Here we describe the spectrum of $H_\alpha(\mathbf{q})$ for a fixed $\mathbf{q}\in\mathbb{R}^3$. Further, if it does not lead to a misunderstanding, we omit $\mathbf{q}$ from the notations.

Since H_α is a rank one perturbation of H^0, the spectrum of H_α is discrete. Moreover, an eigenvalue λ_n of H^0 of the multiplicity k_n is an eigenvalue of H_α of the multiplicity k_n-1, k_n or k_n+1 [if $k_n=1$, the first case means, of course, that λ_n does not belong to $\mathrm{spec}(H_\alpha)$]. For $\lambda\notin\mathrm{spec}(H^0)$ we see from (7) that λ is an eigenvalue of H_α if and only if $\zeta=\lambda$ is a solution to the equation

$$Q(\zeta;\mathbf{q})-\alpha=0. \tag{9}$$

Denote by $(\varepsilon_n)_{n\in\mathbb{N}}=(\varepsilon_n(\mathbf{q}))_{n\in\mathbb{N}}$ the strictly increasing sequence of all the poles of $Q(\zeta;\mathbf{q})$. Since $(\partial Q/\partial E)(E;\mathbf{q})>0$ for $E\in\mathbb{R}\backslash\mathrm{spec}(H^0)$, Eq. (9) has exactly one solution on each interval $(-\infty,\varepsilon_0),(\varepsilon_0,\varepsilon_1),\ldots$. Denote such solutions, which do not belong to $\mathrm{spec}(H^0)$, by $\mathcal{E}_0,\mathcal{E}_1,\ldots$, where $\mathcal{E}_0<\mathcal{E}_1<\cdots$. The following theorem completely describes the eigenvalues and the eigenfunctions of $H_\alpha(\mathbf{q})$.

Theorem 1: *Let $\mathbf{q}\in\mathbb{R}^3$ be fixed. The spectrum of $H_\alpha=H_\alpha(\mathbf{q})$ is discrete and consists of four nonintersecting parts $\sigma_1,\sigma_2,\sigma_3,\sigma_4$ described as follows.*

(1) σ_1 is the set of all solutions $\mathcal{E}_n$ to the Eq. (9), which do not belong to $\mathrm{spec}(H^0)$. *The multiplicity of $\mathcal{E}_n$ in the spectrum of H^0 is equal to 1.*
(2) σ_2 is the set of all $\lambda_n\in\sigma(\mathbf{q})$ that are multiple eigenvalues of H^0. The multiplicity of the eigenvalue $\lambda_n\in\sigma_2$ in the spectrum of H_α is equal to k_n-1.
(3) σ_3 consists of all λ_n, $\lambda_n\in\mathrm{spec}\,(H^0)\backslash\sigma(\mathbf{q})$, that are not solutions of (9). *The multiplicity of the eigenvalue λ_n in* $\mathrm{spec}(H_\alpha)$ *is equal to k_n.*
(4) σ_4 consists of all λ_n, $\lambda_n\in\mathrm{spec}\,(H^0)\backslash\sigma(\mathbf{q})$, such that λ_n is a solution of (9). *The multiplicity of the eigenvalue λ_n in* $\mathrm{spec}(H_\alpha)$ *is equal to k_n+1.*

The corresponding eigensubspaces are described as follows.

(1) The subspace spanned by the normalized eigenfunction

$$\Phi_n=\left[\frac{\partial Q}{\partial\zeta}(\mathcal{E}_n;\mathbf{q})\right]^{-1/2}g_{\mathbf{q}}(\mathcal{E}_n)\,.$$

(2) The orthogonal complement in L_n of the function

$$\Psi_n(\mathbf{x})=\sum_{k=1}^{k_n}\overline{F_{n,k}(\mathbf{q})}F_{n,k}(\mathbf{x})\,,$$

or, equivalently, the subspace of L_n of the form $\{f\in L_n: f(\mathbf{q})=0\}$.
(3) The subspace L_n.
(4) The direct sum of L_n and the space spanned by the function $g_{\mathbf{q}}(\lambda_n)$, which is orthogonal to L_n.

Proof: The proof is based on direct calculations with the help of following statements:
(A) *The orthoprojector $P(E_0)$ on the eigenspace of a self-adjoint operator T corresponding to an isolated eigenvalue E_0 has the form*

$$P(E_0)=-\mathrm{Res}[(T-\zeta)^{-1};\zeta=E_0].$$

(B) *Suppose P_1,P_2 and P_1+cP_2, where $c\in\mathbb{C}$, are orthoprojectors in a Hilbert space and $P_2\neq 0$, then c equals* 0, 1 *or* -1.

The first statement is well known; we omit the easy proof of the second one. Denote by $A(\zeta)$,

$$A(\zeta)=[Q(\zeta;\mathbf{q})-\alpha]^{-1}|g_{\mathbf{q}}(\zeta)\rangle\langle g_{\mathbf{q}}(\zeta)|,$$

the second term in the representation (7) of the resolvent. Further, denote for $E_0\in\mathbb{R}$

$$P_\alpha(E_0)=-\mathrm{Res}[R_\alpha(\zeta);\zeta=E_0]\,,$$

$$P^0(E_0)=-\mathrm{Res}[R^0(\zeta);\zeta=E_0]\,,$$

$$T(E_0)=\mathrm{Res}[A(\zeta);\zeta=E_0]\,;$$

therefore, according to (7)

$$P_\alpha(E_0)=P^0(E_0)+T(E_0)\,.$$

Start with the proof of the first assertion of Theorem. It is obvious that $\sigma_1 \subset \operatorname{spec}(H_\alpha)$. Let $\mathcal{E}_n \in \sigma_1$, then in a vicinity of $\mathcal{E}_n$ we have the following expansion:

$$Q(\zeta;\mathbf{q}) - \alpha = \frac{\partial}{\partial \zeta} Q(\mathcal{E}_n;\mathbf{q})(\zeta - \mathcal{E}_n) + O(\zeta - \mathcal{E}_n)^2. \tag{10}$$

Therefore,

$$T(\mathcal{E}_n) = \left[\frac{\partial}{\partial \zeta} Q(\mathcal{E}_n;\mathbf{q}) \right]^{-1} |g_{\mathbf{q}}(\mathcal{E}_n)\rangle\langle g_{\mathbf{q}}(\mathcal{E}_n)| . \tag{11}$$

Since obviously $P^0(\mathcal{E}_n) = 0$, we have $P_\alpha(\mathcal{E}_n) = T(\mathcal{E}_n)$ and the normalized eigenfunction corresponding to $\mathcal{E}_n$ is

$$\Phi_n = \left[\frac{\partial Q}{\partial \zeta}(\mathcal{E}_n;\mathbf{q}) \right]^{-1/2} g_{\mathbf{q}}(\mathcal{E}_n) . \tag{12}$$

Now consider an eigenvalue λ_n of H^0. In this case $P_\alpha(\lambda_n) = P^0(\lambda_n) + T(\lambda_n)$. According to (8), in a neighborhood W of λ_n we have the following representation

$$g_{\mathbf{q}}(\zeta) = \Psi_n(\cdot;\mathbf{q})(\lambda_n - \zeta)^{-1} + f(\zeta) ,$$

where f is analytic function in W with values in $L^2(\mathbb{R}^3)$ and

$$\Psi_n(\mathbf{x};\mathbf{q}) = \sum_{k=1}^{k_n} \overline{F_{n,k}(\mathbf{q})} F_{n,k}(\mathbf{x}) .$$

Consider the following three cases: (a) $\lambda_n \in \sigma(\mathbf{q})$; (b) $\lambda_n \notin \sigma(\mathbf{q})$ and $Q(\lambda_n;\mathbf{q}) - \alpha \neq 0$; (c) $\lambda_n \notin \sigma(\mathbf{q})$ and $Q(\lambda_n;\mathbf{q}) - \alpha = 0$.

Let us start with the case (a). Since λ_n is a pole of $Q(\cdot;\mathbf{q})$, we have $\Psi_n(\cdot;\mathbf{q}) \neq 0$ and therefore $T = cP$, where P is the orthoprojector on the one-dimensional space spanned by $\Psi_n(\cdot;\mathbf{q})$. Since $\Psi_n(\cdot;\mathbf{q}) \in L_n$, in virtue of statement (B) $c = -1$, and the assertion (2) of Theorem is proven.

In the case (b) according to Lemma 1, $F_{n,k}(\mathbf{q}) = 0$ for all $k = 1,\ldots,k_n$; hence $\Psi_n(\cdot,\mathbf{q}) = 0$ and $T(\lambda_n) = 0$. This implies assertion (3) of Theorem.

Finally, in the case (c) we can use (10)–(12) with $\zeta = \lambda_n$ instead of $\zeta = \mathcal{E}_n$, and obtain

$$T(\lambda_n) = |\Phi_n\rangle\langle\Phi_n| ,$$

according to (B), this get the statement (4) of Theorem. ■

For $n \in \mathbb{N}$ denote by A_n the set of all $\alpha \in \mathbb{R}$ such that the solution $\mathcal{E}_n \equiv \mathcal{E}_n(\alpha)$ of Equation (9) does not belong to the spectrum of H^0. Lemma 2 shows that $\mathbb{R} \backslash A_n$ is finite, moreover, if V bounded from below, then $A_0 = \mathbb{R}$.

For all $\mathbf{q} \in \mathbb{R}^3$ we will denote $\varepsilon_{-1}(\mathbf{q}) = \lambda_{-1} = -\infty$. Using Lemmas 1 and 3 we get immediately the following proposition.

Proposition 1: For each $n \in \mathbb{N}$ the function $\alpha \mapsto \mathcal{E}_n(\alpha)$ strictly increases on A_n. Moreover,

$$\lim_{\alpha \to +\infty} \mathcal{E}_n(\alpha) = \varepsilon_n , \qquad \lim_{\alpha \to -\infty} \mathcal{E}_n(\alpha) = \varepsilon_{n-1} .$$

■

Remark: For $n = 0$ we have an interesting phenomenon of falling the considered particle on the point $\mathbf{q}$ (the falling on the attractive center; cf. Ref. 21 for the case of a one-dimensional oscillator). Indeed, using estimate (b′) from Theorem B.7.1 of Ref. 31, we obtain without any difficulty $|\Phi_0(\mathbf{x})|^2 \to \delta(\mathbf{x} - \mathbf{q})$ in an appropriate space of distributions as $\alpha \to -\infty$ (and therefore

$\mathcal{E}_0 \to -\infty$). According to the standard interpretation of quantum mechanics, this relation means that the probability to find the particle in a domain not containing the point $\mathbf{q}$ tends to zero as $\mathcal{E}_0$ tends to $-\infty$.

V. DEPENDENCE OF THE SPECTRUM OF $H_\alpha(\mathbf{q})$ ON $\mathbf{q}$

Here we are going to analyze the dependence of the eigenvalues of H_α on $\mathbf{q}$. It is clear that $\mathcal{E}_n(\mathbf{q})$ are continuous branches of the multi-valued function defined by Eq. (9). This branches can intersect at values λ_n where a monodromy arises. To get a univalent enumeration of these branches, we modify the parametrization of the eigenvalues of H_α given by Theorem 1 (the enumeration of the numbers $\mathcal{E}_n(\mathbf{q})$ depends on the enumeration of poles $\varepsilon_n \in \mathrm{spec}(H^0)$, which in its turn depends obviously on $\mathbf{q}$). For $n=-1,0,\ldots$ consider the sets X_n defined as follows: $X_{-1} = \mathbb{R}^3$, and

$$X_n = \{\mathbf{q} \in \mathbb{R}^3 : \exists f \in L_n \text{ s.t. } f(\mathbf{q}) \neq 0\} = \{\mathbf{q} \in \mathbb{R}^3 : \lambda_n \in \sigma(\mathbf{q})\},$$

for $n \geqslant 0$. For all $n \in \mathbb{N}$ the set $\mathbb{R}^3 \backslash X_n$ is nowhere dense in $\mathbb{R}^3$ (see in Ref. 38, Theorem XIII.63). According to Lemma 1, for $n \geqslant 0$, the set X_n coincides with the set of all $\mathbf{q} \in \mathbb{R}^3$ such that λ_n is a pole of the function $Q(\cdot;\mathbf{q})$. Since we do not suppose the potential V is smooth, the function $Q(\zeta;\mathbf{q})$ on the set $(\lambda_{n-1},\lambda_n) \times (X_{n-1} \cap X_n)$, $n \geqslant 0$, is not, generally speaking, smooth. Nevertheless, it is monotone and real analytic with respect to the first argument ζ and continuous with respect to the second argument $\mathbf{q}$. In this case the following simple variant of Implicit Function Theorem is applicable (see in Ref. 40 for the proof):

Let J be an open nonempty interval of the real line $\mathbb{R}$, X be a topological space, and $F: J \times X \to \mathbb{R}$ be a separately continuous function such that each partial function $t \mapsto F(t,x)$, $x \in X$, is strictly monotone. Suppose that $F(t_0,x_0)=0$ for some $(t_0,x_0) \in J \times X$. Then there are an open neighborhood U of the point x_0 in X and a continuous function $f: U \to J$ such that (1) $F(f(x),x)=0$ for all $x \in U$; (2) if U' is another neighborhood of x_0, and $g: U' \to J$ is a function with the property: $F(g(x),x)=0$ for all $x \in U'$, then $U' \subset U$, and $f_{|U'} = g$.

According to this version of Implicit Function Theorem, for any $\mathbf{q} \in X_{n-1} \cap X_n$ there exists a unique solution $E_n(\mathbf{q})$ to Eq. (9) that belongs to $(\lambda_{n-1},\lambda_n)$ and $\mathbf{q} \mapsto E_n(\mathbf{q})$ is a continuous function in $X_{n-1} \cap X_n$.

Proposition 2: Every function $E_n(\mathbf{q})$, $n=0,1,\ldots$, has a continuous extension to the whole space $\mathbb{R}^3$.

Proof: Fix $n=0,1,\ldots$, and let a point $\mathbf{q}$, $\mathbf{q} \in \mathbb{R}^3 \backslash (X_{n-1} \cap X_n)$, be given. Choose a sequence $(\mathbf{q}_k)_{k \in \mathbb{N}}$ from $X_{n-1} \cap X_n$ which tends to $\mathbf{q}$. First we note that the sequence $(E_n(\mathbf{q}_k))_{k \in \mathbb{N}}$ is bounded in $\mathbb{R}$. It is trivial for $n>0$. If $n=0$, the sequence is bounded from above. We prove that it is bounded from below as well. Otherwise $E_0(\mathbf{q}_{k_l}) \to -\infty$ for some subsequence $(\mathbf{q}_{k_l})$. Since $Q(E;\mathbf{q}) \to -\infty$ as $E \to -\infty$, there exists $A < \lambda_0$ such that $Q(A;\mathbf{q}) < \alpha$. Then there exists $N \in \mathbb{N}$ such that $Q(A;\mathbf{q}_{k_l}) < \alpha$ and $E_0(\mathbf{q}_{k_l}) < A$ if $l \geqslant N$. Therefore, for $k \geqslant N$ we have

$$Q(E_0(\mathbf{q}_{k_l});\mathbf{q}_{k_l}) - \alpha < Q(A;\mathbf{q}_{k_l}) - \alpha < 0,$$

and we get a contradiction with the definition of $E_0(\mathbf{q}_{k_l})$.

By Bolzano–Weierstrass we can extract a subsequence $(\mathbf{q}_{k_l})$ from the sequence $(\mathbf{q}_k)$ such that the subsequence $(E_n(\mathbf{q}_{k_l}))$ has a limit, which we denote by E'. To prove that the sequence $(E_n(\mathbf{q}_k))$ tends to E' and E' is independent of the choice of a sequence $(\mathbf{q}_k)$ tending to $\mathbf{q}$ we need the following lemma concerning properties of E'.

Lemma 5: The limit E' has the properties:

(1) E' is not a pole of the function $\zeta \mapsto Q(\zeta;\mathbf{q})$;
(2) if $\lambda_{n-1} < E' < \lambda_n$, then E' is a unique solution of Eq. (9) in the interval $(\lambda_{n-1},\lambda_n)$;
(3) if $E' = \lambda_{n-1}$, then $\lim_{E \to E'} [Q(E;\mathbf{q}) - \alpha] \geqslant 0$;
(4) if $E' = \lambda_n$, then $\lim_{E \to E'} [Q(E;\mathbf{q}) - \alpha] \leqslant 0$.

Proof of the lemma:

(1) First consider the case $n>0$. The function $\tilde{Q}_n(\zeta;\mathbf{q})=[Q(\zeta;\mathbf{q})-\alpha](\zeta-\lambda_{n-1})(\zeta-\lambda_n)$ is continuous on the interval $(\lambda_{n-2},\lambda_{n+1})\times\mathbb{R}^3$. Since $\tilde{Q}_n(E_n(\mathbf{q}_{k_l});\mathbf{q}_{k_l})=0$, passing to the limit $l\to\infty$ we get $\tilde{Q}_n(E';\mathbf{q})=0$. Suppose $\zeta=E'$ is a pole of $Q(\zeta;\mathbf{q})$, then $\tilde{Q}_n(E';\mathbf{q})=\mathrm{Res}[Q(\zeta;\mathbf{q});\zeta=E']\neq 0$, and we get a contradiction. For $n=0$, we consider $\tilde{Q}_0(\zeta;\mathbf{q})=[Q(\zeta;\mathbf{q})-\alpha](\zeta-\lambda_0)$, and get the same result.
(2) It is sufficient to pass to the limit $l\to\infty$ in the identity $Q(E_n(\mathbf{q}_{k_l});\mathbf{q}_{k_l})=0$.
(3) In virtue of statement (1) of the lemma, the function $\zeta\mapsto Q(\zeta;\mathbf{q})$ is continuous in a neighborhood of E', and therefore there exists a limit $\lim_{\zeta\to\lambda_{n-1}}[Q(\zeta;\mathbf{q})-\alpha]=L$. Assume that $L<0$, then $Q(E,\mathbf{q})-\alpha<0$ for some $E\in(\lambda_{n-1},\lambda_n)$. Choose some m such that $E_n(\mathbf{q}_{k_m})<E$. Since $Q(\zeta;\mathbf{q})$ increases on the interval $(\lambda_{n-1},\lambda_n)$ as the function of ζ, we obtain a contradiction:

$$0=Q(E_n(\mathbf{q}_{k_m});\mathbf{q}_{k_m})-\alpha<Q(E;\mathbf{q}_{k_m})-\alpha<0\,.$$

Statement (4) can be proven similarly to (3). ■

Let us return to the proof of the proposition. We prove that if a sequence $(\mathbf{p}_k)_{k\in\mathbb{N}}$ from $X_{k-1}\cap X_k$ converges to the point $\mathbf{q}$, then $E_n(\mathbf{p}_k)\to E'$.

Suppose $E_n(\mathbf{p}_k)$ does not converge to E', then there exists a subsequence $(\mathbf{p}_{k_l})$ such that $E_n(\mathbf{p}_{k_l})\to E^*$, $E^*\neq E'$. Assume $E^*<E'$. Taking into account item (2) of Lemma 5 we get $E^*=\lambda_{n-1}$ or $E'=\lambda_n$. In both the cases we have

$$\lim_{\zeta\to E^*}[Q(\zeta;\mathbf{q})-\alpha]\geqslant 0 \quad\text{and}\quad \lim_{\zeta\to E'}[Q(\zeta;\mathbf{q})-\alpha]\leqslant 0.$$

Take some real numbers E_1 and E_2 such that $E^*<E_1<E_2<E'$. Then by the strict monotonicity of $\zeta\mapsto Q(\zeta;\mathbf{q})$ we have

$$0\leqslant Q(E_1;\mathbf{q})-\alpha<Q(E_2,\mathbf{q})-\alpha\leqslant 0\,.$$

This is a contradiction. ■

The following theorem is the main result of this section.

Theorem 2: *For each fixed $\alpha\in\mathbb{R}$ there is a sequence $(E_n(\mathbf{q}))_{n\in\mathbb{N}}$ of continuous functions of $\mathbf{q}\in\mathbb{R}^3$ with the following properties:*

(1) $\lambda_{n-1}\leqslant E_n(\mathbf{q})\leqslant\lambda_n$ *for all* $n\in\mathbb{N}$.
(2) For each $\mathbf{q}\in\mathbb{R}^3$ *the set consisting of all* $E_n(\mathbf{q})$ *and all the numbers* λ_n *with multiplicities* $k_n>1$ *form the complete collection of the eigenvalues of the operator* $H_\alpha(\mathbf{q})$.
(3) If $\lambda_{n-1}<E_n(\mathbf{q})<\lambda_n$, *then* $E_n(\mathbf{q})$ *is a unique solution of the Eq. (9) on the interval* $(\lambda_{n-1},\lambda_n)$.
(4) If $\zeta=\lambda_n$ *is a pole of the function* $\zeta\mapsto Q(\zeta;\mathbf{q})$, *then* $E_{n-1}(\mathbf{q})<\lambda_n<E_n(\mathbf{q})$.
(5) If $\zeta=\lambda_n$ *is not a pole of the function* $\zeta\mapsto Q(\zeta;\mathbf{q})$, *then we have the following assertions:*
(a) if $Q(\lambda_n;\mathbf{q})-\alpha<0$, *then* $E_n(\mathbf{q})=\lambda_n<E_{n+1}(\mathbf{q})$;
(b) if $Q(\lambda_n;\mathbf{q})-\alpha>0$, *then* $E_n(\mathbf{q})<\lambda_n=E_{n+1}(\mathbf{q})$;
(c) if $Q(\lambda_n;\mathbf{q})-\alpha=0$, *then* $E_n(\mathbf{q})=\lambda_n=E_{n+1}(\mathbf{q})$.

Proof: Consider the functions $E_n(\mathbf{q})$ given by Proposition 2. Then (1) is obvious by definition of $E_n(\mathbf{q})$. Assertion (2) follows from Theorem 1. Assertions (3) and (4) were proven in Lemma 5. It remains to prove (5).

Let λ_n be not a pole of $\zeta\mapsto Q(\zeta;\mathbf{q})$. Suppose $Q(\lambda_n;\mathbf{q})-\alpha<0$. For any positive integer m we choose a number E'_m such that $\lambda_n-1/m<E'_m<\lambda_n$; then $Q(E'_m;\mathbf{q})-\alpha<0$. Further, we choose points $\mathbf{q}_m\in\mathbb{R}^3$ such that λ_{n-1} and λ_n are not poles of the function $\zeta\mapsto Q(\zeta;\mathbf{q}_m)$ (that is $\mathbf{q}_m\in X_{m-1}\cap X_m$), and such that $|\mathbf{q}-\mathbf{q}_m|<1/m$ and $Q(E'_m;\mathbf{q}_m)-\alpha<0$. Then $\zeta=E_n(\mathbf{q}_m)$ is a solution

of the equation $Q(\zeta;\mathbf{q}_m)-\alpha=0$ lying in the interval $(\lambda_{n-1},\lambda_n)$. Since $Q(\zeta;\mathbf{q}_m)$ is a strictly monotone function of ζ on this interval, the inequalities $E'_m<E_n(\mathbf{q}_m)<\lambda_n$ take place for all m. Thus $E_n(\mathbf{q}_m)\to\lambda_n$ and $\mathbf{q}_m\to\mathbf{q}$ as $m\to\infty$; therefore, $\lambda_n=E_n(\mathbf{q})$ by the definition of the function $E_n(\mathbf{q})$. According to Lemma 5, $Q(\lambda_n;\mathbf{q})-\alpha\geqslant 0$, if $\lambda_n=E_{n+1}(\mathbf{q})$; therefore $\lambda_n<E_{n+1}(\mathbf{q})$. Hence, item (5a) is proved. The proofs of items (5b) and (5c) are similar. ■

Theorem 2 gives a useful description of the spectrum of H_α. Namely, denote by M the set $\{m\in\mathbb{N}: k_m>1\}$ and together with the functions $E_n(\mathbf{q})$ introduce a sequence of constant functions $\Lambda_m^{(k)}(\mathbf{q})=\lambda_m$, where $m\in M$, $k=1,\ldots,k_m-1$. Then $E_n(\mathbf{q})\leqslant\Lambda_n^{(k)}(\mathbf{q})\leqslant E_{n+1}(\mathbf{q})$ for all $n\in M$, $k=1,\ldots,k_n-1$, and for any fixed $\mathbf{q}\in\mathbb{R}^3$ the union of the sequences $(E_n(\mathbf{q}))_{n\in\mathbb{N}}$ and $(\Lambda_m^{(k)}(\mathbf{q}))_{m\in M,k=1,\ldots,k_m-1}$ forms the complete set of the eigenvalues of $H_\alpha(\mathbf{q})$ multiplicity counting. If $\mathbf{q}\in\cap_{n=0}^{\infty}X_n$, then every $E_n(\mathbf{q})$ is distinct from the numbers $\Lambda_m^{(k)}(\mathbf{q})$. Since $\mathbb{R}\backslash\cap_{n=0}^{\infty}X_n$ is the set of the first Baire category, for a generic $\mathbf{q}$ the point perturbation levels $E_n(\mathbf{q})$ are distinct from the levels of the unperturbed operator H^0.

VI. POINT PERTURBATIONS OF THE HARMONIC OSCILLATOR

Here we apply the results of the previous sections to the Hamiltonian (2) with the potential

$$V(\mathbf{r})=\frac{\mu\Omega_x^2}{2}x^2+\frac{\mu\Omega_y^2}{2}y^2+\frac{\mu\Omega_z^2}{2}z^2\,, \tag{13}$$

where Ω_j $(j=x,y,z)$ are the frequencies of the oscillator. The function V can be considered as a confinement potential of a quantum well in $\mathbb{R}^3$ with the characteristic sizes

$$L_j=\sqrt{\frac{\hbar}{2\mu\Omega_j}},\qquad j=x,y,z$$

(numbers $\sqrt{2}L_j$ are called also *length parameters* of the oscillator[41]). Therefore the operator with potential (13) can be used as the Hamiltonian of a (generally speaking, asymmetric) quantum dot.[1] It is convenient to pass to dimensionless coordinates $\mathbf{x}=\mathbf{r}/L$, where $L=\sqrt[3]{L_xL_yL_z}$. In the coordinates $\mathbf{x}=(x_1,x_2,x_3)$ the operator $\hat{H}^0$ takes the form $\hat{H}^0=\hbar\Omega H^0$, where

$$H^0=-\Delta+\tfrac{1}{4}(\omega_1^2x_1^2+\omega_2^2x_2^2+\omega_3^2x_3^2)\,,$$

$$\Omega=\sqrt[3]{\Omega_x\Omega_y\Omega_z}\,,\quad \omega_1=\frac{\Omega_x}{\Omega},\quad \omega_2=\frac{\Omega_y}{\Omega},\quad \omega_3=\frac{\Omega_z}{\Omega}$$

(hence, $\omega_1\omega_2\omega_3=1$).

Further we discuss the properties of H^0. The spectrum of this operator consists of the eigenvalues

$$\lambda_{n_1n_2n_3}=\omega_1(n_1+1/2)+\omega_2(n_2+1/2)+\omega_3(n_3+1/2)\,,$$

where $n_1,n_2,n_3\in\mathbb{N}$. The corresponding normalized eigenfunctions are

$$\Phi_{n_1n_2n_3}(\mathbf{x})=\varphi_{n_1}(x_1)\varphi_{n_2}(x_2)\varphi_{n_3}(x_3)\,,$$

where

$$\varphi_{n_j}(x_j)=\left(\frac{\omega_j}{2\pi}\right)^{1/4}(2^{n_j}n_j!)^{-1/2}\exp\left(-\frac{1}{4}\omega_jx_j^2\right)H_n\left(\sqrt{\frac{\omega_j}{2}}x_j\right)$$

is the oscillator function [$H_n(x)$ is the Hermite polynomial of degree n].

If the frequencies $\omega_1, \omega_2, \omega_3$ are independent over the ring $\mathbb{Z}$ (this is the generic case), then the spectrum of H^0 is simple; therefore, the multiplicity of the eigenvalues of $H_\alpha(\mathbf{q})$ does not exceed 2 and the part σ_2 of the spectrum $\mathrm{spec}\,(H_\alpha(\mathbf{q}))$ is always empty. On the other hand, since $H_n(0)=0$ if and only if n is odd, $\lambda_{n_1,n_2,n_3} \in \mathrm{spec}(H_\alpha(0))$ if and only if one of the numbers n_j $(j=1,2,3)$ is odd; hence, $\mathrm{spec}(H^0)\backslash\sigma(0)$ is always infinite. In addition, for all $n>0$ the set $\mathbb{R}^3\backslash X_n$ is infinite.

In general case, there are no explicit expressions for the Green functions of the harmonic oscillator in terms of commonly used elementary or special functions. Nevertheless, in a number of cases, the representation of the Green function $G^0(\mathbf{x},\mathbf{y};E)$ as the Laplace transform of the heat kernel $K(\mathbf{x},\mathbf{y};t)$ for H^0 is very useful to investigate some properties of the Krein $\mathcal{Q}$-function. The heat kernel for H^0 has the form (see, e.g., in Ref. 42):

$$K^0(\mathbf{x},\mathbf{y};t)=\prod_{j=1}^{3}\left(\frac{1}{4\pi \mathrm{sh}\omega_j t}\right)^{1/2}\exp\left(-\frac{\omega_j}{4\mathrm{sh}\omega_j t}((x_j^2+y_j^2)\mathrm{ch}\omega_j t-2x_j y_j)\right).$$

Using the heat kernel K^f for the free Hamiltonian $H^f=-\Delta$,

$$K^f(\mathbf{x},\mathbf{y};t)=(4\pi t)^{-3/2}\exp\left(-\frac{(\mathbf{x}-\mathbf{y})^2}{4t}\right),$$

and the $\mathcal{Q}$-function for H_f,

$$Q^f(\zeta)=-\frac{\sqrt{-\zeta}}{4\pi},$$

we get immediately from the formula

$$G(\mathbf{x},\mathbf{y};E)=\int_0^\infty e^{tE}K(\mathbf{x},\mathbf{y};t)\,dt,$$

that for $\mathrm{Re}\,\zeta<(\omega_1+\omega_2+\omega_3)/2$ the following representation of the $\mathcal{Q}$-function for H^0 takes place:

$$Q(\zeta;\mathbf{q})=-\frac{\sqrt{-\zeta}}{4\pi}+\frac{1}{(4\pi)^{3/2}}\int_0^\infty\left(\prod_{j=1}^{3}\left(\frac{1}{\mathrm{sh}\omega_j t}\right)^{1/2}\exp\left(-\frac{1}{2}q_j^2\omega_j\mathrm{th}\frac{\omega_j t}{2}\right)-\frac{1}{t^{3/2}}\right)e^{\zeta t}\,dt. \quad (14)$$

It is clear from (14) that $(\partial Q/\partial q_j)(E;\mathbf{q})<0$ for $q_j>0$, if $E<\lambda_0=(\omega_1+\omega_2+\omega_3)/2$. Since $\partial Q/\partial E>0$ for $E\in\mathbb{R}\backslash\mathrm{spec}\,(H^0)$, (9) implies that $\partial E_0/\partial q_j>0$. In particular, the depth of the lowest impurity level $\lambda_0-E_0(\mathbf{q})$ decreases if $|\mathbf{q}|$ increases in such a way that the inner product $\mathbf{a}\cdot\mathbf{q}$ remains positive for each vector $\mathbf{a}$ with positive coordinates. In the spherically symmetric case $\omega_1=\omega_2=\omega_3$, we have $\partial Q/\partial q<0$, where $q=|\mathbf{q}|>0$, and the depth decreases with increasing of q. This phenomenon was discovered numerically for a spherically symmetric quantum dot in Ref. 14 and called *positional disorder*. We see that the positional disorder is common to each parabolic quantum dot, not only to the spherically symmetric one. The similar result is valid in the two-dimensional case, i.e., for the case of impurities in a quantum well (see numerical results in Ref. 14). Our arguments are valid in the two-dimensional case also, thus we have a strict proof for the positional disorder in a two-dimensional quantum well.

The more detailed analysis is possible in the case of the *isotropic oscillator:* $\Omega_x=\Omega_y=\Omega_z$ $(=\Omega)$, i.e., in the case of a spherically symmetric quantum dot. In this case $\omega_1=\omega_2=\omega_3=1$ and the spectrum of H^0 consists of the eigenvalues

$$\lambda_n=n+\tfrac{3}{2},\quad n\in\mathbb{N},$$

where λ_n has the multiplicity $k_n=(n+1)(n+2)/2$. In this case there are natural units of length (namely, L) and of energy ($\hbar\Omega$). Therefore, the following very important scaling properties takes place. Denote by $\hat{Q}(\zeta;\mathbf{q})$ the Krein $\mathcal{Q}$-function for the operator $\hat{H}^0$ keeping the notation $Q(\zeta;\mathbf{q})$ for the $\mathcal{Q}$-function of H^0. Then

$$\hat{Q}(\zeta;\mathbf{q})=\frac{1}{\hbar\Omega L^3}Q\left(\frac{\zeta}{\hbar\Omega};\frac{\mathbf{q}}{L}\right)=4\pi\frac{\mu}{2\pi\hbar^2 L}Q\left(\frac{\zeta}{\hbar\Omega};\frac{\mathbf{q}}{L}\right).$$

Denote $\mu/(2\pi\hbar^2 L)$ by α^0; obviously, α^0 is strength of the point potential corresponding to the scattering length L. Then Eq. (9) takes the form

$$4\pi Q\left(\frac{\zeta}{\hbar\Omega};\frac{\mathbf{q}}{L}\right)=\frac{\alpha}{\alpha^0}, \tag{15}$$

or, equivalently,

$$4\pi Q\left(\frac{\zeta}{\hbar\Omega};\frac{\mathbf{q}}{L}\right)=\frac{L}{\ell_s}.$$

Equation (15) shows that a change of the frequency Ω does not change the numerical values of energy levels in the spectrum of $\hat{H}^0$ if L is used as the unit of length, $\hbar\Omega$ as the unit of energy and α^0 as the unit of point potential strength.

In the case of isotropic oscillator, the set $\sigma(\mathbf{q})$ has a simple description:

Proposition 3: Let $\Omega_x=\Omega_y=\Omega_z$. *Then* $\sigma(\mathbf{q})=\{\lambda_{2n}: n\in\mathbb{N}\}$, *if* $\mathbf{q}=0$, *and* $\sigma(\mathbf{q})=\mathrm{spec}(H^0)$ *otherwise*.

Proof: Each λ_n is equal to $\lambda_{n_1n_2n_3}$, where $n_1+n_2+n_3=n$. If n is odd, then at least one of n_j is odd, and $\Psi_{n_1n_2n_3}(0)=0$. Therefore, $\lambda_n\notin\sigma(0)$. On the other hand, if n is even, then $\Psi_{n00}(0)\neq 0$, and therefore, $\lambda_n\in\sigma(0)$.

Let now $\mathbf{q}\neq 0$. First we remark that for all $n\in\mathbb{N}$ the following assertion is valid:

Lemma 6: If $H_n(x_0)=0$, *then* $H_{n+1}(x_0)\neq 0$.

Proof of the lemma: For all $n\in\mathbb{N}$ the following relation takes place:[43]

$$H'_{n+1}(x)=2(n+1)H_n(x).$$

If $H_n(x_0)=H_{n+1}(x_0)=0$, then $H'_n(x_0)=0$. Since $y=H_n(x)$ is a solution to the differential equation $y''-2xy'+2ny=0$, we have $H_n(x)=0$ for all x; but this is impossible. ■

Let us return to the proof of the proposition. Suppose that $\mathbf{q}\neq 0$; without loss of generality we can assume $q_2\neq 0$. Since $H_1(x)=0$ only for $x=0$, and $H_0(x)\neq 0$ for all x, we have $\lambda_0,\lambda_1\in\sigma(\mathbf{q})$. Let $n>1$. Suppose that $\Phi_{n-1,1,0}(\mathbf{q})=0$, then according to Lemma 6, $\Phi_{n,0,0}(\mathbf{q})\neq 0$. ■

Using Proposition 3 we can give the complete description of the spectrum $H_\alpha(\mathbf{q})$ in the case of an isotropic H^0. Moreover, in this case the explicit form of the Green function $G^0(\mathbf{x},\mathbf{x}';\zeta)$ is known, and therefore, we can give the explicit form of the Krein $\mathcal{Q}$-function and eigenfunction of $H_\alpha(\mathbf{q})$. In particular, the equation for the point perturbation levels $E_n(\mathbf{q})$ can be obtained in an explicit form. The mentioned Green function has the form[18]

$$G^0(\mathbf{x},\mathbf{y};\zeta)=-\frac{1}{2(2\pi)^{3/2}}\Gamma\left(\frac{1}{2}-\zeta\right)\left[\frac{U(-\zeta;\xi)U'(-\zeta;-\eta)+U'(-\zeta;\xi)U(-\zeta;-\eta)}{|\mathbf{x}-\mathbf{y}|}\right.$$
$$\left.+\frac{U(-\zeta;\xi)U'(-\zeta;-\eta)-U'(-\zeta;\xi)U(-\zeta;-\eta)}{|\mathbf{x}+\mathbf{y}|}\right], \tag{16}$$

where $\xi=(|\mathbf{x}+\mathbf{y}|+|\mathbf{x}-\mathbf{y}|)/2$, $\eta=(|\mathbf{x}+\mathbf{y}|-|\mathbf{x}-\mathbf{y}|)/2$, $U(\nu;z)$ is the parabolic cylinder function[44] (in the Whittaker notation $U(\nu;z)=D_{-\nu-1/2}(z)$), and U' denotes the derivative of U with respect to the second argument

$$U'(\zeta;y)=\frac{\partial}{\partial y}U(\zeta;y)\,.$$

Using (16), we get the following expression for the Q-function:

$$Q(\zeta;\mathbf{q})=-\frac{1}{8(2\pi)^{3/2}}\Gamma\left(\frac{1}{2}-\zeta\right)\Big[(q^2-4\zeta)U(-\zeta,q)U(-\zeta,-q)+4U'(-\zeta,q)U'(-\zeta,-q)$$
$$-\frac{2}{q}(U'(-\zeta,q)U(-\zeta,-q)-U(-\zeta,q)U'(-\zeta,-q))\Big], \tag{17}$$

where $q=|\mathbf{q}|$. Due to the symmetry of the problem, the $\mathcal{Q}$-function depends on q only, so we shall write often $Q(\zeta;q)$ instead of $Q(\zeta;\mathbf{q})$. Introducing the notation $\mathcal{U}(\zeta;y)=U(\zeta;y)U(\zeta;-y)$, we can rewrite (17) in the sometimes more useful form

$$Q(\zeta;\mathbf{q})=-\frac{1}{4(2\pi)^{3/2}}\Gamma\left(\frac{1}{2}-\zeta\right)\left[(q^2-4\zeta)\mathcal{U}(-\zeta;q)-\frac{1}{q}\mathcal{U}'(-\zeta;q)-\mathcal{U}''(-\zeta;q)\right], \tag{18}$$

where the prime denotes the derivative with respect to the second argument as before. Passing to limit we get at $q=0$

$$Q(\zeta;0)=-\frac{1}{\sqrt{8}\pi}\frac{\Gamma\left(\frac{3}{4}-\frac{\zeta}{2}\right)}{\Gamma\left(\frac{1}{4}-\frac{\zeta}{2}\right)}. \tag{19}$$

It is interesting to compare (19) with the Krein $\mathcal{Q}$-function $Q^{(1)}(\zeta;0)$ for the one-dimensional harmonic oscillator:[26]

$$Q^{(1)}(\zeta;0)=2^{-3/2}\frac{\Gamma\left(\frac{1}{4}-\frac{\zeta}{2}\right)}{\Gamma\left(\frac{3}{4}-\frac{\zeta}{2}\right)}.$$

Curiously, in the case of the free Hamiltonian $H^0=-\Delta$, the $\mathcal{Q}$-functions Q_d for $d=1$ and for $d=3$ are also related as follows:

$$Q_1^{-1}(\zeta)=-8\pi Q_3(\zeta)\,. \tag{20}$$

Namely, for the free Hamiltonian $Q_1(\zeta)=(2\sqrt{-\zeta})^{-1}$, $Q_3(\zeta)=-(4\pi)^{-1}\sqrt{-\zeta}$. For $q\neq 0$ relation (20) for $\mathcal{Q}$-functions of the harmonic oscillators is violated.

It is useful to consider the behavior of the function $\zeta\mapsto Q(\zeta;q)$ near the singular points, i.e., near the poles and in a neighborhood of $-\infty$. Using properties of the parabolic cylinder functions,[43] we have

$$Q(\zeta;0)=-\frac{(2n+1)!!}{(2\pi)^{3/2}(2n)!!}\left(\frac{1}{\zeta-\lambda_{2n}}-\ln 2+1-\frac{1}{2}\sum_{k=1}^{n}\frac{1}{k(1+2k)}+O(\zeta-\lambda_{2n})\right),$$

as $\zeta\to\lambda_{2n}$. If $\mathbf{q}\neq 0$, the coefficients for corresponding asymptotics are cumbrous enough, and we give the leading term only:

$$Q(\zeta;q)=-\frac{\exp(-q^2/2)}{(2\pi)^{3/2}2^{n+2}n!}(2(n+1)H_n^2(q/\sqrt{2})+\sqrt{2}(q^{-1}-q)H_n(q/\sqrt{2})H_{n+1}(q/\sqrt{2})$$
$$+H_{n+1}^2(q/\sqrt{2}))(\zeta-\lambda_n)^{-1}+O(1)\,, \tag{21}$$

as $\zeta\to\lambda_n$.

For $\mathrm{Re}\,\zeta\to-\infty$, we have

$$Q(\zeta;q)=-\frac{\sqrt{-\zeta}}{4\pi}\left(1-\frac{q^2}{8}\zeta^{-1}+\frac{8-q^4}{128}\zeta^{-2}+O(\zeta^{-3})\right). \tag{22}$$

It is important to note that the leading term in (22) coincides with the Krein $\mathcal{Q}$-function for the free Hamiltonian $-\Delta$.

Now consider the properties of the function $q\mapsto Q(\zeta;q)$. Since $U(\nu;z)$ is an entire function of z, the function $q\mapsto Q(\zeta;q)$ at $\zeta\notin\mathrm{spec}(H^0)$ can be extended to a real analytic even function on $\mathbb{R}$ [see (18)]. In particular,

$$\frac{\partial}{\partial q}Q(\zeta;0)=0\,.$$

As to the second derivative, we can obtain after some algebra

$$\frac{\partial^2}{\partial q^2}Q(\zeta;0)=\frac{1}{8\sqrt{6}\pi}\left[(4\zeta^2+1)\frac{\Gamma\left(\frac{1}{4}-\frac{\zeta}{2}\right)}{\Gamma\left(\frac{3}{4}-\frac{\zeta}{2}\right)}-8\zeta\frac{\Gamma\left(\frac{3}{4}-\frac{\zeta}{2}\right)}{\Gamma\left(\frac{1}{4}-\frac{\zeta}{2}\right)}\right]. \tag{23}$$

For the fixed $\zeta\in\mathbb{R}\backslash\mathrm{spec}(H^0)$, the asymptotics of Q at $q\to\infty$ is given by

$$Q(\zeta;q)=-\frac{1}{8\pi}\left[q-\frac{2\zeta}{q}-\frac{1+2\zeta^2}{q^3}+O\left(\frac{1}{q^5}\right)\right]. \tag{24}$$

This follows from the asymptotics for $\mathcal{U}(\zeta;q)$ at $q\to\infty$:[45]

$$\mathcal{U}(\zeta;q)=\frac{\sqrt{2\pi}}{\Gamma\left(\frac{1}{2}+\zeta\right)}\left[\frac{1}{X}+O\left(\frac{1}{X^5}\right)\right],$$

where $X=\sqrt{q^2+4\zeta}$.

Further the following formula will be also useful

$$\frac{\partial Q}{\partial\zeta}(\zeta;0)=\frac{1}{4\sqrt{2}\pi}\frac{\Gamma\left(\frac{3}{4}-\frac{\zeta}{2}\right)}{\Gamma\left(\frac{1}{4}-\frac{\zeta}{2}\right)}G\left(\frac{1}{2}-\zeta\right). \tag{25}$$

Here and below we use the standard notations[43]

$$G(z)=\psi\left(\frac{z}{2}+\frac{1}{2}\right)-\psi\left(\frac{z}{2}\right);\qquad \psi(z)=\frac{\Gamma'(z)}{\Gamma(z)}.$$

The plot of the graphs for the function $Q(\zeta;q)$ is shown in Figs. 1 and 2.

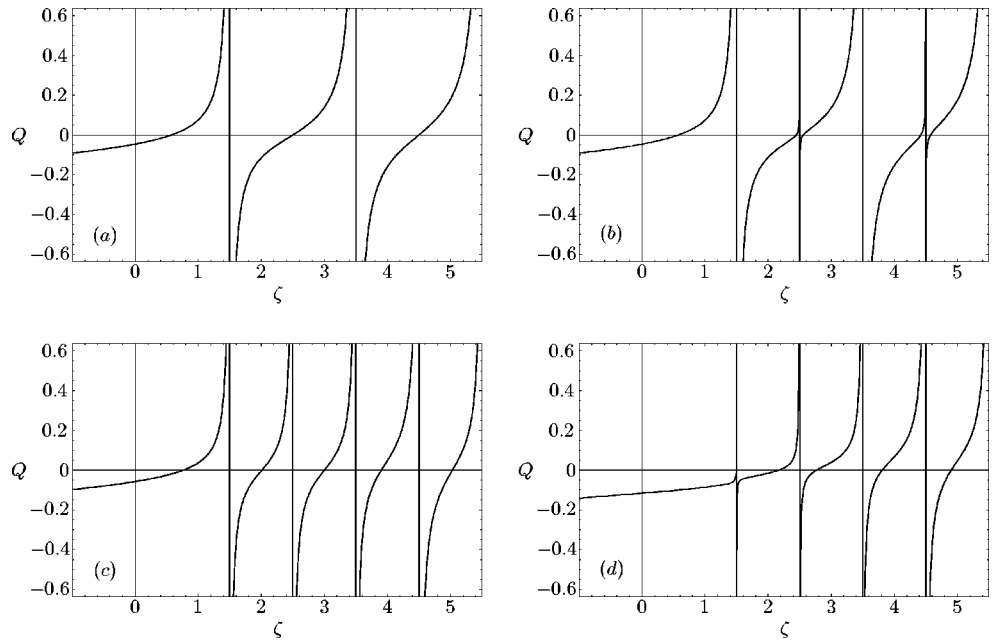

FIG. 1. Q as a function of ζ for (a) $q=0$, (b) $q=1/10$, (c) $q=1$, (d) $q=3$.

In the case of an isotropic oscillator, the functions $E_n(\mathbf{q})$ depend only on q and we will denote them by $E_n(q)$. Further properties of these functions [and, in particular, of the spectrum of $H_\alpha(\mathbf{q})$] for the isotropic case are given in Theorem 3 below, which is one of the main results of the article.

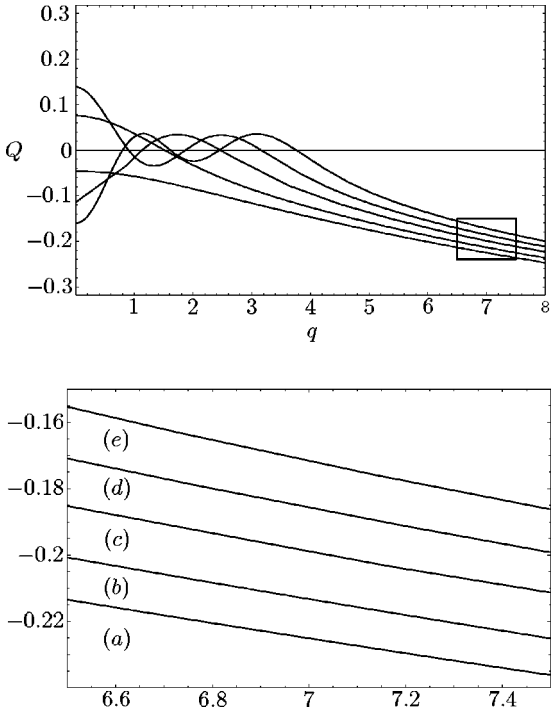

FIG. 2. Q as a function of q for (a) $\zeta=0$, (b) $\zeta=1$, (c) $\zeta=2$, (d) $\zeta=3$, (e) $\zeta=4$.

Theorem 3: *The following assertions take place.*

(1) The functions $E_n(q)$, $n\in\mathbb{N}$ *are real-analytic. If* $\alpha=0$ *and* $n>0$, *then in a vicinity of zero, these functions are continuous branches of a two-valued analytic function.*

(2a) $E_0(0)<\lambda_0$ *for each* α, $\alpha\in\mathbb{R}$.

(2b) If $\alpha>0$, *then* $E_{2n+1}(0)=\lambda_{2n+1}$ *and* $\lambda_{2n+1}<E_{2n+2}(0)<\lambda_{2n+2}\forall n\in\mathbb{N}$.

(2c) If $\alpha<0$, *then* $\lambda_{2n}<E_{2n+1}(0)<\lambda_{2n+2}$ *and* $E_{2n+2}(0)=\lambda_{2n+2}\forall n\in\mathbb{N}$.

(2d) If $\alpha=0$, *then* $E_{2n+1}(0)=E_{2n+2}(0)=\lambda_{2n+1}\forall n\in\mathbb{N}$.

(3a) If $\alpha\neq 0$, *then for any* $n>0$

$$\frac{\partial E_n}{\partial q}(0)=0\,. \tag{26}$$

If $n=0$, *then* (26) *is valid for any* α.

(3b) *If* $\alpha>0$ (*respectively,* $\alpha<0$), *then*

$$\frac{\partial^2 E_n}{\partial q^2}(0)=\frac{1}{8\sqrt{6}G\left(\frac{1}{2}-E_n(0)\right)}\left(\frac{4E_n^2(0)+1}{8\pi^2\alpha^2}-8E_n(0)\right), \tag{27}$$

for any even (respectively, odd) n. *If* $n=0$, *then* (27) *is valid for any* α.

(3c) *If* $\alpha=0$, *then* $(\partial E_{2n+1}/\partial q)(0)<0$, $(\partial E_{2n+2}/\partial q)(0)>0$, *and* $(|(\partial E_{2n+1}/\partial q)(0)|=|(\partial E_{2n+2}/\partial q)(0)|\forall n\in\mathbb{N}$.

(4) *If* $q\neq 0$, *then* $\lambda_{n-1}<E_n(q)<\lambda_n\forall n\in\mathbb{N}$.

(5) $\lim_{q\to\infty}E_n(q)=\lambda_n\forall n\in\mathbb{N}$.

Proof: Item (4) follows immediately from Proposition 3 and the definition of the functions E_n. Formula (19) shows that $Q(\zeta;0)=0$ if and only if $\zeta=\lambda_{2n+1}$ for some $n\in\mathbb{N}$; therefore, items (2a)–(2d) follow from Theorem 2. Using the standard version of the implicit function theorem and the Proposition 3 again, we see that $E_n(q)$ are real analytic at $q>0$. Moreover, item (3) of Theorem 2 implies that (i) $E_n(q)$ are real-analytic at $q=0$ for even n if $\alpha>0$, (ii) $E_n(q)$ are real-analytic at $q=0$ for odd n if $\alpha<0$, and (iii) $E_0(q)$ is real-analytic at $q=0$ for any α. In all these cases, the derivatives of E_n can be found from the equations

$$\frac{\partial Q}{\partial\zeta}\frac{\partial E_n}{\partial q}+\frac{\partial Q}{\partial q}=0\,,$$

$$\frac{\partial Q}{\partial\zeta}\frac{\partial^2 E_n}{\partial q^2}+\frac{\partial^2 Q}{\partial\zeta^2}\left(\frac{\partial E_n}{\partial q}\right)^2+2\frac{\partial^2 Q}{\partial\zeta\partial q}\frac{\partial E_n}{\partial q}+\frac{\partial^2 Q}{\partial q^2}=0. \tag{28}$$

Since $(\partial Q/\partial q)(E;0)=0$ if $E\notin\mathrm{spec}(H^0)$, equation (26) follows from (28) in the considered cases. In virtue of (26), the second derivative of E_n is given by

$$\frac{\partial^2 E_n}{\partial q^2}(0)=-\frac{\partial^2 Q}{\partial q^2}\left(\frac{\partial Q}{\partial\zeta}\right)^{-1}(E_n(0);0). \tag{29}$$

Substituting (23) and (25) into (29) and using (9) we get (27).

Now consider the singular case when $E_n(0)$, $n\geqslant 1$, coincides with a point of the form λ_{2m+1}. In a neighborhood of the point $(E_n(0),0)$, introduce the function

$$\tilde{Q}_\alpha(\zeta;q)=\frac{Q(\zeta;q)-\alpha}{\Gamma\left(\frac{1}{2}-\zeta\right)},$$

which is smooth with respect to (ζ,q) and analytic with respect to the first argument ζ. In a vicinity of $(E_n(0),0)$ we have

$$\tilde{Q}_\alpha(E_n(q);q)=0\,. \tag{30}$$

Further,

$$\frac{\partial\tilde{Q}_\alpha}{\partial\zeta}=\frac{1}{\Gamma(1/2-\zeta)}\,\frac{\partial Q}{\partial\zeta}+(Q-\alpha)\frac{\Gamma'(1/2-\zeta)}{\Gamma^2(1/2-\zeta)}. \tag{31}$$

Since $(\partial Q/\partial\zeta)(\zeta;0)$ is a finite number at $\zeta=\lambda_{2m+1}$ and $\Gamma(1/2-\zeta)$ has a pole at λ_{2m+1}, the first term in (31) vanishes at the point $(\lambda_{2m+1},0)$. The value of the function $\Gamma'(1/2-\zeta)/\Gamma^2(1/2-\zeta)$ at $\zeta=\lambda_{2m+1}$ is a nonzero finite number. Finally, $Q(\lambda_{2m+1},0)=0$; thus $\partial\tilde{Q}_\alpha/\partial q$ vanishes at the point λ_{2m+1} if and only if $\alpha=0$. Therefore, if $\alpha\neq 0$, then each function $E_n(q)$ has an analytic continuation in a neighborhood of the point $q=0$. Since $q\mapsto\tilde{Q}_\alpha(\lambda_{2m+1};q)$ is an even function, we get easily (26).

Let now $\alpha=0$. Then

$$\frac{\partial^2\tilde{Q}_0}{\partial\zeta^2}=\frac{1}{\Gamma(1/2-\zeta)}\,\frac{\partial^2 Q}{\partial\zeta^2}+2\,\frac{\Gamma'(1/2-\zeta)}{\Gamma^2(1/2-\zeta)}\,\frac{\partial Q}{\partial\zeta}-Q\,\frac{\Gamma''(1/2-\zeta)\Gamma(1/2-\zeta)-2\Gamma'^2(1/2-\zeta)}{\Gamma^3(1/2-\zeta)}. \tag{32}$$

It is easy to see that the first and last terms in (32) vanishes at the point $(\lambda_{2m+1},0)$, whereas the second one does not. Therefore, $\partial^2\tilde{Q}_0/\partial\zeta^2\neq 0$ at the point $(\lambda_{2m+1},0)$, and $E_n(q)$ being solutions of (30), are continuous branches a two-valued analytic function in a vicinity of $(\lambda_{2m+1},0)$. Obviously, at the point $(\lambda_{2m+1},0)$ the following relation is valid

$$\frac{\partial^2\tilde{Q}_0}{\partial\zeta^2}\left(\frac{\partial E_n}{\partial q}\right)^2+2\,\frac{\partial^2\tilde{Q}_0}{\partial\zeta\partial q}\,\frac{\partial E_n}{\partial q}+\frac{\partial\tilde{Q}_0}{\partial\zeta}\,\frac{\partial^2 E_n}{\partial q^2}+\frac{\partial^2\tilde{Q}_0}{\partial q^2}=0\,.$$

Since $\partial\tilde{Q}_0/\partial\zeta=0$ at the considered point, we get the quadratic equation for $\partial E_n/\partial q$:

$$\frac{\partial^2\tilde{Q}_0}{\partial\zeta^2}\left(\frac{\partial E_n}{\partial q}\right)^2+\frac{\partial^2\tilde{Q}_0}{\partial q^2}=0\,.$$

As a result, we complete the proof of items (1) and (3c). It remains to prove (5). Fix $n\in\mathbb{N}$ and let ε, $0<\varepsilon<1$, is given. According to (24) we can choose $q_0>0$ such that $Q(\lambda_n-\varepsilon;q)-\alpha<0$ if $q\geqslant q_0$. Since $Q(E_n(q);q)-\alpha=0$ and the function $E\mapsto Q(E;q)$ increases in the interval $\lambda_{n-1}<E<\lambda_n$, we have $E_n(q)>\lambda_n-\varepsilon$ as $q\geqslant q_0$. Moreover, $E_n(q)<\lambda_n$, and the proof is completed. ■

The structure of $\mathrm{spec}(H_\alpha(q))$ given by Theorem 3 is presented in Table I. The peculiarities of this table at $q=0$ can be understood from the point of view the symmetry group of the problem. It is well known that for a generic spherically symmetric potential $V(\mathbf{r})$, the eigenvalues λ of the operator $H^0=-\Delta+V$ are parametrized by three quantum numbers: $\lambda=\lambda_{n_r,l,m}$, where n_r $(n_r=0,1,\ldots)$ is the so called principal (or total) quantum number; l $(l=0,1,\ldots)$ is the orbital quantum number, and m $(m=-l,-l+1,\ldots,l-1,l)$ is the magnetic quantum number. Each eigenvalue $\lambda_{n_r,l,m}$ is degenerate with multiplicity $2l+1$, namely, $\lambda_{n_r,l,m}=\lambda_{n_r,l,m'}$ if $m,m'\in\{-l,-l+1,\ldots,l-1,l\}$. This degeneracy is related to the invariance of H^0 with respect to the rotation group $\mathrm{SO}(3)$: eigensubspaces of H^0 carry an irreducible representation of this group. In general, $\lambda_{n_r,l,m}\neq\lambda_{n_r',l',m'}$ if $n_r\neq n_r'$ or $l\neq l'$. The eigenvalues of an isotropic harmonic oscillator have an additional (so-called accidental) degeneracy: Each eigensubspace L_n is decomposed on the sub-

spaces $L_n^{(l)}$ with angular momentum $l=n,n-2,\ldots,0$ (if n is even) or $l=n,n-2,\ldots,1$ (if n is odd). This accidental degeneracy is related to the invariance of the Hamiltonian H^0 of an isotropic harmonic oscillator with respect to the group $\mathbb{U}(3)$. Indeed,

$$H^0=\sum_{j=1}^{3} a_j^+ a_j+\tfrac{3}{2},$$

where a_j^+ and a_j are standard creation and annihilation operators.[41] Therefore, H^0 is invariant with respect to the transformation

$$a_j\to a_j'=\sum_{j=1}^{3} u_{kj}a_j, \qquad a_j^+\to a'^+_j=\sum_{j=1}^{3} u_{kj}^* a_j^+,$$

where (u_{jk}) is a unitary matrix. If $q=0$, then $H_\alpha(0)$ is a spherically symmetric perturbation of H^0 that violates the $\mathbb{U}(3)$-symmetry. To prove this, we note that operators $a_j^+ a_k$ are generators of the Lie group $\mathfrak{u}(3)$. Therefore, if $H_\alpha(0)$ is invariant with respect to the considered representation of $\mathbb{U}(3)$, we must have $[H_\alpha(0),H^0]=0$. On the other hand it is easy to show that for $\zeta\in\mathbb{C}\backslash\mathbb{R}$ the operator $[R_\alpha(\zeta),R^0(\zeta)]$ has a nonzero integral kernel.

Since point perturbations cannot change states with nonzero angular momentum l (see, e.g., 8), the part σ_2 (at $q=0$) may contain only even eigenvalues λ_{2n} and we see this in Table I. Since all states from L_n have the same parity $(-1)^n$, the isotropic oscillator has no stationary states with a nonzero dipole momentum.[35] On the other hand every eigensubspace of $H_0(0)$ with eigenvalue from σ_4 have an eigenfunction with $l=0$ (this is the eigenfunction from item 4 of Theorem 1). Therefore, point perturbations of an isotropic harmonic oscillator can lead to an appearance of eigenstates with nonzero dipole momentum.

An alternative tool to understand the energy degeneracy of the three-dimensional isotropic oscillator gives the supersymmetry theory.[46–48] We will not dwell here on this approach, nevertheless note that the analysis performed in the cited papers requires a modification in the s-channel only.

The functions E_n depend not only on the position parameter q, but also on the strength α; we will denote these dependencies as $E_n=E_n(q,\alpha)$. If $E(q,\alpha_0)$ coincides with one of the numbers $\mathcal{E}_m$, then in a vicinity of α_0, the function $\alpha\mapsto E_n(q,\alpha)$ is a continuous branch of the inverse function to $E\mapsto Q(E;q)$. It is already known from Proposition 1 that the following limits take place:

$$\lim_{\alpha\to+\infty} E_n(q;\alpha)=\lambda_n, \qquad \lim_{\alpha\to-\infty} E_n(q;\alpha)=\lambda_{n-1},$$

where $\lambda_{-1}=-\infty$. Now we make more precise this behavior. From (22) we get the asymptotics of the function $E_0(q;\alpha)$ for the fixed $q\geqslant 0$ as $\alpha\to-\infty$,

$$E_0(q;\alpha)=-16\pi^2\alpha^2+\frac{q^2}{4}+\frac{1}{128\pi^2\alpha^2}+O\left(\frac{1}{\alpha^4}\right), \tag{33}$$

or in terms of the point perturbation of the initial operator (1)

$$E_0(q;\alpha)=-\frac{\hbar^2}{2\mu l_s^2}+\frac{\mu\Omega^2 q^2}{2}+\frac{\mu\Omega^2 l_s^2}{4}+O(l_s^4), \tag{34}$$

where the scattering length l_s tends to 0. Expression (34) means that up to the infinitely small term $O(l_s^2)$ the ground state of $\hat{H}_\alpha(\mathbf{q})$ equals to the ground state of the point perturbation of the free Hamiltonian $-\hbar^2\Delta/2\mu$ with the same scattering length l_s shifted by the potential $V(\mathbf{r})=\mu\Omega^2\mathbf{r}^2/2$ at the point $\mathbf{r}=\mathbf{q}$. Equation (34) shows that at least for the isotropic harmonic oscillator its potential can be recovered from the dependence of the ground state of the point perturbation on the position of the potential support. It is reasonable to suppose that this is true for more general forms of the potential V; we consider this conjecture elsewhere.

Now consider the behavior of $E_n(q;\alpha)$ in a vicinity of the poles of $Q(\zeta,q)$. We start with the general case $q\neq 0$. Using (21) we get as $\alpha\to\pm\infty$

$$\begin{aligned}E_n(q;\alpha)=\lambda_n^{\pm}-\frac{\exp(-q^2/2)}{(2\pi)^{3/2}2^{n+2}n!}&(2(n+1)H_n^2(q/\sqrt{2})+\sqrt{2}(q^{-1}-q)H_n(q/\sqrt{2})H_{n+1}(q/\sqrt{2})\\&+H_{n+1}^2(q/\sqrt{2}))\alpha^{-1}+O(\alpha^{-2}),\end{aligned} \tag{35}$$

where $\lambda_n^+=\lambda_n$ and $n\geqslant 0$ as $\alpha\to+\infty$, and $\lambda_n^-=\lambda_{n-1}$ and $n\geqslant 1$ as $\alpha\to-\infty$.

In the case $q=0$, we are in position to give a compact form for more precise asymptotics of $E_n(q;\alpha)$. Denote

$$\Lambda_n(\alpha)=\frac{(2n+1)!!}{(2\pi)^{3/2}(2n)!!}\alpha^{-1}-\left(\frac{(2n+1)!!}{(2\pi)^{3/4}(2n)!!}\right)^2\left(\ln 2-1+\frac{1}{2}\sum_{k=1}^{n}\frac{1}{k(1+2k)}\right)\alpha^{-2}.$$

For eigenvalues with even indices we have

$$E_{2n}(0;\alpha)=\begin{cases}\lambda_{2n-1} \text{ for } \alpha\leqslant 0 \text{ and } n\geqslant 1\\ -16\pi^2\alpha^2+\dfrac{1}{128\pi^2}\alpha^{-2}+O(\alpha^{-4}) \text{ for } \alpha\to-\infty \text{ and } n=0\\ \lambda_{2n}-\Lambda_n(\alpha)+O(\alpha^{-3}) \text{ for } \alpha\to+\infty \text{ and } n\geqslant 0.\end{cases} \tag{36}$$

For the odd indices

$$E_{2n+1}(0;\alpha)=\begin{cases}\lambda_{2n+1} \text{ for } \alpha\geqslant 0\\ \lambda_{2n}-\Lambda_n(\alpha)+O(\alpha^{-3}) \text{ for } \alpha\to-\infty.\end{cases} \tag{37}$$

Formulas (35)–(37) explain peculiarities in the plots of functions E_n on Figs. 3 and 4. Note that in Eqs. (33)–(37) the remainder terms depend on n.

The isotropic harmonic oscillator has an equidistant spectrum. After the perturbation by a zero-range potential, the distances between energy levels are changed and become dependent on the energy index n. This is important in the connection with the problem of the controlled modulation of the binding energy of the impurity center in quantum dots, that can be used to design nonlinear opto-electronic active elements.[6] The asymptotic formulas (34)–(37) give very accurate expressions for the excited energies in the most interesting case of a deep zero-range well

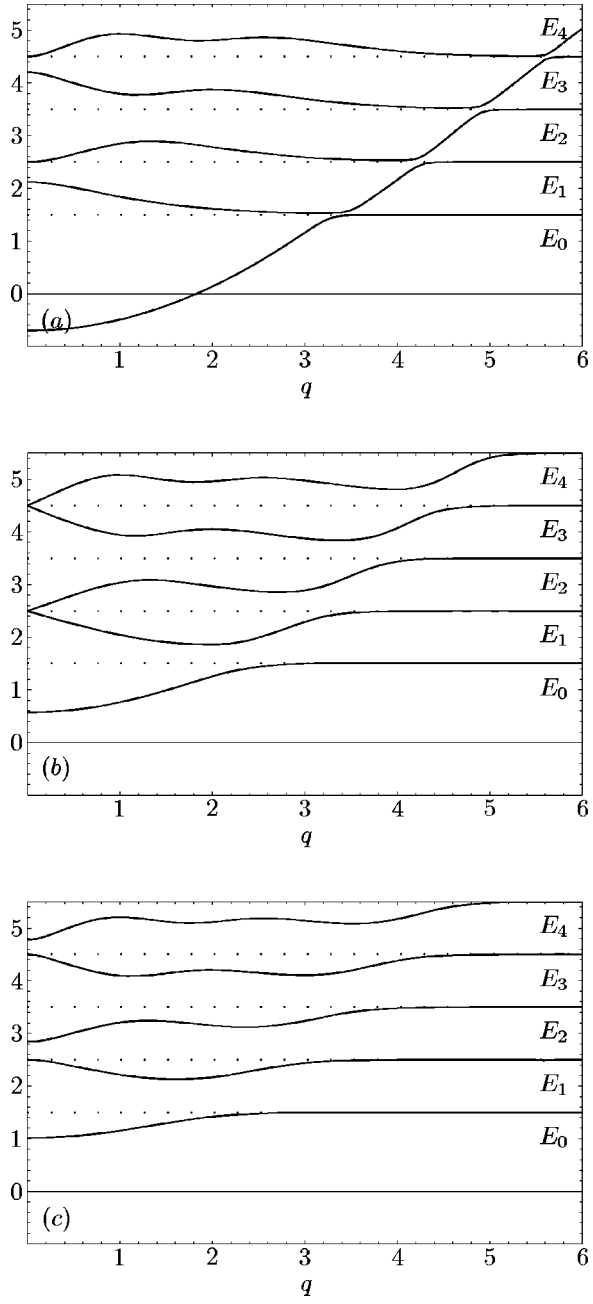

FIG. 3. E_n as a function of q for (a) $\alpha=-\alpha^0$, (b) $\alpha=0$, (c) $\alpha=\alpha^0$.

($\alpha\to-\infty$) as well as for the case of a shallow well ($\alpha\to+\infty$), which confirm numerical results from Ref. 6. Note also that Proposition 1 and Theorem 3 imply a remarkable distinction between the excited energy for the ground state and that for the other ones: The energy $E_1(q;\alpha)-E_0(q;\alpha)$ can take an arbitrary value depending on q and α; on the other hand, energies $\lambda_n-E_n(q;\alpha)$ and $E_{n+1}(q;\alpha)-\lambda_n(n\geqslant 1)$ are bounded by 1. Since at fixed α, $\alpha\ll-1$, the function $q\mapsto E_1(q;\alpha)-E_0(q;\alpha)$ is injective for moderate values of q, the position of an impurity in the quantum dot may be determined from the spectroscopy data.

We show the plot of the energies $E_1(q;\alpha)-E_0(q;\alpha)$ and $\lambda_1-E_1(q;\alpha)$ as functions of q and α on Figs. 5 and 6, respectively.

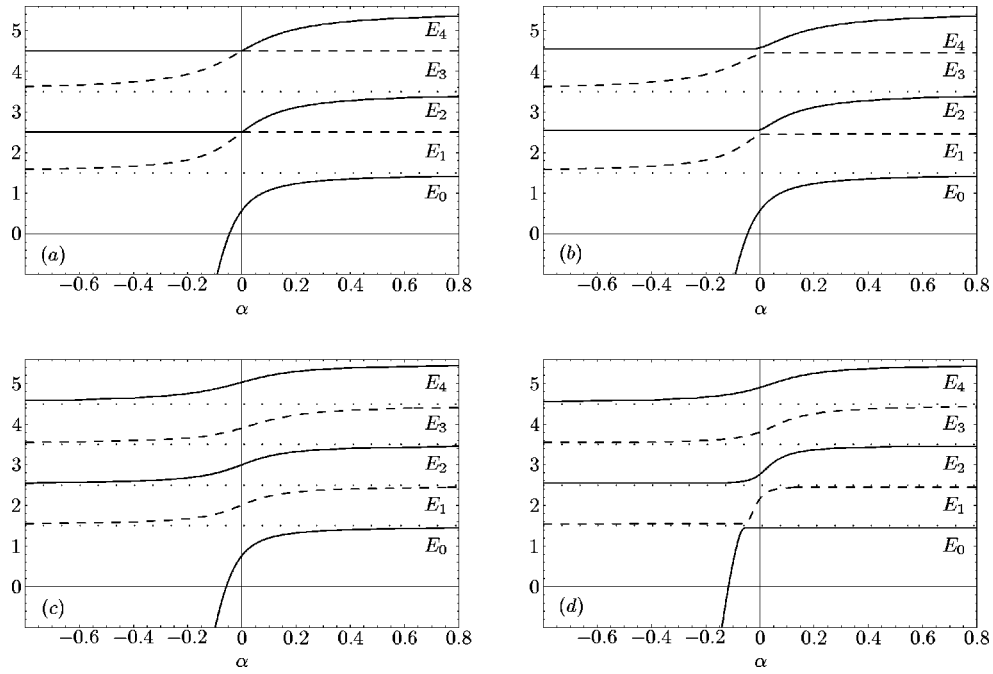

FIG. 4. E_n as a function of α for (a) $q=0$, (b) $q=1/10$, (c) $q=1$, (d) $q=3$.

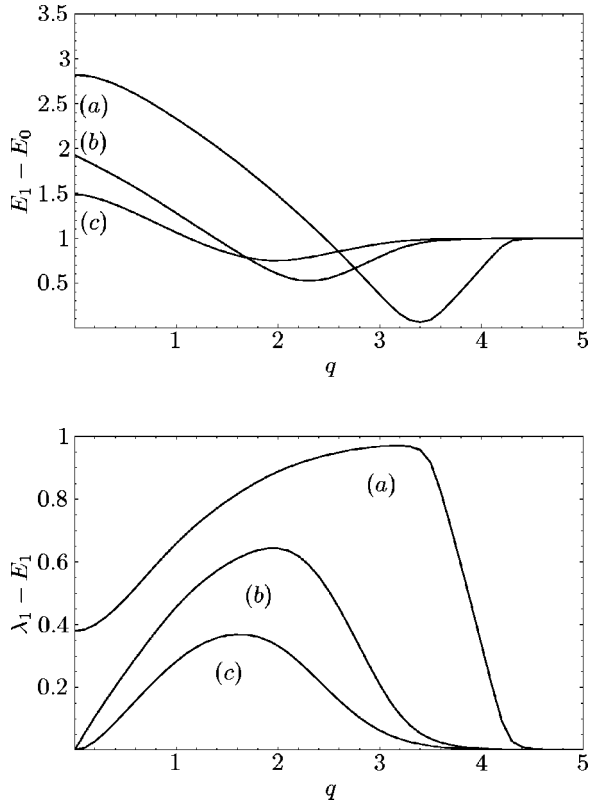

FIG. 5. The exciting energy as a function of q for (a) $\alpha=-\alpha^0$, (b) $\alpha=0$, (c) $\alpha=\alpha^0$.

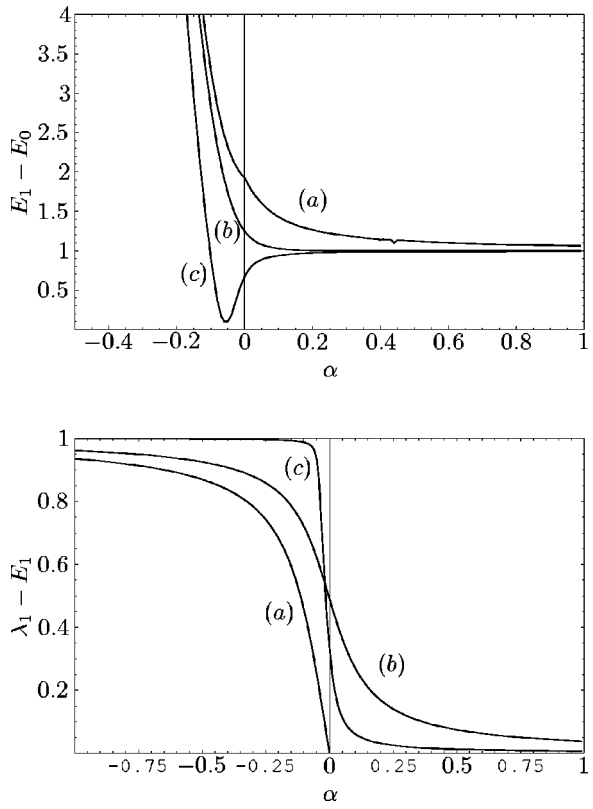

FIG. 6. The exciting energy as a function of α for (a) $q=0$, (b) $q=1$, (c) $q=3$.

In conclusion we give the following remark. Let $q:[0,\infty)\to\mathbb{R}$ be a smooth function obeying the conditions

(H1) $q\geqslant 0$ and the function $r\mapsto q(r)+r^2/4$ is nondecreasing;
(H2) $q'(r)\leqslant 0$, and let κ_0 and κ_1 be the first two eigenvalues of the operator $H^0+q=-\Delta+r^2/4+q(r)$. It is proven in Ref. 49 that $\kappa_0/\kappa_1<\lambda_0/\lambda_1$, if $q\neq 0$. Using Theorems 3 and A it is easy to construct smooth functions q with properties (H1) and
(H2a) $q'(r)\geqslant 0$, such that $\kappa_0/\kappa_1>\lambda_0/\lambda_1$.

(Received 20 November 2002; accepted 19 December 2003)

We consider a simple one-dimensional quantum system consisting of a heavy and a light particle interacting via a point interaction. The initial state is chosen to be a product state, with the heavy particle described by a coherent superposition of two spatially separated wave packets with opposite momentum and the light particle localized in the region between the two wave packets. We characterize the asymptotic dynamics of the system in the limit of small mass ratio, with an explicit control of the error. We derive the corresponding reduced density matrix for the heavy particle and explicitly compute the (partial) decoherence effect for the heavy particle induced by the presence of the light one for a particular set up of the parameters. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1647692]

I. INTRODUCTION

Decoherence has become the terminology for the irreversible suppression of interference of the wave function of a quantum system due to the interaction with an ''environment.'' [7,3] The usual picture of decoherence, in the simple setting of a two particle system, goes as follows. Suppose one has a particle M with initial wave function $\varphi(x)=\varphi_l(x)+\varphi_r(x)$, representing the superposition of two wave packets φ_l, more or less supported ''on the left of the origin'' and heading to the right, and φ_r supported more or less on the ''right of the origin'' with an average velocity pointing to the left. Suppose that another particle m, described initially by the wave packet $\Phi(y)$, passes by and interacts with M. Assuming a small mass ratio between the second and the first particle, it is conceivable that the evolution of M will not be much affected by the interaction, while the scattering process undergone by the particle m will depend strongly on the position of the heavier particle. After interaction (which is assumed to be very fast) one then expects that the wave function describing the state of the system is of the type $\psi(x,y)=\varphi_l(x)\Phi_l(y)+\varphi_r(x)\Phi_r(y)$, where Φ_l and Φ_r will have spatial supports concentrated in distant regions for all later times. Therefore, in the configuration space of the entire system the entangled state will appear as the sum of two disjoint components and the possibility of interference of the heavy particle wave packets will be reduced.

Notice that the reduced density matrix of the particle M has in this ideal case negligible off-diagonal elements. In this sense, interference has been reduced and the motion of the particle M has become more ''classical.'' That is the way decoherence plays a role in the explanation of the emergence of classical behavior from quantum mechanics.

For the relevance of the mechanism of decoherence in the classical limit of Quantum Mechanics in the language of Bohmian Mechanics see Ref. 1.

In this respect it is an interesting problem to separate ''pure decoherence'' from the other

[a)]Electronic mail: duerr@mathematik.uni-muenchen.de
[b)]Electronic mail: figari@na.infn.it
[c)]Electronic mail: teta@univaq.it

effects which an environment usually produces, which are dissipation and fluctuation. That is, one would like to have the motion of the system not much affected by the interaction with the environment, while the environment produces decoherence. It is unclear whether these desiderata, namely a good decoherence rate and a more or less unperturbed motion can be consistently fulfilled in realistic physical models.[6]

Explicit models where one can rigorously establish decoherence in this sense have been worked out in the last years. One such model has been studied in Ref. 4 where the interaction of a particle with the radiation field has been considered. We shall now study another interaction which elaborates closer the idea of scattering of light particles (the environment) off a heavy particle (the system) (see Refs. 8, 5, and 11 for similar ideas).

We consider a very simple one-dimensional model of a system (a heavy particle of mass M) plus environment (one light particle of mass m) interacting via a short range force (δ-interaction). We consider this case as useful preparation for the treatment of a three-dimensional gas of light particles interacting with the heavy particle, which we shall address in subsequent work.

We wish to stress some features that make the two-particle model with δ-interaction (which has the advantage of being analytically easily accessible) particularly suitable as a model for decoherence:

(1) There exists a simple dimensionless parameter in the problem, namely the fraction of the masses $\epsilon = m/M$;
(2) letting ϵ become small while keeping M fixed allows to approximate the solution of the Schrödinger equation of the two body problem by a scattering solution in which the heavy particle acts as a scattering center for the light one. The error is $\mathcal{O}(\epsilon)$. The time scale on which this approximation holds is of course given by the time the light particle needs to pass the heavy particle. This approximation is the starting point of the analysis in Ref. 8;
(3) the decoherence effect (i.e., the amount by which the off diagonal elements of the reduced density matrix are reduced) can be explicitely computed [see (3.20) and the discussion following it] and is, in the relevant regime, of the order of $\alpha_0 m \hbar^{-2} \delta$, where δ is the initial spread of the light particle and α_0 is the strength of the potential [$(\alpha_0 m)^{-1}\hbar 2$ is the effective range of interaction] all of which can also be chosen ϵ-dependent.

We wish to warn the reader that the point interaction we look at here in form of the δ-potential is for finite α_0 not a hard core interaction. The case $\alpha_0 \to \infty$ corresponds to hard core.

The paper is organized as follows.

In Sec. II we introduce the model and characterize the asymptotic dynamics of the two-particle system for small mass ratio and state the main approximation result.

In Sec. III we show the attenuation of the off-diagonal terms in the reduced density matrix for the heavy particle and we compute explicitly the probability distribution for the position of the heavy particle, showing reduction of the interference effects with respect to the noninteracting case.

In Sec. IV we give the proof of the main result of the paper.

In the Appendix we recall the derivation of the explicit solution of the Schrödinger equation of the two-body system in interaction via a delta potential in dimension one.

II. EXPRESSION FOR SMALL MASS RATIO

In this section we shall study the Schrödinger equation for the two-particle system in one dimension described by the Hamiltonian

$$H = -\frac{\hbar^2}{2M}\Delta_R - \frac{\hbar^2}{2m}\Delta_r + \alpha_0 \delta(r-R), \quad \alpha_0 > 0. \tag{2.1}$$

In (2.1) we have denoted by R the position coordinate of the heavy particle with mass M and by r the position coordinate of the light particle with mass m. The interaction potential is chosen to be a repulsive point interaction of strenth α_0.

It is well known that (2.1) is a well defined positive and self-adjoint operator in $L^2(\mathbb{R}^2,drdR)$, which is also a solvable model.[2]

In fact, for an arbitrary initial state $\psi_0=\psi_0(r,R)$, the solution of the Schrödinger equation can be explicitely written as (see Ref. 10 and the Appendix)

$$\psi(t,r,R)=\int dr'dR'\,\psi_0(r',R')U_0^{\nu}\left(t,\frac{M}{\nu}(R-R')+\frac{\mu}{M}(r-r')\right)\cdot\left[U_0^{\mu}(t,(r-R)-(r'-R'))-\frac{\mu\alpha_0}{\hbar^2}\int_0^{\infty}du e^{-(\mu\alpha_0/\hbar^2)u}U_0^{\mu}(t,u+|r-R|+|r'-R'|)\right], \tag{2.2}$$

where we have introduced the reduced mass and the total mass of the system

$$\mu=\frac{mM}{m+M},\qquad \nu=m+M, \tag{2.3}$$

and the integral kernel of the free unitary group $U_0^{\mathcal{M}}(t)$ corresponding to the mass $\mathcal{M}>0$

$$U_0^{\mathcal{M}}(t,x-x')=e^{-i(t/\hbar)H_0^{\mathcal{M}}}(x-x')=\sqrt{\frac{\mathcal{M}}{2\pi i\hbar t}}e^{i(\mathcal{M}/2\hbar t)(x-x')^2},\qquad x,x'\in\mathbb{R}. \tag{2.4}$$

We are interested in the case of an initial state in a product form. Then we fix two real valued smooth functions (for ease of formulation we assume that they are in Schwartz space $\mathcal{S}$)

$$f,g\in\mathcal{S},\qquad \|f\|=\|g\|=1, \tag{2.5}$$

where $\|\cdot\|$ denotes the norm in $L^2(\mathbb{R})$. For later use, it will be convenient to choose g even. Using f and g we define now the states in such a way that we can easily read of the relevant physical scales, i.e., we code the states by the physical parameters $R_0,P_0,\sigma,r_0,q_0,\delta$ as follows:

$$f_{\sigma,R_0,P_0}(R)=\frac{1}{\sqrt{2}}[f^{+}_{\sigma,R_0,P_0}(R)+f^{-}_{\sigma,R_0,P_0}(R)], \tag{2.6}$$

$$f^{\pm}_{\sigma,R_0,P_0}(R)=\frac{1}{\sqrt{\sigma}}f\left(\frac{R\pm R_0}{\sigma}\right)e^{\pm i(P_0/\hbar)R}, \tag{2.7}$$

$$g_{\delta,r_0,q_0}(r)=\frac{1}{\sqrt{\delta}}g\left(\frac{r-r_0}{\delta}\right)e^{i(q_0/\hbar)r}, \tag{2.8}$$

$$\sigma,\delta,R_0,P_0,q_0>0,\quad r_0\in\mathbb{R},\qquad R_0>\sigma+\delta+|r_0|. \tag{2.9}$$

The choice (2.9) is not essential for the most part of the paper, but it sets already a geometrical picture which puts the results in the right perspective [see below (2.10)]. Later on we shall use this particular choice for computing effects. Note that the spread of the wave function of M is not given by σ but by R_0.

The initial state that we consider in the following is

$$\psi_0(r,R)=g_{\delta,r_0,q_0}(r)f_{\sigma,R_0,P_0}(R). \tag{2.10}$$

The initial state (2.10) is a (pure) product state for the whole system, i.e., no correlation is assumed between the two particles at time zero.

The heavy particle is assumed to be in a superposition of two spatially separated wave packets, one localized in $R=-R_0$ with mean value of the momentum P_0 and the other localized in $R=R_0$ with mean value of the momentum $-P_0$. The light particle is localized around r_0, in the region between the two wave packets, with positive mean momentum q_0.

To simplify the notation, in the rest of the paper we shall drop the dependence of the initial state on R_0, P_0, r_0, q_0. Moreover, for the convenience of the reader, we collect here some notation which will be used later on

$$\epsilon=\frac{m}{M}, \qquad \mu=\frac{\epsilon}{1+\epsilon}M, \qquad \nu=(1+\epsilon)M, \tag{2.11}$$

$$\alpha=\frac{\alpha_0 m}{\hbar^2}, \tag{2.12}$$

$$k_0=\frac{q_0}{\hbar}, \qquad K=\frac{P_0}{\hbar}+k_0, \tag{2.13}$$

$$T \;:\; L^2(\mathbb{R}^2, dr dR)\to L^2(\mathbb{R}^2, dx_1 dx_2),$$

$$(Th)(x_1,x_2)\equiv h\left(x_2+\frac{M}{m+M}x_1, x_2-\frac{m}{m+M}x_1\right), \tag{2.14}$$

$$\Delta^{\pm}=(\pm R_0-\sigma, \pm R_0+\sigma), \tag{2.15}$$

and finally c will denote a positive numerical constant.

We shall now characterize the asymptotic behavior of the wave function for small value of the mass ratio ϵ for the initial state (2.10). Letting m become small, keeping M fixed, the light particle moves with speed at least $v\sim\hbar/\delta m$ due to the uncertainty principle and the time by which the light particle passes M is of the order of R_0/v thus decreases with m, so that M does not change much its position during the passing of m.

The limit dynamics will hence describe a situation in which the light particle is scattered by the heavy one being in some fixed position, while the heavy particle moves freely. Nevertheless, we shall find that the free motion of the heavy particle is modified by the scattering event. In this heuristic argument we kept all the other physical parameters fixed except for the interaction strength. In fact, in order to keep the interaction effective on the light particle we need to scale α_0 in such a way that $\alpha_0 m\approx\mathcal{O}(1)$. There is of course no need to keep the other parameters fixed, in fact one may well imagine δ and R_0 increasing with m, so that the kinetic energy of m stays finite and the spread of the M increases. We shall not discuss such choices here, but the estimates are detailed enough, so that other scalings can be easily discussed. This might become relevant in a model where the heavy particle is immersed in a gas of light particles. In order to formulate the main result of this section, we define the integral operator

$$(W_+^{\gamma,x_0}h)(k)=\frac{1}{\sqrt{2\pi}}\int dx h(x)(e^{-ikx}+\mathcal{R}_\gamma(k)e^{-ix_0k}e^{i|k||x-x_0|}), \qquad \gamma>0,\ x_0\in\mathbb{R}, \tag{2.16}$$

$$\mathcal{R}_\gamma(k)=-\frac{\gamma}{\gamma-i|k|}, \tag{2.17}$$

where the integral kernel in (2.16) is the generalized eigenfunction of the Hamiltonian

$$H_{\gamma,x_0} = -\tfrac{1}{2}\Delta + \gamma\delta(\cdot - x_0), \tag{2.18}$$

and $\mathcal{R}_\gamma(k)$ is the corresponding reflection coefficient (see e.g., Ref. 2). Moreover we introduce the wave operator Ω_+^{γ,x_0} associated to H_{γ,x_0}, explicitly given by

$$(\Omega_+^{\gamma,x_0}h)(x) = [(W_+^{\gamma,x_0})^{-1}\tilde{h}](x), \tag{2.19}$$

where $\tilde{h}$ denotes the Fourier transform of h.

With the above notation the asymptotic wave function, which will be denoted by $\psi^a(t)$, is explicitely characterized in the following theorem.

Theorem 1: *Let $\sigma_1>0$, $\delta_1>0$, $\alpha_1>0$, $k_1<\infty$ and let the initial state be given by (2.10) with $\sigma\geqslant\sigma_1$, $\delta\geqslant\delta_1$, $\alpha\geqslant\alpha_1$, $k_0\leqslant k_1$.*

Then for any $t>0$ there exist time independent constants A, B such that

$$\|\psi(t)-\psi^a(t)\| < \left(\frac{A}{t}+B\right)\epsilon, \tag{2.20}$$

where

$$\begin{aligned}\psi^a(t,r,R) &= \sqrt{\frac{m}{i\hbar t}}\,e^{i(m/2\hbar t)\,r^2}\int dy\, f_\sigma(y)U_0^M(t,R-y)(W_+^{\alpha,y}g_\delta)\left(\frac{mr}{\hbar t}\right)\\ &= \sqrt{\frac{m}{i\hbar t}}\,e^{i(m/2\hbar t)\,r^2}\int dy\, f_\sigma(y)U_0^M(t,R-y)[(\Omega_+^{\alpha,y})^{-1}g_\delta]\left(\frac{mr}{\hbar t}\right).\end{aligned} \tag{2.21}$$

Remark 1: Note that $\psi^a(t,r,R)$ is close to what we described in the introduction. Think of f_σ as consisting of two well concentrated wave packets, then the light particle scattered wave function is correlated with the two average positions of the heavy particles, as one can see observing that the integration variable y in $[(\Omega_+^{\alpha,y})^{-1}g_\delta]$ appears as a scattering center.

The result of theorem 1 can be rephrased in terms of reduced density matrix for the heavy particle, which is defined by the integral operator $\hat{\rho}(t)$ in $L^2(\mathbb{R})$ given by the kernel

$$\hat{\rho}(t,R,R') = \int dr\,\psi(t,r,R)\overline{\psi}(t,r,R'). \tag{2.22}$$

We also introduce the integral operator $\hat{\rho}^a(t)$ defined by

$$\begin{aligned}\hat{\rho}^a(t,R,R') &= \int dr\,\psi^a(t,r,R)\overline{\psi^a}(t,r,R')\\ &= \int dy\, f_\sigma(y)U_0^M(t,R-y)\int dz\,\overline{f_\sigma}(z)\overline{U_0^M}(t,R'-z)\mathcal{I}(y,z),\end{aligned} \tag{2.23}$$

where

$$\mathcal{I}(y,z) \equiv \int dk\,(W_+^{\alpha,y}g_\delta)(k)\overline{(W_+^{\alpha,z}g_\delta)}(k) = ((\Omega_+^{\alpha,z})^{-1}g_\delta,(\Omega_+^{\alpha,y})^{-1}g_\delta). \tag{2.24}$$

Formula (2.24), obtained through heuristic considerations, has been the main ingredient in the description of scattering induced decoherence in Ref. 8.

Observe that, from (2.23) and (2.24) one has

$$\hat{\rho}^a(t) = U_0^M(t)\hat{\rho}_0^a U_0^M(-t), \tag{2.25}$$

where $\hat{\rho}_0^a$ is defined by the integral kernel

$$\hat{\rho}_0^a(y,z)=f_\sigma(y)\overline{f_\sigma}(z)\mathcal{I}(y,z). \tag{2.26}$$

It is easily seen that $\mathcal{I}(y,z)=\overline{\mathcal{I}}(z,y)$, $|\mathcal{I}(y,z)|\leqslant 1$ and the equality holds only if $y=z$. Then $\hat{\rho}_0^a$ is a self-adjoint and trace-class operator, with $Tr(\hat{\rho}_0^a)=1$; it is also positive since

$$\begin{aligned}(h,\hat{\rho}_0^a h)&=\int dy\overline{h}(y)\int dz h(z)f_\sigma(y)\overline{f_\sigma}(z)\int dk(W^{\alpha,y}g_\delta)(k)\overline{(W^{\alpha,z}g_\delta)}(k)\\&=\int dk\left|\int dy\overline{h}(y)f_\sigma(y)(W^{\alpha,y}g_\delta)(k)\right|^2.\end{aligned} \tag{2.27}$$

Moreover we have

$$Tr((\hat{\rho}_0^a)^2)=\int dydz|f_\sigma(y)|^2|f_\sigma(z)|^2|\mathcal{I}(y,z)|^2<1. \tag{2.28}$$

We conclude that $\hat{\rho}_0^a$ and its free evolution $\hat{\rho}^a(t)$ are density matrices describing mixture states and by Theorem 1, for any $t>0$, one has

$$Tr(|\hat{\rho}(t)-\hat{\rho}^a(t)|)<\left(\frac{A}{t}+B\right)\epsilon. \tag{2.29}$$

This means that in our asymptotic regime the motion of the heavy particle is a free evolution. On the other hand, the presence of the light particle has a relevant effect, since it produces a transition of the initial state of the heavy particle from $\hat{\rho}_0(y,z)=f_\sigma(y)\overline{f_\sigma}(z)$ to $\hat{\rho}_0^a(y,z)$. We shall see in the next section that this is the origin of the decoherence effect on the heavy particle.

Finally, it is worth to mention that the dynamics of the system can be equivalently described by the Wigner function. From (2.23) and (2.24) we see that the asymptotic form of the reduced Wigner function describing the motion of the heavy particle is the free evolution of

$$\hat{W}_0^a(R,P)=\frac{1}{2\pi}\int dxe^{iPx}f_\sigma\left(R-\frac{\hbar}{2}x\right)\overline{f_\sigma}\left(R+\frac{\hbar}{2}x\right)\mathcal{I}\left(R-\frac{\hbar}{2}x,R+\frac{\hbar}{2}x\right). \tag{2.30}$$

III. SIZE OF DECOHERENCE

Here we discuss an application of formulas (2.23) and (2.24) to a concrete example of quantum evolution and we give an explicit computation of the decoherence effect.

We shall consider the initial state (2.10) with the further assumptions (which are only done for ease of presentation)

$$f,g\in C_0^\infty(-1,+1) \tag{3.1}$$

and

$$\sigma \ll \frac{1}{\alpha} \ll R_0-|r_0|, \qquad \delta \ll R_0-|r_0|, \tag{3.2}$$

i.e., the spreading in position of the wave packets (which are superposed in a gross superposition) of the heavy particle is much smaller than the effective range of the interaction and this, in turn, is much smaller than the separation between the two particles. Moreover the light particle is well separated from each wave packet of the heavy one.

Notice that (3.2) obviously implies $\sigma/R_0\ll 1$.

Using assumptions (3.2) we can give an estimate of the basic object $\mathcal{I}(y,z)$ for $y,z\in\Delta^{\pm}$ and then we can find a more suitable expression for the reduced density matrix of the heavy particle. In order to formulate the result, we define the parameter

$$\Lambda=\int dk|\tilde{g}_{\delta}(k)|^2\mathcal{T}_{\alpha}(k)=1+\int dk|\tilde{g}_{\delta}(k)|^2\mathcal{R}_{\alpha}(k), \tag{3.3}$$

where

$$\mathcal{T}_{\gamma}(k)=-\frac{ik}{\gamma-ik}=1+\mathcal{R}_{\gamma}(k), \qquad \gamma>0, \tag{3.4}$$

is the transmission coefficient associated to a point interaction of strength γ (see e.g., Ref. 2). Then we have

Proposition 2: Assume (3.2). Then

$$\sup_{y,z\in\Delta^{\pm}}|\mathcal{I}(y,z)-1|<c\left(\alpha\sigma+\frac{1}{\alpha(R_0-|r_0|)}+\frac{\delta}{R_0-|r_0|}\right), \tag{3.5}$$

$$\sup_{y\in\Delta^{+},z\in\Delta^{-}}|\mathcal{I}(y,z)-\Lambda|=\sup_{y\in\Delta^{-},z\in\Delta^{+}}|\mathcal{I}(y,z)-\overline{\Lambda}|<c\left(\frac{1}{\alpha(R_0-|r_0|)}+\frac{\delta}{R_0-|r_0|}\right). \tag{3.6}$$

Proof: Using the shorthand notation $\beta=\alpha\delta$, we note that for $y\in\Delta^{-}$

$$\frac{1}{\sqrt{\delta}}(W_{+}^{\alpha,y}g_{\delta})\left(\frac{k}{\delta}\right)=e^{i(k_0\delta-k)r_0/\delta}\tilde{g}(k-k_0\delta)+\mathcal{R}_{\beta}(k)e^{i(k_0\delta+|k|)\,r_0/\delta-i(k+|k|)\,y/\delta}\tilde{g}(|k|+k_0\delta), \tag{3.7}$$

and for $y\in\Delta^{+}$

$$\frac{1}{\sqrt{\delta}}(W_{+}^{\alpha,y}g_{\delta})\left(\frac{k}{\delta}\right)=e^{i(k_0\delta-k)r_0/\delta}\tilde{g}(k-k_0\delta)+\mathcal{R}_{\beta}(k)e^{i(k_0\delta-|k|)\,r_0/\delta-i(k-|k|)\,y/\delta}\tilde{g}(|k|-k_0\delta), \tag{3.8}$$

where we have used the fact that

$$\tilde{g}_{\delta}(k)=\sqrt{\delta}\tilde{g}(k\delta-k_0\delta)e^{-i(k-k_0)r_0}. \tag{3.9}$$

Then for $y,z\in\Delta^{-}$ we have

$$\begin{aligned}\mathcal{I}(y,z)&=1+\int dk|\tilde{g}(|k|+k_0\delta)|^2|\mathcal{R}_{\beta}(k)|^2e^{-i(k+|k|)\,(y-z)/\delta}+\int dk\bar{\tilde{g}}(k-k_0\delta)\tilde{g}(|k|+k_0\delta)\mathcal{R}_{\beta}\\&\quad\times(k)e^{i(k+|k|)\,(r_0-y)/\delta}+\int dk\bar{\tilde{g}}(|k|+k_0\delta)\tilde{g}(k-k_0\delta)\overline{\mathcal{R}_{\beta}}(k)e^{-i(k+|k|)\,(r_0-z)/\delta}\\&=1+\int_0^{\infty}dk|\tilde{g}(k+k_0\delta)|^2|\mathcal{R}_{\beta}(k)|^2(e^{-2ik\,(y-z)/\delta}-1)+\int_0^{\infty}dk\bar{\tilde{g}}(k-k_0\delta)\tilde{g}(k+k_0\delta)\\&\quad\times\mathcal{R}_{\beta}(k)e^{2ik\,(r_0-y)/\delta}+\int_0^{\infty}dk\bar{\tilde{g}}(k+k_0\delta)\tilde{g}(k-k_0\delta)\overline{\mathcal{R}_{\beta}}(k)e^{-2ik\,(r_0-z)/\delta}\\&\equiv1+a_1+a_2+a_3,\end{aligned} \tag{3.10}$$

where we have used the identity $\mathcal{R}_\beta+\overline{\mathcal{R}_\beta}+2|\mathcal{R}_\beta|^2=0$ and the fact that $\tilde{g}$ is even.

Using (3.2) we easily estimate a_1

$$|a_1|\leqslant 2\,\frac{|y-z|}{\delta}\int_0^\infty dk|\tilde{g}(k+k_0\delta)|^2k|\mathcal{R}_\beta(k)|^2\leqslant 4\,\frac{\sigma}{\delta}\int_0^\infty dk|\tilde{g}(k+k_0\delta)|^2k|\mathcal{R}_\beta(k)|^2\leqslant 2\ \ \alpha\sigma. \tag{3.11}$$

For the estimate of a_2 it is convenient to integrate by parts

$$\begin{aligned}
|a_2|&=\left|\frac{1}{2i}\,\frac{\delta}{r_0-y}\int_0^\infty dk\bar{\tilde{g}}(k-k_0\delta)\tilde{g}(k+k_0\delta)\mathcal{R}_\beta(k)\,\frac{d}{dk}e^{2ik(r_0-y)/\delta}\right|\\
&=\frac{\delta}{2|r_0-y|}\left|\int_0^\infty dk\,\frac{d}{dk}(\bar{\tilde{g}}(k-k_0\delta)\tilde{g}(k+k_0\delta)\mathcal{R}_\beta(k))e^{2ik\,(r_0-y)/\delta}-|\tilde{g}(k_0\delta)|^2\right|\\
&\leqslant\frac{\delta}{R_0-|r_0|}\left[\frac{1}{2\pi}\left(\int dr|g(r)|\right)^2+\frac{1}{\beta}\int_0^\infty dk|\bar{\tilde{g}}(k-k_0\delta)\tilde{g}(k+k_0\delta)|\right.\\
&\quad\left.+\int_0^\infty dk|\bar{\tilde{g}}'(k-k_0\delta)\tilde{g}(k+k_0\delta)|+\int_0^\infty dk|\bar{\tilde{g}}(k-k_0\delta)\tilde{g}'(k+k_0\delta)|\right]\\
&\leqslant\frac{\delta}{R_0-|r_0|}\left[\frac{1}{2\pi}\left(\int dr|g(r)|\right)^2+\frac{1}{\beta}\|g\|^2+2\|\tilde{g}'\|\right]\\
&\leqslant\frac{\delta}{R_0-|r_0|}\left(\frac{1}{\pi}+2\|\tilde{g}'\|\right)+\frac{1}{\alpha(R_0-|r_0|)}.
\end{aligned}\tag{3.12}$$

The term a_3 is analyzed exacly in the same way and then we get the estimate (3.5) for $y,z\in\Delta^-$. Since in the case $y,z\in\Delta^+$ the computation is similar we conclude that (3.5) holds.

In order to prove (3.6) we consider the case $y\in\Delta^+$ and $z\in\Delta^-$ (the case $y\in\Delta^-$ and $z\in\Delta^+$ can be treated exactly in the same way) and we obtain

$$\begin{aligned}
\mathcal{I}(y,z)&=1+\int dk\bar{\tilde{g}}(|k|+k_0\delta)\tilde{g}(|k|-k_0\delta)|\mathcal{R}_\beta(k)|^2e^{-2i|k|\,r_0/\delta+i(|k|-k)\,y/\delta+i(|k|+k)\,z/\delta}\\
&\quad+\int dk\bar{\tilde{g}}(k-k_0\delta)\tilde{g}(|k|-k_0\delta)\mathcal{R}_\beta(k)e^{-i(|k|-k)\,(r_0-y)/\delta}\\
&\quad+\int dk\bar{\tilde{g}}(|k|+k_0\delta)\tilde{g}(k-k_0\delta)\overline{\mathcal{R}_\beta}(k)e^{-i(|k|+k)\,(r_0-z)/\delta}\\
&=1+\int_0^\infty dk(|\tilde{g}(k-k_0\delta)|^2\mathcal{R}_\beta(k)+|\tilde{g}(k+k_0\delta)|^2\overline{\mathcal{R}_\beta}(k))\\
&\quad+\int_0^\infty dk\bar{\tilde{g}}(k+k_0\delta)\tilde{g}(k-k_0\delta)|\mathcal{R}_\beta(k)|^2e^{-2ik\,(r_0-z)/\delta}\\
&\quad+\int_0^\infty dk\bar{\tilde{g}}(k+k_0\delta)\tilde{g}(k-k_0\delta)\overline{\mathcal{R}_\beta}(k)e^{-2ik(r_0-z)/\delta}\\
&\quad+\int_0^\infty dk\bar{\tilde{g}}(k+k_0\delta)\tilde{g}(k-k_0\delta)|\mathcal{R}_\beta(k)|^2e^{-2ik\,(r_0-y)/\delta}\\
&\quad+\int_0^\infty dk\bar{\tilde{g}}(k+k_0\delta)\tilde{g}(k-k_0\delta)\mathcal{R}_\beta(k)e^{-2ik(r_0-y)/\delta}.
\end{aligned}\tag{3.13}$$

The estimate of the last four terms of (3.13) proceeds exactly as the estimate of a_2 in (3.12). On the other hand,

$$1+\int_0^\infty dk(|\tilde{g}(k-k_0\delta)|^2\mathcal{R}_\beta(k)+|\tilde{g}(k+k_0\delta)|^2\overline{\mathcal{R}_\beta}(k))=\int dk|\tilde{g}(k-k_0\delta)|^2\left(\frac{-ik}{\beta-ik}\right), \tag{3.14}$$

and this concludes the proof of the proposition. □

Proposition 2 allows us to find a further approximate form for the reduced density matrix.

Corollary 3: Under the assumptions (3.2) and for any $t\geqslant 0$ we have

$$[Tr((\hat{\rho}^a(t)-\hat{\rho}^f(t))^2)]^{1/2}<c\left(\alpha\sigma+\frac{1}{\alpha(R_0-|r_0|)}+\frac{\delta}{R_0-|r_0|}\right), \tag{3.15}$$

where

$$\hat{\rho}^f(t)=U_0^M(t)\hat{\rho}_0^f U_0^M(-t), \tag{3.16}$$

$$\hat{\rho}_0^f(y,z)=\frac{1}{2}f_\sigma^+(y)\overline{f_\sigma^+}(z)+\frac{1}{2}f_\sigma^-(y)\overline{f_\sigma^-}(z)+\frac{\Lambda}{2}f_\sigma^+(y)\overline{f_\sigma^-}(z)+\frac{\overline{\Lambda}}{2}f_\sigma^-(y)\overline{f_\sigma^+}(z). \tag{3.17}$$

Proof:

$$\begin{aligned}Tr((\hat{\rho}^a(t)-\hat{\rho}^f(t))^2)&=Tr((\hat{\rho}_0^a-\hat{\rho}_0^f)^2)\\&=\frac{1}{4}\int dydz|f_\sigma^+(y)\overline{f_\sigma^+}(z)(\mathcal{I}(y,z)-1)+f_\sigma^-(y)\overline{f_\sigma^-}(z)(\mathcal{I}(y,z)-1)\\&\quad+f_\sigma^+(y)\overline{f_\sigma^-}(z)(\mathcal{I}(y,z)-\Lambda)+f_\sigma^-(y)\overline{f_\sigma^+}(z)(\mathcal{I}(y,z)-\overline{\Lambda})|^2\\&\leqslant\sup_{y,z\in\Delta^+}|\mathcal{I}(y,z)-1|^2+\sup_{y,z\in\Delta^-}|\mathcal{I}(y,z)-1|^2+\sup_{y\in\Delta^+,z\in\Delta^-}|\mathcal{I}(y,z)-\Lambda|^2\\&\quad+\sup_{y\in\Delta^-,z\in\Delta^+}|\mathcal{I}(y,z)-\overline{\Lambda}|^2.\end{aligned} \tag{3.18}$$

Using proposition 2 we conclude the proof. □

From corollary 3 and theorem 1 we conclude that the reduced density matrix for the heavy particle in the position representation can be approximated by the density matrix

$$\begin{aligned}\hat{\rho}^f(t,R,R')&=\frac{1}{2}(U_0^M(t)f_\sigma^+)(R)(U_0^M(-t)\overline{f_\sigma^+})(R')+\frac{1}{2}(U_0^M(t)f_\sigma^-)(R)(U_0^M(-t)\overline{f_\sigma^-})(R')\\&\quad+\frac{\Lambda}{2}(U_0^M(t)f_\sigma^+)(R)(U_0^M(-t)\overline{f_\sigma^-})(R')+\frac{\overline{\Lambda}}{2}(U_0^M(t)f_\sigma^-)(R)(U_0^M(-t)\overline{f_\sigma^+})(R'),\end{aligned} \tag{3.19}$$

with an explicit control of the error.

If the interaction with the light particle is switched off, i.e., for $\alpha=0$, we have $\Lambda=1$ and then (3.19) reduces to the pure state corresponding to the coherent superposition of the free evolution of the two wave packets $f_\sigma^\pm$.

On the other hand, if $\alpha>0$ one easily sees that $0<|\Lambda|<1$ and then (3.19) is a mixed state for which the interference terms are reduced by the factor Λ and this is the typical manifestation of the (partial) decoherence effect induced by the light particle on the heavy one.

The relevant parameter Λ [see (3.3)] is defined in terms of the probability distribution of the momentum of the light particle $|\tilde{g}_\delta(k)|^2$ and of the transmission coefficient $\mathcal{T}_\alpha(k)$.

Then the decoherence effect is emphasized if the fraction of transmitted wave for the light particle is small.

In particular, rescaling the integration variable in (3.3), one can also write

$$\Lambda = 1 - \int dz |\tilde{g}(z)|^2 \frac{\alpha\delta}{\alpha\delta - i(z + k_0\delta)}. \tag{3.20}$$

Notice that decoherence is maximal when the wavelength of the light particle is smaller then or comparable to the scattering length of the interaction ($k_0 \sim \alpha$) and minimal for k_0 large with respect to α. Nevertheless it is worth stressing that (3.20) is an asymptotic formula whose effectivness is guaranteed only in the range of validity of the assumptions of theorem 1, from where it is derived.

For $k_0 \ll \alpha$ the effect of decoherence is given by

$$\Lambda \simeq \int dz |\tilde{g}(z)|^2 |\mathcal{T}_{\alpha\delta}(z)|^2 = 1 - \int dz |\tilde{g}(z)|^2 \frac{\alpha^2\delta^2}{\alpha^2\delta^2 + z^2}, \tag{3.21}$$

where we have used the fact that $\tilde{g}$ is even.

A further interesting question is the analysis of $\hat{\rho}^f(t)$ in the momentum representation. Since momentum is a constant of motion, the density matrix is simply given by

$$\begin{aligned}\frac{1}{\hbar}\tilde{\rho}_0^f\left(\frac{P}{\hbar}, \frac{P'}{\hbar}\right) &= \frac{1}{2\hbar}\tilde{f}_\sigma^+\left(\frac{P}{\hbar}\right)\overline{\tilde{f}_\sigma^+}\left(\frac{P'}{\hbar}\right) + \frac{1}{2\hbar}\tilde{f}_\sigma^-\left(\frac{P}{\hbar}\right)\overline{\tilde{f}_\sigma^-}\left(\frac{P'}{\hbar}\right) + \frac{\Lambda}{2\hbar}\tilde{f}_\sigma^+\left(\frac{P}{\hbar}\right)\overline{\tilde{f}_\sigma^-}\left(\frac{P'}{\hbar}\right) \\ &\quad + \frac{\overline{\Lambda}}{2\hbar}\tilde{f}_\sigma^-\left(\frac{P}{\hbar}\right)\overline{\tilde{f}_\sigma^+}\left(\frac{P'}{\hbar}\right).\end{aligned} \tag{3.22}$$

It is then clear that the decoherence effect is present also in the momentum representation and it is measured by the same parameter Λ.

Moreover, if $\tilde{f}_\sigma^+$ and $\tilde{f}_\sigma^-$ are well separated, one easily realizes that the probability distribution of the momentum remains essentially unchanged with respect to the unperturbed case $\Lambda = 1$, the error being of order ϵ.

We analyze now the evolution in the position representation of the heavy particle exploiting the approximate reduced density matrix $\hat{\rho}^f(t)$.

We shall explicitely show that the typical interference fringes produced by the superposition state when the interaction with the light particle is absent, i.e., for $\Lambda = 1$, are in fact reduced when the light particle is present, i.e., for $|\Lambda| < 1$.

In order to see the effect more clearly we assume

$$\frac{\sigma}{R_0} \ll \frac{\hbar}{\sigma P_0}. \tag{3.23}$$

The effect of the interference terms becomes more relevant when the supports of the two wave packets $U_0^M(t) f_\sigma^\pm$ have the maximal overlapping and this approximately happens at the time $t = \tau \equiv R_0 M / P_0$. Then, from (3.19), we consider

$$\begin{aligned}n(\tau, R) \equiv \hat{\rho}^f(\tau, R, R) = \tfrac{1}{2}[&|(U_0^M(\tau) f_\sigma^+)(R)|^2 + |(U_0^M(\tau) f_\sigma^-)(R)|^2 \\ &+ 2\Re(\Lambda (U_0^M(\tau) f_\sigma^+)(R) \overline{(U_0^M(\tau) f_\sigma^-)}(R))].\end{aligned} \tag{3.24}$$

Using (3.23) and a standard scattering estimate (see, e.g., Ref. 9) we obtain

$$\begin{aligned}(U_0^M(\tau) f_\sigma^+)(R) &= \sqrt{\frac{P_0\sigma}{2\pi\hbar R_0}} \int dx f\left(\frac{x + R_0}{\sigma}\right) e^{i(P_0/\hbar)x + i(P_0/2\hbar R_0)(R-x)^2} \\ &= \sqrt{\frac{P_0\sigma}{i\hbar R_0}} e^{i(P_0/\hbar)(R^2/2R_0 + R - R_0/2)} \tilde{f}\left(\frac{P_0\sigma}{\hbar R_0} R\right) + \mathcal{E}_0(R),\end{aligned} \tag{3.25}$$

$$\|\mathcal{E}_0\| < \frac{P_0\sigma^2}{2\hbar R_0}\|\Delta\tilde{f}\|. \tag{3.26}$$

Proceeding analogously for $(U_0^M(\tau)f_\sigma^-)(R)$ we find

$$n(\tau,R) = \frac{P_0\sigma}{\hbar R_0}\left|\tilde{f}\left(\frac{P_0\sigma}{\hbar R_0}R\right)\right|^2\left(1+|\Lambda|\cos\left(\frac{2P_0}{\hbar}R+\varphi\right)\right)+\mathcal{E}_1(R), \tag{3.27}$$

$$\|\mathcal{E}_1\|_{L^1} < c\ \frac{P_0\sigma^2}{\hbar R_0}, \tag{3.28}$$

where

$$\Lambda = |\Lambda|e^{i\varphi}. \tag{3.29}$$

For $|\Lambda|<1$, formula (3.27) shows that the presence of the light particle determines a reduction of the amplitude of the oscillations and a shift of the corresponding phases.

Notice that the shift is negligible if $k_0 \ll \alpha$.

IV. PROOF OF THEOREM 1

The proof of theorem 1 will be obtained through the proof of three lemmas.

Lemma 4: Given the initial state (2.10), for any $t \geqslant 0$ one has

$$\|\psi(t)-\psi_1(t)\| < C_1\,\epsilon, \tag{4.1}$$

where

$$\psi_1(t,r,R) = \int dy f_\sigma(y) U_0^\nu\left(t, \frac{M}{\nu}R+\frac{\mu}{M}r-y\right)\int dr' g_\delta(r'+y)U_{\alpha_0}^\mu(t,r-R,r') \tag{4.2}$$

and

$$C_1 = \left[\int dx x^2 \int dy \left|\frac{\partial}{\partial y}(f_\sigma(y)g_\delta(x+y))\right|^2\right]^{1/2}. \tag{4.3}$$

Proof: Using the relative and the center of mass coordinates [see (2.14)], from (A4) one has

$$(T\psi(t))(x_1,x_2) = (U_0^\nu(t)U_{\alpha_0}^\mu(t)T\psi_0)(x_1,x_2), \tag{4.4}$$

where $U_{\alpha_0}^\mu(t)$ is defined in (A10) of the Appendix and

$$(T\psi_0)(x_1,x_2) = f_\sigma\left(x_2-\frac{\mu}{M}x_1\right)g_\delta\left(x_2+\frac{M}{\nu}x_1\right). \tag{4.5}$$

Moreover

$$\begin{aligned}(T\psi_1(t))(x_1,x_2) &= \int dx_2' dx_1' f_\sigma(x_2')g_\delta(x_1'+x_2')U_0^\nu(t,x_2-x_2')U_{\alpha_0}^\mu(t,x_1,x_1') \\ &\equiv (U_0^\nu(t)U_{\alpha_0}^\mu(t)T\psi_{01})(x_1,x_2),\end{aligned} \tag{4.6}$$

where

$$\psi_{01}(r,R)=f_\sigma\left(\frac{M}{\nu}R+\frac{\mu}{M}r\right)g_\delta\left(r-R+\frac{M}{\nu}R+\frac{\mu}{M}r\right). \tag{4.7}$$

Then we have with $\mu/M=\epsilon/(1+\epsilon)$, $(M/\nu)-1=-\epsilon/(1+\epsilon)$

$$\begin{aligned}\|\psi(t)-\psi_1(t)\|^2&=\|T\psi(t)-T\psi_1(t)\|^2\\&=\|T\psi_0-T\psi_{01}\|^2\\&=\int dx_1dx_2\left|f_\sigma\left(x_2-\frac{\mu}{M}x_1\right)g_\delta\left(x_2+\frac{M}{\nu}x_1\right)-f_\sigma(x_2)g_\delta(x_1+x_2)\right|^2\\&=\int dx_1dx_2\left|f_\sigma\left(x_2-\frac{\epsilon}{1+\epsilon}x_1\right)g_\delta\left(x_2+x_1-\frac{\epsilon}{1+\epsilon}x_1\right)-f_\sigma(x_2)g_\delta(x_1+x_2)\right|^2\\&=\int dx_1dx_2\left|F\left(x_1,x_2-\frac{\epsilon}{1+\epsilon}x_1\right)-F(x_1,x_2)\right|^2,\end{aligned} \tag{4.8}$$

where $F(x_1,x_2)=f_\sigma(x_2)g_\delta(x_1+x_2)$. By a simple Plancherel argument, we have that

$$\begin{aligned}&\int dx_1dx_2\left|F\left(x_1,x_2-\frac{\epsilon}{1+\epsilon}x_1\right)-F(x_1,x_2)\right|^2\\&\quad=\int dx_1\int dk|\tilde F(x_1,k)\left(e^{-i(\epsilon/1+\epsilon)x_1k}-1\right)|^2\\&\quad\leqslant\int dx_1\int dk|\tilde F(x_1,k)|^2\left(\frac{\epsilon}{1+\epsilon}x_1k\right)^2=\left(\frac{\epsilon}{1+\epsilon}\right)^2\int dx_1x_1^2\int dx_2\left|\frac{\partial}{\partial x_2}F(x_1,x_2)\right|^2,\end{aligned} \tag{4.9}$$

from which the lemma follows. □

Since a small value of m in the interacting unitary group $U^\mu_{\alpha_0}(t)$ is equivalent to a large value of t, in the next lemma we use a typical scattering estimate to approximate $U^\mu_{\alpha_0}(t)$ in (4.2).

Lemma 5: Given the initial state (2.10), for any $t>0$ one has

$$\|\psi_1(t)-\psi_2(t)\|<\frac{C_2}{t}\epsilon, \tag{4.10}$$

where

$$\begin{aligned}\psi_2(t,r,R)=&\sqrt{\frac{m}{2\pi i\hbar t}}\sqrt{\frac{M}{2\pi i\hbar t}}e^{i(m/2\hbar t)r^2+i(M/2\hbar t)R^2}\int d\xi f_\sigma(\xi)e^{i(M/2\hbar t)\xi^2}e^{-i((M/\hbar t)R+(m/\hbar t)r)\xi}\\&\cdot\int dr'g_\delta(r'+\xi)\left(e^{-i(\mu/\hbar t)(r-R)r'}-\frac{e^{i(\mu/\hbar t)|r-R||r'|}}{1-i\dfrac{\hbar}{\alpha_0t}|r-R|}\right)\end{aligned} \tag{4.11}$$

and

$$\begin{aligned}C_2=c\frac{M}{\hbar}\Bigg\{&\int dxx^4|f_\sigma(x)|^2+\int dx|f_\sigma(x)|^2\Bigg[\int dyy^4|g_\delta(y+x)|^2+\frac{1}{\alpha^3}\left(\int dy|g_\delta(y+x)|\right)^2\\&+\frac{1}{\alpha}\left(\int dy|y||g_\delta(y+x)|\right)^2+\alpha\left(\int dyy^2|g_\delta(y+x)|\right)^2\Bigg]\Bigg\}^{1/2}.\end{aligned} \tag{4.12}$$

Proof: We shall first estimate the difference $\psi_1(t)-\hat\psi_2(t)$, where $\hat\psi_2(t)$ is explicitly given by

$$\hat{\psi}_2(t,r,R)=\sqrt{\frac{\mu}{2\pi i\hbar t}}e^{i(\mu/2\hbar t)(r-R)^2}\int dy f_\sigma(y)U_0^\nu\left(t,\frac{M}{\nu}R+\frac{\mu}{M}r-y\right)\int dr' g_\delta(r'+y)$$
$$\cdot\left(e^{-i(\mu/\hbar t)(r-R)r'}-\frac{e^{i(\mu/\hbar t)|r-R||r'|}}{1-i\dfrac{\hbar}{\alpha_0 t}|r-R|}\right). \tag{4.13}$$

From (4.2) we have

$$(T\psi_1)(t,x_1,x_2)=\int dy U_0^\nu(t,x_2-y)\varphi_1(t,x_1,y), \tag{4.14}$$

$$\varphi_1(t,x_1,x_2)=f_\sigma(x_2)\int dr' g_\delta(r'+x_2)U_{\alpha_0}^\mu(t,x_1,r'), \tag{4.15}$$

and analogously for $\hat{\psi}_2(t)$ we write

$$(T\hat{\psi}_2(t))(x_1,x_2)=\int dy U_0^\nu(t,x_2-y)\varphi_2(t,x_1,y), \tag{4.16}$$

$$\varphi_2(t,x_1,x_2)=\sqrt{\frac{\mu}{2\pi i\hbar t}}e^{i(\mu/2\hbar t)x_1^2}f_\sigma(x_2)\int dr' g_\delta(r'+x_2)\left(e^{-i(\mu/\hbar t)x_1 r'}-\frac{e^{i(\mu/\hbar t)|x_1||r'|}}{1-i\dfrac{\hbar|x_1|}{\alpha_0 t}}\right). \tag{4.17}$$

Using the isometric character of the operators T and $U_0^\nu(t)$ and the explicit expression of $U_{\alpha_0}^\mu(t)$ [see (A10)], we have

$$\begin{aligned}\|\psi_1(t)-\hat{\psi}_2(t)\|^2&=\|T\psi_1(t)-T\psi_2(t)\|^2\\&=\|\varphi_1(t)-\varphi_2(t)\|^2\\&\leqslant 2\int dx_1dx_2\left|f_\sigma(x_2)\int dr' g_\delta(r'+x_2)\right.\\&\quad\times\left.\left(U_0^\mu(t,x_1-r')-\sqrt{\frac{\mu}{2\pi i\hbar t}}e^{i(\mu/2\hbar t)x_1^2-i(\mu/\hbar t)x_1r'}\right)\right|^2\\&\quad+2\int dx_1dx_2\left|f_\sigma(x_2)\int dr' g_\delta(r'+x_2)\left(\frac{\mu\alpha_0}{\hbar^2}\int_0^\infty du e^{-(\mu\alpha_0/\hbar^2)u}\right.\right.\\&\quad\left.\left.\times U_0^\mu(t,u+|x_1|+|r'|)-\sqrt{\frac{\mu}{2\pi i\hbar t}}\frac{1}{1-i\dfrac{\hbar|x_1|}{\alpha_0 t}}e^{i(\mu/2\hbar t)x_1^2+i(\mu/\hbar t)|x_1||r'|}\right)\right|^2\\&\equiv(I)+(II).\end{aligned} \tag{4.18}$$

A standard estimate for the free unitary group (see, e.g., Ref. 9) gives

$$
\begin{aligned}
(I) &= \frac{\mu}{\pi\hbar t}\int dx_2 |f_\sigma(x_2)|^2 \int dx_1 \left| \int dr' g_\delta(r'+x_2)(e^{i(\mu/2\hbar t)\, r'^2}-1)e^{-i\,(\mu/\hbar t)\, x_1 r'}\right|^2 \\
&= \frac{1}{\pi}\int dx_2 |f_\sigma(x_2)|^2 \int d\overline{x_1} \left| \int dr' g_\delta(r'+x_2)(e^{i(\mu/2\hbar t)\, r'^2}-1)e^{-i\overline{x_1} r'}\right|^2 \\
&= 2\int dx_2 |f_\sigma(x_2)|^2 \int dr' |g_\delta(r'+x_2)|^2 |e^{i(\mu/2\hbar t)\, r'^2}-1|^2 \\
&\leqslant \frac{1}{2}\left(\frac{\mu}{\hbar t}\right)^2 \int dx_2 |f_\sigma(x_2)|^2 \int dr' r'^4 |g_\delta(r'+x_2)|^2 \\
&= \frac{\epsilon^2 M^2}{2(1+\epsilon)^2\hbar^2 t^2}\int dx_2 |f_\sigma(x_2)|^2 \int dr' r'^4 |g_\delta(r'+x_2)|^2,
\end{aligned}
\tag{4.19}
$$

where in the second line of (4.19) we used Plancherel theorem.

Concerning (II), we introduce the change of variables

$$
v = \frac{\mu\alpha_0}{\hbar^2}u, \qquad y_1 = \frac{\mu}{\hbar t}x_1, \tag{4.20}
$$

and use the identity

$$
\int_0^\infty dv\, e^{-v+i\,(\hbar|x_1|/\alpha_0 t)\, v} = \frac{1}{1-i\dfrac{\hbar|x_1|}{\alpha_0 t}}. \tag{4.21}
$$

Then

$$
\begin{aligned}
(II) &= \frac{1}{\pi}\int dx_2 |f_\sigma(x_2)|^2 \int dy_1 \left| \int dr' g_\delta(r'+x_2) e^{i|y_1||r'|}\right. \\
&\quad \cdot \left(e^{i(\mu/2\hbar t)\, r'^2}\int_0^\infty dv\, e^{-v+i\,[(1+\epsilon)/\alpha]\,|y_1|v + i[(1+\epsilon)m/2\hbar t\alpha^2]v^2 + i\,(m/\hbar t\alpha)\,|r'|v} \right. \\
&\quad \left.\left. - \int_0^\infty dv\, e^{-v+i1+\epsilon/\alpha\,|y_1|v}\right)\right|^2 \\
&\leqslant \frac{2}{\pi}\int dx_2 |f_\sigma(x_2)|^2 \int dy_1 \left| \int dr' g_\delta(r'+x_2) e^{i|y_1||r'|} e^{i(\mu/2\hbar t)\, r'^2}\int_0^\infty dv\, e^{-v+i[(1+\epsilon)/\alpha]\,|y_1|v}\right. \\
&\quad \left. \cdot (e^{i[(1+\epsilon)m/2\hbar t\alpha^2]v^2 + i(m/\hbar t\alpha)\,|r'|v} - 1)\right|^2 + \frac{2}{\pi}\int dx_2 |f_\sigma(x_2)|^2 \int dy_1 \left| \int dr' g_\delta(r'+x_2)\right. \\
&\quad \left. \times e^{i|y_1||r'|}(e^{i(\mu/2\hbar t)\, r'^2}-1)\frac{1}{1-i\dfrac{1+\epsilon}{\alpha}|y_1|}\right|^2 \equiv (III)+(IV).
\end{aligned}
\tag{4.22}
$$

The estimate of (IV) is trivial

$$
\begin{aligned}
(IV) &\leqslant \frac{1}{2\pi}\left(\frac{\mu}{\hbar t}\right)^2 \int dx_2 |f_\sigma(x_2)|^2 \int dy_1 \frac{1}{1+\left(\dfrac{1+\epsilon}{\alpha}\right)^2 y_1^2}\left(\int dr' r'^2 |g_\delta(r'+x_2)|\right)^2 \\
&\leqslant \frac{\epsilon^2 M^2 \alpha}{2(1+\epsilon)^3\hbar^2 t^2}\int dx_2 |f_\sigma(x_2)|^2 \left(\int dr' r'^2 |g_\delta(r'+x_2)|\right)^2.
\end{aligned}
\tag{4.23}
$$

For the estimate of (III) it is convenient to integrate by parts the integral in the variable v

$$(III)=\frac{2}{\pi}\int dx_2|f_\sigma(x_2)|^2\int dy_1\frac{1}{1+\left(\frac{1+\epsilon}{\alpha}\right)^2 y_1^2}\left|\int dr' g_\delta(r'+x_2)e^{i|y_1||r'|}e^{i(\mu/2\hbar t)\,r'^2}\right.$$
$$\left.\cdot\int_0^\infty dv e^{-v+i[(1+\epsilon)/\alpha]\,|y_1|v+i[(1+\epsilon)m/2\hbar t\alpha^2]v^2+i\,(m/\hbar t\alpha)\,|r'|v}\frac{(1+\epsilon)\mu}{\hbar t\alpha}\left(\frac{1+\epsilon}{\alpha}v+|r'|\right)\right|^2$$
$$\leqslant\frac{2(1+\epsilon)\mu^2}{\pi\hbar^2t^2\alpha}\int dx_2|f_\sigma(x_2)|^2\int dy_1\frac{1}{1+y_1^2}\left[\int dr'|g_\delta(r'+x_2)|\int_0^\infty dv e^{-v}\left(\frac{1+\epsilon}{\alpha}v+|r'|\right)\right]^2$$
$$\leqslant\frac{2\epsilon^2M^2}{(1+\epsilon)\hbar^2t^2\alpha}\int dx_2|f_\sigma(x_2)|^2\left[\int dr'|g_\delta(r'+x_2)|\left(\frac{1+\epsilon}{\alpha}+|r'|\right)\right]^2. \tag{4.24}$$

Finally, it remains to analyze the difference $\psi_2(t)-\hat{\psi}_2(t)$. Using the explicit expression of $U_0^\nu(t)$ we have

$$\psi_2(t,r,R)-\hat{\psi}_2(t,r,R)=\sqrt{\frac{m}{2\pi i\hbar t}}\sqrt{\frac{M}{2\pi i\hbar t}}e^{i(m/2\hbar t)\,r^2+i\,(M/2\hbar t)\,R^2}$$
$$\times\int d\xi f_\sigma(\xi)(e^{i(M/2\hbar t)\,\xi^2}-e^{i(\nu/2\hbar t)\,\xi^2})e^{-i[(M/\hbar t)\,R+\,(m/\hbar t)r]\xi}$$
$$\cdot\int dr' g_\delta(r'+\xi)\left(e^{-i\,(\mu/\hbar t)(r-R)r'}-\frac{e^{i(\mu/\hbar t)\,|r-R||r'|}}{1-i\frac{\hbar}{\alpha_0 t}|r-R|}\right). \tag{4.25}$$

Exploiting Plancherel theorem and the fact that the operator (2.16) is unitary one easily sees that

$$\|\psi_2(t)-\hat{\psi}_2(t)\|^2\leqslant\left(\frac{M}{2\hbar t}\right)^2\epsilon^2\int d\xi\xi^4|f_\sigma(\xi)|^2. \tag{4.26}$$

From (4.18), (4.19), (4.22), (4.23), (4.24), (4.26) we conclude the proof of the lemma. □

In the last step we approximate (4.13) using the fact that the coordinates of the heavy particle are slowly varying with respect to the coordinates of the light one.

Lemma 6: Given the initial state (2.10), for any $t>0$ we have

$$\|\psi_2(t)-\psi^a(t)\|<C_3(t)\,\epsilon, \tag{4.27}$$

where

$$C_3(t)=\left[\int dz z^2\int dx\left|\frac{\partial}{\partial x}(\tilde{f}_\sigma(z-x)\tilde{g}_\delta(x))\right|^2\right]^{1/2}+\frac{1}{\sqrt{2}\pi}\left\{\int dxdz\left[\frac{\alpha^2+z^2}{\alpha^2+x^2}\left(\int dr'|\zeta(z,r')|\right)^2\right.\right.$$
$$\left.\left.+\frac{\alpha^2z^2}{\alpha^2+x^2}\left(\int dr'|r'||\zeta(z,r')|\right)^2\right]\right\}^{1/2}, \tag{4.28}$$

with

$$C_3(t)<\frac{C_4}{t}+C_5 \tag{4.29}$$

and

$$\hat f_\sigma(\xi)=f_\sigma(\xi)e^{i(M/2\hbar t)\,\xi^2},\qquad \zeta(z,r')=\int d\xi \hat f_\sigma(\xi)g_\delta(r'+\xi)e^{-iz\xi}. \quad (4.30)$$

Proof: From (2.21) and (4.11) we have

$$\begin{aligned}\psi_2(t,r,R)-\psi^a(t,r,R)&=\sqrt{\frac{m}{2\pi i\hbar t}}\sqrt{\frac{M}{2\pi i\hbar t}}e^{i(m/2\hbar t)\,r^2+i\,(M/2\hbar t)\,R^2}\int d\xi f_\sigma(\xi)e^{i(M/2\hbar t)\,\xi^2}e^{-i[(M/\hbar t)R+\,(m/\hbar t)\,r]\xi}\\&\cdot\Bigg[\int dr' g_\delta(r'+\xi)(e^{-i(\mu/\hbar t)(r-R)r'}-e^{-i(m/\hbar t)rr'})+\int dr' g_\delta(r'+\xi)\\&\times\left(\frac{e^{i(\mu/\hbar t)\,|r-R||r'|}}{1-i\dfrac{\hbar}{\alpha_0 t}|r-R|}-\frac{e^{i(m/\hbar t)\,|r||r'|}}{1-i\dfrac{\hbar}{\alpha_0 t}|r|}\right)\Bigg]\equiv(\psi_2-\psi^a)_{fr}(t,r,R)+(\psi_2-\psi^a)_{in}(t,r,R).\end{aligned} \quad (4.31)$$

We will estimate separatly the two terms $(\psi_2-\psi^a)_{fr}(t)$ and $(\psi_2-\psi^a)_{in}(t)$.

Introducing the new integration variables

$$x=\frac{m}{\hbar t}r,\qquad z=\frac{MR+mr}{\hbar t}, \quad (4.32)$$

and the function $\hat f_\sigma(\xi)$ defined in (4.30), we have

$$\begin{aligned}\|(\psi_2-\psi^a)_{fr}(t)\|^2&=\frac{1}{(2\pi)^2}\int dxdz\left|\int d\xi\hat f_\sigma(\xi)e^{-iz\xi}\int dr' g_\delta(r'+\xi)\right.\\&\left.\times(e^{-i(x-[\epsilon/(1+\epsilon)]\,z)r'}-e^{-ixr'})\right|^2\\&=\frac{1}{2\pi}\int dxdz\left|\int d\xi\hat f_\sigma(\xi)e^{-iz\xi}\left(\tilde g_\delta\left(x-\frac{\epsilon}{1+\epsilon}z\right)e^{i(x-[\epsilon/(1+\epsilon)]\,z)\xi}-\tilde g_\delta(x)e^{ix\xi}\right)\right|^2\\&=\int dxdz\left|\tilde{\hat f}_\sigma\left(z-x+\frac{\epsilon}{1+\epsilon}z\right)\tilde g_\delta\left(x-\frac{\epsilon}{1+\epsilon}z\right)-\tilde{\hat f}_\sigma(z-x)\tilde g(x)\right|^2\\&=\int dxdz\left|G\left(x-\frac{\epsilon}{1+\epsilon}z,z\right)-G(x,z)\right|^2,\end{aligned} \quad (4.33)$$

where we introduced the function $G(x,z)=\tilde{\hat f}_\sigma(z-x)\tilde g(x)$.

Proceeding as in (4.9) we find

$$\|(\psi_2-\psi^a)_{fr}(t)\|^2\leqslant\left(\frac{\epsilon}{1+\epsilon}\right)^2\int dz z^2\int dx\left|\frac{\partial}{\partial x}(\tilde{\hat f}_\sigma(z-x)\tilde g(x))\right|^2. \quad (4.34)$$

For the estimate of $(\psi_2-\psi^a)_{in}(t)$ we use again the change of variables (4.32) and we introduce the function $\zeta(z,r')$ defined in (4.30).

Then we have

$$\|(\psi_2-\psi^a)_{in}\|^2\leqslant\frac{1}{(2\pi)^2}\int dxdz\left|\int dr'\zeta(z,r')\left(\frac{e^{i|x-[\epsilon/(1+\epsilon)]z||r'|}}{1-\frac{i}{\alpha}|(1+\epsilon)x-\epsilon z|}-\frac{e^{i|x||r'|}}{1-\frac{i}{\alpha}|x|}\right)\right|^2$$

$$\leqslant\frac{1}{2\pi^2}\int dxdz\left|\frac{1}{1-\frac{i}{\alpha}|(1+\epsilon)x-\epsilon z|}-\frac{1}{1-\frac{i}{\alpha}|x|}\right|^2\left(\int dr'|\zeta(z,r')|\right)^2$$

$$+\frac{1}{2\pi^2}\int dxdz\frac{\alpha^2}{\alpha^2+x^2}\left|\int dr'\zeta(z,r')(e^{i|x-[\epsilon/(1+\epsilon)]z||r'|}-e^{i|x||r'|})\right|^2$$

$$\leqslant\frac{\epsilon^2}{2\pi^2}\int dxdz\left[\frac{\alpha^2+z^2}{\alpha^2+x^2}\left(\int dr'|\zeta(z,r')|\right)^2+\frac{\alpha^2z^2}{\alpha^2+x^2}\left(\int dr'|r'||\zeta(z,r')|\right)^2\right], \tag{4.35}$$

where we have used the estimates

$$\left|\frac{1}{1-\frac{i}{\alpha}|(1+\epsilon)x-\epsilon z|}-\frac{1}{1-\frac{i}{\alpha}|x|}\right|^2=\frac{\alpha^2}{\alpha^2+x^2}\frac{(|x|-|(1+\epsilon)x-\epsilon z|)^2}{\alpha^2+((1+\epsilon)x-\epsilon z)^2}$$

$$\leqslant\epsilon^2\frac{\alpha^2}{\alpha^2+x^2}\frac{(x-z)^2}{\alpha^2+((1+\epsilon)x-\epsilon z)^2}\leqslant\left(\frac{\epsilon}{1+\epsilon}\right)^2\frac{\alpha^2+z^2}{\alpha^2+x^2} \tag{4.36}$$

and

$$|e^{i|x-[\epsilon/(1+\epsilon)]z||r'|}-e^{i|x||r'|}|\leqslant\frac{\epsilon}{1+\epsilon}|z||r'|. \tag{4.37}$$

The function $\zeta(z,r')$ is smooth and, using repeated integration by parts, one easily sees that it is rapidly decreasing when its first argument goes to infinity. The computation is long but straightforward and we omit the details. The conclusion is that the integral in the last line of (4.35) is finite. Along the same line one can verify that (4.29) holds, where the constants C_4, C_5 are independent of time and then the proof of the lemma follows.

Proof of theorem 1: This is now a simple consequence of lemmas 4, 5, 6. Furthermore the constants A,B can now be estimated, since they are given by $A=C_2+C_4$, $B=C_1+C_5$ [see (4.1), (4.10), (4.27), (4.29)] and then the dependence of A,B on the physical parameters characterising the initial state and the interaction can be seen from (4.3), (4.12), and (4.28).

We notice that, by simple rearrangments and rescaling, one can make such dependence more explicit. For instance, concerning C_1 one has

$$C_1^2=\int dz\int dy(z-y)^2|g'_\delta(z)f_\sigma(y)+g_\delta(z)f'_\sigma(y)|^2$$

$$\leqslant2(2R_0)^2\left(\int dz|g'_\delta\left(z|^2+\int dy|f'_\sigma(y)|^2\right)\right.$$

$$\leqslant16\left[\|g'\|^2\left(\frac{R_0}{\delta}\right)^2+\left(\frac{R_0q_0}{\hbar}\right)^2+2\|f'\|^2\left(\frac{R_0}{\sigma}\right)^2+2\left(\frac{R_0P_0}{\hbar}\right)^2\right], \tag{4.38}$$

where we have used the fact that $(z-y)^2\leqslant(2R_0)^2$ for $z\in supp\ \ g_\delta$, $y\in supp\ \ f_\sigma$ and we have rescaled the integration variables.

A longer but similar computation can also be done for the other constants C_2, C_4, C_5. □

APPENDIX: EXPLICIT SOLUTION OF THE TWO-BODY PROBLEM

We recall here the solution of the Schrödinger equation

$$i\hbar \frac{\partial \psi(t)}{\partial t} = H\psi(t), \qquad \psi(0)=\psi_0, \tag{A1}$$

where H is the self-adjoint Hamiltonian in $L^2(\mathbb{R}^2, drdR)$ given by (2.1). Using the unitary operator T [see (2.14)] one obviously has

$$THT^{-1} = H_0^{\nu} + H_{\alpha_0}^{\mu}, \qquad H_0^{\nu} = -\frac{\hbar^2}{2\nu}\Delta_{x_2}, \qquad H_{\alpha_0}^{\mu} = -\frac{\hbar^2}{2\mu}\Delta_{x_1} + \alpha_0\delta(x_1), \tag{A2}$$

where (x_1, x_2) are the relative and the center of mass coordinates

$$x_1 = r - R, \qquad x_2 = \frac{mr + MR}{m+M}. \tag{A3}$$

Then the solution of (A1) can be written as

$$\begin{aligned}\psi(t,r,R) &= (T^{-1}U_0^{\nu}(t)U_{\alpha_0}^{\mu}(t)T\psi_0)(r,R) \\ &= \int dr'dR'\,\psi_0(r',R')U_0^{\nu}\left(t, \frac{M}{\nu}(R-R') + \frac{\mu}{M}(r-r')\right)U_{\alpha_0}^{\mu}(t, r-R, r'-R'),\end{aligned} \tag{A4}$$

where the interacting unitary group $U_{\alpha_0}^{\mu}(t)$ is given by

$$U_{\alpha_0}^{\mu}(t,x,x') = e^{-i(t/\hbar)H_{\alpha_0}^{\mu}}(x,x'), \qquad x,x' \in \mathbb{R}. \tag{A5}$$

We remark that the evolution (A4) factorizes into a product of a free evolution in the center of mass coordinate and a one-body interacting evolution in the relative coordinate only if the initial state is of the form $\psi(r,R) = \psi_1[(M/\nu)R + (\mu/M)r]\psi_2(r-R)$.

In order to compute $(U_{\alpha_0}^{\mu}(t)\varphi_0)(x) \equiv \varphi(t,x)$ one has to solve the one-body Schrödinger equation

$$i\hbar \frac{\partial \varphi(t)}{\partial t} = -\frac{\hbar^2}{2\mu}\Delta_x\varphi(t) + \alpha_0\delta(x)\varphi(t), \qquad \varphi(0)=\varphi_0. \tag{A6}$$

Defining the rescaled wave function

$$\theta(s,z) = \varphi\left(\hbar s, \frac{\hbar}{\sqrt{\mu}}z\right), \tag{A7}$$

one finds that $\theta(s)$ satisfies the corresponding equation with $\mu = \hbar = 1$

$$i\frac{\partial \theta(s)}{\partial s} = -\frac{1}{2}\Delta_z\theta(s) + \alpha_0\frac{\sqrt{\mu}}{\hbar}\delta(z)\theta(s), \qquad \theta(0)=\theta_0, \quad \theta_0(z) = \varphi_0\left(\frac{\hbar}{\sqrt{\mu}}z\right). \tag{A8}$$

The solution of (5.8) can be found in Ref. 10.

$$\theta(s,z) = (\hat{U}_0^1(s)\theta_0)(z) - \alpha_0\frac{\sqrt{\mu}}{\hbar}\int_0^{\infty} dv\, e^{-\alpha_0(\sqrt{\mu}/\hbar)v}\int dz'\,\hat{U}_0^1(s, v+|z|+|z'|)\theta_0(z'), \tag{A9}$$

where $\hat{U}_0^1(s)$ is the free propagator with $\hbar=1$. Noticing that $(U^{\mu}_{\alpha_0}(t)\varphi_0)(x)=\varphi(t,x)=\theta(t/\hbar\,,(\sqrt{\mu}/\hbar)\,x)$ one has

$$(U^{\mu}_{\alpha_0}(t)\varphi_0)(x)=(U^{\mu}_0(t)\varphi_0)(x)-\frac{\mu\alpha_0}{\hbar^2}\int_0^{\infty}du e^{-(\mu\alpha_0/\hbar^2)u}\int dx' U^{\mu}_0(t,u+|x|+|x'|)\varphi_0(x'). \tag{A10}$$

Using (A4) and (A10), we finally obtain the complete solution (2.2) of the Schrödinger equation (A1).

(Received 28 October 2002; accepted 12 November 2003)

Consider a complex energy z for an N-particle Hamiltonian H and let χ be any wave packet accounting for any channel flux. The time-independent mean-field (TIMF) approximation of the inhomogeneous, linear equation $(z-H)|\Psi\rangle=|\chi\rangle$ consists of replacing Ψ by a product or Slater determinant ϕ of single-particle states φ_i. This results, under the Schwinger variational principle, in self-consistent TIMF equations $(\eta_i-h_i)|\varphi_i\rangle=|\chi_i\rangle$ in single-particle space. The method is a generalization of the Hartree–Fock (HF) replacement of the N-body homogeneous linear equation $(E-H)|\Psi\rangle=0$ by single-particle HF diagonalizations $(e_i-h_i)|\varphi_i\rangle=0$. We show how, despite strong nonlinearities in this mean-field method, threshold singularities of the *inhomogeneous* TIMF equations are linked to solutions of the *homogeneous* HF equations. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1666978]

I. INTRODUCTION

After the success of the mean-field approach for bound state systems in various fields of physics, it was only natural to try the mean-field concept for scattering states as well. The original attempt[1] was the time-dependent Hartree–Fock (TDHF) method, where one solves the single-particle equations of motion as *initial* value problem in time. From the resulting solutions at various impact parameters, one may then calculate the classical cross section. With no specification of the final state, the method is restricted to inclusive reactions. A serious, conceptual problem arises from spurious cross-channel correlations:[2,3] when projecting the TDHF Slater determinant for large times on an orthogonal set of channel wave functions, the expansion coefficients and the respective S-matrix vary in time *ad infinitum*. To overcome the shortcomings of TDHF, the time-dependent mean-field (TDMF) approach[2–4] expands the density in two sets of (biorthogonal) single-particle wave functions and solves the equations of motion as a *boundary* value problem in time, fixing initial and final densities. It has been proven that for TDMF an S-matrix can be defined which becomes asymptotically constant.[2] The problem with TDMF lies in combining self-consistency with given boundary conditions in time.[3,5] No practicable algorithm for this highly ''nonlocal'' problem exists up to date for use in actual numerical calculations. A third approach is the time-independent mean field (TIMF) method,[6] based on a Schwinger-type variational principle[7] for matrix elements of the resolvent or T-operator between given initial and final states. The method uses two sets of variational single-particle functions, analogous to TDMF, and leads to inhomogeneous equations of Hartree–Fock type which can be solved iteratively for given total energy of the system. TIMF is free of the conceptual and practical problems of TDHF and TDMF, respectively, and has been tested successfully on a number of simple systems. It can be extended to incorporate particle–hole correlations, as has also been done for TDHF, within a

b)Electronic mail: weiguny@uni-muenster.de

generalized random-phase-approximation.[8] The present paper goes beyond the above problems[9] by studying the continuum singularities of this TIMF approach for collisions.

Consider a finite number N of particles. Factorized wave packets (shifted Gaussians in momentum representation for example) make an overcomplete basis in their Hilbert space of wave functions. Hence, the calculation of a retarded Green's function amplitude $\mathcal{D}\equiv\langle\chi|(z-H)^{-1}|\chi\rangle$, where (i) χ is a product, $|\chi\rangle=\Pi_{i=1}^{N}|\chi_i\rangle$, and (ii) each single-particle wave function χ_i is real rather than complex, makes a fully generic problem. Such factorization simplifications are not physically restrictive and help in the analysis of a mean-field theory of collisions, the subject of this paper.

For the sake of simplicity, we deal so far with spinless, distinct particles only and short-range interactions v_{ij} for the Hamiltonian $H=\Sigma_{i=1}^{N}p_i^2/(2m_i)+\Sigma_{i>j=1}^{N}v_{ij}$. The case of identical particles can be treated later and, in the following, any reference to a Hartree method may be understood as a reference to a Hartree–Fock (HF) method if necessary. Again for simplicity, we consider the calculation of diagonal collision amplitudes only, $\langle\mathbf{k}|V(E^+-H)^{-1}V|\mathbf{k}\rangle$, Born term subtracted. Generalizations to distinct prior and post interactions, V,V', are kept for future work. The state $|\mathbf{k}\rangle$ is taken as a plane wave of relative motion in any two cluster channel ground state, and the product $|\chi\rangle\equiv V|\mathbf{k}\rangle$ is a square integrable state in the N-particle space. Finally, z is any complex number $E+i\Gamma$, and the usual limit E^+ at the end of any calculation reads $\Gamma\to+0$.

It is trivial to use the Schwinger variational principle[7] and show that $\mathcal{D}$ is the stationary value of the functional

$$\mathcal{F}\equiv\frac{\langle\Psi'|\chi\rangle\langle\chi|\Psi\rangle}{\langle\Psi'|(z-H)|\Psi\rangle} \tag{1}$$

under variations of Ψ,Ψ'. The corresponding Euler–Lagrange equations read, with retarded boundary conditions and arbitrary norms and phases of Ψ and Ψ'

$$(z-H)|\Psi\rangle=|\chi\rangle,\quad \langle\Psi'|(z-H)=\langle\chi|. \tag{2}$$

The variational equations which occur in the time-independent mean-field (TIMF)[6] theory of collisions read

$$(\eta_i-h_i)|\varphi_i\rangle=|\chi_i\rangle,\ \langle\varphi_i'|(\eta_i-h_i)=\langle\chi_i|,\ i=1,\ \ldots,N. \tag{3}$$

They are obtained from Eq. (1) when χ, and the approximation ϕ, respectively ϕ', chosen for Ψ, respectively Ψ', are products of single-particle orbitals, $\chi_i,\varphi_i,\varphi_i'$, respectively. Such TIMF equations are very simple.[6] Except for a single-particle density operator ρ defined nondiagonally as $\rho(\mathbf{r}',\mathbf{r})=\Sigma_i\varphi_i(\mathbf{r}')\varphi_i'^{*}(\mathbf{r})$, they are just Hartree(–Fock) equations completed by a right-hand side, representing the image of the channel in single-particle space. In the following, $\mathcal{F}$ is restricted to such factorized source functions χ and trial functions ϕ,ϕ' and will be labeled F. A saddle value under such a restriction of ϕ,ϕ' is not necessarily unique anymore. It will be denoted by D instead of $\mathcal{D}$ and may request an additional, identifying label. Now our claim is: *bound and unbound solutions of the usual Hartree(–Fock) equations*

$$(e_i-h_i)|\varphi_i\rangle=0, \tag{4}$$

induce singularities of the one-body variational conditions, Eqs. (3).

This reminds one, naturally, of the strict connection between the singularities of the linear, inhomogeneous problem $(z-H)|\Psi\rangle=|\chi\rangle$ in the N-body space and the solutions of the linear, homogeneous Schrödinger equation $(E-H)|\Psi\rangle=0$ in the same space. Because of the nonlinear nature of Eqs. (3)–(4) in single-particle space, our claim is not obvious, and will be qualified in this paper.

Actually, in a previous paper,[10] the claim was already substantiated in part: those energies E_H, for which a bound Hartree(–Fock) solution ϕ_H is found, generate poles of the approximate

amplitude D provided by saddle points of the restriction F. Furthermore $(z-E_H)D \to |\langle\chi|\phi_H\rangle|^2/\langle\phi_H|\phi_H\rangle$ when $z\to E_H$. Despite the nonlinearity of the approximation, such a residue at such a pole is almost expected. The analogy with the poles of $\mathcal{D}$ at exact eigenvalues for bound states is striking. We are now interested in a more difficult question, namely, is there a similar analogy at higher energies, when singularities of scattering and rearrangement collisions (thresholds, cuts) occur?

In Sec. II we briefly recall a very simple, soluble model,[11] used earlier among several other models to validate D as an approximation of $\mathcal{D}$. The model is reintroduced for pedagogical reasons first, to illustrate a derivation of Eqs. (3). Then, and mainly, it is used to provide a complete investigation of singularities, for it boils down to manipulations of polynomials. In Sec. III we introduce an enriched model, exactly soluble too. Section IV contains a generalization and discussion of the results obtained in Secs. II and III. Finally, Sec. V contains our conclusion.

II. FIRST MODEL, BARE PROPAGATION, SYMMETRIC MEAN FIELD, TWO-BODY THRESHOLD

In this soluble model, there are only two one-dimensional particles with just their kinetic energies, and different masses $m_i=1/(2a_i)$; hence, $H=a_1p_1^2+a_2p_2^2$. While the inversion of $z-H$ is numerically trivial and allows a good validation[11] of the TIMF approximation, the formal expression of $(z-H)^{-1}$ in terms of one-body propagators $(\eta_1-a_1p_1^2)^{-1}$ and $(\eta_2-a_2p_2^2)^{-1}$ is less trivial, as it demands a convolution. The TIMF method consists of replacing the convolution by just one product, namely,

$$(z-a_1p_1^2-a_2p_2^2)^{-1}|\chi_1\chi_2\rangle \propto (\eta_1-a_1p_1^2)^{-1}|\chi_1\rangle(\eta_2-a_2p_2^2)^{-1}|\chi_2\rangle\,. \tag{5}$$

This comes from variations $\delta/\delta\varphi_i$ of the functional F. An additional simplification results from a further remark: in those representations where χ and H are real, one finds from Eqs. (2) that $|\Psi'\rangle=|\Psi^*\rangle$, hence the possibility of just one trial function Ψ if one uses a Euclidean $(|)$ rather than a Hermitian $\langle|\rangle$ metric,

$$\mathcal{F}\equiv\frac{(\Psi|\chi)\,(\chi|\Psi)}{(\Psi|(z-H)|\Psi)}=\frac{(\chi|\Psi)^2}{(\Psi|(z-H)|\Psi)}\,. \tag{6}$$

For the present two-particle model, the factorization of χ into two single-particle wave packets with real wave functions χ_1,χ_2 allows us to use the following form of F:

$$F=\frac{(\chi_1\chi_2|\varphi_1\varphi_2)^2}{(\varphi_1\varphi_2|\,(z-a_1p_1^2-a_2p^2)\,|\varphi_1\varphi_2)}=\frac{(\chi_1|\varphi_1)^2(\chi_2|\varphi_2)^2}{z(\varphi_1|\varphi_1)(\varphi_2|\varphi_2)-(\varphi_1|a_1p_1^2|\varphi_1)(\varphi_2|\varphi_2)-(\varphi_1|\varphi_1)(\varphi_2|a_2p_2^2|\varphi_2)}\,. \tag{7}$$

We assume that χ_1,χ_2 are real in the momentum representation. The functional being insensitive to the norms and global phases of φ_1,φ_2, elementary manipulations of $\delta F/\delta\varphi_i$ yield, in the same momentum representation

$$\varphi_i(p)=\frac{\chi_i(p)}{\eta_i-a_ip^2}\,,\qquad i=1,2, \tag{8}$$

with

$$\eta_i=z-\frac{\int dp\;\varphi_j^2(p)\,a_jp^2}{\int dp\;\varphi_j^2(p)}=z-\eta_j-\frac{\int dp\;\chi_j^2(p)(a_jp^2-\eta_j)^{-1}}{\int dp\;\chi_j^2(p)(a_jp^2-\eta_j)^{-2}}\,,\qquad i=1,2,\ j=1,2,\ \text{and}\ j\neq i. \tag{9}$$

It is convenient at this stage to define the integrals

$$I_i = -(\chi_i|\varphi_i) = \int dp\, \frac{\chi_i^2(p)}{a_i p^2 - \eta_i}, \qquad i = 1,2, \tag{10}$$

and notice that Eqs. (9) then read

$$I_j \frac{d\eta_j}{dI_j} = z - \sum_{i=1}^{2} \eta_i, \qquad j = 1,2. \tag{11}$$

If furthermore one defines auxiliary variables ω_i by the conditions

$$\eta_i = a_i \omega_i^2, \quad \Im\omega_i > 0, \qquad i = 1,2, \tag{12}$$

then it is useful to define $J_j \equiv a_j I_j$. And, Eqs. (11) become

$$2\, a_j \omega_j J_j \frac{d\omega_j}{dJ_j} = z - \sum_{i=1}^{2} a_i\, \omega_i^2, \quad j = 1,2, \tag{13}$$

where a contour in the upper half plane of the complex variable p defines the integrals

$$J_j = \int dp\, \frac{\chi_j^2(p)}{p^2 - \omega_j^2}, \qquad j = 1,2. \tag{14}$$

The special cases $\Im\eta_j \to 0$, while $\Re\eta_j \geqslant 0$ define cuts in the complex η_j plane. These correspond to $\Im\omega_j \to 0$ in the ω_j plane.

When the two particles are identical, it may be interesting to symmetrize and antisymmetrize Eqs. (13) as

$$\sum_{i=1}^{2} a_i\, \omega_i\, J_i \frac{d\omega_i}{dJ_i} = z - \sum_{i=1}^{2} a_i\, \omega_i^2, \tag{15}$$

and

$$a_1\, \omega_1\, J_1 \frac{d\omega_1}{dJ_1} - a_2\, \omega_2\, J_2 \frac{d\omega_2}{dJ_2} = 0, \tag{16}$$

and identify cases where the mean field might break their symmetry. But, we shall keep the particles, and/or their channel wave packets distinct for a while.

A soluble model, involving only the manipulation of polynomials, is obtained if one chooses the forms of the wave packets as follows:

$$\chi_j(p) = \left[\frac{\gamma_j}{\pi[(p - K_j)^2 + \gamma_j^2]} \right]^{1/2}, \quad j = 1,2, \tag{17}$$

yielding the simple result

$$J_j = \frac{i\gamma_j}{\omega_j[(\omega_j - K_j)^2 + \gamma_j^2]} + \frac{1}{(K_j + i\gamma_j)^2 - \omega_j^2} = \frac{-\omega_j - i\gamma_j}{\omega_j(\omega_j - K_j + i\gamma_j)(\omega_j + K_j + i\gamma_j)}. \tag{18}$$

Resulting polynomial equations turn out to have a lower degree if $K_j = 0$, for then J_j becomes $J_j = -1/[\omega_j(\omega_j + i\gamma_j)]$. As will be found in this and the next sections, two kinds of singularities emerge: (i) "physical" ones, which essentially depend on z and are not very sensitive to "technical" parameters K_j, a_j, γ_j, and (ii) "technical" singularities, more sensitive to such parameters. The analytical continuation provided across η cuts[12] by this ω representation is clear.

Once Eqs. (13) have been solved, the saddle-point values of the functional read, using Eqs. (7)–(11)

$$D=\frac{(a_1\omega_1^2+a_2\omega_2^2-z)J_1J_2}{a_1a_2}. \tag{19}$$

The search for singularities of D as a function of the physical energy z thus consists of eliminating ω_1,ω_2 between Eqs. (13) and Eq. (19). The former reads, after elementary manipulations which take advantage of Eq. (18) when $K_1=K_2=0$

$$2a_1x^2y+a_1\gamma_2x^2-a_2\gamma_2y^2+2yz+\gamma_2z=0,\quad 2a_2y^2x+a_2\gamma_1y^2-a_1\gamma_1x^2+2xz+\gamma_1z=0, \tag{20}$$

where it was convenient to set $\omega_1=ix$, $\Re x>0$, and $\omega_2=iy$, $\Re y>0$. Equivalently, if we scale x and y into $x=\gamma_1x'$ and $y=\gamma_2y'$, respectively, the same equations read

$$(A_1x'^2+z)\,(1+2y')-A_2y'^2=0,\ (A_2y'^2+z)\,(1+2x')-A_1x'^2=0\,, \tag{21}$$

with $A_1\equiv a_1\gamma_1^2$ and $A_2\equiv a_2\gamma_2^2$. An elimination of y between Eqs. (20) gives

$$\begin{aligned}&2a_1^3\gamma_1x^7-a_1^2(4z-a_1\gamma_1^2+a_2\gamma_2^2)x^6-a_1z(8z-a_1\gamma_1^2+4a_2\gamma_2^2)x^4-2a_1\gamma_1z(3z+a_2\gamma_2^2)x^3\\&\quad-z^2(4z+a_1\gamma_1^2+4a_2\gamma_2^2)x^2-4z^2\gamma_1(z+a_2\gamma_2^2)x-\gamma_1^2z^2(z+a_2\gamma_2^2)=0,\end{aligned} \tag{22a}$$

$$y=-\frac{\gamma_2\,(a_1\,x^3+2\,x\,z+\gamma_1\,z)}{(2\,x+\gamma_1)\,(a_1\,x^2+z)}\ . \tag{22b}$$

The multiplicity of solutions is thus 7, which raises a problem for the identification of a solution, if possible unique, which accounts for a physical approximation.

In turn, if one inserts Eq. (18) into Eq. (19), one obtains D as a rational function of ω_1,ω_2, or x,y as well. Upon taking advantage of Eq. (22b), this rational fraction reduces into a rational fraction of x only, hence a polynomial relation between D and x, with degree 1 for D

$$\begin{aligned}&a_1^2a_2\gamma_2^2x^3(\gamma_1+x)^2(a_1x^3+\gamma_1z+2xz)D\\&\quad=4a_1^3x^7(x+\gamma_1)+a_1^2(a_1\gamma_1^2+a_2\gamma_2^2+12z)x^6+12a_1^2\gamma_1zx^5+a_1z(3a_1\gamma_1^2+4a_2\gamma_2^2\\&\qquad+12z)x^4+2a_1\gamma_1z(a_2\gamma_2^2+6z)x^3+z^2(3a_1\gamma_1^2+4a_2\gamma_2^2+4z)x^2\\&\qquad+4\gamma_1z^2(a_2\gamma_2^2+z)x+\gamma_1^2z^2(a_2\gamma_2^2+z).\end{aligned} \tag{23}$$

The same result is obtained if one uses Eq. (7) instead of Eq. (19).

An elimination of x between Eq. (23) and Eq. (22a) finally gives a direct, polynomial condition relating D and z

$$\begin{aligned}&z_1^2z_2^2(z_1+1)(z_2+1)(z_1+z_2+1)\overline{D}^7-4z_1z_2(z_1+1)(z_2+1)(z_1z_2-4z_1-4z_2-4)\overline{D}^6\\&\quad-4[3z_1^3z_2^2+3z_1^2z_2^3+(20z_1^3z_2+58z_1^2z_2^2+20z_1z_2^3)+(16z_1^3+88z_1^2z_2+88z_1z_2^2+16z_2^3)\\&\quad+(32z_1^2+84z_1z_2+32z_2^2)+16(z_1+z_2)]\overline{D}^5+16[3z_1^2z_2^2+39(z_1^2z_2+z_1z_2^2)\\&\quad+(32z_1^2+91z_1z_2+32z_2^2)+48(z_1+z_2)+16]\overline{D}^4+16[3z_1^2z_2+3z_1z_2^2-(8z_1^2+91z_1z_2+8z_2^2)\\&\quad-88(z_1+z_2)-64]\overline{D}^3+192[-z_1z_2+4(z_1+z_2)+8]\overline{D}^2-64(z_1+z_2+16)\overline{D}+256=0,\end{aligned} \tag{24}$$

where $z_i = a_i \gamma_i^2 / z$ and D is scaled as $D = \overline{D}/z$. The degree 7 for x in Eq. (22a) is correctly reflected here by the same degree for D (and $\overline{D}$). Conversely, given an amplitude D, the degree of the polynomial condition, Eq. (24), with respect to z, is 4. Hence, there are 7 approximate amplitudes offered by TIMF for each energy, while the inverse problem, ''given the TIMF amplitude, find the energy,'' has 4 solutions.

This model, although soluble, thus creates a complicated Riemann surface. Criteria are necessary to select one physical sheet, or physical pieces of sheets. Obvious candidates are the conditions $\Re x \geqslant 0, \Re y \geqslant 0$ when Eqs. (20) are solved. Concerning Eq. (24), the very definition of $\mathcal{D}$ demands that $\mathcal{D}$ be real and negative if z is real and negative. When $z > 0$ with a slight and positive imaginary part, then $\Im \mathcal{D}$ must be negative. Those roots D which show the same properties should thus help the identification of suitable sheets.

The argument is made much simpler if the ''technical'' parameters $a_1 \gamma_1^2$ and $a_2 \gamma_2^2$ are taken equal to some common value θ. This amounts, in some sense, to consider identical particles, although a_1 may still differ from a_2. Then, Eq. (24) factorizes as

$$[4 - 4(\theta + z)D + \theta(\theta + z)D^2]^2 [16 + 8(3\theta - 4z)D + 4(3\theta^2 + 10\theta z + 4z^2)D^2 + \theta^2(2\theta + z)D^3] = 0. \tag{25}$$

If θ is used as a unit for z and similarly $1/\theta$ is used as a unit for D, this reads as well

$$[4 - 4(1 + z)D + (1 + z)D^2] = 0, \tag{26a}$$

$$[16 + 8(3 - 4z)D + 4(3 + 10z + 4z^2)D^2 + (2 + z)D^3] = 0. \tag{26b}$$

The presence of a squared polynomial as the first factor in Eq. (25) reflects a ''symmetry breaking'' by the mean-field approximation. Indeed, when analyzing the corresponding solutions of Eqs. (20), one finds that each pair of roots $\{x,y\}$, with $x \neq y$, is accompanied by a pair $\{y,x\}$, generating the same value of D. Such a degeneracy thus makes, out of 4 of all the 7 solutions for $\{x,y\}$, two distinct values for D. All told, D then takes 5 distinct values. The remaining 3 solutions account for the degree 3 present in the second factor of Eq. (25). It is easy to verify that such 3 solutions are ''symmetric,'' namely, $x = y$. Notice that the symmetry breaking generates a rational inverse function

$$z_{bk} = \frac{(D_{bk} - 2)^2}{D_{bk}(4 - D_{bk})}, \tag{27}$$

while the symmetry conservation generates an equation of degree 2 for z. Since z_{bk} must be counted twice, one recovers the 4 solutions of the inverse problem.

It turns out that the symmetry breaking sector violates the double condition, $\Re x > 0$, $\Re y > 0$. Hence, the properties of this sector are listed in the Appendix only. Turning now to the symmetric amplitude D_{sy}, the choice of a physical branch is reasonably easy; see Figs. 1 and 2. In Fig. 1, the lower half plane contains a loop acceptable as a physical candidate. We verified that $\Re x > 0$ for this loop. Despite a suitable $\Re x > 0$ if $z > 0$, the other branch in Fig. 1 is clearly not acceptable, for it contains values D_{sy} with positive imaginary parts. Nor can one accept the third branch, seen in Fig. 2, despite its correct sign for $\Im D_{sy}$, for it violates both the limit $\mathcal{D} \to 0$ when $|z| \to \infty$ and the obvious condition ''$\Re \mathcal{D} < 0$ if z is real and negative.'' Furthermore, $\Re x$ is found unsatisfactory for this third branch.

Two values of z generate branching for D_{sy}. With a single root $D = -1/5$, reasonable, a double root $D = 16$, unphysical, occurs for $z = -27/16$, with expansion $D = 16 - 256/9\,(z + 27/16) \pm 8192/243\,[-(z + 27/16)^3]^{1/2}$. Hence, a familiar square-root cut can be used to disentangle the two corresponding sheets, both unphysical. The value $z = -27/16$ does not represent a natural threshold for the present model. More physical, obviously, is the triple-root singularity, $D = -2$, which occurs at $z = 0$, the true threshold. It is illustrated by Fig. 3, where a tiny imaginary

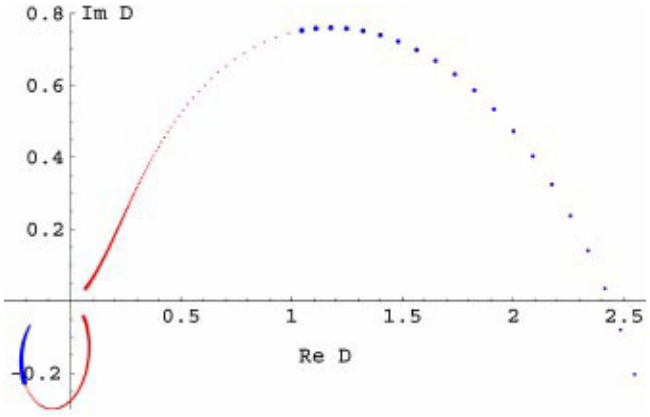

FIG. 1. Complex D plane. Two trajectories of symmetry conserving amplitudes as functions of $\Re z$ when $\Im z=1$. Growing blue dots: $\Re z$ grows from $-\infty$ to -0. Growing red dots: $\Re z$ increases from $+0$. The third trajectory lies far in the lower half. Color is available online at www-spht.cea.fr/articles/t02/148/

part $\Im z=0.0001$ was added in order to separate branches. It is noticed here that, although the physical branch gives real values of D_{sy} when $z<0$ and complex values of the same when $z>0$, there are always one real root and two complex conjugate roots on both sides in the vicinity of $z=0$. This happens indeed because the corresponding discriminant, $\Delta_3=256z^2(27+16z)^3/(2+z)^4$, actually changes sign, not for $z=0$, but rather for $z=-27/16$. This helps to understand the nature of the unphysical singularity occurring at $z=-27/16$. It gives an early ''warning'' of the (cubic) physical threshold singularity, $z=0$. An elementary, but slightly tedious calculation provides the expansions of the 3 branches in the vicinity of $z=0$, namely, $D=-2-j\,2^{2/3}\,3\,z^{1/3}+\mathcal{O}(z^{2/3})$, where j is either 1, or any one of its complex cubic roots $(-1\pm i\sqrt{3})/2$.

Consider Eqs. (21) and set $A_1=A_2$ to factorize the resultant, Eq. (22a). Then, scale x, y, and z as proportional to γ_1, γ_2, and A_1, respectively. For the sake of simple numbers, this strictly amounts to setting a common value $a_1=a_2=\gamma_1=\gamma_2=1$; hence, $A_1=A_2=1$, for those reduced equations which govern the scaled variables and parameters. For the symmetry sector, $x=y$, both equations, Eqs. (20), then boil down to $2x^3+2xz+z=0$. It is trivial to find that, at threshold $z\to 0$, all three roots have a leading term $x=(-z/2)^{1/3}+\mathcal{O}(z^{2/3})$, while, as already found,

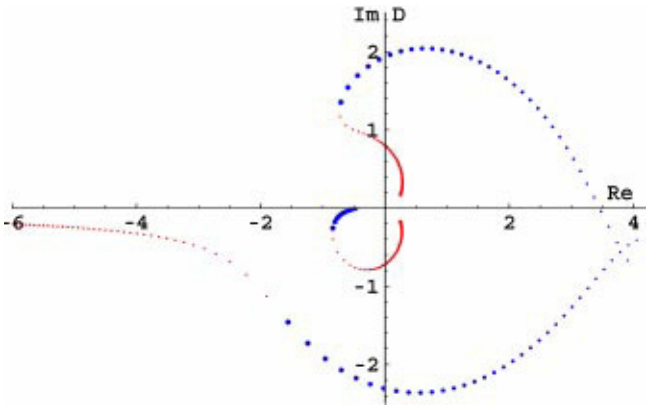

FIG. 2. Complex D plane. All trajectories D_{sy} when $\Im z=0.075$. Scales of trajectories made compatible by replacing radii from the origin by their square roots. Hence, for instance, announcing the double root $D=16$ when $z=-27/16$, blue branches cross each other near $\sqrt{D}=4$. Growing blue dots: $\Re z$ grows from $-\infty$ to -0. Growing red dots: $\Re z$ increases from $+0$.

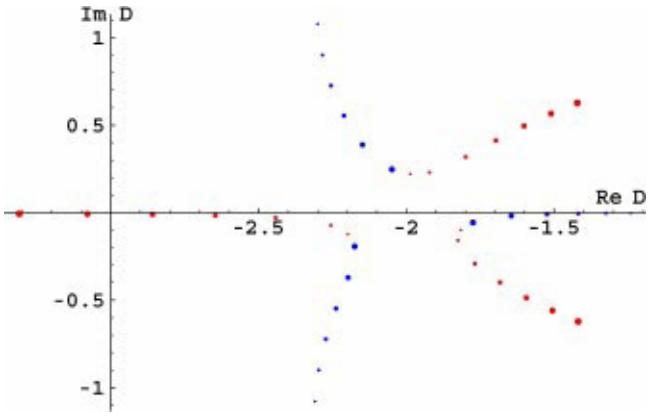

FIG. 3. Complex D plane. Triple merging $D_{sy}\rightarrow -2$, with $\Im z=0.0001$, $-0.09<\Re z<0.09$. Lower right branch physical.

$D_{sy}=-2+\mathcal{O}(z^{1/3})$. Obviously, below threshold, one must select the real root x, which gives a real amplitude. Conversely, above threshold, one must select that complex x which gives a retarded amplitude.

All told, for D_{sy}, cuts needed in the z plane are a cut from 0 to $+\infty$ for the cubic branching and, for instance, a "technical" cut from $-\infty$ to $-27/16$ to create an additional seam between the second and the third sheets.

Now we consider additional cuts, namely, those created by the condition $\Im\omega=0$, or, identically, by the condition $\Re x=0$. These occur because the solutions of realistic problems demand numerical, iterative calculations of η_i and φ_i before obtaining D. This means inversions of operators $(a_i\omega_i^2-h_i)$ in sequences of successive approximations of ω's (and self-consistent h's when potentials are involved). Obviously, every time $\Im\omega$ vanishes or becomes too small, numerical precautions are in order. Also, since the physical energy is on shell, $z=E+i0^+$, with a retardation boundary condition for many-body propagation, one would feel more comfortable with retardation also for the single-particle energies $\eta\propto\omega^2$. Advanced $\eta's$ are not to be ruled out *a priori*, because it is well known that mean-field approximations can be excellent while breaking many-body symmetries. But, clearly, branches of x's which cross such cuts $\Re x=0$ deserve some cautious scrutiny.

For the present case where $A_1=A_2$ for "symmetric" bare propagations, and still with simple numbers $a_i=\gamma_i=1$, our results are shown in Figs. 4 and 5. (For the academic, "symmetry breaking" case, see the Appendix and Figs. 13 and 14.) Figure 4 is a contour plot of the product $\Re x_1\Re x_2\Re x_3$ of the real parts of the 3 roots as functions of z in the z plane. Darker areas indicate an increasing positive product (two out of the three $\Re x$'s are <0), while the lighter areas mean a more and more negative one (one negative $\Re x$ only). The product vanishes along the contour line separating the light gray area from the moderate gray one. It will be noticed that this line contains the point $z=0$. Hence, the cut relevant to D and that relevant to x's both contain the two-body threshold. Notice, however, that, except at such a threshold, a real z induces complex η's. Namely, propagation energy cuts *do not follow the real axis* in the z plane.

The next figure, Fig. 5, shows the trajectories of the roots when we freeze $\Re z=0.1$, above threshold, and let $\Im z$ run from -1 to $+1$, hence allowing one $\Re x$, then a second one, to change their signs. The sizes of dots are coded as follows: minimal for $\Im z=-1$, growing until $\Im z=0$, minimal again for small positive values of $\Im z$, then growing again until $\Im z=1$. The lower branch is the best candidate for physical roots, because it provides a growing retardation, $0<\Im\eta\equiv\Im(-x^2)$, when $\Im z$ is positive and grows. As predicted from Fig. 4, there is an interval for $\Im z$ where 2 roots x have a positive $\Re x$.

To conclude this section, the main result derived from this elementary model with bare propagation of two particles lies in the systematic, *physical*, two-body threshold found at $z=0$ in the energy plane (z plane) for all the mean-field quantities, whether amplitudes D or propagation

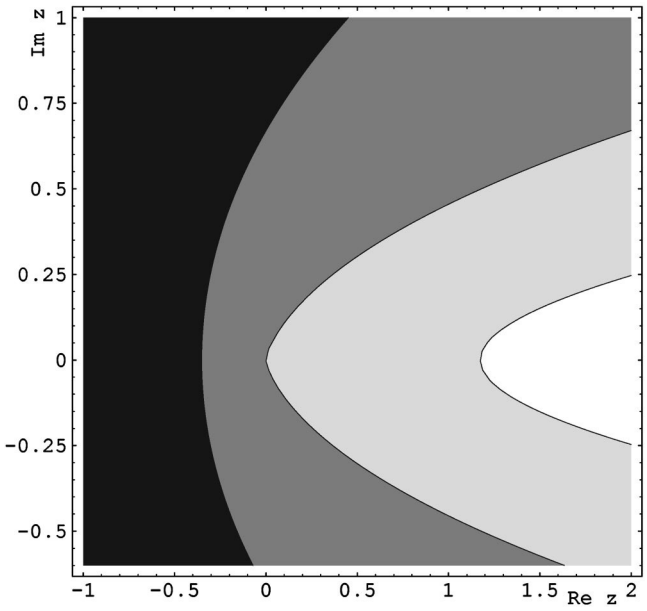

FIG. 4. Complex z plane. Cut caused by the condition $\Re x = 0$ for symmetry conserving roots. The cut is the contour line separating the lighter gray area from the darker gray one.

energies η. This threshold is, obviously, a common feature of both the exact problem and the corresponding Hartree problem. For amplitudes D, a cut in the z plane extends from the threshold 0 to $+\infty$, as seen in both the ''symmetric'' and ''breaking'' submodels. For propagation energies η, the cut starts from $z=0$, indeed, but deviates from the real semiaxis. For both Ds and η's, the cost of the nonlinearity of the TIMF approach is reflected in additional, unphysical, ''technical'' singularities. But, such unphysical singularities are not beyond interpretation either, as shown by the analytical properties listed in this section. Incidentally, as discussed earlier,[13] unphysical singularities may be washed out by a linear admixture of the various solutions of the nonlinear mean-field problem. The next sections will show even better how physical cuts remain a significant feature of the TIMF approximation.

