one by using the Thiele–Padé extrapolation.[50,62] The result for $n_{12}=40$ is $E(40)=-2.903\,708\,8$ compared to the exact result obtained with the explicitely correlated functions $-2.903\,724\,377$.[8] Extrapolating the values given in the Table II from n_{12} equal to 30 to n_{12} equal to 40 with respect to n_{12}^{-3} we obtained $-2.903\,724\,0$. Extrapolating from the interval $n_{12}=28$ to $n_{12}=38$ we obtained $-2.903\,723\,98$, so reliable part of the extrapolated result is $E_{\mathrm{extr}}=-2.903\,724$. The dependence of $E(n_{12})$ on n_{12}^{-3} was guessed by analyzing the values from $n_{12}=20$ to $n_{12}=40$. It is seen that the extrapolation improves the variational result by two orders.

The slow convergence of the CI method for the ground state of helium is well known and was analyzed in detail in several papers.[38,39,41,42] This slow convergence is related to slow convergence of the multipole expansion for the ground state energy because of the cusp of the wave function for $r_1=r_2$. For this reason the multipole expansion of r_{12}^{-1} has been abandoned in the accurate calculations of two electron atoms and the explicitely correlated functions were introduced. Nevertheless, even for the two-electron atoms the standard CI is more advantegeous than the use of the explicitely correlated functions in the cases when the electron–electron correlation is not so strong. This appears first for the highly ionized two-electron atoms when the interaction between the electrons is supressed by the factor $1/Z$. For such systems, the relativistic and QED effects become very important and it is much easier to calculate the pertinent matrix elements of the

TABLE III. The variational energy levels $E(\eta)$ of the first excited S-state of helium obtained by diagonalization of the generalized eigenvalue problem (27) with the optimized choices of the parameter η. *Order* denotes the order of the truncated matrix. The relative error is calculated with respect to the value -2.1459740292 given in Ref. 64. ∞ denotes the extrapolated value, the extrapolation was made with respect to n_{12}^{-3}.

relativistic and QED operators in the basis considered in this paper than in the basis of the explicitely correlated functions. Second, for the excited states, especially for the states with total angular momenta larger than zero, the electron–electron correlation is decreased due to the different angular distribution of the electron orbitals. Intuitively, the electron-electron correlation is the strongest in the case of the S-states and especially for the ground state where the electrons, roughly speaking, occupy the same orbital. From Table III it is seen that already for the first excited S-state the performance of the method is better. It is expected than in the combination with the complex scaling method the performance of the method for higher excited states will further improve.[27]

Finally, let us point out that to judge overall performance of the technique described we should have in mind the last sentences from the Introduction.

VI. CONCLUSIONS

In this paper the use of so(2,1) Lie algebra for calculation of the spectra of the two-electron atoms was suggested. It was shown that by applying this algebra we were able to express all the necessary matrix elements in the analytic form. Particularly, we succeeded in expressing the repulsion integrals in terms of the hypergeometric functions. This was done in three steps, all of them are completely novel from the methodological point of view.

First, we formulated analog of the Wigner–Eckart theorem for so(2,1) algebra. In this way we reduced the repulsion integrals over four radial functions to the repulsion integrals over two radial functions. Second, combining algebraic technique with the integration by parts we derived recurrence relations for the repulsion integrals over two radial functions. Third, we solved the recurrence relations, in form of the difference equations in two variables, in terms of the hypergeometric functions. These *analytic and numerical stable* formulas for the repulsion integrals are the main result of this paper. It solves the problem of the numerical stability and enables us to make the large scale CI calculation with analytic basis functions.

As an illustration, the full CI calculation with increasing basis set for the ground state of helium was made. It is well-known that the electron–electron correlation is in this case very strong. Nevertheless, we showed that by means of the Thiele–Padé extrapolation more accurate results can be obtained. This extrapolation technique is rather straightforward. With more sophisticated technique of extrapolation we can expect even better results. This will be published in the forthcoming paper in which also the methodical problems of extrapolation (including *ab initio* estimate of the error) will be discussed. Our calculation cannot, of course, compete with that

obtained by means of the explicitely correlated functions. However, since the numerical difficulties are encountered also within that approach, some of the ideas introduced in this paper could be usefull also in those calculations.

Also, one may expect that the ideas introduced in this paper can be applied to Gaussian functions used in most of quantum chemical calculations.

In this paper we restricted our attention to the calculation of the states with the total square of the angular momentum equal to zero and to the singlet spin states and we used just one screening constant to optimize the energy. However, only slight modifications are necessary to deal also with the states of different symmetry and with more screening constants. These modifications will be discussed in the forthcoming paper.

The method described in this paper can also be used for calculation of $1/Z$ expansion (see, e.g., Refs. 9, 63), the variational and perturbational calculation of atoms with more than two electrons, the inclusion of the relativistic and QED corrections for the two-electron atoms with large Z and the calculation of the dynamical problems on helium like one- and two-photon transitions.[64,65]

(Received 24 February 2004; accepted 12 April 2004;
published online 8 June 2004)

Eigenfunctions and eigenvalues of the free magnetic Schrödinger operator, describing a spinless particle confined to an infinite layer of fixed width, are discussed in detail. The eigenfunctions are realized as an orthonormal basis of a suitable Hilbert space. Four different classes of temporally stable coherent states associated with the operator are presented. The first two classes are derived as coherent states with one degree of freedom and the last two classes are derived with two degrees of freedom. The dynamical algebra of each class is found. Statistical quantities associated to each class of coherent states are calculated explicitly. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1760846]

I. INTRODUCTION

By generalizing the definition of canonical coherent states (CS), Gazeau and Klauder[9] proposed a method to construct temporally stable CS for a quantum system with one degree of freedom. Since then, the method has been successfully applied to different quantum systems.[2,8] As an extension of Ref. 9, a method was presented to build CS for systems with several degrees of freedom.[11,16] Motivated from the recent interest on temporally stable coherent states, we present in this article four different classes of CS using the spectrum of the free magnetic Schrödinger operator

$$H_0=\frac{1}{2M}\left(\mathbf{P}-\frac{e}{c}\mathbf{A}\right)^2, \tag{1.1}$$

where $\mathbf{A}$ is the magnetic vector potential, e is the charge of the particle, c is the speed of light, and $\mathbf{P}=-i\hbar\nabla$ with $\hbar$ being the Planck's constant divided by 2π. By constructing the CS for the operator H_0 we also demonstrate the method proposed in Ref. 16 and analyze the temporal stability and action identity conditions for the multidimensional case. These features were excluded from the discussion of Ref. 16.

The article is organized as follows: In Sec. II, we introduce the detailed description of the free magnetic Schrödinger operator (1.1), exploring its spectrum and the eigenvectors. In Sec. III we realize the eigenfunctions of Sec. II as an orthonormal basis of a Hilbert space. For the sake of completeness in Sec. IV we discuss the definition of the Gazeau–Klauder CS. In Sec. V, associated with the spectrum of (1.1), two classes of CS with one degree of freedom are constructed. In Sec.

[a)]Electronic mail: santhar@vax2.concordia.ca
[b)]Electronic mail: nsaad@upei.ca

VI, two classes of CS with two degrees of freedom are constructed. In Sec. VII, a detailed classification of the dynamical algebra is provided. In Sec. VIII we explicitly calculate the quantum statistical quantities associated with the CS.

II. THE FREE MAGNETIC SCHRÖDINGER OPERATOR

Consider an infinite layer of fixed width d, that is, $\Sigma=\mathbb{R}^2\times[0,d]$. Suppose the layer is placed into a perpendicular homogeneous magnetic field of intensity $\mathbf{B}=(0,0,B)$, where B is a constant. The Hamiltonian of this system can be written using (1.1) as

$$H_0=\frac{1}{2M}\left(\mathbf{P}^2-\frac{e}{c}\mathbf{P}\cdot\mathbf{A}-\frac{e}{c}\mathbf{A}\cdot\mathbf{P}+\frac{e^2}{c^2}\mathbf{A}^2\right). \tag{2.1}$$

When the circular gauge $\mathbf{A}=-\frac{1}{2}\mathbf{r}\times\mathbf{B}=\frac{1}{2}|B|(-y,x,0)$ is chosen, we have for a state vector ψ

$$\mathbf{P}\cdot\mathbf{A}\psi=-i\hbar(\nabla\cdot\mathbf{A})\psi-i\hbar\mathbf{A}\cdot\nabla\psi=\mathbf{A}\cdot\mathbf{P}\psi.$$

Consequently, a spinless quantum particle confined to the layer is described by the free magnetic Schrödinger operator

$$H_0=\frac{1}{2M}\left(\mathbf{P}^2-\frac{2e}{c}\mathbf{A}\cdot\mathbf{P}+\frac{e^2}{c^2}\mathbf{A}^2\right) \tag{2.2}$$

acting in $L^2(\Sigma)$ with Dirichlet boundary conditions

$$\psi(\mathbf{x},0)=\psi(\mathbf{x},d)=0,\quad \mathbf{x}=(x,y)\in\mathbb{R}^2.$$

In the absence of an additional interaction, the operator H_0 can be written as

$$H_0=-\frac{\hbar^2}{2M}\nabla^2+\frac{ie\hbar|B|}{2Mc}\left(x\frac{\partial}{\partial y}-y\frac{\partial}{\partial x}\right)+\frac{e^2|B|^2}{8Mc^2}(x^2+y^2). \tag{2.3}$$

The presence of the potential x^2+y^2 suggests the use of the cylindrical coordinates for the separation of the variables. Thus we have

$$H_0=-\frac{\hbar^2}{2M}\nabla^2+\frac{e^2|B|^2}{8Mc^2}r^2+\frac{ie\hbar|B|}{2Mc}\frac{\partial}{\partial\theta}, \tag{2.4}$$

where

$$\nabla^2=\frac{\partial^2}{\partial r^2}+\frac{1}{r}\frac{\partial}{\partial r}+\frac{1}{r^2}\frac{\partial^2}{\partial\theta^2}+\frac{\partial^2}{\partial z^2}.$$

If we define the cyclotron frequency $\omega_c=-(e|B|/Mc)$, then

$$H_0=-\frac{\hbar^2}{2M}\nabla^2+\frac{M\omega_c^2}{8}r^2+\frac{\omega_c}{2}L_z, \tag{2.5}$$

where

$$L_z=-i\hbar\frac{\partial}{\partial\theta}.$$

Let

$$\Psi(r,\theta,z)=\psi(r,\theta)\chi(z),$$

we can easily find that the differential equation satisfied by $\chi(z)$ and obeying boundary conditions $\chi(0)=\chi(d)=0$ yields

$$\chi_n(z)\equiv\sqrt{\frac{2}{d}}\sin\left(\frac{\pi nz}{d}\right),\quad n=1,2,\ldots, \tag{2.6}$$

which form an orthonormal basis in $L^2[0,d]$. Note that the case of $n=0$ correspondence to $\chi_0(z)=0$ is physically insignificant. The corresponding eigenvalues are

$$\epsilon_n=\frac{\hbar^2}{2M}\left(\frac{\pi(n+1)}{d}\right)^2,\quad n=0,1,2,\ldots\ . \tag{2.7}$$

This solution is usually ignored in most of the research on such problems[8,10,16] on account of the interest being confined to the motion of the particle in the plane at right angles to the magnetic field.

On the other hand, the differential equation satisfied by $\psi(r,\theta)$ describes a two-dimensional particle in the perpendicular homogeneous field in the circular gauge. Setting $\psi(r,\theta)=\phi(r)e^{il\theta}$ with l an integer, one can easily show after some algebraic calculations, that the differential equation satisfied by

$$\phi(r)=\left(\frac{e|B|}{2\hbar c}\right)^{|l|/2}r^{|l|}e^{-(e|B|/4\hbar c)r^2}G\left(\sqrt{\frac{e|B|}{2\hbar c}}r\right) \tag{2.8}$$

is

$$\frac{d^2G}{d\xi^2}+\left(\frac{|l|+1}{\xi}-1\right)\frac{dG}{d\xi}+\frac{\lambda-2-2|l|}{4\xi}G=0,$$

where $\xi=(e|B|/2\hbar c)r^2$ and $\lambda=(4Mc/e|B|\hbar)\epsilon_{ml}-2l$. This is known as Kummer's differential equation, which has a solution

$$G(\xi)={}_1F_1\left(\frac{-\lambda+2+2|l|}{4};|l|+1;\xi\right)$$

with the eigenvalue condition $(-\lambda+2+2|l|)/4=-m$, where $m=0,1,2,\ldots$ are the principal quantum numbers and $l=0,\pm1,\pm2,\ldots$ are the angular momentum quantum numbers. The eigenvalue condition yields the Landau levels

$$\epsilon_{ml}=\frac{e|B|\hbar}{2Mc}(2m+l+|l|+1),$$

and the eigenfunctions become

$$\psi_{m,l}(r,\theta)=N_{ml}r^{|l|}e^{-(e|B|/4\hbar c)r^2}{}_1F_1\left(-m;|l|+1;\frac{e|B|}{2\hbar c}r^2\right)e^{il\theta}, \tag{2.9}$$

where N_{ml} is a normalization constant and ${}_1F_1$ is the confluent hypergeometric function defined by

$${}_1F_1(-m;\gamma;z)=\sum_{k=0}^{m}\frac{(-m)_k}{(\gamma)_k\ k!}z^k.$$

The Pochhammer symbol $(a)_k$ is defined by $(a)_0=1$ and $(a)_k=a(a+1)(a+2)\cdots(a+k-1)$ for $k=1,2,3,\ldots$, and may be expressed in terms of the gamma function by $(a)_k=\Gamma(a+k)/\Gamma(a)$,

when a is not a negative integer $-m$. In the exceptional cases, $(-m)_k=0$ if $k>m$ and otherwise $(-m)_k=(-1)^k m!/(m-k)!$. The normalization constant N_{ml} follows out of the inner product relation

$$\langle \psi_{ml}|\psi_{m'l'}\rangle=\int_0^{2\pi}\int_0^{\infty}\psi_{ml}(r,\theta)\overline{\psi_{m'l'}(r,\theta)}rdrd\theta=\delta_{mm'}\delta_{ll'}. \tag{2.10}$$

This yields

$$N_{ml}^{-2}=\left(\frac{2\hbar c}{e|B|}\right)^{|l|+1}\frac{\pi\Gamma(|l|+1)}{(|l|+1)_m}m!,$$

and by means of the identities

$$\int_0^{\infty}r^{2\gamma-1}e^{-sr^2}{}_1F_1(-n;\gamma;sr^2){}_1F_1(-m;\gamma;sr^2)dr=\frac{1}{2}\frac{n!\Gamma(\gamma)}{s^{\gamma}(\gamma)_n}\delta_{mn} \tag{2.11}$$

and

$$\int_0^{2\pi}e^{i(l-l')\theta}d\theta=0 \text{ or } 2\pi \text{ according as } l\neq l' \text{ or } l=l'$$

we readily conclude that $\{\psi_{ml}(r,\theta)\}$ is indeed an orthonormal set with respect to the measure $rdrd\theta$, where $0\leqslant\theta<2\pi$. Finally, the spectrum of the free Hamiltonian H_0 is

$$E(m,l,n)=\frac{e|B|\hbar}{2Mc}(2m+l+|l|+1)+\frac{\hbar^2}{2M}\left(\frac{\pi(n+1)}{d}\right)^2,\quad n=0,1,2,\ldots. \tag{2.12}$$

We immediately observe that the energy levels ϵ_{ml} for positive l, yield

$$E(m,l,n)=\frac{e|B|\hbar}{2Mc}(2m+2l+1)+\frac{\hbar^2}{2M}\left(\frac{\pi(n+1)}{d}\right)^2,\quad n=0,1,2,\ldots. \tag{2.13}$$

For l negative or zero, we have $|l|+l=0$ which cause the infinite degeneracy of Landau levels ϵ_{ml}. Thereby the spectrum (2.12) becomes

$$E(m,n)=\frac{e|B|\hbar}{2Mc}(2m+1)+\frac{\hbar^2}{2M}\left(\frac{\pi(n+1)}{d}\right)^2,\quad n=0,1,2,\ldots. \tag{2.14}$$

This particular expression of the spectrum[13] was the starting point of the interesting study of Exner and Nemcova[6] concerning the spectral properties of a Hamiltonian describing the motion of a spinless quantum particle confined to an infinite planar layer with hard walls and interacting with a periodic lattice of point perturbations as well as in a homogeneous magnetic field perpendicular to the layer. They remark therein that the spectrum (2.14) is nondegenerate if the ratio of the coefficients $|B|$ and π^2/d^2 is irrational.[7] We shall claim this in the next section.

For simplicity we may assume hereafter that $e=\hbar=2M=c=1$, and hence we summarize the situation as follows. For each $n=0,1,2,\ldots$ there is an orthonormal set of wave functions $\Psi_{mln}(r,\theta,z)\equiv\psi_{ml}(r,\theta)\chi_n(z)$, eigensolutions for the Hamiltonian H_0, given by

$$\Psi_{mln}(r,\theta,z)=\sqrt{\left(\frac{|B|}{2}\right)^{|l|+1}\frac{2(|l|+1)_m}{\pi\, d\, m!\Gamma(|l|+1)}}\,r^{2|l|}e^{-(|B|/4)r^2}$$
$$\times{}_1F_1\left(-m;|l|+1;\frac{|B|r^2}{2}\right)e^{il\theta}\sin\left(\frac{(n+1)\pi z}{d}\right) \tag{2.15}$$

in the state Hilbert space $\mathfrak{L}^2(\Sigma)$, which actually is the direct product $\mathfrak{L}^2[0,\infty)\otimes L^2[0,2\pi)\otimes L^2[0,d])$.

III. DENSITY ARGUMENT

Making use of the tensor product concept immediately preceding, we lump the tensor product $\mathfrak{L}^2[0,\infty)\otimes L^2[0,2\pi)$ of the first two Hilbert spaces into the Hilbert space $\mathfrak{L}^2([0,\infty)\times[0,2\pi))$, which consists of all complex-valued Lebesgue measurable functions h on $[0,\infty)\times[0,2\pi)$ with

$$\int_0^\infty \int_0^{2\pi} |h(r,\theta)|^2 r\,d\theta dr<\infty.$$

Let $\mathfrak{L}^2(\Sigma')\equiv\mathfrak{L}^2([0,\infty)\times[0,2\pi))\otimes L^2[0,d]$, where

$$\left\{\Psi_{ml}(r,\theta)=\sqrt{\left(\frac{|B|}{2}\right)^{|l|+1}\frac{(|l|+1)_m}{\pi\, m!\Gamma(|l|+1)}}\,r^{2|l|}e^{-(|B|/4)\,r^2}{}_1F_1\left(-m;|l|+1;\frac{|B|r^2}{2}\right)e^{il\theta}\right\}$$

with $m=0,1,2,\ldots$ and $l=0,\pm1,\pm2,\ldots$ is an orthonormal system of the Hilbert space $\mathfrak{L}^2([0,\infty)\times[0,2\pi))$ and

$$\left\{\sqrt{\frac{2}{d}}\sin\left(\frac{\pi(n+1)z}{d}\right):n=0,1,2,\ldots\right\}$$

is an orthonormal basis of the Hilbert space $L^2[0,d]$. If we can show that $\{\Psi_{ml}:m=0,1,2,\ldots,l=0,\pm1,\pm2,\ldots\}$ is an orthonormal basis of the Hilbert space $\mathfrak{L}^2([0,\infty)\times[0,2\pi))$, then $\{\Psi_{mln}:m=0,1,2,\ldots,l=0,\pm1,\pm2,\ldots,n=0,1,2,\ldots\}$ becomes an orthonormal basis (Ref. 22, p. 52, Theorem 3.12) of the Hilbert space $\mathfrak{L}^2(\Sigma')$.

Theorem 3.1: *The set* $\{\Psi_{ml}:m=0,1,2,\ldots,l=0,\pm1,\pm2,\ldots\}$ *is an orthonormal basis of the Hilbert space* $\mathfrak{L}^2([0,\infty)\times[0,2\pi))$.

Proof: Let us assume that it is not. Thus there exist a nontrivial $\Psi\in\mathfrak{L}^2([0,\infty)\times[0,2\pi))$ satisfying

$$\int_0^\infty\int_0^{2\pi}\Psi_{ml}(r,\theta)\overline{\Psi(r,\theta)}r\,dr\,d\theta=0 \quad \text{for all } m=0,1,2,\ldots \text{ and } l=0,\pm1,\pm2,\ldots .$$

Since the linear hull[18]

$$(\text{L.H.})\left({}_1F_1\left(-k;|l|+1;\frac{|B|r^2}{2}\right)(0\leqslant k\leqslant m)\right)=(\text{L.H.})(r^{2k}(0\leqslant k\leqslant m)),$$

it follows after taking suitable linear combination of the orthonormal set $\{\Psi_{kl}:0\leqslant k\leqslant n\}$ with l fixed, that

$$\int_0^\infty\int_0^{2\pi}r^{2|l|+2m}e^{-(|B|r^2/4)}e^{il\theta}\overline{\Psi(r,\theta)}r\,dr\,d\theta=\int_0^\infty r^{2|l|+2m+1}e^{-(|B|r^2/4)}\int_0^{2\pi}e^{il\theta}\overline{\Psi(r,\theta)}\,d\theta\,dr=0$$

for all $m=0,1,2,\ldots$ and $l=0,\pm1,\pm2,\ldots$. By a further linear combination involving the complex parameter s, namely,

$$e_m(sr^2)=\sum_{k=0}^{m}\frac{(sr^2)^k}{k!}, \tag{3.1}$$

we obtain, by means of Lebesgue dominated convergence theorem[20] applied in terms of the following inequality:

$$|r^{2|l|+1}e_m(-sr^2)e^{-(|B|r^2/4)}e^{il\theta}| \leqslant r^{2|l|+1}e^{(|s|-(|B|/4))r^2}|\Psi(r,\theta)| \in L^1([0,\infty)\times[0,2\pi))$$

for all $m=0,1,2,\ldots$ and after taking limit $m\to\infty$, that the holomorphic function of variable s,

$$\int_0^\infty \int_0^{2\pi} r^{2|l|+1}e^{-(s+(|B|/4))r^2}e^{il\theta}\overline{\Psi(r,\theta)}dr = \int_0^\infty r^{2|l|+1}e^{-(s+(|B|/4))r^2}\int_0^{2\pi} e^{il\theta}\overline{\Psi(r,\theta)}d\theta dr = 0$$

for all s in the half-plane $\Re(s) > -(|B|/4)$. We arrive at this conclusion by means of analytic continuation of the fact that the immediately preceding holomorphic function takes on the value 0 if $|s|<|B|/4$. We make the substitution $r=\sqrt{t}$, and thus achieve

$$\int_0^\infty t^{|l|}e^{-(s+(|B|/4))t}\int_0^{2\pi} e^{il\theta}\overline{\Psi(\sqrt{t},\theta)}d\theta dt = 0 \quad \text{for all} \quad l=0,\pm 1,\pm 2,\ldots .$$

Utilizing the uniqueness of Laplace transform,[3] we conclude that

$$\int_0^{2\pi} e^{il\theta}\overline{\Psi(r,\theta)}d\theta = 0 \quad \text{a.e. in } r \text{ on } [0,\infty) \text{ for } l=0,\pm 1,\pm 2,\ldots .$$

In consequence hereof, there exist Lebesgue measurable subsets E_l of $[0,\infty)$, such that their complements in $[0,\infty)$ have one-dimensional Lebesgue measure zero, i.e., $\mu_1((0,\infty)\backslash E_l)=0$ for all $l=0,\pm 1,\pm 2,\ldots$. We define $E=\cap_{l=-\infty}^{\infty}E_l$ and note

$$\int_0^{2\pi} e^{il\theta}\overline{\Psi(r,\theta)}d\theta = 0 \quad \forall r\in E \quad \text{and} \quad \mu_1((0,\infty)\backslash E)=0,$$

which follows directly from

$$(0,\infty)\backslash\left(\bigcap_{l=-\infty}^{\infty} E_l\right) = \bigcup_{l=-\infty}^{\infty}((0,\infty)\backslash E_l) \quad \text{with} \quad \mu_1((0,\infty)\backslash E) \leqslant \sum_{l=-\infty}^{\infty}\mu_1((0,\infty)\backslash E_l)=0.$$

Thus it becomes clear that

$$\int_0^{2\pi} e^{il\theta}\overline{\Psi(r,\theta)}d\theta = 0 \quad \forall\ r\in E \ \text{ and } \ \forall\ l=0,\pm 1,\pm 2,\ldots .$$

Since $\Psi(r,\theta)\in\mathfrak{L}^2([0,\infty)\times[0,2\pi))$, namely,

$$\int_0^\infty\int_0^{2\pi}|\Psi(r,\theta)|^2 r d\theta dr = \int_0^{2\pi}\int_0^\infty |\Psi(r,\theta)|^2 r dr d\theta = \int\int_{[0,\infty)\times[0,2\pi)} |\Psi(r,\theta)|^2 d\mu(r,\theta) < \infty$$

with $d\mu(r,\theta)=rdrd\theta$, which follows from the Tonelli–Hobson theorem,[21] we may conclude without loss of generality that

$$\int_0^{2\pi} e^{il\theta}\overline{\Psi(r,\theta)}d\theta = 0 \quad \forall\ l=0,\pm 1,\pm 2,\ldots \ \text{ and } \ r\in E \ \text{ with } \ \Psi(r,\cdot)\in\mathfrak{L}^2[0,\infty).$$

We consequently have for $r\in E$ with $\Psi(r,\cdot)\in\mathfrak{L}^2[0,\infty)$ that

$$\int_0^{2\pi}|\Psi(r,\theta)|^2 d\theta = 0 \quad \text{for all } r \text{ satisfying } \int_0^{2\pi}|\Psi(r,\theta)|^2 d\theta < \infty.$$

Because this holds for almost all $r\in[0,\infty)$, it follows that

$$\int_0^\infty\int_0^{2\pi}|\Psi(r,\theta)|^2 r\,d\theta\,dr=0,$$

which in turn implies Ψ is a trivial $\mathfrak{L}^2([0,\infty)\times[0,2\pi))$-function. Hence $\{\Psi_{ml}:m=0,1,2,\ldots,l=0,\pm1,\pm2,\ldots\}$ is an orthonormal basis of $\mathfrak{L}^2([0,\infty)\times[0,2\pi))$. □

Thus $\{\Psi_{mln}:m=0,1,2,\ldots,l=0,\pm1,\pm2,\ldots,n=0,1,2,\ldots\}$ is an orthonormal basis of $\mathfrak{L}^2(\Sigma')=\mathfrak{L}^2([0,\infty)\times[0,2\pi))\otimes L^2[0,d]$.

We shall also consider the case where $|l|+l=0$, where in this case the spectrum takes the form

$$E(m,n)=|B|(2m+1)+\left(\frac{\pi(n+1)}{d}\right)^2. \tag{3.2}$$

We fix $l=0$ for the wave function ψ_{mnl} of (2.15). In this case $\psi_{mnl}:=\psi_{mn}$ can be written as $\psi_{mn}=\phi_m\otimes\chi_n$ where

$$\phi_m(r)=\sqrt{|B|}e^{-(|B|/4)r^2}\,{}_1F_1\left(-m;1;\frac{|B|r^2}{2}\right)\quad\text{and}\quad\chi_n(z)=\sqrt{\frac{2}{d}}\sin\left(\frac{\pi(n+1)z}{d}\right).$$

From (2.11) we have

$$\int_0^\infty e^{-(|B|/2)r^2}\,{}_1F_1\left(-n;1;\frac{|B|r^2}{2}\right)\,{}_1F_1\left(-m;1;\frac{|B|r^2}{2}\right)r\,dr=\frac{1}{|B|}\,\delta_{mn}.$$

Thus $\{\phi_m:m=0,1,2,\ldots\}$ is an orthonormal system in the Hilbert space $\mathfrak{L}^2[0,\infty)$.

Corollary 3.1: When $|B|$ and π^2/d^2 are irrationally related, the spectrum $E(m,n)$ of (3.2) is nondegenerate and the set of vectors

$$\{\psi_{mn}=\phi_m\otimes\chi_n:m=0,1,2,\ldots;n=0,1,2,\ldots\}$$

forms an orthonormal basis of the Hilbert space $\mathfrak{L}^2[0,\infty)\otimes L^2[0,d]$.

Proof: If we have two pairs (m,n) and (m',n') such that $E(m,n)=E(m',n')$, then

$$\frac{\pi^2}{|B|d^2}=\frac{2(m'-m)}{(n+1)^2-(n'+1)^2}$$

is a rational number. To prove $\mathfrak{B}_1=\{\psi_{mn}:m=0,1,2,\ldots;n=0,1,2,\ldots\}$ is an orthonormal basis of $\mathfrak{L}^2[0,\infty)\otimes L^2[0,d]$ it is enough to show that $\mathfrak{B}_2=\{\phi_m:\ m=0,1,2,\ldots\}$ is an orthonormal basis of $\mathfrak{L}^2[0,\infty)$. Suppose $\mathfrak{B}_2$ is not an orthonormal basis of $\mathfrak{L}^2[0,\infty)$, then there exists a nontrivial $\phi\in\mathfrak{L}^2[0,\infty)$ such that

$$\int_0^\infty\phi_m(r)\overline{\phi(r)}r\,dr=0$$

for all $m=0,1,2,\ldots$. Since

$$(\text{L.H.})\left({}_1F_1\left(-k;1;\frac{|B|r^2}{2}\right)(0\leqslant k\leqslant m)\right)=(\text{L.H.})(r^{2k}\ (0\leqslant k\leqslant m)),$$

we have after taking suitable linear combination of the orthonormal set $\{\phi_k:0\leqslant k\leqslant m\}$ that

$$\int_0^\infty r^{2m+1}e^{-(|B|r^2/2)}\overline{\phi(r)}\,dr=0\quad\text{for all}\quad m=0,1,2,\ldots\ .$$

By a further linear combination of (3.1) and by means of the Lebesgue dominated convergence theorem applied to

$$|e_m(-sr^2)e^{-(|B|r^2/4)}| \leqslant e^{|s|-(|B|r^2/4)}|\phi(r)| \in L^1[0,\infty); \quad m=0,1,2,\ldots$$

we obtain

$$\int_0^\infty e^{-(s+(|B|/4))r^2}\overline{\phi(r)}r\,dr=0$$

for all s such that $\Re e(s)>-(|B|/4)$. By letting $r=\sqrt{t}$ we have

$$\int_0^\infty e^{-st}e^{-(|B|t/4)}\overline{\phi(\sqrt{t})}\,dt=0$$

for all s such that $\Re e(s)>-(|B|/4)$. Uniqueness of the Laplace transform yields

$$e^{-(|B|t/4)}\overline{\phi(\sqrt{t})}=0 \text{ a.e. in } t \text{ on } [0,\infty) \quad \text{or} \quad \phi(r)=0 \text{ a.e. in } r \text{ on } [0,\infty)$$

and consequently

$$\int_0^\infty |\phi(r)|^2 r\,dr=0.$$

Hereby ϕ is trivial in $\mathfrak{L}^2([0,\infty))$, which contradict the assumption. Thus $\{\phi_m : m=0,1,2,\ldots\}$ is an orthonormal basis of $\mathfrak{L}^2[0,\infty)$. □

Remark 3.2: Since

$$\bigoplus_{l=-\infty}^{\infty} \mathfrak{L}^2[0,\infty)\otimes\{e^{il\theta}\}\otimes L^2[0,d]=\mathfrak{L}^2[0,\infty)\otimes L^2[0,2\pi)\otimes L^2[0,d],$$

one can prove for each fixed $l<0$ that the spectrum $E(m,n)$ is nondegenerate and the set of vectors $\{\psi_{mnl} : m=0,1,2,\ldots;\ n=0,1,2,\ldots;\ l \text{ fixed and } <0\}$ is an orthonormal basis of the subspace $\mathfrak{L}^2[0,\infty)\otimes\{e^{il\theta}\}\otimes L^2[0,d]$.

IV. GAZEAU–KLAUDER COHERENT STATES

In this section, we introduce the general features of Gazeau–Klauder CS. Let H be a Hamiltonian with a bounded below discrete spectrum $\{e_m\}_{m=0}^\infty$ and it has been adjusted so that $H\geqslant 0$. Further assume that the eigenvalues e_m are nondegenerate and arranged in increasing order $e_0<e_1<e_2<\cdots$. For such a Hamiltonian, a class of CS was suggested by Gazeau and Klauder,[9] the so-called *Gazeau–Klauder coherent states* (GKCS), as

$$|J,\alpha\rangle=\mathcal{N}(J)^{-1}\sum_{m=0}^{\infty}\frac{J^{m/2}e^{-ie_m\alpha}}{\sqrt{\rho(m)}}\eta_m, \tag{4.1}$$

where $J\geqslant 0$, $-\infty<\alpha<\infty$, $\{\eta_m\}_{m=0}^\infty$ is the set of eigenfunctions of the Hamiltonian and $\rho(m)=e_1e_2\cdots e_m=e_m!$. In order to be GKCS the states (4.1) need to satisfy the following:

(a) For each J,α the state is normalized, i.e., $1=\langle J,\alpha|J,\alpha\rangle=\mathcal{N}(J)^{-2}\Sigma_{m=0}^\infty J^m/\rho(m)$;
(b) the set of states $\{|J,\alpha\rangle : J\in[0,\infty),\alpha\in(-\infty,\infty)\}$ satisfies a resolution of the identity

$$\lim_{\delta\to\infty}\frac{1}{2\delta}\int_{-\delta}^{\delta}d\alpha\int_0^\infty \lambda(J)dJ|J,\alpha\rangle\langle J,\alpha|=I, \tag{4.2}$$

where $\lambda(J)$ is an appropriate weight function;

(c) the states are temporally stable, i.e., $e^{-iHt}|J,\alpha\rangle=|J,\alpha+t\rangle$;
(d) the states satisfy the action identity, i.e., $\langle J,\alpha|H|J,\alpha\rangle=J$.

Condition (d) requires $e_0=0$. In the case where only conditions (a)–(c) are satisfied we phrase the resulting CS as "temporally stable CS." In the case where $e_0\neq 0$ one can shift the spectrum backward by e_0 and work with the shifted spectrum.

The dynamical algebra of the system can be defined as follows: The generalized annihilation, creation, and number operators defined on the state Hilbert space $\mathfrak{H}$ with respect to the basis $\{\eta_m\}_{m=0}^{\infty}$ can be given by (see Refs. 1, 12, 17)

$$\begin{aligned}\mathfrak{a}\eta_m&=\sqrt{e_m}\,\eta_{m-1},\quad \text{with}\quad \mathfrak{a}\eta_0=0,\\ \mathfrak{a}^\dagger\eta_m&=\sqrt{e_{m+1}}\,\eta_{m+1},\\ \mathfrak{n}\eta_m&=e_m\eta_m\quad(\mathfrak{n}=\mathfrak{a}^\dagger\mathfrak{a}),\end{aligned}\tag{4.3}$$

and the commutators take the form

$$\begin{aligned}[\mathfrak{a},\mathfrak{a}^\dagger]\eta_m&=(e_{m+1}-e_m)\eta_m,\\ [\mathfrak{n},\mathfrak{a}^\dagger]\eta_m&=(e_{m+1}-e_m)\mathfrak{a}^\dagger\eta_m,\\ [\mathfrak{n},\mathfrak{a}]\eta_m&=(e_{m-1}-e_m)\mathfrak{a}\eta_m.\end{aligned}\tag{4.4}$$

The algebra generated by the operators $\{\mathfrak{a},\mathfrak{a}^\dagger,\mathfrak{n}\}$ and its deformations (up to isomorphisms) serve as a dynamical algebra of the Hamiltonian.

In Ref. 16 the definition (4.1) was generalized to multidimensions as

$$|\mathbf{J},\mathbf{b}\rangle=\mathcal{N}(\mathbf{J})^{-1}\sum_{\{n_1,\ldots,n_r\}}\frac{\mathbf{J}^{\mathbf{n}/2}}{\sqrt{\rho(\mathbf{n})}}e^{-i\mathbf{b}e(\mathbf{n})}|\mathbf{n}\rangle,\tag{4.5}$$

where the sum runs over all possible values of the variables n_j, $\mathcal{N}$ is a normalization factor, and $\rho(\mathbf{n})$ is an arbitrary positive function of all the indices. Further, $\mathbf{J}^{\mathbf{n}/2}=\Pi_{j=1}^{r}J_j^{n_j/2}$, $\mathbf{b}\cdot e(\mathbf{n})=\alpha_1e_1(\mathbf{n})+\cdots+\alpha_re_r(\mathbf{n})$ and $|\mathbf{n}\rangle=|n_1\rangle\otimes\cdots\otimes|n_r\rangle$, where $\{|n_j\rangle\}$ forms an orthonormal basis for an appropriate Hilbert space $\mathfrak{H}_j$. Using (4.5) GKCS for the rth degree of freedom is defined as

$$|n_1,\ldots,n_{r-1},J_r,\alpha_r\rangle=\mathcal{N}_r(J_r)^{-1}\sum_{n_r}\frac{J_r^{n_r/2}}{\sqrt{\rho_r}}e^{-i\alpha_re_r(\mathbf{n})}|\mathbf{n}\rangle,\tag{4.6}$$

where the normalization factor $\mathcal{N}_r$ and the function ρ_r may depend on the other indices. In addition to the normalization condition, when $n_1,\ldots,n_{r-1}$ are fixed, the states (4.6) should satisfy a resolution of the identity on the subspace obtained by fixing $n_1,n_2,\ldots,n_{r-1}$:

$$\int|n_1,\ldots,n_{r-1},J_r,\alpha_r\rangle\langle n_1,\ldots,n_{r-1},J_r,\alpha_r|\,d\mu(J_r,\alpha_r)=I_{n_1,n_2,\ldots,n_{r-1}}.\tag{4.7}$$

For the multidimensional case, if one takes $\rho_j(\mathbf{n})=\rho_j(n_1,n_2,\ldots,n_j)$ and $e_j(\mathbf{n})=e_j(n_1,n_2,\ldots,n_j)$,

$$|\mathbf{J},\mathbf{b}\rangle=\mathcal{N}_1^{-1}\sum_{n_1}\frac{J_1^{n_1/2}}{\sqrt{\rho_1}}e^{i\alpha_1e_1}\mathcal{N}_2^{-1}\sum_{n_2}\frac{J_2^{n_2/2}}{\sqrt{\rho_2}}e^{i\alpha_2e_2}\cdots\mathcal{N}_r^{-1}\sum_{n_r}\frac{J_r^{n_r/2}}{\sqrt{\rho_r}}e^{i\alpha_re_r}|\mathbf{n}\rangle,\tag{4.8}$$

where $\mathcal{N}_j=\mathcal{N}_j(J_j,\ldots,J_r;n_1,\ldots,n_{j-1})$. If ρ_j and e_j are independent of n_k, $k<j$ then the states (4.8) may give us simple tensor product of states. For the states (4.8) a resolution of the identity takes the following form:

$$\lim_{\delta\to\infty}\frac{1}{2\delta}\int_{-\delta}^{\delta}d\alpha_1\int_0^{\infty}\lambda_1(J_1)\lim_{\delta\to\infty}\frac{1}{2\delta}\int_{-\delta}^{\delta}d\alpha_2\int_0^{\infty}\lambda_1(J_1,J_2,n_1)\cdots\lim_{\delta\to\infty}\frac{1}{2\delta}\int_{-\delta}^{\delta}d\alpha_r$$
$$\times\int_0^{\infty}\lambda_r(J_1,\ldots,J_r,n_1,\ldots,n_{r-1})|n_1,\ldots,n_r,\mathbf{J},\mathbf{b}\rangle\langle n_1,\ldots,n_r,\mathbf{J},\mathbf{b}|dJ_1\cdots dJ_r$$
$$=I_{\mathfrak{H}_1}\otimes\cdots\otimes I_{\mathfrak{H}_r},$$

where λ_j, $j=1,2,\ldots,r$ are positive weight functions. For the multidimensional case, the temporal stability and the action identity can also be added. We will discuss these issues through the problem of this paper in Sec. VI.

In the following sections, when $l=0$ we derive temporally stable CS for the Hamiltonian H_0 with the spectrum $E(m,n)$ on the subspace $\mathfrak{L}^2[0,\infty)\otimes 1/\sqrt{2\pi}\otimes L^2[0,d]$, which is indeed a subspace of $\mathfrak{L}^2(\Sigma)$. However, $\mathfrak{L}^2[0,\infty)\otimes 1/\sqrt{2\pi}\otimes L^2[0,d]$ is isomorphic (in the Hilbert space sense) to $1/\sqrt{2\pi}\otimes\mathfrak{L}^2[0,\infty)\otimes L^2[0,d]$ as subspaces of $\mathfrak{L}^2[0,\infty)\otimes L^2[0,2\pi]\otimes L^2[0,d]$ and $L^2[0,2\pi]\otimes\mathfrak{L}^2[0,\infty)\otimes L^2[0,d]$, respectively. Nevertheless, the subspace $1/\sqrt{2\pi}\otimes\mathfrak{L}^2[0,\infty)\otimes L^2[0,d]$ is (Hilbert space) isomorphic to $\mathfrak{L}^2[0,\infty)\otimes L^2[0,d]$ and hence, we may consider the Hilbert space $\mathfrak{L}^2[0,\infty)\otimes L^2[0,d]$ instead of the subspace $\mathfrak{L}^2[0,\infty)\otimes 1/\sqrt{2\pi}\otimes L^2[0,d]$ to which it is isomorphic. Therefore, the action of the Hamiltonian H_0 on $\mathfrak{L}^2[0,\infty)\otimes 1/\sqrt{2\pi}\otimes L^2[0,d]$ carries to the Hilbert space $\mathfrak{L}^2[0,\infty)\otimes L^2[0,d]$. Hereafter we refer the Hilbert space $\mathfrak{L}^2[0,\infty)\otimes L^2[0,d]$ as the state Hilbert space of the Hamiltonian H_0 for $l=0$.

The GKCS studied in Ref. 8 for the Landau levels may be regarded as a set of GKCS constructed in the absence of n and l from the spectrum $E(m,l,n)$ of (2.12). The GK-like CS (in the terminology of Ref. 16) studied in Ref. 16 can be taken as a class of CS for the spectrum $E(m,l,n)$ in the absence of n.

V. CS WITH ONE DEGREE OF FREEDOM

We introduce two classes of temporally stable CS with the form (4.6) for the spectrum (3.2), by first fixing n followed by another class where m is fixed. In both cases the orthonormal basis is denoted by the same symbol $\psi_{m,n}$. However, it should be clear that in each case the other index is fixed and the vectors $\psi_{m,n}$ belong to the corresponding subspace of the state Hilbert space $\mathfrak{L}^2[0,\infty)\otimes L^2[0,d]$. For sake of simplicity $|B|:=B$.

A. When *n* is fixed

Here we discuss a class of temporally stable CS for the first degree of freedom (the freedom through m). Since the energy spectrum of the Landau problem is $E_m=B(2m+1)$, the following set of CS can also be considered as a set of CS with a forward shift of the Landau levels. Further, the construction also serves as a preparatory step of the formation of CS for two degrees of freedom. Let

$$\rho(m)=E(1,n)E(2,n)\cdots E(m,n),$$

where $E(m,n)$ is given by (3.2). We have

$$\rho(m)=\prod_{k=1}^{m}\left(B(2k+1)+\left(\frac{\pi(n+1)}{d}\right)^2\right)=(2B)^m(\gamma)_m,$$

where

$$\gamma = 1 + \frac{Bd^2 + \pi^2 (n+1)^2}{2Bd^2}.$$

Let us study the following class of vectors:

$$|J,\alpha,n\rangle = \mathcal{N}(J,n)^{-1} \sum_{m=0}^{\infty} \frac{J^{m/2} e^{-iE(m,n)\alpha}}{\sqrt{\rho(m)}} \psi_{m,n}. \tag{5.1}$$

The normalization condition $\langle J,\alpha,n|J,\alpha,n\rangle = 1$ yields

$$\mathcal{N}(J,n)^2 = \sum_{m=0}^{\infty} \frac{J^m}{2^m B^m (\gamma)_m} = {}_1F_1\left(1;\gamma;\frac{J}{2B}\right) > 0, \tag{5.2}$$

which converges for all $J>0$. For a resolution of the identity, let $-\infty<\alpha<\infty$ and set a measure

$$d\mu(J,\alpha) = d\nu(J)d\alpha = \frac{1}{2^\gamma B^\gamma \Gamma(\gamma)} {}_1F_1\left(1;\gamma;\frac{J}{2B}\right) e^{-(J/2B)} J^{\gamma-1} dJ d\alpha.$$

The knowledge of Eqs. (4.2) and (4.7) leads to

$$\begin{aligned}
\int_0^\infty \int |J,\alpha,n\rangle\langle J,\alpha,n| d\mu(J,\alpha) &= \sum_{m=0}^{\infty} \sum_{l=0}^{\infty} \frac{|\psi_{m,n}\rangle\langle\psi_{l,n}|}{\sqrt{\rho(m)\rho(l)}} \int_0^\infty \int \frac{J^{m/2+l/2}}{\mathcal{N}(J,n)^2} e^{i(E(m,n)-E(l,n))\alpha} d\nu(J) d\alpha \\
&= \sum_{m=0}^{\infty} \frac{|\psi_{m,n}\rangle\langle\psi_{m,n}|}{2^{m+\gamma} B^{m+\gamma} (\gamma)_m \Gamma(\gamma)} \int_0^\infty J^{m+\gamma-1} e^{-(J/2B)} dJ \\
&= \sum_{m=0}^{\infty} |\psi_{m,n}\rangle\langle\psi_{m,n}| = I_n,
\end{aligned}$$

where we employed the identity[5]

$$\int_0^\infty e^{-ax} x^{s-1} dx = a^{-s}\Gamma(s) \tag{5.3}$$

with $s = m+\gamma$ and $a = 1/2B$. For the temporal stability, since for fixed n

$$H_0 \psi_{m,n} = E(m,n)\psi_{m,n}, \qquad m = 0,1,2,\ldots$$

and

$$e^{-iE(m,n)\alpha} e^{-iH_0 t} \psi_{m,n} = e^{-iE(m,n)\alpha} e^{-iE(m,n)t} \psi_{m,n} = e^{-iE(m,n)(\alpha+t)} \psi_{m,n}$$

we have

$$e^{-iH_0 t} |J,\alpha,n\rangle = |J,\alpha+t,n\rangle. \tag{5.4}$$

Thus the states $|J,\alpha,n\rangle$ form a set of temporally stable CS. Since $E(0,n) \neq 0$ the action identity cannot be obtained. The overlap of two states takes the form

$$\langle J,\alpha,n|J',\alpha',n\rangle = \frac{e^{-i(\alpha-\alpha')(B+(\pi^2(n+1)^2/d^2))}}{\sqrt{{}_1F_1\left(1;\gamma;\frac{J}{2B}\right) {}_1F_1\left(1;\gamma;\frac{J'}{2B}\right)}} {}_1F_1\left(1;\gamma;\frac{JJ' e^{-2iB(\alpha-\alpha')}}{2B}\right).$$

If $\alpha=\alpha'$ we get

$$\langle J,\alpha,n|J',\alpha,n\rangle=\frac{{}_1F_1\left(1;\gamma;\frac{\sqrt{JJ'}}{2B}\right)}{\sqrt{{}_1F_1\left(1;\gamma;\frac{J}{2B}\right)\ {}_1F_1\left(1;\gamma;\frac{J'}{2B}\right)}}.$$

Remark 5.1: (a) In (5.1) instead of taking $\rho(m)=E(1,n)\cdots E(m,n)$ if we take $\rho(m)=e(1,m)\cdots e(m,n)$ with $e(m,n)=E(m,n)-E(0,n)$, then we can have $0=e(0,n)<e(1,n)<\cdots$ and thereby we can have a set of GKCS. In this case, $\rho(m)=2^mB^m m!$, $\mathcal{N}(J)^2=e^{J/(2B)}$ and a resolution of the identity is obtained with the measure $d\mu(J,\alpha)=(1/2B\mathcal{N}^2(J))\,e^{-J/(2B)}d\alpha dJ$. The temporal stability and the action identity follow straightforwardly.

(b) The spectrum of the isotonic oscillator

$$H=-\frac{d^2}{dx^2}+x^2+\frac{A}{x^2}\qquad(A\geqslant 0)$$

is $\epsilon_m=2(2m+\gamma)$, where $\gamma=1+\frac{1}{2}\sqrt{1+4A}$. Since this spectrum is nondegenerate and the eigenfunctions form an orthonormal basis of the Hilbert space $L^2[0,\infty)$,[19] when $B=2$ and ψ_{mn} is replaced by the wave functions of H, the set of CS given in (5.1) can also be considered as a set of temporally stable CS for H with a forward shift of the spectrum.

B. When *m* is fixed

We discuss a class of temporally stable CS for the second degree of freedom obtained through n by fixing m. That is, the following class of CS can be considered as a class of CS constructed with the effective part of the spectrum due to the infinite layer. The other aim of this subsection is to facilitate the calculations of the following sections. For fixed m let

$$\rho(n)=E(m,1)E(m,2)\cdots E(m,n).$$

Thereby

$$\rho(n)=\prod_{k=1}^{n}\left(B(2m+1)+\left(\frac{\pi(k+1)}{d}\right)^2\right)=\left(\frac{\pi}{d}\right)^{2n}(\beta)_n(\overline{\beta})_n,$$

where

$$\beta=2+\frac{id}{\pi}\sqrt{B(2m+1)}$$

and $\overline{\beta}$ is the complex conjugate of β. Note that, the product $(\beta)_n(\overline{\beta})_n$ is a real positive number. Consider the set of vectors

$$|J,\alpha,m\rangle=\mathcal{N}(J,m)^{-1}\sum_{n=0}^{\infty}\frac{J^{n/2}}{\sqrt{\rho(n)}}e^{-iE(m,n)\alpha}\psi_{m,n}. \tag{5.5}$$

The normalization factor $\mathcal{N}(J,m)$ is obtained, by demanding $\langle J,\alpha,m|J,\alpha,m\rangle=1$, in the following form:

$$\mathcal{N}(J,m)^2=\sum_{n=0}^{\infty}\frac{J^n}{\rho(n)}=\sum_{n=0}^{\infty}\frac{\left(\frac{d^2J}{\pi^2}\right)^n}{(\beta)_n(\overline{\beta})_n}={}_1F_2\left(1;\overline{\beta},\beta;\frac{d^2J}{\pi^2}\right), \tag{5.6}$$

which is a real positive function and defined for all $J\geqslant 0$. For $J>0$ and $-\infty<\alpha<\infty$ set

$$d\mu(J,\alpha)=\mathcal{N}(J,m)^2\lambda(J)dJd\alpha.$$

For a resolution of the identity, we have

$$\int_0^{\infty}\int|J,\alpha,m\rangle\langle J,\alpha,m|d\mu(J,\alpha)=\sum_{n=0}^{\infty}\frac{|\psi_{m,n}\rangle\langle\psi_{m,n}|}{\rho(n)}\int_0^{\infty}J^n\lambda(J)dJ=\sum_{n=0}^{\infty}|\psi_{m,n}\rangle\langle\psi_{m,n}|=I_m$$

if there is a density $\lambda(J)$ to satisfy

$$\int_0^{\infty}J^n\lambda(J)dJ=\rho(n)=\left(\frac{\pi}{d}\right)^{2n}(\beta)_n(\overline{\beta})_n. \tag{5.7}$$

Since

$$\int_0^{\infty}2K_{2\eta}(2\sqrt{x})x^{s-1}dx=\Gamma(s-\eta)\Gamma(s+\eta) \tag{5.8}$$

the density

$$\lambda(J)=\frac{2d^2}{\pi^2\Gamma(\beta)\Gamma(\overline{\beta})}K_{\beta-\overline{\beta}}\left(\frac{2d}{\pi}\sqrt{J}\right) \tag{5.9}$$

satisfies (5.7), where K is the modified Bessel function of the third kind of imaginary order[4] and may be regarded as the kernel of the Kontorovich–Lebedev transform[15] in the light of (5.8). The temporal stability follows similar to the previous case. Thus we have a set of temporally stable CS without the action identity. As in the previous case, when $\alpha=\alpha'$ the overlap of two states takes the form

$$\langle J,\alpha,m|J',\alpha,m\rangle=\frac{{}_1F_2\left(1;\overline{\beta},\beta;\frac{d^2\sqrt{JJ'}}{\pi^2}\right)}{\sqrt{{}_1F_2\left(1;\overline{\beta},\beta;\frac{d^2J}{\pi^2}\right)\ {}_1F_2\left(1;\overline{\beta},\beta;\frac{d^2J'}{\pi^2}\right)}}.$$

Remark 5.2: (a) Let $E_n=E(m,n)-E(m,0)$. In (5.5) if we replace the $\rho(n)=E(m,1)\cdots E(m,n)$ by $\rho(n)=E_1\cdots E_n=n!(n+2)!/2$ we can have the action identity and thereby a class of GKCS. In this case the normalization factor takes the form $\mathcal{N}(J)^2=J/[2I_2(2\sqrt{J})]$ and a resolution of the identity can be obtained with the measure $d\mu(J,\alpha)=\mathcal{N}(J)^2\lambda(J)d\alpha dJ$, where

$$\lambda(J)=\frac{1}{2}G_{0,2}^{2,0}\left(J\ \middle|\ \begin{matrix}-\\2,0\end{matrix}\right),$$

which is given in terms of the MeijerG-function (see Ref. 14, p. 303, formula (37)).

(b) A class of GKCS for the infinite well potential with the spectrum $\mathbf{e}_n = n(n+2)$ is given in Ref. 2. When $d=\pi$ the above class of CS can be considered as a class of temporally stable CS for the infinite well with a forward shift of the spectrum. In this case the state Hilbert space has to be replaced by the Hilbert space of the infinite well.

VI. CS WITH TWO DEGREES OF FREEDOM

In this section we present two different classes of CS with two degrees of freedom in the form (4.8). In the first case, we present a class of CS as a tensor product of two classes of states by setting ρ_1, ρ_2, e_1, and e_2 independent. In the second case, within the multiple sum, by letting one sum depends on the other through ρ_1, ρ_2, e_1, and e_2, we present a class of CS where the resulting CS cannot be considered as a tensor product of two states. Further, both classes are considered as temporally stable CS for the Hamiltonian H_0 with the spectrum $E(m,n)$.

A. When summations are independent

Let $e_m = B(2m+1)$, $\epsilon_n = [\pi(n+1)/d]^2$, $\rho_1(m) = e_1 e_2 \cdots e_m = e_m!$, and $\rho_2(n) = \epsilon_1 \epsilon_2 \cdots \epsilon_n = \epsilon_n!$. Thus

$$\rho_1(m) = \prod_{k=1}^{m} [B(2k+1)] = 2^m B^m \left(\frac{3}{2}\right)_m ,$$

$$\rho_2(n) = \prod_{j=1}^{n} \left(\frac{\pi(j+1)}{d}\right)^2 = \left(\frac{\pi}{d}\right)^{2n} (2)_n (2)_n .$$

The set of vectors under consideration is as follows:

$$|J_1, J_2, \alpha_1, \alpha_2\rangle = \mathcal{N}_1(J_1)^{-1} \mathcal{N}_2(J_2)^{-1} \left[\sum_{m=0}^{\infty} \frac{J_1^{m/2}}{\sqrt{\rho_1(m)}} e^{-i e_m \alpha_1} \sum_{n=0}^{\infty} \frac{J_2^{n/2}}{\sqrt{\rho_2(n)}} e^{-i \epsilon_n \alpha_2} \phi_m \otimes \chi_n \right]. \tag{6.1}$$

Since

$$\langle J_1, J_2, \alpha_1, \alpha_2 | J_1, J_2, \alpha_1, \alpha_2 \rangle = \mathcal{N}_1(J_1)^{-2} \sum_{m=0}^{\infty} \frac{J_1^m}{\rho_1(m)} \mathcal{N}_2(J_2)^{-2} \sum_{n=0}^{\infty} \frac{J_2^n}{\rho_2(n)},$$

the normalization requirement $\langle J_1, J_2, \alpha_1, \alpha_2 | J_1, J_2, \alpha_1, \alpha_2 \rangle = 1$ yields

$$\mathcal{N}_2(J_2)^2 = \sum_{n=0}^{\infty} \frac{J_2^n}{\rho_2(n)} = \sum_{n=0}^{\infty} \frac{1}{(2)_n \ (2)_n} \left(\frac{d^2 J_2}{\pi^2}\right)^n = {}_1F_2\left(1; 2, 2; \frac{d^2 J_2}{\pi^2}\right)$$

and

$$\mathcal{N}_1(J_1)^2 = \sum_{m=0}^{\infty} \frac{J_1^m}{2^m B^m \left(\frac{3}{2}\right)_m} = {}_1F_1\left(1; \frac{3}{2}; \frac{J_1}{2B}\right).$$

For $J_1, J_2 \in (0,\infty)$ and $-\infty < \alpha_1, \alpha_2 < \infty$, let us assume that the measure

$$d\mu(J_1, J_2, \alpha_1, \alpha_2) = \mathcal{N}_1(J_1)^2 \mathcal{N}_2(J_2)^2 \lambda_1(J_1) \lambda_2(J_2) dJ_1 dJ_2 d\alpha_1 d\alpha_2 . \tag{6.2}$$

The weight functions $\lambda_1(J_1)$ and $\lambda_2(J_2)$ will be chosen to satisfy a resolution of the identity. In this case, we have

$$\int_0^\infty \int_0^\infty \int \int |J_1,J_2,\alpha_1,\alpha_2\rangle\langle J_1,J_2,\alpha_1,\alpha_2| d\mu(J_1,J_2,\alpha_1,\alpha_2)$$

$$= \sum_{m=0}^{\infty} \frac{|\phi_m\rangle\langle\phi_m|}{\rho_1(m)} \int_0^\infty J_1^m \lambda_1(J_1) dJ_1 \otimes \sum_{n=0}^{\infty} \frac{|\chi_n\rangle\langle\chi_n|}{\rho_2(n)} \int_0^\infty J_2^n \lambda_2(J_2) dJ_2$$

$$= \sum_{m=0}^{\infty} |\phi_m\rangle\langle\phi_m| \otimes \sum_{n=0}^{\infty} |\chi_n\rangle\langle\chi_n| = I_{\mathfrak{L}^2[0,\infty)} \otimes I_{L^2[0,d]}$$

under the assumption that the densities $\lambda_1(J_1)$ and $\lambda_2(J_2)$ are such that

$$\int_0^\infty J_1^m \lambda_1(J_1) dJ_1 = \rho_1(m) = 2^m B^m \left(\frac{3}{2}\right)_m \tag{6.3}$$

and

$$\int_0^\infty J_2^n \lambda_2(J_2) dJ_2 = \rho_2(n) = \left(\frac{\pi}{d}\right)^{2n} (2)_n (2)_n . \tag{6.4}$$

The density

$$\lambda_1(J_1) = \sqrt{\frac{J}{2\pi B^3}} e^{-(J/2B)}$$

satisfies (6.3) and the density

$$\lambda_2(J_2) = \frac{2d^4}{\pi^4 J_2} K_0\left(\frac{2d\sqrt{J_2}}{\pi}\right),$$

where K_0 is the modified Bessel function of order 0, will prove (6.4). Since $\psi_{m,n} = \phi_m \otimes \chi_n$ and $H_0 \psi_{m,n} = E(m,n)\psi_{m,n}$ we have

$$H_0(\phi_m \otimes \chi_n) = (e_m + \epsilon_n)\phi_m \otimes \chi_n .$$

Therefore, we have

$$e^{-iH_0 t} \phi_m \otimes \chi_n = e^{-i(e_m+\epsilon_n)t} \phi_m \otimes \chi_n$$

and thereby

$$e^{-iH_0 t} |J_1,J_2,\alpha_1,\alpha_2\rangle = |J_1,J_2,\alpha_1+t,\alpha_2+t\rangle.$$

Thus the states $|J_1,J_2,\alpha_1,\alpha_2\rangle$ are temporally stable.

Remark 6.1: (a) Since $H_0\phi_m \otimes \chi_n = (e_m+\epsilon_n)\phi_m \otimes \chi_n$, even under the assumption $e_0 = \epsilon_0 = 0$ (i.e., even if we shift the spectrum backward), we cannot have the action identity. Therefore, we only have a set of temporally stable CS.

(b) If we shift e_m and ϵ_n backward by e_0 and ϵ_0 we get $\tilde{e}_m = e_m - e_0 = 2Bm$ and $\tilde{\epsilon}_n = \epsilon_n - \epsilon_0 = \pi^2 n(n+2)/d^2$ and thereby $\tilde{\rho}_1(m) = \tilde{e}_1 \cdots \tilde{e}_m = 2^m B^m m!$ and $\tilde{\rho}_2(n) = \tilde{\epsilon}_n \cdots \tilde{\epsilon}_n = \pi^{2n} n!(n+2)!/(2d^{2n})$. In (6.1) when we replace $\rho_1(m), \rho_2(n), e_m$ and ϵ_n by $\tilde{\rho}_1(m), \tilde{\rho}_2(n), \tilde{e}_m$ and $\tilde{\epsilon}_n$ we get

$$\tilde{\mathcal{N}}_2(J_2)^2 = {}_0F_1\left(-;3;\frac{J_2 d^2}{\pi^2}\right) = \frac{2\pi^2}{J_2 d^2} I_2\left(\frac{2d\sqrt{J_2}}{\pi}\right)$$

and

$$\tilde{\mathcal{N}}_1(J_1)^2 = e^{J_1/2B}.$$

In this case, a resolution of the identity is obtained with the measure

$$d\mu(J_1,J_2,\alpha_1,\alpha_2) = \tilde{\mathcal{N}}_1(J_1)^2 \tilde{\mathcal{N}}_2(J_2)^2 \tilde{\lambda}_1(J_1)\tilde{\lambda}_2(J_2) dJ_1 dJ_2 d\alpha_1 d\alpha_2,$$

where

$$\tilde{\lambda}_1(J_1) = \frac{1}{2B} e^{-J_1/(2B)}$$

and

$$\tilde{\lambda}_2(J_2) = \frac{\pi^2}{2d^2} G^{2,0}_{0,2}\left(\frac{J_2\pi^2}{d^2} \;\Big|^{-}_{2,0} \right).$$

The temporal stability follows easily.

B. When summations depend one on the other

For fixed m let

$$\rho_1(m,n) = E(m,1)E(m,2)\cdots E(m,n).$$

From Sec. V B we have

$$\rho_1(m,n) = \left(\frac{\pi}{d}\right)^{2n} (\beta)_n (\overline{\beta})_n,$$

where β and $\overline{\beta}$ are as in Sec. V B. Let

$$\rho_2(m) = e_1 \cdots e_m = 2^m B^m \left(\frac{3}{2}\right)_m.$$

Consider the following set of vectors:

$$|J_1,J_2,\alpha_1,\alpha_2\rangle = \mathcal{N}_1(J_1,J_2)^{-1} \sum_{m=0}^{\infty} \frac{J_1^{m/2}}{\sqrt{\rho_2(m)}} e^{-ie_m\alpha_1} \mathcal{N}_2(J_2,m)^{-1}$$

$$\times \sum_{n=0}^{\infty} \frac{J_2^{n/2}}{\sqrt{\rho_1(m,n)}} e^{-i\epsilon_n\alpha_2} \phi_m \otimes \chi_n. \tag{6.5}$$

In order to obtain the normalization factor let us compute the norm of the vector $|J_1,J_2,\alpha_1,\alpha_2\rangle$,

$$\langle J_1,J_2,\alpha_1,\alpha_2|J_1,J_2,\alpha_1,\alpha_2\rangle = \mathcal{N}_1(J_1,J_2)^{-2} \sum_{m=0}^{\infty} \frac{J_1^m}{\rho_2(m)} \mathcal{N}_2(J_2,m)^{-2} \sum_{n=0}^{\infty} \frac{J_2^n}{\rho_1(m,n)} = 1$$

if

$$\mathcal{N}_2(J_2,m)^2 = \sum_{n=0}^{\infty} \frac{J_2^n}{\rho_1(m,n)} \tag{6.6}$$

and

$$\mathcal{N}_1(J_1,J_2)^2=\sum_{m=0}^{\infty}\frac{J_1^m}{\rho_2(m)\mathcal{N}_2(J_2,m)^2}. \tag{6.7}$$

By (5.6) we have

$$\mathcal{N}_2(J_2,m)^2={}_1F_2\left(1;\beta,\overline{\beta};\frac{d^2J_2}{\pi^2}\right)\geqslant 1 \quad \forall \quad J_2\in(0,\infty).$$

Thus, we have

$$\mathcal{N}_1(J_1,J_2)^2=\sum_{m=0}^{\infty}\frac{J_1^m}{\rho_2(m)\,{}_1F_2\left(1;\overline{\beta},\beta;\frac{d^2J_2}{\pi^2}\right)}\leqslant\sum_{m=0}^{\infty}\frac{J_1^m}{\rho_2(m)}=\sum_{m=0}^{\infty}\frac{\left(\frac{J_1}{2B}\right)^m}{\left(\frac{3}{2}\right)_m}={}_1F_1\left(1;\frac{3}{2};\frac{J_1}{2B}\right),$$

which converges for all $J_1\geqslant 0$. For $J_1,J_2\in[0,\infty)$ and $-\infty<\alpha_1,\alpha_2<\infty$ we have

$$\begin{aligned}&\int_0^{\infty}\int_0^{\infty}\int\int|J_1,J_2,\alpha_1,\alpha_2\rangle\langle J_1,J_2,\alpha_1,\alpha_2|\lambda_1(J_1)\lambda_2(J_2,m)dJ_1dJ_2d\alpha_1d\alpha_2\\&=\sum_{m=0}^{\infty}\sum_{n=0}^{\infty}\frac{|\phi_m\rangle\langle\phi_m|\otimes|\chi_n\rangle\langle\chi_n|}{\rho_2(m)\rho_1(m,n)}\int_0^{\infty}\frac{J_1^m}{\mathcal{N}_1(J_1,J_2)^2}\lambda_1(J_1)dJ_1\int_0^{\infty}\frac{J_2^n}{\mathcal{N}_2(J_2,m)^2}\lambda_2(J_2,m)dJ_2\\&=\sum_{m=0}^{\infty}\sum_{n=0}^{\infty}|\phi_m\langle\phi_m|\otimes|\chi_n\rangle\langle\chi_n|=I_{\mathfrak{L}^2[0,\infty)}\otimes I_{L^2[0,d]}\end{aligned}$$

if there are densities $\lambda_1(J_1)$ and $\lambda_2(J_2,m)$ such that

$$\int_0^{\infty}\frac{J_1^m}{\mathcal{N}_1(J_1,J_2)^2}\lambda_1(J_1)dJ_1\int_0^{\infty}\frac{J_2^n}{\mathcal{N}_2(J_2,m)^2}\lambda_2(J_2,m)dJ_2=\rho_2(m)\rho_1(m,n). \tag{6.8}$$

Let

$$\lambda_2(J_2)=\mathcal{N}_2(J_2,m)^2\Lambda_2(J_2,m) \qquad \text{and} \qquad \lambda_1(J_1)=\mathcal{N}_1(J_1,J_2)^2\Lambda_1(J_1).$$

Then (6.8) reduces to

$$\int_0^{\infty}J_1^m\Lambda_1(J_1)dJ_1\int_0^{\infty}J_2^n\Lambda_2(J_2,m)dJ_2=\rho_2(m)\rho_1(m,n). \tag{6.9}$$

If we combine (6.3) and (6.4) we can have (6.9). Thus we have a resolution of the identity. By the same argument of Sec. VI A we have

$$e^{-iH_0t}|J_1,J_2,\alpha_1,\alpha_2\rangle=|J_1,J_2,\alpha_1+t,\alpha_2+t\rangle.$$

Thus the states $|J_1,J_2,\alpha_1,\alpha_2\rangle$ are temporally stable.

Remark 6.2: (a) Instead of defining the states as in (6.5), if we define them as (notice that the change will not affect the calculations preceding this remark; thereby the following class of vectors also forms a set of CS)

$$|J_1,J_2,\alpha_1,\alpha_2\rangle=\mathcal{N}_1(J_1,J_2)^{-1}\sum_{m=0}^{\infty}\frac{J_1^{m/2}}{\sqrt{\rho_2(m)}}e^{-ie_m\alpha_1}\mathcal{N}_2(J_2,m)^{-1}$$

$$\times\sum_{n=0}^{\infty}\frac{J_2^{n/2}}{\sqrt{\rho_1(m,n)}}e^{-iE(m,n)\alpha_2}\phi_m\otimes\chi_n, \tag{6.10}$$

we can have

$$e^{iH_0t}|J_1,J_2,\alpha_1,\alpha_2\rangle=|J_1,J_2,\alpha_1,\alpha_2+t\rangle.$$

Still we have the temporal stability, but only the second part of the states evolve with time. In this case, if we shift the spectrum so that $E(m,0)=0$ we can have an action identity in the following sense:

$$\langle J_1,J_2,\alpha_1,\alpha_2|H_0|J_1,J_2,\alpha_1,\alpha_2\rangle=\mathcal{N}_1(J_1,J_2)^{-2}\sum_{m=0}^{\infty}\frac{J_1^m}{\rho_2(m)}\mathcal{N}_2(J_2,m)^{-2}\sum_{n=1}^{\infty}\frac{J_2^mE(m,n)}{\rho_1(m,n)}=J_2.$$

(b) If we shift e_m and $E(m,n)$ backward by e_0 and $E(m,0)$ we get $\tilde{e}_m=e_m-e_0=2Bm$ and $\tilde{E}(m,n)=E(m,n)-E(m,0)=\pi^2n(n+2)/d^2$, which is the same case considered in Remark 6.1.

VII. DYNAMICAL ALGEBRA

In this section we discuss the dynamical algebra associated to each set of temporally stable states of the previous sections. Here we follow the operator structure developed in Sec. IV. That is, we follow the annihilation, creation and the number operators of (4.3).

A. For the states of Sec. V A

When n is fixed the spectrum $E(m,n)=B(2m+1)+(\pi(n+1)/d)^2$ can be written as

$$\overline{E}(m)=b_1m+c_1,$$

where $b_1=2B$ and $c_1=B+(\pi(n+1)/d)^2$ are constants. The corresponding generators take the form (4.3) with $x_m=\overline{E}(m)$. From (4.4) the commutators take the form

$$[\mathfrak{a},\mathfrak{a}^\dagger]=b_1I,\qquad[\mathfrak{n},\mathfrak{a}]=b_1\mathfrak{a}^\dagger,\qquad[\mathfrak{n},\mathfrak{a}]=-b_1\mathfrak{a}.$$

Thus the dynamical algebra is isomorphic to the Weyl–Heisenberg algebra, $\mathfrak{g}_{\mathrm{W-H}}$. To get the exact commutation relations of the Weyl–Heisenberg algebra one can define a new set of operators as follows:

$$\overline{\mathfrak{a}}=\frac{1}{\sqrt{b_1}}\mathfrak{a},\qquad\overline{\mathfrak{a}}^\dagger=\frac{1}{\sqrt{b_1}}\mathfrak{a}^\dagger,\qquad\overline{\mathfrak{n}}=\frac{1}{\sqrt{b_1}}\mathfrak{n}.$$

In terms of these new operators one gets

$$[\overline{\mathfrak{a}},\overline{\mathfrak{a}}^\dagger]=I,\qquad[\overline{\mathfrak{n}},\overline{\mathfrak{a}}^\dagger]=\overline{\mathfrak{a}}^\dagger,\qquad[\overline{\mathfrak{n}},\overline{\mathfrak{a}}]=-\overline{\mathfrak{a}}.$$

B. For the states of Sec. V B

When m is fixed the spectrum

$$E(m,n)=B(2m+1)+(\pi(n+1)/d)^2$$

can be written as

$$\tilde{E}(n)=b_2(n+1)^2+c_2,$$

where $b_2=\pi^2/d^2$ and $c_2=B(m+1)$ are constants. The corresponding generators take the form (4.3) with $e_n=\tilde{E}(n)$. Let us see the commutation relations. It can be easily seen that

$$[\mathfrak{a},\mathfrak{a}^\dagger]\psi_{m,n}=b_2(2n+3)\psi_{m,n}.$$

As it was done in Ref. 2, let us define a new set of operators

$$\bar{\mathfrak{a}}=\frac{1}{\sqrt{b_2}}\mathfrak{a},\qquad \bar{\mathfrak{a}}^\dagger=\frac{1}{\sqrt{b_2}}\mathfrak{a}^\dagger,\qquad \bar{\mathfrak{n}}\psi_{m,n}=\left(n+\frac{3}{2}\right)\psi_{m,n}. \tag{7.1}$$

With these new operators we obtain

$$[\bar{\mathfrak{a}},\bar{\mathfrak{a}}^\dagger]=2\bar{\mathfrak{n}},\qquad [\bar{\mathfrak{n}},\bar{\mathfrak{a}}]=-\bar{\mathfrak{a}},\qquad [\bar{\mathfrak{n}},\bar{\mathfrak{a}}^\dagger]=\bar{\mathfrak{a}}^\dagger. \tag{7.2}$$

The above commutation relations are the ones satisfied by the generators of the algebra $\mathfrak{su}(1,1)$ of the classical group SU(1,1). Thus in this case the dynamical algebra is isomorphic to $\mathfrak{su}(1,1)$.

C. For the states of Sec. VI A

Since $\rho_1(m)=e_m!$, $\rho_2(n)=\epsilon_n!$, $e_m=B(2m+1)$ and $\epsilon_n=\pi^2(n+1)^2/d^2$, let us define two sets of operators as follows:

$$\mathfrak{a}_1\phi_m=\sqrt{e_m}\phi_{m-1},\qquad \mathfrak{a}_1^\dagger\phi_m=\sqrt{e_{m+1}}\phi_{m+1},\qquad \mathfrak{n}_1\phi_m=e_m\phi_m, \tag{7.3}$$

$$\mathfrak{a}_2\chi_n=\sqrt{\epsilon_n}\chi_{n-1},\qquad \mathfrak{a}_2^\dagger\chi_n=\sqrt{\epsilon_{n+1}}\chi_{n+1},\qquad \mathfrak{n}_2\chi_n=\epsilon_n\chi_n. \tag{7.4}$$

For the operators $\mathfrak{a}_1,\mathfrak{a}_1^\dagger,\mathfrak{n}_1$, the commutators take the form,

$$[\mathfrak{a}_1,\mathfrak{a}_1^\dagger]=2BI,\qquad [\mathfrak{n}_1,\mathfrak{a}_1^\dagger]=2B\mathfrak{a}_1^\dagger,\qquad [\mathfrak{n}_1,\mathfrak{a}_1]=-2B\mathfrak{a}_1.$$

Thus the dynamical algebra is isomorphic to $\mathfrak{g}_{\mathrm{W-H}}$. To get the exact commutation relations of $\mathfrak{g}_{\mathrm{W-H}}$ one can define a new set of operators as follows:

$$\bar{\mathfrak{a}}_1=\frac{1}{\sqrt{2B}}\mathfrak{a}_1,\qquad \bar{\mathfrak{a}}_1^\dagger=\frac{1}{\sqrt{2B}}\mathfrak{a}_1^\dagger,\qquad \bar{\mathfrak{n}}_1=\frac{1}{\sqrt{2B}}\mathfrak{n}_1.$$

In terms of these new operators one gets

$$[\bar{\mathfrak{a}}_1,\bar{\mathfrak{a}}_1^\dagger]=I,\qquad [\bar{\mathfrak{n}}_1,\bar{\mathfrak{a}}_1^\dagger]=\bar{\mathfrak{a}}_1^\dagger,\qquad [\bar{\mathfrak{n}}_1,\bar{\mathfrak{a}}_1]=-\bar{\mathfrak{a}}_1.$$

For the operators $\mathfrak{a}_2,\mathfrak{a}_2^\dagger$ we get

$$[\mathfrak{a}_2,\mathfrak{a}_2^\dagger]\chi_n=\frac{2\pi^2}{d^2}\left(n+\frac{3}{2}\right)\chi_n.$$

By defining a new set of operators

$$\bar{\mathfrak{a}}_2=\frac{d}{\pi}\mathfrak{a}_2,\qquad \bar{\mathfrak{a}}_2^\dagger=\frac{d}{\pi}\mathfrak{a}_2^\dagger,\qquad \bar{\mathfrak{n}}_2\chi_n=\left(n+\frac{3}{2}\right)\chi_n, \tag{7.5}$$

it can readily be seen that the commutators take the following form:

$$[\bar{\mathfrak{a}}_2,\bar{\mathfrak{a}}_2^\dagger]=2\bar{\mathfrak{n}}_2,\qquad [\bar{\mathfrak{n}}_2,\bar{\mathfrak{a}}_2]=-\bar{\mathfrak{a}}_2,\qquad [\bar{\mathfrak{n}}_2,\bar{\mathfrak{a}}_2^\dagger]=\bar{\mathfrak{a}}_2^\dagger, \tag{7.6}$$

which are the commutation relations satisfied by the generators of the algebra $\mathfrak{su}(1,1)$. Now for the set of CS we define the following set of operators:

$$\mathfrak{a}=\mathfrak{a}_1\otimes\mathfrak{a}_2, \qquad \mathfrak{a}^\dagger=\mathfrak{a}_1^\dagger\otimes\mathfrak{a}_2^\dagger, \qquad \mathfrak{n}=\mathfrak{n}_1\otimes\bar{\mathfrak{n}}_2. \tag{7.7}$$

Thus the algebra associated to the CS is isomorphic to the tensor product of the two algebras, $\mathfrak{g}_{\mathrm{W-H}}$ and $\mathfrak{su}(1,1)$, that is, $\mathfrak{g}_{\mathrm{W-H}}\otimes\mathfrak{su}(1,1)$. If we take the operators as

$$\bar{\mathfrak{a}}=\bar{\mathfrak{a}}_1\otimes\bar{\mathfrak{a}}_2, \qquad \bar{\mathfrak{a}}^\dagger=\bar{\mathfrak{a}}_1^\dagger\otimes\bar{\mathfrak{a}}_2^\dagger, \qquad \bar{\mathfrak{n}}=\bar{\mathfrak{n}}_1\otimes\bar{\mathfrak{n}}_2, \tag{7.8}$$

we get the exact commutation relations of $\mathfrak{g}_{\mathrm{W-H}}\otimes\mathfrak{su}(1,1)$. One can also define another set of operators as follows:

$$\mathbf{a}\phi_m\otimes\chi_n=\sqrt{e_m\epsilon_n}\,\phi_{m-1}\otimes\chi_{n-1}, \qquad \mathbf{a}\phi_0\otimes\chi_0=0,$$

$$\mathbf{a}^\dagger\phi_m\otimes\chi_n=\sqrt{e_{m+1}\epsilon_{n+1}}\,\phi_{m+1}\otimes\chi_{n+1},$$

$$\mathbf{n}\phi_m\otimes\chi_n=e_m\epsilon_n\phi_m\otimes\chi_n. \tag{7.9}$$

Observe that here also the CS become the eigenstates of **a**. But it may be difficult to identify this algebra to a known type.

D. For the states of Sec. VI B

Since $\rho_1(m)=e_m!$, $\rho_2(n)=E(m,n)!$, let us define two sets of operators as follows:

$$\mathfrak{a}_1\phi_m=\sqrt{e_m}\,\phi_{m-1}, \quad \mathfrak{a}_1^\dagger\phi_m=\sqrt{e_{m+1}}\,\phi_{m+1}, \quad \mathfrak{n}_1\phi_m=e_m\phi_m,$$

$$\mathfrak{a}_2\chi_n=\sqrt{E(m,n)}\,\chi_{n-1}, \quad \mathfrak{a}_2^\dagger\chi_n=\sqrt{E(m,n+1)}\,\chi_{n+1}, \quad \mathfrak{a}_2\chi_n=E(m,n)\chi_n.$$

Again an analog of Sec. VII A can be worked out for the operators $\mathfrak{a}_1,\mathfrak{a}_1^\dagger,\mathfrak{n}_1$. Thus the operators generate the algebra $\mathfrak{g}_{\mathrm{W-H}}$. Since within the second sum of the CS m is considered as a constant we are in the exact situation of Sec. VII B. Thus the algebra generated by $\mathfrak{a}_2,\mathfrak{a}_2^\dagger,\mathfrak{n}_2$ is isomorphic to the algebra $\mathfrak{su}(1,1)$. The rest of the details follows from Sec. VII C.

VIII. STATISTICAL QUANTITIES

Quantum revivals are associated with wave functions. A revival of a wave function occurs when a wave function evolves in time to a state closely reproducing its initial form. Further the weighting distribution is crucial for understanding the temporal behavior of the wave function. In the case of the states (4.1), the probability of finding the state η_m in the state $|J,\alpha\rangle$ is given by

$$P(m,J)=|\langle\eta_m|J,\alpha\rangle|^2.$$

A quantitative estimate is given by the so-called Mandel parameter,

$$Q=\frac{\langle J,\alpha|\mathfrak{n}^2|J,\alpha\rangle-\langle J,\alpha|\mathfrak{n}|J,\alpha\rangle^2-\langle J,\alpha|\mathfrak{n}|J,\alpha\rangle}{\langle J,\alpha|\mathfrak{n}|J,\alpha\rangle},$$

where $\mathfrak{n}\eta_m=e_m\eta_m$. If the photon distribution is Poissonian, then $Q=0$. If $Q<0$ it is called sub-Poissonian and if $Q>0$ it is called super-Poissonian.[2] In this section we explicitly calculate the weighting distribution and the Mandel parameter for each of the CS discussed in the above sections.

A. For the states of Eq. (5.1)

For this class of states we obtain

$$P(m,J)=\frac{|J|^m}{\mathcal{N}(J,n)^2\rho(m)}=\frac{(J/2B)^m}{{}_1F_1\left(1;\gamma;\frac{J}{2B}\right)(\gamma)_m}.$$

Since $\mathfrak{n}|\psi_{m,n}\rangle=E(m,n)|\psi_{m,n}\rangle$ and $E(0,n)\neq 0$ we have

$$\mathfrak{n}|J,\alpha,n\rangle=\mathcal{N}(J,n)^{-1}\sum_{m=0}^{\infty}\frac{J^{m/2}E(m,n)}{\sqrt{\rho(m)}}e^{-iE(m,n)\alpha}|\psi_{m,n}\rangle$$

and

$$\mathfrak{n}^2|J,\alpha,n\rangle=\mathcal{N}(J,n)^{-1}\sum_{m=0}^{\infty}\frac{J^{m/2}E(m,n)^2}{\sqrt{\rho(m)}}e^{-iE(m,n)\alpha}|\psi_{m,n}\rangle.$$

Thus

$$\langle J,\alpha,n|\mathfrak{n}|J,\alpha,n\rangle=\frac{J}{\gamma}\frac{{}_1F_1\left(2;1+\gamma;\frac{J}{2B}\right)}{{}_1F_1\left(1;\gamma;\frac{J}{2B}\right)}+\omega,$$

where $\omega=B+(\pi(n+1)/d)^2$ and thereby $E(m,n)=2Bm+\omega$. Further

$$\langle J,\alpha,n|\mathfrak{n}^2|J,\alpha,n\rangle=\frac{1}{{}_1F_1\left(1;\gamma;\frac{J}{2B}\right)}\left[\frac{2J(B+\omega)}{\gamma}{}_1F_1\left(2;\gamma+1;\frac{J}{2B}\right)+\frac{2J^2}{\gamma(\gamma+1)}{}_1F_1\left(3;\gamma+2;\frac{J}{2B}\right)\right]+\omega^2.$$

Therefore

$$Q=\frac{2J(B+\omega)(\gamma+1){}_1F_1\left(2;\gamma+1;\frac{J}{2B}\right)+2J^2{}_1F_1\left(3;\gamma+2;\frac{J}{2B}\right)+\gamma(\gamma+1)\omega^2{}_1F_1\left(1;\gamma;\frac{J}{2B}\right)}{(\gamma+1)\left[J{}_1F_1\left(2;\gamma+1;\frac{J}{2B}\right)+\gamma\omega{}_1F_1\left(1;\gamma;\frac{J}{2B}\right)\right]}$$
$$-\frac{J{}_1F_1\left(2;\gamma+1;\frac{J}{2B}\right)}{\gamma{}_1F_1\left(1;\gamma;\frac{J}{2B}\right)}-\omega-1.$$

For particular values of B,d, and n the sign of Q can be determined.

B. For the states of Eq. (5.5)

We have

$$P(n,J)=\frac{d^{2n}J^n}{\pi^{2n}(\beta)_n(\overline{\beta})_{n1}F_2\left(1;\beta,\overline{\beta};\frac{d^2J}{\pi^2}\right)}.$$

For fixed m, $E(m,n)=p+q(n+1)^2$, where $p=B(2m+1)$ and $q=\pi^2/d^2$. Since $E(m,0)\neq 0$ and $\mathfrak{n}|\psi_{mn}\rangle=E(m,n)|\psi_{mn}\rangle$ we have

$$\langle J,\alpha,m|\mathfrak{n}|J,\alpha,m\rangle=p+\frac{q}{\mathcal{N}(J,m)^2}\sum_{n=0}^{\infty}\frac{J^n(n+1)^2}{\rho(n)}=p+qQ_1,$$

where

$$Q_1=\frac{1}{{}_1F_2\left(1;\overline{\beta},\beta;\frac{d^2J}{\pi^2}\right)}\left[{}_1F_2\left(2;\overline{\beta},\beta;\frac{d^2J}{\pi^2}\right)+\frac{2Jd^2}{|\beta|^2\pi^2}{}_1F_2\left(3;\overline{\beta}+1,\beta+1;\frac{d^2J}{\pi^2}\right)\right]$$

and

$$\langle J,\alpha,m|\mathfrak{n}^2|J,\alpha,m\rangle=\mathcal{N}(J,m)^{-2}\sum_{n=0}^{\infty}\frac{J^nd^{2n}(p+q(n+1)^2)^2}{\pi^{2n}(\beta)_n(\overline{\beta})_n}=p^2+2pqQ_1+q^2Q_2,$$

where

$$Q_2=\frac{1}{{}_1F_2\left(1;\overline{\beta},\beta;\frac{d^2J}{\pi^2}\right)}\left[\frac{2Jd^2+\pi^2}{\pi^2}{}_1F_2\left(2;\overline{\beta},\beta;\frac{d^2J}{\pi^2}\right)-\frac{2Jd^2(\pi^2|\beta|^2-Jd^2-7\pi^2)}{|\beta|^2\pi^4}\right.$$

$$\left.\times{}_1F_2\left(3;\overline{\beta}+1,\beta+1;\frac{d^2J}{\pi^2}\right)-\frac{6J^2d^4(\beta+\overline{\beta}-5)}{|\beta|^2\pi^4(\beta+1)(\overline{\beta}+1)}{}_1F_2\left(4;\overline{\beta}+2,\beta+2;\frac{d^2J}{\pi^2}\right)\right].$$

Thus

$$Q=\frac{p^2+2pqQ_1+q^2Q_2}{p+qQ_1}-p-qQ_1-1.$$

Here again for specific values of B, d, and m the sign of Q can be determined.

C. For the states of Eq. (6.1)

The probability of finding the state $\phi_m\otimes\chi_n$ in the state $|J_1,J_2,\alpha_1,\alpha_2\rangle$ is given by

$$P(m,n,J_1,J_2)=\frac{J_1^mJ_2^n}{{}_1F_1\left(1;\frac{3}{2};\frac{J_1}{2B}\right){}_0F_1\left(-;1;\frac{J_2d^2}{\pi^2}\right)2^mB^m\left(\frac{\pi}{d}\right)^{2n}(2)_n(2)_n\left(\frac{3}{2}\right)_m}.$$

Since $\mathfrak{n}_1\phi_m=e_m\phi_m$, $\mathfrak{n}_2\chi_n=\epsilon_n\chi_n$, $\mathfrak{n}=\mathfrak{n}_1\otimes\mathfrak{n}_2$, and $e_0\neq 0,\epsilon_0\neq 0$ we have

$$\langle J_1,J_2,\alpha_1,\alpha_2|\mathfrak{n}|J_1,J_2,\alpha_1,\alpha_2\rangle=\frac{B\pi^2Q_4}{d^2}[2Q_3+1],$$

where

$$Q_3=\frac{1}{\mathcal{N}_1(J_1)^2}\sum_{m=0}^{\infty}\frac{J_1^m m}{2^m B^m\left(\frac{3}{2}\right)_m}=\frac{J}{3B\mathcal{N}_1(J_1)^2}{}_1F_1\left(2;\frac{5}{2};\frac{J}{2B}\right)$$

and

$$Q_4=\frac{1}{\mathcal{N}_2(J_2)^2}\sum_{m=0}^{\infty}\frac{d^{2m}J_2^m(m+1)^2}{\pi^{2m}(2)_m(2)_m}.$$

Further

$$\begin{aligned}\langle J_1,J_2,\alpha_1,\alpha_2|\mathfrak{n}^2|J_1,J_2,\alpha_1,\alpha_2\rangle&=\langle J_1,J_2,\alpha_1,\alpha_2|\mathfrak{n}_1^2\otimes\mathfrak{n}_2^2|J_1,J_2,\alpha_1,\alpha_2\rangle\\&=\mathcal{N}_1(J_1)^{-2}\sum_{m=0}^{\infty}\frac{J_1^m e_m^2}{e_m!}\mathcal{N}_2(J_2)^{-2}\sum_{n=0}^{\infty}\frac{J_2^n\epsilon_n^2}{\epsilon_n!}\\&=\frac{B^2\pi^4Q_6}{d^4}[4Q_5+4Q_3+1],\end{aligned}$$

where

$$Q_5=\frac{1}{\mathcal{N}_1(J_1)^2}\sum_{m=0}^{\infty}\frac{J_1^m m^2}{2^m B^m\left(\frac{3}{2}\right)_m}$$

and Q_6 can be obtained from Q_2 by substituting $J=J_2,\beta=\overline{\beta}=2$ and $\mathcal{N}(J,m)=\mathcal{N}_1(J_1)$ in the expression of Q_2. Q_4 can be obtained from Q_1 by the same substitution. Thereby we have

$$Q=\frac{B\pi^2Q_6(4Q_5+4Q_3+1)}{d^2Q_4(2Q_3+1)}-\frac{B\pi^2Q_4(2Q_3+1)}{d^2}-1.$$

For specific values of B and d the sign of Q can be determined.

D. For the states of Eq. (6.5)

The probability of finding the state $\phi_m\otimes\chi_n$ in the state $|J_1,J_2,\alpha_1,\alpha_2\rangle$ is given by

$$P(m,n,J_1,J_2)=\frac{J_1^m J_2^n}{{}_1F_2\left(1;\beta,\overline{\beta};\frac{d^2J_2}{\pi^2}\right)\mathcal{N}_1(J_1,J_2)^2 2^m B^m\left(\frac{3}{2}\right)_n\left(\frac{\pi}{d}\right)^{2n}(\beta)_n(\overline{\beta})_n}.$$

Further, by taking $\mathfrak{n}_1\phi_m=e_m\phi_m$, $\mathfrak{n}_2\chi_n=E(m,n)\chi_n$ and $\mathfrak{n}=\mathfrak{n}_1\otimes\mathfrak{n}_2$ one can find Q as in the previous section. Since we do not have a closed form for $\mathcal{N}_1(J_1,J_2)$ we avoid calculating it.

IX. CONCLUSION

Eigenfunctions and eigenvalues of the free magnetic Schrödinger operator $H_0=(1/2M)(\mathbf{P}-e/c\,\mathbf{A})^2$ were discussed. The eigenfunctions were realized as an orthonormal basis of a Hilbert space. Four classes of temporally stable CS associated to the eigenfunctions and eigenvalues of the

operator H_0 were demonstrated. The first two classes were constructed with one degree of freedom and the last two with two degrees of freedom. To each class of CS the corresponding dynamical algebra was specified. The dynamical algebras were identified to the Weyl–Heisenberg algebra, $\mathfrak{su}(1,1)$ algebra and their tensor products. For each class of CS, quantum statistical quantities were calculated explicitly.

We prove rigorous upper bounds for the bulk heat transport in infinite Prandtl number Rayleigh–Bénard convection with or without rotation. For the rotation free case, our estimate shows that the Nusselt number is bounded by Rayleigh number according to $\mathrm{Nu}\leqslant c\,\mathrm{Ra}^{4/11}$ with constant $c<2$. In the presence of rotation, we prove $\mathrm{Nu}\leqslant c\,\mathrm{Ra}^{4/11}(\frac{1}{2}\sqrt{\mathrm{Ta}}+1)^{4/11}$ with constant $c<2$. Moreover, for weak rotating constraint ($\mathrm{Ta}\leqslant O(\mathrm{Ra}^{1/2})$), the Nusselt number is uniformly bounded above by $\mathrm{Nu}\leqslant c\,\mathrm{Ra}^{4/11}$. © *2004 American Institute of Physics.*

I. INTRODUCTION

We derive upper bound for the bulk heat transport in infinite Prandtl number Rayleigh–Bénard convection with or without rotation. Rayleigh–Bénard convection describes motion of a fluid layer which is heated from below. Typically, the motion is modeled by Boussinesq equations. These are a system of equations consisting of the heat advection–diffusion equation for the local temperature coupled with the incompressible Navier–Stokes equation via a bouyancy force proportional to the local temperature.

One of the fundamental quantities of interest for Boussinesq equations is the total heat transport across the layer, which is expressed in terms of Nusselt number in standard nondimensional formulation. A major goal is to identify a functional relation in the form Nu(Ra,Ta), where Nu is the Nusselt number, Ra denotes the Rayleigh number, and Ta represents the Taylor number. In high Rayleigh number flows, this relation is expected to take the scaling form $\mathrm{Nu}\sim\mathrm{Ra}^{\alpha}$, and much effort has been put into determining the value of α (e.g., Refs. 6, 13, 15, 23, and 29). There is no unambigious experimental value of α though. Many experiments show that α varies between 2/7 and 1/3 (see, e.g., Refs. 1–4, 6, 7, 19–21, 26–31). On the other hand, the best known rigorous bounds uniform in Prandtl number is $\mathrm{Nu}\leqslant c\,\mathrm{Ra}^{1/2}$.[8,17]

In this paper, we focus our attention on the infinite Prandtl number limit of the Boussinesq equations. In this case, the vector field is linearly slaved to the temperature field, and one can prove global existence and uniqueness of smooth solutions.[14] In particular, in absence of rotation, the scaling law is expected to be $\mathrm{Nu}\sim\mathrm{Ra}^{1/3}$, based on arguments of marginally stable boundary layer analysis[18,22] or on the basis of sophisticated asymptotic approximations of an upper bound analysis utilizing mild statistical assumptions.[3] A 1/3 exponent with logarithmic corrections in the form $\mathrm{Nu}\leqslant c\,\mathrm{Ra}^{1/3}(\log\mathrm{Ra})^{2/3}$ was proved by Constantin and Doering,[9] the value of c is not explicitly evaluated though. An estimate in the form $\mathrm{Nu}\leqslant c\,\mathrm{Ra}^{2/5}$ with explicit prefactor $c<1$ was obtained in Ref. 10.

Less results are known for the rotating convective heat transport. To date, the only known rigorous estimates are a uniform bound[10]

$$\mathrm{Nu}\leqslant c\,\mathrm{Ra}^{2/5}$$

with constant $c<1$ independent of rotation rate, and the rotation dependent bound[12]

a)Electronic mail: xiayan@math.msu.edu

$$\mathrm{Nu} \leqslant 1 + c\,\mathrm{Ra}^2/\sqrt{\mathrm{Ta}}$$

with c independent of Ra, Ta. Moreover, when the rotation rate is fast enough, the purely conductive solution is the globally and nonlinearly attractive fixed point.

Our main results are rigorous upper bounds of the form $\mathrm{Nu} \leqslant c\,\mathrm{Ra}^{4/11}$ in absence of rotation and $\mathrm{Nu} \leqslant c\,\mathrm{Ra}^{4/11}(\frac{1}{2}\sqrt{\mathrm{Ta}}+1)^{4/11}$ when $\mathrm{Ta} \neq 0$. Both are for infinite Prandtl number system and prefactor c is calculated explicitly. Observe our estimate in the rotating case is particularly interesting for weakly rotating infinite Prandtl system. Moreover, we show that for weakly rotating constraint $\mathrm{Ta} \leqslant O(\mathrm{Ra}^{1/2})$, the Nusselt number is uniformly controlled by $O(\mathrm{Ra}^{4/11})$. This is in the same spirit as Ref. 11, where it is shown that for moderate rotation $\mathrm{Ta} \leqslant \mathrm{Ra}^{1/3}(\log \mathrm{Ra})^{5/3}$, the Nusselt number is controlled by $O(\mathrm{Ra}^{1/3}(\log \mathrm{Ra})^{5/3})$.

Our proof relies on a modified background field method. This method, based on an idea of Hopf in study of Navier–Stokes equations,[16] was revived and successful in handling rigorous bounds for bulk-flow quantities in several fundamental fluid flows. When applied to Rayleigh–Bénard convection with fixed temperature boundary conditions, the method has been successful in deriving many best known to date rigorous bounds. For example, a uniform bound for all Prandtl number $0 < \mathrm{Pr} \leqslant \infty$ in the form $\mathrm{Nu} \leqslant c\,\mathrm{Ra}^{1/2}$;[8] a 1/3 bound with logarithm corrections $\mathrm{Nu} \leqslant c\,\mathrm{Ra}^{1/3}(\log \mathrm{Ra})^{2/3}$ for infinite Prandtl number convection without rotation;[9] a uniform 2/5 bound independent of rotaion rate $\mathrm{Nu} \leqslant c\,\mathrm{Ra}^{2/5}$ for infinite number convection with or without rotation.[10] Most recently, numerical techniques based on background method have been developed (see, e.g., Refs. 24 and 25). In particular, using an enlarged set of test functions, Plasting[25] derived numerical results in the form $\mathrm{Nu} \leqslant 0.139\,\mathrm{Ra}^{1/3}$ as $\mathrm{Ra} \to \infty$.

The starting point of this variational method is to decompose the temperature field into background and fluctuating components. The background profile is time independent and carry the boundary conditions of the temperature field. For each background, there is a quadratic form naturally associated. The main task is to estimate the quadratic form. Usually, there are two approaches to bound the heat flux. The first one is to adjust the background so that the quadratic form is positive semidefinite and the Nusselt number is bounded above by a quadratic form of the derivative of the background. The second is to esimtate the quadratic form in terms of the background, the upper bound on the Nusselt number is then estimated through minimizing a certain intergral of the background. Both approaches depend on estimates for higher derivatives of the vertical velocity. The only difference is the following: in the first approach, the quadratic form is decomposed into its Fourier modes in horizontal direction, and analysis depends on estimates for Fourier modes of the vertical velocity; while in the second approach, vertical velocity is estimated directly through the associated PDE. In this paper, we shall follow the same decomposition of the temperature field, while major modifications come at the point of estimating the quadratic form. We estimate the quadratic form in terms of the background, by estimating its Fourier modes. The main technical interest of this paper is some new estimates on higher derivatives for Fourier modes of the vertical velocity. Based on these estimates, we can estimate each Fourier mode of the quadratic form from below, which turns out to be sufficient for our purpose when summing up.

The rest of the paper is organized as follows. In Sec. II we recall the basic equations together with some necessary notations. Section III is devoted to the major estimates on the vertical velocity. The upper bound on the total heat flux for rotation free system is presented in Sec. IV and the bounds for rotating system are derived in the last two sections.

II. FORMULATION OF THE PROBLEM

Consider an incompressible Newtonian fluid confined to horizontal rigid isothermal plates separated by vertical distance h. The top plate is held at constant temperature T_2 and the bottom plate is held at constant temperature T_1. In the standard nondimensional units the fluid velocity field $\mathbf{u}(\mathbf{x},t)=(u,v,w)$ and temperature field $\mathbf{T}(\mathbf{x},t)$, pressure field $p(\mathbf{x},t)$ are governed by Boussinesq equations[5]

$$\mathbf{u}_t + \mathbf{u}\cdot\nabla\mathbf{u} + \mathrm{Pr}\sqrt{\mathrm{Ta}}\,\mathbf{k}\times\mathbf{u} + \mathrm{Pr}\,\nabla p = \mathrm{Pr}\,\Delta\mathbf{u} + \mathrm{Pr}\,\mathrm{Ra}\,\mathbf{k}T,$$

$$\nabla\cdot\mathbf{u} = 0,$$

$$T_t + \mathbf{u}\cdot\nabla T = \Delta T,$$

with boundary conditions

$$\mathbf{u}|_{z=0,1} = 0, \quad T|_{z=1} = 0, \quad T|_{z=0} = 1, \quad \left.\frac{\partial w}{\partial z}\right|_{z=0,1} = 0.$$

Here $\mathbf{k}$ is the z direction, $\mathrm{Pr} = \nu/\kappa$ is the Prandtl number (a ratio of the material parameters, ν is the kinematic viscosity, and κ is the thermal diffusivity), Rayleigh number $\mathrm{Ra} = g\alpha(T_1 - T_2)h^3/\nu\kappa$ is a ratio of the overall buoyancy force to the damping coefficients [g is the acceleration of gravity, α is the thermal expansion coefficient, $(T_1 - T_2)$ is the temperature drop across the gap, h is the gap width] and Taylor number $\mathrm{Ta} = (2\Omega h^2/\nu)^2$ measures the rotation (Ω is the rotation rate). Lengths are measured in units of h and $\mathbf{u}$, T, p are periodic in x and y directions with periods L_x/h and L_y/h, respectively.

In this paper, we are concerned with the infinite Prandtl number model where the equation for the velocity field is reduced to

$$\sqrt{\mathrm{Ta}}\,\mathbf{k}\times\mathbf{u} + \boldsymbol{\nabla} p = \boldsymbol{\Delta}\mathbf{u} + \mathrm{Ra}\,\mathbf{k}T.$$

Eliminating the pressure term from the equation above, we immediately obtain

$$\Delta^2 w - \sqrt{\mathrm{Ta}}\,\frac{\partial\zeta}{\partial z} = -\mathrm{Ra}\,\Delta_H T \tag{2.1}$$

and

$$-\Delta\zeta - \sqrt{\mathrm{Ta}}\,\frac{\partial w}{\partial z} = 0. \tag{2.2}$$

Here $\zeta = v_x - u_y$ is the vertical vorticity and $\Delta_H = \partial_x^2 + \partial_y^2$ denotes the horizontal Laplacian. The boundary conditions for (2.1), (2.2) are

$$w|_{z=0,1} = 0, \quad \zeta|_{z=0,1} = 0, \quad \left.\frac{\partial w}{\partial z}\right|_{z=0,1} = 0.$$

The ultimate goal is to find a functional relation of the form Nu(Ra,Ta). At current stage, only upper bounds on Nu have been obtained. Here Nu is the Nusselt number which is defined as the ratio of the total vertical heat flux to the conductive heat flux. Standard derivations give a variety of expressions for the Nusselt number in terms of solutions of (2.1) and (2.2),

$$\mathrm{Nu} = 1 + \frac{1}{\mathcal{A}}\left\langle \int_V wT\,\mathrm{d}V \right\rangle = \frac{1}{\mathcal{A}}\langle\|\nabla T\|^2\rangle = \frac{1}{\mathrm{Ra}}\,\frac{1}{\mathcal{A}}\langle\|\nabla\mathbf{u}\|^2\rangle.$$

Here and throughout the paper, we use the following notations:

$$\int_V \mathrm{d}V = \int_0^{L_x/h}\int_0^{L_y/h}\int_0^1 \mathrm{d}z\,\mathrm{d}y\,\mathrm{d}x$$

for the volume integration,

$$\mathcal{A}=\frac{L_x L_y}{h^2}$$

for the nondimensional area of the layer,

$$\|f\|=\left(\int_V |f|^2\,\mathrm{d}V\right)^{1/2}$$

for the L_2 norm on the domain, and

$$\langle f\rangle=\limsup_{t\to\infty}\frac{1}{t}\int_0^t f(s)\,\mathrm{d}s$$

for the long time average of f.

We also need the following notations for functions defined on [0,1]:

$$\|g\|_2=\left(\int_0^1 g^2(z)\,\mathrm{d}z\right)^{1/2}$$

denotes the L_2 norm on [0,1] and

$$\|g\|_\infty=\sup_{0\leqslant z\leqslant 1} g(z)$$

represents the L_∞ norm on [0,1].

A useful variational principle was introduced by Constantin and Doering[8–10] to prove rigorous upper bounds on Nu, building upon a method of analysis for the Navier–Stokes equations introduced by Hopf.[16] The starting point of this variational principle is to decompose the temperature field into a steady background profile and a time-dependent fluctuation field,

$$T(\mathbf{x},t)=\tau(z)+\theta(\mathbf{x},t),$$

where $\tau(z)$ inherits the boundary conditions of T and θ satisfies homogeneous boundary conditions in the z direction and periodic in horizontal directions. Under this decomposition, standard manipulation yields the following fundamental relation:

$$\mathrm{Nu}=\int_0^1 \tau'(z)^2\,\mathrm{d}z-\frac{1}{\mathcal{A}}\left\langle\int_V(|\nabla\theta|^2+2\tau'(z)w\theta)\mathrm{d}V\right\rangle=\int_0^1\tau'(z)^2\,\mathrm{d}z-\frac{1}{\mathcal{A}}\langle Q(\theta)\rangle,$$

where $Q(\theta)=\int_V(|\nabla\theta|^2+2\tau'(z)w\theta)\mathrm{d}V$ is a quadratic form. There are two ways to estimate upper bound of Nu based on this relation. The first approach is to choose background profile τ to ensure $Q(\theta)\geqslant 0$, then the Nusselt number is bounded above by $\int_0^1\tau'(z)^2\,\mathrm{d}z$; the second approach amounts to estimate the indefinite term in $Q(\theta)$ in terms of Ra and the functional form of τ, followed by an appropriate choice of τ to balance this estimate with $\int_0^1\tau'(z)^2\,\mathrm{d}z$. In both approaches, $\tau(z)$ is chosen so that the support of $\tau'(z)$ is concentrated near the boundaries where w,θ vanish. With such choice of background profile, both approaches rely on detailed growth estimates for θ and w in the boundary layer near $z=0$ and $z=1$. More precisely, in the first approach, one decomposes $Q(\theta)$ into Fourier modes $Q_{\mathbf{m}}(\theta_{\mathbf{m}})$ in horizontal direction, then adjusts τ to ensure $Q_{\mathbf{m}}(\theta_{\mathbf{m}})\geqslant 0$ for each $\mathbf{m}$. The argument relies on growth estimates for each Fourier mode $w_{\mathbf{m}}$ of the vertical velocity; in the second approach, w is estimated directly through the associated PDE.

Motivated by these two approaches, we estimate Q by estimating its Fourier modes $Q_{\mathbf{m}}(\theta_{\mathbf{m}})$. Recall for each horizontal wave number $\mathbf{m}=[(2\pi h/L_x)\,m_x,(2\pi h/L_y)\,m_y]$ $[|\mathbf{m}|=m,\ (m_x,m_y)\in\mathbf{Z}^2]$,

$$Q_{\mathbf{m}}(\theta_{\mathbf{m}})=\int_0^1\left|\frac{\mathrm{d}\theta_{\mathbf{m}}}{\mathrm{dz}}\right|^2+m^2|\theta_{\mathbf{m}}|^2+\tau'(w_{\mathbf{m}}^*\theta_{\mathbf{m}}+w_{\mathbf{m}}\theta_{\mathbf{m}}^*)\mathrm{dz}.$$

Here $\theta_{\mathbf{m}}(z)$, $w_{\mathbf{m}}(z)$ are the Fourier coefficients for θ and w, respectively. We choose the following profile of τ:

$$\tau(z)=\begin{cases}1-\dfrac{z}{2\delta}, & 0\leqslant z\leqslant\delta,\\ \dfrac{1}{2}, & \delta\leqslant z\leqslant 1-\delta,\\ \dfrac{1-z}{2\delta}, & 1-\delta\leqslant z\leqslant 1.\end{cases}\tag{2.3}$$

We obtain some new estimates on higher derivatives of $w_{\mathbf{m}}$. Based on this, we can bound $Q_{\mathbf{m}}(\theta_{\mathbf{m}})$ in terms of Ra, Ta, δ and $\|\theta_{\mathbf{m}}\|_2$, and the Nusselt number is bounded above by

$$\int_0^1\tau'(z)^2\,\mathrm{dz}-\sum_{\mathbf{m}}Q_{\mathbf{m}}(\theta_{\mathbf{m}}).$$

It turns out that the second term can be bounded above in terms of Ra, Ta, and the functional form of τ. The estimates on Nu then follows. Our main results are the following Theorems.

Theorem 2.1: *For infinite Prandtl number convection without rotation, we have the following estimates on the Nusselt number*:

$$\mathrm{Nu}\leqslant 1.26\,\mathrm{Ra}^{4/11}.$$

Theorem 2.2: *For rotating system, we have*

$$\mathrm{Nu}\leqslant 1.3\,\mathrm{Ra}^{4/11}\,\mathrm{Ta}^{1/6}+0.13\,\mathrm{Ra}^{4/11}\,\mathrm{Ta}^{-5/3}+0.18\,\mathrm{Ra}^{2/11}\,\mathrm{Ta}^{1/6}$$

and

$$\mathrm{Nu}\leqslant 1.26\,\mathrm{Ra}^{4/11}\left(\frac{\sqrt{\mathrm{Ta}}}{2}+1\right)^{4/11}.$$

We also have the following theorem for weakly rotating system.

Theorem 2.3: *There exist constants $B_1,B_2>0$ independent of Ra,Ta, such that when $Ta\leqslant B_1\,Ra^{1/2}$,*

$$Nu\leqslant B_2\,Ra^{4/11}.$$

III. ESTIMATES ON VERTICAL VELOCITY

In this section, we derive estimates for higher derivatives of $w_{\mathbf{m}}$ for Fourier modes $|\mathbf{m}|\geqslant 1$. Our main estimate is

Proposition 3.1: For $|\mathbf{m}|=m\geqslant 1$, if $w_{\mathbf{m}}$ satisfies

$$\left(-\frac{\mathrm{d}^2}{\mathrm{dz}^2}+m^2\right)^2 w_{\mathbf{m}}=f_{\mathbf{m}},$$

$$w_{\mathbf{m}}(0)=w_{\mathbf{m}}(1)=\frac{\mathrm{d}w_{\mathbf{m}}}{\mathrm{dz}}(0)=\frac{\mathrm{d}w_{\mathbf{m}}}{\mathrm{dz}}(1)=0,$$

then

$$\left\| \frac{\mathrm{d}^2 w_{\mathbf{m}}}{\mathrm{d}z^2} \right\|_{\infty} \leqslant C_1 m^{-3/2} \|f_{\mathbf{m}}\|_2 .$$

Here

$$C_1 = \left[1 + \frac{e^2+1}{e^2-1} \cdot \frac{4\cosh 1 + 2\sinh 1}{\sinh 1 - 1} \right] \approx 64.8734.$$

We prove Proposition 3.1 in several steps. First we recall some basic facts. For $m>0$, the solution to

$$\left(\frac{\mathrm{d}^2}{\mathrm{d}z^2} - m^2 \right) u = f$$

with zero Dirichlet boundary conditions,

$$u(0) = u(1) = 0$$

is given using the Green's function $G^{(m)}(z,\zeta)$ by

$$u(z) = G^{(m)}(f)(z) = \int_0^1 G^{(m)}(z,\zeta) f(\zeta)\,\mathrm{d}\zeta.$$

Recall that the Green's function is calculated from two independent solutions to the homogeneous ODE with one point boundary conditions,

$$G^{(m)}(z,\zeta) = \frac{1}{U_m} \begin{cases} y_1(z) y_2(\zeta), & z < \zeta, \\ y_1(\zeta) y_2(z), & z \geqslant \zeta. \end{cases}$$

Here $U_m = y_1(z) y_2'(z) - y_1'(z) y_2(z)$ is the Wronskian.

We will take

$$y_1(z) = \frac{e^{mz} - e^{-mz}}{2m}, \quad y_2(z) = y_1(z-1),$$

and therefore the Wronskian $U_m = y_1 y_2' - y_1' y_2$ satisfies

$$U_m(z) = y_1(1) = \frac{e^m - e^{-m}}{2m}.$$

In particular, we can write the Green's function explicitly as

$$G^{(m)}(z,\zeta) = \frac{1}{2m^2 U_m} [\cosh(m(z+\zeta-1)) - \cosh(m(1-|z-\zeta|))]. \tag{3.1}$$

To prove Proposition 3.1, we decompose

$$w_{\mathbf{m}} = u_{\mathbf{m}} + h_{\mathbf{m}}$$

with

$$u_{\mathbf{m}}(z)=\int_0^1 G^{(m)}(z,\zeta)g_{\mathbf{m}}(\zeta)\mathrm{d}\zeta,$$

$$g_{\mathbf{m}}(\zeta)=\int_0^1 G^{(m)}(\zeta,\zeta')f_{\mathbf{m}}(\zeta')\mathrm{d}\zeta', \tag{3.2}$$

$$h_{\mathbf{m}}(z)=A_{\mathbf{m}}(1-z)y_1(z)+B_{\mathbf{m}}zy_2(z) \tag{3.3}$$

with

$$A_{\mathbf{m}}=\frac{1}{U_m^2-1}(u'_{\mathbf{m}}(0)+U_m u'_{\mathbf{m}}(1)),$$

$$B_{\mathbf{m}}=\frac{1}{U_m^2-1}(U_m u'_{\mathbf{m}}(0)+u'_{\mathbf{m}}(1)).$$

One can check directly that $u_{\mathbf{m}},h_{\mathbf{m}}$ satisfies

$$\left(\frac{\mathrm{d}^2}{\mathrm{d}z^2}-m^2\right)^2 u_{\mathbf{m}}=f_{\mathbf{m}},$$

$$\left(\frac{\mathrm{d}^2}{\mathrm{d}z^2}-m^2\right)^2 h_{\mathbf{m}}=0,$$

with $u_{\mathbf{m}}=0$, $h_{\mathbf{m}}=0$, and $h'_{\mathbf{m}}=-u'_{\mathbf{m}}$ on the boundaries.

We claim the following estimates:

$$\left\|\frac{\mathrm{d}^2u_{\mathbf{m}}}{\mathrm{d}z^2}\right\|_\infty\leqslant\frac{c_1}{m^{3/2}}\|f_{\mathbf{m}}\|_2,\quad \left\|\frac{\mathrm{d}^2h_{\mathbf{m}}}{\mathrm{d}z^2}\right\|_\infty\leqslant\frac{c_2}{m^{3/2}}\|f_{\mathbf{m}}\|_2. \tag{3.4}$$

Here c_i are constants independent of m.

First we prove the following lemma.

Lemma 3.2: If

$$g(z)=\int_0^1 G^{(m)}(z,\zeta)f(\zeta)\mathrm{d}\zeta,$$

then

$$\|g\|_\infty\leqslant\frac{1}{m^2}\|f\|_\infty,\quad \left\|\frac{\mathrm{d}g}{\mathrm{d}z}\right\|_\infty\leqslant 2\,\frac{e^2+1}{e^2-1}\,\frac{1}{m}\|f\|_\infty,$$

$$\|g\|_\infty\leqslant\frac{1}{2}\,\frac{\|f\|_2}{m^{3/2}},\quad \left\|\frac{\mathrm{d}g}{\mathrm{d}z}\right\|_\infty\leqslant\frac{1}{\sqrt{2}}\sqrt{\frac{e^2+1}{e^2-1}}\frac{\|f\|_2}{\sqrt{m}}.$$

Proof: From explicit formula of $G^{(m)}(z,\zeta)$, we can write

$$
\begin{aligned}
g(z) &= \int_0^1 \frac{1}{2m^2U_m}[\cosh(m(z+\zeta-1))-\cosh(m(1-|z-\zeta|))]f(\zeta)\mathrm{d}\zeta \\
&= \int_0^1 \frac{1}{2m^2U_m}\cosh(m(z+\zeta-1))f(\zeta)\mathrm{d}\zeta - \int_0^z \frac{1}{2m^2U_m}\cosh(m(1-z+\zeta))f(\zeta)\mathrm{d}\zeta \\
&\quad - \int_z^1 \frac{1}{2m^2U_m}\cosh(m(1-\zeta+z))f(\zeta)\mathrm{d}\zeta \\
&= \int_0^z \frac{\cosh m(z+\zeta-1)-\cosh m(1-z+\zeta)}{2m\sinh m}f(\zeta)\mathrm{d}\zeta \\
&\quad + \int_z^1 \frac{\cosh m(z+\zeta-1)-\cosh m(1-\zeta+z)}{2m\sinh m}f(\zeta)\mathrm{d}\zeta. \qquad (3.5)
\end{aligned}
$$

Observe for $0\leqslant z,\ \zeta\leqslant 1$,

$$|z+\zeta-1|\leqslant 1-z+\zeta$$

and

$$|z+\zeta-1|\leqslant 1-\zeta+z.$$

Therefore the following inequality always holds when $0\leqslant z,\ \zeta\leqslant 1$:

$$
\begin{aligned}
&\cosh m(z+\zeta-1)-\cosh m(1-z+\zeta)\leqslant 0, \\
&\cosh m(z+\zeta-1)-\cosh m(1-\zeta+z)\leqslant 0, \\
&\sinh m(z+\zeta-1)+\sinh m(1-z+\zeta)\geqslant 0, \\
&\sinh m(z+\zeta-1)-\sinh m(1-\zeta+z)\leqslant 0.
\end{aligned} \qquad (3.6)
$$

In particular, (3.6) implies

$$
\begin{aligned}
\|g\|_\infty &\leqslant \frac{\|f\|_\infty}{2m\sinh m}\left(\int_0^z(\cosh m(1-z+\zeta)-\cosh m(z+\zeta-1))\mathrm{d}\zeta\right) \\
&\quad + \frac{\|f\|_\infty}{2m\sinh m}\left(\int_z^1(\cosh m(1-\zeta+z)-\cosh m(z+\zeta-1))\right) \\
&= \frac{\|f\|_\infty}{2m\sinh m}\left(\frac{\sinh m(1-z+\zeta)-\sinh m(z+\zeta-1)}{m}\Big|_0^z\right) \\
&\quad + \frac{\|f\|_\infty}{2m\sinh m}\left(\frac{-\sinh m(1-\zeta+z)-\sinh m(z+\zeta-1)}{m}\Big|_z^1\right) \\
&= \frac{\|f\|_\infty}{m^2\sinh m}(\sinh m-\sinh(mz)-\sinh(m(1-z)))\leqslant \frac{\|f\|_\infty}{m^2}. \qquad (3.7)
\end{aligned}
$$

Apply Cauchy–Shwartz inequality twice, we can estimate $\|g\|_\infty$ in terms of L_2 norm of f as follows:

$$\|g\|_\infty \leqslant \frac{1}{2m\sinh m}\left(\int_0^z [\cosh m(z+\zeta-1)-\cosh m(1-z+\zeta)]^2\,\mathrm{d}\zeta\right)^{1/2}\left(\int_0^z f^2\right)^{1/2}$$
$$+\frac{1}{2m\sinh m}\left(\int_z^1 [\cosh m(z+\zeta-1)-\cosh m(1-\zeta+z)]^2\mathrm{d}\zeta\right)^{1/2}\left(\int_z^1 f^2\right)^{1/2}$$
$$\leqslant \frac{\|f\|_2}{2m\sinh m}\left(\int_0^z [\cosh m(z+\zeta-1)-\cosh m(1-z+\zeta)]^2+\int_z^1 [\cosh m(z+\zeta-1)\right.$$
$$\left.-\cosh m(1-\zeta+z)]^2\right)^{1/2} \leqslant \frac{\|f\|_2}{2m\sinh m}\left(\int_0^z [\cosh^2 m(1-z+\zeta)-\cosh^2 m(z+\zeta-1)]\mathrm{d}\zeta\right.$$
$$\left.+\int_z^1 [\cosh^2 m(1-\zeta+z)-\cosh^2 m(z+\zeta-1)]\right)^{1/2}$$
$$\leqslant \frac{\|f\|_2}{2m\sinh m}\left(\int_0^z \frac{\cosh 2m(1-z+\zeta)-\cosh 2m(z+\zeta-1)}{2}\right.$$
$$\left.+\int_z^1 \frac{\cosh 2m(1-\zeta+z)-\cosh 2m(z+\zeta-1)}{2}\right)^{1/2}$$
$$\leqslant \frac{\|f\|_2}{2m\sinh m}\left(\frac{\sinh 2m-\sinh(2mz)-\sinh(2m(1-z))}{2m}\right)^{1/2}$$
$$\leqslant \frac{\|f\|_2}{2m\sinh m}\left(\frac{\sinh 2m-2\sinh m}{2m}\right)^{1/2}=\frac{\|f\|_2}{\sqrt{2}m^{3/2}}\frac{\sinh\frac{m}{2}}{\sqrt{\sinh m}}=\frac{\|f\|_2}{2m^{3/2}}\sqrt{\frac{e^m-1}{e^m+1}}\leqslant\frac{1}{2}\frac{\|f\|_2}{m^{3/2}}. \quad (3.8)$$

Here we used the fact that when $0\leqslant z\leqslant 1$,

$$\sinh 2m-\sinh(2mz)-\sinh(2m(1-z))\leqslant\sinh 2m-2\sinh m,$$

and when $m\geqslant 1$,

$$\frac{e^m-1}{e^m+1}\leqslant 1.$$

To estimate $\|\,\mathrm{d}g/\mathrm{d}z\,\|_\infty$, we differentiate the explicit expression $g(z)$, we get

$$\frac{\mathrm{d}g}{\mathrm{d}z}=\int_0^z \frac{\sinh m(z+\zeta-1)+\sinh m(1-z+\zeta)}{2\sinh m}f(\zeta)\mathrm{d}\zeta$$
$$+\int_z^1 \frac{\sinh m(z+\zeta-1)-\sinh m(1-\zeta+z)}{2\sinh m}f(\zeta)\mathrm{d}\zeta. \quad (3.9)$$

Observe that for $0\leqslant z,\ \zeta\leqslant 1$,

$$\sinh m(z+\zeta-1)+\sinh m(1-z+\zeta)\geqslant 0,$$

$$\sinh m(z+\zeta-1)-\sinh m(1-\zeta+z)\leqslant 0.$$

Apply this to (3.9), we get

$$\begin{aligned}\left\|\frac{dg}{dz}\right\|_\infty &\leqslant \frac{\|f\|_\infty}{2\sinh m}\int_0^z [\sinh m(z+\zeta-1)+\sinh m(1-z+\zeta)]d\zeta \\ &\quad + \frac{\|f\|_\infty}{2\sinh m}\int_z^1 [\sinh m(1-\zeta+z)-\sinh m(z+\zeta-1)]d\zeta \\ &= \frac{\|f\|_\infty}{2\sinh m}\left(\frac{\cosh m(z+\zeta-1)+\cosh m(1-z+\zeta)}{m}\Big|_0^z\right. \\ &\quad \left. + \frac{-\cosh m(1-\zeta+z)-\cosh m(z+\zeta-1)}{m}\Big|_z^1\right) \\ &= \frac{\|f\|_\infty}{m\sinh m}(\cosh m-\cosh m(1-z)-\cosh mz+\cosh m(2z-1)) \\ &\leqslant \frac{2\|f\|_\infty\cosh m}{m\sinh m} \leqslant \frac{2(e^2+1)}{m(e^2-1)}\|f\|_\infty . \end{aligned} \tag{3.10}$$

Here we used the fact that when $0\leqslant z\leqslant 1$,

$$\cosh mz \geqslant 0, \quad \cosh m(2z-1)\leqslant \cosh m,$$

and when $m\geqslant 1$

$$\frac{\cosh m}{\sinh m}\leqslant \frac{e^2+1}{e^2-1}.$$

We can also estimate $\|\,dg/dz\,\|_\infty$ in terms of $\|f\|_2$ as follows:

$$\begin{aligned}\left\|\frac{dg}{dz}\right\|_\infty &\leqslant \frac{1}{2\sinh m}\left[\int_0^z(\sinh m(z+\zeta-1)+\sinh m(1-z+\zeta))^2\right]^{1/2}\left(\int_0^z f^2\right)^{1/2} \\ &\quad + \frac{1}{2\sinh m}\left[\int_z^1(\sinh m(1-\zeta+z)-\sinh m(z+\zeta-1))^2\right]^{1/2}\left(\int_z^1 f^2\right)^{1/2} \\ &\leqslant \frac{\|f\|_2}{2\sinh m}\left(\int_0^z[\sinh m(z+\zeta-1)+\sinh m(1-z+\zeta)]^2\,d\zeta\right. \\ &\quad \left. + \int_z^1[\sinh m(1-\zeta+z)-\sinh m(z+\zeta-1)]^2\,d\zeta\right)^{1/2} \\ &\leqslant \frac{\|f\|_2}{2\sinh m}\left(2\int_0^z[\sinh^2 m(z+\zeta-1)+\sinh^2 m(1-z+\zeta)]d\zeta\right. \\ &\quad \left. + 2\int_z^1[\sinh^2 m(1-\zeta+z)+\sinh^2 m(z+\zeta-1)]d\zeta\right)^{1/2} \\ &\leqslant \frac{\|f\|_2}{2\sinh m}\left(\int_0^z[\cosh 2m(z+\zeta-1)+\cosh 2m(1-z+\zeta)]d\zeta\right. \\ &\quad \left. + \int_z^1[\cosh 2m(1-\zeta+z)+\cosh 2m(z+\zeta-1)]d\zeta\right)^{1/2}\end{aligned}$$

$$=\frac{\|f\|_2}{2\sinh m}\left(\frac{\sinh 2m(z+\zeta-1)+\sinh 2m(1-z+\zeta)}{2m}\Big|_0^z\right.$$
$$\left.+\frac{-\sinh 2m(1-\zeta+z)+\sinh 2m(z+\zeta-1)}{2m}\Big|_z^1\right)^{1/2}$$
$$=\frac{\|f\|_2}{2\sinh m}\frac{(2\sinh 2m)^{1/2}}{\sqrt{2m}}=\frac{\|f\|_2}{\sqrt{2m}}\left(\frac{e^{2m}+1}{e^{2m}-1}\right)^{1/2}\leqslant\frac{\|f\|_2}{\sqrt{2m}}\left(\frac{e^2+1}{e^2-1}\right)^{1/2}. \tag{3.11}$$

□

For

$$u_{\mathbf{m}}(z)=\int_0^1 G^{(m)}(z,\zeta)g_{\mathbf{m}}(\zeta)\mathrm{d}\zeta$$

and

$$g_{\mathbf{m}}(z)=\int_0^1 G^{(m)}(z,\zeta)f_{\mathbf{m}}(\zeta)\mathrm{d}\zeta,$$

Lemma 3.2 immediately implies the following estimates:

$$\|u_{\mathbf{m}}\|_\infty\leqslant\frac{1}{m^2}\|g_{\mathbf{m}}\|_\infty,\quad \|u_{\mathbf{m}}\|_\infty\leqslant\frac{1}{2}\frac{\|g_{\mathbf{m}}\|_2}{m^{3/2}},$$
$$\left\|\frac{\mathrm{d}u_{\mathbf{m}}}{\mathrm{d}z}\right\|_\infty\leqslant 2\frac{e^2+1}{e^2-1}\frac{\|g_{\mathbf{m}}\|_\infty}{m},\quad \left\|\frac{\mathrm{d}u_{\mathbf{m}}}{\mathrm{d}z}\right\|_\infty\leqslant\frac{1}{\sqrt{2}}\sqrt{\frac{e^2+1}{e^2-1}}\frac{\|g_{\mathbf{m}}\|_2}{m^{1/2}}, \tag{3.12}$$
$$\|g_{\mathbf{m}}\|_\infty\leqslant\frac{1}{2}\frac{1}{m^{3/2}}\|f_{\mathbf{m}}\|_2,$$
$$\left\|\frac{\mathrm{d}g_{\mathbf{m}}}{\mathrm{d}z}\right\|_\infty\leqslant\frac{1}{\sqrt{2}}\sqrt{\frac{e^2+1}{e^2-1}}\frac{1}{\sqrt{m}}\|f_{\mathbf{m}}\|_2.$$

In particular, estimates in (3.12) are useful in the following lemma.

Lemma 3.3: Let

$$u_{\mathbf{m}}(z)=\int_0^1 G^{(m)}(z,\zeta)g_{\mathbf{m}}(\zeta)\mathrm{d}\zeta,\quad g_{\mathbf{m}}(\zeta)=\int_0^1 G^{(m)}(\zeta,\zeta')f_{\mathbf{m}}(\zeta')\mathrm{d}\zeta',$$

then

$$\left\|\frac{\mathrm{d}^2u_{\mathbf{m}}}{\mathrm{d}z^2}\right\|_\infty\leqslant\frac{1}{m^{3/2}}\|f_{\mathbf{m}}\|_2.$$

Proof: From explicit expression of $G^{(m)}(z,\zeta)$, we have

$$u_{\mathbf{m}}(z)=\int_0^1\frac{\cosh m(z+\zeta-1)}{2m\sinh m}g_{\mathbf{m}}(\zeta)\mathrm{d}\zeta-\int_0^z\frac{\cosh m(1-z+\zeta)}{2m\sinh m}g_{\mathbf{m}}(\zeta)\mathrm{d}\zeta$$
$$-\int_z^1\frac{\cosh m(1-\zeta+z)}{2m\sinh m}g_{\mathbf{m}}(\zeta)\mathrm{d}\zeta.$$

Differentiate twice, we get

$$\begin{aligned}\frac{d^2u_{\mathbf{m}}}{dz^2}&=\int_0^1\frac{m\cosh m(z+\zeta-1)}{2\sinh m}g_{\mathbf{m}}(\zeta)d\zeta+g_{\mathbf{m}}(z)-\int_0^z\frac{m\cosh m(1-z+\zeta)}{2\sinh m}g_{\mathbf{m}}(\zeta)d\zeta\\&\quad-\int_z^1\frac{m\cosh m(1-\zeta+z)}{2\sinh m}g_{\mathbf{m}}(\zeta)d\zeta\\&=\int_0^z\frac{m[\cosh m(z+\zeta-1)-\cosh m(1-z+\zeta)]}{2\sinh m}g_{\mathbf{m}}(\zeta)d\zeta+g_{\mathbf{m}}(z)\\&\quad+\int_z^1\frac{m[\cosh m(z+\zeta-1)-\cosh m(1-\zeta+z)]}{2\sinh m}g_{\mathbf{m}}(\zeta)d\zeta.\end{aligned}$$

Recall for $0\leqslant z,\ \zeta\leqslant 1$,

$$\begin{aligned}&\cosh m(z+\zeta-1)-\cosh m(1-z+\zeta)\leqslant 0,\\&\cosh m(z+\zeta-1)-\cosh m(1-\zeta+z)\leqslant 0,\\&\sinh m(z+\zeta-1)+\sinh m(1-z+\zeta)\geqslant 0,\\&\sinh m(z+\zeta-1)-\sinh m(1-\zeta+z)\leqslant 0.\end{aligned}\tag{3.13}$$

Equation (3.13) implies the following estimates:

$$\begin{aligned}\left\|\frac{d^2u_{\mathbf{m}}}{dz^2}\right\|_\infty&\leqslant\|g_{\mathbf{m}}\|_\infty+\frac{m\|g_{\mathbf{m}}\|_\infty}{2\sinh m}\left(\int_0^z[\cosh m(1-z+\zeta)-\cosh m(z+\zeta-1)]d\zeta\right.\\&\qquad\left.+\int_z^1[\cosh m(1-\zeta+z)-\cosh m(z+\zeta-1)]d\zeta\right)\\&=\|g_{\mathbf{m}}\|_\infty+\frac{m\|g_{\mathbf{m}}\|_\infty}{2\sinh m}\left(\frac{\sinh m(1-z+\zeta)-\sinh m(z+\zeta-1)}{m}\Big|_0^z\right.\\&\qquad\left.-\frac{\sinh m(1-\zeta+z)+\sinh m(z+\zeta-1)}{m}\Big|_z^1\right)\\&=\|g_{\mathbf{m}}\|_\infty+\frac{\sinh m-\sinh mz-\sinh m(1-z)}{\sinh m}\|g_{\mathbf{m}}\|_\infty\\&\leqslant 2\|g_{\mathbf{m}}\|_\infty\leqslant 2\,\frac{1}{2}\,\frac{1}{m^{3/2}}\|f_{\mathbf{m}}\|_2=\frac{1}{m^{3/2}}\|f_{\mathbf{m}}\|_2.\end{aligned}\tag{3.14}$$

Next we shall prove estimates on derivatives of $h_{\mathbf{m}}$, first we state two simple lemmas.
Lemma 3.4: Let $a\geqslant 0$, $m\geqslant 1$, $u(z)=m(1-z)\sinh m(z+a)$, $0\leqslant z\leqslant 1$, *then*

$$\max_{0\leqslant z\leqslant 1}u(z)\leqslant\sinh m(1+a).$$

Proof: Differentiate u, we have

$$u'(z)=m^2(1-z)\cosh m(z+a)-m\sinh m(z+a)$$

$$=\frac{m}{2}[e^{m(z+a)}(m(1-z)-1)+e^{-m(z+a)}(m(1-z)+1)].$$

In particular,

$$u'(z)>0 \quad \text{when} \quad m(1-z)-1\geqslant 0.$$

On the other hand, $u'(1)<0$, therefore $\max_{0\leqslant z\leqslant 1} u(z)$ is achieved at some $0<z_0<1$ with

$$m(1-z_0)\leqslant 1.$$

Therefore

$$\max_{0\leqslant z\leqslant 1} u(z)=u(z_0)=m(1-z_0)\sinh m(z_0+a)\leqslant \sinh m(1+a).$$

□

Remark 3.5: Consider $v(z)=mz\sinh m(a-z)$, $a\geqslant 1$, $0\leqslant z\leqslant 1$, then a direct corollary of the previous lemma is $\max_{0\leqslant z\leqslant 1} v(z)\leqslant \sinh ma$.

Lemma 3.6: When $m\geqslant 1$, we have

$$\text{(a)} \quad \frac{\cosh m}{\sinh m-m}\leqslant \frac{\cosh 1}{\sinh 1-1},$$

$$\text{(b)} \quad \frac{\sinh m}{\sinh m-m}\leqslant \frac{\sinh 1}{\sinh 1-1},$$

$$\text{(c)} \quad \frac{m}{\sinh m-m}\leqslant \frac{1}{\sinh 1-1}.$$

Proof: Since

$$\frac{\sinh m}{\sinh m-m}=1+\frac{m}{\sinh m-m},$$

we only need to prove (a) and (c).

Let

$$f_1(x)=\frac{\cosh x}{\sinh x-x}, \quad f_2(x)=\frac{x}{\sinh x-x}.$$

Then

$$f_1'(x)=\frac{1}{(\sinh x-x)^2}[\sinh x(\sinh x-x)-\cosh x(\cosh x-1)]$$

$$=\frac{1}{2(\sinh x-x)^2}(-2-xe^x+xe^{-x}+e^x+e^{-x}).$$

Observe that when $x\geqslant 1$, $(x+1)e^{-x}\leqslant 2$, we have

$$f_1'(x)\leqslant 0 \quad \text{for} \quad x\geqslant 1.$$

Thus $\max_{m\geqslant 1} f_1(m)\leqslant f_1(1)$.

Similarly

$$f_2'(x)=\frac{1}{(\sinh x-x)^2}(\sinh x-x\cosh x)\leqslant 0 \quad \text{when } x\geqslant 1,$$

therefore $\max_{m\geqslant 1} f_2(m)\leqslant f_2(1)$.

Now we estimate derivatives of $h_{\mathbf{m}}$ for $|\mathbf{m}|=m\geqslant 1$.

Lemma 3.7: $h_{\mathbf{m}}=A_{\mathbf{m}}(1-z)y_1(z)+B_{\mathbf{m}}zy_2(z)$,

$$A_{\mathbf{m}}=\frac{u_{\mathbf{m}}'(0)+U_m u_{\mathbf{m}}'(1)}{U_m^2-1},\quad B_{\mathbf{m}}=\frac{u_{\mathbf{m}}'(0)U_m+u_{\mathbf{m}}'(1)}{U_m^2-1},\quad y_1(z)=\frac{e^{mz}-e^{-mz}}{2m},\quad y_2(z)=y_1(z-1).$$

Then there exists $c_1>0$ independent of m such that

$$\left\|\frac{\mathrm{d}^2 h_{\mathbf{m}}}{\mathrm{d}z^2}\right\|_\infty \leqslant c_1\frac{1}{m^{3/2}}\|f_{\mathbf{m}}\|_2.$$

Proof: Differentiate $h_{\mathbf{m}}$ directly, we have

$$\frac{\mathrm{d}^2 h_{\mathbf{m}}}{\mathrm{d}z^2}=-2A_{\mathbf{m}}y_1'(z)+A_{\mathbf{m}}y_1''(z)(1-z)+2B_{\mathbf{m}}y_2'(z)+B_{\mathbf{m}}y_2''(z)z.$$

Recall

$$\begin{aligned} y_1'(z)&=\frac{e^{mz}+e^{-mz}}{2},\quad y_2'(z)=\frac{e^{m(z-1)}+e^{-m(z-1)}}{2},\\ y_1''(z)&=\frac{m(e^{mz}-e^{-mz})}{2},\quad y_2''(z)=\frac{m(e^{m(z-1)}-e^{-m(z-1)})}{2}, \end{aligned} \tag{3.15}$$

and

$$\begin{aligned} |A_{\mathbf{m}}|&\leqslant\frac{U_m+1}{U_m^2-1}\|u_{\mathbf{m}}'\|_\infty=\frac{m}{\sinh m-m}\|u_{\mathbf{m}}'\|_\infty,\\ |B_{\mathbf{m}}|&\leqslant\frac{U_m+1}{U_m^2-1}\|u_{\mathbf{m}}'\|_\infty=\frac{m}{\sinh m-m}\|u_{\mathbf{m}}'\|_\infty. \end{aligned} \tag{3.16}$$

Equations (3.15) and (3.16) and Lemma 3.4, Lemma 3.6 imply

$$\begin{aligned} \|h_{\mathbf{m}}''\|_\infty &\leqslant 2|A_{\mathbf{m}}|\cosh m+2|B_{\mathbf{m}}|\cosh m+|A_{\mathbf{m}}|\max_{0\leqslant z\leqslant 1}(m(1-z)\sinh mz)\\ &\quad+|B_m|\max_{0\leqslant z\leqslant 1}(mz\sinh m(1-z))\\ &\leqslant\frac{4m\cosh m}{\sinh m-m}\|u_{\mathbf{m}}'\|_\infty+\frac{2m\sinh m}{\sinh m-m}\|u_{\mathbf{m}}'\|_\infty\leqslant\frac{4\cosh m+2\sinh m}{\sinh m-m}m\frac{1}{m}2\frac{e^2+1}{e^2-1}\|g_{\mathbf{m}}\|_\infty\\ &\leqslant 2\frac{e^2+1}{e^2-1}\frac{4\cosh m+2\sinh m}{\sinh m-m}\frac{1}{2m^{3/2}}\|f_{\mathbf{m}}\|_2\leqslant\frac{e^2+1}{e^2-1}\frac{4\cosh m+2\sinh m}{\sinh m-m}\frac{1}{m^{3/2}}\|f_{\mathbf{m}}\|_2\\ &\leqslant\frac{e^2+1}{e^2-1}\frac{4\cosh 1+2\sinh 1}{\sinh 1-1}\frac{1}{m^{3/2}}\|f_{\mathbf{m}}\|_2. \end{aligned}$$

Summarize the estimates on the higher derivatives of $u_{\mathbf{m}}$, $h_{\mathbf{m}}$, we have proved

$$\|w''_{\mathbf{m}}\|_\infty \leqslant C_1 \frac{1}{m^{3/2}} \|f_{\mathbf{m}}\|_2$$

with

$$C_1 = \left[1 + \frac{e^2+1}{e^2-1} \cdot \frac{4\cosh 1 + 2\sinh 1}{\sinh 1 - 1}\right] \approx 64.8734.$$

IV. HEAT FLUX COVECTION WITHOUT ROTATION

In this section, we prove upper bound on heat flux convection in absence of rotation. We first quote the following Lemma from Ref. 10.

Lemma 4.1 (Ref. 10): *If* $w_{\mathbf{m}}(z)$ *satisfies*

$$\left(-\frac{\mathrm{d}^2}{\mathrm{d}z^2} + m^2\right)^2 w_{\mathbf{m}} = \mathrm{Ra}\, m^2 \theta_{\mathbf{m}},$$

$$w_{\mathbf{m}}(0) = w_{\mathbf{m}}(1) = \frac{\mathrm{d}w_{\mathbf{m}}}{\mathrm{d}z}(0) = \frac{\mathrm{d}w_{\mathbf{m}}}{\mathrm{d}z}(1) = 0,$$

then there is a constant C_2 *independent of* m *such that* $\|\mathrm{d}^2 w_{\mathbf{m}}/\mathrm{d}z^2\|_\infty \leqslant C_2\, \mathrm{Ra}\, m \|\theta_{\mathbf{m}}\|_2$. *In particular, one can choose* $C_2^2 = 2/(7-\sqrt{41})$.

Lemma 4.1 and Proposition 3.1 implies the growth of $w_{\mathbf{m}}$ near boundaries. By Proposition 3.1, when $|\mathbf{m}| \geqslant 1$, the growth of $w_{\mathbf{m}}$ near the boundary at $z=0$ is controlled by

$$|w_{\mathbf{m}}(z)| = \left|\int_0^z \int_0^\zeta \frac{\mathrm{d}^2 w_{\mathbf{m}}}{\mathrm{d}z^2}(\zeta')\mathrm{d}\zeta'\,\mathrm{d}\zeta\right| \leqslant \frac{1}{2} z^2 \left\|\frac{\mathrm{d}^2 w_{\mathbf{m}}}{\mathrm{d}z^2}\right\|_\infty \leqslant \frac{1}{2} z^2 C_1\, \mathrm{Ra}\sqrt{m}\, \|\theta_{\mathbf{m}}\|_2. \tag{4.1}$$

For $|\mathbf{m}| \leqslant 1$, Lemma 4.1 implies the growth of $w_{\mathbf{m}}$ near $z=0$ is limited by

$$|w_{\mathbf{m}}(z)| = \left|\int_0^z \int_0^\zeta \frac{\mathrm{d}^2 w_{\mathbf{m}}}{\mathrm{d}z^2}(\zeta')\mathrm{d}\zeta'\,\mathrm{d}\zeta\right| \leqslant \frac{1}{2} z^2 \left\|\frac{\mathrm{d}^2 w_{\mathbf{m}}}{\mathrm{d}z^2}\right\|_\infty \leqslant \frac{1}{2} z^2 C_2\, \mathrm{Ra}\, m \|\theta_{\mathbf{m}}\|_2 \leqslant \frac{1}{2} z^2 C_2\, \mathrm{Ra} \|\theta_{\mathbf{m}}\|_2. \tag{4.2}$$

An analogous pointwise bound holds near $z=1$ when $|\mathbf{m}| \geqslant 1$ and $|\mathbf{m}| \leqslant 1$.

On the other hand, the growth of $\theta_{\mathbf{m}}$ near the boundary is estimated by

$$|\theta_{\mathbf{m}}(z)| = \left|\int_0^z \frac{\mathrm{d}\theta_{\mathbf{m}}}{\mathrm{d}z}(\zeta)\mathrm{d}\zeta\right| \leqslant \sqrt{z}\sqrt{\int_0^{1/2} \left|\frac{\mathrm{d}\theta_{\mathbf{m}}}{\mathrm{d}z}\right|^2} \tag{4.3}$$

for $0 \leqslant z \leqslant \frac{1}{2}$, a similar estimate holds for the growth of $\theta_{\mathbf{m}}$ near $z=1$.

When $|\mathbf{m}| \geqslant 1$, the indefinite term in $Q_{\mathbf{m}}$ now can be bounded according to (4.1) and (4.3) as

$$\begin{aligned}
\left|\int_0^1 \tau'(z)(w^*_{\mathbf{m}}\theta_{\mathbf{m}} + \theta^*_{\mathbf{m}} w_{\mathbf{m}})\mathrm{d}z\right| &\leqslant \frac{1}{\delta}\int_0^\delta |w_{\mathbf{m}}(z)||\theta_{\mathbf{m}}(z)|\mathrm{d}z + \frac{1}{\delta}\int_{1-\delta}^1 |w_{\mathbf{m}}(z)||\theta_{\mathbf{m}}(z)|\mathrm{d}z \\
&\leqslant \frac{1}{\delta}\int_0^\delta \frac{1}{2} z^2 C_1\, \mathrm{Ra}\sqrt{m}\, \|\theta_{\mathbf{m}}\|_2 \sqrt{z}\sqrt{\int_0^{1/2}\left|\frac{\mathrm{d}\theta_{\mathbf{m}}}{\mathrm{d}z}\right|^2}\,\mathrm{d}z \\
&\quad + \frac{1}{\delta}\int_{1-\delta}^1 \frac{1}{2}(1-z)^2 C_1\, \mathrm{Ra}\sqrt{m}\, \|\theta_{\mathbf{m}}\|_2 \sqrt{1-z}\sqrt{\int_{1/2}^1 \left|\frac{\mathrm{d}\theta_{\mathbf{m}}}{\mathrm{d}z}\right|^2}\,\mathrm{d}z
\end{aligned}$$

$$\leqslant \frac{1}{7}\delta^{5/2}C_1\,\mathrm{Ra}\sqrt{m}\|\theta_{\mathbf{m}}\|_2\left(\sqrt{\int_0^{1/2}\left|\frac{\mathrm{d}\theta_{\mathbf{m}}}{\mathrm{d}z}\right|^2}+\sqrt{\int_{1/2}^1\left|\frac{\mathrm{d}\theta_{\mathbf{m}}}{\mathrm{d}z}\right|^2}\right)$$

$$\leqslant \frac{\sqrt{2}}{7}\delta^{5/2}C_1\,\mathrm{Ra}\sqrt{m}\|\theta_{\mathbf{m}}\|_2\left\|\frac{\mathrm{d}\theta_{\mathbf{m}}}{\mathrm{d}z}\right\|_2. \tag{4.4}$$

When $|\mathbf{m}|\leqslant 1$, the indefinite term in $Q_{\mathbf{m}}$ is estimated via (4.2) and (4.3),

$$\left|\int_0^1 \tau'(z)(w_{\mathbf{m}}^*\theta_{\mathbf{m}}+\theta_{\mathbf{m}}^*w_{\mathbf{m}})\mathrm{d}z\right| \leqslant \frac{1}{\delta}\int_0^\delta |w_{\mathbf{m}}(z)||\theta_{\mathbf{m}}(z)|\mathrm{d}z+\frac{1}{\delta}\int_{1-\delta}^1 |w_{\mathbf{m}}(z)||\theta_{\mathbf{m}}(z)|\mathrm{d}z$$

$$\leqslant \frac{1}{\delta}\int_0^\delta \frac{1}{2}z^2C_2\,\mathrm{Ra}\,m\|\theta_{\mathbf{m}}\|_2\sqrt{z}\sqrt{\int_0^{1/2}\left|\frac{\mathrm{d}\theta_{\mathbf{m}}}{\mathrm{d}z}\right|^2}\,\mathrm{d}z$$

$$+\frac{1}{\delta}\int_{1-\delta}^1 \frac{1}{2}(1-z)^2C_2\,\mathrm{Ra}\|\theta_{\mathbf{m}}\|_2\sqrt{1-z}\sqrt{\int_{1/2}^1\left|\frac{\mathrm{d}\theta_{\mathbf{m}}}{\mathrm{d}z}\right|^2}\,\mathrm{d}z$$

$$\leqslant \frac{1}{7}C_2\delta^{5/2}\,\mathrm{Ra}\|\theta_{\mathbf{m}}\|_2\left(\sqrt{\int_0^{1/2}\left|\frac{\mathrm{d}\theta_{\mathbf{m}}}{\mathrm{d}z}\right|^2}+\sqrt{\int_{1/2}^1\left|\frac{\mathrm{d}\theta_{\mathbf{m}}}{\mathrm{d}z}\right|^2}\right)$$

$$\leqslant \frac{\sqrt{2}}{7}C_2\delta^{5/2}\,\mathrm{Ra}\|\theta_{\mathbf{m}}\|_2\left\|\frac{\mathrm{d}\theta_{\mathbf{m}}}{\mathrm{d}z}\right\|_2. \tag{4.5}$$

For $|\mathbf{m}|\geqslant 1$, (4.4) implies

$$\left|\int_0^1 \tau'(z)(w_{\mathbf{m}}^*\theta_{\mathbf{m}}+\theta_{\mathbf{m}}^*w_{\mathbf{m}})\mathrm{d}z\right| \leqslant \frac{(\sqrt{2})^4}{64\times 7^4}C_1^4\delta^{10}\,\mathrm{Ra}^4\|\theta_{\mathbf{m}}\|_2^2+m^2\|\theta_{\mathbf{m}}\|_2^2+\left\|\frac{\mathrm{d}\theta_{\mathbf{m}}}{\mathrm{d}z}\right\|_2^2. \tag{4.6}$$

In particular, this implies when $|\mathbf{m}|\geqslant 1$, $Q_{\mathbf{m}}$ is bounded below by

$$Q_{\mathbf{m}}(\theta_{\mathbf{m}})\geqslant -\frac{C_1^4}{16\times 7^4}\delta^{10}\,\mathrm{Ra}^4\|\theta_{\mathbf{m}}\|_2^2. \tag{4.7}$$

On the other hand, for $|\mathbf{m}|\leqslant 1$, (4.5) gives

$$\left|\int_0^1 \tau'(z)(w_{\mathbf{m}}^*\theta_{\mathbf{m}}+\theta_{\mathbf{m}}^*w_{\mathbf{m}})\mathrm{d}z\right| \leqslant \frac{C_2\sqrt{2}}{7}\delta^{5/2}\,\mathrm{Ra}\|\theta_{\mathbf{m}}\|_2\left\|\frac{\mathrm{d}\theta_{\mathbf{m}}}{\mathrm{d}z}\right\|_2 \leqslant \frac{C_2^2}{98}\delta^5\,\mathrm{Ra}^2\|\theta_{\mathbf{m}}\|_2^2+\left\|\frac{\mathrm{d}\theta_{\mathbf{m}}}{\mathrm{d}z}\right\|_2^2. \tag{4.8}$$

Hence for $|\mathbf{m}|\leqslant 1$, $Q_{\mathbf{m}}$ is bounded below by

$$Q_{\mathbf{m}}(\theta_{\mathbf{m}})\geqslant -\frac{C_2^2}{98}\delta^5\,\mathrm{Ra}^2\|\theta_{\mathbf{m}}\|_2^2. \tag{4.9}$$

Therefore the convective heat flux

$$\begin{aligned}\mathrm{Nu} &\leqslant \frac{1}{2\delta} - \frac{1}{\mathcal{A}}\left\langle \int_0^{L_x/h}\int_0^{L_y/h} \sum_{\mathbf{m}} Q_{\mathbf{m}}(\theta_{\mathbf{m}})\,dx\,dy \right\rangle \\ &\leqslant \frac{1}{2\delta} + \frac{C_2^2}{98}\delta^5\,\mathrm{Ra}^2 \sum_{|\mathbf{m}|\leqslant 1} \|\theta_{\mathbf{m}}\|_2^2 + \frac{C_1^4}{16\times 7^4}\delta^{10}\,\mathrm{Ra}^4 \sum_{|\mathbf{m}|\geqslant 1} \|\theta_{\mathbf{m}}\|_2^2 \\ &\leqslant \frac{1}{2\delta} + \max\left(\frac{C_2^2}{98}\delta^5\,\mathrm{Ra}^2, \frac{C_1^4}{16\times 7^4}\delta^{10}\,\mathrm{Ra}^4\right).\end{aligned}$$

The last inequality used the fact that $|\theta(\mathbf{x},t)|\leqslant 1$ and

$$\sum_{\mathbf{m}} \|\theta_{\mathbf{m}}\|_2^2 \leqslant \frac{1}{\mathcal{A}}\int_V \theta^2\,\mathrm{d}V \leqslant 1.$$

In fact, apply Maximum principle to T, we have $0\leqslant T(\mathbf{x},t)\leqslant 1$. Choice of τ implies $0\leqslant \tau(z)\leqslant 1$, therefore

$$|\theta(\mathbf{x},t)| = |T(\mathbf{x},t) - \tau(z)| \leqslant 1.$$

Choose $\delta = [(8\times 7^4/10C_1^4)\,\mathrm{Ra}^{-4}]^{1/11}$, we get

$$\mathrm{Nu} \leqslant c\,\mathrm{Ra}^{4/11}$$

with

$$c = \left(\frac{1}{2\delta} + \frac{C_1^4}{16\times 7^4}\delta^{10}\,\mathrm{Ra}^4\right)\mathrm{Ra}^{-4/11} \approx 1.26.$$

□

V. UPPER BOUND FOR ROTATIONAL SYSTEM

In this section, we discuss the bound on Nusselt number for rotational system. We follow similar ideas as in Sec. IV. We first prove the following estimates.

Lemma 5.1: For $|\mathbf{m}|\geqslant 1$,

$$\left\|\frac{\mathrm{d}^2 w_{\mathbf{m}}}{\mathrm{d}z^2}\right\|_\infty \leqslant c_1\,\mathrm{Ra}\sqrt{m}\,\|\theta_{\mathbf{m}}\|_2 + \frac{c_1}{2}\mathrm{Ra}\sqrt{\mathrm{Ta}}\,\|\theta_{\mathbf{m}}\|_2$$

with $c_1 \approx 64.87$.

Lemma 5.2: For $|\mathbf{m}|\leqslant 1$,

$$\left\|\frac{\mathrm{d}^2 w_{\mathbf{m}}}{\mathrm{d}z^2}\right\|_\infty \leqslant c_2\,\mathrm{Ra}\left(\frac{\mathrm{Ta}}{4}+1\right)^{1/4}\|\theta_{\mathbf{m}}\|_2 \tag{5.1}$$

with $c_2 = 6^{1/4}$.

To prove Lemma 5.1 and Lemma 5.2. We need the following Lemma.

Lemma 5.3:

$$\left\|\frac{\mathrm{d}\zeta_{\mathbf{m}}}{\mathrm{d}z}\right\|_2 \leqslant \frac{1}{2}\mathrm{Ra}\|\theta_{\mathbf{m}}\|_2, \quad \left\|\frac{\mathrm{d}^2 w_{\mathbf{m}}}{\mathrm{d}z^2}\right\|_2 \leqslant \frac{1}{2}\mathrm{Ra}\|\theta_{\mathbf{m}}\|_2,$$

$$\left\|\frac{\mathrm{d}^4 w_{\mathbf{m}}}{\mathrm{d}z^4}\right\|_2^2 \leqslant 6\left(\mathrm{Ta}\left\|\frac{\mathrm{d}\zeta_{\mathbf{m}}}{\mathrm{d}z}\right\|_2^2 + \mathrm{Ra}^2 m^4\|\theta_{\mathbf{m}}\|_2^2\right).$$

Proof: Recall $w_{\mathbf{m}}, \zeta_{\mathbf{m}}$ satisfies

$$\left(-\frac{\mathrm{d}^2}{\mathrm{d}z^2}+m^2\right)\zeta_{\mathbf{m}}=\sqrt{\mathrm{Ta}}\frac{\mathrm{d}w_{\mathbf{m}}}{\mathrm{d}z}, \tag{5.2}$$

$$\left(-\frac{\mathrm{d}^2}{\mathrm{d}z^2}+m^2\right)^2 w_{\mathbf{m}}-\sqrt{\mathrm{Ta}}\frac{\mathrm{d}\zeta_{\mathbf{m}}}{\mathrm{d}z}=\mathrm{Ra}\,m^2\theta_{\mathbf{m}} \tag{5.3}$$

subject to boundary conditions

$$\zeta_{\mathbf{m}}(0)=\zeta_{\mathbf{m}}(1)=0,$$

$$w_{\mathbf{m}}(0)=w_{\mathbf{m}}(1)=\frac{\mathrm{d}w_{\mathbf{m}}}{\mathrm{d}z}(0)=\frac{\mathrm{d}w_{\mathbf{m}}}{\mathrm{d}z}(1)=0.$$

Equation (5.2) multiplied by $\zeta_{\mathbf{m}}$+(5.3) multiplied by $w_{\mathbf{m}}$, integrate by parts using boundary constraints, we obtain

$$\int_0^1\left(\left|\frac{\mathrm{d}\zeta_{\mathbf{m}}}{\mathrm{d}z}\right|^2+m^2\zeta_{\mathbf{m}}^2+\left|\frac{\mathrm{d}^2w_{\mathbf{m}}}{\mathrm{d}z^2}\right|^2+2m^2\left|\frac{\mathrm{d}w_{\mathbf{m}}}{\mathrm{d}z}\right|^2+m^4w_{\mathbf{m}}^2\right)\mathrm{d}z$$
$$=\int_0^1\mathrm{Ra}\,m^2\theta_{\mathbf{m}}w_{\mathbf{m}}\leqslant\int_0^1\frac{\mathrm{Ra}^2\,\theta_{\mathbf{m}}^2(z)}{4}\mathrm{d}z+\int_0^1 m^4w_{\mathbf{m}}^2.$$

In particular, we have

$$\left\|\frac{\mathrm{d}\zeta_{\mathbf{m}}}{\mathrm{d}z}\right\|_2\leqslant\frac{1}{2}\mathrm{Ra}\|\theta_{\mathbf{m}}\|_2,\quad \left\|\frac{\mathrm{d}^2w_{\mathbf{m}}}{\mathrm{d}z^2}\right\|_2\leqslant\frac{1}{2}\mathrm{Ra}\|\theta_{\mathbf{m}}\|_2. \tag{5.4}$$

On the other hand, move $\sqrt{\mathrm{Ta}}\,\mathrm{d}\zeta_{\mathbf{m}}/\mathrm{d}z$ to the right, squaring (5.3), integrate by parts, we get

$$\left\|\frac{\mathrm{d}^4w_{\mathbf{m}}}{\mathrm{d}z^4}\right\|_2^2-2m^2\int_0^1\left[\frac{\mathrm{d}^4w_{\mathbf{m}}^*}{\mathrm{d}z^4}\frac{\mathrm{d}^2w_{\mathbf{m}}}{\mathrm{d}z^2}+\frac{\mathrm{d}^2w_{\mathbf{m}}^*}{\mathrm{d}z^2}\frac{\mathrm{d}^4w_{\mathbf{m}}}{\mathrm{d}z^4}\right]\mathrm{d}z+6m^4\left\|\frac{\mathrm{d}^2w_{\mathbf{m}}}{\mathrm{d}z^2}\right\|_2^2+4m^6\left\|\frac{\mathrm{d}w_{\mathbf{m}}}{\mathrm{d}z}\right\|_2^2+m^8\|w_{\mathbf{m}}\|_2^2$$
$$\leqslant 2\,\mathrm{Ta}\left\|\frac{\mathrm{d}\zeta_{\mathbf{m}}}{\mathrm{d}z}\right\|_2^2+2\,\mathrm{Ra}^2\,m^4\|\theta_{\mathbf{m}}\|_2^2.$$

The indefinite term above can be estimated by its neighboring terms. For $\epsilon>0$,

$$\left|2m^2\int_0^1\frac{\mathrm{d}^4w_{\mathbf{m}}^*}{\mathrm{d}z^4}\frac{\mathrm{d}^2w_{\mathbf{m}}}{\mathrm{d}z^2}+\frac{\mathrm{d}^2w_{\mathbf{m}}^*}{\mathrm{d}z^2}\frac{\mathrm{d}^4w_{\mathbf{m}}}{\mathrm{d}z^4}\right|\leqslant\epsilon\left\|\frac{\mathrm{d}^4w_{\mathbf{m}}}{\mathrm{d}z^4}\right\|_2^2+\frac{4m^4}{\epsilon}\left\|\frac{\mathrm{d}^2w_{\mathbf{m}}}{\mathrm{d}z^2}\right\|_2^2.$$

Choose $\epsilon=\frac{2}{3}$, we have

$$\left\|\frac{\mathrm{d}^4w_{\mathbf{m}}}{\mathrm{d}z^4}\right\|_2^2\leqslant 6\left(\mathrm{Ta}\left\|\frac{\mathrm{d}\zeta_{\mathbf{m}}}{\mathrm{d}z}\right\|_2^2+\mathrm{Ra}^2\,m^4\|\theta_m\|_2^2\right).$$

□

Proof of Lemma 5.1: Since

$$\left(-\frac{\mathrm{d}^2}{\mathrm{d}z^2}+m^2\right)^2 w_{\mathbf{m}}=\sqrt{\mathrm{Ta}}\frac{\mathrm{d}\zeta_{\mathbf{m}}}{\mathrm{d}z}+\mathrm{Ra}\,m^2\theta_{\mathbf{m}}.$$

By Lemma 5.3, $\| \mathrm{d}\zeta_{\mathbf{m}}/\mathrm{d}z \|_2 \leqslant \frac{1}{2}\mathrm{Ra}\| \theta_{\mathbf{m}}\|_2$, therefore for $|\mathbf{m}| \geqslant 1$, by Proposition 3.1,

$$\left\| \frac{\mathrm{d}^2 w_{\mathbf{m}}}{\mathrm{d}z^2} \right\|_\infty \leqslant c_1 m^{-3/2}\left(\sqrt{\mathrm{Ta}}\frac{1}{2}\mathrm{Ra}\| \theta_{\mathbf{m}}\|_2 + \mathrm{Ra}\, m^2 \| \theta_{\mathbf{m}}\|_2 \right) \leqslant \frac{c_1}{2}\mathrm{Ra}\sqrt{\mathrm{Ta}}\| \theta_{\mathbf{m}}\|_2 + c_1\, \mathrm{Ra}\sqrt{m}\| \theta_{\mathbf{m}}\|_2 .$$

To prove Lemma 5.2, we need the following lemma from Ref. 10.

Lemma 5.4 (Ref. 10): *Let $f(z)$ be a smooth real valued function satisfying both homogeneous Dirichlet and Neumann boundary conditions on [0,1]. Then*

$$\left\| \frac{\mathrm{d}^2 f}{\mathrm{d}z^2} \right\|_\infty \leqslant \sqrt{2\left\| \frac{\mathrm{d}^4 f}{\mathrm{d}z^4} \right\|_2 \left\| \frac{\mathrm{d}^2 f}{\mathrm{d}z^2} \right\|_2}.$$

An immediate corollary of Lemma 5.4 is

Lemma 5.5: Let $w(z)$ be a smooth complex valued function satisfying both homogeneous Dirichlet and Neumann boundary conditions on [0,1]. Then

$$\left\| \frac{\mathrm{d}^2 w}{\mathrm{d}z^2} \right\|_\infty \leqslant \sqrt{2\left\| \frac{\mathrm{d}^4 w}{\mathrm{d}z^4} \right\|_2 \left\| \frac{\mathrm{d}^2 w}{\mathrm{d}z^2} \right\|_2}.$$

Proof: Write $w(z) = u(z) + iv(z)$, then $u(z), v(z)$ are real valued smooth functions satisfying both homogeneous Dirichlet and Neumann boundary conditions on [0,1]. Therefore

$$\begin{aligned} \left| \frac{\mathrm{d}^2 w}{\mathrm{d}z^2}(z) \right|_2^2 &= \left| \frac{\mathrm{d}^2 u}{\mathrm{d}z^2}(z) \right|_2^2 + \left| \frac{\mathrm{d}^2 v}{\mathrm{d}z^2}(z) \right|_2^2 \leqslant 2\left\| \frac{\mathrm{d}^2 u}{\mathrm{d}z^2} \right\|_2 \left\| \frac{\mathrm{d}^4 u}{\mathrm{d}z^4} \right\|_2 + 2\left\| \frac{\mathrm{d}^2 v}{\mathrm{d}z^2} \right\|_2 \left\| \frac{\mathrm{d}^4 v}{\mathrm{d}z^4} \right\|_2 \\ &\leqslant \frac{1}{\epsilon}\left\| \frac{\mathrm{d}^2 u}{\mathrm{d}z^2} \right\|_2^2 + \epsilon\left\| \frac{\mathrm{d}^4 u}{\mathrm{d}z^4} \right\|_2^2 + \frac{1}{\epsilon}\left\| \frac{\mathrm{d}^2 v}{\mathrm{d}z^2} \right\|_2^2 + \epsilon\left\| \frac{\mathrm{d}^4 v}{\mathrm{d}z^4} \right\|_2^2 = \frac{1}{\epsilon}\left\| \frac{\mathrm{d}^2 w}{\mathrm{d}z^2} \right\|_2^2 + \epsilon\left\| \frac{\mathrm{d}^4 w}{\mathrm{d}z^4} \right\|_2^2 \end{aligned}$$

for any $\epsilon > 0$. Minimize the right-hand side in ϵ, we obtain

$$\left| \frac{\mathrm{d}^2 w}{\mathrm{d}z^2}(z) \right|_2^2 \leqslant 2\left\| \frac{\mathrm{d}^2 w}{\mathrm{d}z^2} \right\|_2 \left\| \frac{\mathrm{d}^4 w}{\mathrm{d}z^4} \right\|_2 .$$

□

Proof of Lemma 5.2: By Lemma 5.3, we have $\| \mathrm{d}^2 w_{\mathbf{m}}/\mathrm{d}z^2 \|_2 \leqslant \frac{1}{2}\mathrm{Ra}\| \theta_{\mathbf{m}}\|_2$ and

$$\begin{aligned} \left\| \frac{\mathrm{d}^4 w_{\mathbf{m}}}{\mathrm{d}z^4} \right\|_2^2 &\leqslant 6\left(\mathrm{Ta}\left\| \frac{\mathrm{d}\zeta_{\mathbf{m}}}{\mathrm{d}z} \right\|_2^2 + \mathrm{Ra}^2 m^4 \| \theta_{\mathbf{m}}\|_2^2 \right) \\ &\leqslant 6\left(\frac{1}{4}\mathrm{Ta}\,\mathrm{Ra}^2 \| \theta_{\mathbf{m}}\|_2^2 + \mathrm{Ra}^2 \| \theta_{\mathbf{m}}\|_2^2 \right) = 6\,\mathrm{Ra}^2 \| \theta_m\|_2^2 \left(\frac{1}{4}\mathrm{Ta} + 1 \right). \end{aligned}$$

It then follows from Lemma 5.5 that

$$\left\| \frac{\mathrm{d}^2 w_{\mathbf{m}}}{\mathrm{d}z^2} \right\|_\infty \leqslant \mathrm{Ra}\| \theta_{\mathbf{m}}\|_2 6^{1/4}\left(\frac{1}{4}\mathrm{Ta} + 1 \right)^{1/4} \leqslant \mathrm{Ra}\| \theta_{\mathbf{m}}\|_2 6^{1/4}\left(\frac{\sqrt{\mathrm{Ta}}}{2} + 1 \right).$$

In the last inequality, we used the fact that

$$\left(\frac{1}{4}\mathrm{Ta} + 1 \right)^{1/4} \leqslant \left(\frac{\sqrt{\mathrm{Ta}}}{2} + 1 \right).$$

Proof of Theorem 2.2: Theorem 2.2 now follows from the same line of proof as in Sec. IV. In fact, estimates in Lemma 5.1 imply for $|\mathbf{m}|\geqslant 1$, the growth of $w_{\mathbf{m}}$ near $z=0$ is controlled by (similar estimates near $z=1$)

$$|w_{\mathbf{m}}(z)|\leqslant \tfrac{1}{2}z^2\|w_{\mathbf{m}}''\|_\infty \leqslant \tfrac{1}{2}z^2 c_1\sqrt{m}\,\mathrm{Ra}\|\theta_{\mathbf{m}}\|_2+\tfrac{1}{4}z^2c_1\,\mathrm{Ra}\sqrt{\mathrm{Ta}}\|\theta_{\mathbf{m}}\|_2,$$

this together with growth estimate on $\theta_{\mathbf{m}}$,

$$|\theta_{\mathbf{m}}(z)|\leqslant\sqrt{z}\left(\int_0^{1/2}\left|\frac{\mathrm{d}\theta_{\mathbf{m}}}{\mathrm{d}z}\right|^2\right)^{1/2}$$

imply the following estimates for the indefinite term in $Q_{\mathbf{m}}(\theta_{\mathbf{m}})$:

$$\begin{aligned}
\left|\int_0^1\tau'(w_{\mathbf{m}}^*\theta_{\mathbf{m}}+w_{\mathbf{m}}\theta_{\mathbf{m}}^*)\right| &\leqslant \frac{1}{\delta}\left(\int_0^\delta\frac{1}{2}z^{5/2}\|w_{\mathbf{m}}''\|_\infty\left(\int_0^{1/2}\left|\frac{\mathrm{d}\theta_{\mathbf{m}}}{\mathrm{d}z}\right|^2\right)^{1/2}\right.\\
&\quad\left.+\int_{1-\delta}^1\frac{1}{2}z^{5/2}\|w_{\mathbf{m}}''\|_\infty\left(\int_{1/2}^1\left|\frac{\mathrm{d}\theta_{\mathbf{m}}}{\mathrm{d}z}\right|^2\right)^{1/2}\right)\\
&\leqslant \frac{c_1}{7}\delta^{5/2}\sqrt{m}\,\mathrm{Ra}\|\theta_{\mathbf{m}}\|_2\left[\left(\int_0^{1/2}\left|\frac{\mathrm{d}\theta_{\mathbf{m}}}{\mathrm{d}z}\right|^2\right)^{1/2}+\left(\int_{1/2}^1\left|\frac{\mathrm{d}\theta_{\mathbf{m}}}{\mathrm{d}z}\right|^2\right)^{1/2}\right]\\
&\quad+\frac{c_1}{14}\delta^{5/2}\,\mathrm{Ra}\sqrt{\mathrm{Ta}}\|\theta_{\mathbf{m}}\|_2\left[\left(\int_0^{1/2}\left|\frac{\mathrm{d}\theta_{\mathbf{m}}}{\mathrm{d}z}\right|^2\right)^{1/2}+\left(\int_{1/2}^1\left|\frac{\mathrm{d}\theta_{\mathbf{m}}}{\mathrm{d}z}\right|^2\right)^{1/2}\right]\\
&\leqslant \frac{\sqrt{2}c_1}{7}\delta^{5/2}\sqrt{m}\,\mathrm{Ra}\|\theta_{\mathbf{m}}\|_2\left\|\frac{\mathrm{d}\theta_{\mathbf{m}}}{\mathrm{d}z}\right\|_2+\frac{\sqrt{2}c_1}{14}\delta^{5/2}\,\mathrm{Ra}\sqrt{\mathrm{Ta}}\|\theta_{\mathbf{m}}\|_2\left\|\frac{\mathrm{d}\theta_{\mathbf{m}}}{\mathrm{d}z}\right\|_2\\
&\leqslant \frac{(\sqrt{2})^4c_1^4}{16\times 7^4}\delta^{10}\,\mathrm{Ra}^4\|\theta_{\mathbf{m}}\|_2^2+m^2\|\theta_{\mathbf{m}}\|_2^2+\frac{1}{2}\left\|\frac{\mathrm{d}\theta_{\mathbf{m}}}{\mathrm{d}z}\right\|_2^2+\frac{c_1^2}{4\times 49}\delta^5\,\mathrm{Ra}^2\,\mathrm{Ta}\|\theta_{\mathbf{m}}\|_2^2\\
&\quad+\frac{1}{2}\left\|\frac{\mathrm{d}\theta_{\mathbf{m}}}{\mathrm{d}z}\right\|_2^2. \qquad (5.5)
\end{aligned}$$

Therefore when $|\mathbf{m}|\geqslant 1$, $Q_{\mathbf{m}}(\theta_{\mathbf{m}})$ is bounded below by

$$Q_{\mathbf{m}}(\theta_{\mathbf{m}})\geqslant-\frac{(\sqrt{2})^4c_1^4}{16\times 7^4}\delta^{10}\,\mathrm{Ra}^4\|\theta_{\mathbf{m}}\|_2^2-\frac{c_1^2}{4\times 49}\delta^5\,\mathrm{Ra}^2\,\mathrm{Ta}\|\theta_{\mathbf{m}}\|_2^2.$$

On the other hand, for $|\mathbf{m}|\leqslant 1$, Lemma 3.3 gives

$$\begin{aligned}
\left|\int_0^1\tau'(w_{\mathbf{m}}^*\theta_{\mathbf{m}}+w_{\mathbf{m}}\theta_{\mathbf{m}}^*)\right| &\leqslant \frac{1}{\delta}\int_0^\delta|w_{\mathbf{m}}||\theta_{\mathbf{m}}|\mathrm{d}z+\frac{1}{\delta}\int_{1-\delta}^1|w_{\mathbf{m}}||\theta_{\mathbf{m}}|\mathrm{d}z\\
&\leqslant \frac{\sqrt{2}c_2}{7}\delta^{5/2}\,\mathrm{Ra}\left(\frac{\sqrt{\mathrm{Ta}}}{2}+1\right)\|\theta_{\mathbf{m}}\|_2\left\|\frac{\mathrm{d}\theta_{\mathbf{m}}}{\mathrm{d}z}\right\|_2\\
&\leqslant \frac{c_2^2}{98}\delta^5\,\mathrm{Ra}^2\left(\frac{\sqrt{\mathrm{Ta}}}{2}+1\right)^2\|\theta_{\mathbf{m}}\|_2^2+\left\|\frac{\mathrm{d}\theta_{\mathbf{m}}}{\mathrm{d}z}\right\|_2^2.
\end{aligned}$$

Therefore when $|\mathbf{m}|\leqslant 1$, $Q_{\mathbf{m}}(\theta_{\mathbf{m}})$ is bounded from below by

$$Q_{\mathbf{m}}(\theta_{\mathbf{m}}) \geqslant -\frac{c_2^2}{98}\delta^5 \mathrm{Ra}^2\left(\frac{\sqrt{\mathrm{Ta}}}{2}+1\right)^2 \|\theta_{\mathbf{m}}\|_2^2 \tag{5.6}$$

and

$$\begin{aligned}
\mathrm{Nu} &\leqslant \int_0^1 \tau'(z)^2\,\mathrm{d}z - \frac{1}{\mathcal{A}}\int_0^{L_x/h}\int_0^{L_y/h}\sum_{\mathbf{m}} Q_{\mathbf{m}}(\theta_{\mathbf{m}})\mathrm{d}x\,\mathrm{d}y \\
&\leqslant \frac{1}{2\delta} + \frac{c_2^2}{98}\delta^5 \mathrm{Ra}^2\left(\frac{\sqrt{\mathrm{Ta}}}{2}+1\right)^2 \sum_{|\mathbf{m}|\leqslant 1}\|\theta_{\mathbf{m}}\|_2^2 + \frac{c_1^4}{4\times 7^4}\delta^{10}\mathrm{Ra}^4 \sum_{|\mathbf{m}|\geqslant 1}\|\theta_{\mathbf{m}}\|_2^2 \\
&\quad + \frac{c_1^2}{4\times 49}\delta^5 \mathrm{Ra}^2\,\mathrm{Ta}\sum_{|\mathbf{m}|\geqslant 1}\|\theta_{\mathbf{m}}\|_2^2 \\
&\leqslant \frac{1}{2\delta} + \max\left(\frac{c_2^2}{98}\delta^5 \mathrm{Ra}^2\left(\frac{\sqrt{\mathrm{Ta}}}{2}+1\right)^2, \frac{c_1^4}{4\times 7^4}\delta^{10}\mathrm{Ra}^4 + \frac{c_1^2}{4\times 49}\delta^5 \mathrm{Ra}^2\,\mathrm{Ta}\right) \\
&= \frac{1}{2\delta} + \frac{c_1^4}{4\times 7^4}\delta^{10}\mathrm{Ra}^4 + \frac{c_1^2}{4\times 49}\delta^5 \mathrm{Ra}^2\,\mathrm{Ta}.
\end{aligned}$$

The last inequality uses the fact that $|\theta(\mathbf{x},t)|\leqslant 1$ and

$$\sum_{|\mathbf{m}|\leqslant 1}\|\theta_{\mathbf{m}}\|_2^2 \leqslant \frac{1}{\mathcal{A}}\int_V \theta^2\,\mathrm{d}V \leqslant 1.$$

Choose $\delta=(2\times 7^4/10\cdot c_1^4)^{1/11}\mathrm{Ra}^{-4/11}\mathrm{Ta}^{-1/6}$, we get

$$\begin{aligned}
\mathrm{Nu} &\leqslant \frac{1}{2}\left(\frac{10c_1^4}{2\times 7^4}\right)^{1/11}\mathrm{Ra}^{4/11}\mathrm{Ta}^{1/6} + \frac{c_1^4}{4\times 7^4}\left(\frac{2\times 7^4}{10\cdot c_1^4}\right)^{10/11}\mathrm{Ra}^{4/11}\mathrm{Ta}^{-5/3} \\
&\quad + \frac{c_1^2}{4\times 49}\left(\frac{2\times 7^4}{10\cdot c_1^4}\right)^{5/11}\mathrm{Ra}^{2/11}\mathrm{Ta}^{1/6} \\
&= 1.3\,\mathrm{Ra}^{4/11}\mathrm{Ta}^{1/6} + 0.13\,\mathrm{Ra}^{4/11}\mathrm{Ta}^{-5/3} + 0.18\,\mathrm{Ra}^{2/11}\mathrm{Ta}^{1/6}.
\end{aligned}$$

To prove the second bound, we observe that

$$|w_{\mathbf{m}}(z)| \leqslant \tfrac{1}{2}z^2\|w_{\mathbf{m}}''\|_\infty \leqslant \tfrac{1}{2}z^2 c_1\sqrt{m}\,\mathrm{Ra}\|\theta_{\mathbf{m}}\|_2 + \tfrac{1}{4}z^2 c_1\,\mathrm{Ra}\sqrt{\mathrm{Ta}}\|\theta_{\mathbf{m}}\|_2 \leqslant \tfrac{1}{2}z^2 c_1\,\mathrm{Ra}(\tfrac{1}{2}\sqrt{\mathrm{Ta}}+1)\sqrt{m}\|\theta_{\mathbf{m}}\|_2, \tag{5.7}$$

therefore when $|\mathbf{m}|\geqslant 1$,

$$Q_{\mathbf{m}}(\theta_{\mathbf{m}}) \geqslant -\frac{c_1^4}{16\times 7^4}\left[\mathrm{Ra}\left(\frac{1}{2}\sqrt{\mathrm{Ta}}+1\right)\right]^4 \delta^{10}\|\theta_{\mathbf{m}}\|_2^2$$

and

$$\begin{aligned}
\mathrm{Nu} &\leqslant \frac{1}{2\delta} + \frac{c_2^2}{98}\delta^5 \mathrm{Ra}^2\left(\frac{\sqrt{\mathrm{Ta}}}{2}+1\right)^2 \sum_{|\mathbf{m}|\leqslant 1}\|\theta_{\mathbf{m}}\|_2^2 + \frac{c_1^4}{16\times 7^4}\left[\mathrm{Ra}\left(\frac{1}{2}\sqrt{\mathrm{Ta}}+1\right)\right]^4 \delta^{10}\sum_{|\mathbf{m}|\geqslant 1}\|\theta_{\mathbf{m}}\|_2^2 \\
&\leqslant \frac{1}{2\delta} + \frac{c_1^4}{16\times 7^4}\left[\mathrm{Ra}\left(\frac{1}{2}\sqrt{\mathrm{Ta}}+1\right)\right]^4 \delta^{10}.
\end{aligned}$$

Choose $\delta=(8\times 7^4/10c_1^4)^{1/11}[\mathrm{Ra}(\frac{1}{2}\sqrt{\mathrm{Ta}}+1)]^{-4/11}$, we get

$$\mathrm{Nu} \leqslant c[\mathrm{Ra}(\tfrac{1}{2}\sqrt{\mathrm{Ta}}+1)]^{4/11},$$

$$c=\left(\frac{1}{2\delta}+\frac{c_1^4}{16\times 7^4}\delta^{10}\,\mathrm{Ra}^4\left(\frac{\sqrt{\mathrm{Ta}}}{2}+1\right)^4\right)\mathrm{Ra}^{-4/11}\left(\frac{\sqrt{\mathrm{Ta}}}{2}+1\right)^{-4/11}\approx 1.26.$$

□

VI. UNIFORM BOUND FOR WEAKLY ROTATING SYSTEM

In this section, we prove Theorem 2.3. We shall need the following expression for Nu in terms of the velocity field

$$\mathrm{Nu}=\frac{1}{\mathcal{A}}\frac{1}{\mathrm{Ra}}\langle\|\nabla\mathbf{u}\|^2\rangle.$$

In particular, for $\mathbf{u}=(u,v,w)$, this relation implies

$$\sum_{\mathbf{m}}\|w'_{\mathbf{m}}\|_2^2\leqslant\frac{1}{\mathcal{A}}\langle\|\nabla w\|^2\rangle\leqslant\mathrm{Ra}\,\mathrm{Nu}.$$

Here $w_{\mathbf{m}}(z)$ is the Fourier modes of w.

We start with the background field decomposition. As in Sec. V, we work with Fourier modes to estimate the quadratic form. We shall use slightly different versions of estimates on higher derivatives of $w_{\mathbf{m}}$. Corresponding versions of Lemma 5.1 and Lemma 5.2 are the following.

Lemma 6.1: For $|\mathbf{m}|\geqslant 1$,

$$\|w''_{\mathbf{m}}\|_\infty\leqslant\frac{C_1}{m^2}\sqrt{\mathrm{Ta}}\|w'_{\mathbf{m}}\|_2+c_1\,\mathrm{Ra}\sqrt{m}\|\theta_{\mathbf{m}}\|_2.$$

Here c_1 is the same constant as in Lemma 5.1, C_1 is a constant independent of m, Ra, Ta.

Lemma 6.2. For $|\mathbf{m}|\leqslant 1$,

$$\|w''_{\mathbf{m}}\|_\infty\leqslant 6^{1/4}\sqrt{\mathrm{Ra}\|\theta_{\mathbf{m}}\|_2(\mathrm{Ta}\|w'_{\mathbf{m}}\|_2+\mathrm{Ra}\|\theta_{\mathbf{m}}\|_2)}.$$

To prove Lemma 6.1 and 6.2, we first prove the following Lemma.

Lemma 6.3: If $g_{\mathbf{m}}$ *satisfies*

$$\left(\frac{\mathrm{d}^2}{\mathrm{d}z^2}-m^2\right)g_{\mathbf{m}}=h_{\mathbf{m}},$$

then

$$\left\|\frac{\mathrm{d}g_{\mathbf{m}}}{\mathrm{d}z}\right\|_2\leqslant\|h_{\mathbf{m}}\|_2,$$

and when $|\mathbf{m}|\geqslant 1$

$$\left\|\frac{\mathrm{d}g_{\mathbf{m}}}{\mathrm{d}z}\right\|_2\leqslant\frac{c_0}{\sqrt{m}}\|h_{\mathbf{m}}\|_2$$

with $c_0=1/\sqrt{2}\sqrt{(e^2+1)(e^2-1)}\approx 0.810\,258$.

Proof: From explicit expression of the Green's function, we have

$$g_{\mathbf{m}}(z)=\int_0^1 \frac{\cosh m(z+\zeta-1)}{2m\sinh m}h_{\mathbf{m}}(\zeta)\mathrm{d}\zeta-\int_0^1 \frac{\cosh m(1-|z-\zeta|)}{2m\sinh m}h_{\mathbf{m}}(\zeta)\mathrm{d}\zeta.$$

Differentiate, we get

$$\frac{\mathrm{d}g_{\mathbf{m}}}{\mathrm{d}z}(z)=\int_0^1 \frac{\sinh m(z+\zeta-1)}{2\sinh m}h_{\mathbf{m}}(\zeta)\mathrm{d}\zeta-\int_0^z \frac{\sinh m(1-z+\zeta)}{2\sinh m}h_{\mathbf{m}}(\zeta)\mathrm{d}\zeta$$
$$-\int_z^1 \frac{\sinh m(1+z-\zeta)}{2\sinh m}h_{\mathbf{m}}(\zeta)\mathrm{d}\zeta.$$

In particular,

$$\left|\frac{\mathrm{d}g_{\mathbf{m}}}{\mathrm{d}z}(z)\right|\leqslant\int_0^1\left|\frac{\sinh m(z+\zeta-1)}{2\sinh m}h_{\mathbf{m}}(\zeta)\right|\mathrm{d}\zeta+\int_0^z\left|\frac{\sinh m(1-z+\zeta)}{2\sinh m}h_{\mathbf{m}}(\zeta)\right|\mathrm{d}\zeta$$
$$+\int_z^1\left|\frac{\sinh m(1+z-\zeta)}{2\sinh m}h_{\mathbf{m}}(\zeta)\right|\mathrm{d}\zeta\leqslant\int_0^1|h_{\mathbf{m}}|\mathrm{d}\zeta\leqslant\|h_{\mathbf{m}}\|_2.$$

Here we use the fact that when $0\leqslant z,\ \zeta\leqslant 1$,

$$|\sinh m(z+\zeta-1)|\leqslant\sinh m,$$

$$|\sinh m(1-|z-\zeta|)|\leqslant\sinh m.$$

On the other hand, from Lemma 3.2, we have when $|\mathbf{m}|\geqslant 1$,

$$\left\|\frac{\mathrm{d}g_{\mathbf{m}}}{\mathrm{d}z}\right\|_\infty\leqslant\frac{1}{\sqrt{2}\sqrt{m}}\sqrt{\frac{e^2+1}{e^2-1}}\|h_{\mathbf{m}}\|_2.$$

The conclusion of the Lemma follows directly. □

A direct corollary of Lemma 6.3 is

$$\left\|\frac{\mathrm{d}\zeta_{\mathbf{m}}}{\mathrm{d}z}\right\|_2\leqslant\frac{c_0}{\sqrt{m}}\sqrt{\mathrm{Ta}}\|w'_{\mathbf{m}}\|_2\quad\text{for }|\mathbf{m}|\geqslant 1 \tag{6.1}$$

and

$$\left\|\frac{\mathrm{d}\zeta_{\mathbf{m}}}{\mathrm{d}z}\right\|_2\leqslant\sqrt{\mathrm{Ta}}\|w'_{\mathbf{m}}\|_2\quad\text{for }|\mathbf{m}|\leqslant 1. \tag{6.2}$$

Proof of Lemma 6.1: When $|\mathbf{m}|\geqslant 1$, Proposition 3.1 and (6.1) derives

$$\|w''_{\mathbf{m}}\|_\infty\leqslant\frac{c_1}{m^{3/2}}\left(\sqrt{\mathrm{Ta}}\left\|\frac{\mathrm{d}\zeta_{\mathbf{m}}}{\mathrm{d}z}\right\|_2+\mathrm{Ra}\,m^2\|\theta_{\mathbf{m}}\|_2\right)\leqslant\frac{c_1}{m^{3/2}}\mathrm{Ra}\,m^2\|\theta_{\mathbf{m}}\|_2+\frac{c_1}{m^{3/2}}\sqrt{\mathrm{Ta}}\frac{c_0}{\sqrt{m}}\sqrt{\mathrm{Ta}}\|w'_{\mathbf{m}}\|_2$$
$$=c_1\,\mathrm{Ra}\sqrt{m}\|\theta_{\mathbf{m}}\|_2+\frac{C_1}{m^2}\mathrm{Ta}\|w'_{\mathbf{m}}\|_2,$$

with $C_1=c_1c_0$.

Proof of Lemma 6.2: By Lemma 5.3 and (6.2),

$$\left\| \frac{\mathrm{d}^4 w_{\mathbf{m}}}{\mathrm{d}z^4} \right\|_2^2 \leqslant 6\left(\mathrm{Ta} \left\| \frac{\mathrm{d}\zeta_{\mathbf{m}}}{\mathrm{d}z} \right\|_2^2 + \mathrm{Ra}^2 \| \theta_{\mathbf{m}} \|_2^2 \right) \leqslant 6(\mathrm{Ta}^2 \| w'_{\mathbf{m}} \|_2^2 + \mathrm{Ra}^2 \| \theta_{\mathbf{m}} \|_2^2)$$

and

$$\left\| \frac{\mathrm{d}^2 w_{\mathbf{m}}}{\mathrm{d}z^2} \right\|_2 \leqslant \frac{1}{2} \mathrm{Ra} \| \theta_{\mathbf{m}} \|_2 ,$$

conclusion follows from Lemma 5.5.

We are now ready to estimate $Q_{\mathbf{m}}(\theta_{\mathbf{m}})$. The indefinite term in $Q_{\mathbf{m}}(\theta_{\mathbf{m}})$ can be estimated as follows. For $|\mathbf{m}| \geqslant 1$,

$$\begin{aligned}
\left| \int_0^1 \tau' (w_{\mathbf{m}} \theta_{\mathbf{m}}^* + w_{\mathbf{m}}^* \theta_{\mathbf{m}}) \mathrm{d}z \right| &\leqslant \frac{1}{\delta} \int_0^\delta \frac{1}{2} z^2 \left(c_1 \, \mathrm{Ra} \sqrt{m} \| \theta_{\mathbf{m}} \|_2 |\theta_{\mathbf{m}}(z)| + \frac{C_1}{m^2} \sqrt{\mathrm{Ta}} \| w'_{\mathbf{m}} \|_2 |\theta_{\mathbf{m}}(z)| \right) \mathrm{d}z \\
&\quad + \frac{1}{\delta} \int_{1-\delta}^1 \frac{1}{2} (1-z)^2 \left(c_1 \, \mathrm{Ra} \sqrt{m} \| \theta_{\mathbf{m}} \|_2 |\theta_{\mathbf{m}}(z)| \right. \\
&\quad \left. + \frac{C_1}{m^2} \sqrt{\mathrm{Ta}} \| w'_{\mathbf{m}} \|_2 |\theta_{\mathbf{m}}(z)| \right) \mathrm{d}z \\
&\leqslant \frac{1}{\delta} \int_0^\delta \frac{1}{2} z^{5/2} c_1 \, \mathrm{Ra} \sqrt{m} \| \theta_{\mathbf{m}} \|_2 \left(\int_0^{1/2} \left| \frac{\mathrm{d}\theta_{\mathbf{m}}}{\mathrm{d}z} \right|^2 \right)^{1/2} \mathrm{d}z \\
&\quad + \frac{1}{\delta} \int_{1-\delta}^1 \frac{1}{2} (1-z)^{5/2} c_1 \, \mathrm{Ra} \sqrt{m} \| \theta_{\mathbf{m}} \|_2 \left(\int_{1/2}^1 \left| \frac{\mathrm{d}\theta_{\mathbf{m}}}{\mathrm{d}z} \right|^2 \right)^{1/2} \mathrm{d}z \\
&\quad + \frac{1}{\delta} \int_0^\delta \frac{1}{2} z^{5/2} \frac{C_1}{m^2} \sqrt{\mathrm{Ta}} \| w'_{\mathbf{m}} \|_2 \left(\int_0^{1/2} \left| \frac{\mathrm{d}\theta_{\mathbf{m}}}{\mathrm{d}z} \right|^2 \right)^{1/2} \mathrm{d}z \\
&\quad + \frac{1}{\delta} \int_{1-\delta}^1 \frac{1}{2} (1-z)^{5/2} \frac{C_1}{m^2} \sqrt{\mathrm{Ta}} \| w'_{\mathbf{m}} \|_2 \left(\int_{1/2}^1 \left| \frac{\mathrm{d}\theta_{\mathbf{m}}}{\mathrm{d}z} \right|^2 \right)^{1/2} \mathrm{d}z \\
&\leqslant \frac{\sqrt{2}}{7} c_1 \delta_1^{5/2} \mathrm{Ra} \sqrt{m} \| \theta_{\mathbf{m}} \|_2 \left\| \frac{\mathrm{d}\theta_{\mathbf{m}}}{\mathrm{d}z} \right\|_2 + \frac{\sqrt{2}}{7} \delta^{5/2} \frac{C_1}{m^2} \sqrt{\mathrm{Ta}} \| w'_{\mathbf{m}} \|_2 \left\| \frac{\mathrm{d}\theta_{\mathbf{m}}}{\mathrm{d}z} \right\|_2 \\
&\leqslant \frac{c_1^4}{4 \times 7^4} \delta^{10} \mathrm{Ra}^4 \| \theta_{\mathbf{m}} \|_2^2 + m^2 \| \theta_{\mathbf{m}} \|_2^2 + \frac{1}{2} \left\| \frac{\mathrm{d}\theta_{\mathbf{m}}}{\mathrm{d}z} \right\|_2^2 + \frac{C_1^2}{49} \delta^5 \frac{\mathrm{Ta}}{m^4} \| w'_{\mathbf{m}} \|_2^2 \\
&\quad + \frac{1}{2} \left\| \frac{\mathrm{d}\theta_{\mathbf{m}}}{\mathrm{d}z} \right\|_2^2 . \qquad (6.3)
\end{aligned}$$

Therefore for $|\mathbf{m}| \geqslant 1$, $Q_{\mathbf{m}}(\theta_{\mathbf{m}})$ is bounded from below by

$$Q_{\mathbf{m}}(\theta_{\mathbf{m}}) \geqslant - \frac{c_1^4}{4 \times 7^4} \delta^{10} \mathrm{Ra}^4 \| \theta_{\mathbf{m}} \|_2^2 - \frac{C_1^2}{49} \delta^5 \frac{\mathrm{Ta}}{m^4} \| w'_{\mathbf{m}} \|_2^2 .$$

On the other hand, for $|\mathbf{m}| \leqslant 1$,

$$\left|\int_0^1 \tau'(w_{\mathbf{m}}\theta_{\mathbf{m}}^*+w_{\mathbf{m}}^*\theta_{\mathbf{m}})\mathrm{d}z\right| \leqslant \frac{6^{1/4}\sqrt{2}}{7}\delta^{5/2}\sqrt{\mathrm{Ra}\|\theta_{\mathbf{m}}\|_2(\mathrm{Ta}\|w'_{\mathbf{m}}\|_2+\mathrm{Ra}\|\theta_{\mathbf{m}}\|_2)}\left\|\frac{\mathrm{d}\theta_{\mathbf{m}}}{\mathrm{d}z}\right\|_2$$
$$\leqslant \frac{\sqrt{6}}{98}\delta^5[\mathrm{Ra}\|\theta_{\mathbf{m}}\|_2(\mathrm{Ta}\|w'_{\mathbf{m}}\|+\mathrm{Ra}\|\theta_{\mathbf{m}}\|_2)]+\left\|\frac{\mathrm{d}\theta_{\mathbf{m}}}{\mathrm{d}z}\right\|_2^2,$$

therefore

$$Q_{\mathbf{m}}(\theta_{\mathbf{m}}) \geqslant -\frac{\sqrt{6}}{98}\delta^5[\mathrm{Ra}\|\theta_{\mathbf{m}}\|_2(\mathrm{Ta}\|w'_{\mathbf{m}}\|+\mathrm{Ra}\|\theta_{\mathbf{m}}\|_2)] \quad \text{for } |\mathbf{m}|\leqslant 1.$$

Hence

$$\begin{aligned}
\mathrm{Nu} &\leqslant \frac{1}{2\delta}-\frac{1}{\mathcal{A}}\int_0^{L_x/h}\int_0^{L_y/h}\sum_{\mathbf{m}} Q_{\mathbf{m}}(\theta_{\mathbf{m}})\mathrm{d}x\,\mathrm{d}y \\
&\leqslant \frac{1}{2\delta}+\sum_{|\mathbf{m}|\leqslant 1}\frac{\sqrt{6}}{98}\delta^5[\mathrm{Ra}\|\theta_{\mathbf{m}}\|_2(\mathrm{Ta}\|w'_{\mathbf{m}}\|+\mathrm{Ra}\|\theta_{\mathbf{m}}\|_2)]+\sum_{1\leqslant|\mathbf{m}|}\frac{c_1^4}{4\times 7^4}\delta^{10}\mathrm{Ra}^4\|\theta_{\mathbf{m}}\|_2^2 \\
&\quad +\sum_{|\mathbf{m}|\geqslant 1}\frac{C_1^2}{49}\delta^5\,\mathrm{Ta}\frac{1}{m^4}\|w'_{\mathbf{m}}\|_2^2 \\
&\leqslant \frac{1}{2\delta}+\sum_{|\mathbf{m}|\leqslant 1}\frac{\sqrt{6}}{98}\delta^5\,\mathrm{Ra}^2\|\theta_{\mathbf{m}}\|_2^2+\sum_{|\mathbf{m}|\geqslant 1}\frac{c_1^4}{4\times 7^4}\delta^{10}\,\mathrm{Ra}^4\|\theta_{\mathbf{m}}\|_2^2 \\
&\quad +\frac{\sqrt{6}}{98}\delta^5\,\mathrm{Ra}\,\mathrm{Ta}\left(\sum_{|\mathbf{m}|\leqslant 1}\|w'_{\mathbf{m}}\|_2^2\right)^{1/2}\left(\sum_{|\mathbf{m}|\leqslant 1}\|\theta_{\mathbf{m}}\|_2^2\right)^{1/2}+\frac{C_1^2}{49}\delta^5\,\mathrm{Ta}\sum_{|\mathbf{m}|\geqslant 1}\frac{1}{m^4}\|w'_{\mathbf{m}}\|_2^2 \\
&\leqslant \frac{1}{2\delta}+\max\left(\frac{\sqrt{6}}{98}\delta^5\,\mathrm{Ra}^2,\frac{c_1^4}{4\times 7^4}\delta^{10}\,\mathrm{Ra}^4\right)+\frac{\sqrt{6}}{98}\delta^5\,\mathrm{Ra}\,\mathrm{Ta}\sqrt{\mathrm{Ra}\,\mathrm{Nu}}+\frac{C_1^2}{49}\delta^5\,\mathrm{Ta}\,\mathrm{Ra}\,\mathrm{Nu}.
\end{aligned}$$

Choose

$$\delta=\left(\frac{2\times 7^4}{10\cdot c_1^4}\mathrm{Ra}^{-4}\right)^{1/11},$$

we have

$$\begin{aligned}
\mathrm{Nu} &\leqslant \left(\frac{1}{2}\left(\frac{10\cdot c_1^4}{2\times 7^4}\right)^{1/11}+\frac{c_1^4}{4\times 7^4}\left(\frac{2\times 7^4}{10\cdot c_1^4}\right)^{10/11}\right)\mathrm{Ra}^{4/11}+\frac{\sqrt{6}}{98}\left(\frac{10\cdot c_1^4}{2\times 7^4}\right)^{-5/11}\mathrm{Ra}^{-7/22}\,\mathrm{Ta}\sqrt{\mathrm{Nu}} \\
&\quad +\frac{C_1^2}{49}\left(\frac{10\cdot c_1^4}{2\times 7^4}\right)^{-5/11}\mathrm{Ra}^{-9/11}\,\mathrm{Ta}\,\mathrm{Nu} \\
&\approx 1.43\,\mathrm{Ra}^{4/11}+0.0002\,\mathrm{Ra}^{-7/22}\,\mathrm{Ta}\sqrt{\mathrm{Nu}}+0.47\,\mathrm{Ra}^{-9/11}\,\mathrm{Ta}\,\mathrm{Nu},
\end{aligned}$$

without loss of generality, we assume $\mathrm{Ra}\geqslant 1$ and choose $B_1=1/0.94$, it follows that there exist constants $B_2>0$ such that when $\mathrm{Ta}\leqslant B_1\,\mathrm{Ra}^{1/2}$, $\mathrm{Nu}\leqslant B_2\,\mathrm{Ra}^{4/11}$. □

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 45, NUMBER 7 JULY 2004

A diffusion process in curved space–time

F. Debbasch[a)]
E.R.G.A., UMR 8112, 4 Place Jussieu, F-75231 Paris Cedex 05, France

(Received 21 September 2003; accepted 19 March 2004;
published online 9 June 2004)

We construct a curved space–time generalization of the special relativistic Ornstein–Uhlenbeck Process. This is done by deriving a manifestly covariant Kolmogorov equation that describes diffusion in curved space–times. The simple case of diffusion in a spatially flat Friedmann–Robertson–Walker universe is then considered. It is proven that, at least in these space–times, Kolmogorov equation admits as possible solution a natural generalization of the flat space–time Jüttner equilibrium solution. The first correction to Jüttner's distribution in a slowly expanding universe is also obtained explicitly. © *2004 American Institute of Physics.*

I. INTRODUCTION

Relativistic irreversible phenomena are notoriously difficult to model.[1–3] In 1997, Debbasch, Mallick, and Rivet[4] introduced a new diffusion process, the Relativistic Ornstein–Uhlenbeck Process (ROUP). This process is not only the simplest possible model of relativistic diffusion, it is also the simplest toy–model of relativistic irreversible phenomena. Up to now, the ROUP has only been studied in the special relativistic realm; this has notably shed new light on the respective status of special relativistic hydrodynamics and special relativistic kinetic theory.[5] The aim of the present article is to lay down the basis for the study of the ROUP in curved space–time.

The matter is organized as follows. A first section reviews the principal results pertaining to the special relativistic case. An important point made in that section is that the ROUP can be defined in flat space–time by two different but completely equivalent approaches. The first one consists in specifying the stochastic equations of motion for the particle whose diffusion is modelled by the process. The other approach consists in writing down the transport or Kolmogorov equation verified by the phase-space density associated to the diffusing particle. Both routes have naturally been explored in the special relativistic case. It turns out that, to extend the definition of the ROUP to the general relativistic case, it is easier to write directly the transport equation associated to the process in curved space–time. This equation is obtained in Sec. II of this article, as a direct generalization of the manifestly covariant Kolmogorov equation associated to the ROUP in flat space–time. Section III is devoted to a simple but enlightening application of the formalism just developed. The spatially flat homogeneous and isotropic Friedmann–Robertson–Walker universes are surely among the simplest solutions to Einstein's equations and are also of particular physical relevance; it is, therefore, quite natural to investigate the properties of the ROUP in these space–times. In the study of Galilean and relativistic flat space–time diffusion processes, an important role is played by the invariant measure(s) of the process, i.e., the equilibrium solution(s) to the transport equation. In the absence of any force-field, the invariant measure of the special relativistic process is space and time independent in the rest-frame of the fluid in which the particle diffuses. In this frame, it is also isotropic in momentum space. In the case of diffusion occurring in a spatially flat Friedmann model, one should not expect to find a time-independent solution to the transport equation. The question is, therefore: Does Kolmogorov equation then admit a generalized equilibrium solution, i.e., a solution which is, in the so-called comoving coordinates, independent of spatial position and isotropic in momentum space? It is

a)Electronic mail: fabrice.debbasch@wanadoo.fr

proven in Sec. III that such a solution can be obtained perturbatively as a series expansion where the small parameter is the ratio of the characteristic ''microscopic'' relaxation time of the diffusion process (in flat space–time) to the characteristic evolution-time of the expansion factor of the universe. Unicity of the expansion is also proven and the first correction to the special relativistic Jütnner equilibrium solution is explicitly derived. As a conclusion, Sec. IV reviews all the new results of the article and puts them into perspective by comparing them with similar results already obtained on the general relativistic Boltzmann equation. Finally, Sec. IV also mentions some of the many possible extensions to this work.

II. THE SPECIAL RELATIVISTIC ORNSTEIN–UHLENBECK PROCESS

A. Basics

To present the special relativistic Ornstein–Uhlenbeck process most succinctly, it is best to use the image of a Brownian special relativistic particle diffusing in a surrounding (special relativistic) fluid. The diffusion process has originally been defined[4] by a couple of covariant stochastic equations which determine, in an arbitrary Lorentz frame, the time-evolution of both the position and momentum of the diffusing particle.

Let us suppose now that the fluid which surrounds the particle is in a state of global equilibrium. Then, there exists a Lorentz frame $\mathcal{R}$ where this fluid is at rest; this frame is usually called the global rest-frame of the fluid; it constitutes a naturally preferred Lorentz frame for the diffusion process.[6] In this reference frame, the equations of motion for the diffusing particle take the simple form

$$\begin{cases} \dfrac{d}{dt}\mathbf{x} = \dfrac{\mathbf{p}}{m\gamma}, \\ \dfrac{d}{dt}\mathbf{p} = -\alpha\dfrac{\mathbf{p}}{\gamma} + \sqrt{2D}\dfrac{d\mathbf{W}}{dt}, \end{cases} \tag{1}$$

where $d\mathbf{W}/dt$ indicates that the stochastic part $\mathbf{F}_s$ of the force which acts on the diffusing particle is, up to the multiplicative constant $\sqrt{2D}$, the derivative of the Wiener process, i.e., a Gaussian white noise. The positive constant α enters the definition of the deterministic part $\mathbf{F}_d$ of the force acting on the particle and plays the role of a friction coefficient. And the Lorentz factor $\gamma(\mathbf{p})$ is defined by

$$\gamma(\mathbf{p}) = \left(1 + \frac{\mathbf{p}^2}{m^2c^2}\right)^{1/2}. \tag{2}$$

Let now $\Pi(t,\mathbf{x},\mathbf{p})$ be the phase-space distribution function of the diffusing particle in $\mathcal{R}$. More precisely, let $\Pi(t,\mathbf{r},\mathbf{p})d^3xd^3p$ be the probability to find in $\mathcal{R}$ the diffusing particle at time t in the volume d^3xd^3p centered on $(\mathbf{x},\mathbf{p})$. It is possible to derive from (1) a transport equation verified by Π. One obtains from (1) (see Ref. 4)

$$\partial_t\Pi + \nabla_{\mathbf{x}}.\left(\frac{\mathbf{p}}{m\gamma}\Pi\right) + \nabla_{\mathbf{p}}.\left(-\alpha\frac{\mathbf{p}}{\gamma}\Pi\right) = D\ \Delta_{\mathbf{p}}\Pi. \tag{3}$$

As just presented, (3) is merely a consequence of (1). A stronger result actually applies. Quite generally speaking, the correspondence between a sufficiently regular Itô process and its forward Kolmogorov equation is one-to-one.[7] Consequently, the transport equation (3) can also be considered as implying the stochastic equations of motion (1).

Equations (1) or (3) fully define the process in $\mathcal{R}$. By Lorentz transforming all quantities involved in these equations, it is then possible to obtain the stochastic equations which fix the motion of the particle in another arbitrary Lorentz frame; and one can also be led to the transport

equation associated to the process in this same Lorentz frame.[6] Either of these new equations entirely defines the process in this other Lorentz frame. Therefore, Eqs. (1) or (3) entirely define the process, in all Lorentz frames.

This formulation of the special relativistic Ornstein–Uhlenbeck process is perfectly covariant, but it is not manifestly covariant. It is impossible to obtain a simple manifestly covariant form of the stochastic equations of motion. One can, however, write down a manifestly covariant Kolmogorov equation for the process. This equation will be presented in the next section. It will serve as a starting point for the extension of the process to the general relativistic realm.

B. Manifestly covariant special relativistic Kolmogorov equation

The idea behind the manifestly covariant formulation[8] is to introduce a new, unphysical distribution function f, defined over the extended phase-space $\mathbb{R}^8=\{(x^\mu,p^\mu)\}$, and whose restriction to the mass-shell gives back, in any Lorentz-frame, the physical distribution function Π:

$$\Pi(t,\mathbf{x},\mathbf{p})=\int_{p\in\mathcal{P}} f(t,\mathbf{x},p^0,\mathbf{p})\ \delta(p^0-mc\,\gamma(\mathbf{p}))\ \ dp^0. \tag{4}$$

Naturally, given a distribution Π, it is always possible to find at least one f which verifies (4), but the solution is generally *not* unique. The domain $\mathcal{P}$ contains the mass-shell and is defined by

$$\mathcal{P}=\{p\in\mathbb{R}^4; p.U>0\}, \tag{5}$$

where U stands for the 4-velocity of the fluid in which the particle diffuses. This is the largest domain in which all coefficients of the manifestly covariant Kolmogorov equation are defined and regular.[8] One can choose the function f to be a Lorentz scalar and Kolmogorov equation (3) can be rewritten as

$$\int_{p\in\mathcal{P}} \frac{1}{p^0}\mathcal{L}(f)\ \ \delta(p^0-mc\,\gamma(\mathbf{p}))\,dp^0=0, \tag{6}$$

where the differential operator $\mathcal{L}$ is defined by[8]

$$\mathcal{L}(f)=\partial_{x^\mu}(p^\mu f)+\partial_{p^\mu}(mc\ \ F_d^\mu f)+DK^{\mu\rho\beta\nu}\partial_{p^\rho}\left(\ \frac{p_\mu p_\beta}{p.U}\partial_{p^\nu}f\right). \tag{7}$$

The manifestly covariant expression of the deterministic 4-force F_d^μ is

$$F_d^\mu=-\lambda_\nu^\mu p^\nu\frac{p^2}{m^2c^2}+\lambda_\beta^\alpha\frac{p_\alpha p^\beta}{m^2c^2}p^\mu, \tag{8}$$

with

$$\lambda_\nu^\mu=\frac{\alpha(mc)^2}{(p.U)^2}\Delta_\nu^\mu, \tag{9}$$

$$\Delta_{\mu\nu}=\eta_{\mu\nu}-U_\mu U_\nu. \tag{10}$$

Δ is evidently the projector unto the subspace of momentum 4-space orthogonal to U. The tensor K is itself defined by

$$K^{\mu\rho\beta\nu}=\ \ U^\mu U^\beta\Delta^{\rho\nu}-U^\mu U^\nu\Delta^{\rho\beta}+U^\rho U^\nu\Delta^{\mu\beta}-U^\rho U^\beta\Delta^{\mu\nu}. \tag{11}$$

The manifestly covariant special relativistic Kolmogorov equation is $\mathcal{L}(f) = 0$. It can serve as a manifestly covariant definition of the special relativistic Ornstein–Uhlenbeck process because its restriction to the mass-shell is, in $\mathcal{R}$, identical to Eq. (3), which itself fully defines the process in all Lorentz frames.

III. THE GENERAL RELATIVISTIC ORNSTEIN–UHLENBECK PROCESS

The general relativistic Ornstein–Uhlenbeck process will be defined by a general relativistic, manifestly covariant extension of the special relativistic transport equation $\mathcal{L}(f)=0$.

A. Choice of the extended phase-space

There are two natural candidates for the general relativistic extended phase-space. If one momentarily leaves aside the constraint $p.U$, the first candidate is the bundle tangent to the space–time manifold; its elements are most naturally represented, within a chart (coordinate system), by the four space–times coordinates x^μ and four contravariant momentum components p^μ. The second candidate is the bundle *co*tangent to space–time, whose elements can be represented by the four space–time coordinates x^μ and the four covariant momentum components p_μ.

The distinction between these two possibilities is rather academic in special relativity since, in flat space–time, the contravariant and covariant components of p differ at the most by a sign. This is generally not so in curved space–time and, although both possibilities naturally give back the same physics, experience in relativistic kinetic theory teaches that choosing the cotangent bundle as phase-space is usually the most technically convenient solution.[9] Remember also that momenta in Hamiltonian formalism naturally appear through their covariant components, i.e., as covector, and not as (tangent) vectors.[10]

To avoid any possible confusion and to simplify some notations in the next section, we will adopt the following nonstandard convention. p will always stand for a vector tangent to space–time and only its so-called contravariant components p^μ will appear in the text. Elements of the cotangent space will be denoted by q and only their covariant components q_μ will appear below.

The extended phase-space is thus chosen to be $\{(x^\mu,q_\mu)\in\mathbb{R}^8; q.U=q_\mu U^\mu>0\}$. Note that, in curved space–time, the components U^μ generally depend on x (since U is normed to unity). Thus, generally speaking, the condition $q.U>0$ also involves x.

B. Choice of measures on the extended phase-space

The curved space–time equivalent to the completely antisymmetric symbol $\epsilon_{\mu\nu\rho\alpha}$ is[11]

$$E_{\mu\nu\rho\alpha}=\sqrt{-\det g}\ \ \epsilon_{\mu\nu\rho\alpha}; \tag{12}$$

its purely contravariant components read

$$E^{\mu\nu\rho\alpha}=\frac{1}{\sqrt{-\det g}}\epsilon^{\mu\nu\rho\alpha}. \tag{13}$$

The natural four-dimensional volume measure in space–time is, therefore, simply $(1/4!)\ E_{\mu\nu\rho\alpha}dx^\mu\wedge dx^\nu\wedge dx^\rho\wedge dx^\alpha=\sqrt{-\det g}\,d^4x$ and the natural 4d-volume measure in momentum space is $(1/4!)\ E^{\mu\nu\rho\alpha}dq_\mu\wedge dq_\nu\wedge dq_\rho\wedge dq_\alpha=(\sqrt{-\det g})^{-1}d^4q$.

However, four-dimensional volume integrals in space–time or in momentum space do not appear in physics; indeed, only integrals over three-dimensional space-like submanifolds of space–time are needed and, as far as momentum space is concerned, only integrals over the three-dimensional mass-shell have physical relevance. Let us now recall what measures are to be used in both cases.[9]

The measure

$$dS_\mu=\frac{1}{3!}E_{\mu\nu\rho\alpha}dx^\nu\wedge dx^\rho\wedge dx^\alpha \tag{14}$$

will be used on space-like three-dimensional submanifolds of space–time. This measure behaves like a pseudo-cotangent vector to space–time. In particular, it can be integrated against tangent vector fields to yield pseudo-scalars.

As far as momentum space is concerned, it is customary to proceed differently; one usually does not introduce directly a measure defined on the mass-shell but one works rather with a measure which is defined over the whole momentum space but which enforces itself the mass-shell restriction. The simplest procedure is to define this measure $d\Sigma$ to be[9]

$$d\Sigma = \theta(q_0)\,\delta(g^{\mu\nu}(x)q_\mu q_\nu - m^2c^2)\,\frac{1}{4!}E^{\mu\nu\rho\alpha}dq_\mu\wedge dq_\nu\wedge dq_\rho\wedge dq_\alpha$$

$$= \theta(q_0)\,\delta(g^{\mu\nu}(x)q_\mu q_\nu - m^2c^2)\;\;(\sqrt{-\det g})^{-1}d^4q. \tag{15}$$

This measure is clearly a pseudo-scalar.

Given an arbitrary coordinate system, one can choose the three independent ''spatial'' components $(q_1,q_2,q_3)=\mathbf{q}$ as coordinates on the mass-shell. On the mass-shell, the component q_0 can then be considered to be a positive function of both x and $\mathbf{q}$, implicitly defined by $g^{\mu\nu}(x)q_\mu q_\nu = m^2c^2$. This function will be denoted by $mc\,\gamma(x,\mathbf{q})$. The zeroth *contravariant* component of q, $g^{0\mu}(x)q_\mu$, is then also a function of x and $\mathbf{q}$, which will be denoted by $mc\,\tilde{\gamma}(x,\mathbf{q})$. It is then straightforward to prove that, for any field ϕ (not necessarily scalar) defined over the extended phase-space, one has, for all t and $\mathbf{x}$,

$$\int_{q.U>0}\phi(t,\mathbf{x},q_0,\mathbf{q})\;\;d\Sigma = \int_{\mathbb{R}^3}\phi(t,\mathbf{x},mc\,\gamma(t,\mathbf{x},\mathbf{q}),\mathbf{q})\,\frac{1}{\sqrt{-\det g}}\,\frac{d^3q}{mc\,\tilde{\gamma}(t,\mathbf{x},\mathbf{q})}. \tag{16}$$

Similarly, the restrictions of dS_μ to the three-dimensional submanifolds of space–time defined by an equation of the form $t=a$, where a is an arbitrary real number, read

$$dS_\mu = (\sqrt{-\det g}\;\,d^3x,0,0,0). \tag{17}$$

It follows from (16) and (17) that, for an arbitrary field ϕ,

$$\int_{q.U>0}\phi(t,\mathbf{x},q_0,\mathbf{q})\;\;dS_\mu d\Sigma = \int_{\mathbb{R}^6}\phi(t,\mathbf{x},mc\,\gamma(t,\mathbf{x},\mathbf{q}),\mathbf{q})d^3x[d^3q/mc\,\tilde{\gamma}(t,\mathbf{x},\mathbf{q})]. \tag{18}$$

Equations (16) and (18) will be used in the next sections to transcribe manifestly covariant, off-shell relations into nonmanifestly covariant, on-shell results.

C. Manifestly covariant general relativistic Kolmogorov equation

The operator $\mathcal{L}$, as defined by (7), is manifestly invariant under Lorentz transformation, but not under arbitrary coordinate changes. Let us then examine each contribution to (7) separately and find a reasonable generalization of (7) to curved space–times. Let us start with the projector Δ. Its proper general relativistic expression is

$$\Delta_{\mu\nu} = g_{\mu\nu} - U_\mu U_\nu. \tag{19}$$

Definition (11) of the tensor K is then perfectly valid, as is expression (9) for the tensor λ, taking care of replacing p by q:

$$\lambda^{\mu\nu} = \frac{\alpha(mc)^2}{(q_\mu U^\mu)^2}\,\Delta^{\mu\nu}. \tag{20}$$

The same goes also for the definition (8) of the deterministic 4-force; thus, the general relativistic deterministic 4-force is defined as a function of q by

$$F_{d\mu} = -\lambda^{\nu}_{\mu} q_{\nu} \frac{g^{\mu\nu} q_{\mu} q_{\nu}}{m^2 c^2} + \lambda^{\alpha\beta} \frac{q_{\alpha} q_{\beta}}{m^2 c^2} q_{\mu}. \tag{21}$$

Let us now examine if the various partial derivatives appearing in (7) should be modified for the general relativistic realm.

Let ϕ be an arbitrary field defined over phase-space. To simplify the discussion, let us suppose ϕ behaves like a scalar under arbitrary coordinate changes in space–time. Let us consider such a change of coordinates. Then, with obvious notations,

$$\phi'(x^{\mu'}, q_{\nu'}) = \phi(x^{\mu}, q_{\nu}). \tag{22}$$

Since

$$q_{\nu} = \frac{\partial x^{\nu'}}{\partial x^{\nu}} q_{\nu'}, \tag{23}$$

one has

$$\frac{\partial}{\partial x^{\mu'}} \phi' = \frac{\partial x^{\mu}}{\partial x^{\mu'}} \frac{\partial \phi}{\partial x^{\mu}} + \frac{\partial^2 x^{\nu'}}{\partial x^{\mu} \partial x^{\nu}} \frac{\partial x^{\mu}}{\partial x^{\mu'}} q_{\nu'} \frac{\partial \phi}{\partial q_{\nu}} \tag{24}$$

and

$$\frac{\partial}{\partial q_{\nu'}} \phi' = \frac{\partial x^{\nu'}}{\partial x^{\nu}} \frac{\partial \phi}{\partial q_{\nu}}. \tag{25}$$

Equation (25) proves that the operator $\partial/\partial q_{\nu}$ transforms scalar fields into vector fields tangent to space–time. This can easily be generalized to fields of arbitrary tensor type. The notion of partial differentiation with respect to impulse components is thus a perfectly generally covariant notion and the operator $\partial/\partial q_{\nu}$ transforms arbitrary tensor fields of type (a,b) into tensor fields of type $(a+1,b)$. This can be easily understood without any calculation if one remembers that, at any point in space–time, momentum space is a *flat* four-dimensional manifold. The concept of partial differentiation with respect to one of the coordinates used on that manifold is therefore a perfectly covariant and natural geometrical concept.

On the other hand, Eq. (24) proves that, even for scalar fields, partial differentiation with respect to one of the space–time coordinates is *not* a covariant notion. This again is quite simple to understand.

In passing from x to $x+dx$, the usual partial differentiation maintains the *components* of q constant. In flat space–time, this amounts to maintaining the vector q itself constant. But in curved space–time, the basis covectors in q space are themselves x dependent. Maintaining the components of q constant is therefore not equivalent to maintaining the covector q itself constant. Of these two notions, the second (maintaining the covector itself constant) is an invariant one, while the other is not. The correct general relativistic concept is, therefore: Derivative with respect to the space–time degrees of freedom, maintaining the covector q constant, and not its components in the local coordinate basis.

Let now q be defined at x and let q_{ν} be its components in the local coordinate basis. The covector "equal" to q at point $x+dx$ is obtained by parallel transporting q from x to $x+dx$; let this covector at point $x+dx$ have components $q_{\nu}+dq_{\nu}$ in the coordinate basis (at point $x+dx$). By definition one has[11,12]

$$dq_{\nu} = +\Gamma^{\alpha}_{\nu\mu} q_{\alpha} dx^{\mu}, \tag{26}$$

where the Γ's are the Christoffel symbols.

One, therefore, defines[9] a new operator D_μ, acting on arbitrary fields defined over the eight-dimensional phase-space, by

$$D_\mu = \nabla_\mu + \Gamma^\alpha_{\mu\nu} q_\alpha \frac{\partial}{\partial q_\nu}, \tag{27}$$

where ∇ stands for the usual covariant derivative operator with respect to space–time degrees of freedom. Thus defined, D_μ is generally covariant and transforms arbitrary tensor fields of type (a,b) into tensor fields of type $(a,b+1)$.

Using D_μ, one can write the following relativistic generalization of definition (7):

$$\mathcal{L}(f) = D_\mu(g^{\mu\nu}(x) q_\nu f) + \frac{\partial}{\partial q_\mu}(mcF_{d\mu} f) + DK^\mu{}_\rho{}^\beta{}_\nu \; \partial_{q_\rho}\left(\frac{q_\mu q_\beta}{q_\mu U^\mu} \partial_{q_\nu} f \right), \tag{28}$$

with F_d and K given by Eqs. (19)–(21).

The general relativistic Ornstein–Uhlenbeck process is then defined by the manifestly covariant tranport equation $\mathcal{L}(f)=0$, where f represents the scalar probability distribution of the diffusing particle in its extended eight-dimensional phase-space.

Note that (28) is not the only possible generalization of (7) to curved space–time. It is merely the simplest and, therefore, the most natural one. No other generalization will be envisaged in this article.

Let me finally stress that the general relativistic Kolmogorov equation involves the fluid surrounding the diffusing particle (through U) as well as the Einstein gravitational field (through the metric g). Since U and g can be prescribed independently (the only constraint being $U^2=1$), one can consider that the general relativistic Ornstein–Uhlenbeck process describes the stochastic motion of a diffusing particle interacting with both a surrounding fluid in arbitrary motion and an arbitrary gravitationnal field.

D. Transition to an on-shell formulation

It is useful, in view of practical applications, to elaborate briefly about how this manifestly covariant ''off-shell'' formulation can be transcribed, in an arbitrary coordinate system, into a more standard, covariant but not manifestly covariant on-shell treatment, which involves a ''physical'' distribution function defined on the mass-shell only.

Let ϕ be an arbitrary field defined over the extended phase-space. Its mean-value $\overline{\phi}(x)$ at point x is, by definition,

$$\overline{\phi}(x) = \int_{q.U>0} \phi(x,q) f(x,q) d\Sigma. \tag{29}$$

The field $\overline{\phi}$ represents a spatial density. For example, if $\phi(x,q)=g^{\mu\nu}(x)q_\mu$, $\overline{\phi}$ is simply the usual particle 4-current j^μ. As any spatial density, $\overline{\phi}$ is ultimately to be integrated against dS_μ on an arbitrary space-like three-dimensional submanifold S of space–time. Let us choose a coordinate system in which this submanifold is a constant-time submanifold and let us consider the quantities $\overline{\phi}\, dS_\mu$ in greater detail. Because of equation (17), only $\overline{\phi}\, dS_0$ does not vanish. Using (16) and (18), one can write it under the form

$$\overline{\phi}(x) dS_0 = d^3x \int_{\mathbb{R}^3} \phi(t,\mathbf{x},mc\,\gamma(t,\mathbf{x},\mathbf{q}),\mathbf{q}) f(t,\mathbf{x},mc\,\gamma(t,\mathbf{x},\mathbf{q}),\mathbf{q}) \frac{d^3q}{mc\,\tilde{\gamma}(t,\mathbf{x},\mathbf{q})}. \tag{30}$$

This in turn can be rewritten as

$$\overline{\phi} dS_0 = d^3x \int_{\mathbb{R}^3} \frac{\phi(t,\mathbf{x},mc\gamma(t,\mathbf{x},\mathbf{q}),\mathbf{q})}{mc\tilde{\gamma}(t,\mathbf{x},\mathbf{q})} \Pi(t,\mathbf{x},\mathbf{q}) \quad d^3q, \tag{31}$$

with Π defined by

$$\Pi(t,\mathbf{x},\mathbf{q}) = \int_{\mathbb{R}} f(t,\mathbf{x},q_0,\mathbf{q}) \delta(q_0 - mc\gamma(t,\mathbf{x},\mathbf{q})) dq_0. \tag{32}$$

To understand the physical meaning of Π, let us elaborate further on the case where $\phi(x,q) = g^{\mu\nu}(x) q_\nu$; as mentioned earlier, $\overline{\phi}$ then coincides with the 4-current j^μ and the only non-vanishing components of $\overline{\phi} dS_\nu = j^\mu dS_\nu$ are $j^\mu dS_0$. The quantity $j^0 dS_0$ represents the probability dn of finding the diffusing particle at time t in the volume d^3x centered on $\mathbf{x}$. Equation (31) gives

$$j^0(t,\mathbf{x}) dS_0 = dn = d^3x \int_{\mathbb{R}^3} \Pi(t,\mathbf{x},\mathbf{q}) d^3q, \tag{33}$$

which proves that Π plays, in the considered coordinate system, the role of a standard probability distribution. Inspecting the other components $j^k dS_0$ trivially confirms this interpretation of Π.

Now, to the dynamics of Π. In each coordinate system, the manifestly covariant Kolmogorov equation can be transcribed into a transport equation for Π; this transport equation fully characterizes the general relativistic Ornstein–Uhlenbeck process in the chosen coordinate system. This transport equation is however not manifestly covariant and its general expression is neither simple nor particularly tractable. It was, therefore, not deemed useful to reproduce this expression here. In any practical application, the best is to obtain this equation directly from the covariant Kolmogorov equation, which is easier to write down. This will be done in the next section on a very simple space–time background.

IV. DIFFUSION IN A SPATIALLY FLAT FRIEDMANN–ROBERTSON–WALKER UNIVERSE

A. Kolmogorov equation for *f* in comoving coordinates

In comoving coordinates, the space–time metric of a spatially flat Friedmann–Robertson–Walker universe takes the well-known form[12]

$$\begin{aligned} ds^2 &= c^2 dt^2 - a^2(t) \quad (dx_1^2 + dx_2^2 + dx_3^2) \\ &= c^2 dt^2 - a^2(t) \quad d\mathbf{x}^2, \end{aligned} \tag{34}$$

where $a(t)$ is the so-called expansion factor of the universe. Its evolution is fixed via Einstein's equation by the equation of state of the matter present in the universe and by suitable initial conditions. Quite naturally, the fluid in which the particle diffuses will be taken to be the matter in the universe. This matter follows the expansion and is at rest in the comoving frame. Consequently, in the comoving coordinates,

$$(U^\mu) = (1,0,0,0). \tag{35}$$

And the components of the projector Δ are

$$\Delta_{\mu\nu} = \begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & -a^2(t) & 0 & 0 \\ 0 & 0 & -a^2(t) & 0 \\ 0 & 0 & 0 & -a^2(t) \end{pmatrix}. \tag{36}$$

The only nonvanishing Christoffel symbols are[12]

$$\Gamma^0_{11}=\Gamma^0_{22}=\Gamma^0_{33}=a\dot{a} \tag{37}$$

and

$$\Gamma^1_{01}=\Gamma^2_{02}=\Gamma^3_{03}=\frac{\dot{a}}{a}. \tag{38}$$

Evaluating directly the various contributions to (28), one first obtains

$$\begin{cases} g^{0\nu}q_\nu=q_0, \\ g^{i\nu}q_\nu=-\dfrac{1}{a^2(t)}q_i \end{cases} \tag{39}$$

and

$$D_0=\frac{\partial}{\partial t}+\frac{\dot{a}}{a}\sum_{i=1}^{3} q_i\frac{\partial}{\partial q_i}, \tag{40}$$

$$D_i=\frac{\partial}{\partial x^i}+\frac{\dot{a}}{a}q_i\frac{\partial}{\partial q_0}+\dot{a}a\ q_0\frac{\partial}{\partial q_i}+\frac{\dot{a}}{a}q_0, \tag{41}$$

where $i=1,2,3$.

As for $F_{d\mu}$, one finds that, in comoving coordinates,

$$F_{d\mu}=\frac{\alpha}{q_0}(g^{\rho\nu}(x)q_\rho q_\nu U_\mu-q_0q_\mu), \tag{42}$$

so that

$$F_{d0}=-\frac{\alpha}{a^2(t)}\frac{1}{q_0}\sum_{i=1}^{3} q_i\ q_i \tag{43}$$

and

$$F_{di}=-\alpha\ q_i \tag{44}$$

for $i=1,2,3$.

It is then easy to check that, in comoving coordinates,

$$D_\mu(g^{\mu\nu}(x)q_\nu f)=q_0\frac{\partial f}{\partial t}-\frac{1}{a^2}\sum_{i=1}^{3} q_i\frac{\partial f}{\partial x^i}-\frac{\dot{a}}{a^3}\sum_{i=1}^{3} q_i\ q_i\frac{\partial f}{\partial q_0} \tag{45}$$

and

$$\frac{\partial}{\partial q_\mu}(mc\ F_{d\mu}f)=-\alpha mc\left[\sum_{i=1}^{3}\frac{\partial}{\partial q_i}(q_if)+\frac{\partial}{\partial q_0}\left(\frac{1}{a^2}\frac{1}{q_0}\sum_{i=1}^{3} q_i\ q_i\ f\right)\right]. \tag{46}$$

Finally, a direct evaluation of the components of K in comoving coordinates delivers

$$K^{\mu}{}_{\rho}{}^{\beta}{}_{\nu}\ \partial_{q_\rho}\left(\ \frac{q_\mu q_\beta}{q_\mu U^\mu}\partial_{q_\nu} f\right) = -\ \frac{\partial}{\partial q_0}\left[\sum_{i=1}^{3} q_i \frac{\partial f}{\partial q_i}\ +\ \frac{1}{a^2}\frac{1}{q_0}\sum_{i=1}^{3} q_i\ q_i \frac{\partial f}{\partial q_0}\right]$$
$$-\ \frac{a^2}{q_0}\sum_{i=1}^{3}\frac{\partial}{\partial q_i}\left[\ \frac{\partial f}{\partial q_i}\ +\ \frac{1}{a^2}\frac{1}{q_0} q_i \frac{\partial f}{\partial q_0}\right]. \tag{47}$$

Combining the last three equations leads to the Kolmogorov equation verified by f.

B. Kolmogorov equation for the physical distribution Π

Using (35), one easily finds that

$$\gamma(t,\mathbf{x},\mathbf{q}) = \left(1 + \ \frac{\mathbf{q}^2}{a^2(t)\ \ m^2c^2}\right)^{1/2}, \tag{48}$$

where the notation $\Sigma_{i=1}^{3} q_i\ q_i = \mathbf{q}^2$ has been used. Since in this case γ does not depend on $\mathbf{x}$, we will adopt the shorter notation $\gamma(t,\mathbf{q})$ for the remainder of this section.

Let us now define, for an arbitary field $h(t,\mathbf{x},q_0,\mathbf{q})$, the field $\tilde{h}(t,\mathbf{x},\mathbf{q})$ by

$$\tilde{h}(t,\mathbf{x},\mathbf{q}) = \int_{\mathbb{R}} h(t,\mathbf{x},q_0,\mathbf{q})\,\delta(q_0 - mc\,\gamma(t,\mathbf{q}))\,dq_0. \tag{49}$$

In particular, $\Pi = \tilde{f}$.

Taking into account expression (48) for γ, the standard properties of δ lead to

$$\frac{\partial}{\partial t}\tilde{h}(t,\mathbf{x},\mathbf{q}) = \int_{\mathbb{R}}\left[\ \frac{\partial}{\partial t}h(t,\mathbf{x},q_0,\mathbf{q}) - \ \frac{\dot{a}}{a^3}\frac{1}{q_0}\mathbf{q}^2\frac{\partial f}{\partial q_0}\right]\ \delta(q_0 - mc\,\gamma(t,\mathbf{q}))\ \ dq_0, \tag{50}$$

$$\frac{\partial}{\partial \mathbf{x}}\tilde{h}(t,\mathbf{x},\mathbf{q}) = \int_{\mathbb{R}}\frac{\partial}{\partial \mathbf{x}}h(t,\mathbf{x},q_0,\mathbf{q})\ \ \delta(q_0 - mc\,\gamma(t,\mathbf{q}))\ \ dq_0 \tag{51}$$

and

$$\frac{\partial}{\partial \mathbf{q}}\tilde{h}(t,\mathbf{x},\mathbf{q}) = \int_{\mathbb{R}}\left[\ \frac{\partial}{\partial \mathbf{q}}h(t,\mathbf{x},q_0,\mathbf{q}) + \ \frac{1}{a^2}\frac{1}{q_0}\mathbf{q}\frac{\partial f}{\partial q_0}\right]\ \delta(q_0 - mc\,\gamma(t,\mathbf{q}))\ \ dq_0. \tag{52}$$

Using these three relations, it is possible to deduce from the transport equation $\mathcal{L}(f) = 0$ a transport equation for the physical distribution $\Pi(t,\mathbf{x},\mathbf{q})$. More precisely, the equation

$$\int_{\mathbb{R}}\frac{1}{q_0}\mathcal{L}(f)\,\delta(q_0 - mc\,\gamma(t,\mathbf{q}))\,dq_0 = 0 \tag{53}$$

is equivalent to

$$\frac{\partial}{\partial t}\Pi - \ \frac{1}{a^2(t)}\ \frac{\partial}{\partial \mathbf{x}}.\left(\frac{\mathbf{q}}{m\,\gamma(t,\mathbf{q})}\Pi\right) + \ \frac{\partial}{\partial \mathbf{q}}.\ \left(-\alpha\frac{\mathbf{q}}{\gamma(t,\mathbf{q})}\Pi\right) - D\ \ a^2(t)\frac{\partial^2}{\partial \mathbf{q}^2}\Pi = 0. \tag{54}$$

The stochastic equations of motion which correspond to this transport equation are

$$\begin{cases} \dfrac{d}{dt}\mathbf{x} = -\ \dfrac{1}{a^2(t)}\ \dfrac{\mathbf{q}}{m\gamma(t,\mathbf{q})}, \\ \dfrac{d}{dt}\mathbf{q} = -\alpha\dfrac{\mathbf{q}}{\gamma(t,\mathbf{q})} + \sqrt{2D}\ \ a(t)\dfrac{d\mathbf{W}}{dt}. \end{cases} \tag{55}$$

These equations clearly show that the process is time-inhomogeneous.

C. Proof of the existence and unicity of a perturbative expression for the generalized equilibrium solution

One of the first questions to ask about a time-homogeneous diffusion process is whether or not the process admits an invariant measure.[7] The Galilean and the special relativistic Ornstein–Uhlenbeck process both admit invariant measures;[4,13] their densities Π are both time and space independent and coincide, respectively, with the Maxwell and Maxwell–Jüttner equilibrium distributions at temperature $T=D/k_B\alpha$.

Considering the process (55) is not time-homogeneous, it surely makes no sense to search for standard, time- and space-independent equilibrium solutions to (55). But, since the process describes diffusion in a universe which is spatially homogeneous and isotropic, it seems reasonable to search for solutions to (55) which depend only on the time and momentum variables, and which coincide with the Maxwell–Jüttner distribution at temperature T when the expansion factor $a(t)$ is set constant, equal to unity. These solutions will be said to describe generalized equilibriums.

They verify

$$\frac{\partial}{\partial t}\Pi = \ \frac{\partial}{\partial \mathbf{q}}\cdot\ \left(\alpha\frac{\mathbf{q}}{\gamma(t,\mathbf{q})}\Pi + D\ \ a^2(t)\frac{\partial}{\partial \mathbf{q}}\Pi\right). \tag{56}$$

Unfortunately, it does not seem possible to obtain exact solutions to (56) valid for an arbitrary $a(t)$. It is, however, possible to solve (56) perturbatively in situations where $a(t)$ varies slowly with respect to the natural "microscopic" time scale $\tau=1/\alpha$.

The best-known method for finding slowly varying solutions to transport equations has been introduced by Chapman and Enskog; it was originally developed in Galilean physics to solve approximately the Boltzmann equation in near-equilibrium situations.[14,15] The method has then been extended to the relativistic Boltzmann equation;[9] it has also been used to exhibit near-equilibrium solutions to other Galilean transport equations (including Kolmogorov equations),[13,16] and the Kolmogorov equation associated to the special relativistic Ornstein–Uhlenbeck process has been recently solved by a Chapman–Enskog expansion.[5]

As far as the general relativistic Ornstein–Uhlenbeck process is concerned, Chapman's and Enskog's method can be used for two different purposes. As in the special relativistic case, it can naturally be implemented to find solutions to Kolmogorov equation which are close to the generalized equilibrium solution. But it can also be used to find a perturbative expression for the generalized equilibrium solution itself, valid when the coefficients of (56) are, through the expansion factor $a(t)$, "slowly varying" functions of the time coordinate.

Let us make the discussion precise by introducing $a_0=a(t=0)$ and the "slow" dimensionless time-variable $\bar{t}$, defined by

$$\bar{t} = \epsilon\ \alpha\ t, \tag{57}$$

where ϵ is an arbitrary infinitesimal. We propose to solve the transport equation perturbatively in ϵ for cases where the expansion-factor $a(t)$ can be written

$$a(t) = a_0\ \ \bar{a}(\bar{t}) \tag{58}$$

with

$$\frac{\partial \overline{a}}{\partial \overline{t}} = O(1). \tag{59}$$

A convenient length-scale is

$$\lambda = a_0 \frac{1}{m\alpha} \sqrt{\frac{D}{\alpha}}, \tag{60}$$

which corresponds to the momentum-scale ζ:

$$\zeta = m\lambda\alpha. \tag{61}$$

We therefore define the dimensionless quantities

$$\overline{\mathbf{x}} = \frac{\mathbf{x}}{\lambda}, \tag{62}$$

$$\overline{\mathbf{q}} = \frac{\mathbf{q}}{\zeta} \tag{63}$$

and

$$\overline{\Pi}(\overline{t}, \overline{\mathbf{x}}, \overline{\mathbf{q}}) = \zeta^3 \Pi(t, \mathbf{x}, \mathbf{q}). \tag{64}$$

Solving Eq. (56) is equivalent to solving

$$\epsilon \frac{\partial}{\partial \overline{t}} \overline{\Pi} = \frac{\partial}{\partial \overline{\mathbf{q}}} \cdot \left(\frac{\overline{\mathbf{q}}}{\overline{\gamma}(\overline{t}, \overline{\mathbf{q}})} \overline{\Pi} + \overline{a}^2(\overline{t}) \frac{\partial}{\partial \overline{\mathbf{q}}} \overline{\Pi} \right) \tag{65}$$

with

$$\overline{\gamma}(\overline{t}, \overline{\mathbf{q}}) = \left(1 + \frac{Q^2}{\overline{a}^2(\overline{t})} \overline{\mathbf{q}}^2 \right)^{1/2}, \tag{66}$$

$$Q^2 = \frac{D}{\alpha m^2 c^2}. \tag{67}$$

We also impose the normalization condition

$$\int_{\mathbb{R}^3} \overline{\Pi}(\overline{t}, \overline{\mathbf{q}}) d^3\overline{q} = \int_{\mathbb{R}^3} \Pi(t, \mathbf{q}) d^3q = 1, \tag{68}$$

which is the direct equivalent of the normalization usually chosen for equilibrium distributions in flat space–time.[4]

As indicated earlier, we search a solution to (65) in the form of a perturbation series in ϵ:

$$\overline{\Pi}(\overline{t}, \overline{\mathbf{q}}) = \sum_{k=0}^{\infty} \epsilon^k \overline{\Pi}_k(\overline{t}, \overline{\mathbf{q}}), \tag{69}$$

where all the partial derivatives of the functions $\overline{\Pi}_k$ are supposed to be $O(1)$. We also assume, as is usually done in similar calculations, that all $\overline{\Pi}_k$ decrease at infinity more rapidly than any power of $\overline{\mathbf{q}}$.

The normalization condition (68) does not suffice to determine the $\overline{\Pi}_k$ unambiguously. Following the Chapman–Enskog method, we impose the subsidiary condition

$$\int_{\mathbb{R}^3} \overline{\Pi}_k(\overline{t},\overline{\mathbf{q}})\, d^3\overline{q} = \delta_{k0} \tag{70}$$

for all $k \geqslant 0$.

Inserting (69) into (65) leads, for all $k \geqslant 0$, to

$$\frac{\partial}{\partial \overline{\mathbf{q}}} \cdot \left(\frac{\overline{\mathbf{q}}}{\overline{\gamma}(\overline{t},\overline{\mathbf{q}})} \overline{\Pi}_k + \overline{a}^2(\overline{t}) \frac{\partial}{\partial \overline{\mathbf{q}}} \overline{\Pi}_k \right) = \frac{\partial}{\partial \overline{t}} \overline{\Pi}_{k-1}, \tag{71}$$

with the convention that $\overline{\Pi}_{-1} = 0$.

It is quite easy to find a solution to (70) and (71) at order $k=0$. It reads

$$\overline{\Pi}_0(\overline{t},\overline{\mathbf{q}}) = \frac{1}{4\pi} \frac{1}{\overline{a}^3(\overline{t})} \frac{1}{Q^2\, K_2(1/Q^2)} \exp\left(- \frac{\overline{\gamma}(\overline{t},\overline{\mathbf{q}})}{Q^2} \right). \tag{72}$$

This is indeed the only (normalized) solution to (71) which decreases at infinity more rapidly than any power of $\overline{\mathbf{q}}$.[4] $\overline{\Pi}_0$ thus turns out to be identical with the Jüttner distribution at time t.[9,17] This distribution would describe an actual, standard equilibrium if the expansion factor were time independent.

Let now $\overline{\Pi}_{k-1}$ be a function verifying (70). Let us prove that one can then find a function $\overline{\Pi}_k$ which satisfies both (70) and (71).

The solvability condition for (71), conceived as an equation for $\overline{\Pi}_k$, is simply that the integral of its right-hand side with respect to $d^3\overline{q}$ vanishes (see Refs. 15 and 18 for extensive discussions of the role of solvability conditions in the Chapman–Enskog method). The fact that $\overline{\Pi}_{k-1}$ verifies (70), therefore, ensures that (71) admits solutions. Let $\overline{\Pi}_k^*$ be one of these solutions and let

$$I^* = \int_{\mathbb{R}^3} \overline{\Pi}_k^*(\overline{t},\overline{\mathbf{q}})\, d^3\overline{q}. \tag{73}$$

It is then obvious that the function $\overline{\Pi}_k$ defined by

$$\overline{\Pi}_k = \overline{\Pi}_k^* - I^* \overline{\Pi}_0 \tag{74}$$

verifies both (70) and (71); this proves the statement.

Since we could exhibit a function $\overline{\Pi}_0$ which verifies both (70) and (71) at order 0, we conclude that a function $\overline{\Pi}_k$ verifying these two equations exists at all order. This proves that Eq. (65) admits a perturbative solution of the form (69) verifying (70).

Unicity can be proven by the following argument. We have already mentioned that $\overline{\Pi}_0$ given by (72) is the only solution to (70) and (71) at order 0 which decreases sufficiently rapidly at infinity. Suppose that $\overline{\Pi}_{k-1}$ is known and unique, and let $\overline{\Pi}_k^1$ and $\overline{\Pi}_k^2$ be two solutions to (70) and (71) at order k. Their difference $\Delta\overline{\Pi}_k$ then verifies

$$\frac{\partial}{\partial \overline{\mathbf{q}}} \cdot \left(\frac{\overline{\mathbf{q}}}{\overline{\gamma}(\overline{t},\overline{\mathbf{q}})} \Delta\overline{\Pi}_k + \overline{a}^2(\overline{t}) \frac{\partial}{\partial \overline{\mathbf{q}}} \Delta\overline{\Pi}_k \right) = 0, \tag{75}$$

which is identical to the equation verified by $\overline{\Pi}_0$. Moreover, $\Delta\overline{\Pi}_k$ decreases at least as rapidly as $\overline{\Pi}_k^1$ and $\overline{\Pi}_k^2$ at infinity. It therefore follows that $\Delta\overline{\Pi}_k$ is proportional to $\overline{\Pi}_0$. By (70), the integral of $\Delta\overline{\Pi}_k$ over momentum space vanishes. The proportionality constant between $\Delta\overline{\Pi}_k$ and $\overline{\Pi}_0$ therefore vanishes too, and so does $\Delta\overline{\Pi}_k$. This proves that (70) ensures the existence and unicity of a perturbative solution to (65).

A final remark concerning this solution. Equation (71) makes obvious that $\overline{\Pi}_k$ is even in $\overline{\mathbf{q}}$ if $\overline{\Pi}_{k-1}$ is. Since $\overline{\Pi}_0$ is an even function of $\overline{\mathbf{q}}$, so are all the $\overline{\Pi}_k$'s and, consequently, so is $\overline{\Pi}$ too. It is therefore isotropic, as expected. Let me mention two interesting consequences. By parity, the first moments of $\overline{\Pi}$ vanish. This means that the particle current density 3-vector associated to the generalized equilibrium solution vanishes in the comoving frame, as it should. On the contrary, some second moments of $\overline{\Pi}$ do not vanish. This means in particular that the energy k_BT, which can be interpreted as the mean-value of the energy of the diffusing particle when the distribution function coincides with Π_0,[19] is actually *not* the mean-value of the particle-energy for the real generalized equilibrium distribution. This point will be further elaborated upon in forthcoming publications fully dedicated to specific examples of physical interest.

D. Explicit expression for the first correction to Jütnner's distribution

It is perhaps useful to evaluate explicitly the function $\overline{\Pi}_1$, which represents the first correction to the special relativistic equilibrium solution.

Equation (72) leads to

$$\frac{\partial}{\partial\overline{t}}\overline{\Pi}_0=\frac{\dot{\overline{a}}}{\overline{a}}\left(-3+\frac{1}{\overline{a}^2}\frac{\overline{\mathbf{q}}^2}{\overline{\gamma}}\right). \tag{76}$$

It is best to introduce A_1 defined by

$$\overline{\Pi}_1(\overline{t},\overline{\mathbf{q}})=A_1(\overline{t},\overline{\mathbf{q}})\overline{\Pi}_0(\overline{t},\overline{\mathbf{q}}) \tag{77}$$

and Eq. (71) for $\overline{\Pi}_1$ is equivalent to

$$\overline{a}^2\left(\frac{\partial^2}{\partial\overline{\mathbf{q}}^2}A_1-\frac{1}{\overline{a}^2}\frac{\overline{\mathbf{q}}}{\overline{\gamma}}\cdot\frac{\partial}{\partial\overline{\mathbf{q}}}A_1\right)=\frac{\dot{\overline{a}}}{\overline{a}}\left(-3+\frac{1}{\overline{a}^2}\frac{\overline{\mathbf{q}}^2}{\overline{\gamma}}\right). \tag{78}$$

The general solution to this equation is

$$A_1(\overline{t},\overline{\mathbf{q}})=a_{12}\frac{\overline{\mathbf{q}}^2}{2}+a_{10} \tag{79}$$

with

$$a_{12}=-\frac{\dot{\overline{a}}}{\overline{a}}\frac{1}{\overline{a}^2}, \tag{80}$$

a_{10} being an arbitrary real integration constant.

This constant is fixed by the normalization condition (70). Since $\overline{\Pi}_0$ is normed to unity, one has

$$a_{10}=-a_{12}\int_{\mathbb{R}^3}\frac{\overline{\mathbf{q}}^2}{2}\overline{\Pi}_0 d^3\overline{q}. \tag{81}$$

Because of (72),

$$\int_{\mathbb{R}^3} \overline{\mathbf{q}}^2 \overline{\Pi}_0 \; d^3\overline{q} = \frac{1}{\overline{a}^3(\overline{t})} \frac{1}{Q^2 \; K_2(1/Q^2)} \int_{\mathbb{R}} \overline{q}^4 \exp\left(- \frac{\overline{\gamma}}{Q^2} \right) \; d\overline{q}. \tag{82}$$

Introducing $\theta = Q\overline{q}/\overline{a}$, one can write

$$\int_{\mathbb{R}} \overline{q}^4 \exp\left(- \frac{\overline{\gamma}}{Q^2} \right) d\overline{q} = \frac{\overline{a}^5}{Q^5} \int_{\mathbb{R}} ch\,\theta \; sh^4\theta \exp\left(- \frac{1}{Q^2} ch\,\theta \right) \; d\theta. \tag{83}$$

A simple integration by part shows that

$$\int_{\mathbb{R}} ch\,\theta \; sh^4\theta \exp\left(- \frac{1}{Q^2} ch\,\theta \right) \; d\theta = \frac{1}{5Q^2} \int_{\mathbb{R}} sh^6\theta \exp\left(- \frac{1}{Q^2} ch\,\theta \right) d\theta, \tag{84}$$

which leads to (see Ref. 20)

$$\int_{\mathbb{R}} ch\,\theta \; sh^4\theta \exp\left(- \frac{1}{Q^2} ch\,\theta \right) \; d\theta = \frac{1}{5Q^2} \Gamma(7/2) \frac{1}{\sqrt{\pi}} (2Q^2)^3 \; K_3(1/Q^2). \tag{85}$$

Using the fact that[20] $\Gamma(\frac{7}{2}) = 15\sqrt{\pi}/8$, one finds

$$\int_{\mathbb{R}} \overline{q}^4 \exp\left(- \frac{\overline{\gamma}}{Q^2} \right) d\overline{q} = \frac{3\overline{a}^5}{Q} K_3\left(\frac{1}{Q^2} \right) \tag{86}$$

and

$$a_{10} = - \frac{1}{2} \frac{\overline{a}^2}{Q^3} \frac{K_3(1/Q^2)}{K_2(1/Q^2)} a_{12}. \tag{87}$$

The function $\overline{\Pi}_1$ is, therefore, given by

$$\overline{\Pi}_1(\overline{t}, \overline{\mathbf{q}}) = - \frac{\dot{\overline{a}}}{\overline{a}} \frac{1}{2\overline{a}^2} \left(\overline{\mathbf{q}}^2 - \frac{\overline{a}^2}{Q^3} \frac{K_3(1/Q^2)}{K_2(1/Q^2)} \right) \overline{\Pi}_0(\overline{t}, \overline{\mathbf{q}}). \tag{88}$$

V. CONCLUSION

In this article, the construction of the relativistic Ornstein–Uhlenbeck process has been extended from flat to curved space–time. The general relativistic Ornstein–Uhlenbeck process has been defined through a manifestly covariant Kolmogorov equation. This transport equation fixes the space–time evolution of the scalar one-particle distribution function defined over the relativistic eight-dimensional extended phase-space. Given an arbitrary coordinate system in space–time, the manifestly covariant Kolmogorov equation can be transcribed into a more conventional transport equation which fixes the time-evolution of the usual one particle distribution function, defined at any instant over the standard six-dimensional phase-space.

As a simple application, both transport equations have been explicitly written down in a spatially flat Friedmann–Robertson–Walker universe and the corresponding stochastic equations of motion have also been derived. At least for a spatially flat Friedmann–Robertson–Walker model, there is a unique natural generalization of the flat space–time equilibrium Jüttner distribution. In comoving coordinates, this generalized equilibrium solution is independent of the space coordinates and isotropic in 3-momentum space. It has been proven that this solution can be obtained perturbatively as a series expansion where the small parameter is the ratio of the characteristic ''microscopic'' relaxation-time of the diffusion process (in flat space–time) to the characteristic evolution-time of the expansion factor of the universe. The first order correction to the Jüttner distribution has also been obtained explicitly.

Let me now put these results into perspective by comparing them with what is known about the solutions to the other transport equation which has been studied extensively in curved space–time, i.e., the general relativistic Boltzmann equation.

Quite expectedly, this equation has also been studied in spatially flat Friedmann–Robertson–Walker space–times.[19] There is naturally no time-independent equilibrium solution and, therefore, only generalized equilibriums similar to those discussed in the present article may exist. No exact calculation of such solutions is possible, just as no exact expression can be obtained for the solutions to (56).

As has been done in this article, approximate expressions for generalized equilibrium solutions (to Boltzmann equation) have been searched for in situations where the expansion factor $a(t)$ is a slowly varying function of time, i.e., when the expansion factor varies only on time scales much larger than the characteristic time associated to the collisions between particles.

But, for Boltzmann equation, only the first correction to Jüttner's distribution seems to have been considered and evaluated.[19] In particular, no general expansion like (69) has ever been proven to exist, nor has the unicity of the solution ever been examined, let alone been proven.

I would like now to end this article by mentioning some of its many possible extensions. On the technical side, the proof of the existence of a generalized equilibrium distribution for the general relativistic Ornstein–Uhlenbeck process should be extended to the other Friedmann–Robertson–Walker metrics and, possibly, to more general curved space–times. For example, are there generalized equilibrium distributions for particles diffusing in a fluid orbiting a black-hole?

At least in cases where a generalized equilibrium solution exists, one should be able to construct a conditional entropy 4-current for the process (the entropy 4-current for the process in flat space–time has already been obtained in Ref. 8). The exact physical interpretation of a conditional entropy (as opposed to the Boltzmann–Gibbes entropy) is still a matter of debate, even for Galilean stochastic processes (a good introductory dicussion can be found in Ref. 21); determining a reasonable interpretation of a conditional entropy 4-current in curved space–time will certainly not be straightforward either and may involve addressing the possibility of applying the very concept of entropy to the space–time itself (see Refs. 12 and 22 for a discussion of this issue in the context of nonquantum gravitation and Ref. 23 for a pedagogical presentation of the superstrings approach to black-holes thermodynamics).

In another direction, the Chapman–Enskog procedure will also permit the large-scale study of the diffusion process in situations close to the generalized equilibrium configurations and, thus, contribute to a better understanding of the relationship between hydrodynamics and statistical physics (kinetic theory) in the presence of a gravitational field.

Finally, it has already been mentioned that the curved space–time diffusion process presented in this article is only one of the possible extensions of the special relativistic Ornstein–Uhlenbeck process. It is certainly the simplest and most natural one, but this does not make other extensions uninteresting. In particular, one can wonder how a curvature-dependent form of the friction coefficient or of the amplitude of the noise would change the properties of the process. This will also be investigated in forthcoming articles.

published online 9 June 2004)

An easily programmable algorithm is given for the computation of SO(5) spherical harmonics needed to complement the radial (beta) wave functions to form an orthonormal basis of wave functions for the five-dimensional harmonic oscillator. It is shown how these functions can be used to compute the (Clebsch–Gordan a.k.a. Wigner) coupling coefficients for combining pairs of irreps in this space to other irreps. This is of particular value for the construction of the matrices of Hamiltonians and transition operators that arise in applications of nuclear collective models. Tables of the most useful coupling coefficients are given in the Appendix. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1763004]

I. INTRODUCTION

The group SO(5) is used as a dynamical group in several contexts in nuclear physics and elsewhere. For example, in an SO(3) basis, it plays a central role in the classification of states of the nuclear collective model[1–3] and the Interacting Boson Model;[4] in an $SO(4)\cong SU(2)\times SU(2)$ basis, it is also used in a neutron–proton pairing model[5] and in a model of high temperature superconductivity.[6,7] In application of such models, there is a need for SO(5) spherical harmonics as basis wave functions and SO(5) Clebsch–Gordan (CG) coefficients for the calculation of matrix elements of the various tensor operators that appear. Many SO(5) coupling coefficients have been given in an SO(4) basis[8] and in a U(2) basis.[9] In this paper, we construct them in an SO(3) (angular momentum) basis.

It will be recalled that standard SO(3) spherical harmonics are eigenfunctions of the Laplacian on a two-dimensional sphere S_2. The geometry of S_2 is inferred by regarding it as an SO(3) orbit in the real three-dimensional Euclidean space $\mathbb{R}^3$ generated by rotating a point in this space through all possible angles. Because a point on such a sphere is invariant under SO(2) rotations about the radial line through that point, it follows that a sphere is isomorphic to the factor space SO(3)/SO(2). SO(3) spherical harmonics are also an orthonormal basis of functions for the Hilbert space $\mathcal{L}^2(S_2)\simeq\mathcal{L}^2(\mathrm{SO}(3)/\mathrm{SO}(2))$ of square integrable functions on S_2 relative to the SO(3)-invariant measure; the invariant measure assigns a *volume* to an element on S_2 equal to its area on a sphere of unit radius. It is known from the Peter–Weyl theorem that a complete orthonormal basis of functions on the group SO(3), relative to its invariant measure, is given to within norm factors by Wigner functions $\{\mathcal{D}^l_{mn}\}$, i.e., matrix coefficient functions on SO(3) defined in terms of basis states $\{|lm\rangle, m=-l,\ldots,l\}$ for an SO(3) irrep $\hat{R}^l$ of highest weight l by

$$\mathcal{D}^l_{mn}(\Omega)=\langle lm|\hat{R}^l(\Omega)|ln\rangle\,,\quad \Omega\in\mathrm{SO}(3)\,. \tag{1}$$

It follows that an (unnormalized) basis of functions for $\mathcal{L}^2(\mathrm{SO}(3)/\mathrm{SO}(2))$ is given by reducing the set of functions $\{\mathcal{D}^l_{mn}\}$ to the subset $\{\mathcal{D}^l_{m0}\}$ of well-defined functions on the SO(3)/SO(2) coset space. Standard spherical harmonics are normalized and conventionally defined as the complex conjugates of these functions

$$Y_{lm}(\theta,\varphi)=\sqrt{\frac{2l+1}{4\pi}}(\mathcal{D}^{l}_{m0}(\Omega(\theta,\varphi)))^{*}=\sqrt{\frac{2l+1}{4\pi}}\mathcal{D}^{l}_{0m}(\Omega^{-1}(\theta,\varphi)), \tag{2}$$

where $\Omega(\theta,\varphi)$ denotes a group element, defined to within an SO(3)/SO(2) coset, by a pair of spherical coordinates (θ,φ) for the sphere. This identity shows that there is a set of spherical harmonics $\{Y_{lm}, m=-l,\ldots,l\}$ associated with every SO(3) irrep and that they are given by the matrix coefficient (Wigner) functions for these irreps.

SO(5) spherical harmonics are similarly defined. They are eigenfunctions of the Laplacian on the four-sphere and an orthonormal basis of functions for the Hilbert space $\mathcal{L}^2(S_4)$ relative to the SO(5)-invariant measure. A four-sphere is isomorophic to the surface generated by rotating a point about the origin in a real five-dimensional Euclidean space $\mathbb{R}^5$ with all elements of the SO(5) rotation group. Since any point in $\mathbb{R}^5$ remains unchanged under the subgroup $\mathrm{SO}(4)\subset\mathrm{SO}(5)$ of rotations about the radial line through the point, such a four-sphere is isomorphic to the factor space SO(5)/SO(4). Moreover, the SO(5)-invariant measure on such a four-sphere is given by the area of elements on a four-sphere of unit radius as defined by the Euclidean measure of volumes in $\mathbb{R}^5$.

The above observations imply that SO(5) spherical harmonics can be defined, in a generalization of Eq. (1) to SO(5), in terms of a subset of Wigner functions. However, there are two differences. First, only a subset of SO(5) irreps are needed to define SO(5) spherical harmonics, namely those carried by subspaces of the Hilbert space $\mathcal{L}^2(\mathbb{R}^5)$ of the five-dimensional harmonic oscillator. Second, the Wigner functions for these SO(5) irreps are not known in analytical form. Thus, we construct SO(5) spherical harmonics by a simple algorithm that could also be used for standard spherical harmonics if one did not already have analytical expressions for the SO(3) rotation matrices. The algorithm is based on the observation that the spherical harmonics of the fundamental five-dimensional irrep of SO(5) are simple and known. We then observe that any product of bounded functions in $\mathcal{L}^2(S_4)$ is another function in $\mathcal{L}^2(S_4)$. Thus they are readily used to generate a basis for $\mathcal{L}^2(S_4)$. Given the inner product, it is then straightforward to Gram–Schmidt orthonormalize this basis to obtain the spherical harmonics.

Spherical harmonics for SO(5) were computed by Bès,[10] for values of the angular momentum $L=0,\ldots,6$, by solving the Schrödinger equation

$$\hat{\Lambda}\Psi_{v\alpha LM}=v(v+3)\Psi_{v\alpha LM} \tag{3}$$

for $\hat{\Lambda}$, the SO(5) Casimir operator, as a system of coupled differential equations, where v labels a so-called one-row irrep of type $[v,0]$ of SO(5), L and M are angular momentum quantum numbers and α is a multiplicity label; v is referred to as a *seniority* quantum number (a terminology introduced by Racah in atomic physics). Unfortunately, this approach becomes prohibitively complicated for $L>6$ because of the number of coupled equations.[10]

An algorithm for constructing a basis for the five-dimensional harmonic oscillator as products of radial (beta) wave functions and SO(5) spherical harmonics, was given by Chacón, Moshinsky, and Sharp[11] and used in many nuclear collective model calculations.[12] The construction of SO(5) spherical harmonics presented herein has substantial overlap with the CMS approach. However, by restricting the calculations to $\mathcal{L}^2(S_4)$, as opposed to the five-dimensional harmonic oscillator Hilbert space, much of the complexity of the CMS approach is avoided. As a result, the construction becomes simple and more versatile. The methods used here were initiated in some recent collective model calculations.[3] As shown in the following, they provide an efficient algorithm for computing the CG coefficients needed for SO(5) tensor coupling in the space of the five-dimensional harmonic oscillator.

II. THE FOUR-SPHERE AS A SUBMANIFOLD OF $\mathbb{R}^5$

The five-dimensional vector space $\mathbb{R}^5$ can be given many physical interpretations. For present purposes, it is convenient to think of an element $Q\in\mathbb{R}^5$ as the quadrupole tensor of a distribution

of particles in $\mathbb{R}^3$. Q is then realized as a real 3×3 traceless symmetric matrix. The independent entries $\{Q_{ij}\}$ of Q can be considered its components relative to nonorthogonal axes and its length $\|Q\|$ conveniently defined by

$$\|Q\|^2=\mathrm{Tr}(Q^2)=\sum_{ij} Q_{ij}^2 . \tag{4}$$

Thus, the four-sphere S_4 is identified with the set of 3×3 real symmetric matrices that satisfy the constraints

$$\mathrm{Tr}(Q)=0 , \quad \mathrm{Tr}(Q^2)=1 . \tag{5}$$

Convenient coordinates for S_4 are constructed by use of various SO(5) subgroup actions. The group SO(5) is itself the subgroup of SL(5,$\mathbb{R}$) transformations of $\mathbb{R}^5$ that leave the lengths of vectors, i.e., $\mathrm{Tr}(Q^2)$, invariant. The group SO(3) also has a natural action on $\mathbb{R}^5$ in which an element $\Omega\in\mathrm{SO}(3)$ transforms a matrix Q into the matrix $\Omega Q\Omega^{-1}$. This SO(3) action is observed to leave both $\mathrm{Tr}(Q^2)$ and $\mathrm{Tr}(Q^3)$ invariant. Thus, SO(3) is identified with the subgroup of SO(5) that leaves $\mathrm{Tr}(Q^3)$ invariant. It is realized as a subset of SO(5) matrices by the $L=2$ irrep $\mathcal{D}^2$ [cf. Eq. (8)]. Note that this particular SO(3) subgroup is distinct from the $\mathrm{SO}(3)\subset\mathrm{SO}(4)\subset\mathrm{SO}(5)$ subgroup.

Any matrix $Q\in\mathbb{R}^5$ can be brought to diagonal form by some SO(3) transformation. Conversely, any $Q\in\mathbb{R}^5$ can be expressed in the form

$$Q=\Omega^{-1}\overline{Q}\Omega \tag{6}$$

for some diagonal matrix $\overline{Q}$ and some element $\Omega\in\mathrm{SO}(3)$. Thus, a set of coordinates for a point $Q\in S_4$ is given by a triple of coordinates (e.g., Euler angles) for the SO(3) rotation Ω and another coordinate γ that defines the diagonal matrix $\overline{Q}$ [subject to the two constraints of Eq. (5)].

A coordinate system for S_4 extends immediately to a system of spherical polar coordinates for $\mathbb{R}^5$ by the addition of the radial coordinate $\beta=\|Q\|\equiv\sqrt{\mathrm{Tr}(Q^2)}$. Such coordinates are related to the standard spherical components for a quadrupole tensor Q given in terms of the matrix entries $\{Q_{ij}\}$ by

$$q_0=\frac{1}{\sqrt{6}}(2Q_{33}-Q_{11}-Q_{22}) ,$$

$$q_{\pm 1}=\mp(Q_{31}\pm iQ_{32}) ,$$

$$q_{\pm 2}=\tfrac{1}{2}(Q_{11}-Q_{22}\pm 2iQ_{12}) . \tag{7}$$

These spherical functions of q transform under SO(3) in the same way as $L=2$ spherical harmonics, i.e.,

$$\hat{R}(\Omega)q_\nu=\sum_\mu q_\mu\mathcal{D}^2_{\mu\nu}(\Omega) . \tag{8}$$

Now, the spherical components of a diagonal matrix $\overline{Q}$ are given by

$$\overline{q}_0=\frac{1}{\sqrt{6}}(2\overline{Q}_{33}-\overline{Q}_{11}-\overline{Q}_{22}) , \quad \overline{q}_{\pm 1}=0 , \quad \overline{q}_{\pm 2}=\frac{1}{2}(\overline{Q}_{11}-\overline{Q}_{22}) , \tag{9}$$

with $\mathrm{Tr}(Q)=\overline{Q}_{11}+\overline{Q}_{22}+\overline{Q}_{33}=0$. Thus, if $\|q\|=\|Q\|=\beta$, then

$$\|q\|^2=\sum_{\nu}(-1)^{\nu}q_{\nu}q_{-\nu}\equiv \mathrm{Tr}(Q^2)=\overline{q_0^2}+2\overline{q_2^2}=\beta^2\,. \tag{10}$$

This means that $\overline{q_\nu}$ can be expressed

$$\overline{q_\nu}=\delta_{\nu,0}\beta\cos\gamma+\delta_{\nu,\pm 2}\frac{1}{\sqrt{2}}\beta\sin\gamma\,. \tag{11}$$

The functions $\{q_\nu\}$ are then given in terms of (β,γ,Ω) by

$$q_\nu(\beta,\gamma,\Omega)=\hat{R}(\Omega)\overline{q_\nu}=\beta\cos\gamma\,\mathcal{D}^2_{0\nu}(\Omega)+\frac{1}{\sqrt{2}}\beta\sin\gamma\,(\mathcal{D}^2_{2\nu}(\Omega)+\mathcal{D}^2_{-2\nu}(\Omega))\,. \tag{12}$$

This is a standard expression for the spherical components of a quadrupole tensor in the nuclear collective model.[1]

For present purposes, the restriction of these functions to S_4, i.e., fixing $\beta=1$, gives the set of functions

$$\mathcal{Q}_\nu(\gamma,\Omega)=\cos\gamma\,\mathcal{D}^2_{0\nu}(\Omega)+\frac{1}{\sqrt{2}}\sin\gamma\,(\mathcal{D}^2_{2\nu}(\Omega)+\mathcal{D}^2_{-2\nu}(\Omega))\,, \tag{13}$$

which are both a basis for the fundamental five-dimensional $v=1$ irrep of SO(5) and of the five-dimensional $L=2$ irrep of its SO(3) subgroup. Thus, to within a normalization factor, they are the fundamental SO(5) spherical harmonics in an SO(3) basis.

The Laplacian on $\mathbb{R}^5$ has a well-known expression[1] in terms of the above spherical polar coordinates

$$\nabla^2=\frac{1}{\beta^4}\frac{\partial}{\partial\beta}\beta^4\frac{\partial}{\partial\beta}-\frac{1}{\beta^2}\hat{\Lambda}\,, \tag{14}$$

where

$$\hat{\Lambda}=-\frac{1}{\sin 3\gamma}\frac{\partial}{\partial\gamma}\sin 3\gamma\frac{\partial}{\partial\gamma}+\sum_{k=1}^{3}\frac{\overline{L_k^2}}{4\sin^2(\gamma-2\pi k/3)} \tag{15}$$

is a realization of the (second order) SO(5) Casimir for the irreps carried by $\mathcal{L}^2(S_4)$ and $\{\overline{L_1},\overline{L_2},\overline{L_3}\}$ are three components of SO(3) angular momentum in the so-called *intrinsic frame*, i.e., the frame in which the quadrupole components have values

$$\overline{\mathcal{Q}_\nu}=\cos\gamma\,\delta_{\nu 0}+\frac{1}{\sqrt{2}}\sin\gamma\,(\delta_{\nu 2}+\delta_{\nu,-2})\,. \tag{16}$$

The volume element for $\mathbb{R}^5$ is given by

$$\mathrm{d}v(\beta,\gamma,\Omega)=\beta^4\,\mathrm{d}\beta\,\mathrm{d}v(\gamma,\Omega) \tag{17}$$

(Refs. 1, 2), where

$$\mathrm{d}v(\gamma,\Omega)=\sin 3\gamma\,\mathrm{d}\gamma\,\mathrm{d}\Omega \tag{18}$$

is the SO(5)-invariant measure on S_4 and $\mathrm{d}\Omega$ is the SO(3)-invariant measure. Note, however, that the range of γ is restricted to $0\leqslant\gamma\leqslant\pi/3$ because of the equivalence of the coordinates

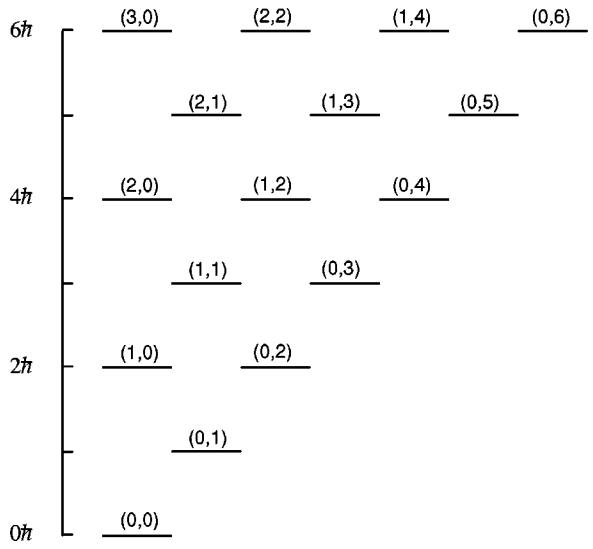

FIG. 1. The energy-level spectrum of the five-dimensional harmonic oscillator with levels labeled by (n,v), where n is the radial (beta) quantum number and v labels an SO(5) irrep of highest weight $[v,0]$. Each level shown represents a multiplet of states that span an SO(5) irrep. Each SO(5) $[v,0]$ irrep is reproduced an infinite number of times at energy intervals of $2\hbar\omega$. The states of a column of SO(5) irreps span an infinite-dimensional $\mathrm{SU}(1,1)\times\mathrm{SO}(5)$ irrep.

$$\pm\gamma, \quad \pm\gamma+2\pi/3, \quad \pm\gamma-2\pi/3, \tag{19}$$

as shown in Ref. 2 (p. 678).

III. THE HILBERT SPACE $\mathcal{L}^2(S_4)$

Observation: The Hilbert space $\mathcal{L}^2(S_4)$ is the carrier space for a direct sum of SO(5) irreps of highest weight $[v,0]$ with v running over the non-negative integers.

This observation is inferrred by a ''separation of variables'' technique, decomposing $\mathbb{R}^5$ into radial and spherical components.

The harmonic oscillator Hamiltonian spectrum comprises sets of energy levels of energy $n\hbar\omega$ with n taking all non-negative integer values. The states of each energy level span a U(5) irrep of highest weight $\{n\}\equiv\{n,0,0,0,0\}$ each of which restricts to a direct sum of $\mathrm{SO}(5)\subset\mathrm{U}(5)$ irreps given by the branching rule

$$\{n\}\downarrow[n,0]\oplus[n-2,0]\oplus[n-4,0]\oplus\cdots\oplus[1,0] \quad \text{or} \quad [0,0], \tag{20}$$

where $[v_1,v_2]$ labels an SO(5) irrep by its highest weight. The decomposition of the Hilbert space $\mathcal{L}^2(\mathbb{R}^5)$ into energy eigenspaces of the five-dimensional harmonic oscillator is illustrated schematically in Fig. 1. It is seen that only the so-called one-row SO(5) irreps of type $[v,0]$ occur in $\mathcal{L}^2(\mathbb{R}^5)$. However, each $[v,0]$ irrep occurs repeatedly at $2\hbar\omega$ intervals to form a column of such irreps. Because the volume element (17) is a product of a volume element $\beta^4\,\mathrm{d}\beta$ for $\mathbb{R}^+$ and a volume element $\mathrm{d}v(\gamma,\Omega)$ for S_4, it follows that $\mathcal{L}^2(\mathbb{R}^5)\simeq\mathcal{L}^2(\mathbb{R}^+\times S_4)$ is the tensor product space $\mathcal{L}^2(\mathbb{R}^+)\otimes\mathcal{L}^2(S_4)$. It also follows that the Hilbert space $\mathcal{L}^2(\mathbb{R}^5)$ is a direct sum of irreducible $\mathrm{SU}(1,1)\times\mathrm{SO}(5)$ subspaces. In fact, it is known from invariant theory[13,14] that the decomposition of $\mathcal{L}^2(\mathbb{R}^5)$ into $\mathrm{SU}(1,1)\times\mathrm{SO}(5)$ irreducible subspaces is multiplicity free. Complete sets of irreducible SO(5) subspaces are given by the eigenspaces of the energy levels shown in Fig. 1. They are shown with all states belonging to equivalent SO(5) irreps in the same column. Thus, the states of each column of SO(5) irreps span an irrep of the direct product group SU(1,1)

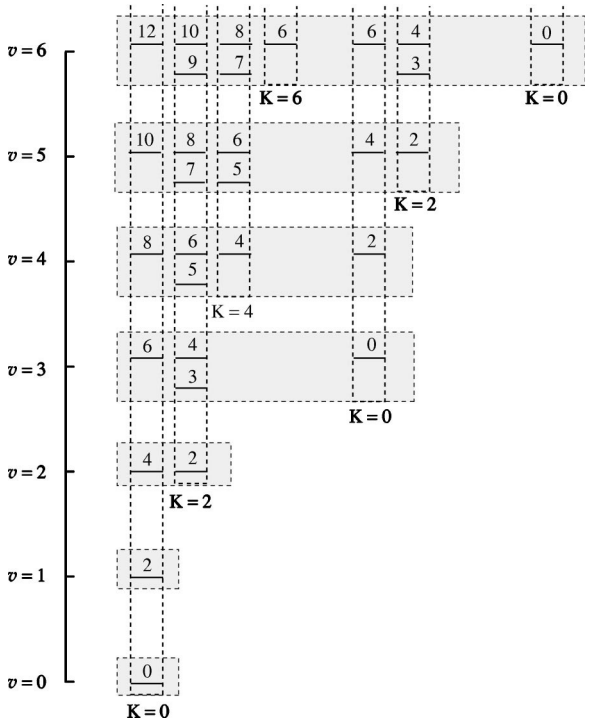

FIG. 2. The spectrum of SO(3) (angular momentum) irreps for $\mathcal{L}^2(S_4)$ put into sequences of K bands. The SO(3) irreps are labeled by their angular momenta L. Angular momentum irreps belonging to a common SO(5) irrep are put into a common shaded area.

$\times$SO(5). It is seen that every SO(5) irrep $[v,0]$ with v taking a non-negative integer value gives rise to a column. It follows that $\mathcal{L}^2(S_4)$ contains each SO(5) irrep $[v,0]$ just once, as claimed in the observation.

The decomposition of $\mathcal{L}^2(S_4)$ into SO(3) subspaces is inferred from the SO(5)$\downarrow$SO(3) branching rules, given for the one-row irreps by Kemmer *et al.*[15] who show that an irrep $[v,0]$ of SO(5) restricts to a direct sum of SO(3) irreps of angular momentum L given by

$$L = 2k, \quad 2k-2, \quad 2k-3, \quad 2k-4, \quad \ldots, \quad k$$

$$k = v, \quad v-3, \quad v-6, \quad \ldots, \quad k_{\min}, \tag{21}$$

where $k_{\min}=0$, 1, or 2.

The angular momentum states contained in the $v=0,\ldots,6$ irreps are shown in Fig. 2. It is seen that they fall into sequences of bands that can be characterized by the value K of the lowest angular momentum of each band. The band structure follows a recognizable pattern. A sequence of $K=0,2,4,6,\ldots$ bands appear with lowest states at intervals of $v=2$ with each band comprising a sequence of angular momentum states

$$L = 0,2,4,6,\ldots \quad \text{for } K=0,$$

$$L = K, K+1, K+2, K+3,\ldots \quad \text{for } K>0. \tag{22}$$

This sequence is then repeated at intervals of $v=3$. Such K bands are familiar in the context of rotor models. However, in the present context, K should simply be regarded as a convenient label for a set of basis wave functions.

We proceed to the construction of basis wave functions for $\mathcal{L}^2(S_4)$. First recall that the five quadrupole moments $\{\mathcal{Q}_\nu\}$ of Eq. (13), regarded as functions on S_4, provide a basis for a realization of the fundamental $v=1$ irrep of SO(5). From the observation that products of bounded square-integrable functions on S_4 are also square integrable functions on S_4 it follows that $\mathcal{L}^2(S_4)$ is spanned by polynomials in the $\{\mathcal{Q}_\nu\}$ coordinates with the understanding that $\|\mathcal{Q}\|^2 = \Sigma_\nu(-1)^\nu \mathcal{Q}_\nu \mathcal{Q}_{-\nu}=1$.

It can be seen, by inspection of Fig. 2, that the subspace of highest-weight SO(3) states in $\mathcal{L}^2(S_4)$; i.e., the space spanned by $M=L$ polynomials, is spanned by the polynomials

$$\Phi_{tKL}=\Phi(n)\equiv[\Phi_{002}]^{n_1}[\Phi_{022}]^{n_2}[\Phi_{100}]^{n_3}[\Phi_{023}]^{n_4}, \tag{23}$$

where $n=[n_1,n_2,n_3,n_4]$ is a quartet of non-negative integers,

$$\Phi_{002}\propto \mathcal{Q}_2\,, \tag{24}$$

$$\Phi_{022}\propto[\mathcal{Q}\otimes\mathcal{Q}]_{22}\,, \tag{25}$$

$$\Phi_{100}\propto[\mathcal{Q}\otimes\mathcal{Q}\otimes\mathcal{Q}]_{0}\,, \tag{26}$$

$$\Phi_{023}\propto[\mathcal{Q}\otimes\mathcal{Q}\otimes\mathcal{Q}]_{33}\,, \tag{27}$$

and

$$t=n_3,\quad K=2n_2+2n_4,\quad L=2n_1+2n_2+3n_4,\quad n_4=0 \text{ or } 1\,. \tag{28}$$

The square brackets in these equations indicate standard SO(3) angular-momentum coupling; i.e.,

$$[\mathcal{Q}\otimes\mathcal{Q}]_{LM}=\sum_{\mu\nu}(2,\nu,2,\mu|LM)\mathcal{Q}_\mu\mathcal{Q}_\nu\,, \tag{29}$$

where $(2,\nu,2,\mu|LM)$ is an SO(3) CG coefficient.

The polynomials $\{\Phi_{tKL}\}$ can be put into one-to-one correspondence with the SO(3) irreps depicted in Fig. 2. Note that each SO(3) irrep of angular momentum L corresponds to a single state in the subspace of highest-weight $M=L$ states. A moment's reflection on this correspondence and the shifts induced by each of the generator functions indicates what the indices n_i and the labels t and K mean. The lowest SO(3) irrep corresponds to the $(t=K=L=0)$ unit function for which $n_1=n_2=n_3=n_4=0$; at this point, we are not concerned with normalizations or even orthogonality of wave functions—merely with the construction of a basis. The function Φ_{002} is the basis function identified with the lowest $K=0$, $L=2$ irrep of Fig. 2. Thus, the set $\{[\Phi_{002}]^{n_1}\}$ corresponds to the sequence of $\{L=2n_1\}$ angular momenta irreps of the $K=0$ band and, in general, Φ_{002} is a $\Delta K=0$, $\Delta L=2$ shift operator on the Φ basis functions. Similarly, it is seen that Φ_{022} is a $\Delta K=2$, $\Delta L=2$ shift operator and Φ_{023} is a $\Delta K=2$, $\Delta L=3$ shift operator. Finally, Φ_{100} is a $\Delta t=1$, $\Delta K=\Delta L=0$ shift operator. A basis function Φ_{tKL} is assigned an index $t=i-1$ when it appears in the ith occurrence of the K band (e.g., $t=0$ for irreps of the lowest $K=0$ band and $t=1$ for irreps of the first excited $K=0$ band). Thus, t is the number of Φ_{100} zero-coupled triplets in parallel with a corresponding index in Ref. 11. It is stressed, however, that neither t nor K is a good quantum number because the Φ_{tKL} basis functions do not form an orthogonal set.

The generator functions and, hence, the complete set of basis functions $\{\Phi_{tKL}\}$ are conveniently expressed in the form

$$\Phi_{tKL}(\gamma,\Omega)=\sum_{\kappa\geqslant 0}^{\text{even}} F^n_\kappa(\gamma)\sqrt{\frac{2L+1}{16\pi^2(1+\delta_{\kappa 0})}}[\mathcal{D}^L_{\kappa L}(\Omega)+(-1)^L\mathcal{D}^L_{-\kappa L}(\Omega)]. \tag{30}$$

For the generator functions, the $\{F^n_\kappa\}$ functions are

$$F_0^{[1000]}(\gamma)=\cos\gamma\,,\quad F_2^{[1000]}(\gamma)=\sin\gamma\,, \tag{31}$$

$$F_0^{[0100]}(\gamma)=\cos 2\gamma\,,\quad F_2^{[0100]}(\gamma)=-\sin 2\gamma\,, \tag{32}$$

$$F_0^{[0010]}(\gamma)=\cos 3\gamma\,, \tag{33}$$

$$F_0^{[0001]}(\gamma)=0\,,\quad F_2^{[0001]}(\gamma)=\sin 3\gamma\,. \tag{34}$$

From the observation that

$$\mathcal{D}^{L_2}_{\kappa_2 L_2}(\Omega)\mathcal{D}^{L_1}_{\kappa_1 L_1}(\Omega)=\sum_{\kappa}\,(L_1\kappa_1,L_2\kappa_2|L\kappa)\,\mathcal{D}^{L}_{\kappa L}(\Omega)\,, \tag{35}$$

with $L=L_1+L_2$, it is now easy to build up the complete $\{\Phi_{tKL}\}$ basis, for the $M=L$ subspace, defined by F^n_κ functions in the form

$$F^n_\kappa(\gamma)=\sum_{i=0}^{n_1}\sum_{j=0}^{n_2} f^n_{ij\kappa}\,(\cos\gamma)^{n_1-i}\,(\sin\gamma)^i\,(\cos 2\gamma)^{n_2-j}\,(\sin 2\gamma)^j\,(\cos 3\gamma)^{n_3}\,(\sin 3\gamma)^{n_4}\,. \tag{36}$$

The overlaps and norms of basis wave functions, expressed in the form (30), are given by

$$\langle\Phi_{tKL}|\Phi_{t'K'L'}\rangle=\delta_{LL'}\sum_{\kappa\geqslant 0}^{\text{even}}\int_0^{\pi/3}F^n_\kappa(\gamma)F^{n'}_\kappa(\gamma)\sin 3\gamma\,\mathrm{d}\gamma\,. \tag{37}$$

These integrals can be carried out analytically, in the monomial basis given by Eq. (36), with the help of a computer to keep track of the coefficients. Thus, the overlaps of the basis wave functions can be computed in exact arithmetic using one of the several algebraic computer programs available; the present calculations were done with MAPLE.

IV. COMPUTATION OF SO(5) SPHERICAL HARMONICS

Having determined the overlaps of the above-defined basis functions $\{\Phi(n)\}$, it is is now a routine procedure to transform them to an orthonormal basis of SO(5) spherical harmonics.

The important observations are (i) that a polynomial $\Phi(n)$ is a linear combination of spherical harmonics of seniority $v\leqslant N$, where $N=n_1+2n_2+3n_3+3n_4$ and (ii) that q-parity is invariant under SO(5) transformations, where a polynomial is said to have even or odd q-parity if the polynomial is, respectively, of even or odd degree in $\{q_\nu\}$. As a consequence of these observations, the $\{\Phi(n)\}$ basis has a natural ordering and is readily transformed to an orthonormal (spherical harmonic) basis $\{\Psi_{v\alpha L}\}$ by a sequential Gram–Schmidt orthonormalization; α is a multiplicity index.

The first step is to identify which among the first of a specified number of states of a given angular momentum L have even q-parity (Π) and which odd. It is determined, for example, that for the first 12 states of $L=7$

$$\Pi(L_i)=\begin{cases}\text{even} & \text{for } i=2,4,6,8,10,12\\ \text{odd} & \text{for } i=1,3,5,7,9,11.\end{cases} \tag{38}$$

The next step is to identify the $n=[n_1,n_2,n_3,n_4]$ indices and the basis wave functions associated with these states. It is determined, for example, that $n=[2,0,0,1]$ for the state 7_1 (the first $L=7$ state) and $n=[0,2,0,1]$ for the next 7_3 odd-parity state and that the corresponding basis wave functions are given, in terms of their $[F^n_0,F^n_2,\ldots]$ functions, by

$$\Phi([2,0,0,1]) \sim \Big[0,\ 6\sqrt{\frac{3}{1001}}\sin 3\gamma\cos^2\gamma + \frac{1}{2}\sqrt{\frac{3}{1001}}\sin^2\gamma\sin 3\gamma,$$
$$3\sqrt{\frac{2}{91}}\cos\gamma\sin\gamma\sin 3\gamma, \frac{1}{2}\sqrt{\frac{3}{7}}\sin^2\gamma\sin 3\gamma\Big], \tag{39}$$

$$\Phi([0,2,0,1]) \sim \Big[0,\ 6\sqrt{\frac{3}{1001}}\sin 3\gamma\cos^2 2\gamma + \frac{1}{2}\sqrt{\frac{3}{1001}}\sin^2 2\gamma\sin 3\gamma,$$
$$-3\sqrt{\frac{2}{91}}\cos 2\gamma\sin 2\gamma\sin 3\gamma, \frac{1}{2}\sqrt{\frac{3}{7}}\sin^2 2\gamma\sin 3\gamma\Big].$$

The overlap matrix for these wave functions is next determined and from it the Gram–Schmidt transformation to an orthonormal basis of spherical harmonics. For the above two $L=7$ states one obtains the Gram–Schmidt transformation in the form

$$\left[\left[\frac{48}{1001}, \frac{304}{6825}\right], \quad \begin{bmatrix} 1 & 0 \\ -\frac{4}{15} & 1 \end{bmatrix}\right], \tag{40}$$

where the first vector gives the squared norms of the orthogonalized vectors, and the matrix that follows is the transformation from the Φ functions to an orthogonal set. Thus the first two $L=7$ spherical harmonics, $\Psi_{v\alpha L}$, which, from Fig. 2, are seen to have seniority $v=5$ and 7, respectively, are given by

$$\Psi_{5,1,7} = \sqrt{\frac{1001}{48}}\Phi([2,0,0,1]), \quad \Psi_{7,1,7} = \sqrt{\frac{6825}{304}}\left(\Phi([0,2,0,1]) - \frac{4}{15}\Phi([2,0,0,1])\right). \tag{41}$$

Note that the multiplicity index α is restricted to 1 for $L=7$ because all states of $L=7$ are multiplicity free.

V. SO(5) CLEBSCH–GORDAN COEFFICIENTS

Given SO(5) spherical harmonics $\{\Psi_{v\alpha L}\}$ in an SO(3) basis, the Clebsch–Gordan coefficients of type $(v_1\alpha_1 L_1, v_2\alpha_2 L_2 \| v_3\alpha_3 L_3)$ are obtained by simply evaluating the overlap integrals

$$\int \Psi^*_{v_3\alpha_3 L_3 M_3}(\gamma,\Omega)\,[\Psi_{v_2\alpha_2 L_2}(\gamma,\Omega)\otimes\Psi_{v_1\alpha_1 L_1}(\gamma,\Omega)]_{L_3 M_3}\sin 3\gamma\,\mathrm{d}\gamma\,\mathrm{d}\Omega$$
$$= \langle v_3\|\hat{\Psi}_{v_2}\|v_1\rangle\,(v_1\alpha_1 L_1, v_2\alpha_2 L_2\|v_3\alpha_3 L_3), \tag{42}$$

where $\hat{\Psi}_{v_2}$ is interpreted as a tensor operator whose components act on other wave functions by simple multiplication, i.e.,

$$[\hat{\Psi}_{v_2\alpha_2 L_2 M_2}\Psi_{v_1\alpha_1 L_1 M_1}](\gamma,\Omega) = \Psi_{v_2\alpha_2 L_2 M_2}(\gamma,\Omega)\Psi_{v_1\alpha_1 L_1 M_1}(\gamma,\Omega). \tag{43}$$

Thus, $\langle v_3\|\hat{\Psi}_{v_2}\|v_1\rangle$ is an SO(5)-reduced matrix element of this operator. The norms and phases of the CG coefficients are here defined by choosing the $\langle v_3\|\hat{\Psi}_{v_2}\|v_1\rangle$ factors to be positive and normalizing the coefficients such that

$$\sum_{\alpha_1 L_1 \alpha_2 L_2} (v_1\alpha_1 L_1, v_2\alpha_2 L_2\|v_3\alpha_3 L_3)^2 = 1. \tag{44}$$

TABLE I. The $(v_1\alpha_1L_1, v_2\alpha_2L_2\|v_3\alpha_3L_3)$ CG coefficients for $v_1=v_2=2$. Note, that the $v=2$ and $v=4$ irreps are multiplicity free so that $\alpha_1=\alpha_2=\alpha_3=1$ in all cases. Cf. the Appendix for an explanation of the notations.

$v_1\cdot L_1$	$v_2\cdot L_2$	4.2	4.4	4.5	4.6	4.8
2.2	2.2	$-\frac{2}{21}\sqrt{66}$	$\frac{1}{63}\sqrt{2145}$	0	0	0
2.4	2.2	$\frac{1}{42}\sqrt{330}$	$\frac{2}{63}\sqrt{78}$	$\frac{1}{2}\sqrt{2}$	$\frac{1}{14}\sqrt{70}$	0
2.2	2.4	$\frac{1}{42}\sqrt{330}$	$\frac{2}{63}\sqrt{78}$	$-\frac{1}{2}\sqrt{2}$	$\frac{1}{14}\sqrt{70}$	0
2.4	2.4	$\frac{2}{21}\sqrt{3}$	$\frac{20}{63}\sqrt{3}$	0	$-\frac{1}{7}\sqrt{14}$	1

Thus, tables of SO(5) CG coefficients are computed by evaluating the integrals of Eq. (42) and multiplying by normalization factors such that Eq. (44) is satisfied. An example of a table of CG coefficients obtained in this way is shown in Table I.

Tables of CG coefficients for $v_1\leqslant 9$ and $v_2=1$ are given in the Appendix. Other coefficients can be obtained from them by use of the following symmetry relations.

VI. PHASES AND SYMMETRY RELATIONS

It follows from the definition given in the first paragraph of Sec. V, that the CG coefficients satisfy the symmetry relation

$$(v_2\alpha_2L_2, v_1\alpha_1L_1\|v_3\alpha_3L_3)=(-1)^{L_1+L_2-L_3}(v_1\alpha_1L_1, v_2\alpha_2L_2\|v_3\alpha_3L_3)\,. \tag{45}$$

They also satisfy the symmetry relation

$$(v_3\alpha_3L_3, v_2\alpha_2L_2\|v_1\alpha_1L_1)=(-1)^{L_1+L_2-L_3}\sqrt{\frac{\dim(v_1)}{\dim(v_3)}\frac{(2L_3+1)}{(2L_1+1)}}(v_1\alpha_1L_1, v_2\alpha_2L_2\|v_3\alpha_3L_3)\,, \tag{46}$$

where $\dim(v)$ is the dimension of the SO(5) irrep of seniority v.

The latter relationship is derived by first using the identity

$$\Psi^*_{v_3\alpha_3L_3M_3}=(-1)^{L_3+M_3}\Psi_{v_3\alpha_3L_3,-M_3}=\sqrt{2L_3+1}\;(L_3M_3,L_3,-M_3|00)\,\Psi_{v_3\alpha_3L_3,-M_3} \tag{47}$$

to rewrite Eq. (42) in the coupled form

$$\frac{1}{\sqrt{2L_3+1}}\int[\Psi_{v_3\alpha_3L_3}(\gamma,\Omega)\otimes\Psi_{v_2\alpha_2L_2}(\gamma,\Omega)\otimes\Psi_{v_1\alpha_1L_1}(\gamma,\Omega)]_0\sin 3\gamma\,d\gamma\,d\Omega$$
$$=\langle v_3\|\|\hat{\Psi}_{v_2}\|\|v_1\rangle\,(v_1\alpha_1L_1, v_2\alpha_2L_2\|v_3\alpha_3L_3)\,. \tag{48}$$

The integrand on the left of this equation can then be reordered to give

$$\langle v_3\|\|\hat{\Psi}_{v_2}\|\|v_1\rangle\,(v_1\alpha_1L_1, v_2\alpha_2L_2\|v_3\alpha_3L_3)$$
$$=(-1)^{L_1+L_2-L_3}\sqrt{\frac{2L_1+1}{2L_3+1}}\langle v_1\|\|\hat{\Psi}_{v_2}\|\|v_3\rangle\,(v_3\alpha_3L_3, v_2\alpha_2L_2\|v_1\alpha_1L_1)\,. \tag{49}$$

Next observe that, if $\{|v\,\nu\rangle\}$ is any complete orthonormal basis for an SO(5) irrep of seniority v, then the unitarity of the CG coefficients implies that

$$\sum_{\nu_1\nu_2\nu_3} (\upsilon_1\nu_1,\upsilon_2\nu_2|\upsilon_3\nu_3)^2 = \dim(\upsilon_3)\,, \tag{50}$$

and, hence, that

$$\sum_{\alpha_1 L_1,\alpha_2 L_2,\alpha_3 L_3} (2L_3+1)(\upsilon_1\alpha_1 L_1,\upsilon_2\alpha_2 L_2\|\upsilon_3\alpha_3 L_3)^2 = \dim(\upsilon_3)\,. \tag{51}$$

Squaring both sides of Eq. (49), and applying this identity, then gives

$$\frac{\langle \upsilon_1\|\|\hat{\Psi}_{\upsilon_2}\|\|\upsilon_3\rangle}{\langle \upsilon_3\|\|\hat{\Psi}_{\upsilon_2}\|\|\upsilon_1\rangle} = \sqrt{\frac{\dim(\upsilon_3)}{\dim(\upsilon_1)}} \tag{52}$$

and the desired result (46).

VII. CONCLUDING REMARKS

Basis wave functions for the irreps of SO(5) can be defined and constructed in many ways. If one is concerned with a particular irrep, then vector coherent state (VCS) methods provide a construction both of an orthonormal basis and the matrix elements of the SO(5) Lie algebra; e.g., Rowe and Hecht[21] gave an algorithm for deriving the so-called one-row irreps and, recently, a construction for the generic SO(5) irreps has been developed by Turner, Rowe, Repka, and Bahri.[22] However, if one needs basis wave functions for many one-row irreps [i.e., SO(5) spherical harmonics], e.g., for nuclear collective model calculations, the more direct method presented above is simpler. This method simplifies that of Chacón *et al.*[11] by restricting the active space to $\mathcal{L}^2(S_4)$ rather than the Hilbert space

$$\mathcal{L}^2(\mathbb{R}^+)\otimes\mathcal{L}^2(S_4) \simeq \mathcal{L}^2(\mathbb{R}^5)\,, \tag{53}$$

where $\mathcal{L}^2(\mathbb{R}^+)$ is the Hilbert space of radial (beta) wave functions; many complications and subtle concepts (like traceless bosons) are thereby avoided.

Clebsch–Gordan coefficients can also be computed in many ways. For complex situations, sophisticated algebraic methods have been developed (cf. Refs. 9, 17–19, and references therein). However, it is possible to compute the coefficients relating one-row irreps of many groups directly from their spherical harmonics in parallel with Wigner's method[20] for SU(2); this is demonstrated above for SO(5). It is generally most useful to generate CG coefficients as they are needed with a program rather than a set of tables. A simple MAPLE code based on the above algorithm has been developed and was used to give the results reported in this paper. A faster routine (using floating point arithmetic) is being prepared[16] and will be made generally available in the near future. Some of the most useful coefficients, from which many others can be derived, are given (in exact arithmetical form) in the Appendix.

Given such CG coefficients, and knowledge of a complete basis of beta wave functions (cf. Ref. 3), it is possible to do many model calculations, e.g., in the Hilbert space $\mathcal{L}^2(\mathbb{R}^5)$ of the five-dimensional harmonic oscillator or in the space of a U(5) or U(6) irrep spanned by wave functions classified by SO(5) quantum numbers. For example, the matrix elements of the infinitesimal generators of SO(5) are easily computed by expressing them as coupled products

$$L_k = -\sqrt{10}\ (d^\dagger\otimes d)_{1k}, \quad O_\nu = -\sqrt{10}\ (d^\dagger\otimes d)_{3\nu}, \tag{54}$$

of the raising and lowering operators $\{d^\dagger_\nu, d_\nu\}$ of the five-dimensional harmonic oscillator. For example, the reduced matrix elements of the octupole tensor O are given by

$$\langle v j L_3 \| O \| v i L_1 \rangle = -\sqrt{70}\ \upsilon \sum_{kL_2} (-1)^{L_1 - L_2} \sqrt{(2L_1+1)(2L_3+1)}\ W(L_1 2 L_3 2; L_2 3)$$
$$\times (\upsilon - 1, k L_2, 12 \| v j L_3)\, (\upsilon - 1, k L_2, 12 \| v i L_1)\,. \tag{55}$$

We have ascertained that this expression gives precisely the same matrix elements, albeit to within a unitary transformation between subsets of states of an irrep having the same angular momentum, as those quoted by Rowe and Hecht.[21] Matrix elements of other bilinear combinations of the d-boson operators within the space of the five-dimensional harmonic oscillator are also easily computed. Morever, because the matrix elements of $L=0$ s-boson operators are well-known, the SO(5) CG coefficients are all that are needed to compute the matrix elements of any bilinear combination of boson operators in the space of the six-dimensional harmonic oscillator.

APPENDIX: TABLES OF BASIC SO(5) CLEBSCH–GORDAN COEFFICIENTS

The following tables give the CG coefficients $(v_1, \alpha_1, L_1; 1,1,2 \| v_3, \alpha_3, L+3)$. The tables are shown in the form in which they are computed. The first two columns give the values of $v_1 \cdot L_1$ and $v_2 \cdot L_2 = 1 \cdot 2$. The subsequent columns are headed by the value of $v_3 \cdot L_3$. The multiplicity indices are not given explicitly. Instead, if a given value of $v \cdot L$ has a multiplicity, it is simply repeated as, for example, for $v \cdot L = 6.6$.

$$\begin{bmatrix} v_1 \cdot L_1 & v_2 \cdot L_2 & 2.2 & 2.4 \\ 1.2 & 1.2 & -1 & 1 \end{bmatrix}$$

$$\begin{bmatrix} v_1 \cdot L_1 & v_2 \cdot L_2 & 3.0 & 3.3 & 3.4 & 3.6 \\ 2.2 & 1.2 & 1 & -\frac{\sqrt{35}}{7} & \frac{\sqrt{231}}{21} & 0 \\ 2.4 & 1.2 & 0 & -\frac{\sqrt{14}}{7} & -\frac{\sqrt{210}}{21} & 1 \end{bmatrix}$$

$$\begin{bmatrix} v_1 \cdot L_1 & v_2 \cdot L_2 & 4.2 & 4.4 & 4.5 & 4.6 & 4.8 \\ 3.0 & 1.2 & \frac{\sqrt{330}}{30} & 0 & 0 & 0 & 0 \\ 3.3 & 1.2 & -\frac{\sqrt{66}}{12} & -\frac{\sqrt{4290}}{90} & \frac{\sqrt{210}}{20} & 0 & 0 \\ 3.4 & 1.2 & \frac{\sqrt{70}}{20} & -\frac{\sqrt{2002}}{66} & -\frac{\sqrt{462}}{44} & \frac{\sqrt{330}}{22} & 0 \\ 3.6 & 1.2 & 0 & -\frac{4\sqrt{165}}{495} & -\frac{\sqrt{715}}{55} & -\frac{\sqrt{154}}{22} & 1 \end{bmatrix}$$

(Received 1 December 2003; accepted 19 April 2004;
published online 9 June 2004)

The constraint distribution in nonholonomic mechanics has a double role. On the one hand, it is a kinematic constraint, that is, it is a restriction on the motion itself. On the other hand, it is also a restriction on the allowed variations when using D'Alembert's principle to derive the equations of motion. We will show that many systems of physical interest where D'Alembert's principle does not apply can be conveniently modeled within the general idea of the principle of virtual work by the introduction of both kinematic constraints and variational constraints as being independent entities. This includes, for example, elastic rolling bodies and pneumatic tires. Also, D'Alembert's principle and Chetaev's principle fall into this scheme. We emphasize the geometric point of view, avoiding the use of local coordinates, which is the appropriate setting for dealing with questions of global nature, like reduction. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1763245]

I. INTRODUCTION

Nonholonomic mechanics: The universal formalism created by Lagrange is not appropriate to derive the equations of motion for systems with rolling constraints, that is, this motion is not described by classical variational principles. Several systems with rolling constraints, like the idealized rigid ball rolling on a plane with only one point of contact and many others, are successfully described geometrically by distributions on configuration space and the corresponding equations of motion are derived by D'Alembert's principle, which has been the purpose of extensive research[3,5,14,17,18,22,30] for more than a century (see also, for instance, Refs. 24, 2, 7, and 8 for a list of references and historical remarks). However, as we will see in the examples studied in the present work the dynamics of elastic rolling bodies is not generally described by D'Alembert's principle, even in those cases where the restriction on the motion is given by linear constraints. On the other hand, *second order constraints*, that is, subsets of the second order tangent bundle rather than the tangent bundle of the configuration space, naturally appear in several examples. The purpose of the present work is to establish the basic geometric definitions and procedures within the general idea of the principle of virtual work, generalizing D'Alembert's principle to deal with nonlinear and higher order constraints. One of our main examples will be elastic rolling bodies, like pneumatic tires, where some second order constraints appear naturally.

In D'Alembert's principle the constraint distribution has a double role. On one hand, it is a *kinematic constraint*, that is, it is a restriction on the motion itself. On the other hand, it is, *in*

addition, a *variational constraint*. This perspective was already adopted in Ref. 13 where a general approach to nonholonomic constrained systems considered as implicit differential equations was considered. There it was discussed that the kinematical constraints defining a submanifold on the tangent space of the configuration space of the system and the reaction or control forces described by a subbundle of the cotangent bundle of the configuration space, where independent entities and a condition for the compatibility of both ingredients was obtained. In this paper we will push forward this point of view by considering nonlinear higher order nonholonomic constraints, not only constraints on the velocities but on higher order derivatives.

We will show that many systems of physical interest where D'Alembert's principle does not apply, can be conveniently modeled by a principle based in the introduction of both higher order *kinematic constraints* and higher order *variational constraints* as being independent entities. This includes, for example, elastic rolling bodies and pneumatic tires. Also, D'Alembert's principle and Chetaev's principle fall into this scheme.

Our point of view is geometric, avoiding the use of local coordinates, which is appropriate for dealing global problems, like reduction. We also write equations of motion for systems with higher order constraints in an intrinsic fashion, using the natural structures of the tangent bundle and higher order bundles.

Basic notation: As usual we will consider that the configuration space of a Lagrangian system is a smooth manifold Q of dimension n with local coordinates q^i. We shall introduce higher order tangent bundles in order to deal with higher order constraints. Thus, by definition, two given curves in Q, say, $q_1(t)$ and $q_2(t)$, $t\in(-a,a)$, have a contact of order k at $q_0=q_1(0)=q_2(0)$ if there is a local chart (φ,U) such that $q_i(0)\in U$, for $i=1,2$, and $D_t^s(\varphi\circ q_1)(0)=D_t^s(\varphi\circ q_2)(0)$, for $s=0,\ldots,k$. This is a well-defined equivalence relation, and the equivalence class of a given curve $q(t)$ is denoted $[q]^{(k)}$. For each $q_0\in Q$, let $T^{(k)}_{q_0}Q$ be the set of all $[q]^{(k)}$ such that $q(0)=q_0$, and let $T^{(k)}Q$ be the collection of all $T^{(k)}_{q_0}Q$, for $q_0\in Q$. It is well known (see, for instance, Refs. 19 and 9 and references therein) that $\tau^k:T^{(k)}Q\to Q$, where $\tau^k([q]^{(k)})=q(0)$, is a fiber bundle, called the tangent bundle of order k of Q. There are natural maps $\tau^{(l,k)}:T^{(k)}Q\to T^{(l)}Q$, for $k,l=1,2,\ldots$, given by $\tau^{(l,k)}([q]^{(k)})=[q]^{(l)}$. It is easy to see that $T^{(1)}Q\equiv TQ$. Also, we can identify $T^{(0)}Q\equiv Q$, via $[q]^{(0)}\equiv q(0)$.

In local coordinates, we have $q=(q^1,\ldots,q^n)$, and, for $s=1,2,\ldots$, we denote $q^{(s)}=(q^{1,(s)},\ldots,q^{n,(s)})$, where

$$q^{i,(s)}=\frac{\mathrm{d}^s q^i}{\mathrm{d}t^s}(0),$$

where $i=1,\ldots,n$. Then we have, $[q]^{(k)}=(q^{(0)},\ldots,q^{(k)})$.

Denote by $j_k:T^{(k)}Q\to T(T^{(k-1)}Q)$ the canonical immersion defined by $j_k([q]^{(k)})=[q^{(k-1)}]^{(1)}$ where $q^{(k-1)}$ is the lift to $T^{(k-1)}Q$ of the curve q, that is, the curve $q^{(k-1)}:(-a,a)\to T^{(k-1)}Q$ is defined as $q^{(k-1)}(t)=[q_t]^{(k-1)}$ where $q_t(s)=q(t+s)$.

In this paper, it will be useful to introduce, geometrically, the concept of implicit differential equations. This concept has often received less attention than the notion of an explicit differential equation in the differential geometry literature (see Refs. 21, 23, and 13). Geometrically, a system of implicit kth-order differential equations is a submanifold M of $T^{(k)}Q$ and a curve $\gamma:I\to Q$ is a solution to the differential equation M, if its k-lift $\gamma^{(k)}(s)\in M$ for all $s\in I$. The implicit differential equation will be said to be integrable at a point if there exists a solution γ such that its k-lift passes through it. The integrable part of M is the subset of all integrable points of M. The system is said to be integrable if its integrable part coincides with M. A notorious algorithm has been developed to extract the integrable part of an arbitrary implicit differential equation,[23] but it will not be the objective of this paper to discuss this issue for systems with higher order nonholonomic constraints and we will restrict ourselves to the description of the corresponding implicit differential equation, leaving the questions of the existence and uniqueness of its solutions for future discussion.

In Sec. II we describe a first example of the elastic rolling ball, where some of the features of the general procedure already appear. In Secs. III and IV we show how to study Rocard's theory and also Greidanus's theory of a pneumatic tire (see Refs. 11, 26, and 27 and also Ref. 24) as a nonholonomic system with higher order constraints and, motivated by the previous examples, in Sec. IV we establish a general principle for dealing with systems involving higher order constraints. The distinction between kinematic constraints and variational constraints as being independent entities is a key point to this discussion. In Sec. V intrinsic equations of motion for systems with higher order constraints are derived. In Sec. VI further examples are provided and some basic results about reduction and the equations for Lagrangian systems with symmetries with higher-order nonholonomic constraints are discussed.

II. A SIMPLE EXAMPLE: THE ELASTIC HOMOGENEOUS ROLLING BALL

The main purpose of this section is to show an example that can be treated using D'Alembert's principle and also using some other procedures involving different types of constraints, including second order nonlinear constraints. All those procedures are equivalent in the sense that they give equivalent systems of equations.

Let us consider an elastic ball subjected to gravity and rolling on a plane. Without loss of generality we will assume that the radius of the ball is 1, for simplicity. For a static ball the contact between the ball and the plane is a circle, whose diameter was calculated by Hertz,[12] see also Ref. 16, p. 27. The effect of internal viscosity, adhesion and other dissipative forces is important in some cases,[4] however, in the present section we shall assume that heat dissipation is small, in other words, we will consider only the idealized model of a perfect elastic ball. Also, we shall consider only the important case where the circle of contact is small and the motion is quasistatic, which, in particular, implies that the zone of contact is approximately a circle of the same size as the contact circle in the static case (see Ref. 16). This also implies that the size and inertia of the flattened part of the sphere is negligible. Now we shall define the *nonsliding condition*. It is given by the condition that the points of the sphere belonging to the circle of contact cannot slide against the plane. It is clear that this has to be understood in an approximate sense since the exact solution of elasticity equations is not known in general, not even under the quasistatic assumption. More precisely, we accept the following approximate model. We assume that for all kinematic and dynamical purposes the ball is rigid, it has only one point of contact a with the plane, representing the center of the circle of contact, which does not slides, and the spatial angular velocity and the translation velocity combine in such a way that the velocity of points z of the surface of the ball near a have a velocity which is of order $|a-z|^2$. This is a rigorous way of defining the constraint given by the nonsliding condition, in the case where there is a circle rather than a point of contact. It is easy to prove that, in fact, the nonsliding condition is satisfied if and only if the vertical component of the spatial angular velocity is 0, that is, $\omega_3 = 0$. We emphasize that this model is realistic only for slow motion and small deformation. In agreement with all these physical assumptions we have the following geometric model.

Kinematics of the elastic rolling ball. The manifold $Q=\mathrm{SO}(3)\times\mathbb{R}^2$ is the configuration space for the model. A position of the system is given by a point $(A,a)\in Q$, where a is the point of contact of the sphere with the plane representing in the approximation described above the center of the circle of contact. Let $V=\dot{a}$ be the translation velocity of the ball and let $\omega=\dot{A}A^{-1}$ be the spatial angular velocity $\omega=(\omega_1,\omega_2,\omega_3)$, after the identification of $\mathfrak{so}(3)$ with $\mathbb{R}^3$. We have $\dot{V}=\ddot{a}$ and $\dot{\omega}=\ddot{A}A^{-1}-\dot{A}A^{-1}\dot{A}A^{-1}$. The following two equations describe the nonsliding constraint:

$$V=(\omega_2,-\omega_1), \tag{1}$$

$$\omega_3=0. \tag{2}$$

The first equation represents the usual nonsliding condition for a rigid rolling ball while the second expresses the fact that there is really a circle of contact rather than a point, and that the points of that circle belonging to the sphere have zero velocity with respect to the plane, at least to first

order approximation. The previous equations define a distribution, which is the *kinematic constraint* for the system of the elastic rolling ball. We will show that, provided that we accept higher order constraints, there are other equivalent ways of choosing the constraints all of them giving equivalent equations of motion. For instance, let the curve $a(t)$ in the plane have curvature radius $r(t)$. Then we define the constraint

$$r^2\omega_3^2=\omega_1^2+\omega_2^2, \tag{3}$$

whose physical meaning is that the instantaneous motion of the sphere is a superposition of a rotation about some vertical axis, with angular velocity ω_3, and the motion of rolling on the plane with speed

$$|V|=\sqrt{\omega_1^2+\omega_2^2}, \tag{4}$$

and the point of contact is located at a distance r from the vertical axis. This is an example of a *second order constraint*, it is a *kinematic constraint* in the terminology introduced in Sec. IV and it is equivalent to the constraint (2), in the sense that it gives equivalent equations of motion, as we will explain later. However, as we have said before the nonsliding condition is satisfied only if $r=\infty$, which of course implies $\omega_3=0$. Equation (1) has the following consequence:

$$\dot{V}=(\dot{\omega}_2,-\dot{\omega}_1).$$

Let $\mathbf{t}$ and $\mathbf{n}$ be the tangent and normal vectors to the curve $a(t)$. We have

$$|V|\mathbf{n}=\pm(\omega_1,\omega_2),$$

and also

$$\dot{V}=\frac{\mathrm{d}|V|}{\mathrm{d}t}\mathbf{t}+\frac{|V|^2}{r}\mathbf{n}.$$

Then we can deduce

$$\langle|V|\mathbf{n},\dot{V}\rangle=\pm(\omega_1\dot{\omega}_2-\omega_2\dot{\omega}_1) \tag{5}$$

$$=\frac{|V|^3}{r}, \tag{6}$$

from which we obtain the constraint (3) in the form

$$\omega_1\dot{\omega}_2-\omega_2\dot{\omega}_1=\omega_3(\omega_1^2+\omega_2^2), \tag{7}$$

where the choice of the sign $\pm$ is the only one consistent with the standard choice for the direction of the normal $\mathbf{n}$ and the sign of ω_3 for the given physical description. We have a subset $C\subseteq T^{(2)}Q$, given by (1) and (7), rewritten in terms of $\dot{a}$, A, $\dot{A}$, and $\ddot{A}$. This is a *second order kinematic constraint*. Observe that, in this example, the projection $\tau_Q^{(1,2)}:T^{(2)}Q\to TQ$ defines a distribution $D\subseteq TQ$, by $D=\tau_Q^{(1,2)}(C)$, which is given by (1), and that rewritten in terms of A, $\dot{A}$, a, and $\dot{a}$, gives an expression linear in $\dot{A}$ and $\dot{a}$.

Dynamics of the elastic rolling ball: The Lagrangian is given by the kinetic energy

$$L(A,a,\dot{A},\dot{a})=\tfrac{1}{2}I(\dot{A}A^{-1})^2+\tfrac{1}{2}M(\dot{a})^2,$$

where I is the moment of inertia of the ball with respect to any of its symmetry axis, and M is the mass of the ball. The dynamics of the elastic rolling ball is given by the following variational description, as we will see later,

$$\delta\int_{t_0}^{t_1}\left(\frac{1}{2}I(\dot{A}A^{-1})^2+\frac{1}{2}M(\dot{a})^2\right)\mathrm{d}t=0, \tag{8}$$

$$(\delta A(t_i),\delta a(t_i))=0 \quad \text{for } i=0,1, \tag{9}$$

$$(\delta A(t),\delta a(t))\in D_{(A(t),a(t))} \quad \text{for all} \quad t, \tag{10}$$

$$(\dot{A}(t),\dot{a}(t))\in D_{(A(t),a(t))} \quad \text{for all} \quad t, \tag{11}$$

$$\omega_3=0. \tag{12}$$

We will show that we can replace the last equation by Eq. (7) and we will obtain an equivalent system. We note that in this formulation the *constraints on the variations* are the same as in the case of the rigid rolling ball (see, for instance, Refs. 24 and 2). However, the *kinematic constraints* are not, in other words, the motion is effectively constrained by our choice of the last equation, namely, either Eq. (2) or Eq. (7). For any of those choices, we derive from the previous principle a *differential-algebraic system* of equations and we will have existence and uniqueness of solution for those initial conditions compatible with the constraints.

By applying the usual integration by parts argument, we obtain the equations of motion. However, as it already happens in the case of the rigid body, this is not completely trivial unless one is willing to use reduction arguments, (see, for instance, Refs. 6 and 7). We will postpone the details of the computation until Sec. VI. We obtain,

$$(I+M)\dot{\omega}_1=0, \tag{13}$$

$$(I+M)\dot{\omega}_2=0, \tag{14}$$

$$(I+M)\dot{\omega}_3=0, \tag{15}$$

$$(\omega_2,-\omega_1)=V, \tag{16}$$

$$\omega_3=0. \tag{17}$$

Of course this system is over determined, but it is correct. The fifth equation, which coincides with Eq. (2), may be replaced by Eq. (7) and we obtain a system which is clearly equivalent. The first four equations are exactly the equations for the rigid rolling ball and they imply that $\dot{\omega}=0$ and also that the translation velocity V is constant. We can show that there is solution provided that the initial condition (ω_0,V_0) satisfies the constraints given by the last two equations and that this solution is unique.

We must remark at this point that the only guiding idea to establish the previous procedure is the principle of virtual work, and one should check that the final equations are consistent with the basic laws of mechanics, essentially Newton's law, so the force should be equal to the rate of change of linear momentum and the torque should be equal to the rate of change of angular momentum. In the case of the elastic rolling ball the forces of the constraint must satisfy the following conditions: the resultant force exerted by the plane on the ball has a positive component in the vertical upwards direction while the torque has a zero horizontal component. All this is obviously compatible with the previous system of equations. Moreover, the same equations can be derived by an elementary exercise in rational mechanics. We observe that preservation of energy is satisfied in this example. As a final remark to this example we observe that even if the constraints (1), (2) are linear, we have not applied D'Alembert's principle. However, it will become clear at the end in Sec. VI that D'Alembert's principle gives correct equations of motion in this example, and it is perhaps the best procedure in this case since it produces a nonoverdetermined system. Showing that it is not always the case that D'Alembert's principle can be applied is part of the purpose of the present work. It is also clear from what we have explained so far that, for a

given system, there is in principle the possibility of introducing several classes of higher order constraints which are equivalent in the sense that they lead to equivalent equations of motion.

The case of the nonhomogeneous elastic ball and also the case of the nonhomogeneous viscoelastic ball could be interesting, for instance because of possible applications to spherical robots, and can be treated with the methods of the present work. In particular, the nonsliding condition (2) will be part of the kinematic constraints. The case of the symmetric elastic or viscoelastic rolling ball, in which two of the three moments of inertia of the ball are equal, presents an extra symmetry and we can expect that some kind of reduction by this symmetry will help to understand the behavior of the reduced variables such as the angular momentum. The case of the rigid symmetric rolling ball has been studied in Ref. 6.

III. AN EXAMPLE OF NONLINEAR HIGHER ORDER NONHOLONOMIC CONSTRAINTS

In the example of the elastic rolling ball described in the preceding section the second order constraint gives rise to a distribution D defined by (1) which provides a restriction for the variations to obtain some of the equations of motion. The rest of the equations of motion are the ones given by the same distribution, plus an extra equation provided by the nonlinear second order constraint (7) or, equivalently, by the linear constraint (2). This gives a procedure whose correctness in the example under consideration is established by the fundamental principles of mechanics.

Rocard's theory of a pneumatic tire: Before we try to establish any general procedure we will describe another example where the restrictions, both kinematic restrictions and restrictions on the variations, are of an entirely different nature. This is the simplified model of a pneumatic tire rolling on a plane according to Rocard's theory, as described, for instance, in Refs. 27, 26, 24. For simplicity we shall study the case of a single elastic pneumatic tire whose plane is constrained to remain vertical while it rolls without sliding. The zone of contact of the pneumatic tire with the plane is a small surface with a central point of contact $x=(x_1,x_2)$, which for simplicity we will assume that it coincides with the projection of the center of the wheel on the plane. The nonsliding condition means that the velocity of the points of the tire belonging to the zone of contact with respect to the plane is zero. In an approximate sense this nonsliding condition implies that the vertical component of the angular velocity of the small piece of surface of the pneumatic in contact with the floor is zero. However, contrary to what we have assumed for the homogeneous elastic rolling ball, the fact that the vertical component of the angular velocity of the zone of contact is zero does not mean that the vertical component of the angular velocity of the plane of the tire is zero. This is because according to Rocard's theory the elasticity of the material allows for a small angle ϵ between the axis of the zone of contact (an oblong-like symmetric zone), which is assumed to have the direction of $\dot{x}$, and the plane of the wheel. We will call K the corresponding constant of elasticity. It turns out that the nonsliding condition for the small zone of contact is not the relevant constraint. Instead, there will appear another second order constraint of a different nature. Finally, we must remark that the previous description of Rocard's theory gives only an approximation, and for more accurate results one must have into account some other observed effects. For instance, the projection x of the center of the wheel onto the plane is not exactly the center of the zone of contact, which produce a small torque not taken into account in the simplified model described above. Part, but only part, of this problem is taken into account in the simplified version of Greidanu's theory described later in the present work.

Taking into account all the physical considerations explained above we will describe Rocard's theory by the following geometric model. For all kinematic and dynamical purposes the wheel is simply an undeformable disk kept vertical and rolling on a plane, where the point of contact is $x=(x_1,x_2)$. We choose once for all a normal vector $N=(-\sin\theta,\cos\theta)$ rigidly fixed to the wheel. Then the angle between the plane of the wheel and the x_1 axis is θ. The angle between the velocity vector $\dot{x}$ and the plane of the wheel is called ϵ, with the physical meaning that we have explained before. Therefore, the angle between the axis x_1 and $\dot{x}$ is $\theta-\epsilon$, and the vector $\mathbf{n}$, normal to the trajectory of the point x and pointing in the direction of the concavity of the curve, is $\mathbf{n}=(-\sin(\theta-\epsilon),\cos(\theta-\epsilon))$. The angle of rotation of the wheel about its own axis is called ψ. In order to obtain precise formulas one should be careful about the sign conventions. Positive angles

in the x_1x_2 plane satisfy the usual convention. Thus the angle between the x_1 axis and the x_2 axis is, by definition, $(1/2)\pi$ while the angle between the x_2 axis and the x_1 axis is $-(1/2)\pi$. The sign for the angle ψ is established by the convention that the vector angular velocity is of the form $\dot{\psi}N$. The configuration space of the system is $Q=\mathbb{T}^3\times\mathbb{R}^2$, and a generic point is $q=(q_1,q_2,q_3,q_4,q_5)\equiv(\psi,\theta,\epsilon,x_1,x_2)$. The Lagrangian is given by

$$L(q,\dot{q})=\tfrac{1}{2}I\dot{\psi}^2+\tfrac{1}{2}J\dot{\theta}^2+\tfrac{1}{2}M\dot{x}^2-\tfrac{1}{2}K\epsilon^2,$$

where I is the moment of inertia of the wheel with respect to its axis, J is the moment of inertia of the wheel with respect to any one of its diameters, M is the mass of the wheel, and K is the constant of elasticity introduced before, which by definition satisfies $T=-K\epsilon$, where T is the vertical torque. The kinetic energy due to the velocity of rotation $\dot{\epsilon}$ of the small flattened piece of material about the zone of contact is small and we will assume that it is 0 for simplicity, which is also in agreement with general standard assumptions for this kind of approximate models.[24]

Next we shall describe the kinematic constraints and the variational constraints. The kinematic constraint C_K, is given by the equations

$$\dot{x}_1=\dot{\psi}\cos(\theta-\epsilon), \tag{18}$$

$$\dot{x}_2=\dot{\psi}\sin(\theta-\epsilon), \tag{19}$$

$$-\ddot{\psi}\,\mathrm{tg}\,\epsilon+\dot{\psi}(\dot{\theta}-\dot{\epsilon})=(\mathrm{sign}\,\dot{\psi})\frac{a}{M}\mathrm{tg}\,\epsilon. \tag{20}$$

The first two equations represent the nonsliding condition for the center of the zone of contact, and they are the same as the ones that appear in the case of a rigid rolling disk, or wheel, except for the small angle ϵ. We should emphasize that here we are working to first order approximation only, which means that powers of ϵ greater than 1 may be neglected. The last equation comes from Rocard's condition,

$$|F|=a\sin|\epsilon|,$$

where a is a positive physical constant and F is the force normal to the wheel exerted by the floor, while the wheel is rolling with nonzero velocity. More precisely, F is the N component of the centripetal force, that is we have $F=\langle M\ddot{x},N\rangle$. The sign conventions are encoded in the following more precise version of Rocard's formula

$$F=(\mathrm{sign}\,\dot{\psi})a\sin\epsilon,$$

where ϵ must be interpreted as being the angle between the normal $\mathbf{n}$ to the curve and N if $F>0$ while it must be interpreted as being the angle between $\mathbf{n}$ and $-N$ if $F<0$. Recall that Rocards's formula is valid for ϵ close to 0 only. A couple of remarks are in order for future use. First, as we have said before, Rocard's theory is valid modulo infinitesimals of order $(\sin\epsilon)^2$. Second, with the previous sign conventions and according to Rocard's formula it is not difficult to show that $\epsilon(\dot{\theta}-\dot{\epsilon})\geqslant 0$. It also follows from the expression of Rocard's formula given by (20) that for $\epsilon=0$ the curve $x(t)$ must have a point of inflection, that is $\dot{\theta}-\dot{\epsilon}=0$.

It is clear that (20) involves the first and second derivatives of some of the variables with respect to time, moreover, the dependence on the first derivatives is nonlinear, therefore it is far from the typical constraints of D'Alembert type. To obtain equation (20) we may assume, without loss of generality, that $\dot{\psi}>0$. We simply differentiate (18) and (19) with respect to time, and replace in the equation $(\mathrm{sign}\,\dot{\psi})a\sin\epsilon=\langle M\ddot{x},N\rangle$. Now let us consider the following variational constraints C_V, to be imposed on variations δq:

$$\delta\psi\cos\theta-\delta x_1=0, \tag{21}$$

$$\delta\psi\sin\theta-\delta x_2=0, \tag{22}$$

$$\delta\theta-\delta\epsilon=0. \tag{23}$$

Consider the curves $q(t)$ satisfying

$$\delta\int_{t_0}^{t_1}L(q,\dot{q})\mathrm{d}t=0,$$

for variations δq satisfying $\delta q(t_i)=0$, for $i=1,2$, and also the variational constraints C_V. Those curves are the ones satisfying the following *dynamic equations*:

$$I\ddot{\psi}+M\ddot{x}_1\cos\theta+M\ddot{x}_2\sin\theta=0, \tag{24}$$

$$J\ddot{\theta}+K\epsilon=0, \tag{25}$$

obtained by the usual integration by parts arguments. These dynamic equations give balance between forces of the constraint and rate of change of momentum. The resultant of the forces exerted by the plane of contact on the wheel has positive upwards vertical component which is compensated by gravity, while the horizontal component, which is given by $M\ddot{x}$, is decomposed in the directions $(\cos\theta,\sin\theta)$ and $(-\sin\theta,\cos\theta)$. The first one is compensated by the rate of change of the angular momentum $I\ddot{\psi}$ and the second is compensated by the nonsliding constraint force. The vertical component of the torque of the forces exerted by the plane on the wheel is $K\epsilon$ which is compensated by $J\ddot{\theta}$. The other components of the torque are automatically compensated because we are assuming that the wheel is forced to remain vertical. The system of dynamic equations together with the kinematic constraints equations C_K completely describe the motion of the wheel.

In the previous example, we should emphasize, again, the distinction between *kinematic constraints* and *variational constraints*. They are conceptually different, and this difference is implicit in the usual statement of the principle of virtual work. However, in the literature this distinction is usually not emphasized, and for good reason, since in those cases where D'Alembert's principle can be applied the variational constraints and the kinematic constraints coincide. Nonholonomic systems that cannot be treated using D'Alembert method have been considered for instance by Chetaev[10] where a procedure to deal with general first order nonlinear constraints is devised (see also Refs. 1 and 25). In Marle[22] it is clearly stated that constraint forces cannot be derived in general from the kinematic constraints and have to be added as part of the physical description of the system. Furthermore in Ref. 13 it was explicitly stated a formulation for first order Lagrangian and Poisson nonholonomic systems where kinematic constraints and constraint forces are given as independent entities.

In the case of the elastic rolling ball the forces of the constraint are normal to the direction of the motion of the ball and there is no dissipation of energy. However, for a viscoelastic rolling ball there is certainly dissipation of energy and the component of the force of the constraint in the direction of the motion can be calculated using results from Ref. 4. This kind of system can also be approached using the kind of generalization of D'Alembert's principle described in Sec. IV. The rate of dissipation of energy for a pneumatic tire rolling according to Rocard's theory can be easily calculated. Since the energy is given by $E=(1/2)I\dot{\psi}^2+(1/2)J\dot{\theta}^2+(1/2)M\dot{x}^2+(1/2)K\epsilon^2$, using the kinematic constraints (18), (19) and the dynamic equations derived before we can show after some easy calculations that $\dot{E}=-(M\dot{\psi}^2+K)\epsilon(\dot{\theta}-\dot{\epsilon})$, modulo infinitesimals of order ϵ^2. Since $\epsilon(\dot{\theta}-\dot{\epsilon})\geqslant 0$ as we have explained before we have $\dot{E}\leqq 0$, which means that in general there is dissipation of energy. The limit case $\epsilon=0$ gives $\dot{E}=0$, which reveals that Rocard's theory does

not take into account the relatively small dissipation of energy that occurs when the tire rolls in a straight line. To prove the previous formula we proceed as follows. We can easily see that $\dot{E}=I\dot{\psi}\ddot{\psi}+J\dot{\theta}\ddot{\theta}+M\dot{x}\cdot\ddot{x}+K\epsilon\dot{\epsilon}$. By differentiating (18) and (19) we can easily see that $\dot{x}\cdot\ddot{x}=\dot{\psi}\ddot{\psi}$ and from this and the dynamic equation (25) we obtain $(I+M)\dot{\psi}\ddot{\psi}-K\epsilon(\dot{\theta}-\dot{\epsilon})=0$. Using (18), (19), and (24) we obtain, modulo higher order infinitesimals, that $(I+M)\ddot{\psi}=-M\dot{\psi}\epsilon(\dot{\theta}-\dot{\epsilon})$ therefore $(I+M)\ddot{\psi}\dot{\psi}=-M\dot{\psi}^2\epsilon(\dot{\theta}-\dot{\epsilon})$, from which we finally obtain $\dot{E}=-(M\dot{\psi}^2+K)\epsilon(\dot{\theta}-\dot{\epsilon})$. From a general point of view we may say that the distinction between variational and kinematic constraints implies that the infinitesimal work of the constraint forces in general does not vanish for some admissible infinitesimal displacements, which is the reason why the forces of the constraint may produce work.

In the next section we define a class of nonholonomic systems with higher order nonlinear constraints based on the introduction of both kinematic and variational constraints. We will also show that procedures like D'Alembert's principle or Chetaev's procedure fall into this scheme. We propose that questions of a general nature on nonholonomic systems, like reduction by the symmetry, Legendre transformation, and many others should be approached for the general case of higher order constraints using the scheme based on the introduction of both kinematic and variational constraints.

IV. A PRINCIPLE OF VIRTUAL WORK FOR LAGRANGIAN SYSTEMS WITH NONLINEAR HIGHER ORDER NONHOLONOMIC CONSTRAINTS

Let Q be a configuration space of dimension n and let $L:TQ\to\mathbb{R}$ be a given Lagrangian. Then we have the Euler–Lagrange operator $\mathcal{EL}:T^{(2)}Q\to T^*Q$ which is given in coordinates by

$$\mathcal{EL}_i([q]^{(2)})\,\delta q^i=\left(\frac{\mathrm{d}}{\mathrm{d}t}\frac{\partial L}{\partial\dot{q}^i}([q]^{(2)})-\frac{\partial L}{\partial q}([q]^{(2)})\right)\delta q^i.$$

A *kinematic constraint of order k* is, by definition, a subset $C_K\subseteq T^{(k)}Q$, for some $k=0,1,2,\ldots$. The subset C_K is often defined by equations $R_K([q]^{(k)})=0$, where $R_K:T^{(k)}Q\to\mathbb{R}^r$, for some $r=1,2,\ldots$. For example, if $k=0$ and R_K is a submersion then C_K is a nonsingular holonomic constraint. If $k=1$ and $R_K(q,\dot{q})=R_{Ki}(q)\dot{q}^i$ defines a distribution of constant rank, we have the typical situation of D'Alembert's principle. If $R_K(q,\dot{q})$ is a general function we have the situation considered by Chetaev.[10] In the case of the elastic rolling ball we have, if we choose the constraint given by Eq. (2) as we have explained before, $n=5$, $k=1$, $r=3$, and

$$R_K(A,a,\dot{A},\dot{a})=(\omega_2-\dot{a}_1,-\omega_1-\dot{a}_2,\omega_3).$$

Alternatively, as we have explained before, if we choose the constraint given by Eq. (7), we have, $n=5$, $k=2$, $r=3$,

$$R_K(A,a,\dot{A},\dot{a},\ddot{A},\ddot{a})=(\omega_2-\dot{a}_1,-\omega_1-\dot{a}_2,\omega_1\dot{\omega}_2-\omega_2\dot{\omega}_1-\omega_3(\omega_1^2+\omega_2^2)). \tag{26}$$

In the case of the Rocard's theory of a pneumatic tire, we have $n=5$, $k=2$, $r=3$, and

$$R_K(\psi,\theta,\epsilon,x_1,x_2,\dot{\psi},\dot{\theta},\dot{\epsilon},\dot{x}_1,\dot{x}_2)=\Big(\dot{x}_1-\dot{\psi}\cos(\theta-\epsilon),\dot{x}_2-\dot{\psi}\sin(\theta-\epsilon),-\ddot{\psi}\,\mathrm{tg}\,\epsilon+\dot{\psi}(\dot{\theta}-\dot{\epsilon})$$
$$-(\mathrm{sign}\,\dot{\psi})\frac{a}{M}\mathrm{tg}\,\epsilon\Big). \tag{27}$$

A *constraint on the variations of order l* is a subset $C_V\subseteq T^{(l)}Q\times_Q TQ$ defined by equations $R_V([q]^{(l)},\delta q)=0$ where R_V is linear in the variable δq, so we shall write as usual $R_V([q]^{(l)},\delta q)=R_V([q]^{(l)})\,\delta q$ or, in coordinates, $R_V([q]^{(l)},\delta q)=R_{Vi}([q]^{(l)})\,\delta q^i$. For each $[q]^{(l)}\in T^{(l)}Q$, we let $C_V([q]^{(l)})=\{\delta q\in TQ:([q]^{(l)},\delta q)\in C_V\}$.

Statement of the principle: The main object defined in this paper is the class of Lagrangian nonholonomic systems defined by data (L, C_K, C_V) whose *dynamical equations* are derived by using the variational principle

$$\delta \int_{t_0}^{t_1} L(q,\dot{q})\mathrm{d}t = 0,$$

where variations δq are restricted by $\delta q \in C_V([q]^{(l)})$, or, equivalently, $R_V([q]^{(l)}) \cdot \delta q = 0$. Then the *equations of motion* are given by the *dynamical equations*

$$\mathcal{EL}_i([q]^{(2)}) \in R_V([q]^{(l)})^o$$

and the *kinematic constraint* equations $[q]^{(l)} \in C_K$ or, equivalently,

$$R_K([q]^{(k)}) = 0.$$

Equations of motion will be derived in the next section.

The previous principle, which is contained in the general idea of the principle of virtual work, imposes, through the dynamical equations, restrictions on the forces of the constraints. But, contrary to what happens with D'Alembert's principle, the forces of the constraints derived from the principle stated above will in general produce work.

The class of higher order nonholonomic systems just defined contains several important classes of nonholonomic systems. For example, for the class of nonholonomic systems that are tractable using D'Alembert's principle we have, by definition, $k=1$, $l=0$ and C_K is the distribution where for each $q \in Q$ the space of the distribution is $C_V(q) \subseteq TQ$. Thus, the kinematic constraint and the constraint on the variations essentially coincide in this case. In the case of nonlinear kinematic constraints considered by Chetaev given by $R_K(q,\dot{q}) = 0$ we have $l=1$ and the variational constraints are defined, according to Chetaev, by

$$R_V(q,\dot{q}) \cdot \delta q = \frac{\partial R_K(q,\dot{q})}{\partial \dot{q}} \cdot \delta q.$$

Remark 4.1: In the mathematical literature one finds some examples of higher order constraints in nonholonomic problems (for instance, see Refs. 28, 25, 15, and 29). In the previous references an extension of the Chetaev principle for kinematic second order constraints is applied, namely,

$$(R_K)_i(q,\ \dot{q},\ \ddot{q}) = 0, \quad 1 \leqslant i \leqslant m$$

and variational constraints R_V are derived from the kinematic constraints by

$$R_V(q,\dot{q},\ddot{q}) \cdot \delta q = \frac{\partial R_K}{\partial \ddot{q}} \cdot \delta q = 0.$$

In the case of the elastic rolling ball the variational constraints are given by (10). In the case of the pneumatic tire according to Rocard's theory the kinematic constraints are given by (18), (19), (20) and the variational constraints are given by (21), (22), (23).

We emphasize once again that the notions of kinematic constraints and variational constraints are independent and one should not attempt, for instance, to derive variational constraints from kinematic constraints by a universal procedure. In order to illustrate further the necessity of such a point of view we will describe next the example of Greidanus's theory of a pneumatic tire, where the kinematic constraint defines a distribution like in D'Alembert's principle but the variational constraints are not given by the same distribution, therefore they are not the ones prescribed by D'Alembert's principle.

Pneumatic tires according to Greidanus: Several approaches to the dynamics of a pneumatic tire like those of Rocard, Greidanus, Keldys, and others can be found in Refs. 11, 27, 26, 24. To describe Greidanu's approach we shall consider the simpler setting of Rocard's approach described before, but this time we allow, in addition, for a lateral deformation ξ. The absolute value of the quantity ξ is the distance between the projection of the center of the wheel on the plane (x_1,x_2) and the center of the zone of contact. In the Rocard's approach described above the value of ξ is 0. We must remark that we are considering in this paper only the case of Greidanus's theory in which the wheel is kept vertical. The physical reason for the appearance of the displacement ξ is of course the lateral deformation due to the centrifugal force given the elasticity of the material.

The kinematic constraints are

$$\dot{x}_1=\dot{\psi}\cos(\theta-\epsilon), \tag{28}$$

$$\dot{x}_2=\dot{\psi}\sin(\theta-\epsilon), \tag{29}$$

$$\dot{\theta}-\dot{\epsilon}=\dot{\psi}(\alpha\xi+\beta\epsilon). \tag{30}$$

The first two equations are the same as in Rocard's approach. The last one expresses the fact that the curvature of the trajectory of the center of the contact zone is, for a given speed of rotation of the wheel, proportional to a linear combination of the deformation parameters ξ and ϵ, where $\alpha>0$ and $\beta>0$. This replaces Rocard's constraint. We see that the kinematic constraints define a distribution. The variational constraints are

$$\delta x_1=\delta\psi\cos\theta, \tag{31}$$

$$\delta x_2=\delta\psi\sin\theta, \tag{32}$$

$$\delta\theta-\delta\epsilon=0. \tag{33}$$

These variational constraints are different from the kinematic constraints, therefore we are not using here D'Alembert's principle. The projection of the center of the wheel on the plane is the point (y_1,y_2) given by

$$y_1=x_1+\xi\sin\theta, \tag{34}$$

$$y_2=x_2-\xi\cos\theta. \tag{35}$$

It is more convenient to calculate the kinematic constraints and the variational constraints in terms of y_1 and y_2 instead of x_1 and x_2. The kinematic constraints are

$$\dot{y}_1=\dot{\psi}\cos(\theta-\epsilon)+\dot{\xi}\sin\theta+\xi(\cos\theta)\dot{\theta}, \tag{36}$$

$$\dot{y}_2=\dot{\psi}\sin(\theta-\epsilon)-\dot{\xi}\cos\theta+\xi(\sin\theta)\dot{\theta}, \tag{37}$$

$$\dot{\theta}-\dot{\epsilon}=\dot{\psi}(\alpha\xi+\beta\epsilon). \tag{38}$$

The variational constraints are

$$\delta y_1=\delta\psi\cos\theta+\delta\xi\sin\theta+\xi(\cos\theta)\delta\theta, \tag{39}$$

$$\delta y_2=\delta\psi\sin\theta-\delta\xi\cos\theta+\xi(\sin\theta)\delta\theta, \tag{40}$$

$$\delta\theta-\delta\epsilon=0. \tag{41}$$

The Lagrangian is

$$L(\psi,\theta,\epsilon,y_1,y_2,\xi,\dot{\psi},\dot{\theta},\dot{\epsilon},\dot{y}_1,\dot{y}_2,\dot{\xi})=\tfrac{1}{2}I\dot{\psi}^2+\tfrac{1}{2}J\dot{\theta}^2+\tfrac{1}{2}M((\dot{y}_1)^2+(\dot{y}_2)^2)-\tfrac{1}{2}\alpha\xi^2-\tfrac{1}{2}\beta\epsilon^2.$$

Then, equations of motion are given by kinematic constraints (36), (37), (38) and dynamic equations

$$I\ddot{\psi}+M\ddot{y}_1\cos\theta+M\ddot{y}_2\sin\theta=0, \tag{42}$$

$$J\ddot{\theta}+M\xi\ddot{y}_1\cos\theta+M\xi\ddot{y}_2\sin\theta+\beta\epsilon=0, \tag{43}$$

$$-M\ddot{y}_1\sin\theta+M\ddot{y}_2\cos\theta-\alpha\xi=0. \tag{44}$$

We can easily check that the previous equations represent the balance between rate of change of momentum and forces of the constraints.

For high values of α the deformation ξ remains small. Moreover, for $\alpha\to\infty$ we have $\xi\to 0$ and the dynamic equations (42), (43) of Greidanu's theory become the equations (24), (25) of Rocard's theory, provided that $K=\beta$. Using this and the fact that the two first kinematic constraints (18), (19) of Rocard's theory coincide with the first two kinematic constraints (28), (29) of Greidanu's theory and also the fact that for $\alpha\to\infty$ the mechanical energy E for both theories tend to the same value, one can prove, proceeding as in the case of Rocard's theory, that at least for high values of α a pneumatic tire moving according to Greidanus theory is a dissipative system. This shows that D'Alembert's principle does not provides a good model for this kind of system, even though the kinematic constraints are linear.

V. EQUATIONS OF MOTION

Let us recall some basic facts of the geometry of the tangent bundle. The *vertical endomorphism S* is defined in local natural coordinates $(q^A,\dot{q}^A)$ on TQ by

$$S=\frac{\partial}{\partial\dot{q}^A}\otimes \mathrm{d}\,q^A \quad .$$

The Liouville vector field Δ on TQ is locally defined by

$$\Delta=\dot{q}^A\frac{\partial}{\partial\dot{q}^A} \quad .$$

A second order differential equation is a vector field Γ on TQ such that $S(\Gamma)=\Delta$. We have the following local expression for Γ:

$$\Gamma=\dot{q}^A\frac{\partial}{\partial q^A}+F^A(q,\dot{q})\frac{\partial}{\partial\dot{q}^A} \quad .$$

An integral curve of Γ is always the tangent prolongation of its projection $q(t)$ on Q, called a *solution* of Γ. It satisfies the following explicit system of second order differential equations:

$$\frac{\mathrm{d}^2q^A}{\mathrm{d}t^2}=F^A(q,\dot{q}) \quad .$$

We also note that the kernel and image of S consist of vertical vector fields. Moreover, S acts by duality on forms and the kernel and image of S^* consists of horizontal one-forms.

Given a Lagrangian function $L:TQ\to\mathbb{R}$, we construct the two-form $\omega_L=-\mathrm{d}(S^*(\mathrm{d}L))$ on TQ, and the energy function $E_L=\Delta L-L$ (see Ref. 20). A remarkable property of S and ω_L is the following $i_S\omega_L=0$, or, in other words,

$$S^*\circ\hat{\omega}_L=-\hat{\omega}_L\circ S, \tag{45}$$

where $\hat{\omega}_L$ denotes the map $T(TQ)\to T^*(TQ)$ defined by contraction with ω_L.

Observe that if L is regular, then ω_L is a symplectic form, and there is a unique vector field Γ_L satisfying

$$i_{\Gamma_L}\omega_L = \mathrm{d}E_L,$$

or, in other words, Γ_L is the Hamiltonian vector field with Hamiltonian energy E_L. It is well known that Γ_L is a second order differential equation on TQ, namely, the Euler–Lagrange equations for L.

Without the regularity condition, the Euler–Lagrange equations form a system of second order differential equations in Q, in implicit form, that is, a submanifold D_2 of $T^{(2)}Q$, determined by

$$D_2=\{w\in T^{(2)}Q \;\mid\; i_{j_2(w)}\omega_L(\tau^{(1,2)}(w))=\mathrm{d}E_L(\tau^{(1,2)}(w))\} \tag{46}$$

or, in other words,

$$D_2=\{w\in T^{(2)}Q \;\mid\; \mathcal{EL}(w)=0\}\quad .$$

The class of higher order nonholonomic systems studied in this paper, are determined by data (L,C_K,C_V). Next we will show that the equations of motion of this kind of systems is a system of implicit kth-order differential equations. In what follows, and without loss of generality, we will always suppose that $k\geqslant l$ and $k\geqslant 2$.

In our case the constraint on the variations are determined by a subset $C_V\subseteq T^{(l)}Q\times_Q TQ$. Therefore for each point $[q]^{(l)}$ we obtain the annihilator $C_V^0([q]^{(l)})\subseteq T_q^*Q$ of $C_V([q]^{(l)})$. Denote by $F_V([q]^{(l)})$ the subspace of $T^*(TQ)$ determined by $F_V([q]^{(l)})=(\tau_Q)^*(C_V^0([q]^{(l)}))$. Now, we shall define the subset of $T^{(k)}Q$:

$$M_V=\{[q]^{(k)}\in T^kQ \;\mid\; i_{j_2([q]^{(2)})}\omega_L([q]^{(1)})-\mathrm{d}E_L([q]^{(1)})\in F_V([q]^{(l)})\}\quad .$$

Therefore, the nonholonomic system associated to (L,C_K,C_V), determines a kth-order implicit system given by the submanifold $M_{KV}=C_K\cap M_V$. The solutions of the problem (L,C_K,C_V) are the curves $\gamma: I\to Q$ such that $\gamma^{(k)}\subset M_{KV}$.

VI. FURTHER RESULTS AND EXAMPLES

The scheme generalizing D'Alembert principle, for the case of higher order constraints described in Sec. IV is not of course the most general case. It is not the purpose of the present work to expose the most general possible formalism, but on the contrary, to provide a scheme which is useful in a variety of problems in mechanics. This scheme is also useful to deal with important questions of a general character in mechanics, like reduction, Legendre transformation and others. Some of these questions will be the purpose of future work and in this section we will consider some partial results only.

Reduction of invariant systems with higher order constraints on a group: In this paragraph we explain how to reduce invariant Lagrangian systems with higher order nonholonomic constraints on a group. The more general case of systems on a principal bundle will be the purpose of a future work. However, in the present section we will show how to proceed in an example where the bundle is trivial, which illustrates some of the features of the general theory. Assume that the configuration space is a group G and that the Lagrangian L, the kinematic constraint C_K and the constraint on the variations C_V are left invariant. For right invariant systems we can proceed in a similar way. For each $r=1,2,\ldots$ we have an identification

$$\alpha_r: T^{(r)}G/G\to r\mathfrak{g},$$

where $r\mathfrak{g}=\mathfrak{g}\oplus\cdots\oplus\mathfrak{g}$, is the direct sum of r copies of $\mathfrak{g}$. This identification is uniquely defined by the map $[g]^{(r)}\to[v]^{(r)}$, where $v=g^{-1}\dot{g}$, and $[v]^{(r)}=(v^{(0)},v^{(1)},\ldots,v^{(r-1)})$, where, by definition, we have

$$v^{(i)}=\frac{\mathrm{d}^i}{\mathrm{d}t^i}v,$$

for $r=0,1,\ldots,r-1$. Under the identification α_k, the quotient of the kinematic constraint C_K/G, becomes a subset, called *reduced kinematic constraint*, $\mathfrak{C}_K\subseteq k\mathfrak{g}$. Similarly, for each $r=1,2,\ldots$ we have an identification

$$\beta_r:(T^{(r)}G\times_G TG)/G\to r\mathfrak{g}\oplus\mathfrak{g}.$$

This identification is uniquely defined by the map $([g]^{(r)},\delta g)\to([v]^{(r)},\eta)$ with $[v]^{(r)}=(v^{(0)},v^{(1)},\ldots,v^{(r-1)})$, as before, and $\eta=g^{-1}\delta g$. Under the identification β_l, the quotient of the constraint on the variations C_V/G, becomes a subset, called *reduced variational constraints*, $\mathfrak{C}_D\subseteq l\mathfrak{g}\oplus\mathfrak{g}$. Since the equations $R_K([g]^{(k)})=0$ and $R_V([g]^{(l)},\delta g)=0$ are invariant, we have reduced equations $\mathfrak{R}_K([v]^{(k)})=0$ and $\mathfrak{R}_V([v]^{(l)},\eta)=0$. Since $R_V([g]^{(l)},\delta g)=R_V([g]^{(l)})\cdot\delta g$ is linear in δg, we have that $\mathfrak{R}_V([g]^{(l)})\cdot\eta$ is also linear in η. The Lagrangian L gives rise to a reduced Lagrangian $l:\mathfrak{g}\to\mathbb{R}$. We have the following theorem.

Theorem 6.1: *The following conditions are equivalent*:

(i) *The curve $g(t)$ satisfies*

$$\delta\int_{t_0}^{t_1}L(g,\dot{g})\mathrm{d}t=0,$$

for all δg such that $\delta g(t)\in C_V([g]^{(l)}(t))$, for all $t\in[t_0,t_1]$ [equivalently $R_V([g]^{(l)}(t),\delta g(t))=0$ for all $t\in[t_0,t_1]$] and $\delta g(t_i)=0$ for $i=0,1$; $[g]^{(k)}(t)\in C_K$ [equivalently $R_K([g]^{(k)}(t))=0$ for all $t\in[t_0,t_1]$].

(ii) *The curve $g(t)$ satisfies the equation*

$$\left(\frac{\partial L}{\partial g}-\frac{\mathrm{d}}{\mathrm{d}t}\frac{\partial L}{\partial\dot{g}}\right)([g]^{(2)}(t))\cdot\delta g=0,$$

for all δg such that $\delta g(t)\in C_V([g]^{(l)}(t))$, for all $t\in[t_0,t_1]$ [equivalently $R_V([g]^{(l)}(t),\delta g(t))=0$ for all $t\in[t_0,t_1]$] and $\delta g(t_i)=0$ for $i=0,1$; $[g]^{(k)}(t)\in C_K$ [equivalently $R_K([g]^{(k)}(t))=0$ for all $t\in[t_0,t_1]$].

(iii) *The curve $v(t)=g^{-1}(t)\dot{g}(t)$ satisfies*

$$\delta\int_{t_0}^{t_1}l(v)\mathrm{d}t=0$$

for all $\delta v=\dot{\eta}+[v,\eta]$ where $\eta(t)\in\mathfrak{C}_V([v]^{(l)}(t))$ for all $t\in[t_0,t_1]$ [equivalently $\mathfrak{R}_V([v]^{(l)}(t),\eta(t))=0$ for all $t\in[t_0,t_1]$] and $\eta(t_i)=0$, for $i=0,1$; $[v]^{(k)}(t)\in\mathfrak{C}_K$ [equivalently $\mathfrak{R}_K([v]^{(k)}(t))=0$ for all $t\in[t_0,t_1]$].

(iv) *The curve $v(t)=g^{-1}(t)\dot{g}(t)$ satisfies the equation*

$$\left(-\frac{\mathrm{d}}{\mathrm{d}t}\frac{\partial l}{\partial v}+\mathrm{ad}^*\frac{\partial l}{\partial v}\right)([v]^{(2)}(t))\cdot\eta$$

for all η such that $\eta(t)\in\mathfrak{C}_V([v]^{(l)}(t))$ for all $t\in[t_0,t_1]$ [equivalently $\mathfrak{R}_V([v]^{(l)}(t),\eta(t))=0$ for all $t\in[t_0,t_1]$] and $\eta(t_i)=0$, for $i=0,1$; $[v]^{(k)}(t)\in\mathfrak{C}_K$ [equivalently $\mathfrak{R}_K([v]^{(k)}(t))=0$ for all $t\in[t_0,t_1]$].

The proof of this theorem can be performed proceeding as in Ref. 7. The idea of the proof is simple. Given a curve $g(t)$ such that $[g]^{(k)}(t)\in C_K$ for all $t\in[t_0,t_1]$ we take variations $\delta g(t)=g(t)\eta(t)$ for all $t\in[t_0,t_1]$ such that $\delta g(t)\in C_V([g]^{(l)}(t))$ for all $t\in[t_0,t_1]$. Since $v(t)=g^{-1}(t)\dot{g}(t)$ we can easily check that $\delta v(t)=\eta(t)+[v(t),\eta(t)]$. The rest of the proof follows by keeping track of the reduction of both the kinematic constraints and the variational constraints.

Symmetry of the elastic rolling ball: An interesting case occurs when, for each $[g]^{(l)}$, $C_V([g]^{(l)})$ depends only on g giving rise to a distribution D on G. This happens in the case of the rolling ball studied in Sec. II. Let us see how the previous theorem applies to this case. First of all we observe that the configuration space is the direct product group $\mathrm{SO}(3)\times\mathbb{R}^2$. Since we are assuming an homogeneous ball the kinetic energy Lagrangian is not only left invariant but also right invariant. This is important because the constraints are also right invariant. We can thus reduce by the right action of the group on itself. For $\eta=(\alpha,w)$ and taking into account that the Lie bracket in $\mathfrak{so}(3)$ is *minus* the standard one because we are reducing by *right* actions, we have

$$\delta\int_{t_0}^{t_1}\left(\frac{1}{2}I\omega^2+\frac{1}{2}MV^2\right)\mathrm{d}t=0, \tag{47}$$

$$\delta\omega=\dot{\alpha}-[\omega,\alpha], \tag{48}$$

$$\alpha(t_i)=0 \quad \text{for } i=0,1, \tag{49}$$

$$\delta V=\dot{w}, \tag{50}$$

$$w(t_i)=0 \quad \text{for } i=0,1, \tag{51}$$

$$w=(\alpha_2,-\alpha_1), \tag{52}$$

$$V=(\omega_2,-\omega_1), \tag{53}$$

$$\omega_3=0. \tag{54}$$

Equations (48), (50), (51) represent the reduced variational constraints while Eqs. (52), (53), (54) represent the reduced kinematic constraints [as we have explained before, Eq. (54) can be replaced by $\omega_2\dot{\omega}_1-\omega_1\dot{\omega}_2=\omega_3(\omega_1^2+\omega_2^2)$]. We obtain the equations of motions written in Sec. II, that is Eqs. (13), (14), (15), (16), (17). The reduced version of D'Alembert's principle consists of all the previous conditions plus the condition $\alpha_3=0$, which of course corresponds to the kinematic constraint $\omega_3=0$. The D'Alembert equations are (13), (14), (16), (17).

Rigid ball rolling on a moving plane: For dealing with examples where the configuration space is a principal bundle rather than a group and the constraints and also the Lagrangian are invariant we need to generalize the previous theory, which we plan to do as part of future works. However, some simple examples can be worked out directly as we will see next. Let us consider a rigid ball rolling on a plane while this plane is being continuously deformed according to the law $\varphi_t:\mathbb{R}^2\to\mathbb{R}^2$. The Eulerian velocity is $v_t(x)=\dot{\varphi}_t\circ\varphi_t^{-1}(x)$ and we will assume that $v_t(x)=v(x)$ is independent of t. For a rigid ball rolling on a fixed plane, that is when $v(x)=0$, the system is governed by the D'Alembert principle which in this case is like the principle of virtual work described in Sec. II for an elastic ball except that one should eliminate the kinematic constraint $\omega_3=0$. When $v(x)\neq 0$ there is an extra force since the point a of the ball which is in contact with the plane, is moving with velocity $v(a)$, that is, the kinematic constraint becomes $(\omega_2,-\omega_1)=\dot{a}-v(a)$. By differentiating with respect to t we obtain $(\dot{\omega}_2,-\dot{\omega}_1)=\ddot{a}-Dv(a)\dot{a}$. Using this it can be easily seen that the force exerted by the floor on the ball is $M((\dot{\omega}_2,-\dot{\omega}_1)+Dv(a)\cdot(\omega_2,-\omega_1)+Dv(a)\cdot v(a))$. Equations of motion can be easily derived by direct application of the basic rules of mechanics and we obtain

$$(I+M)(\dot{\omega}_2,-\dot{\omega}_1)=-MDv(a)\cdot[(\omega_2,-\omega_1)+v(a)], \tag{55}$$

$$\dot{\omega}_3=0. \tag{56}$$

Now we want to obtain the same equations using the formalism of the principle stated in Sec. IV. As in the case of the elastic rolling ball this is not straightforward, which emphasizes the advan-

tages of having a way of reducing by the symmetry as we will show next. The example under consideration is invariant with respect to the right action of SO(3) only because in this case the kinematic constraint is not necessarily invariant under translations. As we have said before in this simple example a general theory of reduction for systems on a principal bundle is not needed. Moreover, it is not difficult to prove directly that the following reduced principle of virtual work gives the correct equations of motion,

$$\delta \int_{t_0}^{t_1} \left(\frac{1}{2} I \omega^2 + \frac{1}{2} M \dot{a}^2 \right) \mathrm{d}t = 0, \tag{57}$$

$$\delta \omega = \dot{\alpha} - [\omega, \alpha], \tag{58}$$

$$\alpha(t_i) = 0 \quad \text{for } i = 0,1, \tag{59}$$

$$\delta a = (\alpha_2, -\alpha_1), \tag{60}$$

$$(\omega_2, -\omega_1) = \dot{a} - v(a). \tag{61}$$

Equations (58), (59), and (60) represent the variational constraints while Eq. (61) is the kinematic constraint.

published online 9 June 2004)

We study the separability of the state space of loop quantum gravity. In the standard construction, the kinematical Hilbert space of the diffeomorphism-invariant states is nonseparable. This is a consequence of the fact that the knot space of the equivalence classes of graphs under diffeomorphisms is noncountable. However, the continuous moduli labeling these classes do not appear to affect the physics of the theory. We investigate the possibility that these moduli could be only the consequence of a poor choice in the fine-tuning of the mathematical setting. We show that by simply choosing a minor extension of the functional class of the classical fields and coordinates, the moduli disappear, the knot classes become countable, and the kinematical Hilbert space of loop quantum gravity becomes separable. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1763247]

I. INTRODUCTION

Loop quantum gravity (LQG) is a background-independent quantization of classical general relativity which yields a discrete, combinatorial picture of Planck-scale quantum geometry. (For an introduction and references, see, for instance, Ref. 9.) Quantum space turns out to be described in terms of a basis of abstract spin-network states, or s-knot states, labeled by discrete quantum numbers. However, the picture is not truly entirely discrete. If the nodes of the s-knots have sufficiently high valence (that is, when a sufficiently high number of links meet), s-knots are labeled also by certain *continuous* moduli parameters. The existence of these moduli was pointed out in Ref. 11 and their structure studied in Ref. 6. Below we give an example of one of these moduli explicitly. These moduli are puzzling. They are virtually undetectable by the operators that represent physical measurements, as well as by the hamiltonian operator that governs the dynamics, and therefore they do not appear to play any significant role in the theory. Still, they spoil the discreetness of the picture and they change the structure of the space of the diffeomorphism-invariant states, $\mathcal{H}_{\text{diff}}$, rather drastically, making it nonseparable. (The space $\mathcal{H}_{\text{diff}}$ is denoted $\mathcal{K}_{\text{diff}}$ in Ref. 9.)

Nonseparability (absence of a countable basis) is generally regarded as pathological in quantum field theory (QFT). A classic discussion on this issue is in Ref. 13. As pointed out in Ref. 14, the nonseparability of $\mathcal{H}_{\text{diff}}$ is not necessarily unacceptable, because $\mathcal{H}_{\text{diff}}$ is a kinematical space that must still be reduced by the hamiltonian constraint equation. But it is nevertheless disturbing. Do we have to interpret it as an indication of a difficulty of the background-independent loop quantization?

In this paper, motivated by the fact that the moduli do not appear to have any physical significance, we consider the possibility that they are indeed spurious. We study the possibility that they are the consequence of a poor choice in setting up the details of the mathematical framework of the theory. It is not unusual that a naive way of setting up a QFT produces a nonseparable

Hilbert space, which is later cured, making it separable. Indeed, recall that Fock space itself, the prototypical QFT state space, was born precisely to cure nonseparability. A free scalar field can be decomposed into an infinite set of oscillators φ_i, $i=1,\ldots,\infty$. If we quantize each degree of freedom φ_i as a standard quantum harmonic oscillator, we are immediately led to a state space which is the tensor product of an infinite number of separable Hilbert spaces

$$\mathcal{H}=\bigotimes_{i=1,\ldots,\infty} H_i. \tag{1}$$

A basis in $\mathcal{H}$ is given by an infinite sequence of nonnegative integers $|n_1,n_2,\ldots,n_i,\ldots\rangle$, and such infinite sequences are noncountable (for instance, the states with $n_i<10$ are put into one-to-one correspondence with the real numbers $0\leqslant x<1$ by the decimal representation of x); hence $\mathcal{H}$ is nonseparable. Fock found a way to circumvent the problem by simply selecting the subspace $\mathcal{F}$ of $\mathcal{H}$ spanned by basis vectors where an arbitrary but finite number of n_i differ from zero. It is $\mathcal{F}$, called today Fock space, which is the appropriate state space for free QFT. Unlikely $\mathcal{H}$, the Fock space $\mathcal{F}$ provides an *irreducible* representation of the field algebra of the creation and annihilation operators. Thus, a straightforward and simple minded quantization strategy leading to a nonseparable state space has been later corrected to get rid of the nonseparability. Can we do the same in quantum gravity? Are there physical reasons for doing the same in quantum gravity?

In classical field theory, the choice of the functional class of fields and coordinates is to a large extent just a matter of convenience. We can work with solutions of the field equations that are smooth (C^∞), or just twice differentiable (C^2), sometimes distributional, or piecewise constant as in the lattice approximation, or else, according to what is more convenient. The relation between the formal apparatus of field theory and reality is only via the smearing of fields on finite regions of space, and therefore we never empirically test the functional class of a physical field. In quantum gravity, the smooth category is generally chosen, because it appears to be a natural and convenient setting. In the background-independent loop construction, the gauge invariance of general relativity washes away virtually any remnant of the functional class we started from, because the entire short-scale structure is canceled by the gauge transformations. Virtually, but not entirely. Indeed, as we show below, the nodes of sufficiently high valence have a surprising ''rigidity'' under smooth transformation, and this rigidity turns out to be the one responsible for the moduli. Therefore the nonseparability of $\mathcal{H}_{\text{diff}}$ is a bizarre remnant of the initial choice of the smooth category. It is therefore natural to explore the possibility of using a slightly different functional class of fields to start with.

Here we explore a minimal extension of this kind, where fields are allowed isolated points of nondifferentiability. The gauge invariance group of the theory becomes then a ''small'' extension of the diffeomorphism group, which we call *extended diffeomorphism* and denote $Diff^*$. As far as we can see, none of the physical results, physical predictions or physical consequences of LQG studied so far, are affected. However, the knot classes, now formed by graphs under $Diff^*$, turn out to be countable. The continuous moduli disappear and $\mathcal{H}_{\text{diff}}$ becomes separable. The theory describes a quantum structure of space–time that is genuinely combinatorial at the Planck scale.

These results can be taken as evidence that the moduli associated to high-valence nodes are indeed spurious. If we build LQG using the setting described here, or a variant of the same, the moduli are not anymore present, and the kinematical Hilbert space of the diffeomorphism invariant states of LQG is separable.

In Sec. II we review the basic mathematical setting of LQG and the origin of the nonseparability. This paper is mathematically self-contained but for physical motivations and details see Ref. 9. In Sec. III we introduce our main tool, $Diff^*$, and show that the equivalence classes of graphs under $Diff^*$ are countable and the resulting space $\mathcal{H}_{\text{diff}}$ is separable. In Sec. IV, we show that the modification introduced has no effect on the geometrical operators of LQG. We discuss in particular the area operator. In Sec. V we summarize and conclude.

II. NONSEPARABILITY

A. $\mathcal{H}_{\text{diff}}$, the space of the quantum states of physical space

We begin by briefly reviewing the basic mathematical setting of the kinematics of LQG. Classical general relativity can be defined on a four-dimensional differentiable manifold M with topology $\Sigma \times R$, where Σ is a three-dimensional differentiable manifold with a fixed arbitrary topology. The gravitational field can be taken to be a smooth (that is, infinitely differentiable) pseudo-Riemannian metric tensor g on M, satisfying the Einstein equations. Call $\mathcal{E}$ the space of such fields. The corresponding Hamiltonian theory can be defined on Σ. The configuration variable of general relativity can be defined as a smooth local connection one-form A on a SU(2)-principal bundle $\mathcal{P}$ over Σ. Call $\mathcal{A}$ the space of such connections.

We shall use extensively the notion of graph, whose relevance for quantum gravity was first realized by Lewandowski. Here a graph Γ is a finite collection of $L(\Gamma)$ smooth oriented one-dimensional submanifolds of Σ, called links and noted l, overlapping (if they do) only at endpoints, called nodes and denoted n. We say that the link l ends at the node n if n is a boundary point of l. The valence of a node n is the number of links ending at n. We call $\mathcal{G}$ the space of such graphs.

Quantum states are limit of sequences of cylindrical functions, converging in the norm defined below. A cylindrical function $\Psi_{\Gamma,f}: \mathcal{A} \to \mathbb{C}$ is defined as follows. Let $\mathrm{U}_l(A) \in \mathrm{SU}(2)$ be the holonomy of the connection A along l

$$\mathrm{U}_l(A) \equiv \mathcal{P} \exp \int_l A, \tag{2}$$

$\mathcal{P}$ denotes path ordering. A graph Γ defines a map $p_\Gamma: \mathcal{A} \to [\mathrm{SU}(2)]^{\times L(\Gamma)}$; $A \to (\mathrm{U}_l(A))$. By composing this map with a complex valued function f on $[\mathrm{SU}(2)]^{\times L(\Gamma)}$, we obtain the cylindrical function $\Psi_{\Gamma,f} = f \circ p_\Gamma$, given by

$$\Psi_{\Gamma,f}(A) \equiv f(\mathrm{U}_{l_1}(A), \ldots, \mathrm{U}_{l_{L(\Gamma)}}(A)). \tag{3}$$

Since it is always possible to write any two cylindrical functions in terms of the same graph (a cylindrical function on a graph Γ can be re-expressed on another graph Γ' that contains Γ), we can define a scalar product on the space of states using the Haar measure on SU(2)

$$\langle \Psi_{(\Gamma,f)} | \Psi_{(\Gamma,f')} \rangle \equiv \int \mathrm{dU}_1 \cdots \mathrm{dU}_{L(\Gamma)}\, \overline{f(\mathrm{U}_1, \ldots, \mathrm{U}_{L(\Gamma)})} f'(\mathrm{U}_1, \ldots, \mathrm{U}_{L(\Gamma)}). \tag{4}$$

The kinematical Hilbert space $\mathcal{K}$ of LQG is defined as the completion in the Hilbert norm (4) of the space of the cylindrical functions.

Local SU(2) gauge transformations act naturally on this space and the invariant states form a proper subspace $\mathcal{K}_0$. An orthonormal basis in $\mathcal{K}_0$ can be obtained using the spin-network states.[11,3] Consider a graph Γ and color each link l with a unitary irreducible representations j_l of SU(2). At each node n, fix a basis in the space of the invariant elements (the "intertwiners") in the tensor product of the representation spaces associated to the links that end at n, and color the node with an intertwiner i_n of this basis (see Ref. 9 for details). The triple $S = (\Gamma, j_l, i_n)$ is called a spin network. Let the function f_S be defined by the representation matrices for each link l in the representation j_l, contracted with the invariant tensors at each node. The state $\Psi_S[A] \equiv \Psi_{\Gamma,f_S}[A] \equiv \langle A|S \rangle$ is a spin network state. Varying the graph Γ in $\mathcal{G}$, the irreducible representations j_l and the intertwiners i_n in the chosen bases, we obtain an orthonormal basis in $\mathcal{K}_0$.

Finite linear combinations of spin-network states form a dense subspace $\mathcal{S}$ in $\mathcal{K}_0$. Sequences of states that converge weakly on $\mathcal{S}$, form the dual $\mathcal{S}'$. The Gelfand triple $(\mathcal{S} \subset \mathcal{K}_0 \subset \mathcal{S}')$ describes the space of the SU(2) invariant states of the theory. Now, $\mathcal{K}_0$ carries a natural unitary representation $\Psi[A] \to \mathrm{U}_\phi \Psi[A] = \Psi[\phi^{-1} A]$ of the group $Diff_\Sigma$ of the diffeomorphisms of Σ

$$\phi:\Sigma\to\Sigma, \tag{5}$$

which extends naturally to $\mathcal{S}'$ by duality (we have indicated with ϕ also the pull back action generated by the diffeomorphism ϕ on forms). The diffeomorphism invariant states form a linear subspace $\mathcal{H}_{\text{diff}}$ of $\mathcal{S}'$. This space describes the diff-invariant quantum states of the gravitational field; that is, the quantum states of physical space.

A map $P_{\text{diff}}:\mathcal{S}\to\mathcal{S}'$ is naturally defined by

$$(P_{\text{diff}}\Psi)(\Psi')=\sum_{\Psi''=\mathrm{U}_\phi\Psi}\langle\Psi'',\Psi'\rangle, \tag{6}$$

where the sum is over all distinct states Ψ'' that are equal to $\mathrm{U}_\phi\Psi$ for some $\phi\in Diff$. This sum converges and is well defined. The state $P_{\text{diff}}\Psi\in\mathcal{S}'$ is diff-invariant because clearly states related by diffeomorphisms are projected by P_{diff} on the same element of $\mathcal{H}_{\text{diff}}$,

$$P_{\text{diff}}\Psi_S=P_{\text{diff}}(\mathrm{U}_\phi\Psi_S). \tag{7}$$

Furthermore, the states of this form span $\mathcal{H}_{\text{diff}}$. The linear space $\mathcal{H}_{\text{diff}}$ is naturally equipped with a Hilbert space structure by the scalar product

$$\langle P_{\text{diff}}\Psi_S,P_{\text{diff}}\Psi_{S'}\rangle_{\mathcal{H}_{\text{diff}}}\equiv(P_{\text{diff}}\Psi_S)(\Psi_{S'}). \tag{8}$$

Equivalently, the Hilbert space $\mathcal{H}_{\text{diff}}$ can be defined by the bilinear form

$$\langle\Psi,\Psi'\rangle_{\mathcal{H}_{\text{diff}}}\equiv\langle\Psi|P_{\text{diff}}|\Psi'\rangle\equiv\sum_{\Psi''=\mathrm{U}_\phi\Psi}\langle\Psi'',\Psi'\rangle. \tag{9}$$

We can unravel the structure of $\mathcal{H}_{\text{diff}}$ by studying the action of a diffeomorphism on a spin-network state. Since the holonomy transforms as

$$\mathrm{U}_l(\phi^{-1}A)=\mathrm{U}_{\phi\circ l}(A), \tag{10}$$

shifting A with $\phi\in Diff(\Sigma)$ is equivalent to shifting the curve l. Consequently, the (representation of the) spatial diffeomorphism group acts directly on the spin network of a spin-network state,

$$\mathrm{U}_\phi|S\rangle=|\phi\circ S\rangle. \tag{11}$$

Since $|\phi\circ S\rangle$ may be formed by invariant tensors that are not in the intertwiner basis chosen at the nodes, $|\phi\circ S\rangle$ may fail to be a basis state even if $|S\rangle$ is; but as the spaces of intertwiners are finite dimensional, it will be a finite linear combination of basis states, all having the same graph $\Gamma'=\phi\circ\Gamma$. In particular, given a spin-network state, there is a finite group of transformations g_k, $k=1,\ldots,K$, in the (tensor over the nodes of the) spaces of the intertwiners, that can be obtained by a diffeomorphism mapping the graph into itself. We can therefore write

$$\langle S|P_{\text{diff}}|S'\rangle=\begin{cases}0 & \text{if } \Gamma'\neq\phi\circ\Gamma,\\ \displaystyle\sum_k\langle S|g_k|S'\rangle & \text{if } \Gamma'=\phi\circ\Gamma.\end{cases} \tag{12}$$

From the first line, we see that two spin networks S and S' define orthogonal states in $\mathcal{H}_{\text{diff}}$ if the corresponding graphs Γ and Γ' belong to different equivalence classes under diffeomorphism transformations. We call these equivalence classes "diff-knot classes" and indicate them as K_d, where "d" is for diffeomorphism. The basis states in $\mathcal{H}_{\text{diff}}$ are therefore firstly labeled by a diff-knot class K_d. Call $\mathcal{H}_{K_d}$ the subspace of $\mathcal{H}_{\text{diff}}$ spanned by the basis states labeled by the knot class K_d. The states in $\mathcal{H}_{K_d}$ are then only distinguished by the coloring of links and nodes. Hence

$\mathcal{H}_{K_d}$ is separable. These colorings are however not necessarily orthogonal because of the nontrivial action of the discrete group. A diagonalization of the matrix of the bilinear form in the second line of expression (12) yields states $|s\rangle = |K_d, c\rangle$, where the discrete label c depends only on colorings. The states $|s\rangle = |K_d, c\rangle$ are called s-knot states.

If $|s\rangle = P_{\text{diff}}|S\rangle$, the state $|s\rangle$ represents the diffeomorphism equivalence class to which the spin network S belongs. In going from the spin-network state $|S\rangle$ to the s-knot state $|s\rangle$, we preserve the information in $|S\rangle$ except for it's location in Σ. This is the quantum analog to the fact that physically distinguishable solutions of the classical Einstein equations are not fields, but equivalence classes of fields under diffeomorphisms. It reflects the core of the conceptual revolution of general relativity: spatial localization concerns only the *relative* location of the dynamical fields, and not their location in a background space. Accordingly, the s-knot states are not quantum excitations *in* space, they are quantum excitation *of* space. An s-knot does not reside ''somewhere'': the s-knot itself defines the ''where.''

However, a remnant of the background structure oddly remains, when a node has sufficiently high valence, as we show in the next section.

B. Moduli space structure

We have seen above that quantum states of the gravitational field are labeled by diff-knot classes. Following Ref. 6, we now study the structure of these classes and the way this affects the structure of $\mathcal{H}_{\text{diff}}$. The key point that we underline below is the fact that diff-knots are not countable, hence $\mathcal{H}_{\text{diff}}$ is nonseparable.

To begin with, consider usual knots, namely ones without intersections. These can be defined in two equivalent manners. Let $\mathcal{L}$ be the space of loops without intersections, namely the space of smooth embeddings of S_1 into Σ. We denote loops in $\mathcal{L}$ as $\alpha,\beta,\ldots$. Consider *two* equivalence relations on this space. First (see, for instance, Ref. 5) we say that α and β are iso-equivalent, and write $\alpha \sim_i \beta$, if there is a *continuous* ambient isotopy relating the two; that is, a one parameter family of *homeomorphisms* $h_t : \Sigma \to \Sigma$, $t \in [0,1]$, such that h_0 is the identity map on Σ while h_1 maps α to β. We call the equivalence classes of loops in $\mathcal{L}$ under this equivalence relation ''iso-knots.'' Next, (see, for instance, Ref. 2) we say that α and β are diff-equivalent, and write $\alpha \sim_d \beta$ if there exists a *diffeomorphism* ϕ of Σ in the connected component of the identity, such that $\alpha = \phi \circ \beta$ (or, equivalently, if there exists a *smooth* ambient isotopy relating the two). We denote the corresponding equivalence classes in $\mathcal{L}$ as ''diff-knots.'' A classic result of knot theory states that two loops are diff-equivalent if and only if they are iso-equivalent. Hence diffeomorphism equivalence is the same as isotopy, as far as loops without intersections are concerned, and a diff-knot is also an iso-knot. (This is also equivalent to the existence of a *smooth homotopy* between α and β, that is, a smooth one-parameter family of embeddings α_t, $t \in [0,1]$, such that $\alpha_0 = \alpha$ and $\alpha_1 = \beta$. However, this is *not* equivalent to the existence of a *continuous homotopy* between α and β, since, perhaps surprisingly, any two knots can be related by continuous homotopy. See, for instance, Ref. 8, p. 14 or Ref. 5, exercise 3.5.4, p. 53.)

However, this result does not extend to the case in which intersections, or nodes, are present; something peculiar happens at the intersection points. Let $\mathcal{G}$ be the space of the graphs defined in the preceding section, of which $\mathcal{L}$ is a subset. Define isotopy equivalence and diff-equivalence between graphs precisely as we did for loops. Let us indicate iso-knots by K_i and the space of the iso-knots as $\mathcal{K}_i$. Similarly, let us indicate diff-knots by K_d and the space of the diff-knots as $\mathcal{K}_d$. Thus

$$\mathcal{K}_i = \frac{\mathcal{G}}{\sim_i}, \quad \mathcal{K}_d = \frac{\mathcal{G}}{\sim_d}. \tag{13}$$

It is still easy to see that diff-equivalence implies iso-equivalence, because a diffeomorphism in the connected component of the identity is indeed connected to the identity by a smooth one parameter family of diffeomorphisms which generates the isotopy. But now the converse is not

true: there are iso-equivalent graphs that are not diff-equivalent. Furthermore, while iso-knots are countable, diff-knots are not: they are distinguished by moduli. (In general, a "modulus" is a continuous parameter labeling equivalence classes.)

The roots of this fact, which at first might seem surprising, can be illustrated using a simple example presented by Arnold in his book on catastrophe theory.[1] Let L_n be the set of all n-tuples of lines in the plane, passing through the origin. Say that two n-tuples are equivalent if they can be mapped into each other by a linear transformation of the plane, and let T_n be the space of the equivalence classes of n-tuples under this equivalence relation. The spaces T_1, T_2, and T_3 are discrete, but T_4 is a one-dimensional space. Indeed the group of linear transformation of the plane, GL(2), is four dimensional, but it does not act effectively on T_n because the dilatations do not affect lines through the origin, hence we can consider just its SL(2) subgroup, which is three dimensional. But L_4 is four dimensional, and the dimension of $T_4 = L_4/\mathrm{SL}(2)$ is $4-3=1$. More explicitly, if $\phi_1,\ldots,\phi_4$ are the angles formed by the lines with a given axis, then it is easy to see that

$$\lambda(\phi_1,\ldots,\phi_4) = \frac{\sin(\phi_1-\phi_3)\sin(\phi_2-\phi_4)}{\sin(\phi_1-\phi_4)\sin(\phi_2-\phi_3)} \tag{14}$$

is invariant under linear transformations. Indeed, let $\vec{v}_1,\ldots,\vec{v}_4$ be four vectors of arbitrary length parallel to the four lines. The ratio

$$\lambda(\vec{v}_1,\ldots,\vec{v}_4) = \frac{(\vec{v}_1\times\vec{v}_3)\ \ (\vec{v}_2\times\vec{v}_4)}{(\vec{v}_1\times\vec{v}_4)\ \ (\vec{v}_2\times\vec{v}_3)}, \tag{15}$$

where $\vec{v}_1\times\vec{v}_2 = \det(\vec{v}_1,\vec{v}_2)$ is the two-dimensional (2D) vector product, is invariant under linear transformations because the vector product transforms with the determinant of the linear transformation. On the other hand, the ratio does not depend on the length of the vectors, and is equal to (14). Therefore λ is a continuous modulus that distinguishes GL(2) equivalence classes in L_4, and T_4 is a continuous space.

The same happens in three dimensions. Here GL(3) has nine dimensions, of which only eight affect the n-tuplets of lines through the origin; five lines through the origin are determined by 10 angles; hence in three-dimensions (3D) $T_n = L_n/\mathrm{GL}(3)$ is only discrete for $n<5$. If $\vec{v}_1,\ldots,\vec{v}_5$ are five vectors of arbitrary length parallel to the five lines, the ratio

$$\lambda(\vec{v}_1,\ldots,\vec{v}_5) = \frac{\vec{v}_1\cdot(\vec{v}_2\times\vec{v}_3)\ \ \vec{v}_1\cdot(\vec{v}_4\times\vec{v}_5)}{\vec{v}_1\cdot(\vec{v}_2\times\vec{v}_5)\ \ \vec{v}_1\cdot(\vec{v}_4\times\vec{v}_3)}, \tag{16}$$

where $\vec{v}_1\cdot(\vec{v}_2\times\vec{v}_3) = \det(\vec{v}_1,\vec{v}_2,\vec{v}_3)$ is the triple product, is invariant under linear transformation. It classifies quintuplets of straight lines into equivalence classes. The invariant (15) is well known in projective geometry since the 19th century, as the *cross ratio*. It distinguishes orbits of quadruplets of points generated by the action of the projective group on the real projective line. The generalization of the cross-ratio projective invariant to higher dimensions has been studied by Hilbert.

Let us return to nodes. Consider for simplicity a graph Γ with a single node n. Say that the node is five valent. Let Γ' be a node iso-equivalent to Γ. The graph Γ' will have a single five-valent node n' as well. Say, for simplicity, that n' is located at the same point p as n. Can we always find a diffeomorphism ϕ that sends Γ' into Γ? A condition on ϕ is that $\phi(p)=p$. The tangent map $\phi_*: T_p \to T_p$ defines a linear action on the tangent space T_p of Σ at p. The tangents to the five links of Γ at p determine a quintuplet of straight lines in T_p. Similarly, the tangents to the links of Γ' determine another quintuplet of straight lines in T_p. A condition on ϕ is then that the linear transformation ϕ_* maps the first quintuplet of lines into the second. As observed above, in general such a linear transformation does not exist. Equivalence classes under linear transformations of quintuplets of lines are distinguished by continuous moduli. If $\vec{v}_i(\Gamma,n)$, $i=1,\ldots,5$ are the tangents to the five links of Γ at the node n, in an arbitrary parametrization and an arbitrary coordinate system, the quantity

$$\lambda(\Gamma,n)=\lambda(\vec{v}_1(\Gamma,n),\ldots,\vec{v}_5(\Gamma,n)), \tag{17}$$

where the function on the right-hand side is defined in (16), does not depend either on the parametrization or on the coordinates chosen, and is invariant under diffeomorphisms. Hence if $\lambda(\Gamma,n)\neq\lambda(\Gamma',n')$, the two iso-equivalent graphs Γ and Γ' are not diff-equivalent. The function (17) is an example of the continuous moduli that distinguish diff-knots.

In general, a single iso-knot K_i is therefore formed by a continuous set of diff-knots K_d; diff-knots are labeled by moduli at the intersections. These moduli have a structure far richer than Hilbert's projective invariants. Indeed, it is not only the tangent structure that may distinguish iso-equivalent nodes, but also, for sufficiently high valence, the higher derivatives of the links at the intersection. For instance, assume that the tangents of the links at the node of two graphs are the same, but their curvatures differ. Under a diffeomorphism ϕ, the transformation of these curvatures is determined by the second derivatives of ϕ at the node, but these are finite in number as well (they are 18) and therefore for a sufficiently high valence they are not sufficient, in general, to map all curvatures of one graph into the curvatures of the second. We refer to Ref. 6 for a detailed analysis of the structure of the moduli.

We have seen in the preceding section that the diff-knots K_d label a basis in $\mathcal{H}_{\text{diff}}$. Since they are not countable, the kinematical state space $\mathcal{H}_{\text{diff}}$ space admits a continuous basis and therefore is nonseparable. Thus the root of the nonseparability of the state space of LQG is the ''rigidity'' of the diffeomorphisms at isolated points: the differential structure of the underlying manifold is rigid in the sense that it produces the linear structure of the tangent spaces T_p, which leaves quantities such as the cross-ratio (14) invariant.

C. Discussion

The nonseparability of the kinematical Hilbert space $\mathcal{H}_{\text{diff}}$ is disturbing for several reasons.

First, the background independence of general relativity implies that the localization of the dynamical fields on the coordinate manifold has no physical meaning: only relative localization of dynamical objects with respect to one another is physically significant. In the classical theory, background independence is implemented by the fact that diffeomorphisms turn out to be gauges. When implementing gauge invariance in the quantum theory, the localization of the spin network in the manifold is washed away by the gauge transformation, and only the discrete combinatorial relations remain—but not completely so. The moduli distinguishing diff-knots are a remnant of the localization of the spin network in the coordinate manifold. It is difficult to reconcile the presence of this remnant with the physical principle, underlying general relativity, that wants the localization on the coordinate manifold to be physically irrelevant.

Second, recall that loop states and spin-network states form a good basis in lattice Yang–Mills theory, but in continuous Yang–Mills theory they are ''too singular'' and ''too many,'' because of their continuous dependence on position. In gravity, the continuous dependence of position is gauged away by diffeomorphism invariance, dramatically reducing the size of the resulting state space.[10,12] This is the reason for which the loop basis becomes viable thanks to background independence, and therefore the rationale underlying the background-independent loop quantization. It is quite puzzling that this dramatic reduction of the state space fails to be complete because of the moduli.

Third, if we accept the formalization of generally covariant quantum theory described in Ref. 9, the Hilbert space $\mathcal{H}_{\text{diff}}$ describes distinguishable quantum states. A realistic space of distinguishable quantum states should be described by a separable Hilbert space.[13]

Now, if the continuous moduli had a physical meaning, they should affect measurements, or affect the dynamics. Two states that differ only by different values of their moduli should in principle be distinguishable by means of physical measurements. However, as mentioned in the introduction, this does not appear to be the case. The only effect of the moduli appears to be to vastly enlarging the kinematical Hilbert space, with no visible effect on the physics of the theory. One is therefore naturally led to the idea that these moduli may be spurious.

Above we have observed that the moduli are a consequence of the incapacity of diffeomorphisms to act at vertices in a way sufficiently general to map iso-equivalent graphs into each other. Diffeomorphisms are ''rigid'' at vertices. If gauge transformations included maps $\phi:\Sigma\to\Sigma$ less rigid at nodes (homeomorphisms, for instance), the continuous moduli would disappear: states distinguished by different moduli would become gauge equivalent. So, it is natural to ask: what is it that forces gauge transformations $\phi:\Sigma\to\Sigma$ implementing background independence, to be diffeomorphisms? Namely to be smooth?

To a large extent, the answer is just the conventional way we set up the theory. It is simple and convenient to use smooth fields on a smooth manifold, and stay in the smooth category. The moduli are a consequence of this choice, which might have little to do with physics. It is therefore natural to investigate the possibility of a different mathematical starting point, that would not affect classical physics, but would free the quantum theory from the moduli.

A very natural setting one may consider is the piecewise smooth category. Another possibility, investigated by Zapata[15] is to start from a piecewise linear manifold. With these choices, the moduli disappear and $\mathcal{H}_{\text{diff}}$ becomes separable. In this paper we investigate a minimal choice: we consider fields that are *everywhere continuous and smooth everywhere except possibly at a finite number of points*. We call these fields ''almost smooth.'' This minor enlargement of the space of the fields has practically no effect on the classical theory, nor on the physical results of LQG. But it gets rid of moduli and nonseparability.

III. EXTENDED DIFFEOMORPHISM GROUP

We now define a modified theory, where the gauge group is an extension of the diffeomorphism group. We show that the knot classes defined by the equivalence relation determined by this extended gauge group are countable, and lead to a separable $\mathcal{H}_{\text{diff}}$.

A. Almost smooth physical fields

Consider a four-dimensional differentiable manifold M with topology $\Sigma\times R$, as before. However, we now allow the gravitational field g to be almost smooth, as defined in the preceding section, that is, g is a continuous field which is smooth everywhere except possibly at a finite number of points, which we call the singular points of g. Any such g can be seen as a (pointwise) limit of a sequence of smooth fields. We say that g is a solution of the Einstein equations if it is the limit of a sequence of smooth solutions of the Einstein equations. Call $\mathcal{E}^*$ the space of such fields.

Let now ϕ be an invertible map from M to M such that ϕ and ϕ^{-1} are continuous and are infinitely differentiable everywhere except possibly at a finite number of points. The space of these maps form a group under composition, because the composition of two homeomorphisms that are smooth except at a finite number of singular points is clearly an homeomorphisms which is smooth except at a finite number of singular points. We call this group the *extended diffeomorphism group* and we denote it as $Diff^*_M$. It is clear that if $g\in\mathcal{E}^*$ then $(\phi g)\in\mathcal{E}^*$ for any $\phi\in Diff^*_M$. Hence $Diff^*_M$ is a gauge group for the theory.

In the Hamiltonian theory, we can now take almost smooth connections A on Σ. Notice that the holonomy of an almost smooth connection on a link l is well defined, because it is the product of the holonomies on the portions in which l is partitioned by the eventual singular points of A. We can thus define cylindrical functions, $\mathcal{K}$ and $\mathcal{K}_0$ as before. However, the gauge group *Diff* is now replaced by the gauge group *Diff**, formed by the homeomorphisms of Σ that are almost smooth (with their inverse). The group *Diff* considered above is a dense subgroup of *Diff**. (*Diff** can be given a topological group structure as a subgroup of the homeomorphism group of Σ. The question of whether it can be given a Lie group structure is more difficult.) Notice that *Diff** has a well-defined action on the space of the graphs $\mathcal{G}$. Unlike *Diff*, *Diff** does not preserve the number of nodes of a graph, because a singular point of ϕ may break a link into two links and create a bivalent node.

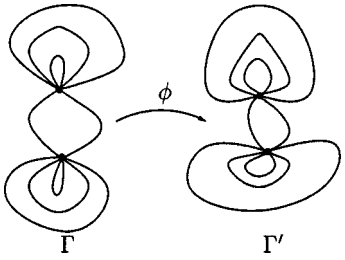

FIG. 1. Two graphs living in the same iso-knot but not in the same diff-knot.

The construction $\mathcal{H}_{\text{diff}}$ is the same as before, with the only difference that ϕ in (12) is now in $Diff^*$. Hence $\mathcal{H}_{\text{diff}}$ is now spanned by a basis of states $|s\rangle = |K_{d^*}, c\rangle$ where c is a discrete quantum number as before, but K_{d^*} is an element of $\mathcal{K}_{d^*}$, namely an equivalence class of graphs under *extended* diffeomorphisms

$$\mathcal{K}_{d^*} = \frac{\mathcal{G}}{\sim_{d^*}}, \tag{18}$$

where $\Gamma \sim_{d^*} \Gamma'$ if there is a $\phi \in Diff^*$ such that $\Gamma' = \phi \circ \Gamma$. We denote the elements K_{d^*} of $\mathcal{K}_{d^*}$ as diff*-knots.

B. *Diff**-knots are countable

We now prove that diff*-knots are countable. Two diff-equivalent graphs are also diff*-equivalent, because *Diff* is a subgroup of $Diff^*$. Therefore diff*-knots are equivalence classes of diff-knots. To prove that diff*-knots are countable it is sufficient to prove that any two diff-knots distinguished by a continuous parameter are diff*-equivalent. For this, it is sufficient to consider two iso-equivalent but diff-inequivalent graphs Γ and Γ'. Our strategy will be to explicitly build an extended diffeomorphism mapping Γ into Γ' (see Fig. 1). Since iso-knots are countable, this will be sufficient to show that $\mathcal{K}_{d^*}$ is countable.

Choose an arbitrary smooth metric g on Σ. Consider a node n of Γ, say with valence v. Consider the open ball B_n of fixed radius $\epsilon(n)$ about n. Let S_r be the spheres of radius $r(n)$, $0 < r(n) < \epsilon(n)$, centered at the same point n. Introduce (nonmetrical) angular coordinates $(\theta, \phi)_r$ on each sphere S_r of radius r, smooth in r. By choosing ϵ sufficiently small, each link l ending at n will intersect each sphere only once, say in the point with coordinates $(\theta_l, \phi_l)_r$. (No fold-backs, see Fig. 2.) Now, we can always choose the coordinates $(\theta, \phi)_r$ in such a way that the coordinates $(\theta_l, \phi_l)_r$ of the link l are independent from r, and are equal to v arbitrarily chosen values (θ_l, ϕ_l). This construction can be repeated for the node n' of Γ' which is isotopically associated to the

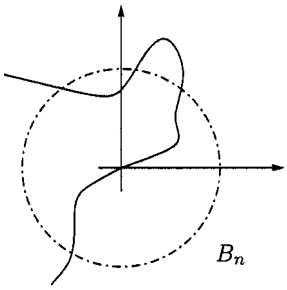

FIG. 2. A link presenting fold-backs.

node n. For the coordinates on the ball $B_{n'}$ around the node n' we use the notation (r',θ',ϕ') and we choose $(\theta'_{l'}=\theta_l,\phi'_{l'}=\phi_l)$, namely equal angular coordinates for corresponding links. We call Γ_n the restriction of Γ to B_n and Γ'_n the restriction of Γ' to $B_{n'}$.

Consider now the space $\Sigma\backslash B_n$ obtained by removing all balls B_n, for all nodes n, from Σ, and the space $\Sigma\backslash B'_n$ obtained removing all balls $B_{n'}$. Let $\tilde{\Gamma}$ be the restriction of Γ to $\Sigma\backslash B_n$ and $\tilde{\Gamma}'$ be the restriction of Γ' to $\Sigma\backslash B_{n'}$. Under the hypothesis we made that Γ and Γ' are iso-equivalent, a smooth invertible map

$$\tilde{\phi}:\Sigma\backslash B_n\to\Sigma\backslash B'_n,$$
$$\tilde{\Gamma}\mapsto\tilde{\Gamma}' \tag{19}$$

exists, because we are here in the simpler case of loops without intersections (on a space with boundaries), where standard knot-theory results apply. The failure of iso-equivalence to yield diffeo-equivalence regards *only* the neighborhoods of the nodes.

To prove that Γ and Γ' are diff*-equivalent, we have therefore just to construct maps

$$\phi_n:B_n\to B'_n,$$
$$\Gamma_n\mapsto\Gamma'_n \tag{20}$$

such that $\tilde{\phi}$ and ϕ_n, taken together, give an almost smooth map $\phi:\Sigma\to\Sigma$. Let ϕ_n be given simply by

$$\phi_n:B_n\to B'_n,$$
$$(r,\theta,\phi)\mapsto(r'=r,\theta'=\theta,\phi'=\phi). \tag{21}$$

$\tilde{\phi}$ can be chosen so that at the boundaries of the balls ϕ is smooth. Hence ϕ is smooth for all $r>0$. The map ϕ_n can immediately be continued to $r=0$, yielding by continuity $\phi_n(n)=n'$. But there is no reason for this continuation to be smooth, and in fact, in general it will not be. Hence ϕ is not in *Diff*. But it is in *Diff**, because it is continuous, invertible, and smooth everywhere except at the nodes, which are finite in number. Therefore iso-equivalent graphs Γ and Γ' are diff*-equivalent. Therefore we have the following.

Proposition 1: The space of the diff-knots $\mathcal{K}_{d*}$ is countable.*

It follows immediately that we have Proposition 2.

Proposition 2: If $\phi\in Diff^*$, the space $\mathcal{H}_{\text{diff}}$ defined by the bilinear form (12) is separable.

Therefore we have shown that a minor extension of the functional space of the fields considered eliminates the continuous moduli and the nonseparability of the kinematical state space of LQG.

IV. OPERATORS

In this section we discuss some consequences of the extension of *Diff* to *Diff** and clarify some apparent difficulties that this extension raises.

A. Conical singularities and area operator

If the gauge group is *Diff**, a smooth two-dimensional surface is gauge equivalent to a "singular" surface, that is a surface with conical singularities. The area operator $A(\mathcal{S})$ of LQG has been defined for smooth surfaces $\mathcal{S}$. Is it well defined also for a singular surface $\mathcal{S}$? Naively, one may think that $A(\mathcal{S})$ is ill defined for a singular $\mathcal{S}$, for the following reason. Consider a two-dimensional surface $\mathcal{S}$ embedded in Σ. Let $x=(x^a)$, $a=1,2,3$ be coordinates on Σ and $u=(u^m)$, $m=1,2$ coordinates on $\mathcal{S}$; the embedding is given by the functions $x^a(u)$. Let $g_{ab}(x)$ be the 3D metric, namely the gravitational field. The classical expression for the area of $\mathcal{S}$ is

$$A(\mathcal{S})=\int_{\mathcal{S}} \mathrm{d}^2u \quad \sqrt{\det g_{mn}(u)}, \tag{22}$$

where

$$g_{mn}(u)=\frac{\partial x^a(u)}{\partial u^m}\frac{\partial x^b(u)}{\partial u^n}g_{ab}(x(u)) \tag{23}$$

is the two-dimensional metric induced on the surface. The area operator is constructed by expressing the area in terms of the variable canonically conjugated to A, which is the inverse densitized triad $E^a_i(x), i=1,2,3$, related to the metric by $\det q\, q^{ab}=E^a_i(x)E^b_j(x)\delta^{ij}$. This gives

$$A(\mathcal{S})=\int_A \mathrm{d}^2u \ \sqrt{n_a\ n_b\ E^a_i\ E^b_j\ \delta^{ij}}, \tag{24}$$

where

$$n_a(u)=\epsilon_{abc}\frac{\partial x^b(u)}{\partial u^1}\frac{\partial x^c(u)}{\partial u^2} \tag{25}$$

is the one-form normal to the surface $\mathcal{S}$. If $\mathcal{S}$ is singular at a point p, the normal $n_a(u)$ is not defined at p. This has no effect on the expression of the classical area (24) because the singular point is a set of measure zero. Obviously, indeed, the area of a cone is defined in the same manner as the area of a smooth surface. However, what happens at single points becomes important for the LQG quantum operator $A(\mathcal{S})$ that corresponds to the classical quantity (24). A spin-network state determined by a spin-network S that crosses the surface at a single point p contributes to the area of the surface. In the derivation of this contribution, the tangent to the link of S at p gets contracted with the normal $n_a(p)$. If this is ill defined, we might expect a problem.

The proper way of addressing this issue is in the context of a quantization of the area operator based on a well-defined regularization. Several equivalent regularization schemes to define area operator are discussed in the literature. Not all of these schemes can be immediately adapted to a surface with conical singularities, but the regularization discussed in Ref. 4, which uses a smearing transversal to the surface, remains well defined for singular surfaces. This regularization is based on a continuous family of surfaces $\mathcal{S}_\lambda$, with $\lambda\in[-\delta/2,\delta/2]$, where δ is a positive real number, such that $\mathcal{S}_0=\mathcal{S}$. To extend the technique to singular surfaces, we demand that $\mathcal{S}_\lambda$ is a smooth surface for $\lambda\neq 0$ and that $\mathcal{S}_0=\mathcal{S}$ is singular. The area of $\mathcal{S}$ is then written as the limit

$$A(\mathcal{S})=\lim_{\delta\to 0}\frac{1}{\delta}\int_{-\delta/2}^{\delta/2}\mathrm{d}\lambda\, A(\mathcal{S}_\lambda)=\lim_{\delta\to 0}\frac{1}{\delta}\int_{\mathcal{D}}\mathrm{d}^3\sigma\sqrt{n_a n_b E^{aj}E^b_j}, \tag{26}$$

where $\mathcal{D}=\mathcal{S}\times[-\delta/2,\delta/2]$. The nonvanishing contribution of the last integral comes now from the entire one-dimensional intersection between the spin network and the three-dimensional region $\mathcal{D}$. In this, the contribution of the singular points of the $\lambda=0$ surface have measure zero. The fact that $\mathcal{S}$ has singular points is therefore irrelevant, and the operator $A(\mathcal{S})$ is well defined also for singular surfaces.

Recall that the LQG operator $A(\mathcal{S})$ is *Diff*-covariant in the sense that

$$A(\phi(\mathcal{S}))=\mathrm{U}_\phi A(\mathcal{S})\mathrm{U}_{\phi^{-1}} \tag{27}$$

for all $\phi\in Diff$. The above construction implies immediately that (27) remains true also if $\phi\in Diff^*$, because the differentiable structure at the intersection point plays no role in the definition of $A(\mathcal{S})$. The action of the area operator of a singular surface $\mathcal{S}$ is therefore immediately

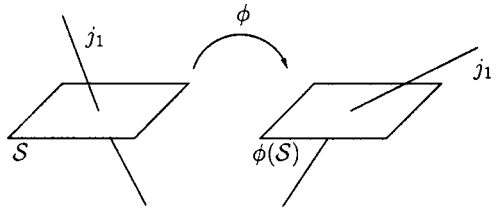

FIG. 3. An extended diffeomorphism may generate a conical singularity but does not change the topological relation between a surface $\mathcal{S}$ and the link of a spin network.

obtained by (27) by choosing ϕ such that $\phi(\mathcal{S})$ is smooth. We see that what matters is not the linear structure at the intersection point, but just the topological relation between the surface and the spin networks defining the quantum states. (See Fig. 3.)

From this, it follows immediately that we have Proposition 3.

Proposition 3: The spectrum of the operator $A(\mathcal{S})$ where $\mathcal{S}$ is singular (has a finite number of conical singularities) is the same as the spectrum of the operator $A(\mathcal{S})$ where $\mathcal{S}$ is smooth.

In conclusion, extended diffeomorphisms are indistinguishable from ordinary diffeomorphisms as far as the area operator is concerned. An extended diffeomorphism may generate singular points in the surface or in the spin network, but does not affect the topological relation between a surface and the spin network, and the area depends only on this relation.

B. Volume and Hamiltonian

Call $V(\mathcal{R})$ the volume of a 3D region $\mathcal{R}$ in Σ. There exist two versions of the volume operator $V(\mathcal{R})$ in LQG.[7] The first [let us call it $V_1(\mathcal{R})$ here], used for instance in Ref. 9, depends only on the intertwiners of the nodes inside $\mathcal{R}$. The second [let us call it $V_2(\mathcal{R})$ here], used for instance in Ref. 14, depends also on whether or not the links at the nodes are linearly dependent. The operator $V_1(\mathcal{R})$ is *Diff**-covariant, that is

$$V_1(\phi(\mathcal{R})) = \mathrm{U}_\phi V_1(\mathcal{R}) \mathrm{U}_{\phi^{-1}} \tag{28}$$

for all $\phi \in Diff^*$. The operator $V_2(\mathcal{R})$, on the other hand, does not transform well under $\phi \in Diff^*$, because an extended diffeomorphism can modify the linear dependence of the links at the node. Therefore the formulation of LQG considered here requires the use of the version $V_1(\mathcal{R})$ of the volume operator.

Finally, the Hamiltonian can be defined entirely in terms of the volume operator and holonomy operators, and is not affected by the modification of the theory considered here.

V. CONCLUSION

We have studied the problem of the separability of the background-independent space of the quantum states of the gravitational field, $\mathcal{H}_{\mathrm{diff}}$, in loop quantum gravity. We have shown that a small extension of the functional class of the classical fields leads to an enlargement of the gauge group of the theory. In particular *Diff* is enlarged to *Diff**, the group of homeomorphisms that are smooth (with their inverse) except possibly at a finite number of points. The space of the knot classes become countable and the kinematical Hilbert space $\mathcal{H}_{\mathrm{diff}}$ is separable. The area, volume, and Hamiltonian operator are naturally covariant under this extended gauge invariance, provided that the appropriate regularization and the appropriate version of the volume operator are chosen. The spectra of area and volume, in particular, are unaffected. We expect that analogous results could be obtained also using other mathematical settings, in particular the piecewise smooth category.

We take these results as indications that the continuous moduli that made $\mathcal{H}_{\mathrm{diff}}$ nonseparable might be physically spurious. Using the setting described in this paper, the theory appears to be cleaner and to realize more completely its purely combinatorial character as well as background

independence. If we adopt this point of view, background independent quantum microphysics is entirely discrete and smoothness can be seen, *a posteriori*, just as a property arising from averaging over regions much larger than the Planck scale.

Note added: After the posting of this work in the Archives, J. Lewandowski has informed us that related ideas have been developed by him and A. Ashtekar in work which is still unpublished.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 45, NUMBER 7 JULY 2004

The loss of stability of surface superconductivity

Y. Almog[a)]
Faculty of Mathematics, Technion-Israel Institute of Technology, Haifa 32000, Israel

(Received 9 September 2003; accepted 9 March 2004;
published online 10 June 2004)

The Ginzburg–Landau equations in a half-plane are considered in the large κ limit. We look at the reduced set of equations obtained in that limit. It is proved that the one-dimensional solution presented by Pan [Commun. Math. Phys. **228**, 327 (2002)] undergoes a bifurcation for an infinite number of applied magnetic field values which are lower than H_{C_2}. We also prove that each bifurcating mode is energetically preferable to the one-dimensional surface superconductivity solution, and thus, prove that the surface superconductivity becomes unstable for applied fields which are lower than H_{C_2} © *2004 American Institute of Physics.*
[DOI: 10.1063/1.1755859]

I. INTRODUCTION

Consider a planar superconducting body which is placed at a sufficiently low temperature (below the critical one) under the action of an applied magnetic field. Its energy is given by the Ginzburg–Landau energy functional which can be represented in the following dimensionless form:[1]

$$E=\int_{\Omega}\left(-|\Psi|^2+\frac{|\Psi|^4}{2}+|h-h_{\mathrm{ex}}|^2+\left|\frac{i}{\kappa}\nabla\Psi+A\Psi\right|^2\right)dx_1dx_2\,, \tag{1.1}$$

in which Ψ is the (complex) superconducting order parameter, such that $|\Psi|$ varies from $|\Psi|=0$ (when the material is at a normal state) to $|\Psi|=1$ (for the purely superconducting state). The magnetic vector potential is denoted by A (the magnetic field is, then, given by $h=\nabla\times A$), h_{ex} is the constant applied magnetic field, and κ is the Ginzburg–Landau parameter which is a material property. Superconductors for which $\kappa<1/\sqrt{2}$ are called type I superconductors, and those for which $\kappa>1/\sqrt{2}$ are called type II. Ω is a connected domain of superconductor, whose Gibbs free energy is given by E. Note that E is invariant to the gauge transformation

$$\Psi\to e^{i\kappa\eta}\Psi;\quad A\to A+\nabla\eta, \tag{1.2}$$

where η is any smooth function.

For sufficiently large magnetic fields it is well known, both from experimental observations[2] and both from theoretical predictions,[3] that superconductivity is destroyed and the material must be in the normal state. If the applied magnetic field is then decreased there is a critical field where the material enters the superconducting phase once again. This field is called ''the onset field'' and is denoted by H_{C_3}.

It is well-known that at the bifurcation from the normal state, superconductivity remains concentrated near the boundary. Alternatively we can say that Ψ decays exponentially fast away from the boundaries as either κ or the size of Ω tend to infinity, which is the reason why the phenomenon has been termed surface superconductivity. This result has first been obtained for a half-plane,[4] then also for disks,[5] and for general smooth domains in $\mathbb{R}^2$.[6–9] It was extended later to weakly nonlinear cases in the large κ limit.[10]

a)Electronic mail: almog@math.technion.ac.il

In the absence of boundaries the critical field at which superconductivity nucleates is denoted by H_{C_2} and is smaller than H_{C_3} ($H_{C_3}\approx 1.7\kappa$ whereas $H_{C_2}=\kappa$). Furthermore, the bifurcating modes are periodic lattices, named after Abrikosov[11–13] which have been observed experimentally.[14] It has been conjectured, therefore, by Rubinstein[15] that superconductivity remains concentrated near the boundary for $H_{C_2}<h_{\text{ex}}<H_{C_3}$. When $h_{\text{ex}}\approx H_{C_2}$ (either for κ large or for large domains) a bifurcation of Abrikosov's lattices far away from the wall was conjectured.[15]

Recently, it has been proved both in the large κ limit,[16,17] and in the large domain limit[18] that as long as $H_{C_2}<h_{\text{ex}}<H_{C_3}$ superconductivity remains concentrated near the boundaries. From a different direction, Sandier and Serfaty[19] showed for the global minimizer of (1.1) that as $h_{\text{ex}}\to H_{C_2}$ from below and $\kappa\to\infty$, superconductivity vanishes in the domain's interior, away from the boundaries.

Despite the above-mentioned progress the transition from the surface superconductivity solution to the mixed state, where Abrikosov's lattices appear in the bulk of the material, has not been clarified yet. In particular, if the applied magnetic field is decreased below H_{C_2} it has not been proved yet that:

(1) The surface superconductivity solution becomes unstable, i.e., it is not a local minimizer of E for $h_{\text{ex}}<H_{C_2}$.
(2) The bifurcating mode is indeed the global minimizer and has to be periodic.

In the present contribution we prove, in the large κ limit, for a domain wall, that the surface superconductivity solution in a half-plane is not a local minimizer of E for $h_{\text{ex}}<H_{C_2}$, and hence cannot be stable. To this end we assume, just like Pan[16] did, that the global minimizer is essentially one-dimensional in the boundary layer. In addition to the instability proof, we find the bifurcating modes and show, by an heuristic argument, that when properly superposed, Abrikosov's lattices can be formed. However, since linear superposition of modes is impossible, in view of the equation's nonlinearity, further research is necessary in that direction.

The Euler–Lagrange equations associated with (1.1), known as the steady state Ginzburg–Landau equations, are given in the form

$$\left(\frac{i}{\kappa}\nabla+A\right)^2\Psi=\Psi(1-|\Psi|^2), \tag{1.3a}$$

$$-\nabla\times\nabla\times A=\frac{i}{2\kappa}(\Psi^*\nabla\Psi-\Psi\nabla\Psi^*)+|\Psi|^2A, \tag{1.3b}$$

and the natural boundary conditions by

$$\left(\frac{i}{\kappa}\nabla+A\right)\Psi\cdot\hat{n}=0, \tag{1.4a}$$

$$h=h_{\text{ex}}. \tag{1.4b}$$

In Refs. 16 and 17 it is proved that as $\kappa\to\infty$, $h_{\text{ex}}-\kappa\gg 1/\kappa$ we have, near the boundary

$$\Psi(x_0+\xi/\kappa)\xrightarrow[\kappa\to\infty]{}\psi(\xi)\quad\text{pointwise},$$

where $x_0\in\partial\Omega$, $\xi\in\mathbb{R}^2_+$,

$$\mathbb{R}^2_+=\{(x_1,x_2);\ \ x_1>0\}$$

and ψ must satisfy

$$(i\nabla + x_1 \hat{i}_2)^2 \psi = \lambda \psi (1 - |\psi|^2) \quad \text{in } \mathbb{R}^2_+, \tag{1.5a}$$

$$\frac{\partial \psi}{\partial x_1} = 0 \quad \text{on } \partial \mathbb{R}^2_+, \tag{1.5b}$$

where

$$\lambda = \frac{\kappa}{h_{\text{ex}}}.$$

Let

$$\mathcal{H} = \{u \in H^1(z,\infty) | xu \in L^2(z,\infty)\}, \tag{1.6}$$

where z is a real number, and let

$$\beta(z) = \inf_{\phi \in \mathcal{H}} \frac{\int_z^\infty |\phi'|^2 + x^2 |\phi|^2}{\int_z^\infty |\phi|^2}. \tag{1.7}$$

The dependence of β on z has been studied in Refs. 20 and 21 afterward. In particular, it has been proved that there exist $z_1(\lambda)$ and $z_2(\lambda)$ such that $\lambda > \beta(z)$ if and only if $z_1 < z < z_2$, and that $z_2(1) = 0$ and $z_1(1) = -\infty$. It is also proved in Ref. 7 that

$$\beta_0 = \inf_{z \in \mathbb{R}} \beta(z) = \lim_{\kappa \to \infty} \frac{\kappa}{H_{C_3}} \approx 0.59.$$

The same result was also proved in Ref. 8.

Pan[16] conjectured that any bounded solution of (1.5a) for $\beta_0 < \lambda \leqslant 1$ must be in the form

$$\psi = e^{i(\omega_0 x_2 + c)} f(x_1), \tag{1.8}$$

where ω_0 is a real number and $f(x_1, \lambda)$ satisfies in $\mathbb{R}_+$

$$-f'' + (x - \omega_0)^2 f = \lambda f (1 - f^2); \quad f'(0) = 0. \tag{1.9}$$

In Ref. 16 it is proved that if $\beta(-\omega_0) < \lambda \leqslant 1$ and

$$-z_2 < \omega_0 < -z_1$$

then there exists a solution for (1.9). Furthermore, it is proved in Ref. 16 the

$$f(x) \sim x^{-1-\lambda/2} e^{-1/2 x^2} \quad \text{as } x \to \infty. \tag{1.10}$$

The discussion in Ref. 16 was limited to the case $\lambda \leqslant 1$, since this is the regime where the surface superconductivity solution is expected to be the global minimizer of E. Nevertheless, it is not difficult to show that the above existence result and (1.10) still hold when $\lambda > 1$ for any $\omega_0 \geqslant 0$. We bring the proof in Appendix A.

Weaker conjectures can be made instead of assuming that (1.8) is the unique class of bounded solutions of (1.5a). Consider the energy functional

$$\mathcal{E}(\psi) = \int_{\mathbb{R}^2_+} |(i\nabla + x_1 \hat{i}_2)\psi|^2 + \lambda(\tfrac{1}{2}|\psi|^4 - |\psi|^2), \tag{1.11}$$

where $\hat{i}_2$ is a unit vector in the x_2 direction, and let

$$H^1_{\mathrm{mag}}(\Omega)=\{\phi\in L^2(\Omega)\,|\,\partial_{x_1}\phi\in L^2,\quad \partial_{x_2}\phi+ix_1\phi\in L^2\}. \tag{1.12}$$

It is well known[16] that when $\lambda>\beta_0$ we have

$$\inf_{\phi\in H^1_{\mathrm{mag}}(R^2_+)}\mathcal{E}(\phi)=-\infty.$$

We therefore modify the definition of H^1_{mag} so it would guarantee the existence of a global minimizer to $\mathcal{E}$ in the modified space. We thus apply the transformation

$$x_1\to x_1-\omega_0;\quad \psi\to e^{-i\omega_0 x_2}\psi$$

to obtain

$$\mathcal{E}(\psi)=\int_{-\omega_0}^{\infty}dx_1\int_{\mathbb{R}}dx_2\left\{|(i\nabla+x_1\hat{i}_2)\psi|^2+\lambda\left(\frac{1}{2}|\psi|^4-|\psi|^2\right)\right\}, \tag{1.13}$$

and define the space

$$\mathcal{P}_L^{\omega_0}=\{\phi\in H^1_{\mathrm{mag}}([-\omega_0,\infty)\times\mathbb{R})\,|\,\phi(x_1,x_2+L)=\phi(x_1,x_2)\}. \tag{1.14}$$

We can now conjecture, just like Pan[16] did, that

$$\psi=f(x_1,\lambda)$$

is the global minimizer of $\mathcal{E}$ in $\mathcal{P}_L^{\omega_0}$, for every $L>0$ and $\omega_0\geqslant 0$.

We note that Pan[16] studied the same problem for $\lambda>1$ and found that the global minimizer of (1.11) in $\mathcal{P}_L^{\omega_0}$ decays exponentially fast away from the wall. Moreover, it is proved in Ref. 16 that the global minimizer of (1.1) in a smooth bounded domain must tend, as $\kappa\to\infty$, to a periodic solution whose period is of $O(\kappa)$.

Periodic solutions have already been studied in the absence of boundaries.[11–13] Periodicity was imposed in those works in both the x_1 and the x_2 directions. In this work we add the effect of a planar wall: We impose periodicity only in the direction which is parallel to the wall, whereas away from the wall we expect the solution to decay. This problem, which is still much simpler than the determination of the global minimizer of (1.1), is much closer to real situations than the problem in $\mathbb{R}^2$.[11–13]

The present contribution can be summarized by the following theorem.

Theorem 1.1: *There exists $n_0\in\mathbb{N}$, which may depend on $\omega=2\pi/L$ and ω_0, and a sequence $\{\lambda_n\}_{n=n_0}^{\infty}$, such that*

(1) There exists a solution to (1.5a) in $\mathcal{P}_L^{\omega_0}$ which bifurcates from $\psi=f(x_1,\lambda)$, in some right semi-neighborhood of λ_n for every $n\geqslant n_0$.

(2) For every $n\geqslant n_0$

$$1+C_1\exp\left\{\frac{-(n\omega+\omega_0)^2}{2}\right\}<\lambda_n<1+C_2\exp\left\{\frac{-(n\omega+\omega_0)^2}{2}\right\}, \tag{1.15}$$

where C_1 and C_2 are positive and independent of n.

(3) Denote the bifurcating solution in $\mathcal{P}_L^{\omega_0}$ by $\psi_n(x_1,\lambda)$. Then

$$\mathcal{E}(\psi_n,\lambda)<\mathcal{E}(f,\lambda)$$

in some right semi-neighborhood of λ_n for every $n\geqslant n_0$.

In the next section we discuss the linearized equation and prove (1.15). Statements 1 and 3 are proved in Sec. III. Finally, in Sec. IV we briefly summarized the results obtained in Secs. II and III and list some related open problems.

II. LINEAR ANALYSIS

Consider the problem

$$(i\nabla + x_1\hat{i}_2)^2\psi = \lambda\psi(1-|\psi|^2) \quad (x_1,x_2)\in(-\omega_0,\infty)\times\mathbb{R}, \tag{2.1a}$$

$$\psi_{x_1}(-\omega_0,x_2)=0; \quad \psi(x_1,x_2+L)=\psi(x_1,x_2). \tag{2.1b}$$

Let

$$u=\psi(x_1,x_2)-f(x_1,\lambda), \tag{2.2}$$

wherein f satisfies (1.9). Denote by $\mathbb{X}$ the space

$$\mathbb{X}=\{u\in C^2\{[-\omega_0,\infty)\times\mathbb{R}\}\cap\mathcal{P}_L^{\omega_0}|u_{x_1}(-\omega_0,x_2)=0\}$$

with the C^2 norm. Let $F:\mathbb{R}^+\times\mathbb{X}\to C\{[-\omega_0,\infty)\times\mathbb{R}\}$ be the operator

$$F(\lambda,u)=(i\nabla+x_1\hat{i}_2)^2u-\lambda[u-f^2(2u+\overline{u})-f(2|u|^2+u^2)-|u|^2u]. \tag{2.3}$$

Clearly, if $u\in\mathbb{X}$ satisfies $F(u,\lambda)=0$ for some $\lambda>\beta_0$, then $\psi=u+f$ is a solution of (2.1). Furthermore, since $F(\lambda,0)\equiv 0$ for all $\lambda>\beta_0$ we can consider the linear bifurcation of nontrivial solutions of $F(u,\lambda)=0$ from $u\equiv 0$. Let F_u denote the Fréchet derivative of F. Then, the linearized form of $F(u,\lambda)=0$ near $u\equiv 0$ is

$$F_u(0,\lambda)\phi=0$$

or

$$(i\nabla+x_1\hat{i}_2)^2\phi-\lambda[\phi-f^2(2\phi+\overline{\phi})]=0. \tag{2.4}$$

Our first result proves the existence of nontrivial solutions in $\mathbb{X}$ for (2.4) and gives the corresponding critical values of λ.

Theorem 2.1: *There exists $n_0(\omega_0,\omega)\in\mathbb{N}$ and a sequence $\{\lambda_n\}_{n=n_0}^{\infty}$, such that when $\lambda=\lambda_n$ non trivial solutions of (2.4) exist. Furthermore, for all $n\geqslant n_0$ λ_n satisfies (1.15).*

Proof: Since we look for periodic solutions we multiply (2.4) by $e^{-in\omega x_2}$ where $n\in\mathbb{N}$ and integrate with respect to x_2 over $[-\pi/\omega,\pi/\omega]$ to obtain

$$-\hat{\phi}_n''+[(x-n\omega)^2-\lambda]\hat{\phi}_n+\lambda f^2(2\hat{\phi}_n+\overline{\hat{\phi}_{-n}})=0, \tag{2.5a}$$

$$-\hat{\phi}_{-n}''+[(x+n\omega)^2-\lambda]\hat{\phi}_{-n}+\lambda f^2(2\hat{\phi}_{-n}+\overline{\hat{\phi}_n})=0, \tag{2.5b}$$

$$\hat{\phi}_n'(-\omega_0)=\hat{\phi}_{-n}'(-\omega_0)=0, \tag{2.5c}$$

where

$$\hat{\phi}_n(x_1)=\int_{-\pi/\omega}^{\pi/\omega}\phi(x_1,x_2)e^{-in\omega x_2}dx_2. \tag{2.6}$$

To prove the lower bound in (1.15) we need the following perturbation lemma.

Lemma 2.2: Let $\mathcal{H}(\xi)$ be defined by (1.6), and let

$$\alpha(\xi,g)=\inf_{\substack{\phi\in\mathcal{H}\\ \|\phi\|_{L^2(-\xi,\infty)}=1}}\int_{-\xi}^{\infty}|\phi'|^2+(x^2+g(x+\xi))|\phi|^2dx,$$

where $g:[0,\infty)\to\mathbb{R}$ *is continuous and decays as* $x\to\infty$. *Then,*

$$\alpha=1+\int_{-\xi}^{\infty}gv^2+\delta(\xi). \tag{2.7a}$$

In which v *is the quasi-mode*

$$v=c_\xi\chi(x+\xi)e^{-x^2/2} \tag{2.7b}$$

whose $L^2(-\xi,\infty)$ *norm is unity,* χ *is a* C^∞ *cutoff function satisfying*

$$\chi=\begin{cases}0, & 0\leqslant x<\frac{1}{2}\\ 1, & 1<x\end{cases} \tag{2.7c}$$

and, for sufficiently large ξ,

$$\delta(\xi)\leqslant 2\int_{-\xi}^{\infty}g^2v^2+Ce^{-\xi^2}, \tag{2.7d}$$

where C *is independent of* ξ.

Proof: Denote by $\mathcal{P}$ the operator

$$\mathcal{P}=:-\frac{d^2}{dx^2}+x^2+g,$$

and let

$$\nu=1+\int_{-\xi}^{\infty}gv^2.$$

Then,

$$(\mathcal{P}-\nu)v=c_\xi[-\chi''+2x\chi'+g\chi]e^{-x^2/2}-(\nu-1)v,$$

and hence,

$$\left|\int_{-\xi}^{\infty}v(\mathcal{P}-\nu)v\right|\leqslant\int_{-\xi}^{\infty}\left|-\frac{\chi''}{\chi}+2x\frac{\chi'}{\chi}\right|v^2\leqslant Ce^{-\xi^2}. \tag{2.8}$$

Let $\{\mu_j\}_{j=0}^{\infty}$ denote the eigenvalues and $\{u_j\}_{j=0}^{\infty}$ the corresponding eigenmodes, whose L^2 norm is unity, of the following problem:

$$\mathcal{P}u_j=\mu_ju_j,\quad x>\xi,$$

$$u_j'(-\xi)=0.$$

It is well known,[22] that $\mu_j\uparrow\infty$ and that $\{u_j\}_{j=0}^{\infty}$ are square integrable and orthogonal. Let

$$\tilde{v}=v-a_0u_0, \tag{2.9a}$$

where

$$a_0=\int_{-\xi}^{\infty}vu_0. \tag{2.9b}$$

Substituting (2.9) in (2.8) we obtain (note that $\mu_0=\alpha$)

$$a_0^2|\alpha-\nu|\leqslant\int_{-\xi}^{\infty}|\tilde{v}(\mathcal{P}-\nu)\tilde{v}|+Ce^{-\xi^2}. \tag{2.10}$$

To estimate the first term on the right-hand side of (2.10) we make use of the following inequality:

$$\int_{-\xi}^{\infty}|(\mathcal{P}-\nu)\tilde{v}|^2\leqslant\int_{-\xi}^{\infty}|(\mathcal{P}-\nu)v|^2=\int_{-\xi}^{\infty}\left|-\frac{\chi''}{\chi}+2x\frac{\chi'}{\chi}+g-(\nu-1)\right|^2v^2\leqslant\int_{-\xi}^{\infty}g^2v^2+Ce^{-\xi^2}. \tag{2.11}$$

Since the distance of ν from the spectrum of $\mathcal{P}$ in $\mathcal{H}\backslash\mathrm{Span}(u_0)$ is $|\mu_1-\nu|$ we have

$$(\mu_1-\nu)^2\int_{-\xi}^{\infty}|\tilde{v}|^2\leqslant\int_{-\xi}^{\infty}|(\mathcal{P}-\nu)\tilde{v}|^2\leqslant\int_{-\xi}^{\infty}|(\mathcal{P}-\nu)v|^2. \tag{2.12}$$

It is not difficult to show, using standard arguments from semi-classical analysis (cf. for instance theorem 3.4.1 in Ref. 23), that

$$\mu_1\xrightarrow[\xi\to\infty]{}3. \tag{2.13}$$

Hence, for sufficiently large ξ,

$$\int_{-\xi}^{\infty}|\tilde{v}(\mathcal{P}-\nu)\tilde{v}|\leqslant\left[\int_{-\xi}^{\infty}|\tilde{v}|^2\int_{-\xi}^{\infty}|(\mathcal{P}-\nu)\tilde{v}|^2\right]^{1/2}\leqslant\int_{-\xi}^{\infty}|(\mathcal{P}-\nu)v|^2.$$

Substituting (2.10) in the above inequality yields

$$a_0^2|\alpha-\nu|\leqslant\int_{-\xi}^{\infty}g^2v^2+Ce^{-\xi^2}. \tag{2.14}$$

By (2.12) and (2.13) we have

$$a_0^2=1-\int_{-\xi}^{\infty}|\tilde{v}|^2\geqslant1-\int_{-\xi}^{\infty}g^2v^2-Ce^{-\xi^2}$$

from which (2.7) can be easily obtained. □

We now continue the proof of Theorem 2.1. Let

$$\alpha_n(\lambda)=:\alpha(-n\omega-\omega_0,\lambda f^2). \tag{2.15}$$

Since, by (1.10)

$$\int_{-n\omega-\omega_0}^{\infty}f^2(x+n\omega+\omega_0)e^{-x^2}\geqslant C(n\omega+\omega_0)^{\lambda-1}\exp\{-\tfrac{1}{2}(n\omega+\omega_0)^2\},$$

we have, by (2.7),

$$\alpha_n\geqslant1+C(n\omega+\omega_0)^{\lambda-1}\exp\{-\tfrac{1}{2}(n\omega+\omega_0)^2\}. \tag{2.16}$$

We now define the functional

$$\mathcal{J}(\chi_n,\chi_{-n})=:\int_{-\omega_0}^{\infty}|\chi_n'|^2+(x-n\omega)^2|\chi_n|^2+|\chi_{-n}'|^2+(x+n\omega)^2|\chi_{-n}|^2-\lambda[|\chi_n|^2+|\chi_{-n}|^2 - f^2(|\chi_n|^2+|\chi_n+\overline{\chi}_{-n}|^2+|\chi_{-n}|^2)]. \tag{2.17}$$

Let $(\phi_n,\phi_{-n})\in\mathcal{H}\times\mathcal{H}$ satisfy (2.5a) and (2.5b) and

$$\int_{-\omega_0}^{\infty}(|\phi_n|^2+|\phi_{-n}|^2)=1.$$

Multiplying (2.5a) by $\overline{\phi}_n$ and the complex conjugate of (2.5b) by ϕ_{-n} and integrating their sum over $[-\omega_0,\infty)$ we obtain

$$\mathcal{J}(\phi_n,\phi_{-n})=0.$$

However, from the definition of α_n it follows that

$$\int_{-\omega_0}^{\infty}|\phi_n'|^2+(x-n\omega)^2|\phi_n|^2-\lambda(1-f^2)|\phi_n|^2\geqslant(\alpha_n-\lambda)\int_{-\omega_0}^{\infty}|\phi_n|^2.$$

Furthermore, for sufficiently large n, we have $(x+n\omega)^2>(x-n\omega)^2$ for every $x\in[-\omega_0,\infty)$, and hence

$$\mathcal{J}(\phi_n,\phi_{-n})\geqslant(\alpha_n-\lambda). \tag{2.18}$$

Consequently, the value of λ for which the minimal value of $\mathcal{J}$ vanishes, must be greater than α_n. Therefore, by (2.16) the lower bound in (1.15) is proved.

To prove the upper bound we need, once again, to prove an auxiliary result:

Lemma 2.3: Let

$$\gamma_n(\lambda)=\inf_{\substack{(\chi_n,\chi_{-n})\in\mathcal{H}\times\mathcal{H}\\ \|\chi_n\|_{L^2}^2+\|\chi_{-n}\|_{L^2}^2=1}}\mathcal{J}(\chi_n,\chi_{-n}).$$

Then,

(1) For every $\lambda\geqslant 1$, *there exists a minimizer in* $\mathcal{H}\times\mathcal{H}$.
(2) γ_n *is a continuous function of* λ.

Proof: Since the proof is rather standard, we bring here only the main details and very briefly. Let $\{\phi_n^m,\phi_{-n}^m\}_{m=1}^{\infty}$ denote a minimizing sequence satisfying $\|\phi_n^m\|^2+\|\phi_{-n}^m\|^2=1$ for all m. Obviously,

$$\int_a^{\infty}|\phi_n^m|^2+|\phi_{-n}^m|^2\leqslant\frac{C}{a^2},$$

otherwise $\limsup_{m\to\infty}\mathcal{J}(\phi_n^m,\phi_{-n}^m)=\infty$. It is easy to show that the minimizing sequence is bounded in $H^1\times H^1$, and hence, there exists a subsequence which converges weakly to (ϕ_n,ϕ_{-n}). Clearly,

$$1\geqslant\int_{-\omega_0}^{a}|\phi_n|^2+|\phi_{-n}|^2\geqslant 1-\frac{C}{a^2},$$

and hence $\|\phi_n\|^2+\|\phi_{-n}\|^2=1$. To complete the proof of existence we need yet to show that E is weakly lower semicontinuous. This, however, is a very simple task. For instance,

$$\int_{-\omega_0}^{\infty} (\phi_n^m)' \overline{\phi_n'} \to \int_{-\omega_0}^{\infty} |\phi_n'|^2$$

in view of the weak convergence. Applying the Cauchy–Schwarz inequality we obtain

$$\liminf_{m\to\infty} \|(\phi_n^m)'\| \geqslant \|\phi_n'\|.$$

Similar treatment can be given to the rest of the terms in (2.17).

The proof that $\gamma_n(\lambda)$ is continuous is completely straightforward. □

We now calculate $\mathcal{J}(w_n,0)$ where $w_n = \exp\{-(x-n\omega)^2/2\}$. It is not difficult to show that

$$\mathcal{J}(w_n,0) \leqslant (1-\lambda)\sqrt{\pi} + \int_{-\omega_0}^{\infty} f^2 w_n^2 + Ce^{-(\omega_0+n\omega)^2} \leqslant (1-\lambda)\sqrt{\pi} + Ce^{-(\omega_0+n\omega)^2/2}.$$

Hence, there exists $C>0$ such that when

$$\lambda > 1 + Ce^{-(\omega_0+n\omega)^2/2},$$

we have $\mathcal{J}(w_n,0)<0$, and therefore, $\gamma_n(\lambda)<0$. Since, in view of (2.18), for sufficiently large n, $\gamma_n(\lambda)>0$ whenever $\lambda<\alpha_n$, and since $\gamma_n(\lambda)$ must be continuous, there exists λ_n satisfying (1.15) and $\gamma_n(\lambda_n)=0$. By lemma 2.3 there exists a minimizer which must satisfy (2.5), which completes the proof of the theorem. □

We note that the above theorem proves, only for sufficiently large n, that bifurcating modes can exist and that $\lambda_n>1$. Nevertheless, it seems plausible to conjecture that the bifurcation may take place only for $\lambda>1$. Furthermore, it appears reasonable to believe that λ_n is monotone decreasing, from which the previous conjecture readily follows.

It still remains necessary to find the dimension of the space of solutions of (2.4) for $\lambda=\lambda_n$. Consider then, (2.5), once again. Let $\phi_n^r = \Re\phi_n$, and $\phi_n^i = \Im\phi_n$. Then, the real part satisfies

$$-(\phi_n^r)'' + [(x-n\omega)^2 - \lambda]\phi_n^r + \lambda f^2(2\phi_n^r + \phi_{-n}^r) = 0, \tag{2.19a}$$

$$-(\phi_{-n}^r)'' + [(x+n\omega)^2 - \lambda]\phi_{-n}^r + \lambda f^2(2\phi_{-n}^r + \phi_n^r) = 0, \tag{2.19b}$$

$$(\phi_n^r)'(-\omega_0) = (\phi_{-n}^r)'(-\omega_0) = 0, \tag{2.19c}$$

whereas the imaginary part satisfies

$$-(\phi_n^i)'' + [(x-n\omega)^2 - \lambda]\phi_n^i + \lambda f^2(2\phi_n^i - \phi_{-n}^i) = 0, \tag{2.20a}$$

$$-(\phi_{-n}^i)'' + [(x+n\omega)^2 - \lambda]\phi_{-n}^i + \lambda f^2(2\phi_{-n}^i - \phi_n^i) = 0, \tag{2.20b}$$

$$(\phi_n^i)'(-\omega_0) = (\phi_{-n}^i)'(-\omega_0) = 0. \tag{2.20c}$$

Consequently, if (ϕ_n^r, ϕ_{-n}^r) is a solution of (2.19), then $(\phi_n^r, -\phi_{-n}^r)$ is a solution of (2.20). By (2.6) we have

$$\phi = \phi_n e^{in\omega x_2} + \phi_{-n} e^{-in\omega x_2}.$$

Substituting in the above a linear combination of the two independent modes (ϕ_n^r, ϕ_{-n}^r) and $(i\phi_n^r, -i\phi_{-n}^r)$ we obtain

$$\phi = C\phi_n^r e^{in\omega x_2} + \overline{C}\phi_{-n}^r e^{-in\omega x_2},$$

where $C\in\mathbb{C}$ is an arbitrary constant. We can now represent ϕ, upon substituting $C=|C|e^{-ix_2^0}$, in the following form:

$$\phi=|C|[\phi_n^r e^{in\omega(x_2-x_2^0)}+\phi_{-n}^r e^{-in\omega(x_2-x_2^0)}].$$

Consequently, the additional mode stands for translations in the x_2 direction and is, therefore, of very limited interest. Furthermore, since λ_n must be of even multiplicity in $\mathbb{X}$, it is not possible to apply the Crandall–Rabinowitz theorem.[24] Thus, it is desirable to confine the discussion to an appropriate *real* subspace of $\mathbb{X}$. We thus define

$$\mathbb{X}^*=\{u\in\mathbb{X}|\overline{u}(x_1,x_2)=u(x_1,L-x_2)\}.$$

In this space, we have $\phi_n=\phi_n^r$ for all n, and hence we need only to show that the solution space of (2.19) is one-dimensional.

Lemma 2.4: λ_n *is a simple eigenvalue of (2.19).*

Proof: Let (ϕ_n,ϕ_{-n}) and $(\tilde{\phi}_n,\tilde{\phi}_{-n})$ be two different solutions of (2.19). We show that they must be linearly dependent. To this end we first multiply (2.19a) by $\tilde{\phi}_n$ to obtain

$$\int_{-\omega_0}^{\infty} f^2(\phi_n\tilde{\phi}_{-n}-\tilde{\phi}_n\phi_{-n})=0.$$

Hence,

$$\exists x_0\in(-\omega_0,\infty)\quad [\phi_n\tilde{\phi}_{-n}-\tilde{\phi}_n\phi_{-n}]_{x=x_0}=0.$$

Consequently,

$$\exists C\in\mathbb{R}\ \text{ such that }\ \begin{bmatrix}\chi_n\\ \chi_{-n}\end{bmatrix}=\begin{bmatrix}\phi_n\\ \phi_{-n}\end{bmatrix}+C\begin{bmatrix}\tilde{\phi}_n\\ \tilde{\phi}_{-n}\end{bmatrix} \tag{2.21}$$

vanishes at $x=x_0$. Since (χ_n,χ_{-n}) is a solution of (2.19) we must have $\mathcal{J}(\chi_n,\chi_{-n})=0$. Let then,

$$\tilde{\chi}_n=\begin{cases}\chi_n & x_0\leqslant x\\ -\chi_n & -\omega_0\leqslant x<x_0\end{cases}.$$

Clearly, $\mathcal{J}(\tilde{\chi}_n,\tilde{\chi}_{-n})=0$, and hence, $(\tilde{\chi}_n,\tilde{\chi}_{-n})$ is a minimizer, which must have a continuous derivative at x_0. Consequently, $\chi_n'(x_0)=\chi_{-n}'(x_0)=0$ from which we conclude that $\chi_n\equiv\chi_{-n}\equiv 0$. □

III. WEAKLY NONLINEAR ANALYSIS

In the previous section, we showed that the linearized equation (2.4) has nontrivial solutions for a sequence of eigenvalues satisfying (1.15). However, our goal is to prove that each of these eigenvalues is a bifurcation point for the nonlinear equation

$$F(\lambda,u)=0, \tag{3.1}$$

where F is defined in (2.3).

In this section we prove the existence of a bifurcating branch at $(0,\lambda_n)$, for sufficiently large n. Furthermore, we prove that the bifurcation is supercritical and prove that the bifurcating branch is energetically lower than $u\equiv 0$, representing the one-dimensional solution (1.8).

A. Existence of the bifurcation

Theorem 3.1: *Equation (3.1) has a bifurcation point at* $(0,\lambda_n)$ *in* $\overset{*}{\mathbb{W}}$.

Proof: We use Theorem 1.7 in Ref. 24 to prove the existence of bifurcation. In view of the results of the previous section it remains to show that

$$F_{\lambda u}\phi \notin R(F_u(0,\lambda_n)),$$

where ϕ spans the solution space of (2.4) in $\mathbb{X}*$ at $\lambda=\lambda_n$. Alternatively, we can write

$$\Re\left\{\int_{-\omega_0}^{\infty}\overline{\phi}F_{\lambda u}\phi\right\}\neq 0. \tag{3.2}$$

The above condition may be applied also by applying to (3.1) the Taylor expansion

$$u=\epsilon u^{(0)}+\epsilon^2\tilde{u}, \tag{3.3a}$$

$$\lambda=\lambda^{(0)}+\epsilon\tilde{\lambda}. \tag{3.3b}$$

In the above $\lambda^{(0)}=\lambda_n$ satisfies (1.15), and $u^{(0)}$ is a solution of (2.4). Theorem 1.18 in Ref. 24 guarantees that

$$\tilde{u}=u^{(1)}+\epsilon u^{(2)}+O(\epsilon^2), \tag{3.4a}$$

$$\tilde{\lambda}=\lambda^{(1)}+\epsilon\lambda^{(2)}+O(\epsilon^2). \tag{3.4b}$$

This Taylor expansion, in powers of ϵ, would be useful while investigating whether the bifurcation is subcritical or supercritical and while estimating the energy of the bifurcating branch near the bifurcation point.

The $O(\epsilon^2)$ equation is given by

$$\begin{aligned}(i\nabla+x_1\hat{i}_2)^2u^{(1)}-\lambda^{(0)}[u^{(1)}-(f(x,\lambda^{(0)}))^2(2u^{(1)}+\overline{u}^{(1)})]\\ =\lambda^{(1)}g_\lambda+\lambda^{(0)}f(x,\lambda^{(0)})[2|u^{(0)}|^2+(u^{(0)})^2],\end{aligned} \tag{3.5a}$$

where

$$g_\lambda=\frac{\partial}{\partial\lambda}\{\lambda[u^{(0)}-(f(x,\lambda))^2(2u^{(0)}+\overline{u}^{(0)})]\}|_{\lambda=\lambda^{(0)}}, \tag{3.5b}$$

which is exactly equation 1.20 in Ref. 24 applied to our particular case. Multiplying (3.5a) by $\overline{u}^{(0)}$ we obtain after some manipulation that

$$\lambda^{(1)}I_\lambda=\lambda^{(0)}\Re\left\{\int f|u^{(0)}|^2(u^{(0)}+2\overline{u}^{(0)})\right\}, \tag{3.6a}$$

where

$$I_\lambda=\frac{\partial}{\partial\lambda}\left\{\lambda\int|u^{(0)}|^2-\frac{1}{2}f^2(x,\lambda^{(0)})|u^{(0)}+\overline{u}^{(0)}|^2-f^2|u^{(0)}|^2\right\}\Bigg|_{\lambda=\lambda^{(0)}}. \tag{3.6b}$$

Condition (3.2) is a solvability condition of (3.5). By (3.6) it can be expressed in the form $I_\lambda\neq 0$.

In the previous section we showed that when $\lambda^{(0)}=\lambda_n$ we have

$$u^{(0)}=\phi_n e^{i\omega n x_2}+\phi_{-n}e^{-i\omega n x_2}, \tag{3.7}$$

where (ϕ_n,ϕ_{-n}) is a solution of (3.6). Hence,

$$I_\lambda=\frac{2\pi}{\omega}\int_{-\omega_0}^{\infty}|\phi_n'|^2+(x-n\omega)^2|\phi_n|^2+|\phi_{-n}'|^2+(x+n\omega)^2|\phi_{-n}|^2$$
$$-2\lambda_n^2 f\frac{\partial f}{\partial\lambda}(|\phi_n|^2+|\phi_n+\overline{\phi}_{-n}|^2+|\phi_{-n}|^2). \tag{3.8}$$

In the following, we prove that $I_\lambda>0$. To this end we need first the following lemma.

Lemma 3.2: Let

$$\tilde{\beta}_n=\inf_{\phi\in\mathcal{H}}\frac{\int_{-\omega_0}^{\infty}|\phi'|^2+(x-n\omega)^2|\phi|^2-2\lambda_n^2 f\frac{\partial f}{\partial\lambda}|\phi|^2}{\int_{-\omega_0}^{\infty}|\phi|^2}. \tag{3.9}$$

Then, $\lim\tilde{\beta}_n=1$.

Proof: We first prove that

$$\left\|\frac{\partial f}{\partial\lambda}\right\|_\infty\leqslant C.$$

The equation satisfied by $\partial f/\partial\lambda=f_\lambda$ is

$$-f_\lambda''+[x^2-\lambda+3\lambda f^2]f_\lambda=f(1-f^2);\quad f_\lambda'(0)=0.$$

Clearly, there exists x_0 such that

$$x>x_0\Rightarrow x^2-\lambda+3\lambda f^2>1.$$

Suppose now, for a contradiction, that at some $x_1>x_0$, for some $\lambda=\lambda_0$ we have $f_\lambda(x_1,\lambda_0)>1$ and $f_\lambda'(x_1,\lambda_0)>0$. Then, since for $x>x_0$ f_λ cannot have a maximum greater than 1 we must have $f_\lambda(x,\lambda_0)>1$ for all $x>x_1$. Since both f_λ and f_λ' are continuous in λ there must be a neighborhood $(\lambda_0-\epsilon,\lambda_0+\epsilon)$ where $f_\lambda(x_1,\lambda)>1$ and $f_\lambda'(x_1,\lambda)>0$. Consequently,

$$x\geqslant x_1;\quad\lambda\in(\lambda_0-\epsilon,\lambda_0+\epsilon)\Rightarrow f_\lambda(x,\lambda)>1,$$

and hence,

$$f(x,\lambda_0+\epsilon)-f(x,\lambda_0-\epsilon)\geqslant 2\epsilon$$

for all $x\geqslant x_1$, contradicting (1.10). Thus, for $x>x_0$ we have

$$f_\lambda(x,\lambda)>1\Rightarrow f_\lambda'(x,\lambda)\leqslant 0$$

from which we can conclude that, for $x>x_0$,

$$f_\lambda(x,\lambda)\leqslant\max(f_\lambda(x_0,\lambda),1)\leqslant C(\lambda),$$

where C is independent of x. In a similar manner we can obtain a lower bound for f_λ, and hence,

$$\left|f\frac{\partial f}{\partial\lambda}\right|\leqslant Cx^{(\lambda-1)/2}\exp\{-x^2/2\}. \tag{3.10}$$

The lemma now follows from (2.7) with $g=-2\lambda_n^2 f\partial f/\partial\lambda$ and $\xi=-n\omega-\omega_0$. □

We now return to the proof of Theorem 3.1. From (3.8) it easily follows that

$$I_\lambda \geqslant \frac{4\pi}{\omega}\tilde{\beta}_n,$$

and hence, for sufficiently large n, I_λ must be positive, which proves our theorem.

B. Nature of the bifurcation

In the following we show that in some neighborhood of $(0,\lambda_n)$ in $X^*\times\mathbb{R}$ we must have $\lambda>\lambda_n$ along the bifurcating branch. Alternatively, we can state that the bifurcation is supercritical. From a physical point of view we can say that if we decrease the applied magnetic field (and consequently increase λ) below the critical field which corresponds to λ_n then the bifurcating branch continues to develop, i.e., $\|u\|$ increases.

Consider then, once again, (3.6). Using (3.7) it is not difficult to show that $\lambda^{(1)}=0$, which is a natural result in as much as we do not expect the sign of $\lambda-\lambda^{(0)}$ to depend on the sign of ϵ. Hence,

$$(i\nabla+x_1\hat{i}_2)^2u^{(1)}-\lambda^{(0)}[u^{(1)}-f^2(2u^{(1)}+\overline{u^{(1)}})]=\lambda^{(0)}f[2|u^{(0)}|^2+(u^{(0)})^2]. \tag{3.11}$$

The next order equation is given by

$$\begin{aligned}(i\nabla+x_1\hat{i}_2)^2u^{(2)}-\lambda^{(0)}&[u^{(2)}-f^2(2u^{(2)}+\overline{u^{(2)}})]\\ &=\lambda^{(2)}g_\lambda-\lambda^{(0)}\{|u^{(0)}|^2u^{(0)}+2f[u^{(0)}\overline{u^{(1)}}+u^{(1)}\overline{u^{(0)}}+u^{(1)}u^{(0)}]\}.\end{aligned} \tag{3.12}$$

The above equation no longer follows directly from Theorem 1.18 in Ref. 24. Nevertheless, it can be easily obtained, using the implicit function Theorem, in the same way it is used in the proof of equation 1.20 in Ref. 24.

Multiplying (3.12) by $\overline{u^{(0)}}$ and integrating by parts we obtain

$$\lambda^{(2)}I_\lambda=\lambda^{(0)}\int |u^{(0)}|^4+2f|u^{(0)}|^2(u^{(1)}+\overline{u^{(1)}})+2f\overline{u^{(0)}})^2u^{(1)}. \tag{3.13}$$

We now multiply (3.11) by $u^{(1)}$ to obtain

$$\begin{aligned}\int |(i\nabla+x_1\hat{i}_2)u^{(1)}|^2-\lambda^{(0)}&[|u^{(1)})|^2-2f^2|u^{(1)})|^2-\tfrac{1}{2}f^2(\overline{u^{(1)}}^2+(u^{(1)})^2)]\\ &=\lambda^{(0)}\int 2f|u^{(0)}|^2(u^{(1)}+\overline{u^{(1)}})+\tfrac{1}{2}f[\overline{u^{(0)}}^2u^{(1)}+\overline{u^{(1)}}(u^{(0)})^2].\end{aligned} \tag{3.14}$$

Hence,

$$\lambda^{(2)}I_\lambda=\lambda^{(0)}\int |u^{(0)}|^4+2\int |(i\nabla+x_1\hat{i}_2)u^{(1)}|^2-\lambda^{(0)}[|u^{(1)}|^2-f^2|u^{(1)})|^2-\tfrac{1}{2}f^2|\overline{u^{(1)}}+u^{(1)}|^2]. \tag{3.15}$$

By (2.17) and (3.7) we obtain, that if we substitute $u^{(0)}$ instead of $u^{(1)}$ in the second integral on the right hand side of (3.15) it must vanish identically. Furthermore, except for a finite number of n values, (3.7) must span the solution space of (2.4) in $\mathbb{X}^*$ when $\lambda^{(0)}=\lambda_n$. Hence, $u^{(0)}$ must serve as the nontrivial global minimizer of the second integral on the right hand side of (3.15). Consequently,

$$\int |(i\nabla + x_1\hat{i}_2)u^{(1)}|^2 - \lambda^{(0)}[|u^{(1)}|^2 - f^2|u^{(1)})|^2 - \tfrac{1}{2}f^2|\overline{u^{(1)}} + u^{(1)}|^2] \geqslant 0 \tag{3.16}$$

and hence,

$$\lambda^{(2)} \geqslant \frac{\lambda^{(0)}}{I_\lambda} \int |u^{(0)}|^4 > 0. \tag{3.17}$$

This proves our assertion, namely, that $\lambda > \lambda^{(0)}$ along the bifurcating branch, or, that the bifurcation is supercritical.

C. Energy

In this subsection we prove that (1.8) is not a local minimizer of (1.13) for $\lambda > 1$. To this end we show that for every $n \geqslant n_0$, there exist a right neighborhood of λ_n in $\mathbb{R}$ such that $\mathcal{E}(f+u,\lambda) < \mathcal{E}(f,\lambda)$. Let

$$\mathcal{E}_0(\lambda) = \mathcal{E}(f,\lambda) = \frac{2\pi}{\omega}\int_{-\omega_0}^{\infty} |f'| + x^2 f^2 + \lambda\left[\frac{1}{2}f^4 - f^2\right].$$

Let further

$$\begin{aligned}\Delta\mathcal{E}(u,\lambda) &= \mathcal{E}(f+u) - \mathcal{E}_0(\lambda) \\ &= 2\Re\left\{\int (i\nabla + x_1\hat{i}_2)f\cdot(-i\nabla + x_1\hat{i}_2)\overline{u}\right\} + \int |(i\nabla + x_1\hat{i}_2)u|^2 + 2\lambda\Re\left\{\int |f|^2[f\overline{u} + |u|^2]\right. \\ &\quad \left. + \tfrac{1}{2}f^2\overline{u}^2 + |u|^2[f\overline{u} + \tfrac{1}{4}|u|^2] - f\overline{u} - \tfrac{1}{2}|u|^2\right\}.\end{aligned}$$

Using (1.9) and integration by parts yields

$$\Delta\mathcal{E}(u,\lambda) = \int |(i\nabla + x_1\hat{i}_2)u|^2 + \lambda\int 2|f|^2|u|^2 + 2|u|^2\Re(f\overline{u}) + \lambda\int \frac{1}{2}|u|^4 - |u|^2 + \tfrac{1}{2}|f\overline{u} + \overline{\psi}_0 u|^2. \tag{3.18}$$

We now multiply the (3.1) by $\overline{u}$ and integrate to obtain

$$\int |(i\nabla + x_1\hat{i}_2)u|^2 = -\lambda\int 2|f|^2|u|^2 + |u|^2(2f\overline{u} + u\overline{\psi}_0) + f^2\overline{u}^2 + |u|^4 - |u|^2.$$

Combining the above with (3.18) we obtain

$$\Delta\mathcal{E}(u,\lambda) = -\frac{1}{2}\lambda\int [|f+u|^2 - |f|^2]|u|^2. \tag{3.19}$$

We now expand $\Delta\mathcal{E}$ in powers of ϵ. By (3.4) we have

$$\Delta\mathcal{E} = \epsilon^3\Delta\mathcal{E}^{(0)} + \epsilon^4\Delta\mathcal{E}^{(1)} + O(\epsilon^5).$$

Substituting (3.4) into (3.19) yields

$$\Delta\mathcal{E}^{(0)} = -\lambda^{(0)}\int |u^{(0)}|^2\Re(f\overline{u^{(0)}}) = 0.$$

Once again, this result corresponds to the natural expectation that the sign of ΔE does not depend on the sign of ϵ. The next order term is expressible in the form

$$\Delta\mathcal{E}^{(1)}=-\lambda^{(0)}\int\frac{1}{2}|u^{(0)}|^4+|u^{(0)}|^2\Re(f\overline{u^{(1)}})+2\Re(f\overline{u^{(0)}})\Re(u^{(0)}\overline{u^{(1)}}). \tag{3.20}$$

Using (3.14) we obtain

$$\Delta\mathcal{E}^{(1)}=-\lambda^{(0)}\int\frac{1}{2}|u^{(0)}|^4-\left\{\int|(i\nabla+x_1\hat{i}_2)u^{(1)}|^2-\lambda^{(0)}[|u^{(1)}|^2-f^2|u^{(1)})|^2-\frac{1}{2}f^2|\overline{u^{(1)}}+u^{(1)}|^2\right]$$

and by (3.16) we have

$$\Delta\mathcal{E}^{(1)}\leqslant-\frac{1}{2}\lambda^{(0)}\int|u^{(0)}|^4<0,$$

which proves our assertion, and hence completes the proof of theorem 1.1.

IV. CONCLUDING REMARKS

In Sec. II we proved the existence of a set of critical values $\{\lambda_n\}_{n=n_0}^{\infty}$ for which nontrivial solutions of (2.4) exist. We also show that $\lambda_n\downarrow 1$ exponentially fast according to (1.15). However, there might exist, finitely many, additional values of λ for which nontrivial solutions of (2.4) can exist. It would be reasonable to conjecture that $\{\lambda_n\}_{n=1}^{\infty}$ is monotone decreasing, yet, this hypothesis is proved only for large n. In fact, it is not proved yet that $\lambda_n>1$ for all n.

One can formulate the above conjecture in the following alternative manner: Let $\omega=1$ and

$$\gamma(\lambda,\alpha)=\inf_{\substack{(\phi_\alpha,\phi_{-\alpha})\in\mathcal{H}\times\mathcal{H}\\ \|\phi_\alpha\|_{L^2}^2+\|\phi_{-\alpha}\|_{L^2}^2=1}}\mathcal{J}(\phi_\alpha,\phi_{-\alpha}),$$

where $\mathcal{J}$ is defined in (2.17). We look for values of λ and α for which $\gamma=0$. For sufficiently large α it is proved in Sec. II that there exists $\alpha_0>0$ and a function $\lambda(\alpha):[\alpha_0,\infty)\to\mathbb{R}$ such that $\gamma(\lambda(\alpha),\alpha)=0$, and such that $\lambda(\alpha)\downarrow 1$ as $\alpha\to\infty$. If one can show that $\lambda(\alpha)$ can be continued into $\mathbb{R}_+$ such that $\lambda(\alpha)$ is monotone decreasing, the the above conjecture is proved.

In Sec. III we proved:

(1) Existence of the bifurcation points;
(2) super-criticality of the bifurcation;
(3) that the bifurcating solution is energetically preferable to the one-dimensional surface superconductivity solution.

Statements 1 and 2 were proved only for sufficiently large n. For n which is not large, the existence of nontrivial solutions of (2.4) does not guarantee $I_\lambda>0$, and hence the bifurcation points do not necessarily exist. In fact, even if the bifurcation from $(\lambda_n,0)$ exists, it is not clear that it must be supercritical (if $I_\lambda<0$ then a subcritical bifurcation exists).

In contrast, statement 3 is correct whenever a bifurcating solution exists. It is correct even for n which is not necessarily large, and even in the unlikely situation that the bifurcation takes place at $\lambda<1$. The surface superconductivity one-dimensional solution becomes therefore locally unstable at each bifurcation point.

Finally, we note that if it was possible to linearly superpose the bifurcating modes then the resulting combination would have the form

$$\psi=f+\sum_{n=-\infty}^{\infty}C_n\phi_n e^{i\omega n x_2},$$

and since

$$\phi_n \sim e^{-1/2(x_1 - n\omega)^2}$$

as $n \to \infty$ for $x_1 \sim O(n)$ we have

$$\psi \sim e^{i\omega P x_2} \sum_{n=-\infty}^{\infty} C_{n+P} e^{i\omega n x_2} e^{-1/2[x_1 - (n+P)\omega]^2} \tag{4.1}$$

for $P \gg 1$ and $x \sim O(P)$. The above formula thus approximates ψ far away from the wall at $x_1 = 0$. If

$$\exists N: \quad C_{n+N} = C_n \ \forall n.$$

Then the right-hand-side of (4.1) is periodic, or an Abrikosov lattice.[11–13]

Clearly, it is impossible to linearly superpose modes since the equations are nonlinear and since the bifurcations take place at different values of λ. Nevertheless, if $0 < \lambda - 1 \ll 1$ then $0 < \lambda - \lambda_n < \lambda - 1$ for almost every n. Hence, one might expect that the effect of nonlinearity tends to 0 as $\lambda \to 1$, and thus, that the solution far away from the wall can be approximated by an Abrikosov lattice.

APPENDIX A: THE ONE-DIMENSIONAL SOLUTION

Theorem A.1: *Let $\mathcal{H}$ and $\beta(z)$ be, respectively, defined by (1.6) and (1.7). Let $\lambda > \beta(z)$. Then, there exists a positive solution in $\mathcal{H}$ to the equation*

$$-f'' + x^2 f = \lambda f(1 - f^2); \quad f'(z) = 0. \tag{A1}$$

Moreover,

$$f(x) \sim x^{-1-\lambda/2} e^{-1/2 x^2} \quad as \quad x \to \infty. \tag{A2}$$

Proof: Let

$$\epsilon_z(\phi) = \int_z^{\infty} (\phi')^2 + x^2 \phi^2 - \lambda \left[\phi^2 - \frac{1}{2} \phi^4 \right] dx.$$

We first prove the existence of a minimizer $\mathcal{H}$. Clearly, there exists $x_0 > z$ such that for $x \geqslant x_0$ we have $x^2 \geqslant \lambda + 1$. Then, since

$$\phi^2 - \tfrac{1}{2}\phi^4 \leqslant \tfrac{1}{2}$$

we have for all $\phi \in \mathcal{H}$

$$\epsilon_z(\phi) \geqslant -\frac{\lambda}{2}(x_0 - z).$$

Since ϵ_z is semibounded there is a minimizing sequence $\{\phi_n\}_{n=1}^{\infty}$ in $\mathcal{H}$. As

$$\frac{1}{x_0 - z} \left(\int_z^{x_0} \phi_n^2 \right)^2 \leqslant \int_z^{x_0} \phi_n^4 \leqslant 2 \int_z^{x_0} \phi_n^2 + C,$$

where C is independent of n, we obtain that $\|\phi_n\|_{L^2[z,x_0]} \leqslant C$. Recalling that $x^2-\lambda \geqslant 1$ in $[x_0,\infty)$ yields $\|\phi_n\|_{L^2(z,\infty)} \leqslant C$ and hence $\|\phi_n\|_{H^1(z,\infty)} \leqslant C$. Thus, there is a subsequence which converges weakly in $H^1(z,\infty)$ to a limit, which we denote by f. We skip the proof of lower semicontinuity–some of the details can be found in the proof of lemma 2.4.

Since f is a minimizer of ϵ_z in $\mathcal{H}$ it must satisfy (A1). Suppose for a contradiction that it changes sign at $x=x_1$. Then let

$$g=\begin{cases} f(x) & x \leqslant x_1 \\ -f(x) & x>x_1 \end{cases}.$$

Clearly, $\epsilon_z(f)=\epsilon_z(g)$, and thus, g must be a minimizer and, therefore, a solution of (A1). Thus, either $f \equiv 0$, or f does not change its sign (both f and $-f$ are minimizers).

We now prove that f is nontrivial. Let u_z be the minimizer of the fraction on the right-hand-side of (1.7) such that $\|u_z\|_2=1$. Then

$$\epsilon_z(cu_z)=-c^2[\lambda-\beta(z)]+c^4\int_z^\infty |u_z|^4.$$

Therefore, for sufficiently small c the minimizer must be nontrivial.

It remains necessary, yet, to prove (A2). We first prove that $f \to 0$ as $x \to \infty$. Suppose first, for a contradiction, that for some $x_2>x_0$ we have $f'(x_2)>0$. Then, since f cannot have a maximum for $x>x_0$, f must be greater than $f(x_2)$, contradicting $f \in \mathcal{H}$. Thus, $f' \leqslant 0$ for all $x>x_0$ from which we easily conclude that $f \to 0$ at infinity.

Let $w(x,t)$, where $t>x_0$, denote the decaying solution of

$$-w''+[x^2-\lambda]w=0; \quad x>t \quad w(t,t)=1.$$

By the maximum principle we must have that $f<f(t)w$ for all $x>x_0$. Let $f(x)=f(t)v(x,t)w(x,t)$. Substituting in (A1) we obtain

$$v'=-\frac{\lambda}{f(t)w^2}\int_x^\infty f^3(s)w(s,t)ds \geqslant -\lambda f^2(t)\int_x^\infty w^2(s,t)ds.$$

The properties of w have been obtain in Ref. 21 but can be also found in chapter 19 of Ref. 25. From both references we find that as $t \to \infty$, $x \to \infty$

$$w \sim \left(\frac{x}{t}\right)^{\lambda-1/2} e^{-1/2(x^2-t^2)} \quad \forall x \geqslant t$$

and hence, for all $x>t$

$$-2\lambda f^2(t)\frac{x^{\lambda-2}}{t^{\lambda-1}}e^{t^2-x^2} \leqslant v' < 0.$$

Since v is decreasing it must converge to a limit as $x \to \infty$. Integrating the above inequality by parts we obtain

$$v_\infty(t)=\lim_{x\to\infty} v(x,t) \geqslant 1-\lambda\frac{f^2(t)}{t}.$$

For sufficiently large t we, therefore, have $v_\infty(t)>0$, proving (A2).

(Received 19 March 2004; accepted 7 April 2004;
published online 10 June 2004)

We prove the existence of a transmutation operator between two weighted Sturm–Liouville operators. We also provide an explicit formula for the transmutation operator and a construction algorithm. An example and an application to an inverse spectral problem are also considered. © *2004 American Institute of Physics.*

I. INTRODUCTION

Let L_1 and L_2, where

$$\begin{cases} L_1(\varphi) := -\dfrac{1}{w(x)}\varphi''(x,\lambda) + q(x)\varphi(x,\lambda) = \lambda\varphi(x,\lambda) & x \geqslant 0 \\ \varphi(0,\lambda) = 0, \end{cases} \tag{1.1}$$

$$\begin{cases} L_2(y) := -\dfrac{1}{w(x)}y''(x,\lambda) = \lambda y(x,\lambda) & x \geqslant 0 \\ y(0,\lambda) = 0, \end{cases} \tag{1.2}$$

and $w(x) \geqslant 0$, $qw, w \in L^{\mathrm{loc}}[0,\infty)$, be singular differential operators acting in the Hilbert space $L^2_w(0,\infty) := \{f$ measurable: $\int_0^\infty |f(x)|^2 w(x)dx < \infty\}$. The operator L_1 can be viewed as a perturbation of the more simple operator L_2, in which w is known as the density of the string and is allowed to vanish inside $[0,\infty)$. The string is well known to have numerous applications in prediction theory, Gaussian processes, function theory, moment problems and inverse problems, see Refs. 5–9.

Recall that the operator L_2 is in the limit-point case at infinity when $\int_0^\infty x^2 w(x)dx = \infty$ and (1.2) then defines a self-adjoint operator acting in $L^2_w(0,\infty)$. In case $\int_0^\infty x^2 w(x)dx < \infty$, then L_2 is in the limit circle at $x = \infty$ and we need to add a boundary condition at $x = \infty$. Thus without loss of generality, in all that follows, we can assume that both operators L_1 and L_2 are self-adjoint operators, adding a boundary condition at $x = \infty$, in the limit circle case. Denote, respectively, by σ_1 and σ_2 their spectra and by $\varphi(x,\lambda)$ and $y(x,\lambda)$ their eigensolutions which we normalize by $\varphi'(0,\lambda) = y'(0,\lambda) = 1$. It is known that the spectra are simple and the pair of transforms associated with L_1 is given by

$$\begin{aligned} &\mathbb{F}_1(f)(\lambda) = \int_0^\infty f(x)\varphi(x,\lambda)w(x)dx \quad \text{for } f \in L^2_w(0,\infty), \\ &f(x) = \int_{\sigma_1} \mathbb{F}_1(f)(\lambda)\overline{\varphi(x,\lambda)}d\Gamma_1(\lambda) \quad \text{for } \mathbb{F}_1(f) \in L^2_{\Gamma_1}(\sigma_1). \end{aligned} \tag{1.3}$$

Similarly for L_2 we have

[a]Electronic mail: boumenir@westga.edu
[b]Electronic mail: vu@westga.edu

$$\mathbb{F}_2(f)(\lambda)=\int_0^\infty f(x)y(x,\lambda)w(x)dx \quad \text{for } f\in L^2_w(0,\infty),$$
$$f(x)=\int_{\sigma_2}\mathbb{F}_2(f)(\lambda)\overline{y(x,\lambda)}d\Gamma_2(\lambda) \quad \text{for } \mathbb{F}_2(f)\in L^2_{\Gamma_2}(\sigma_2). \tag{1.4}$$

We recall that λ belongs to the discrete spectrum, only in the case when the solution $y(x,\lambda)\in L^2_w(0,\infty)$. Thus if λ is in the continuous spectrum, then the eigensolutions are outside $L^2_w(0,\infty)$, i.e., $\int_0^\infty|y(x,\lambda)|^2w(x)dx=\infty$. An operator which transforms solutions $\varphi(x,\lambda)$ into $y(x,\lambda)$, i.e., $y(x,\lambda)=V\varphi(x,\lambda)$ for all values $\lambda\in\mathbb{C}$, is called a transmutation operator and plays a crucial role in the inverse spectral problem. For example if V exists then it is easy to see that

$$L_2V\varphi=L_2y=\lambda y=\lambda V\varphi=VL_1\varphi.$$

Since the set of eigenfunctionals φ is complete in $L^2_w(0,\infty)$, see Ref. 1, then $L_2V=VL_1$ and if we also assume that V^{-1} exists then

$$L_1=V^{-1}L_2V,$$

which means that we can reconstruct L_1 from the knowledge of V and L_2. In other words given w and V we can reconstruct the potential q. More details about the theory of transmutation operators and their applications can be found in Refs. 2–4 and 11.

The existence and construction of the operator V is at the heart of the theory of inverse problems. Note that the only well understood case of the transmutation operator is when $w(x)=1$. In this case V is a Volterra-type integral operator of the second kind, whose kernel satisfies a second order hyperbolic differential equation, see Ref. 10. In this paper we are concerned with the existence and construction of the transmutation operator V between L_1 and L_2 for a general nonnegative w. We will show that V is again a Volterra type integral operator of the second kind. Its construction, under some extra smoothness conditions on w and q, does not require any partial differential equation. Since a Volterra integral operator of the second kind has an inverse, the result of this paper can be used in the inverse problem of reconstructing the potential q.

II. EXISTENCE OF THE TRANSMUTATION OPERATOR

Our starting point is to use the variation of parameters to solve

$$\varphi''(x,\lambda)+\lambda w(x)\varphi(x,\lambda)=q(x)w(x)\varphi(x,\lambda),$$

which leads to the obvious relation between φ and y,

$$\varphi(x,\lambda)=y(x,\lambda)+\int_0^x G(x,t,\lambda)q(t)\varphi(t,\lambda)w(t)dt, \tag{2.1}$$

that can be rewritten in the form

$$y(x,\lambda)=\varphi(x,\lambda)-\int_0^x G(x,t,\lambda)q(t)\varphi(t,\lambda)w(t)dt, \tag{2.2}$$

where

$$G(x,t,\lambda)=y_1(x,\lambda)y_2(t,\lambda)-y_2(x,\lambda)y_1(t,\lambda), \tag{2.3}$$

and y_1 and y_2 are the fundamental solutions of the equation

$$y''(x,\lambda)+\lambda w(x)y(x,\lambda)=0$$

satisfying the initial conditions

$$y_1(0,\lambda)=1,\ \ y_1'(0,\lambda)=0,\quad y_2(0,\lambda)=0,\ \ y_2'(0,\lambda)=1.$$

At this point observe that although (2.2) is a mapping between y and φ, it does not define an operator, because the kernel $G(x,t,\lambda)$ depends on λ.

Since the solutions y_1 and y_2 are entire functions of λ, it follows that

$$G(x,t,\lambda)=\sum_{n\geqslant 0}\xi_n(x,t)\lambda^n$$

and (2.2) reduces to

$$\begin{aligned} y(x,\lambda)&=\varphi(x,\lambda)-\int_0^x\sum_{n\geqslant 0}\xi_n(x,t)q(t)\lambda^n\varphi(t,\lambda)w(t)dt\\ &=\varphi(x,\lambda)-\int_0^x\sum_{n\geqslant 0}\xi_n(x,t)q(t)L_1^n\varphi(t,\lambda)w(t)dt. \end{aligned}$$

Having replaced λ^n by operator L_1^n we arrive at the operator

$$Vf(x)=f(x)-\int_0^x\sum_{n\geqslant 0}\xi_n(x,t)q(t)L_1^nf(t)w(t)dt, \tag{2.4}$$

that is defined at least over the set $\{\varphi(t,\lambda)\}_{\lambda\in R}$. To find the domain of definition of V, observe first that

Proposition 1: For any $x>0$, there exists a sequence $\lambda_n\nearrow\infty$ such that $\{\varphi(t,\lambda_n)\}_{n\geqslant 0}$ is an orthogonal basis in $L_w^2(0,x)$.

Proof: First consider the regular self-adjoint differential operator on the interval $[0,x]$ with a Dirichlet boundary condition at the right end point

$$\begin{cases} L_x(\varphi_x)=-\dfrac{1}{w(t)}\varphi_x''(t,\lambda)+q(t)\varphi_x(t,\lambda)=\lambda\varphi_x(t,\lambda), & 0\leqslant t\leqslant x\\ \varphi_x(0,\lambda)=0, \quad \varphi_x(x,\lambda)=0. \end{cases} \tag{2.5}$$

This new regular self-adjoint problem on $[0,x]$ has a discrete spectrum, $\sigma_x:=\{\lambda_n\}\subset\mathbb{R}$ and obviously its eigenfunctions $\{\varphi_x(t,\lambda_n)\}_{n\geqslant 0}$ are orthogonal and form a basis in $L_w^2(0,x)$. But the solutions $\varphi_x(t,\lambda_n)$ and $\varphi(t,\lambda_n)$ differ by a constant multiplier only, so the set $\{\varphi(t,\lambda_n)\}_{n\geqslant 0}$ is also an orthogonal basis in $L_w^2(0,x)$. Thus the functional $V(f)(x)$ is defined on an orthogonal basis of $L_w^2(0,x)$.

Proposition 2: For any $x>0$ and $\lambda>0$ we have $\sup_{0\leqslant t\leqslant x}|G(x,t,\lambda)|\leqslant|x-t|$.

Proof: From Lemma 1 of Sec. III it is not difficult to see that the sequence $\xi_n(x,t)$ changes signs, and therefore $G(x,t,\lambda)=\Sigma_{n\geqslant 0}\xi_n(x,t)\lambda^n$ is an alternating series. The remainder theorem for alternating series yields

$$|G(x,t,\lambda)|\leqslant\xi_0(x,t)=(x-t)\quad \text{when}\ \ 0\leqslant t\leqslant x\quad \text{and}\ \ \lambda>0.$$

$G(x,t,\lambda)$ is uniformly bounded on $\lambda>0$, and since there is possibly only a finite number of nonpositive eigenvalues, $G(x,t,\lambda)$ is then bounded over the whole set σ_x of eigenvalues. From (2.1) it follows

$$|V\varphi(x,\lambda_n)-\varphi(x,\lambda_n)|\leqslant\sqrt{\int_0^x|G(x,t,\lambda_n)q(t)|^2w(t)dt}\ \ \|\varphi(t,\lambda_n)\|\leqslant C(x)\|\varphi(t,\lambda_n)\|.$$

Since $V-1$ is a bounded functional on the orthogonal basis $\{\varphi(t,\lambda)\}_{\lambda\in[0,1]}$ it can be extended uniquely to a linear bounded functional on $L^2_w(0,x)$. By the Riesz representation theorem, there exists $H(x,.)\in L^2_w(0,x)$ such that

$$Vf(x)-f(x)=\int_0^x H(x,t)f(t)w(t)dt$$

for all $f\in L^2_w(0,x)$. In particular

$$V\varphi(x,\lambda)-\varphi(x,\lambda)=\int_0^x H(x,t)\varphi(t,\lambda)w(t)dt$$

which leads to

Proposition 3: Assume that $w,qw\in L^{\mathrm{loc}}[0,\infty)$ and L_1 is self-adjoint then there exists a transmutation operator V such that

$$y(x,\lambda)=V\varphi(x,\lambda)=\varphi(x,\lambda)+\int_0^x H(x,t)\varphi(t,\lambda)w(t)dt, \tag{2.6}$$

where $H(x,.)\in L^2_w(0,x)$.

Remark: The completeness of $\varphi(x,\lambda)$ is a result of the self-adjointness of L_1. We could have used the operator L_2, whose classification is simpler, instead of L_1 to obtain a similar result. Recall that end-point classification for L_2 depends on the convergence of $\int_0^\infty x^2w(x)dx$ only.

Proposition 4: Assume that $w,\ qw\in L^{\mathrm{loc}}[0,\infty)$ and L_2 is self-adjoint then there exists a transmutation operator V^{-1} such that

$$\varphi(x,\lambda)=V^{-1}y(x,\lambda)=y(x,\lambda)+\int_0^x K(x,t)y(t,\lambda)w(t)dt,$$

where $K(x,.)\in L^2_w(0,x)$.

III. CONSTRUCTION OF THE TRANSMUTATION OPERATOR

Although the Riesz representation theorem guarantees the existence of the transmutation operator V, see Proposition 3, it does not help us construct its kernel $H(x,t)$. In this section we show how Green's function $G(x,t,\lambda)$ can be used to construct the transmutation operator.

We would like now to remove the λ appearing in the integral term in (3.7). From the uniform convergence of the $G(x,t,\lambda)=\Sigma_{n\geqslant 0}\xi_n(x,t)\lambda^n$ over $t\in(0,x),\ \lambda\in(0,1)$ we deduce that

$$\int_0^x G(x,\ t,\ \lambda)q(t)\varphi(t,\lambda)\,w(t)\,dt=\sum_{n\geqslant 0}\ \int_0^x q(t)\xi_n(x,t)\ \ L_1^n\varphi(t,\lambda)\,w(t)\,dt.$$

Since $G(x,x,\lambda)=0$, then $\xi_n(x,x)=0$ for any n. To simplify the integration by part, we assume $q\in C_0^\infty(0,\infty)$ and $w\in C^\infty(0,\infty)$, thus $q^{(n)}(0)=0$ for all $n\geqslant 0$ and

$$\int_0^x q(t)\xi_n(x,t)\ \ L_1\varphi(t,\lambda)\,w(t)\,dt$$

$$= -\int_0^x q(t)\xi_n(x,t)\ \ \varphi''(t,\lambda)dt + \int_0^x q^2(t)\xi_n(x,t)\ \ \varphi(t,\lambda)\,w(t)\,dt$$

$$= [-q(t)\xi_n(x,t)\ \ \varphi'(t,\lambda) + \partial_t[q(t)\xi_n(x,t)]\ \ \varphi(t,\lambda)]\big|_{t=0}^{t=x}$$

$$+ \int_0^x L_1[q(t)\xi_n(x,t)]\ \ \varphi(t,\lambda)\,w(t)\,dt$$

$$= q(x)[\partial_t\xi_n(x,t)]_{t=x}\ \ \varphi(x,\lambda) + \int_0^x L_1[q(t)\xi_n(x,t)]\ \ \varphi(t,\lambda)\,w(t)\,dt.$$

We will show that the term outside the integral vanishes. For that purpose we now prove few Lemmas that are also needed in the sequel.

Lemma 1: For each fixed x, $L_2\xi_n(x,.) = \xi_{n-1}(x,.)$ *and* $L_2\xi_0(x,.) = 0$

Proof: From the fact that $L_2G(x,t,\lambda) = \lambda G(x,t,\lambda)$, where L_2 acts on the t variable and the uniform convergence we have

$$\sum_{n\geqslant 0} L_2\xi_n(x,t)\lambda^n = \sum_{n\geqslant 1} \xi_{n-1}(x,t)\lambda^n$$

and so the Lemma follows.

Lemma 2: For each fixed x, we have

$$L_1^{n+1}\xi_n(x,t) = \sum_{k=0}^{n} L_1^k(q(t)\xi_k(x,t)).$$

Proof: From

$$L_1^{k+1}\xi_k(x,t) = L_1^k(L_2 + q(t))\ \ \xi_k(x,t) = L_1^k L_2\ \ \xi_k(x,t) + L_1^k(q(t)\ \ \xi_k(x,t)),$$

$$L_1^{k+1}\xi_k(x,t) = L_1^k\ \ \xi_{k-1}(x,t) + L_1^k(q(t)\xi_k(x,t)),$$

it follows that

$$L_1\ \ \xi_0(x,t) = L_2\ \ \xi_0(x,t) + q(t)\ \ \xi_0(x,t) = q(t)\ \ \xi_0(x,t)$$

and

$$\sum_{k=1}^{n} L_1^{k+1}\xi_k(x,t) = \sum_{k=1}^{n} L_1^k\xi_{k-1}(x,t) + \sum_{k=1}^{n} L_1^k(q(t)\ \ \xi_k(x,t)),$$

$$L_1^{n+1}\xi_n(x,t) = L_1\xi_0(x,t) + \sum_{k=1}^{n} L_1^k(q(t)\xi_k(x,t)) = \sum_{k=0}^{n} L_1^k(q(t)\xi_k(x,t)).$$

Lemma 3: $\xi_n(x,t) = \Sigma_{k\geqslant 2n} a_{nk}(x)\,(x-t)^k/k!$.