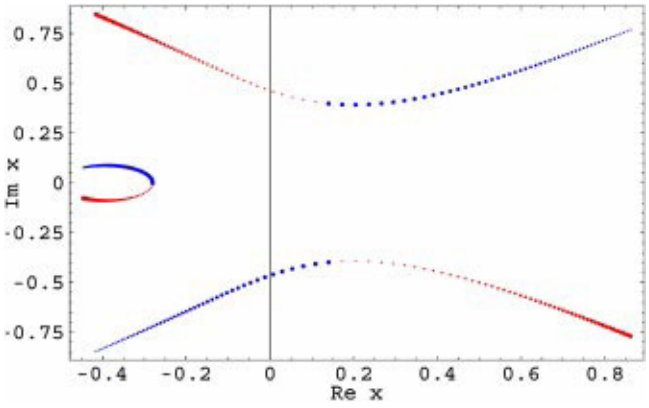

FIG. 5. Complex x plane. Trajectories of the symmetry conserving x's when $\Re z = 0.1$, while $\Im z$ crosses the cut shown by Fig. 4. Blue dots growing when $\Im z$ grows from -1 to 0. Red dots growing when $\Im z$ grows from 0 to 1.

III. SECOND SOLUBLE MODEL, ONE-BODY THRESHOLD

Here again we consider two one-dimensional particles, and particle 2 is still free with a pure kinetic energy $h_2=a_2p_2^2$ for its Hamiltonian. But, now the complete Hamiltonian $H=h_1+h_2$, while still separable, involves a bound state for particle 1, because we set $h_1=a_1p_1^2-\lambda|\chi_1\rangle\langle\chi_1|$, with an attractive enough potential. For technical reasons which will soon become clear, the form $\lambda|\chi_1\rangle\langle\chi_1|$ of this potential makes use of the same wave packet χ_1 taken as a channel wave packet. The numerical inversion of $z-H$ is still easy and allows another good validation of the TIMF approximation. The formal expression of $(z-H)^{-1}$ in terms of one-body propagators $(\eta_1-h_1)^{-1}$ and $(\eta_2-h_2)^{-1}$ demands again a convolution and the TIMF method consists in replacing the convolution by a product

$$(z-h_1-h_2)^{-1}|\chi_1\chi_2\rangle\propto(\eta_1-h_1)^{-1}|\chi_1\rangle\,(\eta_2-h_2)^{-1}|\chi_2\rangle. \tag{28}$$

This comes again from variations $\delta/\delta\varphi_i$ of the functional F. And, a further remark can be repeated: in those representations where χ and H are real, we obtain $|\Psi'\rangle=|\Psi^*\rangle$; see Eqs. (2). Hence, the possibility of just one trial function ϕ under a Euclidean rather than a Hermitian metric; see Eq. (6). The factorization of χ into two real wave packets χ_1,χ_2 essentially retains Eq. (7), which actually becomes

$$\begin{aligned}F&=\frac{(\chi_1\chi_2|\varphi_1\varphi_2)^2}{(\varphi_1\varphi_2|\,(z-h_1-h_2)\,|\varphi_1\varphi_2)}\\&=\frac{(\chi_1|\varphi_1)^2(\chi_2|\varphi_2)^2}{z(\varphi_1|\varphi_1)(\varphi_2|\varphi_2)-(\varphi_1|h_1|\varphi_1)(\varphi_2|\varphi_2)-(\varphi_1|\varphi_1)(\varphi_2|h_2|\varphi_2)}.\end{aligned} \tag{29}$$

We use the same χ_1,χ_2, real in the momentum representation. The functional being always insensitive to the norms and global phases of φ_1,φ_2, the same manipulations of $\delta F/\delta\varphi_i$ yield, in the same momentum representation

$$|\varphi_1)=(\eta_1-h_1)^{-1}|\chi_1),\quad(\eta_1-a_1p_1^2)|\varphi_1)=|\chi_1)-\lambda|\chi_1)(\chi_1|\varphi_1),$$

$$\varphi_1(p)=\frac{\chi_1(p)}{\eta_1-a_1p^2}[1-\lambda(\chi_1|\varphi_1)], \tag{30}$$

$$\varphi_2(p)=\frac{\chi_2(p)}{\eta_2-a_2p^2}, \tag{31}$$

where it is better, temporarily at least, to retain the factor $\nu=[1-\lambda(\chi_1|\varphi_1)]$ for φ_1. The same quantity ν, as will be seen shortly, cannot be discarded from the self-consistency conditions of the pair η_1,η_2

$$\eta_1=z-\frac{\int dp\;\varphi_2^2(p)\,a_2p^2}{\int dp\;\varphi_2^2(p)}=z-\eta_2-\frac{\int dp\;\chi_2^2(p)(a_2p^2-\eta_2)^{-1}}{\int dp\;\chi_2^2(p)(a_2p^2-\eta_2)^{-2}}, \tag{32}$$

$$\eta_2=z-\frac{(\varphi_1|h_1|\varphi_1)}{(\varphi_1|\varphi_1)}=z-\eta_1-\frac{(\varphi_1|(h_1-\eta_1)|\varphi_1)}{(\varphi_1|\varphi_1)}=z-\eta_1-\frac{(\chi_1|(h_1-\eta_1)^{-1}|\chi_1)}{(\chi_1|(h_1-\eta_1)^{-2}|\chi_1)}. \tag{33}$$

Indeed, it is necessary to consider the matrix element

$$\mathcal{I}_1=(\chi_1|(h_1-\eta_1)^{-1}|\chi_1), \tag{34}$$

and notice that Eqs. (32)–(33) become

$$I_2\frac{d\eta_2}{dI_2}=z-\eta_1-\eta_2=-\frac{(\chi_2|\varphi_2)}{(\varphi_2|\varphi_2)},\qquad \mathcal{I}_1\frac{d\eta_1}{d\mathcal{I}_1}=z-\eta_1-\eta_2=-\frac{(\chi_1|\varphi_1)}{(\varphi_1|\varphi_1)}. \tag{35}$$

The integrals I_1, I_2 were already defined by Eq. (10). Returning to $\mathcal{I}_1$, and to the factor ν which accounts for the separable potential present in h_1, an elementary manipulation of Eq. (30) gives

$$(\chi_1|\varphi_1)=-\mathcal{I}_1,\quad \mathcal{I}_1=\frac{I_1}{1-\lambda I_1}. \tag{36}$$

Again, we define auxiliary variables ω_i by Eq. (12) and integrals $J_j\equiv a_jI_j$ by contours in the upper half plane of the complex variable p. Then, Eqs. (35) become

$$2\,a_2\omega_2J_2\frac{d\omega_2}{dJ_2}=z-a_1\omega_1^2-a_2\omega_2^2,\quad 2\,a_1\omega_1\mathcal{I}_1\frac{d\omega_1}{d\mathcal{I}_1}=z-a_1\omega_1^2-a_2\omega_2^2. \tag{37}$$

It will be recalled here that a (unique) bound state occurs for h_1 for any positive value of λ, at an energy $\eta_0<0$, defined by the well-known condition

$$\frac{1}{\lambda}=\int dp\,\frac{\chi_1^2(p)}{a_1p^2-\eta_0}=\frac{J_1(\omega_0)}{a_1},\quad \eta_0=a_1\omega_0^2,\quad \Re\omega_0=0,\quad \Im\omega_0>0. \tag{38}$$

Indeed, the right-hand side is monotonically increasing when η_0 runs from $-\infty$ to 0 and the same right-hand side diverges at $\eta_0=0$, see Eq. (18), because of our choice of a Lorentzian form for χ_1^2. Accordingly, an explicit form of Eq. (38) is

$$\lambda+a_1\omega_0(\omega_0+i\gamma_1)=0,\quad \Re\omega_0=0,\quad \Im\omega_0>0, \tag{39}$$

or, in terms of η_0

$$(\eta_0+\lambda)^2+a_1\gamma_1^2\,\eta_0=0, \tag{40}$$

with obvious scaling properties. (Indeed, if the scale is set by λ for instance, it is convenient to define $A_1=a_1\gamma_1^2$, and the relevant scales are, obviously, A_1/λ and η_0/λ.) Threshold singularities are expected for Eqs. (32)–(33) when z reaches the one-body threshold η_0, besides the already-found two-body threshold $z=0$.

The saddle-point value D deduced from Eq. (29) reads, upon taking advantage of Eqs. (30)–(37)

$$D=(a_1\omega_1^2+a_2\omega_2^2-z)\,\mathcal{I}_1\,I_2\,. \tag{41}$$

This formula, Eq. (41), is an obvious generalization of Eq. (19). In the same way as we did in the previous section, we shall again eliminate ω_1 and ω_2, or rather the strictly equivalent variables $x=-i\omega_1$ and $y=-i\omega_2$, between Eqs. (37) and Eq. (41). It is then useful to define a parameter $A_2=a_2\gamma_2^2$, quite similar to A_1, and it is also easy to predict that the solution $D(z)$ scales in terms of A_1/λ, A_2/λ, z/λ, and λD. The Lorentzian choice for χ_1,χ_2, induces the following forms for Eqs. (37), when we replace a_1,a_2 by $A_1/\gamma_1^2, A_2/\gamma_2^2$, respectively:

$$A_1\gamma_2^2x^2+2A_1\gamma_2x^2y-A_2\gamma_1^2y^2+\gamma_1^2\gamma_2^2z+2\,\gamma_1^2\gamma_2yz=0, \tag{42a}$$

$$2\,\gamma_1\gamma_2^2\lambda x+A_2\gamma_1^2y^2+2A_2\gamma_1xy^2-A_1\gamma_2^2x^2+\gamma_1^2\gamma_2^2z+2\,\gamma_1\gamma_2^2xz=0, \tag{42b}$$

$$\frac{y}{\gamma_2}=-\frac{(\lambda\gamma_1^2+A_1x^2)\,x+(\gamma_1+2x)\gamma_1^2z}{(\gamma_1+2x)(A_1x^2+\gamma_1^2z)}. \tag{42c}$$

These scale obviously in terms of x/γ_1 and y/γ_2. It is then convenient to set $\gamma_1=\gamma_2=1$ in Eqs. (42).

Simultaneously, under the same replacement of a_1,a_2 by $A_1/\gamma_1^2, A_2/\gamma_2^2$, respectively, we can take advantage of Eqs. (36) and (18) (with $K_1=K_2=0$) to let Eq. (41) become

$$[\,A_1A_2(x^2y^2+\gamma_2x^2y+\gamma_1xy^2+\gamma_1\gamma_2xy)-A_2\gamma_1^2(y+\gamma_2)\lambda y\,]\,D+A_1\gamma_2^2x^2+A_2\gamma_1^2y^2+\gamma_1^2\gamma_2^2z=0. \tag{43}$$

Set $\gamma_1=\gamma_2=1$. The elimination of x and y between Eqs. (42)–(43) yields a degree 7 polynomial condition for D

$$\begin{aligned}\mathcal{P}(D,z,A_1,A_2,\lambda)\equiv{}&A_2^2(A_1+4\lambda)^2[\,(z+\lambda)^2+A_1z\,][\,(z+\lambda+A_2)^2+A_1(z+A_2)\,]D^7\\&-4A_2(A_1+4\lambda)[\,(z+\lambda)^2+A_1z\,][A_1A_2^2+5A_1A_2\lambda+8A_2^2\lambda+12A_2\lambda^2+4\lambda^3\\&+(-3A_1A_2-4A_2^2+4A_1\lambda+4A_2\lambda+4\lambda^2)z-4(A_1+2A_2+\lambda)z^2-4z^3]D^6\\&+\cdots-64z(A_1+A_2+20\lambda+16z)\,D+256z=0\,,\end{aligned} \tag{44}$$

which is too cumbersome to be listed here entirely. A factor $[(z+\lambda)^2+A_1z]$ forces its coefficients for both D^7 and D^6 to vanish when $z=\eta_0$; see Eq. (40). Hence, two roots D diverge at the expected one-body threshold. We also notice that for $z=0$ the two lowest degree coefficients of $\mathcal{P}$ vanish; hence, a double root $D=0$ occurs. But, for the sake of simplicity in this section, we shall not elaborate much on the exact nature of this two-body threshold singularity for this second model. Similarities with the behavior of the first model around $z=0$ are likely. In the following, we rather study in some detail the singularity at $z=\eta_0$.

The degree 7 for D is familiar from the model of the previous section. But, the degree for z is now 5 rather than 4. We verified that the limit $\lambda\to0$ factorizes $\mathcal{P}(D,z,A_1,A_2,\lambda)$ into a factor z and a polynomial with degree 4 for z.

It is convenient to set special values for a numerical investigation, for instance $a_1=\gamma_1=A_1=\gamma_2=1$ and $a_2=A_2=\lambda=2$. The full polynomial then reads

$$\begin{aligned}\mathcal{P}={}&3(1+z)(4+z)[27(3+z)(6+z)D+12(-108-9z+14z^2+2z^3)]D^6\\&-4(-2808+477z+5984z^2+3480z^3+690z^4+44z^5)\,D^5\\&+8(-584+1760z+3323z^2+1387z^3+200z^4+8z^5)D^4-8(-140+1195z+1471z^2+420z^3\\&+32z^4)\,D^3+32(-4+107z+82z^2+12z^3)D^2-16z(43+16z)D+64z.\end{aligned} \tag{45}$$

Here, the bound state lies at $\eta_0=-1$ with $\omega_0=i$. The second solution, $\omega_0=-2i, \eta_0=-4$, of Eqs. (39)–(40) violates the condition $\Re x>0$, and hence pertains to an unphysical sheet.

The 7 trajectories shown in Fig. 6 are those of the roots of $\mathcal{P}$, Eq. (45), when $\Re z$ runs from -7.5 to $+4$. This range suffices here to obtain a reasonable estimate of the root behavior when the energy runs from $-\infty$ to $+\infty$. For the sake of graphical convenience, a renormalization $D/(1+|D|)$ forces large Ds back to the trigonometric circle. Also, a small imaginary part $\Im z=0.2$ is set to enforce the rule $\Im\mathcal{D}<0$. Black dots (or lines when nearing dots fuse) correspond to $\Re z<-4.1$. Green and red ones correspond to $-3.9<\Re z<-1.1$ and $-0.9<\Re z$, respectively. Finally, blue and yellow ones investigate neighborhoods, $-4.1<\Re z<-3.9$ and $-1.1<\Re z<-0.9$, of expected singularities at $z=-4$ and $z=-1$, respectively. It turns out that Fig. 6 does not yield much information out of such ''blue'' and ''yellow'' segments, although it is clear that only two ''loops'' satisfy both rules $\Im D<0$, $\forall\Re z$ and $\lim_{|z|\to\infty}D=0$. Clearly, for a thorough investigation of all branchings and divergences, we should eliminate D between $\mathcal{P}$ and its derivative $\partial\mathcal{P}/\partial D$, then study the neigborhoods of all the roots of the obtained resultant

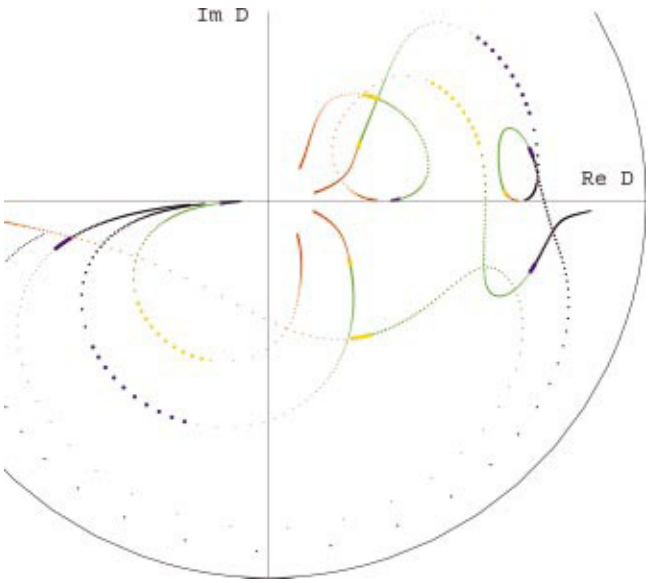

FIG. 6. (Color) Complex D plane. Trajectories of the 7 roots of Eq. (45) when $-7.5\leqslant \Re z\leqslant 4$ and $\Im z=0.2$. Black dots or lines correspond to $\Re z<-4.1$. Blue, green, yellow, and red ones correspond to $-4.1<\Re z<-3.9$, $-3.9<\Re z<-1.1$, $-1.1<\Re z<-0.9$, and $-0.9<\Re z$, respectively. Only two trajectories always keep $\Im D<0$ and cancel D when $|z|\to\infty$.

$$\mathcal{R}=z(1+z)^2(2+z)(3+z)(4+z)^2(6+z)(32+7z)^2\ \ (2\,426\,112+17\,293\,824z+54\,026\,784z^2 +121\,209\,152z^3+233\,641\,545z^4+328\,920\,768z^5+307\,812\,074z^6+191\,171\,112z^7 +79\,534\,245z^8+21\,923\,392z^9+3\,826\,944z^{10}+380\,928z^{11}+16\,384z^{12})^3\,. \tag{46}$$

This straightforward but lengthy task gives results too cumbersome to be published here, naturally. Still, it might be useful to compare Fig. 6 with a superposition of Figs. 2 and 11, keeping in mind that symmetry breaking double roots of the previous model will now be disentangled. Indeed, under the already-mentioned two criteria, namely, (i) $D\to 0$ if $|z|\to\infty$, and (ii) $\Im D<0$, only the ''tiny'' loops selected from Figs. 2 and 11 survive. Letting $\Im z\to 0$, we obtained graphical evidence that such two loops grow in such a way that their ''blue'' and ''yellow'' segments show the diverging roots predicted from the factor $(1+z)(4+z)$ in front of D^7 and D^6. With the same renormalization $D/(1+|D|)$, Fig. 7 confirms that two branches only are compatible with rules (i) and (ii), when we freeze $\Re z=-1$ and let $\Im z>0$ run. One of the ''good'' candidate roots diverges for $z=-1$; see the green segment in the lower left part of Fig. 7. The other good candidate, $D_1\simeq 0.31-0.21i$ (see the small green segment at the beginning of the smallest trajectory in the lower right angle of Fig. 7), is a simple root as a function of z in this area, and deserves little comment. The diverging root, however, because of its quadratic branching, deserves a study of its reciprocal, $d\equiv D^{-1}$. We set $z=-1+Z$ and expand $\mathcal{P}$, Eq. (45), at lowest orders with respect to d and Z

$$d^7\,\mathcal{P}(d^{-1},Z-1,A_1=1,A_2=2,\lambda=2)=270\,(2d^2+9Z)+\mathcal{O}(Z\,d)\,. \tag{47}$$

The neglected term is of order $Z^{3/2}$, because, obviously, the leading order of the double root is $d=\pm 3(-Z)^{1/2}/\sqrt{2}$, real below and imaginary above threshold, respectively. A similar, straightforward argument for the vicinity of the additional, but unphysical threshold at $z=-4$ yields the leading order $d=\pm 3(-4-z)^{1/2}/(2\sqrt{2})$.

Among all the singularities of this second model, we shall mainly discuss the physical threshold $z=-1$. Eliminate z between Eq. (42a) and Eq. (42b), or, equivalently, subtract the equations, Eqs. (37), from each other, hence

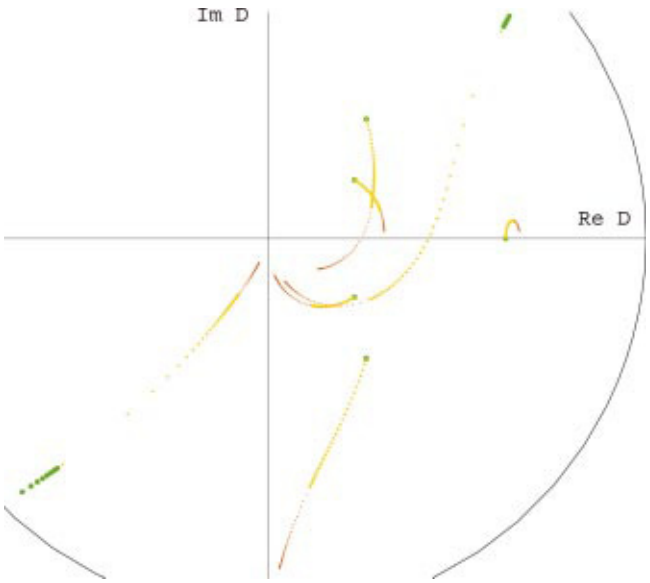

FIG. 7. (Color) Complex D plane. Trajectories of the 7 roots of Eq. (45) if $\Re z=-1$. Green, yellow, and red mean $0<\Im z<0.01$, $0.01<\Im z<2$, and $2<\Im z<8$, respectively. Again, only two trajectories maintain $\Im D<0$ and cancel D when $|z|\to\infty$.

$$a_2\omega_2 J_2\frac{d\omega_2}{dJ_2}=a_1\omega_1\mathcal{I}_1\frac{d\omega_1}{d\mathcal{I}_1}, \tag{48}$$

a relation similar to Eq. (16). To prove the statement that the static HF energy η_0 indeed defines a threshold solution of the TIMF equations, Eqs. (37), it is enough to set $\eta_1\to\eta_0$, $\eta_2\to 0$, and $z\to\eta_0$. This automatically induces $z-a_1\omega_1^2-a_2\omega_2^2\to 0$, naturally. Set $\gamma_1=\gamma_2=1$, for a trivial scaling. Then, Eq. (48) reads

$$\frac{A_2 y^2(1+y)}{1+2y}=\frac{x[A_1 x(1+x)-\lambda]}{1+2x}. \tag{49}$$

When $A_1=1$ and $A_2=\lambda=2$, we know that the limits of interest are $x\to 1$, $y\to 0$, and $z\to -1$. These satisfy the condition, $\Re x>0$; hence, only $\Re y$ must be investigated. Define $X=x-1$ and $Z=z+1$. Then, Eq. (49) boils down to $2y^2=X$, at leading orders in y and X. Accordingly, Eq. (42b), for instance, boils down to $2y^2+Z=0$. For $z<-1$ (below threshold) the solution $y\to\sqrt{(-z-1)/2}$ is acceptable, with, simultaneously, $x\to -z$. For $z>-1$ (above threshold), however, we find that a small, but positive $\Im z$ is necessary to allow the condition $\Re y>0$. This occurs because for $Z>0$ the leading order, $y^2\to -Z/2$, actually generates $\Im y$ only. An expansion up to higher orders is thus necessary for the knowledge of $\Re y$. A straightforward, but slightly lengthy calculation, yields

$$y=iZ'-\frac{i}{3}Z'^3-\frac{2}{3}Z'^4+\frac{13i}{18}Z'^5+\mathcal{O}(Z'^6), \tag{50}$$

where Z', a positive number, is defined as $Z'=\sqrt{Z/2}=\sqrt{(z+1)/2}$. The "formal conjugate" of this expansion

$$y=-iZ'+\frac{i}{3}Z'^3-\frac{2}{3}Z'^4-\frac{13i}{18}Z'^5+\mathcal{O}(Z'^6), \tag{51}$$

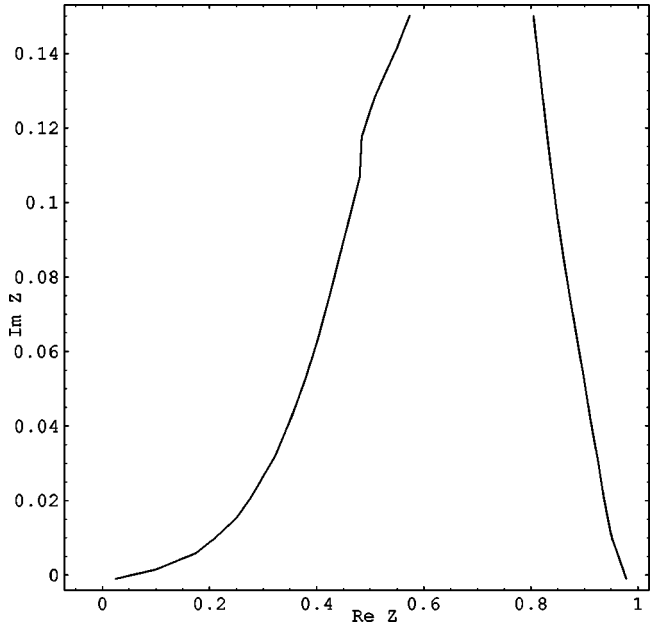

FIG. 8. Complex $Z \equiv z+1$ plane. Below the plotted line, both roots described by Eqs. (50)–(51) show $\Re y<0$. Above that line, one of them shows $\Re y>0$. The line contains both thresholds $Z=0$ and $Z=1$.

also holds, naturally. (Equivalently, it means the opposite choice of Z', namely, $Z'=-\sqrt{Z/2}$.) Both expansions induce a negative $\Re y$ as long as Z is real and positive. The sign of this $\Re y$ can be easily reversed, however, as soon as, above that threshold $z=-1$, an imaginary part $\Im z$ is implemented. Another slightly cumbersome calculation defines, upon taking advantage of either Eq. (50) or Eq. (51), the condition for the border at which one of such roots acquires a positive real part. This is illustrated by Fig. 8. Near to that threshold $z=-1$, the leading orders of the border condition give $(\Im z)^2=\frac{2}{9}(\Re z+1)^5$. Other numerical values for the parameters γ_i, A_i, etc. modify the numerical analysis, naturally, but leave intact the conclusion, namely, that $|\Im z|$ must have at least a nonvanishing value above the threshold if one needs one of these two roots to be compatible with the condition, $\Re y>0$.

We show in Fig. 9 the trajectories of y for $0<\Im z<\infty$ when $\Re z=-0.6$ is frozen at an intermediate value between the thresholds $z=-1$ and $z=0$. Only one branch is of interest, because all the other branches either stay in the $\Re y<0$ sector or the x partner root shows $\Re x<0$. The tiny blue segment at the beginning of this branch corresponds to $\Im z<0.03$, imaginary parts too small for letting y acquire a positive real part; see Fig. 8.

IV. A THEOREM

We return to the case where N is any finite particle number. The two-body interaction $V=\Sigma_{i>j}v_{ij}$ contained in the physical Hamiltonian H is assumed to be made of short-ranged potentials v_{ij}. Then, the TIMF mean fields U_i are also short ranged. For details of a further antisymmetrization with identical fermions, where the mean potential will be the same U for all particles, we refer to Ref. 8; the short range of U remains, whether one considers its direct or exchange part. At present, we still retain the case of distinct particles. Equation (3) reads again

$$(\eta_i-t_i-U_i)|\varphi_i\rangle=|\chi_i\rangle,\ \langle\varphi_i'|(\eta_i-t_i-U_i)=\langle\chi_i'|\,, \tag{52}$$

with

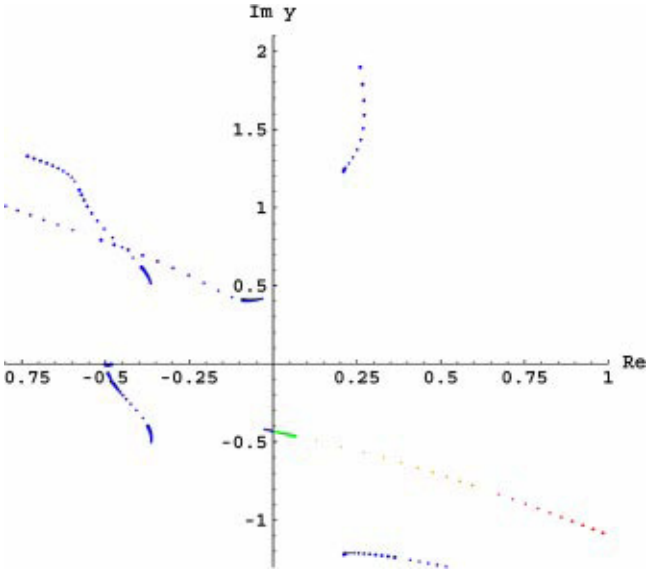

FIG. 9. Complex y plane. Trajectories of y when $\Re z=-0.6$ and $\Im z$ increases from 0. Blue lines are trajectories for which either $\Re x$ or $\Re y$ or both are negative. Only one branch, that long one in the lower right quadrant, survives the double condition, $\Re x>0$, $\Re y>0$. Tiny blue segment, $0<\Im z<0.03$. Green segment, $0.04<\Im z<0.2$. Orange one, $0.3<\Im z<1.8$. Red one, $2<\Im z<4$.

$$\eta_i = z - \frac{\langle \phi' | H | \phi \rangle}{\langle \phi' | \phi \rangle} + \frac{\langle \varphi_i' | (t_i + U_i) | \varphi_i \rangle}{\langle \varphi_i' | \varphi_i \rangle}. \tag{53}$$

Notice that we now process a generalized argument, since we can also study nondiagonal elements $\langle \chi' | (z-H)^{-1} | \chi \rangle$, where χ and χ' are products made of orbitals χ_i and χ_i', respectively. The Euclidean restriction is not implemented anymore. The trial functions ϕ and ϕ' are the products made of orbitals φ_i and φ_i', respectively. All such quantities and wave functions depend on z, but we stress here that, because of the short range of U_i, the spectrum of $h_i = t_i + U_i$ has a fixed continuum, extending from 0 to $+\infty$ on the real axis of the η_i complex plane. In general, U_i is complex and the poles of $(\eta_i - h_i)^{-1}$ need not be real; as a matter of fact, they move as functions of z (and of the choices of χ and χ'). But, the continuum cut for the spectrum of h_i always remains the same. It is therefore legitimate to ask the question, "What happens if one of the η_i's vanishes, hitting the threshold of the continuum of h_i?" Incidentally, it will be noticed that there are many trajectories (sheets) of such η_i's as functions of z. The multiplicity comes not only from the existence of N "momenta," $\omega_i \propto \pm\sqrt{\eta_i}$, with their $\pm$ ambiguity,[12] but it is also due to the nonlinearity of the mean-field theory. For instance, in our second model we found seven sheets; see the seven roots for each quantity $D(z)$, $x(z)$, $y(z)$ driven by z.

As a preliminary remark, we use Eqs. (53) to notice that the mismatch between any propagation energy η_i and the corresponding self-energy $\langle \varphi_i' | (t_i + U_i) | \varphi_i \rangle / \langle \varphi_i' | \varphi_i \rangle$ does not depend on i. Furthermore, we can take advantage of Eqs. (52) to relate the self- and propagation energies as

$$\frac{\langle \varphi_i' | (t_i + U_i) | \varphi_i \rangle}{\langle \varphi_i' | \varphi_i \rangle} = \eta_i + \frac{\mathcal{K}_i \, d\eta_i}{d\mathcal{K}_i}, \quad \mathcal{K}_i = \langle \chi_i' | (h_i - \eta_i)^{-1} | \chi_i \rangle = -\langle \varphi_i' | \chi_i \rangle = -\langle \chi_i' | \varphi_i \rangle. \tag{54}$$

In other terms, the mismatch is measured by the ratio $\langle \chi_i' | \varphi_i \rangle / \langle \varphi_i' | \varphi_i \rangle = \langle \varphi_i' | \chi_i \rangle / \langle \varphi_i' | \varphi_i \rangle$ as a function of η_i. When calculated at self-consistent $\eta_i(z)$'s, such ratios do not depend on i anymore.

Assume that the special vanishing η_s reads $\eta_s = i\varepsilon^2$, where ε is real, positive, and infinitesimal. This means that we select in the z complex plane a trajectory which in turn induces an η_s

trajectory leading to retarded, outgoing boundary conditions for that special φ_s and its partner φ'_s. For the sake of simplicity, set the inverse mass coefficient a_s to unity, or, equivalently, renormalize η_s and U_s accordingly. In physical three dimensions, the partial wave components $\varphi_{s\ell}$ are described by differential equations of the form

$$-\frac{d^2\varphi_{s\ell}}{dr^2}+\left[\frac{\ell(\ell+1)}{r^2}+U_{s\ell}(r)-i\varepsilon^2\right]\varphi_{s\ell}(r)$$
$$=\chi_{s\ell}(r)-\sum_{\ell'}\int_0^\infty dr'\,U_{s\ell\ell'}(r,r')\,\varphi_{s\ell'}(r'),\qquad \forall\ell\,, \tag{55}$$

where $U_{s\ell\ell'}$ is a short notation accounting for, if necessary, partial wave coupling and/or nonlocal parts of U_s. The source term χ_s is expanded in partial waves as well, naturally. It is then convenient to denote the right-hand sides of Eqs. (55) as source terms $\xi_{s\ell}(r)$. These are short ranged, obviously again. Similar equations hold for φ'_s.

For each ℓ, let $\sigma_{s\ell}(r)$ be the regular solution, usually normalized as $\sigma'_{s\ell}(0)=1$, of the homogeneous, left-hand side of Eqs. (55). The short range of U_s, and similar short ranges assumed for χ and χ', make it that, when $r\to\infty$, then $\varphi_{s\ell}(r)$ becomes $\simeq\exp[(i-1)\varepsilon r/\sqrt{2}]\int_0^\infty dr'\,\sigma_{s\ell}(r')\,\xi_{s\ell}(r')$, with a similar asymptotic formula for $\varphi'_{s\ell}$. Let C, a real and strictly positive number, be any convenient lower bound for the absolute values of these integrals $\int\sigma\xi$ and $\int\sigma\xi'$ in a neighborhood of $\varepsilon\to0$. This C exists, since such integrals are usually finite and nonvanishing when $\varepsilon=0$. It is clear that, as $\varepsilon\to0$, there are no longer any exponential decays or any asymptotic oscillations in the product $\varphi_s\varphi'_s$. Then, at this limit for ε, the integral $\langle\varphi'_s|\varphi_s\rangle$ diverges, while obviously an integral such as $\langle\chi'_s|\varphi_s\rangle$ remains finite. The "mismatch" cancels out.

This indicates that, for any $i\neq s$, the ratios $\mathcal{K}_i\,d\eta_i/d\mathcal{K}_i$ vanish simultaneously at their respective energies η_i. Besides threshold limits for each η_i, there is an easy interpretation for such a situation, namely, each among such $N-1$ propagation energies converges towards a bound state energy of its h_i. Indeed, let de_i be an infinitesimal difference between η_i and an isolated eigenvalue of h_i. Then, it is trivial, in an energy representation with biorthogonal eigenstates of h_i, to see that $\mathcal{K}_i$ diverges at order $(de_i)^{-1}$, while $d\mathcal{K}_i/d\eta_i$ diverges at order $(de_i)^{-2}$.

The situation is thus representative of a Hartree(–Fock) solution for the $N-1$ particle system. This is confirmed by the observation that, since $\langle\varphi'_s|\varphi_s\rangle$ diverges, the potential $U_{i/s}$ induced by particle s upon any particle $i\neq s$ vanishes. Indeed, the short range of v in the formula

$$U_{i/s}(r_i)=\frac{\int dr'\,v_{is}(r_i-r')\,\varphi'_s(r')\,\varphi_s(r')}{\langle\varphi'_s|\varphi_s\rangle}, \tag{56}$$

makes the numerator converge $\forall r_i$, while the denominator diverges. Any matrix element $\langle\varphi'_i\varphi'_s|v|\varphi_i\varphi_s\rangle$ will vanish too, for the same reason. Furthermore, the full matrix element $\langle\phi'|H|\phi\rangle/\langle\phi'|\phi\rangle$ can always be split as

$$\frac{\langle\phi'|H|\phi\rangle}{\langle\phi'|\phi\rangle}=\frac{\langle\phi'_{-s}|H_{-s}|\phi_{-s}\rangle}{\langle\phi'_{-s}|\phi_{-s}\rangle}+\frac{\langle\varphi'_s|(t_s+U_s)|\varphi_s\rangle}{\langle\varphi'_s|\varphi_s\rangle}, \tag{57}$$

where the subscript $-s$ refers to the subsystem where particle s is removed. At the limit under study, both η_s and $\mathcal{K}_s\,d\eta_s/d\mathcal{K}_s$ vanish. Hence, according to Eq. (54), the self-energy for particle s vanishes and the full matrix element $\langle\phi'|H|\phi\rangle/\langle\phi'|\phi\rangle$ reduces to the subsystem value, $\langle\phi'_{-s}|H_{-s}|\phi_{-s}\rangle/\langle\phi'_{-s}|\phi_{-s}\rangle$. Furthermore, setting $i=s$ in Eq. (53), we find that $z\to\langle\phi'_{-s}|H_{-s}|\phi_{-s}\rangle/\langle\phi'_{-s}|\phi_{-s}\rangle$. The threshold for the continuum of particle s in the z plane corresponds to the Hartree(–Fock) binding energy of the subsystem.

Conversely, if z converges towards a Hartree(–Fock) bound state energy of an $N-1$ particle system, it is easy to verify that at least one solution of the TIMF equations for the N particle system consists of a threshold wave for the additional particle, as a spectator of the static solution for the subsystem.

Notice that several special particles, not just one, can be forced into their continuum thresholds simultaneously. For instance, if particle s and s' are such that $\eta_s=\eta_{s'}=0$, then all potentials $U_{i/s}$ and $U_{i/s'}$, including $U_{s/s'}$ and $U_{s'/s}$, vanish, and $z=\langle \phi'_{-s-s'}|H_{-s-s'}|\phi_{-s-s'}\rangle/\langle \phi'_{-s-s'}|\phi_{-s-s'}\rangle$, a subsystem energy for $N-2$ particles.

It can also be noticed that such singularities do not depend upon the source terms χ and χ'. Indeed, the locations of such thresholds derive from homogeneous equations, where only H appears.

The present theorem can be phrased in a way which generalizes the theorem of Ref. 10: not only the mean-field binding energies of a system of N particles define singularities of the TIMF propagator, but the mean-field binding energies of its subsystems define thresholds of cuts where the additional particles become unbound.

V. DISCUSSION AND CONCLUSION

There are two parts in this work, namely, on the one hand, a couple of very special, analytical models, see Secs. II and III, and on the other hand, a theorem of a more general validity.

The systems described by our models are physically trivial, since they make noninteracting particles. But, their mathematical interest is different. As stated at the beginning of this work, it is important, for large particle numbers, to validate the replacement of convolutions by straight products, and our models allow a detailed study of all singularities and nonlinearities introduced by the mean-field approximation. We investigated three representations, namely what happens in (i) the z plane (propagation energy); see, for instance, Fig. 4; (ii) the D plane (TIMF amplitude); see, for instance, Fig. 1; (iii) pseudomomentum planes, such as, for instance the case of $x=-i\sqrt{\eta_1/a_1}$; see Fig. 5. Since our models automatically implement an analytic continuation from physical to unphysical sheets, there is no cut to consider in the pseudomomentum complex planes. It is obvious, however, that for both pseudomomenta x and y the imaginary axis represents both rims of the cut which would be necessary in their respective η plane. Accordingly (see for instance Fig. 8), values of z for which the real part of a pseudomomentum vanishes, or identically for which a propagation energy $\eta(z)$ becomes real and positive, make cuts in the z representation. The zoology of the TIMF solutions turns out to be surprisingly rich. The main two conclusions provided by the models can be listed as follows.

(i) Except when the many-body propagation energy z has too small an imaginary part, the TIMF equations always generate at least one branch of solutions where each single particle undergoes a retarded propagation and the TIMF amplitude D shows all suitable properties needed for a reasonable approximation of a Green's function matrix element; and

(ii) The threshold of a single-particle continuum induces the threshold of a cut singularity in the z representation; if one calls "projectile" that special particle becoming unbound, and "target" the system made by the other particle, the corresponding threshold value for the full propagation energy z is the binding energy of the "target."

The theorem derived in Sec. IV, valid for any particle number $N\geqslant 2$, extends this numerical and analytical evidence. Hence, the mean-field theory of collisions mimics the connection between singularities of the inhomogeneous problem $(z-H)|\Psi\rangle=|\chi\rangle$ and the solutions of the homogeneous Schrödinger equation $(E-H)|\Psi\rangle=0$. At this stage of our work, the similarity is restricted, however: we considered only partitions where a target is surrounded by one or several unbound particles, and we have not proven thresholds defined by mean-field energies of partitions $N_1+N_2=N$, $N_1\geqslant 2$, $N_2\geqslant 2$, into two clusters, each of them carrying its full internal energy. Nor have we considered even finer partitions $N_1+N_2+N_3=N$, with $N_1\geqslant 2$, $N_2\geqslant 2$, $N_3\geqslant 2$, and so on. Last

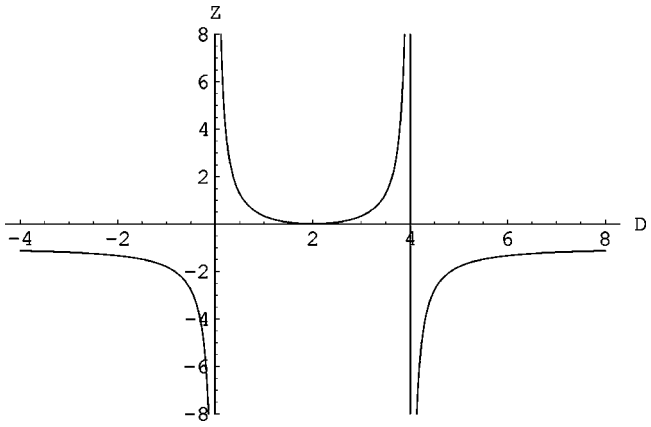

FIG. 10. Scaled energy z (unit θ) as a function of the "symmetry breaking" amplitude D (unit $1/\theta$).

but not least, the present work lacks a clear description of the shapes of the cuts beyond their thresholds. The preliminary result obtained at the stage of Fig. 8, with a "border equation" like $(\Im z)^2=\frac{2}{9}(\Re z+1)^5$, is an omen of subtle arguments yet to be phrased.

Despite such questions still open, the TIMF approximation now appears like a theory of collisions endowed with properties, such as poles and thresholds, with sound interpretations in terms of Hartree(–Fock) energies of subsystems. The special role played by single-particle energy propagators $(\eta-h)^{-1}$ in the definition of such properties is a logical consequence of the factorization of trial wave functions, an essential ingredient of practical approximations. With the present and foregoing studies, TIMF appears as a reliable and practicable alternative to resonating group (RGM) or generator coordinate (GCM) studies for application in nuclear astrophysics where there is still a demand for microscopic rather than phenomenological calculations of processes relevant to element synthesis.

APPENDIX: THE SYMMETRY BREAKING BRANCH OF THE FIRST MODEL

For the symmetry breaking sector of the first model, we again set $a_i=\gamma_i=1$, scaling x,y,z and ensuring the factorization of the resultant, Eq. (22a). It is easy to analyze the singularities of the direct solution of Eq. (26a)

$$D_{bk}=2\pm 2\left(\frac{z_{bk}}{1+z_{bk}}\right)^{1/2}, \tag{A1}$$

in terms of one cut from -1 to 0 in the complex z plane, or, alternately, two cuts from $-\infty$ to -1 and from 0 to $+\infty$, and observe that the square-root singularity at $z=0$ seems to represent a very traditional threshold singularity. Less physical, the role of $z=-1$ is to reflect the discriminant $\Delta_2=4z/(1+z)$ of Eq. (26a).

In the forthcoming figures, we keep $\theta=1$, as a natural scale for energies and inverse amplitudes. Figure 10 shows the graph of z_{bk} when D_{bk} is real and takes on all values from $-\infty$ to $+\infty$. The symmetry axis at $D=2$ is obvious from Eq. (27). Since the physical amplitude is negative when z is negative, the right lower branch of the graph is clearly unphysical, while the left lower branch is a reasonable candidate for approximations. (Notice, however, that no real estimate of the

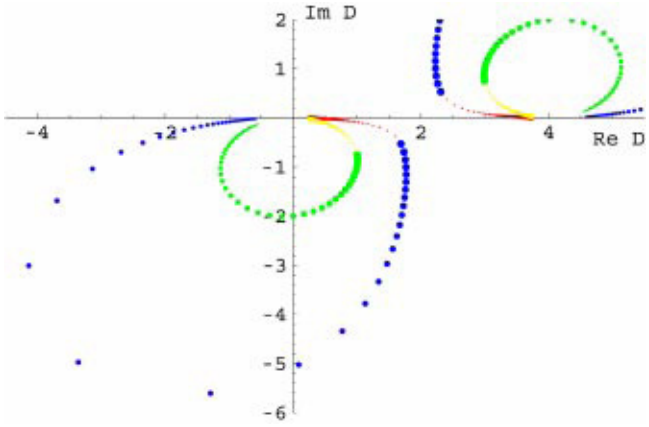

FIG. 11. Complex D plane. Trajectories of symmetry breaking D when $\Im z=0.075$ (outer loops) and $\Im z=0.4$ (inner ones). For $\Im z=0.075$, blue dots growing for $\Re z$ growing between $-\infty$ and 0^- and red ones growing for $\Re z$ growing from 0^+ to $+\infty$. For $\Im z=0.4$, blue and red replaced by green and yellow, respectively.

amplitude is offered for $-1\leqslant z\leqslant 0$.) In turn, the right upper branch is also ruled out, as $\mathcal{D}$ must vanish when $z\to+\infty$. This leaves the left upper branch as a tolerable candidate for physical approximates of the real (principal) part of $\mathcal{D}$ when z is positive.

Rather than considering inverse functions $z(D)$, we then show in Figs. 11–12 the trajectories, in a complex plane "D," of the solutions of Eq. (26a) when $\Re z$ takes on all values from $-\infty$ to $+\infty$ and $\Im z$ is frozen at some fixed value Γ. The physical situation corresponds to $\Gamma=0^+$, naturally, but Figs. 11–12 use larger values of Γ for graphical convenience. For Fig. 11, we use $\Gamma=0.075$ and $\Gamma=0.4$, which generate for D_{bk} two "outer loops" and two "inner loops," respectively. The role of $D=2$ as a symmetry center is obvious. The shrinking of the loops when Γ increases comes from the fact that, as $|z|\to\infty$, the dominant part of the symmetry breaking equation is $D(D-4)=0$. Conversely, the evolution of such loops into "angles" when $\Gamma\to 0$ is transparent in Fig. 12, obtained with $\Gamma=0.02$.

Only those solutions which lie in the lower half plane can be retained as physical candidates, according to the condition "if $\Im z>0$, then $\Im\mathcal{D}<0$." Hence, the general physical behavior of D_{bk} is as follows.

(i) When z is real and increases from $-\infty$ to -1, then D decreases from 0^- to $-\infty$;

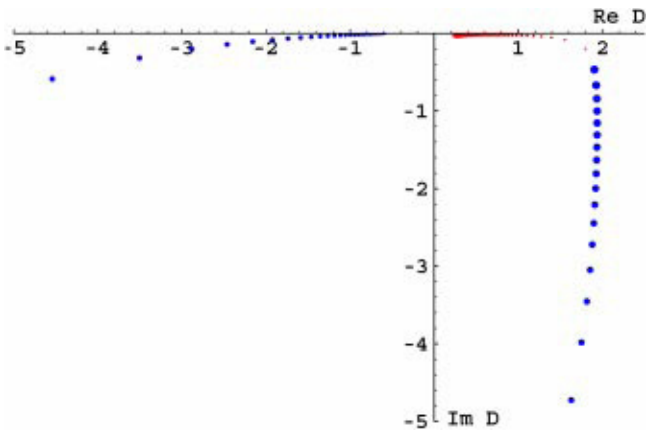

FIG. 12. Complex D plane. Lower loop trajectory of D_{bk} when $\Im z=0.02$ Blue dots growing for $\Re z$ growing between $-\infty$ and 0^-. Red ones growing for $\Re z$ growing from 0^+ to $+\infty$.

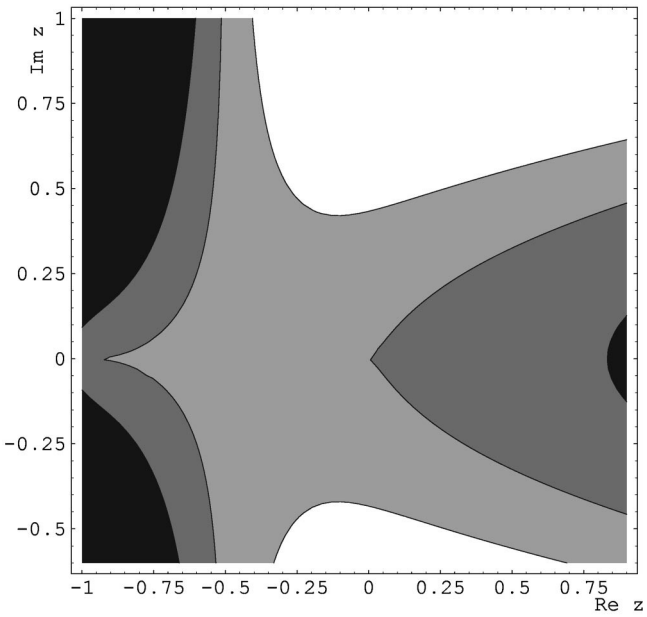

FIG. 13. Complex z plane. Cuts caused by the condition $\Re x=0$ for symmetry breaking roots. The cuts are the borders between light gray and darker gray areas.

(ii) When z is real and increases from -1 to 0, then D varies from $2-i\infty$ to 2; and
(iii) When $\Im z=0^+$ and $\Re z$ increases from 0 to $+\infty$, then D decreases from $2+i0^-$ to $i0^-$. This infinitesimal imaginary part hints that D_{bk} can at best approximate the principal part of $\mathcal{D}$. This was already deduced from Fig. 10.

The "breaking" factor of the factorizing resultant between Eqs. (20) reads

$$x^4-2\,x^3\,z-x^2\,z-2\,x\,z\,(1+z)-z\,(1+z)=0, \tag{A2}$$

keeping in mind that its roots must be paired as (x,y). Figure 13 displays a contour plot of the product of the corresponding four real parts of the roots as functions of z. The corresponding cut in the z plane is the border between the light gray and the darker gray areas. It is now made of two branches. The right-hand branch, while not located on the real axis of the z plane, again contains the two-body threshold $z=0$.

Then, Fig. 14 shows the trajectories of the four roots when we freeze $\Re z=0.1$ and let $\Im z$ run from -1 to $+1$, allowing z to cross twice the right-hand side cut shown by Fig. 13. The sizes of the dots are coded like those of Fig. 5: minimal for $\Im z=-1$, growing until $\Im z=0$, minimal again for small positive values of $\Im z$, growing again until $\Im z=1$. The "vertical" branch on the right-hand side of Fig. 14 has the unsatisfactory property that its "y partner," according to Eq. (22b), is the loop-like, tiny branch on the left-hand side of Fig. 14. Hence, $\Re x\,\Re y<0$. In turn, the two "horizontal" branches on Fig. 14 are "$x-y$" partners and are partly located inside the right-hand side of the complex x,y plane. But, actually the double condition, $\Re x>0$, $\Re y>0$, is never satisfied. It must be concluded that the symmetry breaking sector is unphysical.

A trivial manipulation of Eqs. (20) shows that the pairing of roots, for this sector and such special parameters, follows the rule

$$x\,y=z-x-y, \qquad \text{hence} \qquad y=\frac{z-x}{x+1}, \tag{A3}$$

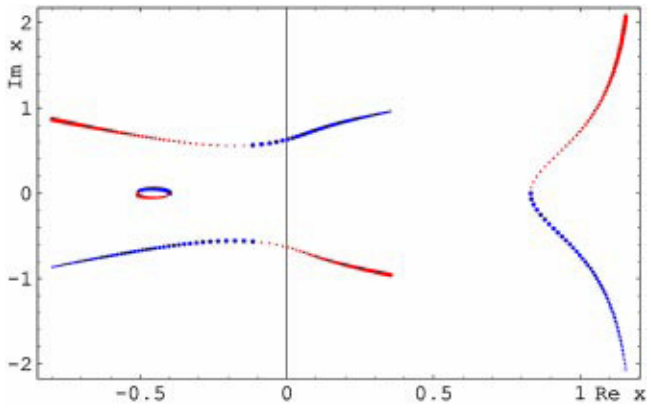

FIG. 14. Complex x plane. Trajectories of the symmetry breaking x's when $\Re z=0.1$, while $\Im z$ runs through one of the cuts shown by Fig. 13. Blue dots growing when $\Im z$ grows from -1 to 0. Red dots growing when $\Im z$ grows from 0 to 1.

which is its own inverse tranform, naturally. The rule is equivalent to Eq. (22b), but simpler. Then, if one defines $s\equiv x+y$, it is easy to reduce Eq. (A2) into

$$(z-s)^2=z(z+1), \qquad \text{or} \qquad z-s=\pm[z(z+1)]^{1/2}, \tag{A4}$$

while shortening Eq. (A3) into

$$x\,y=z-s=\pm[z(z+1)]^{1/2}. \tag{A5}$$

This means that Eq. (A2) factorizes into two distinct equations

$$x^2-x[z-(z+z^2)^{1/2}]+(z+z^2)^{1/2}=0\,, \tag{A6a}$$

$$x^2-x[z+(z+z^2)^{1/2}]-(z+z^2)^{1/2}=0\,. \tag{A6b}$$

It is easy to verify that each of these is invariant under the transform, Eq. (A3); hence, each yields a pair (x,y). A detailed analysis of all cases for such equations is trivial, but too lengthy to be published. Rather, it is enough and easy, actually, to set $\Im z=0$, and plot, for instance for Eq. (A6a), its two numerical roots as functions of z. It turns out that at least one of the roots always has a negative real part. The same phenomenon occurs for Eq. (A6b). All told, the symmetry breaking sector does not respect the constraints requested simultaneously for $\Re x$ and $\Re y$.

(Received 14 February 2003; accepted 9 January 2004)

A treatment of the spin-statistics relation in nonrelativistic quantum mechanics due to Berry and Robbins [Proc. R. Soc. London Ser. A **453**, 1771–1790 (1997)] is generalized within a group-theoretical framework. The construction of Berry and Robbins is reformulated in terms of certain locally flat vector bundles over n-particle configuration space. It is shown how families of such bundles can be constructed from irreducible representations of the group SU($2n$). The construction of Berry and Robbins, which leads to a definite connection between spin and statistics (the physically correct connection), is shown to correspond to the completely symmetric representations. The spin-statistics connection is typically broken for general SU($2n$) representations, which may admit, for a given value of spin, both Bose and Fermi statistics, as well as parastatistics. The determination of the allowed values of the spin and statistics reduces to the decomposition of certain zero-weight representations of a (generalized) Weyl group of SU($2n$). A formula for this decomposition is obtained using the Littlewood–Richardson theorem for the decomposition of representations of U($m+n$) into representations of U(m) $\times$U(n). © *2004 American Institute of Physics.* [DOI: 10.1063/1.1666979]

I. INTRODUCTION

In nonrelativistic quantum mechanics, the spin-statistics relation specifies the behavior of many-body wavefunctions for indistinguishable particles under the exchange of a pair of particle labels, and asserts that the wavefunctions either remain the same or change sign according to whether the spin of the particles, s, is integral or half-odd-integral. Nonrelativistic quantum mechanics can be formulated in a logically consistent way without the spin-statistics relation or else with the wrong (i.e., physically incorrect) spin-statistics relation. Therefore, if one is to derive the spin-statistics relation from within a nonrelativistic theory, the nonrelativistic theory must be reformulated, with postulates different from the standard ones. Whether such a reformulation serves to explain the spin-statistics relation is, to some extent, a matter of judgment, and depends on the naturalness and simplicity of the assumptions introduced.

Such a reformulation was presented by Berry and Robbins[3] (referred to in what follows as BR). In BR, the representation of spin was made to depend on position so that, in contrast to the standard formulation, the n-particle wavefunction was single-valued on configuration space. The statistics of the wavefunction was determined by a topological property of this position-dependent spin representation. A calculation showed that the statistics were in accord with the physically correct spin-statistics relation. The construction was based on Schwinger's representation of spin

a)Electronic mail: jon.harrison@physik.uni-ulm.de
b)Electronic mail: j.robbins@bristol.ac.uk

as number states of harmonic oscillators. Its implementation assumed without proof the solution of a certain topological problem; a solution was subsequently found by Atiyah.[2] The extension to relativistic wave equations was discussed by Anandan.[1]

To be compelling, a derivation of the spin-statistics relation should be based on general physical and mathematical principles, rather than a particular construction. In BR, it was suggested that certain properties of the construction introduced therein might be sufficient to ensure the correct spin-statistics relation. Later, it was shown that this is not the case,[4] as alternative constructions exist which possess these properties but yield the wrong statistics. Thus, a nonrelativistic derivation of the spin-statistics relation from general principles remains to be established along these lines. For a discussion of other nonstandard approaches to the spin-statistics relation, see Refs. 5 and 6. Our purpose here is to investigate a certain group-theoretical generalization of the construction in BR. We begin in Sec. II by framing the underlying requirement, namely, that wavefunctions be single-valued, in a geometrical context. The setting for the quantum description of n indistinguishable particles are certain vector bundles over configuration space, which we call n-spin bundles. n-spin bundles carry a representation of the spin-statistics group $\Sigma(n)$, which is (nearly) the group generated by permutations and independent rotations of n spinors (the precise definition is given in Sec. II A). The particular representation of $\Sigma(n)$ characterizes the spin and statistics of the particles. The statistics are then embodied in a topological property of the n-spin bundle, namely, the monodromy of its flat connection. This formulation is in the spirit of earlier treatments by Leinaas and Myrheim[13] and Sorkin.[17]

In Sec. III it is shown that n-spin bundles can be constructed from irreducible representations $\Gamma^{\mathbf{f}}$ of the group SU($2n$). The construction in BR is seen to be a particular case, corresponding to the completely symmetric representations of SU($2n$). For the completely symmetric representations, one obtains a definite connection between spin and statistics, indeed the physically correct connection. In contrast, an arbitrary representation of SU($2n$) does not necessarily engender a definite relation between spin and statistics; whether or not it does depends on the decomposition of certain representations of the spin-statistics group constructed from $\Gamma^{\mathbf{f}}$.

This decomposition is carried out in Sec. IV. The calculation involves the evaluation of integrals over characters of the spin-statistics group, and makes use of the Littlewood–Richardson formula for the decomposition of representations of U($k+l$) into representations of U(k) $\times$U(l). It turns out that for an arbitrary representation of SU($2n$) and a given value of spin, various choices of statistics may be realized, including parastatistics (which correspond to representations of the symmetric group of dimension greater than one).

Section V contains a summary and discussion of the results. A connection to a more general problem in representation theory is described in the Appendix.

Throughout this paper we will use the following notation: Given n elements $a_1,\ldots,a_n$ of a set $\mathcal{A}$, we let A denote the ordered n-tuple $(a_1,\ldots,a_n)$. The action of a permutation $\sigma\in S_n$ on A is denoted by $\sigma\cdot A$ and defined by

$$\sigma\cdot A=(a_{\sigma^{-1}(1)},\ldots,a_{\sigma^{-1}(n)}). \tag{1.1}$$

Many of the results presented here are discussed in greater detail by Harrison.[10]

II. BUNDLE DESCRIPTION OF *n*-PARTICLE QUANTUM MECHANICS

The configuration space C_n for n particles in three-dimensional space is the set of n-tuples $R=(\mathbf{r}_1,\ldots,\mathbf{r}_n)$. We will suppose the particles cannot coincide, so that $\mathbf{r}_j\neq\mathbf{r}_k$. If the particles are indistinguishable, then permuted configurations R and $\sigma\cdot R$ are to be regarded as being the same. We describe here a framework for quantum mechanics in which wavefunctions of identical particles are single-valued on configuration space; that is, the wavefunction at permuted configurations is the same.

We first introduce in Sec. II A the particular irreducible representations of the spin-statistics group $\Sigma(n)$, denoted by $Q^{s\lambda}$, which correspond to n identical spins. n-spin-s bundles with statistics λ are defined in Sec. II B. These are flat, Hermitian vector bundles over configuration

space whose fibers carry an irreducible representation of the spin-statistics group equivalent to $Q^{s\lambda}$. This representation is required to be compatible with indistinguishability and the flat connection. Wavefunctions are taken to be sections of the bundle, and operators representing quantum observables are defined on them. The relation to the standard formulation of quantum mechanics, as well as that of BR, is discussed.

A. Representations of the spin-statistics group for identical spinors

Let S_n denote the symmetric group. The irreducible representations, Λ^λ, of S_n are characterized by Young tableaux, λ, of n boxes (equivalently, partitions of n). Let d_λ denote the dimension of the representation Λ^λ. Let $|a\rangle$, $a=1,\ldots,d_\lambda$, denote an orthonormal basis for $\mathbb{C}^{d_\lambda}$ (with respect to the standard inner product). For $\sigma\in S_n$, we write

$$\Lambda^\lambda(\sigma)|a\rangle=\Lambda^\lambda_{a',a}(\sigma)|a'\rangle, \tag{2.1}$$

where here and elsewhere a sum over repeated indices is implied. We may take Λ^λ to be unitary, so that $\Lambda^\lambda_{a',a}(\sigma)$ is a unitary matrix.

Let

$$\mathrm{SU}(2)^n=\underbrace{\mathrm{SU}(2)\times\cdots\times\mathrm{SU}(2)}_{n\ \text{times}} \tag{2.2}$$

denote the direct product of n copies of SU(2). $\mathrm{SU}(2)^n$ describes the independent rotations of n spinors. Denote elements of $\mathrm{SU}(2)^n$ by $U=(u_1,\ldots,u_n)$, with $u_j\in\mathrm{SU}(2)$. States of n spinors, all of spin s, are unchanged if pairs of spinors are rotated through 2π, regardless of whether s is integral or half-odd-integral. Let $\mathrm{Nul}(n)\subset\mathrm{SU}(2)^n$ denote the subgroup generated by pairs of 2π-rotations. It consists of elements of the form

$$U_0=((-1)^{e_1}\mathrm{I}_2,\ldots,(-1)^{e_n}\mathrm{I}_2),\quad \text{where}\ \ (-1)^{e_1}\cdots(-1)^{e_n}=1 \tag{2.3}$$

(I_2 is the 2×2 identity matrix). The *n-spin group*, denoted by $\mathrm{Spn}(n)$, is defined by

$$\mathrm{Spn}(n)=\mathrm{SU}(2)^n/\mathrm{Nul}(n), \tag{2.4}$$

and represents in a one-to-one fashion the independent rotations of n spinors of the same spin. Given $U\in\mathrm{SU}(2)^n$, let

$$\overline{U}=U\ \ \mathrm{Nul}(n) \tag{2.5}$$

denote the corresponding element of $\mathrm{Spn}(n)$ [that is, $\overline{U}$ is the coset of $\mathrm{SU}(2)^n$ containing elements which differ from U by an even number of 2π rotations].

The *spin-statistics group*,

$$\Sigma(n)=\mathrm{Spn}(n)\rtimes S_n, \tag{2.6}$$

is the semidirect product of the n-spin group and the symmetric group. Elements are denoted by $(\overline{U},\sigma)$, where $U\in\mathrm{SU}(2)^n$ and $\sigma\in S_n$, and multiplication is given by

$$(\overline{U},\sigma)(\overline{U'},\sigma')=(\overline{U(\sigma\cdot U')},\sigma\sigma'). \tag{2.7}$$

[It is easy to check that the right-hand side of (2.7) is unchanged if U and U' are multiplied by an even number of 2π rotations.] For brevity, when $\mathrm{Spn}(n)$ and S_n are to be regarded as subgroups of $\Sigma(n)$, we will denote their elements simply by $\overline{U}$ and σ respectively, rather than by $(\overline{U},\mathrm{I}_{S_n})$ and $(\mathrm{I}_{\mathrm{Sp}(n)},\sigma)$.

The complete set of irreducible representations of the spin-statistics group can be obtained from the general representation theory of semidirect products (see, e.g., Ref. 16). Here we shall only be interested in representations whose restriction to $\mathrm{Spn}(n)$ describes n spinors all of spin s, where s is integral or half-odd-integral. It is easily established that each such irreducible representation of $\Sigma(n)$ is characterized by s and, additionally, by an irreducible representation λ of S_n. We denote this representation by $Q^{s\lambda}$, and describe it in the following.

$Q^{s\lambda}$ acts on the $(2s+1)^n d_\lambda$-dimensional vector space $\mathcal{V}^{s\lambda}$ given by

$$\mathcal{V}^{s\lambda}=\underbrace{\mathbb{C}^{2s+1}\otimes\cdots\otimes\mathbb{C}^{2s+1}}_{n\ \text{times}}\otimes\mathbb{C}^{d_\lambda}. \tag{2.8}$$

Let

$$|M,a\rangle=|m_1\rangle\otimes\cdots\otimes|m_n\rangle\otimes|a\rangle, \tag{2.9}$$

where $M=(m_1,\ldots,m_n)$ and m_j ranges between $-s$ and s in integer steps, denote a basis for $\mathcal{V}^{s\lambda}$ orthonormal with respect to the standard inner products on $\mathbb{C}^{2s+1}$ and $\mathbb{C}^{d_\lambda}$. For $\overline{U}\in\mathrm{Spn}(n)$, $Q^{s\lambda}(\overline{U})$ is given by

$$Q^{s\lambda}(\overline{U})|M,a\rangle=D^s_{m_1',m_1}(u_1)\cdots D^s_{m_n',m_n}(u_n)|M,a\rangle, \tag{2.10}$$

where $D^s_{m,m'}(u)$ denotes the standard spin-s representation of SU(2) on $\mathbb{C}^{2s+1}$, and $M'=(m_1',\ldots,m_n')$. [It is easy to check that the right-hand side of (2.10) is unchanged if $U=(u_1,\ldots,u_n)$ is multiplied by an element of $\mathrm{Nul}(n)$.] For $\sigma\in S_n$, $Q^{s\lambda}(\sigma)$ is given by

$$Q^{s\lambda}(\sigma)|M,a\rangle=\Lambda^\lambda_{a',a}|\sigma\cdot M,a'\rangle. \tag{2.11}$$

That is, the spin labels M are permuted while $|a\rangle$ transforms according to the representation Λ^λ of S_n. For a general element $(\overline{U},\sigma)\in\Sigma(n)$, the expression for $Q^{s\lambda}(\overline{U},\sigma)$ follows from (2.10) and (2.11) and the multiplication law (2.7).

B. *n*-spin-*s* bundles with statistics λ

For our purposes, a k-dimensional Hermitian vector bundle, $\mathcal{E}$, over the configuration space C_n will be regarded as a field of k-dimensional subspaces, $\mathcal{E}_R$, of a finite-dimensional Hilbert space, $\mathcal{V}$, depending smoothly on $R\in C_n$. $\mathcal{E}_R$ is called the fiber of $\mathcal{E}$ at R. A Hermitian inner product on $\mathcal{E}_R$ is induced by the Hermitian inner product on $\mathcal{V}$. A section of $\mathcal{E}$ is a function $|\Psi(R)\rangle$ on configuration space taking values in $\mathcal{E}_R$. The inner product of two sections is given by

$$\int_{C_n}\langle\Psi(R)|\Phi(R)\rangle\,dR. \tag{2.12}$$

The space of square-integrable sections forms a Hilbert space.

To represent spin s and statistics λ, each fiber $\mathcal{E}_R$ must carry a representation of the spin-statistics group unitarily equivalent to $Q^{s\lambda}$. Denote this representation by L_R. We require that L_R depend smoothly on R.

Operators representing spin, position and momentum may be defined on wavefunctions as follows. We consider the spin operators, denoted $\mathbf{S}^{op}=(\mathbf{s}_1^{op},\ldots,\mathbf{s}_n^{op})$, first. Consider the rotation of the rth spinor about an axis $\hat{\mathbf{e}}_a$ by an angle t holding the other spinors fixed. This is described by $U_{(r,a)}(t)=(u_1(t),\ldots,u_n(t))\in\mathrm{SU}(2)^n$, where

$$u_j(t)=\begin{cases}\exp(-\mathrm{i}t\sigma_a/2), & j=r,\\ \mathrm{I}_2, & \text{otherwise}\end{cases} \tag{2.13}$$

(here σ_1, σ_2, σ_3 are the Pauli matrices). Then $s^{op}_{r,a}$, the ath component of $\mathbf{s}^{op}_r$, is given by

$$\left|(s^{op}_{r,a}\Psi)(R)\right\rangle = \frac{1}{\mathrm{i}}\frac{d}{dt}\bigg|_{t=0} L_R(\overline{U}_{(r,a)}(t))\left|\Psi(R)\right\rangle. \tag{2.14}$$

As the representation L_R is unitary, $\mathbf{s}^{op}_j$, as defined by (2.14), is self-adjoint. The representation property of L_R implies that the standard commutation relations for spin are satisfied.

Position operators, $R^{op}=(\mathbf{r}^{op}_1,\ldots,\mathbf{r}^{op}_n)$, are defined componentwise by

$$\left|(r^{op}_{j,a}\Psi)(R)\right\rangle = r_{j,a}\left|\Psi(R)\right\rangle. \tag{2.15}$$

$\mathbf{r}^{op}_j$ is Hermitian with respect to the inner product (2.12), self-adjoint on a suitable domain, and the position operators commute amongst each other and with the spin operators.

The definition of momentum operators requires a Hermitian connection on $\mathcal{E}$. A Hermitian connection associates to piecewise smooth paths $R(t)\in C_n$ a family of unitary maps between the fibers $\mathcal{E}_{R(t)}$. These unitary maps describe the parallel transport of spinors along $R(t)$. Momentum operators may be defined in terms of the covariant derivative with respect to this connection.

A characteristic property of a connection is its curvature, which describes parallel transport around infinitesimal closed paths. Nonvanishing curvature corresponds physically to the presence of gauge (e.g., magnetic) fields. In order that our theory be capable of describing physics in the absence of fields, we shall require that $\mathcal{E}$ admit a flat connection. This condition is not automatically satisfied; the existence of a flat connection depends on the topology of the bundle (just as the fact that a two-torus admits a flat Riemannian metric, while a two-sphere does not, is a consequence of their different Euler characteristics).

For a flat connection, parallel transport around a closed path is trivial, provided the path is contractible. In C_n, every closed path is contractible (C_n is simply connected). Therefore, parallel-transport with respect to a flat connection on $\mathcal{E}$ is path-independent, and depends only on the endpoints of the path. Therefore, a flat Hermitian connection on $\mathcal{E}$ is characterized by unitary maps $T_{R'\leftarrow R}:\mathcal{E}_R\rightarrow\mathcal{E}_{R'}$ describing parallel transport from R to R'. Path independence then implies that

$$T_{R''\leftarrow R'}T_{R'\leftarrow R}=T_{R''\leftarrow R}. \tag{2.16}$$

Momentum operators $P^{op}=(\mathbf{p}^{op}_1,\ldots,\mathbf{p}^{op}_n)$ are defined as follows. Let

$$E_{(j,a)}=(0,\ldots,0,\hat{\mathbf{e}}_a,0,\ldots,0) \tag{2.17}$$

denote the tangent vector in configuration space on which the jth particle moves with unit velocity in the direction $\hat{\mathbf{e}}_a$ while the other particles stay fixed. Then the ath component of $\mathbf{p}^{op}_j$ is given by

$$\left|(p^{op}_{j,a}\Psi)(R)\right\rangle = \frac{d}{dt}\bigg|_0 (T_{R\leftarrow R+tE_{(j,a)}}\left|\Psi(R+tE_{(j,a)})\right\rangle). \tag{2.18}$$

$p^{op}_{j,a}$ is Hermitian with respect to the inner product (2.12) and is self-adjoint on a suitable domain. From (2.15) it is easily verified that the position and momentum operators satisfy the standard commutation relations. That the momentum operators commute amongst themselves follows from the fact that

$$T_{R\leftarrow R+tE}T_{R+tE\leftarrow R+tE+uF}=T_{R\leftarrow R+uF}T_{R+uF\leftarrow R+tE+uF}, \tag{2.19}$$

which in turn follows from the path independence (2.16) of the connection, provided the displacements tE and uF are small enough so as not to make the particles coincide.

The requirement that spin and momentum commute is equivalent to the requirement that parallel transport be compatible with the representation L_R. That is, we should have that $L_{R'}(\overline{U},\sigma)T_{R'\leftarrow R}=T_{R'\leftarrow R}L_R(\overline{U},\sigma)$.

As a basis for subsequent discussion, let us formulate the standard description of n-particle quantum mechanics within the framework described above. (In this case, the vector bundle description is unnecessary, of course, and appears artificial.) For this, take the fibers $\mathcal{E}_R$ to be everywhere equal to the fixed vector space $\mathcal{V}^{s\lambda}$. Take L_R, the representation of the spin-statistics group, to be everywhere equal to the standard representation $Q^{s\lambda}$. Parallel transport is everywhere taken to be trivial; i.e., $T_{R'\leftarrow R}$ is just the identity map on $\mathcal{V}^{s\lambda}$. Then $\mathcal{E}$ is just the Cartesian product $C_n\times\mathcal{V}^{s\lambda}$, and wavefunctions $|\Psi(R)\rangle$ are just $\mathcal{V}^{s\lambda}$-valued functions on C_n. Wavefunctions may be expanded in the standard basis $|M,a\rangle$ [cf. (2.9)],

$$|\Psi(R)\rangle=\sum_M\sum_{a=1}^{d_\lambda}\psi_{M,a}(R)|M,a\rangle. \tag{2.20}$$

The definitions (2.14), (2.15) and (2.18) of the position, spin and momentum operators yield the standard operations on the coefficients $\psi_{M,a}(R)$,

$$\mathbf{r}_j^{op}\psi^S_{M,a}(R)=\mathbf{r}_j\psi^S_{M,a}(R), \tag{2.21}$$

$$\mathbf{p}_j^{op}\psi^S_{M,a}(R)=-\mathrm{i}\nabla_{\mathbf{r}_j}\psi^S_{M,a}(R), \tag{2.22}$$

$$\mathbf{e}^{-\mathrm{i}\theta\mathbf{s}^{op}_{j,a}}\psi^S_{M,a}(R)=\sum_{m'=-s}^{s}D^s_{m_j,m'}(\mathrm{e}^{-\mathrm{i}\theta\cdot\sigma_a})\psi^S_{M',a}(R), \tag{2.23}$$

where, in (2.23), M' differs from M only in the jth component, in which m_j is replaced by m'.

We now introduce the requirement, basic to the formulation in BR, that for indistinguishable particles, the values of the wavefunction at permuted configurations should be the same. That is, we require that

$$|\Psi(\sigma\cdot R)\rangle=|\Psi(R)\rangle,\quad \sigma\in S_n. \tag{2.24}$$

(Note that for this condition to be sensible, the fibers at R and $\sigma\cdot R$ must be the same.) In this case, the wavefunction is single-valued as a function of configurations in which the particles are no longer labeled. Wavefunctions in the standard description are not single-valued in this sense. Indeed, in the standard description, the coefficients of the wavefunction at permuted configurations are related by

$$\psi_{M,a}(\sigma\cdot R)=\Lambda^\lambda_{a,a'}\psi_{\sigma^{-1}\cdot M,a'}(R), \tag{2.25}$$

so that the wavefunctions themselves satisfy

$$|\Psi(\sigma\cdot R)\rangle=L_{\sigma\cdot R}(\sigma)|\Psi(R)\rangle. \tag{2.26}$$

Descriptions based on single-valued wavefunctions, but physically equivalent to the standard description, are obtained by rewriting (2.26) as

$$|\Psi(\sigma\cdot R)\rangle=L_{\sigma\cdot R}(\sigma)T_{\sigma\cdot R\leftarrow R}|\Psi(R)\rangle. \tag{2.27}$$

In the standard description, (2.27) is the same as (2.26), since $T_{\sigma\cdot R\leftarrow R}$ is just the identity in this case. In contrast, for single-valued wavefunctions, (2.27) becomes

$$L^{-1}_{\sigma\cdot R}(\sigma)=T_{\sigma\cdot R\leftarrow R}. \tag{2.28}$$

Thus, for a description in terms of single-valued wavefunctions to be equivalent to the standard one, parallel transport is necessarily a nontrivial operation; between permuted configurations, parallel transport induces the corresponding permutation of spins.

Let us now formalize the preceding considerations. An n-spin-s bundle with statistics λ, denoted by $\mathcal{E}^{s\lambda}$, is defined to be a $(2s+1)d_\lambda$-dimensional Hermitian vector bundle over the configuration space C_n endowed with the following properties:

(A) There exists a smooth family, L_R, of unitary irreducible representations of the spin-statistics group $\Sigma(n)$ acting on the fibers $\mathcal{E}_R$, unitarily equivalent to $Q^{s\lambda}$.

(B) The fibers at permuted configurations are the same, i.e.,

$$\mathcal{E}_{\sigma\cdot R}=\mathcal{E}_R. \tag{2.29}$$

(C) There exists a flat Hermitian connection on $\mathcal{E}^{s\lambda}$, characterized by unitary maps $T_{R'\leftarrow R}$ describing parallel transport from R to R', satisfying the composition rule

$$T_{R''\leftarrow R'}T_{R'\leftarrow R}=T_{R''\leftarrow R}. \tag{2.30}$$

Parallel transport is compatible with the representation L_R in the sense that

$$L_{R'}(\overline{U},\sigma)T_{R'\leftarrow R}=T_{R'\leftarrow R}L_R(\overline{U},\sigma). \tag{2.31}$$

(D) Parallel transport between permuted fibers induces permutations, i.e.,

$$T_{\sigma\cdot R\leftarrow R}=L_{\sigma\cdot R}(\sigma^{-1}). \tag{2.32}$$

The Hilbert space $\mathcal{H}$ of wavefunctions describing n indistinguishable particles of spin s and statistics λ is the space of sections of $\mathcal{E}^{s\lambda}$ with inner product (2.12) satisfying the single-valuedness condition

$$|\Psi(\sigma\cdot R)\rangle=|\Psi(R)\rangle. \tag{2.33}$$

Observables are generated by combinations of the position, momentum and spin operators, $\mathbf{r}_j^{op}$, $\mathbf{p}_j^{op}$ and $\mathbf{s}_j^{op}$, given by (2.15), (2.22) and (2.14), respectively, which are invariant under permutations. These permutation-invariant operators preserve the single-valuedness condition (2.33).

To establish explicitly the equivalence between this formulation and the standard one, as well as the treatment in BR, it is useful to introduce a parallel-transported basis for the fibers $\mathcal{E}_R$. To this end, we fix a reference configuration $R_0\in C_n$. Since L_{R_0} is unitarily equivalent to $Q^{s\lambda}$, there exists an orthonormal basis $|M,a(R_0)\rangle$ of $\mathcal{E}_{R_0}$ for which

$$L_{R_0}(\overline{U},\sigma)|M,a(R_0)\rangle=Q^{s\lambda}_{M'a',Ma}(\overline{U},\sigma)|M',a'(R_0)\rangle. \tag{2.34}$$

A basis for $\mathcal{E}_R$ is defined via parallel transport as follows:

$$|M,a(R)\rangle=T_{R\leftarrow R_0}|M,a(R_0)\rangle. \tag{2.35}$$

Because the representation L_R is compatible with the flat connection, it follows that (2.34) holds for all R.

Wavefunctions $|\Psi(R)\rangle$ may be expanded in terms of this basis as

$$|\Psi(R)\rangle=\psi_{M,a}(R)|M,a(R)\rangle. \tag{2.36}$$

From the definitions (2.15), (2.18) and (2.14), it is readily verified that the position, momentum and spins operators act on the components $\psi_{M,a}(R)$ as the standard operators (2.21)–(2.23). The condition (2.32) implies that the components at permuted configurations are related as in (2.25), in accord with the standard formulation.

Apart from allowing parastatistics, the framework described here is equivalent to the one given in Sec. 2 of BR. There are, however, some differences in the formulation. In BR, properties (A)–(D) are expressed directly in terms of the parallel-transported basis. For example, instead of property (C), BR require that the parallel-transported basis satisfy

$$\langle M'(R)|\nabla_{\mathbf{r}_j} M(R)\rangle = 0. \tag{2.37}$$

In this way, the formalism and terminology of vector bundles is avoided.

An advantage of the present formulation is that properties required by physical considerations are distinguished from those which depend on convention. For example, (2.37) implies the existence of a flat connection, but it implies, additionally, that it is a particular connection which is flat—namely, the connection induced by the inner product on $\mathcal{V}$, according to which vectors are parallel-transported by translating them to an infinitesimally displaced fiber and there projecting them perpendicularly. This choice of connection, while convenient, is nevertheless a matter of convention, and is not required by physical considerations.

Finally, we note that we could, if we wished, impose the single-valuedness condition more directly by taking n-particle configuration space to be the identified configuration space $\overline{C}_n = C_n/S_n$ consisting of (unordered) sets $X=\{\mathbf{r},\mathbf{s},\ldots,\mathbf{t}\}$ of n distinct points in $\mathbb{R}^3$. (This is the point of view taken by Leinaas and Myrheim[13]) Then wavefunctions would become functions of X, or, more precisely, sections of an n-spin bundle over the identified configuration space $\overline{C}_n$. However, such a reformulation involves some additional mathematical complication, and, for this reason, we will confine our consideration of it to the following informal remarks.

The complication is due to the fact that there are no global Euclidean coordinates on $\overline{C}_n$; it is no longer sensible to refer to position, spin and momentum operators for a particular particle. In place of individual momenta, for example, one must introduce generalized momentum operators, which are related to covariant derivatives along smooth vector fields on $\overline{C}_n$. A formulation in terms of $\overline{C}_n$ does have some attractive aspects, though. Parallel transport between permuted fibers in C_n becomes transport from a single fiber to itself around a noncontractible closed path in $\overline{C}_n$. In this way, the statistics of the particles is reflected in the monodromy of the flat connection, a topological property of the bundle.

III. SPIN BUNDLES SU($2n$) REPRESENTATIONS

In this section we describe the construction of n-spin bundles from representations of SU($2n$). The construction is based on a connection between SU($2n$) and the spin-statistics group $\Sigma(n)$ (Sec. III A), which associates a representation $\Delta^{\mathbf{f}}$ of $\Sigma(n)$ to an irreducible representation $\Gamma^{\mathbf{f}}$ of SU($2n$) (Sec. III B). In general, the representation $\Delta^{\mathbf{f}}$ is reducible. n-spin bundles are constructed from the representations $\Gamma^{\mathbf{f}}$ and $\Delta^{\mathbf{f}}$ and an S_n-equivariant map from C_n to SU(n)/T(n) (Sec. III C).

Whether $\Gamma^{\mathbf{f}}$ determines a spin-statistics relation is discussed in Sec. III D. The question is related to the decomposition of $\Delta^{\mathbf{f}}$ into its irreducible components. A definite statistics for a given value of spin requires that $\Delta^{\mathbf{f}}$ should contain only one irreducible representation of $\Sigma(n)$ with that spin. This is the case for the completely symmetric representations, which correspond to the construction in BR. The general case is discussed in Sec. IV.

A. The spin-statistics group and SU($2n$)

Consider SU($2n$), the group of $2n$-dimensional unitary matrices of unit determinant. SU$(2)^n$ may be identified as a subgroup of SU($2n$), with $U=(u_1,\ldots,u_n)\in \mathrm{SU}(2)^n$ identified with the matrix

$$U=\begin{pmatrix} u_1 & & & \\ & u_2 & & 0 \\ & & \ddots & \\ & 0 & & u_n \end{pmatrix}. \tag{3.1}$$

[For simplicity, we will use the same symbol, in this instance U, for both an element of $\mathrm{SU}(2)^n$ and for the corresponding matrix in $\mathrm{SU}(2n)$, and will do the same for some other subgroups of $\mathrm{SU}(2n)$ to be introduced below. Taken in context this usage should not introduce any ambiguity.] Similarly, $\mathrm{SU}(n)$, the group of n-dimensional unitary matrices with unit determinant, may be identified with a subgroup of $\mathrm{SU}(2n)$, with $g\in\mathrm{SU}(n)$, with components denoted by g_{rt}, $1\leqslant r,t\leqslant t$, identified with the $\mathrm{SU}(2n)$-matrix

$$g=\begin{pmatrix} g_{11}\mathrm{I}_2 & \cdots & g_{1n}\mathrm{I}_2 \\ \vdots & \ddots & \vdots \\ g_{n1}\mathrm{I}_2 & \cdots & g_{nn}\mathrm{I}_2 \end{pmatrix}. \tag{3.2}$$

Finally, we let $T(n)$ denote the subgroup of diagonal matrices in $\mathrm{SU}(n)$. From (3.2), $T(n)$ may be identified as the subgroup of $\mathrm{SU}(2n)$ consisting of diagonal matrices of the form

$$t(\Theta)=\begin{pmatrix} \mathrm{e}^{\mathrm{i}\theta_1}\mathrm{I}_2 & & & \\ & \mathrm{e}^{\mathrm{i}\theta_2}\mathrm{I}_2 & & 0 \\ & & \ddots & \\ & 0 & & \mathrm{e}^{\mathrm{i}\theta_n}\mathrm{I}_2 \end{pmatrix}, \tag{3.3}$$

where $\Theta=(\theta_1,\ldots,\theta_n)$ is an n-tuple of phases satisfying

$$\mathrm{e}^{\mathrm{i}\theta_1}\cdots\mathrm{e}^{\mathrm{i}\theta_n}=1. \tag{3.4}$$

Note that $\mathrm{SU}(2)^n\cap T(n)$ is just the subgroup $\mathrm{Nul}(n)$ of null rotations, which consists of $\mathrm{SU}(2n)$-matrices of the form

$$U_0=\begin{pmatrix} (-1)^{e_1}\mathrm{I}_2 & & & \\ & (-1)^{e_2}\mathrm{I}_2 & & \\ & & \ddots & \\ & & & (-1)^{e_n}\mathrm{I}_2 \end{pmatrix}, \tag{3.5}$$

where $(-1)^{e_1}\cdots(-1)^{e_n}=1$.

Let $N(n)\subset\mathrm{SU}(n)$ denote the normalizer of $T(n)$ in $\mathrm{SU}(n)$, i.e., the subgroup of $\mathrm{SU}(n)$ which leaves $T(n)$ invariant under conjugation. It is straightforward to show that elements of $N(n)$ may be parametrized by a permutation $\sigma\in S_n$ and an n-tuple of phases $\Phi=(\phi_1,\ldots,\phi_n)$ satisfying

$$\mathrm{e}^{\mathrm{i}\phi_1}\cdots\mathrm{e}^{\mathrm{i}\phi_n}=\mathrm{sgn}(\sigma) \tag{3.6}$$

[here $\mathrm{sgn}(\sigma)$ denotes the parity of σ], and are of the form

$$y_{rt}(\sigma,\Phi)=\delta_{r,\sigma(t)}\mathrm{e}^{\mathrm{i}\phi_t}. \tag{3.7}$$

Multiplication in $N(n)$ is given by $y(\sigma,\Phi)y(\sigma',\Phi')=y(\sigma\sigma',\sigma'^{-1}\cdot\Phi+\Phi')$, so that, formally, $N(n)$ may be regarded as the semidirect product, $S_n\rtimes T(n)$. The quotient $N(n)/T(n)$, the Weyl group of $\mathrm{SU}(n)$, is isomorphic to S_n.

Let $M(n)$ denote the normalizer of $T(n)$ in $\mathrm{SU}(2n)$, i.e., the subgroup of $\mathrm{SU}(2n)$ which leaves $T(n)$ invariant under conjugation. Clearly $M(n)$ contains $N(n)$ as a subgroup. $M(n)$ also

contains the SU($2n$)-centralizer of $T(n)$, denoted by $Z(n)$, i.e., the subgroup of SU($2n$) whose elements commute with all elements of $T(n)$. It is straightforward to show that elements of $Z(n)$ are of the form $U\,t(\Theta)$, where $U\in \mathrm{SU}(2)^n$. and $t(\Theta)\in T(n)$. It is then straightforward to show that elements of $M(n)$ can be expressed as products of elements of $Z(n)$ and $N(n)$, and thus are of the form

$$x(U,\sigma,\Phi)=Uy(\sigma,\Phi), \tag{3.8}$$

where the phases Φ satisfy (3.6). Multiplication in $M(n)$ is given by

$$x(U,\sigma,\Phi)\,x(U',\sigma',\Phi')=x(U\sigma\cdot U',\sigma\sigma',\sigma'^{-1}\cdot\Phi+\Phi'). \tag{3.9}$$

The parametrization $x(U,\sigma,\Phi)$ of (3.8) is not unique. If U is replaced by UU_0, with $U_0\in \mathrm{Nul}(n)$ given by (3.5), and Φ is replaced by Φ', where $\phi_j'=\phi_j+e_j\pi$, then $x(U,\sigma,\Phi)$ is unchanged. In this way, we see that, formally, $M(n)$ is isomorphic to $\mathrm{SU}(2)^n\ltimes N(n)/\mathrm{Nul}(n)$.

From these considerations, it follows that the quotient $M(n)/T(n)$ is isomorphic to the spin-statistics group, i.e.,

$$\Sigma(n)=\mathrm{Spn}(n)\rtimes S_n\cong M(n)/T(n). \tag{3.10}$$

The isomorphism is given explicitly by

$$(\overline{U},\sigma)\mapsto x(U,\sigma,\Phi)T(n), \tag{3.11}$$

where $x(U,\sigma,\Phi)T(n)$ denotes a coset in $M(n)/T(n)$. This association between SU($2n$) and the spin-statistics group is the basis of the constructions to follow.

B. Representations of the spin-statistics group from representations of SU($2n$)

Let $\Gamma^{\mathbf{f}}$ denote a unitary irreducible representation of SU($2n$), labeled by a Young tableau $\mathbf{f}=(f_1,\ldots,f_{2n})$ of up to $2n$ rows (in fact, the last row of $\mathbf{f}$ may be taken to be empty). Let $\mathcal{V}$ denote the Hermitian inner product space on which $\Gamma^{\mathbf{f}}$ acts. (Of course, $\mathcal{V}$ depends on the choice of representation, but to simplify the notation we will not indicate this explicitly.)

Under the restriction of $\Gamma^{\mathbf{f}}$ to $T(n)$, $\mathcal{V}$ may be decomposed into a direct sum of orthogonal subspaces, $\mathcal{V}^K$, on which $\Gamma^{\mathbf{f}}(t(\Theta))$ is represented by the phase factor $\exp \mathrm{i}(K\cdot\Theta)$. Here $K=(k_1,\ldots,k_n)$ is an n-tuple of integers, and $K\cdot\Theta=\Sigma_j k_j\theta_j$. The subspace $\mathcal{V}^0$, corresponding to $K=(0,\ldots,0)$, consists of vectors which are invariant under $\Gamma^{\mathbf{f}}(T(n))$.

Let us determine the action of $M(n)$ on the subspaces $\mathcal{V}^K$. Given $x(U,\Phi,\sigma)\in M(n)$, it follows from (3.9) that

$$\begin{aligned}\Gamma^{\mathbf{f}}(t(\Theta))\Gamma^{\mathbf{f}}(x(U,\sigma,\Phi))\cdot\mathcal{V}^K&=\Gamma^{\mathbf{f}}(x(U,\sigma,\Phi))\Gamma^{\mathbf{f}}(t(\sigma^{-1}\cdot\Theta))\cdot\mathcal{V}^K\\&=\mathrm{e}^{\mathrm{i}(K\cdot(\sigma^{-1}\cdot\Theta))}\Gamma^{\mathbf{f}}(x(U,\sigma,\Phi))\cdot\mathcal{V}^K=\mathrm{e}^{\mathrm{i}(\sigma\cdot K)\cdot\Theta}\Gamma^{\mathbf{f}}(x(U,\sigma,\Phi))\cdot\mathcal{V}^K.\end{aligned} \tag{3.12}$$

Thus, under the action of $M(n)$, the subspaces $\mathcal{V}^K$ are mapped into one another according to

$$\Gamma^{\mathbf{f}}(x(U,\Phi,\sigma))\cdot\mathcal{V}^K=\mathcal{V}^{\sigma\cdot K}. \tag{3.13}$$

It follows from (3.13) that $\mathcal{V}^0$ is invariant under $M(n)$. Therefore $\Gamma^{\mathbf{f}}$ restricts to a representation of $M(n)$ on $\mathcal{V}^0$. Since $T(n)\subset M(n)$ belongs to the kernel of this representation [as $T(n)$ leaves vectors in $\mathcal{V}^0$ invariant], $\Gamma^{\mathbf{f}}(M(n))$ reduces to a representation of the quotient $M(n)/T(n)$, which we denote by $\Delta^{\mathbf{f}}$. Since $M(n)/T(n)\cong\Sigma(n)$ (cf. 3.10), $\Delta^{\mathbf{f}}$ is in fact a representation of the spin-statistics group. From (3.11), $\Delta^{\mathbf{f}}$ is given by

$$\Delta^{\mathbf{f}}(\overline{U},\sigma)=\Gamma^{\mathbf{f}}(x(U,\Phi,\sigma)). \tag{3.14}$$

In general, the representation $\Delta^{\mathbf{f}}$ of $\Sigma(n)$ is reducible. Let $\nu(\mathbf{f},s\lambda)$ denote the multiplicity with which the irreducible representation $Q^{s\lambda}$, given by (2.10), appears in the decomposition of $\Delta^{\mathbf{f}}$. This multiplicity will play a central role in what follows.

C. Construction of *n*-spin bundles

Let $\Xi: C_n \to \mathrm{SU}(n)/T(n)$ denote a smooth map from n-particle configuration space C_n to the coset space $\mathrm{SU}(n)/T(n)$. Such a map may be represented by $g(R)$, an $\mathrm{SU}(n)$-valued function on C_n which is smooth up to right multiplication by an element of $T(n)$. [That is, discontinuities in $g(R)$ can be removed locally by multiplying on the right by a discontinuous $T(n)$-valued function.] The symmetric group S_n acts on C_n as permutations (i.e., $R \mapsto \sigma \cdot R$) and on $\mathrm{SU}(n)/T(n)$ as the Weyl group [i.e., for $y(\sigma,\Phi) \in N(n)$, $g\,T(n) \mapsto g y^{-1}(\sigma,\Phi)\,T(n)$]. Ξ is said to be equivariant with respect to S_n if, for all $\sigma \in S_n$, $\Xi \circ \sigma = \sigma \circ \Xi$. In terms of $g(R)$, S_n-equivariance is equivalent to

$$g(\sigma \cdot R)\,T(n) = g(R) y^{-1}(\sigma,\Phi)\,T(n). \tag{3.15}$$

Atiyah[2] has shown that there exist continuous (and therefore smooth) S_n-equivariant maps from C_n to $\mathrm{SU}(n)/T(n)$. Let $g(R)$ represent any such equivariant map [the results which follow do not depend on the particular choice of $g(R)$].

As in Sec. III B, let $\Gamma^{\mathbf{f}}$ be an irreducible representation of $\mathrm{SU}(2n)$, and $\Delta^{\mathbf{f}}$ the associated representation of the spin-statistics group $\Sigma(n)$. Suppose $\nu(\mathbf{f},s\lambda) > 0$, i.e., $\mathcal{V}^0$ contains a subspace, which we denote by $\mathcal{V}^{s\lambda}$, which transforms under $\Delta^{\mathbf{f}}$ according to the irreducible representation $Q^{s\lambda}$ of $\Sigma(n)$. We may then construct an n-spin-s bundle $\mathcal{E}^{s\lambda}$ as follows. The fibers $\mathcal{E}^{s\lambda}_R \subset \mathcal{V}$ are given by

$$\mathcal{E}^{s\lambda}_R = \Gamma^{\mathbf{f}}(g(R)) \cdot \mathcal{V}^{s\lambda}. \tag{3.16}$$

Since $g(R)$ is smooth up to right multiplication by a $T(n)$-valued function and $\mathcal{V}^{s\lambda}$ is invariant under $\Gamma^{\mathbf{f}}(T(n))$, it follows that $\mathcal{E}^{s\lambda}_R$ depends smoothly on R.

Let us verify that $\mathcal{E}^{s\lambda}$ has the properties (A)–(D) listed in Sec. II B. For (A), we define the representation L_R on $\mathcal{E}^{s\lambda}_R$ by

$$L_R(\overline{U},\sigma) = \Gamma^{\mathbf{f}}(g(R)) \Delta^{\mathbf{f}}(\overline{U},\sigma) \Gamma^{\mathbf{f}^\dagger}(g(R)), \tag{3.17}$$

where $\Delta^{\mathbf{f}}(\overline{U},\sigma)$ is the representation of $\Sigma(n)$ given by (3.14). By assumption, $\Delta^{\mathbf{f}}$ is unitarily equivalent to $Q^{s\lambda}$ on $\mathcal{V}^{s\lambda}$, so it is evident from (3.17) that L_R is unitarily equivalent to $Q^{s\lambda}$ for all R. Since the right-hand side of (3.17) is unchanged if $g(R)$ is multiplied on the right by a (possibly discontinuous) $T(n)$-valued function, it is clear that L_R depends smoothly on R.

For (B), from the definition (3.16) and the equivariance property (3.15), we have that

$$\mathcal{E}^{s\lambda}_{\sigma \cdot R} = \Gamma^{\mathbf{f}}(g(\sigma \cdot R)) \cdot \mathcal{V}^{s\lambda} = \Gamma^{\mathbf{f}}(g(R)) \Gamma^{\mathbf{f}}(y^{-1}(\sigma,\Phi)) \cdot \mathcal{V}^{s\lambda} = \Gamma^{\mathbf{f}}(g(R)) \cdot \mathcal{V}^{s\lambda} = \mathcal{E}^{s\lambda}_R. \tag{3.18}$$

Thus the fibers at permuted configurations are the same.

For (C), we define the unitary maps $T_{R' \leftarrow R}$ describing flat parallel transport between the fibers at R and R' by

$$T_{R' \leftarrow R} = \Gamma^{\mathbf{f}}(g(R')) \Gamma^{\mathbf{f}^\dagger}(g(R)). \tag{3.19}$$

The right-hand side is unchanged if $g(R)$ is multiplied on the right by a $T(n)$-valued function, so $T_{R' \leftarrow R}$ is well defined and depends smoothly on R and R'. The composition law (2.30) is easily verified. Compatibility with the representations L_R [cf. (2.31)] follows from the definition of L_R in (3.17) and the representation property of $\Gamma^{\mathbf{f}}$.

For (D), from (3.19), parallel transport $T_{\sigma\cdot R\leftarrow R}$ between permuted fibers R and $\sigma\cdot R$ is given by $\Gamma^{\mathbf{f}}(g(\sigma\cdot R))\Gamma^{\mathbf{f}^\dagger}(g(R))$. The equivariance condition (3.15) implies this is equal to $\Gamma^{\mathbf{f}}(g(R))\Gamma^{\mathbf{f}}(y^{-1}(\sigma,\Phi))\Gamma^{\mathbf{f}^\dagger}(g(R))$. From (3.17), the condition (2.32) follows.

D. Spin-statistics relations from SU(2n) representations?

Given an irreducible representation $\Gamma^{\mathbf{f}}$ of SU($2n$), the preceding construction determines the statistics for spin s unambiguously, provided that there is just one representation $Q^{s\lambda}$ with spin s in the decomposition of $\Delta^{\mathbf{f}}$; equivalently, given $\mathbf{f}$ and s, the multiplicity $\nu(\mathbf{f},s,\lambda)$ should vanish for all but one λ.

This is the case for the completely symmetric representations of SU($2n$). The completely symmetric representations correspond to Young tableaux with a single row. Let Γ^d denote the representation for a single row of d boxes. Γ^d may be realized on the space $\mathcal{V}$ of homogeneous polynomials of degree d in $2n$ variables, $z=(z_1,\ldots,z_{2n})\in\mathbb{C}^{2n}$, and is given by $\Gamma^d(f)\cdot P(z)=P(f^{-1}\cdot z)$ for $f\in\mathrm{SU}(2n)$. Γ^d is unitary with respect to the inner product

$$\langle P,Q\rangle=\int_{\mathbb{C}^{2n}}\mathrm{e}^{-z^*\cdot z/2}P^*(z)Q(z)\,d^{4n}z \tag{3.20}$$

on $\mathcal{V}$.

An orthogonal basis for $\mathcal{V}$ is given by the monomials

$$\prod_{r=1}^{n} z_{1,r}^{a_r}z_{2,r}^{b_r}, \tag{3.21}$$

where the sum of the exponents a_j and b_j is given by d. The subspace $\mathcal{V}^0$, whose vectors are invariant under $T(n)$, consists of polynomials which are invariant under $z\mapsto t^{-1}(\Theta)\cdot z$, where

$$t^{-1}(\Theta)\cdot z=(\mathrm{e}^{-\mathrm{i}\theta_1}z_1,\mathrm{e}^{-\mathrm{i}\theta_1}z_2,\ldots,\mathrm{e}^{-\mathrm{i}\theta_n}z_{2n-1},\mathrm{e}^{-\mathrm{i}\theta_n}z_{2n}). \tag{3.22}$$

Such polynomials are linear combinations of the monomials (3.21) for which a_r+b_r is independent of r, so that $a_r+b_r=d/n$. Thus, for $\mathcal{V}^0$ to be nontrivial, d must be divisible by n.

Let us assume this is the case, so that d/n is integral. Then $s=d/2n$ is either integral or half-odd-integral. Let $m_r=a_r-s$. Then $a_r=s+m_r$ and $b_r=s-m_r$. It follows that $\mathcal{V}^0$ is spanned by the $(2s+1)^n$ monomials

$$\prod_{r=1}^{n} z_{1,r}^{s+m_r}z_{2,r}^{s-m_r}, \tag{3.23}$$

where $-s\leqslant m_r\leqslant s$ and $s\pm m_r$ is integral. Under Spn(n), $\mathcal{V}^0$ transforms as n spin-s spinors. As the dimension of $\mathcal{V}^0$ is $(2s+1)^n$, it follows that there is a single irreducible representation $Q^{s\lambda}$ with multiplicity one in the decomposition of $\Delta^{\mathbf{f}}$, and that $d_\lambda=1$, i.e., λ is either the completely symmetric or the completely antisymmetric representation of S_n.

λ may be determined by considering the action of permutations on an element of $\mathcal{V}^0$, for example,

$$P_s(z)\overset{\mathrm{def}}{=}z_2^{2s}z_4^{2s}\cdots z_{2n}^{2s}. \tag{3.24}$$

From (3.7), under $y^{-1}(\sigma,\Phi)$, the even components transform as $z_{2j}\mapsto\mathrm{e}^{-\mathrm{i}\phi_j}z_{2\sigma(j)}$. Thus, under $y(\sigma,\Phi)$, $P_s(z)$ is multiplied by the phase factor $\mathrm{e}^{2s\mathrm{i}\phi_1}\cdots\mathrm{e}^{2s\mathrm{i}\phi_n}$. From (3.6), this phase factor is just $\mathrm{sgn}^{2s}(\sigma)$. Thus, the completely symmetric representations of SU($2n$) of dimension $d=2ns$

lead to n-spin-bundles with spin s and Bose or Fermi statistics according to the parity of $2s$, in accord with the physically correct spin-statistics relation. This is precisely the result obtained in BR.

IV. CALCULATION OF THE MULTIPLICITIES

Given an arbitrary representation $\Gamma^{\mathbf{f}}$ of $\mathrm{SU}(2n)$, we wish to determine for which spins an n-spin-s bundle can be constructed, and, for those spins, whether the constructions have a definite type of statistics. To this end, we calculate the multiplicities $\nu(\mathbf{f},s\lambda)$ with which the irreducible representation $Q^{s\lambda}$ of $\Sigma(n)$ appears in the representation $\Delta^{\mathbf{f}}$. This is given by the following integral:

$$\nu(\mathbf{f},s\lambda)=\int_{\Sigma(n)} d\mu_{\Sigma(n)}\, X^{s\lambda *}(\overline{U},\sigma)X^{\mathbf{f}}(\overline{U},\sigma). \tag{4.1}$$

Here $X^{s\lambda}$ and $X^{\mathbf{f}}$ denote the characters of the $\Sigma(n)$-representations $Q^{s\lambda}$ and $\Delta^{\mathbf{f}}$, respectively, and $d\mu_{\Sigma(n)}$ denotes the normalized Haar measure on $\Sigma(n)$. Before evaluating the integral (4.1) in Sec. IV B, we first introduce some background material and notation.

A. Preliminaries

1. Character formula for U(k)

Irreducible representations of the k-dimensional unitary group $\mathrm{U}(k)$ are labeled by Young tableaux $\boldsymbol{\alpha}=(\alpha^1,\ldots,\alpha^k)$ of k rows (some of which may be empty), where $\alpha^1\geqslant\cdots\geqslant\alpha^k\geqslant 0$ specify the number of boxes in each row. Let

$$|\boldsymbol{\alpha}|=\alpha^1+\cdots+\alpha^k \tag{4.2}$$

denote the number of boxes in the tableau. Denote the eigenvalues of matrices in $\mathrm{U}(k)$ by $(\exp i\xi_1,\ldots,\exp i\xi_k)$, and their eigenphases by $\boldsymbol{\xi}=(\xi_1,\ldots,\xi_k)$. The characters $K_k^{\boldsymbol{\alpha}}$ of the irreducible representations are functions of $\boldsymbol{\xi}$ and are given by the Weyl character formula,

$$K_k^{\boldsymbol{\alpha}}(\boldsymbol{\xi})=\frac{\begin{vmatrix} e^{i(\alpha^1+k-1)\xi_1} & e^{i(\alpha^1+k-1)\xi_2} & \cdots & e^{i(\alpha^1+k-1)\xi_k} \\ e^{i(\alpha^2+k-2)\xi_1} & e^{i(\alpha^2+k-2)\xi_2} & \cdots & e^{i(\alpha^2+k-2)\xi_k} \\ \vdots & \vdots & & \vdots \\ e^{i\alpha^k\xi_1} & e^{i\alpha^k\xi_2} & \cdots & e^{i\alpha^k\xi_k} \end{vmatrix}}{\begin{vmatrix} e^{i(k-1)\xi_1} & e^{i(k-1)\xi_2} & \cdots & e^{i(k-1)\xi_k} \\ e^{i(k-2)\xi_1} & e^{i(k-2)\xi_2} & \cdots & e^{i(k-2)\xi_k} \\ \vdots & \vdots & & \vdots \\ 1 & 1 & \cdots & 1 \end{vmatrix}}. \tag{4.3}$$

Irreducible representations of $\mathrm{SU}(k)$ are obtained by restriction. On $\mathrm{SU}(k)$, the representation $\boldsymbol{\alpha}+r$, which is obtained by adding r columns of k boxes to $\boldsymbol{\alpha}$, is equivalent to the representation $\boldsymbol{\alpha}$. $\mathrm{SU}(k)$ representations can be uniquely labeled by Young tableaux of $k-1$ rows (some of which may be empty).

2. The Littlewood–Richardson theorem

Given an irreducible representation $\boldsymbol{\gamma}$ of $\mathrm{U}(k+l)$, its restriction to the subgroup $\mathrm{U}(k)\times\mathrm{U}(l)$ is, in general, reducible, and may be decomposed into a sum of tensor products of irreducible representations $\boldsymbol{\alpha}$ and $\boldsymbol{\beta}$ of $\mathrm{U}(k)$ and $\mathrm{U}(l)$, respectively. In terms of characters, this decomposition takes the form

$$K^{\gamma}_{k+l}(\boldsymbol{\xi},\boldsymbol{\eta})=\sum_{\boldsymbol{\alpha},\boldsymbol{\beta}} Y^{\gamma}_{\boldsymbol{\alpha}\boldsymbol{\beta}} K^{\boldsymbol{\alpha}}_{k}(\boldsymbol{\xi}) K^{\boldsymbol{\beta}}_{l}(\boldsymbol{\eta}), \tag{4.4}$$

where $\boldsymbol{\xi}$ and $\boldsymbol{\eta}$ denote the eigenphases of elements of U(k) and U(l), respectively. The coefficients $Y^{\gamma}_{\boldsymbol{\alpha}\boldsymbol{\beta}}$ in the decomposition are given by the Littlewood–Richardson theorem, according to which $Y^{\gamma}_{\boldsymbol{\alpha}\boldsymbol{\beta}}$ is the number of times that the tableau $\boldsymbol{\gamma}$ can be constructed from $\boldsymbol{\alpha}$ and $\boldsymbol{\beta}$ by the following procedure: Boxes from the first row of $\boldsymbol{\beta}$ are added to $\boldsymbol{\alpha}$ so as to produce a new tableau, with the condition that no two boxes are placed in the same column of the new tableau. This is repeated with the second row of $\boldsymbol{\beta}$, with the additional condition that, on counting added boxes in the new tableau column-wise from right to left, and row-wise from top to bottom, the number of added boxes from the first row of $\boldsymbol{\beta}$ must always be greater than or equal to the number of added boxes from the second row. The procedure is continued for the other rows until all boxes from $\boldsymbol{\beta}$ have been added to $\boldsymbol{\alpha}$. It is evident that $\boldsymbol{\gamma}$ can be constructed in this way only if the number of boxes in $\boldsymbol{\gamma}$ equals the number of boxes in $\boldsymbol{\alpha}$ and $\boldsymbol{\beta}$ together; that is, $Y^{\gamma}_{\boldsymbol{\alpha}\boldsymbol{\beta}}$ vanishes unless $|\boldsymbol{\gamma}| = |\boldsymbol{\alpha}| + |\boldsymbol{\beta}|$.

Equation (4.4) generalizes to the decomposition of irreducible representations $\boldsymbol{\gamma}$ of U($k_1 + \cdots + k_c$) restricted to the subgroup U(k_1)$\times\cdots\times$U(k_n), as follows:

$$K^{\gamma}_{k_1+\cdots+k_c}(\boldsymbol{\xi}_1,\ldots,\boldsymbol{\xi}_c)=\sum_{\boldsymbol{\alpha}_1,\ldots,\boldsymbol{\alpha}_c} Y^{\gamma}_{\boldsymbol{\alpha}_1,\ldots,\boldsymbol{\alpha}_c} \prod_{b=1}^{c} K^{\boldsymbol{\alpha}_b}_{k_b}(\boldsymbol{\xi}_b). \tag{4.5}$$

Here the $\boldsymbol{\alpha}_b$'s are tableaux labeling irreducible representations of U(k_b), and the $\boldsymbol{\xi}_b$ denote the eigenphases of elements of U(k_b). The c-fold coefficients $Y^{\gamma}_{\boldsymbol{\alpha}_1,\ldots,\boldsymbol{\alpha}_c}$ may be obtained from the twofold coefficients $Y^{\gamma}_{\boldsymbol{\alpha}\boldsymbol{\beta}}$ by performing the c-fold decomposition inductively.

With (4.5), the $(k_1+\cdots+k_c)$-fold determinants in the Weyl character formula (4.3) are reduced to sums of products of ratios of smaller, k_b-fold determinants. However, this simplification comes at a price; the Littlewood–Richardson coefficients are not easily calculated, and closed-form expressions for them are not known.

The original statement of the Littlewood–Richardson theorem appears in Ref. 14. A modern version with proof may be found in Ref. 15. The application of the Littlewood–Richardson theorem to the unitary groups is discussed by Hagen and MacFarlane[8] and Itzykson and Nauenberg.[11] A more detailed discussion of the rules for multiplying Young tableaux can be found in Ref. 9.

3. Characters for U(2) and SU(2)

We will need some results and notation particular to the groups SU(2) and U(2). Irreducible characters of SU(2) are denoted by $\chi^{s}_{\mathrm{SU}(2)}(\psi)$, where s is the spin and $e^{\pm i\psi}$ denotes the eigenvalues of elements of SU(2), and are given by

$$\chi^{s}_{\mathrm{SU}(2)}(\psi)=\frac{\sin((2s+1)\psi)}{\sin(\psi)}. \tag{4.6}$$

Irreducible representations of U(2) are labeled by tableaux $\boldsymbol{\alpha}=(\alpha^1,\alpha^2)$ of two rows. The U(2)-characters $K^{\boldsymbol{\alpha}}_{2}(\xi_1,\xi_2)$ are related to the SU(2)-characters $\chi^{s}_{\mathrm{SU}(2)}(\psi)$ by

$$K^{\boldsymbol{\alpha}}_{2}(+\psi+\theta,-\psi+\theta)=e^{i|\boldsymbol{\alpha}|\theta}\chi^{S(\boldsymbol{\alpha})}_{\mathrm{SU}(2)}(\psi), \tag{4.7}$$

where

$$S(\boldsymbol{\alpha})=(\alpha^1-\alpha^2)/2 \tag{4.8}$$

denotes the value of spin associated with the U(2)-representation $\boldsymbol{\alpha}$.

The Clebsch–Gordan coefficients $C(s_1,s_2,s_3)$ for SU(2) are defined by

$$C(s_1,s_2,s_3)=\frac{1}{\pi}\int_0^{2\pi} d\psi \sin^2(\psi)\chi^{s_1}_{\mathrm{SU}(2)}(\psi)\chi^{s_2}_{\mathrm{SU}(2)}(\psi)\chi^{s_3}_{\mathrm{SU}(2)}(\psi) \tag{4.9}$$

[note that $\sin^2(\psi)$ is the Haar measure with respect to classes of SU(2)], and give the multiplicity of the trivial representation in the decomposition of the tensor product of three SU(2)-representations with spins s_1, s_2 and s_3. It is an elementary result that $C(s_1,s_2,s_3)$ equals one if $|s_1-s_2|\leqslant s_3\leqslant s_1+s_2$, and is zero otherwise. We define the r-fold Clebsch–Gordan coefficients by

$$C(s_1,\ldots,s_r)=\frac{1}{\pi}\int_0^{2\pi} d\psi \sin^2(\psi)\chi^{s_1}_{\mathrm{SU}(2)}(\psi)\cdots\chi^{s_r}_{\mathrm{SU}(2)}(\psi). \tag{4.10}$$

These are given inductively by

$$C(s_1,\ldots,s_r,s_{r+1})=\sum_s C(s_1,\ldots,s_{r-1},s)C(s,s_r,s_{r+1}). \tag{4.11}$$

4. Cycle decomposition of permutations

The following notations will be used for permutations. Let $\sigma\in S_n$. Denote the factorization of σ into disjoint cycles by

$$\sigma=\hat{\sigma}_1\cdots\hat{\sigma}_{c(\sigma)}, \tag{4.12}$$

where $c(\sigma)$ denotes the number of cycles in the factorization. Denote the length of a cycle in the decomposition, say $\hat{\sigma}_b$, by $|\hat{\sigma}_b|$.

Let $\sigma\in S_n$ and $U=(u_1,\ldots,u_n)\in \mathrm{SU}(2)^n$. For each cycle $\hat{\sigma}_b$ in the factorization of σ, let $\hat{u}_b$ denote the product of the corresponding components of U, taken in the reverse order. That is, if $\hat{\sigma}_b=(jk\cdots l)$, then

$$\hat{u}_b=u_l\cdots u_k u_j. \tag{4.13}$$

Similarly, given an n-tuple of phases, $\Theta=(\theta_1,\ldots,\theta_n)$, let

$$\hat{\theta}_b=\theta_l+\cdots+\theta_k+\theta_j. \tag{4.14}$$

Clearly

$$\theta_1+\cdots+\theta_n=\hat{\theta}_1+\cdots+\hat{\theta}_{c(\sigma)}. \tag{4.15}$$

B. Evaluation of the integral

To evaluate the character integral (4.1), it will be convenient to regard $X^{s\lambda}$ and $X^{\mathbf{f}}$ as characters on $\mathrm{SU}(2)^n\rtimes\Sigma(n)$, i.e., as functions of U and σ rather than $\overline{U}$ and σ. Then

$$\nu(\mathbf{f},s\lambda)=\frac{1}{n!}\sum_{\sigma\in S_n}\int_{\mathrm{SU}(2)^n} du_1\cdots du_n X^{s\lambda}(U,\sigma)^* X^{\mathbf{f}}(U,\sigma), \tag{4.16}$$

where du_j denotes the normalized Haar measure on SU(2).

The character $X^{s\lambda}(U,\sigma)$ may be evaluated as follows. From (2.10) and (2.11),

$$\begin{aligned} X^{s\lambda}(U,\sigma)&=\sum_{a=1}^{d_\lambda}\sum_M \langle M,a|Q^{s\lambda}(U,\sigma)|M,a\rangle \\ &=\left(\sum_{a=1}^{d_\lambda}\Lambda_{a,a}(\sigma)\right)\left(\sum_M D^s_{m_{\sigma(1)},m_1}(u_1)\cdots D^s_{m_{\sigma(n)},m_n}(u_n)\right). \end{aligned} \tag{4.17}$$

The sum over a yields $\chi^{\lambda}_{S_n}(\sigma)$, the character of the S_n-representation Λ^{λ}. The sum over M factorizes into a product over the disjoint cycles $\hat{\sigma}_b$ of σ and yields

$$\mathrm{Tr}\, D^s(\hat{u}_1)\cdots \mathrm{Tr}\, D^s(\hat{u}_{c(\sigma)}), \tag{4.18}$$

where $\hat{u}_b \in \mathrm{SU}(2)$ is given by (4.13). Let $e^{\pm i\hat{\xi}_b}$ denote the eigenvalues of $\hat{u}_b$. Then

$$X^{s\lambda}(U,\sigma) = \chi^{\lambda}_{S_n}(\sigma) \prod_{b=1}^{c(\sigma)} \chi^{s}_{\mathrm{SU}(2)}(\hat{\xi}_b). \tag{4.19}$$

We note that $X^{s\lambda}(U,\sigma)$ is real, since the characters of S_n and SU(2) are real.

The character $X^{\mathbf{f}}(U,\sigma)$ in (4.16) may be expressed as

$$X^{\mathbf{f}}(U,\sigma) = \mathrm{Tr}\,(\Gamma^{\mathbf{f}}(x(U,\sigma,\Phi))P^0). \tag{4.20}$$

Here the trace is taken over the carrier space $\mathcal{V}$ of the representation $\Gamma^{\mathbf{f}}$, Φ denotes phases satisfying $e^{i\phi_1}\cdots e^{i\phi_n} = \mathrm{sgn}(\sigma)$, and P^0 denotes the Hermitian projection onto the subspace $\mathcal{V}^0$ given by

$$P^0 = \frac{1}{(2\pi)^{n-1}} \int d^{n-1}\Theta'\, \Gamma^{\mathbf{f}}(t(\Theta')), \tag{4.21}$$

where the Θ'-integral is taken over $0 \leqslant \theta'_j \leqslant 2\pi$ subject to the condition that $e^{i\theta'_1}\cdots e^{i\theta'_n} = 1$. Substituting (4.21) into (4.20) we get that

$$X^{\mathbf{f}}(U,\sigma) = \frac{1}{(2\pi)^{n-1}} \int d^{n-1}\Theta'\, \mathrm{Tr}\,\Gamma^{\mathbf{f}}(x(U,\sigma,\Theta'+\Phi)) = \frac{1}{(2\pi)^{n-1}} \int d^{n-1}\Theta\, \mathrm{Tr}\,\Gamma^{\mathbf{f}}(x(U,\sigma,\Theta)), \tag{4.22}$$

where the integral over $\Theta = (\theta_1,\ldots,\theta_n)$ in the last expression is restricted to $e^{i\theta_1}\cdots e^{i\theta_n} = \mathrm{sgn}(\sigma)$. It is convenient to incorporate this restriction using the identity

$$\frac{1}{(2\pi)^{n-1}} \int d^{n-1}\Theta = \sum_{q=-\infty}^{\infty} (\mathrm{sgn}\,\sigma)^q \frac{1}{(2\pi)^n} \int e^{iq(\theta_1+\cdots+\theta_n)}\,. \tag{4.23}$$

We note that as Θ on the right-hand side of (4.23) is unconstrained, $x(U,\sigma,\Theta)$ is, in general, an element of U($2n$) rather than SU($2n$). Let $\boldsymbol{\mu}$ denote the eigenphases of $x(U,\sigma,\Theta)$. Then $\mathrm{Tr}\,\Gamma^{\mathbf{f}}(x(U,\sigma,\Theta)) = K^{\mathbf{f}}_{2n}(\boldsymbol{\mu})$, and (4.22) becomes

$$X^{\mathbf{f}}(U,\sigma) = \sum_{q=-\infty}^{\infty} (\mathrm{sgn}\,\sigma)^q \frac{1}{(2\pi)^n} \int_0^{2\pi} d^n\Theta\, e^{-iq(\theta_1+\cdots\theta_n)} K^{\mathbf{f}}_{2n}(\boldsymbol{\mu}). \tag{4.24}$$

To determine the eigenphases $\boldsymbol{\mu}$ of $x(U,\sigma,\Theta)$, it is convenient to represent vectors in $\mathbb{C}^{2n}$ as linear combinations of terms $|v_j\rangle\otimes|j\rangle$, where $|v_j\rangle \in \mathbb{C}^2$ and $|j\rangle$ is an orthonormal basis for $\mathbb{C}^n$. From (3.7) and (3.8), the action of $x(U,\sigma,\Theta)$ is then given by

$$x(U,\sigma,\Theta)\sum_{j=1}^{n} |\xi_j\rangle\otimes|j\rangle = \sum_{j=1}^{n} e^{i\theta_j}(u_{\sigma(j)}|\xi_j\rangle)\otimes|\sigma(j)\rangle. \tag{4.25}$$

Let $\hat{\sigma}_b = (jk\cdots l)$ be a cycle in σ, and, as above, let $e^{\pm i\hat{\xi}_b}$ denote the eigenvalues of $\hat{u}_b$. Let $|\pm w_b\rangle \in \mathbb{C}^2$ denote the associated eigenvectors of $\hat{u}_b$. It is readily verified that $|\pm w_b\rangle\otimes|l\rangle$ are eigenvectors of $x^m(U,\sigma,\Theta)$, with eigenvalues $e^{im(\pm\hat{\xi}_b+\hat{\theta}_b)/|\hat{\sigma}_b|}$, if and only if m is a multiple of $|\hat{\sigma}_b|$.

In general, if $|v\rangle$ is an eigenvector of some positive integer power $|\hat{\sigma}_b|$ of a matrix M, with ρ the associated eigenvalue of $M^{|\hat{\sigma}_b|}$, and if $|v\rangle$ is not an eigenvector of any smaller positive power of M, then M has eigenvalues $e^{2\pi i p/|\hat{\sigma}_b|}\rho^{1/|\hat{\sigma}_b|}$, where $p=1,\ldots,|\hat{\sigma}_b|$. From these considerations we may deduce that to each cycle $\hat{\sigma}_b$ in σ are associated $2|\hat{\sigma}_b|$ eigenphases of $x(U,\sigma,\Theta)$, denoted by $\boldsymbol{\eta}_b=(\boldsymbol{\eta}_{b,1},\ldots,\boldsymbol{\eta}_{b,|\hat{\sigma}_b|})$ and given explicitly by

$$\boldsymbol{\eta}_{b,p}=\left(\frac{+\hat{\xi}_b+\hat{\theta}_b+2\pi p}{|\hat{\sigma}_b|},\frac{-\hat{\xi}_b+\hat{\theta}_b+2\pi p}{|\hat{\sigma}_b|}\right),\quad p=1,\ldots,|\hat{\sigma}_b|. \tag{4.26}$$

The full set of eigenvalues of $x(U,\sigma,\Theta)$ is

$$\boldsymbol{\mu}=(\boldsymbol{\eta}_1,\ldots,\boldsymbol{\eta}_{c(\sigma)}). \tag{4.27}$$

From (4.27) it is apparent that $x(U,\sigma,\Theta)\in \mathrm{U}(2n)$ is unitarily equivalent to the element of $\mathrm{U}(2|\sigma_1|)\times\cdots\times\mathrm{U}(2|\sigma_{c(\sigma)}|)$ with eigenphases $\boldsymbol{\eta}_1,\ldots,\boldsymbol{\eta}_{c(\sigma)}$ for the factors. From the Littlewood–Richardson formula (4.5), the character $K^{\mathbf{f}}_{2n}(\boldsymbol{\mu})$ in (4.24) is given by

$$K^{\mathbf{f}}_{2n}(\boldsymbol{\mu})=K^{\mathbf{f}}_{2n}(\boldsymbol{\eta}_1,\ldots,\boldsymbol{\eta}_{c(\sigma)})=\sum_{\boldsymbol{\beta}_1,\ldots,\boldsymbol{\beta}_{c(\sigma)}} Y^{\mathbf{f}}_{\boldsymbol{\beta}_1,\ldots,\boldsymbol{\beta}_{c(\sigma)}}\prod_{b=1}^{c(\sigma)} K^{\boldsymbol{\beta}_b}_{|\hat{\sigma}_b|}(\boldsymbol{\eta}_b), \tag{4.28}$$

where the $\boldsymbol{\beta}_b$'s are tableaux labeling representations of $\mathrm{U}(2|\hat{\sigma}_b|)$. As noted in Sec. IV A 2, the sum in (4.28) may restricted to those $\boldsymbol{\beta}_b$ satisfying

$$\sum_{b=1}^{c(\sigma)}|\boldsymbol{\beta}_b|=|\mathbf{f}|. \tag{4.29}$$

From (4.26), the characters $K^{\boldsymbol{\beta}_b}_{|\hat{\sigma}_b|}(\boldsymbol{\eta}_b)$ can themselves be expressed as a product of U(2)-characters by applying the Littlewood–Richardson theorem once more, as follows:

$$K^{\boldsymbol{\beta}_b}_{|\hat{\sigma}_b|}(\boldsymbol{\eta}_b)=K^{\boldsymbol{\beta}_b}_{|\hat{\sigma}_b|}(\boldsymbol{\eta}_{b,1},\ldots,\boldsymbol{\eta}_{b,|\hat{\sigma}_b|})=\sum_{\boldsymbol{\alpha}_1,\ldots,\boldsymbol{\alpha}_{|\hat{\sigma}_b|}} Y^{\boldsymbol{\beta}_b}_{\boldsymbol{\alpha}_1,\ldots,\boldsymbol{\alpha}_{|\hat{\sigma}_b|}}\prod_{p=1}^{|\hat{\sigma}_b|} K^{\boldsymbol{\alpha}_p}_2(\boldsymbol{\eta}_{b,p}). \tag{4.30}$$

Here the $\boldsymbol{\alpha}_p$'s are tableaux labeling representations of U(2), and the sum in (4.30) may be restricted to those $\boldsymbol{\alpha}_p$ satisfying

$$\sum_{p=1}^{|\hat{\sigma}_b|}|\boldsymbol{\alpha}_p|=|\boldsymbol{\beta}_b|. \tag{4.31}$$

Finally, the U(2)-characters are given explicitly [cf. (4.7) and (4.26)] by

$$K^{\boldsymbol{\alpha}_p}_2(\boldsymbol{\eta}_{b,p})=e^{i|\boldsymbol{\alpha}_p|(2\pi p+\hat{\theta}_b)/|\hat{\sigma}_b|}\chi^{S(\boldsymbol{\alpha}_p)}_{\mathrm{SU}(2)}(\hat{\xi}_b/|\hat{\sigma}_b|). \tag{4.32}$$

To proceed, we substitute the expression (4.19) for $X^{s\lambda}(U,\sigma)$ and the expressions (4.24) and (4.28)–(4.32) for $X^{\mathbf{f}}(U,\sigma)$ into the integral (4.16). The integration over $\mathrm{SU}(2)^n$ can be arranged so that $\hat{u}_1,\ldots,\hat{u}_{c(\sigma)}\in\mathrm{SU}(2)$ are amongst the integration variables. Since the integrand depends only on the $\hat{u}_b$'s, any remaining SU(2)-integrals are trivially evaluated. Moreover, since the integrand depends only on the eigenphases $\hat{\xi}_b$, we can make the replacement

$$\int_{\mathrm{SU}(2)} d\hat{u}_b\to\frac{1}{\pi}\int_0^{2\pi} d\hat{\xi}_b\sin^2(\hat{\xi}_b). \tag{4.33}$$

Similarly, the Θ-integral in (4.16) can be arranged so that $\hat{\theta}_1,\ldots,\hat{\theta}_{c(\sigma)}$ are amongst the variables of integration; in view of (4.15), the integrand depends only on the $\hat{\theta}_b$'s, so the integrals over any remaining components of Θ are trivially evaluated. Finally, as the terms in the S_n-sum in (4.16) depend only the conjugacy class of σ and not on σ itself, we may make the replacement

$$\sum_{\sigma\in S_n}\rightarrow\sum_{[\sigma]\in S_n}\Omega_{[\sigma]}, \tag{4.34}$$

where $[\sigma]$ denotes the conjugacy class of σ and $\Omega_{[\sigma]}$ denotes the number of elements in $[\sigma]$ ($\Omega_{[\sigma]}$ may be explicitly expressed in terms of the cycle lengths $|\hat{\sigma}_1|,\ldots,|\hat{\sigma}_{c(\sigma)}|$). In this way, Eq. (4.16) for the multiplicities may be expressed as

$$\nu(\mathbf{f},s\lambda)=\frac{1}{n!}\sum_{[\sigma]\in S_n}\Omega_{[\sigma]}\chi^{\lambda}_{S_n}(\sigma)\sum_{q=-\infty}^{\infty}(\operatorname{sgn}\sigma)^q\sum_{\boldsymbol{\beta}_1,\ldots,\boldsymbol{\beta}_{c(\sigma)}}Y^{\mathbf{f}}_{\boldsymbol{\beta}_1,\ldots,\boldsymbol{\beta}_{c(\sigma)}}\prod_{b=1}^{c(\sigma)}I_b\,J_b\,. \tag{4.35}$$

The factor I_b, which contains the integral over θ_b, is given by

$$I_b=\frac{1}{2\pi}\int_0^{2\pi}d\hat{\theta}_b\,\mathrm{e}^{\mathrm{i}(|\boldsymbol{\beta}_b|/|\hat{\sigma}_b|-q)\hat{\theta}_b}, \tag{4.36}$$

where we have used (4.31). The factor J_b, which contains the integral over $\hat{\xi}_b$ and the sum over the U(2)-tableaux $\boldsymbol{\alpha}_p$, is given by

$$\begin{aligned}J_b=&\sum_{\boldsymbol{\alpha}_1,\ldots,\boldsymbol{\alpha}_{|\hat{\sigma}_b|}}Y^{\boldsymbol{\beta}_b}_{\boldsymbol{\alpha}_1,\ldots,\boldsymbol{\alpha}_{|\hat{\sigma}_b|}}\,\mathrm{e}^{2\pi\mathrm{i}(\sum_{p=1}^{|\hat{\sigma}_b|}p|\boldsymbol{\alpha}_p|)/|\hat{\sigma}_b|}\times\frac{1}{\pi}\\&\times\int_0^{2\pi}d\hat{\xi}_b\sin^2(\hat{\xi}_b)\chi^{s}_{\mathrm{SU}(2)}(\hat{\xi}_b)\chi^{S(\boldsymbol{\alpha}_1)}_{\mathrm{SU}(2)}(\hat{\xi}_b/|\hat{\sigma}_b|)\cdots\chi^{S(\boldsymbol{\alpha}_{|\hat{\sigma}_b|})}_{\mathrm{SU}(2)}(\hat{\xi}_b/|\hat{\sigma}_b|).\end{aligned} \tag{4.37}$$

The $\hat{\theta}_b$-integral in (4.36) is trivial, and vanishes unless

$$q|\hat{\sigma}_b|=|\boldsymbol{\beta}_b|. \tag{4.38}$$

Summing over b in (4.38) and using (4.29), we get that

$$q=\frac{|\mathbf{f}|}{n}. \tag{4.39}$$

Since q is an integer, it follows that at least one of the I_b's must vanish [and, therefore, $\nu(\mathbf{f},s\lambda)$ must vanish] unless n divides $|\mathbf{f}|$. Assuming this to be so, the sum over q in (4.35) collapses to $q=|\mathbf{f}|/n$.

We consider next the expression for J_b. Since the integrand is 2π-periodic in $\hat{\xi}_b$, we can make the replacement

$$\int_0^{2\pi}d\hat{\xi}_b\rightarrow\int_0^{2\pi}d\hat{\psi}_b\,, \tag{4.40}$$

where $\hat{\psi}_b=\hat{\xi}_b/|\hat{\sigma}_b|$. Using the identity

$$\sin^2(r\hat{\psi}_b)\chi^{s}_{\mathrm{SU}(2)}(r\hat{\psi}_b)=\sin^2(\hat{\psi}_b)\chi^{rs+(r-1)/2}_{\mathrm{SU}(2)}(\hat{\psi}_b)\chi^{(r-1)/2}_{\mathrm{SU}(2)}(\hat{\psi}_b), \tag{4.41}$$

which follows from the definition (4.6), the resulting integral over $\hat{\psi}_b$ is of the form (4.10), and yields a $(|\hat{\sigma}_b|+2)$-fold Clebsch–Gordan coefficient. We obtain

$$J_b = \sum_{\boldsymbol{\alpha}_1,\ldots,\boldsymbol{\alpha}_{|\hat{\sigma}_b|}} Y^{\boldsymbol{\beta}_b}_{\boldsymbol{\alpha}_1,\ldots,\boldsymbol{\alpha}_{|\hat{\sigma}_b|}} \mathrm{e}^{2\pi\mathrm{i}(\Sigma_{p=1}^{|\hat{\sigma}_b|} p|\boldsymbol{\alpha}_p|)/|\hat{\sigma}_b|} \times C(|\hat{\sigma}_b|s+\tfrac{1}{2}(|\hat{\sigma}_b|-1),\tfrac{1}{2}(|\hat{\sigma}_b|-1),S(\boldsymbol{\alpha}_1),\ldots,S(\boldsymbol{\alpha}_{|\hat{\sigma}_b|})). \tag{4.42}$$

From (4.35), (4.39) and (4.42), we get our main result for the multiplicities,

$$\nu(\mathbf{f},s\lambda) = \frac{1}{n!}\sum_{[\sigma]\in S_n} \Omega_{[\sigma]}\chi^{\lambda}_{S_n}(\sigma)(\operatorname{sgn}\sigma)^{|\mathbf{f}|/n}A_{[\sigma]}, \tag{4.43}$$

where

$$A_{[\sigma]} = \sum_{\substack{\boldsymbol{\beta}_1,\ldots,\boldsymbol{\beta}_{c(\sigma)} \\ |\boldsymbol{\beta}_b|=|\hat{\sigma}_b|\cdot|\mathbf{f}|/n}} Y^{\mathbf{f}}_{\boldsymbol{\beta}_1,\cdots,\boldsymbol{\beta}_{c(\sigma)}} \times \prod_{b=1}^{c(\sigma)} \left[\sum_{\boldsymbol{\alpha}_1,\cdots,\boldsymbol{\alpha}_{|\hat{\sigma}_b|}} Y^{\boldsymbol{\beta}_b}_{\boldsymbol{\alpha}_1,\ldots,\boldsymbol{\alpha}_{|\hat{\sigma}_b|}} \mathrm{e}^{2\pi\mathrm{i}(\Sigma_{p=1}^{|\hat{\sigma}_b|} p|\boldsymbol{\alpha}_p|)/|\hat{\sigma}_b|} \times C(|\hat{\sigma}_b|s+\tfrac{1}{2}(|\hat{\sigma}_b|-1),\tfrac{1}{2}(|\hat{\sigma}_b|-1),S(\boldsymbol{\alpha}_1),\ldots,S(\boldsymbol{\alpha}_{|\hat{\sigma}_b|})) \right]. \tag{4.44}$$

For $\sigma=\mathrm{I}=(1)\cdots(n)$ (i.e., the identity element in S_n), the expression (4.44) simplifies considerably. In this case, $c(\sigma)=n$ and $|\sigma_b|=1$, so that each $\boldsymbol{\beta}_b$ is a U(2)-tableaux with $|\boldsymbol{\beta}_b| = |\mathbf{f}|/n$. The sum over $\boldsymbol{\alpha}_p$ collapses to $\boldsymbol{\alpha}=\boldsymbol{\beta}_b$, and the corresponding Clebsch–Gordan coefficient, $C(s,0,S(\boldsymbol{\beta}_b))$, vanishes unless $S(\boldsymbol{\beta}_b)=s$. It follows that the $\boldsymbol{\beta}_b$ must all coincide with the U(2)-tableaux $\boldsymbol{\beta}(\mathbf{f},n,s)$ given by

$$\boldsymbol{\beta}(\mathbf{f},s) = ((|\mathbf{f}|/2n+s),(|\mathbf{f}|/2n-s)). \tag{4.45}$$

We then obtain

$$A_{[I]} = Y^{\mathbf{f}}_{\underbrace{\boldsymbol{\beta}(\mathbf{f},s),\ldots,\boldsymbol{\beta}(\mathbf{f},s)}_{n\ \text{times}}}. \tag{4.46}$$

Some simplification in (4.44) also occurs for n-cycles in S_n, e.g., $\sigma=(12\cdots n)$, In this case $c(\sigma)=1$ and $|\hat{\sigma}|=n$, so that the sum over $\boldsymbol{\beta}$ collapses to $\boldsymbol{\beta}=\mathbf{f}$. We obtain

$$A_{[(12\cdots n)]} = \sum_{\boldsymbol{\alpha}_1,\ldots,\boldsymbol{\alpha}_n} Y^{\mathbf{f}}_{\boldsymbol{\alpha}_1,\ldots,\boldsymbol{\alpha}_n} \mathrm{e}^{2\pi\mathrm{i}(\Sigma_{p=1}^{n} p|\boldsymbol{\alpha}_p|)/n} \times C(ns+\tfrac{1}{2}(n-1),\tfrac{1}{2}(n-1),S(\boldsymbol{\alpha}_1),\ldots,S(\boldsymbol{\alpha}_n)). \tag{4.47}$$

The sum $\Sigma_\lambda \nu(\mathbf{f},s\lambda)$ gives the number of n-spin-s representations, regardless of statistics. Using the character relation (see, e.g., Ref. 9),

$$\sum_{\lambda} \chi^{\lambda}(\sigma) = \begin{cases} n!, & \sigma=\mathrm{I}, \\ 0, & \text{otherwise}, \end{cases} \tag{4.48}$$

we obtain from (4.43) and (4.46) a simple expression for these summed multiplicities,

$$\sum_{\lambda} \nu(\mathbf{f},s\lambda) = Y^{\mathbf{f}}_{\underbrace{\boldsymbol{\beta}(\mathbf{f},s),\ldots,\boldsymbol{\beta}(\mathbf{f},s)}_{n \text{ times}}}. \tag{4.49}$$

C. Examples

In Sec. III D, we considered the case of completely symmetric representations, for which $\mathbf{f}=(d)$. There we showed that $\nu((d),s\lambda)$ vanishes unless $d=2ns$ and unless λ is the trivial (respectively, alternating) representation according to whether s is integral (respectively, half-odd-integral). This particular case is readily obtained from the general formulas (4.43) and (4.44). Instead of doing so, we sketch below the analogous calculation for the completely antisymmetric representations of SU(2n). The result turns out to be rather different from the symmetric case, in that only $s=\frac{1}{2}$ constructions are supported; the completely antisymmetric representations do not provide a systematic description for all spins. The $s=\frac{1}{2}$ statistics turn out to be bosonic in this case.

Completely antisymmetric representations of SU(2n) correspond to single-columned tableaux of between 1 and $2n-1$ rows (the $2n$-rowed tableau is equivalent to the trivial representation). Denote the d-rowed representation by $\mathbf{f}=(1)^d$. From (4.39), $\nu((1)^d,s\lambda)$ vanishes unless $d=n$ and, from (4.45) and (4.49), unless $s=\frac{1}{2}$. In this case, the expressions (4.43) and (4.44) simplify considerably. The sums over the $\boldsymbol{\alpha}_p$'s collapse to the single term where all the $|\boldsymbol{\alpha}_p|$'s are equal to one, and the sums over the $\boldsymbol{\beta}_b$'s collapse to the single term where $\boldsymbol{\beta}_b=(1)^{|\hat{\sigma}_b|}$. For these terms, the Littlewood–Richardson coefficients and Clebsch–Gordan coefficients appearing in (4.44) are all equal to one. We get that

$$A_{[\sigma]} = \prod_{b=1}^{c(\sigma)} \mathrm{e}^{2\pi \mathrm{i}(\Sigma_{p=1}^{|\hat{\sigma}_b|} p)/|\hat{\sigma}_b|} = \prod_{b=1}^{c(\sigma)} (-1)^{|\hat{\sigma}_b|+1} = \prod_{b=1}^{c(\sigma)} \operatorname{sgn}(\hat{\sigma}_b) = \operatorname{sgn}(\sigma). \tag{4.50}$$

Substituting the preceding into (4.43), we obtain

$$\nu\left((1)^n,\frac{1}{2}\lambda\right) = \frac{1}{n!} \sum_{[\sigma]\in S_n} \Omega_{[\sigma]} \chi^{\lambda}_{S_n}(\sigma), \tag{4.51}$$

which vanishes unless λ is the trivial representation of S_n.

This result can also be obtained by following the calculation of Sec. III D and regarding $z=(z_1,\ldots,z_{2n})$ as Grassmann variables. Equivalently, this may be regarded as the n-particle version of the ''anti-Schwinger'' construction of Ref. 4, wherein the raising/lower operators of Ref. 3 are made to satisfy anticommutation relations. The anticommutation relations are responsible for the restriction to $s=\frac{1}{2}$.

Next, we consider general representations for the case of two particles, $n=2$. For simplicity, we label the even and odd representations of S_2 by $\lambda=+$ and $\lambda=-$, respectively, with characters $\chi^{\pm}_{S_2}(\sigma)=\pm\operatorname{sgn}(\sigma)$. As in (4.45), let

$$\boldsymbol{\beta}(\mathbf{f},s) = ((|\mathbf{f}|/4+s),(|\mathbf{f}|/4-s)). \tag{4.52}$$

From (4.52) we can deduce that the multiplicities $\nu(\mathbf{f},s\pm)$ vanish unless $|\mathbf{f}|$ is even and $|\mathbf{f}|/4-s$ is a non-negative integer. From (4.43), (4.46) and (4.47), we get

$$\nu(\mathbf{f},s\pm) = \frac{1}{2} Y^{\mathbf{f}}_{\boldsymbol{\beta}(\mathbf{f},s),\boldsymbol{\beta}(\mathbf{f},s)} \pm \frac{(-1)^{2s}}{2} \sum_{\boldsymbol{\alpha}_1,\boldsymbol{\alpha}_2} Y^{\mathbf{f}}_{\boldsymbol{\alpha}_1,\boldsymbol{\alpha}_2} (-1)^{|\boldsymbol{\alpha}_1|} C(2s+\tfrac{1}{2},\tfrac{1}{2},S(\boldsymbol{\alpha}_1),S(\boldsymbol{\alpha}_2)). \tag{4.53}$$

The simplest cases are the tableaux $\mathbf{f}=(2,0)$ and $\mathbf{f}=(1,1)$ with $|\mathbf{f}|=2$. Then $s=\frac{1}{2}$ is the only permitted value of the spin, and $\boldsymbol{\beta}(\mathbf{f},s)$ contains a single box. The tableau (2,0) corresponds to a completely symmetric representation. As discussed in Sec. III D, this yields Fermi statistics for

spin-$\frac{1}{2}$, so that $\nu(\mathbf{f},\frac{1}{2}+)=0$ and $\nu(\mathbf{f},\frac{1}{2}-)=1$. Equation (4.53) is readily evaluated for the tableau (1,1), and one finds the opposite result, namely, Bose statistics for spin-$\frac{1}{2}$ (this case is equivalent to the ''anti-Schwinger construction'' discussed in Ref. 4).

For larger tableaux one typically finds that for each permitted value of spin, both multiplicities $\nu(\mathbf{f},s+)$ and $\nu(\mathbf{f},s-)$ are nonzero. Constructions based on such tableaux do not determine a spin-statistics relation. The smallest tableau where this occurs is $\mathbf{f}=(3,2,1)$ with $s=\frac{1}{2}$. Evaluation of (4.53) shows there is one Fermi and one Bose representation. In fact, for larger tableaux one typically finds that $\nu(\mathbf{f},s+)$ and $\nu(\mathbf{f},s-)$ are nearly equal, and there are arguments to suggest they are either exactly equal, or else differ by 1, according to whether their sum, given by $Y^{\mathbf{f}}_{\boldsymbol{\beta}(\mathbf{f},s),\boldsymbol{\beta}(\mathbf{f},s)}$, is even or odd. It turns out that most of the terms in the sum over tableaux in (4.53) cancel. First, since the summand is symmetric in $\boldsymbol{\alpha}_1$ and $\boldsymbol{\alpha}_2$, apart from the sign factor $(-1)^{|\boldsymbol{\alpha}_1|}$, only terms for which $|\boldsymbol{\alpha}_1|$ and $|\boldsymbol{\alpha}_2|$ have the same parity contribute. Amongst these remaining terms, the sign factor is responsible for additional cancellations, due to the following fact: If $\boldsymbol{\alpha}_1+\boldsymbol{\epsilon}$ is the tableau obtained by adding one box to the first row of $\boldsymbol{\alpha}_1$, and $\boldsymbol{\alpha}_2-\boldsymbol{\epsilon}$ is the tableau obtained by removing one box from the first row of $\boldsymbol{\alpha}_2$, then the rules for multiplying tableaux imply that

$$Y^{\mathbf{f}}_{\boldsymbol{\alpha}_1,\boldsymbol{\alpha}_2}=Y^{\mathbf{f}}_{\boldsymbol{\alpha}_1+\boldsymbol{\epsilon},\boldsymbol{\alpha}_2-\boldsymbol{\epsilon}}. \tag{4.54}$$

Details may be found in Ref. 10.

To demonstrate the possibility of parastatistics, we consider the simplest case of three particles and the smallest SU(6) tableau, $\mathbf{f}=(2,1)$. From (4.45), it follows that $s=\frac{1}{2}$ is the only permitted value of spin, and that $\boldsymbol{\beta}(\mathbf{f},\frac{1}{2})=(1)$ consists of a single box. Let $\lambda=E$ denote the two-dimensional representation of S_3 [corresponding to the tableau (2,1)], with characters

$$\chi^E_{S_3}(\mathrm{I})=2,\quad \chi^E_{S_3}((12))=0,\quad \chi^E_{S_3}((123))=-1, \tag{4.55}$$

and classes

$$\Omega_{[\mathrm{I}]}=1,\quad \Omega_{[(12)]}=3,\quad \Omega_{[(123)]}=2 \tag{4.56}$$

(see, e.g., Ref. 9). From (4.43), (4.46) and (4.47), we get

$$\begin{aligned}\nu((2,1),\tfrac{1}{2}E)=&\ \tfrac{1}{6}Y^{(2,1)}_{(1),(1),(1)}\\ &-\tfrac{1}{6}\times 2\sum_{\boldsymbol{\alpha}_1,\boldsymbol{\alpha}_2,\boldsymbol{\alpha}_3} Y^{(2,1)}_{\boldsymbol{\alpha}_1,\boldsymbol{\alpha}_2,\boldsymbol{\alpha}_3}\mathrm{e}^{\mathrm{i}(2\pi/3)(|\boldsymbol{\alpha}_1|+2|\boldsymbol{\alpha}_2|)}C(\tfrac{5}{2},1,S(\boldsymbol{\alpha}_1),S(\boldsymbol{\alpha}_2),S(\boldsymbol{\alpha}_3)).\end{aligned} \tag{4.57}$$

There are four sets of U(2)-tableaux $\boldsymbol{\alpha}_1$, $\boldsymbol{\alpha}_2$ and $\boldsymbol{\alpha}_3$ which may be multiplied to obtain the SU(6) tableau (2,1) (including cases where one or more of the $\boldsymbol{\alpha}_j$ are empty, which we denote by $\boldsymbol{\alpha}_j=0$). For each combination we determine the Littlewood–Richardson coefficient $Y^{(2,1)}_{\boldsymbol{\alpha}_1,\boldsymbol{\alpha}_2,\boldsymbol{\alpha}_3}$, the Clebsch-Gordan coefficient $C(\frac{5}{2},1,S(\boldsymbol{\alpha}_1),S(\boldsymbol{\alpha}_2),S(\boldsymbol{\alpha}_3))$, and the phase factor $\mathrm{e}^{\mathrm{i}(2\pi/3)(|\boldsymbol{\alpha}_1|+2|\boldsymbol{\alpha}_2|)}$. The results are summarized in the table below.

$\boldsymbol{\alpha}_1$	$\boldsymbol{\alpha}_2$	$\boldsymbol{\alpha}_3$	Y	C	$\mathrm{e}^{\mathrm{i}2\pi/3}$
(2,1)	0	0	1	0	1
(1,1)	(1)	0	1	0	$\mathrm{e}^{\mathrm{i}2\pi/3}$
(2)	(1)	0	1	1	$\mathrm{e}^{\mathrm{i}2\pi/3}$
(1)	(1)	(1)	2	1	1

(4.58)

Substituting (4.58) into (4.57), we obtain

$$\nu((2,1), \tfrac{1}{2}E) = 1. \tag{4.59}$$

That is, a 3-spin-$\frac{1}{2}$ bundle with parastatistics may be constructed from the representation $\Gamma^{(2,1)}$ of SU(6).

V. DISCUSSION

We have reformulated the quantum kinematics of BR for indistinguishable spinning particles in terms of vector bundles over n-particle configuration space. Within this geometrical framework, our main results concern a representation-theoretic generalization of the construction in BR. We have shown that n-spin bundles can be constructed from irreducible representations $\Gamma^{\mathbf{f}}$ of the group SU($2n$). The construction makes use of representations $\Delta^{\mathbf{f}}$ of the spin-statistics group $\Sigma(n)$ associated to $\Gamma^{\mathbf{f}}$, as well the existence of a continuous, S_n-equivariant map from $\mathrm{SU}(n)/T(n)$ to configuration space C_n.[2]

The construction in BR is based on particular representations of SU($2n$), namely, the completely symmetric representations. For a given number, n, of indistinguishable particles with spin s, there is a unique completely symmetric representation of SU($2n$), namely, the $2ns$-fold symmetric tensor product of SU($2n$) with itself, which leads to a description of the quantum kinematics (i.e., which supports an n-spin bundle with spin s). The statistics is necessarily in accord with the physically correct spin-statistics relation.

Representations of SU($2n$) other than the completely symmetric representations, corresponding to Young tableaux $\mathbf{f}$ of more than one row, typically support multiple values of spin s, and for a given spin may support distinct values of the statistics λ, including parastatistics. The values of spin and statistics supported by a given representation $\Gamma^{\mathbf{f}}$ are determined by the multiplicities $\nu(\mathbf{f}, s\lambda)$ of the irreducible representations of the spin-statistics group, $\Sigma(n)$, in the decomposition of $\Delta^{\mathbf{f}}$.

Our main calculation is an evaluation of the multiplicities $\nu(\mathbf{f}, s\lambda)$ using character methods. Equations (4.43) and (4.44) give the multiplicities as a finite sum over characters of the symmetric group S_n, the n-fold Clebsch–Gordan coefficients of SU(2), and the Littlewood–Richardson coefficients for the decomposition of representations of $\mathrm{U}(n+m)$ into representations of $\mathrm{U}(n) \times \mathrm{U}(m)$.

Our calculation is related to a more general problem in representation theory, namely, the decomposition of zero-weight representations of the Weyl group W of a compact, connected Lie group G associated with an irreducible representation of G. It would be interesting to see if alternative methods could be brought to bear on our calculation, as well as whether the methods used here might prove useful in other contexts. Our construction of n-spin-bundles is similarly related to the construction of flat zero-weight bundles over the coset space G/T (where T is a maximal torus of G), whose decomposition into a direct sum of subbundles irreducible under monodromy leads to the decomposition problem described above.

Concerning the spin-statistics relation, in the first instance our results are similar to those of Ref. 3. Within the group-theoretical framework considered here, the requisite properties introduced in Sec. II do not determine a connection between spin and statistics. When general representations of SU($2n$) are admitted alongside the completely symmetric representations, the spin-statistics relation is lost.

As argued in the Introduction, a derivation of the spin-statistics relation from a reformulation of quantum mechanics should be based on principles whose physical motivation is clear. The role played by the group SU($2n$) in our considerations is not well motivated in this respect. One could offer as motivation the fact that SU($2n$) incorporates both rotations of n spins [i.e., $\mathrm{SU}(2)^n$] and the permutations S_n, but of course it is not the only group which does so.

However, the role played by the completely symmetric representations deserves further consideration. They provide, at least as far as we have discerned, the only systematic means, within the given framework, of associating a representation to a particular value of spin. It is suggestive, too, that the scheme which works treats the spins in a completely symmetrical way; this would

seem appropriate for indistinguishable particles. Indeed, characteristic aspects of the completely symmetric representations may indicate a different approach to this nonrelativistic treatment of the spin-statistics relation, which we hope to report on in future.

APPENDIX: GENERAL SETTING

The construction of n-spin bundles described in Sec. III is closely related to the following general problem (see, e.g., Ref. 12). Let Γ be an irreducible unitary representation on a vector space $\mathcal{V}$ of a compact Lie group G with maximal torus T. $\mathcal{V}$ may be decomposed into weight spaces, $\mathcal{V}^\mu$, labeled by weights μ of T. The zero-weight space $\mathcal{V}^0$ carries a representation Δ of the Weyl group, W, of G, which is, in general, reducible. One can then ask for the decomposition of this representation of the Weyl group into its irreducible components.

To each weight space $\mathcal{V}^\mu$ of the representation Γ is associated a Hermitian vector bundle $\mathcal{E}^\mu$ over G/T with Abelian G-invariant Hermitian connection. The curvature of this connection depends linearly on μ, and therefore vanishes on the zero-weight bundle $\mathcal{E}^0$. If G is simply connected, then $\mathcal{E}^0$ is trivial. However, the quotient bundle $\overline{\mathcal{E}^0}=\mathcal{E}^0/W$ over the quotient space $(G/T)/W$, while locally flat, may be nontrivial. For simply connected G, the fundamental group of the quotient space is just the Weyl group W, and the monodromy of the flat connection yields a representation of W, which is precisely the representation Δ described above.

This setting can be further generalized by regarding G as a subgroup of a Lie group F, and regarding Γ as the restriction to G of a representation of F. In this case, the natural structure group for the zero-weight bundle is the generalized Weyl group $V=M/T$, where M is the F-normalizer of T.

The construction of Sec. III is an example belonging to this more general setting, with $F=\mathrm{SU}(2n)$, $G=\mathrm{SU}(n)$, and $T=T(n)$. The Weyl group of $\mathrm{SU}(n)$ is just S_n, and the generalized Weyl group V is the spin-statistics group, $\Sigma(n)=\mathrm{SU}(2)^n\rtimes S_n/\mathrm{Nul}(n)$. The n-spin bundles are pullbacks, via the S_n-equivariant map $\Xi: C_n\to \mathrm{SU}(n)/T(n)$, of zero-weight bundles over $\mathrm{SU}(n)/T(n)$.

This point of view is elaborated below.

1. Generalized Weyl group

Let G be a compact, connected semisimple Lie group with maximal torus T. Let N denote the normalizer of T, and $W=N/T$ the Weyl group of G. Suppose G is a subgroup of a compact, connected Lie group F. Let M denote the F-normalizer of T, i.e., the subgroup of F which leaves T invariant under conjugation. We call

$$V=M/T \tag{A1}$$

the generalized Weyl group of G. Clearly the Weyl group W is a subgroup of V.

Let Z denote the F-centralizer of T, i.e., the subgroup of F whose elements commute with all elements of T. Z is a normal subgroup of M. Therefore, the group ZN, consisting of products zy of $z\in Z$ and $y\in N$, is a subgroup of M, and

$$ZN/T\cong Z/T\rtimes W, \tag{A2}$$

where in the semidirect product $Z/T\rtimes W$, an element $y\,T\in W$ acts on $z\,T\in Z/T$ according to $z\,T\to(yzy^{-1})\,T$. The isomorphism (A2) follows from consideration of the map

$$zy \in ZN \mapsto (z\,T, y\,T) \in Z/T \rtimes W. \tag{A3}$$

To show that this map is well defined, we need to check that $zy = z'y'$ implies that $z\,T = z'\,T$ and $y\,T = y'\,T$. But $zy = z'y'$ implies that $z' = z\tau$ and $y' = \tau^{-1}y$, where $\tau \in Z \cap N$. Since G is compact and connected, $Z \cap N = T$, so $\tau \in T$ as required. It is evident that the map preserves multiplication and that it is surjective. The kernel of the map consists of elements zy where $z, y \in T$, and therefore is just T itself, so that (A2) follows.

The spin-statistics group $\Sigma(n)$ is an example of a generalized Weyl group, with $F = \mathrm{SU}(2n)$, $G = \mathrm{SU}(n)$, and $T = T(n)$. The Weyl group W is isomorphic to S_n, Z/T is isomorphic to $\mathrm{Spn}(n)$, and V, the generalized Weyl group, is isomorphic to the semidirect product $\mathrm{Spn}(n) \rtimes S_n$, which is just $\tilde{\Sigma}(n)$.

2. Zero-weight representations of the generalized Weyl group

Let it be given $T \subset G \subset F$ and $N \subset M$ as above. Let $\mathfrak{f}$ denote the (real) Lie algebra of F, $\mathrm{Exp}: \mathfrak{f} \to F$ the exponential map, and ad the adjoint representation of F on $\mathfrak{f}$. Let $\mathfrak{g} \subset \mathfrak{f}$ denote the Lie algebra of G, and $\mathfrak{t} \subset \mathfrak{g}$ the Lie algebra of T (i.e., the Cartan subalgebra of G), with dual $\mathfrak{t}^*$. Denote the pairing between $\mu \in \mathfrak{t}^*$ and $\tau \in \mathfrak{t}$ by $\mu \cdot \tau$. The adjoint representation restricts to a representation of M on $\mathfrak{t}$, denoted $\mathrm{ad}(M)$. The co-adjoint representation of M on $\mathfrak{t}^*$, denoted $\mathrm{ad}^*(M)$, is defined by

$$(\mathrm{ad}^*(x) \cdot \mu) \cdot \tau = \mu \cdot (\mathrm{ad}(x) \cdot \tau). \tag{A4}$$

Let $\ker_{\mathfrak{t}}(\mathrm{Exp})$ denote the lattice in $\mathfrak{t}$ mapped to the identity in T. A weight μ of T is an element of τ^* which is integer-valued on $\ker_{\mathfrak{t}}(\mathrm{Exp})$. Irreducible representations of T are labeled by weights, and are given explicitly by $\mathrm{Exp}\,\tau \mapsto \exp(2\pi i \mu \cdot \tau)$.

Let Γ denote an irreducible unitary representation of F on a finite-dimensional Hilbert space $\mathcal{V}$. $\mathcal{V}$ may be decomposed into a direct sum of generalized weight spaces $\mathcal{V}^\mu$ on which $\Gamma(T)$ acts with weight μ. (In case $F = G$, this is the usual weight-space decomposition of $\mathcal{V}$.) Let $\mathcal{V}^0$ denote the zero-weight space, i.e., the subspace of vectors invariant under T, for which $\mu = 0$.

For $x \in M$ and $\mathrm{Exp}\,\tau \in T$, we have that

$$\begin{aligned}\Gamma(\mathrm{Exp}\,\tau) \cdot (\Gamma(x) \cdot \mathcal{V}^\mu) &= \Gamma(x) \cdot (\Gamma(\mathrm{Exp}\,(\mathrm{ad}\,(x^{-1}) \cdot \tau)) \cdot \mathcal{V}^\mu) \\ &= \exp(2\pi i \mu \cdot (\mathrm{ad}\,(x^{-1} \cdot \tau)))\Gamma(x) \cdot \mathcal{V}^\mu \\ &= \exp(2\pi i (\mathrm{ad}^*(x^{-1}) \cdot \mu) \cdot t)(\Gamma(x) \cdot \mathcal{V}^\mu),\end{aligned} \tag{A5}$$

so that

$$\Gamma(x) \cdot \mathcal{V}^\mu = \mathcal{V}^{\mathrm{ad}^*(x^{-1}) \cdot \mu}. \tag{A6}$$

It follows that the zero-weight space, $\mathcal{V}^0$, is invariant under M, so that Γ restricts to a representation of M on $\mathcal{V}^0$. Since T is contained in the kernel, $\Gamma(M)$ reduces to a representation of the generalized Weyl group $V = M/T$ on $\mathcal{V}^0$. Denote this representation by Δ^Γ. In general, Δ^Γ is reducible. Let Δ denote an irreducible representation of $\mathcal{V}$, and let $\nu(\Gamma, \Delta)$ denote the multiplicity of Δ in the decomposition of Δ^Γ into its irreducible components. The multiplicities $\nu(\Gamma, \Delta)$ are naturally associated with a pair of irreducible representations Γ and Δ of a compact connected Lie group F and the generalized Weyl group V. A natural question is how to compute them. In case $F = G = \mathrm{SU}(n)$, this question has been discussed by Kostant.[12]

3. Weight bundles over G/T

Associated to the weight space $\mathcal{V}^\mu$ is a vector bundle $\mathcal{E}^\mu$ over G/T. $\mathcal{E}^\mu$ is a subbundle of the trivial bundle $G/T \times \mathcal{V}$, with fibers $\mathcal{E}_{g\,T}$ given by $\Gamma(g) \cdot \mathcal{V}^\mu$. By virtue of its embedding in the

trivial bundle, there is an induced G-invariant connection on $\mathcal{E}^\mu$, according to which a vector $|\psi(t)\rangle \in \mathcal{E}_{g(t)\,T}$ is parallel transported along a curve $g(t)\,T \in G/T$ if and only if $|\dot{\psi}(t)\rangle$ is orthogonal (with respect to the inner product on $\mathcal{V}$) to the fiber $\mathcal{E}_{g(t)\,T}$.

It is straightforward to derive an explicit formula for parallel transport along a one-parameter subgroup,

$$g(t) = \mathrm{Exp}\,(t\xi), \tag{A7}$$

where $\xi \in \mathfrak{g}$. We note that Γ gives a representation on $\mathcal{V}$ of $\mathfrak{f}$, and, by restriction, of $\mathfrak{g}$, by anti-Hermitian linear transformations. We denote these Lie-algebra representations by Γ as well. Let $\mathfrak{t}^\perp \subset \mathfrak{g}$ denote the orthogonal complement of $\mathfrak{t}$ in $\mathfrak{g}$ with respect to the Killing form (as G is compact and semisimple, the Killing form is negative definite). It is a standard result (see, e.g., Ref. 7) that $\Gamma(\mathfrak{t}^\perp)$ maps $\mathcal{V}^\mu$ into a direct sum of orthogonal subspaces $\mathcal{V}^{\mu'}$ (the difference $\mu' - \mu$ is, in fact, a root of $\mathfrak{g}$). Given $\xi \in \mathfrak{g}$, let $\xi^{\mathfrak{t}} + \xi^{\mathfrak{t}^\perp}$ denote its (unique) decomposition into components in $\mathfrak{t}$ and $\mathfrak{t}^\perp$, respectively. Then, for $|\psi\rangle \in \mathcal{V}^\mu$, we have that

$$\Gamma(\xi)|\psi\rangle = 2\pi \mathrm{i}(\mu \cdot \xi^{\mathfrak{t}})|\psi\rangle + \{\text{ vectors orthogonal to } \mathcal{V}^\mu\}. \tag{A8}$$

It follows from (A8) that the parallel transport of $|\psi\rangle$ along $g(t)$ is given by

$$|\psi(t)\rangle = \exp(-2\pi \mathrm{i}\mu \cdot \xi^{\mathfrak{t}})\Gamma(g(t))|\psi\rangle. \tag{A9}$$

It follows that the induced connection (A9) is Abelian; under parallel transport around a closed curve in G/T, a vector in $\mathcal{E}^\mu$ returns to itself up to a phase factor.

Let

$$X_\xi(g\,T) = \frac{d}{dt}\mathrm{Exp}\,(t\xi)g\,T|_0,$$

$$X_\eta(g\,T) = \frac{d}{dt}\mathrm{Exp}\,(t\eta)g\,T|_0$$

denote tangent vector fields at $g\,T$ generated by the left action of G. From (A9) one can deduce that the scalar-valued curvature two-form Ω^μ on X_ξ, X_η is given by

$$\Omega^\mu(X_\xi, X_\eta)(g\,T) = \mathrm{i}\mu \cdot ([\xi, \eta]^{\mathfrak{t}} - [\xi^{\mathfrak{t}}, \eta^{\mathfrak{t}}]). \tag{A10}$$

Since the left-invariant vector fields span the tangent bundle of G/T, (A10) determines Ω^μ. The curvature form, like the connection, is invariant under the action of G.

4. Zero-weight bundle and representations of the generalized Weyl group

Suppose the representation Γ of F has a nontrivial zero-weight space $\mathcal{V}^0$. From (A10), the curvature of the associated zero-weight bundle $\mathcal{E}^0$ vanishes, so that induced connection on $\mathcal{E}^0$ is flat. In this case, parallel transport with respect to a flat connection depends only on the homotopy class of the path in G/T. If G/T is simply connected, parallel transport is path independent, and $\mathcal{E}^0$ is globally flat, and therefore trivial. This is the case if G itself is simply connected, as we will assume from now on. As G is compact and connected, $g(t) \in G$ can be expressed $\mathrm{Exp}\,(t\xi(t))$ for some $\xi(t) \in \mathfrak{g}$. It follows from (A9) that parallel transport in $\mathcal{E}$ along $g(t)\,T$ is given by

$$|\phi(t)\rangle = \Gamma(g(t))|\phi\rangle. \tag{A11}$$

The zero-weight bundle $\mathcal{E}^0$, in contrast to weight bundles with nonzero weights, descends from a bundle over G/T to a bundle over G/N. We denote this reduced bundle by $\overline{\mathcal{E}^0}$. $\overline{\mathcal{E}^0}$ is a

subbundle of the trivial bundle $G/N\times\mathcal{V}$, with fibers given by $\overline{\mathcal{E}}_{g\,N}=\Gamma(g)\mathcal{V}^0$. (Note that since N leaves $\mathcal{V}^0$ invariant, this expression does not depend on the choice of representative g for $g\,N$.) The flat connection on $\mathcal{E}$ passes to $\overline{\mathcal{E}}$.

In general, the G/N is not simply connected; its fundamental group is isomorphic to the Weyl group $W=N/T$, as follows from the fact that $G/N=(G/T)/(N/T)=(G/T)/W$, and G/T is simply connected by assumption. An isomorphism between W and $\pi_1(G/N,N)$, the fundamental group based at the identity coset $\mathrm{I}\,N$, is given explicitly as follows. Let $g(t)\,N$ denote a closed path in G/N beginning and ending at N. For definiteness, take $0\leqslant t\leqslant 1$ and $g(0)=\mathrm{I}$. Then $g(1)\,N=\mathrm{I}\,N$ implies that $g(1)\in N$. The map

$$g(t)\,N\mapsto g(1)\,T \tag{A12}$$

depends only on the homotopy class of $g(t)\,N$. It is easily verified that (A12) preserves group multiplication, and is $1-1$ (since T is connected and G is simply connected) and onto (since G is connected).

Because G/N is not simply connected, parallel transport with respect to the flat connection need not be trivial, and can depend on the homotopy class of the path. For closed paths, parallel transport generates a unitary representation of the fundamental group, the monodromy of the connection. In view of the preceding, the monodromy at the identity coset N is naturally regarded as a representation of the Weyl group W. We denote this representation by Δ^Γ, and compute it as follows. Given $y\in N$, let $g(t)\in G$ be a smooth path in G with $g(0)=\mathrm{I}$ and $g(1)=y$. From (A11), parallel transport in $\overline{\mathcal{E}}$ along $g(t)\,N$ is given by

$$|\psi(t)\rangle=\Gamma(g(t))|\psi\rangle. \tag{A13}$$

Δ^Γ is obtained from parallel transport at $t=1$, so that

$$\Delta^\Gamma(y)=\Gamma(y). \tag{A14}$$

This is just the restriction to N of the representation Δ^Γ of the generalized Weyl group V on $\overline{\mathcal{E}}_N$.

At an arbitrary fiber $\overline{\mathcal{E}}_{g\,N}$ of the quotient bundle we can define a unitary representation of the generalized Weyl group V, which we denote by $L_{g\,N}(y)$. For example, we can take $L_{g\,N}(y)=\Gamma(g)\Gamma(y)\Gamma^\dagger(g)$. A different choice of representative g for $g\,N$ would yield a different but equivalent representation. Therefore, there is a well-defined decomposition of $\overline{\mathcal{E}}$ into a direct sum of subbundles $\overline{\mathcal{E}}^\alpha$ whose fibers transform according to irreducible representations Δ of V. This decomposition is determined by the multiplicities $\nu(\Gamma,\Delta)$ discussed in Appendix Sec. 1.

Bound states in coupled guides. I. Two dimensions

C. M. Linton[a] and K. Ratcliffe
Department of Mathematical Sciences, Loughborough University, LE11 3TU, United Kingdom

(Received 2 December 2003; accepted 16 January 2004)

Bound states that can occur in coupled quantum wires are investigated. We consider a two-dimensional configuration in which two parallel waveguides (of different widths) are coupled laterally through a finite length window and construct modes which exist local to the window connecting the two guides. We study both modes above and below the first cutoff for energy propagation down the coupled guide. The main tool used in the analysis is the so-called residue calculus technique, in which complex variable theory is used to solve a system of equations which is derived from a mode-matching approach. For bound states below the first cutoff a single existence condition is derived, but for modes above this cutoff (but below the second cutoff), two conditions must be satisfied simultaneously. A number of results have been presented which show how the bound-state energies vary with the other parameters in the problem.

I. INTRODUCTION

Over the past decade or so there have been a number of theoretical investigations into the phenomena of bound states in quantum waveguides, and acoustic resonances (or trapped modes) in acoustic waveguides. Though the two physical phenomena occur on vastly different scales, they are intimately related. It is our intention in this and the following article to show how some of the techniques that have been developed for the calculation of resonant frequencies in the acoustic context can be used to provide accurate and efficient tools for the evaluation of bound-state energies in a particular class of quantum configurations.

Theoretical investigations into quantum wires and quantum waveguides became important when it became possible to manufacture crystalline structures of high purity within a semiconductor material which are of the order of tens of nanometers in size and on whose boundaries the wave functions are usually suppressed. As described in Duclos and Exner (1995), these properties make it reasonable to model the motion of an electron within such a microstructure as a free (spinless) particle in an infinite guide with a vanishing potential on the guide boundary. The underlying equation is of course the Schrödinger equation, but for stationary problems this reduces to the Helmholtz equation, and thus the situation has direct analogs in the theories of acoustic and electromagnetic waves. Of interest here is the possible existence of nontrivial solutions which have finite energy. In quantum waveguides such solutions are known as bound states and their existence was explicitly demonstrated for the first time in Exner and Šeba (1989) for the case of a curved, thin planar strip and a review of early theoretical work on bound states in curved quantum waveguides (in both two and three dimensions) can be found in Duclos and Exner (1995). Some early experimental work, in which computed bound-state energies were verified, is reported in Carini *et al.* (1992). The existence of bound states can have a significant influence on electron transport in mesoscopic systems.

In the acoustics literature, the same bounded solutions are typically referred to as acoustic resonances, and the study of this phenomenon dates back to the experimental and theoretical work of Parker (1966, 1967). In Parker's setup the guide was a rigid duct, so the appropriate boundary

[a]Electronic mail: c.m.linton@lboro.ac.uk

conditions on the guide walls were of Neumann rather than Dirichlet type. Also, rather than being curved, the duct was perturbed by the inclusion of one or more splitter plates of finite length. Parker showed that such a geometry could support a nontrivial solution which was localized near to the plate(s) and which could be excited by vortex shedding from the plate edges when a mean flow of a certain speed was created in the duct. These resonances are extremely important in a number of engineering applications such as flow-induced vibration in cooler tubes and the design of turbomachinery; see Parker and Stoneman (1989), and the references cited therein.

Parker's modes were rediscovered in the early 1990s in a completely different physical situation: linear water waves in a wall-sided channel containing an obstacle. Here, there are circumstances in which the depth dependence can be removed from the problem, leaving the Helmholtz equation to be solved in a two-dimensional parallel-plate waveguide in which is situated a bounded obstacle. If this is a strip, then the problem is identical to the one considered by Parker. After some initial work showing that shapes other than plates could support bounded solutions (in this context usually called trapped modes) Evans, Levitin, and Vassiliev (1994) proved that this was the case for a very wide class of geometries.

The early work on these trapped modes focused on geometries which were symmetric about the guide centerline. This allows for a decomposition of the problem into independent symmetric and antisymmetric parts, the latter exhibiting a cutoff frequency below which it is impossible for energy to escape down the guide. In more formal language, the operator in the antisymmetric problem has a continuous spectrum which is bounded away from zero, and the region below the continuous spectrum can be searched for discrete eigenvalues, corresponding to trapped modes. Perhaps the first function theoretical treatment of a problem of this type is that of Jones (1953), in which the author used comparison principles to prove the existence of discrete eigenvalues below the continuous spectrum for a class of semi-infinite guides.

The use of operator decomposition to create a gap below the continuous spectrum has proved extremely useful in the search for trapped modes/acoustic resonances and has been extended to cover a number of different situations; see, for example, Linton and McIver (1998); Groves (1998); Davies and Parnovski (1998). It is, however, merely a device which makes resonances relatively easy to find in certain situations, but it tells us nothing about the existence or otherwise of discrete eigenvalues embedded within the continuous spectra of the relevant operators. Little has been achieved for this more difficult problem, though some early progress is reported in Evans and Porter (1998); McIver *et al.* (2001), and McIver, Linton, and Zhang (2002), and this will be discussed in Sec. IV below.

The specific focus of our attention in this and the subsequent article is the study of coupled quantum waveguides and techniques that can be used to establish the existence of and compute the energies for bound states both in the discrete spectrum and embedded within the continuous spectrum. In two dimensions the guides we will consider consist of two straight parallel waveguides connected through a window in the common boundary. Experimental observations of a waveguide with a similar configuration can be found in Hirayama *et al.* (1992) and Hirayama *et al.* (1993). A numerical model, based on classical rebound effects in a straight wire for the experimental specification described in Hirayama *et al.* (1992), was provided in Takagaki and Ploog (1994).

One of the first theoretical treatments of resonances in coupled guides was that of Kunze (1993), who calculated the transmissivity of a wire coupled either to infinite space or to another wire via a small hole. Kunze showed that there are energies at which near resonances or quasi-bound states in the wire become possible, and that these states cause a sharp downward dip in the conductance of the wire. However, it is the treatment given by Exner *et al.* (1996) which forms the starting point for our work. Exner *et al.* studied the bound states and scattering problems in parallel quantum waveguides of unequal width coupled laterally through a boundary window. The same type of variational argument as that employed by Evans, Levitin, and Vassiliev (1994) was used to show that the system always has at least one bound state for any window width. Moreover, the boundary-value problem was solved using a mode-matching technique, which allows one to construct the corresponding wave functions and determine how the bound-state energies depend

on the parameters of the problem. Work by Bulla *et al.* (1997) showed that if the window was small enough so that only one simple eigenvalue below the continuous spectrum was present, this eigenvalue could be bounded from below, and this result was extended by Exner and Vugalter (1996), who showed that for a sufficiently small window a two-sided asymptotic estimate for the gap between the continuous spectrum and this eigenvalue could be obtained. The case of a coupled waveguide containing a finite number of windows in the common boundary was considered in Exner and Vugalter (1997), who showed that if the windows are small enough there is just one isolated eigenvalue. Upper and lower bounds of the gap between this eigenvalue and the continuous spectrum were found using a variational approach. Other extensions to this type of analysis, including the incorporation of a magnetic field, or three laterally coupled guides, have been treated in Popov (2002) and Popov and Frolov (2003).