Proof: From (2.3) we have

$$\frac{\partial^2}{\partial t^2}G(x,t,\lambda) = -\lambda w(t)G(x,t,\lambda)$$

and Leibnitz's formula then yields

$$\frac{\partial^k}{\partial t^k}G(x,t,\lambda)=-\lambda\frac{\partial^{k-2}}{\partial t^{k-2}}[w(t)G(x,t,\lambda)]=-\lambda\sum_{j=0}^{k-2}\binom{k-2}{j}(w(t))^{(k-2-j)}\frac{\partial^j}{\partial t^j}G(x,t,\lambda). \tag{3.1}$$

For each fixed x we can also write

$$G(x,t,\lambda)=\sum_{k\geqslant 0} f_k(x,\lambda)\frac{(t-x)^k}{k!}, \tag{3.2}$$

where $f_k(x,\lambda)=(\partial^k/\partial t^k)\,G(x,t,\lambda)_{|t=x}$. Thus it follows from (3.1) that the sequence f_k satisfies a recurrence relation

$$f_k(x,\lambda)=-\lambda\sum_{j=0}^{k-2}\binom{k-2}{j}(w(x))^{(k-2-j)}f_j(x,\lambda). \tag{3.3}$$

The first two terms are (3.2)

$$f_0(x,\lambda)=0, \qquad f_1(x,\lambda)=W(y_1,y_2)=1.$$

From (3.3) it follows that f_k is a polynomial in λ of degree at most $[k/2]$

$$f_k(x,\lambda)=\sum_{j=1}^{[k/2]} a_{jk}(x)\lambda^j,$$

which leads to

$$G(x,t,\lambda)=\sum_{k\geqslant 1} f_k(x,\lambda)\frac{(t-x)^k}{k!}=\sum_{k\geqslant 1}\sum_{j=1}^{[k/2]} a_{jk}(x)\lambda^j\frac{(t-x)^k}{k!}=\sum_{j\geqslant 1}\left(\sum_{[k/2]\geqslant j} a_{jk}(x)\frac{(t-x)^k}{k!}\right)\lambda^j$$

and so

$$\xi_n(x,t)=\sum_{[k/2]\geqslant n} a_{nk}(x)\frac{(t-x)^k}{k!}=\sum_{k\geqslant 2n} a_{nk}(x)\frac{(t-x)^k}{k!}.$$

Thus using the above Lemma we have proven that

Proposition 5: If $n\geqslant 1$, *then* $\partial^k\xi_n(x,t)/\partial t^k{}_{|t=x}=0$ *for* $k=0,\ldots,2n-1$.

Using the above result we have

$$\begin{aligned}\int_0^x & q(t)\xi_n(x,t)\;\; L_1\varphi(t,\lambda)\,w(t)\,dt\\ &=q(x)[\partial_t\xi_n(x,t)]_{t=x}\;\;\varphi(x,\lambda)+\int_0^x L_1[q(t)\xi_n(x,t)]\;\;\varphi(t,\lambda)\,w(t)\,dt\\ &=\int_0^x L_1[q(t)\xi_n(x,t)]\;\;\varphi(t,\lambda)\,w(t)\,dt\end{aligned}$$

and in general for $k<n$,

$$\int_0^x L_1^k[q(t)\xi_n(x,t)]\ \ L_1\varphi(t,\lambda)\,w(t)\,dt$$
$$= -L_1^k[q(t)\xi_n(x,t)]_{|t=x}\varphi'(x,\lambda)+\partial_t L_1^k[q(t)\xi_n(x,t)]_{|t=x}\quad \varphi(x,\lambda)$$
$$+\int_0^x L_1^{k+1}[q(t)\xi_n(x,t)]\ \ \varphi(t,\lambda)\,w(t)\,dt.$$

Consider the first boundary term. We have

$$L_1^k[q(t)\xi_n(x,t)]_{|t=x}=\sum_{j=0}^{2k} A_j(t)\frac{\partial^j \xi_n(x,t)}{\partial t^j}_{|t=x} \tag{3.4}$$

which vanishes as long as $k<n$ (3.4). Similarly $(\partial/\partial t)\,L_1^k[q(t)\xi_n(x,t)]_{|t=x}=0$ and thus all boundary terms vanish if $k<n$.

Thus we have proven

Proposition 6: Assume that $w\geqslant 0$, and $w,\ q\in C^\infty(0,\infty)$. Then for any $n\geqslant 0$, we have

$$\int_0^x q(t)\xi_n(x,t)\ L_1^n\varphi(t,\lambda)\,w(t)\,dt=\int_0^x L_1^n[q(t)\xi_n(x,t)]\ \varphi(t,\lambda)\,w(t)\,dt.$$

The next step is to start from (2.6) and (2.2) to deduce that

$$-\int_0^x H(x,t)\varphi(t,\lambda)\,w(t)\,dt=\lim_{m\to\infty}\sum_{n=0}^{m}\ \int_0^x q(t)\xi_n(x,t)\ \ \lambda^n\varphi(t,\lambda)\,w(t)\,dt$$
$$=\lim_{m\to\infty}\sum_{n=0}^{m}\ \int_0^x q(t)\xi_n(x,t)L_1^n\varphi(t,\lambda)\,w(t)\,dt$$
$$=\lim_{m\to\infty}\sum_{n=0}^{m}\ \int_0^x L_1^n(q(t)\xi_n(x,t))\ \ \varphi(t,\lambda)\,w(t)\,dt$$
$$=\lim_{m\to\infty}\int_0^x\sum_{n=0}^{m}\ L_1^n(q(t)\xi_n(x,t))\ \ \varphi(t,\lambda)\,w(t)\,dt$$
$$=\lim_{m\to\infty}\int_0^x\sum_{n=0}^{m}\ L_1^n(q(t)\xi_n(x,t))\ \ \varphi(t,\lambda)\,w(t)\,dt$$
$$=\lim_{m\to\infty}\int_0^x L_1^{m+1}\xi_m(x,t)\ \ \varphi(t,\lambda)\,w(t)\,dt. \tag{3.5}$$

Since $\{\varphi(t,\lambda)\}_{0<\lambda<1}$ is dense in $L_w^2(0,x)$, the sequence $L_1^{m+1}\xi_m(x,.)$ converges weakly to $-H(x,.)$ in $L_w^2(0,x)$. We now show that $L_1^{m+1}\xi_m(x,.)$ is a bounded sequence in $L_w^2(0,x)$. As done previously, from (3.5) we have

$$\int_0^x L_1^{m+1}\xi_m(x,t)\ \ \varphi(t,\lambda)\,w(t)\,dt=\int_0^x G_m(x,t,\lambda)\varphi(t,\lambda)\,w(t)\,dt,$$

where

$$G_m(x,t,\lambda)=\sum_{n=0}^{m}\ \xi_n(x,t)\,\lambda^n$$

is the partial sum of the MacLaurin series of the Green function $G(x,t,\lambda)$. Since $G_m(x,t,\lambda)$ converges uniformly to $G(x,t,\lambda)$ for $t\in(0,x)$ and $\lambda\in(0,1)$, and $G(x,t,\lambda)$ is bounded there, then $G_m(x,t,\lambda)$ is uniformly bounded for $t\in(0,x)$ and $\lambda\in(0,1)$. Now

$$\left|\int_0^x L_1^{m+1}\xi_m(x,t)\ \varphi(t,\lambda)\,w(t)\,dt\right| = \left|\int_0^x G_m(x,t,\lambda)\varphi(t,\lambda)\,w(t)\,dt\right| \leqslant \sqrt{\int_0^x |G_m(x,t,\lambda)|^2 w(t)\,dt}\ \|\varphi(.,\lambda)\|,$$

which means

$$\|L_1^{m+1}\xi_m(x,.)\| \leqslant \sup_{m\geqslant 0}\ \sup_{\lambda\in(0,1)} \sqrt{\int_0^x |G_m(x,t,\lambda)|^2 w(t)\,dt} = C<\infty.$$

Thus the sequence $L_1^{m+1}\xi_m(x,.)$ is bounded in $L_w^2(0,\ x)$. But a bounded and weakly convergent sequence in a Hilbert space converges strongly to the same limit. Hence we have proven

Proposition 7: For each fixed $x>0$, $L_1^{m+1}\xi_m(x,t)\to -H(x,t)$, *strongly in* $L_w^2(0,\ x)$ *as* $m\to\infty$.

This proposition allows us to construct the kernel $H(x,t)$ of the transmutation operator V from the Green function $G(x,t,\lambda)$. To illustrate the above theory, we now present a very simple example which corresponds to the case $w(x)=x^\alpha$ where $\alpha>-1$. Clearly L_2 is in the limit point at $x=\infty$. Consider the Bessel operators defined by

$$S_1\begin{cases} L_1(\varphi) := -\dfrac{1}{x^\alpha}\dfrac{d^2}{dx^2}\varphi(x,\lambda)+q(x)\varphi(x,\lambda)=\lambda\varphi(x,\lambda), \quad x\geqslant 0 \\ \varphi(0,\lambda)=0, \quad \varphi'(0,\lambda)=1, \end{cases}$$

$$S_2\begin{cases} L_2(y) := -\dfrac{1}{x^\alpha}\dfrac{d^2}{dx^2}y(x,\lambda)=\lambda y(x,\lambda), \quad x\geqslant 0 \\ y(0,\lambda)=0 \quad y'(0,\lambda)=1. \end{cases}$$

Here $q\in L_{x^\alpha}^{\mathrm{loc}}[0,\infty)$.

Denote the normalized eigensolutions of the operator L_2

$$y''(x,\lambda)+\lambda x^\alpha y(x,\lambda)=0 \tag{3.6}$$

by

$$\mathcal{J}_1(x,\lambda)=a(\lambda)\sqrt{x}\mathbf{J}_{1/(\alpha+2)}\left(\frac{2\sqrt{\lambda}}{\alpha+2}x^{(\alpha+2)/2}\right),$$

$$\text{where}\quad a(\lambda)=\Gamma\left(\frac{\alpha+3}{\alpha+2}\right)(\alpha+2)^{1/(\alpha+2)}\lambda^{-\{1/[2(\alpha+2)]\}},$$

$$\mathcal{J}_2(x,\lambda)=b(\lambda)\sqrt{x}\mathbf{J}_{-1/(\alpha+2)}\left(\frac{2\sqrt{\lambda}}{\alpha+2}x^{\alpha+2/2}\right),$$

$$\text{where}\quad b(\lambda)=\Gamma\left(\frac{\alpha+1}{\alpha+2}\right)(\alpha+2)^{-[1/(\alpha+2)]}\lambda^{1/[2(\alpha+2)]}.$$

Here $\mathbf{J}_\nu(x)$ is the Bessel function. It is readily seen from $\mathbf{J}_\nu(x)\approx[1/\Gamma(1+\nu)](x/2)^\nu$ as $x\to 0$ that

$$\mathcal{J}_1(0,\lambda)=0 \quad \mathcal{J}_1'(0,\lambda)=1 \quad \text{and} \quad \mathcal{J}_2(0,\lambda)=1 \quad \mathcal{J}_2'(0,\lambda)=0,$$
$$\varphi(x,\lambda)=\mathcal{J}_1(x,\lambda)+\int_0^x G(x,\ t,\ \lambda)q(t)\varphi(t,\lambda)t^{\alpha}dt, \tag{3.7}$$

where Green's function is

$$\begin{aligned}G(x,\ t,\ \lambda)&=\mathcal{J}_1(x,\lambda)\mathcal{J}_2(t,\lambda)-\mathcal{J}_2(x,\lambda)\mathcal{J}_1(t,\lambda)\\&=\Gamma\left(\frac{\alpha+3}{\alpha+2}\right)\Gamma\left(\frac{\alpha+1}{\alpha+2}\right)\sqrt{xt}\\&\quad\times\left[\mathbf{J}_{1/(\alpha+2)}\left(\frac{2\sqrt{\lambda}}{\alpha+2}x^{(\alpha+2)/2}\right)\mathbf{J}_{-[1/(\alpha+2)]}\left(\frac{2\sqrt{\lambda}}{\alpha+2}t^{(\alpha+2)/2}\right)-\mathbf{J}_{1/(\alpha+2)}\right.\\&\quad\left.\times\left(\frac{2\sqrt{\lambda}}{\alpha+2}t^{(\alpha+2)/2}\right)\mathbf{J}_{-[1/(\alpha+2)]}\left(\frac{2\sqrt{\lambda}}{\alpha+2}x^{(\alpha+2)/2}\right)\right].\end{aligned}$$

A direct calculation with $\nu=1/(\alpha+2)$, reduces

$$\begin{aligned}\mathbf{J}_{\nu}(2\sqrt{\lambda}\nu x^{1/2\nu})\mathbf{J}_{-\nu}(2\sqrt{\lambda}\nu t^{1/2\nu})&=\sum_{n,k\geqslant 0}\frac{(-1)^n(2\sqrt{\lambda}\nu x^{1/2\nu})^{\nu+2n}}{n!\Gamma(\nu+n+1)}\frac{(-1)^k(2\sqrt{\lambda}\nu t^{1/2\nu})^{-\nu+2k}}{k!\Gamma(-\nu+k+1)}\\&=\sqrt{\frac{x}{t}}\sum_{n,k\geqslant 0}\frac{(-1)^{n+k}}{n!k!\Gamma(\nu+n+1)\Gamma(-\nu+k+1)}(2\nu)^{2n+2k}\\&\quad\times x^{n/\nu}t^{k/\nu}\lambda^{n+k},\end{aligned}$$

$$\begin{aligned}&\mathbf{J}_{\nu}(2\sqrt{\lambda}\nu t^{1/2\nu})\mathbf{J}_{-\nu}(2\sqrt{\lambda}\nu x^{1/2\nu})\\&\quad=\sqrt{\frac{t}{x}}\sum_{n,k\geqslant 0}\frac{(-1)^{n+k}}{n!k!\Gamma(\nu+k+1)\Gamma(-\nu+n+1)}(2\nu)^{2n+2k}t^{k/\nu}x^{n/\nu}\lambda^{n+k}.\end{aligned}$$

Therefore we arrive at an explicit formula for $G(x,t,\lambda)$,

$$\begin{aligned}G(x,\ t,\ \lambda)&=\Gamma(1+\nu)\Gamma(1-\nu)\sum_{n,k\geqslant 0}\frac{(-4\nu^2)^{n+k}(x-t)x^{n/\nu}t^{k/\nu}}{n!k!\Gamma(\nu+n+1)\Gamma(-\nu+k+1)}\lambda^{n+k}\\&=\sum_{n,k\geqslant 0}g_{nk}(x,t)\lambda^{n+k}\\&=\sum_{j\geqslant 0}\xi_j(x,t)\lambda^j,\end{aligned}$$

where

$$\xi_j(x,\ t)=(x-t)\sum_{k=0}^{j}\frac{1}{(1+\nu)_{j-k}}\frac{1}{(1-\nu)_k}(-4\nu^2)^j\frac{x^{(j-k)/\nu}}{(j-k)!}\frac{t^{k/\nu}}{k!} \tag{3.8}$$

and $(a)_n=a(a+1)\cdots(a+n-1)$. We arrive at

Proposition 8: If $w(x)=x^{\alpha}$ *where* $\alpha>-1$ *and* $q\in C_0^{\infty}(0,\infty)$, *then*

$$H(x,t)=-\lim_{m\to\infty}(-t^{-\alpha}D^2+q(t))^{m+1}\xi_m(x,\ t)$$

in $L^2_w(0,x)$, *with* $\xi_m(x,\ t)$ *being given by (3.8).*

IV. APPLICATIONS

We now briefly outline an interesting application of the transmutation operator $V^{-1}=1+K$. Using the above notation the Gelfand–Levitan theory would read as follows: Recover the potential q from the given spectral function Γ_1. To do so, we assume that we know $y(x,\lambda)$, Γ_2 and w such that the following function:

$$F(x,t)=\int y(x,\lambda)y(t,\lambda)d\sigma(\lambda),$$

where $\sigma(\lambda)=\Gamma_1(\lambda)-\Gamma_2(\lambda)$, is at least C^2 in x,t. Then we would form the linear integral equation

$$K(x,t)+F(x,t)+\int_0^x K(x,s)F(s,t)w(s)ds=0 \quad \text{for } 0<t<x,$$

which we solve for $K(x,t)$. Then define the function φ from the relation

$$\varphi(x,\lambda)=y(x,\lambda)+\int_0^x K(x,t)y(t,\lambda)w(t)dt.$$

It is then easy to show that there exists a function q such that

$$q(x)=\frac{1}{w(x)}\frac{d}{dx}[K(x,x)w(x)]+\frac{d}{dx}K(x,x)$$

and the newly constructed φ is a solution of Eq. (1.1).

The above analysis of constructing transmutation operators can be extended to the more general Sturm–Liouville operators

$$L_3(y)(x):=-\frac{1}{w(x)}(p(x)y'(x))'+q(x)y(x),$$

where $1/p,w,qw\in L^{\text{loc}}[0,\infty)$ and $p>0, w\geqslant 0$. To get the transmutation operator between L_2 and L_3 we can relate L_3 to L_1 in a very simple way. Denote by

$$\phi(t(x))=y(x),$$

where $t(x)=\int_0^x[1/p(t)]\,dt$. Then it follows that $\phi(t)$ satisfies $\phi'(t(x))=p(x)y'(x)$ and from

$$-\frac{1}{w(x)p(x)}p(x)(p(x)y'(x,\lambda))'+q(x)y(x,\lambda)=\lambda y(x,\lambda)$$

we deduce that

$$-\frac{1}{W(t)}\phi''(t,\lambda)+Q(t)\phi(t,\lambda)=\lambda\phi(t,\lambda),$$

which is similar to L_1 with $W(t(x))=w(x)p(x)$ and $Q(t(x))=q(x)$.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 45, NUMBER 7 JULY 2004

Covariant Poisson equation with compact Lie algebras

Antti Salmela[a)]
Theoretical Physics Division, Department of Physical Sciences, P.O. Box 64, 00014 University of Helsinki, Helsinki, Finland

(Received 25 February 2003; accepted 20 April 2004; published online 10 June 2004)

The covariant Poisson equation for Lie algebra-valued mappings defined on $\mathbb{R}^3$ is studied using functional analytic methods. Weighted covariant Sobolev spaces are defined and used to derive sufficient conditions for the existence and smoothness of solutions to the covariant Poisson equation. These conditions require, apart from suitable continuity, appropriate local L^p integrability of the gauge potential and global weighted L^p integrability of the curvature form and the source. The possibility of nontrivial asymptotic behavior of a solution is also considered. As a by-product, weighted covariant generalizations of Sobolev embeddings are established. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1763001]

I. INTRODUCTION

Let us consider two mappings Z and F taking values in some compact Lie algebra $\mathcal{G}$. The covariant generalization of Poisson's equation on $\mathbb{R}^3$ is then

$$\Delta(A)Z=F, \tag{1}$$

where

$$\Delta(A)=\sum_{k=1}^{3}\nabla_k^2,$$

$$\nabla_k=\partial_k+[A_k,\cdot\,],$$

and A_k stands for a $\mathcal{G}$-valued gauge potential. This equation arises frequently in gauge theories and it is mostly connected with Gauss's law. In the Lagrangian formulation of Yang–Mills theory this connection is explicit, since Gauss's law reads

$$\Delta(A)A_0=\sum_{k=1}^{3}\nabla_k\dot{A}_k-J_0,\quad \dot{A}_k=\frac{\partial A_k}{\partial t},$$

J_0 denoting the matter density. In the Hamiltonian formalism the Gauss law becomes a divergence equation

$$\sum_{k=1}^{3}\nabla_k E_k=J_0,$$

but if we split the color-electric field E_k into longitudinal and transverse components by

$$E_k=E_k^L+E_k^T,$$

a)Electronic mail: Antti.Salmela@Helsinki.Fi

$$\sum_{k=1}^{3} \nabla_k E_k^L = J_0, \quad \sum_{k=1}^{3} \nabla_k E_k^T = 0,$$

then a solution for the longitudinal component is given by

$$E_k^L = \nabla_k \Phi,$$

where Φ satisfies the covariant Poisson equation

$$\Delta(A)\Phi = J_0.$$

In addition to these cases the Poisson equation also arises if one tries to transform an arbitrary gauge potential $\mathcal{A}_\mu$ into an equivalent potential

$$A_\mu = \omega^{-1}\mathcal{A}_\mu\omega + \omega^{-1}\partial_\mu\omega,$$

where A_μ satisfies the generalized Coulomb gauge condition

$$\sum_{k=1}^{3} \nabla_k \dot{A}_k = 0,$$

which was proposed by Cronström in Ref. 1. It turns out that the gauge transformation matrix ω takes the form of a time-ordered exponential

$$\omega(x^0,\mathbf{x}) = \left[T\exp\left(-\int_0^{x^0} Z(\tau,\mathbf{x})\, d\tau \right) \right] \omega(0,\mathbf{x}),$$

where Z satisfies the Poisson equation

$$\Delta(\mathcal{A})Z = \sum_{k=1}^{3} \nabla_k(\mathcal{A})\dot{\mathcal{A}}_k.$$

These are the most important physical reasons for studying this equation. From a purely mathematical point of view the covariant Poisson equation is also interesting, because it is a special case of an elliptic system of partial differential equations which probably has not been considered before in the literature. Research has been done regarding solutions of the whole set of classical Yang–Mills equations,[2–5] but these approaches lead to hyperbolic evolution equations where Gauss's law becomes a constraint which must hold at all times. The Cauchy data of the problem is assumed to satisfy the constraint and the evolution equations are used to show that the constraint then persists. The starting point of this paper is quite different, because time evolution is not present in the covariant Poisson equation. Time serves only as a parameter of the mappings in question, but no specific evolution equations are required to hold.

The line of thought and the most important results of this paper are included in the next three sections. Section II deals with the existence of a distributional solution to the covariant Poisson equation. Conditions for making this solution smoother are derived in Sec. III, and the possibility of constructing a solution formula is touched upon in Sec. IV. Proofs are gathered in the last section, but the preceding sections are meant to be comprehensible even without reference to the proofs. The notations and conventions used in this paper are summarized below. Gauge potentials are written as

$$A_k(x) = A_k^a(x)T_a,$$

where the Lie algebra generators T_a satisfy

$$[T_a, T_b] = f_{ab}{}^c T_c .$$

Summation over repeated indices is implied. The components A_k^q and the structure constants $f_{ab}{}^c$ are real, because all compact Lie algebras are real. The curvature form of the gauge potential is defined as

$$G_{kl} = \partial_l A_k - \partial_k A_l - [A_k, A_l],$$

and the covariant divergence of G_{kl} is

$$(\nabla \cdot G)_k = \sum_{j=1}^{3} \nabla_j G_{jk} .$$

The definition of a compact Lie algebra implies that there exists a positive definite inner product

$$(X, Y) = h_{ab} X^a Y^b,$$

which is invariant under the adjoint action of the gauge group. The infinitesimal form of this property states that

$$(X, [Y, Z]) = -([Y, X], Z) \quad \text{for all } X, Y, Z \in \mathcal{G}. \tag{2}$$

If $\mathcal{G}$ is semisimple, this inner product can be chosen to be the negative of the Killing form (i.e., $h_{ab} = -f_{ac}{}^d f_{bd}{}^c$). The norm induced by this inner product will be denoted by $|\cdot|$. More generally, for $\mathcal{G}$-valued tensors $X_{i_1 \cdots i_r}$ the norm with nth covariant derivatives reads

$$|\nabla^n X| = \left(\sum_{k_1} \cdots \sum_{k_n} \sum_{i_1} \cdots \sum_{i_r} |\nabla_{k_1} \cdots \nabla_{k_n} X_{i_1 \cdots i_r}|^2 \right)^{1/2},$$

and the norm $|\partial^n X|$ with ordinary derivatives is defined analogously. Within the context of L^p norms it is always understood that the notation $\|X\|_p$ stands for $\| |X| \|_p$. We will also need multi-index notations for the covariant derivatives. Due to the noncommuting nature of these derivatives it is appropriate to deviate here from the usual definition and instead let a multi-index α denote an n-tuple of ordered coordinate indices

$$\alpha = (k_1, \ldots, k_n)$$

with the notation for covariant derivatives

$$\nabla^\alpha X = \nabla_{k_1} \cdots \nabla_{k_n} X.$$

The partial derivatives ∂^α are defined similarly. The order of a multi-index is simply $|\alpha| = n$, and the symbol ∇^n stands for the collection of all covariant derivatives ∇^α of order n. At this point the reader should take care so as not to confuse the collection of second order covariant derivatives ∇^2 with the covariant Laplacian $\Delta(A)$, and the same warning also applies to the norms $|\nabla^2 X|$ and $|\Delta(A) X|$, which have different meanings. Throughout the paper positive constants will be denoted by C, but the values of the constants may change from line to line as they are inessential for the proofs.

II. EXISTENCE OF A WEAK SOLUTION

A weak solution of the covariant Poisson equation (1) satisfies

$$-\int \sum_{k=1}^{3} (\nabla_k \tilde{\Phi}, \nabla_k Z)\, d^3x = \int (\tilde{\Phi}, F)\, d^3x \quad \text{for all } \tilde{\Phi} \in C_c^\infty(\mathbb{R}^3, \mathcal{G}),$$

when the weak covariant derivatives $\nabla_k Z$ and their commutators with A_k are locally integrable. The subscript c above refers to compact support. In order to control the asymptotic behavior of Z in subsequent calculations, introduce weights by writing

$$\tilde{\Phi}(x)=\frac{1}{w(x)^{1-\sigma}}\Phi(x), \quad w(x)=(1+|x|^2)^{1/2}, \quad 0<\sigma\leqslant 1.$$

This leads to an equivalent definition

$$\int \sum_{k=1}^{3} \frac{1}{w^{1-\sigma}}(\nabla_k\Phi,\nabla_k Z)\, d^3x - (1-\sigma)\int \sum_{k=1}^{3} \frac{x_k}{w^{3-\sigma}}(\Phi,\nabla_k Z)\, d^3x$$

$$= -\int \frac{1}{w^{1-\sigma}}(\Phi,F)\, d^3x \quad \text{for all } \Phi\in C_c^{\infty}(\mathbb{R}^3,\mathcal{G}). \tag{3}$$

The proof that there exists a solution to this equation is based on the well-known theorem by Lax and Milgram.[6,7] In order to apply this theorem we identify the left-hand side of the definition (3) as a bilinear mapping $B(\Phi,Z)$ and the right-hand side as a linear functional $f(\Phi)$. A suitably defined Sobolev space will play the role of a Hilbert space. We start by defining an inner product on the space $C_c^1(\mathbb{R}^3,\mathcal{G})$ by

$$\langle\Phi,\Psi\rangle_1=\int \frac{1}{w^{1-\sigma}}\sum_{k=1}^{3}(\nabla_k\Phi,\nabla_k\Psi)\, d^3x, \tag{4}$$

where it is assumed that $A_k\in L^2_{\mathrm{loc}}(\mathbb{R}^3,\mathcal{G})$. The norm associated with this inner product will be denoted by $\|\cdot\|_{1,2}$. In order to check that this formula really defines an inner product we need the following two results:

Lemma 1: Let $\mathcal{G}$ be a compact Lie algebra. Then there exists a constant $C>0$ such that

$$|[X,Y]|\leqslant C|X|\,|Y|$$

for all elements $X,Y\in\mathcal{G}$.

Proof: See Sec. V A.

Proposition 1: Let $A_k\in L^2_{\mathrm{loc}}(\mathbb{R}^3,\mathcal{G})$. Then the inequality

$$\left(\int \frac{1}{w^{3-\sigma}}|\Phi|^2\, d^3x\right)^{1/2}\leqslant C\left(\int \frac{1}{w^{1-\sigma}}\sum_{k=1}^{3}|\nabla_k\Phi|^2\, d^3x\right)^{1/2} \tag{5}$$

holds for all mappings $\Phi\in C_c^1(\mathbb{R}^3,\mathcal{G})$. The constant C does not depend on Φ.

Proof: See Sec. V B.

Lemma 1 together with Hölder's inequality ensures that the expression (4) is defined, and Proposition 1 guarantees that the norm $\|\Phi\|_{1,2}$ vanishes only when $\Phi\equiv 0$. The first order Sobolev space is now defined as the completion of $C_c^1(\mathbb{R}^3,\mathcal{G})$ in the norm $\|\cdot\|_{1,2}$, i.e.,

$$H_1(\mathbb{R}^3,\mathcal{G})=\overline{C_c^1(\mathbb{R}^3,\mathcal{G})}.$$

It goes without saying that this Sobolev space depends on σ, which is kept fixed in forthcoming calculations. Considering Cauchy sequences in $H_1(\mathbb{R}^3,\mathcal{G})$ with elements of class $C_c^1(\mathbb{R}^3,\mathcal{G})$ we can extend the inner product (4) and Proposition 1 to $H_1(\mathbb{R}^3,\mathcal{G})$. As a result, we see that the norm $\|\cdot\|_{1,2}$ can be extended to $H_1(\mathbb{R}^3,\mathcal{G})$ as it only vanishes for mappings equivalent to zero. Let us now apply the Lax–Milgram theorem to the bilinear mapping B of Eq. (3). Employing Schwarz's inequality and Proposition 1 yields

$$|B(Y,Z)|\leqslant[1+C(1-\sigma)]\|Y\|_{1,2}\|Z\|_{1,2} \quad \text{for all } Y,Z\in H_1(\mathbb{R}^3,\mathcal{G}),$$

which establishes the boundedness of B. Coercivity is proved by examining the second term of B with mappings of class $C_c^1(\mathbb{R}^3,\mathcal{G})$ first. Equation (2) shows that almost everywhere

$$(\Phi,\nabla_k\Phi)=(\Phi,\partial_k\Phi)=\tfrac{1}{2}\partial_k|\Phi|^2,$$

and this leads to the identity

$$-(1-\sigma)\int\sum_{k=1}^{3}\frac{x_k}{w^{3-\sigma}}(\Phi,\nabla_k\Phi)\,d^3x=-\frac{1}{2}(1-\sigma)\int\sum_{k=1}^{3}\partial_k\left(\frac{x_k}{w^{3-\sigma}}|\Phi|^2\right)d^3x+\frac{1}{2}(1-\sigma)\int\frac{3+\sigma|x|^2}{w^{5-\sigma}}|\Phi|^2\,d^3x.$$

The first integral on the right-hand side can be converted into a surface integral which vanishes due to the compact support of Φ. The second integral is non-negative and hence

$$-(1-\sigma)\int\sum_{k=1}^{3}\frac{x_k}{w^{3-\sigma}}(\Phi,\nabla_k\Phi)\,d^3x\geqslant 0.$$

Taking a Cauchy sequence (Φ_m) of mappings belonging to $C_c^1(\mathbb{R}^3,\mathcal{G})$ and converging to an arbitrary element Z in $H_1(\mathbb{R}^3,\mathcal{G})$ we see that the inequality above holds for Z also. Indeed, the integrals with Φ_m converge to the integral with Z by virtue of Proposition 1 and Schwarz's inequality. As a result,

$$B(Z,Z)\geqslant\|Z\|_{1,2}^2\quad\text{for all}\quad Z\in H_1(\mathbb{R}^3,\mathcal{G})$$

and the coercivity condition is satisfied. Now the Lax–Milgram theorem yields a solution to Eq. (3) whenever the right-hand side defines a bounded linear functional on $H_1(\mathbb{R}^3,\mathcal{G})$. By Schwarz's inequality the condition

$$\|w^{(1/2)(1+\sigma)}F\|_2<\infty \tag{6}$$

suffices for that purpose. We can summarize the result as follows:

Theorem 1: *Suppose that $A_k\in L^2_{\mathrm{loc}}(\mathbb{R}^3,\mathcal{G})$ and the condition (6) is satisfied. Then there exists in $H_1(\mathbb{R}^3,\mathcal{G})$ a weak solution of the covariant Poisson equation (1).*

Some words about the asymptotic behavior of the solution are appropriate at this stage. Roughly speaking, the mappings of $H_1(\mathbb{R}^3,\mathcal{G})$ tend to zero at infinity like some negative power of the radius $|x|$. In fact, there is a more general theorem by Cronström[8] stating that two classical solutions of the covariant Poisson equation are equal if their difference vanishes at infinity. Thus in order to obtain more solutions we must consider mappings with nontrivial behavior at infinity. Let us assume that a mapping Z_0 solves the Poisson equation asymptotically in the sense that

$$\|w^{(1/2)(1+\sigma)}(F-\Delta(A)Z_0)\|_2<\infty. \tag{7}$$

Then by Theorem 1 there exists a solution $Y\in H_1(\mathbb{R}^3,\mathcal{G})$ to the equation

$$\Delta(A)Y=F-\Delta(A)Z_0$$

and accordingly, a mapping defined by

$$Z=Y+Z_0 \tag{8}$$

solves the original equation (1). Since the mapping Y tends to zero at infinity in a generalized sense, the asymptotic behavior of Z is now determined by Z_0. Solutions with nontrivial behavior

can thus be obtained by constructing such a mapping Z_0 that the condition (7) is in force. To a great extent the details of the construction depend on the asymptotic behavior of the source F.

III. SMOOTHNESS OF SOLUTIONS

Now that we have proved the existence of a distributional solution to the Poisson equation, it is time to consider the smoothness properties of this solution. The standard technique is to define higher order Sobolev spaces and then apply the fact that these spaces are continuously embedded in the spaces of mappings with continuous and bounded derivatives. Then it remains to derive a suitable *a priori* estimate which enables us to conclude that a solution under certain assumptions belongs to a higher order Sobolev space. Let us begin with the definitions of nth order Sobolev spaces. Throughout this section the following local assumptions are supposed to hold:

Assumption: If $n=2$, we assume that

$$A_k \in C(\mathbb{R}^3,\mathcal{G}), \quad \partial^1 A_k \in L^3_{\mathrm{loc}}(\mathbb{R}^3,\mathcal{G}), \quad \partial^2 A_k \in L^1_{\mathrm{loc}}(\mathbb{R}^3,\mathcal{G}), \quad G_{kl} \in C(\mathbb{R}^3,\mathcal{G}), \tag{9a}$$

while in the case $n \geqslant 3$ these assumptions are replaced by

$$A_k \in C^{n-3}(\mathbb{R}^3,\mathcal{G}), \quad \partial^{n-2} A_k \in L^q_{\mathrm{loc}}(\mathbb{R}^3,\mathcal{G}) \quad \textit{for some } q>3, \quad \partial^{n-1} A_k \in L^2_{\mathrm{loc}}(\mathbb{R}^3,\mathcal{G}),$$

$$G_{kl} \in C^{n-3}(\mathbb{R}^3,\mathcal{G}). \tag{9b}$$

These conditions enable us to define a higher order inner product on the space $C^n_c(\mathbb{R}^3,\mathcal{G})$ by

$$\langle \Phi,\Psi\rangle_n = \sum_{p=1}^{n} \int w^{(2p-3)(1-\sigma)} \sum_{k_1=1}^{3} \cdots \sum_{k_p=1}^{3} (\nabla_{k_1}\cdots\nabla_{k_p}\Phi, \nabla_{k_1}\cdots\nabla_{k_p}\Psi)\, d^3x.$$

The corresponding norm will be denoted by $\|\cdot\|_{n,2}$. Now the nth order Sobolev space is defined as

$$H_n(\mathbb{R}^3,\mathcal{G}) = \overline{C^n_c(\mathbb{R}^3,\mathcal{G})},$$

where the closure is taken in the norm $\|\cdot\|_{n,2}$. These spaces are going to be embedded in the spaces $C^{n-2}_B(\mathbb{R}^3,\mathcal{G})$ consisting of $C^{n-2}(\mathbb{R}^3,\mathcal{G})$ mappings for which the norm

$$\|\Phi\|_{n-2,\infty} = \max_{0 \leqslant p \leqslant n-2} \sup_{x\in\mathbb{R}^3} \{w(x)^{p(1-\sigma)} |\nabla^p \Phi(x)|\}$$

is finite. Note that $A_k \in C^{n-3}(\mathbb{R}^3,\mathcal{G})$ at this stage and the covariant derivatives in this definition thus yield continuous mappings. We can now formulate the embedding property exactly:

Theorem 2 (Sobolev embeddings): *Suppose that the assumptions (9) hold. Then the spaces $H_n(\mathbb{R}^3,\mathcal{G})$ are continuously embedded in the spaces $C^{n-2}_B(\mathbb{R}^3,\mathcal{G})$, i.e.,*

$$H_n(\mathbb{R}^3,\mathcal{G}) \subset C^{n-2}_B(\mathbb{R}^3,\mathcal{G}). \tag{10}$$

Proof: See Sec. V C.

The following *a priori* estimate establishes the inductive chain that allows us to include the distributional solution into higher order Sobolev spaces:

Proposition 2: Suppose that the conditions (9) are in force. Then the inequality

$$\|\Phi\|_{n,2} \leqslant C(\|\Phi\|_{n-1,2} + \|w^{(n-3/2)(1-\sigma)} \nabla^{n-2} \Delta(A)\Phi\|_2) \tag{11}$$

holds for all $\Phi \in C^{n+1}_c(\mathbb{R}^3,\mathcal{G})$. The constant C is independent of Φ, but it depends on weighted L^p norms of the curvature form as follows:

$$C = C(\|w^{2(1-\sigma)} G\|_\infty, \|w^{2(1-\sigma)} (\nabla \cdot G)\|_3),$$

when $n=2$, *whereas*

$$C=C(\|w^{(p+2)(1-\sigma)}\nabla^p G\|_\infty,\|w^{(p+2)(1-\sigma)}\nabla^p(\nabla\cdot G)\|_3),\quad p=0,\ldots,n-3,$$

when $n\geqslant 3$. *The constant is finite when the norms in question are finite.*

Proof: See Sec. V D.

It should be mentioned that the form of this estimate is not unique as there is some freedom in choosing the curvature norms which are to be bounded. The guideline here has been to keep the asymptotic requirements on the curvature as mild as possible and to make the transition to the unweighted case $\sigma=1$ easy. It is possible to relax the local assumptions, but that might happen at the cost of asymptotic conditions. The reason for worrying about the asymptotic behavior of the curvature form is a paper by Coleman[9] in which he shows that the only nonsingular solution satisfying the source-free Yang–Mills equations is the vacuum solution provided that the condition

$$\lim_{|x|\to\infty}|x|^{3/2+\epsilon}G^a_{\mu\nu}(x,t)=0,\quad 0<\epsilon<\tfrac{1}{2}$$

holds uniformly in time in the region $t>0$. It is easy to check that the norms of Proposition 2 escape this condition since $\sigma=1$ in the source-free case. When sources are present, the solution will always be nontrivial. Now in order to extend Proposition 2 to mappings in $H_n(\mathbb{R}^3,\mathcal{G})$ we employ the following density result:

Lemma 2: Suppose that the conditions (9) are in force. If

$$Z\in H_{n-1}(\mathbb{R}^3,\mathcal{G})\ \ and\ \ w^{(n-3/2)(1-\sigma)}\nabla^{n-2}\Delta(A)Z\in L^2(\mathbb{R}^3,\mathcal{G}),\tag{12}$$

then there exists a sequence (Φ_m) *of mappings belonging to* $C_c^\infty(\mathbb{R}^3,\mathcal{G})$ *such that* $\Phi_m\to Z$ *in* $H_{n-1}(\mathbb{R}^3,\mathcal{G})$ *and also*

$$\|w^{(n-3/2)(1-\sigma)}\nabla^{n-2}\Delta(A)(Z-\Phi_m)\|_2\to 0.$$

Proof: See Sec. V E.

Taking a Cauchy sequence (Φ_m) of $C_c^\infty(\mathbb{R}^3,\mathcal{G})$ mappings converging to Z in both norms of Lemma 2 and inserting it into the estimate (11) shows that the sequence also converges in $H_n(\mathbb{R}^3,\mathcal{G})$ towards Z. As a result,

$$Z\in H_n(\mathbb{R}^3,\mathcal{G})\subset C_B^{n-2}(\mathbb{R}^3,\mathcal{G}).$$

If the derivatives of Z satisfy the Poisson equation (1) in a distributional sense, the covariant Laplacian norms of Z can then be replaced by the corresponding norms of F. In short:

Theorem 3: *Suppose that the assumptions (9) hold and the curvature norms of Proposition 2 are finite. If in addition*

$$\|w^{(p+1/2)(1-\sigma)}\nabla^p F\|_2<\infty,\quad p=0,\ldots,n-2,\tag{13}$$

then the solution of the covariant Poisson equation given by Theorem 1 belongs to $C_B^{n-2}(\mathbb{R}^3,\mathcal{G})$.

When solutions with nontrivial asymptotic behavior are constructed by writing Z in the form (8), this theorem can be used to deduce the smoothess properties of Y, replacing only F with $F-\Delta(A)Z_0$ in the condition (13). The ultimate smoothness of Z then depends on the properties of Z_0.

IV. CONCLUSIONS

Theorems 1 and 3 are the main results regarding solutions of the covariant Poisson equation. All the assumptions of these theorems are only sufficient, and it remains an open question to determine the necessary conditions. However, it is likely that some bounds should be imposed on the curvature form. In fact, similar studies by Aubin,[10] Cantor,[11] and Eichhorn[12] on Riemannian

manifolds and vector bundles indicate that bounds are also needed for the curvature tensor and its derivatives in these approaches. As regards the smoothness assumptions (9), the fact that they are all local is consistent with the principles of fibre bundle theory in the sense that gauge potentials are considered as local objects. Global integrability conditions can be imposed on the curvature form without problems because the Lie algebra norms $|\nabla^p G|$ and $|\nabla^p(\nabla\cdot G)|$ are gauge invariant.

A slight shortcoming of the Lax–Milgram theorem is the fact that it does not give an explicit formula for the solution whose existence it proves. A formal procedure exists for separable Hilbert spaces, though. Following the proof of separability for ordinary Sobolev spaces (see, e.g., Ref. 7, Sec. 6.3) it is straightforward to check that the weighted covariant Sobolev space $H_1(\mathbb{R}^3,\mathcal{G})$ is indeed separable. Then it is possible, at least in principle, to construct a countable orthonormal basis $\{\Psi_n\}$ for $H_1(\mathbb{R}^3,\mathcal{G})$. Expressing Z and Φ in Eq. (3) as generalized Fourier series,

$$Z=\sum_{n=1}^{\infty} a_n\Psi_n, \quad \Phi=\sum_{n=1}^{\infty} b_n\Psi_n,$$

we see that the coefficients a_n are to be determined from the equation

$$a_n-\sum_{m=1}^{\infty} a_m(1-\sigma)\int \sum_{k=1}^{3}\frac{x_k}{w^{3-\sigma}}(\Psi_n,\nabla_k\Psi_m)\,d^3x=-\int \frac{1}{w^{1-\sigma}}(F,\Psi_n)\,d^3x.$$

The superficial simplicity of this solution formula hides the practical difficulties in constructing an orthonormal basis for $H_1(\mathbb{R}^3,\mathcal{G})$. Also in traditional approaches to the covariant Poisson equation the solution formulas tend to be too complicated. Employing suitable asymptotic conditions and inverting the ordinary Laplacian it is possible to convert the equation into an integral equation. No matter whether one iterates the resulting equation or applies Fredholm's formulas, the solution will always be rather complicated. Maybe we should not even expect the covariant Poisson equation to have simple and elegant solutions.

V. PROOFS

A. Lemma 1

This result is almost self-evident because the structure constants are bounded. Anyway, let us be explicit and consider the norm of the commutator

$$|[X,Y]|^2=X^aM_{ae}X^e,$$

$$M_{ae}=h_{cd}f_{ab}{}^{c}f_{ef}{}^{d}Y^bY^f.$$

Using Cauchy's inequality

$$X^aX^e\leqslant \tfrac{1}{2}[(X^a)^2+(X^e)^2]$$

we can derive the bound

$$|[X,Y]|^2\leqslant C(Y)\sum_{a=1}^{d}(X^a)^2, \tag{14}$$

where

$$C(Y)=\max_{1\leqslant a\leqslant d}\left\{\sum_{e=1}^{d}|M_{ae}|\right\}$$

and d denotes the dimension of the algebra. Applying similar techniques to the matrix M_{ae} we can also bound its elements by

$$|M_{ae}| \leqslant \tilde{C}_{ae} \sum_{b=1}^{d} (Y^b)^2,$$

where the matrix $\tilde{C}_{ae}$ is independent of Y. Hence we obtain an identical bound for the constant $C(Y)$ above. The proof is completed by noting that the metric tensor h_{ab} has strictly positive eigenvalues and the norm $|\cdot|$ is thus equivalent with the d-dimensional Euclidean norm appearing in inequality (14). □

B. Proposition 1

Let us begin with a more general theorem due to Gurka and Opic[13] regarding real functions on $\mathbb{R}^3$.

Theorem 4 (Gurka–Opic): *Let $1 \leqslant p < \infty$ and let $\overline{v_0}$, $\overline{v_1}$ be real, measurable, almost everywhere positive and finite functions of one real variable. Suppose further that they are bounded below and above by positive constants on every compact interval of the positive real axis and that there exists a constant $k > 0$ and a number $t_0 \in]0,\infty[$ such that*

$$\overline{v_0}(t) \geqslant k\, \overline{v_1}(t) t^{-p} \quad for\ all \quad t \geqslant t_0.$$

Finally, if

$$\sup_{0<\tau<\infty} \left(\int_0^\tau \overline{v_0}(t) t^2\, dt \right)^{1/p} \left(\int_\tau^\infty [\overline{v_1}(t) t^2]^{-1/(p-1)} dt \right)^{1-1/p} < \infty, \tag{15}$$

then there exists a constant $C > 0$ such that

$$\left(\int |u(x)|^p\, \overline{v_0}(|x|)\, d^3x \right)^{1/p} \leqslant C \left(\sum_{i=1}^{3} \int |\partial_i u(x)|^p\, \overline{v_1}(|x|)\, d^3x \right)^{1/p} \tag{16}$$

for all integrable functions u such that the norms of the inequality are finite. The constant C is independent of u.

Proof: This is a special case of Theorem 14.5. in Ref. 13. In their remarks Gurka and Opic state without proof that the conditions (15) and (16) are actually equivalent. □

We can now make use of this theorem and choose

$$p = 2, \quad \overline{v_0}(t) = (1+t^2)^{-[(3-\sigma)/2]}, \quad \overline{v_1}(t) = (1+t^2)^{-[(1-\sigma)/2]}, \quad 0 < \sigma \leqslant 1.$$

This leads to the inequality

$$\left(\int \frac{1}{w^{3-\sigma}} |u|^2\, d^3x \right)^{1/2} \leqslant C \left(\int \frac{1}{w^{1-\sigma}} \sum_{k=1}^{3} |\partial_k u|^2\, d^3x \right)^{1/2}, \tag{17}$$

which holds in particular for all $u \in C_c^1(\mathbb{R}^3)$. Condition (15) fails for $\sigma = 0$, indicating that the inequality (17) cannot be improved by setting σ to zero. In order to derive the inequality (5) we make use of a trick employed by Ginibre and Velo in Ref. 3. Namely, for a mapping $\Phi \in C_c^1(\mathbb{R}^3, \mathcal{G})$ we define a family of functions

$$u_\delta(x) = (|\Phi(x)|^2 + \delta^2)^{1/2} - \delta, \quad \delta > 0. \tag{18}$$

Clearly $u_\delta \in C_c^1(\mathbb{R}^3)$ and

$$\partial_k u_\delta = (|\Phi|^2 + \delta^2)^{-1/2} (\partial_k \Phi, \Phi). \tag{19}$$

As before, we note that

$$(\partial_k\Phi,\Phi)=(\nabla_k\Phi,\Phi) \tag{20}$$

whenever A_k is finite. Since $A_k\in L^2_{\mathrm{loc}}(\mathbb{R}^3,\mathcal{G})$, it follows that $\nabla_k\Phi\in L^2(\mathbb{R}^3,\mathcal{G})$ and Eq. (20) holds almost everywhere. Combining Eqs. (19) and (20) we see that

$$|\partial_k u_\delta|\leqslant|\nabla_k\Phi| \tag{21}$$

almost everywhere. Inequalities (17) and (21) finally yield inequality (5) in the limit $\delta\to 0$. □

C. Sobolev embeddings (10)

These embeddings constitute an obvious generalization of well-known results for real functions. Sobolev embeddings for Riemannian vector bundles have previously been derived by Cantor[11] and Eichhorn,[12] but the results are not directly applicable here, because they deal with unweighted inequalities only. For this reason it may be appropriate to present a derivation of the embeddings (10) here. The most essential part of the proof consists of deriving weighted generalizations of the ordinary embeddings, and the rest follows by employing the trick (18). Although there are very general weighted inequalities in Refs. 13 and 14 already, they are of little use here, because inequalities involving L^∞ norms are not included in them. For that reason we are going to proceed using a method presented in Chap. VI.6 of Ref. 15. Yet there is a small improvement in the calculations below compared with those of Ref. 15. Namely, it proved to be possible to lower the Sobolev space weight factors of the nth partial derivatives from $w^{n-[(3-\sigma)/2]}$ to $w^{(n-3/2)(1-\sigma)}$, which in turn leads to milder asymptotic conditions in Theorem 3. Let us begin with the familiar interpolation inequalities for real functions:[16]

Theorem 5 (Gagliardo–Nirenberg–Sobolev): *Let* $1\leqslant q\leqslant\infty$, $1\leqslant r\leqslant\infty$, $1\leqslant p\leqslant\infty$, $0\leqslant a\leqslant 1$ *and assume that the following relation holds true*:

$$\frac{1}{p}=\frac{1-a}{r}+a\left(\frac{1}{q}-\frac{1}{3}\right).$$

In the case $p=\infty$ *assume further that* $r<\infty$ *and* $a<1$. *Now if* $r<\infty$ *or* $q\geqslant 3$, *then there exists a constant* C, *depending only on* p, q, *and* r, *such that the inequality*

$$\|v\|_p\leqslant C\,\|v\|_r^{1-a}\,\|\partial v\|_q^a \tag{22}$$

holds for all functions $v\in L^r$ *whose derivatives lie in* L^q. *In the case* $r=\infty$, $q<3$ *the inequality holds for functions which in addition tend to zero at infinity or which lie in* L^{r_0} *for some finite* $r_0>0$.

The next step is to perform a change of variables by

$$y_k=\frac{x_k}{w(x)^{1-\sigma}},\quad 0<\sigma\leqslant 1.$$

This mapping is one-to-one and smooth in the range of σ and we can define a new function u by

$$u(y)=v(x(y)).$$

It is easily seen that

$$\int |u(y)|^r\,d^3y=\int |v(x)|^r(\det M)\,w(x)^{-3(1-\sigma)}\,d^3x,$$

where

$$M_{kl}=\delta_{kl}-(1-\sigma)\frac{x_k x_l}{1+|x|^2},\quad \det M=\frac{1+\sigma|x|^2}{1+|x|^2},\quad \sigma\leqslant\det M\leqslant 1.$$

As a result, we obtain the inequalities

$$\sigma^{1/r}\|w^{-(3/r)(1-\sigma)}v\|_r\leqslant\|u\|_r\leqslant\|w^{-(3/r)(1-\sigma)}v\|_r. \tag{23}$$

This is also valid if $r=\infty$, because the norms of u and v are equal then. For the derivative norm we need to know in addition that

$$|\partial u|^2=\sum_{k,l=1}^{3}\frac{\partial v}{\partial x_k}[M^{-1}(M^{-1})^T]_{kl}\frac{\partial v}{\partial x_l}w(x)^{2(1-\sigma)},$$

$$|\xi|^2\leqslant\sum_{k,l=1}^{3}\xi_k[M^{-1}(M^{-1})^T]_{kl}\xi_l\leqslant\frac{1}{\sigma^2}|\xi|^2\quad\text{for all}\quad\xi\in\mathbb{R}^3.$$

These properties together with the previous ones enable us to establish the inequality

$$\sigma^{1/q}\|w^{(1-(3/q))(1-\sigma)}\partial v\|_q\leqslant\|\partial u\|_q\leqslant\frac{1}{\sigma}\|w^{(1-(3/q))(1-\sigma)}\partial v\|_q. \tag{24}$$

Combining the inequalities (22)–(24) we are finally led to

$$\|w^{-(3/p)(1-\sigma)}v\|_p\leqslant C\sigma^{-a-1/p}\|w^{-(3/r)(1-\sigma)}v\|_r^{1-a}\|w^{(1-(3/q))(1-\sigma)}\partial v\|_q^a.$$

It is still possible to go a step further by defining a new function u through

$$v(x)=w(x)^\beta u(x),\quad \beta\in\mathbb{R},$$

and a fairly straightforward application of Minkowski's inequality then yields

$$\|w^{\beta-(3/p)(1-\sigma)}u\|_p\leqslant C\|w^{\beta-(3/r)(1-\sigma)}u\|_r^{1-a}(\|w^{\beta+(1-(3/q))(1-\sigma)}\partial u\|_q + |\beta|\,\|w^{\beta-1+(1-(3/q))(1-\sigma)}u\|_q)^a.$$

Now the trick (18) allows us to pass over to Lie algebra-valued mappings and to replace $|u|$ by $|\Phi|$ and $|\partial u|$ by $|\nabla\Phi|$ in the inequality above. In addition to that, it is only required that the weak derivatives of u_δ are given by the formula

$$\partial_k u_\delta=(|\Phi|^2+\delta^2)^{-1/2}(\nabla_k\Phi,\Phi).$$

Following the proof by Ginibre and Velo[3] it suffices to assume that there exists a sequence $(\Phi)_m$ of continuously differentiable mappings satisfying

$$\Phi_m\to\Phi\quad\text{in}\ L^1_{\mathrm{loc}}(\mathbb{R}^3,\mathcal{G})\ \text{and almost everywhere},$$

$$\nabla_k\Phi_m\to\nabla_k\Phi\quad\text{in}\ L^1_{\mathrm{loc}}(\mathbb{R}^3,\mathcal{G})$$

in order to guarantee the validity of the derivative formula. In particular, Φ does not have to be continuous—local integrability of Φ and its covariant derivatives suffices. Using standard smoothing techniques (see Sec. V E) it is possible to prove that a sequence $(\Phi)_m$ with the desired properties can be constructed if A_k is continuous. Thus

$$\|w^{\beta-(3/p)(1-\sigma)}\Phi\|_p\leqslant C\|w^{\beta-(3/r)(1-\sigma)}\Phi\|_r^{1-a}(\|w^{\beta+(1-(3/q))(1-\sigma)}\nabla\Phi\|_q + |\beta|\,\|w^{\beta-(3/q)(1-\sigma)}\Phi\|_q)^a,$$

where we have also made use of the fact that $w^{-1}\leqslant w^{-(1-\sigma)}$. More generally, we can now apply the above inequality to mth covariant derivatives of Φ provided that the norms on the right-hand side are finite and the assumptions of Theorem 5 are in force. For the Sobolev embeddings we need the following three applications of this inequality:
(1)

$$\|w^{(n-2)(1-\sigma)}\nabla^{n-2}\Phi\|_\infty\leqslant C\,\|w^{(n-5/2)(1-\sigma)}\nabla^{n-2}\Phi\|_6^{1-a}(\|w^{(n-1-3/q)(1-\sigma)}\nabla^{n-1}\Phi\|_q + (n-2)\,\|w^{(n-2-3/q)(1-\sigma)}\nabla^{n-2}\Phi\|_q)^a, \tag{25a}$$

$$q>3,\quad a=\frac{q}{3(q-2)},$$

(2)

$$\|w^{(n-5/2)(1-\sigma)}\nabla^{n-2}\Phi\|_6\leqslant C\,(\|w^{(n-5/2)(1-\sigma)}\nabla^{n-1}\Phi\|_2+(n-2)\,\|w^{(n-7/2)(1-\sigma)}\nabla^{n-2}\Phi\|_2), \tag{25b}$$

(3)

$$\|w^{(n-1-3/q)(1-\sigma)}\nabla^{n-1}\Phi\|_q\leqslant C\,\|w^{(n-5/2)(1-\sigma)}\nabla^{n-1}\Phi\|_2^{1-b}(\|w^{(n-3/2)(1-\sigma)}\nabla^{n}\Phi\|_2 + (n-1)\,\|w^{(n-5/2)(1-\sigma)}\nabla^{n-1}\Phi\|_2)^b, \tag{25c}$$

$$q\leqslant 6,\quad b=3\left(\frac{1}{2}-\frac{1}{q}\right).$$

Here it is assumed that $\Phi\in C_c^n(\mathbb{R}^3,\mathcal{G})$ and the conditions (9) are satisfied. Combining these inequalities and recalling the definitions of the norms $\|\cdot\|_{n,2}$ and $\|\cdot\|_{n-2,\infty}$ we get

$$\|w^{(n-2)(1-\sigma)}\nabla^{n-2}\Phi\|_\infty\leqslant C\,\|\Phi\|_{n,2},$$

and hence

$$\|\Phi\|_{n-2,\infty}\leqslant C\,\|\Phi\|_{n,2}\quad\text{for all}\quad\Phi\in C_c^n(\mathbb{R}^3,\mathcal{G}).$$

Taking a Cauchy sequence $(\Phi)_m\in C_c^n(\mathbb{R}^3,\mathcal{G})$ converging to an element $Z\in H_n(\mathbb{R}^3,\mathcal{G})$ proves the embedding (10) in the limit $m\to\infty$. □

D. Proposition 2

The proof is elementary in principle but tedious in practice. It consists of two parts, the first being straightforward calculus with smooth enough gauge potentials, while in the second part the smoothness assumptions are relaxed by examining the convergence properties of the curvature norms. We begin by assuming that $A_k\in C^n(\mathbb{R}^3,\mathcal{G})$ and then consider a mapping $\Psi\in C_c^3(\mathbb{R}^3,\mathcal{G})$. Making use of the fact that

$$[\nabla_k,\nabla_l]_{\mathrm{op}}\Psi=-[G_{kl},\Psi],$$

where $[\cdot,\cdot]_{\mathrm{op}}$ stands for the operator commutator of two covariant derivatives, we deduce the identity

$$\begin{aligned}w^\beta|\nabla_k\nabla_l\Psi|^2=&\,\partial_l[w^\beta(\nabla_k\Psi,\nabla_k\nabla_l\Psi)]-\partial_k[w^\beta(\nabla_k\Psi,\nabla_l\nabla_l\Psi)]-\partial_k[w^\beta([G_{kl},\Psi],\nabla_l\Psi)]\\&-\partial_k[(\partial_l w^\beta)(\nabla_k\Psi,\nabla_l\Psi)]+(\partial_k\partial_l w^\beta)(\nabla_k\Psi,\nabla_l\Psi)+(\partial_l w^\beta)(\nabla_k\nabla_k\Psi,\nabla_l\Psi)\\&+(\partial_k w^\beta)(\nabla_l\nabla_l\Psi,\nabla_k\Psi)+(\partial_k w^\beta)([G_{kl},\Psi],\nabla_l\Psi)+w^\beta([\nabla_k G_{kl},\Psi],\nabla_l\Psi)\\&-2w^\beta(\nabla_k\Psi,[G_{kl},\nabla_l\Psi])+w^\beta(\nabla_k\nabla_k\Psi,\nabla_l\nabla_l\Psi).\end{aligned}$$

Integrating this equation with the help of the Gauss–Green theorem, the surface terms vanish due to the compact support of Ψ. Let us denote this support by K. Using now Lemma 1 and the inequality

$$|\partial^k w^\beta| \leqslant C w^{\beta-k}$$

together with Hölder's inequality we find the estimate

$$\begin{aligned}\|w^{\beta/2}\nabla^2\Psi\|_2^2 \leqslant C(&\|w^{\beta/2-1}\nabla\Psi\|_2^2 + \|w^{\beta/2}\Delta(A)\Psi\|_2 \|w^{\beta/2-1}\nabla\Psi\|_2 \\ &+ \|w^{2(1-\sigma)}G\|_{\infty,K} \|w^{\beta/2-(2-\sigma)}\Psi\|_2 \|w^{\beta/2-(1-\sigma)}\nabla\Psi\|_2 \\ &+ \|w^{2(1-\sigma)}(\nabla\cdot G)\|_{3,K} \|w^{\beta/2-(1-\sigma)}\Psi\|_6 \|w^{\beta/2-(1-\sigma)}\nabla\Psi\|_2 \\ &+ \|w^{2(1-\sigma)}G\|_{\infty,K} \|w^{\beta/2-(1-\sigma)}\nabla\Psi\|_2^2 + \|w^{\beta/2}\Delta(A)\Psi\|_2^2).\end{aligned}$$

Let us apply this inequality by choosing

$$\Psi = \nabla_{l_1}\cdots\nabla_{l_{n-2}}\Phi, \quad \beta = (2n-3)(1-\sigma).$$

If $n=2$, we employ Proposition 1, inequality (25b), the property $w^{-1} \leqslant w^{-(1-\sigma)}$ and finally Cauchy's inequality to get

$$\begin{aligned}\|w^{(1-\sigma)/2}\nabla^2\Phi\|_2^2 \leqslant C\{&\|w^{(1-\sigma)/2}\Delta(A)\Phi\|_2^2 + (1 + \|w^{2(1-\sigma)}G\|_{\infty,K} \\ &+ \|w^{2(1-\sigma)}(\nabla\cdot G)\|_{3,K}) \|w^{-[(1-\sigma)/2]}\nabla\Phi\|_2^2\}. \end{aligned} \tag{26}$$

This establishes a prestage of inequality (11), where the curvature norms are local, i.e., they are taken over the support of Φ. The constant C depends on Φ only through these curvature norms. For higher order derivatives with $n \geqslant 3$ we use inequality (25b) to bound the derivative norms up to the $(n-1)$th order. The highest order term with the covariant Laplacian is handled by writing

$$\nabla_k\nabla_k\nabla_{l_1}\cdots\nabla_{l_{n-2}}\Phi = \nabla_{l_1}\cdots\nabla_{l_{n-2}}\nabla_k\nabla_k\Phi + [\nabla_k\nabla_k, \nabla_{l_1}\cdots\nabla_{l_{n-2}}]_{\mathrm{op}}\Phi$$

and employing the decomposition

$$\begin{aligned}[\nabla_k\nabla_k, \nabla_{l_1}\cdots\nabla_{l_{n-2}}]_{\mathrm{op}}\Phi = -\sum_{p=0}^{n-3}\sum_{s_1=0}^{1}\cdots\sum_{s_p=0}^{1}(&[\nabla_{l_1}^{s_1}\cdots\nabla_{l_p}^{s_p}\nabla_k G_{kl_{p+1}}, \nabla_{l_1}^{1-s_1}\cdots\nabla_{l_p}^{1-s_p}\nabla_{l_{p+2}}\cdots\nabla_{l_{n-2}}\Phi] \\ &+ 2[\nabla_{l_1}^{s_1}\cdots\nabla_{l_p}^{s_p}G_{kl_{p+1}}, \nabla_{l_1}^{1-s_1}\cdots\nabla_{l_p}^{1-s_p}\nabla_k\nabla_{l_{p+2}}\cdots\nabla_{l_{n-2}}\Phi]),\end{aligned}$$

which can be proved by induction. If $p=0$ or $p=n-3$ this formula requires some interpretation, suppressing those sums and derivatives that become ill-defined. The important thing is to notice that the terms of this decomposition, when summed over k, are bounded in the Lie algebra norm by the norms

$$|\nabla^p(\nabla\cdot G)|\,|\nabla^{n-3-p}\Phi|, \quad |\nabla^p G|\,|\nabla^{n-2-p}\Phi|, \quad 0 \leqslant p \leqslant n-3.$$

Therefore, upon using Hölder's and Cauchy's inequalities together with the estimate (25b), we deduce the bound

$$\begin{aligned}\|w^{(n-3/2)(1-\sigma)}\nabla^n\Phi\|_2^2 \leqslant C\Bigg\{ & \|w^{(n-3/2)(1-\sigma)}\nabla^{n-2}\Delta(A)\Phi\|_2^2 \\ & + \sum_{p=0}^{n-3} (\|w^{(p+2)(1-\sigma)}\nabla^p(\nabla\cdot G)\|_{3,K}^2 \|\Phi\|_{n-2-p,2}^2 \\ & + \|w^{(p+2)(1-\sigma)}\nabla^p G\|_{\infty,K}^2 \|\Phi\|_{n-2-p,2}^2) \\ & + (1+\|w^{2(1-\sigma)}G\|_{\infty,K} + \|w^{2(1-\sigma)}(\nabla\cdot G)\|_{3,K}) \|\Phi\|_{n-1,2}^2 \Bigg\}, \end{aligned} \tag{27}$$

which in turn leads to an inequality like (11) with local curvature norms.

We are now done with the first part of the proof. The requirement $A_k \in C^n(\mathbb{R}^3,\mathcal{G})$ was dictated by the Gauss–Green theorem, but we can relax this condition by a few orders of smoothness. In fact, the assumptions (9) will prove to be sufficient for Proposition 2 to hold. The technique is to apply the estimates (26) and (27) to mollified gauge potentials. If the norms appearing in these inequalities converge to the original norms in the limit when the mollification is removed, we have succeeded in proving the inequalities with relaxed smoothness assumptions. Mollification is defined by the usual formula

$$A_k^{(\delta)}(x) = (\eta_\delta * A_k)(x) = \int \eta_\delta(x-y)A_k(y)\, d^3y$$

with

$$\eta_\delta(x) = \frac{1}{\delta^3}\eta\left(\frac{x}{\delta}\right), \quad \eta(x) = \begin{cases} C\exp\left(-\dfrac{1}{1-|x|^2}\right), & |x|<1 \\ 0, & |x|\geqslant 1, \end{cases} \quad \int \eta(x)\, d^3x = 1.$$

It is also assumed that all derivatives of the gauge potential A_k up to the highest order implied by the curvature norms are at least locally integrable. This assumption ensures that the order of differentiation and mollification can be reversed. The covariant derivative related to the mollified potential will be denoted by

$$\nabla_k^{(\delta)} = \partial_k + [A_k^{(\delta)}, \cdot\,],$$

and the corresponding curvature form is

$$\hat{G}_{kl}^{(\delta)} = \partial_l A_k^{(\delta)} - \partial_k A_l^{(\delta)} - [A_k^{(\delta)}, A_l^{(\delta)}].$$

Also define a mollified norm $|\nabla^p G|^{(\delta)}$ by

$$|\nabla^p G|^{(\delta)} = \left(\sum_{k_1} \cdots \sum_{k_p} \sum_l \sum_m \left| \int \eta_\delta(x-y)\nabla_{k_1}\cdots\nabla_{k_p} G_{lm}(y)\, d^3y \right|^2 \right)^{1/2}.$$

It is well-known that in the limit $\delta \to 0$

$$\|w^{(p+2)(1-\sigma)}|\nabla^p G|^{(\delta)}\|_{\infty,K} \to \|w^{(p+2)(1-\sigma)}|\nabla^p G|\,\|_{\infty,K}, \tag{28}$$

when $\nabla^p G_{lm} \in C(\mathbb{R}^3,\mathcal{G})$. However, we eventually need the result

$$\|w^{(p+2)(1-\sigma)}|(\nabla^{(\delta)})^p \hat{G}^{(\delta)}|\,\|_{\infty,K} \to \|w^{(p+2)(1-\sigma)}|\nabla^p G|\,\|_{\infty,K}, \tag{29}$$

and this can be proved using the limit (28) combined with the estimate

$$\| w^{(p+2)(1-\sigma)}(|\nabla^p G|^{(\delta)} - |(\nabla^{(\delta)})^p \hat{G}^{(\delta)}|)\|_{\infty,K}$$
$$\leqslant \sum_{k_1} \cdots \sum_{k_p} \sum_{l} \sum_{m} \| w^{(p+2)(1-\sigma)} |\, \eta_\delta * (\nabla_{k_1} \cdots \nabla_{k_p} G_{lm}) - \nabla^{(\delta)}_{k_1} \cdots \nabla^{(\delta)}_{k_p} \hat{G}^{(\delta)}_{lm}| \,\|_{\infty,K}. \tag{30}$$

Using the decomposition

$$\nabla_{k_1} \cdots \nabla_{k_p} G_{lm} = \sum_{j=0}^{p} \sum_{i_1=1}^{i_2-1} \cdots \sum_{i_j=j}^{p} \partial_{k_1} \cdots \partial_{k_{i_1-1}} (\mathrm{ad} A_{k_{i_1}}) \partial_{k_{i_1+1}} \cdots \partial_{k_{i_j-1}} (\mathrm{ad}\, A_{k_{i_j}}) \partial_{k_{i_j+1}} \cdots \partial_{k_p} G_{lm} \tag{31}$$

with the notation $\mathrm{ad}\, A_k = [A_k, \cdot\,]$ and recalling the definition of the curvature form we see that each term of this decomposition takes the form

$$\mathrm{ad}(\partial^{\alpha_{i_1}} A_{k_{i_1}}) \cdots \mathrm{ad}(\partial^{\alpha_{i_j}} A_{k_{i_j}}) \partial^{\alpha_{i_{j+1}}} A_{k_{p+2}}, \tag{32a}$$

where the multi-indices α_{i_j} satisfy

$$\sum_{s=1}^{j+1} |\alpha_{i_s}| = p+1-j, \quad 0 \leqslant j \leqslant p+1. \tag{32b}$$

Since there are a finite number of terms in the formulas (30) and (31) altogether, it suffices to consider each term separately. In inequality (30) the contribution from each term of the form (32a) is

$$\begin{aligned}
&\| w^{(p+2)(1-\sigma)} |\, \eta_\delta * (\mathrm{ad}(\partial^{\alpha_{i_1}} A_{k_{i_1}}) \cdots \mathrm{ad}(\partial^{\alpha_{i_j}} A_{k_{i_j}}) \partial^{\alpha_{i_{j+1}}} A_{k_{p+2}}) \\
&\quad - \mathrm{ad}(\partial^{\alpha_{i_1}} A^{(\delta)}_{k_{i_1}}) \cdots \mathrm{ad}(\partial^{\alpha_{i_j}} A^{(\delta)}_{k_{i_j}}) \partial^{\alpha_{i_{j+1}}} A^{(\delta)}_{k_{p+2}} | \,\|_{\infty,K} \\
&\leqslant \operatorname*{ess\,sup}_{x \in K} C \left| \int d^3y_1 \cdots d^3y_{j+1}\, \eta_\delta(x-y_1) \cdots \eta_\delta(x-y_{j+1}) \right. \\
&\qquad \times \{ \mathrm{ad}(\partial^{\alpha_{i_1}} A_{k_{i_1}}(y_{j+1})) \cdots \mathrm{ad}(\partial^{\alpha_{i_j}} A_{k_{i_j}}(y_{j+1})) \partial^{\alpha_{i_{j+1}}} A_{k_{p+2}}(y_{j+1}) \\
&\qquad \left. - \mathrm{ad}(\partial^{\alpha_{i_1}} A_{k_{i_1}}(y_1)) \cdots \mathrm{ad}(\partial^{\alpha_{i_j}} A_{k_{i_j}}(y_j)) \partial^{\alpha_{i_{j+1}}} A_{k_{p+2}}(y_{j+1}) \} \right| \qquad (33a) \\
&\leqslant C \sum_{s=1}^{j} \operatorname*{ess\,sup}_{x \in K} \left| \int d^3y_1 \cdots d^3y_{j+1}\, \eta_\delta(x-y_1) \cdots \eta_\delta(x-y_{j+1}) \right. \\
&\qquad \times \mathrm{ad}(\partial^{\alpha_{i_1}} A_{k_{i_1}}(y_{j+1})) \cdots \mathrm{ad}(\partial^{\alpha_{i_s}} A_{k_{i_s}}(y_{j+1}) - \partial^{\alpha_{i_s}} A_{k_{i_s}}(y_s)) \\
&\qquad \left. \times \mathrm{ad}(\partial^{\alpha_{i_{s+1}}} A_{k_{i_{s+1}}}(y_{s+1})) \cdots \partial^{\alpha_{i_{j+1}}} A_{k_{p+2}}(y_{j+1}) \right|, \quad j \geqslant 1, \qquad (33b)
\end{aligned}$$

and in the case $j=0$ expression (33a) vanishes. The constant C corresponds to the upper bound of the weight factor on K, and in deriving the last inequality the formula

$$\mathrm{ad}\, B_1 \cdots \mathrm{ad}\, B_m - \mathrm{ad}\, C_1 \cdots \mathrm{ad}\, C_m = \sum_{s=1}^{m} \mathrm{ad}\, B_1 \cdots \mathrm{ad}(B_s - C_s) \mathrm{ad}\, C_{s+1} \cdots \mathrm{ad}\, C_m$$

was used. Applying now Hölder's inequality and Lemma 1 to the expression (33b) we see that each term in the sum is bounded by

$$\operatorname*{ess\,sup}_{\substack{y_s,y_{j+1}\in K_\delta\\ |y_s-y_{j+1}|\leqslant 2\delta}}\left|\partial^{\alpha_{i_s}}A_{k_{i_s}}(y_{j+1})-\partial^{\alpha_{i_s}}A_{k_{i_s}}(y_s)\right|\prod_{\substack{r=1\\ r\neq s}}^{j+1}\operatorname*{ess\,sup}_{y\in K_\delta}\left|\partial^{\alpha_{i_r}}A_{k_{i_r}}(y)\right|,$$

$$K_\delta=\{x\in\mathbb{R}^3\,|\,\mathrm{dist}(x,K)\leqslant\delta\}.$$

Since now

$$|\alpha_{i_s}|\leqslant p\leqslant p_{\max}=\begin{cases}0, & n=2,\\ n-3, & n\geqslant 3,\end{cases}$$

the bound above tends to zero in the limit $\delta\to 0$ for gauge potentials of class $C^{p_{\max}}(\mathbb{R}^3,\mathcal{G})$. As a result,

$$\|\,w^{(p+2)(1-\sigma)}(|\nabla^p G|^{(\delta)}-|(\nabla^{(\delta)})^p\hat{G}^{(\delta)}|)\|_{\infty,K}\to 0,$$

and together with the limit (28) this establishes the desired convergence property (29). The L^3 curvature norm is treated similarly. We define a mollified norm

$$|\nabla^p(\nabla\cdot G)|^{(\delta)}=\left(\sum_{k_1}\cdots\sum_{k_p}\sum_m\left|\int\eta_\delta(x-y)\nabla_{k_1}\cdots\nabla_{k_p}\sum_l\nabla_l G_{lm}(y)\,d^3y\right|^2\right)^{1/2},$$

which satisfies

$$\|w^{(p+2)(1-\sigma)}|\nabla^p(\nabla\cdot G)|^{(\delta)}\|_{3,K}\xrightarrow[\delta\to 0]{}\|w^{(p+2)(1-\sigma)}|\nabla^p(\nabla\cdot G)|\,\|_{3,K}\tag{34}$$

when $|\nabla^p(\nabla\cdot G)|\in L^3_{\mathrm{loc}}$. An estimate for the norm

$$\|\,w^{(p+2)(1-\sigma)}(|\nabla^p(\nabla\cdot G)|^{(\delta)}-|(\nabla^{(\delta)})^p(\nabla^{(\delta)}\cdot\hat{G}^{(\delta)})|)\|_{\,3,K}\tag{35}$$

is obtained by decomposing the expression

$$\nabla_{k_1}\cdots\nabla_{k_p}\sum_l\nabla_l G_{lm}$$

into terms of the form (32) with p replaced by $p+1$ as there is one additional derivative now. As before, only terms with $j\geqslant 1$ contribute to the norm (35), these contributions being bounded by the integrals

$$\begin{aligned}&\int_K d^3x\left|\int d^3y_1\cdots d^3y_{j+1}\,\eta_\delta(y_1)\cdots\eta_\delta(y_{j+1})\,\mathrm{ad}(\partial^{\alpha_{i_1}}A_{k_{i_1}}(x-y_{j+1}))\cdots\right.\\ &\left.\times\,\mathrm{ad}(\partial^{\alpha_{i_s}}A_{k_{i_s}}(x-y_{j+1})-\partial^{\alpha_{i_s}}A_{k_{i_s}}(x-y_s))\,\mathrm{ad}(\partial^{\alpha_{i_{s+1}}}A_{k_{i_{s+1}}}(x-y_{s+1}))\cdots\partial^{\alpha_{i_{j+1}}}A_{k_{p+3}}(x-y_{j+1})\right|^3\\ &\leqslant C\operatorname*{ess\,sup}_{|y_1|\leqslant\delta}\cdots\operatorname*{ess\,sup}_{|y_{j+1}|\leqslant\delta}\int_K d^3x\,(|\,\partial^{\alpha_{i_1}}A_{k_{i_1}}(x-y_{j+1})|\cdots|\,\partial^{\alpha_{i_s}}A_{k_{i_s}}(x-y_{j+1})-\partial^{\alpha_{i_s}}A_{k_{i_s}}(x-y_s)|\\ &\quad\times|\,\partial^{\alpha_{i_{s+1}}}A_{k_{i_{s+1}}}(x-y_{s+1})|\cdots|\,\partial^{\alpha_{i_{j+1}}}A_{k_{p+3}}(x-y_{j+1})|)^3.\end{aligned}\tag{36}$$

The last inequality was derived by employing Lemma 1 and Hölder's inequality repeatedly. Now if $j \geqslant 2$, we have $|\alpha_{i_s}| \leqslant p_{\max}$ and the integrand of the estimate (36) is continuous, meaning that the whole expression vanishes in the limit $\delta \to 0$. In the case $j=1$ there are two multi-indices satisfying

$$|\alpha_{i_1}| + |\alpha_{i_2}| \leqslant p_{\max} + 1.$$

If one of them takes the maximal value, the other vanishes and accordingly, we can make use of the fact that $\partial^{p_{\max}+1} A_k \in L^3_{\mathrm{loc}}(\mathbb{R}^3, \mathcal{G})$ and employ Hölder's inequality to get such a bound for the integral (36) that it vanishes when δ is sent to zero. As a result, the norm (35) also has a vanishing limit, and combined with the limit (34) we get

$$\| w^{(p+2)(1-\sigma)} | (\nabla^{(\delta)})^p (\nabla^{(\delta)} \cdot \hat{G}^{(\delta)}) | \|_{3,K} \to \| w^{(p+2)(1-\sigma)} | \nabla^p (\nabla \cdot G) | \|_{3,K}. \tag{37}$$

It still remains to consider the convergence of the Sobolev norms. Let us denote by $\|\Phi\|^{(\delta)}_{n,2}$ the norm evaluated with the mollified gauge potential. From the estimate

$$| \|\Phi\|_{n,2} - \|\Phi\|^{(\delta)}_{n,2} | \leqslant \sum_{p=1}^{n} \sum_{k_1} \cdots \sum_{k_p} \| w^{(p-3/2)(1-\sigma)} | \nabla_{k_1} \cdots \nabla_{k_p} \Phi - \nabla^{(\delta)}_{k_1} \cdots \nabla^{(\delta)}_{k_p} \Phi | \|_2 \tag{38}$$

and the decomposition of the derivatives $\nabla_{k_1} \cdots \nabla_{k_p} \Phi$ into terms of the form

$$\mathrm{ad}(\partial^{\alpha_{i_1}} A_{k_{i_1}}) \cdots \mathrm{ad}(\partial^{\alpha_{i_j}} A_{k_{i_j}}) \partial^{\alpha_{i_{j+1}}} \Phi,$$

$$\sum_{s=1}^{j+1} |\alpha_{i_s}| = p - j, \quad 0 \leqslant j \leqslant p$$

it is evident that each term in inequality (38) is bounded by integrals of the form

$$\begin{aligned}
&\int_K d^3x \left| \int d^3y_1 \cdots d^3y_j \, \eta_\delta(y_1) \cdots \eta_\delta(y_j) \mathrm{ad}(\partial^{\alpha_{i_1}} A_{k_{i_1}}(x)) \cdots \mathrm{ad}(\partial^{\alpha_{i_s}} A_{k_{i_s}}(x) - \partial^{\alpha_{i_s}} A_{k_{i_s}}(x - y_s)) \right. \\
&\left. \times \mathrm{ad}(\partial^{\alpha_{i_{s+1}}} A_{k_{i_{s+1}}}(x - y_{s+1})) \cdots \partial^{\alpha_{i_{j+1}}} \Phi(x) \right|^2 \\
&\leqslant C \operatorname*{ess\,sup}_{|y_1| \leqslant \delta} \cdots \operatorname*{ess\,sup}_{|y_j| \leqslant \delta} \int_K d^3x \, (|\partial^{\alpha_{i_1}} A_{k_{i_1}}(x)| \cdots |\partial^{\alpha_{i_s}} A_{k_{i_s}}(x) - \partial^{\alpha_{i_s}} A_{k_{i_s}}(x - y_s)| \\
&\quad \times |\partial^{\alpha_{i_{s+1}}} A_{k_{i_{s+1}}}(x - y_{s+1})| \cdots |\partial^{\alpha_{i_{j+1}}} \Phi(x)|)^2
\end{aligned} \tag{39}$$

with $j \geqslant 1$. Inspection of all possible values of the multi-indices $|\alpha_{i_s}|$ indicates that the previous smoothness assumptions, complemented by $\partial^{n-1} A_k \in L^2_{\mathrm{loc}}(\mathbb{R}^3, \mathcal{G})$, are sufficient to make the bound (39) vanish in the limit $\delta \to 0$. What this means is that

$$\|\Phi\|^{(\delta)}_{n,2} \to \|\Phi\|_{n,2},$$

and together with the limits (29) and (37) this completes the proof of inequalities (26) and (27) under the relaxed assumptions (9). Replacing the local curvature norms by global ones we finally find ourselves at the end of this long proof. □

E. Lemma 2

Intuitively this lemma is rather obvious, but strictly speaking we do not yet know that a smooth enough sequence converging in $H_{n-1}(\mathbb{R}^3, \mathcal{G})$ also converges in the norm involving the

covariant Laplacian. The proof follows the usual steps, beginning with approximations with truncated mappings and ending with density results for mollified mappings. A sequence of truncated mappings is defined by

$$Z_m(x)=\tau_m(x)Z(x)$$

with

$$\tau_m(x)=\tau\left(\frac{x}{m}\right),\quad \tau(x)=\begin{cases}1, & 0\leqslant|x|\leqslant 1,\\ 0, & |x|\geqslant 2.\end{cases}$$

When $1\leqslant|x|\leqslant 2$, it is assumed that τ is infinitely smooth and $0\leqslant\tau(x)\leqslant 1$. In order to approximate the Sobolev norm we notice that

$$\|Z_m-Z\|_{n-1,2}\leqslant\sum_{p=1}^{n-1}\sum_{k_1}\cdots\sum_{k_p}\|w^{(p-3/2)(1-\sigma)}\nabla_{k_1}\cdots\nabla_{k_p}(Z_m-Z)\|_2 \tag{40}$$

and then estimate each term in the sum separately. The covariant derivatives are decomposed as

$$\nabla_{k_1}\cdots\nabla_{k_p}(Z_m-Z)=(\tau_m-1)\nabla_{k_1}\cdots\nabla_{k_p}Z+\sum_{|\alpha|\leqslant p-1}{}'\ (\partial^{\alpha_c}\tau_m)\,\nabla^{\alpha}Z, \tag{41}$$

where the prime indicates that the indices of α are assumed to be in ascending order,

$$\alpha=(k_{i_1},\ldots,k_{i_q}),\quad 1\leqslant i_1<\cdots<i_q\leqslant p,$$

and where α_c stands for the complement of α, i.e.,

$$\alpha_c=(k_1,\ldots,k_p)\backslash\alpha.$$

The norm of the first term in the decomposition (41) can be made small by using the result that

$$\int_{|x|\geqslant m}w^{(2p-3)(1-\sigma)}|\nabla^p Z|^2\,d^3x\xrightarrow[m\to\infty]{}0, \tag{42}$$

when $Z\in H_{n-1}(\mathbb{R}^3,\mathcal{G})$. For the remaining terms with $|\alpha|\geqslant 1$ we deduce the bound

$$\int w^{(2p-3)(1-\sigma)}|\partial^{\alpha_c}\tau_m|^2\,|\nabla^{\alpha}Z|^2\,d^3x\leqslant\left(\sup_{1\leqslant|x|/m\leqslant 2}w^{2(p-|\alpha|)(1-\sigma)}|\partial^{\alpha_c}\tau_m|^2\right)\times\int_{1\leqslant|x|/m\leqslant 2}w^{(2|\alpha|-3)(1-\sigma)}|\nabla^{\alpha}Z|^2\,d^3x. \tag{43}$$

The factor on the right-hand side is bounded, because

$$\sup_{1\leqslant|x|/m\leqslant 2}w(x)^{2(p-|\alpha|)(1-\sigma)}|\partial^{\alpha_c}\tau_m(x)|^2\leqslant m^{-2(p-|\alpha|)\sigma}\sup_{1\leqslant\xi\leqslant 2}w(\xi)^{2(p-|\alpha|)(1-\sigma)}|\partial^{\alpha_c}\tau(\xi)|^2,$$

$$\xi=\frac{x}{m},$$

and the integral in the formula (43) tends to zero by virtue of the limit (42). Similarly, the term with $|\alpha|=0$, $\alpha_c=(k_1,\ldots,k_p)$ is seen to converge to zero by the estimates

$$\int w^{(2p-3)(1-\sigma)}\left|\partial^{\alpha_c}\tau_m\right|^2|Z|^2\,d^3x \leqslant \left(\sup_{1\leqslant|x|/m\leqslant 2} w^{2p-2(p-1)\sigma}\left|\partial^{\alpha_c}\tau_m\right|^2\right) \times \int_{1\leqslant|x|/m\leqslant 2} w^{-(3-\sigma)}|Z|^2\,d^3x$$

and

$$\sup_{1\leqslant|x|/m\leqslant 2} w(x)^{2p-2(p-1)\sigma}\left|\partial^{\alpha_c}\tau_m(x)\right|^2 \leqslant m^{-2(p-1)\sigma}\sup_{1\leqslant\xi\leqslant 2} w(\xi)^{2p-2(p-1)\sigma}\left|\partial^{\alpha_c}\tau(\xi)\right|^2.$$

The norm with the covariant Laplacian is handled similarly, employing the decomposition

$$\nabla_{k_1}\cdots\nabla_{k_{n-2}}\Delta(A)(Z_m-Z)=(\tau_m-1)\nabla_{k_1}\cdots\nabla_{k_{n-2}}\Delta(A)Z+\sum_l{\sum_{|\alpha|\leqslant n-1}}'\ (\partial^{\hat{\alpha}_c}\tau_m)\,\nabla^{\alpha}Z$$

with

$$\hat{\alpha}_c=(k_1,\ldots,k_{n-2},l,l)\backslash\alpha.$$

The first term yields a norm tending to zero due to the assumption (12), and the other terms are made small by the limit (42). Since there are a finite number of terms in both decompositions, we see that it is possible to choose a truncated mapping Z_m arbitrarily close to Z in both norms.

The mapping Z_m above vanishes (modulo sets of measure zero) outside some compact set K. Therefore we can define a mapping of class $C_c^{\infty}(\mathbb{R}^3,\mathcal{G})$ by

$$\Phi^{(\delta)}(x)=\int \eta_\delta(y)Z_m(x-y)\,d^3y.$$

Let us now estimate the distance of this mapping from Z_m in the two norms in question. Making use of formula (40) with Z replaced by $\Phi^{(\delta)}$ we are led to consider weighted L^2 norms of the derivatives $\left|\nabla^p(\Phi^{(\delta)}-Z_m)\right|$. For this purpose we write

$$\nabla_k^{(x)}Z_m(x-y)=(\nabla_k^{(x-y)}+\mathrm{ad}\mathcal{A}_k(x,y))Z_m(x-y),$$

$$\mathcal{A}_k(x,y)=A_k(x)-A_k(x-y),$$

and derive a decomposition similar to Eq. (31),

$$\begin{aligned}\nabla_{k_1}^{(x)}\cdots\nabla_{k_p}^{(x)}Z_m(x-y)&=\sum_{j=0}^{p}\sum_{i_1=1}^{i_2-1}\cdots\sum_{i_j=j}^{p}\nabla_{k_1}^{(x-y)}\cdots\nabla_{k_{i_1-1}}^{(x-y)}\\&\quad\times(\mathrm{ad}\mathcal{A}_{k_{i_1}})\nabla_{k_{i_1+1}}^{(x-y)}\cdots\nabla_{k_{i_j-1}}^{(x-y)}(\mathrm{ad}\mathcal{A}_{k_{i_j}})\nabla_{k_{i_j+1}}^{(x-y)}\cdots\nabla_{k_p}^{(x-y)}Z_m(x-y)\\&=\nabla_{k_1}^{(x-y)}\cdots\nabla_{k_p}^{(x-y)}Z_m(x-y)+\cdots,\end{aligned}\tag{44}$$

where the remaining terms take the form

$$\mathrm{ad}(\nabla_{(x-y)}^{\alpha_{i_1}}\mathcal{A}_{k_{i_1}})\cdots\mathrm{ad}(\nabla_{(x-y)}^{\alpha_{i_j}}\mathcal{A}_{k_{i_j}})\nabla_{(x-y)}^{\alpha_{i_{j+1}}}Z_m(x-y)\tag{45a}$$

with

$$\sum_{s=1}^{j+1}|\alpha_{i_s}|=p-j\,,\quad 1\leqslant j\leqslant p\,.\tag{45b}$$

The first term of the decomposition (44) is combined with the pth covariant derivative of $Z_m(x)$ to get a bound

$$\int_{K_\delta} d^3x\, w(x)^{(2p-3)(1-\sigma)} \left| \int d^3y\ \eta_\delta(y)(\nabla_{k_1}^{(x-y)}\cdots\nabla_{k_p}^{(x-y)} Z_m(x-y) - \nabla_{k_1}^{(x)}\cdots\nabla_{k_p}^{(x)} Z_m(x)) \right|^2$$

$$\leqslant C \operatorname*{ess\,sup}_{|y|\leqslant\delta} \int_{K_\delta} d^3x \,|\, \nabla_{k_1}^{(x-y)}\cdots\nabla_{k_p}^{(x-y)} Z_m(x-y) - \nabla_{k_1}^{(x)}\cdots\nabla_{k_p}^{(x)} Z_m(x) \,|^{\,2},$$

which tends to zero in the limit $\delta\to 0$, because now $\nabla^p Z_m \in L^2_{\mathrm{loc}}(\mathbb{R}^3,\mathcal{G})$. For terms of the form (45) we get bounds of the form

$$\operatorname*{ess\,sup}_{|y|\leqslant\delta} \int_{K_\delta} d^3x\, (|\nabla_{(x-y)}^{\alpha_{i_1}} \mathcal{A}_{k_{i_1}}| \cdots |\nabla_{(x-y)}^{\alpha_{i_j}} \mathcal{A}_{k_{i_j}}|\, |\nabla_{(x-y)}^{\alpha_{i_{j+1}}} Z_m(x-y)|)^2.$$

Making use of Hölder's inequality and the fact that Z_m is continuous for $n\geqslant 3$ we can check that conditions (9) are sufficient to make this integral converge to zero as $\delta\to 0$. The Laplacian norm is treated identically, writing

$$\nabla_{k_1}^{(x)}\cdots\nabla_{k_{n-2}}^{(x)} \Delta^{(x)}(A) Z_m(x-y) = \nabla_{k_1}^{(x-y)}\cdots\nabla_{k_{n-2}}^{(x-y)} \Delta^{(x-y)}(A) Z_m(x-y) + \cdots,$$

where the remaining terms take the form (45) with p replaced by n. For the first term we use the property that $\nabla^{n-2}\Delta(A) Z_m \in L^2_{\mathrm{loc}}(\mathbb{R}^3,\mathcal{G})$ and for the others the properties

$$Z_m \in L^6_{\mathrm{loc}}(\mathbb{R}^3,\mathcal{G}), \quad n\geqslant 2,$$

$$Z_m \in C(\mathbb{R}^3,\mathcal{G}), \quad \nabla^1 Z_m \in L^6_{\mathrm{loc}}(\mathbb{R}^3,\mathcal{G}), \quad n\geqslant 3.$$

There being only a finite number of terms, we can thus always find a mapping $\Phi^{(\delta)}$ arbitrarily close to Z_m in both norms. Accordingly, we can construct a sequence (Φ_m) converging to Z in these norms. □

(Received 15 December 2003; accepted 29 March 2004; published online 14 June 2004)

A bi-Hamiltonian system is a system of differential equations which can be written in Hamiltonian form in two distinct ways. The applications of Gelfand–Zakharevich bi-Hamiltonian structure, which is an extension of a Poisson–Nijenhuis structure on phase space, has been extensively explored by Falqui, Magri, and Pedroni in the context of separation of variables. It is well known that the integrable Hamiltonian systems defined by the Adler–Kostant–Symes (AKS) scheme contains bi-Hamiltonian structure. In this paper we unveil the connection between Adler–Kostant–Symes formalism applied to loop algebra and the Gelfand–Zakharevich bi-Hamiltonian structure by superposition the results of Fordy and Kulish in the AKS scheme. We also study the commuting flows of the AKS hierachy and its connection to the Zakharov–Shabat hierarchy. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1756698]

I. INTRODUCTION

One of the many important aspects of soliton theory is the interpretation of soliton equations as completely integrable Hamiltonian systems.[13] A particularly important notion to have arisen in this theory is that of bi-Hamiltonian systems (cf. Ref. 5), i.e., they are Hamiltonian with respect to two different compatible Hamiltonian operators.

In 1978 Magri[29] proved a remarkable theorem that, subject to some technical hypothesis, any such bi-Hamiltonian system is completely integrable in the sense that it possesses an infinite number of conservation laws in involution. Bi-Hamiltonian systems appear to be very special situation, yet, they occur in numerous situations as model equations for more complicated physical systems. Examples include the Korteweg–de Vries (KdV) equation, the Boussinesq equation, and most of the other soliton equations. Later Magri's result has been further refined by Gelfand and Dorfman,[17,18] and Fuchssteiner and Fokas.[16]

From the Poisson geometry's point of view, a bi-Hamiltonian manifold is a Poisson manifold endowed with a pair of compatible Poisson brackets.[10,11] A direct consequence of compatibility is the existence of an infinite [in the case of partial differential equations (PDEs)] sequence of Hamiltonians which commute with respect to all the compatible Poisson brackets.

In the late 1970s, Adler[3] proposed a scheme for deriving such Hamiltonian operators starting from a given Lax operator. Gelfand and Dikii[19] proved that Adler's scheme indeed produces Hamiltonian operators. Adler's approach was based on Lie algebraic structure on the space of pseudodifferential operators. This paper represents a beautiful extension of work of Kostant.[27] The crucial observation is that in both cases the corresponding symplectic structure is the orbit symplectic structure of Kostant and Kirillov.

Later, Symes[38,39] has ellucided the extension of the classical Toda system results to Hamiltonian systems on so-called Toda orbits, a wider class than the Jacobi sets of split semisimple Lie algebras considered by Kostant.[27]

Following the above scheme, we are now able to construct in a systematic way completely integrable systems. This scheme is popularly called Adler–Kostant–Symes (AKS) scheme. The AKS scheme applying to some Lie algebra $\mathfrak{g}$ equipped with an ad-invariant nondegenerate bilin-

ear form yields various integrable systems. In other words, this construction associates Hamiltonian systems that are in many cases integrable with certain Lie algebraic data. It was shown by Reyman and Semenov-Tian-Shansky[33–36] that these systems may be viewed as symmetry reductions of corresponding Hamiltonian systems on cotangent bundles of Lie groups generated by Hamiltonians invariant under left and right translations.

We assume the Lie algebra $\mathfrak{g}$ be a vector space, presented as the linear sum of two subalgebras $\mathfrak{g}=k+l$. The bilinear form $\langle .,. \rangle$ induces an isomorphism $\mathfrak{g}\simeq\mathfrak{g}^*$. Hence, with the help of bilinear form we can identify $k^*\simeq l^\perp$ and $l^*\simeq k^\perp$ where

$$\langle k^\perp, k\rangle = \langle l^\perp, l\rangle = 0.$$

So $k^\perp$ acquires a Poisson structure from that of l^*. The co-adjoint action of L on $k^\perp\simeq l^*$ is given by

$$g\circ p = \pi_{k^\perp}(gpg^{-1})$$

for $g\in L$ and $p\in k^\perp$. Then the infinitesimal action is $\eta(p)=\pi_k^\perp[\eta,p]$ for $\eta\in l$.

The symplectic manifold here is some co-adjoint L-orbit $\mathcal{M}\subset k^\perp\simeq l^*$. We associate to it a Hamiltonian equation of suitable ad-invariant function $f:\mathfrak{g}^*\to R$ for all $f|_{\mathcal{M}}$.

We know many important equations can be derived from this approach, for example, Adler and van Moerbeke[4] obtained Euler–Arnold–Poincaré equation as a geodesic flow on ellipsoid, Ratiu[32] obtained the Neumann equation, and so on. These are all finite-dimensional systems. To apply this formalism to partial differential equation we must work with the infinite-dimensional Lie algebras. This was demonstrated on loop algebras by Reyman, Semenov-Tian-Shansky, and Frenkel.[33–36]

Using a pencil of R-matrices on the Lie algebra, Burrough[6] proved that the KdV hierarchies have an Adler–Kostant–Symes construction on the underlying current algebra. The co-adjoint orbits are reduced by Hamiltonian symmetries (cf. Ref. 30). The reduction process reproduces the gauge group and the bi-Hamiltonian structure.

Thus, this entices one to apply AKS method to construct hierarchy of commuting Hamiltonians of various integrable systems related to infinite-dimensional Lie algebras. At this stage of integrable systems, all of us are looking for a unified theory of various integrable systems. Naturally, AKS scheme is considered to be very appealing. Recently, people turn their attention to the self-dual Yang–Mills (SDYM) equations. The SDYM equations are an important example of a multidimensional integrable system, with all the properties one would expect from an integrable system. An additional property is that this system contains many lower-dimensional systems (such as the KdV and NLS equations) via a process of dimensional reduction. Naturally, almost all integrable equations on $(1+1)$ can be derived from the four-dimensional SDYM equation by reductions. Thus, various reductions of the SDYM equation become a primary source to construct large classes of integrable systems. We have seen that the AKS scheme also yields various 1 $+1$ dimensional integrable equations.

This idea has been generalized to hierarchy level by Ablowitz, Chakravarty, and Takhtajan.[1] They developed the notion of a self-dual Yang–Mills hierarchy (with first member the original self-dual Yang–Mills equations) by introducing an infinite number of higher-order times in such a way that all the flows commute, together with a recursion operator which takes one between adjacent members of the hierarchy. In our earlier work[23,24] we have shown that the PDE version of the AKS hierarchy is the reduction of $1+1$ dimensional SDYM hierarchy.

We have already said that a differential equation is called bi-Hamiltonian if it can be written in Hamiltonian form in two distinct ways with respect to two different Poisson structures $\{.,.\}_0$ and $\{.,.\}_1$:

$$\dot{f}=\{f,H_0\}_0=\{f,H_1\}_1$$

for some functions $H_0, H_1\in C^\infty(M)$.

Suppose one of the Poisson structures is nondegenerate, then this allows us to define a recursion operator $R=P_1P_0^{-1}$, where P_0 and P_1 are the Poisson tensors associated with the brackets $\{.,.\}_0$ and $\{.,.\}_1$, respectively. This recursion operator R can be used to construct a family of functions which are first integrals to the Hamiltonian system and these functions turn out to be in involution with respect to both Poisson brackets. This suffices to show the integrability in the sense Liouville of the Hamiltonian system.[2]

Thus an important class of bi-Hamiltonian manifold occurs when one element of the Poisson pencil is everywhere invertible. As a remarkable consequence of the compatibility of P_0 and P_1 the Nijenhuis torsion of N (or recursion operator), defined by its action on a pair of vector fields X and Y as

$$T(N)(X,Y)=[NX.NY]-N([NX,Y]+[X,NY]-N[X,Y]),$$

vanishes identically.

The recursion operator is interpreted as Nijenhuis operators, and possessses the Nijenhuis property, for finite-dimensional systems was introduced in 1951, and for infinite-dimensional systems by Fuchssteiner.[15] In the infinite-dimensional case Nijenhuis operators are nonlocal, and this problem has been overcomed by Gelfand and Dorfman[18] in by working with Nijenhuis relations instead of Nijenhuis operators. The connection between bi-Hamiltonian structures and AKS scheme and the Lie pencil of R-matrices has been studied in Refs. 25, 31, and 34.

Recently, the famous Italian School of integrable systems[9–12] has considered a more general case of a Poisson manifold together with a pencil of Poisson tensors. The assumption of polynomial Casimirs allows one to use the theory of Gelfand–Zakharevich (GZ) manifolds.[20–22] The Gelfand–Zakharevich bi-Hamiltonian structure is an extension of a Poisson–Nijenhuis structure[28,41] on phase space. The polynomial Casimirs are computed in the spirit of the GZ scheme. Under some technical assumptions the resulting system is separable in Darboux–Nijenhuis coordinates. Thus, they found a new test of separability for a special class of Hamiltonian integrable systems defined on bi-Hamiltonian manifolds. This defines the notion of Stäckel-separable systems,[26] criteria for separability and outline the construction of these separating coordinates. An interesting fact is that the eigenvalues of the Nijenhuis tensor account for one-half of the separating variables. Actually, this is the main issue studied by both the classical Eisenhart–Benenti theory of separability of natural systems defined on cotangent bundles to Riemannian manifolds, as well as the present theory of separation of variables for systems admitting a Lax representation (see Ref. 37, and references therein).

In fact, Italian school unveiled the deep links connecting the classical theory of separation of variables (of the Hamilton–Jacobi equations) and the geometry of Gelfand–Zakharevich bi-Hamiltonian manifolds.

In this paper we address the Gelfand–Zakharevich geometry from the point of view that the Adler–Kostant–Symes scheme superposed with the Fordy–Kulish decomposition.[14] We show how the integrable systems appearing in the AKS program yield the Gelfand–Zakharevich bi-Hamiltonian structure. We also study the commuting flows of nonextended AKS hierarchy (hierarchy of AKS equation without cocycle) and its connection to the Zakharov–Shabat hierarchy.

This paper is organized as follows: In Sec. II we discuss the Kostant–Kirillov structure on co-adjoint orbits and the Adler–Kostant–Symes scheme. A self-contained review of this subject is given. We apply this scheme in Sec. III to obtain several standard integrable systems, such as nonlinear Schrödinger, coupled KdV, Chen–Liu–Lee[40] or derivative nonlinear Schrödinger equations, related to Hermitian symmetric spaces. This type of construction has an important geometrical significance from the point of harmonic maps. In an important paper Burstall *et al.* showed how to construct a large class of harmonic and pluriharmonic maps called ''(pluri)harmonic maps of finite type'' from tori to symmetric spaces G/H, where G is a compact Lie group. Section IV is devoted to the AKS hierarchy and Zakharov–Shabat hierarchy (or the hierarchy of ''zero curvature'' equation). We formulate the Zakharov–Shabat hierarchy from the AKS hierarchy. In Sec. V we establish how the Gelfand–Zakharevich bi-Hamiltonian geometry can be carried out

from the Adler–Kostant–Symes formalism. Here the polynomial Casimirs will be interpreted as ad-invariant functions. We conclude this paper with some modest remarks.

II. ADLER–KOSTANT–SYMES SCHEME

Let G be a connected compact semisimple Lie group with the Lie algebra $\mathfrak{g}$, endowed with a nondegenerate ad-invariant and symmetric inner product $\langle .,. \rangle : \mathfrak{g} \times \mathfrak{g} \to \mathfrak{g}$, that is,

$$\langle X,[Y,Z]\rangle = \langle [X,Y],Z\rangle \quad \forall X,Y,Z \in \mathfrak{g}.$$

Its dual space $\mathfrak{g}^*$ has a natural Poisson structure

$$\{g_1,g_2\}(\alpha) = \left\langle \alpha, \left[\frac{\delta g_1}{\delta \mu}, \frac{\delta g_2}{\delta \mu} \right] \right\rangle,$$

of two smooth functions g_1 and g_2 on $\mathfrak{g}^*$. The functional derivative of g (or gradient of g) at μ is the unique element $\delta f/\delta \mu$ of $\mathfrak{g}$ defined by

$$\lim_{\epsilon \to 0} \frac{1}{\epsilon}[f(\mu + \epsilon \delta \mu) - f(\mu)] = \left\langle \delta \mu, \frac{\delta f}{\delta \mu} \right\rangle.$$

Here the gradient of g_i are interpreted as elements of $\mathfrak{g}$ due to the identification of $\mathfrak{g} \simeq \mathfrak{g}^{**}$.

Let us introduce an additional structure from which, in addition to the ordinary bracket, a modified bracket can be defined as follows.

Let

$$R : \mathfrak{g} \to \mathfrak{g}$$

be an R-matrix, and this defines another Lie bracket on $\mathfrak{g}$,

$$[X,Y]_R = \tfrac{1}{2}([RX,Y] + [X,RY]), \tag{1}$$

such a pair $(\mathfrak{g},R)$ is called a double Lie algebra. It is known that $(\mathfrak{g},R)$ is a double Lie algebra if and only if the following bilinear map:

$$B_R : (\mathfrak{g},R) \times (\mathfrak{g},R) \to (\mathfrak{g},R)$$

is given by

$$B_R(X,Y) = [RX,RY] - R([X,Y]_R) \tag{2}$$

is ad-invariant, that is, the equation

$$[X,B_R(Y,Z)] + [Y,B_R(Z,X)] + [Z,B_R(X,Y)] = 0 \tag{3}$$

holds for all $X,Y,Z \in \mathfrak{g}$.

It is clear that the trivial solution $B_R(X,Y) = 0$ yields the Yang–Baxter equation. The second solution satisfies the so-called modified Yang–Baxter equation

$$B_R(X,Y) = -[X,Y]. \tag{4}$$

The best known class of R-matrices arise when the Lie algebra $\mathfrak{g}$ split into a direct sum of two subalgebras $\mathfrak{g} = \mathfrak{g}_+ \oplus \mathfrak{g}_-$. Since there is a vector space decomposition of $\mathfrak{g}$ into a direct sum of two Lie subalgebras, hence, we set

$$R = P_+ - P_-, \tag{5}$$

where $P_{\pm}$ be the corresponding projection onto $\mathfrak{g}_{\pm}$. Under this identification, the bracket is

$$[X,Y]_R=[X_+,Y_+]-[X_-,Y_-],$$

where $X_{\pm}=P_{\pm}X$.

By $\mathfrak{g}^*$ and $\mathfrak{g}_R^*$ we denote the dual of $\mathfrak{g}$ endowed with the Lie–Poisson structures arising from $[.,.]$ and $[.,.]_R^*$, respectively. The Poisson bi-vectors arising from the Lie brackets $[.,.]$ and $[.,.]_R$ are related by $P_R=R^*P+PR$, where R is considered to be a pointwise lift of the map R on $\mathfrak{g}$ to the vector fields over $\mathfrak{g}$ and R^* is the transpose of this map.

The R-matrix construction on $\mathfrak{g}$ allows us to define an additional Lie–Poisson bracket of the following form:

$$\{f,g\}(\mu)=\langle\mu,[R(\nabla f),(\nabla g)]+[\nabla f,R(\nabla g)]\rangle, \quad f,g\in C^{\infty}(\mathfrak{g}^*). \tag{6}$$

We wish to take a look at the special case of an R-structure (6) given by a splitting into two subalgebras. With $\mathfrak{g}=\mathfrak{g}_-\oplus\mathfrak{g}_+$, $R=P_+-P_-$, $\mu\in\mathfrak{g}^*$ one computes the Lie–Poisson bracket arising from $[.,.]_R$,

$$\{f,g\}(\mu)=2\langle\mu,[(\nabla f)_+,(\nabla g)_+]\rangle-2\langle\mu,[(\nabla f)_-,(\nabla g)_-]\rangle. \tag{7}$$

Definition 1: We say a smooth function $H:\mathfrak{g}^*\to\mathbf{R}$ is Ad^* invariant if

$$H(Ad_g^*\alpha)=H(\alpha)$$

for all $\alpha\in\mathfrak{g}^*$ and $g\in G$.

Theorem 2 (AKS): *Let $\mathfrak{g}$ be Lie algebra with R-matrix $R:\mathfrak{g}\to\mathfrak{g}$, then the ad^* invariant functions on $\mathfrak{g}^*$ are in involution with respect to*

$$\{f,g\}(\mu)=\langle\mu,[R(\nabla f),(\nabla g)]+[\nabla f,R(\nabla g)]\rangle.$$

Then the Hamiltonian flow on the co-adjoint orbits in $L\subset\in\mathfrak{g}^*$ is

$$\frac{\mathrm{d}}{\mathrm{d}t}L=ad^*_{R(\nabla H)}L+R^*ad^*_{\nabla H}L, \tag{8}$$

where R^* is the transpose of R.

A. Loop algebra and AKS scheme

In this section we apply the AKS construction on loop algebra.

Let $\Omega\mathfrak{g}=\mathrm{gl}(n,\mathbf{C})\otimes\mathbf{C}[\lambda,\lambda^{-1}]$ be a loop algebra of semi-infinite formal Laurent series in λ with coefficients in $\mathrm{gl}(n,\mathbf{C})$. An element $X(\lambda)\in\Omega g$ can be expressed as a formal series of the form

$$X(\lambda)=\sum_{i=\infty}^{m}x_i\lambda^i \quad \text{for all} \quad x_i\in\mathrm{gl}(n,\mathbf{C}),$$

the Lie bracket with $Y(\lambda)=\Sigma_{j=-\infty}^{l}y_j\lambda^j$ is given by

$$[X(\lambda),Y(\lambda)]=\sum_{k=-\infty}^{m+l}\sum_{i+j=k}[x_i,y_j]\lambda^k.$$

We will now consider the extended loop algebra $\widetilde{\Omega g}$, the one-dimensional central extension of Ωg defined by two cocycle

$$\omega(X,Y) := \langle \partial X(\lambda), Y(\lambda) \rangle \equiv \int_{S^1} X'(\lambda) Y(\lambda) \mathrm{d}x,$$

where $\partial: \mathfrak{g} \to \mathfrak{g}^*$.

We define extended loop group ΩG to be

$$0 \to R \to \widetilde{\Omega G} \to \Omega G \to 1.$$

The corresponding loop algebra $\widetilde{\Omega \mathfrak{g}} = \Omega \mathfrak{g} \oplus \mathbf{R}$. The Lie bracket of the extended loop algebra $\widetilde{\Omega \mathfrak{g}}$ satisfies

$$[(X(\lambda),a),(Y(\lambda),b)] = \left([X,Y], \int_{S^1} \mathrm{tr}(XY') \right),$$

where $X \in \Omega \mathfrak{g}$ and $a \in \mathbf{R}$.

We define a nondegenerate ad-invariant bilinear form on $\Omega \mathfrak{g}$,

$$\langle X(\lambda), Y(\lambda) \rangle = \mathrm{res}_{\lambda=0} \, \mathrm{tr}(\lambda^{-1} X(\lambda) Y(\lambda)) = \mathrm{tr}(X(\lambda) Y(\lambda))_0,$$

and this bilinear form can be extended to define the bilinear form on $\widetilde{\Omega \mathfrak{g}}$ by

$$\langle (X,a),(Y,b) \rangle = ab + \int_{S^1} \mathrm{tr}(XY).$$

We assume that the algebra $\widetilde{\Omega \mathfrak{g}}$ as a vector space, and it is presented as the linear sum of two subalgebras

$$\widetilde{\Omega \mathfrak{g}} = \widetilde{\Omega \mathfrak{g}}^+ \oplus \widetilde{\Omega \mathfrak{g}}^-,$$

where $\widetilde{\Omega \mathfrak{g}}^+$ denote the subalgebra of $\widetilde{\Omega \mathfrak{g}}$ given by the polynomial in λ and $\widetilde{\Omega \mathfrak{g}}^-$ is the subalgebra of strictly negative series.

By means of ad-invariant bilinear form $\langle , \rangle$ we identify

$$(\widetilde{\Omega \mathfrak{g}}^+)^* \simeq (\widetilde{\Omega \mathfrak{g}}^-)^\perp \quad \text{and} \quad (\widetilde{\Omega \mathfrak{g}}^-)^* \simeq (\widetilde{\Omega \mathfrak{g}}^-)^\perp.$$

This induces another decomposition $\widetilde{\Omega \mathfrak{g}} = \Omega \mathfrak{g}^{+\perp} \oplus \Omega \mathfrak{g}^{-\perp}$.

Definition 3: Let $(\Omega \mathfrak{g}, R)$ be a double Lie algebra on which we define a modified Lie algebraic structure and suppose ω be a two cocycle on $\Omega \mathfrak{g}$. Then

$$\omega_R(X,Y) = \omega(RX,Y) + \omega(X,RY)$$

is a two cocycle on $\Omega \mathfrak{g}_R$.

We want to find the co-adjoint representation of $\widehat{\Omega g}_R$ on the dual space $\widehat{\Omega g}_R^*$. We use the following identity:

$$\langle ad_R^*(X,a)(U,c),(Y,b) \rangle + \langle (U,c), ad_R(X,a)(Y,b) \rangle = 0.$$

Proposition 4: The co-adjoint representation of the loop algebra $\hat{g}_R$ on its dual is given by the following expresion:

$$ad_R^*(X,a)(\alpha,c) = ((ad^* RX)(\alpha) - cRX', 0) + R^*(ad^* X(\alpha) - cX', 0).$$

Note that the symbols ad^* and ad_R^* stand, respectively, for the co-adjoint representations of the algebras $\Omega \mathfrak{g}$ and $\Omega \mathfrak{g}_R$. The proof of this proposition is fairly easy, so we omit it.

The dual space $\widetilde{\Omega g}^{\perp}$ stratifies into Poisson submanifolds corresponding to different values of the parameter; each of them is endowed with a Poisson bracket. Let us fix $c=1$, so we confine us to a hyperplane in $\widetilde{\Omega g}^*$. By abuse of notation we shall continue to call it $\widetilde{\Omega g}^*$.

Let $\hat{f}_1$ and $\hat{f}_2$ be the ad-invariant function and when they are restricted to $\Omega g^{-}{}^* \sim \Omega g^{+\perp}$ these satisfy $\{\hat{f}_1,\hat{f}_2\}_{\Omega g^{-}{}^*}=0$.

Lemma 5: Suppose H is Ad^* invariant function on g^* then

$$ad_R^*(\mathrm{d}H(\alpha),a)(\alpha,1)=((ad^*R(\mathrm{d}H(\alpha))(\alpha)+R(\mathrm{d}H)',0).$$

It should be again be noted that the gradient of a function is the vector field $\nabla H : \mathfrak{g}^* \to \mathfrak{g}$, such that $\langle \nabla H(\mu), X(\mu)\rangle = \mathrm{d}H(X(\mu))$ for all $\mu \in \mathfrak{g}^*$.

The co-adjoint representation leaves invariant the hyperplanes $e=$constant. Thus we conclude: (1) The center of the $\hat{g}$ acts trivially on $\hat{g}^*$, the space of $\hat{g}^*$ is a natural G-module.

(2) $\hat{G}$ acts on $\hat{g}^*$ by gauge transformation.

The Poisson bracket is

$$\begin{aligned}\{f,g\}(\mu+cI)&=\langle \hat{\mu},[\hat{R}(\nabla \hat{f}),\nabla \hat{g}]+[\nabla f,\hat{R}(\nabla \hat{g})]\rangle\\ &=\langle \hat{\mu},[\hat{R}(\nabla f),\nabla g]+\omega(R(\nabla f),\nabla g)I+[\nabla f,R(\nabla g)]+\omega(\nabla f,R(\nabla g))I\rangle\\ &=\langle \hat{\mu},[\hat{R}(\nabla f),\nabla g]+[\nabla f,R(\nabla g)]+c\langle R\partial(\nabla f),\nabla g\rangle+c\langle \partial\nabla f,R(\nabla g)\rangle,\end{aligned}$$

where $\hat{R}$ is the R-matrix on $\hat{\mathfrak{g}}$, it satisfies

$$\hat{R}:\widetilde{\Omega \mathfrak{g}}\to\widetilde{\Omega \mathfrak{g}},\quad \hat{R}(k+\alpha I):=R(k).$$

Proposition 6: The Poisson bracket in the space of $\widetilde{\Omega \mathfrak{g}}^*$ for the two smooth functions has the form

$$\{f_1,f_2\}(Y)=\langle[\hat{R}(\nabla f_1),\nabla f_2],Y\rangle+[\nabla f,R(\nabla g)]+\int_{S^1}R\nabla f_1\frac{\mathrm{d}\nabla f_2}{\mathrm{d}x}+\int_{S^1}\nabla f_1 R\frac{\mathrm{d}\nabla f_2}{\mathrm{d}x},$$

where $Y \in \Omega g$.

In presence of cocycle, that is, when an ad-invariant function satisfies

$$[X,\nabla H]=\frac{\partial \nabla H}{\partial x},$$

∇H is obtained recursively,

$$\nabla H=\lambda^2 h_2+\lambda h_1+h_0+\lambda^{-1}h_{-1}+\cdots.$$

Theorem 7: *Let $\widetilde{\Omega g}^{+}=\widetilde{\Omega \mathfrak{g}}^{+}\oplus\widetilde{\Omega \mathfrak{g}}^{-}$ and $M\subset\widetilde{\Omega \mathfrak{g}}^{+}$ a co-adjoint orbit equipped with a natural weak orbit symplectic structure ω. Let $H_i:\widetilde{\Omega \mathfrak{g}}\to\mathbf{R}$ be the set ad-invariant functions in $I(\mathfrak{g}^*)$ restricted to $(\widetilde{\Omega \mathfrak{g}}^{+})^{\perp}$ is an involutive system on the co-adjoint orbit. The Hamiltonian equations of motion on $\widetilde{\Omega \mathfrak{g}}^*$ generated by the Hamiltonian (ad-invariant function) have the form*

$$\frac{\partial L}{\partial t}=ad^*_{R(\nabla H)}L+\frac{\partial}{\partial x}(R(\nabla H)). \tag{9}$$

So this defines a flat connection $L\,\mathrm{d}x+P\,\mathrm{d}t$ on a cylinder $S^1\times\mathbf{R}$ associated with the above zero curvature equation. In order to apply the Adler–Kostant–Symes scheme we require the knowledge of the ad-invariant function.

When we deal with the AKS scheme for the group without cocycles we obtain a dynamical equation instead of a partial differential equation.

Corollary 8: Let H be the ad-invariant function on $\Omega\mathfrak{g}^*$. The associated Hamiltonian vector fields have orbits L in the symplectic leaves of $\Omega\mathfrak{g}^*$, foliated by co-adjoint action. Then the Hamiltonian flow corresponding to the function $H \in C^\infty(\mathfrak{g}^*)$ is

$$\frac{dL}{dt} = [R\nabla H, L]. \tag{10}$$

Using $R = P_+ - P_-$ in (10) we obtain

$$\frac{dL}{dt} = 2[P_+ \nabla H, L].$$

B. Bi-Hamiltonian chain

In this section we construct the bi-Hamiltonian chain from the AKS method.

Let us consider again

$$[L, \nabla F] + \partial_x(\nabla F) = 0,$$

where

$$L = \lambda^2 A + \lambda Q + W^{\text{off}} + WA,$$

where $A = \left(\begin{smallmatrix} 1 & 0 \\ 0 & -1 \end{smallmatrix}\right)$ and $Q = \left(\begin{smallmatrix} 0 & q \\ r & 0 \end{smallmatrix}\right)$.

Let us make an ansatz,

$$\nabla F = F_0 + \lambda^{-1} F_1 + \lambda^{-2} F_2 + \cdots,$$

where

$$F_i = F_i^{\text{off}} + f_i A = \begin{pmatrix} f_0 & F_0^+ \\ F_0^- & -f_0 \end{pmatrix}.$$

Here F_i^{off} is the off-diagonal elements, that is, $F_i^{\text{off}} \in m$, and $A \in k$. Equating all the powers of λ we obtain

$$\begin{aligned} [A, F_n] &= [Q, F_{n-1}] + [W^{\text{off}}, F_{n-2}] + W[A, F_{n-2}] + F_{(n-2)x} \\ &= [Q, F_{n-1}^{\text{off}}] + [W^{\text{off}}, F_{n-2}] + W[A, F_{n-2}^{\text{off}}] + F_{(n-2)x}^{\text{off}} + f_{(n-2)x} A \\ &\quad + [Q, f_{n-1} A] + [W^{\text{off}}, f_{n-2} A], \end{aligned}$$

where we tacitly assume

$$F_0 = A, \quad F_1 = Q + f_1 A.$$

So we have two recursive relations

$$F_n^{\text{off}} = -f_{n-1} Q - f_{n-2} W^{\text{off}} + W F_{n-2}^{\text{off}} + ad_A^{-1} F_{(n-2)x}^{\text{off}}, \tag{11}$$

$$[Q, F_{n-1}^{\text{off}}] + [W^{\text{off}}, F_{n-2}^{\text{off}}] + f_{(n-2)x} = 0. \tag{12}$$

Let us study the chain. Suppose $F_0^{\text{off}} = 0$ and $f_0 = 1$. We also assume $F_1^{\text{off}} = Q$. Thus F_2^{off} is given by (11) and f_1 by (12).

Thus we obtain

(1) F_2^{off} is given by f_1, f_0, F_0^{off},
(2) F_3^{off} is given by f_2, f_1, F_1^{off},
(3) F_4^{off} is given by f_3, f_2, F_2^{off},
(4) f_{1x} is given by F_1^{off}, F_0^{off},
(5) f_{2x} is given by F_3^{off}, F_1^{off},

etc. Hence the chain is completed.

III. AKS HIERARCHY AND ZAKHAROV–SHABAT HIERARCHY

In this section we focus on the construction and properties of AKS hierachy. We consider the Adler–Kostant–Symes equation without cocycle. Since it is always possible to construct the zero curvature form of the AKS equation from this version.

A. AKS hierarchy

Let $\mathfrak{g}$ be a Lie algebra with standard splitting. Let the Hamiltonians be

$$H_i(\Gamma)=\tfrac{1}{2}\operatorname{tr}_0\lambda^{-(n-i)}L^2, \qquad 0\leqslant i\leqslant n.$$

Thus we obtain

$$\langle \nabla H_i, X\rangle = \mathrm{d}H_i(X)=\operatorname{tr}_0(\lambda^{-(n-i)}LX),$$

and from the degeneracy of tr_0 this implies

$$\nabla H_i=\lambda^{-(n-i)}L.$$

Let us consider an invariant submanifold to be

$$\Lambda=\left\{ L(\lambda)\ \ L(\lambda)=\sum_{i=0}^{n} Q_{n-i}\lambda^i,\ \ Q_{n-i}\in\mathfrak{g}\right\}.$$

Let $L:\mathbf{R}^{n+1}\to\Lambda$ be a function of $t_0,\ldots,t_n$ taking values in Λ, that is

$$L(t_0,\ldots,t_n,\lambda)=\sum_{i=0}^{n} Q_{n-i}\lambda^i\in\Lambda\subset\mathfrak{g}^{-}*.$$

Thus the Hamiltonian equations of motion for H_i is given by

$$\frac{\mathrm{d}}{\mathrm{d}t_i}L=[(\lambda^{-(n-i)}L)_+,L]. \tag{13}$$

Proposition 9: All the equations of the AKS hierarchy commute each other.
Proof: Let us rewrite (∇H_i) as B_i and $\partial/\partial t_i$ as ∂_i. Let $i>j$ and

$$B_i=\lambda^{i-j}B_j+Q_i+Q_{i-1}\lambda+\cdots+Q_{j+1}\lambda^{i-j-1}.$$

Hence,

$$\partial_i B_j=\partial_i(\lambda^{-(n-j)}L)_+=(\lambda^{-(n-j)}\partial_i L)_+=(\lambda^{-(n-j)}[B_i,L])_+=[B_i,\lambda^{-(n-j)}L]_+.$$

Thus we obtain

$$\begin{aligned}\partial_i B_j - \partial_j B_i &= [B_i, \lambda^{-(n-j)}L]_+ - [B_j, \lambda^{-(n-i)}L]_+ \\ &= [B_i - \lambda^{i-j}B_j, \lambda^{-(n-j)}L]_+ \\ &= [B_i - \lambda^{i-j}B_j, (\lambda^{-(n-j)}L)_+]_+ + [B_i - \lambda^{i-j}B_j, \lambda^{-(n-j)}L)_-]_+ \\ &= [B_i, B_j] + [B_i - \lambda^{i-j}B_j, \lambda^{-(n-j)}L)_-]_+ .\end{aligned}$$

The last expression can be further reduced to

$$\begin{aligned}&[B_i - \lambda^{i-j}B_j, (\lambda^{-(n-j)}L)_-]_+ \\ &\quad = [Q_i + Q_{i-1}\lambda + \cdots + Q_{j+1}\lambda^{i-j-1}, Q_n\lambda^{-(n-j)}Q)_+ \cdots + Q_{j+1}\lambda^{-(i+j+1)}]_+ \\ &\quad = [Q_i + \cdots + Q_{j+1}\lambda^{i-j-1}, Q_n\lambda^{-(n-j)} + \cdots + Q_{i-1}\lambda^{-(i-j-1)}]_+ = 0,\end{aligned}$$

since the greatest degree in λ in the expression above is $i-j-1+(-(i-j+1))=-2$. □

B. Higher flows

In this section we will consider the higher flows of the Hamiltonians of the form

$$H_{i,j} := \frac{1}{j+1}\mathrm{tr}_0(\lambda^{-(jn-i)}L^{j+1}),$$

where $1 \leqslant j,\ l \leqslant m = \mathrm{rank}\, g,\ 0 \leqslant i \leqslant jn$, and $0 \leqslant k \leqslant ln$.

The gradient of $H_{i,j}$ is

$$\nabla H_{i,j} = \lambda^{(jn-i)}L^j - \mathrm{tr}(\lambda^{-(jn-i)}L^j)I.$$

Thus we obtain

$$B_{i,j} := (\nabla H_{i,j})_+ = (\lambda^{-(jn-i)}L^j)_+ - \mathrm{tr}(\lambda^{-(jn-i)}L^j)_+ I.$$

Theorem 10: *Let the Hamiltonians be* $H = \nabla_{i,j} = \lambda^{(jn-i)}L^j - \mathrm{tr}(\lambda^{-(jn-i)}L^j)I$ *for all* $0 \leqslant i \leqslant jn$. *Let us assume the invariant submanifold to be* $\gamma = \{L(\lambda): L(\lambda) = \Sigma_0^n Q_{n-i}\lambda^i\}$. *Let* $L: \mathbf{R}^{n+1} \to \gamma$ *be a function of* $t_0, \ldots, t_n$ *taking values in* γ, *given by*

$$L(t_0, \ldots t_n, \lambda) = \sum_{i=0}^{n} Q_{n-i}\lambda^i \in \gamma \subset \mathfrak{g}^- * = \mathfrak{g}^{+\perp}.$$

This generates a Hamiltonian flow for $H_{i,j}$,

$$\partial_{i,j}L = [B_{i,j}, L] \quad \text{with} \quad \partial_{i,j} = \frac{\partial}{\partial t_{i,j}}. \tag{14}$$

Lemma 11: Let $0 \leqslant i \leqslant jn$ *and* $0 \leqslant k \leqslant ln$. Then

$$\partial_{i,j}L^q = [B_{i,j}, L^q]. \tag{15}$$

Proof: It is to show

$$\partial_{i,j}L^n = \sum L \cdots \partial_{i,j}L \cdots L = \sum L \cdots [B_{i,j}, L] \cdots L = [B_{i,j}, L^q].$$

□

Lemma 12:

$$\partial_{i,j}B_{k,l}-\partial_{k,l}B_{i,j}=[B_{i,j},B_{k,l}]. \tag{16}$$

Proof: It is given by

$$\begin{aligned}
&\partial_{i,j}B_{k,l}-\partial_{k,l}B_{i,j}\\
&\quad=\partial_{i,j}(\lambda^{-(ln-k)}L^l)_+-\partial_{i,j}\,\mathrm{tr}(\lambda^{-(ln-k)}L^l)_+I-\partial_{k,l}(\lambda^{-(jn-i)}L^j)_++\partial_{k,l}\,\mathrm{tr}(\lambda^{-(jn-i)}L^j)_+I\\
&\quad=[B_{i,j},\lambda^{-(ln-k)}L^l]_+-[B_{k,l},\lambda^{-(jn-i)}L^j]_+\\
&\quad=[B_{i,j},B_{k,l}]+[B_{i,j},(\lambda^{-(ln-k)}L^l)_-]_+-[B_{k,l},\lambda^{-(jn-i)}L^j]_+\\
&\quad=[B_{i,j},B_{k,l}]+[\lambda^{-(jn-i)}L^j,(\lambda^{-(ln-k)}L^l)_-])_++[\lambda^{-(jn-i)}L^j,(\lambda^{-(ln-k)}L)_+]_+\\
&\quad=[B_{i,j},B_{k,l}]+[\lambda^{-(jn-i)}L^j,\lambda^{-(ln-k)}L^l]\\
&\quad=[B_{i,j},B_{k,l}].
\end{aligned}$$

□

Theorem 13: *All operators ∂_{ij} commute.*
Proof: We obtain

$$\begin{aligned}
\partial_{k,l}\partial_{i,j}L^q&=[\partial_{k,l}B_{i,j},L^q]+[B_{i,j},\partial_{k,l}L^q]\\
&=[\partial_{i,j}B_{k,l}-[B_{i,j},B_{k,l}],L^q]+[B_{i,j},[B_{k,l},L^q]]\\
&=[\partial_{i,j}B_{k,l},L^q]+[B_{k,l},[B_{i,j},L^q]\\
&=\partial_{i,j}\partial_{k,l}L^q,
\end{aligned}$$

where we have used Eq. (16) and the Jacobi identity. □

Thus, we have given an alternative proof of Dickey's result.[8]

Remark: We get an equivalent form of the zero curvature equations of the hierarchy

$$\partial_{ij}w=B_{ij}w. \tag{17}$$

The expression w is called a formal Baker function. The same equation can also be expressed as

$$w\partial_{ij}w^{-1}=\partial_{ij}-B_{ij}.$$

Thus, w acts like a dressing operator. It can be shown that the operators ∂_{ij} commute. This fact and the commutativity of operator (17) imply the zero curvature equation.

IV. HERMITIAN SYMMETRIC SPACES AND INTEGRABLE SYSTEMS

Let G be a semisimple Lie group and $\mathfrak{g}$ be the corresponding Lie algebra. Let M be a homogeneous space of $\mathcal{G}$, so, M is a differentiable manifold on which G acts transitively. There is a homeomorphism of the coset space G/K onto M for some isotropy subgroup K of G at a point of M. Let k be the Lie algebra of K and $\mathfrak{g}$ satisfies

$$\mathfrak{g}=k\oplus m \quad \text{and } [k,k]\subset k,$$

where m is the vector space complement of k. The Lie algebra $\mathfrak{g}$ splits in such a way that M is equipped with two kinds of extra structure, these are

(1) left translation of m around G gives rise to a canonical connection on the principle K bundle: $G\to G/K$.
(2) When $x\in M$, the map $\mathfrak{g}\to T_xM$ given by

$$\eta \mapsto \frac{\mathrm{d}}{\mathrm{d}t}\bigg|_{t=0} \exp(t\,\eta.x),$$

restricts to give an isomorphism $[m]_x \to T_xM$.

The inverse map

$$\omega_x : T_xM \to [m]_x$$

defines a $\mathfrak{g}$-valued one form on M, known as Maurer Cartan form.

If k and m satisfy

$$[k,m] \subset m$$

then G/K is called reductive homogeneous space. We can associate to these spaces a canonical connection with curvature and torsion. Curvature and torsion at a fixed point p are given purely in terms of the Lie bracket operation,

$$(R(X,Y)Z)_p = -[[X,Y]_k, Z], \quad X,Y,Z \in m,$$

$$T(X,Y)_p = -[X,Y]_m, \quad X,Y \in m.$$

If k and m satisfy above two conditions and also satisfy

$$[m,m] \subset k,$$

then G/K is a symmetric space. Here the curvature satisfies

$$(R(X,Y)Z)_p = -[[X,Y],Z], \quad X,Y,Z \in m.$$

Here $[X,Y] \in k$ happens automatically due to $[m,m] \in k$.

Let h be the Cartan subalgebra of $\mathfrak{g}$ which is the maximal Abelian subalgebra of diagonalizable elements of $\mathfrak{g}$. In terms of the Weyl basis

$$[H_i, H_j] = 0, \quad [H_i, X_\alpha] = \alpha(H_i) X_\alpha,$$

$$[X_\alpha, X_\beta] = N_{\alpha,\beta} X_{\alpha+\beta} (\alpha+\beta \in \Delta) = \sum_{i=1}^{mh} C_{\alpha,i} H_i (\alpha+\beta = 0),$$

for any $H_i \in h$ and $X_\alpha \in \mathfrak{g}\ h$, and $N_{\alpha,\beta}$ and $C_{\alpha,i}$ are structure constants and Δ is a set of all roots.

The components R^i_{jkl} and T^i_{jk} of the curvature and torsion with respect to a basis X_i of T_pM are defined by

$$R(X_k, X_l) X_j = R^i_{jkl} X_i, \quad T(X_j, X_k) = T^i_{jk} X_i,$$

and the component of the metric $g(X,Y) = \mathrm{tr}(ad(X)ad(Y))$ is $g_{ij} = g(X_i, X_j)$.

Let ϱ be an element of h we select the isotropy group K such that its Lie algebra is k. This is given by the centralizer

$$C_g(\varrho) = \{X \in g | [X, \varrho] = 0\}.$$

If ϱ is regular, i.e., the eigenvalues $\alpha(\varrho)$ of $ad\,\varrho$ are mutually distinct then $C_g(\varrho) = h$ and here $[h,m] \subset m$.

In this case since $k = h$ hence the corresponding coset space G/K decomposition is essentially Cartan decomposition.

When $k=C_g(\varrho)\supset h$, then the eigenvalues $\alpha(\varrho)$ coalesce, and thus $C_g(\varrho)$ becomes larger than h. Hence in this case the homogeneous space G/K becomes smaller.

In the case of Hermitian symmetric spaces $\alpha(\varrho)$ have eigenvalues $\{0,\pm\alpha\}$. Thus g splits up into

$$g=k\oplus m^+\oplus m^-.$$

If we set $X^0\in k$, $X^\pm\in m^\pm$ for any $X\in g$,

$$[\varrho,X^0]=0,\quad [\varrho,X^\pm]=\pm\alpha X^\pm,$$

here eigenvalues $\alpha(\varrho)$ take the same eigenvalue for all $X^\pm\in m^\pm$. From the second commutation relation we can assert that Hermitian symmetric space has almost complex structure.

A. Computation of ad-invariant functions through example

Let us compute the ad^* invariant functions.

Suppose L be an arbitrary element of the orbit, then the gradient of the ad-invariant function F, in presence of the cocycle must satisfy

$$[L,\nabla H]+\frac{\partial\nabla H}{\partial x}=0.$$

In the absence of any central extension, H would have satisfied $ad^*_{\nabla H}L=0$ whose immediate solution is $H=\mathrm{tr}(L^p)$, where $p\in\mathbf{Z}_+$.

Let us discuss the method of obtaining ad-invariant function in presence of cocycle through an example. We expand ∇H in the powers of λ and set

$$\nabla H=\lambda^4h_4+\lambda^3h_3+\lambda^2h_2+\lambda h_1+h_0+\lambda^{-1}h_{-1}+\lambda^{-2}h_{-2}+\cdots$$

in the above equation for

$$L=\lambda^2A+\lambda Q+W,$$

where

$$A=\begin{pmatrix}-i & 0\\ 0 & i\end{pmatrix},$$

$$Q=\begin{pmatrix}0 & q\\ r & 0\end{pmatrix},$$

$$W=\begin{pmatrix}0 & 0\\ 0 & \frac{i}{2}rq\end{pmatrix}.$$

Thus equating various powers of λ we obtain the following recursive relations:

$$\lambda^6:\quad [A,h_4]=0,$$

$$\lambda^5:\quad [A,h_3]+[Q,h_4]=0,$$

$$\lambda^4:\quad [A,h_2]+[Q,h_3]+[W,h_4]=\frac{\partial h_4}{\partial x},$$

$$\lambda^3: \quad [W,h_3]+[Q,h_2]+[A,h_1]=\frac{\partial h_3}{\partial x},$$

$$\lambda^2: \quad [A,h_0]+[Q,h_1]+[W,h_2]=\frac{\partial h_2}{\partial x},$$

$$\lambda^1: \quad [Q,h_0]+[W,h_1]=\frac{\partial h_1}{\partial x},$$

$$\lambda^0: \quad [W,h_0]=\frac{\partial h_0}{\partial x}.$$

It is easy to see that h_4 and h_3 follows from the first two expressions:

$$h_4=2A, \quad h_3=2Q.$$

h_2 follows from the λ^4 term. Let us choose

$$h_2=2W+2w, \quad \text{s.t.}[A,w]=0,$$

where

$$w=\begin{pmatrix} -\frac{i}{2}rq & 0 \\ 0 & 0 \end{pmatrix}.$$

Thus we write $h_2=-iqr\sigma_3$.

Equating the λ^3 term we obtain

$$[A,h_1]=h_{3x}-2[Q,w],$$

or

$$h_1=\frac{i}{2}h_{3x}^{+}-\frac{i}{2}h_{3x}^{-}-i[Q,w]^{+}+i[Q,w]^{-}.$$

Thus

$$h_1=\begin{pmatrix} 0 & iq_x+\frac{1}{2}q^2r \\ -ir_x+\frac{1}{2}qr^2 & 0 \end{pmatrix}.$$

It is easy to see that the λ^2 term,

$$[A,h_0]+[Q,h_1]=\frac{\partial h_2}{\partial x}, \quad \text{since } [W,h_2]=0,$$

boils down to $[A,h_0]=0$. Hence, we say h_0 is a diagonal matrix. This should be evaluated from the λ^1 relation. Thus equating the λ^1 term we obtain

$$h_0=\begin{pmatrix} 0 & 0 \\ 0 & \frac{1}{2}(r_xq-q_xr)+\frac{i}{4}r^2q^2 \end{pmatrix}.$$

Equating λ^0 we obtain a set of stationary equations,

$$q_{xx}-iqq_xr=0, \quad r_{xx}+irr_xq=0. \tag{18}$$

Thus, we obtain the ∇H function.

Lemma 14:

$$\nabla H=\lambda^4\begin{pmatrix}-2i & 0\\ 0 & 2i\end{pmatrix}+\lambda^3\begin{pmatrix}0 & 2q\\ 2r & 0\end{pmatrix}+\lambda^2\begin{pmatrix}-iqr & 0\\ 0 & iqr\end{pmatrix}$$
$$+\lambda\begin{pmatrix}0 & iq_x+\frac{1}{2}q^2r\\ -ir_x+\frac{1}{2}qr^2 & 0\end{pmatrix}+\begin{pmatrix}0 & 0\\ 0 & \frac{1}{2}(r_xq-q_xr)+\frac{i}{4}r^2q^2\end{pmatrix}.$$

Thus plucking it into the extended Adler–Kostant–Symes (AKS) equation we obtain the Chen–Lee–Liu type derivative Schrödinger equation,

$$iq_t=q_{xx}-iqrq_x,$$

$$ir_t=-r_{xx}-ir_xqr.$$

B. Nonlinear Schrödinger equation

In this case we assume

$$L=\lambda A+Q, \tag{19}$$

and our ansatz is

$$\nabla H=h_2\lambda^2+h_1\lambda+h_0.$$

Thus equating λ^3 and λ^2 terms we obtain $h_2=A$ and $h_1=Q$. Then equating λ^1 we obtain

$$[A,h_0]=Q_x.$$

This gives rise to

$$h_0=\frac{i}{2}Q_x^+-\frac{i}{2}Q_x^--\frac{i}{2}[Q^-,Q^+].$$

The λ^0 term gives rise to the stationary nonlinear Schrödinger equation.

Lemma 15:

$$\nabla H=A\lambda^2+Q\lambda+\frac{i}{2}Q_x^+-\frac{i}{2}Q_x^--\frac{i}{2}[Q^-,Q^+].$$

Thus substituting the value of ∇H in the extended AKS equation we obtain the nonlinear Schrödinger equation for

$$Q=\begin{pmatrix}0 & q\\ q^* & 0\end{pmatrix}.$$

C. Lie–Poisson structure on orbit and the Falqui–Magri–Pedroni construction

Let us consider a manifold $M=\mathfrak{g}^*$ equipped with two Poisson tensors P_0 and P_1, such that the Poisson pencil on $\mathfrak{g}^*$,

$$\{f,g\}_\lambda=\left\langle Q+\lambda A,\left[\frac{\delta f}{\delta Q},\frac{\delta g}{\delta Q}\right]\right\rangle, \tag{20}$$

where A is any fixed element in $\mathfrak{g}^*$ and f and g are defined on the dual space of $\mathfrak{g}^*$.

Let us study a dynamical flow of $f\in C^*(\mathfrak{g})$. The following equation

$$\frac{\mathrm{d}f}{\mathrm{d}t}=\left\langle \frac{\delta f}{\delta Q},\dot{Q}\right\rangle$$

defines a flow passing through the point Q.

Let G denote a semisimple Lie group and $\mathfrak{g}$ its Lie algebra. Then any smooth function f on $\mathfrak{g}^*$ gives rise to a Hamiltonian flow on T_e^*G, the cotangent space of G at the identity, by extending f to a Hamiltonian H which is left invariant. The Lie–Poisson equations are the Hamiltonian equations on the dual of a Lie algebra and represent an abstraction of the Euler equations for a rigid dynamics and ideal incompressible fluid.

The Lie–Poisson equation is

$$\dot{Q}=-ad^*_{\delta H/\delta Q}Q,$$

where $ad_\xi:\mathfrak{g}\to\mathfrak{g}$ is the adjoint map and $ad^*_\xi:\mathfrak{g}^*\to\mathfrak{g}^*$ is its dual.

Thus the Euler–Poincaré flow

$$\dot{Q}=\left[\lambda A+Q,\frac{\delta f}{\delta Q}\right] \tag{21}$$

coincides with the Adler–Kostant–Symes equation.

FMP Construction: The polynomial extension of the above scheme was given by the Italian school. Consider two copies of the algebra $\mathfrak{g}$. Let us denote (Q_0,Q_1) be a point in $\mathfrak{g}^*\times\mathfrak{g}^*\in M$. Let us consider the flow

$$\frac{\mathrm{d}f}{\mathrm{d}t}=\left\langle \frac{\delta f}{\delta Q_0},\dot{Q}_0\right\rangle+\left\langle \frac{\delta f}{\delta Q_1},\dot{Q}_1\right\rangle.$$

The copies of the algebras are intertwined by the Poisson brackets. Magri *et al.* have chosen the following Poisson brackets:

$$\{f,g\}_0=\left\langle A,\left[\frac{\delta f}{\delta Q_0},\frac{\delta g}{\delta Q_1}\right]+\left[\frac{\delta f}{\delta Q_1},\frac{\delta g}{\delta Q_0}\right]\right\rangle,$$

$$\{f,g\}_1=\left\langle A,\left[\frac{\delta f}{\delta Q_1},\frac{\delta g}{\delta Q_1}\right]+\left[\frac{\delta f}{\delta Q_0},\frac{\delta g}{\delta Q_0}\right]\right\rangle.$$

Definition 16: Let us define two sets of equations

$$\dot{Q}_0=\left[A,\frac{\delta f}{\delta Q_1}\right]+\left[Q_1,\frac{\delta f}{\delta Q_0}\right],\quad \dot{Q}_1=\left[A,\frac{\delta f}{\delta Q_0}\right]$$

and

$$\dot{Q}_0 = -\left[Q_0, \frac{\delta f}{\delta Q_0}\right], \quad \dot{Q}_1 = \left[A, \frac{\delta f}{\delta Q_1}\right].$$

It must be noted that the definitions of Q_0 and Q_1 are compatible with the Poisson structures. Combining these two sets,

$$\dot{Q}_0 = -\left[Q_0 + \lambda Q_1, \frac{\delta f}{\delta Q_0}\right] - \left[\lambda A, \frac{\delta f}{\delta Q_1}\right], \tag{22}$$

$$\dot{Q}_1 = -\left[\lambda A, \frac{\delta f}{\delta Q_0}\right] + \left[A, \frac{\delta f}{\delta Q_1}\right]. \tag{23}$$

Hence we obtain

$$(\lambda^2 A + \lambda Q_1 + Q_0)_t = -\left[\lambda^2 A + \lambda Q_1 + Q_0, \frac{\delta f}{\delta Q_0}\right]. \tag{24}$$

Thus we assert the following.

Claim 17: The AKS equation (without cocycle) superposed with the Fordy–Kulish decomposition yields the Falqui–Magri–Pedroni scheme.

Generalization of FMP construction: The FMP construction can be easily extended to more general frame work. In this case one can identify the FMP scheme with the extended AKS equation or AKS equation with cocycle.

Definition 18: Let us define two sets of equations

$$\dot{Q}_0 = \left[A, \frac{\delta f}{\delta Q_1}\right] + \left[Q_1, \frac{\delta f}{\delta Q_0}\right] - \left(\frac{\delta f}{\delta Q_1}\right)_x, \quad \dot{Q}_1 = \left[A, \frac{\delta f}{\delta Q_0}\right]$$

and

$$\dot{Q}_0 = -\left[Q_0, \frac{\delta f}{\delta Q_0}\right] + \left(\frac{\delta f}{\delta Q_0}\right)_x, \quad \dot{Q}_1 = \left[A, \frac{\delta f}{\delta Q_1}\right] + \left(\frac{\delta f}{\delta Q_1}\right)_x,$$

all these extra derivative terms are generated from the cocycle terms.

Combining these two sets,

$$\dot{Q}_0 = -\left[Q_0 + \lambda Q_1, \frac{\delta f}{\delta Q_0}\right] - \left[\lambda A, \frac{\delta f}{\delta Q_1}\right] + \left(\frac{\delta f}{\delta Q_0}\right)_x - \lambda\left(\frac{\delta f}{\delta Q_1}\right)_x, \tag{25}$$

$$\dot{Q}_1 = -\left[\lambda A, \frac{\delta f}{\delta Q_0}\right] + \left[A, \frac{\delta f}{\delta Q_1}\right] + \left(\frac{\delta f}{\delta Q_1}\right)_x. \tag{26}$$

Again combining these two expressions we obtain

$$(\lambda^2 A + \lambda Q_1 + Q_0)_t = -\left[\lambda^2 A + \lambda Q_1 + Q_0, \frac{\delta f}{\delta Q_0}\right] + \left(\frac{\delta f}{\delta Q_0}\right)_x. \tag{27}$$

Thus we obtain the extended AKS equation from the FMP construction.

V. CONNECTION TO GELFAND–ZAKHAREVICH CONSTRUCTION

Suppose L be an arbitrary element of the orbit, then the gradient of the ad-invariant function F, in presence of the cocycle must satisfy

$$[L,\nabla F]+\frac{\partial \nabla F}{\partial x}=0.$$

The gradient of F is obtained from the power series expansion of gl,

$$\nabla F=\lambda^2 h_2+\lambda h_1+h_0+\lambda^{-1}h_{-1}+\lambda^{-2}h_{-2}+\cdots.$$

Actually the dual space of loop algebra is endowed with two Poisson tensors P_0 and P_1, given by

$$P_0=[A,\cdot],\quad P_1=\frac{\mathrm{d}}{\mathrm{d}x}+[Q,\cdot]. \tag{28}$$

Hence the Poisson pencil is $P_\lambda=P_0+\lambda P_1$. The associated Poisson bracket is given by

$$\{f,g\}_\lambda=\langle \mathrm{d}f,P_\lambda\,\mathrm{d}g\rangle, \tag{29}$$

and it is well known that $\{f,g\}_\lambda$ satisfies the Jacobi identity.

Let $\{,\}_1$ and $\{,\}_2$ be two compatible Poisson brackets on M. Then every vector field which is Hamiltonian with respect to both brackets is called bi-Hamiltonian vector field and a sequence of functions $\{f_i|i\in\mathbf{Z}\}$ is called bi-Hamiltonian hierarchy if

$$\{\cdot,f_i\}_2=\{\cdot,f_{i+1}\}_1.$$

It is known that all functions f_i of a bi-Hamiltonian hierachy $\{f_i|i\in\mathbf{Z}\}$ are in involution with respect to both Poisson brackets. This follows straight from the Lenard scheme:

$$\{f_i,f_j\}_1=\{f_i,f_{j-1}\}_2=\{f_{i+1},f_{j-1}\}_1=\cdots=\{f_j,f_i\}_1,$$

so $\{f_i,f_j\}_1=0$ by skew symmetry.

The parameter λ plays an interesting role in this construction. It is known that this parameter λ influences all the major geometrical objects on the Poisson manifold. This is cited in the work of Gelfand and Zakharevich.

The same thing can be repeated from the Poisson bi-vectors point of view, and this view point is closer to the Gelfand–Zakharevich formalism.

Proposition 19: Let f and g be two functions on a bi-Hamiltonian manifold M which satisfy $P_0\mathrm{d}f=P_1\mathrm{d}g$. Then the Poisson brackets $\{f,g\}_i$, $i=0,1$ vanish.

Proof: It follows straight from

$$\{f,g\}_0=\langle \mathrm{d}f,\ P_0\,\mathrm{d}g\rangle=-\langle \mathrm{d}g,\ P_0\,\mathrm{d}f\rangle=\langle \mathrm{d}g,\ P_1\,\mathrm{d}g\rangle=0.$$

Similarly for $\{f,g\}_1$. □

A Hamiltonian vector field is called bi-Hamiltonian vector field if it satisfies

$$\mathcal{X}_H=P_0^\sharp\,\mathrm{d}H=P_1^\sharp\,\mathrm{d}H, \tag{30}$$

where $P_i^\sharp: T^*M\to TM$ is the bundle homomorphism associated to P_i-Poisson bi-vectors.

The Gelfand–Zakharevich construction relies on Weinstein's work of local Poisson structure.[42] It states that under a suitable assumptions on the regularity of the Poisson brackets, the Poisson bi-vector P on an open dense set of M is rank $2n$. M is foliated there in regular Poisson submanifolds, called generic symplectic leaves, generically these are common level sets of k functions $C_1,\ldots,C_k$ called Casimir functions of P. The key property of the Casimirs of P is that their differentials lie in the kernel of P. The dimension of M is related with the integers n and k by $\dim M=2n+k$.

Now we state the theorem of Gelfand and Zakharevich.[20,21]

Theorem 20: *On a* $(2n+1)$*-dimensional bi-Hamiltonian manifold, whose Poisson pencil has maximal rank, the leaves of the suppost are generically Lagrangian submanifolds of dimension n contained on each symplectic leaf of dimension* $2n$.

This theorem is difficult to digest. To better understand the essence of the Gelfand–Zakharevich theorem, we tacitly assume the approach of the Falqui, Magri, and Pedroni viewpoint. There first amplification is to reformulate the Lenard scheme in terms

$$(P_1+\lambda P_0)\mathrm{d}C(\lambda)=0. \tag{31}$$

One must note that the Casimirs of a single Poisson bracket are uninteresting functions, Casimirs of pencil of Poisson bracket compactly encode nontrivial dynamics and constants of motion.

The main concent of the Gelfand–Zakharevich theorem is that there exists a Casimir function depending polynomially on the parameter λ, and that the degree of the polynomial is exactly n if dim $= 2n+1$. Thus we can write the Casimir function in the form

$$C(\lambda)=C_0\lambda^n+C_1\lambda^{n-1}+\cdots+C_n. \tag{32}$$

Thus the Poisson pencil selects $n+1$ distinguished functions $(C_0,C_1,C_2,\ldots,C_n)$. Their common level sets are the leaves of the support of the pencil.

This can be expressed as

$$P_\lambda\,\mathrm{d}C_\lambda=0.$$

This yields a chain

$$P_0\,\mathrm{d}C_0=0,$$

$$P_0\,\mathrm{d}C_1=\mathcal{X}_1=P_1\,\mathrm{d}C_0,$$

$$\cdots,$$

$$P_0\,\mathrm{d}C_n=\mathcal{X}_n=P_1\,\mathrm{d}C_{n-1},$$

$$0=P_1\,\mathrm{d}C_n,$$

where $\mathcal{X}_1,\ldots,\mathcal{X}_n$ are bi-Hamiltonian vector fields.

A bi-Hamiltonian manifold endowed with a Poisson pencil with at least one of the elements of the Poisson pencil is invertible then such a manifold is called *regular bi-Hamiltonian manifolds*. On a regular bi-Hamiltonian manifold we can define a class of canonical coordinates, called the Darboux–Nijenhuis coordinates. It is known that *one-half* of the Darboux–Nijenhuis coordinates are algebraically provided by the Nijenhuis tensor itself, and the remaining *one-half* can always be found by quadratures. This would take us to separation of variables.

VI. CONCLUSION AND OUTLOOK

In this paper we have studied a special class of bi-Hamiltonian geometry—the torsionless Gelfand–Zakharevich bi-Hamiltonian hierarchy and its connection to the Adler–Kostant–Symes hierarchy. This AKS hierarchy is the reduction of $1+1$ dimensional SDYM hierarchy. We have extracted many interesting properties of the Gelfand–Zakharevich geometry from the AKS construction. We present a dictionary below.

AKS scheme	GZ–FMP scheme
AKS construction applied to loop algebra superposed with Fordy–Kulish decomposition	FMP equation
Ad-invariant functions	Casimirs of pencil of Poisson operators
Poisson structures related to dressed and undressed orbits	Pencil of compatible Poisson structures

This fact once again suggests that the classical separation of variables admitting a Lax representation can be studied via AKS construction, which is of course known to mathematicians.

Recently in an interesting paper Burstall *et al.*[7] have shown how to reformulate the (pluri)harmonic map equations for maps of a surface into a Lie group G as zero-curvature equations so that the (pluri)harmonic maps correspond to loops of flat connections. It would be rather fascinating if one tried to unevil the connection between the (pluri)harmonic maps of a surface into a Lie group G in light of Gelfand–Zakharevich bi-Hamiltonian geometry. Certainly the proximity between the two subjects will entice harmonic maps specialists to study bi-Hamiltonian geometry.

The method we have discussed in this paper can be seen as a kind of bridge between bi-Hamiltonian and the Lie algebraic nature of integrable system. The author believes that this paper would further support the program of Italian school.

ACKNOWLEDGMENTS

The work owes a lot to our past discussions with Professor Walter Oevel when he was actively working on integrable systems. The author would like to thank Professor Jean-Pierre Dufour, Professor Miciej Blaszak, Professor Jerry Marsden, Professor Peter Olver, Professor Thanasis Fokas, Professor Nguyen Tien Zung, and Professor Darryl Holm for several stimulating discussions and correspondences. The author is particularly grateful to Dr. Woon Wang for explaining the AKS hierarchy and its connection to Bogomolny hierarchy. In fact, part of Sec. III in this paper has appeared in Dr. Wang's unpublished thesis.

(Received 21 October 2003; accepted 1 April 2004;
published online 14 June 2004)

A systematic approach to the C*-Weyl algebra $\mathcal{W}(E,\sigma)$ over a possibly degenerate pre-symplectic form σ on a real vector space E of possibly infinite dimension is elaborated in an almost self-contained manner. The construction is based on the theory of Kolmogorov decompositions for σ-positive-definite functions on involutive semigroups and their associated projective unitary group representations. The σ-positive-definite functions provide also the C*-norm of $\mathcal{W}(E,\sigma)$, the latter being shown to be *-isomorphic to the twisted group C*-algebra of the discrete vector group E. The connections to related constructions are indicated. The treatment of the fundamental symmetries is outlined for arbitrary pre-symplectic σ. The construction method is especially applied to the trivial symplectic form $\sigma=0$, leading to the commutative Weyl algebra over E, which is shown to be isomorphic to the C*-algebra of the almost periodic continuous function on the topological dual E'_τ of E with respect to an arbitrary locally convex Hausdorff topology τ on E. It is demonstrated that the almost periodic compactification aE'_τ of E'_τ is independent of the chosen locally convex τ on E, and that aE'_τ is continuously group isomorphic to the character group $\hat{E}$ of E. Applications of the results to the procedures of strict and continuous deformation quantizations are mentioned in the outlook. [DOI: 10.1063/1.1757036]

I. INTRODUCTION

In the present investigation we analyze mathematically the canonical commutation relations (CCR) in Weyl form[1,2] for a general type of physical system, in which the degrees of freedom are to be described partially in classical and partially in quantum mechanical terms. For the quantized degrees of freedom the incompatibility of position and momentum is significant, for the classical degrees of freedom it is not, resp., may be neglected. In a coordinate-independent manner we express the existing degrees of freedom for the considered system in terms of a pre-symplectic space (E,σ) of arbitrary dimension. By definition, E is a real vector space, which is equipped with a possibly degenerate pre-symplectic form σ, a real-bilinear, antisymmetric mapping $\sigma: E\times E \to \mathbb{R}$. [The more general set up, in which (E,σ) is replaced by a pre-symplectic manifold, is not treated under the headline ''Weyl algebra'' in the literature.]

A combination of the ansatz of Weyl with the abstract set up of Dirac[3] leads to the notion of *algebraic* Weyl relations, resp., of an algebraic Weyl system, connected with the pre-symplectic space (E,σ). In Ref. 4 Dirac developed formal strategies to define functions, which map

[a)]Electronic mail: alfred.rieckers@uni-tuebingen.de

q-numbers onto q-numbers, and generalize the operations of differentiation and integration. Such a formalism would then allow for functions of the q-number Weyl elements and their derivatives. The mathematically much more refined Hilbert space formalism of von Neumann[5,6] has pushed aside Dirac's q-number analysis. In algebraic quantum theory (cf. Refs. 7–9 and references therein) one seeks, however, for a synthesis of the abstract and the Hilbert space approach: One starts with a rather universal *-algebraic formalism, but restricts oneself to bounded elements with a finite norm. The ultimate model calculations are then performed by means of a representation of the algebraic structure in terms of Hilbert space operators. There, the limits to unbounded (self-adjoint) operators may also be carried through. (An early discussion, which relates Hilbert space Weyl systems with C*-algebras, may be found, in the case of nondegenerate, infinite dimensional, symplectic forms, in Ref. 10.)

In the spirit of algebraic quantum theory we assume now for a general physical system, with the degrees of freedom (E,σ), that there exists a family $\{W(f)|f\in E\}$ of elements in a complex *-algebra, which are linearly independent and which satisfy the Weyl relations (we set, henceforth, $\hbar$ equal to unity),

$$W(f)W(g)=\exp\left\{-\frac{i}{2}\sigma(f,g)\right\}W(f+g),\quad \forall f,g\in E. \qquad (1.1)$$
$$W(f)^*=W(-f),$$

We call the family of all $W(f)$, $f\in E$, which satisfies the preceding requirements, an *abstract Weyl system* and refer to E as its *test function space*.

A Weyl system is considered as a concise minimal structure, which is necessary to characterize the set of observables. It is, of course, natural to form its linear hull, which is a sub-*-algebra (cf. Sec. III B), but the properties of the latter are already implied by those of the Weyl system. Because of the assumed linear independence of the abstract Weyl elements, all abstract Weyl systems are algebraically *-isomorphic and we speak of *the* abstract Weyl system associated with a given pre-symplectic space (E,σ).

If E has the finite dimension $2n$ and σ is a nondegenerate symplectic form, then we are back with the original Weyl relations, considered by Weyl and von Neumann, but now in abstract q-number form. There exists an ordered symplectic basis, which, written as a $2n$-tupel, has the structure $(\mathbf{e},\eta\mathbf{e})=(e_1,\ldots,e_n,\eta e_1,\ldots,\eta e_n)$ such that $\sigma(e_i,\eta e_j)=\delta_{ij}$ and $\sigma(e_i,e_j)=0$ for all $1\leqslant i,j\leqslant n$. Here η is an imaginary unit in the real vector space E.[11] It holds by definition: $\eta^{-1}=-\eta$, $\sigma(\eta f,\eta g)=\sigma(f,g)$, and $\sigma(f,\eta f)\geqslant 0$ for all $f,g\in E$. Each $f\in E$ has the expansion $f=\mathbf{r}\cdot\mathbf{e}+\mathbf{s}\cdot\eta\mathbf{e}=\sum_{i=1}^{n}[r_ie_i+s_i\eta e_i]$, where $\mathbf{r},\mathbf{s}\in\mathbb{R}^n$. By means of the symplectic basis, we obtain σ in normal form and find for the Weyl multiplication law,

$$W(f)W(f')=\exp\left\{-\frac{i}{2}(\mathbf{r}\cdot\mathbf{s}'-\mathbf{s}\cdot\mathbf{r}')\right\}W(f+f'). \qquad (1.2)$$

A *realization* of an abstract Weyl system in a complex Hilbert space $\mathcal{H}_R$ is a family of possibly not linearly independent, but unitary operators $W_R(f)$, $f\in E$, in $\mathcal{H}_R$, which satisfy Eq. (1.1). Especially, for an infinite dimensional test function space E there are essentially different realizations of an abstract Weyl system over a given (E,σ). The physical meaning of a Weyl system depends on its realization. A realization of an abstract Weyl system is called *regular*, if the function $\mathbb{R}\ni t\mapsto W_R(tf)\in\mathcal{U}(\mathcal{H}_R)$ is continuous in the weak, resp. strong, operator topology [$\mathcal{U}(\mathcal{H}_R)$ denotes the group of unitaries acting on $\mathcal{H}_R$]. Stone's theorem implies, in a regular realization, the exponential form of the Weyl operators, that is

$$W_R(f)=\exp\{i\Phi_R(f)\}, \qquad (1.3)$$

where the so-called field operators $\Phi_R(f)$, $f\in E$, are self-adjoint, depending real-linearly on f. They satisfy on a common dense domain in $\mathcal{H}_R$ the commutation relations

$$[\Phi_R(f),\Phi_R(g)]=i\sigma(f,g),\quad f,g\in E. \tag{1.4}$$

For finitely many degrees of freedom and nondegenerate σ this reduces to the original CCR (Refs. 12, 13, 3),

$$\begin{matrix} p_iq_j-q_jp_i=:[p_i,q_j]=-i\delta_{i,j}\mathbb{1}, \\ [q_i,q_j]=0=[p_i,p_j], \end{matrix}\quad 1\leqslant i,j\leqslant n, \tag{1.5}$$

if one employs a symplectic basis $(\mathbf{e},\eta\,\mathbf{e})$ and writes

$$\Phi_R(f)=\mathbf{r}\cdot\mathbf{q}^R+\mathbf{s}\cdot\mathbf{p}^R,\quad \text{again denoting}\quad f=\mathbf{r}\cdot\mathbf{e}+\mathbf{s}\cdot\eta\mathbf{e}, \tag{1.6}$$

where $\mathbf{q}^R=(q_j^R):=(\Phi_R(e_j))$ and $\mathbf{p}^R=(p_j^R):=(\Phi_R(\eta e_j))$ for $1\leqslant j\leqslant n$.

In the finite dimensional case with *nondegenerate* σ there holds the well-known von Neumann–Stone uniqueness theorem:[2,14,15–17] Each regular, unitary realization of an abstract Weyl system is unitarily equivalent to a direct sum of Schrödinger representations. [In the Schrödinger representation $R\equiv S$, we have $\mathcal{H}_S=L^2(\mathbb{R}^n)$, and $q_j^S=x_j$ and $p_j^S=-i(\partial/\partial x_j)$ for $1\leqslant j\leqslant n$.]

A direct sum of Schrödinger representations is employed, if one deals with different systems in an alternative manner, e.g., with a microscopic particle, which is either an electron or a positron. The operators which commute with the represented Weyl elements—and typically arise in direct sum representations—define so-called superselection rules as, e.g., the electric charge (cf., e.g., Refs. 18–21). They express, thus, also physically important quantities, which are compatible with all other observables. Let us denote them by the more general term *classical observables*, since—as is indicated below—in many body physics also dynamical effects may lead to central observables. The (bounded) classical observables may be incorporated into the abstract Weyl system, if one extends the orginally nondegenerate symplectic form to a degenerate one, denoted again by σ, which then displays a nontrivial null space,

$$\ker_\sigma:=\{h\in E\,|\,\sigma(h,f)=0,\forall f\in E\}. \tag{1.7}$$

Clearly, for $h\in\ker_\sigma$ the associated Weyl element $W(h)$ commutes with all other Weyl elements and signifies a classical observable—if we call the non-Hermitian functions of Weyl elements also observables—in the sense of abstract q-numbers.

For infinitely many degrees of freedom the algebraic approach is especially useful. (For an account of the early papers on this topic, cf., e.g., Refs. 22, 23, 8.) In the physical applications the infinite dimensional test function space E is often a complex-linear dense subspace of a one-Boson Hilbert space, and the nondegenerate symplectic form is the imaginary part of the pertinent scalar product. The degrees of freedom of the quantized field are, so to speak, tested by means of (smooth) functions taken from the one-Boson Hilbert space. This smearing of the quantized fields in terms of test functions had been already requested by physical arguments.[24,25]

It is well known, that for a nondegenerate symplectic form σ there exists, up to *-isomorphisms, a unique C*-algebra $\mathcal{W}(E,\sigma)$, which is the norm-closure of the linear span of the abstract Weyl system (cf. Refs. 26–30). For nondegenerate σ the simple C*-algebra $\mathcal{W}(E,\sigma)$ is in quantum field theory and in many body physics used as the primary observable algebra of a Boson system.[31,32] It contains the universal observables the system always displays, irrespective of the external influences it may experience. All of these primary observables are present in each nontrivial Hilbert space representation.

A field theoretic example, where the primary observable algebra is a Weyl algebra with a degenerate symplectic form, exhibiting genuine superselection rules, is elaborated in Ref. 33. Another example, which we shall investigate more closely in future work, is the nonrelativistic photon algebra, where only the transversal components of the canonical fields give rise to nonvanishing values of σ. In these cases one encounters nontrivial Hilbert space realizations of the Weyl relations, in which the classical observables are not faithfully represented. As is emphasized in Ref. 34, apparently the first systematic investigation of the C*-Weyl algebra over a pre-symplectic

test function space, this feature reflects the nonuniqueness of the corresponding abstract C*-Weyl algebra: The CCR (in Weyl form) alone do not determine the primary observable algebra.

Let us recall that the choice of a special Hilbert space representation, where the Weyl elements are given by unitary operators in $\mathcal{L}(\mathcal{H}_\Pi)$, the bounded operators in the representation Hilbert space $\mathcal{H}_\Pi$, is usually induced by the selection of a distinguished state, as, e.g., a coherent state, or a ground, resp. equilibrium, state. In the GNS-representation $\Pi:\mathcal{W}(E,\sigma)\to\mathcal{L}(\mathcal{H}_\Pi)$ over a regular state with a special ordered structure (e.g., optical coherence, or thermodynamic phase ordering; cf. Ref. 9, Section 3.3) the field operators $\Phi_\Pi(f)=(d/dt)\Pi(W(tf))|_{t=0}$ may exhibit a classical part in addition to the quantum mechanical part. This peculiar feature is a manifestation of the underlying ordered structure the system attains under a special influence (e.g., optical pumping, resp. low temperature) and clearly transcends the purely algebraic regime of the theory. This most interesting effect leads in a natural manner to a continuous extension of (E,σ) to a larger pre-symplectic space and to its associated Weyl algebra (cf. Refs. 35–38). These extended Weyl algebras deserve special attention, also in the context of modern quantization and dequantization strategies. They add to the motivation to study Weyl algebras with a pre-symplectic test function space.

Before outlining our method and describing its implications, let us mention various mathematical approaches, which bear a certain technical relationship to our construction. Common to almost all of these ansatzes is that the test function space E is considered merely as a topological, Abelian group. The physical terminology of a Weyl system realized in a Hilbert space is then a projective representation of this group in the mathematical language. The theory of projective group representations begins already with Schur (cf. Ref. 39) and has especially been advocated by Mackey.[40] Further investigations are contained in Refs. 41 and 42. The connection to representations of generalized (nowadays called ''twisted'') L^1-algebras has been developed in Ref. 43 and further pursued in Refs. 44–48.

In Ref. 34 the Weyl algebra $\mathcal{W}(E,\sigma)$ over the pre-symplectic space (E,σ) is defined as the twisted group C*-algebra corresponding to the multiplier

$$E\times E\ni(f,g)\mapsto\exp\left\{-\frac{i}{2}\sigma(f,g)\right\}. \tag{1.8}$$

Hereby the test function space E is taken as a real vector group (and not only as a group) and is equipped with the discrete topology. (See Sec. III E for special implications of a vector group.)

In Ref. 49 Kolmogorov decompositions are used in the form of algebraic inducing, and thus there is a certain similarity to our method.

The ''Weyl algebra'' over compact manifolds, especially over the torus group,[50] provides prominent examples for a noncommutative geometry (cf. Refs. 51–53, and references therein).

The problem of nonregular states and discontinuous quasi-free dynamical systems is treated already in Refs. 54 and 55, and more recently in Ref. 56. In our context, related developments were undertaken in Refs. 37 and 38.

Let us also mention the work[58] of Weaver, in which for (infinite dimensional) Hilbert spaces E, with the imaginary part of the scalar product taken as the symplectic form σ, deformed von Neumann and C*-algebras are constructed in special realizations.

In our present exposition we do not rely on earlier results but we start anew from an arbitrary pre-symplectic test function space (E,σ) (where the inifinite dimensional case is, of couse, the interesting one). We give a straight-forward and almost self-contained construction method for a natural C*-Weyl algebra $\mathcal{W}(E,\sigma)$, associated with (E,σ), which does not use a special realization or Hilbert space representation. That means that we work directly with the linear hull $\Delta(E,\sigma)$ of the abstract Weyl elements and with the states on this abstract *-algebra, where the latter are given in terms of the σ-positive definite functions $\mathcal{C}(E,\sigma)$ on E. These data are shown to determine a distinguished C*-norm on $\Delta(E,\sigma)$, and the subsequent norm-completion of $\Delta(E,\sigma)$ leads already to $\mathcal{W}(E,\sigma)$. The clear-cut strategy appears useful for quantum field theoretic applications.

More specifically, we collect in Sec. II the basic notions and prove some necessary results concerning projective representations of J-involutive groups, in the case that an antisymmetric bicharacter Σ is given, employing Kolmogorov decompositions.[57] These techniques are then applied to the GNS-representations of so-called U*-algebras (where a ''representation'' is here always realized in terms of *bounded* operators). We prove especially an original extension theorem for Σ-positive definite functions (Prop. 2-2). In this manner we adapt the even more general results of Ref. 29 to our requirements and refine some of their arguments.

In Sec. III the formalism is specialized to Weyl systems connected with the pre-symplectic space (E,σ), now considered a J-involutive group. According to the previously derived results, each σ-positive definite function in $C(E,\sigma)$ defines a Hilbert space representation of the abstract Weyl system, resp., of $\Delta(E,\sigma)$ (whereas, in general, GNS-constructions for *-algebras would lead to unbounded operators.)

As indicated above, the C*-norm is introduced on $\Delta(E,\sigma)$ by means of $C(E,\sigma)$ without considering, at first, the Hilbert space realizations. In contradistinction to Ref. 34 and to Ref. 58 our approach is completely algebraic and emphasizes the uniqueness of $\mathcal{W}(E,\sigma)$, if all of the σ-positive definite functions $C(E,\sigma)$ are taken into account for defining the C*-norm.

Of course, it is valuable to acquire information on the connection between the abstract Weyl algebra $\mathcal{W}(E,\sigma)$ and the represented Weyl systems. In Prop. 3-4 it is demonstrated that the abstract C*-norm is also obtainable as the supremum of all operator norms of the representations. In Theorem 3-7 it is shown that $\mathcal{W}(E,\sigma)$ is the unique C*-algebra, whose represention give all Weyl systems in Hilbert spaces.

The homeorphism between $C(E,\sigma)$ and the total state space of $\mathcal{W}(E,\sigma)$, which we found in the literature only for *nondegenerate* σ as a map of the *continuous* functions in $C(E,\sigma)$ onto the *regular* states on $\mathcal{W}(E,\sigma)$, is proven in Theorem 3-5. A fundamental role in the analysis of $\mathcal{W}(E,\sigma)$ plays the tracial state, which we show to be faithful in Corollary 3-6 (a fact already stated, but not completely proven, in Ref. 34 and also mentioned within a more special context in Ref. 58).

In Sec. III D the gauge transformations of the second kind and the symplectic transformations, that are the fundamental structural symmetries, are introduced in a more general manner than in the previous literature.

The norm estimates in Sec. III E, concerning beside the C*-norm two other Banach norms, refine and supplement essentially the considerations regarding this topic in Ref. 34. It is demonstrated, besides other things, that the chosen C*-norm is the only C*-norm, which majorizes the $\|\cdot\|_2$-norm.

In Sec. IV we treat, as a special case of the general formalism, the commutative Weyl algebra $\mathcal{W}(E,0)$ with the totally degenerate pre-symplectic form—the zero form $\sigma=0$—on an arbitrary real vector space E. We derive several *-isomorphic C*-algebras of functions, which illuminate the structure of this commutative C*-algebra. More precisely, it follows that

$$\mathcal{W}(E,0)\cong \mathrm{AP}(E'_\tau)=C(aE'_\tau)\cong C(\hat{E}). \tag{1.9}$$

Observe that in group theoretical language the commutative Weyl algebra is just the group C*-algebra of the discrete vector group E (with a trivial multiplier). Here $\mathrm{AP}(E'_\tau)$ is the commutative C*-algebra of the continuous almost periodic functions on the topological dual E'_τ of E, where E is equipped with a locally convex Hausdorff topology τ. The symbols $\mathrm{C}(aE'_\tau)$, resp. $\mathrm{C}(\hat{E})$, denote the C*-algebras of the continuous, $\mathbb{C}$-valued functions over the indicated compact spaces. The first compact space is the almost periodic compactification aE'_τ of the dual E'_τ[59] (cf. also Ref. 60 for connecting almost periodic functions and compactifications). The second is the topological character group $\hat{E}$ of E, the latter being regarded as a discrete additive group. [As the classical pendent of Weyl algebras, $\mathrm{AP}(E'_\tau)$ appears already in Ref. 58, but only in the special case of E'_τ being a Hilbert space.]

The *-isomorphism $\mathcal{W}(E,0)\cong\mathrm{C}(\hat{E})$ is identified as the Gelfand representation of the commutative C*-Weyl algebra $\mathcal{W}(E,0)$. As a consequence the state space of $\mathcal{W}(E,0)$ is affine homeo-

morphic to the Bauer simplex of probability measures on the compact character group $\hat{E}$; cf. Ref. 61.

By use of the *-isomorphism $C(aE'_\tau)\cong C(\hat{E})$ in Eq. (1.9), we deduce that the embedding $F\mapsto\exp\{iF(\cdot)\}$ of E'_τ into the character group $\hat{E}$ extends continuously to a continuous group isomorphism between the topological compact groups aE'_τ and $\hat{E}$. As a consequence of this, the almost periodic compactification aE'_τ of the topological dual E'_τ is independent from the chosen locally convex Hausdorff topology τ on E, that is,

$$aE'_{\tau_1}\cong aE'_{\tau_2}\cong\hat{E},$$

for two given locally convex topologies τ_1, resp., τ_2 on E.

These apparently still unpublished results on the classical Weyl algebra enable the free choice of a topology in the field theoretic phase space E'_τ without losing the uniqueness of the observable algebra.

In order to emphasize again that our mathematical developments are motivated by physical intentions, namely to clarify the structure of systems which exhibit quantum and classical features simultaneously and to relate also the extreme cases with each other in terms of the deformation concepts, we draw some conclusions in Sec. V and give an outlook on related works under preparation.

II. POSITIVE-DEFINITENESS AND KOLMOGOROV DECOMPOSITION

A. Projective representations of J-involutive groups

Let first X be an arbitrary (nonempty) set. A mapping $K:X\times X\to\mathbb{C}$, $(x,y)\mapsto K(x,y)$ is called a *kernel* on X, whereas a mapping $C:X\to\mathbb{C}$, $x\mapsto C(x)$ is named a *function*.

A kernel K on X is called *positive-definite*, if for every number $n\in\mathbb{N}$ and all $z_1,\ldots,z_n\in\mathbb{C}$ and all $x_1,\ldots,x_n\in X$ we have $\Sigma_{i,j=1}^{n}\overline{z_i}z_jK(x_i,x_j)\geqslant 0$. Every positive-definite kernel K on X admits a *Kolmogorov decomposition*,[57,29] that is a mapping $v:X\to\mathcal{H}_v$ from X into a complex Hilbert space $\mathcal{H}_v$, which satisfies

$$K(x,y)=(v(x)|v(y)),\quad \forall x,y\in X, \tag{2.1}$$

where $(\cdot|\cdot)$ is the right-linear complex scalar product on $\mathcal{H}_v$. Conversely, a kernel is positive-definite, if it possesses a Kolmogorov decomposition. The Kolmogorov decomposition $v:X\mapsto\mathcal{H}_v$ of K is called minimal, if the set $\{v(x)|x\in X\}$ is total in $\mathcal{H}_v$. If the Kolmogorov decomposition $v:X\to\mathcal{H}_v$ is not minimal, then one constructs a minimal Kolmogorov decomposition by restricting $\mathcal{H}_v$ to the closure of the linear hull of $\{v(x)|x\in X\}$. It is immediately checked that the minimal Kolmogorov decomposition is unique up to unitary equivalence.[29]

We assume from now on that X is a semigroup, i.e., X is equipped with an associative (possibly noncommutative) operation $\circ:X\times X\to X$ and a neutral element $e\in X$, which is defined to satisfy $e\circ x=x\circ e=x$ for all $x\in X$. There may exist some elements in X which are invertible, possessing an element $x^{-1}\in X$ such that $x^{-1}\circ x=x\circ x^{-1}=e$. At least the neutral element e is invertible with $e^{-1}=e$. The inverse x^{-1} is unique and invertible with $(x^{-1})^{-1}=x$. If $x,y\in X$ are invertible, then $x\circ y$ is invertible with $(x\circ y)^{-1}=y^{-1}\circ x^{-1}$.

In addition, suppose to be given an involution J on the semigroup X, that is a mapping $J:X\to X$ satisfying $J^2(x)=x$ and $J(x\circ y)=J(y)\circ J(x)$ for all $x,y\in X$, defining the involutive semigroup (X,J). It follows that

$$X_J:=\{x\in X|J(x)\circ x=x\circ J(x)=e\} \tag{2.2}$$

is a group with the group operation $\circ$, called the *J-involutive group corresponding to* (X,J). Its neutral element just is e, and the inversion is given by $J(x)=x^{-1}$, $x\in X_J$. It holds $J(X_J)=X_J$. Examples are found below.

A kernel Σ on the semigroup X is called an *antisymmetric bicharacter*, if, for all $x, y, z \in X$, one has

$$|\Sigma(x,y)|=1, \quad \Sigma(x,x)=1, \quad \Sigma(x,y\circ z)=\Sigma(x,y)\Sigma(x,z), \quad \Sigma(x\circ y,z)=\Sigma(x,z)\Sigma(y,z).$$

It follows that $\Sigma(x,y)=\overline{\Sigma(y,x)}$ and $\Sigma(x,e)=1$ for all $x, y \in X$. Furthermore, it is $\Sigma(x,y^{-1})=\overline{\Sigma(x,y)}$ for every $x \in X$ and each invertible element $y \in X$. The antisymmetric bicharacter Σ is called *nondegenerate*, if $\Sigma(x,y)=\Sigma(x,z)\ \forall x \in X$ implies $y=z$. Note that a nondegenerate Σ yields the semigroup X to be commutative, since $\Sigma(x,y\circ z)=\Sigma(x,y)\Sigma(x,z)=\Sigma(x,z)\Sigma(x,y)=\Sigma(x,z\circ y)$. We consider here, however, possibly degenerate Σs.

The triplet (X,J,Σ) of the quantities just described is denoted a *projective involutive semigroup*.

A function $C:X\to\mathbb{C}$ on (X,J,Σ) is called Σ*-positive-definite*, if the associated kernel K_C is positive definite, where

$$K_C:X\times X\to\mathbb{C}, \quad (x,y)\mapsto K_C(x,y):=\overline{\Sigma(x,y)}C(J(x)\circ y). \tag{2.3}$$

Explicitly, C is Σ-positive-definite, if

$$\sum_{i,j=1}^{n} \overline{z_i} z_j \overline{\Sigma(x_i,x_j)} C(J(x_i)\circ x_j) \geqslant 0,$$

for every number $n \in \mathbb{N}$, all $z_1,\ldots,z_n \in \mathbb{C}$, and all $x_1,\ldots,x_n \in X$. A Kolmogorov decomposition of C is defined as a Kolmogorov decomposition for the kernel K_C.

A *unitary* Σ*-representation* $(U,\mathcal{H}_U)$ of the group X_J is a mapping $U:X_J \ni x\mapsto U(x)$ from X_J into the unitary operators acting on the complex Hilbert space $\mathcal{H}_U$ such that the relations [cf. also Eq. (1.1)],

$$U(x)U(y)=\Sigma(x,y)U(x\circ y), \quad U(x)^*=U(x)^{-1}=U(x^{-1}), \quad \forall x,y \in X_J, \tag{2.4}$$

are fulfilled. In other words, $(U,\mathcal{H}_U)$ is a projective group representation with respect to the multiplier Σ.

Theorem 2-1 (Σ-representation): *Let C be a Σ-positive-definite function on the projective involutive semigroup (X,J,Σ), and let $v:X\to\mathcal{H}_v$ be the minimal Kolmogorov decomposition of C. Then there exists a unique mapping $V:X_J \ni x\mapsto V(x)$ from the group X_J into the unitary operators on the Hilbert space $\mathcal{H}_v$, such that*

$$V(x)v(y)=\Sigma(x,y)v(x\circ y), \quad \forall y \in X, \quad \forall x \in X_J.$$

Furthermore, the mapping V is a unitary Σ-representation of the J-involutive group X_J.

Proof: For a fixed $x \in X_J$ let us consider the mapping $v^x:X\to\mathcal{H}_v$ defined by $v^x(z):=\Sigma(x,z)v(x\circ z)$ for all $z \in X$. With $J(x\circ y)=J(y)\circ J(x)=J(y)\circ x^{-1}$, the properties of Σ, and Eq. (2.3) we conclude that $(v^x(y)|v^x(z))=K_C(y,z)$ for all $y, z \in X$. Thus the map $v^x:X\to\mathcal{H}_v$ is a Kolmogorov decomposition of C, too, which is minimal since x is invertible. But two minimal Kolmogorov decompositions are unitarily equivalent. Consequently, there exists a unique unitary $V(x)$ on $\mathcal{H}_v$, such that $v^x(z)=V(x)v(z)$ for all $z \in X$. It is straightforward to verify that in application to the total elements $\{v(z)|z \in X\}$ the mapping $V:X_J \ni x\mapsto V(x)$ is a unitary Σ-representation. ■

B. Extension of Σ-positive-definite functions

In this subsection let X be a group with the group operation $\circ$. We define the involution J by $J(x):=x^{-1}$ for all $x \in X$, and thus we have $X=X_J$.

We have $C(e)\geqslant 0$ for every Σ-positive-definite function C on the projective group (X,Σ) by Eq. (2.1). So let us define $\mathcal{C}(X,\Sigma)$ to be the convex set of all normalized, Σ-positive-definite functions $C:X\to\mathbb{C}$, where normalization means $C(e)=1$. The restriction of the antisymmetric bicharacter Σ from X to a subgroup $G\subseteq X$ is also denoted by Σ.

Proposition 2-2: Let G be a subgroup of X. If $C_G\in\mathcal{C}(G,\Sigma)$ is extended trivially to X by putting $C(x):=C_G(x)$ for $x\in G$ and $C(x):=0$ elsewhere, then $C\in\mathcal{C}(X,\Sigma)$. Moreover, the restriction $C\mapsto C|_G$ from X to G is a surjective affine map from $\mathcal{C}(X,\Sigma)$ onto $\mathcal{C}(G,\Sigma)$.

Proof: Let $u:G\to\mathcal{H}$ be a Kolmogorov decomposition of C_G. There exists a subset $I\subset X$ such that X decomposes into the disjoint union $X=\cup_{w\in I}w\circ G$. For each $w\in I$ let $\mathcal{H}_w$ be a copy of $\mathcal{H}$, and perform the direct sum $\mathcal{K}:=\oplus_{w\in I}\mathcal{H}_w$; κ_w be the component of $\kappa\in\mathcal{K}$ in $\mathcal{H}_w$. For $z\in I$ put $u^z:G\to\mathcal{K}$ with $(u^z(y))_w=u(y)\in\mathcal{H}_w$ for $z=w$ but $(u^z(y))_w=0$ for $z\neq w$. Define the map $v:X\to\mathcal{K}$ by $v(x):=\Sigma(x,z)u^z(z^{-1}\circ x)$ for $x\in z\circ G$. With the properties of Σ and Eq. (2.3) we derive that $(v(x)|v(y))=K_C(x,y)$ for all $x, y\in X$. Thus v is a Kolmogorov decomposition of C implying $C\in\mathcal{C}(X,\Sigma)$. ■

Let us present a simple example. Consider the trivial subgroup $G:=\{e\}$. Then $\mathcal{C}(\{e\},\Sigma)$ consists of a single element, which extends trivially to $C_{\mathrm{tr}}\in\mathcal{C}(X,\Sigma)$ satisfying $C_{\mathrm{tr}}(e)=1$ and $C_{\mathrm{tr}}(x)=0$ for $e\neq x\in X$. In Subsection 3.2 we construct from the function C_{tr} a tracial state ω_{tr} on the twisted group C*-algebra, which explains the index "tr."

C. The GNS representation of U*-algebras

Let $\mathcal{A}$ be a complex *-algebra. A linear functional ω on $\mathcal{A}$ is called *positive*, if $\langle\omega;A^*A\rangle\geqslant 0$ for all $A\in\mathcal{A}$, where $\langle\cdot;\cdot\rangle$ means the algebraic duality relation. A representation $(\Pi,\mathcal{H}_\Pi)$ of the *-algebra $\mathcal{A}$ is a *-homomorphism Π from $\mathcal{A}$ into the C*-algebra $\mathcal{L}(\mathcal{H}_\Pi)$ of all *bounded* operators on the complex Hilbert space $\mathcal{H}_\Pi$; it is called nondegenerate, if $\Pi(\mathcal{A})\mathcal{H}_\Pi$ is dense in $\mathcal{H}_\Pi$ [equivalently, $\Pi(\mathbb{1})=\mathbb{1}_\Pi$, whenever $\mathcal{A}$ contains an identity $\mathbb{1}$]. Because of the absence of a norm, there exist *-algebras, which do not admit any nontrivial representation. Especially, certain *-algebras of unbounded operators as, e.g., the *-algebra of the polynomials of the position and momentum operators, $Q=x$, resp., $P=-i(d/dx)$ in $\mathrm{L}^2(\mathbb{R})$, do not possess any nontrivial representation (by bounded operators).

A Gelfand-Naimark-Segal construction $(\Pi_\omega,\mathcal{H}_\omega,\Omega_\omega)$ of a positive linear functional ω on the *-algebra $\mathcal{A}$ is defined as for C*-algebras: $(\Pi_\omega,\mathcal{H}_\omega)$ is a representation of $\mathcal{A}$ and $\Omega_\omega\in\mathcal{H}_\omega$ a cyclic vector [i.e., $\Pi_\omega(\mathcal{A})\Omega_\omega$ is dense in $\mathcal{H}_\omega$], such that $\langle\omega;A\rangle=(\Omega_\omega|\Pi_\omega(A)\Omega_\omega)\forall A\in\mathcal{A}$. Two different GNS representations of a positive linear functional ω are unitarily equivalent.

In the operator algebraic textbooks, e.g. Refs. 62–64; also Ref. 65, the existence of the GNS construction is derived in a way, which requires the norm-completeness of the *-algebra $\mathcal{A}$ (as is the case for Banach *—resp. C*—algebras) to demonstrate the boundedness of the representing operators. Our derivation is based on Ref. 29. It demands $\mathcal{A}$ to be a U*-algebra instead of requiring the mentioned norm-completeness. A U*-algebra $\mathcal{A}$ is a*-algebra with identity $\mathbb{1}$, such that every element of $\mathcal{A}$ is a (finite) linear combination of unitary elements from $\mathcal{A}$ ($U\in\mathcal{A}$ is called unitary, if $UU^*=U^*U=\mathbb{1}$). Especially every Banach *—resp. C*—algebra with an identity is a U*-algebra, and so is the pre-Weyl algebra in Eq. (3.2) below.

Let our *-algebra $\mathcal{A}$ possess an identity $\mathbb{1}$. We obtain an involutive semigroup $(\mathcal{A},J)$ by defining the operation $\circ$ as the algebraic product—implying $\mathbb{1}$ to be the neutral element—and by introducing the involution J as the algebraic *-operation $J(A):=A^*$, $\forall A\in\mathcal{A}$. So the J-involutive group $\mathcal{A}_J$ consists of all unitary elements of $\mathcal{A}$. Put $\Sigma:=1$. Then each positive linear functional $\omega:\mathcal{A}\ni A\mapsto\langle\omega;A\rangle$ is a 1-positive-definite function with associated positive-definite kernel $K_\omega(A,B)=\langle\omega;A^*B\rangle$ for $A, B\in\mathcal{A}$. Whereas the minimal Kolmogorov decomposition exists for every positive linear functional ω on an arbitrary *-algebra (also on those without an identity), a GNS representation of ω may not exist.

Theorem 2-3: *The GNS representation exists for every positive linear functional on a U*-algebra $\mathcal{A}$.*

Proof: ω being a linear form implies the minimal Kolmogorov decomposition $v_\omega:\mathcal{A}\to\mathcal{H}_\omega$ of ω, resp. of the kernel K_ω, to be linear, too. By Theorem 2-1 there exists a unitary representation

Π_ω of the unitary group $\mathcal{A}_J$, which we extend linearly to a representation of the whole U*-algebra $\mathcal{A}$. v being linear yields $\Pi_\omega(A)v_\omega(B)=v_\omega(AB)$ for all $A, B\in\mathcal{A}$, which implies the independence of $\Pi_\omega(A)$ from the linear decomposition of A into unitaries. Finally, set $\Omega_\omega := v_\omega(\mathbb{1})$. ■

The extension from the unitaries to the whole U*-algebra in the above proof fits well to the construction of the Weyl algebra in the next section; see especially Observation 3-2.

III. THE C*-WEYL ALGEBRA

Throughout the present section let (E,σ) be a fixed *pre-symplectic space*, namely a real vector space equipped with an $\mathbb{R}$-bilinear mapping $\sigma: E\times E\to\mathbb{R}$, $(f,g)\mapsto\sigma(f,g)$, which is antisymmetric, i.e., $\sigma(f,f)=0$, $\forall f\in E$ or equivalently, $\sigma(f,g)=-\sigma(g,f)$, $\forall f, g\in E$.

In order to conform with Sec. II A we consider E as a commutative group with the addition $\circ := +$ as the group operation. The involution J is defined as forming the additive inverses $J(f) := -f$, and thus we have $E_J=E$ for the J-involutive group. The antisymmetric bicharacter Σ is chosen as in Eq. (1.8), i.e., as $\Sigma(f,g) := \exp\{-(i/2)\sigma(f,g)\}$. Instead of $\mathcal{C}(E,\Sigma)$ we write $\mathcal{C}(E,\sigma)$ for the set of normalized, σ-positive-definite functions $C: E\to\mathbb{C}$. The nondegeneracy of Σ is equivalent to the nondegeneracy of σ, i.e., $(\sigma(f,g)=0\,\forall f\in E)\Rightarrow g=0$. In our investigation, however, σ may be degenerate, and in Sec. IV we even treat the trivial case of a vanishing pre-symplectic form.

In the Introduction we associated with a pre-symplectic space (E,σ) an abstract Weyl system, which consists of linearly independent Weyl elements $W(f)$, $f\in E$, in a *-algebra, fulfilling the Weyl relations

$$W(f)W(g)=\exp\left\{-\frac{i}{2}\sigma(f,g)\right\}W(f+g),\quad W(f)^*=W(-f),\quad \forall f,g\in E', \tag{3.1}$$

cf. Eq. (1.1). In the present section we search for an appropriate C*-Weyl algebra, which be naturally given, resp. generated, by the abstract Weyl system.

A. Weyl systems as projective group representations

In the Introduction we discriminated conceptually between the abstract Weyl system and its Hilbert space realizations $(W_R,\mathcal{H}_R)$ in terms of unitary operators, the latter simply called *Weyl systems*. Up to now, we did not deal with the existence either of the abstract or of the (Hilbert space) Weyl systems.

In mathematical investigations Weyl systems over (E,σ) are viewed as unitary σ-representations $W_R: E\ni f\mapsto W_R(f)$ of the additive group E on the complex Hilbert space $\mathcal{H}_R$. That means that the operator product of the unitary Weyl operators $W_R(f)\in\mathcal{L}(\mathcal{H}_R)$, $f\in E$, represents, by satisfying the Weyl relations (3.1), the addition of E homomorphically up to a phase factor, given by the bicharacter $\Sigma(f,g)$.

There is the following connection between Weyl systems and σ-positive-definite functions on (E,σ).

Theorem 3-1: *The following assertions are valid.*

(a) *Let $C\in\mathcal{C}(E,\sigma)$ be a σ-positive-definite function. Then there exists a Weyl system $(W_C,\mathcal{H}_C)$ over (E,σ) and a normalized vector $\Omega_C\in\mathcal{H}_C$, such that $\{W_C(f)\Omega_C|f\in E\}$ is total in $\mathcal{H}_C$ and the function C is given by the expectations $C(f)=(\Omega_C|W_C(f)\Omega_C)$ for all $f\in E$.*

(b) *Let $(W_R,\mathcal{H}_R)$ be a Weyl system over (E,σ). Then for every density operator ρ on $\mathcal{H}_R$ (a positive trace class operator with $\mathrm{tr}[\rho]=1$) the mapping $E\ni f\mapsto C_\rho(f) := \mathrm{tr}[\rho W_R(f)]$ is an element of $\mathcal{C}(E,\sigma)$.*

Proof: Part (a) is an application of Theorem 2-1 to the present case with $E_J=E$, where $\Omega_C := v_C(0)$ for the minimal Kolmogorov decomposition $v_C: E\to\mathcal{H}_C$ of C. Part (b): The relation

$C_\rho(0)=1$ is immediate, since $W_R(0)=\mathbb{1}_R$ is the identity on $\mathcal{H}_R$. If $A=\Sigma_{j=1}^n z_j W_R(f_j)$ is an arbitrary linear combination of Weyl operators with different f_j's, then we obtain by the positivity of ρ and by the Weyl relations that

$$0\leqslant \mathrm{tr}[\rho A^*A]=\sum_{i,j=1}^n \overline{z}_i z_j \exp\left\{\frac{i}{2}\sigma(f_i,f_j)\right\}\mathrm{tr}[\rho W_R(f_j-f_i)]$$

$$=\sum_{i,j=1}^n \overline{z}_i z_j \exp\left\{\frac{i}{2}\sigma(f_i,f_j)\right\}C_\rho(f_j-f_i),$$

which is the σ-positive-definiteness of C_ρ. Hence $C_\rho\in\mathcal{C}(E,\sigma)$. ■

Observe, that for a given $C\in\mathcal{C}(E,\sigma)$ the elements of $W_C(E)$, need not be linearly independent.

B. Construction of the Weyl algebra

In order to construct the desired *-algebra for the Weyl relations, we have a need for a mapping W from E into a subset of linearly independent elements of a vector space $\mathcal{F}$. The latter means, of course, that the image $W(E)\subset\mathcal{F}$ consists of linearly independent elements $W(f)\in\mathcal{F}$, $f\in E$.

As a main example one may choose $\mathcal{F}$ as the linear space of all $\mathbb{C}$-valued functions on E and define for every $f\in E$ the element $W(f)$ as the Kronecker delta function $W(f):E\to\mathbb{C}$ satisfying $W(f)[g]=1$ for $g=f$ and $W(f)[g]=0$ for $g\neq f$. The set of these $W(f)$ is clearly linearly independent.

For any linearly independent family $W(E)\subset\mathcal{F}$ we denote by $\Delta(E,\sigma)$ the vector space of all (finite) complex linear combinations of the $W(f)$, $f\in E$,

$$\Delta(E,\sigma):=\mathrm{LH}\{W(f)|f\in E\}. \tag{3.2}$$

Here LH means the complex linear hull, so an arbitrary element of $\Delta(E,\sigma)$ is given by $A=\Sigma_{j=1}^n z_j W(f_j)$ with some $n\in\mathbb{N}$ and $z_j\in\mathbb{C}$ and $f_j\in E$. In the above example $A=\Sigma_{j=1}^n z_j W(f_j)$ is a $\mathbb{C}$-valued function on E with $A[g]=0$ for $g\in\{f_1,\ldots,f_n\}$ and $A[g]=z_j\in\mathbb{C}$ for $g=f_j$, whenever the f_j's are mutually different.

Defining the product and the *-operation as in the Weyl relations in Eq. (3.1) every polynomial of the $W(f)$, now rightly called *Weyl elements*, reduces to a linear combination, which implies that $\Delta(E,\sigma)$ becomes a *-algebra. Obviously, all of the $\Delta(E,\sigma)$ are *-isomorphic to each other and we speak of *the* *-algebra $\Delta(E,\sigma)$ associated with (E,σ). It contains the abstract Weyl system as a sub-family. (Our main example proves now the existence of the abstract Weyl system.)

Moreover, $\Delta(E,\sigma)$ is a U*-algebra, where its identity is given by $\mathbb{1}:=W(0)$ (and not by the unit function in the main example), and every Weyl element $W(f)$ is unitary.

Observation 3-2: Since the Weyl elements $W(f)\in\Delta(E,\sigma)$, $f\in E$, are linearly independent we may identify each $f\in E$ with the associated Weyl element $W(f)$. Thus every function $\Gamma:E\to\mathcal{V}$ from E into a vector space $\mathcal{V}$ extends uniquely to a linear mapping $\Gamma_{ext}:\Delta(E,\sigma)\to\mathcal{V}$ by setting

$$\Gamma_{ext}\left(\sum_{j=1}^n z_j W(f_j)\right):=\sum_{j=1}^n z_j\Gamma(f_j), \tag{3.3}$$

where $n\in\mathbb{N}$ and $z_j\in\mathbb{C}$ and the different $f_j\in E$ are arbitrary. (Note that this extension coincides with the extension from the unitaries $\mathcal{A}_J$ onto the whole U-algebra $\mathcal{A}$ given in the proof of the GNS representation in Theorem 2-3.)*

We use the Observation to extend normalized σ-positive-definite functions and Weyl systems from E to states and representations of the *-algebra $\Delta(E,\sigma)$.

Lemma 3-3: The following assertions are valid.

(a) *For each $C\in\mathcal{C}(E,\sigma)$ let ω_C be the linear functional on $\Delta(E,\sigma)$, which is obtained by the linear extension of the prescription $\langle\omega_C;W(f)\rangle:=C(f)$ to all of $\Delta(E,\sigma)$ in terms of Eq. (3.3). Then the mapping $C\mapsto\omega_C$ constitutes an affine bijection from $\mathcal{C}(E,\sigma)$ onto the convex set of all states on the *-algebra $\Delta(E,\sigma)$. (A state ω is a positive linear functional satisfying the normalization condition $\langle\omega;\mathbb{1}\rangle=1$.)*

(b) *Let $(W_R,\mathcal{H}_R)$ be a Weyl system over (E,σ). Then there exists a unique representation $(\Pi_R,\mathcal{H}_R)$ of the *-algebra $\Delta(E,\sigma)$ such that $\Pi_R(W(f))=W_R(f)$ for all $f\in E$. Conversely, every nondegenerate representation $(\Pi,\mathcal{H}_\Pi)$ of $\Delta(E,\sigma)$ induces a Weyl system $(W_\Pi,\mathcal{H}_\Pi)$ via $W_\Pi(f):=\Pi(W(f))$ for all $f\in E$.*

(c) *Let $C\in\mathcal{C}(E,\sigma)$ with associated Weyl system $(W_C,\mathcal{H}_C)$ over (E,σ) and normalized vector $\Omega_C\in\mathcal{H}_C$ according to Theorem 3-1(a). Furthermore, let ω_C and the representation $(\Pi_C,\mathcal{H}_C)$ of $\Delta(E,\sigma)$ be determined as described in the parts (a) and (b). Then $(\Pi_C,\mathcal{H}_C,\Omega_C)$ is the GNS representation of the state ω_C on $\Delta(E,\sigma)$.* [*Note that $\Delta(E,\sigma)$ is a U*-algebra, and thus every state admits a GNS representation by Theorem 2-3.*]

Proof: (a) The positivity of the so defined linear form ω_C follows from the σ-positive-definiteness of $C\in\mathcal{C}(E,\sigma)$ and the Weyl relations with

$$\langle\omega_C;A^*A\rangle=\sum_{i,j=1}^{n}\bar{z}_i z_j\exp\left\{\frac{i}{2}\sigma(f_i,f_j)\right\}C(f_j-f_i)\geqslant 0,\quad A:=\sum_{j=1}^{n}z_j W(f_j). \tag{3.4}$$

And the normalization is given by $\langle\omega_C;\mathbb{1}\rangle=\langle\omega_C;W(0)\rangle=C(0)=1$. Conversely, if ω is a state on $\Delta(E,\sigma)$, then as in (3.4) the σ-positive-definiteness of $E\ni f\mapsto\langle\omega;W(f)\rangle$ is derived.

With the extension (3.3) the parts (b) and (c) are immediate. ■

A simple example $C_{\mathrm{tr}}\in\mathcal{C}(E,\sigma)$ is given by $C_{\mathrm{tr}}(0):=1$ and $C_{\mathrm{tr}}(f):=0$ for $0\neq f\in E$, defined at the end of Sec. II B. It is immediately checked that the minimal Kolmogorov decomposition of C_{tr} is determined to be $v_{\mathrm{tr}}:E\to 1^2(E)$ with $v_{\mathrm{tr}}(f)[g]=1$ for $f=g$ and $v_{\mathrm{tr}}(f)[g]=0$ for $f\neq g$. Here $1^2(E)$ is the Hilbert space of square summable sequences over E, i.e., its elements are functions $\phi:E\to\mathbb{C}$, $g\mapsto\phi[g]$ satisfying $\|\phi\|_2^2=\Sigma_{g\in E}|\phi[g]|^2<\infty$. According to Theorem 2-1 the associated Weyl system W_{tr} acts on $1^2(E)$ as the projective shifts,

$$(W_{\mathrm{tr}}(f)\phi)[g]=\exp\left\{-\frac{i}{2}\sigma(f,g)\right\}\phi[g-f],\quad \forall g\in E,\quad \phi\in 1^2(E).$$

The state ω_{tr} associated to C_{tr} satisfies

$$\langle\omega_{\mathrm{tr}};AB\rangle=\langle\omega_{\mathrm{tr}};BA\rangle,\quad \forall A,B\in\Delta(E,\sigma), \tag{3.5}$$

hence it is a tracial state on $\Delta(E,\sigma)$. Note, in case of a nondegenerate σ it follows from the Weyl relations that ω_{tr} is the only tracial state. If $A:=\Sigma_{j=1}^{n}z_j W(f_j)$ is an arbitrary element of $\Delta(E,\sigma)$ with different f_j's, then

$$\langle\omega_{\mathrm{tr}};A^*A\rangle=\sum_{j=1}^{n}|z_j|^2. \tag{3.6}$$

The tracial state ω_{tr} is the only state which is invariant under all gauge transformations γ_χ defined in Sec. III D below. By the proof of Theorem 3-1(a) its GNS representation $(\Pi_{\mathrm{tr}},1^2(E),\Omega_{\mathrm{tr}})$ has the cyclic vector $\Omega_{\mathrm{tr}}=v_{\mathrm{tr}}(0)$, where $\Pi_{\mathrm{tr}}(W(f))=W_{\mathrm{tr}}(f)$, $\forall f\in E$.

For an arbitrary representation $(\Pi,\mathcal{H}_\Pi)$ of $\Delta(E,\sigma)$ define the representation $(\tilde{\Pi},\tilde{\mathcal{H}}_\Pi)$ by

$$(\tilde{\Pi}(W(f))\psi)[g]=W_\Pi(f)\psi[g-f],\quad \forall g\in E,\quad \psi\in\tilde{\mathcal{H}}_\Pi, \tag{3.7}$$

on the Hilbert space $\tilde{\mathcal{H}}_\Pi := 1^2(E,\mathcal{H}_\Pi) = \mathcal{H}_\Pi \otimes 1^2(E)$. Here the representation $\Pi_{\rm tr}$ is interesting in so far as the fact that the representation $\tilde{\Pi}$ is quasi-equivalent to $\Pi_{\rm tr}$. Exactly, by direct computation one immediately verifies that

$$U_\Pi \tilde{\Pi}(A) U_\Pi^* = \mathbb{1}_\Pi \otimes \Pi_{\rm tr}(A), \quad \forall A \in \Delta(E,\sigma),$$

with the unitary U_Π on $\mathcal{H}_{\tilde{\Pi}}$ defined by $(U_\Pi \psi)[g] = W_\Pi(-g)\psi[g] \forall g \in E$. Consequently,

$$\|\Pi(A)\| \leqslant \|\tilde{\Pi}(A)\| = \|\Pi_{\rm tr}(A)\|, \quad \forall A \in \Delta(E,\sigma), \tag{3.8}$$

where the inequality sign is a direct consequence of the definition of $\tilde{\Pi}$ in (3.7).

A (vector space) norm $\|\cdot\|$ is called a *-algebra norm, if the product and the *-operation are norm-continuous, i.e., $\|AB\| \leqslant \|A\|\|B\|$ and $\|A^*\| = \|A\|$. If in addition the *-algebra norm $\|\cdot\|$ satisfies the C*-norm property $\|A^*A\| = \|A\|^2$ for all $A \in \Delta(E,\sigma)$, then it is called a *C*-norm*.

We now introduce a C*-norm on $\Delta(E,\sigma)$. Two further norms on $\Delta(E,\sigma)$ are given in Sec. III E.

Proposition 3-4 (C*-norm)*: The mapping,*

$$\Delta(E,\sigma) \ni A \mapsto \|A\| := \sup\{\sqrt{\langle \omega_C ; A^*A\rangle} \,|\, C \in \mathcal{C}(E,\sigma)\}, \tag{3.9}$$

defines a C-norm on the *-algebra $\Delta(E,\sigma)$. It may also be expressed as*

$$\|A\| = \sup\{\|\Pi_R(A)\| \,|\, \textit{all Weyl systems } (W_R,\mathcal{H}_R) \textit{ over } (E,\sigma)\}, \quad \forall A \in \Delta(E,\sigma). \tag{3.10}$$

Moreover, $\|\cdot\|$ is the unique C-norm on $\Delta(E,\sigma)$, such that every representation Π of $\Delta(E,\sigma)$ is $\|\cdot\|$-continuous, i.e., $\|\Pi(A)\| \leqslant \|A\|$, $\forall A \in \Delta(E,\sigma)$.*

Proof: Let $(W_R,\mathcal{H}_R)$ be a Weyl system over (E,σ). Theorem 3-1(b) yields that for every normalized $\psi \in \mathcal{H}_R$ the mapping $E \ni f \mapsto (\psi|W_R(f)\psi) =: C_R^\psi(f)$ is an element of $\mathcal{C}(E,\sigma)$. Hence,

$$\begin{aligned}\|\Pi_R(A)\| &= \sup\{\|\Pi_R(A)\psi\| \,|\, \psi \in \mathcal{H}_R, \|\psi\| = 1\} \\ &= \sup\{\sqrt{(\psi|\Pi_R(A^*A)\psi)} \,|\, \psi \in \mathcal{H}_R, \|\psi\| = 1\} = \sup\{\sqrt{\langle \omega_{C_R^\psi}; A^*A\rangle} \,|\, \psi \in \mathcal{H}_R, \|\psi\| = 1\}.\end{aligned}$$

Consequently, Eq. (3.10) follows from Theorem 3-1(a), ensuring that $A \mapsto \|A\|$ is a semi-norm. Since $\|A\|^2 \geqslant \langle \omega_{\rm tr}; A^*A\rangle$ it follows from Eq. (3.6) that $\|A\| = 0$, if and only if $A = 0$, i.e., the strict positivity of $\|\cdot\|$. So, $\|\cdot\|$ being indeed a C*-norm is a consequence of the C*-norm property of the norms on the bounded operators on Hilbert spaces. It follows from Eq. (3.10) and Lemma 3-3(b) that every representation Π of $\Delta(E,\sigma)$ satisfies $\|\Pi(A)\| \leqslant \|A\|$ for all $A \in \Delta(E,\sigma)$.

Suppose a further C*-norm $\|\cdot\|'$ on $\Delta(E,\sigma)$ exists, such that every representation Π of $\Delta(E,\sigma)$ is $\|\cdot\|'$-continuous. Π extends continuously to the $\|\cdot\|'$-completion, and thus $\|\Pi(A)\| \leqslant \|A\|'$ by a standard result, e.g., Ref. 62, Lemma 2.3.1. Let Π be a faithful representation of the $\|\cdot\|'$-completion (the existence of faithful representations of a C*-algebra is also a standard result, e.g., Ref. 62, Theorem 2.1.10), then $\|\Pi(A)\| = \|A\|'$ for all $A \in \Delta(E,\sigma)$. By our above construction we in have in addition $\|\Pi(A)\| \leqslant \|A\|$. Hence $\|A\|' \leqslant \|A\|$ for all $A \in \Delta(E,\sigma)$. Interchanging the roles of $\|\cdot\|$ and $\|\cdot\|'$ yields $\|\cdot\| = \|\cdot\|'$. ■

A further uniqueness characterization of the C*-norm on $\Delta(E,\sigma)$ is given in Corollary 3-11 below.

By the above result every representation of the *-algebra $\Delta(E,\sigma)$ extends continuously to its $\|\cdot\|$-completion,

$$\mathcal{W}(E,\sigma) := \overline{\Delta(E,\sigma)} \tag{3.11}$$

(the overbar indicates the $\|\cdot\|$-completion). The C*-algebra $\mathcal{W}(E,\sigma)$ is called the *Weyl algebra* over the pre-symplectic space (E,σ). In the literature also the notion of CCR algebra is found.

By a $\|\cdot\|$-continuous extension, especially of the GNS representations and thus of the states, we obtain immediately the following characterization of the state space of the Weyl algebra.

Theorem 3-5 (state space): *The map $C\mapsto\omega_C$ is an affine homeomorphism from $\mathcal{C}(E,\sigma)$ onto the state space $\mathcal{S}(\mathcal{W}(E,\sigma))$ of $\mathcal{W}(E,\sigma)$, where on $\mathcal{C}(E,\sigma)$ it is considered the topology of pointwise convergence and on $\mathcal{S}(\mathcal{W}(E,\sigma))$ the weak *-topology.*

If E_0 is a subspace of E—the restriction of σ from E to E_0 is also denoted by σ—then the question arises as to how the associated Weyl algebras $\mathcal{W}(E_0,\sigma)$ and $\mathcal{W}(E,\sigma)$ are related to each other. We may do the same construction for $\Delta(E_0,\sigma)$ as above. $\Delta(E_0,\sigma)$ may be regarded as a sub-*-algebra of $\Delta(E,\sigma)$, when identifying the Weyl elements $W(f)\in\Delta(E_0,\sigma)$ with the associated Weyl elements $W(f)\in\Delta(E,\sigma)$ for each $f\in E_0$ [in our main example, where the Weyl elements are Kronecker functions, every $A\in\Delta(E_0,\sigma)$ is a $\mathbb{C}$-valued function on E_0, which extends trivially to a function on E by putting $A[g]=0$ for $g\in E\backslash E_0$]. Because of Proposition 2-2 the definition (3.9) leads to the same C*-norm on the *-algebra $\Delta(E_0,\sigma)$ as the C*-norm arising by a restriction of the C*-norm on $\Delta(E,\sigma)$,

$$\|A\|=\sup\{\sqrt{\langle\omega_{C'};A^*A\rangle}\,|\,C'\in\mathcal{C}(E_0,\sigma)\}=\sup\{\sqrt{\langle\omega_C;A^*A\rangle}\,|\,C\in\mathcal{C}(E,\sigma)\},\quad A\in\Delta(E_0,\sigma).$$

Consequently, $\mathcal{W}(E_0,\sigma)=\overline{\Delta(E_0,\sigma)}$ is a sub-C*-algebra of $\overline{\Delta(E,\sigma)}=\mathcal{W}(E,\sigma)$. If the inclusion $E_0\subset E$ is proper, then Eq. (3.6) yields that $\|A-W(f)\|\geqslant 1$ for all $A\in\mathcal{W}(E_0,\sigma)$ and $f\in E\backslash E_0$. Thus, $\mathcal{W}(E_0,\sigma)=\mathcal{W}(E,\sigma)$, if and only if $E_0=E$.

Corollary 3-6: The tracial state $\omega_{tr}\in\mathcal{S}(\mathcal{W}(E,\sigma))$ is faithful, i.e., $\langle\omega_{tr};A^*A\rangle\neq 0$ for all $A\in\mathcal{W}(E,\sigma)\backslash\{0\}$.

Proof: Because of (3.5) we have that $\{A\,|\,\langle\omega_{\rm tr};A^*A\rangle=0\}$ is a closed *-ideal of $\mathcal{W}(E,\sigma)$ (e.g., Ref. 63, Lemma I.9.6]), which is easily identified to coincide with the kernel of the GNS representation $\Pi_{\rm tr}$. But Eq. (3.8) yields that $\|\Pi(A)\|\leqslant\|\Pi_{\rm tr}(A)\|\forall A\in\mathcal{W}(E,\sigma)$ for every representation Π. Hence $\Pi_{\rm tr}$ is a faithful representation of $\mathcal{W}(E,\sigma)$, or equivalently, $\ker(\Pi_{\rm tr})=\{0\}$. ■

C. Uniqueness of the Weyl algebra

The previous construction demonstrates the existence of the C*-Weyl algebra $\mathcal{W}(E,\sigma)$. The next result characterizes its uniqueness in the desired sense, namely, that every Weyl system arises from one of its representations. Observe that in the assumptions the linear independence of the Weyl elements is replaced by the weaker condition that the elements $W(f)$ all be nonzero.

Theorem 3-7 (uniqueness): *$\mathcal{W}(E,\sigma)$ is the unique C*-algebra (up to *-isomorphy) generated by nonzero elements $W(f)$, $f\in E$, satisfying the following two assumptions:*

(U1) The elements $W(f)$, $f\in E$, fulfill the Weyl relations, Eq. (3.1).

(U2) Every Weyl system $(W_R,\mathcal{H}_R)$ over (E,σ) arises from a representation $(\Pi_R,\mathcal{H}_R)$ of $\mathcal{W}(E,\sigma)$ with $W_R(f)=\Pi_R(W(f))$ for all $f\in E$ (a relation which characterizes the representation Π_R uniquely).

Proof: The fact the Weyl algebra $\mathcal{W}(E,\sigma)$ from Eq. (3.11) satisfies the relations (U1) and (U2) has already been established. So let us demonstrate its uniqueness.

Suppose there exists a further C*-algebra $\mathcal{W}'(E,\sigma)$ with norm $\|\cdot\|'$ generated by nonzero elements $W'(f)$, $f\in E$, satisfying the assumptions (U1) and (U2). We show the linear independence of the $W'(f)$, $f\in E$. Consider the Weyl system $(W_{\rm tr},\mathcal{H}_{\rm tr})$ with normalized vector $\Omega_{\rm tr}\in\mathcal{H}_{\rm tr}$, such that $C_{\rm tr}(f)=(\Omega_{\rm tr}|W_{\rm tr}(f)\Omega_{\rm tr})$, $\forall f\in E$, which corresponds to the tracial $C_{\rm tr}\in\mathcal{C}(E,\sigma)$ according to Theorem 3-1(a). Then by assumption (U2) there exists a representation $(\Pi_{\rm tr},\mathcal{H}_{\rm tr})$ of $\mathcal{W}'(E,\sigma)$ with $W_{\rm tr}(f)=\Pi_{\rm tr}(W'(f))$. But we then have for $B:=\sum_{j=1}^n z_jW'(f_j)$ with different f_j's that

$$\|B\|'^2\geqslant\|\Pi_{\rm tr}(B)\|^2\geqslant(\Omega_{\rm tr}|\Pi_{\rm tr}(B^*B)\Omega_{\rm tr})=\sum_{i,j=1}^n\overline{z}_iz_j\exp\left\{\frac{i}{2}\sigma(f_i,f_j)\right\}C_{\rm tr}(f_j-f_i)=\sum_{j=1}^n|z_j|^2.$$

Hence $B=0$, if and only if $z_j=0$ for all $j=1,...,n$, expressing the linear independence.

The linear independence of the $W'(f)$, $f\in E$, implies the linear extensibility of the mapping $W(f)\mapsto W'(f)$, $\forall f\in E$ to a *-isomorphism from $\Delta(E,\sigma)$ onto the *-algebra $\mathrm{LH}\{W'(f)|f\in E\}$, so we may incorporate the norm $\|\cdot\|'$ also into $\Delta(E,\sigma)$ by setting $\|\Sigma_j z_j W(f_j)\|' := \|\Sigma_j z_j W'(f_j)\|'$. The $\|\cdot\|$-completion of $\Delta(E,\sigma)$ gives $\mathcal{W}(E,\sigma)$, and its $\|\cdot\|'$-completion gives $\mathcal{W}'(E,\sigma)$ up to an *-isomorphism. By assumption (U2) we now have two norms on $\Delta(E,\sigma)$, such that for both of which every Weyl system arises from a *continuous* representation of the *-algebra $\Delta(E,\sigma)$. The one-to-one correspondence between Weyl systems and nondegenerate representations from Lemma 3-3(b) implies that every representation of $\Delta(E,\sigma)$ is continuous with respect to both of the norms. By Proposition 3-4 the two norms must then coincide. ■

Let us communicate some additional results from the literature.

(a) The Weyl algebra $\mathcal{W}(E,\sigma)$ is simple, if and only if σ is nondegenerate. (It is shown in Ref. 28, resp., in the proof of Ref. 23, Theorem 5.2.8 that one has equality in Eq. (3.8), i.e., $\|\Pi(A)\|=\|\tilde{\Pi}(A)\|=\|\Pi_{\mathrm{tr}}(A)\|$, $\forall A\in\Delta(E,\sigma)$ for every representation Π of $\Delta(E,\sigma)$, if and only if σ is nondegenerate. The essential point is that the characters $f\mapsto\exp\{i\sigma(g,f)\}$, $g\in E$, are dense in the character group $\hat{E}$ of E for nondegenerate σ, only, by Lemma 4-2 [then the locally convex topology on E arising from the semi-norms $f\mapsto|\sigma(g,f)|$, $g\in E$, is Hausdorff].) Consequently, in case of a nondegenerate σ for the uniqueness of $\mathcal{W}(E,\sigma)$ in Theorem 3-7 it suffices that assumption (U1) is valid, and so the second uniqueness condition (U2) is necessary for the degenerate case, only.
(b) The C*-Weyl algebra $\mathcal{W}(E,\sigma)$ is not separable for $E\neq\{0\}$.
(c) A detailed analysis of the closed *-ideals of $\mathcal{W}(E,\sigma)$ (the kernels of representations), resp., of C*-norms on $\Delta(E,\sigma)$ is given in Ref. 34.

We finally present an easy example, which illustrates that for degenerate σ the Weyl algebra $\mathcal{W}(E,\sigma)$ cannot be simple. The degeneracy of σ is equivalent to a nontrivial null space $\ker_\sigma$, the latter being defined in Eq. (1.7). Then the symplectic form $\tilde{\sigma}$ on the quotient $\tilde{E}:=E/\ker_\sigma$ defined by $\tilde{\sigma}(\tilde{f},\tilde{g}):=\sigma(f,g)$ is nondegenerate ($\tilde{f}$ denotes the equivalence class containing f). Since $\mathcal{W}(\tilde{E},\tilde{\sigma})$ is simple, every nondegenerate representation $(\tilde{\Pi},\mathcal{H}_\Pi)$ is faithful. But $W_\Pi(f):=\tilde{\Pi}(\tilde{W}(\tilde{f}))$, $f\in E$, defines a Weyl system $(W_\Pi,\mathcal{H}_\Pi)$ over the original degenerate pre-symplectic space (E,σ) [the Weyl elements of $\mathcal{W}(\tilde{E},\tilde{\sigma})$ are denoted by $\tilde{W}(\tilde{f})$]. Hence by the above Theorem there exists a unique representation $(\Pi,\mathcal{H}_\Pi)$ of $\mathcal{W}(E,\sigma)$ with $W_\Pi(f)=\Pi(W(f))$ for each $f\in E$. It follows that

$$\Pi(W(f))=\Pi(W(g)),\ \text{but}\ \|W(f)-W(g)\|=2,\quad \text{for}\ 0\neq f-g\in\ker_\sigma$$

(the latter follows from Proposition 3-10 below). It holds $\Pi(\mathcal{W}(\ker_\sigma,0))=\mathbb{C}\mathbb{1}_\Pi$ for the commutative (σ vanishes on $\ker_\sigma$) sub-C*-Weyl algebra $\mathcal{W}(\ker_\sigma,0)$ of $\mathcal{W}(E,\sigma)$. Whereas the abstract Weyl elements $W(f)$, $f\in E$, are linearly independent, the represented Weyl operators $\Pi(W(f))=W_\Pi(f)$, $f\in E$, become linearly dependent.

D. Gauge and Bogoliubov *-automorphisms

For states and representations the continuous extension from $\Delta(E,\sigma)$ to its completion $\mathcal{W}(E,\sigma)$ has been already discussed. Here we consider *-isomorphisms, resp. *-anti-isomorphisms, in terms of such an extension.

*Proposition 3-8: Let $(\tilde{E},\tilde{\sigma})$ be a further pre-symplectic space, and suppose β to be an *-(anti-)-isomorphism from $\Delta(E,\sigma)$ onto $\Delta(\tilde{E},\tilde{\sigma})$. Then β is an isometry and extends continuously to a unique *-(anti-)isomorphism from $\mathcal{W}(E,\sigma)$ onto $\mathcal{W}(\tilde{E},\tilde{\sigma})$.*

Proof: Let Π be a faithful representation of the C*-Weyl algebra $\mathcal{W}(\tilde{E},\tilde{\sigma})$. Then $\Pi\circ\beta$ is a representation of $\Delta(E,\sigma)$, and thus we have $\|\beta(A)\|=\|(\Pi\circ\beta)(A)\|\leq\|A\|$, $\forall A\in\Delta(E,\sigma)$. The same argumentation for β^{-1} yields $\|\beta^{-1}(B)\|\leq\|B\|$, $\forall B\in\Delta(\tilde{E},\tilde{\sigma})$. Thus $\|\beta(A)\|=\|A\|$, $\forall A\in\Delta(E,\sigma)$. The extension may now be performed, since the algebraic operations are norm-continuous. ■

We specialize the above result to the case $(\tilde{E},\tilde{\sigma})=(E,\sigma)$, that is, to *-automorphisms on $\Delta(E,\sigma)$. The most basic *-automorphisms are the gauge transformations of the second kind and the Bogoliubov transformations, which are going to be treated according to the scheme described above.

Regarding E as an additive group, we denote by $\hat{E}$ the commutative group of all characters on E. For $\chi\in\hat{E}$ the associated gauge transformation of the second kind is the *-automorphism γ_χ on the *-algebra $\Delta(E,\sigma)$ satisfying

$$\gamma_\chi(W(f))=\chi(f)W(f),\quad \forall f\in E, \tag{3.12}$$

which extends continuously to $\mathcal{W}(E,\sigma)$ by Proposition 3-8. It follows that the mapping

$$\hat{E}\ni\chi\mapsto\gamma_\chi\in *\text{-aut}(\mathcal{W}(E,\sigma)) \tag{3.13}$$

is a representation of the commutative group $\hat{E}$ in terms of the group *-aut$(\mathcal{W}(E,\sigma))$ of all *-automorphisms on the Weyl algebra $\mathcal{W}(E,\sigma)$.

A symplectic transformation T on (E,σ) is a bijective $\mathbb{R}$-linear mapping $T:E\to E$ which respects the pre-symplectic form σ, that is,

$$\sigma(f,g)=\sigma(Tf,Tg),\quad \forall f,g\in E. \tag{3.14}$$

The set symp(E,σ) of all symplectic transformations on (E,σ) consitutes a group, where the group operation is given by the usual multiplication for operators. If $\dim_{\mathbb{R}}(E)>1$, then the group symp(E,σ) is noncommutative. The Bogoliubov transformation corresponding to $T\in\text{symp}(E,\sigma)$ is the unique *-automorphism α_T on $\Delta(E,\sigma)$, resp. on $\mathcal{W}(E,\sigma)$, satisfying

$$\alpha_T(W(f))=W(Tf),\quad \forall f\in E. \tag{3.15}$$

We get the following representation of the group symp(E,σ) by *-automorphisms on $\mathcal{W}(E,\sigma)$,

$$\text{symp}(E,\sigma)\ni T\mapsto\alpha_T\in *\text{-aut}(\mathcal{W}(E,\sigma)). \tag{3.16}$$

E. Norm estimates

In addition to the C*-norm $\|\cdot\|$ from Proposition 3-4 we introduce two further norms $\|\cdot\|_1$ and $\|\cdot\|_2$ on the *-algebra $\Delta(E,\sigma)$.

Proposition 3-9 (additional norms)*: Let us define two additional norms on* $\Delta(E,\sigma)$ *by*

$$\|A\|_1:=\sum_{j=1}^{n}|z_j|,\quad \|A\|_2:=\sqrt{\langle\omega_{\text{tr}};A^*A\rangle}=\sqrt{\sum_{j=1}^{n}|z_j|^2},$$

for arbitrary elements $A:=\Sigma_{j=1}^{n}z_jW(f_j)$ *of* $\Delta(E,\sigma)$ *with different* f_j*'s [cf. Eq.* (3.6)*]. Then there hold the inequalities*

$$\|A\|_2\leq\|A\|\leq\|A\|_1,\quad \forall A\in\Delta(E,\sigma). \tag{3.17}$$

$\|\cdot\|_1$ *is an *-algebra norm on the *-algebra* $\Delta(E,\sigma)$*, whereas the product is not* $\|\cdot\|_2$*-continuous.*

Proof: The first inequality sign in (3.17) follows from $\|A\|^2\geq\langle\omega_{\text{tr}};A^*A\rangle$ by the construction in Eq. (3.9). The second inequality sign in Eq. (3.17) follows from $\|W(f)\|=1$. The rest is immediate. ■

Generally the norms $\|\cdot\|_1$, $\|\cdot\|_2$, and the C*-norm $\|\cdot\|$ are different, which we are going to show. Especially, inequality (3.17) implies for $u,v\in\mathbb{C}$ and $f\neq g$ that

$$\sqrt{|u|^2+|v|^2}=\|uW(f)+vW(g)\|_2\leq\|uW(f)+vW(g)\|\leq\|uW(f)+vW(g)\|_1=|u|+|v|.$$

In the literature it is well known that $\|W(f)-W(g)\|=2$, where for its demonstration it suffices that E is an Abelian group. The following Proposition strengthens these results, making use from E being really a vector group.

Proposition 3-10: We have $\|uW(f)+vW(g)\|=\|uW(f)+vW(g)\|_1=|u|+|v|$ *for all* $u, v \in \mathbb{C}$ *and* $f\neq g$. *Further on, for* $B:=\mathbb{1}+W(f)-W(-f)$ *with* $f\neq 0$ *it holds that*

$$\|B\|_2^2=3<\|B\|^2=\|B^*B\|=\|B^*B\|_1=5<\|B\|_1^2=9.$$

Proof: Let $0\neq f\in E$ and put $E_0:=\mathbb{R}f$. Observe that $\sigma|_{\mathbb{R}f}=0$ acts trivially on the one-dimensional subspace $\mathbb{R}f$ of E. Let $z\in\mathbb{C}$. We have $W(f)+z\mathbb{1}\in\Delta(\mathbb{R}f,0)$. For every $x\in\mathbb{R}$ the continuous character $C_x(tf):=\exp\{itx\}$, $\forall t\in\mathbb{R}$ is an element of $\mathcal{C}(\mathbb{R}f,0)$. For all $x\in\mathbb{R}$ we get

$$\begin{aligned}\|W(f)+z\mathbb{1}\|^2 &\geqslant \langle \omega_{C_x};(W(f)+z\mathbb{1})^*(W(f)+z\mathbb{1})\rangle \\ &= 1+|z|^2+2\,\mathrm{Re}(zC_x(-f))=1+|z|^2+2\,\mathrm{Re}(z\exp\{-ix\}).\end{aligned}$$

Now choose $x\in\mathbb{R}$ such that $z\exp\{-ix\}=|z|$. Then we obtain $\|W(f)+z\mathbb{1}\|\geqslant 1+|z|$. Consequently the estimation (3.17) implies $\|W(f)+z\mathbb{1}\|=1+|z|$. For $f\neq g$ the Weyl relations now imply

$$\|W(f)+zW(g)\|=\|W(-g)(W(f)+zW(g))\|=\left\|W(f-g)+z\exp\left\{-\frac{i}{2}\sigma(g,f)\right\}\mathbb{1}\right\|=1+|z|.$$

Moreover, by Corollary 4-4 below we actually have $\|A\|=\sup_{x\in\mathbb{R}}|\langle\omega_{C_x};A\rangle|=\sup_{x\in\mathbb{R}}\sqrt{\langle\omega_{C_x};A^*A\rangle}$ for all $A\in\Delta(\mathbb{R}f,0)$, which finally implies $\|\mathbb{1}+W(f)-W(-f)\|^2=5$. ■

For $j=1,2$ the completion $\overline{\Delta(E,\sigma)}^j$ of $\Delta(E,\sigma)$ with respect to the norm $\|\cdot\|_j$ coincides with the sequence space $\overline{\Delta(E,\sigma)}^j\cong 1^j(E)$, where here the Weyl elements are considered as Kronecker delta functions on E. Because the tracial state ω_{tr} is faithful by Corollary 3-6, it follows from Eq. (3.17) that $\|\cdot\|_2$ extends $\|\cdot\|_1$-, resp. $\|\cdot\|$-continuously, to a norm on the completions $\overline{\Delta(E,\sigma)}^1$ and $\mathcal{W}(E,\sigma)=\overline{\Delta(E,\sigma)}$, respectively (and not only to a semi-norm). Consequently we get the inclusions

$$\Delta(E,\sigma)\subseteq\overline{\Delta(E,\sigma)}^1\subseteq\mathcal{W}(E,\sigma)\subseteq\overline{\Delta(E,\sigma)}^2, \tag{3.18}$$

which, by the above reasoning, are realized in terms of injective, continuous, *-algebraic homomorphisms, with the exception of the last one, which is not product homomorphic. The inclusions are proper for nontrivial E, since the occurring three norms are not equivalent. Observe that the inner product $(\cdot|\cdot)_2$ on the Hilbert space $\overline{\Delta(E,\sigma)}^2$ satisfies $(A|B)_2=\langle\omega_{\mathrm{tr}};A^*B\rangle$ for all $A, B\in\mathcal{W}(E,\sigma)$.

Corollary 3-11: If there exists a further C-norm* $\|\cdot\|'$ *on* $\Delta(E,\sigma)$ *with* $\|A\|_2\leqslant\|A\|'$ *for all* $A\in\Delta(E,\sigma)$, *then* $\|\cdot\|'=\|\cdot\|$.

Proof: Take a faithful representation Π of $\Delta(E,\sigma)$ with respect to the norm $\|\cdot\|'$. Then Π is $\|\cdot\|$-continuous by Proposition 3-4, i.e., $\|A\|_2\leqslant\|A\|'=\|\Pi(A)\|\leqslant\|A\|$. Especially, Π extends $\|\cdot\|$-continuously to all of $\mathcal{W}(E,\sigma)$. So $\|A\|_2\leqslant\|\Pi(A)\|$, $\forall A\in\mathcal{W}(E,\sigma)$ yields $\Pi(A)=0$, if and only if $A=0$. This is the faithfulness of Π, which is equivalent to $\|\Pi(A)\|=\|A\|$. ■

$\overline{\Delta(E,\sigma)}^1$ together with the product and *-operation as in the Weyl relations (3.1) constitutes a Banach-*-algebra, however, its norm $\|\cdot\|_1$ does not satisfy the C*-norm property in virtue of Proposition 3-10.

F. Connection to the twisted group C*-algebra

In order to establish the connection to harmonic analysis of locally compact groups, we regard E as an Abelian group with respect to the addition equipped with the discrete topology. The corresponding Borel sets are all subsets of E. The set of all regular complex Borel measures equipped with a twisted convolution product is a standard Banach-*-algebra, which we denote by

$M(E,\sigma)$ in our case. More precisely, every element B of $M(E,\sigma)$ is of the form $B=\Sigma_k z_k \delta_{f_k}$ with the point measures δ_{f_k} and some $z_k \in \mathbb{C}$. The norm $\|B\|_1=\Sigma_k|z_k|<\infty$ is the total variation norm. Thus $M(E,\sigma)$ coincides with $1^1(E)$, which may also be viewed as the space $L^1(E)$ with respect to the Haar measure, i.e., the counting measure. We introduce in $M(E,\sigma)$ the *-operation $B\mapsto B^*$, given by $B^*(\Lambda)=\overline{B(-\Lambda)}$ for all $B\in M(E,\sigma)$ and for all subsets $\Lambda\subseteq E$, and define an associative product: For B, $C\in M(E,\sigma)$ the twisted convolution is given as

$$BC(\Lambda) := \int_E dB(f) \int_E dC(g) \exp\left\{ -\frac{i}{2}\sigma(f,g)\right\} \Lambda(f+g), \quad \forall \Lambda \subseteq E, \tag{3.19}$$

where $E \ni f \mapsto \Lambda(f)$ means the characteristic function of the set Λ, [i.e., $\Lambda(f)=1$ for $f\in\Lambda$ and $\Lambda(f)=0$ elsewhere]. The Banach-*-algebra $M(E,\sigma)$, which possesses the identity δ_0 is called the *twisted algebra* of the discrete additive group E with respect to the multiplier from Eq. (1.8).[64] For the point measures one obtains a projective realization of the Abelian group E (Weyl relations),

$$\delta_f \delta_g = \exp\left\{ -\frac{i}{2}\sigma(f,g)\right\} \delta_{f+g}, \quad \delta_f^* = \delta_{-f}, \quad \forall f,g \in E. \tag{3.20}$$

The twisted group C*-algebra is defined as the enveloping C*-algebra of the twisted group Banach-*-algebra $M(E,\sigma)$, that is the completion of $M(E,\sigma)$ with respect to the C*-norm,

$$\|B\| := \sup\{\|\Pi(B)\| | \Pi \text{ representation of } M(E,\sigma)\}, \quad B\in M(E,\sigma), \tag{3.21}$$

which resembles the construction in Eq. (3.10). That this definition provides indeed a norm follows from the fact that there exists a faithful representation. Hence the representations of $M(E,\sigma)$ and those of its enveloping C*-algebra are in one-to-one correspondence given by continuous extension, resp., restriction (see, e.g., Ref. 63, Sect. I.9; Ref. 66, Sect. 7.1).

Collecting our notions we get the following connection with the previous subsections.

Corollary 3-12: The mapping $W(f)\leftrightarrow \delta_f$, $\forall f\in E$ *defines a unique isometric *-isomorphism between the Banach-*-algebras* $\Delta(E,\sigma)^1$ *and* $M(E,\sigma)$, *which extends continuously to an *-isomorphism between the C*-Weyl algebra* $\mathcal{W}(E,\sigma)$ *and the enveloping C*-algebra of* $M(E,\sigma)$.

IV. THE COMMUTATIVE WEYL ALGEBRA AND ALMOST PERIODIC COMPACTIFICATIONS

Throughout the present section suppose E to be a fixed, arbitrary, real vector space.

A. Spectrum of the commutative C*-Weyl algebra

Let us specialize the construction of the C*-Weyl algebra from Sect. III to the case of the trivial pre-symplectic form $\sigma=0$ on E. Then we obtain the commutative C*-Weyl algebra $\mathcal{W}(E,0)$, which is uniquely (in the sense of Theorem 3-7) generated by nonzero Weyl elements $W(f)$, $f\in E$, satisfying the commutative Weyl relations [cf. Eq. (3.1)]

$$W(f)W(g)=W(f+g), \quad W(f)^*=W(-f), \quad \forall f,g\in E. \tag{4.1}$$

Note, that $\mathcal{C}(E,0)$ is just the convex set of all normalized, positive-definite functions $C:E\to\mathbb{C}$ (e.g., Ref. 67, Eq. 32.1), and $\mathcal{W}(E,0)$ is the group C*-algebra of the discrete vector group E.

For later purposes we determine the spectrum $\Sigma(\mathcal{W}(E,0))$ of the commutative C*-Weyl algebra $\mathcal{W}(E,0)$, which consists of the pure states on $\mathcal{W}(E,0)$ (Ref. 62, Proposition 2.3.27). Since $\mathcal{W}(E,0)$ contains an identity, the spectrum $\Sigma(\mathcal{W}(E,0))$ is a compact subset of the compact state space $\mathcal{S}(\mathcal{W}(E,0))$ (Ref. 63, Sect. 1.3). Since the group $\hat{E}$ of all characters on E is a subset of $\mathcal{C}(E,0)$, it follows from Theorem 3-5 that for each character $\chi\in\hat{E}$ there exists a unique state ω_χ on $\mathcal{W}(E,0)$.

Proposition 4-1: It holds that $\Sigma(\mathcal{W}(E,0))=\{\omega_\chi|\chi\in\hat{E}\}$.

Proof: Since $\Sigma(\mathcal{W}(E,0))\subset\mathcal{S}(\mathcal{W}(E,0))$ every element of the spectrum $\Sigma(\mathcal{W}(E,0))$ is of the type ω_C with some $C\in\mathcal{C}(E,0)$ by Theorem 3-5. By definition of the spectrum (Ref. 62, Definition 2.3.25) we have $\langle\omega_C;AB\rangle=\langle\omega_C;A\rangle\langle\omega_C;B\rangle$ for all A, $B\in\mathcal{W}(E,0)$. Especially, with the Weyl relations (4.1) we conclude that

$$C(f+g)=\langle\omega_C;W(f+g)\rangle=\langle\omega_C;W(f)W(g)\rangle=\langle\omega_C;W(f)\rangle\langle\omega_C;W(g)\rangle=C(f)C(g),$$

for all f, $g\in E$, which implies that C is a character on E. Conversely, if $\chi\in\hat{E}\subseteq\mathcal{C}(E,0)$ is a character on E, then the corresponding state ω_χ satisfies

$$\langle\omega_\chi;W(f)W(g)\rangle=\langle\omega_\chi;W(f+g)\rangle=\chi(f+g)=\chi(f)\chi(g)=\langle\omega_\chi;W(f)\rangle\langle\omega_\chi;W(g)\rangle,$$

for all f, $g\in E$. Taking linear combinations of the Weyl elements we arrive at $\langle\omega_\chi;AB\rangle=\langle\omega_\chi;A\rangle\langle\omega_\chi;B\rangle$ for all A, $B\in\Delta(E,0)$, which by continuity extends to all A, $B\in\mathcal{W}(E,0)$. Hence $\omega_\chi\in\Sigma(\mathcal{W}(E,0))$. ■

B. Commutative C*-algebra of almost periodic functions

The subsequent commutative *-resp. C*-algebras are algebras of $\mathbb{C}$-valued functions on certain sets Λ (specified below), where the *-algebraic operations are defined pointwise in the usual way:

$$(\psi+z\phi)[\lambda]:=\psi[\lambda]+z\phi[\lambda],\quad(\psi\phi)[\lambda]:=\psi[\lambda]\phi[\lambda],\quad\psi^*[\lambda]:=\overline{\psi[\lambda]},\tag{4.2}$$

for all points $\lambda\in\Lambda$. The identity $\mathbb{1}$ is the constant function $\mathbb{1}[\lambda]=1$, $\forall\lambda\in\Lambda$, and the C*-norm is the sup-norm,

$$\|\psi\|:=\sup\{|\psi[\lambda]||\lambda\in\Lambda\}.\tag{4.3}$$

Let be given a locally convex Hausdorff vector space topology τ on E. On the topological dual of E with respect to τ, denoted by E'_τ, we define for each $f\in E$ the periodic function $\xi(f)$ as the bounded $\sigma(E'_\tau,E)$-continuous mapping,

$$\xi(f):E'_\tau\to\mathbb{C},\quad F\mapsto\exp\{iF(f)\}=:\xi(f)[F],\quad F\in E'_\tau.\tag{4.4}$$

The $\xi(f)$, $f\in E$, are linearly independent (by Hahn-Banach arguments, cf., e.g., Ref. 65, Sec. IV.3). The linear hull $\mathrm{LH}\{\xi(f)|f\in E\}$ is actually a commutative *-algebra, where the product and the *-operation from Eq. (4.2) give a realization of the commutative Weyl relations (4.1),

$$\xi(f)\xi(g)=\xi(f+g),\quad\xi(f)^*=\xi(-f),\quad\forall f,g\in E.$$

Its completion with respect to the sup-norm (4.3) coincides with the commutative C*-algebra $\mathrm{AP}(E'_\tau)$ of the almost periodic, $\sigma(E'_\tau,E)$-continuous, $\mathbb{C}$-valued functions on E'_τ, (Ref. 67, Eqs. 18.2 and 33.26).

In Ref. 59 the Gelfand representation of $\mathrm{AP}(E'_\tau)$ is constructed in terms of the so-called almost periodic compactification aE'_τ of E'_τ: For every $F\in E'_\tau$ the translation T_F is a bounded operator acting on the Banach space $\mathrm{AP}(E'_\tau)$ by $(T_F\psi)[G]:=\psi[G-F]$, $\forall G\in E'_\tau$ for each $\psi\in\mathrm{AP}(E'_\tau)$. (For the Gelfand representation, cf., e.g., Ref. 62, Sect. 2.3.5; Ref. 63, Sect. I.3.) The mapping $F\mapsto T_F$ constitutes a group representation of the additive group E. The closure of the group $\{T_F|F\in E'_\tau\}$ with respect to the strong operator topology leads to a compact commutative group, which is called the almost periodic compactification aE'_τ, and into which the additive group E'_τ is injectively, densely, and continuously embedded via $F\mapsto T_F$. In this sense we consider E'_τ as a dense subgroup of aE'_τ.

Each $\psi \in \mathrm{AP}(E'_\tau)$ extends uniquely to a continuous function on aE'_τ, in which sense $\mathrm{AP}(E'_\tau)$ is *-isomorphic to the C*-algebra $\mathrm{C}(aE'_\tau)$ of the continuous, $\mathbb{C}$-valued functions on the compact group aE'_τ. In the following we identify these two C*-algebras. Note that for finite dimensional E the almost periodic compactification of E'_τ coincides with its Bohr compactification.

C. Continuous functions algebra on the character group

The character group $\hat{E}$ is compact in the so-called Δ-resp. P-topology arising from the discrete topology on E, cf., e.g., Ref. 67, Eqs. 23.13 and 23.15. This topology on $\hat{E}$ coincides with the topology of pointwise convergence.

Similarly to (4.4) we define for each $f \in E$ the bounded continuous evaluation map,

$$\eta(f): \hat{E} \to \mathbb{C}, \quad \chi \mapsto \chi(f) =: \eta(f)[\chi]. \tag{4.5}$$

It suffices to evaluate the $\eta(f)$, $f \in E$, on the τ-continuous characters to prove their linear independence similarly to that of the $\xi(f)$, $f \in E$, [cf. also Lemma 4-2(a)]. Also here the linear hull is actually a commutative *-algebra, where the product and the *-operation from Eq. (4.2) provide the following realization of the commutative Weyl relations (4.1),

$$\eta(f)\,\eta(g) = \eta(f+g), \quad \eta(f)^* = \eta(-f), \quad \forall f,g \in E.$$

The Stone-Weierstrass theorem implies that the completion of the *-algebra $\mathrm{LH}\{\eta(f) | f \in E\}$ with respect to the sup-norm (4.3) coincides with the commutative C*-algebra $\mathrm{C}(\hat{E})$ of all continuous, $\mathbb{C}$-valued functions on the compact set $\hat{E}$.

D. *-Isomorphic commutative algebras

Let us first point out connections between the topological dual E'_τ and the character group $\hat{E}$.

Lemma 4-2: Let our real vector space E be equipped with a locally convex Hausdorff topology τ. The following two assertions are valid:

(a) The mapping $F \mapsto \exp\{iF(\cdot)\}$ is a bijection from E'_τ onto the group $\hat{E}_\tau$ of all τ-continuous characters on the additive group E.

(b) $\hat{E}_\tau$ is dense in $\hat{E}$ with respect to the topology of pointwise convergence.

Proof: Part (a) is well known, e.g., Ref. 68, Sec. IV-1.2, resp., Ref. 67, Eq. 23.32(a). Part (b). $\hat{E}_\tau$ is a subgroup of $\hat{E}$ with the annihilator

$$A(\hat{E}_\tau) = \{f \in E | \chi(f) = 1, \forall \chi \in \hat{E}_\tau\} = \{f \in E | \exp\{iF(f)\} = 1, \forall F \in E'_\tau\}.$$

But by the assumptions on τ and E the Hahn-Banach theorem is valid, and thus there exists for every $0 \neq g \in E$ a $G \in E'_\tau$ with $G(g) = 1$ (cf., e.g., Ref. 65, Corollary IV.3.15). Consequently, $A(\hat{E}_\tau) = \{0\}$. A vanishing annihilator implies $\hat{E}_\tau$ to be dense in $\hat{E}$ with respect to the Δ-topology on $\hat{E}$, Ref. 67, Eq. 23.24. ■

In Theorem 4-5 below the bijection $E'_\tau \ni F \mapsto \exp\{iF(\cdot)\} \in \hat{E}_\tau$ from part (a) of the above lemma is shown to extend continuously to a group isomorphism between the compact groups aE'_τ and $\hat{E}$. For the proof of this result we need, however, the *-isomophic structure of the considered commutative algebras, which is of interest for its own.

Theorem 4-3: *Let the real vector space E be equipped with a locally convex Hausdorff topology τ. There exist unique *-isomorphisms,*

$$\mathcal{W}(E,0) \cong \mathrm{AP}(E'_\tau) \cong \mathrm{C}(\hat{E}),$$

which satisfy $W(f) \leftrightarrow \xi(f) \leftrightarrow \eta(f)$ for all $f \in E$.

Consequently, the C-algebra $\mathrm{AP}(E'_\tau) = \mathrm{C}(aE'_\tau)$ is independent from the chosen locally convex Hausdorff topology τ on E.*

Proof: The elements $\xi(f)$ are linearly independent, as well as the $\eta(f)$, and as the Weyl elements $W(f)$, $f\in E$. Hence the linear extensions of the bijections $W(f)\leftrightarrow\xi(f)\leftrightarrow\eta(f)\forall f\in E$ lead to *-isomorphisms between the commutative *-algebras $\Delta(E,0)$, $\mathrm{LH}\{\xi(f)|f\in E\}$, and $\mathrm{LH}\{\eta(f)|f\in E\}$ (using the fact that every polynomial of the generating elements reduces to a linear combination).

Let us first prove the *-isomorphism $\mathrm{AP}(E'_\tau)\cong\mathrm{C}(\hat{E})$! Since $\hat{E}_\tau\cong E'_\tau$ is dense in $\hat{E}$ by the above lemma, we have for arbitrary linear combinations,

$$\left\|\sum_{j=1}^{n} z_j\eta(f_j)\right\| = \sup_{\chi\in\hat{E}}\left|\sum_{j=1}^{n} z_j\chi(f_j)\right| = \sup_{F\in E'_\tau}\left|\sum_{j=1}^{n} z_j\exp\{iF(f_j)\}\right| = \left\|\sum_{j=1}^{n} z_j\xi(f_j)\right\|,$$

which leads to the *-isomorphism $\mathrm{C}(\hat{E})\cong\mathrm{AP}(E'_\tau)$.

We turn to the *-isomorphism $\mathcal{W}(E,0)\cong\mathrm{C}(\hat{E})$! Denote by β the *-isomorphism from $\Delta(E,0)$ onto $\mathrm{LH}\{\eta(f)|f\in E\}$, given by $\beta(\Sigma_{j=1}^{n}z_jW(f_j))=\Sigma_{j=1}^{n}z_j\eta(f_j)$ for arbitrary $z_j\in\mathbb{C}$, $f_j\in E$, and $n\in\mathbb{N}$. If Π is a faithful representation of $\mathrm{C}(\hat{E})$, then $\Pi\circ\beta$ is a representation of $\Delta(E,0)$. From the last assertion in Proposition 3-4 it follows that $\|\beta(A)\|=\|(\Pi\circ\beta)(A)\|\leqslant\|A\|$ for all $A\in\Delta(E,0)$.

We now show the converse relation $\|\beta(A)\|\geqslant\|A\|$. $\hat{E}$ being compact, the states on the commutative C*-algebra $\mathrm{C}(\hat{E})$ are the probability measures $M_p(\hat{E})$ on $\hat{E}$, i.e., for the state $\mu\in M_p(\hat{E})$ we have the expectations $\langle\mu;B\rangle=\int_{\hat{E}}B\,d\mu$ for all $B\in\mathrm{C}(\hat{E})$ (see, e.g., Ref. 69, Theorem 7.3.5; Ref. 65, Proposition IV.4.1). With Bochner's theorem (Ref. 67, Eq. 33.3) it follows that the Fourier transformation $C_\mu(f):=\int_{\hat{E}}\eta(f)\,d\mu=\langle\mu;\eta(f)\rangle$, $\forall f\in E$ is an affine bijection from $M_p(\hat{E})$ onto $\mathcal{C}(E,0)$. Thus with the construction of the states on $\Delta(E,0)$ from the elements of $\mathcal{C}(E,0)$ given in Lemma 3-3(a) we conclude that $\langle\omega_{C_\mu};A\rangle=\langle\mu;\beta(A)\rangle$ for every $A\in\Delta(E,0)$. Finally with Eq. (3.9) it follows that

$$\|A\|^2=\sup\{\langle\omega_{C_\mu};A^*A\rangle|\mu\in M_p(\hat{E})\}=\sup\{\langle\mu;\beta(A^*A)\rangle|\mu\in M_p(\hat{E})\}\leqslant\|\beta(A)\|^2,$$

for all $A\in\Delta(E,0)$, where we have used $\|\mu\|=1$ in the estimation $\langle\mu;B^*B\rangle\leqslant\|B^*B\|=\|B\|^2$. Hence $\|A\|=\|\beta(A)\|$ for all $A\in\Delta(E,0)$.

The existence of the *-isomorphism $\mathcal{W}(E,0)\cong\mathrm{C}(\hat{E})$ may also be proved without the use of Bochner's theorem, as we are going to show. Restricting the affine homeomorphism $\mathcal{C}(E,0)\ni C\mapsto\omega_C\in\mathcal{S}(\mathcal{W}(E,0))$ in Theorem 3-5 to the subset $\hat{E}\subseteq\mathcal{C}(E,0)$, it follows with Proposition 4.1 that the mapping $\chi\mapsto\omega_\chi$ is a homeomorphism from $\hat{E}$ onto the spectrum $\Sigma(\mathcal{W}(E,0))$ [on $\hat{E}$ we consider the topology of pointwise convergence and on $\Sigma(\mathcal{W}(E,0)]$ the weak *-topology inherited from the dual $\mathcal{W}(E,0)^*$, resp. from the state space $\mathcal{S}(\mathcal{W}(E,0))$. Thus we may identify the commutative C*-algebras $\mathrm{C}(\Sigma(\mathcal{W}(E,0))$ and $\mathrm{C}(\hat{E})$. Consequently the *-isomorphism β from $\mathcal{W}(E,0)$ onto $\mathrm{C}(\hat{E})$ with $\beta(W(f))=\eta(f)$ for all $f\in E$ is nothing other than the Gelfand representation of the commutative C*-algebra $\mathcal{W}(E,0)$. It fulfills $\beta(A)(\chi)=\langle\omega_\chi;A\rangle$ for all $A\in\mathcal{W}(E,0)$ and each $\chi\in\hat{E}$. ■

The above Theorem simplifies the construction of the norm on $\Delta(E,0)$ given in Eq. (3.9).

Corollary 4-4: For the C-norm $\|\cdot\|$ on $\Delta(E,0)$ from Eq.* (3.9) *we have for all $A\in\mathcal{W}(E,0)$ that*

$$\|A\|=\sup\{|\langle\omega_\chi;A\rangle||\chi\in\hat{E}_\tau\cong E'_\tau\}=\sup\{\sqrt{\langle\omega_\chi;A^*A\rangle}|\chi\in\hat{E}_\tau\cong E'_\tau\}. \tag{4.6}$$

E. Universality of almost periodic compactifications

Let Λ be a compact set and $\mathrm{C}(\Lambda)$ the commutative C*-algebra of the continuous, $\mathbb{C}$-valued functions on Λ. It is well known (e.g., Ref. 63, Proposition 1.4.5), that the mapping $\Lambda\ni\lambda\mapsto\delta_\lambda$ defined by the point evaluation $\langle\delta_\lambda;B\rangle:=B[\lambda]$, $\forall B\in\mathrm{C}(\Lambda)$ [$\delta_\lambda\in M_p(\Lambda)$ is the point measure at

$\lambda \in \Lambda]$ is a homeomorphism from Λ onto the spectrum $\Sigma(\mathrm{C}(\Lambda))$ (pure states) of the C*-algebra $\mathrm{C}(\Lambda)$, where on $\Sigma(\mathrm{C}(\Lambda))$ we consider the weak *-topology. Hence the *-isomorphism $\mathrm{AP}(E'_\tau) = \mathrm{C}(aE'_\tau) \cong \mathrm{C}(\hat{E})$ from Theorem 4-3 leads to the following conclusion.

Theorem 4-5: *Let our real vector space E be equipped with a locally convex Hausdorff topology τ. The embedding $E'_\tau \ni F \mapsto \exp\{iF(\cdot)\} \in \hat{E}$ extends continuously to a continuous group isomorphism between the compact groups aE'_τ and $\hat{E}$.*

Consequently, the almost periodic compactification aE'_τ of the dual E'_τ is independent from the chosen locally convex Hausdorff topology τ on E.

Proof: Denote by γ the *-isomorphism from $\mathrm{AP}(E'_\tau) = \mathrm{C}(aE'_\tau)$ onto $\mathrm{C}(\hat{E})$ satisfying $\gamma(\xi(f)) = \eta(f)$ for all $f \in E$ from Theorem 4-3. The (restriction of the) dual mapping γ^* is a homeomorphism from $\Sigma(\mathrm{C}(\hat{E}))$ onto $\Sigma(\mathrm{C}(aE'_\tau))$. Using the homeomorphisms $\Sigma(\mathrm{C}(\hat{E})) \cong \hat{E}$ and $\Sigma(\mathrm{C}(aE'_\tau)) \cong aE'_\tau$, we conclude that the mapping γ^* gives rise to a homeomorphism $\tilde{\gamma}$ from $\hat{E}$ onto aE'_τ.

Now we specify $\tilde{\gamma}$. From Eqs. (4.4) and (4.5) it follows that we have $\xi(f)[F] = \exp\{iF(f)\} = \eta(f)[\exp\{iF(\cdot)\}]$ for all $F \in E'_\tau$, which implies

$$\langle \delta_F ; B \rangle = B[F] = \gamma(B)[\exp\{iF(\cdot)\}] = \langle \delta_{\exp\{iF(\cdot)\}} ; \gamma(B) \rangle = \langle \gamma^*(\delta_{\exp\{iF(\cdot)\}}); B \rangle, \quad \forall F \in E'_\tau,$$

for every $B \in \mathrm{AP}(E'_\tau) = \mathrm{C}(aE'_\tau)$. Equivalently we have $\delta_F = \gamma^*(\delta_{\exp\{iF(\cdot)\}})$ for all $F \in E'_\tau$. Consequently, $\tilde{\gamma}(\exp\{iF(\cdot)\}) = F$ for all $F \in E'_\tau$. Now observe that $\hat{E}_\tau$ is dense in $\hat{E}$ by Lemma 4-2, and that E'_τ is dense in aE'_τ. ■

V. CONCLUSIONS AND OUTLOOK

The preceding treatment of a distinguished C*-Weyl algebra over a general pre-symplectic space (E,σ) decisively takes advantage of the Kolmogorov decomposition for Σ-positive-definite functions on projective involutive semigroups (cf. Sect. II A). In our case, the projective involutive semigroup is the additive group E with the antisymmetric bicharacter $\Sigma(f,g) = \exp\{-i/2\hbar\sigma(f,g)\}$, $f, g \in E$, where we now make explicit Planck's constant $\hbar$, for discussing some physical conclusions.

Each Σ-positive-definite function $C \in \mathcal{C}(E,\hbar\sigma)$, including the nonregular ones, determines a Weyl system $(\mathcal{W}_C, \mathcal{H}_C)$ in the Hilbert space $\mathcal{H}_C$, as well as a norm for each element A in the U*-algebra $\Delta(E,\hbar\sigma)$, given by the linear hull of the abstract Weyl system. The supremum of these norms is the natural C*-norm in $\Delta(E,\hbar\sigma)$. The C*-norm-completion of $\Delta(E,\hbar\sigma)$ leads to the C*-Weyl algebra $\mathcal{W}(E,\hbar\sigma)$, with Weyl elements $W^\hbar(f)$, $f \in E$.

The fundamental symmetries may be treated in complete analogy to Bogoliubov and gauge automorphisms in the case of a nondegenerate symplectic form; cf. Sec. III D. For $\sigma = 0$ our treatment produces a smeared classical field theory over the flat Poisson manifold E'_τ, which in general decomposes into several symplectic leaves. It has a surprising analogy to the procedure of second quantization, especially for the symmetry generators, as will be shown in the forthcoming work.

In $\mathcal{W}(E,\hbar\sigma)$ there are also natural generalizations of L^1- and L^2-norms, which we have analyzed in more detail than in the mentioned literature. Completing $\Delta(E,\hbar\sigma)$ with respect to the L^1-norm leads to a Banach-*-algebra, which is *-isomorphic to the twisted convolution algebra of the discrete finite measures on (E,σ). Let us stress in view of future applications that the presented method, based on Kolmogorov decompositions, is quite generally applicable to discrete Abelian groups with only the exception of Proposition 3-10.

As will be substantiated by subsequent work, it is a powerful technical instrument to have a unique C*-Weyl algebra over $(E,\hbar\sigma)$, for every pre-symplectic space E and for every $\hbar \in \mathbb{R}$. For the classical case $\hbar = 0$, discussed in Sec. IV, the C*-algebraic set up leads in many respects to a fresh point of view. In Ref. 70 we treat the commutative Weyl algebra as the C*-algebra of observables for a classical Hamiltonian field theory, which—similarly to the more familiar quantum case—is formulated in terms of the smeared field formalism. This provides not only a smooth

transition between the quantized and the classical theory but offers also new mathematical and calculational possibilities for dealing with classical fields. This applies especially to Hamiltonian electrodynamics in suitable flat gauges. The Poisson bracket $\{\cdot,\cdot\}$ of the classical field theory is commonly formulated as

$$\{A,B\}[F] := -\sigma(d_F A, d_F B), \quad \forall F \in E'_\tau, \quad A,B \in \mathcal{P},$$

where the constant Poisson tensor field on the flat phase space E'_τ arises from a nontrivial pre-symplectic form σ on the test function space E (cf. also Refs. 71, 72). The Poisson algebra $\mathcal{P}$ consists of suitable differentiable functions $A: E'_\tau \to \mathbb{C}$ on phase space, which constitute a dense set in $\mathrm{AP}(E'_\tau)$.

In this context let us emphasize that the introduction of the quantized observable algebras for a given pre-symplectic space (E,σ) does not, for itself, constitute a quantization of the classical theory. A family of canonical quantizations may be introduced within the frame of the C*-Weyl algebras, however, by associating with the classical algebraic Weyl elements $W^0(f) \in \mathcal{W}(E,0)$, $f \in E$, certain elements $Q_\hbar(W^0(f)) \in \mathcal{W}(E,\hbar\sigma)$. It is a natural—but by no means the only—choice to set $Q_\hbar(W^0(f)) := W^\hbar(f)$, that is, to relate the Weyl elements in $\mathcal{W}(E,\hbar\sigma)$ with the classical Weyl elements, and to extend this mapping in a linear and *-preserving manner. In Ref. 73 this quantization is elaborated in the case of degenerate σ, so that one employs the general C*-Weyl algebras $\mathcal{W}(E,\hbar\sigma)$, $\hbar \in \mathbb{R}$, described in the main text. This form of a Weyl quantization is identified in Ref. 73 as a *strict deformation quantization* in the sense of Refs. 74 and 75 of certain Poisson algebras $(\mathcal{P},\{\cdot,\cdot\})$, which are sub-*-algebras of the commutative Weyl algebra $\mathcal{W}(E,0) \cong \mathrm{AP}(E'_\tau)$. These constructions, conforming with the strategy of algebraic quantum field theory, generalize then the set up of Weaver,[76] who erects over an infinite-dimensional Hilbert space as test function space E, with the nondegenerate $\sigma(\cdot,\cdot) = \mathrm{Im}(\cdot|\cdot)$, a strict deformation quantization by using a special von Neumann algebra.

Considering the set of all Planck parameters $\mathbb{R} \ni \hbar$ simultaneously, one obtains in Ref. 73 a family of the general C*-Weyl algebras $(\mathcal{W}(E,\hbar\sigma))_{\hbar\in\mathbb{R}}$, which can be turned into a certain *continuous field of C*-algebras* in the sense of Ref. 77. In this manner one arrives at a continuous quantization,[75] which exhibits especially strong continuity properties for the classical limit $\hbar \to 0$.

Algebraic and Dirac–Hestenes spinors and spinor fields

Waldyr A. Rodrigues, Jr.[a)]
Institute of Mathematics, Statistics and Scientific Computation, IMECC–UNICAMP CP 6065, 13083-970 Campinas, SP, Brazil

(Received 25 November 2003; accepted 5 April 2004;
published online 14 June 2004)

Almost all presentations of Dirac theory in first or second quantization in physics (and mathematics) textbooks make use of covariant Dirac spinor fields. An exception is the presentation of that theory (first quantization) offered originally by Hestenes and now used by many authors. There, a new concept of spinor field (as a sum of nonhomogeneous even multivectors fields) is used. However, a careful analysis (detailed below) shows that the original Hestenes definition cannot be correct since it conflicts with the meaning of the Fierz identities. In this paper we start a program dedicated to the examination of the mathematical and physical basis for a comprehensive definition of the objects used by Hestenes. In order to do that we give a *preliminary* definition of algebraic spinor fields (ASF) and Dirac–Hestenes spinor fields (DHSF) on Minkowski space–time as some equivalence classes of pairs (Ξ_u, ψ_{Ξ_u}), where Ξ_u is a spinorial frame field and ψ_{Ξ_u} is an appropriate sum of multivectors fields (to be specified below). The necessity of our definitions are shown by a careful analysis of possible formulations of Dirac theory and the meaning of the set of Fierz identities associated with the bilinear covariants (on Minkowski space–time) made with ASF or DHSF. We believe that the present paper clarifies some misunderstandings (past and recent) appearing on the literature of the subject. It will be followed by a sequel paper where definitive definitions of ASF and DHSF are given as appropriate sections of a vector bundle called the *left* spin-Clifford bundle. The bundle formulation is essential in order to be possible to produce a coherent theory for the covariant derivatives of these fields on arbitrary Riemann–Cartan space–times. The present paper contains also Appendixes A–E which exhibits a truly useful collection of results concerning the theory of Clifford algebras (including many tricks of the trade) necessary for the intelligibility of the text. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1757037]

I. INTRODUCTION

Physicists usually make first contact with Dirac spinors and Dirac spinor fields when they study relativistic quantum theory. At that stage they are supposed to have had contact with a good introduction to relativity theory and know the importance of the Lorentz and Poincaré groups. So, they are told that Dirac spinors are elements of a complex four-dimensional space $\mathbb{C}^4$, which are the carrier space of a particular representation of the Lorentz group. They are told that when you do Lorentz transformations Dirac spinors behave in a certain way, which is different from the way vectors and tensors behave under the same transformation. Dirac matrices are introduced as certain matrices on $\mathbb{C}(4)$ satisfying certain anticommutation rules and it is said that they close a particular Clifford algebra, known as Dirac algebra. The next step is to introduce Dirac wave functions. These are mappings, $\Psi: \mathcal{M} \to \mathbb{C}^4$, from Minkowski space–time $\mathcal{M}$ (at that stage often introduced as an affine space) to the space $\mathbb{C}^4$, which must have the structure of a Hilbert space. After that, Dirac equation, which is a first order partial differential equation is introduced for $\Psi(x)$. Physics come into play by interpreting $\Psi(x)$ as the quantum wave function of the electron. Problems with

a)Electronic mail: walrod@mpc.com.br or walrod@ime.unicamp.br

this theory are discussed and it is pointed out that the difficulties can only be solved in relativistic quantum theory, where the Dirac spinor field, gains a new status. It is no more simply a mapping $\Psi:\mathcal{M}\rightarrow\mathbb{C}^4$, but a more complicated object [it becomes an operator valued distribution in a given Hilbert space (see, e.g., Ref. 162 for a correct characterization of these objects)] whose expectation values on certain one particle states can be represented by objects like Ψ. From a pragmatic point of view, only this knowledge is more than satisfactory. However, that approach, we believe, is not a satisfactory one to any scientist with an enquiring mind, in particular to one that is worried with the foundations of quantum theory. For such person the first questions which certainly occur are what is the geometrical meaning of the Dirac spinor wave function? From where did this concept come from?

Pure mathematicians, who study the theory of Clifford algebras, e.g., using Chevalley's classical books,[38,39] learn that spinors are elements of certain minimal *ideals* (do not worry if you did not know the meaning of this concept, it is not a difficult one and is introduced in Appendix B) in Clifford algebras. In particular Dirac spinors are the elements of a minimal ideal in a particular Clifford algebra, the Dirac algebra. Of course, the relation of that approach (*algebraic spinors*), with the one learned by physicists (covariant spinors) is known (see, e.g., Refs. 14, 67, and 68), but is not well known by the great majority of physicists, even for many which specialize in general relativity and more advanced theories, like string and *M*-theory.

Now, the fact is that the algebraic spinor concept (algebraic spinor fields on Minkowski space–time will be studied in details in what follows, and in Ref. 126 where the concept is introduced using fiber bundle theory on general Lorentzian manifolds) (as it is the case of the covariant spinor concept) fail to reveal the true geometrical meaning of spinor in general and Dirac spinors in particular.

In 1966, Hestenes[81] introduced a new definition of spinor field, that he called later *operator* spinor field. Objects in this class which in this paper, will be called Dirac–Hestenes spinor fields, have been introduced by Hestenes as mappings $\psi:\mathcal{M}\rightarrow\mathbb{R}^0_{1,3}$, where $\mathbb{R}^0_{1,3}$ is the even subalgebra of $\mathbb{R}_{1,3}$, a particular Clifford algebra, technically known as the *space–time* algebra. [$\mathbb{R}_{1,3}$ is not the original Dirac algebra, which is the Clifford algebra $\mathbb{R}_{4,1}$, but is closely related to it, indeed $\mathbb{R}_{1,3}$ is the even subalgebra of the Dirac algebra (see the Appendix B for details).] Hestenes in a series of remarkable papers[80,82–85,75] applied his new concept of spinor to the study of Dirac theory. He introduced an equation, now known as the Dirac–Hestenes equation, which does *not* contain (explicitly) imaginary numbers and obtained a very clever interpretation of that theory through the study of the geometrical meaning of the so-called bilinear covariants, which are the observables of the theory. He further developed an interpretation of quantum theory from his formalism,[88,89] that he called the *Zitterbewegung* interpretation. Also, he showed how his approach suggests a geometrical link between electromagnetism and the weak interactions, different from the original one of the standard model.[87]

Hestenes papers and his book with Sobczyk[86] have been the inspiration for a series of international conferences on *"Clifford Algebras and their Applications in Mathematical Physics"* which in 2002 has had its sixth edition. A consultation of the table of contents of the last two conferences[1,145,2] certainly will show that Clifford algebras and their applications generated a wider interest among many physicists, mathematicians, and even in engineering and computer sciences. (In what follows we quote some of the principal papers that we have had opportunity to study. We apologize to any author who thinks that his work is a worthy one concerning the subject and is not quoted in the present paper.) Physicists used Clifford algebras concepts and Hestenes methods, in many different applications. As some examples, we quote some developments in relativistic quantum theory as, e.g., Refs. 36, 37, 45, 46, 48–52, 56, 58, 74, and 70. The papers by De Leo and collaborators exhibit a close relationship between Hestenes methods and quaternionic quantum mechanics, as developed, e.g., by Adler,[4] a subject that is finding a renewed interest. Also, Clifford algebra methods have been used[102,135,149,151,152,165–168] to give an intuitive and geometrical clear picture of the dynamics of superparticles.[3,11,12,140,143,153,160,163] Also, that papers clarify the meaning of Grassmann variables and their calculus.[17] The relation with the *Zitterbewegung* model of Barut and collaborators[8–10] appears in a novel and less speculative way. Even

more, in Ref. 151 it is shown that the concept of Dirac–Hestenes spinor field is closely related to the concepts of superfields as introduced by Witten.[169] Clifford algebras methods have also been used in disclosing a surprising connection between the Dirac and Maxwell and Seiberg–Witten[159] equations, as studied, e.g., in Refs. 155, 164, and 168, which suggest several physical developments. Applications of Clifford algebras methods in general relativity appeared also, e.g., in Refs. 35, 90, 54, 55, 57, 58, 62, 103–105, 119, 134, and 154, and suggest new ways for looking to the gravitational field. Clifford algebras methods, have been applied successfully also in quantum field theory, as, e.g., in Refs. 60 and 138 and more recently in string and p-brane theories, with noticeable results[25–34,136,137] which are worth being more carefully investigated.

Of course, Clifford algebras and Dirac operators are standard topics of research in Mathematics (see, e.g., Ref. 20), but we must say that Hestenes ideas have been an inspiring idea for mathematicians also. In particular, the concept of Clifford valued functions with domain in a manifold (the operator spinor fields are particular functions of this type) developed in a new, beautiful and powerful branch of mathematics.[47] Hestenes ideas, as we said, have found also their use in engineering and computer sciences, as in the study of neural circuits[91,92] and robotics and perception action systems.[18,19,99,100,42,59,101,125,161]

Having made all this propaganda, which we hope have awakened the reader's interest in studying Clifford algebras, we must remark, that (as often happens for every pioneer work) the concept of Dirac–Hestenes spinor field, as originally introduced by Hestenes, and used by many other researchers, is not a concept free of criticisms and objections from the mathematical point of view.

However, it is an important concept and one of the objectives of this paper and also of Ref. 126 is to give a presentation of the subject free of all previous criticisms, which are discussed in the next sections. The reader may ask if the enterprising for learning the theory presented below is worth the time. We think that the answer is yes, whether it be a physicist or mathematician. To encourage physicists, which may eventually become interested in the subject after reading the above propaganda, we say that the mathematical tools used, even if they may look complex at first sight, are indeed nothing more than easy additions to the contents of a linear algebra course. The main reward to someone that studies what follows is that they will start seeing some subjects that they thought were well known, under a new and (we believe) illuminating point of view. This hopefully may help anyone who is searching for new physical theories. For mathematicians, we say that the point of view developed here is somewhat new in relation to the original Chevalley's one and we believe, it is more satisfactory. In particular, the present paper serves as a preliminary step towards a rigorous theory of algebraic and Dirac–Hestenes spinor fields as sections of some well-defined fiber bundles, and the theory of the covariant derivatives of these fields. Having said all that, what is the present paper about?

We give definitions of algebraic spinor fields (ASF) and Dirac–Hestenes spinor fields (DHSF) living on Minkowski space–time and show how Dirac theory can be formulated in terms of these objects. [Minkowski space–time is parallelizable and as such admits a spin structure. In general, a spin structure does not exist for an arbitrary manifold equipped with a metric of signature (p,q). The conditions for existence of a spin structure in a general manifold are discussed in Refs. 93, 131, and 133. For the case of Lorentzian manifolds, see Ref. 72.] We start our presentation in Sec. II by studying a not-well-known subject, namely, the geometrical equivalence of representation modules of simple Clifford algebras $\mathcal{C}\ell(V,\mathbf{g})$. This concept, together with the concept of *spinorial frames* play a crucial role in our definition of algebraic spinors (AS) and of ASF. Once we grasp the definition of AS and particularly of Dirac AS we define Dirac–Hestenes spinors (DHS) in Sec. IV. Whereas AS may be associated to any real vector space of arbitrary dimension $n=p+q$ equipped with a nondegenerated metric of arbitrary signature (p,q), this is not the case for DHS. (ASF can be defined on more general manifolds called spin manifolds. This will be studied in Ref. 126. There, we show that the concept of Dirac–Hestenes spinor fields which exists for four-dimensional Lorentzian spin manifolds modeling a relativistic space–time, can be generalized for the case of general *spin* manifold of dimension $n=p+q$ [equipped with a metric of signature (p,q), only if the spinor bundle structure $P_{\mathrm{Spin}^e_{p,q}}M$ is trivial].) However, these objects exist for a

four-dimensional vector space V equipped with a metric of Lorentzian signature and this fact makes them very much important mathematical objects for physical theories. Indeed, as we shall show in Sec. V it is possible to express Dirac equation in a consistent way using DHSF living on Minkowski space–time. Such equation is called the Dirac–Hestenes equation (DHE). In Sec. VII we express the Dirac equation using ASF. In Sec. IV we define Clifford fields and then ASF and DHSF. We observe here that our definitions of ASF and DHSF as some equivalence classes of pairs (Ξ_u, ψ_{Ξ_u}), where Ξ_u is a *spinorial coframe* field and ψ_{Ξ_u} is an appropriated Clifford field, i.e., a sum of multivector (or multiform) fields are not the usual ones that can be found in the literature. [Take notice that in this paper the term spinorial (co)frame field (defined below) is related, but distinct from the concept of a spin (co)frame, which is a section of a particular principal bundle called the spin (co)frame bundle (see Sec. IV and Ref. 126 for more details).] These definitions that, of course, come after the definitions of AS and DHS are essentially different from the definition of spinors given originally by Chevalley.[38,39] There, spinors are simply defined as elements of a minimal ideal carrying a modular representation of the Clifford algebra $\mathcal{C}\ell(V,\mathbf{g})$ associated to a structure $(V,\mathbf{g})$, where V is a real vector space of dimension $n=p+q$ and $\mathbf{g}$ is a metric of signature (p,q). And, of course, in that book there is no definition of DHS. Concerning DHS we mention that our definition of these objects is different also from the originally given in Refs. 79–81. [The definitions of AS, DHS, ASF, and DHSF given below are an improvement over preliminary tentative definitions of these objects given in Ref. 150. Unfortunately, that paper contains some equivocated results and errors (besides many misprints), which we correct here and in Ref. 126. We take the opportunity to apologize for any incovenience and misunderstandings that Ref. 150 may have caused. Some other papers where related (but not equivalent) material to the one presented in the present paper and in Ref. 126 can be found in Refs. 14–41, 44–69, 73–78, 93–109, 121–133, 144, and 146.] In view of these statements a justification for our definitions must be given and part of Sec. V and Sec. VI are devoted to such an enterprise. There it is shown that our definitions are the only ones compatible with the DHE and the meaning of the Fierz identities.[43,66] We discuss in Sec. VIII some misunderstandings resulting from the presentations of the standard Dirac equation when written with covariant Dirac spinors and also some misunderstandings concerning the DHE. It is important to emphasize here that the definitions of ASF, DHSF on Minkowski space–time and of the spin–Dirac operator given in Sec. V although correct are to be considered only as preliminaries. Indeed, these objects can be defined in a truly satisfactory way on a general Riemann–Cartan space–time only after the introduction of the concepts of the Clifford and the left (and right) spin–Clifford bundles. Moreover, a comprehensive formulation of Dirac equation on these manifolds requires a theory of connections acting on sections of these bundles. This nontrivial subject is studied in a forthcoming paper.[126] Section IX presents our conclusions. Finally we recall that our notations and some necessary results for the intelligibility of the paper are presented in Appendixes A–E. Although the appendixes contain known results, we decided to write them for the benefit of the reader, since the material cannot be found in a single reference. In particular Appendix A contains some of the ''tricks of the trade'' necessary to perform quickly calculations with Clifford algebras. If the reader needs more details concerning the theory of Clifford algebras and their applications than the ones provided by the Appendixes, the Refs. 14, 63, 64, 78, 86, 109, 141, 142 will certainly help. A final remark is necessary before we start our enterprise: the theory of the Dirac–Hestenes spinor fields of this (and the sequel paper[126]) does not contradict the standard theory of covariant Dirac spinor fields that is used by physicists and indeed it will be shown that the standard theory is no more than a matrix representation of theory described below.

Some acronyms are used in the present paper (to avoid long sentences) and they are summarized below for the reader's convenience:

AS, Algebraic spinor;

ASF, Algebraic spinor field;

CDS, Covariant Dirac spinor;

DHE, Dirac–Hestenes equation;

DHSF, Dirac–Hestenes spinor field.

II. ALGEBRAIC SPINORS

This section introduces the algebraic ideas that motivated the theory of ASF (which will be developed with full rigor in Ref. 126), i.e., we give a precise definition of AS. The algebraic side of the theory of DHSF, namely the concept of DHS is given in Sec. III. The justification for that definition will become clear in Secs. V and VI.

A. Geometrical equivalence of representation modules of simple Clifford algebras $\mathcal{C}\ell(V,\mathbf{g})$

We start with the introduction of some notations and clarification of some subtleties.

(i) In what follows V is a n-dimensional vector space over the real field $\mathbb{R}$. The dual space of V is denoted V^*. Let

$$\mathbf{g}: V\times V\to\mathbb{R} \tag{1}$$

be a metric of signature (p,q).

(ii) Let $\mathrm{SO}(V,\mathbf{g})$ be the group of endomorphisms of V that preserves $\mathbf{g}$ and the space orientation. This group is isomorphic to $\mathrm{SO}_{p,q}$ (see Appendix C), but there is no natural isomorphism. We write $\mathrm{SO}(V,\mathbf{g})\simeq\mathrm{SO}_{p,q}$. Also, the connected component to the identity is denoted by $\mathrm{SO}^e(V,\mathbf{g})$ and $\mathrm{SO}^e(V,\mathbf{g})\simeq\mathrm{SO}^e_{p,q}$. In the case $p=1$, $q=3$, $\mathrm{SO}^e(V,\mathbf{g})$ preserves besides orientation also the time orientation. In this paper we are mainly interested in $\mathrm{SO}^e(V,\mathbf{g})$.

(iii) We denote by $\mathcal{C}\ell(V,\mathbf{g})$ the Clifford algebra of V associated to $(V,\mathbf{g})$ and by $\mathrm{Spin}^e(V,\mathbf{g})$ $(\simeq\mathrm{Spin}^e_{p,q})$ the connected component of the spin group $\mathrm{Spin}(V,\mathbf{g})\simeq\mathrm{Spin}_{p,q}$ (see Appendix C for the definitions). [We reserve the notation $\mathbb{R}_{p,q}$ for the Clifford algebra of the vector space $\mathbb{R}^n$ equipped with a metric of signature (p,q), $p+q=n$. $\mathcal{C}\ell(V,\mathbf{g})$ and $\mathbb{R}_{p,q}$ are isomorphic, but there is no canonical isomorphism. Indeed, an isomorphism can be exhibited only after we fix an orthonormal basis of V.] Let $\mathbf{L}$ denote 2:1 homomorphism $\mathbf{L}:\mathrm{Spin}^e(V,\mathbf{g})\to\mathrm{SO}^e(V,\mathbf{g})$, $u\mapsto\mathbf{L}(u)\equiv\mathbf{L}_u$. $\mathrm{Spin}^e(V,\mathbf{g})$ acts on V identified as the space of 1-vectors of $\mathcal{C}\ell(V,\mathbf{g})\simeq\mathbb{R}_{p,q}$ through its adjoint representation in the Clifford algebra $\mathcal{C}\ell(V,\mathbf{g})$ which is related with the vector representation of $\mathrm{SO}^e(V,\mathbf{g})$ as follows [$\mathrm{Aut}(\mathcal{C}\ell(V,\mathbf{g}))$ denotes the (inner) automorphisms of $\mathcal{C}\ell(V,\mathbf{g})$]:

$$\mathrm{Spin}^e(V,g)\ni u\mapsto \mathrm{Ad}_u\in\mathrm{Aut}(\mathcal{C}\ell(V,\mathbf{g}))$$

$$\mathrm{Ad}_u|_V: V\to V, \mathbf{v}\mapsto u\mathbf{v}u^{-1}=\mathbf{L}_u\cdot\mathbf{v}. \tag{2}$$

In Eq. (2) $\mathbf{L}_u\cdot\mathbf{v}$ denotes the standard action $\mathbf{L}_u$ on $\mathbf{v}$ [see Eq. (5)] and where identified (without much ado) $\mathbf{L}_u\in\mathrm{SO}^e(V,\mathbf{g})$ with $\mathbf{L}_u\in\mathbf{V}\otimes\mathbf{V}^*$, $\mathbf{g}(\mathbf{L}_u\cdot\mathbf{v},\mathbf{L}_u\cdot\mathbf{v})=\mathbf{g}(\mathbf{v},\mathbf{v})$.

(iv) We denote by $\mathcal{C}\ell(V,\mathbf{g})$ the Clifford algebra of V associated to $(V,\mathbf{g})$ and by $\mathrm{Spin}^e(V,\mathbf{g})$ $(\simeq\mathrm{Spin}^e_{p,q})$ the connected component of the spin group $\mathrm{Spin}(V,\mathbf{g})\simeq\mathrm{Spin}_{p,q}$ (see Appendix C for the definitions).

(v) Let $\mathcal{B}$ be the set of all oriented and time oriented orthonormal basis [we will call the elements of $\mathcal{B}$ (in what follows) simply by orthonormal basis] of V. Choose among the elements of $\mathcal{B}$ a basis $b_0=\{\mathbf{E}_1,\ldots,\mathbf{E}_p,\mathbf{E}_{p+1},\ldots,\mathbf{E}_{p+q}\}$, hereafter called the fiducial frame of V. With this choice, we define a 1–1 mapping

$$\Sigma:\mathrm{SO}^e(V,\mathbf{g})\to\mathcal{B}, \tag{3}$$

given by

$$\mathbf{L}_u \mapsto \Sigma(\mathbf{L}_u) \equiv \Sigma_{\mathbf{L}_u} = \mathbf{L}_u b_0, \tag{4}$$

where $\Sigma_{\mathbf{L}_u} = \mathbf{L}_u b_0$ is a short for $\{\mathbf{e}_1, \ldots, \mathbf{e}_p, \mathbf{e}_{p+1}, \ldots, \mathbf{e}_{p+q}\} \in \mathcal{B}$, such that denoting the action of $\mathbf{L}_u$ on $\mathbf{E}_i \in b_0$ by $\mathbf{L}_u \cdot \mathbf{E}_i$ we have

$$\mathbf{e}_i = \mathbf{L}_u \cdot \mathbf{E}_i \equiv L_i^j \mathbf{E}_j, \quad i,j = 1,2,\ldots,n. \tag{5}$$

In this way, we can identify a given vector basis b of V with the isometry $\mathbf{L}_u$ that takes the fiducial basis b_0 to b. The fiducial basis b_0 will be also denoted by $\Sigma_{\mathbf{L}_0}$, where $\mathbf{L}_0 = e$, is the identity element of $\mathrm{SO}^e(V,\mathbf{g})$.

Since the group $\mathrm{SO}^e(V,\mathbf{g})$ is not simple connected their elements cannot distinguish between frames whose spatial axes are rotated in relation to the fiducial vector frame $\Sigma_{\mathbf{L}_0}$ by multiples of 2π or by multiples of 4π. For what follows it is crucial to make such a distinction. This is done by introduction of the concept of spinorial frames.

Definition 1: Let $b_0 \in \mathcal{B}$ be a fiducial frame and choose an arbitrary $u_0 \in \mathrm{Spin}^e(V,\mathbf{g})$. Fix once and for all the pair (u_0, b_0) with $u_0 = 1$ and call it the fiducial spinorial frame.

Definition 2: The space $\mathrm{Spin}^e(V,\mathbf{g}) \times \mathcal{B} = \{(u,b), ubu^{-1} = u_0 b_0 u_0^{-1}\}$ will be called the space of spinorial frames and denoted by Θ.

Remark 3: It is crucial for what follows to observe here that the definition 2 implies that a given $b \in \mathcal{B}$ determines two and only two spinorial frames, namely (u,b) and $(-u,b)$, since $\pm ub(\pm u^{-1}) = u_0 b_0 u_0^{-1}$.

(vi) We now parallel the construction in (v) but replacing $\mathrm{SO}^e(V,\mathbf{g})$ by its universal covering group $\mathrm{Spin}^e(V,\mathbf{g})$ and $\mathcal{B}$ by Θ. Thus, we define the 1–1 mapping

$$\Xi : \mathrm{Spin}^e(V,\mathbf{g}) \to \Theta,$$

$$u \mapsto \Xi(u) \equiv \Xi_u = (u,b), \tag{6}$$

where $ubu^{-1} = b_0$.

The fiducial spinorial frame will be denoted in what follows by Ξ_0. It is obvious from Eq. (6) that $\Xi(-u) = \Xi_{(-u)} = (-u,b) \neq \Xi_u$.

Definition 4: The natural right action of $a \in \mathrm{Spin}^e(V,\mathbf{g})$ denoted by $\cdot$ on Θ is given by

$$a \cdot \Xi_u = a \cdot (u,b) = (ua, \mathrm{Ad}_{a^{-1}} b) = (ua, a^{-1} b a). \tag{7}$$

Observe that if $\Xi_{u'} = (u',b') = u' \cdot \Xi_0$ and $\Xi_u = (u,b) = u \cdot \Xi_0$ then,

$$\Xi_{u'} = (u^{-1}u') \cdot \Xi_u = (u', u^{-1} u b u^{-1} u').$$

Note that there is a natural 2–1 mapping

$$\mathbf{s} : \Theta \to \mathcal{B}, \quad \Xi_{\pm u} \mapsto b = (\pm u^{-1}) b_0 (\pm u), \tag{8}$$

such that

$$\mathbf{s}((u^{-1}u') \cdot \Xi_u)) = \mathrm{Ad}_{(u^{-1}u')^{-1}}(\mathbf{s}(\Xi_u)). \tag{9}$$

Indeed, $\mathbf{s}((u^{-1}u') \cdot \Xi_u)) = \mathbf{s}((u^{-1}u') \cdot (u,b)) = u'^{-1} u b (u'^{-1} u)^{-1} = b' = \mathrm{Ad}_{(u^{-1}u')^{-1}} b = \mathrm{Ad}_{(u^{-1}u')^{-1}}(\mathbf{s}(\Xi_u))$. This means that the natural right actions of $\mathrm{Spin}^e(V,\mathbf{g})$, respectively, on Θ and $\mathcal{B}$, commute. In particular, this implies that the spinorial frames $\Xi_u, \Xi_{-u} \in \Theta$, which are, of course distinct, determine the same vector frame $\Sigma_{\mathbf{L}_u} = \mathbf{s}(\Xi_u) = \mathbf{s}(\Xi_{-u}) = \Sigma_{\mathbf{L}_{-u}}$. We have

$$\Sigma_{\mathbf{L}_u} = \Sigma_{\mathbf{L}_{-u}} = \mathbf{L}_{u^{-1}u_0} \Sigma_{\mathbf{L}_{u_0}}, \quad \mathbf{L}_{u^{-1}u_0} \in \mathrm{SO}^e_{p,q}. \tag{10}$$

Also, from Eq. (9), we can write explicitly

$$u_0\Sigma_{\mathbf{L}_{u_0}}u_0^{-1}=u\Sigma_{\mathbf{L}_u}u^{-1},\quad u_0\Sigma_{\mathbf{L}_{u_0}}u_0^{-1}=(-u)\Sigma_{\mathbf{L}_{-u}}(-u)^{-1},\quad u\in \mathrm{Spin}^e(V,\mathbf{g}), \tag{11}$$

where the meaning of Eq. (11) of course, is that if $\Sigma_{\mathbf{L}_u}=\Sigma_{\mathbf{L}_{-u}}=b=\{\mathbf{e}_1,\ldots,\mathbf{e}_p,\mathbf{e}_{p+1},\ldots,\mathbf{e}_q\}\in\mathcal{B}$ and $\Sigma_{\mathbf{L}_{u_0}}=b_0\in\mathcal{B}$ is the fiducial frame, then

$$u_0\mathbf{E}_ju_0^{-1}=(\pm u)\mathbf{e}_j(\pm u^{-1}). \tag{12}$$

In resume we can say that the space Θ of spinorial frames can be thought of as an extension of the space $\mathcal{B}$ of vector frames, where even if two vector frames have the same ordered vectors, they are considered distinct if the spatial axes of one vector frame is rotated by a odd number of 2π rotations relative to the other vector frame and are considered the same if the spatial axes of one vector frame is rotated by an even number of 2π rotations relative to the other frame. Even if this construction seems to be impossible at first sight, Aharonov and Susskind[6] warrants that it can be implemented physically.

(vii) Before we proceed an important digression on our notation used below is necessary. We recalled in Appendix B how to construct a minimum left (or right) ideal for a given real Clifford algebra once a vector basis $b\in\mathcal{B}$ for $V\hookrightarrow\mathcal{C}\ell(V,\mathbf{g})$ is given. That construction suggests to label a given primitive idempotent and its corresponding ideal with the subindex b. However, taking into account the above discussion of vector and spinorial frames and their relationship we find useful for what follows [especially in view of the definition 5 and the definitions of algebraic and Dirac–Hestenes spinors (see definitions 6 and 8 below)] to label a given primitive idempotent and its corresponding ideal with the subindex Ξ_u. Recall after all, that a given idempotent is according to definition 6 representative of a particular spinor in a given spinorial frame Ξ_u.

(viii) Next we recall Theorem 49 of Appendix B which says that a minimal left ideal of $\mathcal{C}\ell(V,\mathbf{g})$ is of the type

$$I_{\Xi_u}=\mathcal{C}\ell(V,\mathbf{g})e_{\Xi_u}, \tag{13}$$

where e_{Ξ_u} is a primitive idempotent of $\mathcal{C}\ell(V,\mathbf{g})$.

It is easy to see that all ideals $I_{\Xi_u}=\mathcal{C}\ell(V,\mathbf{g})e_{\Xi_u}$ and $I_{\Xi_{u'}}=\mathcal{C}\ell(V,\mathbf{g})e_{\Xi_{u'}}$ such that

$$e_{\Xi_{u'}}=(u'^{-1}u)e_{\Xi_u}(u'^{-1}u)^{-1}, \tag{14}$$

$u,u'\in\mathrm{Spin}^e(V,g)$ are isomorphic. We have the following.

Definition 5: Any two ideals $I_{\Xi_u}=\mathcal{C}\ell(V,\mathbf{g})e_{\Xi_u}$ and $I_{\Xi_{u'}}=\mathcal{C}\ell(V,\mathbf{g})e_{\Xi_{u'}}$ such that their generator idempotents are related by Eq. (14) are said geometrically equivalent.

But take care, no *equivalence relation* has been defined until now. We observe moreover that we can write

$$I_{\Xi_{u'}}=I_{\Xi_u}(u'^{-1}u)^{-1}, \tag{15}$$

a equation that will play a key role in what follows.

B. Algebraic spinors of type I_{Ξ_u}

Let $\{I_{\Xi_u}\}$ be the set of all ideals geometrically equivalent to a given minimal $I_{\Xi_{u_0}}$ as defined by Eq. (15). Let

$$\mathfrak{T}=\{(\Xi_u,\Psi_{\Xi_u})|u\in\mathrm{Spin}^e(V,\mathbf{g}),\Xi_u\in\Theta,\Psi_{\Xi_u}\in I_{\Xi_u}\}. \tag{16}$$

Let $\Xi_u,\Xi_u\in\Theta$, $\Psi_{\Xi_u}\in I_{\Xi_u}$, $\Psi_{\Xi_{u'}}\in I_{\Xi_{u'}}$. We define an equivalence relation $\mathcal{R}$ on $\mathfrak{T}$ by setting

$$(\Xi_u,\Psi_{\Xi_u})\sim(\Xi_{u'},\Psi_{\Xi_{u'}}) \tag{17}$$

if and only if $u\mathbf{s}(\Xi_u)u^{-1}=u'\mathbf{s}(\Xi_{u'})u'^{-1}$ and

$$\Psi_{\Xi_{u'}}u'^{-1}=\Psi_{\Xi_u}u^{-1}. \tag{18}$$

Definition 6: An equivalence class

$$\Psi_{\Xi_u}=[(\Xi_u,\Psi_{\Xi_u})]\in\mathfrak{T}/\mathcal{R} \tag{19}$$

is called an algebraic spinor of type I_{Ξ_u} for $\mathcal{C}\ell(V,\mathbf{g})$. $\psi_{\Xi_u}\in I_{\Xi_u}$ is said to be a representative of the algebraic spinor Ψ_{Ξ_u} in the spinorial frame Ξ_u.

We observe that the pairs (Ξ_u,Ψ_{Ξ_u}) and $(\Xi_{-u},-\Psi_{\Xi_{-u}})$ are equivalent, but the pairs (Ξ_u,Ψ_{Ξ_u}) and $(\Xi_{-u},-\Psi_{\Xi_{-u}})$ are not. This distinction is *essential* in order to give a structure of linear space (over the real field) to the set $\mathfrak{T}$. Indeed, a natural linear structure on $\mathfrak{T}$ is given by

$$a[(\Xi_u,\Psi_{\Xi_u})]+b[(\Xi_u,\Psi'_{\Xi_u})]=[(\Xi_u,a\Psi_{\Xi_u})]+[(\Xi_{u'},b\Psi'_{\Xi_u})],$$

$$(a+b)[(\Xi_u,\Psi_{\Xi_u})]=a[(\Xi_u,\Psi_{\Xi_u})]+b[(\Xi_u,\Psi_{\Xi_u})]. \tag{20}$$

The definition that we just gave is not a standard one in the literature.[38,39] However, the fact is that the standard definition (licit as it is from the mathematical point of view) is *not* adequate for a comprehensive formulation of the Dirac equation using algebraic spinor fields or Dirac–Hestenes spinor fields as we show in a preliminary way in Sec. V and in a rigorous and definitive way in a sequel paper.[126]

As observed on Appendix D a given Clifford algebra $\mathbb{R}_{p,q}$ may have minimal ideals that are not geometrically equivalent since they may be generated by primitive idempotents that are related by elements of the group $\mathbb{R}^{\star}_{p,q}$ which are not elements of $\mathrm{Spin}^e(V,\mathbf{g})$ (see Appendix C where different, nongeometrically equivalent primitive ideals for $\mathbb{R}_{1,3}$ are shown). These ideals may be said to be of different types. However, from the point of view of the representation theory of the real Clifford algebras (Appendix B) all these primitive ideals carry equivalent (i.e., isomorphic) modular representations of the Clifford algebra and no preference may be given to any one. (The fact that there are ideals that are algebraically, but not geometrically equivalent seems to contain the seed for new physics, see Refs. 123, and 124.) In what follows, when no confusion arises and the ideal I_{Ξ_u} is clear from the context, we use the wording algebraic spinor for any one of the possible types of ideals.

Remark 7: We observe here that the idea of definition of algebraic spinor fields as equivalent classes has it seed in a paper by Riez.[147] *However, Riez used in his definition simply orthonormal frames instead of the spinorial frames of our approach. As such, Riez defintion generates contradictions, as it is obvious from our discussion above.*

C. Algebraic Dirac spinors

These are the algebraic spinors associated with the Clifford algebra $\mathcal{C}\ell(\mathcal{M})\simeq\mathbb{R}_{1,3}$ (the space–time algebra) of Minkowski space–time $\mathcal{M}=(V,\boldsymbol{\eta})$, where V is a four-dimensional vector space over $\mathbb{R}$ and η is a metric of signature (1,3).

Some special features of this important case are as follows.

(a) The group $\mathrm{Spin}^e(\mathcal{M})$ is the universal covering of $\mathcal{L}^{\uparrow}_{+}$, the special and orthochronous Lorentz group that is isomorphic to the group $\mathrm{SO}^e(\mathcal{M})$ which preserves space–time orientation and also the time orientation[120] (see also Appendix B).

(b) $\mathrm{Spin}^e(\mathcal{M})\subset\mathcal{C}\ell^0(\mathcal{M})$, where $\mathcal{C}\ell^0(\mathcal{M})\simeq\mathbb{R}_{1,3}$ is the even subalgebra of $\mathcal{C}\ell(\mathcal{M})$ and is called the Pauli algebra (see Appendix C).

The most important property is a coincidence given by Eq. (21) below. It permits us to define a new kind of spinors.

III. DIRAC–HESTENES SPINORS (DHS)

Let $\Xi_u \in \Theta$ be a spinorial frame for $\mathcal{M}$ such that $\mathbf{s}(\Xi_u)=\{e_0,e_1,e_2,e_3\}\in\mathcal{B}$. Then, it follows from Eq. (D18) of Appendix D that

$$I_{\Xi_u}=\mathcal{C}\ell(\mathcal{M})e_{\Xi_u}=\mathcal{C}\ell^0(\mathcal{M})e_{\Xi_u}, \tag{21}$$

if

$$e_{\Xi_u}=\tfrac{1}{2}(1+e_0). \tag{22}$$

Then, each $\Psi_{\Xi_u}\in I_{\Xi_u}$ can be written as

$$\Psi_{\Xi_u}=\psi_{\Xi_u}e_{\Xi_u}, \quad \psi_{\Xi_u}\in\mathcal{C}\ell^0(\mathcal{M}). \tag{23}$$

From Eq. (18) we get

$$\psi_{\Xi_{u'}}u'^{-1}ue_{\Xi_u}=\psi_{\Xi_u}e_{\Xi_u}, \quad \psi_{\Xi_u},\psi_{\Xi_{u'}}\in\mathcal{C}\ell^0(\mathcal{M}). \tag{24}$$

A possible solution for Eq. (24) is

$$\psi_{\Xi_{u'}}u'^{-1}=\psi_{\Xi_u}u^{-1}. \tag{25}$$

Let $\Theta\times\mathcal{C}\ell(\mathcal{M})$ and consider an equivalence relation $\mathcal{E}$ such that

$$(\Xi_u,\phi_{\Xi_u})\sim(\Xi_{u'},\phi_{\Xi_{u'}}) \pmod{\mathcal{E}} \tag{26}$$

if and only if $\psi_{\Xi_{u'}}$ and ψ_{Ξ_u} are related by

$$\phi_{\Xi_{u'}}u'^{-1}=\phi_{\Xi_u}u^{-1}. \tag{27}$$

This suggests the following.

Definition 8: The equivalence classes $[(\Xi_u,\phi_{\Xi_u})]\in(\Theta\times\mathcal{C}\ell(\mathcal{M}))/\mathcal{E}$ *are the Hestenes spinors. Among the Hestenes spinors, an important subset is the one consisted of Dirac–Hestenes spinors where* $[(\Xi_u,\psi_{\Xi_u})]\in(\Theta\times\mathcal{C}\ell^0(\mathcal{M}))/\mathcal{E}$. *We say that* $\phi_{\Xi_u}(\psi_{\Xi_u})$ *is a representative of a Hestenes (Dirac–Hestenes) spinor in the spinorial frame* Ξ_u.

How to justify the above definitions of algebraic and Dirac–Hestenes spinors? The question is answered in the next section.

IV. CLIFFORD FIELDS, ASF AND DHSF

The objective of this section is to introduce the concepts of Dirac–Hestenes spinor fields (DHSF) and algebraic spinor fields (ASF) living on Minkowski space–time. A definitive theory of these objects that can be applied for arbitrary Riemann–Cartan space–times can be given only after the introduction of the Clifford and left (and right) spin–Clifford bundles and the theory of connections acting on these bundles. This theory will be presented in Ref. 126 and the presentation given below (which can be followed by readers that have only a rudimentary knowledge of the theory of fiber bundles) must be considered as a preliminary one.

Let $(M,\eta,\tau,\uparrow,\nabla)$ be Minkowski space–time, where M is diffeomorphic to $\mathbb{R}^4$, η is a constant metric field, ∇ is the Levi–Civita connection of η. M is oriented by $\tau\in\sec\Lambda^4M$ and is also time oriented by $\uparrow$ (Refs. 156–158).

Let ($P_{\mathrm{SO}^e_{1,3}}M$ is the orthonormal frame bundle, $\sec P_{\mathrm{SO}^e_{1,3}}M$ means a section of the frame bundle) $\{e_a\}\in\sec P_{\mathrm{SO}^e_{1,3}}M$ be an orthonormal (moving) frame, not necessarily a coordinate frame

and let $\gamma^a \in \sec T^*M$ $(a=0,1,2,3)$ be such that the set $\{\gamma^a\}$ is dual to the set $\{e_a\}$, i.e., $\gamma^a(e_b) = \delta^a_b$. (Orthonormal moving frames are not to be confused with the concept of reference frames. The concepts are related, but distinct.[156–158])

The set $\{\gamma^a\}$ will be called also a (moving) frame. Let $\gamma_a = \eta_{ab}\gamma^b$, $a,b=0,1,2,3$. The set $\{\gamma_a\}$ will be called the reciprocal frame to the frame $\{\gamma^a\}$. Recall that [$\check{\eta}$ is the metric of the contangent space and $\check{\eta}(\gamma^a,\gamma^b) = \eta^{ab} = \eta_{ab} = \mathrm{diag}(1,-1,-1,-1)$] $(T^*_xM,\check{\eta}) \simeq \mathcal{M}$. We will denote $(T^*_xM,\check{\eta})$ by $\mathcal{M}^*$. Now, due to the affine structure of Minkowski space–time we can identify all the cotangent spaces as usual. Consider then the Clifford algebra $\mathcal{C}\ell(\mathcal{M}^*)$ generated by the coframe $\{\gamma^a\}$, where now we can take $\gamma^a: x \mapsto \Lambda^1(\mathcal{M}^*) \subset \mathcal{C}\ell(\mathcal{M}^*)$. We have

$$\gamma^a(x)\,\gamma^b(x) + \gamma^b(x)\,\gamma^a(x) = 2\,\eta^{ab}, \quad \forall x \in M. \tag{28}$$

Definition 9 (preliminary): A Clifford field is a mapping

$$C: M \ni x \mapsto C(x) \in \mathcal{C}\ell(\mathcal{M}^*). \tag{29}$$

In a coframe $\{\gamma^a\}$ the expression of a Clifford field is

$$\mathcal{C} = S + A_a\gamma^a + \frac{1}{2!}B_{ab}\gamma^a\gamma^b + \frac{1}{3!}T_{abc}\gamma^a\gamma^b\gamma^c + P\gamma^5, \tag{30}$$

where $S, A_a, B_{ab}, T_{abc}, P$ are scalar functions (the ones with two or more indices antisymmetric on that indices) and $\gamma^5 = \gamma^0\gamma^1\gamma^2\gamma^3$ is the volume element. Saying with other words, a Clifford field is a sum of nonhomogeneous differential forms. [This result follows once we recall that as a vector space the Clifford algebra $\mathcal{C}\ell(\mathcal{M}^*)$ is isomorphic to the the Grassmann algebra $\Lambda(V^*) = \Sigma_{p=0}^4 \Lambda^p(V^*)$, where $\Lambda^p(V^*)$ is the space of p-forms. This is clear from the definition of Clifford algebra given in the Appendix A. Recall that $\mathcal{M}^* = (V^* \simeq T^*M, \check{\eta})$.]

Here is the point where a minimum knowledge of the theory of fiber bundles is required. Minkowski space–time is parallelizable and admits a spin structure. See, e.g., Refs. 72, 131–139, and 126. This means that Minkowski space–time has a spin strucutre, i.e., there exists a principal bundle called the spin frame bundle and denoted by $P_{\mathrm{Spin}^e_{1,3}M}$ that is the double covering of $P_{\mathrm{SO}^e_{1,3}M}$, i.e., there is a 2:1 mapping $\rho: P_{\mathrm{Spin}^e_{1,3}M} \to P_{\mathrm{SO}^e_{1,3}M}$. The elements of $P_{\mathrm{Spin}^e_{1,3}M}$ are called the spin frame fields (when there is no possibility of confusion we abreviate spin frame field simply as spin frame), and if $F_u \in P_{\mathrm{Spin}^e_{1,3}M}$ then $\rho(F_u) = \{e_a\} \in P_{\mathrm{SO}^e_{1,3}M}$ (once we fix a spin frame and associate it to an arbitrary but fixed element of $u \in P_{\mathrm{Spin}^e_{1,3}M}$). This means, that as in Sec. I, we distinguish frames that differ from a 2π rotation. Besides $P_{\mathrm{SO}^e_{1,3}M}$, we introduce also $P'_{\mathrm{SO}^e_{1,3}M}$, the coframe orthonormal bundle, such that for $\{\gamma^a\} \in P'_{\mathrm{SO}^e_{1,3}M}$ there exists $\{e_a\} \in P_{\mathrm{SO}^e_{1,3}M}$, such that $\gamma^a(e_b) = \delta^a_b$. Note that $\{\gamma^a\} \in P'_{\mathrm{SO}^e_{1,3}M}$, but, as already observed, keep in mind that each $\gamma^a: x \mapsto \Lambda^1(\mathcal{M}^*) \subset \mathcal{C}\ell(\mathcal{M}^*)$. To proceed choose a fiducial coframe $\{\Gamma^a\} \in P'_{\mathrm{SO}^e_{1,3}M}$, dual to a fiducial frame $\rho(F_{u_0}) \equiv \{E_a\} \in \sec P_{\mathrm{SO}^e_{1,3}M}$.

Now, let

$$u: x \mapsto u(x) \in \mathrm{Spin}^e(\mathcal{M}^*) \subset \mathcal{C}\ell^0(\mathcal{M}^*). \tag{31}$$

In complete analogy with Sec. I let $\Theta'_{\mathcal{M}} = \mathrm{Spin}^e(\mathcal{M}^*) \times P'_{\mathrm{SO}^e_{1,3}M}$ be the space of spinorial coframe fields. We define also the 1–1 mapping

$$\begin{gathered} \Xi: \mathrm{Spin}^e(\mathcal{M}^*) \to \Theta'_{\mathcal{M}}, \\ u \mapsto \Xi(u) \equiv \Xi_u = (u, \{u^{-1}\Gamma_a u\}). \end{gathered} \tag{32}$$

Note that there is a 2–1 natural mapping

$$\mathbf{s}':\Theta'_{\mathcal{M}}\ni\Xi_u\mapsto\{\gamma^a\}\in P'_{\mathrm{SO}^e_{1,3}}M,$$
$$\gamma^a=u^{-1}\Gamma^a u. \tag{33}$$

Also, denoting the action of $a(x)\in\mathrm{Spin}^e(\mathcal{M}^*)$ on $\Theta'_{\mathcal{M}}$ by $a\cdot\Xi_u=(ua,\{\gamma^a\})$ we have

$$\Xi_{u'}=(u^{-1}u')\cdot\Xi_u, \tag{34}$$

$$\mathbf{s}'((u^{-1}u')\cdot\Xi_u))=\mathrm{Ad}_{(u^{-1}u')^{-1}}(\mathbf{s}'(\Xi_u)). \tag{35}$$

As in the preceding section we have associated $1\in\mathrm{Spin}^e(\mathcal{M}^*)$ to the fiducial spinorial coframe field, but of course we could associate any other element $u_0;x\mapsto u_0(x)\in\mathrm{Spin}^e(\mathcal{M}^*)$ to the fiducial spinorial coframe. In this general case, writing Ξ_{u_0} for the fiducial spinorial coframe, we have $\mathbf{s}'(\Xi_{u_0})=\{\Gamma^a\}$.

Note that $\mathbf{s}'(\Xi_u)=\mathbf{s}'(\Xi_{(-u)})$ and that any other coframe field $\mathbf{s}'(\Xi_u)$ is then related to $\mathbf{s}'(\Xi_{u_0})$ by

$$u_0\mathbf{s}'(\Xi_{u_0})u_0^{-1}=\pm u\mathbf{s}'(\Xi_u)(\pm u^{-1})=\pm u\mathbf{s}'(\Xi_{(-u)})(\pm u^{-1}), \tag{36}$$

where the meaning of this equation is analogous to the one given to Eq. (11), through Eq. (12).

Taking into account the results of the preceding sections and of the Appendixes A and B we are lead to the following definitions.

Let $\{I_{\Xi_u}\}$ be the set of all ideals geometrically equivalent to a given minimal $I_{\Xi_{u_0}}$ as defined by Eq. (15) where now u, u' are Clifford fields defined by mappings like the one defined in Eq. (31).

Let

$$\mathfrak{T}_{\mathcal{M}}=\{(x,(\Xi_u,\Psi_{\Xi_u}))|x\in M,u(x)\in\mathrm{Spin}^e(\mathcal{M}^*),\Xi_u\in\Theta'_{\mathcal{M}},$$
$$\Psi_{\Xi_u}:x\mapsto\Psi_{\Xi_u}(x)\in I_{\Xi_u},\Psi_{\Xi_{u'}}:x\mapsto\in\Psi_{\Xi_u}(x)\in I_{\Xi_{u'}}\}. \tag{37}$$

Consider an equivalence relation $\mathcal{R}_{\mathcal{M}}$ on $\mathfrak{T}_{\mathcal{M}}$ such that

$$(x,(\Xi_u,\Psi_{\Xi_u}))\sim(y,(\Xi_{u'},\Psi_{\Xi_{u'}})) \tag{38}$$

if and only if $x=y$,

$$u(x)\mathbf{s}'(\Xi_{u(x)})u^{-1}(x)=u'(x)\mathbf{s}'(\Xi_{u'(x)})u'^{-1}(x) \tag{39}$$

and

$$\Psi_{\Xi_{u'}}u'^{-1}=\Psi_{\Xi_u}u^{-1}. \tag{40}$$

Definition 10 (preliminary): An algebraic spinor field (ASF) of type I_{Ξ_u} for $\mathcal{M}^*$ is an equivalence class $\Psi_{\Xi_u}=[(x,(\Xi_u,\Psi_{\Xi_u}))]\in\mathfrak{T}_{\mathcal{M}}/\mathcal{R}_{\mathcal{M}}$. We say that $\Psi_{\Xi_u}\in I_{\Xi_u}$ is a representative of the ASF Ψ_{Ξ_u} in the spinorial coframe field Ξ_u.

Consider an equivalence relation $\mathcal{E}_{\mathcal{M}}$ on the set $M\times\Xi_{\mathcal{M}}\times\mathcal{C}\ell(\mathcal{M}^*)$ such that [given $\psi_{\Xi_u}:x\mapsto\psi_{\Xi_u}(x)\in\mathcal{C}\ell(\mathcal{M}^*)$, $\psi_{\Xi_{u'}}:x\mapsto\in\psi_{\Xi_u}(x)\in\mathcal{C}\ell(\mathcal{M}^*)$] $((x,(\Xi_u,\psi_{\Xi_u})))$ and $((y,(\Xi_{u'},\psi_{\Xi_{u'}})))$ are equivalent if and only if $x=y$,

$$u(x)\mathbf{s}'(\Xi_{u(x)})u^{-1}(x)=u'(x)\mathbf{s}'(\Xi_{u'(x)})u'^{-1}(x) \tag{41}$$

and

$$\psi_{\Xi_u}, u'^{-1} = \psi_{\Xi_u} u^{-1}. \tag{42}$$

Definition 11 (preliminary): An equivalence class $\psi = [(x, (\Xi_u, \psi_{\Xi_u}))] \in M \times \Xi_{\mathcal{M}} \times \mathcal{C}\ell(\mathcal{M}^*)/\mathcal{E}_{\mathcal{M}}$ *is called a Hestenes spinor field for* $\mathcal{M}^*$. $\psi_{\Xi_u} \in \mathcal{C}\ell(\mathcal{M}^*)$ *is said to be a representative of the Hestenes spinor field* ϕ_{Ξ_u} *in the spinorial coframe field* Ξ_u. *When* $\psi_{\Xi_u}: x \mapsto \psi_{\Xi_u}(x) \in \mathcal{C}\ell^0(\mathcal{M}^*)$, $\psi_{\Xi_u}: x \mapsto \in \psi_{\Xi_u}(x) \in \mathcal{C}\ell^0(\mathcal{M}^*)$ *we call the equivalence class a Dirac–Hestenes spinor field (DHSF).*

V. THE DIRAC–HESTENES EQUATION (DHE)

In our preliminary presentation of the Dirac equation (on Minkowski space–time) that follows we shall restrict our exposition to the case where any spinorial coframe field appearing in the equations that follows, e.g., $\mathbf{s}'(\Xi_u) = \{\gamma^a\}$ is teleparallel and constant. By this we mean that $\forall x, y \in M$ and $a = 0,1,2,3$,

$$\gamma^a(x) \equiv \gamma^a(y), \tag{43}$$

$$\nabla_{e_a} \gamma^b = 0. \tag{44}$$

Equation (43) has meaning due to the affine structure of Minkowski space–time which permits the usual identification of all tangent spaces (and of all cotangent spaces) of the manifold and Eq. (44), is the definition of a teleparallel frame. Of course, the unique solution for Eq. (44) is $\gamma^\mu = \mathrm{d}x^\mu$, where $\{x^\mu\}$ are the coordinate functions of a global Lorentz chart of Minkowski space–time. Such a restriction is a necessary one in our elementary presentation, because otherwise we would need first to study the theory of the covariant derivative of spinor fields, a subject that simply cannot be appropriately introduced with the present formalism, thus clearly showing its limitation. Thus, to continue our elementary presentation we need some results of the general theory of the covariant derivatives of spinor fields studied in details in Ref. 126.

Using the results of the preceding sections and of the Appendixes we can show[80,148] that the usual Dirac equation[5,53] (which, as well known is written in terms of covariant Dirac spinor fields) for a representative of a DHSF in interaction with an electromagnetic potential $A: x \mapsto A(x) \in \Lambda^1(\mathcal{M}^*) \subset \mathcal{C}\ell(\mathcal{M}^*)$ is

$$\mathbf{D}^s \psi_{\Xi_u} \gamma_2 \gamma_1 - m \psi_{\Xi_u} \gamma_0 + qA \psi_{\Xi_u} = 0. \tag{45}$$

[Covariant Dirac spinor fields are defined in an obvious way once we take into account the definition of covariant Dirac spinors given by Eq. (E6) and Eq. (E7) of the Appendix E. See also Refs. 41, 131–133.]

Remark 12: It is important for what follows to have in mind that although each representative $\psi_{\Xi_u}: x \mapsto \psi_{\Xi_u}(x) \in \mathcal{C}\ell^0(\mathcal{M}^*)$ *of a* DHSF *is a sum of nonhomogeneous differential forms, spinor fields are not a sum of nonhomogeneous differential forms. Thus, they are mathematical objects of a nature different from that of Clifford fields*. (*Not* taking this difference into account can lead to misconceptions, as, e.g., some appearing in Ref. 71. See our comments in Ref. 155 on that paper.) *The crucial difference between a Clifford field, e.g., an electromagnetic potential A and a* DHSF *is that A is frame independent whereas a* DHSF *is frame dependent.*

In the DHE the spinor covariant derivative $\mathbf{D}^s$ is a first order differential operator, often called the spin–Dirac operator. [If we use more general frames, that are not Lorentzian coordinate frames, e.g., $\Xi_u = \{\gamma^a\}$ then $\mathbf{D}^s \psi_{\Xi_u}(x) = \gamma^a \nabla^s_{e_a} \psi_{\Xi_u}(x) = \gamma^a (e_a + \frac{1}{2}\omega_a) \psi_{\Xi_u}(x)$, where ω_a is a two form field associated with the spinorial connection, which is zero only for teleparallel frame fields,

if they exist. Details in Ref. 126.] Let $\nabla^s_{f_a}$ be the spinor covariant derivative. We have the following representation for $\mathbf{D}^s$ in an arbitrary orthonormal frame $\{t^a\}$ dual of the frame $\{f_a\} \in P_{\mathrm{SO}^e_{1,3}}$,

$$\mathbf{D}^s = t^a \nabla^s_{f_a}. \tag{46}$$

In a teleparallel spin (co)frame $\mathbf{s}'(\Xi_u) = \{\gamma^\mu\}$ the above equation reduces to

$$\mathbf{D}^s = \mathrm{d}x^\mu \frac{\partial}{\partial x^\mu}. \tag{47}$$

The spin–Dirac operator in an arbitrary orthonormal frame acts on a product $(C\psi_{\Xi_u})$ where C is a Clifford field and ψ_{Ξ_u} a representative of a DHSF (or a Hestenes field) as a modular derivation,[20,126] i.e.,

$$\mathbf{D}^s(C\psi_{\Xi_u}) = t^a \nabla^s_{f_a}(C\psi_{\Xi_u}) = t^a[(\nabla_{f_a} C)\psi_{\Xi_u} + C(\nabla^s_{f_a}\psi_{\Xi_u})].$$

Also in Eq. (45) m and q are real parameters (mass and charge) identifying the elementary fermion described by that equation. (Note that we used natural unities in which the value of the velocity of light is $c=1$ and the value of Planck's constant is $\hbar = 1$.)

Now, from Eq. (42) we have

$$\psi_{\Xi_{u'}} = \psi_{\Xi_u} s^{-1}, \quad \Xi_{u'} = s \cdot \Xi_u, \tag{48}$$

$$A \mapsto A, \tag{49}$$

where $s: x \mapsto s(x) \in \mathrm{Spin}^e(\mathcal{M}^*) \subset \mathcal{C}\ell^0(\mathcal{M}^*)$ is to be considered a Clifford field. Consider the case where $s(x) = s(y) = s$, $\forall x, y \in M$. Such equation has a precise meaning due to our restriction to teleparallel frames. We see that the DHE is trivially covariant under this kind of transformation, which can be called a right gauge transformation.

Returning to the DHE we see also that the equation is covariant under active Lorentz gauge transformations, or left gauge transformations. Indeed, under an active left Lorentz gauge transformation (without changing the spinorial coframe field), we have

$$\begin{gathered} \psi_{\Xi_u} \mapsto \psi'_{\Xi_u} = s\psi_{\Xi_u}, \quad A \mapsto sAs^{-1}, \\ \mathbf{D}^s \psi_{\Xi_u} \mapsto \mathbf{D}'^s \psi'_{\Xi_u} = s\mathbf{D}^s \psi_{\Xi_u}. \end{gathered} \tag{50}$$

The justification for the active left Lorentz gauge transformation law $\mathbf{D}^s \psi_{\Xi_u} \mapsto \mathbf{D}'^s \psi'_{\Xi_u} = s\mathbf{D}^s \psi_{\Xi_u}$ is the following. (A study of active local left Lorentz gauge transformations will be presented elsewhere, for it needs the concept of gauge covariant derivatives.) The Dirac operator is a 1-form valued derivative operator $\mathbf{D}^s = \mathrm{d}x^\mu (\partial/\partial x^\mu)$. Then, under an active Lorentz gauge transformation s it must transform like a vector, i.e., $\mathbf{D}^s \mapsto \mathbf{D}'^s = s\, \mathrm{d}x^\mu\, s^{-1} (\partial/\partial x^\mu)$.

Note that ψ'_{Ξ_u} is a representative (in the spinorial coframe field Ξ_u) of a new spinor. Then, it follows, of course, that the representative of the new spinor in the spinorial coframe field $\Xi_{u'}$ is

$$\psi'_{\Xi_{u'}} = s\psi_{\Xi_u} s^{-1}. \tag{51}$$

We also recall that the DHE is invariant under simultaneous left and right (constants) gauge Lorentz transformations. In this case the relevant transformations are

$$\psi_{\Xi_u} \mapsto \psi'_{\Xi_u} = s\psi_{\Xi_u} s^{-1},$$
$$A \mapsto sAs^{-1}, \quad \mathbf{D}'^{s}\psi'_{\Xi_{u'}} = s\mathbf{D}^{s}\psi_{\Xi_u} s^{-1}. \tag{52}$$

VI. JUSTIFICATION OF THE TRANSFORMATION LAWS OF DHSF BASED ON THE FIERSZ IDENTITIES

We now give another justification for the definition of Dirac spinors and DHSF presented in the preceding sections. We start by recalling that a usual covariant Dirac spinor field determines a set of p-form fields, called bilinear covariants, which describe the physical contents of a particular solution of the Dirac equation described by that field. The same is true also for a DHSF.

In order to present the bilinear covariants using that fields, we introduce first the notion of the Hodge dual operator of a Clifford field $\mathcal{C}: M \ni x \mapsto \mathcal{C}(x) \in \mathcal{C}\ell(\mathcal{M}^*)$. We have the following.

Definition 13: The Hodge dual operator is the mapping

$$\star : \mathcal{C} \to \star\mathcal{C} = \widetilde{\mathcal{C}}\gamma_5, \tag{53}$$

where $\widetilde{\mathcal{C}}$ is the reverse of C [Eq. (A5), Appendix A].

Then, in terms of a representative of a DHSF in the spinorial frame field Ξ_u the bilinear covariants of Dirac theory reads (with $J = J_\mu\gamma^\mu$, $S = \frac{1}{2}S_{\mu\nu}\gamma^\mu\gamma^\nu$, $K = K_\mu\gamma^\mu$)

$$\psi_{\Xi_u}\widetilde{\psi}_{\Xi_u} = \sigma + \star\omega, \quad \psi_{\Xi_u}\gamma^0\widetilde{\psi}_{\Xi_u} = J,$$
$$\psi_{\Xi_u}\gamma^1\gamma^2\widetilde{\psi}_{\Xi_u} = S, \quad \psi_{\Xi_u}\gamma^0\gamma^3\widetilde{\psi}_{\Xi_u} = \star S, \tag{54}$$
$$\psi_{\Xi_u}\gamma^3\widetilde{\psi}_{\Xi_u} = K, \quad \psi_{\Xi_u}\gamma^0\gamma^1\gamma^2\widetilde{\psi}_{\Xi_u} = \star K.$$

The so-called *Fierz identities* are

$$J^2 = \sigma^2 + \omega^2, \quad J\cdot K = 0, \quad J^2 = -K^2, \quad J\wedge K = -(\omega + \star K)S, \tag{55}$$

$$S \llcorner J = \omega K, \quad S \llcorner K = \omega J,$$
$$(\star S) \llcorner J = -\sigma K, \quad (\star S) \llcorner K = -\sigma J, \tag{56}$$
$$S\cdot S = \omega^2 - \sigma^2, \quad (\star S)\cdot S = -2\sigma\omega,$$

$$JS = -(\omega + \star\sigma)K,$$
$$SJ = -(\omega - \star\sigma)K,$$
$$KS = -(\omega + \star\sigma)J,$$
$$SK = -(\omega - \star\sigma)J, \tag{57}$$
$$S^2 = \omega^2 - \sigma^2 - 2\sigma(\star\omega),$$
$$S^{-1} = -S(\sigma - \star\omega)^2/J^2 = KSK/J^4.$$

The proof of these identities using the DHSF is almost a triviality and can be done in a few lines. This is not the case if you use covariant Dirac spinor fields (columns matrix fields). In this case you will need to perform several pages of matrix algebra calculations.

The importance of the bilinear covariants is due to the fact that we can recover from them the associate covariant Dirac spinor field (and thus the DHSF) except for a phase. This can be done with an algorithm due to Crawford[43] and presented in a very pedagogical way in Ref. 109.

Let us consider, e.g., the equation $\psi_{\Xi_u}\gamma_0\tilde{\psi}_{\Xi_u}=J$ in (54). Now, $J(x)\in\Lambda^1(\mathcal{M}^*)\subset\mathcal{C}\ell(\mathcal{M}^*)$ is an intrinsic object on Minkowski space–time and according to the accepted first quantization interpretation theory of the Dirac equation it is proportional to the electromagnetic current generated by an elementary fermion. The expression of J in terms of the representative of a DHSF in the spinorial coframe $\Xi_{u'}$ is (of course)

$$\psi_{\Xi_{u'}}\gamma_0'\tilde{\psi}_{\Xi_{u'}}=J. \tag{58}$$

Now, since

$$\gamma_0'=(u'^{-1}u)\,\gamma_0(u'^{-1}u)^{-1}, \tag{59}$$

we see that we must have

$$\psi_{\Xi_{u'}}=\psi_{\Xi_u}(u'^{-1}u)^{-1}, \tag{60}$$

which justifies the definition of DHSF given above [see Eq. (40)].

We observe also that if $\psi_{\Xi_u}\tilde{\psi}_{\Xi_u}=\sigma+\star\omega\neq 0$, then we can write

$$\psi_{\Xi_u}=\rho^{1/2}e^{1/2\,\beta\gamma^5}R, \tag{61}$$

where $\forall x\in M$,

$$\begin{aligned}&\rho(x)\in\Lambda^0(\mathcal{M}^*)\subset\mathcal{C}\ell(\mathcal{M}^*),\\ &\beta(x)\in\Lambda^0(\mathcal{M}^*)\subset\mathcal{C}\ell(\mathcal{M}^*),\\ &R\in\mathrm{Spin}^e_{1,3}(\mathcal{M}^*)\subset\mathcal{C}\ell(\mathcal{M}^*).\end{aligned} \tag{62}$$

With this result the current J can be written

$$J=\rho v \tag{63}$$

with $v=R\gamma^0R^{-1}$. Equation (63) discloses the secret geometrical meaning of DHSF. These objects rotate and dilate vector fields, this being the reason why they are sometimes called operator spinors.[80–86,109]

VII. DIRAC EQUATION IN TERMS OF ASF

We recall from Eq. (D2) of Appendix D that

$$e'_{\Xi_u}=\tfrac{1}{2}(1+\gamma_3\gamma_0) \tag{64}$$

is also a primitive idempotent field (here understood as a Hestenes spinor field) that is algebraically, but not geometrically equivalent to the idempotent field $e_{\Xi_u}=\frac{1}{2}(1+\gamma_0)$. Let $I'_{\Xi_u}=\mathcal{C}\ell(\mathcal{M}^*)e'_{\Xi_u}$ be a minimal left ideal generated by e'_{Ξ_u}. Now, multiply the DHE [Eq. (45)] on the left, first by the primitive idempotent e_{Ξ_u} and then by the primitive idempotent e'_{Ξ_u}. We get after some algebra

$$\mathbf{D}^s\Phi_{\Xi_u}-m\Phi_{\Xi_u}(\star 1)+qA\Phi_{\Xi_u}=0, \tag{65}$$

where $\star 1=\gamma_5$ is the oriented volume element of Minkowski space–time and

$$\Phi_{\Xi_u}=\psi_{\Xi_u}e_{\Xi_u}e'_{\Xi_u}\in I'_{\Xi_u}=\mathcal{C}\ell(\mathcal{M}^*)e'_{\Xi_u}. \tag{66}$$

Equation (65) is one of the many faces of the original equation found by Dirac in terms of ASF and using teleparallel orthonormal frames.

Of course, Eq. (65), as it is the case of the DHE [Eq. (45)] is compatible with the transformation law of ASF that follows directly from the transformation law of AS given in Sec. II. In contrast to the DHE, in Eq. (65) there seems to be no explicit reference to elements of a spinorial coframe field (except for the indices Ξ_u) since $\star 1$, the volume element is invariant under (Lorentz) gauge transformations. We emphasize also that the transformation law for ASF is compatible with the presentation of Fierz identities using these objects, as the interested reader can verify without difficulty.

VIII. MISUNDERSTANDINGS CONCERNING COORDINATE REPRESENTATIONS OF THE DIRAC AND DIRAC–HESTENES EQUATIONS

We investigate now some subtleties of the Dirac and Dirac–Hestenes equations. We start by pointing out and clarifying some misunderstandings that often appears in the literature of the subject of the DHE when that equation is presented in terms of a representative of a DHSF in a global coordinate chart (M,φ) of the maximal atlas of M with Lorentz coordinate functions $\langle x^\mu\rangle$ associated to it (see, e.g., Ref. 156). In that case, $\mathbf{s}'(\Xi_u)=\{\gamma^\mu=\mathrm{d}x^\mu\}$. After that we study the (usual) matrix representation of Dirac equation and show how it hides many features that are only visible in the DHE.

Let $\{e_\mu=\partial/\partial x^\mu\}$ and $\{e'_\mu=\partial/\partial x'^\mu\}$. The spinorial coframe fields Ξ_u and $\Xi_{u'}$ (as defined in the preceding section) are associated to the coordinate bases (dual basis) $\mathbf{s}'(\Xi_u)=\{\gamma^\mu=\mathrm{d}x^\mu\}$ and $\mathbf{s}'(\Xi_{u'})=\{\gamma'^\mu=dx'^\mu\}$, corresponding to the global Lorentz charts (M,φ) and (M,φ'). The DHE is written in the charts $\langle x^\mu\rangle$ and $\langle x'^\mu\rangle$ as

$$\begin{aligned}
&\gamma^\mu\left(\frac{\partial}{\partial x^\mu}\Psi_{\Xi_u}+qA_\mu\Psi_{\Xi_u}\gamma_1\gamma_2\right)\gamma_2\gamma_1-m\Psi_{\Xi_u}\gamma_0=0,\\
&\gamma'^\mu\left(\frac{\partial}{\partial x'^\mu}\Psi'_{\Xi_{u'}}+qA'_\mu\Psi_{\Xi_{u'}}\gamma'_1\gamma'_2\right)\gamma'_2\gamma'_1-m\Psi_{\Xi_{u'}}\gamma'_0=0,
\end{aligned} \tag{67}$$

where $\mathbf{D}^s=\gamma^\mu(\partial/\partial x^\mu)=\gamma'^\mu(\partial/\partial x'^\mu)$ and where (Ψ_{Ξ_u},A_μ) and $(\Psi_{\Xi_{u'}},A'_\mu)$ are the coordinate representations of (ψ_{Ξ_u},A) and $(\psi_{\Xi_{u'}},A)$, i.e., for any $x\in M$, we have

$$\begin{aligned}
&A=A'_\mu(x'^\mu)\mathrm{d}x'^\mu=A_\mu(x^\mu)\mathrm{d}x^\mu,\\
&A'_\mu(x'^0,x'^1,x'^2,x'^3)=\mathbf{L}^\nu_\mu A_\nu(x^0,x^1,x^2,x^3),\\
&(\Psi_{\Xi_{u'}}U'^{-1})|_{(x'^0(x),x'^1(x),x'^2(x),x'^3(x))}=(\Psi_{\Xi_u}U^{-1})|_{(x^0(x),x^1(x),x^2(x),x^3(x))},
\end{aligned} \tag{68}$$

with U and U' the coordinate representations of u and u' [see Eq. (42)] and L^ν_μ is an appropriate Lorentz transformation.

Now, taking into account that the complexification of the algebra $\mathcal{C}\ell(\mathcal{M}^*)$, i.e., $\mathbb{C}\otimes\mathcal{C}\ell(\mathcal{M}^*)$ is isomorphic to the Dirac algebra $\mathbb{R}_{4,1}$ (Appendix C), we can think of all the objects appearing in Eqs. (67) as having values also in $\mathbb{C}\otimes\mathcal{C}\ell(\mathcal{M}^*)$. Multiply then, both sides of each one of the Eqs. (67) by the following primitive idempotents fields [considered as complexified Hestenes spinor fields (see Definition 8)] of $\mathbb{C}\otimes\mathcal{C}\ell(\mathcal{M}^*)$ [see Eq. (D14) of Appendix D]

$$f_{\Xi_u} = \tfrac{1}{2}(1+\gamma^0)\tfrac{1}{2}(1+i\gamma^1\gamma^2),$$
$$f_{\Xi_{u'}} = \tfrac{1}{2}(1+\gamma'^0)\tfrac{1}{2}(1+i\gamma'^1\gamma'^2). \tag{69}$$

Next, look for a matrix representation in $\mathbb{C}(4)$ of the resulting equations. We get (using the notation of Appendix D)

$$\overline{\gamma}^\mu\left(i\frac{\partial}{\partial x^\mu}\right) + qA_\mu(x^\mu)\Psi(x^\mu) - m\Psi(x^\mu) = 0, \tag{70}$$

$$\underline{\gamma}^\mu\left(i\frac{\partial}{\partial x'^\mu}\right) + qA'_\mu(x'^\mu)\Psi'(x'^\mu) - m\Psi'(x'^\mu) = 0, \tag{71}$$

where $\Psi(x^\mu), \Psi'(x'^\mu)$ are the matrix representations [Eq. (D15), Appendix D] of Ψ_{Ξ_u} and $\Psi_{\Xi_{u'}}$. The matrix representations of the spinors are related by an equation analogous to Eq. (E2) of Appendix E, except that now, these equations refer to fields. The $\{\underline{\gamma}^\mu\}$, $\mu = 0,1,2,3$ is the set of Dirac matrices given by Eq. (D13) of Appendix D. Of course, we arrived at the usual form of the Dirac equation, except for the irrelevant fact that in general the Dirac spinor is usually represented by a column spinor field, and here we end with a 4×4 matrix field, which however has non-null elements only in the first column. [The reader can verify without great difficulty that Eq. (65) also has a matrix representation analogous to Eq. (71) but with a set of gamma matrices differing from the set $\{\underline{\gamma}^\mu\}$ by a similarity transformation.]

Equation (70), that is the usual presentation of Dirac equation in Physics textbooks, hides several important facts. First, it hides the basic dependence of the spinor fields on the spinorial frame field, since the spinorial frames Ξ_u, $\Xi_{u'}$ are such that $\mathbf{s}'(\Xi_u) = \{\gamma^\mu\}$ and $\mathbf{s}'(\Xi_{u'}) = \{\gamma'^\mu\}$ are mapped on the same set of matrices, namely $\{\underline{\gamma}^\mu\}$. Second, it hides an obvious geometrical meaning of the theory, as first disclosed by Hestenes.[80,81] Third, taking into account the discussion in a preceding section, we see that the usual presentation of the Dirac equation does not leave clear at all if we are talking about passive or active Lorentz gauge transformations. Finally, since diffeomorphisms on the world manifold are in general erroneous associated with coordinate transformations in many Physics textbooks, Eq. (70) suggests that spinors must change under diffeomorphisms in a way different from the true one, for indeed Dirac spinor fields (and also, DHSF) are scalars under diffeomorphisms, an issue that we will discuss in another publication.

IX. CONCLUSIONS

In this paper we investigated how to define algebraic and Dirac–Hestenes spinor fields on *Minkowski* space–time. We showed first, that in general, algebraic spinors can be defined for any real vector space of any dimension and equipped with a nondegenerated metric of arbitrary signature, but that is not the case for *Dirac–Hestenes spinors*. These objects exist for a four-dimensional real vector space equipped with a metric of Lorentzian signature. It is this fact that makes them very important objects (and gave us the desire to present a rigorous mathematical theory for them), since as shown in Secs. V and VII the Dirac equation can be written in terms of *Dirac–Hestenes spinor fields* or *algebraic spinor fields*. We observe that our definitions of algebraic and Dirac–Hestenes spinor fields as some equivalence classes in appropriate sets are not the standard ones and the core of the paper was to give genuine motivations for them. We observe moreover that the definitions of Dirac–Hestenes spinor fields and of the spin–Dirac operator given in Sec. V although correct are to be considered only as preliminaries. The reason is that any rigorous presentation of the theory of the spin–Dirac operator (an in particular, on a general Riemann–Cartan space–time) can only be given after the introduction of the concepts of Clifford and spin–Clifford bundles over these space–times. This is studied in a sequel paper.[126] In Ref. 155

we show some nontrivial applications of the concept of Dirac–Hestenes spinor fields by proving (mathematical) Maxwell–Dirac equivalences of the first and second kinds and showing how these equivalences can eventually put some light on a possible physical interpretation of the famous Seiberg–Witten equations for Minkowski space–time.

Noted added: After we finished the writing of the present paper and of Ref. 126, we learned about the very interesting papers by Marchuck.[110–118] There, a different point of view concerning the writing of the Dirac equation using tensor fields is developed. (Reference 110, indeed, uses a particular case of objects that we called extensors in a recent series of papers.[63–65,127–130]) We will discuss Marchuck papers elsewhere.

ACKNOWLEDGMENTS

The author is grateful to Dr. V. V. Fernández, Dr. A. Jadczyk, Dr. P. Lounesto, Dr. D. Miralles, Dr. A. M. Moya, Dr. I. Porteous, and Dr. J. Vaz, Jr., and especially to R. A. Mosna for discussions and to F. G. Rodrigues for help with LaTex. The author is also grateful to CNPq (Brazil) for a generous research grant (Contract No. 201560/82-8). Thanks are also due to the Department of Mathematical Sciences of the University of Liverpool (where part of this research was done) for providing a Visiting Professor position and an enjoyable atmosphere for research. The paper is dedicated to the memory of the late P. Lounesto who collaborated with the author in the past on the subject of this paper and from whom he learned a lot about the theory of Clifford algebras.

APPENDIX A: SOME FEATURES ABOUT REAL AND COMPLEX CLIFFORD ALGEBRAS

In this appendix we fix the notations that we used and introduce the main ideas concerning the theory of Clifford algebras necessary for the intelligibility of the paper.

1. Definition of the Clifford algebra $\mathcal{C}\ell(\mathbf{V},\mathbf{b})$

In this paper we are interested only in Clifford algebras of a vector space (we reserve the notation V for real vector spaces) $\mathbf{V}$ of finite dimension n over a field $\mathbb{F}=\mathbb{R}$ or $\mathbb{C}$. Let $\mathbf{q}:\mathbf{V}\to\mathbb{F}$ be a nondegenerate quadratic form over $\mathbf{V}$ with values in $\mathbb{F}$ and $\mathbf{b}:\mathbf{V}\times\mathbf{V}\to\mathbb{F}$ the associated bilinear form (which we call a metric in the case $\mathbb{F}=\mathbb{R}$). We use the notation

$$x\cdot y=\mathbf{b}(x,y)=\tfrac{1}{2}(\mathbf{q}(x+y)-\mathbf{q}(x)-\mathbf{q}(y). \tag{A1}$$

Let $\Lambda\mathbf{V}=\Sigma_{i=0}^{n}\Lambda^{i}\mathbf{V}$ be the exterior algebra of $\mathbf{V}$ where $\Lambda^{i}\mathbf{V}$ is the $\binom{n}{i}$ dimensional space of the i-vectors. $\Lambda^{0}\mathbf{V}$ is identified with $\mathbb{F}$ and $\Lambda^{1}\mathbf{V}$ is identified with $\mathbf{V}$. The dimension of $\Lambda\mathbf{V}$ is 2^{n}. A general element $X\in\Lambda\mathbf{V}$ is called a multivector and can be written as

$$X=\sum_{i=0}^{n}\langle X\rangle_{i},\quad \langle X\rangle_{i}\in\Lambda^{i}\mathbf{V}, \tag{A2}$$

where

$$\langle\ \rangle_{i}:\Lambda\mathbf{V}\to\Lambda^{i}\mathbf{V} \tag{A3}$$

is the projector in $\Lambda^{i}\mathbf{V}$, also called the i-part of X.

Definition 14: The main involution or grade involution is an automorphism

$$\hat{}:\Lambda\mathbf{V}\ni\mathbf{X}\mapsto\hat{\mathbf{X}}\in\Lambda\mathbf{V} \tag{A4}$$

such that

$$\hat{X}=\sum_{k=0}^{n}(-1)^{k}\langle X\rangle_{k}. \tag{A5}$$

$\hat{X}$ is called the grade involution of X or simply the involuted of X.

Definition 15: The reversion operator is the anti-automorphism

$$\tilde{}:\Lambda\mathbf{V}\ni\mathbf{X}\mapsto\tilde{\mathbf{X}}\in\Lambda\mathbf{V} \tag{A6}$$

such that

$$\tilde{X}=\sum_{k=0}^{n}(-1)^{1/2\,k(k-1)}\langle X\rangle_k, \tag{A7}$$

$\tilde{X}$ is called the reverse of X.

The composition of the grade evolution with the reversion operator, denote by $-$ is called by some authors (e.g., Refs. 109, 141, 142) the conjugation and, $\overline{X}$ is called the conjugate of X. We have $\overline{X}=(\tilde{X})=(\hat{X})$.

Since the grade and reversion operators are involutions on the vector space of multivectors, we have that $\hat{\hat{X}}=X$ and $\tilde{\tilde{X}}=X$. both involutions commute with the k-part operator, i.e., $\widehat{\langle X\rangle_k}=\langle\hat{X}\rangle_k$ and $\widetilde{\langle X\rangle_k}=\langle\tilde{X}\rangle_k$, for each $k=0,1,\ldots,n$.

Definition 16: The exterior product of multivectors X and Y is defined by

$$\langle X\wedge Y\rangle_k=\sum_{j=0}^{k}\langle X\rangle_j\wedge\langle Y\rangle_{k-j}, \tag{A8}$$

for each $k=0,1,\ldots,n$. Note that on the right-hand side there appears the exterior product of j-vectors and $(k-j)$-vectors with $0\leqslant j\leqslant n$. (We assume that the reader is familiar with the exterior algebra. We only caution that there are some different definitions of the exterior product in terms of the tensor product differing by numerical factors. This may lead to some confusions, if care is not taken. Details can be found in Refs. 63 and 64.)

This exterior product is an internal composition law on $\Lambda\mathbf{V}$. It is associative and satisfies the distributives laws (on the left and on the right).

Definition 17: The vector space $\Lambda\mathbf{V}$ endowed with this exterior product Λ is an associative algebra called the exterior algebra of multivectors.

We recall now some of the most important properties of the exterior algebra of multivectors.

For any $\alpha,\beta\in\mathbb{F}$, $X\in\Lambda\mathbf{V}$,

$$\begin{aligned}&\alpha\wedge\beta=\beta\wedge\alpha=\alpha\beta\ \ (\text{product of }\mathbb{F}\text{ numbers}),\\&\alpha\wedge X=X\wedge\alpha=\alpha X\ \ (\text{multiplication by scalars}).\end{aligned} \tag{A9}$$

For any $X_j\in\Lambda^j\mathbf{V}$ and $Y_k\in\Lambda^k\mathbf{V}$

$$X_j\wedge Y_k=(-1)^{jk}Y_k\wedge X_j. \tag{A10}$$

For any $X,Y\in\Lambda\mathbf{V}$

$$\begin{aligned}&\widehat{X\wedge Y}=\hat{X}\wedge\hat{Y},\\&\widetilde{X\wedge Y}=\tilde{X}\wedge\tilde{Y}.\end{aligned} \tag{A11}$$

2. Scalar product of multivectors

Definition 18: A scalar product between the multivectors $X,Y\in\Lambda\mathbf{V}$ is given by

$$X\cdot Y=\sum_{i=0}^{n}\langle X\rangle_i\cdot\langle Y\rangle_i, \tag{A12}$$

where $\langle X\rangle_0\cdot\langle Y\rangle_0=\langle X\rangle_0\langle Y\rangle_0$ is the multiplication in the field $\mathbb{F}$ and $\langle X\rangle_i\cdot\langle Y\rangle_i$ is given by Eq. (A2), and writing

$$\begin{aligned}\langle X\rangle_k&=\frac{1}{k!}X^{i_1i_2\cdots i_k}b_{i_1}\wedge b_{i_2}\cdots b_{i_k},\\ \langle Y\rangle_k&=\frac{1}{k!}Y^{i_1i_2\cdots i_k}b_{i_1}\wedge b_{i_2}\cdots b_{i_k}\end{aligned} \tag{A13}$$

where $\{b_k\},k=1,2,\ldots,n$ is an arbitrary basis of $\mathbf{V}$ we have

$$\langle X\rangle_k\cdot\langle Y\rangle_k=\frac{1}{(k!)^2}X^{i_1i_2\cdots i_k}Y^{j_1j_2\cdots j_k}(b_{i_1}\wedge b_{i_2}\cdots b_{i_k})\cdot(b_{j_1}\wedge b_{j_2}\cdots b_{j_k}), \tag{A14}$$

with

$$(b_{i_1}\wedge b_{i_2}\cdots b_{i_k})\cdot(b_{j_1}\wedge b_{j_2}\cdots b_{j_k})=\begin{vmatrix} b_{i_1}\cdot b_{j_1} & \cdots & \cdots & b_{i_1}\cdot b_{j_k}\\ \cdots & \cdots & \cdots & \cdots\\ \cdots & \cdots & \cdots & \cdots\\ b_{i_k}\cdot b_{j_1} & \cdots & \cdots & b_{i_k}\cdot b_{j_k}\end{vmatrix}. \tag{A15}$$

It is easy to see that for any $X,Y\in\Lambda\mathbf{V}$,

$$\begin{aligned}\hat{X}\cdot Y&=X\cdot\hat{Y},\\ \tilde{X}\cdot Y&=X\cdot\tilde{Y}.\end{aligned} \tag{A16}$$

Remark 19: Observe that the definition of the scalar product given in this paper by Eq. (A12) differs by a signal from the scalar product of multivectors defined, e.g., in Ref. 79. Our definition is a natural one if we start the theory with the euclidean Clifford algebra of multivectors of a real vector space $\mathbf{V}$. The euclidean Clifford algebra is fundamental for the construction of the theory of extensors and extensor fields.[63–65,127–130]

3. Interior algebras

Definition 20: We define two different contracted products *for arbitrary multivectors $X,Y\in\Lambda\mathbf{V}$ by*

$$\begin{aligned}(X\lrcorner Y)\cdot Z&=Y(\tilde{X}\wedge Z),\\ (X\llcorner Y)&=X\cdot(Z\wedge\tilde{Y}),\end{aligned} \tag{A17}$$

where $Z\in\Lambda\mathbf{V}$. The internal composition rules $\lrcorner$ *and* $\llcorner$ *will be called, respectively, the left and the right contracted product.*

These contracted products $\lrcorner$ and $\llcorner$ are internal laws on $\Lambda\mathbf{V}$. Both contract products satisfy the distributive laws (on the left and on the right) but they are *not* associative.

Definition 21: The vector space $\Lambda\mathbf{V}$ *endowed with each one of these contracted products (either* $\lrcorner$ *or* $\llcorner$*) is a nonassociative algebra. They are called the interior algebras of multivectors*.

We present now some of the most important properties of the interior products:

(a) For any $\alpha,\beta\in\mathbb{F}$, and $X\in\Lambda\mathbf{V}$,

$$\alpha\lrcorner\beta=\alpha\llcorner\beta=\alpha\beta \text{ (product in } \mathbb{F}),$$
$$\alpha\lrcorner X=X\llcorner\alpha=\alpha X \text{ (multiplication by scalars)}. \tag{A18}$$

(b) For any $X_j\in\Lambda^j\mathbf{V}$ and $Y_k\in\Lambda^k\mathbf{V}$ with $j\leqslant k$,

$$X_j\lrcorner Y_k=(-1)^{j(k-j)}Y_k\llcorner X_j. \tag{A19}$$

(c) For any $X_j\in\Lambda^j\mathbf{V}$ and $Y_k\in\Lambda^k\mathbf{V}$,

$$X_j\lrcorner Y_k=0, \text{ if } j>k,$$
$$X_j\llcorner Y_k=0, \text{ if } j<k. \tag{A20}$$

(d) For any $X_k,Y_k\in\Lambda^k\mathbf{V}$

$$X_j\lrcorner Y_k=X_j\llcorner Y_k=\tilde{X}_k\cdot Y_k=X_k\cdot\tilde{Y}_k. \tag{A21}$$

(e) For any $v\in\mathbf{V}$ and $X,Y\in\Lambda\mathbf{V}$

$$v\lrcorner(X\wedge Y)=(v\lrcorner X)\wedge Y+\hat{X}\wedge(v\lrcorner Y). \tag{A22}$$

4. Clifford algebra $\mathcal{C}\ell(\mathbf{V},\mathbf{b})$

Definition 22: The Clifford product of multivectors X *and* Y (*denoted by juxtaposition) is given by the following axiomatic:*

(i) For all $\alpha\in\mathbb{F}$ and $X\in\Lambda\mathbf{V}$: $\alpha X=X\alpha$ equals multiplication of multivector X by scalar α.
(ii) For all $v\in\mathbf{V}$ and $X\in\Lambda\mathbf{V}$: $vX=v\lrcorner X+v\wedge X$ and $Xv=X\llcorner v+X\wedge v$.
(iii) For all $X,Y,Z\in\Lambda\mathbf{V}$: $X(YZ)=(XY)Z$.

The Clifford product is an internal law on $\Lambda\mathbf{V}$. It is associative [by the axiom (iii)] and satisfies the distributives laws (on the left and on the right). The distributive laws follow from the corresponding distributive laws of the contracted and exterior products.

Definition 23: The vector space of multivectors over $\mathbf{V}$ *endowed with the Clifford product is an associative algebra with unity called* $\mathcal{C}\ell(\mathbf{V},\mathbf{b})$.

5. Relation between the exterior and the Clifford algebras and the tensor algebra

Modern algebra books give the

Definition 24: The exterior algebra of $\mathbf{V}$ *is the quotient algebra* $\Lambda\mathbf{V}=T(\mathbf{V})/I$, *where* $T(\mathbf{V})$ *is the tensor algebra of* $\mathbf{V}$ *and* $I\subset T(\mathbf{V})$ *is the bilateral ideal generated by the elements of the form* $\mathbf{x}\otimes\mathbf{x}$, $\mathbf{x}\in\mathbf{V}$.

Definition 25: The Clifford algebra of $(\mathbf{V},\mathbf{b})$ *is the quotient algebra* $\mathcal{C}\ell(\mathbf{V},\mathbf{b})=T(\mathbf{V})/I_b$, *where* I_b *is the bilateral ideal generated by the elements of the form* $\mathbf{x}\otimes\mathbf{x}-\mathbf{2b}(\mathbf{x},\mathbf{x})$, $\mathbf{x}\in\mathbf{V}$.

We can show that this definition is equivalent to the one given above. [When the exterior algebra is defined as $\Lambda\mathbf{V}=T(\mathbf{V})/I$ and the Clifford algebra as $\mathcal{C}\ell(\mathbf{V},\mathbf{b})=T(\mathbf{V})/I_{\mathbf{b}}$, the (associative) exterior product of the multivectors in the terms of the tensor product of these multivectors is fixed once and for all. We have, e.g., that for $x,y\in\mathbf{V}$, $x\wedge y=\frac{1}{2}(x\otimes y-y\otimes x)$. However, keep in mind that it is possible to define an (associative) exterior product in $\Lambda\mathbf{V}$ differing from the above one by numerical factors, and indeed in Refs. 63–65, 127–130 we used another choice. When reading a text on the subject it is a good idea to have in mind the definition used by the author, for otherwise confusion may result.] The space $\mathbf{V}$ is naturally *embedded* on $\mathcal{C}\ell(\mathbf{V},\mathbf{b})$, i.e.,

$$\mathbf{V}\overset{i}{\hookrightarrow}T(\mathbf{V})\overset{j}{\rightarrow}T(\mathbf{V})/I_{\mathbf{b}}=\mathcal{C}\ell(\mathbf{V},\mathbf{b}),$$
$$\text{and}\quad \mathbf{V}\equiv j\circ i(\mathbf{V})\subset\mathcal{C}\ell(\mathbf{V},\mathbf{b}). \tag{A23}$$

Let $\mathcal{C}\ell^0(\mathbf{V},\mathbf{b})$ and $\mathcal{C}\ell^1(\mathbf{V},\mathbf{b})$ be, respectively, the j-images of $\oplus_{i=0}^{\infty}T^{2i}(\mathbf{V})$ and $\oplus_{i=0}^{\infty}T^{2i+1}(\mathbf{V})$ in $\mathcal{C}\ell(\mathbf{V},\mathbf{b})$. The elements of $\mathcal{C}\ell^0(\mathbf{V},\mathbf{b})$ form a subalgebra of $\mathcal{C}\ell(\mathbf{V},\mathbf{b})$ called the even subalgebra of $\mathcal{C}\ell(\mathbf{V},\mathbf{b})$. Also, there is a canonical vector isomorphism $\Lambda\mathbf{V}\rightarrow\mathcal{C}\ell(\mathbf{V},\mathbf{b})$, which permits to speak of the embeddings $\Lambda^p\mathbf{V}\subset\mathcal{C}\ell(\mathbf{V},\mathbf{b})$, $0\leqslant p\leqslant n$, where n is the dimension of $\mathbf{V}$ (Ref. 20). [The isomorphism is compatible with the filtrations of the filtered algebra $\Lambda\mathbb{V}$, i.e., $(\Lambda^r\mathbb{V})\wedge(\Lambda^s\mathbb{V})\subseteq\Lambda^{r+s}\mathbb{V}$.]

6. Some useful properties of the real Clifford algebras $\mathcal{C}\ell(V,\mathbf{g})$

We now collect some useful formulas which hold for a real Clifford algebra $\mathcal{C}\ell(V,\mathbf{g})$ and which has been used in calculations in the text and Appendixes. (As the reader can verify, many of these properties are also valid for the complex Clifford algebras.)

For any $v\in V$ and $X\in\Lambda V$,

$$\begin{aligned} v\lrcorner X&=\tfrac{1}{2}(vX-\overline{X}v)\quad\text{and}\quad X\lrcorner v=\tfrac{1}{2}(Xv-v\overline{X}),\\ v\wedge X&=\tfrac{1}{2}(vX+\overline{X}v)\quad\text{and}\quad X\wedge v=\tfrac{1}{2}(Xv+v\overline{X}). \end{aligned}\tag{A24}$$

For any $X,Y\in V$,

$$X\cdot Y=\langle\tilde{X}Y\rangle_0=\langle X\tilde{Y}\rangle_0.\tag{A25}$$

For any $X,Y,Z\in V$,

$$\begin{aligned} (XY)\cdot Z&=Y\cdot(\tilde{X}Z)=X\cdot(Z\tilde{Y}),\\ X\cdot(YZ)&=(\tilde{Y}X)\cdot Z=(X\tilde{Z})\cdot Y. \end{aligned}\tag{A26}$$

For any $X,Y\in V$,

$$\begin{aligned} \overline{XY}&=\overline{X}\,\overline{Y},\\ \widetilde{XY}&=\tilde{Y}\tilde{X}. \end{aligned}\tag{A27}$$

Let $I\in\Lambda^nV$ then for any $v\in V$ and $X\in\Lambda V$,

$$I(v\wedge X)=(-1)^{n-1}v\lrcorner(IX).\tag{A28}$$

Equation (A22) is sometimes called the duality identity and plays an important role in the applications involving the Hodge dual operator [see Eq. (53)].

For any $X,Y,Z\in V$,

$$\begin{aligned} X\lrcorner(Y\wedge Z)&=(X\wedge Y)\lrcorner Z,\\ (X\llcorner Y)\llcorner Z&=X\llcorner(Y\wedge Z). \end{aligned}\tag{A29}$$

For any $X,Y\in V$,

$$X\cdot Y=\langle\tilde{X}Y\rangle_0.\tag{A30}$$

For $X_r\in\Lambda^rV$, $Y_s\in\Lambda^sV$ we have

$$X_rY_s=\langle X_rY_s\rangle_{|r-s|}+\langle X_rY_s\rangle_{|r-s|+2}+\cdots+\langle X_rY_s\rangle_{r+s}.\tag{A31}$$

(We observe also that when $K=\mathbb{R}$ and the quadratic form is Euclidean then $X\cdot Y$ is positive definite.)

APPENDIX B: REPRESENTATION THEORY OF THE REAL CLIFFORD ALGEBRAS $\mathbb{R}_{p,q}$

The real Clifford algebras $\mathbb{R}_{p,q}$ are associative algebras and they are simple or semisimple algebras. For the intelligibility of the present paper, it is then necessary to have in mind some results concerning the presentation theory of associative algebras, which we collect in what follows, without presenting proofs.

1. Some results from the representation theory of associative algebras

Let $\mathbf{V}$ be a set and $\mathbb{K}$ a division ring. Give to the set $\mathbf{V}$ a structure of finite-dimensional linear space over $\mathbb{K}$. Suppose that $\dim_{\mathbb{K}}\mathbf{V}=n$, where $n\in\mathbb{Z}$. We are interested in what follows in the cases where $\mathbb{K}=\mathbb{R}$, $\mathbb{C}$ or $\mathbb{H}$. When $\mathbb{K}=\mathbb{R}$, $\mathbb{C}$ or $\mathbb{H}$, we call $\mathbf{V}$ a vector space over $\mathbb{K}$. When $\mathbb{K}=\mathbb{H}$ it is necessary to distinguish between right or left $\mathbb{H}$-linear spaces and in this case $\mathbf{V}$ will be called a right or left $\mathbb{H}$-module. Recall that $\mathbb{H}$ is a division ring (sometimes called a noncommutative field or a skew field) and since $\mathbb{H}$ has a natural vector space structure over the real field, then $\mathbb{H}$ is also a division algebra.

Let $\dim_{\mathbb{R}}\mathbf{V}=2m=n$. In this case it is possible to give the following.

Definition 26: A linear mapping

$$\mathbf{J}:\mathbf{V}\to\mathbf{V}, \tag{B1}$$

such that

$$\mathbf{J}^2=-\mathrm{Id}_{\mathbf{V}}, \tag{B2}$$

is called a complex structure mapping.

*Definition 27: The pair (***V**,**J***) will be called a complex vector space structure and denote by* $\mathbf{V}_{\mathbb{C}}$ *if the following product holds. Let* $\mathbb{C}\ni z=a+ib$ *and let* $\mathbf{v}\in\mathbf{V}$. *Then*

$$z\mathbf{v}=(a+ib)\mathbf{v}=a\mathbf{v}+b\mathbf{J}\mathbf{v}. \tag{B3}$$

It is obvious that $\dim_{\mathbb{C}}=m/2$.

Definition 28: Let $\mathbf{V}$ *be a vector space over* $\mathbb{R}$. *A* complexification *of* $\mathbf{V}$ *is a complex structure associated with the real vector space* $\mathbf{V}\oplus\mathbf{V}$. *The resulting complex vector space is denoted by* $\mathbf{V}^{\mathbb{C}}$. *Let* $\mathbf{v},\mathbf{w}\in\mathbf{V}$. *Elements of* $\mathbf{V}^{\mathbb{C}}$ *are usually denoted by* $\mathbf{c}=\mathbf{v}+i\mathbf{w}$, *and if* $\mathbb{C}\ni z=a+ib$ *we have*

$$z\mathbf{c}=a\mathbf{v}-b\mathbf{w}+i(a\mathbf{w}+b\mathbf{v}). \tag{B4}$$

Of course, we have that $\dim_{\mathbb{C}}\mathbf{V}^{\mathbb{C}}=\dim_{\mathbb{R}}\mathbf{V}$.

Definition 29: A $\mathbb{H}$*-module is a real vector space* $\mathbf{V}$ *carrying three linear transformation,* **I**, **J**, *and* **K** *each one of them satisfying*

$$\begin{gathered}\mathbf{I}^2=\mathbf{J}^2=-\mathbf{I}\mathrm{d}_{\mathbf{S}},\\ \mathbf{IJ}=-\mathbf{JI}=\mathbf{K},\quad \mathbf{JK}=-\mathbf{KJ}=\mathbf{I},\quad \mathbf{KI}=-\mathbf{IK}=\mathbf{J}.\end{gathered} \tag{B5}$$

Definition 30: Any subset $I\subseteq\mathcal{A}$ *such that*

$$\begin{gathered}a\psi\in I,\forall a\in\mathcal{A},\forall\psi\in I,\\ \psi+\phi\in I,\forall\psi,\phi\in I\end{gathered} \tag{B6}$$

is called a left ideal of $\mathcal{A}$.

Remark 31: An analogous definition holds for right ideals where Eq. (B6) reads $\psi a \in I, \forall a \in \mathcal{A}, \forall \psi \in I$, *for* bilateral *ideals where in this case Eq. (B6) reads* $a\psi b \in I, \forall a, b \in \mathcal{A}, \forall \psi \in I$.

Definition 32: An associative $\mathcal{A}$ *algebra on the* field $\mathbb{F}$ ($\mathbb{R}$ or $\mathbb{C}$) *is* simple *if the only bilateral ideals are the zero ideal and* $\mathcal{A}$ *itself.*

We give without proofs the following theorems.

Theorem 33: *All minimal left (respectively, right) ideals of* $\mathcal{A}$ *are of the form* $J = \mathcal{A}e$ (*respectively,* $e\mathcal{A}$), *where* e *is a primitive idempotent of* $\mathcal{A}$.

Theorem 34: *Two minimal left ideals of* $\mathcal{A}$, $J = \mathcal{A}e$ *and* $J = \mathcal{A}e'$ *are* isomorphic *if and only if there exist a non-null* $X' \in J'$ *such that* $J' = JX'$.

We recall that $e \in \mathcal{A}$ *is an* idempotent *element if* $e^2 = e$. *An idempotent is said to be* primitive *if it cannot be written as the sum of two nonzero annihilating (or orthogonal) idempotent,* i.e., $e \neq e_1 + e_2$, *with* $e_1 e_2 = e_2 e_1 = 0$ *and* $e_1^2 = e_1$, $e_2^2 = e_2$.

Not all algebras are simple and in particular semisimple algebras are important for our considerations. A definition of semisimple algebras requires the introduction of the concepts of nilpotent ideals and radicals. To define these concepts adequately would lead us to a long incursion on the theory of associative algebras, so we avoid to do that here. We only quote that semisimple algebras are the direct sum of simple algebras. Then, the study of semisimple algebras is reduced to the study of simple algebras.

Now, let $\mathcal{A}$ be an associative and simple algebra on the field $\mathbb{F}$ ($\mathbb{R}$ or $\mathbb{C}$), and let $\mathbf{S}$ be a finite-dimensional linear space over a division ring $\mathbb{K} \subseteq \mathbb{F}$.

Definition 35: *A* representation *of* $\mathcal{A}$ *in* $\mathbf{S}$ *is a* $\mathbb{K}$ *algebra homomorphism* [we recall that a $\mathbb{K}$-algebra homomorphism is a $\mathbb{K}$-linear map ρ such that $\forall X, Y \in \mathcal{A}$, $\rho(XY) = \rho(X)\rho(Y)$] $\rho: \mathcal{A} \to \mathbf{E} = \mathrm{End}_{\mathbb{K}}\mathbf{S}$ ($\mathbf{E} = \mathrm{End}_{\mathbb{K}}\mathbf{S} = \mathrm{Hom}_{\mathbb{K}}(\mathbf{S}, \mathbf{S})$ *is the endomorphism algebra of* $\mathbf{S}$) *which maps the unit element of* $\mathcal{A}$ *to* $\mathbf{Id}_{\mathbf{E}}$. *The dimension* $\mathbb{K}$ *of* $\mathbf{S}$ *is called the* degree *of the representation.*

The addition in $\mathbf{S}$ together with the mapping $\mathcal{A} \times \mathbf{S} \to \mathbf{S}$, $(a, x) \mapsto \rho(a)x$ turns $\mathbf{S}$ in a left $\mathcal{A}$-module, called the left *representation module*. [We recall that there are left and right modules, so we can also define right modular representations of $\mathcal{A}$ by defining the mapping $\mathbf{S} \times \mathcal{A} \to \mathbf{S}$, $(x, a) \mapsto x\rho(a)$. This turns $\mathbf{S}$ in a right $\mathcal{A}$-module, called the right *representation module*.]

Remark 36: It is important to recall that when $\mathbb{K} = \mathbb{H}$ *the usual recipe for* $\mathrm{Hom}_{\mathbb{H}}(\mathbf{S}, \mathbf{S})$ *to be a linear space over* $\mathbb{H}$ *fails and in general* $\mathrm{Hom}_{\mathbb{H}}(\mathbf{S}, \mathbf{S})$ *is considered as a linear space over* $\mathbb{R}$, *which is the center of* $\mathbb{H}$.

Remark 37: We also have that if $\mathcal{A}$ *is an algebra over* $\mathbb{F}$ *and* $\mathbf{S}$ *is an* $\mathcal{A}$*-module, then* $\mathbf{S}$ *can always be considered as a vector space over* $\mathbb{F}$ *and if* $e \in \mathcal{A}$, *the mapping* $\chi: a \to \chi_a$ *with* $\chi_a(\mathbf{s}) = a\mathbf{s}$, $\mathbf{s} \in \mathbf{S}$, *is a homomorphism* $\mathcal{A} \to \mathbf{E} = \mathrm{End}_{\mathbb{F}}\mathbf{S}$, *and so it is a representation of* $\mathcal{A}$ *in* $\mathbf{S}$. *The study of* $\mathcal{A}$ *modules is then equivalent to the study of the* $\mathbb{F}$ *representations of* $\mathcal{A}$.

Definition 38: A representation ρ *is faithful if its kernel is zero, i.e.,* $\rho(a)x = 0, \forall x \in \mathbf{S} \Rightarrow a = 0$. *The kernel of* ρ *is also known as the* annihilator *of its module.*

Definition 39: ρ *is said to be* simple *or irreducible if the only invariant subspaces of* $\rho(a)$, $\forall a \in \mathcal{A}$, *are* $\mathbf{S}$ *and* $\{0\}$.

Then, the representation module is also simple. That means that it has no proper submodules.

Definition 40: ρ *is said to be semisimple, if it is the direct sum of simple modules, and in this case* $\mathbf{S}$ *is the direct sum of subspaces which are globally invariant under* $\rho(a)$, $\forall a \in \mathcal{A}$.

When no confusion arises $\rho(a)x$ may be denoted by $a \cdot x$, $a * x$ or ax.

Definition 41: Two $\mathcal{A}$*-modules* $\mathbf{S}$ *and* $\mathbf{S}'$ *(with the exterior multiplication being denoted, respectively, by* $\cdot$ *and* $*$*) are* isomorphic *if there exists a bijection* $\varphi: \mathbf{S} \to \mathbf{S}'$ *such that*

$$\varphi(x + y) = \varphi(x) + \varphi(y), \quad \forall x, y \in \mathbf{S},$$

$$\varphi(a \cdot x) = a * \varphi(x), \quad \forall a \in \mathcal{A},$$

and we say that representation ρ *and* ρ' *of* $\mathcal{A}$ *are equivalent if their modules are isomorphic.*

This implies the existence of a $\mathbb{K}$-linear isomorphism $\varphi: \mathbf{S} \to \mathbf{S}'$ such that $\varphi \circ \rho(a) = \rho'(a) \circ \varphi$, $\forall a \in \mathcal{A}$ or $\rho'(a) = \varphi \circ \rho(a) \circ \varphi^{-1}$. If $\dim \mathbf{S} = n$, then $\dim \mathbf{S}' = n$.

TABLE I. Representation of the Clifford algebras $\mathbb{R}_{p,q}$ as matrix algebras.

$p-q$ mod 8	0	1	2	3	4	5	6	7
$\mathbb{R}_{p,q}$	$\mathbb{R}(2^{[n/2]})$	$\mathbb{R}(2^{[n/2]})$ $\oplus$ $\mathbb{R}(2^{[n/2]})$	$\mathbb{R}(2^{[n/2]})$	$\mathbb{C}(2^{[n/2]})$	$\mathbb{H}(2^{[n/2]-1})$	$\mathbb{H}(2^{[n/2]-1})$ $\oplus$ $\mathbb{H}(2^{[n/2]-1})$	$\mathbb{H}(2^{[n/2]-1})$	$\mathbb{C}(2^{[n/2]})$

Definition 42: A complex representation *of $\mathcal{A}$ is simply a real representation $\rho:\mathcal{A}\to\mathrm{Hom}_{\mathbb{R}}(\mathbf{S},\mathbf{S})$ for which*

$$\rho(X)\circ\mathbf{J}=\mathbf{J}\circ\rho(X),\quad \forall X\in\mathcal{A}. \tag{B7}$$

This means that the image of ρ commutes with the subalgebra generated by $\{\mathbf{Id}_{\mathbf{S}}\}\sim\mathbb{C}$.

Definition 43: A quaternionic representation of $\mathcal{A}$ is a representation $\rho:\mathcal{A}\to\mathrm{Hom}_{\mathbb{R}}(\mathbf{S},\mathbf{S})$ such that

$$\rho(X)\circ\mathbf{I}=\mathbf{I}\circ\rho(X),\quad \rho(X)\circ\mathbf{J}=\mathbf{J}\circ\rho(X),\quad \rho(X)\circ\mathbf{K}=\mathbf{K}\circ\rho(X),\quad \forall X\in\mathcal{A}. \tag{B8}$$

This means that the representation ρ has a commuting subalgebra isomorphic to the quaternion ring.

The following theorem[61,109] is crucial.

Theorem 44 (Wedderburn): *If $\mathcal{A}$ is simple algebra over $\mathbb{F}$ then $\mathcal{A}$ is isomorphic to $\mathbb{D}(m)$, where $\mathbb{D}(m)$ is a matrix algebra with entries in $\mathbb{D}$ (a division algebra), and m and $\mathbb{D}$ are unique (modulo isomorphisms).*

Now, it is time to specialize our results to the Clifford algebras over the field $\mathbb{F}=\mathbb{R}$ or $\mathbb{C}$. We are particularly interested in the case of real Clifford algebras. In what follows we take $(\mathbf{V},\mathbf{b})=(\mathbb{R}^n,\mathbf{g})$. We denote by $\mathbb{R}^{p,q}$ a real vector space of dimension $n=p+q$ endowed with a nondegenerate metric $\mathbf{g}:\mathbb{R}^n\times\mathbb{R}^n\to\mathbb{R}$. Let $\{E_i\}$, $(i=1,2,\ldots,n)$ be an orthonormal basis of $\mathbb{R}^{p,q}$,

$$\mathbf{g}(E_i,E_j)=g_{ij}=g_{ji}=\begin{cases}+1, & i=j=1,2,\ldots,p\\ -1, & i=j=p+1,\ldots,p+q=n\\ 0, & i\neq j.\end{cases} \tag{B9}$$

Definition 45: The Clifford algebra $\mathbb{R}_{p,q}=\mathcal{C}\ell(\mathbb{R}^{p,q})$ is the Clifford algebra over $\mathbb{R}$, generated by 1 and the $\{E_i\}$ $(i=1,2,\ldots,n)$, such that $E_i^2=\mathbf{q}(E_i)=\mathbf{g}(E_i,E_i)$, $E_iE_j=-E_jE_i$ $(i\neq j)$, and $E_1E_2\ldots E_n\neq\pm 1$.

$\mathbb{R}_{p,q}$ is obviously of dimension 2^n and as a vector space it is the direct sum of vector spaces $\Lambda^k\mathbb{R}^n$ of dimensions $\binom{n}{k}$, $0\leqslant k\leqslant n$. The canonical basis of $\Lambda^k\mathbb{R}^n$ is given by the elements $e_A=E_{\alpha_1}\cdots E_{\alpha_k}$, $1\leqslant\alpha_1<\cdots<\alpha_k\leqslant n$. The element $e_J=E_1\cdots E_n\in\Lambda^k\mathbb{R}^n\subset\mathbb{R}_{p,q}$ commutes (n odd) or anticommutes (n even) with all vectors $E_1\cdots E_n\in\Lambda^1\mathbb{R}^n\equiv\mathbb{R}^n$. The center $\mathcal{C}\ell_{p,q}$ is $\Lambda^0\mathbb{R}^n\equiv\mathbb{R}$ if n is even and it is the direct sum $\Lambda^0\mathbb{R}^n\oplus\Lambda^0\mathbb{R}^n$ if n is odd.

All Clifford algebras are semisimple. If $p+q=n$ is even, $\mathbb{R}_{p,q}$ is simple and if $p+q=n$ is odd we have the following possibilities.

(a) $\mathbb{R}_{p,q}$ is simple $\leftrightarrow c_J^2=-1\leftrightarrow p-q\neq 1\pmod 4\leftrightarrow$ center of $\mathbb{R}_{p,q}$ is isomorphic to $\mathbb{C}$;

(b) $\mathbb{R}_{p,q}$ is not simple (but is a direct sum of two simple algebras)$\leftrightarrow c_J^2=+1\leftrightarrow p-q=1\pmod 4\leftrightarrow$ center of $\mathbb{R}_{p,q}$ is isomorphic to $\mathbb{R}\oplus\mathbb{R}$.

Now, for $\mathbb{R}_{p,q}$ the division algebras $\mathbb{D}$ are the division rings $\mathbb{R}$, $\mathbb{C}$ or $\mathbb{H}$. The explicit isomorphism can be discovered with some hard but not difficult work. It is possible to give a general classification off all real (and also the complex) Clifford algebras and a classification table can be found, e.g., in Refs. 141 and 142. Table I is reproduced and $[n/2]$ means the integer part of $n/2$.

Now, to complete the classification we need the following theorem.[141]

Theorem 46 (Periodicity):

$$\mathbb{R}_{n+8}=\mathbb{R}_{n,0}\otimes\mathbb{R}_{8,0},\quad \mathbb{R}_{0,n+8}=\mathbb{R}_{0,n}\otimes\mathbb{R}_{0,8},$$
$$\mathbb{R}_{p+8,q}=\mathbb{R}_{p,q}\otimes\mathbb{R}_{8,0},\quad \mathbb{R}_{p,q+8}=\mathbb{R}_{p,q}\otimes\mathbb{R}_{0,8}. \tag{B10}$$

Remark 47: We emphasize here that since the general results concerning the representations of simple algebras over a field $\mathbb{F}$ applies to the Clifford algebras $\mathbb{R}_{p,q}$ we can talk about real, complex or quaternionic representation of a given Clifford algebra, even if the natural matrix identification is not a matrix algebra over one of these fields. A case that we shall need is that $\mathbb{R}_{1,3}\simeq\mathbb{H}(2)$. But it is clear that $\mathbb{R}_{1,3}$ has a complex representation, for any quaternionic representation of $\mathbb{R}_{p,q}$ is automatically complex, *once we restrict $\mathbb{C}\subset\mathbb{H}$ and of course, the complex dimension of any $\mathbb{H}$-module must be even. Also, any complex representation of $\mathbb{R}_{p,q}$ extends automatically to a representation of $\mathbb{C}\otimes\mathbb{R}_{p,q}$.*

Remark 48: *Now, $\mathbb{C}\otimes\mathbb{R}_{p,q}$ is an abbreviation for the* complex *Clifford algebra $\mathcal{C}\ell_{p+q}=\mathbb{C}\otimes\mathbb{R}_{p,q}$, i.e., it is the tensor product of the algebras $\mathbb{C}$ and $\mathbb{R}_{p,q}$, which are subalgebras of the finite-dimensional algebra $\mathcal{C}\ell_{p+q}$ over $\mathbb{C}$.*

For the purposes of the present paper we must keep in mind that

$$\mathbb{R}_{0,1}\simeq\mathbb{C},$$
$$\mathbb{R}_{0,2}\simeq\mathbb{H},$$
$$\mathbb{R}_{3,0}\simeq\mathbb{C}(2),$$
$$\mathbb{R}_{1,3}\simeq\mathbb{H}(2), \tag{B11}$$
$$\mathbb{R}_{3,1}\simeq\mathbb{R}(4),$$
$$\mathbb{R}_{4,1}\simeq\mathbb{C}(4).$$

$\mathbb{R}_{3,0}$ is called the Pauli algebra, $\mathbb{R}_{1,3}$ is called the *space–time* algebra, $\mathbb{R}_{3,1}$ is called *Majorana* algebra and $\mathbb{R}_{4,1}$ is called the *Dirac* algebra. Also the following particular results have been used in the text and below:

$$\mathbb{R}^0_{1,3}\simeq\mathbb{R}^0_{3,1}=\mathbb{R}_{3,0},\quad \mathbb{R}^0_{4,1}\simeq\mathbb{R}_{1,3},$$
$$\mathbb{R}_{4,1}\simeq\mathbb{C}\otimes\mathbb{R}_{3,1},\quad \mathbb{R}_{4,1}\simeq\mathbb{C}\otimes\mathbb{R}_{3,1}, \tag{B12}$$

which means that the Dirac algebra is the complexification of both the space–time or the Majorana algebras.

Equation (B11) show moreover, in view of Remark 7 that the space–time algebra has a complexification matrix representation in $\mathbb{C}(4)$. Obtaining such a representation is fundamental for the present work and it is given in Appendix D.

2. Minimal lateral ideals of $\mathbb{R}_{p,q}$

It is important for the objectives of this paper to know some results concerning the minimal lateral ideals of $\mathbb{R}_{p,q}$. The identification table of these algebras as matrix algebras helps a lot. Indeed, we have[61] the following theorem.

Theorem 49: *The maximum number of pairwise orthogonal idempotents in $\mathbb{K}(m)$ (where $\mathbb{K}=\mathbb{R}$, $\mathbb{C}$ or $\mathbb{H}$) is m.*

The decomposition of $\mathbb{R}_{p,q}$ into minimal ideals is then characterized by a spectral set $\{e_{pq,j}\}$ of idempotents elements of $\mathbb{R}_{p,q}$ such that

(a) $\Sigma_{i=1}^{n} e_{pq,i}=1$,
(b) $e_{pq,j}e_{pq,k}=\delta_{jk}e_{pq,j}$,

(c) the rank of $e_{pq,j}$ is minimal and nonzero, i.e., is primitive.

By rank of $e_{pq,j}$ we mean the rank of the $\Lambda\mathbb{R}^{p,q}$ morphism, $e_{pq,j}:\phi\mapsto\phi e_{pq,j}$. Conversely, any $\phi\in\mathbf{I}_{pq,j}$ can be characterized by an idempotent $e_{pq,j}$ of minimal rank$\neq 0$, with $\phi=\phi e_{pq,j}$.

We now need to know the following theorem.[109]

Theorem 50: *A minimal left ideal of* $\mathbb{R}_{p,q}$ *is of the type*

$$\mathbf{I}_{pq}=\mathbb{R}_{p,q}e_{pq},$$

where

$$e_{pq}=\tfrac{1}{2}(1+e_{\alpha_1})\cdots\tfrac{1}{2}(1+e_{\alpha_k}) \tag{B13}$$

is a primitive idempotent of $\mathbb{R}_{p,q}$ *and were* $e_{\alpha_1},\cdots,e_{\alpha_k}$ *are commuting elements in the canonical basis of* $\mathbb{R}_{p,q}$ *generated in the standard way through the elements of the basis* Σ *such that* $(e_{\alpha_i})^2=1$, $(i=1,2,\ldots,k)$ *generate a group of order* 2^k, $k=q-r_{q-p}$ *and* r_i *are the Radon–Hurwitz numbers, defined by the recurrence formula* $r_{i+8}=r_i+4$ *and*

i	0	1	2	3	4	5	6	7
r_i	0	1	2	2	3	3	3	3

(B14)

Recall that $\mathbb{R}_{p,q}$ is a ring and the minimal lateral ideals are modules over the ring $\mathbb{R}_{p,q}$. They are *representation modules* of $\mathbb{R}_{p,q}$, and indeed we have (recall the table above) the following theorem.[141]

Theorem 51: *If* $p+q$ *is even or odd with* $p-q\neq 1$ *(mod 4), then*

$$\mathbb{R}_{p,q}=\mathrm{Hom}_{\mathbb{K}}(I_{pq})\simeq\mathbb{K}(m), \tag{B15}$$

where (as we already know) $\mathbb{K}=\mathbb{R}$, $\mathbb{C}$ *or* $\mathbb{H}$. *Also,*

$$\dim_{\mathbb{K}}(I_{pq})=m \tag{B16}$$

and

$$\mathbb{K}\simeq e\mathbb{K}(m)e, \tag{B17}$$

where e *is the representation of* $\mathbf{e}_{pq}$ *in* $\mathbb{K}(m)$.

If $p+q=n$ *is odd, with* $p-q=1$ *(mod 4), then*

$$\mathbb{R}_{p,q}=\mathrm{Hom}_{\mathbb{K}}(I_{pq})\simeq\mathbb{K}(m)\oplus\mathbb{K}(m), \tag{B18}$$

with

$$\dim_{\mathbb{K}}(I_{pq})=m \tag{B19}$$

and

$$e\mathbb{K}(m)e\simeq\mathbb{R}\oplus\mathbb{R}$$

or (B20)

$$e\mathbb{K}(m)e\simeq\mathbb{H}\oplus\mathbb{H}.$$

With the above isomorphisms we can immediately identify the minimal left ideals of $\mathbb{R}_{p,q}$ with the column matrices of $\mathbb{K}(m)$.

Algorithm for finding primitive idempotents of $\mathbb{R}_{p,q}$: With the ideas introduced above it is now a simple exercise to find primitive idempotents of $\mathbb{R}_{p,q}$. First we look at Table I and find the matrix algebra to which our particular Clifford algebra $\mathbb{R}_{p,q}$ is isomorphic. Suppose $\mathbb{R}_{p,q}$ is simple. (Once we know the algorithm for a simple Clifford algebra it is straightfoward to devise an algorithm for the semisimple Clifford algebras.) Let $\mathbb{R}_{p,q}\simeq\mathbb{K}(m)$ for a particular $\mathbb{K}$ and m. Next we take an element $e_{\alpha_1}\in\{e_A\}$ from the canonical basis $\{e_A\}$ of $\mathbb{R}_{p,q}$ such that

$$e_{\alpha_1}^2=1, \tag{B21}$$

then construct the idempotent $e_{pq}=(1+e_{\alpha_1})/2$ and the ideal $\mathbf{I}_{pq}=\mathbb{R}_{p,q}e_{pq}$ and calculate $\dim_{\mathbb{K}}(I_{pq})$. If $\dim_{\mathbb{K}}(I_{pq})=m$, then e_{pq} is primitive. If $\dim_{\mathbb{K}}(I_{pq})\neq m$, we choose $e_{\alpha 2}\in\{e_A\}$ such that $e_{\alpha 2}$ commutes with e_{α_1} and $e_{\alpha_2}^2=1$ [see Theorem 39 and construct the idempotent $e'_{pq}=(1+e_{\alpha_1})(1+e_{\alpha_1})/4$]. If $\dim_{\mathbb{K}}(I'_{pq})=m$, then e'_{pq} is primitive. Otherwise we repeat the procedure. According to the Theorem 39 the procedure is finite.

These results will be used in Appendix D in order to obtain necessary results for our presentation of the theory of algebraic and Dirac–Hestenes spinors (and spinors fields).

APPENDIX C: $\mathbb{R}^{\star}_{p,q}$, CLIFFORD, PINOR AND SPINOR GROUPS

The set of the invertible elements of $\mathbb{R}_{p,q}$ constitutes a non-Abelian group which we denote by $\mathbb{R}^{\star}_{p,q}$. It acts naturally on $\mathbb{R}_{p,q}$ as an algebra homomorphism through its adjoint representation

$$\mathrm{Ad}:\mathbb{R}^{\star}_{p,q}\rightarrow\mathrm{Aut}(\mathbb{R}_{p,q});u\mapsto\mathrm{Ad}_u,\ \text{with}\ \mathrm{Ad}_u(x)=uxu^{-1}. \tag{C1}$$

Definition 52: The Clifford–Lipschitz *group is the set*

$$\Gamma_{p,q}=\{u\in\mathbb{R}^{\star}_{p,q}|\forall x\in\mathbb{R}^{p,q},uxu^{-1}\in\mathbb{R}^{p,q}\}. \tag{C2}$$

Definition 53: The set $\Gamma^{+}_{p,q}=\Gamma_{p,q}\cap\mathbb{R}_{p,q}$ *is called* special *Clifford–Lipshitz group.*

Definition 54: The Pinor group $\mathrm{Pin}_{p.q}$ *is the subgroup of* $\Gamma_{p,q}$ *such that*

$$\begin{gathered}\mathrm{Pin}_{p,q}=\{u\in\Gamma_{p,q}|N(u)=\pm 1\},\\ N:\mathbb{R}_{p,q}\rightarrow\mathbb{R}_{p,q},N(x)=\langle\overline{x}x\rangle_0.\end{gathered} \tag{C3}$$

Definition 55: The Spin group $\mathrm{Spin}_{p,q}$ *is the set*

$$\mathrm{Spin}_{p,q}=\{u\in\Gamma_{p,q}|N(u)=\pm 1\}. \tag{C4}$$

It is easy to see that $\mathrm{Spin}_{p,q}$ is not connected.

Definition 56: The group $\mathrm{Spin}^{e}_{p,q}$ *is the set*

$$\mathrm{Spin}^{e}_{p,q}=\{u\in\Gamma_{p,q}|N(u)=+1\}. \tag{C5}$$

The superscript e, means that $\mathrm{Spin}^{e}_{p,q}$ is the connected component to the identity. We can prove that $\mathrm{Spin}^{e}_{p,q}$ is connected for all pairs (p,q) with the exception of $\mathrm{Spin}^{e}(1,0)\simeq\mathrm{Spin}^{e}(0,1)$.

We recall now some classical results[120] associated with the pseudo-orthogonal groups $\mathrm{O}_{p,q}$ of a vector space $\mathbb{R}^{p,q}$ $(n=p+q)$ and its subgroups.

Let $\mathbf{G}$ be a diagonal $n\times n$ matrix whose elements are

$$G_{ij}=\mathrm{diag}(1,1,\ldots,-1,-1,\ldots-1), \tag{C6}$$

with p positive and q negative numbers.

Definition 57: $O_{p,q}$ is the set of $n\times n$ real matrices $\mathbf{L}$ *such that*

$$\mathbf{L}\mathbf{G}\mathbf{L}^T=\mathbf{G},\quad \det\mathbf{L}^2=1. \tag{C7}$$

Equation (C7) shows that $\mathrm{O}_{p,q}$ is not connected.

Definition 58: $SO_{p,q}$, the special (proper) pseudo-orthogonal group is the set of $n\times n$ real matrices $\mathbf{L}$ *such that*

$$\mathbf{L}\mathbf{G}\mathbf{L}^T=\mathbf{G},\quad \det\mathbf{L}=1. \tag{C8}$$

When $p=0$ $(q=0)$ $\mathrm{SO}_{p,q}$ is connected. However, $\mathrm{SO}_{p,q}$ is not connected and has two connected components for $p,q\geqslant 1$. The group $\mathrm{SO}^e_{p,q}$, the connected component to the identity of $\mathrm{SO}_{p,q}$ will be called the special *orthocronous* pseudo-orthogonal group. [This nomenclature comes from the fact that $\mathrm{SO}^e(1,3)=\mathcal{L}^{\uparrow}_{+}$ is the special (proper) orthochronous Lorentz group. In this case the set is easily defined by the condition $L^0_0\geqslant +1$. For the general case see Ref. 120.]

Theorem 59: *$Ad_{|\mathrm{Pin}_{p,q}}:\mathrm{Pin}_{p,q}\to \mathrm{O}_{p,q}$ is onto with kernel $\mathbb{Z}_2$. $Ad_{|\mathrm{Spin}_{p,q}}:\mathrm{Spin}_{p,q}\to\mathrm{SO}_{p,q}$ is onto with kernel $\mathbf{Z}_2$. $Ad_{|\mathrm{Spin}^e_{p,q}}:\mathrm{Spin}^e_{p,q}\to\mathrm{SO}^e_{p,q}$ is onto with kernel $\mathbf{Z}_2$. We have*

$$\mathrm{O}_{p,q}=\frac{\mathrm{Pin}_{p,q}}{\mathbb{Z}_2},\quad \mathrm{SO}_{p,q}=\frac{\mathrm{Spin}_{p,q}}{\mathbb{Z}_2},\quad \mathrm{SO}^e_{p,q}=\frac{\mathrm{Spin}^e_{p,q}}{\mathbb{Z}_2}. \tag{C9}$$

The group homomorphism between $\mathrm{Spin}^e_{p,q}$ and $\mathrm{SO}^e(p,q)$ will be denoted by

$$\mathbf{L}:\mathrm{Spin}^e_{p,q}\to\mathrm{SO}^e_{p,q}. \tag{C10}$$

The following theorem that first appears in Porteous book[141] is very important. (In particular, when Theorem 49 is taken into account together with some of the coincidence between the complexifications of some low dimensions Clifford algebras it becomes clear that the construction of Dirac–Hestenes spinors [and its representation as in Eq. (D20)] for Minkowski vector space has no generalization for vector spaces of arbitrary dimensions and signatures.[109])

Theorem 60 (Porteous): *For $p+q\leqslant 5$, $\mathrm{Spin}^e(p,q)=\{u\in\mathbb{R}_{p,q}|u\tilde{u}=1\}$.*

Lie algebra of $\mathrm{Spin}^e_{1,3}$: It can be shown[109] that for each $u\in\mathrm{Spin}^e_{1,3}$ it holds $u=\pm e^F$, $F\in\Lambda^2\mathbb{R}^{1,3}\subset\mathbb{R}_{1,3}$ and F can be chosen in such a way to have a positive sign in Eq. (C8), except in the particular case $F^2=0$ when $u=-e^F$. From Eq. (C8) it follows immediately that the Lie algebra of $\mathrm{Spin}^e_{1,3}$ is generated by the bivectors $F\in\Lambda^2\mathbb{R}^{1,3}\subset\mathbb{R}_{1,3}$ through the commutator product. More details on the relations of Clifford algebras and the rotation groups may be found, e.g., in Refs. 7 and 170.

APPENDIX D: SPINOR REPRESENTATIONS OF $\mathbb{R}_{4,1}$, $\mathbb{R}^{+}_{4,1}$, AND $\mathbb{R}_{1,3}$

Let $b_0=\{E_0,E_1,E_2,E_3\}$ be an orthogonal basis of $\mathbb{R}^{1,3}\subset\mathbb{R}_{1,3}$, such that $E_\mu E_\nu+E_\nu E_\mu=2\eta_{\mu\nu}$, with $\eta_{\nu\mu}=\mathrm{diag}(+1,-1,-1,-1)$. Now, with the results of Appendix B we can verify without difficulties that the elements e, e', $e''\in\mathbb{R}_{1,3}$,

$$e=\tfrac{1}{2}(1+E_0), \tag{D1}$$

$$e'=\tfrac{1}{2}(1+E_3E_0), \tag{D2}$$

$$e''=\tfrac{1}{2}(1+E_1E_2E_3), \tag{D3}$$

are primitive idempotents of $\mathbb{R}_{1,3}$ The minimal left ideals, $I=\mathbb{R}_{1,3}e$, $I'=\mathbb{R}_{1,3}e'$, $I''=\mathbb{R}_{1,3}e''$ are *right* two dimension linear spaces over the quaternion field (e.g., $\mathbb{H}e=e\mathbb{H}=e\mathbb{R}_{1,3}e$). According to a definition given originally in Ref. 150 these ideals are algebraically equivalent. For example, $e'=ueu^{-1}$, with $u=(1+E_3)\notin\Gamma_{1,3}$.

Definition 61: The elements $\Phi\in\mathbb{R}_{1,3}\frac{1}{2}(1+E_0)$ *are called* mother *spinors*.

The above denomination has been given (with justice) by Lounesto.[109] It can be shown[67,68] that each Φ can be written

$$\Phi=\psi_1 e+\psi_2 E_3E_1e+\psi_3E_3E_0e+\psi_4E_1E_0e=\sum_i\ \psi_i s_i\,, \tag{D4}$$

$$s_1=e,\quad s_2=E_3E_1e,\quad s_3=E_3E_0e,\quad s_4=E_1E_0e \tag{D5}$$

and where the ψ_i are *formally* complex numbers, i.e., each $\psi_i=(a_i+b_iE_2E_1)$ with a_i, $b_i\in\mathbb{R}$ and the set $\{s_i,i=1,2,3,4\}$ is a basis in the mother spinors space.

We recall from the general result of Appendix C that $\mathrm{Pin}_{1,3}/\mathbb{Z}_2\simeq\mathrm{O}_{1,3}$, $\mathrm{Spin}_{1,3}/\mathbb{Z}_2\simeq\mathrm{SO}_{1,3}$, $\mathrm{Spin}^e_{1,3}/\mathbb{Z}_2\simeq\mathrm{SO}^e_{1,3}$, and $\mathrm{Spin}^e_{1,3}\simeq\mathrm{Sl}(2,\mathbb{C})$ is the universal covering group of $\mathcal{L}^{\uparrow}_{+}\equiv\mathrm{SO}^e_{1,3}$, the *special* (proper) *orthocronous* Lorentz group.

In order to determine the relation between $\mathbb{R}_{4,1}$ and $\mathbb{R}_{3,1}$ we proceed as follows: let $\{F_0,F_1,F_2,F_3,F_4\}$ be an orthonormal basis of $\mathbb{R}_{4,1}$ with

$$-F_0^2=F_1^2=F_2^2=F_3^2=F_4^2=1,F_AF_B=-F_BF_A(A\neq B;A,B=0,1,2,3,4).$$

Define the pseudoscalar

$$\mathbf{i}=F_0F_1F_2F_3F_4,\quad \mathbf{i}^2=-1,\quad \mathbf{i}F_A=F_A\mathbf{i},\quad A=0,1,2,3,4. \tag{D6}$$

Define

$$\mathcal{E}_\mu=F_\mu F_4\,. \tag{D7}$$

We can immediately verify that $\mathcal{E}_\mu\mathcal{E}_\nu+\mathcal{E}_\nu\mathcal{E}_\mu=2\,\eta_{\mu\nu}$. Taking into account that $\mathbb{R}_{1,3}\simeq\mathbb{R}^0_{4,1}$ we can explicitly exhibit here this isomorphism by considering the map $\mathrm{j}:\mathbb{R}_{1,3}\to\mathbb{R}_{4,1}$ generated by the linear extension of the map $\mathrm{j}^{\#}:\mathbb{R}^{1,3}\to\mathbb{R}_{4,1}$, $\mathrm{j}^{\#}(F_\mu)=\mathcal{E}_\mu=F_\mu F_4$, where $\mathcal{E}_\mu$ $(\mu=0,1,2,3)$ is an orthogonal basis of $\mathbb{R}^{1,3}$. Also $\mathrm{j}(1_{\mathbb{R}_{1,3}})=1_{\mathbb{R}^+_{4,1}}$, where $1_{\mathbb{R}_{1,3}}$ and $1_{\mathbb{R}^+_{4,1}}$ are the identity elements in $\mathbb{R}_{1,3}$ and $\mathbb{R}^+_{4,1}$. Now consider the primitive idempotent of $\mathbb{R}_{1,3}\simeq\mathbb{R}^0_{4,1}$,

$$e_{41}=\mathrm{j}(e)=\tfrac{1}{2}(1+\mathcal{E}_0) \tag{D8}$$

and the minimal left ideal $I_{4,1}=\mathbb{R}_{4,1}e_{41}$.

In what follows we use (when convenient) for minimal idempotents and the minimal ideals generated by them, the labels involving the notion of spinorial frames discussed in Sec. II. Let then, Ξ_0 be a fiducial spinorial frame. The elements [in what follows we use (when convenient) for minimal idempotents and the minimal ideals generated by them, the labels involving the notion of spin frames discussed in Sec. II] $Z_{\Xi_0}\in I_{4,1}$ can be written analogously to $\Phi\in\mathbb{R}_{1,3}\frac{1}{2}(1+E_0)$ as

$$Z_{\Xi_0}=\sum\ z_i\overline{s_i}\,, \tag{D9}$$

where

$$\overline{s_1}=e_{41},\quad \overline{s_2}=\mathcal{E}_1\mathcal{E}_3e_{41},\quad \overline{s_3}=\mathcal{E}_3\mathcal{E}_0e_{41},\quad \overline{s_4}=\mathcal{E}_1\mathcal{E}_0e_{41} \tag{D10}$$

and where

$$z_i = a_i + \mathcal{E}_2\mathcal{E}_1 b_i$$

are formally complex numbers, a_i, $b_i \in \mathbb{R}$.

Consider now the element $f_{\Xi_0} \in \mathbb{R}_{4,1}$,

$$f_{\Xi_0} = e_{41}\tfrac{1}{2}(1+\mathbf{i}\mathcal{E}_1\mathcal{E}_2) = \tfrac{1}{2}(1+\mathcal{E}_0)\tfrac{1}{2}(1+\mathbf{i}\mathcal{E}_1\mathcal{E}_2), \tag{D11}$$

with **i** defined as in Eq. (D6).

Since $f_{\Xi_0}\mathbb{R}_{4,1}f_{\Xi_0} = \mathbb{C}f_{\Xi_0} = f_{\Xi_0}\mathbb{C}$ it follows that f_{Ξ_0} is a primitive idempotent of $\mathbb{R}_{4,1}$. We can easily show that each $\Phi_{\Xi_0} \in I_{\Xi_0} = \mathbb{R}_{4,1}f_{\Xi_0}$ can be written

$$\Psi_{\Xi_0} = \sum_i \psi_i f_i, \quad \psi_i \in \mathbb{C},$$
$$f_1 = f_{\Xi_0}, \quad f_2 = -\mathcal{E}_1\mathcal{E}_3 f_{\Xi_0}, \quad f_3 = \mathcal{E}_3\mathcal{E}_0 f_{\Xi_0}, \quad f_4 = \mathcal{E}_1\mathcal{E}_0 f_{\Xi_0} \tag{D12}$$

with the methods described in Refs. 67 and 68 we find the following representation in $\mathbb{C}(4)$ for the generators $\mathcal{E}_\mu$ of $\mathbb{R}_{4,1} \simeq \mathbb{R}_{1,3}$:

$$\mathcal{E}_0 \mapsto \underline{\gamma}_0 = \begin{pmatrix} \mathbf{1}_2 & 0 \\ 0 & -\mathbf{1}_2 \end{pmatrix} \leftrightarrow \mathcal{E}_i \mapsto \underline{\gamma}_i = \begin{pmatrix} 0 & -\sigma_i \\ \sigma_i & 0 \end{pmatrix}, \tag{D13}$$

where $\mathbf{1}_2$ is the unit 2×2 matrix and σ_i $(i=1,2,3)$ are the standard Pauli matrices. We immediately recognize the $\underline{\gamma}$-matrices in Eq. (D13) as the standard ones appearing, e.g., in Ref. 13.

The matrix representation of $\Psi_{\Xi_0} \in I_{\Xi_0}$ will be denoted by the same letter without the index, i.e., $\Psi_{\Xi_0} \mapsto \boldsymbol{\Psi} \in \mathbb{C}(4)f$, where

$$f = \tfrac{1}{2}(1 + i\,\underline{\gamma}_1\underline{\gamma}_2) \quad i = \sqrt{-1}. \tag{D14}$$

We have

$$\boldsymbol{\Psi} = \begin{pmatrix} \psi_1 & 0 & 0 & 0 \\ \psi_2 & 0 & 0 & 0 \\ \psi_3 & 0 & 0 & 0 \\ \psi_4 & 0 & 0 & 0 \end{pmatrix}, \quad \psi_i \in \mathbb{C}. \tag{D15}$$

Equations (D13), (D14), and (D15) are sufficient to prove that there are bijections between the elements of the ideals $\mathbb{R}_{1,3}\frac{1}{2}(1+E_0)$, $\mathbb{R}_{4,1}\frac{1}{2}(1+\mathcal{E}_0)$, and $\mathbb{R}_{4,1}\frac{1}{2}(1+\mathcal{E}_0)\frac{1}{2}(1+\mathbf{i}\mathcal{E}_1\mathcal{E}_2)$.

We can easily find that the following relation exist between $\Psi_{\Xi_0} \in \mathbb{R}_{4,1}f_{\Xi_0}$ and $Z_{\Xi_0} \in \mathbb{R}_{4,1}\frac{1}{2}(1+\mathcal{E}_0)$, $\Xi_0 = (u_0, \Sigma_0)$ being a spinorial frame (see Sec. I)

$$\Psi_{\Xi_0} = Z_{\Xi_0}\tfrac{1}{2}(1+\mathbf{i}\mathcal{E}_1\mathcal{E}_2). \tag{D16}$$

Decomposing Z_{Ξ_0} into even and odd parts relative to the $\mathbf{Z}_2$-graduation of $\mathbb{R}^0_{4,1} \simeq \mathbb{R}_{1,3}$, $Z_{\Xi_0} = Z^0_{\Xi_0} + Z^1_{\Xi_0}$ we obtain $Z^0_{\Xi_0} = Z^1_{\Xi_0}\mathcal{E}_0$ which clearly shows that all information of Z_{Ξ_0} is contained in $Z^0_{\Xi_0}$. Then,

$$\Psi_{\Xi_0} = Z^0_{\Xi_0}\tfrac{1}{2}(1+\mathcal{E}_0)\tfrac{1}{2}(1+\mathbf{i}\mathcal{E}_1\mathcal{E}_2). \tag{D17}$$

Now, if we take into account[150] that $\mathbb{R}^{0}_{4,1}\frac{1}{2}(1+\mathcal{E}_0)=\mathbb{R}^{00}_{4,1}\frac{1}{2}(1+\mathcal{E}_0)$ where the symbol $\mathbb{R}^{00}_{4,1}$ means $\mathbb{R}^{00}_{4,1}\simeq\mathbb{R}^{0}_{1,3}\simeq\mathbb{R}_{3,0}$ we see that each $Z_{\Xi_0}\in\mathbb{R}_{4,1}\frac{1}{2}(1+\mathcal{E}_0)$ can be written

$$Z_{\Xi_0}=\psi_{\Xi_0}\tfrac{1}{2}(1+\mathcal{E}_0),\quad \psi_{\Xi_0}\in\mathbb{R}^{00}_{4,1}\simeq\mathbb{R}^{0}_{1,3}. \tag{D18}$$

Then setting $Z^{0}_{\Xi_0}=\psi_{\Xi_0}/2$, Eq. (D18) can be written

$$\Psi_{\Xi_0}=\psi_{\Xi_0}\tfrac{1}{2}(1+\mathcal{E}_0)\tfrac{1}{2}(1+\mathbf{i}\mathcal{E}_1\mathcal{E}_2)=Z^{0}_{\Xi_0}\tfrac{1}{2}(1+\mathbf{i}\mathcal{E}_1\mathcal{E}_2). \tag{D19}$$

The matrix representation of Z_{Ξ_0} and ψ_{Ξ_0} in $\mathbb{C}(4)$ (denoted by the same letter in boldface without index) in the spin basis given by Eq. (D12) are

$$\Psi=\begin{pmatrix}\psi_1 & -\psi_2^* & \psi_3 & \psi_4^*\\ \psi_2 & \psi_1^* & \psi_4 & -\psi_3^*\\ \psi_3 & \psi_4^* & \psi_1 & -\psi_2^*\\ \psi_4 & -\psi_3^* & \psi_2 & \psi_1^*\end{pmatrix},\quad \mathbf{Z}=\begin{pmatrix}\psi_1 & -\psi_2^* & 0 & 0\\ \psi_2 & \psi_1^* & 0 & 0\\ \psi_3 & \psi_4^* & 0 & 0\\ \psi_4 & -\psi_3^* & 0 & 0\end{pmatrix}. \tag{D20}$$

APPENDIX E: WHAT IS A COVARIANT DIRAC SPINOR (CDS)

As we already know $f_{\Xi_0}=\frac{1}{2}(1+\mathcal{E}_0)\frac{1}{2}(1+\mathbf{i}\mathcal{E}_1\mathcal{E}_2)$ [Eq. (D12)] is a primitive idempotent of $\mathbb{R}_{4,1}\simeq\mathbb{C}(4)$. If $u\in\mathrm{Spin}(1,3)\subset\mathrm{Spin}(4,1)$ then all ideals $I_{\Xi_u}=I_{\Xi_0}u^{-1}$ are geometrically equivalent to I_{Ξ_0}. Now, let $\mathbf{s}(\Xi_u)=\{\mathfrak{E}_0,\mathfrak{E}_1,\mathfrak{E}_2,\mathfrak{E}_3\}$ and $\mathbf{s}(\Xi_{u'})=\{\mathfrak{E}'_0,\mathfrak{E}'_1,\mathfrak{E}'_2,\mathfrak{E}'_3\}$ with $\mathbf{s}(\Xi_u)=u^{-1}\mathbf{s}(\Xi_0)u$, $\mathbf{s}(\Xi_{u'})=u'^{-1}\mathbf{s}(\Xi_0)u'$ be two arbitrary basis for $\mathbb{R}^{1,3}\subset\mathbb{R}_{4,1}$. From Eq. (D13) we can write

$$I_{\Xi_u}\ni\Psi_{\Xi_u}=\sum\ \psi_i f_i,\quad \text{and } I_{\Xi'_u}\ni\Psi_{\Xi_{u'}}=\sum\ \psi'_i f'_i, \tag{E1}$$

where

$$f_1=f_{\Xi_u},\quad f_2=-\mathfrak{E}_1\mathfrak{E}_3 f_{\Xi_u},\quad f_3=\mathfrak{E}_3\mathfrak{E}_0 f_{\Xi_u},\quad f_4=\mathfrak{E}_1\mathfrak{E}_0 f_{\Xi_u}$$

and

$$f'_1=f_{\Xi_{u'}},\quad f'_2=-\mathfrak{E}'_1\mathfrak{E}'_3 f_{\Xi_{u'}},\quad f'_3=\mathfrak{E}'_3\mathfrak{E}'_0 f_{\Xi_{u'}},\quad f_4=\mathfrak{E}'_1\mathfrak{E}'_0 f_{\Xi_{u'}}.$$

Since $\Psi_{\Xi_{u'}}=\Psi_{\Xi_u}(u'^{-1}u)^{-1}$, we get

$$\Psi_{\Xi_{u'}}=\sum_i\ \psi_i(u'^{-1}u)^{-1}f'_i=\sum_{i,k}\ S_{ik}[(u^{-1}u')]\psi_i f_k=\sum_k\ \psi'_k f_k.$$

Then

$$\psi'_k=\sum_i\ S_{ik}(u^{-1}u')\psi_i, \tag{E2}$$

where $S_{ik}(u^{-1}u')$ are the matrix components of the representation in $\mathbb{C}(4)$ of $(u^{-1}u')\in\mathrm{Spin}^{e}_{1,3}$. As proved in Refs. 67 and 68 the matrices $S(u)$ correspond to the representation $D^{(1/2,0)}\oplus D^{(0,1/2)}$ of $\mathrm{SL}(2,\mathbb{C})\simeq\mathrm{Spin}^{e}_{1,3}$.

We remark that all the elements of the set $\{I_{\Xi_u}\}$ of the ideals geometrically equivalent to I_{Ξ_0} under the action of $u \in \mathrm{Spin}^e_{1,3} \subset \mathrm{Spin}^e_{4,1}$ have the same image $I = \mathbb{C}(4)f$ where f is given by Eq. (D11), i.e.,

$$f = \tfrac{1}{2}(1+\underline{\gamma}_0)(1+i\underline{\gamma}_1\underline{\gamma}_2), \quad i = \sqrt{-1}, \tag{E3}$$

where $\underline{\gamma}_\mu$, $\mu = 0,1,2,3$ are the Dirac matrices given by Eq. (D14).

Then, if

$$\begin{gathered}\gamma: \mathbb{R}_{4,1} \to \mathbb{C}(4) \equiv \mathrm{End}(\mathbb{C}(4)f), \\ x \mapsto \gamma(x): \mathbb{C}(4)f \to \mathbb{C}(4)f\end{gathered} \tag{E4}$$

it follows that

$$\gamma(\mathfrak{E}_\mu) = \gamma(\mathfrak{E}'_\mu), \quad \gamma(f_\mu) = \gamma(f'_\mu) \tag{E5}$$

for all $\{\mathfrak{E}_\mu\}$, $\{\mathfrak{E}'_\mu\}$ such that $\mathfrak{E}'_\mu = (u'^{-1}u)\mathfrak{E}_\mu(u'^{-1}u)^{-1}$. Observe that *all information* concerning the geometrical images of the spinorial frames Ξ_u, $\Xi_{u'}, \ldots,$ under **s** disappear in the matrix representation of the ideals I_{Ξ_u}, $I_{\Xi_{u'}}, \ldots,$ in $\mathbb{C}(4)$ since all these ideals are mapped in the same ideal $I = \mathbb{C}(4)f$.

With the above remark and taking into account the definition of algebraic spinors given in Sec. II C and Eq. (E2) we are lead to the following.

Definition 62: A covariant Dirac spinor (CDS) for $\mathbb{R}^{1,3}$ *is an equivalence class of pairs* $(\Xi^m_u, \boldsymbol{\Psi})$, *where* Ξ^m_u *is a matrix spinorial frame associated to the spinorial frame* Ξ_u *through the* $S(u^{-1}) \in D^{(1/2,0)} \oplus D^{(0,1/2)}$ *representation of* $\mathrm{Spin}^e_{1,3}$, $u \in \mathrm{Spin}^e_{1,3}$. *We say that* $\Psi, \Psi' \in \mathbb{C}(4)f$ *are equivalent and write*

$$(\Xi^m_u, \Psi) \sim (\Xi^m_{u'}, \Psi') \tag{E6}$$

if and only if

$$\Psi' = S(u'^{-1}u)\Psi, \quad u\mathbf{s}\Xi_u u^{-1} = u'\mathbf{s}(\Xi_{u'})u'^{-1}. \tag{E7}$$

Remark 63: The definition of CDS just given agrees with that given in Ref. 40 except for the irrelevant fact that there, as well as in the majority of Physics textbook's, authors use as the space of representatives of a CDS a complex four-dimensional space $\mathbb{C}^4$ *instead of* $I = \mathbb{C}(4)f$.

(Received 25 November 2003; accepted 5 April 2004; published online 14 June 2004)

Our main objective in this paper is to clarify the *ontology* of Dirac–Hestenes spinor fields (DHSF) and its relationship with even multivector fields, on a Riemann–Cartan spacetime (RCST) $\mathfrak{M}=(M,g,\nabla,\tau_g,\uparrow)$ admitting a spin structure, and to give a mathematically rigorous derivation of the so-called Dirac–Hestenes equation (DHE) in the case where $\mathfrak{M}$ is a Lorentzian spacetime (the general case when $\mathfrak{M}$ is a RCST will be discussed in another publication). To this aim we introduce the Clifford bundle of multivector fields $(\mathcal{C}\ell(M,g))$ and the *left* $(C\ell^{l}_{\mathrm{Spin}^{e}_{1,3}}(M))$ and *right* $(\mathcal{C}\ell^{r}_{\mathrm{Spin}^{e}_{1,3}}(M))$ spin-Clifford bundles on the spin manifold (M,g). The relation between *left ideal algebraic spinor fields* (LIASF) and Dirac–Hestenes *spinor* fields (both fields are sections of $\mathcal{C}\ell^{l}_{\mathrm{Spin}^{e}_{1,3}}(M)$) is clarified. We study in detail the theory of covariant derivatives of Clifford fields as well as that of left and right spin-Clifford fields. A consistent Dirac equation for a DHSF $\Psi\in\sec\mathcal{C}\ell^{l}_{\mathrm{Spin}^{e}_{1,3}}(M)$ (denoted DE$\mathcal{C}\ell^{l}$) on a Lorentzian spacetime is found. We also obtain a *representation* of the DE$\mathcal{C}\ell^{l}$ in the Clifford bundle $\mathcal{C}\ell(M,g)$. It is such equation that we call the DHE and it is satisfied by Clifford fields $\psi_{\Xi}\in\sec\mathcal{C}\ell(M,g)$. This means that to each DHSF $\Psi\in\sec\mathcal{C}\ell^{l}_{\mathrm{Spin}^{e}_{1,3}}(M)$ and spin frame $\Xi\in\sec P_{\mathrm{Spin}^{e}_{1,3}}(M)$, there is a well-defined sum of even multivector fields $\psi_{\Xi}\in\sec\mathcal{C}\ell(M,g)$ (EMFS) associated with Ψ. Such an EMFS is called a *representative* of the DHSF on the given spin frame. And, of course, such a EMFS (the representative of the DHSF) is *not* a spinor field. With this crucial distinction between a DHSF and its *representatives* on the Clifford bundle, we provide a consistent theory for the covariant derivatives of Clifford and spinor fields of all kinds. We emphasize that the DE$\mathcal{C}\ell^{l}$ and the DHE, although related, are equations of different mathematical natures. We study also the local Lorentz invariance and the electromagnetic gauge invariance and show that only for the DHE such transformations are of the same mathematical nature, thus suggesting a possible link between them. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1757038]

I. INTRODUCTION

The main objective of this paper is to clarify the *ontology* of Dirac–Hestenes spinor fields (DHSF) (for the genesis of these objects we quote Ref. 19) on general Riemann–Cartan spacetimes (RCST) and to give a mathematically justified account of the Dirac–Hestenes equation

a)Electronic mail: mosna@ifi.unicamp.br
b)Electronic mail: walrod@mpc.com.br or walrod@ime.unicamp.br

(DHE) on Lorentzian spacetimes, subjects that have been a matter of many misunderstandings and controversies (as discussed in Ref. 34). Recall that the flat spacetime DHE represents the state of an electron by a map Ψ with values in the even part of the Clifford algebra $\mathbb{R}_{1,3}$. However, a covariant formulation of the DHE on a (possibly curved) Lorentzian spacetime cannot promote Ψ, in a canonical way, to a section of the Clifford bundle $\mathcal{C}\ell(M,g)$ (whose objects transform as tensors and therefore cannot describe spin-1/2 particles). In Ref. 34, DHSF on a Minkowski spacetime were defined as equivalence classes of Clifford fields. Here we follow a different approach, and define DHSF as even sections of an appropriate spinorial Clifford bundle. The objects satisfying the Dirac–Hestenes equation are then even multivector fields which are *representatives* of DHSF on the tensorial Clifford bundle. Moreover, such a representative is manifestly spin-frame dependent, so that no contradiction arises in representing spinors by Clifford fields.

To achieve our goals, we introduce in Sec. II the Clifford bundle of multivector fields $(\mathcal{C}\ell(M,g))$, and the *left* $(\mathcal{C}\ell^{l}_{\mathrm{Spin}^{e}_{1,3}}(M))$ and *right* $(\mathcal{C}\ell^{r}_{\mathrm{Spin}^{e}_{1,3}}(M))$ spin-Clifford bundles on the spin manifold (M,g), and study in detail how these bundles are related. [Of course, all the results of the present paper could also be obtained in the case where $\mathcal{C}\ell(M,g)$ is a Clifford bundle of nonhomogeneous differential forms.] Left algebraic spinor fields and Dirac–Hestenes spinor fields [both fields are sections of $\mathcal{C}\ell^{l}_{\mathrm{Spin}^{e}_{1,3}}(M)$] are defined and the relation between them is established. In Sec. IV, a consistent Dirac equation for a DHSF $\Psi \in \sec \mathcal{C}\ell^{l}_{\mathrm{Spin}^{e}_{1,3}}(M)$ (denoted DE$\mathcal{C}\ell^{l}$) on a Lorentzian manifold is found. In Sec. V, we obtain a *representation* of the DE$\mathcal{C}\ell^{l}$ in the Clifford bundle, an equation we call the Dirac–Hestenes equation (DHE), which is satisfied by Clifford fields $\psi_{\Xi} \in \sec \mathcal{C}\ell(M,g)$. This means that to each DHSF $\Psi \in \sec \mathcal{C}\ell^{l}_{\mathrm{Spin}^{e}_{1,3}}(M)$ and to each *spin frame* $\Xi \in \sec P_{\mathrm{Spin}^{e}_{1,3}}(M)$ there is a well-defined sum of even multivector fields $\psi_{\Xi} \in \sec \mathcal{C}\ell(M,g)$ (EMFS) associated with Ψ. Such an EMFS is called a *representative* of the DHSF on the given spin frame. And, of course, such an EMFS (the representative of the DHSF) is *not* a spinor field. With this crucial distinction between a DHSF and their EMFS representatives, we present in Sec. V an *effective* spinorial connection for the representatives of a DHSF on $\mathcal{C}\ell(M,g)$, thus providing a consistent theory for the covariant derivatives of Clifford and spinor fields of all kinds.

We emphasize that the DE$\mathcal{C}\ell^{l}$ and the DHE, although related, are of different mathematical natures. This issue has been particularly scrutinized in Secs. IV and V. We study also the local Lorentz invariance and the electromagnetic gauge invariance and show that only for the DHE such transformations are of the same mathematical nature, thus suggesting a possible link between them. In a sequel paper we are going to investigate this issue and also (a) the formulation of the DE$\mathcal{C}\ell$ and DHE in an arbitrary Riemann–Cartan spacetime through the use of a variational principle (we shall use in our approach to the subject the techniques of the multivector and extensor calculus developed in Refs. 12–14, 25–28); (b) the theory of the Lie derivative of the LIASF and DHSF; and (c) the claim in Ref. 17 that the existence of spinor fields in a Lorentzian manifold requires a minimum amount of curvature. This problem is important in view of the proposed teleparallel theories of the gravitational field.

Finally, in the Appendix we derive some formulas employed in the main text for the covariant derivative of Clifford and spinor fields, using the general theory of covariant derivatives on associated vector bundles. In general, our notation corresponds to that in Ref. 34.

A few acronyms are used in the present paper (to avoid long sentences) and they are summarized below for the reader's convenience:

DHE—Dirac–Hestenes Equation

DHSF—Dirac–Hestenes Spinor Field

DE$\mathcal{C}\ell^{l}$—Dirac equation for a DHSF $\Psi \in \sec \mathcal{C}\ell^{l}_{\mathrm{Spin}^{e}_{1,3}}(M)$

EMFS—Even Multivector Fields

LIASF—Left Ideal Algebraic Spinor Field

PFB—Principal Fiber Bundle

RIASF—Right Ideal Algebraic Spinor Field
RCST—Riemann–Cartan Spacetime

II. THE CLIFFORD BUNDLE OF SPACETIME AND THEIR IRREDUCIBLE MODULE REPRESENTATIONS

A. The Clifford bundle of spacetime

Let M be a four dimensional, real, connected, paracompact and noncompact manifold. Let TM $[T^*M]$ be the tangent [cotangent] bundle of M.

Definition 1: A Lorentzian manifold is a pair (M,g), *where* $g \in \sec T^{2,0}M$ *is a Lorentzian metric of signature* (1,3), *i.e., for all* $x \in M$, $T_xM \simeq T_x^*M \simeq \mathbb{R}^{1,3}$, *where* $\mathbb{R}^{1,3}$ *is the vector Minkowski space.*

Definition 2: A spacetime $\mathfrak{M}$ *is a pentuple* $(M,g,\nabla,\tau_g,\uparrow)$ *where* $(M,g,\tau_g,\uparrow)$ *is an oriented Lorentzian manifold (oriented by* τ_g*) and time oriented by an appropriated equivalence relation (denoted* $\uparrow$*) for the timelike vectors at the tangent space* T_xM, $\forall x \in M$. *(See Ref. 35 for details.)* ∇ *is a linear connection for* M *such that* $\nabla g = 0$.

Definition 3: Let $\mathbf{T}$ *and* $\mathbf{R}$ *be respectively, the torsion and curvature tensors of* ∇. *If in addition to the requirements of the previous definitions,* $\mathbf{T}(\nabla)=0$, *then* $\mathfrak{M}$ *is said to be a Lorentzian spacetime. The particular Lorentzian spacetime where* $M \simeq \mathbb{R}^4$ *and such that* $\mathbf{R}(\nabla)=0$ *is called Minkowski spacetime and will be denoted by* $\mathcal{M}$. *When* $\mathbf{T}(\nabla)$ is possibly nonzero, $\mathfrak{M}$ *is said to be a Riemann–Cartan spacetime (RCST). A particular RCST such that* $\mathbf{R}(\nabla)=0$ *is called a teleparallel spacetime.*

In what follows $P_{\mathrm{SO}^e_{1,3}}(M)$ denotes the principal bundle of oriented *Lorentz tetrads*. [We assume that the reader is acquainted with the structure of $P_{\mathrm{SO}^e_{1,3}}(M)$, whose sections are the time oriented and oriented orthonormal frames, each one associated by a local trivialization to a *unique* element of $SO^e_{1,3}(M)$. See, e.g., Refs. 16, 22, 29, 30.]

It is well known[32] that the natural operations on metric vector spaces, such as direct sum, tensor product, exterior power, etc., carry over canonically to vector bundles with metrics. We have the following definition.

Definition 4: The Clifford bundle of the Lorentzian manifold (M,g) *is the bundle of algebras,*

$$\mathcal{C}\ell(M,g) = \bigcup_{x \in M} \mathcal{C}\ell(T_xM,g_x), \tag{1}$$

where $\mathcal{C}\ell(T_xM,g_x)$ *is the Clifford algebra associated with* (T_xM,g_x) *(see, e.g. Ref. 34).*

As is well known,[4,5,10] $\mathcal{C}\ell(M,g)$ is a *quotient* (or *factor*) bundle, namely

$$\mathcal{C}\ell(M,g) = \frac{\tau M}{\mathcal{J}(M,g)}, \tag{2}$$

where $\tau M = \oplus_{r=0}^{\infty} T^{0,r}M$ and $T^{(0,r)}M$ is the space of r-contravariant tensor fields, and $\mathcal{J}(M,g)$ is the bundle of ideals whose fibers are the two-sided ideals in τM generated by the elements of the form $a\otimes b + b\otimes a - 2g(a,b)$, with $a,b \in TM$. In what follows, we denote the real Clifford algebra associated to $\mathbb{R}^{p,q}$ by $\mathbb{R}_{p,q}$. The even subalgebra of $\mathbb{R}_{p,q}$ will be denoted by $\mathbb{R}^0_{p,q}$ (see, e.g., Ref. 34).

Let $\pi_c : \mathcal{C}\ell(M,g) \to M$ be the canonical projection of $\mathcal{C}\ell(M,g)$ and let $\{U_\alpha\}$ be an open covering of M. There are trivialization mappings $\psi_i : \pi_c^{-1}(U_i) \to U_i \times \mathbb{R}_{1,3}$ of the form $\psi_i(p) = (\pi_c(p), \psi_{i,x}(p)) = (x, \psi_{i,x}(p))$. If $x \in U_i \cap U_j$ and $p \in \pi_c^{-1}(x)$, then

$$\psi_{i,x}(p) = h_{ij}(x)\psi_{j,x}(p), \tag{3}$$

for $h_{ij}(x) \in \mathrm{Aut}(\mathbb{R}_{1,3})$, where $h_{ij} : U_i \cap U_j \to \mathrm{Aut}(\mathbb{R}_{1,3})$ are the transition mappings of $\mathcal{C}\ell(M,g)$. We know that every automorphism of $\mathbb{R}_{1,3}$ is *inner* and it follows that

$$h_{ij}(x)\psi_{j,x}(p)=g_{ij}(x)\psi_{i,x}(p)g_{ij}(x)^{-1}, \tag{4}$$

for some $g_{ij}(x)\in\mathbb{R}^{\star}_{1,3}$, the group of invertible elements of $\mathbb{R}_{1,3}$.

Now, the group $\mathrm{SO}^{e}_{1,3}$ has as it is well known (see, e.g., Refs. 2, 3, 5, 21, 34) a natural extension in the Clifford algebra $\mathbb{R}_{1,3}$. Indeed we know that $\mathbb{R}^{\star}_{1,3}$ acts naturally on $\mathbb{R}_{1,3}$ as an algebra automorphism through its adjoint representation. A set of *lifts* of the transition functions of $\mathcal{C}\ell(M,g)$ is a set of $\mathbb{R}^{\star}_{1,3}$-valued functions $\{g_{ij}\}$ such that if

$$\begin{gathered}\mathrm{Ad}:g\mapsto \mathrm{Ad}_g,\\ \mathrm{Ad}_g(a)=gag^{-1},\forall a\in\mathbb{R}_{1,3},\end{gathered} \tag{5}$$

then $\mathrm{Ad}_{g_{ij}}=h_{ij}$ in all intersections.

Also $\sigma=\mathrm{Ad}|_{\mathrm{Spin}^{e}_{1,3}}$ defines a group homeomorphism $\sigma:\mathrm{Spin}^{e}_{1,3}\to\mathrm{SO}^{e}_{1,3}$ which is onto with kernel $\mathbb{Z}_2$. [Recall that $\mathrm{Spin}^{e}_{1,3}=\{a\in\mathbb{R}^{0}_{1,3}:a\tilde{a}=1\}\simeq\mathrm{SL}(2,\mathbb{C})$ is the universal covering group of the restricted Lorentz group $\mathrm{SO}^{e}_{1,3}$. See, e.g., Ref. 34.] We have that $\mathrm{Ad}_{-1}=$identity, and so $\mathrm{Ad}:\mathrm{Spin}^{e}_{1,3}\to\mathrm{Aut}(\mathbb{R}_{1,3})$ descends to a representation of $\mathrm{SO}^{e}_{1,3}$. Let us call Ad' this representation, i.e., $\mathrm{Ad}':\mathrm{SO}^{e}_{1,3}\to\mathrm{Aut}(\mathbb{R}_{1,3})$. Then we can write $\mathrm{Ad}'_{\sigma(g)}a=\mathrm{Ad}_g a=gag^{-1}$.

From this it is clear that the structure group of the Clifford bundle $\mathcal{C}\ell(M,g)$ is reducible from $\mathrm{Aut}(\mathbb{R}_{1,3})$ to $\mathrm{SO}^{e}_{1,3}$. This follows immediately from the Lorentzian structure of (M,g) and the fact that $\mathcal{C}\ell(M,g)$ is the exterior bundle where the fibers are equipped with the Clifford product. Thus the transition maps of the principal bundle of oriented Lorentz tetrads $P_{\mathrm{SO}^{e}_{1,3}}(M)$ can be (through Ad') taken as transition maps for the Clifford bundle. We then have[5]

$$\mathcal{C}\ell(M,g)=P_{\mathrm{SO}^{e}_{1,3}}(M)\times_{\mathrm{Ad}'}\mathbb{R}_{1,3}, \tag{6}$$

i.e., the Clifford bundle is an associated vector bundle to the principal bundle $P_{\mathrm{SO}^{e}_{1,3}}(M)$ of orthonormal Lorentz frames.

Definition 5: Sections of $\mathcal{C}\ell(M,g)$ are called Clifford fields. (We note that the term Clifford fields was used in Ref. 34 for mappings from Minkowski spacetime to the Clifford algebra $\mathbb{R}_{1,3}$.)

B. Spinor bundles

Definition 6: A spin structure on M consists of a principal fiber bundle $\pi_s:P_{\mathrm{Spin}^{e}_{1,3}}(M)\to M$ (called the Spin Frame Bundle) with group $\mathrm{Spin}^{e}_{1,3}$ and a map

$$s:P_{\mathrm{Spin}^{e}_{1,3}}(M)\to P_{\mathrm{SO}^{e}_{1,3}}(M), \tag{7}$$

satisfying the following conditions.

(i) $\pi(s(p))=\pi_s(p)\forall p\in P_{\mathrm{Spin}^{e}_{1,3}}(M)$; π is the projection map of the bundle $P_{\mathrm{SO}^{e}_{1,3}}(M)$.

(ii) $s(pu)=s(p)Ad_u$, $\forall p\in P_{\mathrm{Spin}^{e}_{1,3}}(M)$ and $Ad:\mathrm{Spin}^{e}_{1,3}\to\mathrm{Aut}(\mathbb{R}_{1,3})$, $Ad_u:\mathbb{R}_{1,3}\ni x\mapsto uxu^{-1}\in\mathbb{R}_{1,3}$.

Recall that minimal left (right) ideals of $\mathbb{R}_{p,q}$ are left (right) modules for $\mathbb{R}_{p,q}$.[34] In Ref. 34, covariant, algebraic and Dirac–Hestenes spinors [when $(p,q)=(1,3)$] were defined as certain equivalence classes in appropriate sets, and a *preliminary* definition for fields of these objects living on *Minkowski* spacetime was given. We are now interested in defining algebraic Dirac spinor fields and also Dirac–Hestenes spinor fields, on a general Riemann–Cartan spacetime (Definition 3), as sections of appropriate vector bundles (spinor bundles) associated to $P_{\mathrm{Spin}^{e}_{1,3}}(M)$. The compatibility between $P_{\mathrm{Spin}^{e}_{1,3}}(M)$ and $P_{\mathrm{SO}^{e}_{1,3}}(M)$, as captured in Definition 6, is essential for that matter.

It is therefore natural to ask the following: When does a spin strucute exist on an oriented manifold M? The answer, which is a classical result (Refs. 1, 4, 5, 10, 15, 22, 29–31, 33, 32) is that the necessary and sufficient conditions for the existence of a spin structure on M is that the second Stiefel–Whitney class $w_2(M)$ of M is trivial. Moreover, when a spin structure exists, one can show that it is unique (modulo isomorfisms) if and only if $H^1(M,\mathbb{Z}_2)$ is trivial.

Remark 7: For a spacetime $\mathfrak{M}$ (Definition 2), a spin structure exists if and only if $P_{\mathrm{SO}^e_{1,3}}(M)$ is a trivial *bundle. This was originally shown by Geroch.*[16]

Definition 8: We call global sections $\xi \in \sec P_{\mathrm{SO}^e_{1,3}}(M)$ Lorentz frames *and global sections $\Xi \in \sec P_{\mathrm{Spin}^e_{1,3}}(M)$* spin frames.

Remark 9: Recall that a principal bundle is trivial if and only if it admits a global section. Therefore, Geroch's result says that a (noncompact) spacetime admits a spin structure if and only if it admits a (globally defined) Lorentz frame. In fact, it is possible to replace $P_{\mathrm{SO}^e_{1,3}}(M)$ by $P_{\mathrm{Spin}^e_{1,3}}(M)$ in Remark 7 (see Ref. 16, Footnote 25). In this way, when a (noncompact) spacetime admits a spin structure, the bundle $P_{\mathrm{Spin}^e_{1,3}}(M)$ is trivial and, therefore, every bundle associated to it is also trivial.

Definition 10: An oriented manifold endowed with a spin structure will be called a spin manifold.

We now present the most usual definitions of spinor bundles appearing in the literature and next we find appropriate vector bundles such that particular sections are LIASF or DHSF. [We recall that there are some other (equivalent) definitions of spinor bundles that we are not going to introduce in this paper as, e.g., the one given in Ref. 6 in terms of mappings from $P_{\mathrm{Spin}^e_{1,3}}$ to some appropriate vector space.]

Definition 11: A real spinor bundle for M is a vector bundle,

$$S(M) = P_{\mathrm{Spin}^e_{1,3}}(M) \times_{\mu_l} \mathbf{M}, \tag{8}$$

where $\mathbf{M}$ is a left module for $\mathbb{R}_{1,3}$ and μ_l is a representation of $\mathrm{Spin}^e_{1,3}$ *on $End(\mathbf{M})$ given by left multiplication by elements of* $\mathrm{Spin}^e_{1,3}$.

Definition 12: The dual bundle $S^\star(M)$ is a real spinor bundle,

$$S^\star(M) = P_{\mathrm{Spin}^e_{1,3}}(M) \times_{\mu_r} \mathbf{M}^\star, \tag{9}$$

where $\mathbf{M}^\star$ is a right module for $\mathbb{R}_{1,3}$ and μ_r is a representation of $\mathrm{Spin}^e_{1,3}$ *in $End(\mathbf{M})$ given by right multiplication by (inverse) elements of* $\mathrm{Spin}^e_{1,3}$. *[More precisely, this means that given $u \in \mathrm{Spin}^e_{1,3}$, $a \in \mathbf{M}^*$, $\mu_r(u)a = au^{-1}$, so that $\mu_r(uu')a = a(uu')^{-1} = au'^{-1}u^{-1} = \mu_r(u)\mu_r(u')a$.]*

Definition 13: A complex spinor bundle for M is a vector bundle,

$$S_c(M) = P_{\mathrm{Spin}^e_{1,3}}(M) \times_{\mu_c} \mathbf{M}_c, \tag{10}$$

where $\mathbf{M}_c$ is a complex left module for $\mathbb{C}\otimes\mathbb{R}_{1,3} \simeq \mathbb{R}_{4,1} \simeq \mathbb{C}(4)$, and where μ_c is a representation of $\mathrm{Spin}^e_{1,3}$ *in* $\mathrm{End}(\mathbf{M}_c)$ *given by left multiplication by elements of* $\mathrm{Spin}^e_{1,3}$.

Definition 14: The dual complex spinor bundle for M is a vector bundle,

$$S_c^\star(M) = P_{\mathrm{Spin}^e_{1,3}}(M) \times_{\mu_c} \mathbf{M}_c^\star, \tag{11}$$

where $\mathbf{M}_c^\star$ is a complex right module for $\mathbb{C}\otimes\mathbb{R}_{1,3} \simeq \mathbb{R}_{4,1} \simeq \mathbb{C}(4)$, and where μ_c is a representation of $\mathrm{Spin}^e_{1,3}$ *in $End(\mathbf{M}_c)$ given by right multiplication by (inverse) elements of* $\mathrm{Spin}^e_{1,3}$. *[More precisely, this means that given $u \in \mathrm{Spin}^e_{1,3}$, $a \in \mathbf{M}^*$, $\mu_r(u)a = au^{-1}$.]*

Taking, e.g., $\mathbf{M}_c = \mathbb{C}^4$ and μ_c the $D^{(1/2,0)} \oplus D^{(0,1/2)}$ representation of $\mathrm{Spin}^e_{1,3} \cong \mathrm{SL}(2,\mathbb{C})$ in $\mathrm{End}(\mathbb{C}^4)$, we immediately recognize the usual definition of the covariant spinor bundle of M as given, e.g., in (Refs. 7, 8, 9, 15, 29, 30).

C. Left spin-Clifford bundle

As shown in Ref. 34, besides the ideal $I=\mathbb{R}_{1,3}\frac{1}{2}(1+E_0)$, other ideals exist in $\mathbb{R}_{1,3}$ that are only *algebraically* equivalent to this one. (This fact gives rise to a large class of multivector Dirac equations in flat spacetime, generalizing the Dirac–Hestenes equation.[23,24]) In order to capture all possibilities we recall that $\mathbb{R}_{1,3}$ can be considered as a module over itself by left (or right) multiplication. We are thus led to the following definition.

Definition 15: The left real spin-Clifford bundle of M is the vector bundle,

$$\mathcal{C}\ell^{l}_{\mathrm{Spin}^e_{1,3}}(M)=P_{\mathrm{Spin}^e_{1,3}}(M)\times_l\mathbb{R}_{1,3}, \tag{12}$$

where l is the representation of $\mathrm{Spin}^e_{1,3}$ *on* $\mathbb{R}_{1,3}$ *given by $l(a)x=ax$. Sections of $\mathcal{C}\ell^{l}_{\mathrm{Spin}^e_{1,3}}(M)$ are called left spin-Clifford fields.*

Remark 16: $\mathcal{C}\ell^{l}_{\mathrm{Spin}^e_{1,3}}(M)$ is a "principal $\mathbb{R}_{1,3}$-bundle," i.e., it admits a free action of $\mathbb{R}_{1,3}$ on the right,[5] which is denoted by R_g, $g\in\mathbb{R}_{1,3}$. This will be considered in Sec. V.

Remark 17: There is a natural *embedding $P_{\mathrm{Spin}^e_{1,3}}(M)\hookrightarrow\mathcal{C}\ell^{l}_{\mathrm{Spin}^e_{1,3}}(M)$ which comes from the embedding* $\mathrm{Spin}^e_{1,3}\hookrightarrow\mathbb{R}^0_{1,3}$. *(The symbol $A\hookrightarrow B$ means that A is embedded in B and $A\subseteq B$.) Hence (as we shall see in more details below), every real left spinor bundle (see Definition 15) for M can be captured from $\mathcal{C}\ell^{l}_{\mathrm{Spin}^e_{1,3}}(M)$, which is a vector bundle very different from $\mathcal{C}\ell(M,g)$. Their relation is presented below, but before that we give the following definition.*

Definition 18: Let $I(M)$ be a subbundle of $\mathcal{C}\ell^{l}_{\mathrm{Spin}^e_{1,3}}(M)$ such that there exists a primitive idempotent **e** *of* $\mathbb{R}_{1,3}$ *(see, e.g., Ref. 34) with*

$$R_{\mathbf{e}}\Psi=\Psi\mathbf{e}=\Psi, \tag{13}$$

for all $\Psi\in\sec I(M)\subset\sec\mathcal{C}\ell^{l}_{\mathrm{Spin}^e_{1,3}}(M)$. *Then, $I(M)$ is called a subbundle of left ideal algebraic spinor fields. Any $\Psi\in\sec I(M)\subset\sec\mathcal{C}\ell^{l}_{\mathrm{Spin}^e_{1,3}}(M)$ is called a left ideal algebraic spinor field (LIASF). $I(M)$ can be thought of as a real spinor bundle for M such that* **M** *in Eq. (8) is a minimal left ideal of* $\mathbb{R}_{1,3}$.

Definition 19: Two subbundles $I(M)$ and $I'(M)$ of LIASF are said to be geometrically equivalent if the idempotents e, $e'\in\mathbb{R}_{1,3}$ (appearing in the previous definition) are related by an element $u\in\mathrm{Spin}^e_{1,3}$, i.e., $e'=ueu^{-1}$.

Definition 20: The right *real spin-Clifford bundle of M is the vector bundle*

$$\mathcal{C}\ell^{r}_{\mathrm{Spin}^e_{1,3}}(M)=P_{\mathrm{Spin}^e_{1,3}}(M)\times_r\mathbb{R}_{1,3}. \tag{14}$$

Sections of $\mathcal{C}\ell^{r}_{\mathrm{Spin}^e_{1,3}}(M)$ are called right spin-Clifford fields.

In Eq. (14) r refers to the representation of $\mathrm{Spin}^e_{1,3}$ on $\mathbb{R}_{1,3}$ given by $r(a)x=xa^{-1}$. As in the case for the left real spin-Clifford bundle, there is a natural embedding $P_{\mathrm{Spin}^e_{1,3}}(M)\hookrightarrow\mathcal{C}\ell^{r}_{\mathrm{Spin}^e_{1,3}}(M)$ which comes from the embedding $\mathrm{Spin}^e_{1,3}\hookrightarrow\mathbb{R}^0_{1,3}$. There exists also a natural left action L_a of $a\in\mathbb{R}_{1,3}$ on $\mathcal{C}\ell^{r}_{\mathrm{Spin}^e_{1,3}}(M)$. This will be proved in Sec. V.

Definition 21: Let $I^{\star}(M)$ be a subbundle of $\mathcal{C}\ell^{r}_{\mathrm{Spin}^e_{1,3}}(M)$ such that there exists a primitive idempotent element **e** *of* $\mathbb{R}_{1,3}$ *with*

$$L_{\mathbf{e}}\Psi=e\Psi=\Psi, \tag{15}$$

for any $\Psi \in \sec I^{\star}(M) \subset \sec \mathcal{C}\ell^{r}_{\mathrm{Spin}^{e}_{1,3}}(M)$. *Then,* $I^{\star}(M)$ *is called a subundle of right ideal algebraic spinor fields. Any* $\Psi \in \sec I^{\star}(M) \subset \sec \mathcal{C}\ell^{r}_{\mathrm{Spin}^{e}_{1,3}}(M)$ *is called a right ideal algebraic spinor field (RIASF).* $I^{\star}(M)$ *can be thought of as a real spinor bundle for M such that* $\mathbf{M}^{\star}$ *in Eq. (9) is a minimal right ideal of* $\mathbb{R}_{1,3}$.

Definition 22: Two subbundles $I^{*}(M)$ *and* $I^{*\prime}(M)$ *of RIASF are said to be geometrically equivalent if the idempotents* e, $e' \in \mathbb{R}_{1,3}$ *(appearing in the previous definition) are related by an element* $u \in \mathrm{Spin}^{e}_{1,3}$, *i.e.,* $e' = ueu^{-1}$.

Proposition 23: In a spin manifold, we have

$$\mathcal{C}\ell(M,g) = P_{\mathrm{Spin}^{e}_{1,3}}(M) \times_{\mathrm{Ad}} \mathbb{R}_{1,3}.$$

Proof: Remember once again that the representation,

$$\mathrm{Ad}: \mathrm{Spin}^{e}_{1,3} \to \mathrm{Aut}(\mathbb{R}_{1,3}), \quad \mathrm{Ad}_{u} a = uau^{-1}, \quad u \in \mathrm{Spin}^{e}_{1,3},$$

is such that $\mathrm{Ad}_{-1} =$ identity and so Ad descends to a representation Ad′ of $\mathrm{SO}^{e}_{1,3}$ which we considered above. It follows that when $P_{\mathrm{Spin}^{e}_{1,3}}(M)$ exists $\mathcal{C}\ell(M,g) = P_{\mathrm{Spin}^{e}_{1,3}}(M) \times_{\mathrm{Ad}} \mathbb{R}_{1,3}$. ■

D. Bundle of modules over a bundle of algebras

Proposition 24: $S(M)$ [*or* $\mathcal{C}\ell^{l}_{\mathrm{Spin}^{e}_{1,3}}(M)$] *is a bundle of (left)* modules *over the bundle of algebras* $\mathcal{C}\ell(M,g)$. *In particular, the sections of the spinor bundle S(M) [or* $\mathcal{C}\ell^{l}_{\mathrm{Spin}^{e}_{1,3}}(M)$*] constitute a module over the sections of the Clifford bundle.*

For the proof, see Ref. 5, p. 97.

Corollary 25: Let Φ, $\Psi \in \sec C\ell^{l}_{\mathrm{Spin}^{e}_{1,3}}(M)$ *and* $\Psi \neq 0$. *Then there exists* $\psi \in \sec \mathcal{C}\ell(M,g)$ *such that*

$$\Psi = \psi\Phi. \tag{16}$$

Proof: It is an immediate consequence of Proposition 24. ■

So, the corollary allows us to identify a *correspondence* between some sections of $\mathcal{C}\ell(M,g)$ and some sections of $I(M)$ or $\mathcal{C}\ell^{l}_{\mathrm{Spin}^{e}_{1,3}}(M)$ once we fix a section on $\mathcal{C}\ell^{l}_{\mathrm{Spin}^{e}_{1,3}}(M)$. This and other correspondences will be essential for the theory of Sec. V. Once we clarified the meaning of a bundle of modules $S(M)$ over a bundle of algebras $\mathcal{C}\ell(M,g)$, we can give the following.

Definition 26: Two real left spinor bundles (see Definition 15) are equivalent if and only if they are equivalent as bundles of $\mathcal{C}\ell(M,g)$ *modules.*

Remark 27: Of course, geometrically equivalenty real left spinor bundles are equivalent.

Remark 28: In what follows we denote the complexified left spin Clifford bundle by $\mathbb{C}\ell^{l}_{\mathrm{Spin}^{e}_{1,3}}(M) = P_{\mathrm{Spin}^{e}_{1,3}}(M) \times_{l} \mathbb{C}\otimes\mathbb{R}_{1,3} \equiv P_{\mathrm{Spin}^{e}_{1,3}}(M) \times_{r} \mathbb{R}_{4,1}$ *and the complexified right spin Clifford bundle by* $\mathbb{C}\ell^{r}_{\mathrm{Spin}^{e}_{1,3}}(M) = P_{\mathrm{Spin}^{e}_{1,3}}(M) \times_{r} \mathbb{C}\otimes\mathbb{R}_{1,3} \equiv P_{\mathrm{Spin}^{e}_{1,3}}(M) \times_{r} \mathbb{R}_{4,1}$.

III. DIRAC–HESTENES SPINOR FIELDS

Let $\mathbf{E}^{\mu}$, $\mu = 0,1,2,3$ be the canonical basis of $\mathbb{R}^{1,3} \hookrightarrow \mathbb{R}_{1,3}$ which generates the algebra $\mathbb{R}_{1,3}$. They satisfy the basic relation $\mathbf{E}^{\mu}\mathbf{E}^{\nu} + \mathbf{E}^{\nu}\mathbf{E}^{\mu} = 2\eta^{\mu\nu}$. As shown, e.g., in Ref. 34,

$$\mathbf{e} = \frac{1}{2}(1 + \mathbf{E}^{0}) \in \mathbb{R}_{1,3}, \tag{17}$$

is a primitive idempotent of $\mathbb{R}_{1,3}$ and

$$\mathbf{f}=\frac{1}{2}(1+\mathbf{E}^0)\frac{1}{2}(1+i\mathbf{E}^2\mathbf{E}^1)\in\mathbb{C}\otimes\mathbb{R}_{1,3} \tag{18}$$

is a primitive idempotent of $\mathbb{C}\otimes\mathbb{R}_{1,3}$. Now, let $\mathbf{I}=\mathbb{R}_{1,3}\mathbf{e}$ and $\mathbf{I}_{\mathbb{C}}=\mathbb{C}\otimes\mathbb{R}_{1,3}\mathbf{f}$ be, respectively, the minimal left ideals of $\mathbb{R}_{1,3}$ and $\mathbb{C}\otimes\mathbb{R}_{1,3}$ generated by $\mathbf{e}$ and $\mathbf{f}$. Let $\phi=\phi\mathbf{e}\in\mathbf{I}$ and $\Psi=\Psi\mathbf{f}\in\mathbf{I}_{\mathbb{C}}$. Then, any $\phi\in\mathbf{I}$ can be written as

$$\phi=\psi\mathbf{e}, \tag{19}$$

with $\psi\in\mathbb{R}^0_{1,3}$. Analogously, any $\Psi\in\mathbf{I}_{\mathbb{C}}$ can be written as

$$\Psi=\psi\mathbf{e}\frac{1}{2}(1+i\mathbf{E}^2\mathbf{E}^1), \tag{20}$$

with $\psi\in\mathbb{R}^0_{1,3}$.

Now, $\mathbb{C}\otimes\mathbb{R}_{1,3}\simeq\mathbb{R}_{4,1}\simeq\mathbb{C}(4)$, where $\mathbb{C}(4)$ is the algebra of the 4×4 complex matrices. We can verify that

$$\begin{pmatrix}1&0&0&0\\0&0&0&0\\0&0&0&0\\0&0&0&0\end{pmatrix} \tag{21}$$

is a primitive idempotent of $\mathbb{C}(4)$ which is a matrix representation of $\mathbf{f}$. In this way we can prove (as shown, e.g., in Ref. 34) that there is a bijection between column spinors, i.e., elements of $\mathbb{C}^4$ (the complex 4-dimensional vector space) and the elements of $\mathbf{I}_{\mathbb{C}}$. All that, plus the definitions of the left real and complex spin bundles and the subbundle $I(M)$, suggests the following.

Definition 29: Let $\Phi\in\sec I(M)\subset\sec\mathcal{C}\ell^{l}_{\mathrm{Spin}^e_{1,3}}(M)$ *be as in Definition 18, i.e.,*

$$R_{\mathbf{e}}\Phi=\Phi\mathbf{e}=\Phi,\quad \mathbf{e}^2=\mathbf{e}=\frac{\mathbf{1}}{\mathbf{2}}(\mathbf{1}+\mathbf{E^0})\in\mathbb{R}_{1,3}. \tag{22}$$

A Dirac–Hestenes Spinor field (DHSF) associated with Φ *is an even section* ψ *of* $\mathcal{C}\ell^{l}_{\mathrm{Spin}^e_{1,3}}(M)$ *such that*

$$\Phi=\psi\mathbf{e}. \tag{23}$$

[Note that it is meaningful to speak about even (or odd) elements in $C\ell^{l}_{\mathrm{Spin}^e_{1,3}}(M)$ since $\mathrm{Spin}^e_{1,3}\subseteq\mathbb{R}^0_{1,3}$.]

Remark 30: An equivalent definition of a DHSF is the following. Let $\Psi\in\sec\mathbb{C}\ell^{l}_{\mathrm{Spin}^e_{1,3}}(M)$ *be such that*

$$R_{\mathbf{f}}\Psi=\Psi\mathbf{f}=\Psi,\quad \mathbf{f}^2=\mathbf{f}=\frac{\mathbf{1}}{\mathbf{2}}(\mathbf{1}+\mathbf{E^0})\frac{\mathbf{1}}{\mathbf{2}}(\mathbf{1}+\mathbf{iE^2E^1})\in\mathbb{C}\otimes\mathbb{R}_{1,3}. \tag{24}$$

Then, a DHSF associated to Ψ *is an even section* ψ *of* $\mathcal{C}\ell^{l}_{\mathrm{Spin}^e_{1,3}}(M)\subset\mathbb{C}\ell^{l}_{\mathrm{Spin}^e_{1,3}}(M)$ *such that*

$$\Psi=\psi\mathbf{f}. \tag{25}$$

Remark 31: In what follows, when we refer to a Dirac–Hestenes spinor field ψ *we omit for simplicity the wording associated with* Φ *(or* Ψ*). It is very important to observe that DHSF are not sums of even multivector (tensor) fields although, under a local trivialization,* ψ

$\in \sec C\ell^{l}_{\mathrm{Spin}^{e}_{1,3}}(M)$ *is mapped on an even element of* $\mathbb{R}_{1,3}$. *We emphasize that DHSF are particular sections of a spinor bundle, not of the Clifford bundle. However, we show in Sec. V how these objects have representatives in the Clifford bundle.*

IV. THE MANY FACES OF THE DIRAC EQUATION

A. Dirac equation for covariant Dirac fields

As is well known,[8] a *covariant* Dirac spinor field is a section $\Psi \in \sec S_c(M) = P_{\mathrm{Spin}^{e}_{1,3}}(M) \times_{\mu_l} \mathbb{C}^4$. Let $(U=M,\Phi), \Phi(\boldsymbol{\Psi}) = (x, |\Psi(x)\rangle)$ be a global trivialization corresponding to a spin frame Ξ (Definition 8), such that

$$s(\Xi) = \{e_a\} \in P_{\mathrm{SO}^{e}_{1,3}}(M), \quad e^a \in \sec C\ell(M,g),$$
$$e^a e^b + e^b e^a = 2\eta^{ab}, a,b = 0,1,2,3 \tag{26}$$

(see Definition 6). The usual Dirac equation in a Lorentzian spacetime for the spinor field Ψ—in interaction with an electromagnetic field $A \in \sec\Lambda^1(M) \subset \sec \mathcal{C}\ell(M,g)$—is then[11]

$$i\gamma^a(\boldsymbol{\nabla}^{s}_{e_a} + iqA_a)|\Psi(x)\rangle - m|\Psi(x)\rangle = 0, \tag{27}$$

where $\gamma^a \in \mathbb{C}(4)$, $a = 0,1,2,3$ is a set of *constant* Dirac *matrices* satisfying

$$\gamma^a\gamma^b + \gamma^b\gamma^a = 2\eta^{ab}. \tag{28}$$

[We denote the space of sections of p-vectors by $\sec\Lambda^p(M)$.]

B. Dirac equation in $\mathcal{C}\ell^{l}_{\mathrm{Spin}^{e}_{1,3}}(M,g)$

Due to the one-to-one correspondence between *ideal* sections of $\mathbb{C}\ell^{l}_{\mathrm{Spin}^{e}_{1,3}}(M)$, $\mathcal{C}\ell^{l}_{\mathrm{Spin}^{e}_{1,3}}(M)$ and of $S_c(M)$ as explained in Sec. III, we can *translate* the Dirac equation (27) for a covariant spinor field into an equation for a spinor field, which is a section of $\mathbb{C}\ell^{l}_{\mathrm{Spin}^{e}_{1,3}}(M)$, and finally write an equivalent equation for a DHSF $\psi \in \sec C\ell^{l}_{\mathrm{Spin}^{e}_{1,3}}(M)$. In order to do that we introduce the spin-Dirac operator.

Definition 32: The (spin) Dirac operator acting on sections of $C\ell^{l}_{\mathrm{Spin}^{e}_{1,3}}(M)$ *is the first order differential operator*,[5]

$$D^s = e^a\boldsymbol{\nabla}^{s}_{e_a}, \tag{29}$$

where $\{e^a\}$ *is as in Eq. (26) and* ∇^s *is the spinor covariant derivative (see the Appendix).*

Now we give the details of the inverse translation. We start with the following equation which we call Dirac equation in $\mathcal{C}\ell^{l}_{\mathrm{Spin}^{e}_{1,3}}(M)$, denoted DE$\mathcal{C}\ell^{l}$:

$$D^s\psi\mathbf{E}^{21} - m\psi\mathbf{E}^0 - qA\boldsymbol{\psi} = 0, \tag{30}$$

where $\psi \in \sec \mathcal{C}\ell^{l}_{\mathrm{Spin}^{e}_{1,3}}(M)$ is a DHSF and the $\mathbf{E}^a \in \mathbb{R}_{1,3}$ are such that $\mathbf{E}^a\mathbf{E}^b + \mathbf{E}^b\mathbf{E}^a = 2\eta^{ab}$. Multiplying Eq. (30) on the right by the idempotent $\mathbf{f} = \frac{1}{2}(1+\mathbf{E}^0)\frac{1}{2}(1+i\mathbf{E}^2\mathbf{E}^1) \in \mathbb{C}\otimes\mathbb{R}_{1,3}$ we get after some simple algebraic manipulations the following equation for the (complex) left ideal spin-Clifford field $\Psi = \psi\mathbf{f} \in \sec \mathbb{C}\ell^{l}_{\mathrm{Spin}^{e}_{1,3}}(M)$:

$$iD^s\Psi - m\Psi - qA\Psi = 0. \tag{31}$$

Now we can easily show, using the methods of Ref. 34, that given any global trivializations $(U=M,\Theta)$ and $(U=M,\Phi)$, of $\mathcal{C}\ell(M,g)$ and $\mathcal{C}\ell^{l}_{\mathrm{Spin}^{e}_{1,3}}(M)$, there exists matrix representations of the $\{e^a\}$ that are equal to the Dirac matrices $\boldsymbol{\gamma}^a$ [appearing in Eq. (27)]. In that way the correspondence between Eqs. (27), (30) and (31) is proved.

Remark 33: We emphasize at this point that we call Eq. (30) the DE$\mathcal{C}\ell^{l}$. *It looks similar to the Dirac–Hestenes equation (on Minkowski spacetime) discussed in Ref. 34, but it is indeed very different regarding its mathematical nature. It is an intrinsic equation satisfied by a legitimate spinor field, namely a DHSF* $\psi\in\sec\mathcal{C}\ell^{l}_{\mathrm{Spin}^{e}_{1,3}}(M)$. *The question naturally arises: May we write an equation with the same mathematical information of Eq. (30) but satisfied by objects living on the Clifford bundle* $\mathcal{C}\ell(M,g)$ *of an arbitrary Lorentzian spacetime, admitting a spin structure? In the next section we show that the answer to that question is yes.*

C. Electromagnetic gauge invariance of the DE$\mathcal{C}\ell^{l}$

Proposition 34: The DE$\mathcal{C}\ell^{l}$ *is invariant under electromagnetic gauge transformations,*

$$\psi\mapsto\psi'=\psi e^{q\mathbf{E}^{21}\chi}, \tag{32}$$

$$A\mapsto A+\partial\chi, \tag{33}$$

$$\omega_{e_a}\mapsto\omega_{e_a}, \tag{34}$$

$$\psi,\psi'\in\sec\mathcal{C}\ell^{l}_{\mathrm{Spin}^{e}_{1,3}}(M), \tag{35}$$

$$A\in\sec\Lambda^{1}(M)\subset\sec\mathcal{C}\ell(M,g), \tag{36}$$

with ψ,ψ' *distinct DHSF, and where* $\chi:M\to\mathbb{R}\subset\mathbb{R}_{1,3}$ *is a gauge function.*

Proof: The proof is obtained by direct verification. ■

Remark 35: We note that, for the DE$\mathcal{C}\ell^{l}$, *local rotations and electromagnetic gauge transformations are very different mathematical transformations, without any obvious geometrical link between them, differently of what seems to be the case for the Dirac–Hestenes equation, which is studied in the next section.*

V. THE DIRAC–HESTENES EQUATION (DHE)

We obtained above a Dirac equation, which we called DE$C\ell^{l}$, describing the motion of spinor fields represented by sections Ψ of $C\ell^{l}_{\mathrm{Spin}^{e}_{1,3}}(M,g)$ in interaction with an electromagnetic field $A\in\sec C\ell(M,g)$,

$$D^{s}\Psi\mathbf{E}^{21}-qA\Psi=m\Psi\mathbf{E}^{0}, \tag{37}$$

where $D^{s}=e^{a}\boldsymbol{\nabla}^{s}_{e_a}$, $\{e^a\}$ is given by Eq. (26), $\boldsymbol{\nabla}^{s}_{e_a}$ is the natural spinor covariant derivative acting on $\sec C\ell^{l}_{\mathrm{Spin}^{e}_{1,3}}(M,g)$ (see the Appendix), and $\{\mathbf{E}^a\}\in\mathbb{R}^{1,3}\subseteq\mathbb{R}_{1,3}$ is such that $\mathbf{E}^a\mathbf{E}^b+\mathbf{E}^b\mathbf{E}^a=2\eta^{ab}$. As we already mentioned, although Eq. (37) is written in a kind of Clifford bundle [i.e. $C\ell^{l}_{\mathrm{Spin}^{e}_{1,3}}(M,g)$], it does not suffer from the inconsistency of representing spinors as pure differential forms and, in fact, the object Ψ behaves as it should under Lorentz transformations.

As a matter of fact, Eq. (37) can be thought of as a mere *rewriting* of the usual Dirac equation, where the role of the constant gamma matrices is undertaken by the constant elements $\{\mathbf{E}^a\}$ in $\mathbb{R}_{1,3}$ and by the set $\{e^a\}$. In this way, Eq. (37) is *not* a kind of Dirac–Hestenes equation as discussed, e.g., in Ref. 34. It suffices to say that (i) the state of the electron, represented by Ψ, is not a *Clifford field* and (ii) the $\mathbf{E}^a$'s are just *constant* elements of $\mathbb{R}_{1,3}$ and not sections of vectors in $\mathcal{C}\ell(M,g)$. Nevertheless, as we show in the following, Eq. (37) does lead to a multivector Dirac

equation once we carefully employ the theory of right and left actions on the various Clifford bundles introduced earlier. It is the multivector equation to be derived below that we call the DHE (of course, we can write an equivalent multiform equation). We shall need several preliminary results that we collect in the next two subsections.

A. The various natural actions on the vector bundles associated to $P_{\mathrm{Spin}^e_{1,3}}(M)$

Recall that, when M is a spin manifold the following occurs.

(i) The elements of $\mathcal{C}\ell(M,g)=P_{\mathrm{Spin}^e_{1,3}}(M)\times_{\mathrm{Ad}}\mathbb{R}_{1,3}$ are equivalence classes $[(p,a)]$ of pairs (p,a), where $p\in P_{\mathrm{Spin}^e_{1,3}}(M)$, $a\in\mathbb{R}_{1,3}$ and $(p,a)\sim(p',a')\Leftrightarrow p'=pu^{-1}$, $a'=uau^{-1}$, for some $u\in\mathrm{Spin}^e_{1,3}$.

(ii) The elements of $\mathcal{C}\ell^l_{\mathrm{Spin}^e_{1,3}}(M)$ are equivalence classes of pairs (p,a), where $p\in P_{\mathrm{Spin}^e_{1,3}}(M)$, $a\in\mathbb{R}_{1,3}$ and $(p,a)\sim(p',a')\Leftrightarrow p'=pu^{-1}$, $a'=ua$, for some $u\in\mathrm{Spin}^e_{1,3}$.

(iii) The elements of $\mathcal{C}\ell^r_{\mathrm{Spin}^e_{1,3}}(M)$ are equivalence classes of pairs (p,a), where $p\in P_{\mathrm{Spin}^e_{1,3}}(M)$, $a\in\mathbb{R}_{1,3}$ and $(p,a)\sim(p',a')\Leftrightarrow p'=pu^{-1}$, $a'=au^{-1}$, for some $u\in\mathrm{Spin}^e_{1,3}$.

In this way, it is possible to define the following natural actions on these associated bundles.

Proposition 36: There is a natural right action of $\mathbb{R}_{1,3}$ *on* $\mathcal{C}\ell^l_{\mathrm{Spin}^e_{1,3}}(M)$ *and a natural left action of* $\mathbb{R}_{1,3}$ *on* $\mathcal{C}\ell^r_{\mathrm{Spin}^e_{1,3}}(M,g)$.

Proof: Given $b\in\mathbb{R}_{1,3}$ and $\alpha\in\mathcal{C}\ell^l_{\mathrm{Spin}^e_{1,3}}(M,g)$, select a representative (p,a) for α and define $\alpha b:=[(p,ab)]$. If another representative (pu^{-1},ua) is chosen for α, we have $(pu^{-1},uab)\sim(p,ab)$ and thus αb is a well-defined element of $\mathcal{C}\ell^l_{\mathrm{Spin}^e_{1,3}}(M)$. ■

Let us denote the space of $\mathbb{R}_{1,3}$-valued smooth functions on M by $\mathcal{F}(M,\mathbb{R}_{1,3})$. Then, the above proposition immediately yields the following.

Corollary 37: There is a natural right action of $\mathcal{F}(M,\mathbb{R}_{1,3})$ *on* $\sec\mathcal{C}\ell^l_{\mathrm{Spin}^e_{1,3}}(M)$ *and a natural left action of* $\mathcal{F}(M,\mathbb{R}_{1,3})$ *on* $\sec\mathcal{C}\ell^r_{\mathrm{Spin}^e_{1,3}}(M,g)$.

Proposition 38: There is a natural left action of $\sec\mathcal{C}\ell(M,g)$ *on* $\sec\mathcal{C}\ell^l_{\mathrm{Spin}^e_{1,3}}(M)$ *and a natural right action of* $\sec\mathcal{C}\ell(M,g)$ *on* $\sec\mathcal{C}\ell^r_{\mathrm{Spin}^e_{1,3}}(M)$.

Proof: Given $\alpha\in\sec\mathcal{C}\ell(M,g)$ and $\beta\in\sec\mathcal{C}\ell^l_{\mathrm{Spin}^e_{1,3}}(M,g)$, select representatives (p,a) for $\alpha(x)$ and (p,b) for $\beta(x)$ [with $p\in\pi^{-1}(x)$] and define $(\alpha\beta)(x):=[(p,ab)]\in\mathcal{C}\ell^l_{\mathrm{Spin}^e_{1,3}}(M,g)$. If alternative representatives (pu^{-1},uau^{-1}) and (pu^{-1},ub) are chosen for $\alpha(x)$ and $\beta(x)$, we have

$$(pu^{-1},uau^{-1}ub)=(pu^{-1},uab)\sim(p,ab),$$

and thus $(\alpha\beta)(x)$ is a well-defined element of $\mathcal{C}\ell^l_{\mathrm{Spin}^e_{1,3}}(M,g)$. ■

Proposition 39: There is a natural pairing,

$$\sec\mathcal{C}\ell^l_{\mathrm{Spin}^e_{1,3}}(M)\times\sec\mathcal{C}\ell^r_{\mathrm{Spin}^e_{1,3}}(M)\to\sec\mathcal{C}\ell(M,g).$$

Proof: Given $\alpha\in\sec\mathcal{C}\ell^l_{\mathrm{Spin}^e_{1,3}}(M)$ and $\beta\in\sec\mathcal{C}\ell^r_{\mathrm{Spin}^e_{1,3}}(M)$, select representatives (p,a) for $\alpha(x)$ and (p,b) for $\beta(x)$ [with $p\in\pi^{-1}(x)$] and define $(\alpha\beta)(x):=[(p,ab)]\in\mathcal{C}\ell(M,g)$. If alternative representatives (pu^{-1},ua) and (pu^{-1},bu^{-1}) are chosen for $\alpha(x)$ and $\beta(x)$, we have $(pu^{-1},uabu^{-1})\sim(p,ab)$ and thus $(\alpha\beta)(x)$ is a well-defined element of $C\ell(M,g)$. ■

Proposition 40: There is a natural pairing,

$$\sec \mathcal{C}\ell^{r}_{\mathrm{Spin}^{e}_{1,3}}(M)\times \sec \mathcal{C}\ell^{l}_{\mathrm{Spin}^{e}_{1,3}}(M)\to \mathcal{F}(M,\mathbb{R}_{1,3}).$$

Proof: Given $\alpha\in \sec \mathcal{C}\ell^{r}_{\mathrm{Spin}^{e}_{1,3}}(M)$ and $\beta\in \sec \mathcal{C}\ell^{l}_{\mathrm{Spin}^{e}_{1,3}}(M)$, select representatives (p,a) for $\alpha(x)$ and (p,b) for $\beta(x)$ [with $p\in\pi^{-1}(x)$] and define $(\alpha\beta)(x):=ab\in\mathbb{R}_{1,3}$. If alternative representatives (pu^{-1},au^{-1}) and (pu^{-1},ub) are chosen for $\alpha(x)$ and $\beta(x)$, we have $au^{-1}ub=ab$ and thus $(\alpha\beta)(x)$ is a well-defined element of $\mathbb{R}_{1,3}$. ■

B. Fiducial sections associated with a spin frame

We start by exploring the possibility of defining ''unit sections'' on the various vector bundles associated with the principal bundle $P_{\mathrm{Spin}^{e}_{1,3}}(M)$. It immediately follows from the definition given by Eq. (1) that the unit section $\mathbf{1}\in\sec\mathcal{C}\ell(M,g)$, given by $x\mapsto 1\in\mathcal{C}\ell(T_xM,g_x)$, is certainly well defined. For future reference, let us consider how this can also be seen from the associated bundle structure of $P_{\mathrm{Spin}^{e}_{1,3}}(M)\times_{ad}\mathbb{R}_{1,3}$.

Let

$$\Phi_i:\pi^{-1}(U_i)\to U_i\times \mathrm{Spin}^{e}_{1,3},\quad \Phi_j:\pi^{-1}(U_j)\to U_j\times \mathrm{Spin}^{e}_{1,3}$$

be two local trivializations for $P_{\mathrm{Spin}^{e}_{1,3}}(M)$, with

$$\Phi_i(u)=(\pi(u)=x,\phi_{i,x}(u)),\quad \Phi_j(u)=(\pi(u)=x,\phi_{j,x}(u)).$$

Recall that the transition function on $g_{ij}:U_i\cap U_j\to\mathrm{Spin}^{e}_{1,3}$ is then given by

$$g_{ij}(x)=\phi_{i,x}(u)\circ\phi_{j,x}(u)^{-1},$$

which does not depend on u.

Proposition 41: $\mathcal{C}\ell(M,g)$ has a naturally defined global unit section.

Proof: For the associated bundle $\mathcal{C}\ell(M,g)=P_{\mathrm{Spin}^{e}_{1,3}}(M)\times_{\mathrm{Ad}}\mathbb{R}_{1,3}$, the transition functions corresponding to local trivializations,

$$\Psi_i:\pi_c^{-1}(U_i)\to U_i\times\mathbb{R}_{1,3},\quad \Psi_j:\pi_c^{-1}(U_j)\to U_j\times\mathbb{R}_{1,3},\tag{38}$$

are given by $h_{ij}(x)=Ad_{g_{ij}(x)}$. Define the local sections

$$\mathbf{1}_i(x)=\Psi_i^{-1}(x,1),\quad \mathbf{1}_j(x)=\Psi_j^{-1}(x,1),\tag{39}$$

where 1 is the unit element of $\mathbb{R}_{1,3}$. Since $h_{ij}(x)\cdot 1=\mathrm{Ad}_{g_{ij}(x)}(1)=g_{ij}(x)1g_{ij}(x)^{-1}=1$, we see that the expressions above uniquely define a global section $\mathbf{1}\in\mathcal{C}\ell(M,g)$ with $\mathbf{1}|_{U_i}=\mathbf{1}_i$. ■

It is clear that such a result can be immediately generalized for the Clifford bundle $\mathcal{C}\ell_{p,q}(M,g)$, of any n-dimensional manifold endowed with a metric of arbitrary signature (p,q) (where $n=p+q$). Now, we observe also that the left (and also the right) spin-Clifford bundle can be generalized in an obvious way for any spin manifold of arbitrary finite dimension $n=p+q$, with a metric of arbitrary signature (p,q). However, another important difference between $\mathcal{C}\ell(M,g)$ and $\mathcal{C}\ell^{l}_{\mathrm{Spin}^{e}_{p,q}}(M)$ or $\mathcal{C}\ell^{r}_{\mathrm{Spin}^{e}_{1,3}}(M,g)$ is that these latter bundles only admit a global unit section if they are *trivial*.

Proposition 42: There exists an unit section on $\mathcal{C}\ell^{r}_{\mathrm{Spin}^{e}_{p,q}}(M)$ [and also on $\mathcal{C}\ell^{l}_{\mathrm{Spin}^{e}_{p,q}}(M)$] if and only if $P_{\mathrm{Spin}^{e}_{p,q}}(M)$ is trivial.

Proof: We show the necessity for the case of $\mathcal{C}\ell^{r}_{\mathrm{Spin}^{e}_{p,q}}(M)$, the sufficiency is trivial. [The proof for the case of $\mathcal{C}\ell^{l}_{\mathrm{Spin}^{e}_{p,q}}(M)$ is analogous.] For $\mathcal{C}\ell^{r}_{\mathrm{Spin}^{e}_{p,q}}(M)$, the transition functions corresponding to local trivializations,

$$\Omega_i:\pi_{sc}^{-1}(U_i)\to U_i\times\mathbb{R}_{p,q},\quad \Omega_j:\pi_{sc}^{-1}(U_j)\to U_j\times\mathbb{R}_{p,q},\tag{40}$$

are given by $k_{ij}(x)=R_{g_{ij}(x)}$, with $R_a:\mathbb{R}_{p,q}\to\mathbb{R}_{p,q}, x\mapsto xa^{-1}$. Let 1 be the unit element of $\mathbb{R}_{1,3}$. A unit section in $\mathcal{C}\ell^{r}_{\mathrm{Spin}^e_{p,q}}(M)$—if it exists—is written in terms of these two local trivializations as

$$\mathbf{1}^r_i(x)=\Omega_i^{-1}(x,1),\quad \mathbf{1}^r_j(x)=\Omega_j^{-1}(x,1),\tag{41}$$

and we must have $\mathbf{1}^r_i(x)=\mathbf{1}^r_j(x)$, $\forall x\in U_i\cap U_j$. As $\Omega_i(\mathbf{1}^r_i(x))=(x,1)=\Omega_j(\mathbf{1}^r_j(x))$, we have $\mathbf{1}^r_i(x)=\mathbf{1}^r_j(x)\Leftrightarrow 1=k_{ij}(x)\cdot 1\Leftrightarrow 1=1g_{ij}(x)^{-1}\Leftrightarrow g_{ij}(x)=1$. This proves the proposition. ■

Remark 43: For general spin manifolds, the bundle $P_{\mathrm{Spin}^e_{p,q}}(M)$ is not necessarily trivial for arbitrary (p,q), but Geroch's theorem (Remark 9) warrants that, for the special case $(p,q)=(1,3)$ with M noncompact, $P_{\mathrm{Spin}^e_{1,3}}(M)$ is trivial. By the above proposition, we then see that $\mathcal{C}\ell^{r}_{\mathrm{Spin}^e_{1,3}}(M)$ and also $\mathcal{C}\ell^{l}_{\mathrm{Spin}^e_{1,3}}(M)$ have global "unit sections." It is most important to note, however, that each different choice of a (global) trivialization Ω_i on $\mathcal{C}\ell^{r}_{\mathrm{Spin}^e_{1,3}}(M)$ [respectively, $\mathcal{C}\ell^{l}_{\mathrm{Spin}^e_{p,q}}(M)$] induces a different global unit section $\mathbf{1}^r_i$ (respectively, $\mathbf{1}^l_i$). Therefore, even in this case there is no canonical unit section on $\mathcal{C}\ell^{r}_{\mathrm{Spin}^e_{1,3}}(M,g)$ [respectively, on $\mathcal{C}\ell^{l}_{\mathrm{Spin}^e_{1,3}}(M,g)$].

By Remark 9, when the (noncompact) spacetime M is a spin manifold, the bundle $P_{\mathrm{Spin}^e_{1,3}}(M)$ admits global sections. With this in mind, let us fix a spin frame Ξ for M. This induces a global trivialization for $P_{\mathrm{Spin}^e_{1,3}}(M)$, which we denote by $\Phi_\Xi:P_{\mathrm{Spin}^e_{1,3}}(M)\to M\times\mathrm{Spin}^e_{1,3}$, with $\Phi_\Xi^{-1}(x,1)=\Xi(x)$. As we show in the following, the spin frame Ξ can also be used to induce certain fiducial global sections on the various vector bundles associated with $P_{\mathrm{Spin}^e_{1,3}}(M)$.

(i) $\mathcal{C}\ell(M,g)$ Let $\{\mathbf{E}^a\}$ be a fixed orthonormal basis of $\mathbb{R}^{1,3}\subseteq\mathbb{R}_{1,3}$ (which can be thought of as the *canonical* basis of $\mathbb{R}^{1,3}$). We define basis sections in $\mathcal{C}\ell(M,g)=P_{\mathrm{Spin}^e_{1,3}}(M)\times_{\mathrm{Ad}}\mathbb{R}_{1,3}$ by $e_a(x)=[(\Xi(x),\mathbf{E}_a)]$. Of course, this induces a multivector basis $\{e_I(x)\}$ for each $x\in M$. Note that a more precise notation for e_a would be, for instance, $e_a^{(\Xi)}$.

(ii) $\mathcal{C}\ell^{l}_{\mathrm{Spin}^e_{1,3}}(M)$ Let $\mathbf{1}^l_\Xi\in\sec\mathcal{C}\ell^{l}_{\mathrm{Spin}^e_{1,3}}(M)$ be defined by $\mathbf{1}^l_\Xi(x)=[(\Xi(x),1)]$. Then the natural right action of $\mathbb{R}_{1,3}$ on $\mathcal{C}\ell^{l}_{\mathrm{Spin}^e_{1,3}}(M)$ leads to $\mathbf{1}^l_\Xi(x)a=[(\Xi(x),a)]$ for all $a\in\mathbb{R}_{1,3}$. It follows from Corollary 37 that an arbitrary section $\alpha\in\sec\mathcal{C}\ell^{l}_{\mathrm{Spin}^e_{1,3}}(M)$ can be written as $\alpha=\mathbf{1}^l_\Xi f$, with $f\in\mathcal{F}(M,\mathbb{R}_{1,3})$.

(iii) $\mathcal{C}\ell^{r}_{\mathrm{Spin}^e_{1,3}}(M,g)$ Let $\mathbf{1}^r_\Xi\in\sec\mathcal{C}\ell^{r}_{\mathrm{Spin}^e_{1,3}}(M,g)$ be defined by $\mathbf{1}^r_\Xi(x)=[(\Xi(x),1)]$. Then the natural left action of $\mathbb{R}_{1,3}$ on $\mathcal{C}\ell^{r}_{\mathrm{Spin}^e_{1,3}}(M)$ leads to $a\mathbf{1}^r_\Xi(x)=[(\Xi(x),a)]$ for all $a\in\mathbb{R}_{1,3}$. It follows from Corollary 37 that an arbitrary section $\alpha\in\sec\mathcal{C}\ell^{r}_{\mathrm{Spin}^e_{1,3}}(M)$ can be written as $\alpha=f\mathbf{1}^r_\Xi$, with $f\in\mathcal{F}(M,\mathbb{R}_{1,3})$.

Now recall (Definition 6) that a spin structure on M is a 2-1 bundle map $s:P_{\mathrm{Spin}^e_{1,3}}(M)\to P_{\mathrm{SO}^e_{1,3}}(M)$ such that $s(pu)=s(p)\mathrm{Ad}_u$, $\forall p\in P_{\mathrm{Spin}^e_{1,3}}(M)$, $u\in\mathrm{Spin}^e_{1,3}$, where $\mathrm{Ad}:\mathrm{Spin}^e_{1,3}\to\mathrm{SO}^e_{1,3}$, $\mathrm{Ad}_u:x\mapsto uxu^{-1}$. We see that the specification of the global section in the case (i) above is compatible with the Lorentz frame $\{e_a\}=s(\Xi)$ assigned by s. More precisely, for each $x\in M$, the element $s(\Xi(x))\in P_{\mathrm{SO}^e_{1,3}}(M)$ is to be regarded as a proper isometry $s(\Xi(x)):\mathbb{R}^{1,3}\to T_xM$, so that $e_a(x):=s(p)\cdot\mathbf{E}_a$ yields a Lorentz frame $\{e_a\}$ on M, which we denoted by $s(\Xi)$. On the other hand, $\mathcal{C}\ell(M,g)$ is isomorphic to $P_{\mathrm{Spin}^e_{1,3}}(M)\times_{\mathrm{Ad}}\mathbb{R}_{1,3}$, and we can always arrange things so that $e_a(x)$ is represented in this bundle as $e_a(x)=[(\Xi(x),\mathbf{E}_a)]$. In fact, all we have to do is to verify that this identification is covariant under a change of frames. To see that, let $\Xi'\in\sec(P_{\mathrm{Spin}^e_{1,3}}(M))$ be another spin frame on M. From the principal bundle structure of $P_{\mathrm{Spin}^e_{1,3}}(M)$, we know that, for each $x\in M$, there exists (a unique) $u(x)\in\mathrm{Spin}^e_{1,3}$ such that

$\Xi'(x)=\Xi(x)u(x)$. If we define, as above, $e'_a(x)=s(\Xi'(x))\cdot\mathbf{E}_a$, then $e'_a(x)=s(\Xi(x)u(x))\cdot\mathbf{E}_a$ $=s(\Xi(x))\mathrm{Ad}_{u(x)}\cdot\mathbf{E}_a=[(\Xi(x),\mathrm{Ad}_{u(x)}\cdot\mathbf{E}_a)]=[(\Xi(x)u(x),\mathbf{E}_a)]=[(\Xi'(x),\mathbf{E}_a)]$, which proves our claim.