We treat the same geometry as that considered in Exner *et al.* (1996) with a coupled guide of total width d formed by two parallel guides of width b and $d-b$ linked via a window of length $2a$ in their common boundary. After setting up the problem in Sec. II we investigate the existence of bound states below the first cutoff for the coupled guide in Sec. III. Our starting point is a mode-matching analysis, but rather than solve the resulting system of equations numerically as in Exner *et al.* (1996), we use the so-called residue calculus technique described in Mittra and Lee (1971) to derive an approximate solution which is extremely accurate unless a/d is very small. This approximation also provides a very useful insight into how to solve the full problem in a numerically efficient way, and we show how an exponentially convergent linear system can be derived. Numerical results are presented and comparisons between the approximate and full solutions made. We find that bound states occur for any values of the parameters a/d and b/d. We also use a variational argument to prove the existence of bound states for a sufficiently wide window and to provide estimates to the bound-state energies. It is shown that the upper bound of these estimates provides a very good approximation to the actual computed energies.

The residue calculus technique is readily adapted to the more difficult problem of searching for resonances above the first cutoff in the coupled guide, and bound states above the first cutoff and below the second cutoff are investigated in Sec. IV. The bound-state energies are shown to correspond to the intersection of two curves in parameter space, and we find that the number of parameters which can be fixed is reduced by 1. Thus, if we fix the b/d, then bound states occur only for specific window widths. The possible existence of resonances between the second and third cutoffs is also discussed. Here, we require the intersection of three lines and no solutions appear to exist.

When the two guides which are coupled have identical widths ($b/d=1/2$) the resulting problem has an extra symmetry, and this leads to some different results. Below the first cutoff there is essentially no difference and the results are just those obtained from the previous analysis in the limit as $b/d\to 1/2$, though the extra symmetry means that the equal-width problem could be solved rather more easily. However, above the cutoff we find that bound states are found in a different energy band, with those that were found for the unequal-width case disappearing as $b/d\to 1/2$. Some results for these new modes are presented.

II. FORMULATION

We consider a pair of two-dimensional waveguides of widths b and c, coupled laterally through a window of width $2a$ in their common boundary. The total width is $d=b+c$, and we assume without loss of generality that $b>d/2$. The case when $b=d/2$ can be treated more simply due to the extra symmetry in that case, and this in fact leads to a qualitative change in some of the results which will be explored in Sec. IV. Cartesian axes are chosen so that the x axis coincides with the lower boundary of the waveguide, and the y axis is chosen so that the waveguide is symmetric about the line $x=0$, as shown in Fig. 1. Our geometry is thus defined by two nondimensional parameters: the width of the window in the common boundary compared to the width of the whole guide, and the height of the window compared to the width of the full coupled guide ($2a/d$ and b/d, respectively).

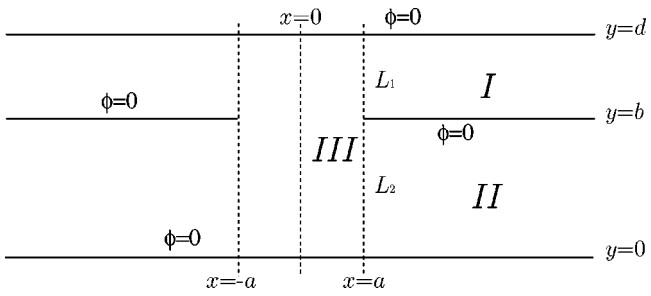

FIG. 1. Definition sketch.

Initially we shall seek a solution which is even (symmetric) about $x=0$, by considering the region $x>0$ and seeking a function $\phi(x,y)$ which satisfies

$$\frac{\partial \phi}{\partial x}=0 \quad \text{on} \quad x=0, \quad 0<y<d. \tag{2.1}$$

The function $\phi(x,y)$ must also satisfy the Helmholtz equation within the waveguide

$$(\nabla^2+k^2)\phi=0, \quad 0<y<d \quad \text{except on} \quad y=b, \quad x>a. \tag{2.2}$$

In the acoustic context $k=\omega/c$, where ω is the frequency of oscillation and c is the speed of sound, whereas in the related quantum-mechanical problem $k^2=2mE/\hbar^2$, in which m is the mass of the electron, and E is its total energy. In what follows, the parameter k will be referred to as the energy. The function ϕ satisfies Dirichlet boundary conditions on the waveguide walls

$$\phi=0 \quad \text{on} \quad y=0, \quad x>0, \tag{2.3}$$

$$\phi=0 \quad \text{on} \quad y=b, \quad x>a, \tag{2.4}$$

$$\phi=0 \quad \text{on} \quad y=d, \quad x>0, \tag{2.5}$$

and a radiation condition specifying that no waves propagate out to infinity

$$\phi\to 0 \quad \text{as} \quad x\to\infty, \tag{2.6}$$

which can be shown (using Green's theorem) to be equivalent in this problem to the statement that ϕ must possess finite energy

$$\int_\Omega |\nabla\phi|^2 \mathrm{d}\Omega<\infty, \tag{2.7}$$

where Ω is the interior of the coupled guide. We finally assume ϕ is nonsingular, and that

$$\nabla\phi=O(r^{-1/2}) \quad \text{as} \quad r\equiv\{(x-a)^2+(y-b)^2\}^{1/2}\to 0, \tag{2.8}$$

anticipating a singularity in the derivative of ϕ at the edge of the window.

It is useful to split the domain into three regions as shown in Fig. 1. Region *I* is $b<y<d$, $x>a$, region *II* is $0<y<b$, $x>a$, and region *III* is $0<y<d$, $0<x<a$. We can represent the function ϕ by a function ϕ_i $(i=1,2,3)$ in each region, with the following continuity conditions applied at the boundaries between the regions:

$$\phi_i=\phi_3, \quad \frac{\partial \phi_i}{\partial x}=\frac{\partial \phi_3}{\partial x}, \quad \text{on} \quad L_i, \quad i=1,2, \tag{2.9}$$

where L_1 is $x=a$, $b<y<d$, L_2 is $x=a$, $0<y<b$, and we will write L_3 for $L_1 \cup L_2$. We then introduce the complete orthogonal sets

$$\Psi_n^{(1)}(y)=2^{1/2}\sin \nu_n(d-y), \quad \nu_n=n\pi/c, \quad n\in\mathbb{N}, \tag{2.10}$$

$$\Psi_n^{(2)}(y)=2^{1/2}\sin \mu_n(b-y), \quad \mu_n=n\pi/b, \quad n\in\mathbb{N}, \tag{2.11}$$

$$\Psi_n^{(3)}(y)=2^{1/2}\sin \lambda_n(d-y), \quad \lambda_n=(n+1)\pi/d, \quad n\in\mathbb{N}_0, \tag{2.12}$$

which satisfy

$$\frac{1}{|L_i|}\int_{L_i}\Psi_n^{(i)}(y)\Psi_m^{(i)}(y)\mathrm{d}y=\delta_{mn}, \quad i=1,2,3, \tag{2.13}$$

where δ_{mn} is the Kronecker delta. Here and throughout, we use the symbol $\mathbb{N}$ for the set {1, 2, 3,...} and the symbol $\mathbb{N}_0$ for the set {0, 1, 2,...}.

Separation of variables shows that the eigenfunction expansions for the three regions can be written

$$\phi_1(x,y)=\sum_{n=1}^{\infty} U_n^{(1)}\frac{\mathrm{e}^{-\alpha_n(x-a)}}{-\alpha_n}\Psi_n^{(1)}(y), \quad \alpha_n=(\nu_n^2-k^2)^{1/2}, \tag{2.14}$$

$$\phi_2(x,y)=\sum_{n=1}^{\infty} U_n^{(2)}\frac{\mathrm{e}^{-\beta_n(x-a)}}{-\beta_n}\Psi_n^{(2)}(y), \quad \beta_n=(\mu_n^2-k^2)^{1/2}, \tag{2.15}$$

$$\phi_3(x,y)=\sum_{n=0}^{\infty} U_n^{(3)}\frac{\cosh \gamma_n x}{\gamma_n \sinh \gamma_n a}\Psi_n^{(3)}(y), \quad \gamma_n=(\lambda_n^2-k^2)^{1/2}, \tag{2.16}$$

where $U_n^{(i)}$, $i=1,2,3$, are unknown complex constants and various factors have been introduced for convenience. If we restrict the energy by

$$kb<\pi, \tag{2.17}$$

then, since $b>d/2$, the values of α_n and β_n, $n\in\mathbb{N}$ will all be real and positive. As these terms appear in the eigenfunction expansions as coefficients of negative exponentials, the restriction on energy produces exponential decay down the guide in both regions *I* and *II*. We define $kb=\pi$ as the first cutoff of the coupled waveguide and consider the case of bound states whose energies are below this cutoff.

III. BOUND STATES BELOW THE FIRST CUTOFF

If $kb<\pi$ then α_n, β_n, and γ_n, $n\in\mathbb{N}$, are all real and positive. However, provided $kd>\pi$, γ_0 will be purely imaginary and the corresponding mode will be oscillatory in region *III*. We thus anticipate that a necessary condition for the existence of bound states will be

$$\pi<kd<\frac{d\pi}{b}. \tag{3.1}$$

If we apply the continuity conditions (2.9), we obtain

$$\sum_{n=0}^{\infty} U_n^{(3)} \frac{\coth \gamma_n a}{\gamma_n} \Psi_n^{(3)}(y) = \begin{cases} \displaystyle\sum_{n=1}^{\infty} U_n^{(1)} \frac{\Psi_n^{(1)}(y)}{-\alpha_n}, & y \in L_1, \\ \displaystyle\sum_{n=1}^{\infty} U_n^{(2)} \frac{\Psi_n^{(2)}(y)}{-\beta_n}, & y \in L_2, \end{cases} \tag{3.2}$$

and

$$\sum_{n=0}^{\infty} U_n^{(3)} \Psi_n^{(3)}(y) = \begin{cases} \displaystyle\sum_{n=1}^{\infty} U_n^{(1)} \Psi_n^{(1)}(y), & y \in L_1, \\ \displaystyle\sum_{n=1}^{\infty} U_n^{(2)} \Psi_n^{(2)}(y), & y \in L_2. \end{cases} \tag{3.3}$$

We can convert (3.2) and (3.3) into an infinite system of linear algebraic equations by multiplying each by $\Psi_m^{(3)}$, $m \in \mathbb{N}_0$, and integrating over L_3. This leads to

$$U_m^{(3)} = \sum_{n=1}^{\infty} U_n^{(1)} d_{nm} + \sum_{n=1}^{\infty} U_n^{(2)} e_{nm}, \quad m \in \mathbb{N}_0, \tag{3.4}$$

$$U_m^{(3)} \frac{\coth \gamma_m a}{\gamma_m} = \sum_{n=1}^{\infty} \frac{U_n^{(1)}}{-\alpha_n} d_{nm} + \sum_{n=1}^{\infty} \frac{U_n^{(2)}}{-\beta_n} e_{nm}, \quad m \in \mathbb{N}_0, \tag{3.5}$$

where we have defined

$$d_{nm} = \frac{1}{d} \int_{L_1} \Psi_n^{(1)}(y) \Psi_m^{(3)}(y) \mathrm{d}y = \frac{2\nu_n (-1)^n \sin \lambda_m c}{d(\gamma_m^2 - \alpha_n^2)}, \quad m \in \mathbb{N}_0, \ n \in \mathbb{N}, \tag{3.6}$$

$$e_{nm} = \frac{1}{d} \int_{L_2} \Psi_n^{(2)}(y) \Psi_m^{(3)}(y) \mathrm{d}y = \frac{2\mu_n \sin \lambda_m c}{d(\gamma_m^2 - \beta_n^2)}, \quad m \in \mathbb{N}_0, \ n \in \mathbb{N}. \tag{3.7}$$

It is necessary that $\gamma_m \neq \alpha_n$ and $\gamma_m \neq \beta_n$ for any n and m and we can ensure this by assuming that b/d is irrational, although Evans, Linton, and Ursell (1993), Appendix D, show how continuity arguments can be used to remove this restriction so that the conditions for bound states that are obtained are valid for all values of b/d.

Eliminating $U_m^{(3)}$ from (3.4) and (3.5), and substituting for d_{nm} and e_{nm} from (3.6) and (3.7), we can derive

$$\sum_{n=1}^{\infty} U_n \left(\frac{1}{\alpha_n - \gamma_m} + \frac{\zeta_m}{\alpha_n + \gamma_m} \right) - \sum_{n=1}^{\infty} V_n \left(\frac{1}{\beta_n - \gamma_m} + \frac{\zeta_m}{\beta_n + \gamma_m} \right) = 0, \quad m \in \mathbb{N}_0, \tag{3.8}$$

where we have defined

$$U_n = \frac{U_n^{(1)} (-1)^n \nu_n}{\alpha_n}, \quad V_n = \frac{U_n^{(2)} \mu_n}{\beta_n}, \quad \zeta_m = \mathrm{e}^{-2\gamma_m a}. \tag{3.9}$$

So far we have only used the boundary conditions (2.1)–(2.6) and not the condition (2.8), which anticipates the singular behavior near the edge. Since $\Sigma_{n=1}^{\infty} n^{\tau} e^{-nx} = O(x^{-1-\tau})$ as $x \to 0+$ (see, e.g., Martin, 1995), consideration of the gradient of ϕ near the edge shows that

$$U_n, V_n = O(n^{-1/2}) \ \text{ as } \ n \to \infty. \tag{3.10}$$

A. Approximate solution

We now derive an approximate solution to (3.8) for large a, taking into account the asymptotic behavior required from (3.10). Note that since γ_m, $m\in\mathbb{N}$, is real, the terms ζ_m, $m\in\mathbb{N}$, appearing in (3.8) decay rapidly to zero as $a/d\to\infty$. A good approximation for large a is therefore to set $\zeta_m=0$ for $m\in\mathbb{N}$. The idea for this type of approximation (which is equivalent to assuming that the two edges at $x=\pm a$, $y=b$ can be treated independently) goes back to Hurd (1954), who was studying the propagation of electromagnetic surface waves along a comb grating. We would then have

$$\sum_{n=1}^{\infty}\left(\frac{U_n}{\alpha_n-\gamma_m}-\frac{V_n}{\beta_n-\gamma_m}\right)=-\delta_{m0}\zeta_0\sum_{n=1}^{\infty}\left(\frac{U_n}{\alpha_n+\gamma_0}-\frac{V_n}{\beta_n+\gamma_0}\right),\quad m\in\mathbb{N}_0, \tag{3.11}$$

a system of equations that can be solved explicitly using a method originally described in Whitehead (1951) and Berz (1951).

Consider the quantities

$$I_m=\lim_{N\to\infty}\frac{1}{2\pi\mathrm{i}}\int_{C_N}\frac{f(z)}{z-\gamma_m}\mathrm{d}z,\quad J_m=\lim_{N\to\infty}\frac{1}{2\pi\mathrm{i}}\int_{C_N}\frac{f(z)}{z+\gamma_m}\mathrm{d}z,\quad m\in\mathbb{N}_0, \tag{3.12}$$

where C_N is a sequence of contours (to be determined) on which $z\to\infty$ as $N\to\infty$ and $f(z)$ is a meromorphic function which is assumed to have the following properties:

(P1) $f(z)$ has simple poles at $z=\alpha_n$ and $z=\beta_n$, $n\in\mathbb{N}$;
(P2) $f(z)$ has simple zeros at $z=\gamma_n$, $n\in\mathbb{N}$, but not at $z=\gamma_0$; and
(P3) $f(z)=o(1)$ as $|z|\to\infty$ on C_N as $N\to\infty$.

Condition P3 ensures that $I_m=0$ and $J_m=0$. Applying Cauchy's residue theorem to the integrals in (3.12), we find

$$\sum_{n=1}^{\infty}\frac{R(f:\alpha_n)}{\alpha_n-\gamma_m}+\sum_{n=1}^{\infty}\frac{R(f:\beta_n)}{\beta_n-\gamma_m}+\delta_{m0}f(\gamma_0)=0, \tag{3.13}$$

$$\sum_{n=1}^{\infty}\frac{R(f:\alpha_n)}{\alpha_n+\gamma_m}+\sum_{n=1}^{\infty}\frac{R(f:\beta_n)}{\beta_n+\gamma_m}+f(-\gamma_m)=0, \tag{3.14}$$

where $R(f:z_0)$ represents the residue of $f(z)$ at $z=z_0$, and $m\in\mathbb{N}_0$, in each case. If we normalize $f(z)$ by setting

$$f(\gamma_0)=1, \tag{3.15}$$

then a comparison of (3.13) and (3.14) with (3.11) shows that the required solution of (3.11) is given by

$$U_n=R(f:\alpha_n),\quad V_n=-R(f:\beta_n),\quad n\in\mathbb{N}, \tag{3.16}$$

provided (3.10) is satisfied and

$$f(-\gamma_0)\zeta_0=-1. \tag{3.17}$$

If we can determine a suitable $f(z)$ and sequence of contours C_N, then (3.17) is the condition for the existence of bound states.

The method by which $f(z)$ can be constructed follows closely that given in Evans, Linton, and Ursell (1993), and we will simply note here that the a sequence of contours C_N can be constructed so that the function

$$f(z)=h_1 g(z), \tag{3.18}$$

where

$$h_1=\exp\left\{\frac{\gamma_0}{\pi}(b\ln(d/b)+c\ln(d/c))\right\}\prod_{n=1}^{\infty}\frac{(1-\gamma_0/\alpha_n)(1-\gamma_0/\beta_n)}{(1-\gamma_0/\gamma_n)}, \tag{3.19}$$

$$g(z)=\exp\left\{\frac{-z}{\pi}(b\ln(d/b)+c\ln(d/c))\right\}\prod_{n=1}^{\infty}\frac{(1-z/\gamma_n)}{(1-z/\alpha_n)(1-z/\beta_n)}, \tag{3.20}$$

has all the necessary properties. In fact, $f(z)=O(z^{-1/2})$ as $|z|\to\infty$ on C_N as $N\to\infty$. Note that the fact that $\gamma_n\sim(n+1)\pi/d$ rather than $n\pi/d$ (while $\alpha_n\sim n\pi/c$ and $\beta_n\sim n\pi/b$) is crucial.

The condition for the existence of bound states (3.17) is

$$f(\mathrm{i}\gamma')=-\mathrm{e}^{-2\mathrm{i}\gamma' a}, \tag{3.21}$$

where

$$\gamma'=\mathrm{i}\gamma_0=(k^2-(\pi/d)^2)^{1/2}, \tag{3.22}$$

and this reduces to

$$\gamma'(a-\Theta)=\chi+(n-\tfrac{1}{2})\pi, \quad n \text{ an integer}, \tag{3.23}$$

where

$$\Theta=\frac{1}{\pi}(b\ln(d/b)+c\ln(d/c)), \tag{3.24}$$

$$\chi=\sum_{n=1}^{\infty}\left(\tan^{-1}\left(\frac{\gamma'}{\gamma_n}\right)-\tan^{-1}\left(\frac{\gamma'}{\alpha_n}\right)-\tan^{-1}\left(\frac{\gamma'}{\beta_n}\right)\right). \tag{3.25}$$

For the case of antisymmetry about $x=0$, condition (2.1) is replaced by

$$\phi=0 \text{ on } x=0,\ 0<y<d, \tag{3.26}$$

and the system of equations (3.8) becomes

$$\sum_{n=1}^{\infty}U_n\left(\frac{1}{\alpha_n-\gamma_m}-\frac{\zeta_m}{\alpha_n+\gamma_m}\right)-\sum_{n=1}^{\infty}V_n\left(\frac{1}{\beta_n-\gamma_m}-\frac{\zeta_m}{\beta_n+\gamma_m}\right)=0,\ m\in\mathbb{N}_0. \tag{3.27}$$

The approximate existence condition (3.21) becomes

$$f(\mathrm{i}\gamma')=\mathrm{e}^{-2\mathrm{i}\gamma' a}, \tag{3.28}$$

with exactly the same function f as before, and this reduces to

$$\gamma'(a-\Theta)=\chi+n\pi, \quad n \text{ an integer}, \tag{3.29}$$

where Θ and χ are defined as before.

B. Full solution

The approximate solution derived above can be used as the basis for a very efficient numerical solution to the problem. The ideas behind the method are described in detail in Mittra and Lee (1971), and briefly in Jones (1994), Sec. 2.12. We form a solution to (3.8) by considering the quantities

$$I_m = \lim_{N\to\infty} \frac{1}{2\pi \mathrm{i}} \int_{C_N} f(z) \left(\frac{1}{z-\gamma_m} + \frac{\zeta_m}{z+\gamma_m} \right) \mathrm{d}z, \quad m \in \mathbb{N}_0, \tag{3.30}$$

where now $f(z)$ must satisfy

(P1) $f(z)$ has simple poles at $z=\alpha_n$ and $z=\beta_n$, $n\in\mathbb{N}$, and
(P2) $f(z)=o(1)$ as $|z|\to\infty$ on C_N as $N\to\infty$.

We now let

$$f(z) = g(z)h(z), \tag{3.31}$$

where $g(z)$ is given by (3.20) and

$$h(z) = 1 + \sum_{n=1}^{\infty} \frac{A_n}{z-\gamma_n}, \tag{3.32}$$

for some unknown constants A_n. The function $h(z)$ is chosen to cancel the zeros of $g(z)$ at γ_n, and we anticipate that as $a\to\infty$, $h(z)$ will tend rapidly to 1, since the exponential terms ζ_n will decay rapidly to zero. Thus, the constants A_m will also tend to zero rapidly as $a\to\infty$.

If we apply Cauchy's residue theorem to the integral in (3.30), we obtain

$$\sum_{n=1}^{\infty} R(f:\alpha_n) \left(\frac{1}{\alpha_n-\gamma_m} + \frac{\zeta_m}{\alpha_n+\gamma_m} \right) + \sum_{n=1}^{\infty} R(f:\beta_n) \left(\frac{1}{\beta_n-\gamma_m} + \frac{\zeta_m}{\beta_n+\gamma_m} \right) + f(\gamma_m) + \zeta_m f(-\gamma_m) = 0, \quad m \in \mathbb{N}_0. \tag{3.33}$$

Comparing (3.33) with (3.8), we see that $U_n = R(f:\alpha_n)$, $V_n = -R(f:\beta_n)$, $n\in\mathbb{N}$, provided (3.10) is satisfied and

$$f(\gamma_m) + \zeta_m f(-\gamma_m) = 0, \quad m \in \mathbb{N}_0. \tag{3.34}$$

For $m\in\mathbb{N}$ this is equivalent to an infinite system of equations for the unknowns A_m

$$A_m + B_m \sum_{n=1}^{\infty} \frac{A_n}{\gamma_m+\gamma_n} = B_m, \quad m \in \mathbb{N}, \tag{3.35}$$

where

$$B_m = 2\gamma_m \mathrm{e}^{2\gamma_m(\Theta-a)} \frac{(\alpha_m-\gamma_m)(\beta_m-\gamma_m)}{(\alpha_m+\gamma_m)(\beta_m+\gamma_m)} \prod_{\substack{n=1 \\ n\neq m}}^{\infty} \frac{(1+\gamma_m/\gamma_n)(1-\gamma_m/\alpha_n)(1-\gamma_m/\beta_n)}{(1+\gamma_m/\alpha_n)(1+\gamma_m/\beta_n)(1-\gamma_m/\gamma_n)}. \tag{3.36}$$

Unlike (3.8), this system of equations is real and the presence of the factor ζ_m in B_m shows that as $a\to\infty$, the coefficients A_m decay exponentially to zero. Moreover, the terms B_m decay exponentially as $m\to\infty$ and so the system can be solved very efficiently via a numerical truncation

technique. It can be proved, using the methods described in Evans (1992), Appendix B, and Evans, Linton, and Ursell (1993), Appendix C, that the infinite system (3.35) has a unique solution A_n with $\Sigma_{n=1}^{\infty} A_n^2 < \infty$ provided a/d is sufficiently large.

We now return to the one condition still to be satisfied, namely, (3.34) with $m=0$. This is

$$e^{2i\gamma' a} = -\frac{f(-i\gamma')}{f(i\gamma')}. \tag{3.37}$$

Now, since A_n and γ_n are real for $n \in \mathbb{N}$, we can write

$$\frac{h(-i\gamma')}{h(i\gamma')} = e^{2i\sigma}, \tag{3.38}$$

where

$$\sigma = \arg(h(-i\gamma')) = \arg\left(1 - \sum_{n=1}^{\infty} \frac{A_n}{\gamma_n + i\gamma'}\right). \tag{3.39}$$

Then, with χ and Θ as before, the condition for the existence of bound states (3.37) reduces to

$$\gamma'(a-\Theta) = \chi + \sigma + (n - \tfrac{1}{2})\pi, \quad n \text{ an integer.} \tag{3.40}$$

This condition differs from the approximate condition (3.23) by the inclusion of the term σ. This depends on a/d, but it is clear that as $a/d \to \infty$, $\sigma \to \arg(1) = 0$.

For the case of antisymmetry about $x=0$, (3.34) becomes

$$f(\gamma_m) - \zeta_m f(-\gamma_m) = 0, \quad m \in \mathbb{N}_0, \tag{3.41}$$

with the infinite system of equations equivalent to (3.35) being

$$A_m - B_m \sum_{n=1}^{\infty} \frac{A_n}{\gamma_m + \gamma_n} = -B_m, \quad m \in \mathbb{N}, \tag{3.42}$$

and B_m is given by (3.36) as before. The condition for antisymmetric modes, equivalent to (3.40), is thus

$$\gamma'(a-\Theta) = \chi + \sigma' + n\pi, \quad n \text{ an integer,} \tag{3.43}$$

where σ' is the argument of $h(-i\gamma')$ with the constants A_n given by the solution of (3.42).

C. Results

The systems of Eqs. (3.35) and (3.42) need to be solved by truncation but, due to the exponential convergence of the B_m terms, only a small truncation parameter is needed. In the following results a truncation parameter of 5 was used to assure high accuracy for all parameter values, but a 2×2 system is adequate unless a/d is very small. Figure 2 shows results for $b/d = 0.6$ and compares the nondimensional bound-state energies, kd/π, computed from the approximate solution (dashed lines) with those found from the full solution (solid lines). The two curves on the left of the figure correspond to the first symmetric (about $x=0$) mode, and the other two correspond to the first antisymmetric mode. For all but the smallest values of a/d, the results computed from the full and approximate methods are indistinguishable. Only when a/d is less than about 0.5 do the full solution and the approximate solution produce significantly different results.

In Fig. 3 a typical set of nondimensional bound-state energies, kd/π, computed from the full solutions (3.40) and (3.43), is plotted against a/d, for $b/d = 0.75$. The solid lines correspond to modes symmetric about $x=0$ and the dashed lines correspond to modes antisymmetric about x

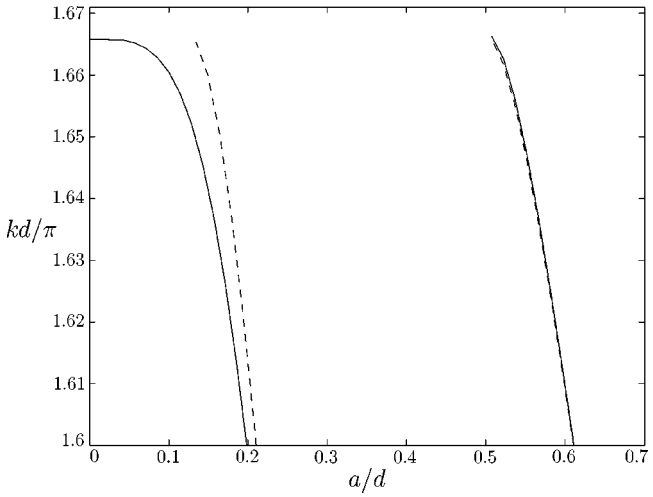

FIG. 2. A comparison of the nondimensional bound-state energies, kd/π, for modes symmetric and antisymmetric about $x=0$ for the approximate solution (dashed) and the full solution (solid) plotted against a/d when $b/d=0.6$.

$=0$. We see that as a/d increases the number of modes present also increases, and the modes appear alternatively symmetric and antisymmetric from the cutoff $kd=d\pi/b=4\pi/3$, and decrease towards $kd=\pi$.

The variation of nondimensional bound-state energies with b/d when $a/d=3$ is shown in Fig. 4. The solid lines represent symmetric modes, the dashed lines correspond to antisymmetric modes, and the dotted line represents the upper cutoff $kb=\pi$. It is clear that as b/d increases from 0.5, the number of modes present decreases and the energy of each of the modes decreases slightly. The figure shows that modes are present for any value of b/d in the interval $[0.5, 1)$.

D. Variational methods

Trapped modes occurring in two-dimensional acoustic waveguides containing long obstacles symmetric about the centerline were considered by Khallaf, Parnovski, and Vassiliev (2000). In their paper the authors use variational arguments to provide estimates for the trapped mode

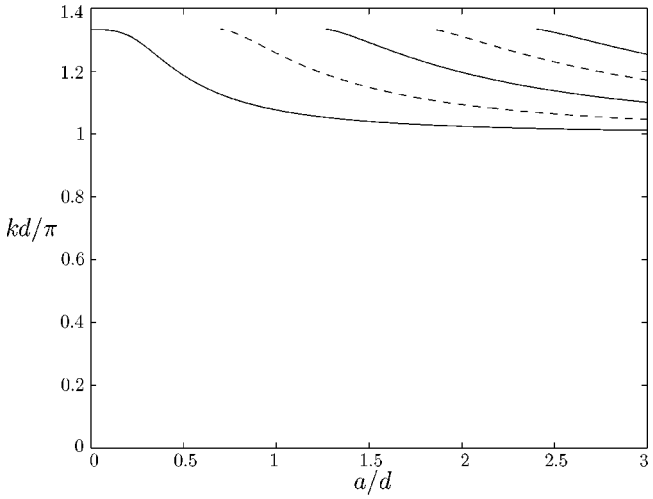

FIG. 3. Nondimensional bound-state energies, kd/π, for modes symmetric (—) and antisymmetric (– –) about $x=0$, plotted against a/d when $b/d=0.75$.

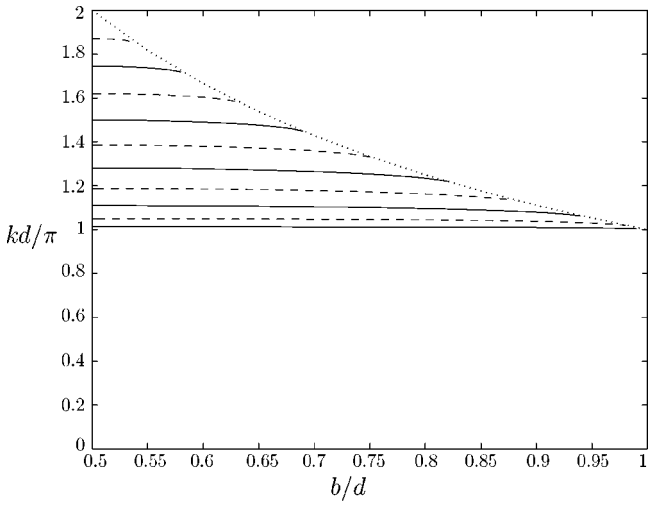

FIG. 4. Nondimensional bound-state energies, kd/π, for modes symmetric (—) and antisymmetric (––) about $x=0$, plotted against b/d when $a/d=3$. The dotted line is the curve $kb=\pi$.

frequencies and also to prove that the number of trapped modes occurring is asymptotically proportional to the obstacle's length. We will extend their method to provide estimates for the bound-state energies in our problem and to prove existence for a sufficiently large window. The main difference between the two problems is that the laterally coupled guide under consideration here is not symmetric about the centerline of the waveguide.

Our waveguide can be thought of as an unbounded domain Ω defined as

$$\Omega=\{(0,\infty)\times(0,d)\}\backslash\{[a,\infty)\times[b]\}, \tag{3.44}$$

where $a>0$ and $\frac{1}{2}<b/d<1$. We are trying to find estimates for values of λ for which there is a nontrivial solution $\phi(x,y)$ to the boundary-value problem

$$-\nabla^2\phi=\lambda\phi \quad \text{in} \quad \Omega, \tag{3.45}$$

subject to the boundary conditions (2.3)–(2.6), and (2.1) for symmetric modes or (3.26) for antisymmetric modes. In other words, we seek the eigenvalues of $-\nabla^2$ (defined on an appropriate domain) and since wave-like modes can propagate to infinity if $kb>\pi$, the continuous spectrum for either the symmetric or the antisymmetric problem is the semi-interval $[\pi^2/b^2,\infty)$.

We consider the Rayleigh quotient defined by

$$Q(\phi)=\frac{\displaystyle\int_\Omega|\nabla\phi|^2\mathrm{d}\Omega}{\displaystyle\int_\Omega|\phi|^2\mathrm{d}\Omega}, \tag{3.46}$$

and set

$$\lambda_1=\inf_{\phi\in\mathcal{H}_0^1\backslash\{0\}} Q(\phi). \tag{3.47}$$

(The symbol λ_n has a different meaning in this section than elsewhere in the paper.) Here, $\mathcal{H}_0^1$ is the Sobolev space consisting of all functions in $L^2(\Omega)$ which also have square-integrable first partial derivatives and which vanish on the boundary of Ω at the same places that the solution ϕ does. In particular, the symbol $\mathcal{H}_0^1$ represents different spaces in the symmetric and antisymmetric problems, since in the latter case functions in $\mathcal{H}_0^1$ must vanish on $x=0$, $0<y<d$. It is a standard result (see, e.g., Edmunds and Evans 1987, Chap. XI) that $\lambda_1>0$ is the lowest point of the

spectrum of our operator and, if $\lambda_1 < \pi^2/b^2$, then λ_1 must be an eigenvalue of the problem (the smallest) and the function φ_1 for which $Q(\varphi_1)=\lambda_1$ is the associated eigenfunction (bound state). We can define

$$\lambda_n = \inf_{\substack{\phi \in \mathcal{H}_0^1 \setminus \{0\} \\ \phi \perp \varphi_i,\, i=1,2,\ldots,n-1}} Q(\phi), \tag{3.48}$$

and if $\lambda_n < \pi^2/b^2$, λ_n is the nth eigenvalue for the problem (arranged in order of increasing size and accounting for multiplicity). If $\lambda_{n+1}=\pi^2/b^2$, there will be exactly n eigenvalues below the first cutoff. We label the eigenvalues below the continuous spectrum as $\lambda_{j,s}$ for the symmetric problem (and we assume that there are n_s of them) and $\lambda_{j,a}$ for the antisymmetric problem (of which there are n_a).

We now use the idea of Dirichlet–Neumann bracketing (see, e.g., Courant and Hilbert 1953) which is a consequence of the variational principle outlined above. The domain Ω is split into the regions *I*, *II*, and *III* defined previously and we consider the eigenvalues associated with each region separately when an artificial boundary condition is imposed on L_3. We denote the jth eigenvalue occurring in region i with a Dirichlet (respectively, Neumann) condition on L_3 as $\lambda_j^{i,D}$ (respectively, $\lambda_j^{i,N}$). We also define a counting function $N^{i,D}(\lambda)$ [respectively, $N^{i,N}(\lambda)$], as the number of eigenvalues less than λ in region i, with a Dirichlet (respectively, Neumann) condition on L_3. An extra subscript (s or a) will be used whenever it is necessary to distinguish between the symmetric and antisymmetric problems. If $\lambda < \pi^2/b^2$ we have

$$N^{I,D}(\lambda)+N^{II,D}(\lambda)+N_s^{III,D}(\lambda) \leqslant N_s(\lambda) \leqslant N^{I,N}(\lambda)+N^{II,N}(\lambda)+N_s^{III,N}(\lambda), \tag{3.49}$$

where $N_s(\lambda)$ is the total number of eigenvalues below λ for the symmetric problem. Note that $N_s(\pi^2/b^2)=n_s$.

A straightforward calculation shows that

$$\{\lambda_{j,s}^{III,D}\}_{j=1}^{\infty} = \{(n-1/2)^2\pi^2/a^2+(m\pi)^2/d^2\}_{n,m=1}^{\infty}, \tag{3.50}$$

$$\{\lambda_{j,s}^{III,N}\}_{j=1}^{\infty} = \{(n-1)^2\pi^2/a^2+(m\pi)^2/d^2\}_{n,m=1}^{\infty}, \tag{3.51}$$

and that there are no eigenvalues in regions *I* or *II*, and so (3.49) becomes

$$N_s^{III,D}(\lambda) \leqslant N_s(\lambda) \leqslant N_s^{III,N}(\lambda), \tag{3.52}$$

provided $\lambda < \pi^2/b^2$. It then follows (see, e.g., Behnke *et al.*, 2000) that

$$\lambda_{j,s}^{III,N} \leqslant \lambda_{j,s} \leqslant \lambda_{j,s}^{III,D}, \tag{3.53}$$

for all j for which $\lambda_{j,s} < \pi^2/b^2$. Hence

$$\frac{\pi^2}{a^2}(j-1)^2+\frac{\pi^2}{d^2} \leqslant \lambda_{j,s} \leqslant \frac{\pi^2}{a^2}(j-1/2)^2+\frac{\pi^2}{d^2}. \tag{3.54}$$

For the antisymmetric problem the eigenfunction expansions and eigenvalues can be recalculated and (3.54) becomes

$$\frac{\pi^2}{a^2}(j-1/2)^2+\frac{\pi^2}{d^2} \leqslant \lambda_{j,a} \leqslant \frac{\pi^2}{a^2}j^2+\frac{\pi^2}{d^2}. \tag{3.55}$$

The result of superimposing these intervals onto Fig. 3 is shown in Fig. 5. Each mode appears between two estimates as required, and it can be seen that as a/d increases along each curve, the estimate coming from the upper bound gives a better approximation to the energy.

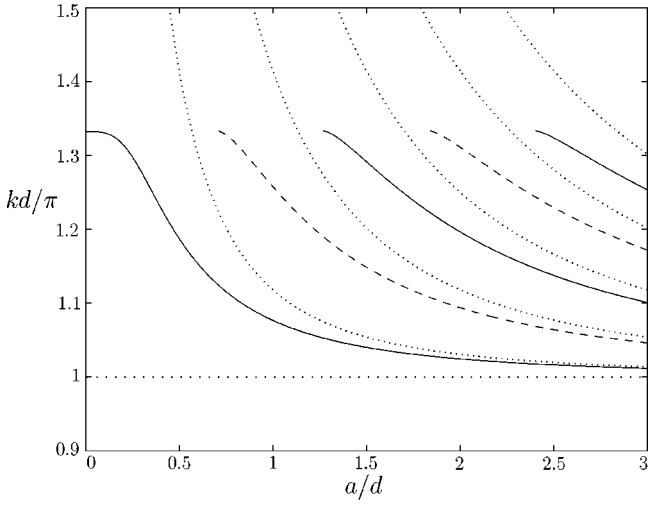

FIG. 5. Nondimensional bound-state energies, kd/π, for modes symmetric and antisymmetric about $x=0$ for the full solution (solid and dashed, respectively), and the estimated intervals (dotted), plotted against a/d when $b/d=0.75$.

Each interval of (3.54) and (3.55) whose right-end value is less than π^2/b^2 contains precisely one eigenvalue. Thus, there are at least n_s symmetric bound states provided

$$a/d > (n_s - \tfrac{1}{2})/\sqrt{d^2/b^2 - 1}. \tag{3.56}$$

Similarly, there are at least n_a antisymmetric bound states provided

$$a/d > n_a/\sqrt{d^2/b^2 - 1}. \tag{3.57}$$

As $b/d \to 1$, the required value of a/d tends to infinity in both cases. Similar results were found by Exner *et al.* (1996).

IV. BOUND STATES BELOW THE SECOND CUT-OFF

In this section we look for bound states whose energies are above the cutoff given by (2.17), i.e., $kb > \pi$. Any such mode corresponds to an eigenvalue embedded in the continuous spectrum of the relevant operator. Numerical evidence for the existence of an isolated trapped mode embedded in the continuous spectrum was given by Evans and Porter (1998) for the case of a rigid circular cylinder placed on the centerline of a guide with either Neumann or Dirichlet boundary conditions on its walls. In each case the trapped mode was shown to occur for a single cylinder radius and at a specific frequency.

More recently, McIver *et al.* (2001) showed that this trapped mode was not isolated, but part of a continuous branch of modes which exist for ellipses with varying aspect ratio. The ellipses are defined by two geometrical parameters a and b, say, where $(x/a)^2 + (y/b)^2 = 1$, and embedded trapped modes were found to exist for families of ellipses given by $a = a(b)$, with the corresponding frequency being of the form $k = k(b)$. Further examples of branches of embedded trapped modes in geometries defined by two geometrical parameters were computed in McIver, Linton, and Zhang (2002).

In general, it appears that for a given energy there will be a number of possible wave-like modes which can transmit the energy down the guide, and in order for a bound state to exist the amplitudes of these modes must be zero. If one considers a geometry defined by a sufficient number of parameters then it may be possible to determine relationships between these parameters which lead to bound states. The numbers of parameters needed will depend on the energy band considered and the boundary conditions for the problem (see, e.g., Linton *et al.*, 2002).

Here, we will use this idea to find bound states between the first and second cutoffs for a coupled waveguide (which is defined by two geometrical parameters). We set up the problem with eigenfunction expansions similar to those in Sec. II. The second cutoff is defined as the energy below which only one mode can propagate in the region $x>a$, i.e., one mode in either region *I* or region *II*. We also restrict the energy in such a way that two wave-like modes exist in the inner region, the reason for which will become clear later. Thus, we assume

$$2\pi<kd<\frac{d\pi}{c}, \quad \text{when} \quad 1/2<b/d\leqslant 2/3, \tag{4.1}$$

$$2\pi<kd<\frac{2d\pi}{b}, \quad \text{when} \quad 2/3\leqslant b/d<1. \tag{4.2}$$

For the symmetric problem the eigenfunction expansions for the three regions are

$$\phi_1(x,y)=\sum_{n=1}^{\infty} U_n^{(1)}\frac{e^{-\alpha_n(x-a)}}{-\alpha_n}\Psi_n^{(1)}(y), \quad \alpha_n=(\nu_n^2-k^2)^{1/2}, \tag{4.3}$$

$$\phi_2(x,y)=\sum_{n=2}^{\infty} U_n^{(2)}\frac{e^{-\beta_n(x-a)}}{-\beta_n}\Psi_n^{(2)}(y), \quad \beta_n=(\mu_n^2-k^2)^{1/2}, \tag{4.4}$$

$$\phi_3(x,y)=\sum_{n=0}^{\infty} U_n^{(3)}\frac{\cosh\gamma_n x}{\gamma_n\sinh\gamma_n a}\Psi_n^{(3)}(y), \quad \gamma_n=(\lambda_n^2-k^2)^{1/2}, \tag{4.5}$$

where $\Psi_n^{(1)}(y)$, $\Psi_n^{(2)}(y)$, and $\Psi_n^{(3)}(y)$ are given by (2.10)–(2.12). These expansions are the same as (2.14)–(2.16) except that the sum in region *II* starts from $n=2$, as we set the amplitude of the mode corresponding to β_1 equal to zero. With the restriction of frequency given by (4.1) and (4.2), γ_0 and γ_1 (and β_1) are purely imaginary whereas α_1, α_n, β_n and γ_n, $n\geqslant 2$ are all real and positive.

After matching on $x=a$, we obtain

$$\sum_{n=1}^{\infty} U_n\left(\frac{1}{\alpha_n-\gamma_m}+\frac{\zeta_m}{\alpha_n+\gamma_m}\right)-\sum_{n=2}^{\infty} V_n\left(\frac{1}{\beta_n-\gamma_m}+\frac{\zeta_m}{\beta_n+\gamma_m}\right)=0, \quad m\in\mathbb{N}_0, \tag{4.6}$$

where U_n, V_n, and ζ_m are defined in (3.9). The only difference between (4.6) and (3.8) is that the summation for V_n starts from $n=2$ instead of $n=1$. The condition (3.10) describing the behavior of U_n and V_n for large n remains the same.

We now consider the same quantities as in (3.30), except that now $f(z)$ must have simple poles at $z=\alpha_n$, $n\in\mathbb{N}$, and $z=\beta_n$, $n\geqslant 2$ as well as being $o(1)$ as $z\to\infty$. We choose

$$f(z)=\exp(-z\Theta)g(z)h(z), \tag{4.7}$$

where Θ is given by (3.24) and

$$g(z)=\frac{1}{1-z/\alpha_1}\prod_{n=2}^{\infty}\frac{1-z/\gamma_n}{(1-z/\alpha_n)(1-z/\beta_n)}, \quad h(z)=1+\sum_{n=2}^{\infty}\frac{A_n}{z-\gamma_n}. \tag{4.8}$$

The function $g(z)$ has the same behavior as $z\to\infty$, as that given in (3.20) since one linear factor has been removed from both the numerator and the denominator. Cauchy's residue theorem then gives

$$\sum_{n=1}^{\infty} R(f:\alpha_n)\left(\frac{1}{\alpha_n-\gamma_m}+\frac{\zeta_m}{\alpha_n+\gamma_m}\right)+\sum_{n=2}^{\infty} R(f:\beta_n)\left(\frac{1}{\beta_n-\gamma_m}+\frac{\zeta_m}{\beta_n+\gamma_m}\right)+f(\gamma_m)+\zeta_m f(-\gamma_m)$$
$$=0, \quad m\in\mathbb{N}_0, \tag{4.9}$$

and hence $U_n=R(f:\alpha_n)$ and $V_n=-R(f:\beta_n)$, provided (3.10) is satisfied and

$$f(\gamma_m)+\zeta_m f(-\gamma_m)=0, \quad m\in\mathbb{N}_0. \tag{4.10}$$

The coefficients A_n, $n=2,3,...$, can be found from a real, exponentially convergent system of equations

$$A_m+B_m\sum_{n=2}^{\infty}\frac{A_n}{\gamma_m+\gamma_n}=B_m, \quad m=2,3,..., \tag{4.11}$$

where

$$B_m=2\gamma_m e^{2\gamma_m(\Theta-a)}\frac{(\alpha_1-\gamma_m)(\alpha_m-\gamma_m)(\beta_m-\gamma_m)}{(\alpha_1+\gamma_m)(\alpha_m+\gamma_m)(\beta_m+\gamma_m)}\prod_{\substack{n=2\\ n\neq m}}^{\infty}\frac{(1-\gamma_m/\alpha_n)(1-\gamma_m/\beta_n)(1+\gamma_m/\gamma_n)}{(1+\gamma_m/\alpha_n)(1+\gamma_m/\beta_n)(1-\gamma_m/\gamma_n)}. \tag{4.12}$$

Whereas in the nonembedded case we had one extra condition to be satisfied, we now have two; namely (4.10) with $m=0$ and $m=1$. With $\gamma_j=-i\gamma_j'$, where $\gamma_j'=(k^2-\lambda_j^2)^{1/2}$, these conditions reduce to

$$e^{2i\gamma_j' a}=-\frac{f(-i\gamma_j')}{f(i\gamma_j')}, \quad j=0,1. \tag{4.13}$$

For bound states to exist, we must therefore have

$$\gamma_j'(a-\Theta)=\chi_j+\sigma_j+(n_j-\tfrac{1}{2})\pi, \quad j=0,1, \tag{4.14}$$

satisfied simultaneously, where

$$\chi_j=-\tan^{-1}\left(\frac{\gamma_j'}{\alpha_1}\right)+\sum_{n=2}^{\infty}\left(\tan^{-1}\left(\frac{\gamma_j'}{\gamma_n}\right)-\tan^{-1}\left(\frac{\gamma_j'}{\alpha_n}\right)-\tan^{-1}\left(\frac{\gamma_j'}{\beta_n}\right)\right), \tag{4.15}$$

$$\sigma_j=\arg(h(-i\gamma_j'))=\arg\left(1-\sum_{n=2}^{\infty}\frac{A_n}{\gamma_n+i\gamma_j'}\right), \tag{4.16}$$

and n_0 and n_1 are an arbitrary pair of integers.

For the case of antisymmetry about $x=0$, the conditions change to

$$\gamma_j'(a-\Theta)=\chi_j+\sigma_j'+n_j\pi, \quad j=0,1, \tag{4.17}$$

where σ_j' is the argument of $h(-i\gamma_j')$ with the A_n coefficients coming from

$$A_m-B_m\sum_{n=2}^{\infty}\frac{A_n}{\gamma_m+\gamma_n}=-B_m, \quad m=2,3,..., \tag{4.18}$$

and B_m given by (4.12).

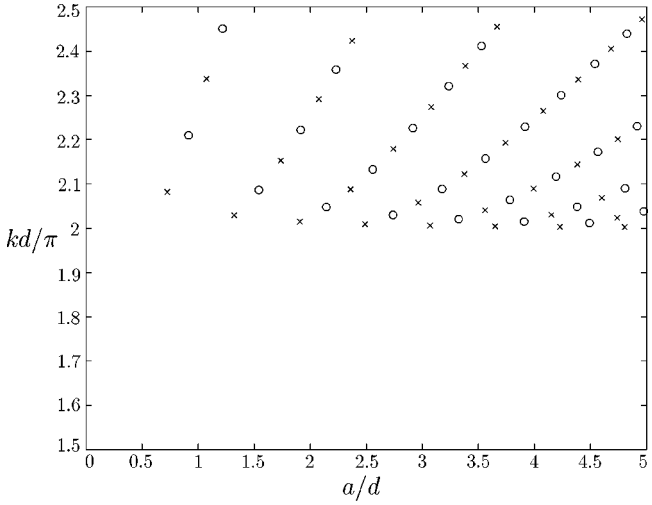

FIG. 6. Nondimensional bound-state energies for modes symmetric ($\times$) and antisymmetric ($\bigcirc$) about $x=0$ plotted against a/d, when $b/d=0.6$.

A. Results

For the numerical results in this section, the system of Eqs. (4.11) and (4.18) were truncated to 5×5 systems. However, in view of the fact that no modes are found for a/d smaller than about 0.7, the approximate solution in which we set $\sigma_j=0$, $j=0,1$, gives indistinguishable results.

In Fig. 6 a typical set of nondimensional bound-state energies, kd/π, are plotted against a/d when $b/d=0.6$, for which the relevant energy range is given by (4.1) as $2<kd/\pi<2.5$. The modes symmetric about $x=0$ are represented by a cross and the modes antisymmetric about $x=0$ are shown by a circle. A detailed view of just five of these bound states is given in Fig. 7, which also shows the solid lines corresponding to solutions of (4.14) and dashed lines corresponding to solutions of (4.17) for $j=0,1$, labeled with the corresponding n_0 and n_1 values. The bound states correspond to the intersections of two lines. Modes only exist for certain values of a/d, but as a/d increases the number of bound states present in a small a/d interval increases.

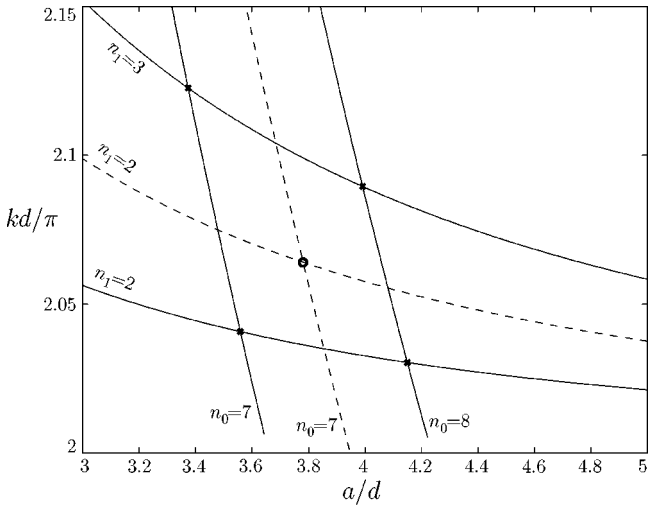

FIG. 7. A detailed view of part of Fig. 6 showing the curves corresponding to the solutions of (4.14) (solid curves) and (4.17) (dashed curves) for $j=0,1$, labeled with the corresponding n_0 and n_1 values. The embedded bound states are denoted by $\times$ (symmetric) and $\bigcirc$ (antisymmetric).

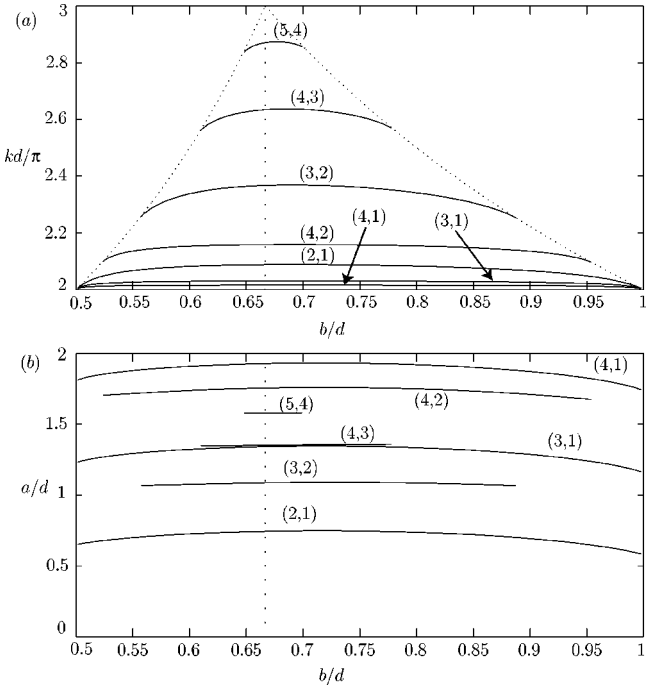

FIG. 8. Variation of (*a*) kd/π and (*b*) a/d with b/d for modes symmetric about $x=0$. The curves are labeled with the values of (n_0,n_1) used to generate them.

The bound states symmetric about $x=0$ obtained by keeping the integers n_0 and n_1 in (4.14) constant and varying either kd/π or a/d against b/d are shown in Figs. 8(a) and (b), respectively. The vertical dotted line corresponds to the value $b/d=2/3$, and the other two dotted lines correspond to the upper cutoffs given in (4.1) and (4.2). Only a selection of results for which $a/d<2$ are given. It can be seen from Fig. 8(a) that the highest energy states appear when (n_0,n_1) take the form $(N,N-1)$, with N large and the lower energies occur when $(n_0,n_1)=(N,1)$ with N large. Figure 8(b) shows that the lower values of a/d appear when (n_0,n_1) take the form $(N,N-1)$ with N small and as n_0 increases a/d increases. The figures also demonstrate that modes exist for any value of b/d in the range (0.5, 1) (but for only specific values of a/d).

In Linton *et al.* (2002) acoustic resonances were found between the second and third cutoffs for wave propagation down a rigid waveguide containing an off-center rigid plate aligned with the guide walls. The coupled waveguide problem under consideration here can be set up for energies between the second and third cutoffs, with three wave-like modes appearing in the region $x<a$ and two propagating modes in the region $x>a$. Using the same techniques as above, we find that bound states exist provided three conditions are satisfied simultaneously. However, these three conditions are found to be inconsistent.

B. The case $b/d=1/2$

If $2b=d$ the waveguide is symmetric about the midline parallel to the walls and this can be used to simplify the analysis. The problem can be decomposed into one symmetric about the midline and one antisymmetric about this line, and the latter problem is that of a parallel-plate waveguide with Dirichlet conditions on both walls, where there are no bound states. We thus restrict attention to the symmetric problem. Bound states below the first cutoff are precisely those which are obtained by letting $b/d\to 1/2$ in the preceding analysis.

However, in Sec. IV we found embedded bound states in the frequency range $2\pi<kd<d\pi/c$ when $1/2<b/d\leqslant 2/3$. These modes do not exist when $b/d=1/2$. The additional symmetry

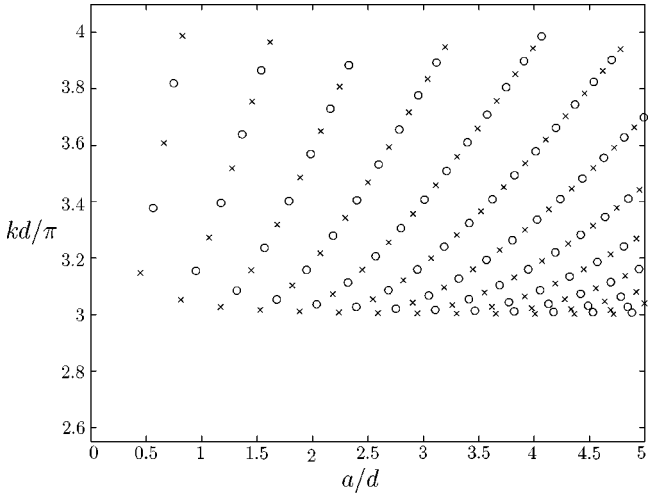

FIG. 9. Nondimensional bound-state energies, kd/π, for modes symmetric ($\times$) and antisymmetric ($\bigcirc$) about $x=0$ plotted against a/d when $b/d=1/2$.

in the problem when $b/d=0.5$ allows embedded modes to be found in a higher energy band in this case. In fact, we now require

$$3\pi<kd<4\pi, \tag{4.19}$$

to allow for two wave-like modes in the inner region and one in $x>a$. The problem is set up much as before; here, we will simply present some results.

In Fig. 9 the nondimensional bound-state energies are plotted against a/d. The modes symmetric about $x=0$ are shown by crosses and the modes antisymmetric about $x=0$ by circles. Just as in Fig. 7, the bound states correspond to the intersection of pairs of curves on which one of the two necessary conditions for bound states is satisfied. It can be seen that there are no bound states when a/d is below some critical value, and that bound states occur only for specific values of the plate length. As a/d increases, the number of bound states present in a small a/d interval increases as before.

V. CONCLUSION

In this article we have investigated the bound states that can occur in coupled quantum wires. Specifically, we have considered a two-dimensional configuration in which two parallel waveguides (of different widths) are coupled laterally through a finite length window and constructed modes which exist local to the window connecting the two guides. The geometry of the problem can be described in terms of the two parameters a/d and b/d, where the complete guide is made up of two guides of widths b and $d-b$, and the coupling window has length $2a$.

Initially we sought modes below the first cutoff for the guide. Modes for which the energy is below this cutoff cannot propagate down the guide and so if any are found they must be localized in space. The main tool used in the analysis is the residue calculus method, in which a function of a complex variable is constructed which has the property that when Cauchy's residue theorem is applied for some suitable contour, the system of equations derived from a mode-matching approach is obtained. The unknown coefficients then correspond to the residues of the complex function. If we assume that the window between the guides is long compared to the guide width, then this method allows us to solve the problem explicitly, and this approximate solution can then be used as the basis for a full numerical solution. This leads to an exponentially convergent system of equations and high accuracy can be achieved with only a very few equations. In fact, for all but the smallest values of a/d, the explicit approximate solution is quite sufficient.

A number of results have been presented which show that as the window length varies bound states occur alternately symmetric and antisymmetric about the line of symmetry of the guide, and that more modes appear as the window gets larger or as the widths of the two parts of the guide get closer together (i.e., as $b/d \to 1/2$). Using a variational principle we were able to provide upper and lower bounds for the bound-state energies and prove the existence of such states for a sufficiently large window. As a/d increases, the bound-state energies tend towards their upper bounds.

For modes whose energies are above the first cutoff we were able to use a similar residue calculus technique to compute bound-state energies. Here, we are seeking bound states whose energies are embedded in the continuous spectrum of the relevant operator, and this leads to the need to satisfy two conditions simultaneously, where there was only one below the cutoff. Below the cutoff we could fix either a/d or b/d and vary the other to get solutions. Above the cutoff, bound states occur for any values of $b/d \in (0.5,1)$ but only for specific values of the parameter a/d. When $b/d = 1/2$, the region in which these embedded modes occur is shifted to a higher energy band.

Bound states in coupled guides. II. Three dimensions

C. M. Linton[a] and K. Ratcliffe
Department of Mathematical Sciences, Loughborough University, LE11 3TU, United Kingdom

(Received 2 December 2003; accepted 16 January 2004)

We compute bound-state energies in two three-dimensional coupled waveguides, each obtained from the two-dimensional configuration considered in paper I [J. Math. Phys. **45**, 1359–1379 (2004)] by rotating the geometry about a different axis. The first geometry consists of two concentric circular cylindrical waveguides coupled by a finite length gap along the axis of the inner cylinder, and the second is a pair of planar layers coupled laterally by a circular hole. We have also extended the theory for this latter case to include the possibility of multiple circular windows. Both problems are formulated using a mode-matching technique, and in the cylindrical guide case the same residue calculus theory as used in paper I is employed to find the bound-state energies. For the coupled planar layers we proceed differently, computing the zeros of a matrix derived from the matching analysis directly. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1675932]

I. INTRODUCTION

Here we extend the ideas from paper I [J. Math. Phys. **45**, 1359–1379 (2004)] to three dimensions and consider two distinct types of problem. First, we treat the case where the two-dimensional laterally coupled waveguide discussed in paper I is rotated about the x axis to produce a three-dimensional waveguide. The guide then consists of a pair of concentric circular cylindrical guides of widths b and d coupled by a finite gap in the inner cylinder. We seek bound states whose energies are below the first cutoff for wave propagation down the guide using the residue calculus technique. Second, we consider the case where the coupled waveguide considered in paper I is rotated about the y axis. The waveguide consists of two planar layers of widths b and $d-b$ coupled through a circular hole of radius a in the common boundary. In fact, we set up the problem for an arbitrary number of arbitrarily sized circular windows.

Early work on acoustic resonances in circular cylindrical waveguides was done by Ursell (1991), who considered a rigid cylinder with a rigid sphere placed on the axis. Using the method of multipole expansions, Ursell able to prove the existence of resonant states with certain angular variation, provided the sphere was sufficiently small. The method presented in this paper is similar to that used by Evans and Linton (1994), who developed an approximate solution for the existence of trapped modes in an infinitely long, rigid, circular cylindrical tube containing a concentric, rigid, open-ended circular cylinder of finite length. Linton and McIver (1998) proved that acoustic resonances can exist when any rigid, thin obstacle is placed in a rigid cylindrical waveguide of constant cross section in such a way that its normal is everywhere perpendicular to the generators of the cylinder. Similar results were also given in Groves (1998) and Davies and Parnovski (1998). The example of a cylindrical sleeve inside a circular cylindrical waveguide with Neumann conditions on all boundaries considered in Evans and Linton (1994) was recalculated using the residue calculus technique and extended to cover different angular variations.

In all the above examples, Neumann boundary conditions were imposed on the cylindrical waveguide. A cylindrical guide with Dirichlet conditions on the boundary was considered by Witsch (1990). Witsch used the same idea as Ursell in that he specified the angular variation to

[a]Electronic mail: c.m.linton@lboro.ac.uk

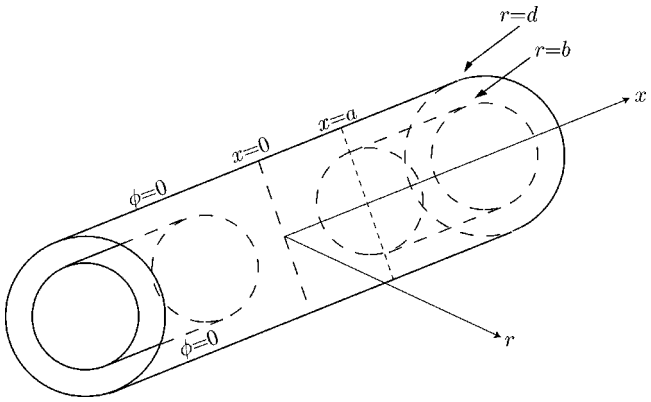

FIG. 1. Definition sketch.

produce a cutoff and then used a minimum–maximum principle to provide examples of eigenvalues that can occur in the waveguide.

Much less work has been done on the second problem. Exner and Vugalter (1997) considered the case when the hole was sufficiently small so that only one eigenvalue occurred below the continuous spectrum. The authors were then able to provide upper and lower asymptotic bounds on the gap between the eigenvalue and the continuous spectrum. Further asymptotic results were derived in Popov (2002).

II. COUPLED CYLINDRICAL GUIDES

In this section we consider a rotation of the waveguide used in paper I about the x axis. We introduce cylindrical polar coordinates (r,θ,x) so that the outer surface of the guide is at $r=d$. Inside the guide is placed an infinite, concentric cylinder of radius b $(<d)$, which has a gap of length $2a$ along its axis. The inner cylinder is placed so that its surface is at $r=b$ and the gap is at $-a<x<a$, as shown in Fig. 1. The resulting geometry is axisymmetric about the line $r=0$; hence, we are able to look for modes with angular variation $\cos m\theta$, where $m\in\mathbb{N}_0$. The quantity m is to be regarded as fixed in what follows.

The geometry is symmetric about $x=0$, allowing us only to consider the region $x>0$ and seek modes which are either symmetric or antisymmetric about $x=0$. We begin by seeking modes symmetric about $x=0$ by looking for nontrivial solutions $\phi(r,\theta,x)$, which satisfy

$$\frac{\partial\phi}{\partial x}=0 \quad \text{on } x=0,\ 0<r<d. \tag{2.1}$$

The function $\phi(r,\theta,x)$ must also satisfy the Helmholtz equation within the waveguide

$$(\nabla^2+k^2)\,\phi=0, \quad 0<r<d, x>0 \quad \text{except on } r=b,\ x>a, \tag{2.2}$$

and is subject to Dirichlet boundary conditions on the cylinders

$$\phi=0 \quad \text{on } r=b,\ x>a, \tag{2.3}$$

$$\phi=0 \quad \text{on } r=d,\ x>0, \tag{2.4}$$

and a radiation condition that stops waves propagating to infinity,

$$\phi\to 0 \quad \text{as } x\to\infty. \tag{2.5}$$

Finally, we assume that ϕ is nonsingular and

$$\frac{\partial \phi}{\partial \rho} = O(\rho^{-1/2}) \quad \text{as } \rho = [(x-a)^2 + (r-b)^2]^{1/2} \to 0, \tag{2.6}$$

anticipating singular behavior in the derivative of ϕ at the edge. The changes resulting from replacing (2.1) by an antisymmetric condition will be discussed later.

As in the two-dimensional case considered in paper I, we divide the interior of the guide into three parts. Region I is the annular region between the outer and inner cylinders, i.e., $\{r,\theta,x: b<r<d, x>a\}$, region II is the interior of the inner cylinder, i.e., $\{r,\theta,x: 0<r<b, x>a\}$, and region III is the gap of the inner cylinder, i.e., $\{r,\theta,x: 0<r<d, 0<x<a\}$. We can represent the function ϕ by a function $\phi_i(r,\theta,x) = \hat{\phi}_i(r,x)\cos m\theta$, $(i=1,2,3, m \in \mathbb{N}_0)$ in each region and apply the following continuity conditions at each region's boundary:

$$\hat{\phi}_i = \hat{\phi}_3, \quad \frac{\partial \hat{\phi}_i}{\partial x} = \frac{\partial \hat{\phi}_3}{\partial x}, \quad \text{on } L_i, \ \ i=1,2, \tag{2.7}$$

where L_1 is $x=a, b<r<d$, L_2 is $x=a, 0<r<b$, and we write $L_3 = L_1 \cup L_2$.

Complete orthogonal sets of functions of r in each of the three regions are defined in terms of Bessel functions as follows. Let ν_{mn} be the nth positive zero of the cross product $J_m(\eta d)\, Y_m(\eta b) - Y_m(\eta d)\, J_m(\eta b)$; then, functions appropriate for region I are

$$\Psi^{(1)}_{mn}(r) = p^{(1)}_{mn}[J_m(\nu_{mn} r)\, Y_m(\nu_{mn} b) - Y_m(\nu_{mn} r)\, J_m(\nu_{mn} b)], \quad n \in \mathbb{N}. \tag{2.8}$$

This function satisfies (2.3) and (2.4), and with

$$p^{(1)}_{mn} = \frac{\nu_{mn}\pi^{1/2}}{2^{1/2}} \left(\frac{J^2_m(\nu_{mn} b)}{J^2_m(\nu_{mn} d)} - 1 \right)^{-1/2}, \tag{2.9}$$

we have the orthogonality condition (see Jones, 1986, p. 228)

$$\int_{L_i} r\, \Psi^{(i)}_{mn}(r)\, \Psi^{(i)}_{ms}(r)\, \mathrm{d}r = \delta_{ns}, \quad n,s \in \mathbb{N}, \tag{2.10}$$

with $i=1$, where δ_{ns} is the Kronecker delta.

Similarly, for region II we let j_{mn} be the nth non-negative zero of $J_m(\eta)$ and define $\mu_{mn} b = j_{mn}$. We then define

$$\Psi^{(2)}_{mn}(r) = p^{(2)}_{mn}\ J_m(\mu_{mn} r), \quad n \in \mathbb{N}, \tag{2.11}$$

where

$$p^{(2)}_{mn} = \frac{2^{1/2}}{b\ J_{m+1}(\mu_{mn} b)}, \tag{2.12}$$

which satisfies (2.3) and the orthogonality condition (2.10) with $i=2$.

For region III we let $\lambda_{mn} d = j_{m,n+1}$, and define

$$\Psi^{(3)}_{mn}(r) = p^{(3)}_{mn}\ J_m(\lambda_{mn} r) \quad n \in \mathbb{N}_0, \tag{2.13}$$

where

$$p^{(3)}_{mn} = \frac{2^{1/2}}{d\ J_{m+1}(\lambda_{mn} d)}. \tag{2.14}$$

Then, $\Psi^{(3)}_{mn}$ satisfies (2.4) and the orthogonality condition (2.10) with $i=3$.

The appropriate eigenfunction expansions for $\hat{\phi}$ are now

$$\hat{\phi}_1(r,x)=\sum_{n=1}^{\infty} U_{mn}^{(1)}\frac{e^{-\alpha_{mn}(x-a)}}{-\alpha_{mn}}\Psi_{mn}^{(1)}(r), \quad \alpha_{mn}=(\nu_{mn}^2-k^2)^{1/2}, \tag{2.15}$$

$$\hat{\phi}_2(r,x)=\sum_{n=1}^{\infty} U_{mn}^{(2)}\frac{e^{-\beta_{mn}(x-a)}}{-\beta_{mn}}\Psi_{mn}^{(2)}(r), \quad \beta_{mn}=(\mu_{mn}^2-k^2)^{1/2}, \tag{2.16}$$

$$\hat{\phi}_3(r,x)=\sum_{n=0}^{\infty} U_{mn}^{(3)}\frac{\cosh\gamma_{mn}x}{\gamma_{mn}\sinh\gamma_{mn}a}\Psi_{mn}^{(3)}(r), \quad \gamma_{mn}=(\lambda_{mn}^2-k^2)^{1/2}. \tag{2.17}$$

For decay down the guide we require α_{mn} and β_{mn} to be real and positive for all n, and so we must have

$$kd<\nu_{m1}d \quad \text{and} \quad kd<\mu_{m1}d. \tag{2.18}$$

So as to allow one wave-like mode in the inner region, we also require γ_{m0} to be purely imaginary, but γ_{mn} to be real and positive for all other values of n, and hence

$$kd>\lambda_{m0}d=j_{m1}. \tag{2.19}$$

We therefore anticipate that a necessary condition for the existence of bound states is

$$j_{m1}<kd<\min(\mu_{m1}d,\nu_{m1}d). \tag{2.20}$$

A. Bound states below the first cutoff

We now use the continuity conditions (2.7) and proceed as in paper I. We obtain

$$U_{ms}^{(3)}=\sum_{n=1}^{\infty} U_{mn}^{(1)}\ d_{ns}+\sum_{n=1}^{\infty} U_{mn}^{(2)}\ e_{ns}, \quad s\in\mathbb{N}_0, \tag{2.21}$$

$$U_{ms}^{(3)}\frac{\coth\gamma_{ms}a}{\gamma_{ms}}=\sum_{n=1}^{\infty}\frac{U_{mn}^{(1)}}{-\alpha_{mn}}d_{ns}+\sum_{n=1}^{\infty}\frac{U_{mn}^{(2)}}{-\beta_{mn}}e_{ns}, \quad s\in\mathbb{N}_0, \tag{2.22}$$

where we have defined

$$d_{ns}=\frac{1}{d}\int_{L_1} r\Psi_{mn}^{(1)}(r)\Psi_{ms}^{(3)}(r)\,\mathrm{d}r, \tag{2.23}$$

$$e_{ns}=\frac{1}{d}\int_{L_2} r\Psi_{mn}^{(2)}(r)\Psi_{ms}^{(3)}(r)\,\mathrm{d}r. \tag{2.24}$$

Using various standard integrals, recurrence relations, and Wronskian relations for Bessel functions, we can show that, provided $\nu_{mn}\neq\lambda_{ms}$ and $\mu_{mn}\neq\lambda_{ms}$

$$d_{ns}=-\frac{2\,\nu_{mn}J_m(\lambda_{ms}b)}{(\nu_{mn}^2-\lambda_{ms}^2)\,\pi^{1/2}d\,J_{m+1}(\lambda_{ms}d)}\left(\frac{J_m^2(\nu_{mn}b)}{J_m^2(\nu_{mn}d)}-1\right)^{-1/2}, \quad s\in\mathbb{N}_0,\ n\in\mathbb{N}, \tag{2.25}$$

$$e_{ns}=\frac{2\,\mu_{mn}J_m(\lambda_{ms}b)}{d\,J_{m+1}(\lambda_{ms}d)\,(\mu_{mn}^2-\lambda_{ms}^2)}, \quad s\in\mathbb{N}_0,\ n\in\mathbb{N}. \tag{2.26}$$

Eliminating $U^{(3)}_{mn}$ from (2.21) and (2.22) and using (2.25) and (2.26), we obtain after some simplification

$$\sum_{n=1}^{\infty} U_{mn}\left(\frac{1}{\alpha_{mn}-\gamma_{ms}}+\frac{\zeta_{ms}}{\alpha_{mn}+\gamma_{ms}}\right)-\sum_{n=1}^{\infty} V_{mn}\left(\frac{1}{\beta_{mn}-\gamma_{ms}}+\frac{\zeta_{ms}}{\beta_{mn}+\gamma_{ms}}\right)=0, \tag{2.27}$$

where $s\in\mathbb{N}_0$ and we have defined

$$U_{mn}=\frac{U^{(1)}_{mn}\,\nu_{mn}}{\pi^{1/2}\,\alpha_{mn}}\left(\frac{J_m^2(\nu_{mn}b)}{J_m^2(\nu_{mn}d)}-1\right)^{-1/2},\quad V_{mn}=\frac{U^{(2)}_{mn}\,\mu_{mn}}{\beta_{mn}},\ \text{and}\ \zeta_{ms}=\mathrm{e}^{-2\gamma_{ms}a}. \tag{2.28}$$

The singular behavior required by condition (2.6) again influences the asymptotic behavior of U_{mn} and V_{mn} as $n\to\infty$. As in paper I, we can show that the edge condition is satisfied if both $U_{mn}=O(n^{-1/2})$ and $V_{mn}=O(n^{-1/2})$ as $n\to\infty$.

We now use the residue calculus technique of Mittra and Lee (1971), exactly as in paper I; the details are different but the procedure is essentially the same as before. We will make just one remark. The standard infinite product representation of the gamma function can be used to show that

$$\prod_{n=1}^{\infty}\frac{\left(1-\dfrac{zd}{(n+m/2+3/4)\pi}\right)}{\left(1-\dfrac{zc}{n\pi}\right)\left(1-\dfrac{zb}{(n+m/2-1/4)\pi}\right)}=\frac{\Gamma(m/2+7/4)\ \Gamma(1-zc/\pi)\ \Gamma(m/2+3/4-zb/\pi)}{\Gamma(m/2+7/4-zd/\pi)\ \Gamma(m/2+3/4)}, \tag{2.29}$$

and then the asymptotic forms [see Abramowitz and Stegun, 1965, Eqs. (9.5.12) and (9.5.27)]

$$\lambda_{mn}d=j_{m,n+1}\sim(n+m/2+3/4)\pi+O(1/n), \tag{2.30}$$

$$\mu_{mn}b=j_{mn}\sim(n+m/2-1/4)\pi+O(1/n), \tag{2.31}$$

$$\nu_{mn}(d-b)\sim n\pi+O(1/n) \tag{2.32}$$

as $n\to\infty$ can be used together with Stirling's formula to derive the necessary asymptotic form for the function $f(z)$ equivalent to (3.18) of paper I.

The condition for the existence of bound states turns out to be

$$\gamma'_m(a-\Theta)=\chi_m+\sigma_m+(n-\tfrac{1}{2})\pi,\quad n\ \text{an integer}, \tag{2.33}$$

where

$$\Theta=\frac{1}{\pi}(b\ln(d/b)+c\ln(d/c)), \tag{2.34}$$

$$\chi_m=\sum_{n=1}^{\infty}\left(\tan^{-1}\left(\frac{\gamma'_m}{\gamma_{mn}}\right)-\tan^{-1}\left(\frac{\gamma'_m}{\alpha_{mn}}\right)-\tan^{-1}\left(\frac{\gamma'_m}{\beta_{mn}}\right)\right), \tag{2.35}$$

and

$$\sigma_m=\arg\left(1-\sum_{n=1}^{\infty}\frac{A_{mn}}{\gamma_{mn}+\mathrm{i}\gamma'_m}\right), \tag{2.36}$$

where the coefficients A_{mn} are the solutions to the exponentially convergent system of equations

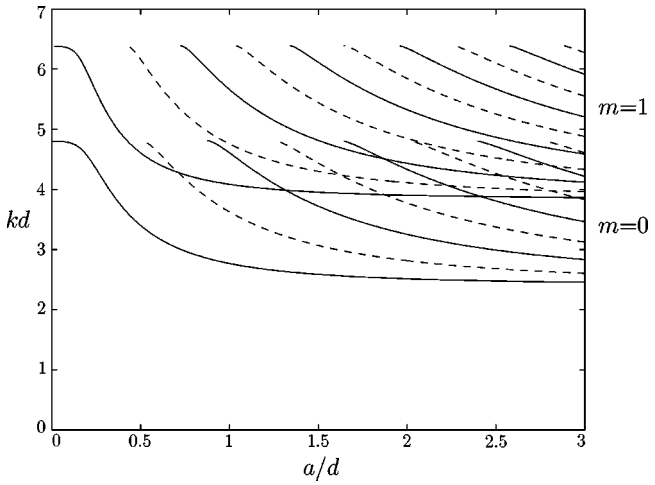

FIG. 2. Nondimensional bound-state energies for modes symmetric (—) and antisymmetric (– –) about $x=0$ plotted against a/d when $b/d=0.5$.

$$A_{ms}+D_{ms}\sum_{n=1}^{\infty}\frac{A_{mn}}{\gamma_{ms}+\gamma_{mn}}=D_{ms}, \quad s\in\mathbb{N}, \tag{2.37}$$

with

$$D_{ms}=2\gamma_{ms}\,\mathrm{e}^{2\gamma_{ms}(\Theta-a)}\frac{(\alpha_{ms}-\gamma_{ms})(\beta_{ms}-\gamma_{ms})}{(\alpha_{ms}+\gamma_{ms})(\beta_{ms}+\gamma_{ms})}$$
$$\times\prod_{\substack{n=1\\ n\neq s}}^{\infty}\frac{(1+\gamma_{ms}/\gamma_{mn})(1-\gamma_{ms}/\alpha_{mn})(1-\gamma_{ms}/\beta_{mn})}{(1+\gamma_{ms}/\alpha_{mn})(1+\gamma_{ms}/\beta_{mn})(1-\gamma_{ms}/\gamma_{mn})}. \tag{2.38}$$

For the case of antisymmetry about $x=0$, we replace the boundary condition (2.1) by

$$\phi=0 \quad \text{on } x=0, \quad 0<r<d, \tag{2.39}$$

and the equivalent condition to (2.33) is

$$\gamma_m'(a-\Theta)=\chi_m+\sigma_m'+n\pi, \quad n \text{ an integer}, \tag{2.40}$$

where χ_m and Θ are as before and σ_m' is as in (2.36) but with the coefficients A_{mn} coming from the system of equations

$$A_{ms}-D_{ms}\sum_{n=1}^{\infty}\frac{A_{mn}}{\gamma_{ms}+\gamma_{mn}}=-D_{ms}, \quad s\in\mathbb{N}. \tag{2.41}$$

B. Results

The results in this section are computed with the systems of equations (2.37) and (2.41) truncated to 5×5 systems. Typical results for the nondimensional bound-state energies when $m=0$ and 1 are shown in Figs. 2 and 3. In both figures the solid lines correspond to modes symmetric about $x=0$ and the dashed lines to modes antisymmetric about $x=0$.

In Fig. 2 nondimensional bound-state energies are plotted against a/d when $b/d=0.5$. As a/d increases, more and more modes appear alternately symmetric and antisymmetric about $x=0$ for each value of m. The upper and lower cutoffs for the existence of bound states are given by (2.20)

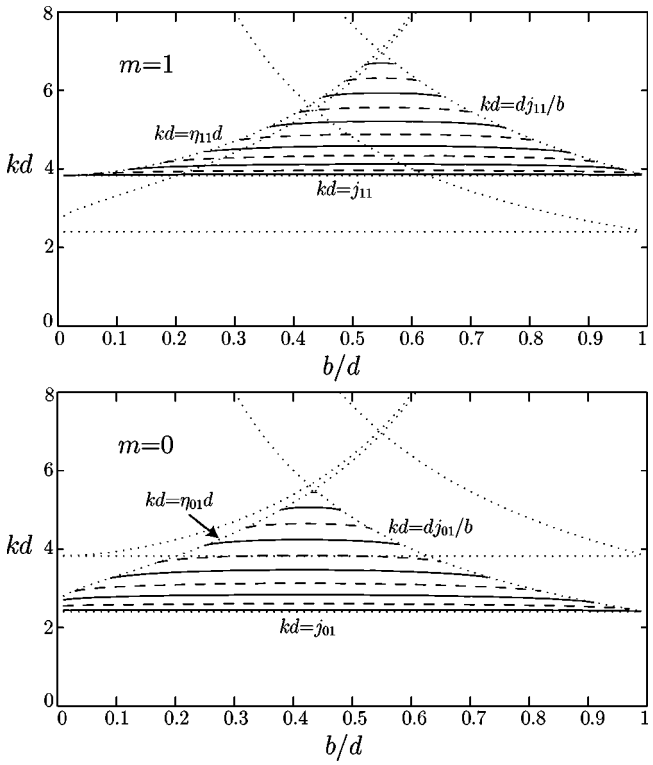

FIG. 3. Nondimensional bound-state energies for modes symmetric (—) and antisymmetric (– –) about $x=0$ plotted against b/d when $a/d=3$.

and depend on m. When $m=0$ the modes appear from the cutoff given by the minimum of $kd=j_{01}/0.5\approx 4.810$ and $kd=\nu_{01}d\approx 6.246$, i.e., $kd=2j_{01}$, and tend to $kd=j_{01}\approx 2.405$ as a/d increases. This minimum value changes, however, when $m=1$, as the upper cutoff becomes $kd=\nu_{11}d\approx 6.393$, which is less than $kd=2\,j_{11}\approx 7.663$. As a/d increases the modes corresponding to $m=1$ tend to $kd=j_{11}\approx 3.832$.

In Fig. 3 nondimensional bound-state energies are plotted against b/d when $a/d=3$. The upper plot corresponds to $m=1$ and the lower plot to $m=0$. The dotted lines appearing on both plots are the upper and lower cutoffs for the two different m values and show where the frequency ranges lie with respect to each other. When $b/d\to 0$ the only upper cutoff present for both plots is the one corresponding to $kd=\eta_{m1}$, whereas when $b/d\to 1$ the upper cutoff is shown by $kd=d\,j_{m1}/b$ for both values of m. When $m=0$ the upper cutoff changes from $kd=\eta_{01}d$ to $kd=j_{01}d/b$ when $b/d\approx 0.436$, and the largest number of modes appears at this value. Results for higher values of m show that as m increases, the value of b/d when the upper cutoff changes also increases.

III. LATERALLY COUPLED PLANAR WAVEGUIDES

We now turn our attention to the case where the two-dimensional laterally coupled waveguide considered in paper I is rotated about the y axis to produce a three-dimensional waveguide consisting of two planar layers of widths b and $c=d-b$ coupled laterally through a circular hole of radius a in the common boundary. We assume for convenience that $b>d/2$.

Circular cylindrical polar coordinates (r,θ,z) are introduced so that the waveguide is axisymmetric about $r=0$ and the planes lie at $z=0$, $z=b$ and $z=d$. We seek nontrivial solutions ϕ to

$$(\nabla^2+k^2)\,\phi=0,\quad 0<z<d,\quad r\geqslant 0\ \text{ except on } x=b,\quad r>a, \tag{3.1}$$

subject to the boundary conditions

$$\phi=0 \quad \text{on } z=0, \quad r\geqslant 0, \tag{3.2}$$

$$\phi=0 \quad \text{on } z=b, \quad r>a, \tag{3.3}$$

$$\phi=0 \quad \text{on } z=d, \quad r\geqslant 0, \tag{3.4}$$

and a radiation condition specifying that no waves propagate out to infinity

$$\phi\to 0 \quad \text{as } r\to\infty. \tag{3.5}$$

The guide is divided into three regions. Region I is $\{r,\theta,z: r>a, b<z<d\}$, region II is $\{r,\theta,z: r>a, 0<z<b\}$, and region III is $\{r,\theta,z: r<a, 0<z<d\}$. As the geometry is axisymmetric about $r=0$, we are able to look for a mode with angular variation $\cos m\theta$, $m\in\mathbb{N}_0$, and can write $\phi_i(r,\theta,z)=\hat{\phi}_i(r,z)\cos m\theta$ $(i=1,2,3)$, in each region and apply the continuity conditions

$$\hat{\phi}_i=\hat{\phi}_3, \quad \frac{\partial\hat{\phi}_i}{\partial r}=\frac{\partial\hat{\phi}_3}{\partial r}, \quad \text{on } L_i, \quad i=1,2, \tag{3.6}$$

where L_1 is $r=a, b<z<d$, L_2 is $r=a, 0<z<b$ and we write L_3 for $L_1\cup L_2$.

Suitable eigenfunction expansions in each region are

$$\hat{\phi}_1(r,z)=\sum_{n=1}^{\infty} U_{mn}^{(1)}\frac{K_m(\alpha_n r)}{\alpha_n K_m'(\alpha_n a)}\Psi_n^{(1)}(z), \quad \alpha_n=(\nu_n^2-k^2)^{1/2}, \tag{3.7}$$

$$\hat{\phi}_2(r,z)=\sum_{n=1}^{\infty} U_{mn}^{(2)}\frac{K_m(\beta_n r)}{\beta_n K_m'(\beta_n a)}\Psi_n^{(2)}(z), \quad \beta_n=(\mu_n^2-k^2)^{1/2}, \tag{3.8}$$

$$\hat{\phi}_3(r,z)=\sum_{n=0}^{\infty} U_{mn}^{(3)}\frac{I_m(\gamma_n r)}{\gamma_n I_m'(\gamma_n a)}\Psi_n^{(3)}(z), \quad \gamma_n=(\lambda_n^2-k^2)^{1/2}, \tag{3.9}$$

where I_m and K_m are modified Bessel functions and

$$\Psi_n^{(1)}(z)=2^{1/2}\sin\nu_n(d-z), \quad \nu_n=n\pi/c, \quad n\in\mathbb{N}, \tag{3.10}$$

$$\Psi_n^{(2)}(z)=2^{1/2}\sin\mu_n(b-z), \quad \mu_n=n\pi/b, \quad n\in\mathbb{N}, \tag{3.11}$$

$$\Psi_n^{(3)}(z)=2^{1/2}\sin\lambda_n(d-z), \quad \lambda_n=(n+1)\pi/d, \quad n\in\mathbb{N}_0, \tag{3.12}$$

which satisfy

$$\frac{1}{|L_i|}\int_{L_i}\Psi_n^{(i)}(y)\Psi_m^{(i)}(y)\,\mathrm{d}y=\delta_{mn}, \quad i=1,2,3. \tag{3.13}$$

As in paper I, we anticipate that a necessary condition for the existence of bound states will be

$$\pi<kd<\frac{d\pi}{b}, \tag{3.14}$$

since then γ_0 will be purely imaginary whereas α_n, β_n and γ_n, $n\in\mathbb{N}$, will all be real and positive. The mode corresponding to γ_0 will therefore be oscillatory in region III and all the other modes will decay away from the hole.

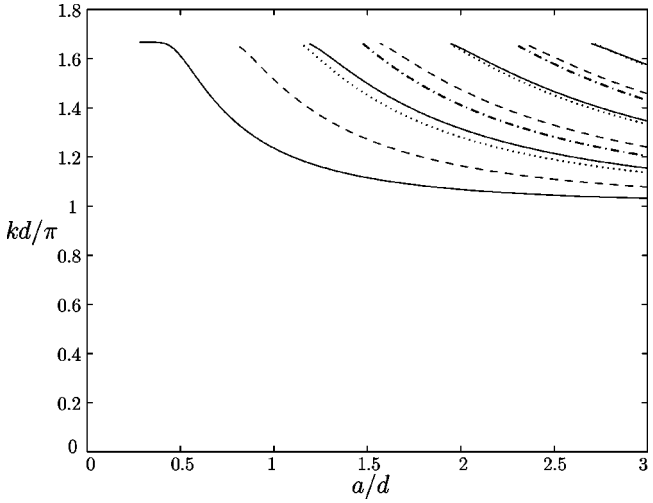

FIG. 4. Nondimensional bound-state energies, kd/π, plotted against a/d when $b/d=0.6$. The solid lines correspond to $m=0$, the dashed lines to $m=1$, the dotted lines to $m=2$, and the dot-dashed lines to $m=3$.

We now apply the continuity conditions (3.6), multiply each of the resulting equations by $\Psi_s^{(3)}, s\in\mathbb{N}_0$ and integrate over L_3, then eliminate $U_{ms}^{(3)}$ to obtain

$$\sum_{n=1}^{\infty} U_{mn}^{(1)} d_{ns}\left(\frac{I_m(\gamma_n a)}{\gamma_s I_m'(\gamma_s a)}-\frac{K_m(\alpha_n a)}{\alpha_n K_m'(\alpha_n a)}\right)+\sum_{n=1}^{\infty} U_{mn}^{(2)} e_{ns}\left(\frac{I_m(\gamma_n a)}{\gamma_s I_m'(\gamma_s a)}-\frac{K_m(\beta_n a)}{\beta_n K_m'(\beta_n a)}\right)=0,$$

$$s\in\mathbb{N}_0, \tag{3.15}$$

where d_{ns} and e_{ns} are given by

$$d_{ns}=\frac{1}{d}\int_{L_1}\Psi_n^{(1)}(y)\Psi_s^{(3)}(y)\,dy=\frac{2\nu_n(-1)^n\sin\lambda_s c}{d(\gamma_s^2-\alpha_n^2)},\quad s\in\mathbb{N}_0,\ \ n\in\mathbb{N}, \tag{3.16}$$

$$e_{ns}=\frac{1}{d}\int_{L_2}\Psi_n^{(2)}(y)\Psi_s^{(3)}(y)\,dy=\frac{2\mu_n\sin\lambda_s c}{d(\gamma_s^2-\beta_n^2)},\quad s\in\mathbb{N}_0,\ \ n\in\mathbb{N}. \tag{3.17}$$

Equation (3.15) is not amenable to the same residue calculus treatment as we have used in our other examples. Here, we solve it directly by truncating the value of n and $s+1$ with a truncation parameter N. We then have to find the values of kd for which the determinant of a (real) $2N\times 2N$ matrix is zero.

Figure 4 shows a typical set of nondimensional bound-state energies, kd/π, plotted against a/d when $b/d=0.6$. The results were computed using a truncation parameter $N=5$. The solid lines correspond to the modes when $m=0$, the dashed lines are when $m=1$, the dotted lines are when $m=2$, and the dot-dashed lines are for $m=3$. As the value of a/d is increased the bound states appear from the upper cutoff $kd=5\pi/3$ and tend to the lower cutoff $kd=\pi$. The results suggest that that bound states occur for all a/d except when the hole is small, and that as the value of m is increased the value of a/d below which modes do not exist increases.

However, Exner and Vugalter (1997) used variational techniques to show that for sufficiently small a/d there is just one bound state and that the ground-state eigenvalue, kd, then satisfies

$$\frac{d}{b}\left(1-\frac{1}{\pi^2}\exp(-c_1/a^3)\right)^{1/2}\leqslant kd\leqslant\frac{d}{b}\left(1-\frac{1}{\pi^2}\exp(-c_2/a^3)\right)^{1/2}, \tag{3.18}$$

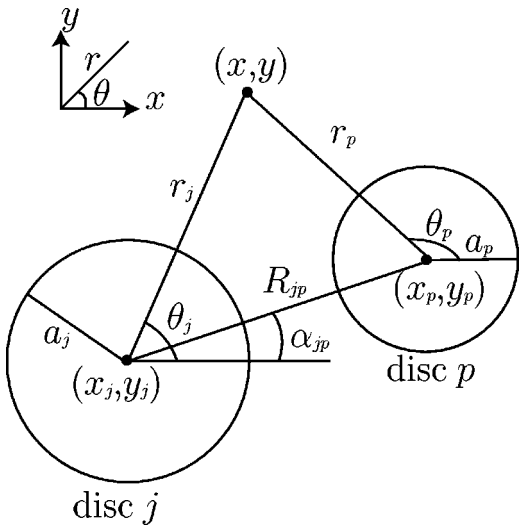

FIG. 5. Plan view of two disks.

for some positive c_1 and c_2. It is clear that for small windows, this will produce values of kd which differ from the upper cutoff by an extremely small amount and this explains why we were unable to compute bound-state energies when a/d is less than about 0.25.

It is fairly simple to extend the work above and consider the case of a pair of planar layers coupled laterally by a number of holes. For simplicity, we will consider the case where the two layers have the same width (i.e., $b/d=0.5$) and the additional symmetry allows us to consider the symmetric and antisymmetric parts of the solution independently. The antisymmetric part is trivial, and so the problem then reduces to that of a planar guide of width b with Dirichlet boundary conditions on both walls, except for a number of circular disks on one side on which Neumann conditions are applied. The method that we use to analyze multiple circular windows is a standard technique in studying the scattering of waves by arrays of circular cylinders; see, e.g., Linton and McIver (2001), Chap. 6.

We consider P ($\geqslant 1$) disks and introduce $P+1$ cylindrical polar coordinate systems, so that (r,θ,z) is centered at the origin and (r_j,θ_j,z), $j=1,\ldots,P$, are centered at the center of the jth disk, which is assumed to have radius a_j. The walls of the waveguide are at $z=0$ and $z=b$. The various parameters relating to the relative positions and sizes of the disks are shown in Fig. 5. The domain is divided up into $P+1$ parts and we represent the solution in the region above the jth disk by ϕ_j^I, $j=1,\ldots,P$ and the solution exterior to the disks by ϕ^{II}. We look for nontrivial solutions to the Helmholtz equation in the guide subject to the boundary conditions

$$\phi^{II}=0 \quad \text{on } z=0, \tag{3.19}$$

$$\phi_j^I=\phi^{II}=0 \quad \text{on } z=b, \quad j=1,\ldots,P, \tag{3.20}$$

$$\frac{\partial\phi_j^I}{\partial z}=0 \quad \text{on } z=0, \quad r_j<a_j, \quad j=1,\ldots,P, \tag{3.21}$$

$$\phi^{II}\to 0 \quad \text{as } r\to\infty. \tag{3.22}$$

We also need to apply continuity conditions at each region's boundary

$$\phi_j^I=\phi^{II}, \quad \frac{\partial\phi_j^I}{\partial r_j}=\frac{\partial\phi^{II}}{\partial r_j} \quad \text{on } r_j=a_j, \quad j=1,\ldots,P. \tag{3.23}$$

Separation of variables reveals that the appropriate eigenfunction expansions are

$$\phi_j^I = \sum_{m=-\infty}^{\infty} \sum_{n=0}^{\infty} A_{mn}^j \frac{I_m(\alpha_n r_j)}{\alpha_n I_m'(\alpha_n a_j)} \Psi_n^{(1)}(z)\, \mathrm{e}^{\mathrm{i}m\theta_j}, \quad j=1,\ldots,P, \tag{3.24}$$

$$\phi^{II} = \sum_{p=1}^{P} \sum_{m=-\infty}^{\infty} \sum_{n=0}^{\infty} B_{mn}^p \frac{K_m(\beta_n r_p)}{\beta_n K_m'(\beta_n a_p)} \Psi_n^{(2)}(z)\, \mathrm{e}^{\mathrm{i}m\theta_p}, \tag{3.25}$$

where $\alpha_n = (\mu_n^2 - k^2)^{1/2}$, $\beta_n = (\nu_n^2 - k^2)^{1/2}$, and

$$\Psi_n^{(1)}(z) = 2^{1/2} \sin \mu_n (b-z), \quad \mu_n = (n+\tfrac{1}{2})\pi/b, \quad n \in \mathbb{N}_0, \tag{3.26}$$

$$\Psi_n^{(2)}(z) = 2^{1/2} \sin \nu_n z, \quad \nu_n = n\pi/b, \quad n \in \mathbb{N}. \tag{3.27}$$

If we restrict the energy so that

$$\pi < kd < 2\pi, \tag{3.28}$$

then α_0 is purely imaginary, whereas α_n and β_n, $n \in \mathbb{N}$ will all be real and positive. This restriction allows for wave-like modes local to each disk, with decay as r becomes large.

In order to apply the continuity conditions (3.23), the eigenfunction expansion in region *II* must be written in terms of the coordinates r_j and θ_j. This can be achieved using Graf's addition theorem, which shows that provided $r_j < R_{jp}$ for all p, we can write

$$\begin{aligned}\phi^{II}(r_j,\theta_j,z) = &\sum_{m=-\infty}^{\infty} \sum_{n=1}^{\infty} B_{mn}^j \frac{K_m(\beta_n r_j)}{\beta_n K_m'(\beta_n a_j)} \Psi_n^{(2)}(z)\, \mathrm{e}^{\mathrm{i}m\theta_j} \\ &+ \sum_{\substack{p=1 \\ p\neq j}}^{P} \sum_{m=-\infty}^{\infty} \sum_{n=1}^{\infty} \sum_{s=-\infty}^{\infty} B_{mn}^p \frac{I_s(\beta_n r_j)}{\beta_n K_m'(\beta_n a_j)} K_{m-s}(\beta_n R_{jp})\, \mathrm{e}^{\mathrm{i}s\theta_p} \Psi_n^{(2)}(z)\, \mathrm{e}^{\mathrm{i}(m-s)\alpha_{jp}},\end{aligned} \tag{3.29}$$

where R_{jp} is the distance between the centers of disks j and p, and α_{jp} is the angle of the center of disk p from disk j, measured as shown in Fig. 5.

We can then apply the matching conditions (3.23) and convert the resulting equations into an infinite system by multiplying each by $\Psi_t^{(1)}(z)\mathrm{e}^{-\mathrm{i}w\theta_j}$, $t \in \mathbb{N}_0$, $w \in \mathbb{Z}$, $j=1,\ldots,P$, and integrating over z in $(0,b)$ and θ_j in $(0, 2\pi)$. We obtain, after eliminating A_{mn}^j

$$\sum_{p=1}^{P} \sum_{m=-\infty}^{\infty} \sum_{n=1}^{\infty} B_{mn}^p Z_{nmp,twj} = 0, \quad t \in \mathbb{N}_0, \quad w \in \mathbb{Z}, \quad j=1,\ldots,P, \tag{3.30}$$

where

$$Z_{nmp,twj} = \begin{cases} d_{tt} X_{twj} \delta_{mw} \delta_{nt} & p = j, \\ d_{nt} Y_{nmp,twj} & p \neq j, \end{cases} \tag{3.31}$$

$$X_{twj} = X_{t(-w)j} = \frac{I_w(\alpha_t a_j)}{\alpha_t I_w'(\alpha_t a_j)} - \frac{K_w(\beta_t a_j)}{\beta_t K_w'(\beta_t a_j)}, \tag{3.32}$$

$$Y_{nmp,twj} = K_{m-w}(\beta_n R_{jp})\, \mathrm{e}^{\mathrm{i}(m-w)\alpha_{jp}} \left(\frac{I_w(\alpha_t a_j) I_w'(\beta_n a_j)}{\alpha_t I_w'(\alpha_t a_j) K_m'(\beta_n a_j)} - \frac{I_w(\beta_n a_j)}{\beta_n K_m'(\beta_n a_j)} \right), \tag{3.33}$$

and

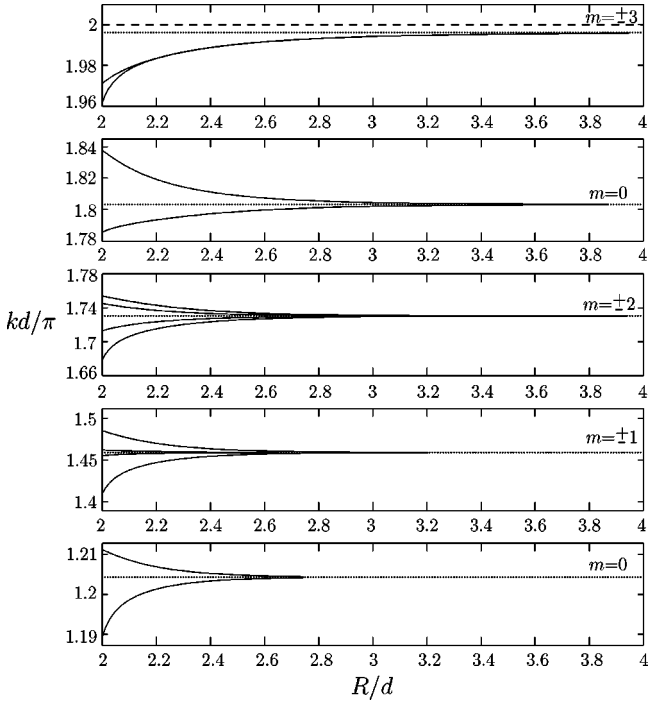

FIG. 6. Nondimensional bound-state energies, kd/π, plotted against R/d for the case of two identical windows with radius $a=d$. The dotted lines correspond to the bound states from the single-disk case with $a/d=1$ and are labeled with the appropriate values of m. The dashed line corresponds to the upper cutoff.

$$d_{nt}=\frac{2}{d}\int_0^{d/2}\Psi_n^{(2)}(z)\Psi_t^{(1)}(z)\,\mathrm{d}z=\frac{4\nu_n(-1)^t}{d(\mu_t^2-\nu_n^2)}. \tag{3.34}$$

A. Results

We solve (3.30) by introducing truncation parameters M and N so that m and w vary between $\pm M$, and n and $t+1$ vary between 1 and N. Then, we write

$$\lambda_1=n+N(m+M)+N(2M+1)(p-1), \tag{3.35}$$

$$\lambda_2=1+t+N(w+M)+N(2M+1)(j-1), \tag{3.36}$$

so that any positive integer λ_i between 1 and $N(2M+1)P$ corresponds to a unique triple (n,m,p) for $i=1$, or (t,w,j) for $i=2$. To find a solution of (3.30) we are required to find frequencies kd so that the determinant of the resulting $N(2M+1)P\times N(2M+1)P$ matrix is zero. For the results below, truncation parameters $N=5$ and $M=3$ were used.

We consider the case of two circular windows. In this situation the bound-state energies will be independent of the angle between the centers of the two disks (α_{12} and α_{21}, in Fig. 5). That this is the case can be demonstrated as follows. The matrix Z has a 2×2 block structure and, if we multiply the rows in the blocks corresponding to $j=1$ by $\exp(-\mathrm{i}m\alpha_{12})$, the rows in the blocks corresponding to $j=2$ by $\exp(-\mathrm{i}m\alpha_{21})$, the columns in the blocks corresponding to $p=1$ by $\exp(\mathrm{i}w\alpha_{21})$, and the columns in the blocks corresponding to $p=2$ by $\exp(\mathrm{i}w\alpha_{12})$, the resulting matrix is independent of the angles α_{12} and α_{21} and its determinant is a nonzero multiple of the determinant of Z and so will vanish for the same values of kd.

Figure 6 shows the nondimensional bound-state energies, kd/π plotted against nondimensional separation R/d for two identical windows with radius $a=d$. The dotted lines are the bound-state energies from the single-window case when $a/d=1$ and are labeled with the appro-

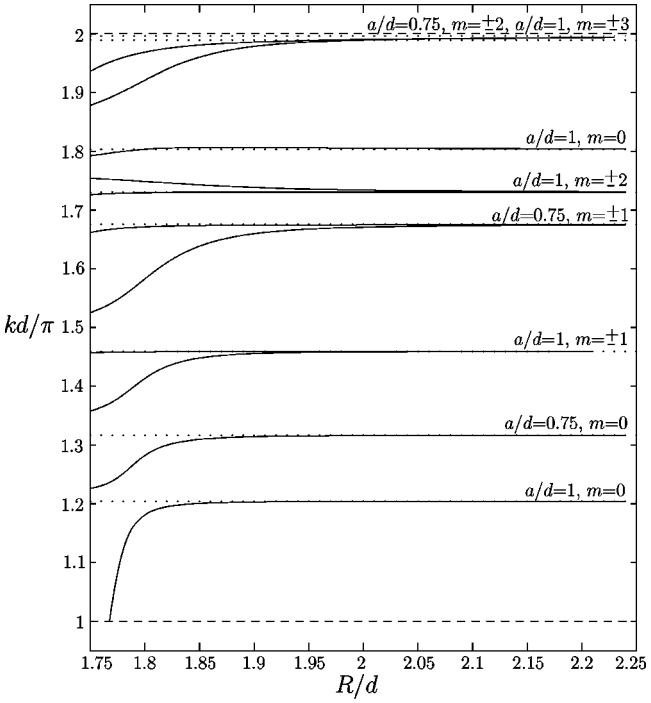

FIG. 7. Nondimensional bound-state energies, kd/π, plotted against R/d for the case of two windows of radii $a/d=1$ and $a/d=0.75$. The dotted lines correspond to the bound states from the single-window case with $a/d=1$ and $a/d=0.75$ and are labeled with the appropriate values of m. The dashed lines correspond to the upper and lower cutoffs.

priate values of m. They represent the limits for the energies as $R/d\to\infty$. The dashed line is the upper cutoff $kd=2\pi$. All possible modes appear in the figure. However, if we took a larger value of a/d we would have to use a larger truncation parameter M to find all the modes.

When the two disks are touching, i.e., when $R/d=2$, there are 14 bound states. There are two modes around each dotted line corresponding to $m=0$ and four modes around the other dotted lines (two for the positive value of m and two for the negative value of m). The exception occurs when $m=\pm 3$, as this mode is close to the upper cutoff and so only a single mode appears below the dotted line for each m. As the value of R/d is increased, which means that the disks are moved apart, each pair of modes converges towards the limiting case.

Figure 7 shows the nondimensional bound-state energies, kd/π plotted against R/d for two circular windows for which $a/d=1$ and $a/d=0.75$, respectively. The dotted lines are the bound-state energies from the single-window cases when $a/d=1$ and $a/d=0.75$, and are labeled with the appropriate values of m and again represent the limits for the energies as $R/d\to\infty$. The dashed lines are the upper and lower cutoffs. All possible modes appear in the figure. Between the two cutoffs we find that there are five modes from the single-window case with $a/d=1$ and three modes from the single-window case when $a/d=0.75$. When the two windows are touching, i.e., when $R/d=1.75$, the bound-state energies are very different from the single-window values, but as the separation is increased, the energies quickly approach the single-window values. Similar types of results were found by Evans and Porter (1997), who computed trapped modes in the vicinity of multiple cylinders in a channel.

IV. CONCLUSION

We have computed bound-state energies below the first cutoff in two three-dimensional coupled waveguides, each obtained from the two-dimensional configuration considered in paper I by rotating the geometry about a different axis.

First, we have studied bound states in a waveguide consisting of two concentric circular cylindrical waveguides coupled by a finite length gap along the axis of the inner cylinder. The same residue calculus method which was used in paper I was used to compute bound-state energies below the first cutoff for wave propagation down the guide. We were able to look for modes with a given angular variation $\cos m\theta$, $m \in \mathbb{N}_0$, and the bound states found are either symmetric or antisymmetric about the line of symmetry perpendicular to the axis of the cylinder. The available energy band for bound states is dependent on the values of m and the ratio of the two radii. The results show that bound states occur for any value of the gap length and ratio of radii, and the energies increase as m increases.

Second, we have considered the problem in which a pair of planar layers is coupled laterally by a circular hole. The sophisticated residue calculus theory is not available in this case, but we were able to compute bound states by searching for the zeros of the determinant of a matrix found from a mode-matching approach. For this problem we can again consider a given angular variation $\cos m\theta$, $m \in \mathbb{N}_0$, and find modes in each case.

We then extended the theory to cover the case of a number of circular windows connecting two planar guides of equal width and presented results for two circles, both when they have the same radius and when they do not. In both situations we find that when the windows are far apart the bound states are equivalent to those occurring in the single-window cases, but that the energies vary considerably as the windows are moved closer together.

In the presence of a variable magnetic field, the Weyl pseudodifferential calculus must be modified. The usual modification, based on "the minimal coupling principle" at the level of the classical symbols, does not lead to gauge invariant formulas if the magnetic field is not constant. We present a gauge covariant quantization, relying on the magnetic canonical commutation relations. The underlying symbolic calculus is a deformation, defined in terms of the magnetic flux through triangles, of the classical Moyal product. © *2004 American Institute of Physics.*

I. INTRODUCTION

The correspondence principle of quantum mechanics asks that for a given physical system there should be a systematic way to convert classical observables into quantum observables. We use for this the rather vague term of *quantization*. For many given systems a true, manageable quantization is problematic, but there are important situations in which commonly accepted solutions exist. The purpose of the present article is to propose what we think to be the correct solution for the case of a nonrelativistic spinless particle, moving in $\mathbb{R}^N$, in the presence of a variable magnetic field. From the mathematical point of view, our results may be considered as a first step towards a quantization of symplectic manifolds.

General principles assert essentially that classical observables are functions in phase space, while quantum observables should be self-adjoint operators in some Hilbert space. Rather often, for some basic observables (positions, momenta,...) the prescription is either essentially unique (may be due to some commutation relations), or at least generally accepted. Thus, for many physical systems, quantization of all phase-space functions could be regarded as a sort of functional calculus. But since, as a rule, the basic observables do not commute, one cannot rely on the usual spectral theory to define this functional calculus. Roughly, quantization may be seen as the mathematical problem of defining functions of several noncommuting self-adjoint operators. Of course, the features of the physical system both impose constraints and offer empirical suggestions with respect to this procedure.

In the absence of any magnetic field, a nonrelativistic spinless particle moving in $\mathbb{R}^N$ is quantized through the Weyl pseudodifferential calculus. If f is a suitable function ("symbol") defined on the phase space $\mathbb{R}^{2N}$, the corresponding operator is defined to act in the Hilbert space $L^2(\mathbb{R}^N)$ by the formula

$$[\mathfrak{Op}(f)u](x) := \int_{\mathbb{R}^{2N}} dy \quad dp \quad e^{i(x-y)\cdot p} f\left(\frac{x+y}{2}, p\right) u(y). \tag{1}$$

In a certain sense (which can be made precise and which will be discussed below), we may write $\mathfrak{Op}(f) = f(Q,P)$ and interpret it as the action on the symbol f of the functional calculus associated to the family of operators $(Q_1,\ldots,Q_N,P_1,\ldots,P_N)$, where Q_j is the multiplication by the jth coordinate and $P_j := -i\partial_j$. The well-known rules of commutation between these position

[b]Author to whom correspondence should be addressed. Electronic mail: radu.purice@imar.ro

and momentum quantum observables play a decisive role in determining the explicit formula above. They are thus also basic in deducing the explicit product rule $(f,g)\mapsto f\circ g$ and involution $f\mapsto f^\circ$ leading to $\mathfrak{Op}(f)\mathfrak{Op}(g)=\mathfrak{Op}(f\circ g)$ and $\mathfrak{Op}(f)^*=\mathfrak{Op}(f^\circ)$.

When a magnetic field B is turned on, we are faced with the problem of modifying the formula for $\mathfrak{Op}(f)$ in a way taking into account the presence of the magnetic field in a correct, physical way. A mistaken procedure which appears from time to time in the literature is the following: One chooses a vector potential A corresponding to the magnetic field ($B=dA$) and, by an (unjustified) application of the minimal coupling principle, one sets $\mathfrak{Op}_A(f):=\mathfrak{Op}(f_A)$, with $f_A(x,p):=f(x,p-A(x))$. This is meant to be the action on f of the functional calculus associated with the family $Q_1,\ldots,Q_N,\Pi_1,\ldots,\Pi_N$, where $\Pi_j:=P_j-A_j(Q)$ is the jth component of the vector potential. But the resulting formula

$$[\mathfrak{Op}_A(f)u](x):=\int_{\mathbb{R}^{2N}}dy\quad dk\quad e^{i(x-y)\cdot k}f\left(\frac{x+y}{2},k-A\left(\frac{x+y}{2}\right)\right)u(y) \tag{2}$$

$$=\int_{\mathbb{R}^{2N}}dy\quad dp\quad e^{i(x-y)\cdot p}e^{i(x-y)\cdot A((x+y)/2)}f\left(\frac{x+y}{2},p\right)u(y) \tag{3}$$

cannot be the right one, since it lacks gauge covariance: If one chooses another vector potential A' associated to B, differing from the initial one by the gradient of a scalar function, $A'=A+\nabla\rho$, then *the expected formula* $e^{i\rho}\mathfrak{Op}_A(f)e^{-i\rho}=\mathfrak{Op}_{A'}(f)$ *does not hold*. In fact, this formula is restored if one replaces the phase factor $e^{i(x-y)\cdot A((x+y)/2)}$ by $e^{i(x-y)\cdot\int_0^1 dsA((1-s)x+sy)}$. It is reassuring to note that $-(x-y)\cdot\int_0^1 dsA((1-s)x+sy)$ is in fact the circulation $\Gamma^A([x,y])$ of the vector potential A through the segment leading from x to y. Thus the formula we propose instead of (2) is

$$[\mathfrak{Op}^A(f)u](x):=\int_{\mathbb{R}^{2N}}dy\quad dp\quad e^{i(x-y)\cdot p}e^{-i\Gamma^A([x,y])}f\left(\frac{x+y}{2},p\right)u(y). \tag{4}$$

The main purpose of our article is to give an explanation of these facts. As a prologue for doing this, in the next section we review some facts related to canonical commutation relations and Weyl calculus when no magnetic field is present. The main topic will be the justification of the formula for $\mathfrak{Op}(f)$ as a sort of integrated form of *the Weyl system*, which is a family of unitary operators $\{W(\xi)\}_\xi$ indexed by the points of the phase space and containing the relevant information on the commutation relations between the operators Q and P. We claim no originality (see, for example, Ref. 18); we include this here because it seems to be an argument largely ignored, which is basic to our approach. The symbolic calculus beyond the Weyl prescription is the famous Moyal product. Other references emphasizing the connection between quantum mechanics and pseudodifferential theory are Refs. 15 and 10.

When a magnetic field is present, the Weyl system has to be modified. Instead of the group of translations, appearing naturally in the formula giving $W(\xi)$ [see (8)], one has to work with the magnetic translations, forming a sort of generalized projective representation of $\mathbb{R}^N$. This is presented in the Sec. III.

In Sec. IV, the formula $\mathfrak{Op}^A$ for the functional calculus with magnetic field is deduced. For this we apply the same strategy as in Sec. II, but using now the magnetic Weyl system, introduced in Sec. III. The setting relies on the choice of a vector potential, but now gauge covariance is available; equivalent vector potentials lead to unitarily equivalent operators. The basic expression for $\mathfrak{Op}^A(f)$ requires rather strong conditions on the function f. But for large classes of magnetic fields one can extend it, as in the nonmagnetic case, to all tempered distributions, by a suitable interpretation of $\mathfrak{Op}^A(f)$ as a linear continuous operator from the Schwartz space $\mathcal{S}(\mathbb{R}^N)$ to its dual. This is based on a study of the distribution kernel of this operator. These and some other fundamental facts are also considered in Sec. IV.

Beyond these operators lies a symbolic calculus which is *manifestly gauge invariant*, being defined only in terms of the magnetic field. The composition is a magnetic correction of the Moyal product, while the involution is just the usual complex conjugation of functions. In Sec. V we study this symbolic calculus. Once again an important problem is to extend the formulas when obvious integrability conditions are not satisfied. This is a more complicated task for the product than it was for the quantization itself, especially if one aims at obtaining *-algebras. We postpone the application of the machinery of oscillatory integrals and classical symbol function spaces to a future article. For our present purposes the strategy of extension by duality methods (see Refs. 13 and 14 for the nonmagnetic case) is more fruitful. It will lead to a large, interesting *-algebra of distributions which will be called *the magnetic Moyal algebra*.

Of course, for certain problems, a well-justified norm on (restricted) *-algebras of symbols could be very useful. It happens that this is easier to achieve after performing a partial Fourier transform. Surprisingly, one naturally encounters certain C^*-algebras which were studied in pure mathematics, with little connection with physics. These are special types of twisted crossed products, associated to twisted actions of $\mathbb{R}^N$ on suitable Abelian C^*-algebras of position observables. They were already related to quantum magnetic fields in Ref. 23; see also Refs. 11, 5 and 6 for related works. In a future publication we shall extend their study and outline the connection with our pseudodifferential calculus.

Concerning the difference between the expressions (2) [or (3)] and (4) some comments are necessary. In Sec. IV D we shall outline some situations when they give the same result. By admitting the convenient assumption that the components of A are smooth functions with tempered growth, both (2) and (4) can be extended to any tempered distribution f. Then *we shall have* $\mathfrak{Op}_A(f)=\mathfrak{Op}^A(f)$ *for all* f *if and only if* A *is linear* (this is one of the most important cases appearing usually in the literature). Remark that this condition corresponds to a constant magnetic field, but *it is not gauge invariant*: for some other A' with $dA'=B=\text{const}$, $\mathfrak{Op}_{A'}$ and $\mathfrak{Op}^{A'}$ will be different! (The pseudodifferential calculus corresponding to a linear A was developed in Ref. 7 in connection with some problems in pure PDE theory; in fact the term ''magnetic field'' is never explicitly mentioned.) One will also have $\mathfrak{Op}_A(f)=\mathfrak{Op}^A(f)$ *for any* A if f is a polynomial of order $\leqslant 2$. The most studied magnetic operators are the Schrödinger magnetic Hamiltonians $(P-A(Q))^2+V(Q)$, cf. Ref. 1 and 24, for instance. They are obtained by quantizing the sum between a quadratic function depending only on p and a function depending only on x, so no care is needed in this case. However, even their study may involve applying the Weyl calculus to more complicated symbols. Anyhow, for polynomials of order three in p, (2) and (4) already give different results. We remark that using the Weyl calculus coupled with the minimal coupling principle [as in (2)] for a nonconstant magnetic field and a complicated symbol is still legitimate as long as this is a technical tool and not the quantization of the classical observable represented by the symbol. This is often the case in solid state physics, in arguments concerning the Peierls substitution, as in Refs. 12 and 29.

Our feeling is that the magnetic Weyl calculus elaborated in this article is both an interesting mathematical object and a significant formalism for theoretical physics. From the mathematical point of view, we consider it interesting to use our calculus for some specific classes of symbols and obtain more detailed results and also to connect it with strict deformation quantization. Moreover, obtaining precise estimations on the C^*-norm of the objects in the Moyal algebra and some variants of Calderon–Vaillancourt theorems is of much interest in spectral analysis, deformation quantization and semiclassical limit. These results may be then applied for quantum Hamiltonians (of Schrödinger or relativistic type) and obtain spectral and propagation information and to study their semiclassical limit and its dependence on the chosen quantization procedure. In this article we intended to be accessible to people that are only vaguely familiar with pseudodifferential theory; more technical developments or applications are deferred to future works. We were encouraged in this attitude by a discussion with Joseph Avron and Omri Gat. A paper devoted to some C^*-algebras aspects of our magnetic Weyl calculus is in preparation in collaboration with Serge Richard.

II. CANONICAL COMMUTATION RELATIONS AND PSEUDODIFFERENTIAL CALCULUS WITHOUT MAGNETIC FIELDS

One of the main virtues of the standard pseudodifferential calculus (in Weyl form) lies in the fact that it gives an answer to a fundamental problem in quantum mechanics. It can be figured out as the quantization of a physical system composed of a nonrelativistic particle without internal structure, moving in a Euclidean configuration space. We review this topic briefly, since it gives a solid motivation for our later treatment of the case in which a magnetic field is added. Further details may be found in Refs. 10 and 18, for example. At the root of this approach lie the canonical commutation relations satisfied by the basic observables of the system, the positions and the momenta, and this is the main point we want to emphasize.

A. Framework

We have in view an N-dimentional nonrelativistic particle without internal structure (called simply *a particle*) that is described classically in *the phase space* $\Xi := X \times X^\star$, where $X := \mathbb{R}^N$ is *the configuration space* and $X^\star$ is its dual. The space Ξ is naturally endowed with the symplectic form $\sigma: \Xi \times \Xi \to \mathbb{R}$ given by

$$\sigma((q',p'),(q'',p'')) := q'' \cdot p' - q' \cdot p'',$$

where $q \cdot p$ denotes the canonical pairing on $X \times X^\star$.

The classical observables are (smooth) real functions defined on Ξ. A particular role is played by the Poisson bracket

$$\{f,g\} := \sigma(\nabla f, \nabla g) = \sum_{j=1}^{N} (\partial_{p_j} f \ \partial_{q_j} g - \partial_{p_j} g \ \partial_{q_j} f).$$

Real functions of class C^∞ on the phase space form an infinite-dimentional Lie algebra under the pointwise vector operations and the Poisson bracket.

The associated quantum system is described on the Hilbert space $\mathcal{H} = L^2(X)$ in terms of the family of self-adjoint operators $(Q_j)_{j=1,\ldots,N}$ and $(P_j)_{j=1,\ldots,N}$ (here Q_j is the operator of multiplication with the jth component of the variable in $\mathcal{H}$ and $P_j := -i\partial_j$). The operators $(Q_j, P_j)_{j=1,\ldots,N}$ are the quantum version of the classical observables position and momenta, given by the the canonical variables in phase space $q_1, \ldots, q_N, p_1, \ldots, p_N$. These canonical variables satisfy the relations

$$\{q_i, q_j\} = 0, \ \{p_i, p_j\} = 0, \ \{p_i, q_j\} = \delta_{ij}, \quad i,j = 1, \ldots, N,$$

and the corresponding quantum observables should satisfy at their turn

$$i[Q_i, Q_j] = 0, \ i[P_i, P_j] = 0, \ i[P_i, Q_j] = \delta_{ij}, \ i,j = 1, \ldots, N,$$

as they actually do, at least formally.

B. The Weyl system

In principle, the choice of the Hilbert space $L^2(X)$ and of the explicit form of the operators Q_j and P_j should be justified. It is widely accepted the vague prescription that to the canonical variables q_j and p_j one should ascribe self-adjoint operators $\mathfrak{Op}(q_j)$ and $\mathfrak{Op}(p_j)$ acting in some Hilbert space $\mathcal{H}$, satisfying

$$i[\mathfrak{Op}(q_i), \mathfrak{Op}(q_j)] = 0, \ i[\mathfrak{Op}(p_i), \mathfrak{Op}(p_j)] = 0, \ i[\mathfrak{Op}(p_i), \mathfrak{Op}(q_j)] = \delta_{ij}, \ i,j = 1, \ldots, N. \quad (5)$$

But an axiomatic approach relying on this formula is hard to conceive. The typical difficulties related to the (inevitable) nonboundedness of the operators $\mathfrak{Op}(q_j)$ and $\mathfrak{Op}(p_j)$ cannot be solved by *a priori* arguments.

For this and for several other reasons, it is preferable to rephrase all in terms of bounded operators. For $q \in X$ and $p \in X^\star$, let us set $U(q) := e^{-iq\cdot P}$ and $V(p) := e^{-iQ\cdot p}$. These are unitary operators in $L^2(X)$ given explicitly by

$$[U(q)u](y) = u(y-q) \quad \text{and} \quad [V(p)u](y) = e^{-iy\cdot p}u(y), \quad u \in L^2(X),\ y \in X. \tag{6}$$

The maps $q \mapsto U(q)$ and $p \mapsto V(p)$ are strongly continuous unitary representations of X, respectively X^*, in $L^2(X)$ and *the Weyl form of the canonical commutation relations,*

$$U(q)V(p) = e^{iq\cdot p}\ V(p)U(q), \quad q \in X,\ p \in X^\star, \tag{7}$$

holds. Now there is no ambiguity in addressing the abstract problem of the classification of triples $(\mathcal{H},U,V)$, where $\mathcal{H}$ is a Hilbert space and $U: X \to \mathcal{U}(\mathcal{H})$, $V: X^\star \to \mathcal{U}(\mathcal{H})$ are strongly continuous unitary representations satisfying (7). And there is a simple answer, given by the Stone–von Neumann Theorem (for a more explicit statement and for the proof we look to Ref. 10): If one also assumes irreducibility of the family $\{U(q),V(p) \mid q \in X, p \in X^\star\}$, then any solution is unitarily equivalent to (6) (which is called *the Schrödinger representation*). And a non-irreducible triple is just a multiple of this Schrödinger representation.

A convenient way to condense the two objects U and V into a single one is to define *the Weyl system* $\{W(\xi) \mid \xi \in \Xi\} \subset \mathcal{U}(\mathcal{H})$ by

$$W(q,p) := e^{(i/2)\,q\cdot p}\ U(-q)V(p) = e^{-(i/2)\,q\cdot p}\ V(p)U(-q), \quad q \in X, \quad p \in X^\star. \tag{8}$$

A short calculation shows that W satisfies

$$W(\xi)W(\eta) = e^{(i/2)\,\sigma(\xi,\eta)}\ W(\xi+\eta), \qquad \xi,\eta \in \Xi, \tag{9}$$

i.e., W is a projective representation of the group Ξ with two-cocycle (phase factor) $e^{(i/2)\,\sigma}$.

Of course, W can be defined for any abstract triple $(\mathcal{H},U,V)$. But, as a consequence of the Stone–von Neumann Theorem, it is enough to work with the Schrödinger representation. The corresponding W will be called *the Schrödinger Weyl system* and is explicitly given on $L^2(X)$ by

$$[W(q,p)u](y) = e^{-i((1/2)\,q+y)\cdot p}\ u(y+q). \tag{10}$$

The representations U and V can be recovered easily from W by $U(q) = W(-q,0)$ and $V(p) = W(0,p)$. One easily justifies the formula $W(\xi) = e^{-i\sigma(\xi,R)}$, where $R = (Q,P)$; $\sigma(\xi,R)$ signifies here the (suitable defined) self-adjoint operator $Q\cdot p - q\cdot P$.

The Weyl system is a convenient way to codify the commutation relations between the basic operators Q and P. In the next paragraph, the quantization by pseudodifferential operators will be obtained as an integrated form of this Weyl system.

C. Pseudodifferential operators

If a family of self-adjoint operators $S_1,\ldots,S_m$ is given such that for any i,j, S_i and S_j commute, then one can define a functional calculus for this family by one of the two formulas

$$f(S) = \int_{\mathbb{R}^m} f(\lambda)\,dE_S(\lambda) = \int_{\mathbb{R}^m} dt\ \check{f}(t)e^{-it\cdot S}.$$

Here E_S is the spectral measure (on $\mathbb{R}^m$) of the family $S_1,\ldots,S_m$, under suitable assumptions $t\cdot S := t_1S_1 + \cdots + t_mS_m$ is a well-defined self-adjoint operator and $\check{f}$ is the inverse Fourier tranform of f, conveniently normalized.

If, once again, $S_1,\ldots,S_m$ are self-adjoint, but they no longer commute, there is usually no reasonable spectral measure E_S. One can try to use the operator version of the Fourier inversion formula to define a functional calculus. The key point would be the ability of defining a suitable

analog of $e^{-it\cdot S}$. This strategy is outlined in Ref. 2 (see also Ref. 3) for very general situations. But the properties of the resulting functional calculus are quite modest if the commutation relations of the operators S_j have no interesting peculiarities.

We shall show how this program can be implemented for the case $m=2N$, $S_j=Q_j$ if $j=1,\ldots,N$ and $S_j=P_j$ for $j=N+1,\ldots,2N$. In an analoguous but more complicated way, in Sec. IV we shall do the same for $S_j=Q_j$ if $j=1,\ldots,N$ and $S_j=\Pi_j^A$ for $j=N+1,\ldots,2N$, with $\Pi_j^A=P_j-A_j(Q)$ the jth component of the magnetic momentum defined by a vector potential A. But we stop for a moment to fix some conventions on Fourier transforms that will also be useful later on.

In fact, we are faced with two problems: normalization and the choice of a good definition on the symplectic space. The Lebegue measures on X, $X^\star$ and Ξ are not the most convenient Haar (=positive, translational invariant Borel) measures, since they lead to the appearance of spurious constants. Let us start with two arbitrary Haar measures dx on X and dp on X^*. One defines at the level of tempered distributions

$$\mathcal{F}_X,\overline{\mathcal{F}}_X:\mathcal{S}'(X)\to\mathcal{S}'(X^*),\ \mathcal{F}_{X^\star},\overline{\mathcal{F}}_{X^\star}:\mathcal{S}'(X^\star)\to\mathcal{S}'(X),$$

uniquely determined by the following actions on integrable functions:

$$(\mathcal{F}_X u)(p)=\int_X dx\ \ e^{-ix\cdot p}u(x),\ \ (\overline{\mathcal{F}}_X u)(p)=\int_X dx\ \ e^{ix\cdot p}u(x),$$

$$(\mathcal{F}_{X^\star} v)(x)=\int_{X^\star} dp\ \ e^{-ix\cdot p}v(p),\ \ (\overline{\mathcal{F}}_{X^\star} v)(p)=\int_{X^\star} dp\ \ e^{ix\cdot p}v(p).$$

It is easily shown that there exists $c>0$ such that

$$\overline{\mathcal{F}}_{X^*}\circ\mathcal{F}_X=c\ \ \mathrm{id}_{\mathcal{S}'(X)}\qquad\text{and}\qquad\mathcal{F}_X\circ\overline{\mathcal{F}}_{X^\star}=c\ \ \mathrm{id}_{\mathcal{S}'(X^\star)}.$$

Thus, by redefining dx and dp, one gets $\mathcal{F}_X^{-1}=\overline{\mathcal{F}}_{X^\star}$ and $\mathcal{F}_{X^\star}^{-1}=\overline{\mathcal{F}}_X$. We fix such a choice for dx and dp, but obviously $d\xi:=dx\otimes dp$ does not depend on this choice. We also set the symplectic Fourier transforms

$$\mathcal{F}_\Xi,\mathcal{F}_\Xi^{-1}:\mathcal{S}'(\Xi)\to\mathcal{S}'(\Xi),$$

$$(\mathcal{F}_\Xi f)(\xi)=(\mathcal{F}_\Xi^{-1}f)(\xi):=\int_\Xi d\eta\ \ e^{i\sigma(\xi,\eta)}f(\eta)$$

and note that $\mathcal{F}_\Xi=\mathcal{I}\circ(\overline{\mathcal{F}}_X\otimes\mathcal{F}_{X^\star})$, where $\mathcal{I}:\mathcal{S}'(X^\star\times X)\to\mathcal{S}'(X\times X^\star)$, $(\mathcal{I}g)(x,p):=g(p,x)$.

Now, for any Weyl system $(\mathcal{H},W)$ we define (at least) for functions $f:\Xi\to\mathbb{C}$ with integrable symplectic Fourier transform

$$\mathfrak{Op}(f):=\int_\Xi d\xi\ \ (\mathcal{F}_\Xi^{-1}f)(\xi)\ \ W(\xi).\tag{11}$$

We do not insist on the precise interpretation of this formula; this will be done later on in the more complicated magnetic case.

Once again, by the Stone–von Neumann theorem, we are satisfied with the case of the Schrödinger representation. By introducing the explicit form of the Schrödinger Weyl system, one gets immediatly for any $u\in L^2(X)$

$$[\mathfrak{Op}(f)u](x)=\int_X dy\int_{X^\star} dp\ \ e^{i(x-y)\cdot p}f\left(\frac{x+y}{2},p\right)u(y)\tag{12}$$

and this is exactly the Weyl prescription to quantize classical symbols.

We note that $\mathfrak{Op}(f)$ is an integral operator with kernel $K_f(x,y) := [(1\otimes \overline{\mathcal{F}}_{X^*})f]((x+y)/2, x-y)$.

Then, by an elementary application of Schwartz's kernel theorem, one gives a sense to $\mathfrak{Op}(f)$ for any $f\in\mathcal{S}'(\Xi)$ as a continuous linear operator from $\mathcal{S}(X)$ to $\mathcal{S}'(X)$. In fact, all these operators are of the form $\mathfrak{Op}(f)$ for some unique tempered distribution f.

D. The Moyal algebra

We turn now to the symbolic calculus. It is easy to see that by setting

$$(f\circ g)(\xi) := 4^N \int_\Xi d\eta \int_\Xi d\zeta \;\; e^{-2i\sigma(\xi-\eta,\xi-\zeta)} f(\eta) g(\zeta) \tag{13}$$

one will have $\mathfrak{Op}(f)\mathfrak{Op}(g) = \mathfrak{Op}(f\circ g)$, and that $\mathfrak{Op}(f)^* = \mathfrak{Op}(f^\circ)$, with $f^\circ(x) := \overline{f(x)}$.

The noncommutative composition law $\circ$ is often called *the Moyal product* (or *the Weyl product*). It makes sense for suitable symbols, say $f,g\in\mathcal{S}(\Xi)$. For many purposes it is useful to extend it to larger classes of functions and distributions. The standard approach (see Refs. 10, 18, 19, 28 and many others) is via oscillatory integrals. Better suited to our setting is the approach by duality of Refs. 4, 13 and 14 that we review now briefly.

Let us denote by $(\cdot,\cdot)$ the duality $\mathcal{S}'(X)\times\mathcal{S}(X)\to\mathbb{C}$. By a simple calculation we see that for any three functions f, g and h in $\mathcal{S}(\Xi)$ we have

$$(f, g\circ h) = (f\circ g, h) = (h, f\circ g) = (h\circ f, g) = (g, h\circ f).$$

Thus, we can extend $\circ$ to mappings $\mathcal{S}(\Xi)\times\mathcal{S}'(\Xi)\to\mathcal{S}'(\Xi)$ and $\mathcal{S}'(\Xi)\times\mathcal{S}(\Xi)\to\mathcal{S}'(\Xi)$ by $(f\circ G, h) := (G, h\circ f)$ and $(F\circ g, h) := (F, g\circ h)$, for $f,g,h\in\mathcal{S}(\Xi)$ and $F,G\in\mathcal{S}'(\Xi)$. This is already useful and allows composing n symbols if all except one are in the Schwartz space.

Now set $\mathcal{M}(\Xi) := \{F\in\mathcal{S}'(\Xi) \,|\, F\circ\mathcal{S}(\Xi)\subset\mathcal{S}(\Xi) \text{ and } \mathcal{S}(\Xi)\circ F\subset\mathcal{S}(\Xi)\}$. Just by some abstract nonsense one checks that $\mathcal{M}(\Xi)$ is a *-algebra under (the extension of) the Moyal product $\circ$ and the involution $^\circ$. In Ref. 13 $\mathcal{M}(\Xi)$ is called *the Moyal algebra* and some of its properties are studied. In particular it is shown that $\mathcal{M}(\Xi)$ is stable under all sorts of Fourier transforms, and it contains all the distributions with compact support and (thus) large classes of analytic functions. It also contains the family of C^∞ functions on Ξ with all the derivatives dominated by the same (arbitrary) polynomial.

We will reconsider this topic in greater detail in Sec. V, where the magnetic field will also be present.

III. THE MAGNETIC WEYL SYSTEM

We consider a quantum particle without internal structure moving in $X=\mathbb{R}^N$, in the presence of a variable magnetic field. The *magnetic field* is described by a closed continuous field of two-forms B defined on $\mathbb{R}^N$. In the standard coordinate system on $\mathbb{R}^N$, it is represented by a continuous function taking real antisymmetric matrix values and verifying the cocycle relation $\partial_j B_{kl} + \partial_k B_{lj} + \partial_l B_{jk} = 0$ in a distributional sense. The reader will verify for himself that many constructions and assertions will still be valid for locally integrable fields; we assumed continuity for simplicity and to have a uniform framework.

It is well-known that any such field B may be written as the (distributional) differential dA of a field of one-forms A, *the vector potential*, that is highly nonunique (the gauge ambiguity); by using coordinates, one has $B_{jk} = \partial_j A_k - \partial_k A_j$ for each $j,k = 1,\ldots,N$.

In this section we shall deduce a formula for the analog of the Weyl system of Sec. II B, but in which the magnetic field is also taken into account. One may proceed as in Sec. II B, with the single modification which consists in replacing the translations by the magnetic translations [exponentials of $q\cdot\Pi^A$, where $\Pi^A := P - A(Q)$ is the magnetic momentum]. Just for a change, we

proceed in a different, but equivalent, way. First we get directly the formula for our magnetic Weyl system by exponentiating the self-adjoint operators $\sigma[(q,p),(Q,\Pi^A)]=Q\cdot p-q\cdot(P-A(Q))$, $(q,p)\in\Xi$. Then the magnetic translations and the magnetic form of the Weyl commutation relations are deduced as consequences.

The magnetic translations have long since appeared in the physical literature (see Refs. 22 and 31, for example), especially in connection with problems in solid state physics. Most of the time they were used for the case of a constant field; some references are Refs. 5, 6, 16, 17 and 26.

We stress that the new objects appearing in the magnetic case are two phase factors: One is defined as the imaginary exponential of the circulation of the vector potential; it enters the definition of the magnetic translations, the magnetic Weyl system and (as a consequence, in Sec. IV) in the expression of the magnetic pseudodifferential operators. The other one, an imaginary exponential of the flux of the magnetic field, appears in connection with multiplicative properties of the magnetic translations and of the magnetic Weyl system and (as a consequence, in Sec. V) in the expression of the composition law defining the symbolic calculus. We hope that our treatment will constitute a source of unification of the various ''nonintegrable phase factors'' scattered in the literature on quantum magnetic fields.

A. The magnetic Weyl system

Given a k-form C on X and a compact k-surface $\gamma\subset X$, we define

$$\Gamma^C(\gamma):=\int_\gamma C$$

(this integral having a well-defined invariant meaning). We shall mainly encounter circulations of one-forms along linear segments ($\gamma=[x,y]$) and fluxes of two-forms through triangles ($\gamma=\langle x,y,z\rangle$).

We denote by $\mathcal{H}$ the Hilbert space $L^2(X)$. For each $t\in\mathbb{R}$ we define

$$W_t^A:\Xi\to\mathcal{U}(\mathcal{H}),\quad W_t^A(x,p):=e^{-it(Q+tx/2)\cdot p}\Lambda^A(Q;tx)e^{itx\cdot P},\tag{14}$$

where we introduced the exponential of the circulation of the vector potential

$$\Lambda^A(q;x):=e^{-i\Gamma^A([q,q+x])}=e^{-ix\cdot\int_0^1 ds\ A(q+sx)}.\tag{15}$$

We make the convention that the vector potential will always be taken continuous. This is, indeed, always possible, since B is supposed continuous, by *the transversal gauge*

$$A_i(x)=-\sum_{j=1}^N\int_0^1 ds\ B_{ij}(sx)sx_j.\tag{16}$$

Noncontinuous vector potentials are not really useful in our framework, but they could also be handled either directly or by exploiting gauge covariance.

The next lemma says that $\{W_t^A(x,p)\}_{t\in\mathbb{R}}$ is the evolution group of the self-adjoint operator $Q\cdot p-x\cdot\Pi^A$, suitably defined.

Lemma 1: We have $W_t^A(x,p)=e^{-it\sigma[(x,p),(Q,\Pi^A)]}$, *where the self-adjoint operator* $\sigma[(x,p),(Q,\Pi^A)]$ *is the closure of the restriction at* $\mathcal{S}(X)$ *of the sum* $S+T$, *with* $S=Q\cdot p+x\cdot A(Q)$ *and* $T=-x\cdot P$.

Proof: It is known that $S+T$ is indeed essentially self-adjoint on $C_c^\infty(X)$ (see Refs. 21 and 8). Thus, we can apply Trotter's formula (see Ref. 27, Th. VII.31). We set $S=a(Q)$ and calculate

$$
\begin{aligned}
&(e^{-(i/n)\,ta(Q)}e^{(i/n)\,tx\cdot P})^n\\
&\quad=e^{-(i/n)\,ta(Q)}e^{(i/n)\,tx\cdot P}e^{-(i/n)\,ta(Q)}e^{-(i/n)\,tx\cdot P}\\
&\qquad\cdot e^{2i/n\,tx\cdot P}e^{-(i/n)\,ta(Q)}e^{-(2i/n)\,tx\cdot P}\\
&\qquad\times e^{(3i/n)\,tx\cdot P}\cdots e^{[(n-1)i/n]\,tx\cdot P}e^{-(i/n)\,ta(Q)}e^{-[(n-1)i/n]\,tx\cdot P}e^{(ni/n)\,tx\cdot P}\\
&\quad=e^{-(it/n)[a(Q)+a(Q+\,tx/n)+\cdots+a(Q+\,(n-1)tx/n)]}e^{itx\cdot P}.
\end{aligned}
$$

One notes the appearance of a Riemman sum at the exponent, hence the last expression converges strongly to $e^{-i\int_0^t ds\;\; a(Q+sx)}e^{itx\cdot P}$. The proof is ended by remarking that

$$
\int_0^t ds\;\;\{(y+sx)\cdot p+x\cdot A(y+sx)\}=ty\cdot p+\frac{t^2}{2}x\cdot p+\Gamma^A[y,y+tx].
$$

■

Another, more annoying, proof would consist in showing that for all $\xi\in\Xi$, $t\mapsto W_t(\xi)$ is a strongly continuous unitary group in $\mathcal{H}$ and then doing the necessary derivations.

We note the obvious formula $W_t^A(\xi)=W_1^A(t\xi)$. The operator $W_1^A(\xi)$ will be denoted simply by $W^A(\xi)$.

Definition 2: The family $\{W^A(\xi)\}_{\xi\in\Xi}$ will be called *the magnetic Weyl system associated to the vector potential A*. We write down here, for further use, the action of $W^A(\xi)$ on vectors $u\in\mathcal{H}=L^2(X)$:

$$
[W^A(x,p)u](y)=e^{-i(y+x/2)\cdot p}e^{-i\Gamma^A([y,y+x])}u(y+x). \tag{17}
$$

The usual Weyl system was a projective representation of Ξ. Now the situation is of the same nature, but more involved. For $x,y,q\in X$, let us define

$$
\Omega^B(q;x,y):=e^{-i\Gamma^B(\langle q,q+x,q+x+y\rangle)}. \tag{18}
$$

We note that this is a continuous function of q for fixed x and y, thus it defines a multiplication operator in $\mathcal{H}$.

Proposition 3: For any $\xi=(x,k),\eta=(y,l)\in\Xi$ *one has*

$$
W^A(\xi)W^A(\eta)=e^{(i/2)\,\sigma(\xi,\eta)}\Omega^B(Q;x,y)W^A(\xi+\eta). \tag{19}
$$

Proof: By the Stokes theorem coupled with the relation $B=dA$, one gets for any $x,y,q\in X$ the equality $\Omega^B(q;x,y)=\Lambda^A(q;x)\Lambda^A(q+x;y)[\Lambda^A(q;x+y)]^{-1}$. Then (19) follows by a routine calculation. ■

Let us denote by $C(X;U(1))$ the group (with pointwise multiplication) of all continuous functions on X, taking values in $U(1)$, the multiplicative group of complex numbers of modulus 1. One can interpret Ω^B as a function $\Omega^B:X\times X\to C(X;U(1))$. This function satisfies the following two-cocycle conditions:

$$
\begin{gathered}
\Omega^B(q;x,0)=\Omega^B(q;0,y)=1,\\
\Omega^B(q;x+y,z)\Omega^B(q;x,y)=\Omega^B(q+x;y,z)\Omega^B(q;x,y+z).
\end{gathered} \tag{20}
$$

They follow easily by direct calculations (for the second one use the Stokes theorem for the closed two-form B and the tetrahedron of vertices $q,q+x,q+x+y$ and $q+x+y+z$), but are also easy consequences of Proposition 3. We also note that $\Omega^B(q;x,-x)=1$.

B. The magnetic canonical commutation relations

By restricting to X, respectively $X^\star$, we recover the usual *magnetic translations*, respectively, the unitary group, generated by the position operators:

$$\begin{aligned} U^A(x) &:= W^A(-x,0) = \Lambda^A(Q;-x)e^{-ix\cdot P} = \Lambda^A(Q;-x)U(x), \\ V(p) &:= W^A(0,p) = e^{-iQ\cdot p}. \end{aligned} \tag{21}$$

One has, analogously to (8),

$$W^A(x,p) := e^{(i/2)\,x\cdot p}\ \ U^A(-x)V(p) = e^{-(i/2)\,x\cdot p}\ \ V(p)U^A(-x), \quad x\in X,\ \ p\in X^\star. \tag{22}$$

We get easily from (19) (or by direct calculation) the commutation rules

$$V(p)V(k) = V(k)V(p), \quad U^A(x)V(p) = e^{ix\cdot p}V(p)U^A(x) \tag{23}$$

and

$$U^A(x)U^A(y) = \Omega^B(Q;-x,-y)U^A(x+y), \tag{24}$$

that are the magnetic extension of the Weyl form of the canonical commutation relations.

For any $x\in X$ and any $p\in X^\star$, the applications $\mathbb{R}\ni t\mapsto U^A(tx)\in\mathcal{U}(\mathcal{H})$ and $\mathbb{R}\ni t\mapsto V(tp)\in\mathcal{U}(\mathcal{H})$ are one-parameter unitary groups on $\mathcal{H}$. We define self-adjoint generators (choosing $x=e_j$, resp. $p=\epsilon_j$ the jth element of the canonical orthogonal basis in $\mathbb{R}^N$)

$$\begin{aligned} Q_j &:= i\frac{\partial}{\partial t}\bigg|_{t=0} V(t\epsilon_j), \\ \Pi_j^A &:= i\frac{\partial}{\partial t}\bigg|_{t=0} U^A(te_j) = P_j - A_j(Q). \end{aligned} \tag{25}$$

On the common domain formed of C^∞-functions with compact support we have the following commutation relations:

$$i[Q_j,Q_k]=0, \quad i[Q_j,\Pi_k]=\delta_{jk} \quad i[\Pi_j,\Pi_k]=B_{jk}(Q). \tag{26}$$

If the magnetic field is not constant (or at least polynomial), they are much more complex than in the nonmagnetic case; the successive commutators of the components of B with the magnetic momenta are nontrivial.

IV. MAGNETIC PSEUDODIFFERENTIAL OPERATORS

Our intention is to elaborate a functional calculus for the *noncommutative* family of self-adjoint operators $\{Q_j,\Pi_k\}_{j,k=1}^N$. We shall call it *the Weyl calculus with magnetic field*. As in the nonmagnetic case, we obtain it by an analog of the Fourier inversion formula, the magnetic Weyl system of the preceding section playing the part of the imaginary exponential. The resulting formula has the right gauge covariance. The operators involved are all integral operators and by the kernel theorem they can also be defined for symbols which are tempered distributions. The problem of identifying finite-rank, Hilbert–Schmidt and compact operators is also addressed. For this, an extension of the classical Fourier–Wigner transform (cf. Ref. 10) is of great help. It also shows *a posteriori* the irreducibility of our magnetic Weyl system. In the final part of the section we compare the magnetic Weyl calculus and the composition of the usual Weyl caculus with the minimal coupling prescription. They are different but, striking enough, they give the same result in many important cases. This explains perhaps the fact that the quantization of observables in a magnetic field has not been treated properly before in a suitable generality. We note, however, that

in Ref. 22 one finds (in a nonsystematic setting) the right attitude for the case of periodic symbols depending only on p. We thank George Nenciu for drawing our attention to this reference.

Let us finally remark that for a constant magnetic field, using a linear vector potential, one is lead to a change of the canonic symplectic form of the space $\Xi = X \times X^\star$, while for nonconstant magnetic fields one is quantizing a symplectic manifold (with a nonconstant symplectic form of the special type $\sigma_B := \sigma + B$) associated to the same linear space Ξ.

A. The functional calculus

We define the linear mapping

$$\mathfrak{Op}^A : \mathcal{F}_\Xi L^1(\Xi) \to \mathcal{B}(L^2(X)), \quad \mathfrak{Op}^A(f) := \int_\Xi d\xi \ \ (\mathcal{F}_\Xi^{-1} f)(\xi) \ \ W^A(\xi) \tag{27}$$

in a weak sense: if $u, v \in \mathcal{H} := L^2(X)$, then $\langle v, \mathfrak{Op}^A(f) u \rangle = \int_\Xi d\xi \ \ (\mathcal{F}_\Xi^{-1} f)(\xi) \langle v, W^A(\xi) u \rangle$. It clearly satisfies the estimate $\|\mathfrak{Op}^A(f)\| \leqslant \|\mathcal{F}_\Xi^{-1} f\|_{L^1}$.

Using the expression of the operators $W^A(\xi)$ given in (14) and (15) we obtain, at least formally, the explicit form of the operators $\mathfrak{Op}^A(f)$,

$$(\mathfrak{Op}^A(f) u)(x) = \int_X dy \int_{X^\star} dk \ \ e^{i(x-y)\cdot k} \tilde{\Lambda}^A(x,y) f\left(\frac{x+y}{2}, k\right) u(y), \tag{28}$$

where $\tilde{\Lambda}^A(x,y) := e^{-i\Gamma^A([x,y])} = \Lambda^A(x; y-x)$. For $A = 0$ this is the usual Weyl prescription to quantize a classical symbol, encountered in the theory of pseudodifferential operators. For general (continuous) A this is, in our opinion, the right formula that should stand for $f(Q, \Pi^A)$.

In fact, the precise sense of (27) and (28) and of their equivalence depends on our assumptions on f and u. In the next paragraphs, under certain hypothesis on the magnetic field, we shall cover the very general case in which f is a tempered distribution; then both formulas will make sense with a suitable reinterpretation and actually define the same object. If f is subject to suitable strong decay assumptions, then no special condition is needed (except our standing convention that A is continuous). All is smooth, for example, if f is in the Schwartz class $\mathcal{S}(\Xi)$. On the other hand, once again without any assumption on the magnetic field, (27) can be extended straightforwardly to f's that are Fourier transforms of bounded complex measures on Ξ. Now, of course, (28) needs a reinterpretation.

To advocate our choice of the mapping $\mathfrak{Op}^A$, an important point is to note *gauge covariance*:

Proposition 4: Let A and A' be two continuous vector potentials defining the same continuous magnetic field: $dA = B = dA'$. *Then there exists a real C^1-function ρ on X such that $A' = A + \nabla\rho$ and we have $e^{i\rho(Q)} W^A(\xi) e^{-i\rho(Q)} = W^{A+\nabla\rho}(\xi)$ for all $\xi \in \Xi$ and $e^{i\rho(Q)} \mathfrak{Op}^A(f) e^{-i\rho(Q)} = \mathfrak{Op}^{A+\nabla\rho}(f)$ for all $f \in \mathcal{F}_\Xi L^1(\Xi)$.*

Proof: It is well-known (cf. Ref. 20, for example) that if $dA = B = dA'$ and A, A' have L^1_{loc}-components, then there exists ρ (in some suitable local Sobolev space that does not matter here) such that $A' - A = \nabla\rho$ in a distributional sense. Now, since in our case A and A' are continuous, ρ will be of class C^1 by a simple argument. The two identities are verified by trivial calculations based on the relation

$$e^{i\rho(Q)} e^{ix\cdot P} e^{-i\rho(Q)} = e^{-i[\rho(Q+x)-\rho(Q)]} e^{ix\cdot P} = e^{-ix\cdot \int_0^1 ds \ \ \nabla\rho(Q+sx)} e^{ix\cdot P}.$$

■

Remark: One implements Planck's constant, at the level of the physical momentum, by setting $P = \hbar D := -i\hbar\nabla$. This gives for the magnetic Weyl system

$$W^A_\hbar(x,p) = e^{-i(Q + (\hbar/2)x)\cdot p} e^{-(i/\hbar)\Gamma^A([Q, Q+\hbar x])} e^{i\hbar x\cdot D}$$

and the $\hbar$-dependent magnetic two-cocycle will be $\Omega_\hbar^B(q;x,y)=e^{-(i/\hbar)\,\Gamma^B(\langle q,q+\hbar x,q+\hbar x+\hbar y\rangle)}$. We collect here, for the convenience of the reader, formulas for the magnetic Weyl calculus,

$$(\mathfrak{Op}_\hbar^A(f)u)(x)=\hbar^{-N}\int_X dy\int_{X^\star}dk\;\; e^{(i/\hbar)(x-y)\cdot k}e^{-(i/\hbar)\,\Gamma^A([x,y])}f\left(\frac{x+y}{2},k\right)u(y),$$

and for the magnetic Moyal product (subject of Sec. V),

$$(f\circ_\hbar^B g)(\xi)=\left(\frac{2}{\hbar}\right)^{2N}\int_\Xi d\eta\int_\Xi d\zeta\;\; e^{-2(i/\hbar)\,\sigma(\xi-\eta,\xi-\zeta)}e^{-(i/\hbar)\,\Gamma^B(\langle q-y+x,x-q+y,y-x+q\rangle)}f(\eta)g(\zeta).$$

In the sequel $\hbar$ will always be 1.

Remark: One often uses instead of (1) *the τ-quantizations* ($\tau\in[0,1]$), given by (cf. Ref. 28)

$$[\mathfrak{Op}_{(\tau)}(f)u](x):=\int_{\mathbb{R}^{2N}}dy\;\; dp\;\; e^{i(x-y)\cdot p}f((1-\tau)x+\tau y,p)u(y).$$

They are somehow connected with the ordering of Q and P in the expression of $f(Q,P)$. The cases $\tau=0$ and $\tau=1$ are called respectively *the right* and *the left quantization*. Rather often, in texbooks, only the case $\tau=0$ is treated. But the Weyl prescription $\mathfrak{Op}\equiv\mathfrak{Op}_{(1/2)}$ is preferred in quantum mechanics because of its nice property $\mathfrak{Op}(f)^*=\mathfrak{Op}(\overline{f})$.

We obtain the magnetic analog of $\mathfrak{Op}_{(\tau)}$ by replacing $W^A(\xi)$ with

$$W_{(\tau)}^A(x,p):=e^{i(1-\tau)x\cdot p}U^A(-x)V(p)=e^{-i\tau x\cdot p}V(p)U^A(-x),\quad x\in X,p\in X^\star.$$

A short formal calculation shows that the definition $\mathfrak{Op}_{(\tau)}^A(f):=\int_\Xi d\xi\;\;(\mathcal{F}_\Xi^{-1}f)(\xi)\;\;W_{(\tau)}^A(\xi)$ leads to

$$[\mathfrak{Op}_{(\tau)}^A(f)u](x):=\int_{\mathbb{R}^{2N}}dy\;\; dp\;\; e^{i(x-y)\cdot p}e^{-i\Gamma^A([x,y])}f((1-\tau)x+\tau y,p)u(y),$$

which allows a rigorous treatment analogous to that given for $\mathfrak{Op}^A\equiv\mathfrak{Op}_{(1/2)}^A$ in the sequel.

B. The distribution kernel

$\mathfrak{Op}^A(f)$ is an integral operator having a kernel that can be defined in terms of f and "the phase function" $\tilde{\Lambda}^A$. In fact, let us introduce the one-to-one linear change of variables $(x,y)\mapsto S(x,y):=(x+y/2,x-y/2)$ and denote by the same symbol S the induced transformation on functions $(S\Phi)(x,y):=\Phi(S(x,y))=\Phi(x+y/2,x-y/2)$. The explicit form of the inverse is $S^{-1}(x,y)=((x+y)/2,x-y)$. We can now define [on $\mathcal{S}(\Xi)$ for instance] the map

$$K^A:=\tilde{\Lambda}^A S^{-1}(\mathbf{1}\otimes\overline{\mathcal{F}}_{X^\star}),\tag{29}$$

composed of a partial Fourier transform, a change of variables and a multiplication operator. It is easy to verify that $\mathfrak{Op}^A(f)$ is the integral operator with kernel K^Af. For functions Φ defined on $X\times X$ we shall denote by $\mathfrak{Int}(\Phi)$ the integral operator on $L^2(X)$ with kernel Φ, so that one can write $\mathfrak{Op}^A(f)=\mathfrak{Int}(K^Af)$.

For further use we shall introduce two more notations, trying to emphasize the special role played by the phase factor $\tilde{\Lambda}^A$. We define "the zero magnetic field analog" of K^A, the map $K:=S^{-1}(\mathbf{1}\otimes\overline{\mathcal{F}}_{X^\star})$ and the magnetic integral operator associated to a kernel Φ as $\mathfrak{Int}^A(\Phi):=\mathfrak{Int}(\tilde{\Lambda}^A\Phi)$. With these notations one may write for any $f\in\mathcal{S}(\Xi)$

$$\mathfrak{Op}^A(f)=\mathfrak{Int}(K^Af)=\mathfrak{Int}^A(Kf).\tag{30}$$

We use now these facts to extend the operation $\mathfrak{Op}^A$ to distributions. Let us assume that the components of the magnetic field are C^∞_{pol} functions, i.e., they are indefinitely derivable and any derivative is polynomially bounded. These types of functions are also called *with tempered growth*; their main virtue is that by multiplication they leave the Schwartz space $\mathcal{S}$ invariant, hence they define by duality multiplication operators on $\mathcal{S}'$. The formula (16) for the transversal gauge shows that the vector potential A can also be chosen of class C^∞_{pol}. By easy calculations, $\widetilde{\Lambda}^A$ will also be C^∞_{pol} in both variables. Then it is clear that K^A defines isomorphisms $\mathcal{S}(\Xi)\tilde{\to}\mathcal{S}(X\times X)$ and $\mathcal{S}'(\Xi)\tilde{\to}\mathcal{S}'(X\times X)$.

On the other hand, let us recall that for any finite dimensional vector space $\mathcal{V}$, the spaces $\mathcal{S}(\mathcal{V})$ and $\mathcal{S}'(\mathcal{V})$ are nuclear and we have linear topological isomorphisms (see, for example, Ref. 30, Theorem 51.6 and its Corollary)

$$\mathcal{S}(X)\otimes\mathcal{S}(X)\cong\mathcal{S}(X\times X),\quad \mathcal{S}'(X)\otimes\mathcal{S}'(X)\cong\mathcal{S}'(X\times X). \tag{31}$$

Here the tensor product is the closure of the algebraic tensor product for the injective or the projective topologies that coincide in this case (we refer to Ref. 30, Theorem 50.1). We shall be interested in the following spaces of linear continuous operators: $\mathcal{L}[\mathcal{S}(X),\mathcal{S}'(X)]$, $\mathcal{L}[\mathcal{S}'(X),\mathcal{S}(X)]$ and $\mathcal{L}[\mathcal{S}(X)]\cong\mathcal{L}[\mathcal{S}'(X)]$. On all these spaces we consider the topology of uniform convergence on bounded sets. It is easy to see that we have the continuous linear injections

$$\mathcal{L}[\mathcal{S}'(X),\mathcal{S}(X)]\subset\mathcal{B}[L^2(X)]\subset\mathcal{L}[\mathcal{S}(X),\mathcal{S}'(X)]. \tag{32}$$

The conclusions of Sec. 50 in Ref. 30 and the Corollary of Theorem 51.6 in Ref. 30 imply that, isomorphically,

$$\mathfrak{Int}:\mathcal{S}(X\times X)\tilde{\to}\mathcal{L}[\mathcal{S}'(X),\mathcal{S}(X)],\quad \mathfrak{Int}:\mathcal{S}'(X\times X)\tilde{\to}\mathcal{L}[\mathcal{S}(X),\mathcal{S}'(X)]. \tag{33}$$

By putting together the information above about the operations K^A and $\mathfrak{Int}$, we get the following result concerning our functional calculus:

Proposition 5: If the potential vector A is of class C^∞_{pol}, the map $\mathfrak{Op}^A$ defines linear topological isomorphisms

$$\mathfrak{Op}^A:\mathcal{S}(\Xi)\tilde{\to}\mathcal{L}[\mathcal{S}'(X),\mathcal{S}(X)],\quad \mathfrak{Op}^A:\mathcal{S}'(\Xi)\tilde{\to}\mathcal{L}[\mathcal{S}(X),\mathcal{S}'(X)].$$

So "any" operator is (in a unique way) a magnetic pseudodifferential operator of the form $\mathfrak{Op}^A(f)$ for some tempered distribution f and the regularizing operators are exactly those with symbol in the Schwartz space.

Gauge covariance can be extended to this setting; we leave the details to the reader:

Proposition 6: Let A and A' be two vector potentials of class C^∞_{pol} defining the same magnetic field, $dA=B=dA'$. Then there exists a real function $\rho\in C^\infty_{pol}(X)$ such that $A'=A+\nabla\rho$ and $e^{i\rho(Q)}\mathfrak{Op}^A(f)e^{-i\rho(Q)}=\mathfrak{Op}^{A+\nabla\rho}(f)$ for any $f\in\mathcal{S}'(\Xi)$; this second identity is valid in $\mathcal{L}[\mathcal{S}(X),\mathcal{S}'(X)]$.

C. The magnetic Fourier–Wigner transformation and special classes of operators

Definition 7: (a) For any pair of vectors u,v from $\mathcal{H}=L^2(X)$ we define the function

$$\mathcal{W}^A_{u,v}:\Xi\to\mathbb{C},\quad \mathcal{W}^A_{u,v}(\xi):=\langle v,W^A(\xi)u\rangle, \tag{34}$$

called *the magnetic Fourier–Wigner transform of the couple* (u,v).

(b) The map $(v,u)\mapsto\mathcal{W}^A_{u,v}$ will be called *the magnetic Fourier–Wigner transformation* (defined by the vector potential A).

In fact $\mathfrak{Op}^A(f)$ was defined by $\langle v,\mathfrak{Op}^A(f)u\rangle=\int_\Xi d\xi\ \ (\mathcal{F}^{-1}_\Xi f)(\xi)\mathcal{W}^A_{u,v}(\xi),\ \ u,v\in\mathcal{H}$.

Proposition 8: (*a*) *The magnetic Fourier–Wigner transformation extends to a unitary operator* $\mathcal{W}^A:L^2(X\times X)\to L^2(\Xi)$.

(*b*) *If A is of class* C^∞_{pol}, *then the magnetic Fourier–Wigner transformation defines isomorphisms* $\mathcal{W}^A:\mathcal{S}(X\times X)\to\mathcal{S}(\Xi)$ *and* $\mathcal{W}^A:\mathcal{S}'(X\times X)\to\mathcal{S}'(\Xi)$.

Proof: Using the explicit form of $W^A(\xi)$ we obtain

$$\mathcal{W}^A_{u,v}=[(\mathbf{1}\otimes\mathcal{F}_X)\mathfrak{I}S(\tilde{\Lambda}^A)^{-1}](u\otimes\overline{v}), \tag{35}$$

where $\mathfrak{I}$ is the composition with the change of variables $(x,y)\mapsto(y,x)$ on $X\times X$. Under the right asumption, each of the maps $\mathbf{1}\otimes\mathcal{F}_X$, $\mathfrak{I}$, S and $(\tilde{\Lambda}^A)^{-1}$ is an isomorphism between the corresponding spaces. One also uses the reinterpretation $\mathcal{W}^A_{u,v}\equiv\mathcal{W}^A_{u\otimes\overline{v}}$. ■

An important direct consequence of this result is the following.

Corollary 9: The Weyl system with magnetic field $W^A:\Xi\to\mathcal{U}[L^2(X)]$ *is irreducible, i.e., there are no nontrivial subspaces of* $L^2(X)$ *invariant under all the operators* $\{W^A(\xi)|\xi\in\Xi\}$.

Proof: Suppose that $\mathcal{K}$ is a closed nontrivial subspace of $L^2(X)$, invariant under all the operators $W^A(\xi)$, $\xi\in\Xi$. Let $v\in\mathcal{K}^\perp$ be different from 0. Then for any $u\in\mathcal{K}\backslash\{0\}$ we have $W^A(\xi)u\in\mathcal{K}$ for any $\xi\in\Xi$, so that

$$\mathcal{W}^A_{u,v}(\xi)=\langle v,W^A(\xi)u\rangle=0,\quad\forall\xi\in\Xi.$$

Thus we deduce that $\|\mathcal{W}^A_{u,v}\|_{L^2(\Xi)}=0$. But $\|\mathcal{W}^A_{u,v}\|_{L^2(\Xi)}=\|u\|\|v\|$ and we get a contradiction. ■

Remark: The Fourier–Wigner transformation also serves to express the operators $\mathfrak{Op}^A(F)$ in a convenient way. Let us stick, for example, to the case in which A has tempered growth. Then for all $u,v\in\mathcal{S}(X)$ and $F\in\mathcal{S}'(\Xi)$, one has $\langle v,\mathfrak{Op}^A(F)u\rangle=\langle\overline{\mathcal{W}^A_{u,v}},\mathcal{F}^{-1}_\Xi F\rangle$, the left-hand-side being interpreted as the anti-duality between $\mathcal{S}(X)$ and $\mathcal{S}'(X)$, while the right-hand-side as the anti-duality between $\mathcal{S}(\Xi)$ [cf. Proposition 8, (b)] and $\mathcal{S}'(\Xi)$.

We shall identify now finite-rank, Hilbert–Schmidt and compact operators.

Proposition 10: (*a*) *For any* $u,v\in\mathcal{H}$ *we have* $|u\rangle\langle v|=\mathfrak{Op}^A(\mathcal{F}_\Xi\mathcal{W}^A_{u,v})$.

(*b*) $\mathfrak{Op}^A$ *induces a unitary map from* $L^2(\Xi)$ *to* $\mathcal{B}_2(\mathcal{H})$, *the ideal of Hilbert–Schmidt operators.*

(*c*) *The family* $\mathfrak{Op}^A[\mathcal{F}_\Xi L^1(\Xi)]$ *is dense in the closed ideal* $\mathcal{K}(\mathcal{H})$ *of all compact operators in* $\mathcal{H}$.

Proof: (a) The operator $|u\rangle\langle v|$ is an integral operator having the kernel $u\otimes\overline{v}$. Thus

$$|u\rangle\langle v|=\mathfrak{Int}(u\otimes\overline{v})=\mathfrak{Op}^A[(K^A)^{-1}(u\otimes\overline{v})].$$

One has

$$(K^A)^{-1}(u\otimes\overline{v})=(\mathbf{1}\otimes\mathcal{F}_X)S(\tilde{\Lambda}^A)^{-1}(u\otimes\overline{v})=(\mathbf{1}\otimes\mathcal{F}_X)\mathfrak{I}(\mathbf{1}\otimes\overline{\mathcal{F}_{X\star}})(\mathbf{1}\otimes\mathcal{F}_X)\mathfrak{I}S(\tilde{\Lambda}^A)^{-1}(u\otimes\overline{v}).$$

But, by a simple calculation, one gets $(\mathbf{1}\otimes\mathcal{F}_X)\mathfrak{I}(\mathbf{1}\otimes\overline{\mathcal{F}_{X\star}})=\mathcal{F}_\Xi$. The point (a) follows by taking (35) into account.

(b) On the intersection $\mathcal{F}_\Xi L^1(\Xi)\cap L^2(\Xi)$ we have $\mathfrak{Op}^A=\mathfrak{Int}\circ K^A$, where $K^A:L^2(\Xi)\to L^2(X\times X)$ is unitary and $\mathfrak{Int}:L^2(X\times X)\to\mathcal{B}_2(\mathcal{H})$ is also unitary (a classical result). But $\mathcal{F}_\Xi L^1(\Xi)\cap L^2(\Xi)$ is dense in $L^2(\Xi)$.

(c) By (b), for all $f\in\mathcal{F}_\Xi L^1(\Xi)\cap L^2(\Xi)$ the operator $\mathfrak{Op}^A(f)$ is Hilbert–Schmidt, hence compact. The space $\mathcal{F}_\Xi L^1(\Xi)\cap L^2(\Xi)$ is dense in $L^2(\Xi)$, thus $\mathfrak{Op}^A[\mathcal{F}_\Xi L^1(\Xi)\cap L^2(\Xi)]$ is dense in $\mathcal{B}_2(\mathcal{H})$ with respect to the Hilbert–Schmidt norm, hence also with respect to the operator norm. It follows that $\mathfrak{Op}^A[\mathcal{F}_\Xi L^1(\Xi)\cap L^2(\Xi)]$ is dense in $\mathcal{K}(\mathcal{H})$. But $\mathfrak{Op}^A[\mathcal{F}_\Xi L^1(\Xi)]$ is also contained in $\mathcal{K}(\mathcal{H})$, since $\mathcal{F}_\Xi L^1(\Xi)\cap L^2(\Xi)$ is dense in $\mathcal{F}_\Xi L^1(\Xi)$ and $\|\mathfrak{Op}^A(f)\|_{\mathcal{B}(\mathcal{H})}\leqslant\|f\|_{\mathcal{F}_\Xi L^1}:=\|\mathcal{F}^{-1}_\Xi f\|_{L^1}$, $\forall f$. ■

We see that $\mathfrak{Op}^A$ has a strong tendency towards irreducibility: $\mathcal{K}(\mathcal{H})$ is, of course, irreducible, thus, by density, $\mathfrak{Op}^A[\mathcal{F}_\Xi L^1(\Xi)\cap L^2(\Xi)]$ is also an irreducible family of operators in $\mathcal{H}$. Other results of this type may be obtained by density.

D. The correct form of the minimal coupling principle

The loose form of the minimal coupling principle says that "when a magnetic field $B=dA$ is turned on, one should replace the canonical variable p with $p-A(x)$." The question is, of course, at which stage should this replacement be performed when quantization of a classical observable f is intended. The wrong answer is to compose $f:\Xi\to\mathbb{C}$ with the change of variables $(x,p)\mapsto(x,p-A(x))$ and then apply the Weyl calculus. As seen in the Introduction, this would give a gauge non-covariant formula. The right approach is to apply to f itself a modified (magnetic) Weyl calculus. And this modification is governed actually by the sound, elementary form of the minimal coupling principle: the quantum observable P is replaced by $\Pi^A=P-A(Q)$ and this object determines the expression of the Weyl system W^A, used in the definition of $f(Q,\Pi^A)$. One could say that this is correct, since W^A summarizes the commutation relations of the family of operators $(Q_1,\ldots,Q_N;\Pi_1^A,\ldots,\Pi_N^A)$ for which a functional calculus is requested.

However, one could ask for a more sophisticated (and not so clear ideologically) form of the minimal coupling principle: find a transformation T^A acting on phase-space functions such that, for any f, $f(Q,\Pi^A)$ is obtained (also) by Weyl quantizing the symbol $T^Af\equiv f^A$. A brief examination of this topic follows.

Let us assume, for convenience, that B and A are of class C^∞_{pol}. Both $\mathfrak{Op}^A$ and $\mathfrak{Op}$ are one-to-one (even isomorphic) from $\mathcal{S}'(\Xi)$ to $\mathcal{L}[\mathcal{S}(X),\mathcal{S}'(X)]$. Using notations from Sec. IV B, one has

$$\mathfrak{Op}^A(f)=\mathfrak{Op}(f^A)\Leftrightarrow\mathfrak{Int}(K^Af)=\mathfrak{Int}(Kf^A)\Leftrightarrow f^A=K^{-1}K^Af.$$

By using explicit formulas for K^A and K and the identity $S\tilde{\Lambda}^AS^{-1}=\tilde{\Lambda}^A\circ S$, one gets $f^A=T^Af$, with

$$T^A:\mathcal{S}'(\Xi)\to\mathcal{S}'(\Xi),\quad T^A:=(\mathbf{1}\otimes\mathcal{F}_X)(\tilde{\Lambda}^A\circ S)(\mathbf{1}\otimes\overline{\mathcal{F}}_{X^\star}).$$

Formally (or for suitable f's)

$$(T^Af)(x,p)=\int_X\int_{X^\star}dydk\;\; e^{iy\cdot[k-p+\int_{-1/2}^{1/2}dt\;\; A(x+ty)]}f(x,k)$$

$$=\int_X dy\;\; e^{-iy\cdot[p-\int_{-1/2}^{1/2}dt\;\; A(x+ty)]}(\mathbf{1}\otimes\overline{\mathcal{F}}_{X^\star})]f(x,y).$$

One should compare this rather complicated formula (a sort of minimal coupling principle for all observables) with

$$(M^Af)(x,p):=f(x,p-A(x))=\int_X\int_{X^\star}dydk\;\; e^{iy\cdot[k-p+A(x)]}f(x,k).$$

The rigorous expression behind this formal integral is

$$M^A:\mathcal{S}'(\Xi)\to\mathcal{S}'(\Xi),\quad M^A:=(\mathbf{1}\otimes\mathcal{F}_X)\Sigma^A(\mathbf{1}\otimes\overline{\mathcal{F}}_{X^\star}),$$

with $\Sigma^A(x,y)=e^{iy\cdot A(x)}$, $x,y\in X$.

A comparison of the explicit formulas for T^A and M^A shows once again the difference between the correct and the mistaken quantizations in a magnetic field: *The correct one involves circulations of the magnetic potential A through segments* $[x_1,x_2]$, *while for the wrong one the same circulations are calculated by using the constant value* $A_{x_1,x_2}:=A((x_1+x_2/2))$, *taken at the middle of the respective segment.*

One has a complete characterization of the vector potentials for which the wrong quantization is good:

Lemma 11: One has $T^A=M^A$ [*which is equivalent to* $\mathfrak{Op}^A(f)=\mathfrak{Op}(M^Af)$, $\forall f\in\mathcal{S}'(\Xi)$] *if and only if* A *is linear*.

Proof: $\mathbf{1}\otimes\mathcal{F}_X$ and $\mathbf{1}\otimes\overline{\mathcal{F}}_{X^\star}$ being one-to-one, we have $T^A=M^A$ if and only if $\tilde{\Lambda}^A\circ S=\Sigma^A$, i.e., if and only if $y\cdot\int_{-1/2}^{1/2}dt\ [A(x+ty)-A(x)]=0$, $\forall x,y\in X$. A simple application of Taylor's formula shows that this is equivalent to the annulation of all the second derivatives of all the components of A. ■

One of the most important examples is the constant magnetic field. In this case, everybody would choose a linear potential vector A and no care is needed in the choice of the quantization procedure. Most articles involving a functional calculus in a magnetic field are written for constant B *and* linear A. Note, however, that the identity $T^A=M^A$ *is not gauge invariant.*

However, one can have $T^Af=M^Af$ for any A for certain special functions f. This is obviously true if f depends only on the variable $x\in X$. Actually, in this case $\mathfrak{Op}^A(f)=\mathfrak{Op}(M^Af)=f(Q)$. Let us give some more interesting examples.

Proposition 12: Let f *be a polynomial of order* m *in* p, *not depending on the variable in* X. *If* $m\leqslant 2$, *then* $T^Af=M^Af$, *hence* $\mathfrak{Op}^A(f)=\mathfrak{Op}(M^Af)$. *This is no longer true for* $m=3$.

Proof: Let us consider the monomial $f_\alpha(x,p):=p^\alpha$. Then we have $(\mathbf{1}\otimes\overline{\mathcal{F}}_{X^\star})f_\alpha=(-i\partial)^\alpha\delta$, thus $(T^Af)(x,p)=[(i\partial_y)^\alpha e^{-i\tau^A(x,p;y)}]|_{y=0}$ and $(M^Af)(x,p)=[(i\partial_y)^\alpha e^{-i\mu^A(x,p;y)}]|_{y=0}$, where the two phases are defined by $\tau^A(x,p;y):=y\cdot[p-\int_{-1/2}^{1/2}dt\ A(x+ty)]$ and $\mu^A(x,p;y):=y\cdot[p-A(x)]$. We concentrate on the cases $m=1,2,3$. The following list of relations is needed:

$$i\partial_{y_j}e^{-i\varphi}=(\partial_{y_j}\varphi)e^{-i\varphi},\quad i^2\partial_{y_k}\partial_{y_j}e^{-i\varphi}=(i\partial_{y_k}\partial_{y_j}\varphi+\partial_{y_k}\varphi\ \ \partial_{y_j}\varphi)e^{-i\varphi},$$

$$i^3\partial_{y_l}\partial_{y_k}\partial_{y_j}e^{-i\varphi}=(-\partial_{y_l}\partial_{y_k}\partial_{y_j}\varphi+i\partial_{y_j}\varphi\ \ \partial_{y_l}\partial_{y_k}\varphi+i\partial_{y_k}\varphi\ \ \partial_{y_l}\partial_{y_j}\varphi+i\partial_{y_l}\varphi\ \ \partial_{y_k}\partial_{y_j}\varphi+\partial_{y_l}\varphi\ \ \partial_{y_k}\varphi\ \ \partial_{y_j}\varphi)e^{-i\varphi}.$$

Note that $\partial_{y_j}\mu^A(x,p;y)=p_j-A_j(x)$, while the higher-order derivatives vanish.

A simple calculation gives

$$\partial_{y_j}\tau^A(x,p;y)=p_j-\int_{-1/2}^{1/2}dt\ \ A_j(x+ty)-\sum_{n=1}^{N}y_n\int_{-1/2}^{1/2}tdt\ \ (\partial_jA_n)(x+ty),$$

and by taking the value in $y=0$ one gets $[\partial_{y_j}\tau^A(x,p;y)]|_{y=0}=[\partial_{y_j}\mu^A(x,p;y)]|_{y=0}=p_j-A_j(x)$. Thus $T^Af=M^Af$ for any first-order polynomial. This is not amaizing: $\mathfrak{Op}^A(p_j)=\Pi^A$ was accepted as a basic principle.

One also has

$$\partial_{y_k}\partial_{y_j}\tau^A(x,p;y)=-\int_{-1/2}^{1/2}tdt\ \ (\partial_jA_k+\partial_kA_j)(x+ty)-\sum_{n=1}^{N}y_n\int_{-1/2}^{1/2}t^2dt\ \ (\partial_k\partial_jA_n)(x+ty).$$

By "miracle" this term vanishes in $y=0$; then straightforwardly $T^Af=M^Af$ also for second-order polynomials. This is significant, since most of the time people considered the case $f(x,p)=|p|^2$, leading to the magnetic Laplacian $\Delta^A=(\Pi^A)^2$; no care is needed in this case.

The situation changes drastically for third order polynomials. One has

$$\partial_{y_l}\partial_{y_k}\partial_{y_j}\tau^A(x,p;y)=-\int_{-1/2}^{1/2}t^2dt\ \ (\partial_k\partial_jA_l+\partial_l\partial_jA_k+\partial_l\partial_kA_j)(x+ty)$$
$$-\sum_{n=1}^{N}y_n\int_{-1/2}^{1/2}t^3dt\ \ (\partial_l\partial_k\partial_jA_n)(x+ty),$$

which in $y=0$ takes the value $-\frac{1}{12}(\partial_k\partial_jA_l+\partial_l\partial_jA_k+\partial_l\partial_kA_j)(x)$. In this case $T^Af\neq M^Af$. ■

V. THE MAGNETIC MOYAL ALGEBRA

We come now to an important point in the development of our functional calculus. The product of the operators $\mathfrak{Op}^A(f)$ and $\mathfrak{Op}^A(g)$ is again an integral operator with a kernel $K^A(f \circ^B g)$, which can formally be associated to the function on Ξ obtained by the following noncommutative composition law, called *the magnetic Moyal product of the functions f and g*:

$$(f\circ^B g)(\xi)=4^N\int_\Xi d\eta\int_\Xi d\zeta\ \ e^{-2i\sigma(\xi-\eta,\xi-\zeta)}e^{-i\Gamma^B(\langle q-y+x,x-q+y,y-x+q\rangle)}f(\eta)g(\zeta)$$

$$=4^N\int_\Xi d\eta\int_\Xi d\zeta\ \ e^{-2i\sigma(\eta,\zeta)}e^{-i\Gamma^B(\langle q-x-y,q+x-y,q+y-x\rangle)}f(\xi-\eta)g(\xi-\zeta);\quad (36)$$

here $\xi=(q,p)$, $\eta=(x,k)$, $\zeta=(y,l)$. Thus we have $\mathfrak{Op}^A(f\circ^B g)=\mathfrak{Op}^A(\underline{f})\mathfrak{Op}^A(g)$. We can also define an involution (the same as in the nonmagnetic case) by $f^\circ(\xi):=\overline{f(\xi)}$ such that $\mathfrak{Op}^A(f^\circ)=\mathfrak{Op}^A(f)^*$.

The integral defining $f\circ^B g$ is absolutely convergent only for restricted classes of symbols. One seeks to extend the composition law $\circ^B$ to large classes of distributions in such a way as to obtain (together with the involution $^\circ$) *-algebras. For any choice of a magnetic potential, the functional calculus with magnetic field will be a representation of these *-algebras. But the algebras themselves are completely intrinsic, being defined only in terms of the magnetic field. We shall do this extension by duality, following the approach of Refs. 4 and 13 (see also Refs. 14 and 9) valid in the absence of the magnetic field. We obtain a magnetic analog of the Moyal algebra outlined in Sec. II D; the terminology is that of the references above and it is suggested by some early fundamental work of Moyal (cf. Ref. 25).

The standard technique of extending the composition law, based on oscillatory integrals and classes of symbols, is less appropriate for our present purposes. But we intend to deal with this topic in a subsequent publication.

A. The magnetic Moyal product

Before discussing rigorously the sense of formula (36) for various assumptions on f, g and B, we make some formal remarks. Note that if $B=0$, (36) reduces to the usual composition of symbols (13) in the Weyl quantization. The magnetic correction consists of a phase factor defined in terms of the flux of the magnetic field through suitable triangles. The associativity of the above composition law comes from the two-cocycle condition, the second identity in (20). For this just notice that $e^{-i\Gamma^B(\langle q-y+x,x-q+y,y-x+q\rangle)}=\Omega^B(q-y+x;2y-2q,2q-2x)$ and do the right calculation. Finally, it is easy to check that $\mathfrak{Op}^A(f\circ^B g)=\mathfrak{Op}^A(f)\mathfrak{Op}^A(g)$ whenever everything is well-defined.

In general, if no special assumption on B is imposed, it is not so easy to define and use sharply the magnetic Moyal product. For $f,g\in\mathcal{F}_\Xi L^1(\Xi)$ both $\mathfrak{Op}^A(f)$ and $\mathfrak{Op}^A(g)$ are defined as bounded linear operators in $\mathcal{H}=L^2(X)$, but it is not clear if their product is of the form $\mathfrak{Op}^A(h)$ for some h (eventually in $\mathcal{F}_\Xi L^1(\Xi)$). On the other hand, if $f,g\in L^1(\Xi)$, then the integral in (36) is absolutely convergent and defines a bounded continuous function on Ξ. However, we do not see why this function should be integrable and, anyway, applying $\mathfrak{Op}^A$ to all these is problematic. One can also take advantage of Proposition 10(b) to endow $L^2(\Xi)$ with the structure of a *-algebra, the composition law coinciding with (36) on suitable subsets.

In fact many other solutions exist but *they do not seem to be natural enough in the present framework*. In a future publication we will give another (equivalent) form of the magnetic Moyal product (a ''very twisted convolution'') for which it will be relatively easy to define nice normed *-algebras. Their pull-backs in the pseudo-differential representation involve a partial Fourier transformation that does not have an explicitly expressible range. So we postpone the study of magnetic composition laws for general (continuous) magnetic fields and turn to a special case which is, however, very comprehensive.

Proposition 13: Assume that the components of the magnetic field B are of class C^∞_{pol}.

(*a*) *For any* $f,g\in\mathcal{S}(\Xi)$ *one has* $f\circ^B g\in\mathcal{S}(\Xi)$. *The map* $\circ^B:\mathcal{S}(\Xi)\times\mathcal{S}(\Xi)\to\mathcal{S}(\Xi)$ *is bilinear and continuous.*

(*b*) *For any continuous vector potential* A *such that* $dA=B$, *one has* $\mathfrak{Op}^A(f\circ^B g)=\mathfrak{Op}^A(f)\mathfrak{Op}^A(g)$.

Proof: One can prove that $\mathcal{S}(\Xi)\circ^B\mathcal{S}(\Xi)\subset\mathcal{S}(\Xi)$ directly, estimating $\xi^\alpha\partial^\beta(f\circ^B g)$ by involved manipulations in (36). This also gives the required continuity. We prefer to outline a simpler proof, based on integral kernels.

Let us choose $A\in C^\infty_{\mathrm{pol}}(X,X^\star)$ such that $dA=B$; this is possible by (16). We know that the maps $K^A:=\widetilde{\Lambda}^A S^{-1}(\mathbf{1}\otimes\overline{\mathcal{F}}_{X^\star}):\mathcal{S}(\Xi)\to\mathcal{S}(X\times X^\star)$, $\mathfrak{Int}:\mathcal{S}(X\times X^\star)\to\mathcal{L}[\mathcal{S}'(X),\mathcal{S}(X)]$ and $\mathfrak{Op}^A:\mathcal{S}(\Xi)\to\mathcal{L}[\mathcal{S}'(X),\mathcal{S}(X)]$ are topological isomorphisms and that $\mathfrak{Op}^A=\mathfrak{Int}\circ K^A$. One checks easily that $K^A(f\circ^B g)=K^A(f)\ddagger K^A(g)$, where $(L\ddagger M)(x,y):=\int_X dz\ L(x,z)M(z,y)$ is the composition rule of integral kernels (leading to the product of the integral operators involved). These facts and the continuity of $\ddagger:\mathcal{S}(X\times X^\star)\times\mathcal{S}(X\times X^\star)\to\mathcal{S}(X\times X^\star)$ imply both the points (a) and (b) for $A\in C^\infty_{\mathrm{pol}}(X,X^\star)$.

The general case of a continuous A in (b) is solved by gauge covariance, cf. Proposition 4 (we consider here $\mathcal{L}[\mathcal{S}'(X),\mathcal{S}(X)]$ embedded in $\mathcal{B}[L^2(X)]$). ■

Since $\mathcal{S}(\Xi)$ is obviously stable under involution, $(\mathcal{S}(\Xi),\circ^B,^\circ)$ is a *-algebra (all the axioms are easily verified) and $\mathfrak{Op}^A:\mathcal{S}(\Xi)\to\mathcal{L}[\mathcal{S}'(X),\mathcal{S}(X)]$ is a *-isomorphism. Unfortunately, $\mathcal{S}(\Xi)$ is too small for many purposes. For instance, functions depending only on x or on p are not included.

B. Extension by duality

We start extending by duality the magnetic Moyal product with an asymmetric version: we shall compose a Schwartz test function with a tempered distribution. The result is *a priori* a tempered distribution, but we shall be able to get more precise information in certain cases. The components of the magnetic field will be always considered to be in C^∞_{pol}, thus the conclusions of Proposition 13 hold.

The duality approach is facilitated by the next lemma:

Lemma 14: For any functions f *and* g *in* $\mathcal{S}(\Xi)$ *we have*

$$\int_\Xi d\xi\ \ (f\circ^B g)(\xi)=\int_\Xi d\xi\ \ (g\circ^B f)(\xi)=\int_\Xi d\xi\ \ f(\xi)g(\xi)=\langle\overline{f},g\rangle\equiv(f,g).$$

Proof: Of course, one needs only to show that $\int_\Xi d\xi\ \ (f\circ^B g)(\xi)=\int_\Xi d\xi\ \ f(\xi)g(\xi)$; the other identities are trivial consequences.

The calculation will be straightforward by regularization. We choose sequences $(a_n)_{n\in\mathbb{N}}\in\mathcal{S}(X)$, $(b_n)_{n\in\mathbb{N}}\in\mathcal{S}(X^\star)$ such that $a_n\to 1$ in $\mathcal{S}'(X)$ and $b_n\to 1$ in $\mathcal{S}'(X^\star)$. Then it is shown easily that

$$\int_X\int_{X^\star}dq\ \ dp\ \ (f\circ^B g)(q,p)a_n(q)b_m(p)\to\int_X\int_{X^\star}dq\ \ dp\ \ f(q,p)g(q,p)$$

for $n,m\to\infty$. For this we use the explicit formula for $f\circ^B g$, Fubini's theorem, the fact that the Fourier transforms of a_n and b_m converge respectively to the distribution δ and the annulation of $\Gamma^B(\langle q-y+x,x-q+y,y-x+q\rangle)$ for $x=y$. We leave the details to the reader. ■

Corollary 15: For any three functions f, g *and* h *in* $\mathcal{S}(\Xi)$ *we have*

$$(f\circ^B g,h)=(f,g\circ^B h)=(g,h\circ^B f).$$

Proof: Easy consequence of the lemma, the associativity of $\circ^B$ and the symmetry of $(\cdot,\cdot)$. ■

Definition 16: For any distribution $F\in\mathcal{S}'(\Xi)$ and any function $f\in\mathcal{S}(\Xi)$ we define

$$(F\circ^B f,h):=(F,f^\circ\circ^B h),\quad (f\circ^B F,h):=(F,h\circ^B f^\circ),\quad \forall h\in\mathcal{S}(\Xi).$$

By using Proposition 13(a) and the definition it is straightforward to see the following.

Proposition 17: The above definition provides two bilinear continuous mappings $\mathcal{S}'(\Xi)\times\mathcal{S}(\Xi)\to\mathcal{S}'(\Xi)$, *resp.* $\mathcal{S}(\Xi)\times\mathcal{S}'(\Xi)\to\mathcal{S}'(\Xi)$.

One easily checks that $(F\circ^B g)^\circ = g^\circ\circ^B F^\circ$ and $(g\circ^B F)^\circ = F^\circ\circ^B g^\circ$, for all $F\in\mathcal{S}'(\Xi)$ and $g\in\mathcal{S}(\Xi)$. Associativity results as $(f_1\circ^B F)\circ^B f_2 = f_1\circ^B(F\circ^B f_2)$, for $f_1, f_2\in\mathcal{S}(\Xi)$, $F\in\mathcal{S}'(\Xi)$ obviously hold, so one can define unambiguously $f_1\circ^B\cdots\circ^B f_n$ if one f_j is a tempered distribution and all the others are Schwartz test functions. Lemma 14 implies immediately that $1\circ^B f = f = f\circ^B 1$, $\forall f\in\mathcal{S}(\Xi)$.

Proposition 18: For any vector potential A with tempered growth, $\mathfrak{Op}^A$ *is an involutive linear continuous map*: $\mathcal{S}'(\Xi)\mapsto\mathcal{L}[\mathcal{S}(X),\mathcal{S}'(X)]$, *satisfying* $\mathfrak{Op}^A(F\circ^B g)=\mathfrak{Op}^A(F)\mathfrak{Op}^A(g)$ *and* $\mathfrak{Op}^A(g\circ^B F)=\mathfrak{Op}^A(g)\mathfrak{Op}^A(F)$ *for all* $F\in\mathcal{S}'(\Xi)$ *and* $g\in\mathcal{S}(\Xi)$.

Proof: We already know that $\mathfrak{Op}^A:\mathcal{S}'(\Xi)\mapsto\mathcal{L}[\mathcal{S}(X),\mathcal{S}'(X)]$ is an isomorphism of topological vector spaces. The involution on $\mathcal{L}[\mathcal{S}(X),\mathcal{S}'(X)]$ is defined by antiduality ($\langle T^*v,u\rangle=\langle v,Tu\rangle$, $\forall u,v\in\mathcal{S}(X)$). Then the formula $\mathfrak{Op}^A(F)^*=\mathfrak{Op}^A(F^\circ)$ follows readily from the Remark in Sec. IV C. The relations $\mathfrak{Op}^A(F\circ^B g)=\mathfrak{Op}^A(F)\mathfrak{Op}^A(g)$ and $\mathfrak{Op}^A(g\circ^B F)=\mathfrak{Op}^A(g)\mathfrak{Op}^A(F)$ follow by approximating $F\in\mathcal{S}'(\Xi)$ with elements f_n of $\mathcal{S}(\Xi)$; all the continuity properties which are needed are already proved.

C. The magnetic Moyal *-algebras

Definition 19: (a) The spaces of distributions

$$\mathcal{M}_L(\Xi) := \{F\in\mathcal{S}'(\Xi) \;\mid\; F\circ^B f\in\mathcal{S}(\Xi),\quad \forall f\in\mathcal{S}(\Xi)\}$$

and

$$\mathcal{M}_R(\Xi) := \{F\in\mathcal{S}'(\Xi) \;\mid\; f\circ^B F\in\mathcal{S}(\Xi),\quad \forall f\in\mathcal{S}(\Xi)\}$$

will be called, respectively, *the left* and *the right magnetic Moyal algebras*.

(b) Their intersection

$$\mathcal{M}(\Xi) := \mathcal{M}_L(\Xi)\cap\mathcal{M}_R(\Xi)$$

will be called *the magnetic Moyal algebra*.

The three spaces above depend on the magnetic field so, in principle, they would deserve an index B.

For any two distributions F and G in $\mathcal{M}(\Xi)$ we can extend the magnetic Moyal product by

$$(F\circ^B G,h) := (F,G\circ^B h),\quad \forall h\in\mathcal{S}(\Xi).$$

Proposition 20: The set $\mathcal{M}(\Xi)$ *together with the composition law* $\circ^B$ *defined as above and the complex conjugation* $F\mapsto F^\circ$ *is an unital *-algebra, containing* $\mathcal{S}(\Xi)$ *as a self-adjoint two-sided ideal*.

All the verifications are trivial. Since the constant functions are obviously in $\mathcal{M}(\Xi)$, it is already clear that the *-algebra $\mathcal{S}(\Xi)$ is enlarged. We shall see in Sec. V D that this enlargement is substantial.

We study now the behavior of $\mathfrak{Op}^A$ on symbols belonging to the magnetic Moyal algebra.

Proposition 21: $\mathfrak{Op}^A$ *is an isomorphism of *-algebras betweeen* $\mathcal{M}(\Xi)$ *and* $\mathcal{L}[\mathcal{S}(X)]\cap\mathcal{L}[\mathcal{S}'(X)]$.

Proof: Let us denote simply $\mathcal{S}=\mathcal{S}(X)$ and $\mathcal{S}'=\mathcal{S}'(X)$. We identify $\mathcal{L}(\mathcal{S})\equiv\mathcal{L}(\mathcal{S},\mathcal{S})$ with the family of all the elements $T\in\mathcal{L}(\mathcal{S},\mathcal{S}')$ such that $T\mathcal{S}\subset\mathcal{S}$. By the closed graph theorem, such a T will automatically be continuous (and linear) as a mapping $\mathcal{S}\mapsto\mathcal{S}$. $\mathcal{L}(\mathcal{S})$ is obviously an algebra with the composition of operators.

Another algebra is $\mathcal{L}(\mathcal{S}')\equiv\mathcal{L}(\mathcal{S}',\mathcal{S}')$, which may be identified with the family of elements $T\in\mathcal{L}(\mathcal{S},\mathcal{S}')$ that admit a continuous extension to $\mathcal{S}'$. We recall that the involution on $\mathcal{L}(\mathcal{S},\mathcal{S}')$ is defined by antiduality $(\langle T^*u,w\rangle=\langle u,Tw\rangle,\ \forall u,w\in\mathcal{S})$. Then, plainly, $\mathcal{L}(\mathcal{S})^*=\mathcal{L}(\mathcal{S}')$ and $\mathcal{L}(\mathcal{S}')^*=\mathcal{L}(\mathcal{S})$. Thus $\mathcal{L}(\mathcal{S})\cap\mathcal{L}(\mathcal{S}')$ is a *-algebra.

We know that $\mathfrak{Op}^A$ is one-to-one; we calculate now $\mathfrak{Op}^A[\mathcal{M}(\Xi)]$. By the definition of $\mathcal{M}(\Xi)$ and Proposition 5, T is in $\mathfrak{Op}^A[\mathcal{M}(\Xi)]$ if and only if $T\mathcal{L}(\mathcal{S}',\mathcal{S})\subset\mathcal{L}(\mathcal{S}',\mathcal{S})$ and $\mathcal{L}(\mathcal{S}',\mathcal{S})T\subset\mathcal{L}(\mathcal{S}',\mathcal{S})$. The last inclusion is equivalent to $T^*\mathcal{L}(\mathcal{S}',\mathcal{S})\subset\mathcal{L}(\mathcal{S}',\mathcal{S})$. It is easy to see that $T\mathcal{L}(\mathcal{S}',\mathcal{S})\subset\mathcal{L}(\mathcal{S}',\mathcal{S})$ if and only if $T\in\mathcal{L}(\mathcal{S})$. One implication is trivial and the other one follows once again from the closed graph theorem and from the fact that for any $v\in\mathcal{S}$ there exist $u\in S'$ and $S\in\mathcal{L}(\mathcal{S}',\mathcal{S})$ such that $Su=v$. Then, by taking also T^* into account, we see that $\mathfrak{Op}^A[\mathcal{M}(\Xi)]=\mathcal{L}(\mathcal{S})\cap\mathcal{L}(\mathcal{S}')$.

Let $F,G\in\mathcal{M}(\Xi)$. We calculate for $u\in\mathcal{S}'$ and $h\in\mathcal{S}(\Xi)$

$$\mathfrak{Op}^A(F\circ^B G)[\mathfrak{Op}^A(h)u]=\mathfrak{Op}^A(F\circ^B G\circ^B h)u=\mathfrak{Op}^A(F)[\mathfrak{Op}^A(G\circ^B h)u]$$
$$=[\mathfrak{Op}^A(F)\mathfrak{Op}^A(G)]\mathfrak{Op}^A(h)u,$$

where we used Proposition 18. Since any $v\in\mathcal{S}$ can be written as $\mathfrak{Op}^A(h)u$ for some $u\in\mathcal{S}'$ and $h\in\mathcal{S}(\Xi)$, the multiplicative property of $\mathfrak{Op}^A$ on $\mathcal{M}(\Xi)$ is shown.

The involutivity of $\mathfrak{Op}^A$ is valid on $\mathcal{S}'(\Xi)$, as remarked before. ■

Remark: Propositions 20 and 21 are the most important results. We note here rapidly some extra results concerning the magnetic Moyal algebras, all of an elementary nature. One also defines by duality products of the form $F_1\circ^B G\circ^B F_2\in\mathcal{S}'(\Xi)$ for $F_1\in\mathcal{M}_R(\Xi)$, $F_2\in\mathcal{M}_L(\Xi)$ and $G\in\mathcal{S}'(\Xi)$; $\mathcal{S}'(\Xi)$ is a $(\mathcal{M}_R(\Xi),\mathcal{M}_L(\Xi))$-bimodule. In fact $\mathcal{M}_L\circ^B\mathcal{M}_L\subset\mathcal{M}_L$ and $\mathcal{M}_R\circ^B\mathcal{M}_R\subset\mathcal{M}_R$, hence $\mathcal{M}_L$ and $\mathcal{M}_R$ are algebras. But they are different and correspond to each other by complex conjugation, so $\mathcal{M}$ is optimally defined as a *-algebra by the present methods. The proof of Proposition 21 also leads to $\mathfrak{Op}^A\mathcal{M}_L(\Xi)=\mathcal{L}(\mathcal{S})$ and $\mathfrak{Op}^A\mathcal{M}_R(\Xi)=\mathcal{L}(\mathcal{S}')$.

The next striking result shows once more the importance of the magnetic Moyal algebras.

Proposition 22: One has $\mathcal{S}'(\Xi)\circ^B\mathcal{S}(\Xi)\subset\mathcal{M}_R(\Xi)$ *and* $\mathcal{S}(\Xi)\circ^B\mathcal{S}'(\Xi)\subset\mathcal{M}_L(\Xi)$.

Proof:

$$\mathfrak{Op}^A[\mathcal{S}'(\Xi)\circ^B\mathcal{S}(\Xi)]=\mathfrak{Op}^A[\mathcal{S}'(\Xi)]\mathfrak{Op}^A[\mathcal{S}(\Xi)]=\mathcal{L}(\mathcal{S},\mathcal{S}')\mathcal{L}(\mathcal{S}',\mathcal{S})=\mathcal{L}(\mathcal{S}')\subset\mathfrak{Op}^A\mathcal{M}_R(\Xi),$$

thus $\mathcal{S}'(\Xi)\circ^B\mathcal{S}(\Xi)\subset\mathcal{M}_R(\Xi)$. The other inclusion is proved analogously. ■

We note that both the inclusions are strict. For zero magnetic field $f\circ G$ is smooth if $f\in\mathcal{S}(\Xi)$ and $G\in\mathcal{S}'(\Xi)$, cf. Ref. 13.

D. Some important subclasses

We keep the setting of the preceding paragraphs, i.e., the components of B (and those of A when necessary) are of class C^∞_{pol}. Simple examples show readily that $\mathcal{M}(\Xi)$ is much larger than $\mathcal{S}(\Xi)$. One shows easily that if $f(x,p)=f_1(x)$ depends only on the variable in X, then $\mathfrak{Op}^A(f)=f_1(Q)$. If f_1 has tempered growth, then $f_1(Q)\in\mathcal{L}(\mathcal{S})\cap\mathcal{L}(\mathcal{S}')$, thus $f\in\mathcal{M}(\Xi)$ by Proposition 21. It is also quite obvious that $\mathcal{F}_\Xi L^1(\Xi)\subset\mathcal{M}(\Xi)$, since $W^A(\xi)$ is a continuous operator in $\mathcal{S}$ for all $\xi\in\Xi$. Actually, the same argument would also show that Fourier transforms of bounded, complex measures on Ξ are also in the magnetic Moyal algebra. In the sequel we shall outline a less evident example.

Let $C^\infty_{\mathrm{pol,u}}(\Xi)\subset\mathcal{S}'(\Xi)$ be the space of indefinitely derivable complex functions on Ξ having uniform polynomial growth at infinity; i.e., $f\in C^\infty_{\mathrm{pol,u}}(\Xi)$ when it is indefinitely derivable and there exists $m\in\mathbb{N}$ (depending on f) such that for any multi-index $a\in\mathbb{N}^{2N}$ one has $|(\partial^a f)(\xi)|\leqslant C_a\langle\xi\rangle^m$ for all $\xi\in\Xi$.

Proposition 23: $C^\infty_{\mathrm{pol,u}}(\Xi)\subset\mathcal{M}(\Xi)$.

Proof: First we reduce our proof to a precise estimate. Classes of functions $\mathcal{T}(\Xi)$ will be denoted briefly by $\mathcal{T}$.

For any $m\in\mathbb{R}$ we set $S_0^m:=\{f\in C^\infty|\langle\cdot\rangle^{-m}\partial^a f\in L^\infty,\ \forall a\in\mathbb{N}^{2N}\}$ and $R_0^m:=\{f\in C^\infty|\langle\cdot\rangle^{-m}\partial^a f\in L^1,\ \forall a\in\mathbb{N}^{2N}\}$. The reason for introducing these function spaces is the fact that $C^\infty_{\mathrm{pol,u}}(\Xi)=\cup_{m\in\mathbb{R}}S_0^m=\cup_{m\in\mathbb{R}}R_0^m$. This follows from $R_0^m\subset S_0^m\subset R_0^{m+2N+\varepsilon}$, valid for any $m\in\mathbb{R}$ and any $\varepsilon>0$, which is shown by trivial estimates. So the proposition will be proved if we show that $R_0^m\subset\mathcal{M},\ \forall m\in\mathbb{R}$.

In fact the spaces S_0^m were introduced only for comparison. They are the first constituents of $C^\infty_{\mathrm{pol,u}}$ you would think of, but technically the classes R_0^m are better suited, since L^1-inequalities in initial spaces are within reach (for example we have $\|f\circ^B g\|_\infty\leqslant\|f\|_1\|g\|_1$). R_0^m is a locally convex space with the family of norms $\{r_n^m\}_{n\in N}$, where $r_n^m(f):=\Sigma_{|a|\leqslant n}\|\partial^a[\langle\cdot\rangle^{-m}f]\|_1$ (other, equivalent, family is obtained by writing ∂^a and $\langle\cdot\rangle^{-m}$ in reversed order.)

Since $\mathcal{S}$ is dense in R_0^m, to show that $R_0^m\subset\mathcal{M}$ it will be sufficient to prove that for any $g\in\mathcal{S}$ the mappings $\mathcal{S}\ni f\mapsto f\circ^B g\in\mathcal{S}$ and $\mathcal{S}\ni f\mapsto g\circ^B f\in\mathcal{S}$ are continuous if on the initial space $\mathcal{S}$ we consider the topology induced from R_0^m. We shall treat the first mapping; in fact this is enough, since R_0^m is left invariant by complex conjugation.

In the sequel we shall always write $\xi=(q,p)$, $\eta=(x,k)$ and $\zeta=(y,l)$. We also set $\phi^B(q,x,y):=e^{-i\Gamma^B(\langle q-y+x,x-q+y,y-x+q\rangle)}$; it is a function in C^∞_{pol} with $|\phi^B(q,x,y)|=1$. By taking into account the discussion above and the form of the seminorms on $\mathcal{S}$, we see that it is enough to prove that for any $g\in\mathcal{S}$, $\alpha,\beta,\gamma,\delta\in\mathbb{N}^N$ and $m\in\mathbb{R}$ (we shall take m to be an even positive integer) there exist $n\in\mathbb{N}$ and $C<\infty$ (they both depend on everything) such that

$$\|q^\alpha p^\beta\partial_q^\gamma\partial_p^\delta(f\circ^B g)\|_\infty\leqslant Cr_n^m(f).$$

Now the proof will proceed in several steps:

Step 1: A simple calculation gives

$$[q^\alpha p^\beta\partial_q^\gamma\partial_p^\delta(f\circ^B g)](q,p)=\sum_{\gamma'\leqslant\gamma}C_{\gamma'}^{\alpha\beta\gamma\delta}\int_\Xi\int_\Xi d\eta\ \ d\zeta\ \ q^\alpha p^\beta(k-l)^{\gamma'}(y-x)^\delta \times e^{-2i\sigma(\xi-\eta,\xi-\zeta)}(\partial_q^{\gamma-\gamma'}\phi^B)(q,x,y)f(\eta)g(\zeta).$$

The Leibnitz rule was used, as well as the two identities

$$\partial_p^\delta e^{-2i\sigma(\xi-\eta,\xi-\zeta)}=(2i)^{|\delta|}(y-x)^\delta e^{-2i\sigma(\xi-\eta,\xi-\zeta)},$$

$$\partial_q^{\gamma'}e^{-2i\sigma(\xi-\eta,\xi-\zeta)}=(2i)^{|\gamma'|}(k-l)^{\gamma'}e^{-2i\sigma(\xi-\eta,\xi-\zeta)}.$$

Step 2: Having in view the form of r_n^m, we write $f(\eta)=\langle\eta\rangle^m[\langle\eta\rangle^{-m}f(\eta)]$ (m even). By developing, the factor $\langle\eta\rangle^m$ contributes with terms of the form $x^\mu k^\nu$. Thus, we need to estimate objects as

$$\int_\Xi\int_\Xi d\eta\ \ d\zeta\ \ q^{\alpha_1}x^{\alpha_2}(y-x)^{\alpha_3}p^{\alpha_4}k^{\alpha_5}(k-l)^{\alpha_6}e^{-2i\sigma(\xi-\eta,\xi-\zeta)}\varphi(q,x,y)[\langle\eta\rangle^{-m}f(\eta)]g(\eta).$$

Here φ is C^∞_{pol} in all the variables; the zeroth order derivative is no longer bounded and this will cause some complications.

Step 3: The heart of the proof lies in exploiting the nice properties of the factor $e^{-2i\sigma(\xi-\eta,\xi-\zeta)}$ by integrations by parts (an oscillatory integral technique). This works efficiently only with respect to certain of the variables. We produce these variables by making linear combinations of other, non-convenient ones. Let us write, for instance, $p=(p-l)+l$, $k-l=(k-p)+(p-l)$ and $k=(k-l)+l=(k-p)+(p-l)+l$. Then, plainly, we are reduced to estimating terms of the form

$$\int_\Xi \int_\Xi d\eta \;\; d\zeta \;\; q^{\beta_1} x^{\beta_2} (y-x)^{\beta_3} l^{\beta_4} (p-k)^{\beta_5} (p-l)^{\beta_6} e^{-2i\sigma(\xi-\eta,\xi-\zeta)} \varphi(q,x,y)$$
$$\times [\langle \eta \rangle^{-m} f(\eta)] g(\eta).$$

Step 4: We use

$$(p-k)^{\beta_5}(p-l)^{\beta_6} e^{-2i\sigma(\xi-\eta,\xi-\zeta)} = (2i)^{-|\beta_5|}(-2i)^{-|\beta_6|} \partial_y^{\beta_5} \partial_x^{\beta_6} [e^{-2i\sigma(\xi-\eta,\xi-\zeta)}].$$

After an integration by parts and an application of Leibnitz's rule we see that we are reduced to bound terms as

$$\int_\Xi \int_\Xi d\eta \;\; d\zeta \;\; \psi(q,x,y) e^{-2i\sigma(\xi-\eta,\xi-\zeta)} \partial_x^{\gamma_1} [\langle \eta \rangle^{-m} f(\eta)] l^{\gamma_2} (\partial_y^{\gamma_3} g)(\zeta)$$

for some unbounded C^∞_{pol}-function ψ. Actually, only the polynomial estimate on ψ itself will count now.

Step 5: Polynomial bounds are very democratic with respect to the choice of variables; use for example inequalities of the form $\langle x+y \rangle \leqslant 2^{1/2} \langle x \rangle \langle y \rangle$. Thus we can write

$$\psi(q,x,y) = \left[\frac{\psi(q,x,y)}{\langle y \rangle^j \langle q-x \rangle^j \langle q-y \rangle^j} \right] \;\; [\langle y \rangle^j \langle q-x \rangle^j \langle q-y \rangle^j]$$

and the first factor will be bounded for j large enough. By developing, we need to estimate

$$\int_\Xi \int_\Xi d\eta \;\; d\zeta \;\; \rho(q,x,y)(q-x)^{\delta_1}(q-y)^{\delta_2} e^{-2i\sigma(\xi-\eta,\xi-\zeta)} \partial_x^{\delta_3} [\langle \eta \rangle^{-m} f(\eta)] y^{\delta_4} l^{\delta_5} (\partial_y^{\delta_6} g)(\zeta),$$

where now ρ is bounded.

Step 6: But one has

$$(q-x)^{\delta_1}(q-y)^{\delta_2} e^{-2i\sigma(\xi-\eta,\xi-\zeta)} = (-2i)^{-|\delta_1|}(2i)^{-|\delta_2|} \partial_l^{\delta_1} \partial_k^{\delta_2} e^{-2i\sigma(\xi-\eta,\xi-\zeta)}.$$

We perform our last integration by parts, reducing ourselves to estimate

$$\int_\Xi \int_\Xi d\eta \;\; d\zeta \;\; \rho(q,x,y) e^{-2i\sigma(\xi-\eta,\xi-\zeta)} \partial_k^{\delta_2} \partial_x^{\delta_3} [\langle \eta \rangle^{-m} f(\eta)] y^{\delta_4} [\partial_l^{\delta_1} \partial_y^{\delta_6} (l^{\delta_5} g)](\zeta).$$

Step 7: Obviously, this integral is dominated for any ξ by $\| \partial_k^{\delta_2} \partial_x^{\delta_3} \times [\langle \cdot \rangle^{-m} f] \|_1 \;\; \| y^{\delta_4} [\partial_l^{\delta_1} \partial_y^{\delta_6} (l^{\delta_5} g)] \|_1$. The first factor is part of the norm $r_n^m(f)$ for some large n and the second is one of the seminorms of g in $\mathcal{S}$. The proposition is proved and, as a bonus, we found out that $(f,g) \mapsto f \circ^B g$ extends to a bilinear *jointly continuous* mapping: $R_0^m \times \mathcal{S} \to \mathcal{S}$. ■

The class $C^\infty_{\mathrm{pol,u}}(\Xi)$ is indeed convenient. It has a very explicit definition and it contains all the polynomials in x and p. It also contains the classical symbol spaces $S^m(\Xi) := \{ f \in C^\infty(\Xi) \,|\, |(\partial^a f)(\xi)| \leqslant C_a \langle \xi \rangle^{m-|a|}, \;\; \forall a \in \mathbb{N}^{2N} \}$ for all m.

The magnetic Moyal algebra is large indeed, but many distributions, even with a good behavior at infinity, are not inside. The one-rank projection $|u\rangle\langle u|$ is in $\mathcal{L}(\mathcal{S})$ if and only if $u \in \mathcal{S}$. Thus, by Proposition 21, there are plenty of elements in $L^2(\Xi)$ not belonging to $\mathcal{M}(\Xi)$.

ACKNOWLEDGMENTS

Our understanding of the pseudodifferential theory without magnetic fields was influenced by unpublished lecture notes of Vladimir Georgescu and a book in preparation by Gruia Arsu. We are grateful to George Nenciu and Mihai Pascu for useful discussions. Part of this work was done

while the authors were visiting the Department of Theoretical Physics of the University of Geneva. We are grateful to Werner Amrein for his kind hospitality. We also acknowledge partial support from the EURROMMAT Pogramme (Contract No. ICA1-CT-2000-70022), the CERES Programme (Contract No. 38/2002) and the CNCSIS Grant No. 33536/2003.

Note added. After inserting the preprint of this paper on the mp-arc electronic archieve, T. A. Osborn brought to our attention the paper ''Symplectic area, quantization, and dynamics in electromagnetic fields,'' J. Math. Phys. **43**, 756–788 (2002) by M. V. Karasev and T. A. Osborn and the more recent preprint ''Quantum Magnetic Algebras and Magnetic Curvature,'' arXiv:quant-ph/0311053 by the same authors, where a gauge invariant quantization in the presence of an inhomogeneous electromagnetic tensor is developed in a way similar to ours. The above papers are concerned mainly with the geometric aspects related to this calculus and some interesting connections with grupoids. Our approach motivated by C^*-algebraic methods in spectral analysis for quantum Hamiltonians [see our previous paper: M. Măntoiu and R. Purice, *The Algebra of Observables in a Magnetic Field*, Mathematical Results in Quantum Mechanics (Taxco, 2001), Contemporary Mathematics Vol. 307 (AMS, Providence, RI, 2002), pp. 239–245] aims mainly to the analytic aspects of this quantization procedure (the main results of our Sec V).

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 45, NUMBER 4 APRIL 2004

On the absolutely continuous and negative discrete spectra of Schrödinger operators on the line with locally integrable globally square summable potentials

Alexei Rybkin[a)]
Department of Mathematical Sciences, University of Alaska, Fairbanks, Fairbanks, Alaska 99775

(Received 6 October 2003; accepted 16 December 2003)

For one-dimensional Schrödinger operators with potentials q subject to $\Sigma_{n=-\infty}^{\infty}(\int_n^{n+1}|q(x)|dx)^2<\infty$, we prove that the absolutely continuous spectrum is $[0,\infty)$, extending the 1999 result due to Dieft–Killip. As a by-product we show that under the same condition the sequence of the negative eigenvalues is 3/2-summable improving the relevant result by Lieb–Thirring. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1650048]

I. INTRODUCTION

The main object of our consideration is the Schrödinger operator,

$$H=-d^2/dx^2+q(x), \quad \text{on } \mathbb{R}:=(-\infty,\infty), \tag{1.1}$$

with a real slowly decaying potential q. For the background information, literature, and open problems we refer to the recent surveys[12,13] by Simon. In this paper we will be concerned with the essential support of the absolutely continuous (a.c.) spectrum $\sigma_{\text{a.c.}}(H)$ of H for L_2-type potentials without smoothness assumptions. It was proved in 1999 by Dieft–Killip[2] that

$$q\in L_2(\mathbb{R})+L_1(\mathbb{R})\Rightarrow\sigma_{\text{a.c.}}(H)=\mathbb{R}_+:=[0,\infty), \tag{1.2}$$

settling down one conjecture due to Kiselev–Last–Simon[8] which drew considerable attention. We are unable to review here the extensive literature devoted to it and refer the interested reader to, e.g., Christ–Kiselev,[1] Killip,[6] and the literature cited therein. Relevant to our note, the best Christ–Kiselev result is

$$q\in l_p(L_1(\mathbb{R})), \quad 1<p<2\Rightarrow\sigma_{\text{a.c.}}(H)=\mathbb{R}_+, \tag{1.3}$$

where $l_p(L_1)$ stands for the Birman–Solomyak class $(0<p\leqslant\infty)$,

$$f\in l_p(L_1(\mathbb{R}))\Leftrightarrow\left\{\int_n^{n+1}|f(x)|dx\right\}\in l_p(\mathbb{Z}), \quad \mathbb{Z}=\{0,\pm1,\pm2,\dots\}.$$

Since $L_2+L_1\subset l_2(L_1)$ there is a certain mismatch between (1.2) and (1.3). Killip[7] informed the author about his conjecture that (1.3) holds for $p=2$. In the present article we give an affirmative answer to this question. Actually we prove even more.

Theorem 1: *Let q be real valued and from $l_2(L_1(\mathbb{R}))$. Then*

$$\sigma_{\text{a.c.}}(H)=\mathbb{R}_+, \tag{1.4}$$

and the negative discrete spectrum $\{-\kappa_j^2\}$ satisfies

a)Electronic mail: ffavr@uaf.edu

$$\sum_j \kappa_j^3 < \infty. \tag{1.5}$$

Note that (1.5) extends the Lieb–Thirring bounds,[9]

$$\sum_j \kappa_j^3 \leqslant C \int_{\mathbb{R}} q^2(x)dx,$$

to include $l_2(L_1)$ potentials. The improved bounds will be given in Ref. 11.

We note that a complete treatment of rather general Dirac operators with square summable potentials was recently done by Denisov[3] who besides a proper analog of (1.2) also proved the existence of relevant wave operators.

II. A LEMMA ON A WKB-TYPE ASYMPTOTICS

The following technical lemma will play a crucial role in our consideration.

Lemma 1: Let $q \in l_2(L_1(\mathbb{R}_+))$, then the equation,

$$-u'' + q(x)u = \lambda^2 u, x \in \mathbb{R}_+, \tag{2.1}$$

has a solution $\Psi(x,\lambda)$ which can be represented in the domain Λ of all points (x,λ), $x \in \mathbb{R}_+$ and $\lambda \in \mathbb{C}_+ := \{\lambda \in \mathbb{C}: \operatorname{Im}\lambda > 0\}$ such that

$$(\operatorname{Im}\lambda)^{-1}(2 + (\operatorname{Im}\lambda)^{-1})^2 \|q\chi_x\|^2_{l_2(L_1)} < 1/4 \tag{2.2}$$

[where χ_x is the indicator of (x,∞)] in the form

$$\Psi(x,\lambda) = y(x,\lambda)\exp\left\{ i\lambda x + \int_0^x Q(s,\lambda)ds \right\}, \tag{2.3}$$

where

$$Q(x,\lambda) := -\int_x^\infty e^{2i\lambda(s-x)} q(s)ds, \tag{2.4}$$

and $y(x,\lambda)$ is some continuous function satisfying $((x,\lambda) \in \Lambda)$,

$$|y(x,\lambda) - 1| \leqslant 4(\operatorname{Im}\lambda)^{-1}(2 + (\operatorname{Im}\lambda)^{-1})^2 \|q\chi_x\|^2_{l_2(L_1)}. \tag{2.5}$$

Proof: Let us prove first that if $q \in l_2(L_1(\mathbb{R}_+))$ then $Q(\cdot,\lambda) \in L_2(\mathbb{R})$ for every $\operatorname{Im}\lambda > 0$. Indeed, by Jensen's inequality,

$$\begin{aligned}
|Q(x,\lambda)|^2 &= \left| \sum_{n \geqslant 0} \int_n^{n+1} e^{2i\lambda s} q(s+x)ds \right|^2 \\
&\leqslant \left\{ \sum_{n \geqslant 0} e^{-2n \operatorname{Im}\lambda} \left(\int_n^{n+1} |q(s+x)|ds \right) \right\}^2 \\
&\leqslant \sum_{n \geqslant 0} e^{-2n \operatorname{Im}\lambda} \cdot \sum_{n \geqslant 0} e^{-2 \operatorname{Im}\lambda n} \left(\int_n^{n+1} |q(s+x)|ds \right)^2 \\
&= \frac{1}{1 - e^{-2 \operatorname{Im}\lambda}} \sum_{n \geqslant 0} e^{-2 \operatorname{Im}\lambda n} \left(\int_n^{n+1} |q(s+x)|ds \right)^2.
\end{aligned} \tag{2.6}$$

Integrating (2.6) with respect to x one has

$$\|Q(\cdot,\lambda)\|_2^2 \leqslant \left(1+\frac{1}{2\operatorname{Im}\lambda}\right)\sum_{n\geqslant 0} e^{-2\operatorname{Im}\lambda n}\int_0^\infty\left(\int_n^{n+1}|q(s+x)|ds\right)^2 dx. \tag{2.7}$$

Observe now that

$$\begin{aligned}\int_0^\infty\left(\int_n^{n+1}|q(s+x)|ds\right)^2 dx &= \sum_{m\geqslant 0}\int_m^{m+1}\left(\int_x^{x+1}|q|\right)^2 dx\\ &\leqslant \sum_{m\geqslant 0}\left(\int_m^{m+2}|q|\right)^2\\ &\leqslant 2\sum_{m\geqslant 0}\left\{\left(\int_m^{m+1}|q|\right)^2+\left(\int_{m+1}^{m+2}|q|\right)^2\right\}\\ &= 4\sum_{m\geqslant 0}\left(\int_m^{m+1}|q|\right)^2\\ &= 4\|q\|_{l_2(L_1)}^2.\end{aligned} \tag{2.8}$$

Plugging (2.8) into (2.7), one has

$$\|Q(\cdot,\lambda)\|_2^2 \leqslant \left(1+\frac{1}{2\operatorname{Im}\lambda}\right)\sum_{n\geqslant 0} e^{-\operatorname{Im}\lambda n}\cdot 4\|q\|_{l_2(L_1)}^2 \leqslant \left(2+\frac{1}{\operatorname{Im}\lambda}\right)^2\|q\|_{l_2(L_1)}^2,$$

that is

$$\|Q^2(\cdot,\lambda)\|_1 \leqslant \|Q(\cdot,\lambda)\|_2^2 \leqslant \left(2+\frac{1}{\operatorname{Im}\lambda}\right)^2\|q\|_{l_2(L_1)}^2. \tag{2.9}$$

By inspection

$$\Theta(x,\lambda) := \exp\left\{i\lambda x+\int_0^x Q(s,\lambda)ds\right\}$$

is a solution to

$$-u''+(q(x)+Q^2(x,\lambda))u=\lambda^2 u. \tag{2.10}$$

If $u_1(x,\lambda)=\Theta(x,\lambda)$ is a solution to (2.10) then as the other solution we choose

$$u_2(x,\lambda)=\Theta(x,\lambda)\int_0^x \Theta^{-2}(s,\lambda)ds.$$

Rewriting the original equation (2.1) as

$$-u''+(q(x)+Q^2(x,\lambda))u-\lambda^2 u=Q^2(x,\lambda)u, \tag{2.11}$$

by variation of parameters one easily verifies (formally) that (2.11) implies ($y=\Theta^{-1}u$)

$$y(x,\lambda)=1+\int_x^\infty K(x,s,\lambda)y(s,\lambda)ds, \tag{2.12}$$

with the kernel

$$K(x,s,\lambda) := Q^2(s,\lambda)\cdot\Theta^2(s,\lambda)\int_x^s \Theta^{-2}(t,\lambda)dt. \tag{2.13}$$

To justify this formal computation it is enough to show that $K(x,\cdot,\lambda)\in L_1$ for every $x\in\mathbb{R}_+$, $\lambda\in\mathbb{C}_+$. By (2.9), $Q^2(\cdot,\lambda)\in L_1$ and it is only left to demonstrate that $\Theta^2(s,\lambda)\int_x^s\Theta^{-2}(t,\lambda)dt$ is bounded. Indeed,

$$\begin{aligned}\left|\Theta^2(s,\lambda)\int_x^s\Theta^{-2}(t,\lambda)dt\right| &= \left|\int_x^s \exp^2\left\{i\lambda(s-t)+\int_t^s Q(t,\lambda)dt\right\}dt\right| \\ &\leqslant \left|\int_0^{s-x}\exp^2\left\{-\operatorname{Im}\lambda\, t\left(1-\frac{1}{\operatorname{Im}\lambda}\|Q(\cdot,\lambda)\|_\infty\right)\right\}\right| \\ &\leqslant \int_0^\infty \exp(-\operatorname{Im}\lambda\, t)dt = \frac{1}{\operatorname{Im}\lambda}\end{aligned}$$

and, by (2.9), we have

$$\|K(x,\cdot,\lambda)\|_1 \leqslant \frac{1}{\operatorname{Im}\lambda}\|Q^2(\cdot,\lambda)\|_1 \leqslant \frac{1}{\operatorname{Im}\lambda}\left(2+\frac{1}{\operatorname{Im}\lambda}\right)^2\|q\|^2_{l_2(L_1)}.$$

The standard iteration procedure completes the proof. ■

Remark 1: One can easily see that, up to a factor, solution (2.3) has the WKB-type asymptotic behavior,

$$\Psi(x,\lambda)\sim\exp\left\{i\lambda x+\frac{1}{2i\lambda}\int_0^x q(s)ds\right\},\quad x\to\infty, \tag{2.14}$$

for every $\lambda\in\mathbb{C}_+$. We, by no means, claim that Lemma 1 proves (2.14) for almost all real λ for every potential q from $l_2(L_1(\mathbb{R}_+))$. Theorem 1 would be immediately proven then. It is a very difficult open question and the best known result here belongs to Christ–Kiselev.[1] Using some very elaborate techniques, they showed that (2.14) holds for a.e. real λ for $q\in l_p(L_1(\mathbb{R}_+))$,$1<p<2$. This was exactly their way to prove (1.3). Our approach requires (2.14) only for $\lambda\in\mathbb{C}_+$.

III. PROOF OF THEOREM 1

We employ the standard approach. We first get all necessary formulas for the truncated potentials $\tilde{q}$ defined as

$$\tilde{q}(x)=q(x)\chi_{[-a,a]}(x),\quad a>0;$$

$\chi_{[-a,a]}$ denotes the characteristic function of $[-a,a]$, and then pass to the limit when $\tilde{q}\to q$ (i.e., $a\to\infty$). In the sequel, we agree to put $\tilde{}$ on top of every object related to $\tilde{q}$.

Let us evaluate the transmission coefficient $\tilde{T}(\lambda)$ for $\lambda\in\mathbb{C}_+$ in two different ways. Following Faddeev–Zhakharov[4] (adopting the convention $\int := \int_{-\infty}^{\infty}$),

$$\tilde{T}(\lambda)=\prod_j\frac{\lambda+i\tilde{\kappa}_j}{\lambda-i\tilde{\kappa}_j}\exp\left\{i\int\frac{\tilde{f}(k)}{k-\lambda}dk\right\}, \tag{3.1}$$

where $-\tilde{\kappa}_j^2$ are negative eigenvalues of $\tilde{H}$ and

$$\tilde{f}(k) := \frac{1}{\pi}\log|\tilde{T}(k)|^{-1}. \tag{3.2}$$

Due to the general properties of the transmission coefficient, the function $\tilde{f}$ is integrable, nonnegative, and even and hence

$$\int \frac{\widetilde{f}(k)}{k-\lambda}dk=-\frac{1}{\lambda}\int \widetilde{f}(k)dk+\frac{1}{\lambda^2}\int \frac{k^2\widetilde{f}(k)}{k-\lambda}dk=-\frac{1}{\lambda}\int \widetilde{f}(k)dk+\frac{2}{\lambda}\int_0^\infty \frac{k^2\widetilde{f}(k)}{k^2-\lambda^2}dk. \quad (3.3)$$

We have used here the obvious identity

$$\frac{1}{k-\lambda}=-\frac{k}{\lambda^2}-\frac{1}{\lambda}+\frac{1}{\lambda^2}\frac{k^2}{k-\lambda}.$$

By the first Buslaev–Faddeev–Zhakharov trace formula,[4]

$$-2\sum_j \widetilde{\kappa}_j+\int \widetilde{f}(k)dk=\frac{1}{2}\int \widetilde{q}(x)dx, \quad (3.4)$$

and (3.3) can be continued,

$$\int \frac{\widetilde{f}(k)}{k-\lambda}dk=-\frac{1}{\lambda}\int \widetilde{f}(k)dk+\frac{2}{\lambda}\int_0^\infty \frac{k^2\widetilde{f}(k)}{k^2-\lambda^2}dk=-\frac{2}{\lambda}\sum_j \widetilde{\kappa}_j-\frac{1}{2\lambda}\int \widetilde{q}(x)dx+\frac{2}{\lambda}\int_0^\infty \frac{k^2\widetilde{f}(k)}{k^2-\lambda^2}dk. \quad (3.5)$$

Plugging (3.5) into (3.1) one has

$$\widetilde{T}(\lambda)=\prod_j \frac{\lambda+i\widetilde{\kappa}_j}{\lambda-i\widetilde{\kappa}_j}e^{2i/\lambda\widetilde{\kappa}_j}\cdot \exp\left\{\frac{2i}{\lambda}\int_0^\infty \frac{k^2\widetilde{f}(k)}{k^2-\lambda^2}dk\right\}\exp\left\{\frac{1}{2i\lambda}\int \widetilde{q}(x)dx\right\}. \quad (3.6)$$

On the other hand, following Hinton–Klaus–Shaw,[5]

$$\widetilde{T}(\lambda)=\frac{2i\lambda}{\widetilde{m}_+(\lambda^2)+\widetilde{m}_-(\lambda^2)}(\widetilde{F}_+(\lambda)\widetilde{F}_-(\lambda))^{-1}, \quad (3.7)$$

where $\widetilde{m}_\pm$ are the Weyl m-functions associated with $-d^2/dx^2+\widetilde{q}(x), u(\pm 0)=0$ on $L_2(\mathbb{R}_\pm)$ and $\widetilde{F}_\pm$ are the Jost functions of $\widetilde{H}=-d^2/dx^2+\widetilde{q}(x)$ on $L_2(\mathbb{R})$ corresponding to $\pm\infty$, respectively. We recall that for $q\in L_1(\mathbb{R})$ the equation

$$-u''+q(x)u=\lambda^2 u, x\in\mathbb{R}, \quad \operatorname{Im}\lambda^2\geqslant 0,$$

has two linearly independent solutions $u_\pm(x,\lambda)$, referred to as Jost, subject to

$$u_\pm(x,\lambda)=e^{\pm i\lambda x}(1+o(1)), x\to\pm\infty.$$

Functions $F_\pm$ and $m_\pm$ are related to $u_\pm$ by

$$F_\pm(\lambda):=u_\pm(0,\lambda), \quad m_\pm(\lambda^2):=\pm\frac{d}{dx}\log u_\pm(x,\lambda)\big|_{x=0}. \quad (3.8)$$

Evaluate now $\widetilde{F}_+(\lambda)\widetilde{F}_-(\lambda)$ in (3.7). Since $\widetilde{F}_+$ and $\widetilde{F}_-$ are similar we handle only $\widetilde{F}_+$. Directly by definition (2.4), one verifies that

$$\int_0^a \widetilde{Q}(s,\lambda)ds=\frac{1}{2i\lambda}\int_0^a \widetilde{q}(s)ds-\frac{\widetilde{Q}(a,\lambda)-\widetilde{Q}(0,\lambda)}{2i\lambda}=\frac{1}{2i\lambda}\int_0^a \widetilde{q}(s)ds+\frac{1}{2i\lambda}\widetilde{Q}(0,\lambda), \quad (3.9)$$

where we have observed that $\widetilde{Q}(a,\lambda)=0$. Comparing u_+ with the solution Ψ from Lemma 1, one has

$$\tilde{u}_+(x,\lambda)=\tilde{\Psi}(x,\lambda)\exp\left\{-\int_0^a \tilde{Q}(s,\lambda)ds\right\}$$
$$=\tilde{\Psi}(x,\lambda)\exp\left\{-\frac{1}{2i\lambda}\int_0^\infty \tilde{q}(s)ds\right\}\exp\left\{\frac{1}{2i\lambda}\int_0^\infty e^{2i\lambda s}\tilde{q}(s)ds\right\}. \tag{3.10}$$

It follows from (3.8), (3.9), and (2.2) that

$$\tilde{F}_+(\lambda)=\tilde{y}_+(\lambda)\exp\left\{-\frac{1}{2i\lambda}\int_0^\infty \tilde{q}(s)ds\right\}\exp\left\{\frac{1}{2i\lambda}\int_0^\infty e^{2i\lambda s}\tilde{q}(s)ds\right\}, \tag{3.11}$$

where $\tilde{y}_+(\lambda):=\tilde{y}(+0,\lambda)$. Analogously,

$$\tilde{F}_-(\lambda)=\tilde{y}_-(\lambda)\exp\left\{-\frac{1}{2i\lambda}\int_{-\infty}^0 \tilde{q}(s)ds\right\}\exp\left\{\frac{1}{2i\lambda}\int_{-\infty}^0 e^{-2i\lambda s}\tilde{q}(s)ds\right\}$$

with some function $\tilde{y}_-$ admitting a similar to the (2.3) estimate. Thus

$$(\tilde{F}_+(\lambda)\tilde{F}_-(\lambda))^{-1}=\tilde{y}^{-1}(\lambda)\exp\left\{\frac{1}{2i\lambda}\int \tilde{q}(x)dx\right\}\exp\left\{\frac{i}{2\lambda}\int e^{2i\lambda|x|}\tilde{q}(x)dx\right\}, \tag{3.12}$$

where $\tilde{y}:=\tilde{y}_+\tilde{y}_-$. Inserting (3.12) into (3.7), we finally arrive at

$$\tilde{T}(\lambda)=\tilde{y}^{-1}(\lambda)\frac{2i\lambda}{\tilde{m}_+(\lambda^2)+\tilde{m}_-(\lambda^2)}\exp\left\{\frac{1}{2i\lambda}\int \tilde{q}(x)dx\right\}\exp\left\{\frac{i}{2\lambda}\int e^{2i\lambda|x|}\tilde{q}(x)dx\right\}. \tag{3.13}$$

Equate now the right hand sides of (3.6) and (3.13). Taking $\lambda=i$ and observing that the divergent factor $\exp\{-\frac{1}{2}\int\tilde{q}(x)dx\}$ drops out from both sides, we obtain

$$\prod_j \frac{1+\tilde{\kappa}_j}{1-\tilde{\kappa}_j}e^{-2\tilde{\kappa}_j}\cdot\exp\left\{2\int_0^\infty\frac{k^2}{1+k^2}\tilde{f}(k)dk\right\}=\left\{\frac{-2\tilde{y}^{-1}(i)}{\tilde{m}_+(-1)+\tilde{m}_-(-1)}\right\}\exp\left\{\frac{1}{2}\int e^{-2|x|}\tilde{q}(x)dx\right\}. \tag{3.14}$$

Taking notice that due to basic facts of perturbation theory a change of the potential q on a finite interval does not effect the conclusions of the theorem, we alter, if needed, our potential to satisfy condition (2.2) for $\lambda=i$ for all $x\geqslant 0$ and $\sup|\tilde{\kappa}_j|<1$. This makes every factor in (3.14) positive and one can pass in (3.14) to the logarithms

$$\sum_j\left(\log\frac{1+\tilde{\kappa}_j}{1-\tilde{\kappa}_j}-2\tilde{\kappa}_j\right)+\int_0^\infty\frac{2k^2}{1+k^2}\tilde{f}(k)dk=\frac{1}{2}\int e^{-2|x|}\tilde{q}(x)dx+2\tilde{\omega}, \tag{3.15}$$

where

$$\tilde{\omega}:=-\tilde{y}^{-1}(i)\{\tilde{m}_+(-1)+\tilde{m}_-(-1)\}^{-1}. \tag{3.16}$$

The sum in (3.15) has the lower bound $\frac{2}{3}\Sigma_j\tilde{\kappa}_j^3$. Indeed, setting for the time being $\alpha=\tilde{\kappa}_j$ one has

$$\log\frac{1+\alpha}{1-\alpha}-2\alpha=\log(1+\alpha)-\log(1-\alpha)-2\alpha$$
$$=\sum_{n\geqslant 0}(-1)^n\frac{\alpha^n}{n+1}+\sum_{n\geqslant 0}\frac{\alpha^n}{n+1}-2\alpha$$
$$=2\sum_{n\geqslant 1}\frac{\alpha^{2n+1}}{2n+1}\geqslant\frac{2}{3}\alpha^3,$$

and thus

$$\sum_j\left(\log\frac{1+\tilde\kappa_j}{1-\tilde\kappa_j}-2\tilde\kappa_j\right)\geqslant\frac{2}{3}\sum_j\tilde\kappa_j^3.$$

It follows from (3.15) that

$$\frac{1}{3}\sum_j\tilde\kappa_j^3+\int_0^\infty\frac{k^2}{1+k^2}\tilde f(k)dk\leqslant\frac{1}{4}\int e^{-2|x|}\tilde q(x)dx+\tilde\omega. \tag{3.17}$$

Show now that the right hand side of (3.17) is uniformly bounded as $\tilde q\to q$. Indeed, by (2.2) and (2.5),

$$|\tilde y(i)|^{-1}=|\tilde y_+(i)|^{-1}|\tilde y_-(i)|^{-1}\leqslant 2\cdot 2=4.$$

The other factor in (3.16) goes to $(m_+(-1)+m_-(-1))^{-1}$ due to the general properties of the Weyl m-function[14] and hence $\tilde\omega$ is uniformly bounded as $\tilde q\to q$. Since

$$\int e^{-2|x|}\tilde q(x)dx\to\int e^{-2|x|}q(x)dx,\quad \tilde q\to q,$$

we see that the right hand side of (3.17) is uniformly bounded too. Since both terms on the left hand side of (3.17) are positive, recalling (3.2), we arrive at

$$\int_0^\infty\frac{k^2}{1+k^2}\log|\tilde T(k)|^{-1}dk\leqslant C, \tag{3.18}$$

$$\sum_j\tilde\kappa_j^3\leqslant C, \tag{3.19}$$

with some finite constant C dependent only on q. Estimate (3.18) allows one now to use a lemma by Deift–Killip[2] (see also Ref. 10). Thus (1.4), i.e., $\sigma_{\text{a.c.}}(H)=\mathbb{R}_+$, is proven.

It is left to establish (1.5). We can actually pass to the limit in (3.19). To this end consider the operator $H_-:=-d^2/dx^2+q_-(x)$ where q_- is the negative part of q. In obvious notation, estimate (3.19) for $\tilde H_-$ reads (with possibly different constant) as

$$\sum_j(\tilde\kappa_j^{(-)})^3\leqslant C. \tag{3.20}$$

But $0<a<b$ implies $q_-(x)\chi_{[-a,a]}(x)\geqslant q_-(x)\chi_{[-b,b]}(x)$, which, in turn, yields

$$-d^2/dx^2+q_-(x)\chi_{[-a,a]}(x)\supseteq -d^2/dx^2+q_-(x)\chi_{[-a,a]}(x),$$

and it follows from the standard fact of perturbation theory that $\tilde{\kappa}_j^{(-)}$ is a nondecreasing function of the cutoff point a for every fixed j. The latter combined with the uniform bound (3.20) immediately yields

$$\sum_j (\kappa_j^{(-)})^3 \leqslant C. \tag{3.21}$$

What is left to observe that, by the same perturbation principal, $\kappa_j \leqslant \kappa_j^{(-)}$ (since $H_- \subseteq H$) and (3.21) implies (1.5). The theorem is proven.

Remark 2: Identity (3.15) can actually be viewed as the first formula in a certain chain of sum rules. Our elementary arguments provide a short-cut to Theorem 1 but yet are not fine enough to derive those formulas in a compact form. The adequate approach is rather operator theoretical and will be discussed in Ref. 11 where we also plan to improve on the results of Ref. 10 in the spirit of Theorem 1. At this point we only notice that (3.15) resembles the second (sic) Buslaev–Faddeev–Zhakharov trace formula

$$\frac{1}{3}\sum_j \tilde{\kappa}_j^3 + \int_0^\infty k^2 \tilde{f}(k)\,dk = \frac{1}{16}\int \tilde{q}^2(x)\,dx,$$

which was the main new insight of Ref. 2 proving (1.2) and which higher order analogs were used in Ref. 10.

Quantum-mechanical scattering in exterior domains with impenetrable periodic boundaries and short-range potentials

A. W. Sáenz[a)]
Naval Research Laboratory, Washington, DC 20375,
and Catholic University of America, Washington, DC 20064

(Received 10 July 2003; accepted 11 December 2003)

We study the scattering of a nonrelativistic particle in an exterior domain (=open connected subset) $\Omega \subset \mathbf{R}^{\nu}(\nu \geqslant 2)$ containing a half-space and contained in another half-space, and having an impenetrable periodic boundary $\partial\Omega$. "Impenetrable" means that (generalized) homogeneous Dirichlet conditions are imposed on $\partial\Omega$. We prove the existence and completeness of the wave operators $W_{\pm} = \lim_{t \to \pm\infty} \exp(itH_1)\mathcal{P}\exp(-itH_0)$ corresponding to the scattering of a nonrelativistic particle in Ω by the combined effect of the boundary and a short-range potential present in Ω. Here $H_0 = -\Delta$ is the negative distributional Laplacian in the Hilbert space $\mathcal{H}_0 = L^2(\mathbf{R}^{\nu})$, $H_1 = -\Delta_{\mathrm{D}}(\Omega) + V$, $\Delta_{\mathrm{D}}(\Omega)$ being the Dirichlet Laplacian in the Hilbert space $\mathcal{H} = L^2(\Omega)$, V an operator of multiplication in $\mathcal{H}$ by a bounded measurable function $V(x)$ on Ω having the periodicity of the boundary, and $\mathcal{P}: \mathcal{H}_0 \to \mathcal{H}$ an identification operator. The operators $W_{\pm}$ model the quantum-mechanical scattering of low-energy atoms by crystal surfaces, with V modeling the interaction between the incident particles and the surface atoms. This interaction is idealized by assuming that $V(x)$ depends solely on x_{ν} when $x_{\nu} > a$, a being a sufficiently large positive constant, and x_{ν} the component of $x \in \mathbf{R}^{\nu}$ directed perpendicularly to the surfaces of the above two half-spaces. Under this and other hypotheses on Ω and V stated precisely in the paper, we prove that $W_{\pm}$ exist as partially isometric operators whose initial sets have a transparent physical meaning. Moreover, we prove the following: (a) $\mathrm{Ran}\, W_{\pm} = \mathcal{H}_{\mathrm{scatt}}$; and (b) $W_{\pm}$ are asymptotically complete, in the sense that $\mathcal{H} = \mathcal{H}_{\mathrm{scatt}} \oplus \mathcal{H}_{\mathrm{surf}}$. Here $\mathcal{H}_{\mathrm{scatt}}$ and $\mathcal{H}_{\mathrm{surf}}$ are suitably defined subspaces of scattering and surface states of $\mathcal{H}$. These results are proved by using direct-integral techniques, asymptotic methods from the theory of ODEs, and methods analogous to those of Lyford. The present paper generalizes an earlier one by the author for the case $V = 0$. © *2004 American Institute of Physics.*

I. INTRODUCTION

Theoretical studies of classical scattering, both acoustic and electromagnetic, by corrugated surfaces go at least as far back as Lord Rayleigh and have an enormous literature.[1] Quantum mechanical scattering of low-energy atomic beams by crystal surfaces, modeled as impenetrable corrugated surfaces, has also received much attention.[2] Much less work has been done on scattering by such surfaces at a rigorous mathematical level. This includes research by Wilcox[3,4] and the present author.[5,6]

In Ref. 5, we studied quantum-mechanical scattering of nonrelativistic particles by an impenetrable periodic boundary, i.e., such that the pertinent wave functions obeyed (generalized) homogeneous Dirichlet conditions thereon. In the present paper we generalize this work to the case in which a short-range potential is present, which models the interaction between the particle and the

a)Electronic mail: saenz@dave.nrl.navy.mil

surface atoms of a crystal. In more detail, we consider the quantum-mechanical scattering of such a particle in an exterior domain (=open connected subset) $\Omega\subset\mathbf{R}^\nu(\nu\geqslant 2)$ with an impenetrable corrugated boundary $\partial\Omega$ by the combined effect of the boundary and a short-range potential present in Ω. ''Impenetrable'' means that the particle's wave function obeys (generalized) homogeneous Dirichlet conditions on $\partial\Omega$. Our point of view will be that of time-dependent two-Hilbert-space scattering theory, in which the scattering is described by the wave operators

$$W_\pm = W_\pm(H_1,H_0;\mathcal{P}) = s-\lim_{t\to\pm\infty}\exp(itH_1)\mathcal{P}\exp(-itH_0). \tag{1.1}$$

Here H_0 is the ''unperturbed'' Hamiltonian, defined as the negative distributional Laplacian $-\Delta$ in $\mathcal{H}_0=L^2(\mathbf{R}^\nu)$, while $H_1=H+V$ is the corresponding ''perturbed'' Hamiltonian, H being the negative Dirichlet Laplacian $-\Delta_{\mathrm{D}}(\Omega)$ in $\mathcal{H}=L^2(\Omega)$ and V a maximal operator of multiplication in $\mathcal{H}$ by a real-valued measurable function, also denoted by V, which models the above short-range interaction between the particle and the surface atoms. Moreover, $\mathcal{P}$: $\mathcal{H}_0\to\mathcal{H}$ is a suitable bounded operator (identification operator).

As to Ω, we assume that it contains a half-space and is contained in another half-space. We also suppose that it has the periodicity property $(\tilde{x},x_\nu)\in\Omega\Rightarrow(\tilde{x}+n,x_\nu)\in\Omega$ for all $n\in\mathbf{Z}^{\nu-1}$, where we write $x\in\mathbf{R}^\nu$ as $(\tilde{x},x_\nu)\in\mathbf{R}^{\nu-1}\times\mathbf{R}$, x_ν being in a direction perpendicular to the boundaries of these half-spaces. No smoothness or regularity conditions are imposed on $\partial\Omega$ by virtue of a theorem of Lyford,[7] as we shall explain in more detail in Sec. II. As to the potential function V, we assume it to be periodic in the sense that $V(x)=V(\tilde{x},x_\nu)=V(\tilde{x}+n,x_\nu)$ for all $x\in\Omega$ and all $n\in\mathbf{Z}^{\nu-1}$. We also suppose that $V(x)$ has certain boundedness and integrability properties, and depends only on x_ν for $x_\nu>a$, where a is a sufficiently large positive constant. The last condition allows us to use powerful results on the asymptotic behavior of solutions of ODEs in the relevant proofs. On the other hand, it is a physically reasonable requirement, since for a large class of short-range potentials with the mentioned periodicity property, $V(\tilde{x},x_\nu)$ tends pointwise to a function independent of $\tilde{x}$ for $x_\nu\to\infty$.[8]

Our principal results are Theorems 3.1 and 3.2. The former asserts the completeness of the wave operators (1.1), and more precisely that $\mathrm{Ran}\,W_+=\mathrm{Ran}\,W_-=\mathcal{H}_{\mathrm{scatt}}$. Here $\mathcal{H}_{\mathrm{scatt}}$ is the subspace of scattering states, consisting of those functions $f\in\mathcal{H}$ that are evanescent from each region bounded by $\partial\Omega$ and a plane $x_\nu=\mathrm{const}$. Theorem 3.2 states that $W_\pm$ are asymptotically complete, i.e., that $\mathcal{H}_{\mathrm{scatt}}$ is the orthogonal complement with respect to $\mathcal{H}$ of the subspace $\mathcal{H}_{\mathrm{surf}}$ of surface states. The latter subspace, first introduced in Ref. 9, consists of all $f\in\mathcal{H}$ that remain ''close'' to $\partial\Omega$ for all time. [Rigorous definitions of $\mathcal{H}_{\mathrm{scatt}}$ and $\mathcal{H}_{\mathrm{surf}}$ are given by Eqs. (3.4) and (3.5), respectively.]

The organization of this paper is as follows. In Sec. II we define the self-adjoint operators H,H^0,H_1,V needed to construct $W_\pm$ in (1.1). Section III has two subsections. In Sec. III A we state Theorems 3.1 and 3.2, and Sec. III B is devoted to an overview of the methods of proof of these theorems, which rely heavily on direct-integral methods. A proof of Theorem 3.1 is given in Sec. IV by using a theorem of Lyford[10] based on work of Birman and Belopol'skii[11] and employing a version of a theorem of Stinespring.[12] In preparation for proving Theorem 3.2, we devote Sec. V to studying the spectrum of a family of self-adjoint operators $h_\theta[\theta\in(0,1)^{\nu-1}]$ defined in Sec. II, whose direct integral is unitarily equivalent to H, and prove that each h_θ has an empty singular continous spectrum. In Sec. V the asymptotic properties of solutions of a second-order ODE satisfied by the expansion coefficients of certain locally square-integrable functions play an important role. In particular, the above spectral and asymptotic properties are essential ingredients of the proof of Theorem 3.2 presented in Sec. VI. There are three appendixes. Appendix A explains our function-space notation, while Appendixes B and C state, respectively, a key local compactness property and a lemma on asymptotic solutions of ODEs of the above type, both of these results being used in Sec. V.

II. SELF-ADJOINTNESS OF A HAMILTONIAN OF A NONRELATIVISTIC PARTICLE IN AN EXTERIOR DOMAIN Ω WITH AN IMPENETRABLE PERIODIC BOUNDARY AND SUBJECTED TO A SHORT-RANGE POTENTIAL

For future reference, it is convenient to restate here the assumed properties of the exterior domain $\Omega\subset\mathbf{R}^{\nu}(\nu\geqslant 2)$ that were mentioned in Sec. I:

(I) $\mathbf{R}^{\nu-1}\times[\beta,\infty)\subset\Omega\subset\mathbf{R}^{\nu-1}\times[\alpha,\infty)$, for some $0<\alpha<\beta<1/2$.

(II) (Periodicity) Write the points $x\in\mathbf{R}^{\nu}(\nu\geqslant 2)$ as $(\tilde{x},x_{\nu})$, where $\tilde{x}\in\mathbf{R}^{\nu-1}$,

$$x_{\nu}\in\mathbf{R}.\ \text{For all}\ \ n\in\mathbf{Z}^{\nu-1},\ \ (\tilde{x},x_{\nu})\in\Omega\Rightarrow(\tilde{x}+n,x_{\nu})\in\Omega.$$

We consider a nonrelativistic particle in Ω whose evolution is governed by a self-adjoint Hamiltonian operator H_1 acting in the Hilbert space $\mathcal{H}=L^2(\Omega)$, and defined as the operator sum

$$H_1=H+V, \tag{2.1}$$

where (in suitable units) H denotes the kinetic energy operator of the particle, confined in Ω by the surface $\partial\Omega$ on which we impose a generalized homogeneous Dirichlet condition, and V models its interaction with the surface atoms.

More precisely,

$$H=-\Delta_{\mathrm{D}}(\Omega), \tag{2.2}$$

where $\Delta_{\mathrm{D}}(\Omega)$ is the Dirichlet Laplacian in $\mathcal{H}$, acting by Δ (distributional Laplacian) on the functions in its domain,

$$D(\Delta_{\mathrm{D}}(\Omega))=L^2(\Delta;\Omega)\cap H_0^1(\Omega). \tag{2.3}$$

Here $L^2(\Delta;\Omega)$ denotes the Hilbert space defined in Appendix A and $H_0^1(\Omega)$ the usual Sobolev space. These and other function spaces used in this paper are defined in that appendix. By (2.2), (2.3), and a remarkable theorem of Lyford,[7] the operator H is self-adjoint for an *arbitrary domain* $\Omega\subset\mathbf{R}^{\nu}$, and not merely for the domain Ω considered here.

We define V as a maximal operator of multiplication in $L^2(\Omega)$ by a real-valued measurable function on Ω, which will also be denoted by V and assumed to satisfy the following requirement.

Condition 1: V has the periodicity property

$$V(x)=V(\tilde{x},x_{\nu})=V(\tilde{x}+n,x_{\nu}),\ \ x\in\Omega,n\in\mathbf{Z}^{\nu-1}, \tag{2.4a}$$

is bounded on Ω, and has the integrability property

$$V\big|\omega\in L^2(\omega). \tag{2.4b}$$

Here ω denotes the irregular semi-infinite cylinder $\omega=\{x=(\tilde{x},x_{\nu})\in\Omega:\tilde{x}\in(0,1)^{\nu-1}\}$, whose axis is parallel to the x_{ν} axis.

Remarks: (1) The properties of the function V which are stated in this condition and the fact that it is real-valued entail that the corresponding operator V is bounded and self-adjoint, and hence that its domain is $\mathcal{H}$. Thus H_1, as the operator sum of the (unbounded) self-adjoint operator H and V is itself self-adjoint. Indeed, V is infinitesimally small wrt H, or $V\ll H$ in symbols.[13]

(2) If the function V had not been required to be essentially bounded, H_1 could have been defined by (2.1), understood in the sense of quadratic forms. However, this would greatly complicate the treatment of the problems discussed in the paper. The boundedness of this function is very natural from a physical viewpoint, since for the models of atomic crystal surfaces of interest here, the atomic cores lie in the complement $\mathbf{R}^{\nu}\backslash\Omega$ of Ω, and hence Ω contains no infinite singularities of V.[2] Finally, the integrability condition (2.4b), which is reasonable for short-range potentials, plays an important role in the proof of the key Lemma 4.2.

III. SCATTERING BY IMPENETRABLE PERIODIC BOUNDARIES WITH SHORT-RANGE POTENTIALS: MAIN RESULTS AND STRATEGY OF PROOF

A. Statement of main results

As mentioned in Sec. I, Theorems 3.1 and 3.2 are our principal results. Before stating them, we make some definitions and a further assumption on V.

Let K_1, K_2 be self-adjoint operators in the respective Hilbert spaces $\mathcal{H}_1$, $\mathcal{H}_2$, K_1 having a purely absolutely continous spectrum, and let $B:\mathcal{H}_1\to\mathcal{H}_2$ be a bounded operator. We define the wave operators

$$W_{\pm}(K_2,K_1;B)=s-\lim_{t\to\pm\infty}\exp(itK_2)\,B\exp(-itK_1), \tag{3.1}$$

if they exist. The wave operators studied in this paper have the form (3.1).

Theorems 3.1 and 3.2 deal with properties of the wave operators,

$$W_{\pm}:=W_{\pm}(H_1,H_0;\mathcal{P}), \tag{3.2}$$

which, as mentioned in the Introduction, describe scattering by the impenetrable periodic boundary $\partial\Omega$ when the short-range potential V acts in the exterior domain Ω. As in Sec. II, $H_0=-\Delta$, the negative distributional Laplacian acting in the Hilbert space $\mathcal{H}_0=L^2(\mathbf{R}^\nu)$, and $\mathcal{P}:\mathcal{H}_0\to\mathcal{H}=L^2(\Omega)$ is defined by

$$(\mathcal{P}f)(x)=\begin{cases} f(x), & x\in\Omega,\\ 0, & x\in\mathbf{R}^\nu\backslash\Omega,\end{cases}$$
$$f\in\mathcal{H}_0,\quad x\in\Omega. \tag{3.3a}$$

For any measurable subset $A\subset\mathbf{R}^\nu$, we identify $L^2(A)$ with the subspace of $L^2(\mathbf{R}^\nu)$ composed of all f such that $f(x)=0$ a.e. on $\mathbf{R}^\nu\backslash A$. Thus, the requirements $\mathcal{P}:\mathcal{H}_0\to\mathcal{H}$ and (3.3a) are consistent.

By Theorem 3.1, the wave operators (3.2) can be written as $W_{\pm}(H_1,H_0;J)$, a form that has certain technical advantages. Here $J:\mathcal{H}_0\to\mathcal{H}$ is given by

$$(Jf)=\begin{cases} j(x_\nu)f(x), & x=(\tilde{x},x_\nu)\in\Omega,\\ 0, & x\in\mathbf{R}^\nu\backslash\Omega,\end{cases} \tag{3.3b}$$

where $j\in C^\infty(\mathbf{R})$ is such that

$$j(y)=\begin{cases} 0, & y\leqslant 1/2,\\ 1, & y\geqslant 1.\end{cases} \tag{3.3c}$$

The requirements $J:\mathcal{H}_0\to\mathcal{H}$ and (3.3b) are therefore consistent.

An important role in what follows is played by the subspaces $\mathcal{H}_{\text{scatt}}$, $\mathcal{H}_{\text{surf}}$ of scattering and surface states, respectively, defined by

$$\mathcal{H}_{\text{scatt}}=\{f\in L^2(\Omega):\ \lim_{t\to\pm\infty}\|\exp(-itH_1)f\|_{\Omega_r}=0,1<r<\infty\}, \tag{3.4}$$

$$\mathcal{H}_{\text{surf}}=\{f\in L^2(\Omega):\ \lim_{t\to\pm\infty}\|\exp(-itH_1)f\|_{\Omega\backslash\Omega_r}=0,1<r<\infty\}, \tag{3.5}$$

whose physical significance was mentioned in Sec. I. Here $\|\cdot\|_M$ denotes the $L^2(M)$ norm for a measurable subset $M\subset\mathbf{R}^\nu$ and $M_r=\{(\tilde{x},x_\nu)\in\mathbf{R}^\nu:x_\nu<r\}$. We will also use the notation $M_{r,\infty}=\{x\in M:x_\nu>r\}$.

Besides assuming that V satisfies condition **1**, we will suppose that it has the following property, unless we make an explicit statement to the contrary.

Condition 2: $V(\tilde{x},x_\nu)=w(x_\nu)\forall x=(\tilde{x},x_\nu)\in\omega_{a,\infty}$, where $w\in C^\infty((a,\infty))\cap L^1((a,\infty))$ and $a>1$ is a constant.

Remarks: We have already commented on the mathematical convenience and physical reasonableness of this condition in Sec. I. The infinite differentiability of w in condition 2 is imposed for ease of exposition, while the integrability requirement therein plays an essential role in proving various key lemmas.

Theorem 3.1: Let conditions 1 and 2 be satisfied. Then we have the following:

(a) The operators $W_\pm=W_\pm(H_1,H_0;\mathcal{P})$ exist and equal $W_\pm(H_1,H_0;J)$;

(b) $W_\pm$ are complete in the usual sense:

$$(W_\pm)^*W_\pm=E_\pm, \tag{3.6a}$$

$$W_\pm(W_\pm)^*=P_{\text{scatt}}, \tag{3.6b}$$

where $E_\pm$ and P_{scatt} are projection operators having domains $\mathcal{H}_0$ and $\mathcal{H}$, respectively, with $E_\pm\mathcal{H}_0=\mathcal{H}_\pm$ and $P_{\text{scatt}}\mathcal{H}=\mathcal{H}_{\text{scatt}}$. The initial sets of the partially isometric operators $W_\pm$ are explicitly given by

$$\mathcal{H}_\pm=\{f\in\mathcal{H}_0:\hat{f}(k)=0,\ \text{for a.e. } k=(k_1,\ldots,k_\nu)\in\mathbf{R}^\nu,\quad \text{with } k_\nu\lessgtr 0\}, \tag{3.7}$$

$\hat{f}$ denoting the $L^2(\mathbf{R}^\nu)$ Fourier transform of f:

$$\hat{f}(k)=(2\pi)^{-\nu/2}L^2(\mathbf{R}^\nu)-\lim_{r\to\infty}\int_{[-r\cdot r]^\nu}\exp(-ik\cdot x)f(x)dx. \tag{3.8}$$

Remark: Equation (3.7) has a transparent physical meaning. Intuitively, in order for a wave packet f_t in Ω evolving as $\exp(-itH_0)f$ for large negative times, to arrive "near" $\partial\Omega$ at time $t=0$, its Fourier transform $\hat{f}_t$ must have for $t\to\infty$ support intersecting the region of momentum space with $k_\nu<0$ in a set of positive measure. Again intuitively, if a wave packet g_t in Ω, which was "near" $\partial\Omega$ at $t=0$ is scattered, then the support of $\hat{g}_t$ must, for large positive times, intersect the momentum–space region with $k_\nu>0$ in a set of positive measure. This interpretation reinforces our contention that the wave operators $W_\pm(H_1,H_0;\mathcal{P})$ are appropriate for describing quantum-mechanical scattering of nonrelativistic particles by the impenetrable periodic surface $\partial\Omega$ in the framework of the present model.

Theorem 3.2: Let conditions 1, 2 be satisfied. Then $W_\pm$ are asymptotically complete, in the sense that

$$\mathcal{H}=\mathcal{H}_{\text{scatt}}\oplus\mathcal{H}_{\text{surf}}. \tag{3.9}$$

B. Methods of proof

A central idea in the proofs of Theorems 3.1 and 3.2 is to replace the study of the wave operators $W_\pm(H^0,H_0;\mathcal{P})$, in the technically more convenient form $W_\pm(H_1,H_0;J)$, by that of $W_\pm(H_1,H_0;J^0)$ and the related infinite family $\{W_\pm(h^1_\theta,h^0_\theta;\eta),\theta\in G\}$ of wave operators constructed by direct-integral methods. Here $H^0=-\Delta_{\text{D}}(\Omega^0)$, the negative Dirichlet Laplacian in the Hilbert space $\mathcal{H}^0=L^2(\Omega^0)$, acting by the negative distributional Laplacian on the functions in its domain, defined by (2.3), with Ω replaced by Ω^0, the half-space $\{(\tilde{x},x_\nu)\in R^\nu:x_\nu>0\}$. Furthermore, $J^0:\mathcal{H}^0\to\mathcal{H}=L^2(\Omega)$ is defined as J was in (3.3b), but with $\mathcal{H}_0$ replaced by $\mathcal{H}^0$. The above family of wave operators indexed by θ will be defined later in this section, after we introduce the necessary direct-integral machinery on which our proofs are heavily dependent.[14]

We define the single-fiber direct integrals,

$$\mathcal{K}^0=\int_G^{\oplus} L^2(\omega^0)d\theta, \tag{3.10a}$$

$$\mathcal{K}=\int_G^{\oplus} L^2(\omega)d\theta, \tag{3.10b}$$

of Hilbert spaces, where $d\theta$ is a Lebesgue measure in $\mathbf{R}^{\nu-1}$ and where we note the relation

$$\omega^0 := G\times\mathbf{R}_+ \supset \omega = \Omega\cap\omega^0, \tag{3.11}$$

between the cylinders ω^0 and ω, G denoting the open $(\nu-1)$-dimensional cube $(0,1)^{\nu-1}$. Note that $\omega^0\backslash\omega$ is bounded, as follows from (3.11) and properties (I) and (II) of Ω. This boundedness is important for our purposes.

We define the unitary operators U^0, U with domains $\mathcal{H}^0=L^2(\Omega^0)$, $\mathcal{H}=L^2(\Omega)$ and ranges $\mathcal{K}^0$, $\mathcal{K}$, respectively, as follows. For $f\in L^2(\Omega)$ of bounded support, we set

$$(Uf)_\theta(x)=\sum_{n\in\mathbf{Z}^{\nu-1}} \exp(-2\pi i n\cdot\theta) f(\tilde{x}+n,x_\nu),$$
$$\theta\in G,\quad x=(\tilde{x},x_\nu)\in\omega, \tag{3.12}$$

where only a finite number of terms in the sum in (3.12) are nonvanishing on ω. The set of all such f's is dense in $L^2(\Omega)$, and it is easy to prove that U can be extended to the whole of $L^2(\Omega)$ as a unitary operator onto $\mathcal{K}$. The operator U^0 is defined in the same way as U, except with Ω, ω replaced by Ω^0, ω^0, respectively. U^0, U have the crucial properties

$$U^0H^0(U^0)^{-1}=\int_G^{\oplus} h_\theta^0 d\theta, \tag{3.13a}$$

$$UHU^{-1}=\int_G^{\oplus} h_\theta d\theta, \tag{3.13b}$$

where h_θ^0 and h_θ are self-adjoint operators in $L^2(\omega^0)$, $L^2(\omega)$, respectively. The operator h_θ ($\theta\in G$) has domain

$$D(h_\theta)=\{f\in L^2(\Delta;\omega)\cap H^1(\omega): f \text{ has an extension,}$$
$$\tilde{f}\in L^2_{\mathrm{loc}}(\Delta;\overline{\Omega})\cap H^1_{0,\mathrm{loc}}(\overline{\Omega}), \text{ with property } P_\theta\}, \tag{3.14}$$

and acts as the negative distributional Laplacian on every $f\in D(h_\theta)$.

A function $g:\Omega\to\mathbf{C}$ is said to have property P_θ ($\theta\in G$) if it has the form $f(x)=f(\tilde{x},x_\nu)$ $=\exp(2\pi i\theta\cdot\tilde{x})\times u(\tilde{x},x_\nu)$, where $u(\tilde{x}+n,x_\nu)=u(\tilde{x},x_\nu)$ $\forall n\in\mathbf{Z}^{\nu-1}$.

Each h_θ^0 ($\theta\in G$) is defined in the same way as h_θ, except with ω replaced by ω^0 (Ref. 15).

An obvious formal consequence of Eqs. (3.13b) and (2.1), that is easily derived rigorously, is that

$$UH_1U^{-1}=\int_G^{\oplus} h_\theta^1 d\theta, \tag{3.15}$$

where each h_θ^1 is a self-adjoint operator defined as the operator sum,

$$h_\theta^1=h_\theta+v_\theta,\quad \theta\in G, \tag{3.16}$$

v_θ denoting the maximal operator of multiplication in $L^2(\omega)$ by the bounded, real, measurable function $v_\theta = V|\omega$. Since $UVU^{-1} = \int_G^\oplus v_\theta \, d\theta$, as one shows by using the periodicity property (2.4a) and arguments similar, but simpler, than those used to prove (3.13b), and since $V \ll H$, we infer that $v_\theta \ll h_\theta$,[16] and hence that each h_θ^1 is self-adjoint by the Kato–Rellich theorem.

The relation

$$U \exp(itH_1)U^{-1} = \int_G^\oplus \exp(ith_\theta^1) d\theta, \quad t \in \mathbf{R}, \tag{3.17a}$$

formally expected in view of (3.15), follows immediately from two facts. First, it holds if its rhs is replaced by $\exp(itUH_1U^{-1})$.[17] Second, $\exp(itUH_1U^{-1}) = U\exp(itH_1)U^{-1}$.[18] Analogously,

$$U^0 \exp(itH^0)(U^0)^{-1} = \int_G^\oplus \exp(ith_\theta^0) d\theta, \quad t \in \mathbf{R}. \tag{3.17b}$$

Relations (3.17) will be used to prove Theorem 3.1.

The connection between the wave operators $W_\pm(H_1, H_0; \mathcal{P}) = W_\pm(H_1, H_0; J)$ and $W_\pm(H, H; J^0)$ that is of interest for our purposes is expressed by the relation

$$W_\pm(H_1, H_0; J) = W_\pm(H_1, H^0; J^0) W_\pm(H^0, H_0; \mathcal{P}_0), \tag{3.18}$$

following from the existence of the wave operators on the rhs of (3.18) and the fact that $J = J^0\mathcal{P}_0$. The existence of $W_\pm(H, H; J^0)$ will be proved in Sec. IV, while that of $W_\pm(H^0, H_0; \mathcal{P}^0)$, describing scattering from a flat surface, was proved previously.[19] A decisive step in proving Theorem 3.1 is to show that the wave operators $W_\pm(h_\theta^1, h_\theta^0; \eta)$ $(\theta \in G)$ are partial isometries that are complete in the usual sense, where $\eta: L^2(\omega^0) \to L^2(\omega)$ is defined by

$$(\eta f)(x) = \begin{cases} j(x_\nu) f(x), & x = (\tilde{x}, x_\nu) \in \omega, \\ 0, & x \in \omega^0 \setminus \omega, \end{cases} \qquad f \in L^2(\omega^0). \tag{3.19}$$

The fact that in the present Dirichlet context ω posseses the local compactness property for every bounded subset of $H^1(\omega)$ (Lemma B.1) is crucial in the proof of Theorem 3.1, which is based on a variant of results of Birman and Belopol'skii.[11] Once the completeness of the operators $W_\pm(h_\theta^1, h_\theta^0; \eta)$ is proved, Theorem 3.1 readily follows. As mentioned in Sec. I, a key step in demonstrating Theorem 3.2 is to show that each h_θ^1 $(\theta \in G)$ has an empty singular continous spectrum, a fact asserted by Lemma 5.4.

IV. PROOF OF THEOREM 3.1

It is based on Lemmas 4.1 and 4.2 and Eq. (6.3a). These lemmas concern properties of the wave operators,

$$W_\pm^\theta := W_\pm(h_\theta^1, h_\theta^0; \eta), \quad \theta \in G, \tag{4.1}$$

$$\mathcal{W}_\pm = W_\pm(H_1, H^0; J^0), \tag{4.2}$$

where $J^0 = J|\Omega^0$ and $\eta = J|\omega^0$, in accord with (3.19). Equation (6.3a), in whose derivation the absence of the singular continous spectrum of the h_θ^1 plays an essential role, asserts the equality of the projection operators P_{ac} and P_{scatt}. Here

$$UP_{\mathrm{ac}}U^{-1} = \int_G^\oplus P_{\mathrm{ac}}(h_\theta^1) d\theta, \tag{4.3}$$

$P_{\mathrm{ac}}(h_\theta^1)$ denoting the orthogonal projection from $L^2(\omega)$ onto the subspace of the absolute continuity of $L^2(\omega)$ wrt h_θ^1. Definition (4.3) makes sense because each function $\theta \mapsto P_{\mathrm{ac}}(h_\theta^1)$ from G into the space of bounded linear operators in $L^2(\omega)$ is measurable and each $P_{\mathrm{ac}}(h_\theta^1)$ is bounded.[20]

Lemma 4.1: Suppose that condition 1 holds and that $\forall\, \theta \in G$ the wave operators $W_\pm^\theta$ in (4.1) exist and are partial isometries that are complete in the usual sense:

$$(W_\pm^\theta)^* W_\pm^\theta = I_{L^2(\omega^0)}, \tag{4.4a}$$

$$W_\pm^\theta (W_\pm^\theta)^* = P_{\mathrm{ac}}(h_\theta^1), \tag{4.4b}$$

where $I_{L^2(\omega^0)}$ is the unit operator in $L^2(\omega^0)$. Then the wave operators $\mathcal{W}_\pm$ in (4.2) exist and are complete in the sense that

$$(\mathcal{W}_\pm)^* \mathcal{W}_\pm = I_{L^2(\Omega^0)}, \tag{4.5a}$$

$$\mathcal{W}_\pm (\mathcal{W}_\pm)^* = P_{\mathrm{ac}}, \tag{4.5b}$$

where $I_{L^2(\Omega^0)}$ is the unit operator in $L^2(\Omega^0)$.

Proof: Define

$$\mathcal{W}_t = \exp(itH_1) J^0 \exp(-itH^0), \quad t \in \mathbf{R}, \tag{4.6}$$

and note that

$$U J^0 (U^0)^{-1} = \mathcal{J} := \int_G^\oplus \eta_\theta \, d\theta, \tag{4.7}$$

where $\eta_\theta = \eta(\theta \in G)$. To prove (4.7), it suffices to show that $UJ^0 f = \mathcal{J} U^0 f$ when $f \in L^2(\Omega^0)$ is equivalent to a function of bounded support, as can be done by using, in particular, (3.12) and the fact that for each such f only a finite number of summands in (3.12) do not vanish a.e.

By (4.6), (3.17), and (4.7),

$$\mathcal{W}_t = U^{-1} \left(\int_G^\oplus \mathcal{W}_t^\theta \, d\theta \right) U^0, \quad t \in \mathbf{R}, \tag{4.8}$$

where

$$\mathcal{W}_t^\theta = \exp(ith_\theta^1)\, \eta_\theta \exp(-ith_\theta^0), \quad \theta \in G, \quad t \in \mathbf{R}. \tag{4.9}$$

Supposing that $\mathcal{W}_\pm^\theta = s - \lim_{t \to \pm\infty} \mathcal{W}_t^\theta$ exists for each $\theta \in G$, and using (4.8) and unitarity, we see that

$$\begin{gathered} \| \mathcal{W}_{t_1} f - \mathcal{W}_{t_2} f \|_\Omega^2 = \int_G \| \mathcal{W}_{t_1} g_\theta - \mathcal{W}_{t_2} g_\theta \|_\omega^2 \, d\theta, \\ f \in L^2(\Omega^0), \quad t_1, t_2 \in \mathbf{R}, \end{gathered} \tag{4.10}$$

where $g = U^0 f \in \mathcal{K}^0 g$ [see (3.10a)]. Now,

$$\|\mathcal{W}_{t_1} g_\theta - \mathcal{W}_{t_2} g_\theta\|_\omega \leqslant 2\|g_\theta\|_\omega, \tag{4.11}$$

at each such t_1, t_2, θ, since $\|\mathcal{W}_t g_\theta\|_\omega \leqslant 1$ for $t \in \mathbf{R}$, $\theta \in G$. By (4.10), (4.11), and dominated convergence,

$$\lim_{t_1, t_2 \to \pm\infty} \|\mathcal{W}_{t_1} f - \mathcal{W}_{t_2} f\|_\Omega^2 = \int_G \lim_{t_1, t_2 \to \pm\infty} \|\mathcal{W}_{t_1}^\theta g_\theta - \mathcal{W}_{t_2}^\theta g_\theta\|_\omega^2 \, d\theta = 0. \tag{4.12}$$

Hence, $\mathcal{W}_\pm$ exists if $\mathcal{W}_\pm^\theta$ exist for each $\theta \in G$.

Next, we show that if Eqs. (4.4) hold for every such θ, then so do (4.5). Indeed, from (4.8) we find taking strong limits and again using dominated convergence:

$$\mathcal{W}_\pm = U^{-1}\left(\int_G^\oplus \mathcal{W}_\pm^\theta \, d\theta \right) U^0, \tag{4.13a}$$

which implies

$$(\mathcal{W}_\pm)^* = (U^0)^{-1}\left(\int_G^\oplus (\mathcal{W}_\pm^\theta)^* d\theta \right) U. \tag{4.13b}$$

But (4.13), (4.4), and (4.3) entail (4.5). □

Lemma 4.2: Equations (4.4) hold $\forall\, \theta \in G$ if condition 1 is satisfied.

Before proving this lemma, we will use it to prove Theorem 3.1.

Proof of Theorem 3.1: (a) Since $W_\pm(H_1, H^0; J^0)$ exist by Lemmas 4.1 and 4.2, and $W_\pm(H^0, H_0; \mathcal{P}_0)$ exists, $W_\pm(H_1, H_0; J)$ exists by (3.18). That $W_\pm(H_1, H_0; \mathcal{P}) = W_\pm(H_1, H_0; J)$ follows by arguments virtually identical to those invoked in an analogous connection in the proof of part (a) of Theorem 2.1 of Ref. 5.

(b) By $W_\pm(H_1, H_0; \mathcal{P}) = W_\pm(H_1, H_0; J)$, (3.18), (4.5), and the corollary to Lemma B.1 in Appendix B of Ref. 5 there follows a modified version of Eqs. (3.6) with P_{scatt} replaced by P_{ac}. This result and (6.3a) entail that Eqs. (3.6) hold in their originally stated form. [We remind the reader that (6.3a) is derived in Sec. VI under the assumption that conditions 1 and 2 hold.] Equation (3.7) follows by arguments similar to ones adduced in the proof of part (b) of Theorem 2.1 of Ref. 5. □

Proof of Lemma 4.2: Assume that **1** is satisfied. Then Lemma 4.2 holds if statements (i)–(iii) below are true for all $\theta \in G$ and all bounded intervals $\delta \subset \mathbf{R}$:[10]

(i) $\eta D(h_\theta^0) \subset D(h_\theta^1)$, $\eta^* D(h_\theta^1) \subset D(h_\theta^0)$.

(ii) $(\eta^* \eta - I_{L^2(\omega^0)}) E(\delta; h_\theta^0)$ and $(\eta \eta^* - I_{L^2(\omega)}) E(\delta; h_\theta^1)$ are compact, where $E(\delta; h_\theta^0), E(\delta; h_\theta^1)$ are the spectral measures of h_θ^0, h_θ^1, respectively.

(iii) $(h_\theta^1 \eta - \eta h_\theta^0) E(\delta; h_\theta^0)$ is trace class.

We proceed to prove (i)–(iii), fixing $\theta \in G$ and a bounded interval $\delta \subset \mathbf{R}$ until further notice.

Proof of (i): Since $D(h_\theta^1) = D(h_\theta)$, the relations (i) hold in the present case since they do in the case $V = 0$ (Ref. 5, pp. 2878–2879).

Proof of (ii): The first property (ii) was proved when $V = 0$ (Ref. 5, p. 2879). Hence we only need to establish the compactness of $(\eta \eta^* - I_{L^2(\omega)}) E(\delta; h_\theta^1)$. Since $\eta \eta^* - I_{L^2(\omega)}$ is multiplication by a $C^\infty(\omega)$ function of bounded support, it suffices to show that for an arbitrary sequence $\{g_m\}_{m \in \mathbf{N}}$ bounded in $L^2(\omega)$ ($\mathbf{N}$ = the positive integers), the sequence $\{u_m = E(\delta; h_\theta^1) g_m\}_{m \in \mathbf{N}}$ is precompact in $L^2(\omega(r))$ for large enough $r > 0$. Here is the proof. We first show that $\{u_m\}_{m \in \mathbf{N}}$ is bounded in $H^1(\omega)$. Obviously, it is bounded in $L^2(\omega)$. Also, by $u_m \in D(h_\theta^1) = D(h_\theta) \subset D_\theta$, $\forall m \in \mathbf{N}$, (3.16), the boundedness of the operators v_θ and $h_\theta^1 E(\delta; h_\theta^1)$ and that of the sequence $\{u_m\}_{m \in \mathbf{N}}$ in $L^2(\omega)$, it follows that

$$\begin{aligned}\|\nabla u_m\|_\omega^2 &= \langle \nabla u_m, \nabla u_m\rangle_\omega \\ &= \langle u_m, h_\theta u_m\rangle_\omega \\ &\leqslant \langle u_m, h_\theta^1 u_m\rangle_\omega + |\langle u_m, v_\theta u_m\rangle_\omega| \\ &\leqslant \langle u_m, h_\theta^1 u_m\rangle_\omega + \text{const}\|u_m\|_\omega^2 \leqslant \text{const}\|u_m\|_\omega^2 \leqslant \text{const},\end{aligned} \tag{4.14}$$

where "const" is independent of m, and where $\|\cdot\|_M$, $\langle\cdot\rangle_M$ denote the norm and inner product in $L^2(M)$, respectively, for a measurable subset $M\subset\mathbf{R}^\nu$.[21] Hence $\{u_m\}$ is bounded in $H^1(\omega)$. By Lemma B.1, we thus conclude that $\{u_m\}$ is precompact in $L^2(\omega(r))$ for each $r>0$ for which $\omega(r)\neq\varnothing$.

Proof of (iii): We continue to assume that $\theta\in G$ is fixed and that $\delta\subset\mathbf{R}$ is a fixed bounded interval. We will need the fact (Ref. 5, p. 2876) that the spectral measure $E(\cdot;h_\theta^0)$ of h_θ^0 is given by

$$\begin{gathered}(E(\delta;h_\theta^0)f)(x) = \sum_{n\in\mathbf{Z}^{\nu-1}} \int_{\mathbf{R}_+} \chi_\delta(\kappa_n(\xi)) w_n(x,\xi)\tilde{f}_n(\xi)\,d\xi, \\ f\in L^2(\omega^0), \quad \text{a.e. } x\in\omega^0,\end{gathered} \tag{4.15}$$

where

$$\begin{gathered}\tilde{f}_n(\xi) = L^2(\mathbf{R}_+) - \lim_{r\to\infty} \int_{\omega^0(r)} w_n(x,\xi) f(x)\,dx, \\ w_n(x,\xi) = (2/\pi)^{1/2} \exp[2\pi i(n+\theta).\tilde{x}]\sin\xi x_\nu, \\ f\in L^2(\omega_0), \quad n\in\mathbf{Z}^{\nu-1}, \quad \text{a.e. } \xi\in\mathbf{R}_+ .\end{gathered} \tag{4.16}$$

Here χ_δ is the characteristic function of the interval δ, $\kappa_{n\theta}(\xi)=\xi^2+4\pi^2|n+\theta|^2$, and $\mathbf{R}_+ = [0,\infty)$. The θ-dependence of various functions is suppressed for notational convenience. Since δ is bounded, only a finite number of terms in the sum (4.15) are nonzero for a.e. $x\in\omega^0$.

Note that the mapping $\mathcal{U}$ from $L^2(\omega^0)$ onto $\mathcal{C}=\Sigma_{n\in\mathbf{Z}^{\nu-1}}\oplus L^2(\mathbf{R}_+)$ defined by $\mathcal{U}f = \{\tilde{f}_n\}_{n\in\mathbf{Z}^{\nu-1}}$ is unitary. Hence condition (iii) is equivalent to the condition that

$$(h_\theta^1\eta - \eta h_\theta^0)E(\delta;h_\theta^0)\mathcal{U}^*$$

be trace class from $\mathcal{C}$ to $L^2(\omega^0)$. In turn, the latter condition is equivalent to requiring that the mapping

$$\tilde{f}_n \to (h_\theta^1\eta - \eta h_\theta^0)\int_{\mathbf{R}_+} \tilde{f}_n(\xi) w_n(\cdot,\xi)\chi_\delta(\kappa_n(\xi))\,d\xi$$

be trace class from $L^2(\mathbf{R}_+)$ to $L^2(\omega)$ for each $n\in\mathbf{Z}^{\nu-1}$. This equivalence follows from the facts that only a finite number of summands in (4.15) are nonvanishing a.e. on ω^0 and that the sum of a finite number of trace class operators with the same domains and ranges is trace class. Hence we fix $n\in\mathbf{Z}^{\nu-1}$ and proceed as follows. We first remark that

$$\begin{gathered}(h_\theta^1\eta - \eta h_\theta^0)\int_{\mathbf{R}_+} \tilde{f}_n(\xi) w_n(\cdot,\xi)\chi_\delta(\kappa_n(\xi))\,d\xi = \int_{\mathbf{R}_+} M_n(\cdot,\xi)\tilde{f}_n(\xi)\,d\xi := B_n\tilde{f}_n, \\ f\in L^2(\omega^0), \quad n\in\mathbf{Z}^{\nu-1},\end{gathered} \tag{4.17a}$$

where

$$M_n = M_n'(x,\xi) + M_n''(x,\xi), \tag{4.17b}$$

and where

$$M_n'(x,\xi) = -\{[d^2 j(x_\nu)/dx_\nu{}^2] w_n(x,\xi) + 2[d^2 j(x_\nu)/dx_\nu{}^2] \partial w_n(x,\xi)/\partial\xi]\} \chi_\delta(\kappa_n(\xi)), \tag{4.17c}$$

$$M_n''(x,\xi) = V(x) j(x_\nu) w_n(x,\xi) \chi_\delta(\kappa_n(\xi)), \tag{4.17d}$$

$\forall n \in \mathbf{Z}^{\nu-1}, x \in \omega^0, \xi \in \mathbf{R}_+$, where, by definition, $V(x) = 0$ on $\omega^0 \backslash \omega$. Equations (4.17) can be readily justified. Indeed, note that $\int_{\mathbf{R}_+} \tilde{f}_n(\xi) w_n(x,\xi) \chi_\delta(\kappa_n(\xi)) d\xi$ is an infinitely differentiable function of x on ω by dominated convergence. Consequently, the operator $h_\theta^1 \eta - \eta h_\theta^0$ acts on this function (which is in its domain) by $(-\Delta + V|\omega) j + j\Delta$, where Δ may be interpreted as the usual, rather than the weak Laplacian, and may be taken inside the integral sign by dominated convergence. Given these facts, (4.17) follows by a brief calculation.

Write $B_n = B_n' + B_n''$, where B_n', B_n'' are defined by (4.17a), but with M_n replaced by M_n', M_n'', respectively. Thus, in order to prove (iii) it suffices to show that B_n', B_n'' are trace class. This will now be done for B_n'', the proof for B_n' being analogous.

Note that

$$\int_{\mathbf{R}_+} \left(\int_\omega |M_n''(x,\xi)|^2 \, dx \right) d\xi < \infty, \tag{4.18}$$

in view of (4.17d), $V|\omega \in L^2(\omega)$, the boundedness of j, w_n, and the fact that $\chi_\delta(\kappa_n(\cdot))$ is of bounded support. Note also that as a mapping from $\mathbf{R}_+$ to $L^2(\omega)$, $M_n''(\cdot\,,\xi)$ is continuous and has a continuous first derivative $\partial M_n''(\cdot\,,\xi)/\partial\xi$ on this support. The proof of these two facts is elementary. By a version of a theorem of Stinespring[12] due to Lyford,[22] these properties of $M_n''(\cdot\,,\xi)$ imply that B_n'' is trace class.

V. SPECTRUM OF $h_\theta^1 (\theta \in G)$

A. Preliminary remarks

In this section, we will once more fix $\theta \in G$, which again allows us to simplify the notation by omitting θ from various symbols. In particular, we write

$$k_n = 4\pi^2 |n + \theta|^2, \quad n \in \mathbf{Z}^{\nu-1}. \tag{5.1}$$

If $f \in L^2_{\mathrm{loc}}(\overline{\omega})$ has an extension to $L^2_{\mathrm{loc}}(\overline{\Omega})$ having property P_θ, then it has the $L^2_{\mathrm{loc}}(\overline{\omega}_{1,\infty})$-convergent series representation

$$f(x) = \sum_{n \in \mathbf{Z}^{\nu-1}} f_n(x_\nu) \eta_n(\tilde{x}), \quad \text{a.e. } x \in \omega_{1,\infty}, \tag{5.2a}$$

in the open cylindrical subset $\omega_{1,\infty}$ of ω, where we recall that $\omega_{r,\infty} = \{x \in \omega : x_\nu > r\}$ and where

$$f_n(x_\nu) = \int_G \eta_n(\tilde{x}) f(\tilde{x}, x_\nu) d\tilde{x}, \quad n \in \mathbf{Z}^{\nu-1}, \quad \text{a.e. } x_\nu > 1, \tag{5.2b}$$

the set of functions

$$\eta_n(\tilde{x}) = \exp[2\pi i (n + \theta).\tilde{x}], \quad \tilde{x} \in G, \ n \in \mathbf{Z}^{\nu-1}, \tag{5.2c}$$

being a complete orthonormal set in $L^2(G)$.

By condition 2, $V(x)=w(x_\nu), \forall x \in \omega_{a,\infty}$ for a fixed $a>1$, where $w \in C^\infty((a,\infty))$. Suppose that this condition holds and that f is as stated in the previous paragraph, and in addition is a weak (and therefore strict) solution of the elliptic equation,

$$-\Delta f + w(x_\nu) f = \zeta f, \quad x \in \omega_{a,\infty}, \tag{5.3}$$

for some $\zeta \in \mathbf{C}$. Then the restriction of f to $\omega_{a,\infty}$ is equivalent to a $C^\infty(\omega_{a,\infty})$ function,[23] with which we will identify it w.l.g. This fact, the P_θ property of f, and (5.1), (5.2b), and (5.2c) entail (via differentiation under the integral sign and partial integration) that $\int_G \Delta f(\tilde{x},x_\nu).\eta_n(\tilde{x})d\tilde{x} = -d^2 f_n(x_\nu)/dx_\nu^2 + k_n f_n(x_\nu)$ for $x_\nu > a$. In turn, this leads to

$$\frac{d^2 f_n(x_\nu)}{dx_\nu^2} - [k_n - \zeta + w(x_\nu)] f_n(x_\nu) = 0, \quad x_\nu > a, \ \ n \in \mathbf{Z}^{\nu-1}, \tag{5.4}$$

with the aid of (5.2b) and (5.3). Our discussions of the spectrum of h_θ^1 in this section depend in an essential way on the asymptotic behavior of the solutions of this ODE for $x_\nu \to \infty$.

B. Point spectrum of h_θ^1

By Lemma 4.2, the absolutely continuous spectrum of h_θ^1 coincides with the spectrum of h_θ^0, since the latter spectrum is purely absolutely continuous. In this and the next section, we will discuss the singular spectrum of h_θ^1. The main result of the present section, stated in Lemma 5.1, is that the eigenvalues of h_θ^1 in suitable intervals are isolated and have finite multiplicity. This result will be used in Sec. V C to show that the singular continuous spectrum of h_θ^1 is empty.

Lemma 5.1: Let conditions 1, 2 be satisfied. Let $I \subset \mathbf{R}$ be a compact interval $[A,B]$ or a semi-infinite interval of the form $(-\infty,B]$, no k_n's being contained in either of these intervals [recall (5.1)]. Then h_θ^1 has a finite number of eigenvalues in I, each having finite multiplicity.

Proof: It will be by contradiction. Let $\{\phi_m\}_{m \in \mathbf{N}}$ be an infinite orthonormal set of eigenfunctions of h_θ^1 with eigenvalues λ_m lying in a compact interval $[A,B]$ or $(-\infty,B]$ not containing any k_n's. We claim that $\{\phi_m\}_{m \in \mathbf{N}}$ is bounded in $H^1(\omega)$. This follows from two facts. First, since the ϕ_m are orthonormal, this sequence is trivially bounded in $L^2(\omega)$. Second, for each $m \in \mathbf{N}$,

$$\|\nabla \phi_m\|_\omega^2 = \langle \phi_m, -\Delta \phi_m \rangle_\omega = \langle \phi_m, h_\theta^1 \phi_m - v_\theta \phi_m \rangle_\omega = \lambda_m + |\langle \phi_m, v_\theta \phi_m \rangle_\omega| \leqslant B + \text{const}, \tag{5.5}$$

where "const" is independent of m. The first equality in (5.5) follows from $\phi_m \in D(h_\theta^1)$ and the formula mentioned in Ref. 21, and to derive the rest of (5.5) we have used (3.16), $v_\theta \ll h_\theta$, the boundedness of v_θ, $\lambda_m \leqslant B$, and the fact that $\|\phi_m\|_\omega = 1$.

Next, we use the boundedness of $\{\phi_m\}_{m \in \mathbf{N}}$ in $H^1(\omega)$ and other arguments to show that this sequence has a subsequence that is Cauchy in $L^2(\omega)$. This is absurd and will thus complete the proof of the lemma.

Since each $\phi_m \in L^2(\omega)$ and its Fourier coefficients $(\phi_m)_n(x_\nu)$ in the expansion (5.2a) satisfy a differential equation of the type (5.4) (with ζ replaced by λ_m), and in view of Lemma C.1 [see especially Eqs. (C.3a) and (C.4a)] and the definition of $\sqrt{z}(z \in \mathbf{C})$ in Appendix C, it follows that

$$\phi_m(\tilde{x},x_\nu) = \phi_m(\tilde{x},b+y) = \sum_{n \in Z^{\nu-1}, k_n > \lambda_m} C_{mn} \exp(-\sqrt{k_n - \lambda_m}\, y)[1 + \rho(y, k_n - \lambda_m)]\, \eta_n(\tilde{x}),$$
$$x \in \omega_{b,\infty}, \tag{5.6}$$

in the $L^2(\omega_{b,\infty})$ sense. Here $b > a$ is a constant, $y = x_\nu - b > a - b$ [i.e., J in Lemma C.1 is $(a-b,\infty) \supset [0,\infty)$ in the present case], the C_{mn} are constants, and

$$|\rho(y,\kappa)| = \exp\left(\int_y^\infty |q(\xi)|\, d\xi/\kappa \right) - 1, \quad \kappa > 0, \ \ y \geqslant 0, \tag{5.7}$$

where $q(y)=w(x_\nu)$. Since $\int_0^\infty |q(\xi)|d\xi<\infty$ by 2, (5.7) makes sense. Using (5.6) and the orthonormality of the $\eta_n(\tilde{x})$, and choosing $r>0$ so large that

$$0<\rho(r,p)<1/2, \tag{5.8a}$$

where $p=\min\{\sqrt{k_n-B}:k_n>B\}$, we obtain

$$\begin{aligned}\|\phi_m\|^2_{\omega_{b+r,\infty}} &= \sum_{n\in\mathbf{Z}^{\nu-1},k_n>\lambda_m} |C_{mn}|^2 \int_r^\infty \exp(-2\sqrt{k_n-\lambda_m}y).[1+\rho(y,k_n-\lambda_m)] \\ &\leqslant \sum_{n\in\mathbf{Z}^{\nu-1},k_n>\lambda_m} |C_{mn}|^2 \exp(-2\sqrt{k_n-\lambda_m}r).[1+\rho(r,p)]^2/2\sqrt{k_n-\lambda_m} \\ &< (9/8) \sum_{n\in\mathbf{Z}^{\nu-1},k_n>\lambda_m} |C_{mn}|^2 \exp(-2\sqrt{k_n-\lambda_m}r)/\sqrt{k_n-\lambda_m}. \end{aligned} \tag{5.9a}$$

Actually, we will choose $r>0$ even larger, and in fact so large that

$$0<\rho(r/2,p)<1/2, \tag{5.8b}$$

which implies (5.8a). Doing this and proceeding similarly to the way in which we derived (5.8a), we see that both

$$\|\phi_m\|_{\omega_{b+r/2,\infty}} > (1/8) \sum_{n\in\mathbf{Z}^{\nu-1}} |C_{mn}|^2 \exp(\sqrt{k_n-\lambda_m}r)/\sqrt{k_n-\lambda_m}, \tag{5.9b}$$

and (5.9a) hold. By (5.9a) and (5.9b),

$$\|\phi_m\|^2_{\omega_{b+r,\infty}} < 9\exp(-pr)\|\phi_m\|^2_{\omega_{b+r/2,\infty}} \leqslant 9\exp(-pr)\|\phi_m\|^2_{\omega} \leqslant 9\exp(-pr). \tag{5.10}$$

Now, the sequence $\{\phi_m\}_{m\in\mathbf{N}}$ is bounded in $H^1(\omega)$ and each $\phi_m\in D(h_\theta)$. Hence, by the local compactness (LC) property of ω (Lemma B.1), $\{\phi_m\}_{m\in\mathbf{N}}$ has a subsequence $\{\phi_m\}_{m\in\mathcal{T}}$ that is Cauchy in $L^2_{\mathrm{loc}}(\overline{\omega})$. That is,

$$\|\phi_m-\phi_n\|_{\omega_{b+s}}\to 0, \quad \text{for } m,n\in\mathcal{J} \quad \text{and } m,n\to\infty, \tag{5.11}$$

$\forall s>0$, where $\mathcal{J}\subset\mathbf{N}$ is independent of s by the LC property. Henceforth, the indices m,n will be assumed to be in $\mathcal{J}$.

It is now easy to show that $\{\phi_m\}_{m\in\mathcal{T}}$ is Cauchy in $L^2(\omega)$. Indeed, note that for an arbitrary $\varepsilon>0$ there exists $n_0\in\mathcal{J}$, such that

$$\begin{aligned}\|\phi_m-\phi_n\|^2_{\omega_{b+r,\infty}} &= \|\phi_m\|^2_{\omega_{b+r,\infty}} + \|\phi_n\|^2_{\omega_{b+r,\infty}} + 2\|\phi_m\|_{\omega_{b+r,\infty}}\cdot\|\phi_n\|_{\omega_{b+r,\infty}} \\ &\leqslant 36\exp(-pr)\leqslant \varepsilon^2/2, \quad \forall m,n\geqslant n_0, \end{aligned} \tag{5.12}$$

if r is large enough. W.l.g., we will assume that r is so large that (5.12), as well as (5.8b), and therefore also (5.8a), obtain. Moreover, by (5.11) there exists $n_1\in\mathcal{J}$ such that

$$\|\phi_m-\phi_n\|^2_{\omega_{b+r}} \leqslant \varepsilon^2/2, \quad \forall m,n\geqslant n_1. \tag{5.13}$$

An immediate consequence of (5.11) and (5.13) is that the subsequence $\{\phi_m\}_{m\in\mathcal{J}}$ is Cauchy in $L^2(\omega)$. Since this is impossible, h^1_θ has a finite number of eigenvalues in I, each having finite multiplicity. □

C. Absence of the singular continous spectrum of h_θ^1

This fact is asserted by Lemma 5.4. A key preliminary step in its proof is Lemma 5.3, which states an important boundedness property of the resolvent of h_θ^1 at points of the complex plane approaching certain points of the real axis. In this section we assume that conditions 1 and 2 are satisfied.

Before proving Lemmas 5.3 and 5.4, we introduce some terminology. We first define the set

$$\mathcal{D}_\theta=\{f\in L^2_{\mathrm{loc}}(\Delta;\overline{\omega})\cap H^1_{\mathrm{loc}}(\overline{\omega}):\ f\ \text{has an extension,}$$

$$\text{to } L^2_{\mathrm{loc}}(\Delta;\overline{\Omega})\cap H^1_{0,\mathrm{loc}}(\overline{\Omega})\ \text{with property } P_\theta\}. \tag{5.14}$$

Second, $f\in L^2_{\mathrm{loc}}(\overline{\omega})$ will be said to satisfy the outgoing (resp., incoming) radiation condition in ω if

$$f_n(x_\nu)\sim\begin{cases}\text{const}\exp(-\sqrt{k_n-\lambda}\,x_\nu), & \text{if } k_n>\lambda,\\ \text{const}\exp(\pm i\sqrt{|k_n-\lambda|}\,x_\nu), & \text{if } k_n<\lambda,\end{cases} \tag{5.15}$$

holds for $x_\nu\to\infty$ with the $+$ (resp., $-$) sign for some $\lambda\in\mathbf{R}$ and all $n\in\mathbf{Z}^{\nu-1}$. Third, we set

$$\Lambda=\{\lambda\in\mathbf{R}:\ \lambda\notin\sigma_p(h_\theta^1),\lambda\neq k_n,\forall n\in\mathbf{Z}^{\nu-1}\}, \tag{5.16}$$

where $\sigma_p(h_\theta^1)$ denotes the point spectrum of h_θ^1.

The next lemma will be used to prove Lemma 5.3.

Lemma 5.2: Suppose that $f\in\mathcal{D}_\theta$ satisfies the incoming or outgoing radiation condition in ω and that the equation

$$-\Delta f+\tilde{V}f=\lambda f \tag{5.17}$$

holds for some $\lambda\in\Lambda$ in the distributional sense, where $\tilde{V}$ is the maximal operator of multiplication by the function $V|\omega$, V denoting the function with properties 1, 2 that was introduced in Sec. III A. Then $f=0$.

Proof: We will prove the lemma by contradiction in the case when $f\in\mathcal{D}_\theta$ satisfies the outgoing radiation condition. It can be proved similarly when the incoming radiation condition obtains. Obviously, the Fourier coefficients $f_n(x_\nu)$ of $f(x)$ satisfy the ODE (5.4) with ζ replaced by $\lambda\forall y=x_\nu-b\geqslant 0$. Moreover, using Lemma C.1 [particularly (C.3a) and (C.3b)], we see that in the present case f has the $L^2_{\mathrm{loc}}(\overline{\omega}_{b,\infty})$-convergent series representation,

$$f(x)=\sum_{n\in\mathbf{Z}^{\nu-1}}\gamma_n\exp(\sigma_n\sqrt{|k_n-\lambda|}y)[1+\rho_n(y)]\,\eta_n(\tilde{x}),\quad \text{a.e. } x\in\omega_{b,\infty}, \tag{5.18a}$$

where the γ_n's are constants and $\sigma_n=-1$, i in the respective cases $k_n>\lambda$, $k_n<\lambda$ (the only ones possible since $\lambda\in\Lambda$), and where $\rho_n(y)=o(1)$ as $y\to\infty$. Again using Lemma C.1 and arguments analogous to those adduced to derive (5.18a), one can show that $\partial f/\partial x_\nu$ is represented by the $L^2_{\mathrm{loc}}(\overline{\omega}_{b,\infty})$-convergent series:

$$\frac{\partial f(x)}{\partial x_\nu}=\sum_{n\in Z^{\nu-1}}\gamma_n\sigma_n\sqrt{|k_n-\lambda|}\exp(\sigma_n\sqrt{|k_n-\lambda|}y)[1+\tilde{\rho}_n(y)]\,\eta_n(\tilde{x}),$$

$$\text{a.e. } x\in\omega_{b,\infty}, \tag{5.18b}$$

where each $\tilde{\rho}_n(y)=o(1)$ as $y\to\infty$. Note that the only summands in (5.18a) and (5.18b) not vanishing a.e. are those for which either $k_n>\lambda$ or $k_n<\lambda$, since $\lambda\in\Lambda$.

By Lemma C.5 of Ref. 5, (5.18), and the orthonormality of the η_n, it follows that

$$\int_G \left[\overline{f} \frac{\partial f(x)}{\partial x_\nu} - f \frac{\partial \overline{f}(x)}{\partial x_\nu} \right] (\tilde{x}, x_\nu) d\tilde{x} = \sum_{n \in \mathbf{Z}^{\nu-1}} \left[\overline{f}_n \frac{df_n}{dx_\nu} - f_n \frac{d\overline{f}_n}{dx_\nu} \right] (x_\nu) = 0, \quad x_\nu > b. \tag{5.19}$$

Using the reality of the summands in (5.18b) when $k_n > \lambda$, one sees that the contribution of such summands to the sum in (5.19) vanishes. On the other hand, the contribution of the terms with $k_n < \lambda$, for which $\sigma_n = i$, has the form shown on the lhs of the equation,

$$\sum_{n \in Z^{\nu-1}, k_n < \lambda} |\gamma_n|^2 [1 + \psi_n(y)] = 0, \ x_\nu > b \tag{5.20}$$

(except for an unimportant factor $2i$). Here $\psi_n(y) = o(1)$ as $y \to \infty$. Since the sum (5.20) contains only a finite number of nonvanishing terms, we conclude that $\gamma_n = 0$ if $k_n < \lambda$. By this result and (5.18a),

$$f(x) = \sum_{n \in \mathbf{Z}^{\nu-1}, k_n > \lambda} \gamma_n \exp(-\sqrt{k_n - \lambda} y)[1 + \rho_n(y)] \eta_n(\tilde{x}), \quad \text{a.e. } x \in \omega_{b,\infty}. \tag{5.18c}$$

Consequently, $f \in L^2(\omega_{b,\infty})$. Since $f \in L^2_{\mathrm{loc}}(\overline{\omega})$ holds as well, we conclude that $f \in L^2(\omega)$. Moreover, since $\Delta f = v(x) f + \lambda f$ a.e. on ω and $v \in L^2(\omega)$, we see that $\Delta f \in L^2(\omega)$, and hence that $f \in L^2(\Delta; \omega)$. Now, $f \in \mathcal{D}_\theta$ by hypothesis and $\mathcal{D}_\theta \cap L^2(\Delta; \omega) = D(h_\theta)$ by Lemma 7.2 of Ref. 5 (where "$\subset$," "$\cap$" should read "$\cap$," "$\subset$," respectively). Therefore, $f \in D(h_\theta) = D(h^1_\theta)$ and $h^1_\theta f = \lambda f$. But since $\lambda \notin \sigma_p(h^1_\theta)$, it follows that $f = 0$. □

The next lemma states in a precise fashion the boundedness property of the resolvent $R_\zeta = (h^1_\theta - \zeta 1_{L^2(\omega)})^{-1}$ alluded to above.

Lemma 5.3: Let $[\gamma, \delta] \subset \Lambda$ be a compact interval and $b \in (a, \infty)$. Suppose $f \in L^2(\omega)$, $\operatorname{supp} f \subset \omega_b$, and $\|f\|_{\omega_b} = 1$. Then

$$\|R_{\lambda \pm i\sigma} f\|_{1,\omega_c} \leqslant K_{bc}, \tag{5.21}$$

$\forall c \in (b, \infty)$, provided that $\lambda \in [\gamma, \delta]$ and $\sigma \in (0,1)$, where K_{bc} is a constant independent of λ, σ, f. (See Appendix A for the definition of $\|\cdot\|_{1,A}$.)

Proof: We will prove it by contradiction for the case of the + sign in (5.21), the proof for the − sign being similar. Suppose the lemma is false for some finite $c > b \geqslant a > 1$, where a is the constant in condition 2. Then there exist sequences $\{\zeta_k = \lambda_k + i\sigma_k\}_{k \in \mathbf{N}}$ and $\{f_k\}_{k \in \mathbf{N}}$, with $\lambda_k \in [\gamma, \delta]$, $\sigma_k \in (0,1)$ and $\|f_k\|_{\omega_c} = 1$, $\operatorname{supp} f_k \subset \omega_b$ $\forall k \in \mathbf{N}$, such that

$$\|R_{\zeta_k} f_k\|_{1,\omega_b} \geqslant k, \tag{5.22}$$

for each such k. Since $[\gamma, \delta] \times (0,1) \in \mathbf{R}^2$ is bounded, $\{\zeta_k\}_{k \in \mathbf{N}}$ will be assumed to converge w.l.g. Hence $\lambda_k \to \lambda \in [\gamma, \delta]$ and $\sigma_k \downarrow 0 (k \to \infty)$. For $\sigma_k \to \sigma \neq 0$ would contradict (5.22).

Define

$$u_k = \|R_{\zeta_k} f_k\|^{-1}_{1,\omega_c} R_{\zeta_k} f_k, \quad g_k = \|R_{\zeta_k} f_k\|^{-1}_{1,\omega_c} f_k, \quad k \in \mathbf{N}. \tag{5.23}$$

Hence $\|u_k\|_{1,\omega_c} = 1$ for all such k and $g_k \to 0$ in $L^2(\omega)$ as $k \to \infty$. Now $u_k \in D(h_\theta) \subset D_\theta$. Since the sequence $\{u_k\}_{k \in \mathbf{N}}$ is obviously bounded in $H^1(\omega)$, Lemma B.1 implies that it has a subsequence $\{u_k\}_{k \in \mathcal{K}}$, independent of c and Cauchy in $L^2(\omega_c)$. Directly from the definitions,

$$-\Delta u_k + w(y) u_k = \zeta_k u_k + g_k = \zeta_k u_k, \quad k \in N, \quad \text{a.e. } x \in \omega_{b,\infty}, \tag{5.24}$$

since supp $f_k \subset \omega_b$. Taking into account (5.24), condition 2, and Lemma C.1, together with the facts that $u_k \in L^2(\omega)$ and that $\mathrm{Re}\sqrt{k_n-\zeta_k}>0$, $\forall n \in \mathbf{Z}^{\nu-1} \forall k \in \mathbf{N}$, since $\mathrm{Im}\,\zeta_k \neq 0$ at each such k (recall the second sentence of the second paragraph of Appendix C), it follows that every such u_k is represented by the $L^2(\omega_{b,\infty})$-convergent series,

$$u_k(x)=\sum_{n\in\mathbf{Z}^{\nu-1}} (u_k)_n(x_\nu)\,\eta_n(\tilde{x}), \quad \text{a.e. } x\in\omega_{b,\infty}, \tag{5.25a}$$

where

$$(u_k)_n(x_\nu)=C_{kn}\exp(-\sqrt{k_n-\zeta_k}\,y)[1+\rho_{kn}(y)],$$
$$n\in\mathbf{Z}^{\nu-1}, \quad y\geqslant 0. \tag{5.25b}$$

Here

$$\rho_{kn}(y)\leqslant Q(y)=\exp\left(\int_y^\infty |w(\xi)|\,d\xi/P\right)-1, \quad y\geqslant 0, \tag{5.25c}$$

with $P=\min\{\sqrt{|k_m-\zeta_j|}, m\in\mathbf{Z}^{\nu-1}, j\in\mathbf{N}, \mathrm{Re}\,\zeta_j\in[\gamma,\delta], \mathrm{Im}\,\zeta_j\in(0,1)\}$.

We claim that

$$\|u_k\|_{b+jr,b+(j+1)r}\leqslant\|u_k\|_{b+r,b+2r}, \quad j=0,1,2,3,\ldots, \tag{5.26}$$

if r is so large that

$$0<Q(r)<1, \quad \exp(-2rP)\frac{[1+Q(r)]^2}{[1-Q(r)]^2}\leqslant 1. \tag{5.27}$$

This claim can be proved similarly to (5.9a).

Since $\{u_k\}_{k\in\mathcal{K}}$ is Cauchy in $L^2(\omega_c)$ and (5.26) holds, this subsequence is also Cauchy in $L^2_{\mathrm{loc}}(\overline{\omega})$. By $\Delta u_k=-[\zeta_k+V(x)]u_k$ (a.e. $x\in\omega$), $\{u_k\}_{k\in\mathcal{K}}$ is Cauchy in $L^2_{\mathrm{loc}}(\Delta;\overline{\omega})$ as well. Therefore, $u_k\to u\in\mathcal{D}_\theta$ in $L^2_{\mathrm{loc}}(\Delta;\overline{\omega})$ by Lemma 7.1 of Ref. 5, with

$$-\Delta u(x)+V(x)u=\lambda u(x), \quad \text{a.e. } x\in\omega, \tag{5.28}$$

$\lambda\in[\gamma,\delta]$ denoting the limit of the sequence $\{\zeta_k\}_{k\in\mathbf{N}}$ as above.

We now show that u satisfies the outgoing radiation condition, and hence that $u=0$ by Lemma 5.2. But since $\|u_k\|_{1,\omega_b}=1$ $(k\in\mathcal{K})$, this is absurd and will complete the proof.

We will write $y=x_\nu$ for convenience. Since $u_k\to u$ in $L^2_{\mathrm{loc}}(\overline{\omega})$, it follows that $(u_k)_n\to u_n \in L^2_{\mathrm{loc}}(\overline{\mathbf{R}}_+)$ by Schwarz's inequality, where $\mathbf{R}_+=[0,\infty)$. By a standard smoothness argument, this entails pointwise convergence: $(u_k)_n(y)\to u_n(y)$ for $y\geqslant 0$ as $k\to\infty$. We thus have for each such y by (5.24), (5.28), and other arguments, analogous to those used to prove (5.4):

$$\frac{d^2(u_k)}{dy^2}-[k_n-\zeta_k+w(y)](u_k)_n=0, \tag{5.29a}$$

$$\frac{d^2u_n}{dy^2}-[k_n-\lambda+w(y)]u_n=0. \tag{5.29b}$$

Fixing $n\in\mathbf{Z}^{\nu-1}$, and since $\lambda\in\Lambda$, either $k_n>\lambda$ [case (a)] or $k_n<\lambda$ [case (b)]. We note that

$$\exp(-\sqrt{k_n-\zeta_k}\,y)\sim\begin{cases}\exp(i\sqrt{|k_n-\lambda|}\,y) & \text{in case (a)},\\ \exp(-\sqrt{|k_n-\lambda|}\,y) & \text{in case (b)},\end{cases} \tag{5.30}$$

as $k\to\infty$. By the pointwise convergence property of $(u_k)_n(y)$, together with (5.25b), (5.30), and Lemma C.1, it follows that $u_n(y)$ can be written as the linear combination,

$$u_n(y)=C_n'\exp(i\sqrt{|k_n-\lambda|}y)[1+\rho_n^+(y)]+D_n'\exp(-i\sqrt{|k_n-\lambda|}y)[1+\rho_n^+(y)]$$
$$\equiv C_n'u_n^+(y)+D_n'u_n^-(y), \tag{5.31}$$

where $\rho_n^\pm(y)=o(y)$ as $y\to\infty$ and $u_n^\pm(y)$ are linearly independent solutions of (5.29b) for $y\geqslant 0$. Note also that by (C5) and the definition of $u_n^+(y)$,

$$u_n(y)=\lim_{k\to\infty}\{C_{nk}\exp(-\sqrt{k_n-\zeta_k}y)[1+\rho_{kn}(y)]\}=C_nu_n^+(y), \tag{5.32}$$

at each such y, where the limit $C_{kn}\to C_n\in\mathbf{C}$ as $k\to\infty$ exists.[24] By (5.31) and (5.32),

$$C_nu_n^+(y)=C_n'u_n^+(y)+D_n'u_n^-(y),\quad y\geqslant 0. \tag{5.33}$$

But (5.33) and the linear independence of $u_n^\pm(y)$ implies that $D_n'=0$. Hence $u(y)$ satisfies the outgoing radiation condition. □

The main result of this section is as follows.

Lemma 5.4: h_θ^1 has an empty singular continuous spectrum.

Proof: Follows from Lemma 5.3 by the same arguments used to prove Lemma 7.6 in Ref. 5.□

VI. PROOF OF THEOREM 3.2

It will be given after some preliminary remarks, definitions, and lemmas. We will assume that conditions 1 and 2 hold throughout this section.

Denoting by $\mathcal{H}_{\rm ac}(h_\theta^1)$ and $\mathcal{H}_p(h_\theta^1)$ the subspace of absolute continuity of $L^2(\omega)$ wrt h_θ^1 and the closed span of the eigenfunctions of h_θ^1, respectively, it follows that

$$L^2(\omega)=\mathcal{H}_{\rm ac}(h_\theta^1)\oplus\mathcal{H}_p(h_\theta^1),\quad \theta\in G, \tag{6.1}$$

since the subspace of singular continuity of $L^2(\omega)$ wrt h_θ^1 is the zero subspace by Lemma 5.4.[25] The projection operators $P_{\rm ac}$, P_s with domain $\mathcal{H}=L^2(\Omega)$ play an important role in this section. The former operator was defined in (4.3), and we define

$$UP_sU^{-1}=\int_G^\oplus P_p(h_\theta^1)d\theta, \tag{6.2}$$

where U is the unitary operator from $\mathcal{H}$ onto the single-fiber direct integral $\int_G^\oplus L^2(\omega)d\theta$ of Hilbert spaces introduced in Sec. III B and $P_p(h_\theta^1)$ the projection from $L^2(\omega)$ into $\mathcal{H}_p(h_\theta^1)$. Needless to say, P_s exists for reasons analogous to those guaranteeing the existence of $P_{\rm ac}$ that were mentioned in Sec. IV. As a byproduct of results in the present section, we will see that the equations

$$\mathrm{Ran}\,P_{\rm ac}=\mathcal{H}_{\rm scatt}, \tag{6.3a}$$

$$\mathrm{Ran}\,P_s=\mathcal{H}_{\rm surf} \tag{6.3b}$$

hold, the first of which was used to prove Theorem 3.1.

The next three lemmas are needed to prove Theorem 3.2.

Lemma 6.1: (a) $\mathcal{H}_{\rm scatt}$ and $\mathcal{H}_{\rm surf}$ are mutually orthogonal subspaces of $\mathcal{H}$.

Proof: The same as that of Lemma 8.1, Ref. 5.

Lemma 6.2: $\mathrm{Ran}\,P_{\rm ac}\subset\mathcal{H}_{\rm scatt}$.

Proof: Let $f\in\mathrm{Ran}\,P_{\rm ac}$. Then $g:=Uf=\int_G^\oplus g_\theta\,d\theta$ is such that $g_\theta\in\mathcal{H}_{\rm ac}(h_\theta^1)$ for a.e. $\theta\in G$. Fix $\theta\in G$ for which this holds and fix $a\geqslant 1$. Let X_a be the operator of multiplication in $L^2(\omega)$ by the characteristic function of $\omega_a=\{x\in\omega: x_\nu<a\}$. Let $[c,d]\subset\mathbf{R}$ be compact, with $c=\inf$ of the spec-

trum of h_θ^1, and denote by $E(\cdot;h_\theta^1)$ the spectral measure of h_θ^1. Then by the LC property of ω (defined as stated in the Remark to Lemma B.1), $X_a E([c,d];h_\theta^1)$ is a compact operator in $L^2(\omega)$. By $g_\theta \in \mathcal{H}_{\mathrm{ac}}(h_\theta^1)$ and the Riemann–Lebesgue lemma, $s-\lim_{t\to\pm\infty} X_a E([c,d];h_\theta^1)\exp(-ith_\theta^1)g_\theta = 0$. Since $X_a E([c,d];h_\theta^1)$ is compact, $s-\lim_{t\to\pm\infty} X_a E([c,d];h_\theta^1)\exp(-ith_\theta^1)g_\theta=0$. Since $s-\lim_{d\to\infty} E([c,d];h_\theta^1)=I_{L^2_{(\omega)}}$, it follows that[26]

$$\lim_{t\to\pm\infty} \|\exp(-ith_\theta^1)g_\theta\|_{\omega_a}=0. \tag{6.4}$$

By (3.17a) and (3.12),

$$\|\exp(-itH_1)f\|_{\Omega_a}^2=\int_G \|\exp(-ith_\theta^1)g_\theta\|_{\omega_a}^2\, d\theta, \tag{6.5}$$

if f is of bounded support, but a simple density argument allows us to drop this requirement. By (6.5), together with

$$\|\exp(-ith_\theta^1)g_\theta\|_{\omega_a}\leqslant\|g_\theta\|_{\omega_a}, \tag{6.6}$$

and the dominated convergence theorem, we infer that

$$\lim_{t\to\pm\infty} \|\exp(-itH_1)f\|_{\Omega_a}^2=\int_G \lim_{t\to\pm\infty} \|\exp(-ith_\theta^1)g_\theta\|_{\omega_a}^2\, d\theta=0, \tag{6.7}$$

and hence that $f\in\mathcal{H}_{\mathrm{scatt}}$. □

Lemma 6.3: $\mathrm{Ran}\, P_s\subset\mathcal{H}_{\mathrm{surf}}$.

Proof: Similar to that of a result of Davies and Simon.[27]

Proof of Theorem 3.2: By (6.1) and Lemmas 6.1–6.3,

$$\mathcal{H}=\mathrm{Ran}\, P_{\mathrm{ac}}\oplus\mathrm{Ran}\, P_s\subset\mathcal{H}_{\mathrm{scatt}}\oplus\mathcal{H}_{\mathrm{surf}}, \tag{6.8}$$

which immediately implies

$$\mathcal{H}=\mathcal{H}_{\mathrm{scatt}}\oplus\mathcal{H}_{\mathrm{surf}}, \tag{6.9}$$

thus proving Theorem 3.2. □

Equations (6.3) are direct consequences of Lemma 6.1, (6.4), and (6.5).

ACKNOWLEDGMENTS

The author is indebted to his colleagues of the Seminar of Functional Analysis, Mathematics Department, Catholic University, Washington, DC, and to Professor B. Simon for their helpful comments. He also thanks ONR for its partial support of this research at NRL.

APPENDIX A: FUNCTION SPACE NOTATION

For a measurable subset $A\subset\mathbf{R}^\nu(\nu\geqslant 2)$, the norm and inner product in the complex vector space $L^2(A)$ will be written as

$$\|\cdot\|_A,\ \langle\ \rangle_A,$$

respectively. $L^2(\Delta;A)$ denotes the complex Hilbert space of all $f\in L^2(A)$ such that $\Delta f\in L^2(A)$, equipped with the norm

$$\|f\|_{\Delta;A}=(\|f\|_A^2+\|\Delta f\|_A^2)^{1/2},$$

where Δ and all other partial differential operators in this appendix should be understood in the distributional sense.

The only Sobolev spaces used in this paper are $H^1(A)$ and $H_0^1(A)\subset H^1(A)$. The norm of $H^1(A)$ is denoted by

$$\|f\|_{1,A}=\left(\|f\|_A^2+\sum_{i=1}^{\nu}\|\partial f/\partial x_i\|_A^2\right)^{1/2}.$$

$L^2_{\mathrm{loc}}(\Delta;\overline{A})$ denotes the Fréchet space of (equivalence classes of) complex-valued functions f on A with $f|A(r)$, $\partial f/\partial x_i|A(r)\in L^2(A(r))$ $[r>0,A(r)\neq\varnothing]$, whose topology is generated by the seminorms

$$\|\cdot\|_{1,A(r)},\quad r>0,\quad A(r)\neq\varnothing.$$

We also need $H^1_{\mathrm{loc}}(\overline{A})$, the Fréchet space composed of all such functions f on A with $f|A(r)$, $\partial f/\partial x_i|A(r)\in L^2(A(r))$ for all such r, whose topology is generated by the seminorms

$$\|\cdot\|_{1,A(r)},\quad r>0,\quad A(r)\neq\varnothing.$$

Finally, $H^1_{0,\mathrm{loc}}(\overline{A})$ is a (closed) subspace of $H^1_{\mathrm{loc}}(\overline{A})$ that is the completion of $C_0^\infty(A)$ in the $H^1_{\mathrm{loc}}(\overline{A})$ topology.

For Fréchet spaces, $\overline{A}$ has been used to indicate integrability up to the boundary.

APPENDIX B: LOCAL COMPACTNESS OF ω

The main purpose of this appendix is to state Lemma B.1, which we use to prove Lemmas 5.1 and 5.3.

An open subset $A\subset\mathbf{R}^\nu(\nu\geqslant 2)$ is said to have the local compactness (LC) property for a bounded subset $B\subset H^1(A)$ if B is precompact in $L^2(A(r))$ for each $r>0$, with $A(r)\neq\varnothing$, i.e., if for each such r every sequence $\{f_n\}_{n\in\mathbf{N}}\subset B$ has a subsequence $\{f_{n_k}\}$ such that $\{f_{n_k}|A(r)\}$ is Cauchy in $L^2(A(r))$.

Lemma B.1: ω has the LC property for every bounded subset $H^1(\omega)\subset D(h_\theta)$, $\forall\,\theta\in G$.

Remarks: In the case $A=\omega$ considered in the lemma, the above definition of LC is equivalent to that obtained by replacing $\omega(r)$ by ω_r.

Proof: This is a special case of Lemma 4.6 of Ref. 5.

APPENDIX C: LEMMA ON ASYMPTOTIC SOLUTIONS OF A SECOND-ORDER ODE

The lemma stated in this appendix is used in the proofs of Lemmas 5.1–5.3. In it and throughout the paper, we define the square root of a complex number z by $\sqrt{z}=\exp(i\phi/2)\sqrt{|z|}$ for $\phi:=\arg z\in(-\pi,\pi)$ and set $\sqrt{z}=i\sqrt{|z|}$ for $z<0$. It is important to note that this definition implies that $\mathrm{Re}\,\sqrt{z}>0$ if $\mathrm{Im}\,\sqrt{z}\neq 0$.

Lemma C.1: Let $z\in\mathbf{C}\backslash\{0\}$ and suppose that $q\in C^1(J)$ is absolutely integrable over J, where $J\supset[0,\infty)$ is an open interval. Then for $0\leqslant y<\infty$ the differential equation,

$$\frac{d^2u}{dy^2}-[z+q(y)]u=0, \tag{C1}$$

has two solutions $u_\pm(y;z)$, linearly independent over this interval, satisfying the initial conditions

$$u_\pm(y;0)=1,\quad \frac{du_\pm(y;0)}{dy}=\pm\sqrt{z}, \tag{C2}$$

and such that

$$u_{\pm}(y;z)=\exp(\pm\sqrt{z}y)[1+\rho_{\pm}(y;z), \tag{C3a}$$

$$\frac{du_{\pm}(y;z)}{dy}=\pm\sqrt{z}\exp(\sqrt{z}y)[1+\sigma_{\pm}(y;z)], \tag{C3b}$$

where $\rho_{\pm}(y)$, $\sigma_{\pm}(y)$ are $o(1)$ as $y\to\infty$ and are real for $0\leqslant y<\infty$ if $z>0$. Moreover,

$$|\rho_{-}(y;z)|\leqslant\exp\left(\int_y^{\infty}|q(\xi)|d\xi/\sqrt{|z|}\right)-1, \tag{C4a}$$

$$|\sigma_{-}(y;z)|\leqslant\exp\left(\int_0^{\infty}|q(\xi)|d\xi/\sqrt{|z|}\right)\left[\exp\left(\int_y^{\infty}|q(\xi)|d\xi/\sqrt{|z|}\right)-1\right] \tag{C4b}$$

for y in the latter interval. Finally, if $(z_j)_{j\in\mathbf{N}}\subset\mathbf{C}\backslash\{0\}$ denotes a sequence converging to $\hat{z}\in\mathbf{C}\backslash\{0\}$, then

$$\lim_{j\to\infty}u_{-}(y;z_j)=u_{-}(y;\hat{z}), \tag{C5}$$

for $0\leqslant y\leqslant\infty$.

Remark: Properties of $\rho_{+}(y;z)$, $\sigma_{+}(y;z)$, and $u_{+}(y;z)$ analogous to those stated in (C4a), (C4b), and (C5), respectively, are readily derivable, but will not be needed.

Proof: Proofs of Eqs. (C3) are given in Ref. 28 for the case when $\mathrm{Re}\,\sqrt{z}\neq 0$. These equations follow more easily by integral-equation arguments. In the remaining case, namely $z=-1$, they are readily proved by the integral-equation approach used to derive (C4), which we now sketch.[29] To prove (C4a), one sets $u_{-}(y;z)=\exp(-\sqrt{z}y)U(y;z)$, constructs a singular Volterra integral equation for $U(y;z)$, and obtains an estimate for this function by solving it by successive approximations. Inequality (C4b) follows by differentiating the above expression for $u_{-}(y;z)$ and using this estimate and one for $\partial U(y;z)/\partial y$ that is derivable analogously. Finally, (C5) follows by a standard uniform-convergence argument using the solution of the said Volterra equation. □

[14] For the general theory of direct integrals, see J. Dixmier, *Les algèbres d'operateurs dans l'espace Hilbertien*, 2nd ed. (Gauthier-Villars, Paris, 1969), Chap. II. For most (but not all) of our needs, the treatment in M. Reed and B. Simon, *Methods of Modern Mathematical Physics IV: Analysis of Operators* (Academic, New York, 1978), Sec. XIII.16, suffices.

[15] The self-adjointness of the h_θ's, the measurability of the functions $\theta\mapsto h_\theta$, and (3.13a) are asserted by Lemmas 4.2, C.1 (where "$\theta\mapsto H_\theta$" should read "$\theta\mapsto h_\theta$"), and 4.5 of Ref. 5. The corresponding properties of the h_θ^0's are provable similarly.

[17] Reed and Simon, Ref. 14, Theorem XIII.85 (c), p. 284.

[18] This relation follows from the definition $\exp(itA)=s-\lim_{n\to\infty}[1-(itA/n)]^{-n}$ $(t\in\mathbf{R})$ for a self-adjoint operator A in a separable Hilbert space. See, e.g., T. Kato, *Perturbation Theory of Linear Operators* (Springer-Verlag, New York, 1966), Chap. IX, Sec. 1, paragraphs 2,3.

[19] See Ref. 5, Appendix B.1.

[20] The measurability of these functions follows from (4.4b) (which holds by Lemma 4.2) and the fact that each function $\theta\mapsto W_\theta^\pm$ is measurable, i.e., that for all $f\in L^2(\omega^0)$, $g\in L^2(\omega)$, the functions $\theta\mapsto\langle g,W_\theta^\pm f\rangle_\omega$ are measurable in the usual sense. The latter property follows from the measurability of $\theta\mapsto h_\theta^0$, $\theta\mapsto h_\theta$, and the existence of the $W_\theta^\pm$'s as strong limits.

[21] The second equality (4.14) is a special case of the formula $\langle\nabla f,\nabla g\rangle_\omega=\langle f,-\Delta g\rangle_\omega$, holding $\forall f,g\in D(h_\theta)$ by the alternative definition (4.8) of $D(h_\theta)$ in Ref. 5.

[23] M. Reed and B. Simon, Ref. 14, Theorem IX. 26, p. 54.

[24] The fact that $C_{kn}\to C_n$ as $k\to\infty$ for each n follows from two facts. First, the limit as $k\to\infty$ of the y-dependent factor of C_{kn} inside the brackets $\{\cdot\}$ in (5.31) exists and is not identically zero by (C5). Second, let $\{c_k\},\{d_k\},\{e_k\}$ be sequences in $\mathbf{C}$ such that $d_k\to d\neq 0$, $e_k\to e$. Then $\lim_k c_k=e/d$.

(Received 20 May 2003; accepted 15 January 2004)

We propose the extension of some structural aspects that have successfully been applied in the development of the theory of quantum fields propagating on a general space–time manifold so as to include superfield models on a supermanifold. We only deal with the limited class of supermanifolds which admit the existence of a smooth body manifold structure. Our considerations are based on the Catenacci–Reina–Teofillatto–Bryant approach to supermanifolds. In particular, we show that the class of supermanifolds constructed by Bonora–Pasti–Tonin satisfies the criteria which guarantee that a supermanifold admits a Hausdorff body manifold. This construction is the closest to the physicist's intuitive view of superspace as a manifold with some anticommuting coordinates, where the odd sector is topologically trivial. The paper also contains a new construction of superdistributions and useful results on the wavefront set of such objects. Moreover, a generalization of the spectral condition is formulated using the notion of the wavefront set of superdistributions, which is equivalent to the requirement that all of the component fields satisfy, on the body manifold, a microlocal spectral condition proposed by Brunetti–Fredenhagen–Köhler. © *2004 American Institute of Physics.*

I. INTRODUCTION

There are topics in the physical literature which do not exhaust themselves, but always deserve new analyses. Among these, the program to a quantum gravity theory has a significant part, remaining an open problem of physics and an active area of current research. In spite of the fact that many attempts have been made to include gravity in the quantization program, a satisfactory and definitive theory still does not exist. Many lines of research in quantum gravity developed over the last decades, under different names, such as the Supergravity, Kaluza–Klein, String, Twistors, D-brane, Loop Quantum Gravity, Noncommutative Geometry and Topos theories, have elucidated the role of quantum gravity, without, however, providing conclusive results (see, for instance, Ref. 1 for a recent review of the status of quantum gravity). Whereas these good ideas stay only as good promises in the direction of a final theory of the quantum gravity, and since the relevant scale of the Standard Model, or any of its supersymmetric extensions, is much below the typical gravity scale, it seems appropriate to treat, in an intermediate step, some aspects of gravity in quantum field theory by considering the approach which describes the matter quantum fields under the influence of a gravitational background. This framework has a wide range of physical applicability, the most prominent being the gravitational effect of particle creation in the vicinity of blackholes, raised up for the first time by Hawking.[2]

The study of quantum field theories on a general manifold has become an area of intensive

[a)]Present address: Universidade Federal do Espírito Santo (UFES), Departamento de Física, Campus Universitário de Goiabeiras, Vitória, ES, Brasil. Electronic mail: dhtf@terra.com.br

research activity, and a substantial progress has been made on a variety of interesting problems. In particular, great strides have been made towards the understanding of the question of how the spectral condition can be defined. While most of the Wightman axioms can be implemented on a curved space–time, the spectral condition (which expresses the positivity of the energy) represents a serious conceptual problem. On a flat space–time the Poincaré covariance, in particular the translations, guarantees the positivity of the spectrum, and fixes a unique vacuum state; but on a general curved space–time, due the absence of a global Poincaré group, there does not exist a useful notion of a vacuum state. As a result, the concept of particles becomes ambiguous, and the problem of the physical interpretation becomes much more difficult. One possible resolution to this difficulty is to choose some quantities other than particles content to label quantum states. Such an advice was given by Wald[3] with the purpose of finding the expectation value of the energy-momentum tensor. For free fields, this approach leads to the concept of Hadamard states. The latter are thought to be good candidates for describing physical states, at least for free quantum field theories in curved spacetime, according to the work of DeWitt and Brehme[4] (see Refs. 5, 6, 7 for a general review and references). In a seminal work, Radzikowski[8] showed that the global Hadamard condition can be locally characterized in terms of the wavefront set, and proved a conjecture by Kay[9] that a locally Hadamard quasifree Klein–Gordon state on any globally hyperbolic curved space–time must be globally Hadamard. His proof relies on a general *wavefront set spectrum condition* for the two-point distribution, which has made the connection with the spectral condition much more transparent (see also Refs. 10, 11).

The wavefront set was introduced by the mathematicians Hörmander and Duistermaat around 1971 (Refs. 12, 13) in their studies on the propagation of singularities of pseudodifferential operators, which rely on what is now known as a microlocal point of view. This subject is growing of importance, with a range of applications going beyond the original problems of linear partial equations. In particular, the link with quantum field theories on a curved space–time is now firmly established, especially after Radzikowski's work. A considerable amount of recent papers devoted to this subject[10,11,14–20] emphasizes the importance of the microlocal technique to solving some previously unsolved problems.

At the same time, it seems that not so much attention has been drawn to supersymmetric theories in this direction. Much of the progress made in understanding the physics of elementary particles has been achieved through a study of supersymmetry. The latter is a subject of considerable interest amongst physicists and mathematicians. It is not only fascinanting in its own right; in the 30 years that have passed since its proposal, supersymmetry has been studied intensively in the belief that such theories may play a part in a unified theory of the fundamental forces, and many issues are understood much better now. Although no clear signal has been observed up to now, supersymmetry is believed to be detectable, at least if certain minimal models of particle physics turn out to be realized in nature, and calculations and phenomenological analysis of supersymmetry models are well-justified in view of the forthcoming generation of machines, as the new super collider LHC being buit at CERN, which is expected to operate in a few years time and will have probably enough high energy to reveal some of the predicted supersymmetry particles, such as neutralinos, sleptons and may be indirectly squarks. It also has proven to be a tool to link the quantum field theory and noncommutative geometry.[21,22] Furthermore, in recent years the supersymmetry have been instrumental in uncovering nonperturbative aspects of quantum theories.[23,24] All of this gives strong motivations for trying to get a deeper understanding of the structure and of the properties of supersymmetric field theories.

This work is inspired in the structurally significant, recent results on quantum fields propagating in a globally hyperbolic, curved space–time, and represents a natural attempting to construct a generalization of some of the conventional mathematical structures used in quantum field theory, such as manifolds, so as to include superfield models in supermanifolds (curved superspaces). These structural questions are not without physical interest and relevance! It is the purpose of the present paper to study how such a construction can be achieved.

The outline of the paper is as follows: We shall begin in Sec. II by describing some global properties of supermanifolds according to Rogers,[25] and the problem of constructing their bodies

in the sense of Catenacci *et al.*[26] and Bryant.[27] Then, by working with a class of G^∞ supermanifolds constructed by Bonora–Pastin–Tonin[28] (BPT-supermanifolds), we demonstrate that this class of supermanifolds satisfies the criteria which guarantee that a supermanifold admits a Hausdorff body manifold. In Sec. III, superdistributions on superspace are defined. We derive some results not contained in Ref. 29. In particular, we generalize straightforwardly the notion of distributions defined on a manifold to distributions defined on a supermanifold. In Sec. IV, we discuss the algebraic formalism so as to include supersymmetry on a supermanifold. The results from this section may be seen as a natural extension of the ''Haag–Kastler–Dimock'' axioms[30,31] for local ''observables'' to supermanifolds. In Sec. V, we summarize some basics on the description of Hadamard (super)states. The focus of the Sec. VI will be on the extension of the Hörmander's description of the singularity structure (wavefront set) of a distribution to include the supersymmetric case. This fills a gap in the literature between the usual textbook presentation of the singularity structure of superfunctions and the rigorous mathematical treatment based on microlocal analysis. In Sec. VII, we present the characterization of a type of microlocal spectral condition for a superstate ω^{susy} with m-point superdistribution ω_m^{susy} on a supermanifold, in terms of the wavefront set of superdistributions, which is equivalent to the requirement that all of the component fields satisfy the microlocal spectral conditions[11] on the body manifold. This is in accordance with the DeWitt's remark[32] which asserts that in physical applications of supersymmetric quantum field theories, the spectral condition of the GNS-Hilbert superspace is restricted to the ordinary GNS-Hilbert space that sits inside the GNS-Hilbert superspace. Finally, Sec. VIII contains our final considerations.

II. NOTIONS OF SUPERMANIFOLDS

This section introduces some few basic fundamentals on the theory of supermanifolds. We follow here the work of Rogers[25] which is both general and mathematically rigorous. Rogers' theory has an advantage, a supermanifold is an ordinary Banach manifold endowed with a Grassmann algebra structure, so that the topological constructions have their standard meanings. In this context see also Refs. 32–39.

We start by introducing first some definitions and concepts of a Grassmann–Banach algebra, i.e., a Grassmann algebra endowed with a Banach algebra structure. This leads to the key concept of supercommutative superalgebra.

Definition 2.1: An algebra is said to be a supercommutative superalgebra Λ*—or a* $\mathbb{Z}_2$*-graded commutative algebra—if* Λ *is the direct sum* $\Lambda=\Lambda_0\oplus\Lambda_1$ *of two complementary subspaces such that* $\mathbb{1}\in\Lambda_0$ *and* $\Lambda_0\Lambda_0\subset\Lambda_0$, $\Lambda_0\Lambda_1\subset\Lambda_1$, $\Lambda_1\Lambda_1\subset\Lambda_0$. *Moreover, for all homegeneous element* x, y *in* Λ, $xy=(-1)^{|x||y|}yx$, *where* $|x|=0$ *if* $x\in\Lambda_0$ *and* $|x|=1$ *if* $x\in\Lambda_1$. *In particular, it follows that the square of odd elements is zero*.

Elements from Λ_0 and Λ_1 are said to be homegeneous if they have a definite parity, i.e., an element $x\in\Lambda_0$ is said to have *even* parity, while an element $x\in\Lambda_1$ is said to have *odd* parity. Products of homogeneous elements of the same parity are even and of elements of different parities are odd.

We shall assume that the superalgebra Λ is a Banach space with norm $\|\cdot\|$ satisfying the condition

$$\|xy\|\leqslant\|x\|\|y\|\ ,\forall x,y\in\Lambda;\quad \|\mathbb{1}\|=1\ .$$

Let L be a finite positive integer and $\mathcal{G}$ denote a Grassmann algebra, such that $\mathcal{G}$ can naturally be decomposed as the direct sum $\mathcal{G}=\mathcal{G}_0\oplus\mathcal{G}_1$, where $\mathcal{G}_0$ consists of the even (commuting) elements and $\mathcal{G}_1$ consists of the odd (anti-commuting) elements in $\mathcal{G}$, respectively. Let M_L denote the set of sequences $\{(\mu_1,\ldots,\mu_k)|1\leqslant k\leqslant L;\mu_i\in\mathbb{N};1\leqslant\mu_1<\cdots<\mu_k\leqslant L\}$. Let Ω represent the empty sequence in M_L, and (j) denote the sequence with just one element j. A basis of $\mathcal{G}$ is given by monomials of the form $\{\xi_\Omega,\xi^{\mu_1}\xi^{\mu_2},\ldots,\xi^{\mu_1}\xi^{\mu_2}\cdots\xi^{\mu_k}\}$ for all $\mu\in M_L$, such that $\xi_\Omega=\mathbb{1}$ and $\xi^{(i)}\xi^{(j)}+\xi^{(j)}\xi^{(i)}=0$ for $1\leqslant i,j\leqslant L$. Futhermore, there is no other independent relations among the generators. By $\mathcal{G}_L$ we denote the Grassmann algebra with L generators, where the even and the

odd elements, respectively, take their values. L being assumed a finite integer (the number of generators L could be possibly infinite), it means that the sequence terminates at $\xi^1\cdots\xi^L$ and there are only 2^L distinct basis elements. An arbitrary element $q\in\mathcal{G}_L$ has the form

$$q=q_{\mathbf{b}}+\sum_{(\mu_1,\ldots,\mu_k)\in M_L} q_{\mu_1,\ldots,\mu_k}\xi^{\mu_1}\cdots\xi^{\mu_k}\ , \tag{2.1}$$

where $q_{\mathbf{b}}, q_{\mu_1\cdots\mu_k}$ are real numbers. An even or odd element is specified by 2^{L-1} real parameters. The number $q_{\mathbf{b}}$ is called the body of q, while the remainder $q-q_{\mathbf{b}}$ is the soul of q, denoted $s(q)$. The element q is invertible if, and only if, its body is nonzero.

With reference to supersymmetric field theories, the commuting variable x has the form

$$x=x_{\mathbf{b}}+x_{ij}\xi^i\xi^j+x_{ijkl}\xi^i\xi^j\xi^k\xi^l+\cdots\ , \tag{2.2}$$

where $x_{\mathbf{b}}, x_{ij}, x_{ijkl},\ldots$ are real variables. Similarly, the anticommuting variables (in the Weyl representation) θ and $\overline{\theta}=(\theta)^*$ have the form

$$\theta=\theta_i\xi^i+\theta_{ijk}\xi^i\xi^j\xi^k+\cdots\ ,\quad \overline{\theta}=\overline{\theta}_i\xi^i+\overline{\theta}_{ijk}\xi^i\xi^j\xi^k+\cdots\ , \tag{2.3}$$

where $\theta_i, \theta_{ijk},\ldots$ are complex variables. The summation over repeated indices is to be understood unless otherwise stated.

Remark 2.1: As pointed out by Vladimirov–Volovich,[40] from the physical point of view, superfields are not functions of $\theta_i, \theta_{ijk},\ldots$ and $x_{\mathbf{b}}, x_{ij}, x_{ijkl},\ldots$, but only depend on these variables through θ and x, as it occurs with ordinary complex analysis where analytic functions of the complex variables $z=x+iy$ are not arbitrary functions of the variables x and y, but functions that depend on x and y through z. ■

The Grassmann algebra may be topologized. Consider the complete norm on $\mathcal{G}_L$ defined by[41]

$$\|q\|_p=\left(|q_{\mathbf{b}}|^p+\sum_{(\mu)=1}^{L}|q_{\mu_1\cdots\mu_k}|^p\right)^{1/p}\ . \tag{2.4}$$

A useful topology on $\mathcal{G}$ is the topology induced by this norm. The norm $\|\cdot\|_1$ is called the Rogers norm and $\mathcal{G}_L(1)$ the Rogers algebra.[25] The Grassmann algebra $\mathcal{G}$ equipped with the norm (2.4) becomes a Banach space. In fact $\mathcal{G}$ becomes a Banach algebra, i.e., $\|\mathbb{1}\|=1$ and $\|qq'\|\leqslant\|q\|\|q'\|$ for all $q,q'\in\mathcal{G}$.

Definition 2.2: A Grassmann–Banach algebra is a Grassmann algebra endowed with a Banach algebra structure.

A superspace must be constructed using as a building block a Grassmann–Banach algebra $\mathcal{G}_L$ and not only a Grassmann algebra.

Definition 2.3: Let $\mathcal{G}_L=\mathcal{G}_{L,0}\oplus\mathcal{G}_{L,1}$ be a Grassmann–Banach algebra. Then the (m,n)-dimensional superspace is the topological space $\mathcal{G}_L^{m,n}=\mathcal{G}_{L,0}^m\times\mathcal{G}_{L,1}^n$, which generalizes the space $\mathbb{R}^m$, consisting of the Cartesian product of m copies of the even part of $\mathcal{G}_L$ and n copies of the odd part.

For an (m,n)-dimensional superspace, a typical element of this set used in physics is denoted by $(z)=(z_1,\ldots,z_{m+n})=(x_1,\ldots,x_m,\theta_1,\ldots,\theta_{n/2},\overline{\theta}_1,\ldots,\overline{\theta}_{n/2})$. For instance, for the (4,4)-dimensional Minkowski superspace, which is the space of, e.g., $N=1$ Wess–Zumino model formulated in superfield language and modeled as $\mathcal{G}_L^{4,4}=\mathcal{G}_{L,0}^4\times\mathcal{G}_{L,1}^4$, $(z)=(x_1,\ldots,x_4,\theta_1,\theta_2,\overline{\theta}_1,\overline{\theta}_2)$. The norm on $\mathcal{G}_L^{4,4}$ is defined by $\|z\|=\Sigma_{i=1}^4\|x_i\|+\Sigma_{j=1}^2\|\theta_j\|+\Sigma_{k=1}^2\|\overline{\theta}_k\|$. The topology on $\mathcal{G}_L^{4,4}$ is the topology induced by this norm—which is also the product topology.

In supersymmetric quantum field theory, superfields are functions in superspace usually given by their (terminating) standard expansions in powers of the odd coordinates

$$F(x,\theta,\overline{\theta})=\sum_{(\gamma)=0}^{\Gamma} f_{(\gamma)}(x)(\theta)^{(\gamma)}\ , \tag{2.5}$$

where $(\theta)^{(\gamma)}$ comprises all monomials in the anticommuting variables θ and $\overline{\theta}$ (belonging to odd part of a Grassmann–Banach algebra) of degree $|\gamma|$; $f_{(\gamma)}(x)$ is called a component field, whose Lorentz properties are determined by those of $F(x,\theta,\overline{\theta})$ and by the power (γ) of (θ). The following notation, extended to more than one θ variable, is used (2.5): $(\theta)=(\theta_1,\overline{\theta_1},\ldots,\theta_n,\overline{\theta_n})$, and (γ) is a multi-index $(\gamma_1,\overline{\gamma_1},\ldots,\gamma_n,\overline{\gamma_n})$ with $|\gamma|=\Sigma_{r=1}^{n}(\gamma_r+\overline{\gamma_r})$ and $(\theta)^{(\gamma)}=\Pi_{r=1}^{n}\theta_r^{\gamma_r}\overline{\theta}_r^{\overline{\gamma}_r}$. In Eq. (2.5), for a (4,4)-dimensional superspace, $\Gamma=(2,2)$.

Rogers[25] considered superfields in $\mathcal{G}_L^{m,n}$ as G^∞ superfunctions, i.e., functions whose coefficients $f_{(\gamma)}(x)$ of their expansions are smooth functions of $\mathbb{R}^m$ into $\mathcal{G}_L$, extended from $\mathbb{R}^m$ to all of $\mathcal{G}_L^{m,0}$ by z-continuation,[25] which maps functions of real variables into functions of variables in $\mathcal{G}_L^{m,0}$.

Definition 2.4: Let U be an open set in $\mathcal{G}_L^{m,0}$ and let $\epsilon:\mathcal{G}_L^{m,0}\to\mathbb{R}^m$ be the body projection which associates to each m-tuple $(x_1,\ldots,x_m)\in\mathcal{G}_L^{m,0}$ an m-tuple $(\epsilon(x_1),\ldots,\epsilon(x_m))\in\mathbb{R}^m$. Let V be an open set in $\mathbb{R}^m$ with $V=\epsilon(U)$. We get through z-continuation—or "Grassmann analytic continuation"—of a function $f\in C^\infty(V,\mathcal{G}_L)$ a function $z(f)\in G^\infty(U,\mathcal{G}_L)$, which admits an expansion in powers of the soul of x

$$z(f)(x_1,\ldots,x_m)=\sum_{i_1=\cdots=i_m=0}^{L}\frac{1}{i_1!\cdots i_m!}[\partial_1^{i_1}\cdots\partial_m^{i_m}]f(\epsilon(x))s(x_1)^{i_1}\cdots s(x_m)^{i_m}\ ,$$

where $s(x_i)=(x_i-\epsilon(x_i))$ and $\epsilon(x_i)=(x_i)_{\mathbf{b}}$.

One should keep always in mind that the continuation involves only the even variables $z:C^\infty(\epsilon(U))\to G^\infty(U)$, and that $z(f)(x_1,\ldots,x_m)$ is a supersmooth function if their components are smooth for soulless values of x. This justifies the formal manipulations in the physics literature, where superfields are manipulated as if their even arguments were ordinary numbers:[37] a supersmooth function is completely determined when its components are known on the body of superspace.

According to Definition 2.4, the superfield $F(x,\theta,\overline{\theta})\in G^\infty(U,\mathcal{G}_L)$ admits an expansion

$$F(x,\theta,\overline{\theta})=\sum_{(\gamma)=0}^{\Gamma} z(f_{(\gamma)})(x)(\theta)^{(\gamma)}\ ,$$

but here with suitable $f_{(\gamma)}\in C^\infty(\epsilon(U),\mathcal{G}_L)$.

Now, we are going to consider some helpful aspects about supermanifolds, based on the work of Rogers,[25] replacing the simple superspace $\mathcal{G}_L^{m,n}$ by a more general supermanifold. Rogers used the concept of G^∞ superfunctions to define the concept of G^∞ supermanifolds (which can be considered as Banach real manifolds C^∞ modeled on $\mathcal{G}_L^{m,n}$ of dim $N=2^{L-1}(m+n)$), with a structure allowing for the definitions of neighboring points and continuous superfunctions. An (m,n)-dimensional G^∞ supermanifold generalizes the concept of an m-dimensional C^∞ manifold: just as a manifold is a Hausdorff topological space such that every point has a neighborhood homeomorphic to $\mathbb{R}^m$ and has local coordinates $(x_1(p),\ldots,x_m(p))$ in $\mathbb{R}^m$, a supermanifold is a topological space which locally looks like $\mathcal{G}_L^{m,n}$ (but not necessarily in its global extent) and has local coordinates $(x_1(p),\ldots,x_m(p),\theta_1(p),\ldots,\theta_n(p))$ in $\mathcal{G}_L^{m,n}$, and whose transition functions fulfill a suitable supersmoothness condition.

Definition 2.5: A supermanifold is in general a paracompact Hausdorff topological space $\mathcal{M}$, together with an atlas of charts $\{(X_\alpha,k_\alpha)|\alpha\in I\}$, over a Grassmann–Banach algebra $\mathcal{G}_L$, where the X_α cover $\mathcal{M}$ and each coordinate function k_α is a homeomorphic local map from X_α onto an open subset $\tilde{X}_\alpha\subset\mathcal{G}_L^{m,n}$, also Hausdorff.

The existence of infinitely differentiable coordinates systems makes the supermanifold differentiable. The differentiable structure in this topological space is due to G^r ($r=p$ or $p=\infty$) structure of transition functions, $k_\beta \circ k_\alpha^{-1}$, between overlapping coordinate patches, $k_\alpha(X_\alpha \cap X_\beta)$ and $k_\beta(X_\alpha \cap X_\beta)$, required to be supersmooth morphisms for any $\alpha,\beta \in I$. The local coordinates are:

$$u_i = p_i \circ k_\alpha \mapsto (i=1,\ldots,m),$$

$$v_j = p_{j+m} \circ k_\alpha \mapsto (j=1,\ldots,n).$$

In this sense $\mathcal{G}_L^{m,n}$ is an example of G^∞ supermanifold, unlike of the coarse topology in the DeWitt sense[32] whose structure cannot be even a metric one.

Definition 2.6: Let $\tilde{X}_\alpha$ be an open in $\mathcal{G}_L^{m,n}$ and $f:\tilde{X}_\alpha \to \mathcal{G}_L$, then:

(a) f is called G^0 in $\tilde{X}_\alpha$ if f is continuous in $\tilde{X}_\alpha$.

(b) f is called G^1 in $\tilde{X}_\alpha$ if exist $m+n$ functions $G_k f:\tilde{X}_\alpha \to \mathcal{G}_L$, $k=1,\ldots,m+n$ and functions $\eta:\mathcal{G}_L^{m,n} \to \mathcal{G}_L$ such that

$$f(a+h,b+k) = f(a,b) + \sum_{i=1}^{m} h_i\{G_i f(a,b)\} + \sum_{j=1}^{n} k_j\{G_{j+m} f(a,b)\} + \|h,k\|\eta(h,k),$$

and $\eta(h,k) \to 0$ when $\|h,k\| \to 0$. In this sense, $G_i f \to f_i'$.

We can generalize to G^p, with finite p in the following: f is G^p in $\tilde{X}_\alpha$ if is possible choose $G_k f$ which are G^{p-1} with $f \in G^1$ em $\tilde{X}_\alpha$. If it is true to all p, f is called G^∞. In fact, any function which is absolutely convergent (power series) is G^∞ on $\tilde{X}_\alpha$, in other words,

$$f(z) = \sum_{k_1 \cdots k_{m+n}=0}^{\infty} a_{k_1 \cdots k_{m+n}} z_1^{k_1} \cdots z_{m+n}^{k_{m+n}},$$

$$f:\tilde{X}_\alpha \to \mathcal{G}_L, \quad \tilde{X}_\alpha \subset \mathcal{G}_L^{m,n} \quad \text{and} \quad a_{k_1 \cdots k_{m+n}} \in \mathcal{G}_L.$$

Another important fact is the C^∞ structure:

$$[D^p f(z)][\ell^1,\ell^2,\ldots,\ell^p] = \sum_{k_1 \ldots k_p=1}^{m+n} l_{k_1}^1 \cdots l_{k_p}^p (G_{k_p} G_{k_{p-1}} \cdots G_{k_1} f)(z),$$

for all $z \in \tilde{X}_\alpha$ open in $\mathcal{G}_L^{m,n}$ and $l_{k_1}^1 \cdots l_{k_p}^p \in (\mathcal{G}_L^{m,n})^p$. The latter denotes a product space of p copies of $\mathcal{G}_L^{m,n}$. In this way the p derivative of $f \in \mathcal{L}[(\mathcal{G}_L^{m,n})^p, \mathcal{G}_L]$ are elements of continuous p-linear maps of $(\mathcal{G}_L^{m,n})^p$ into $\mathcal{G}_L$. This formalism is interesting and agrees to the Hörmander's one[42] (p. 11), where $f^{(p)} \in L^p(X_\alpha, X_\beta)$, are elements of continuous p-linear forms from X_α to X_β.