Proposition 44:

$$(i)\ \mathbf{E}_a=\mathbf{1}^r_\Xi(x)e_a(x)\mathbf{1}^l_\Xi(x),\ \forall x\in M,$$

$$(ii)\ \mathbf{1}^l_\Xi\mathbf{1}^r_\Xi=1\in\mathcal{C}\ell(M,g),$$

$$(iii)\ \mathbf{1}^r_\Xi\mathbf{1}^l_\Xi=1\in\mathbb{R}_{1,3}.$$

Proof: This follows from the form of the various actions defined in Propositions 36–40. For example, for each $x\in M$, we have $\mathbf{1}^r_\Xi(x)e_a(x)=[(\Xi(x),1\mathbf{E}_a)]=[(\Xi(x),\mathbf{E}_a)]\in\sec\mathcal{C}\ell^r_{\mathrm{Spin}^e_{1,3}}(M)$ (from Proposition 38). Then, it follows from Proposition 40 that $\mathbf{1}^r_\Xi(x)e_a(x)\mathbf{1}^l_\Xi(x)=\mathbf{E}_a1=\mathbf{E}_a$, $\forall x\in M$. ■

Let us now consider how the various global sections defined above transform when the spin frame Ξ is changed. Let $\Xi'\in\sec P_{\mathrm{Spin}^e_{1,3}}(M)$ be another spin frame with $\Xi'(x)=\Xi(x)u(x)$, where $u(x)\in\mathrm{Spin}^e_{1,3}$. Let e_a, $\mathbf{1}^r_\Xi$, $\mathbf{1}^l_\Xi$ and e'_a, $\mathbf{1}^r_{\Xi'}$, $\mathbf{1}^l_{\Xi'}$ be the global sections, respectively, defined by Ξ and Ξ' (as above). We then have the following.

Proposition 45: Let Ξ,Ξ' be two spin frames related by $\Xi'=\Xi u$, where $u:M\to\mathrm{Spin}^e_{1,3}$. Then

$$(i)\ e'_a=Ue_aU^{-1},$$

$$(ii)\ \mathbf{1}^l_{\Xi'}=\mathbf{1}^l_\Xi u=U\mathbf{1}^l_\Xi, \tag{42}$$

$$(iii)\ \mathbf{1}^r_{\Xi'}=u^{-1}\mathbf{1}^r_\Xi=\mathbf{1}^r_\Xi U^{-1},$$

where $U\in\sec\mathcal{C}\ell(M,g)$ is the Clifford field associated to u by $U(x)=[(\Xi(x),u(x))]$. Also, in (ii) and (iii), u and u^{-1}, respectively, act on $\mathbf{1}^l_\Xi\in\sec\mathcal{C}\ell^l_{\mathrm{Spin}^e_{1,3}}(M)$ and $\mathbf{1}^r_\Xi\in\sec\mathcal{C}\ell^r_{\mathrm{Spin}^e_{1,3}}(M)$ according to Proposition 37.

Proof: (i) We have

$$e'_a(x)=[(\Xi'(x),\mathbf{E}_a)]=[(\Xi(x)u(x),\mathbf{E}_a)]=[(\Xi(x),u(x)\mathbf{E}_au(x)^{-1})]=[(\Xi(x),u(x))]$$
$$\times[(\Xi(x),\mathbf{E}_a)][(\Xi(x),u(x)^{-1})]=U(x)e_a(x)U(x)^{-1}. \tag{43}$$

(iii) It follows from Proposition 38 that

$$\mathbf{1}^r_{\Xi'}(x)=[(\Xi'(x),1)]=[(\Xi(x)u(x),1)]=[(\Xi(x),1u(x)^{-1})]=[(\Xi(x),u(x)^{-1})]=u(x)^{-1}\mathbf{1}^r_\Xi(x), \tag{44}$$

where in the last step we used Proposition 37 and the fact that $\mathbf{1}^r_\Xi(x)=[(\Xi(x),1)]$. To demonstrate the second part, note that

$$u^{-1}(x)\mathbf{1}^r_\Xi(x)=[(\Xi(x),u(x)^{-1})]=[(\Xi(x),1u(x)^{-1})]=[(\Xi(x),1)][(\Xi(x),u(x)^{-1})]$$
$$=\mathbf{1}^r_\Xi(x)U^{-1}(x), \tag{45}$$

for all $x\in M$. It is important to note that in the last step we have a product between an element of $\mathcal{C}\ell^r_{\mathrm{Spin}^e_{1,3}}(M)$ [i.e., $[(\Xi(x),1)]$] and an element of $\mathcal{C}\ell(M,g)$ [i.e., $[(\Xi(x),u(x)^{-1})]$]. ■

We emphasize that the right unit sections associated with spin frames are *not* constant in any covariant way. In fact, we have the following.

Proposition 46: Let $\mathbf{1}^r_\Xi \in \sec \mathcal{C}\ell^{\,r}_{\mathrm{Spin}^e_{1,3}}(M)$ *be the right unit section associated to the spin frame* Ξ. *Then*

$$\boldsymbol{\nabla}^s_{e_a}\mathbf{1}^r_\Xi = -\frac{1}{2}\mathbf{1}^r_\Xi \omega_{e_a}, \tag{46}$$

where ω_{e_a} *is the connection 1-form (Proposition 54) written in the basis* $\{e_a\}$.

Proof: It follows from Eq. (A9) of the Appendix. ■

C. Representatives of DHSF on the Clifford bundle

Let $\{\mathbf{E}^a\}$ be, as before, a fixed orthonormal basis of $\mathbb{R}^{1,3}\subseteq\mathbb{R}_{1,3}$. Remember that these objects are fundamental to the Dirac equation (37) in terms of sections Ψ of $\mathcal{C}\ell^{\,l}_{\mathrm{Spin}^e_{1,3}}(M,g)$:

$$D^s\Psi\mathbf{E}^{21} - qA\Psi = m\Psi\mathbf{E}^0.$$

Let $\Xi \in \sec P_{\mathrm{Spin}^e_{1,3}}(M)$ be a spin frame on M and define the sections $\mathbf{1}^l_\Xi$, $\mathbf{1}^r_\Xi$ and e_a, respectively, on $\mathcal{C}\ell^{\,l}_{\mathrm{Spin}^e_{1,3}}(M)$, $\mathcal{C}\ell^{\,r}_{\mathrm{Spin}^e_{1,3}}(M)$ and $\mathcal{C}\ell(M,g)$, as above. Now we can use Proposition 44 to write the above equation in terms of sections of $\mathcal{C}\ell(M,g)$:

$$(D^s\Psi)\mathbf{1}^r_\Xi e^{21}\mathbf{1}^l_\Xi - qA\Psi = m\Psi\mathbf{1}^r_\Xi e^0\mathbf{1}^l_\Xi. \tag{47}$$

Right-multiplying by $\mathbf{1}^r_\Xi$ yields, using Proposition 44,

$$e^a(\boldsymbol{\nabla}^s_{e_a}\Psi)\mathbf{1}^r_\Xi e^{21} - qA\Psi\mathbf{1}^r_\Xi = m\Psi\mathbf{1}^r_\Xi e^0. \tag{48}$$

It follows from Proposition 59 that

$$(\boldsymbol{\nabla}^s_{e_a}\Psi)\mathbf{1}^r_\Xi = \boldsymbol{\nabla}_{e_a}(\Psi\mathbf{1}^r_\Xi) - \Psi\boldsymbol{\nabla}^s_{e_a}(\mathbf{1}^r_\Xi) = \boldsymbol{\nabla}_{e_a}(\Psi\mathbf{1}^r_\Xi) + \frac{1}{2}\Psi\mathbf{1}^r_\Xi\omega_a, \tag{49}$$

where Proposition 46 was employed in the last step. Therefore

$$e^a\left[\boldsymbol{\nabla}_{e_a}(\Psi\mathbf{1}^r_\Xi) + \frac{1}{2}\Psi\mathbf{1}^r_\Xi\omega_a\right]e^{21} - qA(\Psi\mathbf{1}^r_\Xi) = m(\Psi\mathbf{1}^r_\Xi)e^0. \tag{50}$$

Thus it is natural to define, for each spin frame Ξ, the Clifford field $\psi_\Xi \in \sec C\ell(M,g)$ (see Proposition 39) by

$$\psi_\Xi := \Psi\mathbf{1}^r_\Xi. \tag{51}$$

We then have

$$e^a\left[\boldsymbol{\nabla}_{e_a}\psi_\Xi + \frac{1}{2}\psi_\Xi\omega_a\right]e^{21} - qA\psi_\Xi = m\psi_\Xi e^0. \tag{52}$$

A comment about the nature of spinors is in order. As we repeatedly said in the previous sections, spinor fields should not be ultimately regarded as fields of multivectors (or multiforms), for their behavior under Lorentz transformations is not tensorial (they are able to distinguish between 2π and 4π rotations). So, how can the identification above be correct? The answer is that the definition in Eq. (51) is intrinsically spin-frame dependent. Clearly, this is the price one ought to pay if one wants to make sense of the procedure of representing spinors by differential forms.

Note also that the covariant derivative acting on ψ_Ξ in Eq. (52) is the tensorial covariant derivative ∇_V on $C\ell(M,g)$, as it should be. However, we see from the expression above that ∇_V always acts on ψ_Ξ together with the term $\frac{1}{2}\psi_\Xi\omega_a$. Therefore, it is natural to define an "effective covariant derivative" $\nabla_V^{(s)}$ acting on ψ_Ξ by

$$\nabla_{e_a}^{(s)}\psi_\Xi := \nabla_a\psi_\Xi + \frac{1}{2}\psi_\Xi\omega_a . \tag{53}$$

Then, Proposition 54 yields

$$\nabla_{e_a}^{(s)}\psi_\Xi = \partial_{e_a}(\psi_\Xi) + \frac{1}{2}\omega_a\psi_\Xi , \tag{54}$$

which emulates the spinorial covariant derivative, as it should. We observe moreover that if $U \in \sec C\ell(M,g)$ and if $\psi_\Xi \in \sec C\ell(M,g)$ is a representative of a Dirac-Hestenes spinor field then

$$\nabla_{e_a}^{(s)}(U\psi_\Xi) = (\nabla_{e_a}U)\psi_\Xi + U\nabla_{e_a}^{(s)}\psi_\Xi . \tag{55}$$

(This is the derivative used in Ref. 34, there introduced in an *ad hoc* way.)

With this notation, we finally have the Dirac–Hestenes equation for the *representative* Clifford field $\psi_\Xi \in \sec C\ell(M,g)$, on a Lorentzian spacetime:

$$e^a\nabla_{e_a}^{(s)}\psi_\Xi e^{21} - qA\psi_\Xi = m\psi_\Xi e^0, \tag{56}$$

where ψ_Ξ is the representative of a DHSF Ψ of $\mathcal{C}\ell^l_{\mathrm{Spin}^e_{1,3}}(M,g)$, relative to the spin frame Ξ. (The DHE on a Riemann–Cartan spacetime will be discussed in another publication.)

Let us finally show that this formulation recovers the usual transformation properties characteristic of the Hestenes's formalism as described, e.g., in Ref. 34. For that matter, consider two spin frames $\Xi, \Xi' \in \sec P_{\mathrm{Spin}^e_{1,3}}(M)$, with $\Xi'(x) = \Xi(x)u(x)$, where $u(x) \in \mathrm{Spin}^e_{1,3}$. It follows from Proposition 45 that $\psi_{\Xi'} = \Psi\mathbf{1}^r_{\Xi'} = \Psi u^{-1}\mathbf{1}^r_\Xi = \Psi\mathbf{1}^r_\Xi U^{-1} = \psi_\Xi U^{-1}$. Therefore, the various spin frame dependent Clifford fields from Eq. (56) transform as

$$\begin{aligned} e'_a &= Ue_aU^{-1}, \\ \psi_{\Xi'} &= \psi_\Xi U^{-1}. \end{aligned} \tag{57}$$

These are exactly the transformation rules one expects from fields satisfying the Dirac–Hestenes equation (see, e.g., Ref. 34).

D. Bilinear covariants

1. Bilinear covariants associated to a DHSF

We are now in position to give a precise definition of the bilinear covariants of the Dirac theory, associated with a given DHSF.

Definition 47: Recalling that $\Lambda^p(M) \hookrightarrow \mathcal{C}\ell(M,g)$, $p = 0,1,2,3,4$, *and recalling Propositions 39 and 40, the bilinear covariants associated to a DHSF* $\Psi \in \sec C\ell^l_{\mathrm{Spin}^e_{1,3}}(M)$ *[and* $\tilde{\Psi} \in \sec \mathcal{C}\ell^r_{\mathrm{Spin}^e_{1,3}}(M)$*] are the following sections of* $\mathcal{C}\ell(M,g)$:

$$\begin{aligned} S &= \Psi\tilde{\Psi} = \sigma + e_5\,\omega \in \sec(\Lambda^0(M) + \Lambda^4(M)), \\ J &= \Psi\mathbf{E}_0\tilde{\Psi} \in \sec\Lambda^1(M), \quad K = \Psi\mathbf{E}_3\tilde{\Psi} \in \sec\Lambda^1(M), \end{aligned} \tag{58}$$

$$M = \Psi \mathbf{E}_{12} \tilde{\Psi} \in \sec \Lambda^2(M),$$

where $\Psi = \Psi \frac{1}{2}(1 + \mathbf{E}_0)$, *and* $e_5 = e_0 e_1 e_2 e_3$.

Remark 48: Of course, since all bilinear covariants in Eq. (58) are sections of $\mathcal{C}\ell(M,g)$, *they have the right transformation properties under arbitrary local Lorentz transformations, as required. As shown, e.g., in Ref. 21 these bilinear covariants and their Hodge duals satisfy a set of identities, called the Fierz identities (see, e.g., Ref. 34) that are crucial for the physical interpretation of the Dirac equation (in first and second quantizations).*

Remark 49: Crumeyrolle[10] *gives the name of* amorphous *spinor fields to ideal sections of the Clifford bundle* $\mathcal{C}\ell(M,g)$. *Thus an amorphous spinor field* ϕ *is a section of* $\mathcal{C}\ell(M,g)$ *such that* $\phi P = \phi$, *where* $P = P^2$ *is an idempotent section of* $\mathcal{C}\ell(M,g)$. *However, these fields and also the so-called Dirac–Kähler (Refs. 18, 20) fields, which are also sections of* $\mathcal{C}\ell(M,g)$, *cannot be used in a physical theory of fermion fields since they do not have the correct transformation law under a Lorentz rotation of the local spin frame.*

2. Bilinear covariants associated to a representative of a DHSF

We note that the bilinear covariants, when written in terms of $\psi_\Xi := \Psi \mathbf{1}^r_\Xi$, read (from Proposition 44) as

$$S = \psi_\Xi \tilde{\psi}_\Xi = \sigma + e_5\, \omega \in \sec(\Lambda^0(M) + \Lambda^4(M)),$$

$$J = \psi_\Xi e_0 \tilde{\psi}_\Xi \in \sec \Lambda^1(M), \quad K = \psi_\Xi e_3 \tilde{\psi}_\Xi \in \sec \Lambda^1(M),$$

$$M = \psi_\Xi e_1 e_2 \tilde{\psi}_\Xi \in \sec \Lambda^2(M),$$

where $e_5 = e_0 e_1 e_2 e_3$. These are all intrinsic quantities, as they should be.

E. Electromagnetic gauge invariance of the DHE

Proposition 50: The DHE is invariant under electromagnetic gauge transformations,

$$\psi_\Xi \mapsto \psi'_\Xi = \psi_\Xi e^{q e_{21} \chi}, \tag{59}$$

$$A \mapsto A + \partial\chi, \tag{60}$$

$$\omega_{e_a} \mapsto \omega_{e_a}, \tag{61}$$

where $\psi_\Xi, \psi'_\Xi \in \sec C\ell^0(M,g)$, $A \in \sec \Lambda^1(M) \subset \sec C\ell(M,g)$ *and where* $\chi \in \sec \Lambda^0(M) \subset \sec C\ell(M,g)$ *is a gauge function.*

Proof: It is a direct calculation. ■

But, what are the meanings of these transformations? Equation (59) looks similar to Eq. (57) defining the change of a representative of a DHSF once we change the spin frame, but here we have an active transformation, since we did *not* change the spin frame. On the other hand, Eq. (60) does not correspond either to a passive (no transformation at all) or active local Lorentz transformation for A. Nevertheless, writing $\chi = \theta/2$ yields

$$\begin{aligned}
e^{-qe^{21}\theta/2} e^0 e^{qe^{21}\theta/2} &= e'^0 = e^0, \\
e^{-qe^{21}\theta/2} e^1 e^{qe^{21}\theta/2} &= e'^1 = \cos q\theta \;\; e^1 + \sin q\theta \;\; e^2, \\
e^{-qe^{21}\theta/2} e^2 e^{qe^{21}\theta/2} &= e'^2 = -\sin q\theta \;\; e^1 + \cos q\theta \;\; e^2, \\
e^{-qe^{21}\theta/2} e^3 e^{qe^{21}\theta/2} &= e'^3 = e^3.
\end{aligned} \tag{62}$$

We see that Eqs. (62) define a spin frame Ξ' to which corresponds, as we already know, a basis $\{e'^0, e'^1, e'^2, e'^3\}$ for $\Lambda^1(M) \hookrightarrow C\ell(M,g)$. We can then think of the electromagnetic gauge transformation as a rotation in the spin plane e^{21} by identifying ψ'_Ξ in Eq. (59) with $\psi_{\Xi'}$, the representative of the DHSF in the spin frame Ξ' and by supposing that instead of transforming the spin connection ω_{e_a} as in Eq. (A7) it is taken as fixed and instead of maintaining the electromagnetic potential A fixed it is transformed as in Eq. (60). We observe that, since in the theory of the gravitational field ω_{e_a} is associated with some aspects of that field, our interpretation for the electromagnetic gauge transformation suggests a possible nontrivial coupling between electromagnetism and gravitation, *if* the Dirac–Hestenes equation is taken as a fundamental representation of fermionic matter. We will explore this possibility in another publication.

VI. CONCLUSIONS

In this paper, we hope to have clarified the ontology of Dirac–Hestenes spinor fields [on a general spacetime $\mathfrak{M}=(M,g,\nabla,\tau_g,\uparrow)$ of the Riemann–Cartan type admitting a spin structure] and its relationship with sums of even multivector fields (or differential forms). This has been achieved through the introduction of the Clifford bundle of multivector fields $(\mathcal{C}\ell(M,g))$ and the *left* $(\mathcal{C}\ell^l_{\mathrm{Spin}^e_{1,3}}(M))$ and *right* $(\mathcal{C}\ell^r_{\mathrm{Spin}^e_{1,3}}(M))$ spin-Clifford bundles on a spin manifold (M,g), as well as a study of the relations among these bundles. Left algebraic spinor fields and Dirac–Hestenes spinor fields [both fields are sections of $\mathcal{C}\ell^l_{\mathrm{Spin}^e_{1,3}}(M)$] have been defined and the relation between them has been established. Moreover, a consistent Dirac equation for a DHSF $\Psi \in \sec \mathcal{C}\ell^l_{\mathrm{Spin}^e_{1,3}}(M)$ (denoted DE$\mathcal{C}\ell^l$) on a Lorentzian spacetime was found. We succeeded also in obtaining in a consistent way a *representation* of the DE$\mathcal{C}\ell^l$ in the Clifford bundle. It is such equation satisfied by Clifford fields $\psi_\Xi \in \sec \mathcal{C}\ell(M,g)$ that we called the Dirac–Hestenes equation (DHE). This means that to each DHSF $\Psi \in \sec \mathcal{C}\ell^l_{\mathrm{Spin}^e_{1,3}}(M)$ and $\Xi \in \sec P_{\mathrm{Spin}^e_{1,3}}(M)$ there is a well-defined even nonhomogeneous multivector field $\psi_\Xi \in \sec \mathcal{C}\ell(M,g)$ (EMFS) associated with Ψ. Such a EMFS is called a *representative* of the DHSF on the given spin frame. And, of course, such a EMFS (the representative of the DHSF) is *not* a spinor field. With this crucial distinction between a DHSF and their EMFS representatives we presented a consistent theory for Clifford and spinor fields of all kinds.

We emphasize that the DE$\mathcal{C}\ell^l$ and the DHE, although related, are of different mathematical natures. This issue has been particularly scrutinized in Secs. IV and V. We studied also the local Lorentz invariance and the electromagnetic gauge invariance and showed that only for the DHE such transformations are of the same mathematical nature, something that suggests by itself a possible link between them.

APPENDIX: COVARIANT DERIVATIVES OF CLIFFORD AND SPINOR FIELDS

1. Covariant derivative of Clifford fields

In this appendix, $(M,g,\nabla,\tau_g,\uparrow)$ denotes a general *Riemann–Cartan* spacetime (see Definition 3). Since $\mathcal{C}\ell(M,g)=\tau M/J(M,g)$, it is clear that any metric compatible $(\nabla g=0)$ connection

defined in τM passes to the quotient $\tau M/J(M,g)$, and thus define an algebra bundle connection.[10] In this way, the covariant derivative of a Clifford field $A \in \sec \mathcal{C}\ell(M,g)$ is completely determined.

We will find formulas for the covariant derivative of Clifford fields and of DHSF using the general theory of connections in principal bundles and covariant derivatives in associate vector bundles, as described in many excellent textbooks, e.g., Refs. 8, 15, 29, 30.

Let (E,M,π_1,G,F) denoted by $E=P\times_\rho F$ be a vector bundle associated to a PFB (P,M,π,G) by the linear representation ρ of G in $F=\mathbf{V}$.

Definition 51: Let $\sigma:\mathbb{R}\supset I\to M$, $t\mapsto\sigma(t)$ *be a curve in* M *with* $x_0=\sigma(0)\in M$, *and let* $p_0 \in \pi^{-1}(x_0)$. *The parallel transport of* p_0 *along* σ *is given by the curve* $\hat{\sigma}:\mathbb{R}\supset I\to P, t\mapsto\hat{\sigma}(t)$ *defined by*

$$\frac{d}{dt}\hat{\sigma}(t)=\Gamma_p\left(\frac{d}{dt}\sigma(t)\right), \tag{A1}$$

with $p_0=\hat{\sigma}(0)$ *and* $\pi(\hat{\sigma}(t))=\sigma(t)$. *We also denote* $p_{\|t}=\hat{\sigma}(t)$.

In Eq. (A1), $\Gamma_p: T_xM\to T_pP$ is a connection on (P,M,π,G) (see, e.g., definition (a) on p. 358 of Ref. 8).

Consider the trivializations of P,

$$\Phi_i:\pi^{-1}(U_i)\to U_i\times G,\quad \Phi_i(p)=(\pi(p),\phi_{i,x}(p)),$$

and E,

$$\Xi_i:\pi_1^{-1}(U_i)\to U_i\times F,\quad \Xi_i(q)=(\pi_1(q),\chi_i(q))=(x,\chi_i(q)).$$

Then, we have the following.

Definition 52: The parallel transport *of* $\Psi_0\in E$, $\pi_1(\Psi_0)=x_0$, *along the curve* $\sigma:\mathbb{R}\supset I\to M$, $t\mapsto\sigma(t)$ *from* $x_0=\sigma(0)\in M$ *to* $x=\sigma(t)$ *is the element* $\Psi_{\|t}\in E$ *such that the following occurs*:

(i) $\pi_1(\Psi_{\|t})=x$,
(ii) $\chi_i(\Psi_{\|t})=\rho(\phi_i(p_{\|t})\circ\phi_i(p_0)^{-1})\chi_i(\Psi_0)$.
(iii) $p_{\|t}\in P$ is the parallel transport of $p_0\in P$ along σ from x_0 to x.

Definition 53: Let v *be a vector at* x_0 *tangent to the curve* σ *(as defined above). The covariant derivative of* $\Psi\in\sec E$ *along* v *is denoted* $(D_v^E\Psi)_{x_0}\in\sec E$ *and*

$$(D_v^E\Psi)(x_0)\equiv(D_v^E\Psi)_{x_0}=\lim_{t\to 0}\frac{1}{t}(\Psi_{\|t}^0-\Psi_0), \tag{A2}$$

where $\Psi_{\|t}^0$ *is the parallel transport of the vector* $\Psi_t\equiv\Psi(\sigma(t))$ *of the given section* $\Psi\in\sec E$ *along* σ *from* $\sigma(t)$ *to* x_0. *The only requirements on* σ *are that* $\sigma(0)=x_0$ *and*

$$\left.\frac{d}{dt}\sigma(t)\right|_{t=0}=v. \tag{A3}$$

Proposition 54: Let $V\in\sec TM$. *The covariant derivative of a Clifford field* $A \in\sec\mathcal{C}\ell(M,g)$ *is given by*

$$\nabla_V A=V(A)+\frac{1}{2}[\omega_V,A], \tag{A4}$$

where $V(A):=V(A^I)e_I$ *and* ω_V *is the connection 1-form* $V\mapsto\omega_V=-\frac{1}{2}V^a\Gamma_{abc}e^b\wedge e^c$, *written in the basis* $\{e_a\}$, *with* Γ_{abc} *given by* $\nabla_{e_a}e_b=\Gamma_{ab}{}^c e_c=\Gamma_{abc}e^c$.

Proof: Writing $A(t)=A(\sigma(t))$ in terms of the multivector basis $\{e_I\}$ of sections associated to a given spin frame, as in Sec. V B, we have $A(t)=A^I(t)e_I(t)=A^I(t)[(\Xi(t),E_I)]=[(\Xi(t),A^I(t)E_I)]=[(\Xi(t),a(t))]$, with $a(t):=A^I(t)E_I\in\mathbb{R}_{1,3}$. If follows from item (ii) of Definition 52 that

$$A^0_{\|t}=[(\Xi(0),g(t)a(t)g(t)^{-1})], \tag{A5}$$

for some $g(t)\in \mathrm{Spin}^e_{1,3}$, with $g(0)=1$. Thus

$$\lim_{t\to 0}\frac{1}{t}(g(t)a(t)g(t)^{-1}-a(0))=\left[\frac{dg}{dt}ag^{-1}+g\frac{da}{dt}g^{-1}+ga\frac{dg^{-1}}{dt}\right]_{t=0}$$
$$=\dot a(0)+\dot g(0)a(0)-a(0)\dot g(0)=V(A^I)E_I+[\dot g(0),a(0)],$$

where $\dot g(0)\in \mathrm{Lie}(\mathrm{Spin}^e_{1,3})=\Lambda^2(\mathbb{R}^{1,3})$. Therefore

$$\boldsymbol{\nabla}_V A=V(A^I)e_I+\frac{1}{2}[\omega_V,A],$$

for some $\omega_V\in \sec\Lambda^2(M)$. In particular, calculating the covariant derivative of the basis 1-vector fields e_b yields $V^a\Gamma_{ab}{}^c e_c=\boldsymbol{\nabla}_V e_b=\frac{1}{2}[\omega_V,e_b]$, so that $\omega_V=-\frac{1}{2}V^a\Gamma_{abc}e^b\wedge e^c$. ■

Remark 55: Equation (A4) shows that the covariant derivative preserves the degree of a homogeneous Clifford field, as can be easily verified.

The general formula Eq. (A4) and the associative law in the Clifford algebra immediately yields the following.

Corollary 56: The covariant derivative $\boldsymbol{\nabla}_V$ on $\mathcal{C}\ell(M,g)$ acts as a derivation on the algebra of sections, i.e., for $A,B\in\sec\mathcal{C}\ell(M,g)$ and $V\in\sec TM$, it holds that

$$\boldsymbol{\nabla}_V(AB)=(\boldsymbol{\nabla}_V A)B+A(\boldsymbol{\nabla}_V B). \tag{A6}$$

Under a change of gauge (local Lorentz transformation) $e^a\mapsto e'^a=Ue^aU^{-1}$, with $U\in\sec\mathcal{C}\ell(M,g), U\tilde U=\tilde U U=1$, the corresponding transformation law for ω_V is as follows.

Corollary 57: Under a change of gauge (local Lorentz transformation), ω_V transforms as

$$\frac{1}{2}\omega_V\mapsto U\frac{1}{2}\omega_V U^{-1}+(\boldsymbol{\nabla}_V U)U^{-1}. \tag{A7}$$

Proof: It is a simple calculation using Eq. (A4). ■

2. Covariant derivatives of spinor fields

The spinor bundles introduced in Sec. II, like $I(M)=P_{\mathrm{Spin}^e_{1,3}}(M)\times_\ell I$, $I=\mathbb{R}_{1,3}\frac{1}{2}(1+E_0)$, and $\mathcal{C}\ell^l_{\mathrm{Spin}^e_{1,3}}(M)$, $\mathcal{C}\ell^r_{\mathrm{Spin}^e_{1,3}}(M)$ (and subbundles) are examples of vector bundles. Thus, the general theory of covariant derivative operators on associate vector bundles can be used (as in the previous section) to obtain formulas for the covariant derivatives of sections of these bundles. Given $\Psi\in\sec\mathcal{C}\ell^l_{\mathrm{Spin}^e_{1,3}}(M)$ and $\Phi\in\sec\mathcal{C}\ell^r_{\mathrm{Spin}^e_{1,3}}(M)$, we denote the corresponding covariant derivatives by $\boldsymbol{\nabla}^s_V\Psi$ and $\boldsymbol{\nabla}^s_V\Phi$. [Recall that $I^l(M)\hookrightarrow C\ell^l_{\mathrm{Spin}^e_{1,3}}(M)$ and $I^r(M)\hookrightarrow C\ell^r_{\mathrm{Spin}^e_{1,3}}(M)$.]

Proposition 58: Given $\Psi\in\sec\mathcal{C}\ell^l_{\mathrm{Spin}^e_{1,3}}(M)$ and $\Phi\in\sec\mathcal{C}\ell^r_{\mathrm{Spin}^e_{1,3}}(M)$,

$$\boldsymbol{\nabla}^s_V\Psi=V(\Psi)+\frac{1}{2}\omega_V\Psi, \tag{A8}$$

$$\nabla^s_V \Phi = V(\Psi) - \frac{1}{2}\Psi\,\omega_V. \tag{A9}$$

Proof: It is analogous to that of Proposition 54, with the difference that Eq. (A5) should be substituted by $\Psi^0_{\|t}=[(\Xi(0),g(t)a(t))]$ and $\Phi^0_{\|t}=[(\Xi(0),a(t)g(t)^{-1})]$. ■

Proposition 59: Let ∇ be the connection on $\mathcal{C}\ell(M,g)$ to which ∇^s is related. Then, for any $V\in\sec TM$, $A\in\sec\mathcal{C}\ell(M,g)$, $\Psi\in\sec\mathcal{C}\ell^l_{\mathrm{Spin}^e_{1,3}}(M)$) and $\Phi\in\sec\mathcal{C}\ell^r_{\mathrm{Spin}^e_{1,3}}(M)$,

$$\nabla^s_V(A\Psi) = A\nabla^s_V\Psi + (\nabla_V A)\Psi, \tag{A10}$$

$$\nabla^s_V(\Phi A) = \Phi\nabla_V A + (\nabla^s_V\Phi)A. \tag{A11}$$

Proof: Recalling that $\mathcal{C}\ell^l_{\mathrm{Spin}^e_{1,3}}(M)$ $[\mathcal{C}\ell^r_{\mathrm{Spin}^e_{1,3}}(M)]$ is a module over $\mathcal{C}\ell(M,g)$, the result follows from a simple computation. ■

Finally, let $\Psi\in\sec\mathcal{C}\ell^l_{\mathrm{Spin}^e_{1,3}}(M)$ be such that $\Psi\mathbf{e}=\Psi$ where $\mathbf{e}^2=\mathbf{e}\in\mathbb{R}_{1,3}$ is a primitive idempotent. Then, since $\Psi\mathbf{e}=\Psi$,

$$\nabla^s_V\Psi = \nabla^s_V(\Psi\mathbf{e}) = V(\Psi\mathbf{e}) + \frac{1}{2}\omega_V\Psi\mathbf{e} = \left[V(\Psi)+\frac{1}{2}\omega_V\Psi\right]\mathbf{e} = (\nabla^s_V\Psi)\mathbf{e}, \tag{A12}$$

from where we verify that the covariant derivative of a LIASF is indeed a LIASF.

Bounds are derived for the space–time averaged temperature $\langle T \rangle$ of a fluid layer in the Boussinesq approximation between fixed-temperature horizontal boundaries subject to uniform heating H throughout the volume. The analysis is carried out for both finite and infinite Prandtl number fluids. While the average temperature $\langle T \rangle \sim H$ in the purely conductive state, convection enhances the heat transport beyond static conduction reducing the temperature. Lower bounds to the average temperature of the layer scale with the magnitude of the imposed heat flux, with one scaling exponent for the arbitrary Prandtl number case and another for the infinite Prandtl number model. Specifically, it is proven here that at large heating rates where convection is important, $\langle T \rangle \geqslant c_1 H^{2/3}$ for finite Prandtl number fluids and $\langle T \rangle \geqslant c_2 H^{5/7}$ for infinite Prandtl number fluids. Explicit prefactors c_1 and c_2 for the scaling bounds are computed as well. © *2004 American Institute of Physics.*

I. INTRODUCTION

Turbulent transport of mass, momentum, and heat remains one of the most important problems for modern theoretical physics and applied mathematics. For incompressible fluid flows, fundamental models such as the Navier–Stokes and related equations are believed to quantitatively describe these phenomena. However the complexity of the dynamics in these systems of nonlinear partial differential equations prohibits exact solutions, and the wide range of length and time scales in turbulent solutions makes direct numerical simulation extremely challenging and expensive. One mathematical approach to the analysis of these systems is to derive rigorous bounds on physically relevant quantities.[12,3,8] This approach is of more than just mathematical interest because it turns out that in some cases the bounds tend to capture aspects of the turbulent scaling of the quantities with respect to the control parameters (e.g., the Reynolds or Rayleigh number). In the case of Rayleigh–Bénard convection, for example, where a fluid layer between horizontal plates is heated from below, the enhancement of the heat flux due to convection, usually measured by a Nusselt number, can be bounded from above in terms of the temperature drop across the layer[11,1,9,6,10,14] expressed in terms of the Rayleigh number.

In this paper we consider the problem of convective heat transport in a fluid layer between fixed-temperature horizontal boundaries with uniform heating throughout the volume. This problem is motivated by geophysical applications;[7,17] the Earth's plate tectonics is a result of convection in the mantle which is predominantly driven by uniform heating due to radioactive decay of elements distributed throughout the mantle. Mantle dynamics is generally modeled as the flow of a high (infinite) Prandtl number fluid with strongly temperature dependent viscosity. The models we focus on here are simpler, with constant material parameters. The boundary conditions for mantle convection are complicated—especially on ''top''—but we restrict the investigation here to rigid no-slip isothermal boundaries in order to make progress. In principle, if all the relevant

materical and boundary effects could be included, the kinds of bounds derived here could be used to put limits on the thermal history of the Earth. A distinct engineering application of this kind of analysis is to the problem of nuclear reactor meltdown.[4]

The rest of this paper is organized as follows: in the next section we present the details of the models we will analyze. In a brief Sec. III we apply the "background" method[9] to the arbitrary Prandtl number problem to derive a scaling lower bound on the space–time averaged temperature of the layer along with an explicit prefactor. In the following Sec. IV we apply a multiple boundary layer asymptotic theory[1] to sharpen the estimate, increasing the prefactor in the lower bound by a factor of 4. Section V is concerned with the infinite Prandtl number problem, and the background method utilizing a recently derived inequality[10] results in a scaling lower bound with a smaller exponent. In the concluding Sec. VI we summarize our results in the context of direct numerical simulations, and discuss some possible areas for further development of this approach.

II. GOVERNING EQUATIONS

The fluid layer is confined between two parallel plates of horizontal extent L_x and L_y separated by vertical (z) distance d. The no-slip upper and lower plates are held at fixed temperatures T_0 and T_1, respectively; the temperature difference $\Delta T = T_0 - T_1$ which will eventually be taken to be zero for the work presented here. A uniform volumetric heat flux H (with units power/volume) is pumped into the layer. The governing equations for the velocity field $\mathbf{u}$, the pressure p and the temperature T in the standard Boussinesq approximation are

$$\frac{\partial \mathbf{u}}{\partial t} + \mathbf{u}\cdot\nabla\mathbf{u} = -\nabla p + \nu\nabla^2\mathbf{u} + \hat{\mathbf{k}} g\alpha T, \tag{1a}$$

$$\frac{\partial T}{\partial t} + \mathbf{u}\cdot\nabla T = \kappa\nabla^2 T + \gamma, \tag{1b}$$

$$\nabla\cdot\mathbf{u} = 0, \tag{1c}$$

with the boundary conditions

$$\mathbf{u}|_{z=0,d} = 0, \quad T|_{z=0} = T_0, \quad T|_{z=d} = T_1, \tag{1d}$$

where ν is the viscosity, g is the acceleration of gravity along the z axis (in the $-\hat{\mathbf{k}}$ direction), α is the thermal expansion coefficient, κ is the thermal diffusion coefficient and $\gamma = H/\rho c$, where ρ is the density and c is the specific heat capacity of the fluid. We impose periodic boundary conditions in the horizontal directions with periods L_x and L_y.

Using d^2/κ as the unit of time, d as the unit of length, and $\gamma d^2/\kappa$ as the unit of temperature, the governing equations are put into the nondimensional form

$$\mathrm{Pr}^{-1}\left(\frac{\partial \mathbf{u}}{\partial t} + \mathbf{u}\cdot\nabla\mathbf{u}\right) + \nabla p = \nabla^2\mathbf{u} + RT\hat{\mathbf{k}}, \tag{2a}$$

$$\frac{\partial T}{\partial t} + \mathbf{u}\cdot\nabla T = \nabla^2 T + 1, \tag{2b}$$

where $\mathrm{Pr} = \nu/\kappa$ is the Prandtl number and $R = g\alpha d^5\gamma/\kappa^2\nu$ is the heat Rayleigh number.[16] We consider R, proportional to the internal heating rate, to be the control parameter. The boundary conditions in nondimensional form are

$$\mathbf{u}|_{z=0,1} = 0, \quad T|_{z=0} = \tilde{T}, \quad T|_{z=1} = 0, \tag{2c}$$

where $\tilde{T}=(\kappa/\gamma d^2)\Delta T$; this shows that $R\tilde{T}$ is the usual Rayleigh number $\mathrm{Ra}=g\alpha\Delta T d^3/\nu\kappa$ for bottom heating.

In the following discussion, we only consider the special case where both boundaries are held at the same temperature, i.e., $\Delta T=0$ or $\tilde{T}=0$. With this boundary condition, the static conduction solution has a quadratic profile:

$$T=\tfrac{1}{2}z(1-z), \tag{3}$$

which becomes unstable for sufficiently large R.[19] Once convection sets in, the flow tends to lower the average temperature of the fluid, so the estimate of interest is the minimum possible bulk average temperature for a given value R. We define the space–time average of a function $f(\mathbf{x},t)$ as

$$\langle f\rangle=\lim_{t\to\infty}\frac{1}{t}\int_0^t ds\,\frac{d^2}{L_xL_y}\int dxdydz f(\mathbf{x},s). \tag{4}$$

In the following discussion, we apply the background and multiple boundary layer methods to derive lower bounds for the bulk average (nondimensional) temperature with respect to R in the form $\langle T\rangle\geqslant cR^{\alpha}$ as $R\to\infty$.

III. BACKGROUND METHOD FOR FINITE Pr

To apply the background method, first we decompose the temperature field $T(x,y,z,t)$ into a time-independent background profile $\tau(z)$ and a fluctuating part $\theta(x,y,z,t)$:

$$T(x,y,z,t)=\tau(z)+\theta(x,y,z,t). \tag{5}$$

The boundary conditions of $T(x,y,z,t)$ are contained in $\tau(z)$:

$$\tau(0)=\tau(1)=0 \tag{6}$$

and the fluctuating part $\theta(x,y,z,t)$ satisfies homogeneous boundary conditions

$$\theta(x,y,0,t)=\theta(x,y,1,t)=0. \tag{7}$$

The velocity field $\mathbf{u}$ is divergence-free with no-slip boundary conditions:

$$\nabla\cdot\mathbf{u}=0,\quad \mathbf{u}|_{z=0,1}=0. \tag{8}$$

With this decomposition the governing Eqs. (2) become

$$\mathrm{Pr}^{-1}\left(\frac{\partial\mathbf{u}}{\partial t}+\mathbf{u}\cdot\nabla\mathbf{u}\right)+\nabla p=\nabla^2\mathbf{u}+\tau\hat{\mathbf{k}}+R\theta\hat{\mathbf{k}}, \tag{9a}$$

$$\frac{\partial\theta}{\partial t}+\mathbf{u}\cdot\nabla\theta=\nabla^2\theta+\tau''+1-w\tau'. \tag{9b}$$

Then taking the space–time average of $\mathbf{u}\cdot(9\mathrm{a})$ yields

$$\langle|\nabla\mathbf{u}|^2\rangle=R\langle w\theta\rangle, \tag{10}$$

and averaging $\theta\cdot(9\mathrm{b})$ and $\tau\cdot(9\mathrm{b})$ yield, respectively,

$$\langle w\theta\tau'\rangle=-\langle|\nabla\theta|^2\rangle-\langle\theta_z\tau'\rangle+\langle\theta\rangle, \tag{11}$$

$$-\langle w\theta\tau'\rangle=-\langle\theta_z\tau'\rangle+\langle\tau\rangle-\langle\tau'^2\rangle. \tag{12}$$

The difference of the above two identities is

$$(\langle\theta\rangle-\langle\tau\rangle)=\langle|\nabla\theta|^2\rangle+2\langle w\theta\tau'\rangle-\langle\tau'^2\rangle. \tag{13}$$

Since $\langle T\rangle=\langle\tau\rangle+\langle\theta\rangle$, we have

$$\langle T\rangle=\langle|\nabla\theta|^2\rangle+2\langle w\theta\tau'\rangle+2\langle\tau\rangle-\langle\tau'^2\rangle. \tag{14}$$

The identity (10) can also be written as

$$0=\frac{a}{R}\langle|\nabla\mathbf{u}|^2\rangle-a\langle w\theta\rangle, \tag{15}$$

where a is a positive number (a ''balance parameter'') to be adjusted to yield the best prefactor.[13] Adding Eq. (15) to Eq. (14) enables us to express the average temperature as follows:

$$\langle T\rangle=2\langle\tau\rangle-\langle\tau'^2\rangle+H, \tag{16}$$

where

$$H=\langle|\nabla\theta|^2\rangle+\langle(2\tau'-a)w\theta\rangle+\frac{a}{R}\langle|\nabla\mathbf{u}|^2\rangle. \tag{17}$$

If the functional H is positive semidefinite among the fields $\mathbf{u}$ and θ satisfying

$$\nabla\cdot\mathbf{u}=0,\quad \mathbf{u}|_{z=0,1}=0,\quad \theta|_{z=0,1}=0,$$

then we have a lower bound for $\langle T\rangle$:

$$\langle T\rangle\geqslant 2\langle\tau\rangle-\langle\tau'^2\rangle. \tag{18}$$

So the goal is to choose a background profile τ satisfying the boundary conditions (6) guaranteeing that H is positive semidefinite while making the lower bound in (18) as large as possible.

If we could take a linear background profile with the slope $a/2>0$, then $2\tau'-a$ would vanish and thus the functional H would clearly be non-negative, but this choice can not allow both $\tau(0)$ and $\tau(1)$ to vanish simultaneously. However, the indefinite term in H is proportional to $w\theta$ that vanishes at the boundaries. This suggests that we can take $2\tau'=a$ in the middle while introducing two boundary layers to enforce τ's boundary conditions. These considerations lead us to focus on the family of piecewise linear background profiles

$$\tau(z)=\begin{cases}\left(\dfrac{a}{2}+\dfrac{b}{\delta_1}\right)z, & 0\leqslant z<\delta_1,\\ \dfrac{a}{2}z+b, & 1-\delta_1\leqslant z\leqslant 1-\delta_2,\\ -\left[\dfrac{a}{2}\left(\dfrac{a}{\delta_2}-1\right)+\dfrac{b}{\delta_2}\right](z-1), & 1-\delta_2\leqslant z\leqslant 1,\end{cases} \tag{19}$$

where δ_1 (δ_2) is the thickness of the boundary layer at $z=0$ ($z=1$) introduced to satisfy the boundary conditions (see Fig. 1). Then

$$\langle T\rangle\geqslant 2\langle\tau\rangle-\langle\tau'^2\rangle=\frac{a}{2}(1-\delta_2)+b(1-\delta_1-\delta_2)-\left\{\frac{a^2}{4}\left(\frac{1}{\delta_2}-1\right)+b^2\left(\frac{1}{\delta_1}+\frac{1}{\delta_2}\right)+\frac{ab}{\delta_2}\right\}, \tag{20}$$

provided the quadratic functional H in (17) is positive definite. Before estimating the size of H, we can maximize $2\langle\tau\rangle-\langle\tau'^2\rangle$ over a and b, and this procedure yields

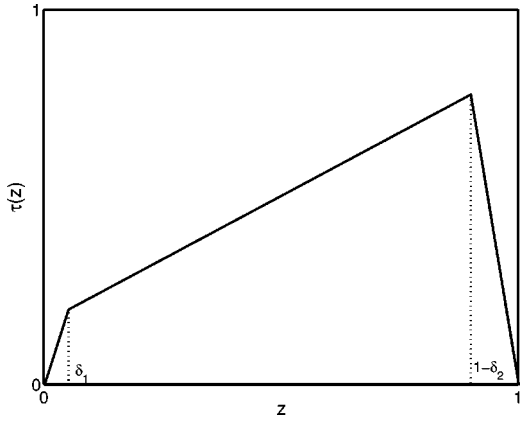

FIG. 1. The background profile for finite Prandtl number.

$$\langle T\rangle \geqslant \tfrac{1}{4}(1-\delta_1)(1-\delta_2)(\delta_1+\delta_2) \tag{21}$$

with

$$\begin{cases} a=\delta_2-\delta_1 \\ b=\dfrac{\delta_1}{2}(1-\delta_2). \end{cases} \tag{22}$$

Then using the inequality[9]

$$\left|\int_0^1 w\theta\right| \leqslant \left(\frac{c}{4}\|\mathbf{u}\|_2^2+\frac{1}{c}\|\theta\|_2^2\right) \tag{23}$$

for any $c>0$, the term $\langle(2\tau'-a)w\theta\rangle$ can be estimated by

$$\begin{aligned}|\langle(2\tau'-a)w\theta\rangle| &\leqslant \frac{b\delta_1}{2}\left[\frac{c_1}{4}\langle|\nabla\mathbf{u}|^2\rangle+\frac{1}{c_1}\langle|\nabla\theta|^2\rangle\right]+\frac{(a+2b)\delta_2}{4}\left[\frac{c_2}{4}\langle|\nabla\mathbf{u}|^2\rangle+\frac{1}{c_2}\langle|\nabla\theta|^2\rangle\right] \\ &= \frac{\delta_1^2(1-\delta_2)}{4}\left[\frac{c_1}{4}\langle|\nabla\mathbf{u}|^2\rangle+\frac{1}{c_1}\langle|\nabla\theta|^2\rangle\right]+\frac{\delta_2^2(1-\delta_1)}{4}\left[\frac{c_2}{4}\langle|\nabla\mathbf{u}|^2\rangle+\frac{1}{c_2}\langle|\nabla\theta|^2\rangle\right].\end{aligned}$$

Then

$$H\geqslant\left[1-\frac{\delta_1^2(1-\delta_2)}{4c_1}-\frac{\delta_2^2(1-\delta_1)}{4c_2}\right]\langle|\nabla\theta|^2\rangle+\left[\frac{a}{R}-\frac{\delta_1^2(1-\delta_2)c_1}{16}-\frac{\delta_2^2(1-\delta_1)c_2}{16}\right]\langle|\nabla\mathbf{u}|^2\rangle.$$

Thus H is positive semidefinite if

$$1-\frac{\delta_1^2(1-\delta_2)}{4c_1}-\frac{\delta_2^2(1-\delta_1)}{4c_2}\geqslant 0 \tag{24}$$

and

$$\frac{a}{R}-\frac{\delta_1^2(1-\delta_2)c_1}{16}-\frac{\delta_2^2(1-\delta_1)c_2}{16}\geqslant 0. \tag{25}$$

We can choose $c_1=c_2=c$ and then it is sufficient to require

$$[\delta_1^2(1-\delta_2)+\delta_2^2(1-\delta_1)]^2=\frac{64(\delta_2-\delta_1)}{R}, \tag{26}$$

and

$$c=\frac{a}{4}. \tag{27}$$

Now the lower bound of $\langle T\rangle$ in (21) can be maximized over δ_1 and δ_2 subject to condition (26). But before fully optimizing the bound in (21) we consider the special case where there is only one boundary layer in the background field at $z=1$, i.e., the choice $\delta_1=0$. Although this will not give us the optimal bound, it is still a rigorous lower bound which is easier to compute and which can be compared with the optimal bound later.

For $\delta_1=0$ we should set $b=0$ in the general background profile (19). Thus (21) becomes

$$\langle T\rangle \geqslant \tfrac{1}{4}(1-\delta_2)\delta_2, \tag{28}$$

and the constraint (26) is simplified to be

$$\delta_2^3=\frac{64}{R}. \tag{29}$$

We can now write down the estimate

$$\langle T\rangle \geqslant R^{-1/3}(1-4R^{-1/3}). \tag{30}$$

So as $R\to\infty$, $\langle T\rangle \geqslant R^{-1/3}$ with prefactor 1.

To fully optimize the bound, we need to maximize the right-hand side of the inequality (21) subject to the constraint (26):

$$\langle T\rangle \geqslant \max_{\delta_1,\delta_2}\left\{\frac{1}{4}(1-\delta_1)(1-\delta_2)(\delta_1+\delta_2)\right\}, \tag{31}$$

with δ_1 and δ_2 satisfying

$$[\delta_1^2(1-\delta_2)+\delta_2^2(1-\delta_1)]^2=\frac{64(\delta_2-\delta_1)}{R}. \tag{32}$$

This is easily done numerically and the result is shown in Fig. 2. It is seen from the graph that this better bound follows the same scaling as in (30), i.e., $\sim R^{-1/3}$ as $R\to\infty$. The prefactor can be measured from the graph, showing that the asymptotic prefactor is improved slightly:

$$\langle T\rangle \geqslant 1.09R^{-1/3} \quad \text{as} \quad R\to\infty. \tag{33}$$

IV. MULTIPLE BOUNDARY LAYER METHOD FOR FINITE Pr

In this section, we will derive the lower bound of the bulk average temperature using the homogeneous ratio approach introduced by Howard[11] and the multiple boundary layer method due to Busse.[1] First we decompose the temperature and velocity fields into their horizontal average and fluctuating parts:

$$T=\overline{T}+\theta, \quad \text{with} \quad \overline{\theta}=0 \quad \text{and} \quad \overline{\mathbf{u}}=0, \tag{34}$$

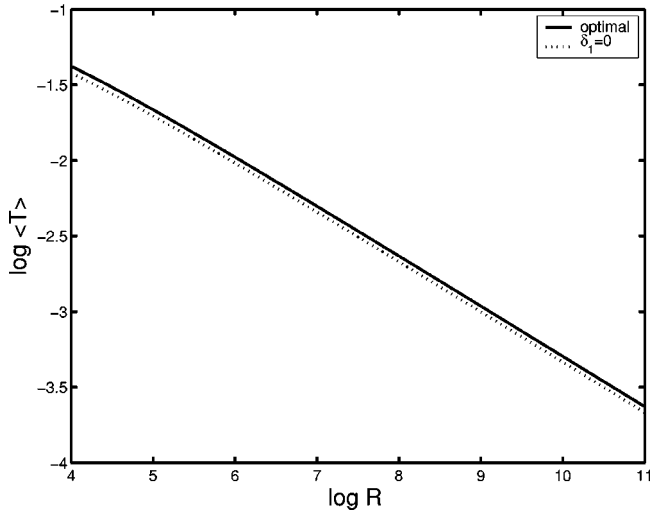

FIG. 2. The solid line is the fully optimized lower bound of the bulk average temperature compared to the estimate (30) (the dotted line).

where overline denotes the horizontal average. We will assume that the flow is statistically stationary so that the horizontal average is time-independent and the fluctuating part has vanishing horizontal mean. This is most easily justified in the limit of a horizontally infinite layer, so we take

$$\overline{f}(z)=\lim_{L_x,L_y\to\infty}\frac{1}{L_xL_y}\int f(x,y,z,t)\;\;dxdy. \tag{35}$$

The horizontal average of the temperature Eq. (2b) is

$$\frac{d\overline{w\theta}}{dz}=\frac{d^2\overline{T}}{d^2z}+1. \tag{36}$$

Integrate once to obtain

$$\overline{w\theta}=\frac{d\overline{T}}{dz}+z+c. \tag{37}$$

The integration constant c here is determined by integrating above equation over $[0,1]$, yielding

$$\frac{d\overline{T}}{dz}=\overline{w\theta}-\langle w\theta\rangle-\left(z-\frac{1}{2}\right). \tag{38}$$

Using the decomposition (34) along with (36), Eq. (2b) can be written

$$\frac{\partial\theta}{\partial t}+w\frac{d\overline{T}}{dz}+\mathbf{u}\cdot\nabla\theta=\nabla^2\theta+\frac{d^2\overline{T}}{d^2z}+1=\nabla^2\theta+\frac{d\overline{w\theta}}{dz}. \tag{39}$$

Multiplying both sides by θ and integrate over the bulk, we deduce

$$\left\langle w\theta\frac{d\overline{T}}{dz}\right\rangle=-\langle|\nabla\theta|^2\rangle. \tag{40}$$

Together with Eq. (38), we find the ''power integral''

$$\left\langle \left(z-\frac{1}{2} \right) w\theta \right\rangle = \langle |\nabla \theta|^2 \rangle + \langle (\overline{w\theta} - \langle w\theta \rangle)^2 \rangle. \tag{41}$$

Another power integral is derived by multiplying Eq. (2a) by **u** and integrating over the bulk:

$$\langle |\nabla \mathbf{u}|^2 \rangle = R \langle w\theta \rangle. \tag{42}$$

Finally, we derive an expression for the average temperature by multiplying Eq. (38) by z and integrating over $[0,1]$:

$$\langle T \rangle = -\left\langle \left(z-\frac{1}{2} \right) w\theta \right\rangle + \frac{1}{12}. \tag{43}$$

In summary we have the following balances:

$$\langle |\nabla \mathbf{u}|^2 \rangle = R \langle w\theta \rangle, \tag{44}$$

$$\langle (z-\tfrac{1}{2}) w\theta \rangle = \langle |\nabla \theta|^2 \rangle + \langle (\overline{w\theta} - \langle w\theta \rangle)^2 \rangle, \tag{45}$$

$$\langle T \rangle = -\langle (z-\tfrac{1}{2}) w\theta \rangle + \tfrac{1}{12}. \tag{46}$$

Now rewrite (45) as

$$1 = \frac{\langle |\nabla \theta|^2 \rangle + \langle (\overline{w\theta} - \langle w\theta \rangle)^2 \rangle}{\left\langle \left(z-\frac{1}{2} \right) w\theta \right\rangle} \tag{47}$$

and multiply the $\frac{1}{12}$ in (46) so disguised to find

$$\langle T \rangle = \frac{\langle |\nabla \theta|^2 \rangle + \langle (\overline{w\theta} - \langle w\theta \rangle)^2 \rangle - 12\left\langle \left(z-\frac{1}{2} \right) w\theta \right\rangle^2}{12\left\langle \left(z-\frac{1}{2} \right) w\theta \right\rangle}. \tag{48}$$

Let

$$h(z) = \sqrt{12}(z-\tfrac{1}{12}). \tag{49}$$

Notice that

$$\langle h \rangle = 0, \quad \langle h^2 \rangle = 1. \tag{50}$$

Then

$$\langle (\overline{w\theta} - h\langle hw\theta \rangle - \langle w\theta \rangle)^2 \rangle = \langle \overline{w\theta}^2 \rangle - \langle w\theta \rangle^2 - \langle hw\theta \rangle^2. \tag{51}$$

Thus together with (44), the average temperature can be expressed as

$$\begin{aligned} \langle \sqrt{12} RT \rangle &= R \frac{\langle |\nabla \theta|^2 \rangle + \langle (\overline{w\theta} - \langle w\theta \rangle)^2 \rangle - \langle hw\theta \rangle^2}{\langle hw\theta \rangle} \\ &= \frac{\langle |\nabla \theta|^2 \rangle \langle |\nabla \mathbf{u}|^2 \rangle}{\langle w\theta \rangle \langle hw\theta \rangle} + R \frac{\langle (\overline{w\theta} - h\langle hw\theta \rangle - \langle w\theta \rangle)^2 \rangle}{\langle hw\theta \rangle}. \end{aligned} \tag{52}$$

The variational problem can be formulated as follows:
Given $\mu = R\langle hw\theta\rangle$, *find the minimum of the functional*

$$\mathcal{F} = \frac{\langle|\nabla\theta|^2\rangle\langle|\nabla\mathbf{u}|^2\rangle}{\langle hw\theta\rangle\langle w\theta\rangle} + \mu\frac{\langle(\overline{w\theta} - h\langle hw\theta\rangle - \langle w\theta\rangle)^2\rangle}{\langle hw\theta\rangle^2} \tag{53}$$

among the $\mathbf{u}$, θ *fields with*

$$\nabla\cdot\mathbf{u} = 0, \quad \mathbf{u}|_{z=0,1} = 0, \quad \theta|_{z=0,1} = 0, \tag{54}$$

where

$$w = \mathbf{u}\cdot\hat{\mathbf{k}}, \quad h(z) = \sqrt{12}(z - \tfrac{1}{2}). \tag{55}$$

Since the functional $\mathcal{F}$ is homogeneous in both w and θ, we can impose two normalization conditions

$$\langle hw\theta\rangle = 1, \quad \langle w^2\rangle = \langle\theta^2\rangle. \tag{56}$$

We are seeking the minimum of the functional $\mathcal{F}$ as $\mu\to\infty$. This implies that $\overline{w\theta} = h + \langle w\theta\rangle$ [here and in the following discussion the normalization conditions (56) have been assumed] throughout most of the interval $0<z<1$, which makes the second term in the functional vanish in this interval. Only near the boundary $z=0,1$ the boundary conditions prevent a close appoach of $\overline{w\theta}$ to $h+\langle w\theta\rangle$. And the contribution to the functional is thus from possible boundary layers at $z=0,1$. (Note: the boundary layers are distinct in this problem, as is the case for a similar analysis of circular Couette flow where the inner and outer cylinders must be handled seperately.[2]) Since $h(1)+\langle w\theta\rangle = \sqrt{3} + \langle|\nabla\mathbf{u}|^2\rangle > 0$ [from Eq. (44) and definition (49)] there must be a boundary layer at $z=1$. At $z=0$, $h(0)+\langle w\theta\rangle = -\sqrt{3}+\langle w\theta\rangle$ is indefinite. Thus the existence of a boundary layer at $z=0$ depends on whether $h(0)+\langle w\theta\rangle$ is zero. Without loss of generality we assume there are two boundary layers at $z=0,1$ respectively, and make the ansatz

$$w = \sum\ w_n\phi_n + w_n^*\phi_n^*, \quad \theta = \sum\ \theta_n\phi_n + \theta_n^*\phi_n^*, \tag{57}$$

where ϕ_n and ϕ_n^* satisfy

$$\Delta_2\phi_n = -\alpha_n^2\phi_n, \quad \Delta_2\phi_n^* = -\alpha_n^{*2}\phi_n^*. \tag{58}$$

We introduce the following boundary layer variables:

$$w = \begin{cases} \mu^{-p_n}\hat{w}(\zeta_n) & \text{for } 1-z = O(\mu^{-r_n}), \\ \mu^{-s_n}\tilde{w}(\zeta_{n-1}) & \text{for } 1-z = O(\mu^{-r_{n-1}}), \end{cases} \tag{59}$$

$$\theta = \begin{cases} \mu^{p_n}\hat{\theta}(\zeta_n) & \text{for } 1-z = O(\mu^{-r_n}), \\ \mu^{s_n}\tilde{\theta}(\zeta_{n-1}) & \text{for } 1-z = O(\mu^{-r_{n-1}}), \end{cases} \tag{60}$$

$$w^* = \begin{cases} \mu^{-p_n}\hat{w}^*(\zeta_n^*) & \text{for } z = O(\mu^{-r_n}), \\ \mu^{-s_n}\tilde{w}^*(\zeta_{n-1}^*) & \text{for } z = O(\mu^{-r_{n-1}}), \end{cases} \tag{61}$$

$$\theta^* = \begin{cases} \mu^{p_n}\hat{\theta}^*(\zeta_n^*) & \text{for } z = O(\mu^{-r_n}), \\ \mu^{s_n}\tilde{\theta}^*(\zeta_{n-1}^*) & \text{for } z = O(\mu^{-r_{n-1}}), \end{cases} \tag{62}$$

where

$$\zeta_n=(1-z)\mu^{r_n},\quad \zeta_n^*=z\mu^{r_n}. \tag{63}$$

The boundary layer structure is such that in the interior

$$\tilde{w}_1\tilde{\theta}_1+\tilde{w}_1^*\tilde{\theta}_1^*\approx h+\langle w\theta\rangle, \tag{64}$$

and in the boundary layers

$$\tilde{w}_n\tilde{\theta}_n+\hat{w}_{n-1}\hat{\theta}_{n-1}\approx h_1+\langle w\theta\rangle,\quad \tilde{w}_n^*\tilde{\theta}_n^*+\hat{w}_{n-1}^*\hat{\theta}_{n-1}^*\approx h_0+\langle w\theta\rangle \tag{65}$$

for $n=1,\ldots,N-1$, where

$$h_0=h(0)=-\sqrt{3},\quad h_1=h(1)=\sqrt{3}.$$

With the boundary layer approximations, the functional becomes

$$\begin{aligned}\hat{\mathcal{F}}_N=\frac{1}{\langle w\theta\rangle}\Bigg\{&\sum_1^N \mu^{2p_n+r_n}\Bigg(\int_0^\infty \hat{\theta}_n'^2 d\zeta_n+\int_0^\infty \hat{\theta}_n^{*\prime 2} d\zeta_n^*\Bigg)+\sum_2^N \mu^{q_n-r_n+2s_n}\Bigg(b_n^2\int_0^\infty \tilde{\theta}_n^2 d\zeta_{n-1}\\&+b_n^{*2}\int_0^\infty \tilde{\theta}_n^{*2} d\zeta_{n-1}^*\Bigg)+\mu^{q_1}(b_1^2\langle\tilde{\theta}_1^2\rangle+b_1^{*2}\langle\tilde{\theta}_1^{*2}\rangle)\Bigg\}\Bigg\{\sum_1^N \mu^{3r_n-2p_n-q_n}\Bigg(\frac{1}{b_n^2}\int_0^\infty \hat{w}_n''^2 d\zeta_n\\&+\frac{1}{b_n^{*2}}\int_0^\infty \hat{w}_n^{*\prime\prime 2} d\zeta_n^*\Bigg)+\sum_2^N \mu^{q_n-r_{n-1}-2s_n}\Bigg(b_n^2\int_0^\infty \tilde{w}_n^2 d\zeta_{n-1}+b_n^{*2}\int_0^\infty \tilde{w}_n^{*2} d\zeta_{n-1}^*\Bigg)\mu^{q_1}(b_1^2\langle\tilde{w}_1^2\rangle\\&+b_1^{*2}\langle\tilde{w}_1^{*2}\rangle)\Bigg\}+\Bigg\{\mu^{1-r_N}\Bigg(\int_0^\infty(\hat{w}_N\hat{\theta}_N-h_1-\langle w\theta\rangle)^2 d\zeta_N+\int_0^\infty(\hat{w}_N^*\hat{\theta}_N^*-h_0-\langle w\theta\rangle)^2 d\zeta_N^*\Bigg)\Bigg\}.\end{aligned} \tag{66}$$

Balancing the exponents in the above expression yields

$$r_n=\frac{1-4^{-n}}{3-4^{-n}},\quad q_n=\frac{2-4^{-n}}{3-4^{-n}},\quad s_n=0,\quad 2p_n=\frac{4^{-n}}{3-4^{-n}}. \tag{67}$$

Then we have

$$\hat{\mathcal{F}}_N=\mu^{2/3-4^{-N}}F_N, \tag{68}$$

where

$$\begin{aligned}F_N=\frac{1}{\langle w\theta\rangle}\Bigg\{&\sum_1^N\Bigg(\int_0^\infty \hat{\theta}_n'^2 d\zeta_n+\int_0^\infty \hat{\theta}_n^{*\prime 2} d\zeta_n^*\Bigg)\sum_2^N\Bigg(b_n^2\int_0^\infty \tilde{\theta}_n^2 d\zeta_{n-1}+b_n^{*2}\int_0^\infty \tilde{\theta}_n^{*2} d\zeta_{n-1}^*\Bigg)+(b_1^2\langle\tilde{\theta}_1^2\rangle\\&+b_1^{*2}\langle\tilde{\theta}_1^{*2}\rangle)\Bigg\}\Bigg\{\sum_1^N\Bigg(\frac{1}{b_n^2}\int_0^\infty \hat{w}_n''^2 d\zeta_n+\frac{1}{b_n^{*2}}\int_0^\infty \hat{w}_n^{*\prime\prime 2} d\zeta_n^*\Bigg)\sum_2^N\Bigg(b_n^2\int_0^\infty \tilde{w}_n^2 d\zeta_{n-1}\\&+b_n^{*2}\int_0^\infty \tilde{w}_n^{*2} d\zeta_{n-1}^*\Bigg)+(b_1^2\langle\tilde{w}_1^2\rangle+b_1^{*2}\langle\tilde{w}_1^{*2}\rangle)\Bigg\}+\Bigg\{\int_0^\infty(\hat{w}_N\hat{\theta}_N-h_1-\langle w\theta\rangle)^2 d\zeta_N\\&+\int_0^\infty(\hat{w}_N^*\hat{\theta}_N^*-h_0-\langle w\theta\rangle)^2 d\zeta_N^*\Bigg\}.\end{aligned} \tag{69}$$

Now the Euler–Lagrange equations for the functional F_N can be written down:

$$\frac{1}{\langle w\theta\rangle}\frac{D_\theta}{b_n^2}\hat{w}_n^{(4)}-\mu^{r_N-r_n}\hat{\theta}_n(h_1+\langle w\theta\rangle-\hat{w}_n\hat{\theta}_n-\tilde{w}_{n+1}\tilde{\theta}_{n+1})=0, \tag{70}$$

$$\frac{1}{\langle w\theta\rangle}D_w\hat{\theta}_n''+\mu^{r_N-r_n}\hat{w}_n(h_1+\langle w\theta\rangle-\hat{w}_n\hat{\theta}_n-\tilde{w}_{n+1}\tilde{\theta}_{n+1})=0, \tag{71}$$

$$n=1,\ldots,N, \tag{72}$$

$$\frac{b_{n+1}^2}{\langle w\theta\rangle}D_\theta\tilde{w}_{n+1}-\mu^{r_N-r_n}\tilde{\theta}_{n+1}(h_1+\langle w\theta\rangle-\hat{w}_n\hat{\theta}_n-\tilde{w}_{n+1}\tilde{\theta}_{n+1})=0, \tag{73}$$

$$\frac{b_{n+1}^2}{\langle w\theta\rangle}D_w\tilde{\theta}_{n+1}-\mu^{r_N-r_n}\tilde{w}_{n+1}(h_1+\langle w\theta\rangle-\hat{w}_n\hat{\theta}_n-\tilde{w}_{n+1}\tilde{\theta}_{n+1})=0, \tag{74}$$

$$n=1,\ldots,N-1. \tag{75}$$

And for $\tilde{w}_1$, $\tilde{\theta}_1$,

$$\frac{D_\theta}{\langle w\theta\rangle}b_1^2\tilde{w}_1-\tilde{\theta}_1\left\{\frac{D_\theta D_w}{2\langle w\theta\rangle^2}(h\langle w\theta\rangle+1)+\mu^{r_N}(h+\langle w\theta\rangle-\tilde{w}_1\tilde{\theta}_1-\tilde{w}_1^*\tilde{\theta}_1^*)+h\left(\int_0^\infty(\hat{w}_N\hat{\theta}_N-h_1\right.\right.$$
$$\left.\left.-\langle w\theta\rangle)^2d\zeta_N+\int_0^\infty(\hat{w}_N^*\hat{\theta}_N^*-h_0-\langle w\theta\rangle)^2d\zeta_N^*\right)\right\}=0, \tag{76}$$

and

$$\frac{D_w}{\langle w\theta\rangle}b_1^2\tilde{\theta}_1-\tilde{w}_1\left\{\frac{D_\theta D_w}{2\langle w\theta\rangle^2}(h\langle w\theta\rangle+1)+\mu^{r_N}(h+\langle w\theta\rangle-\tilde{w}_1\tilde{\theta}_1-\tilde{w}_1^*\tilde{\theta}_1^*)+h\left(\int_0^\infty(\hat{w}_N\hat{\theta}_N-h_1\right.\right.$$
$$\left.\left.-\langle w\theta\rangle)^2d\zeta_N+\int_0^\infty(\hat{w}_N^*\hat{\theta}_N^*-h_0-\langle w\theta\rangle)^2d\zeta_N^*\right)\right\}=0. \tag{77}$$

The same set of equations are also satisfied by the starred quantities $\tilde{w}_n^*,\tilde{\theta}_n^*,\hat{w}_n^*,\hat{\theta}_n^*$.

From Eqs. (76) and (77), we have

$$D_\theta\tilde{w}_1^2=D_w\tilde{\theta}_1^2, \tag{78}$$

$$D_\theta\tilde{w}_1^{*2}=D_w\tilde{\theta}_1^{*2}. \tag{79}$$

Adding these two identities yields

$$D_\theta\langle\tilde{w}_1^2+\tilde{w}_1^{*2}\rangle=D_w\langle\tilde{\theta}_1^2+\tilde{\theta}_1^{*2}\rangle. \tag{80}$$

Hence the normalization condition $\langle w^2\rangle=\langle\theta^2\rangle$ implies

$$D_\theta=D_w=D. \tag{81}$$

This identity together with Eqs. (76) and (77) yields

$$\tilde{w}_1^2=\tilde{\theta}_1^2,\quad b_1=b_1^*. \tag{82}$$

Equation (73) together with Eq. (75) gives

$$D_\theta \tilde{w}_{n+1}^2 = D_w \tilde{\theta}_{n+1}^2 .$$

The same identity holds for $\tilde{w}_{n+1}^*$ and $\tilde{\theta}_{n+1}^*$. Therefore

$$\tilde{w}_{n+1}^2 = \tilde{\theta}_{n+1}^2, \quad \tilde{w}_{n+1}^{*2} = \tilde{\theta}_{n+1}^{*2} \quad \text{for } n = 1, \ldots, N-1. \tag{83}$$

Substituting the above identity back into Eq. (73), we have

$$h_1 + \langle w\theta \rangle - \hat{w}_n \hat{\theta}_n - \tilde{w}_{n+1}\tilde{\theta}_{n+1} = \mu^{r_n - r_N} b_{n+1}^2 \frac{D}{\langle w\theta \rangle}, \tag{84}$$

$$h_0 + \langle w\theta \rangle - \hat{w}_n^* \hat{\theta}_n^* - \tilde{w}_{n+1}^* \tilde{\theta}_{n+1}^* = \mu^{r_n - r_N} b_{n+1}^{*2} \frac{D}{\langle w\theta \rangle} \tag{85}$$

for $n = 1, \ldots, N-1$. Then Eqs. (70) and (72) become

$$\frac{1}{b_n^2} \hat{w}_n^{(4)} - b_{n+1}^2 \hat{\theta}_n = 0, \tag{86}$$

$$\hat{\theta}_n'' + b_{n+1}^2 \hat{w}_n = 0, \quad n = 1, \ldots, N-1. \tag{87}$$

The above equations hold in the region where $\hat{w}_n \hat{\theta}_n \neq h_1 + \langle w\theta \rangle$. When the equality holds, then from Eq. (70) and Eq. (72) we can derive

$$\frac{\hat{w}_n^{(4)}}{b_n^2} = -\frac{\hat{\theta}_n \hat{\theta}_n''}{w_n} = (h_1 + \langle w\theta \rangle)^2 \frac{\hat{w}_n'' \hat{w}_n - 2\hat{w}_n'^2}{\hat{w}_n^5}. \tag{88}$$

With the following change of variables,

$$\begin{cases} \zeta = b_n^{1/3} b_{n+1}^{2/3} \zeta_n, \\ \hat{\Omega} = b_n^{-1/3} b_{n+1}^{1/3} (h_1 + \langle hw\theta \rangle)^{-1/2} \hat{w}_n, \\ \hat{\Theta} = b_n^{1/3} b_{n+1}^{-1/3} (h_1 + \langle hw\theta \rangle)^{-1/2} \hat{\theta}_n, \end{cases} \tag{89}$$

Eqs. (86), (87), and (88) become

$$\begin{cases} \hat{\Omega}^{(4)} - \hat{\Theta} = 0, \\ \hat{\Theta}'' + \hat{\Omega} = 0, \\ \hat{\Omega}^{(4)} = \dfrac{\hat{\Omega}''\hat{\Omega} - 2\hat{\Omega}'^2}{\hat{\Omega}^5}. \end{cases} \tag{90}$$

Starred quantities satisfy the same equations with h_1 replaced by h_0. This set of differential equations has been studied in Ref. 1, where the constant β is defined

$$3\beta = \int_0^\infty \hat{\Omega}''^2 d\zeta + \int_0^\infty (1 - \hat{\Omega}\hat{\Theta}) d\zeta = 1.847 \tag{91}$$

and the following integrals are evaluated:

$$\int_0^\infty \frac{w_n''^2}{b_n^2} d\zeta_n + \int_0^\infty b_{n+1}^2 \tilde{w}_{n+1}^2 d\zeta_n = 3\beta(h_1 + \langle w\theta\rangle) b_n^{-1/3} b_{n+1}^{4/3}, \quad n = 1, \ldots, N-1. \tag{92}$$

When $n = N$, the differential equations for $\hat{w}_N$ and $\hat{\theta}_N$ are

$$\frac{D}{\langle w\theta\rangle b_N^2} \hat{w}_N^{(4)} - (h_1 + \langle w\theta\rangle - \hat{w}_N \hat{\theta}_N) \hat{\theta}_N = 0, \tag{93}$$

$$\frac{D}{\langle w\theta\rangle b_N^2} \hat{\theta}_N'' + (h_1 + \langle w\theta\rangle - \hat{w}_N \hat{\theta}_N) \hat{w}_N = 0. \tag{94}$$

Then with the following change of variables,

$$\begin{cases} \zeta = b_N^{1/3} (h_1 + \langle w\theta\rangle)^{1/3} \left(\dfrac{D}{\langle w\theta\rangle} \right)^{-1/3} \zeta_N, \\ \Omega = b_N^{-1/3} (h_1 + \langle hw\theta\rangle)^{-1/3} \left(\dfrac{D}{\langle w\theta\rangle} \right)^{-1/6} \hat{w}_N, \\ \Theta = b_N^{1/3} (h_1 + \langle hw\theta\rangle)^{-2/3} \left(\dfrac{D}{\langle w\theta\rangle} \right)^{1/6} \hat{\theta}_N, \end{cases} \tag{95}$$

Eqs. (93) and (94) become

$$\Omega^{(4)} - (1 - \Omega\Theta)\Theta = 0, \tag{96}$$

$$\Theta'' + (1 - \Omega\Theta)\Omega = 0. \tag{97}$$

In Howard's paper[11] the following result is given:

$$\sigma = \int_0^\infty \Omega''^2 d\zeta = \int_0^\infty \Theta'^2 d\zeta = \tfrac{1}{4} \int_0^\infty (1 - \Omega\Theta)^2 d\zeta = 0.337. \tag{98}$$

Thus the following integrals can be expressed in σ:

$$\int_0^\infty \frac{(\hat{w}^{(4)})^2}{b_N^2} d\zeta_N = \sigma (h_1 + \langle w\theta\rangle)^{5/3} \left(\frac{D}{\langle w\theta\rangle} \right)^{-2/3} b_N^{-1/3}, \tag{99}$$

$$\int_0^\infty \hat{\theta}_N'^2 d\zeta_N = \sigma (h_1 + \langle w\theta\rangle)^{5/3} \left(\frac{D}{\langle w\theta\rangle} \right)^{-2/3} b_N^{-1/3}, \tag{100}$$

$$\int_0^\infty (h_1 + \langle hw\theta\rangle - \hat{w}_N \hat{\theta}_N)^2 d\zeta_N = 4\sigma (h_1 + \langle w\theta\rangle)^{5/3} \left(\frac{D}{\langle w\theta\rangle} \right)^{1/3} b_N^{-1/3}. \tag{101}$$

Putting the above integrals together, the functional F_N can then be expressed as

$$F_N = \frac{D^2}{\langle w\theta\rangle} \tag{102}$$

$$+ 4\sigma (h_1 + \langle w\theta\rangle)^{5/3} \left(\frac{D}{\langle w\theta\rangle} \right)^{1/3} b_N^{-1/3} + 4\sigma (h_0 + \langle w\theta\rangle)^{5/3} \left(\frac{D}{\langle w\theta\rangle} \right)^{1/3} b_N^{*-1/3}, \tag{103}$$

and

$$D=\sum_{n=1}^{N-1} 3\beta\left\{\left[\frac{b_{n+1}^4}{b_n}\right]^{1/3}(h_1+\langle w\theta\rangle)+\left[\frac{b_{n+1}^{*4}}{b_n^*}\right]^{1/3}(h_0+\langle w\theta\rangle)\right\}+\sigma\left(\frac{D}{\langle w\theta\rangle}\right)^{-2/3}\{(h_1+\langle w\theta\rangle)^{5/3}b_N^{-1/3}$$
$$+(h_0+\langle w\theta\rangle)^{5/3}b_N^{*-1/3}\}+b_1^2\langle w\theta\rangle. \tag{104}$$

Minimizing F_N with respect to b_n and b_n^* yields

$$\frac{\partial D}{\partial b_1}=0\Rightarrow 2b_1\langle w\theta\rangle=\beta\left[(h_1+\langle w\theta\rangle)\left(\frac{b_2}{b_1}\right)^{4/3}+(h_0+\langle w\theta\rangle)\left(\frac{b_2^*}{b_1}\right)^{4/3}\right], \tag{105}$$

$$\frac{\partial D}{\partial b_n}=0\Rightarrow\left[\frac{b_{n+1}}{b_n}\right]^{4/3}=4\left[\frac{b_n}{b_{n-1}}\right]^{1/3}, \tag{106}$$

$$\frac{\partial D}{\partial b_n^*}=0\Rightarrow\left[\frac{b_{n+1}^*}{b_n^*}\right]^{4/3}=4\left[\frac{b_n^*}{b_{n-1}^*}\right]^{1/3}, \tag{107}$$

$$\frac{\partial F_N}{\partial b_N}=0\Rightarrow\left[\frac{b_{N+1}}{b_N}\right]^{4/3}=4\left[\frac{b_N}{b_{N-1}}\right]^{1/3}, \tag{108}$$

$$\frac{\partial D}{\partial b_N^*}=0\Rightarrow\left[\frac{b_{N+1}^*}{b_N^*}\right]^{4/3}=4\left[\frac{b_N^*}{b_{N-1}^*}\right]^{1/3}, \tag{109}$$

where

$$b_{N+1}=\left(\frac{\sigma}{\beta}\right)^{4/3}\left(\frac{(h_1+\langle w\theta\rangle)\langle w\theta\rangle}{D}\right)^{1/2}, \tag{110}$$

$$b_{N+1}^*=\left(\frac{\sigma}{\beta}\right)^{4/3}\left(\frac{(h_0+\langle w\theta\rangle)\langle w\theta\rangle}{D}\right)^{1/2}. \tag{111}$$

From the above relations, the b_n can be determined:

$$b_{n+1}=4^{n-1}\left[\left(\frac{b_{N+1}}{4^{N-1}}\right)^{1-4^{-n}}\cdot(4b_1)^{4^{-n}-4^{-N}}\right]^{1/1-4^{-N}}. \tag{112}$$

And b_{n+1}^* has a similar form:

$$b_{n+1}^*=4^{n-1}\left[\left(\frac{b_{N+1}^*}{4^{N-1}}\right)^{1-4^{-n}}\cdot(4b_1)^{4^{-n}-4^{-N}}\right]^{1/1-4^{-N}}. \tag{113}$$

It is clear from the above expressions that $b_n\neq b_n^*$ for $n\neq 1$ since b_N [Eq. (110)] is different from b_N^* [Eq. (111)]. Finally, b_1 can be solved from (106) and the recursion relation

$$b_1=\left\{\frac{\beta}{2^{5/3}\langle w\theta\rangle}\left(\frac{\sigma}{\beta}\right)^{3/4(1-4^{-N})}[(h_1+\langle w\theta\rangle)^{4/(1-4^{-N})/3-4^{-N}}\right.$$
$$\left.+(h_0+\langle w\theta\rangle)^{4/(1-4^{-N})/3-4^{-N}}]\right\}^{1-4^{-N}/3-4^{-N}}. \tag{114}$$

Putting all these together, the prefactor F_N is a function of $\langle w\theta\rangle$ only:

$$F_N=\frac{D^2}{\langle w\theta\rangle}\frac{3-4^{-N}}{1-4^{-N}}$$

$$=(3-4^{-N})(1-4^{-N})2^{-4N4^{-N}/3-4^{-N}}\cdot\left(2^{5/3}\beta\times\left(\frac{\sigma}{\beta}\right)^{3/4(1-4^{-N})}\right)^{4(1-4^{-N})/3-4^{-N}}$$

$$\times\left[\frac{(h_1+\langle w\theta\rangle)^{3-2\cdot4^{-N}/2(1-4^{-N})}+(h_0+\langle w\theta\rangle)^{3-2\cdot4^{-N}/2(1-4^{-N})}}{\langle w\theta\rangle^{1-3\cdot4^{-N}/4(1-4^{-N})}}\right]^{4(1-4^{-N})/3-4^{-N}}. \tag{115}$$

Now the value of $\langle w\theta\rangle$ can be determined by setting $dF_N/d\langle w\theta\rangle$ to zero. The resulting equation for $\langle w\theta\rangle$ is

$$(\alpha-1)x^{(3-2c)/2(1-c)}-\alpha x-\alpha x^{1/(1-c)}+(\alpha-1)=0, \tag{116a}$$

where

$$x=\frac{\sqrt{3}+\langle w\theta\rangle}{\sqrt{3}-\langle w\theta\rangle},\quad \alpha=\frac{3-2c}{1-3c},\quad c=4^{-N}. \tag{116b}$$

For general values of N, the above equation has to be solved numerically:

$$N=1,\quad \langle w\theta\rangle=0.4831,$$

$$N=2,\quad \langle w\theta\rangle=0.9259,$$

$$N=3,\quad \langle w\theta\rangle=1.0120,$$

$$\vdots$$

When $N\to\infty$, the above equation can be solved exactly:

$$\langle w\theta\rangle_\infty=\frac{3\sqrt{3}}{5}=1.039. \tag{117}$$

This shows that there indeed is a boundary layer at $z=0$ since all $\langle w\theta\rangle$'s are less than $h_0=\sqrt{3}$.

Now we can write down the scaling of $\langle T\rangle$ as $N\to\infty$:

$$\langle T\rangle=\frac{1}{\sqrt{12}R}F_\infty\mu^{2/3}=10.285\mu^{2/3}R^{-1}. \tag{118}$$

Recalling the identity (46):

$$\langle T\rangle=-\langle(z-\tfrac{1}{2})w\theta\rangle+\tfrac{1}{12},$$

we know that as $\mu\to\infty$

$$\mu\sim\frac{1}{\sqrt{12}}R. \tag{119}$$

This leads to the scaling bound on $\langle T\rangle$ with respect to R:

$$\langle T\rangle\geqslant 4.421R^{-1/3}. \tag{120}$$

The profiles of $\tilde{w}_1$ and $\tilde{\theta}_1$ can be determined from the fact that in the interior of the interval $0<z<1$,

$$\tilde{w}_1\tilde{\theta}_1 \approx h+\langle w\theta\rangle, \quad \text{and} \quad \tilde{w}_1=\tilde{\theta}_1. \tag{121}$$

In the case $N\to\infty$, $h=2\sqrt{3}z-(2\sqrt{3}/5)$. And then

$$\tilde{w}_1=\sqrt{\left|2\sqrt{3}z-\frac{2\sqrt{3}}{5}\right|}, \quad \tilde{\theta}_1=\pm\sqrt{\left|2\sqrt{3}z-\frac{2\sqrt{3}}{5}\right|}. \tag{122}$$

However, whether θ changes sign in $0<z<1$ can not be inferred from the variational problem since only the product of w and θ appears in the functional $\mathcal{F}$. Thus the possibility of w changing its sign cannot be excluded.

V. BACKGROUND METHOD FOR INFINITE Pr

As can be seen from the momentum equation (2a), the velocity field is instantaneously slaved to the temperature field in the limit $\mathrm{Pr}\to\infty$. Then it is straightforward to extract the equation satisfied by the vertical velocity w for a given fluctuation field θ:

$$\Delta^2 w=-R\Delta_H\theta. \tag{123}$$

The incompressibility condition on the velocity field combined with the no-slip boundary conditions at $z=0$ and $z=1$ imply that both w and $\partial w/\partial z$ vanish at the rigid boundaries. To implement the background analysis we decompose the temperature field as we did for the finite Pr case and notice that identies (10) and (14) still hold. This observation leads to the bound (18):

$$\langle T\rangle \geqslant 2\langle\tau\rangle-\langle\tau'^2\rangle, \tag{124}$$

provided the functional (17)

$$H=\langle|\nabla\theta|^2\rangle+\langle(2\tau'-a)w\theta\rangle+\frac{a}{R}\langle|\nabla\mathbf{u}|^2\rangle \tag{125}$$

is positive semidefinite among divergence free velocity fields satisfying Eq. (123) and no-slip boundary conditions at $z=0,1$, and temperature fields $\theta(x,y,z,t)$ vanishing at $z=0,1$. The constraint on the background field $\tau(z)$ is the same: $\tau(0)=\tau(1)=0$.

It is convenient to find the sufficient conditions for the non-negativity of H in its Fourier series representation $H=\Sigma_{\mathbf{k}}H_{\mathbf{k}}$, where

$$H_{\mathbf{k}}\{\theta_{\mathbf{k}}\}=\int_0^1\left[|D\theta_{\mathbf{k}}|^2+k^2|\theta_{\mathbf{k}}|^2+\left(\tau'-\frac{a}{2}\right)(w_{\mathbf{k}}^*\theta_{\mathbf{k}}+w_{\mathbf{k}}\theta_{\mathbf{k}}^*)+\frac{a}{R}\left(\frac{1}{k^2}|D^2w_{\mathbf{k}}|^2+2|Dw_{\mathbf{k}}|^2\right.\right.$$
$$\left.\left.+k^2|w_{\mathbf{k}}|^2\right)\right]dz, \tag{126}$$

where $w_{\mathbf{k}}(z)$ and $\theta_{\mathbf{k}}(z)$ are the Fourier components of w and θ corresponding to wave number $\mathbf{k}$, satisfying

$$(-D^2+k^2)^2w_{\mathbf{k}}=Rk^2\theta_{\mathbf{k}}. \tag{127}$$

Then $H\geqslant 0$ iff each $H_{\mathbf{k}}$ is positive semidefinite for complex valued functions $\theta_{\mathbf{k}}$ of a single (real) variable z where $w_{\mathbf{k}}$ solves the fourth-order linear boundary value problem above with both homogeneous Dirichlet and Neumann boundary conditions on $[0,1]$.

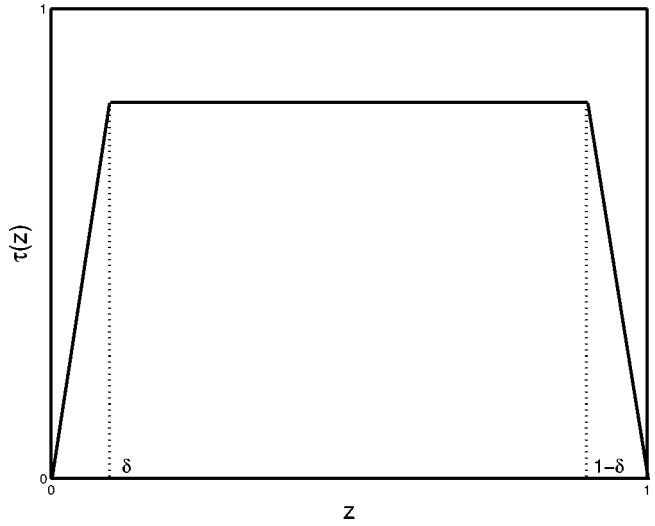

FIG. 3. The background profile for infinite Prandtl number.

We need to choose the background field $\tau(z)$ before we can estimate the magnitude of $H_{\mathbf{k}}$. Since the expressions for the lower bound (18) and the functional H (17) have the same forms as in the finite Pr case, we can choose the same background profile (19). And consequently, after maximizing the bound over a and b, we arrive at the same expression (21):

$$\langle T\rangle \geqslant \tfrac{1}{4}(1-\delta_1)(1-\delta_2)(\delta_1+\delta_2). \tag{128}$$

This expression is invariant if we exchange δ_1 and δ_2, and the estimate (132) is pointwise. This suggests that the maximum of the right-hand side of (21) occurs when $\delta_1=\delta_2=\delta$. And then

$$\begin{cases} a=0\,, \\ b=\dfrac{\delta(1-\delta)}{2} \end{cases} \tag{129}$$

by Eq. (22). The background profile becomes

$$\tau(z)=\begin{cases} \dfrac{1-\delta}{2}z\,, & 0\leqslant z<\delta, \\ \dfrac{\delta(1-\delta)}{2}, & 1-\delta\leqslant z\leqslant 1-\delta, \\ \dfrac{1-\delta}{2}(1-z)\,, & 1-\delta\leqslant z\leqslant 1, \end{cases} \tag{130}$$

and the bound is

$$\langle T\rangle \geqslant \frac{\delta(1-\delta)^2}{2} \tag{131}$$

as long as δ is chosen to ensure H is semipositive definite (see Fig. 3).

In the following we will use the inequality, proved in Ref. 10, for solutions of (127):

$$|w_{\mathbf{k}}| \leqslant \frac{1}{2} z^2 \frac{R}{\sqrt{C}} k \|\theta_{\mathbf{k}}\| \tag{132}$$

for $z \in [0, \frac{1}{2}]$, where $C = \frac{1}{2}(7 - \sqrt{41})$. (A similar estimate holds on the other end of the unit interval.) Applying this estimate, we have

$$\begin{aligned}
&\left| \int_0^1 \left(\tau' - \frac{a}{2} \right) (w_{\mathbf{k}}^* \theta_{\mathbf{k}} + w_{\mathbf{k}} \theta_{\mathbf{k}}^*) dz \right| \\
&= \left| \int_0^1 \tau' (w_{\mathbf{k}}^* \theta_{\mathbf{k}} + w_{\mathbf{k}} \theta_{\mathbf{k}}^*) dz \right| \\
&\leqslant 2 \frac{1-\delta}{2} \int_0^{\delta} |w_{\mathbf{k}}| |\theta_{\mathbf{k}}| dz + 2 \frac{1-\delta}{2} \int_{1-\delta}^1 |w_{\mathbf{k}}| |\theta_{\mathbf{k}}| dz \\
&\leqslant (1-\delta) \int_0^{\delta} \frac{1}{2} z^2 \left(\frac{R}{\sqrt{C}} k \|\theta_{\mathbf{k}}\| \right) \sqrt{z \int_0^{1/2} |D\theta_{\mathbf{k}}(z')|^2 dz'} dz + (1-\delta) \int_{1-\delta}^1 \frac{1}{2} (1-z)^2 \\
&\quad \times \left(\frac{R}{\sqrt{C}} k \|\theta_{\mathbf{k}}\| \right) \times \sqrt{(1-z) \int_{1/2}^1 |D\theta_{\mathbf{k}}(z')|^2 dz'} dz \\
&\leqslant (1-\delta) \frac{R}{\sqrt{C}} k \|\theta_{\mathbf{k}}\| \frac{1}{7} \delta_1^{7/2} \sqrt{\int_0^{1/2} |D\theta_{\mathbf{k}}(z')|^2 dz'} \\
&\quad + (1-\delta) \frac{R}{\sqrt{C}} k \|\theta_{\mathbf{k}}\| \frac{1}{7} \delta_1^{7/2} \sqrt{\int_{1/2}^1 |D\theta_{\mathbf{k}}(z')|^2 dz'} \\
&\leqslant (1-\delta) \frac{R}{\sqrt{C}} \frac{\delta^{7/2}}{7} \frac{k}{2} \left(\frac{k \|\theta_{\mathbf{k}}\|^2}{\sqrt{2}} + \frac{\sqrt{2}}{k} \int_0^{1/2} |D\theta_{\mathbf{k}}(z')|^2 dz' \right) \\
&\quad + (1-\delta) \frac{R}{\sqrt{C}} \frac{\delta^{7/2}}{7} \frac{k}{2} \left(\frac{k \|\theta_{\mathbf{k}}\|^2}{\sqrt{2}} + \frac{\sqrt{2}}{k} \int_0^{1/2} |D\theta_{\mathbf{k}}(z')|^2 dz' \right) \\
&= (1-\delta) \frac{R}{\sqrt{C}} \frac{1}{7} \delta^{7/2} \frac{1}{\sqrt{2}} (k^2 \|\theta_{\mathbf{k}}\|^2 + \|D\theta_{\mathbf{k}}\|^2).
\end{aligned} \tag{133}$$

Then

$$H \geqslant k^2 \left(1 - \frac{(1-\delta)\delta^{7/2}}{7\sqrt{2}} \frac{R}{\sqrt{C}} \right) (k^2 \|\theta_{\mathbf{k}}\|^2 + \|D\theta_{\mathbf{k}}\|^2). \tag{134}$$

Choosing δ such that

$$\frac{(1-\delta)\delta^{7/2}}{14} \frac{R}{\sqrt{C}} = 1, \tag{135}$$

the non-negativity of H is ensured. Then as $R \to \infty$, $\delta \sim (7\sqrt{2C}/R)^{2/7}$ and thus

$$\langle T \rangle \geqslant \frac{1}{2} \delta = \frac{1}{2} \left(\frac{7\sqrt{2C}}{R} \right)^{2/7}. \tag{136}$$

VI. SUMMARY AND DISCUSSION

The preceeding sections we have proven that for the finite (or arbitrary) Prandtl number case, in nondimensional units,

$$\langle T\rangle \geqslant c_1 R^{-1/3}, \tag{137}$$

and for the infinite Prandtl number model,

$$\langle T\rangle \geqslant c_2 R^{-2/7}. \tag{138}$$

In dimensional units of temperature and heat flux these results are

$$\langle T\rangle \geqslant \tilde{c}_1 H^{2/3} \tag{139}$$

for arbitrary Pr (see Ref. 4 for a similar estimate in that case of an internally heated self-gravitating sphere), and

$$\langle T\rangle \geqslant \tilde{c}_2 H^{5/7} \tag{140}$$

for the infinite Pr.

Recent numerical experiments[18] on thermal convection with internal heating in a fluid layer with infinite Prandtl number suggest that

$$\langle T\rangle \propto R^{-0.234}. \tag{141}$$

The observed exponent 0.234 is smaller than the rigorous estimate derived here, $2/7 \approx 0.286$, but consistent with the bound. In the case of Rayleigh–Bénard convection, the methods employed here produce scaling (upper) bounds on the heat transport[1,9,10] that are also consistent—but not in total agreement—with observed high Rayleigh number scalings.

It is worthwhile to note that the ''optimal'' background profile that the analysis suggests (Fig. 1) is suggestive of the mean temperature profile one expects for the internal heating problem. That is, the buoyancy force driving the convection will concentrate the warmer fluid near the top of the layer. Interestingly, this is not the case for the infinite Pr problem where the ''optimal'' temperature background maintains the symmetry of the conduction solution. It remains an open problem to apply the multiple boundary layer analysis to the case of infinite Pr, as it has previously been applied for the case of Rayleigh–Bénard convection.[5] A full (numerical) solution of the optimal background variational problem, as has recently been accomplished for Rayleigh–Bénard convection with finite Prandtl number,[15] could improve the estimates further.

ACKNOWLEDGMENTS

This research was initiated while the authors were participants in the 2002 Geophysical Fluid Dynamics (GFD) Program at Woods Hole Oceanographic Institution. We are grateful to that staff and Fellows of the GFD program for helpful discussions. Two of us (L.L. and C.R.D.) thank Professor C. R. Lithgow-Bertelloni for her suggestions and encouragement. (Received 31 March 2004; published online 14 June 2004)

[DOI: 10.1063/1.1760847]

In the above paper, formulas (22) and (23), while correct for the S-wave, $\ell=0$, are not correct for higher waves. The correct formulas are as follows. In order to secure a bound state, we must match continuously the interior wave function for $r<R_0$, formula (21), to the exterior solution which vanishes at infinity, namely, $ar^{-\ell}$.[1] It follows that, in the right-hand side of our formula (22), $j'_{\ell,1}$, the first maximum of the radial Bessel function, must be replaced by the first solution x of

$$\frac{J'_{\ell+1/2}(x)}{J_{\ell+1/2}(x)}=-\frac{\ell+\frac{1}{2}}{x}. \tag{1}$$

As a consequence, the same modification must be made in the right-hand side of (23). As explained in Ref. 1, the solution x of formula (1) above is larger than $j'_{\ell,1}$, and is located between this value and the first zero, $j_{\ell,1}$, of $J_{\ell+1/2}(x)$. We would like to thank Dr. Fabian Brau, who brought the mistake to our attention.

(Received 23 March 2004; published online 14 June 2004)

[DOI: 10.1063/1.1763248]

Errors have propagated into several related/equivalent formulas in Ref. 1 as a consequence of one fundamental minus sign error:

(1) The right-hand sides of Eqs. (15a) and (15b) have been erroneously shown as copies of Eqs. (14a) and (14b). The correct form is

$$\mathrm{P}_{123}\sum_{i<j}^{3}\boldsymbol{\lambda}_i\cdot\boldsymbol{\lambda}_j=\frac{16}{9}+\frac{2}{3}\sum_{i<j}^{3}\boldsymbol{\lambda}_i\cdot\boldsymbol{\lambda}_j-\frac{1}{2}d^{abc}\boldsymbol{\lambda}_1^a\boldsymbol{\lambda}_2^b\boldsymbol{\lambda}_3^c-\frac{i}{2}f^{abc}\boldsymbol{\lambda}_1^a\boldsymbol{\lambda}_2^b\boldsymbol{\lambda}_3^c,$$

$$\mathrm{P}_{132}\sum_{i<j}^{3}\boldsymbol{\lambda}_i\cdot\boldsymbol{\lambda}_j=\frac{16}{9}+\frac{2}{3}\sum_{i<j}^{3}\boldsymbol{\lambda}_i\cdot\boldsymbol{\lambda}_j-\frac{1}{2}d^{abc}\boldsymbol{\lambda}_1^a\boldsymbol{\lambda}_2^b\boldsymbol{\lambda}_3^c+\frac{1}{2}if^{abc}\boldsymbol{\lambda}_1^a\boldsymbol{\lambda}_2^b\boldsymbol{\lambda}_3^c.$$

(2) The second row, fourth column entries in the SU(3) crossing matrices C, Eq. (17) and C^2, Eq. (18) should switch signs, i.e., $\pm 1/2\rightarrow\mp 1/2$, or explicitly

$$\mathbf{C}=\begin{pmatrix}\frac{1}{9} & \frac{1}{6} & \frac{1}{4} & \frac{1}{4}\\ \frac{16}{9} & \frac{2}{3} & -\frac{1}{2} & -\frac{1}{2}\\ \frac{80}{81} & -\frac{5}{27} & \frac{13}{18} & -\frac{5}{18}\\ -\frac{16}{9} & \frac{1}{3} & \frac{1}{2} & -\frac{1}{2}\end{pmatrix},$$

$$\mathbf{C}^2=\begin{pmatrix}\frac{1}{9} & \frac{1}{6} & \frac{1}{4} & -\frac{1}{4}\\ \frac{16}{9} & \frac{2}{3} & -\frac{1}{2} & \frac{1}{2}\\ \frac{80}{81} & -\frac{5}{27} & \frac{13}{18} & \frac{5}{18}\\ \frac{16}{9} & -\frac{1}{3} & -\frac{1}{2} & -\frac{1}{2}\end{pmatrix}.$$

(3) Moreover, Eqs. (20a), (20b) need to have the signs in their last terms changed, as follows:

$$\delta_{\alpha\delta}\boldsymbol{\lambda}_{\gamma\rho}\cdot\boldsymbol{\lambda}_{\sigma\beta}+\delta_{\gamma\rho}\boldsymbol{\lambda}_{\alpha\delta}\cdot\boldsymbol{\lambda}_{\sigma\beta}+\delta_{\sigma\beta}\boldsymbol{\lambda}_{\gamma\rho}\cdot\boldsymbol{\lambda}_{\alpha\delta}$$
$$=\frac{2}{3}(\delta_{\alpha\beta}\boldsymbol{\lambda}_{\gamma\delta}\cdot\boldsymbol{\lambda}_{\sigma\rho}+\delta_{\gamma\delta}\boldsymbol{\lambda}_{\alpha\beta}\cdot\boldsymbol{\lambda}_{\sigma\rho}+\delta_{\sigma\rho}\boldsymbol{\lambda}_{\gamma\delta}\cdot\boldsymbol{\lambda}_{\alpha\beta})+\frac{16}{9}\delta_{\alpha\beta}\delta_{\gamma\delta}\delta_{\sigma\rho}$$
$$-\frac{1}{2}d^{abc}\boldsymbol{\lambda}^{a}_{\alpha\beta}\boldsymbol{\lambda}^{b}_{\gamma\delta}\boldsymbol{\lambda}^{c}_{\sigma\rho}-\frac{1}{2}if^{abc}\boldsymbol{\lambda}^{a}_{\alpha\beta}\boldsymbol{\lambda}^{b}_{\gamma\delta}\boldsymbol{\lambda}^{c}_{\sigma\rho},$$

$$\delta_{\alpha\rho}\boldsymbol{\lambda}_{\gamma\beta}\cdot\boldsymbol{\lambda}_{\sigma\delta}+\delta_{\gamma\beta}\boldsymbol{\lambda}_{\alpha\rho}\cdot\boldsymbol{\lambda}_{\sigma\delta}+\delta_{\sigma\beta}\boldsymbol{\lambda}_{\gamma\rho}\cdot\boldsymbol{\lambda}_{\alpha\delta}$$
$$=\frac{2}{3}(\delta_{\alpha\beta}\boldsymbol{\lambda}_{\gamma\delta}\cdot\boldsymbol{\lambda}_{\sigma\rho}+\delta_{\gamma\delta}\boldsymbol{\lambda}_{\alpha\beta}\cdot\boldsymbol{\lambda}_{\sigma\rho}+\delta_{\sigma\rho}\boldsymbol{\lambda}_{\gamma\delta}\cdot\boldsymbol{\lambda}_{\alpha\beta})+\frac{16}{9}\delta_{\alpha\beta}\delta_{\gamma\delta}\delta_{\sigma\rho}$$
$$-\frac{1}{2}d^{abc}\boldsymbol{\lambda}^{a}_{\alpha\beta}\boldsymbol{\lambda}^{b}_{\gamma\delta}\boldsymbol{\lambda}^{c}_{\sigma\rho}+\frac{1}{2}if^{abc}\boldsymbol{\lambda}^{a}_{\alpha\beta}\boldsymbol{\lambda}^{b}_{\gamma\delta}\boldsymbol{\lambda}^{c}_{\sigma\rho}.$$

All other results, as well as the conclusions of the paper remain unchanged.

Symmetry operators for Riemann's method

Peter J. Zeitsch
School of Mathematics and Statistics, University of Sydney, NSW 2006, Sydney, Australia

(Received 26 January 2004; accepted 13 April 2004;
published online 25 June 2004)

Riemann's method is one of the definitive ways of solving Cauchy's problem for a second order linear hyperbolic partial differential equation in 2 variables. Chaundy's equation, with 4 parameters, is the most general self-adjoint equation for which the Riemann function is known. Here we show that Chaundy's equation possesses a two-dimensional vector space of second-order symmetry operators. Hence a new equivalence class of Riemann functions, admitting no first-order symmetries and obtainable only via a higher order symmetry, is found. A new 5 parameter Riemann function is then subsequently derived. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1763003]

I. INTRODUCTION

The most general self-adjoint partial differential equation (PDE) for which the Riemann function is known is that derived by Chaundy,[1]

$$U_{rs}+\left[\frac{m_1(1-m_1)}{(r+s)^2}-\frac{m_2(1-m_2)}{(r-s)^2}+\frac{m_3(1-m_3)}{(1-rs)^2}-\frac{m_4(1-m_4)}{(1+rs)^2}\right]U=0, \tag{1}$$

where $m_1,\ldots,m_4$ are real valued constants. For this equation the Riemann function, $R(r,s,r_0,s_0)$, is given by

$$R(r,s,r_0,s_0)=F_B(m_1,m_2,m_3,m_4,1-m_1,1-m_2,1-m_3,1-m_4,1,z_1,z_2,z_3,z_4), \tag{2}$$

where

$$z_1=-\frac{(r-r_0)(s-s_0)}{(r+s)(r_0+s_0)}, \quad z_2=\frac{(r-r_0)(s-s_0)}{(r-s)(r_0-s_0)}, \tag{3}$$

$$z_3=-\frac{(r-r_0)(s-s_0)}{(1-rs)(1-r_0s_0)}, \quad z_4=\frac{(r-r_0)(s-s_0)}{(1+rs)(1+r_0s_0)}, \tag{4}$$

and F_B is a Lauricella hypergeometric function of four variables.[2] Recall that for a self-adjoint equation such as (1), the Riemann function must satisfy[3]

$$\begin{gathered} L[R]=0, \\ \frac{\partial R}{\partial r}=0 \quad \text{on} \quad s=s_0, \\ \frac{\partial R}{\partial s}=0 \quad \text{on} \quad r=r_0, \\ R(r_0,s_0,r_0,s_0)=1. \end{gathered} \tag{5}$$

When $m_1(1-m_1)=m_3(1-m_3)=m_4(1-m_4)=0$, Chaundy's PDE simplifies to the Euler–Poisson–Darboux (EPD) equation which is the original problem solved by Riemann. For the EPD equation, the Riemann function F_B reduces to the standard hypergeometric function

$$R(r,s,r_0,s_0)={}_2F_1(m_2,1-m_2,1,z_2). \tag{6}$$

It is well known[4,5] that the EPD equation possesses a three-dimensional Lie algebra of first-order symmetry operators isomorphic to sl(2,R). From standard results in Lie theory,[5] the group SL(2,R) acts locally on the solution space of the EPD equation by

$$U(r,s)\to U\left(\frac{\alpha r+\beta}{\gamma r+\delta},\frac{\alpha s+\beta}{\gamma s+\delta}\right),\quad \begin{pmatrix}\alpha & \beta\\ \gamma & \delta\end{pmatrix}\in \mathrm{SL}(2,R). \tag{7}$$

Using (7), it is straightforward to show that the Riemann function for the EPD equation can be represented in terms of the hypergeoemtric function (6). This was first shown by Bluman.[7] Subsequently Daggit[8] and Ibragimov[9] extended this concept to more general problems. They considered a generic PDE, to which they could impose restrictions on the coefficients, so that a symmetry algebra isomorphic to sl(2,R) was obtained for the reduced equations. This led to invertible mappings from the candidate equations to the EPD equation, likewise for the solutions. In this way an extensive equivalence class of Riemann functions was derived. Apart from confluent contractions such as the Telegrapher's equation,[10] the EPD equation is the only PDE for which this approach has been shown to work.

A few calculations reveal that (1) possesses no nontrivial first-order symmetry operators whatsoever. Hence the theory developed for sl(2,R) is not applicable to Chaundy's equation. However in this paper we show that if the symmetry operators are extended to second-order,[6] then Chaundy's full PDE in fact admits a two-dimensional vector space that leads to 4 inequivalent orbits. For each of these orbits there exists a separable coordinate system for (1). They constitute a new equivalence class of Riemann functions, admitting no first-order symmetries and obtainable only via higher order symmetries. Two of the separable forms of (1) are completely new while the other two generalize several Riemann functions already found in the literature.

In Sec. II, the symmetries for (1) are calculated. In Sec. III the corresponding separable coordinate systems and separable forms of Chaundy's equation are found. In Sec. IV a new 5 parameter Riemann function is derived by combining two of the separable forms of Chaundy's equation in an addition formula due to Olevskiĭ.[11] The five parameter Riemann function is important as it incorporates one more essential parameter than Chaundy's equation.

II. SYMMETRY CALCULATIONS

Standard techniques[6] exist in the literature for seeking separable forms of (1). Following Ref. 6 we define the second-order operator

$$S=f_1\partial_{rr}+f_2\partial_{ss}+f_3\partial_r+f_4\partial_s+f_5. \tag{8}$$

We say that (8) is a symmetry operator for (1) provided

$$[S,L]=QL, \tag{9}$$

where

$$L=\partial_{rs}+\left[\frac{m_1(1-m_1)}{(r+s)^2}-\frac{m_2(1-m_2)}{(r-s)^2}+\frac{m_3(1-m_3)}{(1-rs)^2}-\frac{m_4(1-m_4)}{(1+rs)^2}\right] \tag{10}$$

and

$$Q=h_1\partial_r+h_2\partial_s+h_3 \tag{11}$$

is a first-order differential operator (here Q may vary with S) and $f_1,\ldots,h_3$ are arbitrary functions of r and s. Evaluating (9) produces 10 equations for the unknown functions $f_1,\ldots,h_3$. The solution of these equations is long and involved.

When $m_1(1-m_1),\ldots,m_4(1-m_4)$ are all nonzero, solving (9) yields a two-dimensional vector space of operators. The symmetries, S_1 and S_2, form a basis and have differential part

$$S_1=(r^4+1)\partial_{rr}+(s^4+1)\partial_{ss}+2r^3\partial_r+2s^3\partial_s, \tag{12}$$

$$S_2=r^2\partial_{rr}+s^2\partial_{ss}+r\partial_r+s\partial_s. \tag{13}$$

Importantly, there are no first-order symmetries, which means that Chaundy's equation is Class II in the sense of Miller.[6]

The dimension of the vector space now varies depending on the pivots for the constants $m_1,\ldots,m_4$. However the only new case is that stated above, where $m_1(1-m_1),\ldots,m_4(1-m_4)$ are all nonzero. All other cases reduce to equations for which the symmetries are well documented. The pivots found during the calculation of (9) fall into two types

$$m_i(1-m_i)=0, \quad i=1,\ldots,4$$

and

$$m_i(1-m_i)=m_j(1-m_j), \quad i,j=1,\ldots,4; \quad i\neq j$$

or a combination of both. Letting any one of $m_1(1-m_1),\ldots,m_4(1-m_4)$ equal to zero does not increase the dimension of the vector space from two. The next possibility is when any two of $m_1(1-m_1),\ldots,m_4(1-m_4)$ equal zero. This leads to 6 possible equations. However as Chaundy pointed out,[1] if we apply the discrete group

$$(r,s)=(-R,S),$$

$$(r,s)=\left(\frac{1}{R},S\right), \tag{14}$$

$$(r,s)=\left(\frac{1-R}{1+R},\frac{1-S}{1+S}\right),$$

to (1), then the suffixes, (1,2,3,4) on the constants m, become (2,1,4,3), (4,3,2,1) or (3,2,1,4), respectively. Hence the 6 PDEs can all be mapped to the harmonic equation

$$U_{rs}+\left[\frac{m_1(1-m_1)}{(r+s)^2}-\frac{m_2(1-m_2)}{(r-s)^2}\right]U=0. \tag{15}$$

The Riemann function for (15) has been documented by Henrici.[12] More recently Iwasaki[10] solved (15) in terms of a system of F_4 functions.[2] The symmetries for (15) have been studied by Kalnins and Miller.[13] In effect the vector space is four-dimensional with 3 second order symmetries and 1 first order symmetry. For more detail, see Ref. 13.

The next pivot occurs when we let $m_1(1-m_1)=m_2(1-m_2)$ and $m_3(1-m_3)=m_4(1-m_4)$ (or any combination of two constants) in (1) to obtain

$$U_{rs}-4rs\left[\frac{m_1(1-m_1)}{(r^2-s^2)^2}-\frac{m_3(1-m_3)}{(1-r^2s^2)^2}\right]U=0.$$

As Chaundy pointed out, now make the change of variables $r=R^{1/2}$, $s=S^{1/2}$ which gives

$$U_{RS}-\left[\frac{m_1(1-m_1)}{(R-S)^2}-\frac{m_3(1-m_3)}{(1-RS)^2}\right]U=0.$$

Then applying the discrete group (14), we arrive at the Harmonic equation (15). Setting three constants equal to zero leads to the EPD equation in all cases under the action of the discrete group (14). As shown in Ref. 4 this leads to an eight-dimensional vector space, and nine inequivalent separable coordinate systems.

Hence we continue by focusing our attention on the new case when all constants are arbitrary: the two-dimensional vector space with symmetry operators (12) and (13).

III. THE SEPARABLE COORDINATE SYSTEMS

Taking a linear combination of the operators (12) and (13), there are then four inequivalent orbits namely,

- $S_1+2qS_2, \quad q>1,$
- $S_1+2S_2,$
- $S_1-2S_2,$
- $S_1+2qS_2, \quad q<-1,$

where q is a real valued constant. Alternatively consider S_2 by itself. In this case the discrete symmetry (14) maps S_2 to

$$S_2'=\frac{(R^2-1)^2}{4}\partial_{RR}+\frac{(S^2-1)^2}{4}\partial_{SS}+\frac{R(R^2-1)}{2}\partial_R+\frac{S(S^2-1)}{2}\partial_S,$$

which is equivalent to S_1-2S_2. Also this discrete symmetry maps the case when $-1<q<1$ to the case when $q>1$ above. Hence we may ignore these possibilities and conclude that, in total, there are 4 inequivalent orbits for the two symmetries S_1 and S_2. We are now in a position to calculate the separable coordinate systems and to analyze their effect on (1).

System 1: S_1+2qS_2, where $q>1$.

The separable coordinates are

$$r=b\frac{\mathrm{sn}[a(\xi+\eta)]}{\mathrm{cn}[a(\xi+\eta)]}, \quad s=b\frac{\mathrm{sn}[a(\xi-\eta)]}{\mathrm{cn}[a(\xi-\eta)]}, \tag{16}$$

where $2q=(1+b^4)/b^2$, $k^2=1-b^4$, $0<b<1$ and k is the modulus of the Jacobian elliptic functions.[14]

When (16) is substituted into (1) the following separable equation is found:

$$\begin{aligned}U_{\xi\xi}-U_{\eta\eta}+\Bigg\{a^2\Bigg[&m_1(1-m_1)\left(\frac{\mathrm{dn}^2 a\xi}{\mathrm{sn}^2 a\xi\,\mathrm{cn}^2 a\xi}-k^4\frac{\mathrm{sn}^2 a\eta\,\mathrm{cn}^2 a\eta}{\mathrm{dn}^2 a\eta}\right)\\&-m_2(1-m_2)\left(\frac{\mathrm{dn}^2 a\eta}{\mathrm{sn}^2 a\eta\,\mathrm{cn}^2 a\eta}-k^4\frac{\mathrm{sn}^2 a\xi\,\mathrm{cn}^2 a\xi}{\mathrm{dn}^2 a\xi}\right)\Bigg]\\&+4a^2b^2\Bigg[m_3(1-m_3)\left(\frac{\mathrm{dn}^2 a\xi}{(\mathrm{cn}^2 a\xi-b^2\mathrm{sn}^2 a\xi)^2}+\frac{\mathrm{dn}^2(a\eta)}{(\mathrm{cn}^2 a\eta+b^2\mathrm{sn}^2 a\eta)^2}-1\right)\\&-m_4(1-m_4)\left(\frac{\mathrm{dn}^2 a\xi}{(\mathrm{cn}^2 a\xi+b^2\mathrm{sn}^2 a\xi)^2}+\frac{\mathrm{dn}^2 a\eta}{(\mathrm{cn}^2 a\eta-b^2\mathrm{sn}^2 a\eta)^2}-1\right)\Bigg]\Bigg\}U=0.\end{aligned} \tag{17}$$

The Riemann function for (17) is obtained by substituting (16) into (3), (4) and (2). Hence

$$R(\xi,\eta,\xi_0,\eta_0)=F_B(m_1,m_2,m_3,m_4,1-m_1,1-m_2,1-m_3,1-m_4,1,z_{11},z_{12},z_{13},z_{14}), \quad (18)$$

where

$$z_5=\frac{(\mathrm{sn}\,a\,\eta\mathrm{cn}\,a\,\eta_0\mathrm{dn}\,a\,\xi_0-\mathrm{sn}\,a\,\eta_0\mathrm{cn}\,a\,\eta\mathrm{dn}\,a\,\xi)^2-(\mathrm{sn}\,a\,\xi\mathrm{cn}\,a\,\xi_0\mathrm{dn}\,a\,\eta_0-\mathrm{sn}\,a\,\xi_0\mathrm{cn}\,a\,\xi\mathrm{dn}\,a\,\eta)^2}{4\mathrm{sn}\,a\,\xi\,\mathrm{sn}\,a\,\xi_0\,\mathrm{cn}\,a\,\xi\,\mathrm{cn}\,a\,\xi_0\,\mathrm{dn}\,a\,\eta\,\mathrm{dn}\,a\,\eta_0},$$

$$z_6=\frac{(\mathrm{sn}\,a\,\xi\mathrm{cn}\,a\,\xi_0\mathrm{dn}\,a\,\eta_0-\mathrm{sn}\,a\,\xi_0\mathrm{cn}\,a\,\xi\mathrm{dn}\,a\,\eta)^2-(\mathrm{sn}\,a\,\eta\mathrm{cn}\,a\,\eta_0\mathrm{dn}\,a\,\xi_0-\mathrm{sn}\,a\,\eta_0\mathrm{cn}\,a\,\eta\mathrm{dn}\,a\,\xi)^2}{4\mathrm{sn}\,a\,\eta\,\mathrm{sn}\,a\,\eta_0\,\mathrm{cn}\,a\,\eta\,\mathrm{cn}\,a\,\eta_0\,\mathrm{dn}\,a\,\xi\,\mathrm{dn}\,a\,\xi_0},$$

$$z_7=b^2\frac{(\mathrm{sn}\,a\,\eta\mathrm{cn}\,a\,\eta_0\mathrm{dn}\,a\,\xi_0-\mathrm{sn}\,a\,\eta_0\mathrm{cn}\,a\,\eta\mathrm{dn}\,a\,\xi)^2-(\mathrm{sn}\,a\,\xi\mathrm{cn}\,a\,\xi_0\mathrm{dn}\,a\,\eta_0-\mathrm{sn}\,a\,\xi_0\mathrm{cn}\,a\,\xi\mathrm{dn}\,a\,\eta)^2}{(\mathrm{cn}^2a\,\xi-b^2\mathrm{sn}^2a\,\xi)(\mathrm{cn}^2\,a\,\eta+b^2\mathrm{sn}^2\,a\,\eta)(\mathrm{cn}^2a\,\xi_0-b^2\mathrm{sn}^2a\,\xi_0)(\mathrm{cn}^2\,a\,\eta_0+b^2\mathrm{sn}^2\,a\,\eta_0)},$$

$$z_8=b^2\frac{(\mathrm{sn}\,a\,\xi\mathrm{cn}\,a\,\xi_0\mathrm{dn}\,a\,\eta_0-\mathrm{sn}\,a\,\xi_0\mathrm{cn}\,a\,\xi\mathrm{dn}\,a\,\eta)^2-(\mathrm{sn}\,a\,\eta\mathrm{cn}\,a\,\eta_0\mathrm{dn}\,a\,\xi_0-\mathrm{sn}\,a\,\eta_0\mathrm{cn}\,a\,\eta\mathrm{dn}\,a\,\xi)^2}{(\mathrm{cn}^2a\,\xi+b^2\mathrm{sn}^2a\,\xi)(\mathrm{cn}^2\,a\,\eta-b^2\mathrm{sn}^2\,a\,\eta)(\mathrm{cn}^2a\,\xi_0+b^2\mathrm{sn}^2a\,\xi_0)(\mathrm{cn}^2\,a\,\eta_0-b^2\mathrm{sn}^2\,a\,\eta_0)}.$$

To the best of the author's knowledge, Chaundy's equation written as (17) and the associated Riemann function (18) have not previously been published, including subcases. They are completely new.

System 2: For the symmetry S_1+2S_2 we find the separable coordinate system

$$r=\tan\left[a\,\frac{(\xi+\eta)}{2}\right], \quad s=\tan\left[a\,\frac{(\xi-\eta)}{2}\right]. \quad (19)$$

Substituting (19) into (1) yields

$$U_{\xi\xi}-U_{\eta\eta}+a^2\left[\frac{m_1(1-m_1)}{\sin^2 a\,\xi}-\frac{m_2(1-m_2)}{\sin^2 a\,\eta}+\frac{m_3(1-m_3)}{\cos^2 a\,\xi}-\frac{m_4(1-m_4)}{\cos^2 a\,\eta}\right]U=0. \quad (20)$$

The Riemann function for (20) is then

$$R(\xi,\eta,\xi_0,\eta_0)=F_B(m_1,m_2,m_3,m_4,1-m_1,1-m_2,1-m_3,1-m_4,1,z_9,z_{10},z_{11},z_{12}), \quad (21)$$

where

$$z_9=\frac{\cos a(\xi-\xi_0)-\cos a(\eta-\eta_0)}{2\sin a\,\xi\sin a\,\xi_0}, \quad z_{10}=\frac{\cos a(\eta-\eta_0)-\cos a(\xi-\xi_0)}{2\sin a\,\eta\sin a\,\eta_0}, \quad (22)$$

$$z_{11}=\frac{\cos a(\xi-\xi_0)-\cos a(\eta-\eta_0)}{2\cos a\,\xi\cos a\,\xi_0}, \quad z_{12}=\frac{\cos a(\eta-\eta_0)-\cos a(\xi-\xi_0)}{2\cos a\,\eta\cos a\,\eta_0}. \quad (23)$$

System 3: For the symmetry S_1-2S_2 we find the separable coordinate system

$$r=\tanh\left[a\,\frac{(\xi+\eta)}{2}\right], \quad s=\tanh\left[a\,\frac{(\xi-\eta)}{2}\right]. \quad (24)$$

Substituting (24) into (1) yields

$$U_{\xi\xi}-U_{\eta\eta}+a^2\left[\frac{m_1(1-m_1)}{\sinh^2 a\,\xi}-\frac{m_2(1-m_2)}{\sinh^2 a\,\eta}+\frac{m_3(1-m_3)}{\cosh^2 a\,\eta}-\frac{m_4(1-m_4)}{\cosh^2 a\,\xi}\right]U=0. \quad (25)$$

The Riemann function for (25) is now

$$R(\xi,\eta,\xi_0,\eta_0)=F_B(m_1,m_2,m_3,m_4,1-m_1,1-m_2,1-m_3,1-m_4,1,z_{13},z_{14},z_{15},z_{16}), \quad (26)$$

where

$$z_{13}=\frac{\cosh a(\eta-\eta_0)-\cosh a(\xi-\xi_0)}{2\sinh a\xi\sinh a\xi_0},\quad z_{14}=\frac{\cosh a(\xi-\xi_0)-\cosh a(\eta-\eta_0)}{2\sinh a\eta\sinh a\eta_0},\tag{27}$$

$$z_{15}=\frac{\cosh a(\eta-\eta_0)-\cosh a(\xi-\xi_0)}{2\cosh a\eta\cosh a\eta_0},\quad z_{16}=\frac{\cosh a(\xi-\xi_0)-\cosh a(\eta-\eta_0)}{2\cosh a\xi\cosh a\xi_0}.\tag{28}$$

For (25) the Riemann function when $m_2(1-m_2)=m_3(1-m_3)=m_4(1-m_4)=0$ was first published by Cohn[15] but no connection to Chaundy or the EPD equation was made. The two parameter equation that results when $m_3(1-m_3)=m_4(1-m_4)=0$ was derived by Kalnins[13] although the focus was not on Riemann functions but rather separation of variables. The full equation (25) was first derived by Papadakis and Wood[16] but no connection to symmetry operators was made.

System 4: For the symmetry $S=S_1+2qS_2$, where $q<-1$ we find the separable coordinate system

$$r=b\,\mathrm{sn}\,a(\xi+\eta),\quad s=b\,\mathrm{sn}\,a(\xi-\eta),\tag{29}$$

where $k=b^2$, $2q=-(1+b^4)/b^2$, and $0<b<1$. As in system 1, a is arbitrary and k is the modulus of the elliptic functions. Substituting (29) into (1) yields

$$\begin{aligned}U_{\xi\xi}-U_{\eta\eta}+\Bigg\{a^2\Bigg[m_1(1-m_1)\Bigg(\frac{\mathrm{cn}^2a\xi\,\mathrm{dn}^2a\xi}{\mathrm{sn}^2a\xi}-(1-k^2)^2\frac{\mathrm{sn}^2a\eta}{\mathrm{cn}^2a\eta\,\mathrm{dn}^2a\eta}\Bigg)-m_2(1-m_2)\\ \times\Bigg(\frac{\mathrm{cn}^2a\eta\,\mathrm{dn}^2a\eta}{\mathrm{sn}^2a\eta}-(1-k^2)^2\frac{\mathrm{sn}^2a\xi}{\mathrm{cn}^2a\xi\mathrm{dn}^2a\xi}\Bigg)\Bigg]+4a^2b^2\Bigg[m_3(1-m_3)\Bigg(\frac{\mathrm{cn}^2a\xi\,\mathrm{dn}^2a\xi}{(1-b^2\mathrm{sn}^2a\xi)^2}\\ +\frac{\mathrm{cn}^2a\eta\,\mathrm{dn}^2a\eta}{(1+b^2\mathrm{sn}^2a\eta)^2}-1\Bigg)-m_4(1-m_4)\Bigg(\frac{\mathrm{cn}^2a\xi\,\mathrm{dn}^2a\xi}{(1+b^2\mathrm{sn}^2a\xi)^2}+\frac{\mathrm{cn}^2a\eta\,\mathrm{dn}^2a\eta}{(1-b^2\mathrm{sn}^2a\eta)^2}-1\Bigg)\Bigg]\Bigg\}U=0.\end{aligned}\tag{30}$$

The Riemann function for (30) is then

$$R(\xi,\eta,\xi_0,\eta_0)=F_B(m_1,m_2,m_3,m_4,1-m_1,1-m_2,1-m_3,1-m_4,1,z_{17},z_{18},z_{19},z_{20}),\tag{31}$$

where

$$z_{17}=\frac{(\mathrm{sn}\,a\eta\,\mathrm{cn}\,a\xi\,\mathrm{dn}\,a\xi_0-\mathrm{sn}\,a\eta_0\,\mathrm{cn}\,a\xi_0\,\mathrm{dn}\,a\xi)^2-(\mathrm{sn}\,a\xi\,\mathrm{cn}\,a\eta\,\mathrm{dn}\,a\eta_0-\mathrm{sn}\,a\xi_0\,\mathrm{cn}\,a\eta_0\,\mathrm{dn}\,a\eta)^2}{4\mathrm{sn}\,a\xi\,\mathrm{sn}\,a\xi_0\,\mathrm{cn}\,a\eta\,\mathrm{cn}\,a\eta_0\,\mathrm{dn}\,a\eta\,\mathrm{dn}\,a\eta_0},$$

$$z_{18}=\frac{(\mathrm{sn}\,a\xi\,\mathrm{cn}\,a\eta\,\mathrm{dn}\,a\eta_0-\mathrm{sn}\,a\xi_0\,\mathrm{cn}\,a\eta_0\,\mathrm{dn}\,a\eta)^2-(\mathrm{sn}\,a\eta\,\mathrm{cn}\,a\xi\,\mathrm{dn}\,a\xi_0-\mathrm{sn}\,a\eta_0\,\mathrm{cn}\,a\xi_0\,\mathrm{dn}\,a\xi)^2}{4\mathrm{sn}\,a\eta\,\mathrm{sn}\,a\eta_0\,\mathrm{cn}\,a\xi\,\mathrm{cn}\,a\xi_0\,\mathrm{dn}\,a\xi\,\mathrm{dn}\,a\xi_0},$$

$$z_{19}=b^2\frac{(\mathrm{sn}\,a\eta\,\mathrm{cn}\,a\xi\,\mathrm{dn}\,a\xi_0-\mathrm{sn}\,a\eta_0\,\mathrm{cn}\,a\xi_0\,\mathrm{dn}\,a\xi)^2-(\mathrm{sn}\,a\xi\,\mathrm{cn}\,a\eta\,\mathrm{dn}\,a\eta_0-\mathrm{sn}\,a\xi_0\,\mathrm{cn}\,a\eta_0\,\mathrm{dn}\,a\eta)^2}{(1-b^2\mathrm{sn}^2\,a\xi)(1+b^2\mathrm{sn}^2\,a\eta)(1-b^2\mathrm{sn}^2\,a\xi_0)(1+b^2\mathrm{sn}^2\,a\eta_0)},$$

$$z_{20}=b^2\frac{(\mathrm{sn}\,a\xi\,\mathrm{cn}\,a\eta\,\mathrm{dn}\,a\eta_0-\mathrm{sn}\,a\xi_0\,\mathrm{cn}\,a\eta_0\,\mathrm{dn}\,a\eta)^2-(\mathrm{sn}\,a\eta\,\mathrm{cn}\,a\xi\,\mathrm{dn}\,a\xi_0-\mathrm{sn}\,a\eta_0\,\mathrm{cn}\,a\xi_0\,\mathrm{dn}\,a\xi)^2}{(1+b^2\mathrm{sn}^2\,a\xi)(1-b^2\mathrm{sn}^2\,a\eta)(1+b^2\mathrm{sn}^2\,a\xi_0)(1-b^2\mathrm{sn}^2\,a\eta_0)}.$$

As for system 1, Chaundy's equation written as (30) is completely new. We have now established all possible separable coordinate systems for Chaundy's full equation.

IV. A FIVE PARAMETER RIEMANN FUNCTION

In Ref. 11 Olevskiĭ showed that the Riemann function $R_{\rho_1-\rho_2}$, for the equation

$$U_{yy}-U_{xx}+(\rho_1(y)-\rho_2(x))U=0, \tag{32}$$

can be given by

$$R_{\rho_1-\rho_2}(x,y,x_0,y_0)=R_{\rho_1}(x,y,x_0,y_0)+\int_{x-x_0}^{y-y_0}R_{\rho_1}(t,y,0,y_0)\frac{\partial}{\partial t}R_{\rho_2}(x,t,x_0,0)dt, \tag{33}$$

where R_{ρ_1} and R_{ρ_2} are the Riemann functions for

$$U_{yy}-U_{xx}+\rho_1(y)U=0$$

and

$$U_{yy}-U_{xx}-\rho_2(x)U=0.$$

Looking through the results from the previous section, (20) and (25) can both be applied to (33). First let $m_1(1-m_1)=m_3(1-m_3)=0$ and $a\to\lambda_1$ in (20) to obtain

$$U_{\xi\xi}-U_{\eta\eta}-\lambda_1^2\left[\frac{m_2(1-m_2)}{\sin^2\lambda_1\eta}+\frac{m_4(1-m_4)}{\cos^2\lambda_1\eta}\right]U=0, \tag{34}$$

which has the Riemann function

$$R_4(\xi,\eta,\xi_0,\eta_0)=F_3(m_2,m_4,1-m_2,1-m_4,1,z_{10},z_{12}), \tag{35}$$

where z_{10} and z_{12} are defined in (22) and (23). Analogously we can obtain

$$U_{\xi\xi}-U_{\eta\eta}+\lambda_2^2\left[\frac{m_1(1-m_1)}{\sinh^2\lambda_2\xi}-\frac{m_3(1-m_3)}{\cosh^2\lambda_2\xi}\right]U=0 \tag{36}$$

from the PDE (25). The Riemann function for (36) is

$$R_5(\xi,\eta,\xi_0,\eta_0)=F_3(m_1,m_3,1-m_1,1-m_3,1,z_{13},z_{16}), \tag{37}$$

where z_{13} and z_{16} were defined in (27) and (28).

Combining (34) and (36) in (33) we find that the Riemann function for the equation

$$U_{\xi\xi}-U_{\eta\eta}+\left[\lambda_2^2\left(\frac{m_1(1-m_1)}{\sinh^2\lambda_2\xi}-\frac{m_3(1-m_3)}{\cosh^2\lambda_2\xi}\right)-\lambda_1^2\left(\frac{m_2(1-m_2)}{\sin^2\lambda_1\eta}+\frac{m_4(1-m_4)}{\cos^2\lambda_1\eta}\right)\right]U=0 \tag{38}$$

is given by

$$\begin{aligned}R(\xi,\eta,\xi_0,\eta_0)=&F_3(m_2,m_4,1-m_2,1-m_4,1,z_{33},z_{34})\\&+\int_{\xi-\xi_0}^{\eta-\eta_0}F_3(m_2,m_4,1-m_2,1-m_4,1,u_1(t),u_2(t))\\&\times\frac{\partial}{\partial t}F_3(m_1,m_3,1-m_1,1-m_3,1,v_1(t),v_2(t))dt,\end{aligned} \tag{39}$$

where

$$u_1(t)=\frac{\cos\lambda_1(\eta-\eta_0)-\cos\lambda_1 t}{2\sin\lambda_1\eta\sin\lambda_1\eta_0},\quad u_2(t)=\frac{\cos\lambda_1(\eta-\eta_0)-\cos\lambda_1 t}{2\cos\lambda_1\eta\cos\lambda_1\eta_0}$$

$$v_1(t)=\frac{\cosh\lambda_2 t-\cosh\lambda_2(\xi-\xi_0)}{2\sinh\lambda_2\xi\sinh\lambda_2\xi_0},\quad v_2(t)=\frac{\cosh\lambda_2(\xi-\xi_0)-\cosh\lambda_2 t}{2\cosh\lambda_2\xi\cosh\lambda_2\xi_0}.$$

The ratio λ_1/λ_2 is essential in (38). It is possible to transform away either λ_1 or λ_2 via a change of variables, but not both. It is useful to write the equation as (38) though, which at first glance incorporates six parameters, as the equation is then symmetric. Effectively a five parameter Riemann function has been obtained. Equation (38) contains one more essential parameter than Chaundy's equation (1). There is strong evidence to suggest that (38) is not isomorphic to Chaundy's equation (1). There are several reasons for this. First (38) possesses no nontrivial first-order symmetries and repeating the calculations of Sec. II shows that it has no second-order symmetry operators either. So combining (34) and (36) in the addition formula destroys the symmetries found in Sec. II. Of course this does not rule out the possibility of a contact, or other type of transformation, between (1) and (38) but the author believes that this is unlikely. Secondly, during the course of analyzing Chaundy's equation the unusual fact that the independent variables $z_1,\ldots,z_4$ of (1) are linearly dependent was discovered. In fact a few calculations will show that

$$\frac{1}{z_1}+\frac{1}{z_2}+\frac{1}{z_3}+\frac{1}{z_4}=2,$$

where $z_1,\ldots,z_4$ are given by (3) and (4). If a parallel calculation is performed with the independent variables of (38), then this linear relationship is lost. Effectively

$$\frac{1}{z_9}+\frac{1}{z_{11}}+\frac{1}{z_{13}}+\frac{1}{z_{16}}\neq 2.$$

The loss of such a property adds further weight to the conjecture that the two equations are not isomorphic.

Riemann functions and the group $E(1,1)$

Peter J. Zeitsch

(Received 26 January 2004; accepted 13 April 2004;
published online 25 June 2004)

Historically Lie algebras of first-order symmetry operators have proven to be a useful method for finding equivalence classes of Riemann functions. Here this idea is extended to higher order symmetries. The approach is to seek self-adjoint linear hyperbolic partial differential equations that separate variables in more than one coordinate system under the action of the group $E(1,1)$. The equations derived admit no nontrivial first-order operators and can only be obtained from second-order symmetry operators. Using this symmetry structure, a new equivalence class of Riemann functions can then be found. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1763002]

I. INTRODUCTION

The idea of applying first-order symmetry operators to Riemann's method has been well investigated.[1–6] The hyperbolic partial differential equation in two variables (PDE),

$$L[U]=U_{yy}-U_{xx}+a(x,y)U_y-b(x,y)U_x+c(x,y)U=0, \tag{1}$$

will admit a four-dimensional Lie algebra of first order symmetries if and only if the invariants

$$p=\frac{k}{h}, \quad q=\frac{\ln|h|_{yy-xx}}{h}, \tag{2}$$

are constants (if $h=0$ then swap k and h). When p or q (or both of them) is not constant then the symmetry algebra is two-dimensional or less. Here h and k are Laplace invariants of (1),

$$h=\left(\frac{\partial}{\partial y}+\frac{\partial}{\partial x}\right)(a+b)+\frac{1}{2}(a^2-b^2)-c, \quad k=\left(\frac{\partial}{\partial y}-\frac{\partial}{\partial x}\right)(a-b)+\frac{1}{2}(a^2-b^2)-c.$$

When p and q are constant with $q\neq 0$, removing the trivial symmetry of scaling solutions by a constant yields a symmetry algebra isomorphic to sl(2,R). Using this fact, it is straightforward to show that an invertible transformation exists between (1) and the Euler–Poisson–Darboux equation (EPD),

$$U_{yy}-U_{xx}-\frac{m(1-m)}{x^2}U=0. \tag{3}$$

This is Riemann's original example.[7] Bluman[1] was the first to show how to explicitly calculate the Riemann function from the symmetry operators as

$$R(x,y,x_0,y_0)={}_2F_1(m,1-m;1;z_0), \tag{4}$$

where

$$z_0=\frac{(y-y_0)^2-(x-x_0)^2}{4xx_0}, \tag{5}$$

and ${}_2F_1$ is the hypergeometric function. The case when $q=0$ corresponds to confluent forms of the EPD equation. Recall that the Riemann function must satisfy (1) and

$$R_x+R_y=\tfrac{1}{2}(a+b)R \quad \text{on} \quad y-y_0=x-x_0, \tag{6}$$

$$R_x-R_y=-\tfrac{1}{2}(a-b)R \quad \text{on} \quad y-y_0=-(x-x_0), \tag{7}$$

$$R(x_0,y_0,x_0,y_0)=1. \tag{8}$$

In this paper we consider the self-adjoint form of (1),

$$U_{yy}-U_{xx}+V(x,y)U=0. \tag{9}$$

In direct analogy to the results for Lie algebras of first-order operators isomorphic to sl(2,R), the aim here is to derive Riemann functions for (9) by applying second-order linear symmetry operators. Effectively we shall seek restrictions on the coefficient $V(x,y)$ in (9) so that the Riemann function can be determined. In Ref. 8 a link between second-order symmetry operators and Riemann's method was established where it was shown that Chaundy's equation[9] admitted a two-dimensional vector space of second-order operators that lead to 4 inequivalent orbits. Chaundy's PDE is the most general self-adjoint equation for which the Riemann function is known. Each orbit corresponded to a separable coordinate system. In this way a new equivalence class of Riemann functions was found. So by carefully choosing the form of $V(x,y)$ in (9) a rich symmetry structure can be built. The goal is then to connect these resulting PDEs to their Riemann functions by using the properties of the symmetries.

Here we shall derive the separable forms of (9) under the action of the group $E(1,1)$. The group $E(1,1)$ is chosen as it is the symmetry group for the Laplace equation ($V(x,y)\equiv$const in (9)).[10] By seeking those equations that separate variables in more than one coordinate system, suitable restrictions on $V(x,y)$ can be determined so that vector spaces of second-order symmetry operators are obtained. Equation (9) will not admit $E(1,1)$ as a symmetry group but the pure differential parts of the second-order symmetry operators belong to the enveloping algebra of the Lie algebra $e(1,1)$ of first-order differential operators that commute with $L'=\partial_{yy}-\partial_{xx}$. The PDEs found are then candidate equations for which the Riemann function is sought. The trick is to identify the Riemann function in one of the candidate equations. In many cases this is possible by linking the proposed PDE to the separable forms of Chaundy's equation found in Ref. 8 and to other known results. In fact one case will prove to be a new confluent form of Chaundy's equation.[9]

Unlike earlier symmetry studies, the equations derived here admit no nontrivial first-order symmetry operators. They are obtainable only via second-order symmetries. In this way, we shall construct a new equivalence class of Riemann functions. The study is then a natural extension of the results already derived for first-order operators.

In Sec. II, the separable forms of (9) are found. Section III details the calculation of those equations that separate variables in more than 1 coordinate system. In Sec. IV the Riemann functions are found where possible. Section V summarizes the results.

II. DERIVATION OF THE SEPARABLE POTENTIALS

For the group $E(1,1)$, the inequivalent second-order symmetric operators and the associated separable coordinate systems were established by Kalnins.[10] Define $P_1=\partial_y$, $P_2=\partial_x$, and $M=x\partial_y+y\partial_x$, then the second-order symmetry operators have differential part

$$M^2, \quad P_1P_2, \quad \{M,P_1\}, \quad \{M,P_2\}, \quad \{M,P_1+P_2\}+(P_1-P_2)^2,$$

$$P_2^2, \quad M^2-P_1P_2, \quad M^2\pm(P_1+P_2)^2, \quad M^2\pm P_2^2,$$

$$(P_1+P_2)^2, \quad \{M,P_1-P_2\},$$

where $\{\alpha,\beta\}=\alpha\beta+\beta\alpha$. Standard techniques exist in the literature for calculating the separable forms of (9). Taking the first operator and following Winternitz[11] and Miller,[12] define

$$L=\partial_{yy}-\partial_{xx}+V(x,y), \tag{10}$$

$$S=M^2+f(x,y), \tag{11}$$

where $f(x,y)$ is an arbitrary function. S is a symmetry operator of (9) provided that

$$[L,S]=0. \tag{12}$$

In Ref. 11 the function $V(x,y)$ is called the potential function. So for historical reasons, we shall also use this nomenclature. The search for multiseparable potentials has been an active area of investigation now for nearly 40 years. Multiseparable systems, such as the ones sought here, are called superintegrable in the literature.[11,13–17]

For the symmetry M^2, solving (12) yields three equations

$$xy\frac{\partial V}{\partial y}+y^2\frac{\partial V}{\partial x}-\frac{\partial f}{\partial x}=0, \tag{13}$$

$$xy\frac{\partial V}{\partial x}+x^2\frac{\partial V}{\partial y}+\frac{\partial f}{\partial y}=0, \tag{14}$$

$$x^2\frac{\partial^2 V}{\partial y^2}+2xy\frac{\partial^2 V}{\partial x\partial y}+y^2\frac{\partial^2 V}{\partial x^2}+x\frac{\partial V}{\partial x}+y\frac{\partial V}{\partial y}+\frac{\partial^2 f}{\partial y^2}-\frac{\partial^2 f}{\partial x^2}=0. \tag{15}$$

Eliminating f from (13) and (14) produces a special case of the well-known Bertrand–Darboux equation

$$xy\left(\frac{\partial^2 V}{\partial y^2}+\frac{\partial^2 V}{\partial x^2}\right)+(y^2+x^2)\frac{\partial^2 V}{\partial y\partial x}+3y\frac{\partial V}{\partial x}+3x\frac{\partial V}{\partial x}=0. \tag{16}$$

Now make the change of variables

$$x=e^{\xi}\cosh\eta,$$

$$y=e^{\xi}\sinh\eta$$

in (16) which is in fact the separable coordinate system for the Laplace equation corresponding to the symmetry M^2.[10] Thus we obtain

$$V_{\xi\eta}+2V_{\eta}=0$$

which has the solution

$$V=\frac{V_1(\xi)+V_2(\eta)}{e^{2\xi}}$$

and

TABLE I. Separable potentials.

Symmetry	Separable coordinates	Potential
(A) P_1P_2, P_2^2, $(P_1+P_2)^2$	$x\ y$	$V_1(x)+V_2(y)$
(B) M^2	$x=e^{\xi}\cosh\eta$ $y=e^{\xi}\sinh\eta$	$\frac{V_1(\xi)+V_2(\eta)}{e^{2\xi}}$
(C) $\{M,P_1\}$, $\{M,P_2\}$	$x=\frac{1}{2}(\xi^2+\eta^2)$ $y=\xi\eta$	$\frac{V_1(\xi)+V_2(\eta)}{\eta^2-\xi^2}$
(D) $\{M,P_1+P_2\}+(P_1-P_2)^2$	$x=\frac{1}{2}(\xi-\eta)^2-(\xi+\eta)$ $y=\frac{1}{2}(\xi-\eta)^2+(\xi+\eta)$	$\frac{V_1(\xi)+V_2(\eta)}{\eta-\xi}$
(E) $M^2-P_1P_2$	$x=\frac{1}{2}\cosh\left(\frac{\xi-\eta}{2}\right)+\frac{1}{2}\sinh\left(\frac{\xi+\eta}{2}\right)$ $y=\frac{1}{2}\cosh\left(\frac{\xi-\eta}{2}\right)-\frac{1}{2}\sinh\left(\frac{\xi+\eta}{2}\right)$	$\frac{V_1(\xi)+V_2(\eta)}{\sinh\xi-\sinh\eta}$
(F) $M^2-(P_1+P_2)^2$	$x=\cosh(\xi-\eta)-e^{\xi+\eta}$ $y=\cosh(\xi-\eta)+e^{\xi+\eta}$	$\frac{V_1(\xi)+V_2(\eta)}{e^{2\xi}-e^{2\eta}}$
(G) $M^2+(P_1+P_2)^2$	$x=\sinh(\xi-\eta)-e^{\xi+\eta}$ $y=\sinh(\xi-\eta)+e^{\xi+\eta}$	$\frac{V_1(\xi)+V_2(\eta)}{e^{2\xi}+e^{2\eta}}$
(H) $M^2+P_2^2$	$x=\sinh\xi\cosh\eta$ $y=\cosh\xi\sinh\eta$	$\frac{V_1(\xi)+V_2(\eta)}{\sinh^2\xi+\cosh^2\eta}$
(I) $M^2-P_2^2$	$x=\sin\xi\sin\eta$ $y=\cos\xi\cos\eta$	$\frac{V_1(\xi)+V_2(\eta)}{\cos^2\eta-\cos^2\xi}$
	$x=\sinh\xi\sinh\eta$ $y=\cosh\xi\cosh\eta$	$\frac{V_1(\xi)+V_2(\eta)}{\cosh^2\xi-\cosh^2\eta}$
(J) $\{M,P_1-P_2\}$	No separable coordinates	No separable potential

$$S=M^2-V_2(\eta).$$

This is then the form of the separable potential for the symmetry M^2. The other cases are analogous and the results are summarized in Table I.

III. POTENTIALS WITH TWO OR MORE INVARIANTS

In order to obtain a separable potential with a corresponding known Riemann function, we seek separability in more than one coordinate system. The idea is then to identify the Riemann function for the equation in one of its different coordinate systems. First we shall consider those cases which separate variables in Cartesian and one other coordinate system. Hence start with the systems A and B.

A. Invariants A and B

We must find a potential which can be written in the form

$$V(x,y)=V_1(x)+V_2(y)=f(\xi)+\frac{g(\eta)}{e^{2\xi}}, \tag{17}$$

where $x=e^{\xi}\cosh\eta$, $y=e^{\xi}\sinh\eta$. From (17) it follows that

$$\frac{\partial^2}{\partial\xi\partial\eta}e^{2\xi}[V_1(e^{\xi}\cosh\eta)+V_2(e^{\xi}\sinh\eta)]=0,$$

which can be solved by separation of variables to obtain

$$V(x,y)=\alpha(y^2-x^2)+\frac{\beta_1}{y^2}+\frac{\beta_2}{x^2}, \tag{18}$$

where α is the separation constant and β_1 and β_2 are constants of integration. This leads to the following pair of equations:

$$U_{yy}-U_{xx}+\left[\alpha(y^2-x^2)+\frac{\beta_1}{y^2}+\frac{\beta_2}{x^2}\right]U=\lambda U, \tag{19}$$

$$U_{\xi\xi}-U_{\eta\eta}+\left[\alpha e^{4\xi}-\lambda e^{2\xi}+\frac{\beta_1}{\sinh^2\eta}+\frac{\beta_2}{\cosh^2\eta}\right]U=0. \tag{20}$$

Note that an extra constant λ has been introduced. This is because the group $E(1,1)$ guarantees Liouville-type potentials.[11]

The potential (18) also arises for other invariants as a similar calculation on systems A and H as well as A and I produces the same potential (18). Hence using the corresponding coordinate systems for each of these invariants, we find the following separable equations:

$$U_{\xi\xi}-U_{\eta\eta}+\left[\alpha(\cos^4\eta-\cos^4\xi-\cos^2\eta+\cos^2\xi)+\lambda(\cos^2\xi-\cos^2\eta)\right.$$
$$\left.+\beta_1\left(\frac{1}{\cos^2\xi}-\frac{1}{\cos^2\eta}\right)+\beta_2\left(\frac{1}{\sin^2\eta}-\frac{1}{\sin^2\xi}\right)\right]U=0, \tag{21}$$

$$U_{\xi\xi}-U_{\eta\eta}+\left[\alpha(\cosh^4\eta-\cosh^4\xi-\cosh^2\eta+\cosh^2\xi)\mp\lambda(\cosh^2\eta\pm\cosh^2\xi)\right.$$
$$\left.+\beta_1\left(\frac{1}{\cosh^2\xi}\pm\frac{1}{\cosh^2\eta}\right)+\beta_2\left(\frac{1}{\sinh^2\eta}\pm\frac{1}{\sinh^2\xi}\right)\right]U=0. \tag{22}$$

B. Invariants A and E

For the invariants A and E, we find the potential

$$V(x,y)=\alpha(y^2-x^2)+\beta.$$

Subsequent searches also produce this potential for the invariants A and F as well as G. This results in the equations

$$U_{yy}-U_{xx}+\alpha(y^2-x^2)U=\lambda U, \tag{23}$$

$$U_{\xi\xi}-U_{\eta\eta}+[\alpha(e^{4\xi}-e^{4\eta})-\lambda(e^{2\xi}\pm e^{2\eta})]U=0, \tag{24}$$

$$U_{\xi\xi}-U_{\eta\eta}+[\alpha(\sinh^2\xi-\sinh^2\eta)-\lambda(\sinh\xi-\sinh\eta)]U=0. \tag{25}$$

Equation (23) is clearly a subcase of (19). Thus any results obtained for the Riemann function of (19) will consequently encompass (23)–(25).

C. Invariants A and C

Here take

$$x = \tfrac{1}{2}(\xi^2 + \eta^2),$$

$$y = \xi\eta.$$

In this case a few calculations show that

$$V(x,y) = \alpha(4x^2 - y^2) + \beta x + \frac{\gamma}{y^2}. \tag{26}$$

So one obtains the two equations

$$U_{yy} - U_{xx} + \left[\alpha(4x^2 - y^2) + \beta x + \frac{\gamma}{y^2}\right]U = \lambda U, \tag{27}$$

$$U_{\xi\xi} - U_{\eta\eta} + \left[\alpha(\eta^6 - \xi^6) + \frac{\beta}{2}(\eta^4 - \xi^4) + \lambda(\eta^2 - \xi^2) + \gamma\left(\frac{1}{\xi^2} - \frac{1}{\eta^2}\right)\right]U = 0. \tag{28}$$

D. Invariants A and D

Here we try

$$x = \tfrac{1}{2}(\xi - \eta)^2 - (\xi + \eta),$$

$$y = \tfrac{1}{2}(\xi - \eta)^2 + (\xi + \eta).$$

This choice of coordinates results in the potential

$$V(x,y) = \alpha(y - x) + \beta.$$

Hence we obtain the two equations

$$U_{yy} - U_{xx} + \alpha(y - x)U = \lambda U, \tag{29}$$

$$U_{\xi\xi} - U_{\eta\eta} + [8\alpha(\xi^2 - \eta^2) - 4\lambda(\xi - \eta)]U = 0, \tag{30}$$

where the constant λ incorporates β.

E. Other combinations of invariants

The study of those potentials which separate variables in Cartesian and one other coordinate system is now complete. However direct calculation shows that other combinations of invariants do not yield new nontrivial potentials. To qualify this, consider the invariants B and C. They give

$$V(x,y) \equiv \frac{1}{\xi^2 - \eta^2}\left(\alpha + \frac{\beta_1}{\xi^2} + \frac{\beta_2}{\eta^2}\right),$$

or in other words, the two equations

$$U_{\phi\phi} - U_{rr} + \left[\frac{\alpha}{2}e^r + \frac{1}{4}\left(\frac{\beta_1}{\cosh^2(\phi/2)} + \frac{\beta_2}{\sinh^2(\phi/2)}\right)\right]U = \lambda e^{2r}U,$$

$$U_{\xi\xi}-U_{\eta\eta}+\left(\alpha+\lambda(\eta^2-\xi^2)+\frac{\beta_1}{\xi^2}+\frac{\beta_2}{\eta^2}\right)U=0.$$

Both of these equations have already been seen in this paper. This then exhausts the possibilities for the group $E(1,1)$.

IV. THE CORRESPONDING RIEMANN FUNCTIONS

In order to make the reference potentials of Sec. III useful, we must find the accompanying Riemann functions for each case. The key is that the nine coordinate systems of Table I are contained within the set of transformations, T, consisting of

$$x=\phi(\xi+\eta)+\psi(\xi-\eta),$$

$$y=\phi(\xi+\eta)-\psi(\xi-\eta),$$

where $\phi,\psi\in C^2$ are arbitrary functions, and ϕ',ψ' do not vanish. This is the general solution of the vibrating string equations

$$\frac{\partial\xi}{\partial y}=\frac{\partial\eta}{\partial x},\quad \frac{\partial\xi}{\partial x}=\frac{\partial\eta}{\partial y}.$$

Importantly the Riemann function $R(x,y,x_0,y_0)$ is conformally invariant under T.[18] This means that the conditions (6)–(8), which essentially define Riemann's method, remain consistent with respect to functional structures if the variables x,y are replaced by ξ, η. Hence if the Riemann function can be found for one of the equations corresponding to a given set of invariants, then the Riemann function for the remaining equations can simply be obtained by a transformation of variables.

All the equations found in Sec. III are of the form

$$U_{yy}-U_{xx}+[\rho_1(y)-\rho_2(x)]U=0. \tag{31}$$

Olevskiĭ[19] showed that the Riemann function, $R_{\rho_1-\rho_2}$ of (31) can be given by

$$R_{\rho_1-\rho_2}(x,y,x_0,y_0)=R_{\rho_1}(x,y,x_0,y_0)+\int_{y-y_0}^{x-x_0}R_{\rho_1}(x,t;x_0,0)\frac{\partial}{\partial t}R_{\rho_2}(t,y,0,y_0)dt, \tag{32}$$

where for instance R_{ρ_1} is the Riemann function for (31) with $\rho_2=0$. This addition formula greatly simplifies the task of finding the Riemann solution. Among the families of equations that we have generated it is simply a question of picking the right equation for which the Riemann function can most easily be identified in the literature.

A. Riemann function for the invariants A, B, H, and I

Of the equations (19)–(22) found in Sec. III A, the keys to finding the Riemann function are (19) and (20). Unfortunately though, the author must impose the restriction that either $\alpha=0$ or $\lambda=0$ in order to satisfy Riemann's method. To illustrate why this is the case take (20). For this equation, Olevskiĭ's addition formula means that instead of treating the whole equation it is only necessary to find the Riemann functions for

$$U_{\xi\xi}-U_{\eta\eta}+(\alpha e^{4\xi}-\lambda e^{2\xi})U=0 \tag{33}$$

and

$$U_{\xi\xi}-U_{\eta\eta}+\left[\frac{\beta_1}{\sinh^2\eta}+\frac{\beta_2}{\cosh^2\eta}\right]U=0. \tag{34}$$

The Riemann function for (34) is straightforward. In Ref. 8 the hyperbolic form of Chaundy's equation

$$U_{\xi\xi}-U_{\eta\eta}+\left[\frac{m_1(1-m_1)}{\sinh^2\xi}-\frac{m_2(1-m_2)}{\sinh^2\eta}+\frac{m_3(1-m_3)}{\cosh^2\eta}-\frac{m_4(1-m_4)}{\cosh^2\xi}\right]=0, \tag{35}$$

has the Riemann function

$$R(\xi,\eta,\xi_0,\eta_0)=F_B(m_1,m_2,m_3,m_4;1-m_1,1-m_2,1-m_3,1-m_4;1;z_1,z_2,z_3,z_4),$$

where

$$z_1=\frac{\cosh(\eta-\eta_0)-\cosh(\xi-\xi_0)}{2\sinh\xi\sinh\xi_0},\quad z_2=\frac{\cosh(\xi-\xi_0)-\cosh(\eta-\eta_0)}{2\sinh\eta\sinh\eta_0}, \tag{36}$$

$$z_3=\frac{\cosh(\eta-\eta_0)-\cosh(\xi-\xi_0)}{2\cosh\eta\cosh\eta_0},\quad z_4=\frac{\cosh(\xi-\xi_0)-\cosh(\eta-\eta_0)}{2\cosh\xi\cosh\xi_0}. \tag{37}$$

Setting $m_1=m_4=0$ and $\beta_1=-m_2(1-m_2)$, $\beta_2=m_3(1-m_3)$ reduces the solution to

$$R(\xi,\eta,\xi_0,\eta_0)=F_3(m_2,m_3;1-m_2,1-m_3;1,z_2,z_3),$$

which satisfies (34). Equation (33) is harder to deal with. Cohn[2] has shown how to find the Riemann function for (33) when either $\alpha=0$ or $\lambda=0$. However if both α and λ are nonzero the problem is much more difficult. The differing coefficients in the exponentials prevent the equation from being a confluent form of (35). Olevskiĭ's addition formula could be applicable here as Zhdanov, Revenko and Fushchych[20] have shown that (33) itself is separable. Unfortunately the other separable forms of the equation do not eliminate the differing coefficients. Furthermore Zhdanov *et al.* list (33) as one of the inequivalent separable forms of the equation $U_{yy}-U_{xx}+V(x)U=0$. Hence it is not easily transformable to any other PDE for which the Riemann solution is known. So in order to satisfy Riemann's method one must choose either α or λ to be zero.

If $\alpha=0$ the Riemann function for the whole equation (19) is then[21]

$$R(x,y,x_0,y_0)=F_B(m_1,1-m_1,m_2,1-m_2,1,z_5,z_6,z_7),$$

where $\beta_1=m_1(1-m_1)$, $\beta_2=-m_2(1-m_2)$ with

$$z_5=\frac{(x-x_0)^2-(y-y_0)^2}{4yy_0},\quad z_6=\frac{(y-y_0)^2-(x-x_0)^2}{4xx_0}, \tag{38}$$

and

$$z_7=\frac{\lambda}{4}[(x-x_0)^2-(y-y_0)^2]. \tag{39}$$

To further our analysis, consider the new option of taking $\lambda=0$. From Cohn,[2] the Riemann function for (33) with $\lambda=0$ is

$$R(\xi,\eta,\xi_0,\eta_0)=J_0(z_8),$$

where

$$z_8=\tfrac{1}{2}\sqrt{\alpha(e^{2(\xi+\eta)}-e^{2(\xi_0+\eta_0)})(e^{2(\xi-\eta)}-e^{2(\xi_0-\eta_0)})}.$$

Putting this all together, and using (32), the Riemann function for

$$U_{\xi\xi}-U_{\eta\eta}+\left[\alpha e^{4\xi}-\frac{m_1(1-m_1)}{\sinh^2\eta}+\frac{m_2(1-m_2)}{\cosh^2\eta}\right]U=0 \tag{40}$$

is given by

$$R(\xi,\eta,\xi_0,\eta_0)=J_0(z_8)+\int_{\eta-\eta_0}^{\xi-\xi_0}J_0[u_1(t)]dF_3[m_1,m_2,1-m_1,1-m_2,1,v_1(t),v_2(t)], \tag{41}$$

where

$$v_1(t)=\frac{\cosh(t)-\cosh(\eta-\eta_0)}{2\sinh\eta\sinh\eta_0},\quad v_2(t)=\frac{\cosh(\eta-\eta_0)-\cosh(t)}{2\cosh\eta\cosh\eta_0}, \tag{42}$$

$$u_1(t)=\tfrac{1}{2}\sqrt{\alpha(e^{2(\xi+t)}-e^{2(\xi_0)})(e^{2(\xi-t)}-e^{2(\xi_0)})}. \tag{43}$$

Rewriting the PDE (9) as

$$U_{\xi\xi}-U_{\eta\eta}+[V(\xi)-V(\eta)]U=0$$

we gain the following new potentials for which the Riemann function is now known:

$$V(\xi)=c_1\xi^2+\frac{c_2(1-c_2)}{\xi^2},$$

$$V(\xi)=c_1(\cos^4\xi-\cos^2\xi)+\frac{c_2(1-c_2)}{\cos^2\xi}-\frac{c_3(1-c_3)}{\sin^2\xi},$$

$$V(\xi)=c_1(\cosh^4\xi-\cosh^2\xi)+\frac{c_2(1-c_2)}{\cosh^2\xi}-\frac{c_3(1-c_3)}{\sinh^2\xi}.$$

A link to Chaundy's equation: A closer inspection of (40) shows that it is in fact a confluent form of Chaundy's equation[9]

$$U_{rs}+\left[\frac{m_1(1-m_1)}{(r+s)^2}-\frac{m_2(1-m_2)}{(r-s)^2}+\frac{m_3(1-m_3)}{(1-rs)^2}-\frac{m_4(1-m_4)}{(1+rs)^2}\right]U=0. \tag{44}$$

The Riemann function for this equation is

$$R(r,s,r_0,s_0)=F_B(m_1,m_2,m_3,m_4;1-m_1,1-m_2,1-m_3,1-m_4;1;z_9,z_{10},z_{11},z_{12}), \tag{45}$$

where

$$z_9=-\frac{(r-r_0)(s-s_0)}{(r+s)(r_0+s_0)},\quad z_{10}=\frac{(r-r_0)(s-s_0)}{(r-s)(r_0-s_0)}, \tag{46}$$

$$z_{11}=-\frac{(r-r_0)(s-s_0)}{(1-rs)(1-r_0s_0)},\quad z_{12}=\frac{(r-r_0)(s-s_0)}{(1+rs)(1+r_0s_0)}. \tag{47}$$

In Ref. 8 it was shown that there exists a second-order symmetry operator that maps (44) to (35), and likewise the Riemann solutions via the separable coordinate system $r=\exp(\xi+\eta)$, $s=\exp(\xi-\eta)$. So now choose the hyperbolic form (35) of Chaundy's equation and let $m_1(1-m_1)=m_4(1-m_4)=\alpha/2$ which may then be rewritten as

$$U_{\xi\xi}-U_{\eta\eta}+\left[\frac{\alpha}{\sinh^2 2\xi}-\frac{m_2(1-m_2)}{\sinh^2\eta}+\frac{m_3(1-m_3)}{\cosh^2\eta}\right]=0. \tag{48}$$

Translate the origin by setting

$$\xi\mapsto\xi-\nu,\quad \xi_0\mapsto\xi_0-\nu,\quad \alpha\mapsto\frac{\alpha}{4}e^{4\nu} \tag{49}$$

and take the limit as $\nu\to\infty$. This reduces (48) to (40).

In Ref. 8, Chaundy's equation was shown to possess a two-dimensional vector space of second-order symmetry operators. Hence the increased dimension of the vector space admitted by the confluent form (40) of Chaundy's equation is new.

B. Comments on the Riemann function for the invariants A, E, F, and G

As previously mentioned, the Riemann function (40) derived in Sec. IV A also includes the equations of Sec. III D. Unfortunately though, the restrictions placed on the coefficients α and λ imply that (23)–(25) are reduced to readily obtainable confluent forms of Chaundy's equation (44). To see this take (24), with $\alpha=0$, say. This produces the reference potential

$$V(\xi)=e^{4\xi}.$$

But the transformation (49) applied to both ξ and η in (35) yields (24) with either α or λ equal to zero depending on the scaling used. This potential has therefore already been discussed.

Similarly for (25), if $\lambda=0$, then no new potential is found. Letting $\alpha=0$ results in the potential

$$V(\xi)=\sinh\xi,$$

which is not among the potentials from Sec. IV A. However such an option is easily obtained from the Klein–Gordon or Telegrapher's equation, which is itself a confluent form of Chaundy's equation.[21] So the results for these invariants are included only for completeness. In order to obtain significant results from Sec. III D the Riemann function for the full equation (24) would need to be found. Unfortunately this remains an open problem.

C. Riemann function for the invariants A and C

For the two equations found in Sec. III C, the problem of finding the Riemann function when α, β, γ, and λ are all nonzero is quite difficult. The author has not had any success in this regard. However if we let $\alpha=0$, then the Riemann function can easily be obtained. So consider (27) with $\alpha=0$,

$$U_{yy}-U_{xx}+\left[\beta x+\frac{\gamma}{y^2}\right]U=\lambda U. \tag{50}$$

There are then two ways to separate variables in (50) as the constant λ may be grouped with either of the independent variables. Of the two options, take the equations

$$U_{yy}-U_{xx}+\left[\frac{\gamma(1-\gamma)}{y^2}-\lambda\right]U=0 \tag{51}$$

and

$$U_{yy}-U_{xx}+\beta xU=0. \tag{52}$$

Note that γ has been rescaled. From Ref. 21 the Riemann function for (51) is

$$R_1(x,y,x_0,y_0)=\Xi_2(\gamma,1-\gamma,1,z_5,z_7), \tag{53}$$

where z_5 is given by (38) and z_7 by (39).

On the other hand, in order to solve (52), the results of Wahlberg[22] are required who found that the Riemann function for

$$U_{yy}-U_{xx}+(1+\delta x)U=0 \tag{54}$$

can be represented by the contour integral

$$R(x,y,x_0,y_0)=\frac{1}{2\pi i}\int_\Gamma \exp\left\{\left[1+\frac{\delta}{2}(x+x_0)\right]z-\frac{(y-y_0)^2-(x-x_0)^2}{4z}-\frac{\delta^2}{12}z^3\right\}\frac{dz}{z},$$

where Γ is defined by $|z|=\rho$, encircling the origin in the positive direction (since the integrand is analytic everywhere except at $z=0$, Γ can be taken to be any closed contour encircling the origin in the positive direction).

Alternatively, as Wahlberg showed, expanding $\exp(-\delta^2z^3/12)$ of the integrand as a power series then applying the formula

$$J_n(\alpha)=\frac{1}{2\pi i}\int_\Gamma z^{-n-1}\exp\left[\frac{1}{2}\alpha\left(z-\frac{1}{z}\right)\right]dz$$

for the Bessel function of order n, gives

$$R(x,y,x_0,y_0)=\sum_{n=0}^{\infty}\frac{\Omega^n}{n!}J_{3n}(\Delta), \tag{55}$$

where

$$\Omega=\frac{\delta^2}{96}\left(\frac{(y-y_0)^2-(x-x_0)^2}{1+\frac{\delta}{2}(x+x_0)}\right)^{3/2}, \tag{56}$$

$$\Delta=\left\{\left[1+\frac{\delta}{2}(x+x_0)\right][(y-y_0)^2-(x-x_0)^2]\right\}^{1/2}. \tag{57}$$

By inspection, (52) is just (54) up to translation in x. Specifically if we let

$$x\mapsto x-\frac{1}{\delta},\quad x_0\mapsto x_0-\frac{1}{\delta},\quad \delta\mapsto\beta,$$

then (54) yields (52) as required. For the Riemann function, applying this same change of variables to (55) gives

$$R_2(x,y,x_0,y_0)=\sum_{n=0}^{\infty}\frac{\Omega_2^n}{n!}J_{3n}(\Delta_2), \tag{58}$$

where now

$$\Omega_2=\frac{\beta^2}{96}\left[\frac{(y-y_0)^2-(x-x_0)^2}{\frac{\beta}{2}(x+x_0)}\right]^{3/2}, \tag{59}$$

$$\Delta_2=\left\{\frac{\beta}{2}(x+x_0)[(y-y_0)^2-(x-x_0)^2]\right\}^{1/2}. \tag{60}$$

Applying Olevskiĭ's addition formula (32), the Riemann function for (50) is

$$R(x,y,x_0,y_0)=R_2(x,y,x_0,y_0)+\int_{y-y_0}^{x-x_0}R_2(x,t;x_0,0)\frac{\partial}{\partial t}R_1(t,y,0,y_0)dt, \tag{61}$$

where R_1 and R_2 are defined by (53)–(60). From (28) another new reference potential for (9) is then

$$V(\xi)=\frac{c_1}{2}\xi^4+c_2\xi^2+\frac{c_3(1-c_3)}{\xi^2}.$$

A quick calculation shows that (50) has a trivial first-order symmetry algebra. Hence (50) and (28) with $\alpha=0$ are not isomorphic to any other equations via a point transformation. Furthermore the second-order symmetries used here are inequivalent as are the equations they generate so we may also state that (50) and (28) are not transformable to any other equation via a second-order operator. Hence precluding the possibility of contact transformations we may conclude that the Riemann functions for these two equations are new.

D. Riemann function for the invariants A and D

For the two equations found in Sec. III D, the Riemann function is most easily found for (29). Applying Olevskiĭ's addition formula to (29) requires the Riemann functions for

$$U_{yy}-U_{xx}+\alpha xU=0 \tag{62}$$

and

$$U_{yy}-U_{xx}+(\alpha y-\lambda)U=0. \tag{63}$$

Equation (62) is just (52) with $\alpha=\beta$. Hence the Riemann function for (62) is (58)–(60) with $\alpha=\beta$. Similarly interchanging the roles of x and y and translating the origin by

$$y\mapsto y-\frac{1}{\delta}+\frac{\lambda}{\delta},\quad y_0\mapsto y_0-\frac{1}{\delta}+\frac{\lambda}{\delta},\quad \delta\mapsto-\alpha$$

transforms (54) into (63). Hence the Riemann function for this equation is

$$R_3(x,y,x_0,y_0)=\sum_{n=0}^{\infty}\frac{\Omega_3^n}{n!}J_{3n}(\Delta_3), \tag{64}$$

where

$$\Omega_3=\frac{\alpha^2}{96}\left[\frac{(y-y_0)^2-(x-x_0)^2}{\lambda+\frac{\alpha}{2}(y+y_0)}\right]^{3/2}, \tag{65}$$

$$\Delta_3=\left\{\left[\frac{\alpha}{2}(y+y_0)+\lambda\right][(y-y_0)^2-(x-x_0)^2]\right\}^{1/2}. \tag{66}$$

Now applying Olevskiĭ's addition formula (32), the Riemann function for (29) is

$$R(x,y,x_0,y_0)=R_2(x,y,x_0,y_0)+\int_{y-y_0}^{x-x_0}R_2(x,t;x_0,0)\frac{\partial}{\partial t}R_3(t,y,0,y_0)dt, \tag{67}$$

where R_2 and R_3 are given, respectively, by (58)–(60) with $\beta=\alpha$ and (64)–(66).

From (30) we obtain the potential

$$V(\xi)=c_1\xi^2+c_2\xi.$$

Applying similar arguments to the previous section, both (29) and (30) also represent new equations for which the Riemann function is now known.

V. SUMMARY

The aim of this paper was to develop a methodology for deriving equivalence classes of Riemann functions from second-order symmetry operators in an analogous way to the theory already in place for first-order symmetries. So let us collect together the results. For the PDE

$$U_{\xi\xi}-U_{\eta\eta}+[V(\xi)-V(\eta)]U=0$$

the following is a list of all potentials, $V(\xi)$, for which the Riemann function was found under the action of the group $E(1,1)$.

Case 1: $V(\xi)=c_1\xi^4/2+c_2\xi^2+c_3(1-c_3)/\xi^2$.

$$R(\xi,\eta,\xi_0,\eta_0)=R_2(\xi,\eta,\xi_0,\eta_0)+\int_{L_l}^{L_u}R_2\left[\frac{1}{2}(\xi^2+\eta^2),t,\frac{1}{2}(\xi_0^2+\eta_0^2),0\right]\frac{\partial}{\partial t}R_1(t,\xi\eta,0,\xi_0\eta_0)dt,$$

such that $L_l=\xi\eta-\xi_0\eta_0$, $L_u=\frac{1}{2}(\xi^2-\xi_0^2+\eta^2-\eta_0^2)$ and

$$R_1(t,\xi\eta,0,\xi_0\eta_0)=\Xi_2(c_3,1-c_3,1,u_1(t),u_2(t)),$$

where

$$u_1(t)=\frac{(t^2-\xi\eta-\xi_0\eta_0)^2}{4\xi\xi_0\eta\eta_0},\quad u_2(t)=\frac{c_2}{4}[t^2-(\xi\eta-\xi_0\eta_0)^2],$$

and

$$R_2(\xi,\eta,\xi_0,\eta_0)=\sum_{n=0}^{\infty}\frac{\Omega_2^n}{n!}J_{3n}(\Delta_2),$$

where

$$\Omega_2=\frac{\beta^2}{96}\left\{\frac{[(\eta+\eta_0)^2-(\xi+\xi_0)^2][(\xi-\xi_0)^2-(\eta-\eta_0)^2]}{\beta(\xi^2+\eta^2+\xi_0^2+\eta_0^2)}\right\}^{3/2},$$

$$\Delta_2=\left\{\frac{\beta}{8}(\xi^2+\eta^2+\xi_0^2+\eta_0^2)[(\eta+\eta_0)^2-(\xi+\xi_0)^2][(\xi-\xi_0)^2-(\eta-\eta_0)^2]\right\}^{1/2},$$

with

$$R_2\left[\frac{1}{2}(\xi^2+\eta^2),t,\frac{1}{2}(\xi_0^2+\eta_0^2),0\right]=\sum_{n=0}^{\infty}\frac{\Omega_2'^n(t)}{n!}J_{3n}(\Delta_2'(t)),$$

where

$$\Omega_2'=\frac{\beta^2}{96}\left\{\frac{4t^2-[(\xi^2-\xi_0^2)+(\eta^2-\eta_0^2)]^2}{\beta(\xi^2+\xi_0^2+\eta^2+\eta_0^2)}\right\}^{3/2},$$

$$\Delta_2'=\left\{\frac{\beta}{16}(\xi^2+\xi_0^2+\eta^2+\eta_0^2)[4t^2-[(\xi^2-\xi_0^2)+(\eta^2-\eta_0^2)]^2]\right\}^{1/2}.$$

Case 2: $V(\xi)=c_1\xi^2+c_2\xi$.

$$R(\xi,\eta,\xi_0,\eta_0)=R_2(\xi,\eta,\xi_0,\eta_0)+\int_{L_l}^{L_u}R_2\left[\frac{1}{2}(\xi-\eta)^2-(\xi+\eta),t,\frac{1}{2}(\xi_0-\eta_0)^2-(\xi_0+\eta_0),0\right]$$
$$\times\frac{\partial}{\partial t}R_3\left[t,\frac{1}{2}(\xi-\eta)^2+(\xi+\eta),0,\frac{1}{2}(\xi_0-\eta_0)^2+(\xi_0+\eta_0)\right]dt$$

such that $L_l=\frac{1}{2}[(\xi-\eta)^2-(\xi_0-\eta_0)^2]+(\xi-\xi_0)+(\eta-\eta_0)$, $L_u=\frac{1}{2}[(\xi-\eta)^2-(\xi_0-\eta_0)^2]-(\xi-\xi_0)-(\eta-\eta_0)$ and

$$R_2(\xi,\eta,\xi_0,\eta_0)=\sum_{n=0}^{\infty}\frac{\Omega_2^n}{n!}J_{3n}(\Delta_2),$$

where

$$\Omega_2=\frac{\beta^2}{96}\left\{\frac{4[(\xi+\xi_0)-(\eta+\eta_0)][(\xi-\xi_0)^2-(\eta-\eta_0)^2]}{\beta[[(\xi-\eta)^2+(\xi_0-\eta_0)^2]-2(\xi+\xi_0+\eta+\eta_0)]}\right\}^{3/2},$$

$$\Delta_2=\left\{\frac{\beta}{4}[(\xi-\eta)^2+(\xi_0-\eta_0)^2-2(\xi+\xi_0+\eta+\eta_0)]\right.$$
$$\left.\times[[(\xi+\xi_0)-(\eta+\eta_0)][(\xi-\xi_0)^2-(\eta-\eta_0)^2]]\right\}^{1/2},$$

as well as

$$R_2\left[\frac{1}{2}(\xi-\eta)^2-(\xi+\eta),t,\frac{1}{2}(\xi_0-\eta_0)^2-(\xi_0+\eta_0),0\right]=\sum_{n=0}^{\infty}\frac{\Omega_2'^n}{n!}J_{3n}(\Delta_2'),$$

where

$$\Omega_2'=\frac{\beta^2}{96}\left\{\frac{4t^2-[(\xi-\eta)^2-(\xi_0-\eta_0)^2-2(\xi-\xi_0+\eta-\eta_0)]^2}{\beta[(\xi-\eta)^2+(\xi_0-\eta_0)^2-2(\xi+\xi_0+\eta+\eta_0)]}\right\}^{3/2},$$

$$\Delta_2'=\left\{\frac{\beta}{16}[(\xi-\eta)^2+(\xi_0-\eta_0)^2-2(\xi+\xi_0+\eta+\eta_0)]\right.$$
$$\left.\times[4t^2-[(\xi-\eta)^2-(\xi_0-\eta_0)^2-2(\xi-\xi_0+\eta-\eta_0)]^2]\right\}^{1/2},$$

and

$$R_3\left[t,\frac{1}{2}(\xi-\eta)^2+(\xi+\eta),0,\frac{1}{2}(\xi_0-\eta_0)^2+(\xi_0+\eta_0)\right]=\sum_{n=0}^{\infty}\frac{\Omega_3'^n}{n!}J_{3n}(\Delta_3'),$$

where

$$\Omega_3'=\frac{\alpha^2}{96}\left\{\frac{[(\xi-\eta)^2-(\xi_0-\eta_0)^2+2(\xi-\xi_0+\eta-\eta_0)]^2-4t^2}{4\lambda+\alpha[(\xi-\eta)^2+(\xi_0-\eta_0)^2+2(\xi+\xi_0+\eta+\eta_0)]}\right\}^{3/2},$$

$$\Delta_3'=\frac{1}{16}\{[\alpha[(\xi-\eta)^2+(\xi_0-\eta_0)^2+2(\xi+\xi_0+\eta+\eta_0)]+4\lambda]$$
$$\times[[(\xi-\eta)^2-(\xi_0-\eta_0)^2-2(\xi-\xi_0+\eta-\eta_0)]^2-4t^2]\}^{1/2}.$$

Case 3: $V(\xi)=-c_1\cos^2\xi+c_2(1-c_2)/\cos^2\xi-c_3(1-c_3)/\sin^2\xi.$

$$R(\xi,\eta,\xi_0,\eta_0)=F_B(c_2,c_3,1-c_2,1-c_3;1;z_{13},z_{14},z_{15}),$$

where

$$z_{13}=\frac{[\cos(\eta+\eta_0)-\cos(\xi+\xi_0)][\cos(\xi-\xi_0)-\cos(\eta-\eta_0)]}{4\cos\xi\cos\eta\cos\xi_0\cos\eta_0},$$

$$z_{14}=\frac{[\cos(\eta+\eta_0)-\cos(\xi+\xi_0)][\cos(\eta-\eta_0)-\cos(\xi-\xi_0)]}{4\sin\xi\sin\eta\sin\xi_0\sin\eta_0},$$

$$z_{15}=\frac{c_1}{4}[\cos(\eta+\eta_0)-\cos(\xi+\xi_0)][\cos(\xi-\xi_0)-\cos(\eta-\eta_0)].$$

Case 4: $V(\xi)=-c_1\cosh^2\xi+c_2(1-c_2)/\cosh^2\xi-c_3(1-c_3)/\sinh^2\xi.$

$$R(\xi,\eta,\xi_0,\eta_0)=F_B(c_2,c_3,1-c_2,1-c_3;1;z_{16},z_{17},z_{18}),$$

where

$$z_{16}=\frac{[\cosh(\eta+\eta_0)-\cosh(\xi+\xi_0)][\cosh(\xi-\xi_0)-\cosh(\eta-\eta_0)]}{4\cosh\xi\cosh\eta\cosh\xi_0\cosh\eta_0},$$

$$z_{17}=\frac{[\cosh(\eta+\eta_0)-\cosh(\xi+\xi_0)][\cosh(\eta-\eta_0)-\cosh(\xi-\xi_0)]}{4\sinh\xi\sinh\eta\sinh\xi_0\sinh\eta_0},$$

$$z_{18}=\frac{c_1}{4}[\cosh(\eta+\eta_0)-\cosh(\xi+\xi_0)][\cosh(\xi-\xi_0)-\cosh(\eta-\eta_0)].$$

Case 5: $V(\xi)=c_1(\cos^4\xi-\cos^2\xi)+c_2(1-c_2)/\sin^2\xi-c_3(1-c_3)/\cos^2\xi.$

$$R(\xi,\eta,\xi_0,\eta_0)=R_4(\xi,\eta,\xi_0,\eta_0)+\int_{L_l}^{L_u}R_4\left[\frac{1}{2}\ln(\sin^2\eta-\cos^2\xi),t,\frac{1}{2}\ln(\sin^2\eta_0-\cos^2\xi_0),0\right]$$
$$\times\frac{\partial}{\partial t}R_5\left[t,\frac{1}{2}\ln\left(\frac{\tan\eta\tan\xi+1}{\tan\eta\tan\xi-1}\right),0,\frac{1}{2}\ln\left(\frac{\tan\eta_0\tan\xi_0+1}{\tan\eta_0\tan\xi_0-1}\right)\right]dt$$

with

$$L_l=\frac{1}{2}\ln\left[\frac{(\tan\eta\tan\xi+1)(\tan\eta_0\tan\xi_0-1)}{(\tan\eta\tan\xi-1)(\tan\eta_0\tan\xi_0+1)}\right],$$

$$L_u=\frac{1}{2}\ln\left(\frac{\sin^2\eta-\cos^2\xi}{\sin^2\eta_0-\cos^2\xi_0}\right)$$

and

$$R_4(\xi,\eta,\xi_0,\eta_0)=J_0(z_{19}),$$

$$R_4\left[\frac{1}{2}\ln(\sin^2\eta-\cos^2\xi),t,\frac{1}{2}\ln(\sin^2\eta_0-\cos^2\xi_0),0\right]=J_0(u_3(t)),$$

$$R_5\left[t,\frac{1}{2}\ln\left(\frac{\tan\eta\tan\xi+1}{\tan\eta\tan\xi-1}\right),0,\frac{1}{2}\ln\left(\frac{\tan\eta_0\tan\xi_0+1}{\tan\eta_0\tan\xi_0-1}\right)\right]=F_3(c_2,c_3,1-c_2,1-c_3,1,v_3(t),v_4(t)),$$

where

$$z_{19}=\frac{1}{2}\sqrt{c_1\left[(\sin^2\eta-\cos^2\xi)\left(\frac{\tan\eta\tan\xi+1}{\tan\eta\tan\xi-1}\right)-(\sin^2\eta_0-\cos^2\xi_0)\left(\frac{\tan\eta_0\tan\xi_0+1}{\tan\eta_0\tan\xi_0-1}\right)\right]}$$
$$\times\sqrt{\left[(\sin^2\eta-\cos^2\xi)\left(\frac{\tan\eta\tan\xi-1}{\tan\eta\tan\xi+1}\right)-(\sin^2\eta_0-\cos^2\xi_0)\left(\frac{\tan\eta_0\tan\xi_0-1}{\tan\eta_0\tan\xi_0+1}\right)\right]},$$

$$u_3(t)=\tfrac{1}{2}\sqrt{c_1[e^{2t}(\sin^2\eta-\cos^2\xi)-(\sin^2\eta_0-\cos^2\xi_0)]}$$
$$\times\sqrt{[e^{-2t}(\sin^2\eta-\cos^2\xi)-(\sin^2\eta_0-\cos^2\xi_0)]},$$

$$v_3(t)=(\sqrt{(\sin^2\xi-\cos^2\eta)(\sin^2\xi_0-\cos^2\eta_0)}\cosh t-\sin\xi\sin\xi_0\sin\eta\sin\eta_0$$
$$+\cos\xi\cos\xi_0\cos\eta\cos\eta_0)/2\cos\xi\cos\xi_0\cos\eta\cos\eta_0,$$

$$v_4(t)=(\sin\xi\sin\xi_0\sin\eta\sin\eta_0+\cos\xi\cos\xi_0\cos\eta\cos\eta_0$$
$$-\sqrt{(\sin^2\xi-\cos^2\eta)(\sin^2\xi_0-\cos^2\eta_0)}\cosh t)/2\sin\xi\sin\xi_0\sin\eta\sin\eta_0.$$

Case 6: $V(\xi)=c_1(\cosh^4\xi-\cosh^2\xi)+c_2(1-c_2)/\sinh^2\xi-c_3(1-c_3)/\cosh^2\xi.$

$$R(\xi,\eta,\xi_0,\eta_0)=R_6(\xi,\eta,\xi_0,\eta_0)+\int_{L_l}^{L_u}R_6\left[\frac{1}{2}\ln(\cosh^2\xi-\cosh^2\eta),t,\frac{1}{2}\ln(\cosh^2\xi_0-\cosh^2\eta_0),0\right]$$
$$\times\frac{\partial}{\partial t}R_7\left[t,\frac{1}{2}\ln\left(\frac{\tanh\xi+\tanh\eta}{\tanh\xi-\tanh\eta}\right),0,\frac{1}{2}\ln\left(\frac{\tanh\xi_0+\tanh\eta_0}{\tanh\xi_0-\tanh\eta_0}\right)\right]dt$$

with

$$L_l=\frac{1}{2}\ln\left[\frac{(\tanh\xi+\tanh\eta)(\tanh\xi_0-\tanh\eta_0)}{(\tanh\xi-\tanh\eta)(\tanh\xi_0+\tanh\eta_0)}\right],$$

$$L_u=\frac{1}{2}\ln\left(\frac{\cosh^2\xi-\cosh^2\eta}{\cosh^2\xi_0-\cosh^2\eta_0}\right)$$

and

$$R_6(\xi,\eta,\xi_0,\eta_0)=J_0(z_{20}),$$

$$R_6\left[\frac{1}{2}\ln(\cosh^2\xi-\cosh^2\eta),t,\frac{1}{2}\ln(\cosh^2\xi_0-\cosh^2\eta_0),0\right]=J_0(u_4(t)),$$

$$R_7\left[t,\frac{1}{2}\ln\left(\frac{\tanh\xi+\tanh\eta}{\tanh\xi-\tanh\eta}\right),0,\frac{1}{2}\ln\left(\frac{\tanh\xi_0+\tanh\eta_0}{\tanh\xi_0-\tanh\eta_0}\right)\right]=F_3(c_2,c_3,1-c_2,1-c_3,1,v_5(t),v_6(t)),$$

where

$$z_{20}=\frac{1}{2}\sqrt{c_1\left[(\cosh^2\xi-\cosh^2\eta)\left(\frac{\tanh\xi+\tanh\eta}{\tanh\xi-\tanh\eta}\right)-(\cosh^2\xi_0-\cosh^2\eta_0)\left(\frac{\tanh\xi_0+\tanh\eta_0}{\tanh\xi_0-\tanh\eta_0}\right)\right]}$$
$$\times\sqrt{\left[(\cosh^2\xi-\cosh^2\eta)\left(\frac{\tanh\xi-\tanh\eta}{\tanh\xi+\tanh\eta}\right)-(\cosh^2\xi_0-\cosh^2\eta_0)\left(\frac{\tanh\xi_0-\tanh\eta_0}{\tanh\xi_0+\tanh\eta_0}\right)\right]},$$

$$u_4(t)=\tfrac{1}{2}\sqrt{c_1[e^{2t}(\cosh^2\xi-\cosh^2\eta)-(\cosh^2\xi_0-\cosh^2\eta_0)]}$$
$$\times\sqrt{[e^{-2t}(\cosh^2\xi-\cosh^2\eta)-(\cosh^2\xi_0-\cosh^2\eta_0)]}$$

$$v_5(t)=(\sqrt{(\cosh^2\xi-\cosh^2\eta)(\cosh^2\xi_0-\cosh^2\eta_0)}\cosh t-\sinh\xi\sinh\xi_0\cosh\eta\cosh\eta_0$$
$$+\cosh\xi\cosh\xi_0\sinh\eta\sinh\eta_0)/2\cosh\xi\cosh\xi_0\sinh\eta\sinh\eta_0,$$

$$v_6(t)=(\sinh\xi\sinh\xi_0\cosh\eta\cosh\eta_0-\cosh\xi\cosh\xi_0\sinh\eta\sinh\eta_0$$
$$-\sqrt{(\cosh^2\xi-\cosh^2\eta)(\cosh^2\xi_0-\cosh^2\eta_0)}\cosh t)/2\sinh\xi\sinh\xi_0\cosh\eta\cosh\eta_0.$$

Case 7: $V(\xi)=(c_1\sinh\xi)/2$,

$$R(\xi,\eta,\xi_0,\eta_0)=J_0(z_{21}),$$

where

$$z_{21}=2\sqrt{c_1\left[\cosh\frac{(\xi-\xi_0)}{2}-\cosh\frac{(\eta-\eta_0)}{2}\right]\left[\cosh\frac{(\xi+\xi_0)}{2}-\cosh\frac{(\eta+\eta_0)}{2}\right]}.$$

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 45, NUMBER 8 AUGUST 2004

Invariant and group theoretical integrations over the U(n) group

S. Aubert[a] and C. S. Lam[b]
Department of Physics, McGill University, 3600 University Street, Montreal, QC, Canada H3A 2T8

(Received 10 December 2003; accepted 22 April 2004; published online 25 June 2004)

In a previous article, an ''invariant method'' to calculate monomial integrals over the U(n) group was introduced. In this paper, we study the more traditional group-theoretical method, and compare its strengths and weaknesses with those of the invariant method. As a result, we are able to introduce a ''hybrid method'' which combines the respective strengths of the other two methods. There are many examples in the paper illustrating how each of these methods works. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1765214]

I. INTRODUCTION

This article deals with the calculation of integrals of the form

$$\int (dU)\, U^*_{i_1 j_1} \cdots U^*_{i_p j_p} U_{k_1 l_1} \cdots U_{k_q l_q} \tag{1}$$

over the U(n) group, where (dU) is the invariant Haar measure normalized to $\int (dU) = 1$, and U_{ij} is a U(n) matrix element, with U^*_{ij} being its complex conjugate.

These integrals and their generating functions are useful in many areas of physics, including two-dimensional quantum gravity,[1] QCD, matrix models, and statistical and condensed-matter problems of various sorts.[2] They are also needed in the parton saturation problem at small Feynman-x.[3]

The integral (1) depends on the indices $I=\{i_1 \cdots i_p\}, J=\{j_1 \cdots j_p\}, K=\{k_1 \cdots k_q\}$, and $L=\{l_1 \cdots l_q\}$, so it will be denoted as $\langle IJ|KL\rangle$:

$$\langle IJ|KL\rangle = \int (dU)\, U^*_{IJ} U_{KL}\,, \tag{2}$$

where $U^*_{IJ} = \Pi_{a=1}^{p} U^*_{i_a j_a}$, and similarly for U_{KL}. Since the matrix elements commute, $U^*_{IJ} = U^*_{I_P J_P}$, where $I_P = \{i_{P(1)} \cdots i_{P(p)}\}$ is obtained from I by a permutation $P \in S_p$ of its p indices. Hence

$$\langle IJ|KL\rangle = \langle I_P J_P | K_T L_T\rangle \tag{3}$$

for any $P \in S_p$ and $T \in S_q$.

The integral is nonzero only when $p=q$, a number which will be referred to as the *degree* of the integral. Without loss of generality, it turns out that we may assume $K=I$ and L to be a permutation of J, namely, $L=J_Q$ for some $Q \in S_p$. The value of the integral depends on what the index sets I,J, and what the element Q are, so even for a given p, there are many distinct cases. The best way to distinguish them is to represent each integral by a diagram in a way to be explained in the next section.

[b]Electronic mail: lam@physics.mcgill.ca

Integral (1) has been computed using a graphical technique.[4] It can also be obtained using the Itzykson–Zuber formula[5] as a generating function, or directly from group theory[6] using the Frobenius formula.[7] We shall refer to this last method as the *group-theoretical method* (GTM). In the GTM, a general formula is available to compute (1). It involves a triple sum over an expression containing characters of the symmetric group S_p, as well as the dimensions of irreducible representations of S_p and of the unitary group $\mathrm{U}(n)$. One of the sums is taken over all the relevant irreducible representations, and the others are taken over the symmetry groups of the index sets I and J. These sums could be long and tedious for a large p, and for most symmetry groups.

A different way to calculate (1) was introduced in a recent paper.[8] This method relies only on the unitary nature of the matrix elements, and the invariance of the Haar measure. In particular, no knowledge of group theory is necessary. The invariance of the Haar measure, as well as the off-diagonal unitarity relation, are used to derive relations between integrals of the same degree. The diagonal unitarity relation connects integrals of degree p with ones of degree $p-1$. Through a chain of these relations, the desired integral is finally related to the basic integral of degree 0, which is $\int dU=1$. The desired integral is then solved from this chain of relations. We have called this method the *invariant method* (IM).

The purpose of this paper is to compare the pros and cons of the GTM with the IM. In order to do so we must first study and understand better the nature of the GTM. Armed with this comparison, we will be able to design a new *hybrid method* which combines the strengths of these two other methods.

The IM is reviewed in Sec. II. It is used to derive a new ''double-fan'' relation needed in the example for the hybrid method.

The GTM is reviewed and studied in Sec. III. It can be used to derive simple relations, but the relations derived in this way are nowhere as powerful as those derived with the IM. The group-theoretical formula can be used to calculate any integral, but generally that is tedious and has to be done integral by integral. However, for integrals whose two symmetry groups are disjoint, or one is contained in the other, systematics emerge to make the calculation simpler. Several of these ''orderly'' integrals are studied in Sec. III.

A comparison of the strengths and weaknesses of the two methods is to be found in Sec. IV. Armed with an understanding of their relative merits, we design a ''hybrid method'' in Sec. V to take advantage of their respective strengths. This method is illustrated by the calculation of a class of ''double-fan'' integrals. There are also four Appendixes showing details of various calculations.

II. THE INVARIANT METHOD (IM)

A. A brief review

The invariant method presented in a previous paper[8] can be used to calculate the integral (1). The method exploits the unitarity of the $\mathrm{U}(n)$ group elements,

$$\sum_{j=1}^{n} U_{ij}^{*}U_{lj}=\sum_{j=1}^{n} U_{ji}^{*}U_{jl}=\delta_{il}, \tag{4}$$

and the invariance of the Haar measure, in the form

$$\int (dU)\, f(U,U^{*})=\int (dU)\, f(U^{*},U)=\int (dU)\, f(U^{T},U^{*\,T})=\int (dU)\, f(VU,V^{*}U^{*})$$
$$=\int (dU)\, f(UV,U^{*}V^{*}), \tag{5}$$

for any function f and any $V\in \mathrm{U}(n)$.

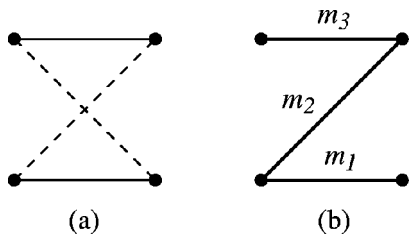

FIG. 1. Examples of U(n) integral diagrams. (a) The unique exchange integral for $p=2$; (b) a Z-integral with arbitrary multiplicities m_1, m_2, and m_3.

The unitarity relation (4) relates integrals of the same degree if $i \neq l$, and it relates integrals of degree p to integrals of degree $p-1$ if $i=l$. Other relations between integrals of the same degree can be obtained from (5), by suitable choices of V. Here are some of them discussed in the previous paper.[8]

(1) Using $V_{ij}=e^{i\phi}\delta_{ij}$, it follows that p must be equal to q in order to avoid the vanishing of integral (2). The number p will be called the *degree* of the integral.

(2) Using $V_{ij}=e^{i\phi_i}\delta_{ij}$, it follows that (2) is nonzero only when $K=I_M$ and $L=J_R$ for some $M,R\in S_p$. Using (3), and denoting RM^{-1} by Q, only integrals of the type

$$\langle IJ|IJ_Q\rangle=\int (dU)\, U^*_{IJ}\, U_{IJ_Q} \tag{6}$$

are nonzero, so from now on we need to consider only integrals of this type.

An integral with $J_Q=J$ will be called a *direct integral*. For such integrals we may always choose $Q=e$, the identity permutation. Otherwise, the integral is an *exchange integral*.

Integrals are represented diagrammatically as follows. Each distinct value in the index set I is represented by a dot on the left (L-dot), and each distinct value of the index set J or J_Q is represented by a dot on the right (R-dot). The factor U^*_{ij} is shown as a thin solid line between the L-dot i and the R-dot j, and the factor U_{ij} is shown as a dotted line between these two dots. The factor $U^*_{ij}U_{ij}$ is represented by a thick line, or more generally, the factor $U^{*m}_{ij}U^n_{ij}$ is represented by a thick line with a pair of numbers (m,n) written beside it. If $m=n$, then only a single number m is written. The numbers (m,n) or m will be known as the *multiplicities* of the line. See Fig. 1 for an illustration.

(3) With V chosen to be a permutation matrix of n objects, it follows that

$$\langle IJ|KL\rangle=\langle I'J|K'L\rangle=\langle IJ'|KL'\rangle,$$

where I' is obtained from I by a reassignment of the values of its indices, e.g., if $I=(334)$, then I' may be (558). K' is obtained from K by the *same* reassignment, and similarly for J' and L'. As a result, there is no need to know the values of the indices of the L-dots, nor the R-dots. This is why the dots in Fig. 1 are not labeled.

(4) As a consequence of the first two equalities in (5), an integral remains the same under the interchange of the solid lines with the dotted lines, or the L-dots with the R-dots.

(5) Using $V=R(ab)$, the rotation matrix in the (a,b) plane, a "spin-off relation" is obtained. Consider an R-dot imbedded in an arbitrary integral $M_0=\langle IJ|IJ_Q\rangle$, with d pairs of solid-dotted lines attached to the dot. Now spin off e pairs of these lines to create a new R-dot and a new integral. There are many ways to choose the e pair of lines, each possibly corresponds to a different integral. Let M_e be the sum of all these integrals. Then the quantities M_0 and M_e are related by the spin-off relation

$$M_e=M_0\binom{d}{e}, \tag{7}$$

where $\binom{e}{d}$ is the binomial coefficient. The relation is local in that it is independent of the structure of the rest of the diagram. The same relation can also be used to spin off an L-dot.

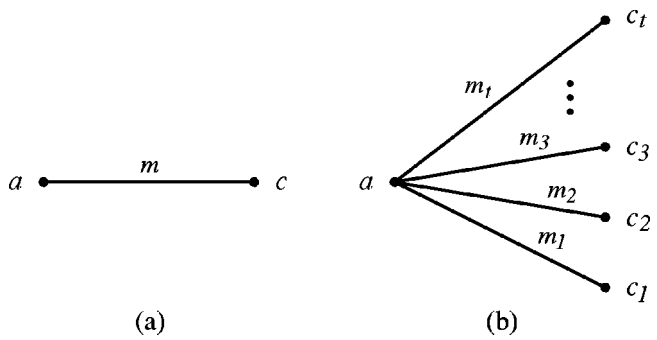

FIG. 2. The fan diagrams shown here can be a part of a larger diagram. In that case, there may be many more dots and many more lines in the complete diagram, provided none of the additional lines land on the R-dots shown. (a) A closed fan; (b) a partially opened fan. If all $m_i=1$, then it is said to be a fully opened fan, or just an opened fan.

In what follows, we summarize two general results obtained in the previous paper[8] using the IM.

1. The fan relation

The *fan relation*

$$\int (dU)\, A\, |U_{ac_1}|^{2m_1}\cdots|U_{ac_t}|^{2m_t} = \frac{\left(\prod_{j=1}^{t} m_j!\right)}{\left(\sum_{j=1}^{t} m_j\right)!} \int (dU)\, A\, |U_{ac}|^{2m} \tag{8}$$

relates integrals of the same $m=\Sigma_{j=1}^{t} m_j$, where A is an arbitrary product of matrix elements of U and U^* whose column indices are different from $c_1, c_2, \ldots, c_t$. The column index c on the right could be taken to be one of the c_i's.

Diagrammatically, the integral on the right of (8) is shown in Fig. 2(a), and the integral on the left is shown in Fig. 2(b). The additional lines and dots corresponding to the factor A are not shown, because they do not affect the spin-off relation. We shall refer to Fig. 2(a) as a *closed fan*, and Fig. 2(b) as a *partially opened fan*. If every $m_i=1$, then it will be said to be a *fully opened fan*, or simply an *opened fan*.

In particular, a closed fan integral is $m!$ times an opened fan integral. In fact, this relation between the two types of fans immediately gives rise to the relation (8) between a closed fan and a partially opened fan. To see it, note that each branch of a partially opened fan is itself a closed fan. By opening up all of them, we get the fully opened fan integral, multiplied by a multiplicity factor $\Pi_j m_j!$ from all the branches. Thus a closed fan is $m!/\Pi_j m_j!$ times a partially opened fan, as given by (8).

2. The Z-integral and the fan integral

In Ref. 8, we also obtained a general formula for integrals of the type shown in Fig. 1(b), for arbitrary non-negative integers m_1, m_2, and m_3. We call that the "Z-formula" because of the shape of the graph. It is

$$\begin{aligned} Z(m_1,m_2,m_3) &\equiv \int (dU)\, |U_{ij}|^{2m_1} |U_{il}|^{2m_2} |U_{kl}|^{2m_3} \\ &= \frac{m_1!\, m_2!\, m_3!\, (n-2)!(n-1)!\, (n+m_1+m_3-2)!}{(n+m_1-2)!\, (n+m_3-2)!\, (n+m_1+m_2+m_3-1)!}. \end{aligned} \tag{9}$$

In the special case where $m_2=m_3=0$, this becomes

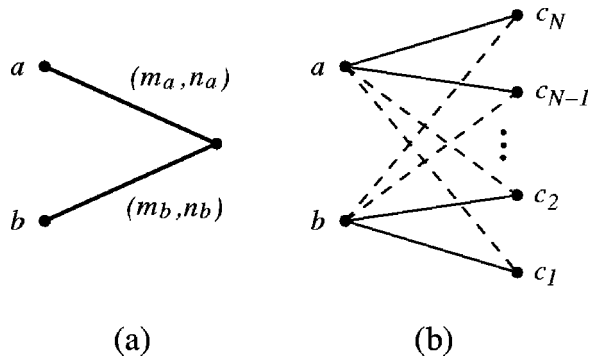

FIG. 3. Double-fan diagrams. (a) A closed diagram; (b) a fully opened diagram.

$$F(m) \equiv Z(m,0,0) = \frac{m!(n-1)!}{(n+m-1)!}, \tag{10}$$

which is the integral for Fig. 2(a) when there are no additional dots or lines around.

B. Double-fan relation

The fan relation can be generalized to a double-fan relation, connecting the closed ''double-fan'' diagram of Fig. 3(a) with a (fully) opened double-fan diagram such as Fig. 3(b). As in Fig. 2, there may be additional dots and lines in the integral, but none of them may end up on the R-dots shown. From that relation, we can also deduce relations between a closed double-fan and a partially opened double-fan, as done in the single-fan case.

The double-fan relation is considerably more complicated than the single-fan relation (8), because there are many more double-fan graphs. Each R-dot of a (fully) opened (double-fan) graph such as Fig. 3(b) falls into one of four *basic patterns*: $[A_a]$,$[A_b]$,$[B_a]$, and $[B_b]$, shown in Fig. 4. If the solid and dotted lines end up on the same L-dot, the pattern is a $[B]$; otherwise it is an $[A]$. The subscripts a and b tell us which L-dot the *solid* line emerges from.

Suppose there are α_i number of $[A_i]$ and β_i number of $[B_i]$ patterns in a (fully) opened (double-fan) graph. Then there are m_a solid and n_a dotted lines emerging from the L-dot a, and m_b solid and n_b dotted lines emerging from the L-dot b, where

$$\begin{aligned} m_a &= \alpha_a + \beta_a, \quad n_a = \alpha_b + \beta_a, \\ m_b &= \alpha_b + \beta_b, \quad n_b = \alpha_a + \beta_b. \end{aligned} \tag{11}$$

The total number of R-dots in the opened graph is $N = m_a + m_b = n_a + n_b$.

When these N R-dots are merged together, we get the closed (double-fan) graph depicted in Fig. 3(a), which will be denoted by $[(m_a n_a)(m_b n_b)]$. If $N=1$, this is just one of the four basic patterns discussed before. If $N>1$, we will call it a *compound pattern*.

From (11), we see that if we replace α_i and β_i by $\alpha_i' = \alpha_i + \xi$ and $\beta_i' = \beta_i - \xi$, with any integral ξ which keeps α_i' and β_i' non-negative, then we get the same closed graph by collapsing

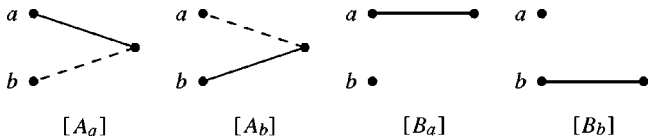

FIG. 4. The four basic patterns for the R-dots of a fully opened double-fan graph.

this new opened graph. Conversely, it will be shown in Appendix A that the closed graph $[(m_a n_a)(m_b n_b)]$ can be spinned off into a sum of several opened graphs, one for each (α_i', β_i'). The double-fan relation expressing that quantitatively is

$$[(m_a n_a)(m_b n_b)] = \sum v(\alpha_a' \alpha_b' \beta_a' \beta_b')\, [A_a]^{\alpha_a'} [A_b]^{\alpha_b'} [B_a]^{\beta_a'} [B_b]^{\beta_b'}$$

$$\equiv \sum [\alpha_a' A_a + \alpha_b' A_b + \beta_a' B_a + \beta_b' B_b], \tag{12}$$

where

$$v(\alpha_a' \alpha_b' \beta_a' \beta_b') = \frac{m_a!\, n_a!\, m_b!\, n_b!}{\alpha_a'!\, \alpha_b'!\, \beta_a'!\, \beta_b'!}, \tag{13}$$

and the sum is over all solutions $(\alpha_a', \alpha_b', \beta_a', \beta_b')$ of (11).

The double fan becomes a single fan if the L-dot b is not connected, namely, if $m_b = n_b = 0$ and $m_a = n_a \equiv m$. In that case (12) becomes

$$[m\, B_a] = m!\, [B_a]^m,$$

which is just (8) (when all $m_i = 1$) in another notation.

III. GROUP-THEORETICAL METHOD (GTM)

A. A brief review

Using group theory, the integral (6) can be turned into a multiple sum.[5,6] In the notation used in Appendix A of Ref. 8, the formula is

$$\langle IJ | IJ_Q \rangle = \sum_{R \in \mathcal{G}_I} \sum_{S \in \mathcal{G}_J} \sum_f \frac{d_f^2}{(p!)^2 \tilde{d}_f} \chi_f(SQR), \tag{14}$$

where p is the degree of the integral. The symbols $\mathcal{G}_I$ and $\mathcal{G}_J$ represent the symmetry groups of the row and column index sets. More precisely, $\mathcal{G}_X = \{P \in S_p | P(X) = X\}$, with X being either I or J. The irreducible representations of the symmetric and unitary groups are both labeled by a sequence $f = (f_1, f_2, \ldots, f_p)$, with $f_1 \geqslant f_2 \geqslant \cdots \geqslant f_p \geqslant 0$. $\chi_f(P)$ is the character of $P \in S_p$ in the irreducible representation with signature f. The dimension of the irreducible representation f is given by $d_f = \chi_f(e)$ for S_p, and by $\tilde{d}_f$ for U(n). A formula for $\tilde{d}_f$ is

$$\tilde{d}(f_1, \ldots, f_n) = \frac{D(f_1 + (n-1), f_2 + (n-2), \ldots, f_n)}{D(n-1, n-2, \ldots, 0)}, \tag{15}$$

where $D(x_1, \ldots, x_n)$ is the Vandermonde determinant given by $\Pi_{i<k}(x_i - x_k)$.

Since $\chi_f(g)$ depends only on the class c_g that g belongs to, we may write it as $\chi_f(c_g)$. With this notation, Eq. (14) can be rewritten as

$$\langle IJ | IJ_Q \rangle = \sum_c N[c]\, \xi[c], \tag{16}$$

where the sum is taken over all classes c of S_p,

$$N[c] = \sum_{R \in \mathcal{G}_I} \sum_{S \in \mathcal{G}_J} \delta(SQR \in c) \tag{17}$$

is the number of elements of the type SQR in the class c, and

$$\xi[c]=\sum_f \frac{d_f^2}{(p!)^2\tilde{d}_f}\chi_f(c). \tag{18}$$

It is not difficult to see that Q is not unique, because $Q'=SQ=QT$ for any $S\in\mathcal{G}_J$ and any $T\in\mathcal{G}_{J_Q}$ is another possible Q. It does not matter which Q we pick in (17). That equation can also be written as

$$N[c]=\sum_{R\in\mathcal{G}_I}\sum_{T\in\mathcal{G}_{J_Q}}\delta(QTR\in c). \tag{19}$$

It is straightforward but generally very tedious to compute $N[c]$, because we need to calculate the product QTR for every $T\in\mathcal{G}_{J_Q}$, every $R\in\mathcal{G}_I$, and determine what class c the product belongs to. Then we have to count up all the products that are in a given class c to get $N[c]$. However, the task becomes considerably more manageable if either $\mathcal{G}_I$ and $\mathcal{G}_{J_Q}$ are disjoint, or if one is contained in the other. We shall refer to integrals with those properties as *orderly*. Further simplification occurs for direct integrals, because in that case Q can always be chosen to be the identity e, so the triple product is reduced to a double product TR.

The calculation of $\xi[c]$ in (18) is simpler than the calculation of $N[c]$, but still we know of no closed form of it valid for every class c and every symmetric group S_p. The best we can do is to compute them case by case. Results are given in Sec. III C. Each $\xi[c]$ is actually an orderly integral with $\mathcal{G}_I=\mathcal{G}_J=e$, to be referred to as a *primitive integral*.

Other integrals can be computed in terms of the primitive integrals, if $N[c]$ is known. We shall discuss two orderly integrals for which $N[c]$ can easily be obtained. In Sec. III D, we discuss the *stack integrals*, which are direct integrals with $\mathcal{G}_I=\mathcal{G}_J$. In Sec. III E, we discuss the fully opened double-fan integrals of the type $[A_a]^\alpha[A_b]^\alpha$.

Relations between orderly integrals may be obtained without knowing the explicit values of $\xi[c]$, if their $N[c]$'s are related in a simple way. This is the case for the single-fan relation, and the double-fan relation with $n_a=m_b=0$ and $m_a=n_b=m$. They will be discussed in Sec. III B. However, general double-fan integrals are not orderly, so we cannot obtain the general double-fan relation by the group-theoretical method, at least not in the present way. We will also show that the closed (single-)fan *integral* can also be computed without explicitly knowing what $\xi[c]$ are. This is one of the very few cases where integrals can be obtained group-theoretically without explicitly knowing $\xi[c]$.

That leaves the nonorderly integrals, for which each term of the summand in (19) has to be calculated separately to get $N[c]$. The first nonorderly integral occurs in degree $p=3$. In Sec. III F, we shall show how to calculate some of the $p=3$ and $p=4$ nonorderly integrals.

B. Single-fan and simple double-fan relations

The single-fan integrals are orderly. The index sets for the closed fan Fig. 2(a) are

$$\begin{pmatrix} label \\ I \\ J \\ J_Q \end{pmatrix}=\begin{pmatrix} 1 & \cdots & m & \cdots \\ a & \cdots & a & \cdots \\ c & \cdots & c & \\ c & \cdots & c & \end{pmatrix}. \tag{20}$$

The first row gives the index labels, and the next three rows give the values of the indices in the sets I,J, and J_Q, respectively. Different letters are understood to correspond to different values. Additional dots and lines may be present in the graph, as long as none of the lines end up in the R-dots shown. These additional lines and dots are not drawn because they do not affect the fan

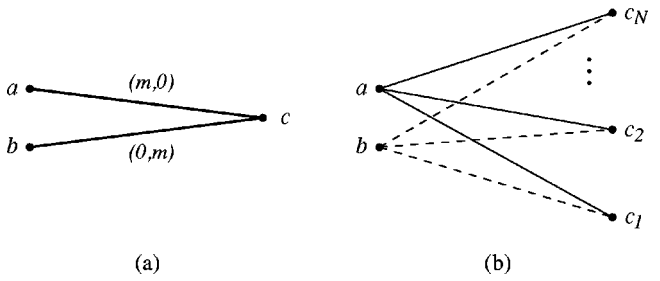

FIG. 5. Double-fan diagrams with $n_a=m_b=0$, and $m_a=n_b=m$. (a) A closed fan; (b) a fully opened fan.

relation in any way. Similarly, they are not shown in the index sets in (20) other than the ellipses in the first two rows, which remind us that there may be more lines connected to the L-dots. Such ellipses are absent in the last two rows because no additional lines are allowed to be connected to the R-dots shown.

Similarly, the index sets for the fully opened fan, Fig. 2(b) with all $m_i=1$, are

$$\begin{pmatrix} label \\ I \\ J \\ J_Q \end{pmatrix} = \begin{pmatrix} 1 & \cdots & m & \cdots \\ a & \cdots & a & \cdots \\ c_1 & \cdots & c_m & \\ c_1 & \cdots & c_m & \end{pmatrix}. \tag{21}$$

Using S_m to denote the symmetric group for the permutation of the first m labels, the symmetric groups for Fig. 2(a) can be read off from (20) to be $\mathcal{G}_I \supset S_m$ and $\mathcal{G}_J=\mathcal{G}_{J_Q}=S_m$. Similarly, the symmetric groups for Fig. 2(b) can be read off from (21) to be $\mathcal{G}_I \supset S_m$ and $\mathcal{G}_J=\mathcal{G}_{J_Q}=e$. We may choose $Q=e$ in both cases. Then for Fig. 2(a), $T\mathcal{G}_I=\mathcal{G}_I$ for every $T\in\mathcal{G}_{J_Q}$, hence $N[c]=m!\Sigma_{R\in\mathcal{G}_I}\delta(R\in c)$. But the last sum is simply the $N[c]$ for Fig. 2(b) and (21). Hence it follows from (16) that the fan relation (with all $m_i=1$) is true.

Next, let us derive the double-fan relation (12) and (13) for the case $n_a=m_b=0$ and $m_a=n_b$. The solution of (11) is now unique. It gives $\alpha_a=m_a=n_b\equiv m$, and $\alpha_b=\beta_a=\beta_b=0$. The double-fan relation (12) then becomes

$$[m\,A_a]=m!\,[A_a]^m. \tag{22}$$

The closed double-fan is shown in Fig. 5(a). Its index sets are

$$\begin{pmatrix} label \\ I \\ J \\ J_Q \end{pmatrix} = \begin{pmatrix} 1 & \cdots & m & \cdots & n & \ldots & n+m & \cdots \\ a & \cdots & a & \cdots & b & \cdots & b & \cdots \\ c & \cdots & c & & & & & \\ & & & & c & \cdots & c & \end{pmatrix}. \tag{23}$$

The opened double-fan is shown in Fig. 5(b). Its index sets are

$$\begin{pmatrix} label \\ I \\ J \\ J_Q \end{pmatrix} = \begin{pmatrix} 1 & \cdots & m & \cdots & n & \ldots & n+m & \cdots \\ a & \cdots & a & \cdots & b & \cdots & b & \cdots \\ c_1 & \cdots & c_m & & & & & \\ & & & & c_1 & \cdots & c_m & \end{pmatrix}. \tag{24}$$

We may choose $Q=(1,n)(2,n+1)\cdots(m,n+m)$ in both cases. For (23), $\mathcal{G}_I \supset S_m \otimes S'_m$, $\mathcal{G}_J = S_m$, and $\mathcal{G}_{J_Q} = S'_m$, where S_m is the permutation group of the first m labels, and S'_m is the permutation group for the labels $(n,n+1,\ldots,n+m)$. For (24), $\mathcal{G}_I \supset S_m \otimes S'_m$, but $\mathcal{G}_J = \mathcal{G}_{J_Q} = e$.

For Fig. 5(a), $T\mathcal{G}_I = \mathcal{G}_I$ for every $T \in \mathcal{G}_{J_Q}$. Hence $N[c] = m! \Sigma_{T \in \mathcal{G}_I} \delta(QR \in c)$. But the last sum is simply the $N[c]$ of Fig. 5(b). In this way (22) is proven by the GTM.

The fan *integral* (10) can also be obtained from the GTM. It is given by Fig. 2(a) without extra dots and lines, or (20) without the ellipses at the end. Then $\mathcal{G}_I = S_m$, and $N[c] = m! \Sigma_R \delta(R \in c)$. From (16) and (18), we get

$$\langle IJ|IJ_Q\rangle \equiv F(m) = m! \sum_{R \in \mathcal{G}_I} \sum_f \frac{d_f^2}{(m!)^2 \tilde{d}_f} \chi_f(R) \tag{25}$$

$$= \frac{1}{m!} \sum_f \frac{d_f^2}{\tilde{d}_f} \sum_{R \in S_m} \chi_f(R)\ \chi^*_{(m)}(R) = \frac{d^2_{(m)}}{\tilde{d}_{(m)}} \tag{26}$$

$$= \frac{m!(n-1)!}{(m+n-1)!}. \tag{27}$$

In getting from (25) to (26), the character $\chi^*_{(m)}(R) = 1$ of the totally symmetric representation (m) of the permutation group has been inserted, and the orthogonality relation of the characters has been used. To get to (27), $d_{(m)} = \chi_{(m)}(e) = 1$ as well as $\tilde{d}_{(m)} = (m+n-1)!/(n-1)!m!$ (see (15)) have been used.

The result in (27) agrees with the result (10). It is one of the very few cases where the value of the integrals can be obtained group-theoretically without knowing the values of the individual $\xi[c]$'s.

C. Primitive integrals

Integrals in which both symmetry groups $\mathcal{G}_I$ and $\mathcal{G}_J$ consist only of the identity e will be called *primitive*. This happens when all the indices i_a in the set I assume distinct values, and all the indices j_b in the set J are also different. The corresponding diagrams have p dots each on both columns, and precisely one solid and one dotted lines connecting to each of the dots. The primitive diagrams for $p \leqslant 3$ are shown in Fig. 6, and the ones for $p = 4,5$ are contained in Appendix C.

Since $\mathcal{G}_I = \mathcal{G}_J = e$, it follows from (17) that $N[c] = \delta(Q \in c)$, where Q can be any element of S_p. The primitive integrals (16) are simply $\xi[c]$, one for each class c of S_p. We may therefore use an element of each cycle structure to label the primitive integrals, as is done in Fig. 6. Diagrammatically, the cycle structure is translated into the loop structure of its diagram, as can be seen in Fig. 6. Using (18) along with (15) and the character tables found in Appendix B (note that $d_f = \chi_f(e)$), the primitive integrals for $p \leqslant 3$ can be easily computed, and the results are displayed in Table I. The results for $p = 4,5$ can also be found in Table IV of Appendix C.

D. Stack integrals

The stack diagrams (see Fig. 7) are direct integrals made up of disconnected lines of arbitrary multiplicities. As such, $Q = e$, and J differs from I only by relabeling. Using item 3 of Sec. II B, we may assume $J = I$. Hence stack integrals are integrals of the form $\langle II|II\rangle$.

Let $p_1, p_2, \ldots, p_t$ be the multiplicities of the disconnected lines in a stack diagram. Then $\mathcal{G}_I = \mathcal{G}_J \equiv \mathcal{G} = S_{p_1} \otimes S_{p_2} \otimes \cdots \otimes S_{p_t}$, and $N[c]$ is nonzero only when the class c is a direct product of the classes c_i of the groups S_{p_i}. In that case,

$$N[c] = \prod_{i=1}^{t} p_i!\, n_i(c_i), \tag{28}$$

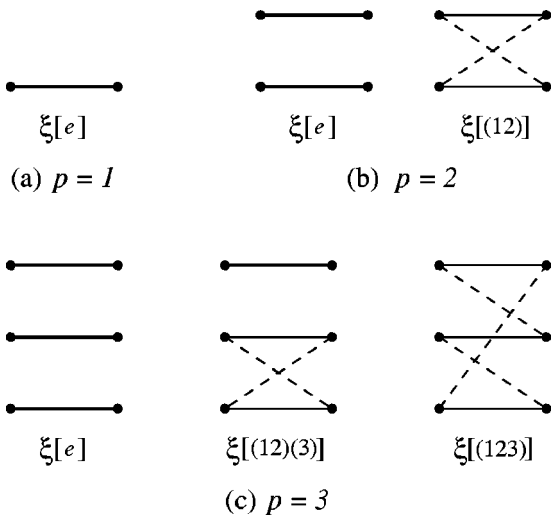

FIG. 6. Primitive diagrams for (a) $p=1$, (b) $p=2$, and (c) $p=3$. The identity element is everywhere denoted by e.

where $n_i(c_i)$ is the number of elements of S_{p_i} in the class c_i. In other words,

$$n_i(c_i)=\frac{p_i!}{\prod_{j=1}^{p_i} j^{\alpha_j}\alpha_j!}\ , \tag{29}$$

where the class c_i consists of α_j cycles of length j. Denoting the stack integral $\langle II|II\rangle$ by $\Xi(p_1,p_2,\ldots,p_t)$, we get

$$\Xi(p_1,p_2,\ldots,p_t)=\sum_{c_1,c_2,\ldots}\left(\prod_{i=1}^{t} p_i!\, n_i(c_i)\right)\xi(c_1\otimes c_2\otimes\cdots\otimes c_t). \tag{30}$$

All stack diagrams can be obtained by making the assignment $f_i\to p_i$ from each representation. In this way, we expect a same number of stack digrams as of primitive diagrams, or classes. Using the ξ expressions obtained in the preceding subsection, the stack integrals for $p\leqslant 3$ can be computed to yield the expressions in Table II.

E. Special double-fan integrals

The index sets for the fully opened double-fan integrals $[A_a]^\alpha[A_b]^\alpha$ (Fig. 3(b) with $N=2\alpha$) are

TABLE I. Algebraic expressions for the primitive diagrams of $p=1,2,3$.

		$\xi[c]$	
c	$p=1$	$p=2$	$p=3$
e	$\frac{1}{n}$	$\frac{1}{n^2-1}$	$\frac{n^2-2}{n(n^2-1)(n^2-4)}$
(12)		$\frac{-1}{n(n^2-1)}$	$\frac{-1}{(n^2-1)(n^2-4)}$
(123)			$\frac{2}{n(n^2-1)(n^2-4)}$

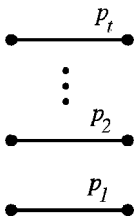

FIG. 7. Arbitrary stack diagram, $\Xi(p_1,p_2,\ldots,p_t)$, of degree $p=\Sigma_{i=1}^{t}p_i$.

$$\begin{pmatrix} label \\ I \\ J \\ J_Q \end{pmatrix} = \begin{pmatrix} 1 & \cdots & \alpha & \alpha+1 & \ldots & 2\alpha \\ b & \cdots & b & a & \cdots & a \\ c_1 & \cdots & c_\alpha & c_{\alpha+1} & \cdots & c_{2\alpha} \\ c_{\alpha+1} & \cdots & c_{2\alpha} & c_1 & \cdots & c_\alpha \end{pmatrix}. \tag{31}$$

Hence both $\mathcal{G}_J$ and $\mathcal{G}_{J_Q}$ consist only of the identity e. As for $\mathcal{G}_I$, it is given by $S_\alpha \otimes S_\alpha$, where the permutation groups S_α act respectively on the b and a indices in I. The element Q maps J_Q to J, i.e., $Q=(1,\alpha+1)(2,\alpha+2)\cdots(\alpha,2\alpha)$.

The fully opened integral can be computed using (16), with $N[c]$ given by (17) or (19). Thus,

$$N[c]=\sum_{R\in\mathcal{G}_I}\sum_{T\in\mathcal{G}_{J_Q}}\delta(QTR\in c)=\sum_{R\in\mathcal{G}_I}\delta(QR\in c) \quad = \quad \sum_{Q'}\delta(Q'\in c), \tag{32}$$

where the last sum is over *every* permutation Q' that sends *all* b indices in (31) to the positions labeled from $\alpha+1$ to 2α, and similarly *all* a indices to the positions labeled from 1 to α. As a consequence, the allowed cycles of Q' must be of even length, and they can be specified by a sequence of non-negative integers $(k)\equiv(k_1k_2\cdots k_\alpha)$, k_i being the number of cycles of length $2i$. The number of Q' with the class structure (k) that is related to c is given by

$$N[c]=\frac{(\alpha!)^2}{\prod_{i=1}^{\alpha} i^{k_i}\cdot k_i!}. \tag{33}$$

In order to see how this is arrived at, consider an example where $k_1=2$, $k_2=2$, and all other k_i values are zero. Then Q' is of the form $(ba)(ba)(baba)(baba)$, where the b and a letters should take the distinct index labels in $(1,\ldots,\alpha)$ and $(\alpha+1,\ldots,2\alpha)$, respectively. Another Q' with the same cycle structure can thus be obtained by permuting individually all the a and b labels. This accounts for the numerator in (33). However, such permutations do not necessarily give distinct Q' elements. The cyclic nature of a cycle tells us that each cycle of length $2i$ will appear i times; this accouts for the i^{k_i} factor in the denominator. Moreover, no new Q' is obtained if we permute cycles of the same length; that accounts for the other factor $k_i!$ in the denominator.

TABLE II. Algebraic expressions for the stack diagrams of $p=1$, 2, and 3.

$\Xi(p_1,\ldots,p_p)$	
$\Xi(1)=\frac{1}{n}$	$\Xi(3)=\frac{3!}{n(n+1)(n+2)}$
$\Xi(2)=\frac{2}{n(n+1)}$	$\Xi(2,1)=\frac{2}{(n-1)n(n+2)}$
$\Xi(1,1)=\frac{1}{n^2-1}$	$\Xi(1,1,1)=\frac{n^2-2}{n(n^2-1)(n^2-4)}$

TABLE III. Values of the monomial integrals $[A_a]^\alpha[A_b]^\alpha$ for $\alpha=1,2,3$.

α	$[A_a]^\alpha[A_b]^\alpha$
1	$\frac{-1}{n(n^2-1)}$
2	$\frac{2}{(n^2-1)n^2(n+2)(n+3)}$
3	$\frac{-6}{(n-1)n^2(n+1)^2(n+2)(n+3)(n+4)(n+5)}$

We may now return to (16) to calculate the integral $[A_a]^\alpha[A_b]^\alpha$ in terms of the primitive integrals $\xi[c]$. The results for the first few α values are listed in Table III.

F. Nonorderly integrals

All integrals with degree $p<3$ are orderly. The nonorderly integrals of $p=3$ are shown in Fig. 8, and those related to them by the fan relation (8). The calculation of $N[c]$ and the integral for each of them is discussed below. The integrals will be labeled by their figure, e.g., integral $I(8a)$.

The index sets for Fig. 8(a) are

$$\begin{pmatrix} label \\ I \\ J \\ J_Q \end{pmatrix} = \begin{pmatrix} 1 & 2 & 3 \\ b & b & a \\ d & c & c \\ d & c & c \end{pmatrix}. \tag{34}$$

They give rise to the symmetry groups $\mathcal{G}_I=\{e,(12)\}$ and $\mathcal{G}_J=\mathcal{G}_{J_Q}=\{e,(23)\}$. Moreover, the element Q can be taken to be the identity element. In order to obtain the coefficients $N[c]$ of Eq. (16), we need to compute QTR for all $T\in\mathcal{G}_{J_Q}$ and $R\in\mathcal{G}_I$. That triple product is $Q\mathcal{G}_{J_Q}\mathcal{G}_I=\{e,(12),(23),(132)\}$. As a result,

$$I(8a)=Z(1,1,1)=\xi[e]+2\xi[(12)(3)]+\xi[(123)]=\frac{1}{(n^2-1)(n+2)}. \tag{35}$$

In the same way, the index sets of Fig. 8(b) are

$$\begin{pmatrix} label \\ I \\ J \\ J_Q \end{pmatrix} = \begin{pmatrix} 1 & 2 & 3 \\ b & a & a \\ e & d & c \\ d & e & c \end{pmatrix}, \tag{36}$$

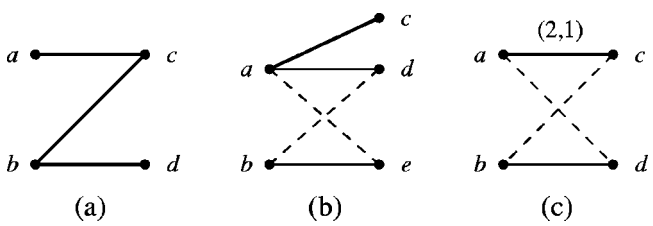

FIG. 8. Nonorderly integrals of $p=3$.

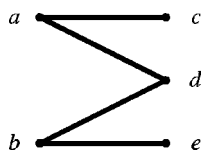

FIG. 9. Sigma integral with all lines being of multiplicity one.

and hence the symmetry groups are $\mathcal{G}_{J_Q}=\{e\}$ and $\mathcal{G}_I=\{e,(23)\}$, and the exchange element is $Q=(12)$. We thus obtain $Q\mathcal{G}_{J_Q}\mathcal{G}_I=\{(12),(123)\}$, from which

$$I(8b)=\xi[(12)(3)]+\xi[(123)]=\frac{-1}{(n^2-1)n(n+2)} \tag{37}$$

follows.

Finally, for Fig. 8(c), the index sets are

$$\begin{pmatrix} label \\ I \\ J \\ J_Q \end{pmatrix}=\begin{pmatrix} 1 & 2 & 3 \\ b & a & a \\ d & c & c \\ c & d & c \end{pmatrix}. \tag{38}$$

The relevant symmetry groups are $\mathcal{G}_{J_Q}=\{e,(13)\}$ and $\mathcal{G}_I=\{e,(23)\}$. With $Q=(12)$, the set $Q\mathcal{G}_{J_Q}\mathcal{G}_I$ is {(12), (13), (123), (132)}, and formula (16) gives

$$I(8c)=2(\xi[(12)(3)]+\xi[(123)])=\frac{-2}{(n^2-1)n(n+2)}. \tag{39}$$

The calculation of $Q\mathcal{G}_{J_Q}\mathcal{G}_I$ is not that cumbersome for $p=3$, but it gets worse pretty quickly as p increases. For example, let us look at some examples of $p=4$.

Let us first calculate $Z(2,1,1)$ of Fig. 1(b), whose index sets are

$$\begin{pmatrix} label \\ I \\ J \\ J_Q \end{pmatrix}=\begin{pmatrix} 1 & 2 & 3 & 4 \\ b & b & b & a \\ d & d & c & c \\ d & d & c & c \end{pmatrix}. \tag{40}$$

Then $Q=e$, $\mathcal{G}_{J_Q}=\{e,(12),(34),(12)(34)\}$ and $\mathcal{G}_I=\{e,(12),(13),(23),(123),(132)\}$. Thus $Q\mathcal{G}_{J_Q}\mathcal{G}_I=\{e,(12),(13),(23),(123),(132),(12),e,(132),(123),(23),(13),(34),(12)(34),(143),(243),(1243),(1432),(12)(34),(34),(1432),(1243),(243),(143)\}$, hence

$$\begin{aligned} Z(2,1,1)&=2\xi[e]+8\xi[(12)(3)(4)]+8\xi[(123)(4)]+2\xi[(12)(34)]+4\xi[(1234)] \\ &=\frac{2}{(n-1)n(n+2)(n+3)}. \end{aligned} \tag{41}$$

Our last example is the Σ-integral, shown in Fig. 9. Its index sets are

$$\begin{pmatrix} label \\ I \\ J \\ J_Q \end{pmatrix} = \begin{pmatrix} 1 & 2 & 3 & 4 \\ b & b & a & a \\ e & d & d & c \\ e & d & d & c \end{pmatrix}. \tag{42}$$

Hence $Q=e$, $\mathcal{G}_{J_Q}=\{e,(23)\}$ and $\mathcal{G}_I=\{e,(12),(34),(12)(34)\}$. Multiplying such elements accordingly, the set $\{e,(12),(34),(12)(34),(23),(132),(234),(1342)\}$ is obtained for $Q\mathcal{G}_{J_Q}\mathcal{G}_I$. Hence

$$\begin{aligned} \Sigma &= \xi[e]+3\xi[(12)(3)(4)]+2\xi[(123)(4)]+\xi[(12)(34)]+\xi[(1234)] \\ &= \frac{n+1}{(n-1)n^2(n+2)(n+3)}. \end{aligned} \tag{43}$$

IV. COMPARISON OF THE IM AND THE GTM

We have discussed the computation of U(n) integrals (2) in two ways: the IM in Sec. II, and the GTM in Sec. III. Each of these two methods has its own merits, and drawbacks, and in a way they complement each other. The purpose of this section is to compare their relative stong and weak points.

The IM is based solely on the unitarity condition (4) and the invariance of the Haar Measure (5). The method is simple because there is no need to know group theory. The conditions relate integrals of the same degree, and also integrals of degree p to integrals of degree $p-1$. Through these relations, specific integrals such as the fan integrals (10) and the Z-integrals (9) can be obtained, and the general relation such as the single-fan relation (8) and the double-fan relation (12) can be worked out.

The GTM has the advantage of being general, in the sense that all integrals can be computed using the formula (14) or (16). The price to pay is that we have to know the characters of the irreducible representations of the appropriate symmetric group, and a triple sum has to be carried out, which can prove to be very tedious for integrals of high degrees. Furthermore, unlike the IM, relations between integrals are hard to come by, so one must calculate the integrals one by one. There are however certain classes of integrals, the orderly integrals, for which relations can be developed, and the quantity $N[c]$ in (16) can be relatively easily computed. Then we merely have to know the primitive integrals $\xi[c]$ in (16) to get the value of the orderly integral on hand. The stack integrals (30) and the special opened double-fan integrals (33) are examples of this kind. The primitive integrals $\xi[c]$ themselves must be calculated using (18).

To summarize, the IM gives a huge number of relations but it is not easy to obtain the value of any specific integral. The GTM allows us to calculate any specific integral, albeit rather tedious at times, but it is difficult to obtain relations between integrals. In the next section, we shall discuss a *hybrid method* which makes use of the advantages of both methods. We shall use the general GTM formula to calculate a specific set of integrals, and then use the IM relations to obtain all the other integrals.

In the rest of this section, we shall enlarge these general remarks about the IM and GTM, by using specific examples presented in the last two sections as concrete illustrations.

The single-fan relation (8) can be obtained by both the IM and the GTM. However the double-fan relation (12) in its general form can be obtained only by the IM, because most of the integrals involved are not orderly, making it hard to derive relations using the GTM. Nevertheless, in special cases involving only orderly integrals, (22), the GTM can also be used to derive the relation.

The Z-formula (9) is obtained using the IM, by a series of relations connecting it down to $\int dU=1$. Since the Z-integrals are not orderly, it is hard to compute them using the GTM except at low degrees. The calculation of those by the GTM is shown in Eqs. (35) and (41).

However, since the values of the integrals in the IM are obtained only through relations, it may be relatively complicated to calculate just one specific integral. This is where the GTM is

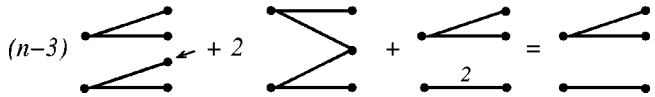

FIG. 10. Unitarity sum relation involving the Σ diagram (second from the left). The sum is performed on the index indicated by an arrow. Using the fan relation (8), the unitary sum can be written as $([(n-3)/4]+\frac{1}{2})Z(2,0,2)+2\Sigma=\frac{1}{2}Z(2,0,1)$.

superior, because of the general formula (14) valid for any one integral. For example, it is easy to obtain the Σ integral (43), assuming of course the $\xi[c]$'s to be already known. We can also obtain it using the IM, as we shall show below, but that involves a few steps because we must get it from relations. To see how that is done, look at Fig. 10, which is the unitarity relation applied to the dot of the first diagram indicated by an arrow. The first and third diagrams can be related to $Z(2,0,2)$ by using the fan relation (8), and similarly the diagram on the right can be related to $Z(2,0,1)$. Using the Z-formula (9), we then obtain

$$\Sigma=\frac{1}{4}\left[Z(2,0,1)-\left(\frac{n-3}{2}+1\right)Z(2,0,2)\right]=\frac{n+1}{(n-1)n^2(n+2)(n+3)}, \tag{44}$$

the same as the result (43) obtained by the GTM.

V. HYBRID METHOD

Having understood the relative merits of the GTM and the IM, it is possible to combine their strengths into a more efficient hybrid calculational scheme.

The strategy is to start with one or more integrals that can be computed by the GTM with relative ease. Generally speaking, such integrals are ordered. Once they are obtained, the many relations of the IM can be used to calculate other integrals from them.

To illustrate this strategy, we will consider how the hybrid method can be used to calculate all double-fan integrals.

By a double-fan integral, we mean any integral with two L-dots and any number of R-dots. Figure 3(a) shows a closed (double-fan) integral (with the understanding that there are no extra dots or lines than those shown), and Fig. 3(b) shows a fully opened (double-fan) integral. We may also have partially opened (double-fan) integrals, in which every branch, namely, every R-dot with its connecting lines, can be regarded as a closed integral. See Fig. 11 for an example of a partially opened integral.

As in Sec. II B, a fully opened integral is denoted by $[A_a]^{\alpha_a}[A_b]^{\alpha_b}[B_a]^{\beta_a}[B_b]^{\beta_b}$, and its corresponding closed integral is denoted by $[\alpha_a A_a+\alpha_b A_b+\beta_a B_a+\beta_b B_b]$. For a partially opened integral, we will denote it as a product of the closed integrals of each branch. See Fig. 11 for examples.

Using (12) and (13), all double-fan integrals can be expressed as sums of fully opened integrals. Integrals of the form $[A_a]^{\alpha}[A_b]^{\alpha}$ are given by (33) and Table III, but we still have to

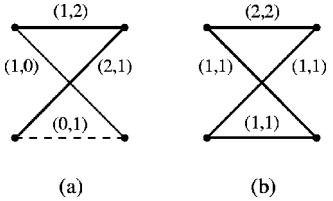

FIG. 11. Partially opened double-fan integrals. (a) There are two equivalent forms for this graph: $[A_a+2A_b][A_a]$ and $[A_b+B_a+B_b][A_a]$. (b) There are four equivalent forms for this graph: $[A_a+A_b+B_a][A_a+A_b]$, $[2B_a+B_b][A_a+A_b]$, $[A_a+A_b+B_a][B_a+B_b]$, $[2B_a+B_b][B_a+B_b]$.

know how to calculate a fully opened integral when $\beta_i \neq 0$. As shown in Appendix D, the IM allows us to relate them to those with $\beta_i = 0$, by using the following formula:

$$[A_a]^\alpha [A_b]^\alpha [B_a]^{\beta_a} [B_b]^{\beta_b} = \sum_{e=0}^{\min(\beta_a,\beta_b)} \left\{ (-1)^e e! \binom{\beta_a}{e} \binom{\beta_b}{e} (n+2\alpha-1+2e) \cdot \frac{(n+2\alpha-2+e)!\,(n+2\alpha-1+2e)!}{(n+2\alpha+\beta_a-1+e)!\,(n+2\alpha+\beta_b-1+e)!} [A_a]^{\alpha+e} [A_b]^{\alpha+e} \right\}. \tag{45}$$

We close this section by showing how to use (12) and (13) to calculate the integrals in Fig. 11.

A. Figure 11(a)

There are two equivalent forms for this diagram. One is

$$[A_a + 2A_b][A_a] = (2[A_a][A_b]^2)[A_a] = 2[A_a]^2[A_b]^2 \tag{46}$$

and the other is

$$[A_b + B_a + B_b][A_a] = 4([A_b][B_a][B_b])[A_a] = 4[A_a][A_b][B_a][B_b], \tag{47}$$

where Eqs. (12) and (13) have been used. The integral $I(11a)$ is obtained by adding up (46) and (47).

Using (45), we can express all fully opened integrals in the form $[A_a]^\alpha [A_b]^\alpha$. Applying this to the present case, we get

$$[A_a][A_b][B_a][B_b] = \frac{1}{(n+2)^2}[A_a][A_b] - \frac{1}{(n+2)}[A_a]^2[A_b]^2. \tag{48}$$

Using Table III, we finally obtain

$$I(11a) = 2[A_a]^2[A_b]^2 + 4[A_a][A_b][B_a][B_b] = \frac{2n}{(n+2)}[A_a]^2[A_b]^2 + \frac{4}{(n+2)^2}[A_a][A_b] = \frac{-4}{(n^2-1)n(n+2)(n+3)}.$$

B. Figure 11(b)

As shown in Fig. 11(b), $I(11b)$ has four equivalent forms. For one branch, the factors are

$$[A_a + A_b + B_a] = 4\,[A_a][A_b][B_a],$$
$$[2B_a + B_b] = 2\,[B_a]^2[B_b], \tag{49}$$

and for the other branch, they are

$$[A_a + A_b] = [A_a][A_b],$$
$$[B_a + B_b] = [B_a][B_b]. \tag{50}$$

Hence

$$I(11b) = 4\,[A_a]^2[A_b]^2[B_a] + 6\,[A_a][A_b][B_a]^2[B_b] + 2\,[B_a]^3[B_b]^2. \tag{51}$$

We will now express each of the three monomial integrals in (51) in terms of $[A_a]^\alpha[A_b]^\alpha$. First, with respect to (45), $[A_a]^2[A_b]^2[B_a]$ is characterized by $\alpha=2$, $\beta_a=1$, and $\beta_b=0$. The vanishing of β_b causes (45) to consist of the single term

$$[A_a]^2[A_b]^2[B_a]=\frac{1}{(n+4)}[A_a]^2[A_b]^2. \tag{52}$$

Second, $[A_a][A_b][B_a]^2[B_b]$ has $\alpha=1$, $\beta_a=2$, $\beta_b=1$, and the sum in (45) gives

$$[A_a][A_b][B_a]^2[B_b]=\frac{1}{(n+2)^2(n+3)}[A_a][A_b]-\frac{2}{(n+2)(n+4)}[A_a]^2[A_b]^2. \tag{53}$$

Finally, $[B_a]^3[B_b]^2$, having $\alpha=0$, $\beta_a=3$, $\beta_b=2$, can be expressed as

$$[B_a]^3[B_b]^2=\frac{1}{n^2(n+1)^2(n+2)}-\frac{6}{n(n+2)^2(n+3)}[A_a][A_b]+\frac{6}{(n+1)(n+2)(n+4)}[A_a]^2[A_b]^2 \tag{54}$$

from Eq. (45). Using the fan relation, notice that $[B_a]^3[B_b]^2$ can also be reduced to $(1/3!)\times(1/2!)\,Z(3,0,2)$.

The expressions of $[A_a][A_b]$ and $[A_a]^2[A_b]^2$ in terms of n have already been determined in Example 1. The final answer is obtained by inserting (52)–(54) into (51). The result is

$$\begin{aligned}[A_a+A_b+B_a][A_a+A_b]&=\frac{2}{n^2(n+1)^2(n+2)}+\frac{6(n-2)}{n(n+2)^2(n+3)}[A_a][A_b]\\&\quad+\frac{4(n^2+2)}{(n+1)(n+2)(n+4)}[A_a]^2[A_b]^2\\&=\frac{2(n^2+2n+4)}{(n^2-1)n^2(n+2)(n+3)(n+4)},\end{aligned}$$

which can be verified using the plain group theoretical formula (14).

VI. CONCLUSION

In this article, we have pursued the goal of finding an efficient method to calculate the monomial integral (1) or (2). We find that the IM discussed in Sec. II is superior for deriving relations between integrals, but the GTM is able to give a formula to calculate any integral. The GTM formula involves a triple sum whose computation is often tedious and prone to mistakes. The sums simplify for orderly integrals, in which the invariant groups $\mathcal{G}_I$ and $\mathcal{G}_{J_Q}$ are either disjoint, or one is contained in the other. For nonorderly integrals, the hybrid method is probably the most efficient. It uses the IM to relate them to some orderly integrals that can be calculated by the GTM with relative ease.

APPENDIX A: DERIVATION OF EQUATIONS (12) AND (13)

To prove (12) and (13), we use the rotation technique discussed in item 5 of Sec. II A, and Eq. (7), to spin off from the R-dot of Fig. 3(a) a new R-dot attached to a pair of solid-dotted lines. Depending on whether the basic pattern of this new R-dot is $[A_a]$, $[A_b]$, $[B_a]$, or $[B_b]$, we get the graphs shown in Figs. 12(a), 12(b), 12(c), and 12(d), respectively.

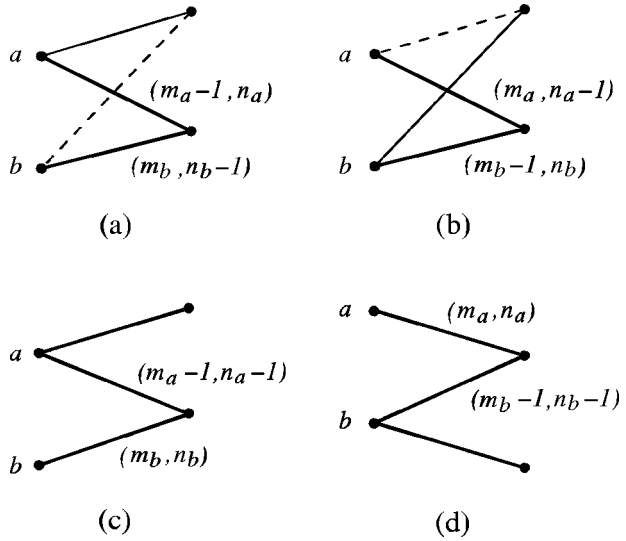

FIG. 12. Diagrams that result from rotating away the pairs of lines (a) $[A_a]$, (b) $[A_b]$, (c) $[B_a]$, and (d) $[B_b]$, from the compound pattern of Fig. 3.

Repeating this spin-off operation over and over again on the R-dot still containing a compound pattern, eventually we come to a graph where every R-dot is given by a basic pattern. The resulting integrals are given in (12), corresponding to the decompositions of the compound pattern into a sum of all possible fully opened integrals obtained by spinning off.

The coefficient $v(\alpha'_a\alpha'_b\beta'_a\beta'_b)$ of these basic integrals is derived from a combination of three factors:

(1) Each time that we spin off a basic pattern from a compound pattern with d pairs of solid-dotted lines, there is a factor $1/d$ arising from Eq. (7), by taking $e=1$. Since we start from a compound pattern with N pairs of lines, by the time we come to a fully-opened pattern we have accumulated a factor $1/N!$.
(2) The N R-dots in the final pattern that is fully opened can be spinned off in a different sequential order. According to (7), they must be summed over. This gives rise to a factor $N!/\alpha'_a!\alpha'_b!\beta'_a!\beta'_b!$.
(3) At any time when we spin off a basic pattern, we can choose its single pair of solid-dotted lines in all possible ways. Equation (7) says that we must sum over all these possibilities. The mulitipliciy factor is given by the number of permutations of these lines that lead back to the same basic integral. It is a factor of $m_a!\, m_b!\, n_a!\, n_b!$.

Assembling these three factors, we get

$$v(\alpha'_a\alpha'_b\beta'_a\beta'_b)=\frac{m_a!\, m_b!\, n_a!\, n_b!}{\alpha'_a!\alpha'_b!\beta'_a!\beta'_b!}, \tag{A1}$$

which is identical to (13).

APPENDIX B: CHARACTER TABLES

The character tables for $p=2,3$ are given here in the form used by Hamermesh in Ref. 9. The rows are labeled by the partitions that define the representations, and the columns are labeled by the cycle structures that define the classes. The number of elements in each class, $n(c)$, is written above the classes. The table for $p=1$ is trivial, and it consists of the sole value 1.

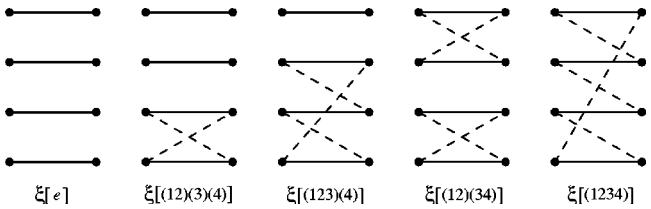

FIG. 13. The $p=4$ primitive diagrams.

1. $p=2$

Part.\Class	1 (1^2)	1 (2)
(2)	1	1
(1^2)	1	-1

2. $p=3$

Part.\Class	1 (1^3)	3 (1,2)	2 (3)
(3)	1	1	1
(2,1)	2	0	-1
(1^3)	1	-1	1

APPENDIX C: PRIMITIVE DIAGRAMS FOR $p=4$ AND $p=5$

Using (14) and the character tables for S_4 and S_5,[9] the algebraic expressions for the primitive diagrams of Fig. 13 and Fig. 14 can be obtained, and they are given in Table IV.

APPENDIX D: DERIVATION OF EQUATION (45)

We would like to express the general fully-opened integral $[A_a]^{\alpha}[A_b]^{\alpha}[B_a]^{\beta_a}[B_b]^{\beta_b}$ in terms of the special ones of the form $[A_a]^{\alpha'}[A_b]^{\alpha'}$. The idea is to apply a unitarity sum on the $[B_a]$ or $[B_b]$ basic patterns to get rid of them. To get the final result we also need to apply the fan relation (8) or the double-fan relations (12) and (13). Our approach is to first determine how can

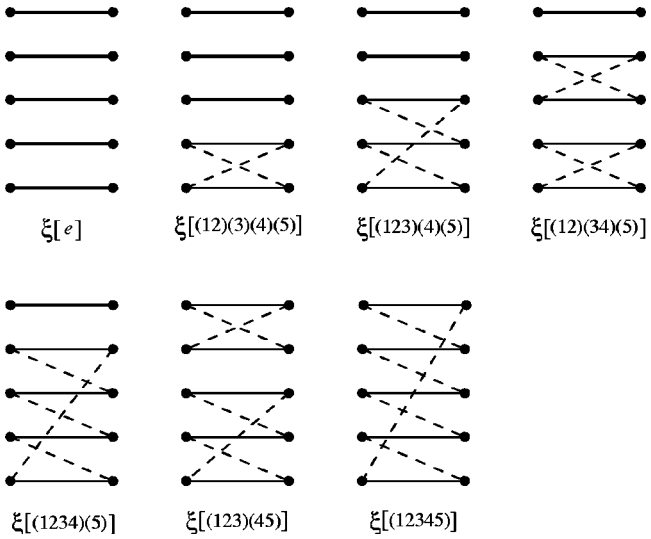

FIG. 14. The $p=5$ primitive diagrams.

(12)(3)(4)	$\frac{-1}{n(n^2-1)(n^2-9)}$	$\frac{-(n^2-2)(n^2-12)}{n^2(n^2-1)(n^2-4)(n^2-9)(n^2-16)}$
(123)(4)	$\frac{2n^2-3}{n^2(n^2-1)(n^2-4)(n^2-9)}$	$\frac{2}{n(n^2-1)(n^2-4)(n^2-16)}$
(12)(34)	$\frac{n^2+6}{n^2(n^2-1)(n^2-4)(n^2-9)}$	$\frac{n^2-2}{n(n^2-1)(n^2-4)(n^2-9)(n^2-16)}$
(1234)	$\frac{-5}{n(n^2-1)(n^2-4)(n^2-9)}$	$\frac{-5n^2+24}{n^2(n^2-1)(n^2-4)(n^2-9)(n^2-16)}$
(123)(45)		$\frac{-2(n^2+12)}{n^2(n^2-1)(n^2-4)(n^2-9)(n^2-16)}$
(12345)		$\frac{14}{n(n^2-1)(n^2-4)(n^2-9)(n^2-16)}$

$[A_a]^\alpha[A_b]^\alpha[B_a]^{\beta_a}$ be reduced to fully opened integrals involving only the $[A_a]$ and $[A_b]$ patterns. With such an information at hand, we will then try to reduce the more general $[A_a]^\alpha[A_b]^\alpha[B_a]^{\beta_a}[B_b]^{\beta_b}$ integrals into the $[A_a]^\alpha[A_b]^\alpha[B_a]^{\beta_a}$ integrals.

Let us apply a unitarity sum on one of the $[B_a]$ patterns in $[A_a]^\alpha[A_b]^\alpha[B_a]^{\beta_a}$:

$$\begin{aligned}(n-(2\alpha+\beta_a-1))\,[A_a]^\alpha[A_b]^\alpha[B_a]^{\beta_a}+(\beta_a-1)\,[A_a]^\alpha[A_b]^\alpha[B_a]^{\beta_a-2}[2B_a]\\ +\ \alpha([A_a]^\alpha[A_b]^{\alpha-1}[A_b+B_a][B_a]^{\beta_a-1}+[A_a]^{\alpha-1}[A_a+B_a][A_b]^\alpha[B_a]^{\beta_a-1})\\ =[A_a]^\alpha[A_b]^\alpha[B_a]^{\beta_a-1}.\end{aligned} \tag{D1}$$

Using (8), $[2B_a]$, in the second term above, can be rewritten as $2[B_a]^2$. Furthermore, Eq. (13) tells us that $[A_b+B_a]$ and $[A_a+B_a]$ can, respectively, be rewritten as $2[A_b][B_a]$ and $2[A_a]\times[B_a]$, and the term in parentheses above simplifies to $4[A_a]^\alpha[A_b]^\alpha[B_a]^{\beta_a}$. As a result, relation (D1) reduces to

$$[A_a]^\alpha[A_b]^\alpha[B_a]^{\beta_a}=\frac{1}{n+2\alpha+\beta_a-1}[A_a]^\alpha[A_b]^\alpha[B_a]^{\beta_a-1}. \tag{D2}$$

Using the relation (D2) recursively on its right-side, until no $[B_a]$ remains, we obtain

$$\begin{aligned}[A_a]^\alpha[A_b]^\alpha[B_a]^{\beta_a}&=\frac{1}{(n+2\alpha+\beta_a-1)}\,\frac{1}{(n+2\alpha+\beta_a-2)}\cdots\frac{1}{(n+2\alpha)}[A_a]^\alpha[A_b]^\alpha\\ &=\frac{(n+2\alpha-1)!}{(n+2\alpha+\beta_a-1)!}[A_a]^\alpha[A_b]^\alpha,\end{aligned} \tag{D3}$$

and the first step of the work is completed.

Assuming that $\beta_b\leqslant\beta_a$, let us perform a unitarity sum on a $[B_b]$ pattern in $[A_a]^\alpha[A_b]^\alpha[B_a]^{\beta_a}[B_b]^{\beta_b}$:

$$(n-(2\alpha+\beta_a+\beta_b-1))\,[A_a]^{\alpha}[A_b]^{\alpha}[B_a]^{\beta_a}[B_b]^{\beta_b}+(\beta_b-1)\,[A_a]^{\alpha}[A_b]^{\alpha}[B_a]^{\beta_a}[B_b]^{\beta_b-2}[2B_b]$$
$$+\beta_a\,[A_a]^{\alpha}[A_b]^{\alpha}[B_a]^{\beta_a-1}[B_a+B_b][B_b]^{\beta_b-1}+\alpha([A_a]^{\alpha}[A_b]^{\alpha-1}[A_b+B_b][B_a]^{\beta_a}[B_b]^{\beta_b-1}$$
$$+\;[A_a]^{\alpha-1}[A_a+B_b][A_b]^{\alpha}[B_a]^{\beta_a}[B_b]^{\beta_b-1})=[A_a]^{\alpha}[A_b]^{\alpha}[B_a]^{\beta_a}[B_b]^{\beta_b-1}. \tag{D4}$$

Relation (8), or formula (13), again permits us to make some simplifications, i.e., $[2B_b]=2[B_b]^2$, $[B_a+B_b]=[A_a][A_b]+[B_a][B_b]$, $[A_b+B_b]=2[A_b][B_b]$, $[A_a+B_b]=2[A_a][B_b]$. By making the proper substitutions in (D4), the recursion equation,

$$[A_a]^{\alpha}[A_b]^{\alpha}[B_a]^{\beta_a}[B_b]^{\beta_b}=\frac{1}{(n+2\alpha+\beta_b-1)}\{[A_a]^{\alpha}[A_b]^{\alpha}[B_a]^{\beta_a}[B_b]^{\beta_b-1}$$
$$-\;\beta_a[A_a]^{\alpha+1}[A_b]^{\alpha+1}[B_a]^{\beta_a-1}[B_b]^{\beta_b-1}\},$$

results. The above can be solved to give

$$[A_a]^{\alpha}[A_b]^{\alpha}[B_a]^{\beta_a}[B_b]^{\beta_b}=\sum_{e=0}^{\beta_b}\left\{(-1)^e e!\binom{\beta_a}{e}\binom{\beta_b}{e}(n+2\alpha-1+2e)\right.$$
$$\left.\cdot\,\frac{(n+2\alpha-2+e)!}{(n+2\alpha+\beta_b-1+e)!}[A_a]^{\alpha+e}[A_b]^{\alpha+e}[B_a]^{\beta_a-e}\right\},$$

which upon substitution of (D3) yields the desired Eq. (45).

SLE-type growth processes and the Yang–Lee singularity

Frédéric Lesage[a] and Jørgen Rasmussen[b]

(Received 10 November 2003; accepted 27 April 2004; published online 25 June 2004)

The recently introduced SLE growth processes are based on conformal maps from an open and simply connected subset of the upper half-plane to the half-plane itself. We generalize this by considering a hierarchy of stochastic evolutions mapping open and simply connected subsets of smaller and smaller fractions of the upper half-plane to these fractions themselves. The evolutions are all driven by one-dimensional Brownian motion. Ordinary chordal SLE appears at grade one in the hierarchy. At grade two we find a direct correspondence to conformal field theory through the explicit construction of a level-four null vector in a highest-weight module of the Virasoro algebra. This conformal field theory has central charge $c=-22/5$ and is associated with the Yang–Lee singularity. Our construction may thus offer a novel description of this statistical model. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1765747]

I. INTRODUCTION

A new approach to the description of conformal field theories (CFTs) in two dimensions has recently appeared where instead of discussing objects in terms of local fields and their fusions, one is rather interested in a description based on spatially extended quantities defined through geometry. The differential equations of the stochastic Löwner evolution (SLE) have emerged as a mathematically precise way of describing certain CFTs directly in the continuum, without reference to an underlying lattice.

The chordal SLE processes are constructed through conformal maps from a subset of the upper half-plane onto the half-plane itself. The processes are driven by the random one-dimensional Brownian motion. Properties thereby described have an intrinsic geometrical nature.

The study of these stochastic evolutions or growth processes was initiated by Schramm[1] and has been pursued further in Refs. 2–10, for example. A review for physicists may be found in Ref. 11, while Ref. 12 contains a mathematical introduction.

An explicit relationship between SLE and CFT has been elucidated recently[13,14] by considering random walks on the Virasoro group. The link is found through a singular vector at level two in highest-weight modules. The kernel of the vector corresponds to conserved quantities under the random process.

Although the correspondence exists, the number of CFTs having geometrical properties described by SLE is still very limited. Furthermore, there is no apparent pattern assisting in the identification of these new descriptions of field theories.

The aim of the present work is to show that there might be conformal systems described by generalizations of SLE. The approach of Bauer and Bernard[13,14] may be extended to more general walks than the one generating SLE. A particular class of extensions corresponds to a hierarchy of stochastic evolutions in which SLE appears at grade one. These growth processes are associated to conformal maps of open and simply connected subsets of smaller and smaller fractions of the upper half-plane onto the fractions themselves, and are all driven by one-dimensional Brownian motion. Using two-sided Brownian motion the stochastic processes may be extended to also

[a]Electronic mail: lesage@crm.umontreal.ca
[b]Electronic mail: rasmusse@crm.umontreal.ca

describing flows from fractions of the upper half-plane to subsets thereof. At grade two in the hierarchy we find a link to the Yang–Lee singularity through the construction of a level-four null vector. This in turn potentially offers a new geometrical description of that statistical model.

II. STOCHASTIC EVOLUTIONS

A. Stochastic Löwner evolution

Let Y_t be a real-valued continuous function, $t \geqslant 0$. For each element in the upper half-plane, $z \in \mathbb{H}$, we consider the solution $g_t(z)$ to Löwner's differential equation

$$\partial_t g_t(z) = \frac{2}{g_t(z) - Y_t}, \quad g_0(z) = z. \tag{1}$$

The factor 2 is conventional but could be changed by renormalization. Let $\tau = \tau(z)$ denote the time such that the solution $g_t(z)$ exists for all $t \in [0,\tau]$, while for increasing time $\lim_{t\to\tau} g_t(z) = Y_\tau$. Following Refs. 1, 8, and 12, one may define the evolving hull K_t as the closure of $\{z \in \mathbb{H}: \tau(z) \leqslant t\}$. In time, it is an increasing sequence of compact sets. As a conformal map from the simply connected domain $\mathbb{H}\backslash K_t$ onto the open half-plane $\mathbb{H}$, g_t is uniquely determined by the so-called hydrodynamic normalization at infinity:

$$\lim_{z\to\infty} (g_t(z) - z) = 0. \tag{2}$$

Stochastic Löwner evolutions are growth processes defined by choosing standard one-dimensional (and one-sided) Brownian motion, B_t, as the driving function: $Y_t = \sqrt{\kappa} B_t$, with $B_0 = 0$. The parameter κ characterizes the process which is denoted SLE_κ. For $t,s \geqslant 0$, the expectation value is normalized as $\mathbf{E}[(\sqrt{\kappa}B_t)(\sqrt{\kappa}B_s)] = \kappa \min(t,s)$.

One defines the function

$$f_t(z) := g_t(z) - Y_t. \tag{3}$$

It follows that it satisfies the differential equation

$$\partial_t f_t(z) = \frac{2}{f_t(z)} - \partial_t Y_t, \quad f_0(z) = z. \tag{4}$$

When Y_t denotes Brownian motion its time derivative is thought of as white noise: $dB_t/dt \sim W_t$. The inverse of the function f_t is related to the inverse of the SLE map: $f_t^{-1}(z) = g_t^{-1}(z + Y_t)$. The trace γ of SLE is then defined by

$$\gamma(t) := \lim_{z\to 0} f_t^{-1}(z). \tag{5}$$

By construction, z is an element of $\mathbb{H}$, so the limit is taken from the upper half-plane only. The nature of the trace is known to depend radically on κ (Ref. 8): for $0 \leqslant \kappa \leqslant 4$ it is a simple curve, for $4 < \kappa < 8$ a self-intersecting curve, whereas for $8 < \kappa$ it is space filling. The Hausdorff dimension of the SLE_κ trace is discussed in Refs. 8, 15, 16.

B. Hierarchy of stochastic evolutions

For positive integer n, we define the open subset of $\mathbb{H}$,

$$\mathbb{H}_n = \{z \in \mathbb{H}: z = re^{i\theta};\ r \in \mathbb{R}_>;\ 0 < \theta < \pi/n\}. \tag{6}$$

Note that $\mathbb{H}_1$ is the upper half-plane itself. We now introduce a hierarchy of Löwner-type differential equations whose solutions have properties similar to the SLE maps. For positive integer n we define the differential equation

$$\partial_t g_t(z) = \frac{2}{g_t^{n-1}(z)(g_t^n(z) - Y_t)}, \quad g_0(z) = z \tag{7}$$

with $Y_0 = 0$. For each $z \in \mathbb{H}_n$ the solution is well-defined up to a time $\tau_n(z)$. Similarly to the ordinary SLE case, the differential equation (7) describes the evolution of the hull $K_t^{(n)}$ defined as the closure of $\{z \in \mathbb{H}_n : \tau_n(z) \leqslant t\}$.

The solution to (7) is a conformal map from $\mathbb{H}_n \backslash K_t^{(n)}$ onto $\mathbb{H}_n$. To see this, one may generalize the proof of Proposition 2.2 in Ref. 12. One first verifies that $\partial_z g_t(z)$ is well-defined by analyzing $\partial_t \partial_z g_t(z)$. From the evaluation of $\partial_t(g_t(z) - g_t(z'))$ (which is shown to have $(g_t(z) - g_t(z'))$ as a factor), one deduces that $g_t(z) \neq g_t(z')$ when $z \neq z'$. It has thereby been established that g_t is a conformal transformation of $\mathbb{H}_n \backslash K_t^{(n)}$. To show that $g_t(\mathbb{H}_n \backslash K_t^{(n)}) = \mathbb{H}_n$, one studies the inverse flow $h_t(w)$, $w \in \mathbb{H}_n$, which is a solution to

$$\partial_t h_t(w) = -\frac{2}{h_t^{n-1}(w)(h_t^n(w) - Y_{t_0 - t})}, \quad h_0(w) = w \tag{8}$$

for some $t_0 \geqslant 0$. The solution $h_t(w)$ is well-defined for $0 \leqslant t \leqslant t_0$ since $\partial_t \operatorname{Im}(h_t^n(w)) > 0$ and $|h_t^{n-1}| \geqslant \min\{|h_t^n(w)|, 1\}$. This ensures that the solution cannot hit the singularities. With $z = h_{t_0}(w)$, $g_t(z) = h_{t_0 - t}(w)$ is seen to be a solution to (7) (implying that $h_t(w)$ is indeed the inverse flow), and $g_{t_0}(z) = w$ showing that $w \in g_{t_0}(\mathbb{H}_n \backslash K_t^{(n)})$.

The solution to (7) is determined uniquely by the hydrodynamic normalization at infinity (2). It has the power series expansion

$$g_t(z) = z + \frac{2t}{z^{2n-1}} + \mathcal{O}(1/|z|^{(2n)}), \quad z \to \infty. \tag{9}$$

We refer to the process as being of grade n.

When $n = 1$ (and $Y_t = \sqrt{\kappa} B_t$) we recover the ordinary SLE equation (1). In a subsequent section we shall focus on grade $n = 2$ as it is in this case we find a new relation to CFT and the Yang–Lee singularity.

Two important properties of ordinary SLE are scale invariance and a sort of stationarity. These apply to solutions to (7) as well. In the spirit of Proposition 2.1 in Ref. 8 (see also Ref. 3), we have that the growth process defined by (7) is scale invariant in the following sense. For $\alpha > 0$ the process $t \mapsto \alpha^{-1/(2n)} K_{\alpha t}^{(n)}$ has the same law as $t \mapsto K_t^{(n)}$, while the process $(z,t) \mapsto \alpha^{-1/(2n)} g_{\alpha t}(\alpha^{1/(2n)} z)$ has the same law as $(z,t) \mapsto g_t(z)$. Also, the map $\tilde{g}(z) := (g_{t_1} \circ g_{t_0}^{-1}) \times (z + Y_{t_0}) - Y_{t_0}$ has the same law as $g_{t_1 - t_0}$ when $t_1 > t_0 > 0$. Moreover, $\tilde{g}$ is independent of g_{t_0}. These assertions can be proved by a simple adaptation of the proof for ordinary SLE.

We define f_t through

$$f_t^n(z) = g_t^n(z) - Y_t. \tag{10}$$

It follows that $f_t(z)$ satisfies the differential equation

$$\partial_t f_t(z) = \frac{2}{f_t^{2n-1}(z)} - \frac{1/n}{f_t^{n-1}(z)} \partial_t Y_t, \quad f_0(z) = z \tag{11}$$

with a canonical choice of boundary condition. The solution respects the hydrodynamic normalization at infinity (2), and it corresponds to choosing the "principal root" in the relation (10). As in ordinary SLE, we use f_t to define an SLE-type trace for the hierarchy of evolutions:

$$\gamma_n(t) := \lim_{z\to 0} f_t^{-1}(z). \tag{12}$$

To illustrate our construction, we now consider the situation where the driving function vanishes for all t: $Y_t \equiv 0$ (corresponding to $\kappa \equiv 0$). The differential equation becomes

$$\partial_t g_t(z) = \frac{2}{g_t^{2n-1}(z)}, \quad g_0(z) = z \tag{13}$$

with solution

$$g_t(z) = (z^{2n} + 4nt)^{1/(2n)}. \tag{14}$$

The trace reads

$$\gamma_n(t) = |(4nt)^{1/(2n)}| e^{i\pi/(2n)} \tag{15}$$

while the hull is

$$K_t^{(n)} = \{re^{i\pi/(2n)} : r \in [0, |(4nt)^{1/(2n)}|]\}. \tag{16}$$

Following Ref. 8 on ordinary SLE, we may take B to be two-sided Brownian motion (or more generally, Y to be defined for negative t as well). Equation (7) can then also be solved for negative t, in which case g_t is a conformal map from $\mathbb{H}_n$ into a subset of $\mathbb{H}_n$. Indeed, Lemma 3.1 in Ref. 8 extends to our case. In the extended version it states that the map $z \mapsto g_{-t}(z)$ has the same distribution as the mapping of z into the principal nth root of $((g_t^{-1}((z^n + Y_t)^{1/n}))^n - Y_t)$. To see this we first observe that for $z \in \mathbb{H}_n$ the principal nth root of $(z^n + x)$ for x real also lies in $\mathbb{H}_n$. For $t_1 \in \mathbb{R}$ we then define the function $\hat{g}_t^{(t_1)}$ as the principal root in the functional relation

$$(\hat{g}_t^{(t_1)}(z))^n = (g_{t_1+t} \circ g_{t_1}^{-1}((z^n + Y_{t_1})^{1/n}))^n - Y_{t_1}. \tag{17}$$

It follows that $\hat{g}_t^{(t_1)}(z)$ is a solution to

$$\partial_t \hat{g}_t^{(t_1)}(z) = \frac{2}{(\hat{g}_t^{(t_1)}(z))^{n-1}((\hat{g}_t^{(t_1)}(z))^n - (Y_{t_1+t} - Y_{t_1}))}, \quad \hat{g}_0^{(t_1)}(z) = z. \tag{18}$$

We note that $\hat{Y}_t^{(t_1)} := Y_{t_1+t} - Y_{t_1}$ has the same law as Y_t as maps from $\mathbb{R}$ to $\mathbb{R}$, and since

$$(\hat{g}_{-t_1}^{(t_1)}(z))^n = (g_{t_1}^{-1}((z^n + Y_{t_1})^{1/n}))^n - Y_{t_1}, \tag{19}$$

the assertion of the extended lemma follows.

With two-sided Brownian motion at hand, we may define alternatively to (10)

$$f_t^n(z) = g_{-t}^n(z) - Y_{-t} \tag{20}$$

satisfying

$$\partial_t f_t(z) = \frac{-2}{f_t^{2n-1}(z)} - \frac{1/n}{f_t^{n-1}(z)} \partial_t Y_{-t}, \quad f_0(z) = z. \tag{21}$$

Choosing the driving function as $Y_t = \sqrt{\kappa} B_{-t}$ we have

$$df_t(z) = \frac{-2}{f_t^{2n-1}(z)} dt - \frac{\sqrt{\kappa}/n}{f_t^{n-1}(z)} dB_t, \quad f_0(z) = z. \tag{22}$$

This will appear in the link to the Yang–Lee singularity addressed below.

It is remarked that our construction may be interpreted as chordal SLE in $\mathbb{H}_n$. To appreciate this, we introduce $\phi_n(z)=z^n$ and let $G_t^{(n)}(z)$ denote the map in (7) when $Y_t=\sqrt{\kappa}B_t$. $G_t^{(1)}(z)$ thus corresponds to chordal SLE in the upper half-plane $\mathbb{H}_1=\mathbb{H}$. We then have that

$$\hat{G}_t^{(n)}(z)=\phi_n^{-1}\circ G_{nt}^{(1)}\circ\phi_n(z) \tag{23}$$

(where ϕ_n^{-1} singles out the principal root) satisfies (7) albeit with $\hat{\kappa}=n\kappa$. As a consequence, $K_t^{(n)}$ is seen to correspond to $\phi_n^{-1}(K_{nt}^{(1)})$.

III. RELATION TO CONFORMAL FIELD THEORY

A. Ordinary SLE

Bauer and Bernard[13,14] have recently discussed a direct relationship between SLE_κ and CFT. Their construction starts from a random walk on the (somewhat formal) Virasoro group:

$$G_t^{-1}dG_t=-2L_{-2}dt+\sqrt{\kappa}L_{-1}\circ dB_t,\quad G_0=1, \tag{24}$$

here written in the Stratonovich interpretation. We shall rather discuss it in the Ito form where it reads

$$G_t^{-1}dG_t=\left(-2L_{-2}+\frac{\kappa}{2}L_{-1}^2\right)dt+\sqrt{\kappa}L_{-1}dB_t,\quad G_0=1. \tag{25}$$

G_t is an element of Vir_- obtained by exponentiating the negative modes, L_n, $n<0$, of the Virasoro algebra. We write a generic element $G\in\mathrm{Vir}_-$ as

$$G=\cdots e^{x_2L_{-2}}e^{x_1L_{-1}} \tag{26}$$

and recall the definition of the Virasoro algebra:

$$[L_n,L_m]=(n-m)L_{n+m}+\frac{c}{12}n(n^2-1)\,\delta_{n+m,0}. \tag{27}$$

The central charge c plays a prominent role in CFT. As we shall discuss, it is through the construction of singular vectors in highest-weight modules of the Virasoro algebra that the connection to SLE_κ is established.[13,14]

The conformal transformation generated by (25) acts on a primary field of weight Δ as

$$G_t^{-1}\phi_\Delta(z)G_t=(\partial_z f_t(z))^\Delta\phi_\Delta(f_t(z)) \tag{28}$$

for some conformal map f_t to be determined. (For simplicity, we do not distinguish explicitly between boundary and bulk primary fields, nor do we write the antiholomorphic part.) Using that the Virasoro generators act as

$$[L_n,\phi_\Delta(z)]=(z^{n+1}\partial_z+\Delta(n+1)z^n)\phi_\Delta(z), \tag{29}$$

one finds that the conformal map associated to the random process (25) must be a solution to the stochastic differential equation

$$df_t(z)=\frac{2}{f_t(z)}dt-\sqrt{\kappa}dB_t,\quad f_0(z)=z \tag{30}$$

corresponding to (4). This follows from computing the Ito differential of (28) and is discussed in more details in Refs. 13, 14.

Observables of the random process (25) are thought of as functions on the Virasoro group, $F(G_t)$, and a goal is to find the evolution for the expectation values of these observables. With the left-invariant vector fields, ∇_ℓ, defined by

$$\nabla_\ell F(G_t)=\frac{d}{du}F(G_t e^{uL_\ell})|_{u=0} \tag{31}$$

one has[13] that the expectation value $\mathbf{E}[F(G_t)]$ satisfies

$$\partial_t \mathbf{E}[F(G_t)]=\mathbf{E}\left[\left(-2\nabla_{-2}+\frac{\kappa}{2}\nabla_{-1}^2\right)F(G_t)\right]. \tag{32}$$

We shall be interested in observables of the form $F_\Delta(G_t)=G_t|\Delta\rangle$ where $|\Delta\rangle$ is the highest-weight vector of weight Δ in the Verma module $\mathcal{V}_\Delta=\mathrm{Vir}_-|\Delta\rangle$ (see Refs. 13, 14 and below). In this case the expectation value reads

$$\partial_t \mathbf{E}[G_t|\Delta\rangle]=\mathbf{E}\left[G_t\left(-2L_{-2}+\frac{\kappa}{2}L_{-1}^2\right)|\Delta\rangle\right]. \tag{33}$$

For some values of κ (in relation to the central charge c), the linear combination $-2L_{-2}+(\kappa/2)L_{-1}^2$ will produce a singular vector when acting on the highest-weight vector in a highest-weight module. This is an important point as it enables one, through the representation theory of the algebra, to find quantities conserved in mean under the random process.

The Verma module $\mathcal{V}_\Delta$ contains the singular vector at level two

$$|\Delta;2\rangle=\left(L_{-2}-\frac{\kappa}{4}L_{-1}^2\right)|\Delta\rangle \tag{34}$$

provided $L_1|\Delta;2\rangle=L_2|\Delta;2\rangle=0$. It is straightforward to show that this implies the parametrizations

$$c_\kappa=1-\frac{3(4-\kappa)^2}{2\kappa},\quad \Delta_\kappa=\frac{6-\kappa}{2\kappa}. \tag{35}$$

The expectation value of the observable $F_\Delta(G_t)=G_t|\Delta\rangle$ thus vanishes (33):

$$\partial_t \mathbf{E}[G_t|\Delta\rangle]=0. \tag{36}$$

We see that this direct relationship between SLE_κ evolutions and CFT is through the existence of a level-two singular vector in a highest-weight module. As discussed in Ref. 14, this relationship provides links between conformal correlation functions and probabilities in SLE_κ.

B. Extended SLE

Since Brownian motion played a significant role in the derivation of (32) and (33), and hence in the correspondence between SLE and CFT, it remains unclear how to treat more general random processes than (25). An extension invites itself, though. Namely, consider the random walk

$$G_t^{-1}dG_t=v_{-n}L_{-2n}dt+\sqrt{\kappa}u_{-n}L_{-n}\circ dB_t,\quad G_0=1 \tag{37}$$

or in the Ito interpretation

$$G_t^{-1}dG_t=\left(v_{-n}L_{-2n}+\frac{\kappa u_{-n}^2}{2}L_{-n}^2\right)dt+\sqrt{\kappa}u_{-n}L_{-n}dB_t,\quad G_0=1. \tag{38}$$

In this case we have

$$\partial_t \mathbf{E}[F(G_t)] = \mathbf{E}\left[\left(v_{-n}\nabla_{-2n} + \frac{\kappa u_{-n}^2}{2}\nabla_{-n}^2\right)F(G_t)\right] \tag{39}$$

and in particular

$$\partial_t \mathbf{E}[G_t|\Delta\rangle] = \mathbf{E}\left[G_t\left(v_{-n}L_{-2n} + \frac{\kappa u_{-n}^2}{2}L_{-n}^2\right)|\Delta\rangle\right]. \tag{40}$$

To relate this to the SLE-type differential equations discussed above, we write (11) and (22) uniformly as

$$df_t(z) = \frac{2(-1)^{s+1}}{(f_t(z))^{2n-1}}dt - \frac{\sqrt{\kappa}/n}{(f_t(z))^{n-1}}dB_t, \tag{41}$$

where $s=1$ or $s=2$ depending on the choice of relation (10) or (20), respectively. Taking the Ito differential of the right-hand side of (28) results in

$$d\{(\partial_z f_t(z))^{\Delta}\phi_{\Delta}(f_t(z))\} = \left[\left(2(-1)^{s+1} + \frac{\kappa(n-1)}{2n^2}\right)L_{-2n}dt - \frac{\sqrt{\kappa}}{n}L_{-n}dB_t, (\partial_z f_t(z))^{\Delta}\phi_{\Delta}(f_t(z))\right]$$
$$+ \frac{\kappa}{2n^2}[L_{-n},[L_{-n},(\partial_z f_t(z))^{\Delta}\phi_{\Delta}(f_t(z))]]dt \tag{42}$$

while the Ito differential of the left-hand side of (28) generated by the random walk (38) reads

$$d\{G_t^{-1}\phi_{\Delta}(f_t(z))G_t\} = [-v_{-n}L_{-2n}dt - \sqrt{\kappa}u_{-n}L_{-n}dB_t, G_t^{-1}\phi_{\Delta}(f_t(z))G_t]$$
$$+ \frac{\kappa u_{-n}^2}{2}[L_{-n},[L_{-n},G_t^{-1}\phi_{\Delta}(f_t(z))G_t]]dt. \tag{43}$$

A comparison of the two Ito differentials suggests considering the walk

$$G_t^{-1}dG_t = \left(\left(2(-1)^s - \frac{\kappa(n-1)}{2n^2}\right)L_{-2n} + \frac{\kappa}{2n^2}L_{-n}^2\right)dt + \frac{\sqrt{\kappa}}{n}L_{-n}dB_t. \tag{44}$$

According to this, we should be looking for singular vectors of the form

$$|\Delta;2n\rangle = \left(\left(2(-1)^s - \frac{\kappa(n-1)}{2n^2}\right)L_{-2n} + \frac{\kappa}{2n^2}L_{-n}^2\right)|\Delta\rangle. \tag{45}$$

The upset, however, is that for $n>1$

$$L_1|\Delta;2n\rangle = \left(\left((2n+1)\left(2(-1)^s - \frac{\kappa(n-1)}{2n^2}\right) + \frac{(n+1)\kappa}{2n^2}\right)L_{-(2n-1)} + \frac{(n+1)\kappa}{n^2}L_{-n}L_{-(n-1)}\right)|\Delta\rangle$$
$$\neq 0 \tag{46}$$

for all κ. This means that (45) can be a singular vector only when $n=1$, and is then given by (34) (when $s=1$). One should not be completely discouraged by this. The pivotal property of the state $(L_{-2} - \kappa/4L_{-1}^2)|\Delta\rangle$ appearing in (33) and applications thereof,[14] is that it vanishes in the quotient space of $\mathcal{V}_{\Delta}$ where all singular vectors have been factored out. In other words, it is a null vector.

This means that we do not have to insist that the vector (45) is a (primitive) singular vector itself, but only require that it is a linear combination of descendants of (primitive) singular vectors. An example is provided below.

IV. YANG–LEE SINGULARITY

Generically, the Verma module $\mathcal{V}_\Delta$ is irreducible. Minimal models[17,18] are examples of CFTs for which it is reducible. They are labeled by a pair of positive and co-prime integers $p>p'$, and are denoted $\mathcal{M}(p,p')$. The central charge is

$$c=1-6\frac{(p-p')^2}{pp'} \tag{47}$$

while the spectrum of primary fields or highest-weight representations have conformal weights

$$\Delta_{r,s}=\frac{(rp-sp')^2-(p-p')^2}{4pp'},\quad 1\leqslant r<p',\quad 1\leqslant s<p, \tag{48}$$

with $\Delta_{p'-r,p-s}=\Delta_{r,s}$. There are two singular vectors not being descendants of singular vectors themselves, and they appear at levels rs and $(p'-r)(p-s)$.

For $p'=2$, there is only one primary field admitting a singular vector at level two, in which case $(r,s)=(1,2)$. For $p'>2$, on the other hand, there are two such fields, labeled by (1,2) and (2,1), respectively. It is easily verified that

$$\Delta_{1,2}=\Delta_{\kappa=4p/p'},\quad \Delta_{2,1}=\Delta_{\kappa=4p'/p}. \tag{49}$$

It follows that SLE_κ and $\mathrm{SLE}_{16/\kappa}$, with $\kappa=4p/p'$, may be linked to the same minimal model, albeit via two different primary fields in the model.

The simplest example of a null vector of the form (45) for $n>1$ that we have found is a level-four vector in the minimal model $\mathcal{M}(5,2)$ with $c=-22/5$, cf. (47). This model offers a CFT description of the statistical Yang–Lee singularity. Unlike ordinary SLE (except $\mathrm{SLE}_{\kappa=6}$ which is known to correspond to percolation, and has central charge $c=0$), the null vector appears in the *identity module* having singular vectors

$$|0\rangle_1=L_{-1}|0\rangle,$$

$$|0\rangle_4=\left(L_{-4}+\frac{5}{27}L_{-3}L_{-1}-\frac{5}{3}L_{-2}^2+\frac{125}{27}L_{-2}L_{-1}^2-\frac{125}{108}L_{-1}^4\right)|0\rangle. \tag{50}$$

The null vector of our interest reads

$$|0;4\rangle=|0\rangle_4+\left(-\frac{5}{27}L_{-3}-\frac{125}{27}L_{-2}L_{-1}+\frac{125}{108}L_{-1}^3\right)|0\rangle_1=\left(L_{-4}-\frac{5}{3}L_{-2}^2\right)|0\rangle. \tag{51}$$

Comparing this to (45), we find that the Yang–Lee singularity is related to a grade-two SLE-type evolution with

$$\kappa=40 \tag{52}$$

and $s=2$. There is no non-negative solution for κ when $s=1$. In summary, this SLE-type evolution reads

$$\partial_t g_t(z)=\frac{2}{g_t(z)(g_t^2(z)-\sqrt{40}B_t)},\quad g_0(z)=z \tag{53}$$

or in terms of $f_t(z)$, cf. (22) and (41):

$$df_t(z)=\frac{-2}{f_t^3(z)}dt-\frac{\sqrt{10}}{f_t(z)}dB_t, \quad f_0(z)=z. \tag{54}$$

This provides a novel approach to the Yang–Lee model, and may eventually lead to an explicit geometric realization.

V. CONCLUSION

As observed by Bauer and Bernard,[13,14] SLE may be linked to CFT through the construction of a singular vector in a Virasoro highest-weight module. We have extended their approach, and found that the Yang–Lee singularity may be described by a generalization of the SLE differential equation. This new stochastic evolution appears at grade two in a hierarchy of SLE-type growth processes in which ordinary SLE appears at grade one. Their approach has recently been extended also to stochastic evolutions in superspace and superconformal field theory.[19] Another extension will appear elsewhere where it is discussed how SLE-type growth processes may be linked to CFT via (nonprimary) descendant fields. A possible classification of these links will also be addressed.

(Received 24 November 2003; accepted 22 April 2004; published online 25 June 2004)

We perform the complete group classification in the class of nonlinear Schrödinger equations of the form $i\psi_t+\psi_{xx}+|\psi|^\gamma\psi+V(t,x)\psi=0$, where V is an arbitrary complex-valued potential depending on t and x, γ is a real nonzero constant. We construct all the possible inequivalent potentials for which these equations have nontrivial Lie symmetries using a combination of algebraic and compatibility methods. The proposed approach can be applied to solving group classification problems for a number of important classes of differential equations arising in mathematical physics. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1765748]

I. INTRODUCTION

Nonlinear Schrödinger equations (NSchEs) are important objects for investigation in different fields of physics and mathematics. They are used in geometric optics,[6] nonlinear quantum mechanics,[4] and the theory of Bose–Einstein condensation. NSchEs also have a number of applications in wave propagation in inhomogeneous medium and arise as a model of plasma phenomena. The cubic Schrödinger equation is one of the most known integrable models of mathematical physics. At the same time the physical interpretation of some known types of nonlinear Schrödinger equations is not completely clear and is an interesting problem to solve.

Schrödinger equations have been investigated by means of symmetry methods by a number of authors. (See, e.g., Refs. 7–13,15,17,18, and references therein for classical Lie symmetries.) In fact, group classification for Schrödinger equations was first performed by Lie. More precisely, his classification[14] of all the linear equations with two independent complex variables contains, in an implicit form, solving the classification problem for the linear $(1+1)$-dimensional Schrödinger equations with an arbitrary potential. And it is follows from Lie's proof that the equations for the harmonic and repulsive oscillators and free fall are locally equivalent to the free Schrödinger equation.

To the best of our knowledge, actual investigations of Lie symmetries for Schrödinger equations were started in 1970s with the linear case.[15,17,18] The next considered class covered $(1+n)$-dimensional NSchEs with nonlinearities of the form $f(|\psi|)\psi$, which are notable for their symmetry properties because any such equation is invariant with respect to the Galilean group. It turned out that extensions of this invariance group are possible only for the logarithm and power functions, and there exists the power value $\gamma=4/n$ which is special with respect to the symmetry

[a]Electronic mail: rop@imath.kiev.ua
[b]Electronic mail: ivanova@imath.kiev.ua
[c]Electronic mail: eshraghi@theory.ipm.ac.ir

point of view.[7] Namely, the free Schrödinger equation and the NSchE with the nonlinearity $|\psi|^{4/n}\psi$ are distinctive ones from a lot of similar equations, since they admit the complete Galilei group extended with both the scale and conformal transformations. (Here n is the number of spatial variables, and for $n=1$ and $n=2$ they are the quintic and cubic equations, respectively, that stand out against the other NSchEs.) This NSchE has also other special properties, and the value $\gamma=4/n$ is called now the critical power.

The results mentioned above formed a basis for symmetry studying more extended classes of NSchEs. So, finishing the series of papers[8–12] on group analysis and exact solutions of NSchEs, Gagnon and Winternitz[12] investigated a general class of $(1+1)$-dimensional variable coefficient cubic SchEs. It is the symmetry approach that was applied by Doebner and Goldin to obtain new equations which generalize the Schrödinger equation and can be used in nonlinear quantum mechanics.[4] These equations were investigated in more detail with the symmetry point of view by a number of authors.[5,16,26] The complete group classification of constant coefficient NSchEs with nonlinearities of the general form $F=F(\psi,\psi^*)$ was performed by Nikitin and Popovych.[19]

Group classification is one of symmetry methods used to choose physically relevant models from parametric classes of systems of (partial or ordinary) differential equations. The parameters can be constants or functions of independent variables, unknown functions and their derivatives. Exhaustive consideration of the problem of group classification for a parametric class $\mathcal{L}$ of systems of differential equations includes the following steps:

(1) Finding the group $G^{\rm ker}$ (the kernel of maximal invariance groups) of local transformations that are symmetries for all systems from $\mathcal{L}$.
(2) Construction of the group $G^{\rm equiv}$ (the equivalence group) of local transformations which transform $\mathcal{L}$ into itself.
(3) Description of all possible $G^{\rm equiv}$-inequivalent values of parameters that admit maximal invariance groups wider than $G^{\rm ker}$.

Following Lie, one usually considers infinitesimal transformations instead of finite ones. This approach essentially simplifies the problem of group classification, reducing it to problems for Lie algebras of vector fields. See Refs. 1,2,19,21,22,24–26 for precise formulation of group classification problems and more details on the used methods.

In this paper we study a class of NSchEs of the form

$$i\psi_t+\psi_{xx}+|\psi|^{\gamma}\psi+V\psi=0, \tag{1}$$

where the potential $V=V(t,x)$ is an arbitrary complex-valued smooth function of the variables t and x, γ is a real nonzero constant. (Here and below subscripts of functions denote differentiation with respect to the respective variables.) To find a complete set of inequivalent cases of V admitting extensions of the maximal Lie invariance algebra, we combine the classical Lie approach, studying the algebra generated by all the possible Lie symmetry operators for equations from class (1) (the adjoint representation, the inequivalent one-dimensional subalgebras, etc.) and investigation of compatibility of classifying equations. The subclass of (1) where $\gamma=2$ (the cubic SchEs with potentials) has been investigated in Ref. 23 in a similar way.

In fact, here we solve three classification problems for different classes of equations having the form (1): with the potentials depending only on t (Sec. III), with the stationary potentials (Sec. IV) and the general case with arbitrary potentials (Sec. II). Moreover, it is proved in Sec. II the constant γ can be assumed as *fixed* under our consideration. And there exists a special constant $\hat{\gamma}$ depending on the power γ ($\hat{\gamma}=\gamma^{-1}(4-\gamma)$), which arises at the beginning of the classification procedure when classification condition (3) is constructed and explicitly appears in the final results of classification. The value $\gamma=4$ (quintic nonlinearity, it is the same that $\hat{\gamma}=0$) is special with respect to group classification in class (1).

The classification approach used in this paper allows us to formulate a necessary and sufficient condition of mutual equivalence for the cases of extensions of maximal invariance algebras in algebraic terms (Corollary 2). The classical stationary potentials (free particle, the harmonic and

repulsive oscillators, free fall, radial free particle, the radial harmonic and repulsive oscillators[15]) naturally arise under the group classification with respect to the (smaller) equivalence group in the class of stationary potentials. Using Corollary 2 and the complete equivalence group of class (1) we easily construct transformations of these x-dependent potentials to x-free ones in explicit form (see Remark 8).

II. GENERAL CASE $V=V(t,x)$

Consider an operator $Q=\xi^t\partial_t+\xi^x\partial_x+\eta\partial_\psi+\eta^*\partial_{\psi^*}$ from the maximal Lie invariance algebra $A^{\max}(\gamma,V)$ of Eq. (1) with a power γ and a potential V. Here ξ^t, ξ^x, and η are smooth functions of t, x, ψ, and ψ^*. The infinitesimal invariance condition[21,20] of Eq. (1) with respect to the operator Q implies the linear overdetermined system on the coefficients of Q:

$$\xi^t_\psi=\xi^t_{\psi^*}=\xi^t_x=0,\quad \xi^x_\psi=\xi^x_{\psi^*}=0,\quad \xi^t_t=2\xi^x_x,\quad \eta_{\psi^*}=\eta_{\psi\psi}=0,\quad \psi\eta_\psi=\eta,$$

$$2\eta_{\psi x}=i\xi^x_t,\quad \gamma(\eta_\psi+\eta^*_\psi)=-2\xi^t_t,\quad i\eta_{\psi t}+\eta_{\psi xx}+\xi^tV_t+\xi^xV_x+\xi^t_tV=0.$$

Therefore, the following theorem holds:

Theorem 1: *Any operator Q from $A^{\max}(\gamma,V)$ of Eq. (1) with arbitrary potential V lies in the linear span of operators of the form*

$$D(\xi)=\xi\partial_t+\frac{1}{2}\xi_t x\partial_x+\frac{1}{8}\xi_{tt}x^2M-\frac{1}{\gamma}\xi_tI,\quad G(\chi)=\chi\partial_x+\frac{1}{2}\chi_t xM,\quad \lambda M. \tag{2}$$

Here $\chi=\chi(t)$, $\xi=\xi(t)$ and $\lambda=\lambda(t)$ are arbitrary smooth functions of t, $M=i(\psi\partial_\psi-\psi^*\partial_{\psi^*})$, $I=\psi\partial_\psi+\psi^*\partial_{\psi^*}$. Moreover, the coefficients of $Q=D(\xi)+G(\chi)+\lambda M\in A^{\max}(\gamma,V)$ should satisfy the classifying condition

$$\xi V_t+\left(\frac{1}{2}\xi_t x+\chi\right)V_x+\xi_tV=\frac{1}{8}\xi_{ttt}x^2+\frac{1}{2}\chi_{tt}x+\lambda_t+i\frac{\hat\gamma}{4}\xi_{tt}. \tag{3}$$

Here and below $\hat\gamma=\gamma^{-1}(4-\gamma)$.

Theorem 2: *The Lie algebra of the kernel of maximal Lie invariance groups of equations from class* (1) *is $A^{\ker}=\langle M\rangle$.*

Remark 1: Sometimes (e.g., for reduction and construction of solutions) it is convenient to use the amplitude ρ and the phase φ instead of the wave function $\psi=\rho e^{i\varphi}$. Then Eq. (1) is replaced by the system for two real-valued functions ρ and φ:

$$\rho_t+2\rho_x\varphi_x+\rho\varphi_{xx}+\rho\,\mathrm{Im}\,V=0,\quad -\rho\varphi_t-\rho(\varphi_x)^2+\rho_{xx}+\rho^{\gamma+1}+\rho\,\mathrm{Re}\,V=0.$$

Operators (2) have the same form with $M=\partial_\varphi$, $I=\rho\partial_\rho$.

To study equivalence transformations for class (1), both the infinitesimal and direct methods are used. In the framework of the infinitesimal method we consider a first-order differential operator of the most general form in the space of the variables t, x, ψ, ψ^*, V, V^*, and γ, i.e.,

$$Q=\xi^t\partial_t+\xi^x\partial_x+\eta\partial_\psi+\eta^*\partial_{\psi^*}+\theta\partial_V+\theta^*\partial_{V^*}+\Gamma\partial_\gamma,$$

where ξ^t, ξ^x, η, θ, and Γ may depend on all the variables, and assume it being an infinitesimal symmetry operator for the system

$$i\psi_t+\psi_{xx}+|\psi|^\gamma\psi+V\psi=0,\quad \gamma_t=\gamma_x=\gamma_\psi=\gamma_{\psi^*}=0,\quad V_\psi=V_{\psi^*}=0. \tag{4}$$

(Under the prolongation procedure for equivalence transformations we suppose ψ is a function of t and x as well as V and γ are functions of t, x, ψ, and ψ^*.)

Theorem 3: *The Lie algebra A^{equiv} of the equivalence group G^{equiv} of class (1) is generated by the operators*

$$D'(\xi)=D(\xi)+\frac{1}{8}\xi_{ttt}x^2(\partial_V+\partial_{V*})+\frac{i}{\gamma}\xi_{tt}(\partial_V-\partial_{V*})-\xi_t(V\partial_V+V^*\partial_{V*}),$$

$$G'(\chi)=G(\chi)+\tfrac{1}{2}\chi_{tt}x(\partial_V+\partial_{V*}),\quad M'(\lambda)=\lambda M+\lambda_t(\partial_V+\partial_{V*}).$$

In the framework of the direct method we look for all local transformations in the space of the variables t, x, ψ, ψ^*, V, V^*, and γ, which preserve system (4).

Theorem 4: *The equivalence group G^{equiv} of the class (1) is generated by the family of continuous transformations*

$$\tilde t=T,\quad \tilde x=x\sqrt{T_t}+X,\quad \tilde\psi=\psi\frac{1}{(T_t)^{1/\gamma}}\exp\left(\frac{i}{8}\frac{T_{tt}}{T_t}x^2+\frac{i}{2}\frac{X_t}{\sqrt{T_t}}x+i\Psi\right),\quad \tilde\gamma=\gamma,$$

$$\tilde V=\frac{1}{T_t}\left(V+\frac{1}{8}\left(\frac{T_{tt}}{T_t}\right)_t x^2+\frac{1}{2}\left(\frac{X_t}{\sqrt{T_t}}\right)_t x+i\frac{\hat\gamma}{4}\frac{T_{tt}}{T_t}-\left(\frac{1}{4}\frac{T_{tt}}{T_t}x+\frac{1}{2}\frac{X_t}{\sqrt{T_t}}\right)^2+\Psi_t\right) \tag{5}$$

and two discrete transformations: the space reflection I_x ($\tilde t=t$, $\tilde x=-x$, $\tilde\psi=\psi$, $\tilde\gamma=\gamma$, $\tilde V=V$) and the Wigner time reflection I_t ($\tilde t=-t$, $\tilde x=x$, $\tilde\psi=\psi^*$, $\tilde\gamma=\gamma$, $\tilde V=V^*$). Here T, X, and Ψ are arbitrary smooth functions of t, $T_t>0$.

We also prove the stronger statement than Theorem 4.

Theorem 5: *If two equations from class (1) with the parameter values (γ,V) and $(\tilde\gamma,\tilde V)$ are transformed each to other by local transformations, then $\tilde\gamma=\gamma$. Moreover, since $\gamma\neq0$ any transformation of such type belongs to G^{equiv}.*

Remark 2: It follows from Theorems 4 and 5 that there exist no equivalence and, moreover, local transformations changing γ. Therefore, we can assume that γ *is fixed* in our consideration below and omit it from notations of the maximal Lie invariance algebras of an equation of form (1), etc.

Remark 3: The linear span of operators of the form (2) (γ is fixed!) is an (infinite-dimensional) Lie algebra $A^{\cup}$ under the usual Lie bracket of vector fields. Since for any $Q\in A^{\cup}$, where $(\xi^t,\xi^x)\neq(0,0)$ we can find V satisfying condition (3), then $A^{\cup}=\langle\cup_V A^{\max}(V)\rangle$. The nonzero commutation relations between the basis elements of $A^{\cup}$ are the following ones:

$$[D(\xi^1),D(\xi^2)]=D(\xi^1\xi^2_t-\xi^2\xi^1_t),\quad [D(\xi),G(\chi)]=G(\xi\chi_t-\tfrac{1}{2}\xi_t\chi),\quad [D(\xi),\lambda M]=\xi\lambda_t M,$$

$$[G(\chi^1),G(\chi^2)]=\tfrac{1}{2}(\chi^1\chi^2_t-\chi^2\chi^1_t)M.$$

We use the notation $\mathrm{Aut}(A^{\cup})$ for the automorphism group acting on $A^{\cup}$, which is generated by all the one-parameter groups corresponding to the adjoint representations of operators of $A^{\cup}$ into $A^{\cup}$ and two discrete transformations $\mathrm{Ad}\,I_x$ and $\mathrm{Ad}\,I_t$ included additionally. The actions of $\mathrm{Ad}\,I_x$ and $\mathrm{Ad}\,I_t$ on the basis elements of $A^{\cup}$ are defined by the formulas $\mathrm{Ad}\,I_x\,G(\chi)=G(-\chi)$ (the other basis operators do not change) and $\mathrm{Ad}\,I_t\,D(\xi)=D(\tilde\xi)$, $\mathrm{Ad}\,I_t\,G(\chi)=G(\tilde\chi)$, $\mathrm{Ad}\,I_t\,\lambda M=\tilde\lambda M$, where $\tilde\xi(t)=-\xi(-t)$, $\tilde\chi(t)=\chi(-t)$, and $\tilde\lambda(t)=-\lambda(-t)$.

Corollary 1: $A^{\mathrm{equiv}}\simeq A^{\cup}$, $G^{\mathrm{equiv}}\simeq\mathrm{Aut}(A^{\cup})$, *and the isomorphism is determined by means of prolongation of operators from $A^{\cup}$ to the space (V,V^*).*

Corollary 2: Let A^1 and A^2 be the maximal Lie invariance algebras of equations from class (1) for some potentials, and $\mathcal{V}^i=\{V|A^{\max}(V)=A^i\}$, $i=1,2$. Then $\mathcal{V}^1\sim\mathcal{V}^2 \mathrm{mod} G^{\mathrm{equiv}}$ iff $A^1\sim A^2 \bmod \mathrm{Aut}(A^{\cup})$.

0	$V(t,x)$	M
1	$iW(t)$	$M,\ \partial_x,\ G(t)$
2	$\frac{i}{2}\frac{\hat\gamma t+\nu}{t^2+1}$	$M,\ \partial_x,\ G(t),\ D(t^2+1)$
3	$i\nu t^{-1},\ \nu\neq0,\ \frac{\hat\gamma}{2}$	$M,\ \partial_x,\ G(t),\ D(t)$
4	i	$M,\ \partial_x,\ G(t),\ \partial_t$
5	$0,\ \gamma\neq4$	$M,\ \partial_x,\ G(t),\ \partial_t,\ D(t)$
	$\gamma=4$	$M,\ \partial_x,\ G(t),\ \partial_t,\ D(t),\ D(t^2)$
6	$V(x)$	$M,\ \partial_t$
7	$(\alpha+i\beta)x^{-2},\ \gamma\neq4$	$M,\ \partial_t,\ D(t)$
	$\gamma=4$	$M,\ \partial_t,\ D(t),\ D(t^2)$

Lemma 1: A complete list of $\mathrm{Aut}\,A^{\cup}$*-inequivalent one-dimensional subalgebras of* $A^{\cup}$ *is exhausted by the algebras* $\langle\partial_t\rangle$, $\langle\partial_x\rangle$, $\langle tM\rangle$, $\langle M\rangle$.

Proof: Consider any operator $Q\in A^{\cup}$, i.e., $Q=D(\xi)+G(\chi)+\lambda M$. Depending on the values of ξ, χ and λ it is equivalent under $\mathrm{Aut}(A^{\cup})$ and multiplication by a number to one from the following operators: $D(1)$ if $\xi\neq0$; $G(1)$ if $\xi=0$ and $\chi\neq0$; tM if $\xi=\chi=0$, $\lambda_t\neq0$; M if $\xi=\chi=\lambda_t=0$.

Corollary 3: If $A^{\max}(V)\neq A^{\ker}$, *then* $V_tV_x=0 \bmod G^{\mathrm{equiv}}$.

Proof: Under the corollary assumption there exists an operator $Q=D(\xi)+G(\chi)+\lambda M\in A^{\max}(V)$ which do not belong to $\langle M\rangle$. Condition (3) implies $(\xi,\chi)\neq(0,0)$. Therefore, in force of Lemma 1 $\langle Q\rangle\sim\langle\partial_t\rangle$ or $\langle\partial_x\rangle \bmod \mathrm{Aut}\,A^{\cup}$, i.e., $V_tV_x=0 \bmod G^{\mathrm{equiv}}$.

Theorem 6: *A complete set of inequivalent cases of V admitting extensions of the maximal Lie invariance algebra of Eq. (1) is exhausted by the potentials given in Table I.*

For convenience we use below the double numeration T. N. of classification cases where T is a table number and N is a row number.

Remark 4: We mean that the invariance algebras for Cases 1.0, 1.1, 1.6 and analogous ones from Tables II and III are maximal if these cases are inequivalent under the corresponding equivalence group to the other, more specialized, cases from the same table.

Remark 5: There exists a discrete equivalence transformation τ for the set of potentials $i\nu t^{-1}$, $\nu\in\mathbb{R}$, which has form (5) with $T=-t^{-1}$, $X=0$, $\Psi=0$. It transforms ν in the following way: $\nu\to\hat\gamma/2-\nu$. For the cases under consideration to be completely inequivalent, we have to assume additionally that $\nu\geqslant\hat\gamma/4$ (or $\nu\leqslant\hat\gamma/4$) in Case 1.3. Since $I_t\in G^{\mathrm{equiv}}$ we can assume analogously

$\nu\geqslant 0$ in Case 1.2 and $\beta\geqslant 0$ in Case 1.7. Moreover, τ is a discrete symmetry transformation for Case 1.3 ($\nu=\hat{\gamma}/4$) and, as a limit of the continuous transformations generated by the operator $D(t^2+1)$, for Case 1.2.

If we use Corollary 3 then to prove Theorem 6 it is sufficient to study two cases: $V_x=0$ and $V_t=0$. In fact, below we obtain the complete results of group classifications for both special cases and then unite them for the general case under consideration.

III. CASE $V=V(t)$

Consider the equations from class (1) with potentials satisfying the additional assumption $V_x=0$, i.e., $V=V(t)$. The following chain of lemmas gives complete solving of classification problem in this subclass.

Lemma 2: $A^{\ker}_{V_x=0}=\langle M,G(1),G(t)\rangle$.

Lemma 3: $A^{\rm equiv}_{V_x=0}=\langle M'(\lambda)\ \forall\lambda=\lambda(t),G'(1),G'(t),D'(1),D'(t),D'(t^2)\rangle$. $G^{\rm equiv}_{V_x=0}$ *is generated by* I_t, I_x *and the transformations of form* (5), *where* $T=(a_1t+a_0)/(b_1t+b_0)$, $X=c_1t+c_0$, Ψ *is an arbitrary smooth function of* t. a_i, b_i *and* c_i *are arbitrary constants such that* $a_1b_0-b_1a_0>0$.

Lemma 4: For any $V=V(t)$: $V\sim iW \bmod G^{\rm equiv}_{V_x=0}$, *where* $W=\operatorname{Im}V$, i.e., $W=W(t)\in\mathbb{R}$.

Lemma 5: $A^{\ker}_{\{iW\}}=A^{\ker}_{V_x=0}$. $A^{\max}(iW)\subset A^{\cup}_{\{iW\}}=A^{\ker}_{\{iW\}}\supset S$, *where* $S=\langle D(1),D(t),D(t^2)\rangle$. $A^{\cup}_{\{iW\}}=\cup_W A^{\max}(iW)$.

$A^{\rm equiv}_{\{iW\}}=\langle M,G'(1),G'(t),D'(1),D'(t),D'(t^2)\rangle$. $\quad G^{\rm equiv}_{\{iW\}}=G^{\rm equiv}_{V_x=0}\big|_{\Psi=\rm const}$. $\quad A^{\cup}_{\{iW\}}\simeq A^{\rm equiv}_{\{iW\}}=\mathrm{pr}_{(V,V*)}A^{\cup}_{\{iW\}}$.

Lemma 6: $S\simeq sl(2,\mathbb{R})$. *The complete list of* $A^{\cup}_{\{iW\}}$*-inequivalent proper subalgebras of* S *is exhausted by the algebras* $\langle D(1)\rangle$, $\langle D(t)\rangle$, $\langle D(t^2+1)\rangle$, $\langle D(1),D(t)\rangle$.

Lemma 7: Let A^1 *and* A^2 *be the maximal Lie invariance algebras of equations from class (1) for some potentials from* $\{iW(t)\}$, *and* $\mathcal{W}^i=\{W(t)\,|\,A^{\max}(iW)=A^i\}$, $i=1,2$. *Then* $\mathcal{W}^1\sim\mathcal{W}^2 \bmod G^{\rm equiv}_{\{iW\}}$ *iff* $A^1\cap S\sim A^2\cap S \bmod \mathrm{Aut}(S)$.

Lemma 8: If $A^{\max}_{\{iW\}}\neq A^{\ker}_{V_x=0}$ *the potential* $iW(t)$ *is* $G^{\rm equiv}_{\{iW\}}$*-equivalent to one from Cases* 1.2–1.5.

Remark 6: If $\gamma\neq 4$ or $W\neq$ const $A^{\max}(iW)\not\supset S$ (otherwise, condition (3) would imply an incompatible system for W). If $W=$ const $W\in\{0,1\} \bmod G^{\rm equiv}_{\{iW\}}$ (Cases 1.5 and 1.4 correspondingly). Cases 1.2ν and 1.2$\tilde{\nu}$ (1.3ν and 1.3$\tilde{\nu}$ where $\nu,\tilde{\nu}\geqslant\gamma/4$) are $G^{\rm equiv}$-inequivalent if $\nu\neq\tilde{\nu}$. Since $D(t^2+1)$ cannot be contained in any two-dimensional subalgebra of S it is not possible to extend $A^{\max}$ in Case 1.2. There are two possibilities for extension of $A^{\max}(i\nu t^{-1})$, namely with either $D(1)$ (for $\nu=0$, Case 1.5) or $D(t^2)$ (for $\nu=(4-\gamma)/(2\gamma)$ that is equivalent to Case 1.5 with respect to $G^{\rm equiv}_{\{iW\}}$). That is why for $\nu=0$, $\gamma=4$ dimension of $A^{\max}$ is greatest.

IV. CASE $V=V(x)$

Consider class (1) with the additional assumption $V_t=0$, i.e., $V=V(x)$.

Lemma 9: $A^{\ker}_{V_t=0}=\langle M,D(1)\rangle$.

Lemma 10: $A^{\text{equiv}}_{V_t=0}=\langle M'(1),M'(t),G'(1),D'(1),D'(t)\rangle$. $G^{\text{equiv}}_{V_t=0}$ *is generated by* I_t, I_x *and the transformations of form* (5), *where* $T_{tt}=X_t=\Psi_{tt}=0$.

Lemma 11: If $A^{\max}(V)\neq A^{\ker}_{V_t=0}$ *the potential* $V(x)$ *is* $G^{\text{equiv}}_{V_t=0}$*-equivalent to one from cases of either Table II if* $\gamma\neq 4$ *or Table III if* $\gamma=4$. (*Since* $I_t\in G^{\text{equiv}}$ *we can assume* $\nu\geqslant 0$ *in Cases 2.5, 2.6, 3.5–3.7,* $\nu>0$ *in Case 2.4 and* $\beta\geqslant 0$ *in Cases 2.1, 3.1–3.3.*)

Proof: Let $V=V(x)$ and $A^{\max}(V)\neq A^{\ker}_{V_t=0}$. Consider an arbitrary operator $Q=D(\xi)+G(\chi)+\lambda M\in A^{\max}(V)$. Under Lemma's assumption, condition (3) implies a set of equations on V of the general form

$$(ax+b)V_x+2aV=c_2x^2+c_1x+\tilde{c}_0+ic_0,\quad \text{where}\quad a,b,c_2,c_1,\tilde{c}_0,c_0=\text{const}\in\mathbb{R}.$$

The exact number k of such equations with the linear independent sets of coefficients can be equal to either 1 or 2. (The value $k=0$ corresponds to the general case $V_t=0$ without any extensions of $A^{\max}$.)

For $k=1$ $(a,b)\neq(0,0)$ and there exist two possibilities $a=0$ and $a\neq 0$. If $a=0$ without loss of generality we can put $b=1$. Then condition (3) results in $\xi_t=0$, $c_2=c_0=0$, i.e., $V_x=c_1x+\tilde{c}_0$, and then $k=2$ that it is impossible.

Therefore, $a\neq 0$ and we can put $a=1$. $\tilde{c}_0,b=0 \bmod G^{\text{equiv}}_{V_t=0}$. Condition (3) results in $\chi=0$ (then $c_1=0$), $\lambda_t=0$, $\hat{\gamma}\xi_{tt}=2c_0\xi_t$, and $\hat{\gamma}c_2=c_0^2$. For $\gamma=4$, $c_0=0$, and $c_2\in\{-4,0,4\} \bmod G^{\text{equiv}}_{V_t=0}$ and these possibilities in the value of c_2 give Cases 3.1–3.3. If $\gamma\neq 4$ we obtain Cases 2.1 ($c_0=0$) and 2.2 ($c_0\neq 0$).

The condition $k=2$ results in $V=d_2x^2+d_1x+\tilde{d}_0+id_0$. $\tilde{d}_0=0 \bmod G^{\text{equiv}}_{V_t=0}$. Considering different possibilities for values of the constants d_2, d_1, and d_0 and taking into account the value of γ (either $\gamma\neq 4$ or $\gamma=4$), we obtain all the other classification cases:

$$d_2=d_1=d_0=0\ \rightarrow\ 2.7,3.8;\quad d_2=d_1=0,\ d_0\neq 0\ \rightarrow\ 2.3,3.4;$$

$$d_2=d_0=0,\ d_1\neq 0\ \rightarrow\ 2.8,3.9;\quad d_2=0,\ d_0,d_1\neq 0\ \rightarrow\ 2.4,3.5;$$

$$d_2<0,\ (d_0,\hat{\gamma})\neq(0,0)\ \rightarrow\ 2.5,3.6;\quad d_2<0,\ d_0=\hat{\gamma}=0\ \rightarrow\ 3.11;$$

$$d_2>0,\ \hat{\gamma}^2d_2\neq d_0^2\ \rightarrow\ 2.6,3.7;\quad d_2>0,\ \hat{\gamma}^2d_2=d_0^2\ \rightarrow\ 2.9,3.10.$$

Remark 7: To prove Theorem 6, it is sufficient to consider only the case $k=1$, $a\neq 0$ in Lemma 11 since other cases of extensions of $A^{\max}(V)$ with $V=V(x)$ admit operators of the form $G(\chi)+\lambda M$ ($\chi\neq 0$) and, therefore (by Corollary 2), are equivalent to Cases 1.1–1.5.

Remark 8: The number N_1 for each line of Tables II and III is equal to the number of the same or equivalent case in Table I. The corresponding equivalence transformations have the form (5) where the functions T, X, and Ψ are as follows:

$$2.2,\ 3.2\rightarrow 1.7,\quad 2.6,\ 3.7\rightarrow 1.3\left(\tilde{\nu}=\frac{\hat{\gamma}-\nu}{4}\right),\quad 2.9,\ 3.10\rightarrow 1.5:\quad T=-e^{-4t},\ X=\Psi=0;$$

$$3.3\rightarrow 1.7,\quad 2.5,\ 3.6\rightarrow 1.2(\tilde{\nu}=\nu),\quad 3.11\rightarrow 1.5:\quad T=\tan 2t,\ X=\Psi=0;$$

$$2.4,\ 3.5\rightarrow 1.4:\quad T=|\nu|t,\ X=-\sqrt{|\nu|}\,t^2,\ \Psi=\frac{t^3}{3};$$

$$2.8,\ \ 3.9\to 1.5:\quad T=t,\ \ X=-t^2,\ \ \Psi=\frac{t^3}{3}.$$

Remark 8 completes the proof of Theorem 6.

V. CONCLUSION

The results of group classification obtained in this paper can be extended to a more general class of $(1+n)$-dimensional NSchEs with potentials

$$i\psi_t+\Delta\psi+F(\psi,\psi^*)+V(t,\vec{x})\psi=0, \tag{6}$$

where $F=F(\psi,\psi^*)$ is an arbitrary complex-valued smooth function of the variables ψ and ψ^*. We have already described all possible inequivalent forms of the parameter-function F (without any restriction on the dimension n) for which an equation of the form (6) with a some potential V has an extension of the maximal Lie invariance algebra. We believe that the classification method suggested in this paper can be effectively applied to complete the group classification in (6) for the small values of n. This method can be also a tool to investigate symmetries of other classes of PDEs, and we will attempt to prove general statements on its applicability.

Another direction for us to develop the above results is construction of both invariant and partially invariant exact solutions of equations having the form (1) by means of using found Lie symmetries, and knowledge of explicit forms for equivalence transformations (see Theorem 4 and Remark 8) allows us to reduced consideration of known stationary potentials to simpler x-free ones. We also plan to study conditional and generalized symmetries of (1) to find non-Lie exact solutions.

As it was shown by Carles,[3] the equivalence transformations (5) also give an easy and effective way to produce new results on existence, uniqueness, estimations, etc., of solutions for some equations (1) by means of using known results on other potentials.

(Received 28 February 2004; accepted 21 April 2004; published online 2 July 2004)

As an extension of the theory of Dyson's Brownian motion models for the standard Gaussian random-matrix ensembles, we report a systematic study of Hermitian matrix-valued processes and their eigenvalue processes associated with the chiral and nonstandard random-matrix ensembles. In addition to the noncolliding Brownian motions, we introduce a one-parameter family of temporally homogeneous noncolliding systems of the Bessel processes and a two-parameter family of temporally inhomogeneous noncolliding systems of Yor's generalized meanders and show that all of the ten classes of eigenvalue statistics in the Altland–Zirnbauer classification are realized as particle distributions in the special cases of these diffusion particle systems. As a corollary of each equivalence in distribution of a temporally inhomogeneous eigenvalue process and a noncolliding diffusion process, a stochastic-calculus proof of a version of the Harish–Chandra (Itzykson–Zuber) formula of integral over unitary group is established. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1765215]

I. INTRODUCTION

It is interesting to consider today mathematical-physical sequences of the two classic papers[10,11] by Dyson of random matrix theory, which appeared sequentially in the same volume of the journal in 1962. In one of them,[11] following the early work of Wigner, he gave a logical foundation for his classification scheme of random-matrix ensembles based on the group representation theory of Weyl and established the standard (Wigner–Dyson) random matrix theory for the three ensembles called the Gaussian unitary, orthogonal, and symplectic ensembles (GUE, GOE, and GSE). He introduced in the other paper[10] the Hermitian matrix-valued Brownian motions, which are associated with these Gaussian random-matrix ensembles, and studied the stochastic processes of eigenvalues of the matrix-valued processes. Combining the standard perturbation theory of the quantum mechanics and a simple but essential consideration of the scaling of Brownian motions, he generally proved that the obtained eigenvalue processes are identified with the one-dimensional systems of Brownian particles with the repulsive two-body forces proportional to the inverse of distances between particles. These processes are now called Dyson's Brownian motion models $\mathbf{Y}(t)=(Y_1(t),Y_2(t),\ldots,Y_N(t))$ described by the stochastic differential equations

$$dY_i(t)=dB_i(t)+\frac{\beta}{2}\sum_{1\leqslant j\leqslant N,j\neq i}\frac{1}{Y_i(t)-Y_j(t)}dt,\quad t\in[0,\infty),1\leqslant i\leqslant N, \tag{1}$$

a)Electronic mail: katori@phys.chuo-u.ac.jp
b)Electronic mail: tanemura@math.s.chiba-u.ac.jp

with $\beta=1,2,4$ for GOE, GUE, and GSE, respectively, where $B_i(t), 1\leqslant i\leqslant N$ are independent one-dimensional standard Brownian motions. Dyson's classification scheme has been extended. In addition to the standard three random-matrix ensembles, their *chiral versions* (chGUE, chGOE, and chGSE) were studied in the particle physics of QCD associated with consideration of the gauge groups and quantum numbers called flavors.[54,53,27,51] After that extension, Altland and Zirnbauer introduced more four ensembles called the classes C, CI, D, and DIII for the solid-state physics of mesoscopic systems considering the particle-hole symmetry, which plays an important role in the Bogoliubov–de Gennes framework of the BCS mean-field theory of superconductivity.[1,2] These totally ten Gaussian ensembles are systematically argued by Zirnbauer[56] based on Cartan's classification scheme of symmetric spaces[23] and Efetov's supersymmetry theory.[13]

One consequence of a combination of the two papers by Dyson may be to give a systematic study of matrix-valued diffusion processes (i.e., diffusion processes in groups or algebraic spaces) and perform the classification of eigenvalue processes as generalization of Dyson's Brownian motion models. This line has been taken by Bru,[6,7] Grabiner,[21] König and O'Connell,[36] and others, and one purpose of the present paper is to clarify the relationship between statistics of (nonstandard) random matrix theory and stochastic processes of interacting diffusion particles in the type of Dyson's Brownian motion models studied in the probability theory. We will claim in Sec. II that the matrix-valued processes called the Wishart process by Bru[7] and the Laguerre process by König and O'Connell[36] are the stochastic versions of chGOE and chGUE, respectively, in the sense of Dyson,[10] and derive in Sec. III the diffusion processes describing the eigenvalue statistics of the classes C and D of Altland and Zirnbauer, following Bru's matrix-version of the stochastic calculus based on the Ito rule for differentials.

Due to the strong repulsive forces in the processes of the types of Dyson's Brownian motion models, particle collisions are suppressed. Impossibility of collision may be generally proved by the same argument as Bru, who showed that the collision time between two eigenvalues of the Wishart process is infinite ($\tau=+\infty$ a.s.).[6] For the $\beta=2$ (GUE) case of Dyson's Brownian motion model (1), if $\mathbf{Y}(0)\in\mathbb{W}_N^{\mathrm{A}}$, then $\mathbf{Y}(t)\in\mathbb{W}_N^{\mathrm{A}}$ for all $t>0$ with probability 1, where $\mathbb{W}_N^{\mathrm{A}}$ denotes the Weyl chamber of type A_{N-1}; $\mathbb{W}_N^{\mathrm{A}}=\{\mathbf{x}\in\mathbb{R}^N; x_1<x_2<\cdots<x_N\}$. Using the Karlin–McGregor formula[28,29] the transition density of the absorbing Brownian motion in $\mathbb{W}_N^{\mathrm{A}}$ from the state $\mathbf{x}$ at time s to the state $\mathbf{y}$ at time $t(>s)$ is given by the determinant

$$f^{\mathrm{A}}(t-s,\mathbf{y}|\mathbf{x})=\det_{1\leqslant i,j\leqslant N}[G^{\mathrm{A}}(t-s,y_j|x_i)],\quad \mathbf{x},\mathbf{y}\in\mathbb{W}_N^{\mathrm{A}}, \tag{2}$$

where each element is the Gaussian heat-kernel $G^{\mathrm{A}}(t,y|x)=e^{-(x-y)^2/2t}/\sqrt{2\pi t}$. Grabiner[21] pointed out that the transition probability density of process (1) with $\beta=2$ is given by

$$p^{\mathrm{A}}(s,\mathbf{x};t,\mathbf{y})=\frac{1}{h^{\mathrm{A}}(\mathbf{x})}f^{\mathrm{A}}(t-s,\mathbf{y}|\mathbf{x})h^{\mathrm{A}}(\mathbf{y}),$$

where $h^{\mathrm{A}}(\mathbf{x})=\Pi_{1\leqslant i<j\leqslant N}(x_j-x_i)$. Since $h^{\mathrm{A}}(\mathbf{x})$ is a strictly positive harmonic function in $\mathbb{W}_N^{\mathrm{A}}$, this is regarded as the h-transform in the sense of Doob,[9] and it implies that the eigenvalue process of GUE is realized as the noncolliding Brownian motions (i.e., the h-transform of an absorbing Brownian motion in the Weyl chamber of type A_{N-1}). König and O'Connell also showed that the eigenvalue process of the Laguerre process, which corresponds to chGUE, is realized as the noncolliding system of the squared Bessel processes.[36] In Sec. IV, we show that the eigenvalue processes of random matrices in the symmetry classes C and D of Altland and Zirnbauer are realized as the noncolliding system of the *Brownian motions with an absorbing wall at the origin*[35] (i.e., the h-transform of an absorbing Brownian motion in the Weyl chamber of type C_N) and as the noncolliding system of the *reflecting Brownian motions* (i.e., the h-transform of an absorbing Brownian motion in the Weyl chamber of type D_N), respectively. These three kinds of systems are

discussed as special cases of a family of noncolliding systems of diffusion particles with one parameter $\nu > -1$, in which each particle is following the $d=2(\nu+1)$-dimensional Bessel process defined by the transition probability density[5,48]

$$G^{(\nu)}(t,y|x)=\frac{y^{\nu+1}}{x^{\nu}}\frac{1}{t}e^{-(x^2+y^2)/2t}I_{\nu}\left(\frac{xy}{t}\right) \quad \text{for} \quad x>0,y\geqslant 0,$$

$$G^{(\nu)}(t,y|0)=\frac{y^{2\nu+1}}{2^{\nu}\Gamma(\nu+1)t^{\nu+1}}e^{-y^2/2t} \quad \text{for} \quad y\geqslant 0, \tag{3}$$

where Γ denotes the Gamma function and I_{ν} is the modified Bessel function; $I_{\nu}(z)=\Sigma_{n=0}^{\infty}(z/2)^{2n+\nu}/\{\Gamma(n+1)\Gamma(\nu+n+1)\}$.

How can we realize other six eigenvalue processes in Altland–Zirnbauer's ten classes of random-matrix ensembles as well by noncolliding systems of diffusion processes? In our previous papers[31,32] we considered the situation that the noncolliding condition is imposed not forever but for a finite time-interval $(0,T]$ to define the temporally inhomogeneous noncolliding Brownian motions $\mathbf{X}(t)=(X_1(t),X_2(t),\ldots,X_N(t))$. Of course, we can see that $\mathbf{X}(t)\to\mathbf{Y}(t)$ in distribution as $T\to\infty$. We observed for the finite time-interval $t\in[0,T]$ that, if we set $\mathbf{X}(0)=\mathbf{Y}(0)=\mathbf{0}$ with $\mathbf{0}=(0,0,\ldots,0)\in\mathbb{R}^N$, then

$$P(\mathbf{X}(\cdot)\in d\mathbf{w})=\frac{C[\mathrm{A}]T^{\psi[\mathrm{A}]}}{C[\mathrm{A}']h^{\mathrm{A}}(\mathbf{w}(T))}P(\mathbf{Y}(\cdot)\in d\mathbf{w}), \tag{4}$$

where $C[\mathrm{A}]=(2\pi)^{N/2}\Pi_{i=1}^{N}\Gamma(i)$, $C[\mathrm{A}']=2^{N/2}\Pi_{i=1}^{N}\Gamma(i/2)$, and $\psi[\mathrm{A}]=N(N-1)/4$. This is regarded as a multivariate version of the Imhof relation in the probability theory,[25] since it implies the absolute continuity in distribution of the temporally homogeneous process $\mathbf{Y}(t)$ and the inhomogeneous process $\mathbf{X}(t)$ in $[0,T]$, but from the viewpoint of random matrix theory the important consequence of this equality is the fact that the process $\mathbf{X}(t)$ exhibits a transition in distribution from the eigenvalue statistics of GUE to that of GOE and thus the GOE distribution is realized at the final time $t=T$. In Sec. V, we develop this argument by replacing the Brownian motions $X_i(t),1\leqslant i\leqslant N$ by the *generalized meanders* with two parameters $(\nu,\kappa),\nu>-1,\kappa\in[0,2(\nu+1))$, introduced as the temporally inhomogeneous diffusions associated with the Bessel process by Yor,[55] whose transition probability density is given by

$$G_T^{(\nu,\kappa)}(s,x;t,y)=\frac{1}{h_T^{(\nu,\kappa)}(s,x)}G^{(\nu)}(t-s,y|x)h_T^{(\nu,\kappa)}(t,y) \tag{5}$$

for $0\leqslant s<t\leqslant T,x,y\geqslant 0$ with $h_T^{(\nu,\kappa)}(t,x)=\int_0^{\infty}dz\ G^{(\nu)}(T-t,z|x)z^{-\kappa}$. By choosing the two parameters (ν,κ) appropriately, this family of noncolliding systems of generalized meanders provides such diffusion processes that exhibit the transitions from chGUE to chGOE and from class C to class CI. We will also consider the processes, in which the noncolliding condition collapses at the final time $t=T$ in the ways that all particles collide simultaneously or only pairwise collisions occur. In the special cases in the latter situation, we have the processes showing the transitions from GUE to GSE, from chGUE to chGSE, and from class D to class DIII.

The present study of the temporally inhomogeneous noncolliding diffusion processes gives two kinds of by-products. (i) Topology of path-configurations of our processes on the spatio-temporal plane $\mathbb{R}\times[0,T]$ is determined by the conditions at $t=0$ and $t=T$. We will be able to discuss the topology of random directed polymer networks[8,14] using the random matrix theory. Such correspondence between the topology of path-configurations and random-matrix ensembles is recently used by Sasamoto and Imamura to analyze one-dimensional polynuclear growth models.[49] (ii) A variety of versions of Harish–Chandra (Itzykson–Zuber) formulas of integrals

over unitary groups[22,26] are derived as corollaries of the equivalence in distribution of the eigenvalue processes of matrix-valued processes and noncolliding diffusion processes. Other remarks are given in Sec. VI.

II. BRU'S THEOREM

A. Hermitian matrix-valued stochastic processes

We denote the space of $N\times N$ Hermitian matrices by $\mathcal{H}(N)$, the group of $N\times N$ unitary matrices by $\mathrm{U}(N)$, and the group of $N\times N$ real orthogonal matrices by $\mathrm{O}(N)$. We also use the notations $\mathcal{S}(N)$ and $\mathcal{A}(N)$ for the spaces of $N\times N$ real symmetric and real antisymmetric matrices, respectively. We consider complex-valued processes $\xi_{ij}(t)\in\mathbb{C}, 1\leqslant i,j\leqslant N, t\in[0,\infty)$, with the condition $\xi_{ji}(t)^*=\xi_{ij}(t)$, and define the matrix-valued processes by $\Xi(t)=(\xi_{ij}(t))_{1\leqslant i,j\leqslant N}\in\mathcal{H}(N)$. We denote by $U(t)=(u_{ij}(t))_{1\leqslant i,j\leqslant N}$ the family of unitary matrices which diagonalize $\Xi(t)$ so that

$$U(t)^\dagger\Xi(t)U(t)=\Lambda(t)=\mathrm{diag}\{\lambda_1(t),\lambda_2(t),\ldots,\lambda_N(t)\},$$

where $\{\lambda_i(t)\}_{i=1}^N$ are eigenvalues of $\Xi(t)$ and we assume their increasing order

$$\lambda_1(t)\leqslant\lambda_2(t)\leqslant\cdots\leqslant\lambda_N(t). \tag{6}$$

Define $\Gamma_{ij}(t), 1\leqslant i,j\leqslant N$, by $\Gamma_{ij}(t)dt=(U(t)^\dagger d\Xi(t)U(t))_{ij}(U(t)^\dagger d\Xi(t)U(t))_{ji}$, where $d\Xi(t)=(d\xi_{ij})_{1\leqslant i,j\leqslant N}$. We denote by $\mathbf{1}(\omega)$ the indicator function: $\mathbf{1}(\omega)=1$ if the condition ω is satisfied, and $\mathbf{1}(\omega)=0$ otherwise. The following theorem is proved for the stochastic process of eigenvalues $\boldsymbol{\lambda}(t)=(\lambda_1(t),\lambda_2(t),\ldots,\lambda_N(t))$.

Theorem 1: *Assume that $\xi_{ij}(t), 1\leqslant i<j\leqslant N$ are continuous semimartingales. The process $\boldsymbol{\lambda}(t)=(\lambda_1(t),\lambda_2(t),\ldots,\lambda_N(t))$ satisfies the stochastic differential equations*

$$d\lambda_i(t)=dM_i(t)+dJ_i(t),\quad 1\leqslant i\leqslant N,$$

where $M_i(t)$ is the martingale with quadratic variation $\langle M_i\rangle_t=\int_0^t\Gamma_{ii}(s)ds$ and $J_i(t)$ is the process with finite variation given by

$$dJ_i(t)=\sum_{j=1}^N\frac{1}{\lambda_i(t)-\lambda_j(t)}\mathbf{1}(\lambda_i(t)\neq\lambda_j(t))\Gamma_{ij}(t)dt+d\Upsilon_i(t),$$

where $d\Upsilon_i(t)$ is the finite-variation part of $(U(t)^\dagger d\Xi(t)U(t))_{ii}$.

Since this theorem is obtained by simple generalization of Theorem 1 in Bru,[6] we call it Bru's theorem here. A key point to derive the theorem is applying the Ito rule for differentiating the product of matrix-valued semimartingales: If X and Y are $N\times N$ matrices with semimartingale elements, then

$$d(X^\dagger Y)=(dX)^\dagger Y+X^\dagger(dY)+(dX)^\dagger(dY).$$

B. Four basic examples

Let $\mathbb{N}=\{0,1,2,..\}$ and assume $\nu\in\mathbb{N}$. Let $B_{ij}(t)$, $\tilde{B}_{ij}(t)$, $1\leqslant i\leqslant N+\nu$, $1\leqslant j\leqslant N$ be independent one-dimensional standard Brownian motions. For $1\leqslant i,j\leqslant N$ we set

$$s_{ij}(t)=\begin{cases}\frac{1}{\sqrt{2}}B_{ij}(t), & \text{if } i<j,\\ B_{ii}(t), & \text{if } i=j,\\ \frac{1}{\sqrt{2}}B_{ji}(t), & \text{if } i>j,\end{cases}\quad\text{and}\quad a_{ij}(t)=\begin{cases}\frac{1}{\sqrt{2}}\widetilde{B}_{ij}(t), & \text{if } i<j,\\ 0, & \text{if } i=j,\\ -\frac{1}{\sqrt{2}}\widetilde{B}_{ji}(t), & \text{if } i>j.\end{cases}$$

Here we show four basic examples of Hermitian matrix-valued processes and applications of Theorem 1.

(i) The first example of the Hermitian matrix-valued process is defined by

$$\Xi(t)=(\xi_{ij}(t))_{1\leqslant i,j\leqslant N}=(s_{ij}(t)+\sqrt{-1}a_{ij}(t))_{1\leqslant i,j\leqslant N},\quad t\in[0,\infty).$$

By definition $d\xi_{ij}(t)d\xi_{k\ell}(t)=\delta_{i\ell}\delta_{jk}dt$, $1\leqslant i,j,k,\ell\leqslant N$, and thus $\Gamma_{ij}(t)=1$. Therefore $\boldsymbol{\lambda}(t)$ solves the equations of Dyson's Brownian motion model (1) with $\beta=2$.

(ii) The second example is given by

$$\Xi(t)=(s_{ij}(t))_{1\leqslant i,j\leqslant N}\in\mathcal{S}(N),\quad t\in[0,\infty).$$

In this case $d\xi_{ij}(t)d\xi_{k\ell}(t)=(\delta_{i\ell}\delta_{jk}+\delta_{ik}\delta_{j\ell})dt/2$, $1\leqslant i,j,k,\ell\leqslant N$, and thus $\Gamma_{ij}(t)dt=(1+\delta_{ij})dt/2$, $1\leqslant i,j\leqslant N$. Then $\boldsymbol{\lambda}(t)$ solves (1) with $\beta=1$.

(iii) We consider an $(N+\nu)\times N$ matrix-valued process by $M(t)=(B_{ij}(t)+\sqrt{-1}\widetilde{B}_{ij})_{1\leqslant i\leqslant N+\nu,1\leqslant j\leqslant N}$ and define the $N\times N$ Hermitian matrix-valued process by

$$\Xi(t)=M(t)^{\dagger}M(t),\quad t\in[0,\infty).\tag{7}$$

Since the matrix $\Xi(t)$ is positive definite, the eigenvalues are non-negative. By definition we see that the finite-variation part of $d\xi_{ij}(t)$ is $2(N+\nu)\delta_{ij}dt$ and $d\xi_{ij}(t)d\xi_{k\ell}(t)=2(\xi_{i\ell}(t)\delta_{jk}+\xi_{kj}(t)\delta_{i\ell})dt$, $1\leqslant i,j,k,\ell\leqslant N$, which imply that $d\Upsilon_i(t)=2(N+\nu)dt$ and $\Gamma_{ij}(t)=2(\lambda_i(t)+\lambda_j(t))$, $1\leqslant i,j\leqslant N$. Since $\langle M_i\rangle_t=\int_0^t 4\lambda_i(s)ds$, the stochastic differential equations for $\boldsymbol{\lambda}(t)$ are given by

$$d\lambda_i(t)=2\sqrt{\lambda_i(t)}dB_i(t)+\beta\left\{(N+\nu)+\sum_{1\leqslant j\leqslant N:j\neq i}\frac{\lambda_i(t)+\lambda_j(t)}{\lambda_i(t)-\lambda_j(t)}\right\}dt,\quad 1\leqslant i\leqslant N,\tag{8}$$

with $\beta=2$.

(iv) Set $B(t)=(B_{ij}(t))_{1\leqslant i\leqslant N+\nu,1\leqslant j\leqslant N}$ and define

$$\Xi(t)=B(t)^{T}B(t)\in\mathcal{S}(N),\quad t\in[0,\infty).\tag{9}$$

We see that the finite-variation part of $d\xi_{ij}(t)$ is $(N+\nu)\delta_{ij}dt$ and $d\xi_{ij}(t)d\xi_{k\ell}(t)=(\xi_{ik}(t)\delta_{j\ell}+\xi_{i\ell}(t)\delta_{jk}+\xi_{jk}(t)\delta_{i\ell}+\xi_{j\ell}(t)\delta_{ik})dt$, $1\leqslant i,j,k,\ell\leqslant N$. Then $d\Upsilon_i(t)=(N+\nu)dt$ and $\Gamma_{ij}(t)=(\lambda_i(t)+\lambda_j(t))(1+\delta_{ij})$, $1\leqslant i,j\leqslant N$. The equations for $\boldsymbol{\lambda}(t)$ are given by (8) with $\beta=1$.

The process (9) was called the Wishart process and studied as matrix generalization of squared Bessel process by Bru.[7] König and O'Connell[36] called the process (7) the Laguerre process and studied its eigenvalue process (8) with $\beta=2$.

C. Relation with the standard and chiral random matrix theories

Here we assume that $B_{ij}(0)=\widetilde{B}_{ij}(0)=0$ for all $1\leqslant i\leqslant N+\nu,1\leqslant j\leqslant N$, and thus the initial distribution of $\Xi(t)$ is the pointmass on an $N\times N$ zero matrix O; $\mu(\Xi\in\cdot;0)=\delta_O$. In this case the distributions of $\Xi(t)$'s are related with those studies in the standard (Wigner–Dyson) random matrix theory[40] and the chiral random matrix theory.[54,53,27,51]

(i) *Example (i) and GUE:* For GUE with variance $\sigma^2=t$ of random matrices in the space $\mathcal{H}(N)\cong\mathbb{R}^{d[\mathrm{A}]}$ with $d[\mathrm{A}]=N^2$, the probability density of eigenvalues $\boldsymbol{\lambda}$ in the condition (6) is given as[40]

$$q^{\mathrm{GUE}}(\boldsymbol{\lambda};t)=\frac{t^{-d[\mathrm{A}]/2}}{C[\mathrm{A}]}\exp\left\{-\frac{|\boldsymbol{\lambda}|^2}{2t}\right\}h^{\mathrm{A}}(\boldsymbol{\lambda})^2,$$

where $|\boldsymbol{\lambda}|^2=\Sigma_{i=1}^N\lambda_i^2$. For (1) with $\beta=2$, $p^{\mathrm{A}}(0,\mathbf{0};t,\boldsymbol{\lambda})=q^{\mathrm{GUE}}(\boldsymbol{\lambda};t)$, $t>0$.

(ii) *Example (ii) and GOE:* The probability density of eigenvalues $\boldsymbol{\lambda}$ with the condition (6) is given as[40]

$$q^{\mathrm{GOE}}(\boldsymbol{\lambda};t)=\frac{t^{-d[\mathrm{A}']/2}}{C[\mathrm{A}']}\exp\left\{-\frac{|\boldsymbol{\lambda}|^2}{2t}\right\}h^{\mathrm{A}}(\boldsymbol{\lambda})$$

for GOE with variance $\sigma^2=t$ in $\mathcal{S}(N)\cong\mathbb{R}^{d[\mathrm{A}']}$, $d[\mathrm{A}']=N(N+1)/2$. If we denote by $p^{\mathrm{A}'}(s,\boldsymbol{\lambda};t,\boldsymbol{\lambda}')$ the transition probability density of the process (1) with $\beta=1$ from $\boldsymbol{\lambda}$ at time s to $\boldsymbol{\lambda}'$ at time $t(>s)$, then $p^{\mathrm{A}'}(0,\mathbf{0};t,\boldsymbol{\lambda})=q^{\mathrm{GOE}}(\boldsymbol{\lambda};t)$, $t>0$.

(iii) *Example (iii) and chiral GUE:* We denote by $\mathcal{M}(N+\nu,N;\mathbb{C})$ and $\mathcal{M}(N+\nu,N;\mathbb{R})$ the spaces of $(N+\nu)\times N$ complex and real matrices, respectively. We see that $\mathcal{M}(N+\nu,N;\mathbb{C})\cong\mathbb{R}^{2N(N+\nu)}$ and write its volume element as $\mathcal{V}(dM),M\in\mathcal{M}(N+\nu,N;\mathbb{C})$. The chiral Gaussian unitary ensemble (chGUE) with variance t is the ensemble of matrices $M\in\mathcal{M}(N+\nu,N;\mathbb{C})$ with the probability density

$$\mu_\nu^{\mathrm{chGUE}}(M;t)=\frac{t^{-N(N+\nu)/2}}{(2\pi)^{N(N+\nu)}}\exp\left\{-\frac{1}{2t}\mathrm{Tr}\,M^\dagger M\right\} \tag{10}$$

with respect to $\mathcal{V}(dM)$. It is known[24] that any matrix $M\in\mathcal{M}(N+\nu,N;\mathbb{C})$ has a family of pairs $(U,V),U\in\mathrm{U}(N+\nu),V\in\mathrm{U}(N)$, which transform M as $M=U^\dagger KV$, where $K\in\mathcal{M}(N+\nu,N;\mathbb{R})$ is in the form

$$K=\begin{pmatrix}\hat{K}\\ O\end{pmatrix}\quad\text{with}\quad\hat{K}=\mathrm{diag}\{\kappa_1,\kappa_2,...,\kappa_N\},\quad\kappa_i\geqslant 0,1\leqslant i\leqslant N,$$

and the $\nu\times N$ zero matrix O. We assume that U and V are chosen so that

$$0\leqslant\kappa_1\leqslant\kappa_2\leqslant\cdots\leqslant\kappa_N. \tag{11}$$

The matrices (U,K,V) can be regarded as "polar coordinates" in the space $\mathcal{M}(N+\nu,N;\mathbb{C})$. We have $M^\dagger M=V^\dagger\Lambda V$, where $\Lambda=\mathrm{diag}\{\lambda_1,\lambda_2,...,\lambda_N\}$ with the relations $\lambda_i=\kappa_i^2$, $1\leqslant i\leqslant N$. Then $\boldsymbol{\kappa}=(\kappa_1,\kappa_2,\ldots,\kappa_N)$ is a set of nonnegative square roots of the eigenvalues of $M^\dagger M$. Let $d\mu(U,V)$ be the Haar measure of the space $\mathrm{U}(N+\nu)\times\mathrm{U}(N)$ normalized as $\int_{\mathrm{U}(N+\nu)\times\mathrm{U}(N)}d\mu(U,V)=1$ and $d\boldsymbol{\kappa}=\Pi_{i=1}^N d\kappa_i$. Then we can show that

$$\mathcal{V}(dM)=\frac{(2\pi)^{N(N+\nu)}}{C_\nu}h^{((2\nu+1)/2)}(\boldsymbol{\kappa})^2 d\boldsymbol{\kappa}d\mu(U,V), \tag{12}$$

where $C_\nu=2^{N(N+\nu-1)}\Pi_{i=1}^N\{\Gamma(i)\Gamma(i+\nu)\}$ and

$$h^{(\alpha)}(\boldsymbol{\kappa})=\prod_{1\leqslant i<j\leqslant N}(\kappa_j^2-\kappa_i^2)\prod_{k=1}^N\kappa_k^\alpha.$$

For any pair of unitary matrices $U\in\mathrm{U}(N+\nu)$ and $V\in\mathrm{U}(N)$, the probability $\mu_\nu^{\mathrm{chGUE}}(M;t)\mathcal{V}(dM)$ is invariant under the automorphism $M\to U^\dagger MV$. By integrating over $d\mu(U,V)$, we obtain the probability density of $\boldsymbol{\kappa}$ with the condition (11) as[54,53,27,51]

$$q_\nu^{\mathrm{chGUE}}(\boldsymbol{\kappa};t)=\frac{t^{-N(N+\nu)}}{C_\nu}\exp\left\{-\frac{|\boldsymbol{\kappa}|^2}{2t}\right\}h^{((2\nu+1)/2)}(\boldsymbol{\kappa})^2.$$

König and O'Connell[36] studied the process (8) with $\beta=2$ as a multivariate version of squared Bessel process. Here we consider the multivariate version of Bessel process by extracting the square roots of eigenvalues $\lambda_i(t)\geqslant 0$ of $\Xi(t)=M(t)^\dagger M(t)$. Setting $\kappa_i(t)=\sqrt{\lambda_i(t)}\geqslant 0, 1\leqslant i\leqslant N$ in (8) with $\beta=2$ and applying the Ito rule for differentials, we find that $\boldsymbol{\kappa}(t)$ solves the stochastic differential equations

$$dZ_i(t)=dB_i(t)+\frac{\beta}{2}\left[\frac{\gamma}{Z_i(t)}+\sum_{j:j\neq i}\left\{\frac{1}{Z_i(t)-Z_j(t)}+\frac{1}{Z_i(t)+Z_j(t)}\right\}\right]dt,\quad 1\leqslant i\leqslant N, \tag{13}$$

with $(\beta,\gamma)=(2,(2\nu+1)/2)$. If we denote the transition probability density of this process by $p^{(\nu)}(s,\cdot\,;t,\cdot\,)$ for $0\leqslant s<t<\infty$, then

$$p^{(\nu)}(0,\mathbf{0};t,\boldsymbol{\kappa})=q_\nu^{\mathrm{chGUE}}(\boldsymbol{\kappa};t),\quad t>0. \tag{14}$$

(iv) *Example (iv) and chiral GOE:* We can see $\mathcal{M}(N+\nu,N;\mathbb{R})\cong\mathbb{R}^{N(N+\nu)}$. The chiral Gaussian orthogonal ensemble (chGOE) with variance t is the ensemble of matrices $B\in\mathcal{M}(N+\nu,N;\mathbb{R})\subset\mathcal{M}(N+\nu,N;\mathbb{C})$ with the probability density

$$\mu_\nu^{\mathrm{chGOE}}(B;t)=\frac{t^{-N(N+\nu)/2}}{(2\pi)^{N(N+\nu)/2}}\exp\left\{-\frac{1}{2t}\mathrm{Tr}\,B^TB\right\} \tag{15}$$

with respect to the volume element $\mathcal{V}'(dB)$ of $\mathcal{M}(N+\nu,N;\mathbb{R})$. We can show that

$$\mathcal{V}'(dB)=\frac{(2\pi)^{N(N+\nu)/2}}{C_{\nu,\nu+1}}h^{(\nu)}(\boldsymbol{\kappa})d\boldsymbol{\kappa}d\mu(U,V), \tag{16}$$

where $d\mu(U,V)$ is the normalized Haar measure of the space $\mathrm{O}(N+\nu)\times\mathrm{O}(N)$ and we have used the notation $C_{\nu,\kappa}=2^{N(N+2\nu-\kappa-1)/2}\pi^{-N/2}\Pi_{i=1}^N\{\Gamma(i/2)\Gamma((i+2\nu+1-\kappa)/2)\}$ and thus $C_{\nu,\nu+1}=2^{N(N+\nu-2)/2}\pi^{-N/2}\Pi_{i=1}^N\{\Gamma(i/2)\Gamma((i+\nu)/2)\}$. The probability density of $\boldsymbol{\kappa}$ with (11) is given as[54,53,27,51]

$$q_\nu^{\mathrm{chGOE}}(\boldsymbol{\kappa};t)=\frac{t^{-N(N+\nu)/2}}{C_{\nu,\nu+1}}\exp\left\{-\frac{|\boldsymbol{\kappa}|^2}{2t}\right\}h^{(\nu)}(\boldsymbol{\kappa}).$$

By setting $\kappa_i(t)=\sqrt{\lambda_i(t)}, 1\leqslant i\leqslant N$ in (8) with $\beta=1$, we can show that $\boldsymbol{\kappa}(t)=(\kappa_1(t),\kappa_2(t),\ldots,\kappa_N(t))$ solves (13) with $(\beta,\gamma)=(1,\nu)$. If we denote the transition probability density of this process $\boldsymbol{\kappa}(t)$ by $p^{(\nu)'}(s,\cdot\,;t,\cdot\,)$ for $0\leqslant s<t<\infty$, then $p^{(\nu)'}(0,\mathbf{0};t,\boldsymbol{\kappa})=q_\nu^{\mathrm{chGOE}}(\boldsymbol{\kappa};t)$, $t>0$.

III. HERMITIAN MATRIX-VALUED PROCESSES WITH ADDITIONAL SYMMETRIES

A. Subspaces of unitary and Hermitian matrices

The Pauli spin matrices are defined as

$$\sigma_1=\begin{pmatrix}0&1\\1&0\end{pmatrix},\quad \sigma_2=\begin{pmatrix}0&-\sqrt{-1}\\\sqrt{-1}&0\end{pmatrix},\quad \sigma_3=\begin{pmatrix}1&0\\0&-1\end{pmatrix},$$

which satisfy the algebra $\sigma_\mu^2=I_2$, $\mu=1,2,3$, and $\sigma_\mu\sigma_\rho=\sqrt{-1}\Sigma_{\omega=1}^3\varepsilon_{\mu\rho\omega}\sigma_\omega$ for $1\leqslant\mu\neq\rho\leqslant 3$, where I_N denotes the $N\times N$ unit matrix and $\varepsilon_{\mu\rho\omega}$ the totally antisymmetric unit tensor. They give the infinitesimal generators $\{X_\mu\}$ of SU(2) by $X_\mu=\sqrt{-1}\sigma_\mu/2$. For $N\geqslant 2$, define the $2N\times 2N$ matrices $\Sigma_\mu=I_N\otimes\sigma_\mu$, $\mu=1,2,3$. The matrices $\{\Sigma_\mu\}$ satisfy the same algebra as $\{\sigma_\mu\}$. We will use σ_0 to represent I_2.

We introduce six spaces of matrices as subspaces of $\mathcal{H}(2N)$,

$$\mathcal{H}_{\mu\pm}(2N)=\{H\in\mathcal{H}(2N):H^T\Sigma_\mu=\pm\Sigma_\mu H\},\quad \mu=1,2,3.$$

It is easy to see that $\mathcal{H}_{3+}(2N)=\mathcal{S}(2N)$ and $\mathcal{H}_{3-}(2N)=\sqrt{-1}\mathcal{A}(2N)$. Since we have already studied the matrix-valued process in $\mathcal{S}(N)$ as the example (ii) in Sec. II B, we will consider here the five subspaces of $\mathcal{H}(2N)$; $\sqrt{-1}\mathcal{A}(2N)$ and $\{\mathcal{H}_{\mu\sigma}(2N)\}$ with $\mu=1,2,\sigma=\pm$. We also introduce the three subspaces of $\mathrm{U}(2N)$:

$$\mathrm{U}_0(2N)=\{U\in\mathrm{U}(2N):U^TU=\Sigma_1\},$$

$$\mathrm{U}_\mu(2N)=\{U\in\mathrm{U}(2N):U^T\Sigma_\mu U=\Sigma_\mu^T\},\quad \mu=1,2.$$

The conditions imply that these subspaces, $\mathcal{H}_{\mu\sigma}(2N)$ and $\mathrm{U}_\mu(2N)$, have additional symmetries compared to $\mathcal{H}(2N)$ and $\mathrm{U}(2N)$. Concerning the eigenvalues and eigenvectors of the Hermitian matrices, the following lemma may be easily proved.

Lemma 2: Assume that Ω *denotes a diagonal matrix in the form* $\mathrm{diag}\{\omega_1,\omega_2,\ldots,\omega_N\}$ *with* $\omega_1\leqslant\omega_2\leqslant\cdots\leqslant\omega_N$.

(i) *Any* $H\in\sqrt{-1}\mathcal{A}(2N)$ *can be diagonalized by* $U\in\mathrm{U}_0(2N)$ *as* $U^\dagger HU=\Omega\otimes\sigma_3$.
(ii) *For* $\mu=1,2$ *any* $H\in\mathcal{H}_{\mu+}(2N)$ *can be diagonalized by* $U\in\mathrm{U}_\mu(2N)$ as $U^\dagger HU=\Omega\otimes\sigma_0$.
(iii) *For* $\mu=1,2$ *any* $H\in\mathcal{H}_{\mu-}(2N)$ *can be diagonalized by* $U\in\mathrm{U}_\mu(2N)$ as $U^\dagger HU=\Omega\otimes\sigma_3$.

Remark:

(a) Observing the pairing of eigenvalues in a way, $(\omega_i,-\omega_i),1\leqslant i\leqslant N$, for $\sqrt{-1}\mathcal{A}(2N)$ stated in Lemma 2 (i), the Gaussian random-matrix ensemble of antisymmetric Hermitian matrices was discussed by Mehta in Sec. 3.4 of Ref. 40.

(b) The condition for $\mathrm{U}_2(2N)$ addition to the unitarity is equivalent with $J=UJU^T$, where

$$J=I_N\otimes\begin{pmatrix}0&1\\-1&0\end{pmatrix}.$$

Then $\mathrm{U}_2(2N)$ forms the N-dimensional symplectic group. That is, $\mathrm{U}_2(2N)=\mathrm{Sp}(N,\mathbb{C})\cap\mathrm{U}(2N)$. (It is called the unitary-symplectic group $\mathrm{USp}(2N)$ in Ref. 19.) The matrices $H\in\mathcal{H}_{2+}(2N)$ are said to be *self-dual Hermitian matrices* in the random matrix theory.[40] The pairwise degeneracy stated in Lemma 2 (ii) for $\mathcal{H}_{2+}(2N)$ is known as the *Kramers doublet* in the quantum mechanics.

(c) The condition for $\mathcal{H}_{2-}(2N)$ addition to Hermiticity is rewritten as $H^TJ+JH=0$, which means that $H\in\mathcal{H}_{2-}(2N)$ satisfies the symplectic Lie algebra (see, for example, Ref. 18), that is, $\mathcal{H}_{2-}(2N)=\mathfrak{sp}(2N,\mathbb{C})\cap\mathcal{H}(2N)$. Similarly, we can see $\mathcal{H}_{1-}(2N)=\mathfrak{so}(2N,\mathbb{C})\cap\mathcal{H}(2N)$, where $\mathfrak{so}(2N,\mathbb{C})$ denotes the orthogonal Lie algebra. We can also see that $\mathrm{U}_1(2N)=\mathrm{SO}(2N,\mathbb{C})\cap\mathrm{U}(2N)$, where $\mathrm{SO}(2N,\mathbb{C})$ denotes the orthogonal Lie group.

(d) We can see that $\mathcal{H}_{\mu-}(2N)\cong\hat{\mathcal{H}}_{\mu-}(2N)$, $\mu=1,2$, where

$$\hat{\mathcal{H}}_{1-}(2N)=\left\{H=\begin{pmatrix}H_1&A_2\\A_2^\dagger&-H_1^T\end{pmatrix}:H_1\in\mathcal{H}(N),A_2\in\mathcal{A}(N;\mathbb{C})\right\},$$

$$\hat{\mathcal{H}}_{2-}(2N)=\left\{H=\begin{pmatrix}H_1&A_2\\A_2^\dagger&-H_1^T\end{pmatrix}:H_1\in\mathcal{H}(N),A_2\in\mathcal{S}(N;\mathbb{C})\right\},$$

where $\mathcal{S}(N;\mathbb{C})$ and $\mathcal{A}(N;\mathbb{C})$ denote the spaces of the $N\times N$ complex symmetric and complex antisymmetric matrices, respectively. Altland and Zirnbauer studied $\hat{\mathcal{H}}_{2-}(2N)$ and $\hat{\mathcal{H}}_{1-}(2N)$ as the sets of the Hamiltonians in the Bogoliubov–de Gennes formalism for the BCS mean-field theory of superconductivity, where the pairing of positive and negative eigenvalues $(\omega_i,-\omega_i)$, $1\leqslant i\leqslant N$, stated in Lemma 2 (iii) for $\mu=1$ and 2 represents the particle-hole symmetry in the Bogoliubov–de Gennes theory. They called $\hat{\mathcal{H}}_{2-}(2N)$ and

$\hat{\mathcal{H}}_{1-}(2N)$ the sets of Hermitian matrices in the symmetry classes C and D,[56,1,2] since $\mathfrak{sp}(2N,\mathbb{C})=\mathrm{C}_N$ and $\mathfrak{so}(2N,\mathbb{C})=\mathrm{D}_N$ in Cartan's notations (see Ref. 23).

B. Representation using Pauli matrices and application of Bru's theorem

Let $B_{ij}^{\rho}(t)$, $\tilde{B}_{ij}^{\rho}(t)$, $0\leqslant\rho\leqslant 3$, $1\leqslant i\leqslant j\leqslant N$ be independent one-dimensional standard Brownian motions starting from the origin. Put

$$s_{ij}^{\rho}(t)=\begin{cases}\dfrac{1}{\sqrt{2}}B_{ij}^{\rho}(t), & \text{if } i<j,\\ B_{ii}^{\rho}(t), & \text{if } i=j,\end{cases}\quad\text{and}\quad a_{ij}^{\rho}(t)=\begin{cases}\dfrac{1}{\sqrt{2}}\tilde{B}_{ij}^{\rho}(t), & \text{if } i<j,\\ 0, & \text{if } i=j,\end{cases}\tag{17}$$

with $s_{ij}^{\rho}(t)=s_{ji}^{\rho}(t)$ and $a_{ij}^{\rho}(t)=-a_{ji}^{\rho}(t)$ for $i>j$ and define $s^{\rho}(t)=(s_{ij}^{\rho}(t))_{1\leqslant i,j\leqslant N}\in\mathcal{S}(N)$, $t\in[0,\infty)$ and $a^{\rho}(t)=(a_{ij}^{\rho}(t))_{1\leqslant i,j\leqslant N}\in\mathcal{A}(N)$, $t\in[0,\infty)$, for $0\leqslant\rho\leqslant 3$.

We can see that the Hermitian matrix-valued process given as the first example (i) in Sec. II B can be represented, if we double the size of matrix to $2N$, as $\Xi(t)=\Sigma_{\rho=0}^{3}\{(s^{\rho}(t)\otimes\sigma_{\rho})+\sqrt{-1}(a^{\rho}(t)\otimes\sigma_{\rho})\}$. By choosing four terms in the eight terms, we define the following four different types of $2N\times 2N$ Hermitian matrix-valued processes:

$$\Xi_{\mu\sigma}(t)=\sum_{\rho=0}^{3}(\xi_{\mu\sigma}^{\rho}(t)\otimes\sigma_{\rho})\in\mathcal{H}_{\mu\sigma}(2N)\quad\text{for}\quad\mu=1,2,\quad\sigma=\pm,$$

where

$$\xi_{\mu+}^{\rho}(t)=\begin{cases}s^{\rho}(t) & \text{if } \mu=1,\ \rho\neq 3 \text{ or } \mu=2,\ \rho=0,\\ \sqrt{-1}a^{\rho}(t) & \text{if } \mu=1,\ \rho=3 \text{ or } \mu=2,\ \rho\neq 0,\end{cases}$$

$$\xi_{\mu-}^{\rho}(t)=\begin{cases}\sqrt{-1}a^{\rho}(t) & \text{if } \mu=1,\ \rho\neq 3 \text{ or } \mu=2,\ \rho=0,\\ s^{\rho}(t) & \text{if } \mu=1,\ \rho=3 \text{ or } \mu=2,\ \rho\neq 0.\end{cases}$$

We apply Theorem 1 to the five processes, $\sqrt{-1}\mathcal{A}(2N)$ and $\{\Xi_{\mu\sigma}(t)\}$ with $\mu=1,2,\sigma=\pm$. The results are listed below.

(a) $\sqrt{-1}\mathcal{A}(2N)$: Since $\Gamma_{ij}(t)=\{1-((\Sigma_1)_{ij})^2\}/2$, $1\leqslant i,j\leqslant 2N$, the equations of non-negative eigenvalues are

$$d\omega_i(t)=\frac{1}{\sqrt{2}}dB_i(t)+\frac{1}{2}\sum_{j:1\leqslant j\leqslant N,j\neq i}\left\{\frac{1}{\omega_i(t)-\omega_j(t)}+\frac{1}{\omega_i(t)+\omega_j(t)}\right\}dt,\quad 1\leqslant i\leqslant N.$$

By changing the time unit as $t\to 2t$, this equation can be identified with (13) with $(\beta,\gamma)=(2,0)$.

(b) $\mathcal{H}_{1+}(2N)$: Since $\Gamma_{ij}(t)=\{1+((\Sigma_1)_{ij})^2\}$, $1\leqslant i,j\leqslant 2N$, the distinct eigenvalues solve Dyson's Brownian motion model (1) with $\beta=4$.

(c) $\mathcal{H}_{1-}(2N)$: We see $\Gamma_{ij}(t)=\{1-((\Sigma_1)_{ij})^2\}$, $1\leqslant i,j\leqslant 2N$. Then the non-negative eigenvalues solve Eq. (13) with $(\beta,\gamma)=(2,0)$.

(d) $\mathcal{H}_{2+}(2N)$: Since $\Gamma_{ij}(t)=\{1+((\Sigma_2)_{ij})^2\}$, $1\leqslant i,j\leqslant 2N$, the distinct eigenvalues solve the Eq. (1) with $\beta=4$.

(e) $\mathcal{H}_{2-}(2N)$: We can see $\Gamma_{ij}(t)=\{1-((\Sigma_2)_{ij})^2\}$, $1\leqslant i,j\leqslant 2N$. Then the non-negative eigenvalues solve Eq. (13) with $(\beta,\gamma)=(2,1)$.

C. Relation with standard and nonstandard random matrix theories

(i) The eigenvalues of any matrix in the space $\mathcal{H}_{2+}(2N)\cong\mathbb{R}^{d[\mathrm{A}'']}$ with $d[\mathrm{A}'']=N(2N-1)$ are pairwise degenerated (the Kramers doublets) as $\boldsymbol{\lambda}=(\omega_1,\omega_1,\omega_2,\omega_2,\ldots,\omega_N,\omega_N)$. We assume that the N distinct eigenvalues are always arranged in the increasing order $\omega_1\leqslant\omega_2\cdots\leqslant\omega_N$. For GSE with variance t, the probability density of the N distinct eigenvalues in this ordering is given by[40]

$$q^{\mathrm{GSE}}(\boldsymbol{\omega};t)=\frac{t^{-d[\mathrm{A}'']/2}}{C[\mathrm{A}'']}\exp\left\{-\frac{|\boldsymbol{\omega}|^2}{2t}\right\}h^{\mathrm{A}}(\boldsymbol{\omega})^4,$$

where $C[\mathrm{A}'']=(2\pi)^{N/2}\Pi_{i=1}^{N}\Gamma(2i)$. If we denote the transition probability density of the process (1) with $\beta=4$ by $p^{\mathrm{A}''}(s,\cdot\,;t,\cdot\,)$ for $0\leqslant s<t<\infty$, then $p^{\mathrm{A}''}(0,\mathbf{0};t,\boldsymbol{\omega})=q^{\mathrm{GSE}}(\boldsymbol{\omega};t)$, $t>0$.

(ii) We can see that $\mathcal{H}_{2-}(2N)\cong\mathbb{R}^{d[\mathrm{C}]}$ and $\mathcal{H}_{1-}(2N)\cong\mathbb{R}^{d[\mathrm{D}]}$ with $d[\mathrm{C}]=N(2N+1)$ and $d[\mathrm{D}]=N(2N-1)$. The probability densities of the processes $\Xi_{2-}(t)$ and $\Xi_{1-}(t)$ with respect to the volume elements $\mathcal{V}(dH)$ of $\mathcal{H}_{2-}(2N)$ and $\mathcal{V}'(dH)$ of $\mathcal{H}_{1-}(2N)$ are given by

$$\mu^{\mathrm{C}}(H;t)=\frac{t^{-d[\mathrm{C}]/2}}{c[\mathrm{C}]}\exp\left\{-\frac{1}{4t}\mathrm{Tr}\,H^2\right\},\quad \mu^{\mathrm{D}}(H;t)=\frac{t^{-d[\mathrm{D}]/2}}{c[\mathrm{D}]}\exp\left\{-\frac{1}{4t}\mathrm{Tr}\,H^2\right\},$$

where $c[\mathrm{C}]=2^{3N/2}\pi^{N(2N+1)/2}$ and $c[\mathrm{D}]=2^{N/2}\pi^{N(2N-1)/2}$, respectively. As stated in Lemma 2 (iii), the eigenvalues are in the form $\boldsymbol{\lambda}(t)=(\omega_1(t),-\omega_1(t),\omega_2(t),-\omega_2(t),\ldots,\omega_N(t),-\omega_N(t))$. We will assume that

$$0\leqslant\omega_1\leqslant\omega_2\leqslant\cdots\leqslant\omega_N. \tag{18}$$

Then we have the expressions for volume elements

$$\mathcal{V}(dH)=\frac{c[\mathrm{C}]}{C[\mathrm{C}]}h^{\mathrm{C}}(\boldsymbol{\omega})^2d\boldsymbol{\omega}dU,\quad \mathcal{V}'(dH)=\frac{c[\mathrm{D}]}{C[\mathrm{D}]}h^{\mathrm{D}}(\boldsymbol{\omega})^2d\boldsymbol{\omega}dU', \tag{19}$$

where dU and dU' denote the Haar measures of $\mathrm{U}_2(2N)$ and $\mathrm{U}_1(2N)$, respectively, normalized as $\int_{\mathrm{U}_2(2N)}dU=1$ and $\int_{\mathrm{U}_1(2N)}dU'=1$. Here $C[\mathrm{C}]=C_{1/2}=(\pi/2)^{N/2}\Pi_{i=1}^{N}\Gamma(2i)$ and $C[\mathrm{D}]=C_{-1/2}=(\pi/2)^{N/2}\Pi_{i=1}^{N}\Gamma(2i-1)$, and $h^{\mathrm{C}}(\boldsymbol{\omega})\equiv h^{(1)}(\boldsymbol{\omega}),h^{\mathrm{D}}(\boldsymbol{\omega})\equiv h^{(0)}(\boldsymbol{\omega})$. At each time $t>0$, for any $U\in\mathrm{U}_2(2N)$, the probability $\mu^{\mathrm{C}}(H;t)\mathcal{V}(dH)$ is invariant under the automorphism $H\to U^{\dagger}HU$ for $H\in\mathcal{H}_{2-}(2N)$, and for any $U'\in\mathrm{U}_1(2N)$, $\mu^{\mathrm{D}}(H;t)\mathcal{V}'(dH)$ is invariant under the automorphism $H\to U'^{\dagger}HU'$ for $H\in\mathcal{H}_{1-}(2N)$. Altland and Zirnbauer named these two Gaussian random-matrix ensembles the classes C and D, respectively (see Remark (d) in Sec. III A).[1,2,56] The probability densities of the N non-negative eigenvalues with condition (18) are then obtained as

$$q^{\sharp}(\boldsymbol{\omega};t)=\frac{t^{-d[\sharp]/2}}{C[\sharp]}\exp\left\{-\frac{|\boldsymbol{\omega}|^2}{2t}\right\}h^{\sharp}(\boldsymbol{\omega})^2\quad\text{for}\quad\sharp=\mathrm{C},\mathrm{D}.$$

If we denote the transition probability densities of the processes (13) with $(\beta,\gamma)=(2,1)$ and with $(\beta,\gamma)=(2,0)$ by $p^{\mathrm{C}}(s,\cdot\,;t,\cdot\,)$ and $p^{\mathrm{D}}(s,\cdot\,;t,\cdot\,)$ for $0\leqslant s<t<\infty$, respectively, then

$$p^{\sharp}(0,\mathbf{0};t,\boldsymbol{\omega})=q^{\sharp}(\boldsymbol{\omega};t),\quad t>0\quad\text{for}\quad\sharp=\mathrm{C},\mathrm{D}. \tag{20}$$

D. Real symmetric matrix-valued processes

Here after, we denote the Hermitian matrix-valued processes $\Xi_{2-}(t)$ and $\Xi_{1-}(t)$ by $\Xi^{\mathrm{C}}(t)$ and $\Xi^{\mathrm{D}}(t)$, respectively. They are given by

$$\Xi^{\mathrm{C}}(t)=\sqrt{-1}a^0(t)\otimes\sigma_0+s^1(t)\otimes\sigma_1+s^2(t)\otimes\sigma_2+s^3(t)\otimes\sigma_3,$$

$$\Xi^{\mathrm{D}}(t)=\sqrt{-1}a^0(t)\otimes\sigma_0+\sqrt{-1}a^1(t)\otimes\sigma_1+\sqrt{-1}a^2(t)\otimes\sigma_2+s^3(t)\otimes\sigma_3. \tag{21}$$

Since $\sigma_\rho, \rho=0,1,3$, are real matrices and σ_2 is a pure imaginary matrix, if we define the processes as

$$\Xi^{\mathrm{C}'}(t)=s^1(t)\otimes\sigma_1+s^3(t)\otimes\sigma_3, \quad \Xi^{\mathrm{D}'}(t)=\sqrt{-1}a^2(t)\otimes\sigma_2+s^3(t)\otimes\sigma_3, \tag{22}$$

then $\Xi^{\mathrm{C}'}(t)\in\mathcal{S}_{2-}(2N)$ and $\Xi^{\mathrm{D}'}(t)\in\mathcal{S}_{1-}(2N)$, where $\mathcal{S}_{2-}(2N)\equiv\{S\in\mathcal{S}(2N):S^T\Sigma_2=-\Sigma_2S\}\cong\mathbb{R}^{d[\mathrm{C}']}$ and $\mathcal{S}_{1-}(2N)\equiv\{S\in\mathcal{S}(2N):S^T\Sigma_1=-\Sigma_1S\}\cong\mathbb{R}^{d[\mathrm{D}']}$ with $d[\mathrm{C}']=N(N+1)$ and $d[\mathrm{D}']=N^2$. The probability densities of $\Xi^{\mathrm{C}'}(t)$ and $\Xi^{\mathrm{D}'}(t)$ are given by

$$\mu^{\mathrm{C}'}(S;t)=\frac{t^{-d[\mathrm{C}']/2}}{c[\mathrm{C}']}\exp\left\{-\frac{1}{4t}\mathrm{Tr}\,S^2\right\}, \quad \mu^{\mathrm{D}'}(S;t)=\frac{t^{-d[\mathrm{D}']/2}}{c[\mathrm{D}']}\exp\left\{-\frac{1}{4t}\mathrm{Tr}\,S^2\right\}$$

with $c[\mathrm{C}']=2^N\pi^{N(N+1)/2}$ and $c[\mathrm{D}']=2^{N/2}\pi^{N^2/2}$, respectively. Set $\mathrm{O}_2(2N)=\mathrm{O}(2N)\cap\mathrm{Sp}(2N;\mathbb{R})$ and $\mathrm{O}_1(2N)=\mathrm{O}(2N)\cap\mathrm{SO}(2N;\mathbb{R})$ and denote their normalized Haar measures by dV and dV', respectively The eigenvalues are in the form $\boldsymbol{\lambda}(t)=(\omega_1(t),-\omega_1(t),\omega_2(t),-\omega_2(t),\ldots,\omega_N(t),-\omega_N(t))$. Under condition (18), we have the expressions for volume elements

$$\mathcal{V}(dS)=\frac{c[\mathrm{C}']}{C[\mathrm{C}']}h^{\mathrm{C}}(\boldsymbol{\omega})d\boldsymbol{\omega}dV, \quad \mathcal{V}'(dS)=\frac{c[\mathrm{D}']}{C[\mathrm{D}']}h^{\mathrm{D}}(\boldsymbol{\omega})d\boldsymbol{\omega}dV', \tag{23}$$

where $C[\mathrm{C}']=C_{1/2,1}=\Pi_{i=1}^N\Gamma(i)$ and $C[\mathrm{D}']=C_{-1/2,0}=2^{(N-2)/2}\Gamma(N/2)\Pi_{i=1}^{N-1}\Gamma(i)$. The probability densities of the N nonnegative eigenvalues with (18) are given as

$$q^{\sharp'}(\boldsymbol{\omega};t)=\frac{t^{-d[\sharp']/2}}{C[\sharp']}\exp\left\{-\frac{|\boldsymbol{\omega}|^2}{2t}\right\}h^{\sharp}(\boldsymbol{\omega}) \quad \text{for} \quad \sharp=\mathrm{C},\mathrm{D}.$$

It is remarked that the random-matrix ensemble with the distributions $\mu^{\mathrm{C}'}(S;t)$, whose nonnegative eigenvalue-distribution is given by $q^{\mathrm{C}'}(\boldsymbol{\omega};t)$, is the random-matrix ensemble in the symmetry class CI studied by Altland and Zirnbauer.[1,2,56]

By applying Theorem 1, we can show that the non-negative eigenvalues of $\Xi^{\mathrm{C}'}(t)$ solve Eq. (13) with $(\beta,\gamma)=(1,1)$ and those of $\Xi^{\mathrm{D}'}(t)$, Eq. (13) with $(\beta,\gamma)=(1,0)$. If we denote the transition probability densities of these processes by $p^{\mathrm{C}'}(s,\cdot;t,\cdot)$ and $p^{\mathrm{D}'}(s,\cdot;t,\cdot)$ for $0\leqslant s<t<\infty$, respectively, then $p^{\sharp'}(0,\mathbf{0};t,\boldsymbol{\omega})=q^{\sharp'}(\boldsymbol{\omega};t)$, $t>0$ for $\sharp=\mathrm{C},\mathrm{D}$.

IV. TEMPORALLY HOMOGENEOUS PROCESSES

Assume that $\nu>-1$, and we consider the process $\mathbf{Y}^{(\nu)}(t)=(Y_1^{(\nu)}(t),Y_2^{(\nu)}(t),\ldots,Y_N^{(\nu)}(t))$, $t\in[0,\infty)$, which solves the stochastic differential Eq. (13) with $(\beta,\gamma)=(2,(2\nu+1)/2)$, that is,

$$dY_i^{(\nu)}(t)=dB_i(t)+\left[\frac{2\nu+1}{2Y_i^{(\nu)}(t)}+\sum_{j:j\neq i}\left\{\frac{1}{Y_i^{(\nu)}(t)-Y_j^{(\nu)}(t)}+\frac{1}{Y_i^{(\nu)}(t)+Y_j^{(\nu)}(t)}\right\}\right]dt, \tag{24}$$

$1\leqslant i\leqslant N$. Remark that if $\nu=1/2$ and $-1/2$, the equation is reduced to (13) with $(\beta,\gamma)=(2,1)$ and $(\beta,\gamma)=(2,0)$, respectively. The Kolmogorov backward equation (the Fokker–Planck equation) for (24) is

$$\frac{\partial}{\partial t}p^{(\nu)}(s,\mathbf{x};t,\mathbf{y})=\frac{1}{2}\Delta_{\mathbf{x}}p^{(\nu)}(s,\mathbf{x};t,\mathbf{y})+\mathbf{b}(\mathbf{x})\cdot\nabla_{\mathbf{x}}p^{(\nu)}(s,\mathbf{x};t,\mathbf{y}),$$

where $\mathbf{b}(\mathbf{x})=(b_1(\mathbf{x}),\ldots,b_N(\mathbf{x}))$ with $b_i(\mathbf{x})=(\partial/\partial x_i)\ln h^{((2\nu+1)/2)}(\mathbf{x})$. By simple calculation, we can confirm the following:

Lemma 3: Set

$$f^{(\nu)}(t,\mathbf{y}|\mathbf{x})=\det_{1\leqslant i,j\leqslant N}[G^{(\nu)}(t,y_j|x_i)]. \tag{25}$$

Then the transition probability density $p^{(\nu)}(s,\mathbf{x};t,\mathbf{y})$ *from the state* $\mathbf{x}$ *at time* s *to the state* $\mathbf{y}$ *at time* $t(>s)$ *of the process (24) is given by*

$$p^{(\nu)}(s,\mathbf{x};t,\mathbf{y})=\frac{1}{h^{(0)}(\mathbf{x})}f^{(\nu)}(t-s,\mathbf{y}|\mathbf{x})h^{(0)}(\mathbf{y}),\quad \mathbf{x},\mathbf{y}\in\mathbb{W}_N^{\mathrm{C}}. \tag{26}$$

Since $I_{1/2}(x)=(e^x-e^{-x})/\sqrt{2\pi x}$, $I_{-1/2}(x)=(e^x+e^{-x})/\sqrt{2\pi x}$, if we set

$$G^{\mathrm{C}}(t,y|x)=\frac{e^{-(y-x)^2/2t}-e^{-(y+x)^2/2t}}{\sqrt{2\pi t}},\quad G^{\mathrm{D}}(t,y|x)=\frac{e^{-(y-x)^2/2t}+e^{-(y+x)^2/2t}}{\sqrt{2\pi t}}, \tag{27}$$

and $f^{\sharp}(t,\mathbf{y}|\mathbf{x})=\det_{1\leqslant i,j\leqslant N}[G^{\sharp}(t,y_j|x_i)]$, $\sharp=\mathrm{C},\mathrm{D}$, then

$$p^{(1/2)}(s,\mathbf{x};t,\mathbf{y})=\frac{f^{\mathrm{C}}(t-s,\mathbf{y}|\mathbf{x})h^{\mathrm{C}}(\mathbf{y})}{h^{\mathrm{C}}(\mathbf{x})},\quad p^{(-1/2)}(s,\mathbf{x};t,\mathbf{y})=\frac{f^{\mathrm{D}}(t-s,\mathbf{y}|\mathbf{x})h^{\mathrm{D}}(\mathbf{y})}{h^{\mathrm{D}}(\mathbf{x})}. \tag{28}$$

The above implies the following. Let $\mathbb{W}_N^{\mathrm{C}}=\{\mathbf{x}\in\mathbb{R}^N:0<x_1<x_2<\cdots<x_N\}$ and $\mathbb{W}_N^{\mathrm{D}}=\{\mathbf{x}\in\mathbb{R}^N:|x_1|<x_2<\cdots<x_N\}$. The former is the Weyl chamber of type C_N and the latter of type D_N.[18] Since h^{C} and h^{D} vanish at the boundaries of the Weyl chambers $\mathbb{W}_N^{\mathrm{C}}$ and $\mathbb{W}_N^{\mathrm{D}}$, respectively, (28) implies that the processes $\mathbf{Y}^{(1/2)}(t)$ and $\mathbf{Y}^{(-1/2)}(t)$ can be regarded as the N-dimensional absorbing Brownian motions in $\mathbb{W}_N^{\mathrm{C}}$ and in $\mathbb{W}_N^{\mathrm{D}}$, respectively. That is, if $\mathbf{Y}^{(1/2)}(0)\in\mathbb{W}_N^{\mathrm{C}}$ and $\mathbf{Y}^{(-1/2)}(0)\in\mathbb{W}_N^{\mathrm{D}}$, then $\mathbf{Y}^{(1/2)}(t)\in\mathbb{W}_N^{\mathrm{C}}$ and $\mathbf{Y}^{(-1/2)}(t)\in\mathbb{W}_N^{\mathrm{D}}$ for all $t>0$ with probability 1. Moreover, we notice that (27) are the heat-kernels of the one-dimensional Brownian motion with an absorbing wall at the origin, and of the one-dimensional reflecting Brownian motion, respectively.[48] Then, we can also interpret the process $\mathbf{Y}^{(1/2)}(t)$ as the N-particle system of Brownian motions conditioned never to collide with each other nor with the wall at the origin in one-dimension,[35] and the process $\mathbf{Y}^{(-1/2)}(t)$ as the N-particle system of reflecting Brownian motions conditioned never to collide with each other. For $\sharp=\mathrm{C}$ and D, define

$$\mathcal{N}^{\sharp}(t,\mathbf{x})=\int_{\mathbb{W}_N^{\sharp}}d\mathbf{y}\,f^{\sharp}(t,\mathbf{y}|\mathbf{x}),\quad \mathbf{x}\in\mathbb{W}_N^{\sharp}. \tag{29}$$

$\mathcal{N}^{\mathrm{C}}(t,\mathbf{x})$ is the probability that N Brownian motions starting from $\mathbf{x}\in\mathbb{W}_N^{\mathrm{C}}$ does not collide with each other nor with the wall at the origin up to time t, and $\mathcal{N}^{\mathrm{D}}(t,\mathbf{x})$ is equal to the probability that N reflecting Brownian motions starting from $\mathbf{x}\in\mathbb{W}_N^{\mathrm{D}}$ does not collide with each other up to time t, respectively. We will show their long-time asymptotics in the next section. We can prove the following, which are consistent with (14) and (20).

Lemma 4: For $\nu>-1$ *with fixed* $t\in(0,\infty)$, *assume* $\mathbf{y}\in\mathbb{W}_N^{\mathrm{C}}$. *Then*

$$\lim_{|\mathbf{x}|\to 0}p^{(\nu)}(0,\mathbf{x};t,\mathbf{y})=\frac{t^{-N(N+\nu)}}{C_\nu}\exp\left\{-\frac{|\mathbf{y}|^2}{2t}\right\}h^{((2\nu+1)/2)}(\mathbf{y})^2. \tag{30}$$

In particular, if $\nu\in\mathbb{N}$,

$$\lim_{|\mathbf{x}|\to 0}p^{(\nu)}(0,\mathbf{x};t,\mathbf{y})=q_\nu^{\mathrm{chGUE}}(\mathbf{y};t), \tag{31}$$

and

$$\lim_{|\mathbf{x}|\to 0} p^{(1/2)}(0,\mathbf{x};t,\mathbf{y}) = q^{\mathrm{C}}(\mathbf{y};t), \quad \lim_{|\mathbf{x}|\to 0} p^{(-1/2)}(0,\mathbf{x};t,\mathbf{y}) = q^{\mathrm{D}}(\mathbf{y};t). \tag{32}$$

Proof: By definition (25) with (3), if $x_i>0, 1\leqslant \forall i \leqslant N$, $f^{(\nu)}(t,\mathbf{y}|\mathbf{x}) = (1/t^N)\Pi_{k=1}^N (y_k^{\nu+1}/x_k^{\nu}) \times e^{-(|\mathbf{x}|^2+|\mathbf{y}|^2)/2t}\det_{1\leqslant i,j\leqslant N}[I_\nu(x_i y_j/t)]$. We can use (A2) in Appendix A by changing the variables $x_i \to x_i^2/2t$ and $y_j \to y_j^2/2t$ to evaluate $\det_{1\leqslant i,j\leqslant N}[I_\nu(x_i y_j/t)]$ and obtain the asymptotic form of $f^{(\nu)}(t,\mathbf{y}|\mathbf{x})$,

$$f^{(\nu)}(t,\mathbf{y}|\mathbf{x}) = \frac{t^{-N(N+2\nu+1)/2}}{C_\nu} \prod_{1\leqslant i<j\leqslant N} \left\{ \left(\frac{x_j}{\sqrt{t}}\right)^2 - \left(\frac{x_i}{\sqrt{t}}\right)^2 \right\} \prod_{1\leqslant k<\ell\leqslant N} (y_\ell^2 - y_k^2) \prod_{m=1}^N y_m^{2\nu+1} \times \exp\left\{ -\frac{|\mathbf{y}|^2}{2t} \right\} \times \left(1 + \mathcal{O}\left(\frac{|\mathbf{x}|}{\sqrt{t}} \right) \right) \tag{33}$$

in $|\mathbf{x}|/\sqrt{t}\to 0$. Using this form in (26), the limit (30) is proved. ■

V. TEMPORALLY INHOMOGENEOUS PROCESSES

A. Star topology

Using (2) the probability that the Brownian motion started at $\mathbf{x}\in \mathbb{W}_N^{\mathrm{A}}$ does not hit the boundary of $\mathbb{W}_N^{\mathrm{A}}$ up to time $t>0$ is given by $\mathcal{N}^{\mathrm{A}}(t,\mathbf{x}) = \int_{\mathbb{W}_N^{\mathrm{A}}} d\mathbf{y}\, f^{\mathrm{A}}(t,\mathbf{y}|\mathbf{x})$. In the previous papers,[31,32] we gave the asymptotic form

$$f^{\mathrm{A}}(t,\mathbf{y}|\mathbf{x}) = \frac{t^{-N(N+1)/4}}{C[\mathrm{A}]} h^{\mathrm{A}}\left(\frac{\mathbf{x}}{\sqrt{t}}\right) h^{\mathrm{A}}(\mathbf{y}) \exp\left\{ -\frac{|\mathbf{y}|^2}{2t} \right\} \times \left(1 + \mathcal{O}\left(\frac{|\mathbf{x}|}{\sqrt{t}} \right) \right) \tag{34}$$

in $|\mathbf{x}|/\sqrt{t}\to 0$ and showed that $\mathcal{N}^{\mathrm{A}}(t,\mathbf{x}) = (C[\mathrm{A}']/C[\mathrm{A}]) h^{\mathrm{A}}(\mathbf{x}/\sqrt{t}) \times (1+\mathcal{O}(|\mathbf{x}|/\sqrt{t}))$ as $|\mathbf{x}|/\sqrt{t} \to 0$. This estimate gives that for $\mathbf{x}\in \mathbb{W}_N^{\mathrm{A}}$ the noncolliding probability decays in the power-law as $t\to\infty$;[15,21,37] $\mathcal{N}^{\mathrm{A}}(t,\mathbf{x}) \sim t^{-\psi[\mathrm{A}]}$ with the exponent $\psi[\mathrm{A}] = N(N-1)/4$. (Note that (34) is derived readily by using (A1) in Appendix A.) For a given $T>0$, we defined

$$g_T^{\mathrm{A}}(s,\mathbf{x};t,\mathbf{y}) = \frac{f^{\mathrm{A}}(t-s,\mathbf{y}|\mathbf{x})\mathcal{N}^{\mathrm{A}}(T-t,\mathbf{y})}{\mathcal{N}^{\mathrm{A}}(T-s,\mathbf{x})}$$

for $0\leqslant s<t\leqslant T$, $\mathbf{x},\mathbf{y}\in \mathbb{W}_N^{\mathrm{A}}$. Using (34) we showed that as $|\mathbf{x}|\to 0$ it converges to $g_T^{\mathrm{A}}(0,\mathbf{0};t,\mathbf{y}) = (T^{\psi[\mathrm{A}]} t^{-d[\mathrm{A}]/2}/C[\mathrm{A}'])e^{-|\mathbf{y}|^2/2t} h^{\mathrm{A}}(\mathbf{y})\mathcal{N}^{\mathrm{A}}(T-t,\mathbf{y})$. This function $g_T^{\mathrm{A}}(s,\mathbf{x};t,\mathbf{y})$ can be regarded as the transition probability density from the state $\mathbf{x}\in \mathbb{W}_N^{\mathrm{A}}$ at time s to the state $\mathbf{y}\in \mathbb{W}_N^{\mathrm{A}}$ at time $t(>s)$ conditioned to stay inside $\mathbb{W}_N^{\mathrm{A}}$ up to time T and defines a temporally inhomogeneous diffusion process, which we denoted by $\mathbf{X}(t) = (X_1(t), X_2(t), \ldots, X_N(t))$, $t\in[0,T]$ in Sec. I. This represents the N-particle system of Brownian motions conditioned not to collide with each other in a finite time-interval $(0,T]$. The process $\mathbf{X}(t), t\in[0,T]$, starting from $\mathbf{X}(0)=\mathbf{0}$ is illustrated by Fig. 1, whose spatio-temporal path-configuration is said to be in *star topology* in the theory of directed polymer networks.[14] As mentioned in Sec. I, this process exhibits a transition of the eigenvalue statistics from GUE to GOE.[31,32]

In the present section, we consider the temporally inhomogeneous diffusion process associated with $\mathbf{Y}^{(\nu)}(t)$ studied in the previous section. We consider the N-particle system of generalized meanders (5) conditioned that they never collide with each other for a time interval $[0,T]$. The transition probability density is given by

$$g_T^{(\nu,\kappa)}(s,\mathbf{x};t,\mathbf{y}) = \frac{f_T^{(\nu,\kappa)}(s,\mathbf{x};t,\mathbf{y})\mathcal{N}_T^{(\nu,\kappa)}(t,\mathbf{y})}{\mathcal{N}_T^{(\nu,\kappa)}(s,\mathbf{x})} \tag{35}$$

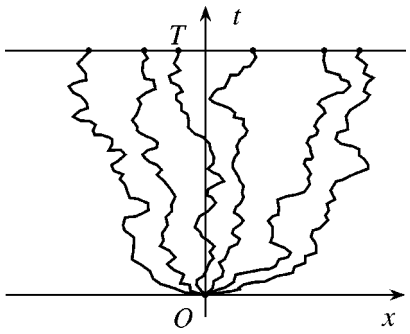

FIG. 1. Process $\mathbf{X}(t), t\in[0,T]$, with $\mathbf{X}(0)=\mathbf{0}$ showing star topology.

for $0\leqslant s<t\leqslant T, \mathbf{x},\mathbf{y}\in\mathbb{W}_N^{\mathrm{C}}$, where $f_T^{(\nu,\kappa)}(s,\mathbf{x};t,\mathbf{y})=\det_{1\leqslant i,j\leqslant N}[G_T^{(\nu,\kappa)}(s,x_i;t,y_j)]$ with (5) and $\mathcal{N}_T^{(\nu,\kappa)}(t,\mathbf{x})=\int_{\mathbb{W}_N^{\mathrm{C}}}d\mathbf{y}f_T^{(\nu,\kappa)}(t,\mathbf{x};T,\mathbf{y})$. Note that $f_T^{(\nu,\kappa)}(s,\mathbf{x};t,\mathbf{y})=f^{(\nu)}(t-s,\mathbf{y}|\mathbf{x})h_T^{(\nu,\kappa)}(t,\mathbf{y})/h_T^{(\nu,\kappa)}(s,\mathbf{x})$, where $h_T^{(\nu,\kappa)}(t,\mathbf{x})=\Pi_{i=1}^N h_T^{(\nu,\kappa)}(t,x_i)$. Since $\lim_{t\to 0}G^{(\nu)}(t,z|w)=\delta(z-w)\mathbf{1}(z\geqslant 0)$, $h_T^{(\nu,\kappa)}(T,\mathbf{x})=\Pi_{j=1}^N x_j^{-\kappa}$ for $\mathbf{x}\in\mathbb{W}_N^{\mathrm{C}}$, and then (35) can be written as

$$g_T^{(\nu,\kappa)}(s,\mathbf{x};t,\mathbf{y})=\frac{1}{\tilde{\mathcal{N}}^{(\nu,\kappa)}(T-s,\mathbf{x})}f^{(\nu)}(t-s,\mathbf{y}|\mathbf{x})\tilde{\mathcal{N}}^{(\nu,\kappa)}(T-t,\mathbf{y}) \tag{36}$$

with

$$\tilde{\mathcal{N}}^{(\nu,\kappa)}(t,\mathbf{x})=\int_{\mathbb{W}_N^{\mathrm{C}}}d\mathbf{y}f^{(\nu)}(t,\mathbf{y}|\mathbf{x})\prod_{i=1}^N y_i^{-\kappa}. \tag{37}$$

Lemma 5: Assume that $\nu>-1$ *and* $\kappa\in[0,2(\nu+1))$. *Let* $\mathbf{x},\mathbf{y}\in\mathbb{W}_N^{\mathrm{C}}$.

(i) *For* $0\leqslant s<t\leqslant T$, $\lim_{T\to\infty}g_T^{(\nu,\kappa)}(s,\mathbf{x};t,\mathbf{y})=p^{(\nu)}(s,\mathbf{x};t,\mathbf{y})$.

(ii) *For* $0<t<T$,

$$g_T^{(\nu,\kappa)}(0,\mathbf{0};t,\mathbf{y})\equiv\lim_{|\mathbf{x}|\to 0}g_T^{(\nu,\kappa)}(0,\mathbf{x};t,\mathbf{y})$$
$$=\frac{T^{N(N+\kappa-1)/2}t^{-N(N+\nu)}}{C_{\nu,\kappa}}\exp\left\{-\frac{|\mathbf{y}|^2}{2t}\right\}h^{(2\nu+1)}(\mathbf{y})\tilde{\mathcal{N}}^{(\nu,\kappa)}(T-t,\mathbf{y}). \tag{38}$$

(iii) *For* $T>0$, $\lim_{t\nearrow T}g_T^{(\nu,\kappa)}(0,\mathbf{0};t,\mathbf{y})=T^{-N(N+2\nu+1-\kappa)/2}/C_{\nu,\kappa}\exp\{-|\mathbf{y}|^2/2T\}h^{(2\nu+1-\kappa)}(\mathbf{y})$.

Proof: Using (33) for (37), we have the estimate of $\tilde{\mathcal{N}}^{(\nu,\kappa)}(t,\mathbf{x})$ in $|\mathbf{x}|/\sqrt{t}\to 0$ as

$$\tilde{\mathcal{N}}^{(\nu,\kappa)}(t,\mathbf{x})=\frac{t^{-N(N+2\nu+1)/2}}{C_\nu}\prod_{1\leqslant i<j\leqslant N}\left\{\left(\frac{x_j}{\sqrt{t}}\right)^2-\left(\frac{x_i}{\sqrt{t}}\right)^2\right\}$$
$$\times\int_{\mathbb{W}_N^{\mathrm{C}}}d\mathbf{y}\prod_{1\leqslant k\leqslant\ell\leqslant N}(y_\ell^2-y_k^2)\prod_{m=1}^N y_m^{2\nu+1-\kappa}\exp\left\{-\frac{|\mathbf{y}|^2}{2t}\right\}\times\left(1+\mathcal{O}\left(\frac{|\mathbf{x}|}{\sqrt{t}}\right)\right)$$
$$=\frac{t^{-N\kappa/2}C_{\nu,\kappa}}{C_\nu}\prod_{1\leqslant i<j\leqslant N}\left\{\left(\frac{x_j}{\sqrt{t}}\right)^2-\left(\frac{x_i}{\sqrt{t}}\right)^2\right\}\times\left(1+\mathcal{O}\left(\frac{|\mathbf{x}|}{\sqrt{t}}\right)\right), \tag{39}$$

where we have used a version of Selberg's integral formula[50,38]

$$\int_{\mathbb{R}^N} d\mathbf{u} \prod_{1\leqslant i<j\leqslant N} |u_j^2-u_i^2|^{2\gamma} \prod_{k=1}^{N} |u_k|^{2\alpha-1} e^{-|\mathbf{u}|^2/2} = 2^{\alpha N+\gamma N(N-1)} \prod_{i=1}^{N} \frac{\Gamma(1+i\gamma)\Gamma(\alpha+\gamma(i-1))}{\Gamma(1+\gamma)}$$

by setting $\alpha=\nu+1-\kappa/2$ and $\gamma=1/2$ (see Eq. (17.6.6) in Ref. 40). By (33) and (39), (i) and (ii) are obtained. Since $\lim_{t\to 0} G^{(\nu)}(t,y|x)=\delta(y-x)\mathbf{1}(y\geqslant 0)$, we have $\lim_{t\to 0} f^{(\nu)}(t,\mathbf{y}|\mathbf{x}) = \Pi_{i=1}^N \delta(y_i-x_i)$ for $\mathbf{x},\mathbf{y}\in\mathbb{W}_N^{\mathrm{C}}$. Then $\lim_{t\to 0}\tilde{\mathcal{N}}^{(\nu,\kappa)}(t,\mathbf{x})=\Pi_{i=1}^N x_i^{-\kappa}\mathbf{1}(\mathbf{x}\in\mathbb{W}_N^{\mathrm{C}})$ and (iii) is obtained. ■

Now we define the process $\mathbf{X}^{(\nu,\kappa)}(t)=(X_1^{(\nu,\kappa)}(t),X_2^{(\nu,\kappa)}(t),\ldots,X_N^{(\nu,\kappa)}(t)), t\in[0,T]$, as the temporally inhomogeneous diffusion process, whose transition probability density is given by (35) for $0\leqslant s<t\leqslant T,\mathbf{x},\mathbf{y}\in\mathbb{W}_N^{\mathrm{C}}$ and (38) for $0<t\leqslant T,\mathbf{y}\in\mathbb{W}_N^{\mathrm{C}}$. This process solves the stochastic differential equations

$$dX_i^{(\nu,\kappa)}(t)=dB_i(t)+\left[\frac{2\nu+1}{2X_i^{(\nu,\kappa)}(t)}+b_i^{(\nu,\kappa)}(T-t,\mathbf{X}^{(\nu,\kappa)}(t))\right]dt, \quad t\in[0,T],1\leqslant i\leqslant N,$$

where $b_i^{(\nu,\kappa)}(t,\mathbf{x})=(\partial/\partial x_i)\ln\tilde{\mathcal{N}}^{(\nu,\kappa)}(t,\mathbf{x})$, $1\leqslant i\leqslant N$.

Here we consider the special cases $(\nu,\kappa)=(1/2,1)$ and $(\nu,\kappa)=(-1/2,0)$. By the definitions (29) and (37), $\tilde{\mathcal{N}}^{(1/2,1)}(t,\mathbf{x})=\mathcal{N}^{\mathrm{C}}(t,x)/\Pi_{i=1}^N x_i$ and $\tilde{\mathcal{N}}^{(-1/2,0)}(t,\mathbf{x})=\mathcal{N}^{\mathrm{D}}(t,x)$, and then (36) gives

$$g_T^{(1/2,1)}(s,\mathbf{x};t,\mathbf{y})=\frac{1}{\mathcal{N}^{\mathrm{C}}(T-s,\mathbf{x})} f^{\mathrm{C}}(t-s,\mathbf{y}|\mathbf{x})\mathcal{N}^{\mathrm{C}}(T-t,\mathbf{y}),$$

$$g_T^{(-1/2,0)}(s,\mathbf{x};t,\mathbf{y})=\frac{1}{\mathcal{N}^{\mathrm{D}}(T-s,\mathbf{x})} f^{\mathrm{D}}(t-s,\mathbf{y}|\mathbf{x})\mathcal{N}^{\mathrm{D}}(T-t,\mathbf{y}),$$

for $0\leqslant s<t\leqslant T,\mathbf{x},\mathbf{y}\in\mathbb{W}_N^{\mathrm{C}}$. That is, we can interpret the process $\mathbf{X}^{(1/2,1)}(t)$ as the N-particle system of Brownian motions conditioned never to collide with each other nor with the wall at the origin in one-dimension during the time-interval $[0,T]$, and the process $\mathbf{X}^{(-1/2,0)}(t)$ as the N-particle system of reflecting Brownian motions conditioned never to collide with each other during the time-interval $[0,T]$, respectively. The asymptotic forms $\mathcal{N}^{\sharp}(t,\mathbf{x})=(C[\sharp']/C[\sharp])h^{\sharp}(\mathbf{x}/\sqrt{t})\times(1+\mathcal{O}(|\mathbf{x}|/\sqrt{t}))$ in $|\mathbf{x}|/\sqrt{t}\to 0$ for $\sharp=\mathrm{C}$ and D are obtained by (39), and thus we can see the power-laws of the noncolliding probabilities, $\mathcal{N}^{\sharp}(t,\mathbf{x})\sim t^{-\psi[\sharp]}$ as $t\to\infty$ for $\mathbf{x}\in\mathbb{W}_N^{\sharp}$, $\sharp=\mathrm{C}$ and D with the exponents $\psi[\mathrm{C}]=N^2/2,\psi[\mathrm{D}]=N(N-1)/2$. As a corollary of Lemma 5, we have the following:

Corollary 6:

(i) For $0<t<T$, *if* $\mathbf{x}\in\mathbb{W}_N^{\mathrm{C}}$,

$$g_T^{(1/2,1)}(0,\mathbf{0};t,\mathbf{x})=\frac{T^{\psi[\mathrm{C}]}t^{-d[\mathrm{C}]/2}}{C[\mathrm{C}']}\exp\left\{-\frac{|\mathbf{x}|^2}{2t}\right\}h^{\mathrm{C}}(\mathbf{x})\mathcal{N}^{\mathrm{C}}(T-t,\mathbf{x}),$$

$$g_T^{(-1/2,0)}(0,\mathbf{0};t,\mathbf{x})=\frac{T^{\psi[\mathrm{D}]}t^{-d[\mathrm{D}]/2}}{C[\mathrm{D}']}\exp\left\{-\frac{|\mathbf{x}|^2}{2t}\right\}h^{\mathrm{D}}(\mathbf{x})\mathcal{N}^{\mathrm{D}}(T-t,\mathbf{x}).$$

(ii) *For* $T>0$, *if* $\mathbf{x}\in\mathbb{W}_N^{\mathrm{C}}$,

$$\lim_{t\nearrow T} g_T^{(1/2,1)}(0,\mathbf{0};t,\mathbf{x})=q^{\mathrm{C}'}(\mathbf{x};T), \quad \lim_{t\nearrow T} g_T^{(-1/2,0)}(0,\mathbf{0};t,\mathbf{x})=q^{\mathrm{D}'}(\mathbf{x};T).$$

Figure 2 illustrates the processes $\mathbf{X}^{(1/2,1)}(t)$ and $\mathbf{X}^{(-1/2,0)}(t)$ both starting from $\mathbf{0}$. The path-configurations are in star topology. In the former any particle can not collide with the wall at the origin, while in the latter the leftmost particle is reflected at the wall. Another corollary of Lemma 5 is the following:

Corollary 7: If $\nu\in\mathbb{N},\mathbf{x}\in\mathbb{W}_N^{\mathrm{C}}$, $\lim_{t\nearrow T} g_T^{(\nu,\nu+1)}(0,\mathbf{0};t,\mathbf{x})=q_\nu^{\mathrm{chGOE}}(\mathbf{x};T)$.

The combination of Lemma 5 (i) with (31) and (32) of Lemma 4, Corollaries 6 and 7 implies that $\mathbf{X}^{(1/2,1)}(t)$, $\mathbf{X}^{(-1/2,0)}(t)$ and $\mathbf{X}^{(\nu,\nu+1)}(t)$ with $\nu\in\mathbb{N}$, all starting from $\mathbf{0}$, exhibit the transitions

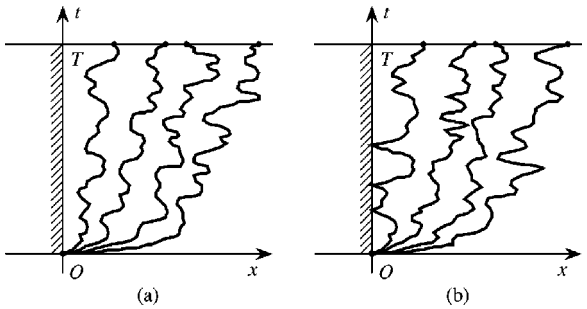

FIG. 2. (a) Process $\mathbf{X}^{(1/2,1)}(t), t \in [0,T]$ with the initial state $\mathbf{0}$ showing star topology. (b) Process $\mathbf{X}^{(-1/2,0)}(t), t \in [0,T]$ with the initial state $\mathbf{0}$ showing star topology.

from the eigenvalue statistics of the class C to the class CI, from the class D to the class associated with $q^{\mathrm{D}'}$ studied in Sec. III D, and from chGUE to chGOE, respectively, as time t goes on from 0 to T. (See Theorem 9 below.)

At the end of this subsection, we discuss the relation between the temporally homogeneous diffusion process $\mathbf{Y}^{(\nu)}(t)$ and the temporally inhomogeneous diffusion process $\mathbf{X}^{(\nu,\kappa)}(t)$ for $t \in [0,T]$. For a time sequence $t_0 \equiv 0 < t_1 < \cdots < t_{\ell-1} < t_\ell \equiv T < \infty$ with $\ell \in \{1,2,\ldots\}$, we consider the multitime probabilities with the initial state $\mathbf{Y}^{(\nu)}(0) = \mathbf{X}^{(\nu,\kappa)}(0) = \mathbf{x}^{(0)}$

$$P^{\mathbf{x}(0)}(\mathbf{Y}^{(\nu)}(t_1) \in d\mathbf{x}^{(1)}, \ldots, \mathbf{Y}^{(\nu)}(t_\ell) \in d\mathbf{x}^{(\ell)}) = \prod_{i=1}^{\ell} p^{(\nu)}(t_{i-1}, \mathbf{x}^{(i-1)}; t_i, \mathbf{x}^{(i)}) d\mathbf{x}^{(i)},$$

and

$$P^{\mathbf{x}(0)}(\mathbf{X}^{(\nu,\kappa)}(t_1) \in d\mathbf{x}^{(1)}, \ldots, \mathbf{X}^{(\nu,\kappa)}(t_\ell) \in d\mathbf{x}^{(\ell)}) = \prod_{i=1}^{\ell} g_T^{(\nu,\kappa)}(t_{i-1}, \mathbf{x}^{(i-1)}; t_i, \mathbf{x}^{(i)}) d\mathbf{x}^{(i)},$$

where we have used the Markov property of the processes. Assume that $\mathbf{x}^{(0)} = \mathbf{0}$ and $\mathbf{x}^{(i)} \in \mathbb{W}_N^{\mathrm{C}}$, $1 \leqslant i \leqslant \ell$. We use formulas (26) and (36) and apply Lemmas 4 and 5. Then we have the equality

$$\prod_{i=1}^{\ell} g_T^{(\nu,\kappa)}(t_{i-1}, \mathbf{x}^{(i-1)}; t_i, \mathbf{x}^{(i)}) = T^{N(N+\kappa-1)/2} \frac{C_\nu}{C_{\nu,\kappa}} \prod_{i=1}^{\ell} p^{(\nu)}(t_{i-1}, \mathbf{x}^{(i-1)}; t_i, \mathbf{x}^{(i)}) \frac{1}{h^{(\kappa)}(\mathbf{x}^{(\ell)})}.$$

Since this equality holds for arbitrary time sequence $t_0 = 0 < t_1 < \cdots < t_{\ell-1} < t_\ell = T < \infty$ with $\ell \in \{1,2,\ldots\}$, we can conclude the following:

Proposition 8: Assume that $\nu > -1, \kappa \in [0, 2(\nu+1))$. If $\mathbf{X}^{(\nu,\kappa)}(0) = \mathbf{Y}^{(\nu)}(0) = \mathbf{0}$, then the distribution of the process $\mathbf{X}^{(\nu,\kappa)}(t)$ is absolutely continuous with that of the process $\mathbf{Y}^{(\nu)}(t)$ for $t \in [0,T]$ and the Radon–Nikodým density is given by

$$\frac{P(\mathbf{X}^{(\nu,\kappa)}(\cdot) \in d\mathbf{w})}{P(\mathbf{Y}^{(\nu)}(\cdot) \in d\mathbf{w})} = \frac{C_\nu T^{N(N+\kappa-1)/2}}{C_{\nu,\kappa} h^{(\kappa)}(\mathbf{w}(T))}.$$

When $N = 1$ and $(\nu,\kappa) = (1/2,1)$, this proposition gives the Imhof relation between the Brownian meander and the three-dimensional Bessel process.[25] The relation stated by (4),[31,32] and the above proposition are regarded as the multivariate generalizations of the Imhof relation.

B. Brownian bridges and temporally inhomogeneous matrix-valued processes

Assume that $\nu \in \mathbb{N}, 0 < T < \infty$. Let $B_{ij}^{\rho}(t), \tilde{B}_{ij}^{\rho}(t), 1 \leqslant i \leqslant N+\nu, 1 \leqslant j \leqslant N, 0 \leqslant \rho \leqslant 3$ be independent one-dimensional standard Brownian motions. For a given matrix $m = (m_{ij}$

$+\sqrt{-1}\tilde{m}_{ij})_{1\leqslant i\leqslant N+\nu,1\leqslant j\leqslant N}$ with $m_{ij},\tilde{m}_{ij}\in\mathbb{R}$, let $(\beta_T^\rho)_{ij}(t:m_{ij}),(\tilde{\beta}_T^\rho)_{ij}(t:\tilde{m}_{ij}),1\leqslant i\leqslant N+\nu,1\leqslant j\leqslant N,0\leqslant\rho\leqslant 3$ be the diffusion processes, which are the solutions of the following stochastic differential equations:

$$(\beta_T^\rho)_{ij}(t:m_{ij})=B_{ij}^\rho(t)-\int_0^t\frac{(\beta_T^\rho)_{ij}(s:m_{ij})-m_{ij}}{T-s}ds,$$

$$(\tilde{\beta}_T^\rho)_{ij}(t:\tilde{m}_{ij})=\tilde{B}_{ij}^\rho(t)-\int_0^t\frac{(\tilde{\beta}_T^\rho)_{ij}(s:\tilde{m}_{ij})-\tilde{m}_{ij}}{T-s}ds,\quad t\in[0,T]. \tag{40}$$

The processes $(\beta_T^\rho)_{ij}(t:m_{ij})$ and $(\tilde{\beta}_T^\rho)_{ij}(t:\tilde{m}_{ij})$ are one-dimensional Brownian bridges of duration T both starting from 0 and ending at m_{ij} and $\tilde{m}_{ij}$, respectively.[55] Next for $z^\rho=(z_{ij}^\rho)_{1\leqslant i,j\leqslant N}\in\mathcal{S}(N)$ and $\tilde{z}^\rho=(\tilde{z}^\rho_{ij})_{1\leqslant i,j\leqslant N}\in\mathcal{A}(N)$, $0\leqslant\rho\leqslant 3$, we set

$$(s_T^\rho)_{ij}(t:z_{ij}^\rho)=\begin{cases}\dfrac{1}{\sqrt{2}}(\beta_T^\rho)_{ij}(t:\sqrt{2}z_{ij}^\rho), & \text{if } i<j,\\ (\beta_T^\rho)_{ii}(t:z_{ii}^\rho), & \text{if } i=j,\end{cases}$$

and

$$(a_T^\rho)_{ij}(t:\tilde{z}^\rho_{ij})=\begin{cases}\dfrac{1}{\sqrt{2}}(\tilde{\beta}_T^\rho)_{ij}(t:\sqrt{2}\tilde{z}^\rho_{ij}), & \text{if } i<j,\\ 0, & \text{if } i=j,\end{cases} \tag{41}$$

with $(s_T^\rho)_{ij}(t:z_{ij}^\rho)=(s_T^\rho)_{ji}(t:z_{ji}^\rho)$ and $(a_T^\rho)_{ij}(t:\tilde{z}^\rho_{ij})=-(a_T^\rho)_{ji}(t:\tilde{z}^\rho_{ji})$ for $i>j$, where $1\leqslant i,j\leqslant N$, $0\leqslant\rho\leqslant 3$ and $t\in[0,T]$. We define the matrix-valued processes $s_T^\rho(t:z^\rho)=((s_T^\rho)_{ij}(t:z_{ij}^\rho))_{1\leqslant i,j\leqslant N}\in\mathcal{S}(N)$ and $a_T^\rho(t:\tilde{z}^\rho)=((a_T^\rho)_{ij}(t:\tilde{z}^\rho_{ij}))_{1\leqslant i,j\leqslant N}\in\mathcal{A}(N)$.

In an earlier paper,[33] we considered the $N\times N$ Hermitian matrix-valued process $\Xi_T(t)=s^0(t)+\sqrt{-1}a_T^0(t:O),t\in[0,T]$, where O denotes the $N\times N$ zero matrix and $s^0(t)$ was defined below (17). This process is the temporally inhomogeneous matrix-valued process realized as an interpolation in duration T of the first and second processes given in Sec. II B. Using the invariance in distribution of the process $\Xi_T(t)$ under unitary transformations and our generalized version of the Imhof relation (4), we proved the equivalence in distribution of its eigenvalue process and $\mathbf{X}(t)$ with $\mathbf{X}(0)=\mathbf{0}$. As a corollary of this equivalence, we derived the formula for any $\sigma\in\mathbb{R}$,

$$\int_{\mathrm{U}(N)}dU\exp\left\{-\frac{1}{2\sigma^2}\mathrm{Tr}(\Lambda_{\mathbf{x}}-U^\dagger\Lambda_{\mathbf{y}}U)^2\right\}=\frac{C[\mathrm{A}]\sigma^{d[\mathrm{A}]}}{h^{\mathrm{A}}(\mathbf{x})h^{\mathrm{A}}(\mathbf{y})}\det_{1\leqslant i,j\leqslant N}[G^{\mathrm{A}}(t,y_j|x_i)], \tag{42}$$

where dU denotes the Haar measure of $\mathrm{U}(N)$ normalized as $\int_{\mathrm{U}(N)}dU=1$, $\Lambda_{\mathbf{x}}=\mathrm{diag}\{x_1,...,x_N\}$ and $\Lambda_{\mathbf{y}}=\mathrm{diag}\{y_1,...,y_N\}$ with $\mathbf{x},\mathbf{y}\in\mathbb{W}_N^{\mathrm{A}}$. This is a stochastic-calculus derivation of the Harish–Chandra (Itzykson–Zuber) integral formula.[22,26] In this subsection, we give extensions of this argument.

As an interpolation of the Laguerre process (7) and the Wishart process (9), we define the matrix-valued process

$$\Xi_T^{\mathrm{LW}}(t)=M_T(t)^\dagger M_T(t),\quad t\in[0,T],$$

where $M_T(t)=(B_{ij}^0(t)+\sqrt{-1}(\tilde{\beta}_T^0)_{ij}(t:O))_{1\leqslant i\leqslant N+\nu,1\leqslant j\leqslant N}\in\mathcal{M}(N+\nu,N;\mathbb{C}),t\in[0,T]$, where O denotes the $(N+\nu)\times N$ zero matrix. Similarly, the interpolations between the processes (21) and (22) are defined by

$$\Xi_T^{\mathrm{C}}(t)=\sqrt{-1}a_T^0(t{:}O)\otimes\sigma_0+s^1(t)\otimes\sigma_1+s_T^2(t{:}O)\otimes\sigma_2+s^3(t)\otimes\sigma_3,$$

$$\Xi_T^{\mathrm{D}}(t)=\sqrt{-1}a_T^0(t{:}O)\otimes\sigma_0+\sqrt{-1}a_T^1(t{:}O)\otimes\sigma_1+\sqrt{-1}a^2(t)\otimes\sigma_2+s^3(t)\otimes\sigma_3,$$

in which O denotes the $N\times N$ zero matrix. Let $\boldsymbol{\kappa}^{\mathrm{LW}}(t)=(\kappa_1^{\mathrm{LW}}(t),\ldots,\kappa_N^{\mathrm{LW}}(t)),t\in[0,T]$ be the square roots of the eigenvalues of $\Xi_T^{\mathrm{LW}}(t)$ with $0\leqslant\kappa_1^{\mathrm{LW}}(t)\leqslant\cdots\leqslant\kappa_N^{\mathrm{LW}}(t)$ and $\boldsymbol{\lambda}^{\sharp}(t)=(\lambda_1^{\sharp}(t),\lambda_2^{\sharp}(t),\ldots,\lambda_N^{\sharp}(t))$ be the non-negative eigenvalues of $\Xi_T^{\sharp}(t)$ with $0\leqslant\lambda_1^{\sharp}(t)\leqslant\cdots\leqslant\lambda_N^{\sharp}(t)$ for $\sharp=\mathrm{C}$ and D. We prove the following equivalence in distribution among the temporally inhomogeneous diffusion processes:

Theorem 9:

(i) *If* $\nu\in\mathbb{N}$ *and* $\mathbf{X}^{(\nu,\nu+1)}(0)=\mathbf{0}$, *then* $\boldsymbol{\kappa}^{\mathrm{LW}}(t)=\mathbf{X}^{(\nu,\nu+1)}(t)$, $t\in[0,T]$ *in distribution.*

(ii) *If* $\mathbf{X}^{(1/2,1)}(0)=\mathbf{X}^{(-1/2,0)}(0)=\mathbf{0}$, *then* $\boldsymbol{\lambda}^{\mathrm{C}}(t)=\mathbf{X}^{(1/2,1)}(t)$ *and* $\boldsymbol{\lambda}^{\mathrm{D}}(t)=\mathbf{X}^{(-1/2,0)}(t)$, $t\in[0,T]$ *in distribution.*

Proof: (i) For a given matrix $m=(m_{ij}+\sqrt{-1}\tilde{m}_{ij})_{1\leqslant i\leqslant N+\nu,1\leqslant j\leqslant N}$, $m_{ij},\tilde{m}_{ij}\in\mathbb{R}$, we consider $\mathcal{M}(N+\nu,N;\mathbb{C})$-valued process $M_T(t{:}m)=((\beta_T^0)_{ij}(t{:}m_{ij})+\sqrt{-1}(\tilde{\beta}_T^0)_{ij}(t{:}\tilde{m}_{ij}))_{1\leqslant i\leqslant N+\nu,1\leqslant j\leqslant N}$, $t\in[0,T]$. From Eqs. (40), we have the equation

$$M_T(t{:}m)=M(t)-\int_0^t\frac{M_T(s{:}m)-m}{T-s}ds,\quad t\in[0,T],\tag{43}$$

where $M(t)=(B_{ij}^0(t)+\sqrt{-1}\tilde{B}_{ij}^0(t))_{1\leqslant i\leqslant N+\nu,1\leqslant j\leqslant N}$. Let m_U and m_O be random matrices with distribution $\mu_\nu^{\mathrm{chGUE}}(\,\cdot\,;T)$ and $\mu_\nu^{\mathrm{chGOE}}(\,\cdot\,;T)$, respectively. Since $(\beta_T^0)_{ij}(t{:}\zeta)$ and $(\tilde{\beta}_T^0)_{ij}(t{:}\zeta)$, $t\in[0,T]$ are Brownian motions when ζ is a Gaussian random variable with variance T independent of $B_{ij}^0(t)$ and $\tilde{B}_{ij}^0(t)$, if m_U and m_O are independent of $M(t),t\in[0,T]$,

$$M_T(t{:}m_U)=M(t),\quad M_T(t{:}m_O)=M_T(t),\quad t\in[0,T]\tag{44}$$

in distribution. Moreover, since the distribution of the process $M(t)$ is invariant under any transformation $M(t)\to U^\dagger M(t)V$, $U\in\mathrm{U}(N+\nu)$, $V\in\mathrm{U}(N)$, the following lemma is obtained by Eq. (43).

Lemma 10: For any $U\in\mathrm{U}(N+\nu)$, $V\in\mathrm{U}(N)$, $U^\dagger M_T(t{:}m)V=M_T(t{:}U^\dagger mV)$, $t\in[0,T]$ *in distribution.*

By this lemma, if m and m' in $\mathcal{M}(N+\nu,N;\mathbb{C})$ have the same radial coordinates, the processes of radial coordinates of $M_T(t{:}m)$ and $M_T(t{:}m'),t\in[0,T]$, are identical in distribution. Let $\Xi_T^{\mathrm{LW}}(t{:}m)=M_T^\dagger(t{:}m)M_T(t{:}m)$. Then the above gives the identification in distribution of the processes of square roots of eigenvalues of $\Xi_T^{\mathrm{LW}}(t{:}m)$ and $\Xi_T^{\mathrm{LW}}(t{:}m'),t\in[0,T]$. Now we denote by $P_T^{\boldsymbol{\kappa}}(\,\cdot\,)$ the probability distribution of the process of square roots of eigenvalues of $\Xi_T^{\mathrm{LW}}(t{:}m)$ conditioned that the square roots of eigenvalues of m is $\boldsymbol{\kappa}=(\kappa_1,\ldots,\kappa_N)$ with condition (11). We also denote by $P(\,\cdot\,)$ and $P_T(\,\cdot\,)$ the distributions of the processes of square roots of eigenvalues of $\Xi(t)=M(t)^\dagger M(t)$ and $\Xi_T(t)=M_T^\dagger(t)M_T(t),t\in[0,T]$, respectively. The equalities (44) give

$$P(\,\cdot\,)=\int_{\mathbb{W}_N^{\mathrm{C}}}d\boldsymbol{\kappa}\,P_T^{\boldsymbol{\kappa}}(\,\cdot\,)q_\nu^{\mathrm{chGUE}}(\boldsymbol{\kappa};T),\quad P_T(\,\cdot\,)=\int_{\mathbb{W}_N^{\mathrm{C}}}d\boldsymbol{\kappa}\,P_T^{\boldsymbol{\kappa}}(\,\cdot\,)q_\nu^{\mathrm{chGOE}}(\boldsymbol{\kappa};T).$$

Then $P_T(\,\cdot\,)$ and $P(\,\cdot\,)$ satisfy the same relation as the generalized Imhof relation between $\mathbf{X}^{(\nu,\nu+1)}(t)$ and $\mathbf{Y}^{(\nu)}(t)$ obtained from Proposition 8 by setting $\nu\in\mathbb{N}$, $\kappa=\nu+1$. Since $P(\,\cdot\,)$ is equal to the distribution of the temporally homogeneous diffusion process $\mathbf{Y}^{(\nu)}(t)$ (see (31) of Lemma 4), we can conclude that $P_T(\,\cdot\,)$ is identical to the distribution of the process $\mathbf{X}^{(\nu,\nu+1)}(t)$.

The second part can be proved by the same argument as the first part. For given $y^\rho, z^\rho \in \mathcal{S}(N), \tilde{y}^\rho, \tilde{z}^\rho \in \mathcal{A}(N), 0 \leqslant \rho \leqslant 3$, put $Y = \sqrt{-1}\tilde{y}^0 \otimes \sigma_0 + y^1 \otimes \sigma_1 + y^2 \otimes \sigma_2 + y^3 \otimes \sigma_3 \in \mathcal{H}_{2-}(2N)$ and $Z = \sqrt{-1}\tilde{z}^0 \otimes \sigma_0 + \sqrt{-1}\tilde{z}^1 \otimes \sigma_1 + \sqrt{-1}\tilde{z}^2 \otimes \sigma_2 + z^3 \otimes \sigma_3 \in \mathcal{H}_{1-}(2N)$. For these Y and Z, we introduce the temporally inhomogeneous matrix-valued processes

$$\Xi_T^{\mathrm{C}}(t:Y) = \sqrt{-1}a_T^0(t:\tilde{y}^0) \otimes \sigma_0 + s_T^1(t:y^1) \otimes \sigma_1 + s_T^2(t:y^2) \otimes \sigma_2 + s_T^3(t:y^3) \otimes \sigma_3,$$

$$\Xi_T^{\mathrm{D}}(t:Z) = \sqrt{-1}a_T^0(t:\tilde{z}^0) \otimes \sigma_0 + \sqrt{-1}a_T^1(t:\tilde{z}^1) \otimes \sigma_1 + \sqrt{-1}a_T^2(t:\tilde{z}^2) \otimes \sigma_2 + s_T^3(t:z^3) \otimes \sigma_3.$$

The key lemma 10 of the proof is replaced by the following:

Lemma 11: For any $U \in \mathrm{U}_2(2N), V \in \mathrm{U}_1(2N)$, $U^\dagger \Xi_T^{\mathrm{C}}(t:Y)U = \Xi_T^{\mathrm{C}}(t:U^\dagger Y U)$, *and* $V^\dagger \Xi_T^{\mathrm{D}}(t:Z)V = \Xi_T^{\mathrm{D}}(t:V^\dagger Z V)$, $t \in [0,T]$ *in distribution.*

For $\sharp = \mathrm{C}$ and D we denote by $P_T^{\sharp,\boldsymbol{\omega}}(\cdot)$ the probability distributions of the processes of nonnegative eigenvalues of $\Xi_T^\sharp(t:Z)$ conditioned that the nonnegative eigenvalues of Z is $\boldsymbol{\omega} = (\omega_1, \ldots, \omega_N)$ with (18). We also denote by $P^\sharp(\cdot)$ and $P_T^\sharp(\cdot)$ the distributions of the processes of nonnegative eigenvalues of $\Xi^\sharp(t)$ and $\Xi_T^\sharp(t), t \in [0,T]$, respectively. Then we have the expressions

$$P^\sharp(\cdot) = \int_{\mathbb{W}_N^{\mathrm{C}}} d\boldsymbol{\omega}\, P_T^{\sharp,\boldsymbol{\omega}}(\cdot) q^\sharp(\boldsymbol{\omega};T), \quad P_T^\sharp(\cdot) = \int_{\mathbb{W}_N^{\mathrm{C}}} d\boldsymbol{\omega}\, P_T^{\sharp,\boldsymbol{\omega}}(\cdot) q^{\sharp\prime}(\boldsymbol{\omega};T) \quad \text{for} \quad \sharp = \mathrm{C}, \mathrm{D}.$$

Comparing them with the $(\nu,\kappa) = (1/2,1)$ and $(\nu,\kappa) = (-1/2,0)$ cases of the generalized Imhof relations obtained from Proposition 8, we have the theorem. ■

As a corollary of Theorem 9, the following integral formulas are derived as proved in Appendix B.

Corollary 12:

(i) *Assume* $\nu \in \mathbb{N}$ *and* $\mathbf{x}, \mathbf{y} \in \mathbb{W}_N^{\mathrm{C}}$. *For any* $\sigma \in \mathbb{R}$,

$$\int_{\mathrm{U}(N+\nu)\times\mathrm{U}(N)} d\mu(U,V) \exp\left\{ -\frac{1}{2\sigma^2} \mathrm{Tr}(K_{\mathbf{x}} - U^\dagger K_{\mathbf{y}} V)^\dagger (K_{\mathbf{x}} - U^\dagger K_{\mathbf{y}} V) \right\}$$
$$= \frac{C_\nu \sigma^{N(N+\nu-2)}}{h^{(\nu)}(\mathbf{x}) h^{(\nu)}(\mathbf{y})} \det_{1 \leqslant i,j \leqslant N} \left[e^{-(x_i^2+y_j^2)/2\sigma^2} I_\nu\left(\frac{x_i y_j}{\sigma^2} \right) \right],$$

where

$$K_{\mathbf{x}} = \begin{pmatrix} \hat{K}_{\mathbf{x}} \\ O \end{pmatrix}, \quad K_{\mathbf{y}} = \begin{pmatrix} \hat{K}_{\mathbf{y}} \\ O \end{pmatrix},$$

with $\hat{K}_{\mathbf{x}} = \mathrm{diag}\{x_1, x_2, \ldots, x_N\}, \hat{K}_{\mathbf{y}} = \mathrm{diag}\{y_1, y_2, \ldots, y_N\}$ *and* $\nu \times N$ *zero matrix* O.

(ii) *Let* $\sharp = \mathrm{C}, \mathrm{D}$. *For* $\mathbf{x}, \mathbf{y} \in \mathbb{W}_N^{\mathrm{C}}$, $\sigma \in \mathbb{R}$,

$$\int_{\tilde{\mathrm{U}}(2N)} dU \exp\left\{ -\frac{1}{4\sigma^2} \mathrm{Tr}(\Lambda_{\mathbf{x}} - U^\dagger \Lambda_{\mathbf{y}} U)^2 \right\} = \frac{C[\sharp] \sigma^{d[\sharp]}}{h^\sharp(\mathbf{x}) h^\sharp(\mathbf{y})} \det_{1 \leqslant i,j \leqslant N} [G^\sharp(\sigma^2, y_j | x_i)],$$

where $\Lambda_{\mathbf{x}} = \mathrm{diag}\{x_1, x_2, \ldots, x_N\} \otimes \sigma_3$, $\Lambda_{\mathbf{y}} = \mathrm{diag}\{y_1, y_2, \ldots, y_N\} \otimes \sigma_3$, $\tilde{\mathrm{U}}(2N) = \mathrm{U}_2(2N)$ *for* $\sharp = \mathrm{C}$ *and* $\tilde{\mathrm{U}}(2N) = \mathrm{U}_1(2N)$ *for* $\sharp = \mathrm{D}$.

They are extensions of the Harish–Chandra (Itzykson–Zuber) formula (42). The formula (i) is found in Ref. 27.

C. Watermelon topology

Consider the N-particle system of Brownian motions starting from $\mathbf{x} \in \mathbb{W}_N^{\mathrm{A}}$ at time $t = 0$ and arriving at $\mathbf{z} \in \mathbb{W}_N^{\mathrm{A}}$ at time $T > 0$, which do not collide with each other during the time interval $[0,T]$. We denote by $g^{\mathrm{A,w}}(0,\mathbf{x};t,\mathbf{y};T,\mathbf{z})$ the probability density of the state $\mathbf{y}$ at time $t \in [0,T]$. It is given by

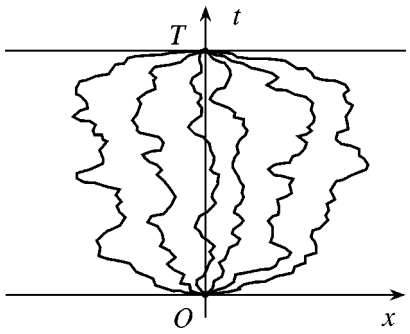

FIG. 3. Process $\mathbf{X}^{\mathrm{A,w}}(t), t\in[0,T]$, showing watermelon topology.

$$g^{\mathrm{A,\,w}}(0,\mathbf{x};t,\mathbf{y};T,\mathbf{z})=\frac{f^{\mathrm{A}}(t,\mathbf{y}|\mathbf{x})f^{\mathrm{A}}(T-t,\mathbf{z}|\mathbf{y})}{f^{\mathrm{A}}(T,\mathbf{z}|\mathbf{x})},\quad \mathbf{y}\in\mathbb{W}_N^{\mathrm{A}}, t\in[0,T]. \tag{45}$$

By using (34), we can obtain the limit $g^{\mathrm{A,\,w}}(0,\mathbf{0};t,\mathbf{y};T,\mathbf{0})=\lim_{|\mathbf{x}|\to 0,|\mathbf{z}|\to 0} g^{\mathrm{A,\,w}}(0,\mathbf{x};t,\mathbf{y};T,\mathbf{z})$. Let $\sigma_T(t)=\sqrt{t(1-t/T)}$.

Proposition 13: For $\mathbf{y}\in\mathbb{W}_N^{\mathrm{A}}$, $g^{\mathrm{A,\,w}}(0,\mathbf{0};t,\mathbf{y};T,\mathbf{0})=q^{\mathrm{GUE}}(\mathbf{y};\sigma_T(t)^2), t\in[0,T]$.

We denote by $\mathbf{X}^{\mathrm{A,\,w}}(t), t\in[0,T]$, the temporally inhomogeneous diffusion process, whose probability density is given by the above. Its path-configuration on the spatio-temporal plane is illustrated by Fig 3. Such a pattern is called *watermelon topology* in the polymer network theory.[14]

For $\nu>-1$, similar to (45) we put

$$g^{(\nu),\mathrm{w}}(0,\mathbf{x};t,\mathbf{y};T,\mathbf{z})=\frac{f^{(\nu)}(t,\mathbf{y}|\mathbf{x})f^{(\nu)}(T-t,\mathbf{z}|\mathbf{y})}{f^{(\nu)}(T,\mathbf{z}|\mathbf{x})}$$

for $\mathbf{x},\mathbf{y},\mathbf{z}\in\mathbb{W}_N^{\mathrm{C}}, t\in[0,T]$. By (33) we have the following $\mathbf{x}\to\mathbf{0}$ limit:

Proposition 14: For $\nu>-1, \mathbf{x}\in\mathbb{W}_N^{\mathrm{C}}, t\in[0,T]$,

$$g^{(\nu),\mathrm{w}}(0,\mathbf{0};t,\mathbf{x};T,\mathbf{0})=\frac{\sigma_T(t)^{-2N(N+\nu)}}{C_\nu}h^{((2\nu+1)/2)}(\mathbf{x})^2\exp\left\{-\frac{|\mathbf{x}|^2}{2\sigma_T(t)^2}\right\}.$$

In particular, if $\nu\in\mathbb{N}$, $g^{(\nu),\mathrm{w}}(0,\mathbf{0};t,\mathbf{x};T,\mathbf{0})=q_\nu^{\mathrm{chGUE}}(\mathbf{x},\sigma_T(t)^2)$, $g^{(1/2),\mathrm{w}}(0,\mathbf{0};t,\mathbf{x};T,\mathbf{0})=q^{\mathrm{C}}(\mathbf{x},\sigma_T(t)^2)$, *and* $g^{(-1/2),\mathrm{w}}(0,\mathbf{0};t,\mathbf{x};T,\mathbf{0})=q^{\mathrm{D}}(\mathbf{x},\sigma_T(t)^2)$.

We note that this expression may be formally obtained by taking $\kappa\to 2(\nu+1)$ limit of (38).

D. Banana topology

For $\varepsilon>0$, we consider a subspace of $\mathbb{W}_{2N}^{\mathrm{A}}$, $\mathbb{B}_{2N}^{\mathrm{A}}(\varepsilon)=\{\mathbf{x}=(x_1,x_2,\ldots,x_{2N})\in\mathbb{W}_{2N}^{\mathrm{A}}: x_{2i}=x_{2i-1}+\varepsilon, 1\leqslant i\leqslant N\}$. For $\mathbf{x}\in\mathbb{W}_{2N}^{\mathrm{A}}$, we will use the notation $\mathbf{x}^{\mathrm{odd}}=(x_1,x_3,\ldots,x_{2N-1})$ and define $\mathcal{N}^{\mathrm{A,\,b}}(t,\mathbf{x};\varepsilon)=\int_{\mathbb{B}_{2N}^{\mathrm{A}}(\varepsilon)}d\mathbf{y}^{\mathrm{odd}}f^{\mathrm{A}}(t,\mathbf{y}|\mathbf{x})$. We consider the process, whose transition probability density is given by

$$g_T^{\mathrm{A,\,b}}(s,\mathbf{x};t,\mathbf{y};\varepsilon)=\frac{f^{\mathrm{A}}(t-s,\mathbf{y}|\mathbf{x})\mathcal{N}^{\mathrm{A,\,b}}(T-t,\mathbf{y};\varepsilon)}{\mathcal{N}^{\mathrm{A,\,b}}(T-s,\mathbf{x};\varepsilon)},\quad \mathbf{x},\mathbf{y}\in\mathbb{W}_{2N}^{\mathrm{A}}, 0\leqslant s<t\leqslant T.$$

This is the $2N$-particle system of noncolliding Brownian motions in $[0,T]$ conditioned that the final state at time $t=T$ is in $\mathbb{B}_{2N}^{\mathrm{A}}(\varepsilon)$. Using (34), we have

$$g_T^{\mathrm{A,\,b}}(0,\mathbf{0};t,\mathbf{y};\varepsilon)\equiv\lim_{|\mathbf{x}|\to 0}g_T^{\mathrm{A,\,b}}(0,\mathbf{x};t,\mathbf{y};\varepsilon)=\left(\frac{t}{T}\right)^{-2N^2}\frac{h^{\mathrm{A}}(\mathbf{y})e^{-|\mathbf{y}|^2/2t}\mathcal{N}^{\mathrm{A,\,b}}(T-t,\mathbf{y};\varepsilon)}{\int_{\mathbb{B}_{2N}^{\mathrm{A}}(\varepsilon)}d\mathbf{z}^{\mathrm{odd}}\,h^{\mathrm{A}}(\mathbf{z})e^{-|\mathbf{z}|^2/2T}}$$

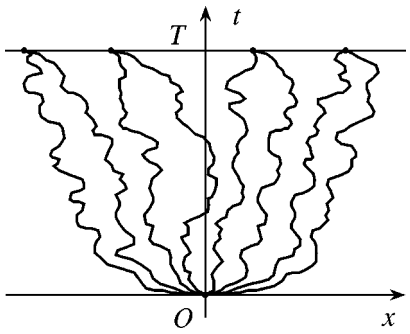

FIG. 4. Process $\mathbf{X}^{\mathrm{A},\mathrm{b}}(t), t\in[0,T]$, showing banana topology.

for $\mathbf{y}\in\mathbb{W}_{2N}^{\mathrm{A}}, t\in(0,T]$. Since $\lim_{t\to 0} f^{\mathrm{A}}(0,\mathbf{y}|\mathbf{x})=\Pi_{i=1}^{N}\delta(x_i-y_i)$, $\lim_{t\to 0}\mathcal{N}^{\mathrm{A},\mathrm{b}}(t,\mathbf{x};\varepsilon)=\mathbf{1}(\mathbf{x}\in\mathbb{B}_{2N}^{\mathrm{A}}(\varepsilon))$, and then for $\mathbf{y}\in\mathbb{W}_{2N}^{\mathrm{A}}$,

$$\lim_{t\nearrow T} g_T^{\mathrm{A},\mathrm{b}}(0,\mathbf{0};t,\mathbf{y};\varepsilon)=\frac{h^{\mathrm{A}}(\mathbf{y})e^{-|\mathbf{y}|^2/2T}}{\int_{\mathbb{B}_{2N}^{\mathrm{A}}(\varepsilon)}d\mathbf{z}^{\mathrm{odd}}\,h^{\mathrm{A}}(\mathbf{z})e^{-|\mathbf{z}|^2/2T}}\mathbf{1}(\mathbf{y}\in\mathbb{B}_{2N}^{\mathrm{A}}(\varepsilon)).$$

As implied in Ref. 41 we can take the limit, $g_T^{\mathrm{A},\mathrm{b}}(s,\mathbf{x};t,\mathbf{y})=\lim_{\varepsilon\to 0} g_T^{\mathrm{A},\mathrm{b}}(s,\mathbf{x};t,\mathbf{y};\varepsilon)$, in the above formulas to have

$$g_T^{\mathrm{A},\mathrm{b}}(s,\mathbf{x};t,\mathbf{y})=\frac{f^{\mathrm{A}}(t-s,\mathbf{y}|\mathbf{x})\mathcal{N}^{\mathrm{A},\mathrm{b}}(T-t,\mathbf{y})}{\mathcal{N}^{\mathrm{A},\mathrm{b}}(T-s,\mathbf{x})}, \tag{46}$$

$$g_T^{\mathrm{A},\mathrm{b}}(0,\mathbf{0};t,\mathbf{y})=\left(\frac{T}{2}\right)^{N(2N+1)/2}\left(\frac{t}{2}\right)^{-2N^2}\frac{h^{\mathrm{A}}(\mathbf{y})}{C[\mathrm{A}'']}e^{-|\mathbf{y}|^2/2t}\mathcal{N}^{\mathrm{A},\mathrm{b}}(T-t,\mathbf{y}), \tag{47}$$

$$g_T^{\mathrm{A},\mathrm{b}}(0,\mathbf{0};T,\mathbf{y})=q^{\mathrm{GSE}}\left(\mathbf{y}^{\mathrm{odd}};\frac{T}{2}\right)\mathbf{1}(\mathbf{y}\in\mathbb{B}_{2N}^{\mathrm{A}}), \tag{48}$$

for $\mathbf{x},\mathbf{y}\in\mathbb{W}_{2N}^{\mathrm{A}}, 0\leqslant s<t<T$, where $\mathcal{N}^{\mathrm{A},\mathrm{b}}(t,\mathbf{x})=\int_{\mathbb{W}_N^{\mathrm{A}}}d\mathbf{y}\,f^{\mathrm{A},\mathrm{b}}(t,\mathbf{y}|\mathbf{x})$ with

$$f^{\mathrm{A},\mathrm{b}}(t,\mathbf{y}|\mathbf{x})=\det_{1\leqslant i\leqslant 2N,1\leqslant j\leqslant N}\left[G^{\mathrm{A}}(t,y_j|x_i)\ \ \frac{x_i}{t}G^{\mathrm{A}}(t,y_j|x_i)\right]$$

for $\mathbf{x}\in\mathbb{W}_{2N}^{\mathrm{A}}$ and $\mathbf{y}\in\mathbb{W}_N^{\mathrm{A}}$, and $\mathbb{B}_{2N}^{\mathrm{A}}=\{\mathbf{x}=(x_1,x_2,\ldots,x_{2N}):\mathbf{x}^{\mathrm{odd}}\in\mathbb{W}_N^{\mathrm{A}}, x_{2i}=x_{2i-1}, 1\leqslant i\leqslant N\}$. We define the temporally inhomogeneous process $\mathbf{X}^{\mathrm{A},\mathrm{b}}(t), t\in[0,T]$ starting from $\mathbf{0}$ or the state in $\mathbb{W}_{2N}^{\mathrm{A}}$ and ending at the state in $\mathbb{B}_{2N}$ as the diffusion process, whose transition probability density is given by (46)–(48). The path-configuration of N particles in this version of noncolliding Brownian motions on the spatio-temporal plane is illustrated by Fig. 4, which we would like to call "banana topology." An important point is that at the final time $t=T$ the particle positions are pairwise degenerated and distinct positions are identical in distribution with the Kramers doublets of eigenvalues of random matrices in GSE as claimed by (48).

Now we consider a $2N\times 2N$ Hermitian matrix-valued temporally inhomogeneous process defined by

$$\begin{aligned}\Xi_T^{\mathrm{b}}(t)=&\{s^0(t)+\sqrt{-1}a_T^0(t:O)\}\otimes\sigma_0+\{s_T^1(t:O)+\sqrt{-1}a^1(t)\}\otimes\sigma_1\\&+\{s_T^2(t:O)+\sqrt{-1}a^2(t)\}\otimes\sigma_2+\{s_T^3(t:O)+\sqrt{-1}a^3(t)\}\otimes\sigma_3,\end{aligned} \tag{49}$$

where the elements of the $N\times N$ matrices $\{s_T^\rho(t:z^\rho),(a_T^\rho:\tilde{z}^\rho)\}_{\rho=1}^3$ are given by (41). By definition, $\Xi_T^{\mathrm{b}}(T)$ distributes with the probability density of GSE. Then the same argument as Theorem 9 may prove the following:

Theorem 15: *Let* $\boldsymbol{\lambda}(t)=(\lambda_1(t),\lambda_2(t),\ldots,\lambda_{2N}(t))$ *be the eigenvalues of the process (49) with* $\lambda_1(t)\leqslant\lambda_2(t)\leqslant\cdots\leqslant\lambda_{2N}(t)$. *If* $\mathbf{X}^{\mathrm{A},\mathrm{b}}(0)=\mathbf{0}$, *then* $\boldsymbol{\lambda}(t)=\mathbf{X}^{\mathrm{A},\mathrm{b}}(t)$, $t\in[0,T]$ *in distribution*

As a corollary of this theorem, we will have the following version of Harish–Chandra formula, which is found as Eq. (3.46) in Ref. 41.

Corollary 16: Let $\mathbf{x}=(x_1,x_2,\ldots,x_{2N})\in\mathbb{W}_{2N}^{\mathrm{A}}$, $\mathbf{y}=(y_1,y_2,\ldots,y_N)\in\mathbb{W}_N^{\mathrm{A}}$. *For any* $\sigma\in\mathbb{R}$

$$\int_{U(2N)}dU\exp\left\{-\frac{1}{2\sigma^2}\mathrm{Tr}(\Lambda_{\mathbf{x}}-U^\dagger\Lambda_y U)^2\right\}=\frac{C_{2N}[\mathrm{A}]\sigma^{(2N)^2}}{h^{\mathrm{A}}(\mathbf{x})h^{\mathrm{A}}(\mathbf{y})^4}f^{\mathrm{A},\mathrm{b}}(\sigma^2,\mathbf{y}|\mathbf{x}),$$

where $\Lambda_{\mathbf{x}}=\mathrm{diag}\{x_1,x_2,\ldots,x_{2N}\}$, $\Lambda_{\mathbf{y}}=\mathrm{diag}\{y_1,y_2,\ldots,y_N\}\otimes\sigma_0$, *and* $C_{2N}[\mathrm{A}]=(2\pi)^N\Pi_{i=1}^{2N}\Gamma(i)$.

It is easy to see by the same argument that the transition probability density given below defines the temporally inhomogeneous diffusion process $\mathbf{X}^{(\nu,\kappa),\mathrm{b}}(t),t\in[0,T],\nu>-1,\kappa\in[0,2(\nu+1))$, associated with $\mathbf{X}^{(\nu,\kappa)}$, which shows the banana topology: Let

$$f^{(\nu),\mathrm{b}}(t,\mathbf{y}|\mathbf{x})=\det_{1\leqslant i\leqslant 2N,1\leqslant j\leqslant N}[G^{(\nu)}(t,y_j|x_i)\quad G_y^{(\nu)}(t,y_j|x_i)]$$

for $\mathbf{x}\in\mathbb{W}_{2N}^{\mathrm{C}},\mathbf{y}\in\mathbb{W}_N^{\mathrm{C}}$, where $G_y^{(\nu)}(t,y|x)=(\partial/\partial y)G^{(\nu)}(t,y|x)$, and let $\tilde{\mathcal{N}}^{(\nu,\kappa),\mathrm{b}}(t,\mathbf{x})=\int_{\mathbb{W}_N^{\mathrm{C}}}d\mathbf{y}\,f^{(\nu),\mathrm{b}}(t,\mathbf{y}|\mathbf{x})\Pi_{i=1}^N y_i^{-\kappa}$ for $\mathbf{x}\in\mathbb{W}_{2N}^{\mathrm{C}}$. Then

$$g_T^{(\nu,\kappa),\mathrm{b}}(s,\mathbf{x};t,\mathbf{y})=\frac{f^{(\nu)}(t-s,\mathbf{y}|\mathbf{x})\tilde{\mathcal{N}}^{(\nu,\kappa),\mathrm{b}}(T-t,\mathbf{y})}{\tilde{\mathcal{N}}^{(\nu,\kappa),\mathrm{b}}(T-s,\mathbf{x})},$$

$$g_T^{(\nu,\kappa),\mathrm{b}}(0,\mathbf{0};t,\mathbf{y})=\frac{2^{N(4N+4\nu-1)}T^{2N^2}t^{-2N(2N+\nu)}}{\hat{C}_\nu}h^{(2\nu+1)}(\mathbf{y})e^{-|\mathbf{y}|^2/2t}\tilde{\mathcal{N}}^{(\nu,\kappa),\mathrm{b}}(T-t,\mathbf{y}),$$

$$g_T^{(\nu,\kappa),\mathrm{b}}(0,\mathbf{0};T,\mathbf{y})=\frac{1}{\hat{C}_\nu}\left(\frac{2}{T}\right)^{2N(N+\nu)}h^{((4\nu-2\kappa+3)/4)}(\mathbf{y}^{\mathrm{odd}})^4e^{-|\mathbf{y}^{\mathrm{odd}}|^2/T}\mathbf{1}(\mathbf{y}\in\mathbb{B}_{2N}^{\mathrm{C}}),\tag{50}$$

for $\mathbf{x},\mathbf{y}\in\mathbb{W}_{2N}^{\mathrm{C}},0\leqslant s<t<T$, where $\hat{C}_\nu=2^{N(2N+2\nu-1)}\Pi_{i=1}^N\{\Gamma(2i)\Gamma(2(i+\nu))\}$ and $\mathbb{B}_{2N}^{\mathrm{C}}=\{\mathbf{x}=(x_1,x_2,\ldots,x_{2N}):\mathbf{x}^{\mathrm{odd}}\in\mathbb{W}_N^{\mathrm{C}},x_{2i}=x_{2i-1},1\leqslant i\leqslant N\}$. We should notice that (50) includes the following special cases:

$$g_T^{(\nu,0),\mathrm{b}}(0,\mathbf{0};T,\mathbf{y})=q_\nu^{\mathrm{chGSE}}\left(\mathbf{y}^{\mathrm{odd}};\frac{T}{2}\right)\mathbf{1}(\mathbf{y}\in\mathbb{B}_{2N}^{\mathrm{C}})\quad\text{for}\quad\nu\in\mathbb{N},$$

$$g_T^{(-1/2,0),\mathrm{b}}(0,\mathbf{0};T,\mathbf{y})=q^{\mathrm{DIII}}\left(\mathbf{y}^{\mathrm{odd}},\frac{T}{2}\right)\mathbf{1}(\mathbf{y}\in\mathbb{B}_{2N}^{\mathrm{C}}).$$

Here

$$q_\nu^{\mathrm{chGSE}}(\boldsymbol{\kappa};t)=\frac{t^{-2N(N+\nu)}}{\hat{C}_\nu}\exp\left\{-\frac{|\boldsymbol{\kappa}|^2}{2t}\right\}\prod_{1\leqslant i<j\leqslant N}(\kappa_j^2-\kappa_i^2)^4\prod_{k=1}^N\kappa_k^{4\nu+3}$$

is the probability density of the N distinct square roots $\boldsymbol{\kappa}=(\kappa_1,\kappa_2,\ldots,\kappa_N)$ with (11) of the eigenvalues of $M^\dagger M$ conditioned that M is a $2N\times 2N$ random matrix in the chiral Gaussian symplectic ensemble (chGSE) with variance t,[54,53,27,51] and

$$q^{\mathrm{DIII}}(\boldsymbol{\omega};t)=\frac{t^{-d[\mathrm{D}'']/2}}{C[\mathrm{D}'']}\exp\left\{-\frac{|\boldsymbol{\omega}|^2}{2t}\right\}\prod_{1\leqslant i<j\leqslant N}(\omega_j^2-\omega_i^2)^4\prod_{k=1}^{N}\omega_k$$

with $d[\mathrm{D}'']=2N(2N-1), C[\mathrm{D}'']=\hat{C}_{-1/2}=2^{2N(N-1)}\Pi_{i=1}^{N}\Gamma(2i)\Gamma(2i-1)$ is the probability density of the non-negative and distinct eigenvalues $\boldsymbol{\omega}=(\omega_1,\omega_2,\ldots,\omega_N)$ with (18) of $4N\times 4N$ matrices in the ensemble in the symmetry class DIII studied by Altland and Zirnbauer.[56,1,2] (Strictly speaking, it is the DIII-even case. The DIII-odd case is obtained by setting $\nu=1/2$, $\kappa=0$ in (50).) The above implies that $\mathbf{X}^{(\nu,0),\mathrm{b}}(t)$ with $\nu\in\mathbb{N}$ and $\mathbf{X}^{(-1/2,0),\mathrm{b}}(t)$, both starting from $\mathbf{0}$, exhibit the transitions from the eigenvalue statistics of chGUE to chGSE and from the class D to the class DIII, respectively, as time t goes on from 0 to T.

A lengthy but explicit expression for the $4N\times 4N$ Hermitian matrix-valued process corresponding to $\mathbf{X}^{(-1/2,0),\mathrm{b}}(t)$ is given as

$$\begin{aligned}\Xi_T^{\mathrm{D,b}}(t)=&\sum_{\rho=0}^{2}\{\sqrt{-1}a_T^{0\rho}(t:O)\otimes(\sigma_0\otimes\sigma_\rho)+\sqrt{-1}a^{1\rho}(t)\otimes(\sigma_1\otimes\sigma_\rho)+s_T^{2\rho}(t:O)\otimes(\sigma_2\otimes\sigma_\rho)\\&+\sqrt{-1}a^{3\rho}(t)\otimes(\sigma_3\otimes\sigma_\rho)\}+\{s^{03}(t)\otimes(\sigma_0\otimes\sigma_3)+s^{13}(t)\otimes(\sigma_1\otimes\sigma_3)\\&+\sqrt{-1}a_T^{23}(t:O)\otimes(\sigma_2\otimes\sigma_3)+s_T^{33}(t:O)\otimes(\sigma_3\otimes\sigma_3)\},\end{aligned}$$

$t\in[0,T]$, where $s^{\mu\rho}(t)$, $s_T^{\mu\rho}(t:O)\in\mathcal{S}(N)$ and $a^{\mu\rho}(t)$, $a_T^{\mu\rho}(t:O)\in\mathcal{A}(N)$, $t\in[0,T]$, are defined similarly to (17) and (41). Identification of its eigenvalue process with $\mathbf{X}^{(-1/2,0),\mathrm{b}}(t)$ gives the following version of the Harish–Chandra integral,

$$\begin{aligned}&\int_{U_1(4N)}dU\exp\left\{-\frac{1}{4\sigma^2}\mathrm{Tr}(\Lambda_{\mathbf{x}}-U^{\dagger}\Lambda_{\mathbf{y}}U)^2\right\}\\&\quad=\frac{C_{2N}[\mathrm{D}]\sigma^{2N(4N+1)}}{h^{\mathrm{D}}(\mathbf{x})h^{(1/4)}(\mathbf{y})^4}\det_{1\leqslant i\leqslant 2N,1\leqslant j\leqslant N}\left[G^{\mathrm{D}}(\sigma^2,y_j|x_i)\ \frac{x_i}{\sigma^2}G^{\mathrm{C}}(\sigma^2,y_j|x_i)\right]\end{aligned}$$

for any $\sigma\in\mathbb{R}$, $\mathbf{x}=(x_1,x_2,\ldots,x_{2N})\in\mathbb{W}_{2N}^{\mathrm{C}}$, $\mathbf{y}=(y_1,y_2,\ldots,y_N)\in\mathbb{W}_N^{\mathrm{C}}$, where $\Lambda_{\mathbf{x}}=\mathrm{diag}\{x_1,x_2,\ldots,x_{2N}\}\otimes\sigma_3$, $\Lambda_{\mathbf{y}}=\mathrm{diag}\{y_1,y_2,\ldots,y_N\}\otimes(\sigma_3\otimes\sigma_0)$, and $C_{2N}[\mathrm{D}]=(\pi/2)^N\ \Pi_{i=1}^{2N}\Gamma(2i-1)$.

VI. CONCLUDING REMARKS

In the present paper we showed that the eigenvalue processes of GUE, chGUE, the class C, and the class D are realized by the temporally homogeneous noncolliding diffusion processes and then the temporally inhomogeneous noncolliding diffusion processes were introduced, which exhibit the transitions in distribution from the eigenvalue statistics of GUE to GOE, GUE to GSE, chGUE to chGOE, chGUE to chGSE, the class C to the class CI, and the class D to the class DIII. They are obtained as the special cases of the noncolliding systems of the Brownian motions and those of Yor's generalized meanders. These inhomogeneous processes are identified with the

eigenvalue processes of the inhomogeneous matrix-valued processes, some of which are regarded as the stochastic versions of two-matrix models studied by Pandey and Mehta[47,41] as demonstrated in Refs. 31, 35. We would like to put emphasis on the fact that in order to prove the identification we have not used any results by Pandey and Mehta, but used the generalized versions of Imhof relations ((4) and Proposition 8). Therefore we can give the proof for the Harish–Chandra (Itzykson–Zuber)-type integration formulas as corollaries. The present study suggests several open problems. Here we list some of them.

(i) It does not seem to be possible to realize the eigenvalue processes of the random matrix ensembles different from GUE, chGUE, the class C and the class D by any temporally homogeneous noncolliding systems of diffusion particles. Is it possible to realize them as the temporally homogeneous diffusion processes with some conditions additional to the simple noncolliding condition?

(ii) Norris, Rogers, and Williams[46] studied other matrix-valued process called Dynkin's Brownian motion $\tilde{\Xi}(t)=G(t)^T G(t)$ with $\partial G(t)=(\partial B(t))G(t)$, where ∂ denotes the Stratonovich differential; $x\partial y=xdy+dxdy/2$ for continuous semimartingales x,y. They showed that the eigenvalues of $\tilde{\Xi}(t)$ are also noncolliding systems and derived the stochastic differential equations similar to (1) for the logarithms of the eigenvalues. As mentioned by Bru (see Remark 2 in Ref. 7), $G(t)$ is a matrix-version of *multiplicative Brownian motion* in a sense, while $B(t)$ is the ordinary additional Brownian motion. Can we discuss (the logarithms of) the eigenvalue processes using the random matrix theory and noncolliding diffusion processes as well?

(iii) In the non-Hermitian random matrix ensembles, eigenvalues are distributed on the complex plane.[20,12] Is it meaningful to consider the stochastic version of non-Hermitian random matrix theory in the sense of Dyson?[10]

For the temporally inhomogeneous noncolliding Brownian motions $\mathbf{X}(t), t\in[0,T]$ with $\mathbf{X}(0)=\mathbf{0}$, the determinantal expressions for the multitime correlation functions were determined by Nagao and the present authors using the self-dual quaternion matrices[44,16,42] and the scaling limits of the infinite particles $N\to\infty$ and the infinite time-interval $T\to\infty$ were investigated.[45,30] Recently Nagao reported the similar calculation on the process, which corresponds to the process $\mathbf{X}^{(1/2,1)}$ in the present paper.[43] Calculation of the multitime correlations for the general process $\mathbf{X}^{(\nu,\kappa)}(t)$ is now in progress and the study of the infinite particle systems will be reported elsewhere.[34]

APPENDIX A: SCHUR FUNCTION EXPANSIONS OF DETERMINANTS

Any sequence $\mu=(\mu_1,\mu_2,\ldots,\mu_N,\ldots)$ of non-negative integers in decreasing order $\mu_1\geqslant\mu_2\geqslant\cdots\geqslant\mu_N\geqslant\cdots$ is called a partition. The nonzero μ_i in μ are called the parts of μ and the number of parts is the length of μ denoted by $\ell(\mu)$. For each partition μ with $\ell(\mu)\leqslant N$, the Schur function defined by $s_\mu(\mathbf{x})=\det_{1\leqslant i,j\leqslant N}(x_i^{\mu_j+N-j})/\det_{1\leqslant i,j\leqslant N}(x_i^{N-j})$ gives a symmetric polynomial of order $|\mu|=\Sigma_{i=1}^N\mu_i$ in N variables $x_1,x_2,\ldots,x_N\in\mathbb{C}$. Note that the denominator is the Vandermonde determinant and $\det_{1\leqslant i,j\leqslant N}(x_i^{N-j})=(-1)^{N(N-1)/2}h^{\mathrm{A}}(\mathbf{x})$.[39,17,52] We can prove the following expansion formulas of the determinants with the bases of the Schur functions:[3,4,36]

$$\frac{\det_{1\leqslant i,j\leqslant N}[e^{x_i y_j}]}{h^{\mathrm{A}}(\mathbf{x})h^{\mathrm{A}}(\mathbf{y})}=\sum_{\mu:\ell(\mu)\leqslant N} a_\mu s_\mu(\mathbf{x})s_\mu(\mathbf{y}),$$

$$\frac{\det_{1\leqslant i,j\leqslant N}[I_\nu(2\sqrt{x_i y_j})]}{\{\Pi_{i=1}^N x_i^{\nu/2}y_i^{\nu/2}\}h^{\mathrm{A}}(\mathbf{x})h^{\mathrm{A}}(\mathbf{y})}=\sum_{\mu:\ell(\mu)\leqslant N} b_\mu^{(\nu)} s_\mu(\mathbf{x})s_\mu(\mathbf{y}),$$

where $a_\mu=1/\Pi_{i=1}^N\Gamma(\mu_i+N-i+1)$ and $b_\mu^{(\nu)}=1/\{\Pi_{i=1}^N\Gamma(\mu_i+N-i+1)\Gamma(\nu+\mu_i+N-i+1)\}$. Since $s_\mu(\mathbf{0})=\mathbf{1}(\mu=\mathbf{0})$ with $\mathbf{0}=(0,0,\ldots,0)\in\mathbb{N}^N$, from the above formulas, we have the following asymptotics of the determinants. As $|\mathbf{x}|\to 0$,

$$\det_{1\leqslant i,j\leqslant N}[e^{x_i y_j}]=\frac{h^{\mathrm{A}}(\mathbf{x})h^{\mathrm{A}}(\mathbf{y})}{\Pi_{i=1}^N\Gamma(i)}\times(1+\mathcal{O}(|\mathbf{x}|)), \tag{A1}$$

$$\det_{1\leqslant i,j\leqslant N}[I_\nu(2\sqrt{x_i y_j})]=\left\{\prod_{i=1}^N x_i^{\nu/2}y_i^{\nu/2}\right\}\frac{h^{\mathrm{A}}(\mathbf{x})h^{\mathrm{A}}(\mathbf{y})}{\Pi_{j=1}^N\Gamma(j)\Gamma(\nu+j)}\times(1+\mathcal{O}(|\mathbf{x}|)). \tag{A2}$$

APPENDIX B: PROOF OF COROLLARY 12

By (38) of Lemma 5 (ii),

$$\begin{aligned}
g_T^{(\nu,\kappa)}(0,\mathbf{0};t,\mathbf{y})&=\frac{T^{N(N+\kappa-1)/2}t^{-N(N+\nu)}}{C_{\nu,\kappa}}\exp\left\{-\frac{|\mathbf{y}|^2}{2t}\right\}h^{(2\nu+1)}(\mathbf{y})\\
&\quad\times\int_{\mathbb{W}_N^{\mathbb{C}}}d\mathbf{z}\det_{1\leqslant i,j\leqslant N}\left[\frac{z_j^{\nu+1}}{y_i^\nu}\frac{1}{T-t}\exp\left\{-\frac{y_i^2+z_j^2}{2(T-t)}\right\}I_\nu\left(\frac{y_i z_j}{T-t}\right)\right]\prod_{k=1}^N z_k^{-\kappa}\\
&=\frac{T^{N(N+\kappa-1)/2}t^{-N(N+\nu)}}{(T-t)^N C_{\nu,\kappa}}\left(\frac{T}{t}\right)^{N(\nu+1-\kappa)}h^{(\nu+1)}(\mathbf{y})\int_{\mathbb{W}_N^{\mathbb{C}}}d\mathbf{z}\exp\left\{-\frac{T}{2t^2}\left(\frac{t}{T}\right)^2|\mathbf{z}|^2\right\}\\
&\quad\times\det_{1\leqslant i,j\leqslant N}\left[\exp\left\{-\frac{T}{2t(T-t)}\left(y_i^2+\frac{t^2}{T^2}z_j^2\right)\right\}I_\nu\left(\frac{T}{t(T-t)}y_i\times\frac{t}{T}z_j\right)\right]\\
&\quad\times\prod_{\ell=1}^N\left(\frac{t}{T}z_\ell\right)^{\nu+1-\kappa}.
\end{aligned}$$

Setting $(t/T)z_i=a_i$, $1\leqslant i\leqslant N$, $t(1-t/T)=\sigma^2$ and $T/t^2=\alpha$, we have

$$\begin{aligned}
g_T^{(\nu,\kappa)}(0,\mathbf{0};t,\mathbf{y})&=\frac{\sigma^{-2N}\alpha^{N(N+2\nu-\kappa+1)/2}}{C_{\nu,\kappa}}h^{(\nu+1)}(\mathbf{y})\\
&\quad\times\int_{\mathbb{W}_N^{\mathbb{C}}}d\mathbf{a}\,e^{-\alpha|\mathbf{a}|^2/2}\det_{1\leqslant i,j\leqslant N}\left[e^{-(y_i^2+a_j^2)/2\sigma^2}I_\nu\left(\frac{y_i a_j}{\sigma^2}\right)\right]\prod_{\ell=1}^N a_\ell^{\nu+1-\kappa}.
\end{aligned} \tag{B1}$$

Proof of (i): We write the transition probability density of the process $M_T(t)$ by $Q_T(s,m_1;t,m_2)$, $0\leqslant s<t\leqslant T$, for $m_1,m_2\in\mathcal{M}(N+\nu,N;\mathbb{C})$. Then by Theorem 9 (i) and the fact (12),

$$g_T^{(\nu,\nu+1)}(0,\mathbf{0};t,\mathbf{y})=\frac{(2\pi)^{N(N+\nu)}}{C_\nu}h^{((2\nu+1)/2)}(\mathbf{y})^2\int_{\mathrm{U}(N+\nu)\times\mathrm{U}(N)}d\mu(U,V)\,Q_T(0,O;t,U^\dagger K_{\mathbf{y}}V). \tag{B2}$$

We introduce the $\mathcal{M}(N+\nu,N;\mathbb{C})$-valued process $M^{(1)}(t)=(m_{ij}^{(1)}(t))_{1\leqslant i\leqslant N+\nu,1\leqslant j\leqslant N}$ and the $\mathcal{M}(N+\nu,N;\mathbb{R})$-valued process $M^{(2)}(t)=(m_{ij}^{(2)}(t))_{1\leqslant i\leqslant N+\nu,1\leqslant j\leqslant N}$, whose elements are defined by

$$m_{ij}^{(1)}(t)=B_{ij}^0(t)-\frac{t}{T}B_{ij}^0(T)+\sqrt{-1}(\tilde{\beta}_T^0)_{ij}(t) \quad \text{and} \quad m_{ij}^{(2)}(t)=\frac{t}{T}B_{ij}^0(T).$$

Then $M_T(t)=M^{(1)}(t)+M^{(2)}(t)$. Note that $\{B_{ij}^0(t)-(t/T)B_{ij}^0(T)\}$ are Brownian bridges of duration T starting at 0 and ending at 0, which are independent of $(t/T)B_{ij}^0(T)$. Hence $M^{(1)}(t)$ is in the chiral GUE distribution and $M^{(2)}(t)$ in the chiral GOE distribution, where $M^{(1)}(t)$ and $M^{(2)}(t)$ are independent from each other. Since $E[m_{ii}^{(1)}(t)^2]=\sigma^2$ and $E[m_{ii}^{(2)}(t)^2]=1/\alpha$, $Q_T(0,O;t,M)$ for $M\in\mathcal{M}(N+\nu,N;\mathbb{C})$ can be written as

$$\begin{aligned}Q_T(0,O;t,M)&=\int_{\mathcal{M}(N+\nu,N;\mathbb{R})}\mathcal{V}(dB)\mu_\nu^{\mathrm{chGOE}}(B;1/\alpha)\mu_\nu^{\mathrm{chGUE}}(M-B;\sigma^2)\\&=\frac{\alpha^{N(N+\nu)/2}\sigma^{-N(N+\nu)}}{C_{\nu,\nu+1}(2\pi)^{N(N+\nu)}}\int_{\mathbb{W}_N^{\mathrm{C}}}d\mathbf{a}\,h^{(\nu)}(\mathbf{a})e^{-\alpha|\mathbf{a}|^2/2-\mathrm{Tr}(M-K_\mathbf{a})^\dagger(M-K_\mathbf{a})/2\sigma^2},\end{aligned}\tag{B3}$$

where we have used the fact (16) and the formulas (10) and (15). Combining (B1) with $\kappa=\nu+1$, (B2) and (B3), we have

$$\begin{aligned}&\frac{C_\nu\sigma^{N(N+\nu-2)}}{h^{(\nu)}(\mathbf{y})}\int_{\mathbb{W}_N^{\mathrm{C}}}d\mathbf{a}\,e^{-\alpha|\mathbf{a}|^2/2}\det_{1\leqslant i,j\leqslant N}\left[\exp\left\{-\frac{y_i^2+a_j^2}{2\sigma^2}\right\}I_\nu\left(\frac{y_ia_j}{\sigma^2}\right)\right]\\&\quad=\int_{\mathbb{W}_N^{\mathrm{C}}}d\mathbf{a}\,h^{(\nu)}(\mathbf{a})e^{-\alpha|\mathbf{a}|^2/2}\int_{\mathrm{U}(N+\nu)\times\mathrm{U}(N)}d\mu(U,V)\,e^{-\mathrm{Tr}(U^\dagger K_\mathbf{y}V-K_\mathbf{a})^\dagger(U^\dagger K_\mathbf{y}V-K_\mathbf{a})/2\sigma^2}.\end{aligned}$$

Since, for each $\sigma\in\mathbb{R}$, this equality holds for any $\alpha>0$, we have the formula (i).

Proof of (ii): By setting $(\nu,\kappa)=(1/2,1)$ and $(\nu,\kappa)=(-1/2,0)$ in (B1) we have the expressions for $\mathbf{x},\mathbf{y}\in\mathbb{W}_N^{\mathrm{C}}$,

$$g_T^{(1/2,1)}(0,\mathbf{0};t,\mathbf{x})=\frac{\alpha^{N(N+1)/2}}{C[\mathrm{C}']}h^{\mathrm{C}}(\mathbf{x})\int_{\mathbb{W}_N^{\mathrm{C}}}d\mathbf{a}\,e^{-\alpha|\mathbf{a}|^2/2}\det_{1\leqslant i,j\leqslant N}[G^{\mathrm{C}}(\sigma^2,a_j|x_i)],$$

$$g_T^{(-1/2,0)}(0,\mathbf{0};t,\mathbf{y})=\frac{\alpha^{N^2/2}}{C[\mathrm{D}']}h^{\mathrm{D}}(\mathbf{y})\int_{\mathbb{W}_N^{\mathrm{D}}}d\mathbf{a}\,e^{-\alpha|\mathbf{a}|^2/2}\det_{1\leqslant i,j\leqslant N}[G^{\mathrm{D}}(\sigma^2,a_j|y_i)].$$

Following the same argument with the proof of (i) and using the equalities (19) and (23), formulas (ii) are proved. ■

(Received 12 February 2004; accepted 3 May 2004; published online 2 July 2004)

We study the lowest energy E of a relativistic system of N identical bosons bound by pair potentials of the form $V(r_{ij})=g(r_{ij}^2)$ in three spatial dimensions. In natural units $\hbar=c=1$ the system has the semirelativistic "spinless-Salpeter" Hamiltonian $H=\Sigma_{i=1}^{N}\sqrt{m^2+p_i^2}+\Sigma_{j>i=1}^{N}g(|\mathbf{r}_i-\mathbf{r}_j|^2)$, where g is monotone increasing and has convexity $g''\geqslant 0$. We use "envelope theory" to derive formulas for general lower energy bounds and we use a variational method to find complementary upper bounds valid for all $N\geqslant 2$. In particular, we determine the energy of the N-body oscillator $g(r^2)=cr^2$ with error less than 0.15% for all $m\geqslant 0$, $N\geqslant 2$, and $c>0$.
 [DOI: 10.1063/1.1767298]

I. INTRODUCTION

We consider a system of N identical bosons interacting by attractive pair potentials $V(r_{ij})$ and obeying the semirelativistic spinless Salpeter equation.[1,2] The Hamiltonian governing the dynamics of the N-particle problem is given by

$$H=\sum_{i=1}^{N}\sqrt{m^2+p_i^2}+\sum_{j>i=1}^{N}V(|\mathbf{r}_i-\mathbf{r}_j|) \tag{1.1}$$

and represents a model system having a relativistically correct expression for the kinetic energy and a static pair potential. One of the reasons for considering such a model is that the extension to the many-particle case poses no fundamental technical problems beyond what are already present in the one-body problem, namely the square root in the kinetic energy and the nonlocality that the definition[3] of the Hamiltonian entails. Our lower bounds use the necessary permutation symmetry of the N-boson problem to effect a "reduction" to an almost equivalent 2-body problem.[4,5] The purpose of the present paper is first to use envelope theory[6–10] to extend our specific energy lower bounds for the harmonic oscillator[11] to apply to smooth transformations of the oscillator having the general form $V(r)=g(r^2)$, where g is monotone increasing and of positive convexity ($g''\geqslant 0$). Secondly, we show that the earlier upper energy bounds (via a Gaussian trial function) for the oscillator $V(r)=cr^2$ can be considerably sharpened; this improvement is carried over to the larger class of pair potentials. We have already shown this[12] for the ultrarelativistic case $m=0$ of

a)Electronic mail: rhall@mathstat.concordia.ca
b)Electronic mail: wolfgang.lucha@oeaw.ac.at
c)Electronic mail: franz.schoeberl@univie.ac.at

the pure oscillator. In this paper we shall generalize these oscillator results to $V(r)=g(r^2)$ and $m\geqslant 0$. For the oscillator $V(r)=cr^2$ itself, the new bounds are separated by less than 0.15% for all $m\geqslant 0$, $c>0$, and $N\geqslant 2$.

In Sec. II we recall some fundamental formulas concerning the one-body harmonic oscillator with Hamiltonian $\sqrt{m^2+p^2}+r^2$ and lowest energy $e(m)$. This problem does not have an exact analytical solution but can be easily solved numerically to yield $e(m)$ to arbitrary accuracy; this result is necessary for our *N*-body lower bounds. As distinct from our earlier work,[11] in this paper we eschew the *P*-representation and its concomitant scaling subtleties, and base all our lower bounds on the function $e(m)$ itself.

In Sec. III we turn to the principal topic of this paper, namely potentials which are smooth transformations $V(r)=g(r^2)$ of the oscillator potential. If g is convex ($g''\geqslant 0$), the graph of $V(r)$ lies above "tangential potentials" $V^{(t)}(r)$ with the general form $V^{(t)}(r)=a(t)+b(t)r^2$, where $t=\hat{r}^2$ is the point of contact with the potential $V(r)$ itself. As $t>0$ varies, $\{V^{(t)}(r)\}$ represents a family of shifted oscillators. Envelope theory allows one to construct energy lower bounds based on this fundamental geometrical idea. In Sec. IV we construct variational upper bounds by use of a translation-invariant Gaussian trial function. In Sec. V we look at the ultrarelativistic case $m\rightarrow 0$, and in Sec. VI we apply our general results to some examples from the family $V(r)=cr^q$, $q\geqslant 2$.

II. THE ONE-BODY OSCILLATOR PROBLEM

We consider the one-body problem with Hamiltonian

$$H_1=\sqrt{m^2+p^2}+r^2\rightarrow e(m), \tag{2.1}$$

where, for coupling $c=1$, $e(m)$ is the lowest eigenvalue as a function of the mass m. In the momentum-space representation, we have an equivalent problem with Hamiltonian

$$\tilde{H}_1=-\Delta+\sqrt{m^2+r^2}\rightarrow e(m). \tag{2.2}$$

Since this Schrödinger problem is easy to solve numerically to arbitrary accuracy, we shall take the position that $e(m)$ is "known" and at our disposal. We note that in the large-m (nonrelativistic or Schrödinger) limit, we have

$$e(m)\simeq e_{\mathrm{NR}}(m)=m+\frac{3}{\sqrt{2m}}. \tag{2.3}$$

The graph of $e(m)-m$ is shown in Fig. 1: $e(m)$ is monotone increasing with m; $e(m)-m$, however, is monotone *decreasing*, in agreement, for large m, with the Feynman–Hellmann theorem for the corresponding nonrelativistic case.

It remains now to use scaling to generalize these results. This is necessary for our later application to the *N*-body problem. For the energy of a more general one-body problem in which the kinetic-energy term is multiplied by the positive factor β, the coupling $\gamma>0$ is included, and a further parameter $\lambda>0$ is allowed for, we have, by scaling arguments,

$$H_1=\beta\sqrt{m^2+\lambda p^2}+\gamma r^2\rightarrow \epsilon(m,\beta,\gamma\lambda)=(\beta^2\gamma\lambda)^{1/3}e\left(m\left(\frac{\beta}{\gamma\lambda}\right)^{1/3}\right). \tag{2.4}$$

III. ENERGY LOWER BOUND FOR $V(r)=g(r^2)$ BY ENVELOPE THEORY

Our hypothesis is that $V(r)=g(r^2)$, where the smooth transformation function g is monotone increasing and its convexity is positive or zero. That is to say, we shall assume $g''\geqslant 0$. These assumptions imply a relation between $V(r)$ and a "tangential potential" $V^{(t)}(r)$ given explicitly by

$$V(r)\geqslant V^{(t)}(r)=g(t)-tg'(t)+g'(t)r^2=a(t)+b(t)r^2, \tag{3.1}$$

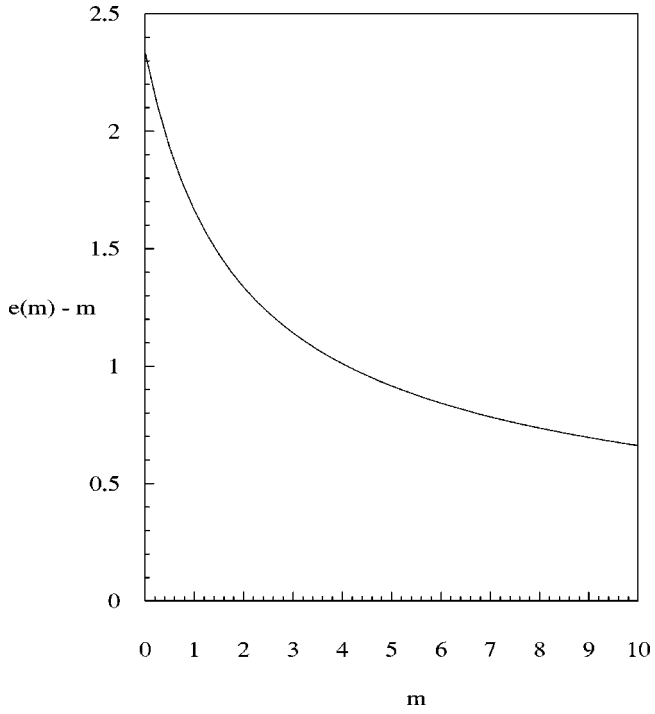

FIG. 1. The energy function $e(m)-m$ of the one-body problem defined by (2.1).

where $t=\hat{r}^2$ is the point of contact between the tangential potential and the potential. For each fixed t, the tangential potential has the form $a+br^2$ of a shifted oscillator. This potential inequality induces, in turn, a spectral inequality as an immediate consequence of the min–max characterization of the spectrum of the Hamiltonian. It is the task of envelope theory[6–10] to generate expressions for this spectral inequality.