Remark 2.2: The discussion of differentiability by Jadczyk–Pilch[33] is simpler than the one given by Rogers.[25] In particular, knowing already that a function f is a C^∞ map between Banach spaces, it is needed only to look at its first derivative to know whether f is supersmooth or not, while according to Rogers an investigation of all derivatives is necessary. However, the concept of supersmoothness by Jadczyk–Pilch, and the concept of G^∞ differentiability by Rogers are equivalent. ■

The body of a supermanifold: Now that the general idea of structure on a supermanifold has been introduced, it is time to restrict our attention to the case of fundamental interest: the problem of constructing the body of a G^∞ supermanifold which serves as the physical space–time. Roughly speaking, the body of a supermanifold $\mathcal{M}$ is an ordinary C^∞ space–time manifold $\mathcal{M}_0$ obtained from $\mathcal{M}$ getting rid of all the soul coordinates. Because of its extreme generality, Rogers' theory includes many topologically exotic supermanifolds which are not physically useful, admitting the

possibility of nontrivial topology in the anticommuting directions and classes of supermanifolds without a body manifold. But, intuition suggests that only a bodied G^∞ supermanifold can be physically relevant!

The question of the existence of the body of a supermanifold was clarified in the papers by Catenacci *et al.*[26] and Bryant.[27] Their approach is independent of the atlas used, and it is based on the fact that any G^∞ supermanifold $\mathcal{M}$ admits a foliation $\mathfrak{F}$. This type of structure is defined and related to the natural notions of quotient and substructure on a supermanifold. As with many important concepts in mathematics, there are several equivalent ways of defining the notion of a foliation. The simplest and most geometric is the following:

Definition 2.7: Let $\mathcal{M}$ be an (m,n)-dimensional supermanifold of class G^r, $0\leqslant r\leqslant p$. A foliation of class G^r, and of codimension m, is a decomposition of $\mathcal{M}$ into disjoint connected subsets $\{\mathfrak{L}_\alpha\}_{\alpha\in A}$, called the leaves of the foliation, such that each point of $\mathcal{M}$ has a neighborhood U and a system of G^r coordinates $(x,\theta): U\to\mathcal{G}^m_{L,0}\times\mathcal{G}^n_{L,1}$ such that for each leaf $\mathfrak{L}_\alpha$, the components of $U\cap\mathfrak{L}_\alpha$ are described by surfaces on which all the body coordinates $\epsilon(x_1),\ldots,\epsilon(x_m)$ are constant. We denote the foliation by $\mathfrak{F}=\{\mathfrak{L}_\alpha\}_{\alpha\in A}$.

The coordinates referred to in Definition 2.7 are said to be distinguished by the foliation $\mathfrak{F}$. Under certain regularity conditions on $\mathfrak{F}$, the quotient space $\mathcal{M}/\mathfrak{F}$ can be given the structure of an ordinary m-dimensional differentiable manifold $\mathcal{M}_0$, which is called the body manifold of $\mathcal{M}$ (for details see Ref. 26). A G^∞ supermanifold whose $\mathfrak{F}$ foliation is regular is called regular itself. On regular supermanifolds the following theorem holds:

Theorem 2.8 (Catenacci–Reina–Teofilatto Theorem): *Let $\mathcal{M}$ be a regular G^∞ supermanifold. Then its body $\mathcal{M}_0$ is a C^∞ manifold.* □

As stated by Bryant,[27] the necessity of regularity of the soul foliation in the sense of Catenacci–Reina–Teofilatto is not sufficient to guarantee that a supermanifold admits a body manifold. He derived necessary and sufficient conditions, namely, that leaves should be closed and do not accumulate, for the existence of a Hausdorff body manifold.

Theorem 2.9 (Bryant Theorem 2.5): *Suppose that $\mathcal{M}$ is a supermanifold. In order that $\mathcal{M}$ admits a body manifold, it is necessary and sufficient that the leaves of the soul foliations are closed in $\mathcal{M}$ and do not accumulate.* □

For our purposes, it will be sufficient to consider the class of G^∞ supermanifolds constructed by Bonora–Pasti–Tonin[28] (we shall call BPT-supermanifolds for brevity), which has important applications in theoretical physics—and fulfills Theorems 2.8 and 2.9, as we shall verify presently. These supermanifolds consist of the Grassmann extensions of *any* ordinary C^∞ space–time manifold. From a given m-dimensional physical space–time, one constructs first an $(m,0)$-dimensional supermanifold, and the (m,n)-dimensional supermanifold by taking the direct product with $\mathcal{G}^{0,n}_L$. This construction is the closest to the physicist's intuitive view of superspace as a manifold with some anticommuting coordinates, with the odd Grassmann variables being topologically trivial.

Remark 2.3: As a matter of fact, in any model involving fermions in a general space–time, the supermanifold will need to be that constructed from the spinor bundle of the manifold in the way which we recall now: Let $\mathcal{M}$ be an m-dimensional body manifold and E be an n-dimensional vector bundle over $\mathcal{M}$. Suppose that $\{U_\alpha\}$ is a covering of $\mathcal{M}$ by coordinate neighborhoods which are also trivialization neighborhoods of E. Then, the corresponding (m,n)-dimensional supermanifold has coordinate transition functions

$$x^i_\alpha=\phi^i_{\alpha\beta}(x_\beta),$$

where $\phi_{\alpha\beta}$ is the z continuation of the transition function for M and

$$\theta^i_\alpha=g_{\alpha\beta}{}^i{}_j(x_\beta)\,\theta^j_\alpha,$$

with $g_{\alpha\beta}: U_\alpha\cap U_\beta\to Gl(n)$ being the transition function for E. It is worthwhile to note that the BPT-supermanifolds are examples of this construction when the bundle E is trivial. ■

For the convenience of the reader, we recall here the construction of Bonora–Pasti–Tonin.[28] Let $\{(U_\alpha,\psi_\alpha)|\alpha\in I\}$ be an atlas for $\mathcal{M}_0$. For each $\alpha\in I$ consider the subset X_α of the Cartesian product $U_\alpha\times\mathcal{G}_L^{m,0}$ defined by

$$X_\alpha=\{(x,\overline{x})|x\in U_\alpha,\overline{x}\in\mathcal{G}_L^{m,0},\quad\text{and}\quad\epsilon(\overline{x})=\psi_\alpha(x)\},\tag{2.6}$$

and define $k_\alpha:X_\alpha\to\mathcal{G}_L^{m,0}$ by $k_\alpha(x,\overline{x})=\overline{x}$ for $(x,\overline{x})\in X_\alpha$. k_α is a homeomorphism and its image is an open subset of $\mathcal{G}_L^{m,0}$.

An important property of the z-continuation is the composition of functions. Let U be an open set in $\mathbb{R}^m$, and let the map $f:\mathbb{R}^m\to\mathcal{G}_L^{k,0}$ be represented by the set of C^∞ functions $\{f_i(x_1,\ldots,x_m),i=1,\ldots,m\}$. Define $z(f)$ as the set of functions $\{z(f_i)\}$. Let V be an open set in $\mathbb{R}^n$, and consider the maps $f:U\to V$ and $g:V'\to\mathcal{G}_L^{k,0}$, respectively, where $V'\subseteq V$, and both f,g are C^∞ functions. Then

$$z(g\circ f)=z(g)\circ z(f).\tag{2.7}$$

Now consider the disjoint union $M=\cup_{\alpha\in I}X_\alpha$. Two points of M are equivalent if and only if $(x,\overline{x})\sim(x',\overline{x'})$, such that $(x,\overline{x})\in X_\alpha$ and $(x',\overline{x'})\in X_\beta$ and $x=x'$, $\overline{x'}=z(\psi_\beta\circ\psi_\alpha^{-1})(\overline{x})$. Of course M is a Hausdorff space. Then consider the space $\mathcal{M}_G$ equal to the space M modulo the equivalence relation above. The k_α's provide $\mathcal{M}_G$ with a G^∞ differentiability structure, so that $\mathcal{M}_G$ is a G^∞ $(m,0)$ supermanifold. Let $\pi_G:\mathcal{M}_G\to\mathcal{M}_0$ be a continuous and open projection. Locally $\pi_G|_{X_\alpha}(x,\overline{x})=x$ for $(x,\overline{x})\in X_\alpha$. Since $\mathcal{M}_G$ is a *regular* supermanifold, we find straightforwardly that $\pi_G\circ k_\alpha^{-1}=\psi_\alpha^{-1}\circ\epsilon$ for $\overline{x}\in k_\alpha(X_\alpha)$. This can be expressed by the commutative diagram:

$$\begin{array}{ccc} X_\alpha & \xleftarrow{k_\alpha^{-1}} & \mathcal{G}_L^{m,0} \\ \pi_G\downarrow & & \downarrow\epsilon \\ U_\alpha & \xleftarrow{\psi_\alpha^{-1}} & \mathbb{R}^m \end{array}$$

Finally, we construct the (m,n)-dimensional supermanifold $\mathcal{M}$ by taking the direct product of $\mathcal{M}_G$ with $\mathcal{G}_L^{0,n}$. The projection $\pi_S:\mathcal{M}\to\mathcal{M}_0$ is the composite map $\pi_G\circ\gamma$, where $\gamma:\mathcal{M}\to\mathcal{M}_G$ is the projection onto the first factor. The map γ is G^∞, unlike π_G which is a C^∞ function but not a G^∞.

Corollary 2.10: Let $\mathcal{M}$ be a BPT-supermanifold. Then the leaves of the soul foliation are regular, closed in $\mathcal{M}$ and do not accumulate.

Proof: First of all, it is worthwhile noticing that, according to the construction of Bonora–Pasti–Tonin, two points of a BPT-supermanifold are in the same leaf if, and only if, they are equivalents in the sense defined above. Then the soul foliation can be defined by $\mathcal{M}/\sim\overset{\text{def}}{=}\mathcal{M}/\mathfrak{F}$. Once verified the corollary, we see that a BPT-supermanifold possesses an ordinary body manifold defined by soul foliation $\mathcal{M}_0\overset{\text{def}}{=}\mathcal{M}/\mathfrak{F}$, where $\mathcal{M}_0$ denotes the body manifold.

In order to show that the leaves of a BPT-supermanifold are closed, the following considerations are needed: we say that the soul foliation of a BPT-supermanifold is a Hausdorff space, and that the structure of their supermanifold is regular. This can be verified through the following theorem by Bryant[27] (Theorem 3.2): Suppose that $\mathcal{M}$ is a supermanifold of dimension (m,n) and $\Gamma=\{U_i,\phi_i\}$ is a good atlas; then the following conditions are equivalent: (i) $\Gamma=\{U_i,\phi_i\}$ is a regular superstructure on $\mathcal{M}$, (ii) when s and t lie in U_i, $s\approx t$ implies $s\sim t$, and (iii) the body map $\epsilon:\mathcal{M}\to\mathcal{M}/\mathfrak{F}$ is locally modeled on $\epsilon_0:B^{m,n}\to\mathbb{R}^m$ in the sense that exist homeomorphisms $\overline{\phi_i}:\epsilon U_i\to\epsilon_0\phi_i U_i$ such that $\overline{\phi_i}\circ\epsilon_{|U_I}=\epsilon_0\circ\phi$. When these conditions are satisfied, $\mathcal{M}/\mathfrak{F}$ is Hausdorff and is a smooth manifold of dimension m with charts $\{\epsilon U_i,\overline{\phi_i}\}$. For the case of the equivalence relation $(s\sim t)$ of a BPT-supermanifold, we see that it must be $\approx$ in the Bryant sense because embodies $\sim$ and is transitive. Then $\approx$ implies $\sim$ on the same charts. This means that the conditions of the Theorem 3.2 by Bryant must be properties of the BPT foliation, and hence is

Hausdorff and regular. Now, the fact that the leaves of a BPT-supermanifold are closed is clear: each point $(\epsilon(s))$ of $\mathcal{M}/\sim$ is closed, given that the BPT-supermanifolds is a Hausdorff space, and the inverse application theorem guarantees that a leaf is necessarily closed, since being F the leaf in $\mathcal{M}$, $F=\epsilon^{-1}\epsilon(s)$ where ϵ^{-1} is a continuous map.

Finally, we shall verify that the leaves of a BPT-supermanifold do not accumulate. First, we shall suppose that the leaves of soul foliation accumulate[43] in a given pair of points, e.g., $s_+, s_- \in \mathcal{M}$. Note that as $\mathcal{M}/\mathfrak{F}$ is Hausdorff, given two points $x \in \mathcal{M}/\mathfrak{F}$ and $y \in \mathcal{M}/\mathfrak{F}$ with $x \neq y$, we can separate them by disjoint open sets. Choice, for example, $\epsilon s_+ = x$ and $\epsilon s_- = y$, where $\epsilon: \mathcal{M} \to \mathcal{M}/\mathfrak{F}$. Then, we also can choose $s_+ \in F' \cup \Sigma_+$ (a transverse submanifold) and $s_- \in F' \cup \Sigma_-$ (another transverse submanifold). If this is true, s_+, s_- must be in the same leaf, by indicating that $\epsilon s_+ = \epsilon s_-$ contradicting the statement which a soul foliation is Hausdorff. Hence, the leaves do not accumulate. In order to complete the prove, we examine the condition $\epsilon s_+ = \epsilon s_-$. Due the possibility of choosing arbitrary transverse submanifolds, we select $\Sigma(s)$ and $\Sigma(t)$ through the some disjoint neighborhoods of s and t, resp., such that does not exist a U_i which intersects $\Sigma(s)$ and $\Sigma(t)$. But $\epsilon s_+ = \epsilon s_-$ implies that s and t are in the same chart U_i, so the leaves do not accumulate since $\Sigma(s) \cup \Sigma(t) = \varnothing$. □

The existence of a body manifold places us in a position to consider physically interpretable field theories on supermanifolds. In order to establish applicability in a physical system, we need to impose some restrictions regarding to the body manifold $\mathcal{M}_0$, associated with the supermanifold $\mathcal{M}$. Apart from another aspects, the causality principle plays a crucial role in our construction. Therefore, we restrict our body manifold, $(\mathcal{M}_0, g_0)$, to be globally hyperbolic Lorentz manifold, by consisting of a four-dimensional smooth manifold $\mathcal{M}_0$ (any dimension would be possible) that can be smoothly foliated by a family of acausal Cauchy surfaces[6] and a smooth metric g_0 with signature $(+, -, -, -)$. This means that the body manifold must be topologically equivalent to the Cartesian product of $\mathbb{R}$ and a smooth spacelike hypersurface Σ (a Cauchy surface). Σ intersects any endless timelike curve at most once. A four-dimensional globally hyperbolic Lorentz manifold is orientable and time orientable, i.e., at each $x \in \mathcal{M}_0$ we may designate a future and past light cone continuously. Moreover, $\mathcal{M}_0$ is assumed to have a spin structure, so that one can consider spinors defined on it. It can be shown that a four-dimensional globally hyperbolic Lorentz manifold admits a spin structure.[44] In fact, Geroch[44] pointed out that a *noncompact, parallelizable* four-dimensional manifold admits a spin structure. Geroch's parallelizability criterion applies to a four-dimensional globally hyperbolic Lorentz manifold.

Remark 2.4: As it has been emphasized in Ref. 10, a natural background geometry that admits a supersymmetric extension of its isometry group can only be of the anti–de Sitter (AdS) type. In other words, the global supersymmetry should not be compatible with most spacetimes, an exception being the AdS space. This requirement seems to be an extremely restrictive condition, since the AdS space has problems with closed timelike curves, apparently violating causality and leading to problems during quantization. Namely, boundary conditions at infinity are needed. Nevertheless, one should remind that this result refers to extended supergravity theories with gauged SO(N) internal symmetry;[45] this is not, however, our case in this paper. Furthermore, this result can mainly be justified by the heuristic form of introducing the superspace (which may be bypassed taking into account the Rogers' theory of a global supermanifold). As stressed by Bruzzo,[39] "...the usual ways of dealing with superspace field theories are highly unsatisfactory from a mathematical point of view. The superspace is defined formally, and, for instance, general coordinate transformations are mathematically not well defined. As a consequence, there is now room for studying global topological properties of superspace." As it shall be tackled further on, Sec. IV, the mathematical structure of the supermanifolds chosen here leads to a natural formulation of superdiffeormorphisms, G^{∞}, from $(\mathcal{M}, g)$ to $(\mathcal{M}', g')$, from the z-continuation of ordinary diffeomorphisms, so that these structures become, projectively, well-defined isometries whenever $\mathcal{M}' = \mathcal{M}$ and restricted to the ordinary body manifold. ■

III. SUPERDISTRIBUTIONS

In this section, as a natural next step, we extend the definition of the objects most widely used in physics: distributions. We define superdistributions on supermanifolds over the Grassmann–Banach algebra $\mathcal{G}_L$, as continuous linear mappings to $\mathcal{G}_L$ from the test function space of G^∞ superfunctions with compact support. We derive some results not contained in Ref. 29.

A. Distributions on a manifold

To prepare for the extension of the theory of distributions to supermanifolds, we first consider their definition on manifolds. Following Ref. 42, the space–time manifold $\mathcal{M}_0$ (here $\mathcal{M}_0$ denotes an ordinary manifold obtained from a supermanifold $\mathcal{M}$ by throwing away all the soul coordinates) is a Hausdorff space covered by charts (X_α, k_α), where the open sets X_α are homeomorphic neighborhoods to open sets in $\mathbb{R}^n$. A C^∞ structure on $\mathcal{M}_0$ is a family $\mathcal{F}=\{(X_\alpha,k_\alpha)|\alpha\in I\}$, called an atlas, of homeomorphisms k_α, called coordinate functions, of open sets $X_\alpha\subset\mathcal{M}_0$ on open sets $\tilde{X}_\alpha\subset\mathbb{R}^n$, such that (i) if $k_\alpha, k_\beta\in\mathcal{F}$, then the map $k_\beta\circ k_\alpha^{-1}: k_\alpha(X_\alpha\cap X_\beta)\to k_\beta(X_\alpha\cap X_\beta)$ is infinitely differentiable, (ii) $\mathcal{M}_0=\cup_{\alpha\in I}X_\alpha$. Let $f\in C_0^\infty(\mathbb{R}^n)$ denotes the set of C^∞ functions of compact support on $\tilde{X}_\alpha\subset\mathbb{R}^n$. Then, we can represent each f by functions $\overline{f}$ of compact support on $\mathcal{M}_0$ by $f=\overline{f}\circ k_\alpha^{-1}$, for each k_α, where $\overline{f}\in C_0^\infty(\mathcal{M}_0)$. Elements of $\mathcal{D}'(\mathcal{M}_0)$, the topological dual of $C_0^\infty(\mathcal{M}_0)$, are distributions u on $\mathcal{M}_0$, by which we mean collections $\{u_{k_\alpha}\}_{k_\alpha\in\mathcal{F}}$ of distributions $u_{k_\alpha}\in\mathcal{D}'(\tilde{X}_\alpha)$ such that u is uniquely determined by the u_{k_α} and relations $u=u_{k_\alpha}\circ k_\alpha$. Moreover, since for any other coordinate system one has $u=u_{k_\beta}\circ k_\beta$ in $(X_\alpha\cap X_\beta)$, it follows that $u_{k_\beta}=(k_\alpha\circ k_\beta^{-1})^* u_{k_\alpha}=u_{k_\alpha}\circ(k_\alpha\circ k_\beta^{-1})$ in $(X_\alpha\cap X_\beta)$.

B. Distributions on the flat superspace

With the purpose of defining superdistributions on supermanifolds, we must first consider superdistributions on an open set $U\subset\mathcal{G}_L^{m,n}$, where $\mathcal{G}_L^{m,n}$ denotes the flat superspace. We begin by introducing the concept of superdistributions as the dual space of supersmooth functions in $\mathcal{G}_L^{m,0}$, with compact support, equipped with an appropriate topology, called *test superfunctions*. This can be done relatively straightforward in analogy to the notion of distributions as the dual space to the space $C_0^\infty(U)$ of functions on an open set $U\subset\mathbb{R}^m$ which have compact support, since the spaces $\mathcal{G}_L^{m,0}$ and $\mathcal{G}_L^{m,n}$ are regarded as ordinary vector spaces of $2^{L-1}(m)$ and $2^{L-1}(m+n)$ dimensions, respectively, over the real numbers.

Let $\Omega\subset\mathbb{R}^m$ be an open set. $\Omega=\epsilon(U)$ regarded as a subset of $\mathcal{G}_L^{m,0}$, it is identified with the body of some domain in superspace. Let $C_0^\infty(\Omega,\mathcal{G}_L)$ be the space of $\mathcal{G}_L$-valued smooth functions with compact support in $\mathcal{G}_L$. Every function $f\in C_0^\infty(\Omega,\mathcal{G}_L)$ can be expanded in terms of the basis elements of $\mathcal{G}_L$ as

$$f(x)=\sum_{(\mu_1,\ldots,\mu_k)\in M_L^0} f_{\mu_1,\ldots,\mu_k}(x)\xi^{\mu_1}\cdots\xi^{\mu_k}, \tag{3.1}$$

where $M_L^0\overset{\text{def}}{=}\{(\mu_1,\ldots,\mu_k)|0\leqslant k\leqslant L;\mu_i\in\mathbb{N};1\leqslant\mu_1<\cdots<\mu_k\leqslant L\}$ and $f_{\mu_1,\ldots,\mu_k}(x)$ is in the space $C_0^\infty(\Omega)$ of real-valued smooth functions on Ω with compact support. Thus, it follows that the space $C_0^\infty(\Omega,\mathcal{G}_L)$ is isomorphic to the space $C_0^\infty(\Omega)\otimes\mathcal{G}_L$.[29] In accordance with definition 2.4, the smooth functions of $C_0^\infty(\Omega,\mathcal{G}_L)$ can be extended from $\Omega\subset\mathbb{R}^m$ to $U\subset\mathcal{G}_L^{m,0}$ by Taylor expansion.

In order to define superdistributions, we need to give a suitable topological structure to the space $G_0^\infty(U,\mathcal{G}_L)$ of $\mathcal{G}_L$-valued superfunctions on an open set $U\subset\mathcal{G}_L^{m,0}$ which have compact support. According to a proposition by Rogers, every G^∞ superfunction on a compact set $U\subset\mathcal{G}_L^{m,0}$ can be considered as a real-valued C^∞ function on $U\subset\mathbb{R}^N$, where $N=2^{L-1}(m)$, regarding $\mathcal{G}_L^{m,0}$ and $\mathcal{G}_L$ as Banach spaces. In fact, the identification of $\mathcal{G}_L^{m,0}$ with $\mathbb{R}^{2^{L-1}(m)}$ is possible.[26] We have here an example of functoriality. Indeed, let X and Y denote a G^∞ supermanifold and a Banach

manifold C^∞, respectively. Then with each supermanifold X we associate a Banach manifold Y, via a *covariant* functorial relation $\lambda: X \to Y$, and with each G^∞ map ϕ defined on X, a C^∞ map $\lambda(\phi)$ defined on Y.[26]

Following, we shall first consider only the subset C_K^∞ of $C_0^\infty(U \subset \mathbb{R}^N)$ which consists of functions with support in a fixed compact set K. Since by construction C_K^∞ is a Banach space, the functions C_K^∞ have a natural topology given by the finite family of norms

$$\|\phi\|_{K,m} = \sup_{\substack{|p| \leq m \\ x \in K}} |D^p \phi(x)| \ , \quad D^p = \frac{\partial^{|p|}}{\partial x_1^{p_1} \cdots \partial x_m^{p_m}}, \tag{3.2}$$

where $p = (p_1, p_2, \ldots, p_m)$ is a m-tuple of non-negative integers, and $|p| = p_1 + p_2 + \cdots + p_m$ defines the order of the derivative. Next, let U be considered as a union of compact sets K_i which form an increasing family $\{K_i\}_{i=1}^\infty$, such that K_i is contained in the interior of K_{i+1}. That such family exist follows from the Lemma 10.1 of Ref. 46. Therefore, we think of $C_0^\infty(U \subset \mathbb{R}^N)$ as $\cup_i C_{K_i}^\infty(U \subset \mathbb{R}^N)$. We take the topology of $C_0^\infty(U \subset \mathbb{R}^N)$ to be given by the strict inductive limit topology of the sequence $\{C_{K_i}^\infty(U \subset \mathbb{R}^N)\}$. Of another way, we may define convergence in $C_0^\infty(U \subset \mathbb{R}^N)$ of a sequence of functions $\{\phi_k\}$ to mean that for each k, one has supp $\phi_k \subset K \subset U \subset \mathbb{R}^N$ such that for a function $\phi \in C_0^\infty(U \subset \mathbb{R}^N)$ we have $\|\phi - \phi_k\|_{K,m} \to 0$ as $k \to \infty$. This notion of convergence generates a topology which makes $C_0^\infty(U \subset \mathbb{R}^N)$, certainly, a topological vector space.

Now, let F and E be spaces of smooth functions with compact support defined on $U \subset \mathcal{G}_L^{m,0}$ and $U \subset \mathbb{R}^N$, respectively. If $\lambda: \mathsf{E} \to \mathsf{F}$ is a *contravariant* functor which associates with each smooth function of compact support in E, a smooth function of compact support in F, then we have a map

$$\|\phi\|_{K,m} \to \|\lambda(\phi)\|_{K,m}, \tag{3.3}$$

providing $G_0^\infty(U, \mathcal{G}_L)$ with a limit topology induced by a finite family of norms.

We now take a result by Jadczyk–Pilch,[33] later refined by Hoyos *et al.*,[34] which establishes as a natural domain of definition for supersmooth functions a set of the form $\epsilon^{-1}(\Omega)$, where Ω is open in $\mathbb{R}^m$. Let $\epsilon^{-1}(\Omega)$ be the domain of definition for a superfunction $f \in G_0^\infty(\epsilon^{-1}(\Omega), \mathcal{G}_L)$, where $\epsilon^{-1}(\Omega)$ is an open subset in $\mathcal{G}_L^{m,0}$ and Ω is an open subset in $\mathbb{R}^m$, and let $\tilde{\phi} \in C_0^\infty(\Omega, \mathcal{G}_L)$ denotes the restriction of ϕ to $\Omega \subset \mathbb{R}^m \subset \mathcal{G}_L^{m,0}$. Then, it follows that $(\partial_1^{p_1} \cdots \partial_m^{p_m} \phi)^{\sim} = \partial_1^{p_1} \cdots \partial_m^{p_m} \tilde{\phi}$, where the derivatives on the right-hand side are with respect to m real variables. Now, suppose $\Omega = \cup_i \tilde{K}_i$ where each $\tilde{K}_i$ is open and has compact closure in $\tilde{K}_{i+1}$. It follows that $C_0^\infty(\Omega, \mathcal{G}_L) = \cup_i C_{\tilde{K}_i}^\infty(\Omega, \mathcal{G}_L)$. Then, one can give $C_0^\infty(\Omega, \mathcal{G}_L)$ a limit topology induced by finite family of norms[29]

$$\|\tilde{\phi}\|_{\tilde{K},m} = \sup_{\substack{|p| \leq m \\ x \in \tilde{K}}} |D^p \tilde{\phi}(x)| = \sup_{\substack{|p| \leq m \\ x \in \tilde{K}}} \left\{ \sum_{(\mu_1, \ldots, \mu_k) \in M_L^0} |D^p \tilde{\phi}_{\mu_1, \ldots, \mu_k}(x)| \right\}. \tag{3.4}$$

Finally, a suitable topological structure to the space $G_0^\infty(U, \mathcal{G}_L)$ of $\mathcal{G}_L$-valued superfunctions on an open set $U \subset \mathcal{G}_L^{m,n}$ which have compact support, it is obtained immediately by the natural identification of $\mathcal{G}_L^{m,n}$ with $\mathbb{R}^{2^{L-1}(m+n)}$ and by the obvious extension of the construction above, which allows us define a limit topology induced to the space $G_0^\infty(U, \mathcal{G}_L)$ by finite family of norms,

$$\|\lambda(\phi)\|_{K,m+n} = \sup_{\substack{|p| \leq m+n \\ z \in K}} |D^p(\lambda(\phi))(z)| \ , \quad D^p = \frac{\partial^{|q|+|r|}}{\partial x_1^{q_1} \cdots \partial x_m^{q_m} \partial \theta_1^{r_1} \cdots \partial \theta_n^{r_n}} \ . \tag{3.5}$$

The derivatives $\partial^{|q|}/\partial x_1^{q_1} \cdots \partial x_m^{q_m}$ commute while the derivatives $\partial^{|r|}/\partial \theta_1^{r_1} \cdots \partial \theta_n^{r_n}$ anticommute, and $|p| = |q| + |r| = \Sigma_{i=1}^m q_i + \Sigma_{j=1}^n r_j$ defines the total order of the derivative, with $r_j = 0,1$.

We are now ready to define a superdistribution in an open subset U of $\mathcal{G}_L^{m,n}$. The set of all superdistributions in U will be denoted by $\mathfrak{D}'(U)$. A superdistribution is a continuous linear functional $u:G_0^\infty(U)\to\mathcal{G}_L$, where $G_0^\infty(U)$ denotes the test superfunction space of $G^\infty(U)$ superfunctions with compact support in $K\subset U$. The continuity of u on $G_0^\infty(U)$ is equivalent to its boundedness on a neighborhood of zero, i.e., the set of numbers $u(\phi)$ is bounded for all $\phi\in G_0^\infty(U)$. The last statement translates directly into:

Proposition 3.1: A superdistribution u in $U\in\mathcal{G}_L^{m,n}$ is a continuous linear functional on $G_0^\infty(U)$ if and only if to every compact set $K\subset U$, there exists a constant C and $(m+n)$ such that

$$|u(\phi)|\leqslant C\sup_{\substack{|p|\leqslant m+n\\ z\in K}}|D^p(\phi)(z)|,\quad \phi\in G_0^\infty(K).$$

Proof: First, it is worth keeping in mind that $\mathcal{G}_L$ can be identified with $\mathbb{R}^{2^{L-1}}$.[26] In fact, a number system assuming values in some Grassmann algebra with L generators is specified by 2^{L-1} real parameters. Let F and E be spaces of smooth functions with compact support defined on $K\subset U\subset\mathcal{G}_L^{m,n}$ and $K\subset U\subset\mathbb{R}^{2^{L-1}(m+n)}$, respectively. If we have a functorial relation $\lambda:\mathsf{F}\to\mathsf{E}$ and a linear functional $\tilde{u}:\mathsf{E}\to\mathbb{R}^{2^{L-1}}$, we can compose λ with $\tilde{u}$ to obtain the pullback of $\tilde{u}$ by λ, i.e., $u=\lambda^*\tilde{u}=\tilde{u}\circ\lambda$, and hence a linear functional $\lambda^*\tilde{u}:\mathsf{F}\to\mathbb{R}^{2^{L-1}}$. Then, the statement follows if $\tilde{u}$ is continuous on E. But this clear from proposition 21.1 of Ref. 46, which can be applied *verbatim* for a functional $\tilde{u}$ on E. □

C. Distributions on a supermanifold

Next we will obtain an extension of basic results about superdistributions on the flat superspace in the case of general supermanifolds.

Definition 3.2: Let $\mathcal{M}$ a G^∞ supermanifold. For every coordinate system $p_i\circ k_\alpha$ in $\mathcal{M}$ one has a distribution $u_{k_\alpha}\in\mathfrak{D}'(\tilde{X}_\alpha)$ where $\tilde{X}_\alpha$ is an open from $\mathcal{G}_L^{m,n}$ such that

$$u_{k_\beta}=\{(p_i\circ k_\alpha)\circ(k_\beta^{-1}\circ p_i^{-1})\}^*u_{k_\alpha},\quad (i=1,\ldots,m+n),\tag{3.6}$$

in $k_\beta(X_\alpha\cap X_\beta)$, where p_i is a projection into each copies (i) from $\mathcal{G}^{m,n}$, such that $x_i=p_i\circ k_\alpha$ and $y_j=p_{j+m}\circ k_\alpha$, with $(i=1,\ldots,m;j=1,\ldots,n)$. We call the system u_{k_α} a distribution u in $\mathcal{M}$. The set of every distribution in $\mathcal{M}$ is denoted by $\mathfrak{D}'(\mathcal{M})$.

Theorem 3.3: *Let $\tilde{X}_\alpha,\alpha\in I$, be an arbitrary family of open sets in $\mathcal{G}_L^{m,n}$, and set $\tilde{X}=\cup_{\alpha\in I}\tilde{X}_\alpha$. If $u_\alpha\in\mathfrak{D}'(\tilde{X}_\alpha)$ and $u_\alpha=u_\beta$ in $(\tilde{X}_\alpha\cap\tilde{X}_\beta)$ for all $\alpha,\beta\in I$, then there exists one and only one $u\in\mathfrak{D}'(\tilde{X})$ such that u_α is the restriction of u to $\tilde{X}_\alpha$ for every α.*

To prove this theorem, it is interesting to state the following results:

Lemma 3.4: Let $\tilde{X}_1,\ldots,\tilde{X}_k$ be open sets in $\mathcal{G}_L^{m,n}$ and let $\phi\in G_0^\infty(\cup_1^k\tilde{X}_\alpha)$. Then one can find $\phi_\alpha\in G_0^\infty(\tilde{X}_\alpha),\alpha=1,\ldots,k$, such that $\phi=\Sigma_1^k\phi_\alpha$ and if $\phi\geqslant 0$ can take all $\phi_\alpha\geqslant 0$.

Proof: We can choose compact sets $K_1,\ldots,K_k$ with $K_\alpha\subset\tilde{X}_\alpha$, so that the supp $\phi\subset\cup_1^k K_\alpha$. Every point in supp ϕ has a compact neighborhood contained in some $\tilde{X}_\alpha$, a finite number of such neighborhoods can be chosen which cover all of supp ϕ. The union of those which belong to X_α is a compact set $K_\alpha\subset\tilde{X}_\alpha$. Now, if $\tilde{X}$ is an open set in $\mathcal{G}_L^{m,n}$ and K is a compact subset, then one can find $\phi\in G_0^\infty(\tilde{X})$ with $0\leqslant\phi\leqslant 1$ so that $\phi=1$ in a neighborhood of K. So, we can choose $\psi_\alpha\in G_0^\infty(\tilde{X}_\alpha)$ with $0\leqslant\psi_\alpha\leqslant 1$ and $\psi_\alpha=1$ in K_α, then the functions

$$\phi_1=\phi\psi_1,\phi_2=\phi\psi_2(1-\psi_1),\ldots,\phi_k=\phi\psi_k(1-\psi_1)\cdots(1-\psi_{k-1})$$

have the required properties since

$$\sum_1^k \phi_\alpha - \phi = -\phi \prod_1^k (1-\psi_\alpha) = 0,$$

because either ϕ or some $1-\psi_\alpha$ is zero at any point. □

Corollary 3.5: Let $\tilde{X}_1,\ldots,\tilde{X}_k$ be open sets in $\mathcal{G}_L^{m,n}$ and K a compact subset $\subset \tilde{X}_\alpha$. Then one can find $\phi_\alpha \in G_0^\infty(\tilde{X}_\alpha)$ so that $\phi_\alpha \geqslant 0$ and $\Sigma_1^k \phi_\alpha \leqslant 1$ with equality in a neighborhood of K. □

Proof of the Theorem 3.3: If u is a distribution, then

$$u(\phi) = \sum u_\alpha(\phi_\alpha), \quad \text{if} \quad \phi = \sum \phi_\alpha \quad (\text{where } \phi_\alpha \in G_0^\infty(\tilde{X}_\alpha)),$$

and the sum is finite. By the Lemma 3.4, every $\phi \in G_0^\infty(\tilde{X})$ can be written as such a sum. If $\Sigma \phi_\alpha = 0 \Rightarrow \Sigma u_\alpha(\phi_\alpha) = 0$, then we conclude that $\Sigma u_\alpha(\phi_\alpha)$ is independent of how we choose the sum. Let $K = \cup \operatorname{supp} \phi$ compact set $K \subset \tilde{X}$ and using the corollary 3.5, we can choose $\psi_\beta \in G_0^\infty(\tilde{X}_\beta)$ such that $\Sigma \psi_\beta = 1$ in K and the sum is finite. Then $\psi_\beta \phi_\alpha \in G_0^\infty(\tilde{X}_\alpha \cap \tilde{X}_\beta)$ so $u_\alpha(\psi_\beta \phi_\alpha) = u_\beta(\psi_\beta \phi_\alpha)$. Hence

$$\sum u_\alpha(\phi_\alpha) = \sum \sum u_\alpha(\phi_\alpha \psi_\beta) = \sum \sum u_\beta(\phi_\alpha \psi_\beta) = \sum u_\beta\left(\psi_\beta \sum \phi_\alpha\right) = 0.$$

We have shown that if $\Sigma \phi_\alpha = 0 \Rightarrow \Sigma u_\alpha(\phi_\alpha)$ is zero, then u is unique. In order to show that u is distribution, choose a compact set $K \subset \tilde{X}$ and a function $\psi_\beta \in G_0^\infty(\tilde{X}_\beta)$ with $\Sigma \psi_\beta = 1$ in K and finite sum. If $\phi \in G_0^\infty(K)$ we have $\phi = \Sigma \phi \psi_\beta$ with $\phi \psi_\beta \in G_0^\infty(\tilde{X}_\beta)$ so that the first equation this proof gives

$$u(\phi) = \sum u_\beta(\phi \psi_\beta),$$

but, if u_β is a distribution, then

$$|u_\beta(\phi \psi_\beta)| \leqslant C \sup_{\substack{|p| \leqslant m+n \\ z \in K}} |D^p(\phi \psi_\beta)(z)|, \quad \phi \psi_\beta \in G_0^\infty(\tilde{X}_\beta),$$

where $\sup D^p \phi$ can be estimated in terms of ϕ, and so we conclude that

$$|u(\phi)| \leqslant C \sup_{\substack{|p| \leqslant m+n \\ z \in K}} |D^p \phi(z)|, \quad \phi \in G_0^\infty(K).$$

This completes our proof. □

Theorem 3.6: *Let $\mathcal{F}$ be an atlas for $\mathcal{M}$. If for every $p_i \circ k \in \mathcal{F}$ one has a distribution $u_k \in \mathfrak{D}'(\tilde{X}_k)$ and the above definition is true when $p_i \circ k$ and $p_i' \circ k'$ belongs to $\mathcal{F}$, then there is one, and only one, distribution $u \in \mathfrak{D}'(\mathcal{M})$ such that $u \circ (k^{-1} \circ p_i^{-1}) = u_k$ for every $p_i \circ k \in \mathcal{F}$.*

Proof: Let $\psi \in G^\infty$ be a coordinate system in $\mathcal{M}$. Theorem 3.3 states that there exists one, and only one, distribution $U_\psi \in \mathfrak{D}'(\tilde{X}_\psi)$ in such a way for every $p_i \circ k$, $U_\psi = ((p_i \circ k) \circ \psi^{-1})^* u_k$ in $\psi(X_\psi \cap X_k) \subset \tilde{X}_\psi$. If $\psi \in \mathcal{F} \rightarrow U_\psi = u_\psi$, we can choose $p_i \circ k = \psi$. Now, one defines u as a distribution, since U_ψ satisfies (3.6) for both coordinate systems $p_i \circ k$ and $p_i' \circ k'$. □

IV. ALGEBRAIC FRAMEWORK ON A SUPERMANIFOLD

In the usual treatment of quantum field theory in flat spacetime, the existence of a unitary representation of the restricted Poincaré group, $\mathcal{P}_+^\uparrow$, with generators P_μ fulfilling the spectral condition $\mathrm{sp} P_\mu \subset \overline{V}_+$, is very essential. This unitary operator plays a key role in picking out a preferred vacuum state, i.e., a state which is invariant under all translations. We choose a complete

system of physical states, with positive energies, just when it is possible to define this vacuum state and consequently the Fock space, $\mathcal{F}$. One then defines observables as operators on $\mathcal{F}$ which act upon the states. However, the characterization of the vacuum involves global aspects, and in the case of a curved space–time it is not evident how to select a distinguished state. As already mentioned in the Introduction, due the absence of a *global* Poincaré group there is no analogous selection criterium on a curved spacetime: no vacuum state can be used as reference. To understand the significance of this point under another point of view, we take into account that, initially, a theory defined on a globally hyperbolic Lorentz manifold could be reduced to the tangent space at a given point, one neglecting the gravitational effects. One finds that the tangent space theory reduces to a free quantum field theory in a Minkowski space which has local translation invariance and a distinguished invariant state could be established by a *local* unitary mapping. Nevertheless, this unitary operator depends on the region and there exists no unitary operator which does the mapping for all open regions simultaneously. Therefore, the problem of how to characterize the physical states arises. For the discussion of this problem on a general manifold, the setting of the so-called algebraic approach to quantum field theory (see Refs. 6, 7, 47) is particularly appropriate, because it treats all states on equal footing, especially the states arising of unitarily inequivalent representations.

The algebraic approach envolves the theory of $*$-algebras and their states and Hilbert space representations. In this framework the basic objects are the algebras generated by observables localized in a given spacetime region. Fields are not mentioned in this setting and are regarded as a type of coordinates of the algebras. The basic assumption is that *all physical* information must already be encoded in the structure of the local observables. Haag and Kastler introduced a mathematical structure for the set of observables of a physical system by proposing the now so-called Haag–Kastler axioms[30] for nets of C^* algebras, later generalized by Dimock[31] for local observables to globally hyperbolic manifolds. Recently, a new approach to the model independent description of quantum field theories has been introduced by Brunetti–Fredenhagen–Verch,[48] which incorporates in a local sense the principle of general covariance of general relativity, thus giving rise to the concept of a locally covariant quantum field theory. The usual Haag–Kastler–Dimock framework can be regained from this new approach as a special case.

In this section, we intend to discuss the algebraic formalism so as to include supersymmetry on a supermanifold. A straight formulation on a supermanifold can be performed over the algebraic approach easily, since the construction of the algebra *does not depend "a priori" of the manifold*. Let us describe a physical theory in a general supermanifold from an extended formulation of the ordinary theory in curved space–time. An observable algebra can be generated from $\Phi_{sd}(f_{sf})$, where Φ_{sd} are superdistributions (superfields) and f_{sf} test superfunctions. A complete superalgebra, like above, is represented by $\mathfrak{A}_{sa}=\overline{\cup_{\mathcal{O}}\mathfrak{A}_{sa}(\mathcal{O})}$, where $\mathfrak{A}_{sa}$ denotes the superalgebra, with $\mathcal{O}\subset\mathcal{M}$ denoting a bounded open region on a supermanifold $\mathcal{M}$. We shall assume we have assigned to every bounded open region $\mathcal{O}$ in $\mathcal{M}$ the following properties:

(P.1) All $\mathfrak{A}_{sa}(\mathcal{O})$ are $*$-superalgebras containing a common unit element, where it is assumed that the following condition of isotony holds:

$$\mathcal{O}_1\subset\mathcal{O}_2\Rightarrow\mathfrak{A}_{sa}(\mathcal{O}_1)\hookrightarrow\mathfrak{A}_{sa}(\mathcal{O}_2).$$

This condition expresses the fact that the set, which we call in an improper way, of supersymmetric ''observables'' increases with the size of the localization region. (Certainly the set of physically interesting observables are obtained taking the body.)

(P.2) We define the essential notion of locality so that the restriction of a compact region $\mathcal{O}\in\mathcal{M}$ to a compact region of the body of the supermanifold, $\mathcal{O}_{\mathbf{b}}\in\mathcal{M}_0$, is causally separated from another compact region $\mathcal{O}'_{\mathbf{b}}\in\mathcal{M}_0$. This implies in the spacelike commutativity, $[\mathfrak{A}_{sa}(\mathcal{O}),\mathfrak{A}_{sa}(\mathcal{O}')]=0$. We see that this requirement is important, because only with this restriction we can work with causality: the notion of a suitable proper time curve which intersects the Cauchy surface in a global hyperbolic spacetime makes sense only on the body manifold. So, there we can establish an evolution of Cauchy surfaces to give us a criterion to

define a Hadamard form to the vacuum state. A superdistribution on a supermanifold as a two-point function shows us that the causality is well-defined in this context. Therefore, we now state: if $\mathcal{O}_{\mathbf{b}}$ is causally dependent on $\mathcal{O}'_{\mathbf{b}}$, then $\mathfrak{A}_{\mathrm{sa}}(\mathcal{O})\subset\mathfrak{A}_{\mathrm{sa}}(\mathcal{O}')$.

(P.3) Following Dimock,[31] we require that there be an $\mathfrak{A}_{\mathrm{sa}}(\mathcal{O})$ for each supermanifold $\mathcal{M}$ equipped with some supermetric g, which generalizes the Lorentz metric, in a diffeomorphic class. Let $k:\mathcal{M}_0\to\mathcal{M}'_0$ be a C^∞ diffeomorphism on the body manifold, such that $k^*(g'_0)=g_0$, where g_0 is a metric of signature $(+,-,-,-)$ of the body manifold. Then $z(k):\mathcal{M}\to\mathcal{M}'$ is a G^∞ superdiffeomorphism $z(k)$ from $(\mathcal{M},g)$ to $(\mathcal{M}',g')$ such that $z(k)^*(g')=g$, and there is an isomorphism $\alpha_{z(k)}:\mathfrak{A}_{\mathrm{sa}}\to\hat{\mathfrak{A}}_{\mathrm{sa}}$ such that $\alpha_{z(k)}[\mathfrak{A}_{\mathrm{sa}}(\mathcal{O})]=\hat{\mathfrak{A}}_{\mathrm{sa}}(z(k)(\mathcal{O}))$. One can also show that $z(\mathrm{id}_{\mathcal{M}_0})=\mathrm{id}_{\mathcal{M}}$, where $\mathrm{id}_{\mathcal{M}_0}(\mathrm{id}_{\mathcal{M}})$ are the identity functions on $\mathcal{M}_0(\mathcal{M})$, respectively. Hence, $\alpha_{z(\mathrm{id}_{\mathcal{M}_0})}=\alpha_{(\mathrm{id}_{\mathcal{M}})}$ and, by Eq. (2.7), we have $\alpha_{z(k_1)}\circ\alpha_{z(k_2)}=\alpha_{z(k_1\circ k_2)}$.

It is interesting, in a particular way, to choose a suitable $*$-algebra for a formulation of quantum fields in connection to the Gårding–Wightman approach.[49] In quantum field theory, it is natural to work with tensor product over test functions, since is usual the presence of more than one field. Therefore, we introduce a tensor algebra of smooth superfunctions of compact support over $\mathcal{O}\in\mathcal{M}$, where $\mathcal{O}$ is an open region in a supermanifold. Let f_m be a test superfunction in $\mathfrak{D}_m(\mathcal{O})$, so that $F=\oplus_{m\in\mathbb{N}}f_m(z_1,\ldots,z_m)\in\mathfrak{A}_{\mathrm{sa}}(\mathcal{O})$, where here $z_i=(x_i,\theta_i,\overline{\theta_i})$ denotes the supercoordinates. In a same way we take $\omega_m(z_1,\ldots,z_m)\in\mathfrak{D}'_m(\mathcal{O})$, here $\mathfrak{D}'_m$ is the dual space of $\mathfrak{D}_m$ consisting of m-point superdistributions $\omega=\{\omega_m\}_{m\in\mathbb{N}}$, such that ω_m belongs to the dual algebra denoted by $\mathfrak{A}'_{\mathrm{sa}}(\mathcal{O})$. As we are working on involutive superalgebras, let us define the operation of involution $(*)$ by $f_m^*(z_1,\ldots,z_m)=\overline{f_m(z_m,\ldots,z_1)}$, where $f_m^*=\overline{f_m}$ denotes the complex conjugation.

A superstate ω in this class of algebra is a normalized positive linear functional $\omega:\mathfrak{A}_{\mathrm{sa}}(\mathcal{O})\to\mathcal{G}_L$, with $\omega(F^*F)\geqslant 0$ for all $F\in\mathfrak{A}_{\mathrm{sa}}(\mathcal{O})$. The normalization means that $\omega^0=1$. This net of algebra is the Borchers–Uhlmann one.[50] Such an algebra does not contain any specific dynamical information, which can be obtained by specifying a vacuum state on it. Once the vacuum state has been specified, through the GNS construction which fixes a Hilbert superspace and a vacuum vector, one can extract from the corresponding time-ordered, advanced or retarded superfunctions the desired information.

A superstate is said to satisfy the essential property of *local commutativity* if and only if for all $m\geqslant 2$ and all $1\leqslant i\leqslant m-1$ we have

$$\omega_m(f_1\otimes\cdots\otimes f_i\otimes f_{i+1}\otimes\cdots\otimes f_m)=\omega_m(f_1\otimes\cdots\otimes f_{i+1}\otimes f_i\otimes\cdots\otimes f_m),$$

for all $f_i\in G_0^\infty(\mathcal{O})$, such that the restriction of each f_i on compact regions of the body of supermanifold implies that the supp $f_i|_{\mathcal{O}_{\mathbf{b}}}$ and supp $f_{i+1}|_{\mathcal{O}_{\mathbf{b}}}$ are spacelike separated. Furthermore, a superstate ω is ''quasifree'' if the one-point superdistribution and all the truncated m-point superdistributions for $m\neq 2$ vanish, i.e., all m-point superdistributions are obtained from the two-point superdistribution via relation:

$$\omega_{2m+1}(f_1\otimes\cdots\otimes f_m)=0\quad\text{for } m\geqslant 0,$$

$$\omega_{2m}(f_1\otimes\cdots\otimes f_m)=\sum_{\substack{i_1<\cdots<i_{2m}\\ i_k<j_k\\ i_1,\ldots,j_{2m}\ \text{distinct}}}\omega_2(f_{i_1}\otimes f_{j_1})\omega_2(f_{i_2}\otimes f_{j_2})\cdots\omega_2(f_{i_{2m}}\otimes f_{j_{2m}}),$$

for $m\geqslant 1$.

It is a well-known result that the physical model can be described by the GNS construction, showing us how the Hilbert space is constructed and defining what are the operators (just the algebra representation) acting in this space. According to conventional prescription, for getting the

Hilbert space we choose the quotient between the observable algebra and the ideal $\mathcal{N}_\omega$ (to guarantee the scalar product existence). In this stage the problem of several inequivalent representation persists. In flat superspaces, the super-Poincaré invariance of the vacuum state picks out the correct representation.[51] In general supermanifolds the case is more delicated; we will look for (super)Hadamard structures. This is motivated by the ordinary general manifold case. At last, we choose an acceptable Hilbert superspace from the algebraic properties via GNS construction by the following identification:

$$\omega_m(f_1\otimes\cdots\otimes f_m)=\langle\Omega_\omega,\pi_\omega(f_1)\cdots\pi_\omega(f_m)\Omega_\omega\rangle,$$

where here Ω_ω is a distinguished vector in Hilbert superspace, and π_ω is the representation of the elements $F\in\mathfrak{A}_{\mathrm{sa}}(\mathcal{O})$ which play the role of self-adjoint linear operator acting in the Hilbert superspace over test superfunctions. In addition, we use the physical requirements on the body manifold in order to define whole set of superstates which are supposed to be distinguished by a certain generalized form of the spectral condition.[11]

Remark 4.1: The main features of Hilbert superspaces relevant for our purposes are summarized as follows: (i) when the Grassmann algebra $\mathcal{G}_L$ is endowed with the Rogers norm, every Hilbert superspace is of the form $\mathscr{H}=\mathcal{H}\otimes\mathcal{G}_L$, where $\mathcal{H}$ is an ordinary Hilbert space (the existence of such a subspace $\mathcal{H}$ of $\mathscr{H}$ called a base Hilbert space is important in physical applications[52]), (ii) the $\mathcal{G}_L$-valued inner product $\langle\cdot,\cdot\rangle:\mathscr{H}\times\mathscr{H}\to\mathcal{G}_L$ respects the body operation $\langle x_{\mathbf{b}},y_{\mathbf{b}}\rangle=\langle x,y\rangle_{\mathbf{b}}$ and $\langle x,x\rangle_{\mathbf{b}}\geqslant 0$ for all $\in\mathscr{H}$, so that $x\in\mathscr{H}$ has nonvanishing body if and only if $\langle x,x\rangle_{\mathbf{b}}>0$. For generalizations of some basic results of the theory of Hilbert space to Hilbert superspaces we refer to the recent paper,[41] and references therein. ■

V. HADAMARD (SUPER)STATES

As already emphasized, the Hadamard state condition provides a framework in which we may improve our understanding to the problem concerning the determination of physically acceptable states. The motivation for which we adopt the Hadamard structure of the vacuum state in curved space–time quantum field theory is quite simple. In general, as we lost the possibility of picking out a good representation for the model due the fact that now we have no more an invariant structure over the action of an isometry group (in the flat case, the global Poincaré group), we must get another condition to choose. Since we are able to describe some aspects of a manifold observing the evolution of the Cauchy surface (CS) coming from an asymptotic flat space, a new kind of invariance becomes natural, and this invariance arises from the preservation of some particular structure while the CS geometry is changing in determinated manifolds.

In particular, for states whose expectation values of the energy-momentum tensor operator can be defined by using the point separation prescription for renormalization, Fulling *et al.*[53] showed that if such states have a singularity structure of the Hadamard form in an open neighborhood of a Cauchy surface, then they have their forms preservated independently of the Cauchy evolution. In this case, the states are said to have the Hadamard form if they can be expressed as

$$\Delta_{\mathrm{Had}}(x_1,x_2)=\frac{U(x_1,x_2)}{\sigma(x_1,x_2)}+V(x_1,x_2)\ \ln|\sigma(x_1,x_2)|+W(x_1,x_2),$$

where $\sigma(x_1,x_2)$ is one-half of the square of the geodesic distance between x_1 to x_2. In flat space–time or in the $x_1\to x_2$ limit in curved space–time, $\sigma=\frac{1}{2}(x_1-x_2)^2$. It is clear that this sing supp $\Delta_{\mathrm{Had}}=\{(x_1,x_2)|\sigma=\frac{1}{2}(x_1-x_2)^2=0\}$ (we recall that the singular support of a distribution $u\in\mathcal{D}'(X)$ is the smallest closed subset Y of X such that $u|_{X\setminus Y}$ is of class C^∞). U, V, and W are regular functions for all choices of x_1 and x_2. The functions U and V are geometrical quantities independent of the quantum state, and only W carries information about the state. Therefore, for free quantum field models in ordinary globally hyperbolic manifolds, the Hadamard form plays an important role: it is a strong candidate to describe an acceptable physical representation.

The search for the Hadamard form in the superspace case is simple, since the latter is, in general, obtainable by applying the function $\delta^2(\overline{\theta}-\overline{\theta'})$ (or $\delta^2(\theta-\theta')$) and an exponential structure $e^{E(\partial_x,\theta,\overline{\theta})}$ to the ordinary Hadamard form Δ_{Had} (see proposition 7.3 below and Refs. 54, 55 for details), such that the *singularity structure region is not affected*, i.e., it has a short distance behavior analogous to the short distance behavior discussed in the case of a general spacetime manifold.[56] This issue is recaptured in Sec. VI. Since we can deal with a supermanifold which has a body manifold being a globally hyperbolic one (to guarantee this we just report to the construction of Bonora–Pasti–Tonin[28]), it is important to establish that only *projectively* super-Hadamard structures make sense. The obvious explanation for this statement is that the structure must cover the global time notion, and consequently the argument of causality, but over a supermanifold the notion of causal curves are not well defined unless projectively. The tool to extend the Hadamard structure to the supersymmetric environment arises from the fact that the existence and uniqueness of the Grassmannian continuation (z-continuation) for C^∞ functions is checked. By a body projection, we always get the ordinary Hadamard structure such that the latter must be invariant by CS evolution on the body manifold. This is a consistent result, since we will show in the next section, through an alternative and equivalent characterization of the Hadamard condition due Radzikowski[8] which involves the notion of the wavefront set of a superdistribution, that the structure of singularity is not changed and is condensed in the ordinary region of any Green superfunction, corroborating to the fact that only on the body of a supermanifold the causality makes sense.

VI. MICROLOCAL ANALYSIS IN SUPERSPACE

Important progress in understanding the significance of the Hadamard form relates it to Hörmander's concept of wavefront sets and microlocal analysis,[8] in a particular way by the wavefront set of their two-point functions. It satisfies the Hadamard condition if its wavefront set contains only positive frequencies propagating forward in time and negative frequencies backward in time.

The focus in this section will be on the extension of the Hörmander's description of the singularity structure (wavefront set) of a distribution to include the supersymmetric case. The well-known result that the singularities of a superdistribution may be expressed in a very simple way through the ordinary distribution is proved by functional analytical methods, in particular the methods of microlocal analysis formulated in superspace language.

A. Standard facts on microlocal analysis

The study of singularities of solutions of differential equations is simplified and the results are improved by taking what is now known as microlocal analysis. This leads to the definition of the wavefront set, denoted (WF), of a distribution, a refined description of the singularity spectrum. A similar notion was developed in other versions by Sato,[57] Iagolnitzer,[58] and Sjöstrand.[59] The definition, as known nowadays, is due to Hörmander. He used this terminology due to an existing analogy between his studies on the ''propagation'' of singularities and the classical construction of propagating waves by Huyghens.

The key point of the microlocal analysis is the transference of the study of singularities of distributions from the configuration space only to the rather phase space, by exploring in frequency space the decay properties of a distribution at infinity and the smoothness properties of its Fourier transform. For a distribution u we introduce its wavefront set $\mathrm{WF}(u)$ as a subset in phase space $\mathbb{R}^n\times\mathbb{R}^n$. The functorially correct definition of phase space is $\mathbb{R}^n\times(\mathbb{R}^n)^*$. We shall here ignore any attempt to distinguish between $\mathbb{R}^n$ and $(\mathbb{R}^n)^*$. We shall be thinking of points (x,k) in phase space as specifying those singular directions k of a ''bad'' behavior of the Fourier transform $\hat{u}$ at infinity that are responsible for the nonsmoothness of u at the point x in position space. So we shall usually want $k\neq 0$. A relevant point is that $\mathrm{WF}(u)$ is independent of the coordinate system chosen, and it can be described locally.

As it is well-known,[42,60] a distribution of compact support, $u \in \mathcal{E}'(\mathbb{R}^n)$, is a smooth function if, and only if, its Fourier transform, $\hat{u}$, rapidly decreases at infinity (i.e., as long as supp u does not touch the singularity points). By a fast decay at infinity, one must understand that for all positive integer N exists a constant C_N, which depends on N, such that

$$|\hat{u}(k)| \leqslant (1+|k|)^{-N} C_N, \quad \forall\, N \in \mathbb{N};\ k \in \mathbb{R}^n. \tag{6.1}$$

If, however, $u \in \mathcal{E}'(\mathbb{R}^n)$ is not smooth, then the directions along which $\hat{u}$ does not fall off sufficiently fast may be adopted to characterize the singularities of u.

For distributions does not necessarily of compact support, still we can verify if its Fourier transform rapidly decreases in a given region V through the technique of localization. More precisely, if $V \subset X \subset \mathbb{R}^n$ and $u \in \mathcal{D}'(X)$, we can restrict u to a distribution $u|_V$ in V by setting $u|_V(\phi) = u(\phi)$, where ϕ is a smooth function with support contained in a region V, with $\phi(x) \neq 0$, for all $x \in V$. The distribution ϕu can then be seen as a distribution of compact support on $\mathbb{R}^n$. Its Fourier transform will be defined as a distribution on $\mathbb{R}^n$, and must satisfy, in absence of singularities in $V \in \mathbb{R}^n$, the property (6.1). From this point of view, all development is local in the sense that only the behavior of the distribution on the arbitrarily small neighborhood of the singular point, in the configuration space, is relevant.

Let $u \in \mathcal{D}'(\mathbb{R}^n)$ be a distribution and $\phi \in C_0^\infty(V)$ a smooth function with support $V \subset \mathbb{R}^n$. Then, ϕu has compact support. The Fourier transform of ϕu produces a smooth function in frequency space.

Lemma 6.1: Consider $u \in \mathcal{D}'(\mathbb{R}^n)$ and $\phi \in C_0^\infty(V)$. Then $\widehat{\phi u}(k) = u(\phi e^{-ikx})$. Moreover, the restriction of u to $V \subset \mathbb{R}^n$ is smooth on V if, and only if, for every $\phi \in C_0^\infty(V)$ and each positive integer N there exists a constant $C(\phi, N)$, which depends on N and ϕ, such that $|\widehat{\phi u}(k)| \leqslant (1+|k|)^{-N} C(\phi, N)$, for all $N \in \mathbb{N}$ and $k \in \mathbb{R}^n$. □

If $u \in \mathcal{D}'(\mathbb{R}^n)$ is singular in x, and $\phi \in C_0^\infty(V)$ is $\phi(x) \neq 0$; then ϕu is also singular in x and has compact support. However, in some directions in k-space $\widehat{\phi u}$ until will be asymptotically limited. This is called the set of *regular directions* of u.

Definition 6.2: Let $u(x)$ be an arbitrary distribution, not necessarily of compact support, on an open set $X \subset \mathbb{R}^n$. Then, the set of pairs composed by singular points x in configuration space and by its associated nonzero singular directions k in Fourier space

$$\mathrm{WF}(u) = \{(x,k) \in X \times (\mathbb{R}^n \backslash 0) \,|\, k \in \Sigma_x(u)\}, \tag{6.2}$$

is called **wavefront set** *of u. $\Sigma_x(u)$ is defined to be the complement in $\mathbb{R}^n \backslash 0$ of the set of all $k \in \mathbb{R}^n \backslash 0$ for which there is an open conic neighborhood M of k such that $\widehat{\phi u}$ rapidly decreases in M, for $|k| \to \infty$.*

Remarks 6.1: We will now collect some basic properties of the wavefront set:

(1) The $\mathrm{WF}(u)$ is conic in the sense that it remains invariant under the action of dilatations, i.e., when we multiply the second variable by a positive scalar. This means that if $(x,k) \in \mathrm{WF}(u)$ then $(x, \lambda k) \in \mathrm{WF}(u)$ for all $\lambda > 0$.
(2) From the definition of $\mathrm{WF}(u)$, it follows that the projection onto the first variable, $\pi_1(\mathrm{WF}(u)) \to x$, consists of those points that have no neighborhood wherein u is a smooth function, and the projection onto the second variable, $\pi_2(\mathrm{WF}(u)) \to \Sigma_x(u)$, is the cone around k attached to a such point denoting the set of high-frequency directions responsible for the appearance of a singularity at this point.
(3) The wavefront set of a smooth function is the empty set.
(4) For all smooth function ϕ with compact support $\mathrm{WF}(\phi u) \subset \mathrm{WF}(u)$.
(5) For any partial linear differential operator P, with C^∞ coefficients, we have
$$\mathrm{WF}(Pu) \subseteq \mathrm{WF}(u)\ .$$
(6) If u and v are two distributions belonging to $\mathcal{D}'(\mathbb{R}^n)$, with wavefront sets $\mathrm{WF}(u)$ and $\mathrm{WF}(v)$, respectively; then the wavefront set of $(u+v) \in \mathcal{D}'(\mathbb{R}^n)$ is contained in $\mathrm{WF}(u) \cup \mathrm{WF}(v)$.

(7) If U,V are open set of $\mathbb{R}^n$, $u\in\mathcal{D}'(V)$, and $\chi:U\to V$ a diffeomorphism such that $\chi^*u\in\mathcal{D}'(U)$ is the distribution pulled back by χ, then $\mathrm{WF}(\chi^*u)=\chi^*\mathrm{WF}(u)$. ■

Another result, which we merely state, is needed to complete this briefing on microlocal analysis.

Theorem 6.3 (Wavefront set of pushforwards of a distribution): *Let $f:X\to Y$ be a submersion, and let $u\in\mathcal{E}'(X)$. Then*

$$\mathrm{WF}(f_*u)\subset\{(f(x),\eta)|x\in X,(x,{}^tf'_x\eta)\in\mathrm{WF}(u)\ \text{or}\ {}^tf'_x\eta=0\},$$

where ${}^tf'_x$ denotes the transpose matrix of the Jacobian matrix f'_x of f. □

B. Wavefront set of a superdistribution

It is already well-known that the singularity structure of Feynman (or more precisely Wightman) superfunctions is completely associated with the ''bosonic'' sector of the superspace. Although claims exist that the result is completely obvious, we do not think that a clear proof is available in the literature, to the best of our knowledge. In fact, there is a certain gap in the scientific literature between the usual textbook presentation of the singularity structure of superfunctions and the very mathematical treatement based on microlocal analysis. The purpose of the present subsection is to fill this gap. As expected, our result confirms that the decay properties of an ordinary distribution hold also to the case of a superdistribution, i.e., no new singularity appear by taking into account the structure of the superspace.

Lemma 6.4: Let $X\subset\mathcal{G}_L^{m,0}$ be an open set, and u be a superdistribution on X taking values in $\mathcal{G}_L$, i.e., a linear functional $u:G_0^\infty(X)\to\mathcal{G}_L$. Let ϕ be a supersmooth function with compact support $K\subset X$. Then ϕu is also supersmooth on K, if its components $(\phi u)(\epsilon(x))$ are smooth on a compact set $K'\subset\Omega$, where Ω is the body of superspace. Therefore, the following estimate holds:

$$|\widehat{\phi u}(k)|\leqslant(1+|k_{\mathbf{b}}|)^{-N}C(N,\phi)\ .$$

Indication of Proof: A schematic proof may be constructed along the lines suggested by DeWitt:[32] from definition 2.4 follows that functions of x are in one-to-one correspondence with functions of $x_{\mathbf{b}}$; this implies that in working with integrals over $\mathcal{G}_L^{m,0}$ one may for many purposes proceed as if one were working over the body of superspace, $\Omega=\{(x,0,0)\in X|\epsilon(x)\in\mathbb{R}^m\}$. Because $\phi u(x)$ vanishes at infinity, independently of their souls, the contour in $\mathcal{G}_{L,0}^m$ may be displaced to coincide with Ω, without affecting the value of the integral. So, the theory of the Fourier transforms remains unchanged in form. For the sake of simplicity, we take the case for which $s(x)=(x-\epsilon(x))$ is a smooth singled-valued function of $\epsilon(x)=x_{\mathbf{b}}$ and $L=2$ is the number of generators of $\mathcal{G}_2^{1,0}$. This implies

$$\begin{aligned}\widehat{\phi u}(k)&=\int dx\ e^{ikx}\phi u(x)\\&=\int dx_{\mathbf{b}}\ e^{ik_{\mathbf{b}}x_{\mathbf{b}}}(\phi u(x_{\mathbf{b}})+i\,x_{\mathbf{b}}\phi u(x_{\mathbf{b}})k_{ij}\xi^i\xi^j)\\&=\widehat{\phi u}(k_{\mathbf{b}})+(\widehat{\phi u})'(k_{\mathbf{b}})k_{ij}\xi^i\xi^j\ .\end{aligned}$$

The proof follows one making use of repeated integrations-by-parts generalizing the fact $-i\,k_{\mathbf{b}}^{-1}(d/dx_{\mathbf{b}}\,e^{ik_{\mathbf{b}}x_{\mathbf{b}}})=e^{ik_{\mathbf{b}}x_{\mathbf{b}}}$,

$$\widehat{\phi u}(k)=\frac{(i)^{|\beta|}}{k_{\mathbf{b}}^\beta}\left\{\int dx_{\mathbf{b}}\ e^{-ik_{\mathbf{b}}x_{\mathbf{b}}}(D^\beta_{x_{\mathbf{b}}}(\phi u(x_{\mathbf{b}}))+D^\beta_{x_{\mathbf{b}}}(x_{\mathbf{b}}\phi u(x_{\mathbf{b}}))k_{ij}\xi^i\xi^j)\right\}.$$

Taking the absolute value of both sides and using the Banach algebra property of $\mathcal{G}_L$, we get the estimate

$$|\widehat{\phi u}(k)| \leqslant |\widehat{\phi u}(k_{\mathbf{b}})| + |(\widehat{\phi u})'(k_{\mathbf{b}})||k_{ij}|$$
$$\leqslant (1+|k_{\mathbf{b}}|)^{-|\beta|}\left(\sup_{\substack{|\beta|\leqslant m \\ x_{\mathbf{b}}\in K'}} |D^{\beta}_{x_{\mathbf{b}}}(\phi u(x_{\mathbf{b}}))| + \sup_{\substack{|\beta|\leqslant m \\ x_{\mathbf{b}}\in K'}} |D^{\beta}_{x_{\mathbf{b}}}(x_{\mathbf{b}}\phi u(x_{\mathbf{b}}))||k_{ij}| \right). \quad (6.3)$$

This inequality clearly implies our assertion. Hence, in order that (6.3) be smooth, we only need that $\widehat{\phi u}(k)$ be rapidly decreasing as $|k_{\mathbf{b}}|\to\infty$. The proof may be generalized to include the case in which $s(x)$ is a multivalued function of the body and L is finite arbitrarily. We finish the proof by observing that as expected the soul part of k has a polynomial behavior. □

Lemma 6.5: By replacing $\mathcal{G}_L^{m,0}$ by $\mathcal{G}_L^{m,n}$ in the Lemma 6.4, then in this case the following estimate holds:

$$|\widehat{\phi u}(k,\theta,\overline{\theta})| \leqslant (1+|k_{\mathbf{b}}|)^{-N} C(N,\phi_{(\gamma)})\|\theta_1\|\|\overline{\theta}_1\|\cdots\|\theta_n\|\|\overline{\theta}_n\| \ .$$

Proof: First, we note that both u and ϕ are G^{∞} superfunctions which can be expanded as a polinomial in the odd coordinates whose coefficients are functions defined over the even coordinates,

$$u(x,\theta,\overline{\theta}) = \sum_{(\gamma)=0}^{\Gamma} z(u_{(\gamma)})(x)(\theta)^{(\gamma)} \quad \text{and} \quad \phi(x,\theta,\overline{\theta}) = \sum_{(\gamma)=0}^{\Gamma} z(\phi_{(\gamma)})(x)(\theta)^{(\gamma)} \ .$$

Then, the proof follows essentially by similar arguments to the proof of the previous lemma, taking into account the polinomial behavior of odd variables, θ and $\overline{\theta}$. In fact, $\phi u(x,\theta,\overline{\theta})$ is *linear* function in each odd coordinates separately, because each odd coordinate is nilpotent, and no higher power of a odd coordinate can appear, i.e., $\phi u(x,\theta,\overline{\theta})$ is an absolutely convergent serie in the odd coordinates w.r.t. the Rogers norm $\|\cdot\|_1$. Indeed, $\phi u(x,\theta,\overline{\theta})$ is analytic in the odd coordinates. This suggests that to take the Fourier transform of $\phi u(x,\theta,\overline{\theta})$ on the even variables must be sufficient to infer on the smoothness properties of $\phi u(x,\theta,\overline{\theta})$:

$$\widehat{\phi u}(k,\theta,\overline{\theta}) = \sum_{(\gamma)=0}^{\Gamma}\sum_{(\mu)=0}^{L} (\widehat{\phi u})_{(\gamma),(\mu)}(k_{\mathbf{b}})(\xi)^{(\mu)}(\theta)^{(\gamma)}$$
$$= \sum_{(\gamma)=0}^{\Gamma}\left[\int dx_{\mathbf{b}}\ e^{ik_{\mathbf{b}}x_{\mathbf{b}}}((\phi u)_{(\gamma)}(x_{\mathbf{b}}) + i\,x_{\mathbf{b}}(\phi u)_{(\gamma)}(x_{\mathbf{b}})k_{ij}\xi^i\xi^j + \cdots)\right](\theta)^{(\gamma)}. \quad (6.4)$$

Then, taking the absolute value of both sides of (6.4), we obtain from the Banach algebra property of $\mathcal{G}_L$ and for each integer N the estimate

$$|\widehat{\phi u}(k,\theta,\overline{\theta})| = \left|\sum_{(\gamma)=0}^{\Gamma}\sum_{(\mu)=0}^{L} (\widehat{\phi u})_{(\gamma),(\mu)}(k_{\mathbf{b}})(\xi)^{(\mu)}(\theta)^{(\gamma)}\right|$$
$$\leqslant \sum_{(\gamma)=0}^{\Gamma}\sum_{(\mu)=0}^{L} |(\widehat{\phi u})_{(\gamma),(\mu)}(k_{\mathbf{b}})|\|(\theta)^{(\gamma)}\|$$
$$\leqslant (1+|k_{\mathbf{b}}|)^{-N} C(N,\phi_{(\gamma)})\|\theta_1\|\|\overline{\theta}_1\|\cdots\|\theta_n\|\|\overline{\theta}_n\|. \quad (6.5)$$

This proves the lemma. □

So, the odd sector of superspace does not produce any effect on the singular structure of u. Combining the results above, we have proven.

Theorem 6.6: *The singularities of a superdistribution u are located at specific values of the body of x, the coordinates of the* **physical space–time**, *independently of the odd coordinates.* □

Comment 6.1: That the body of the superspace is responsible for carrying all its singular structure is not too surprising. Apparently, there exists no reason to have superspaces whose topological properties are substantially different from its body, which is responsible for carrying all observables, reflecting some measurable properties of the model. ■

We sum up the preceding discussion as follows:

Definition 6.7 (Wavefront set of a superdistribution): The wavefront set $\mathrm{WF}(u)$ *of a superdistribution* u *in a superspace* $\mathcal{M}$ *is the complement of the set of all regular directed points in the cotangent bundle* $T^*\mathcal{M}_0$, *where* $\mathcal{M}_0=\epsilon(\mathcal{M})$ *is the body of superspace, excluding the trivial point* $k_{\mathbf{b}}=0$.

There is a more precise version of definition 6.7. As we have seen in Sec. III all of the foregoing definitions and statements about supermanifolds may be converted into corresponding definitions and statements about ordinary manifolds, since associated with a supermanifold $\mathcal{M}$ of dimension (m,n) is a family of ordinary manifolds, of dimensions $N=2^{L-1}(m+n)$, $(L=1,2,\ldots)$. The resulting manifold is called the Lth skeleton of $\mathcal{M}$ and denoted by $\mathcal{S}_L(\mathcal{M})$.[32] With the aid of the family of skeletons we can define the pushforward (or direct image) of a superdistribution. Let $X\subset\mathcal{S}_L(\mathcal{M})$ and $Y\subset\mathcal{M}_0$ be open sets and let ϵ be the natural projection from $\mathcal{S}_L(\mathcal{M})$ (or $\mathcal{M}$) to $\mathcal{M}_0$, the body map. If we introduce local coordinates $x=(x_1,\ldots,x_N)$ in X, then Y is defined by $x_{\mathbf{b}}=(x_1,\ldots,x_m)$. There is a local relationship between the body and the skeletons given by

$$\mathcal{S}_L(X)\overset{\text{diff.}}{=}Y\times\mathbb{R}^{2^{L-1}(m+n)-m}\ .$$

Now, let u be a superdistribution on X, then the pushforward ϵ_*u defined by $\epsilon_*u(\varphi)=u(\epsilon^*\varphi)$, $\varphi\in C_0^\infty(Y)$, it is a superdistribution on Y. Using these concepts, we can establish the following:

Corollary 6.8: Let $\epsilon: X\subset\mathcal{S}_L(\mathcal{M})\to Y\subset\mathcal{M}_0$ *be the body projection, and let* $u\in\mathfrak{D}'(X)$. *Then*

$$\mathrm{WF}(\epsilon_*u)\subset\{(x_{\mathbf{b}},k_{\mathbf{b}})\in T^*\mathcal{M}_0\backslash 0\,|\,\exists\, x'=(x_{m+1},\ldots,x_{N'}),(x_{\mathbf{b}},x',k_{\mathbf{b}},0)\in\mathrm{WF}(u)\},$$

where $N'=2^{L-1}(m+n)-m$.

Proof: If $x=(x_{\mathbf{b}},x')$, where $x_{\mathbf{b}}\in Y$, $x'\in\mathbb{R}^{N'}$ and $\epsilon: X\to Y$ is the body map, then the Jacobian matrix is of the form $\epsilon'_x=(1,0)$ and the statement follows by theorem 6.3. Thus, with any superspace $\mathcal{M}$ and body of superspace $\mathcal{M}_0$ the singularities of a superdistribution ϵ_*u are located in a natural way in the set of projections of those points of the wavefront set of the superdistribution u where singular directions are parallel to the $x_{\mathbf{b}}$-axis. □

Example 6.1: For the model of Wess–Zumino, which consist of a chiral superfield Φ in self-interaction, the Feynman superpropagators, in flat superspace, are[54]

$$\begin{aligned}
\Delta^{\mathrm{F}}_{\Phi\Phi}(x,\theta,\overline{\theta};x',\theta',\overline{\theta'})&=-i\,m\,\delta^2(\theta-\theta')e^{i(\theta\sigma^\mu\overline{\theta}-\theta'\sigma^\mu\overline{\theta'})\partial_\mu}\Delta_{\mathrm{F}}(x-x'),\\
\Delta^{\mathrm{F}}_{\overline{\Phi}\Phi}(x,\theta,\overline{\theta};x',\theta',\overline{\theta'})&=e^{i(\theta\sigma^\mu\overline{\theta}+\theta'\sigma^\mu\overline{\theta'}-2\theta\sigma^\mu\overline{\theta'})\partial_\mu}\Delta_{\mathrm{F}}(x-x'),\\
\Delta^{\mathrm{F}}_{\overline{\Phi}\overline{\Phi}}(x,\theta,\overline{\theta};x',\theta',\overline{\theta'})&=i\,m\,\delta^2(\overline{\theta}-\overline{\theta'})e^{-i(\theta\sigma^\mu\overline{\theta}-\theta'\sigma^\mu\overline{\theta'})\partial_\mu}\Delta_{\mathrm{F}}(x-x'),
\end{aligned}\tag{6.6}$$

where $\delta^2(\theta-\theta')=(\theta-\theta')^2$, with $x,\theta,\overline{\theta}$ having the form (2.2) and (2.3), respectively. According to our analysis, the wavefront set of Feynman superprogators have the form

$$\mathrm{WF}(\Delta^{\mathrm{F}}_{\mathrm{susy}})=\{(x_{\mathbf{b}},k_{\mathbf{b}};x'_{\mathbf{b}},-k'_{\mathbf{b}};x,0;x',0)\,|\,(x_{\mathbf{b}},k_{\mathbf{b}};x'_{\mathbf{b}},-k'_{\mathbf{b}})\in\mathrm{WF}(\Delta^{\mathrm{F}}_{\mathrm{susy}}|_{\mathcal{M}_0})\},$$

where $\mathrm{susy}=(\Phi\Phi;\overline{\Phi}\Phi;\overline{\Phi}\overline{\Phi})$, $x=(x_{m+1},\ldots,x_{N'})$, $x'=(x'_{m+1},\ldots,x'_{N'})$, $\Delta^{\mathrm{F}}_{\mathrm{susy}}|_{\mathcal{M}_0}\equiv\epsilon_*\Delta^{\mathrm{F}}_{\mathrm{susy}}$ is the direct image of Feynman superpropagators on the body of superspace, and $\mathrm{WF}(\Delta^{\mathrm{F}}_{\mathrm{susy}}|_{\mathcal{M}_0})\subset O\cup D$,[8] with the off-diagonal piece given by

$$O=\{(x_{\mathbf{b}},k_{\mathbf{b}};x'_{\mathbf{b}},-k'_{\mathbf{b}})\in T^*\mathcal{M}_0^2|(x_{\mathbf{b}},k_{\mathbf{b}})\sim(x'_{\mathbf{b}},k'_{\mathbf{b}}),x_{\mathbf{b}}\neq x'_{\mathbf{b}},$$

$$k_{\mathbf{b}}\in\overline{V}_{\pm}\quad\text{if}\quad x_{\mathbf{b}}\in J_{\pm}(x'_{\mathbf{b}})\},$$

where the equivalence relation $(x_{\mathbf{b}},k_{\mathbf{b}})\sim(x'_{\mathbf{b}},k'_{\mathbf{b}})$ means that there is a lightlike geodesic γ connecting $x_{\mathbf{b}}$ and $x'_{\mathbf{b}}$, such that at the point $x_{\mathbf{b}}$ the covector $k_{\mathbf{b}}$ is tangent to γ and $k'_{\mathbf{b}}$ is the vector parallel transported along the curve γ at $x'_{\mathbf{b}}$ which is again tangent to γ.

The diagonal piece is given by

$$D=\{(x_{\mathbf{b}},k_{\mathbf{b}};x_{\mathbf{b}},-k_{\mathbf{b}})\in T^*\mathcal{M}_0^2\backslash 0|x_{\mathbf{b}}\in\mathcal{M}_0,k_{\mathbf{b}}\in T^*\mathcal{M}_0^2\backslash 0\}.$$

For this reason, the Feynman superpropagators are singular only for pairs of points on the body of superspace that can be connected by a lightlike geodesic. ■

We end this section quoting the main lesson on the microlocal analysis that we can use, i.e., the one about how the wavefront set may be lifted from superdistributions on open sets of $\mathcal{G}_L^{m,n}$ to superdistributions on a smooth supermanifold $\mathcal{M}$. Such an extension can be achieved in analogy with the ordinary case. Let $\mathcal{O}$ be an open neighborhood of $z\in\mathcal{M}$, which is assumed without loss generality to be covered by a single coordinate patch, and $u\in\mathfrak{D}'(\mathcal{O})$ be a superdistribution. Then, there exists a diffeomorphism $\chi:\mathcal{O}\to U\subset\mathcal{G}_L^{m,n}$, so that $\chi^*u\in\mathfrak{D}'(U)$ is the superdistribution pulled back by χ. Therefore $\mathrm{WF}(\chi^*u)=\chi^*\mathrm{WF}(u)$. Now, let ϕ be a supersmooth function with compact support contained within $\mathcal{O}$ with $\phi(z)\neq 0$—one should keep always in mind that each component $\phi_{(\gamma)}(\epsilon(x))$ of $\phi(z)$ is a smooth function and with support contained within $\mathcal{O}_{\mathbf{b}}$, where $\mathcal{O}_{\mathbf{b}}$ denotes an open neighborhood of $x_{\mathbf{b}}\in\mathcal{M}_0$. Hence, the superdistribution $u\phi$ can be seen as a superdistribution on $\mathcal{G}_L^{m,n}$ which is of compact support, and given that there are no points belonging to the $\mathrm{WF}(u)$, the Fourier transform, $\widehat{u\phi}$, of $u\phi$ is well defined as a superdistribution on $\mathcal{G}_L^{m,n}$ and satisfies the Lemma 6.5.

VII. A TYPE OF MICROLOCAL SPECTRAL CONDITION

We come back to the question of the Hadamard superstates. As repeatedly stated in this paper, Hadamard states have acquired a prominent status in connection with the spectral condition, and are recognized as defining the class of physical states for quantum field theories on a globally hyperbolic space–time. Important progress in understanding the significance of Hadamard states was achieved by Radzikowski (with some gaps filled by Köhler[10]) who succeeded in characterizing the class of these states in terms of the wavefront set of their two-point function ω_2 satisfying a certain condition. He called this condition the wavefront set spectral condition (WFSSC). He proposed that a quasifree state ω of the Klein–Gordon field over a globally hyperbolic manifold is a Hadamard state if and only if its two-point distribution ω_2 has wavefront set

$$\mathrm{WF}(\omega_2)=\{(x_1,k_1);(x_2,k_2)\in T^*\mathcal{M}_0^2\backslash\{0\}|(x_1,k_1)\sim(x_2,-k_2)\quad\text{and}\quad k_1^0\geqslant 0\},\qquad(7.1)$$

so that x_1 and x_2 lie on a single null geodesic γ, $(k_1)^\mu=g^{\mu\nu}(k_1)_\nu$ is tangent to γ and future pointing, and when k_1 is parallel transported along γ from x_1 to x_2 yields $-k_2$. If $x_1=x_2$, we have $k_1^2=0$ and $k_1=k_2$. Radzikowski in fact showed that this condition is similar to the spectral condition of axiomatic quantum field theory.[49]

Note that Eq. (7.1) restricts the singular support of $\omega_2(x_1,x_2)$ to points x_1 and x_2 which are null related. Hence, ω_2 must be smooth for all other points. This is known be true for theory of quantized fields on Minkowski space for spacelike related points. The key is the Bargman–Hall–Wightman theorem which shows that this is obtainable by applying complex Lorentz transformations to the primitive domain of analyticity determined by the spectral condition. However, a similar prediction on the smoothness does not exist for timelike related points. Radzikowski suggested to extend the right-hand side of Eq. (7.1) to all causally related points, in order to include possible singularities at timelike related points.

The microlocal characterization of Hadamard states may be applied equally well to a n-point function, with $n>2$. This generalization was achieved by Brunetti *et al.*[11] They suggested a prescription which we recall now. Let $\mathcal{G}_m$ denotes the set of all finite graphs,[61] into some Lorentz manifold $\mathcal{M}_0$, whose vertices represent points in the set $V=\{x_1,\ldots,x_m\}\in\mathcal{M}_0$, and whose edges e represent connections between pairs x_i,x_j by smooth curves (geodesics) $\gamma(e)$ from x_i to x_j. To each edge e one assigns a covariantly constant causal covector field k_e which is future directed if $i<j$, but not related to the tangent vector of the curve. If e^{-1} denotes the edge with opposite direction as e, then the corresponding curve $\gamma(e^{-1})$ is the inverse of $\gamma(e)$, which carries the momentum $k_{e^{-1}}=-k_e$.

Definition 7.1 [μSC (Ref. 11)]: A state ω with m-point distribution ω_m is said to satisfy the Microlocal Spectral Condition if, and only if, for any m

$$\mathrm{WF}(\omega_m)\subseteq\Gamma_m,$$

where Γ_m is the set $\{(x_1,k_1),\ldots,(x_m,k_m)\}$ for which there exists a graph $G\in\mathcal{G}_m$ as described above with $k_i=\Sigma k_e(x_i)$ where the sum runs over all edges which have the point x_i as their sources. The trivial momentum configuration $k_1=\cdots=k_m=0$ is excluded.

Passing from a smooth manifold to a smooth supermanifold, it seems reasonable to require that a superstate satisfies a certain type of microlocal spectrum condition. A completely analogous statement to definition 7.1 can be achieved, once more with the aid of the family of skeletons, $\mathcal{S}_L(\mathcal{M})$, and the graph theory. Let $\mathcal{G}_r$ be a set of finite "*supergraphs*," into some $\mathcal{S}_L(\mathcal{M})$, whose vertices represent points in the set $V=\{x_1,\ldots,x_r\}\in\mathcal{S}_L(\mathcal{M})$. Locally the traditional notion of a supergraph drawing is that its vertices are represented by points in the hyperplane $\mathbb{R}^{2^{L-1}(m+n)}$, its edges are represented by curves—that are piecewise linear—between these points, and different curves meet only in common endpoints. If $\epsilon_0:\mathbb{R}^{2^{L-1}(m+n)}\to\mathbb{R}^m$ is the canonical projection, then $\tilde{G}=\epsilon_0 G$ is a graphy composed by the projection of those points of a supergraph whose edges e represent connections between pairs $x_{\mathbf{b}_i},x_{\mathbf{b}_j}\in\mathbb{R}^m$ by curves from $x_{\mathbf{b}_i}$ to $x_{\mathbf{b}_j}$. Then, according to Brunetti *et al.*,[11] an immersion of a graph $\tilde{G}$ into the body manifold $\mathcal{M}_0$ is an assignment of vertices of $\tilde{G}$ to points in $\mathcal{M}_0$, and of the edges of $\tilde{G}$ to piecewise smooth curves in $\mathcal{M}_0$, $e\to\gamma(e)$ with source $s(\gamma(e))=x_{\mathbf{b}}(s(e))$ and target $t(\gamma(e))=x_{\mathbf{b}}(t(e))$, respectively, together with a covariantly constant causal covector field $k_{\mathbf{b}_e}$ on γ such that: (i) if e^{-1} denotes the edge with opposite direction as e, then the corresponding curve $\gamma(e^{-1})$ is the inverse of $\gamma(e)$; (ii) for every edge e the covector $k_{\mathbf{b}_e}$ is directed toward future if $x_{\mathbf{b}}(s(e))<x_{\mathbf{b}}(t(e))$; (iii) $k_{\mathbf{b}_{e^{-1}}}=-k_{\mathbf{b}_e}$. Using this construction, we establish:

Definition 7.2 (susyμSC): A superstate ω^{susy} with r-point superdistribution ω_r^{susy} is said to satisfy a supersymmetric microlocal spectral condition if, and only if, for any r,

$$\mathrm{WF}(\omega_r^{\mathrm{susy}})=\{(x_{\mathbf{b}_1},x_1',k_{\mathbf{b}_1},0);\ldots;(x_{\mathbf{b}_r},x_r',k_{\mathbf{b}_r},0)\,|\,\mathrm{WF}(\epsilon_*\omega_r^{\mathrm{susy}})\subseteq\tilde{\Gamma}_r\},$$

where $\tilde{\Gamma}_r$ is the set $\{(x_{\mathbf{b}_1},k_{\mathbf{b}_1});\ldots;(x_{\mathbf{b}_r},k_{\mathbf{b}_r})\}$ for which there exists a graph $\tilde{G}$ as described above with $k_{\mathbf{b}_i}=\Sigma k_{\mathbf{b}_e}(x_{\mathbf{b}_i})$ where the sum runs over all edges which have the point $x_{\mathbf{b}_i}$ as their sources. The trivial momentum configuration $k_{\mathbf{b}_1}=\cdots=k_{\mathbf{b}_r}=0$ is excluded.

Remarks 7.1: We would like to call attention to two important points:

(1) Definition 7.2 indicates that for a superstate ω^{susy} the (susyμSC) is equivalent to the requirement that all of the component fields satisfy the microlocal spectral conditions[11] on the body manifold. This observation is significant because it is in agreement with the DeWitt's remark which asserts that, in physical applications of supersymmetric quantum field theories, the spectral condition of the GNS-Hilbert superspace is restricted to the ordinary GNS-Hilbert space that sits inside the GNS-Hilbert superspace.

(2) Definition 7.2 provides us with a "global" microlocal spectral condition. In our setting the word "global" means that the singular support of all component fields is embodied in

WF($\epsilon_* \omega_m^{\text{susy}}$). This is typical feature of supersymmetric theories in superspace language. For instance, for the chiral superfield of Wess–Zumino,[54] in analogy to the scalar component field, the Hadamard condition for a spinorial component field is formulated in terms of its two-point distribution ω_2. The latter are obtainable by applying the adjoint of the spinorial operator to a suitable auxiliary Hadamard state of the squared spinorial equation. For fixed spinor indices the wavefront set of the latter is contained in the r.h.s. of Eq. (7.1) and derivatives do not enlarge the wavefront set. ■

Next we give a example of an application of our definiton. We restrict ourselves to the simplest case of massive chiral/antichiral fields of the Wess–Zumino model in flat superspace, leaving other cases as the Wess–Zumino model, or supersymmetric gauge theories in curved superspace for future works.

The free Wess–Zumino model in flat superspace: The simplest $N=1$ supersymmetric model in four dimension is the free model of Wess–Zumino,[54] which consists of a chiral superfield $\Phi(x,\theta,\overline{\theta})$, resp., antichiral superfield $\overline{\Phi}(x,\theta,\overline{\theta})$, obeying the differential constraint $\overline{D}_{\dot{\alpha}}\Phi=0$, resp., $D_\alpha\Phi=0$. As usual,

$$D_\alpha=\frac{\partial}{\partial\theta^\alpha}-i\sigma^\mu_{\alpha\dot{\alpha}}\overline{\theta}^{\alpha}\partial_\mu, \quad \overline{D}_{\dot{\alpha}}=-\frac{\partial}{\partial\overline{\theta}^{\alpha}}+i\theta^\alpha\sigma^\mu_{\alpha\dot{\alpha}}\partial_\mu, \tag{7.2}$$

is a supersymmetric covariant derivatives. Our notations and conventions are those of Ref. 56. The elements of the $N=1$ superspace are parametrized by even and odd coordinates $z^M=(x^\mu,\theta^\alpha,\overline{\theta^\alpha})$, with $\mu=(0,\ldots,3)$, $\alpha=(1,2)$, $\dot{\alpha}=(\dot{1},\dot{2})$, where θ and its complex conjugate $\overline{\theta}$, are odd coordinates and by construction they anticommute with each other. In this case the body manifold is $\mathbb{R}^m$ and the body map is the augmentation map $\epsilon:\mathcal{G}_L^{m,n}\to\mathbb{R}^m$.

The superfield $\Phi(z)$ is a function mapping superspace into the even part of a Grassmann algebra.[25] With the help of the commutation rule $\overline{D}_\alpha\,(e^{-i\theta\sigma^\mu\overline{\theta}\partial_\mu}\phi)=e^{-i\theta\sigma^\mu\overline{\theta}\partial_\mu}(-\partial/\partial\overline{\theta^\alpha})\phi$, the chiral superfield can be expanded in powers of the odd coordinates as

$$\Phi(z)=e^{-i\theta\sigma^\mu\overline{\theta}\partial_\mu}(\varphi(x)+\theta\psi(x)+\theta^2F(x)), \tag{7.3}$$

with $\varphi\overset{\text{def}}{=}2^{-1/2}(A+iB)$ and $F\overset{\text{def}}{=}2^{-1/2}(D-iE)$. A, B, and ψ are, respectively, the scalar, pseudoscalar, and spin-1/2 physical component fields of Φ, whereas D and E are their scalar and pseudoscalar auxiliary components. The latter are necessary for a classical off-shell closure of the supersymmetry algebra (they do not correspond to propagating degrees of freedom in that appear through nonderivative terms).

As above, the antichiral superfield $\overline{\Phi}(z)$, with the help of the commutation rule $D_\alpha\,(e^{i\theta\sigma^\mu\overline{\theta}\partial_\mu}\phi)=e^{i\theta\sigma^\mu\overline{\theta}\partial_\mu}(\partial/\partial\theta^\alpha)\phi$, can be expanded in component fields:

$$\overline{\Phi}(z)=e^{i\theta\sigma^\mu\overline{\theta}\partial_\mu}(\varphi^*(x)+\overline{\theta\psi}(x)+\overline{\theta}^2F^*(x)). \tag{7.4}$$

The quantum version of the Wess–Zumino model is based on the classical field equations

$$\frac{1}{16}\overline{D}^2\overline{\Phi}+\frac{m}{4}\Phi=0, \quad \frac{1}{16}D^2\Phi+\frac{m}{4}\overline{\Phi}=0. \tag{7.5}$$

Applying the operator D^2 to the first equation (resp., $\overline{D}^2$ to the second equation), multiplying the second equation by $4m$ (resp., the first equation), and using the commutation relation $[D^2,\overline{D}^2]=8iD\sigma^\mu\overline{D}\partial_\mu+16\Box$; one may combine them in order to find

$$(\Box_x+m^2)\Phi=0, \quad (\Box_x+m^2)\overline{\Phi}=0. \tag{7.6}$$

To our classical superfields Φ and $\overline{\Phi}$, we associate quantum superfields, an operator-valued ''superdistributions,'' smeared with ''supertest'' functions,

$$F(z)=e^{-i\theta\sigma^{\mu}\overline{\theta}\partial_{\mu}}(f(x)+\theta\chi(x)+\theta^{2}h(x)),$$

$$\overline{F}(z)=e^{i\theta\sigma^{\mu}\overline{\theta}\partial_{\mu}}(f^{*}(x)+\overline{\theta\chi}(x)+\overline{\theta}^{2}h^{*}(x)), \tag{7.7}$$

with $F(z),\overline{F}(z)\in G_{0}^{\infty}(U,\mathcal{G}_{L})$, the $\mathcal{G}_{L}$-valued superfunctions on an open set $U\subset\mathcal{G}_{L}^{m,n}$ which have compact support.

For all $F(z),G(z)\in G_{0}^{\infty}(U,\mathcal{G}_{L})$, we define the commutation relations

$$[\Phi(\overline{F}),\Phi(\overline{G})]=\int d\mu(z)d\mu(z')\ \Delta_{\Phi\Phi}^{\mathrm{PJ}}(z,z')\overline{F}(z)\overline{G}(z'),$$

$$[\overline{\Phi}(F),\Phi(\overline{G})]=\int d\mu(z)d\mu(z')\ \Delta_{\overline{\Phi}\Phi}^{\mathrm{PJ}}(z,z')F(z)\overline{G}(z'), \tag{7.8}$$

$$[\overline{\Phi}(F),\overline{\Phi}(G)]=\int d\mu(z)d\mu(z')\ \Delta_{\overline{\Phi}\overline{\Phi}}^{\mathrm{PJ}}(z,z')F(z)G(z'),$$

where $d\mu(z)\overset{\mathrm{def}}{=}d^{8}z=d^{4}xd^{2}\theta d^{2}\overline{\theta}$. We call $\Delta_{\Phi\Phi}^{\mathrm{PJ}}$, $\Delta_{\overline{\Phi}\Phi}^{\mathrm{PJ}}$, and $\Delta_{\overline{\Phi}\overline{\Phi}}^{\mathrm{PJ}}$ the Pauli–Jordan superdistributions, fundamental solutions of the homogeneous equations (7.6). In fact they are two-point distributions, elements of $\mathfrak{D}'(U)$.

The vacuum expectation value of the product $\Phi(F)\Phi(G)$ satisfies the relation

$$(\Omega,\Phi(F)\Phi(G)\Omega)=(w_{2}^{\mathrm{susy}}(z,z'),F(z)G(z')). \tag{7.9}$$

The distribution $w_{2}^{\mathrm{susy}}(z,z')$ extends the Wightman formalism. For this reason, we call $w_{2}^{\mathrm{susy}}(z,z')$ Wightman superdistribution of two-points.

The Wightman superdistribution of n-points will be symbolically written under the form[51]

$$w_{n}^{\mathrm{susy}}(z_{1},,\ldots,z_{n})=(\Omega,\Phi(x_{1};\theta_{1},\overline{\theta}_{1})\cdots\Phi(x_{n};\theta_{n},\overline{\theta}_{n})\Omega), \tag{7.10}$$

and

$$w_{n}^{\mathrm{susy}}(F_{n})=\int\prod_{i=1}^{n}d\mu_{i}\ w_{n}^{\mathrm{susy}}(z_{1},\ldots,z_{n})F_{n}(z_{1},\ldots,z_{n}). \tag{7.11}$$

In this definition, we have fixed the order in which we take the superdistribution and the supertest function.

Proposition 7.3: The two-point Hadamard, Pauli–Jordan, and Wightman superdistributions have the following dependence in $x,\theta,\overline{\theta}$:

$$\Delta_{\Phi\Phi}^{X}(x,\theta,\overline{\theta};x',\theta',\overline{\theta'})=-i\,m\,\delta^{2}(\theta-\theta')e^{i(\theta\sigma^{\mu}\overline{\theta}-\theta'\sigma^{\mu}\overline{\theta'})\partial_{\mu}}\Delta_{X}(x-x'),$$

$$\Delta_{\overline{\Phi}\Phi}^{X}(x,\theta,\overline{\theta};x',\theta',\overline{\theta'})=e^{i(\theta\sigma^{\mu}\overline{\theta}+\theta'\sigma^{\mu}\overline{\theta'}-2\theta\sigma^{\mu}\overline{\theta'})\partial_{\mu}}\Delta_{X}(x-x'), \tag{7.12}$$

$$\Delta_{\overline{\Phi}\overline{\Phi}}^{X}(x,\theta,\overline{\theta};x',\theta',\overline{\theta'})=i\,m\,\delta^{2}(\overline{\theta}-\overline{\theta'})e^{-i(\theta\sigma^{\mu}\overline{\theta}-\theta'\sigma^{\mu}\overline{\theta'})\partial_{\mu}}\Delta_{X}(x-x'),$$

where $X=(\mathrm{Had,PJ,W})$.

Idea of proof: We start from (6.6) and use the fact that in terms of even and odd solutions of the homogeneous wave equation, the function $\Delta_{\mathrm{F}}(x-x')$ can be written as

$$\Delta_F(x-x') = \tfrac{1}{2}[\, i\,\Delta_{\mathrm{Had}}(x-x') + \varepsilon(x^0-x^{0'})\Delta_{\mathrm{PJ}}(x-x')]. \tag{7.13}$$

Then, by replacing (7.13) in (6.6), we immediately get the Hadamard and Pauli–Jordan superdistribution as stated. The Wightman superdistribution is obtained directly from the fact the $\Delta_{\mathrm{PJ}}(x-x') = \Delta_W(x-x') - \Delta_W(x-x')$ and $\Delta_{\mathrm{Had}}(x-x') = -i(\Delta_W(x-x') + \Delta_W(x-x'))$. □

Proposition 7.4: Let ω^{susy} be a state for the quantum Wess–Zumino model on the flat superspace, whose r-point superdistributions ω_r^{susy} satisfy the Wightman axioms.[62] *Then ω^{susy} satisfies definition 7.2.*

Proof: This is an immediate consequence of corollary 6.8 above and theorem 4.6 of Ref. 11.□

VIII. FINAL CONSIDERATIONS

Having proposed an extension of some structural aspects that have successfully been applied in the development of the theory of quantum fields propagating on a general space–time manifold so as to include superfield models on a supermanifold, it would be interesting to consider the perturbative treatment of interacting quantum superfield models, in particular the formulation of renormalization theory on supermanifolds. The main problem which still remains in this rather restrictive framework is the mathematically consistent definition of all powers of Wick ''superpolynomials'' and their time-ordered products for the noninteracting theory, which serve as building blocks for a perturbative definition of interacting superfields. Another work devoted to its solution is in progress,[64] such that covariance with respect to supersymmetry is manifestly preserved. The renormalization scheme underlying our construction is the one of Epstein–Glaser. It is formulated, unlike the other renormalization schemes, in configuration space. Therefore, it becomes appropriate to define carefully perturbative renormalization on a generic spacetime manifold. Recently, Brunetti and Fredenhagen[16] (with some gaps filled by Hollands and Wald[65]) have shown that the Wick polynomials and their time-ordered products can be defined in globally hyperbolic spacetimes. By the methods of this paper we can define powers of Wick ''superpolynomials'' and their time-ordered products for the noninteracting theory.

ACKNOWLEDGMENTS

We would like to thank Professor O. Piguet and Professor J.A. Helayël-Neto for some helpful comments on a preliminary draft of this paper. C.M.M.P. is supported by the Brazilian agency CAPES.

Variational derivation of relativistic fermion–antifermion wave equations in QED

Andrei G. Terekidi and Jurij W. Darewych
Department of Physics and Astronomy, York University, Toronto, Ontario, M3J 1P3, Canada

(Received 16 July 2003; accepted 17 December 2003)

We present a variational method for deriving relativistic two-fermion wave equations in a Hamiltonian formulation of QED. A reformulation of QED is performed, in which covariant Green functions are used to solve for the electromagnetic field in terms of the fermion fields. The resulting modified Hamiltonian contains the photon propagator directly. The reformulation permits one to use a simple Fock-space variational trial state to derive relativistic fermion–antifermion wave equations from the corresponding quantum field theory. We verify that the energy eigenvalues obtained from the wave equation agree with known results for positronium. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1649794]

I. INTRODUCTION

The description of relativistic bound and quasibound (i.e., unstable) few body systems continues to be an active area of research. The traditional method of treating relativistic bound states in quantum field theory (QFT) is by means of the Bethe–Salpeter (BS) equation. However, this approach has a number of difficulties, including the appearance of relative-time coordinates and negative-energy solutions. In practice, the interaction kernels (potentials) in the BS equation are obtained from covariant perturbation theory, which may be of questionable validity for strongly coupled systems. In addition, the BS formalism is difficult to implement for systems of more than two particles.

An alternative approach might be the variational method, which is nonperturbative in principle. The variational method has not been widely used in quantum field theory, in contrast to nonrelativistic systems describable by the Schrödinger theory, in part because of the difficulty of constructing realistic yet tractable trial states.

It has been pointed out in previous publications[1,2] that various models in QFT, including QED, can be reformulated, using mediating-field Green functions, into a form particularly convenient for variational calculations. This approach was applied recently to the study of relativistic two-body states in the scalar Yukawa (Wick–Cutkosky) theory.[3–5] In the present paper we shall implement this approach to the realistic QED theory, where comparison with experimentally verified results are possible. In particular, we shall use the reformulated QED Hamiltonian to derive a relativistic fermion–antifermion wave equation and discuss its solution.

The reformulation of QED is presented in Sec. II, while the Hamiltonian and equal time quantization are given in Sec. III. In Sec. IV we use the variational principle with simple Fock-space trial states to derive the relativistic fermion–antifermion equations, and present their ''partial wave'' decomposition for all possible J^{PC} states. The relativistic radial equations are presented in Sec. V, while their nonrelativistic and semirelativistic limits are given in Sec. VI. In Sec. VII the energy eigenvalues are shown to yield the correct fine and hyperfine structure for all states. Concluding remarks are given in Sec. VIII.

II. REFORMULATION OF FIELD EQUATIONS AND LAGRANGIAN

The Lagrangian of QED is ($\hbar = c = 1$)

$$\mathcal{L} = \overline{\psi}(x)(i\gamma^\mu \partial_\mu - m - e\gamma^\mu A_\mu(x))\psi(x) - \tfrac{1}{4}(\partial_\alpha A_\beta(x) - \partial_\beta A_\alpha(x))(\partial^\alpha A^\beta(x) - \partial^\beta A^\alpha(x)). \quad (1)$$

The corresponding Euler–Lagrange equations of motion are the coupled Dirac–Maxwell equations,

$$(i\gamma^{\mu}\partial_{\mu}-m)\psi(x)=e\gamma^{\mu}A_{\mu}(x)\psi(x), \tag{2}$$

and

$$\partial_{\mu}\partial^{\mu}A^{\nu}(x)-\partial^{\nu}\partial_{\mu}A^{\mu}(x)=j^{\nu}(x), \tag{3}$$

where

$$j^{\nu}(x)=e\overline{\psi}(x)\gamma^{\nu}\psi(x). \tag{4}$$

Equations (2) and (3) can be decoupled in part by using the well-known formal solution[6,7] of the Maxwell equation (3), namely,

$$A_{\mu}(x)=A^{0}_{\mu}(x)+\int d^{4}x' D_{\mu\nu}(x-x')j^{\nu}(x'), \tag{5}$$

where $D_{\mu\nu}(x-x')$ is a Green function (or photon propagator in QFT terminology), defined by

$$\partial_{\alpha}\partial^{\alpha}D_{\mu\nu}(x-x')-\partial_{\mu}\partial^{\alpha}D_{\alpha\nu}(x-x')=g_{\mu\nu}\delta^{4}(x-x'), \tag{6}$$

and $A^{0}_{\mu}(x)$ is a solution of the homogeneous (or "free field") equation (3) with $j^{\mu}(x)=0$.

We recall, in passing, that Eq. (6) does not define the covariant Green function $D_{\mu\nu}(x-x')$ uniquely. For one thing, one can always add a solution of the homogeneous equation [Eq. (6) with $g_{\mu\nu}\rightarrow 0$]. This allows for a certain freedom in the choice of $D_{\mu\nu}$, as is discussed in standard texts (e.g., Refs. 6 and 7). In practice, the solution of Eq. (6), like that of Eq. (3), requires a choice of gauge. However, we do not need to specify one at this stage.

Substitution of the formal solution (5) into Eq. (2) yields the "partly reduced" equations,

$$(i\gamma^{\mu}\partial_{\mu}-m)\psi(x)=e\gamma^{\mu}\left(A^{0}_{\mu}(x)+\int d^{4}x' D_{\mu\nu}(x-x')j^{\nu}(x')\right)\psi(x), \tag{7}$$

which is a nonlinear Dirac equation. To our knowledge no exact (analytic or numeric) solution of Eq. (7) for classical fields have been reported in the literature. However, approximate solutions have been discussed by various authors, particularly Barut and co-workers (see Refs. 8, 9, and citations therein). In any case, our interest here is in the quantized field theory.

The partially reduced equation (7) is derivable from the stationary action principle

$$\delta S[\psi]=\delta\int d^{4}x\mathcal{L}_{R}=0 \tag{8}$$

with the Lagrangian density

$$\mathcal{L}_{R}=\overline{\psi}(x)(i\gamma^{\mu}\partial_{\mu}-m-e\gamma_{\mu}A^{\mu}_{0}(x))\psi(x)-\frac{1}{2}\int d^{4}x' j^{\mu}(x')D_{\mu\nu}(x-x')j^{\nu}(x) \tag{9}$$

provided that the Green function is symmetric in the sense that

$$D_{\mu\nu}(x-x')=D_{\mu\nu}(x'-x) \qquad \text{and} \qquad D_{\mu\nu}(x-x')=D_{\nu\mu}(x-x'). \tag{10}$$

One can proceed to do conventional covariant perturbation theory using the reformulated QED Lagrangian (9). The interaction part of (9) has a somewhat modified structure from that of the usual formulation of QED. Thus, there are two interaction terms. The last term of (9) is a "current–current" interaction which contains the photon propagator sandwiched between the fer-

mionic currents. As such, it corresponds to Feynman diagrams without external photon lines. The term containing A_0^μ corresponds to diagrams that cannot be generated by the term containing $D_{\mu\nu}$, including diagrams involving external photon lines (care would have to be taken not to double count physical effects). However, we shall not pursue covariant perturbation theory in this work. Rather, we shall consider a variational approach that allows one to derive relativistic few-fermion equations, and to study their bound and scattering solutions.

III. HAMILTONIAN OF THE QUANTIZED THEORY IN THE EQUAL-TIME FORMALISM

We consider this theory in the quantized, equal-time formalism. To this end we write down the Hamiltonian density corresponding to the Lagrangian (9), with the term for the free $A_0^\mu(x)$ field suppressed since it will not contribute to the results presented in this paper. The relevant expression is

$$\mathcal{H}_R = \mathcal{H}_0 + \mathcal{H}_I, \tag{11}$$

where

$$\mathcal{H}_0 = \psi^\dagger(x)(-i\boldsymbol{\alpha}\cdot\nabla + m\beta)\psi(x), \tag{12}$$

$$\mathcal{H}_I = \frac{1}{2}\int d^4x' j^\mu(x') D_{\mu\nu}(x-x') j^\nu(x). \tag{13}$$

We construct a quantized theory by the imposition of anticommutation rules for the fermion fields, namely,

$$\{\psi_\alpha(\mathbf{x},t), \psi_\beta^\dagger(\mathbf{y},t)\} = \delta_{\alpha\beta}\delta^3(\mathbf{x}-\mathbf{y}), \tag{14}$$

while all other vanish. In addition, if $A_0^\mu \neq 0$, there would be the usual commutation rules for the A_0^μ field, and commutation of the A_0^μ field operators with the ψ field operators.

To specify our notation, we quote the usual Fourier decomposition of the field operators, namely,

$$\psi(x) = \sum_s \int \frac{d^3p}{(2\pi)^{3/2}}\left(\frac{m}{\omega_p}\right)^{1/2}[b_{\mathbf{p}s}u(\mathbf{p},s)e^{-ip\cdot x} + d_{\mathbf{p}s}^\dagger v(\mathbf{p},s)e^{ip\cdot x}], \tag{15}$$

with $p = p^\mu = (\omega_p, \mathbf{p})$, and $\omega_p = \sqrt{m^2+\mathbf{p}^2}$. Dirac spinors u and v for free particles of mass m, where $(\gamma^\mu p_\mu - m)u(\mathbf{p},s) = 0$, $(\gamma^\mu p_\mu + m)v(\mathbf{p},s) = 0$, are normalized such that

$$u^\dagger(\mathbf{p},s)u(\mathbf{p},\sigma) = v^\dagger(\mathbf{p},s)v(\mathbf{p},\sigma) = \frac{\omega_p}{m}\delta_{s\sigma}, \tag{16}$$

$$u^\dagger(\mathbf{p},s)v(\mathbf{p},\sigma) = v^\dagger(\mathbf{p},s)u(\mathbf{p},\sigma) = 0. \tag{17}$$

The creation and annihilation operators $b^\dagger$, b of the (free) fermions of mass m, and $d^\dagger$, d for the corresponding antifermions, satisfy the usual anticommutation relations. The nonvanishing ones are

$$\{b_{\mathbf{p}s}, b_{\mathbf{q}\sigma}^\dagger\} = \{d_{\mathbf{p}s}, d_{\mathbf{q}\sigma}^\dagger\} = \delta_{s\sigma}\delta^3(\mathbf{p}-\mathbf{q}). \tag{18}$$

IV. VARIATIONAL PRINCIPLE AND FERMION–ANTIFERMION TRIAL STATES

Unfortunately we do not know how to obtain exact eigenstates of the Hamiltonian (11). Therefore we shall resort to a variational approximation, based on the variational principle

$$\delta\langle\psi|\hat{H} - E|\psi\rangle_{t=0} = 0. \tag{19}$$

For a fermion–antifermion system, the simplest Fock-space trial state that can be written down in the rest frame is

$$|\psi_T\rangle = \sum_{s_1 s_2} \int d^3\mathbf{p} F_{s_1 s_2}(\mathbf{p}) b^\dagger_{\mathbf{p}s_1} d^\dagger_{-\mathbf{p}s_2}|0\rangle, \tag{20}$$

where $F_{s_1 s_2}$ are four adjustable functions. We use this trial state to evaluate the matrix elements needed to implement the variational principle (19), namely,

$$\langle\psi_T|:\hat{H}_0 - E:|\psi_T\rangle = \sum_{s_1 s_2} \int d^3\mathbf{p} F^*_{s_1 s_2}(\mathbf{p}) F_{s_1 s_2}(\mathbf{p})(2\omega_p - E) \tag{21}$$

and

$$\langle\psi_T|:\hat{H}_I:|\psi_T\rangle = \frac{e^2 m^2}{(2\pi)^3} \sum_{s_1' s_2' s_1 s_2} \int \frac{d^3\mathbf{p} d^3\mathbf{p}'}{\omega_p \omega_{p'}} F^*_{s_1 s_2}(\mathbf{p}) F_{s_1' s_2'}(\mathbf{p}') \times \begin{pmatrix} -\overline{u}(\mathbf{p}, s_1)\gamma^\mu u(\mathbf{p}', s_1') D_{\mu\nu}(p - p')\overline{v}(-\mathbf{p}', s_2')\gamma^\nu v(-\mathbf{p}, s_2) \\ +\overline{u}(\mathbf{p}, s_1)\gamma^\mu v(-\mathbf{p}, s_2) D_{\mu\nu}(p + p')\overline{v}(-\mathbf{p}', s_2')\gamma^\nu u(\mathbf{p}', s_1') \end{pmatrix}, \tag{22}$$

where $p = (\omega_p, \mathbf{p})$, $p' = (\omega_{p'}, \mathbf{p}')$, with $\mathbf{p} + \mathbf{p}' = 0$ (i.e., $p + p' = (2\omega_p, 0)$) in the rest frame, and

$$D_{\mu\nu}(x - x') = \int \frac{d^4 k}{(2\pi)^4} D_{\mu\nu}(k) e^{-ik\cdot(x - x')}. \tag{23}$$

We have normal-order the entire Hamiltonian, since this circumvents the need for mass renormalization which would otherwise arise. Not that there is difficulty with handling mass renormalization in the present formalism (as shown in various earlier papers; see, for example, Ref. 10, and citations therein). It is simply that we are not interested in mass renormalization here, since it has no effect on the two-body bound state energies that we obtain in this paper. Furthermore, the approximate trial state (20), which we use in this work, is incapable of sampling loop effects. Thus, the normal-ordering of the entire Hamiltonian does not ''sweep under the carpet'' loop effects, since none arise at the present level of approximation, that is with the trial state $|\psi_T\rangle$ specified in Eq. (20).

The variational principle (19) leads to the following equation:

$$\sum_{s_1 s_2} \int d^3\mathbf{p}(2\omega_p - E) F_{s_1 s_2}(\mathbf{p})\, \delta F^*_{s_1 s_2}(\mathbf{p}) - \frac{m^2}{(2\pi)^3} \sum_{\sigma_1 \sigma_2 s_1 s_2} \int \frac{d^3\mathbf{p} d^3\mathbf{q}}{\omega_p \omega_q} F_{\sigma_1 \sigma_2}(\mathbf{q})(-i)\mathcal{M}_{s_1 s_2 \sigma_1 \sigma_2}(\mathbf{p}, \mathbf{q})\, \delta F^*_{s_1 s_2}(\mathbf{p}) = 0, \tag{24}$$

where $\mathcal{M}_{s_1 s_2 \sigma_1 \sigma_2}(\mathbf{p}, \mathbf{q})$ is an invariant ''matrix element,'' which contains two terms:

$$\mathcal{M}_{s_1 s_2 \sigma_1 \sigma_2}(\mathbf{p}, \mathbf{q}) = \mathcal{M}^{\text{ope}}_{s_1 s_2 \sigma_1 \sigma_2}(\mathbf{p}, \mathbf{q}) + \mathcal{M}^{\text{ann}}_{s_1 s_2 \sigma_1 \sigma_2}(\mathbf{p}, \mathbf{q}), \tag{25}$$

where

$$\mathcal{M}^{\text{ope}}_{s_1 s_2 \sigma_1 \sigma_2}(\mathbf{p}, \mathbf{q}) = -\overline{u}(\mathbf{p}, s_1)(-ie\gamma^\mu) u(\mathbf{q}, \sigma_1) i D_{\mu\nu}(p - q)\overline{v}(-\mathbf{q}, \sigma_2)(-ie\gamma^\nu) v(-\mathbf{p}, s_2), \tag{26}$$

$$\mathcal{M}^{\text{ann}}_{s_1 s_2 \sigma_1 \sigma_2}(\mathbf{p}, \mathbf{q}) = \overline{u}(\mathbf{p}, s_1)(-ie\gamma^\mu) v(-\mathbf{p}, s_2) i D_{\mu\nu}(p + q)\overline{v}(-\mathbf{q}, \sigma_2)(-ie\gamma^\nu) u(\mathbf{q}, \sigma_1), \tag{27}$$

correspond to the usual one-photon exchange and virtual annihilation Feynman diagrams.

At this point it is worthwhile to make a few comments about our Eq. (24) and to compare its general features with other two-fermion equations, particularly field-theory based approaches. Firstly we note that the present variational derivation leads to momentum-space Salpeter-type equations, with at most four independent components $F_{s_1 s_2}(\mathbf{p})$. The equations have only positive-energy solutions, as is evident from Eq. (24) with the interaction turned off, in which case only $E=2\omega_p>0$ is obtained. This is in contrast to the BS equation, which is a 16-component equation and contains both positive, negative and mixed energy solutions.

The interaction kernels, represented by the covariant $\mathcal{M}$-matrices, result from the variational derivation, that is, they are not put in by hands. This is in contrast to two fermion equations, which are not derived from a underlying quantum field theory, such as various two-body generalizations of the one-body Dirac equation. There are many such equations on the market, for example the eight component two-fermion equation of Pilkuhn.[11] In these treatments QFT effects, such as the virtual annihilation interaction [Eq. (27)] do not arise naturally but need to be added in.

The fact that only the lowest order (''tree level'') diagrams appear in our Eq. (24) is a reflection of the fact that we have used the simplest possible variational ansatz (20). Even so, it is important to note that, because of the reformulation discussed in Secs. II and III, their derivation does not require additional Fock-space terms in the variational state (20) as is the case in traditional (nonreformulated) treatments (e.g., Refs. 12–14).

In the nonrelativistic limit, the functions $F_{s_1 s_2}$ can be written as

$$F_{s_1 s_2}(\mathbf{p})=F(\mathbf{p})\Lambda_{s_1 s_2}, \tag{28}$$

where the nonzero elements of Λ_{ij} for total spin singlet ($S=0$) states are $\Lambda_{12}=-\Lambda_{21}=1/\sqrt{2}$, while for the spin triplet ($S=1$) states the nonzero elements are $\Lambda_{11}=1$ for $m_s=+1$, $\Lambda_{12}=\Lambda_{21}=1/\sqrt{2}$ for $m_s=0$, and $\Lambda_{22}=1$ for $m_s=-1$. We use the notation that the subscripts 1 and 2 of Λ correspond to $m_s=1/2$ and $m_s=-1/2$ (or $\uparrow$ and $\downarrow$) respectively. Substituting (28) into (24), the variational procedure, after multiplying the result by $\Lambda_{s_1 s_2}$ and summing over s_1 and s_2, gives the equation

$$(2\omega_p-E)F(\mathbf{p})=\frac{1}{(2\pi)^3}\int d^3\mathbf{q}\,\mathcal{K}(\mathbf{p},\mathbf{q})F(\mathbf{q}), \tag{29}$$

where

$$\mathcal{K}(\mathbf{p},\mathbf{q})=-i\frac{m^2}{\omega_p\omega_q}\sum_{s_1 s_2\sigma_1\sigma_2}\Lambda_{s_1 s_2}\mathcal{M}_{s_1 s_2\sigma_1\sigma_2}(\mathbf{p},\mathbf{q})\Lambda_{\sigma_1\sigma_2}. \tag{30}$$

To lowest-order in $|\mathbf{p}|/m$ (i.e., in the nonrelativistic limit), the kernel (30) reduces to $\mathcal{K}=e^2/|\mathbf{p}-\mathbf{q}|^2$, and so (29) reduces to the (momentum-space) Schrödinger equation

$$\left(\frac{\mathbf{p}^2}{2\mu}-\varepsilon\right)F(\mathbf{p})=\frac{1}{(2\pi)^3}\int d^3\,\mathbf{q}\,\frac{e^2}{|\mathbf{p}-\mathbf{q}|^2}F(\mathbf{q}), \tag{31}$$

where $\varepsilon=E-2m$ and $\mu=m/2$. This verifies that the relativistic two-fermion equation (24) has the expected nonrelativistic limit.

In the relativistic case we do not complete the variational procedure in (24) at this stage to get equations for the four adjustable functions $F_{s_1 s_2}$, because they are not independent in general. Indeed we require that the trial state be an eigenstate of the total angular momentum operator (in relativistic form), its projection, parity and charge conjugation, namely, that

$$\begin{bmatrix} \hat{\mathbf{J}}^2 \\ \hat{J}_3 \\ \hat{\mathcal{P}} \\ \hat{\mathcal{C}} \end{bmatrix} |\psi_T\rangle = \begin{bmatrix} J(J+1) \\ m_J \\ P \\ C \end{bmatrix} |\psi_T\rangle, \tag{32}$$

where $m_J = J, J-1, \ldots, -J$ as usual. We present explicit forms for the operators $\hat{\mathbf{J}}^2$, $\hat{J}_3$ in Appendix A. The form for $\hat{\mathbf{J}}^2$, Eq. (109), in particular, is not readily found in standard texts and reference books.

The functions $F_{s_1s_2}(\mathbf{p})$ can be written in the general form

$$F_{s_1s_2}(\mathbf{p}) = \sum_{\ell_{s_1s_2}} \sum_{m_{s_1s_2}} f_{s_1s_2}^{\ell_{s_1s_2} m_{s_1s_2}}(p) Y_{\ell_{s_1s_2}}^{m_{s_1s_2}}(\hat{\mathbf{p}}), \tag{33}$$

where $Y_{\ell_{s_1s_2}}^{m_{s_1s_2}}(\hat{\mathbf{p}})$ are the usual spherical harmonics. Here and henceforth we will use the notation $p = |\mathbf{p}|$, etc. (four-vectors will be written as p^μ). The orbital indexes $\ell_{s_1s_2}$ and $m_{s_1s_2}$ depend on the spin indexes s_1 and s_2 and are specified by equations (32). The radial coefficients $f_{s_1s_2}^{\ell_{s_1s_2} m_{s_1s_2}}(p)$ in the expansion (33) also depend on the spin variables.

Substitution of (33) into (20) and then into (32) leads to two categories of relations among the adjustable functions, as shown in Appendixes A and B. It follows that, for trial states of the form (20), the total spin of the system is a good quantum number, and the states of the system separate into singlet states with the total spin $S=0$ (parastates) and into triplet states with $S=1$ (orthostates). We should point out that this phenomenon is characteristic of the fermion antifermion systems, which are charge conjugation eigenstates, and does not arise for systems like $\mu^+ e^-$.

A. The singlet states

In this case $\ell_{s_1s_2} \equiv \ell = J$, $m_{11} = m_{22} = 0$ and $m_{12} = m_{21} = m_J$. The nonzero components of $F_{s_1s_2}(\mathbf{p})$ are $F_{\uparrow\downarrow}(\mathbf{p}) \equiv F_{12}(\mathbf{p})$, $F_{\downarrow\uparrow}(\mathbf{p}) \equiv F_{21}(\mathbf{p})$ and have the form

$$F_{s_1s_2}(\mathbf{p}) = f_{s_1s_2}^{(\mathrm{sgl})J}(p) Y_J^{m_{s_1s_2}}(\hat{\mathbf{p}}), \tag{34}$$

where the relations between $f_{12}^{(\mathrm{sgl})J}(p)$ and $f_{21}^{(\mathrm{sgl})J}(p)$ involve the Clebsch–Gordan (C–G) coefficients $C_{Jm_J}^{(\mathrm{sgl})Jm_{s_1s_2}}$, that is

$$f_{s_1s_2}^{(\mathrm{sgl})J}(p) = C_{Jm_J}^{(\mathrm{sgl})Jm_{s_1s_2}} f^J(p), \tag{35}$$

as is shown in Appendix A. We see that the spin and radial variables separate for the singlet states in the sense that the factors $f_{s_1s_2}^{(\mathrm{sgl})J}(p)$ have a common radial function $f^J(p)$. Thus, for the singlet states we obtain

$$F_{s_1s_2}(\mathbf{p}) = C_{Jm_J}^{(\mathrm{sgl})Jm_{s_1s_2}} f^J(p) Y_J^{m_J}(\hat{\mathbf{p}}). \tag{36}$$

The C–G coefficients $C_{Jm_J}^{(\mathrm{sgl})Jm_{s_1s_2}}$ have a simple form: $C_{Jm_J}^{(\mathrm{sgl})Jm11} = C_{Jm_J}^{(\mathrm{sgl})Jm22} = 0$, $C_{Jm_J}^{(\mathrm{sgl})Jm12} = -C_{Jm_J}^{(\mathrm{sgl})Jm21} = 1$ (see Appendix A). Therefore for the singlet states we can write expression (20) in the explicit form

$$|\psi_T\rangle = \int d^3\mathbf{p} f^J(p) Y_J^{m_J}(\hat{\mathbf{p}}) (b_{\mathbf{p}\uparrow}^\dagger d_{-\mathbf{p}\downarrow}^\dagger - b_{\mathbf{p}\downarrow}^\dagger d_{-\mathbf{p}\uparrow}^\dagger)|0\rangle. \tag{37}$$

These states are characterized by the quantum numbers J, m_J parity $P=(-1)^{J+1}$ and charge conjugation $C=(-1)^J$. As we can see, the quantum numbers ℓ (orbital angular momentum), and total spin S are good quantum numbers for the singlet states as well. The spectroscopical notation is ${}^1J_J$.

B. The triplet states

The solution of the system (32) for $S=1$ leads to two cases (Appendix A), namely, $\ell_{s_1s_2} \equiv \ell = J$, for which

$$F_{s_1s_2}(\mathbf{p}) = f^{(\mathrm{tr})J}_{s_1s_2}(p) Y^{m_{s_1s_2}}_J(\hat{\mathbf{p}}), \tag{38}$$

and $\ell_{s_1s_2} \equiv \ell = J \mp 1$, for which

$$F_{s_1s_2}(\mathbf{p}) = f^{J-1}_{s_1s_2}(p) Y^{m_{s_1s_2}}_{J-1}(\hat{\mathbf{p}}) + f^{J+1}_{s_1s_2}(p) Y^{m_{s_1s_2}}_{J+1}(\hat{\mathbf{p}}), \tag{39}$$

where

$$m_{11} = m_J - 1, \; m_{12} = m_{21} = m_J, \;\; m_{22} = m_J + 1. \tag{40}$$

The expressions for $f^{\ell}_{s_1s_2}(p)$ in both cases involve the C–G coefficients $C^{(\mathrm{tr})\ell m_s}_{Jm_J}$ for $S=1$ listed in Appendix A, that is

$$f^{(\mathrm{tr})\ell}_{s_1s_2}(p) = C^{(\mathrm{tr})\ell m_s}_{Jm_J} f^{\ell}(p), \tag{41}$$

where the index m_s is defined as

$$\begin{aligned} m_s &= +1, \text{ when } \; m_{s_1s_2} = m_{11}, \\ m_s &= 0, \text{ when } \; m_{s_1s_2} = m_{12} = m_{21}, \\ m_s &= -1, \text{ when } \; m_{s_1s_2} = m_{22}. \end{aligned} \tag{42}$$

Thus, for the triplet states with $\ell = J$,

$$F_{s_1s_2}(\mathbf{p}) = C^{(\mathrm{tr})Jm_s}_{Jm_J} f^J(p) Y^{m_{s_1s_2}}_J(\hat{\mathbf{p}}). \tag{43}$$

These functions correspond to states, which can be characterized by the quantum numbers J, m_J, parity $P=(-1)^{J+1}$ and charge conjugation $C=(-1)^{J+1}$. The orbital angular momentum ℓ, as well as the total spin $S=1$, are good quantum numbers in this case. The spectroscopic notation for these states is ${}^3J_J$.

For the triplet states with $\ell = J \mp 1$ we obtain the result

$$F_{s_1s_2}(\mathbf{p}) = C^{(\mathrm{tr})(J-1)m_s}_{Jm_J} f^{J-1}(p) Y^{m_{s_1s_2}}_{J-1}(\hat{\mathbf{p}}) + C^{(\mathrm{tr})(J+1)m_s}_{Jm_J} f^{J+1}(p) Y^{m_{s_1s_2}}_{J+1}(\hat{\mathbf{p}}), \tag{44}$$

which involves two radial functions $f^{J-1}(p)$ and $f^{J+1}(p)$ corresponding to $\ell = J-1$ and $\ell = J+1$. This means that ℓ is not a good quantum number. Such states are characterized by quantum numbers J, m_J, $P=(-1)^J$, charge conjugation $C=(-1)^J$ and spin $S=1$. In spectroscopic notation, these states are a mixture of ${}^3(J-1)_J$ and ${}^3(J+1)_J$ states.

The requirement that the states be charge conjugation eigenstates [the last equation of (32)] is intimately tied to the conservation of total spin. Indeed, a linear combination of singlet and triplet states like

$$F_{s_1s_2}(\mathbf{p}) = C_1 f^{(\mathrm{sgl})J}_{s_1s_2}(p) Y_J^{m_{s_1s_2}}(\hat{\mathbf{p}}) + C_2 f^{(\mathrm{tr})J}_{s_1s_2}(p) Y_J^{m_{s_1s_2}}(\hat{\mathbf{p}}), \tag{45}$$

satisfies the first three equations of (32). However, it is unacceptable for describing a fermion–antifermion system because the first and the second terms in (45) have different charge conjugation. For a system of two particles of different mass (such as $\mu^+ e^-$) charge conjugation is not applicable, so that the total spin would not be conserved.

V. THE RELATIVISTIC RADIAL EQUATIONS AND APPLICATION TO POSITRONIUMLIKE SYSTEMS

We return to Eq. (24) and replace the functions $F_{s_1s_2}(p)$ by the expression (36) for singlet states and by (43) and (44) for triplet states. The variational procedure then leads to the following results:

For the singlet states $\ell = J$, $P = (-1)^{J+1}$, $C = (-1)^J$, the radial equations are

$$(2\omega_p - E) f^J(p) = \frac{m^2}{(2\pi)^3} \int \frac{q^2 dq}{\omega_p \omega_q} \mathcal{K}^{(\mathrm{sgl})}(p,q) f^J(q), \tag{46}$$

where the kernel

$$\mathcal{K}^{(\mathrm{sgl})}(p,q) = -i \sum_{s_1s_2\sigma_1\sigma_2 m_J} \int d\hat{\mathbf{p}}\, d\hat{\mathbf{q}}\, C^{(\mathrm{sgl})s_1s_2\sigma_1\sigma_2}_{Jm_J} \mathcal{M}_{s_1s_2\sigma_1\sigma_2}(\mathbf{p},\mathbf{q}) Y_J^{m_J *}(\hat{\mathbf{p}}) Y_J^{m_J}(\hat{\mathbf{q}}) \tag{47}$$

is defined by the invariant M-matrix and the coefficients

$$C^{(\mathrm{sgl})s_1s_2\sigma_1\sigma_2}_{Jm_J} \equiv C^{(\mathrm{sgl})Jm_\sigma}_{Jm_J} C^{(\mathrm{sgl})Jm_s}_{Jm_J} \Big/ \sum_{\nu_1\nu_2 m_J} (C^{(\mathrm{sgl})Jm_\nu}_{Jm_J})^2. \tag{48}$$

Here we have summed over m_J, because of the $(2J+1)$-fold energy degeneracy.

For the triplet states, we obtain different equations for the $\ell = J$, and $\ell = J \mp 1$ cases. Thus for the states with $\ell = J$, $P = (-1)^{J+1}$, $C = (-1)^{J+1}$ the result is

$$(2\omega_p - E) f^J(p) = \frac{m^2}{(2\pi)^3} \int \frac{q^2 dq}{\omega_p \omega_q} \mathcal{K}^{(\mathrm{tr})}(p,q) f^J(q), \tag{49}$$

where the kernel $K^{(\mathrm{tr})}$ is formally like that of (47), namely,

$$\mathcal{K}^{(\mathrm{tr})}(p,q) = -i \sum_{s_1s_2\sigma_1\sigma_2 m_J} C^{(\mathrm{tr})s_1s_2\sigma_1\sigma_2}_{Jm_J} \int d\hat{\mathbf{p}}\, d\hat{\mathbf{q}}\, \mathcal{M}_{s_1s_2\sigma_1\sigma_2}(\mathbf{p},\mathbf{q}) Y_J^{m_{s_1s_2}*}(\hat{\mathbf{p}}) Y_J^{m_{\sigma_1\sigma_2}}(\hat{\mathbf{q}}). \tag{50}$$

However it involves different C–G coefficients, namely,

$$C^{(\mathrm{tr})s_1s_2\sigma_1\sigma_2}_{Jm_J} = C^{(\mathrm{tr})Jm_\sigma}_{Jm_J} C^{(\mathrm{tr})Jm_s}_{Jm_J} \Big/ \sum_{\nu_1\nu_2 m_J} (C^{(\mathrm{tr})Jm_\nu}_{Jm_J})^2. \tag{51}$$

For the triplet states with $\ell = J \mp 1$, we have two independent radial functions $f^{J-1}(p)$ and $f^{J+1}(p)$. Thus the variational equation (24) leads to a system of coupled equations for $f^{J-1}(p)$ and $f^{J+1}(p)$. It is convenient to write them in matrix form,

$$(2\omega_p - E)\mathbb{F}(p) = \frac{m^2}{(2\pi)^3} \int \frac{q^2 dq}{\omega_p \omega_q} \mathbb{K}(p,q)\mathbb{F}(q), \tag{52}$$

where

$$\mathbb{F}(p)=\begin{bmatrix} f^{J-1}(p) \\ f^{J+1}(p) \end{bmatrix}, \tag{53}$$

and

$$\mathbb{K}(p,q)=\begin{bmatrix} \mathcal{K}_{11}(p,q) & \mathcal{K}_{12}(p,q) \\ \mathcal{K}_{21}(p,q) & \mathcal{K}_{22}(p,q) \end{bmatrix}. \tag{54}$$

The kernels K_{ij} are similar in form to (47) and (50), that is

$$\mathcal{K}_{ij}(p,q)=-i\sum_{\sigma_1\sigma_2 s_1 s_2 m_J} C^{s_1 s_2 \sigma_1 \sigma_2}_{J m_J i j}\int d\hat{\mathbf{p}}\, d\hat{\mathbf{q}}\, \mathcal{M}_{s_1 s_2 \sigma_1 \sigma_2}(\mathbf{p},\mathbf{q}) Y^{m_{\sigma_1\sigma_2}}_{\ell_j}(\hat{\mathbf{q}}) Y^{m_{s_1 s_2}*}_{\ell_i}(\hat{\mathbf{p}}). \tag{55}$$

However the coefficients $C^{s_1 s_2 \sigma_1 \sigma_2}_{J m_J i j}$ are defined by expression

$$C^{s_1 s_2 \sigma_1 \sigma_2}_{J m_J i j}=C^{(\mathrm{tr})\ell_j m_\sigma}_{J m_J} C^{(\mathrm{tr})\ell_i m_s}_{J m_J} \Big/ \sum_{s_1 s_2 m_J} (C^{(\mathrm{tr})\ell_i m_s}_{J m_J})^2, \tag{56}$$

where $\ell_1=J-1$, $\ell_2=J+1$ and m_S is as defined in Eq. (42). The system (52) reduces to a single equation for $J=0$ since $f^{J-1}(p)=0$ in that case.

Our Eq. (24), or its radial components (46), (49), (52), contain the relativistic two-body kinematics (kinetic energy, recoil effects) exactly, but the dynamics are included approximately due to the limited nature of our trial state (20). This limitation is reflected in the fact that the interaction kernels of our equations contain only ''tree-level'' Feynman diagrams. Nevertheless our Eqs. (46), (49), (52) have no negative-energy solutions, in contrast to the BS equation. They are variationally derived, hence the energy eigenvalues obtained from them will give meaningful values for any strength of the coupling.

To our knowledge, it is not possible to obtain analytic solutions of the relativistic radial momentum-space equations (46), (49), and (52). Thus one must resort to numerical or other approximation methods. Numerical solutions of such equations are discussed, for example, in Ref. 10, while a variational approximation has been employed in Ref. 5. However, in this paper we will concentrate on perturbative $O(\alpha^4)$ solutions, since it is important to verify that our equations yield the correct fine structure for systems like positronium.

Our equations will yield energies which are incomplete beyond $O(\alpha^4)$, because our variational trial state (20), as mentioned, reflects only ''tree-level'' Feynman diagrams, that is no radiative corrections are incorporated. One could, of course, augment them by the addition of invariant matrix elements corresponding to higher-order Feynman diagrams (including radiative corrections) to the existing $\mathcal{M}$-matrices in the kernels of our equations, as is done in the BS formalism. Indeed, such an approach has been used in a similar, though not variational, treatment of positronium by Zhang and Koniuk.[15] These authors show that the inclusion of invariant matrix elements corresponding to single-loop diagrams yields positronium energy eigenstates which are accurate to $O(\alpha^5, \alpha^5 \ln \alpha)$. However such augmentation of the kernels ''by hand'' would be contrary to the spirit of the present variational treatment, and we shall not pursue it in this work.

VI. SEMIRELATIVISTIC EXPANSIONS AND THE NONRELATIVISTIC LIMIT

For perturbative solutions of our radial equations, it is necessary to work out expansions of the relevant expressions to first order beyond the nonrelativistic limit. This shall be summarized in the present section. We perform the calculation in the Coulomb gauge, in which the photon propagator has the form[16]

$$D_{00}(\mathbf{k})=\frac{1}{\mathbf{k}^2}, \quad D_{0j}(\mathbf{k})=0, \quad D_{ij}(k^\mu)=\frac{1}{k^\mu k_\mu}\left(\delta_{ij}-\frac{k_i k_j}{\mathbf{k}^2}\right), \tag{57}$$

where $k^\mu=(\omega_p-\omega_q,\mathbf{p}-\mathbf{q})$.

To expand the amplitudes $\mathcal{M}$ of (26) and (27) to one order of $(p/m)^2$ beyond the nonrelativistic limit, we take the free-particle spinors to be

$$u(\mathbf{p},i)=\begin{bmatrix}\left(1+\dfrac{\mathbf{p}^2}{8m^2}\right)\\ \dfrac{(\boldsymbol{\sigma}\cdot\mathbf{p})}{2m}\end{bmatrix}\varphi_i,\quad v(\mathbf{p},i)=\begin{bmatrix}\dfrac{(\boldsymbol{\sigma}\cdot\mathbf{p})}{2m}\\ \left(1+\dfrac{\mathbf{p}^2}{8m^2}\right)\end{bmatrix}\chi_i, \tag{58}$$

as discussed in Appendix C. In this approximation the photon propagator takes on the form

$$D_{00}(\mathbf{p}-\mathbf{q})=\frac{1}{(\mathbf{p}-\mathbf{q})^2},\qquad D_{ij}(\mathbf{p}-\mathbf{q})\simeq-\frac{1}{(\mathbf{p}-\mathbf{q})^2}\left(\delta_{ij}-\frac{(p-q)_i(p-q)_j}{(\mathbf{p}-\mathbf{q})^2}\right). \tag{59}$$

Corresponding calculations give for the orbital part of the $\mathcal{M}$-matrix

$$\mathcal{M}^{\mathrm{ope(orb)}}_{s_1s_2\sigma_1\sigma_2}(\mathbf{p},\mathbf{q})=ie^2\left\{\frac{1}{(\mathbf{p}-\mathbf{q})^2}+\frac{1}{m^2}\left(\frac{1}{4}+\frac{\mathbf{q}\cdot\mathbf{p}}{(\mathbf{p}-\mathbf{q})^2}+\frac{(\mathbf{p}\times\mathbf{q})^2}{(\mathbf{p}-\mathbf{q})^4}\right)\right\}\delta_{s_1\sigma_1}\delta_{s_2\sigma_2}. \tag{60}$$

The terms of the expansion linear in spin correspond to the spin–orbit interaction:

$$\mathcal{M}^{\mathrm{ope(s-o)}}_{s_1s_2\sigma_1\sigma_2}(\mathbf{p},\mathbf{q})=\frac{3e^2}{4m^2}\varphi^\dagger_{s_1}\chi^\dagger_{\sigma_2}\frac{(\boldsymbol{\sigma}^{(+)}-\boldsymbol{\sigma}^{(-)})\cdot(\mathbf{p}\times\mathbf{q})}{(\mathbf{p}-\mathbf{q})^2}\varphi_{\sigma_1}\chi_{s_2}. \tag{61}$$

Here $\boldsymbol{\sigma}^{(+)}$ and $\boldsymbol{\sigma}^{(-)}$ are positron and electron spin matrices, respectively, defined as follows: $\boldsymbol{\sigma}^{(+)}\varphi_{\sigma_1}\chi_{s_2}=(\boldsymbol{\sigma}^{(+)}\varphi_{\sigma_1})\chi_{s_2}$, $\boldsymbol{\sigma}^{(-)}\varphi_{\sigma_1}\chi_{s_2}=\varphi_{\sigma_1}(\boldsymbol{\sigma}^{(-)}\chi_{s_2})$. The quadratic spin terms or spin–spin interaction terms are

$$\mathcal{M}^{\mathrm{ope(s-s)}}_{s_1s_2\sigma_1\sigma_2}(\mathbf{p},\mathbf{q})=\frac{ie^2}{4m^2}\varphi^\dagger_{s_1}\chi^\dagger_{\sigma_2}\left\{-\frac{(\boldsymbol{\sigma}^{(+)}\cdot(\mathbf{p}-\mathbf{q}))(\boldsymbol{\sigma}^{(-)}\cdot(\mathbf{p}-\mathbf{q}))}{(\mathbf{p}-\mathbf{q})^2}+\boldsymbol{\sigma}^{(+)}\cdot\boldsymbol{\sigma}^{(-)}\right\}\varphi_{\sigma_1}\chi_{s_2}. \tag{62}$$

Lastly, the virtual annihilation contribution is given by

$$\mathcal{M}^{\mathrm{ann}}_{s_1s_2\sigma_1\sigma_2}(p,q)=-\frac{ie^2}{4m^2}\varphi^\dagger_{s_1}\chi^\dagger_{\sigma_2}\{\boldsymbol{\sigma}^{(+)}\cdot\boldsymbol{\sigma}^{(-)}\}\varphi_{\sigma_1}\chi_{s_2}, \tag{63}$$

where we have excluded a divergent term, which appears in the Coulomb gauge calculation. This divergence is an artifact of the Coulomb gauge. It does not arise, for example, in the Lorentz gauge, where only expression (63) is obtained. However the Lorentz gauge is not convenient for obtaining all other $O(\alpha^4)$ corrections because it contains spurious degrees of freedom (longitudinal polarization) of the photon.

We have used expressions (60)–(63) to obtain the corresponding radial kernels. Details of the calculations can be found in Appendix D. We use the notation $z=(p^2+q^2)/2pq$, and $Q_\lambda(z)$ is the Legendre function of the second kind.[17] The contributions of the various terms to the kernel are as follows:

Singlet states with $\ell=J$ $(J\geqslant 0)$, $P=(-1)^{J+1}$, $C=(-1)^J$.

Orbital term

$$\mathcal{K}^{(\mathrm{sgl})(\mathrm{o})}(p,q)=\frac{2\pi e^2}{pq}Q_J(z)+\frac{\pi e^2}{m^2}\left(-\frac{J-3}{2}\left(\frac{p}{q}+\frac{q}{p}\right)Q_J(z)+(J+1)Q_{J+1}(z)-2\delta_{J,0}\right). \tag{64}$$

Spin–orbit interaction

$$\mathcal{K}^{(\mathrm{sgl})(\mathrm{s-o})}(p,q)=0. \tag{65}$$

Spin–spin interaction

$$\mathcal{K}^{(\mathrm{sgl})(\mathrm{s-s})}(p,q)=\frac{2\pi e^2}{m^2}\delta_{J,0}. \tag{66}$$

Triplet states with $\ell=J$ $(J\geqslant 1)$, $P=(-1)^{J+1}$, $C=(-1)^{J+1}$.

Orbital term

$$K^{(\mathrm{tr})(\mathrm{o})}(p,q)=\frac{2\pi e^2}{pq}Q_J(z)+\frac{\pi e^2}{m^2}\left(-\frac{J-3}{2}\left(\frac{p}{q}+\frac{q}{p}\right)Q_J(z)+(J+1)Q_{J+1}(z)\right). \tag{67}$$

Spin–orbit interaction

$$K^{(\mathrm{tr})(\mathrm{s-o})}(p,q)=-\frac{3\pi e^2}{m^2}\frac{1}{2J+1}\{Q_{J+1}(z)-Q_{J-1}(z)\}. \tag{68}$$

Spin–spin interaction

$$\mathcal{K}^{(\mathrm{tr})(\mathrm{s-s})}(p,q)=\frac{\pi e^2}{2m^2}\left(\frac{p}{q}+\frac{q}{p}\right)Q_J(z)-\frac{\pi e^2}{m^2}\frac{1}{2J+1}\{JQ_{J+1}(z)+(J+1)Q_{J-1}(z)\}. \tag{69}$$

Triplet states with $\ell=J-1$ $(J\geqslant 1)$, $\ell=J+1$ $(J\geqslant 0)$, $P=(-1)^J$, $C=(-1)^J$.

The off-diagonal elements of the kernel matrix [Eqs. (52)–(54)], K_{12} and K_{21} which are responsible for mixing of states with $\ell=J-1$ and $\ell=J+1$, get a nonzero contribution from the spin-spin interactions only:

$$\mathcal{K}_{12}(p,q)=\mathcal{K}_{21}(p,q)=\frac{\pi e^2}{5m^2}\frac{\sqrt{J(J+1)}}{(2J+1)}\left(\frac{p}{q}Q_{J+1}(z)+\frac{q}{p}Q_{J-1}(z)-2Q_J(z)\right). \tag{70}$$

The contributions to the diagonal elements of the kernel matrix are the following:

Orbital terms

$$\mathcal{K}_{11}^{(\mathrm{o})}(p,q)=\frac{2\pi e^2}{pq}Q_{J-1}(z)+\frac{\pi e^2}{m^2}\left(-\frac{J-4}{2}\left(\frac{p}{q}+\frac{q}{p}\right)Q_{J-1}(z)+JQ_J(z)-2\delta_{J-1,0}\right), \tag{71}$$

$$\mathcal{K}_{22}^{(\mathrm{o})}(p,q)=\frac{2\pi e^2}{pq}Q_{J+1}(z)+\frac{\pi e^2}{m^2}\left(-\frac{J-2}{2}\left(\frac{p}{q}+\frac{q}{p}\right)Q_{J+1}+(J+2)Q_{J+2}\right). \tag{72}$$

Spin–orbit interaction

$$\mathcal{K}_{11}^{(\mathrm{s-o})}(p,q)=\frac{3\pi e^2}{m^2}\frac{J-1}{2J-1}(Q_J(z)-Q_{J-2}(z)), \tag{73}$$

$$\mathcal{K}_{22}^{(\mathrm{s-o})}(p,q)=-\frac{3\pi e^2}{m^2c^2}\frac{J+2}{2J+3}(Q_{J+2}(z)-Q_J(z)). \tag{74}$$

Spin–spin interaction

$$\mathcal{K}_{11}^{(\mathrm{s-s})}(p,q)=\frac{\pi e^2}{2m^2}\frac{1}{2J+1}\left(\left(\frac{p}{q}+\frac{q}{p}\right)Q_{J-1}(z)-2Q_J(z)\right), \tag{75}$$

$$\mathcal{K}_{22}^{(\mathrm{s-s})}(p,q)=\frac{\pi e^2}{2m^2}\frac{1}{2J+3}\left(\left(\frac{p}{q}+\frac{q}{p}\right)Q_{J+1}(z)-2Q_{J+2}(z)\right). \tag{76}$$

Annihilation term

$$\mathcal{K}^{\mathrm{ann}}(p,q)=-\frac{2\pi e^2}{m^2}\delta_{J-1,0}. \tag{77}$$

We note that in the nonrelativistic limit only the first terms of the orbital part of the kernels survive. They have the common form $2\pi i e^2 Q_\ell(z)/pq$, hence all radial equations reduce to the form

$$(2\omega_p-E)f^\ell(p)=\frac{m^2e^2}{\pi\omega_p p}\int_0^\infty dq\,\frac{q}{\omega_q}Q_\ell(z)f^\ell(q). \tag{78}$$

Recalling, also, that

$$\omega_p=\sqrt{m^2+\mathbf{p}^2}\simeq m\left(1+\frac{1}{2}\left(\frac{\mathbf{p}}{m}\right)^2\right), \tag{79}$$

we obtain, in the nonrelativistic limit, the momentum-space Schrödinger radial equations

$$\left(\frac{\mathbf{p}^2}{2\mu}-\varepsilon\right)f^\ell(p)=\frac{\alpha}{\pi}\frac{1}{p}\int_0^\infty dq\,q\,Q_J(z)f^\ell(q), \tag{80}$$

where $\alpha=e^2/4\pi$, $\mu=m/2$, $\varepsilon=E-2m$.

VII. ENERGY LEVELS: FINE AND HYPERFINE STRUCTURE

The relativistic energy eigenvalues $E_{n,J}$ can be calculated from the expression

$$\begin{aligned}E\int_0^\infty dp\,p^2 f^J(p)f^J(p)=&\int_0^\infty dp\,p^2\,2\omega_p f^J(p)f^J(p)\\&-\frac{m^2}{(2\pi)^3}\int_0^\infty\frac{dpp^2}{\omega_p}\int_0^\infty dq\,\frac{q^2}{\omega_q}\mathcal{K}^{(\mathrm{sgl,tr})}(p,q)f^J(p)f^J(q)\end{aligned} \tag{81}$$

for the singlet and $\ell=J$ triplet states.

For the $\ell=J\mp1$ triplet states the corresponding result is [see Eq. (52)]

$$\begin{aligned}E\int_0^\infty dp\,p^2\mathbb{F}^\dagger(p)\mathbb{F}(p)=&\int_0^\infty dp\,p^2\,2\omega_p\mathbb{F}^\dagger(p)\mathbb{F}(p)\\&-\frac{m^2}{(2\pi)^3}\int_0^\infty\frac{dpp^2}{\omega_p}\int_0^\infty dq\,\frac{q^2}{\omega_q}\mathbb{K}(p,q)\mathbb{F}^\dagger(p)\mathbb{F}(q).\end{aligned} \tag{82}$$

To obtain results for E to $O(\alpha^4)$ we use the forms of the kernels expanded to $O(p^2/m^2)$ [Eqs. (64)–(77)] and replace $f^\ell(p)$ by their nonrelativistic (Schrödinger) form (see (D10), Appendix D). The most important integrals that we used for calculating (81) and (82), are given in Appendix D. In Appendix E we show that the contribution of kernels K_{12} and K_{21} in (82), is zero at $O(\alpha^4)$. Thus, the energy corrections for the triplet states with $\ell=J-1$ and $\ell=J+1$ can be calculated independently.

The results will be presented in the form $\Delta\varepsilon=E-2m+\alpha^2m/4n^2$.

A. Singlet states ($\ell = J$ ($J \geqslant 0$), $P = (-1)^{J+1}$, $C = (-1)^J$)

The kinetic energy corrections

$$\Delta\varepsilon_K^{(\mathrm{sgl})} = -\frac{\alpha^4 m}{8}\left(\frac{1}{2J+1}\frac{1}{n^3} - \frac{3}{8}\frac{1}{n^4}\right). \tag{83}$$

The potential energy corrections

$$\Delta\varepsilon_P^{(\mathrm{sgl})(\mathrm{o})} = -\frac{\alpha^4 m}{8}\left(\left(\frac{3}{2J+1} - 2\delta_{J,0}\right)\frac{1}{n^3} - \frac{1}{n^4}\right), \tag{84}$$

$$\Delta\varepsilon_P^{(\mathrm{sgl})(\mathrm{s-o})} = 0, \tag{85}$$

$$\Delta\varepsilon_P^{(\mathrm{sgl})(\mathrm{s-s})} = -\frac{\alpha^4 m}{4}\frac{\delta_{J,0}}{n^3}. \tag{86}$$

The total energy corrections

$$\Delta\varepsilon^{(\mathrm{sgl})} = -\frac{\alpha^4 m}{8}\left(\frac{4}{2J+1}\frac{1}{n^3} - \frac{11}{8n^4}\right). \tag{87}$$

B. Triplet states ($\ell = J$ ($J \geqslant 1$), $P = (-1)^{J+1}$, $C = (-1)^{J+1}$)

The kinetic energy corrections

$$\Delta\varepsilon_K^{(\mathrm{tr})} = -\frac{\alpha^4 m}{8}\left(\frac{1}{2J+1}\frac{1}{n^3} - \frac{3}{8}\frac{1}{n^4}\right). \tag{88}$$

The potential energy corrections

$$\Delta\varepsilon_P^{(\mathrm{tr})(\mathrm{o})} = -\frac{\alpha^4 m}{8}\left(\left(\frac{3}{2J+1} - 2\delta_{J,0}\right)\frac{1}{n^3} - \frac{1}{n^4}\right), \tag{89}$$

$$\Delta\varepsilon_P^{(\mathrm{tr})(\mathrm{s-o})} = -\frac{\alpha^4 m}{8}\frac{3}{J(J+1)(2J+1)}\frac{1}{n^3}, \tag{90}$$

$$\Delta\varepsilon_P^{(\mathrm{tr})(\mathrm{s-s})} = \frac{\alpha^4 m}{8}\frac{1}{J(J+1)(2J+1)}\frac{1}{n^3}. \tag{91}$$

The total energy corrections

$$\Delta\varepsilon^{(\mathrm{tr})} = -\frac{\alpha^4 m}{8}\left(\left(\frac{4}{2J+1} + \frac{2}{J(J+1)(2J+1)}\right)\frac{1}{n^3} - \frac{11}{8}\frac{1}{n^4}\right). \tag{92}$$

C. Triplet states ($\ell = J-1$ ($J \geqslant 1$), $P = (-1)^J$, $C = (-1)^J$)

The kinetic energy corrections

$$\Delta\varepsilon_K^{(\mathrm{tr})(J-1)} = -\frac{\alpha^4 m}{8}\left(\frac{1}{2J-1}\frac{1}{n^3} - \frac{3}{8}\frac{1}{n^4}\right). \tag{93}$$

The potential energy corrections

$$\Delta\varepsilon_P^{(\mathrm{tr})(\mathrm{o})(J-1)}=-\frac{\alpha^4 m}{8}\left[\left(\frac{3}{2J-1}-2\,\delta_{J,1}\right)\frac{1}{n^3}-\frac{1}{n^4}\right], \tag{94}$$

$$\Delta\varepsilon_P^{(\mathrm{tr})(\mathrm{s-o})(J-1)}=\frac{\alpha^4 m}{8}\,\frac{3(1-\delta_{J,1})}{J(2J-1)}\,\frac{1}{n^3}, \tag{95}$$

$$\Delta\varepsilon_P^{(\mathrm{tr})(\mathrm{s-s})(J-1)}=-\frac{\alpha^4 m}{8}\left(\frac{1-\delta_{J,1}}{J(2J+1)(2J-1)}-\frac{2}{3}\,\delta_{J,1}\right)\frac{1}{n^3}, \tag{96}$$

$$\Delta\varepsilon^{(\mathrm{ann})}=\frac{\alpha^4 m}{4}\,\frac{1}{n^3}\,\delta_{J,1}. \tag{97}$$

The total energy corrections

$$\Delta\varepsilon^{(\mathrm{tr})(J-1)}=-\frac{\alpha^4 m}{8}\left(\left(\frac{4}{2J-1}-\frac{2(3J+1)}{J(2J+1)(2J-1)}-2\,\delta_{J,1}\right)\frac{1}{n^3}-\frac{11}{8}\,\frac{1}{n^4}\right). \tag{98}$$

D. Triplet states ($\ell=J+1$ ($J\geqslant 0$), $P=(-1)^J$, $C=(-1)^J$)

The kinetic energy corrections

$$\Delta\varepsilon_K^{(\mathrm{tr})(J+1)}=-\frac{\alpha^4 m}{8}\left(\frac{1}{2J+3}\,\frac{1}{n^3}-\frac{3}{8}\,\frac{1}{n^4}\right). \tag{99}$$

The potential energy corrections

$$\Delta\varepsilon_P^{(\mathrm{tr})(\mathrm{o})(J+1)}=-\frac{\alpha^4 m}{8}\left[\frac{3}{2J+3}\,\frac{1}{n^3}-\frac{1}{n^4}\right], \tag{100}$$

$$\Delta\varepsilon_P^{(\mathrm{tr})(\mathrm{s-o})(J+1)}=-\frac{\alpha^4 m}{8}\,\frac{3}{(J+1)(2J+3)}\,\frac{1}{n^3}, \tag{101}$$

$$\Delta\varepsilon_P^{(\mathrm{tr})(\mathrm{s-s})(J+1)}=-\frac{\alpha^4 m}{8}\,\frac{1}{(J+1)(2J+3)(2J+1)}\,\frac{1}{n^3}. \tag{102}$$

The total energy corrections

$$\Delta\varepsilon^{(\mathrm{tr})(J+1)}=-\frac{\alpha^4 m}{8}\left(\frac{2}{2J+3}\left(2+\frac{3J+2}{(J+1)(2J+1)}\right)\frac{1}{n^3}-\frac{11}{8}\,\frac{1}{n^4}\right). \tag{103}$$

These results are in agreement with the well-known positronium fine structure results.[18,19]

VIII. CONCLUDING REMARKS

We have considered a reformulation of electrodynamics, in which covariant Green functions are used to solve the field equations for the mediating electromagnetic field in terms of the fermion field. This leads to a reformulated Hamiltonian with an interaction term in which the photon propagator appears sandwiched between fermionic currents.

The variational method within a Hamiltonian formalism of quantum field theory is used to determine approximate eigensolutions for bound relativistic fermion–antifermion states. The reformulation enables us to use the simplest possible trial state to derive a relativistic momentum-space Salpeter-type equation for a positroniumlike system. The invariant $\mathcal{M}$ matrices corresponding to one-photon exchange and virtual annihilation Feynman diagrams arise directly in the interaction kernel of this equation.

The trial states are chosen to be eigenstates of the total angular momentum operator $\hat{\mathbf{J}}^2$ and $\hat{J}_3$, along with parity and charge conjugation. A general relativistic reduction of the wave equations to radial form is given. For given J there is a single radial equation for total spin zero singlet states, but for spin triplet states there are, in general two coupled equations. We show how the classification of states follows naturally from the system of eigenvalue equations obtained with our trial state.

It is not possible, as far as we know, to obtain analytic solutions of our relativistic radial equations nor the resulting eigenvalues of the particle–antiparticle system described. However, it is possible to obtain $O(\alpha^4)$ corrections analytically for all states using perturbation theory. The results agree with well known results for positronium, obtained on the basis of the Bethe–Salpeter equation,[19] which lends credence to the validity of our variationally derived equations.

The method presented here can be generalized to include effects higher order in alpha by using dressed propagators in place of the bare propagators. This shall be the subject of a forthcoming work.

APPENDIX A: TOTAL ANGULAR MOMENTUM OPERATOR IN RELATIVISTIC FORM

The total angular momentum operator is defined by expression

$$\hat{\mathbf{J}}=\int d^3\mathbf{x}:\psi^\dagger(x)(\hat{\mathbf{L}}+\hat{\mathbf{S}})\psi(x):, \tag{A1}$$

where $\hat{\mathbf{L}}=\hat{\mathbf{x}}\times\hat{\mathbf{p}}$ and $\hat{\mathbf{S}}=\frac{1}{2}\hat{\boldsymbol{\sigma}}$ are the orbital angular momentum and spin operators. We use the standard representation for the Pauli matrices

$$\hat{\boldsymbol{\sigma}}=\begin{bmatrix}\boldsymbol{\sigma} & 0\\ 0 & \boldsymbol{\sigma}\end{bmatrix}, \tag{A2}$$

$$\sigma_1=\begin{bmatrix}0 & 1\\ 1 & 0\end{bmatrix},\quad \sigma_2=\begin{bmatrix}0 & -i\\ i & 0\end{bmatrix},\qquad \sigma_3=\begin{bmatrix}1 & 0\\ 0 & -1\end{bmatrix}. \tag{A3}$$

Using the field operator $\psi(x)$ in the form (15), after tedious calculations we obtain

$$\begin{aligned}
\hat{J}_1&=\int d^3\mathbf{q}\begin{pmatrix}\hat{L}_{q1}(b^\dagger_{\mathbf{q}\uparrow}b_{\mathbf{q}\uparrow}+b^\dagger_{\mathbf{q}\downarrow}b_{\mathbf{q}\downarrow}+d^\dagger_{\mathbf{q}\uparrow}d_{\mathbf{q}\uparrow}+d^\dagger_{\mathbf{q}\downarrow}d_{\mathbf{q}\downarrow})\\ +\frac{1}{2}(b^\dagger_{\mathbf{q}\uparrow}b_{\mathbf{q}\downarrow}+b^\dagger_{\mathbf{q}\downarrow}b_{\mathbf{q}\uparrow}+d^\dagger_{\mathbf{q}\downarrow}d_{\mathbf{q}\uparrow}+d^\dagger_{\mathbf{q}\uparrow}d_{\mathbf{q}\downarrow})\end{pmatrix},\\
\hat{J}_2&=\int d^3\mathbf{q}\begin{pmatrix}\hat{L}_{q2}(b^\dagger_{\mathbf{q}\uparrow}b_{\mathbf{q}\uparrow}+b^\dagger_{\mathbf{q}\downarrow}b_{\mathbf{q}\downarrow}+d^\dagger_{\mathbf{q}\uparrow}d_{\mathbf{q}\uparrow}+d^\dagger_{\mathbf{q}\downarrow}d_{\mathbf{q}\downarrow})\\ +\dfrac{i}{2}(-b^\dagger_{\mathbf{q}\uparrow}b_{\mathbf{q}\downarrow}+b^\dagger_{\mathbf{q}\downarrow}b_{\mathbf{q}\uparrow}-d^\dagger_{\mathbf{q}\uparrow}d_{\mathbf{q}\downarrow}+d^\dagger_{\mathbf{q}\downarrow}d_{\mathbf{q}\uparrow})\end{pmatrix},\\
\hat{J}_3&=\int d^3\mathbf{q}\begin{pmatrix}\hat{L}_{q3}(b^\dagger_{\mathbf{q}\uparrow}b_{\mathbf{q}\uparrow}+b^\dagger_{\mathbf{q}\downarrow}b_{\mathbf{q}\downarrow}+d^\dagger_{\mathbf{q}\uparrow}d_{\mathbf{q}\uparrow}+d^\dagger_{\mathbf{q}\downarrow}d_{\mathbf{q}\downarrow})\\ +\frac{1}{2}(b^\dagger_{\mathbf{q}\uparrow}b_{\mathbf{q}\uparrow}-b^\dagger_{\mathbf{q}\downarrow}b_{\mathbf{q}\downarrow}+d^\dagger_{\mathbf{q}\uparrow}d_{\mathbf{q}\uparrow}-d^\dagger_{\mathbf{q}\downarrow}d_{\mathbf{q}\downarrow})\end{pmatrix}.
\end{aligned} \tag{A4}$$

Here $\hat{\mathbf{L}}_q$ is the orbital angular momentum operator in momentum representation:

$$(\hat{\mathbf{L}}_q)_i\equiv\hat{L}_{qi}=-i(\mathbf{q}\times\nabla_q)_i\,. \tag{A5}$$

Note that these expressions are valid for any t, since the time-dependent phase factors of the form $e^{i\omega_q t}$ cancel out.

For the operator $\hat{\mathbf{J}}^2=\hat{J}_1^2+\hat{J}_2^2+\hat{J}_3^2$ we have

$$\hat{\mathbf{J}}^2=\int d^3\mathbf{q}\begin{pmatrix}(\hat{\mathbf{L}}_q^2+\frac{3}{4})(b^\dagger_{\mathbf{q}\uparrow}b_{\mathbf{q}\uparrow}+b^\dagger_{\mathbf{q}\downarrow}b_{\mathbf{q}\downarrow}+d^\dagger_{\mathbf{q}\uparrow}d_{\mathbf{q}\uparrow}+d^\dagger_{\mathbf{q}\downarrow}d_{\mathbf{q}\downarrow})\\ +\hat{L}_{q-}b^\dagger_{\mathbf{q}\uparrow}b_{\mathbf{q}\downarrow}+\hat{L}_{q+}b^\dagger_{\mathbf{q}\downarrow}b_{\mathbf{q}\uparrow}+\hat{L}_{q-}d^\dagger_{\mathbf{q}\uparrow}d_{\mathbf{q}\downarrow}+\hat{L}_{q+}d^\dagger_{\mathbf{q}\downarrow}d_{\mathbf{q}\uparrow}\\ +\hat{L}_{q3}(b^\dagger_{\mathbf{q}\uparrow}b_{\mathbf{q}\uparrow}-b^\dagger_{\mathbf{q}\downarrow}b_{\mathbf{q}\downarrow}+d^\dagger_{\mathbf{q}\uparrow}d_{\mathbf{q}\uparrow}-d^\dagger_{\mathbf{q}\downarrow}d_{\mathbf{q}\downarrow})\end{pmatrix}$$
$$+\frac{1}{2}\int d^3\mathbf{q}'d^3\mathbf{q}\begin{pmatrix}2\hat{\mathbf{L}}_{q'}\cdot\hat{\mathbf{L}}_q\begin{pmatrix}b^\dagger_{\mathbf{q}'\uparrow}b_{\mathbf{q}'\uparrow}d^\dagger_{\mathbf{q}\uparrow}d_{\mathbf{q}\uparrow}+b^\dagger_{\mathbf{q}'\uparrow}b_{\mathbf{q}'\uparrow}d^\dagger_{\mathbf{q}\downarrow}d_{\mathbf{q}\downarrow}\\ +b^\dagger_{\mathbf{q}'\downarrow}b_{\mathbf{q}'\downarrow}d^\dagger_{\mathbf{q}\uparrow}d_{\mathbf{q}\uparrow}+b^\dagger_{\mathbf{q}'\downarrow}b_{\mathbf{q}'\downarrow}d^\dagger_{\mathbf{q}\downarrow}d_{\mathbf{q}\downarrow}\end{pmatrix}\\ +\frac{1}{2}(b^\dagger_{q'\uparrow}b_{q'\uparrow}d^\dagger_{q\uparrow}d_{q\uparrow}-b^\dagger_{q'\uparrow}b_{q'\uparrow}d^\dagger_{q\downarrow}d_{q\downarrow})\\ -\frac{1}{2}(b^\dagger_{q'\downarrow}b_{q'\downarrow}d^\dagger_{q\uparrow}d_{q\uparrow}-b^\dagger_{q'\downarrow}b_{q'\downarrow}d^\dagger_{q\downarrow}d_{q\downarrow})\\ +b^\dagger_{q'\uparrow}b_{q'\downarrow}d^\dagger_{q\downarrow}d_{q\uparrow}+b^\dagger_{q'\downarrow}b_{q'\uparrow}d^\dagger_{q\uparrow}d_{q\downarrow}\\ +\hat{L}_{q'+}\begin{pmatrix}b^\dagger_{\mathbf{q}'\uparrow}b_{\mathbf{q}'\uparrow}d^\dagger_{\mathbf{q}\downarrow}d_{\mathbf{q}\uparrow}+b^\dagger_{\mathbf{q}'\downarrow}b_{\mathbf{q}'\downarrow}d^\dagger_{\mathbf{q}\downarrow}d_{\mathbf{q}\uparrow}\\ +b^\dagger_{\mathbf{q}\downarrow}b_{\mathbf{q}\uparrow}d^\dagger_{\mathbf{q}'\uparrow}d_{\mathbf{q}'\uparrow}+b^\dagger_{\mathbf{q}\downarrow}b_{\mathbf{q}\uparrow}d^\dagger_{\mathbf{q}'\downarrow}d_{\mathbf{q}'\downarrow}\end{pmatrix}\\ +\hat{L}_{q'-}\begin{pmatrix}b^\dagger_{\mathbf{q}'\uparrow}b_{\mathbf{q}'\uparrow}d^\dagger_{\mathbf{q}\uparrow}d_{\mathbf{q}\downarrow}+b^\dagger_{\mathbf{q}'\downarrow}b_{\mathbf{q}'\downarrow}d^\dagger_{\mathbf{q}\uparrow}d_{\mathbf{q}\downarrow}\\ +b^\dagger_{\mathbf{q}\uparrow}b_{\mathbf{q}\downarrow}d^\dagger_{\mathbf{q}'\uparrow}d_{\mathbf{q}'\uparrow}+b^\dagger_{\mathbf{q}\uparrow}b_{\mathbf{q}\downarrow}d^\dagger_{\mathbf{q}'\downarrow}d_{\mathbf{q}'\downarrow}\end{pmatrix}\\ +(\hat{L}_{q'3}+\hat{L}_{q3})(b^\dagger_{\mathbf{q}'\uparrow}b_{\mathbf{q}'\uparrow}d^\dagger_{\mathbf{q}\uparrow}d_{\mathbf{q}\uparrow}-b^\dagger_{\mathbf{q}'\downarrow}b_{\mathbf{q}'\downarrow}d^\dagger_{\mathbf{q}\downarrow}d_{\mathbf{q}\downarrow})\\ -(\hat{L}_{q'3}-\hat{L}_{q3})(b^\dagger_{\mathbf{q}'\uparrow}b_{\mathbf{q}'\uparrow}d^\dagger_{\mathbf{q}\downarrow}d_{\mathbf{q}\downarrow}-b^\dagger_{\mathbf{q}'\downarrow}b_{\mathbf{q}'\downarrow}d^\dagger_{\mathbf{q}\uparrow}d_{\mathbf{q}\uparrow})\end{pmatrix}, \tag{A6}$$

where

$$\hat{L}_{q+}=\hat{L}_{q1}+i\hat{L}_{q2}, \qquad \hat{L}_{q-}=\hat{L}_{q1}-i\hat{L}_{q2}. \tag{A7}$$

The requirement that the trial state (20) be an eigenstate of $\hat{\mathbf{J}}^2$ and $\hat{J}_z$ leads to the system of equations

$$\begin{gathered}(\hat{L}_3+1)F_{11}=m_JF_{11},\\ \hat{L}_3F_{12}=m_JF_{12},\\ \hat{L}_3F_{21}=m_JF_{21},\\ (\hat{L}_3-1)F_{22}=m_JF_{22},\\ (J(J+1)-\hat{\mathbf{L}}^2-2-2\hat{L}_3)F_{11}=\hat{L}_-(F_{12}+F_{21}),\\ (J(J+1)-\hat{\mathbf{L}}^2-1)F_{12}=F_{21}+\hat{L}_+F_{11}+\hat{L}_-F_{22},\\ (J(J+1)-\hat{\mathbf{L}}^2-1)F_{21}=F_{12}+\hat{L}_+F_{11}+\hat{L}_-F_{22},\\ (J(J+1)-\hat{\mathbf{L}}^2-2+2\hat{L}_3)F_{22}=\hat{L}_+(F_{12}+F_{21}).\end{gathered} \tag{A8, A9}$$

Substitution of the expressions (33) for $F_{s_1s_2}$ and use of Eq. (A8) gives

$$m_{12}=m_{21}=m_J,\ \ m_{11}=m_J-1,\ \ m_{22}=m_J+1, \tag{A10}$$

$$\ell_{11}=\ell_{22}=\ell_{12}=\ell_{21}=\ell, \tag{A11}$$

and

$$(J(J+1)-\ell(\ell+1)-2m_J)f^{\ell}_{11}(p)=\sqrt{(\ell-m_J+1)(\ell+m_J)}f^{\ell}_{12}(p)+\sqrt{(\ell-m_J+1)(\ell+m_J)}f^{\ell}_{21}(p),$$

$$\begin{aligned}(J(J+1)-\ell(\ell+1)-1)f^{\ell}_{12}(p)&=f^{\ell}_{21}(p)+\sqrt{(\ell+m_J)(\ell-m_J+1)}f^{\ell}_{11}(p)\\&\quad+\sqrt{(\ell-m_J)(\ell+m_J+1)}f^{\ell}_{22}(p),\\(J(J+1)-\ell(\ell+1)-1)f^{\ell}_{21}(p)&=f^{\ell}_{12}(p)+\sqrt{(\ell+m_J)(\ell-m_J+1)}f^{\ell}_{11}(p)\\&\quad+\sqrt{(\ell-m_J)(\ell+m_J+1)}f^{\ell}_{22}(p),\end{aligned} \tag{A12}$$

$$(J(J+1)-\ell(\ell+1)+2m_J)f^{\ell}_{22}(p)=\sqrt{(\ell+m_J+1)(\ell-m_J)}f^{\ell}_{12}(p)+\sqrt{(\ell+m_J+1)(\ell-m_J)}f^{\ell}_{21}(p).$$

The singlet states correspond to the solution $f^{\ell}_{11}(p)=f^{\ell}_{22}(p)=0$, $f^{\ell}_{12}(p)=-f^{\ell}_{21}(p)$ of this system with $\ell=J$ $(J\geqslant 0)$.

For the triplet states the solutions are $f^{\ell}_{12}(p)=f^{\ell}_{21}(p)\equiv f^{\ell}(p)$, and, for $\ell=J-1$ $(J\geqslant 1)$:

$$(J-m_J)f^{J-1}_{11}(p)=\sqrt{(J-m_J)(J+m_J-1)}f^{J-1}(p), \tag{A13}$$

$$(J+m_J)f^{J-1}_{22}(p)=\sqrt{(J+m_J)(J-m_J-1)}f^{J-1}(p), \tag{A14}$$

for $\ell=J$ $(J\geqslant 1)$:

$$m_J f^{J}_{11}(p)=-\sqrt{(J+m_J)(J-m_J+1)}f^{J}(p), \tag{A15}$$

$$m_J f^{J}_{22}(p)=\sqrt{(J-m_J)(J+m_J+1)}f^{J}(p), \tag{A16}$$

for $\ell=J+1$ $(J\geqslant 0)$:

$$(J+1+m_J)f^{J+1}_{11}(p)=-\sqrt{(J-m_J+2)(J+m_J+1)}f^{J+1}(p), \tag{A17}$$

$$(J+1-m_J)f^{J+1}_{22}(p)=-\sqrt{(J-m_J+1)(J+m_J+2)}f^{J+1}(p). \tag{A18}$$

It is convenient to introduce the table of coefficients $C^{(\mathrm{tr})\ell m_s}_{Jm_J}$:

	$m_s=+1$	$m_s=0$	$m_s=-1$
$\ell=J-1$	$\sqrt{\frac{(J+m_J-1)(J+m_J)}{J(2J-1)}}$	$\sqrt{\frac{(J-m_J)(J+m_J)}{J(2J-1)}}$	$\sqrt{\frac{(J-m_J-1)(J-m_J)}{J(2J-1)}}$
$\ell=J$	$-\sqrt{\frac{(J+m_J)(J-m_J+1)}{J(J+1)}}$	$\frac{m_J}{\sqrt{J(J+1)}}$	$\sqrt{\frac{(J-m_J)(J+m_J+1)}{J(J+1)}}$
$\ell=J+1$	$\sqrt{\frac{(J-m_J+1)(J-m_J+2)}{(J+1)(2J+3)}}$	$-\sqrt{\frac{(J-m_J+1)(J+m_J+1)}{(J+1)(2J+3)}}$	$\sqrt{\frac{(J+m_J+2)(J+m_J+1)}{(J+1)(2J+3)}}$

These coefficients coincide with the usual Clebsch–Gordan coefficients for $S=1$ except for a factor 2 in the denominator, which we absorb into the normalization constant.