The kinetic-energy term in the Hamiltonian H does not have the kinetic energy of the center-of-mass removed. Thus the wave function we use must satisfy two fundamental symmetries: translation invariance and boson permutation symmetry (in the individual-particle coordinates). Jacobi relative coordinates may be defined with the aid of an orthogonal matrix B relating the column vectors of the new $[\boldsymbol{\rho}_i]$ and old $[\mathbf{r}_i]$ coordinates given by $[\boldsymbol{\rho}_i]=B[\mathbf{r}_i]$. The first row of B defines a center-of-mass variable $\boldsymbol{\rho}_1$ with every entry $1/\sqrt{N}$, the second row defines a pair distance $\boldsymbol{\rho}_2=(r_1-r_2)/\sqrt{2}$, and the kth row, $k\geqslant 2$, has the first $k-1$ entries $B_{ki}=1/\sqrt{k(k-1)}$, the kth entry $B_{kk}=-\sqrt{(k-1)/k}$, and the remaining entries zero. We define the corresponding momentum variables by $[\boldsymbol{\pi}_i]=(B^{-1})^t[\mathbf{p}_i]=B[\mathbf{p}_i]$. Let us suppose that the (unknown) exact normalized boson ground-state wave function for the N-body harmonic-oscillator problem with $V(r)=cr^2$ is $\Psi=\Psi(\rho_2,\rho_3,\ldots,\rho_N)$ corresponding to energy E. Boson symmetry is a powerful constraint that greatly reduces the complexity of this problem. We immediately obtain [Ref. 11, Eq. (2.3)] the "reduction"

$$E=(\Psi,H\Psi)=\left(\Psi,\left[N\sqrt{m^2+p_N^2}+\frac{N(N-1)}{2}c|\mathbf{r}_1-\mathbf{r}_2|^2\right]\Psi\right). \tag{3.2}$$

Since $|r_1-r_2|^2=2\rho_2^2$, in terms of the Jacobi relative coordinates this becomes

$$E=\left(\Psi,\left[N\sqrt{m^2+\left(\frac{\boldsymbol{\pi}_1}{\sqrt{N}}-\sqrt{\frac{N-1}{N}}\,\boldsymbol{\pi}_N\right)^2}+N(N-1)c\rho_2^2\right]\Psi\right). \tag{3.3}$$

The lemma proved in Ref. 11 allows us to remove the term in the center-of-mass momentum operator π_1 from inside the square root. Boson permutation symmetry furthermore implies [Ref. 11, Eq. (2.5)]

$$(\Psi,\rho_2^2\Psi)=(\Psi,\rho_N^2\Psi), \tag{3.4}$$

even though the wave function Ψ may not be symmetric in the relative coordinates. These results lead to the final reduction

$$E=\left(\Psi,\left[N\sqrt{m^2+\frac{N-1}{N}\pi_N^2}+N(N-1)c\rho_N^2\right]\Psi\right). \tag{3.5}$$

If we now write $r=\rho_N$ and $p=\pi_N$, we see that the exact energy E can be written in the form $E=(\Psi,\mathcal{H}\Psi)$, in which $\mathcal{H}$ is the Hamiltonian for a one-body problem given by

$$\mathcal{H}=\beta\sqrt{m^2+\lambda p^2}+\gamma c r^2, \tag{3.6}$$

with

$$\beta=N,\quad \lambda=\frac{N-1}{N},\quad \text{and}\quad \gamma=N(N-1).$$

It follows that the exact energy E of the oscillator system is bounded below by $\mathcal{E}$, the bottom of the spectrum of the one-body Hamiltonian $\mathcal{H}$.

Thus, for the harmonic oscillator itself, we have from (3.5) and (2.4):

Theorem 1: *A lower bound to the ground-state energy eigenvalue E of the semirelativistic N-body Hamiltonian*

$$H=\sum_{i=1}^{N}\sqrt{m^2+p_i^2}+\sum_{j>i=1}^{N}c|\mathbf{r}_i-\mathbf{r}_j|^2,\quad c>0, \tag{3.7}$$

is provided by the formula

$$E\geqslant(\beta^2\gamma c\lambda)^{1/3}e\left(m\left(\frac{\beta}{\gamma c\lambda}\right)^{1/3}\right), \tag{3.8}$$

where

$$\beta=N,\quad \lambda=\frac{N-1}{N},\quad \gamma=N(N-1).$$

This lower bound yields the exact energy in the Schrödinger limit $m\to\infty$. If we consider the potential $V(r)=g(r^2)$ and use the potential lower bound (3.1), we can maximize the resulting lower bound provided by Theorem 1 to obtain:

Theorem 2: *A lower bound to the ground-state energy eigenvalue E of the semirelativistic N-body Hamiltonian*

$$H=\sum_{i=1}^{N}\sqrt{m^2+p_i^2}+\sum_{j>i=1}^{N}g(|\mathbf{r}_i-\mathbf{r}_j|^2),\quad g'>0,\quad g''\geqslant 0, \tag{3.9}$$

is provided by the formula

$$E\geqslant\max_{t>0}\left[m\beta\frac{e(\nu)}{\nu}+\frac{\gamma}{2}(g(t)-tg'(t))\right], \tag{3.10}$$

where

$$\beta=N, \quad \lambda=\frac{N-1}{N}, \quad \gamma=N(N-1), \quad \nu=m\left(\frac{\beta}{\gamma\lambda g'(t)}\right)^{1/3}.$$

If we consider the family of pure-power potentials of the form $V(r)=cr^q$, then for the harmonic oscillator $q=2$, we use Theorem 1; for more general potentials, with $q>2$, we have $V(r)=g(r^2)=g(t)=ct^{q/2}$. Consequently, we must in this case make the explicit substitutions

$$a(t)=g(t)-tg'(t)=-c\left(\frac{q}{2}-1\right)t^{q/2} \quad \text{and} \quad b(t)=g'(t)=\frac{cq}{2}t^{(q-2)/2}. \tag{3.11}$$

IV. VARIATIONAL UPPER BOUNDS

Improvement over the previous upper energy bounds[11] for the oscillator will be obtained in this paper by avoiding the loosening incurred by use of Jensen's inequality.[3,13] This goal has already been achieved[12] for the ultrarelativistic special case $m=0$ of the N-body harmonic-oscillator problem. We shall now extend this to more general problems with attractive potential $V(r)$ and $m\geqslant 0$.

We use a Gaussian wave function of the form

$$\Phi(\rho_2,\rho_3,\ldots,\rho_N)=C\exp\left(-\frac{\alpha}{2}\sum_{i=2}^{N}\rho_i^2\right), \quad \alpha>0, \tag{4.1}$$

where C is a normalization constant. The factoring property of this function, the boson-symmetry reduction leading to (3.5), and the additional fact that Φ is also symmetric under exchange of the *relative* coordinates allows us to write $r=\rho_2$, and $p=\pi_N\rightarrow\pi_2$, and finally

$$E\leqslant\beta(\phi,\sqrt{m^2+\lambda p^2}\phi)+\frac{\gamma}{2}(\phi,V(\sqrt{2}r)\phi), \tag{4.2}$$

where

$$\beta=N, \quad \lambda=\frac{N-1}{N}, \quad \gamma=N(N-1),$$

and the function $\phi(r)$ is given by

$$\phi(r)=\left(\frac{\alpha}{\pi}\right)^{3/4}\exp\left(-\frac{\alpha r^2}{2}\right). \tag{4.3}$$

The kinetic-energy integral may be written in terms of modified Bessel functions of the second kind,[14,15] which we now discuss. The calculation is best carried out in momentum space with the aid of the three-dimensional Fourier transform $\mathcal{F}$. We have

$$\phi(r)\overset{\mathcal{F}}{\rightarrow}\tilde{\phi}(k)=\left(\frac{1}{\alpha\pi}\right)^{3/4}\exp\left(-\frac{k^2}{2\alpha}\right). \tag{4.4}$$

Thus the expectation of the kinetic energy becomes

$$\langle K\rangle=\beta(\tilde{\phi},\sqrt{m^2+\lambda k^2}\tilde{\phi})=\frac{4\pi\beta}{(\alpha\pi)^{3/2}}\int_0^\infty\exp\left(-\frac{k^2}{\alpha}\right)\sqrt{m^2+\lambda k^2}k^2dk. \tag{4.5}$$

We may write this integral in the form

$$\langle K\rangle = \frac{\beta m\mu}{\sqrt{2\pi}} \exp\left(\frac{\mu^2}{4}\right) K_1\left(\frac{\mu^2}{4}\right), \quad \mu = m\left(\frac{2N}{(N-1)\alpha}\right)^{1/2}, \tag{4.6}$$

where $K_\nu(z)$ is a modified Bessel function of the second kind.[14,15]

The potential-energy integral will depend on the choice of $V(r)$. For the family $V(r) = c\ \mathrm{sgn}(q) r^q$, which we shall study in Sec. V, the integrals may be expressed in terms of the gamma function. Explicitly we have

$$\langle V\rangle = \left(\phi, \left(\frac{c\ \mathrm{sgn}(q)\gamma}{2}(r\sqrt{2})^q\right)\phi\right) = \frac{c\ \mathrm{sgn}(q)\gamma}{\sqrt{\pi}}\Gamma\left(\frac{3+q}{2}\right)\left(\frac{\mu\sqrt{\lambda}}{m}\right)^q. \tag{4.7}$$

With the results in this form we can use the parameter μ as a variational parameter. We have therefore established:

Theorem 3: *For fixed $m>0$, $q>-1$, $c>0$, $N\geqslant 2$, $\beta=N$, $\gamma=N(N-1)$, and $\lambda=(N-1)/N$, the lowest energy E of the N-boson problem for the pair potential $V(r)=c\ \mathrm{sgn}(q) r^q$ is given by the inequality*

$$E \leqslant \min_{\mu>0}\left[\frac{\beta m\mu}{\sqrt{2\pi}} \exp\left(\frac{\mu^2}{4}\right) K_1\left(\frac{\mu^2}{4}\right) + \frac{c\ \mathrm{sgn}(q)\gamma}{\sqrt{\pi}}\Gamma\left(\frac{3+q}{2}\right)\left(\frac{\mu\sqrt{\lambda}}{m}\right)^q\right]. \tag{4.8}$$

We have allowed $q>-1$ here since the upper bound easily accommodates this family of potentials in three spatial dimensions. For $q<-1$, there is no discrete spectrum. In the gravitational case $q=-1$ the minimum upper bound exists provided the coupling is not too large: specifically we require

$$\frac{c\gamma}{4\beta}\sqrt{\frac{2}{\lambda}} = \frac{c}{2}\sqrt{\frac{N(N-1)}{2}} < 1. \tag{4.9}$$

This situation is of course well known from the two-particle attractive Coulomb problem.[16,17] At present we only have close complementary lower bounds for $q\geqslant 2$.

V. THE ULTRARELATIVISTIC LIMIT

The ultrarelativistic case $m\to 0$ may be obtained from Theorems 2 and 3 as a special case. The Hamiltonian for this problem is given explicitly by

$$H = \sum_{i=1}^{N} \sqrt{p_i^2} + \sum_{j>i=1}^{N} c|\mathbf{r}_i - \mathbf{r}_j|^q, \quad c>0, \quad q\geqslant 2. \tag{5.1}$$

For the lower bound we use $g(t)=ct^{q/2}$. The upper bound may either be treated separately or taken from (4.8) by means of the limit $\lim_{z\to 0} zK_1(z)=1$. The bounds we obtain are given by

$$C\left[\frac{z_0}{3}\right]^{3q/[2(1+q)]} \leqslant E \leqslant \frac{C}{\sqrt{\pi}}\left[2\Gamma\left(\frac{3+q}{2}\right)\right]^{1/(1+q)}, \tag{5.2}$$

where $z_0 \approx 2.338\,107\,41$ is the first zero of the Airy function $\mathrm{Ai}(z)$, satisfying $\mathrm{Ai}(z_0)=0$, and the common factor C is given by

$$C = \left(\frac{cq}{2}\right)^{1/(1+q)}\left(1+\frac{1}{q}\right)(N(N-1))^{(2+q)/[2(1+q)]} 2^{3q/[2(1+q)]}.$$

As m increases from zero, the power-law bounds become closer monotonically with m; thus the $m=0$ case provides an upper bound to the error for all m. Since we have explicit formulas for the

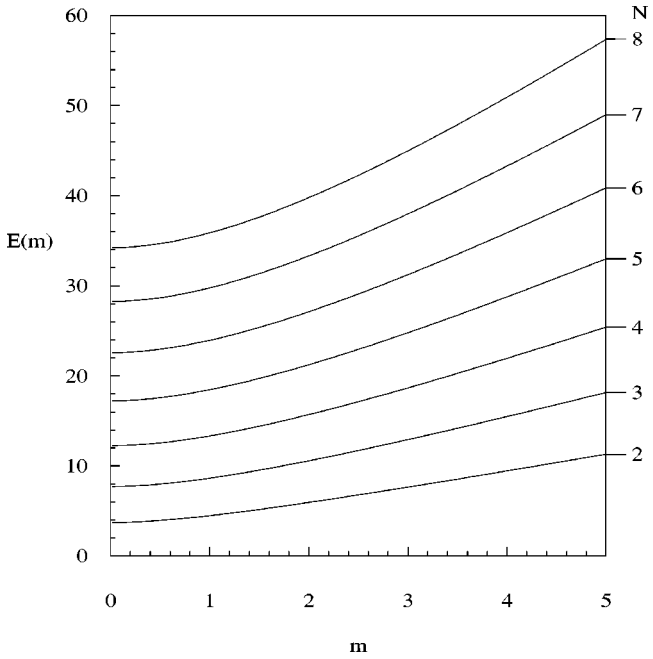

FIG. 2. The ground-state energy $E(m)$ of the relativistic N-boson harmonic-oscillator problem $V(r)=r^2$ for $N=2,3,...,8$. The figure shows the lower bounds given by Eq. (3.8): the upper bounds are everywhere less than 0.15% above these curves and are indistinguishable on the graph. In the Schrödinger limit $m\to\infty$ the upper and lower bounds coalesce to the exact energies.

bounds in terms of N, we are able to make definite statements concerning the percentage separations of the bounds for all N. If we take the energy estimate $\bar{E}$ to be the average of the bounds, the exact energy E is determined by $\bar{E}$ to within 0.15% for the harmonic oscillator $q=2$, and to 3.6% for the cubic ''oscillator'' $q=3$. In the nonrelativistic limit $m\to\infty$ the harmonic-oscillator bounds $q=2$ coalesce to the exact solution of the Schrödinger N-body problem.[11]

VI. EXAMPLES

The examples we consider are from the family $V(r)=cr^q$. In order to have a lower bound, we restrict the power to $q\geqslant 2$. We revisit the oscillator problem because we have considerably improved the upper bound since Ref. 11. Graphs of the lower bounds alone are shown in Fig. 2. The percentage separations are bounded above by the separations at $m=0$, which are there less than 0.15%. With the notation $E_N(m)$ we have explicitly, for the oscillator $q=2$, that the lower and upper estimates have numerical values $E_8^{\mathrm{L}}(1)=35.863\,83$ and $E_8^{\mathrm{U}}(1)=35.899\,53$, respectively. Thus the average of these values determines $E_8(1)$ in this case with error less than 0.05%. As we leave the oscillator and increase q beyond $q=2$, the bounds become less sharp. For $q=\frac{5}{2}$ we show the corresponding bounds in Fig. 3: here the bounds are separated for all m by less than 1.43%. The corresponding graphs for the cubic ''oscillator'' $q=3$ are shown in Fig. 4; in this case the maximum percentage separation (again for all $N\geqslant 2$ and $m\geqslant 0$) is 3.6%.

VII. CONCLUSION

The necessary permutation symmetry of the states of a system of identical particles is a powerful constraint. The approximate ''reduction'' of the N-body problem to a scaled two-body problem is most striking for systems of bosons, or for systems which are compatible with the assumption of permutation symmetry in the spatial variables alone.[4] For systems of fermions, the reduction is to a sum over two-body energies.[5] For the Schrödinger harmonic-oscillator problem, the boson reduction is complete in the sense that the N-body energy is given exactly by the energy

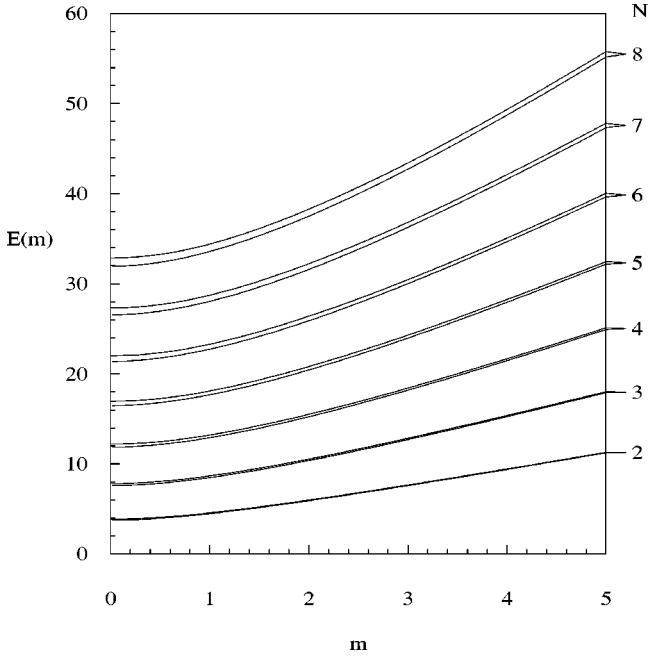

FIG. 3. Upper and lower energy bounds for the ground-state energy $E(m)$ of the relativistic N-boson problem corresponding to $V(r)=r^{5/2}$ for $N=2,3,...,8$. The percentage errors are maximum for $m=0$ where they determine the energies (for all N) with error less than 1.43%.

of a two-body problem. A lower bound by this type of reduction is possible provided either the kinetic-energy term or the potential-energy term has a quadratic form: this allows us to replace, for example, the ''mixed'' pair $\{\pi_N,\rho_2\}$ by $\{\pi_N,\rho_N\}$ in the reduced two-body Hamiltonian $\mathcal{H}$. For the Salpeter problem discussed in this paper, a quadratic form is present in the potential term of the

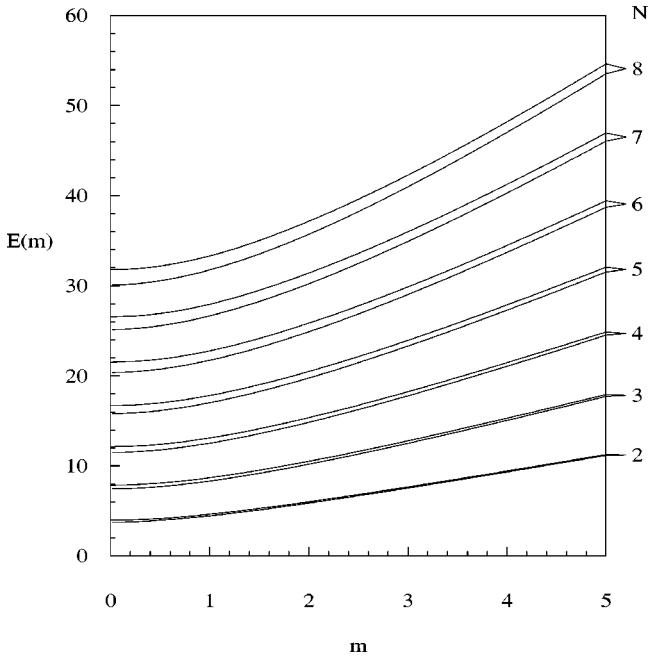

FIG. 4. Upper and lower energy bounds for the ground-state energy $E(m)$ of the relativistic N-boson problem corresponding to $V(r)=r^3$ for $N=2,3,...,8$. The percentage errors are maximum for $m=0$ where they determine the energies (for all N) with error less than 3.6%.

oscillator, and the lower bound obtained for this base problem is then applicable to other problems whose potentials $V(r)$ have the form of smooth convex transformations $g(r^2)$ of the oscillator. The extension beyond the oscillator is effected by the use of "envelope theory." A reduction is also used for our upper bound, but this reduction is allowed for general potentials and for a different reason. The trial function must be a translation-invariant boson function; but we have chosen a Gaussian trial function which has an additional symmetry, namely, it is also symmetric in the relative coordinates. It is this latter symmetry which completes the reduction in the case of the upper bound. Because of all these symmetries, what starts out as a complex many-body problem, appears in the end, for the purpose of finding energy bounds, as a one-body problem.

Langer–Cherry derivation of the multi-instanton expansion for the symmetric double well

Gabriel Álvarez
Departamento de Física Teórica II (Métodos Matemáticos de la Física), Facultad de Ciencias Físicas, Universidad Complutense, 28040 Madrid, Spain

(Received 17 November 2003; accepted 6 May 2004; published online 2 July 2004)

The multi-instanton expansion for the eigenvalues of the symmetric double well is derived using a Langer–Cherry uniform asymptotic expansion of the solution of the corresponding Schrödinger equation. The Langer–Cherry expansion is anchored to either one of the minima of the potential, and by construction has the correct asymptotic behavior at large distance, while the quantization condition amounts to imposing the even or odd parity of the wave function. This method leads to an efficient algorithm for the calculation to virtually any desired order of all the exponentially small series of the multi-instanton expansion, and with trivial modifications can also be used for nonsymmetric double wells. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1767988]

I. INTRODUCTION

One of the early and most typical applications of semiclassical methods in quantum mechanics is the calculation of the exponentially small energy splitting between quasidegenerate levels in a double well, a splitting which is not captured by the usual Rayleigh–Schrödinger perturbation series for the eigenvalues around either one of the minima.[1] Almost every general-use variety of semiclassical approximation has been applied to this problem,[2–4] and many specific methods are still under active development.[5–14]

But in fact, working in the context of the large-order behavior of the coefficients of the perturbation series and partially inspired by the work of Bender and Wu,[15] already in 1981 Zinn-Justin[16,17] conjectured the form of the complete Borel-summable asymptotic expansion for the energy levels of the double well. This expansion consists of the Rayleigh–Schrödinger perturbation series plus an infinite sequence of subseries, where the kth subseries (the kth instanton contribution) is the kth power of an exponentially small factor times a sum of power series and logarithmic terms up to the power $k-1$. To be precise, the multi-instanton expansion cannot be directly summed for physical values of the coupling constant, which lie on a Stokes line of the Borel-summable asymptotic expansions, but has to be summed for, say, complex values, and followed by continuity to the positive real axis.[18–20] The multi-instanton expansion was initially derived by Wentzel–Kramers–Brillouin (WKB) methods as the solution of a modified Bohr–Sommerfeld quantization formula; a very clear and updated presentation of this quantization formula and its relation to the path integral method can be found in Ref. 21.

From a mathematical standpoint, the status of Zinn-Justin's modified quantization formula and of the ensuing multi-instanton expansion were of conjectures until the work of Delabaere, Dillinger, and Pham[22] and Delabaere and Pham.[23,24] These authors, building on previous work by Balian and Bloch,[25] Voros[26] and Écalle,[27,28] gave a rigorous set of rules whereby ''well normalized'' WKB expansions, considered as exact encodings of the true wave functions, can be analytically continued with respect to the coupling constant with a consistent and unique determination of the exponentially small terms. Although in Ref. 22 the authors deliberately emphasize the results which can be obtained without explicit computation of the WKB expansions, the double turning point connection problem pertaining to the double well is solved in terms of a ''reduced elementary connection operator'' (which in turn can be computed by the ''exact matching method'' explained in Ref. 24 and ultimately based on a form of the solution studied by Pham[29] and

Jidoumou[30]) and, besides the general proof of Zinn-Justin's conjecture, they give explicit results of the leading terms of the subseries up to the second instanton contribution for the double well $V(x)=x^4-x^2$.

The purpose of the present paper is threefold. First, to give a complete and self-contained derivation of the multi-instanton expansion for the symmetric double well based on the Langer–Cherry method to obtain Borel-summable uniform asymptotic expansions for the solutions of differential equations with turning points.[31–33] In particular we will see that the results of Cherry[33] avoid the problem of integration constants typical of WKB derivations, which is usually dealt with by regularization procedures essentially equivalent to repeated partial integrations before collapsing the integration path to the real axis.[2,34,35] Second, by using the inverse series of those used in the method of Refs. 22 and 24 we will find an explicit and efficient algorithm for the calculation of the multi-instanton expansion to any order. And third, we will show that an empirical observation made by Hoe *et al.*[36] in the context of the Stark effect can be carried over to the double well, yielding a yet more efficient algorithm which permits the calculation of virtually as many terms as desired of any instanton contribution of the quartic symmetric double well.

Furthermore, with the trivial modifications explained in the last section, the Langer–Cherry method of this paper can be used for any symmetric or nonsymmetric double well.

II. THE SYMMETRIC DOUBLE WELL

Let us briefly recall how the symmetric double well can be obtained by analytic continuation from the standard quartic anharmonic oscillator,[37] whose Schrödinger equation is

$$-\tfrac{1}{2}\Psi''(x)+(\tfrac{1}{2}x^2+Gx^4-\Lambda)\Psi(x)=0. \tag{1}$$

For real and positive values of the coupling constant G we have a well-defined self-adjoint eigenvalue problem on the real line. The spectrum consists of simple positive eigenvalues, and the Rayleigh–Schrödinger perturbation series in the coupling constant G is Borel summable to the exact eigenvalues.[38] To perform the analytic continuation to complex values of G we integrate the Schrödinger equation (1) along a straight line in the complex x plane such that at both ends there exists an exponentially decreasing solution,[39] e.g., $x=te^{-i\arg(G)/6}$ $(t\in\mathbf{R})$. The symmetric double well is reached for $\arg G=-3\pi/2$. To make contact with the usual notation in which the coupling constant g of the double well is real and positive, let

$$G=ge^{-i3\pi/2},\quad \Lambda=-iE,\quad x=ye^{i\pi/4},\quad \Psi(x)=\Phi(y).$$

The resulting equation is

$$-\tfrac{1}{2}\Phi''(y)+(gy^4-\tfrac{1}{2}y^2-E)\Phi(y)=0, \tag{2}$$

integrated along $y=te^{-i\arg(g)/6}$ $(t\in\mathbf{R})$, i.e., the integration path is the real y axis. In this form we immediately recognize the double-well potential

$$V(y)=gy^4-\tfrac{1}{2}y^2,$$

with the symmetric degenerate minima at

$$y_\pm=\pm\frac{1}{2g^{1/2}},$$

and expansions of the potential around the minima given by

$$V(y)=-\frac{1}{16g}+(y-y_\pm)^2\pm 2g^{1/2}(y-y_\pm)^3+g(y-y_\pm)^4.$$

These expansions permit a straightforward calculation of the Rayleigh–Schrödinger perturbation series around either one of the minima. To fix ideas, in the equation

$$-\frac{1}{2}\Phi''(y)+\left[(y-y_+)^2+2g^{1/2}(y-y_+)^3+g(y-y_+)^4-\frac{1}{16g}-E\right]\Phi(y)=0 \tag{3}$$

we take as unperturbed Hamiltonian the harmonic oscillator with force constant $k=2$ and unperturbed eigenvalues

$$E_n^{(0)}=\sqrt{2}(n+1/2), \tag{4}$$

and we take as perturbation the cubic and quartic terms. A parity argument shows that, aside from the trivial term $-1/(16g)$, the resulting series is a power series in g (without odd powers of $g^{1/2}$), which we write as

$$E_n=-\frac{1}{16g}+\sum_{k=0}^{\infty} g^k E_n^{(k)}. \tag{5}$$

From the usual equations of perturbation theory in the intermediate normalization it follows that the $E_n^{(k)}$ are alternatively odd and even polynomials of degree $k+1$ in $E_n^{(0)}$. With just a few lines of code (which take advantage of the fact that knowledge of the perturbed wave function to order k permits the calculation of the perturbed energy to order $2k+1$) we can calculate these perturbation coefficients $E_n^{(k)}$ to high order. To show the pattern and for later reference we list explicitly the lowest four polynomials,

$$E_n^{(1)}=-\tfrac{1}{4}-\tfrac{3}{2}(E_n^{(0)})^2, \tag{6}$$

$$E_n^{(2)}=-\tfrac{19}{8}E_n^{(0)}-\tfrac{17}{4}(E_n^{(0)})^3, \tag{7}$$

$$E_n^{(3)}=-\tfrac{131}{64}-\tfrac{459}{16}(E_n^{(0)})^2-\tfrac{375}{16}(E_n^{(0)})^4, \tag{8}$$

$$E_n^{(4)}=-\frac{22\,709}{256}E_n^{(0)}-\frac{23\,405}{64}(E_n^{(0)})^3-\frac{10\,689}{64}(E_n^{(0)})^5. \tag{9}$$

Finally, note the well-known facts that all the coefficients are negative [which precludes Borel summability of the perturbation series (5) on the real positive g axis], and that the perturbation series, being intrinsically local, does not take into account the presence of the symmetric well.

III. LANGER–CHERRY UNIFORM ASYMPTOTIC EXPANSION

In this section we discuss the calculation of a uniform (in the sense of being smooth across the classical turning points), Borel-summable asymptotic expansion for the double well. The basic strategy is the method of comparison equations[2,3] supplemented with the rigorous results on the analytic behavior of the coefficients by Langer[31,32] and Cherry,[33] and generalized by Lynn and Keller.[40] Gradual implementation of this general strategy for quantum oscillators can be traced back to the early work on the Stark effect by Silverstone *et al.*[41,42] In fact, the idea of matching two Borel-summable asymptotic expansions derived from Langer–Cherry wave functions to obtain discontinuity formulas for the eigenvalues of the quartic anharmonic oscillator with negative coupling constant is essentially contained in Ref. 42, and streamlined and carried out in detail to second order in Ref. 43. Likewise, application of similar methods to the calculation of asymptotic expansions for exponentially small splittings can be traced back at least to the work of Damburg and Propin,[44] where a symmetric double well is considered as a one-dimensional model for exchange forces in quantum chemistry, and especially to the calculation of the asymptotic expan-

sion for large distances of the energy levels of the hydrogen molecular ion by Čížek *et al.*[45] where the role of the Borel summability in the unambiguous calculation of the exponentially small subseries is carefully discussed.

As a first step we scale the independent variable to fix the position of the zeroth order double turning points, and to set g in the role, usually played by $\hbar$, of coefficient of the second-order derivative. The suitable scaling is

$$y=g^{-1/2}(z+1/2), \quad \Phi(y)=\psi(z), \tag{10}$$

which leads to the transformed equation

$$-\frac{g^2}{2}\psi''(z)+\left[z^2(1+z)^2-gE-\frac{1}{16}\right]\psi(z)=0. \tag{11}$$

We build the uniform asymptotic expansion around the minimum at $z=0$ where, aside from a constant term, the bracketed term in Eq. (11) behaves as z^2. Therefore we use as a comparison equation the Weber differential equation,[46] whose exponentially decreasing solution at large positive values of the argument [cf. Eq. (15) in the next section] is the parabolic cylinder function $D_\nu(z)$. Therefore we set

$$\psi(z)=[u'(z)]^{-1/2}D_{\nu/\sqrt{2}-1/2}[g^{-1/2}2^{3/4}u(z)], \tag{12}$$

which substituted into Eq. (11) leads to the equation for $u(z)$,

$$u(z)^2u'(z)^2=z^2(1+z)^2+g\left[\nu u'(z)^2-E(\nu)-\frac{1}{16g}\right]+\frac{g^2}{4}\{u,z\}, \tag{13}$$

where, as usual, $\{u,z\}$ stands for the Schwarzian derivative,

$$\{u,z\}=\frac{u'''(z)}{u'(z)}-\frac{3}{2}\left(\frac{u''(z)}{u'(z)}\right)^2.$$

At this point we call the reader's attention to the as yet unspecified parameter ν. In the next section we will see that the condition for the existence of eigenvalues (the modified quantization condition of Zinn-Justin) is precisely an equation for ν.

Following Langer and Cherry, we solve Eq. (13) by expanding both the function $u(z)$ and the eigenvalue $E(\nu)$ in asymptotic power series:

$$u(z)=\sum_{k=0}^{\infty}u_k(z)g^k,$$

$$E(\nu)=-\frac{1}{16g}+\sum_{k=0}^{\infty}E^{(k)}(\nu)g^k. \tag{14}$$

Substituting these asymptotic expansions into Eq. (13) and equating powers of g we arrive at a system of differential equations which can be solved recursively for the $u_k(z)$ in terms of elementary functions. We list here the first three equations, the last of which shows the general pattern because it already includes a contribution from the Schwarzian derivative,

$$\frac{\mathrm{d}}{\mathrm{d}z}[u_0(z)^2]=2z(1+z),$$

$$\frac{\mathrm{d}}{\mathrm{d}z}[u_0(z)u_1(z)]=\frac{E^{(0)}(\nu)}{2u_0(z)u_0'(z)}+\frac{\nu u_0'(z)}{2u_0(z)},$$

$$\frac{\mathrm{d}}{\mathrm{d}z}[u_0(z)u_2(z)]=\frac{E^{(1)}(\nu)}{2u_0(z)u_0'(z)}+\frac{\nu u_1'(z)}{u_0(z)}-\frac{u_0'(z)^2u_1(z)^2+u_0(z)^2u_1'(z)^2}{2u_0(z)u_0'(z)}-\frac{\{u_0,z\}}{8u_0(z)u_0'(z)}$$
$$-2u_1(z)u_1'(z).$$

Again, we draw on the results of Cherry,[33] which show that the $u_k(z)$ have to be chosen regular at $z=0$. The integration of the equation for $u_0(z)$ is immediate, yielding

$$u_0(z)=z\left(1+\frac{2z}{3}\right)^{1/2}.$$

Next, we note that for $k\geqslant 1$, if $u_k(z)$ is a solution of the corresponding differential equation, so is $u_k(z)+a/u_0(z)$ for any constant a. The integration of these equations for $k\geqslant 1$ is a two-step process: first, we fix the coefficient $E^{(k)}(\nu)$ to avoid the logarithmic singularity at $z=0$; second, we add a suitable multiple of $1/u_0(z)$ to avoid a simple pole at $z=0$ (this procedure is algorithmically easier to implement than the equivalent "integrate from 0 to z" prescription of Cherry[33]). Thus, to avoid a logarithmic singularity of $u_1(z)$ at $z=0$ we must set

$$E^{(0)}(\nu)=\nu,$$

and we get

$$2u_0(z)u_1(z)=\nu\ln[u_0(z)(1+z)/z].$$

Similarly, to avoid a logarithmic singularity in $u_2(z)$ we must set

$$E^{(1)}(\nu)=-\tfrac{1}{4}-\tfrac{3}{2}\nu^2,$$

and the corresponding regular function $u_2(z)$ is given by

$$u_1(z)^2+2u_0(z)u_2(z)=\frac{\nu u_1(z)}{u_0(z)}+\left[\frac{19}{48}-\frac{3}{16(1+z)^2}-\frac{1}{8(1+z)}-\frac{1}{4(3+2z)}\right]$$
$$+\nu^2\left[\frac{17}{8}-\frac{2}{3z}-\frac{1}{8(1+z)^2}-\frac{3}{4(1+z)}-\frac{1}{6(3+2z)}\right].$$

Although the explicit expressions of the $u_k(z)$ quickly become too unwieldy to be calculated by hand, the whole procedure can be easily programmed in a computer and carried out to high order. We list here the next three coefficients of the general asymptotic expansion for the energy $E(\nu)$,

$$E^{(2)}(\nu)=-\tfrac{19}{8}\nu-\tfrac{17}{4}\nu^3,$$

$$E^{(3)}(\nu)=-\tfrac{131}{64}-\tfrac{459}{16}\nu^2-\tfrac{375}{16}\nu^4,$$

$$E^{(4)}(\nu)=-\frac{22\,709}{256}\nu-\frac{23\,405}{64}\nu^3-\frac{10\,689}{64}\nu^5,$$

which are readily identified with the coefficients of the Rayleigh–Schrödinger perturbation series, except that the $E^{(k)}(\nu)$ are polynomials in the as yet unspecified $E_0(\nu)=\nu$.

IV. GENERALIZED QUANTIZATION CONDITION

As we mentioned in the Introduction, there are several methods to derive the generalized quantization condition, sometimes called the secular equation,[47] and there is even an ongoing discussion on whether the more general approaches are fully rigorous or contain unproved assumptions (see, for example, the discussions in Refs. 47 and 48 or the remarks after theorem 1.2.1 in Ref. 24; for yet an independent approach for polynomial potentials see Refs. 49–51).

Since our calculations are rather explicit, we will proceed in a straightforward manner. Note that, by construction, the Langer–Cherry solution (12) has the correct exponentially decreasing asymptotic behavior as z (and therefore y) tends to $+\infty$. Since the double-well potential $V(y)$ is even in y, we will impose the quantization condition by requiring that the solution (12) be even or odd in y or, on account of Eq. (10), that $\psi(-1/2)\neq 0$, $\psi'(-1/2)=0$ for the even solutions, and that $\psi(-1/2)=0$, $\psi'(-1/2)\neq 0$ for the odd solutions. To this end, we recall first the Borel-summable asymptotic expansions of the parabolic cylinder functions, and subsequently devote separate sections to the even and odd solutions. A final section deals with the solution of the generalized quantization condition.

A. Borel-summable asymptotic expansions of the parabolic cylinder functions

The sectors of Borel summability of the asymptotic expansions of the parabolic cylinder functions are ultimately determined by the branch point at $z=1$ of Gauss' hypergeometric function, and can be easily derived, for example, using the relation between the parabolic cylinder functions and the confluent hypergeometric functions.[52] The full expansions can be conveniently written in terms of the formal power series

$$ {}_2F_0(a,b;;z)=\sum_{k=0}^{\infty}(a)_k(b)_k\frac{z^k}{k!}, $$

where $(a)_k$ is the Pochhammer symbol

$$ (a)_0=1, \quad (a)_k=a(a+1)\cdots(a+k-1). $$

It turns out that the complex plane is divided into three nonoverlapping sectors separated by Stokes lines, and that within each of these sectors there is a uniquely defined Borel-summable asymptotic expansion as $z\to\infty$,

$$ D_\nu(z)\sim z^\nu e^{-z^2/4}\,{}_2F_0\left(-\frac{\nu}{2},\frac{1}{2}-\frac{\nu}{2};;-\frac{2}{z^2}\right), \quad -\frac{\pi}{2}<\arg z<\frac{\pi}{2}, \tag{15} $$

$$ \begin{aligned} D_\nu(z)\sim{}& z^\nu e^{-z^2/4}\,{}_2F_0\left(-\frac{\nu}{2},\frac{1}{2}-\frac{\nu}{2};;-\frac{2}{z^2}\right)\\ &+\frac{(2\pi)^{1/2}e^{\pm i\pi(\nu+1)}}{\Gamma(-\nu)}z^{-\nu-1}e^{z^2/4}\,{}_2F_0\left(\frac{1}{2}+\frac{\nu}{2},1+\frac{\nu}{2};;\frac{2}{z^2}\right), \quad \frac{\pi}{2}<\pm\arg z<\pi. \end{aligned} \tag{16} $$

It is worth noting that the expansions are not summable on the Stokes lines, which must be reached by continuity from either side. The validity of the subsequent formal operations with Borel-summable asymptotic expansions is established in Ref. 53.

B. Odd states

The quantization condition for odd states reads

$$ D_{\nu/\sqrt{2}-1/2}[2^{3/4}g^{-1/2}u(-1/2)]=0. \tag{17} $$

We have repeatedly noted that the negative real axis is a Stokes line for the Borel-summable asymptotic expansions of the parabolic cylinder function, and therefore we have to approach it from either side. For concreteness we give the coupling constant g a small positive argument and take

$$\arg g = \epsilon > 0, \quad \arg z = \pi.$$

The argument of the argument of the parabolic cylinder function is

$$\arg[2^{3/4} g^{-1/2} u(z)] = -\tfrac{1}{2}\arg g + \arg[u(z)] \sim -\tfrac{1}{2}\arg g + \arg[u_0(z)] \sim -\tfrac{1}{2}\arg g + \arg z = -\tfrac{1}{2}\epsilon + \pi,$$

and we have to use the plus sign in the asymptotic expansion (16). To simplify the notation, we introduce symbols for the following three formal power series in g whose coefficients are polynomials in ν:

$$u \equiv u\left(-\frac{1}{2}\right) = -\frac{1}{\sqrt{6}} + \sum_{k=1}^{\infty} c_k(\nu) g^k,$$

$$\Sigma_1 \equiv {}_2F_0\left(\frac{1}{4} - \frac{\nu}{2\sqrt{2}}, \frac{3}{4} - \frac{\nu}{2\sqrt{2}}; ; -\frac{g}{u^2\sqrt{2}}\right),$$

$$\Sigma_2 \equiv {}_2F_0\left(\frac{1}{4} + \frac{\nu}{2\sqrt{2}}, \frac{1}{4} + \frac{\nu}{2\sqrt{2}}; ; \frac{g}{u^2\sqrt{2}}\right),$$

where we have separated explicitly the constant term in u; the constant terms in Σ_1 and Σ_2 are obviously 1. Imposing the quantization condition (17) is now straightforward: we substitute the preceding series into the the right-hand side (with the plus sign) of Eq. (16) and find that the parameter ν must be a solution of the equation

$$(2^{3/4} g^{-1/2} u)^{\sqrt{2}\nu} \exp\left[-\frac{2^{1/2} u^2}{g}\right] \frac{\Sigma_1}{\Sigma_2} = -\frac{i(2\pi)^{1/2} e^{i\pi\nu/\sqrt{2}}}{\Gamma\left(\frac{1}{2} - \frac{\nu}{\sqrt{2}}\right)}.$$

To rewrite this quantization condition in a more convenient form we use the following gamma function reflection formula:

$$\Gamma\left(\frac{1}{2} + z\right)\Gamma\left(\frac{1}{2} - z\right) = \frac{\pi}{\cos(\pi z)},$$

and define a function

$$f(\nu) = \frac{i(2\pi)^{1/2}}{\Gamma\left(\frac{1}{2} + \frac{\nu}{\sqrt{2}}\right)} \left(-\frac{2^{3/4} u}{g^{1/2}}\right)^{\sqrt{2}\nu} \exp\left[-\frac{2^{1/2} u^2}{g} + \ln\frac{\Sigma_1}{\Sigma_2}\right]. \tag{18}$$

Then, the quantization condition reads

$$f(\nu) = 1 + e^{-i\pi\sqrt{2}\nu}.$$

By separating the leading behavior of u in the definition of $f(\nu)$ we can show explicitly its dependence as a function of the coupling constant g,

$$f(\nu)=\frac{i(2\pi)^{1/2}2^{3\nu/2\sqrt{2}}}{\Gamma\left(\frac{\nu}{\sqrt{2}}+\frac{1}{2}\right)}\exp\left[-\frac{1}{3\sqrt{2}}\left(\frac{1}{g}+3\nu\ln g+\sum_{k=1}^{\infty}F^{(k)}(\nu)g^{k}\right)\right], \tag{19}$$

where the $F^{(k)}(\nu)$ turn out to be polynomials in ν which can be calculated explicitly in principle to any desired order. We list here the first three, which again will be enough to show the pattern,

$$F^{(1)}(\nu)=\tfrac{19}{8}+\tfrac{51}{4}\nu^{2},$$

$$F^{(2)}(\nu)=\tfrac{459}{16}\nu+\tfrac{375}{8}\nu^{3},$$

$$F^{(3)}(\nu)=\frac{22\,709}{768}+\frac{23\,405}{64}\nu^{2}+\frac{17\,815}{64}\nu^{4}.$$

A comparison of these coefficients with the coefficients $E^{(k)}(\nu)$ shows immediately that the former can be easily written in terms of the latter,

$$F^{(k)}(\nu)=-\frac{1}{k}\frac{\partial E^{(k+1)}(\nu)}{\partial\nu}. \tag{20}$$

If we accept this conjecture, which we have checked explicitly up to $k=10$ but of which we do not have a formal proof, the expression for $f(\nu)$ can be written even more concisely in terms of the general asymptotic series for the eigenvalues $E(\nu)$ defined in Eq. (14):

$$f(\nu)=\frac{i(2\pi)^{1/2}2^{3\nu/2\sqrt{2}}}{\Gamma\left(\frac{\nu}{\sqrt{2}}+\frac{1}{2}\right)}\exp\left[\frac{1}{3\sqrt{2}}\int\frac{\partial E(\nu)}{\partial\nu}\frac{\mathrm{d}g}{g^{2}}\right].$$

From the theoretical point of view the validity of this equation would show that all the information required to calculate the complete asymptotic expansion for the energy levels in the double well is essentially contained in the coefficients of the Rayleigh–Schrödinger perturbation series when expanded as polynomials in the quantum number. Likewise, from a practical, algorithmic point of view, this relation gives an extremely simple and efficient method to calculate the $F^{(k)}(\nu)$ to very high order, avoiding the integration of the differential equation for $u(z)$; these high-order calculations have been recently of some interest for the numerical study of the Borel summation (with subsequent continuation to the real axis) of the multi-instanton series.[20] Finally, we remark that an observation equivalent to Eq. (20) was made by Hoe *et al.*[36] who, in the context of the Stark effect in hydrogenic ions, noticed that the ionization rates could be expressed in terms of the energies by a similar formula. (In fact, the Stark effect Hamiltonian, after separation in parabolic coordinates, is equivalent to a two-dimensional isotropic quartic oscillator.)

C. Even states

Although a parity argument could be invoked at this point, as a consistency check of the Langer–Cherry method we have also calculated the quantization condition for the even states directly as $\psi'(-1/2)=0$, which in terms of the parabolic cylinder and $u(z)$ functions reads

$$\frac{g^{1/2}}{2^{7/4}}\frac{u''(-1/2)}{u'(-1/2)^{2}}=\frac{D'_{\nu/\sqrt{2}-1/2}[2^{3/4}g^{-1/2}u(-1/2)]}{D_{\nu/\sqrt{2}-1/2}[2^{3/4}g^{-1/2}u(-1/2)]},$$

which using a recurrence relation[46] to eliminate the derivative of the parabolic cylinder function can be rewritten as

$$\frac{u(-1/2)}{2^{1/4}g^{1/2}}-\frac{g^{1/2}}{2^{7/4}}\frac{u''(-1/2)}{u'(-1/2)^2}=\frac{D_{\nu/\sqrt{2}+1/2}[2^{3/4}g^{-1/2}u(-1/2)]}{D_{\nu/\sqrt{2}-1/2}[2^{3/4}g^{-1/2}u(-1/2)]}. \tag{21}$$

We use the same notation of the odd case, denoting by u' and u'' the power series for $u'(-1/2)$ and $u''(-1/2)$, respectively, by σ the power series for the left-hand side of Eq. (21), i.e.,

$$\sigma=\frac{u}{2^{1/4}g^{1/2}}-\frac{g^{1/2}}{2^{7/4}}\frac{u''}{(u')^2},$$

and by Σ_3 and Σ_4 the generalized hypergeometric series corresponding to the parabolic cylinder function in the numerator of the right-hand side of Eq. (21),

$$\Sigma_3\equiv{}_2F_0\left(-\frac{1}{4}-\frac{\nu}{2\sqrt{2}},\frac{1}{4}-\frac{\nu}{2\sqrt{2}};;-\frac{g}{u^2\sqrt{2}}\right),$$

$$\Sigma_4\equiv{}_2F_0\left(\frac{3}{4}+\frac{\nu}{2\sqrt{2}},\frac{5}{4}+\frac{\nu}{2\sqrt{2}};;\frac{g}{u^2\sqrt{2}}\right).$$

Proceeding as in the odd case we arrive at the even quantization condition, whose only difference with the odd quantization condition is that in Eq. (18) we must make the replacement,

$$\ln\frac{\Sigma_1}{\Sigma_2}\to\ln\frac{\sigma\Sigma_1+\left(\frac{2^{3/2}u^2}{g}\right)\Sigma_3}{\sigma\Sigma_2+\left(\frac{1}{2}+\frac{\nu}{\sqrt{2}}\right)\Sigma_4},$$

and by substitution of the preceding power series we have checked that

$$\ln\frac{\sigma\Sigma_1+\left(\frac{2^{3/2}u^2}{g}\right)\Sigma_3}{\sigma\Sigma_2+\left(\frac{1}{2}+\frac{\nu}{\sqrt{2}}\right)\Sigma_4}=\ln\frac{\Sigma_1}{\Sigma_2}-i\pi.$$

Therefore, the generalized quantization conditions can be written in the form

$$\pm f(\nu)=1+e^{-i\pi\sqrt{2}\nu},$$

where the plus sign corresponds to odd states and the minus sign to even states. To avoid carrying this double sign, hereafter we will write explicitly the equations for the odd states. The corresponding equations for even states can be recovered immediately by reversing the sign of f and its derivatives.

D. Solution of the generalized quantization condition

In the absence of the second well, the (standard) quantization condition would simply be that the exponentially increasing term in the compound asymptotic expansion for the parabolic cylinder function $D_{\nu/\sqrt{2}-1/2}(2^{3/4}g^{-1/2}u)$ be missing, i.e., that ν be a pole of the gamma function $\Gamma(1/2-\nu/\sqrt{2})$. Then we would have $\nu=\sqrt{2}(n+1/2)=E_n^{(0)}$ $(n=0,1,2,\ldots)$, and we would recover the Rayleigh–Schrödinger perturbation theory series.

Equation (19) shows that, although different from zero, $f(\nu)$ is an exponentially small function of g for $\mathrm{Re}\,g>0$, and therefore we seek solutions of the generalized matching condition in the form

$$\nu_n=\sqrt{2}(n+\tfrac{1}{2}+\Delta n)\quad (n=0,1,2,\ldots),$$

where the correction Δn will be expanded in series of successively exponentially smaller terms. To keep track easily of the exponentially small order we introduce a parameter λ (that ultimately will be set to one) multiplying the matching function $f(\nu)$ and as the ordering parameter in the series for Δn. That is to say, we write the generalized quantization condition in the form

$$\Delta n=\frac{i}{2\pi}\ln\left[1-\lambda f\left(\sqrt{2}\left(n+\frac{1}{2}+\Delta n\right)\right)\right],$$

where

$$\Delta n=\lambda\Delta n_1+\lambda^2\Delta n_2+\lambda^3\Delta n_3+\cdots.$$

By Taylor expansion of the right-hand side of this equation we can find immediately as many corrections Δn_k as desired. Again, we list sufficiently many terms to illustrate the general pattern of the multi-instanton expansion calculated in the next section,

$$\Delta n_1=-\frac{i}{2\pi}f_n,$$

$$\Delta n_2=-\frac{i}{4\pi}f_n^2-\frac{1}{2\sqrt{2}\pi^2}f_nf_n',$$

$$\Delta n_3=-\frac{i}{6\pi}f_n^3-\frac{3}{4\sqrt{2}\pi^2}f_n^2f_n'+\frac{i}{4\pi^3}f_n(f_n')^2+\frac{i}{8\pi^3}f_n^2f_n'',$$

where the primes denote derivatives with respect to ν, and a subindex n denotes the value of the function $f(\nu)$ and its derivatives with respect to ν evaluated at $\nu=\sqrt{2}(n+1/2)$.

V. THE MULTI-INSTANTON EXPANSION

The asymptotic expansion for the eigenvalues of the symmetric double well, i.e., the multi-instanton expansion, is obtained by substitution of the values ν_n into the general asymptotic expansion $E(\nu)$ of Eq. (14). This procedure involves a composition of two Taylor expansions, and the final results are slightly simpler if the derivatives with respect to ν are replaced by derivatives with respect to n with the rule $\partial/\partial\nu=2^{-1/2}\partial/\partial n$. So, the expansion for the eigenvalues up to third exponentially small order is obtained from

$$E\sim E_n+\frac{\sqrt{2}\Delta n}{1!}E_n'+\frac{(\sqrt{2}\Delta n)^2}{2!}E_n''+\frac{(\sqrt{2}\Delta n)^3}{3!}E_n'''+\cdots,$$

which in terms of derivatives of E_n with respect to n can be rewritten as

$$E\sim E_n+\frac{\Delta n}{1!}\frac{\partial E_n}{\partial n}+\frac{(\Delta n)^2}{2!}\frac{\partial^2E_n}{\partial n^2}+\frac{(\Delta n)^3}{3!}\frac{\partial^3E_n}{\partial n^3}+\cdots.$$

Substituting in this expansion the expression for the Δn_k and collecting powers of λ, we write the multi-instanton expansion in the form

$$E\sim E_n+\Delta E_1+\Delta E_2+\Delta E_3+\cdots,$$

where we have already set $\lambda=1$, the subindex labels the exponentially small order, and the explicit expressions for the first three instanton contributions (in terms of derivatives with respect to n) are

$$\Delta E_1 = -\frac{i}{2\pi}\left(f_n \frac{\partial E_n}{\partial n}\right),$$

$$\Delta E_2 = \left[-\frac{i}{4\pi} - \frac{1}{8\pi^2}\frac{\partial}{\partial n}\right]\left(f_n^2 \frac{\partial E_n}{\partial n}\right),$$

$$\Delta E_3 = \left[-\frac{i}{6\pi} - \frac{1}{8\pi^2}\frac{\partial}{\partial n} + \frac{i}{48\pi^3}\frac{\partial^2}{\partial n^2}\right]\left(f_n^3 \frac{\partial E_n}{\partial n}\right).$$

To proceed with the evaluation of the ΔE_k, note that

$$f_n = i\frac{(2\pi)^{1/2}}{\Gamma(n+1)}\left(\frac{2\sqrt{2}}{g}\right)^{n+1/2} e^{-1/3\sqrt{2}g}\left(\sum_{k=0}^{\infty} \gamma_k g^k\right),$$

where the formal power series in the right-hand side of the last equation is defined by

$$\sum_{k=0}^{\infty} \gamma_k g^k \equiv \exp\left[-\frac{1}{3\sqrt{2}}\sum_{k=1}^{\infty} F_n^{(k)} g^k\right] = \exp\left[\frac{1}{6}\sum_{k=1}^{\infty}\frac{1}{k}\frac{\partial E_n^{(k+1)}}{\partial n} g^k\right].$$

Therefore, it is convenient to define the exponentially small coefficient,

$$\xi(n) = \frac{(2\pi)^{1/2}}{\Gamma(n+1)}\left(\frac{2\sqrt{2}}{g}\right)^{n+1/2} e^{-(1/3\sqrt{2}g)}, \tag{22}$$

and the family of power series in g (whose coefficients are again polynomials in $n+1/2$),

$$b_p(n) \equiv \exp\left[-\frac{p}{3\sqrt{2}}\sum_{k=1}^{\infty} F_n^{(k)} g^k\right]\left(\frac{\partial E_n}{\partial n}\right) = \exp\left[\frac{p}{6}\sum_{k=1}^{\infty}\frac{1}{k}\frac{\partial E_n^{(k+1)}}{\partial n} g^k\right]\left(\frac{\partial E_n}{\partial n}\right), \tag{23}$$

so that the function in which the differential operator acts in the expression of ΔE_k is

$$f_n^k \frac{\partial E_n}{\partial n} = i^k \xi(n)^k b_k(n) \quad (k = 1,2,\ldots).$$

Furthermore, we denote

$$\ell = \ln\left(\frac{g}{2\sqrt{2}}\right),$$

so that the derivative with respect to n of the exponentially small coefficient $\xi(n)$ can be written as

$$\xi'(n) = -[\psi(n+1) + \ell]\xi(n),$$

where ψ denotes the logarithmic derivative of the gamma function. [Incidentally, the coefficients of the second instanton contribution are usually[20,22] given in terms of Euler's constant γ; the relation between the two expressions is[46] $\psi(n+1) = -\gamma + \Sigma_{k=1}^{n} k^{-1}$.]

With this notation, the explicit expressions for the one-, two-, and three-instanton contributions read as

$$\Delta E_1 = \frac{\xi(n)}{2\pi} b_1(n), \tag{24}$$

$$\Delta E_2=\frac{\xi(n)^2}{8\pi^2}[b_2'(n)-2b_2(n)(\psi(n+1)+\ell)+2\pi i b_2(n)], \tag{25}$$

$$\Delta E_3=\frac{\xi(n)^3}{48\pi^3}[b_3''(n)-6b_3'(n)(\psi(n+1)+\ell)-b_3(n)[3\psi'(n+1)-9(\ell+\psi(n+1))^2+8\pi^2]$$
$$+6\pi i[b_3'(n)-3b_3(n)(\ell+\psi(n+1))]]. \tag{26}$$

This procedure can be applied without any difficulty to calculate explicitly higher exponentially small corrections. Note that, in general, the solution for Δn_k is a sum of homogeneous terms of degree k in f_n and its derivatives up to $f_n^{(k-1)}$. Since the logarithmic terms come from these derivatives, the expression for ΔE_k will contain $\ell=\ln(g/2\sqrt{2})$ up to the power $k-1$, which is precisely the structure of the multi-instanton expansion as a function of g. Note also that for $k\geqslant 3$ the expression for ΔE_k includes polygamma functions evaluated at integers or, equivalently, Riemann zeta functions.

If we rearrange the preceding expressions for ΔE_k by grouping powers of ℓ, and display explicitly all the dependence on the coupling constant g, we find expansions of the form

$$\Delta E_k=\left(\frac{2\sqrt{2}}{g}\right)^{(n+1/2)k} e^{-k/3\sqrt{2}g}\sum_{m=0}^{k-1}\left[\ln\left(\frac{g}{2\sqrt{2}}\right)\right]^m\sum_{l=0}^{\infty}c_{knml}g^l,$$

which can be easily compared with Eq. (7) of Ref. 20 in which the quantum number (here n) is denoted by N, the order of the instanton contribution (here k) is denoted by n, $g_{(\text{here})}=\sqrt{2}g_{(\text{Ref. 20})}$ and $E_{(\text{here})}=\sqrt{2}E_{(\text{Ref. 20})}$, where the latter two relations follow because we have proceeded by analytic continuation of the standard quartic anharmonic oscillator Hamiltonian [compare the Hamiltonian (1) in Ref. 20 and the Schrödinger equation (11) of the present paper]. To give some examples using only results given explicitly in this paper, from Eqs. (22) and (23) for $p=1$ and (24) as well as the explicit formulas (4)–(9) for the Rayleigh–Schrödinger coefficients as polynomials in $(n+1/2)$ we find

$$\Delta E_1=\frac{1}{2\pi}\frac{(2\pi)^{1/2}}{\Gamma(n+1)}\left(\frac{2\sqrt{2}}{g}\right)^{n+1/2}e^{-(1/3\sqrt{2}g)}\exp\left[\frac{1}{6}\sum_{k=1}^{\infty}\frac{1}{k}\frac{\partial E_n^{(k+1)}}{\partial n}g^k\right]\left(\frac{\partial E_n}{\partial n}\right)$$
$$=\frac{1}{n!\,\pi^{1/2}}\left(\frac{2\sqrt{2}}{g}\right)^{n+1/2}e^{-(1/3\sqrt{2}g)}\left[1-\left[\frac{19}{24}+6\left(n+\frac{1}{2}\right)+\frac{17}{2}\left(n+\frac{1}{2}\right)^2\right]\left(\frac{g}{\sqrt{2}}\right)-\left[\frac{5111}{1152}\right.\right.$$
$$\left.\left.+\frac{115}{8}\left(n+\frac{1}{2}\right)+\frac{2125}{48}\left(n+\frac{1}{2}\right)^2+\frac{23}{2}\left(n+\frac{1}{2}\right)^3-\frac{289}{8}\left(n+\frac{1}{2}\right)^4\right]\left(\frac{g}{\sqrt{2}}\right)^2+\cdots\right],$$

which particularized for $n=0$ reproduces (with due account of the $\sqrt{2}$ factors in the definitions of g and E and recalling that our expressions pertain to the odd states) the corresponding values reported in Eqs. (8) and (9) of Ref. 20. Or, stated directly in terms of $b_1(n)$,

$$\frac{b_1(0)}{\sqrt{2}}=1-\frac{71}{12}\left(\frac{g}{\sqrt{2}}\right)-\frac{6299}{288}\left(\frac{g}{\sqrt{2}}\right)^2-\cdots.$$

Likewise, the explicit expressions for the first three terms of $b_2(n)$ and $b_3(n)$ can be readily calculated from the definition (23) and the coefficients (4)–(9):

$$b_2(n)=\sqrt{2}\left[1-\left[\frac{19}{12}+6\left(n+\frac{1}{2}\right)+17\left(n+\frac{1}{2}\right)^2\right]\left(\frac{g}{\sqrt{2}}\right)-\left[\frac{1007}{288}+\frac{115}{4}\left(n+\frac{1}{2}\right)+\frac{289}{12}\left(n+\frac{1}{2}\right)^2\right.\right.$$
$$\left.\left.+23\left(n+\frac{1}{2}\right)^3-\frac{289}{2}\left(n+\frac{1}{2}\right)^4\right]\left(\frac{g}{\sqrt{2}}\right)^2+\cdots\right], \tag{27}$$

$$b_3(n)=\sqrt{2}\left[1-\left[\frac{19}{8}+6\left(n+\frac{1}{2}\right)+\frac{51}{2}\left(n+\frac{1}{2}\right)^2\right]\left(\frac{g}{\sqrt{2}}\right)-\left[\frac{247}{128}+\frac{345}{8}\left(n+\frac{1}{2}\right)-\frac{153}{16}\left(n+\frac{1}{2}\right)^2\right.\right.$$
$$\left.\left.+\frac{69}{2}\left(n+\frac{1}{2}\right)^3-\frac{2601}{8}\left(n+\frac{1}{2}\right)^4\right]\left(\frac{g}{\sqrt{2}}\right)^2+\cdots\right]. \tag{28}$$

And using Eqs. (25) and (27) particularized for $n=0$ and the relation $\psi(1)=-\gamma$ we can easily reproduce the rest of the coefficients in Eq. (8) of Ref. 20,

$$\frac{b_2(0)}{\sqrt{2}}=1-\frac{53}{6}\left(\frac{g}{\sqrt{2}}\right)-\frac{1277}{72}\left(\frac{g}{\sqrt{2}}\right)^2-\cdots,$$

$$\frac{b_2'(0)-2\psi(1)b_2(0)}{2\sqrt{2}}=\gamma+\left(-\frac{23}{2}-\frac{53}{6}\gamma\right)\left(\frac{g}{\sqrt{2}}\right)+\left(\frac{13}{12}-\frac{1277}{72}\gamma\right)\left(\frac{g}{\sqrt{2}}\right)^2+\cdots.$$

Note that Jentschura and Zinn-Justin state their results in terms of their $\lambda(g)=\ln(-2/g)=-\ln(g/2)+i\pi$, thus grouping formally real and formally complex terms. In our form (24)–(26) of the expressions for the instanton contributions ΔE_k we have kept explicitly separated the formally real and the formally purely imaginary parts of the expansions, among which there is a sequence of cancellations whereby the implicit imaginary parts which arise from the (continuation to the positive real axis of the) Borel sum of the formally real series are canceled by the higher order explicitly imaginary parts. These cancellations where noted by Damburg and Propin[54] in the context of the Stark effect for the hydrogen atom, who in addition conjectured their equivalence to a sequence of dispersion relations. In turn, this sequence, considered from the point of view of the Laplace transformation of ramified functions, is the hallmark of resurgent functions.[48]

The symmetric double well studied in this paper is special in that, provided the conjecture (20) is true, the complete multi-instanton expansion can be generated from the knowledge of the Rayleigh–Schrödinger perturbation theory coefficients expressed as polynomials in the quantum number. As pointed out by Zinn-Justin,[21] in general both the perturbative and one-instanton contributions (equivalently, the $E_n^{(k)}$ and $F_n^{(k)}$ coefficients) are needed to determine the complete multi-instanton expansion. We stress that the Langer–Cherry method presented in this paper is independent of this conjecture, and that it can be applied in the general case. Finally, we also point out that the same method with an obvious modification can be applied for nonsymmetric double wells: since the parity of the eigenstates is lost, the generalized quantization condition is obtained by matching under the barrier the asymptotic expansions of two Langer–Cherry wave functions anchored in the left and right well, respectively. Each one would be calculated exactly by the method of Sec. III [with its own Rayleigh–Schrödinger series and $u(z)$ function], and the matching can be implemented most easily by equating the ratio of the dominant to the subdominant parts of the respective asymptotic expansions on each well.

published online 6 July 2004)

To treat the front-form Hamiltonian approach to quantum field theory, called light cone quantum field theory, in a mathematically rigorous way, the existence of a well-defined restriction of the corresponding free fields to the hypersurface $\{x^0+x^3=0\}$ in Minkowski space is of an essential necessity. However, even in the situation of a real scalar free field such a restriction does canonically not exist; this is called the restriction problem. Furthermore, since the beginning of light cone quantum field theory there is the problem of nonexistence of a well-defined Fock space expansion of a free quantum field in terms of light cone momenta which is called the zero-mode problem. In this paper we present solutions to these long outstanding problems where the study of the zero-mode problem (of the corresponding classical field) will lead us to a solution of the restriction problem. We introduce a new function space of ''squeezed'' smooth functions which can canonically be embedded into the Schwartz space $\mathcal{S}(\mathbb{R}^3)$. The restriction of the free field to $\{x^0+x^3=0\}$ is canonically definable on this function space and we show that the covariant field is uniquely determined by this ''tame'' restriction. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1765746]

I. INTRODUCTION

In studying the strong coupling regime of nonperturbative QCD, quantization of a field theory on the light cone (light cone quantization) is a promising technique to overcome hard problems of classical QCD. There is vast literature on this subject and we refer the interested reader to Ref. 4, and the references therein.

The fundamental idea goes back to Dirac.[7] Let $\mathbb{M}$ denote four-dimensional Minkowski space with coordinates $x=(x^0,x^1,x^2,x^3)=(x^0,\mathbf{x})$. Usually, the dynamics of a physical observable is described by an initial value problem. For example, if $\phi(x^0,\mathbf{x})$ is the amplitude of a classical Klein–Gordon field, then the dynamics of ϕ is determined by $(\Box+m^2)\phi=0$ and by the values of ϕ and $\partial_0\phi$ on the (hyper)plane $\{x=(x^0,\mathbf{x})\in\mathbb{M}:x^0=0\}$ (initial data). As usual, $\Box=\partial^\mu\partial_\mu=\partial_0^2-\Sigma_{i=1}^3\partial_i^2$ denotes the d'Alembert operator. This form of dynamics is called the *instant form*. In Ref. 7, Dirac suggested another form of dynamics, called the *front form*, where the initial data instead are given on the null plane $\Sigma=\{x\in\mathbb{M}:x^0+x^3=0\}$ and the propagation of ϕ is parametrized by different values of $x^0+x^3=\text{const}$. The starting point of the light cone (or light front) quantization is just the use of this front form to describe the dynamics of a quantum field. Note that Σ is a so-called characteristic surface of the Klein–Gordon equation, and it is well known[11] that uniqueness of a solution cannot be guaranteed any more (we treat this problem in Ref. 21 in more detail). Introducing light cone coordinates (LC-coordinates) $\tilde{x}=(x^+,x^1,x^2,x^-)=\kappa(x)$, where $x^\pm=(1/\sqrt{2})(x^0\pm x^3)$ (we use the Kogut–Soper convention[4]) we can describe the front form dynamics of ϕ in this new coordinate system as follows:

Let $\tilde{\phi}=\tilde{\phi}(\tilde{x})=\phi\circ\kappa^{-1}$ be the transformation of ϕ to LC-coordinates. Then the front form dynamics of ϕ is given by $(\tilde{\Box}+m^2)\tilde{\phi}=0$ and by the values of $\tilde{\phi}$ (we will see that derivatives of

a)Electronic mail: ullrichp@in.tum.de

$\tilde{\phi}$ are unnecessary) on the hyperplane $\{\tilde{x}=(x^+,x^1,x^2,x^-)\in\mathbb{R}^4: x^+=0\}$. Here, $\tilde{\Box}=\partial^{\tilde{\mu}}\partial_{\tilde{\mu}}=2\partial_+\partial_- -\Sigma_{i=1}^2\partial_i^2$ denotes the transformed d'Alembert operator to LC-coordinates. Thus, in the following, we are interested in the restriction of $\tilde{\phi}$ to $\{x^+=0\}$.

In this paper we will treat quantum fields in a mathematically rigorous way as operator-valued (tempered) distributions in the sense of Wightman.[20,3] Roughly spoken, a quantum field is a continuous function $f\mapsto\phi(f)$ (Ref. 22) on the test function space $\mathcal{S}(\mathbb{R}^4)$ of rapidly decreasing, smooth, complex-valued functions where, for fixed $f\in\mathcal{S}(\mathbb{R}^4)$, $\phi(f)$ is a linear operator defined on a common dense subspace of a Hilbert space $\mathcal{H}$. In addition, it is given a unitary representation of the proper Poincaré group (or the spinor Poincaré group), and all these have to fulfill the Wightman axioms. But, in this context, what should be the restriction of ϕ to $\{x\in\mathbb{M}:x^0=0\}$ or to $\Sigma=\{x\in\mathbb{M}:x^0+x^3=0\}$? The Wightman axioms do not require the existence of the restriction of a quantum field to a hypersurface.

In Ref. 16, Reed and Simon describe the restriction of a scalar free field ϕ of mass >0 to the hyperplane $\{x\in\mathbb{M}:x^0=0\}$. The restriction is defined as an operator-valued distribution on $\mathcal{S}(\mathbb{R}^3)$. If one wants to define the restriction of ϕ to the null plane $\Sigma=\{x\in\mathbb{M}:x^0+x^3=0\}$ in an analogous way, one is faced with a divergent integral of the form $\int_{x^+>0}(d^3x/2x^+)\,|g(x)|$ $(g\in\mathcal{S}(R^3))$ (Ref. 13)—notice that the function $\Theta(x^+)/x^+$ is not locally integrable. Hence the restriction $\phi|_\Sigma$ of the field ϕ to Σ cannot be defined canonically on the test function space $\mathcal{S}(\mathbb{R}^3)$. However, if one remains in an appropriate proper subspace of $\mathcal{S}(\mathbb{R}^3)$, then the restriction of ϕ to Σ can be defined in the same way as in the Minkowski case. This was done in Ref. 13, where Leutwyler *et al.* pointed out some features of fields on the null plane Σ. Among them they showed that the restrictions of two free scalar fields of different masses (>0) to Σ are unitary equivalent. This is, however, in contrast to the Minkowski case where it is well known that two free scalar fields of different masses give rise to inequivalent restrictions to $\{x^0=0\}$ (cf., e.g., Ref. 16). The reason for this difference lies in the fact that the fields on the null plane are independent of mass and hence this also holds true for the two-point function of a free scalar field on the null plane. Schlieder and Seiler[18] interpreted this feature as a hint that the test function space—a proper subspace of $\mathcal{S}(\mathbb{R}^3)$—on which the fields on the null plane are defined is too restricted. Hence the general question arises whether one throws away physical information by using the restricted test function space in the definition of the null plane fields. Since the fields on the null plane are independent of mass it is clear that the information about the (rest) mass gets lost. In this paper we will show that this is all one loses, i.e., given the mass and the restricted field on the null plane one can restore the covariant field (cf. Theorem VI.7 and Sec. VII). The keystone to prove this is the introduction of a new test function space $\mathcal{S}_{\partial_-}(\mathbb{R}^n)$ which is in our opinion the canonical choice to define the restrictions on the null plane. Since also in the covariant theory the mass is yet a parameter and has to be known *a priori*, the loss of the mass on the null plane is not really a disadvantage of the theory—the mass enters the theory through the Hamiltonian.

A systematic study of fields on the null plane was also done by Driessler.[8,9] Driessler puts his investigations on an axiomatic basement. The fields on the null plane should be defined as operator-valued distributions on the test function space $\mathcal{S}^{(1)}(\mathbb{R}^n)$ (see also Ref. 18), where for technical reasons Driessler introduced the family of test functions $\mathcal{S}^{(\nu)}(\mathbb{R}^n)=\{f\in\mathcal{S}(\mathbb{R}^n): f=\partial_{x^-}^\nu F,\ F\in\mathcal{S}(\mathbb{R}^n)\}$ and $\mathcal{T}_{0,n}=\mathcal{T}_0(\mathbb{R})\otimes\mathcal{D}(\mathbb{R}^{n-1})$, $\mathcal{T}_0(\mathbb{R})=\cap_\nu\mathcal{S}^{(\nu)}(\mathbb{R})$. It turns out that our test function space is related to Driessler's test function spaces by $\mathcal{S}_{\partial_-}(\mathbb{R}^n)=\cap_\nu\mathcal{S}^{(\nu)}(\mathbb{R}^n)$. However, Driessler uses mostly the test function spaces $\mathcal{S}^{(1)}(\mathbb{R}^n)$ and $\mathcal{S}^{(2)}(\mathbb{R}^n)$ in his assertions. In the question of using a "minimal" test function space, as e.g., $\mathcal{T}_{0,n}$, to obtain analogous results Driessler pointed out that unfortunately this lies outside the scope of his methods,[9] Sec. III 3. Nevertheless the results of Driessler are interesting, especially Driessler's no go theorem which gives sufficient conditions for a field to be a free field. However, there is still a gap between Driessler's no go theorem and an analog of Haag's theorem for fields on the null plane. Therefore Driessler suggests in Ref. 9, Sec. IV 2, to investigate the: $P(\phi)_2$:-theories on the null plane which might be possible by using the results of this paper.

In contrast to the former literature, e.g. Refs. 8, 9, 13, 18, where the test function spaces are

given by *ad hoc* definitions to guarantee convergence of the integral $\int_{x^+>0}(d^3x/2x^+)\,|g(x)|$ ($g \in \mathcal{S}(R^3)$) our test function space $\mathcal{S}_{\partial_-}(\mathbb{R}^n)$ arises in a very natural way by adapting the construction of the time zero field as in Ref. 16 to the LC-case (see the commutative diagram (20))—hence $\mathcal{S}_{\partial_-}(\mathbb{R}^n)$ should be the canonical choice to define the restriction of quantum fields to the null plane.

There are early attempts to formulate light-cone field theory in close relationship with covariant field theory, e.g. Ref. 6. However, even in the conventional formalism of quantum fields, i.e., treating fields not as operator-valued distributions, technical problems appeared. The most important one is the so-called zero-mode (or infrared) problem which states that a real scalar free field does not admit a well-defined Fock space expansion in terms of light cone momenta $\tilde{\mathbf{p}}$. To be more precise, the proposed expansion

$$\tilde{\phi}(\tilde{x}) = \frac{1}{(2\pi)^3}\int_{p^+>0}\frac{d^3\tilde{\mathbf{p}}}{2p^+}(\tilde{a}(\tilde{\mathbf{p}})\,e^{-i(x^+\tilde{\omega}(\tilde{\mathbf{p}})+x^-p^+-\mathbf{x}_\perp\cdot\mathbf{p}_\perp)} + \tilde{a}^+(\tilde{\mathbf{p}})\,e^{i(x^+\tilde{\omega}(\tilde{\mathbf{p}})+x^-p^+-\mathbf{x}_\perp\cdot\mathbf{p}_\perp)}) \quad (1)$$

of the Klein–Gordon LC-field $\tilde{\phi}$, which is the transformation $\tilde{\phi}=\phi\circ\kappa^{-1}$ of the Klein–Gordon field ϕ, was seen to be ill-defined since the nonlocally integrable function $\Theta(p^+)/p^+$ appears in the integral. This technical insufficiency has led to pessimism in the development of light cone quantum field theory. However, on the level of Feynman graphs this problem could be avoided as was shown by Ligterink and Bakker.[15] From the point of view of conventional QFT, the restriction of $\tilde{\phi}$ to $\{x^+=0\}$ would not cause any problem if the expansion (1) has been successfully well defined; one just has to put $x^+=0$ in (1). Notice that ϕ, as a solution of the Klein–Gordon equation, has the plane wave expansion

$$\phi(x) = \frac{1}{(2\pi)^3}\int\frac{d^3\mathbf{p}}{2\omega(\mathbf{p})}(a(\mathbf{p})\,e^{-i(x^0\omega(\mathbf{p})-\mathbf{x}\cdot\mathbf{p})} + a^+(\mathbf{p})\,e^{i(x^0\omega(\mathbf{p})-\mathbf{x}\cdot\mathbf{p})}), \quad (2)$$

where $\omega(\mathbf{p})=\sqrt{\mathbf{p}^2+m^2}$ is locally integrable.

Since the investigation of the zero-mode problem (of the classical Klein–Gordon field) leads us in a very natural way to a solution of the restriction problem and since, afterwards, the solution of the restriction problem gives us a way to produce a well-defined Fock space expansion of the real scalar free field, i.e., a solution of the zero-mode problem of the quantized Klein–Gordon field, we treat both problems in this paper. From a general point of view these two problems are really the same. This becomes obvious if one has in view that both problems arise from the appearance of the nonlocally integrable function $\Theta(x^+)/x^+$ which causes the divergences.

The paper is organized as follows. After introducing notations from light cone physics in Sec. II, we investigate the zero-mode problem of the classical Klein–Gordon field in Sec. III. The main result of this section states that the zero-mode problem of the classical Klein–Gordon field does not really exist. We obtain a mapping, denoted ν, cf. (15), which tells us, how we have to transform the amplitudes $a(\mathbf{p})$ and $a^+(\mathbf{p})$, starting from (2), to obtain an expansion (1). This transformation is one to one and hence we may also obtain (2) starting from (1). Moreover, the mapping ν elucidates the zero-mode problem of $\tilde{\phi}$ as follows: Any occurrence of an infrared divergence in (1) is caused by an ultraviolet divergence in (2), and vice versa. Already at this point we run into a new class of functions. If the amplitudes $a(\mathbf{p})$, $a^+(\mathbf{p})$ of ϕ in (2) run through the Schwartz space $\mathcal{S}(\mathbb{R}^3)$, then the transformed amplitudes $\tilde{a}(\tilde{\mathbf{p}})$, $\tilde{a}^+(\tilde{\mathbf{p}})$ of $\tilde{\phi}=\phi\circ\kappa^{-1}$ in (1) run through $\nu^*\mathcal{S}(\mathbb{R}^3)=\{f\circ\nu \mid f\in\mathcal{S}(\mathbb{R}^3)\}$, and vice versa. The functions of $\nu^*\mathcal{S}(\mathbb{R}^3)$, however, live on the open subset $\{(p^+,p^1,p^2) \mid p^+>0\}$ of $\mathbb{R}^3$, and it is possible to embed canonically $\nu^*\mathcal{S}(\mathbb{R}^3)$ into $\mathcal{S}(\mathbb{R}^3)$. Hence, we see, that a proper subspace of $\mathcal{S}(\mathbb{R}^3)$ appears in a very natural way and is, moreover, fully equivalent to $\mathcal{S}(\mathbb{R}^3)$. This subspace is the cornerstone in our solution of the restriction problem. In Sec. IV we recall the well known construction of the (covariant) free scalar massive field ϕ, which obeys the Wightman axioms, and construct in the same way the (covariant) free scalar massive LC-field $\tilde{\phi}$. The LC-field fulfills the Wightman axioms only if we replace in

the axioms the Minkowski bilinear form by the LC-bilinear form. We call these modified axioms the LC-Wightman axioms. This is a rather trivial fact, but nevertheless we decided to write down these axioms, since especially the spectral property (LC-W2) takes on a form, which postulates two positive operators, P_+ and P_-, in contrast to the Minkowski case, where only one operator, P_0, has to be positive. This is seen to be one of the major advantages of light cone field theory. Since ϕ is really a quadruple $(\mathcal{H},U,\phi,D)$, and $\tilde{\phi}$ a quadruple $(\tilde{\mathcal{H}},\tilde{U},\tilde{\phi},\tilde{D})$ we define generally what we mean if we write $\tilde{\phi}=\kappa_*\phi=\phi\circ\kappa^{-1}$. We call $\kappa_*\phi$ the pushforward of ϕ by κ. In Sec. V we consider the problem of restricting the LC-field $\tilde{\phi}$ to $\{x^+=0\}$. Starting from the important commutative diagram (20), we again come across the function space $\nu^*\mathcal{S}(\mathbb{R}^3)$ which, for some reasons, is denoted $\mathcal{S}_{p^+}(\mathbb{R}_{>0}\times\mathbb{R}^2)$. The elements of this function space are called ''squeezed'' rapidly decreasing (smooth) functions and the elements of its dual space are called ''squeezed'' distributions. We show that the function space $\mathcal{S}_{p^+}(\mathbb{R}_{>0}\times\mathbb{R}^2)$ is isomorphic to $\mathcal{S}(\mathbb{R}^3)$ and can canonically be embedded into $\mathcal{S}(\mathbb{R}^3)$. In Sec. VI we use the preliminary work of Sec. V to define the restriction of the LC-field $\tilde{\phi}$ to $\{x^+=0\}$. Furthermore, we compute the equal-time commutator relation. As a highlight we obtain a transformation law between the restriction of $\tilde{\phi}$ to $\{x^+=0\}$ and the restrictions of ϕ and $\partial_0\phi$ to $\{x^0=0\}$. Moreover, we show that the restrictions to $\{x^+=0\}$ of two LC-fields of different masses >0 are unitary equivalent. Hence this is a special property of light cone field theory and not an artifact of a too restricted test function space as thought in Ref. 18. Quite the reverse, if one weakens slightly the definition of unitary equivalence, then it is easy to show that, even in the classical situation, the restrictions to $\{x^0=0\}$ become ''weakly unitary equivalent.'' Finally, in Sec. VII we give a rigorous Fock space expansion of $\tilde{\phi}$ and the time-zero LC-field $\tilde{\varphi}$ treating the fields as bilinear forms. The field operators are obtained by smearing the bilinear forms with test functions. This is the same approach as in the classical case (cf. Ref. 16). Hence, we present finally a solution of the zero-mode problem of the quantized Klein–Gordon field.

II. NOTATION AND CONVENTIONS

A. LC-coordinates and LC-space

We denote n-dimensional Minkowski space by $\mathbb{M}=\mathbb{M}^n$, i.e., $\mathbb{M}^n$ is $\mathbb{R}^n$ together with the symmetric bilinear form $\langle x,y\rangle_{\mathbb{M}}=x^\mu g_{\mu\nu}y^\nu$, where $G=(g_{\mu\nu})$ is the usual Minkowski metric tensor. We introduce LC-coordinates $\tilde{x}$ using the Kogut–Soper convention by $\kappa:\mathbb{R}^n\to\mathbb{R}^n$, $x\mapsto\tilde{x}=(\tilde{x^0},\ldots,\widetilde{x^{n-1}})=\kappa(x)$, where

$$\tilde{x^0}=\frac{1}{\sqrt{2}}(x^0+x^{n-1}),\quad \tilde{x^j}=x^j\quad (j=1,\ldots,n-2),\quad \widetilde{x^{n-1}}=\frac{1}{\sqrt{2}}(x^0-x^{n-1}).$$

Here, we use the so-called index-marked notation where the index carries the mark. Especially in light-cone physics, one usually writes

$$x^+:=\tilde{x^0},\quad \mathbf{x}_\perp:=(\tilde{x^1},\ldots,\widetilde{x^{n-2}}),\quad x^-:=\widetilde{x^{n-1}}$$

and chooses x^+ as the LC-time variable. Because of the Kogut–Soper convention we have $\kappa=\kappa^{-1}$. Next we transform the Minkowski metric tensor G to LC-coordinates by

$$\tilde{G}=(g_{\tilde{\mu}\tilde{\nu}}):=\kappa G\kappa,$$

then

$$\tilde{G}=\begin{pmatrix} 0 & 0 & 0 & \cdots & 1 \\ 0 & -1 & 0 & \cdots & 0 \\ 0 & 0 & \ddots & & 0 \\ \vdots & \vdots & & -1 & \vdots \\ 1 & 0 & \cdots & 0 & 0 \end{pmatrix}.$$

We define the associated bilinear form by $\langle\tilde{x},\tilde{y}\rangle_{\mathbb{L}}:=x^{\tilde{\mu}}g_{\tilde{\mu}\tilde{\nu}}y^{\tilde{\nu}}$. Note that, using the classical LC-notation, we have $\langle\tilde{x},\tilde{y}\rangle_{\mathbb{L}}=x^+y^-+x^-y^+-\mathbf{x}_\perp\cdot\mathbf{y}_\perp$. In analogy to Minkowski space $\mathbb{M}$ we define *LC-space* $\mathbb{L}=\mathbb{L}^n$ as the bilinear space $(\mathbb{R}^n,\langle-,-\rangle_{\mathbb{L}})$. It is obvious that κ preserves the bilinear forms, i.e., κ is an isomorphism (of bilinear spaces) from $\mathbb{M}$ onto $\mathbb{L}$.

Given $\tilde{x}\in\mathbb{L}$, we also define *covariant* LC-coordinates by $x_{\tilde{\mu}}=g_{\tilde{\mu}\tilde{\nu}}x^{\tilde{\nu}}$, and set $\tilde{x}^2:=x^{\tilde{\mu}}x_{\tilde{\mu}}$. A massive relativistic particle with 4-momentum p obeys the energy-momentum relation $p^2-m^2=p^\mu p_\mu-m^2=0$. In LC-coordinates this relation reads $\tilde{p}^2-m^2=p^{\tilde{\mu}}p_{\tilde{\mu}}-m^2=2p^+p^--\mathbf{p}_\perp^2-m^2=0$. Note that the transformation to LC-coordinates preserves the bilinear forms.

The relativistic energy-momentum relation $p^2-m^2=0$ is covariant under the full Lorentz group $\mathcal{L}$, where the transformed relation $\tilde{p}^2-m^2=0$, the *LC-energy-momentum relation*, is not. However, the latter is covariant under the transformed Lorentz group or *LC-Lorentz group* $\tilde{\mathcal{L}}:=\kappa\mathcal{L}\kappa$. Thus in relativistic LC-physics we have to replace the Lorentz group by the LC-Lorentz group and, as a consequence, the Poincaré group $\mathcal{P}=\{(a,\Lambda):a\in\mathbb{M},\ \Lambda\in\mathcal{L}\}$ by the LC-Poincaré group $\tilde{\mathcal{P}}=\{(\tilde{a},\tilde{\Lambda}):\tilde{a}\in\mathbb{L},\ \tilde{\Lambda}\in\tilde{\mathcal{L}}\}$. We also transform the connected component $\mathcal{L}_+^\uparrow=\{\Lambda\in\mathcal{L}:\Lambda_0^0>0,\ \det(\Lambda)=+1\}$ of $\mathcal{L}$ to LC-coordinates by

$$\tilde{\mathcal{L}}_+^\uparrow:=\kappa\mathcal{L}_+^\uparrow\kappa.$$

The coordinate transformation κ induces an isomorphism of Lie groups $\mathcal{L}\tilde{\to}\tilde{\mathcal{L}}$, $\Lambda\mapsto\kappa\Lambda\kappa$. Under this isomorphism the stability group of $\Sigma=\{x^0+x^3=0\}$, i.e., the subgroup of all $\Lambda\in\mathcal{L}$ such that $\Lambda(\Sigma)\subset\Sigma$, is mapped onto the stability group of $\{x^+=0\}$. It is well known[14] that the stability group of $\{x^0=0\}$ is not isomorphic to the stability group of Σ. Hence, the two forms of dynamics are inequivalent.

For the rest of this article we fix some notations.[23] Let

$$\Gamma_m=\{p\in\mathbb{M}^{n+1}:p^2=m^2\},\quad \tilde{\Gamma}_m=\{\tilde{p}\in\mathbb{L}^{n+1}:\tilde{p}^2=m^2\},$$

$$\Gamma_m^\pm=\{p\in\mathbb{M}^{n+1}:p^2=m^2,\ \pm p^0>0\},\quad \tilde{\Gamma}_m^\pm=\{\tilde{p}\in\mathbb{L}^{n+1}:\tilde{p}^2=m^2,\ \pm p^->0\},$$

$$V^\pm=\{p\in\mathbb{M}^{n+1}:p^2>0,\ \pm p^0>0\},\quad \tilde{V}^\pm=\{\tilde{p}\in\mathbb{L}^{n+1}:\tilde{p}^2>0,\ \pm p^->0\}.$$

It is easy to see that $\tilde{\Gamma}_m^\pm=\kappa(\Gamma_m^\pm)$ and $\tilde{V}^\pm=\kappa(V^\pm)$. In addition we will use the following (smooth) parametrizations of the (smooth) submanifolds $\Gamma_m^\pm$, $\tilde{\Gamma}_m^\pm$ of $\mathbb{R}^{n+1}$ (see Fig. 1):

$$\Omega_\pm:\mathbb{R}^n\tilde{\to}\Gamma_m^\pm\subset\mathbb{R}^{n+1},\quad \mathbf{p}\mapsto\Omega_\pm(\mathbf{p}):=(\pm\omega(\mathbf{p}),\mathbf{p})$$

$$\text{with}\ \ \omega(\mathbf{p}):=\sqrt{\mathbf{p}^2+m^2},\ \ \mathbf{p}=(p^1,p^2,\ldots,p^n),\ \ \mathbf{p}^2=\sum_{i=1}^n(p^i)^2,$$

$$\tilde{\Omega}_\pm:\mathbb{R}^n\backslash\{\mp p^+\geqslant 0\}\tilde{\to}\tilde{\Gamma}_m^\pm\subset\mathbb{R}^{n+1},\quad \tilde{\mathbf{p}}\mapsto\tilde{\Omega}_\pm(\tilde{\mathbf{p}}):=\tilde{\Omega}(\tilde{\mathbf{p}}):=(\tilde{\mathbf{p}},\tilde{\omega}(\tilde{\mathbf{p}}))$$

$$\text{with}\ \ \tilde{\omega}(\tilde{\mathbf{p}}):=\frac{\mathbf{p}_\perp^2+m^2}{2p^+},\ \ \mathbf{p}_\perp:=(\tilde{p^1},\tilde{p^2},\ldots,\widetilde{p^{n-1}}),\ \ \mathbf{p}_\perp^2=\sum_{i=1}^{n-1}(\tilde{p^i})^2,$$

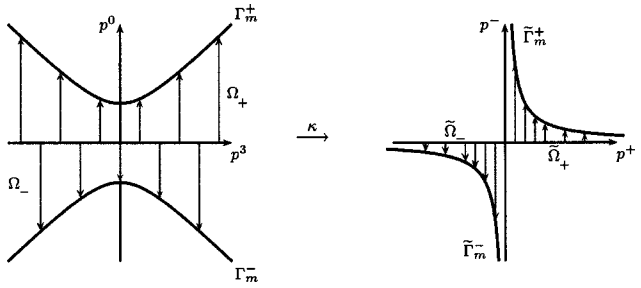

FIG. 1. Parametrizations of $\Gamma_m^{\pm}$ and $\tilde{\Gamma}_m^{\pm}$.

$$\tilde{\mathbf{p}} := (p^+, \mathbf{p}_\perp).$$

Note that $\tilde{\Omega}: \mathbb{R}^n \setminus \{p^+ = 0\} \tilde{\to} \tilde{\Gamma}_m$, $\tilde{\mathbf{p}} \mapsto (\tilde{\mathbf{p}}, \tilde{\omega}(\tilde{\mathbf{p}}))$ is a parametrization of $\tilde{\Gamma}_m$.

B. $\mathbb{M}$- and $\mathbb{L}$-Fourier transformation

In relativistic physics the Fourier transform is defined by using the Minkowski bilinear form instead of the standard Euclidean scalar product. Going over to LC-coordinates the Minkowski bilinear form transforms to LC-bilinear form $\langle -, - \rangle_{\mathbb{L}}$. To fix notations we introduce in this short subsection the so-called $\mathbb{L}$-Fourier transform and notice some properties which follow easily from the definition. Let $\mathcal{S}_n = \mathcal{S}(\mathbb{R}^n)$ denote the Schwartz space of rapidly decreasing, smooth, complex-valued functions. For $f \in \mathcal{S}_n$ define the $\mathbb{X}$-*Fourier transform* $\mathcal{F}_{\mathbb{X}}(f) = f^{\wedge \mathbb{X}}$ by

$$\mathcal{F}_{\mathbb{X}} f := \int f(x)\, e^{i\langle x, - \rangle_{\mathbb{X}}} dx,$$

where $\mathbb{X}$ stands for $\mathbb{M}$ or $\mathbb{L}$. Then $\mathcal{F}_{\mathbb{M}}$ and $\mathcal{F}_{\mathbb{L}}$ are mappings from $\mathcal{S}_n$ to $\mathcal{S}_n$. To emphasize which bilinear form we are just using we also write $\mathcal{S}(\mathbb{M})$, respectively, $\mathcal{S}(\mathbb{L})$ instead of $\mathcal{S}_n$. Thus, we have mappings $\mathcal{F}_{\mathbb{M}}: \mathcal{S}(\mathbb{M}) \to \mathcal{S}(\mathbb{M})$ and $\mathcal{F}_{\mathbb{L}}: \mathcal{S}(\mathbb{L}) \to \mathcal{S}(\mathbb{L})$. Our $\mathbb{M}$-Fourier transform is just the Fourier transform used in relativistic physics. The LC-coordinate transformation $\kappa: \mathbb{M} \to \mathbb{L}$ induces canonically a pullback/pushforward mapping $\kappa^*: \mathcal{S}(\mathbb{L}) \to \mathcal{S}(\mathbb{M})$ ($\kappa_*: \mathcal{S}(\mathbb{M}) \to \mathcal{S}(\mathbb{L})$) which canonically extends to a pullback/pushforward mapping $\kappa^*: \mathcal{S}'(\mathbb{L}) \to \mathcal{S}'(\mathbb{M})$ ($\kappa_*: \mathcal{S}'(\mathbb{M}) \to \mathcal{S}'(\mathbb{L})$), where, as usual, $\mathcal{S}'_n = \mathcal{S}'(\mathbb{R}^n) = \mathcal{S}'(\mathbb{M}) = \mathcal{S}'(\mathbb{L})$ denotes the space of tempered distributions. From the definition immediately follows

$$(\kappa^* \tilde{u})^{\wedge \mathbb{M}} = \kappa^* (\tilde{u}^{\wedge \mathbb{L}}) \quad \text{and} \quad (\kappa_* u)^{\wedge \mathbb{L}} = \kappa_* (u^{\wedge \mathbb{M}}) \tag{3}$$

for all $\tilde{u} \in \mathcal{S}'(\mathbb{L})$, $u \in \mathcal{S}'(\mathbb{M})$. Note that $|\det(\mathrm{D}\kappa)| = 1$ where $\mathrm{D}\kappa$ is the Jacobi matrix of κ. Recall that, in a canonical way, $\mathcal{S}$ is a dense linear subspace of $\mathcal{S}'$. However, $\mathcal{S}$ carries not the subspace topology of $\mathcal{S}'$, the topology on $\mathcal{S}$ is stronger.

Proposition II.1: The mapping $\mathcal{F}_{\mathbb{L}}: \mathcal{S}(\mathbb{L}) \to \mathcal{S}(\mathbb{L})$ is a $\mathbb{C}$-linear homeomorphism with inverse given by

$$f(\tilde{x}) = \frac{1}{(2\pi)^n} \int_{\mathbb{R}^n} f^{\wedge \mathbb{L}}(\tilde{p})\, e^{-i\langle \tilde{p}, \tilde{x} \rangle_{\mathbb{L}}} d^n \tilde{p}.$$

This mapping extends uniquely to a $\mathbb{C}$-linear homeomorphism $\mathcal{F}_{\mathbb{L}}: \mathcal{S}'(\mathbb{L}) \to \mathcal{S}'(\mathbb{L})$ $u \mapsto u^{\wedge \mathbb{L}}$ by the usual formula $u^{\wedge \mathbb{L}}(f) := u(f^{\wedge \mathbb{L}})$.

III. THE KLEIN–GORDON EQUATION AND THE ZERO-MODE PROBLEM

In the canonical quantization procedure of a free scalar field of mass >0 one uses the fact that the classical field ϕ, as a solution of the Klein–Gordon equation, has a plane wave expansion of the form

$$\phi(x)=\frac{1}{(2\pi)^3}\int\frac{d^3\mathbf{p}}{2\omega(\mathbf{p})}(a(\mathbf{p})\,e^{-i(\omega(\mathbf{p})x^0-\mathbf{p}\cdot\mathbf{x})}+a^+(\mathbf{p})\,e^{i(\omega(\mathbf{p})x^0-\mathbf{p}\cdot\mathbf{x})}), \tag{4}$$

where $\omega(\mathbf{p})=\sqrt{\mathbf{p}^2+m^2}$.

Since the beginning of light cone QFT it was thought that there is no well-defined analogous plane wave expansion in terms of LC-momenta.[5,10] This problem is called the *zero-mode problem* (or infrared problem) which we like to explain now in more detail.

In physical literature the expansion of ϕ is obtained by transforming the Klein–Gordon equation (KG-equation) $(\Box+m^2)\phi=0$ via Fourier transformation into the algebraic equation $(p^2-m^2)\phi^{\wedge\mathbb{M}}=0$. This equation is solved by $2\pi\chi(p)\delta(p^2-m^2)$, where $\chi(p)$ is some complex-valued function on Γ_m. Using inverse Fourier transformation one obtains ϕ formally

$$\phi(x)=\frac{1}{(2\pi)^3}\int d^4p\;\chi(p)\;\delta(p^2-m^2)\,e^{-i\langle p,x\rangle_{\mathbb{M}}}.$$

To evaluate the integration over the variable p^0, one views $p^2-m^2=f(p^0)$ as a function of p^0 and uses the identity

$$\delta(f(t))=\sum_{\xi}\frac{1}{|f'(\xi)|}\delta(t-\xi), \tag{5}$$

where the sum runs over all simple roots of f. Applying this formula, yields

$$\delta(p^2-m^2)=\frac{1}{2\omega(\mathbf{p})}(\delta(p^0-\omega(\mathbf{p}))+\delta(p^0+\omega(\mathbf{p}))),$$

where $\mathbf{p}$ has to be viewed as a fixed parameter in $\mathbb{R}^3$. Now, one can evaluate the integration over p^0 by canceling the integration and substituting p^0 by $\omega(\mathbf{p})$ (resp. by $-\omega(\mathbf{p})$), so we obtain

$$\phi(x)=\frac{1}{(2\pi)^3}\int\frac{d^3\mathbf{p}}{2\omega(\mathbf{p})}(\chi(\Omega_+(\mathbf{p}))\,e^{-i\langle\Omega_+(\mathbf{p}),x\rangle_{\mathbb{M}}}+\chi(\Omega_-(\mathbf{p}))\,e^{-i\langle\Omega_-(\mathbf{p}),x\rangle_{\mathbb{M}}})$$

and this is the desired expansion, if we set $a(\mathbf{p})=\chi(\Omega_+(\mathbf{p}))$ and $a^+(\mathbf{p})=\chi(\Omega_-(-\mathbf{p}))$. Recall that $\Omega_\pm(\mathbf{p})=(\pm\omega(\mathbf{p}),\mathbf{p})$.

Now consider the transformed field $\tilde{\phi}=\phi\circ\kappa^{-1}$ which we call the free scalar *LC-field*. The LC-field obeys the transformed Klein–Gordon equation (LCKG-equation) $(\tilde{\Box}+m^2)\tilde{\phi}=0$—recall that $\tilde{\Box}=\partial^{\tilde{\mu}}\partial_{\tilde{\mu}}=2\partial_+\partial_--\partial_\perp^2$. Using the same strategy as in the Minkowski case, we apply $\mathbb{L}$-FT and obtain the algebraic equation $(\tilde{p}^2-m^2)\tilde{\phi}^{\wedge\mathrm{L}}=0$. Again, we solve this by $2\pi\tilde{\chi}(\tilde{p})\delta(\tilde{p}^2-m^2)$, where $\tilde{\chi}(\tilde{p})$ is some complex-valued function on $\tilde{\Gamma}_m$. To use formula (5) we have to consider $\tilde{f}(p^-)=\tilde{p}^2-m^2$ as a function in $p^-\in\mathbb{R}$. This gives

$$\delta(\tilde{p}^2-m^2)=\frac{1}{|2p^+|}\delta\left(p^--\frac{\mathbf{p}_\perp^2+m^2}{2p^+}\right), \tag{6}$$

where we have to exclude $p^+=0$. Note that $\tilde{\mathbf{p}}=(p^+,\mathbf{p}_\perp)$ in Eq. (6) has to be considered as a fixed parameter $\in\mathbb{R}^3\backslash\{p^+=0\}$. Canceling the integration over p^- and substituting p^- by $(\mathbf{p}_\perp^2+m^2)/2p^+$ yields

$$\tilde{\phi}(\tilde{x}) = \frac{1}{(2\pi)^3} \int \frac{d^3\tilde{\mathbf{p}}}{|2p^+|} \tilde{\chi}(\tilde{\Omega}(\tilde{\mathbf{p}}))\, e^{-i\langle \tilde{\Omega}(\tilde{\mathbf{p}}), \tilde{x}\rangle_{\mathrm{L}}},$$

where $\tilde{\Omega}(\tilde{\mathbf{p}}) = (\tilde{\mathbf{p}}, \tilde{\omega}(\tilde{\mathbf{p}}))$ and $\tilde{\omega}(\tilde{\mathbf{p}}) = (\mathbf{p}_\perp^2 + m^2)/2p^+$. If we set $\tilde{a}(\tilde{\mathbf{p}}) := \tilde{\chi}(\tilde{\Omega}(\tilde{\mathbf{p}}))$ and $\tilde{a}^+(\tilde{\mathbf{p}}) := \tilde{\chi}(\tilde{\Omega}(-\tilde{\mathbf{p}}))$, we get the expansion

$$\tilde{\phi}(\tilde{x}) = \frac{1}{(2\pi)^3} \int_{p^+>0} \frac{d^3\tilde{\mathbf{p}}}{2p^+} (\tilde{a}(\tilde{\mathbf{p}})\, e^{-i\langle \tilde{\Omega}(\tilde{\mathbf{p}}), \tilde{x}\rangle_{\mathrm{L}}} + \tilde{a}^+(\tilde{\mathbf{p}})\, e^{i\langle \tilde{\Omega}(\tilde{\mathbf{p}}), \tilde{x}\rangle_{\mathrm{L}}}). \tag{7}$$

Since the nonlocally integrable function $\Theta(p^+)/2p^+$ appears in (7), it was thought[5,10] that the expansion in (7) is not well-defined (as $p^+ \to 0$), and that this divergence is a special property of LC-QFT. In this section we will show that this is not the case. The denominator $2\omega(\mathbf{p})$ in (4) has not the problem to become zero anywhere, however, in classical QFT one usually uses amplitudes χ such that (4) becomes ultraviolet divergent, i.e., as $|\mathbf{p}| \to \infty$. Our analysis will show that the ultraviolet behavior of (4) determines the infrared behavior of (7), and vice versa. Or more precise, the singular behavior of (4) as $p^3 \to -\infty$ (resp. $p^3 \to \infty$) is the same as the singular behavior of (7) as $p^+ \to 0$ (resp. $p^+ \to \infty$).

The keystone to solve this problem is to consider the transformation law between $\chi\delta(p^2 - m^2)$ and $\tilde{\chi}\delta(\tilde{p}^2 - m^2)$. Since, *a priori*, it is not clear whether $\tilde{\chi}\delta(\tilde{p}^2 - m^2)$ can be viewed as a distribution depending on $\tilde{\mathbf{p}}$ as a parameter, we want to avoid formula (5) in the derivation of (4) and (7). Instead we will use the exact definitions of $\chi\delta(p^2 - m^2)$ and $\tilde{\chi}\delta(\tilde{p}^2 - m^2)$ as tempered distributions on $\mathbb{R}^4$ to derive the expansions (4) and (7).

To give a precise definition of $\chi(p)\delta(p^2 - m^2)$ and $\tilde{\chi}(\tilde{p})\delta(\tilde{p}^2 - m^2)$ we first mention that the tempered distributions $\delta(p^2 - m^2)$ and $\delta(\tilde{p}^2 - m^2)$ are well-defined as pullbacks of $\delta \in \mathcal{S}'(\mathbb{R})$ under the mapping $Q(p) = p^2 - m^2 : \mathbb{R}^4 \to \mathbb{R}$, respectively, $\tilde{Q}(\tilde{p}) = \tilde{p}^2 - m^2 : \mathbb{R}^4 \to \mathbb{R}$ (cf. Ref. 11, p. 136). Then, for all $f \in \mathcal{S}(\mathbb{R}^4)$, we have

$$(\delta(p^2 - m^2), f(p)) = \int_{\Gamma_m} \frac{f}{|\nabla Q|}\, dS \tag{8}$$

and

$$(\delta(\tilde{p}^2 - m^2), f(\tilde{p})) = \int_{\tilde{\Gamma}_m} \frac{f}{|\nabla \tilde{Q}|}\, d\tilde{S}, \tag{9}$$

where dS (resp. $d\tilde{S}$) is the canonical surface measure on Γ_m (resp. $\tilde{\Gamma}_m$). Hence, as usual, we identify $\delta(p^2 - m^2)$ with the (positive Borel-) measure $d\mu_m := dS/|\nabla Q|$ on Γ_m, and $\delta(\tilde{p}^2 - m^2)$ with the measure $d\tilde{\mu}_m := d\tilde{S}/|\nabla \tilde{Q}|$ on $\tilde{\Gamma}_m$. Because of the functoriality of the pullback operation,[11] we have $\delta(\tilde{p}^2 - m^2) = \delta(p^2 - m^2) \circ \kappa^{-1}$. This implies that the measure $\tilde{\mu}_m$ is the image measure of μ_m under the mapping $\kappa : \mathbb{M} \to \mathbb{L}$. If we define $\mu_m^\pm$ (resp. $\tilde{\mu}_m^\pm$) as the restriction of μ_m to $\Gamma_m^\pm$ (resp. $\tilde{\Gamma}_m^\pm$) then, because of $\tilde{\Gamma}_m^\pm = \kappa(\Gamma_m^\pm)$, $\tilde{\mu}_m^\pm$ is the image measure of $\mu_m^\pm$ under κ. The following lemma is an easy consequence of the transformation law between a measure and its image measure (cf., e.g., Ref. 2, 19.3).

Lemma III.1: Let ρ be a complex-valued, measurable function on $\Gamma_m^\pm$. Then ρ is $\mu_m^\pm$-integrable iff $\rho \circ \kappa^{-1}$ is $\tilde{\mu}_m^\pm$-integrable, and

$$\int_{\tilde{\Gamma}_m^\pm} \frac{\rho \circ \kappa^{-1}}{|\nabla \tilde{Q}|}\, d\tilde{S} = \int_{\Gamma_m^\pm} \frac{\rho}{|\nabla Q|}\, dS.$$

We denote by $\delta_\pm(p^2-m^2)$ (resp. $\delta_\pm(\tilde{p}^2-m^2)$) the tempered distribution induced by $\mu_m^\pm$ (resp. $\tilde{\mu}_m^\pm$), and we sometimes identify the measure with its induced distribution. Note that (as tempered distributions)

$$\delta_\pm(\tilde{p}^2-m^2)=\delta_\pm(p^2-m^2)\circ\kappa^{-1}$$

and $\delta(p^2-m^2)=\delta_+(p^2-m^2)+\delta_-(p^2-m^2)$ and $\delta(\tilde{p}^2-m^2)=\delta_+(\tilde{p}^2-m^2)+\delta_-(\tilde{p}^2-m^2)$.

When we explained the derivation of the plane wave expansion used in physical literature, we solved the associated division problem by $\chi\,\delta(p^2-m^2)$ where we have not specified the amplitude $\chi(p)$ to get a solution of the KG-equation. In the following we want to specify χ in such a way that $\chi\,\delta(p^2-m^2)$ is a well-defined tempered distribution. However, if we allow only complex-valued functions χ on Γ_m as amplitudes, we do not get all solutions of the KG-equation in $\mathcal{S}'(\mathbb{R}^4)$ because it is well known, e.g. Ref. 3, p. 60, that the general solution $u\in\mathcal{S}'(\mathbb{R}^4)$ of $(p^2-m^2)u=0$ is of the form

$$u=u_+(\mathbf{p})\,\delta_+(p^2-m^2)+u_-(\mathbf{p})\,\delta_-(p^2-m^2) \tag{10}$$

with tempered distributions $u_\pm(\mathbf{p})\in\mathcal{S}'(\mathbb{R}^3)$, where $u_\pm(\mathbf{p})\,\delta_\pm(p^2-m^2)\in\mathcal{S}'(\mathbb{R}^4)$ is defined by

$$(u_\pm(\mathbf{p})\,\delta_\pm(p^2-m^2),f(p))=\left(u_\pm(\mathbf{p}),\frac{f(\pm\omega(\mathbf{p}),\mathbf{p})}{2\omega(\mathbf{p})}\right)=\int\frac{d^3\mathbf{p}}{2\omega(\mathbf{p})}u_\pm(\mathbf{p})\,f(\pm\omega(\mathbf{p}),\mathbf{p}).$$

Note that the mapping $\mathcal{S}(\mathbb{R}^4)\to\mathcal{S}(\mathbb{R}^3)$, $f(p)\mapsto f(\pm\omega(\mathbf{p}),\mathbf{p})/2\omega(\mathbf{p})$ is $\mathbb{C}$-linear and continuous. If we evaluate the surface integral (8) over $\Gamma_m^\pm$ using the parametrization $\Omega_\pm:\mathbb{R}^3\tilde{\to}\Gamma_m^\pm\subset\mathbb{R}^4$, we get

$$(\delta_\pm(p^2-m^2),f(p))=\int_{\Gamma_m^\pm}\frac{f}{|\nabla Q|}\,dS=\int\frac{d^3\mathbf{p}}{2\omega(\mathbf{p})}f(\pm\omega(\mathbf{p}),\mathbf{p}).$$

Hence, $\delta_\pm(p^2-m^2)$ defined by the measure $\mu_m^\pm$ on $\Gamma_m^\pm$ is equal to $u_\pm(\mathbf{p})\,\delta(p^2-m^2)$ in (10) with $u_\pm(\mathbf{p})=1(\mathbf{p})$, where $1(\mathbf{p})=1$ is the constant function. For this reason we make the following definition:

Definition: (a) A function $\chi:\Gamma_m^\pm\to\mathbb{C}$ is a *multiplicator* of $\delta_\pm(p^2-m^2)$ if $\chi(\Omega_\pm(\mathbf{p}))$ is a tempered distribution $\in\mathcal{S}'(\mathbb{R}^3)$, where $\Omega_\pm$ is the introduced parametrization of $\Gamma_m^\pm$. For each such χ we define the tempered distribution $\chi(p)\,\delta_\pm(p^2-m^2)\in\mathcal{S}'(\mathbb{R}^4)$ by

$$(\chi(p)\,\delta_\pm(p^2-m^2),f(p)):=\int\frac{d^3\mathbf{p}}{2\omega(\mathbf{p})}\chi(\Omega_\pm(\mathbf{p}))\,f(\Omega_\pm(\mathbf{p}))=\int_{\Gamma_m^\pm}\frac{\chi f}{|\nabla Q|}\,dS\quad(f\in\mathcal{S}(\mathbb{R}^4)).$$

By $\mathcal{M}_\pm$ we denote the set of all multiplicators of $\delta_\pm(p^2-m^2)$.

(b) A function $\chi:\Gamma_m\to\mathbb{C}$ is called a *multiplicator* of $\delta(p^2-m^2)$ if the restrictions $\chi_\pm:=\chi|_{\Gamma_m^\pm}$ are in $\mathcal{M}_\pm$. For each such χ we define the tempered distribution $\chi(p)\,\delta(p^2-m^2)\in\mathcal{S}'(\mathbb{R}^4)$ by

$$\chi(p)\,\delta(p^2-m^2):=\chi_+(p)\,\delta(p^2-m^2)+\chi_-(p)\,\delta(p^2-m^2),$$

thus

$$(\chi(p)\,\delta(p^2-m^2),f(p))=\int_{\Gamma_m}\frac{\chi f}{|\nabla Q|}\,dS,\quad(f\in\mathcal{S}(\mathbb{R}^4)).$$

By $\mathcal{M}$ we denote the set of all multiplicators of $\delta(p^2-m^2)$.

Notice that, because the mapping $\mathcal{S}(\mathbb{R}^4)\to\mathcal{S}(\mathbb{R}^3)$, $f(p)\mapsto f(\Omega_\pm(\mathbf{p}))/2\omega(\mathbf{p})$ is $\mathbb{C}$-linear and continuous, the distributions $\chi(p)\,\delta_\pm(p^2-m^2)$ and $\chi(p)\,\delta(p^2-m^2)$ are well-defined and tempered.

As mentioned before, if we consider distributions of the form $u=\chi(p)\,\delta(p^2-m^2)$ ($\chi \in \mathcal{M}$), we do not get all solutions of $(p^2-m^2)u=0$ in $\mathcal{S}'(\mathbb{R}^4)$, and thus also not all solutions of $(p^2-m^2)\tilde{u}=0$ in $\mathcal{S}'(\mathbb{R}^4)$ (because κ induces a 1–1 correspondence between these solutions). However, we are mainly interested in the interrelation between the solutions of $(p^2-m^2)u=0$ and $(\tilde{p}^2-m^2)\tilde{u}=0$, and in studying this interrelation we will see that it is important that the definition of $\chi(p)\,\delta_\pm(p^2-m^2)$ does not depend on the chosen parametrizations (or charts) of $\Gamma_m^\pm$–only the sets $\mathcal{M}_\pm$ depend on it. It is not known to the author how to define in general $u_\pm(\mathbf{p})\,\delta_\pm(p^2-m^2)$, where $u_\pm(\mathbf{p}) \in \mathcal{S}'(\mathbb{R}^3)$, without fixing any parametrization of $\Gamma_m^\pm$.

Using the fact[17] that every function $\chi:\mathbb{R}^n \to \mathbb{C}$ such that

$$\int |(1+|x|^2)^{-N}\chi(x)|^p\, d^n x < \infty$$

for some $N \in \mathbb{N}$ and $p \in \mathbb{R}$, $p>0$, is a tempered distribution, it is easy to show that every function in $\mathcal{L}^p(\Gamma_m^\pm, d\mu_m)$ is a multiplicator of $\delta_\pm(p^2-m^2)$. If $\chi_\pm$ runs through $\mathcal{L}^2(\Gamma_m^\pm, d\mu_m)$ the solutions $\phi_\pm = \mathcal{F}_{\mathbb{M}}^{-1}(\chi_\pm(p)\,\delta_\pm(p^2-m^2))$ of the KG-equation run through all physical positive/negative energy states of a relativistic neutral particle of mass $m>0$.[19] Hence, our analysis includes all physically relevant solutions of the KG-equation. It is even possible to leave this restriction and to show that the general solution $\tilde{u}$ in $\mathcal{S}'(\mathbb{R}^4)$ of $(\tilde{p}^2-m^2)\tilde{u}=0$ is of the form

$$\tilde{u}=\tilde{u}_+(\tilde{\mathbf{p}})\,\delta_+(\tilde{p}^2-m^2)+\tilde{u}_-(\tilde{\mathbf{p}})\,\delta_-(\tilde{p}^2-m^2),$$

where $\tilde{u}_\pm(\tilde{\mathbf{p}})$ are so-called squeezed distributions, and $\tilde{u}_\pm(\tilde{\mathbf{p}})\,\delta_\pm(\tilde{p}^2-m^2)$ are defined in an analogous way as $u_\pm(\mathbf{p})\,\delta_\pm(p^2-m^2)$ in (10) (cf. Ref. 21).

Now we like to define $\tilde{\chi}(\tilde{p})\,\delta_\pm(\tilde{p}^2-m^2)$ and $\tilde{\chi}(\tilde{p})\,\delta(\tilde{p}^2-m^2)$.

Definition: (a) Let $\tilde{\mathcal{M}}_\pm := \{\chi\circ\kappa^{-1}: \chi \in \mathcal{M}_\pm\}$. We call every function in $\tilde{\mathcal{M}}_\pm$ a *multiplicator of* $\delta_\pm(\tilde{p}^2-m^2)$. For every such $\tilde{\chi}_\pm \in \tilde{\mathcal{M}}_\pm$ we define $\tilde{\chi}_\pm(\tilde{p})\,\delta_\pm(\tilde{p}^2-m^2) \in \mathcal{S}'(\mathbb{R}^4)$ by

$$(\tilde{\chi}(\tilde{p})\,\delta_\pm(\tilde{p}^2-m^2), f(\tilde{p})) := \int_{\tilde{\Gamma}_m^\pm} \frac{\tilde{\chi} f}{|\nabla \tilde{Q}|}\, d\tilde{S} \quad (f \in \mathcal{S}(\mathbb{R}^4)).$$

(b) A function $\tilde{\chi}:\tilde{\Gamma}_m \to \mathbb{C}$ is called a *multiplicator of* $\delta(\tilde{p}^2-m^2)$ if the restrictions $\tilde{\chi}_\pm := \tilde{\chi}|_{\tilde{\Gamma}_m^\pm}$ are in $\tilde{\mathcal{M}}_\pm$. For each such $\tilde{\chi}$ we define $\tilde{\chi}(\tilde{p})\,\delta(\tilde{p}^2-m^2) \in \mathcal{S}'(\mathbb{R}^4)$ by

$$\tilde{\chi}(\tilde{p})\,\delta(\tilde{p}^2-m^2)=\tilde{\chi}_+(\tilde{p})\,\delta_+(\tilde{p}^2-m^2)+\tilde{\chi}_-(\tilde{p})\,\delta_-(\tilde{p}^2-m^2),$$

hence

$$(\tilde{\chi}(\tilde{p})\,\delta(\tilde{p}^2-m^2), f(\tilde{p})) = \int_{\tilde{\Gamma}_m} \frac{\tilde{\chi} f}{|\nabla \tilde{Q}|}\, d\tilde{S} \quad (f \in \mathcal{S}(\mathbb{R}^4)).$$

By $\tilde{\mathcal{M}}$ ($=\{\chi\circ\kappa^{-1}: \chi \in \mathcal{M}\}$) we denote the set of all multiplicators of $\delta(\tilde{p}^2-m^2)$.

The next proposition shows that $\tilde{\chi}_\pm(\tilde{p})\,\delta(\tilde{p}^2-m^2)$ and $\tilde{\chi}(\tilde{p})\,\delta(\tilde{p}^2-m^2)$ are well-defined tempered distributions and, in addition, we obtain an easy, but important transformation law between the distributions with and without tilde.

Proposition III.2: For every $\tilde{\chi}_\pm \in \tilde{\mathcal{M}}_\pm$, $\tilde{\chi} \in \tilde{\mathcal{M}}$ *the just defined* $\tilde{\chi}_\pm(\tilde{p})\,\delta_\pm(\tilde{p}^2-m^2)$ *and* $\tilde{\chi}(\tilde{p})\,\delta(\tilde{p}^2-m^2)$ *are tempered distributions on* $\mathbb{R}^4$, *and we have*

(i) $\tilde{\chi}_\pm(\tilde{p})\,\delta_\pm(\tilde{p}^2-m^2)=\chi_\pm(p)\,\delta_\pm(p^2-m^2)\circ\kappa^{-1}$,
(ii) $\tilde{\chi}(\tilde{p})\,\delta(\tilde{p}^2-m^2)=\chi(p)\,\delta(p^2-m^2)\circ\kappa^{-1}$,

as distributions (and as complex measures), where $\chi_\pm := \tilde{\chi}_\pm\circ\kappa$ *and* $\chi := \tilde{\chi}\circ\kappa$.

Proof: Clearly (ii) follows from (i), and (i) is just applying Lemma III.1 to $\rho := \chi_\pm f$. □

Using the parametrization $\Omega_\pm$ of $\Gamma_\pm$ (resp. $\tilde{\Omega}_\pm$ of $\tilde{\Gamma}_\pm$) we can evaluate the corresponding surface integral which yields (with $f \in \mathcal{S}(\mathbb{R}^4)$)

$$(\chi_\pm(p)\,\delta_\pm(p^2-m^2), f(p)) = \int \frac{d^3\mathbf{p}}{2\,\omega(\mathbf{p})}\,\chi_\pm(\Omega_\pm(\mathbf{p}))\,f(\Omega_\pm(\mathbf{p})), \tag{11}$$

$$(\tilde{\chi}_\pm(\tilde{p})\,\delta_\pm(\tilde{p}^2-m^2), f(\tilde{p})) = \int_{\pm p^+>0} \frac{d^3\tilde{\mathbf{p}}}{2|p^+|}\,\tilde{\chi}_\pm(\tilde{\Omega}_\pm(\tilde{\mathbf{p}}))\,f(\tilde{\Omega}_\pm(\tilde{\mathbf{p}})). \tag{12}$$

Remark III.3: As we have viewed $\delta_\pm(p^2-m^2)$ (resp. $\delta_\pm(\tilde{p}^2-m^2)$) as positive (Borel-) measures $\mu_m^\pm$ (resp. $\tilde{\mu}_m^\pm$) on $\Gamma_m^\pm$ (resp. $\tilde{\Gamma}_m^\pm$) we do the same with $\chi_\pm(p)\,\delta_\pm(p^2-m^2)$ (resp. $\tilde{\chi}(\tilde{p})\,\delta_\pm(\tilde{p}^2-m^2)$), but these are now complex measures. From measure theory it follows that the function $\chi_\pm(p)$ (resp. $\tilde{\chi}_\pm(\tilde{p})$) is determined by the complex measure $\chi_\pm(p)\,\delta_\pm(p^2-m^2)$ (resp. $\tilde{\chi}_\pm(\tilde{p})\,\delta_\pm(\tilde{p}^2-m^2)$) $\mu_m^\pm$-a.e. (resp. $\tilde{\mu}_m^\pm$-a.e.).

We introduce the following sets of solutions of the KG-equation (resp. LCKG-equation):

$$\mathcal{L}_\pm := \{\mathcal{F}_{\mathbb{M}}^{-1}(2\pi\chi_\pm(p)\,\delta_\pm(p^2-m^2)) : \chi_\pm \in \mathcal{M}_\pm\},$$

$$\tilde{\mathcal{L}}_\pm := \{\mathcal{F}_{\mathbb{L}}^{-1}(2\pi\tilde{\chi}_\pm(\tilde{p})\,\delta_\pm(\tilde{p}^2-m^2)) : \tilde{\chi}_\pm \in \tilde{\mathcal{M}}_\pm\},$$

and also define mappings

$$\alpha_\pm : \mathcal{M}_\pm \to \mathcal{L}_\pm, \quad \chi_\pm \mapsto \mathcal{F}_{\mathbb{M}}^{-1}(2\pi\chi_\pm(p)\,\delta_\pm(p^2-m^2)),$$

$$\tilde{\alpha}_\pm : \tilde{\mathcal{M}}_\pm \to \tilde{\mathcal{L}}_\pm, \quad \tilde{\chi}_\pm \mapsto \mathcal{F}_{\mathbb{L}}^{-1}(2\pi\tilde{\chi}_\pm(\tilde{p})\,\delta_\pm(\tilde{p}^2-m^2)).$$

The reason why there is no zero-mode problem in light cone QFT is caused by the following corollary:

Corollary III.4: Let $\phi_\pm = \mathcal{F}_{\mathbb{M}}^{-1}(2\pi\chi_\pm(p)\,\delta_\pm(p^2-m^2)) \in \mathcal{L}_\pm$ *be a solution of the KG-equation, with* $\chi_\pm \in \mathcal{M}_\pm$. *Then, if* $\tilde{\phi}_\pm = \phi_\pm \circ \kappa^{-1}$ *is the transformed solution, we have* $\tilde{\phi}_\pm = \mathcal{F}_{\mathbb{L}}^{-1}(2\pi\tilde{\chi}_\pm(\tilde{p})\,\delta_\pm(\tilde{p}^2-m^2))$ *with* $\tilde{\chi}_\pm = \chi_\pm \circ \kappa^{-1}$, *i.e., the following diagram commutes*

$$\begin{array}{ccc} \mathcal{M}_\pm & \xrightarrow{\alpha_\pm} & \mathcal{L}_\pm \\ \downarrow{\scriptstyle \kappa_*} & & \downarrow{\scriptstyle \kappa_*} \\ \tilde{\mathcal{M}}_\pm & \xrightarrow{\tilde{\alpha}_\pm} & \tilde{\mathcal{L}}_\pm \end{array}$$

where $\kappa_*(f) = f \circ \kappa^{-1}$.

Notice that κ_* maps the complex vector space $\mathcal{L}^p(\Gamma_m^\pm, d\mu_m) \subset \mathcal{M}_\pm$ (isometrically) isomorphically onto the complex vector space $\mathcal{L}^p(\tilde{\Gamma}_m^\pm, d\tilde{\mu}_m) \subset \tilde{\mathcal{M}}_\pm$.

Proof: Let $u_\pm = 2\pi\chi_\pm(p)\,\delta_\pm(p^2-m^2)$ and $\tilde{u}_\pm = 2\pi\tilde{\chi}_\pm(\tilde{p})\,\delta_\pm(\tilde{p}^2-m^2)$. Then from Proposition III.2 we know $\tilde{u}_\pm = u_\pm \circ \kappa^{-1}$. Now because of (3), we get $\tilde{\phi}_\pm = \phi_\pm \circ \kappa^{-1} = \mathcal{F}_{\mathbb{M}}^{-1}(u_\pm) \circ \kappa^{-1} = \mathcal{F}_{\mathbb{L}}^{-1}(u_\pm \circ \kappa^{-1}) = \mathcal{F}_{\mathbb{L}}^{-1}(\tilde{u}_\pm)$. □

In Corollary III.4 we have considered only the positive/negative frequency part $\phi_\pm = \mathcal{F}_{\mathbb{M}}^{-1}(2\pi\chi_\pm(p)\,\delta_\pm(p^2-m^2))$ of the field

$$\phi = \mathcal{F}_{\mathbb{M}}^{-1}(2\pi\chi(p)\,\delta(p^2-m^2)), \tag{13}$$

with $\chi \in \mathcal{M}$, $\chi|_{\Gamma_m^\pm} = \chi_\pm$. But it is clear that for the transformed field $\tilde{\phi} = \phi \circ \kappa^{-1}$ we also have

$$\tilde{\phi}=\mathcal{F}_{\mathrm{L}}^{-1}(2\pi\tilde{\chi}(\tilde{p})\,\delta(\tilde{p}^2-m^2)) \tag{14}$$

with $\tilde{\chi}=\chi\circ\kappa^{-1}$. We call (13) (resp. (14)) the *abstract plane wave expansion* of ϕ (resp. $\tilde{\phi}$). Because the amplitudes χ and $\tilde{\chi}$ differ only by a linear transformation, nothing gets worse if we go from the abstract plane wave expansion of ϕ to that of $\tilde{\phi}$.

To get a closer connection to the forms (4) and (7) we discuss now at the end of this section the special case, where the integrals in (4) and (7) are absolutely convergent (Lebesgue-) integrals emphasizing again the nonexistence of the zero-mode problem in light cone QFT.

Definition: A solution ϕ (resp. $\tilde{\phi}$) of the KG-equation (resp. LCKG-equation) in $\mathcal{S}'(\mathbb{R}^4)$ has a *convergent plane wave expansion* if ϕ (resp. $\tilde{\phi}$) is a regular distribution and has an integral representation of the form (4) (resp. (7)) where the integral is absolutely convergent (in the sense of Lebesgue).

If ϕ has a convergent plane wave expansion as in (4), we can write the integral as a surface integral

$$\phi(x)=\frac{1}{(2\pi)^3}\int_{\Gamma_m}\frac{\chi(p)\,e^{i\langle p,x\rangle_{\mathbb{M}}}}{|\nabla Q(p)|}dS(p)$$

if we define $\chi(p)$ on Γ_m^+ by $\chi(\Omega_+(\mathbf{p})):=a(\mathbf{p})$, and on Γ_m^- by $\chi(\Omega_-(\mathbf{p})):=a^+(-\mathbf{p})$, $(\mathbf{p}\in\mathbb{R}^3)$. To check this, just evaluate the surface integral using $\Omega_\pm$. Hence it follows $\chi\in\mathcal{L}^1(\Gamma_m,d\mu_m)$ and $\phi=\mathcal{F}_{\mathbb{M}}^{-1}(2\pi\chi(p)\,\delta(p^2-m^2))$. Analogously, if $\tilde{\phi}$ has a convergent plane wave expansion as in (7), we can write the integral as a surface integral

$$\tilde{\phi}(\tilde{x})=\frac{1}{(2\pi)^3}\int_{\tilde{\Gamma}_m}\frac{\tilde{\chi}(\tilde{p})\,e^{i\langle\tilde{p},\tilde{x}\rangle_{\mathrm{L}}}}{|\nabla\tilde{Q}(\tilde{p})|}d\tilde{S}(\tilde{p})$$

if we define $\tilde{\chi}(\tilde{p})$ on $\tilde{\Gamma}_m^+$ by $\tilde{\chi}(\tilde{\Omega}(\tilde{\mathbf{p}})):=\tilde{a}(\tilde{\mathbf{p}})$, and on $\tilde{\Gamma}_m^-$ by $\tilde{\chi}(\tilde{\Omega}(-\tilde{\mathbf{p}})):=\tilde{a}^+(\tilde{\mathbf{p}})$ $(\tilde{\mathbf{p}}\in\mathbb{R}^3,p^+>0)$. As before, it follows $\tilde{\chi}\in\mathcal{L}^1(\tilde{\Gamma}_m,d\tilde{\mu}_m)$ and $\tilde{\phi}=\mathcal{F}_{\mathrm{L}}^{-1}(2\pi\tilde{\chi}(\tilde{p})\,\delta(\tilde{p}^2-m^2))$. Conversely, if ϕ (resp. $\tilde{\phi}$) has an abstract plane wave expansion of the form $\phi=\mathcal{F}_{\mathbb{M}}^{-1}(2\pi\chi(p)\,\delta(p^2-m^2))$ (resp. $\tilde{\phi}=\mathcal{F}_{\mathrm{L}}^{-1}(2\pi\tilde{\chi}(\tilde{p})\,\delta(\tilde{p}^2-m^2))$) with $\chi\in\mathcal{L}^1(\Gamma_m,d\mu_m)$ (resp. $\tilde{\chi}\in\mathcal{L}^1(\tilde{\Gamma}_m,d\tilde{\mu}_m)$), it is easy to see—by evaluating the corresponding surface integrals using $\Omega_\pm$ (resp. $\tilde{\Omega}_\pm$)—that ϕ (resp. $\tilde{\phi}$) has a convergent plane wave expansion. Here we have used only standard facts from integration theory. Notice that, if $\chi(p)\in\mathcal{L}^1(\Gamma_m,d\mu_m)$ and $f(x)\in\mathcal{S}(\mathbb{R}^4)$, then $\chi(p)f(x)\in\mathcal{L}^1(\Gamma_m\times\mathbb{R}^4,d\mu_m(p)\otimes d^4x)$ and we can use Fubini's theorem. The same holds for $\tilde{\chi}(\tilde{p})$ (in the tilde situation). Hence we have proven the following lemma.

Lemma III.5: Let $\phi\in\mathcal{S}'(\mathbb{R}^4)$ (resp. $\tilde{\phi}\in\mathcal{S}'(\mathbb{R}^4)$) be a solution of the KG-equation (resp. LCKG-equation) which is regular (as a distribution). Then

(i) *ϕ has a convergent plane wave expansion as in* (4) *iff ϕ has an abstract plane wave expansion $\phi=\mathcal{F}_{\mathbb{M}}^{-1}(2\pi\chi(p)\,\delta(p^2-m^2))$ with $\chi\in\mathcal{L}^1(\Gamma_m,d\mu_m)$. In this case $a(\mathbf{p})=\chi(\Omega_+(\mathbf{p}))$ and $a^+(\mathbf{p})=\chi(\Omega_-(-\mathbf{p}))$ $(\mathbf{p}\in\mathbb{R}^3)$.*

(ii) *$\tilde{\phi}$ has a convergent plane wave expansion as in* (7) *iff $\tilde{\phi}$ has an abstract plane wave expansion $\tilde{\phi}=\mathcal{F}_{\mathrm{L}}^{-1}(2\pi\tilde{\chi}(\tilde{p})\,\delta(\tilde{p}^2-m^2))$ with $\tilde{\chi}\in\mathcal{L}^1(\tilde{\Gamma}_m,d\tilde{\mu}_m)$. In this case $\tilde{a}(\tilde{\mathbf{p}})=\tilde{\chi}(\tilde{\Omega}(\tilde{\mathbf{p}}))$ and $\tilde{a}^+(\tilde{\mathbf{p}})=\tilde{\chi}(\tilde{\Omega}(-\mathbf{p}))$ $(\tilde{\mathbf{p}}\in\mathbb{R}^3,p^+>0)$.*

Using this lemma we can prove the following proposition:

Proposition III.6: Let $\phi\in\mathcal{S}'(\mathbb{R}^4)$ be a solution of the KG-equation which is a regular distribution. Let $\tilde{\phi}=\phi\circ\kappa^{-1}$ be the transformed solution. Then, ϕ has a convergent plane wave expansion as in (4) *iff $\tilde{\phi}$ has a convergent plane wave expansion as in* (7). *In this case $\tilde{a}(\tilde{\mathbf{p}})=a(\nu(\tilde{\mathbf{p}}))$ and $\tilde{a}^+(\tilde{\mathbf{p}})=a^+(\nu(\tilde{\mathbf{p}}))$ for all $\tilde{\mathbf{p}}\in\mathbb{R}^3$, $p^+>0$, where $\nu(\tilde{\mathbf{p}}):=\Omega_+^{-1}(\kappa^{-1}(\tilde{\Omega}(\tilde{\mathbf{p}})))$.*

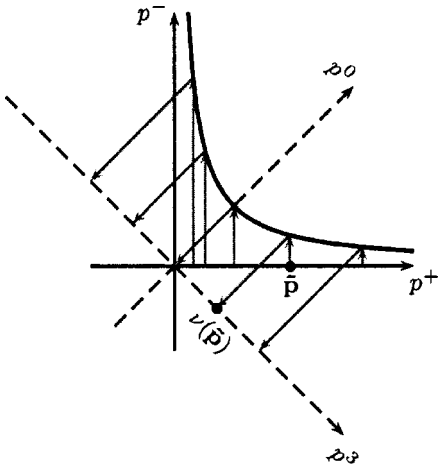

FIG. 2. The mapping $\nu:\mathbb{R}^3\backslash\{p^+\leqslant 0\}\to\mathbb{R}^3$, $\tilde{\mathbf{p}}\to\nu(\tilde{\mathbf{p}})$.

Proof: From Proposition III.2 we know that $\phi=\mathcal{F}_{\mathbb{M}}^{-1}(2\pi\chi(p)\delta(p^2-m^2))$ if and only if $\tilde{\phi}=\mathcal{F}_{\mathbb{L}}^{-1}(2\pi\tilde{\chi}(\tilde{p})\delta(\tilde{p}^2-m^2))$ where $\tilde{\chi}=\chi\circ\kappa^{-1}$. Now use Lemma III.5 to get the first assertion. To obtain the second assertion write, due to Lemma III.5, $\tilde{a}(\tilde{\mathbf{p}})=\tilde{\chi}(\tilde{\Omega}(\tilde{\mathbf{p}}))$ and $\tilde{a}^+(\tilde{\mathbf{p}})=\tilde{\chi}(\tilde{\Omega}\times(-\tilde{\mathbf{p}}))$. Now use $\tilde{\chi}=\chi\circ\kappa^{-1}$, $\Omega_-(-\mathbf{p})=-\Omega_+(\mathbf{p})$ and the second assertion of Lemma III.5 (i).□

As we have seen in Lemma III.5, the integral sign in (4) (resp. (7)) only makes sense if we take the amplitude $\chi(p)$ (resp. $\tilde{\chi}(\tilde{p})$) from the proper subset $\mathcal{L}^1(\Gamma_m,d\mu_m)$ of $\mathcal{M}$ (resp. $\mathcal{L}^1(\tilde{\Gamma}_m,d\tilde{\mu}_m)$ of $\tilde{\mathcal{M}}$). In all other cases the integral sign has to be viewed only symbolically (as usual in distribution theory). If we consider in general $\chi(p)\in\mathcal{M}$ and $\tilde{\chi}(\tilde{p})\in\tilde{\mathcal{M}}$, then $a(\mathbf{p})$ and $a^+(\mathbf{p})$ in (4) are tempered distributions on $\mathbb{R}^3$, however, $\tilde{a}(\tilde{\mathbf{p}})$ and $\tilde{a}^+(\tilde{\mathbf{p}})$ are not. Later we will see that these are squeezed distributions, and therefore we have to use squeezed distributions instead of tempered distributions to define the restriction of $\tilde{\phi}$ to $\{x^+=0\}$.

The mapping ν is extremely useful because it shows us how to define squeezed distributions and, in addition, it gives us the right connection between canonical QFT and light cone QFT. In Fig. 2 we have illustrated the mapping $\nu:\mathbb{R}^3\backslash\{p^+\leqslant 0\}\to\mathbb{R}^3$ to get a better feeling of what happens; the arrays indicate the way of how the value $\nu(\tilde{\mathbf{p}})$ of $\tilde{\mathbf{p}}$ is determined. The explicit formula of ν is

$$\nu(\tilde{\mathbf{p}})=\left(\mathbf{p}_\perp,\frac{1}{\sqrt{2}}\left(p^+-\frac{\mathbf{p}_\perp^2+m^2}{2p^+}\right)\right), \tag{15}$$

where $\tilde{\mathbf{p}}=(p^+,\mathbf{p}_\perp)=(p^+,p^1,p^2)\in\mathbb{R}^3\backslash\{p^+\leqslant 0\}$.

IV. THE REAL SCALAR FREE LC-FIELD, PUSHFORWARD OF QUANTUM FIELDS

As mentioned in the Introduction, the transformed field $\tilde{\phi}=\phi\circ\kappa^{-1}$ of a given quantum field ϕ does not fit in the classical Wightman formalism because the transformation κ to LC-coordinates is not a Lorentz transformation. In this section we will define the quantum field $\tilde{\phi}_m=\phi_m\circ\kappa^{-1}$, if ϕ_m is a free scalar field of mass $m>0$, as a quadruple $(\tilde{\mathcal{H}}_m,\tilde{U}_m,\tilde{\phi}_m,\tilde{D})$ in analogy to the classical free field $(\mathcal{H}_m,U_m,\phi_m,D)$. We will show that $\tilde{\phi}_m$ satisfies a slightly modified version of the classical Wightman axioms, which we will call the LC-Wightman axioms.

Before starting the construction of $\tilde{\phi}_m$, we have to select an appropriate one-particle space $\tilde{\mathfrak{H}}_m$. The one-particle space $\mathfrak{H}_m$ of a relativistic, spinless, neutral particle (resp. antiparticle) of mass $m>0$ living in Minkowski space is $\mathcal{L}^2(\Gamma_m^+,d\mu_m)$ (resp. $\mathcal{L}^2(\Gamma_m^-,d\mu_m)$). That is because the distributions of the form $\phi_\pm=\mathcal{F}_{\mathbb{M}}^{-1}(2\pi\chi_\pm(p)\delta_\pm(p^2-m^2))$, with $\chi_\pm\in\mathcal{L}^2(\Gamma_m^\pm,d\mu_m)$, represent all physically relevant positive/negative frequency solutions of the KG-equation.[19] From Corollary

III.4 it follows that these solutions are in one-to-one correspondence—via κ—with the solutions $\tilde{\phi}_{\pm}=\mathcal{F}_{\mathbb{L}}^{-1}(2\pi\tilde{\chi}_{\pm}(\tilde{p})\delta_{\pm}(\tilde{p}^2-m^2))$, with $\tilde{\chi}_{\pm}\in\mathcal{L}^2(\tilde{\Gamma}_m^{\pm},d\tilde{\mu}_m)$, of the LCKG-equation. Hence we define:

Definition: The one-particle space of a relativistic, spinless, neutral particle (resp. antiparticle) in LC-space of mass $m>0$ is $\tilde{\mathfrak{H}}_m:=\mathcal{L}^2(\tilde{\Gamma}_m^+,d\tilde{\mu}_m)$ (resp. $\mathcal{L}^2(\tilde{\Gamma}_m^-,d\tilde{\mu}_m)$).

Remark IV.1: The coordinate transformation $\kappa:\mathbb{M}\to\mathbb{L}$ induces a canonical isomorphism of complex Hilbert spaces $\kappa_*:\mathfrak{H}_m\tilde{\to}\tilde{\mathfrak{H}}_m$ between the one-particle spaces.

We define the real scalar free LC-field $\tilde{\phi}_m$ of mass $m>0$ in the same way as the real scalar free field ϕ_m was defined in Ref. 16 using the Segal field operator ϕ_S.

Let $\mathfrak{H}$ be a complex Hilbert space and let $\mathcal{F}_\vee(\mathfrak{H})=\oplus_{n=0}^{\infty}\mathfrak{H}^{\vee n}$ be the bosonic Fock space (over $\mathfrak{H}$). By F_0 we denote the dense linear subspace of all finite vectors ψ of $\mathcal{F}_\vee(\mathfrak{H})$, i.e., $\psi=(\psi^{(n)})_{n\in\mathbb{N}}$ such that $\psi^{(n)}=0$ for all but finitely many $n\in\mathbb{N}$. For each $f\in\mathfrak{H}$ the Segal field operator $\phi_S(f)$ is defined as a linear operator on the finite vectors F_0 by

$$\phi_S(f):=\frac{1}{\sqrt{2}}(a(f)+a^*(f)),$$

where $a(f)$ (resp. $a^*(f)$) is the annihilation (resp. creation) operator defined on F_0. Recall that on $\mathfrak{H}^{\vee n}$ (cf. Ref. 3)

$$a^*(f)(\psi_1\vee\cdots\vee\psi_n)=\sqrt{n+1}\,f\vee\psi_1\vee\cdots\vee\psi_n$$

and

$$a(f)(\psi_1\vee\cdots\vee\psi_n)=\frac{1}{\sqrt{n}}\sum_{j=1}^{n}\langle f,\psi_j\rangle\psi_1\vee\cdots\vee\widehat{\psi_j}\vee\cdots\vee\psi_n,$$

where $\widehat{\psi_j}$ means omitting ψ_j. On the finite vectors $a(f)$ is the adjoint operator of $a^+(f)$. It can be shown (Ref. 16, Theorem X.41) that $\phi_S(f)$ is essentially self-adjoint. In the following, we denote the closure of $\phi_S(f)$ also by $\phi_S(f)$. The mapping $f\mapsto\phi_S(f)$ from $\mathfrak{H}$ to the set of all self-adjoint operators on $\mathcal{F}_\vee(\mathfrak{H})$ is called the Segal quantization over $\mathfrak{H}$.

Note that $\mathcal{F}_\vee$ is a (covariant) functor on the category of complex Hilbert spaces. Hence, any linear operator u on $\mathfrak{H}$ induces a linear operator $\mathcal{F}_\vee(u)$—the second quantization of u—on $\mathcal{F}_\vee(\mathfrak{H})$. If u is unitary, then the same holds for $\mathcal{F}_\vee(u)$.

To define the real scalar free field ϕ_m of mass $m>0$, one chooses $\mathfrak{H}_m:=\mathcal{L}^2(\Gamma_m^+,d\mu_m)$ as the one-particle space. Now, let ϕ_S be the Segal quantization over $\mathfrak{H}_m$. Then on $\mathfrak{H}_m^{\vee n}$ the creation and annihilation operator are explicitly given by

$$(a^*(f)\psi)(p_1,\ldots,p_{n+1})=\frac{1}{\sqrt{n+1}}\sum_{j=1}^{n+1}f(p_j)\psi(p_1,\ldots,\widehat{p_j},\ldots,p_{n+1}),$$

$$(a(f)\psi)(p_1,\ldots,p_{n-1})=\sqrt{n}\int_{\Gamma_m^+}\overline{f(p)}\psi(p,p_1,\ldots,p_{n-1})d\mu_m(p),$$

where $\psi(p_1,\ldots,p_n)\in\mathfrak{H}_m^{\vee n}$. We denote by $\mathrm{res}:\mathcal{S}(\mathcal{M})\to\mathfrak{H}_m$ the restriction mapping $f\mapsto f|_{\Gamma_m^+}$. If $f\in\mathcal{S}(\mathbb{M})$ is real-valued, one defines

$$\phi_m(f)=\phi_S(\alpha\cdot\mathrm{res}(f^{\wedge_{\mathbb{M}}})),$$

where $\alpha:=\sqrt{2/(2\pi)^3}$ is a normalizing constant, and for general $f\in\mathcal{S}(\mathbb{M})$

$$\phi_m(f)=\phi_m(\mathrm{Re}\,f)+i\phi_m(\mathrm{Im}\,f).$$

To complete the construction of the real scalar field ϕ_m, one has to define a strongly continuous unitary representation of the restricted Poincaré group $\mathcal{P}_+^\uparrow$. This is done by

$$U_m:\mathcal{P}_+^\uparrow\to\mathcal{B}(\mathcal{F}_\vee(\mathfrak{H}_m)),\quad (a,\Lambda)\mapsto\mathcal{F}_\vee(u_m(a,\Lambda)),$$

where $u_m(a,\Lambda)\in\mathcal{B}(\mathfrak{H}_m)$ is defined by

$$(u_m(a,\Lambda)\psi)(p):=e^{i\langle a,p\rangle_{\mathbb{M}}}\psi(\Lambda^{-1}p).$$

Again we denote by F_0 the dense subspace of all finite vectors of $\mathcal{H}_m:=\mathcal{F}_\vee(\mathfrak{H}_m)$. The following theorem is proven in Ref. 16, Theorem X.42.

Theorem IV.2: *The quadruple* $(\mathcal{H}_m,U_m,\phi_m,F_0)$ *satisfies the Wightman axioms. Moreover,*

$$(\Box+m^2)\phi_m=0,$$

i.e., $\phi_m((\Box+m^2)f)=0$ *for each* $f\in\mathcal{S}(\mathbb{M})$.

If we replace in the preceding construction of ϕ_m all quantities by the corresponding tilde quantities, we obtain the real scalar free LC-field $\tilde{\phi}_m$. More precisely, let $\tilde{\phi}_S$ be the Segal quantization over $\tilde{\mathfrak{H}}_m=\mathcal{L}^2(\tilde{\Gamma}_m^+,d\tilde{\mu}_m)$. The creation and annihilation operators are now given explicitly by

$$(\tilde{a}^*(f)\tilde{\psi})(\tilde{p}_1,\ldots,\tilde{p}_{n+1})=\frac{1}{\sqrt{n+1}}\sum_{j=1}^{n+1}f(\tilde{p}_j)\tilde{\psi}(\tilde{p}_1,\ldots,\widehat{\tilde{p}_j},\ldots,\tilde{p}_{n+1}),$$

$$(\tilde{a}(f)\tilde{\psi})(\tilde{p}_1,\ldots,\tilde{p}_{n-1})=\sqrt{n}\int_{\tilde{\Gamma}_m^+}\overline{f}(p)\tilde{\psi}(\tilde{p},\tilde{p}_1,\ldots,\tilde{p}_{n-1})d\tilde{\mu}_m(\tilde{p}),$$

where $\tilde{\psi}(\tilde{p}_1,\ldots,\tilde{p}_n)\in\tilde{\mathfrak{H}}_m^{\vee n}$. We denote by $\widetilde{\mathrm{res}}:\mathcal{S}(\mathbb{L})\to\tilde{\mathfrak{H}}_m$ the restriction mapping $f\mapsto f|_{\tilde{\Gamma}_m^+}$. If $f\in\mathcal{S}(\mathbb{L})$ is real-valued, we define

$$\tilde{\phi}_m(f)=\tilde{\phi}_S(\alpha\cdot\widetilde{\mathrm{res}}(f^{\wedge_{\mathbb{L}}})),$$

and for general $f\in\mathcal{S}(\mathbb{L})$

$$\tilde{\phi}_m(f)=\tilde{\phi}_m(\mathrm{Re}\,f)+i\tilde{\phi}_m(\mathrm{Im}\,f).$$

We still have to define a strongly continuous unitary representation, now, of the restricted LC-Poincaré group $\tilde{\mathcal{P}}_+^\uparrow=\kappa\mathcal{P}_+^\uparrow\kappa=\{(\kappa a,\kappa\Lambda\kappa):(a,\Lambda)\in\mathcal{P}_+^\uparrow)\}$. Let

$$\tilde{U}_m:\tilde{\mathcal{P}}_+^\uparrow\to\mathcal{B}(\mathcal{F}_\vee(\tilde{\mathfrak{H}}_m)),\quad (\tilde{a},\tilde{\Lambda})\mapsto\mathcal{F}_\vee(\tilde{u}_m(\tilde{a},\tilde{\Lambda})),$$

where $\tilde{u}_m(\tilde{a},\tilde{\Lambda})\in\mathcal{B}(\tilde{\mathfrak{H}}_m)$ is defined by

$$(\tilde{u}_m(\tilde{a},\tilde{\Lambda})\tilde{\psi})(\tilde{p}):=e^{i\langle\tilde{a},\tilde{p}\rangle_{\mathbb{L}}}\tilde{\psi}(\tilde{\Lambda}^{-1}\tilde{p}).$$

Finally, let $\tilde{F}_0$ be the dense subspace of finite vectors of $\tilde{\mathcal{H}}_m:=\mathcal{F}_\vee(\tilde{\mathfrak{H}}_m)$. Immediately from the definitions we obtain the following commutative diagrams:

$$\begin{array}{ccc} D & \xrightarrow{\phi(f)} & \mathcal{H}_m \\ {\scriptstyle \mathcal{F}_{\mathrm{V}}(\kappa_*)}\downarrow\wr & & \downarrow\wr{\scriptstyle \mathcal{F}_{\mathrm{V}}(\kappa_*)} \\ \tilde{D} & \xrightarrow[\tilde{\phi}(\tilde{f})]{} & \tilde{\mathcal{H}}_m \end{array} \qquad \begin{array}{ccc} \mathcal{H}_m & \xrightarrow{U_m(a,\Lambda)} & \mathcal{H}_m \\ {\scriptstyle \mathcal{F}_{\mathrm{V}}(\kappa_*)}\downarrow\wr & & \downarrow\wr{\scriptstyle \mathcal{F}_{\mathrm{V}}(\kappa_*)} \\ \tilde{\mathcal{H}}_m & \xrightarrow[\tilde{U}_m(\tilde{a},\tilde{\Lambda})]{} & \tilde{\mathcal{H}}_m \end{array} \tag{16}$$

with $\tilde{f}=\kappa_*(f)$, $(\tilde{a},\tilde{\Lambda})=(\kappa a,\kappa\Lambda\kappa)$, where $f\in\mathcal{S}(\mathbb{M})$, $(a,\Lambda)\in\mathcal{P}_+^\uparrow$, and $D=F_0$, $\tilde{D}=\tilde{F}_0$.

Using these commutative diagrams and Theorem IV.2, it is easy to see that the quadruple $(\tilde{\mathcal{H}}_m,\tilde{U}_m,\tilde{\phi}_m,\tilde{F}_0)$ satisfies the following axioms, called *LC-Wightman axioms* of a real scalar LC-quantum field $(\tilde{\mathcal{H}},\tilde{U},\tilde{\phi},\tilde{D})$:

LC-W1 (Relativistic invariance of the state space): $\tilde{\mathcal{H}}$ is a separable complex Hilbert space and $\tilde{U}$ is a strongly continuous unitary representation on $\tilde{\mathcal{H}}$ of the restricted LC-Poincaré group $\tilde{\mathcal{P}}_+^\uparrow$.

LC-W2 (Spectral property): The spectrum of the LC-energy-momentum operator $\tilde{P}=(P_{\tilde{\mu}})=(P_+,P_1,P_2,P_-)$ given by $\tilde{U}(\tilde{a},\mathrm{id})=e^{i\tilde{a}^{\tilde{\mu}}P_{\tilde{\mu}}}$ lies in the closed upper LC-light cone $\mathrm{cl}(\tilde{V}^+)=\{\tilde{p}\in\mathbb{L}:\tilde{p}^2\geqslant 0,\ p^-\geqslant 0\}$.

LC-W3 (Existence and uniqueness of the vacuum): There exists in $\tilde{\mathcal{H}}$ a unique (up to a phase factor) unit vector $\tilde{\psi}_0$ (also denoted by $|\tilde{0}\rangle$ and called the vacuum), which is invariant with respect to the translations $\tilde{U}(\tilde{a},\mathrm{id})$, $(\tilde{a}\in\mathbb{L})$.

LC-W4 (Domain of definition and continuity of the field):

(i) For each $f\in\mathcal{S}(\mathbb{L})$, $\tilde{\phi}(f)$ is a linear operator on $\tilde{\mathcal{H}}$ with $\tilde{D}\subset D(\tilde{\phi}(f))$, $\tilde{D}\subset D(\tilde{\phi}(f)^*)$, where $\tilde{D}$ is a dense linear subspace of $\tilde{\mathcal{H}}$.

(ii) $\tilde{\phi}(f)\tilde{D}\subset\tilde{D}$, $\tilde{\phi}(f)^*\tilde{D}\subset\tilde{D}$, $\tilde{U}(\tilde{a},\tilde{\Lambda})\tilde{D}\subset\tilde{D}$, for each $f\in\mathcal{S}(\mathbb{L})$ and $(\tilde{a},\tilde{\Lambda})\in\tilde{P}_+^\uparrow$.

(iii) The vacuum $|\tilde{0}\rangle$ is contained in $\tilde{D}$.

(iv) The mapping $\mathcal{S}(\mathbb{L})\to\tilde{\mathcal{H}}$, $f\mapsto\tilde{\phi}(f)\psi$ is linear and continuous for each $\psi\in\tilde{\mathcal{H}}$.

(v) (Hermiticity) $\tilde{\phi}(f)^*|_{\tilde{D}}=\tilde{\phi}(\overline{f})|_{\tilde{D}}$ for each $f\in\mathcal{S}(\mathbb{L})$.

LC-W5 (Poincaré invariance of the field):

$$\tilde{U}(\tilde{a},\tilde{\Lambda})\tilde{\phi}(f)\tilde{U}(\tilde{a},\tilde{\Lambda})^{-1}=\tilde{\phi}(\{\tilde{a},\tilde{\Lambda}\}.f)$$

on $\tilde{D}$ for each $f\in\mathcal{S}(\mathbb{L})$ and $(\tilde{a},\tilde{\Lambda})\in\tilde{P}_+^\uparrow$, where $\{\tilde{a},\tilde{\Lambda}\}.f(\tilde{x})=f(\tilde{\Lambda}^{-1}(\tilde{x}-\tilde{a}))$.

LC-W6 (Locality, or microcausality): If the supports of f and g in $\mathcal{S}(\mathbb{L})$ are LC-spacelike separated, i.e., if $\langle\tilde{x}-\tilde{y},\tilde{x}-\tilde{y}\rangle_{\mathbb{L}}<0$ for each $\tilde{x}\in\mathrm{supp}(f)$, $\tilde{y}\in\mathrm{supp}(g)$, then on $\tilde{D}$

$$[\tilde{\phi}(f),\tilde{\phi}(g)]=0.$$

LC-W7 (Cyclicity of the vacuum): The set of finite linear combinations of vectors of the form $\tilde{\phi}(f_1)\cdots\tilde{\phi}(f_n)|\tilde{0}\rangle$ is dense in $\tilde{\mathcal{H}}$.

Corollary IV.3: The quadruple $(\tilde{\mathcal{H}}_m,\tilde{U}_m,\tilde{\phi}_m,\tilde{F}_0)$ *satisfies the LC-Wightman axioms. Moreover,*

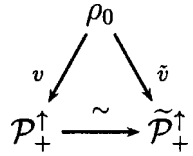
$$(\tilde{\Box}+m^2)\tilde{\phi}_m=0,$$

i.e., $\tilde{\phi}_m((\tilde{\Box}+m^2)f)=0$ *for each* $f\in\mathcal{S}(\mathbb{L})$.

Definition: The quadruple $(\tilde{\mathcal{H}}_m, \tilde{U}_m, \tilde{\phi}_m, \tilde{F}_0)$ from Corollary IV.3 is called the real scalar free LC-field of mass $m>0$.

Remark IV.4: In LC-W1–LC-W7 we have listened the LC-Wightman axioms of a real scalar LC-quantum field. Thereby we have only modified the assertions of the classical Wightman axioms which concern the Minkowski metric and replaced these by using the LC-metric.

Remark IV.5: In relativistic physics it is important to admit also two-valued representations of the restricted Poincaré group $\mathcal{P}_+^\uparrow$; for example to describe particles of half-integral spin, i.e., spinor fields. Hence, one requires in the Wightman axioms[20,3] a unitary representation of the universal covering group of $\mathcal{P}_+^\uparrow$–the Poincaré spinor group $\rho_0 := \{(a, \underset{\sim}{\Lambda}) : a \in \mathbb{M},\ \underset{\sim}{\Lambda} \in \mathrm{SL}(2,\mathbb{C})\}$ Since $\mathcal{P}_+^\uparrow \tilde{\to} \tilde{\mathcal{P}}_+^\uparrow$ $(a,\Lambda) \mapsto (\tilde{a}, \tilde{\Lambda}) := (\kappa a, \kappa \Lambda \kappa^{-1})$ is an isomorphism of complex Lie groups, the Poincaré spinor group is also the universal covering group of $\tilde{\mathcal{P}}_+^\uparrow$ and we have the following commutative diagram



where v and $\tilde{v}$ are the corresponding covering mappings and $\mathcal{P}_+^\uparrow \tilde{\to} \tilde{\mathcal{P}}_+^\uparrow$ is the above given isomorphism. Hence it is natural to generalize axiom LC-W1 by requiring that $\tilde{U}$ is a strongly continuous unitary representation of the Poincaré spinor group ρ_0. Note that $v(a, \underset{\sim}{\Lambda}) = (a, \Lambda(\underset{\sim}{\Lambda}))$ where $\mathrm{SL}(2,\mathbb{C}) \to \mathcal{L}_+^\uparrow$, $\underset{\sim}{\Lambda} \mapsto \Lambda(\underset{\sim}{\Lambda})$ is the universal covering of $\mathcal{L}_+^\uparrow$. Hence we have $\tilde{v}(a,\Lambda) = (a, \tilde{\Lambda}(\underset{\sim}{\Lambda}))$, where $\mathrm{SL}(2,\mathbb{C}) \to \tilde{\mathcal{L}}_+^\uparrow$, $\underset{\sim}{\Lambda} \mapsto \tilde{\Lambda}(\underset{\sim}{\Lambda}) = \kappa \Lambda(\underset{\sim}{\Lambda}) \kappa^{-1}$ is the universal covering mapping of the proper LC-Lorentz group $\tilde{\mathcal{L}}_+^\uparrow$.

Remark IV.6: The spectral condition LC-W2 implies (or is equivalent) that the operators P_+, P_- and $\tilde{P}^2 = 2P_+P_- - P_1^2 - P_2^2$ are positive. Note, that in the Minkowski case we have only the two positive operators P_0 and P^2. The presents of an extra positive momentum operator P_+ is one of the advantages of light cone quantum field theory.

Remark IV.7: For simplicity we have written down the LC-Wightman axioms only for a scalar LC-quantum field. But, it is trivial to generalize these axioms to multi-component LC-quantum fields $\tilde{\phi} = (\tilde{\phi}_l)$, and even to a finite or infinite collection $\{\tilde{\phi}^{(\tau)}\}$ of such fields. As in the Minkowski case (cf. Refs. 3 and 20) one has to generalize the transformation law in LC-W5 to

$$\tilde{U}(\tilde{a}, \underset{\sim}{\Lambda}) \tilde{\phi}_k^{(\tau)}(f) \tilde{U}(\tilde{a}, \underset{\sim}{\Lambda})^{-1} = \sum_l V_{kl}^{(\tau)}(\underset{\sim}{\Lambda}^{-1}) \tilde{\phi}_l^{(\tau)}(\{\tilde{a}, \tilde{\Lambda}(\underset{\sim}{\Lambda})\}.f),$$

where $V_{kl}^{(\tau)}$ is a complex or real finite-dimensional matrix representation of $\mathrm{SL}(2,\mathbb{C})$ and $\tilde{U}$ is a strongly continuous unitary representation of the Poincaré spinor group on $\tilde{\mathcal{H}}$. As in Ref. 3, p. 325, we suppose that $V^{(\tau)}(-1) = \{\pm 1\}$. If $V^{(\tau)}(-1) = 1$, then $(\tilde{\phi}_l)$ is a LC-field with integral spin (tensor LC-field), if $V^{(\tau)}(-1) = -1$, then $(\tilde{\phi}_l)$ is a LC-field with half-integral spin (spinor LC-field).

Moreover, one has to replace the commutator in LC-W6 by

$$[\tilde{\phi}_k^{(\tau)}(f), \tilde{\phi}_l^{(\tau')}(g)] = 0$$

and, if one wants to define a fermionic LC-field, one has to replace the commutator by the anticommutator.

In LC-W7 we have to require that the set of finite linear combinations of vectors of the form $\tilde{\phi}_{l_1}^{(\tau_1)}(f_1) \cdots \tilde{\phi}_{l_n}^{(\tau_n)}(f_n)|\tilde{0}\rangle$ is dense in $\tilde{\mathcal{H}}$. Hence, it should be clear how to modify the general Wightman axioms,[3] p. 324, to obtain the LC-Wightman axioms of a LC-quantum field theory, in general.

The construction of the real scalar free LC-field, especially the commutative diagrams (16), suggests the following definition.

Definition: Let $\phi=(\mathcal{H},U,(\phi_l^{(\tau)}),D)$ be a quantum field obeying the (classical) Wightman axioms. A pushforward of ϕ under $\kappa:\mathbb{M}\to\mathbb{L}$ (or pullback of ϕ under $\kappa^{-1}:\mathbb{L}\to\mathbb{M}$) is a LC-quantum field $\tilde{\phi}=(\tilde{\mathcal{H}},\tilde{U},(\tilde{\phi}_l^{(\tau)}),\tilde{D})$ obeying the LC-Wightman axioms (and transforming according to the same finite-dimensional representation $V_{kl}^{(\tau)}$ as $\phi^{(\tau)}$) together with a unitary linear operator $T:\mathcal{H}\to\tilde{\mathcal{H}}$ such that $T(D)=\tilde{D}$ and such that for each $f\in\mathcal{S}(\mathbb{M})$, $(a,\underset{\sim}{\Lambda})\in\rho_0$ the following diagrams commute

$$\begin{array}{ccc} D & \xrightarrow{\phi_l^{(\tau)}(f)} & \mathcal{H} \\ {\scriptstyle T}\downarrow & & \downarrow{\scriptstyle T} \\ \tilde{D} & \xrightarrow{\tilde{\phi}_l^{(\tau)}(\tilde{f})} & \tilde{\mathcal{H}} \end{array} \qquad \begin{array}{ccc} \mathcal{H} & \xrightarrow{U(a,\Lambda)} & \mathcal{H} \\ {\scriptstyle T}\downarrow & & \downarrow{\scriptstyle T} \\ \tilde{\mathcal{H}} & \xrightarrow{\tilde{U}(\tilde{a},\tilde{\Lambda})} & \tilde{\mathcal{H}} \end{array} \tag{17}$$

with $\tilde{a}:=\kappa a$, $\tilde{f}=\kappa_* f$ and $\tilde{\Lambda}:=\kappa\Lambda\kappa^{-1}$. For short, we write $\tilde{\phi}=\kappa_*(\phi)=(\kappa^{-1})^*(\phi)$.

We summarize the preceding by the following:

Proposition IV.8: The real scalar free LC-field $\tilde{\phi}_m=(\tilde{\mathcal{H}}_m,\tilde{U}_m,\tilde{\phi}_m,\tilde{F}_0)$ of mass $m>0$ together with the unitary operator $\mathcal{F}_\vee(\kappa_*):\mathcal{H}_m\to\tilde{\mathcal{H}}_m$ is a pushforward of the real scalar free field ϕ under $\kappa:\mathbb{M}\to\mathbb{L}$, i.e., $\tilde{\phi}_m=\kappa_*(\phi_m)$.

Remark IV.9: Let ϕ be a quantum field and $\tilde{\phi}=\kappa_*\phi$, with $T:\mathcal{H}\to\tilde{\mathcal{H}}$, a pushforward of ϕ. If $|0\rangle$ is the vacuum of ϕ then $T|0\rangle$ is the vacuum of $\tilde{\phi}$ because $T|0\rangle$ is invariant under $\tilde{U}(\tilde{a},\underset{\sim}{\Lambda})$ for each $(\tilde{a},\underset{\sim}{\Lambda})\in\rho_0$.

Remark IV.10: Given a (general) quantum field $\phi=(\mathcal{H},U,(\phi_l^{(\tau)}),D)$, it is trivial to define a pushforward of ϕ under κ. Let $\tilde{\mathcal{H}}:=\mathcal{H}$ and $\tilde{D}:=D$. Define $\tilde{\phi}_l^{(\tau)}(\tilde{f})$ and $\tilde{U}(\tilde{a},\underset{\sim}{\Lambda})$ by $\tilde{\phi}_l^{(\tau)}(\tilde{f})$ $:=\phi_l^{(\tau)}(\tilde{f}\circ\kappa)$ and $\tilde{U}(\tilde{a},\underset{\sim}{\Lambda}):=U(\kappa^{-1}\tilde{a},\underset{\sim}{\Lambda})$. It is easy to check that $\tilde{\phi}=(\tilde{\mathcal{H}},\tilde{U},(\tilde{\phi}_l^{(\tau)}),\tilde{D})$ together with $T=\mathrm{id}:\mathcal{H}\to\tilde{\mathcal{H}}$ is a pushforward of ϕ.

Remark IV.11: The definition of the pushforward $\kappa_*(\phi)$ of a quantum field ϕ can also be done for any general linear invertible mapping $\kappa:\mathbb{M}\to\mathbb{R}^4$. It is not restricted to the transformation from Minkowski- to LC-coordinates.

The next proposition concerning the (anti-)commutator of a LC-quantum field follows easily from the definition of a pushforward.

Proposition IV.12: Let $\phi=(\mathcal{H},U,(\phi_l^{(\tau)}),D)$ be a quantum field and $\tilde{\phi}=\kappa_*(\phi)$, with $T:\mathcal{H}\to\tilde{\mathcal{H}}$, a pushforward of ϕ. Then for each $f,g\in\mathcal{S}(\mathbb{M})$

$$[\tilde{\phi}_l^{(\tau)}(\kappa_* f),\tilde{\phi}_m^{(\tau')}(\kappa_* g)]_\mp = T[\phi_l^{(\tau)}(f),\phi_m^{(\tau')}(g)]_\mp T^{-1},$$

where $[\_,\_]_\mp$ denotes commutator/anticommutator.

In relativistic physics the so-called Pauli–Jordan commutation function

$$D_m(x)=\frac{1}{i(2\pi)^3}\mathcal{F}_{\mathbb{M}}(\epsilon(p^0)\delta(p^2-m^2))=\frac{1}{i(2\pi)^3}\int d^4p\ \epsilon(p^0)\delta(p^2-m^2)\,e^{i\langle p,x\rangle_{\mathbb{M}}}$$

plays an essential role. One usually splits $D_m(x)$ into its positive and negative frequency parts

$$D_m^{(\pm)}(x)=\frac{\pm 1}{i(2\pi)^3}\mathcal{F}_{\mathbb{M}}(\delta_\pm(p^2-m^2))=\frac{\pm 1}{i(2\pi)^3}\int d^4p\ \delta_\pm(p^2-m^2)\,e^{i\langle p,x\rangle_{\mathbb{M}}}$$
$$=\frac{\pm 1}{2i(2\pi)^3}\int\frac{d^3\mathbf{p}}{\omega(\mathbf{p})}e^{i(\pm\omega(\mathbf{p})x^0-\mathbf{p}\cdot\mathbf{x})},$$

then $D_m(x)=D_m^{(+)}(x)+D_m^{(-)}(x)$.

Now, let $\tilde{D}_m(\tilde{x})=\kappa_*D_m(\tilde{x})=(D_m\circ\kappa^{-1})(\tilde{x})$ be the transformation of D_m to LC-coordinates $\tilde{x}$. We also transform the positive and negative parts of D_m and obtain $\tilde{D}_m^{(\pm)}(\tilde{x})=\kappa_*D_m^{(\pm)}(\tilde{x})=(D_m^{(\pm)}\circ\kappa^{-1})(\tilde{x})$. From (3) we know that M- and L-Fourier transformation commute with κ_* and, since $\delta_\pm(\tilde{p}^2-m^2)=\kappa_*\delta_\pm(p^2-m^2)$, we obtain

$$\tilde{D}_m(\tilde{x})=\frac{1}{i(2\pi)^3}\mathcal{F}_{\mathbb{L}}(\epsilon(p^-)\delta(\tilde{p}^2-m^2))=\frac{1}{i(2\pi)^3}\int d^4\tilde{p}\ \epsilon(p^-)\delta(\tilde{p}^2-m^2)\,e^{i\langle\tilde{p},\tilde{x}\rangle_{\mathbb{L}}}$$

and

$$\tilde{D}_m^{(\pm)}(\tilde{x})=\frac{\pm 1}{i(2\pi)^3}\mathcal{F}_{\mathbb{L}}(\delta_\pm(\tilde{p}^2-m^2))=\frac{\pm 1}{i(2\pi)^3}\int d^4\tilde{p}\ \delta_\pm(\tilde{p}^2-m^2)\,e^{i\langle\tilde{p},\tilde{x}\rangle_{\mathbb{L}}}$$
$$=\frac{\pm 1}{2i(2\pi)^3}\int_{\pm p^+>0}\frac{d^3\tilde{\mathbf{p}}}{|p^+|}e^{i(\tilde{\omega}(\tilde{\mathbf{p}})x^++p^+x^--\mathbf{p}_\perp\cdot\mathbf{x}_\perp)}.$$

Hence, we also have $\tilde{D}_m(\tilde{x})=\tilde{D}_m^{(+)}(\tilde{x})+\tilde{D}_m^{(-)}(\tilde{x})$.

Corollary IV.13: Let $\tilde{\phi}_m(\tilde{x})$ be the real scalar free LC-field of mass $m>0$, i.e., the pushforward of the real scalar free field $\phi_m(x)$. Then

$$[\tilde{\phi}_m(\tilde{x}),\tilde{\phi}_m(\tilde{y})]=\frac{1}{i}\tilde{D}_m(\tilde{x}-\tilde{y}),$$

where $\tilde{D}_m(\tilde{x})=\kappa_*D_m(\tilde{x})=(D_m\circ\kappa^{-1})(\tilde{x})$.

Proposition IV.14: Let $\phi=(\mathcal{H},U,(\phi_l^{(\tau)}),D)$ be a quantum field and $\tilde{\phi}=\kappa_*(\phi)$ a pushforward of ϕ. We denote by

$$w_{l_1,\ldots,l_n}^{(\tau_1\cdots\tau_n)}(x_1,\ldots,x_n)=\langle 0|\,\phi_{l_1}^{(\tau_1)}(x_1)\cdots\phi_{l_n}^{(\tau_n)}(x_n)|0\rangle$$

the Wightman functions of ϕ and by

$$\tilde{w}_{l_1,\ldots,l_n}^{(\tau_1\cdots\tau_n)}(\tilde{x}_1,\ldots,\tilde{x}_n)=\langle\tilde{0}|\,\tilde{\phi}_{l_1}^{(\tau_1)}(\tilde{x}_1)\cdots\tilde{\phi}_{l_n}^{(\tau_n)}(\tilde{x}_n)|\tilde{0}\rangle$$

the Wightman functions of $\tilde{\phi}$. Then

$$\tilde{w}_{l_1,\ldots,l_n}^{(\tau_1\cdots\tau_n)}=w_{l_1,\ldots,l_n}^{(\tau_1\cdots\tau_n)}\circ\oplus^n\kappa^{-1}.$$

Proof: Follows immediately from the left commutative diagram of (17). □

Corollary IV.15: Let $\tilde{\phi}_m$ be the real scalar free LC-field of mass $m>0$. Then

$$\langle\tilde{0}|\,\tilde{\phi}_m(\tilde{x})\tilde{\phi}_m(\tilde{y})|\tilde{0}\rangle=\frac{1}{i}\tilde{D}_m^{(-)}(\tilde{x}-\tilde{y}).$$

Proof: Since $\langle 0|\,\phi_m(x)\phi_m(y)|0\rangle=(1/i)\,D_m^{(-)}(x-y)$, the assertion follows from Proposition IV.14. □

It should be clear that one can translate any covariant statement about Wightman quantum fields to the LC-case. All that we have to do is to rephrase a given statement by using the LC bilinear form $\langle \_,\_\rangle_{\mathbb{L}}$ instead of the Minkowski bilinear form $\langle \_,\_\rangle_{\mathbb{M}}$. In this way we obtain, for example, an analogous reconstruction theorem for LC-quantum fields. We do not want to listen all these transformed statements which can be proven trivially by using the definition of the pushforward of a quantum field. Going over from a quantum field ϕ to the corresponding LC-quantum field $\tilde{\phi}=\kappa_*\phi$ in the context of the covariant four-dimensional Wightman formalism gives, however, no additional insight into the theory. But, as mentioned in the Introduction, we are mainly interested in the use of the front form dynamics to describe the dynamics of a quantum field. So, we have to study the question whether it is possible to use in a mathematically rigorous way the nonrelativistic Hamiltonian formalism in the LC-case.

V. THE RESTRICTION PROBLEM AND SQUEEZED DISTRIBUTIONS

In this section we restrict ourselves to a real scalar free field ϕ_m of mass $m>0$. Let $\tilde{\phi}_m$ be the corresponding real scalar free LC-field. Recall that $\phi_m=(\mathcal{H}_m,U_m,\phi_m,D)$, $\tilde{\phi}_m=(\tilde{\mathcal{H}}_m,\tilde{U}_m,\tilde{\phi}_m,\tilde{D})$, where $\mathcal{H}_m=\mathcal{F}_\vee(\mathfrak{H}_m)$, $\tilde{\mathcal{H}}_m=\mathcal{F}_\vee(\tilde{\mathfrak{H}}_m)$ with $\mathfrak{H}_m=\mathcal{L}^2(\Gamma_m^+,d\mu_m)$, $\tilde{\mathfrak{H}}_m=\mathcal{L}^2(\tilde{\Gamma}_m^+,d\tilde{\mu}_m)$, and that $\tilde{\phi}_m=\kappa_*\phi_m$ is a pushforward of ϕ_m under κ where the unitary operator $T=\mathcal{F}_\vee(\kappa_*):\mathcal{H}_m\to\tilde{\mathcal{H}}_m$ is induced by the canonical unitary operator $\kappa_*:\mathfrak{H}_m\to\tilde{\mathfrak{H}}_m$, $f\mapsto f\circ\kappa^{-1}$.

A. Outline of the restriction problem

The standard way to construct the time-zero field φ_m and its canonical conjugate π_m goes as follows (cf. Ref. 16, p. 215):

Let $g\in\mathcal{S}_3=\mathcal{S}(\mathbb{R}^3)$ be real valued. Since the restriction of $(\delta(x^0)\otimes g(\mathbf{x}))^{\wedge\mathbb{M}}=1\otimes\hat{g}$ to Γ_m^+ ($\hat{g}$ is the usual 3-dim. Fourier transform of g) is in $\mathfrak{H}_m=\mathcal{L}^2(\Gamma_m^+,d\mu_m)$—this is equivalent to $\hat{g}\in\mathcal{L}^2(\mathbb{R}^3,d^3\mathbf{p}/2\omega(\mathbf{p}))$—it is possible to define

$$\varphi_m(g):=\phi_m(\delta(x^0)\otimes g(\mathbf{x}))=\phi_S(\alpha\cdot\mathrm{res}_{\Gamma_m^+}(1\otimes\hat{g})).$$

Then one extends linearly the definition of φ_m to general $g\in\mathcal{S}_3$ by

$$\varphi_m(g):=\varphi_m(\mathrm{Re}\,g)+i\varphi_m(\mathrm{Im}\,g).$$

The canonical conjugate momentum π_m is defined by

$$\pi_m(g)=\frac{\partial}{\partial x^0}\phi_m(\delta(x^0)\otimes g(\mathbf{x}))=\phi_S(\alpha\cdot\mathrm{res}_{\Gamma_m^+}(-ip^0\hat{g}(\mathbf{p})))$$

for each real valued $g\in\mathcal{S}_3$ and one extends the definition to general $g\in\mathcal{S}_3$ again by linearity. Here ϕ_S denotes the Segal quantization over $\mathfrak{H}_m$. Note that π_m is well-defined because $p^0\hat{g}(\mathbf{p})$ is in $\mathfrak{H}_m$.

Now, if one tries to define the time-zero LC-field $\tilde{\varphi}_m$ (and its canonical conjugate $\tilde{\pi}_m$) in an analogous way by

$$\tilde{\varphi}_m(g)=\tilde{\phi}_m(\delta(x^+)\otimes g(\tilde{\mathbf{x}})),$$

one gets into trouble because, for general $g(\tilde{\mathbf{x}})\in\mathcal{S}_3$, the function $(\delta(x^+)\otimes g(\tilde{\mathbf{x}}))^{\wedge\mathbb{L}}$ is not in $\tilde{\mathfrak{H}}_m=\mathcal{L}^2(\tilde{\Gamma}^+,d\tilde{\mu}_m)$. This is easily seen by

$$\|(\delta(x^+)\otimes g(\tilde{\mathbf{x}}))^{\wedge\mathbb{L}}\|_{\tilde{\mathfrak{H}}_m}^2=\int_{p^+>0}\frac{d^3\tilde{\mathbf{p}}}{2p^+}|g^{\sqcap}(\tilde{\mathbf{p}})|^2, \tag{18}$$

where we have denoted by $g^{\sqcap}(\tilde{\mathbf{p}})$ the partial $\mathbb{L}$-Fourier transform $\mathcal{F}_{\mathbb{L}}^{\tilde{\mathbf{x}}\to\tilde{\mathbf{p}}}(g)$ of $g(\tilde{\mathbf{x}})$ defined by

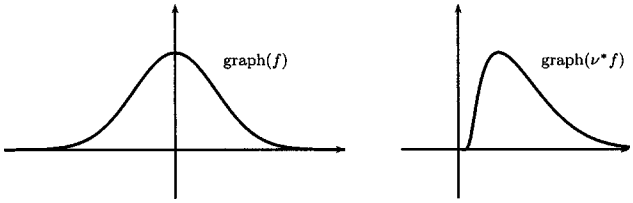


FIG. 3. Graphs of $f(p^2)=\exp(-p^2)$ and $\nu^* f(p^+)=\exp(-\frac{1}{2}(p^+-(1/2p^+))^2)$.

$$g^{\sqcap}(\tilde{\mathbf{p}}) := (\mathcal{F}_{\mathbb{L}}^{\tilde{\mathbf{x}}\to\tilde{\mathbf{p}}} g)(\tilde{\mathbf{p}}) := \int_{\mathbb{R}^3} d^3\tilde{\mathbf{x}}\, g(\tilde{\mathbf{x}})\, e^{i(p^+x^- - \mathbf{p}_\perp\cdot\mathbf{x}_\perp)}. \tag{19}$$

To solve this restriction problem we have to drop the assumption that the restriction of a quantum field has to be defined on $\mathcal{S}(\mathbb{R}^3)$. We will see in a few moments that a completely different function space which is, however, isomorphic to $\mathcal{S}(\mathbb{R}^3)$ is the canonical candidate for a test function space to define the restriction of a LC-quantum field. Consider the following commutative diagram:

$$\begin{array}{ccccc}
\mathcal{S}(\mathbb{M}) & \xrightarrow{\text{res}} & \mathcal{L}^2(\Gamma_m^+, d\mu_m) & \xrightarrow{\Omega_+^*} & \mathcal{L}^2\left(\mathbb{R}^3, \frac{d^3\mathbf{p}}{2\omega(\mathbf{p})}\right) \\
\downarrow{\scriptstyle \kappa_*} & & \downarrow{\scriptstyle \kappa_*} & & \downarrow{\scriptstyle \nu^*} \\
\mathcal{S}(\mathbb{L}) & \xrightarrow{\widetilde{\text{res}}} & \mathcal{L}^2(\tilde{\Gamma}_m^+, d\tilde{\mu}_m) & \xrightarrow{\tilde{\Omega}_+^*} & \mathcal{L}^2\left(\mathbb{R}_{>0}\times\mathbb{R}^2, \frac{d^3\tilde{\mathbf{p}}}{2p^+}\right)
\end{array} \tag{20}$$

Recall that κ_*, Ω_+^*, $\tilde{\Omega}_+^*$, ν^* are isomorphisms (resp. unitary mappings) and $\nu=\Omega_+^{-1}\circ\kappa^{-1}\circ\tilde{\Omega}_+$ (cf. (15)). We write briefly $\text{res}(f)$ (resp. $\widetilde{\text{res}}(f)$) instead of $\text{res}_{\Gamma_m^+}(f)$ (resp. $\text{res}_{\tilde{\Gamma}_m^+}(f)$).

It is well known that the image of $\mathcal{S}(\mathbb{M})$ under the restriction mapping is dense in $\mathcal{L}^2(\Gamma_m^+, d\mu_m)$. Essential for the definition of the time-zero field φ_m on $\mathcal{S}_3=\mathcal{S}(\mathbb{R}^3)$ is the fact that $\text{res}(\mathcal{S}(\mathbb{M}))$ equals $(\Omega_+^*)^{-1}(\mathcal{S}_3)=\{\text{res}(1(p^0)\otimes g(\mathbf{p})): g(\mathbf{p})\in\mathcal{S}_3\}$ (to see this, notice that $\text{res}(f)=\text{res}(1(p^0)\otimes f(\Omega_+(\mathbf{p})))$ and that, given $g(\mathbf{p})\in\mathcal{S}_3$, $f(p):=e^{-(p^0-\omega(\mathbf{p}))^2} g(\mathbf{p})\in\mathcal{S}_4$ and $f(\Omega_+(\mathbf{p}))=g(\mathbf{p})$).

Now, let us look at the lower row of (20). Since this diagram commutes, the image of $\mathcal{S}(\mathbb{L})$ under the restriction mapping is dense in $\mathcal{L}^2(\tilde{\Gamma}_m^+, d\tilde{\mu})$, too. Again, we can describe this image, $\widetilde{\text{res}}(\mathcal{S}(\mathbb{L}))$, as the preimage of some subspace of $\mathcal{L}^2(\mathbb{R}_{>0}\times\mathbb{R}^2, d^3\tilde{\mathbf{p}}/2p^+)$ under $\tilde{\Omega}_+$, especially we have

$$\widetilde{\text{res}}(\mathcal{S}(\mathbb{L})) = (\tilde{\Omega}_+^*)^{-1}(\nu^*(\mathcal{S}_3)) = \{\widetilde{\text{res}}(\tilde{g}(\tilde{\mathbf{p}})\otimes 1(p^-)) : \tilde{g}(\tilde{\mathbf{p}})\in\nu^*(\mathcal{S}_3)\}.$$

Hence we see that the function space

$$\mathcal{S}_{p^+}(\mathbb{R}_{>0}\times\mathbb{R}^2) := \nu^*(\mathcal{S}_3) = \{g\circ\nu : g\in\mathcal{S}_3\}$$

takes on the role of $\mathcal{S}_3$, if we switch from three-dimensional $\mathbf{p}$-space to three-dimensional $\tilde{\mathbf{p}}$-space. We endow $\mathcal{S}_{p^+}(\mathbb{R}_{>0}\times\mathbb{R}^2)$ with the final topology w.r.t. $\nu^*:\mathcal{S}_3\to\mathcal{S}_{p^+}(\mathbb{R}_{>0}\times\mathbb{R}^2)$. Then ν^* becomes an isomorphism of (complex) topological vector spaces.

Before we start to define the restriction of the free LC-field $\tilde{\phi}_m$ to $\{x^+=0\}$, we show some interesting properties of $\mathcal{S}_{p^+}(\mathbb{R}_{>0}\times\mathbb{R}^2)$. To get a first impression of what kind of functions appear in $\mathcal{S}_{p^+}(\mathbb{R}_{>0}\times\mathbb{R}^2)$ and how the mapping $\nu^*:\mathcal{S}_3\to\mathcal{S}_{p^+}(\mathbb{R}_{>0}\times\mathbb{R}^2)$ deforms (squeezes) the functions of $\mathcal{S}_3$ we have drawn in Fig. 3, as an example, the graphs of the functions $f(p)$

$=\exp(-p^2)\in\mathcal{S}_1$ and $(\nu^* f)(p^+)$, where $\nu(p^+)=(1/\sqrt{2})(p^+-1/2p^+)$. In Fig. 3 one can see that ν^* transforms the rapidly decreasing behavior of $f(p)$ as p goes to $-\infty$ to a rapidly decreasing behavior of $\nu^* f(p^+)$ as p^+ goes to zero (from the right).

B. Squeezed distributions

Let us start to study the function space $\mathcal{S}_{p^+}(\mathbb{R}_{>0}\times\mathbb{R}^2)$. We wish to do this in any dimension n, thus first we have to (re)define $\mathcal{S}_{p^+}(\mathbb{R}_{>0}\times\mathbb{R}^n)$ for any $n\geqslant 0$. Also we want to consider the reflected situation and thus introduce $\mathcal{S}_{p^+}(\mathbb{R}_{<0}\times\mathbb{R}^n)$. Let $\mathbb{M}^{n+1}$ (resp. $\mathbb{L}^{n+1}$) be $(n+1)$-dimensional Minkowski space (resp. LC-space) and let $\kappa:\mathbb{M}^{n+1}\to\mathbb{L}^{n+1}$ be the transformation to LC-coordinates as introduced in Sec. II. We have introduced in Sec. II the parametrizations $\Omega_\pm:\mathbb{R}^n\tilde{\to}\Gamma_m^\pm\subset\mathbb{R}^{n+1}$ and $\tilde{\Omega}_\pm:\mathbb{R}_{\gtrless 0}\times\mathbb{R}^{n-1}\tilde{\to}\tilde{\Gamma}_m^\pm\subset\mathbb{R}^{n+1}$ of the smooth submanifolds $\Gamma_m^\pm$ and $\tilde{\Gamma}_m^\pm$. The *(positive/negative) squeezing mapping* $\nu_{\gtrless 0}:\mathbb{R}_{\gtrless 0}\times\mathbb{R}^{n-1}\to\mathbb{R}^n$ is defined by

$$\nu_{\gtrless 0}:=\Omega_\pm^{-1}\circ\kappa^{-1}\circ\tilde{\Omega}_\pm .$$

Note that the previous ν equals now $\nu_{>0}$ and that $\nu_{<0}(-\tilde{\mathbf{p}})=-\nu_{>0}(\tilde{\mathbf{p}})$ for all $\tilde{\mathbf{p}}\in\mathbb{R}_{>0}\times\mathbb{R}^{n-1}$. Furthermore $\nu_{\gtrless 0}$ is a diffeomorphism from $\mathbb{R}_{\gtrless 0}\times\mathbb{R}^{n-1}$ onto $\mathbb{R}^n$. If we define

$$\nu_{\neq 0}:\mathbb{R}^\times\times\mathbb{R}^{n-1}\to\mathbb{R}^n,\qquad \tilde{\mathbf{p}}=(p^+,\mathbf{p}_\perp)\mapsto\left(\mathbf{p}_\perp,\frac{1}{\sqrt{2}}\left(p^+-\frac{\mathbf{p}_\perp^2+m^2}{2p^+}\right)\right),$$

where $(\mathbb{R}^\times=\mathbb{R}\backslash 0)$, then $\nu_{\neq 0}$ is a double covering of $\mathbb{R}^n$ and the restriction of $\nu_{\neq 0}$ to $\mathbb{R}_{\gtrless 0}\times\mathbb{R}^{n-1}$ is $\nu_{\gtrless 0}$. The inverse mapping of $\nu_{\gtrless 0}$ is denoted by $\mu_{\gtrless 0}$, and is explicitly given by

$$\mu_{\gtrless 0}:\mathbb{R}^n\to\mathbb{R}_{\gtrless 0}\times\mathbb{R}^{n-1},\qquad \mathbf{p}=(p^1,\ldots,p^n)\mapsto\left(\frac{p^n\pm\omega(\mathbf{p})}{\sqrt{2}},p^1,\ldots,p^{n-1}\right),$$

where $\omega(\mathbf{p})=\sqrt{\mathbf{p}^2+m^2}$.

Definition: The (complex) topological vector space

$$\mathcal{S}_{p^+}(\mathbb{R}_{\gtrless 0}\times\mathbb{R}^{n-1}):=\nu_{\gtrless 0}^*\mathcal{S}(R^n)=\{f\circ\nu_{\gtrless 0}:f\in\mathcal{S}(\mathbb{R}^n)\}$$

is called the *positive/negative squeezed Schwartz space* (of positive/negative squeezed rapidly decreasing functions), where we have endowed $\mathcal{S}_{p^+}(\mathbb{R}_{\gtrless 0}\times\mathbb{R}^{n-1})$ with the final topology w.r.t. $\nu_{\gtrless 0}^*:\mathcal{S}(\mathbb{R}^n)\to\mathcal{S}_{p^+}(\mathbb{R}_{\gtrless 0}\times\mathbb{R}^{n-1})$.

The next proposition deals with fundamental properties of $\mathcal{S}_{p^+}(\mathbb{R}_{\gtrless 0}\times\mathbb{R}^{n-1})$ which are essential for the sequel. Recall (e.g. Ref. 1) that $\mathbb{C}[X_1,\ldots,X_n]_{X_i}$ denotes the localization of the polynomial ring $\mathbb{C}[X_1,\ldots,X_n]$ by the multiplicative set $\{X_i^k:\mathbb{Z}\ni k\geqslant 0\}$, i.e., $\mathbb{C}[X_1,\ldots,X_n]_{X_i}=\{S/X_i^k:S\in\mathbb{C}[X_1,\ldots,X_n],\ k\geqslant 0\}$. In the following we consider $\mathbb{C}[X_1,\ldots,X_n]_{X_i}$ always as a ring of functions on $\{X_i\neq 0\}$.

Lemma V.1:

(i) *Let $c\in\mathbb{R}$, $c>0$, and let $k\in\mathbb{N}$, $k>1$. Then for all $t\geqslant\max(1,3/c)$*
$$t^{k+1}+1\leqslant t^k\sqrt{t^2+c}.$$

(ii) *Assume $Q\in\mathbb{C}[p^+,\mathbf{p}_\perp]_{p^+}$ and α is a multi-index, let $\mu_{>0}$ as above. Then there is a polynomial $R\in\mathbb{R}[\mathbf{p}]$ such that*
$$|\partial^\alpha(Q\circ\mu_{>0})(\mathbf{p})|\leqslant R(\mathbf{p})\quad\text{for all}\quad\mathbf{p}\in\mathbb{R}^n.$$

(iii) *The functions $\omega\circ\nu_{\gtrless 0}$ are (restrictions of functions) in $\mathbb{C}[p^+,\mathbf{p}_\perp]_{p^+}$, where $\nu_{\gtrless 0}$ is the positive/negative squeezing mapping and $\omega(\mathbf{p})=\sqrt{\mathbf{p}^2+m^2}$.*

Proof:

(i) Let $t\geqslant\max(1,3/c)$ and $k>1$. Then $2t^{k+1}+1\leqslant ct^{2k}$. Adding t^{2k+2} to both sides of this

inequality yields $(t^{k+1}+1)^2 \leqslant t^{2k}(t^2+c)$.

(ii) Clearly $\partial^\alpha(Q\circ\mu_{>0})$ is a polynomial in $1/(\omega(\mathbf{p})+p^n)$, $\omega(\mathbf{p})$, $1/\omega(\mathbf{p})$, and $\mathbf{p}$. It is enough to consider only the cases when $\partial^\alpha(Q\circ\mu_{>0})$ equals one of these functions. Thereby, the only non-trivial case is if it equals $1/(\omega(\mathbf{p})+p^n)$ (note that $\lim_{p^n\to-\infty}\omega(\mathbf{p})+p^n=0$). Let $c(\mathbf{p}') := \Sigma_{i=1}^{n-1}(p^i)^2+m^2$, where $\mathbf{p}'=(p^1,\ldots,p^{n-1})\in\mathbb{R}^{n-1}$. Fix any $k>1$, $k\in\mathbb{N}$. By (i) we have

$$(p^n)^{k+1}+1 \leqslant (p^n)^k\omega(\mathbf{p})$$

for all $\mathbf{p}\in\mathbb{R}^n$ such that $p^n \geqslant \max(1,3/c(\mathbf{p}'))$. Since $c(\mathbf{p}')$ is bounded from below, $\max(1,3/c(\mathbf{p}'))$ is bounded from above by some $C\geqslant 1$. Thus, for all $\mathbf{p}\in\mathbb{R}^n$ such that $p^n \geqslant C$, we obtain

$$\frac{1}{\omega(\mathbf{p})-p^n} \leqslant (p^n)^k.$$

If t is the supremum of $(1/(\omega(\mathbf{p})-p^n)$ on $\{\mathbf{p}\in\mathbb{R}^n : p^n\leqslant C\}$ then $R(\mathbf{p}) := (p^n)^k+t$ is the desired polynomial.

(iii) Since $\mu_{>0}\circ\nu_{>0}$ is the identity on $\mathbb{R}_{>0}\times\mathbb{R}^{n-1}$, we have

$$p^+ = \frac{1}{\sqrt{2}}\left(\omega(\nu_{>0}(\tilde{\mathbf{p}})) + \frac{1}{\sqrt{2}}\left(p^+ - \frac{\mathbf{p}_\perp^2+m^2}{2p^+}\right)\right)$$

from which the assertion follows. □

In the following we denote by $f^\vee$ the function defined by $f^\vee(p) := f(-p)$.

Proposition V.2:

(i) $\mathcal{S}_{p^+}(\mathbb{R}_{>0}\times\mathbb{R}^{n-1})^\vee = \mathcal{S}_{p^+}(\mathbb{R}_{<0}\times\mathbb{R}^{n-1})$.

(ii) *Assume α is a multi-index, $Q\in\mathbb{C}[p^+,\mathbf{p}_\perp]_{p^+}$ and $f\in\mathcal{S}_{p^+}(\mathbb{R}_{\geqslant 0}\times\mathbb{R}^{n-1})$. Then $Q\partial^\alpha f \in \mathcal{S}_{p^+}(\mathbb{R}_{\geqslant 0}\times\mathbb{R}^{n-1})$.*

(iii) *$\mathcal{S}_{p^+}(\mathbb{R}_{\geqslant 0}\times\mathbb{R}^{n-1})$ consists of all $f\in C^\infty(\mathbb{R}_{\geqslant 0}\times\mathbb{R}^{n-1})$ such that*

$$\sup_{\tilde{\mathbf{p}}\in\mathbb{R}_{\geqslant 0}\times\mathbb{R}^{n-1}} |Q(\tilde{\mathbf{p}})\partial^\alpha f(\tilde{\mathbf{p}})| < \infty \tag{21}$$

for all multi-indices α and $Q\in\mathbb{C}[p^+,\mathbf{p}_\perp]_{p^+}$. Furthermore, the topology of $\mathcal{S}_{p^+}(\mathbb{R}_{\geqslant 0}\times\mathbb{R}^{n-1})$ is induced by the semi-norms in the left-hand side of (21).

Proof:

(i) is trivial and (ii) follows immediately from (iii).

(iii) It is enough to show (iii) only for $\mathcal{S}_{p^+}(\mathbb{R}_{>0}\times\mathbb{R}^{n-1})$. We write $\nu := \nu_{>0}$, $\mu := \nu^{-1}$, and $\sup'|Q\partial^\alpha f|$ for the seminorms in (21). We have defined the topology on $\mathcal{S}_{p^+}(\mathbb{R}_{>0}\times\mathbb{R}^{n-1})$ as the final topology w.r.t. the bijection $\nu^*:\mathcal{S}(\mathbb{R}^n)\to\mathcal{S}_{p^+}(\mathbb{R}_{>0}\times\mathbb{R}^{n-1})$. Thus the topology is induced by the family of seminorms

$$\sup_{\mathbf{p}\in\mathbb{R}^n} |R(\mathbf{p})\partial^\alpha(f\circ\mu)(\mathbf{p})|, \quad \alpha \text{ multi-index, } R \text{ polynomial.} \tag{22}$$

A smooth function f is in $\mathcal{S}_{p^+}(\mathbb{R}_{>0}\times\mathbb{R}^{n-1})$ iff $f\circ\mu$ is in $\mathcal{S}(\mathbb{R}^n)$ which means that $\sup|R\partial^\alpha(f\circ\mu)|<\infty$ for all multi-indices α and polynomials R. Assume $f\in\mathbb{C}^\infty(\mathbb{R}_{>0}\times\mathbb{R}^{n-1})$. By the chain rule $R\partial^\alpha(f\circ\mu)$ is a finite sum of terms of the form $S\mu^*(\partial^\beta f)$ where β is a multi-index and S is a polynomial in $1/\omega(\mathbf{p})$, $\omega(\mathbf{p})$, and $\mathbf{p}$. Since $1/\omega(\mathbf{p})$ is a bounded function, we can bound $|S\mu^*(\partial^\beta f)|$ by some $|R\mu^*(\partial^\beta f)|$ where R is a polynomial in $\omega(\mathbf{p})$ and $\mathbf{p}$. By Lemma V.1 (iii) $Q := R\circ\nu$ is in $\mathbb{C}[p^+,\mathbf{p}_\perp]$ and thus $|S\mu^*(\partial^\beta f)|$ is bounded by $|\mu^*(Q\partial^\beta f)|$ with $Q\in\mathbb{C}[p^+,\mathbf{p}_\perp]$. Because $\sup|\mu^*(Q\partial^\beta f)| = \sup'|Q\partial^\beta f|$, we have shown that the seminorms in (22) are continuous w.r.t. the seminorms in (21) and that $f\in\mathcal{S}_{p^+}(\mathbb{R}_{>0}\times\mathbb{R}^{n-1})$ whenever $\sup'|Q\partial^\alpha f|<\infty$ for all $Q\in\mathbb{C}[p^+,\mathbf{p}_\perp]_{p^+}$ and multi-indices α.

Conversely, consider $\sup'|Q\partial^\alpha f|$, where $Q\in\mathbb{C}[p^+,\mathbf{p}_\perp]_{p^+}$ and $f\in C^\infty(\mathbb{R}_{>0}\times\mathbb{R}^{n-1})$. Let $g := f\circ\mu\in\mathbb{C}^\infty(\mathbb{R}^n)$. Then $Q\partial^\alpha(\nu^*g)$ is a finite sum of terms of the form $S\nu^*(\partial^\beta g)$ with $S\in\mathbb{C}[p^+,\mathbf{p}_\perp]_{p^+}$, β multi-index. Because $\sup'|S\nu^*(\partial^\beta g)| = \sup|(\mu^*S)\partial\beta g|$ and, by Lemma V.1 (ii), $|\mu^*S|$ is bounded by some polynomial R, we obtain $\sup|(\mu^*S)\partial^\beta g| \leqslant \sup|R\partial^\beta(f\circ\mu)|$. Es-

pecially, $\sup'|Q\partial^\alpha f|<\infty$ for all $Q\in\mathbb{C}[p^+,\mathbf{p}_\perp]_{p^+}$ and α whenever $f\circ\mu\in\mathcal{S}(\mathbb{R}^n)$, i.e., $f\in\mathcal{S}_{p^+}(\mathbb{R}_{>0}\times\mathbb{R}^{n-1})$. □

To study further the test function space $\mathcal{S}_{p^+}(\mathbb{R}_{\geqslant 0}\times\mathbb{R}^{n-1})$ we introduce a new space, denoted $\mathcal{S}_{p^+}(\mathbb{R}^n)$.

Definition: By $\mathcal{S}_{p^+}(\mathbb{R}^n)$ we denote the set of all $f\in C^\infty(\mathbb{R}^n)$ such that

$$\sup_{(p^+,\mathbf{p}_\perp)\in\mathbb{R}^n\setminus\{p^+=0\}}|(p^+)^k\mathbf{p}_\perp^\beta\partial^\alpha f(p^+,\mathbf{p}_\perp)|<\infty \tag{23}$$

for all $k\in\mathbb{Z}$ and all multi-indices α and β, endowed with the locally convex topology defined by the seminorms in the left-hand side of (23). The function space $\mathcal{S}_{p^+}(\mathbb{R}^n)$ is called *squeezed Schwartz space* (of squeezed rapidly decreasing functions). The dual $\mathcal{S}'_{p^+}(\mathbb{R}^n)$ is called *space of squeezed distributions (or squeezed generalized functions).*

Note that the seminorms in the left-hand side of (23) differ only in the range of the exponent of p^+—which now can also be negative—from the seminorms that define the Schwartz space $\mathcal{S}(\mathbb{R}^n)$.

Theorem V.3:

(i) *$\mathcal{S}_{p^+}(\mathbb{R}^n)\subset\mathcal{S}(\mathbb{R}^n)$, and the topology of $\mathcal{S}_{p^+}(\mathbb{R}^n)$ coincide with the subspace topology induced by $\mathcal{S}(\mathbb{R}^n)$. Moreover, $\mathcal{S}_{p^+}(\mathbb{R}^n)$ is a closed subspace of $\mathcal{S}(\mathbb{R}^n)$.*

(ii) *If $j(f)$ denotes extension by zero of $f\in\mathcal{S}_{p^+}(\mathbb{R}_{\geqslant 0}\times\mathbb{R}^{n-1})$ then we have a mapping $j:\mathcal{S}_{p^+}(\mathbb{R}_{\geqslant 0}\times\mathbb{R}^{n-1})\to\mathcal{S}_{p^+}(\mathbb{R}^n)$ which induces an isomorphism (of topological vector spaces) onto their image, denoted $\mathcal{S}_{p^+\geqslant 0}(\mathbb{R}^n)$.*

(iii) $\mathcal{S}_{p^+}(\mathbb{R}^n)=\mathcal{S}_{p^+}(\mathbb{R}_{<0}\times\mathbb{R}^{n-1})\oplus\mathcal{S}_{p^+}(\mathbb{R}_{>0}\times\mathbb{R}^{n-1})$.

(iv) *Consider the following filtration of $\mathcal{S}(\mathbb{R}^n)$*

$$\mathcal{S}(\mathbb{R}^n)\supset p^+\mathcal{S}(\mathbb{R}^n)\supset(p^+)^2\mathcal{S}(\mathbb{R}^n)\supset\cdots\supset(p^+)^k\mathcal{S}(\mathbb{R}^n)\supset\cdots.$$

Then $\mathcal{S}_{p^+}(\mathbb{R}^n)=\cap_{k\geqslant 0}(p^+)^k\mathcal{S}(\mathbb{R}^n)$, or, if we use categorical language,

$$\mathcal{S}_{p^+}(\mathbb{R}^n)=\varprojlim_{k\geqslant 0}(p^+)^k\mathcal{S}(\mathbb{R}^n)$$

(in the category of topological vector spaces).

(v) *If $Q\in\mathbb{C}[p^+,\mathbf{p}_\perp]_{p^+}$, $g\in\mathcal{S}_{p^+}(\mathbb{R}^n)$, and α is a multi-index, then the mappings*

$$f\mapsto Qf,\quad f\mapsto gf,\quad f\mapsto\partial^\alpha f$$

are continuous linear mappings from $\mathcal{S}_{p^+}(\mathbb{R}^n)$ into $\mathcal{S}_{p^+}(\mathbb{R}^n)$.

Proof:

(i) That $\mathcal{S}_{p^+}(\mathbb{R}^n)$ is a subspace of $\mathcal{S}(\mathbb{R}^n)$ follows immediately from the definition of $\mathcal{S}_{p^+}(\mathbb{R}^n)$. To show that the topology of $\mathcal{S}_{p^+}(\mathbb{R}^n)$ is just the subspace topology induced by $\mathcal{S}(\mathbb{R}^n)$ we have to show that the seminorms $\sup|(p^+)^k\mathbf{p}_\perp^\beta\partial^\alpha f(p^+,\mathbf{p}_\perp)|$ with $k<0$ do not strengthen the topology, i.e., are continuous w.r.t. the seminorms with $k\geqslant 0$. This is easily seen by applying inductively the mean-value theorem of calculus to get $\sup|(p^+)^k g|\leqslant\sup|\partial_+^k g|$ for each $g\in\mathcal{S}_{p^+}(\mathbb{R}^n)$ and $k<0$. The last assertion follows from (iii) because $\mathcal{S}_{p^+}(\mathbb{R}_{\geqslant 0}\times\mathbb{R}^{n-1})$ as a homeomorphic image of $\mathcal{S}(\mathbb{R}^n)$ is itself a Fréchet space and hence $\mathcal{S}_{p^+}(\mathbb{R}^n)$ is a Fréchet space, too.

(ii) Assume $f\in\mathcal{S}_{p^+}(\mathbb{R}_{>0}\times\mathbb{R}^{n-1})$. We have to prove that $j(f)$ is in $\mathcal{S}_{p^+}(\mathbb{R}^n)$. First we have to show that $j(f)$ is a C^∞-function on $\mathbb{R}^n$. This is the case if we have shown, that $\lim_{p^+\to 0}\partial^\alpha f(\tilde{\mathbf{p}})=0$. However, this follows immediately from $\sup'|(1/p^+)\,\partial^\alpha f(\tilde{\mathbf{p}})|<\infty$ which holds for each multi-index α. Since $\sup'|(p^+)^k\mathbf{p}_\perp^\beta\partial^\alpha f|=\sup|(p^+)^k\mathbf{p}_\perp^\beta\partial^\alpha j(f)|$, we see $j(f)\in\mathcal{S}_{p^+}(\mathbb{R}^n)$.

Furthermore, j maps $\mathcal{S}_{p^+}(\mathbb{R}_{>0}\times\mathbb{R}^{n-1})$ homeomorphically onto its image because the family of seminorms in (23) is equivalent to the family of semi-norms $\sup_{p^+\neq 0}|Q\partial^\alpha f|$, $Q\in\mathbb{C}[p^+,\mathbf{p}_\perp]_{p^+}$, α multi-index.

(iii) Each $f\in\mathcal{S}_{p^+}(\mathbb{R}^n)$ can uniquely be written as $f=\chi_{\{p^+<0\}}f+\chi_{\{p^+>0\}}f$ where $\chi_{p^+\geqslant 0}f\in\mathcal{S}_{p^+}(\mathbb{R}_{\geqslant 0}\times\mathbb{R}^{n-1})$. (By χ_A we denote the characteristic function of a set A.)

(iv) Since $\mathcal{S}(\mathbb{R}^n)$ is closed under multiplication by polynomials, the existence of the filtration is obvious. If $f\in\mathcal{S}_{p^+}(\mathbb{R}^n)$, then $(1/(p^+)^k)\,f\in\mathcal{S}_{p^+}(\mathbb{R}^n)\subset\mathcal{S}(\mathbb{R}^n)$ for each $k\geqslant 0$ by (v) or by

Proposition V.2 (ii). Conversely, assume $f \in \cap_{k\geqslant 0}(p^+)^k\mathcal{S}(\mathbb{R}^n)$. It is enough to show that $\sup|\,(1/(p^+)^k)\,\mathbf{p}_\perp^\beta \partial^\alpha f|<\infty$ for all $k>0$ and multi-indices α, β. If l is sufficiently large, then by using the Leibniz formula we obtain $(1/(p^+)^k)\,\partial^\alpha((p^+)^l g)=\Sigma_i P_i(p^+)\partial^{\beta_i} g$ with multi-indices β_i and polynomials P_i for all $g\in\mathcal{S}(\mathbb{R}^n)$. Notice that l does not depend on g. Fix such an l and choose $g\in\mathcal{S}(\mathbb{R}^n)$ such that $f=(p^+)^l g$. Since $g\in\mathcal{S}(\mathbb{R}^n)$ we have $\sup|\,(1/(p^+)^k)\,\mathbf{p}_\perp^\beta \partial^\alpha((p^+)^l g)|<\infty$.

(v) Follows easily from the closed graph theorem.

Remark V.4: From now on we often identify $\mathcal{S}_{p^+}(\mathbb{R}_{\gtrless 0}\times\mathbb{R}^{n-1})$ with $\mathcal{S}_{p^+\gtrless 0}(\mathbb{R}^n)$, i.e., we consider $\nu^*_{\gtrless 0}(f)$ $(f\in\mathcal{S}(\mathbb{R}^n))$ as functions on $\mathbb{R}^n$. Hence we have isomorphisms of Fréchet spaces

$$\nu^*_{\gtrless 0}:\mathcal{S}(\mathbb{R}^n)\tilde{\to}\mathcal{S}_{p^+\gtrless 0}(\mathbb{R}^n) \tag{24}$$

with inverse mappings $(\nu^*_{\gtrless 0})^{-1}=\mu^*_{\gtrless 0}$.

Definition: The elements of the dual space $\mathcal{S}'_{p^+\gtrless 0}(\mathbb{R}^n)$ are called *positive/negative squeezed distributions*.

We identify $\mathcal{S}'_{p^+\gtrless 0}(\mathbb{R}^n)$ with the subspaces $\{u:u|_{p^+\lessgtr 0}=0\}$ of $\mathcal{S}'_{p^+}(\mathbb{R}^n)$.

Each element of $g\in\mathcal{S}_{p^+}(\mathbb{R}^n)$ can be considered in a canonical way as a (regular) squeezed distribution $f\mapsto\int gf$, also denoted g. Hence we obtain canonical inclusion mappings $\mathcal{S}_{p^+}(\mathbb{R}^n)\hookrightarrow\mathcal{S}'_{p^+}(\mathbb{R}^n)$ and $\mathcal{S}_{p^+\gtrless 0}(\mathbb{R}^n)\hookrightarrow\mathcal{S}'_{p^+\gtrless 0}(\mathbb{R}^n)$.

Theorem V.5:

(i) $\mathcal{S}'_{p^+}(\mathbb{R}^n)=\mathcal{S}'_{p^+<0}(\mathbb{R}^n)\oplus\mathcal{S}'_{p^+>0}(\mathbb{R}^n)$.

(ii) *For each* $u\in\mathcal{S}'_{p^+\gtrless 0}(\mathbb{R}^n)$ *there is a sequence* $(u_i)_{i\in\mathbb{N}}$, $u_i\in\mathcal{S}_{p^+\gtrless 0}(\mathbb{R}^n)$, *converging to* u *in* $\mathcal{S}'_{p^+\gtrless 0}(\mathbb{R}^n)$. *The same holds, if we replace* $\mathcal{S}_{p^+\gtrless 0}(\mathbb{R}^n)$ *(resp.* $\mathcal{S}'_{p^+\gtrless 0}(\mathbb{R}^n)$*) by* $\mathcal{S}_{p^+}(\mathbb{R}^n)$ *(resp.* $\mathcal{S}'_{p^+}(\mathbb{R}^n)$*).*

(iii) *The inclusion mappings* $\mathcal{S}_{p^+\gtrless 0}(\mathbb{R}^n)\overset{\iota_{\gtrless 0}}{\hookrightarrow}\mathcal{S}_{p^+}(\mathbb{R}^n)\overset{\iota}{\hookrightarrow}\mathcal{S}(\mathbb{R}^n)$ *induce canonical linear continuous mappings* $\mathcal{S}'(\mathbb{R}^n)\overset{\iota'}{\to}\mathcal{S}'_{p^+}(\mathbb{R}^n)\overset{\iota'_{\gtrless 0}}{\to}\mathcal{S}'_{p^+\gtrless 0}(\mathbb{R}^n)$.

(iv) *The isomorphisms* $\nu^*_{\gtrless 0}:\mathcal{S}(\mathbb{R}^n)\to\mathcal{S}_{p^+\gtrless 0}(\mathbb{R}^n)$ *extend (uniquely) to linear, sequentially continuous, bijective mappings* $\nu^*_{\gtrless 0}:\mathcal{S}'(\mathbb{R}^n)\to\mathcal{S}'_{p^+\gtrless 0}(\mathbb{R}^n)$ *by the formula* $(\nu^*_{\gtrless 0}u)(f)$ $:=u(|\det D\nu_{\gtrless 0}|^{-1}(f\circ\nu^{-1}_{\gtrless 0}))$.

(v) *The inverse mapping of* $\nu^*_{\gtrless 0}:\mathcal{S}'(\mathbb{R}^n)\to\mathcal{S}'_{p^+\gtrless 0}(\mathbb{R}^n)$ *is the (unique) linear, sequentially continuous extension of* $\mu^*_{\gtrless 0}:\mathcal{S}_{p^+\gtrless 0}(\mathbb{R}^n)\to\mathcal{S}(\mathbb{R}^n)$, *also denoted* $\mu^*_{\gtrless 0}$, *and is explicitly given by* $(\mu^*_{\gtrless 0}u)(f)=u(|\det D\mu_{\gtrless 0}|^{-1}(f\circ\mu^{-1}_{\gtrless 0}))$.

Proof:

(i) Follows immediately from Theorem V.3.

(ii) By (iv) and (v) there is a commutative diagram

$$\begin{array}{ccc}
\mathcal{S}'(\mathbb{R}^n) & \xrightarrow{\nu^*_{\gtrless 0}} & \mathcal{S}'_{p^+\gtrless 0}(\mathbb{R}^n) \\
\uparrow{\scriptstyle incl} & & \uparrow{\scriptstyle incl} \\
\mathcal{S}(\mathbb{R}^n) & \xrightarrow{\nu^*_{\gtrless 0}} & \mathcal{S}_{p^+\gtrless 0}(\mathbb{R}^n)
\end{array}$$

where the vertical arrows are inclusion mappings and the horizontal arrows are linear, sequentially continuous, bijective mappings whose inverses are also sequentially continuous. Since to any $u\in\mathcal{S}'(\mathbb{R}^n)$ there is a sequence in $\mathcal{S}(\mathbb{R}^n)$ converging to u,[11] the first part of (ii) follows from the above commutative diagram and the second part is then an easy consequence of (i) and Theorem V.3.

(iii) Is trivial.

(iv) Let $\nu := \nu_{>0}$ and $\mu := \nu^{-1}$. Then $|\det D\nu|^{-1} = (p^n/\omega(\mathbf{p})) + 1$ which can be written as $Q \circ \mu$ with some $Q \in \mathbb{C}[p^+, \mathbf{p}_\perp]_{p^+}$ by Lemma V.1(iii). The mapping $\mathcal{S}_{p^+>0}(\mathbb{R}^n) \to \mathcal{S}(\mathbb{R}^n)$, $f \mapsto |\det D\nu|^{-1}(f \circ \nu^{-1}) = \mu^*(Qf)$ is well-defined and continuous by Theorem V.3(v) and remark V.4, and obviously linear. Hence the extension of ν^* to $\mathcal{S}'(\mathbb{R}^n)$ is well-defined. The linearity and sequential continuity are obvious.

(v) Let ν, μ as in (iii). By computing $|\det D\mu|^{-1}$ one sees that $Q := |\det D\mu|^{-1} \in \mathbb{C}[p^+, \mathbf{p}_\perp]_{p^+}$. As in (iii), it is enough to show that the mapping $\mathcal{S}(\mathbb{R}^n) \to \mathcal{S}_{p^+\gtrless 0}(\mathbb{R}^n)$, $f \mapsto |\det D\mu|^{-1}(f \circ \nu) = Q\nu^*(f)$ is well-defined, linear and continuous. But again this follows immediately from Theorem V.3(v) and remark V.4. □

We finish this section with some density results which we will use in the sequel. By $\mathcal{D}(U)$ we denote the function space of all smooth functions on $\mathbb{R}^n$ with support in an open subset $U \subset \mathbb{R}^n$, endowed with the usual topology,[17,11] i.e., $\mathcal{D}(U) = \lim_{\to K} \mathcal{D}_K$, where K runs through all compact subsets of U, and $\mathcal{D}_K$ is the space of all smooth functions with support in K endowed with the locally convex topology induced by the seminorms $\sup_{|\alpha| \leqslant l} \sup_{x \in K} |\partial^\alpha f(x)|$.

Proposition V.6:

(i) *$\mathcal{S}_{p^+\gtrless 0}(\mathbb{R}^n)$ is a dense subspace of $\mathcal{L}^2(\mathbb{R}^n, \Theta(\pm p^+) d^n\tilde{\mathbf{p}}/2|p^+|)$, and $\mathcal{S}_{p^+}(\mathbb{R}^n)$ is dense in $\mathcal{L}^2(\mathbb{R}^n, d^n\tilde{\mathbf{p}}/2|p^+|)$.*

(ii) *$\mathcal{D}(\mathbb{R}_{\gtrless 0} \times \mathbb{R}^{n-1})$ is dense in $\mathcal{S}_{p^+\gtrless 0}(\mathbb{R}^n)$, and $\mathcal{D}(\mathbb{R}^\times \times \mathbb{R}^{n-1})$ is dense in $\mathcal{S}_{p^+}(\mathbb{R}^n)$. Moreover, the corresponding inclusion mappings are continuous.*

(iii) *The linear subspace generated by the products $f(p^+)g(\mathbf{p}_\perp)$ where $f(p^+) \in \mathcal{S}_{p^+\gtrless 0}(\mathbb{R})$ and $g(\mathbf{p}_\perp) \in \mathcal{S}(\mathbb{R}^{n-1})$ is dense in $\mathcal{S}_{p^+\gtrless 0}(\mathbb{R}^n)$.*

(iv) *The same holds in (iii) if we replace $\mathcal{S}_{p^+\gtrless 0}(\mathbb{R}^n)$ by $\mathcal{S}_{p^+}(\mathbb{R}^n)$.*

Proof:

(i) The mapping $\nu^*_{\gtrless 0}$ induces an isometric isomorphism from $\mathcal{L}^2(\mathbb{R}^n, d^n\mathbf{p}/2\omega(\mathbf{p}))$ onto $\mathcal{L}^2(\mathbb{R}_{\gtrless 0} \times \mathbb{R}^{n-1}, d^n\tilde{\mathbf{p}}/2|p^+|)$ which maps the dense subspace $\mathcal{S}(\mathbb{R}^n)$ of $\mathcal{L}^2(\mathbb{R}^n, d^n\mathbf{p}/2\omega(\mathbf{p}))$ onto $\mathcal{S}_{p^+}(\mathbb{R}_{\gtrless 0} \times \mathbb{R}^{n-1})$. Thus $\mathcal{S}_{p^+}(\mathbb{R}_{\gtrless 0} \times \mathbb{R}^{n-1})$ is a dense subspace of $\mathcal{L}^2(\mathbb{R}_{\gtrless 0} \times \mathbb{R}^{n-1}, d^n\tilde{\mathbf{p}}/2|p^+|)$. Now apply the isometry j, i.e., trivial extension by zero. The second assertion follows then from Theorem V.3.

(ii) Because of Theorem V.3, the second assertion follows from the first. To show that $\mathcal{D}(\mathbb{R}_{\gtrless 0} \times \mathbb{R}^{n-1})$ is dense in $\mathcal{S}_{p^+\gtrless 0}(\mathbb{R}^n)$ recall that $\mathcal{D}(\mathbb{R}^n)$ is dense in $\mathcal{S}(\mathbb{R}^n)$.[17,11] Hence, the image $\nu^*\mathcal{D}(\mathbb{R}^n) = \mathcal{D}(\mathbb{R}_{\gtrless 0} \times \mathbb{R}^{n-1})$ of $\mathcal{D}(\mathbb{R}^n)$ under the linear homeomorphism $\nu^*: \mathcal{S}(\mathbb{R}^n) \xrightarrow{\sim} \mathcal{S}_{p^+\gtrless 0}(\mathbb{R}^n)$, ($\nu := \nu_{\gtrless 0}$, see remark V.4) is a dense subspace of $\mathcal{S}_{p^+\gtrless 0}(\mathbb{R}^n)$. The continuity of the inclusion mappings is obvious since $\mathcal{S}_{p^+\gtrless 0}(\mathbb{R}^n)$ and $\mathcal{S}_{p^+}(\mathbb{R}^n)$ carry the subspace topology induced by $\mathcal{S}(\mathbb{R}^n)$.

(iii) It is well known, e.g. Ref. 11, that the linear subspace generated by the products $f(p^+)g(\mathbf{p}_\perp)$ with $f(p^+) \in \mathcal{D}(\mathbb{R}_{\gtrless 0})$ and $g(\mathbf{p}_\perp) \in \mathcal{D}(\mathbb{R}^{n-1})$ is dense in $\mathcal{D}(\mathbb{R}_{\gtrless 0} \times \mathbb{R}^{n-1})$. Hence, by (ii), it is also dense in $\mathcal{S}_{p^+\gtrless 0}(\mathbb{R}^n)$.

(iv) This follows from (iii) by Theorem V.3. □

VI. TIME-ZERO LC-FIELDS

A. Construction of the fields

After our preliminary work on squeezed distributions, it is now straightforward to define the time-zero LC-fields, i.e., the restriction of the real scalar massive LC-field $\tilde{\phi}_m$ to $\{x^+ = 0\}$ and the corresponding canonical conjugate momentum.

By the commutative diagram (20) we have seen that the function space $\nu^*(\mathcal{S}_3)$ ($\nu = \nu_{>0}$) is the adequate substitute for the space $\mathcal{S}_3 = \mathcal{S}(\mathbb{R}^3)$ if one wants to define the restriction of a real scalar free LC-field $\tilde{\phi}_m$ to the hyperplane $\{x^+ = 0\}$. Both spaces, $\mathcal{S}_3$ and $\nu^*\mathcal{S}_3$, appear completely symmetrically: $\mathcal{S}_3$ is determined by $\mathrm{res}_{\Gamma_m^+}(\mathcal{S}_4) = (\Omega_+^*)^{-1}(\mathcal{S}_3)$ and $\nu^*\mathcal{S}_3$ by $\mathrm{res}_{\tilde{\Gamma}_m^+}(\mathcal{S}_4) = (\tilde{\Omega}_+^*)^{-1}(\nu^*\mathcal{S}_3)$ where $\Omega_+ : \mathbb{R}^3 \to \Gamma_m^+$ and $\tilde{\Omega}_+ : \mathbb{R}_{>0} \times \mathbb{R}^2 \to \tilde{\Gamma}_m^+$ are the canonical parametrizations.

In the Minkowski case the time-zero field φ_m is defined by the formula $\varphi_m(g) := \phi_m(\delta(x^0) \otimes g(\mathbf{x})) = \phi_S(\alpha \cdot \mathrm{res}_{\Gamma_m^+}(1(p^0) \otimes \hat{g}(\mathbf{p})))$ if $g \in \mathcal{S}(\mathbb{R}^3)$ is real-valued, where $\hat{g}$ denotes the usual Fourier transform of g. We would like to define the time-zero LC-field $\tilde{\varphi}_m$ in the same way: $\tilde{\varphi}_m(g) := \tilde{\phi}_m(\delta(x^+) \otimes g(\tilde{x})) = \tilde{\phi}_S(\alpha \cdot \mathrm{res}_{\tilde{\Gamma}_m^+}(g^\sqcap(\tilde{\mathbf{p}}) \otimes 1(p^-)))$ if g is real valued, where $g^\sqcap$ denotes the partial $\mathbb{L}$-Fourier transform of g. In order that this definition makes sense, we first have to determine all g such that $\mathrm{res}_{\tilde{\Gamma}_m^+}(g^\sqcap(\tilde{\mathbf{p}}) \otimes 1(p^-)) \in \mathrm{res}_{\tilde{\Gamma}_m^+}(\mathcal{S}_4)$ which is equivalent to $\mathrm{res}_{p^+>0}(g^\sqcap) \in \nu^* \mathcal{S}_3$ since $\mathrm{res}_{\tilde{\Gamma}_m^+}(g^\sqcap(\tilde{\mathbf{p}}) \otimes 1(p^-)) = (\tilde{\Omega}_+^*)^{-1}(\mathrm{res}_{p^+>0}(g^\sqcap))$ and $\mathrm{res}_{\tilde{\Gamma}_m^+}(\mathcal{S}_4) = (\tilde{\Omega}_+^*)^{-1}(\nu^* \mathcal{S}_3)$. Unlike the classical Fourier transformation, which is a linear homeomorphism from $\mathcal{S}_3$ onto $\mathcal{S}_3$, the partial $\mathbb{L}$-Fourier transformation does not leave the space $\mathcal{S}_{p^+}(\mathbb{R}^3)$ invariant.

Proposition VI.1:

(i) *The partial $\mathbb{L}$-Fourier transformation $\mathcal{F}_{\mathbb{L}}^{\tilde{\mathbf{x}} \to \tilde{\mathbf{p}}}$ defined by*

$$(\mathcal{F}_{\mathbb{L}}^{\tilde{\mathbf{x}} \to \tilde{\mathbf{p}}} g)(\tilde{\mathbf{p}}) = g^\sqcap(\tilde{\mathbf{p}}) = \int_{\mathbb{R}^n} d^n \tilde{\mathbf{x}} \; g(\tilde{\mathbf{x}}) e^{i(p^+ x^- - \mathbf{p}_\perp \cdot \mathbf{x}_\perp)} \quad (g \in \mathcal{S}(\mathbb{R}^n))$$

is a linear homeomorphism from $\mathcal{S}(\mathbb{R}^n)$ onto $\mathcal{S}(\mathbb{R}^n)$ which maps the subspace

$$\mathcal{S}_{\partial_{x^-}}(\mathbb{R}^n) := \bigcap_{m \geqslant 0} \partial_{x^-}^m \mathcal{S}(\mathbb{R}^n) = \{g : \forall m \geqslant 0 \;\; \exists h \in \mathcal{S}(\mathbb{R}^n) \quad g = \partial_{x^-}^m h\}$$

onto the subspace $\mathcal{S}_{p^+}(\mathbb{R}^n)$. We also write $\mathcal{S}_{\partial_-}(\mathbb{R}^n)$ instead of $\mathcal{S}_{\partial_{x^-}}(\mathbb{R}^n)$.

(ii) *Let*

$$\mathcal{S}_{\partial_-,r}(\mathbb{R}^n) := \{g \in \mathcal{S}_{\partial_-}(\mathbb{R}^n) : g \;\; \textit{real valued}\}.$$

Then $\mathcal{F}_{\mathbb{L}}^{\tilde{\mathbf{x}} \to \tilde{\mathbf{p}}}$ maps $\mathcal{S}_{\partial_-,r}(\mathbb{R}^n)$ onto $\{h \in \mathcal{S}_{p^+}(\mathbb{R}^n) : \overline{h} = h^\vee\}$.

Proof:

(i) The partial $\mathbb{L}$-Fourier transformation differs from the classical Fourier transformation only by a permutation and some sign changes of the coordinates, hence the first assertion follows immediately from the classical result.[17] To see the second assertion note that $\mathcal{S}_{p^+}(\mathbb{R}^3) = \cap_{m \geqslant 0} (p^+)^m \mathcal{S}(\mathbb{R}^3)$ by Theorem V.3, and that $\mathcal{F}_{\mathbb{L}}^{\tilde{\mathbf{x}} \to \tilde{\mathbf{p}}}$ maps $\partial_{x^-}^m \mathcal{S}(\mathbb{R}^n)$ onto $(p^+)^m \mathcal{S}(\mathbb{R}^n)$ for each $m \geqslant 0$.

(ii) Let $g \in \mathcal{S}_{\partial_-}(\mathbb{R}^n)$, then $\overline{g^\sqcap} = \overline{g}^{\sqcap\vee}$. Hence $\overline{g^\sqcap} = g^{\sqcap\vee}$ iff $g = \overline{g}$. □

We endow $\mathcal{S}_{\partial_-}(\mathbb{R}^n)$ with the subspace topology inherit from $\mathcal{S}(\mathbb{R}^n)$. Hence we have a linear homeomorphism

$$\mathcal{F}_{\mathbb{L}}^{\tilde{\mathbf{x}} \to \tilde{\mathbf{p}}} : \mathcal{S}_{\partial_-}(\mathbb{R}^n) \tilde{\to} \mathcal{S}_{p^+}(\mathbb{R}^n), \quad g \mapsto g^\sqcap.$$

Furthermore,

$$\widetilde{\mathrm{res}}(\mathcal{S}(\mathbb{R}^4)) = \{\widetilde{\mathrm{res}}(g^\sqcap(\tilde{\mathbf{p}}) \otimes 1(p^-)) : g \in \mathcal{S}_{\partial_-}(\mathbb{R}^3)\} \quad (\widetilde{\mathrm{res}} = \mathrm{res}_{\tilde{\Gamma}_m^+}), \tag{25}$$

which guarantees, among other things, that the operators $\tilde{\varphi}_m(g)$, $\tilde{\pi}_m(g)$ will be well-defined for each $g \in \mathcal{S}_{\partial_-}(\mathbb{R}^3)$. Thus, $\mathcal{S}_{\partial_-}(\mathbb{R}^3)$ is the appropriate (smearing) test function space to define the time-zero LC-fields.

Definition: The *time-zero LC-field* (or the restriction of $\tilde{\phi}_m$ to $\{x^+ = 0\}$) $g \mapsto \tilde{\varphi}_m(g)$ and its canonical conjugate momentum $g \mapsto \tilde{\pi}_m(g)$ are defined by

$$\tilde{\varphi}_m(g) := \tilde{\phi}_m(0,g) := \tilde{\phi}_m(\delta(x^+) \otimes \mathrm{Re}\, g(\tilde{\mathbf{x}})) + i \tilde{\phi}_m(\delta(x^+) \otimes \mathrm{Im}\, g(\tilde{\mathbf{x}})),$$

$$\tilde{\pi}_m(g) := (\partial_{x^-} \tilde{\phi}_m)(0,g) = (\partial_{x^-} \tilde{\varphi}_m)(g) = \tilde{\varphi}_m(-\partial_{x^-} g),$$

where $g \in \mathcal{S}_{\partial_-}(\mathbb{R}^3)$.

Remark VI.2: Note that $\partial_{x^-} \tilde{\phi}_m$ is a spatial derivative in contrast to the Minkowski case where the canonical momentum is defined by a time derivative. The difference results from the fact that

the Lagrangian $\tilde{\mathcal{L}}=(\partial^{\tilde{\mu}}\tilde{\phi}_m)(\partial_{\tilde{\mu}}\tilde{\phi}_m)-m^2\tilde{\phi}$ of the LC-Klein–Gordon field depends only linearly on $\partial_{x^+}\tilde{\phi}_m$, especially $\delta\tilde{\mathcal{L}}/[\,\delta(\partial_+\tilde{\phi}_m)]=2\partial_-\tilde{\phi}_m$, where $\partial_\pm=\partial_{x^\pm}$. Recall that in LC-physics the time variable is x^+.

The following theorem summarizes fundamental properties of the field $\tilde{\varphi}_m$ which follow easily from corresponding properties of the Segal quantization $\tilde{\phi}_S$, cf. Ref. 16, Theorem X.41.

Theorem VI.3:

(i) *For each real-valued $g\in\mathcal{S}_{\partial_-}(\mathbb{R}^3)$, the operator $\tilde{\varphi}_m(g)$ is essentially self-adjoint on $\tilde{F}_0$ ($\tilde{F}_0$=dense subspace of finite vectors of $\mathcal{F}_\vee(\tilde{\mathfrak{H}}_m)$, $\tilde{\mathfrak{H}}_m=\mathcal{L}^2(\tilde{\Gamma}_m^+,d\tilde{\mu}_m)$).*

(ii) *The vacuum state $|\tilde{0}\rangle$ is a cyclic vector for the family $\{\tilde{\varphi}_m(g):g\in\mathcal{S}_{\partial_-}(\mathbb{R}^3),\ g$ real-valued$\}$.*

(iii) *If $g_n\to g$ in $\mathcal{S}_{\partial_-}(\mathbb{R}^3)$, then*

$$\tilde{\varphi}_m(g_n)\psi\to\tilde{\varphi}_m(g)\psi,\quad \text{for all } \psi\in\tilde{F}_0$$

and

$$e^{i\tilde{\varphi}_m(g_n)}\psi\to e^{i\tilde{\varphi}_m(g)}\psi,\quad \text{for all } \psi\in\mathcal{F}_\vee(\tilde{\mathfrak{H}}_m).$$

(iv) *If $g,h\in\mathcal{S}_{\partial_-}(\mathbb{R}^3)$ are real-valued and $\psi\in\tilde{F}_0$, then*

$$\tilde{\varphi}_m(g)\tilde{\varphi}_m(h)\psi-\tilde{\varphi}_m(h)\tilde{\varphi}_m(g)\psi=\frac{1}{(2\pi)^3}(\langle g,h\rangle_{\mathcal{S}_{\partial_-}(\mathbb{R}^3)}-\langle h,g\rangle_{\mathcal{S}_{\partial_-}(\mathbb{R}^3)})\psi$$

and

$$e^{i\tilde{\varphi}_m(g)}e^{i\tilde{\varphi}_m(h)}=e^{(2\pi)^{-3}(\langle g,h\rangle_{\mathcal{S}_{\partial_-}(\mathbb{R}^3)}-\langle h,g\rangle_{\mathcal{S}_{\partial_-}(\mathbb{R}^3)})}e^{i\tilde{\varphi}_m(h)}e^{i\tilde{\varphi}_m(g)},$$

where $\langle g,h\rangle_{\mathcal{S}_{\partial_-}(\mathbb{R}^3)}:=\int d^3\tilde{\mathbf{p}}(\Theta(p^+)/2p^+)\overline{g^\sqcap}h^\sqcap$ $(g,h\in\mathcal{S}_{\partial_-}(\mathbb{R}^3))$ and the bar "—" means complex conjugation.

Proof: (i)–(iv) follow immediately from Ref. 16, Theorem X.41. Notice that, if $g\in\mathcal{S}_{\partial_-}(\mathbb{R}^3)$ is real-valued then $\tilde{\varphi}_m(g)=\tilde{\phi}_S(\alpha\cdot\widetilde{\mathrm{res}}(g^\sqcap(\tilde{\mathbf{p}})\otimes 1(p^-)))$ and that, by (25), $\{\widetilde{\mathrm{res}}(g^\sqcap(\tilde{\mathbf{p}})\otimes 1(p^-)):g\in\mathcal{S}_{\partial_-}(\mathbb{R}^3)\}$ is a dense subspace of $\tilde{\mathfrak{H}}_m=\mathcal{L}^2(\tilde{\Gamma}_m^+,d\tilde{\mu}_m)$. □

B. Commutator relation

In order to see that we have really defined the proper time-zero LC-field, we compute the commutator of this field. At this it turns out that our result coincides with the commutator relation determined by a completely different method, namely quantization of constrained systems.[6]

Lemma VI.4: The linear subspace generated by the products $g(\mathbf{x}_\perp)h(x^-)$, where $g(\mathbf{x}_\perp)\in\mathcal{S}(\mathbb{R}^{n-1})$ and $h(x^-)\in\mathcal{S}_{\partial_-}(\mathbb{R})$ is dense in $\mathcal{S}_{\partial_-}(\mathbb{R}^n)$.

Proof: Recall that the partial $\mathbb{L}$-Fourier transformation $\mathcal{F}_{\mathbb{L}}^{\tilde{\mathbf{x}}\to\tilde{\mathbf{p}}}$ is a linear homeomorphism from $\mathcal{S}_{\partial_-}(\mathbb{R}^n)$ onto $\mathcal{S}_{p^+}(\mathbb{R}^n)$. Moreover, $\mathcal{F}_{\mathbb{L}}^{\tilde{\mathbf{x}}\to\tilde{\mathbf{p}}}$ maps the set of products $g(\mathbf{x}_\perp)h(x^-)$ where $g(\mathbf{x}_\perp)\in\mathcal{S}(\mathbb{R}^{n-1})$, $h(x^-)\in\mathcal{S}_{\partial_{x^-}}(\mathbb{R})$ onto the set of products $h(p^+)g(\mathbf{p}_\perp)$ where $h(p^+)\in\mathcal{S}_{p^+}(\mathbb{R})$, $g(\mathbf{p}_\perp)\in\mathcal{S}(\mathbb{R}^{n-1})$. The assertion follows now from Proposition V.6. □

Proposition VI.5: The time-zero LC-field $\tilde{\varphi}_m$ fulfills the following commutator relation on the dense subspace $\tilde{F}_0$:

$$[\tilde{\varphi}_m(g),\tilde{\varphi}_m(h)]=\frac{1}{4i}(\delta(\mathbf{x}_\perp-\mathbf{y}_\perp)\otimes\epsilon(x^--y^-),g(\tilde{\mathbf{x}})\otimes h(\tilde{\mathbf{y}})),$$

with real-valued $g,h\in\mathcal{S}_{\partial_-}(\mathbb{R}^3)$.

Proof: By Theorem VI.3(iv) we have to show that

$$\frac{1}{(2\pi)^3}\int d^3\tilde{\mathbf{p}}\frac{\Theta(p^+)}{2p^+}(\overline{g^\sqcap}h^\sqcap - g^\sqcap\overline{h^\sqcap}) = \frac{1}{4i}(\delta(\mathbf{x}_\perp-\mathbf{y}_\perp)\otimes\epsilon(x^- - y^-), g\otimes h)$$

for all real-valued $g,h\in\mathcal{S}_{\partial_-}(\mathbb{R}^3)$. We know that $\delta(\mathbf{x}_\perp-\mathbf{y}_\perp)\otimes\epsilon(x^- - y^-) = \sigma^*(\delta(\mathbf{z}_\perp)\otimes\epsilon(z^-))$ is a tempered distribution on $\mathbb{R}^3\times\mathbb{R}^3$ which is defined as the pullback of $\delta(\mathbf{z}_\perp)\otimes\epsilon(z^-)$ by the mapping $\sigma:\mathbb{R}^3\times\mathbb{R}^3\to\mathbb{R}^3$, $(\tilde{\mathbf{x}},\tilde{\mathbf{y}})\mapsto\tilde{\mathbf{z}}:=\tilde{\mathbf{x}}-\tilde{\mathbf{y}}$. As a first step we prove

$$\begin{aligned}\frac{1}{4i}(\delta(\mathbf{z}_\perp)\otimes\epsilon(z^-), f(\tilde{\mathbf{z}})) &= \frac{1}{(2\pi)^3}\int d^3\tilde{\mathbf{p}}\frac{\Theta(p^+)}{2p^+}(f^\sqcap(-p^+,\mathbf{p}_\perp) - f^\sqcap(p^+,\mathbf{p}_\perp))\\ &= \frac{1}{(2\pi)^3}\int d^3\tilde{\mathbf{p}}\frac{\Theta(p^+)}{2p^+}(f^\sqcap(-\tilde{\mathbf{p}}) - f^\sqcap(\tilde{\mathbf{p}}))\end{aligned} \tag{26}$$

for all $f(\tilde{\mathbf{z}})\in\mathcal{S}_{\partial_-}(\mathbb{R}^3)$. By Lemma VI.4 it is enough to show (26) if $f(\tilde{\mathbf{z}})$ is of the form $f(\tilde{\mathbf{z}}) = f_-(z^-)f_\perp(\mathbf{z}_\perp)$ with $f_-(z^-)\in\mathcal{S}_{\partial_-}(\mathbb{R})$ and $f_\perp(\mathbf{z}_\perp)\in\mathcal{S}(\mathbb{R}^2)$. Then

$$f^\sqcap(-p^+,\mathbf{p}_\perp) - f^\sqcap(p^+,\mathbf{p}_\perp) = \widehat{f_\perp}(\mathbf{p}_\perp)(\widehat{f_-}(p^+) - \widehat{f_-}(-p^+)),$$

where the "^" means classical Fourier transformation. Hence, the right-hand side of (26) equals, except for the factor $1/2(2\pi)^3$, the product

$$\left(\int d^2\mathbf{p}_\perp\ \widehat{f_\perp}(\mathbf{p}_\perp)\right)\cdot\left(\int dp^+\frac{\Theta(p^+)}{p^+}(\widehat{f_-}(p^+) - \widehat{f_-}(-p^+))\right). \tag{27}$$

Obviously, the first factor of (27) equals $(2\pi)^2(\delta(\mathbf{x}_\perp), f_\perp(\mathbf{x}_\perp))$. To determine the second factor, note that for all $h(p^+)\in\mathcal{S}_{p^+}(\mathbb{R})$

$$\left(\mathrm{PV}\frac{1}{p^+}, h(p^+)\right) = \int dp^+\frac{\Theta(p^+)}{p^+}(h(p^+) - h(-p^+))$$

since $(1/p^+)\,h(p^+)\in\mathcal{L}^1(\mathbb{R},dp^+)$. Hence, the second factor of (27) equals $(\mathrm{PV}(1/p^+), \widehat{f_-}(p^+))$. Finally, $(\mathrm{PV}(1/p^+))^\wedge = (\pi/i)\,\epsilon(x^-)$ which follows, for example, by the Sokhotsky–Plemelj-formulas,[3] p. 55. Thus we have shown (26). Using the explicit formula of the pullback

$$(\delta(\mathbf{x}_\perp-\mathbf{y}_\perp)\otimes\epsilon(x^- - y^-), g(\tilde{\mathbf{x}})\otimes h(\tilde{\mathbf{y}})) = (\delta(\mathbf{z}_\perp)\otimes\epsilon(z^-), (g*h^\vee)(\tilde{\mathbf{z}})),$$

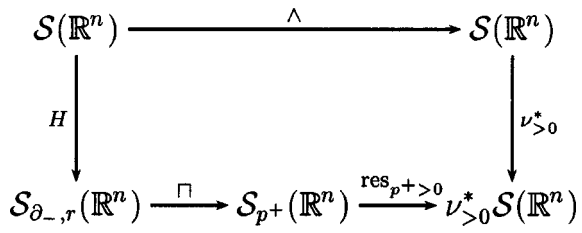
where $g*h^\vee$ denotes the convolution of g and $h^\vee$ (recall $h^\vee(\tilde{\mathbf{y}}) = h(-\tilde{\mathbf{y}})$), we yield the right formula, if we additionally take into account that $(g*h^\vee)^\sqcap = g^\sqcap h^{\vee\sqcap}$ and $h^{\vee\sqcap} = \overline{h^\sqcap} = (h^\sqcap)^\vee$ for real-valued g,h. □

C. Connection between time-zero field and time-zero LC-field

In this short subsection we will prove a transformation law between the time-zero field φ_m and the time-zero LC-field $\tilde{\varphi}_m$. By this transformation law φ_m is completely determined by $\tilde{\varphi}_m$. This shows that the time-zero LC-field, defined on the test function space $\mathcal{S}_{\partial_-}(\mathbb{R}^3)$, carries—besides the mass—as much information as the time-zero field, defined on $\mathcal{S}(\mathbb{R}^3)$, although $\mathcal{S}_{\partial_-}(\mathbb{R}^3)$ is a proper subspace of $\mathcal{S}(\mathbb{R}^3)$. Furthermore, it is possible to recover the covariant field from the time-zero LC-field.

Let $\mathcal{S}_{\partial_-,r}(\mathbb{R}^n)$ denote the real topological (closed) subspace of all real-valued $g\in\mathcal{S}_{\partial_-}(\mathbb{R}^n)$. We need the following auxiliary lemma.

Lemma VI.6: There exists an $\mathbb{R}$*-linear homeomorphism* $H:\mathcal{S}(\mathbb{R}^n)\xrightarrow{\sim}\mathcal{S}_{\partial_-,r}(\mathbb{R}^n)$ *such that the following diagram commutes*:



Proof: Since the classical Fourier transformation "$\wedge$" and the mapping $\nu^*_{>0}$ are linear homeomorphism, we have to show that the composition $\mathrm{res}_{p^+>0} \circ \sqcap$ is bijective. Then, by the open mapping theorem, the inverse is continuous, too. By Proposition VI.1(ii) $\mathcal{F}_{\mathrm{L}}^{\tilde{\mathbf{x}}\to\tilde{\mathbf{p}}}$ maps $\mathcal{S}_{\partial_-,r}(\mathbb{R}^n)$ onto $\{g\in\mathcal{S}_{p^+}(\mathbb{R}^n): \overline{g}=g^\vee\}$. However, $\underline{\mathrm{res}}_{p^+>0}$ is one-to-one on this subspace. An inverse mapping is explicitly given by $g\mapsto j(g)^\vee + j(g)$ $(g\in\nu^*_{>0}\mathcal{S}(\mathbb{R}^n))$, where j denotes extension by zero. □

Recall that $\kappa_*:\mathfrak{H}_m\to\tilde{\mathfrak{H}}_m$ is a unitary operator between the relativistic one-particle spaces $\mathfrak{H}_m=\mathcal{L}^2(\Gamma_m^+,d\mu_m)$, $\tilde{\mathfrak{H}}_m=\mathcal{L}^2(\tilde{\Gamma}_m^+,d\tilde{\mu}_m)$, and induces a unitary operator $\mathcal{F}_\vee(\kappa_*):\mathcal{F}_\vee(\mathfrak{H}_m)\to\mathcal{F}_\vee(\tilde{\mathfrak{H}}_m)$ between the corresponding bosonic Fock spaces. The following theorem gives us a surprising transformation law between the time-zero field and the time-zero LC-field.

Theorem VI.7: *For each real-valued $g\in\mathcal{S}(\mathbb{R}^3)$, the following transformation laws hold*:

$$\varphi_m(g)=\mathcal{F}_\vee(\kappa_*)^{-1}\tilde{\varphi}_m(Hg)\mathcal{F}_\vee(\kappa_*),\quad \pi_m(g)=\mathcal{F}_\vee(\kappa_*)^{-1}\tilde{\varphi}_m(H\mathcal{F}^{-1}(\omega(\mathbf{p})\hat{g}))\mathcal{F}_\vee(\kappa_*),$$

where $H:\mathcal{S}(\mathbb{R}^3)\tilde{\to}\mathcal{S}_{\partial_-,r}(\mathbb{R}^3)$ is the $\mathbb{R}$-linear homeomorphism from Lemma VI.6 and $\mathcal{F}^{-1}$ denotes the classical inverse Fourier transformation.

Proof: Since g is real-valued, $\varphi_m(g)=\phi_S(\alpha\cdot\mathrm{res}(1\otimes\hat{g}))$. On the other hand, $\tilde{\varphi}_m(Hg)=\tilde{\phi}_S(\alpha\cdot\widetilde{\mathrm{res}}((Hg)^\sqcap\otimes 1))$ since Hg is real-valued, too. By inspecting the construction of the Segal quantization, we obtain the following transformation law between ϕ_S and $\tilde{\phi}_S$:

$$\phi_S(f)=\mathcal{F}_\vee(\kappa_*)^{-1}\tilde{\phi}_S(\kappa_* f)\mathcal{F}_\vee(\kappa_*)\quad (f\in\mathfrak{H}_m).$$

Hence, it is enough to show that $\kappa_*\mathrm{res}(1\otimes\hat{g})=\widetilde{\mathrm{res}}((Hg)^\sqcap\otimes 1)$. But this follows easily from the definition of H, i.e., from $\nu^*\hat{g}=(Hg)^\sqcap$, if one takes into account that $\mathrm{res}(1\otimes\hat{g})=(\Omega_+^*)^{-1}(\hat{g})$, $\widetilde{\mathrm{res}}((Hg)^\sqcap\otimes 1)=(\tilde{\Omega}_+^*)^{-1}((Hg)^\sqcap|_{p^+>0})$ and $\kappa_*\circ(\Omega_+^*)^{-1}=(\tilde{\Omega}_+^*)^{-1}\circ\nu^*$. Analogously, one proves the transformation law for the canonical conjugate momentum $\pi_m(g)$. □

Remark VI.8: Let $T:=\{Hg: g\in\mathcal{S}(\mathbb{R}^3),\ \text{real-valued}\}$. Then T is a proper $\mathbb{R}$-linear subspace of $\mathcal{S}_{\partial_-,r}(\mathbb{R}^3)$ by Lemma VI.6. Hence, $T+iT$ is a proper $\mathbb{C}$-linear subspace of $\mathcal{S}_{\partial_-}(\mathbb{R}^3)$. By Theorem VI.7 $\{\tilde{\varphi}_m(h): h\in T+iT\}$ is a commuting family, i.e., the commutator $[\tilde{\varphi}_m(g),\tilde{\varphi}_m(h)]$ vanishes on $\tilde{F}_0$ for all $g,h\in T+iT$. We do not have, however, any physical explanation for this, yet.

Remark VI.9: Since in Theorem VI.7 even the canonical conjugate momentum π_m can be recovered from the time-zero LC-field $\tilde{\varphi}_m$ we see again that the canonical conjugate momentum of $\tilde{\varphi}_m$ is superfluous in LC-physics.

D. Unitary equivalence

In Ref. 13, Leutwyler *et al.* discovered the remarkable fact that the restrictions of free fields of different masses to the plane $\{x^+=\tau\}$ are unitary equivalent. We prove in this subsection an even stronger statement, namely that under a specified unitary transformation the field operators of different masses become identical.

In Sec. II we have introduced the smooth mapping $\tilde{\Omega}_+:\mathbb{R}_{>0}\times\mathbb{R}^2\to\tilde{\Gamma}_m^+$. To emphasize the mass-dependence we write $\tilde{\Omega}_{+,m}$ in the following. This mapping induces a unitary mapping $\tilde{\Omega}_{+,m}^*:\tilde{\mathfrak{H}}_m\to\mathcal{L}^2(\mathbb{R}_{>0}\times\mathbb{R}^2,d^3\tilde{\mathbf{p}}/2p^+)$, where $\tilde{\mathfrak{H}}_m=\mathcal{L}^2(\tilde{\Gamma}_m^+,d\tilde{\mu}_m)$ is the relativistic one-particle LC-space introduced in Sec. IV. We call $\mathcal{L}^2(\mathbb{R}_{>0}\times\mathbb{R}^2,d^3\tilde{\mathbf{p}}/2p^+)=:\tilde{\mathfrak{H}}_{\mathrm{nr}}$ the *nonrelativistic one-*

particle LC-space. Notice that $\tilde{\mathfrak{H}}_{\mathrm{nr}}$ does not depend on the mass m which is a special property of LC-physics and which has the following proposition as a consequence. Recall that furthermore $\tilde{\Omega}^*_{+,m}$ induces a unitary mapping $\mathcal{F}_\vee(\tilde{\Omega}^*_{+,m}):\tilde{\mathcal{H}}_m \to \tilde{\mathcal{H}}_{\mathrm{nr}}$ between the corresponding (bosonic) Fock-spaces $\tilde{\mathcal{H}}_m = \mathcal{F}_\vee(\tilde{\mathfrak{H}}_m)$ and $\tilde{\mathcal{H}}_{\mathrm{nr}} = \mathcal{F}_\vee(\tilde{\mathfrak{H}}_{\mathrm{nr}})$.

Proposition VI.10: Let $\tilde{\varphi}_{m_1}$ and $\tilde{\varphi}_{m_2}$ be time-zero LC-fields with $m_1, m_2 > 0$ and let $U_i = \mathcal{F}_\vee(\tilde{\Omega}^*_{+,m_i}):\tilde{\mathcal{H}}_{m_i} \to \tilde{\mathcal{H}}_{\mathrm{nr}}$ $(i=1,2)$ be the above unitary mappings from the relativistic to the non-relativistic Fock space. Then

$$U_1 \tilde{\varphi}_{m_1}(h) U_1^{-1} = U_2 \tilde{\varphi}_{m_2}(h) U_2^{-1}$$

for all $h \in \mathcal{S}_{\partial_-}(\mathbb{R}^3)$.

Proof: It is enough to prove the assertion for all real-valued $h \in \mathcal{S}_{\partial_-}(\mathbb{R}^3)$. Let $m>0$ and let $\tilde{\phi}_S$ be the Segal quantization over $\tilde{\mathfrak{H}}_m$. Then $\tilde{\varphi}_m(h) = \tilde{\phi}_S(\alpha \cdot \widetilde{\mathrm{res}}(h^\sqcap \otimes 1))$. By definition $\tilde{\phi}_S(f) = (1/\sqrt{2})\,(\tilde{a}^*(f) + \tilde{a}(f))$ where $f \in \tilde{\mathfrak{H}}_m$. Let $U := \mathcal{F}_\vee(\tilde{\Omega}^*_{+,m}):\tilde{\mathcal{H}}_m \to \tilde{\mathcal{H}}_{\mathrm{nr}}$. Because $\widetilde{\mathrm{res}}(g \otimes 1) = (\tilde{\Omega}^*_{+,m})^{-1}(g|_{p^+>0})$, we obtain

$$U\tilde{a}^*(\widetilde{\mathrm{res}}(g\otimes 1))U^{-1}(\psi_1 \vee \cdots \vee \psi_n) = \sqrt{n+1}\,(g|_{p^+>0} \vee \psi_1 \vee \cdots \vee \psi_n),$$

$$U\tilde{a}(\widetilde{\mathrm{res}}g \otimes 1))U^{-1}(\psi_1 \vee \cdots \vee \psi_n) = \frac{1}{\sqrt{n}} \sum_{j=1}^{n} \langle g, \psi_j \rangle_{\tilde{\mathfrak{H}}_{\mathrm{nr}}} (\psi_1 \vee \cdots \vee \widehat{\psi_j} \vee \cdots \vee \psi_n)$$

for all $\psi_1 \vee \cdots \vee \psi_n \in \tilde{\mathfrak{H}}_{\mathrm{nr}}^{\vee n}$ and $g \in \mathcal{S}_{p^+}(\mathbb{R}^3)$. Since $\langle g, \psi_j \rangle_{\tilde{\mathfrak{H}}_{\mathrm{nr}}} = \int_{p^+>0} (d^3\tilde{\mathbf{p}}/2p^+)\overline{g}\psi_j$ does not depend on the mass $m>0$, the same holds for $U\tilde{\varphi}_m(h)U^{-1}$, where $h \in \mathcal{S}_{\partial_-,r}(\mathbb{R}^3)$. □

Remark VI.11: It is well known (cf., e.g., Ref. 16) that unitary equivalence fails, if we consider the restrictions of free fields of different masses $m_1 \neq m_2$ to the plane $\{x^0=0\}$, i.e., time-zero fields φ_{m_1}, φ_{m_2}. The difference to the LC-case lies in the fact that the unitary mapping $\Omega^*_{+,m}$ induced by $\Omega_{+,m}:\mathbb{R}^3 \xrightarrow{\sim} \Gamma^+_m$ maps the relativistic one-particle space $\mathcal{L}^2(\Gamma^+_m, d\mu_m)$ onto the mass-dependent space $\mathcal{L}^2(\mathbb{R}^3, d^3\mathbf{p}/2\omega_m(\mathbf{p}))$; note that $\omega_m(\mathbf{p}) = \sqrt{\mathbf{p}^2+m^2}$. It is indeed possible to obtain a mass-independent Hilbert space by the unitary mapping $\mathcal{L}^2(\mathbb{R}^3, d^3\mathbf{p}/2\omega_m(\mathbf{p})) \to \mathcal{L}^2(\mathbb{R}^3, d^3\mathbf{p})$, $g(\mathbf{p}) \mapsto g(\mathbf{p})/\sqrt{\omega}_m(\mathbf{p})$, however, this does not solve the problem. If $U_m = \mathcal{F}_\vee((1/\sqrt{\omega_m})\,\Omega^*_{+,m}):\mathcal{F}_\vee(\mathcal{L}^2(\tilde{\Gamma}^+_m, d\mu_m)) \to \mathcal{F}_\vee(\mathcal{L}^2(\mathbb{R}^3, d^3\mathbf{p}))$ then only

$$U_{m_1}\varphi_{m_1}(F_{m_1}g)U_{m_1}^{-1} = U_{m_2}\varphi_{m_2}(F_{m_2}g)U_{m_2}^{-1}$$

holds for every $g \in \mathcal{S}(\mathbb{R}^3)$, where $F_m:\mathcal{S}(\mathbb{R}^3) \xrightarrow{\sim} \mathcal{S}(\mathbb{R}^3)$ is the linear homeomorphism defined by $(F_m g)\hat{} = (1/\sqrt{\omega_m})\hat{g}$. Notice that $g \mapsto \sqrt{\omega_m}g$ is a linear homeomorphism from $\mathcal{S}(\mathbb{R}^3)$ onto $\mathcal{S}(\mathbb{R}^3)$. Hence, the fields φ_{m_1} and φ_{m_2} are "unitary equivalent modulo a linear homeomorphism" from $\mathcal{S}_3$ onto $\mathcal{S}_3$ which we call *weakly unitary equivalence*. So in both, the LC-case and the Minkowski-case, we have weakly unitary equivalence, whereas only in the LC-case weakly unitary equivalence equals unitary equivalence.

E. Completeness

Irreducibility of the time-zero LC-field was already obtained by Leutwyler *et al.* in Ref. 13. Since our function space $\mathcal{S}_{\partial_-}(\mathbb{R}^3)$ is even a proper subspace of the function space in Ref. 13, we have to reprove the irreducibility statement.

Proposition VI.12: The family of operators $\{e^{i\tilde{\varphi}_m(h)}: h \in \mathcal{S}_{\partial_-,r}(\mathbb{R}^3)\}$ is irreducible.

Proof: Let $\tilde{\phi}_S$ be the Segal quantization over $\tilde{\mathfrak{H}}_m = \mathcal{L}^2(\tilde{\Gamma}^+_m, d\tilde{\mu}_m)$. By Ref. 16, Lemma 1, p. 232, the family $\{e^{i\tilde{\phi}_S(f)}: f \in \tilde{\mathfrak{H}}_m\}$ is irreducible. For each real-valued $h \in \mathcal{S}_{\partial_-}(\mathbb{R}^3)$, we have

$\tilde{\varphi}_m(h)=\tilde{\phi}_S(\alpha\cdot\widetilde{\mathrm{res}}(h^{\sqcap}\otimes 1))$. By (25), $\{\widetilde{\mathrm{res}}(g^{\sqcap}\otimes 1): g\in\mathcal{S}_{\partial\_}(\mathbb{R}^3)\}$ is dense in $\tilde{\mathfrak{H}}_m$. Now, for each $g\in\mathcal{S}_{\partial\_}(\mathbb{R}^3)$, there exists, by Lemma VI.6, a real-valued $h\in\mathcal{S}_{\partial\_}(\mathbb{R}^3)$ such that $h^{\sqcap}|_{p^+>0}=g^{\sqcap}|_{p^+>0}$. Hence $\{\widetilde{\mathrm{res}}(h^{\sqcap}\otimes 1): h\in\mathcal{S}_{\partial\_,r}(\mathbb{R}^3)\}$ is dense in $\tilde{\mathfrak{H}}_m$, too. □

VII. ANNIHILATION AND CREATION OPERATORS, BILINEAR FORMS

In this final section we produce a closer connection to the standard terminology of LC-quantum field theory. Especially, we want to give expressions like (7) an exact meaning in the operator context. This is well known in Minkowski-case, e.g., Ref. 16, and we will use the same approach in the LC-case. First of all we have to transform our fields to fields acting on the nonrelativistic LC-Fock space $\tilde{\mathcal{H}}_{\mathrm{nr}}=\mathcal{F}_{\vee}(\tilde{\mathfrak{H}}_{\mathrm{nr}})$, where $\tilde{\mathfrak{H}}_{\mathrm{nr}}=\mathcal{L}^2(\mathbb{R}_{>0}\times\mathbb{R}^2, d^3\tilde{\mathbf{p}}/2p^+)$.

Let $U:=\mathcal{F}_{\vee}(\tilde{\Omega}^*_{+,m}):\tilde{\mathcal{H}}_m\to\tilde{\mathcal{H}}_{\mathrm{nr}}$ be the canonical, unitary mapping from the relativistic LC-Fock space $\tilde{\mathcal{H}}_m:=\mathcal{F}_{\vee}(\mathcal{L}^2(\tilde{\Gamma}^+_m, d\tilde{\mu}_m))$ to the nonrelativistic LC-Fock space $\tilde{\mathcal{H}}_{\mathrm{nr}}$. We transform the fields $\tilde{\phi}_m$ and $\tilde{\varphi}_m$ by the formulas

$$\tilde{\boldsymbol{\phi}}_m:=U\tilde{\phi}_m U^{-1},\quad \tilde{\boldsymbol{\varphi}}_m:=U\tilde{\varphi}_m U^{-1}.$$

Because of Proposition VI.10, $\tilde{\boldsymbol{\varphi}}_m$ does not depend on the mass $m>0$. Hence, we cancel the index m in the notation and write in the following $\tilde{\boldsymbol{\varphi}}$ instead of $\tilde{\boldsymbol{\varphi}}_m$. We also transform the annihilation and creation operators by

$$\tilde{\mathbf{a}}(g):=U\tilde{a}(\widetilde{\mathrm{res}}(g(\tilde{\mathbf{p}})\otimes 1(p^-)))U^{-1},\quad \tilde{\mathbf{a}}^+(g):=U\tilde{a}^+(\widetilde{\mathrm{res}}(g(\tilde{\mathbf{p}})\otimes 1(p^-)))U^{-1}$$

for every $g(\tilde{\mathbf{p}})\in\mathcal{S}_{p^+}(\mathbb{R}^3)$. The explicit action on $\tilde{\mathfrak{H}}^{\vee n}_{\mathrm{nr}}$ is given by

$$(\tilde{\mathbf{a}}^+(g)\psi)(\tilde{\mathbf{p}}_1,\ldots,\tilde{\mathbf{p}}_{n+1})=\frac{1}{\sqrt{n+1}}\sum_{j=1}^{n+1} g(\tilde{\mathbf{p}}_j)\psi(\tilde{\mathbf{p}}_1,\ldots,\widehat{\tilde{\mathbf{p}}_j},\ldots,\tilde{\mathbf{p}}_{n+1}),$$

$$(\tilde{\mathbf{a}}(g)\psi)(\tilde{\mathbf{p}}_1,\ldots,\tilde{\mathbf{p}}_{n-1})=\sqrt{n}\int_{p^+>0}\frac{d^3\tilde{\mathbf{p}}}{2p^+}\overline{g}(\tilde{\mathbf{p}})\psi(\tilde{\mathbf{p}},\tilde{\mathbf{p}}_1,\ldots,\tilde{\mathbf{p}}_{n-1}),$$

where $\psi(\tilde{\mathbf{p}}_1,\ldots,\tilde{\mathbf{p}}_n)\in\tilde{\mathfrak{H}}^{\vee n}_{\mathrm{nr}}$ and $g\in\mathcal{S}_{p^+}(\mathbb{R}^3)$. Notice that $\tilde{\mathbf{a}}^+(g)$ is the adjoint of $\tilde{\mathbf{a}}(g)$. The fields $\tilde{\boldsymbol{\phi}}_m$ and $\tilde{\boldsymbol{\varphi}}$ can be written in terms of $\tilde{\mathbf{a}}^+$ and $\tilde{\mathbf{a}}$ as

$$\tilde{\boldsymbol{\phi}}_m(f)=\frac{\alpha}{\sqrt{2}}(\tilde{\mathbf{a}}^+(\tilde{\Omega}^*_+(f^{\wedge\mathrm{L}}))+\tilde{\mathbf{a}}(\tilde{\Omega}^*_+(f^{\wedge\mathrm{L}})))\quad (f\in\mathcal{S}(\mathbb{R}^4),\ \text{real-valued}),$$

$$\tilde{\boldsymbol{\varphi}}(g)=\frac{\alpha}{\sqrt{2}}(\tilde{\mathbf{a}}^+(g^{\sqcap})+\tilde{\mathbf{a}}(g^{\sqcap}))\quad (g\in\mathcal{S}_{\partial\_}(\mathbb{R}^3),\ \text{real-valued}).$$

Notice that, for each $f\in\mathcal{S}(\mathbb{R}^4)$, (the trivial extension by zero of) $\tilde{\Omega}^*_+(f)$ is in $\mathcal{S}_{p^+>0}(\mathbb{R}^3)$.

Recall that we often do not distinguish between functions on $\mathbb{R}_{>0}\times\mathbb{R}^{n-1}$ and there trivial extensions by zero to $\mathbb{R}^n$. In according this, recall that $\nu^*_{>0}\mathcal{S}_n=\mathcal{S}_{p^+>0}(\mathbb{R}^n)$ is dense in $\mathcal{L}^2(\mathbb{R}_{>0}\times\mathbb{R}^{n-1}, d^n\tilde{\mathbf{p}}/2p^+)=\mathcal{L}^2(\mathbb{R}^n,(\Theta(p^+)/2p^+)\,d^n\tilde{\mathbf{p}})$ by Proposition V.6. As in the relativistic case, we define $\tilde{F}_0$ as the dense subspace of all finite vectors of $\tilde{\mathcal{H}}_{\mathrm{nr}}=\mathcal{F}_{\vee}(\tilde{\mathfrak{H}}_{\mathrm{nr}})$. Let

$$\tilde{D}_0:=\{\psi=(\psi_n)_{n\geqslant 0}\in\tilde{F}_0:\psi_n\in\mathcal{S}_{p^+>0}(\mathbb{R}^{3n})\},$$

which is a dense subspace of $\tilde{\mathcal{H}}_{\mathrm{nr}}$. For each $\tilde{\mathbf{p}}\in\mathbb{R}^3$, we define an operator $\tilde{\mathbf{a}}(\tilde{\mathbf{p}}):\tilde{D}_0\to\tilde{D}_0$ by

$$(\tilde{\mathbf{a}}(\tilde{\mathbf{p}})\psi)_n(\tilde{\mathbf{p}}_1,\ldots,\tilde{\mathbf{p}}_n):=\sqrt{n+1}\,\psi_{n+1}(\tilde{\mathbf{p}},\tilde{\mathbf{p}}_1,\ldots,\tilde{\mathbf{p}}_n)\quad (n\geqslant 0),\tag{28}$$

where $\psi=(\psi_n)_{n\geqslant 0}\in\tilde{D}_0$. Notice that $\tilde{\mathbf{a}}(\tilde{\mathbf{p}})=0$ whenever $p^+\leqslant 0$. As in the Minkowski-case, the adjoint of $\tilde{\mathbf{a}}(\tilde{\mathbf{p}})$ is not densely defined, however, the adjoint $\tilde{\mathbf{a}}^+(\tilde{\mathbf{p}})$ exists as bilinear form on $\tilde{D}_0\times\tilde{D}_0$, and is defined by

$$\langle\chi,\tilde{\mathbf{a}}^+(\tilde{\mathbf{p}})\psi\rangle:=\langle\tilde{\mathbf{a}}(\tilde{\mathbf{p}})\chi,\psi\rangle\quad(\chi,\psi\in\tilde{D}_0).\tag{29}$$

Again, $\tilde{\mathbf{a}}^+(\tilde{\mathbf{p}})=0$ whenever $p^+\leqslant 0$. Notice that the brackets on the right-hand side of (29) denote the scalar product of the Fock space $\tilde{\mathcal{H}}_{\mathrm{nr}}$, whereas those on the left-hand side have to be seen only symbolically. One can easily check that

$$\tilde{\mathbf{a}}(g)=\int_{p^+>0}\frac{d^3\tilde{\mathbf{p}}}{2p^+}\tilde{\mathbf{a}}(\tilde{\mathbf{p}})\overline{g}(\tilde{\mathbf{p}})\quad\text{and}\quad\tilde{\mathbf{a}}^+(g)=\int_{p^+>0}\frac{d^3\tilde{\mathbf{p}}}{2p^+}\tilde{\mathbf{a}}^+(\tilde{\mathbf{p}})g(\tilde{\mathbf{p}})$$

for every $g\in\mathcal{S}_{p^+}(\mathbb{R}^3)$ in the sense of integration[24] of bilinear forms. By construction, for every χ, $\psi\in\tilde{\mathcal{H}}_{\mathrm{nr}}$, the functions

$$\mathbb{R}^3\rightrightarrows\mathbb{C},\quad\tilde{\mathbf{p}}\mapsto\langle\chi,\tilde{\mathbf{a}}(\tilde{\mathbf{p}})\psi\rangle,\quad\tilde{\mathbf{p}}\mapsto\langle\chi,\tilde{\mathbf{a}}^+(\tilde{\mathbf{p}})\psi\rangle$$

are in $\mathcal{S}_{p^+>0}(\mathbb{R}^3)$. Hence, it is possible to define bilinear forms $\tilde{\boldsymbol{\phi}}_m(\tilde{x})$ and $\tilde{\boldsymbol{\varphi}}(\tilde{\mathbf{x}})$ ($\tilde{x}\in\mathbb{R}^4$, $\tilde{\mathbf{x}}\in\mathbb{R}^3$) on $\tilde{D}_0\times\tilde{D}_0$ in the following way:

$$\tilde{\boldsymbol{\phi}}_m(\tilde{x}):=\frac{1}{(2\pi)^{3/2}}\int_{p^+>0}\frac{d^3\tilde{\mathbf{p}}}{2p^+}(\tilde{\mathbf{a}}^+(\tilde{\mathbf{p}})\,e^{i\langle\tilde{\Omega}_+(\tilde{\mathbf{p}}),\tilde{x}\rangle_{\mathrm{L}}}+\tilde{\mathbf{a}}(\tilde{\mathbf{p}})\,e^{-i\langle\tilde{\Omega}_+(\tilde{\mathbf{p}}),\tilde{x}\rangle_{\mathrm{L}}}),$$

$$\tilde{\boldsymbol{\varphi}}(\tilde{\mathbf{x}}):=\frac{1}{(2\pi)^{3/2}}\int_{p^+>0}\frac{d^3\tilde{\mathbf{p}}}{2p^+}(\tilde{\mathbf{a}}^+(\tilde{\mathbf{p}})\,e^{i(p^+x^-\,-\,\mathbf{p}_\perp\cdot\mathbf{x}_\perp)}+\tilde{\mathbf{a}}(\tilde{\mathbf{p}})\,e^{-i(p^+x^-\,-\,\mathbf{p}_\perp\cdot\mathbf{x}_\perp)}).$$

Again one easily checks that in the sense of integration of bilinear forms

$$\tilde{\boldsymbol{\phi}}_m(f)=\int d^4\tilde{x}\,\tilde{\boldsymbol{\phi}}_m(\tilde{x})f(\tilde{x}),\quad\tilde{\varphi}(h)=\int d^3\tilde{\mathbf{x}}\,\tilde{\varphi}(\tilde{\mathbf{x}})h(\tilde{\mathbf{x}})$$

for every $f\in\mathcal{S}(\mathbb{R}^4)$, $h\in\mathcal{S}_{\partial_-}(\mathbb{R}^3)$.

By the same approach, however, with $U:=\mathcal{F}_{\vee}(\Omega_+^*):\mathcal{H}_m\to\mathcal{H}_{\mathrm{nr}}$ instead of $\mathcal{F}_{\vee}(\tilde{\Omega}_+^*)$, where $\mathcal{H}_{\mathrm{nr}}=\mathcal{F}_{\vee}(\mathcal{L}^2(\mathbb{R}^3,d^3\mathbf{p}/2\omega(\mathbf{p})))$, one gets analogous formulas for the transformed free field $\boldsymbol{\phi}_m=U\phi_mU^{-1}$ and the transformed time-zero fields $\boldsymbol{\varphi}_m=U\varphi_mU^{-1}$, $\boldsymbol{\pi}_m=U\pi_mU^{-1}$:

$$\boldsymbol{\phi}_m(x):=\frac{1}{(2\pi)^{3/2}}\int_{\mathbb{R}^3}\frac{d^3\mathbf{p}}{2\omega(\mathbf{p})}(\mathbf{a}^+(\mathbf{p})\,e^{i\langle\Omega_+(\mathbf{p}),x\rangle_{\mathbb{M}}}+\mathbf{a}(\mathbf{p})\,e^{-i\langle\Omega_+(\mathbf{p}),x\rangle_{\mathbb{M}}}),$$

$$\boldsymbol{\varphi}_m(\mathbf{x}):=\frac{1}{(2\pi)^{3/2}}\int_{\mathbb{R}^3}\frac{d^3\mathbf{p}}{2\omega(\mathbf{p})}(\mathbf{a}^+(\mathbf{p})\,e^{-i\mathbf{p}\cdot\mathbf{x}}+\mathbf{a}(\mathbf{p})\,e^{i\mathbf{p}\cdot\mathbf{x}}),$$

$$\boldsymbol{\pi}_m(\mathbf{x}):=\frac{i}{(2\pi)^{3/2}}\int_{\mathbb{R}^3}d^3\mathbf{p}(\mathbf{a}^+(\mathbf{p})\,e^{-i\mathbf{p}\cdot\mathbf{x}}-\mathbf{a}(\mathbf{p})\,e^{i\mathbf{p}\cdot\mathbf{x}}).$$

There, $\mathbf{a}(\mathbf{p})$ and $\mathbf{a}^+(\mathbf{p})$ are defined on $D_0:=\{\psi=(\psi_n)_{n\geqslant 0}\in F_0:\psi_n\in\mathcal{S}(\mathbb{R}^{3n})\}$ as in (28) and (29). The interrelation between $\mathbf{a}(\mathbf{p})$, $\mathbf{a}^+(\mathbf{p})$ and $\tilde{\mathbf{a}}(\tilde{\mathbf{p}})$, $\tilde{\mathbf{a}}^+(\tilde{\mathbf{p}})$ is given as follows:

Proposition VII.1: Let $V:=\mathcal{F}_{\vee}(\nu_{>0}^*):\mathcal{H}_{\mathrm{nr}}\to\tilde{\mathcal{H}}_{\mathrm{nr}}$ *be the unitary mapping induced by* $\nu_{>0}$. *Then, in the sense of bilinear forms,*

$$\tilde{\mathbf{a}}(\tilde{\mathbf{p}})=V\mathbf{a}(\nu_{>0}(\tilde{\mathbf{p}}))V^{-1},\quad\tilde{\mathbf{a}}^+(\tilde{\mathbf{p}})=V\mathbf{a}^+(\nu_{>0}(\tilde{\mathbf{p}}))V^{-1}$$

for every $\tilde{\mathbf{p}} \in \mathbb{R}^3$, $p^+ > 0$.

Proof: This follows immediately from the fact that $V = \mathcal{F}_{\vee}(\nu^*_{>0})$ is a unitary mapping and that $\mathbf{a}(\mathbf{p})$ (resp. $\mathbf{a}^+(\mathbf{p})$) and $\tilde{\mathbf{a}}(\tilde{\mathbf{p}})$ (resp. $\tilde{\mathbf{a}}^+(\tilde{\mathbf{p}})$) are both defined by the same kind of formula (28) (resp. (29)). □

Remark VII.2: The reader can easily verify that $\tilde{\boldsymbol{\varphi}}(\tilde{\mathbf{x}}) = \tilde{\boldsymbol{\phi}}_m(0,\tilde{\mathbf{x}})$, i.e., $\tilde{\boldsymbol{\varphi}}$ is the restriction of $\tilde{\boldsymbol{\phi}}_m$ to $\{x^+ = 0\}$. Since, for any χ, $\psi \in \tilde{D}_0$, the functions $\tilde{\mathbf{p}} \mapsto \langle \chi, \tilde{\mathbf{a}}(\tilde{\mathbf{p}}) \rangle$ and $\tilde{\mathbf{p}} \mapsto \langle \chi, \tilde{\mathbf{a}}^+(\tilde{\mathbf{p}}) \rangle$ are in $\mathcal{S}_{p^+}(\mathbb{R}^3)$, the function $\tilde{\mathbf{x}} \mapsto \langle \chi, \tilde{\boldsymbol{\varphi}}(\tilde{\mathbf{x}}) \psi \rangle$ is in $\mathcal{S}_{\partial_-}(\mathbb{R}^3)$ by the above Fock-space expansion of $\tilde{\boldsymbol{\varphi}}(\tilde{\mathbf{x}})$. Hence, it is possible to express $\tilde{\mathbf{a}}(\tilde{\mathbf{p}})$ and $\tilde{\mathbf{a}}^+(\tilde{\mathbf{p}})$ in terms of $\tilde{\boldsymbol{\varphi}}(\tilde{\mathbf{x}})$ by applying the partial LC-Fourier transformation which can be seen as follows: Define a bilinear form $\tilde{\mathbf{b}}(\tilde{\mathbf{p}})$ on $\tilde{D}_0 \times \tilde{D}_0$ by

$$\tilde{\mathbf{b}}(\tilde{\mathbf{p}}) := \begin{cases} \tilde{\mathbf{a}}(\tilde{\mathbf{p}}), & \text{if } p^+ > 0 \\ \tilde{\mathbf{a}}^+(-\tilde{\mathbf{p}}), & \text{if } p^+ < 0. \end{cases}$$

Then, the above Fock-space expansion of $\tilde{\boldsymbol{\varphi}}(\tilde{\mathbf{x}})$ can be rewritten as

$$\tilde{\boldsymbol{\varphi}}(\tilde{\mathbf{x}}) = \frac{1}{(2\pi)^{3/2}} \int_{\mathbb{R}^3} \frac{d^3\tilde{\mathbf{p}}}{2|p^+|} \tilde{\mathbf{b}}(\tilde{\mathbf{p}})\, e^{-i(p^+x^- - \mathbf{p}_\perp \cdot \mathbf{x}_\perp)}.$$

Applying the partial LC-Fourier transformation, we obtain

$$\tilde{\mathbf{b}}(\tilde{\mathbf{p}}) = \frac{2}{(2\pi)^{3/2}} \int_{\mathbb{R}^3} d^3\tilde{\mathbf{x}}\, |p^+| \tilde{\boldsymbol{\varphi}}(\tilde{\mathbf{x}})\, e^{i(p^+x^- - \mathbf{p}_\perp \cdot \mathbf{x}_\perp)},$$

and hence

$$\tilde{\mathbf{a}}(\tilde{\mathbf{p}}) = \frac{2}{(2\pi)^{3/2}} \int_{\mathbb{R}^3} d^3\tilde{\mathbf{x}}\, |p^+| \tilde{\boldsymbol{\varphi}}(\tilde{\mathbf{x}})\, e^{i(p^+x^- - \mathbf{p}_\perp \cdot \mathbf{x}_\perp)},$$

$$\tilde{\mathbf{a}}^+(\tilde{\mathbf{p}}) = \frac{2}{(2\pi)^{3/2}} \int_{\mathbb{R}^3} d^3\tilde{\mathbf{x}}\, |p^+| \tilde{\boldsymbol{\varphi}}(\tilde{\mathbf{x}})\, e^{-i(p^+x^- - \mathbf{p}_\perp \cdot \mathbf{x}_\perp)}.$$

This shows that $\tilde{\boldsymbol{\phi}}_m(x^+,\tilde{\mathbf{x}})$ is uniquely determined by the initial data $\tilde{\boldsymbol{\varphi}}(\tilde{\mathbf{x}}) = \tilde{\boldsymbol{\phi}}_m(0,\tilde{\mathbf{x}})$ on the hypersurface $\{x^+ = 0\}$. Since, moreover, $\boldsymbol{\phi}_m(\tilde{x})$, i.e., $\tilde{x} \mapsto \langle \chi, \boldsymbol{\phi}_m(\tilde{x})\psi \rangle$, is a solution of the LC-Klein–Gordon equation, we establish that $\tilde{\boldsymbol{\phi}}_m(\tilde{x})$ is the unique solution of the Cauchy problem of the LC-Klein–Gordon equation $(\tilde{\Box} + m^2)\tilde{u} = 0$ with initial data $\tilde{u}|_{x^+=0}$ given on $\{x^+ = 0\}$. Since the surface $\{x^+ = 0\}$ is characteristic, uniqueness of the solution cannot be guaranteed any more generally.[12] However, ambiguity is not necessary. It is even possible to show uniqueness (and existence) of the solutions in a very general situation.[21]

Notice that in the Minkowski case, the Cauchy problem of the Klein–Gordon equation with initial data given on $\{x^0 = \text{const}\}$ is always uniquely solvable (cf., e.g., Ref. 3). One needs $\boldsymbol{\varphi}_m(\mathbf{x}) = \boldsymbol{\phi}_m(0,\mathbf{x})$ and the first time-derivative $\boldsymbol{\pi}_m(\mathbf{x}) = \partial_0 \boldsymbol{\phi}_m(0,\mathbf{x})$ as initial data on $\{x^0 = 0\}$ to determine $\boldsymbol{\phi}_m(\mathbf{x})$ uniquely. This can be seen by the fact, that one also needs $\boldsymbol{\varphi}_m(\mathbf{x})$ and $\boldsymbol{\pi}_m(\mathbf{x})$ to express $\mathbf{a}(\mathbf{p})$ and $\mathbf{a}^+(\mathbf{p})$ in terms of initial data on $\{x^0 = 0\}$, e.g.,

$$\mathbf{a}(\mathbf{p}) = \frac{1}{(2\pi)^{3/2}} \int_{\mathbb{R}^3} d^3\mathbf{x} \left(\omega(\mathbf{p}) \boldsymbol{\varphi}_m(\mathbf{x}) + \frac{i}{2} \boldsymbol{\pi}_m(\mathbf{x}) \right) e^{-i\mathbf{p}\cdot x}.$$

The difference between Minkowski- and LC-case is not surprising since $\Box + m^2$ contains ∂_0 with exponent two, whereas in $\tilde{\Box} + m^2$ the derivative ∂_+ appears only linearly. In momentum space this situation is reflected by the fact, that $\Gamma_m \to \mathbb{R}^3$, $(p^0,\mathbf{p}) \mapsto \mathbf{p}$ is a (smooth) double covering, whereas $\tilde{\Gamma}_m \to \mathbb{R}^3 \backslash \{p^+ = 0\}$, $(\tilde{\mathbf{p}},p^-) \mapsto \tilde{\mathbf{p}}$ is a diffeomorphism.

As a final topic we consider products of $\tilde{\mathbf{a}}^+(\tilde{\mathbf{k}})$ and $\tilde{\mathbf{a}}(\tilde{\mathbf{p}})$ $(\tilde{\mathbf{k}},\tilde{\mathbf{p}}\in\mathbb{R}^3)$ and discuss the question when these products are induced by an operator. This is essential in constructing interacting fields obeying the LC-Wightman axioms. Given $\tilde{\mathbf{k}}_1,\ldots,\tilde{\mathbf{k}}_r\in\mathbb{R}^3$ and $\tilde{\mathbf{p}}_1,\ldots,\tilde{\mathbf{p}}_s\in\mathbb{R}^3$, $r,s\geqslant 0$ we define the bilinear form $\tilde{\mathbf{a}}^+(\tilde{\mathbf{k}}_1)\cdots\tilde{\mathbf{a}}^+(\tilde{\mathbf{k}}_r)\tilde{\mathbf{a}}(\tilde{\mathbf{p}}_1)\cdots\tilde{\mathbf{a}}(\tilde{\mathbf{p}}_s)$ on $\tilde{D}_0\times\tilde{D}_0$ by

$$\langle\chi,\tilde{\mathbf{a}}^+(\tilde{\mathbf{k}}_1)\cdots\tilde{\mathbf{a}}^+(\tilde{\mathbf{k}}_r)\tilde{\mathbf{a}}(\tilde{\mathbf{p}}_1)\cdots\tilde{\mathbf{a}}(\tilde{\mathbf{p}}_s)\psi\rangle=\langle\tilde{\mathbf{a}}(\tilde{\mathbf{k}}_r)\cdots\tilde{\mathbf{a}}(\tilde{\mathbf{k}}_1)\chi,\tilde{\mathbf{a}}(\tilde{\mathbf{p}}_1)\cdots\tilde{\mathbf{a}}(\tilde{\mathbf{p}}_s)\psi\rangle$$

for all $\chi,\psi\in\tilde{D}_0$.

Remark VII.3: In Minkowski case, $\mathbf{a}^+(\mathbf{k}_1)\cdots\mathbf{a}^+(\mathbf{k}_r)\mathbf{a}(\mathbf{p}_1)\cdots\mathbf{a}(\mathbf{p}_s)$ is defined by the same kind of formula as $\tilde{\mathbf{a}}^+(\tilde{\mathbf{k}}_1)\cdots\tilde{\mathbf{a}}^+(\tilde{\mathbf{k}}_r)\tilde{\mathbf{a}}(\tilde{\mathbf{p}}_1)\cdots\tilde{\mathbf{a}}(\tilde{\mathbf{p}}_s)$.[16] Hence, it is obvious that the transformation law of Proposition VII.1 extends canonically to

$$\tilde{\mathbf{a}}^+(\tilde{\mathbf{k}}_1)\cdots\tilde{\mathbf{a}}^+(\tilde{\mathbf{k}}_r)\tilde{\mathbf{a}}(\tilde{\mathbf{p}}_1)\cdots\tilde{\mathbf{a}}(\tilde{\mathbf{p}}_s)=U\mathbf{a}^+(\nu_{>0}(\tilde{\mathbf{k}}_1))\cdots\mathbf{a}^+(\nu_{>0}(\tilde{\mathbf{k}}_r))\mathbf{a}(\nu_{>0}(\tilde{\mathbf{p}}_1))\cdots\mathbf{a}(\nu_{>0}(\tilde{\mathbf{p}}_s))U^{-1},$$

where $U:\mathcal{H}_{\mathrm{nr}}\to\tilde{\mathcal{H}}_{\mathrm{nr}}$ is as in Proposition VII.1.

Now, we can easily transfer Theorem X.44 of Ref. 16 to the LC-case. To shorten the notation we introduce the following abbreviations:

$$\tilde{\mathbf{p}}_{1\cdots r}=(\tilde{\mathbf{p}}_1,\ldots,\tilde{\mathbf{p}}_r)\in\mathbb{R}^{3r},\quad p^+_{1\cdots r}=\prod_{i=1}^{r}p_i^+,$$

$$\omega(\mathbf{p}_{1\cdots r})=\prod_{i=1}^{r}\omega(\mathbf{p}_i)=\prod_{i=1}^{r}\sqrt{\mathbf{p}_i^2+m^2},$$

$$\#(\tilde{\mathbf{p}}_{1\cdots r})=\prod_{i=1}^{r}\#(\tilde{\mathbf{p}}_i),\quad \text{where } \# \text{ represents } \mathbf{a},\mathbf{a}^+,\mathbf{a}',\mathbf{a}'^+,\tilde{\mathbf{a}} \text{ or } \tilde{\mathbf{a}}^+.$$

Recall that $\tilde{\mathfrak{H}}_{\mathrm{nr}}=\mathcal{L}^2(\mathbb{R}_{>0}\times\mathbb{R}^2,d^3\tilde{\mathbf{p}}/2p^+)$.

Theorem VII.4: *Suppose* $\tilde{W}(\tilde{k}_{1\cdots n_1},\tilde{p}_{1\cdots n_2})\in\tilde{\mathfrak{H}}_{\mathrm{nr}}^{\otimes(n_1+n_2)}$, *where* $n_1,n_2\geqslant 0$. *Then there is a unique operator* $\tilde{T}_{\tilde{W}}$ on $\tilde{\mathcal{H}}_{\mathrm{nr}}=\mathcal{F}_{\vee}(\tilde{\mathfrak{H}}_{\mathrm{nr}})$ *with the following properties*:

(i) $\tilde{D}_0\subset D(\tilde{T}_{\tilde{W}})$ *is a core for* $\tilde{T}_{\tilde{W}}$.

(ii) $\tilde{T}_{\tilde{W}}=\int_{k_1^+>0\cdots k_{n_1}^+>0}\int_{p_1^+>0\cdots p_{n_2}^+>0}(d^{3n_1}\tilde{\mathbf{k}}_{1\cdots n_1}/k^+_{1\cdots n_1})(d^{3n_2}\tilde{\mathbf{p}}_{1\cdots n_2}/p^+_{1\cdots n_2})\tilde{W}(\tilde{\mathbf{k}}_{1\cdots n_1},\tilde{\mathbf{p}}_{1\cdots n_2})\times\tilde{\mathbf{a}}^+(\tilde{\mathbf{k}}_{1\cdots n_1})\tilde{\mathbf{a}}(\tilde{\mathbf{p}}_{1\cdots n_2})$ *as bilinear forms on* $\tilde{D}_0\times\tilde{D}_0$.

(iii) *If* m_1,m_2 *are non-negative integers such that* $m_1+m_2=n_1+n_2$, then $(1+N)^{-m_1/2}\tilde{T}_{\tilde{W}}(1+N)^{-m_2/2}$ *is a bounded operator with*

$$\|(1+N)^{-m_1/2}\tilde{T}_{\tilde{W}}(1+N)^{-m_2/2}\|\leqslant C_{m_1,m_2}\|\tilde{W}\|_{\tilde{\mathfrak{H}}_{\mathrm{nr}}^{\otimes(n_1+n_2)}},$$

where N *is the number operator and* C_{m_1,m_2} *a constant (cf. Ref. 16, p. 208, 222); especially* $C_{m_1,m_2}=1$, *if* $m_1=n_1$ *and* $m_2=n_2$.

(iv) $\tilde{T}^*_{\tilde{W}}=\int_{k_1^+>0\cdots k_{n_1}^+>0}\int_{p_1^+>0\cdots p_{n_2}^+>0}(d^{3n_1}\tilde{\mathbf{k}}_{1\cdots n_1}/k^+_{1\cdots n_1})(d^{3n_2}\tilde{\mathbf{p}}_{1\cdots n_2}/p^+_{1\cdots n_2})\overline{\tilde{W}(\tilde{\mathbf{k}}_{1\cdots n_1},\tilde{\mathbf{p}}_{1\cdots n_2})}\times\tilde{\mathbf{a}}^+(\tilde{\mathbf{k}}_{1\cdots n_1})\tilde{\mathbf{a}}(\tilde{\mathbf{p}}_{1\cdots n_2})$ *as bilinear forms on* $\tilde{D}_0\times\tilde{D}_0$.

(v) *If* $(\tilde{W}_n)_{n\in\mathbb{N}}$ *converges to* $\tilde{W}$ *in* $\tilde{\mathfrak{H}}_{\mathrm{nr}}^{\otimes(n_1+n_2)}$, *then* $(\tilde{T}_{\tilde{W}_n})_{n\in\mathbb{N}}$ *converges to* $\tilde{T}_{\tilde{W}}$ *strongly on* $\tilde{D}_0$.

(vi) $\tilde{D}_0$ *is contained in* $D(\tilde{T}_{\tilde{W}})\cap D(\tilde{T}^*_{\tilde{W}})$, *and* $\tilde{T}_{\tilde{W}},\tilde{T}^*_{\tilde{W}}$ *are given on* $\tilde{D}_0$ *by the explicit formulas* $(\ell\geqslant 0)$:

$$(\tilde{T}_{\tilde{W}}\psi)_{\ell-n_2+n_1}(\tilde{\mathbf{k}}_{1\cdots\ell-n_2+n_1})=K_{\ell,n_1,n_2}S\int_{p_1^+>0\cdots p_{n_2}^+>0}\frac{d^{3n_2}\tilde{\mathbf{p}}_{1\cdots n_2}}{p^+_{1\cdots n_2}}\tilde{W}(\tilde{\mathbf{k}}_{1\cdots n_1},\tilde{\mathbf{p}}_{1\cdots n_2})$$

$$\psi_l(\tilde{\mathbf{p}}_{1\cdots n_2}, \tilde{\mathbf{k}}_{n_1+1\cdots n_1+\ell-n_2}),$$

$$(\tilde{T}_{\tilde{W}}\psi)_n = 0, \quad if \quad n < n_1 - n_2,$$

$$(\tilde{T}^*_{\tilde{W}}\psi)_{\ell-n_1+n_2}(\tilde{\mathbf{p}}_{1\cdots\ell-n_1+n_2}) = K_{\ell,n_2,n_1}\, S \int_{k_1^+>0\cdots k_{n_1}^+>0} \frac{d^{3n_1}\tilde{\mathbf{k}}_{1\cdots n_1}}{k^+_{1\cdots n_1}} \overline{\tilde{W}(\tilde{\mathbf{k}}_{1\cdots n_1}, \tilde{\mathbf{p}}_{1\cdots n_2})}$$

$$\times \psi_l(\tilde{\mathbf{k}}_{1\cdots n_1}, \tilde{\mathbf{p}}_{n_2+1\cdots n_2+\ell-n_1}),$$

$$(\tilde{T}_{\tilde{W}}\psi)_n = 0, \quad if \quad n < n_2 - n_1,$$

where S denotes the symmetrization operator and K_{ℓ,n_1,n_2} is a constant (cf. Ref. 16, p. 207).

Proof: Let $\nu = \nu_{>0}$ denote the squeezing mapping and $U := \mathcal{F}_\vee(\nu^*): \mathcal{H}_{\rm nr} \to \tilde{\mathcal{H}}_{\rm nr}$ the induced unitary operator. The annihilation and creation operators in Ref. 16 are defined by the same formulas as in (28), (29), however, on the Fock space $\mathcal{H}'_{\rm nr} = \mathcal{F}_\vee(\mathcal{L}^2(\mathbb{R}^3, d^3\mathbf{p}))$, which is also frequently used as the nonrelativistic one-particle space. Let us temporarily denote the creation and annihilation operators acting on $\mathcal{H}'_{\rm nr}$, as in Ref. 16, by $\mathbf{a}'(\mathbf{p})$ and $\mathbf{a}'^+(\mathbf{p})$. Let $V = \mathcal{F}_\vee(v): \mathcal{H}'_{\rm nr} \to \mathcal{H}_{\rm nr}$ be the unitary operator induced by $v: \mathcal{L}^2(\mathbb{R}^3, d^3\mathbf{p}) \to \mathcal{L}^2(\mathbb{R}^3, d^3\mathbf{p}/2\omega(\mathbf{p}))$, $g \mapsto \sqrt{2\omega(\mathbf{p})}g$. It is easy to see that

$$V\mathbf{a}'(\mathbf{p})V^{-1} = \frac{\mathbf{a}(\mathbf{p})}{\sqrt{2\omega(\mathbf{p})}} \quad \text{and} \quad V\mathbf{a}'^+(\mathbf{p})V^{-1} = \frac{\mathbf{a}^+(\mathbf{p})}{\sqrt{2\omega(\mathbf{p})}}$$

in the sense of bilinear forms for every $\mathbf{p} \in \mathbb{R}^3$. Suppose $\tilde{W} \in \tilde{\mathcal{H}}_{\rm nr}^{\otimes(n_1+n_2)}$. Then we define

$$W := (2v^{-1}\nu_*)^{\otimes(n_1+n_2)}\tilde{W} \in \mathcal{L}^2(\mathbb{R}^3, d\mathbf{p})^{\otimes(n_1+n_2)}.$$

Let T_W be the operator from Theorem X.44.[16] We define the operator $\tilde{T}_{\tilde{W}}$ by

$$\tilde{T}_{\tilde{W}} := UVT_W(UV)^{-1}.$$

Then by Theorem X.44,[16] we obtain in the sense of bilinear forms

$$\tilde{T}_{\tilde{W}} = UV\left(\int d^{3n_1}\mathbf{k}_{1\cdots n_1} \int d^{3n_2}\mathbf{p}_{1\cdots n_2} W(\mathbf{k}_{1\cdots n_1}, \mathbf{p}_{1\cdots n_2})\mathbf{a}'^+(\mathbf{k}_{1\cdots n_1})\mathbf{a}'(\mathbf{p}_{1\cdots n_2}) \right) V^{-1}U^{-1}$$

$$= U\left(\int \frac{d^{3n_1}\mathbf{k}_{1\cdots n_1}}{2^{n_1}\omega(\mathbf{k}_{1\cdots n_1})} \int \frac{d^{3n_2}\mathbf{p}_{1\cdots n_2}}{2^{n_2}\omega(\mathbf{p}_{1\cdots n_2})} (v^{\otimes(n_1+n_2)}W)(\mathbf{k}_{1\cdots n_1}, \mathbf{p}_{1\cdots n_2})\mathbf{a}^+(\mathbf{k}_{1\cdots n_1})\mathbf{a}(\mathbf{p}_{1\cdots n_2}) \right) U^{-1}$$

$$= \int_{k_1^+>0\cdots k_{n_1}^+>0} \frac{d^{3n_1}\tilde{\mathbf{k}}_{1\cdots n_1}}{k^+_{1\cdots n_1}} \int_{p_1^+>0\cdots p_{n_1}^+>0} \frac{d^{3n_2}\tilde{\mathbf{p}}_{1\cdots n_2}}{p^+_{1\cdots n_2}} \tilde{W}(\tilde{\mathbf{k}}_{1\cdots n_1}, \tilde{\mathbf{p}}_{1\cdots n_2})\tilde{\mathbf{a}}^+(\tilde{\mathbf{k}}_{1\cdots n_1})\tilde{\mathbf{a}}(\tilde{\mathbf{p}}_{1\cdots n_2})$$

since $\tilde{W} = (2^{-1}\nu^* v)^{\otimes(n_1+n_2)}W$ which proves (ii). In the same way, using the definition of $\tilde{T}_{\tilde{W}}$, we easily obtain from Ref. 16, Theorem X.44 the remaining assertions. □

VIII. CONCLUSIONS

In this paper we have shown that with the aid of squeezed distributions the technical problem of constructing a proper restriction of the free scalar massive field to the lightlike surface $\{x^0 + x^3 = 0\}$ can been solved. Such restriction problems also arise naturally in the theory of distributions and are closely related to the problem that products of distributions are not always ca-

nonically defined; the so-called wave front set plays an essential role there.[11] Hence, squeezed distributions might be helpful in constructing noncanonical restrictions and products of (tempered) distributions which occur in LC-quantum field theories.

We hope that our paper will revive the (axiomatic) development of light-cone (or light-front) quantum field theory by having eliminated some old, technical problems, see also Ref. 21. Moreover, building upon the results of this paper it might now be possible to take advantage of the front-form Hamiltonian approach in constructing explicit models of interacting (LC-)quantum fields obeying the (LC-)Wightman axioms. At least it should now be possible to investigate $:P(\phi)_2:$-theories on the light cone in a mathematically rigorous way—also to find possibly an answer to the question whether there is an analog of Haag's theorem for fields on null planes as suggested by Driessler.[9]

ACKNOWLEDGMENT

I am gratefully indebted to Professor E. Werner for his continuous interest in this work and for helpful discussions and suggestions.

(Received 9 December 2003; accepted 16 April 2004; published online 8 July 2004)

We construct a realization of the L-operator satisfying the RLL-relation of the face-type elliptic quantum group $\mathcal{B}_{q,\lambda}(A_2^{(2)})$. The construction is based on the elliptic analog of the Drinfeld currents of $U_q(A_2^{(2)})$, which forms the elliptic algebra $U_{q,p}(A_2^{(2)})$. We give a realization of the elliptic currents $E(z)$, $F(z)$, and $K(z)$ as a tensor product of the Drinfeld currents of $U_q(A_2^{(2)})$ and a Heisenberg algebra. In the level-one representation, we also give a free field realization of the elliptic currents. Applying these results, we derive a free field realization of the $U_{q,p}(A_2^{(2)})$-analog of the $\mathcal{B}_{q,\lambda}(A_2^{(2)})$-intertwining operators. The resultant operators coincide with those of the vertex operators in the dilute A_L model, which is known to be a RSOS restriction of the $A_2^{(2)}$ face model. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1767296]

I. INTRODUCTION

An elliptic quantum group is a quasitriangular quasi-Hopf algebra obtained as a quasi-Hopf deformation of the affine quantum group $U_q(\mathfrak{g})$ by the twistor satisfying the shifted cocycle condition.[1–3] It is conjectured in Refs. 4 and 3 that the representation theory of the elliptic quantum groups of both the vertex type $\mathcal{A}_{q,p}(\widehat{\mathfrak{sl}}_N)$ and the face type $\mathcal{B}_{q,\lambda}(\mathfrak{g})$, $\mathfrak{g}$ being an affine Lie algebra, enables us to perform an algebraic analysis of the corresponding two dimensional solvable lattice models in the sense of Jimbo and Miwa.[5] In order to perform the analysis, we need to construct explicit representations of both finite and infinite dimensional. For this purpose, the Drinfeld realization of the quantum groups is known to provide a relevant framework. In the previous papers,[6–8] we constructed the Drinfeld realization of the face-type elliptic quantum group $\mathcal{B}_{q,\lambda}(\widehat{\mathfrak{sl}}_N)$ based on the elliptic algebra $U_{q,p}(\widehat{\mathfrak{sl}}_N)$. The Drinfeld generators have both finite and infinite dimensional representations suitable for the calculation of the correlation functions.

In this paper, we investigate the same problem for $\mathcal{B}_{q,\lambda}(A_2^{(2)})$, the face-type elliptic quantum group associated with the twisted affine Lie algebra $A_2^{(2)}$. We first construct the elliptic algebra $U_{q,p}(A_2^{(2)})$ as the algebra of the elliptic analog of the Drinfeld currents of $U_q(A_2^{(2)})$. Basically, the idea given in Appendix A of Ref. 7 can be applied to the twisted case. Namely, dressing the Drinfeld currents of $U_q(A_2^{(2)})$ by the bosons a_m ($m \in \mathbb{Z}_{\neq 0}$) in $U_q(A_2^{(2)})$ and taking a tensor product with a certain Heisenberg algebra $\mathbb{C}\{\mathcal{H}\}$ generated by P,Q, which commutes with $U_q(A_2^{(2)})$, we obtain the elliptic Drinfeld currents. However, we formulate the elliptic algebra $U_{q,p}(A_2^{(2)})$ in an extended form by introducing the new currents $K(u)$, which enables the RLL-formulation of $U_{q,p}(A_2^{(2)})$. Then we discuss a connection between $U_{q,p}(A_2^{(2)})$ and $\mathcal{B}_{q,\lambda}(A_2^{(2)})$. We derive the dynamical RLL-relation of $\mathcal{B}_{q,\lambda}(A_2^{(2)})$ from the RLL-relation of $U_{q,p}(A_2^{(2)})$ by removing a half of the generator Q of the Heisenberg algebra and identifying P with the dynamical parameter in

b)Electronic mail: konno@mis.hiroshima-u.ac.jp

$\mathcal{B}_{q,\lambda}(A_2^{(2)})$. We hence find a structure of $U_{q,p}(A_2^{(2)})$ roughly given by "$\mathcal{B}_{q,\lambda}(A_2^{(2)})\otimes\mathbb{C}\{\mathcal{H}\}$," and in this sense, we regard $U_{q,p}(A_2^{(2)})$ as the Drinfeld realization of $\mathcal{B}_{q,\lambda}(A_2^{(2)})$.

Although the above tensor structure does not preserve the coalgebra structure of $\mathcal{B}_{q,\lambda}(A_2^{(2)})$, the same tensor structure enables us to convert the algebraic objects of $\mathcal{B}_{q,\lambda}(A_2^{(2)})$, such as the intertwining operators, to the $U_{q,p}(A_2^{(2)})$ counterparts. Moreover, in the known cases, it is true that the $U_{q,p}(\mathfrak{g})$ counterparts of the $\mathcal{B}_{q,\lambda}(\mathfrak{g})$ intertwining operators play the role of vertex operators in the restricted solid on solid (RSOS) model associated with $\mathfrak{g}$. We call such "intertwining" operator of $U_{q,p}(\mathfrak{g})$ the vertex operator of $U_{q,p}(\mathfrak{g})$. The elliptic Drinfeld currents in $U_{q,p}(A_2^{(2)})$ admits a free field realization, which is an elliptic extension of those of $U_q(A_2^{(2)})$ obtained in Refs. 9, 10, and 11. By using such realization and applying the tensoring procedure, we derive a free field realization of the vertex operators of $U_{q,p}(A_2^{(2)})$.

The face model associated with the twisted affine Lie algebra $A_2^{(2)}$ was formulated in Ref. 12. Its RSOS restriction is known to be the dilute A_L model.[13,14] The free field formulation of the dilute A_L model was carried out in Ref. 15. There, however, the construction of the vertex operators was done by brute force based on the commutation relations among the vertex operators. We here derive the same vertex operators by using the representation theory of $\mathcal{B}_{q,\lambda}(A_2^{(2)})$ and the Drinfeld realization given by $U_{q,p}(A_2^{(2)})$.

This paper is organized as follows: In the next section, we give a summary of the basic facts on the face type elliptic quantum group $\mathcal{B}_{q,\lambda}(A_2^{(2)})$. In Sec. III, we present a definition and a realization of the elliptic algebra $U_{q,p}(A_2^{(2)})$. New currents $K(u)$ are introduced there. In Sec. IV, we introduce a set of half currents defined from the elliptic currents in $U_{q,p}(A_2^{(2)})$ and derive their commutation relations. Section V is devoted to a construction of a L-operator and the RLL-formulation of $U_{q,p}(A_2^{(2)})$. We then derive the dynamical RLL-relation of $\mathcal{B}_{q,\lambda}(A_2^{(2)})$ from $U_{q,p}(A_2^{(2)})$. According to this result, in Sec. VI, we discuss a free field realization of the two types of vertex operators of the level one $U_{q,p}(A_2^{(2)})$-modules. The final section is devoted to discussions on some remaining problems. In addition, we have three appendixes. In Appendix A, we give a summary of the three-dimensional evaluation representation of $U_{q,p}(A_2^{(2)})$. In Appendix B, we discuss the difference equation for the twistor and give partial results on the solutions. Finally, in Appendix C, we give a proof of some formulas of commutation relations of the half currents.

II. THE ELLIPTIC QUANTUM GROUP $\mathcal{B}_{q,\lambda}(A_2^{(2)})$

In this section, we summarize some basic facts on the face-type elliptic quantum group $\mathcal{B}_{q,\lambda}(A_2^{(2)})$ based on the results in Ref. 3.

A. Notations

Through this article, we fix a complex number $q\neq 0, 0<q<1$ and p given by

$$p=q^{2r},\quad p^*=pq^{-2c}=q^{2r^*}\quad (r^*=r-c;\ r,r^*\in\mathbb{R}_{>0}).$$

We parametrize p as follows:

$$p=e^{-2\pi i/\tau},\ p^*=e^{-2\pi i/\tau^*}\quad (r\tau=r^*\tau^*),$$

$$z=q^{2u}=e^{-2\pi i u/r\tau}.$$

We often use the following Jacobi theta functions,

$$[u]=q^{(u^2/r)-u}\Theta_p(q^{2u})=e^{-(\pi i/4)}\tau^{1/2}q^{-(r/4)}\ \vartheta_1\left(\frac{u}{r}\middle|\tau\right),$$

$$[u]_+=q^{(u^2/r)-u}\Theta_p(-q^{2u})=e^{-(\pi i/4)}\tau^{1/2}q^{-(r/4)}\ \vartheta_0\left(\frac{u}{r}\middle|\tau\right),$$

$[u]^*=[u]|_{r\to r^*,\tau\to\tau^*}$ and $[u]^*_+=[u]_+|_{r\to r^*,\tau\to\tau^*}$. Here

$$\Theta_p(z)=(z,p)_\infty(pz^{-1};p)_\infty(p;p)_\infty,$$

$$(z;t_1,\ldots,t_k)_\infty=\prod_{n_1,\cdots,n_k\geqslant 0}(1-zt_1^{n_1}\cdots t_k^{n_k}).$$

The theta functions satisfy $[-u]=-[u],[-u]_+=[u]_+$ and the quasiperiodicity property

$$[u+r]=-[u],\quad [u+r\tau]=-e^{-\pi i\tau-(2\pi iu/r)}[u], \tag{2.1}$$

$$[u+r]_+=[u]_+,\quad [u+r\tau]_+=e^{-\pi i\tau-(2\pi iu/r)}[u]_+, \tag{2.2}$$

$$\left[u+\frac{r\tau}{2}\right]=ie^{-\pi i(u/r+\tau/4)}[u]_+. \tag{2.3}$$

We use the following normalization for the contour integration:

$$\oint_{C_0}\frac{dz}{2\pi iz}\frac{1}{[-u]}=1,\quad \oint_{C_0}\frac{dz}{2\pi iz}\frac{1}{[-u]^*}=\left.\frac{[u]}{[u]^*}\right|_{u\to 0}, \tag{2.4}$$

where C_0 is a simple closed curve in the u-plane encircling $u=0$ anticlockwise.

B. Definition of the elliptic quantum group $\mathcal{B}_{q,\lambda}(A_2^{(2)})$

Let $U_q(A_2^{(2)})$ be the standard affine quantum group, associated with the Cartan matrix

$$A=\begin{pmatrix}2 & -1\\ -4 & 2\end{pmatrix}. \tag{2.5}$$

The labels of A are $a_0=1,a_1=2$ and colabels are $a_0^\vee=2,a_1^\vee=1$. Let $B=(b_{ij})$ be the symmetrized Cartan matrix $b_{ij}=(a_i^\vee/a_i)\,a_{ij}$. We identify $\mathfrak{h}=\mathbb{C}\alpha_0^\vee\oplus\mathbb{C}\alpha_1^\vee\oplus\mathbb{C}d$ and $\mathfrak{h}^*=\mathbb{C}\alpha_0\oplus\mathbb{C}\alpha_1\oplus\mathbb{C}\Lambda_0$ via the standard invariant bilinear form $(\,,\,)$ given on $\mathfrak{h}$ and $\mathfrak{h}^*$ as follows:

$$(\alpha_i^\vee,\alpha_j^\vee)=a_{ij}\frac{a_j}{a_j^\vee}\quad(0\leqslant i,j\leqslant 1),$$

$$(\alpha_i^\vee,d)=\delta_{i,0}\quad(d,d)=0,$$

$$(\alpha_i,\alpha_j)=\frac{a_i^\vee}{a_i}a_{ij}\quad(0\leqslant i,j\leqslant 1),$$

$$(\alpha_i,\Lambda_0)=\delta_{i,0}\quad(\Lambda_0,\Lambda_0)=0.$$

The central element is given by $c=2\alpha_0^\vee+\alpha_1^\vee$. Let us set $\delta=\alpha_0+2\alpha_1$. Then the following relations hold:

$$(\delta,d)=1,\quad(\delta,\delta)=0,\quad(c,d)=2,\quad(c,c)=0.$$

The identification between $\mathfrak{h}$ and $\mathfrak{h}^*$ is given explicitly by $\alpha_i^\vee=2\alpha_i/(\alpha_i,\alpha_i)$, $c=\delta$, and $d=2\Lambda_0$. Under this, we use $\{\hat{h}_l\}_{l=1,2,3}=\{d,c,\alpha_1^\vee\}$ as a basis of $\mathfrak{h}$ and $\{\hat{h}^l\}_{l=1,2,3}=\{c/2,d/2,\alpha_1^\vee/2\}$ as its dual basis. Our conventions of coalgebra structure of $U_q(A_2^{(2)})$ follows.[3] The coproduct, counit, antipode are denoted by Δ, ε, and S, respectively.

The face-type elliptic quantum group $\mathcal{B}_{q,\lambda}(A_2^{(2)})$ is a quasitriangular quasi-Hopf algebra obtained from $U_q(A_2^{(2)})$ by the deformation via the face-type twistor $F(\lambda)$ $(\lambda \in \mathfrak{h})$. The twistor $F(\lambda)$ is an invertible element in $U_q(A_2^{(2)}) \otimes U_q(A_2^{(2)})$ satisfying

$$(\mathrm{id} \otimes \varepsilon) F(\lambda) = 1 = F(\lambda)(\varepsilon \otimes \mathrm{id}), \tag{2.6}$$

$$F^{(12)}(\lambda)(\Delta \otimes \mathrm{id}) F(\lambda) = F^{(23)}(\lambda + h^{(1)})(\mathrm{id} \otimes \Delta) F(\lambda), \tag{2.7}$$

where $\lambda = \Sigma_l \lambda_l \hat{h}^l$ $(\lambda_l \in \mathbb{C})$, $\lambda + h^{(1)} = \Sigma_l (\lambda_l + \hat{h}_l^{(1)}) \hat{h}^l$ and $\hat{h}_l^{(1)} = \hat{h}_l \otimes 1 \otimes 1$. An explicit construction of the twistor $F(\lambda)$ is given in Ref. 3. As an associative algebra, $\mathcal{B}_{q,\lambda}(A_2^{(2)})$ is isomorphic to $U_q(A_2^{(2)})$, but the coalgebra structure is deformed in the following way:

$$\Delta_\lambda(x) = F(\lambda) \Delta(x) F(\lambda)^{-1} \quad \forall x \in U_q(A_2^{(2)}). \tag{2.8}$$

Δ_λ satisfies a weaker coassociativity

$$(\mathrm{id} \otimes \Delta_\lambda) \Delta_\lambda(x) = \Phi(\lambda)(\Delta_\lambda \otimes \mathrm{id}) \Delta_\lambda(x) \Phi(\lambda)^{-1} \quad \forall \ x \in U_q(A_2^{(2)}), \tag{2.9}$$

$$\Phi(\lambda) = F^{(23)}(\lambda) F^{(23)}(\lambda + h^{(1)})^{-1}. \tag{2.10}$$

Let $\mathcal{R}$ be the universal R matrix of $U_q(A_2^{(2)})$. The universal R matrix of $\mathcal{B}_{q,\lambda}(A_2^{(2)})$ is given by

$$\mathcal{R}(\lambda) = F^{(21)}(\lambda) \mathcal{R} F^{(12)}(\lambda)^{-1}. \tag{2.11}$$

Definition 2.1 (Elliptic quantum group $\mathcal{B}_{q,\lambda}(A_2^{(2)})$): The face-type elliptic quantum group $\mathcal{B}_{q,\lambda}(A_2^{(2)})$ is a quasitriangular quasi-Hopf algebra $(\mathcal{B}_{q,\lambda}(A_2^{(2)}), \Delta_\lambda, \varepsilon, S, \Phi(\lambda), \alpha, \beta, \mathcal{R}(\lambda))$, *where α, β are defined by*

$$\alpha = \sum_i S(k_i) l_i, \quad \beta = \sum_i m_i S(n_i). \tag{2.12}$$

Here we set $\Sigma_i k_i \otimes l_i = F(\lambda)^{-1}$, $\Sigma_i m_i \otimes n_i = F(\lambda)$.

The universal R matrix $\mathcal{R}(\lambda)$ satisfies the dynamical Yang–Baxter equation,

$$\mathcal{R}^{(12)}(\lambda + h^{(3)}) \mathcal{R}^{(13)}(\lambda) \mathcal{R}^{(23)}(\lambda + h^{(1)}) = \mathcal{R}^{(23)}(\lambda) \mathcal{R}^{(13)}(\lambda + h^{(2)}) \mathcal{R}^{(12)}(\lambda). \tag{2.13}$$

Let $(\pi_{V,z}, V_z)$, $V_z = V \otimes \mathbb{C}[z, z^{-1}]$ be a (finite dimensional) evaluation representation of U_q. Taking images of $\mathcal{R}$, we define a R-matrix $R_{VW}^+(z, \lambda)$ and a L-operator $L_V^+(z, \lambda)$ as follows:

$$R_{VW}^+(z_1/z_2, \lambda) = (\pi_{V,z_1} \otimes \pi_{W,z_2}) q^{c \otimes d + d \otimes c} \mathcal{R}(\lambda), \tag{2.14}$$

$$L_V^+(z, \lambda) = (\pi_{V,z} \otimes \mathrm{id}) q^{c \otimes d + d \otimes c} \mathcal{R}(\lambda). \tag{2.15}$$

Then from (2.13), we have the following dynamical RLL-relation:

$$R_{VW}^+(z_1/z_2, \lambda + h) L_V^+(z_1, \lambda) L_W^+(z_2, \lambda + h^{(1)}) = L_W^+(z_2, \lambda) L_V^+(z_1, \lambda + h^{(2)}) R_{VW}^+(z_1/z_2, \lambda). \tag{2.16}$$

Note that in $\mathcal{B}_{q,\lambda}(A_2^{(2)})$, $L_V^+(z, \lambda)$ and $L_V^-(z, \lambda) = (\pi_{V,z} \otimes \mathrm{id}) \mathcal{R}^{(21)}(\lambda)^{-1} q^{-c \otimes d - d \otimes c}$ are not independent operators (Proposition 4.3 in Ref. 3). Hence one dynamical RLL-relation (2.16) characterizes the algebra $\mathcal{B}_{q,\lambda}(A_2^{(2)})$ completely in the sense of Reshetikhin and Semenov-Tian-Shansky.[16]

Through this paper, we parametrize the dynamical variable λ as

$$\lambda=(r^*+3)d+s'c+\frac{1}{2}\left(s+\frac{r\tau}{2}\right)\alpha_1^\vee \quad (r^*\equiv r-c). \tag{2.17}$$

Under this, we set $F(r^*,s)\equiv F(\lambda)$ and $\mathcal{R}(r^*,s)\equiv\mathcal{R}(\lambda)$. Since c is central, no s' dependence should appear. The dynamical shift $\lambda\to\lambda+h$ with $h=cd+(\alpha_1^\vee)^2/2$, changes the universal R-matrix $\mathcal{R}(r^*,s)$ to $\mathcal{R}(r,s+\alpha_1^\vee)$. Let us take $(\pi_{V,z},V_z)$ to be the evaluation representation associated with the vector representation $V\cong\mathbb{C}^3$ of $U_q(A_2^{(2)})$ (see Appendix A). We set

$$R^+(u,s+\alpha_1^\vee)=(\pi_{V,z_1}\otimes\pi_{V,z_2})q^{c\otimes d+d\otimes c}\mathcal{R}(r,s+\alpha_1^\vee),$$

$$L^+(u,s)=(\pi_{V,z}\otimes\mathrm{id})q^{c\otimes d+d\otimes c}\mathcal{R}(r^*,s),$$

where $z_1/z_2=q^{2u}$, $u=u_1-u_2$. From (2.11), we can obtain an explicit expression of $R^+(u,s)$, if we know the finite dimensional representation of the twistor $(\pi_{V,z_1}\otimes\pi_{V,z_2})F(r,s)$. In principle, one can obtain such representation by solving the q-difference equation for the twistor,[3] which is similar to the q-KZ equation for corresponding $U_q(\mathfrak{g})$. In the present case, the q-difference equation splits into the three parts; two 2×2 matrix parts and one 3×3 matrix part (see Appendix B). Each 2×2 matrix parts turns out to be the same as the one of the twistor for $\mathcal{B}_{q,\lambda}(A_1^{(1)})$ in the vector representation after adjusting some q-shift and sign factor, whereas we have no known solutions for the 3×3 matrix part. Writing down the solutions of the 2×2 matrix parts under the parametrization of λ (2.17), we obtain from (2.11) the corresponding matrix elements of $R^+(u,s)$ which coincide with the corresponding matrix elements of the Boltzmann weight for the $A_2^{(2)}$ face model.[12] For the remaining 3×3 matrix part, we conjecture that the same coincidence should occur. We hence assume that the R-matrix $R^+(u,s)$ is given by the following formula:

$$R^+(u,s)=\rho^+(u)\overline{R}(u,s), \tag{2.18}$$

where

$$\overline{R}(u,s)=\begin{pmatrix}
1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0\\
0 & R_{+0}^{+0} & 0 & R_{+0}^{0+} & 0 & 0 & 0 & 0 & 0\\
0 & 0 & R_{+-}^{+-} & 0 & R_{+-}^{00} & 0 & R_{+-}^{-+} & 0 & 0\\
0 & R_{0+}^{+0} & 0 & R_{0+}^{0+} & 0 & 0 & 0 & 0 & 0\\
0 & 0 & R_{00}^{+-} & 0 & R_{00}^{00} & 0 & R_{00}^{-+} & 0 & 0\\
0 & 0 & 0 & 0 & 0 & R_{0-}^{0-} & 0 & R_{0-}^{-0} & 0\\
0 & 0 & R_{-+}^{+-} & 0 & R_{-+}^{00} & 0 & R_{-+}^{-+} & 0 & 0\\
0 & 0 & 0 & 0 & 0 & R_{-0}^{0-} & 0 & R_{-0}^{-0} & 0\\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1
\end{pmatrix}, \tag{2.19}$$

$$R_{+0}^{+0}(u,s)=-\frac{[s+3/2]_+[s-1/2]_+}{[s+1/2]_+^2}\frac{[u]}{[u+1]},$$

$$R_{+0}^{0+}(u,s)=\frac{[s+1/2+u]_+[1]}{[s+1/2]_+[1+u]},$$

$$R_{0+}^{+0}(u,s)=\frac{[-s-1/2+u]_+[1]}{[-s-1/2]_+[1+u]},$$

$$R^{0+}_{0+}(u,s)=R^{-0}_{-0}(u,s)=-\frac{[u]}{[1+u]},$$

$$R^{0-}_{0-}(u,s)=-\frac{[s+1/2]_+[s-3/2]_+}{[s-1/2]^2_+}\frac{[u]}{[u+1]},$$

$$R^{-0}_{0-}(u,s)=\frac{[s-1/2+u]_+[1]}{[s-1/2]_+[1+u]},$$

$$R^{0-}_{-0}(u,s)=\frac{[-s+1/2+u]_+[1]}{[-s+1/2]_+[1+u]},$$

$$R^{+-}_{+-}(u,s)=G^+_sG^-_s\frac{[1/2+u][u]}{[3/2+u][1+u]},$$

$$R^{00}_{+-}(u,s)=-G^-_s\frac{[s+1/2]_+[-s-1-u]_+[1][u]}{[-s+1/2]^2_+[1+u][u+3/2]},$$

$$R^{-+}_{+-}(u,s)=\frac{[-2s+1-u][1]}{[-2s+1][1+u]}-G^-_s\frac{[-2s-1/2-u][u][1]}{[-2s+1][3/2+u][1+u]},$$

$$R^{-+}_{00}(u,s)=-\frac{[-s-1-u]_+[1][u]}{[s+1/2]_+[1+u][u+3/2]},$$

$$R^{-+}_{-+}(u,s)=\frac{[1/2+u][u]}{[3/2+u][1+u]},$$

$$R^{00}_{-+}(u,s)=-\frac{[s-1-u]_+[1][u]}{[-s+1/2]_+[1+u][u+3/2]},$$

$$R^{+-}_{-+}(u,s)=\frac{[2s+1-u][1]}{[2s+1][1+u]}-G^+_s\frac{[2s-1/2-u][u][1]}{[2s+1][3/2+u][1+u]},$$

$$R^{+-}_{00}(u,s)=-G^+_s\frac{[-s+1/2]_+[s-1-u]_+[1][u]}{[s+1/2]^2_+[1+u][u+3/2]},$$

$$R^{00}_{00}(u,s)=\frac{[3+u][1][3/2-u]}{[3][1+u][3/2+u]}+H_s\frac{[1][u]}{[3][1+u]}.$$

Here we have set

$$G^\pm_s=-\frac{[2s\pm2][s]_+}{[2s][s\pm1]_+},\qquad H_s=G^+_s\frac{[s-5/2]_+}{[s+1/2]_+}+G^-_s\frac{[s+5/2]_+}{[s-1/2]_+}. \tag{2.20}$$

The function $\rho^+(u)$ is given by

$$\rho^+(u)=-qz^{1/r}\frac{\{pq^2z\}\{pq^3z\}\{pq^3z\}\{pq^4z\}\{1/z\}\{q/z\}\{q^5/z\}\{q^6/z\}}{\{pz\}\{pqz\}\{pq^5z\}\{pq^6z\}\{q^2/z\}\{q^3/z\}\{q^3/z\}\{q^4/z\}}, \tag{2.21}$$

where $z=q^{2u}$ and

$$\{z\}=(z;p,q^6)_\infty. \tag{2.22}$$

The R-matrix $R^{+}{}^{*}(u,s)=(\pi_{V,z_1}\otimes\pi_{V,z_2})\mathcal{R}(r^{*},s)$ is obtained from $R^{+}(u,s)$ by the replacements $r\to r^{*}$. Hence, under the parametrization (2.17), the dynamical RLL-relation takes the form

$$R^{+(12)}(u,s+\alpha_1^{\vee})L^{+(1)}(u_1,s)L^{+(2)}(u_2,s+\alpha_1^{\vee(1)})=L^{+(2)}(u_2,s)L^{+(1)}(u_1,s+\alpha_1^{\vee(2)})R^{+*(12)}(u,s). \tag{2.23}$$

C. Intertwining operators

Let $\mathcal{F},\mathcal{F}'$ be the highest weight U_q-modules. We denote the type-I and type II intertwining operators of U_q-modules by $\Phi(z)$ and $\Psi^{*}(z)$, respectively,

$$\Phi(z):\ \mathcal{F}\to\mathcal{F}'\otimes W_z,\quad \Psi^{*}(z):\ W_z\otimes\mathcal{F}\to\mathcal{F}'. \tag{2.24}$$

Twisting these operators by $F(r^{*},s)$, we obtain the corresponding intertwining operators $\Phi(v,s)$ and $\Psi^{*}(u,s)$ of $\mathcal{B}_{q,\lambda}$-modules,

$$\Phi_W(u,s)=(\mathrm{id}\otimes\pi_{W,z})F(r^{*},s)\Phi(z), \tag{2.25}$$

$$\Psi_W^{*}(u,s)=\Psi^{*}(z)(\pi_{W,z}\otimes\mathrm{id})F(r^{*},s)^{-1}. \tag{2.26}$$

From the intertwining relation satisfied by $\Phi(z)$ and $\Psi^{*}(z)$, one can derive the following dynamical intertwining relation for the new intertwiners:[3]

$$\Phi_W^{(3)}\left(u_2+\frac{c}{2},s\right)L_V^{+(1)}(u_1,s)=R_{VW}^{+(13)}(u,s+\alpha_1^{\vee})L_V^{+(1)}(u_1,s)\Phi_W^{(3)}\left(u_2+\frac{c}{2},s+\alpha_1^{\vee(1)}\right), \tag{2.27}$$

$$L_V^{+(1)}(u_1,s)\Psi_W^{*(2)}(z_2,s+\alpha_1^{\vee(1)})=\Psi_W^{*(2)}(z_2,s)L_V^{+(1)}(u_1,s+\alpha_1^{\vee(2)})R_{VW}^{+*(12)}(u_1-u_2,s). \tag{2.28}$$

Note that (2.27) and (2.28) are the relations for the operators $V_{z_1}\otimes\mathcal{F}\to V_{z_1}\otimes\mathcal{F}\otimes W_{z_2}$ and $V_{z_1}\otimes W_{z_2}\otimes\mathcal{F}\to V_{z_1}\otimes\mathcal{F}$, respectively.

III. ELLIPTIC ALGEBRA $U_{q,p}(A_2^{(2)})$

In this section, we give a definition of the elliptic algebra $U_{q,p}(A_2^{(2)})$. We follows the idea given in Refs. 7 and 8, where the elliptic algebras $U_{q,p}(\mathfrak{g})$ with nontwisted affine Lie algebra $\mathfrak{g}$ are discussed. We first introduce the currents $e(z,p),f(z,p)$ and $\psi^{\pm}(z,p)$ of the quantum group $U_q(A_2^{(2)})$, by modifying the Drinfeld currents of $U_q(A_2^{(2)})$. We then introduce the new current $k(z)$ in $U_q(A_2^{(2)})$ which is a more basic object than the currents $\psi^{\pm}(z,p)$. Finally modifying them by taking a tensor product with Heisenberg algebra, we introduce the elliptic currents $E(u),F(u)$, $H^{\pm}(u)$, and $K(u)$ forming the elliptic algebra $U_{q,p}(A_2^{(2)})$. The current $K(u)$ plays an essential role in the RLL-formulation of $U_{q,p}(A_2^{(2)})$. Hereafter we set $h=\alpha_1^{\vee}$.

A. Drinfeld currents of $U_q(A_2^{(2)})$

Let us recall the Drinfeld currents of $U_q(A_2^{(2)})$. Let $0<q<1$. We use the standard symbol of q-integer

$$[n]_q=\frac{q^n-q^{-n}}{q-q^{-1}}. \tag{3.1}$$

Definition 3.1 (Drinfeld currents): Let $x_m^{\pm}$ $(m\in\mathbb{Z})$, $a_m(m\in\mathbb{Z}_{\neq 0})$ q^c,q^h,q^d *denote the generators of* $U_q(A_2^{(2)})$. *In terms of the generating functions*

$$x^{\pm}(z)=\sum_{m\in\mathbb{Z}}x_m^{\pm}z^{-m}, \tag{3.2}$$

$$\psi(q^{c/2}z)=q^{h/2}\exp\left((q-q^{-1})\sum_{m>0}a_m z^{-m}\right), \tag{3.3}$$

$$\varphi(q^{-c/2}z)=q^{-h/2}\exp\left(-(q-q^{-1})\sum_{m>0}a_{-m}z^{m}\right), \tag{3.4}$$

the defining relations of $U_q(A_2^{(2)})$ *are given by*

$$q^c:\text{central},\qquad q^d a_m q^{-d}=q^m a_m,\quad q^d q_m^{\pm}q^{-d}=q^m x_m^{\pm}, \tag{3.5}$$

$$q^h x^{\pm}(z)q^{-h}=q^{\pm 2}x^{\pm}(z),\quad q^d q^h=q^h q^d, \tag{3.6}$$

$$[a_m,a_n]=\delta_{m+n,0}\frac{1}{m}([2m]_q-[m]_q)q^{-c|m|}[cm]_q, \tag{3.7}$$

$$[a_m,x^{+}(z)]=\frac{1}{m}([2m]_q-[m]_q)q^{-c|m|}z^m x^{+}(z), \tag{3.8}$$

$$[a_m,x^{-}(z)]=-\frac{1}{m}([2m]_q-[m]_q)z^m x^{-}(z), \tag{3.9}$$

$$(z_1-q^{\pm 2}z_2)(z_1-q^{\mp 1}z_2)x^{\pm}(z_1)x^{\pm}(z_2)=-(q^{\pm 2}z_1-z_2)(q^{\mp 1}z_1-z_2)x^{\pm}(z_2)x^{\pm}(z_1), \tag{3.10}$$

$$[x^{+}(z_1),x^{-}(z_2)]=\frac{1}{q-q^{-1}}(\psi(q^{c/2}z_2)\delta(q^{-c}z_1/z_2)-\varphi(q^{-c/2}z_2)\delta(q^{c}z_1/z_2)), \tag{3.11}$$

$$\sum_{\sigma\in S_3}(q^{\pm 3/2}z_{\sigma(1)}-(q^{1/2}+q^{-1/2})z_{\sigma(2)}+q^{\pm 3/2}z_{\sigma(3)})x^{\pm}(z_{\sigma(1)})x^{\pm}(z_{\sigma(2)})x^{\pm}(z_{\sigma(3)})=0. \tag{3.12}$$

Here $\delta(z)$ *denotes the delta function* $\delta(z)=\Sigma_{m\in\mathbb{Z}}z^m$. *We call the generators* $h,a_m,x_m^{\pm},c,d$ *the Drinfeld generators of* $U_q(A_2^{(2)})$ *and the generating functions* $x^{\pm}(z)$, $\psi(z)$, *and* $\varphi(z)$ *the Drinfeld currents*.

B. Elliptic currents of $U_q(A_2^{(2)})$

We next consider an elliptic modification of the Drinfeld currents $x^{\pm}(z)$, $\psi(z)$, and $\varphi(z)$. Let us introduce the two auxiliary currents $u^{\pm}(z,p)$ by

$$u^{+}(z,p)=\exp\left(\sum_{m>0}\frac{a_{-m}}{[r*m]_q}q^{rm}z^m\right), \tag{3.13}$$

$$u^{-}(z,p)=\exp\left(-\sum_{m>0}\frac{a_m}{[rm]_q}q^{rm}z^{-m}\right). \tag{3.14}$$

Proposition 3.1: The following commutation relations hold:

$$u^+(z_1,p)u^-(z_2,p)$$
$$=u^-(z_2,p)u^+(z_1,p)$$
$$\times\frac{(pq^{-c-2}z_1/z_2;p)_\infty(p^*q^{c+2}z_1/z_2;p^*)_\infty(pq^{-c+1}z_1/z_2;p)_\infty(p^*q^{c-1}z_1/z_2;p^*)_\infty}{(pq^{-c+2}z_1/z_2;p)_\infty(p^*q^{c-2}z_1/z_2;p^*)_\infty(pq^{-c-1}z_1/z_2;p)_\infty(p^*q^{c+1}z_1/z_2;p^*)_\infty}, \tag{3.15}$$

$$u^+(z_1,p)x^+(z_2)=\frac{(p^*q^2z_1/z_2;p^*)_\infty(p^*q^{-1}z_1/z_2;p^*)_\infty}{(p^*q^{-2}z_1/z_2;p^*)_\infty(p^*qz_1/z_2;p^*)_\infty}x^+(z_2)u^+(z_1,p), \tag{3.16}$$

$$u^+(z_1,p)x^-(z_2)=\frac{(p^*q^{c-2}z_1/z_2;p^*)_\infty(p^*q^{c+1}z_1/z_2;p^*)_\infty}{(p^*q^{c+2}z_1/z_2;p^*)_\infty(p^*q^{c-1}z_1/z_2;p^*)_\infty}x^-(z_2)u^+(z_1,p), \tag{3.17}$$

$$u^-(z_1,p)x^+(z_2)=\frac{(pq^{-c-2}z_2/z_1;p)_\infty(pq^{-c+1}z_2/z_1;p)_\infty}{(pq^{-c+2}z_2/z_1;p)_\infty(pq^{-c-1}z_2/z_1;p)_\infty}x^+(z_2)u^-(z_1,p), \tag{3.18}$$

$$u^-(z_1,p)x^-(z_2)=\frac{(pq^2z_2/z_1;p)_\infty(pq^{-1}z_2/z_1;p)_\infty}{(pq^{-2}z_2/z_1;p)_\infty(pqz_2/z_1;p)_\infty}x^-(z_2)u^-(z_1,p), \tag{3.19}$$

$$\psi(z_1,p)u^+(z_2,p)$$
$$=u^+(z_2,p)\psi(z_1,p)$$
$$\times\frac{(q^{r^*+2}z_2/z_1;p)_\infty(q^{r^*-1}z_2/z_1;p)_\infty(q^{r^*-2}z_2/z_1;p^*)_\infty(q^{r^*+1}z_2/z_1;p^*)_\infty}{(q^{r^*-2}z_2/z_1;p)_\infty(q^{r^*+1}z_2/z_1;p)_\infty(q^{r^*+2}z_2/z_1;p^*)_\infty(q^{r^*-1}z_2/z_1;p^*)_\infty}, \tag{3.20}$$

$$\psi(z_1,p)u^-(z_2,p)$$
$$=u^-(z_2,p)\psi(z_1,p)\frac{(q^{r-2}z_1/z_2;p)_\infty(q^{r+1}z_1/z_2;p)_\infty(q^{r+2}z_1/z_2;p^*)_\infty(q^{r-1}z_1/z_2;p^*)_\infty}{(q^{r+2}z_1/z_2;p)_\infty(q^{r-1}z_1/z_2;p)_\infty(q^{r-2}z_1/z_2;p^*)_\infty(q^{r+1}z_1/z_2;p^*)_\infty},$$

$$\psi(z_1,p)x^+(z_2)$$
$$=x^+(z_2)\psi(z_1,p)\frac{(q^{r^*-2}z_2/z_1;p)_\infty(q^{r^*+1}z_2/z_1;p)_\infty(q^{r^*+2}z_1/z_2;p^*)_\infty(q^{r^*-1}z_1/z_2;p^*)_\infty}{(q^{r^*+2}z_2/z_1;p)_\infty(q^{r^*-1}z_2/z_1;p)_\infty(q^{r^*-2}z_1/z_2;p^*)_\infty(q^{r^*+1}z_1/z_2;p^*)_\infty}, \tag{3.21}$$

$$\psi(z_1,p)x^-(z_2)$$
$$=x^-(z_2)\psi(z_1,p)\frac{(q^{r+2}z_2/z_1;p)_\infty(q^{r-1}z_2/z_1;p)_\infty(q^{r-2}z_1/z_2;p^*)_\infty(q^{r+1}z_1/z_2;p^*)_\infty}{(q^{r-2}z_2/z_1;p)_\infty(q^{r+1}z_2/z_1;p)_\infty(q^{r+2}z_1/z_2;p^*)_\infty(q^{r-1}z_1/z_2;p^*)_\infty}. \tag{3.22}$$

Definition 3.2: We define "dressed" currents $e(z,p)$, $f(z,p)$, and $\psi^\pm(z,p)$ by

$$e(z,p)=u^+(z,p)x^+(z), \tag{3.23}$$

$$f(z,p)=x^-(z)u^-(z,p), \tag{3.24}$$

$$\psi^+(z,p)=u^+(q^{c/2}z,p)\psi(z)u^-(q^{-c/2}z,p), \tag{3.25}$$

$$\psi^-(z,p)=u^+(q^{-c/2}z,p)\varphi(z)u^-(q^{c/2}z,p). \tag{3.26}$$

If we introduce the auxiliary current $\psi(z,p)$ by

$$\psi(z,p)=\exp\left(\sum_{m>0}\frac{x^{cm}}{[r^*m]_q}a_{-m}z^m\right)\exp\left(-\sum_{m>0}\frac{1}{[rm]_q}a_mz^{-m}\right), \tag{3.27}$$

we have

$$\psi^{\pm}(q^{\mp(r-c/2)}z)=q^{\pm h/2}\psi(z,p). \tag{3.28}$$

Proposition 3.2: The currents $e(z,p)$, $f(z,p)$, and $\psi(z,p)$ satisfy the following commutation relations:

$$\psi(z_1,p)\psi(z_2,p)=\frac{\Theta_p(q^{-2}z_1/z_2)\Theta_p(qz_1/z_2)}{\Theta_p(q^2z_1/z_2)\Theta_p(q^{-1}z_1/z_2)}\frac{\Theta_{p^*}(q^2z_1/z_2)\Theta_{p^*}(q^{-1}z_1/z_2)}{\Theta_{p^*}(q^{-2}z_1/z_2)\Theta_{p^*}(qz_1/z_2)}\psi(z_2,p)\psi(z_1,p), \tag{3.29}$$

$$\psi(z_1,p)e(z_2,p)=\frac{\Theta_{p^*}(q^{r^*+2}z_1/z_2)\Theta_{p^*}(q^{r^*-1}z_1/z_2)}{\Theta_{p^*}(q^{r^*-2}z_1/z_2)\Theta_{p^*}(q^{r^*+1}z_1/z_2)}e(z_2,p)\psi(z_1,p), \tag{3.30}$$

$$\psi(z_1,p)f(z_2,p)=\frac{\Theta_p(q^{r-2}z_1/z_2)\Theta_p(q^{r+1}z_1/z_2)}{\Theta_p(q^{r+2}z_1/z_2)\Theta_p(q^{r-1}z_1/z_2)}f(z_2,p)\psi(z_1,p), \tag{3.31}$$

$$e(z_1,p)e(z_2,p)=(-1)\frac{\Theta_{p^*}(q^{-2}z_2/z_1)\Theta_{p^*}(q^{-1}z_1/z_2)}{\Theta_{p^*}(q^{-2}z_1/z_2)\Theta_{p^*}(q^{-1}z_2/z_1)}e(z_2,p)e(z_1,p), \tag{3.32}$$

$$f(z_1,p)f(z_2,p)=(-1)\frac{\Theta_p(q^2z_2/z_1)\Theta_p(qz_1/z_2)}{\Theta_p(q^2z_1/z_2)\Theta_p(qz_2/z_1)}f(z_2,p)f(z_1,p), \tag{3.33}$$

$$[e(z_1,p),f(z_2,p)]=\frac{1}{q-q^{-1}}(\psi^+(q^{c/2}z_2)\delta(q^{-c}z_1/z_2)-\psi^-(q^{-c/2}z_2)\delta(q^cz_1/z_2)), \tag{3.34}$$

$$\begin{aligned}&\sum_{\sigma\in S_3}\frac{(p^*q^2z_{\sigma(3)}/z_{\sigma(1)};p^*)_\infty(p^*q^{-1}z_{\sigma(3)}/z_{\sigma(1)};p^*)_\infty(p^*q^{-1}z_{\sigma(3)}/z_{\sigma(2)};p^*)_\infty(p^*q^{-1}z_{\sigma(2)}/z_{\sigma(1)};p^*)_\infty}{(p^*q^{-2}z_{\sigma(3)}/z_{\sigma(1)};p^*)_\infty(p^*qz_{\sigma(3)}/z_{\sigma(1)};p^*)_\infty(p^*qz_{\sigma(3)}/z_{\sigma(2)};p^*)_\infty(p^*qz_{\sigma(2)}/z_{\sigma(1)};p^*)_\infty}\\&\quad\times\left(z_{\sigma(1)}\frac{(q^2z_{\sigma(2)}/z_{\sigma(1)};p^*)_\infty(p^*q^2z_{\sigma(3)}/z_{\sigma(2)};p^*)_\infty}{(p^*q^{-2}z_{\sigma(2)}/z_{\sigma(1)};p^*)_\infty(p^*q^{-2}z_{\sigma(3)}/z_{\sigma(2)};p^*)_\infty}-qz_{\sigma(2)}\right.\\&\quad\left.\times\frac{(p^*q^2z_{\sigma(2)}/z_{\sigma(1)};p^*)_\infty(p^*q^2z_{\sigma(3)}/z_{\sigma(2)};p^*)_\infty}{(p^*q^{-2}z_{\sigma(2)}/z_{\sigma(1)};p^*)_\infty(p^*q^{-2}z_{\sigma(3)}/z_{\sigma(2)};p^*)_\infty}\right)e(z_{\sigma(1)},p)e(z_{\sigma(2)},p)e(z_{\sigma(3)},p)=0,\end{aligned} \tag{3.35}$$

$$\begin{aligned}&\sum_{\sigma\in S_3}\frac{(pqz_{\sigma(2)}/z_{\sigma(1)};p)_\infty(pq^{-2}z_{\sigma(3)}/z_{\sigma(1)};p)_\infty(pqz_{\sigma(3)}/z_{\sigma(2)};p)_\infty(pqz_{\sigma(3)}/z_{\sigma(2)};p)_\infty}{(pq^{-1}z_{\sigma(2)}/z_{\sigma(1)};p)_\infty(pq^2z_{\sigma(3)}/z_{\sigma(1)};p)_\infty(pq^{-1}z_{\sigma(3)}/z_{\sigma(1)};p)_\infty(pq^{-1}z_{\sigma(3)}/z_{\sigma(2)};p)_\infty}\\&\quad\times\left(z_{\sigma(1)}\frac{(q^{-2}z_{\sigma(2)}/z_{\sigma(1)};p)_\infty(pq^{-2}z_{\sigma(3)}/z_{\sigma(2)};p)_\infty}{(pq^2z_{\sigma(2)}/z_{\sigma(1)};p)_\infty(pq^2z_{\sigma(3)}/z_{\sigma(2)};p)_\infty}\right.\\&\quad\left.-q^{-1}z_{\sigma(2)}\frac{(pq^{-2}z_{\sigma(2)}/z_{\sigma(1)};p)_\infty(q^{-2}z_{\sigma(3)}/z_{\sigma(2)};p)_\infty}{(pq^2z_{\sigma(2)}/z_{\sigma(1)};p)_\infty(pq^2z_{\sigma(3)}/z_{\sigma(2)};p)_\infty}\right)f(z_{\sigma(1)},p)f(z_{\sigma(2)},p)f(z_{\sigma(3)},p)=0.\end{aligned} \tag{3.36}$$

C. Basic current $k(z)$

The current $\psi(z,p)$ (3.27) can be expressed by a more basic current $k(z)$. Let us modify a_m and define α_m and β_m by

$$\alpha_m=\begin{cases} a_m, & m>0, \\ \dfrac{[rm]_q}{[r^*m]_q}q^{c|m|}a_m, & m<0, \end{cases} \qquad \beta_m=\alpha_m\frac{[r^*m]_q}{[rm]_q}. \tag{3.37}$$

They satisfy the following commutation relations:

$$[\alpha_m,\alpha_n]=\delta_{m+n,0}\frac{[2m]_q-[m]_q}{m}\frac{[cm]_q[rm]_q}{[r^*m]_q}, \tag{3.38}$$

$$[\beta_m,\beta_n]=\delta_{m+n,0}\frac{[2m]_q-[m]_q}{m}\frac{[cm]_q[r^*m]_q}{[rm]_q}. \tag{3.39}$$

Then the current $\psi(z,p)$ is expressed by

$$\psi(z,p)=:\exp\left(-\sum_{m\neq 0}\frac{\alpha_m}{[rm]_q}z^{-m}\right):=:\exp\left(-\sum_{m\neq 0}\frac{\beta_m}{[r^*m]_q}z^{-m}\right):. \tag{3.40}$$

The colons : : denote the standard normal ordering.

Definition 3.3 (Basic Current): We define the current $k(z)$ by

$$k(z,p)=:\exp\left(-\sum_{m\neq 0}\frac{[m]_q}{[rm]_q([2m]_q-[m]_q)}\alpha_m z^{-m}\right):. \tag{3.41}$$

The current $\psi(z,p)$ is then expressed by $k(z)$ as follows:

$$\psi(z,p)=:k(q^{-1}z,p)k(z,p)^{-1}k(qz,p):. \tag{3.42}$$

By a straightforward calculation, we have the following commutation relations:

Proposition 3.3:

$$k(z_1,p)u^+(z_2,p)=\frac{(q^{r^*+1}z_2/z_1;p)_\infty(q^{r^*-1}z_2/z_1;p^*)_\infty}{(q^{r^*-1}z_2/z_1;p)_\infty(q^{r^*+1}z_2/z_1;p^*)_\infty}u^+(z_2,p)k(z_1,p), \tag{3.43}$$

$$k(z_1,p)u^-(z_2,p)=\frac{(q^{r-1}z_1/z_2;p)_\infty(q^{r+1}z_1/z_2;p^*)_\infty}{(q^{r+1}z_1/z_2;p)_\infty(q^{r-1}z_1/z_2;p^*)_\infty}u^-(z_2,p)k(z_1,p), \tag{3.44}$$

$$k(z_1,p)x^+(z_2)=\frac{(q^{r^*+1}z_1/z_2;p^*)_\infty(q^{r^*-1}z_2/z_1;p)_\infty}{(q^{r^*-1}z_1/z_2;p^*)_\infty(q^{r^*+1}z_2/z_1;p)_\infty}x^+(z_2)k(z_1,p), \tag{3.45}$$

$$k(z_1,p)x^-(z_2)=\frac{(q^{r-1}z_1/z_2;p^*)_\infty(q^{r+1}z_2/z_1;p)_\infty}{(q^{r+1}z_1/z_2;p^*)_\infty(q^{r-1}z_2/z_1;p)_\infty}x^-(z_2)k(z_1,p). \tag{3.46}$$

Proposition 3.4: The currents $e(z,p)$, $f(z,p)$, and $k(z,p)$ satisfy the following commutation relations:

$$k(z_1,p)k(z_2,p)=z^{-1/r^*+1/r}\rho(z_1/z_2)k(z_2,p)k(z_1,p), \tag{3.47}$$

$$k(z_1,p)e(z_2,p)=\frac{\Theta_{p^*}(q^{r^*+1}z_1/z_2)}{\Theta_{p^*}(q^{r^*-1}z_1/z_2)}e(z_2,p)k(z_1), \tag{3.48}$$

$$k(z_1,p)f(z_2,p)=\frac{\Theta_{p}(q^{r-1}z_1/z_2)}{\Theta_{p}(q^{r+1}z_1/z_2)}f(z_2,p)k(z_1,p). \tag{3.49}$$

Here we have set

$$\rho(z)=\frac{\rho^{+*}(z)}{\rho^{+}(z)}, \tag{3.50}$$

where $\rho^{+}(z)$ *is given in (2.21) and* $\rho^{+*}(z)=\rho^{+}(z)|_{r\to r^*}$.

D. Elliptic algebra $U_{q,p}(A_2^{(2)})$

Now we give a definition of the elliptic algebra $U_{q,p}(A_2^{(2)})$. For this purpose, we introduce a Heisenberg algebra $\mathbb{C}\{\mathcal{H}\}$ generated by P, Q, and $\overline{\alpha}$,

$$[P,Q]=1,\quad [Q,\overline{\alpha}]=\pi i,\quad [P,\overline{\alpha}]=0, \tag{3.51}$$

$$[P,P]=[Q,Q]=[\overline{\alpha},\overline{\alpha}]=0. \tag{3.52}$$

Definition 3.4 (Elliptic Currents): We define the elliptic (total) currents $E(z)$, $F(z)$, *and* $K(z)$ *by*

$$E(z)=e(z)e^{\overline{\alpha}}e^{-Q}z^{-P/r^*}, \tag{3.53}$$

$$F(z)=f(z)e^{-\overline{\alpha}}z^{P/r+h/2r}, \tag{3.54}$$

$$K(z)=k(z)e^{-Q}z^{(1/r-1/r^*)P+h/2r}. \tag{3.55}$$

Let us introduce the auxiliary currents $H^{\pm}(z)$ by

$$H^{\pm}(z)=H(q^{\pm(r-c/2)}z), \tag{3.56}$$

$$H(z)=\psi(z)e^{-Q}z^{(1/r-1/r^*)P+h/2r}=\kappa K(qz)K(z)^{-1}K(q^{-1}z), \tag{3.57}$$

where

$$\kappa=\frac{\{pq^8\}\{pq^5\}\{pq^3\}\{pq^4\}^2\{p\}\{p^*q^7\}^*\{p^*q\}^*\{p^*q^2\}^{*2}\{p^*q^6\}^{*2}}{\{pq^7\}\{pq\}\{pq^2\}^2\{pq^6\}^2\{p^*\}^*\{p^*q^8\}^*\{p^*q^5\}^*\{p^*q^3\}^*\{p^*q^4\}^{*2}}. \tag{3.58}$$

From the commutation relations of the currents $e(z,p)$, $f(z,p)$ and $k(z,p)$, we can verify the following relations.

Theorem 3.5: *The elliptic currents* $E(z)$, $F(z)$, *and* $K(z)$ *satisfy the following commutation relations:*

$$K(z_1)K(z_2)=\rho(z_1/z_2)K(z_2)K(z_1), \tag{3.59}$$

$$K(z_1)E(z_2)=-\frac{\left[u_1-u_2+\frac{r^*+1}{2}\right]^*}{\left[u_1-u_2+\frac{r^*-1}{2}\right]^*}E(z_2)K(z_1), \tag{3.60}$$

$$K(z_1)F(z_2)=-\frac{\left[u_1-u_2+\dfrac{r-1}{2}\right]}{\left[u_1-u_2+\dfrac{r+1}{2}\right]}F(z_2)K(z_1), \tag{3.61}$$

$$E(z_1)E(z_2)=-\frac{[u_1-u_2+1]^*[u_1-u_2-\frac{1}{2}]^*}{[u_1-u_2-1]^*[u_1-u_2+\frac{1}{2}]^*}E(z_2)E(z_1), \tag{3.62}$$

$$F(z_1)F(z_2)=-\frac{[u_1-u_2-1][u_1-u_2+\frac{1}{2}]}{[u_1-u_2+1][u_1-u_2-\frac{1}{2}]}F(z_2)F(z_1), \tag{3.63}$$

$$[E(z_1),F(z_2)]=\frac{1}{q-q^{-1}}(H^+(q^{c/2}z_2)\delta(q^{-c}z_1/z_2)-H^-(q^{-c/2}z_2)\delta(q^cz_1/z_2)). \tag{3.64}$$

Here $\rho(z)$ is given in (3.50). The elliptic currents $E(z)$ and $F(z)$ satisfy the following Serre relations:

$$\begin{aligned}&\sum_{\sigma\in S_3}\frac{(p^*q^2z_{\sigma(3)}/z_{\sigma(1)};p^*)_\infty(p^*q^{-1}z_{\sigma(3)}/z_{\sigma(1)};p^*)_\infty(p^*q^{-1}z_{\sigma(3)}/z_{\sigma(2)};p^*)_\infty(p^*q^{-1}z_{\sigma(2)}/z_{\sigma(1)};p^*)_\infty}{(p^*q^{-2}z_{\sigma(3)}/z_{\sigma(1)};p^*)_\infty(p^*qz_{\sigma(3)}/z_{\sigma(1)};p^*)_\infty(p^*qz_{\sigma(3)}/z_{\sigma(2)};p^*)_\infty(p^*qz_{\sigma(2)}/z_{\sigma(1)};p^*)_\infty}\\&\times z_{\sigma(1)}^{-1/2r^*}z_{\sigma(2)}^{-1/r^*}\left(z_{\sigma(1)}\frac{(q^2z_{\sigma(2)}/z_{\sigma(1)};p^*)_\infty(p^*q^2z_{\sigma(3)}/z_{\sigma(2)};p^*)_\infty}{(p^*q^{-2}z_{\sigma(2)}/z_{\sigma(1)};p^*)_\infty(p^*q^{-2}z_{\sigma(3)}/z_{\sigma(2)};p^*)_\infty}-qz_{\sigma(2)}\right.\\&\left.\times\frac{(p^*q^2z_{\sigma(2)}/z_{\sigma(1)};p^*)_\infty(p^*q^2z_{\sigma(3)}/z_{\sigma(2)};p^*)_\infty}{(p^*q^{-2}z_{\sigma(2)}/z_{\sigma(1)};p^*)_\infty(p^*q^{-2}z_{\sigma(3)}/z_{\sigma(2)};p^*)_\infty}\right)E(z_{\sigma(1)})E(z_{\sigma(2)})E(z_{\sigma(3)})=0,\end{aligned} \tag{3.65}$$

and

$$\begin{aligned}&\sum_{\sigma\in S_3}\frac{(pqz_{\sigma(2)}/z_{\sigma(1)};p)_\infty(pq^{-2}z_{\sigma(3)}/z_{\sigma(1)};p)_\infty(pqz_{\sigma(3)}/z_{\sigma(2)};p)_\infty(pqz_{\sigma(3)}/z_{\sigma(2)};p)_\infty}{(pq^{-1}z_{\sigma(2)}/z_{\sigma(1)};p)_\infty(pq^2z_{\sigma(3)}/z_{\sigma(1)};p)_\infty(pq^{-1}z_{\sigma(3)}/z_{\sigma(1)};p)_\infty(pq^{-1}z_{\sigma(3)}/z_{\sigma(2)};p)_\infty}\\&\times z_{\sigma(1)}^{2/r}z_{\sigma(2)}^{1/r}\left(z_{\sigma(1)}\frac{(q^{-2}z_{\sigma(2)}/z_{\sigma(1)};p)_\infty(pq^{-2}z_{\sigma(3)}/z_{\sigma(2)};p)_\infty}{(pq^2z_{\sigma(2)}/z_{\sigma(1)};p)_\infty(pq^2z_{\sigma(3)}/z_{\sigma(2)};p)_\infty}\right.\\&\left.-q^{-1}z_{\sigma(2)}\frac{(pq^{-2}z_{\sigma(2)}/z_{\sigma(1)};p)_\infty(q^{-2}z_{\sigma(3)}/z_{\sigma(2)};p)_\infty}{(pq^2z_{\sigma(2)}/z_{\sigma(1)};p)_\infty(pq^2z_{\sigma(3)}/z_{\sigma(2)};p)_\infty}\right)F(z_{\sigma(1)})F(z_{\sigma(2)})F(z_{\sigma(3)})=0.\end{aligned} \tag{3.66}$$

Definition 3.5 (Elliptic Algebra $U_{q,p}(A_2^{(2)})$): We define the elliptic algebra $U_{q,p}(A_2^{(2)})$ to be the associative algebra generated by the currents $E(z)$, $F(z)$, and $K(z)$ satisfying the relations (3.56)–(3.66).

Corollary 3.6: The construction of $E(z)$, $F(z)$, and $K(z)$ given in (3.53)–(3.55) is a realization of the elliptic algebra $U_{q,p}(A_2^{(2)})$ in terms of the Drinfeld generator of the quantum group $U_q(A_2^{(2)})$ and the Heisenberg algebra $\mathbb{C}\{\mathcal{H}\}$.

For later convenience, let us introduce auxiliary currents $K_\epsilon(z),(\epsilon=0,\pm)$ by

$$K_+(z)=K(q^{r-2}z)=k(q^{r-2}z)e^{-Q}(q^{r-2}z)^{(1/r-1/r^*)P+h/2r}, \tag{3.67}$$

$$K_0(z)=K(q^rz)^{-1}K(q^{r-1}z)=k(q^rz)^{-1}k(q^{r-1}z)q^{(1/r^*-1/r)P-h/2r}, \tag{3.68}$$

$$K_-(z)=K(q^{r+1}z)^{-1}=k(q^{r+1}z)^{-1}(q^{r+1}z)^{(1/r^*-1/r)P-h/2r}e^Q. \tag{3.69}$$

Then one can verify the following relations:

Proposition 3.7:

$$K_+(z_1)E(z_2)=-\frac{\left[u_1-u_2+\frac{c-1}{2}\right]^*}{\left[u_1-u_2+\frac{c-3}{2}\right]^*}E(z_2)K_+(z_1), \tag{3.70}$$

$$K_0(z_1)E(z_2)=\frac{\left[u_1-u_2+\frac{c}{2}\right]^*\left[u_1-u_2+\frac{c-1}{2}\right]^*}{\left[u_1-u_2+\frac{c}{2}-1\right]^*\left[u_1-u_2+\frac{c+1}{2}\right]^*}E(z_2)K_0(z_1), \tag{3.71}$$

$$K_-(z_1)E(z_2)=-\frac{\left[u_1-u_2+\frac{c}{2}\right]^*}{\left[u_1-u_2+\frac{c}{2}+1\right]^*}E(z_2)K_-(z_1), \tag{3.72}$$

$$K_+(z_1)F(z_2)=-\frac{[u_1-u_2-\frac{3}{2}]}{[u_1-u_2-\frac{1}{2}]}F(z_2)K_+(z_1), \tag{3.73}$$

$$K_0(z_1)F(z_2)=\frac{[u_1-u_2-1][u_1-u_2+\frac{1}{2}]}{[u_1-u_2][u_1-u_2-\frac{1}{2}]}F(z_2)K_0(z_1), \tag{3.74}$$

$$K_-(z_1)F(z_2)=-\frac{[u_1-u_2+1]}{[u_1-u_2]}F(z_2)K_-(z_1), \tag{3.75}$$

$$H^{\pm}(q^{\pm c/2}z)=H(q^{\pm r}z)=\kappa K_-(z)^{-1}K_0(z)=\kappa' K_+(qz)K_0(qz)^{-1}. \tag{3.76}$$

Here μ is given in (3.58) and κ' is given by

$$\kappa'=\frac{\{pq^{10}\}\{pq^7\}\{pq^5\}\{pq^6\}^2\{pq^2\}\{p^*q^9\}^*\{p^*q^3\}^*\{p^*q^5\}^{*2}\{p^*q^8\}^{*2}}{\{pq^9\}\{pq^3\}\{pq^5\}^2\{pq^8\}^2\{p^*q^2\}^*\{p^*q^{10}\}^*\{p^*q^7\}^*\{p^*q^5\}^*\{p^*q^6\}^{*2}}. \tag{3.77}$$

IV. HALF-CURRENTS

As a preparation for the RLL-formulation of the elliptic algebra $U_{p,q}(A_2^{(2)})$ in the next section, we here introduce the half currents, and investigate their commutation relations.

Let us first summarize the commutation relations between the Heisenberg algebra $\mathbb{C}\{\mathcal{H}\}$ and the elliptic currents. From (3.53)–(3.55), we have the following relations:

Proposition 4.1:

$$[E(z),P]=E(z),\quad \left[F(z),P+\frac{h}{2}\right]=F(z), \tag{4.1}$$

$$\left[E(z),P+\frac{h}{2}\right]=0,\ [F(z),P]=0, \tag{4.2}$$

$$[K_+(z),P]=K_+(z)=\left[K_+(z),P+\frac{h}{2}\right], \tag{4.3}$$

$$[K_0(z),P]=0=\left[K_0(z),P+\frac{h}{2}\right], \tag{4.4}$$

$$[K_-(z),P]=-K_-(z)=\left[K_-(z),P+\frac{h}{2}\right]. \tag{4.5}$$

Now we define the half currents $E^+_{-,0}(u)$, $E^+_{0,+}(u)$, $E^+_{-,+}(u)$, $F^+_{0,-}(u)$, $F^+_{+,0}(u)$, $F^+_{+,-}(u)$, and $K^+_\epsilon(u),(\epsilon=0,\pm)$, by the following formulas.

Definition 4.1 (Half Currents):

$$K^+_\epsilon(u)=K_\epsilon(z), \qquad (\epsilon=0,\pm), \tag{4.6}$$

$$E^+_{-,0}(u)=a^*_{-0}\oint_{C^*_{-0}}\frac{dz'}{2\pi iz'}E(z')\frac{\left[u-u'-P+\frac{c+1}{2}\right]^*_+[1]^*}{\left[u-u'+\frac{c}{2}\right]^*\left[P-\frac{1}{2}\right]^*_+}, \tag{4.7}$$

$$E^+_{0,+}(u)=a^*_{0+}\oint_{C^*_{0+}}\frac{dz'}{2\pi iz'}E(z')\frac{\left[u-u'-P+\frac{c}{2}\right]^*_+[1]^*}{\left[u-u'+\frac{c-1}{2}\right]^*\left[P-\frac{1}{2}\right]^*_+}, \tag{4.8}$$

$$E^+_{-,+}(u)=a^*_{-+}\oint\oint_{C^*_{-+}}\frac{dz'}{z'}\frac{dz''}{z''}E(z')E(z'')\frac{[1]^{*2}}{\left[P-\frac{1}{2}\right]^*_+[2P-2]^*}$$
$$\times\frac{\left[u-u'-2P+2+\frac{c}{2}\right]^*[u'-u''-P]^*_+}{\left[u-u'+\frac{c}{2}\right]^*\left[u'-u''-\frac{1}{2}\right]^*}, \tag{4.9}$$

$$F^+_{0,-}(u)=a_{0-}\oint_{C_{0-}}\frac{dz'}{2\pi iz'}F(z')\frac{\left[u-u'+P+\frac{h-1}{2}\right]_+[1]}{[u-u']\left[P+\frac{h-1}{2}\right]_+}, \tag{4.10}$$

$$F^+_{+,0}(z)=a_{+0}\oint_{C_{+0}}\frac{dz'}{2\pi iz'}F(z')\frac{\left[u-u'+P+\frac{h}{2}-1\right]_+[1]}{\left[u-u'-\frac{1}{2}\right]\left[P+\frac{h-1}{2}\right]_+}, \tag{4.11}$$

$$F^{+}_{+,-}(u)=a_{+-}\oint\oint_{C_{+-}}\frac{dz'}{2\pi iz'}\frac{dz''}{2\pi iz''}F(z')F(z'')\frac{\left[P+\frac{h}{2}-1\right]_{+}[1]^2}{\left[P+\frac{h-3}{2}\right]_{+}\left[P+\frac{h}{2}-2\right]_{+}[2P+h-2]}$$
$$\times\frac{[u-u'+2P+h-3][u-u''+1]\left[u'-u''+P+\frac{h}{2}-1\right]_{+}}{[u-u'][u-u'']\left[u'-u''+\frac{1}{2}\right]}. \tag{4.12}$$

Here C^{*}_{-0} is a simple closed contour that encircles $pq^{c}z$ but not $q^{c}z$. We abbreviate it as C^{*}_{-0}:$|p^{*}q^{c}z|<|z'|<|q^{c}z|$. Similarly the others are given by

$$C^{*}_{-0}:\ |p^{*}q^{c}z|<|z'|<|q^{c}z|, \tag{4.13}$$

$$C^{*}_{0+}:\ |p^{*}q^{c-1}z|<|z'|<|q^{c-1}z|, \tag{4.14}$$

$$C^{*}_{-+}:\ |p^{*}q^{c}|<|z'|<|q^{c}z|,\ |p^{*}q^{c}z|<|z''|<|q^{c}z|,\ |p^{*}qz'|<|z''|<|qz'|, \tag{4.15}$$

$$C_{0-}:\ |pz|<|z'|<|z|, \tag{4.16}$$

$$C^{*}_{0+}:\ |pq^{-1}z|<|z'|<|q^{-1}z|, \tag{4.17}$$

$$C_{+-}:\ |pz|<|z'|<|z|,\ |pz|<|z''|<|z|,\ |pqz'|<|z''|<|qz'|. \tag{4.18}$$

The constants $a^{*}_{-0},a^{*}_{0+},a^{*}_{-+}$, a_{0-},a_{+0},a_{+-} are chosen to satisfy

$$\frac{\mu a_{0-}a^{*}_{-0}[1]^{*}}{q-q^{-1}}=-1=\frac{\mu' a_{+0}a^{*}_{0+}[1]^{*}}{q-q^{-1}},\quad a_{+-}=a_{0-}a_{0-},\quad a^{*}_{-+}=a^{*}_{-0}a^{*}_{-0}. \tag{4.19}$$

We then verify the following commutation relations.

Theorem 4.5: *The half-currents satisfy the following relations:*

$$K^{+}_{\pm}(u_1)K^{+}_{\pm}(u_2)=\rho(u)K^{+}_{\pm}(u_2)K^{+}_{\pm}(u_1), \tag{4.20}$$

$$K^{+}_{0}(u_1)K^{+}_{0}(u_2)=\frac{\rho(u)\rho(u)}{\rho(u+\frac{1}{2})\rho(u-\frac{1}{2})}K^{+}_{0}(u_2)K^{+}_{0}(u_1), \tag{4.21}$$

$$K^{+}_{-}(u_1)K^{+}_{+}(u_2)=K^{+}_{+}(u_2)K^{+}_{-}(u_1)\rho(u)\frac{[u_1-u_2+1][u_1-u_2+\frac{3}{2}][u_1-u_2]^{*}[u_1-u_2+\frac{1}{2}]^{*}}{[u_1-u_2][u_1-u_2+\frac{1}{2}][u_1-u_2+1]^{*}[u_1-u_2+\frac{3}{2}]^{*}}, \tag{4.22}$$

$$K^{+}_{-}(u_1)K^{+}_{0}(u_2)=\rho(u)\frac{[u_1-u_2]^{*}[u_1-u_2+1]}{[u_1-u_2+1]^{*}[u_1-u_2]}K^{+}_{0}(u_2)K^{+}_{-}(u_1), \tag{4.23}$$

$$K^{+}_{0}(u_1)K^{+}_{+}(u_2)=\rho(u)\frac{[u_1-u_2]^{*}[u_1-u_2+1]}{[u_1-u_2+1]^{*}[u_1-u_2]}K^{+}_{+}(u_2)K^{+}_{0}(u_1), \tag{4.24}$$

$$K^{+}_{-}(u_1)^{-1}E^{+}_{-,0}(u_2)K^{+}_{-}(u_1)=-E^{+}_{-,0}(u_2)\frac{[u+1]^{*}}{[u]^{*}}+E^{+}_{-,0}(u_1)\frac{[P+\frac{1}{2}+u]^{*}_{+}[1]^{*}}{[P+1/2]^{*}_{+}[u]^{*}}, \tag{4.25}$$

$$K_+^+(u_2)^{-1}E_{0,+}^+(u_1)K_+^+(u_2)=-\frac{[u+1]^*}{[u]^*}E_{0,+}^+(u_1)+\frac{[-P+\frac{1}{2}+u]_+^*[1]^*}{[-P+\frac{1}{2}]}{}_+^*[u]^*E_{0,+}^+(u_2), \tag{4.26}$$

$K_-^+(u_1)^{-1}E_{-,+}^+(u_2)K_-^+(u_1)$

$$\begin{aligned}&=E_{-,+}^+(u_2)\frac{[u+\frac{3}{2}]^*[u+1]^*}{[u+\frac{1}{2}]^*[u]^*}+K_-^+(u_1)^{-1}E_{-,0}^+(u_2)K_-^+(u_1)E_{-,0}^+(u_1)\frac{[-P-1-u]_+^*[1]^*}{[P+\frac{1}{2}]_+^*[u+\frac{1}{2}]^*}\\&\quad-E_{-,+}(u_1)\left(\frac{[-2P+1-u]^*[u+\frac{3}{2}]^*[1]^*}{[-2P+1]^*[u+\frac{1}{2}]^*[u]^*}+\frac{[2P-2]^*[P]_+^*[-2P-\frac{1}{2}-u]^*[1]^*}{[2P]^*[P-1]_+^*[-2P+1]^*[u+\frac{1}{2}]^*}\right),\end{aligned} \tag{4.27}$$

$$K_-^+(u_1)F_{0,-}^+(u_2)K_-(u_1)^{-1}=-\frac{[u+1]}{[u]}F_{0,-}^+(u_2)+\frac{\left[-P+\frac{-h+1}{2}+u\right]_+[1]}{\left[-P+\frac{-h+1}{2}\right]_+[u]}F_{0,-}^+(u_2), \tag{4.28}$$

$$K_+^+(u_2)F_{+,0}^+(u_1)K_+^+(u_2)^{-1}=-F_{+,0}^+(u_1)\frac{[u+1]}{[u]}+F_{+,0}^+(u_2)\frac{\left[P+\frac{h+1}{2}+u\right]_+[1]}{\left[P+\frac{h+1}{2}\right]_+[u]}, \tag{4.29}$$

$K_-^+(u_1)F_{+,-}^+(u_2)K_-^+(u_1)^{-1}$

$$\begin{aligned}&=\frac{\left[u+\frac{3}{2}\right][u+1]}{\left[u+\frac{1}{2}\right][u]}F_{+,-}^+(u_2)-\frac{\left[P+\frac{h}{2}-1-u\right]_+[1]}{\left[-P+\frac{-h+1}{2}\right]\left[u+\frac{1}{2}\right]}F_{0,-}^+(u_1)K_-^+(u_1)F_{0,-}^+(u_2)K_-^+(u_1)^{-1}\\&\quad-\left(\frac{\left[u+\frac{3}{2}\right][2P+h+1-u][1]}{\left[u+\frac{1}{2}\right][u][2P+h+1]}+\frac{\left[2P+h-\frac{1}{2}-u\right][1][2P+h+2]\left[P+\frac{h}{2}\right]_+}{[2P+h+1][2P+h]\left[P+\frac{h}{2}+1\right]_+\left[u+\frac{1}{2}\right]}\right)F_{+,-}^+(u_1),\end{aligned} \tag{4.30}$$

$$[E^+_{-,0}(u_1),F^+_{0,-}(u_2)]$$

$$=-K_0^+(u_2)\frac{\left[-P-\frac{1}{2}+u\right]_+^*[1]^*}{\left[-P-\frac{1}{2}\right]_+^*[u]^*}K_-^+(u_2)^{-1}+K_-^+(u_1)^{-1}\frac{\left[-P+\frac{-h+1}{2}+u\right]_+[1]}{\left[-P+\frac{-h+1}{2}\right]_+[u]}K_0^+(u_1), \tag{4.31}$$

$$[E^+_{0,+}(u_1),F^+_{+,0}(u_2)]$$

$$=-K_0^+(u_2)^{-1}\frac{\left[P+\frac{h+1}{2}+u\right]_+[1]}{\left[P+\frac{h+1}{2}\right]_+[u+1]}K_+^+(u_2)+K_+^+(u_1)\frac{\left[P-\frac{1}{2}+u\right]_+^*[1]^*}{\left[P-\frac{1}{2}\right]_+^*[u+1]^*}K_0^+(u_1)^{-1}, \tag{4.32}$$

where $u=u_1-u_2$.

Proof: The relations (4.20)–(4.24) are direct consequences of the commutation relation of the elliptic current $K(z)$. Let us consider the relations (4.25)–(4.32). These relations can be proved by reducing them to identities of the theta functions. We show the relation (4.25). The relations (4.26), (4.28), and (4.29) can be proved in the same way. From the definition of the half current (4.7) and the commutation relation of (3.72), the LHS of (4.25) yields

$$K_-^+(u_1)E^+_{-,0}(u_2)K_-^+(u_1)^{-1}$$
$$=-a^*_{-,0}\oint_{C^*_{-0}}\frac{dz'}{2\pi iz'}E(z')\frac{\left[u_1-u'+\frac{c}{2}+1\right]^*\left[u_2-u'-P+\frac{c-1}{2}\right]_+^*[1]^*}{\left[u_1-u'+\frac{c}{2}\right]^*\left[u_2-u'+\frac{c}{2}\right]^*\left[P+\frac{1}{2}\right]_+^*}. \tag{4.33}$$

Then the equality is verified by the following identity of the theta functions:

$$-\frac{\left[u_1-u'+\frac{c}{2}+1\right]^*\left[u_2-u'-P+\frac{c-1}{2}\right]_+^*}{\left[u_1-u'+\frac{c}{2}\right]^*\left[u_2-u'+\frac{c}{2}\right]^*\left[P+\frac{1}{2}\right]_+^*}=-\frac{\left[u_2-u'-P+\frac{c+1}{2}\right]_+^*[u_1-u_2+1]^*}{\left[u_2-u'+\frac{c}{2}\right]^*[u_1-u_2]^*\left[P-\frac{1}{2}\right]_+^*}$$
$$+\frac{\left[u_1-u'-P+\frac{c+1}{2}\right]_+^*\left[u_1-u_2+P+\frac{1}{2}\right]_+^*[1]^*}{\left[u_1-u'+\frac{c}{2}\right]^*[u_1-u_2]^*\left[P-\frac{1}{2}\right]_+^*\left[P+\frac{1}{2}\right]_+^*}.$$

Next, we show the relation (4.31). The relation (4.32) can be proved in the same way. Integrating the delta function appearing in (3.64) and using (3.76), we have

$$
\begin{aligned}
&(\mu a_{0-}a^{*}_{-0})^{-1}(q-q^{-1})[E^{+}_{-,0}(u_1),F^{+}_{0,-}(u_2)] \\
&\quad=\oint_{C^+}\frac{dz'}{2\pi i z'}K^{+}_{-}(u')^{-1}K^{+}_{0}(u')\frac{\left[u_1-u'-P+\frac{1}{2}\right]^{*}_{+}[1]^{*}\left[u_2-u'+P+\frac{h-1}{2}\right]_{+}[1]}{[u_1-u']^{*}\left[P-\frac{1}{2}\right]^{*}_{+}[u_2-u']\left[P+\frac{h-1}{2}\right]_{+}} \\
&\quad-\oint_{C^-}\frac{dz'}{2\pi i z'}K^{+}_{-}(u'-r)^{-1}K^{+}_{0}(u'-r) \\
&\quad\times\frac{\left[u_1-u'-P+c+\frac{1}{2}\right]^{*}_{+}[1]^{*}\left[u_2-u'+P+\frac{h-1}{2}\right]_{+}[1]}{[u_1-u'+c]^{*}\left[P-\frac{1}{2}\right]^{*}_{+}[u_2-u']\left[P+\frac{h-1}{2}\right]_{+}}.
\end{aligned}
\tag{4.34}
$$

Here the contours $C^{\pm}$ are now

$$C^{+}:\ |p^{*}z_1|,|pz_2|<|z'|<|z_1|,|z_2|, \tag{4.35}$$

$$C^{-}:\ |pz_1|,|pz_2|<|z'|<|q^{2c}z_1|,|z_2|. \tag{4.36}$$

When we change the integration variable $z'\to pz'$ in the second term, the integrand becomes the same as the first term, but the contour C^{-} is changed to $\tilde{C}^{-}$ given by

$$\tilde{C}^{-}:\ |z_1|,|z_2|<|z'|<|p^{-1}q^{2c}z_1|,|p^{-1}z_2|. \tag{4.37}$$

Taking the residues at $z'=z_1,z_2$, we get (4.31).

We give a proof of (4.27) in Appendix C. One can prove (4.30) in a similar way.

Q.E.D.

V. THE L-OPERATOR OF $U_{q,p}(A_2^{(2)})$ AND RELATION TO $\mathcal{B}_{q,\lambda}(A_2^{(2)})$

In this section, we clarify the relation between two elliptic algebras $U_{q,p}(A_2^{(2)})$ and $\mathcal{B}_{q,\lambda}(A_2^{(2)})$. For this purpose, we first construct a L-operator which gives the RLL-formulation of $U_{q,p}(A_2^{(2)})$. Then modifying L-operator by removing the Heisenberg generators $Q,\overline{\alpha}$, we derive the dynamical RLL-relation (5.8) characterizing the elliptic quantum group $\mathcal{B}_{q,\lambda}(A_2^{(2)})$.

A. L-operator of $U_{q,p}(A_2^{(2)})$

Definition 5.1: By using the half-currents, we define the L-operator $\hat{L}^{+}(u)\in \mathrm{End}(\mathbb{C}^3)\otimes U_{q,p}(A_2^{(2)})$ *as follows:*

$$
\hat{L}^{+}(u)=\begin{pmatrix}1 & F^{+}_{+0}(u) & F^{+}_{+-}(u)\\ 0 & 1 & F^{+}_{0-}(u)\\ 0 & 0 & 1\end{pmatrix}\begin{pmatrix}K^{+}_{+}(u) & 0 & 0\\ 0 & K^{+}_{0}(u) & 0\\ 0 & 0 & K^{+}_{-}(u)\end{pmatrix}\begin{pmatrix}1 & 0 & 0\\ E^{+}_{0+}(u) & 1 & 0\\ E^{+}_{-+}(u) & E^{+}_{-0}(u) & 1\end{pmatrix}.
\tag{5.1}
$$

Here matrix elements are the half-currents given in the previous section.

By a direct comparison with the relations of the half-currents appeared in Theorem 4.2, we get the following commutation relations of the L-operator:

Theorem 5.1: *The L-operator* $\hat{L}^{+}(u)$ *satisfies the following* $RLL=LLR^{*}$ *relation:*

$$R^{+(12)}(u_1-u_2,P+h/2)\hat{L}^{+(1)}(u_1)\hat{L}^{+(2)}(u_2)$$
$$=\hat{L}^{+(2)}(u_2)\hat{L}^{+(1)}(u_1)R^{+*(12)}(u_1-u_2,P-(h^{(1)}+h^{(2)})/2). \tag{5.2}$$

The above equation should be understood as equation of the operators acting on the space $\mathbb{C}^3 \otimes \mathbb{C}^3 \otimes U_{q,p}(A_2^{(2)})$. The operator h in LHS acts on $U_{q,p}(A_2^{(2)})$, whereas the operator $h^{(1)}+h^{(2)}$ in RHS acts on $\mathbb{C}^3 \otimes \mathbb{C}^3$ as

$$\begin{pmatrix} 2 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & -2 \end{pmatrix} \otimes 1 + 1 \otimes \begin{pmatrix} 2 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & -2 \end{pmatrix}.$$

B. $U_{q,p}(A_2^{(2)})$ and $\mathcal{B}_{q,\lambda}(A_2^{(2)})$

Based on the above theorem, we give a relation between $U_{q,p}(A_2^{(2)})$ and $\mathcal{B}_{q,\lambda}(A_2^{(2)})$. We argue that the RLL relation (5.2) is equivalent to the dynamical RLL relation of $\mathcal{B}_{q,\lambda}(A_2^{(2)})$. Hence we can regard the elliptic currents in $U_{q,p}(A_2^{(2)})$ as an elliptic analog of the Drinfeld currents in $U_q(A_2^{(2)})$ providing a new realization of the elliptic quantum group $\mathcal{B}_{q,\lambda}(A_2^{(2)})$. In order to show this, we consider the realization of $U_{q,p}(A_2^{(2)})$ given in (3.53)–(3.55) and modify the half-currents in such a way that they have no $Q, \bar{\alpha}$ dependence,

$$k_+(u,P)=K_+(u)e^{Q}, \quad k_0(u,P)=K_0(u) \quad k_-(u,P)=K_-(u)e^{-Q}, \tag{5.3}$$

$$f_{+,0}(u,P)=e^{\bar{\alpha}}F_{+,-}(u), \quad f_{0,-}(u,P)=e^{\bar{\alpha}}F_{0,-}(u), \quad f_{+,-}(u,P)=e^{\bar{\alpha}}F_{+,-}(u)e^{\bar{\alpha}}, \tag{5.4}$$

$$e_{0,+}(u,P)=E_{0,+}(u)e^{Q}e^{-\bar{\alpha}}, \quad e_{-,0}(u,P)=e^{Q}e^{-\bar{\alpha}}E_{-,0}(u),$$
$$e_{-,+}(u,P)=e^{Q}e^{-\bar{\alpha}}E_{-,+}(u)e^{Q}e^{-\bar{\alpha}}. \tag{5.5}$$

We regard them as the currents in $U_q(A_2^{(2)})$ with parameters P and r. Then we define a dynamical L-operator $\hat{L}^+(u,P)$ by

$$\hat{L}^+(u,P)=\begin{pmatrix} 1 & f^+_{+0}(u,P) & f^+_{+-}(u,P) \\ 0 & 1 & f^+_{0-}(u,P) \\ 0 & 0 & 1 \end{pmatrix} \begin{pmatrix} k^+_+(u,P) & 0 & 0 \\ 0 & k^+_0(u,P) & 0 \\ 0 & 0 & k^+_-(u,P) \end{pmatrix}$$
$$\times \begin{pmatrix} 1 & 0 & 0 \\ e^+_{0+}(u,P) & 1 & 0 \\ e^+_{-+}(u,P) & e^+_{-0}(u,P) & 1 \end{pmatrix}. \tag{5.6}$$

The two L-operators $\hat{L}^+(u)$ and $\hat{L}^+(u,P)$ are related by

$$\hat{L}^+(u,P)=\hat{L}^+(u)\begin{pmatrix} e^{Q} & & \\ & 1 & \\ & & e^{-Q} \end{pmatrix}=\hat{L}^+(u)e^{Qh^{(1)}/2}. \tag{5.7}$$

Here

$$h^{(1)}=\begin{pmatrix} 2 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & -2 \end{pmatrix} \otimes 1.$$

Substituting this into (5.2) and moving the factor $e^{-Qh^{(j)}/2}$ $(j=1,2)$ to the right end in the both sides, we get the following statement:

Corollary 5.2: The dynamical L-operator $L^+(u,P)$ satisfies the dynamical RLL relation,

$$R^{+(12)}(u_1-u_2,P+h/2)L^{+(1)}(u_1,P)L^{+(2)}(u_2,P+h^{(1)}/2)$$
$$=L^{+(2)}(u_2,P)L^{+(1)}(u_1,P+h^{(2)}/2)R^{+*(12)}(u_1-u_2,P). \tag{5.8}$$

Comparing this with (2.23), we identify our $L^+(u,P)$ with $L^+(u,s)$ in (2.23) and s with P. We hence regard the elliptic currents $E(z)$, $F(z)$, and $K(z)$ in $U_{q,p}(A_2^{(2)})$ as the Drinfeld currents of the elliptic quantum group $\mathcal{B}_{q,\lambda}(A_2^{(2)})$, although $U_{q,p}(A_2^{(2)})$ and $\mathcal{B}_{q,\lambda}(A_2^{(2)})$ are different by tensoring the Heisenberg algebra $\mathbb{C}\{\mathcal{H}\}$. More precisely, $U_{q,p}(A_2^{(2)})$ is an extension of the algebra $\mathcal{B}_{q,\lambda}(A_2^{(2)})$ by tensoring the Heisenberg algebra $\mathbb{C}\{\mathcal{H}\}$; first tensoring the generators e^Q, e^{α}, then regarding $s=P$ and imposing the commutation relations (3.51) and (3.52). Naively we regard $U_{q,p}(A_2^{(2)})$ as $\mathcal{B}_{q,\lambda}(A_2^{(2)})\otimes_{\mathbb{C}\{P\}}\mathbb{C}\{\mathcal{H}\}$.

VI. VERTEX OPERATORS

Tensoring the Heisenberg algebra breaks down the coalgebra structure of $\mathcal{B}_{q,\lambda}(A_2^{(2)})$. But we can define the $U_{q,p}(A_2^{(2)})$ counterparts of the intertwining operators of $\mathcal{B}_{q,\lambda}(A_2^{(2)})$. We call such operators the vertex operators of $U_{q,p}(A_2^{(2)})$. In this section, we study such vertex operators and compare them with those of the dilute A_L model obtained in Ref. 15.

A. Intertwining relations

We here derive the $U_{q,p}(A_2^{(2)})$ counterparts of the dynamical intertwining relations (2.27)–(2.28). In the next subsection, we use such relations to derive a free field realization of the vertex operators.

Let us first define an extension of the U_q modules by

$$\hat{\mathcal{F}}=\bigoplus_{\mu\in\mathbb{Z}}\mathcal{F}\otimes e^{\mu Q}.$$

Let $\Phi_W(u,P)$ and $\Psi_W^*(u,P)$ be the type I and type II intertwining operators of $\mathcal{B}_{q,\lambda}(A_2^{(2)})$ (2.27)–(2.28). We define type I and type II vertex operators $\hat{\Phi}_W(u),\hat{\Psi}_W^*(u)$ of $U_{q,p}(A_2^{(2)})$ as the following extensions of the corresponding intertwining operators of $\mathcal{B}_{q,\lambda}(A_2^{(2)})$:

$$\hat{\Phi}_W(u)=\Phi_W(u+c/2,P) \quad :\hat{\mathcal{F}}\to\hat{\mathcal{F}}'\otimes W_z, \tag{6.1}$$

$$\hat{\Psi}_W^*(u)=\Psi_W^*(u,P)e^{h^{(1)}Q/2} \quad :W_z\otimes\hat{\mathcal{F}}\to\hat{\mathcal{F}}'. \tag{6.2}$$

From the commutation relation of P and Q, the new operators $\hat{\Phi}_W(u)$ and $\hat{\Psi}_W^*(u)$ satisfy the following "intertwining relations":

$$\hat{\Phi}_W^{(3)}(u_2)\hat{L}_V^{+(1)}(u_1)=R_{VW}^{+(1,3)}(u_1-u_2,P+h/2)\hat{L}_V^{+(1)}(u_1)\hat{\Phi}_W^{(3)}(u_2), \tag{6.3}$$

$$\hat{L}_V^{+(1)}(u_1)\hat{\Psi}_W^{*(2)}(u_2)=\hat{\Psi}_W^{*(2)}(u_2)\hat{L}_V^{+(1)}(u_1)R_{VW}^{+*(1,2)}(u_1-u_2,P-(h^{(1)}+h^{(2)})/2). \tag{6.4}$$

Now let us restrict ourselves to the vector representation $W=V\cong\mathbb{C}v_+\oplus\mathbb{C}v_0\oplus\mathbb{C}v_-$. In this case, the R-matrix $R_{VV}^+(u,P)$ is given by $R^+(u,P)$ in (2.18), and the L-operator $\hat{L}_V^+(u,P)$ by $\hat{L}^+(u,P)$ in (5.6). Let us set the components of the vertex operators $\Phi_j(u),\Psi_j^*(u),(j=\pm,0)$ by

$$\hat{\Phi}\left(u-\frac{1}{2}\right)=\sum_{j=\pm,0}\Phi_j(u)\otimes v_j, \tag{6.5}$$

$$\hat{\Psi}*\left(u-\frac{c+1}{2}\right)(v_j\otimes\cdot)=\Psi_j^*(u), \tag{6.6}$$

and the matrix elements of the L-operator $\hat{L}^+(u)$ by

$$\hat{L}^+(u)v_j=\sum_{m=0,\pm} v_m L^+_{m,j}(u). \tag{6.7}$$

Let us investigate the relations (6.3) and (6.4) in detail. From the components $[(-,-),(j)], j=\pm,0$ of (6.3), we have

$$\Phi_-(u_2+\tfrac{1}{2})L^+_{-,j}(u_1)=\rho^+(u_1-u_2)L^+_{-,j}(u_1)\Phi_-(u_2+\tfrac{1}{2}). \tag{6.8}$$

Putting the definition $L^+_{-,j}(u)=K^+_-(u)E^+_{-,j}(u)$ into the above, we have

$$\Phi_-(u_2+\tfrac{1}{2})K^+_-(u_1)=\rho^+(u_1-u_2)K^+_-(u_1)\Phi_-(u_2+\tfrac{1}{2}), \tag{6.9}$$

$$[\Phi_-(u_1),E^+_{-,0}(u_2)]=0, \tag{6.10}$$

$$[\Phi_-(u_1),E^+_{-,+}(u_2)]=0. \tag{6.11}$$

We have the sufficient condition of (6.10) and (6.11),

$$\Phi_-(u_1)E(u_2)=E(u_2)\Phi_-(u_1), \quad [\Phi_-(z_1),P]=0. \tag{6.12}$$

From the component $[(0,-),(-)]$ of (6.3), we have

$$\begin{aligned}\Phi_-(u_2+\tfrac{1}{2})F^+_{0,-}(u_1)K^+_-(u_1)=&\rho^+(u)\overline{R}^{0-}_{0-}(u,P+h/2)F^+_{0,-}(u_1)K^+_-(u_1)\Phi_-(u_2+\tfrac{1}{2})\\&+\rho^+(u)\overline{R}^{-0}_{0-}(u,P+h/2)K^+_-(u_1)\Phi_0(u_2+\tfrac{1}{2}).\end{aligned} \tag{6.13}$$

Let us assume the operator product $K^+_-(u_1)\Phi_-(u_2+\frac{1}{2})$ has no pole at $u_1-u_2=-1-r$. Later we will check that, for $c=1$, this assumption is satisfied in a free field realization. Then from (6.9), we conclude the operator product $\Phi_-(u_2+\frac{1}{2})K^+_-(u_1)$ has zero at $u_1-u_2=-1-r$. Therefore setting $u_1-u_2=-1-r$ in (6.13), we have

$$0=\frac{[P+h/2+1/2]_+}{[P+h/2-1/2]_+}F^+_{0,-}(u_1)K^+_-(u_1)\Phi_-\left(u_2+\frac{1}{2}\right)+K^+_-(u_1)\Phi_0\left(u_2+\frac{1}{2}\right). \tag{6.14}$$

Then we have

$$\Phi_0(u)=F^+_{0,-}(u-r-\tfrac{1}{2})\Phi_-(u). \tag{6.15}$$

Substituting (6.8) and (6.15) into (6.13), we get

$$\Phi_-(u_1)F(u_2)=-\frac{[u_1-u_2+1/2]}{[u_1-u_2-1/2]}F(u_2)\Phi_-(u_1). \tag{6.16}$$

Similarly, in order to investigate the structure of the component $\Phi_+(u)$, we have, from the components of $[(+,-),(-)]$ of (6.3),

$$\Phi_-(u_2+\tfrac{1}{2})F^+_{+,-}(u_1)K^+_-(u_1)=\rho^+(u)\overline{R}^{+-}_{+-}(u,P+h/2)F^+_{+,-}(u_1)K^+_-(u_1)\Phi_-(u_2+\tfrac{1}{2})$$
$$+\rho^+(u)\overline{R}^{00}_{+-}(u,P+h/2)F^+_{0,-}(u_1)K^+_-(u_1)\Phi_0(u_2+\tfrac{1}{2})$$
$$+\rho^+(u)\overline{R}^{-+}_{+-}(u,P+h/2)K^+_-(u_1)\Phi_+(u_2+\tfrac{1}{2}). \tag{6.17}$$

On the other hand, from the component $[(+,-),(-,-)]$ of RLL relation (5.2), we have

$$K^+_-(u_2)F^+_{+,-}(u_1)K^+_-(u_2)^{-1}=R^{+-}_{+-}(u)F^+_{+,-}(u_1)+R^{00}_{+-}(u)F^+_{0,-}(u_1)K^+_-(u_1)F^+_{0,-}(u_2)K^+_-(u_1)^{-1}$$
$$+R^{-+}_{+-}(u)K^+_-(u_1)F^+_{+,-}(u_2)K^+_-(u_1)^{-1}. \tag{6.18}$$

Putting the above into (6.17), we get

$$\Phi_-(u_2+\tfrac{1}{2})F^+_{+,-}(u_1)K^+_-(u_1)=\rho^+(u)\overline{R}^{-+}_{+-}(u|P+h/2)K_-(u_1)\Phi_+(u_2+\tfrac{1}{2})$$
$$+\rho^+(u)K^+_-(u_2-r)F^+_{+,-}(u_1)K^+_-(u_2-r)^{-1}K^+_-(u_1)\Phi_-(u_2+\tfrac{1}{2})$$
$$+\rho^+(u)\overline{R}^{-+}_{+-}(u|P+h/2)K^+_-(u_1)F^+_{+,-}(u_2-r)\Phi_-(u_2+\tfrac{1}{2}). \tag{6.19}$$

Note that at the point $u_1-u_2=-1-r$, $\rho^+(u)$ has a zero, but $\rho^+(u)\overline{R}^{-+}_{+-}(u|P+h/2)$ have no zeros. In addition, under the same assumption given just below (6.13), the product $\Phi_-(u_2+\frac{1}{2})K^+_-(u_1)$ vanishes at $u_1-u_2=-1-r$. Setting $u_1-u_2=-1-r$ in (6.19), we thus have the following formula for $\Phi_+(z)$:

$$\Phi_+(u)=-F^+_{+,-}(u-r-\tfrac{1}{2})\Phi_-(u). \tag{6.20}$$

In the next section, we construct a free field realization of the type-I vertex operators using the relations (6.9), (6.12), (6.15), (6.16), and (6.20) for $c=1$. We can check that the resultant vertex operators satisfy the intertwining relation (6.3).

Similarly, the sufficient conditions for the type-II vertex operators are extracted from (6.4) as follows:

$$\Psi^*_-\left(u_2+\frac{1+c}{2}\right)K_-(u_1)\rho^{+*}(u)=K^+_-(u_1)\Psi^*_-\left(u_2+\frac{1+c}{2}\right), \tag{6.21}$$

$$\Psi^*_-(u_1)F(u_2)=F(u_2)\Psi^*_-(u_1),\quad [\Psi^*_-(u),P+h/2]=0, \tag{6.22}$$

$$\Psi^*_-(u_1)E(u_2)=-\frac{\left[u_1-u_2-\frac{1}{2}\right]^*}{\left[u_1-u_2+\frac{1}{2}\right]^*}E(u_2)\Psi^*_-(u_1), \tag{6.23}$$

$$\Psi^*_+(u)=-\Psi^*_-(u)E_{-,+}\left(u-\frac{1+c}{2}-r^*\right), \tag{6.24}$$

$$\Psi^*_0(u)=\Psi^*_-(u)E_{-,0}\left(u-\frac{1+c}{2}-r^*\right). \tag{6.25}$$

B. Free field realizations

Now we construct a free field realization of the vertex operators fixing the representation level $c=1$. For this purpose, we introduce the simple root operator α, defined by

$$[h,\alpha]=2,\ [a_m,\alpha]=0,\ [P,\alpha]=0,\ [Q,\alpha]=0,\ [\alpha,\overline{\alpha}]=0. \tag{6.26}$$

If we introduce $\hat{\alpha}$ by

$$\hat{\alpha}=\alpha+\overline{\alpha}, \tag{6.27}$$

we have

$$[h,\hat{\alpha}]=2,\ [a_m,\hat{\alpha}]=0,\ [P,\hat{\alpha}]=0,\ [Q,\hat{\alpha}]=\pi i. \tag{6.28}$$

Then the following statement holds:

Proposition 6.1: For $c=1$, we have the free field realization of the currents $E(z)$ and $F(z)$.

$$E(z)=\epsilon(q):\exp\left(-\sum_{m\neq 0}\frac{1}{[m]_q}\alpha_m z^{-m}\right):e^{\hat{\alpha}}z^{h/2+1/2}e^{-Q}z^{-P/r*}, \tag{6.29}$$

$$F(z)=\epsilon(q):\exp\left(\sum_{m\neq 0}\frac{1}{[m]_q}\beta_m z^{-m}\right):e^{-\hat{\alpha}}z^{-h/2+1/2}z^{P/r+h/2r}. \tag{6.30}$$

Here we have set

$$\epsilon(q)=(q^{1/2}+q^{-1/2})^{-1/2}. \tag{6.31}$$

Together with free field realizations of $K(z)$ (3.55), we get a free field realization of the level one elliptic algebra $U_{q,p}(A_2^{(2)})$.

Now substituting the free field realization of $E(z)$, $F(z)$, $K(z)$ into (3.53)–(3.55), we obtain a realization of the half-currents and the L-operator $\hat{L}^+(u)$ satisfying the RLL-relation (5.2) for $c=1$. Using this L-operator in the ''intertwining relations,'' (6.9), (6.12), (6.15), (6.16), (6.20), for type I and (6.21)–(6.25) for the type II, one can solve them for the vertex operators. The results are stated as follows:

Theorem 6.2: *The highest components of the type-I and type-II vertex operators $\Phi_-(u)$ and $\Psi^*_-(u)$ are realized in terms of the free field by*

$$\Phi_-(z)=:\exp\left(-\sum_{m\neq 0}\frac{1}{[2m]_q-[m]_q}\beta_m z^{-m}\right):e^{\hat{\alpha}}z^{h/2+1/2}z^{-P/r-h/2r-1/r}, \tag{6.32}$$

$$\Psi^*_-(z)=:\exp\left(\sum_{m\neq 0}\frac{[rm]_q}{[2m]_q-[m]_q}\alpha_m z^{-m}\right):e^{-\hat{\alpha}}z^{-h/2+1/2}e^{Q}z^{P/r^*+1/r^*}. \tag{6.33}$$

For the other components of type-I vertex operator $\Phi_j(u)(j=\pm,0)$, we get the following, by using (6.15) and (6.20),

$$\Phi_0(u)=a_{0,-}\oint_{C_0}\frac{dz'}{2\pi iz'}\Phi_-(u)F(z')\frac{\left[u-u'+P+\frac{h}{2}\right]_+}{\left[u-u'+\frac{1}{2}\right]\left[P+\frac{h}{2}+\frac{1}{2}\right]_+}$$

$$=-a_{0,-}\oint_{C_0}\frac{dz'}{2\pi iz'}F(z')\Phi_-(u)\frac{\left[u-u'+P+\frac{h}{2}\right]_+}{\left[u-u'-\frac{1}{2}\right]\left[P+\frac{h}{2}+\frac{1}{2}\right]_+}. \tag{6.34}$$

Here the contour C_0 is specified by the condition.

$$C_0: \quad |q^{-1}z|<|z'|<|p^{-1}q^{-1}z|.$$

The component $\Phi_+(u)$ is given by

$$\Phi_+(u)=-a_{+,-}\oint\oint_{C_+}\frac{dz'}{2\pi iz'}\frac{dz''}{2\pi iz''}\Phi_-(u)F(z')F(z'')\frac{\left[P+\frac{h}{2}\right]_+}{\left[P+\frac{h}{2}-\frac{1}{2}\right]_+\left[P+\frac{h}{2}-1\right]_+[2P+h]}$$

$$\times\frac{\left[u-u'+2P+h-\frac{3}{2}\right]\left[u'-u''+P+\frac{h}{2}\right]_+}{\left[u-u'+\frac{1}{2}\right]\left[u'-u''+\frac{1}{2}\right]}$$

$$=-a_{+,-}\oint\oint_{C^+}\frac{dz'}{2\pi iz'}\frac{dz''}{2\pi iz''}F(z')F(z'')\Phi_-(u)\frac{\left[P+\frac{h}{2}\right]_+}{\left[P+\frac{h}{2}-\frac{1}{2}\right]_+\left[P+\frac{h}{2}-1\right]_+[2P+h]}$$

$$\times\frac{\left[u-u'+2P+h-\frac{3}{2}\right]\left[u'-u''+P+\frac{h}{2}\right]_+\left[u-u''+\frac{1}{2}\right]}{\left[u-u'-\frac{1}{2}\right]\left[u-u''-\frac{1}{2}\right]\left[u'-u''+\frac{1}{2}\right]}. \tag{6.35}$$

The contour C_+ is specified by

$$C_+: \quad |q^{-1}z|<|z'|<|p^{-1}q^{-1}z|, \quad |q^{-1}z|<|z''|<|p^{-1}q^{-1}z|, \quad |pqz'|<|z''|<|qz'|.$$

Similarly, for type-II vertex operators, the component $\Psi_0^*(u)$ is given by

$$\Psi_0^*(u)=a_{-,0}^*\oint_{C_0^*}\frac{dz'}{2\pi iz'}\Psi_-^*(u)E(z')\frac{[u-u'-P]_+^*}{\left[u-u'-\frac{1}{2}\right]^*\left[P-\frac{1}{2}\right]_+^*}$$

$$=-a_{-,0}^*\oint_{C_0^*}\frac{dz'}{2\pi iz'}E(z')\Psi_-^*(u)\frac{[u-u'-P]_+^*}{\left[u-u'+\frac{1}{2}\right]^*\left[P-\frac{1}{2}\right]_+^*}. \tag{6.36}$$

The contour C_0^* satisfies

$$C_0^*: \quad |q^{-1}z|<|z'|<|qz|.$$

The component $\Psi_0^*(u)$ is given by

$$\begin{aligned}\Psi_+^*(u)=&-a_{-,+}^* \oint \oint_{C_+^*} \frac{dz'}{2\pi i z'} \frac{dz''}{2\pi i z''} \Psi_-^*(u)E(z')E(z'') \frac{1}{\left[P-\frac{1}{2}\right]_+^* [2P-2]^*} \\ &\times \frac{\left[u-u'-2P+\frac{3}{2}\right]^* [u'-u''-P]_+^*}{\left[u-u'-\frac{1}{2}\right]^* \left[u'-u''-\frac{1}{2}\right]^*} \\ =&-a_{-,+}^* \oint \oint_{C_+^*} \frac{dz'}{2\pi i z'} \frac{dz''}{2\pi i z''} E(z')E(z'')\Psi_-^*(u) \frac{1}{\left[P-\frac{1}{2}\right]_+^* [2P-2]^*} \\ &\times \frac{\left[u-u'-2P+\frac{3}{2}\right]^* [u'-u''-P]_+^* \left[u-u''-\frac{1}{2}\right]^*}{\left[u-u'+\frac{1}{2}\right]^* \left[u-u''+\frac{1}{2}\right]^* \left[u'-u''-\frac{1}{2}\right]^*}. \end{aligned} \tag{6.37}$$

Here the contour C_+^* is specified by the condition

$$C_+^*: \quad |q^{-1}z|<|z'|<|qz|, \quad |q^{-1}z|<|z''|<|qz|, \quad |q^{-1}z'|<|z''|<|qz'|.$$

In C_0^* and C_+^*, the inequality such as $|q^{-1}z|<|z'|<|qz|$ means that the integration contour encloses the pole $q^{-1}z$ but not qz.

Remark: The free field realizations of the vertex operators (6.32)–(6.37) are the same as those of the dilute A_L model obtained in Ref. 15, up to a gauge transformation.

In addition we can verify the following commutation relation:

Proposition 6.3: The highest components $\Phi_-(u)$ and $\Psi_-^*(u)$ satisfy

$$\Phi_-(u_1)\Psi_-^*(u_2)=\chi(u_1-u_2)\Psi_-^*(u_2)\Phi_-(u_1). \tag{6.38}$$

Here we have set

$$\chi(u)=-z^{-1}\frac{\Theta_{q^6}(qz)\Theta_{q^6}(q^2z)}{\Theta_{q^6}(q/z)\Theta_{q^6}(q^2/z)}. \tag{6.39}$$

C. Commutation relations of the vertex operators

We next study the commutation relations of the vertex operators and show that our realization satisfies the full intertwining relations for $c=1$.

Theorem 6.4: *The free field realizations of the type-I vertex operator $\Phi_\mu(u)$* (6.32), (6.34), (6.35), *and the type-II vertex operator $\Psi_\mu^*(u)$* (6.33), (6.36), (6.37), *satisfy the following commutation relations:*

$$\Phi_{j_2}(u_2)\Phi_{j_1}(u_1)=\sum_{j_1',j_2'=\pm,0} R_{j_1j_2}^{j_1'j_2'}(u_1-u_2,P+h)\ \Phi_{j_1'}(u_1)\Phi_{j_2'}(u_2), \tag{6.40}$$

$$\Psi^*_{j_1}(u_1)\Psi^*_{j_2}(u_2)=\sum_{j_1',j_2'=\pm,0}\Psi^*_{j_2'}(u_2)\Psi^*_{j_1'}(u_1)\ \ R^{*j_1j_2}_{j_1'j_2'}(u_1-u_2,P), \tag{6.41}$$

$$\Phi_j(u_1)\Psi^*_k(u_2)=\chi(u_1-u_2)\ \ \Psi^*_k(u_2)\Phi_j(u_1). \tag{6.42}$$

Here we set

$$R(u,P+h)=\mu(u)\overline{R}(v,P+h),\qquad R^*(u,P)=\mu^*(u)\overline{R}^*(u,P), \tag{6.43}$$

with

$$\mu(u)=z^{(1/r)-1}\frac{\{pq^4z\}\{pq^3z\}\{q^3z\}\{q^2z\}\{pq/z\}\{p/z\}\{q^6/z\}\{q^5/z\}}{\{pq^4/z\}\{pq^3/z\}\{q^3/z\}\{q^2/z\}\{pqz\}\{pz\}\{q^6z\}\{q^5z\}} \tag{6.44}$$

and $\mu^*(u)=\mu(u)|_{r\to r^*}$. *Here* $\chi(u)$ *is given by (6.39).*

The proof is similar to those of Theorem 4.2.

Now let us investigate the intertwining relation for level $c=1$. For this purpose, we construct a L-operator as a composition of type-I and type-II vertex operators.[17]

Theorem 6.5: *For* $c=1$, *the components of the* L*-operator* $\hat{L}^+(u)$ *(5.1) is given by the following product of the type-I and type-II vertex operators:*

$$L^+_{j,k}(u)=g^{-1}\Psi^*_k(u+r)\Phi_j(u+r+1/2)\quad (j,k=\pm,0). \tag{6.45}$$

Here we set

$$g=-\frac{(pq^6;q^6)_\infty(pq^5;q^6)_\infty}{(pq^3;q^6)_\infty(pq^2;q^6)_\infty}\left(\frac{\{q^2p\}\{q^3p\}\{q^3p\}\{q^4p\}}{\{p\}\{qp\}\{q^5p\}\{q^6p\}}\times(p\leftrightarrow p^*)^{-1}\right). \tag{6.46}$$

The proof is similar to the one of Theorem 6.5 in Ref. 8.

Remark: By using the commutation relations of the vertex operators (6.40)–(6.42) and the formula

$$\frac{\rho^+(u)}{\rho^{+*}(u)}=\frac{\mu(u)\chi(\frac{1}{2}-u)}{\mu^*(u)\chi(\frac{1}{2}+u)}, \tag{6.47}$$

one can prove the $RLL=LLR^*$ relation (5.2) for $c=1$ directly.

In the same way, one can verify the ''intertwining relations'' (6.3) and (6.4) of vertex operators.

Corollary 6.6: For $c=1$, *the type-I and the type-II vertex operators* $\hat{\Phi}_V(u)$, $\hat{\Psi}^*_V(u)$ *satisfy the full intertwining relations (6.3) and (6.4) with* $V=W\cong\mathbb{C}^3$.

VII. DISCUSSION

Extending the construction of the elliptic algebra to the twisted affine Lie algebra case, we have derived the elliptic algebra $U_{q,p}(A_2^{(2)})$, $p=q^{2r}$ and shown that it provides the Drinfeld realization of the elliptic quantum group $\mathcal{B}_{q,\lambda}(A_2^{(2)})$. Based on this, we have derived the type-I and type-II vertex operators of $U_{q,p}(A_2^{(2)})$ and identified them with the vertex operators in the dilute A_L model with $r=2(L+1)/(L+2)$. Our result thus gives a representation theoretical foundation to the work.[15]

There are some open problems.

(i) We here studied the simplest twisted elliptic quantum group $\mathcal{B}_{q,\lambda}(A_2^{(2)})$ and associated elliptic algebra $U_{q,p}(A_2^{(2)})$. To generalize our consideration to the higher rank cases associated with $A_{2n}^{(2)}$ and $A_{2n+1}^{(2)}$, or moreover to other types of affine Lie algebras, is an interesting problem.

(ii) Our realization of the elliptic algebra $U_{q,p}(A_2^{(2)})$ based on the Drinfeld currents of $U_q(A_2^{(2)})$ and the Heisenberg algebra $\mathbb{C}\{\mathcal{H}\}$ is valid for a generic level c. In order to perform an algebraic analysis of the solvable lattice models, a free field realization is useful. For example, to consider a fusion of the dilute A_L model, i.e., a higher spin extension, we need a free field realization (Wakimoto construction) of the elliptic algebra $U_{q,p}(A_2^{(2)})$ in a higher level.

(iii) The Wakimoto realization of the affine quantum group $U_q(A_2^{(2)})$ itself is interesting. It should be used to solve the q-KZ equation as well as the q-difference equation for the twistor $F(r,s)$, which we have solved partly (see Appendix B). The same thing is true for the other types of affine Lie algebra and should lead us to a proof of the conjecture on the connection matrix of the q-KZ equation given by Frenkel and Reshetikhin.[18]

(iv) It is known in some cases that the generating functions of the q-deformed Virasoro or W-algebras can be obtained from a fusion of the vertex operators of corresponding elliptic algebra $U_{q,p}(\mathfrak{g})$.[19,20,15,21] It is interesting to examine the same procedure in various $U_{q,p}(\mathfrak{g})$ and derive corresponding q-W algebras. The results should be compared with those in Ref. 22.

(v) It is also an interesting problem to investigate the scaling limit of the half-currents and the L-operators of $U_{q,p}(A_2^{(2)})$ and derive the vertex operators.[19,23] The result should be applied to the Izergin–Korepin model[24] in the massless regime where a generic form of the correlation functions was studied in Ref. 25. The type-II vertex operators should provide the Zamolodchikov–Faddeev algebra for the $A_2^{(2)}$ Toda field theory with imaginary coupling constant, and enable us to derive the soliton S-matrix.

We hope to report on some of the issues listed here in the near future.

ACKNOWLEDGMENTS

The authors would like to thank Robert Weston, Marco Rossi, and colleagues in the Department of Mathematics, Heriot-Watt University, where most of this work was done for their kind hospitality. They are also grateful to Michio Jimbo for sending his note on a construction of the half-currents in $U_q(A_2^{(2)})$ and useful discussions. H.K. was also supported by the JSPS-Royal Society Exchange Fellowship.

APPENDIX A: FINITE DIMENSIONAL REPRESENTATION

The evaluation module (π_w, V_w) in terms of the Drinfeld generators, is defined by the following formulas:

$$\pi_w(h)=2(E_{++}-E_{--}), \quad \pi_w(c)=0, \tag{A1}$$

$$\pi_w(a_m)=\frac{[m]_q}{m}(w/q)^m(q^{-m}E_{++}+(1-q^m)E_{00}-q^{2m}E_{--}), \tag{A2}$$

$$\pi_w(x_k^+)=(w/q)^k(aE_{+0}+q^k bE_{0-}), \tag{A3}$$

$$\pi_w(x_k^-)=(w/q)^k(q^k b^{-1}E_{-0}+a^{-1}E_{0+}). \tag{A4}$$

Here we have used

$$E_{++}=\begin{pmatrix}1&0&0\\0&0&0\\0&0&0\end{pmatrix},$$

$$E_{00}=\begin{pmatrix}0&0&0\\0&1&0\\0&0&0\end{pmatrix},$$

and

$$E_{--}=\begin{pmatrix}0&0&0\\0&0&0\\0&0&1\end{pmatrix},$$

etc. In what follows we set $a=b=1$. We have

$$\pi_w(x^+(z))=E_{+0}\delta(w/qz)+E_{0-}\delta(w/z), \tag{A5}$$

$$\pi_w(x^-(z))=E_{-0}\delta(w/z)+E_{0+}\delta(w/qz), \tag{A6}$$

$$\pi_w(u^+(z,p))=\frac{(pq^3z/w;p)_\infty}{(pqz/w;p)_\infty}E_{++}+\frac{(pq^2z/w;p)_\infty(pq^{-1}z/w;p)_\infty}{(pqz/w;p)_\infty(pz/w;p)_\infty}E_{00}+\frac{(pq^{-2}z/w;p)_\infty}{(pz/w;p)_\infty}E_{--}, \tag{A7}$$

$$\pi_w(u^-(z,p))=\frac{(pq^{-3}w/z;p)_\infty}{(pq^{-1}w/z;p)_\infty}E_{++}+\frac{(pqw/z;p)_\infty(pq^{-2}w/z;p)_\infty}{(pw/z;p)_\infty(pq^{-1}w/z;p)_\infty}E_{00}+\frac{(pq^2w/z;p)_\infty}{(pw/z;p)_\infty}E_{--}. \tag{A8}$$

Let us calculate finite dimensional representation of the elliptic current,

$$\pi_w(e(z,p))=\frac{(pq^3z/w;p)_\infty}{(pqz/w;p)_\infty}E_{+0}\delta(w/qz)+\frac{(pq^2z/w;p)_\infty(pq^{-1}z/w;p)_\infty}{(pqz/w;p)_\infty(pz/w;p)_\infty}E_{0-}\delta(w/z), \tag{A9}$$

$$\pi_w(f(z,p))=\frac{(pqw/z;p)_\infty(pq^{-2}w/z;p)_\infty}{(pw/z;p)_\infty(pq^{-1}w/z;p)_\infty}E_{-0}\delta(w/z)+\frac{(pq^{-3}w/z;p)_\infty}{(pq^{-1}w/z;p)_\infty}E_{0+}\delta(w/qz), \tag{A10}$$

$$\pi_w(k(z,p))=\rho^+(q^{-r+2}z/w)\left(E_{++}+\frac{\Theta_p(q^rz/w)}{\Theta_p(q^{r+2}z/w)}E_{00}+\frac{\Theta_p(q^rz/w)\Theta_p(q^{r-1}z/w)}{\Theta_p(q^{r+2}z/w)\Theta_p(q^{r+1}z/w)}E_{--}\right), \tag{A11}$$

$$\pi_w(\psi(z,p))=\frac{\Theta_p(q^{r+3}z/w)}{\Theta_p(q^{r+1}z/w)}E_{++}+\frac{\Theta_p(q^{r+2}z/w)\Theta_p(q^{r-1}z/w)}{\Theta_p(q^{r+1}z/w)\Theta_p(q^rz/w)}E_{00}+\frac{\Theta_p(q^{r-2}z/w)}{\Theta_p(q^rz/w)}E_{--}. \tag{A12}$$

APPENDIX B: TWISTOR

We here consider the difference equations of the twistor $F(\lambda)$ for $\mathcal{B}_{q,\lambda}(A_2^{(2)})$. The general framework was given in Ref. 3. Let us consider the case of the affine algebra $A_2^{(2)}$. Taking a basis $\{c,d,\alpha_1^\vee\}$ of the Cartan subalgebra $\mathfrak{h}$ of $A_2^{(2)}$. We parametrize the dynamical variable λ as

$$\lambda-\rho=r^*d+s'c+\frac{1}{2}\left(s+\frac{r\tau}{2}\right)\alpha_1^\vee, \qquad \left(\ r^*=r-c,\ \ \tau=-\frac{2\pi i}{\log q^{2r}}\ \right), \tag{B1}$$

where $\rho=3d+\frac{1}{4}\alpha_1^\vee$ is the Weyl vector. Let us set

$$\mathcal{R}(z)=\mathrm{Ad}(z^d\otimes 1)(\mathcal{R}), \tag{B2}$$

$$F(z,p,w)=\mathrm{Ad}(z^d\otimes 1)(F(\lambda)), \tag{B3}$$

$$\mathcal{R}(z;p,w)=\mathrm{Ad}(z^d\otimes 1)(\mathcal{R}(\lambda))=\sigma(F(z^{-1};p,w))\mathcal{R}(z)F(z;p,w)^{-1}, \tag{B4}$$

where $w=q^{2(s+r\tau/2)}$. In particular, for $z=0$, $q^{c\otimes d+d\otimes c}\mathcal{R}(0)$ reduces to the universal R matrix of $U_q(A_1)$. From Ref. 3, we have the difference equation for the twistor,

$$F(pq^{2c^{(1)}}z;p,w)=(\overline{\varphi_w}^{-1}\otimes id)(F(z;p,w))q^T\mathcal{R}(pq^{2c^{(1)}}z), \tag{B5}$$

$$F(0;p,w)=F_{A_1}(w), \tag{B6}$$

where $\overline{\varphi_w}=\mathrm{Ad}(q^{\alpha_1^{\vee 2}/4}w^{\alpha_1^\vee/2})$ and $T=\frac{1}{2}c\otimes d+\frac{1}{2}d\otimes c+\frac{1}{4}\alpha_1^\vee\otimes\alpha_1^\vee$.

We are interested in the vector representation (π_z,V), $V=\mathbb{C}^3$ given in Appendix A. We set

$$F_{VV}(z;p,w)=(\pi_1\otimes\pi_1)F(z;p,w)=(\pi_{z_1}\otimes\pi_{z_2})(F(\lambda)), \tag{B7}$$

$$R_{VV}(z;p,w)=(\pi_1\otimes\pi_1)\mathcal{R}(z;p,w)=(\pi_{z_1}\otimes\pi_{z_2})(\mathcal{R}(\lambda)), \tag{B8}$$

$$R_{VV}(z)=(\pi_1\otimes\pi_1)\mathcal{R}(z)=(\pi_{z_1}\otimes\pi_{z_2})\mathcal{R}, \tag{B9}$$

where $z=z_1/z_2$. The trigonometric R-matrix $R_{VV}(z)$ is given as follows:

$$R_{VV}(z)=\rho_{VV}(z)\overline{R}_{VV}(z), \tag{B10}$$

$$\overline{R}_{VV}(z)=\begin{pmatrix}
1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0\\
0 & b(z) & 0 & c(z) & 0 & 0 & 0 & 0 & 0\\
0 & 0 & d(z) & 0 & e(z) & 0 & f(z) & 0 & 0\\
0 & z\ c(z) & 0 & b(z) & 0 & 0 & 0 & 0 & 0\\
0 & 0 & -q^2z\ \ e(z) & 0 & j(z) & 0 & e(z) & 0 & 0\\
0 & 0 & 0 & 0 & 0 & b(z) & 0 & c(z) & 0\\
0 & 0 & z\ \ n(z) & 0 & -q^2z\ \ e(z) & 0 & d(z) & 0 & 0\\
0 & 0 & 0 & 0 & 0 & z\ \ c(z) & 0 & b(z) & 0\\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1
\end{pmatrix},$$

$$b(z)=-\frac{q(1-z)}{1-q^2z}, \quad c(z)=\frac{1-q^2}{1-q^2z}, \quad d(z)=\frac{(1-z)q^2(1-qz)}{(1-q^2z)(1-q^3z)},$$

$$e(z)=\frac{i(1-q^2)q^{1/2}(1-z)}{(1-q^2z)(1-q^3z)}, \quad f(z)=\frac{(1-q^2)(1+q-q^3z-qz)}{(1-q^2z)(1-q^3z)},$$

$$j(z)=-\frac{q(1-z)}{1-q^2z}+\frac{(1-q^2)(1-q^3)z}{(1-q^2z)(1-q^3z)}, \quad n(z)=\frac{(1-q^2)(1+q^2-q^3z-q^2z)}{(1-q^2z)(1-q^3z)}.$$

The function $\rho_{VV}(z)$ is given by

$$\rho_{VV}(z)=q^{-1}\frac{(1/z;q^6)_\infty(q/z;q^6)_\infty(q^5/z;q^6)_\infty(q^6/z;q^6)_\infty}{(q^2/z;q^6)_\infty(q^3/z;q^6)_\infty^2(q^4/z;q^6)_\infty}. \tag{B11}$$

Noting $\pi_1(c)=0$, we have the difference equation

$$F_{VV}(pz;p,w)^t=R_{VV}(pz)^tK(D_w\otimes 1)^{-1}F_{VV}(z;p,w)^t(D_w\otimes 1), \tag{B12}$$

where X^t means the transpose of X, and we have set

$$K=\mathrm{Diag}(q,1,q^{-1},1,1,1,q^{-1},1,q), \tag{B13}$$

$$D_w=\mathrm{Diag}(q^{-1}w^{-1},1,q^{-1}w). \tag{B14}$$

From the from of $R_{VV}(z)$, one can set

$$F(z;p,w)=f(z)\begin{pmatrix}
1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0\\
0 & X_{11}^{(+)}(z) & 0 & X_{12}^{(+)}(z) & 0 & 0 & 0 & 0 & 0\\
0 & 0 & Y_{11}(z) & 0 & Y_{12}(z) & 0 & Y_{13}(z) & 0 & 0\\
0 & X_{21}^{(+)}(z) & 0 & X_{22}^{(+)}(z) & 0 & 0 & 0 & 0 & 0\\
0 & 0 & Y_{21}(z) & 0 & Y_{22}(z) & 0 & Y_{23}(z) & 0 & 0\\
0 & 0 & 0 & 0 & 0 & X_{11}^{(-)}(z) & 0 & X_{12}^{(-)}(z) & 0\\
0 & 0 & Y_{31}(z) & 0 & Y_{32}(z) & 0 & Y_{33}(z) & 0 & 0\\
0 & 0 & 0 & 0 & 0 & X_{21}^{(-)}(z) & 0 & X_{22}^{(-)}(z) & 0\\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1
\end{pmatrix}.$$

Then the q-difference Eq. (B12) is equivalent to the following equations:

$$f(pz)=q\rho_{VV}(pz)f(z), \tag{B15}$$

$$\begin{pmatrix} X_{11}^{(\pm)}(pz) & X_{12}^{(\pm)}(pz)\\ X_{21}^{(\pm)}(pz) & X_{22}^{(\pm)}(pz)\end{pmatrix}=q^{-1}\begin{pmatrix} X_{11}^{(\pm)}(z) & q^{\pm 1}wX_{12}^{(\pm)}(z)\\ q^{\mp 1}w^{-1}X_{21}^{(\pm)}(z) & X_{22}^{(\pm)}(pz)\end{pmatrix}\begin{pmatrix} b(pz) & c(pz)\\ pz\ \ c(pz) & b(pz)\end{pmatrix}, \tag{B16}$$

$$\begin{pmatrix} Y_{11}(pz) & Y_{12}(pz) & Y_{13}(pz)\\ Y_{21}(pz) & Y_{22}(pz) & Y_{23}(pz)\\ Y_{31}(pz) & Y_{32}(pz) & Y_{33}(pz)\end{pmatrix}=q^{-2}\begin{pmatrix} Y_{11}(z) & wY_{12}(z) & w^2Y_{13}(pz)\\ qw^{-1}Y_{21}(z) & qY_{22}(z) & qwY_{23}(z)\\ w^{-2}Y_{31}(z) & w^{-1}Y_{32}(z) & Y_{33}(z)\end{pmatrix}$$
$$\times\begin{pmatrix} d(pz) & e(pz) & f(pz)\\ -q^2pz\ \ e(pz) & j(pz) & e(pz)\\ pz\ \ n(pz) & -q^2pz\ \ e(pz) & d(pz)\end{pmatrix}. \tag{B17}$$

The two 2×2 matrix equations for $X_{ij}^{(\pm)}(z)$ are the same as the one appeared in the $\widehat{\mathfrak{sl}}_2$ case,[3] if we change $b(z)$ to $-b(z)$ and make the following identification:

$$q^{\pm 1}w=w_{\mathfrak{sl}_2}^{-1},\ \text{i.e.,}\quad -s_{\mathfrak{sl}_2}=s+\frac{r\tau}{2}\pm\frac{1}{2},$$

where $w_{\mathfrak{sl}_2}$ and $s_{\mathfrak{sl}_2}$ denote w and s in Ref. 3, respectively. Hence from the elliptic R matrix for $\mathcal{B}_{q,\lambda}(\widehat{\mathfrak{sl}}_2)$ ((4.18) in Ref. 3), we determine the following parts of our elliptic R-matrix:

$$\begin{pmatrix} R^{+0}_{+0} & R^{0+}_{+0} \\ R^{+0}_{0+} & R^{0+}_{0+} \end{pmatrix} = \begin{pmatrix} -\dfrac{[s+3/2]_+[s-1/2]_+}{[s+1/2]_+^2}\dfrac{[u]}{[u+1]} & e^{\pi i u/r}\dfrac{[1][s+1/2-u]_+}{[s+1/2]_+[u+1]} \\ e^{-(\pi i u/r)}\dfrac{[1][s+1/2+u]_+}{[s+1/2]_+[u+1]} & -\dfrac{[u]}{[u+1]} \end{pmatrix}, \tag{B18}$$

$$\begin{pmatrix} R^{0-}_{0-} & R^{-0}_{0-} \\ R^{0-}_{-0} & R^{-0}_{-0} \end{pmatrix} = \begin{pmatrix} -\dfrac{[s-3/2]_+[s+1/2]_+}{[s-1/2]_+^2}\dfrac{[u]}{[u+1]} & e^{\pi i u/r}\dfrac{[1][s-1/2-u]_+}{[s-1/2]_+[u+1]} \\ e^{-(\pi i u/r)}\dfrac{[1][s-1/2+u]_+}{[s-1/2]_+[u+1]} & -\dfrac{[u]}{[u+1]} \end{pmatrix}. \tag{B19}$$

By a gauge transformation, these yields the corresponding matrix elements in (2.19).

As for the 3×3 part, we have no known solutions. The Wakimoto realization of $U_q(A_2^{(2)})$ should be useful to solve the q-KZ equation for the intertwining operators (vertex operators) of $U_q(A_2^{(2)})$ as well as (B17).

APPENDIX C: PROOF OF THE RELATION (4.27)

Let us set

$$h(v) = -\frac{[v+1]^*[v-1/2]^*}{[v-1]^*[v+1/2]^*}. \tag{C1}$$

In the integrand of the half-current $E^+_{-,+}(u)$ (4.9), we call $E(z')E(z'')$ the operator part, and the ratio of the product of the theta functions the coefficient part. We keep coefficient parts in the right of operator parts. According to the relation (3.62), we have the equality

$$\oint \frac{dz'}{2\pi i z'}\frac{dz''}{2\pi i z''}E(z')E(z'')A(u,u'') = \oint \frac{dz'}{2\pi i z'}\frac{dz''}{2\pi i z''}E(z')E(z'')h(u''-u')A(u'',u'),$$

when the integration contours for z' and z'' are the same. Here we set $z'=q^{2u'}$, $z''=q^{2u''}$. We define "weak equality" in the following sense. The two coefficient functions $A(u',u'')$ and $B(u',u'')$ coupled to $E(z')E(z'')$ in integrals are equal in weak sense if

$$A(u',u'')+h(u''-u')A(u'',u') = B(u',u'')+h(u''-u')B(u'',u').$$

We write the weak equality as

$$A(u',u'') \sim B(u',u'').$$

To prove the equality (4.27), it is enough to show the equalities of coefficient parts in weak sense.

Setting $z_i=q^{2u_i}$ $(i=1,2)$ and $u=u_1-u_2$, let us consider RHS-LHS of (4.27) given as follows:

$$\oint \frac{dz'}{2\pi i z'} \oint \frac{dz''}{2\pi i z''}E(z')E(z'')F(u_1,u_2,u',u'',L),$$

where

$$
\begin{aligned}
&F(u_1,u_2,u',u'',L)\\
&=\frac{[u_2-u'-2P+2+c/2]^*[u'-u''-P]^*_+[1+u]^*[u+3/2]^*[1]^{*2}}{[u_2-u'+c/2]^*[u'-u''-1/2]^*[u]^*[2P-2]^*[P-1/2]^*_+[u+1/2]^*}\\
&\quad+\frac{[u_2-u'-P+(c+1)/2]^*_+[u_1-u'+1+c/2]^*[u_1-u''-P+(c+1)/2]^*_+[u+P+1]^*_+[1]^*}{[u_2-u'+c/2]^*[u_1-u'+c/2]^*[u_1-u''+c/2]^*[P-1/2]^{*2}_+[P+1/2]^*_+[u+1/2]^*}\\
&\quad-\frac{[u_1-u'-2P+2+c/2]^*[u'-u''-P]^*_+[1]^{*2}}{[u_1-u'+c/2]^*[u'-u''-1/2]^*[P-1/2]^*_+[u+1/2]^*}\\
&\quad\times\left(\frac{[u+2P-1]^*[1]^*[u+3/2]^*}{[u]^*[2P-1]^*[2P-2]^*}+\frac{[P]^*_+[u+2P+1/2]^*[1]^*}{[2P]^*[2P-1]^*[P-1]^*_+}\right)\\
&\quad-\frac{[u_2-u'-2P+c/2]^*[u'-u''-P-1]^*_+[u_1-u'+1+c/2]^*[u_1-u''+1+c/2]^*[1]^{*2}}{[u_2-u'+c/2]^*[u'-u''-1/2]^*[u_1-u'+c/2]^*[u_1-u''+c/2]^*[P+1/2]^*_+[2P]^*}.
\end{aligned}
$$

We will show that $F(u_1,u_2,u',u'',L)\sim 0$. For this purpose, we consider the function of u' defined by

$$F(u')=F(u_1,u_2,u',u'',L)+h(u''-u')F(u_1,u_2,u'',u',L).$$

Then it is not so hard to see that $F(u')$ is a quasiperiodic function having zeros at least at $u'=u''$ and $u'=u''+1$. The quasiperiodicity is given by

$$F(u'+\tau^*r^*)=-e^{-(2\pi i/r)(P-3/2)}F(u'),$$

$$F(u'+r^*)=F(u').$$

Therefore if we set

$$G(u')=F(u')\frac{[u'-u''-P+3/2]^*}{[u'-u'']^*},$$

$G(u')$ is a doubly periodic function of u' and $G(u''+1)=0$. It is then enough to show that $G(u')$ is an entire function.

In $G(u')$, some terms have the first order poles at $u'=u_1+c/2$, $u_2+c/2$,$u''+1/2$,$u''-1$. We checked that all the residues of the function $G(u')$ at these poles vanish. For example, at $u'=u_2+c/2$ the residue is given by

$$
\begin{aligned}
\mathrm{Res}_{u'=u_2+c/2}G(u')\frac{dz'}{2\pi iz'}&=-\frac{[u+1]^*[u_2-u''-P+c/2]^*_+[u+3/2]^*[1]^{*2}}{[u]^*[u_2-u''-1/2+c/2]^*[P-1/2]^*_+[u+1/2]^*}\\
&\quad+\frac{[u+1]^*[u_1-u''-P+(c+1)/2]^*_+[u+P+1]^*_+[1]^{*3}}{[u]^*[u_1-u''+c/2]^*[P+1/2]^*_+[P-1/2]^*_+[u+1/2]^*}\\
&\quad+\frac{[u+1]^*[u_1-u''+1+c/2]^*[u_2-u''-P-1+c/2]^*_+[1]^{*2}}{[u]^*[u_1-u''+c/2]^*[u_2-u''-1/2+c/2]^*[P+1/2]^*_+}.
\end{aligned}
$$

One can apply the following theta function identity to combine the first and the third terms,

$$
\begin{aligned}
&[u+x]^*[u-x]^*[v+y]^*_+[v-y]^*_+-[u+y]^*[u-y]^*[v+x]^*_+[v-x]^*_+\\
&\quad=-[x-y]^*[x+y]^*[u+v]^*_+[u-v]^*_+.
\end{aligned}
$$

We thus get

$$\text{first}+\text{third}=-\frac{[u+1]^*[u_1-u''-P+(c+1)/2]_+^*[u+P+1]_+^*[1]^{*3}}{[u]^*[u_1-u''+c/2]^*[P+1/2]_+^*[P-1/2]_+^*[u+1/2]^*}.$$

Therefore $\mathrm{Res}_{u'=u_2+c/2}\,G(u')\,(dz'/2\pi iz')=0$. The other cases can be treated in the similar way.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 45, NUMBER 8 AUGUST 2004

Shouldn't there be an antithesis to quantization?

published online 8 July 2004)

We raise the possibility of developing a theory of constructing quantum dynamical observables independent from quantization and deriving classical dynamical observables from pure quantum mechanical consideration. We do so by giving a detailed quantum mechanical derivation of the classical time of arrival at arbitrary arrival points for a particle in one dimension. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1767297]

I. INTRODUCTION

Recently we raised the problem of deriving classical dynamical observables from pure quantum mechanical consideration, and thus the problem of constructing quantum observables with classical counterparts without quantization.[1] Our motivations have been to break the circularity of quantization when invoking the correspondence principle,[2–4] and to sidestep the well-known existence of obstruction to quantization in important spaces like the Euclidean space.[5–12] The former motivation arises from the need for quantum mechanics to be internally coherent and autonomous from classical mechanics if quantum mechanics were the preponderant of the two mechanical theories. On the other hand, the later motivation arises from the need for observables to satisfy certain commutation relations in keeping with, say, the required evolution properties of the observables. Thus in Ref. 1 we have introduced the idea of *supraquantization*—the derivation of the quantum observable corresponding to a given classical observable without quantization, and the subsequent derivation of the classical observable from its quantum counterpart, as opposed to quantization which is the derivation of the quantum observable corresponding to a given classical observable by means of an associative mapping of the scalar-valued observable to an operator-valued observable.

And to illustrate our point of supraquantization and to demonstrate the general insufficiency of prescriptive quantization—particularly the Weyl quantization[13]—to satisfy required commutator values, we outlined in Ref. 1 without proof a formal quantum mechanical derivation of the local form of the classical time of arrival in the neighborhood of the origin. In this paper, we attempt to place our earlier results on a firm foundation. We do so by (1) developing the quantum mechanical framework suitable to the idea of supraquantization, and by (2) proving explicitly our earlier assertions made within the proposed framework. It is then the aim of this paper to give a quantum mechanical derivation of the classical observable

$$T_x(q,p) = -\operatorname{sgn}(p)\sqrt{\frac{\mu}{2}}\int_x^q \frac{dq'}{\sqrt{H(q,p)-V(q')}}, \tag{1}$$

where $T_x(q,p)$ is the time of arrival of a particle at some point x, whose Hamiltonian is $H(q,p)$. We will do so within the rigged Hilbert space formulation of quantum mechanics.[14–20]

This paper is organized as follows: In Sec. II we outline the quantum mechanical framework in rigged Hilbert space suitable for our purposes. In Sec. III we give a brief review of quantization and Weyl quantization in particular, and discuss the idea of supraquantization, and deal with the

a)Electronic mail: eric.galapon@up.edu.ph

transition to the classical regime. In Sec. IV we summarize the classical solution to the classical time of arrival and introduce the concept of global and local time of arrivals. In Sec. V we formulate our quantum mechanical approach to deriving the classical time of arrival at the origin from pure quantum mechanical consideration. In Sec. VI, we explicitly supraquantize the classical time of arrivals of the harmonic oscillator and the quartic oscillator. In Sec. VII we prove, within the limits stated therein, the general result for arbitrary entire analytic potentials that the time of arrival can be derived from the supraquantization developed in Sec. V. In Sec. VIII we give the extension of our derivation for arbitrary arrival points. And in Sec. IX, we devote some discussion on the relationship between quantization and supraquantization.

In this paper, though we are concerned with the derivation of the corresponding quantum time of arrival operator, we will not delve into the important question whether one can extract quantum time of arrival distributions from the constructed operator,[21–30] nor its relevance in the quantum time problem.[31,32] We leave these issues open in the meantime.

II. THE QUANTUM MECHANICAL FRAMEWORK

A. Single Hilbert space quantum mechanics

In the generalized single Hilbert space formulation of quantum mechanics, to every quantum mechanical system is assigned a generally infinite dimensional Hilbert space $\mathcal{H}$ over the complex field; and to every pure state corresponds to a ray in $\mathcal{H}$; and to every observable corresponds to a generally maximally symmetric densely defined operator in $\mathcal{H}$.[33,34]

If the system is closed or it does not react back to its environment, its evolution is governed by a one parameter unitary group, $U_t = e^{-(i/\hbar)\mathsf{H}t}$, where H is the system Hamiltonian. In Heisenberg representation where states are stationary, observables evolve according to

$$\mathsf{A}_t = e^{i\mathsf{H}t}\mathsf{A}e^{-i\mathsf{H}t}, \tag{2}$$

$$i\hbar\dot{\mathsf{A}}_t = [\mathsf{A}_t, \mathsf{H}], \tag{3}$$

where (3) is the infinitesimal form of (2). If either H or A are unbounded, then Eqs. (2) and (3) should be properly defined to give meaning to them. In particular, Eq. (2) holds for all times t if the domain of A is invariant under $e^{-i\mathsf{H}t}$ for all t. It is possible that the evolution equation and its infinitesimal form hold only in some countable subset of the time coordinate.

While the Hilbert space formulation is successful in describing much of the quantum mechanics we know, it is not sufficient in the sense that it does not accommodate the eigenfunctions of observables with pure continuous spectrum. It is in this context that extension of quantum mechanics in a rigged Hilbert space has been proposed. Moreover, it is within the rigging of $\mathcal{H}$ that will allow us to further generalize observables to include operators that are not necessarily operators in the system Hilbert space.

B. Rigged Hilbert space extension

Let $\mathcal{H}$ be the system Hilbert space. A rigged Hilbert space (RHS) for $\mathcal{H}$ is a triplet, called a Gel'fand triplet, $\Phi^\times \supset \mathcal{H} \supset \Phi$, where Φ is a dense subspace of $\mathcal{H}$, and is a locally convex topological space and is complete with respect to its own topology; on the other hand, $\Phi^\times$ is the space of all continuous linear functionals on Φ: An element F of $\Phi^\times$ assigns to every ϕ in Φ a complex number denoted by $\langle F|\varphi\rangle$ with the properties $\langle F|a\phi_1 + b\phi_2\rangle = a\langle F|\phi_1\rangle + b\langle F|\phi_2\rangle$, for every pair ϕ_1 and ϕ_2 in Φ, and for every pair of complex numbers a and b; and $\lim_{n\to\infty}\langle F|\phi_n\rangle = 0$, for every sequence ϕ_n converging to zero in ϕ.

In extending quantum mechanics in a rigged Hilbert space, one has to specify a particular rigging. But how do we determine the necessary rigging? Our answer to this question is limited to what is relevant and useful to our present purposes. A natural choice is the one provided by the Hamiltonian of the system under consideration. Let H be the Hamiltonian and let its domain be $\mathcal{D}(\mathsf{H})$. We choose Φ in such a way that Φ is a dense subset of $\mathcal{D}(\mathsf{H})$, and that Φ is invariant under

the Hamiltonian, i.e., $\mathsf{H}:\Phi\subseteq\Phi$. Our motivation in choosing this particular rigging is for us to be able to extend the quantum evolution of observables in the rigged Hilbert space, as we will define below. Once Φ is specified, its functional space $\Phi^\times$ is automatically determined.

Given the particular rigging of $\mathcal{H}$ relative to Φ, let $\mathcal{O}$ be the set of all observables whose domains contain Φ. Let A be in $\mathcal{O}$. We define two associated operators to A: its rigged Hilbert space *extension* $\mathsf{A}^\times$, and its rigged Hilbert space *reduction* $\mathsf{A}_\times$.

Definition 1 (Rigged Hilbert space extension): $\mathsf{A}^\times$ *is the extension of* A *in the entire* $\Phi^\times$*, i.e., the operator* $\mathsf{A}^\times$: $\Phi^\times\mapsto\Phi^\times$*, such that* $\langle \mathsf{A}^\times\phi|\varphi\rangle=\langle\phi|\mathsf{A}^\dagger\varphi\rangle$ *for all* ϕ *in* $\Phi^\times$ *and* φ *in* Φ*, where* $\mathsf{A}^\dagger$ *is the adjoint of* A *in* $\mathcal{H}$.

Definition 2 (Rigged Hilbert space reduction): $\mathsf{A}_\times$ *is the reduction of* A *in* Φ*, i.e., the operator* $\mathsf{A}_\times\varphi=\mathsf{A}\varphi$ *for all* φ *in* Φ*, such that there exists a uniquely associated functional* F_A *in* $\Phi^\times$*, for which* $\mathsf{A}_\times\varphi=\langle F_\mathsf{A}|\varphi\rangle=\mathsf{A}\varphi$ *for all* φ *in* Φ*. (See Appendix A for an example and to establish our notation.)*

The rigged Hilbert space extension of A exists if $\mathsf{A}^\dagger$ is in $\mathcal{O}$ and Φ is invariant under $\mathsf{A}^\dagger$, i.e., $\mathsf{A}^\dagger$: $\Phi\subseteq\Phi$. We emphasize that the definition of the rigged Hilbert space reduction of A requires the existence of the functional F_A in $\Phi^\times$ satisfying the stated condition. Of course A will always have a reduction in Φ by restricting its domain to Φ, but it is not necessary that there is always an associated functional F_A in $\Phi^\times$. All throughout we will call F_A as the functional kernel of $\mathsf{A}_\times$.

Now eigenfunctions corresponding to the continuous part of the spectrum of an observable do not belong to the Hilbert space: they are not square integrable and the usual probabilistic interpretation of quantum mechanics fails to hold on them. But these acquire rigorous meaning within the context of a rigged Hilbert space as generalized eigenfunctions residing in the functional space $\Phi^\times$. If one can give physical significance to elements of $\Phi^\times$, it may also be possible to give physical significance to operators taking Φ into $\Phi^\times$, e.g., Hamiltonians with singular potentials in the configuration space, $V(q)\propto\delta(q-q_0)$. This motivates us to introduce the concept of generalized observable.

Definition 3 (Generalized observable): Let F *be in* $\Phi^\times$*. If for all* φ *in* Φ*,* $F(\varphi)=\langle F|\varphi\rangle$ *is in* $\Phi^\times$ *and* $\langle F(\varphi)|\varphi\rangle$ *is real valued, we call* F *to be the functional kernel of a generalized observable* $\mathcal{A}$*. The mapping* $\langle F|\cdot\rangle$: $\Phi\mapsto\Phi^\times$ *defines the generalized observable* $\mathcal{A}$: $\Phi\mapsto\Phi^\times$.

The real valuedness of $\langle F(\varphi)|\varphi\rangle$ is the generalized analogue of the symmetry condition in ordinary Hilbert space quantum mechanics, the numerical value of which is the expectation value of the generalized observable. Since we have the inclusion relation $\Phi^\times\supset\mathcal{H}\supset\Phi$, the rigged Hilbert space reduction of ordinary quantum mechanical observables is a special class of generalized observables. We say that $\mathcal{A}$ has a Hilbert space projection if there exists a dense subspace $\mathcal{D}$ of Φ such that $\langle F|\varphi\rangle$ is in $\mathcal{H}$. Its Hilbert space projection is the closure of the operator F defined by $\langle F|\varphi\rangle=\mathsf{F}\varphi$ for all φ in $\mathcal{D}$. We emphasize that the properties of generalized observables are dictated by Φ. For this reason we denote $\mathcal{O}_\Phi$ to be the set of all generalized observables defined for a given Φ.

Now we give the appropriate generalization of the evolution law for quantum observables. Let H be the system Hamiltonian, whose domain $\mathcal{D}(\mathsf{H})$ contains Φ. Let $\Phi^\times\supset\mathcal{H}\supset\Phi$ be a particular rigging of $\mathcal{H}$, where Φ is invariant under H. Given H, let $\mathsf{H}^\times$ be its RHS-extension. Let $\mathcal{A}$ be a generalized observable in $\mathcal{O}_\Phi$. If Φ is invariant under $U_t=e^{-i\mathsf{H}t}$ for all t, we then take $\mathcal{A}$ to evolve according to

$$\mathcal{A}_t=U_{-t}^\times\mathcal{A}U_t^\times, \tag{4}$$

where $U_t^\times$ is the RHS-extension of U_t in the entire $\Phi^\times$. Under the same assumption, the infinitesimal form of (4) is given by

$$\frac{d\mathcal{A}_t}{dt}=\frac{1}{i\hbar}[\mathcal{A}_t,\mathsf{H}^\times]. \tag{5}$$

Equation (4) requires that $\mathcal{A}$ evolves into a generalized observable. These equations reduce to the standard quantum evolution law when restricted to the Hilbert space. While Eqs. (4) and (5) hold for all t under the assumption that Φ is invariant under U_t, they may still hold for some times, possibly countably infinite, even when Φ is not invariant under U_t for all t.

C. Quantum mechanics in configuration space

For a spin less particle in the real line, the corresponding system Hilbert space is the space of Lebesgue square integrable functions over the real line, $\mathcal{H}=L^2(\mathfrak{R},dq)$. We assume that the particle is under the influence of an everywhere infinitely differentiable (real valued) potential, i.e., of type $C^\infty(\mathfrak{R})$. The formal Hamiltonian

$$\mathsf{H}=-\frac{\hbar^2}{2\mu}\frac{d^2}{dq^2}+V(q) \tag{6}$$

can be assigned a dense domain $\mathcal{D}(\mathsf{H})$ in which it is essentially self-adjoint. The given Hamiltonian allows several possible riggings of the Hilbert space. We choose the rigging $\Phi^\times\supset\mathcal{H}\supset\Phi$, where Φ is the space of infinitely differentiable complex valued functions with compact support in the real line, and $\Phi^\times$ its corresponding functional space. Since $V(q)$ is $C^\infty(\mathfrak{R})$, Φ is invariant under H. We note that Φ is tight enough to allow a larger $\Phi^\times$.

The convergence to zero of a sequence in Φ is defined as follows. A sequence φ_n in Φ converges to zero in Φ if all these functions vanish outside a certain fixed bounded region, the same for all of them, and converge uniformly to zero in the usual sense together with their derivatives of any order.[19,20]

With our chosen rigging, the rigged Hilbert space reduction $\mathsf{A}_\times$ of an operator A in $\mathcal{H}$ with domain containing Φ assumes the familiar form

$$(\mathsf{A}_\times\varphi)(q)=\langle F_{\mathsf{A}}(q)|\varphi\rangle=\int_{\mathfrak{R}}\langle q|\mathsf{A}_\times|q'\rangle\varphi(q')dq', \tag{7}$$

where the functional kernel F_{A} is the complex conjugate of the well-known configuration matrix elements of the operators. Generalized observables, which includes the RHS-reductions of operators in $\mathcal{H}$, assume the similar form

$$(\mathcal{A}\varphi)(q)=\int_{\mathfrak{R}}\langle q|\mathcal{A}|q'\rangle\varphi(q')dq', \tag{8}$$

where the integrations in Eqs. (7) and (8) are understood to be in the distributional sense, in particular symbolic when the integrand is singular, e.g., the Dirac delta function. We note that the functional kernel $\langle q|\mathcal{A}|q'\rangle$ must be symmetric, i.e., $\langle q|\mathcal{A}|q'\rangle=\langle q'|\mathcal{A}|q\rangle^*$, in order to ensure the real valuedness of the expectation value of $\mathcal{A}$ in Φ.

III. QUANTIZATION, SUPRAQUANTIZATION, AND THE TRANSITION TO THE CLASSICAL REGIME

A. Quantization and Weyl-quantization

Let f be a classical observable, a real valued function $f(q,p)$ in the phase space. The problem of quantization is to derive the quantum counterpart of f by some associative mapping Q of the real-valued function $f(q,p)$ to a maximally symmetric operator F in the system Hilbert space $\mathcal{H}$, i.e., $Q(f)\mapsto\mathsf{F}$. A paramount requirement, aside from other requirements, of quantization is that the Poisson bracket of two (classical) observables quantizes into the commutator of the separately quantized observables, in particular $Q(\{f,g\})=(i\hbar)^{-1}[Q(f),Q(g)]$ (for a complete discussion on the requirements of quantization, see Refs. 7, 10).

One of the earliest prescription, which has become the starting point of other quantization schemes, is the Weyl quantization Q_W. In the language of the framework outlined above, Weyl quantization is the bijective mapping of f into some functional of a particular rigging $\Phi^\times \supset \mathcal{H} \supset \Phi$ of the system Hilbert space, i.e., $Q_W: f \mapsto F \in \Phi^\times$ such that $F(\cdot)$ is a generalized observable with a nontrivial Hilbert space projection. The rigging of $\mathcal{H}$ which we have required above is appropriate for Weyl's quantization. Now Q_W is defined by the mapping

$$Q_W: \ f \mapsto \Phi^\times \ni F^* = \langle q|\mathsf{F}_\times|q'\rangle = \frac{1}{2\pi\hbar}\int_{-\infty}^{\infty} f\left(\frac{q+q'}{2}, p\right)\exp\left[\frac{i}{\hbar}(q-q')p\right]dp, \tag{9}$$

where the integration is done in the distributional sense. In the standard formulation, it is assumed, though it is *not* guaranteed, that $F(\cdot)$ has a Hilbert space projection, so that $F(\cdot)$ is the rigged Hilbert reduction $\mathsf{F}_\times$ of a uniquely associated operator F in $\mathcal{H}$. The operator F is the closure of $\mathsf{F}_\times$ in $\mathcal{H}$.

Now suppose that F is the Hilbert operator corresponding to the classical operator f derived by quantization. The classical observable is recovered by mere inversion of the process. In this case one has to determine the rigged Hilbert space reduction $\mathsf{F}_\times$ of the operator F and consequently determine the functional kernel corresponding to $\mathsf{F}_\times$. Given the functional kernel, the classical observable is recovered by means of the inverse Fourier transform

$$f(q,p) = 2\pi\int_{-\infty}^{\infty}\left\langle q+\frac{v}{2}|\mathsf{F}_\times|q-\frac{v}{2}\right\rangle \exp\left(-i\frac{vp}{\hbar}\right)dv. \tag{10}$$

In this expression, taking the limit as $\hbar$ approaches zero is not required, it being just the inverse of the prescribed Weyl-quantization.

Quantization, however, is circular when invoking the correspondence principle; and this is already evident for the Weyl quantization. Moreover, there is a well known obstruction to quantization in Euclidean space (and other spaces) which says that no quantization exists that satisfies the poission-bracket-commutator correspondence requirement for all observables.[5–12] This is unsatisfactory because the said correspondence is necessary, for example, in ensuring that required evolution properties of a certain class of observables are satisfied. This handicap of quantization will be explicitly demonstrated for the Weyl quantization.

If we wish to break the inherent circularity of quantization and to sidestep the obstruction to quantization, we must then find an alternative platform upon which we can construct quantum observables without quantization, which can further allow us to derive the corresponding classical observable. It is here that the idea of supraquantization comes in.

B. Supraquantization

The idea behind supraquantization—the construction of quantum observables without quantization and the subsequent quantum mechanical derivation of its classical counterpart—is not entirely new.

It has its origin in Mackey's earlier effort of restoring the autonomy of quantum mechanics from classical mechanics.[3,4] We recall that the quantization of free particle in one dimension is accomplished by promoting its position and momentum into operators and their Poission bracket into commutator, and the energy into the Hamiltonian operator. Mackey's work obviates these quantization prescriptions by starting not from the classical description but from the axioms of quantum mechanics and the property of free space. Starting from the basic axiom that the proposition for the location of the particle in different volume elements are compatible and the fundamental homogeneity of free space, one derives the position and the momentum operators together with the canonical commutation relation they satisfy. On the other hand, requiring Galilean invariance in the lattice of propositions, one derives the free quantum Hamiltonian (see also Ref. 35). Mackey's work provides an excellent example of the existence of more than one solution to the derivation of the quantum image of a given set of classical observables. By definition Mack-

ey's construction of the position and momentum operators, together with their algebra, is a supraquantization of the classical position and momentum, and their Poisson algebra.

It may be that quantization and supraquantization yield the same results, like the position and momentum for the free particle, but they are unmistakably distinct. Quantization presupposes classical mechanics, while supraquantization upholds the autonomy of quantum mechanics; the former introduces circularity when invoking the correspondence principle, while the latter sanctions the correspondence principle as a legitimate consequence of the acknowledged preponderance of quantum mechanics over classical mechanics. In both methods of obtaining quantum observables, the classical observable plays two different roles. In quantization, it is the starting point; in supraquantization, it is a boundary condition. The correspondence principle requires that if a quantum observable corresponds to a classical observable, then the former should reduce to the latter in the limit of vanishing $\hbar$. Then if supraquantization gives the correct quantum observable, then that observable should approach its classical limit. As a consequence of the role of the classical observable as a boundary condition, supraquantization breaks the vicious circle inherent in the quantization procedure.

But how do we construct quantum observables corresponding to a given classical observable without quantization? The observable may be constructed by appealing to the *postulated properties of the observable under consideration*, or to the *postulated physical properties of the universe*, or to the *axioms of quantum mechanics*, or to *any combination of these*. Mackey's construction of the quantum position and momentum observables without quantization proceeds from the homogeneity of free space (assumed property of free space) and the commutativity of propositions for the location of a free particle (axiom of quantum mechanics).

For a specific class of classical observables, the required supraquantization may be accomplished, in addition to the aforementioned method, by referring to one of the members of the class and employing a transfer principle to the rest. The transfer principle can be expressed as follows:

Transfer Principle: Each element of a class of observables shares a common set of properties with the rest of its class such that when a particular property is identified for a specific element of the class that property can be transferred to the rest of the class without discrimination.

It is the central problem of supraquantization to determine this set of properties shared by the class of observables under consideration, together with the appropriate axioms of mechanics to impose. Obviously supraquantization treats each class of observables on a case to case basis, in contrast to quantization which gives a single rule of association between classical and quantum observables.

But how do we approach the classical limit? We can treat quantization as a first order approximation, especially in those cases where obstruction to quantization occurs, e.g., in Euclidean space, and treat its classical limit as the starting point. This is reasonable because quantization has been successful in cases where consistency is preserved. So for observables defined in $\mathcal{H}=L^2[\mathfrak{R},dq]$ or for generalized observables in a particular rigging of $\mathcal{H}$, the transition to the classical regime is still given by Eq. (10) only that one now has to specifically project the observable into the $\hbar=0$ or $\hbar=\delta$ regime. This is so as some orders of $\hbar$ now generally appear in Eq. (10). The appearance of terms in some orders of $\hbar$ indicates the failure of quantization to consistently satisfy the required commutator values, at least in Weyl's quantization. Thus for all generalized observables $\mathcal{A}$ definable relative to Φ with functional kernel $\langle q|\mathcal{A}_\times|q'\rangle^*$, the classical limit of $\mathcal{A}$ is given by

$$f(q,p)=\lim_{\hbar\to 0} 2\pi\int_{-\infty}^{\infty}\left\langle q+\frac{v}{2}\middle|\mathcal{F}\middle|q-\frac{v}{2}\right\rangle \exp\left(-i\frac{vp}{\hbar}\right)dv \tag{11}$$

whenever the limit exists [Eq. (11) has already been in used, see Refs. 36, 37]. The vanishing of $\hbar$ in the above expression is the statement that classical mechanics is the projection of quantum mechanics. Because classical mechanics is a projection, there is no bijection from classical to

quantum mechanics, except in those cases where the results of quantization and supraquantization agree. This will be made clear when we consider the supraquantization of the classical time of arrival.

IV. THE OBSERVABLE ON CASE: THE CLASSICAL TIME OF ARRIVAL

Consider a particle with mass μ in one dimension whose Hamiltonian is $H(q,p)$. If at $t=0$ the particle is at the point (q,p) in the phase space, the time $t=T_x$ that the particle will arrive at the point $q(t=T_x)=x$ is given by

$$T_x(q,p)=-\mathrm{sgn}(p)\sqrt{\frac{\mu}{2}}\int_x^q \frac{dq'}{\sqrt{H(q,p)-V(q')}}, \tag{12}$$

derived by inverting the (classical) equations of motion. For a given energy the region $\Omega=\Omega_q \times\Omega_p$ in the phase space in which Eq. (12) is finite and real valued is the classically accessible region to the particle for a given arrival point x. An important property of $T_x(q,p)$ is that it evolves according to

$$\frac{dT_x(q,p)}{dt}=-1. \tag{13}$$

This property will be important to us in the supraquantization of the time of arrival.

It is the goal of this paper to show that the time of arrival (12) for entire analytic potentials can be derived within the quantum mechanical framework we have just outlined above. This we will accomplish by constructing the generalized quantum observable corresponding to $T_x(q,p)$ by supraquantization to be developed below. Before we can proceed, we must recognize that $T_x(q,p)$ is only an observable in the region of the phase space accessible to the particle. Supraquantization of $T_x(q,p)$ then must be restricted to these accessible regions. We then proceed by developing a local form of $T_x(q,p)$, i.e., an equivalent expression for $T_x(q,p)$ in some neighborhood of Ω_q, which can be assured to be finite and real valued, thus an observable. It is this local form, which we shall refer to as the local time of arrival, that we will supraquantize and show to be derivable quantum mechanically. The time of arrivals for the rest of the accessible regions are then derived by simple analytic continuation of the local time of arrival. In the following section we develop the local expression for the time of arrival for arbitrary arrival x.

The local time of arrival: Given the Hamiltonian $H=(1/2\mu)p^2+V(q,p)$, let us consider all real valued functions, $T(q,p)$, in the phase space which is canonically conjugate with the Hamiltonian, i.e.,

$$\{H(q,p),T(q,p)\}=1, \tag{14}$$

where $\{,\}$ is the Poisson bracket. The time of arrival at some specified point is one such phase space function. Out of all those $T(q,p)$'s conjugate with $H(q,p)$, let us consider those that can be parametrized by x' and h, where x' is in the configuration axis and h is a fixed function of p alone. We denote these by $T_h^{x'}(q,p)$. The parameters x' and h are defined as follows. Let $K=(1/2\mu)p^2$ be the kinetic energy, and $\mathcal{L}_K$ be the kinetic energy Liovillian operator defined by $\mathcal{L}_K\cdot g=\{K,g\}=-\mu^{-1}p\partial_q g$. The pair of parameters x' and h fixes the inverse of $\mathcal{L}_K$, $\mathcal{L}_K^{-1}$, as follows:

$$\mathcal{L}_K^{-1}\cdot f(q,p)=-\frac{\mu}{p}\int_{x'}^q f(q',p)dq'+h(p). \tag{15}$$

In other words, x' and h define the domain of $\mathcal{L}_K$ such that the inverse $\mathcal{L}_K^{-1}$ can be unambiguously defined.

Now given x' and h we construct $T_h^{x'}$ by the following prescription. Since $\{H,T_h^{x'}\}=\mathcal{L}_H \cdot T_g(q,p)=1$, we express T_h^{-1} in the following form:

$$T_h^{x'}(q,p)=\mathcal{L}_H^{-1}\cdot 1=\frac{1}{\mathcal{L}_K+\mathcal{L}_V}\cdot 1, \tag{16}$$

where K and V are the kinetic and potential energy parts of the Hamiltonian, respectively. Geometric expansion of Eq. (16) yields

$$T_g^{x'}(q,p)=\mathcal{L}_K^{-1}\cdot 1-\mathcal{L}_K^{-1}\cdot\mathcal{L}_V\cdot\mathcal{L}_K^{-1}\cdot 1+\mathcal{L}_K^{-1}\cdot\mathcal{L}_V\cdot\mathcal{L}_K^{-1}\cdot\mathcal{L}_V\cdot\mathcal{L}_K^{-1}\cdot 1\cdots, \tag{17}$$

where $\mathcal{L}_K^{-1}$ is defined by Eq. (15). Assuming that there is a neighborhood in the phase space such that the right-hand side of (17) converges, Eq. (17) can be written in series form

$$T_g^{x'}(q,p)=\sum_{k=0}^{\infty}(-1)^k T_k(q,p,x'), \tag{18}$$

where the $T_k(q,p,x')$'s satisfy the recurrence relation

$$T_0(q,p,x')=\mathcal{L}_K^{-1}\cdot 1,\quad T_k(q,p,x')=\mathcal{L}_K^{-1}\cdot\mathcal{L}_V\cdot T_{k-1}(q,p). \tag{19}$$

The system of recurrence relation (19) is equivalent to the recurrence relation $\{K,T_k\}=\{V,T_{k-1}\}$, subject to the boundary condition $\{K,T_0\}=1$. For a given x' and h, Eqs. (19) assume the explicit forms,

$$T_0(q,p,x')=-\frac{\mu}{p}(q-x')+h(p), \tag{20}$$

$$T_k(q,p,x')=-\frac{\mu}{p}\int_{x'}^{q}\left(\frac{\partial V}{\partial q'}\frac{\partial T_{k-1}}{\partial p}-\frac{\partial V}{\partial p}\frac{\partial T_{k-1}}{\partial q'}\right)dq'+h(p). \tag{21}$$

For autonomous Hamiltonian systems, i.e., $V=V(q)$, Eq. (21) reduces to

$$T_k(q,p,x')=-\frac{\mu}{p}\int_{x'}^{q}\frac{\partial V}{\partial q'}\frac{\partial T_{k-1}}{\partial p}dq'+h(p). \tag{22}$$

Of course Eq. (18) need not converge. However for some conditions to be stated below it converges to the time of arrival in some neighborhood.

Now let $h=0$, $p\neq 0$ and $V(q)$ be continuous at q where q is an interior point of Ω_q. Then there exists a neighborhood of q, $\omega_q\subseteq\Omega_q$, determined by the neighborhood $|V(q)-V(q')|<K_\epsilon\leqslant p^2/2\mu$ such that for every $x\in\omega_q$, T_0^x converges absolutely and uniformly to the classical time of arrival t_x.

We prove this assertion as follows. With $h=0$, Eqs. (20) and (22) reduce to

$$T_0(q,p;x)=-\mu\frac{(q-x)}{p}, \tag{23}$$

$$T_k(q,p,x')=-\frac{\mu}{p}\int_{x}^{q}\frac{\partial V}{\partial q'}\frac{\partial T_{k-1}}{\partial p}dq'. \tag{24}$$

Using Eq. (24) with $x'=x$, and using (23) as the initial value, the first few terms in Eq. (17) can be evaluated to aid us to infer that the kth iterate, T_k, in Eq. (18) is given by

$$T_k(q,p;x) = -\frac{(2k-1)!!}{k!}\frac{\mu^{k+1}}{p^{2k+1}}\int_x^q (V(q)-V(q'))^k dq'. \tag{25}$$

We prove Eq. (25) by induction. Shifting index $k\to(k-1)$ in (25) to get T_{k-1} and substituting T_{k-1} back into Eq. (22), we have

$$T_k(q,p;x) = -\frac{\mu}{p}\int_x^q \frac{\partial V}{\partial q'}\frac{\partial T_{k-1}}{\partial p}dq' = -\frac{(2k-3)!!}{(k-1)!}(2k-1)\frac{\mu^{k+1}}{p^{2k+1}}\int_x^q \frac{\partial V}{\partial q'}\int_x^{q'}(V(q') - V(q''))^{k-1}dq''. \tag{26}$$

Successive integration by parts evaluates the double integration into

$$\begin{aligned}\int_x^q \frac{\partial V}{\partial q'}\int_x^{q'}(V(q')-V(q''))^{k-1}dq'' &= V(q)\int_x^q (V(q)-V(q'))^{k-1}dq' \\ &\quad -\frac{(k-1)}{2}\int_x^q \frac{dV^2}{dq'}\int_x^{q'}(V(q')-V(q''))^{k-2}dq''dq' \\ &= \int_x^q \sum_{j=0}^{k-1}(-1)^j \frac{(k-1)!}{(k-1-j)!(j+1)!}V^{j+1}(q)(V(q) \\ &\quad -V(q'))^{k-1-j} + \frac{(-1)^k}{k}\int_x^q V^k(q')dq' \\ &= \frac{1}{k}\int_x^q (V(q)-V(q'))^k dq'. \end{aligned}\tag{27}$$

Substituting Eq. (27) back into Eq. (26), we get

$$T_k(q,p;x) = -\frac{(2k-3)!!}{(k-1)!}\frac{(2k-1)}{k}\int_x^q (V(q)-V(q'))^k dq', \tag{28}$$

which reproduces and validates Eq. (25). Equation (18) then reduces to the form

$$T_0^x = -\sum_{k=0}^{\infty}(-1)^k \frac{(2k-1)!!}{k!}\frac{\mu^k}{p^{2k+1}}\int_x^q (V(q)-V(q'))^k dq'. \tag{29}$$

Of course Eq. (29) does not necessarily converge. We next tackle this convergence issue.

Let us consider the neighborhood of $V(q)$ given by $|V(q)-V(q')|<K_\epsilon$ for some $K_\epsilon \leqslant p^2(2\mu)^{-1}$. By the continuity of V at q, there exists a neighborhood of q, ω_q, completely determined by the neighborhood $|V(q)-V(q')|<K_\epsilon$. Now let x be in ω_q and consider the closed interval $\Delta=[q,x]$ which is contained in ω_q. Because V is continuous in the neighborhood ω_q, it is likewise continuous in Δ. This implies that, for a fixed q, $|V(q)-V(q')|$ as function of q' in the interval Δ possesses an absolute maximum M_q. Thus we have the inequality,

$$\left|\sum_{k=0}^{\infty}(-1)^k\frac{(2k-1)!!}{k!}\frac{\mu^k}{p^{2k}}\int_q^x (V(q)-V(q'))^k dq'\right| \leqslant \sum_{k=0}^{\infty}\frac{(2k-1)!!}{k!}\frac{\mu^k}{p^{2k}}M_q^k(x-q). \tag{30}$$

The right-hand side of inequality (30) converges absolutely if and only if $\mu p^{-2}M_q<\frac{1}{2}$. Because $M_q<K_\epsilon p^2(2\mu)^{-1}$, the right-hand side of inequality (30) absolutely converges. This implies that

Eq. (18) converges absolutely for every x in ω_q. The absolute convergence of the right-hand side of inequality (30) also implies the uniform converge of Eq. (18) because we can always replace $(x-q)$ by l in (30) where l is the length of any interval containing Δ.

To show that T_g^x converges absolutely and uniformly to T_x, we must show that the indicated integration in each term of the series can be factored out. This happens when the series $\Sigma_{k=0}^{\infty}(-1)^k(2k-1)!!(k!)^{-1}\mu^k p^{-2k}(V(q)-V(q'))^k$ converges uniformly for a fixed q and for every q' in Δ. This, in fact, is ensured by the absolute convergence of (30). Pulling the integral out in Eq. (29), we arrive at

$$T_0^x(q,p) = -\int_x^q \left(\sum_{k=0}^{\infty} (-1)^k \frac{(2k-1)!!}{k!} \frac{\mu^{k+1}}{p^{2k+1}} (V(q)-V(q'))^k \right) dq'$$

$$= -\frac{\mu}{p} \int_x^q \left(\sqrt{1+\frac{2\mu(V(q)-V(q'))}{p^2}} \right)^{-(1/2)} dq'. \tag{31}$$

Writing $p=\mathrm{sgn}(p)\sqrt{|p|^2}$ in Eq. (31) finally yields

$$T_g^x(q,p) = -\mathrm{sgn}(p)\sqrt{\frac{\mu}{2}} \int_x^q \frac{dq'}{\sqrt{H(q,p)-V(q')}}, \tag{32}$$

which is just the time of arrival at x. Thus $T_g^x(q,p)=t_x(q,p)$ in $\omega\subset\Omega$.

Because $T_x(q,p)$ holds in the entire Ω by definition and $T_0^x(q,p)$ holds only in some local neighborhood ω_q of Ω_q, we have the inclusion $T_0^x(q,p)\subset T_x(q,p)$; that is, $T_x(q,p)$ is the analytic continuation of $T_0^x(q,p)$ in $\Omega\backslash\omega$. For this reason we refer to $T_0^x(q,p)$ as the *local time of arrival* at x, and $T_x(q,p)$ as the global time of arrival. As we have mentioned above it is the local form or the local time of arrival that we will derive quantum mechanically, so that the global time of arrival is only derived by extension.

V. SUPRAQUANTIZATION OF THE CLASSICAL TIME OF ARRIVAL

A. The problem

Let $\mathcal{H}$ be the system Hilbert space and $\mathsf{H}=(1/2\mu)\mathsf{p}^2+V(\mathsf{q})$ be its Hamiltonian where $V(q)$ is $C^\infty(\mathfrak{R})$. Following Sec. II C, the rigging of $\mathcal{H}$ is $\Phi^\times\supset\mathcal{H}\supset\Phi$, where Φ is the fundamental space of infinitely differentiable complex valued functions with compact support in $\mathfrak{R}$, and where $\Phi^\times$ is the corresponding functional space for Φ.

The rigged Hilbert space extension of the Hamiltonian H is then explicitly given by

$$\mathsf{H}^\times\phi = -\frac{\hbar^2}{2\mu}\frac{d^2\phi}{dq^2} + V(q)\phi \quad \text{for all} \quad \phi\in\Phi^\times. \tag{33}$$

In this paper we assume that the potential $V(q)$ is at most entire analytic in q, i.e., represented by an everywhere convergent power series in q. The entire analycity of $V(q)$ is consistent with our requirement that Φ is invariant under the action of the Hamiltonian.

Given the Hamiltonian H, our problem is to construct the corresponding generalized time of arrival operator $\mathcal{T}$ consistent with the correspondence principle: $\mathcal{T}$ reducing to the local time of arrival in the classical limit. The operator $\mathcal{T}$ is by hypothesis a generalized observable relative to the rigging provided by Φ, i.e., the operator $\mathcal{T}$: $\Phi\mapsto\Phi^\times$. This operator is then uniquely associated with a functional kernel $F_\mathcal{T}$ defined by $\mathcal{T}:\Phi=\langle F_\mathcal{T}|\cdot\rangle:\Phi$. Explicitly

$$(\mathcal{T}\varphi)(q) = \int_{-\infty}^{\infty} \langle q|\mathcal{T}|q'\rangle\varphi(q')dq', \tag{34}$$

where $\langle q|\mathcal{T}|q'\rangle^*$ is the functional kernel $F_{\mathcal{T}}$. As a generalized observable, the functional kernel must be symmetric, i.e., $\langle q|\mathcal{T}|q'\rangle=\langle q'|\mathcal{T}|q\rangle^*$. Moreover, since $\mathcal{T}$ is the quantum counterpart of the local time of arrival, it has to be that the classical local time of arrival operator is recovered by means of Eq. (11), specifically

$$t_0(q,p)=\lim_{\hbar\to 0} 2\pi\int_{-\infty}^{\infty}\left\langle q+\frac{v}{2}\right|\mathcal{T}\left|q-\frac{v}{2}\right\rangle\exp\left(-i\frac{vp}{\hbar}\right)dv. \tag{35}$$

The problem of constructing $\mathcal{T}$ then reduces to the problem of determining its functional kernel $\langle q|\mathcal{T}|q'\rangle$. It is now the problem of supraquantization to determine $\langle q|\mathcal{T}|q'\rangle$ without appealing to quantization. (We leave the problem whether $\mathcal{T}$ has Hilbert space projection or none open, a problem relevant to the question whether time of arrival distributions can be extracted from $\mathcal{T}$.)

B. The construction of solution

But how do we determine the kernel $\langle q|\mathcal{T}|q'\rangle$ without resorting to quantization? We accomplish this in two steps. First is by identifying the property of $\mathcal{T}$ and implementing this property through the appropriate axiom of quantum mechanics. Being a time of arrival operator, it must at least evolve according to

$$\frac{d\mathcal{T}}{dt}=-\mathcal{I} \tag{36}$$

in which $\mathcal{I}$ is the identity in Φ. We note that it is not necessary that the above evolution law holds for all t. Fortunately, it is sufficient for us to require the condition $\dot{\mathcal{T}}(0)=-\mathcal{I}$, or $\mathcal{T}$ evolves according to Eq. (36) in the neighborhood of $t=0$. This is always satisfied because Φ is assumed to be invariant under the action of $\mathcal{H}$. Imposing this on Eq. (5), we arrive at the canonical commutation relation

$$\langle\tilde{\varphi}|[\mathsf{H}^{\times},\mathcal{T}]\varphi\rangle=i\hbar\langle\tilde{\varphi}|\varphi\rangle \tag{37}$$

satisfied by the Hamiltonian and the time of arrival operator, for all $\tilde{\varphi}$, $\varphi\in\Phi$. Equation (37) is the basic condition satisfied by $\mathcal{T}$ but it is not sufficient to completely determine $\mathcal{T}$.

The second step is by employing a kind of transfer principle we mentioned earlier. We hypothesize that each element of a class of time of arrival observables shares a common set of properties with the rest of its class such that when a particular property is identified for a specific element of the class that property can be transferred to the rest of the class without discrimination.

We exploit this in determining the kernel $\langle q|\mathcal{T}|q'\rangle$ by solving the simplest in the class of time of arrival observables, the free particle. We start by recalling that the free particle is Galilean invariant, a consequence of the homogeneity of free space. It will not matter then where we place the origin. This implies that the commutation relation (37) holds independent of the choice of origin. Because of this and because the free Hamiltonian is Galilean invariant, we require that the time kernel for the free particle must itself be Galilean invariant. Specifically if t_a is translation by a, i.e., $t_a(q)=q+a$ and if $\langle q|\mathcal{T}|q'\rangle$ is the free particle kernel, then the translated free time of arrival operator $\mathcal{T}_a=\int dq\langle t_a(q)|\mathcal{T}|t_a(q')\rangle$ must still satisfy Eq. (37). In addition to translational invariance, $\langle q|\mathcal{T}|q'\rangle$ must be symmetric, and it must be chosen such that Eq. (37) is satisfied given the free Hamiltonian $\mathsf{H}\tilde{\varphi}=-\hbar^2(2\mu)^{-1}\tilde{\varphi}''$, and it must reproduce the free time of arrival at the origin via Eq. (35). A solution satisfying all these requirements is given by

$$\langle q|\mathcal{T}|q'\rangle=\frac{\mu}{i4\hbar}(q+q')\mathrm{sgn}(q-q'). \tag{38}$$

We note though that (38) is not unique. The kernel $\hbar^{-1}\mu|a-a'|$ is dimensionally consistent with (38) and it is Galilean invariant and it commutes with the free Hamiltonian in the entire Φ.

Moreover it vanishes in the classical limit. Then real factors of it can be added to (38) without sacrificing any of the required properties of the free particle kernel. However, $\hbar^{-1}\mu|a-a'|$ arises only because of Galilean invariance which is an exclusive property of the free particle. Since we are aiming at exploiting the assumed transfer principle, we cannot carry it over to the rest of its class.

Having solved the free particle kernel, we proceed in implementing the transfer principle. We hypothesize that all time kernels assume the same form. Thus, from Eq. (38), we assume that the time kernel is given by

$$\langle q|\mathcal{T}|q'\rangle = \frac{\mu}{i\hbar} T(q,q')\mathrm{sgn}(q-q'), \tag{39}$$

where $T(q,q')$ depends on the given Hamiltonian. Inferring from the free particle time kernel, we require that $T(q,q')$ be real valued, symmetric, $T(q,q')=T(q',q)$, and analytic. We determine $T(q,q')$ by imposing condition (37) on $\mathcal{T}$. Substituting Eq. (39) back into the left-hand side of Eq. (37) and performing two successive integration by parts, we arrive at

$$\begin{aligned}\langle\tilde{\varphi}|[\mathsf{H}^{\times},\mathcal{T}]\varphi\rangle = i\hbar\int_{\Sigma}\tilde{\varphi}^{*}(q)\left(\frac{dT(q,q)}{dq}+\frac{\partial T(q',q')}{\partial q}+\frac{\partial T(q,q)}{\partial q'}\right)\varphi(q)dq \\ -i\frac{\mu}{\hbar}\int_{\Sigma}\tilde{\varphi}^{*}(q)\left[\left(-\frac{\hbar^2}{2\mu}\frac{\partial^2}{\partial q^2}+V(q)\right)T(q,q')\right. \\ \left.-\left(-\frac{\hbar^2}{2\mu}\frac{\partial^2}{\partial q'^2}+V(q')\right)T(q,q')\right]\mathrm{sgn}(q-q')\varphi(q')dq'dq,\end{aligned} \tag{40}$$

where Σ is the common support of $\varphi(q)$ and $\tilde{\varphi}(q)$. We point out that our ability to arrive at the above expression has been made possible by extending the formulation in a rigged Hilbert space.

If $\mathsf{H}^{\times}$ and $\mathcal{T}$ are to be canonically conjugate in the distributional sense, then the second term must identically vanish for all $\varphi(q)$, $\tilde{\varphi}(q)\in\Phi(\mathfrak{R})$, while the first term must identically reduce to $i\hbar\langle\tilde{\varphi}|\varphi\rangle$. Because φ and $\tilde{\varphi}$ are arbitrary and $\mathrm{sgn}(q-q)$ is not identically zero, the former is satisfied if and only if $T(q,q')$ satisfies the partial differential equation

$$-\frac{\hbar^2}{2\mu}\frac{\partial^2 T(q,q')}{\partial q^2}+\frac{\hbar^2}{2\mu}\frac{\partial^2 T(q,q')}{\partial q'^2}+(V(q)-V(q'))T(q,q')=0. \tag{41}$$

On the other hand, the later condition is satisfied if and only if $T(q,q')$ satisfies the boundary condition

$$\frac{dT(q,q)}{dq}+\left.\frac{\partial T(q,q')}{\partial q}\right|_{q=q'}+\left.\frac{\partial T(q,q')}{\partial q'}\right|_{q'=q}=1 \tag{42}$$

for all $q,q'\in\mathfrak{R}$. The boundary condition (42) defines a family of operators canonically conjugate to the extended Hamiltonian in the sense required by Eq. (37). This is a reflection of the fact that there are numerous operators that are canonically conjugate to a given Hamiltonian.