APPENDIX B: PARITY AND CHARGE CONJUGATION

We consider the application of the parity operator to the trial state (20):

$$\hat{\mathcal{P}}|\psi_T\rangle=\sum_{s_1s_2}\int d^3\mathbf{p}F_{s_1s_2}(\mathbf{p})\hat{\mathcal{P}}b^\dagger_{ps_1}d^\dagger_{-ps_2}|0\rangle=\sum_{s_1s_2}\int d^3\mathbf{p}F_{s_1s_2}(\mathbf{p})\hat{\mathcal{P}}b^\dagger_{ps_1}\hat{\mathcal{P}}^{-1}\hat{\mathcal{P}}d^\dagger_{-ps_2}\hat{\mathcal{P}}^{-1}\hat{\mathcal{P}}|0\rangle. \tag{B1}$$

Making use of the properties

$$\hat{\mathcal{P}}b^\dagger_{ps_1}\hat{\mathcal{P}}^{-1}=\eta^P b^\dagger_{-ps_1},\qquad \hat{\mathcal{P}}d^\dagger_{-ps_2}\hat{\mathcal{P}}^{-1}=-\eta^P d^\dagger_{ps_2},\qquad \hat{\mathcal{P}}|0\rangle=|0\rangle, \tag{B2}$$

where η^P is the intrinsic parity ($(\eta^P)^2=1$), it follows that

$$\begin{aligned}\hat{\mathcal{P}}|\psi_T\rangle&=\sum_{s_1s_2}\int d^3\mathbf{p}F_{s_1s_2}(\mathbf{p})\hat{\mathcal{P}}b^\dagger_{ps_1}d^\dagger_{-ps_2}|0\rangle\\&=-\sum_{s_1s_2}\int d^3\mathbf{p}F_{s_1s_2}(-\mathbf{p})b^\dagger_{ps_1}d^\dagger_{-ps_2}|0\rangle\\&=P\sum_{s_1s_2}\int d^3\mathbf{p}F_{s_1s_2}(\mathbf{p})b^\dagger_{ps_1}d^\dagger_{-ps_2}|0\rangle,\end{aligned} \tag{B3}$$

where the parity eigenvalue P depends on the symmetry of $F_{s_1s_2}(p)$ in different states:

For the singlet states ($\ell=J$) we get from (36) $F_{s_1s_2}(-p)=(-1)^JF_{s_1s_2}(p)$, so that $P=(-1)^{J+1}$.

For the triplet states with $\ell=J$ we get from (38) $F_{s_1s_2}(-p)=(-1)^JF_{s_1s_2}(p)$, hence $P=(-1)^{J+1}$.

For the triplet states with $\ell=J\pm1$ we get from (39) $F_{s_1s_2}(-p)=(-1)^{J+1}F_{s_1s_2}(p)$, therefore $P=(-1)^J$.

Charge conjugation is associated with the interchange of the particle and antiparticle. Applying the charge conjugation operator to the trial state (20) we get

$$\hat{\mathcal{C}}|\psi_T\rangle=\sum_{s_1s_2}\int d^3\mathbf{p}F_{s_1s_2}(\mathbf{p})\hat{\mathcal{C}}b^\dagger_{ps_1}d^\dagger_{-ps_2}|0\rangle \tag{B4}$$

$$=\sum_{s_1s_2}\int d^3\mathbf{p}F_{s_1s_2}(\mathbf{p})\hat{\mathcal{C}}b^\dagger_{ps_1}\hat{\mathcal{C}}^{-1}\hat{\mathcal{C}}d^\dagger_{-ps_2}\hat{\mathcal{C}}^{-1}\hat{\mathcal{C}}|0\rangle. \tag{B5}$$

Using the relations

$$\hat{\mathcal{C}}b^\dagger_{ps_1}\hat{\mathcal{C}}^{-1}=\eta^C d^\dagger_{ps_1},\qquad \hat{\mathcal{C}}d^\dagger_{-ps_2}\hat{\mathcal{C}}^{-1}=\eta^C b^\dagger_{-ps_2},\qquad \hat{\mathcal{C}}|0\rangle=|0\rangle, \tag{B6}$$

where $(\eta^C)^2=1$, we obtain

$$\begin{aligned}\hat{\mathcal{C}}|\psi_T\rangle&=\sum_{s_1s_2}\int d^3\mathbf{p}F_{s_1s_2}(\mathbf{p})\hat{\mathcal{C}}b^\dagger_{ps_1}d^\dagger_{-ps_2}|0\rangle\\&=-\sum_{s_1s_2}\int d^3\mathbf{p}F_{s_2s_1}(\mathbf{p})b^\dagger_{ps_1}d^\dagger_{-ps_2}|0\rangle\\&=C\sum_{s_1s_2}\int d^3\mathbf{p}F_{s_1s_2}(\mathbf{p})b^\dagger_{ps_1}d^\dagger_{-ps_2}|0\rangle,\end{aligned} \tag{B7}$$

where the charge conjugation quantum number C depends on the symmetry of $F_{s_1s_2}(p)$ in different states:

For the singlet states ($\ell=J$) we get from (36) $F_{s_1s_2}(-p)=(-1)^{J+1}F_{s_1s_2}(p)$, hence $C=(-1)^J$.

For the triplet states with $\ell = J$ we get from (38) $F_{s_1 s_2}(-p) = (-1)^J F_{s_1 s_2}(p)$, therefore $C = (-1)^{J+1}$.

For the triplet states with $\ell = J \pm 1$ we get from (39) $F_{s_1 s_2}(-p) = (-1)^{J+1} F_{s_1 s_2}(p)$, so that $C = (-1)^J$.

APPENDIX C: EXPANSION OF THE SPINORS

We recall the form of the particle spinors:

$$u(\mathbf{p},i) = N_{\mathbf{p}} \begin{bmatrix} 1 \\ \dfrac{(\boldsymbol{\sigma}\cdot\mathbf{p})}{\omega_p + m} \end{bmatrix} \varphi_i , \tag{C1}$$

where

$$\varphi_1 = \begin{bmatrix} 1 \\ 0 \end{bmatrix}, \qquad \varphi_2 = \begin{bmatrix} 0 \\ 1 \end{bmatrix}, \qquad N_{\mathbf{p}} = \sqrt{\frac{\omega_p + m}{2m}}. \tag{C2}$$

The antiparticle or ''positron'' representation for the $v_i(p)$ spinors has the form

$$v(\mathbf{p},i) = N_{\mathbf{p}} \begin{bmatrix} \dfrac{(\boldsymbol{\sigma}\cdot\mathbf{p})}{\omega_p + m} \\ 1 \end{bmatrix} \chi_i , \tag{C3}$$

where

$$\chi_1 = \begin{bmatrix} 0 \\ 1 \end{bmatrix}, \qquad \chi_2 = -\begin{bmatrix} 1 \\ 0 \end{bmatrix}. \tag{C4}$$

The normalization is

$$\overline{u}(\mathbf{p},i) u(\mathbf{p},j) = \delta_{ij} , \qquad \overline{v}(\mathbf{p},i) v(\mathbf{p},j) = -\delta_{ij} . \tag{C5}$$

Expanding in powers of p/m and keeping the lowest non-trivial order terms,

$$\frac{(\boldsymbol{\sigma}\cdot\mathbf{p})}{\omega_p + m} \simeq \frac{(\boldsymbol{\sigma}\cdot\mathbf{p})}{2m}, \tag{C6}$$

$$N_{\mathbf{p}} = \sqrt{\frac{\omega_p + m}{2m}} \simeq 1 + \frac{\mathbf{p}^2}{8m^2}, \tag{C7}$$

we obtain the result

$$u(\mathbf{p},i) \simeq \left(1 + \frac{\mathbf{p}^2}{8m^2}\right) \begin{bmatrix} 1 \\ \dfrac{(\boldsymbol{\sigma}\cdot\mathbf{p})}{2m} \end{bmatrix} \varphi_i = \begin{bmatrix} \left(1 + \dfrac{\mathbf{p}^2}{8m^2}\right) \\ \dfrac{(\boldsymbol{\sigma}\cdot\mathbf{p})}{2m} \end{bmatrix} \varphi_i , \tag{C8}$$

$$v(\mathbf{p},i) \simeq \left(1 + \frac{\mathbf{p}^2}{8m^2}\right) \begin{bmatrix} \dfrac{(\boldsymbol{\sigma}\cdot\mathbf{p})}{2m} \\ 1 \end{bmatrix} \chi_i = \begin{bmatrix} \dfrac{(\boldsymbol{\sigma}\cdot\mathbf{p})}{2m} \\ \left(1 + \dfrac{\mathbf{p}^2}{8m^2}\right) \end{bmatrix} \chi_i . \tag{C9}$$

APPENDIX D: SOME USEFUL IDENTITIES AND INTEGRALS

The following identity is useful for evaluating the $\mathcal{M}$ matrices:

$$\frac{((\mathbf{p}-\mathbf{q})\cdot\mathbf{p})^2}{(\mathbf{p}-\mathbf{q})^4}=\frac{\mathbf{p}^2}{(\mathbf{p}-\mathbf{q})^2}-\frac{(\mathbf{p}\times\mathbf{q})^2}{(\mathbf{p}-\mathbf{q})^4}. \tag{D1}$$

The angular integration in (47), (50), (55) involves the following integrals:

$$\int d\hat{\mathbf{p}}\,d\hat{\mathbf{q}}\,\mathsf{F}(\hat{\mathbf{p}}\cdot\hat{\mathbf{q}})Y_{J'}^{m_J'}(\hat{\mathbf{q}})Y_J^{m_J*}(\hat{\mathbf{p}})=2\pi\delta_{J'J}\delta_{m_J'm_J}\int d(\hat{\mathbf{p}}\cdot\hat{\mathbf{q}})\mathsf{F}(\hat{\mathbf{p}}\cdot\hat{\mathbf{q}})P_J(\hat{\mathbf{p}}\cdot\hat{\mathbf{q}}), \tag{D2}$$

$$\int d(\hat{\mathbf{p}}\cdot\hat{\mathbf{q}})\frac{\hat{\mathbf{p}}\cdot\hat{\mathbf{q}}}{(\mathbf{p}-\mathbf{q})^2}P_J(\hat{\mathbf{p}}\cdot\hat{\mathbf{q}})=\frac{1}{|\mathbf{p}||\mathbf{q}|}\left(\frac{J+1}{2J+1}Q_{J+1}(z)+\frac{J}{2J+1}Q_{J-1}(z)\right), \tag{D3}$$

$$\int d(\hat{\mathbf{p}}\cdot\hat{\mathbf{q}})\frac{(\mathbf{p}\times\mathbf{q})^2}{(\mathbf{p}-\mathbf{q})^4}P_J(\hat{\mathbf{p}}\cdot\hat{\mathbf{q}})=\frac{(J+1)(J+2)}{2(2J+1)}Q_{J+1}(z)-\frac{J(J-1)}{2(2J+1)}Q_{J-1}(z), \tag{D4}$$

where $\mathsf{F}(\hat{\mathbf{p}}\cdot\hat{\mathbf{q}})$ is an arbitrary function of $\hat{\mathbf{p}}\cdot\hat{\mathbf{q}}$, $P_J(x)$ is the Legendre polynomial, and $Q_J(z)$ is the Legendre function of the second kind of order J.

The following integrals are needed for the calculation of the relativistic energy corrections:

$$\int_0^\infty\int_0^\infty dp\,dq\,p^2q^2f^J(p)f^J(q)=2\pi\left(\frac{\alpha\mu}{n}\right)^3\delta_{J,0}, \tag{D5}$$

$$\int_0^\infty\int_0^\infty dp\,dq\,pqf^J(p)f^J(q)Q_J(z_1)=\frac{\pi\alpha\mu}{n^2}, \tag{D6}$$

$$\int_0^\infty\int_0^\infty dp\,dq\,p^2q^2f^J(p)f^J(q)Q_J(z_1)=\int_0^\infty\int_0^\infty dp\,dq\,p^3qf^J(p)f^J(q)Q_J(z_1)$$
$$=\pi\left(\frac{\alpha\mu}{n}\right)^3\left(\frac{4}{2J+1}-\frac{1}{n}\right), \tag{D7}$$

$$\int_0^\infty\int_0^\infty dp\,dq\,p^2q^2f^J(p)f^J(q)Q_{J-1}(z_1)=\pi\left(\frac{\alpha\mu}{n}\right)^3\left(\frac{2}{J}-\frac{1}{n}\right), \tag{D8}$$

$$\int_0^\infty\int_0^\infty dp\,dq\,p^2q^2f^J(p)f^J(q)Q_{J+1}(z_1)=\pi\left(\frac{\alpha\mu}{n}\right)^3\left(\frac{2}{J+1}-\frac{1}{n}\right). \tag{D9}$$

Here f^J is the nonrelativistic hydrogenlike radial wave function in momentum space[19]

$$f^J(p)\equiv f_n^J(p)=\left(\frac{2}{\pi}\frac{(n-J-1)!}{(n+J)!}\right)^{1/2}\frac{n^{J+2}p^J2^{2(J+1)}J!}{(n^2p^2+1)^{J+2}}\mathcal{G}_{n-J-1}^{J+1}\left(\frac{n^2p^2-1}{n^2p^2+1}\right), \tag{D10}$$

where $G_{n-J-1}^{J+1}(x)$ are Gegenbauer functions.

APPENDIX E: $\mathcal{K}_{12}$, $\mathcal{K}_{21}$ KERNELS FOR $\ell=J\mp1$ STATES

The contribution of the kernel $\mathcal{K}_{12}$ to the energy correction is

$$\int dp\,dq\,p^2q^2\mathcal{K}_{12}(p,q)f^{J-1}(p)f^{J+1}(q), \tag{E1}$$

where

$$\mathcal{K}_{12}(p,q)=\sum_{\sigma_1\sigma_2 s_1 s_2} C^{s_1 s_2 \sigma_1 \sigma_2}_{J m_J 12}\int d\hat{\mathbf{p}}\, d\hat{\mathbf{q}}\, \mathcal{M}^{\text{ope(s-s)}}_{s_1 s_2 \sigma_1 \sigma_2}(\mathbf{p},\mathbf{q}) Y^{m_{\sigma_1\sigma_2}}_{J+1}(\hat{\mathbf{q}}) Y^{m_{s_1 s_2}*}_{J-1}(\hat{\mathbf{p}}). \tag{E2}$$

This requires the following integral:

$$\sum_{\sigma_1\sigma_2 s_1 s_2} C^{s_1 s_2 \sigma_1 \sigma_2}_{J m_J 12}\int d^3\mathbf{p}\, d^3\mathbf{q}\, f^{J-1}(p) Y^{m_{s_1 s_2}*}_{J-1}(\hat{\mathbf{p}}) \mathcal{M}^{\text{ope(s-s)}}_{s_1 s_2 \sigma_1 \sigma_2}(\mathbf{p},\mathbf{q}) f^{J+1}(q) Y^{m_{\sigma_1\sigma_2}}_{J+1}(\hat{\mathbf{q}}). \tag{E3}$$

We calculate this form in coordinate space. The Fourier transform of $\mathcal{M}_{s_1 s_2 \sigma_1 \sigma_2}(\mathbf{p},\mathbf{q})$ is

$$\mathcal{M}_{s_1 s_2 \sigma_1 \sigma_2}(\mathbf{p},\mathbf{q})=\int d^3\mathbf{r}\, d^3\mathbf{r}'\, \mathcal{M}_{s_1 s_2 \sigma_1 \sigma_2}(\mathbf{r},\mathbf{r}') e^{-i(\mathbf{p}-\mathbf{q})\cdot(\mathbf{r}-\mathbf{r}')}, \tag{E4}$$

where the $M_{s_1 s_2 \sigma_1 \sigma_2}(\mathbf{r},\mathbf{r}')$ matrix is a local operator in general,[16] that is

$$\mathcal{M}_{s_1 s_2 \sigma_1 \sigma_2}(\mathbf{r},\mathbf{r}')=\mathcal{M}_{s_1 s_2 \sigma_1 \sigma_2}(\mathbf{r})\,\delta(\mathbf{r}-\mathbf{r}'). \tag{E5}$$

We apply this transformation to the $\mathcal{M}^{\text{ope(s-s)}}_{s_1 s_2 \sigma_1 \sigma_2}(\mathbf{p},\mathbf{q})$ matrix [see Eq. (62)]. Because of the angular integration in (E2), only the first term in (62) survives. The Fourier transformation of that term is

$$\frac{(\boldsymbol{\sigma}^{(+)}\cdot(\mathbf{p}-\mathbf{q}))(\boldsymbol{\sigma}^{(-)}\cdot(\mathbf{p}-\mathbf{q}))}{4m^2(\mathbf{p}-\mathbf{q})^2} \quad \rightarrow \quad 3\frac{(\boldsymbol{\sigma}^{(+)}\cdot\mathbf{r})(\boldsymbol{\sigma}^{(-)}\cdot\mathbf{r})}{16\pi m^2 r^5}. \tag{E6}$$

Furthermore,

$$\int d^3\mathbf{p} f^{J-1}(p) Y^{m_{s_1 s_2}*}_{J-1}(\hat{\mathbf{p}}) e^{-i\mathbf{p}\cdot\mathbf{r}}=R^{J-1}_n(r) Y^{m_{s_1 s_2}*}_{J-1}(\hat{\mathbf{r}}), \tag{E7}$$

$$\int d^3\mathbf{q} f^{J+1}(q) Y^{m_{s_1 s_2}*}_{J+1}(\hat{\mathbf{q}}) e^{-i\mathbf{q}\cdot\mathbf{r}}=R^{J+1}_n(r) Y^{m_{s_1 s_2}}_{J+1}(\hat{\mathbf{r}}), \tag{E8}$$

where

$$R^{\ell}_n(r)=-\frac{2}{n^2}\sqrt{\frac{(n-\ell-1)!}{((n+\ell)!)^3}} e^{-r/n}\left(\frac{2r}{n}\right)^{\ell} L^{2\ell+1}_{n+\ell}\left(\frac{2r}{n}\right). \tag{E9}$$

The associated Laguerre function $L^{\mu}_{\lambda}(\rho)$ is related to the confluent hypergeometric function by

$$L^{\mu}_{\lambda}(\rho)=(-1)^{\mu}\frac{(\lambda!)^2}{\mu!(\lambda-\mu)!}F(-\lambda+\mu,\mu+1;\rho). \tag{E10}$$

The generating function for the Laguerre function is

$$U_{\mu}(\rho,u)\equiv(-1)^{\mu}\frac{u^{\mu}}{(1-u)^{\mu+1}}\exp\left(-\frac{u\rho}{1-u}\right)=\sum_{\lambda=\mu}^{\infty}\frac{L^{\mu}_{\lambda}(\rho)}{\lambda!}u^{\lambda}, \tag{E11}$$

hence

$$\sum_{\sigma_1\sigma_2 s_1 s_2} C^{s_1 s_2 \sigma_1 \sigma_2}_{J m_J 12} \int d^3\mathbf{p}\, d^3\mathbf{q}\, f^{J-1}(p) Y^{m_{s_1 s_2}}_{J-1}{}^{*}(\hat{\mathbf{p}}) \mathcal{M}^{\mathrm{ope(s-s)}}_{s_1 s_2 \sigma_1 \sigma_2}(\mathbf{p},\mathbf{q}) f^{J+1}(q) Y^{m_{\sigma_1\sigma_2}}_{J+1}(\hat{\mathbf{q}})$$

$$= \sum_{\sigma_1\sigma_2 s_1 s_2} C^{s_1 s_2 \sigma_1 \sigma_2}_{J m_J 12} \int d^3\mathbf{r}\, R_n^{J-1}(r) Y^{m_{s_1 s_2}}_{J-1}{}^{*}(\hat{\mathbf{r}}) \times \left(3\alpha \frac{(\boldsymbol{\sigma}^{(+)}\cdot\mathbf{r})(\boldsymbol{\sigma}^{(-)}\cdot\mathbf{r})}{16\pi m^2 r^5} \right) R_n^{J+1}(r) Y^{m_{s_1 s_2}}_{J+1}(\hat{\mathbf{r}})$$

$$= \frac{3\alpha}{16\pi m^2} \int dr\, r^2 \frac{1}{r^3} R_n^{J-1}(r) R_n^{J+1}(r)$$

$$\times \sum_{\sigma_1\sigma_2 s_1 s_2} C^{s_1 s_2 \sigma_1 \sigma_2}_{J m_J 12} \int d\hat{\mathbf{r}}\, Y^{m_{s_1 s_2}}_{J-1}{}^{*}(\hat{\mathbf{r}}) (\boldsymbol{\sigma}^{(+)}\cdot\hat{\mathbf{r}}) (\boldsymbol{\sigma}^{(-)}\cdot\hat{\mathbf{r}}) Y^{m_{s_1 s_2}}_{J+1}(\hat{\mathbf{r}}). \tag{E12}$$

It follows that

$$\sum_{\sigma_1\sigma_2 s_1 s_2} C^{s_1 s_2 \sigma_1 \sigma_2}_{J m_J 12} \int d\hat{\mathbf{r}} Y^{m_{s_1 s_2}}_{J-1}{}^{*}(\hat{\mathbf{r}}) (\boldsymbol{\sigma}^{(+)}\cdot\hat{\mathbf{r}}) (\boldsymbol{\sigma}^{(-)}\cdot\hat{\mathbf{r}}) Y^{m_{s_1 s_2}}_{J+1}(\hat{\mathbf{r}}) = \frac{1}{15} \frac{\sqrt{J(J+1)}}{2J+1}, \tag{E13}$$

but

$$\int_0^\infty dr\, r^2 \frac{1}{r^3} R_n^{J-1}(r) R_n^{J+1}(r) = 0. \tag{E14}$$

The last expression can be proved in the following way. Let us consider the more general case

$$\int_0^\infty dr\, r^{\beta+2} R_n^{\ell}(r) R_n^{\ell'}(r). \tag{E15}$$

The generating function for $R_n^{\ell}(r)$ is

$$G_{n\ell}(r,u) = -\frac{2}{n^2} \sqrt{\frac{(n-\ell-1)!}{((n+\ell)!)^3}} e^{-r/n} \left(\frac{2r}{n}\right)^{\ell} (-1)^{2\ell+1} \frac{u^{2\ell+1}}{(1-u)^{2\ell+2}} \exp\left\{ -\frac{u}{1-u} \frac{2r}{n} \right\}. \tag{E16}$$

Then we consider the expression

$$\int_0^\infty dr r^{\beta+2} G_{n\ell}(r,u) G_{n\ell'}(r,v) = \int_0^\infty dr r^{\beta+2} \frac{4}{n^4} \sqrt{\frac{(n-\ell-1)!(n-\ell'-1)!}{((n+\ell)!)^3((n+\ell')!)^3}} e^{-2r/n} \left(\frac{2r}{n}\right)^{\ell+\ell'}$$

$$\times \frac{u^{2\ell+1} v^{2\ell'+1}}{(1-u)^{2\ell+2}(1-v)^{2\ell'+2}} \exp\left\{ -\left(\frac{u}{1-u} + \frac{v}{1-v} \right) \frac{2r}{n} \right\}$$

$$= \frac{4}{n^4} \sqrt{\frac{(n-\ell-1)!(n-\ell'-1)!}{((n+\ell)!)^3((n+\ell')!)^3}} \frac{u^{2\ell+1} v^{2\ell'+1}}{(1-u)^{2\ell+2}(1-v)^{2\ell'+2}}$$

$$\times \int_0^\infty dr \left(\frac{2r}{n}\right)^{\beta+2+\ell+\ell'} \exp\left\{ -\left(1 + \frac{u}{1-u} + \frac{v}{1-v} \right) \frac{2r}{n} \right\}. \tag{E17}$$

It is well known that

$$\int_0^\infty d\rho \rho^\beta e^{-\rho} = \Gamma(\beta+1), \tag{E18}$$

therefore

$$\int_0^\infty dr \left(\frac{2r}{n}\right)^{\beta+2+\ell+\ell'} \exp\left\{-\left(1+\frac{u}{1-u}+\frac{v}{1-v}\right)\frac{2r}{n}\right\}$$
$$= \left(\frac{n}{2}\right)^{\beta+3} \left(\frac{(1-u)(1-v)}{1-uv}\right)^{\beta+3+\ell+\ell'} \Gamma(\beta+3+\ell+\ell') \tag{E19}$$

and

$$\int_0^\infty dr r^{\beta+2} G_{n\ell}(r,u) G_{n\ell'}(r,v) = \frac{2^{-\beta-1}}{n^{-\beta+1}} \sqrt{\frac{(n-\ell-1)!(n-\ell'-1)!}{((n+\ell)!)^3((n+\ell')!)^3}}$$
$$\times \frac{u^{2\ell+1} v^{2\ell'+1} (1-u)^{\beta+1-\ell+\ell'} (1-v)^{\beta+1+\ell-\ell'}}{(1-uv)^{\beta+3+\ell+\ell'}}$$
$$\times \Gamma(\beta+3+\ell+\ell'). \tag{E20}$$

We expand this expression in a series,

$$\int_0^\infty dr r^{\beta+2} G_{n\ell}(r,u) G_{n\ell'}(r,v) = \sum_{\eta\eta'} C_{\eta\eta'}(n,\beta,\ell,\ell') u^\eta u^{\eta'}. \tag{E21}$$

It is not difficult to show[20] that the coefficient $C_{n+\ell,n+\ell'}$ represents the integral

$$C_{n+\ell,n+\ell'}(n,\beta,\ell,\ell') = \int_0^\infty dr r^{\beta+2} R_n^\ell(r) R_n^{\ell'}(r). \tag{E22}$$

Simple but tedious calculations show that this coefficient is zero for $\beta=-3$, $\ell=J-1$, $\ell'=J+1$. Thus the kernel $\mathcal{K}_{12}$ does not contribute to the energy corrections to $O(\alpha^4)$. The same result is obtained for the kernel $\mathcal{K}_{21}$.

(Received 17 November 2003; accepted 12 January 2004)

Due to the growing interest in embeddings of space–time in higher-dimensional spaces we consider a specific type of embedding. After proving an inequality between intrinsically defined curvature invariants and the squared mean curvature, we extend the notion of ideal embeddings from Riemannian geometry to the indefinite case. Ideal embeddings are such that the embedded manifold receives the least amount of tension from the surrounding space. Then it is shown that the de Sitter spaces, a Robertson–Walker space–time and some anisotropic perfect fluid metrics can be ideally embedded in a five-dimensional pseudo-Euclidean space. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1668333]

I. INTRODUCTION

In recent years the ideas of Kaluza and Klein have received new attention. Shortly after the publication of the general theory of relativity Kaluza proposed to unify gravity and electromagnetism by adding an extra dimension. Klein suggested that this fifth dimension would be compactified and unobservable on experimentally accessible energy scales. This idea of compactifying the extra dimension has dominated the search for a unified theory and lead to the 11-dimensional supergravity theory and more recent ten-dimensional superstring theory (see Ref. 1 for an overview).

Instead of compactifying the extra dimensions other approaches have been developed. In the space-time-matter (STM) theory[2] the $(3+1)$-dimensional cosmologies may be recovered from the geometry of $(4+1)$-dimensional, vacuum general relativity. Matter in four dimensions is induced by the shape of the embedded hypersurface and the five-dimensional Ricci flat geometry. More recently the Randall–Sundrum scenario has gained a lot of support. In Refs. 3 and 4 they try to solve the hierarchy problem between the observed Planck and weak scales by embedding the three-brane in a nonfactorizable five-dimensional metric.

From a mathematical point of view the theory of embeddings starts with the definition of a manifold by Riemann. Shortly after the publication of his famous Habilitationsschrift (see, e.g., Ref. 5 for a translation) Schläfli[6] conjectured that any n-dimensional Riemannian manifold could be locally and isometrically embedded in a d-dimensional Euclidean space with $d=n(n+1)/2$. This was proven by Janet and Cartan and extended to manifolds with indefinite metric by Friedman.[7] The Janet–Cartan theorem as it became known implies that we at maximum need ten dimensions to locally and isometrically embed any four-dimensional space–time.

A lesser known theorem by Campbell and Magaard[8] states that any analytical Riemannian space $V_n(s,t)$ can be locally and isometrically embedded in a Ricci flat Riemannian space $V_{n+1}(\tilde{s},\tilde{t})$, with $\tilde{s}=s+1,\tilde{t}=t$ or $\tilde{s}=s,\tilde{t}=t+1$. This theorem has obvious applications in STM theory.[9] For further generalizations of the Campbell–Magaard theorem to embedding spaces

which are Einstein, scalar field sourced or have nondegenerate Ricci tensor see Refs. 10–12.

In applications of the embedding theorems one often starts from a given metric and looks for the embedding space with the minimal dimension or one puts restrictions on the source type.[13–15] In the following we will take a different approach by putting a restriction on the type of embedding. Using some recently defined intrinsic curvature invariants on a manifold we prove an inequality between intrinsic and extrinsic curvatures of an embedded Lorentzian manifold in a pseudo-Euclidean space. For a proof in the Riemannian case see Ref. 16. An embedding for which the equality holds is called ideal and in this case the shape operators take on specified forms. The space–times which satisfy such an ideal embedding in a five-dimensional space are determined. In the remainder all embeddings are local and isometric.

II. Λ-CURVATURES OF CHEN

Starting from a Lorentzian manifold (M,g) with signature $(m-1(+),1(-))$ isometrically embedded in a pseudo-Euclidean space (E_n,η) of signature $(n-1,1)$ or $(m-1,n-m+1)$ we will introduce the intrinsically defined Λ-curvature invariants of Chen.[17]

We denote the Levi-Civita connection on M with ∇ and on E_n with $\tilde{\nabla}$. The covariant derivative in E_n between two tangent vectors X and Y on M can be decomposed in a tangential and normal part,

$$\tilde{\nabla}_X Y = \nabla_X Y + \Omega(X,Y),$$

with $\Omega: TM \times TM \to N(M)$ the second fundamental form. If we choose an orthonormal basis $\{\xi_A\}$ in the normal space $N(M)$ of M and denote the signature of the basis vectors with $\varepsilon_A = \eta(\xi_A,\xi_A) = \pm 1$, we can define Ω as

$$\Omega(X,Y) = \sum_{A=m+1}^{n} \varepsilon_A \eta(\tilde{\nabla}_X Y, \xi_A)\xi_A. \tag{1}$$

In the following greek indices run from 1 to m, latin indices from 1 to n and capital indices from $m+1$ to n, unless otherwise stated.

The integrability conditions for the existence of an embedding are given by the Gauss–Codazzi–Ricci equations,[18,19]

$$R_{\alpha\beta\gamma\mu} = \sum_A \varepsilon_A \{\Omega^A_{\alpha\gamma}\Omega^A_{\beta\mu} - \Omega^A_{\alpha\mu}\Omega^A_{\beta\gamma}\}, \tag{2}$$

$$\nabla_\gamma \Omega^A_{\alpha\beta} - \nabla_\beta \Omega^A_{\alpha\gamma} = \sum_B \varepsilon_B \{S^{BA}{}_\gamma \Omega^B_{\alpha\beta} - S^{BA}{}_\beta \Omega^B_{\alpha\gamma}\}, \tag{3}$$

$$\nabla_\beta S^{BA}{}_\alpha - \nabla_\alpha S^{BA}{}_\beta = \sum_C \varepsilon_C \{S^{CB}{}_\beta S^{CA}{}_\alpha - S^{CB}{}_\alpha S^{CA}{}_\beta\} + g^{\gamma\mu}\{\Omega^B_{\gamma\beta}\Omega^A_{\mu\alpha} - \Omega^B_{\gamma\alpha}\Omega^A_{\mu\beta}\}, \tag{4}$$

with S^{AB}_{α} the torsion vector. For an interpretation of this vector as a gauge field in a Kaluza–Klein view of embeddings see Ref. 20 and as a real connection on space–time see Ref. 21.

The mean curvature vector is defined as

$$\vec{H} = \sum_A \varepsilon_A g^{\alpha\beta}\Omega^A_{\alpha\beta}\,\xi_A.$$

Let $\{e_\alpha\}$ be an orthonormal basis of M. The sectional curvature of a two-plane spanned by the orthonormal vectors $\{e_\alpha, e_\beta\}$ is defined by

$$K(e_\alpha \wedge e_\beta) = \varepsilon_{\alpha\beta} g(R(e_\alpha, e_\beta)e_\beta, e_\alpha),$$

with $\varepsilon_{\alpha\beta} = \varepsilon_\alpha \varepsilon_\beta$. The scalar curvature of an r-plane section L spanned by the orthonormal vectors $\{e_1, \ldots, e_r\}$ is defined as

$$\tau(L) = \sum_{\alpha<\beta} K(e_\alpha \wedge e_\beta), \quad 1 \leqslant \alpha < \beta \leqslant r.$$

The scalar curvature of the whole Lorentzian manifold is denoted by R. Denote the constant $c(n_1, \ldots, n_k)$ by

$$c(n_1, \ldots, n_k) = \frac{2\left(m + k - \sum_{j=1}^{k} n_j\right)}{m + k - 1 - \sum_{j=1}^{k} n_j}.$$

We are now in a situation to define the Λ-curvature invariants of Chen in the pseudo-Riemannian case as

$$\Lambda(n_1, \ldots, n_k) = c(n_1, \ldots, n_k)[R - \inf\{\tau(L_1) + \cdots + \tau(L_k) | L_j \text{ a non-null } n_j\text{-plane section, } L_i \perp L_j\}],$$

and

$$\hat{\Lambda}(n_1, \ldots, n_k) = c(n_1, \ldots, n_k)[R - \sup\{\tau(L_1) + \cdots + \tau(L_k) | L_j \text{ a non-null } n_j\text{-plane section, } L_i \perp L_j\}].$$

Note that in our definition the plane sections can be timelike or spacelike. Let $\{e_1, \ldots, e_m, \xi_{m+1}, \ldots, \xi_n\}$ be an orthonormal basis of E_n. Because we have space–time applications in mind we take M to be time-orientable, i.e., there exists a global nowhere-zero timelike vector field which we denote with e_m. From (1) we have

$$\Omega^A_{m\alpha} = -\eta(e_m, \tilde{\nabla}_{e_\alpha} \xi_A) = -\eta(e_\alpha, \tilde{\nabla}_{e_m} \xi_A),$$

with $A = m+1, \ldots, n$ and $\alpha = 1, \ldots, m-1$.

Definition II.1: An embedding $x: (M, g) \to (E_{n-1,1}, \eta)$ is called causal-type preserving if $\tilde{\nabla}_{e_\alpha} \xi_A$ is spacelike, $\forall\, A = m+1, \ldots, n$ and $\forall\, \alpha = 1, \ldots, m-1$.

Definition II.2: An embedding $x: (M, g) \to (E_{m-1,n-m+1}, \eta)$ is called causal-type preserving if $\tilde{\nabla}_{e_m} \xi_A$ is timelike, $\forall\, A = m+1, \ldots, n$.

From the above we see that causal-type preserving embeddings have $\Omega^A_{m\alpha} = 0$, $\forall\, \alpha = 1, \ldots, m-1$.

III. IDEAL EMBEDDINGS

We can now formulate and prove an inequality relating the above intrinsically defined curvature invariants and the square of the extrinsic mean curvature of the embedded manifold.

Theorem III.1: *Let $x: (M, g) \to (E_n, \eta)$ be a causal-type preserving embedding of a Lorentzian m-dimensional manifold in a n-dimensional pseudo-Euclidean manifold. For any k-tuple $(n_1, \ldots, n_k)$ we have that*

$$\|H\|^2 \geqslant \Lambda(n_1, \ldots, n_k), \tag{5}$$

if (E_n, η) has signature $(n-1, 1)$ and

$$\|H\|^2 \leqslant \hat{\Lambda}(n_1, \ldots, n_k), \tag{6}$$

if (E_n, η) has signature $(m-1, n-m+1)$.

Proof: Starting from the Gauss equation (2) w.r.t. an orthonormal basis $\{e_1,\ldots,e_m,\xi_{m+1},\ldots,\xi_n\}$ we can express the scalar curvature of M as

$$\begin{aligned}2R&=\sum_{\alpha,\beta=1}^{m}\varepsilon_{\alpha\beta}R_{\alpha\beta\alpha\beta}\\&=\sum_{A=m+1}^{n}\varepsilon_A\left(\sum_{\alpha=1}^{m}\varepsilon_\alpha\Omega^A_{\alpha\alpha}\right)^2-\sum_{A=m+1}^{n}\varepsilon_A\sum_{\alpha,\beta=1}^{m}\varepsilon_{\alpha\beta}(\Omega^A_{\alpha\beta})^2\\&=\|H\|^2-\Omega^2.\end{aligned}\tag{7}$$

If we put, with $k\geqslant 1$,

$$\phi=2R-\frac{m+k-1-\sum_{j=1}^{k}n_j}{m+k-\sum_{j=1}^{k}n_j}\|H\|^2,$$

$$\gamma=m+k-\sum_{j=1}^{k}n_j,$$

it is a small calculation to show that

$$\|H\|^2=\gamma(\phi+\Omega^2).\tag{8}$$

We choose ξ_{m+1} along $\vec{H}$ and put $a_\alpha=\varepsilon_\alpha\Omega^{m+1}_{\alpha\alpha}$. Equation (8) becomes

$$\begin{aligned}\varepsilon_{m+1}\left(\sum_{\alpha=1}^{m}a_\alpha\right)^2=\gamma\Bigg\{&\phi+\varepsilon_{m+1}\sum_{\alpha=1}^{m}(a_\alpha)^2+\varepsilon_{m+1}\sum_{\alpha\neq\beta=1}^{m}\varepsilon_{\alpha\beta}(\Omega^{m+1}_{\alpha\beta})^2\\&+\sum_{A=m+2}^{n}\varepsilon_A\sum_{\alpha,\beta=1}^{m}\varepsilon_{\alpha\beta}(\Omega^A_{\alpha\beta})^2\Bigg\}.\end{aligned}\tag{9}$$

If we use the notation

$$\overline{a}_1=a_1,$$

$$\overline{a}_2=a_2+\cdots+a_{n_1},$$

$$\overline{a}_3=a_{n_1+1}+\cdots+a_{n_1+n_2},$$

$$\vdots$$

$$\overline{a}_{k+1}=a_{n_1+\cdots+n_{k-1}+1}+\cdots+a_{n_1+\cdots+n_k},$$

$$\overline{a}_{k+2}=a_{n_1+\cdots+n_k+1},$$

$$\vdots$$

$$\overline{a}_\gamma=a_{m-1},$$

$$\overline{a}_{\gamma+1}=a_m,$$

we have

$$\left(\sum_{\alpha=1}^{\gamma+1}\overline{a}_\alpha\right)^2=\left(\sum_{\alpha=1}^{m}a_\alpha\right)^2,$$

and

$$\sum_{\alpha=1}^{\gamma+1}(\overline{a}_\alpha)^2=\sum_{\alpha=1}^{m}(a_\alpha)^2+\sum_{2\leqslant\alpha_1\neq\beta_1\leqslant n_1}a_{\alpha_1}a_{\beta_1}+\sum_{\alpha_2\neq\beta_2\in Q_2}a_{\alpha_2}a_{\beta_2}+\cdots+\sum_{\alpha_k\neq\beta_k\in Q_k}a_{\alpha_k}a_{\beta_k},$$

with $Q_1=\{1,\ldots,n_1\}$, $Q_2=\{n_1+1,\ldots,n_1+n_2\}$, $\ldots$, $Q_k=\{n_1+\cdots+n_{k-1}+1,\ldots,n_1+\cdots+n_k\}$. Equation (9) becomes

$$\begin{aligned}\varepsilon_{m+1}\left(\sum_{\alpha=1}^{\gamma+1}\overline{a}_\alpha\right)^2=\gamma\Bigg\{&\phi+\varepsilon_{m+1}\sum_{\alpha=1}^{\gamma+1}(\overline{a}_\alpha)^2+\varepsilon_{m+1}\sum_{\alpha\neq\beta=1}^{m}\varepsilon_{\alpha\beta}(\Omega^{m+1}_{\alpha\beta})^2\\&+\sum_{A=m+2}^{n}\varepsilon_A\sum_{\alpha,\beta=1}^{m}\varepsilon_{\alpha\beta}(\Omega^{A}_{\alpha\beta})^2-\varepsilon_{m+1}\sum_{2\leqslant\alpha_1\neq\beta_1\leqslant n_1}a_{\alpha_1}a_{\beta_1}-\cdots\\&-\varepsilon_{m+1}\sum_{\alpha_k\neq\beta_k\in Q_k}a_{\alpha_k}a_{\beta_k}\Bigg\}.\end{aligned}\tag{10}$$

We need the following algebraic lemma:

Lemma III.1:[16] *If* $\overline{a}_1,\ldots,\overline{a}_n,c$ *are* $n+1$ $(n\geqslant 2)$ *real numbers such that*

$$\left(\sum_{i=1}^{n}\overline{a}_i\right)^2=(n-1)\left(\sum_{i=1}^{n}(\overline{a}_i)^2+c\right),$$

we have that $2\overline{a}_1\overline{a}_2\geqslant c$ *and equality holds iff* $\overline{a}_1+\overline{a}_2=\overline{a}_3=\cdots=\overline{a}_n$.

Two separate cases appear. We first look at the case when $\vec{H}$ is spacelike, i.e., $\varepsilon_{m+1}=1$. Using the above lemma Eq. (10) becomes

$$\begin{aligned}\overline{a}_1\overline{a}_2\geqslant\frac{1}{2}\phi+\frac{1}{2}\sum_{\alpha\neq\beta=1}^{m}\varepsilon_{\alpha\beta}(\Omega^{m+1}_{\alpha\beta})^2+\frac{1}{2}\sum_{A=m+2}^{n}\varepsilon_A\sum_{\alpha,\beta=1}^{m}\varepsilon_{\alpha\beta}(\Omega^{A}_{\alpha\beta})^2\\-\frac{1}{2}\sum_{2\leqslant\alpha_1\neq\beta_1\leqslant n_1}a_{\alpha_1}a_{\beta_1}-\cdots-\frac{1}{2}\sum_{\alpha_k\neq\beta_k\in Q_k}a_{\alpha_k}a_{\beta_k}.\end{aligned}$$

Because

$$\sum_{\alpha_j\neq\beta_j}a_{\alpha_j}a_{\beta_j}=2\sum_{\alpha_j<\beta_j}a_{\alpha_j}a_{\beta_j},$$

we have

$$\sum_{j=1}^{k}\sum_{\alpha_j<\beta_j\in Q_j}a_{\alpha_j}a_{\beta_j}\geqslant\frac{1}{2}\phi+\sum_{\alpha<\beta=1}^{m}\varepsilon_{\alpha\beta}(\Omega^{m+1}_{\alpha\beta})^2+\frac{1}{2}\sum_{A=m+2}^{n}\varepsilon_A\sum_{\alpha,\beta=1}^{m}\varepsilon_{\alpha\beta}(\Omega^{A}_{\alpha\beta})^2.\tag{11}$$

Let L_j be an n_j-dimensional subspace of T_pM such that

$$L_j=\text{span}\{e_{n_1+\cdots+n_{j-1}+1},\ldots,e_{n_1+\cdots+n_j}\}.$$

The scalar curvature of the plane section is given by

$$\tau(L_j)=\sum_{\alpha_j<\beta_j\in Q_j}\varepsilon_{\alpha_j\beta_j}\sum_{A=m+1}^{n}\varepsilon_A[\Omega^A_{\alpha_j\alpha_j}\Omega^A_{\beta_j\beta_j}-(\Omega^A_{\alpha_j\beta_j})^2].$$

Then, using the above notation we find

$$\begin{aligned}\tau(L_1)+\cdots+\tau(L_k)=&\sum_{j=1}^{k}\sum_{\alpha_j<\beta_j\in Q_j}a_{\alpha_j}a_{\beta_j}-\sum_{j=1}^{k}\sum_{\alpha_j<\beta_j\in Q_j}\varepsilon_{\alpha_j\beta_j}(\Omega^{m+1}_{\alpha_j\beta_j})^2\\&+\sum_{j=1}^{k}\sum_{\alpha_j<\beta_j\in Q_j}\varepsilon_{\alpha_j\beta_j}\sum_{A=m+2}^{n}\varepsilon_A[\Omega^A_{\alpha_j\alpha_j}\Omega^A_{\beta_j\beta_j}-(\Omega^A_{\alpha_j\beta_j})^2].\end{aligned}$$

If we use the inequality (11) and the notation

$$Q_{k+1}=\{n_1+\cdots+n_k+1,\ldots,m\},$$

$$Q=Q_1\cup\cdots\cup Q_k\cup Q_{k+1},$$

$$Q^2=(Q_1\times Q_1)\cup\cdots\cup(Q_k\times Q_k)\cup(Q_{k+1}\times Q_{k+1}),$$

$$\nabla^2=(Q\times Q)/Q^2,$$

we have

$$\tau(L_1)+\cdots+\tau(L_k)\geqslant\frac{1}{2}\phi+\frac{1}{2}\sum_{A=m+1}^{n}\varepsilon_A\sum_{(\alpha,\beta)\in\nabla^2}\varepsilon_{\alpha\beta}(\Omega^A_{\alpha\beta})^2+\frac{1}{2}\sum_{A=m+2}^{n}\varepsilon_A\sum_{j=1}^{k}\left(\sum_{\alpha\in Q_j}\varepsilon_\alpha\Omega^A_{\alpha\alpha}\right)^2.\tag{12}$$

The signature of the embedding space E_n is chosen to be $(n-1,1)$ such that all $\varepsilon_A=1$ and the condition of causal-type preserving ensures that the terms with possible minus signs appearing on the right-hand side vanish. We have

$$\tau(L_1)+\cdots+\tau(L_k)\geqslant\tfrac{1}{2}\phi.$$

This holds for all mutually orthogonal subspaces L_j, in particular for the infimum,

$$\|H\|^2\geqslant\Lambda(n_1,\ldots,n_k).\tag{13}$$

The case when $\vec{H}$ is timelike is analogous and we find, instead of (12),

$$\begin{aligned}\tau(L_1)+\cdots+\tau(L_k)\leqslant&\frac{1}{2}\phi+\frac{1}{2}\sum_{A=m+1}^{n}\varepsilon_A\sum_{(\alpha,\beta)\in\nabla^2}\varepsilon_{\alpha\beta}(\Omega^A_{\alpha\beta})^2\\&+\frac{1}{2}\sum_{A=m+2}^{n}\varepsilon_A\sum_{j=1}^{k}\left(\sum_{\alpha_j\in Q_j}\varepsilon_{\alpha_j}\Omega^A_{\alpha_j\alpha_j}\right)^2.\end{aligned}$$

We choose the signature of the embedding space to be $(m-1,n-m+1)$, i.e., all normal directions are timelike. We find

$$\tau(L_1)+\cdots+\tau(L_k)\leqslant\tfrac{1}{2}\phi.$$

This holds again for all mutually orthogonal subspaces, in particular for the supremum,

$$\|H\|^2\leqslant\hat{\Lambda}(n_1,\ldots,n_k).\tag{14}$$

It remains to show the inequality when $k=0$. Starting from (7) and again choosing ξ_{m+1} along $\vec{H}$, we find

$$2R=\|H\|^2-\varepsilon_{m+1}\sum_{\alpha=1}^{m}(a_\alpha)^2-\varepsilon_{m+1}\sum_{\alpha\neq\beta=1}^{m}\varepsilon_{\alpha\beta}(\Omega_{\alpha\beta}^{m+1})^2-\sum_{A=m+2}^{n}\varepsilon_A\sum_{\alpha,\beta=1}^{m}\varepsilon_{\alpha\beta}(\Omega_{\alpha\beta}^{A})^2, \tag{15}$$

with $a_\alpha=\varepsilon_\alpha\Omega_{\alpha\alpha}^{m+1}$. We have

$$\sum_{\alpha=1}^{m}(a_\alpha)^2=\left(\sum_{\alpha=1}^{m}a_\alpha\right)^2-2\sum_{\alpha<\beta=1}^{m}a_\alpha a_\beta=\varepsilon_{m+1}\|H\|^2+\sum_{\alpha<\beta=1}^{m}(a_\alpha-a_\beta)^2-(m-1)\sum_{\alpha=1}^{m}(a_\alpha)^2,$$

$$m\sum_{\alpha=1}^{m}(a_\alpha)^2=\varepsilon_{m+1}\|H\|^2+\sum_{\alpha<\beta=1}^{m}(a_\alpha-a_\beta)^2\geqslant\varepsilon_{m+1}\|H\|^2.$$

If $\vec{H}$ is spacelike, (15) with the above inequality becomes

$$2R\leqslant\frac{m-1}{m}\|H\|^2-\sum_{\alpha\neq\beta=1}^{m}\varepsilon_{\alpha\beta}(\Omega_{\alpha\beta}^{m+1})^2-\sum_{A=m+2}^{n}\varepsilon_A\sum_{\alpha,\beta=1}^{m}\varepsilon_{\alpha\beta}(\Omega_{\alpha\beta}^{A})^2.$$

The signature of the embedded space is chosen to be $(n-1,1)$ and because of the condition of causal-type preserving, we find

$$\|H\|^2\geqslant\frac{2m}{m-1}R=\Lambda(0). \tag{16}$$

The proof for the timelike case is similar. ◇

Notice that due to our choice of signature for the embedded space E_n, $\vec{H}$ is always non-null. So we exclude the case of quasi-minimal embeddings.

If there is equality we can determine the form of the second fundamental forms.

Corollary III.1: There is equality in (5) or (6) at a point $p\in M$ iff there exists an orthonormal basis at p such that the second fundamental forms take the form

$$\Omega_{m+1}=\begin{pmatrix} a_1 & & & \\ & a_2 & & \\ & & \ddots & \\ & & & a_n \end{pmatrix},$$

with $a_1+\cdots+a_{n_1}=a_{n_1+1}+\cdots+a_{n_1+n_2}=\cdots=a_{n_1+\cdots+n_{k-1}+1}+\cdots+a_{n_1+\cdots+n_k}=a_{n_1+\cdots+n_k+1}=\cdots=a_m$ *and*

$$\Omega_r=\begin{pmatrix} A_{r1} & & & & & & \\ & A_{r2} & & & & & \\ & & \ddots & & & & \\ & & & A_{rk} & & & \\ & & & & 0 & & \\ & & & & & \ddots & \\ & & & & & & 0 \end{pmatrix},$$

with $Trace(A_{rj})=0$, $r=m+2,\ldots,n$, $j=1,\ldots,k$.

As in Ref. 17 we have the following.

Definition III.1: An isometric embedding $x:(M,g)\to(E_n,\eta)$ *is called an ideal embedding if and only if there exists a* k*-tuple* $(n_1,\ldots,n_k)$ *such that in a neighborhood* U *of a point* $p\in M$ *there is equality in (5) or (6), respectively.*

If the pseudo-Euclidean embedding space has signature $(n-1,1)$, an ideally embedded manifold M means that the squared mean curvature of M is minimal. Because $\vec{H}$ measures the tension on M from the surrounding space an ideal embedding in $E_{n-1,1}$ can be considered as *a best way of living in a best world* for the neighborhood U.[17] In the case of an embedding space with signature $(n-m+1,m-1)$ the situation is reversed. An ideally embedded manifold receives the maximum possible amount of tension from the surrounding space at each point of M. Although this situation is not *ideal* we reserve the notation for both occasions.

IV. IDEALLY EMBEDDED SPACE–TIMES

Using the above notion of ideal embedding gives us a natural set of second fundamental forms to consider. Notice that this is the reverse situation usually adopted in the literature. There one often starts from a given metric and looks for the minimal embedding, i.e., with the least extra dimensions, or one puts some constraints on the curvature tensor through the choice of matter and/or Petrov type (although see Ref. 22 for a different approach).

We will restrict our manifold M to be a four-dimensional space–time embedded in a five-dimensional pseudo-Euclidean space. The torsion vector is zero in this case, so (4) is trivially satisfied and (3) simplifies significantly. We further only study those cases when there is equality for a k-tuple with only spacelike plane sections. The case with a timelike plane section in the k-tuple will be considered separately.

We denote the orthonormal basis of an ideally embedded space–time M for which the second fundamental forms take their special forms as $\{e_\alpha\}=\{\vec{w},\vec{v},\vec{q},\vec{u}\}$ with $u_\alpha u^\alpha=-1$. From the above corollary we have three possible cases:
(i) equality with $k=0$,

$$\Omega_{\alpha\beta}=\mu g_{\alpha\beta};$$

(ii) equality with $k=1$, $n=2$,

$$\Omega_{\alpha\beta}=(\mu-\lambda)w_\alpha w_\beta+\lambda v_\alpha v_\beta+\mu q_\alpha q_\beta-\mu u_\alpha u_\beta;$$

(iii) equality with $k=1$, $n=3$,

$$\Omega_{\alpha\beta}=(\mu-\lambda-\nu)w_\alpha w_\beta+\lambda v_\alpha v_\beta+\nu q_\alpha q_\beta-\mu u_\alpha u_\beta.$$

Before we determine the metrics which can be ideally embedded with one of the above second fundamental forms we mention two results which limit the possible outcomes.

Theorem VI.1:[23] *No nonflat vacuum metric can be embedded in a five-dimensional pseudo-Euclidean space.*

Theorem IV.2:[13] *There are no embedding class one solutions of the Einstein–Maxwell equations with a non-null electromagnetic field.*

A. Case i

If we take as shape operator

$$\Omega_{\alpha\beta}=\mu g_{\alpha\beta},$$

i.e., the embedding is umbilical, the Codazzi equations (3) become

$$g_{\alpha\beta}\nabla_\gamma\mu=g_{\alpha\gamma}\nabla_\beta\mu,$$

or contracting over α and β gives $\nabla_\gamma\mu=0$. The Gauss equations (2) give

$$R_{\alpha\beta\gamma\delta}=2\varepsilon\mu^2 g_{\alpha[\gamma}g_{\delta]\beta},$$

with μ a constant. The space–time is a space of constant curvature, a de Sitter space if $\varepsilon=1$ or an anti-de Sitter space if $\varepsilon=-1$ (Ref. 15, p. 103). Due to our assumption of time-orientability the space obtained from the de Sitter space in which points are identified by reflection through the origin of the embedding space is excluded (Ref. 24, p. 130).

B. Case ii

With respect to the orthonomal basis $\{w^\alpha,v^\alpha,q^\alpha,u^\alpha\}$, u^α timelike, the second fundamental form becomes

$$\Omega_{\alpha\beta}=-\mu u_\alpha u_\beta+\mu q_\alpha q_\beta+\lambda v_\alpha v_\beta+(\mu-\lambda)w_\alpha w_\beta.$$

If we decompose the covariant derivatives,

$$\nabla_\beta u_\alpha=w_\alpha A_\beta+v_\alpha B_\beta+q_\alpha C_\beta,$$

$$\nabla_\beta w_\alpha=u_\alpha A_\beta+v_\alpha D_\beta+q_\alpha E_\beta,$$

$$\nabla_\beta v_\alpha=u_\alpha B_\beta-w_\alpha D_\beta+q_\alpha F_\beta,$$

$$\nabla_\beta q_\alpha=u_\alpha C_\beta-w_\alpha E_\beta-v_\alpha F_\beta,$$

the Codazzi equations give

$$\lambda A_\alpha=\nabla_w\mu\, u_\alpha+\lambda A_v\, v_\alpha-\nabla_u\lambda\, w_\alpha,$$

$$(\lambda-\mu)B_\alpha=-\nabla_v\mu\, u_\alpha-\nabla_u\lambda\, v_\alpha-\lambda A_v\, w_\alpha,$$

$$(2\lambda-\mu)D_\alpha=\lambda A_v\, u_\alpha+(2\lambda-\mu)D_q\, q_\alpha-\nabla_w\lambda\, v_\alpha-\nabla_v(\mu-\lambda)\, w_\alpha, \tag{17}$$

$$\lambda E_\alpha=-\nabla_w\mu\, q_\alpha+(2\lambda-\mu)D_q\, v_\alpha+\nabla_q\lambda\, w_\alpha,$$

$$(\lambda-\mu)F_\alpha=\nabla_v\mu\, q_\alpha+\nabla_q\lambda\, v_\alpha-(2\lambda-\mu)D_q\, w_\alpha,$$

and

$$\nabla_u\mu=\nabla_q\mu=0,$$

with A_v, D_q scalars and $u^\alpha\nabla_\alpha=\nabla_u$, etc. There is no equation for C_α.

The Ricci identities $2\nabla_{[\gamma}\nabla_{\beta]}z_\alpha=z^\sigma R_{\sigma\alpha\beta\gamma}$, with z^α one of the basis vectors, give

$$\nabla_{[\alpha}A_{\beta]}-D_{[\alpha}B_{\beta]}-E_{[\alpha}C_{\beta]}=\varepsilon\mu(\mu-\lambda)\, u_{[\beta}w_{\alpha]}, \tag{18}$$

$$\nabla_{[\alpha}B_{\beta]}+D_{[\alpha}A_{\beta]}-F_{[\alpha}C_{\beta]}=\varepsilon\mu\lambda\, u_{[\beta}v_{\alpha]}, \tag{19}$$

$$\nabla_{[\alpha}C_{\beta]}+E_{[\alpha}A_{\beta]}+F_{[\alpha}B_{\beta]}=\varepsilon\mu^2\, u_{[\beta}q_{\alpha]}, \tag{20}$$

$$\nabla_{[\alpha}D_{\beta]}+B_{[\alpha}A_{\beta]}-F_{[\alpha}E_{\beta]}=\varepsilon\lambda(\mu-\lambda)\, w_{[\beta}v_{\alpha]}, \tag{21}$$

$$\nabla_{[\alpha}E_{\beta]}+C_{[\alpha}A_{\beta]}+F_{[\alpha}D_{\beta]}=\varepsilon\mu(\mu-\lambda)\, w_{[\beta}q_{\alpha]}, \tag{22}$$

$$\nabla_{[\alpha}F_{\beta]}+C_{[\alpha}B_{\beta]}-E_{[\alpha}D_{\beta]}=\varepsilon\mu\lambda\, v_{[\beta}q_{\alpha]}. \tag{23}$$

1. If $\lambda=\mu\neq 0$

From the Codazzi equations we find $\nabla_v\mu = A_v = D_q = 0$ and

$$\nabla_\beta w_\alpha = \nabla_w \ln\lambda\,(u_\alpha u_\beta - v_\alpha v_\beta - q_\alpha q_\beta).$$

Let us denote the projection operator on the timelike hypersurface orthogonal to w^α by $h_\alpha^\beta = \delta_\alpha^\beta - w_\alpha w^\beta$. From the Gauss equations we find that

$$w^\alpha R_{\alpha\beta\gamma\delta}=0\,,$$

and so w^α is a constant vector field (see Ref. 15, p. 553), i.e., $\nabla_\beta w_\alpha = 0$ or $\lambda=\mu=\text{const}$. If we denote with ${}^3R_{\alpha\beta\gamma\delta}$ the Riemann tensor of the timelike hypersurface, the Gauss equations give

$${}^3R_{\alpha\beta\gamma\delta} = R_{\alpha\beta\gamma\delta} = 2\varepsilon\lambda^2 h_{\alpha[\gamma}h_{\delta]\beta}\,.$$

The timelike three-space is a space of constant curvature. We can then choose coordinates such that the metric reads

$$\mathrm{d}s^2 = \mathrm{d}z^2 + \frac{\mathrm{d}y^2+\mathrm{d}x^2-\mathrm{d}t^2}{[1+\frac{1}{4}\varepsilon\lambda^2(y^2+x^2-t^2)]^2}, \tag{24}$$

with $\lambda=\text{const}$. Because the embedding is quasi-umbilical (i.e., there exist functions ϕ and ψ such that $\Omega_{\alpha\beta}=\phi g_{\alpha\beta}+\psi w_\alpha w_\beta$) the metric is conformally flat.[25] The Ricci tensor is

$$R_{\alpha\beta} = 2\varepsilon\lambda^2 h_{\alpha\beta}\,,$$

with Segré type A1, [1(11,1)], and the energy-momentum tensor does not satisfy any of the known energy conditions.[24] Due to the observation that the Universe is accelerating, cosmological models with such a strange equation of state are recently under investigation.

2. If $\lambda=0$, $\mu\neq 0$

From the Codazzi equations we find $\nabla_w\mu = D_q = 0$ and

$$\nabla_\beta v_\alpha = \nabla_v \ln\mu\,(u_\alpha u_\beta - w_\alpha w_\beta - q_\alpha q_\beta).$$

This is the previous case with the roles of v^α and w^α interchanged.

3. If $\mu=2\lambda\neq 0$

The Codazzi equations give $A_v=\nabla_v\lambda=\nabla_w\lambda=0$. Then $A_\alpha=B_\alpha=D_\alpha=E_\alpha=F_\alpha=0$. The Ricci identity (18) gives $\lambda=0$, so we must take $\mu\neq 2\lambda$.

4. If $\lambda\neq 0$, $\mu-\lambda\neq 0$ and $\mu-2\lambda\neq 0$

Let $p_\alpha^\beta = \delta_\alpha^\beta - v_\alpha v^\beta - w_\alpha w^\beta$ be the projection operator on the two-space V_2 orthogonal to v^α and w^α. The second fundamental forms of the embedding of V_2 in the space–time (M,g) are

$$\Omega^v_{\alpha\beta} = p^\gamma_{(\alpha}p^\sigma_{\beta)}\nabla_\gamma v_\sigma = \frac{\nabla_v\mu}{\lambda-\mu}p_{\alpha\beta}\,,$$

and

$$\Omega^w_{\alpha\beta} = -\frac{\nabla_w\mu}{\lambda}p_{\alpha\beta}\,.$$

Using the Gauss equations we find for the Riemann tensor of the timelike two-space V_2,

$$ {}^2R_{\alpha\beta\gamma\delta}=2\left\{\varepsilon\mu^2+\left(\frac{\nabla_v\mu}{\lambda-\mu}\right)^2+\left(\frac{\nabla_w\mu}{\lambda}\right)^2\right\}p_{\alpha[\gamma}p_{\delta]\beta}. \tag{25}$$

It is a small calculation to show that the coefficient has zero-derivative in the u and q directions. The two-space V_2 is a space of constant curvature. We can choose coordinates such that

$$ w_\alpha=(e^{\phi(y,z)},0,0,0),\ v_\alpha=(0,e^{\xi(y,z)},0,0), $$

and the metric reads

$$ \mathrm{d}s^2=e^{2\phi(y,z)}\mathrm{d}z^2+e^{2\xi(y,z)}\mathrm{d}y^2+Y^2(y,z)\{\mathrm{d}x^2-\Sigma^2(x,k)\mathrm{d}t^2\}, \tag{26}$$

with $\Sigma(x,k)=\sin(x)$, x or $\sinh(x)$ if $k=1$, 0 or -1 and

$$ kY^{-2}=\varepsilon\mu^2+\left(\frac{\nabla_v\mu}{\lambda-\mu}\right)^2+\left(\frac{\nabla_w\mu}{\lambda}\right)^2. $$

These metrics have a group G_3 working on the two-surface of constant curvature and therefore have Petrov type D or O. Because the two-surface is timelike the energy-momentum content cannot be a perfect fluid, a null electromagnetic field or pure radiation (see Ref. 15, Chap. 15) and due to Theorems IV.1 and IV.2 also vacuum and an electromagnetic non-null field are not possible. We can, however, interpret this space–time as filled with an anisotropic perfect fluid satisfying the strong energy condition if and only if the extra dimension is timelike ($\varepsilon=-1$) and μ and λ satisfy any of the following conditions:

(1) $\lambda>0,\ \mu>\lambda$,
(2) $\lambda>0,\ -\lambda\leqslant\mu\leqslant\frac{1}{2}\lambda$,
(3) $\lambda<0,\ \frac{1}{2}\lambda\leqslant\mu\leqslant-\lambda$,
(4) $\lambda<0,\ \mu<\lambda$.

C. Case iii

With respect to an orthonormal tetrad $\{w^\alpha,v^\alpha,q^\alpha,u^\alpha\}$ the shape operator takes the form

$$ \Omega_{\alpha\beta}=-\mu u_\alpha u_\beta+\nu q_\alpha q_\beta+\lambda v_\alpha v_\beta+(\mu-\lambda-\nu)w_\alpha w_\beta. \tag{27}$$

If we use the same decompositions of the covariant derivatives as in the previous case, the Codazzi equations give

$$ (\lambda+\nu)A_\alpha=\nabla_w\mu\,u_\alpha+\nabla_u(\mu-\lambda-\nu)\,w_\alpha+(\lambda+\nu)A_v\,v_\alpha+(\lambda+\nu)A_q\,q_\alpha, $$

$$ (\mu-\lambda)B_\alpha=-\nabla_v\mu\,u_\alpha+(\lambda+\nu)A_v\,w_\alpha+\nabla_u\lambda\,v_\alpha+(\mu-\lambda)B_q\,q_\alpha, $$

$$ (\mu-\nu)C_\alpha=-\nabla_q\mu\,u_\alpha+(\lambda+\nu)A_q\,w_\alpha+(\mu-\lambda)B_q\,v_\alpha+\nabla_u\nu\,q_\alpha, $$

$$ (\mu-2\lambda-\nu)D_\alpha=-(\lambda+\nu)A_v\,u_\alpha+\nabla_v(\mu-\lambda-\nu)\,w_\alpha+\nabla_w\lambda\,v_\alpha+(\mu-2\lambda-\nu)D_q\,q_\alpha, $$

$$ (\mu-\lambda-2\nu)E_\alpha=-(\lambda+\nu)A_q\,u_\alpha+\nabla_q(\mu-\lambda-\nu)\,w_\alpha+(\mu-2\lambda-\nu)D_q\,v_\alpha+\nabla_w\nu\,q_\alpha, $$

$$ (\lambda-\nu)F_\alpha=-(\mu-\lambda)B_q\,u_\alpha+(\mu-2\lambda-\nu)D_q\,w_\alpha+\nabla_q\lambda\,v_\alpha+\nabla_v\nu\,q_\alpha, $$

with A_v, A_q, B_q, D_q scalars. The Ricci identities are

$$ \nabla_{[\alpha}A_{\beta]}-D_{[\alpha}B_{\beta]}-E_{[\alpha}C_{\beta]}=\varepsilon\mu(\mu-\lambda-\nu)\,u_{[\beta}w_{\alpha]}, \tag{28}$$

$$ \nabla_{[\alpha}B_{\beta]}+D_{[\alpha}A_{\beta]}-F_{[\alpha}C_{\beta]}=\varepsilon\mu\lambda\,u_{[\beta}v_{\alpha]}, \tag{29}$$

$$\nabla_{[\alpha}C_{\beta]}+E_{[\alpha}A_{\beta]}+F_{[\alpha}B_{\beta]}=\varepsilon\mu\nu\, u_{[\beta}q_{\alpha]}, \tag{30}$$

$$\nabla_{[\alpha}D_{\beta]}+B_{[\alpha}A_{\beta]}-F_{[\alpha}E_{\beta]}=\varepsilon\lambda(\mu-\lambda-\nu)\, w_{[\beta}v_{\alpha]}, \tag{31}$$

$$\nabla_{[\alpha}E_{\beta]}+C_{[\alpha}A_{\beta]}+F_{[\alpha}D_{\beta]}=\varepsilon\nu(\mu-\lambda-\nu)\, w_{[\beta}q_{\alpha]}, \tag{32}$$

$$\nabla_{[\alpha}F_{\beta]}+C_{[\alpha}B_{\beta]}-E_{[\alpha}D_{\beta]}=\varepsilon\nu\lambda\, v_{[\beta}q_{\alpha]}. \tag{33}$$

Using the Gauss equations we find the Ricci tensor,

$$R_{\alpha\beta}=\varepsilon\{-\mu^2u_\alpha u_\beta+\nu(2\mu-\nu)q_\alpha q_\beta+\lambda(2\mu-\lambda)v_\alpha v_\beta+(\mu-\lambda-\nu)(\mu+\lambda+\nu)w_\alpha w_\beta\}. \tag{34}$$

In the generic case the Segré type is A1, [111,1]. We will restrict the calculations in the following to perfect fluid space–times. This means μ, λ and ν must satisfy one of the following conditions:

$$\text{(A)}\quad \mu=3\lambda,\ \ \nu=\lambda,$$

$$\text{(B)}\quad \mu=-\lambda,\ \ \nu=\lambda,$$

$$\text{(C)}\quad \mu=-\nu,\ \ \lambda=-3\nu,$$

$$\text{(D)}\quad \mu=-\lambda,\ \ \nu=-3\lambda.$$

The cases B, C, and D are the same with the roles of the spacelike vectors interchanged. Before we study the above cases in detail we give first the decomposition of the covariant derivative of the timelike direction u^α into its irreducible parts if $\lambda+\nu\neq0$, $\mu-\lambda\neq0$ and $\mu-\nu\neq0$.

The acceleration reads

$$\dot{u}_\alpha=\frac{\nabla_q\mu}{\mu-\nu}q_\alpha+\frac{\nabla_v\mu}{\mu-\lambda}v_\alpha-\frac{\nabla_w\mu}{\lambda+\nu}w_\alpha, \tag{35}$$

the expansion

$$\theta=\frac{\nabla_u(\mu-\lambda-\nu)}{\lambda+\nu}+\frac{\nabla_u\lambda}{\mu-\lambda}+\frac{\nabla_u\nu}{\mu-\nu}, \tag{36}$$

the shear

$$\begin{aligned}\sigma_{\alpha\beta}=&\left\{\frac{2\nabla_u(\mu-\lambda-\nu)}{3(\lambda+\nu)}-\frac{\nabla_u\lambda}{3(\mu-\lambda)}-\frac{\nabla_u\nu}{3(\mu-\nu)}\right\}w_\alpha w_\beta+\frac{(\mu+\nu)A_v}{\mu-\lambda}w_{(\alpha}v_{\beta)}+\frac{(\mu+\lambda)A_q}{\mu-\nu}w_{(\alpha}q_{\beta)}\\&+\left\{-\frac{\nabla_u(\mu-\lambda-\nu)}{3(\lambda+\nu)}+\frac{2\nabla_u\lambda}{3(\mu-\lambda)}-\frac{\nabla_u\nu}{3(\mu-\nu)}\right\}v_\alpha v_\beta+\frac{(2\mu-\lambda-\nu)B_q}{\mu-\nu}v_{(\alpha}q_{\beta)}\\&+\left\{-\frac{\nabla_u(\mu-\lambda-\nu)}{3(\lambda+\nu)}-\frac{\nabla_u\lambda}{3(\mu-\lambda)}+\frac{2\nabla_u\nu}{3(\mu-\nu)}\right\}q_\alpha q_\beta,\end{aligned}$$

and the vorticity

$$\omega_{\alpha\beta}=\frac{(\mu-2\lambda-\nu)A_v}{\mu-\lambda}w_{[\alpha}v_{\beta]}+\frac{(\mu-\lambda-2\nu)A_q}{\mu-\nu}w_{[\alpha}q_{\beta]}+\frac{(\lambda-\nu)B_q}{\mu-\nu}v_{[\alpha}q_{\beta]}. \tag{37}$$

1. If $\mu=-\lambda$ and $\nu=\lambda\neq 0$

From the Codazzi equations we find $B_q=D_q=0$ and $\nabla_v\lambda=\nabla_q\lambda=0$. Projecting the Ricci identity (29) on $u^\alpha v^\beta$ and (30) on $u^\alpha q^\beta$ gives $A_v^2=A_q^2$. If we further project (29) on $u^\alpha q^\beta$ we find $A_vA_q=0$, so

$$A_v=A_q=0\ .$$

Combining (28), (29) and (31) gives

$$(\nabla_w \ln\lambda)^2=4(\nabla_u \ln\lambda)^2, \tag{38}$$

$$\nabla_u\nabla_w \ln\lambda=\tfrac{3}{2}\nabla_u \ln\lambda\ \nabla_w \ln\lambda, \tag{39}$$

and (29) then becomes

$$2\nabla_u\nabla_u \ln\lambda-3(\nabla_u \ln\lambda)^2-4\varepsilon\lambda^2=0. \tag{40}$$

If we differentiate (38) in the direction of u^α and use (39) and (40) we find $\lambda=0$. This case does not lead to ideally embedded perfect fluid space–times.

2. If $\mu=3\lambda$ and $\nu=\lambda$

From the Codazzi equations we find $A_v=A_q=B_q=0$ and $\nabla_w\lambda=\nabla_v\lambda=\nabla_q\lambda=0$. We find that u^α is geodesic, hypersurface orthogonal and shearfree. The expansion of the timelike congruence with tangent u^α is given by $\theta=\frac{3}{2}\nabla_u \ln\lambda$. From the Ricci identities we have the equation

$$2\nabla_u\nabla_u \ln\lambda+(\nabla_u \ln\lambda)^2-12\varepsilon\lambda^2=0\ . \tag{41}$$

It follows that if $\theta=0$, $\lambda=0$ and space–time is flat. Therefore we take $\theta\neq 0$. We then choose coordinates adapted to the timelike vector, $u_\alpha=(0,0,0,u_4)$. The metric becomes

$$\mathrm{d}s^2=h_{ij}\mathrm{d}x^i\mathrm{d}x^j-(u_4)^2\mathrm{d}t^2\ ,$$

with $i,j=1,2,3$. Then $\theta=\theta(t)$, $\lambda=\lambda(t)$ and $u_4=u_4(t)$. The second fundamental form of the embedding of the spacelike hypersurface orthogonal to u^α in (M,g) is

$$\Omega^u_{ij}=\tfrac{1}{3}\theta h_{ij}\ .$$

The Riemann tensor of the three-space reads

$${}^3R_{ijkl}=2\{\varepsilon\lambda^2-\tfrac{1}{9}\theta^2\}h_{i[k}h_{l]j}\ ;$$

the spacelike hypersurface is a space of constant curvature. The metric can be written, after a coordinate transformation $u_4(t)\mathrm{d}t\to\mathrm{d}t$, as

$$\mathrm{d}s^2=a^2(t)\{\mathrm{d}r^2+\Sigma^2(r,k)(\mathrm{d}\phi^2+\sin^2(\phi)\mathrm{d}\psi^2)\}-\mathrm{d}t^2\ , \tag{42}$$

with

$$ka^{-2}=\varepsilon\lambda^2-\tfrac{1}{9}\theta^2, \tag{43}$$

and $\Sigma(r,k)=\sin(r),r$ or $\sinh(r)$ if $k=1,0$ or -1. This metric is a Robertson–Walker metric (see Ref. 26 for the first results on the embedding of R-W models in flat five-dimensional spaces). Combining (41) and (43) $a(t)$ must be a solution of

$$(\partial_t a)^2=\varepsilon c^2a^6-k, \tag{44}$$

with $c=\text{const}$ and $\lambda=ca^2$. From the expression of the Ricci tensor (34) and the Einstein equations we can write the energy ρ and pressure p of the perfect fluid as

$$\kappa\rho=3c^2a^4 \quad \text{and} \quad \kappa p=-7c^2a^4,$$

with $\varepsilon=+1$.

V. CONCLUSION

In the study of embeddings of a space–time in some higher-dimensional space attention has focused primarily on intrinsic properties of the submanifold (e.g., the source type or Petrov type). But the fact that we embed our space–time metric in a greater space gives us the opportunity to consider also extrinsic properties of our model. From this viewpoint an ideal embedding seems to be the most natural and simple type of embedding to study. Ideally embedded space–times receive the least amount of tension from the surrounding space. We found that ideally embedded hypersurfaces in a pseudo-Euclidean space contain the de Sitter spaces and a Robertson–Walker model. Embeddings of the de Sitter and Robertson–Walker models were already considered by Ponce de Leon.[27] It was later realized that his five-dimensional embedding space was flat[2,28] and this was used in, e.g., Ref. 29 to study the structure of the Big Bang.

Furthermore, a class of anisotropic perfect fluid models containing a timelike two-surface of constant curvature has also been shown to be ideally embedded. Because the nonflat vacuum models were excluded from our study due to Theorem IV.1 we will study them in a future paper.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 45, NUMBER 4 APRIL 2004

Homotopy structure of 5d vacua

Eun Kyung Park
The Liberal Arts Course, Kyungsung University, Pusan 608-736, Korea

Pyung Seong Kwon[a)]
Department of Physics, Kyungsung University, Pusan 608-736, Korea

(Received 22 October 2003; accepted 5 January 2004)

It is shown that flat zero-energy solutions (vacua) of the 5d Kaluza–Klein theory admit a nontrivial homotopy structure generated by certain Kaluza–Klein excitations. These vacua consist of an infinite set of homotopically different space–times denoted by $\mathcal{M}_5^{(n)}$, among which $\mathcal{M}_5^{(0)}$ and $\mathcal{M}_5^{(1)}$ are especially identified as $M_4 \times S^1$ and M_5, the vacuum states of the 5d Kaluza–Klein theory and the 5d general relativity, respectively (where M_k represents the k-dimensional Minkowski space).
 [DOI: 10.1063/1.1667611]

The 5d Kaluza–Klein theory is distinguished from the ordinary 5d general relativity by the fact that the background vacuum is assumed to be the product $M_4 \times S^1$ instead of M_5, where M_k represents the k-dimensional Minkowski space. Having zero energy, the manifolds $M_4 \times S^1$ and M_5 are both qualified for the vacuum state of the 5d theory of gravity. Classically, there is no way to determine which is more appropriate than the other. The only basis for choosing $M_4 \times S^1$ as the vacuum state of the 5d Kaluza–Klein theory is that it includes the compactified dimension which is crucial in order to admit an internal gauge group U(1) in the reduced theory. In fact, the compactification is an essential ingredient of any higher dimensional theory (including string theory) based on the Kaluza–Klein theory. The particle spectrum is then obtained by expanding around the vacuum $M_4 \times S^1$; one finds a finite number of massless modes and an infinite tower of massive (excitation) modes. In traditional theories the low-energy physics would be mostly governed by the dynamics of the massless modes alone, because the energy scale of the massive modes is about the order of the Planck scale. However, this is not to be the case anymore once we adopt the scenario that extra dimensions be very large. Recently, it has been suggested that the old hierarchy problem can be solved in the framework of higher-dimensional theories by taking extra dimensions to be very large.[1] In this scenario the energy scale of the massive modes (which is of the order of the inverse of the radius of S^1) could sufficiently lower down to the level of low energy physics, and one can imagine that the massive modes perhaps play an important role even in the low energy limit. In this paper, we examine the effect of the massive excitations on the geometry or topology of the background space–time $M_4 \times S^1$. Then we end up with a remarkable result that 5d vacua admit a nontrivial homotopy structure; 5d vacua consist of an infinite set of homotopically different space–times denoted by $\mathcal{M}_5^{(n)}$, where $\mathcal{M}_5^{(0)}$ and $\mathcal{M}_5^{(1)}$ are especially identified as $M_4 \times S^1$ and M_5, respectively. It is also conjectured that $M_4 \times S^1$ may not be the true physical vacuum of the 5d Kaluza–Klein theory.

We start the discussion with a metric

$$\begin{aligned} ds^2 &= -dt^2 + dr^2 + r^2(d\theta^2 + \sin^2\theta d\phi^2) + \Phi^2(x^\alpha, x^5)[dx^5 + A_\mu(x^\alpha, x^5)dx^\mu]^2 \\ &= \overset{4}{g}_{\mu\nu} dx^\mu dx^\nu + \Phi^2[dx^5 + A_\mu dx^\mu]^2 \\ &= \overset{4}{\eta}_{ab} \omega^a \omega^b + (\omega^5)^2 \quad (\mu, \nu, \alpha = 0,1,2,3; a, b = 0,1,2,3), \end{aligned} \tag{1}$$

[a)]Author to whom correspondence should be addressed. Electronic mail: bskwon@star.ks.ac.kr

where $\overset{4}{\eta}_{ab}$ is the 4d flat Minkowski metric, and

$$\omega^a = e^a_\mu dx^\mu, \quad \omega^5 = \Phi(dx^5 + A_\mu dx^\mu) \tag{2}$$

are basis one-forms of the orthonormal frame. From Eq. (1) we see that the fields Φ and A_μ have x^5-dependence, meaning that they include massive modes. In the reduced 4d sector, Φ and A_μ are identified as the Brans–Dicke scalar and the U(1) gauge potential, respectively. The vierbein $e^a{}_\mu$, on the other hand, are functions of x^α alone,[2] so they commute with ∂_5. The nonvanishing components of Riemann tensor are then calculated in the orthonormal frame to give[3]

$$\overset{5}{R}_{abcd} = -\tfrac{1}{2}(\hat{f}_{ab}\hat{f}_{cd} + \hat{f}_{a[c}\hat{f}_{bd]}), \tag{3}$$

$$\overset{5}{R}_{abc5} = \mathcal{D}_{[a}\hat{f}_{b]c} - F_c\hat{f}_{ab}, \tag{4}$$

$$\overset{5}{R}_{a5b5} = -\mathcal{D}_{(a}F_{b)} - \tfrac{1}{4}\hat{f}_{ac}\hat{f}^c{}_b - F_aF_b, \tag{5}$$

where $\hat{f}_{ab}$ is defined by $\hat{f}_{ab} \equiv \Phi f_{ab}$ and

$$f_{ab} = e_a{}^\mu e_b{}^\nu (D_\mu A_\nu - D_\nu A_\mu) \equiv e_a{}^\mu e_b{}^\nu f_{\mu\nu} \quad (D_\mu \equiv \partial_\mu - A_\mu\partial_5), \tag{6}$$

$$F_a = e_a{}^\mu(\partial_\mu\Phi - \partial_5\hat{A}_\mu)/\Phi \equiv e_a{}^\mu F_\mu \quad (\hat{A}_\mu \equiv \Phi A_\mu), \tag{7}$$

$$\mathcal{D}_a = e_a{}^\mu(\nabla_\mu - A_\mu\partial_5) \equiv e_a{}^\mu\mathcal{D}_\mu, \tag{8}$$

and, in Eq. (8), ∇_μ represents the ordinary covariant derivative associated with the metric $\overset{4}{g}_{\mu\nu}$. Also, $f_{\mu\nu}$ in Eq. (6) is a generalization of the Maxwell field strength; it takes the same form as the conventional Maxwell field strength except that the ordinary derivative ∂_μ is replaced by the covariant derivative[4] D_μ. Without x^5-dependency the derivative D_μ reduces to ∂_μ, and consequently $f_{\mu\nu}$ becomes the conventional Maxwell field strength.

Now we look for flat (vacuum) solutions which satisfy the equations $\overset{5}{R}_{abcd} = \overset{5}{R}_{abc5} = \overset{5}{R}_{a5b5} = 0$. A set of the simplest solutions to these equations may be obtained by setting

$$f_{\mu\nu} = D_\mu A_\nu - D_\nu A_\mu = 0, \tag{9}$$

$$F_\mu = \frac{1}{\Phi}(\partial_\mu\Phi - \partial_5\hat{A}_\mu) = 0, \tag{10}$$

and in particular Eq. (9) is immediately solved by an ansatz

$$A_t = A_\theta = A_\phi = 0, \quad A_r = A_r(r, x^5), \quad \Phi = \Phi(r, x^5). \tag{11}$$

Equation (11) is actually the most general ansatz preserving spherical symmetry, and A_μ in Eq. (11) may be regarded as a pure gauge in the sense that it gives $f_{\mu\nu} = 0$. With this ansatz, the metric in Eq. (1) can be recast into the form

$$ds^2 = -dt^2 + d\hat{r}^2 + r^2(d\theta^2 + \sin^2\theta d\phi^2) + \frac{\Phi^2}{1 + \hat{A}_r^2}(dx^5)^2 \quad (\hat{A}_r \equiv \Phi A_r), \tag{12}$$

where $d\hat{r}$ is defined by

$$d\hat{r}=(1+\hat{A}_r{}^2)^{1/2}dr+\frac{\Phi\hat{A}_r}{(1+\hat{A}_r{}^2)^{1/2}}dx^5. \tag{13}$$

Equation (13) indicates that the variable $\hat{r}$ is a function of r and x^5, i.e., $\hat{r}=f(r,x^5)$ with

$$\frac{\partial f}{\partial r}=(1+\hat{A}_r{}^2)^{1/2}, \quad \frac{\partial f}{\partial x^5}=\frac{\Phi\hat{A}_r}{(1+\hat{A}_r{}^2)^{1/2}}. \tag{14}$$

With the aid of Eq. (10) one then finds from the equations in (14) that the condition $\partial^2 f/\partial r\partial x^5 = \partial^2 f/\partial x^5\partial r$ implies that $\partial_r\hat{A}_r=0$; i.e., $\hat{A}_r$ must be a function of x^5 alone:

$$\hat{A}_r\equiv Y(x^5). \tag{15}$$

Thus the equations in (14) are now integrated to give

$$f=\hat{r}=r(1+Y^2)^{1/2}+g(x^5), \tag{16}$$

$$\Phi=rY'+\frac{(1+Y^2)^{1/2}}{Y}g', \tag{17}$$

where $g(x^5)$, which has been introduced as an integral constant, is an arbitrary function of x^5 alone, and the ''prime'' in Eq. (17) denotes the x^5-derivative. Note that $\hat{A}_r$ and Φ in Eqs. (15) and (17) indeed describe the flat solution satisfying $\overset{5}{R}_{ABCD}=0$; one can readily check that they satisfy Eq. (10). Now we impose the condition

$$\lim_{Y,Y'\to 0}\ \Phi=\text{const}\equiv\Phi_0, \tag{18}$$

which suggests that the solution we are to find is the one that reduces to the Kaluza–Klein vacuum $M_4\times S^1$ as $A_\mu\to 0$; note that $M_4\times S^1$ with $A_\mu=0$ and $\Phi=$const is also a solution to Eq. (10). The condition in Eq. (18) immediately implies that

$$g'=\Phi_0 Y, \tag{19}$$

and therefore Φ in Eq. (17) becomes

$$\Phi=rY'+\Phi_0(1+Y^2)^{1/2}. \tag{20}$$

Using all this, one can show that the metric in Eq. (12) can be converted into the form

$$ds^2=-dt^2+\left(1-\frac{\Phi_0^2Y^2}{R^2}\right)d\rho^2+\frac{\rho^2}{1+Y^2}(d\theta^2+\sin^2\theta d\phi^2)+R^2\left(dx^5+\frac{\Phi_0 Y}{R^2}d\rho\right)^2, \tag{21}$$

where ρ and R are defined by

$$\rho=\hat{r}-g=r(1+Y^2)^{1/2}, \tag{22}$$

$$R=\left[\Phi_0^2Y^2+\left(\rho\frac{Y'}{1+Y^2}+\Phi_0\right)^2\right]^{1/2}. \tag{23}$$

So far, the function $Y(x^5)$ and the constant Φ_0 have been entirely arbitrary except that they should satisfy the condition (18). Now let us take

$$Y_n(x^5)=\tan\frac{nx^5}{2R_c},\quad \Phi_0=\delta_{n0}\quad (n=0,1,2,...), \tag{24}$$

where R_c represents the compactification radius of the fifth-dimension [note that Eq. (24) respects the condition (18) as $n\to 0$]. By Eqs. (15), (20), and (24), the gauge field A_r becomes

$$A_r(r,x^5)=a_n(r)\sin\frac{nx^5}{R_c} \tag{25}$$

with

$$a_n(r)=\frac{R_c}{nr+2R_c\delta_{n0}}, \tag{26}$$

which shows that taking $Y_n(x^5)$ as in Eq. (24) implies that we are considering a situation where the nth excitation of the gauge field (together with the scalar field induced by this gauge field) is present in the background space–time $M_4\times S^1$ [see Eq. (1)]. In this case the field $\Phi(r,x^5)$ takes the form

$$\Phi(r,x^5)=\frac{nr}{2R_c}\sec^2\frac{nx^5}{2R_c}+\delta_{n0}, \tag{27}$$

and we see that $A_r\to 0$, $\Phi\to 1$ for $n=0$. Namely, the $n=0$ state simply describes the compactified vacuum $M_4\times S^1$ without any gauge or scalar field. For $n\neq 0$, on the other hand, both fields are present in the form of $A_r\sim 1/r$ and $\Phi\sim r$, respectively [the presence of the gauge excitation necessarily demands the presence of the scalar field with a behavior of $\Phi\sim r$, as can be checked from Eq. (10)]. Then, what happens to the space–time by the presence of these excitations Φ and A_r? By Eq. (24), the metric (21) simplifies to

$$ds^2=-dt^2+d\rho^2+\rho^2\sin^2\chi_n(d\theta^2+\sin^2\theta d\phi^2)+(\rho d\chi_n+\delta_{n0}dx^5)^2 \tag{28}$$

with χ_n defined by

$$\chi_n(x^5)=\frac{nx^5}{2R_c}+\frac{\pi}{2}, \tag{29}$$

which, after all, implies that the metric (28) is equivalent under (24) to the metric in Eq. (1) with Φ and A_μ given by Eqs. (25) and (27). Indeed, for $n=0$, it reduces to the flat $M_4\times S^1$:

$$ds^2_{(0)}=-dt^2+d\rho^2+\rho^2(d\theta^2+\sin^2\theta d\phi^2)+(dx^5)^2, \tag{30}$$

which is just the metric in Eq. (1) with $A_\mu=0$, $\Phi=1$. For $n\neq 0$, on the other hand, the metric (28) becomes

$$ds^2_{(n)}=-dt^2+d\rho^2+\rho^2[d\chi_n^2+\sin^2\chi_n(d\theta^2+\sin^2\theta d\phi^2)], \tag{31}$$

the 5d flat Minkowski metric! The topology of space–time has been changed by the nonzero excitation modes. The toroidal compactification $M_4\times S^1$ in Eq. (1) has been converted into the noncompact space–time described by the metric in Eq. (31). Furthermore, let us change the variable $x^5\to y_n$ by the equation

$$y_n=x^5+\frac{\pi R_c}{n}. \tag{32}$$

Under Eq. (32), the metric (1) [with A_r and Φ given by Eqs. (25) and (27)] takes the same form as before, i.e.,

$$ds^2 = -dt^2 + dr^2 + r^2(d\theta^2 + \sin^2\theta d\phi^2) + \Phi^2(r, y_n)[dy_n + A_r(r, y_n)dr]^2 \tag{33}$$

with[5]

$$A_r(r, y_n) = -a_n(r)\sin\frac{ny_n}{R_c}, \quad \Phi(r, y_n) = \frac{nr}{2R_c}\csc^2\frac{ny_n}{2R_c} + \delta_{n0}, \tag{34}$$

but χ_n in (31) is now written [from (29)] as

$$\chi_n(y) = \frac{ny_n}{2R_c} \quad (0 \leqslant y_n \leqslant 2\pi R_c). \tag{35}$$

This is remarkable. Equation (35) suggests that the 5d vacua admit a nontrivial homotopy structure. Note that the angle χ_n varies from 0 to $n\pi$ as y_n makes a single turn from 0 to $2\pi R_c$ around S^1, which in turn means that the set of variables (χ_n, θ, ϕ) in (31) covers the hypersurface S^3 n times when (y_n, θ, ϕ) in (33) covers $S^2 \times S^1$ just once. The 3d manifold described by (χ_n, θ, ϕ) can be regarded as a three-loop $\alpha_n(t_1, t_2, t_3)$, where t_i, the coordinates of 3d cube I_3, are defined by the map: $t_1 = y_n/2\pi R_c$, $t_2 = \theta/\pi$ and $t_3 = \phi/2\pi$, which is an homeomorphism $f: S^2 \times S^1 \to I_3$. A collection of these three-loops which cover S^3 n times constitutes the nth equivalence class of the third homotopy group $\pi_3(S^3)$. The spatial subsector of the space–time described by Eq. (31) is essentially a pile of such three-loops. This suggests that the space–time described by Eq. (31) (let us call it $\mathcal{M}_5^{(n)}$) belongs to the $n \neq 0$ homotopy class of $\pi_3(S^3)$, though $M_4 \times S^1$ with no excitations especially belongs to the $n = 0$ class since it is obtained by simply taking[6] $n = 0$. Further, for $n = 1$, it is obvious from Eq. (35) that $\mathcal{M}_5^{(n)}$ is precisely identified as the ordinary 5d Minkowski space M_5. But note that, in general, $\mathcal{M}_5^{(n)}$ is not M_5 itself; $\mathcal{M}_5^{(n)}$ is an n-fold cover of M_5. Namely, it is a fiber bundle over M_5 with fiber F a discrete set of n points. In short, 5d vacua consist of an infinite set of homotopically different space–times $\mathcal{M}_5^{(n)}$, among which the cases of $n = 0$ and $n = 1$ are especially identified as the background vacua of the 5d Kaluza–Klein theory and the 5d general relativity, respectively; i.e., $M_4 \times S^1 = \mathcal{M}_5^{(0)}$, and $M_5 = \mathcal{M}_5^{(1)}$. Such a homotopy structure manifests itself once there is a defect, or a point particle at $\rho = 0$. With a defect or point particle at $\rho = 0$, the spatial subsector of M_5 is not simply connected, and the three-loops which contain $\rho = 0$ are not shrinkable. So each $\mathcal{M}_5^{(n)}$, a pile of such three-loops which enclose the point $\rho = 0$ n times, belongs to a different homotopy class.

Though the above discussion has its own right in 5d Kaluza–Klein theories, it may be applied to any other higher dimensional theories with toroidal compactification. For instance, in the 11-dimensional theory compactified on $X \times S^1/Z_2$ (or equivalently, in the strong coupling limit of the $E_8 \times E_8$ heterotic string) it is believed that the radius of the orbifold S^1 is larger than the volume of the Calabi–Yau manifold X, and there is a regime where our space–time appears five-dimensional.[7,8] To the lowest order of the 11d Newton constant κ, the (5d sector of the) ground state metric takes the form of the 5d Kaluza–Klein vacuum $M_4 \times S^1$. So in this case the vacua of the theory could admit the homotopy structure under discussion. If this is the case, it then follows that the T-duality could break down due to the presence of the excitations. Note that for $n \neq 0$ the compactified dimension S^1 disappears due to the excitation modes; the map $f: S^2 \times S^1 \to S^3$ takes S^1 to the great circle of S^3. Thus the winding number (of the closed string) is not a topological number here and consequently the term corresponding to winding modes does not exist in the mass formula, and it leads to the conjecture that the T-duality might break down in the presence of excitations.

So far, we have considered only the (excitations of the) Kaluza–Klein components (i.e., 5d metric components) as the source of the topology change of the space–time. But in the 5d bulk space–time there also exist other fields besides the Kaluza–Klein components.[8] For instance, we may consider the case where a 5d U(1) gauge field[9] $\mathcal{A}_\mu$ exists in the bulk space–time, with field

strength $\mathcal{F}_{\mu\nu}$ (see, for instance, Ref. 10), and it takes the place of the Kaluza–Klein vector A_μ. Indeed, disregarding the components $\mathcal{F}_{\mu 5}$, one finds that the 4d effective action for $\mathcal{A}_\mu$ takes the same form as the action for A_μ, which suggests that the homotopy structure of the 5d vacua can be generated even by (the excitations of) bulk fields, rather than Kaluza–Klein components.

The result of this paper is quite analogous to the case of the θ-vacua of the Yang–Mills theory. In both cases the vacua admit the same homotopy structure with an infinite set of homotopy classes each of which is characterized by an integer n. In the Yang–Mills theory the integer n is identified with the Pontryagin index $q \sim Tr\int d^4x F^{\mu\nu}\tilde{F}_{\mu\nu}$, and the vacua belonging to different homotopy classes are connected by a Euclidean (instanton) solution. In the present paper the integer n is simply an excitation number of the pure gauge A_μ, and the instanton solution interconnecting two different vacua does not exist here. But notice that in our case there exist gauge transformations which mix the massive and massless modes[11] of A_μ, and consequently the space–times belonging to different classes can be mixed by such gauge transformations. The gauge transformation which mixes the massive and massless modes can be generated by allowing gauge parameter ξ to depend on x^5. For instance, the transformation which mixes the nth and $(n-k)$th modes (in the Fourier exponential series) of A_μ takes the form (see Ref. 11)

$$\delta_k A_{\mu n} = \delta_{nk}\partial_\mu \xi_k + i(n-2k)\xi_k A_{\mu(n-k)}/R_c, \tag{36}$$

where $A_{\mu n}$ and ξ_n are the nth components of the Fourier exponential series

$$A_\mu(x^\alpha, x^5) = \sum_n A_{\mu n}(x^\alpha) e^{inx^5/R_c}, \tag{37}$$

$$\xi(x^\alpha, x^5) = \sum_n \xi_n(x^\alpha) e^{inx^5/R_c}, \tag{38}$$

respectively, and δ_k represents the transformation induced by ξ_k. Since $\mathcal{M}_5^{(n)}$ is equivalent to $\mathcal{M}_5^{(0)}$ plus the nth excitation (in the Fourier sine-series) of A_μ, the transformation (36) apparently mixes $\mathcal{M}_5^{(n)}$ with other space–times belonging to different classes. This is quite remarkable. Note that a gauge transformation essentially does not change the physics of a system. But the above argument suggests that $\mathcal{M}_5^{(n)}$ is not invariant under a ''large'' gauge transformation of the form (36), which immediately leads us to suspect that space–times $\mathcal{M}_5^{(n)}$ (most importantly $\mathcal{M}_5^{(0)} = M_4 \times S^1$ and $\mathcal{M}_5^{(1)} = M_5$) may not be the physical states of the theory. Namely, the suggested conjecture is that $M_4 \times S^1$ may not be the true physical vacuum of the 5d Kaluza–Klein theory; it serves as a vacuum only when we do not consider the ''large'' gauge transformation. The physical vacuum of the 5d Kaluza–Klein theory may perhaps be a superposition of an infinite number of $\mathcal{M}_5^{(n)}$, analogously to the case of the θ-vacua of the Yang–Mills theory.

[2] The x^5-independency of $e^a{}_\mu$ greatly simplifies the calculation. See P. S. Wesson and J. P. Leon, J. Math. Phys. **33**, 3883 (1992); **34**, 4080 (1993).

[3] Note that the constraints $\mathcal{D}_{[a}\hat{f}_{bc]} - F_{[a}\hat{f}_{bc]} = 0$ and $\mathcal{D}_{[a}F_{b]} + (\partial_5 \hat{f}_{ab})/2\Phi = 0$ are required by the symmetry $\overset{5}{R}_{ABCD} = \overset{5}{R}_{CDAB}$, and they have been used to obtain $\overset{5}{R}_{abc5}$ and $\overset{5}{R}_{a5b5}$. Also, note that the 4d sector of the space–time in Eq. (1) is flat, so the 4d Riemann tensor $\overset{4}{R}_{abcd}$ vanishes and does not appear in Eq. (3). The Riemann tensors in Eqs. (3)–(5) are in fact a generalization of those in Y. Thiry, C. R. Acad. Sci. (Paris) **226**, 216 (1948).

[4] The derivative D_μ (more generally $\mathcal{D}_\mu$), acting on a tensor, leaves its components invariant under the gauge transfor-

mation: $x^5 \to x^{5'} = x^5 + f(x^\alpha)$, $A_\mu \to A'_\mu = A_\mu - \partial_\mu f$. For this, see A. Einstein and P. Bergmann, Ann. Math. **39**, 683 (1938). Thus we see that Eqs. (3)–(5) are all expressed in gauge-covariant form.

[5] The metric (33) seems to have a singularity at $y_n = 0$ (or $2\pi R_c$) because $\Phi(r, y_n)$ in (34) is singular there. However, this singularity is obviously artificial; notice that the metric (33) is a flat solution satisfying $R_{ABCD} = 0$ in orthonormal frame.

[6] Equation (35) [i.e., the variable change $x^5 \to y_n$ in Eq. (32)] is in fact applicable to the $n = 0$ case either. Note that since $\lim_{n\to 0} n y_n = \pi R_c$ from (32), we see that the metric (33) reduces to the flat $M_4 \times S^1$ as $n \to 0$. This is the same result that we obtain from the metric (1) with A_r and Φ given by Eqs. (25) and (27).

Classification of static plane symmetric space–times according to their matter collineations

M. Sharif[a)]
Department of Mathematics, University of the Punjab, Quaid-e-Azam Campus Lahore-54590, Pakistan

(Received 10 October 2003; accepted 19 December 2003)

In this paper we classify static plane symmetric space–times according to their matter collineations. These have been studied for both cases when the energy–momentum tensor is nondegenerate and also when it is degenerate. It turns out that the nondegenerate case yields either *four*, *five*, *six*, *seven*, or *ten* independent matter collineations in which *four* are isometries and the rest are proper. There exists three interesting cases where the energy–momentum tensor is degenerate but the group of matter collineations is finite-dimensional. The matter collineations in these cases are either *four*, *six*, or *ten*. © *2004 American Institute of Physics.*

I. INTRODUCTION

There exists a large body of literature on classification of space–times according to their isometries or Killing vectors (KVs) and the groups admitted by them.[1–4] These investigations of symmetries played an important role in the classification of space–times, giving rise to many interesting results with useful applications. As curvature and Ricci tensors play a significant role in understanding the geometric structure of metrics, the energy–momentum tensor enables us to understand the physical structure of space–times. Symmetries of the energy–momentum tensor (also called matter collineations) provide conservation laws on matter fields. These enable us to know how the physical fields, occupying certain region of space–times, reflect the symmetries of the metric.[5]

Some recent literature[6–12] shows keen interest in the study of matter collineations (MCs). In one of the recent papers,[12] the study of MCs has been taken for spherically symmetric space–times and some interesting results have been obtained. In this paper, we address the same problem for static plane symmetric space–times. It turns out that static plane symmetric space–times admit a MC Lie algebra of 10, 7, 6, 5, and 4 dimensions apart from the infinite-dimensional algebras.

Let (M,g) be a space–time, where M is a smooth, connected, Hausdorff four-dimensional manifold and g is a smooth Lorentzian metric of signature $(+\ -\ -\ -)$ defined on M. The manifold M and the metric g are assumed smooth (C^{∞}). We shall use the usual component notation in local charts, and a covariant derivative with respect to the symmetric connection Γ associated with the metric g will be denoted by a semicolon and a partial derivative by a comma. A smooth vector field ξ is said to preserve a matter symmetry[13] on M if, for each smooth local diffeomorphism ϕ_t associated with ξ, the tensors T and $\phi_t^* T$ are equal on the domain U of ϕ_t, i.e., $T=\phi_t^* T$. Equivalently, a vector field ξ^a is said to generate a matter collineation if it satisfies the following equation:

$$\pounds_{\xi} T_{ab}=0, \tag{1}$$

where $\pounds$ is the Lie derivative operator, ξ^a is the symmetry or collineation vector. Every KV is an

[a)]Present address: Department of Mathematical Sciences, University of Aberdeen, Kings College, Aberdeen AB24 3UE Scotland, United Kingdom. Electronic mail: msharif@maths.abdn.ac.uk

MC but the converse is not true, in general. Collineations can be proper (nontrivial) or improper (trivial). We define a proper MC to be a MC which is not a KV, or a homothetic vector (HV). The MC Eq. (1) can be written in component form as

$$T_{ab,c}\xi^c + T_{ac}\xi^c_{,b} + T_{cb}\xi^c_{,a} = 0 \quad (a,b,c = 0,1,2,3). \tag{2}$$

A plane symmetric space–time is a Lorentzian manifold possessing a physical stress–energy tensor. This admits $SO(2)\otimes\Re^2$ as the minimal isometry group in such a way that the group orbits are spacelike surfaces of constant curvature. The metric for static plane symmetric space–times is given in the form[3]

$$ds^2 = e^{\nu(x)}\,dt^2 - dx^2 - e^{\mu(x)}(dy^2 + dz^2), \tag{3}$$

where ν and μ are arbitrary functions of x. The surviving components of the energy–momentum tensor, given in Appendix A, are T_0, T_1, T_2, T_3, where $T_3 = T_2$ and we have used the notation $T_{aa} = T_a$ for the sake of simplicity.

The MC equations can be written as follows:

$$T_{0,1}\xi^1 + 2T_0\xi^0_{,0} = 0, \tag{4}$$

$$T_0\xi^0_{,1} + T_1\xi^1_{,0} = 0, \tag{5}$$

$$T_0\xi^0_{,2} + T_2\xi^2_{,0} = 0, \tag{6}$$

$$T_0\xi^0_{,3} + T_2\xi^3_{,0} = 0, \tag{7}$$

$$T_{1,1}\xi^1 + 2T_1\xi^1_{,1} = 0, \tag{8}$$

$$T_1\xi^1_{,2} + T_2\xi^2_{,1} = 0, \tag{9}$$

$$T_1\xi^1_{,3} + T_2\xi^3_{,1} = 0, \tag{10}$$

$$T_{2,1}\xi^1 + 2T_2\xi^2_{,2} = 0, \tag{11}$$

$$T_2(\xi^2_{,3} + \xi^3_{,2}) = 0, \tag{12}$$

$$T_{2,1}\xi^1 + 2T_2\xi^3_{,3} = 0. \tag{13}$$

These are the first order nonlinear partial differential equations in four variables $\xi^a(x^b)$. We solve these equations for the nondegenerate case, when

$$\det(T_{ab}) = T_0T_1T_2^2 \neq 0, \tag{14}$$

and for the degenerate case, where $\det(T_{ab}) = 0$. The rest of the paper is organized as follows. The next section contains a solution of MC equations when the energy–momentum tensor is nondegenerate. In Sec. III, MC equations are solved for the degenerate energy–momentum tensor and Sec. IV provides some examples admitting proper MCs for the nondegenerate case. Finally, Sec. V contains a summary and discussion of the results obtained.

II. MATTER COLLINEATIONS IN THE NONDEGENERATE CASE

In this section, we shall evaluate MCs only for those cases which have a nondegenerate energy–momentum tensor, i.e., $\det(T_{ab}) \neq 0$. To this end, we set up the general conditions for the solution of MC equations for the nondegenerate case.

When we solve Eqs. (4)–(13) simultaneously, after some algebraic computations, we arrive at the following solution:

$$\xi^0=-\frac{T_2}{T_0}\left[\frac{1}{2}(y^2+z^2)\dot{A}_1+z\dot{A}_2+y\dot{A}_3\right]+A_4, \tag{15}$$

$$\xi^1=-\frac{T_2}{T_1}\left[\frac{1}{2}(y^2+z^2)A_1'+zA_2'+yA_3'\right]+A_5, \tag{16}$$

$$\xi^2=\tfrac{1}{2}z^2(c_1y+c_3)+z(c_2y+c_4)-\tfrac{1}{6}c_1y^3-\tfrac{1}{2}c_3y^2+yA_1+A_3, \tag{17}$$

$$\xi^3=-\tfrac{1}{2}y^2(c_1z+c_2)-y(c_3z+c_4)+\tfrac{1}{6}c_1z^3+\tfrac{1}{2}c_2z^2+zA_1+A_3, \tag{18}$$

where c_1,c_2,c_3,c_4 are arbitrary constants and $A_\mu=A_\mu(t,x)$, $\mu=1,2,3,4,5$ are integration functions. Here an overdot and a prime indicate the differentiation with respect to time and the x coordinate, respectively. When we replace these values of ξ^a in MC, Eqs. (4)–(13), we obtain the following constraints on A_μ:

$$\frac{T_0'}{T_1}A_i'+2\ddot{A}_i=0 \quad (i=1,2,3), \tag{19}$$

$$\dot{A}_i=\sqrt{\frac{T_0}{T_2}}f_i(t),\ \ A_i'=\frac{\sqrt{T_1}}{T_2}g_i(t), \tag{20}$$

$$\dot{A}_4=-\frac{T_0'}{2T_0\sqrt{T_1}}g_5(t),\ \ A_4'=-\frac{\sqrt{T_1}}{T_0}\dot{g}_5(t), \tag{21}$$

$$c_1=0,\ \ T_2'A_1'=0, \tag{22}$$

$$\frac{T_2'}{T_2}A_5+2A_1=0, \tag{23}$$

$$\frac{T_2'}{T_2\sqrt{T_1}}g_2(t)-2c_2=0, \tag{24}$$

$$\frac{T_2'}{T_2\sqrt{T_1}}g_3(t)+2c_3=0, \tag{25}$$

$$\frac{T_2'}{T_2\sqrt{T_1}}g_5(t)+2A_1=0, \tag{26}$$

$$\frac{T_0'}{T_2\sqrt{T_1}}g_i(t)+2\ddot{A}_i=0, \tag{27}$$

where $f_i(t),g_i(t)$, $g_5(t)$ are integration functions. Thus the problem of working out MCs for all possibilities of A_i,A_4,A_5 is reduced to solving the set of Eqs. (15)–(18) subject to the above constraints. We would solve these to classify MCs of the plane symmetry manifolds.

From Eqs. (24)–(26), there arise two main cases:

$$(1)\quad \left(\frac{T_2'}{T_2\sqrt{T_1}}\right)' \neq 0;\ (2)\quad \left(\frac{T_2'}{T_2\sqrt{T_1}}\right)' = 0.$$

Case (1): In this case, we have $T_2' \neq 0$ and hence Eq. (22) gives $A_1 = A_1(t)$. Using these in Eq. (26), it follows that

$$\frac{T_2'}{T_0\sqrt{T_1}} g_5(t) + 2A_1(t) = 0, \tag{28}$$

which implies that $g_5 = 0$ and $A_1 = 0$. Thus we have from Eqs. (21) and (23) $A_5 = 0$, $A_4 = c_0$. Also, Eqs. (24) and (25) yield

$$g_2 = 0 = g_3,\ c_2 = 0 = c_3. \tag{29}$$

Now from Eqs. (19) and (20), we have

$$A_j' = 0,\ \ddot{A}_j = 0,\ \dot{f}_j = 0\ \ (j = 2,3), \tag{30}$$

which gives

$$A_j(t,x) = \sqrt{\frac{T_0}{T_2}} c_j t + c_{j+2}. \tag{31}$$

Since $A_j'(t,x) = 0$ which implies that either

$$(a)\quad \left(\frac{T_0}{T_2}\right)' = 0,\quad \text{or}\ (b)\quad \left(\frac{T_0}{T_2}\right)' \neq 0.$$

In the first case 1(a), we have the following MCs:

$$\begin{gathered}\xi_{(1)} = \partial_t,\ \ \xi_{(2)} = \partial_y,\ \ \xi_{(3)} = \partial_z,\ \ \xi_{(4)} = z\partial_y - y\partial_z, \\ \xi_{(5)} = t\partial_z - \frac{T_2}{T_0} z\partial_t,\quad \xi_{(6)} = t\partial_y - \frac{T_2}{T_0} y\partial_t.\end{gathered} \tag{32}$$

Thus we obtain six independent MCs in which four are the usual isometries of the plane symmetry and the rest are the proper MCs. The MCs for the case 1(b) turns out to be the same as the minimal isometries for the plane symmetry.

Case (2): This case implies that $T_2'/T_2\sqrt{T_1} = \alpha$, where α is an arbitrary constant and can have the following two subcases according as α is nonzero or zero.

$$(a)\quad \alpha \neq 0,\quad (b)\quad \alpha = 0.$$

For the case 2(a), we use Eqs. (20), (22), (24), and (25) so that

$$g_2 = 2c_2/\alpha,\ g_3 = -2c_3/\alpha,\ A_1' = 0, \tag{33}$$

and

$$\left(\frac{T_2}{T_0}\right)' \dot{A}_i = 0. \tag{34}$$

The last equation further gives us the following two possibilities:

$$\text{(i)} \quad \left(\frac{T_2}{T_0}\right)' \neq 0, \quad \text{(ii)} \quad \left(\frac{T_2}{T_0}\right)' = 0.$$

In the first case 2a(i), Eqs. (20), (21), (23), (25), (36), and (37) imply that

$$A_5 = c_5,\ T_0' A_i' = 0,\ A_5 = -\frac{2c_5}{\alpha\sqrt{T_1}},\ A_4' = 0, \tag{35}$$

and

$$\dot{A}_4 = \frac{T_0'}{\alpha T_0 \sqrt{T_1}} c_5. \tag{36}$$

This last equation implies that for $(T_0'/T_0\sqrt{T_1})' \neq 0$, we have the same MCs as KVs. When $T_0'/T_0\sqrt{T_1} = \beta$, where β is an arbitrary constant, this further gives the following two subcases:

$$(*) \quad \beta \neq 0; \quad (**) \quad \beta = 0.$$

The case 2ai(*), in addition to the usual isometries of plan symmetry, gives the following one proper MC:

$$\xi_{(5)} = \frac{\beta}{\alpha} t\partial_t - \frac{2}{\alpha\sqrt{T_1}}\partial_x + y\partial_y + z\partial_z. \tag{37}$$

For the case 2ai(**), we have $T_0 = \text{const}$ and we obtain the following MCs:

$$\xi_{(5)} = yz + \left(\frac{z^2}{2} - \frac{y^2}{2} - \frac{2}{\alpha^2 T_2}\right)\partial_z,$$

$$\xi_{(6)} = yz - \left(\frac{z^2}{2} - \frac{y^2}{2} + \frac{2}{\alpha^2 T_2}\right)\partial_y, \tag{38}$$

$$\xi_{(7)} = y\partial_y + z\partial_z.$$

This implies that we have seven independent MCs in which three are the proper MCs.

In the case 2a(ii), we obtain $T_2 = \gamma T_0$, where γ is an arbitrary constant and this yields the following MCs:

$$\xi_{(5)} = \frac{1}{2}\left(t^2 - \frac{4}{\alpha^2 T_0} - \gamma y^2 - \gamma z^2\right)\partial_t + \frac{2}{\alpha\sqrt{T_1}}\partial_x + ty\partial_y + tz\partial_z,$$

$$\xi_{(6)} = \frac{1}{\gamma} tz\partial_t + \frac{2}{\alpha^2\sqrt{T_1}} z\partial_x + yz\partial_y - \frac{1}{2}\left(\frac{t^2}{\gamma} + \frac{4}{\alpha^2 T_2} + y^2 - z^2\right)\partial_z,$$

$$\xi_{(7)} = z\partial_t - t\partial_z,$$

$$\xi_{(8)} = \frac{1}{\gamma} ty\partial_t + \frac{2}{\alpha^2\sqrt{T_1}} y\partial_x - \frac{1}{2}\left(\frac{t^2}{\gamma} + \frac{4}{\alpha^2 T_2} - y^2 + z^2\right)\partial_y - yz\partial_z,$$

$$\xi_{(9)} = y\partial_t - t\partial_y,$$

$$\xi_{(10)}=t\partial_t+\frac{2}{\alpha\sqrt{T_1}}\partial_x+y\partial_y+z\partial_z. \tag{39}$$

This shows that we have ten independent MCs including six proper MCs.

The case 2(b) implies that $T_2=\text{const}$ which yields that either

$$\text{(i)}\quad \left(\frac{(\sqrt{T_0})'}{\sqrt{T_1}}\right)'=0 \quad \text{or} \quad \text{(ii)}\quad \left(\frac{(\sqrt{T_0})'}{\sqrt{T_1}}\right)'\neq 0$$

For the first possibility 2b(i), we have $(\sqrt{T_0})'/\sqrt{T_1}=\delta$, where δ is an arbitrary constant and gives two possibilities according to whether it is nonzero or zero:

$$(*)\quad \delta\neq 0, \quad (**)\quad \delta=0.$$

For the case 2bi(*), we obtain the following MCs:

$$\begin{aligned}
\xi_{(5)}&=\frac{T_2}{\sqrt{T_0}}z\sin\delta t\partial_t-\frac{T_2}{\sqrt{T_1}}z\cos\delta t\partial_x+\frac{T_0}{\delta}\cos\delta t\partial_z,\\
\xi_{(6)}&=\frac{T_2}{\sqrt{T_0}}z\cos\delta t\partial_t+\frac{T_2}{\sqrt{T_1}}z\sin\delta t\partial_x-\frac{T_0}{\delta}\sin\delta t\partial_z,\\
\xi_{(7)}&=\frac{T_2}{\sqrt{T_0}}y\sin\delta t\partial_t-\frac{T_2}{\sqrt{T_1}}y\cos\delta t\partial_x+\frac{T_0}{\delta}\cos\delta t\partial_y,\\
\xi_{(8)}&=\frac{T_2}{\sqrt{T_0}}y\cos\delta t\partial_t+\frac{T_2}{\sqrt{T_1}}y\sin\delta t\partial_x-\frac{T_0}{\delta}\sin\delta t\partial_y,\\
\xi_{(9)}&=\frac{1}{\sqrt{T_0}}\sin\delta t\partial_t-\frac{1}{\sqrt{T_1}}\cos\delta t\partial_x,\\
\xi_{(10)}&=\frac{1}{\sqrt{T_0}}\cos\delta t\partial_t+\frac{1}{\sqrt{T_1}}\sin\delta t\partial_x,
\end{aligned} \tag{40}$$

which yields ten independent MCs having six proper MCs.

In the case of 2bi(**), we have the following MCs:

$$\begin{aligned}
\xi_{(5)}&=\frac{T_2}{\sqrt{T_1}}z\partial_x-\int\sqrt{T_1}dx\partial_z,\\
\xi_{(6)}&=\frac{T_2}{\sqrt{T_1}}y\partial_x-t\partial_z,\\
\xi_{(7)}&=\frac{T_2}{\sqrt{T_1}}z\partial_t-\int\sqrt{T_1}dx\partial_y,\\
\xi_{(8)}&=\frac{T_2}{\sqrt{T_1}}y\partial_t-t\partial_y,
\end{aligned} \tag{41}$$

$$\xi_{(9)}=\frac{1}{T_0}\int \sqrt{T_1}dx\partial_t-\frac{1}{\sqrt{T_1}}t\partial_x,$$

$$\xi_{(10)}=\frac{1}{\sqrt{T_1}}\partial_x,$$

giving ten independent MCs with six proper MCs.

The case 2b(ii) further implies the following two possibilities:

$$(*)\quad \left(\frac{T_0}{2}\sqrt{T_1}\left(\frac{T_0'}{T_0\sqrt{T_1}}\right)'\right)'=0;\quad (**)\quad \left(\frac{T_0}{2}\sqrt{T_1}\left(\frac{T_0'}{T_0\sqrt{T_1}}\right)'\right)'\neq 0.$$

For 2bii(*), we have $(T_0/2)\sqrt{T_1}(T_0'/T_0\sqrt{T_1})'=\epsilon$, where ϵ is an integration constant and gives further two cases when

$$(+)\quad \epsilon=0 \qquad \text{and} \quad (++)\quad \epsilon\neq 0.$$

In the case 2bii*(+), we have $T_0'/T_0\sqrt{T_1}=\chi\neq 0$, and this gives the following MCs:

$$\xi_{(5)}=\left(\frac{1}{\chi T_0}-\frac{\chi}{4}t^2\right)\partial_t+\frac{1}{\sqrt{T_1}}t\partial_x,$$

$$\xi_{(6)}=\frac{\chi}{2}t\partial_t+\frac{1}{\sqrt{T_1}}\partial_x, \tag{42}$$

yielding six independent MCs.

For the case 2bii*(++), we obtain

$$\xi_{(5)}=\left(\frac{1}{T_0}\partial_t-\frac{1}{\sqrt{T_1}}\partial_x\right)e^{\sqrt{\eta}t},$$

$$\xi_{(6)}=\left(\frac{1}{T_0}\partial_t+\frac{1}{\sqrt{T_1}}\partial_x\right)e^{-\sqrt{\eta}t}, \tag{43}$$

giving six independent MCs.

In the case 2bii(**), we get MCs equal to the KVs.

III. MATTER COLLINEATIONS IN THE DEGENERATE CASE

In this section only those cases will be considered for which the energy–momentum tensor is degenerate, i.e., $\det(T_{ab})=0$. Thus we would discuss the space–times when at least one of the T_a or their combination is zero. When $T_a=0$, we have trivially every direction is an MC. The remaining cases can be classified as follows: (1) When only one T_a is nonzero; (2) when two T_a's are nonzero; and (3) when three T_a's are nonzero.

Case (1): This can further be grouped as follows: (a) $T_0\neq 0$, $T_i=0$; (b) $T_1\neq 0$, $T_j=0$, $(i=1,2,3)$, $(j=0,2,3)$.

The case 1(a) yields two possibilities according as $T_0'=0$ or $T_0'\neq 0$. For the first possibility, we get

$$\xi^0=c_0,\quad \xi^i=\xi^i(x^a). \tag{44}$$

The second possibility implies that

$$\xi^0=\xi^0(t),\quad \xi^1=-\frac{2T_0}{T_0'}\dot{\xi}^0(t),\quad \xi^k=\xi^k(x^a)\quad (k=2,3). \tag{45}$$

Thus we have infinite-dimensional MCs.

The case 1(b) can be solved trivially and gives

$$\xi^1=\frac{c_1}{\sqrt{T_1}},\quad \xi^j=\xi^j(x^a), \tag{46}$$

which implies infinite-dimensional MCs.

Case (2): This case can be divided into the following cases: (a) $T_l=0,\ T_k\neq 0$ ($l=0,1$ and $k=2,3$); (b) $T_l\neq 0,\ T_k=0$.

In the first case, if we take $T_2=$const, then we have the following MCs:

$$\xi^l=\xi^l(x^a),\quad \xi^2=c_0z+c_1,\quad \xi^3=-c_0y+c_2, \tag{47}$$

which gives infinite-dimensional MCs. For $T_2'\neq 0$, we again have infinite-dimensional MCs given by

$$\xi^0=\xi^0(x^a), \tag{48}$$

$$\xi^1=-\frac{T_2}{T_2'}(f'(u)+g'(u)), \tag{49}$$

$$\xi^2=f(u)+g(v), \tag{50}$$

$$\xi^3=\iota(-f(u)+g(v))+c_0, \tag{51}$$

where $u=y+\iota z$ and $v=y-\iota z$.

For the second case 2(b), it follows from Eqs. (4)–(7) and (9)–(10) that $\xi^l=\xi^l(t,x)$, $\xi^k=\xi^k(x^a)$. Also, Eq. (8) yields $\xi^1=f(t)/T_1$. If we use this value in Eqs. (4)–(5) and eliminate ξ^0, we have

$$\ddot{f}(t)=\frac{T_0}{\sqrt{T_1}}\left(\frac{T_0'}{2T_0\sqrt{T_1}}\right)'f(t). \tag{52}$$

From this equation, we see that for $f=0$, we have infinite-dimensional MCs given by

$$\xi^0=c_0,\quad \xi^l=0,\quad \xi^k=\xi^k(x^a). \tag{53}$$

For $f(t)\neq 0$, we have

$$\frac{\ddot{f}(t)}{f(t)}=\frac{T_0}{\sqrt{T_1}}\left(\frac{T_0'}{2T_0\sqrt{T_1}}\right)'=\alpha, \tag{54}$$

where α is an arbitrary constant. This gives two possibilities: either $\alpha=0$ or $\alpha\neq 0$. For the first possibility, we obtain $T_0'/2T_0\sqrt{T_1}=\beta$, an arbitrary constant. This again yields the infinite-dimensional MCs given by

$$\xi^0=c_1\left(-\frac{\beta}{2}t^2-\int\frac{\sqrt{T_1}}{T_0}dx\right)-c_2\beta t+c_0, \tag{55}$$

$$\xi^l=\frac{1}{T_1}(c_1t+c_2), \tag{56}$$

$$\xi^k=\xi^k(x^a). \tag{57}$$

When $\alpha\neq 0$, we have infinite-dimensional MCs as follows:

$$\xi^0=-\frac{T_0'}{2T_0\sqrt{\alpha T_1}}(c_1e^{\sqrt{\alpha}t}-c_2e^{-\sqrt{\alpha}t}+c_3), \tag{58}$$

$$\xi^l=\frac{1}{T_1}(c_1e^{\sqrt{\alpha}t}+c_2e^{-\sqrt{\alpha}t}), \tag{59}$$

$$\xi^k=\xi^k(x^a). \tag{60}$$

Case (3): This case can be divided as follows: (a) $T_0=0,\ T_i\neq 0$; (b) $T_1=0,\ T_j\neq 0$.

In the case 3(a), it is easy to see that Eqs. (4)–(7) imply that ξ^0 is an arbitrary function of four variables while $\xi^i=\xi^i(x,y,z)$. Further, it follows from Eqs. (8)–(11) and (13) that

$$A_1(y,z)_{,kk}-\left(\frac{T_2'}{2T_2\sqrt{T_1}}\right)'\frac{T_2}{\sqrt{T_1}}A_1(y,z)=0. \tag{61}$$

From here we have two possibilities—either $A_1=0$ or $A_1\neq 0$. For the first possibility, we have the following MCs:

$$\xi^0=\xi^0(x^a),\quad \xi^1=0,\quad \xi^2=c_1z+c_2,\quad \xi^3=-c_1y+c_3. \tag{62}$$

When $A_1\neq 0$, we obtain

$$\frac{A_1(y,z)_{,kk}}{A_1(y,z)}=\left(\frac{T_2'}{2T_2\sqrt{T_1}}\right)'\frac{T_2}{\sqrt{T_1}}=\alpha, \tag{63}$$

where α is an arbitrary constant which may be zero or nonzero. The possibility $\alpha=0$ implies that $T_2'/T_2\sqrt{T_1}=\beta$, an arbitrary constant and we have the following MCs:

$$\xi^0=\xi^0(x^a), \tag{64}$$

$$\xi^1=\frac{1}{\sqrt{T_1}}((c_1y+c_2)z+c_3y+c_4), \tag{65}$$

$$\xi^2=-\left[\left(\frac{\beta}{4}y^2+\int\sqrt{T_1}T_2dx\right)c_1z+\frac{\beta c_2}{2}yz+\left(\frac{\beta}{4}(y^2-z^2)+\int\sqrt{T_1}T_2dx\right]c_3+\frac{\beta c_4}{2}y-c_5z+c_7, \tag{66}$$

$$\xi^3=-\left[\left(\frac{\beta}{4}z^2+\int\sqrt{T_1}T_2dx\right)c_1y+\frac{\beta c_3}{2}yz+\left(\frac{\beta}{4}(z^2-y^2)+\int\sqrt{T_1}T_2dx\right)c_2+\frac{\beta c_4}{2}z\right]+c_5y+c_6. \tag{67}$$

For $\alpha\neq 0$, the MCs are given by

$$\xi^0=\xi^0(x^a),\quad \xi^1=0,\quad \xi^2=c_0z+c_1,\quad \xi^3=-c_0y+c_2. \tag{68}$$

In the case 3(b), when $T_0=\gamma$ and $T_2=\delta$, where γ and δ are arbitrary constants, we have the following MCs:

$$\xi^0=c_4y+c_5z+c_0, \tag{69}$$

$$\xi^1=\xi^1(x^a), \tag{70}$$

$$\xi^2=c_1z-\frac{\delta c_4}{\gamma}t+c_3, \tag{71}$$

$$\xi^3=-c_1y-\frac{\delta c_5}{\gamma}t+c_3. \tag{72}$$

If $T_0'\neq 0$ and $T_2'=0$, the MCs are given by

$$\xi^0=f(t),\quad \xi^1=-\frac{2T_0}{T_0'}\dot{f}(t),\quad \xi^2=c_1z+c_2,\quad \xi^3=-c_1y+c_3. \tag{73}$$

When $T_2'\neq 0$ and $T_0'T_2/T_0T_2'=\epsilon=0$, we obtain the following MCs:

$$\xi^0=c_0, \tag{74}$$

$$\xi^1=-\frac{2T_2}{T_2'}(f'(u)+g'(v)), \tag{75}$$

$$\xi^2=f(u)+g(v), \tag{76}$$

$$\xi^3=-\iota(f(u)-g(v))+c_1, \tag{77}$$

where $u=y+\iota z$ and $v=y-\iota z$. For $T_2'\neq 0$, $\epsilon\neq 0$ and $(T_0/T_2)'\neq 0$, the proper MCs are given by

$$\begin{aligned}\xi_{(5)}&=t\partial_t-\frac{2T_0}{T_0'}\partial_x,\\ \xi_{(6)}&=\iota(z\partial_y-y\partial_z).\end{aligned} \tag{78}$$

This gives two proper MCs. If $T_2'\neq 0$, $T_0=\lambda T_2$ and $T_0'\neq 0$, we get

$$\begin{aligned}\xi_{(5)}&=\frac{1}{\lambda}\left[ty\partial_t-\frac{2T_2}{T_2'}y\partial_x+\frac{1}{2}(y^2-z^2-\lambda t^2)\partial y+yz\,\partial z\right],\\ \xi_{(6)}&=tz\partial_t-\frac{2T_2}{T_2'}z\partial_x+yz\,\partial y-\frac{1}{2}(y^2-z^2-\lambda t^2)\partial z,\\ \xi_{(7)}&=t\partial t-\frac{2T_2}{T_2'}\partial_x+y\partial y+z\partial z,\\ \xi_{(8)}&=\frac{1}{2\lambda}(y^2+z^2-\lambda t^2)\partial_t+\frac{2T_2}{T_2'}t\partial_x-ty\,\partial y-tz\,\partial z,\\ \xi_{(9)}&=\frac{1}{\lambda}y\partial t-t\,\partial y,\end{aligned} \tag{79}$$

$$\xi_{(10)}=\frac{1}{\lambda}z\partial t-t\,\partial t,$$

which yields six proper MCs. Finally, when $T_2'\neq 0$ and $(T_0'T_2/T_0T_2')'\neq 0$, we have four independent MCs which are exactly the isometries of the plane symmetry. It is interesting to note that the last three subcases of this case give finite-dimensional MCs even for the degenerate case.

IV. EXAMPLES ADMITTING PROPER MCs

In this section we construct examples which admit proper MCs for the nondegenerate energy–momentum tensor. It can be seen from Eq. (A3) that the energy–momentum tensor will be nonzero when neither of the metric functions ν and μ are constants. If we choose these ν and μ such that $\nu=a\ln x+b$, $\mu=c\ln x+d$, where a,b,c,d are constants with $a\neq c$ then

$$\frac{T_2'}{T_2\sqrt{T_1}}=\frac{2(c-2)}{\sqrt{c(c+2a)}}=\text{const}=\alpha\neq 0, \tag{80}$$

$$\frac{T_0'}{T_0\sqrt{T_1}}=\frac{2(a-2)}{\sqrt{c(c+2a)}}=\text{const}=\beta\neq 0. \tag{81}$$

This shows that $\alpha\neq\beta$ as $a\neq c$ and hence the metric

$$ds^2=x^a\,dt^2-dx^2-x^c(dy^2+dz^2), \tag{82}$$

admits five MCs. It is pointed out that this metric possesses four KVs and therefore we have one proper MC given by Eq. (37). It can easily be shown that this space–time satisfies the conditions of the case 2ai(*).

If we choose $c=2$ and $a\geqslant 0$ but $a\neq 2$ in Eq. (82), it admits six MCs whereas this metric has four isometries and hence in this case we have two proper MCs as given by Eq. (42). The resulting space–time will satisfy the constraints of the case 2bii*(+).

When we choose $a=2$ and $c\geqslant 0$ but $c\neq 2$ in the metric given by Eq. (82), it yields seven MCs in which four are the usual isometries while the remaining three are the proper MCs. This satisfies the conditions of the case 2ai(**). Finally, if we choose $\nu=ax=\mu$, then we obtain ten independent MCs and the constraint equations for the case 2a(ii) are satisfied. The corresponding space–time will take the following form:

$$ds^2=e^{ax}(dt^2-dy^2-dz^2)-dx^2. \tag{83}$$

This is the well known anti-de Sitter metric which has ten KVs and consequently in this case we have no proper MC.

V. DISCUSSION AND CONCLUSION

It is known[14] that when we classify plane symmetric space–times according to their KVs, we get metrics which admit ten isometries (the spaces of constant curvature), a space–time which admits seven KVs (the Einstein metric) and a metric which has five KVs. There do not exist metrics admitting G_9 and G_8 as the maximal isometry groups.[15,16] The metric admitting five isometries is given by

$$ds^2=e^{\nu(x)}dt^2-dx^2-e^{2(x/a)}(dy^2+dz^2)\quad(a\neq 0), \tag{84}$$

where a is an arbitrary constant.

If we take μ to be constant and $\nu(x)$ either $\ln\cosh^2 ax$, or $2ax$ or $\ln\cos^2 ax$, we obtain three different metrics corresponding to each value of ν with six KVs each. This corresponds to the

TABLE I. MCs for the nondegenerate case.

Cases	MCs	Constraints
1a	6	$\left(\frac{T_2'}{T_2\sqrt{T_1}}\right)' \neq 0,\ \left(\frac{T_0}{T_2}\right)' = 0$

2bii**	4	$\left(\frac{T_2'}{T_2\sqrt{T_1}}\right)' = 0,\ \frac{T_2'}{T_2\sqrt{T_1}} = 0,\ \left(\frac{(\sqrt{T_0})'}{T_1}\right)' \neq 0,$ $\left(\frac{T_0}{2}\sqrt{T_1}\left(\frac{T_0'}{T_0\sqrt{T_1}}\right)'\right)' \neq 0$

degenerate case. The six isometries of each metric are given by Eqs. (B2), (B3), and (B3) in Appendix B. These isometries satisfy the algebra $SO(2)\circledS R^2]\otimes SO(1,2)$ isomorphic to $SO(2)\circledS R^2]\otimes SO(3)$ over complex fields. If we choose μ and ν both to be constant, then the space–time turns out to the Minkowski space–time. All metrics other than those given above admit only the minimal isometry group G_4 satisfying the algebra $[SO(2)\circledS R^2]\otimes R$.

In a recent paper,[12] some interesting results have been obtained when we classify spherically symmetric space–times according to their energy–momentum tensor. In this paper, we have extended the same procedure to classify static plane symmetric space–times according to their MCs.

In the nondegenerate case, we obtain either four, five, six, seven, or ten independent MCs. These contain the usual four isometries of the plane symmetry and the rest are the proper MCs. For the degenerate energy–momentum tensor, most of the cases give infinite-dimensional MCs. The cases worth mentioning are those where we have a finite number of MCs even when the energy–momentum tensor is zero. We obtain three such different cases having either four, six, or ten independent MCs. The results are summarized in the form of Tables I and II given below.

From these tables, it follows that each case has different constraints on the energy–momentum tensor. Finally, we have constructed some particular examples satisfying constraints of the four different cases given by 2ai(*), 2ai(**), 2a(ii), and 2bii*(+). We have seen that the constraints

TABLE II. MCs for the degenerate case (only finite cases).

Cases	MCs	Constraints
3bi	6	$T_1=0,\ T_j\neq 0 (j=0,2,3),\ T_2'\neq 0,\ \frac{T_0'T_2}{T_0T_2'}\neq 0,\ \left(\frac{T_0}{T_2}\right)'\neq 0$
3bii	10	$T_1=0,\ T_j\neq 0,\ T_2'\neq 0,\ T_0=\lambda T_2,\ T_0'\neq 0$
3biii	4	$T_1=0,\ T_j\neq 0,\ T_2'\neq 0,\ \frac{T_0'T_2}{T_0T_2'}\neq 0$

of the case 2ai(*) give one proper MC, the case 2ai(**) yields three proper MCs and the constraints of the case 2bii*(+) give two proper MCs. However, the constraints of the case 2a(ii) yield an anti–de Sitter metric which has ten isometries and hence there is no proper MC in this case. In all other cases, we would have four isometries and find the proper MCs immediately.

When the rank of T_a is 3, i.e. $T_1=0$, we obtain the following metric:

$$ds^2=e^{\nu}dt^2-dx^2-e^{-2\nu}(dy^2+dz^2), \tag{85}$$

where ν is an arbitrary function of x only. It can be easily verified that this class of metrics represent perfect fluid dust solutions. The energy–density for the above metrics is given as

$$\rho=(2\nu''-3\nu'^2)e^{\nu/2}. \tag{86}$$

It is remarked here that the general solution of the constraint equations does not necessarily give the interesting metrics. It may not even be necessary to get solved constraints generically. However, it would be interesting to solve the constraints involved or more examples should be constructed.

ACKNOWLEDGMENT

I would like to thank Ministry of Science and Technology (MOST), Pakistan for providing a postdoctoral fellowship at the University of Aberdeen, UK.

APPENDIX A

The surviving components of the Ricci tensor are

$$\begin{aligned} R_0&\equiv R_{00}=\tfrac{1}{4}e^{\nu}(2\nu''+\nu'^2+2\nu'\mu'),\\ R_1&\equiv R_{11}=-\tfrac{1}{4}(2\nu''+\nu'^2+4\mu''+2\mu'^2),\\ R_2&\equiv R_{22}=-\tfrac{1}{4}e^{\mu}(2\mu''+2\mu'^2+\nu'\mu'),\\ R_{33}&=R_{22}. \end{aligned} \tag{A1}$$

The Ricci scalar is given by

$$R=\tfrac{1}{2}(2\nu''+\nu'^2+2\nu'\mu'+3\mu'^2+4\mu''). \tag{A2}$$

Using Einstein field equations, the nonvanishing components of energy–momentum tensor T_{ab} are

$$T_0\equiv T_{00}=-\tfrac{1}{4}e^{\nu}(4\mu''+3\mu'^2),$$

$$T_1 \equiv T_{11} = \tfrac{1}{4}(\mu'^2 + 2\nu'\mu'),$$
$$T_2 \equiv T_{22} = \tfrac{1}{4}e^{\mu}(2\nu'' + \nu'^2 + \nu'\mu' + \mu'^2 + 2\mu''), \tag{A3}$$
$$T_{33} = T_{22}.$$

APPENDIX B

The four independent KVs associated with the plane symmetric space–times are given by[3]

$$\xi_{(1)} = \partial_t, \quad \xi_{(2)} = \partial_y, \quad \xi_{(3)} = \partial_z, \quad \xi_{(4)} = z\partial_y - y\partial_z. \tag{B1}$$

The six independent KVs associated with the plane symmetric space–times with ν either $\ln\cosh^2 ax$, or $2ax$ or $\ln\cos^2 ax$ and μ to be constant are given by

$$\xi_{(1)} = \partial_t, \quad \xi_{(2)} = \partial_y, \quad \xi_{(3)} = \partial_z, \quad \xi_{(4)} = z\partial_y - y\partial_z,$$
$$\xi_{(5)} = \cos at\,\partial_x - \sin at \tanh ax\,\partial_t, \tag{B2}$$
$$\xi_{(6)} = \sin at\,\partial_x - \cos ax \tanh ax\,\partial_t;$$

$$\xi_{(1)} = \partial_t, \quad \xi_{(2)} = \partial_y, \quad \xi_{(3)} = \partial_z,$$
$$\xi_{(4)} = z\partial_y - y\partial_z, \quad \xi_{(5)} = 2t\partial_x - at^2\partial_t, \tag{B3}$$
$$\xi_{(6)} = \partial_x - at\partial_t;$$

$$\xi_{(1)} = \partial_t, \quad \xi_{(2)} = \partial_y, \quad \xi_{(3)} = \partial_z, \quad \xi_{(4)} = z\partial_y - y\partial_z,$$
$$\xi_{(5)} = \cosh at\,\partial_x + \sin at \tan ax\,\partial_t, \tag{B4}$$
$$\xi_{(6)} = \sinh at\,\partial_x + \cos ax \tan ax\,\partial_t.$$

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 45, NUMBER 4 APRIL 2004

Symmetries of the energy-momentum tensor of cylindrically symmetric static space–times

M. Sharif[a)]
Department of Mathematics, University of the Punjab, Quaid-e-Azam Campus Lahore-54590, Pakistan

(Received 4 January 2004; accepted 9 January 2004)

We investigate matter symmetries of cylindrically symmetric static space–times. These are classified for both cases when the energy-momentum tensor is nondegenerate and also when it is degenerate. It is found that the nondegenerate energy-momentum tensor gives either *three*, *four*, *five*, *six*, *seven* or *ten* independent matter collineations in which *three* are isometries and the rest are proper. The worth mentioning cases are those where we obtain the group of matter collineations finite dimensional, even the energy-momentum tensor is degenerate. These are either *three*, *four*, *five* or *ten*. Some examples are constructed satisfying the constraints on the energy-momentum tensor. © *2004 American Institute of Physics.*

I. INTRODUCTION

Let M be a space–time manifold with Lorentz metric g of signature $(+,-,-,-)$. It is assumed that the manifold M, and the metric g, are smooth. There has been recent significant interest in the study of the various symmetries (in particular, Ricci and matter collineations) that arise in the exact solutions of Einstein's field equations (EFEs)

$$R_{ab}-\tfrac{1}{2}Rg_{ab}\equiv G_{ab}=\kappa T_{ab} \quad (a,b=0,1,2,3), \tag{1}$$

where κ is the gravitational constant, G_{ab} is the Einstein tensor, R_{ab} is the Ricci, and T_{ab} is the matter (energy-momentum) tensor. Also, $R=g^{ab}R_{ab}$ is the Ricci scalar. We have assumed here that the cosmological constant $\Lambda=0$. The theoretical basis for the study of the affine, conformal, projective, curvature (CCs) and Ricci collineations (RCs) has been analyzed and many examples have been discovered.[1–5] The symmetries of the energy-momentum tensor have recently been studied.

We define a differentiable vector field ξ on M to be a *matter collineation* if

$$\pounds_{\xi}T_{ab}=0, \tag{2}$$

where $\pounds$ is the Lie derivative operator, ξ^a is the symmetry or collineation vector. The study of matter collineations (MCs) derives from the mathematical interest in the invariance attributes of a geometrical object, i.e., Einstein tensor. Since the Einstein tensor is related to the matter content of the space–time by the EFEs, the investigation of MCs seems to be more relevant from the viewpoint of physics.

The study of symmetries played an important role in the classification of space–times, giving rise to many interesting results with useful applications. It is well known that two different collineations are not in general equivalent. For example, a Killing vector (KV) is a MC but the converse does not hold. Collineations have been classified by means of their relative properness by Katzin *et al.*[6,7] This classification indicates that the basic collineation is the KVs. The role of isometries is to restric the general form of the metric. Consequently, the number of independent

a)Electronic mail: hasharif@yahoo.com

field equations would reduce and it would be easy to find the exact solutions. It is noted that there are well-known metrics which do not have isometries.[8] This does not imply that they do not admit higher symmetries. The symmetry properties given by KVs lead to conservation laws.[9–11] A large number of solutions of the EFEs with different symmetry structures have been found[10] and classified according to their properties.[12] Symmetries of the energy-momentum tensor (also called matter collineations) provide conservation laws on matter fields. These enable us to know how the physical fields, occupying in certain region of space–times, reflect the symmetries of the metric.[13]

There is a large body of recent literature which shows interest in the study of MCs.[14–23] In a recent paper,[22] the study of MCs has been taken for spherically symmetric space–times and some interesting results have been obtained. We have also classified plane symmetric static space–times according to their MCs.[23] In this paper, we extend the procedure to calculate MCs of cylindrically symmetric static space–times both for nondegenerate and also for degenerate cases. Here we would not give details of the calculations as the procedure has been given in different papers.[22,23]

The MC Eq. (2) can be written in component form as

$$T_{ab,c}\xi^c + T_{ac}\xi^c_{,b} + T_{cb}\xi^c_{,a} = 0. \tag{3}$$

The most general form of cylindrically symmetric static space–time is given by

$$ds^2 = e^{\nu(r)}\,dt^2 - dr^2 - e^{\lambda(r)}\,d\theta^2 - e^{\mu(r)}\,dz^2. \tag{4}$$

The only nonzero components of the energy-momentum tensor, given in Appendix A, are T_{00}, T_{11}, T_{22}, T_{33}. We can write the MC equations as follows:

$$T_0'\xi^1 + 2T_0\xi^0_{,0} = 0, \tag{5}$$

$$T_1'\xi^1 + 2T_1\xi^1_{,1} = 0, \tag{6}$$

$$T_2'\xi^1 + 2T_2\xi^2_{,2} = 0, \tag{7}$$

$$T_3'\xi^1 + 2T_3\xi^3_{,3} = 0, \tag{8}$$

$$T_0\xi^0_{0,1} + T_1\xi^1_{,0} = 0, \tag{9}$$

$$T_0\xi^0_{,2} + T_2\xi^2_{,0} = 0, \tag{10}$$

$$T_0\xi^0_{,3} + T_3\xi^3_{,0} = 0, \tag{11}$$

$$T_1\xi^1_{,2} + T_2\xi^2_{,1} = 0, \tag{12}$$

$$T_1\xi^1_{,3} + T_3\xi^3_{,1} = 0, \tag{13}$$

$$T_2\xi^2_{,3} + T_3\xi^3_{,2} = 0, \tag{14}$$

where prime $'$ indicates differentiation with respect to r. These yield the first order nonlinear coupled partial differential equations in four variables $\xi^a(x^b)$. The components of the energy-momentum tensor depend only on r. Here we have used the notation $T_{aa} = T_a$ for the sake of brevity. We solve this set of equations for the nondegenerate case, when

$$\det(T_{ab}) = T_0T_1T_2T_3 \neq 0 \tag{15}$$

and for the degenerate case, where $\det(T_a) = 0$.

The rest of the paper is organized as follows. The next section contains brief comments and results about MCs. In Sec. III, we shall solve the MC equations when the energy-momentum

tensor is nondegenerate and in the next section MC equations are solved for the degenerate energy-momentum tensor. In Sec. V, we shall solve some of the constraints on energy-momentum tensor to obtain exact solution of EFEs. Section VI contains a summary and discussion of the results obtained.

II. SOME GENERAL COMMENTS

Let ξ be a matter collineation. All KVs, homothetic vectors and special conformal Killing vectors are MCs. However, the converse is not always true. In this case, the MC is called proper or nontrivial. The study of MCs has many associated problems. Here we list these in comparison with the other symmetries.

(1) When we define affine and conformal vector fields on M we usually assume that the vector field is at least C^2 and C^3, respectively. Then it follows from Hall *et al.*[4] that ξ^a must be a smooth vector field on M. However, for $k \in Z^+$ there exist MCs on smooth space–times which are C^k but not C^{k+1}.
(2) We know that an affine and conformal vector fields ξ^a on M are uniquely determined by specifying ξ^a and $\xi^a{}_{;b}$ and, respectively, by specifying ξ^a and the components of its first two covariant derivatives $\xi^a{}_{;b}$ and $\xi^a{}_{;bc}$ at some point $p \in M$. However, the value of ξ^a and all its derivatives at some point $q \in M$ may not be enough to determine uniquely a MC ξ^a on M. The fact is that two MCs which agree on a nonempty open subset of M may not agree on M.
(3) The set of all MCs on M is a vector space but in a similar way to the sets of CCs and RCs, and unlike the sets of affine and conformal vector fields, it could be infinite dimensional and could fail to be a Lie algebra. The problem here arises from the fact that such collineations must be C^1 in order that the defining equations make sense. It is unfortunate that a matter, Ricci or curvature collineation might turn out to be precisely C^1 and so the differentiability may be destroyed under the Lie bracket operation. On the other hand, if we assume that MCs are C^∞ then we recover the Lie algebra structure but we are then forced to expel the collineations which are not smooth. The infinite dimensionality may also lead to problems related to the orbits of the resulting local diffeomorphism.[4,24]
(4) If the energy-momentum tensor is of rank 4 everywhere then we can think of this tensor as a metric on the space–time M. It then follows from the theory of Killing vectors that the family of MCs is, in fact, a Lie algebra of smooth vector fields on M, of finite dimension, $\leqslant 10$, and, in addition, $\neq 9$ by Fubini's theorem.[12]

III. MATTER COLLINEATIONS IN THE NONDEGENERATE CASE

In this section, we shall evaluate MCs only for those cases which have nondegenerate energy-momentum tensor, i.e., $T_a \neq 0$.

When we solve Eqs. (5)–(14) simultaneously, we get the following constraint equation:

$$T_0' \xi^1_{,23} = 0. \tag{16}$$

This equation implies that either
(1) $T_0' = 0$,
or
(2) $T_0' \neq 0$.

Case 1: In the first case we have $T_0 = -k_1$, where k_1 is a nonzero constant which implies that the MC equations yield the following four possibilities:

$$(a_1) \quad T_2' = 0, \quad T_3' = 0,$$

$$(a_2) \quad T_2' = 0, \quad T_3' \neq 0,$$

$$(a_3)\quad T_2'\neq 0,\quad T_3'=0,$$

$$(a_4)\quad T_2'\neq 0,\quad T_3'\neq 0.$$

Subcase 1(a_1): This implies that $T_2=k_2$ and $T_3=k_3$, where k_2 and k_3 are nonzero constants. In this case, in addition to the nonproper MCs $\xi_{(1)}$, $\xi_{(2)}$, $\xi_{(3)}$ given in Appendix B, we obtain the following proper MCs:

$$\xi_{(4)}=\theta\partial_t+\frac{k_1}{k_2}t\partial_\theta,$$

$$\xi_{(5)}=-\frac{1}{k_1}\int\sqrt{T_1}\mathrm{d}r\,\partial_t+\frac{1}{\sqrt{T_1}}t\partial_r,$$

$$\xi_{(6)}=z\partial_t+\frac{k_1}{k_3}t\partial_z,$$

$$\xi_{(7)}=\frac{1}{\sqrt{T_1}}\partial_r, \tag{17}$$

$$\xi_{(8)}=\frac{\theta}{\sqrt{T_1}}\partial_r-\frac{1}{k_2}\int\sqrt{T_1}\mathrm{d}r\,\partial_\theta,$$

$$\xi_{(9)}=\frac{z}{\sqrt{T_1}}\partial_r-\frac{1}{k_3}\int\sqrt{T_1}\mathrm{d}r\,\partial_z,$$

$$\xi_{(10)}=z\partial_\theta-\frac{k_2}{k_3}\theta\partial_z.$$

Thus we have 10 independent MCs in which seven are proper.

Subcase 1(a_2): It follows that $T_2=k_2$, $T_3'\neq 0$ which further yields the following two cases:

$$(b_1)\quad\left[\frac{T_3}{\sqrt{T_1}}\left(\frac{T_3'}{2T_3\sqrt{T_1}}\right)'\right]'=0,$$

$$(b_2)\quad\left[\frac{T_3}{\sqrt{T_1}}\left(\frac{T_3'}{2T_3\sqrt{T_1}}\right)'\right]'\neq 0.$$

The case $1a_2(b_1)$ gives

$$\frac{T_3}{\sqrt{T_1}}\left(\frac{T_3'}{2T_3\sqrt{T_1}}\right)'=\alpha_1,$$

where α_1 is an arbitrary constant which may be

$$(c_1)\quad\alpha_1>0,\quad(c_2)\quad\alpha_1=0,\quad\text{or}\quad(c_3)\quad\alpha_1<0.$$

The first option $1a_2b_1(c_1)$, when $\alpha_1>0$, gives the following proper MCs:

$$\xi_{(4)}=\theta\partial_t+\frac{k_1}{k_2}t\partial_\theta,$$

$$\xi_{(5)}=\frac{e^{\sqrt{\alpha_1}z}}{\sqrt{T_1}}\partial_r-\frac{T_3'e^{\sqrt{\alpha_1}z}}{2\sqrt{\alpha_1}T_3\sqrt{T_1}}\partial_z, \tag{18}$$

$$\xi_{(6)}=\frac{e^{-\sqrt{\alpha_1}z}}{\sqrt{T_1}}\partial_r+\frac{T_3'e^{-\sqrt{\alpha_1}z}}{2\sqrt{\alpha_1}T_3\sqrt{T_1}}\partial_z.$$

The second option $1a_2b_1(c_2)$, when $\alpha_1=0$, yields the following three proper MCs:

$$\xi_{(4)}=\theta\partial_t+\frac{k_1}{k_2}t\partial_\theta,$$

$$\xi_{(5)}=\frac{1}{T_1}\partial_r-\alpha_2z\partial_z, \tag{19}$$

$$\xi_{(6)}=\frac{z}{\sqrt{T_1}}\partial_r-\left(\int\frac{\sqrt{T_1}}{T_3}\mathrm{d}r+\alpha_2\frac{z^2}{2}\right)\partial_z,$$

where $\alpha_2=T_3'/2T_3\sqrt{T_1}$ is a nonzero constant.

The third option $1a_2b_1(c_3)$ gives the same MCs as the first case $1a_2b_1(c_1)$.

When we solve MC equations for the case $1a_2(b_2)$, we have only one proper MC given by

$$\xi_{(4)}=\theta\partial_t+\frac{k_1}{k_2}t\partial_\theta. \tag{20}$$

Subcase 1(a_3): The subcase $1(a_3)$ is similar to the subcase $1(a_2)$ and MCs follow by interchanging θ and z coordinates.

Subcase 1(a_4): Here we have $T_2'\neq0$, $T_3'\neq0$ which gives rise to the following two possibilities:

$$(b_1)\quad\left[\frac{T_2}{\sqrt{T_1}}\left(\frac{T_2'}{2T_2\sqrt{T_1}}\right)'\right]'=0,$$

$$(b_2)\quad\left[\frac{T_2}{\sqrt{T_1}}\left(\frac{T_2'}{2T_2\sqrt{T_1}}\right)'\right]'\neq0.$$

The first possibility $1a_4(b_1)$ implies that $(T_2/\sqrt{T_1})(T_2'/2T_2\sqrt{T_1})'=\alpha_3$, where α_3 is an arbitrary constant such that

$$(c_1)\ \ \alpha_3>0,\quad (c_2)\ \ \alpha_3=0,\quad \text{or}\ \ (c_3)\ \ \alpha_3<0.$$

When α_3 is positive, $1a_4b_1(c_1)$, it further gives the following two options:

$$(d_1)\quad\left[\frac{T_3}{\sqrt{T_1}}\left(\frac{T_3'}{2T_3\sqrt{T_1}}\right)'\right]'=0,$$

$$(d_2)\quad\left[\frac{T_3}{\sqrt{T_1}}\left(\frac{T_3'}{2T_3\sqrt{T_1}}\right)'\right]'\neq0.$$

For the option $1a_4b_1c_1(d_1)$, we obtain similar result to the case $1a_2(b_1)$. The option $1a_4b_1c_1(d_2)$ gives the following two cases:

$$(e_1)\ \frac{T_2}{T_3}=\text{constant}\neq 0,\quad (e_2)\ \frac{T_2}{T_3}\neq\text{constant}.$$

The case $1a_4b_1c_1d_2(e_1)$ yields one proper MC,

$$\xi_{(4)}=z\partial_\theta-\frac{T_2}{T_3}\theta\partial_z, \tag{21}$$

and the case $1a_4b_1c_1d_2(e_2)$ gives three independent MCs.

The case $1a_4b_1(c_2)$, when $\alpha_3=0$, yields $T_2'/2T_2\sqrt{T_1}=\alpha_4$, where α_4 is a nonzero constant which gives either

$$(d_1)\ \left[\frac{T_3}{\sqrt{T_1}}\left(\frac{T_3'}{2T_3\sqrt{T_1}}\right)'\right]'=0,$$

or

$$(d_2)\ \left[\frac{T_3}{\sqrt{T_1}}\left(\frac{T_3'}{2T_3\sqrt{T_1}}\right)'\right]'\neq 0.$$

The first possibility $1a_4b_1c_2(d_1)$ further divides into three cases according to $(T_3/\sqrt{T_1})\,(T_3'/2T_3\sqrt{T_1})'=\alpha_1$,

$$(e_1)\ \alpha_1>0,\quad (e_2)\ \alpha_1=0,\quad \text{or}\ (e_3)\ \alpha_1<0.$$

The case $1a_4b_1c_2d_1(e_1)$, when $\alpha_1>0$, MCs turn out to be similar to the case $1a_2b_1(c_1)$. When $\alpha_1=0$, i.e., in the case $1a_4b_1c_2d_1(e_2)$, we have further two options, either

$$(f_1)\ \frac{T_3}{T_2}=k=\text{constant}\neq 0,\quad \text{or}\ (f_2)\ \frac{T_3}{T_2}\neq\text{constant}.$$

In the option $1a_4b_1c_2d_1e_2(f_1)$, we obtain the following four proper MCs:

$$\begin{aligned}
\xi_{(4)}&=-z\partial_\theta+\frac{\theta}{k}\partial_z,\\
\xi_{(5)}&=\frac{1}{\sqrt{T_1}}\partial_r-\alpha_2\theta\partial_\theta-\alpha_2 z\partial_z,\\
\xi_{(6)}&=\frac{\theta}{\sqrt{T_1}}\partial_r-\alpha_2\theta z\partial_z-\left(\int\frac{\sqrt{T_1}}{T_2}\mathrm{d}r+\alpha_2\frac{\theta^2}{2}-k\alpha_2\frac{z^2}{2}\right)\partial_\theta,\\
\xi_{(7)}&=\frac{z}{\sqrt{T_1}}\partial_r-\alpha_2\theta z\partial_\theta-\left(\int\frac{\sqrt{T_1}}{T_2}\mathrm{d}r-\alpha_2\frac{\theta^2}{2k}+\alpha_2\frac{z^2}{2}\right)\partial_z.
\end{aligned} \tag{22}$$

For the option $1a_4b_1c_2d_1e_2(f_2)$, there is only one proper MC

$$\xi_{(4)}=\frac{1}{\sqrt{T_1}}\partial_r+\theta\partial_\theta-\alpha_2 z\partial_z. \tag{23}$$

The case $1a_4b_1c_2d_1(e_3)$, when $\alpha_1<0$, yields similar solution as the case $1a_2b_1(c_3)$. The option $1a_4b_1c_2(d_2)$ gives similar result as the case $1a_4b_1c_1(d_2)$. The possibility $1a_4b_1(c_3)$, when $\alpha_3<0$, also gives similar solution as the case $1a_2b_1(c_1)$.

In the case $1a_4(b_2)$, we have either

$$(c_1)\ \frac{T_2}{T_3}=\text{constant}, \quad \text{or}\ \ (c_2)\ \frac{T_2}{T_3}\neq\text{constant}.$$

For the case $1a_4b_2(c_1)$, it coincides with $1a_4b_1c_1(d_2)$ and in the case $1a_4b_2(c_2)$, we get minimal MCs, i.e., three.

Case 2: Now we evaluate MCs for the case when $T_0'\neq 0$. This case implies that $\xi^1_{,23}=0$. Using this value in Eqs. (12)–(14), we obtain

$$\left(\frac{T_2}{T_3}\right)'\xi^2_{,3}=0. \tag{24}$$

This implies that either

$$(a_1)\ \left(\frac{T_2}{T_3}\right)'=0, \quad \text{or}\ \ (a_2)\ \left(\frac{T_2}{T_3}\right)'\neq 0.$$

Subcase 2(a_1): This yields $T_2/T_3=k_1$, where k_1 is a nonzero constant. Solving MC equations using this value, we obtain the following two cases:

$$(b_1)\ \left(\frac{T_2'}{2T_2\sqrt{T_1}}\right)'=0, \quad (b_2)\quad \left(\frac{T_2'}{2T_2\sqrt{T_1}}\right)'\neq 0.$$

The case $2a_1(b_1)$ implies that $T_2'/2T_2\sqrt{T_1}=\beta_1$, a constant which yields that either

$$(c_1)\ \ \beta_1=0, \quad \text{or}\ \ (c_2)\ \ \beta_2\neq 0.$$

For the case $2a_1b_1(c_1)$, when $\beta_1=0$, it yields the following two groups:

$$(d_1)\quad \left(\frac{(\sqrt{T_0})'}{\sqrt{T_1}}\right)'=0, \quad (d_2)\ \left(\frac{(\sqrt{T_0})'}{\sqrt{T_1}}\right)'\neq 0.$$

The first group $2a_1b_1c_1(d_1)$ gives 10 independent MCs in which seven are proper given by

$$\xi_{(4)}=z\partial_\theta-k_1\theta\partial_z,$$

$$\xi_{(5)}=\frac{1}{\sqrt{T_0}}\theta\sin k_2t\partial_t-\frac{1}{\sqrt{T_1}}\theta\cos k_2t\partial_r+\frac{\sqrt{T_0}}{k_2T_2}\cos k_2t\partial_\theta,$$

$$\xi_{(6)}=-\frac{1}{\sqrt{T_0}}\theta\cos k_2t\partial_t-\frac{1}{\sqrt{T_1}}\theta\sin k_2t\partial_r+\frac{\sqrt{T_0}}{k_2T_2}\sin k_2t\partial_\theta,$$

$$\xi_{(7)}=\frac{1}{k_1\sqrt{T_0}}z\sin k_2t\partial_t-\frac{1}{k_1\sqrt{T_1}}z\cos k_2t\partial_r+\frac{\sqrt{T_0}}{k_2T_2}\cos k_2t\partial_\theta, \tag{25}$$

$$\xi_{(8)}=-\frac{1}{k_1\sqrt{T_0}}z\cos k_2t\partial_t-\frac{1}{k_1\sqrt{T_1}}z\sin k_2t\partial_r+\frac{\sqrt{T_0}}{k_2T_2}\sin k_2t\partial_\theta,$$

$$\xi_{(9)}=\frac{1}{\sqrt{T_0}}\sin k_2 t\partial_t+\frac{1}{\sqrt{T_1}}\cos k_2 t\partial_r,$$

$$\xi_{(10)}=\frac{1}{\sqrt{T_0}}\cos k_2 t\partial_t+\frac{1}{\sqrt{T_1}}\sin k_2 t\partial_r,$$

where $k_2=(\sqrt{T_0})'/\sqrt{T_1}$ is a nonzero constant. The second group $2a_1b_1c_1(d_2)$ gives further two possibilities:

$$(e_1)\quad \frac{T_0}{2\sqrt{T_1}}\left(\frac{T_0'}{T_0\sqrt{T_1}}\right)'=\text{constant}=\beta_2,$$

$$(e_2)\quad \frac{T_0}{2\sqrt{T_1}}\left(\frac{T_0'}{T_0\sqrt{T_1}}\right)'\neq\text{constant}.$$

In the first possibility $2a_1b_1c_1d_2(e_1)$, we further have two options according to

$$(f_1)\ \ \beta_2=0,\quad (f_2)\ \ \beta_2\neq 0.$$

The option $2a_1b_1c_1d_2e_1(f_1)$ gives six independent MCs in which three proper MCs are given by

$$\xi_{(4)}=z\partial_\theta-k_1\theta\partial_z,$$

$$\xi_{(5)}=\left(\frac{1}{\beta_3 T_0}-\frac{\beta_3}{4}t^2\right)\partial_t+\frac{1}{\sqrt{T_1}}t\partial_r, \tag{26}$$

$$\xi_{(6)}=-\frac{\beta_3}{2}t\partial_t+\frac{1}{\sqrt{T_1}}\partial_r,$$

where $\beta_3=T_0'/T_0\sqrt{T_1}$ is a nonzero constant. The possibility $2a_1b_1c_1d_2e_1(f_2)$ also gives six independent MCs. The three proper MCs are

$$\xi_{(4)}=z\partial_\theta-k_1\theta\partial_z,$$

$$\xi_{(5)}=-\frac{T_0'}{2\sqrt{\beta_2}T_0\sqrt{T_1}}e^{\sqrt{\beta_2}t}\partial_t+\frac{1}{\sqrt{T_1}}e^{\sqrt{\beta_2}t}\partial_r, \tag{27}$$

$$\xi_{(6)}=\frac{T_0'}{2\sqrt{\beta_2}T_0\sqrt{T_1}}e^{-\sqrt{\beta_2}t}\partial_t+\frac{1}{\sqrt{T_1}}e^{-\sqrt{\beta_2}t}\partial_r.$$

The case $2a_1b_1c_1d_2(e_2)$ yields the same result as the case $1a_4b_1c_1(d_2)$, i.e., one proper MC.

The possibility $2a_1b_1(c_2)$, i.e., nonzero value of the constant β_1, gives us two more options:

$$(d_1)\ \ \left(\frac{T_2}{T_0}\right)'=0,\quad (d_2)\ \ \left(\frac{T_2}{T_0}\right)'\neq 0.$$

The first option $2a_1b_1c_2(d_1)$ gives 10 independent MCs. The seven proper MCs are

$$\xi_{(4)}=z\partial_\theta-k_1\theta\partial_z,$$

$$\xi_{(5)}=k_3\theta\partial_t+t\partial_\theta,$$

$$\xi_{(6)}=\frac{k_3}{k_1}z\partial_t+t\partial_z,$$

$$\xi_{(7)}=\frac{1}{2}\left(t^2-\frac{4}{\beta_1^2T_0}+k_3\theta^2+\frac{k_3}{k_1}z^2\right)\partial_t-\frac{2}{\beta_1\sqrt{T_1}}t\partial_r+t\theta\partial_\theta+tz\partial_z, \tag{28}$$

$$\xi_{(8)}=-k_1t\theta\partial_t+\frac{2k_1}{\beta_1\sqrt{T_1}}\theta\partial_r+\frac{1}{2}\left(-\frac{k_1}{k_3}t^2+\frac{4k_1}{\beta_1^2T_2}-k_1\theta^2+z^2\right)\partial_\theta-k_1\theta z\partial_z,$$

$$\xi_{(9)}=tz\partial_t-\frac{2}{\beta_1\sqrt{T_1}}z\partial_r+\theta z\partial_\theta+\frac{1}{2}\left(\frac{k_1}{k_3}t^2-\frac{4k_1}{\beta_1^2T_2}-k_1\theta^2+z^2\right)\partial_z,$$

$$\xi_{(10)}=t\partial_t-\frac{2}{\beta_1\sqrt{T_1}}\partial_r+\theta\partial_\theta+z\partial_z,$$

where $k_3=-T_2/T_0$ is a constant.

The second option $2a_1b_1c_2(d_2)$ further yields two possibilities,

$$(e_1)\ \left(\frac{T_0'}{T_0\sqrt{T_1}}\right)'=0,\quad (e_2)\ \left(\frac{T_0'}{T_0\sqrt{T_1}}\right)'\neq 0.$$

If it is zero, i.e., the case $2a_1b_1c_2d_2(e_1)$, we have the following two proper MCs:

$$\xi_{(4)}=z\partial_\theta-k_1\theta\partial_z,$$
$$\xi_{(5)}=\frac{\beta_4}{\beta_1}t\partial_t-\frac{2}{\beta_1\sqrt{T_1}}\partial_r+\theta\partial_\theta+z\partial_z, \tag{29}$$

where $\beta_4=T_0'/T_0\sqrt{T_1}$ is a constant such that $\beta_1\neq\beta_4$. If it is nonzero, i.e., $2a_1b_1c_2d_2(e_2)$, we have the same result as for the case $1a_4b_1c_1(d_2)$.

The case $2a_1(b_2)$, when $(T_2'/2T_2\sqrt{T_1})'\neq 0$, implies that $T_2'\neq 0$ which results the following two possibilities:

$$(c_1)\ \left(\sqrt{\frac{T_0}{T_2}}\right)'=0,\quad (c_2)\ \left(\sqrt{\frac{T_0}{T_2}}\right)'\neq 0.$$

The first possibility $2a_1b_2(c_1)$ gives six independent MCs in which three are the usual isometries and the remaining three are proper MCs given by

$$\xi_{(4)}=z\partial_\theta-k_1\theta\partial_z,$$
$$\xi_{(5)}=\theta\partial_t+k_4^2t\partial_\theta, \tag{30}$$
$$\xi_{(6)}=z\partial_t+k_1k_4^2t\partial_z,$$

where $k_4=\sqrt{T_0/T_2}$ is a constant. The second possibility $2a_1b_2(c_2)$ gives one proper MC as in the case $1a_1b_1c_1(d_2)$.

Subcase 2(a_2): Here we have $(T_2/T_3)'\neq 0$. If we use this constraint in MC Eqs. (7), (8), and (14), we have

$$T_2'\xi^1_{,3}=0=T_3'\xi^1_{,2}. \tag{31}$$

This gives rise to the following three possibilities:

$$(b_1)\quad T_2'=0,\quad T_3'\neq 0,$$

$$(b_2)\quad T_2'\neq 0,\quad T_3'=0,$$

$$(b_3)\quad T_2'\neq 0,\quad T_3'\neq 0.$$

In the first case, we can write

$$\frac{T_0}{\sqrt{T_1}}\left(\frac{T_0'}{2T_0\sqrt{T_1}}\right)'=\gamma_1,\quad \frac{T_3}{\sqrt{T_1}}\left(\frac{T_3'}{2T_3\sqrt{T_1}}\right)'=\gamma_2, \tag{32}$$

where γ_1 and γ_2 are arbitrary constants. From here we have the following four different cases:

$$(c_1)\quad \gamma_1=0,\quad \gamma_2=0,$$

$$(c_2)\quad \gamma_1\neq 0,\quad \gamma_2=0,$$

$$(c_3)\quad \gamma_1=0,\quad \gamma_2\neq 0,$$

$$(c_4)\quad \gamma_1\neq 0,\quad \gamma_2\neq 0.$$

The first case $2a_2b_1(c_1)$ can be divided into the following two options according to

$$(d_1)\quad \left(\frac{T_0}{T_3}\right)'=0,\quad \text{or}\quad (d_2)\quad \left(\frac{T_0}{T_3}\right)'\neq 0.$$

The first option $2a_2b_1c_1(d_1)$ gives seven independent MCs in which four are proper,

$$\begin{aligned}
\xi_{(4)}&=\left(\frac{\gamma_3}{2}t^2-\int\frac{\sqrt{T_1}}{T_0}dr+\frac{\gamma_3}{2k_1}z^2\right)\partial_t+\frac{1}{\sqrt{T_1}}t\partial_r+\gamma_3tz\partial_z,\\
\xi_{(5)}&=\gamma_3tz\partial_t+\frac{1}{\sqrt{T_1}}z\partial_r+\left(\frac{k_1\gamma_3}{2}t^2-\int\frac{\sqrt{T_1}}{T_3}\mathrm{d}r+\frac{\gamma_3}{2}z^2\right)\partial_z,\\
\xi_{(6)}&=\gamma_3t\partial_t+\frac{1}{\sqrt{T_1}}\partial_r+\gamma_3z\partial_z,\\
\xi_{(7)}&=z\partial_t+k_1t\partial_z,
\end{aligned} \tag{33}$$

where $k_1=-T_0/T_3$ and $\gamma_3=-T_0'/2T_0\sqrt{T_1}$ are constants. The second option $2a_2b_1c_1(d_2)$ yields only one proper MC given by

$$\xi_{(4)}=\gamma_3t\partial_t+\frac{1}{\sqrt{T_1}}t\partial_r+\gamma_4tz\partial_z, \tag{34}$$

where $\gamma_4=-T_3'/2T_3\sqrt{T_1}$.

In the case $2a_2b_1(c_2)$, when $\gamma_1\neq 0$, $\gamma_2=0$, we have either

$$(d_1)\quad \gamma_1>0,\quad \text{or}\quad (d_2)\quad \gamma_1<0.$$

For $2a_2b_1c_2(d_1)$, when $\gamma_1>0$, we obtain three independent MCs which are the usual isometries.

The case $2a_2b_1c_2(d_2)$, when $\gamma_1<0$, we have two options

$$(e_1)\ \left(\frac{T_0}{T_3}\right)'=0,\quad \text{or}\ (e_2)\ \left(\frac{T_0}{T_3}\right)'\neq 0.$$

For the case $2a_2b_1c_2d_2(e_1)$, we have only one proper MC given by

$$\xi_{(4)}=\frac{1}{k_1}z\partial_t+t\partial_z. \tag{35}$$

In the case $2a_2b_1c_2d_2(e_2)$, we obtain the minimal symmetry.

The case $2a_2b_1(c_3)$, when $\gamma_1=0$, $\gamma_2\neq 0$, is similar to the previous case $2a_2b_1(c_2)$ by interchanging t and z.

The case $2a_2b_1(c_4)$, when $\gamma_1\neq 0$, $\gamma_2\neq 0$, yields the following four different possibilities:

$$(d_1)\ \ \gamma_1>0,\quad \gamma_2>0,$$

$$(d_2)\ \ \gamma_1>0,\quad \gamma_2<0,$$

$$(d_3)\ \ \gamma_1<0,\quad \gamma_2>0,$$

$$(d_4)\ \ \gamma_1<0,\quad \gamma_2<0.$$

The first possibility further gives two options according to

$$(e_1)\ \ \gamma_2T_0\int\frac{\sqrt{T_1}}{T_0}\mathrm{d}r+\frac{T_3'}{2\sqrt{T_1}}=0,$$

$$\text{or}\ (e_2)\ \ \gamma_2T_0\int\frac{\sqrt{T_1}}{T_0}\mathrm{d}r+\frac{T_3'}{2\sqrt{T_1}}\neq 0.$$

The first option $2a_2b_1c_4d_1(e_1)$ gives the minimal symmetry. The second option $2a_2b_1c_4d_1(e_2)$ further gives two possibilities,

$$(f_1)\ \left(\frac{T_0}{T_3}\right)'=0,\quad (f_2)\ \left(\frac{T_0}{T_3}\right)'\neq 0.$$

The case $2a_2b_1c_4d_1e_2(f_1)$ yields four independent MCs in which the proper MC is given by

$$\xi_{(4)}=z\partial_t+k_1t\partial_z. \tag{36}$$

For the case $2a_2b_1c_4d_1e_2(f_2)$, we have three independent MCs.

All other cases $2a_2b_1c_4(d_2-d_4)$ are similar to the previous case $2a_2b_1c_4(d_1)$.

The case $2a_2(b_2)$, when $T_2'\neq 0$, $T_3'=0$, is similar to the first case $2a_2(b_1)$.

In the third case $2a_2(b_3)$, when $T_2'\neq 0$, $T_3'\neq 0$, we further have the following two possibilities:

$$(c_1)\ \left(\frac{T_2'}{2T_2\sqrt{T_1}}\right)'=0,\quad \left(\frac{T_3'}{2T_3\sqrt{T_1}}\right)'=0,$$

$$(c_2)\ \left(\frac{T_2'}{2T_2\sqrt{T_1}}\right)'\neq 0,\quad \left(\frac{T_3'}{2T_3\sqrt{T_1}}\right)'\neq 0.$$

For the first possibility $2a_2b_3(c_1)$, we obtain the following three options:

$$(d_1)\ \left(\frac{T_2}{T_0}\right)'=0,\quad \left(\frac{T_3}{T_0}\right)'\neq 0,$$

$$(d_2)\ \left(\frac{T_2}{T_0}\right)'\neq 0,\quad \left(\frac{T_3}{T_0}\right)'=0,$$

$$(d_3)\ \left(\frac{T_2}{T_0}\right)'\neq 0,\quad \left(\frac{T_3}{T_0}\right)'\neq 0.$$

The first option $2a_2b_3c_1(d_1)$ yields five independent MCs in which three are the usual KVs and the remaining are the proper MCs given by

$$\xi_{(4)}=\gamma_3 t\partial_t+\frac{1}{\sqrt{T_1}}\partial_r+\gamma_3\theta\partial_\theta+\gamma_4 z\partial_z,$$
$$\xi_{(5)}=k_2\theta\partial_t+t\partial_\theta, \tag{37}$$

where $k_2=-T_2/T_0$ is a nonzero constant. The second option $2a_2b_3c_1(d_2)$ is similar to the first one. The third case $2a_2b_3c_1(d_3)$ implies that either

$$(e_1)\ \left(\frac{T_0'}{2T_0\sqrt{T_1}}\right)'=0,\quad \text{or}\ (e_2)\ \left(\frac{T_0'}{2T_0\sqrt{T_1}}\right)'\neq 0.$$

For the first option $2a_2b_3c_1d_3(e_1)$, we get one proper MC given by

$$\xi_{(4)}=\gamma_3 t\partial_t+\frac{1}{\sqrt{T_1}}\partial_r+\gamma_3\theta\partial_\theta+\gamma_4 z\partial_z. \tag{38}$$

In the second option $2a_2b_3c_1d_3(e_2)$, we obtain the minimal symmetry.

The case $2a_2b_3(c_2)$ also yields the same three possibilities,

$$(d_1)\ \left(\frac{T_2}{T_0}\right)'=0,\quad \left(\frac{T_3}{T_0}\right)'\neq 0,$$

$$(d_2)\ \left(\frac{T_2}{T_0}\right)'\neq 0,\quad \left(\frac{T_3}{T_0}\right)'=0,$$

$$(d_3)\ \left(\frac{T_2}{T_0}\right)'\neq 0,\quad \left(\frac{T_3}{T_0}\right)'\neq 0.$$

It is to be noted that we have excluded the possibility when both are constants as this leads T_2/T_3 to be constant which gives a contradiction. The first case $2a_2b_3c_2(d_1)$ gives only one proper MC, i.e.,

$$\xi_{(4)}=k_2\theta\partial_t+t\partial_\theta. \tag{39}$$

The second case $2a_2b_3c_2(d_2)$ is similar to the previous one and the third case $2a_2b_3c_2(d_3)$ gives the minimal MCs.

IV. MATTER COLLINEATIONS IN THE DEGENERATE CASE

In this section only those cases will be considered for which $\det(T_{ab})=0$ which implies that at least one of the components of the energy-momentum tensor is zero, i.e., $T_a=0$. The trivial case is that when all T_a are zero. In this case, every direction is in a MC. The remaining cases can be divided into three main groups:

(1) when at least one of T_a is nonzero;
(2) when at least two of T_a are nonzero;
(3) when three of T_a are nonzero.

Case 1: This case can further be divided into the following four subcases:

$$(a_1)\quad T_0=0,\quad T_1=0,\quad T_2=0,\quad T_3\neq 0,$$

$$(a_2)\quad T_0=0,\quad T_1=0,\quad T_2\neq 0,\quad T_3=0,$$

$$(a_3)\quad T_0=0,\quad T_1\neq 0,\quad T_2=0,\quad T_3=0,$$

$$(a_4)\quad T_0\neq 0,\quad T_1=0,\quad T_2=0,\quad T_3=0.$$

When we use the values of $1(a_1)$ in MC equations, we obtain $\xi^3=\xi^3(z)$ and Eq. (9) gives

$$\xi^1=-\frac{2T_3}{T_3'}\xi^3_{,3}(z), \tag{40}$$

where $T_3'\neq 0$ and ξ^0, ξ^1 are arbitrary functions of t,r,θ,z. This gives infinite dimensional MCs. The second case $1(a_2)$ is similar to the first one if we interchange the indices 2 and 3.

The third case $1(a_3)$ gives $\xi^1=\xi^1(r)$ and Eq. (7) yields

$$\xi^1=\frac{c_1}{\sqrt{T_1}}, \tag{41}$$

where ξ^0, ξ^2, ξ^3 are arbitrary functions of t,r,θ,z which gives infinite dimensional MCs. The fourth case $1(a_4)$ yields the similar result as the case $1(a_1)$ by interchanging the indices 0 and 3. Thus we obtain infinite dimensional MCs in all the possibilities of the case 1.

Case 2: This case has the following six possibilities:

$$(a_1)\quad T_0=0,\quad T_1=0,\quad T_2\neq 0,\quad T_3\neq 0,$$

$$(a_2)\quad T_0=0,\quad T_1\neq 0,\quad T_2=0,\quad T_3\neq 0,$$

$$(a_3)\quad T_0=0,\quad T_1\neq 0,\quad T_2\neq 0,\quad T_3=0,$$

$$(a_4)\quad T_0\neq 0,\quad T_1=0,\quad T_2=0,\quad T_3\neq 0,$$

$$(a_5)\quad T_0\neq 0,\quad T_1=0,\quad T_2\neq 0,\quad T_3=0,$$

$$(a_6)\quad T_0\neq 0,\quad T_1\neq 0,\quad T_2=0,\quad T_3=0.$$

When we replace the information of the subcase $2(a_1)$ in MC equations, we obtain $\xi^0=\xi^0(t,r,\theta,z)$, $\xi^2=\xi^2(\theta,z)$, $\xi^3=\xi^3(\theta,z)$, and

$$\left(\frac{T_3}{T_2}\right)'\xi^3_{,2}=0. \tag{42}$$

From here we have two options:

$$(b_1)\ \left(\frac{T_3}{T_2}\right)'=0, \quad (b_2)\ \left(\frac{T_3}{T_2}\right)'\neq 0.$$

For the first option $2a_1(b_1)$, MC equations yield

$$\xi^2_{,22}+\frac{1}{c}\xi^2_{,33}=0, \tag{43}$$

$$\xi^3_{,22}+\frac{1}{c}\xi^3_{,33}=0, \tag{44}$$

where $c=T_3/T_2$ is a nonzero constant. If $c>0$, Eqs. (43) and (44) yield the following solution:

$$\xi^2=f_+\left(\theta+\frac{\iota z}{\sqrt{c}}\right)+f_-\left(\theta-\frac{\iota z}{\sqrt{c}}\right), \tag{45}$$

$$\xi^3=g_+\left(\theta+\frac{\iota z}{\sqrt{c}}\right)+g_-\left(\theta-\frac{\iota z}{\sqrt{c}}\right). \tag{46}$$

Replacing the value of ξ^2 in Eq. (8), we obtain

$$\xi^1=-\frac{2T_2}{T_2'}\left[f_{+,2}\left(\theta+\frac{\iota z}{\sqrt{c}}\right)+f_{-,2}\left(\theta-\frac{\iota z}{\sqrt{c}}\right)\right], \tag{47}$$

where $T_2'\neq 0$ and $\xi^0=\xi^0(t,r,\theta,z)$. If we take $T_2=$constant, MC equations give the following solution:

$$\begin{gathered}\xi^0=\xi^0(t,r,\theta,z), \quad \xi^1=\xi^1(t,r,\theta,z),\\ \xi^2=c_1z+c_2, \quad \xi^3=c_1\theta+c_3.\end{gathered} \tag{48}$$

The option $2a_1(b_2)$ further divides into three cases,

$$(c_1)\ \ T_2'=0, \quad T_3'\neq 0,$$

$$(c_2)\ \ T_2'\neq 0, \quad T_3'=0,$$

$$(c_3)\ \ T_2'\neq 0, \quad T_3'\neq 0.$$

In the case $2a_1b_2(c_1)$, we get the following solution:

$$\begin{gathered}\xi^0=\xi^0(t,r,\theta,z), \quad \xi^1=\frac{T_3}{T_3'}f(z),\\ \xi^2=c_1, \quad \xi^3=-\frac{1}{2}\int f(z)dz+c_2.\end{gathered} \tag{49}$$

The case $2a_1b_2(c_2)$ gives the similar results as the case $2a_1b_2(c_1)$ by interchanging θ and z.

If we solve MC equations for the possibility $2a_1b_2(c_3)$, we have the following solution:

$$\xi^0=\xi^0(t,r,\theta,z), \quad \xi^1=\frac{T_2}{T_2'}c_1,$$
$$\xi^2=c_1\theta+c_2, \quad \xi^3=c_3z+c_4. \tag{50}$$

For the subcase $2(a_2)$, we further have the following two options from MC equations:

$$(b_1)\quad \left[\frac{T_3}{\sqrt{T_1}}\left(\frac{T_3'}{2T_3\sqrt{T_1}}\right)'\right]'=0,$$
$$(b_2)\quad \left[\frac{T_3}{\sqrt{T_1}}\left(\frac{T_3'}{2T_3\sqrt{T_1}}\right)'\right]'\neq 0.$$

Also $\xi^0=\xi^0(t,r,\theta,z)$, $\xi^1=\xi^1(r,z)$, $\xi^2=\xi^2(r)$, $\xi^3=\xi^3(r,z)$. The first possibility $2a_2(b_1)$ gives $(T_3/\sqrt{T_1})\,(T_3'/2T_3\sqrt{T_1})'=c$, where c is an arbitrary constant which implies that either

$$(c_1)\ \ c>0, \quad (c_2)\quad c=0, \quad \text{or} \quad (c_3)\quad c<0.$$

The case $2a_2b_1(c_1)$ yields the following solution:

$$\xi^0=\xi^0(t,r,\theta,z),$$
$$\xi^1=\frac{1}{\sqrt{T_1}}(c_1e^{\sqrt{c}z}+c_2e^{-\sqrt{c}z}), \quad \xi^2=\xi^2(r,z), \tag{51}$$
$$\xi^3=-\frac{T_3'}{2\sqrt{c}T_3\sqrt{T_1}}(c_1e^{\sqrt{c}z}-c_2e^{-\sqrt{c}z})+c_3.$$

For the case $2a_2b_1(c_2)$, when $c=0$, we obtain

$$\xi^0=\xi^0(t,r,\theta,z),$$
$$\xi^1=\frac{1}{\sqrt{T_1}}(c_1z+c_2), \quad \xi^2=\xi^2(r,z), \tag{52}$$
$$\xi^3=-c_1\int\frac{\sqrt{T_1}}{T_3}\mathrm{d}r-\frac{T_3'}{2T_3\sqrt{T_1}}\left(c_1\frac{z^2}{2}+c_2z\right)+c_3.$$

In the case $2a_2b_1(c_3)$, when $c<0$, the solution is similar to the previous case $2a_2b_1(c_2)$.

The second possibility $2a_2(b_2)$ gives

$$\xi^0=\xi^0(t,r,\theta,z), \quad \xi^1=0,$$
$$\xi^2=\xi^2(r,z), \quad \xi^3=c_1. \tag{53}$$

The subcase $2(a_3)$ gives similar results as the case $2(a_2)$ by interchanging the indices 2 and 3.

The subcases $2(a_4)$ and $2(a_5)$ yield results similar to the case $2(a_1)$ if we interchange indices 0, 2 and 0, 3, respectively.

The subcase $2(a_6)$ would give similar result as the case $2(a_2)$ by interchanging the indices 0, 3. It is to be noted that we again have infinite dimensional MCs in the case 2.

Case 3: The case, when only one component of the energy-momentum tensor is zero, we have four different subcases:

$$(a_1)\quad T_0=0,\quad T_1\neq 0,\quad T_2\neq 0,\quad T_3\neq 0,$$

$$(a_2)\quad T_0\neq 0,\quad T_1=0,\quad T_2\neq 0,\quad T_3\neq 0,$$

$$(a_3)\quad T_0\neq 0,\quad T_1\neq 0,\quad T_2=0,\quad T_3\neq 0,$$

$$(a_4)\quad T_0\neq 0,\quad T_1\neq 0,\quad T_2\neq 0,\quad T_3=0.$$

The first subcase gives $\xi^0=\xi^0(t,r,\theta,z)$ with the following two possibilities:

$$(b_1)\quad \left[\frac{T_2}{\sqrt{T_1}}\left(-\frac{T_2'}{2T_2\sqrt{T_1}}\right)'\right]'=0,$$

$$(b_2)\quad \left[\frac{T_2}{\sqrt{T_1}}\left(-\frac{T_2'}{2T_2\sqrt{T_1}}\right)'\right]'\neq 0.$$

In the first possibility $3a_1(b_1)$, we have $(T_2/\sqrt{T_1})[-(T_2'/2T_2\sqrt{T_1})]'=\alpha_1$, where α_1 is an arbitrary constant which can be such that

$$(c_1)\quad \alpha_1>0,\quad (c_2)\quad \alpha_1=0,\quad (c_3)\quad \alpha_1<0.$$

The case $3a_1b_1(c_1)$, when $\alpha_1>0$ gives further three options according to $\alpha_2=(T_3/\sqrt{T_1})\times[-(T_3'/2T_3\sqrt{T_1})]'$,

$$(d_1)\quad \alpha_2>0,\quad (d_2)\quad \alpha_2=0,\quad (d_3)\quad \alpha_2<0.$$

The first option $3a_1b_1c_1(d_1)$, when $\alpha_2>0$, gives either

$$(e_1)\quad \sqrt{\frac{\alpha_1}{\alpha_2}}+\sqrt{\frac{\alpha_2}{\alpha_1}}=0,\quad \text{or}\quad (e_2)\quad \sqrt{\frac{\alpha_1}{\alpha_2}}+\sqrt{\frac{\alpha_2}{\alpha_1}}\neq 0.$$

For the first case $3a_1b_1c_1d_1(e_1)$, we obtain

$$\begin{aligned}&\xi^0=\xi^0(t,r,\theta,z),\quad \xi^1=0,\\ &\xi^2=c_1z+c_2,\quad \xi^3=c_1\theta+c_3.\end{aligned}\tag{54}$$

In the second case $3a_1b_1c_1d_1(e_2)$, we have the solution

$$\begin{aligned}&\xi^0=\xi^0(t,r,\theta,z),\quad \xi^1=0,\\ &\xi^2=c_1z+c_2,\quad \xi^3=-c_1k_1\theta+c_3,\end{aligned}\tag{55}$$

where $k_1=T_2/T_3$ is a constant.

The second option $3a_1b_1c_1(d_2)$, when $\alpha_2=0$, yields the following solution:

$$\begin{aligned}&\xi^0=\xi^0(t,r,\theta,z),\\ &\xi^1=\frac{1}{\sqrt{T_1}}[e^{\iota\sqrt{\alpha_1}\theta}(c_1z+c_2)+e^{-\iota\sqrt{\alpha_1}\theta}(c_3z+c_4)],\\ &\xi^2=-\frac{\iota T_2'\sqrt{T_1}}{2T_2\sqrt{T_1}}[e^{\iota\sqrt{\alpha_1}\theta}(c_1z+c_2)-e^{-\iota\sqrt{\alpha_1}\theta}(c_3z+c_4)]+c_5,\end{aligned}\tag{56}$$

$$\xi^3=-\alpha_3\left[e^{\iota\sqrt{\alpha_1}\theta}\left(c_1\frac{z^2}{2}+c_2z\right)+e^{-\iota\sqrt{\alpha_1}\theta}\left(c_3\frac{z^2}{2}+c_4z\right)\right]-[c_1e^{\iota\sqrt{\alpha_1}\theta}+c_3e^{-\iota\sqrt{\alpha_1}\theta}]\int\frac{\sqrt{T_1}}{T_3}dr+c_6,$$

where $\alpha_3=T_3'/2T_3\sqrt{T_1}$ is a constant.

The third option $3a_1b_1c_1(d_3)$, for $\alpha_2<0$, is similar to the first option $3a_1b_1c_1(d_1)$.

Now we come to the case $3a_1b_1(c_2)$ when $\alpha_1=0$ which gives $\alpha_4=-(T_2'/2T_2\sqrt{T_1})$, a constant such that

$$(d_1)\ \ \alpha_4=0,\quad (d_2)\ \ \alpha_4\neq 0.$$

In the case $3a_1b_1c_2(d_1)$, we have $\alpha_2=(T_3/\sqrt{T_1})[-(T_3'/2T_3\sqrt{T_1})]'$ which yields the following options:

$$(e_1)\ \ \alpha_2>0,\quad (e_2)\ \ \alpha_2=0,\quad (e_3)\ \ \alpha_2<0.$$

For the case $3a_1b_1c_2d_1(e_1)$, when $\alpha_2>0$, we have the following MCs:

$$\xi^0=\xi^0(t,r,\theta,z),$$

$$\xi^1=\frac{1}{\sqrt{T_1}}[e^{\iota\sqrt{\alpha_2}\theta}(c_1z+c_2)+e^{-\iota\sqrt{\alpha_2}\theta}(c_3z+c_4)],$$

$$\xi^2=0, \tag{57}$$

$$\xi^3=-\frac{T_3'}{\iota 2\sqrt{\alpha_2}T_3\sqrt{T_1}}(c_1e^{\iota\sqrt{\alpha_2}z}-c_2e^{-\iota\sqrt{\alpha_2}z}).$$

The case $3a_1b_1c_2d_1(e_2)$, when $\alpha_2=0$, we have further two possibilities according to $\alpha_5=-T_3'/2T_3\sqrt{T_1}$, a constant such that

$$(f_1)\ \ \alpha_5=0,\quad (f_2)\ \ \alpha_5\neq 0.$$

For the case $3a_1b_1c_2d_1e_2(f_1)$, we get the following result:

$$\xi^0=\xi^0(t,r,\theta,z),\quad \xi^1=\frac{1}{\sqrt{T_1}}(c_1\theta+c_2z+c_3),$$

$$\xi^2=-\frac{c_1}{T_2}\int\sqrt{T_1}dr,\quad \xi^3=-\frac{c_2}{T_3}\int\sqrt{T_1}dr. \tag{58}$$

For α_5 to be nonzero, i.e., the case $3a_1b_1c_2d_1e_2(f_2)$, we obtain

$$\xi^0=\xi^0(t,r,\theta,z),\quad \xi^1=\frac{1}{\sqrt{T_1}}(c_1z+c_2),$$

$$\xi^2=0,\quad \xi^3=\alpha_5\left(c_1\frac{z^2}{2}+c_2z\right)-c_1\int\frac{\sqrt{T_1}}{T_3}dr. \tag{59}$$

The case $3a_1b_1c_2d_1(e_3)$ when $\alpha_2<0$ is similar to the case $3a_1b_1c_2d_1(e_1)$.

In the case $3a_1b_1c_2(d_2)$ when $\alpha_2\neq 0$, we have $\alpha_2=(T_3/\sqrt{T_1})[-(T_3'/2T_3\sqrt{T_1})]'$, a constant which gives the following three options:

$$(e_1)\ \ \alpha_2>0,\quad (e_2)\ \ \alpha_2=0,\quad (e_3)\ \ \alpha_2<0.$$

The case $3a_1b_1c_2d_2(e_1)$ yields the following solution:

$$\xi^0=\xi^0(t,r,\theta,z),\quad \xi^1=0,$$
$$\xi^2=(c_1z+c_2),\quad \xi^3=-\frac{T_2}{T_3}c_1\theta+c_3. \tag{60}$$

The case $3a_1b_1c_2d_2(e_2)$, when $\alpha_2=0$, gives the following MCs:

$$\xi^0=\xi^0(t,r,\theta,z),\quad \xi^1=\frac{c_1}{T_1},$$
$$\xi^2=(\alpha_3c_1\theta+c_2),\quad \xi^3=\alpha_3c_1z+c_3. \tag{61}$$

The last possibility $3a_1b_1c_2d_2(e_3)$ when α_2 is negative yields similar solution to the positive case $3a_1b_1c_2d_2(e_1)$.

The case $3a_1b_1(c_3)$, when $\alpha_1<0$, is similar to the case $3a_1b_1(c_1)$.

The case $3a_1(b_2)$ yields the following solution:

$$\xi^0=\xi^0(t,r,\theta,z),\quad \xi^1=0,$$
$$\xi^2=c_1z+c_2,\quad \xi^3=c_3\theta+c_4. \tag{62}$$

The case $3(a_2)$ when $T_0\neq0$, $T_1=0$, $T_2\neq0$, $T_3\neq0$ gives the following two options:

$$(b_1)\ \ T_0'=0,\quad (b_2)\ \ T_0'\neq0.$$

The first option $3a_2(b_1)$ gives either

$$(c_1)\ \left(\frac{T_2'T_3}{T_2T_3'}\right)'=0,\quad \text{or}\ \ (c_2)\ \left(\frac{T_2'T_3}{T_2T_3'}\right)'\neq0.$$

The case $3a_2b_1(c_1)$ gives one proper MC,

$$\xi_{(4)}=-\frac{2T_2}{T_2'}\beta_1\partial_r+\beta_1\theta\partial_\theta+z\partial_z, \tag{63}$$

where $\beta_1=T_2'T_3/T_2T_3'$. For the case $3a_2b_1(c_2)$, we have either

$$(d_1)\ \ T_2'=0=T_3',\quad \text{or}\ \ (d_2)\ \ T_2'\neq0,\quad T_3'\neq0.$$

The case $3a_2b_1c_2(d_1)$ yields infinite dimensional MCs. For the case $3a_2b_1c_2(d_2)$, we get three MCs which are the usual KVs.

The case $3a_2(b_2)$ divides into four groups:

$$(c_1)\ \left(\frac{T_0}{T_2}\right)'=0,\quad \left(\frac{T_0}{T_3}\right)'=0,$$
$$(c_2)\ \left(\frac{T_0}{T_2}\right)'=0,\quad \left(\frac{T_0}{T_3}\right)'\neq0,$$
$$(c_3)\ \left(\frac{T_0}{T_2}\right)'\neq0,\quad \left(\frac{T_0}{T_3}\right)'=0,$$

$$(c_4)\ \left(\frac{T_0}{T_2}\right)'\neq 0,\quad \left(\frac{T_0}{T_3}\right)'\neq 0.$$

The first group $3a_2b_2(c_1)$ gives 10 independent MCs in which seven are proper MCs given by

$$\xi_{(4)}=-\frac{k_1}{k_2}z\partial_\theta+\theta\partial_z,$$

$$\xi_{(5)}=\theta\partial_t+k_1t\partial_\theta,$$

$$\xi_{(6)}=z\partial_t+k_2t\partial_z,$$

$$\xi_{(7)}=\left(\frac{\theta^2}{2}+\frac{k_1z^2}{2k_2}+k_1\frac{t^2}{2}\right)\partial_t-\frac{2k_1T_0}{T_0'}t\partial_r+k_1t\theta\partial_\theta+k_1tz\partial_z, \tag{64}$$

$$\xi_{(8)}=t\theta\partial_t-\frac{2T_0}{T_0'}\theta\partial_r+\left(k_1\frac{t^2}{2}+\frac{\theta^2}{2}-\frac{k_1}{k_2}\frac{z^2}{2}\right)\partial_\theta+\theta z\partial_z,$$

$$\xi_{(9)}=tz\partial_t-\frac{2T_0}{T_0'}z\partial_r+\theta z\partial_\theta+\left(k_2\frac{t^2}{2}-\frac{k_2}{k_1}\frac{\theta^2}{2}+\frac{z^2}{2}\right)\partial_z,$$

$$\xi_{(10)}=t\partial_t-\frac{2T_0}{T_0'}\partial_r+\theta\partial_\theta+z\partial_z,$$

where $k_1=-T_0/T_2$ and $k_2=-T_0/T_3$ are nonzero constants.

The second group $3a_2b_2(c_2)$ when $(T_0/T_2)'=0$, $(T_0/T_3)'\neq 0$ can give two more possibilities whether

$$(d_1)\ \left(\frac{T_3'T_0}{T_3T_0'}\right)'=\text{constant},\quad (d_2)\ \left(\frac{T_3'T_0}{T_3T_0'}\right)'\neq\text{constant}.$$

The case $3a_2b_2c_2(d_1)$, we have two proper MC given by

$$\xi_{(4)}=\theta\partial_t+k_1t\partial_\theta,$$
$$\xi_{(5)}=t\partial_t-\frac{2T_0}{T_0'}\partial_r+\theta\partial_\theta+cz\partial_z, \tag{65}$$

where $T_0/T_3=c$ is an arbitrary constant. If it is not constant, i.e., the case $3a_2b_2c_2(d_2)$, we obtain only one proper MC given by

$$\xi_{(4)}=\theta\partial_t+k_1t\partial_\theta. \tag{66}$$

The third group $3a_2b_2(c_3)$ when $(T_0/T_2)'\neq 0$, $(T_0/T_3)'=0$ would give the similar solution as the previous one $3a_2b_2(c_2)$.

The last group $3a_2b_2(c_4)$ when $(T_0/T_2)'\neq 0$, $(T_0/T_3)'\neq 0$ would give the following four possibilities:

$$(d_1)\ \left(\frac{T_0'T_2}{T_0T_2'}\right)'\neq 0,\quad \left(\frac{T_0'T_3}{T_0T_3'}\right)'\neq 0,$$

$$(d_2)\ \left(\frac{T_0'T_2}{T_0T_2'}\right)'\neq 0,\quad \left(\frac{T_0'T_3}{T_0T_3'}\right)'=0,$$

$$(d_3)\ \left(\frac{T_0'T_2}{T_0T_2'}\right)'=0,\quad \left(\frac{T_0'T_3}{T_0T_3'}\right)'\neq 0,$$

$$(d_4)\ \left(\frac{T_0'T_2}{T_0T_2'}\right)'=0,\quad \left(\frac{T_0'T_3}{T_0T_3'}\right)'=0.$$

In the first possibility $3a_2b_2c_4(d_1)$, we have either

$$(e_1)\ \frac{T_2}{T_3}=\text{constant},\quad \text{or}\ (e_2)\ \frac{T_2}{T_3}\neq\text{constant}.$$

The case $3a_2b_2c_4d_1(e_1)$ gives one proper MC. The proper MC is

$$\xi_{(4)}=z\partial_\theta-\frac{T_2}{T_3}\theta\partial_z. \tag{67}$$

For the case $3a_2b_2c_4d_1(e_2)$, we get three MCs which are KVs. The possibilities $3a_2b_2c_4(d_2)$ and $3a_2b_2c_4(d_3)$ are similar to the case $3a_2b_2c_4(d_1)$.

In the last possibility $3a_2b_2c_4(d_4)$, we obtain five MCs in which two are proper, i.e.,

$$\begin{aligned}\xi_{(4)}&=z\partial_\theta-\frac{T_2}{T_3}\theta\partial_z,\\ \xi_{(5)}&=t\partial_t-\frac{2T_0}{T_0'}\partial_r+\frac{1}{\beta_2}\theta\partial_\theta+\frac{1}{\beta_2}\partial_z,\end{aligned} \tag{68}$$

where $T_0'T_2/T_0T_2'=\beta_2$, a constant. We also take T_2/T_3 to be constant.

The subcases $3(a_3)$ and $3(a_4)$ can be proceeded as the subcase $3(a_1)$ and would give similar results.

V. EXAMPLES OF FINITE DIMENSIONAL MATTER COLLINEATIONS

We see from Secs. III and IV that when we find MCs for the cylindrically symmetric static space–times, we obtain different constraints on the energy-momentum tensor. If we solve these constraints, we can have exact solutions of EFEs or a class of solutions that can be obtained. In this section, we would attempt to solve some of these constraints to get explicit forms of the metrics. We are not providing the details. Instead we provide a list of solutions and their properties satisfying the constraints.

(1) When we solve the constraints of the case $2a_1b_2(c_2)$, we obtain the following metric:
$$\mathrm{d}s^2=\cosh^2 cr\,\mathrm{d}t^2-\mathrm{d}r^2-(\cosh cr)^{-1}\,\mathrm{d}\theta^2-(\cosh cr)^{-1}\,\mathrm{d}z^2, \tag{69}$$
where c is an arbitrary constant. This metric admits four MCs and also four isometries. This implies that there is no proper MC in this example but it has seven RCs. This metric has an anisotropic fluid with energy-density positive for $0\leqslant r<(1/c)\tanh^{-1}(2/\sqrt{7})$ and negative for $r\geqslant(1/c)\tanh^{-1}(2/\sqrt{7})$.

(2) If we solve the constraints of the case $2a_2b_3c_1d_3(e_1)$, the space–time would be
$$\mathrm{d}s^2=(r/r_0)^{2a}\,\mathrm{d}t^2-\mathrm{d}r^2-(r/r_0)^{2b}\,\mathrm{d}\theta^2-(r/r_0)^{2c}\,\mathrm{d}z^2, \tag{70}$$
where a, b, c, and r_0 are arbitrary constants such that $a,b,c\neq 0,1$. The components of the energy-momentum tensor for this metric are given in Appendix B. This metric has four MCs with three KVs giving one proper MC.

(3) If we choose the values of a, b, c such that $a=1$, $b=c\neq 1$ in Eq. (70), we get a metric which admits seven MCs and four KVs satisfying the constraints $1a_4b_1c_2d_1e_2(f_1)$. This gives three proper MCs. It is obvious from the energy-momentum tensor given in Eq. (B2) that the energy density will be positive for $0<b<2/3$.

(4) When we take $a=b=c\neq 0,1$ in Eq. (70), we obtain a metric which satisfies the constraints given in $2a_1b_1c_2(d_1)$. This space–time admits 10 MCs with six KVs and hence we have four proper MCs in this example. It can be seen from the energy-momentum tensor that it becomes singular at $r=0$.

(5) If we take $b=c\neq 0,1$ in Eq. (70), we get a metric satisfying the constraints of the case $2a_1b_1c_2d_2(e_1)$ admitting five MCs but three KVs. This is another example admitting proper MCs. We must take $0<b<2/3$ to make the energy-density positive. It is to be noted that the resulting metric would represent a perfect fluid for $b=a(a-1)/(a+1)$ and non-null electromagnetic field when $b=a+1$.

(6) Taking $\nu=\lambda=\mu$ in Eq. (4), it satisfies the constraints of the case $2a_1b_2(c_1)$. This metric admits six MCs and also six KVs.

(7) When we choose $a=b\neq c$ such that $a,c\neq 0,1$ in Eq. (70), we obtain a metric satisfying the constraints of the case $2a_2b_3c_1(d_1)$. This metric admits five MCs with four isometries hence giving one proper MC.

(8) If we take either $\nu=\lambda$ or $\nu=\mu$ in Eq. (4), we have the solution of the constraints given by $2a_2b_3c_2(d_1)$. This metric admits four MCs and four isometries.

(9) Now solving the constraints of the case $2a_2b_3c_2(d_2)$, we obtain the following solution:

$$ds^2=(\cosh cr)^{-1}dt^2-dr^2-\cosh^2 cr\,d\theta^2-(\cosh cr)^{-1}dz^2. \tag{71}$$

It has four MCs and also four KVs but seven RCs. This space–time represents anisotropic tachyonic fluid.

(10) If we take $a=-\frac{1}{4}$, $b=c=\frac{1}{2}$ in Eq. (70), we get $T_1=0$ which gives the degenerate case and hence satisfies the constraints of the case $3a_2b_2c_4(d_4)$. This metric admits five MCs and four KVs. Thus we have one proper MC in this degenerate case.

VI. CONCLUSION

We know from the classification of cylindrically symmetric static space–times according to their isometries that we either get three, four, five, six, seven or ten isometries. The ten and seven KVs are admitted by the well known anti–de Sitter and anti-Einstein universes, respectively. The six isometries are admitted by the Bertotti–Robinson metric with the isometry group $SO(1,1)\times)\Re^3\otimes SO(3)$. There is one class of metrics depending on one arbitrary function with six isometries given by

$$ds^2=e^{\nu}(dt^2-dr^2-d\theta^2-dz^2). \tag{72}$$

There are three cases of five dimensional isometry groups. There are also three classes of metrics depending upon two arbitrary functions having four dimensional isometry groups given by

$$ds^2=e^{\nu}dt^2-dr^2-e^{\mu}(d\theta^2-dz^2), \tag{73}$$

$$ds^2=e^{\nu}(dt^2-dz^2)-dr^2-e^{\lambda}d\theta^2, \tag{74}$$

$$ds^2=e^{\nu}(dt^2-d\theta^2)-dr^2-e^{\mu}dz^2. \tag{75}$$

All other metrics admit minimal isometry group G_3.

This paper presents a complete classification of cylindrically symmetric static space–times according to their MCs. We have solved MC equations for both nondegenerate and degenerate cases. The explicit forms of MCs are given in each case. We have also written the corresponding constraints on the energy-momentum tensor in each case. Finally, we have attempted to solve some of these constraints to find the exact solution of EFEs.

TABLE I. MCs of case (1) for the nondegenerate energy-momentum tensor.

Cases	MCs	Constraints
$1(a_1)$	10	$T_0'=0,\ T_2'=0=T_3'$
$1a_2b_1(c_1)$	6	$T_0'=0,\ T_2'=0,\ T_3'\neq 0,$ $\left[\frac{T_3}{\sqrt{T_1}}\left(\frac{T_3'}{2T_3\sqrt{T_1}}\right)'\right]'=0,\quad \frac{T_3}{\sqrt{T_1}}\left(\frac{T_3'}{2T_3\sqrt{T_1}}\right)'=\alpha_1>0$
$1a_2b_1(c_2)$	6	$T_0'=0,\ T_2'=0,\ T_3'\neq 0,\quad \left[\frac{T_3}{\sqrt{T_1}}\left(\frac{T_3'}{2T_3\sqrt{T_1}}\right)'\right]'=0,$ $\alpha_1=0$
$1a_2b_1(c_3)$	6	$T_0'=0,\ T_2'=0,\ T_3'\neq 0,\quad \left[\frac{T_3}{\sqrt{T_1}}\left(\frac{T_3'}{2T_3\sqrt{T_1}}\right)'\right]'=0,\quad \alpha_1<0$

$1a_4b_2(c_2)$	3	$T_0'=0,\ T_2'\neq 0,\ T_3'\neq 0,\ \left[\frac{T_2}{\sqrt{T_1}}\left(\frac{T_2'}{2T_2\sqrt{T_1}}\right)'\right]'\neq 0,$ $\frac{T_2}{T_3}\neq \text{constant}$

When the energy-momentum tensor is nondegenerate (Sec. III), we obtain either three, four, five, six, seven or ten independent MCs. Out of these MCs, we obtain three isometries and the rest are the nontrivial (proper) MCs. In the degenerate case (Sec. IV), most of the possibilities lead to infinite dimensional MCs. However, there are some worth mentioning cases where we obtain finite dimensional MCs even with degenerate energy-momentum tensor. In these cases, we get either three, four, five or ten independent MCs in which three are the usual KVs and the rest are the proper MCs.

The summary of the results can be given in the form of Tables I–V.

It is seen from Tables I–V that each case has different constraints on the energy-momentum tensor. If we solve these constraints, we may have exact solution of EFEs. We have attempted (Sec. V) 10 different constraints to obtain the energy-momentum tensor and the corresponding space–time. These cases are given by $1a_4b_1c_2d_1e_2(f_1)$, $2a_1b_1c_2(d_1)$, $2a_1b_1c_2d_2(e_1)$, $2a_1b_2(c_1)$, $2a_1b_2(c_2)$, $2a_2b_3c_1(d_1)$, $2a_2b_3c_2(d_1)$, $2a_2b_3c_2(d_2)$, $2a_2b_3c_1d_3(e_1)$, $3a_2b_2c_4(d_4)$. It turns out that the cases $2a_1b_2(c_1)$, $2a_1b_2(c_2)$, $2a_2b_3c_2(d_1)$, $2a_2b_3c_2(d_2)$, $2a_2b_3c_1d_3(e_1)$ provide no proper MC. However, the cases $2a_2b_3c_1(d_1)$ and $3a_2b_2c_4(d_4)$ yield one proper MC, the case $2a_1b_1c_2d_2(e_1)$ gives two proper MCs, the case $1a_4b_1c_2d_1e_2(f_1)$ yields three proper MCs and the case $2a_1b_1c_2(d_1)$ gives four proper MCs. It is interesting to note that $3a_2b_2c_4(d_4)$ is the case where $T_1=0$, i.e., the degenerate case but this provides finite dimensional MCs and we obtain one proper MC in this case.

We have attempted some of the constraints to obtain exact solutions of EFEs which give finite dimensional MCs. We have discussed some of the physical properties of the resulting space–times. It would be interesting to look for more solutions of the constraints or examples should be constructed to satisfy the constraints.

APPENDIX A

The surviving components of the Ricci tensor are

$$
\begin{aligned}
R_{00}&=\tfrac{1}{4}e^{\nu}(2\nu''+\nu'^2+\nu'\lambda'+\nu'\mu'),\\
R_{11}&=-\tfrac{1}{4}(2\nu''+2\lambda''+2\mu''+\nu'^2+\lambda'^2+\mu'^2),\\
R_{22}&=-\tfrac{1}{4}e^{\lambda}(2\lambda''+\nu'\lambda'+\lambda'^2+\lambda'\mu'),\\
R_{33}&=-\tfrac{1}{4}e^{\mu}(2\mu''+\nu'\mu'+\lambda'\mu'+\mu'^2).
\end{aligned}
\tag{A1}
$$

(Received 31 October 2003; accepted 12 December 2003)

We show various Harry Dym type equations and Super Harry Dym equations, introduced by Brunelli, Das, and Popowicz [2003 Supersymmetric extensions of the Harry Dym hierarchy, J. Math. Phys. **44**, 4756–4767 (2003)], follow from the geodesic flows on the Bott–Virasoro group and its supersymmetric generalization, superconformal group. In fact, their bi-Hamiltonian structures can be derived from the Lie Poisson structures on the (super-) Bott–Virasoro orbit. We also show that that m^2KdV or Calogero–Degasperis equation is also connected to the Bott–Virasoro group. © *2004 American Institute of Physics.*
[DOI: 10.1063/1.1645978]

I. INTRODUCTION

The connection between the geodesic equation of the Bott–Virasoro group and the periodic Korteweg–de Vries (KdV) equation follows from the work of Ovsienko and Khesin,[21] Segal,[26,27] Witten,[28] and others.[10,12,13]

The following three systems, the KdV equation, the Camassa–Holm equation, and the Harry Dym equation, are related to various hydrodynamical approximations of the famous Euler equation of an incompressible ideal fluid, and all these equations follow from the geodesic flows on the Bott–Virasoro group.[11,14,20,21]

It is known that the geodesic motion on the group of all volume preserving Hilbert diffeomorphisms of some Sobolev class H^s yields the hydrodynamics of an incompressible ideal fluid. This was formally derived by Arnold.[2] Later, Ebin–Marsden[8] established a proper geometric setting for this problem.

Ovsienko and Khesin[21] showed that the KdV equation is the Euler–Poincaré equation (cf. Refs. 17, 18) for a central extension of the group Diff(S^1) group of diffeomorphisms of the circle parametrized by $x:0\leqslant x\leqslant 2\pi$. For all practical purposes we restrict ourselves to the space of orientation preserving C^∞, the diffeomorphism of S^1, denoted by Diff$_+(S^1)$.

It is natural to consider the Lie algebra $\Omega\mathcal{G}$ of vector fields on S^1 as its algebra. The dual of this algebra is identifed with space of quadratic differential forms $u(x)dx^{\otimes 2}$ by the following pairing:

$$\left\langle u(x)dx^2, \quad f(x)\frac{d}{dx}\right\rangle = \int_0^{2\pi} u(x)f(x)dx.$$

The Lie algebra of vector fields on S^1, $\Omega\mathcal{G}$, has a unique nontrivial central extension by means of $\mathbf{R}$,

$$0\to\mathbf{R}\to\widehat{\Omega\mathcal{G}}\to\Omega\mathcal{G}\to 0,$$

described by the Gelfand–Fuks cocycle (cf. Refs. 11, 12),

a)Electronic mail: partha@bose.res.in

$$\omega_1\left(f\frac{d}{dx},g\frac{d}{dx}\right)=\int_{S^1}f'g''\,dx.$$

The extended Lie algebra of vector fields is called the Virasoro algebra.

The elements of $\hat{\Omega}\mathcal{G}$ can be identifed with the pairs (2π periodic function, real number). The commutator in $\hat{\Omega}\mathcal{G}$ takes the form

$$\left[\left(f(x)\frac{d}{dx},a\right),\left(g(x)\frac{d}{dx},b\right)\right]=\left(fg'-gf',\int_{S^1}f'g''\right). \tag{1}$$

The dual space $\hat{\Omega}\mathcal{G}^*$ can be identified to the set

$$\{(\lambda,u)|\lambda\in\mathbf{R}\ \text{ and } u\ \text{ is a quadratic diffferential}\}.$$

A pairing between a point $(\lambda,f(x)(d/dx))\in\hat{\Omega}\mathcal{G}$ and a point $(\mu,u\,dx^{\otimes 2})$ is given by

$$\lambda\mu+\int_{S^1}f(x)u(x)dx.$$

Theorem 1.1: *There exists a group* $\hat{\mathrm{Diff}}_+(S^1)$ *which is a central extension of* $\mathrm{Diff}_+(S^1)$ *given by Bott's cocycle,*

$$c:\mathrm{Diff}_+(S^1)\times\mathrm{Diff}_+(S^1)\to\mathbf{R},$$

such that

$$c(\sigma_1,\sigma_2)=\int_{S^1}\log(\sigma_1\circ\sigma_2)'d\log\sigma_1', \tag{2}$$

for $\sigma_i\in\mathrm{Diff}_+(S^1)$. *This cocycle satisfes* $c(\sigma_1,\sigma_1^{-1})=0$.

The next theorem follows from the work of Lazutkin and Pankratova.[15]

Theorem 1.2: *The space* $\hat{\Omega}\mathcal{G}^*$ *can be identifed with the* $\hat{\Omega}\mathcal{G}$*-module of Hill's operators,*

$$\{\mu\partial_x^2+q\},$$

acting on distributions of weight $-\frac{1}{2}$ *as* $\hat{\mathrm{Diff}}_+(S^1)$ *modules.*

The theories of infinite-dimensional super integrable system have drawn lots of interst in the last two decades. As a consequence a number of well known integrable equations have been generalized into supersymmetric integrable systems. Ovsienko and Khesin[21] showed that supersymmetric KdV equation, introduced by Kupershmidt, can be obtained as a geodesic flow of an invariant L^2 metric on the group of superconformal transformations of two-dimensional domains.

In an interesting paper Brunelli–Das–Popowicz[3] proposed a supersymmetric version for the well known Harry Dym system. In this paper, we show that these equations also arise as a geodesic flow on the group of a superconformal group.

II. GEODESIC FLOWS AND HARRY DYM EQUATIONS

Let G be a Lie group and $\mathfrak{g}$ be its corresponding Lie algebra and its dual is denoted by $\mathfrak{g}^*$.

The dual space $\mathfrak{g}^*$ to any Lie algebra $\mathfrak{g}$ carries a natural Lie–Poisson structure:

$$\{f,g\}_{\mathrm{LP}}(\mu):=\langle[df,dg],\mu\rangle,$$

for any $\mu\in\mathfrak{g}^*$ and $f,g\in C^\infty(S^1)$.

Lemma 2.1: The Hamiltonian vector field on $\mathfrak{g}^*$ *corresponding to a Hamiltonian function* f*, computed with respect to the Lie–Poisson structure is given by*

$$\frac{d\mu}{dt} = ad^*_{df}\mu. \tag{3}$$

Proof: It follows from the following identities:

$$i_{X_f} dg|_\mu = L_{X_f} g|_\mu = \{f,g\}_{\mathrm{LP}}(\mu) = \langle [dg,df],\mu\rangle = \langle dg, ad^*_{df}\mu\rangle.$$

This implies that $X_f = ad^*_{df}\mu$. Thus the Hamiltonian equation $d\mu/dt = X_f$ yields our result. □

Let I be an inertia operator,

$$I:\mathfrak{g}\to\mathfrak{g}^*,$$

and then $\mu\in\mathcal{G}^*$ evolve by

$$\frac{d\mu}{dt} = (I^{-1}\mu)\cdot\mu, \tag{4}$$

where the right hand side denotes the coadjoint action of $\mathfrak{g}$ on $\mathfrak{g}^*$. This equation is called the Euler–Poincaré equation.

Definition 2.2: The Euler–Poincaré equation on $\mathfrak{g}^*$ *corresponding to the Hamiltonian* $H(\mu) = \frac{1}{2}\langle I^{-1}\mu,\mu\rangle$ *is given by*

$$\frac{d\mu}{dt} = -ad^*_{I^{-1}\mu}\mu.$$

It characterizes an evolution of a point $\mu\in\mathfrak{g}^*$.

Proposition 2.3: Let ΩG *be infnite-dimensional Lie group equipped with a right invariant metric. A curve* $t\to c(t)$ *in* ΩG *is a geodesic of this metric iff* $u(t) = d_{c_t}R_{c_t^{-1}}\dot{c}(t)$ *satisfes*

$$\frac{d}{dt}u(t) = -ad^*_{u(t)}u(t). \tag{5}$$

The Euler–Poincaré equation is the Hamiltonian flow on the coadjoint orbits on the dual of Bott–Virasoro algebra generated by the Hamiltonian

$$H(u\partial_x, a) = \frac{1}{2}\int_{S^1} u^2\,dx + a^2,$$

where a is just a constant.

Lemma 2.4:

$$ad^*_{(\lambda, f(x)\,(d/dx))}(\mu,u) = (0, \tfrac{1}{2}\mu f''' + 2\,f'u + 2\,fu') \equiv (0,\tilde{u}). \tag{6}$$

Proof: It follows from the definition

$$\left\langle ad^*_{(\lambda,f(x)\,(d/dx))}(\mu,u(x)dx^2),\left(\nu,g(x)\frac{d}{dx}\right)\right\rangle=\left\langle(\mu,u\,dx^2),ad_{(\lambda,f(x)\,(d/dx))}\left(\nu,g(x)\frac{d}{dx}\right)\right\rangle$$
$$=\left\langle(\mu,u),\left(\frac{1}{2}\int_{S^1}f'g''dx,\left[f(x)\frac{d}{dx},g(x)\frac{d}{dx}\right]\right)\right\rangle$$
$$=\mu\frac{1}{2}\int_{S^1}f'g''\,dx+\int_{S^1}\left[f(x)\frac{d}{dx},g(x)\frac{d}{dx}\right]u(x)dx.$$

□

The coadjoint action leaves the parameter μ invariant, so we fix $\mu=1$ and by the abusing the notation we continue to denote it by $\hat{\Omega}\mathcal{G}^*$.

On the coadjoint orbit in $\hat{\Omega}\mathcal{G}^*$ we define the Lie–Poisson structure:

$$\{f,g\}(u(x),1)=\int\left[\left(\frac{\delta f}{\delta u}\right)\left(\frac{\delta g}{\delta u}\right)'-\left(\frac{\delta g}{\delta u}\right)\left(\frac{\delta f}{\delta u}\right)'+\left(\frac{\delta f}{\delta u}\right)'\left(\frac{\delta g}{\delta u}\right)''\right]dx,$$

where $\delta f/\delta u(x)$ is called the Fréchet derivative and it is defined by

$$\frac{d}{d\epsilon}f(u+\epsilon v,\lambda)\big|_{\epsilon=0}=\int\frac{\delta f}{\delta u}(x)v(x)dx.$$

Using Eq. (4), we know

$$\tilde{u}=\tfrac{1}{2}f'''+2\,f'u+\xi u'=(\tfrac{1}{2}\partial_x^3+2u\partial_x+u_x)f.$$

The operator $(\frac{1}{2}\partial_x^3+2u\partial_x+u_x)$ is called a symplectic operator. The Euler–Poincaré equation is the Hamiltonian flow on the coadjoint orbits in $\hat{\Omega}\mathcal{G}^*$ generated by the Hamiltonian

$$H(u)=\tfrac{1}{2}\langle(1,u(dx)^{\otimes 2}),(1,u(dx)^{\otimes 2})\rangle.$$

Theorem 2.5: *The Euler–Poincaré equation gives the KdV equation, it is a Hamiltonian flow on the coadjoint orbits in $\hat{\Omega}\mathcal{G}^*$ for the Hamiltonian function $H(u)=\frac{1}{2}u^2$.*

The Harry Dym equation is given by

$$w_t=(w^{-1/2})_{xxx}. \tag{7}$$

This can be written as

$$w_t=\partial^3\left(\frac{\delta H_1}{\delta w}\right)=(\partial w+w\partial)\frac{\partial H_2}{\delta w},$$

where

$$H_1=\int_{S^1}dx(2w^{1/2}),$$

$$H_2=\int_{S^1}dx\left(\frac{1}{8}w^{-5/2}w_x^2\right).$$

Theorem 2.6: *The Euler–Poincaré equation gives the Harry Dym equation, it is a Hamiltonian flow on the coadjoint orbits in* $\Omega\mathcal{G}^*$ *(centerless) for the Hamiltonian function* $H(w)=\int_{S^1}dx(\frac{1}{8}w^{-5/2}w_x^2)$.

Clarkson, Fokas, and Ablowitz[7] proposed a generalization of the Harry Dym equation,

$$w_t=2(w^{-1/2})_{xxx}+\gamma w^{1/2}w_x+\alpha w^{-3/2}w_x+\delta w_x, \tag{8}$$

where γ, α, and δ are coefffents. This equation reduces to the Harry Dym equation when $\gamma=\alpha=\delta=0$.

Theorem 2.7: *The Euler–Poincaré equation yields the generalized Harry Dym equation or Clarkson–Fokas–Ablowitz equation*[7] $(\delta=0)$, *for the Hamiltonian function,*

$$H(w)=\int_{S^1}dx\left(\frac{1}{8}w^{-5/2}w_x^2\right)-\alpha\int_{S^1}dx\,w^{-1/2}+\frac{2}{3}\gamma\int_{S^1}dx\,w^{3/2}.$$

Remark: One can incorporate δw_x term through lightcone coordinate, that is, defining

$$\frac{\partial}{\partial t'}=\frac{\partial}{\partial t}-\gamma\frac{\partial}{\partial x}.$$

Another interesting equation, the Hunter–Zheng equation (cf. Ref. 2) also follows from the same Hamiltonian structure with a Hamiltonian,

$$H=\frac{1}{2}\int_{S^1}(\partial^{-2}w)(\partial^{-1}w)^2\,dx.$$

Let us study the bihamiltonian structure of Harry Dym equation.[22]

Definition 2.8: Let M_P *be a Poisson manifold endowed with two Poisson bracket* $\{\cdot,\cdot\}_0$ *and* $\{\cdot,\cdot\}_1$. *We say that* M_P *is a bi-Hamiltonian manifold if the linear combination,*

$$\{f,g\}_\lambda:=\{f,g\}_0+\lambda\{f,g\}_1,$$

of these brackets satisfes Jacobi identity for any value λ *then* $\{\cdot,\cdot\}_\lambda$ *is called a Poisson pencil.*

In other words, a dynamical system,

$$\frac{d\mu}{dt}=\mathcal{X}_{\mathrm{H}}(\mu),$$

on M is called bi-Hamiltonian if the vector field $\mathcal{X}_{\mathrm{H}}$ is Hamiltonian with respect to both the Poisson brackets $\{\cdot,\cdot\}_0$ and $\{\cdot,\cdot\}_1$.

Let us consider Poisson pencil $\{\cdot,\cdot\}_\lambda$ is the deformation of $\{\cdot,\cdot\}_0$ and the Casimir function of $\{\cdot,\cdot\}_0$.

Let $H(\lambda)$ be the one parameter families of function such that

$$\{H(\lambda),f\}_\lambda=0.$$

Let $H(\lambda)=\Sigma_k H_k\lambda^{-k}$ and suppose $G(\lambda)$ be the another Casimir element on the Poisson pencil then from the recurence relation it can be proved[6] that

$$\{H_k,G_j\}_1=\{H_{k+1},G_j\}_0=0.$$

Hence, we say that the coefficients of the Laurent expansion of the Casimir function of the pencil are in involution with respect to both the basis brackets.

Let us assume $\{\cdot,\cdot\}_0$ to be a constant Poisson bracket.

Definition 2.9: The constant Poisson bracket associated to a point $\mu_0 \in \mathfrak{g}^*$ *is the bracket* $\{\cdot,\cdot\}_0$ *on the dual space* $\mathfrak{g}^*$ *defined by*

$$\{f,g\}_0(\mu) := \langle [df,dg], \mu_0 \rangle,$$

for any two smooth functions f *and* g *on the dual space for any* $\mu \in \mathfrak{g}^*$.

Remark: The constant bracket depends on the choice of the ''freezing'' point μ_0, while the Lie–Poisson bracket is defned by the Lie algebra structure only.

The following proposition was shown by Khesin and Misiolek.[14]

Proposition 2.10: The brackets $\{\cdot,\cdot\}_{LP}$ *and* $\{\cdot,\cdot\}_0$ *are compatible for every "freezing" point* μ_0.

Freezing at the point $(u\,dx^2,a)=(0,1)$ yields a truncated Hamiltonian operator,

$$\mathcal{O}_0 = \partial^3.$$

Theorem 2.11: *The Euler–Poincaré equation corresponds to "freezing" at the point* $(u\,dx^2,a)=(0,1)$ *yields a Harry Dym flow with respect to* $H=\int_{S^1} 2w^{1/2}$.

III. SUPER HARRY DYM EQUATION

Let us consider a Lie superalgebra, the Neveu–Schwarz superalgebra,[16] which contains the Virasoro algebra as its even part.

The first and foremost characteristic property of super algebra is that all the additive groups of its basic and derived structures are $\mathbb{Z}_2$ graded. A vector superspace is a $\mathbb{Z}_2$ graded vector space $V=V_0+V_1$. An element v of V_0 (resp., V_1) is said to be even (resp., odd). The super commutator of a pair of elements $v,w \in V$ is defined to be the element

$$[v,w] = vw - (-1)^{\overline{vw}} wv.$$

The Neveu–Schwartz superalgebra has two parts: bosonic (even) and fermionic (odd). These are given by

$$S\hat{\mathcal{G}}_B = \mathrm{Vect}(S^1) \oplus \mathbf{R}, \tag{9}$$

$$S\hat{\mathcal{G}}_F = C^\infty(S^1). \tag{10}$$

The Neveu–Schwarz superalgebra is an algebra on the space $\mathrm{Vect}(S^1)\oplus C^\infty(S^1)\oplus \mathbf{R}$ with the bilinear operation

$$\left[\begin{pmatrix} f(x)\dfrac{d}{dx} \\ \phi(x) \\ \lambda \end{pmatrix}, \begin{pmatrix} g(x)\dfrac{d}{dx} \\ \psi(x) \\ \mu \end{pmatrix} \right] = \begin{pmatrix} (fg'-f'g+\psi\phi)\dfrac{d}{dx} \\ \left(\left(f\psi'-\dfrac{1}{2}f'\psi\right)-\left(g\phi'-\dfrac{1}{2}g'\phi\right)\right) \\ \left(a_1\displaystyle\int_{S^1} f'g''+a_2\int_{S^1} fg'\,dx \right. \\ \left. \quad +2b_1\displaystyle\int_{S^1}\phi'\psi'\,dx+b_2\int_{S^1}\phi\psi\,dx\right) \end{pmatrix}. \tag{11}$$

Note that this algebra is the extension of $s\,\mathrm{Vect}(S^1)$ by the super Gelfand–Fuchs cocycle,

$$c_{\text{Super}}\left(\left(f(x)\frac{d}{dx},\phi(x)\right),\left(g(x)\frac{d}{dx},\psi(x)\right)\right)$$
$$=a_1\int_{S^1}f'g''\,dx+a_2\int_{S^1}fg'\,dx+2b_1\int_{S^1}\phi'\psi'\,dx+b_2\int_{S^1}\phi\psi\,dx,$$

where the even part of this cocycle is cohomologous to the Gelfands–Fuchs cocycle and, therefore, the corresponding central extension is isomorphic to the Virasoro algebra. Indeed, the first order term is a coboundary.

On this algebra, the ad-invariant, bilinear L^2 norm is given by

$$\left\langle\left(f(x)\frac{d}{dx},\phi(x),a\right),\left(g(x)\frac{d}{dx},\psi(x),b\right)\right\rangle_{L^2}=\int_{S^1}fg\,dx+\int_{S^1}\phi\partial_x^{-1}\psi\,dx+ab.$$

Lemma 3.1:

$$ad_{\hat{f}}^{*}\hat{u}=\begin{pmatrix}2uf'(x)+u'f+af'''+\frac{1}{2}\psi'\phi+\frac{3}{2}\psi\phi'\\ f\psi'+\frac{3}{2}f'\psi+u\phi+b\phi''\end{pmatrix},\tag{12}$$

where a and b are constants.

Hence the super Hamiltonian operator associated to superconformal group is given by

$$\mathcal{O}_{\text{super}}=\begin{pmatrix}\partial u+u\partial+a\partial^3 & \frac{1}{2}\partial\psi+\psi\partial\\ \frac{1}{2}\partial\psi+\psi\partial & u+b\partial^2\end{pmatrix}.\tag{13}$$

Let us consider a ''super freezing'' point,

$$(u\,dx^2,\phi(x),a,b)=(0,0,1,1).$$

Corresponding to this point we defne the constant Poisson bracket $\{\cdot,\cdot\}_0$. This bracket yields the super Harry Dym equation,

$$\begin{pmatrix}w\\ \psi\end{pmatrix}_t=\begin{pmatrix}\partial^3\dfrac{\delta H_1}{\delta w}\\ \partial^2\dfrac{\delta H_1}{\delta\psi}\end{pmatrix}=\begin{pmatrix}\partial^3(w^{-1/2})\\ \partial^2(\psi_x w^{-3/2})\end{pmatrix}.$$

The second Hamiltonian structure is

$$\mathcal{O}_{\text{sHD}}=\begin{pmatrix}\partial u+u\partial & \frac{1}{2}\partial\psi+\psi\partial\\ \frac{1}{2}\partial\psi+\psi\partial & u\end{pmatrix},\tag{14}$$

and the corresponding super Hamiltonian

$$\mathcal{H}=\frac{1}{8}\int_{S^1}(u_x^2u^{-5/2}-16\psi_x\psi_{xx}w^{-5/2}-15\psi\psi_xw_{xx}w^{-7/2}+15\psi\psi_{xx}w_xw^{-7/2})dx$$

yields super Harry Dym equation.[3]

IV. RECIPROCAL TRANSFORMATION AND INTEGRABLE FLOWS CONNECTED TO BOTT–VIRASORO GROUP

In this section we show how several other integrable systems are connected to the geodesic flows on the Bott–Virasoro group via reciprocal transformation. Reciprocal transformations are a useful tool in the study of integrable partial differential equations. These transformations have been extensively employed in contimuum mechanics not only to solve nonlinear boundary value problems. These applications are described in detail in the works of Rogers *et al.*[23,24] In our present context, reciprocal transformation is shown to be a key component[25] to connect the Harry Dym system and modified modified KdV (or m^2KdV) or Calogero–Degasperis system.[4]

Consider the following ''modified'' Gelfands–Fuchs cocycle (cf. Refs. 12, 13) on Vect(S^1):

$$\omega_{m\mathrm{GF}}\left(f(x)\frac{d}{dx},g(x)\frac{d}{dx}\right)=\int_{S^1}(af'g''+bf'g)dx. \tag{15}$$

It is easy to check that the modified action of Vect(S^1) on $\mathrm{vir}^*_{\mathrm{reg}}$ is given by the following lemma.

Lemma 4.1:

$$ad^*_{f(x)\,d/dx\,,\lambda}(u\,dx^2,\mu)=(\mu(af_{xxx}+bf_x)+4f'u+2\,fu',0). \tag{16}$$

Let us choose a specific hyperplane in $\mathrm{vir}^*_{\mathrm{reg}}$ such that $a=1,b=-1$.

Freezing at the point $(u\,dx^2,\mu)=(0,1)$ yields a truncated Hamiltonian operator,

$$\mathcal{O}=(\partial^3-\partial).$$

Theorem 4.2: *The Euler–Poincaré equation corresponds to "freezing" at the point* $(u\,dx^2,a)=(0,1)$ *yields a Camassa–Holm flow,*

$$w_t=(\partial^3-\partial)w^{-1/2}, \tag{17}$$

with respect to $H=\int_{S^1}2w^{1/2}$.

The integrable shallow-water equation investigated in Camassa and Holm,[5] namely,

$$m_t=-(m\partial+\partial m)u,\ \text{where}\ m=u-u_{xx}+\tfrac{1}{2}k \tag{18}$$

has an associated hierarchy determined from the recursion operator $R=\mathcal{O}_2\mathcal{O}_1^{-1}$, where

$$\mathcal{O}_1=\partial-\partial^3,\ \text{where}\ \mathcal{O}_2=m\partial+\partial m$$

are the first and second Hamiltonian operators. Applying the recursion operator R three times (cf. Ref. 1), starting from the shallow-water wave equation (18), gives the equation (17). In the standard Dym equation, the term ∂ is absent. The equation (18) is also called the Fuchsteinner–Fokas–Camassa–Holm equation.[5,9]

Let us substitute $w=A^2\rho^2$ in the Camassa–Holm equation (17). We obtain

$$\rho_t=\alpha\rho^{-1}[(\rho^{-1})_{xxx}-(\rho^{-1})_x], \tag{19}$$

where $2A^3\alpha=1$.

Under the reciprocal transformation

$$dX=\rho dx+\alpha[\rho^{-1}(\rho^{-1})_{xx}-\tfrac{1}{2}[(\rho^{-1})_x]^2-\tfrac{1}{2}(\rho^{-1})^2]dt,\quad dT=dt,$$

and $\Lambda=1/\rho$, we obtain

$$\Lambda_T+\alpha[\Lambda\{(\Lambda)_{XX}-1/2\,(A\Lambda)_X^2-\Lambda^2/2\}]_X=0. \tag{20}$$

Let us set

$$\theta=-A\Lambda,$$

so that

$$\theta_T+\alpha[\,\theta_{XXX}-(1/2)\,\theta_X^3-(3/2)\,e^{-2\theta}\theta_X]=0. \tag{21}$$

The choice $\alpha=-1$ delivers the m^2KdV equation.

Thus, we have seen that the m^2KdV or Calogero–Degasperis equation[4] is also connected to the geodesic flow on the Bott–Virasoro group.

V. CONCLUSION AND OUTLOOK

In this paper we have shown how several Harry Dym type equations are connected to the geodesic flows on the Bott–Virasoro group. We have also studied their superanalogs. These are connected to the geodesic flows on the superconformal group.

This result should be generalized to include deformed integrable systems. Recently Manna and Neveu[19] derived a new integrable classical $1+1$-dimensional equation, given by

$$u_{xxt}=u_x-uu_{xxx}-2u_xu_{xx}+\lambda\partial^2(u_x^3),$$

from the columnar approximation of the Euler equations of an incompressible fluid with surface tension. It would be challenging to connect the Manna–Neveu equation with the Bott–Virasoro group.

ACKNOWLEDGMENTS

The author would like to record here the debt owed for the paper of J.C. Brunelli, A. Das, and Z. Popowicz. He is grateful to the faculty and staff of the Department of Mathematics, UCCS, where the work has been done in an extremely cordial atmosphere. He is grateful to Professor Jerry Marsden, Professor Thanasis Fokas, Professor Darryl Holm, and Professor Sarbarish Chakravarty for many stimulating discussions.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 45, NUMBER 4 APRIL 2004

Superfluidity of a Fermi liquid from the viewpoint of a hierarchy of equations for reduced density matrices

V. A. Golovko[a)]
Moscow State Evening Metallurgical Institute, Lefortovsky Val 26, Moscow 111250, Russia

(Received 20 June 2003; accepted 5 December 2003)

The hierarchy of equations for reduced density matrices relevant to thermodynamic equilibrium with account taken of the spin obtained earlier is modified in order to describe the state of a Fermi system with a condensate. Although the procedure is to some extent analogous with the one carried out by the author earlier for a Bose liquid peculiarities relevant to Fermi statistics complicate considerably the treatment. As in the case of the Bose liquid the condensate phase can be superfluid as well as nonsuperfluid, the physical causes of superfluidity being identical. A new mechanism of fermion pairing that acts even in the case of a purely repulsive Hamiltonian is pointed out. Special attention is given to the thermodynamics of a superfluid Fermi system. The example of a hard-sphere system is used to find out the form of phase diagrams, the character of the phase transition to a condensate phase and the properties of the last. Noticeable dissimilarities from a Bose system with the same Hamiltonian are revealed. Application of the present approach to superconductivity is discussed as well.
[DOI: 10.1063/1.1644903]

I. INTRODUCTION

In a recent paper[1] to be referred to as I a hierarchy of equations for *s*-particle reduced density matrices describing a system of nonzero-spin particles at thermodynamic equilibrium was derived, the hierarchy being a quantum analogue of the equilibrium Bogoliubov–Born–Green–Kirkwood–Yvon (BBGKY) hierarchy. The hierarchy derived is an extension of the hierarchy obtained earlier[2] for spinless particles. The approach proposed in Ref. 2 permitted one not only to deduce the hierarchy but also to construct relevant thermodynamics. In a subsequent publication[3] the approach was used for treatment of Bose condensation and thereupon of superfluidity in Bose systems, a new explanation of the phenomenon being proposed on this basis. At the same time it was shown that the condensate cannot form in the case of spinless fermions and thereby superfluidity cannot exist in this case. Therefore, in order to consider superfluidity in fermionic systems on a base of the approach it was necessary first to incorporate the spin into its framework. This being done in I our aim in the present paper is to study superfluidity of a Fermi liquid leaning upon ideas of Ref. 3, which can provide a new method for studying the phenomenon.

The superfluidity of Fermi systems itself is worthy of special attention since in nature there is a fermionic system, liquid helium-3, which can be superfluid. However, still more important is the fact that consideration of systems comprising noncharged fermions (just noncharged particles are implied in the present paper) represents an essential step towards a treatment of such a phenomenon as superconductivity.

Theoretical studies of superconductivity are based mainly upon ideas of the Bardeen–Cooper–Schrieffer (BCS) theory[4] and of Bogolyubov's method,[5] of which the latest developments are reflected in different reviews.[6–8] In the present paper we shall proceed from the general principles formulated in Refs. 2 and 3 and we shall have no need of resorting to any extra ideas or argumentation of the type presented in the references cited just above. Doubtlessly, different

[a)]Electronic mail: mgvmi-mail@mtu-net.ru

approaches in the theory of superconductivity are of obvious physical interest as long as they enable one to obtain further insight into the essence of the phenomenon, which may have considerable utility especially in the light of problems of high-temperature superconductivity.

The organization of the paper is as follows. In Sec. II we modify the hierarchy obtained in I in order to take account of the situation in which there is an exceptional state, a condensate, proceeding along the lines of Ref. 3 and without resorting to Cooper's idea that fermions combine into pairs that behave like bosons. Nevertheless the condensate can form although the reason for this is more complicated than in the case of bosons owing to the Pauli exclusion principle. The existence of the condensate leads to the possibility of superfluidity just as in Ref. 3. In Sec. III we consider the thermodynamics of a state with condensate. Section IV illustrates application of the general theory established in the preceding sections using, as an example, a system of hard spheres wherein triplet correlations are neglected. In particular we shall construct a phase diagram where a region relevant to the condensate phase will be seen. Since the same example was considered in Ref. 3 this will enable us to compare the fermionic and bosonic condensate phases and to reveal that they exhibit different features. The results obtained and some other relevant questions are discussed in the concluding section.

This paper should be considered to be the second part of a work, the first part being paper I. For this reason we neither repeat the ideas of the present approach nor discuss previous results obtained with its help because all of this can be found in the introduction to paper I. When it is not stipulated explicitly the definitions and notation of I are implied. For the sake of convenience, when referring to an equation of paper I we shall place I in front; so we shall write, e.g., (I.2.16) implying Eq. (2.16) of I.

II. GENERAL EQUATIONS AND THEIR ANALYSIS

A. Hierarchy of equations in the presence of a condensate

When the spin of particles is taken into account the reduced density matrices $R_s(\mathbf{X}_s,\mathbf{X}_s')$ in a condition of thermodynamic equilibrium have the form of (I.2.16), namely,

$$R_s(\mathbf{X}_s,\mathbf{X}_s')=\sum_{\nu,\Gamma_s} n_s(\varepsilon_\nu^{(s)})\Psi_{\nu\Gamma_s}(\mathbf{X}_s)\Psi^*_{\nu\Gamma_s}(\mathbf{X}_s'). \tag{2.1}$$

In this equation the quantities $\varepsilon_\nu^{(s)}$ are eigenvalues of Eq. (I.2.11) and, therefore, ν is in reality a set of numbers that characterize eigenfunctions of Eq. (I.2.11). For this reason the quantities $\varepsilon_\nu^{(s)}$ and thereby $n_s(\varepsilon_\nu^{(s)})$ are defined initially on a discrete point set in the relevant ν-space whose dimensionality depends on the number s. In paper I (see also Ref. 2) it is assumed that in a state of thermodynamic equilibrium the functions $n_s(\varepsilon_\nu^{(s)})$ are universal functions, which implies that n_s's are continuous functions of a continuous variable z, i.e. $n_s=n_s(z)$ while $z=\varepsilon_\nu^{(s)}$ in (2.1).

According to the ideas of Ref. 3 the initial character of $\varepsilon_\nu^{(s)}$ may manifest itself in that the quantity $n_s(\varepsilon_\nu^{(s)})$ has an outlier at a certain $\nu=\nu_0$ depending on the number s, which amounts to saying that $n_s(\varepsilon_{\nu_0}^{(s)})=\Delta n_s+n_s(z_0)$ where $n_s(z_0)$ is the limit of $n_s(z)$ as $z\to z_0=\varepsilon_{\nu_0}^{(s)}$. The part of the system described by Δn_s will be called the condensate according to the commonly accepted terminology. In this case Eq. (2.1) can be recast as

$$R_s(\mathbf{X}_s,\mathbf{X}_s')=R_s^{(c)}(\mathbf{X}_s,\mathbf{X}_s')+R_s^{(n)}(\mathbf{X}_s,\mathbf{X}_s'), \tag{2.2}$$

with

$$R_s^{(c)}(\mathbf{X}_s,\mathbf{X}_s')=\sum_{\Gamma_s}\Phi_s^{(\Gamma_s)}(\mathbf{X}_s)\Phi_s^{(\Gamma_s)*}(\mathbf{X}_s'), \tag{2.3}$$

$$R_s^{(n)}(\mathbf{X}_s,\mathbf{X}_s')=\sum_{\nu,\Gamma_s} n_s(\varepsilon_\nu^{(s)})\Psi_{\nu\Gamma_s}(\mathbf{X}_s)\Psi^*_{\nu\Gamma_s}(\mathbf{X}_s'), \tag{2.4}$$

where the superscript (c) means the condensate fraction and (n) the normal one, the functions $n_s(z)$ in (2.4) being continuous now. When writing down (2.3) we imply that there is no external field that would act on the spins; thereby all solutions with $\nu=\nu_0$ and different spin projections are singled out, none of them being distinguished anyhow. Upon assuming that $\Delta n_s>0$ the unknown quantities Δn_s are incorporated into the functions $\Phi_s^{(\Gamma_s)}(\mathbf{X}_s)$ of (2.3) which because of this differ from $\Psi_{\nu_0\Gamma_s}(\mathbf{X}_s)$ in the normalization. Therefore, according to (I.A10) they have the form

$$\Phi_s^{(\Gamma_s)}(\mathbf{X}_s)=\frac{1}{s!}\sum_{P_{r\sigma}}^{(s)}(\pm)^p\mathsf{P}_{r\sigma}\chi_{\Gamma_s}(\Sigma_s)\varphi_s(\mathbf{x}_s), \tag{2.5}$$

while the functions $\varphi_s(\mathbf{x}_s)$ satisfy the equation following from (I.2.11)

$$\frac{\hbar^2}{2m}\sum_{j=1}^{(s)}\nabla_j^2\varphi_s(\mathbf{x}_s)+[\varepsilon_{(s)}-U_s(\mathbf{x}_s)]\varphi_s(\mathbf{x}_s)=0, \tag{2.6}$$

in which $\varepsilon_{(s)}$ is written for $\varepsilon_{\nu_0}^{(s)}$.

If, by analogy with ν_0, several sets of numbers ν are exceptional the relevant functions will be labeled with an index λ. In this case instead of (2.2) and (2.3) one will have

$$R_s(\mathbf{X}_s,\mathbf{X}_s')=\sum_{\lambda,\Gamma_s}\Phi_{s,\lambda}^{(\Gamma_s)}(\mathbf{X}_s)\Phi_{s,\lambda}^{(\Gamma_s)*}(\mathbf{X}_s')+R_s^{(n)}(\mathbf{X}_s,\mathbf{X}_s'). \tag{2.7}$$

Analogously with (2.2) we introduce also diagonal elements of the density matrices summed up over the spin coordinates defined in (I.2.5):

$$\rho_s(\mathbf{x}_s)=\rho_s^{(c)}(\mathbf{x}_s)+\rho_s^{(n)}(\mathbf{x}_s), \tag{2.8}$$

where upon implying (2.3)

$$\rho_s^{(c)}(\mathbf{x}_s)=\sum_{\Sigma_s,\Gamma_s}|\Phi_s^{(\Gamma_s)}(\mathbf{X}_s)|^2. \tag{2.9}$$

As long as Eq. (2.4) is identical to (2.1) with the same presumptions as to the continuity of $n_s(z)$, for $R_s^{(n)}(\mathbf{X}_s,\mathbf{X}_s')$ we have the same formulas as the ones of I for $R_s(\mathbf{X}_s,\mathbf{X}_s')$. Therefore, the expression for $\rho_s^{(n)}(\mathbf{x}_s)$ coincides with (I.2.27), namely,

$$\rho_s^{(n)}(\mathbf{x}_s)=\frac{1}{2\pi i(2\pi\hbar)^{3s}s!}\int d\mathbf{m}_s\int_C dz n_s(z)\upsilon_s(\mathbf{x}_s,\mathbf{m}_s,z)$$
$$\times\sum_P^{(s)}(\pm)^p\kappa(P)\exp\left[\frac{i}{\hbar}\sum_{k=1}^{s}\mathbf{r}_k(\mathbf{p}_k-\mathsf{P}\mathbf{p}_k)\right], \tag{2.10}$$

with $\kappa(P)=\Sigma_{\Sigma_s}\delta(\mathsf{P}\Sigma_s,\Sigma_s)$ and the function $\upsilon_s(\mathbf{x}_s,\mathbf{m}_s,z)$ satisfying Eq. (I.2.26):

$$\frac{\hbar^2}{2m}\sum_{j=1}^{s}\nabla_j^2\upsilon_s+\frac{i\hbar}{m}\sum_{j=1}^{s}\mathbf{p}_j\nabla_j\upsilon_s+\left[z-\frac{1}{2m}\sum_{k=1}^{s}\mathbf{p}_j^2-U_s(\mathbf{x}_s)\right]\upsilon_s=1. \tag{2.11}$$

When deriving Eq. (I.2.24) from a hierarchy of equations for $R_s(\mathbf{X}_s,\mathbf{X}_s')$ of (2.1) no continuity condition was implied for $n_s(\varepsilon_\nu^{(s)})$ and consequently this equation can be used as it stands:

$$\rho_s(\mathbf{x}_s)\nabla_1U_s(\mathbf{x}_s)=\rho_s(\mathbf{x}_s)\nabla_1\sum_{j=2}^{s}K(|\mathbf{r}_1-\mathbf{r}_j|)+\int\rho_{s+1}(\mathbf{x}_{s+1})\nabla_1K(|\mathbf{r}-\mathbf{r}_{s+1}|)d\mathbf{r}_{s+1}, \tag{2.12}$$

upon supposing that there is no external field $V^{(e)}(\mathbf{r})$. It will be recalled that $K(|\mathbf{r}_i-\mathbf{r}_j|)$ is the two-body potential that describes interaction between particles.

Thus, just as in I we have again obtained a hierarchy of equations for diagonal elements of reduced density matrices at thermodynamic equilibrium, which contains $\rho_s(\mathbf{x}_s)$, $U_s(\mathbf{x}_s)$, $v_s(\mathbf{x}_s,\mathbf{m}_s,z)$ and now $\varphi_s(\mathbf{x}_s)$ in addition. The equations are (2.5), (2.6), (2.8)–(2.12). Equations (2.9), (2.5), and (2.6) determine $\rho_s^{(c)}(\mathbf{x}_s)$ as a functional of the effective potential $U_s(\mathbf{x}_s)$ via an auxiliary function $\varphi_s(\mathbf{x}_s)$ while Eqs. (2.10) and (2.11) determine $\rho_s^{(n)}(\mathbf{x}_s)$ as a functional of the same potential $U_s(\mathbf{x}_s)$ via an auxiliary function $v_s(\mathbf{x}_s,\mathbf{m}_s,z)$. Eq. (2.12) yields a functional dependence of $U_s(\mathbf{x}_s)$ on the full functions $\rho_s(\mathbf{x}_s)$ and $\rho_{s+1}(\mathbf{x}_{s+1})$ of (2.8) thus closing the set of equations and at the same time connecting the sth and $(s+1)$th members of the hierarchy. Note that Eq. (2.12) has a form similar to that of an equation of the classical BBGKY hierarchy.[2] It remains to determine the functions $n_s(z)$, the quantities $\varepsilon_{(s)}$, the normalization of $\varphi_s(\mathbf{x}_s)$, and conditions on solutions of Eq. (2.6), the conditions on solutions of Eq. (2.11) being discussed in Ref. 2 seeing that Eq. (2.11) coincides with Eq. (2.22) of this last reference.

B. Supplementary equations and conditions

In order to find the quantities and conditions listed at the end of the preceding subsection we turn to the interrelation between the reduced density matrices that follows from (I.2.4) at $n=s+1$:

$$(N-s+1)R_{s-1}(\mathbf{X}_{s-1},\mathbf{X}'_{s-1})=\sum_{\sigma_s=1}^{\kappa}\int_V R_s(\mathbf{X}_{s-1},\mathbf{r}_s,\sigma_s,\mathbf{X}'_{s-1},\mathbf{r}_s,\sigma_s)d\mathbf{r}_s, \tag{2.13}$$

where we have made the replacement $s\to s-1$ for convenience sake.[9] In virtue of the linearity of Eq. (2.13) one can require it to be satisfied by $R_s^{(c)}$ and $R_s^{(n)}$ separately.

As long as $R_s^{(n)}$ obeys the same equations as R_s in I Eq. (2.13) permits one to arrive at an equation for $n_s(z)$ identical with (I.2.29). In order to solve this equation uniquely an extra condition on $n_s(z)$ is required. To obtain the condition in question one may reason exactly as in Sec. IV of Ref. 2. Let the system be made up of two mutually noninteracting subsystems A and B, so that the wave function of the system is of the form $\Psi=\Psi_A\Psi_B$. In this case the density matrices should break up into two factors according to the definition of (I.2.2):

$$R_s(\mathbf{X}_s,\mathbf{X}'_s)=C_s^{s_a,s_b}R_{s_a}(\mathbf{X}_{s_a}^{(a)},\mathbf{X}_{s_a}^{(a)\prime})R_{s_b}(\mathbf{X}_{s_b}^{(b)},\mathbf{X}_{s_b}^{(b)\prime}), \tag{2.14}$$

where $s=s_a+s_b$, the constant $C_s^{s_a,s_b}$ depends on the manner in which one normalizes R_{s_a} and R_{s_b} (see Appendix A), the index a refers to the subsystem A and b to B. For simplicity we assume that the subsystem A alone has a condensate. Then as in (2.2)–(2.4) we shall have

$$R_{s_a}(\mathbf{X}_{s_a}^{(a)},\mathbf{X}_{s_a}^{(a)\prime})=\sum_{\Gamma_{s_a}}\Phi_{s_a}^{(\Gamma_{s_a})}(\mathbf{X}_{s_a}^{(a)})\Phi_{s_a}^{(\Gamma_{s_a})*}(\mathbf{X}_{s_a}^{(a)\prime})+\sum_{\nu_a,\Gamma_{s_a}}n_{s_a}(\varepsilon_{\nu_a}^{(s_a)})\Psi_{\nu_a\Gamma_{s_a}}(\mathbf{X}_{s_a}^{(a)})\Psi^*_{\nu_a\Gamma_{s_a}}(\mathbf{X}_{s_a}^{(a)\prime}), \tag{2.15}$$

$$R_{s_b}(\mathbf{X}_{s_b}^{(b)},\mathbf{X}_{s_b}^{(b)\prime})=\sum_{\nu_b,\Gamma_{s_b}}n_{s_b}(\varepsilon_{\nu_b}^{(s_b)})\Psi_{\nu_b\Gamma_{s_b}}(\mathbf{X}_{s_b}^{(b)})\Psi^*_{\nu_b\Gamma_{s_b}}(\mathbf{X}_{s_b}^{(b)\prime}). \tag{2.16}$$

Upon substituting this into (2.14) and taking into account that $\varepsilon_\nu^{(s)}=\varepsilon_{\nu_a}^{(s_a)}+\varepsilon_{\nu_b}^{(s_b)}$ in the present case[2] we shall obtain an expression of the type (2.7) only if

$$n_s(\varepsilon_{\nu_a}^{(s_a)}+\varepsilon_{\nu_b}^{(s_b)})\propto n_{s_a}(\varepsilon_{\nu_a}^{(s_a)})n_{s_b}(\varepsilon_{\nu_b}^{(s_b)}). \tag{2.17}$$

This relation together with (I.2.29) entail Eqs. (I.2.30) and (I.2.31) (details are given in Appendix A), namely,

$$n_s(z)=A_s e^{-z/\tau},\quad A_s=s!\left(\frac{\rho}{\kappa}\right)^{s-1}\left(\frac{2\pi\hbar^2}{m\tau}\right)^{3(s-1)/2}A;\quad n_1(z)\equiv n(z)=Ae^{-z/\tau},\tag{2.18}$$

where $\rho=N/V$ is the average number density, A and τ are constants.

Having found $n_s(z)$ we now turn to the relationship of (2.13) as applied to the condensate part $R_s^{(c)}(\mathbf{X}_s,\mathbf{X}_s')$. Upon placing Eq. (2.3) there and assuming that $s\ll N$ we have, for $s>1$,

$$\sum_{\Gamma_{s-1}}\Phi_{s-1}^{(\Gamma_{s-1})}(\mathbf{X}_{s-1})\Phi_{s-1}^{(\Gamma_{s-1})*}(\mathbf{X}_{s-1}')=\frac{1}{N}\sum_{\sigma_s=1}^{\kappa}\sum_{\Gamma_s}\int_V\Phi_s^{(\Gamma_s)}(\mathbf{X}_{s-1},\mathbf{r}_s,\sigma_s)\Phi_s^{(\Gamma_s)*}(\mathbf{X}_{s-1}',\mathbf{r}_s,\sigma_s)d\mathbf{r}_s.\tag{2.19}$$

Let us find first $\Phi_1^{(\gamma)}(\mathbf{r},\sigma)$ that, according to (2.5), is of the form

$$\Phi_1^{(\gamma)}(\mathbf{r},\sigma)=\delta_{\gamma\sigma}\varphi_1(\mathbf{r}).\tag{2.20}$$

It will be recalled that the spin variable σ and the spin index γ run from 1 to $\kappa=2S+1$ where S is the particle spin. As in I we limit ourselves to consideration of a spatially uniform boundless system upon putting[2] $U_1=0$. Then Eq. (2.6) at $s=1$ becomes

$$\frac{\hbar^2}{2m}\nabla^2\varphi_1(\mathbf{r})+\varepsilon_{(1)}\varphi_1(\mathbf{r})=0.\tag{2.21}$$

We take a solution of this equation which gives $\rho_1^{(c)}=\rho_c=$constant. Analogously to Eq. (2.8) of Ref. 3 this solution is of the form $\varphi_1(\mathbf{r})=C\exp(i\mathbf{p}_0\mathbf{r}/\hbar)$ with $\mathbf{p}_0^2=2m\varepsilon_{(1)}$. The constant C that can be considered to be real because a factor like $e^{i\alpha}$ plays no part for (2.3) may be expressed in terms of ρ_c by (2.9). We introduce the result into (2.20):

$$\Phi_1^{(\gamma)}(\mathbf{r},\sigma)=\delta_{\gamma\sigma}\sqrt{\frac{\rho_c}{\kappa}}\exp\left(\frac{i}{\hbar}\mathbf{p}_0\mathbf{r}\right),\quad \varepsilon_{(1)}=\frac{\mathbf{p}_0^2}{2m}.\tag{2.22}$$

Here we have also written down the quantity $\varepsilon_{(1)}$ as a function of $\mathbf{p}_0$. Below we shall see that all quantities relevant to the condensate are expressed in terms of the condensate density ρ_c and of the vector $\mathbf{p}_0$.

Next, referring again to (2.5) one has

$$\Phi_2^{(\gamma_1,\gamma_2)}(\mathbf{r}_1,\sigma_1,\mathbf{r}_2,\sigma_2)=\tfrac{1}{2}[\delta_{\gamma_1\sigma_1}\delta_{\gamma_2\sigma_2}\varphi_2(\mathbf{r}_1,\mathbf{r}_2)\pm\delta_{\gamma_1\sigma_2}\delta_{\gamma_2\sigma_1}\varphi_2(\mathbf{r}_2,\mathbf{r}_1)].\tag{2.23}$$

We turn now to the relationship (2.19) putting $s=2$. At given $\mathbf{r}_{s-1}=\mathbf{r}_1$ and $\mathbf{r}_{s-1}'=\mathbf{r}_1'$ the main contribution to the integral in (2.19) as $V\to\infty$ results from regions where $|\mathbf{r}_1-\mathbf{r}_2|$ and $|\mathbf{r}_1'-\mathbf{r}_2|$ are large (cf. Sec. IV of Ref. 2). In these regions $U_2\to 0$, and Eq. (2.5) at $s=2$ becomes

$$\frac{\hbar^2}{2m}(\nabla_1^2+\nabla_2^2)\varphi_2^{(\infty)}(\mathbf{r}_1,\mathbf{r}_2)+\varepsilon_{(2)}\varphi_2^{(\infty)}(\mathbf{r}_1,\mathbf{r}_2)=0,\tag{2.24}$$

the superscript (∞) denoting the limiting value of φ_s. By analogy with the solution of Eq. (2.21) the solution of (2.24) can be taken to be

$$\varphi_2^{(\infty)}(\mathbf{r}_1,\mathbf{r}_2)=B_2\exp\left[\frac{i}{\hbar}(\mathbf{q}_1\mathbf{r}_1+\mathbf{q}_2\mathbf{r}_2)\right],\quad \varepsilon_{(2)}=\frac{\mathbf{q}_1^2+\mathbf{q}_2^2}{2m}.\tag{2.25}$$

It should be observed that the solution of (2.24) need not have any symmetry since the symmetry required will emerge after substitution into (2.23). If (2.22) and (2.23) together with (2.25) are inserted into (2.19) at $s=2$, one will obtain that $\mathbf{q}_1=\mathbf{q}_2=\mathbf{p}_0$ and, besides,

$$B_2=\sqrt{\frac{2\rho_c\rho}{\kappa(\kappa\pm1)}},\quad \varepsilon_{(2)}=\frac{\mathbf{p}_0^2}{m}. \tag{2.26}$$

Some comment at this point is in order. In Ref. 3 it was pointed out that in the case of spinless fermions the condensate could not form. This follows directly from (2.26): if one puts $\kappa=1$ (i.e., $S=0$) implying the lower sign in (2.26), then the expression for B_2 makes no sense unless $\rho_c=0$.[10] Existence of the spin of fermions (the spin factor $\kappa\geqslant2$) leads to the result that $B_2\neq0$ if $\rho_c\neq0$. In other words, the spin permits one to surmount the difficulty that arises at $s=2$ in the case of spinless fermions.

If, however, one goes on reasoning in parallel with Ref. 3 farther, in the case of spin-half fermions ($\kappa=2$) one will again encounter an analogous difficulty now at the next stage [$s=3$ in (2.19)]. The difficulty consists in the following. In Ref. 3 when considering an equation identical with (2.6) in the limit of large $|\mathbf{r}_j-\mathbf{r}_k|$'s, one implied simplest asymptotic solutions having the form $\varphi_s^{(\infty)}(\mathbf{x}_s)\propto\exp(i\Sigma\mathbf{q}_k\mathbf{r}_k/\hbar)$ [cf. (2.25)] which always turned out symmetric in $\mathbf{r}_k$ because $\mathbf{q}_k=\mathbf{p}_0$ [see Eq. (2.9) of Ref. 3]. On the other hand if the function $\varphi_s(\mathbf{x}_s)$ in (2.5) is symmetric, in order that $\Phi_s^{(\Gamma_s)}(\mathbf{X}_s)$ be antisymmetric it is necessary that the function relevant to the spin variables shall be antisymmetric. The latter function can be expressed in terms of spinors. When $S=1/2$, however, there is no antisymmetric spinor of rank 3 (see Ref. 11). If $S>1/2$ (i.e., $\kappa>2$) analogous difficulties occur for $s>3$. It would seem that there is no solution to Eq. (2.19) appropriate for fermions.

However, just if $s\geqslant3$ there emerges a favourable circumstance. All solutions of Eq. (2.6) at $s=2$ can be taken to be symmetric or antisymmetric as in the case of the Schrödinger equation[11] that Eq. (2.6) is identical with. It easy to see that antisymmetric solutions are not appropriate for our purposes.[12] In the event that $s\geqslant3$, in addition to symmetric and antisymmetric solutions an equation of the (2.6) type always admits solutions that have no such symmetries.[11] Just these last solutions are helpful for us.

For $s\geqslant3$ we shall take solutions of (2.6) subject to the conditions

$$\varphi_s(\mathbf{x}_s)\to D_s\varphi_{s-1}(\mathbf{x}_{s-1})\exp\left(\frac{i}{\hbar}\mathbf{p}_0\mathbf{r}\right),\quad \text{as}\ \ |\mathbf{r}_s|\to\infty, \tag{2.27}$$

$$\varphi_s(\mathbf{x}_s)\to0,\quad \text{as}\ \ |\mathbf{r}_j|\to\infty\ \ \text{with}\ \ j\neq s, \tag{2.28}$$

where D_s is a constant to be chosen later. The physical bearings of the conditions of (2.27) and (2.28) will be discussed below. Note that the conditions are not symmetric in all $\mathbf{r}_1,\ldots,\mathbf{r}_s$. We place Eq. (2.27) into (2.6), letting $|\mathbf{r}_s|\to\infty$ and making use of the obvious fact[2] that $U_s(\mathbf{x}_s)\to U_{s-1}(\mathbf{x}_{s-1})$ in this limit since $U_1=0$. As a result we have

$$\frac{\hbar^2}{2m}\sum_{j=1}^{s-1}\nabla_j^2\varphi_{s-1}(\mathbf{x}_{s-1})+\left[\varepsilon_{(s)}-\frac{\mathbf{p}_0^2}{2m}-U_{s-1}(\mathbf{x}_{s-1})\right]\varphi_{s-1}(\mathbf{x}_{s-1})=0. \tag{2.29}$$

Upon comparing this with Eq. (2.6) written for $\varphi_{s-1}(\mathbf{x}_{s-1})$ we see that the condition of (2.27) is possible if

$$\varepsilon_{(s)}=\varepsilon_{(s-1)}+\frac{\mathbf{p}_0^2}{2m}. \tag{2.30}$$

Because we know $\varepsilon_{(1)}$ and $\varepsilon_{(2)}$ by (2.22) and (2.26), this relation determines all $\varepsilon_{(s)}$.

We revert now to the right-hand side of (2.19). Again, as in the $s=2$ case, the main contribution to the integral as $V\to\infty$ is due to regions where $|\mathbf{r}_s|$ is large, and thereby the limiting expressions of (2.27) and (2.28) have to be used with account taken of the fact that the vector $\mathbf{r}_s$ is permuted according to (2.5). By virtue of (2.28) all permutations that involve $\mathbf{r}_s$ will give integrals that increase more slowly than V in the limit as $V\to\infty$. For this reason we ought to retain only those permutations that do not affect $\mathbf{r}_s$, which implies making use of (2.27). Then the integral in (2.19) is calculated at once while the summation over σ_s and γ_s is readily carried out thanks to (I.2.12). If one compares the result with the left-hand side of (2.19) wherein (2.5) is put one will see that (2.19) is fulfilled if

$$D_s = s\sqrt{\frac{\rho}{\kappa}}. \tag{2.31}$$

Thus, we have satisfied the last condition to which the density matrices are to be subjected, the condition being (2.19). Together with this, we have uniquely formulated the problem concerning solution of Eq. (2.6) for $s\geqslant 3$: the quantities $\varepsilon_{(s)}$ are defined by (2.30) while the limiting form of $\varphi_s(\mathbf{x}_s)$ must be that of (2.27) and (2.28) wherein D_s is given by (2.31). We see that calculation of $\varphi_{s-1}(\mathbf{x}_{s-1})$ determines the boundary conditions for $\varphi_s(\mathbf{x}_s)$ from which the normalization of $\varphi_s(\mathbf{x}_s)$ follows as well. For $s=2$ the boundary condition is (2.25) with (2.26), while for $s=1$ the solution is known by virtue of (2.22). Just as in Ref. 3 there remain four arbitrary constants τ, A, ρ_c, and $\mathbf{p}_0$ which are to be found from thermodynamic considerations and the normalization condition of (I.2.6).

C. Analysis and discussion of the results obtained

Turning now to the discussion of the physical bearings of the conditions of (2.27) and (2.28) let us first consider the case $s=3$ when $\mathbf{r}_s=\mathbf{r}_3$. The condition of (2.27) is usual and means that, when particle 3 moves away, particles 1 and 2 are described by the wave function $\varphi_2(\mathbf{r}_1,\mathbf{r}_2)$. The condition (2.28) is rather unusual in our case. The fact that a wave function vanishes at infinity implies that there is a bound state. Therefore, the condition of (2.28) amounts to saying that particles 1 and 2 form a bound state in the presence of particle 3 even if there is no bound state when particle 3 is absent [the above function $\varphi_2(\mathbf{r}_1,\mathbf{r}_2)$ corresponds to the scattering of particles according to the discussion of Eq. (3.6) obtained below]. The possibility of such a situation is quite understandable physically. Let us suppose that the interaction between each pair of particles is attractive but rather weak, so that they cannot form a bound state. Approach of a third particle diminishes the potential energy, and thereby the first two particles may form a bound state when the third is near. The aforesaid does not signify that all particles break up into pairs. The condition of (2.28) for $s=4$ is equivalent to saying that three particles form a bound state in the presence of a fourth particle. If one puts $s=5$ in (2.28) one will conclude that four particles form a bound state when a fifth particle is near, and so on. It should be emphasized that the above argument is a simplification, and is presented here for illustrative purposes only. In the matter of an interacting N-body system one cannot speak of states of two, three, etc. particles. The conditions of (2.27) and (2.28) merely imply special correlations that arise in the case under study. From the dynamical point of view there occurs permanent formation and disintegration of groups of bound particles.

Nevertheless from the foregoing it follows that the condition of (2.28) can be fulfilled only if there exists an attractive interaction between the particles. However, this does not at all amount to saying that the interparticle potential $K(\mathbf{r})$ must have an attractive part. The point is that (2.6) contains an effective potential $U_s(\mathbf{x}_s)$, and not $K(\mathbf{r})$. Even in the case of hard spheres the potential $U_s(\mathbf{x}_s)$ has an attractive part which is due to the shielding effect (for an explanation of this effect see, e.g., Ref. 13, Sec. 8.6). Of course, other causes for the existence of an effective attraction in the event of a purely repulsive Hamiltonian are possible. In the BCS theory such an attraction is ascribed to an electron–phonon interaction. As is known it is difficult to explain high-temperature

superconductivity in the framework of the BCS theory. Perhaps, in the last case an important role is played just by the shielding effect that is manifested at any density and temperatures regardless of the Hamiltonian.

Let us make a few remarks in addition. As was shown in Ref. 2, in the case of a Bose system the normal phase cannot exist at temperatures $\theta \approx 0$. For this reason, as the temperature is lowered there must necessarily emerge a condensate phase. With this corresponds the fact that in the boson case the condensate phase exists whatever the interaction potential $K(\mathbf{r})$ is[3] [it occurs even in an ideal gas when $K(\mathbf{r}) \equiv 0$]. In the case of a Fermi system the situation is different. According to I the fermionic normal phase can exist even at $\theta = 0$. Consequently the fermionic condensate phase need not exist necessarily for any $K(\mathbf{r})$. The fermionic condensate phase occurs only when the conditions of (2.27) and (2.28) can be fulfilled. In particular, these conditions cannot be satisfied in an ideal gas. Therefore, the condensate phase cannot form in an ideal Fermi gas as is obvious in advance.

Equation (2.6) can have a solution corresponding to (2.27) and (2.28) in the case of bosons as well. In Ref. 3 it was stated that condensate phases of different types are possible. The solution corresponding to (2.27) and (2.28) provides an extra possible type of the condensate phase for bosons.

If the spin S of fermions is such that $\kappa > 2$ (i.e., $S > 1/2$), symmetric solutions with the simplest limiting form $\varphi_s^{(\infty)}(\mathbf{x}_s) \propto \exp(i\Sigma \mathbf{q}_k \mathbf{r}_k / \hbar)$ as in Ref. 3 are possible up to $s = \kappa$. Only when $s \geqslant \kappa$, solutions must have the limiting form of (2.27) and (2.28). Therefore, a variety of condensate phases may be obtained, depending on the integer s at which (2.27) and (2.28) begin to hold. Realized is the phase that provides an absolute minimum of the appropriate thermodynamic potential.

In the event of a Fermi liquid one can repeat the considerations expounded in Sec. IV of Ref. 3. Consequently, condensate phases of different types, either superfluid ($\mathbf{p}_0 \neq 0$) or nonsuperfluid ($\mathbf{p}_0 = 0$), may happen even in the case $\kappa = 2$.

It might seem at first sight that the first summand in (2.2) corresponds to condensation of fermions in one level, which contradicts the Pauli exclusion principle. In fact there is no contradiction. In paper I (see also Ref. 2) it was emphasized that the quantities $n_s(\varepsilon_\nu^{(s)})$ are no occupation numbers of levels for there are no single-particle levels in an interacting system, so that one cannot speak of condensation of particles in a level. Let us explain the absence of any contradiction with the Pauli principle in more detail. The principle stems from the antisymmetry of fermion wave functions (if states of two fermions coincide the wave function vanishes identically owing to the antisymmetry). In our case all fermion density matrices (and thereby the wave function itself) are antisymmetric with respect to the variables denoted briefly as $\mathbf{X}_s$ and $\mathbf{X}_s'$, which is immediately seen from (I.A10) and (2.5). Just the requirement that $R_s^{(c)}(\mathbf{X}_s, \mathbf{X}_s')$ should not vanish identically compelled us to resort to limiting conditions of types (2.27) and (2.28). In the case of bosons that are not subjected to the Pauli principle, simpler solutions used in Ref. 3 (see also above) are possible.

Concluding the section let us calculate the momentum of the system. To this end, by making use of (2.22) and (2.2)–(2.4), first we find the density matrix R_1:

$$R_1(\mathbf{r}, \sigma, \mathbf{r}', \sigma') = \frac{\delta_{\sigma\sigma'}}{\kappa} \left\{ \rho_c \exp\left[\frac{i}{\hbar} \mathbf{p}_0 (\mathbf{r} - \mathbf{r}') \right] + \rho_n \exp\left[-\frac{m\tau(\mathbf{r} - \mathbf{r}')^2}{2\hbar^2} \right] \right\}. \tag{2.32}$$

The second term is written here with the help of formulas of the next section. The momentum $\mathbf{P}$ of the system can be computed by Eq. (2.13) of Ref. 3 with additional summation over the spin projections, so that $\mathbf{P} = \rho_c V \mathbf{p}_0$. Just as in the boson case of Ref. 3 the situation is analogous with that in which there are $N_c = \rho_c V$ particles that move at a speed of $\mathbf{p}_0 / m$ without any dissipation of energy.

It is worthy of remark that according to (2.32) the density matrices exhibit off-diagonal long range order (ODLRO) since they do not vanish in the limit as $|\mathbf{r} - \mathbf{r}'| \to \infty$. ODLRO is due only to

the condensate fraction because the first summand alone in (2.32) displays this feature. As is known the existence of ODLRO is characteristic of superfluidity.[14]

III. THERMODYNAMICS

A. Transformation of equations

Before proceeding to thermodynamics it is worthwhile to transform some of the equations obtained above. To this end instead of $\varphi_s(\mathbf{x}_s)$ with $s\geqslant 3$ we set up functions $u_s(\mathbf{x}_s)$ according to

$$\varphi_s(\mathbf{x}_s)=u_s(\mathbf{x}_s)\exp\left(\frac{i}{\hbar}\mathbf{p}_0\sum_{k=1}^{s}\mathbf{r}_k\right). \tag{3.1}$$

When substituted into (2.6) with account taken of (2.30), this yields the equation

$$\frac{\hbar^2}{2m}\sum_{j=1}^{s}\nabla_j^2 u_s(\mathbf{x}_s)+\frac{i\hbar\mathbf{p}_0}{m}\sum_{j=1}^{s}\nabla_j u_s(\mathbf{x}_s)-U_s(\mathbf{x}_s)u_s(\mathbf{x}_s)=0. \tag{3.2}$$

Note that this last equation coincides with Eq. (2.10) obtained in Ref. 3 for the boson case. The relevant boundary conditions follow from (2.27) and (2.28):

$$u_s(\mathbf{x}_s)\to D_s u_{s-1}(\mathbf{x}_{s-1}) \quad \text{as} \quad |\mathbf{r}_s|\to\infty, \tag{3.3}$$

$$u_s(\mathbf{x}_s)\to 0, \quad \text{as} \quad |\mathbf{r}_j|\to\infty \quad \text{with} \quad j\neq s. \tag{3.4}$$

At $s=2$ it is more convenient to use another normalization of u_2 upon writing, instead of (3.1),

$$\varphi_2(\mathbf{r}_1,\mathbf{r}_2)=\sqrt{\frac{2\rho_c\rho}{\kappa(\kappa\pm 1)}}\,u_2(\mathbf{r}_1,\mathbf{r}_2)\exp\left[\frac{i}{\hbar}\mathbf{p}_0(\mathbf{r}_1+\mathbf{r}_2)\right]. \tag{3.5}$$

It should be observed that $u_2(\mathbf{r}_1,\mathbf{r}_2)$ is to be symmetric by virtue of (2.25). In the case of homogeneous media we deal with, $u_2(\mathbf{r}_1,\mathbf{r}_2)$ depends only upon the difference $\mathbf{r}=\mathbf{r}_2-\mathbf{r}_1$, while Eq. (3.2) becomes

$$\frac{\hbar^2}{m}\nabla^2 u_2(\mathbf{r})-U_2(\mathbf{r})u_2(\mathbf{r})=0, \tag{3.6}$$

with the condition that $u_2(\mathbf{r})\to 1$ as $|\mathbf{r}|\to\infty$, which follows from (2.25) and (2.26). Such an equation with this condition is characteristic of the problem of scattering of a particle with the propagation vector $\mathbf{k}=0$ by a fixed force field as was noted in Ref. 3. In particular instead of (3.6) one may use Eq. (2.12) of this reference.

In uniform media one can put[2] $U_1=0$, so that Eq. (2.11) with $s=1$ is readily solved to yield

$$\nu_1(\mathbf{p},z)=\frac{1}{z-\mathbf{p}^2/2m}. \tag{3.7}$$

Now we calculate $\rho_1^{(n)}$ by (2.10) with the help of the residue theorem upon inserting (2.18) for $n_1(z)\equiv n(z)$. Next, recalling that $\rho_1^{(c)}=\rho_c$ we find ρ_1 by (2.8) and put it in the normalization condition of (I.2.6) with the result that $\rho=\rho_c+\rho_n$ where $\rho=N/V$ and

$$\rho_n=\frac{\sqrt{\pi}}{2}A\kappa\omega\tau^{3/2} \quad \text{with} \quad \omega=\frac{m^{3/2}}{\sqrt{2}\,\pi^2\hbar^3}. \tag{3.8}$$

In like fashion one gets (2.32) if use is made of (I.3.3) for $R_1^{(n)}$.

Calculation of thermodynamic quantities requires a knowledge of the pair density matrix $\rho_2(\mathbf{r}_1,\mathbf{r}_2)$. We substitute (2.5) and (3.5) into (2.8) with (2.9) and use the symmetry of $u_2(\mathbf{r}_1,\mathbf{r}_2)=u_2(\mathbf{r}_2-\mathbf{r}_1)$ [see the remark following (3.5)]. We take (I.3.12) to calculate $\rho_2^{(n)}$. As a result we obtain the following expression for the pair correlation function $g(\mathbf{r})=\rho_2(\mathbf{r})/\rho^2$:

$$g(\mathbf{r})=\frac{\rho_c}{\rho}u_2^2(\mathbf{r})+\frac{1}{2\pi i(2\sqrt{2}\pi\hbar)^3\rho}\int d\mathbf{q}\int_C dz n(z)\upsilon(\mathbf{r},\mathbf{q},z)\left[\kappa\pm\exp\left(\frac{i}{\hbar}\mathbf{q}\mathbf{r}\right)\right], \tag{3.9}$$

while $\upsilon(\mathbf{r},\mathbf{q},z)$ obeys Eq. (I.3.13) in which $U_2(\mathbf{r})$ replaces $U_2(|\mathbf{r}|)$ since the functions are not spherically symmetric if $\mathbf{p}_0\neq 0$.

The second term in (3.9) may be reduced to a form analogous with the right-hand side of Eq. (I.3.14). For use later we need (3.9) in the case of a spherical symmetry of $U_2(\mathbf{r})$ on condition that the spectrum is continuous. In this case one can use (I.3.16) for the second term in (3.9) with the result that

$$g(\mathbf{r})=f_c u_2^2(\mathbf{r})+\frac{1}{\pi\sqrt{2}\rho}\sum_{l=0}^{\infty}[\kappa\pm(-1)^l](2l+1)\int_0^{\infty}n\left(\frac{\hbar^2k^2}{m}\right)R_{kl}^2(r)dk, \tag{3.10}$$

where $f_c=\rho_c/\rho$ while R_{kl} satisfies Eq. (I.3.17) with the boundary condition of (I.3.18).

B. The thermodynamics of a superfluid Fermi system

General ideas as to constructing thermodynamics in the framework of the present approach were expounded in paper I. Modifications needed in order to take into account the presence of a condensate can be made by analogy with the thermodynamics of a superfluid Bose system presented in Ref. 3. The sole difference with Ref. 3 comes about because of the spin of particles. All thermodynamic formulas of Ref. 3 remain, however, as they stand because the factor κ in (2.32) cancels out owing to summation over the spin projections. Let us summarize the main features of thermodynamics in the present case referring to Ref. 3 for details.

In the preceding section it was established that the density matrices are characterized by four parameters τ, A, ρ_c, and p_0 where p_0 is the magnitude of the vector $\mathbf{p}_0$ (the direction of $\mathbf{p}_0$ plays no role in uniform media). The external parameters are implied to be the average number density $\rho=N/V$ and the temperature θ in units of energy ($\theta=k_BT$). The parameter A is expressed in terms of ρ_c by (3.8) with $\rho_n=\rho-\rho_c$. Instead of ρ_c we shall use $f_c=\rho_c/\rho$ while instead of τ it is more convenient to employ $\tilde{\tau}=\rho_n\tau/\rho=(1-f_c)\tau$.

If there is a superflow characterized by the vector $\mathbf{p}_0$ the system cannot be isotropic. We assume an axial symmetry with the z axis oriented along $\mathbf{p}_0$, so that $g(\mathbf{r})=g(r_\perp,z)$ where $r_\perp=\sqrt{x^2+y^2}$ (by r is meant $|\mathbf{r}|$). It turns out that all thermodynamic quantities can, instead of $g(r_\perp,z)$, be expressed in terms of two spherically symmetric functions (we presume that the interaction potential $K(|\mathbf{r}|)$ is spherically symmetric), namely,

$$\overline{g}(r)=\frac{1}{r}\int_0^r g(\sqrt{r^2-z^2},z)dz,\quad \tilde{g}(r)=\frac{3}{r^3}\int_0^r g(\sqrt{r^2-z^2},z)z^2dz. \tag{3.11}$$

It will be noted that in the case of a spherical symmetry

$$\overline{g}(r)=\tilde{g}(r)=g(r). \tag{3.12}$$

The parameters p_0, $\tilde{\tau}$, and f_c can be found from the following equations:

$$f_c p_0^2=\pi m\rho\int_0^{\infty}r^3\frac{dK}{dr}[\tilde{g}(r)-\overline{g}(r)]dr, \tag{3.13}$$

$$2\theta\frac{\partial\tilde{\tau}}{\partial\theta}+3\rho\frac{\partial\tilde{\tau}}{\partial\rho}-2\tilde{\tau}=\frac{\pi\rho}{3}\int_0^\infty dr r^2\left\{K(r)\left[3(\tilde{g}-\overline{g})-12\rho\frac{\partial\overline{g}}{\partial\rho}+r\left(3\frac{\partial\overline{g}}{\partial r}+\frac{\partial\tilde{g}}{\partial r}\right)\right]\right.$$
$$\left.+r\frac{dK}{dr}\left[2\theta\left(3\frac{\partial\overline{g}}{\partial\theta}-\frac{\partial\tilde{g}}{\partial\theta}\right)+3\rho\left(\frac{\partial\overline{g}}{\partial\rho}-\frac{\partial\tilde{g}}{\partial\rho}\right)\right]\right\}, \tag{3.14}$$

$$\frac{\partial}{\partial f_c}\int_0^\infty r^2\left(2K+r\frac{dK}{dr}\right)\overline{g}(r,\tilde{\tau},f_c,p_0,\rho)dr=0. \tag{3.15}$$

When writing down (3.15) we assumed that $g(\mathbf{r})$ as given by (3.9) does not depend explicitly upon θ while depending on other parameters.

Equation (3.15) plays another important role as well, namely, it yields a line in the ρ-θ plane where a solution relevant to the condensate phase bifurcates off the high-temperature solution. This line represents a phase transition line if the transition is second order. To obtain the equation of the line, in Eq. (3.15) one should put $f_c=0$, $\overline{g}(r)=g(r)$ and $\tilde{\tau}=\tau(\theta,\rho)$ with $\tau(\theta,\rho)$ relevant to the high-temperature phase and given by equations of I. The equality $\tilde{\tau}=\tau(\theta,\rho)$ on the line serves also as boundary condition for Eq. (3.14).

Having solved Eqs. (3.13)–(3.15) one may compute the internal energy E by

$$E=\frac{3}{2}\tilde{\tau}N+2\pi N\rho\int_0^\infty r^2K(r)\overline{g}(r)dr+\frac{\pi}{2}N\rho\int_0^\infty r^3\frac{dK}{dr}[\tilde{g}(r)-\overline{g}(r)]dr. \tag{3.16}$$

The pressure p that is isotropic although there is a flow in the superfluid is given by

$$p=\rho\tilde{\tau}-\frac{\pi\rho^2}{3}\int_0^\infty r^3\frac{dK}{dr}[3\overline{g}(r)-\tilde{g}(r)]dr. \tag{3.17}$$

With $E(\theta,\rho)$ and $p(\theta,\rho)$ at our disposal we can calculate the Helmholtz free energy F with the help of a formula of Appendix B of I and thereupon all thermodynamic quantities.

It should be observed that in the condensate phase the quantity τ plays a secondary part insofar as the function $n(z)$ of (2.18) characterizes now only a part of the particles. The role of τ goes over to $\tilde{\tau}$, which can be seen by comparing (3.16) and (3.17) with (I.3.7) especially when (3.12) holds.

In summary, we see that the equations for density matrices of Sec. II and the equations of the present section permit one to attain a full structural and thermodynamic description of a superfluid Fermi systems, and one has no need of resorting to any extra ideas or argumentation besides those formulated initially in Refs. 2 and 3.

IV. HARD SPHERES UNDER THE NEGLECT OF TRIPLET CORRELATIONS

A. General consideration

In the present section we are coming to an example that illustrates how the general equations derived in the preceding sections can be handled in order to produce concrete physical results. We shall consider a system of hard spheres in which triplet correlations are neglected, the same example being used in paper I as well as in Refs. 2 and 3

In the case of hard spheres

$$K(r)=\begin{cases}\infty & \text{if } r<a\\ 0 & \text{if } r>a.\end{cases} \tag{4.1}$$

If the triplet correlations are disregarded then $U_2(r)=K(r)$ according to I, which drastically simplifies the matter of finding $g(r)$ by (3.10) and of solving Eqs. (3.13)–(3.15).

Before proceeding further a word should be said in this connection. When discussing the conditions of (2.27) and (2.28) we emphasized the specific nature of correlations necessary for the conditions to be feasible, in particular if $s=3$. For this reason, if triplet correlations are negligible the condensate phase could not exist. At the same time when studying the thermodynamics of a hard-sphere system the neglect of triplet correlations may prove to be not a bad approximation even for a condensate phase. The reason lies in the fact that from Eqs. (3.13)–(3.17) it follows that all thermodynamic quantities are determined by integrals of the type

$$I=\int_0^\infty r^n\tilde{K}(r)G(r)dr, \tag{4.2}$$

where $\tilde{K}(r)=K(r)$ or dK/dr, and $G(r)$ depends on $g(r)$ and its derivatives [below we consider the case in which (3.12) holds]. For the hard-sphere potential of (4.1) one has $\tilde{K}(r)\equiv 0$ if $r>a$ and $G(r)\equiv 0$ if $r<a$. Consequently in this instance, only values of the functions at $r=a$ contribute to the integral of (4.2). When two hard spheres come in contact, locations of other hard spheres are of little importance to the two spheres. For this reason the contact value $g(a)$ of the pair correlation function should not depend appreciably upon triplet correlations. This is corroborated by the fact that different quantities calculated in paper I and Ref. 2 upon neglecting the triplet correlations coincide rather well with the ones computed by other authors without disregarding these correlations.

Below we shall find $g(r)$ upon discarding the triplet correlations, with the intention of using solely the contact value $g(a)$. Of course, without special investigation one cannot wholly rely upon all results so obtained: some of them might be rather qualitative than quantitative. In particular, one cannot pass to the limit $a\to 0$ in the formulas deduced below inasmuch as the value $a=0$ corresponds to an ideal gas while the condensate phase cannot exist in an ideal Fermi gas (see Sec. II C).

If $U_2(r)=K(r)$ with $K(r)$ given by (4.1), Eq. (3.6) has a unique solution

$$u_2(r)=1-\frac{a}{r}, \tag{4.3}$$

subject to two conditions, namely, $u_2(a)=0$ and $u_2(r)\to 1$ as $r\to\infty$.

In the approximation used $U_2(\mathbf{r})$ does not depend on $u_2(\mathbf{r})$, hence the second term in (3.10) will differ from (I.5.1) only because of the value of A given now by (3.8). Upon denoting the right-hand side of (I.5.1) with A from (I.3.6) by $g_{\mathrm{I}}(r)$ we are led to

$$g(r)=1-\frac{2af_c}{r}\left(1-\frac{a}{2r}\right)+(1-f_c)[g_{\mathrm{I}}(r)-1]. \tag{4.4}$$

This function corresponds to a spherical symmetry, which entails $p_0=0$ on account of (3.12) and (3.13). Consequently, in the case considered in the present section we shall have a condensate phase without superfluidity just as in the analogous case of bosons treated in Ref. 3. It should be emphasized, however, that this result does nowise amount to saying that the hard-sphere condensate phase is necessarily nonsuperfluid. The result merely signifies that the exact value of p_0 cannot be found if the triplet correlations are disregarded. We note in passing that Eq. (4.4) shows that if $f_c\neq 0$ the decay of spatial correlations is slow as $r\to\infty$, they decay proportionally to $1/r$. Therefore, the condensate phase is characterized by long-range correlations.

We calculate now the integrals entering into Eqs. (3.13)–(3.17) implying (3.12). Upon denoting the first term of (3.10) as $g_c(r)$, in Appendix B it is shown that in the case of the potential of (4.1) and of any continuous function $f(r)$ one has

$$\int_0^\infty f(r)K(r)\frac{\partial g_c}{\partial r}dr=\frac{\rho_c\hbar^2 f(a)}{\rho m a^2}. \tag{4.5}$$

A similar integral in which g_c is replaced by the second term of (3.10) may be calculated like (I.5.2). As a result, integrating by parts we obtain for spin-half fermions

$$\int_0^\infty r^3 g(r)\frac{dK}{dr}dr=-\frac{a\hbar^2}{m}[f_c+(1-f_c)H_2(\overline{\tau})], \tag{4.6}$$

with $\overline{\tau}=a^2m\tau/\hbar^2$ and $H_2(\xi)$ defined in (I.5.6). When integrating by parts we used the fact that in the present case, as can be shown analogously with (I.5.2) and (4.5), one has

$$\int_0^\infty r^2 g(r)K(r)dr=0. \tag{4.7}$$

All of these and (3.12) allow Eq. (3.14) to be reduced to the form

$$2\theta\frac{\partial\tilde{\tau}}{\partial\theta}+3\rho\frac{\partial\tilde{\tau}}{\partial\rho}-2\tilde{\tau}=\frac{4\pi a\hbar^2\rho}{3m}\left\{f_c+(1-f_c)H_2(\overline{\tau})-\frac{a^2m\theta}{\hbar^2}H_2'(\overline{\tau})\frac{\partial\tilde{\tau}}{\partial\theta}\right.$$
$$\left.-[1-H_2(\overline{\tau})+\overline{\tau}H_2'(\overline{\tau})]\theta\frac{\partial f_c}{\partial\theta}\right\}, \tag{4.8}$$

where the prime over $H_2'(\overline{\tau})$ denotes differentiation with respect to the argument. The noteworthy is the fact that (4.8) is akin to Eq. (5.3) of Ref. 3. The internal energy E and the pressure p may be calculated by (3.16) and (3.17) with the help of (4.5) and (4.6), so that

$$E=\frac{3}{2}\tilde{\tau}N,\quad p=\rho\tilde{\tau}+\frac{2\pi a\hbar^2}{3m}\rho^2[f_c+(1-f_c)H_2(\overline{\tau})]. \tag{4.9}$$

The quantity $\overline{\tau}$ that figures in (4.8) and (4.9) can be expressed in terms of the parameters $\tilde{\tau}$ and f_c defined in Sec. III:

$$\overline{\tau}=\frac{a^2m\tilde{\tau}}{\hbar^2(1-f_c)}. \tag{4.10}$$

B. Phase transition

Having established general formulas for a hard-sphere system with condensate let us elucidate now the question as to whether a solution with $f_c>0$ can branch off the high-temperature (normal) solution considered in Sec. V of I, i.e., whether a phase transition to the condensate phase is possible. To this end one has to examine Eq. (3.15) following a remark in Sec. III. Substituting Eqs. (4.6), (4.7), and (4.10) reduces Eq. (3.15) to the form

$$H_2(\overline{\tau})-1-\overline{\tau}H_2'(\overline{\tau})=0. \tag{4.11}$$

According to (I.5.5) the function $f(\xi)=H_2(\xi)-1-\xi H_2'(\xi)$ is positive if $\xi\to\infty$, while $f(\xi)<0$ at $\xi=0$ with regard to (I.5.7). Therefore, the equation $f(\xi)=0$ has at least one solution. A numerical calculation shows that the equation has a unique solution which is $\xi=\xi_0\equiv 0.395\,628\,3$. Now Eq. (4.11) amounts to $\overline{\tau}=\xi_0$. Recall that in the case of spinless bosons Eq. (5.4) of Ref. 3 identical with (4.11) had no solution, and thereupon the condensate phase emerged at another point. According to Appendix C in the condensate phase under study $(\partial p/\partial V)_\theta<0$. Therefore, the condensate phase is stable and the bifurcation line is a second-order phase transitions line [a first-order transition implies the existence of a region where $(\partial p/\partial V)_\theta>0$: see, e.g., the solid curve in Fig. 1 of Ref. 3; a van der Waals isotherm serves as another example].

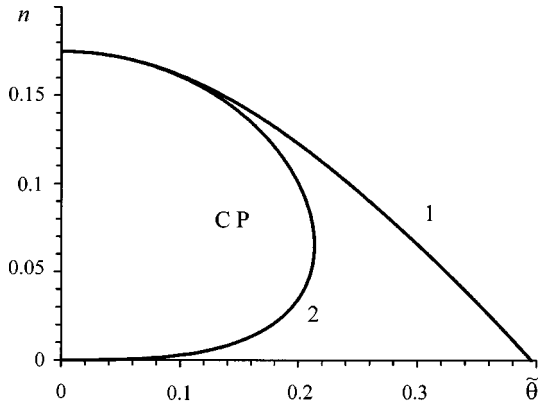

FIG. 1. Line of phase transitions to the condensate phase (CP) in the phase diagram: $\tilde{\theta}=a^2m\theta/\hbar^2$, $n=\pi a^3\rho$. Curve 1 corresponds to Eqs. (4.12) and (4.13), curve 2 corresponds to the approximate equation of (4.15).

In order to find the equation of that line it is necessary to insert the value of $\overline{\tau}$ relevant to the normal phase into Eq. (4.11), that is, into the equation $\overline{\tau}=\xi_0$. We shall consider the normal phase in the approximation corresponding to (I.5.21), which is equivalent to using the well-known method of pseudopotentials. Then

$$\tau=\tau_{\mathrm{id}}+\frac{2\pi a\hbar^2\rho}{3m}, \tag{4.12}$$

where τ_{id} is given by (I.3.10) with $\kappa=2$, that is to say, by

$$\tau_{\mathrm{id}}=\frac{2}{3}\left(\frac{\rho}{2\omega}\right)^{2/3}\frac{G_1(\alpha)}{G_0^{5/3}(\alpha)}, \quad \rho=2\omega\theta^{3/2}G_0(\alpha), \tag{4.13}$$

with α playing the role of a parameter.

After placing (4.12) and (4.13) in the equation $\overline{\tau}=\xi_0$ that amounts to $\tau=\xi_0\hbar^2/a^2m$ we obtain the phase transition line represented by curve 1 in Fig. 1 upon having recourse to numerical calculation. Note that $\tau_{\mathrm{id}}=\theta$ when $\rho=0$ according to (4.13), and thereby at $n=0$ the line terminates at $\tilde{\theta}=\xi_0$. It should be pointed out that if $a\to 0$, that is, if $n\to 0$ we arrive at an ideal gas. At the outset of this section we mentioned that the condensate phase could not occur in an ideal gas. Consequently, one should view the small values of n in Fig. 1 with caution. On the other hand Fig. 1 indicates that the condensate phase in a hard-sphere fermionic system will be observed only if values of n are not too large.

Insofar as the temperatures are supposed to be low, one may use the expansion (I.5.19) instead of the rather complex (4.12) and (4.13). The approximation of (4.12) corresponds to retaining corrections of order $n^{1/3}$, so that in the same approximation by (I.5.19) one has

$$\tau=\frac{2}{5}\left(\frac{3\rho}{4\omega}\right)^{2/3}+\frac{\pi^2\theta^2}{6}\left(\frac{4\omega}{3\rho}\right)^{2/3}+\frac{2\pi a\hbar^2\rho}{3m}. \tag{4.14}$$

In this case one can obtain the equation of the phase transition line in explicit form by equating (4.14) and $\xi_0\hbar^2/a^2m$. In the notation of Fig. 1 this gives

$$\tilde{\theta}=\sqrt{3}\left(\frac{3n}{\pi^2}\right)^{1/3}\sqrt{\xi_0-\frac{1}{5}(3\pi n)^{2/3}-\frac{2}{3}n}. \tag{4.15}$$

The line corresponding to this equation is presented in Fig. 1 by curve 2. At large n curves 1 and 2 are close to each other, however at small n they diverge drastically. This is due to the fact

that the expansion of (I.5.19) fails for small ρ because it is an expansion in powers of θ/ε_0 whereas $\varepsilon_0 \propto \rho^{2/3}$. At the same time curve 2 may reflect the real physical picture better since the curve shows that the condensate phase does not exist if n is too small. However, it is not clear without special analysis whether the use of (4.14) yields all quantities correctly for any ρ and θ.

C. Properties of the condensate phase

Let us turn now to investigation of the condensate phase. In the condensate phase Eq. (4.11) provides a relationship between $\tilde{\tau}$ and f_c according to Sec. III. As (4.11) signifies that $\overline{\tau}=\xi_0$, thanks to (4.10) we have

$$f_c = 1 - \frac{a^2 m \tilde{\tau}}{\xi_0 \hbar^2}. \tag{4.16}$$

Transforming Eq. (4.8) for $\tilde{\tau}$ we note that in the case under study the functions $H_2(\overline{\tau})$ and $H_2'(\overline{\tau})$ are merely constants, which will be denoted as

$$h_2^{(0)} = H_2(\xi_0) = 2.089\,748, \quad h_2 = H_2'(\xi_0) = 2.754\,475. \tag{4.17}$$

Substituting (4.16) and (4.17) into (4.8) yields

$$2\theta\left(1+\frac{2}{3}\pi h_2 a^3 \rho\right)\frac{\partial \tilde{\tau}}{\partial \theta} + 3\rho \frac{\partial \tilde{\tau}}{\partial \rho} - 2\left(1+\frac{2}{3}\pi h_2 a^3 \rho\right)\tilde{\tau} = \frac{4\pi a \hbar^2 \rho}{3m}, \tag{4.18}$$

where we have used the relation $h_2^{(0)} = 1 + \xi_0 h_2$ following from (4.11). We met with equations of the type (4.18) more than once in paper I and Ref. 2 and solved them with the help of the method of characteristics. So, the general solution of (4.18) is

$$\tilde{\tau} = \rho^{2/3} \exp\left(\frac{4}{9}\pi h_2 a^3 \rho\right)\left\{\Phi\left[\frac{\theta}{\rho^{2/3}} \exp\left(-\frac{4}{9}\pi h_2 a^3 \rho\right)\right] + \frac{4\pi\hbar^2}{3m h_2^{1/3}} \nu[a(h_2\rho)^{1/3}]\right\}, \tag{4.19}$$

where $\Phi(x)$ is an arbitrary function and

$$\nu(x) = \int_0^x \exp\left(-\frac{4}{9}\pi \xi^3\right) d\xi. \tag{4.20}$$

The last integral can be calculated analytically in the limits as $x \to 0$ and $x \to \infty$.

In order to find $\Phi(x)$ we must, according to a note in Sec. III about the boundary condition to Eq. (3.14), equate (4.19) and (4.12) on the phase transition line, that is, on curve 1 of Fig. 1. As a result we get the following equations for $\tilde{\tau}(\theta, \rho)$:

$$\tilde{\tau} = \frac{\hbar^2}{m} \rho^{2/3} \exp\left(\frac{4}{9}\pi h_2 a^3 \rho\right)\left\{\frac{\xi_0}{y^2} \exp\left(-\frac{4}{9}\pi h_2 y^3\right) + \frac{4\pi}{3 h_2^{1/3}}[\nu(a h_2^{1/3} \rho^{1/3}) - \nu(h_2^{1/3} y)]\right\}, \tag{4.21}$$

$$2\pi y^3 + \frac{(2\pi^2)^{2/3} G_1(a)}{G_0^{5/3}(\alpha)} y^2 - 3\xi_0 = 0, \tag{4.22}$$

$$\theta = \frac{\hbar^2}{m}\left[\frac{\pi^2 \rho}{\sqrt{2} G_0(\alpha)}\right]^{2/3} \exp\left[\frac{4}{9}\pi h_2 (a^3\rho - y^3)\right]. \tag{4.23}$$

These equations determine the dependence of $\tilde{\tau}$ on θ and ρ via two parameters α and y. For given θ and ρ we solve (4.22) and (4.23) for y upon eliminating α, whereupon we find $\tilde{\tau}$ by (4.21). The parameter α varies from $-\infty$ to $+\infty$ while the parameter y changes from 0 (this is the line n

$=0$) to $y_0=0.381\,814\,7$ (this is the line $\tilde{\theta}=0$). On the phase transition line $y=a\rho^{1/3}$, so that (4.21) yields $\tilde{\tau}=\xi_0\hbar^2/a^2m$, as it should. It is convenient to organize real calculation as follows. For a given α one finds y by solving the cubic equation of (4.22) (one is to choose the positive root that exists always and is unique). Taking a value of ρ one computes θ by (4.23) and moreover the relevant value of $\tilde{\tau}$ by (4.21).

If one proceeds on (4.14) the $\tilde{\tau}(\theta,\rho)$ dependence is given by the two equations

$$\tilde{\tau}=\frac{\hbar^2}{m}\left\{\rho^{2/3}\left[\frac{1}{5}(3\pi^2)^{2/3}+\frac{\pi^{2/3}m^2\theta^2}{3\hbar^4(3\rho^2)^{2/3}}-\frac{2}{3}\pi y\right]+\frac{4\pi a\rho}{3}\right\}, \tag{4.24}$$

$$2\pi y^3+\left[\frac{3}{5}(3\pi^2)^{2/3}+\frac{\pi^{2/3}m^2\theta^2}{\hbar^4(3\rho^2)^{2/3}}\right]y^2-3\xi_0=0. \tag{4.25}$$

Here one has only one parameter y that varies within the same limits as above. In principle, upon solving the cubic equation of (4.25) for y and substituting the result into (4.24) one could obtain the function $\tilde{\tau}(\theta,\rho)$ in explicit form; however, the formula will be fairly complex. Since Eqs. (4.24) and (4.25) do not much simplify the matter, in the following we carry out our investigation on the basis of Eqs. (4.21)–(4.23) that are more exact.

The properties of the function $\tilde{\tau}(\theta,\rho)$ as given by (4.21)–(4.23) are considered in Appendix C. As mentioned above, $\tilde{\tau}=\xi_0\hbar^2/a^2m$ on the phase transition line. Then Eq. (4.16) gives $f_c=0$ as it should. In Appendix C it is shown that $\partial\tilde{\tau}/\partial\theta>0$, and thereupon f_c increases with decreasing temperature. At $\theta=0$ one has $\tilde{\tau}>0$, and therefore, f_c never reaches the value $f_c=1$ (except the case $\rho=0$). The value of $\tilde{\tau}$ at $\theta=0$ can be found by (4.21) and (4.22) upon putting $\alpha=+\infty$. Then (4.22) entails $y=y_0$ [see the discussion following (4.23)] while (4.21) gives the desired value of $\tilde{\tau}$. Now Eq. (4.16) yields the value of f_c at $\theta=0$. This last value changes from 0 at the point where curve 1 of Fig. 1 intersects the n axis, to 1 at the point $n=\tilde{\theta}=0$.

Let us consider the heat capacity $C_V=(\partial E/\partial\theta)_\rho$. The internal energy E is given in (4.9), so that $C_V=\frac{3}{2}N\partial\tilde{\tau}/\partial\theta$. As mentioned above $\partial\tilde{\tau}/\partial\theta>0$, therefore, $C_V>0$ as it should. We may calculate the heat-capacity jump in the phase transition

$$\Delta C_V=C_V^{(c)}-C_V^{(n)}, \tag{4.26}$$

where $C_V^{(c)}$ and $C_V^{(n)}$ are the heat capacities of the condensate and normal phases, respectively, at the phase transition point. Calculation with the use of (4.21)–(4.23) and (4.12) (in the normal phase $E=\frac{3}{2}\tau N$), and of (C2) as well, yields rather a complicated formula, namely,

$$\Delta C_V=\frac{a\rho^{1/3}GN[(1+4\pi h_2a^3\rho/3)G_0^{5/3}+h_2a^2(2\pi^2\rho)^{2/3}(3G_0^2/G_{-1}-G_1)]}{2G_0G_{-1}[(4\pi)^{1/3}G_1+3a\rho^{1/3}G_0^{5/3}+(2\pi^2)^{2/3}h_2a^3\rho G/3G_{-1}]}, \tag{4.27}$$

with $G=G(\alpha)$ defined in Appendix C. Here the parameter α is determined by Eq. (4.23) with $y=a^3\rho$, which then coincides with the second equation of (4.13). Since $G>0$ and $3G_0^2-G_1G_{-1}>0$ (for the Fermi case), from (4.27) one has $\Delta C_V>0$, which corresponds with the Landau theory of phase transitions. The results of numerical calculations of C_V for two values of $n=\pi a^3\rho$ are shown in Fig. 2. We see that the transition from the normal to the condensate phase possesses all properties of an ordinary second-order phase transition.

We cannot compare the results obtained with experimental data on liquid ^{3}He because for liquid ^{3}He $n=0.83$ (see Ref. 2) whereas the hard-sphere condensate phase wherein triplet correlations are negligible can exist only if $n\leqslant 0.1749$ according to Fig. 1. When n is great the role of the triplet correlations becomes essential and the results of this section cannot be applied. Nevertheless it is of interest to estimate the real temperatures that correspond to the phase diagram of Fig. 1. If we take $a=2.56$ Å characteristic of helium[2] the temperature expressed in kelvins will be

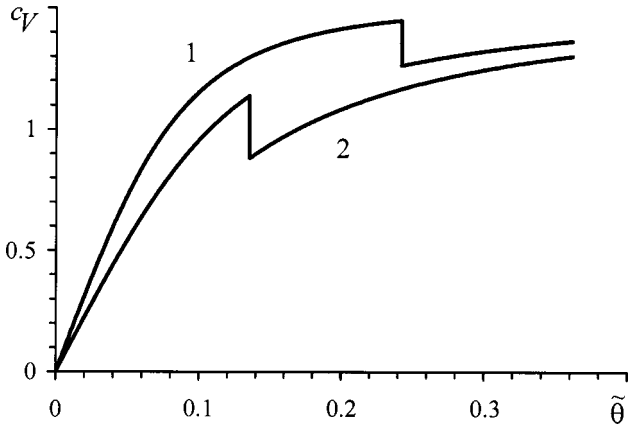

FIG. 2. Temperature dependence of the heat capacity $c_V = C_V/N$ for different values of n. Curve 1: $n = 0.1$, curve 2: $n = 0.15$. The jump of c_V corresponds to the phase transition. The notation is the same as in Fig. 1.

$$T = \frac{\hbar^2}{k_B m a^2}\tilde{\theta} = 2.454\tilde{\theta},$$

where k_B is the Boltzmann constant and the ^{3}He atom mass is taken for m. Consequently the maximum temperature for curve 1 of Fig. 1 ($\tilde{\theta} = 0.3956$) is $T = 0.971$ K, and for curve 2 ($\tilde{\theta} = 0.2136$) it is $T = 0.524$ K. These temperatures far exceed those at which superfluid phases in liquid ^{3}He are observed. Low densities, i.e., small n, when the triplet correlations can be neglected are characteristic of a vapor state. Perhaps the vapor state of ^{3}He would pass into a condensate phase at temperatures close to the ones obtained above.

Concluding the section let us compare the boson and fermion condensate phases [implying the potential $U_2(r)$ considered in the section]. In the boson case[3] the transformation into the condensate phase is a first-order phase transition, the condensate fraction f_c reaches unity even when $\theta \neq 0$, properties of the condensate phase are strongly affected by details of the correlations (in order to find completely E and p for the phase even in a first approximation it is necessary to know the exact value of τ in the normal phase). In the fermion case the transformation into the condensate phase is a second-order phase transition, the condensate fraction f_c never reaches unity even at $\theta = 0$, properties of the condensate phase are not very sensitive to details of the correlations [we were able to find completely the expression for $\tilde{\tau}$ by confining ourselves to the terms written down in (4.12), which amounts to saying that the influence of higher powers of a is alike in the normal and condensate phases]. We see that the properties of the boson and fermion condensate phases differ appreciably even though the interparticle potential is the same.

V. CONCLUDING REMARKS

The present paper shows that the approach proposed in Ref. 2 and extended in paper I in order to take the spin of particles into account enables one to investigate the condensate phase in Fermi systems and superfluidity of these systems, the treatment of the fermionic superfluid being in principle the same as that of a bosonic superfluid. The present theory does not resort to Cooper's idea of fermion pairing although there are some elements of pair formation in the theory but the phenomenon as a whole is rather intricate (see Sec. II C). If one reasons in terms of pairing the present theory indicates at once that, besides the well known mechanism of pairing connected with an electron–phonon interaction and other known mechanisms,[6] a completely different mechanism is possible which acts even in the case of a purely repulsive Hamiltonian. This last mechanism is due to a specific collective effect, namely the shielding effect, and can be efficacious at any temperature whatsoever the Hamiltonian is.

The physical causes of fermion superfluidity and possible peculiarities of the phenomenon are wholly analogous with the ones of boson superfluidity discussed in Ref. 3. At the same time, even if a boson system and a fermion one are described by one and the same Hamiltonian the character of the phase transition to the condensate phase and the properties of this last phase may differ appreciably for the two systems.

The study of fermion superfluidity is an essential step towards a theory of such an important phenomenon as superconductivity, based upon the ideas of the present approach. In the theory, account must be taken of the fact that metals have a crystalline structure whereas only spatially uniform systems were considered in the present paper. Note that some results concerning the study of a crystal on the basis of the approach proposed in Ref. 2 are already published.[15]

Of even greater importance is the fact that a superflow of charged particles is an electrical current, and thereby it always creates a magnetic field. Consequently in order to study superconductivity it is necessary to incorporate electromagnetic interactions in the framework of the present approach. Inasmuch as the quantum hierarchy for reduced density matrices the present approach is based upon is, to a considerable extent, analogous with the classical BBGKY hierarchy[2] one may treat the electromagnetic interactions leaning upon this analogy and resorting, for example, to methods of the theory of plasmas where the classical BBGKY hierarchy is widely employed for charged particle systems.

However, some considerations may be expressed even now as to the influence of the magnetic field upon the phenomena in question. In Ref. 3 it was mentioned that formation of cells with closed superflows in a confined volume would most likely be energetically unprofitable. If, however, the superflow is created by charged particles there appears a magnetic field. For this reason the formation of a pattern of closed streamlines with opposite currents in different cells will be energetically favourable because, owing to this, the magnetic field and thereupon the magnetic energy of the system might decrease just as in the case of a ferromagnet when magnetic domains form.

Reasoning along these lines one can offer a simple explanation for the Meissner effect (a magnetic field does not penetrate into the bulk of a superconductor). An external magnetic field, by acting on the supercurrents in the cells, reconstructs the pattern until the resultant magnetic field within the body (the external field plus that due to the supercurrents) vanishes. This is analogous to the case of a conductor in equilibrium into the interior of which an electrostatic field cannot penetrate. One may also draw a parallel between the action of the magnetic field on the supercurrents and on the ''molecular currents'' in a diamagnetic molecule; inasmuch as the direction of the supercurrent can be arbitrary the superconductior is a perfect diamagnetic while in the molecule the molecular currents are fixed by the structure of the molecule. Of course a full explanation of the Meissner effect and of its peculiarities requires an analysis of the above hierarchy with account taken of electromagnetic interactions.

It is also worth noting that, by analogy with the existence of a critical velocity in Bose systems, there should be a critical supercurrent in charged Fermi systems. When the supercurrent exceeds the critical value, fermion superfluidity (i.e., superconductivity in this instance) breaks down. The value of the critical supercurrent is determined by a formula analogous with (3.13) (cf. Ref. 3).

APPENDIX A: THE CONDITION OF (2.17) ON THE FUNCTIONS $n_s(z)$

In Ref. 2 and paper I the relation of (2.17) was discussed rather briefly. For this reason we consider the relation first for the nondegenerate case, i.e., for the case in which there is no condensate, in more detail.

First of all we find the constant $C_s^{s_a,s_b}$ that figures in Eq. (2.14). If one normalizes R_{s_a} and R_{s_b} in the same manner as R_s, that is, according to (I.2.2) then

$$C_s^{s_a,s_b}=\frac{N!(N_a-s_a)!(N_b-s_b)!}{(N-s)!N_a!N_b!}, \tag{A1}$$

where N_a and N_b are the number of particles in the subsystems A and B, respectively ($N=N_a+N_b$). Equation (A1) can be readily got by integrating (2.14) and applying (I.2.3) to both the sides.

Upon introducing a coefficient of proportionality we rewrite (2.17) as

$$n_s(\varepsilon_{\nu_a}^{(s_a)}+\varepsilon_{\nu_b}^{(s_b)})=B_s^{s_a,s_b}n_{s_b}(\varepsilon_{\nu_a}^{(s_a)})n_{s_b}(\varepsilon_{\nu_b}^{(s_b)}). \tag{A2}$$

In order to find the coefficient $B_s^{s_a,s_b}$ we remark first that to one eigenvalue $\varepsilon_\nu^{(s)}$ of Eq. (I.2.11) correspond $s!$ eigenfunctions $\psi_\nu(\mathbf{x}_s)$ obtained by permutation of s arguments. This degeneracy must be taken into account when one substitutes expressions of the type (2.1) together with (A1) and (A2) into (2.14). To make the number of terms on the left of Eq. (2.14) equal to the one on the right the left side of (2.14) is to be divided by $s!$ and the right side by $s_a!\ s_b!$, so that

$$B_s^{s_a,s_b}=\frac{s!}{s_a!s_b!}C_s^{s_a,s_b}=\frac{\mu_s}{\mu_{s_a}\mu_{s_b}} \quad \text{with} \quad \mu_s=\frac{s!N!}{(N-s)!}\approx s!N^s. \tag{A3}$$

When writing the last expression for μ_s account is taken of the fact that $s\ll N$.

To solve the functional equation of (A2) we denote $\varepsilon_{\nu_a}^{(s_a)}$ by x and $\varepsilon_{\nu_b}^{(s_b)}$ by y, take the logarithm of both the sides and differentiate with respect to x:

$$\frac{1}{n_s(x+y)}\frac{dn_s(x+y)}{d(x+y)}=\frac{1}{n_{s_a}(x)}\frac{dn_{s_a}(x)}{dx}.$$

The right-hand side does not depend on y, hence the left-hand side cannot depend on y either, that is to say, upon $x+y=z$. Therefore,

$$\frac{1}{n_s(z)}\frac{dn_s(z)}{dz}=\text{const.} \tag{A4}$$

Denoting this last constant by $-1/\tau$ and integrating Eq. (A4) yields

$$n_s(z)=A_s e^{-z/\tau}. \tag{A5}$$

To determine the constant A_s we place (A5) into (A2), which gives on account of (A3)

$$\frac{A_s}{\mu_s}=\frac{A_{s_a}}{\mu_{s_a}}\frac{A_{s_b}}{\mu_{s_b}}. \tag{A6}$$

If one writes the indices as arguments and recalls that $s=s_a+s_b$ one will see that Eq. (A6) is identical with Eq. (A2) on condition that one sets $B_s^{s_a,s_b}=1$. Therefore, for A_s/μ_s one will have an expression of the type (A5) with $A_s=1$ and a new constant D instead of $e^{-1/\tau}$, which amounts to saying that $A_s=\mu_s D^s$. Upon substituting this into (A5), using the approximate expression for μ_s of (A3) and introducing a new constant $\zeta=ND$ one has finally

$$n_s(z)=s!\zeta^s e^{-z/\tau}. \tag{A7}$$

The constant ζ can be found by placing (A7) into (I.2.29) with the result that

$$\zeta=\frac{\rho}{\kappa}\left(\frac{2\pi\hbar^2}{m\tau}\right)^{3/2}. \tag{A8}$$

If in paper I one inserts A of (I.3.6) into (I.2.30) one will obtain an expression for $n_s(z)$ that wholly coincides with the one given by (A7) and (A8). This shows that in the nondegenerate case in order to determine the functions $n_s(z)$ uniquely one need not resort to the normalization condition of (I.2.6) that has led to (I.3.6).

We turn now to the degenerate case, that is, to the case in which there is a condensate. First of all it will be noted that the functions $n_s(z)$ satisfy a normalization condition which follows from (2.1) if use is made of (I.2.3):

$$\sum_{\nu} n_s(\varepsilon_{\nu}^{(s)}) = \frac{N!}{(N-s)!}, \tag{A9}$$

where we imply that $\Psi_{\nu\Gamma_s}(\mathbf{X}_s)$'s are normalized to unity. If we assume that $n_s(\varepsilon_{\nu_0}^{(s)}) = \Delta n_s + n_s(z_0)$ as at the outset of Sec. II, the normalization of the continuous part of $n_s(z)$ changes according to (A9). As long as the quantities Δn_s are not known in advance we have no prior knowledge of the new normalization of $n_s(z)$ in (2.4). However, the remark following (2.22) suggests that there is only one parameter, namely ρ_c, that determines the normalization of functions relevant to the condensate fraction because the vector $\mathbf{p}_0$ does not affect the normalization. Therefore the functions $n_s(z)$ contain only one unknown factor as well and Eq. (A2) should be recast as

$$n_s(\varepsilon_{\nu_a}^{(s_a)} + \varepsilon_{\nu_b}^{(s_b)}) = B \;\; B_s^{s_a,s_b} n_{s_a}(\varepsilon_{\nu_a}^{(s_a)}) n_{s_b}(\varepsilon_{\nu_b}^{(s_b)}), \tag{A10}$$

with an unknown coefficient B.

Now we shall arrive again at (A5) but A_s will contain an extra factor, owing to B, that cannot be determined from (I.2.29) because any constant factor in $n_s(z)$ cancels out when $n_s(z)$ is substituted into (I.2.29). Instead of (A7) and (A8), in the degenerate case Eq. (I.2.29) yields (2.18) with a constant A that should be found otherwise. In Sec. III A is calculated from the normalization condition of (I.2.6).

APPENDIX B: DERIVATION OF EQ. (4.5)

Instead of (4.1) we assume the potential

$$K(r) = \begin{cases} K_m & \text{if } r < a \\ 0 & \text{if } r > a. \end{cases} \tag{B1}$$

We consider spherically symmetric solutions. Upon putting $U_2(r) = K(r)$ in (3.6) and writing $u_2(r) = \chi(r)/r$ we get

$$\frac{d^2\chi}{dr^2} - \frac{m}{\hbar^2} K(r)\chi(r) = 0. \tag{B2}$$

Since $u_2 \to 1$ as $r \to \infty$, this equation yields for $r > a$

$$u_2(r) = 1 - \frac{C_1}{r}. \tag{B3}$$

If $r < a$, (B2) leads to the following expression for $u_2(r)$ finite at $r = 0$:

$$u_2(r) = \frac{C_2}{r} \sinh br, \quad b^2 = \frac{m}{\hbar^2} K_m. \tag{B4}$$

As usual the constants C_1 and C_2 are specified by the condition that $u_2(r)$ and its derivative shall be continuous at $r = a$. As a result, when $r < a$

$$u_2(r)=\frac{\sinh br}{br\cosh ba}. \tag{B5}$$

We consider now an integral of the form

$$\int_0^\infty f(r)K(r)\frac{\partial g_c}{\partial r}dr=K_m\frac{\rho_c}{\rho}\int_0^a f(r)\frac{du_2^2}{dr}dr \tag{B6}$$

with an arbitrary function $f(r)$ assumed to be continuous. On the right we have made use of (B1) and replaced $g_c(r)$ by the first term of (3.9). From (B5) it follows that if $r<a$ the function $u_2(r)$ is exponentially small when $b\to\infty$. For this reason only the value of $f(r)$ at $r=a$ is of importance for the integral in (B6). Upon putting $f(r)=f(a)$ the integral is easily evaluated and leads to (4.5) in the limit as $K_m\to\infty$.

APPENDIX C: THE FUNCTION $\tilde{\tau}(\theta,\rho)$ OF (4.21)–(4.23)

If one regards y as a function of θ and ρ, from (4.22) and (4.23) one gets, on account of formulas presented in Appendix F of Ref. 2,

$$\left[6G_1+9\left(\frac{2}{\pi}G_0^5\right)^{1/3}y+2\pi h_2y^3\frac{G}{G_{-1}}\right]\frac{\partial y}{\partial\theta}=-\frac{3Gy}{2\theta G_{-1}}, \tag{C1}$$

where $G=5G_1(\alpha)G_{-1}(\alpha)-9G_0^2(\alpha)$. A numerical calculation shows that $G>0$. Consequently $\partial y/\partial\theta<0$ (in this inequality and below we assume that $\rho\neq 0$). Therefore, y is maximum at $\theta=0$, when $y=y_0$ [see the discussion following (4.23)].

Upon keeping ρ constant and inspecting (4.21) one sees readily that $\tilde{\tau}$ decreases with increasing y, which entails that $\partial\tilde{\tau}/\partial\theta>0$. Therefore, $\tilde{\tau}$ is minimum at $\theta=0$. Substituting $y=y_0$ into (4.21) one obtains numerically that $\tilde{\tau}>0$ at $\theta=0$. Hence, always $\tilde{\tau}>0$.

By analogy with (C1), from (4.21) to (4.23) it follows that

$$\frac{\partial\tilde{\tau}}{\partial\theta}=\frac{2^{1/3}GG_0^{2/3}(3\xi_0+2\pi\xi_0h_2y^3+2\pi y^3)}{\pi^{4/3}y^2G_{-1}[6G_1+9(2G_0^5/\pi)^{1/3}y+2\pi h_2y^3G/G_{-1}]}. \tag{C2}$$

This confirms again that $\partial\tilde{\tau}/\partial\theta>0$. Likewise one can calculate the derivative $\partial\tilde{\tau}/\partial\rho$. One obtains, however, an expression for it which is much more complicated than (C2) and difficult for analytical investigation. A numerical calculation shows that $\partial\tilde{\tau}/\partial\rho>0$.

The pressure p is given by (4.9). With reference to (4.16) and (4.17), one has

$$p=\rho\left(1+\frac{2}{3}\pi h_2a^3\rho\right)\tilde{\tau}+\frac{2\pi a\hbar^2\rho^2}{3m}. \tag{C3}$$

Since $\tilde{\tau}>0$ and $\partial\tilde{\tau}/\partial\rho>0$ it follows immediately from this that $\partial p/\partial\rho>0$, i.e., $(\partial p/\partial V)_\theta<0$.

[9] In fact, we are trying to satisfy the *N*-representability condition [see, e.g., *Density Matrices and Density Functionals*, edited by R. Erdahl, V. H. Smith, Jr. (Reidel, Dordrecht, 1987)], that is, to ascertain that the functions $R_s(\mathbf{X}_s,\mathbf{X}_s')$ are really reduced density matrices that come from an initial density matrix $R_N(\mathbf{X}_N,\mathbf{X}_N')$ and can be obtained from it by integration. The fact that $R_s(\mathbf{X}_s,\mathbf{X}_s')$'s of (2.1) satisfy the hierarchy of (I.2.9) is not sufficient because the differential

equations of (I.2.9) may have various solutions. It should be added that strictly speaking our density matrices are only equilibrium parts of full density matrices and thereby in the present paper we need not solve the *N*-representability problem in full.

[10] To consider, for $\kappa=1$, the case $\rho_c=0$ but $B_2\neq 0$ has no interest for there are no spinless fermions in nature.

A continuous infinite system of point particles interacting via finite-range many-body potentials of superstable type is considered in the framework of classical statistical mechanics. We prove that for any temperature and chemical activity there exists at least one Gibbs state. © *2004 American Institute of Physics.*
[DOI: 10.1063/1.1644323]

I. INTRODUCTION

One of the basic problems of equilibrium statistical mechanics is the construction of Gibbs states for continuous particle systems with many-body interactions. In the pioneering works by Greenberg[7] and Moral[13] the problem was analyzed via Kirkwood–Salsburg equations (KSE). For sufficiently small activity parameter z they proved existence of unique solution of KSE, but with rather unnatural assumptions on the potentials which, in fact, take place only for finite range and positive interactions. In Ref. 17 the convergence of the Brydges–Federbush-type cluster expansion is proved for dilute continuous systems with n-body ($n \leqslant M$) interaction. The proof requires a stable potential satisfying an integrability condition and exponential decay of the many-body potentials at large distances. In the following paper[15] the authors consider the system of hard-core spheres interacting via infinite group of many body potentials (for all n) which are bounded and integrable. They prove the convergence of the Mayer series for the pressure in thermodynamic limit and establish the region of analyticity in the activity z. In the recent work by Belitsky and Pechersky[3] the problem of existence and uniqueness of Gibbs state in $\mathbb{R}^d$ with finite group of n-body interactions was investigated using the technique of Dobrushin's type.[4,5]

In this work we give a simple proof of the existence of Gibbs state with infinite group of many body potentials. We establish some kind of modified Ruelle's bound for finite volume correlation functions. It gives a possibility to prove existence of at least one Gibbs measure in thermodynamic limit. We consider these results as some further development in solving the problem.

In the next section we define the system and formulate main results. Section III is devoted to the proof of these results. The basic technical lemma is outlined in the Appendix.

II. CORRELATION FUNCTIONS

A. Configuration space

Let $\mathbb{R}^d$ be a d-dimensional Euclidean space. By $\mathcal{O}(\mathbb{R}^d)$ and $\mathcal{B}(\mathbb{R}^d)$ we denote the family of all open and Borel sets, respectively. $\mathcal{O}_c(\mathbb{R}^d)$, $\mathcal{B}_c(\mathbb{R}^d)$ denote the systems of all sets in $\mathcal{O}(\mathbb{R}^d)$, $\mathcal{B}(\mathbb{R}^d)$, respectively, which are bounded.

The set of positions $\{x_i\}_{i \in \mathbb{N}}$ of identical particles is considered to be a locally finite subset in $\mathbb{R}^d$ and the set of all such subsets creates the configuration space:

a)Electronic mail: kutoviy@mathematik.uni-bielefeld.de
b)Electronic mail: rebenko@faust.kiev.ua

$$\Gamma=\Gamma_{\mathbb{R}^d}:=\{\gamma\subset\mathbb{R}^d\,|\,|\gamma\cap\Lambda|<\infty,\ \text{for all}\ \ \Lambda\in\mathcal{B}_c(\mathbb{R}^d)\},$$

where $|A|$ denotes the cardinality of the set A. The symbol $|\cdot|$ may also represent the Lebesgue measure of the set, but the meaning will always be clear from the context. For any $\Lambda\in\mathcal{B}(\mathbb{R}^d)$ we denote by γ_Λ the projection of γ on Λ and the corresponding configuration space by Γ_Λ. We also need to define the space of finite configurations Γ_0:

$$\Gamma_0=\bigsqcup_{n\in\mathbb{N}_0}\Gamma^{(n)},\quad \Gamma^{(n)}:=\{\eta\subset\mathbb{R}^d\ \mid\ |\eta|=n\},\quad \mathbb{N}_0=\mathbb{N}\cup\{0\}.$$

For every $\Lambda\in\mathcal{B}_c(\mathbb{R}^d)$ one can define a mapping $N_\Lambda:\Gamma\to\mathbb{N}_0$ of the form

$$N_\Lambda(\eta):=|\eta\cap\Lambda|.$$

The Borel σ-algebra $\mathfrak{B}(\Gamma)$ is equal to $\sigma(N_\Lambda|\Lambda\in\mathfrak{B}_c(\mathbb{R}^d))$ and additionally one may introduce the following filtration

$$\mathfrak{B}_\Lambda(\Gamma):=\sigma(N_{\Lambda'}|\Lambda'\in\mathcal{B}_c(\mathbb{R}^d),\ \Lambda'\subset\Lambda),$$

see Refs. 10 and 11 for details.

By $\mathfrak{B}(\cdot)$ we denote the corresponding σ-algebras on Γ_Λ and Γ_0. For a given intensity measure $\sigma=z\,dx$ $(z>0)$ on $\mathcal{B}(\mathbb{R}^d)$ and any $n\in\mathbb{N}$ the product measure $\sigma^{\otimes n}$ can be considered by restriction as a measure on

$$\widetilde{(\mathbb{R}^d)^n}=\{(x_1,\ldots,x_n)\in(\mathbb{R}^d)^n|\ x_k\neq x_l\ \text{if}\ k\neq l\}$$

and hence as a measure $\sigma^{(n)}$ on $\Gamma^{(n)}$ through the map

$$\mathrm{sym}_n:\widetilde{(\mathbb{R}^d)^n}\ni(x_1,\ldots,x_n)\mapsto\{x_1,\ldots,x_n\}\in\Gamma^{(n)},$$

cf. Ref. 8. For simplicity we will write $(x)_n$ instead of $\{x_1,\ldots,x_n\}\in\Gamma^{(n)}$.

Define the Lebesgue–Poisson measure λ_σ on $\mathfrak{B}(\Gamma_0)$ by the formula:

$$\lambda_\sigma:=\sum_{n\geqslant 0}\frac{1}{n!}\sigma^{(n)}.$$

The restriction of λ_σ to $\mathfrak{B}(\Gamma_\Lambda)$ we also denote by λ_σ. For a more detailed structure of the configuration spaces $\Gamma,\Gamma_0,\Gamma_\Lambda$, see Ref. 1.

B. Interactions and Hamiltonians

We consider a general type of many-body interaction specified by a family of k-body potentials $V_k:\mathbb{R}^{dk}\to\mathbb{R}$, $k\geqslant 2$. About the potentials $\{V_k\}_{k\geqslant 2}$ we will assume:

A1. Finite range: There exists a constant $R>0$, such that for any $k\geqslant 2$

$$V_k(x_1,\ldots,x_k)\equiv 0,\ \text{if}\ \ \mathrm{diam}\{x_1,\ldots,x_k\}>R.$$

A2. Continuity:

$$V_k\in C(\widetilde{(\mathbb{R}^d)^k}),\quad k\geqslant 2.$$

A3. Symmetry: For any $k\geqslant 2$, any $(x_1,\ldots,x_k)\in(\mathbb{R}^d)^k$, and any permutation π of numbers $\{1,\ldots,k\}$

$$V_k(x_1,\ldots,x_k)=V_k(x_{\pi(1)},\ldots,x_{\pi(k)}).$$

A4. Translation invariance: For any $k\geqslant 2$, any $(x_1,\ldots,x_k)\in(\mathbb{R}^d)^k$, and any $a\in\mathbb{R}^d$

$$V_k(x_1,\ldots,x_k)=V_k(x_1+a,\ldots,x_k+a).$$

We are able now to introduce the Hamiltonian $U^V:\Gamma_0\to\mathbb{R}\cup\{\infty\}$, which corresponds to the family of potentials $V:=\{V_k\}_{k\geqslant 2}$ and which is defined by

$$U^V(\eta)=\sum_{k\geqslant 2}\sum_{\{x_1,\ldots,x_k\}\subset\eta}V_k(x_1,\ldots,x_k),\quad \eta\in\Gamma_0,\quad |\eta|\geqslant 2.$$

For the fixed family of potentials V we will write for short $U=U^V$ and for $\Lambda\in\mathcal{B}_c(\mathbb{R}^d)$, $\eta\in\Gamma_\Lambda$ we will sometimes write $U_\Lambda(\eta)$ instead of $U(\eta)$.

A5. Strong superstability: For any $k\geqslant 2$ the potential V_k can be represented as

$$V_k=V_k^+ + V_k^{(\mathrm{st})},$$

where V_k^+ is a non-negative function such that for any $(x_1,\ldots,x_k)\in(\mathbb{R}^d)^k\setminus\widetilde{(\mathbb{R}^d)^k}$

$$V_k^+(x_1,\ldots,x_k)=+\infty,$$

and $V_k^{(\mathrm{st})}$ is stable, i.e., there exists a constant $B\geqslant 0$ such that for any configuration $\eta\in\Gamma_0$ holds

$$U^{V^{(\mathrm{st})}}(\eta)\geqslant -B|\eta|.$$

Let $\lambda\in\mathbb{R}_+$ be arbitrary. For each $r\in\mathbb{Z}^d$ we define an elementary cube

$$\Delta(r)=\{x\in\mathbb{R}^d\,|\,\lambda(r^i-1/2)\leqslant x^i<\lambda(r^i+1/2)\}.$$

These cubes form a partition of $\mathbb{R}^d$, which we denote by $\overline{\Delta_\lambda}$. We will sometimes write Δ instead of $\Delta(r)$, if a cube Δ is considered to be arbitrary and there is no reason to emphasize that it is centered at the concrete point $r\in\mathbb{Z}^d$. By $\mathcal{J}_\lambda(\mathbb{R}^d)$ we denote all finite unions of cubes of the form $\Delta(r)$ (such sets are used in the construction of the Jordan measure).

Let $N\in\mathbb{N}$ and $k\geqslant N+1$ be arbitrary. For any $X_N=\cup_{j=1}^N\Delta_j\in\mathcal{J}_\lambda(\mathbb{R}^d)$ we define

$$I_k^{k_1,\ldots,k_N|\overline{k}}(\Delta_1,\ldots,\Delta_N) := \sup_{(x)_{k_i}^i\subset\Delta_i,\ 1\leqslant i\leqslant N}\ {\sum_{\substack{\Delta_j'\subset X_N^c,\\ 1\leqslant j\leqslant\overline{k}}}}^{*}\ \sup_{y_1\in\Delta_1',\ldots,y_{\overline{k}}\in\Delta_{\overline{k}}'}|V_k^{(\mathrm{st}),-}(x_1^1,\ldots,x_{k_N}^N,y_1,\ldots,y_{\overline{k}})|, \tag{1}$$

where $\overline{k}\geqslant 1$, $k_i\geqslant 1, i=1,\ldots,N$ such that $k_1+\cdots+k_N+\overline{k}=k$, and

$$v_k^{k_1,\ldots,k_N}(\Delta_1,\ldots,\Delta_N):=\inf_{(x)_{k_i}^i\subset\Delta_i,1\leqslant i\leqslant N,}V_k^+(x_1^1,\ldots,x_{k_N}^N), \tag{2}$$

where $k_i\in\mathbb{N}_0$, $(x)_{k_i}^i=\{x_1^i,\ldots,x_{k_i}^i\}$, $1\leqslant i\leqslant N$ such that $k_1+\cdots+k_N=k$. $V_k^{(\mathrm{st}),-}$ denotes the negative part of $V_k^{(\mathrm{st})}$, and the symbol Σ^* means that the sum extends only over different cubes, i.e., $\Delta_i'\neq\Delta_j'$, $i\neq j$, $1\leqslant i,j\leqslant\overline{k}$.

A6. Attraction–repulsion relation: There exists $\lambda=\lambda_0>0$, such that for any $N\in\mathbb{N}$ and any $X_N=\cup_{j=1}^N\Delta_j\in\mathcal{J}_{\lambda_0}(\mathbb{R}^d)$ (we omit dependence on the cubes in the notations of (1) and (2)) the following holds:

(i) for an arbitrary $\Delta\in\overline{\Delta_{\lambda_0}}$ and any $k\geqslant 2$

$$V_k(x_1,\ldots,x_k)\geqslant 0,\qquad \{x_1,\ldots,x_k\}\subset\Delta;$$

(ii) for an arbitrary $k \geqslant N+1$

$$v_k^{k_1,\dots,k_N} \geqslant 4\overline{I}^{(N)}_{k;\,k_1,\dots,k_N}, \qquad v_{N+1}^{k_1,\dots,k_N} \geqslant 4(\overline{I}^{(N)}_{N+1}+B), \tag{3}$$

and

$$\overline{I}^{(N)}_{k;\,k_1,\dots,k_N} = \sum_{l\geqslant 1} l I_{k+l}^{k_1,\dots,k_N|\,l} < \infty, \qquad \overline{I}^{(N)}_{N+1} = \sum_{l\geqslant 1} l I_{N+l}^{1,\dots,1|\,l} < \infty, \tag{4}$$

$$k_1+\cdots+k_N = k.$$

In the sequel we write $\overline{\Delta}$ instead of $\overline{\Delta}_{\lambda_0}$.

Remark 2.1: By the definition, $V_k^{\mathrm{st},-}$ describes attractive part of the k-body interaction. Therefore, $\overline{I_k^{k_1,\dots,k_N|k}}(\Delta_1,\dots,\Delta_N)$ describes only the attractive part of the k-body interaction of fixed particles in cubes $\Delta_1,\dots,\Delta_N$ with "dilute configuration," i.e., no more than one particle is located in any cube Δ from $X_N^c = \mathbb{R}^d \backslash X_N$, $X_N = \cup_{j=1}^N \Delta_j$. Then, condition (4) means that the energy of the k-body interaction decreases sufficiently fast with k. From the assumption **A6** *and the definition of $\overline{I}^{(N)}_{k;\,k_1,\dots,k_N}$ therein, it is clear that at least one cube from $\Delta_1,\dots,\Delta_N$ contains more than one particle, and so $v_k^{k_1,\dots,k_N}$ should be greater than contributions of all $k+l$-body attractive energies of interaction $(l \in N)$ for sufficiently small λ.*

Remark 2.2: From the definition of $\overline{I_k^{k_1,\dots,k_N|k}}(\Delta_1,\dots,\Delta_N)$ (see (1)) it is clear that

$$\overline{I_k^{k_1,\dots,k_N|k}}(\Delta_1,\dots,\Delta_N) \leqslant C_k \lambda^{-d\overline{k}}, \qquad \lambda \to 0,$$

where $C_k = C_k(\lambda) \geqslant 0$ are some constants. Moreover, if $V_k^{(\mathrm{st}),-}$ is bounded from below on $(\mathbb{R}^d)^k \backslash \widetilde{(\mathbb{R}^d)^k}$, then $C_k(\lambda)$ has the following limit at $\lambda \to 0$:

$$C_k(0) = \int_{(\mathbb{R}^d)^{\overline{k}}} |V_k^{(\mathrm{st}),-}(x_1^1,\dots,x_{k_N}^N, y_1,\dots,y_{\overline{k}})| dy_1 \cdots dy_{\overline{k}},$$

where $x_1^1,\dots,x_{k_N}^N$ some fixed points in $\mathbb{R}^d$. For example, if we would have only pair potential, to satisfy (3) the positive part of the potential $V_2^+(x_1,x_2)$ should behave like $|x_1-x_2|^{-d-\varepsilon}$, $|x_1-x_2| \to 0$, for some $\varepsilon > 0$.

In the case of all orders of interactions, the k-body potentials, for $k \geqslant 3$, can be chosen in such a way that constants C_k, $k \geqslant 3$ have behavior like $C^k/k!$, for some constant $C > 0$. Under such condition, $\overline{I_k^{k_1,\dots,k_N|k}}(\Delta_1,\dots,\Delta_N)$ will behave like $\lambda^{-d} C^{k+1} e^{C\lambda^{-d}}/k!$. Therefore, to satisfy (3), the positive part of the potentials $V_k^+(x_1,\dots,x_k)$ should behave like

$$|x_i - x_j|^{-d-\varepsilon} \frac{C^{k+1}}{k!} e^{C|x_i-x_j|^{-d-\varepsilon}}, \qquad |x_i - x_j| \to 0, \quad 1 \leqslant i,j \leqslant k$$

for some $\varepsilon > 0$.

For a given $\overline{\gamma} \in \Gamma$ define the interaction energy between $\eta \in \Gamma_\Lambda$, $\Lambda \in \mathcal{B}_c(\mathbb{R}^d)$ and $\overline{\gamma}_{\Lambda^c} = \overline{\gamma} \cap \Lambda^c$, $\Lambda^c = \mathbb{R}^d \backslash \Lambda$ as

$$W_\Lambda(\eta|\overline{\gamma}) = \sum_{k\geqslant 2} \sum_{\substack{m+n=k \\ m,n\geqslant 1}} \sum_{\substack{\{x_1,\dots,x_m\}\subset \eta \\ \{y_1,\dots,y_n\}\subset \overline{\gamma}_{\Lambda^c}}} V_k(x_1,\dots,x_m,y_1,\dots,y_n).$$

Define

$$U_\Lambda(\eta|\overline{\gamma}) = U_\Lambda(\eta) + W_\Lambda(\eta|\overline{\gamma}).$$

A7. The order of interaction: For any $\Lambda \in \mathcal{B}_c(\mathbb{R}^d)$, $\eta \in \Gamma_\Lambda$ and $\overline{\gamma} \in \Gamma$ the interaction energy $W_\Lambda(\eta|\overline{\gamma})$ does not become $-\infty$ and the partition function

$$Z_\Lambda(\overline{\gamma}) = \int_{\Gamma_\Lambda} \exp\{-U_\Lambda(\eta| \ \overline{\gamma})\}\lambda_\sigma(d\eta) < \infty.$$

Remark 2.3: Assumption **A7** *is important only for the next chapter, where the precise definition of the Gibbs state on the configuration space* Γ *will be given. In fact, for the results of the present paper we do not need fulfillment of* **A7** *for all* $\overline{\gamma} \in \Gamma$, *but only for empty boundary configurations. In turn, this fact is automatically ensured by assumption* **A5**.

C. Gibbs specification and correlation functions

Let $\Lambda \in \mathcal{B}_c(\mathbb{R}^d)$ and let $\overline{\gamma} \in \Gamma$. The finite volume Gibbs state with boundary configuration $\overline{\gamma}$ for U, $z>0$ and $\beta>0$ is

$$\mu_\Lambda(d\eta| \ \overline{\gamma}) = \frac{\exp\{-\beta U_\Lambda(\eta| \ \overline{\gamma})\}}{Z_\Lambda(\overline{\gamma})}\lambda_{z\sigma}(d\eta).$$

Under assumption **A7**, the finite volume Gibbs state is well defined. When $\overline{\gamma}=\varnothing$, let $\mu_\Lambda(d\eta|\varnothing) \equiv \mu_\Lambda(d\eta)$.

The corresponding finite-volume correlation functions for boundary configuration $\overline{\gamma} \in \Gamma$ have the following form:

$$\rho^\Lambda(\eta|\overline{\gamma}) = \frac{1}{Z_\Lambda(\overline{\gamma})}\int_{\Gamma_\Lambda} e^{-\beta U(\eta \cup \gamma|\overline{\gamma})}\lambda_\sigma(d\gamma), \qquad \eta \in \Gamma_\Lambda. \tag{5}$$

Let $\{\pi_\Lambda\}$ denote the specification associated with z, β and the Hamiltonian U (see Ref. 14), which is defined on Γ by

$$\pi_\Lambda(A| \ \overline{\gamma}) = \int_{A'} \mu_\Lambda(d\eta| \ \overline{\gamma}),$$

where $A' = \{\eta \in \Gamma_\Lambda : \ \eta \cup (\overline{\gamma}_{\Lambda^c}) \in A\}$, $A \in \mathfrak{B}(\Gamma)$.

A probability measure μ on Γ is called a Gibbs state for U, β and z if

$$\mu(\pi_\Lambda(A| \ \overline{\gamma})) = \mu(A)$$

for every $A \in \mathfrak{B}(\Gamma)$ and every $\Lambda \in \mathcal{B}_c(\mathbb{R}^d)$.

This relation is the well known (DLR)-equation (Dobrushin–Lanford–Ruelle equation), see Ref. 6 for more details. The class of all Gibbs states which correspond to the specifications $\{\pi_\Lambda\}_{\Lambda \in \mathcal{B}_c(\mathbb{R}^d)}$ we denote by $\mathcal{G}(V,z,\beta)$.

D. Main results

Theorem 2.1: *Suppose that the interaction family V satisfies the assumptions* **A1–A6**. *Then, for any* $\Lambda \in \mathcal{J}_{\lambda_0}(\mathbb{R}^d)$ *and any* $\beta,z>0$ *there exists a constant* $\xi = \xi(\beta,z)$ *(independent of* Λ*) such that the finite volume correlation function* $\rho^\Lambda(\eta) = \rho^\Lambda(\eta|\varnothing)$ *satisfies the following inequality:*

$$\rho^\Lambda(\eta) \leqslant \xi^{|\eta|} e^{-(1/2)U^+(\eta)}, \quad \eta \in \Gamma_\Lambda. \tag{6}$$

Remark 2.4: The estimate (6) without exponent factor at the right-hand side is the well-known Ruelle bound.[18] *We call (6) a generalized Ruelle bound. For the two-body interaction it was obtained in Refs. 1 and 16.*

As a consequence of Theorem 2.1 the following theorem is fulfilled.

Theorem 2.2: *Let the interaction family V satisfy* **A1–A6**. *Then for any* $z>0$ *and* $\beta>0$

$$\mathcal{G}(V,z,\beta)\neq\varnothing.$$

Proof: Existence of the corresponding Gibbs state follows from the arguments which are based on the following observation. Let $\psi\in L^1(\mathbb{R}^d)\cap C(\mathbb{R}^d)$ be any positive function such that $\psi(x)\leqslant 1, x\in\mathbb{R}^d$, and let $\alpha(t)$, $t\in\mathbb{R}_+$ be any continuous decreasing function with the following conditions:

(1) $\alpha_0:=\lim_{t\to 0+}\alpha(t)=+\infty$;
(2) $\alpha_+:=\lim_{t\to+\infty}\alpha(t)\geqslant 1$.

Define,

$$\Gamma^{\alpha,\psi}=\left\{\gamma\in\Gamma\;\middle|\;\sum_{\{x,y\}\subset\gamma}\psi(x)\alpha(|x-y|)\psi(y)<\infty\right\}$$

and

$$E^{\alpha,\psi}(\gamma)=\sum_{\{x,y\}\subset\gamma}\psi(x)\alpha(|x-y|)\psi(y),\quad\gamma\in\Gamma^{\alpha,\psi}.$$

As shown in Ref. 9, for any $0<D<\infty$ the set

$$\{\gamma\in\Gamma\,|\,|E^{\alpha,\psi}(\gamma)|\leqslant D\}$$

is precompact in Γ, which is Polish space.

In this paper we consider α as any continuous decreasing function such that

$$\alpha(|x-y|)\leqslant e^{(1/2)\,V_2^+(x,y)}.$$

Obviously, chosen in such a way, this function satisfies the conditions above. Using the properties of the so-called *K*-transform (see Ref. 8) and the Theorem 2.1, for any $\Lambda\in\mathcal{J}_{\lambda_0}(\mathbb{R}^d)$ we have

$$\int_\Gamma E^{\alpha,\psi}(\gamma)\,d\mu_\Lambda(\gamma)=\int_{\mathbb{R}^{2d}}\psi(x)\alpha(|x-y|)\psi(y)\rho_\Lambda^{(2)}(\{x,y\})\,dx\,dy<C,$$

where $C\in\mathbb{R}_+$ is some constant.

Therefore, by Prokhorov theorem the family of measures

$$\{\mu_\Lambda\,|\,\Lambda\in\mathcal{J}_{\lambda_0}(\mathbb{R}^d)\}$$

is precompact, which implies the existence of at least one limit measure μ when $\Lambda\nearrow\mathbb{R}^d$. We will prove that corresponding limit measure is Gibbsian. Let μ_{Λ_n}, $n\geqslant 1$, where $\Lambda_n\nearrow\mathbb{R}^d$, $n\to\infty$ be the sequence which converges (in the sense of the Prokhorov theorem) to the measure μ, and let ρ^{Λ_n}, ρ be the corresponding correlation functions. It is well-known (see Ref. 6) that probability measure μ on Γ is Gibbs, iff μ fulfills the *Georgii–Nguyen–Zessin* equation (GNZ), i.e., for all positive, $\mathcal{B}(\mathbb{R}^d)\times\mathfrak{B}(\Gamma)$ measurable functions H the following holds

$$\int_\Gamma\sum_{x\in\gamma}H(x,\gamma)\mu(d\gamma)=\int_\Gamma\int_{\mathbb{R}^d}H(x,\gamma\cup\{x\})e^{-\beta W(\{x\}|\gamma)}\sigma(dx)\mu(d\gamma).\tag{7}$$

Moreover, using the Mecke formula (see Ref. 6), one can show that (7) holds for any measure μ_{Λ_n}, $n\geqslant 1$.

Let $\Lambda \in \mathcal{B}_c(\mathbb{R}^d)$. The σ-algebra $\mathfrak{B}(\Gamma)$ is generated by sets of the form $A \cap \tilde{A}$ with $A \in \mathfrak{B}_\Lambda(\Gamma)$, $\tilde{A} \in \mathfrak{B}_{\mathbb{R}^d \setminus \Lambda}(\Gamma)$ and every measure on Γ is uniquely determined by its values on these sets.

Let us prove (7) for the function $H(x,\gamma) = \mathbb{1}_\Lambda(x)\mathbb{1}_A(\gamma)\mathbb{1}_{\tilde{A}}(\gamma)$. Let $n \in \mathbb{N}$ be arbitrary. Using the properties of the K-transform (see Ref. 8) we have

$$\int_{\Gamma_{\Lambda_n}} \sum_{x \in \gamma} \mathbb{1}_\Lambda(x)\mathbb{1}_A(\gamma)\mathbb{1}_{\tilde{A}}(\gamma)\mu_{\Lambda_n}(d\gamma) \leqslant \int_{\Gamma_{\Lambda_n}} \sum_{x \in \gamma} \mathbb{1}_\Lambda(x)\mu_{\Lambda_n}(d\gamma) = \int_\Lambda \rho^{\Lambda_n}(x)\sigma(dx) \leqslant z\xi|\Lambda|. \tag{8}$$

The right-hand side of (7) for the measure μ_{Λ_n} is bounded by

$$\int_{\mathbb{R}^d} \mathbb{1}_\Lambda(x) \int_{\Gamma_{\Lambda_n}} e^{-\beta W(\{x\}|\gamma)} \mu_{\Lambda_n}(d\gamma)\sigma(dx) = \int_{\mathbb{R}^d} \mathbb{1}_\Lambda(x)\rho^{\Lambda_n}(x)\sigma(dx) \leqslant z\xi|\Lambda|, \tag{9}$$

where we have used the definition of the correlation function and Fubini theorem. Hence, there exists some subsequence $\{\mu_{\Lambda_{n_k}}\}_{k \geqslant 1}$ which ensures the fulfillment of (7) for the limit measure μ. The proof for the general positive function H follows from the fact that any positive measurable function can be approximated by the simple functions.

III. THE PROOF OF THEOREM 2.1

The proof is based on the expansion of the Lebesgue–Poisson integral for the correlation functions (5) into the series over some kind of dense configurations (see Ref. 16 and definition (3.4) therein).

A. Cluster expansion in densities of configurations

The main idea of the construction consists in the use of the fact that if two or more particles are in one elementary cube $\Delta \in \overline{\Delta}$ then Gibbs factor $\exp[-\beta V_2(x_i,x_j)] \sim \exp[-\beta b]$, where

$$b = \inf_{\Delta \in \overline{\Delta}} \inf_{x_1,x_2 \in \Delta} V_2^+(x_1,x_2) \tag{10}$$

and $b \to \infty$, when $\lambda \to 0$. The configurations with this property will be called *dense* configurations, as opposed to *dilute* configurations, in which no more than one particle is situated in any cube. The main technical idea consists in separation of the dilute parts of configurations from the dense parts. In order to do this we define an indicator function for the configuration γ_Λ, $\Lambda \in \mathcal{J}_{\lambda_0}(\mathbb{R}^d)$ in the cube Δ:

$$\chi_n^\Delta(\gamma_\Lambda) = \chi_n^\Delta(\gamma_\Delta) = \begin{cases} 1, & \text{for } |\gamma_\Delta| = n, \\ 0, & \text{otherwise.} \end{cases}$$

Then the indicator for *dilute* configurations is defined as

$$\chi_-^\Delta(\gamma_\Delta) = \chi_0^\Delta(\gamma_\Delta) + \chi_1^\Delta(\gamma_\Delta)$$

and for *dense* configurations as

$$\chi_+^\Delta(\gamma_\Delta) = \sum_{n \geqslant 2} \chi_n^\Delta(\gamma_\Delta).$$

To obtain decomposition we use the following partition of the unity:

$$1 = \prod_{\Delta\subset\Lambda}[\chi^{\Delta}_{-}(\gamma_\Delta)+\chi^{\Delta}_{+}(\gamma_\Delta)] = \sum_{\omega}\prod_{\Delta\subset\Lambda}\chi^{\Delta}_{\omega(\Delta)}(\gamma_\Delta), \tag{11}$$

where ω is the map from $\overline{\Delta}\cap\Lambda := \{\Delta\in\overline{\Delta}:\Delta\subset\Lambda\}$ into the set $\{+,-\}$, such that $\omega(\Delta)=+$ or $-$ for any $\Delta\in\overline{\Delta}\cap\Lambda$. Inserting (11) into (5) for $\overline{\gamma}=\varnothing$, we get

$$\rho^{\Lambda}(\eta) = \frac{1}{Z_\Lambda}\sum_{\omega}\int_{\Gamma_\Lambda}\prod_{\Delta\subset\Lambda}\chi^{\Delta}_{\omega(\Delta)}(\gamma_\Delta)e^{-\beta U(\eta\cup\gamma)}\lambda_\sigma(d\gamma), \tag{12}$$

where $Z_\Lambda = Z_\Lambda(\varnothing)$. Now we define the set

$$X = \bigcup_{\Delta\subset\Lambda\,:\,\omega(\Delta)=+}\Delta.$$

Then the sum over ω can be rewritten as the sum over all possible sets X in Λ. Namely,

$$\rho^{\Lambda}(\eta) = \frac{1}{Z_\Lambda}\sum_{\varnothing\subseteq X\subseteq\Lambda}\int_{\Gamma_\Lambda}\tilde{\chi}^{X}_{+}(\gamma)\tilde{\chi}^{X^c}_{-}(\gamma)e^{-\beta U(\eta\cup\gamma)}\lambda_\sigma(d\gamma),$$

where

$$\tilde{\chi}^{X}_{\pm}(\gamma) = \prod_{\Delta\subset X}\chi^{\Delta}_{\pm}(\gamma_\Delta).$$

For any $X\in\mathcal{J}_{\lambda_0}(\mathbb{R}^d)$, $X\subseteq\Lambda$ define graph $G_R(X)$ with vertices in the centers of all elementary cubes $\Delta\subset X$ and lines $l(\Delta,\Delta')$ iff $\mathrm{dist}(\Delta,\Delta')\leqslant R$. The number of lines depends on graph $G_R(X)$.

Definition 3.1: The set X is called R-connected if the corresponding graph $G_R(X)$ is connected in ordinary way.

R-connected set X is denoted by X^R. Then, every set X can be represented as some fixed partition

$$\{X\}^R_n := \{X^R_1,\ldots,X^R_n|\,\mathrm{dist}(X^R_i,X^R_j)>R,\quad \text{for}\quad i\neq j\},$$

and so the sum over all possible X in Λ can be rewritten as the sum over all possible sets $\{X\}^R_n$ (for $n=0, X=\varnothing$). Furthermore, we replace the sum over all such sets by the sum over $X^R_1,\ldots,X^R_n$ independently, and remove the conditions $\mathrm{dist}(X^R_i,X^R_j)>R$ by introducing the *hard-core* potential

$$\chi^{\mathrm{cor}}_R(X)_n = \begin{cases} 0, & \text{there exists } X^R_i, X^R_j,\ i\neq j,\ \mathrm{dist}(X^R_i,X^R_j)\leqslant R,\\ 1, & \text{otherwise.}\end{cases}$$

Then we get

$$\rho^{\Lambda}(\eta) = \frac{1}{Z_\Lambda}\sum_{n\geqslant 0}\frac{1}{n!}\sum_{X^R_1\subseteq\Lambda}\cdots\sum_{X^R_n\subseteq\Lambda}\chi^{\mathrm{cor}}_R(X)_n\int_{\Gamma_\Lambda}\tilde{\chi}^{X}_{+}(\gamma)\tilde{\chi}^{X^c}_{-}(\gamma)e^{-\beta U(\eta\cup\gamma)}\lambda_\sigma(d\gamma). \tag{13}$$

In the sequel, having in mind only R-connected components of X, we drop index R in the notation X^R_i, and summation $\Sigma_{X_1\subseteq\Lambda}\cdots\Sigma_{X_n\subseteq\Lambda}$, for simplicity, will be denoted by $\Sigma_{(X)_n}$. Now, the last step in arranging our decomposition is as follows. Define the set

$$X_0 = \bigcup_{\Delta\subset\Lambda\,:\,\mathrm{dist}(\Delta,\,\eta)\leqslant R}\Delta.$$

This set is fixed for fixed variable of the correlation function $\rho^{\Lambda}(\eta)$. Now, for every $n\geqslant 0$ we split the sum over $(X)_n$ into two sums. The first one is over those X_j, which do not intersect the

region X_0 and the second one over those which intersect X_0. To distinguish the sets X_j which do not intersect and do intersect X_0, the latter sets are denoted by Y_j. There are $n!/k!(n-k)!$ possibilities when any k sets X_j do not intersect X_0 and $(n-k)$ sets Y_j intersect X_0. So the final expansion is the following:

$$\rho^{\Lambda}(\eta) = \frac{1}{Z_\Lambda}\sum_{n\geqslant 0}\sum_{k=0}^{n}\frac{1}{k!(n-k)!}\sum_{(X)_k}\sum_{(Y)_{n-k}}\chi_R^{\mathrm{cor}}((X)_k,(Y)_{n-k}) \times\int_{\Gamma_\Lambda}\lambda_\sigma(d\gamma)\tilde{\chi}_+^X(\gamma)\tilde{\chi}_-^{X^c}(\gamma)e^{-\beta U(\eta\cup\gamma)}, \tag{14}$$

where

$$X=\tilde{X}_k\cup\tilde{Y}_{n-k}:=\left[\bigcup_{i=1}^{k}X_i\right]\bigcup\left[\bigcup_{j=1}^{n-k}Y_j\right].$$

B. The main estimates

As the first step, let us split the exponent in (14) into four parts: the part which corresponds to the positive part of the energy of the configuration η, the interactions of the particles inside the region $X_0\cup\tilde{Y}_{n-k}$, inside $\Lambda\backslash(X_0\cup\tilde{Y}_{n-k})$ and interactions between them. Note that interaction between $X_0\cup\tilde{Y}_{n-k}$ and $\tilde{X}_k$ is zero due to the finite range of potential. Therefore, considering $\gamma\in\Gamma_\Lambda : \gamma\cap\eta=\varnothing$ we get

$$e^{-\beta U(\eta\cup\gamma)}=e^{-\beta U^+(\eta)}E_1E_2E_0,$$

where

$$E_1(X_0\cup\tilde{Y}_{n-k})=e^{-\beta U^{\mathrm{st}}(\eta)}\prod_{l=1}^{n-k}e^{\beta W(\eta\,|\,\gamma_{Y_l})-1/2\,\beta U^+(\gamma_{Y_l})-\beta U^{\mathrm{st}}(\gamma_{Y_l})},$$

$$E_2(X_0\cup\tilde{Y}_{n-k}|(X_0\cup X)^c)=e^{-\beta W(\eta\,|\,\gamma_{X_0\backslash\tilde{Y}_{n-k}})}\prod_{l=1}^{n-k}e^{-\beta[1/2\,U^+(\gamma_{Y_l})+W(\gamma_{Y_l}\,|\,\gamma_{X^c})]},$$

and

$$E_0(\tilde{Y}_{n-k}^c)=e^{-\beta U(\gamma_{\Lambda\backslash\tilde{Y}_{n-k}})}.$$

Lemma 3.1:

$$E_1\leqslant e^{\beta B|\eta|}\prod_{l=1}^{n-k}\prod_{\Delta\subset Y_l}e^{\beta B|\gamma_\Delta|-(1/2)\,\beta U^+(\gamma_\Delta)}. \tag{15}$$

Proof: Using **A5** we have

$$U^{(\mathrm{st})}(\eta\cup\gamma_{\tilde{Y}_{n-k}})\geqslant -B\left(|\eta|+\sum_{l=1}^{n-k}\sum_{\Delta\subset Y_l}|\gamma_\Delta|\right)$$

and

$$W^+(\eta|\gamma_{\tilde{Y}_{n-k}})\geqslant 0,\quad U^+(\gamma_{Y_l})\geqslant\sum_{\Delta\subset Y_l}U^+(\gamma_\Delta).$$

■

Lemma 3.2: For any $\gamma\in\Gamma$ *and* $\overline{\gamma}\in\overline{\Gamma}_{X^c}$, $X\in\mathcal{J}_{\lambda_0}(\mathbb{R}^d)$, $X\subseteq\Lambda$

$$\tfrac{1}{4}U^+(\gamma_X)+W(\gamma_X|\overline{\gamma})\geqslant-\overline{I|\gamma_X|}, \tag{16}$$

where $\overline{I}:=\overline{I}_2^{(1)}$ (*see (4)), and*

$$\overline{\Gamma}_{X^c}=\{\gamma\in\Gamma_{X^c}\,|\;\;|\gamma\cap\Delta|\leqslant 1,\quad\text{for all}\;\;\Delta\subset X^c\}.$$

■

Proof: See Appendix.

Let us define

$$\partial\eta=\bigcup_{\Delta\,:\,\eta\cap\Delta\neq\varnothing}\Delta.$$

Now using the property of infinite divisibility of measure λ_σ and estimate (16) we can calculate the part of integral in (14)

$$\begin{aligned}
&e^{-(1/2)\,\beta U^+(\eta)}\int_{\Gamma_{\tilde{Y}_{n-k}}}\tilde{\chi}_+^{\tilde{Y}_{n-k}}(\gamma)E_1E_2\lambda_\sigma(d\gamma)\\
&\leqslant e^{-(1/4)\,\beta U^+(\eta)+\beta|\eta|\overline{I}}\int_{\Gamma_{\tilde{Y}_{n-k}}}\tilde{\chi}_+^{\tilde{Y}_{n-k}}(\gamma)e^{-\beta W(\eta\,|\,\gamma_{(X_0\cap\partial\eta)\setminus\tilde{Y}_{n-k}})}E_1\\
&\quad\times\prod_{l=1}^{n-k}e^{-\beta[(1/2)\,U^+(\gamma_{Y_l})+W(\gamma_{Y_l}\,|\,\gamma_{X^c})]}\lambda_\sigma(d\gamma).
\end{aligned}\tag{17}$$

Assumption **A6**, estimate (15), and trivial inequality

$$U^+(\eta)\geqslant\sum_{\Delta\subset\partial\eta}U^+(\eta_\Delta)$$

gives us the bound for the integral (17),

$$e^{\beta|\eta|(\overline{I}+B)+\beta\Sigma_{\Delta\subset\partial\eta}\overline{I}|\eta_\Delta|}\prod_{l=1}^{n-k}\prod_{\Delta\subset Y_l}I_\Delta,$$

where

$$I_\Delta=\int_{\Gamma_\Delta}\chi_+^\Delta(\gamma_\Delta)e^{-\beta\,(1/2)\,U^+(\gamma_\Delta)+\beta(B+\overline{I})|\gamma_\Delta|}\lambda_\sigma(d\gamma). \tag{18}$$

Focusing only on the two-body positive part of interaction and taking into account the definition (10) we can estimate the last integral by

$$I_\Delta\leqslant\varepsilon_1=\tfrac{1}{2}z^2\lambda_0^{2d}e^{-\beta(1/2)\,b-2\overline{I}-2B)}\exp\{z\lambda_0^d e^{-\beta(3/2)}\,b-\overline{I}-B)\}, \tag{19}$$

which is finite due to **A6**.

Now taking the maximum of E_0 in variable $\tilde{Y}_{n-k}$ (we denote this maximum by $\overline{Y}_{n-k}$) and using elementary estimate

$$\chi_R^{\mathrm{cor}}((X)_k,(Y)_{n-k})\leqslant\chi_R^{\mathrm{cor}}(X)_k \tag{20}$$

we can estimate the sum over $(Y)_{n-k}$ by the following lemma:

Lemma 3.3 (e.g., Ref. 12):

$$\sum_{Y\cap X_0\neq\varnothing} \varepsilon_1^{|Y|/\lambda^d} \leqslant |\eta| c(d)\left(\frac{R}{\lambda}\right)^d \frac{\varepsilon}{1-\varepsilon} = |\eta| K, \tag{21}$$

where $c(d)$ *is a constant which depends only on* d *and* $\varepsilon = 4c(d)(R/\lambda)^d \varepsilon_1$.

For the *proof* in our case, see Ref. 16.

The last step is as follows. The expansion like (13) can be constructed for partition function Z_{Λ_1} with $\Lambda_1 \subset \Lambda$. Denote it by

$$Z_{\Lambda_1} = \sum_{k\geqslant 0} \frac{1}{k!} Z^{(k)}_{\Lambda_1}. \tag{22}$$

Taking into account all previous estimates we get

$$\begin{aligned}
\rho^{\Lambda}(\eta) &\leqslant \frac{1}{Z_\Lambda} e^{-(1/2)\beta U^+(\eta_\Lambda)+\beta(2\bar{I}+B)|\eta|} \sum_{n\geqslant 0} \sum_{k=0}^{n} \frac{(|\eta|K)^{n-k}}{k!(n-k)!} Z^{k}_{\Lambda\setminus\bar{Y}_{n-k}} \\
&= \frac{1}{Z_\Lambda} e^{-(1/2)\beta U^+(\eta_\Lambda)+\beta(2\bar{I}+B)|\eta|} \sum_{k\geqslant 0} \frac{1}{k!} \sum_{l\geqslant 0} \frac{(|\eta|K)^{l}}{l!} Z^{k}_{\Lambda\setminus\bar{Y}_{l}} \\
&= e^{-(1/2)\beta U^+(\eta_\Lambda)+\beta(2\bar{I}+B)|\eta|} \sum_{l\geqslant 0} \frac{(|\eta|K)^{l}}{l!} \frac{Z_{\Lambda\setminus\bar{Y}_l}}{Z_\Lambda}.
\end{aligned} \tag{23}$$

The fact that $Z_{\Lambda_1} \leqslant Z_{\Lambda_2}$ for $\Lambda_1 \subset \Lambda_2$ gives the inequality

$$\rho^{\Lambda}(\eta) \leqslant e^{-(1/2)\beta U^+(\eta)} e^{|\eta|(\beta(2\bar{I}+B)+K)}.$$

■

APPENDIX: PROOF OF THE LEMMA 3.2

Let $X = \cup_{j=1}^{N} \Delta_j$. Consider the configuration γ with $|\gamma_X| = m, |\gamma_{\Delta_1}| = m_1, \ldots, |\gamma_{\Delta_N}| = m_N$, $m_j \geqslant 1$ for $j = 1, \ldots, N$ and $m_1 + \cdots + m_N = m$. Let in the k-body interaction be involved $\bar{k} \geqslant 1$ particles from the dilute configuration $\bar{\gamma}_{X^c} \in \bar{\gamma}_{X^c}$ and, correspondingly, q_1 particles of γ_X from Δ_1, which are situated in the points $x_1^{(1)}, \ldots, x_{q_1}^{(1)} \in \Delta_1$, $\ldots$, q_N particles $x_1^{(N)}, \ldots, x_{q_N}^{(N)}$ from Δ_N. It is clear that $q_1 + \cdots + q_N + \bar{k} = k$ and $0 \leqslant q_i \leqslant m_i$, $\bar{k} \geqslant 1$. Then the interaction energy between m particles of the configuration γ_X and $\bar{k}$ particles of dilute configuration $\bar{\gamma}_{X^c}$ can be written in the following form:

$$\begin{aligned}
W_k(\gamma_X|\bar{\gamma}_{X^c}) = &\sum_{\substack{0\leqslant q_i\leqslant m_i,\,\bar{k}\geqslant 1 \\ q_1+\cdots+q_N+\bar{k}=k}} \sum_{\{x_1^{(1)},\ldots,x_{q_1}^{(1)}\}\in\gamma_{\Delta_1}} \cdots \sum_{\{x_1^{(N)},\ldots,x_{q_N}^{(N)}\}\in\gamma_{\Delta_N}} \\
&\times \sum_{\{y_1,\ldots,y_{\bar{k}}\}\in\bar{\gamma}_{X^c}} V_k(x_1^{(1)},\ldots,x_{q_1}^{(1)},\ldots,x_1^{(N)},\ldots,x_{q_N}^{(N)},y_1,\ldots,y_{\bar{k}}).
\end{aligned}$$

Then taking into account (1) we obtain

$$-W_k(\gamma_X|\overline{\gamma}_{X^c}) \leqslant \sum_{\substack{0\leqslant q_i\leqslant m_i,\ \overline{k}\geqslant 1 \\ q_1+\cdots+q_N+\overline{k}=k}} \prod_{i=1}^{N} C_{m_i}^{q_i} I_k^{q_1,\ldots,q_N|\overline{k}}(\Delta_1,\ldots,\Delta_N), \tag{A1}$$

where $C_m^k = m!/k!(m-k)!$. Let in the sequence $q_1,\ldots,q_N$ be nonzero correspondingly $q_{l_i}=k_{l_i}$ particles from Δ_{l_i}, $i=1,\ldots,M$ involved in k-body interaction. Changing in (A1) to the summation over $k_{l_1},\ldots,k_{l_M}$:

$$-W_k(\gamma_X|\overline{\gamma}_{X^c}) \leqslant \sum_{M=1}^{\min\{N,\,k-1\}} \sum_{1\leqslant l_1<l_2<\cdots<l_M\leqslant N} \sum_{\substack{1\leqslant k_{l_i}\leqslant m_{l_i},\ \overline{k}\geqslant 1 \\ k_{l_1}+\cdots+k_{l_M}+\overline{k}=k}} \prod_{i=1}^{M} C_{m_{l_i}}^{k_{l_i}} I_k^{k_{l_1},\ldots,k_{l_M}|\overline{k}}(\Delta_{l_1},\ldots,\Delta_{l_M}). \tag{A2}$$

Let among the cubes $\Delta_1,\ldots,\Delta_N$ be N_1 cubes with only one point of γ inside. Without loss of generality, we suppose that $m_j=1$, $j=N-N_1+1,\ldots,N$. We suppose also that $1\leqslant N_1<N$. Split the summation over $1\leqslant l_1<l_2<\cdots<l_M\leqslant N$ into the summation over $1\leqslant l_1<l_2<\cdots<l_S\leqslant N-N_1$ over cubes $\Delta_1,\ldots,\Delta_{N-N_1}$ and the summation over $1\leqslant l_1'<l_2'<\cdots<l_{S'}'\leqslant N_1$ over cubes $\Delta_1',\ldots,\Delta_{N_1}'$. It is clear that $S+S'=M$ and S can take integer values from 0 to M. Therefore, we get additionally $M+1$ sums over S. Every value of $1\leqslant l_1'<\cdots<l_{S'}'\leqslant N_1$ corresponds to the dilute configuration. Hence, using the definition (1) we can apply the following formula:

$$\sum_{1\leqslant l_1'<l_2'<\cdots<l_{S'}'\leqslant N_1} I_k^{k_{l_1},\ldots,k_{l_S},1,\ldots,1|\overline{k}}(\Delta_{l_1},\ldots,\Delta_{l_S},\Delta_{l_1'},\ldots,\Delta_{l_{S'}'}) \leqslant I_k^{k_{l_1},\ldots,k_{l_S}|\overline{k}+S'}(\Delta_{l_1},\ldots,\Delta_{l_S}),$$

yielding

$$-W_k(\gamma_X|\overline{\gamma}_{X^c}) \leqslant \sum_{M=1}^{\min\{N-N_1,\,k-1\}} \sum_{1\leqslant l_1<l_2<\cdots<l_M\leqslant N-N_1} \sum_{l=0}^{\min\{N_1,\,k-M-1\}} \sum_{\substack{1\leqslant k_{l_i}\leqslant m_{l_i},\ \overline{k}\geqslant 1 \\ k_{l_1}+\cdots+k_{l_M}+\overline{k}+l=k}} \prod_{i=1}^{M} C_{m_{l_i}}^{k_{l_i}}$$

$$\times I_k^{k_{l_1},\ldots,k_{l_M}|\overline{k}+l}(\Delta_{l_1},\ldots,\Delta_{l_M}) + N_* \sum_{l_1'=1}^{\min\{N_1,\,k-1\}} I_k^{1|k-1}(\Delta_{l_1}'),$$

where $N_*=\min\{N,k-1\}$. Collecting the terms with $M=1$, $k_{l_1}=1$ in the first sum and the last sum, and selecting also the terms with $k_{l_1}=k_{l_2}=\cdots=k_{l_M}=1$, summing up all inequalities in $k\geqslant 2$ and taking into account that $N_*\leqslant k-1$, we get

$$-W(\gamma_X|\overline{\gamma}_{X^c}) \leqslant \overline{I}|\gamma_X| + W_1 + W_2,$$

where

$$W_1 = \sum_{M=2}^{N-N_1} \sum_{1\leqslant l_1<l_2<\cdots<l_M\leqslant N-N_1} \prod_{i=1}^{M} C_{m_{l_i}}^{1} \sum_{k\geqslant M+1} (k-M) I_k^{1,\ldots,1|k-M}(\Delta_{l_1},\ldots,\Delta_{l_M}),$$

$$W_2 = \sum_{M=1}^{N-N_1} \sum_{1\leqslant l_1<l_2<\cdots<l_M\leqslant N-N_1} \sum_{k\geqslant M+1} \sum_{\substack{1\leqslant k_{l_i}\leqslant m_{l_i} \\ k_{l_1}+\cdots+k_{l_M}=k}} \prod_{i=1}^{M} C_{m_{l_i}}^{k_{l_i}} \times \sum_{l\geqslant 1} l I_{k+l}^{k_{l_1},\ldots,k_{l_M}|l}(\Delta_{l_1},\ldots,\Delta_{l_M}).$$

Using the same arguments, one can get almost the same inequality for the positive part of energy:

$$U^+(\gamma_X)\geqslant U_0,$$

where

$$U_0=\sum_{M=1}^{N-N_1}\sum_{1\leqslant l_1<l_2<\cdots<l_M\leqslant N-N_1}\sum_{k\geqslant M+1}\sum_{\substack{1\leqslant k_{l_i}\leqslant m_{l_i}\\ k_{l_1}+\cdots+k_{l_M}=k}}\prod_{i=1}^{M}C_{m_{l_i}}^{k_{l_i}}\times v_k^{k_{l_1},\ldots,k_{l_M}}(\Delta_{l_1},\ldots,\Delta_{l_M}).$$

Now it is clear from the assumptions **A6** that

$$\tfrac{1}{4}U_0\geqslant W_1,\quad \text{and}\quad \tfrac{1}{4}U_0\geqslant W_2,$$

which gives (16). It is not difficult to see (using direct computation) that condition $1\leqslant N_1<N$ is not essential in the proof of Lemma 3.2. ■

(Received 15 July 2003; accepted 17 December 2003)

The generating functional of the cyclic representation of the canonical commutation relations (CCR) representation for the thermodynamic limit of the grand canonical ensemble of the free Bose gas with attractive boundary conditions is rigorously computed. We use it to study the condensate localization as a function of the homothety point for the thermodynamic limit using a sequence of growing convex containers. The Kac function is explicitly obtained proving nonequivalence of ensembles in the condensate region in spite of the condensate density being zero locally. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1649793]

I. INTRODUCTION

The interest in the phenomenon of standard Bose Einstein Condensation (BEC) revived in recent years is due to the spectacular experimental work on Bosons in traps. We refer, e.g., to Refs. 9 and 12 for experimental and theoretical state of affairs. A renewed interest in old problems connected with the phase transition accompanying BEC is at order. The generic model for BEC is the free Bose gas as already was pointed out by Bose and Einstein in 1925. On the level of mathematical physics, the understanding of the phase transition started with the well known paper of Araki and Woods,[1] where the generating functionals of the cyclic representations of the canonical commutation relations corresponding to the equilibrium states of the free Bose gas are computed for periodic boundary conditions. Lewis and Pulé[7,8,11] computed the grand canonical equilibrium states for a set of boundary conditions including the Dirichlet and Neumann boundary conditions but not the attractive boundary conditions. They are using the Kac method. An important consequence of their result is the explicit computation of a nontrivial Kac density showing nonequivalence of the canonical and grand-canonical ensembles in the condensate region. The next result is found in Ref. 3, where the same conclusion was obtained for generalized condensations in some models of imperfect gases with diagonal interactions.

In the present paper we complete this computation of the equilibrium states for the free Bose gas with *attractive* boundary conditions. About the relevance of this type of boundary conditions, see, e.g., Refs. 4 and 10. This model has a particular type of condensation, namely, condensation in quantum states corresponding to isolated points in the spectrum. It is well known[5,10] that in this case the condensate is situated at the ''boundary'' and *not* uniformly spread out everywhere in space. We give a precise formulation of the generating functional in the frame of the theory of generating functionals on the CCR in order to catch up the condensate. Finally we derive also that there is *nonequivalence* of ensembles, something which was unclear until now because of the fact that the quantum fluctuations show a pattern[6] completely different from the free Bose gas with Dirichlet or Neumann boundary conditions. The intuition behind this fact is related to a wondering peculiarity of the free Bose gas with *attractive* boundary conditions.[5,10] If one takes the thermo-

[a]Electronic mail: lieselot.vandevenne@fys.kuleuven.ac.be
[b]Electronic mail: andre.verbeure@fys.kuleuven.ac.be
[c]Electronic mail: zagrebnov@cpt.univ-mrs.fr

dynamic limit using a sequence of growing convex domains with the point of homothety at the origin of the coordinates, then *locally* the condensation density is always equal to zero. As a by-product, our computations imply that the condensate is spatially situated in a region logarithmically close to the boundary of these increasing domains. In the present paper we take different positions of the homothety point for cubic containers to show that the density of this logarithmic stratum of condensate inherits also a spacial anisotropy due to the choice of cubic containers. Finally remark that for the rotating bucket case,[11] one has also the effect of the condensate being increased at the boundary. But this is an effect of large angular momentum and not of the boundary conditions as in our case.

II. CCR-REPRESENTATIONS AND THE GENERATING FUNCTIONAL

For details about the CCR algebra, we refer to Ref. 2.

Let h be a complex pre-Hilbert space with inner product $(\cdot,\cdot)$. A representation of the CCR over h on a Hilbert space $\mathcal{H}$ is a map $f\mapsto W(f)$ of h into the group $\mathcal{U}(\mathcal{H})$ of unitary operators on a Hilbert space $\mathcal{H}$ satisfying the Weyl relations:

$$W(f_1)W(f_2)=\exp\left\{-\frac{\mathrm{i}}{2}\mathrm{Im}(f_1,f_2)\right\}W(f_1+f_2) \tag{2.1}$$

such that for each $f\in h$ the map $\lambda\mapsto W(\lambda f)$ of $\mathbb{R}$ into $\mathcal{U}(\mathcal{H})$ is strongly continuous. By Stone's theorem, this continuity condition implies the existence of self-adjoint operators $\Phi(f)$ such that

$$W(f)=\exp\{\mathrm{i}\Phi(f)\}. \tag{2.2}$$

These $\Phi(f)$ are called field operators. The map $f\mapsto\Phi(f)$ is linear over $\mathbb{R}$, but not linear over $\mathbb{C}$. Using the $\Phi(f)$ we can now define the creation and annihilation operators $a^*(f)$ and $a(f)$ for $f\in h$ by

$$a^*(f)=2^{-1/2}\{\Phi(f)-\mathrm{i}\Phi(\mathrm{i}f)\}, \tag{2.3}$$

$$a(f)=2^{-1/2}\{\Phi(f)+\mathrm{i}\Phi(\mathrm{i}f)\}. \tag{2.4}$$

A state on the CCR-algebra is a linear functional $\omega: h\to\mathbb{C}$ with the properties

$$\omega(A^*A)\geqslant 0,\quad \omega(\mathbf{1})=1,\quad \text{for } A \text{ linear combinations of the } W(f),\ f\in h.$$

A representation $(W,\mathcal{H},\Omega)$ is called a cyclic representation if Ω is a cyclic vector. A vector Ω is cyclic if the set $\{W(f)\Omega\}_{f\in h}$ is dense in $\mathcal{H}$. To each cyclic representation $(W,\mathcal{H},\Omega)$ of the CCR corresponds a generating functional $\mathbb{E}: h\to\mathbb{C}$ given by

$$\mathbb{E}(f)=\omega(W(f))=(\Omega,W(f)\Omega). \tag{2.5}$$

Proposition 2.1: A functional $\mathbb{E}: h\to\mathbb{C}$ is the generating functional of a cyclic representation of the CCR if and only if it satisfies the following conditions:

(i) $\mathbb{E}(0)=1$,

(ii) $\forall f\in h: \lambda\mapsto\mathbb{E}(\lambda f)$ *is continuous,*

(iii) $\forall$ *finite sets of complex numbers* $c_1,\ldots,c_n$ *and elements* $f_1,\ldots,f_n\in h$: $\Sigma_i\Sigma_j\mathbb{E}(f_i-f_j)\mathrm{e}^{(\mathrm{i}/2)\,\mathrm{Im}(f_i,f_j)}\overline{c_i}c_j\geqslant 0$.

III. KAC-DENSITY AND EQUIVALENCE OF ENSEMBLES

A. Concrete setup

Let $\Lambda_L^\nu=[-L/2,L/2]^\nu$ be a bounded region in $\mathbb{R}^\nu$ with volume $V=L^\nu$. We put $h_L=\mathcal{L}^2(\Lambda_L^\nu)$ for the Hilbert space of the wave functions in Λ_L^ν with the scalar product $(f,g)_{h_L}:=\int_{\Lambda_L^\nu}dx^\nu\overline{f(x)}g(x)$. Then $\Lambda_L^\nu\subseteq\Lambda_{L'}^\nu$ and $h_L\subseteq h_{L'}$ whenever $L\leqslant L'$ via natural imbedding.

Let t_L^σ be the self-adjoint extension of the operator $-\Delta_L$ (with domain $\mathrm{dom}(-\Delta_L)=C_0^\infty(\Lambda_L^\nu)$) determined by the boundary conditions $\partial_n\phi+\sigma\phi=0$ on $\partial\Lambda_L^\nu$. Here ∂_n is the directional derivative in the direction of the outward normal n to $\partial\Lambda_L^\nu$. If the parameter $\sigma<0$, we say that the boundary $\partial\Lambda_L^\nu$ is *attractive*.

First we have to solve the one-dimensional one-body eigenvalue problem on $\Lambda_L=[-L/2,L/2]$:

$$(t_L^\sigma\phi)(x)=\lambda\phi(x)$$

with boundary conditions ($\sigma<0$):

$$\begin{cases}\left(\dfrac{d\phi}{dx}-\sigma\phi\right)_{x=-L/2}=0,\\ \left(\dfrac{d\phi}{dx}+\sigma\phi\right)_{x=L/2}=0.\end{cases}$$

Due to these attractive boundary conditions, there are two negative eigenvalues tending to the same limit $-\sigma^2$ (when $L\to\infty$) and an infinite number of positive eigenvalues (for $L|\sigma|>2$):

$$\epsilon_L(0)<\epsilon_L(1)<0<\epsilon_L(2)<\epsilon_L(3)<\cdots,$$

$$\epsilon_L(0)=-\sigma^2-O(e^{-L|\sigma|}),$$

$$\epsilon_L(1)=-\sigma^2+O(e^{-L|\sigma|}),$$

$$k\geqslant 2:\quad \left(\frac{(k-1)\pi}{L}\right)^2<\epsilon_L(k)<\left(\frac{k\pi}{L}\right)^2. \tag{3.1}$$

The corresponding eigenfunctions $\{\phi_k^L\}_{k\in\mathbb{Z}_+}$ form a basis in h_L and are given by

$$\phi_0^L(x)=\sqrt{\frac{2}{L}}\left(1+\frac{\sinh(L|\sigma|)}{L|\sigma|}\right)^{-1/2}\cosh(-|\sigma|x),$$

$$\phi_1^L(x)=\sqrt{\frac{2}{L}}\left(-1+\frac{\sinh(L|\sigma|)}{L|\sigma|}\right)^{-1/2}\sinh(-|\sigma|x),$$

$$\phi_k^L(x)=\begin{cases}\sqrt{\dfrac{2}{L}}\left(1+\dfrac{\sin(\sqrt{\epsilon_L(k)}L)}{\sqrt{\epsilon_L(k)}L}\right)^{-1/2}\cos(\sqrt{\epsilon_L(k)}x), & \text{for } k \text{ even},\\ \sqrt{\dfrac{2}{L}}\left(1-\dfrac{\sin(\sqrt{\epsilon_L(k)}L)}{\sqrt{\epsilon_L(k)}L}\right)^{-1/2}\sin(\sqrt{\epsilon_L(k)}x), & \text{for } k \text{ odd}.\end{cases}$$

The eigenvalues and the wave functions of the corresponding multidimensional case have the form

$$E_L(\mathbf{k}) = \sum_{i=1}^{\nu} \epsilon_L(k_i),$$

$$\psi_{\mathbf{k}}^L(\mathbf{x}) = \prod_{i=1}^{\nu} \phi_{k_i}^L(x_i),$$

where $\mathbf{k} = \{k_i\}_{i=1}^{\nu} \in \mathbb{Z}_+^{\nu}$ and $\mathbf{x} = \{x_i\}_{i=1}^{\nu} \in \Lambda_L^{\nu}$.

B. Kac density

The Kac density relates expectation values of observables in the *canonical ensemble* and those in the *grand canonical ensemble*. The canonical equilibrium state for a free Bose gas in a cube Λ_L^{ν} of volume $V = L^{\nu}$ with total particle density ρ and inverse temperature β is given by

$$\omega_{L,\beta,\rho}^{\mathrm{can}}(A) = \frac{\mathrm{Tr}_{\mathcal{H}_{L,B}^{(n)}} A^{(n)} \mathrm{e}^{-\beta T_L^{\sigma,(n)}}}{\mathrm{Tr}_{\mathcal{H}_{L,B}^{(n)}} \mathrm{e}^{-\beta T_L^{\sigma,(n)}}}, \quad \text{where } n = [V\rho], \mathrm{dom}(A^{(n)}) \subset \mathcal{H}_L^{(n)}, \tag{3.2}$$

and $T_L^{\sigma,(n)}$ is the n-particle free Bose gas Hamiltonian in the cube Λ_L^{ν} with boundary conditions defined by σ. Now we consider the grand canonical equilibrium state at chemical potential μ and inverse temperature β,

$$\omega_{L,\beta,\mu}^{\mathrm{g.c.}}(A) = \frac{\mathrm{Tr}_{\mathcal{F}_{L,B}} A \exp\{-\beta(T_L^{\sigma} - \mu N_L)\}}{\mathrm{Tr}_{\mathcal{F}_{L,B}} \exp\{-\beta(T_L^{\sigma} - \mu N_L)\}}, \quad \mathrm{dom}(A) \subset \mathcal{F}_{L,B}. \tag{3.3}$$

Here $T_L^{\sigma} = \Sigma_{\mathbf{k} \in \mathbb{Z}_+^{\nu}} E_L(\mathbf{k}) a^*(\psi_{\mathbf{k}}^L) a(\psi_{\mathbf{k}}^L)$ is the free Bose gas Hamiltonian and $N_L = \Sigma_{\mathbf{k} \in \mathbb{Z}_+^{\nu}} N_{L,\mathbf{k}} = \Sigma_{\mathbf{k} \in \mathbb{Z}_+^{\nu}} a^*(\psi_{\mathbf{k}}^L) a(\psi_{\mathbf{k}}^L)$, is the particle number operator in $\mathcal{F}_{L,B}$, the boson Fock space over $\mathcal{L}^2(\Lambda_L^{\nu})$:

$$\mathcal{F}_{L,B} = \mathcal{F}_B(\mathcal{L}^2(\Lambda_L^{\nu})) = \bigoplus_{n=0}^{\infty} \mathcal{H}_{L,B}^{(n)} \tag{3.4}$$

with $\mathcal{H}_{L,B}^{(n)}$ the symmetrized n-particle Hilbert space appropriate for bosons and $\mathcal{H}_{L,B}^{(0)} = \mathbb{C}$.

Notice that in the thermodynamic limit $L \to \infty$ the canonical ensemble state $\omega_{\beta,\rho}^{\mathrm{can}}(\cdot)$ may not coincide with the equilibrium state of the grand canonical ensemble state $\omega_{\beta,\overline{\mu}(\beta,\rho)}^{\mathrm{g.c.}}(\cdot)$ for the corresponding particle density ρ. Here $\overline{\mu}(\beta,\rho) = \lim_{L\to\infty} \overline{\mu}_L(\beta,\rho)$ and $\overline{\mu}_L(\beta,\rho)$ is a solution of the grand canonical particle density equation (see also (3.22))

$$\rho = \omega_{L,\beta,\overline{\mu}_L(\beta,\rho)}^{\mathrm{g.c.}}(N_L/V). \tag{3.5}$$

By virtue of (3.4) the states (3.2) and (3.3) are related by

$$\omega_{L,\beta,\mu}^{\mathrm{g.c.}}(A) = \int_{\mathbb{R}_+} K_{L,\beta,\mu}^{\mathrm{g.c.}}(d\xi)\ \omega_{L,\beta,\xi}^{\mathrm{can}}(A^{([V\xi])}), \tag{3.6}$$

where $A^{(n)} = A \lceil \mathcal{H}_{L,B}^{(n)}$ is a restriction of the operator A on the subspace $\mathcal{H}_{L,B}^{(n)}$ and

$$K_{L,\beta,\mu}^{\mathrm{g.c.}}(\xi) = \frac{\sum_{n=0}^{[V\xi]} \exp(n\beta\mu) \mathrm{Tr}_{\mathcal{H}_{L,B}^{(n)}} \exp(-\beta T_L^{(n)})}{\mathrm{Tr}_{\mathcal{F}_{L,B}} \exp\{-\beta(T_L - \mu N_L)\}}. \tag{3.7}$$

For a given grand canonical density (3.5), the measure (3.7) takes the form

$$K_{L,\beta,\rho}(d\xi) := K^{\text{g.c.}}_{L,\beta,\bar{\mu}_L(\beta,\rho)}(d\xi) = d\xi\, K_{L,\beta}(\xi;\rho), \tag{3.8}$$

and the limit $K_\beta(x;\rho) = \lim_{L\to\infty} K_{L,\beta}(x;\rho)$ is known as the *Kac density*, see, e.g., Ref. 7. If the Kac density happens to be a δ-function with support at ρ, then clearly one has (*strong*) equivalence of ensembles:

$$\omega^{\text{g.c.}}_{\beta,\bar{\mu}(\beta,\rho)}(A) = \omega^{\text{can}}_{\beta,\rho}(A). \tag{3.9}$$

Otherwise there is only *weak* equivalence of ensembles, see Ref. 3.

The limit $\rho_c(\beta) := \lim_{\mu\to-\nu\sigma^2} \lim_{L\to\infty} \omega^{\text{g.c.}}_{L,\beta,\mu}(N_L/V)$ is the critical density for the free Bose gas in a box with attractive boundary conditions. We shall show that in the model the canonical and the grand canonical ensembles are *not* equivalent in the *presence* of the Bose condensate, i.e., for $\rho > \rho_c(\beta)$, or for $\beta > \beta_c(\rho)$, where $\rho_c(\beta_c(\rho)) = \rho$. The nonequivalence of ensembles in the case of the free Bose gas with *attractive boundaries* is not the same phenomenon as in the case of the one with, for example Dirichlet, $\sigma = \infty$, or Neumann, $\sigma = 0$, boundary conditions. In the case of the attractive boundary conditions ($\sigma < 0$), the condensation phenomenon is a *surface effect* (not a bulk effect as in the free Bose gas with $\sigma = \infty$ or $\sigma = 0$): the condensate is located near the walls, see Sec. IV B.

To determine the Kac density, we have to calculate (see (3.6))

$$\begin{aligned}\omega^{\text{g.c.}}_{L,\beta,\bar{\mu}_L(\beta,\rho)}(W(f)) &= \int_{\mathbb{R}_+} K_{L,\beta,\rho}(d\xi)\ \omega^{\text{can}}_{L,\beta,\xi}(W(f)) \\ &= \int_{\mathbb{R}_+} d\xi\ K_{L,\beta}(\xi;\rho)\,\omega^{\text{can}}_{L,\beta,\xi}(W(f))\end{aligned} \tag{3.10}$$

for any test function $f \in C_0^\infty(\mathbb{R}^\nu)$, the C^∞-functions on $\mathbb{R}^\nu$ with compact support. Therefore we first must calculate the limit of the expectation value of the exponential function:

$$\omega^{\text{g.c.}}_{\beta,\rho}(W(f)) := \lim_{L\to\infty} \omega^{\text{g.c.}}_{L,\beta,\bar{\mu}_L(\beta,\rho)}(W(f)) \tag{3.11}$$

with $\{\bar{\mu}_L(\beta,\rho)\}_L$ solutions of the density equation (3.5).

This is possible because the states $\omega^{\text{g.c.}}_{L,\beta,\mu}$, where $\mu < -\nu\sigma^2$, are *quasifree states*, and these are easily obtained by using the *truncated functionals* $\omega_{L,\beta,\rho}(\cdots)_T$, see, e.g., Ref. 2. The functionals are defined by the recursion relations:

$$\omega^{\text{g.c.}}_{L,\beta,\mu}(A_1\cdots A_n) = \sum_{\tau\in P_n} \prod_{J\in\tau} \omega^{\text{g.c.}}_{L,\beta,\mu}(A_{j(1)},\ldots,A_{j(|J|)})_T \tag{3.12}$$

for all A_i ($i = 1,2$) creation or annihilation operators and $n \in \mathbb{N}$. The sum $\tau \in P_n$ is over all partitions τ of a set of n elements into ordered subsets $J = \{j(1),\ldots,j(|J|)\} \in \tau$. One can verify that the truncated functionals associated to the equilibrium states $\omega^{\text{g.c.}}_{L,\beta,\mu}$ satisfy

$$\begin{aligned}&\omega^{\text{g.c.}}_{L,\beta,\mu}(a^\sharp(f))_T = \omega^{\text{g.c.}}_{L,\beta,\mu}(a^\sharp(f)) = 0, \\ &\omega^{\text{g.c.}}_{L,\beta,\mu}(a^*(f_1),a^*(f_2))_T = \omega^{\text{g.c.}}_{L,\beta,\mu}(a(f_1),a(f_2))_T = 0, \\ &\omega^{\text{g.c.}}_{L,\beta,\mu}(a^*(f_1),a(f_2))_T = \left\langle f_2, \frac{1}{e^{\beta(t^\sigma_L-\mu)}-1} f_1 \right\rangle_{h_L},\end{aligned} \tag{3.13}$$

with $f, f_1, f_2, \ldots \in h_L$, the space of testfunctions with support in Λ_L^ν, $a^\sharp = \{a \text{ or } a^*\}$ and t_L^σ is the self-adjoint extension of the Laplacian $-\Delta_L$ corresponding to attractive boundary conditions $\sigma < 0$ on $\partial\Lambda_L^\nu$. Then the nontrivial two-point functions (3.13) are explicitly given by

$$\omega_{L,\beta,\mu}^{\text{g.c.}}(a^*(f_1), a(f_2))_T = \omega_{L,\beta,\mu}^{\text{g.c.}}(a^*(f_1)a(f_2)) = \sum_{\mathbf{k}\in\mathbb{Z}_+^\nu} \overline{\hat{f}_2(\mathbf{k})}\hat{f}_1(\mathbf{k}) \frac{1}{e^{\beta(E_L(\mathbf{k})-\mu)}-1}, \tag{3.14}$$

where the transformation $f(\mathbf{x}) \mapsto \hat{f}(\mathbf{k})$ of $f \in C_0^\infty(\mathbb{R}^\nu)$, is now defined by

$$\hat{f}(\mathbf{k}) := (\psi_{\mathbf{k}}^L, f)_{h_L} = \int_{\Lambda_L^\nu} d\mathbf{x}\, \overline{\psi_{\mathbf{k}}^L(\mathbf{x})} f(\mathbf{x}), \tag{3.15}$$

the Fourier transforms for the basis of t_L^σ (see Sec. III A). Now,

$$\omega_{L,\beta,\mu}^{\text{g.c.}}(W(f)) = \omega_{L,\beta,\mu}^{\text{g.c.}}(e^{i\Phi(f)}) = \exp \sum_{n=1}^{\infty} \frac{i^n}{n!} \omega_{L,\beta,\rho}(\underbrace{\Phi(f), \Phi(f), \ldots, \Phi(f)}_{\text{n times}})_T, \tag{3.16}$$

where the $\omega_{L,\beta,\mu}^{\text{g.c.}}(\Phi(f), \Phi(f), \ldots, \Phi(f))_T$ are the n-point truncated field correlation functions. Because of the fact that $\omega_{L,\beta,\mu}^{\text{g.c.}}$ is a quasifree state, only the two-point truncated correlation function is nonvanishing, yielding

$$\omega_{L,\beta,\mu}^{\text{g.c.}}(W(f)) = \exp(-\tfrac{1}{2}\omega_{L,\beta,\mu}^{\text{g.c.}}(\Phi(f), \Phi(f))_T). \tag{3.17}$$

By virtue of (2.3) and (2.4) it can be rewritten in terms of the creation and annihilation operators $a^*(f)$ and $a(f)$,

$$\omega_{L,\beta,\mu}^{\text{g.c.}}(\Phi(f), \Phi(f))_T = \tfrac{1}{2}(f,f)_{h_L} + \omega_{L,\beta,\mu}^{\text{g.c.}}(a^*(f)a(f)) \tag{3.18}$$

so that the explicit form of the generating functional (3.17) becomes

$$\omega_{\beta,\mu}^{\text{g.c.}}(W(f)) = \lim_{L\to\infty} \omega_{L,\beta,\mu}^{\text{g.c.}}(W(f)) = \exp(-\tfrac{1}{4}(f,f)_{h_L} - \tfrac{1}{2}\lim_{L\to\infty} \omega_{L,\beta,\mu}^{\text{g.c.}}(a^*(f)a(f))). \tag{3.19}$$

A last remark about the thermodynamic limit. Notice that the grand-canonical ensemble for the free Bose gas exists only for $\mu < \inf \operatorname{spec}(t_L^\sigma)$. Therefore, the solution of Eq. (3.5) verifies the inequality $\overline{\mu}_L(\beta,\rho) < -\nu\sigma^2$. Since the *critical density*,

$$\lim_{\mu\to -\nu\sigma^2} \lim_{L\to\infty} \omega_{L,\beta,\mu}^{\text{g.c.}}\left(\frac{N_L}{L^\nu}\right) = \rho_c(\beta) \tag{3.20}$$

for the free Bose gas with attractive boundary conditions $\sigma < 0$ is *finite* for all dimensions greater then, or equal to one,[5,10] Bose–Einstein condensation occurs for $\rho > \rho_c(\beta)$,

$$\rho_0(\beta) := \rho - \rho_c(\beta) = \lim_{L\to\infty} 2^\nu \omega_{L,\beta,\overline{\mu}_L(\beta,\rho)}^{\text{g.c.}}\left(\frac{N_{L,\mathbf{0}}}{L^\nu}\right) > 0, \tag{3.21}$$

where $N_{L,\mathbf{0}}$ is the number-operator on $\mathcal{F}_{L,B}$ of the zero mode $\mathbf{k} = \mathbf{0}$. The factor 2^ν is due to the asymptotic degeneracy of the $\inf \operatorname{spec}(t_L^\sigma) = -\nu\sigma^2 + O(e^{-L|\sigma|})$ for $L \to \infty$, see Sec. III A. Notice that (3.21) implies that the solution of (3.5) for $\rho > \rho_c(\beta)$ has the asymptotics,

$$\overline{\mu}_L(\beta,\rho) = -\nu\sigma^2 - \frac{2^\nu}{\beta(\rho-\rho_c(\beta))L^\nu} + o(L^{-\nu}). \tag{3.22}$$

We use this result in the computations of the thermodynamic limit of the generating functional below.

We conclude this section by the following statement about the explicit form of the Kac density for the thermodynamic limit of the free Bose gas in the *cubic* box with *attractive* boundary conditions.

Theorem 3.1: *For the free Bose gas T_L^σ with attractive boundary conditions $\sigma<0$ the limiting Kac density has the form*

$$K_\beta(\xi;\rho)=\begin{cases}\delta(\xi-\rho), & \text{for } \rho<\rho_c(\beta),\\ \dfrac{2^\nu\theta(\xi-\rho_c(\beta))}{(2^\nu-1)!(\rho-\rho_c(\beta))}\left[\dfrac{2^\nu(\xi-\rho_c(\beta))}{\rho-\rho_c(\beta)}\right]^{2^\nu-1}\exp\left\{-\dfrac{2^\nu(\xi-\rho_c(\beta))}{\rho-\rho_c(\beta)}\right\}, & \text{for } \rho\geqslant\rho_c(\beta).\end{cases} \tag{3.23}$$

Here $\theta(z\leqslant 0)=0$ and $\theta(z>0)=1$.

Proof: By the identity (3.10), the Kac density $K_\beta(\xi;\rho)$ is related to the thermodynamic limit of the characteristic function of the particle density N_L/V for $t\in\mathbb{R}^1$,

$$\begin{aligned}\lim_{L\to\infty}\omega^{\text{g.c.}}_{L,\beta,\overline{\mu}_L(\beta,\rho)}(\exp(itN_L/V))&=\int_{\mathbb{R}_+}K_{\beta,\rho}(d\xi)\ \omega^{\text{can}}_{\beta,\xi}(\exp(it\xi))\\ &=\int_{\mathbb{R}_+}d\xi\ K_\beta(\xi;\rho)\exp(it\xi).\end{aligned} \tag{3.24}$$

To calculate the limit in the left-hand side of (3.24), we use that the state $\omega^{\text{g.c.}}_{L,\beta,\overline{\mu}_L(\beta,\rho)}(\cdot)$ is quasifree. Then

$$\omega^{\text{g.c.}}_{L,\beta,\overline{\mu}_L(\beta,\rho)}(\exp(itN_L/V))=\prod_{\mathbf{k}\in\mathbb{Z}^\nu_+}\left\{\frac{1-\exp[-\beta(E_L(\mathbf{k})-\overline{\mu}_L(\beta,\rho))]}{1-\exp[-\beta(E_L(\mathbf{k})-\overline{\mu}_L(\beta,\rho)-it/\beta L^\nu)]}\right\}. \tag{3.25}$$

Since the 2^ν lowest energy-levels, i.e., the levels for which $\mathbf{k}\in\mathbb{K}_{\leqslant 2^\nu}=\{\mathbf{k}\in\mathbb{Z}^\nu_+ : k_i=0,1;\ i=1,\ldots,\nu\}$ are exponentially degenerated when $L\to\infty$: $E_L(\mathbf{k}\in\mathbb{K}_{\leqslant 2^\nu})=-\nu\sigma^2+O(e^{-L|\sigma|})$, by virtue of (3.22) and (3.25) we get that

$$\lim_{L\to\infty}\omega^{\text{g.c.}}_{L,\beta,\overline{\mu}_L(\beta,\rho)}(\exp(itN_L/V))=\begin{cases}\exp(it\rho), & \text{for } \rho<\rho_c(\beta),\\ [1-it2^{-\nu}(\rho-\rho_c(\beta))]^{-2^\nu}\exp(it\rho_c(\beta)), & \text{for } \rho\geqslant\rho_c(\beta).\end{cases} \tag{3.26}$$

Therefore, by (3.24), the Kac density (3.23) is the Fourier transformation of the right-hand side of (3.26).

IV. THE GENERATING FUNCTIONAL

A. Condensate and generating functional

We are interested in the thermodynamic limit of the generating functional $\omega^{\text{g.c.}}_{\beta,\rho}(W(f))=\lim_{L\to\infty}\omega^{\text{g.c.}}_{L,\beta,\overline{\mu}_L(\beta,\rho)}(W(f))$ for any $f\in C_0^\infty(\mathbb{R}^\nu)$. To this end we choose the box Λ_L^ν with L large enough such that the $\Lambda_f:=\text{supp}(f)$ is contained in Λ_L^ν. We consider here the generating functional $\omega^{\text{g.c.}}_{\beta,\rho}(W(f))$ for f an element in $C_0^\infty(\mathbb{R}^\nu)$.

Theorem 4.1: *The generating functional $\omega^{\text{g.c.}}_{\beta,\rho}(W(f))$ on $C_0^\infty(\mathbb{R}^\nu)$ is given by*

$$\omega^{\text{g.c.}}_{\beta,\rho}(W(f))=\exp(-\tfrac{1}{4}(f,f))\exp(-\tfrac{1}{2}(f,g_\sigma(\beta,\rho)f)), \tag{4.1}$$

with operator $g_\sigma(\beta,\rho)$ on $\mathcal{L}^2(\mathbb{R}^\nu)$ defined by

$$(g_\sigma(\beta,\rho)f)(\mathbf{x})=\int_{\mathbb{R}^\nu} d\mathbf{y} G_\sigma(\beta,\rho)(\|\mathbf{x}-\mathbf{y}\|)f(\mathbf{y}),$$

$$G_\sigma(\beta,\rho)(r)=(4\pi\beta)^{-\nu/2}\sum_{n=1}^{\infty} \mathrm{e}^{-r^2/4n\beta}\frac{\mathrm{e}^{-n\beta\overline{\mu}(\beta,\rho)}}{n^{\nu/2}}, \tag{4.2}$$

where $\overline{\mu}(\beta,\rho)<-\nu\sigma^2$ *for* $\rho<\rho_c(\beta)$ *and* $\overline{\mu}(\beta,\rho)=-\nu\sigma^2$ *for* $\rho\geqslant\rho_c(\beta)$ *are limiting solutions of the grand canonical density equation (3.5).*

Proof: In order to determine the generating functional $\omega^{\mathrm{g.c.}}_{\beta,\rho}(W(f))$, we have to compute $\lim_{L\to\infty}\omega^{\mathrm{g.c.}}_{L,\beta,\overline{\mu}_L(\beta,\rho)}(a^*(f)a(f))$, see (3.19). Since the attractive boundary conditions $\sigma<0$ create a gap in the spectrum $\mathrm{spect}(t_L^\sigma)$, and, respectively, in $\mathrm{spect}(T_L^\sigma)$, the calculations need a separation of the negative eigenvalues from the positive part of the spectrum.

We consider first the one-dimensional case, when there are only two negative eigenvalues tending to $-\sigma^2$ for $L\to\infty$, see Sec. III A. By virtue of (3.14) one gets for a given $f\in C_0^\infty(\mathbb{R}^1)$ that

$$\begin{aligned}\lim_{L\to\infty}\omega^{\mathrm{g.c.}}_{L,\beta,\overline{\mu}_L(\beta,\rho)}(a^*(f)a(f))&=\lim_{L\to\infty}\sum_{k\in\mathbb{Z}^1_+}|\hat{f}(k)|^2\frac{1}{\mathrm{e}^{\beta(\epsilon_L(k)-\overline{\mu}_L(\beta,\rho))}-1}\\&=\lim_{L\to\infty}\Bigg(|\hat{f}(0)|^2\frac{1}{\mathrm{e}^{\beta(\epsilon_L(0)-\overline{\mu}_L(\beta,\rho))}-1}+|\hat{f}(1)|^2\frac{1}{\mathrm{e}^{\beta(\epsilon_L(1)-\overline{\mu}_L(\beta,\rho))}-1}\\&\quad+\sum_{n=1}^{\infty}\mathrm{e}^{n\beta\overline{\mu}_L(\beta,\rho)}\sum_{k=2}^{\infty}\mathrm{e}^{-n\beta\epsilon_L(k)}|\hat{f}(k)|^2\Bigg).\end{aligned} \tag{4.3}$$

As mentioned before, we choose Λ_L large enough such that $\mathrm{supp}(f)=\Lambda_f$ is contained in Λ_L. Then one estimates that $|\hat{f}(0)|^2$ has an asymptotics of the order of $O(e^{-L|\sigma|})$ for large L since

$$\begin{aligned}|\hat{f}(0)|^2&=\left|\int_{\Lambda_f}dx f(x)\overline{\phi_0^L(x)}\right|^2\\&=\frac{2}{L}\left(1+\frac{\sinh(L|\sigma|)}{L|\sigma|}\right)^{-1}\left|\int_{\Lambda_f}dx f(x)\cosh(-|\sigma|x)\right|^2\\&=4|\sigma|e^{-L|\sigma|}\left|\int_{\Lambda_f}dx f(x)\cosh(-|\sigma|x)\right|^2+o(e^{-L|\sigma|}).\end{aligned} \tag{4.4}$$

The integral in the last expression is independent of L, because $\mathrm{supp}(f)$ is finite and inside the box Λ_L. Similarly one gets for $L\to\infty$ that

$$|\hat{f}(1)|^2=4|\sigma|e^{-L|\sigma|}\left|\int_{\Lambda_f}dx f(x)\sinh(-|\sigma|x)\right|^2+o(e^{-L|\sigma|}). \tag{4.5}$$

Consider now the coefficients of $|\hat{f}_L(0)|^2$ and of $|\hat{f}_L(1)|^2$ in (4.3). If $\rho<\rho_c(\beta)$, then $\overline{\mu}(\beta,\rho)<-\sigma^2$, i.e., $\epsilon_L(0)-\overline{\mu}_L(\beta,\rho)>0$ for large L. Therefore, by virtue of (4.3), (4.4), and (4.5), both of those terms are of the order $O(e^{-L|\sigma|})$ for large L. If $\rho\geqslant\rho_c(\beta)$, then $\overline{\mu}_L(\beta,\rho)=-\sigma^2+O(L^{-1})$, and one gets for large L,

$$\left\{|\hat{f}(0)|^2\frac{1}{\mathrm{e}^{\beta(\epsilon_L(0)-\overline{\mu}_L(\beta,\rho))}-1}+|\hat{f}(1)|^2\frac{1}{\mathrm{e}^{\beta(\epsilon_L(1)-\mu_L(\beta,\rho))}-1}\right\}\simeq\tfrac{1}{2}\rho_0(\beta)L\{|\hat{f}(0)|^2+|\hat{f}(1)|^2\}, \tag{4.6}$$

where $\rho_0(\beta)=\rho-\rho_c(\beta)$ is the condensate density. Therefore, again by virtue of (4.4) and (4.5), these terms vanish in the limit $L\to\infty$.

Consider now the last term in the limit (4.3). By virtue of (3.15) for $\nu=1$ (see Sec. III A) we can represent the sum over $k\geqslant 2$ in the following explicit form:

$$\frac{2}{L}\sum_{\{k\geqslant 2:\ \text{even}\}}\left(1+\frac{\sin(\sqrt{\epsilon_L(k)}L)}{\sqrt{\epsilon_L(k)}L}\right)^{-1}\overline{\hat{F}_{L\ \text{even}}(k)}\hat{F}_{L\ \text{even}}(k)\mathrm{e}^{-s\epsilon_L(k)}$$
$$+\frac{2}{L}\sum_{\{k\geqslant 2:\ \text{odd}\}}\left(1-\frac{\sin(\sqrt{\epsilon_L(k)}L)}{\sqrt{\epsilon_L(k)}L}\right)^{-1}\overline{\hat{F}_{L\ \text{odd}}(k)}\hat{F}_{L\ \text{odd}}(k)\mathrm{e}^{-s\epsilon_L(k)}, \tag{4.7}$$

where $s=n\beta$ and

$$\hat{F}_{L\ \text{even}}(k):=\int_{\Lambda_f}dx\cos(\sqrt{\epsilon_L(k)}x)f(x),\ \hat{F}_{L\ \text{odd}}(k):=\int_{\Lambda_f}dx\sin(\sqrt{\epsilon_L(k)}x)f(x). \tag{4.8}$$

Since the spectrum $\{\epsilon_L(k)\}_{k\geqslant 2}$ verifies the conditions (3.1) and $f\in C_0^\infty(\mathbb{R}^1)$, the first and the second series of terms in (4.7) are Darboux–Riemann sums for the corresponding integrals:

$$\lim_{L\to\infty}\left\{\frac{2}{L}\sum_{\{k\geqslant 2:\ \text{even}\}}\left(1+\frac{\sin(\sqrt{\epsilon_L(k)}L)}{\sqrt{\epsilon_L(k)}L}\right)^{-1}\overline{\hat{F}_{L\ \text{even}}(k)}\,\hat{F}_{L\ \text{even}}(k)\mathrm{e}^{-s\epsilon_L(k)}\right.$$
$$\left.+\frac{2}{L}\sum_{\{k\geqslant 2:\ \text{odd}\}}\left(1-\frac{\sin(\sqrt{\epsilon_L(k)}L)}{\sqrt{\epsilon_L(k)}L}\right)^{-1}\overline{\hat{F}_{L\ \text{odd}}(k)}\,\hat{F}_{L\ \text{odd}}(k)\mathrm{e}^{-s\epsilon_L(k)}\right\}$$
$$=\frac{1}{\pi}\int_0^\infty dk\,\overline{\mathrm{Re}(\mathrm{e}^{ik\cdot},f)_{h_L}}\,\mathrm{Re}(\mathrm{e}^{ik\cdot},f)_{h_L}\mathrm{e}^{-sk^2}+\frac{1}{\pi}\int_0^\infty dk\,\overline{\mathrm{Im}(\mathrm{e}^{ik\cdot},f)_{h_L}}\,\mathrm{Im}(\mathrm{e}^{ik\cdot},f)_{h_L}\mathrm{e}^{-sk^2}. \tag{4.9}$$

The last expression of (4.9) yields

$$\frac{1}{2\pi}\int_{-\infty}^\infty dk\,\overline{(\mathrm{e}^{ik\cdot},f)_{h_L}}\,(\mathrm{e}^{ik\cdot},f)_{h_L}\mathrm{e}^{-sk^2}=(4\pi s)^{-1/2}\int_{\mathbb{R}^1}dx\int_{\mathbb{R}^1}dy\,\overline{f(x)}f(y)\exp\left\{-\frac{|x-y|^2}{4s}\right\}. \tag{4.10}$$

Finally, taking into account (4.4)–(4.6), (4.10), and the fact that $\overline{\mu}(\beta,\rho)\leqslant-\sigma^2<0$, we get for the limit (4.3) in the one-dimensional case:

$$\omega^{\mathrm{g.c.}}_{\beta,\rho}(a^*(f)a(f))=(f,g_{\sigma,\nu=1}(\beta,\rho)f)_{h_L}, \tag{4.11}$$

where $g_{\sigma,\nu=1}(\beta,\rho)$ is the integral operator on $\mathcal{L}^2(\mathbb{R}^1)$ defined by

$$(g_{\sigma,\nu=1}(\beta,\rho)f)(x)=\int_{\mathbb{R}^1}dy\ \ G_{\sigma,\nu=1}(\beta,\rho)(|x-y|)f(y)\ ,$$

$$G_{\sigma,\nu=1}(\beta,\rho)(r)=(4\pi\beta)^{-1/2}\sum_{n=1}^\infty\mathrm{e}^{-r^2/4n\beta}\frac{\mathrm{e}^{-n\beta\overline{\mu}(\beta,\rho)}}{n^{1/2}}\ .$$

Using the results for the one-dimensional case, one computes the two-point correlation function $\omega^{\mathrm{g.c.}}_{\beta,\rho}(a^*(f)a(f))$ in the ν-dimensional case. Since the first 2^ν wave functions $\{\psi^L_{\mathbf{k}}(\mathbf{x})\}_{\mathbf{k}\in\mathbb{Z}^\nu_+}$ have the same exponential behavior as in the one-dimensional case and since $\inf_L\mathrm{spect}(t^\sigma_L)=-\nu\sigma^2$, see Sec. III A, we get

$$\lim_{L\to\infty}\omega^{\mathrm{g.c.}}_{L,\beta,\bar{\mu}(\beta,\rho)}(a^*(f)a(f))=\lim_{L\to\infty}\sum_{\mathbf{k}\in\mathbb{Z}^\nu_+}|\hat{f}(\mathbf{k})|^2\frac{1}{\mathrm{e}^{\beta(E_L(\mathbf{k})-\mu_L(\beta,\rho))}-1}$$

$$=\sum_{n=1}^{\infty}\mathrm{e}^{-n\beta\nu\bar{\mu}(\beta,\rho)}(4\pi n\beta)^{-\nu/2}\int_{\mathbb{R}^\nu}d\mathbf{x}\int_{\mathbb{R}^\nu}d\mathbf{y}\overline{f(\mathbf{x})}f(\mathbf{y})$$

$$\times\exp\left\{-\frac{\|\mathbf{x}-\mathbf{y}\|^2}{4n\beta}\right\},$$

which implies (4.2). By virtue of (3.19) this finishes the proof of (4.1) and of the theorem for any particle density ρ.

Theorem 4.1 tells us that the condensate is not traceable by considering only strictly local observables. The characteristic functional on the CCR-C*-algebra of quasilocal observables coincides with the one without condensate. The reason for this is that the condensate is not homogeneous but located in the vicinity of the container boundary.

In order to catch up the presence of the condensate or to get a complete picture of the system, one has to extend the algebra of observables to the weak closure of the CCR-C*-algebra with respect to the limit Gibbs states. In the next paragraph we compute the limit functional on the relevant nonlocalized observables, and obtain a complete picture yielding the existence of sufficiently many fields in the representation of any w^*-limit point of Gibbs states as L tends to infinity. In fact our strategy will be to make a relevant choice of the *homothety point* for the thermodynamic limit of convex containers, in order to catch up the condensate.

Above and below we considered only the easy shape container limit, namely cubic boxes. Because of the particular inhomogeneous spreading of the condensate in the neighborhood of the box boundary, it is clear that this thermodynamic limit treatment can be very much shape dependent. In this paper we do not enter into the details of this specific problem.

B. Condensate localization

Remark 4.2: It sounds curious that in spite of the nonzero condensate density for $\rho>\rho_c(\beta)$, *(3.21), there is no trace of it in the generating functional (4.1). This is in contrast to the Kac density (3.23), which explicitly depends on the condensate density* $\rho-\rho_c(\beta)$. *To understand this difference one has to take into account that (4.1) is localized on the support of the function* $f\in C_0^\infty(\mathbb{R}^\nu)$, *whereas the Kac density is a global function, depending on the condensate even if it is localized at "infinity," sticked to the attractive boundaries.*

In order to make this statement rigorous we start first with the one-dimensional case. Let the function $f\in C_0^\infty(\mathbb{R}^1)$ be such that $\mathrm{supp}(f)=(-\delta,\delta)\subset(-L/2,L/2)$ and $\delta<(\ln L)/2|\sigma|$. Consider its shift over a distance $\gamma_L(\sigma):=L/2-(2|\sigma|)^{-1}\ln L$:

$$f_{\tau_{\gamma_L(\sigma)}}(x)\equiv(\tau_{\gamma_L(\sigma)}f)(x):=f(x-[L/2-(2|\sigma|)^{-1}\ln L]). \tag{4.12}$$

Then $f_{\tau_{\gamma_L(\sigma)}}\in C_0^\infty(-L/2,L/2)$.

To get the generating functional we compute now the limit of the corresponding two-point function (3.19):

$$\lim_{L\to\infty}\omega^{\mathrm{g.c.}}_{L,\beta,\overline{\mu}_L(\beta,\rho)}(a^*(\tau_{\gamma_L(\sigma)}f)a(\tau_{\gamma_L(\sigma)}f))$$

$$=\lim_{L\to\infty}\sum_{k=0}^{\infty}|\hat{f}_{\tau_{\gamma_L(\sigma)}}(k)|^2\frac{1}{e^{\beta(\epsilon_L(k)-\mu_L(\beta,\rho))}-1}$$

$$=\lim_{L\to\infty}\left(|\hat{f}_{\tau_{\gamma_L(\sigma)}}(0)|^2\frac{1}{e^{\beta(\epsilon_L(0)-\overline{\mu}_L(\beta,\rho))}-1}+|\hat{f}_{\tau_{\gamma_L(\sigma)}}(1)|^2\frac{1}{e^{\beta(\epsilon_L(1)-\overline{\mu}_L(\beta,\rho))}-1}\right.$$

$$\left.+\sum_{k=2}^{\infty}|\hat{f}_{\tau_{[\gamma_L(\sigma)]}}(k)|^2\frac{1}{e^{\beta(\epsilon_L(k)-\mu_L(\beta,\rho))}-1}\right). \tag{4.13}$$

Remark 4.3: Notice that in contrast to (4.3), the shift (4.12) corresponds simply to the choice of a new point of homothety for the thermodynamic limit (4.13). In (4.3), the point of homothety coincides with the origin of coordinates $x=0$, whereas in (4.13) this point is $L/2-(2|\sigma|)^{-1}\ln L$.

Now, and in contrast to (4.4), $|\hat{f}_{\tau_{\gamma_L(\sigma)}}(0)|^2$ goes like L^{-1} for large L. Indeed,

$$|\hat{f}_{\tau_{\gamma_L(\sigma)}}(0)|^2=\left|\int_{\gamma_L(\sigma)-\delta}^{\gamma_L(\sigma)+\delta}dx(\tau_{\gamma_L(\sigma)}f)(x)\phi_0^L(x)\right|^2=|\sigma|L^{-1}\left|\int_{-\delta}^{\delta}dxf(x)e^{|\sigma|x}\right|^2+o(L^{-1}).$$

Remark that for $\rho>\rho_c(\beta)$ the first term in (4.13) remains now *finite* in the limit $L\to\infty$. Taking into account (3.21) and (3.22) one gets

$$\lim_{L\to\infty}|\hat{f}_{\tau_{\gamma_L(\sigma)}}(0)|^2\frac{1}{e^{\beta(\epsilon_L(0)-\overline{\mu}_L(\beta,\rho))}-1}=\frac{\rho_0(\beta,\rho)}{2}|\sigma|\left|\int_{-\delta}^{\delta}dxf(x)e^{|\sigma|x}\right|^2. \tag{4.14}$$

The same reasoning for the second term in formula (4.13) gives a similar result:

$$\lim_{L\to\infty}|\hat{f}_{\tau_{\gamma_L(\sigma)}}(1)|^2\frac{1}{e^{\beta(\epsilon_L(1)-\overline{\mu}_L(\beta,\rho))}-1}=\frac{\rho_0(\beta,\rho)}{2}|\sigma|\left|\int_{-\delta}^{\delta}dxf(x)e^{|\sigma|x}\right|^2. \tag{4.15}$$

By the same computations as used in the proof of Theorem 4.1, the third term in (4.13) yields for $\rho>\rho_c(\beta)$:

$$\lim_{L\to\infty}\sum_{k=2}^{\infty}|\hat{f}_{\tau_{\gamma_L(\sigma)}}(k)|^2\frac{1}{e^{\beta(\epsilon_L(k)-\overline{\mu}_L(\beta,\rho))}-1}$$

$$=\sum_{n=1}^{\infty}e^{-n\beta\sigma^2}(4\pi n\beta)^{-1/2}\int_{\mathbb{R}^1}dx\int_{\mathbb{R}^1}dyf(x)\overline{f(y)}\exp\left\{-\frac{|x-y|^2}{4n\beta}\right\}. \tag{4.16}$$

Hence the two-point function for the one-dimensional problem becomes

$$\lim_{L\to\infty}\omega^{\mathrm{g.c.}}_{L,\beta,\overline{\mu}_L(\beta,\rho)}(a^*(\tau_{\gamma_L(\sigma)}f)a(\tau_{\gamma_L(\sigma)}f))$$

$$=\rho_0(\beta,\rho)|\sigma|\left|\int_{\mathbb{R}^1}dxf(x)e^{|\sigma|x}\right|^2+(f,g_{\sigma,\nu=1}(\beta,\rho)f), \tag{4.17}$$

see (4.11) for the definition of the operator $g_{\sigma,\nu=1}(\beta,\rho)$.

It is evident that one gets the same result for the shift of $\mathrm{supp}(f)=(-\delta,\delta)$ over a distance $-\gamma_L(\sigma)=-L/2+(2|\sigma|)^{-1}\ln L$, i.e.,

$$\lim_{L\to\infty} \omega^{\text{g.c.}}_{L,\beta,\overline{\mu}_L(\beta,\rho)}(a^*(\tau_{\pm\gamma_L(\sigma)}f)a(\tau_{\pm\gamma_L(\sigma)}f))$$

$$=\rho_0(\beta,\rho)|\sigma|\left|\int_{\mathbb{R}^1} dx f(x)\mathrm{e}^{\pm|\sigma|x}\right|^2+(f,g_{\sigma,\nu=1}(\beta,\rho)f), \tag{4.18}$$

where

$$(\tau_{\pm\gamma_L(\sigma)}f)(x):=f(x\mp[L/2-(2|\sigma|)^{-1}\ln L]). \tag{4.19}$$

Therefore, taking the thermodynamic limit $L\to\infty$ at one of the homothety points $\pm\gamma_L(\sigma)$, we get that the generating functional depends on the Bose-condensate density for $\rho\geqslant\rho_c(\beta)$:

$$\lim_{L\to\infty} \omega^{\text{g.c.}}_{L,\beta,\overline{\mu}_L(\beta,\rho)}(W(\tau_{\pm\gamma_L(\sigma)}f))=\exp(-\tfrac{1}{4}(f,f))\exp(-\tfrac{1}{2}C^{\pm}_{\sigma,\nu=1}(f)-\tfrac{1}{2}(f,g_{\sigma,\nu=1}f)), \tag{4.20}$$

where, by virtue of (4.18), one has

$$C^{\pm}_{\sigma,\nu=1}(f)=\rho_0(\beta,\rho)|\sigma|\left|\int_{\mathbb{R}^1} dx f(x)\mathrm{e}^{\pm|\sigma|x}\right|^2. \tag{4.21}$$

Remark 4.4: Notice that this result is due to a fine (logarithmic) tuning of the position of the homothety points $\pm\gamma_L(\sigma)$. *Indeed, take* $\pm\gamma_L(a\sigma)$, *for* $0<a<1$, *i.e., the homothety points are more distant from the boundary* $\pm L/2$. *Taking into account the explicit form of the eigenfunctions for* $k=0,1$ *one finds that now* $|\hat{f}_{\tau_{\pm\gamma_L(a\sigma)}}(k=0,1)|^2$ *goes for large* L *like* $L^{-1/a}$. *This implies that both limits (4.14) and (4.15), and hence (4.21), vanish. So, the generating functional (4.20) has the same form as for thermodynamic limit with the homothety point at the origin. In contrast to that, the choice* $1<a$ *means that the homothety points are closer to the boundaries* $\pm L/2$. *Then* $|\hat{f}_{\tau_{\pm\gamma_L(a\sigma)}}(k=0,1)|^2$ *goes slower then* L^{-1}. *This implies that both limits (4.14) and (4.15), and hence (4.21), becomes infinite. So, for* $\rho\geqslant\rho_c(\beta)$ *the generating functional (4.20) is zero, whereas for* $\rho<\rho_c(\beta)$ *it is nontrivial with* $C^{\pm}_{\sigma,\nu=1}(f)=0$.

To interpret these results, consider the *local* particle density:

$$\omega^{\text{g.c.}}_{L,\beta,\overline{\mu}_L(\beta,\rho)}(a^*(x)a(x))=\sum_{k\in\mathbb{Z}^{\nu=1}_+}\frac{|\phi^L_k(x)|^2}{\mathrm{e}^{\beta(\epsilon_L(k)-\overline{\mu}_L(\beta,\rho))}-1}. \tag{4.22}$$

Here $a(x)$ is the Bose-field operator such that $a(f)=\int_{\mathbb{R}^{\nu=1}}dx\overline{f(x)}a(x)$ for $f\in C^\infty_0(\Lambda^{\nu=1}_L)$ and $N(x)=a^*(x)a(x)$ is the local number operator, cf. (3.14). Then by (3.5) and (3.14), the global density is

$$\omega^{\text{g.c.}}_{L,\beta,\overline{\mu}_L(\beta,\rho)}\left(\frac{N_L}{L}\right)=\frac{1}{L}\int_{\Lambda^{\nu=1}_L} dx\,\omega^{\text{g.c.}}_{L,\beta,\overline{\mu}_L(\beta,\rho)}(a^*(x)a(x)). \tag{4.23}$$

Consider the thermodynamic limit of the *local* particle density at the *origin* of the coordinates $x=0$. Taking into account the explicit form of the eigenfunctions, one gets that

$$\rho(\beta,\rho;x=0):=\lim_{L\to\infty}\omega^{\text{g.c.}}_{L,\beta,\overline{\mu}_L(\beta,\rho)}(a^*(x=0)a(x=0))=\frac{1}{\pi}\int_{\mathbb{R}^1_+} dk\frac{1}{\mathrm{e}^{\beta(k^2-\overline{\mu}(\beta,\rho))}-1} \tag{4.24}$$

for $\rho<\rho_c(\beta)$, and

$$\rho(\beta,\rho;x=0)=\lim_{L\to\infty}\omega^{\text{g.c.}}_{L,\beta,\bar{\mu}_L(\beta,\rho)}(a^*(x=0)a(x=0))$$

$$=\frac{1}{\pi}\int_{\mathbb{R}^1_+}dk\,\frac{1}{e^{\beta(k^2+\sigma^2)}-1}=\rho_c(\beta) \tag{4.25}$$

for $\rho\geqslant\rho_c(\beta)$ by (3.22). By inspection of (4.24) and (4.25) based on the explicit formulas for the eigenfunctions one readily gets that

$$\rho(\beta,\rho;x)=\rho(\beta,\rho;x=0) \tag{4.26}$$

for any x in a *bounded* domain D, containing the origin of the coordinates $x=0$. In particular we get that the limiting *local* density for $x\in D$ corresponding to the first two modes ($k=0,1$) is

$$\rho_0(\beta,\rho;x):=\lim_{L\to\infty}\sum_{k=0,1}\frac{|\phi^L_k(x=0)|^2}{e^{\beta(\epsilon_L(k)-\bar{\mu}_L(\beta,\rho))}-1}=0. \tag{4.27}$$

On the other hand, the *global* Bose–Einstein condensation density (3.21) is also related exactly to these two modes:

$$\rho_0(\beta,\rho)=\lim_{L\to\infty}\frac{1}{L}\sum_{k=0,1}\frac{1}{e^{\beta(\epsilon_L(k)-\bar{\mu}_L(\beta,\rho))}-1}=\rho-\rho_c(\beta)>0, \tag{4.28}$$

which is not present in (4.25).

Consider now the local density of the Bose–Einstein condensation (4.27) at the homothety points $\pm\gamma_L(\sigma)$. Then taking into account the explicit form of the eigenfunctions $\phi^L_{k=0,1}(x)$ and (3.22), we get that, in contrast to (4.27), the *local condensate* density is

$$\lim_{L\to\infty}\sum_{k=0,1}\frac{|\phi^L_k(x=\pm\gamma_L(\sigma))|^2}{e^{\beta(\epsilon_L(k)-\mu_L(\beta,\rho))}-1}=\rho_0(\beta,\rho)|\sigma|. \tag{4.29}$$

The same arguments as above show that this condensate local density varies from *zero* to *infinity* when the parameter a in the homothety point positions $\pm\gamma_L(a\sigma)$ varies in the same interval.

Remark 4.5: These observations can be interpreted as follows: the Bose–Einstein condensate for attractive boundary conditions $\sigma<0$ is localized in a logarithmically narrow domain in the vicinity of the boundary. In other words this kind of condensation is a surface phenomenon. At the same time globally it is very "visible," since the Kac density indicates a nonequivalence of ensembles in the presence of the condensate, see Theorem 3.1.

For the generalization to the ν-dimensional case, we start with the corresponding *local condensate* density:

$$\rho_0(\beta,\rho;\mathbf{x}):=\lim_{L\to\infty}\sum_{\mathbf{k}\in\{\mathbb{Z}^\nu_+\,:\,k_\alpha=0,1\,;\,\alpha=1,\ldots,\nu\}}\frac{|\psi^L_{\mathbf{k}}(\mathbf{x})|^2}{e^{\beta(E_L(\mathbf{k})-\bar{\mu}_L(\beta,\rho))}-1}. \tag{4.30}$$

Let $\mathbf{x}$ belong to a bounded domain D^ν, containing the origin of the coordinates $\mathbf{x}=\mathbf{0}$. Then using the explicit expressions for the eigenfunctions $\psi^L_{\mathbf{k}}(\mathbf{x})$, see Sec. III.A, and by the same arguments as above for $\nu=1$, we obtain that the limit (4.30) is *zero* for all densities $\rho>0$.

The *product* structure: $\psi^L_{\mathbf{k}}(\mathbf{x})=\Pi^\nu_{i=1}\phi^L_{k_i}(x_i)$, implies that this conclusion does not change if we consider instead of $\mathbf{x}\in D^\nu$, the condensate density in the vicinity of the points corresponding to the shifts where at *least one* among the ν arguments remains *unshifted*.

On the other hand, this structure and the asymptotics of $\phi^L_{k=0,1}(x)$ for $|x|\to\infty$ yields also that for any $\mathbf{k}\in\{\mathbb{Z}^\nu_+:k_\alpha=0,1\,;\,\alpha=1,\ldots,\nu\}$ one gets

$$\left(\prod_{\alpha=1}^{\nu}\tau_{\pm\gamma_L(a_\alpha\sigma)}\psi_{\mathbf{k}}^L\right)(\mathbf{x}=0)=|\sigma|^{\nu/2}L^{-(1/2)(a_1^{-1}+a_2^{-1}+\cdots+a_\nu^{-1})}+o(L^{-(1/2)(a_1^{-1}+a_2^{-1}+\cdots+a_\nu^{-1})}) \tag{4.31}$$

as $L\to\infty$. Then, by virtue of (3.22), the limit for the local condensate density becomes *nontrivial:*

$$\lim_{L\to\infty}\sum_{\mathbf{k}\in\{\mathbb{Z}_+^\nu:k_\alpha=0,1;\ \alpha=1,\ldots,\nu\}}\frac{\left|\left(\prod_{\alpha=1}^{\nu}\tau_{\pm\gamma_L(a_\alpha\sigma)}\psi_{\mathbf{k}}^L\right)(\mathbf{x}=0)\right|^2}{e^{\beta(E_L(\mathbf{k})-\mu_L(\beta,\rho))}-1}=|\sigma|^\nu(\rho-\rho_c(\beta))>0, \tag{4.32}$$

if and only if

$$a_1^{-1}+a_2^{-1}+\cdots+a_\nu^{-1}=\nu. \tag{4.33}$$

This means that the condensate (up to logarithmic deviations) is localized essentially in the *corners* of the hypercube Λ_L^ν, where $L\to\infty$. We proved the following statement:

Theorem 4.6: *Let* $\mathbf{x}$ *be in a bounded domain* D^ν*, containing the origin of the coordinates* $\mathbf{x}=\mathbf{0}$*, then the thermodynamic limit of the local particle density is*

$$\rho(\beta,\rho;\mathbf{x}):=\lim_{L\to\infty}\sum_{\mathbf{k}\in\mathbb{Z}_+^\nu}\frac{|\psi_{\mathbf{k}}^L(\mathbf{x})|^2}{e^{\beta(E_L(\mathbf{k})-\mu_L(\beta,\rho))}-1}=\frac{1}{\pi^\nu}\int_{\mathbb{R}_+^\nu}d\mathbf{k}\frac{1}{e^{\beta(\mathbf{k}^2-\overline{\mu}(\beta,\rho))}-1}, \tag{4.34}$$

where $\overline{\mu}(\beta,\rho)<-\nu\sigma^2$ *for* $\rho<\rho_c(\beta)$ *and* $\overline{\mu}(\beta,\rho)=-\nu\sigma^2$ *for* $\rho\geqslant\rho_c(\beta)$*. Thus* $\rho(\beta,\rho;\mathbf{x})=\rho_c(\beta)$ *for* $\rho\geqslant\rho_c(\beta)$*, i.e., the local condensate density* $\rho_0(\beta,\rho;\mathbf{x})=0$ *for any* $\rho>0$*. Whereas at the homothety points corresponding to the shifts* $\Pi_{\alpha=1}^\nu\tau_{\pm\gamma_L(a_\alpha\sigma)}$ *with parameters satisfying (4.33), the local condensate density (4.32) is nontrivial. Moreover, besides being inhomogeneous it is also anisotropic and essentially localized in the directions of the corners of the hypercube* $\Lambda_{L\to\infty}^\nu$*. Varying the parameters* $\{a_\alpha\}_{\alpha=1}^\nu$ *in the range* $(0,+\infty)$ *one finds this local condensate density varying from zero to infinity.*

Now we extend Theorem 4.1 on the basis of our discussion above of the condensate localization and Theorem 4.6. Similar to the one-dimensional case, see Remark 4.4, our relevant localized observable in the ν-dimensional case will be a function $f\in\mathcal{C}_0^\infty(\mathbb{R}^\nu)$ such that $\mathrm{supp}(f)=(-\delta_1,\delta_1)\times(-\delta_2,\delta_2)\times\cdots\times(-\delta_\nu,\delta_\nu)\subset\Lambda_L^\nu$ and with $\delta=\max_{i=1,\ldots,\nu}\delta_i$ such that $\delta<(\ln L)/2|\sigma|$. Consider in each coordinate the shift over a distance $\gamma_L(\sigma)=L/2-(2|\sigma|)^{-1}\ln L$:

$$\left(\prod_{\alpha=1}^{\nu}\tau_{\gamma_L(\sigma)}f\right)(\mathbf{x})=f(x_1-(L/2-(2|\sigma|)^{-1}\ln L),\ldots,x_\nu-(L/2-(2|\sigma|)^{-1}\ln L)),$$

then $\Pi_{\alpha=1}^\nu\tau_{\gamma_L(\sigma)}f\in\mathcal{C}_0^\infty(\Lambda_L^\nu)$.

To get the generating functional in the ν-dimensional case, we compute the limit of the corresponding two-point correlation function:

$$\lim_{L\to\infty}\omega^{\text{g. c.}}_{L,\beta,\bar{\mu}_L(\beta,\rho)}\left(a^*\left(\prod_{\alpha=1}^{\nu}\tau_{\gamma_L(\sigma)}f\right)a\left(\prod_{\alpha=1}^{\nu}\tau_{\gamma_L(\sigma)}f\right)\right)$$

$$=\lim_{L\to\infty}\sum_{\mathbf{k}\in\mathbb{Z}_+^\nu}\left|\prod_{\alpha=1}^{\nu}(\hat{f}_{\tau_{\gamma_L(\sigma)}})(\mathbf{k})\right|^2\frac{1}{e^{\beta(E_L(\mathbf{k})-\bar{\mu}_L(\beta,\rho))}-1}$$

$$=\lim_{L\to\infty}\left(\sum_{\mathbf{k}\in\{\mathbb{Z}_+^\nu:k_\alpha=0,1;\alpha=1,\ldots,\nu\}}\left|\prod_{\alpha=1}^{\nu}(\hat{f}_{\tau_{\gamma_L(\sigma)}})(\mathbf{k})\right|^2\frac{1}{e^{\beta(E_L(\mathbf{k})-\bar{\mu}_L(\beta,\rho))}-1}\right.$$

$$\left.+\sum_{n=1}^{\infty}e^{n\beta\bar{\mu}_L(\beta,\rho)}\sum_{\mathbf{k}\in\mathbb{Z}_+^\nu\setminus\{\mathbb{Z}_+^\nu:k_\alpha=0,1;\ \alpha=1,\ldots,\nu\}}e^{-n\beta E_L(\mathbf{k})}\left|\prod_{\alpha=1}^{\nu}(\hat{f}_{\tau_{\gamma_L(\sigma)}})(\mathbf{k})\right|^2\right). \tag{4.35}$$

This thermodynamic limit depends on the homothety point corresponding to the shifts $\Pi_{\alpha=1}^{\nu}\tau_{\pm\gamma_L(a_\alpha\sigma)}$ with parameters $a_\alpha=1$. Notice that the factor $|\Pi_{\alpha=1}^{\nu}\hat{f}_{\tau_{\gamma_L(\sigma)}}(\mathbf{k})|^2$ is of the order $O(L^{-\nu})$ for large L:

$$\left|\prod_{\alpha=1}^{\nu}\hat{f}_{\tau_{\gamma_L(\sigma)}}(\mathbf{k})\right|^2=\left|\int_{\gamma_L(\sigma)-\delta_1}^{\gamma_L(\sigma)+\delta_1}dx_1\cdots\int_{\gamma_L(\sigma)-\delta_\nu}^{\gamma_L(\sigma)+\delta_\nu}dx_\nu\prod_{\alpha=1}^{\nu}(\tau_{\gamma_L(\sigma)}f)(\mathbf{x})\overline{\psi^L_{\mathbf{k}}(\mathbf{x})}\right|^2$$

$$=|\sigma|^\nu L^{-\nu}\left|\int_{\text{supp}(f)}d\mathbf{x}\,f(\mathbf{x})\prod_{\alpha=1}^{\nu}e^{|\sigma|x_\alpha}\right|^2+o(L^{-\nu}), \tag{4.36}$$

and for any $\mathbf{k}\in\{\mathbb{Z}_+^\nu:k_\alpha=0,1;\alpha=1,\ldots,\nu\}$. Hence, by the same reasoning, which implies (4.32), the first 2^ν terms in (4.35) give

$$\lim_{L\to\infty}\sum_{\mathbf{k}\in\{\mathbb{Z}_+^\nu:k_\alpha=0,1;\alpha=1,\ldots,\nu\}}\left|\prod_{\alpha=1}^{\nu}(\hat{f}_{\tau_{\gamma_L(\sigma)}})(\mathbf{k})\right|^2\frac{1}{e^{\beta(E_L(\mathbf{k})-\bar{\mu}_L(\beta,\rho))}-1}$$

$$=\rho_0(\beta,\rho)|\sigma|^\nu\left|\int_{\mathbb{R}^\nu}d\mathbf{x}\,f(\mathbf{x})\prod_{i=1}^{\nu}e^{|\sigma|x_i}\right|^2. \tag{4.37}$$

For the last term in (4.35), we perform the computations as in Theorem 4.1, yielding

$$\lim_{L\to\infty}\sum_{\mathbf{k}\in\mathbb{Z}_+^\nu\setminus\{\mathbb{Z}_+^\nu:k_\alpha=0,1;\ \alpha=1,\ldots,\nu\}}\left|\prod_{\alpha=1}^{\nu}\hat{f}_{\tau_{\gamma_L(\sigma)}}(\mathbf{k})\right|^2\frac{1}{e^{\beta(E_L(\mathbf{k})-\bar{\mu}_L(\beta,\rho))}-1}$$

$$=\sum_{n=1}^{\infty}e^{-n\nu\beta\sigma^2}(4\pi n\beta)^{-\nu/2}\int_{\mathbb{R}^\nu}d\mathbf{x}\int_{\mathbb{R}^\nu}d\mathbf{y}f(\mathbf{x})\overline{f(\mathbf{y})}\exp\left\{-\frac{\|\mathbf{x}-\mathbf{y}\|^2}{4n\beta}\right\}. \tag{4.38}$$

So, taking the thermodynamic limit $L\to\infty$ at one of the homothety points $\{\pm\gamma_L(\sigma)\}_{\alpha=1}^{\nu}$, we get now the generating functional for $\rho\geqslant\rho_c(\beta)$:

$$\lim_{L\to\infty}\omega^{\text{g. c.}}_{L,\beta,\bar{\mu}_L(\beta,\rho)}\left(\prod_{\alpha=1}^{\nu}W(\tau_{\pm\gamma(\sigma)}f)\right)$$

$$=\exp(-\tfrac{1}{4}(f,f))\exp(-\tfrac{1}{2}C_\sigma^{\pm}(\beta,\rho)(f)-\tfrac{1}{2}(f,g_\sigma(\beta,\rho)f)) \tag{4.39}$$

with

$$C_{\sigma}^{\pm}(\beta,\rho)(f)=\rho_0(\beta,\rho)|\sigma|^{\nu}\left|\int_{\mathbb{R}^{\nu}}d\mathbf{x}\,f(\mathbf{x})\prod_{\alpha=1}^{\nu}\mathrm{e}^{\pm|\sigma|x_{\alpha}}\right|^2. \tag{4.40}$$

Remark 4.7: Again this result is due to a fine (logarithmic) tuning of the position of the homothety points $\{\pm\gamma_L(\sigma)\}_{\alpha=1}^{\nu}$ *in the corner directions of the hypercube* Λ_L^{ν}. *Indeed, take as in Theorem 4.6 the shifts* $\Pi_{\alpha=1}^{\nu}\tau_{\pm\gamma_L(a_{\alpha}\sigma)}$, *with* $\Sigma_{\alpha=1}^{\nu}(a_{\alpha})^{-1}>\nu$, *i.e., the homothety points are more distant from the corners of the hypercube. Taking into account the explicit form of the eigenfunctions for* $\mathbf{k}\in\{\mathbb{Z}_+^{\nu}:k_{\alpha}=0,1;\alpha=1,\ldots,\nu\}$, *one finds now that* $|\Pi_{\alpha=1}^{\nu}\hat{f}_{\tau_{\gamma_L(a_{\alpha}\sigma)}}(\mathbf{k})|^2$ *with* $\mathbf{k}\in\{\mathbb{Z}_+^{\nu}:k_{\alpha}=0,1;\alpha=1,\ldots,\nu\}$ *goes like* $L^{-(a_1^{-1}+a_2^{-1}+\cdots+a_{\nu}^{-1})}$ *for large* L. *This implies that the limits of the first* 2^{ν} *terms (4.37), and hence (4.40), vanish. So, the generating functional (4.39) has the same form as for the thermodynamic limit with the homothety point at the origin* $\mathbf{x}=\mathbf{0}$. *In contrast to that, the choice* $0<\Sigma_{\alpha=1}^{\nu}(a_{\alpha})^{-1}<\nu$ *means that the homothety points are too close to the corners of the hypercube* Λ_L^{ν}. *Then* $|\Pi_{\alpha=}^{\nu}\hat{f}_{\tau_{\pm\gamma_L(a_{\alpha}\sigma)}}(\mathbf{k})|^2$ *with* $\mathbf{k}\in\{\mathbb{Z}_+^{\nu}:k_{\alpha}=0,1;\alpha=1,\ldots,\nu\}$ *goes to zero slower then* $L^{-\nu}$. *This implies that the limit (4.40) becomes infinite. So, for* $\rho\geqslant\rho_c(\beta)$ *the generating functional (4.39) is zero, whereas for* $\rho<\rho_c(\beta)$ *it is nontrivial with* $C_{\sigma}^{\pm}(f)=0$.

Therefore, we proved the following theorem:

Theorem 4.8: *The generating functional* $\lim_{L\to\infty}\omega_{L,\beta,\bar{\mu}_L(\beta,\rho)}^{\mathrm{g.\,c.}}(\Pi_{\alpha=1}^{\nu}W(\tau_{\pm\gamma(a_{\alpha}\sigma)}f))$ *on* $C_0^{\infty}(\mathbb{R}^{\nu})$ *is given by*

$$\lim_{L\to\infty}\omega_{L,\beta,\bar{\mu}_L(\beta,\rho)}^{\mathrm{g.\,c.}}\left(\prod_{\alpha=1}^{\nu}W(\tau_{\pm\gamma(a_{\alpha}\sigma)}f)\right)$$

$$=\exp(-\tfrac{1}{4}(f,f))\exp(-\tfrac{1}{2}C_{\mathbf{a}\sigma}^{\pm}(\beta,\rho)(f)-\tfrac{1}{2}(f,g_{\sigma}(\beta,\rho)f)), \tag{4.41}$$

with

$$C_{\mathbf{a}\sigma}^{\pm}(\beta,\rho)(f)=\rho_0(\beta,\rho)|\sigma|^{\nu}\left|\int_{\mathbb{R}^{\nu}}d\mathbf{x}\,f(\mathbf{x})\prod_{i=1}^{\nu}\mathrm{e}^{\pm|\sigma|x_i}\right|^2\chi_{\nu}(\mathbf{a}),$$

$$(g_{\sigma}(\beta,\rho)f)(\mathbf{x})=\int_{\mathbb{R}^{\nu}}d\mathbf{y}G_{\sigma}(\beta,\rho)(\|\mathbf{x}-\mathbf{y}\|)f(\mathbf{y}),$$

$$G_{\sigma}(\beta,\rho)(r)=(4\pi\beta)^{-\nu/2}\sum_{n=1}^{\infty}\mathrm{e}^{-r^2/4n\beta}\frac{\mathrm{e}^{-n\beta\nu\sigma^2}}{n^{\nu/2}}.$$

Here $\bar{\mu}(\beta,\rho)<-\nu\sigma^2$ *for* $\rho<\rho_c(\beta)$ *and* $\bar{\mu}(\beta,\rho)=-\nu\sigma^2$ *for* $\rho\geqslant\rho_c(\beta)$ *are the limiting solutions of the grand canonical density equation (3.5),* $\rho_0(\beta,\rho)=0$ *for* $\rho<\rho_c(\beta)$ *whereas* $\rho_0(\beta,\rho)=\rho-\rho_c(\beta)$ *for* $\rho\geqslant\rho_c(\beta)$ *and the function* $\chi_{\nu}(\mathbf{a})=0,1,+\infty$, *respectively, for* $\nu<\Sigma_{\alpha=1}^{\nu}(a_{\alpha})^{-1}$, $\nu=\Sigma_{\alpha=1}^{\nu}(a_{\alpha})^{-1}$, *and* $\nu>\Sigma_{\alpha=1}^{\nu}(a_{\alpha})^{-1}$.

V. CONCLUDING REMARKS

The main results of our analysis for the free Bose gas with attractive boundary conditions are contained in the Theorems 3.1, 4.1, and 4.8.

In Theorem 3.1, we obtain a Kac density function showing nonequivalence of the canonical and the grand canonical ensemble in the presence of the condensate even if the condensate density is locally zero.

We learn from Theorem 4.1 that the condensation is not visible in the expectation values of strictly localized observables because the Bose condensate is situated near the boundary of an ''infinite container.'' Nevertheless one should observe the effects of condensation in the equilibrium states, i.e., in the generating functional.

Theorem 4.8 yields the answer. We make precise for which type of observables the equilibrium states show their dependence on the condensate. This completes the rigorous analysis of the problem of (non)equivalence of ensembles for the free Bose gas with attractive boundary conditions and the inhomogeneous condensate localization.

Finally we repeat that we analyzed only the problem taking the thermodynamic limits in the sense of homothetically increasing cubes, with the consequence that the condensate is situated anisotropically in the direction of the corners of these cubes and is ''localized at infinity.'' To prove this we tune the homothety point position at the logarithmic (in the units of the cube size) distance from the cube boundary. If instead one looks for the limit of spherical containers, this anisotropy in the positioning of the condensate should disappear. Does one expect spontaneous spherical symmetry breaking of the equilibrium states in this case?

ACKNOWLEDGMENT

The paper was initiated during V.A.Z.'s visit at the Instituut voor Theoretische Fysica, KU Leuven. He wishes to thank the Instituut voor Theoretische Fysica for their hospitality.

(Received 11 November 2003; accepted 28 December 2003)

Extending a recently proposed procedure of construction of various elements of differential geometry on noncommutative algebras, we obtain these structures on noncommutative superalgebras. As an example, a quantum superspace covariant under the action of super-Jordanian $OSp_h(2/1)$ is studied. It is shown that there exist a two-parameter family of torsionless connections, and the curvature computed from this family of connections is bilinear. It is also shown that the connections are not compatible with the metric. © *2004 American Institute of Physics.*

I. INTRODUCTION

Noncommutative geometry is one of the active fields in recent theoretical physics and mathematics. The physical interests seem to be focused on noncommutative differential geometry, since it plays crucial roles in the context of string theory and quantum gravity.[1,2] There exists various approaches to noncommutative differential calculus. For instance, Connes' approach involves the Dirac operator,[1] Dubois–Violette's method is based on derivations,[3] and studies based on quantum groups also exist.[4–6] Analogs of Riemannian connection, curvature and metric on noncommutative algebra $\mathcal{A}$ were introduced in Ref. 7, where the authors used only the left $\mathcal{A}$-module structure of the differential forms. On the other hand, the $\mathcal{A}$-bimodule structure of an algebra of differential forms was used to define a linear connection for a particular differential calculus based on derivations.[8] Mourad also made essential use[9] of the $\mathcal{A}$-bimodule structure to define linear connection, torsion, and curvature on a noncommutative algebra $\mathcal{A}$. In the procedure used in Ref. 9, a noncommutative generalization of the permutation operator on two copies of one-forms was introduced. The generalized permutation operator plays a role in defining the noncommutative differential geometry. A general notion of connection based on a generalized transposition operator was introduced in Ref. 10. The above methodology was found to be useful in other approaches to the noncommutative differential calculi. Furthermore, it was extended to other studies concerning differential calculi on noncommutative algebras such as $SL_q(2)$ covariant quantum plane,[11] two-parameter quantum plane,[12] Jordanian h-deformed quantum plane,[13,14] matrix geometries,[15] and so on. The curvatures corresponding to the connections were also studied[8,9,16] in this context.

In the present work, we follow the line of investigation developed in Refs. 8, 9, 16 to study the noncommutative differential geometry associated with the quantized supergroups. It will be seen that the ideas used there are also appropriate for studying noncommutative differential geometry on quantum superspaces. Following Refs. 8, 9, 16 we can naturally define linear connections, torsions, curvatures, and metrics on noncommutative quantum superspaces. As an example, we will study the quantum superspace covariant under the action of super-Jordanian deformation of OSp(2/1). The super-Jordanian $OSp_h(2/1)$ is introduced as a Hopf algebra dually related to the recently obtained triangular deformation of Lie superalgebra osp(2/1);[17] and it coincides with the deformed OSp(2/1) supergroup studied by Juszczak and Sobczyck.[18] We obtain the most general

form of linear connections on the quantum superspace covariant under the action of $\mathrm{OSp}_h(2/1)$. The curvatures and the metric will also be studied in the sequel.

We first briefly review the construction of a linear connection in a commutative geometry.[9] Let $\mathcal{M}$ be a manifold, and $C(\mathcal{M})$ be an algebra of functions on $\mathcal{M}$. The set of k-forms is denoted by Ω^k. The covariant derivative D is a linear map from Ω^1 to $\Omega^1 \otimes_{C(\mathcal{M})} \Omega^1$ obeying the Leibnitz rule

$$D(f\xi) = df \otimes \xi + fD\xi, \quad f \in C(\mathcal{M}), \quad \xi \in \Omega^1. \tag{1.1}$$

Since functions commute with forms, the Leibnitz rule may also be recast as

$$D(\xi f) = \sigma(\xi \otimes df) + (D\xi) f, \tag{1.2}$$

where σ is a permutation acting on $\Omega^1 \otimes_{C(\mathcal{M})} \Omega^1$:

$$\sigma(\xi \otimes \eta) = \eta \otimes \xi, \quad \xi, \eta \in \Omega^1; \tag{1.3}$$

and the exterior derivative d is nilpotent: $d^2 = 0$. In the context of commutative geometry the two Leibnitz rules (1.1) and (1.2) are equivalent. However, in the noncommutative setting this is not the case, as functions and forms do not commute. The noncommutative covariant derivative is constructed in such a way that it is required[9] to satisfy the two Leibnitz rules. Reflecting the noncommutative nature of functions and forms, the operator σ can no longer be represented by a simple permutation element. It needs to be modified for noncommutative quantum spaces.

Suppose the manifold $\mathcal{M}$ is parallelizable and let ω^i be an arbitrary basis element of Ω^1. The covariant derivative of a one-form is then uniquely determined by $D\omega^i$. The linear connection is defined by $\Gamma^i = -D\omega^i$. Namely, the covariant derivative defines the linear connection. Throughout this article, we use the terms ''linear connection'' and ''covariant derivative'' synonymously. Let π be a projection of $\Omega^1 \otimes_{C(\mathcal{M})} \Omega^1$ onto Ω^2 such that $\pi(\xi \otimes \eta) = \xi \wedge \eta$. Then the map $\Theta: \Omega^1 \to \Omega^2$ defined by $\Theta = d - \pi \circ D$ is a bimodule homomorphism, that is, it maintains $\Theta(f\xi) = f\Theta(\xi)$ and $\Theta(\xi f) = \Theta(\xi) f$, where $f \in C(\mathcal{M})$. The torsion is defined by $\Theta(\omega^i)$. This construction of linear connections will be extended to noncommutative superspaces associated with quantum supergroups.

This paper is organized as follows: In the next section, we extend the differential geometry on noncommutative algebras to noncommutative superalgebras. The super-Jordanian deformation of OSp(2/1) is introduced in Sec. III. The quantum superspace which is covariant under the action of super-Jordanian $\mathrm{OSp}_h(2/1)$ is introduced, and the differential calculus on it in the sense of Wess–Zumino is constructed in Sec. IV. The linear connection on the quantum superspace is studied in Sec. V, and it is observed that the most general torsionless connection is a member of a two-parameter family. In Sec. VI, the curvature obtained from the linear connection is calculated and it is shown that the curvature is bilinear. The metric of the quantum superspace is also studied. We show that the covariant derivative is not compatible with the metric. Section VII contain the concluding remarks.

II. NONCOMMUTATIVE EXTENSION OF SUPERSPACE GEOMETRY

Let $\mathcal{A}$ be a noncommutative algebra with $\mathbb{Z}_2$ grading. The grading is specified by parity of elements of $\mathcal{A}$. An even (odd) element $f \in \mathcal{A}$ has a parity $\hat{f} = 0\ (1)$. It is assumed that a differential calculus over $\mathcal{A}$, describing, in particular, the one-forms and their commutation relations with the elements of $\mathcal{A}$, has been constructed. Let $\Omega^k(\mathcal{A})$ and d denote the space of k-forms over $\mathcal{A}$ and the exterior derivative, respectively. The covariant derivative D is defined as a map $D: \Omega^1 \to \Omega^1 \otimes_{\mathcal{A}} \Omega^1$ subject to the following Leibnitz rules:

$$D(f\xi) = df \otimes \xi + (-1)^{\hat{f}} fD\xi, \tag{2.1}$$

$$D(\xi f) = (-1)^{\hat{\xi}} \sigma(\xi \otimes df) + (D\xi) f, \quad f \in \Omega^0, \quad \xi \in \Omega^1, \tag{2.2}$$

where $\sigma:\Omega^1\otimes_{\mathcal{A}}\Omega^1\to\Omega^1\otimes_{\mathcal{A}}\Omega^1$ refers to a noncommutative generalization of the permutation map. The covariant derivative changes the parity of a k-form ξ by unity: $\widehat{D\xi}=\hat{\xi}+1$, (mod 2). In the commutative case where $\sigma(\xi\otimes\eta)=(-1)^{\hat{\xi}\hat{\eta}}\eta\otimes\xi$, the two Leibnitz rules (2.1) and (2.2) are equivalent up to an overall sign

$$D(\xi f)=(-1)^{\hat{\xi}\hat{f}}D(f\xi). \tag{2.3}$$

Using the definition of the covariant derivative, one can show that the map σ is $\mathcal{A}$-bilinear

$$\sigma(f\xi\otimes\eta)=f\sigma(\xi\otimes\eta),\quad \sigma(\xi\otimes\eta f)=\sigma(\xi\otimes\eta)f,\quad f\in\Omega^0,\quad \xi,\eta\in\Omega^1. \tag{2.4}$$

We now demonstrate the first relation in (2.4). The second relation in (2.4) follows similarly. For arbitrary elements $f,g\in\Omega^0$ and $\xi\in\Omega^1$, we compute $D(f\xi g)$ in two different ways. Regarding it as $D(f\cdot\xi g)$, we apply (2.1) and obtain

$$D(f\xi g)=df\otimes\xi g+(-1)^{\hat{f}}fD(\xi g)=df\otimes\xi g+(-1)^{\hat{f}+\hat{\xi}}f\sigma(\xi\otimes dg)+(-1)^{\hat{f}}f(D\xi)g.$$

Alternately, for the choice $D(f\xi g)=D(f\xi\cdot g)$ the Leibnitz rule (2.2) yields

$$D(f\xi g)=(-1)^{\hat{f}+\hat{\xi}}\sigma(f\xi\otimes dg)+df\otimes\xi g+(-1)^{\hat{f}}f(D\xi)g.$$

As the above two computations must give identical results, it follows $\sigma(f\xi\otimes dg)=f\sigma(\xi\otimes dg)$.

The covariant derivative may be extended as a linear map from the n-fold tensored space $\otimes^n\Omega^1$ to the $(n+1)$-fold tensored space $\otimes^{(n+1)}\Omega^1$. This is done recurrently while maintaining the following extension of the Leibnitz rule

$$D(\omega\otimes\omega')=D\omega\otimes\omega'+(-1)^{\hat{\omega}}\sigma_{12}(\omega\otimes D\omega'), \tag{2.5}$$

where $\omega\in\Omega^1$, $\omega'\in\otimes^{n-1}\Omega^1$ and σ_{12} has a nontrivial structure in the first two sectors:

$$\sigma_{12}=\sigma\otimes\underbrace{1\otimes 1\otimes\cdots\otimes 1}_{n-1\text{ times}}. \tag{2.6}$$

Let π be a projection of $\Omega^1\otimes_{\mathcal{A}}\Omega^1$ onto Ω^2 defined by the wedge product on the forms

$$\pi(\xi\otimes\eta)=\xi\wedge\eta. \tag{2.7}$$

The noncommutativity of $\mathcal{A}$, in general, demands $\xi\wedge\eta\neq-\eta\wedge\xi$. Employing the projection operator π, we define the torsion Θ of the covariant derivative D as a map $\Theta:\Omega^1\to\Omega^2$

$$\Theta:\Omega^1\to\Omega^2,\quad \Theta=d-\pi\circ D. \tag{2.8}$$

The torsion is always left $\mathcal{A}$-linear, whereas the condition

$$\pi\circ(\sigma-1)=0 \tag{2.9}$$

is necessary for it to be right $\mathcal{A}$-linear. More explicitly, the torsion satisfies the relations

$$\Theta(f\xi)=(-1)^{\hat{f}}f\Theta(\xi),\quad \Theta(\xi f)=\Theta(\xi)f,\quad f\in\Omega^0,\ \xi\in\Omega^1. \tag{2.10}$$

The condition (2.9) is necessary for the validity of the second relation in (2.10). Note that the relation (2.9) has a sign difference from the nongraded case.[11,15] Since the proof is straightforward, we show only the second relation. The exterior derivative acts on the one-form ξf as follows:

$$d(\xi f)=(d\xi)f+(-1)^{\hat{\xi}}\xi\wedge df=(d\xi)f+(-1)^{\hat{\xi}}\pi(\xi\otimes df),$$

while the action of $\pi\circ D$ on ξf reads

$$\pi\circ D(\xi f)=\pi((-1)^{\hat{\xi}}\sigma(\xi\otimes df)+(D\xi)f).$$

Consequently, it follows

$$\Theta(\xi f)=\Theta(\xi)f-(-1)^{\hat{\xi}}\pi\circ(\sigma-1)(\xi\otimes df).$$

It is thus evident that condition (2.9) needs to be satisfied for the torsion Θ to be right $\mathcal{A}$-linear.

The curvature is defined by the following map:[16]

$$\pi_{12}D^2 \;:\; \Omega^1\to\Omega^2\otimes_{\mathcal{A}}\Omega^1, \tag{2.11}$$

where $\pi_{12}=\pi\otimes 1$. The torsionless condition $\Theta=0$ and the validity of the constraint (2.9) require the curvature to be left $\mathcal{A}$-linear:

$$\pi_{12}D^2(f\xi)=f\pi_{12}D^2(\xi),\quad f\in\Omega^0,\;\; \xi\in\Omega^1. \tag{2.12}$$

We demonstrate this below. Employing the Leibnitz rule (2.5), we compute

$$D^2(f\xi)=Ddf\otimes\xi+(-1)^{\widehat{df}}\sigma_{12}(df\otimes D\xi)+(-1)^{\hat{f}}df\otimes D\xi+fD^2\xi.$$

The left-hand side in (2.12) now reads

$$\pi_{12}D^2(f\xi)=\pi\circ Ddf\otimes\xi-(-1)^{\hat{f}}\pi_{12}\circ(\sigma_{12}-1)(df\otimes D\xi)+f\pi_{12}D^2(\xi).$$

The first and second terms in the above expression vanish because of the torsionless condition and the constraint (2.9), respectively. Thus the curvature is left $\mathcal{A}$-linear. In general, the curvature is not right $\mathcal{A}$-linear. It is, however, known that there exist some cases for nongraded $\mathcal{A}$ where the curvature is right $\mathcal{A}$-linear.[11] We will find such an example for graded $\mathcal{A}$ in the following sections.

Now let us define a metric. A metric g is a nondegenerate $\mathcal{A}$-bilinear map

$$g \;:\; \Omega^1\otimes_{\mathcal{A}}\Omega^1\to\mathcal{A}. \tag{2.13}$$

The metric is said to be nondegenerate if the following conditions hold: $g(\xi\otimes\eta)=0$ for all $\eta\in\Omega^1$ implies $\xi=0$, and, simultaneously, $g(\xi\otimes\eta)=0$ for all $\xi\in\Omega^1$ implies $\eta=0$. Symmetry of the metric is defined by using the extended permutation σ. A metric satisfying $g\circ\sigma=g$ ($g\circ\sigma=-g$) is known to be symmetric (skew-symmetric) in nature. If the following diagram is commutative, the covariant derivative D is said to be compatible with the metric g, or, in short, D is said to be metric:

$$\begin{array}{ccc}
\Omega^1\otimes_{\mathcal{A}}\Omega^1 & \overset{D}{\longrightarrow} & \Omega^1\otimes_{\mathcal{A}}\Omega^1\otimes_{\mathcal{A}}\Omega^1 \\
g\downarrow & & 1\otimes g\downarrow \\
\mathcal{A} & \overset{d}{\longrightarrow} & \Omega^1.
\end{array}$$

More explicitly, the above compatibility condition reads

$$d\circ g=(1\otimes g)\circ D. \tag{2.14}$$

In the following sections an example of the differential geometry described here will be presented. In this example, the algebra $\mathcal{A}$ is taken to be a quantum superspace covariant under the action of a quantum supergroup $OSp_h(2/1)$. The example will be constructed so as to keep the covariance of all relations.

III. SUPER-JORDANIAN DEFORMATION OF OSp(2/1)

In this section we introduce a quantum deformation of the supergroup OSp(2/1). The conventions adopted here regarding the graded Yang–Baxter equation are same as in Refs. 19 and 20. The quantum supergroup discussed here is the dual Hopf algebra to the super-Jordanian deformed $U_h(\mathrm{osp}(2/1))$ algebra introduced recently. The study of super-Jordanian osp(2/1) algebra was initiated by Kulish.[21] It was further developed by the works of the present authors[17] and Borowiec *et al.*[22] In Ref. 17, the universal $\mathcal{R}$ matrix of the $U_h(\mathrm{osp}(2/1))$ algebra was obtained up to $O(h^3)$ where h is the deformation parameter. Its limiting classical value is described by $h\to 0$. The fundamental representation of the generators of the $U_h(\mathrm{osp}(2/1))$ algebra is obtained by mapping the deformed algebra on its classical counterpart. Although the two deformation maps given in Ref. 17 provide two distinct sets of matrices for the fundamental representation, the pertinent R matrices computed for these two cases are identical. All the terms in the universal $\mathcal{R}$ matrix $O(h^3)$ and above vanish in the fundamental representation, and, therefore, the R matrix in the said representation is determined by the terms up to $O(h^2)$. The R matrix, thus obtained, is given by

$$R=\left(\begin{array}{ccc|ccc|ccc}
1 & \cdot & -h & \cdot & h & \cdot & h & \cdot & h^2/2 \\
\cdot & 1 & \cdot & \cdot & \cdot & -h & \cdot & \cdot & \cdot \\
\cdot & \cdot & 1 & \cdot & \cdot & \cdot & \cdot & \cdot & -h \\
\hline
\cdot & \cdot & \cdot & 1 & \cdot & \cdot & \cdot & h & \cdot \\
\cdot & \cdot & \cdot & \cdot & 1 & \cdot & \cdot & \cdot & -h \\
\cdot & \cdot & \cdot & \cdot & \cdot & 1 & \cdot & \cdot & \cdot \\
\hline
\cdot & \cdot & \cdot & \cdot & \cdot & \cdot & 1 & \cdot & h \\
\cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & 1 & \cdot \\
\cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & 1
\end{array}\right), \tag{3.1}$$

where the dot $(\cdot)$ is used instead of 0 for better readability. The R matrix (3.1) solves the graded Yang–Baxter equation. The inverse of this R matrix is given by $R^{-1}=R(-h)$; and identifying $h=-p$ in (3.1) the R-matrix given in Ref. 18 is reproduced. In Ref. 21, a contraction technique is applied to the R matrix in the fundamental representation of the $U_q(\mathrm{osp}(2/1))$ algebra to obtain a triangular $\tilde{R}$ matrix, which maintains the relation $\tilde{R}^{k\ell}_{ij}=R^{\ell k}_{ji}$ with the R matrix given in (3.1).

Now we explicitly write down the nonstandard deformed supergroup $OSp_h(2/1)$. Since the R matrix (3.1) is the inverse of the one used in Ref. 18, the quantum supergroup $OSp_h(2/1)$ is identical to the one given in Ref. 18, where the deformed supergroup $OSp_h(2/1)$ is constructed by the FRT (Ref. 23) method. Let the inverse scattering matrix T in the fundamental representation of the super-Jordanian deformed $OSp_h(2/1)$ is given by

$$T=(t^i_j)=\left(\begin{array}{ccc} a & \alpha & b \\ \gamma & e & \beta \\ c & \delta & d \end{array}\right), \tag{3.2}$$

where $\hat{i}=0(1)$ for $i=\{1,3\}(\{2\})$, and $\hat{t}^i_j=\hat{i}+\hat{j}$. Thus the entries a,b,c,d,e are even elements, whereas α, β, γ, δ are odd ones. The RTT relation and deformed orthosymplectic conditions

$$T^{\mathrm{st}}JT=J,\quad TJ^{-1}T^{\mathrm{st}}=J^{-1},\quad J=\begin{pmatrix}0&0&1\\0&1&0\\-1&0&-h/2\end{pmatrix} \tag{3.3}$$

determine the relations among the entries of T. The supertransposition of T is defined by $(T^{\mathrm{st}})^i_j=(-1)^{\hat{i}(\hat{i}+\hat{j})}t^j_i$. The matrix J corresponds to the matrix C^{-1} in Ref. 18. An error contained in C of Ref. 18 is corrected. It follows from this definition that $(AB)^{\mathrm{st}}=B^{\mathrm{st}}A^{\mathrm{st}}$, $((A^{\mathrm{st}})^{\mathrm{st}})^i_j=(-1)^{\hat{i}+\hat{j}}A^i_j$. Note that the matrix J has the property

$$(-1)^{\hat{a}+\hat{b}}J_{ab}=J_{ab}. \tag{3.4}$$

This simplifies many relations in the later computations. Following Ref. 18 we express the elements e,β, and γ in terms of the remaining elements a,b,c,d,α. The commutation relations satisfied by the elements a,b,c,d,α and δ are summarized as

$$\begin{gathered}[a,b]=h(1-a^2),\quad [a,c]=hc^2,\quad [a,d]=h(cd-ca),\\ [a,\alpha]=0,\quad [a,\delta]=hc\delta,\quad [b,c]=h(ca+dc),\\ [b,d]=h(d^2-1),\quad [b,\alpha]=h\alpha a,\quad [b,\delta]=h(d\delta+c\alpha),\\ [c,d]=-hc^2,\quad [c,\alpha]=-hc\delta,\quad [c,\delta]=0,\\ [d,\alpha]=h(\delta a-\delta d),\quad [d,\delta]=h\delta c,\quad \{\alpha,\delta\}=h(ac-\delta^2),\\ \alpha^2=\frac{h}{2}(a^2-1),\quad \delta^2=\frac{h}{2}c^2.\end{gathered} \tag{3.5}$$

The other entries of T may be algebraically solved as follows:

$$e=1+\alpha\delta-\frac{h}{2}ac,\quad \beta=\alpha d-\delta b-h\delta d-\frac{h}{2}\gamma,\quad \gamma=\alpha c-\delta a-h\delta c. \tag{3.6}$$

Relations analogous to the classical supergroup OSp(2/1) exist for the nonstandard deformation:

$$ad-bc+\alpha\delta+\frac{h}{2}ac=1,\quad e^{-1}=\left(1-\alpha\delta+\frac{h}{2}ac\right)\left(1-\frac{h^2}{4}c^2\right)^{-1},\quad \alpha\delta+\beta\gamma=\frac{h}{2}(ac-dc). \tag{3.7}$$

For completeness, we also give the commutation relations involving the elements e,β, and γ:

$$\begin{gathered}[a,e]=h\gamma\delta,\quad [b,e]=h(\beta\delta+\gamma\alpha),\quad [c,e]=0,\\ [d,e]=h\gamma\delta,\quad [e,\alpha]=h(e\delta+\gamma a),\quad [e,\beta]=h(d\delta+\gamma e),\\ [e,\gamma]=hc\delta,\quad [e,\delta]=hc\gamma,\quad [a,\beta]=h(\gamma d-\gamma a),\\ [b,\beta]=h\beta d,\quad [c,\beta]=-hc\gamma,\quad [d,\beta]=0,\\ \{\alpha,\beta\}=h(ea-ed),\quad \{\beta,\gamma\}=-h(dc+\gamma^2),\quad \{\beta,\delta\}=hce,\\ [a,\gamma]=h\gamma c,\quad [b,\gamma]=h(\beta c+\gamma a),\quad [c,\gamma]=0,\\ [d,\gamma]=hc\gamma,\quad \{\alpha,\gamma\}=-hce,\quad \{\gamma,\delta\}=0,\\ \beta^2=\frac{h}{2}(1-d^2),\gamma^2=-\frac{h}{2}c^2.\end{gathered} \tag{3.8}$$

As a consequence of the grading, the RTT relation

$$\sum_{x,y} (-1)^{\hat{y}(\hat{x}+\hat{i})} R_{xy}^{k\ell}\, t_i^x\, t_j^y = \sum_{x,y} (-1)^{\hat{y}(\hat{k}+\hat{x})} t_y^\ell\, t_x^k\, R_{ij}^{xy} \tag{3.9}$$

involves extra sign factors in the tensor products of T and the identity matrix.

The coalgebra mappings of the quantum supergroup $OSp_h(2/1)$ are, as usual, given by

$$\Delta(T) = T \dot{\otimes} T, \quad \epsilon(T) = \mathrm{diag}(1,1,1). \tag{3.10}$$

The antipode is obtained from the coproduct:

$$S(T) = \begin{pmatrix} d+\frac{h}{2}c & -\beta-\frac{h}{2}\gamma & -b-\frac{h}{2}(a-d)+\frac{h^2}{4}c \\ \delta & e & -\alpha+\frac{h}{2}\delta \\ -c & \gamma & a-\frac{h}{2}c \end{pmatrix} = J^{-1}T^{\mathrm{st}}J. \tag{3.11}$$

It is easy to see that $TS(T) = S(T)T = \mathrm{diag}(1,1,1)$.

IV. DIFFERENTIAL CALCULUS ON QUANTUM SUPERSPACE

In this section, a quantum superspace covariant under the action of $OSp_h(2/1)$ is introduced and a differential calculus in the sense of Wess and Zumino[6] is constructed. The quantum superspace is a graded algebra, denoted by $\mathcal{A}$, generated by two odd (θ_1, θ_2) and one even (x) elements. The defining relations of the algebra $\mathcal{A}$ read

$$[\theta_1, x] = -hx\theta_2, \quad \{\theta_1, \theta_2\} = 0, \quad [\theta_2, x] = 0,$$

$$\theta_1^2 = -\frac{h}{2}(x^2 - 2\theta_1\theta_2), \quad \theta_2^2 = 0. \tag{4.1}$$

It is straightforward to verify that the relations (4.1) are preserved under the action of $OSp_h(2/1)$ from the left

$$\begin{pmatrix} \theta_1' \\ x' \\ \theta_2' \end{pmatrix} = \begin{pmatrix} a & \alpha & b \\ \gamma & e & \beta \\ c & \delta & d \end{pmatrix} \begin{pmatrix} \theta_1 \\ x \\ \theta_2 \end{pmatrix}. \tag{4.2}$$

The quantum superspace (4.1) has an important difference from that associated to the Jordanian quantum supergroup $GL_h(1/1)$ discussed in Refs. 24 and 25. In the quantum superspace covariant under the action of $GL_h(1/1)$, the deformation parameter h is a Grassmann variable, whereas the quantity h in (4.1) commute with all elements of the quantum superspace.

A scalar element φ exists in the quantum superspace $\mathcal{A}$:

$$\varphi \equiv X^{\mathrm{st}} J X = x^2 - 2\theta_1\theta_2, \tag{4.3}$$

where

$$X = \begin{pmatrix} \theta_1 \\ x \\ \theta_2 \end{pmatrix}, \quad X^{\mathrm{st}} = (-\theta_1, x, -\theta_2). \tag{4.4}$$

Then it is easy to show that φ is preserved by the left action of $\mathrm{OSp}_h(2/1)$. Note that the parity of components of X is $\hat{X}^i = 1 + \hat{i} \pmod 2$. The fourth relation in (4.1) implies that θ_1^2 is also a scalar in the algebra $\mathcal{A}$. Employing a solution of the nongraded Yang-Baxter equation the defining relations (4.1) of the algebra $\mathcal{A}$ may be written in a compact form:

$$X^i X^j = \sum_{k,\ell} B^{ij}_{k\ell} X^\ell X^k, \quad B_{12}B_{13}B_{23} = B_{23}B_{13}B_{12}, \tag{4.5}$$

where the matrix B reads

$$B(h) = \left(\begin{array}{ccc|ccc|ccc} -1 & \cdot & -h & \cdot & -h & \cdot & h & \cdot & -h^2/2 \\ \cdot & 1 & \cdot & \cdot & \cdot & -h & \cdot & \cdot & \cdot \\ \cdot & \cdot & -1 & \cdot & \cdot & \cdot & \cdot & \cdot & -h \\ \hline \cdot & \cdot & \cdot & 1 & \cdot & \cdot & \cdot & h & \cdot \\ \cdot & \cdot & \cdot & \cdot & 1 & \cdot & \cdot & \cdot & -h \\ \cdot & \cdot & \cdot & \cdot & \cdot & 1 & \cdot & \cdot & \cdot \\ \hline \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & -1 & \cdot & h \\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & 1 & \cdot \\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & -1 \end{array}\right). \tag{4.6}$$

The matrix B is related to the R matrix of the deformed supergroup $\mathrm{OSp}_h(2/1)$ as

$$R(h)^{k\ell}_{xy} = (-1)^{1+\hat{k}+(1+\hat{x})\hat{y}} (B(h)^{-1})^{k\ell}_{xy} = (-1)^{1+\hat{k}+\hat{y}+\hat{k}\hat{l}} B(-h)^{k\ell}_{xy}, \tag{4.7}$$

where the last equality follows from the relation $(B(h)^{-1})^{k\ell}_{xy} = (-1)^{\hat{k}\hat{\ell}+\hat{x}\hat{y}} B(-h)^{k\ell}_{xy}$.

The differential calculus on quantum space is an algebra generated by coordinates X^i, differentials $\Xi^i \equiv dX^i$ and derivatives $\partial_i = \partial/\partial X^i$. The parity of differentials and derivatives are, in general, $\hat{\Xi}^i = 1 + \hat{X}^i$, $\hat{\partial}_i = \hat{X}^i$. The differential calculus on quantum superspace using solutions of the nongraded Yang–Baxter equation is developed in Ref. 26. These authors require the exterior derivative d, which maps a k-form to a $(k+1)$-form, to maintain three properties: (i) nilpotency, (ii) graded Leibnitz rule

$$d(f \wedge g) = (df) \wedge g + (-1)^{\hat{f}} f \wedge dg, \quad f \in \Omega^p, \ g \in \Omega^q, \tag{4.8}$$

and (iii) its action on a function $f(X^i)$ is given by $df = \Sigma_i \Xi^i \partial_i f$. Employing these properties, the following commutation relations among X^i, Ξ^i and ∂_i may be determined:

$$\Xi^i \wedge \Xi^j = \sum_{k,\ell} (-1)^{\hat{X}^i + \hat{\Xi}^\ell} B^{ij}_{k\ell} \Xi^\ell \wedge \Xi^k, \quad X^i \Xi^j = \sum_{k,\ell} (-1)^{\hat{X}^i} B^{ij}_{k\ell} \Xi^\ell X^k,$$

$$\partial_j X^i = \delta_{ij} + \sum_{k,\ell} B^{i\ell}_{kj} X^k \partial_\ell, \quad \partial_j \Xi^i = \sum_{k,\ell} (-1)^{\hat{X}^j} (B^{-1})^{ki}_{j\ell} \Xi^\ell \partial_k,$$

$$\partial_i \partial_j = \sum_{k,\ell} B^{k\ell}_{ij} \partial_\ell \partial_k. \tag{4.9}$$

Our convention of the matrix B differs from that in Ref. 26. We use the Yang–Baxter equation of the form (4.5), whereas the Yang–Baxter equation in the braid group form $F_{12}F_{23}F_{12} = F_{23}F_{12}F_{23}$ is used in Ref. 26. They are related as $F^{k\ell}_{ij} = B^{k\ell}_{ji}$. The relations (4.9) are covariant under the action of the super-Jordanian $\mathrm{OSp}_h(2/1)$:

$$X'^i=\sum_j t^i_j X^j, \quad \Xi'^i=\sum_j (-1)^{\hat{i}+\hat{j}} t^i_j \Xi^j, \quad \partial'_i=\sum_j (-1)^{\hat{i}+\hat{j}}((T^{st})^{-1})^i_j \partial_j. \tag{4.10}$$

To show the covariance, we need RTT-type relations for T and T^{st} with the matrix B. They are obtained via (3.9) and (4.5):

$$\sum_{i,j} (-1)^{\hat{b}+\hat{j}+\hat{i}\hat{j}+\hat{b}\hat{i}} t^a_i t^b_j B^{ij}_{cd}=\sum_{i,j} (-1)^{\hat{c}+\hat{i}+\hat{c}\hat{d}+\hat{d}\hat{i}} B^{ab}_{ij} t^j_d t^i_c, \tag{4.11}$$

$$\sum_{i,j} (-1)^{\hat{i}+\hat{a}+\hat{i}\hat{j}+\hat{i}\hat{b}} \tau^a_i \tau^b_j B^{cd}_{ij}=\sum_{i,j} (-1)^{\hat{d}+\hat{j}+\hat{d}\hat{i}+\hat{c}\hat{d}} B^{ij}_{ab} \tau^j_d \tau^i_c, \tag{4.12}$$

$$\sum_{i,j} (-1)^{\hat{i}+\hat{b}\hat{i}+\hat{c}\hat{i}+\hat{d}\hat{j}} \tau^a_i t^b_j B^{jd}_{ci}=\sum_{i,j} (-1)^{\hat{c}+\hat{i}+\hat{j}+\hat{i}\hat{c}} B^{bi}_{ja} t^j_c \tau^i_d, \tag{4.13}$$

$$\sum_{i,j} (-1)^{\hat{c}+\hat{i}+\hat{j}+\hat{c}\hat{i}} (B^{-1})^{ib}_{aj} t^j_c \tau^i_d=\sum_{i,j} (-1)^{\hat{i}+\hat{b}\hat{i}+\hat{c}\hat{i}+\hat{j}\hat{d}} \tau^a_i t^b_j (B^{-1})^{dj}_{ic}, \tag{4.14}$$

where $\tau=(T^{\mathrm{st}})^{-1}$. Introducing the notations $\xi_1=d\theta_1$, $\eta=dx$, $\xi_2=d\theta_2$, the explicit form of the $OSp_h(2/1)$ covariant differential calculus on the quantum superspace $\mathcal{A}$ is summarized as follows:

(1) Coordinates

$$[\theta_1,x]=-hx\theta_2, \quad \{\theta_1,\theta_2\}=0, \quad [\theta_2,x]=0,$$
$$\theta_1^2=-\frac{h}{2}(x^2-2\theta_1\theta_2), \quad \theta_2^2=0. \tag{4.15}$$

(2) Differentials

$$\xi_1\wedge\eta-\eta\wedge\xi_1=h\eta\wedge\xi_2, \quad \xi_1\wedge\xi_2-\xi_2\wedge\xi_1=h\xi_2\wedge\xi_2,$$
$$\eta\wedge\xi_2-\xi_2\wedge\eta=0, \quad \eta\wedge\eta=-\frac{h}{2}\xi_2\wedge\xi_2. \tag{4.16}$$

(3) Coordinates and differentials

$$[\theta_1,\xi_1]=h\left(\theta_1\xi_2+x\eta-\theta_2\xi_1-\frac{h}{2}\theta_2\xi_2\right), \quad \{\theta_1,\eta\}=hx\xi_2,$$
$$[\theta_1,\xi_2]=h\theta_2\xi_2, \quad [x,\xi_1]=-h\theta_2\eta, \quad [x,\eta]=-h\theta_2\xi_2,$$
$$[x,\xi_2]=0, \quad [\theta_2,\xi_1]=-h\theta_2\xi_2,$$
$$\{\theta_2,\eta\}=0, \quad [\theta_2,\xi_2]=0. \tag{4.17}$$

(4) Derivatives and coordinates

$$\partial_1\theta_1=1-\theta_1\partial_1+h\theta_2\partial_1, \quad \partial_1 x=x\partial_1, \quad \partial_1\theta_2=-\theta_2\partial_1,$$
$$\partial_x\theta_1=\theta_1\partial_x-hx\partial_1, \quad \partial_x x=1+x\partial_x+h\theta_2\partial_1, \quad \partial_x\theta_2=\theta_2\partial_x,$$
$$\partial_2\theta_1=-\theta_1\partial_2-h\left(\theta_1\partial_1+x\partial_x+\theta_2\partial_2+\frac{h}{2}\theta_2\partial_1\right),$$
$$\partial_2 x=x\partial_2-h\theta_2\partial_x, \quad \partial_2\theta_2=1-\theta_2\partial_2+h\theta_2\partial_1,$$
$$\text{where } \partial_1=\frac{\partial}{\partial\theta_1}, \ \partial_x=\frac{\partial}{\partial x}, \ \partial_2=\frac{\partial}{\partial\theta_2}. \tag{4.18}$$

(5) Derivatives and differentials

$$\partial_1\xi_1=\xi_1\partial_1-h\xi_2\partial_1,\quad \partial_1\eta=-\eta\partial_1,\quad \partial_1\xi_2=\xi_2\partial_1,$$
$$\partial_x\xi_1=\xi_1\partial_x-h\eta\partial_1,\quad \partial_x\eta=\eta\partial_x+h\xi_2\partial_1,\quad \partial_x\xi_2=\xi_2\partial_x,$$
$$\partial_2\xi_1=\xi_1\partial_2+h\left(\xi_1\partial_1+\eta\partial_x+\xi_2\partial_2+\frac{h}{2}\xi_2\partial_1\right),$$
$$\partial_2\eta=-\eta\partial_2+h\xi_2\partial_x,\quad \partial_2\xi_2=\xi_2\partial_2-h\xi_2\partial_1. \tag{4.19}$$

(6) Derivatives

$$\partial_1^2=0,\quad \partial_1\partial_x=\partial_x\partial_1,\quad \partial_1\partial_2=-\partial_2\partial_1,$$
$$\partial_x\partial_2=\partial_2\partial_x-h\partial_1\partial_x,\qquad \partial_2^2=h(\partial_1\partial_2-\tfrac{1}{2}\partial_x^2). \tag{4.20}$$

V. $OSp_h(2/1)$ SYMMETRIC TORSIONLESS CONNECTIONS

We have seen that a scalar $\varphi(\sim\theta_1^2)$ exists in the quantum superspace $\mathcal{A}$. This scalar is an $OSp_h(2/1)$ invariant zero-form. Invariant one and two-forms under the action of the deformed supergroup $OSp_h(2/1)$ also exist in the differential calculus $\mathcal{A}$:

$$\varrho=\sum_{a,b} J_{ab}X^a\Xi^b=\theta_1\xi_2+x\eta-\theta_2\xi_1-\frac{h}{2}\theta_2\xi_2, \tag{5.1}$$

$$\chi=\sum_{a,b} J_{ab}\Xi^a\wedge\Xi^b=0. \tag{5.2}$$

It is evident that the invariant two-form χ is trivial. It is straightforward to verify the invariance of ϱ and χ under the transformation (4.10). Note that the ϱ appears on the right-hand side of the first relation in (4.17). It is easy to find the commutation relations between the invariant forms and the basis elements (X^a,Ξ^a). For the zero-form φ these relations read

$$X^a\varphi=\varphi X^a,\quad \Xi^a\varphi=\varphi\Xi^a. \tag{5.3}$$

The commutation properties of the invariant one-form ϱ are succinctly given by

$$X^a\varrho=(-1)^{\hat{X}^a}\varrho X^a,\quad \Xi^a\wedge\varrho=(-1)^{\hat{\Xi}^a}\varrho\wedge\Xi^a. \tag{5.4}$$

In a more expanded version the above relations read

$$[x,\varrho]=\{\theta_i,\varrho\}=0,\quad i=(1,2), \tag{5.5}$$

$$\eta\wedge\varrho+\varrho\wedge\eta=0,\quad \xi_i\wedge\varrho-\varrho\wedge\xi_i=0. \tag{5.6}$$

It is also straightforward to verify the relation

$$\varrho\wedge\varrho=0. \tag{5.7}$$

In order to determine the covariant derivative, it is necessary to find the action of the extended permutation σ on $\Omega^1\otimes\Omega^1$. This can be done by applying the covariant derivative D on the second relation in (4.9). Using the Leibnitz rules, we obtain

$$\Xi^i\otimes\Xi^j+(-1)^{\hat{X}^i}X^iD\Xi^j=\sum_{k,\ell}(-1)^{\hat{X}^i}B^{ij}_{k\ell}\ \{(-1)^{\hat{\Xi}^\ell}\sigma(\Xi^\ell\otimes\Xi^k)+(D\Xi^\ell)X^k\}.$$

This relation implies that the action of σ on $\Xi^\ell\otimes\Xi^k$, and the commutation relations between X^i and $D\Xi^j$ may be consistently described as

$$\Xi^i\otimes\Xi^j=\sum_{k,\ell}\ (-1)^{\hat{X}^i+\hat{\Xi}^\ell}B^{ij}_{k\ell}\ \ \sigma(\Xi^\ell\otimes\Xi^k), \tag{5.8}$$

$$X^iD\Xi^j=\sum_{k,\ell}\ B^{ij}_{k\ell}\ \ (D\Xi^\ell)X^k. \tag{5.9}$$

Using the property (4.7) the exchange relation (5.8) may be solved yielding the action of σ on the tensored space of one-forms as follows:

$$\sigma(\Xi^k\otimes\Xi^\ell)=\sum_{i,j}\ (-1)^{\hat{i}\hat{j}}R^{\ell k}_{ij}\ \ \Xi^i\otimes\Xi^j\equiv\sum_{i,j}\ \check{R}^{k\ell}_{ij}\ \ \Xi^i\otimes\Xi^j. \tag{5.10}$$

The matrix $\check{R}$ has two important properties, namely, $\check{R}$ is idempotent and satisfies a nongraded Yang–Baxter equation

$$\check{R}^2=1,\quad \check{R}_{12}\check{R}_{23}\check{R}_{12}=\check{R}_{23}\check{R}_{12}\check{R}_{23}. \tag{5.11}$$

As a consequence of the exchange of the superscripts in the definition (5.10) of $\check{R}$, it satisfies a different form of Yang–Baxter equation from the one obeyed by R. The operator σ, therefore, exhibits identical properties:

$$\sigma^2=1,\quad \sigma_{12}\sigma_{23}\sigma_{12}=\sigma_{23}\sigma_{12}\sigma_{23}. \tag{5.12}$$

The map σ may now be explicitly written as follows:

$$\begin{aligned}
\sigma(\xi_1\otimes\xi_1)&=\xi_1\otimes\xi_1-h\left(\xi_1\otimes\xi_2+\eta\otimes\eta-\xi_2\otimes\xi_1-\frac{h}{2}\xi_2\otimes\xi_2\right),\\
\sigma(\xi_1\otimes\eta)&=\eta\otimes\xi_1+h\xi_2\otimes\eta,\\
\sigma(\xi_1\otimes\xi_2)&=\xi_2\otimes\xi_1+h\xi_2\otimes\xi_2,\\
\sigma(\eta\otimes\xi_1)&=\xi_1\otimes\eta-h\,\eta\otimes\xi_2,\\
\sigma(\eta\otimes\eta)&=-\eta\otimes\eta-h\xi_2\otimes\xi_2,\\
\sigma(\eta\otimes\xi_2)&=\xi_2\otimes\eta,\\
\sigma(\xi_2\otimes\xi_1)&=\xi_1\otimes\xi_2-h\xi_2\otimes\xi_2,\\
\sigma(\xi_2\otimes\eta)&=\eta\otimes\xi_2,\\
\sigma(\xi_2\otimes\xi_2)&=\xi_2\otimes\xi_2.
\end{aligned} \tag{5.13}$$

The map σ being $\mathcal{A}$-bilinear, the following relations hold:

$$\begin{aligned}
&\sigma(\xi_1\otimes\varrho)=\varrho\otimes\xi_1,\quad \sigma(\eta\otimes\varrho)=-\varrho\otimes\eta,\quad \sigma(\xi_2\otimes\varrho)=\varrho\otimes\xi_2,\\
&\sigma(\varrho\otimes\xi_1)=\xi_1\otimes\varrho,\quad \sigma(\varrho\otimes\eta)=-\eta\otimes\varrho,\quad \sigma(\varrho\otimes\xi_2)=\xi_2\otimes\varrho,\\
&\sigma(\varrho\otimes\varrho)=-\varrho\otimes\varrho.
\end{aligned} \tag{5.14}$$

The explicit form of the map σ being known, the relations (5.12) and (2.9) may be verified by direct computation.

To derive the action of the covariant derivative D on Ξ^a, we compare the relation (5.9) with (4.5) and the second relation in (4.9). The comparison suggests that $D\Xi^a$ contains X^a and Ξ^a as factors. Another important observation is that $D\Xi^a$ has the same transformation property as X^a under the action of $\mathrm{OSp}_h(2/1)$ namely,

$$D\Xi'^a = \sum_i t_i^a D\Xi^i. \tag{5.15}$$

Thus the most general form of $D\Xi^a$ may be given by

$$D\Xi^a = c_0 X^a \varpi + c_1(-1)^{\hat{a}}\Xi^a \otimes \varrho + c_2 \varrho \otimes \Xi^a, \tag{5.16}$$

where c_i $(i=0,1,2)$ are real parameters and $\varpi \in \Omega^1 \otimes \Omega^1$ satisfies

$$\varpi' = \varpi, \quad X^a \varpi = \varpi X^a. \tag{5.17}$$

It is not difficult to see that each term on the right-hand side of (5.16) has the same transformation property as X^a under the action of the deformed supergroup $\mathrm{OSp}_h(2/1)$. Furthermore, each term of (5.16) satisfies the same commutation relation as (5.9). As we have seen in the beginning of this section, the $\mathrm{OSp}_h(2/1)$ invariant two-form χ is trivial so that the only possible choice for ϖ is given by

$$\varpi = \varrho \otimes \varrho. \tag{5.18}$$

In this way, we have seen that (5.16) and (5.18) describe the most general linear connection.

Let us recall that our main interest is in torsionless connections, as the torsion-free condition is necessary for making the curvature left $\mathcal{A}$-linear. We restrict the linear connection obtained above to be torsion-free: $\Theta\Xi^a = 0$. As the nilpotency of d constrains $d\Xi^a = 0$, we obtain

$$\Theta\Xi^a = -\pi \circ D\Xi^a = -c_0 \varrho \wedge \varrho - c_1(-1)^{\hat{\Xi}^a}\Xi^a \wedge \varrho - c_2 \varrho \wedge \Xi^a = -(c_1+c_2)\varrho \wedge \Xi^a = 0, \tag{5.19}$$

where we have used the relations (5.4) and (5.7). The torsion-free condition thus requires $c_2 = -c_1$. Therefore, the general form of the $\mathrm{OSp}_h(2/1)$ symmetric torsionless connections is given by the following two-parameter family:

$$D\Xi^a = c_0 X^a \varrho \otimes \varrho + c_1((-1)^{\hat{a}}\Xi^a \otimes \varrho - \varrho \otimes \Xi^a). \tag{5.20}$$

More explicitly these connections read

$$\begin{aligned} D\xi_1 &= c_0\theta_1 \varrho \otimes \varrho + c_1(\xi_1 \otimes \varrho - \varrho \otimes \xi_1), \\ D\eta &= c_0 x \varrho \otimes \varrho - c_1(\eta \otimes \varrho + \varrho \otimes \eta), \\ D\xi_2 &= c_0\theta_2 \varrho \otimes \varrho + c_1(\xi_2 \otimes \varrho - \varrho \otimes \xi_2). \end{aligned} \tag{5.21}$$

For the torsionless connections (5.20), it is easy to see

$$D\varrho = \sum_{a,b} J_{ab}\,\Xi^a \otimes \Xi^b + (c_0\varphi - 2c_1)\varrho \otimes \varrho. \tag{5.22}$$

Applying (2.7), (5.2), (5.7) it immediately follows that

$$\pi(D\varrho) = 0. \tag{5.23}$$

VI. CURVATURE AND METRIC

A two-parameter family of $OSp_h(2/1)$ symmetric torsion-free connections was obtained in the previous section. Since the generalized permutation operator σ satisfies the relation (2.9), the curvature computed from the connections are left $\mathcal{A}$-linear. Recall that curvatures are, in general, not right $\mathcal{A}$-linear. In the present case, however, the curvature is also right $\mathcal{A}$-linear. We exhibit this by explicit computation. We also discuss the metric on the quantum superspace $\mathcal{A}$. It, however, turns out that the connections are not compatible with the metric.

To obtain the curvature, we apply $\pi_{12}D$ on (5.20). Each term is computed separately and listed below:

$$\pi_{12}D(X^a\varrho\otimes\varrho)=\Xi^a\wedge\varrho\otimes\varrho-\sum_{b,c}\ (-1)^{\hat{X}^a}J_{bc}\,X^a\varrho\wedge\Xi^b\otimes\Xi^c,$$

$$\pi_{12}D((-1)^{\hat{a}}\Xi^a\otimes\varrho)=\sum_{b,c}\ J_{bc}\,\Xi^a\wedge\Xi^b\otimes\Xi^c+(c_0\varphi-2c_1)\Xi^a\wedge\varrho\otimes\varrho,$$

$$\pi_{12}D(\varrho\otimes\Xi^a)=-c_1\Xi^a\wedge\varrho\otimes\varrho.$$

Combining the above results, the curvature is obtained as follows:

$$\pi_{12}D^2\Xi^a=(c_0-c_1^2+c_0c_1\varphi)\Xi^a\wedge\varrho\otimes\varrho+(c_0(-1)^{\hat{a}}X^a\varrho+c_1\Xi^a)\wedge\Lambda, \tag{6.1}$$

where

$$\Lambda=\sum_{a,b}\ J_{ab}\,\Xi^a\otimes\Xi^b=\xi_1\otimes\xi_2+\eta\otimes\eta-\xi_2\otimes\xi_1-\frac{h}{2}\xi_2\otimes\xi_2. \tag{6.2}$$

Note that $\pi(\Lambda)=\chi=0$. Expanding the first term in the right-hand side of (6.1) as

$$\Xi^a\wedge\varrho\otimes\varrho=\sum_{b,c}\ (-1)^{\hat{X}^b}J_{bc}\,\Xi^aX^b\wedge\varrho\otimes\Xi^c,$$

we express the curvature in terms of a two-form ω

$$\pi_{12}D^2\Xi^a=\sum_b\ \omega_b^a\otimes\Xi^b, \tag{6.3}$$

where

$$\omega_b^a=\sum_k\ J_{kb}\{(-1)^{\hat{k}}\{c_0(-1)^{\hat{a}}X^a\Xi^k-(c_0-c_1^2+c_0c_1\varphi)\Xi^aX^k\}\wedge\varrho+c_1\Xi^a\wedge\Xi^k\}. \tag{6.4}$$

We now prove that the curvature obtained above is right $\mathcal{A}$-linear. To this end, we note that the following relation may be established by direct computation:

$$[X^a,\Lambda]=0. \tag{6.5}$$

Employing the second relation in (4.9), in conjunction with the left $\mathcal{A}$-linearity of the curvature, we obtain

$$\pi_{12}D^2(\Xi^bX^a)=\sum_{i,j}\ (-1)^{\hat{X}^i}(B^{-1})_{ij}^{ab}X^i\pi_{12}D^2\Xi^j. \tag{6.6}$$

Substituting (6.1) into (6.6), and then transferring X^i to the right via Eqs. (4.9), (5.3), (5.4), (6.5), we demonstrate the intended result

$$\pi_{12}D^2(\Xi^b X^a)=(\pi_{12}D^2\Xi^b)X^a, \tag{6.7}$$

establishing the right $\mathcal{A}$-linearity of the curvature. In the above computation we have used the fact that the matrices B_{ij}^{ab} and $(B^{-1})_{ij}^{ab}$ maintain the following relationship regarding the parity of their indices: $\hat{a}+\hat{b}=\hat{i}+\hat{j}$.

Let us now turn to the metric, which is considered as a bilinear map $g:\Omega^1\otimes_{\mathcal{A}}\Omega^1\to\mathcal{A}$. To completely determine the metric we need to know the action of the map g on the basis elements of $\Omega^1\otimes\Omega^1$. Setting $g^{ab}=g(\Xi^a\otimes\Xi^b)$, we require that g^{ab} to be invariant under the action of $\mathrm{OSp}_\hbar(2/1)$:

$$g'^{ab}\equiv g(\Xi'^a\otimes\Xi'^b)=\sum_{k,\ell} g((-1)^{\hat{a}+\hat{k}}t_k^a\,\Xi^k\otimes(-1)^{\hat{b}+\hat{\ell}}t_\ell^b\,\Xi^\ell)=\sum_{k,\ell}(-1)^{\hat{a}+\hat{b}+\hat{k}+\hat{\ell}}t_k^a\,g^{k\ell}(t^{st})_\ell^b.$$

The above result, in conjunction with the identity (3.3), immediately yields $g'^{ab}=g^{ab}$, provided we choose $g^{k\ell}=(-1)^{\hat{k}+\hat{\ell}}(J^{-1})_{k\ell}=(J^{-1})_{k\ell}$. The $\mathrm{OSp}_\hbar(2/1)$ invariant metric, therefore, is given by

$$g^{ab}=g(\Xi^a\otimes\Xi^b)=(J^{-1})_{ab}=\begin{pmatrix}-\frac{h}{2} & 0 & -1\\ 0 & 1 & 0\\ 1 & 0 & 0\end{pmatrix}. \tag{6.8}$$

Denoting the components of g^{-1} by g_{ab}, we note that the invariant one-form ϱ may be written in terms of the metric

$$\varrho=\sum_{a,b} g_{ab}X^a\Xi^b.$$

The structure of the metric (6.8) implies

$$d\circ g(\Xi^a\otimes\Xi^b)=0. \tag{6.9}$$

The compatibility condition (2.14) now reads

$$(1\otimes g)\circ D(\Xi^a\otimes\Xi^b)=0. \tag{6.10}$$

To compute the left-hand side in (6.10), we start by ordering the one-forms in the expression of ϱ to the left:

$$\varrho=\xi_2\theta_1+\eta x-\xi_1\theta_2+\frac{h}{2}\xi_2\theta_2=\sum_{a,b}(-1)^{\hat{X}^b}J_{ab}\,\Xi^aX^b. \tag{6.11}$$

We now readily obtain

$$g(\varrho\otimes\Xi^a)=X^a,\quad g(\Xi^a\otimes\varrho)=(-1)^{\hat{X}^a}X^a. \tag{6.12}$$

Following (2.5) the action of the covariant derivative on $\Omega^1\otimes\Omega^1$ is given as

$$D(\Xi^a\otimes\Xi^b)=D\Xi^a\otimes\Xi^b+(-1)^{\hat{\Xi}^a}\sigma_{12}(\Xi^a\otimes D\Xi^b). \tag{6.13}$$

Substituting (5.20) into (6.13), we observe that, as a consequence of the bilinearity of g, we may treat the first (proportional to c_0) and the second (proportional to c_1) terms in the right hand side of (5.20) separately. For the choice $c_1=0$, we then obtain

$$D(\Xi^a\otimes\Xi^b)=c_0(X^a\varrho\otimes\varrho\otimes\Xi^b+\varrho\otimes\Xi^a\otimes\varrho X^b),$$

which, in turn, yields

$$(1\otimes g)\circ D(\Xi^a\otimes\Xi^b)=(-1)^{\hat{X}^a}2c_0\varrho X^aX^b. \tag{6.14}$$

For the alternate choice $c_0=0$, it follows that

$$D(\Xi^a\otimes\Xi^b)=c_1\{(-1)^{\hat{a}}\Xi^a\otimes\varrho\otimes\Xi^b-2\varrho\otimes\Xi^a\otimes\Xi^b+(-1)^{\hat{a}+\hat{b}}\sigma_{12}(\Xi^a\otimes\Xi^b\otimes\varrho)\}.$$

The right-hand side in (6.10) now reads

$$(1\otimes g)\circ D(\Xi^a\otimes\Xi^b)=c_1\{(-1)^{\hat{a}}\Xi^aX^b-2g^{ab}\varrho+(-1)^{\hat{a}+\hat{b}}(1\otimes g)\circ\sigma_{12}(\Xi^a\otimes\Xi^b\otimes\varrho)\}. \tag{6.15}$$

The last term is computed by using (5.13) and (6.12). The result is listed below:

$$(1\otimes g)\circ D(\xi_1\otimes\xi_1)=0,$$

$$(1\otimes g)\circ D(\xi_1\otimes\eta)=c_1(\xi_1x+\eta\theta_1-h\xi_2x),$$

$$(1\otimes g)\circ D(\xi_1\otimes\xi_2)=c_1\left(\eta x-\frac{h}{2}\xi_2\theta_2+\varrho\right),$$

$$(1\otimes g)\circ D(\eta\otimes\xi_1)=-c_1(\xi_1x+\eta\theta_1+h\eta\theta_2),$$

$$(1\otimes g)\circ D(\eta\otimes\eta)=-c_1(2\eta x-h\xi_2\theta_2+2\varrho),$$

$$(1\otimes g)\circ D(\eta\otimes\xi_2)=-c_1(\eta\theta_2+\xi_2x),$$

$$(1\otimes g)\circ D(\xi_2\otimes\xi_1)=-c_1\left(\eta x-\frac{h}{2}\xi_2\theta_2+\varrho\right),$$

$$(1\otimes g)\circ D(\xi_2\otimes\eta)=c_1(\eta\theta_2+\xi_2x),$$

$$(1\otimes g)\circ D(\xi_2\otimes\xi_2)=0. \tag{6.16}$$

Together with (6.14), it has been shown that $(1\otimes g)\circ D\neq 0$, except for the trivial choice $c_0=c_1=0$. Thus the covariant derivative D is not compatible with the metric.

VII. CONCLUDING REMARKS

In the present work we have studied noncommutative spaces, linear connections, curvatures, and metrics associated with the quantized supergroups. Our approach is a naive extension of the differential geometry developed in Refs. 8, 9, 16. We have demonstrated that the ideas of these authors may be appropriately adapted to study the geometric objects related to the quantum supergroups. Specifically, we applied the extended differential geometry to the quantum superspace covariant under the quantum supergroup $OSp_h(2/1)$. We have seen that our particular example has a two-parameter family of $OSp_h(2/1)$ symmetric torsion-free connections. It turned

out that the curvature of the connection was bilinear. The connection was, however, not compatible with the metric. These properties are specific to our example. There could be other quantum superspace endowed with linear connections compatible with metric.

It may be of interest to recall the results related to the quantum spaces covariant under quantized SL(2) groups, and compare them with the present results. It is well-known that SL(2) admits two inequivalent deformations: the standard q-deformation and the Jordanian h-deformation. The quantum space for q-deformed SL(2) has a one-parameter family of torsionless linear connections and it has been shown that there can be no compatible metric,[11] whereas the quantum space of h-deformed SL(2) is more classical. It has a two-parameter family of torsion-free linear connections. A one-parameter subfamily of these connections is known to be compatible with a metric.[14] On the other hand, the Lie superalgebra osp(2/1) admits three inequivalent deformations.[27] We are thus able to consider three deformations of the supergroup OSp(2/1): q-deformation,[20] h-deformation,[28] and super-Jordanian deformation. The q and h-deformations have the SL(2) counterparts, while super-Jordanian does not. The super-Jordanian deformation can be regarded as an algebra intermediate between q and h-deformations. We have seen that the quantum space for super-Jordanian $\mathrm{OSp}_h(2/1)$ is less classical since the connections are not metric. This leads us to the anticipate that the quantum space for h-deformed OSp(2/1) has connections which are metric, while the connections on the quantum spaces related to the standard q-deformed supergroup $\mathrm{OSp}_q(2/1)$ are not metric. This will be presented in a future work.

(Received 5 May 2003; accepted 13 January 2004)

The Hasegawa–Mima equation is the simplest nonlinear model to investigate drift waves and drift-wave turbulence. In this article, we establish the existence and uniqueness of a global weak solution for the Cauchy problem of the two-dimensional Hasegawa–Mima equation. Moreover, if the background particle density is homogeneous in the x-direction, there is a unique global regular solution. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1667607]

I. INTRODUCTION

We consider the existence and uniqueness of a global solution for the following two-dimensional (2D) Hasegawa–Mima equation,

$$\partial_t(u-\Delta u)+k\partial_y u+\{u,\Delta u\}=0, \qquad (x,y)\in R^2, \quad t>0, \tag{1}$$

with initial datum

$$u(x,y,t=0)=u_0(x,y), \tag{2}$$

where k is a constant, Δ is the 2D Laplacian, and $\{\cdot,\cdot\}$ denotes the Poisson bracket

$$\{f,g\}=(\partial_x f)(\partial_y g)-(\partial_x f)(\partial_y g).$$

Equation (1) is the simplest and powerful 2D turbulent system. In plasma,[6] Eq. (1) describes the time evolution of drift wave, and u describes the electrostatic fluctuations, where $k=\partial_x \ln n_0$ and n_0 is the background particle density.[13] In geophysical fluids,[12] Eq. (1) describes the temporal evolution of geostrophic motion and is called the quasi-geostrophic potential vorticity equation for the Rossby wave, and u is the geostrophic stream function. If we eliminate the term u_t of Eq. (1), then Eq. (1) is changed into the Euler equation for inviscid incompressible homogeneous fluids. The Euler equation has been actively studied by many authors (see Refs. 2–4, 10, 14, and 15 and references therein). The Hasegawa–Mima equation has been actively studied by way of numerical simulation and analysis of Fourier ansatz, and some important characteristics of the 2D turbulence have been found (see, e.g., Refs. 1, 5–8, and 11–13 and references therein), but rigorous results are lacking. In the present work, we establish that Cauchy problem (1) and (2) is global well-posed. Our main results are stated as follows.

Theorem 1: *Let $k=0$, initial data $u_0\in H^m(R^2)\cap W^2_\infty(R^2)$. Then for all time $T>0$ and integer $m\geqslant 3$ there is a unique regular solution u of problem (1) and (2) such that $u\in L^\infty([0,T];H^m(R^2))$, $u_t\in L^\infty([0,T];H^{m-1}(R^2))$.*

Theorem 2: *Let initial data $u_0\in H^2(R^2)$. Then for all time $T>0$ there is a weak solution u of problem (1) and (2) such that $u\in L^\infty([0,T];H^2(R^2))$ and $u_t\in L^\infty([0,T];H^1(R^2))$. If u_0*

[a]Electronic mail: gbl@mail.iapcm.ac.cn
[b]Electronic mail: han_yongqian@mail.iapcm.ac.cn

$\in H^2(R^2)\cap W^2_\infty(R^2)$, *then the weak solution* u *of problem (1) and (2) is unique and for all* $2\leqslant p<\infty$ *we have* $u\in L^\infty([0,T];W^2_p(R^2))$. *Moreover, if* $u_0\in H^2(R^2)\cap W^2_\infty(R^2)$ *and* $k=0$, *then* $u\in L^\infty([0,T];H^2(R^2)\cap W^2_\infty(R^2))$.

Definition 1: Let $T>0$, $u_0\in H^m(R^2)$, $m\geqslant 2$, *and function* $u\in L^\infty([0,T];H^m(R^2))$ *such that*

$$\int_0^T\int_{R^2}((u-\Delta u)\phi_t+ku\phi_y+\{u,\phi\}\Delta u)dx\ \ dy\ \ dt+\int_{R^2}u_0\phi(x,y,0)dx\ \ dy=0,$$
$$\forall\phi\in C^1([0,T];C_0^\infty(R^2)),\qquad \phi(x,y,t)|_{t=T}=0. \tag{3}$$

If $m=2$, *the function* u *is said to be a weak solution of (1) and (2) in the interval* $[0,T]$. *If* $m\geqslant 3$, *the function* u *is said to be a regular solution of (1) and (2) in the interval* $[0,T]$.

We first establish the existence and uniqueness of the global solution for the perturbed Hasegawa–Mima equation

$$\partial_t(u-\Delta u)+k\partial_y u+\{u,\Delta u\}-\lambda\Delta(u-\Delta u)=0 \tag{4}$$

with initial datum

$$u(x,y,t=0)=u_0(x,y), \tag{5}$$

where constant $0<\lambda<1$, and obtain the uniform *a priori* estimates for the solution of problem (4) and (5) relative to the coefficient λ. Let $\lambda\to 0$, and then Theorems 1 and 2 are proved.

In this paper, we use a variety of function spaces: Lebesgue space $L^p=L^p(R^2)$, Sobolev spaces $H^k(R^2)$ and $W^k_p(R^2)$, and the spaces $L^q([0,T];X)$ and $C([0,T];X)$, where X is one of the spaces just mentioned. In order to simplify the exposition, different positive constants might be denoted by the same letter C; if necessary, by $C(\cdots)$ denote the constant depending only on the quantities appearing in parentheses. The rest of this work is organized as follows. In Sec. II, we establish *a priori* estimates. In Sec. III, we establish the existence and uniqueness of solution for the problem (4) and (5). In Sec. IV, we give the proof of Theorems 1 and 2.

II. *A PRIORI* ESTIMATES

In this section, we establish *a priori* estimates of solutions for the problem (4) and (5).

Lemma 1: Let initial data $u_0\in H^m(R^2)$ $(m\geqslant 2)$ *and* u *be the smooth solution of problem (4) and (5). Then we have that*

$$\|u(\cdot,t)\|_{H^2}+\lambda\int_0^t\|u(\cdot,\tau)\|_{H^3}d\tau\leqslant C(\|u_0\|_{H^2}),\qquad \forall t\geqslant 0. \tag{6}$$

If $u_0\in H^2(R^2)\cap W^2_\infty(R^2)$, *then for all* $2<p<\infty$ *we have that*

$$\|u(\cdot,t)\|_{W^2_p}\leqslant C(\|u_0\|_{H^2},\|u_0\|_{W^2_\infty})(1+pt^2),\qquad \forall t\geqslant 0. \tag{7}$$

Moreover, if $u_0\in H^2(R^2)\cap W^2_\infty(R^2)$ *and* $k=0$, *then we have that*

$$\|u(\cdot,t)\|_{W^2_\infty}\leqslant C(\|u_0\|_{H^2},\|u_0\|_{W^2_\infty}),\qquad \forall t\geqslant 0. \tag{8}$$

Here constants $C(\cdots)$ *are independent of* p *and* λ.

Proof: Taking the scalar product of the function $2u$ and the equation (4), and then integrating the result over R^2 for the space variable (x,y) and over $[0,t]$ for the temporal variable t, we have

$$\|u(\cdot,t)\|_{L^2}^2+\|\nabla u(\cdot,t)\|_{L^2}^2+2\lambda\int_0^t(\|\nabla u(\cdot,\tau)\|_{L^2}^2+\|\Delta u(\cdot,\tau)\|_{L^2}^2)d\tau=\|u_0\|_{L^2}^2+\|\nabla u_0\|_{L^2}^2,\quad \forall t\geqslant 0, \tag{9}$$

where we have used the fact

$$\int_{R^2}\{u,\Delta u\}u(x,y,t)\ \ dxdy=0,\qquad \forall t\geqslant 0.$$

Similarly, taking the scalar product of $-2\Delta u$ and the equation (4), and then integrating the result over R^2 for the space variable (x,y) and over $[0,t]$ for the temporal variable t, we have

$$\begin{aligned}&\|\nabla u(\cdot,t)\|_{L^2}^2+\|\Delta u(\cdot,t)\|_{L^2}^2+2\lambda\int_0^t(\|\Delta u(\cdot,\tau)\|_{L^2}^2+\|\nabla\Delta u(\cdot,\tau)\|_{L^2}^2)d\tau\\&\quad=\|\Delta u_0\|_{L^2}^2+\|\nabla u_0\|_{L^2}^2,\qquad \forall t\geqslant 0,\end{aligned} \tag{10}$$

where we have used the following fact:

$$\int_{R^2}\{u,\Delta u\}\Delta u(x,y,t)\ \ dxdy=0,\qquad \forall t\geqslant 0.$$

Putting together (9) and (10), we obtain (6).

Now taking the scalar product of $p|u-\Delta u|^{p-2}(u-\Delta u)$ (for all $2<p<\infty$) and the equation (4), and then integrating the result over R^2 for the space variable (x,y), we get

$$\begin{aligned}&\frac{d}{dt}\|u(\cdot,t)-\Delta u(\cdot,t)\|_{L^p}^p-p\lambda\int_{R^2}\Delta(u-\Delta u)\cdot|u-\Delta u|^{p-2}(u-\Delta u)\ \ dx\ \ dy\\&\quad\leqslant pk\|\nabla u(\cdot,t)\|_{L^p}\|u(\cdot,t)-\Delta u(\cdot,t)\|_{L^p}^{p-1},\quad \forall t\geqslant 0,\end{aligned} \tag{11}$$

where we have used the following fact:

$$\int_{R^2}\{u,\Delta u\}|u-\Delta u|^{p-2}(u-\Delta u)(x,y,t)\ \ dxdy=0,\qquad \forall t\geqslant 0.$$

Note that

$$\begin{aligned}\|\nabla u(\cdot,t)\|_{L^p}^p&=-(p-1)\int_{R^2}(|\partial_x u|^{p-2}u\cdot\partial_x^2 u+|\partial_y u|^{p-2}u\cdot\partial_y^2 u)\ dx\ \ dy\\&\leqslant p\|\nabla u(\cdot,t)\|_{L^p}^{p-2}\|u(\cdot,t)\|_{L^p}(\|u(\cdot,t)-\Delta u(\cdot,t)\|_{L^p}+\|u(\cdot,t)\|_{L^p}),\end{aligned} \tag{12}$$

$$\|u(\cdot,t)\|_{L^p}\leqslant\|u(\cdot,t)\|_{L^2}^{2/p}\|u(\cdot,t)\|_{L^\infty}^{(p-2)/p}\leqslant\|u(\cdot,t)\|_{L^2}+\|u(\cdot,t)\|_{L^\infty}. \tag{13}$$

Integrating by parts, we get

$$\begin{aligned}&-p\lambda\int_0^t\int_{R^2}\Delta(u-\Delta u)\cdot|u-\Delta u|^{p-2}(u-\Delta u)\ \ dx\ \ dy\ \ d\tau\\&\quad=p(p-1)\lambda\int_0^t\int_{R^2}(\nabla(u-\Delta u))^2|u-\Delta u|^{p-2}\ \ dx\ \ dy\ \ d\tau\geqslant 0.\end{aligned} \tag{14}$$

Inserting (6) and (12)–(14) into (11), for all $2<p<\infty$ we get

$$\frac{d}{dt}\|u(\cdot,t)-\Delta u(\cdot,t)\|_{L^p}\leqslant Ck\sqrt{p}(1+\|u(\cdot,t)-\Delta u(\cdot,t)\|_{L^p}^{1/2}),\quad \forall t\geqslant 0, \tag{15}$$

where constant C is independent of λ and p.

In the case $k=0$, using (6), (13), and (15) and the following fact,

$$\begin{aligned}\|u_0-\Delta u_0\|_{L^p}\leqslant\|u_0\|_{L^p}+\|\Delta u_0\|_{L^p}&\leqslant C\|u_0\|_{H^1}+\|\Delta u_0\|_{L^2}^{2/p}\|\Delta u_0\|_{L^\infty}^{(p-2)/p}\\&\leqslant C\|u_0\|_{H^1}+\|\Delta u_0\|_{L^2}+\|\Delta u_0\|_{L^\infty},\end{aligned} \tag{16}$$

we get

$$\|\Delta u(\cdot,t)\|_{L^p(R^2)}\leqslant C,\qquad \forall t\geqslant 0,\quad 2\leqslant p<\infty, \tag{17}$$

where constant C is independent of λ and p. Fixing $N>0$, one has

$$\|\Delta u(\cdot,t)\|_{L^p(B_N)}\leqslant\|\Delta u(\cdot,t)\|_{L^p(R^2)}\leqslant C,\qquad \forall t\geqslant 0,\quad 2\leqslant p<\infty,$$

where constant C is independent of N, λ and p; $B_N=\{(x,y)\in R^2|\ \ x^2+y^2\leqslant N^2\}$. Let $p\to\infty$. We get

$$\|\Delta u(\cdot,t)\|_{L^\infty(B_N)}=\lim_{p\to\infty}\|\Delta u(\cdot,t)\|_{L^p(B_N)}\leqslant C,\qquad \forall t\geqslant 0,$$

where constant C is independent of N and λ. Let $N\to\infty$. We have

$$\|\Delta u(\cdot,t)\|_{L^\infty(R^2)}=\lim_{N\to\infty}\|\Delta u(\cdot,t)\|_{L^\infty(B_N)}\leqslant C,\qquad \forall t\geqslant 0. \tag{18}$$

Estimate (8) is proved.

In the case $k\neq 0$, using (15) and (16), for all $2<p<\infty$ one has

$$\|u(\cdot,t)-\Delta u(\cdot,t)\|_{L^p}\leqslant C(1+pt^2),\qquad \forall t\geqslant 0, \tag{19}$$

where constant C is independent of λ and p. Putting together (6), (13), and (19), we get estimate (7).

This completes the proof of Lemma 1.

Lemma 2: Let initial data $u_0\in H^m(R^2)\cap W_\infty^2(R^2)$ $(m\geqslant 3)$ and u be the smooth solution of problem (4) and (5). Then for all time $0<T<\infty$ one has the following estimates:

$$\|\nabla\Delta u(\cdot,t)\|_{L^2}^2+\lambda\int_0^t\|\Delta^2 u(\cdot,s)\|_{L^2}^2 ds\leqslant C(T,\|u_0\|_{H^3},\|u_0\|_{W_\infty^2}),\qquad \forall t\in[0,T], \tag{20}$$

where constant $C(\cdots)$ is independent of λ in the case $k=0$.

Proof: Differentiating Eq. (4) with respect to (x,y), we get

$$\partial_t\nabla(u-\Delta u)+k\partial_y\nabla u+\{u,\nabla\Delta u\}+\{\nabla u,\Delta u\}-\lambda\nabla\Delta(u-\Delta u)=0. \tag{21}$$

Taking the scalar product of $-2\nabla\Delta u$ and the equation (21), and then integrating the result over R^2 for the space variable (x,y), we have

$$\begin{aligned}&\frac{d}{dt}(\|\Delta u(\cdot,t)\|_{L^2}^2+\|\nabla\Delta u(\cdot,t)\|_{L^2}^2)+2\lambda(\|\nabla\Delta u(\cdot,t)\|_{L^2}^2+\|\Delta^2 u(\cdot,t)\|_{L^2}^2)\\&\quad\leqslant 2\|\partial^2 u(\cdot,t)\|_{L^\infty}\|\nabla\Delta u(\cdot,t)\|_{L^2}^2,\end{aligned} \tag{22}$$

where ∂^2 denotes the differential operator of the second order: $\partial^\alpha=\partial_x^{\alpha_1}\partial_y^{\alpha_2}$, $\alpha_1+\alpha_2=2$, and we have used the following facts:

$$\int_{R^2}\partial_y\nabla u\cdot\nabla\Delta u \quad dx \quad dy=0, \qquad \int_{R^2}\{u,\nabla\Delta u\}\cdot\nabla\Delta u \quad dx \quad dy=0, \quad \forall t\geqslant 0.$$

In the case $k=0$, inserting estimate (8) into (22) and employing Gronwall's inequality, we get (20), where the constant C is independent of λ.

In the case $k\neq 0$, applying estimate (6), Gagliardo–Nirenberg's inequality and Hölder's inequality, one has that

$$\begin{aligned}
&\|\partial^2 u(\cdot,t)\|_{L^\infty}\leqslant C\|\Delta u(\cdot,t)\|_{L^2}^{1/2}\|\Delta^2 u(\cdot,t)\|_{L^2}^{1/2},\\
&\|\nabla\Delta u(\cdot,t)\|_{L^2}\leqslant C\|\Delta u(\cdot,t)\|_{L^2}^{1/2}\|\Delta^2 u(\cdot,t)\|_{L^2}^{1/2},\\
&\|\partial^2 u(\cdot,t)\|_{L^\infty}\|\nabla\Delta u(\cdot,t)\|_{L^2}^2\leqslant C\|\Delta u(\cdot,t)\|_{L^2}^{3/2}\|\Delta^2 u(\cdot,t)\|_{L^2}^{3/2}\\
&\qquad\leqslant\lambda\|\Delta^2 u(\cdot,t)\|_{L^2}^2+C(\lambda).
\end{aligned}\tag{23}$$

Putting together (22) and (23), we obtain (20).

The proof of this lemma is completed.

Lemma 3: Let initial data $u_0\in H^m(R^2)\cap W_\infty^2(R^2)$ $(m\geqslant 2)$ and u be the smooth solution of problem (4) and (5). One then has the following estimates:

$$\|u(\cdot,t)\|_{H^m}^2+\lambda\int_0^t\|u(\cdot,\tau)\|_{H^{m+1}}^2 d\tau\leqslant C(T,\|u_0\|_{H^m}), \qquad \forall T>0, \quad t\in[0,T], \tag{24}$$

where constant $C(\cdots)$ is independent of λ in the case $k=0$.

Proof: This lemma is proved by mathematical induction as follows. For the case of $2\leqslant m\leqslant 3$, estimates (24) have been proved in Lemmas 1 and 2. Assume that (24) is valid for the case $m=M\geqslant 3$.

Differentiating Eq. (4) with respect to (x,y), we get

$$\partial_t\partial^\alpha(u-\Delta u)+k\partial_y\partial^\alpha u+\sum_{\beta_1+\beta_2=\alpha}\{\partial^{\beta_1}u,\partial^{\beta_2}\Delta u\}-\lambda\partial^\alpha\Delta(u-\Delta u)=0, \tag{25}$$

where α, β_1 and β_2 are multi-index and ∂^α is a differential operator of the $(M-1)$th order. Taking the scalar product of $-2\partial^\alpha\Delta u$ and the equation (25), and then integrating the result over R^2 for the space variable (x,y), we have

$$\begin{aligned}
&\frac{d}{dt}(\|\partial^\alpha\nabla u(\cdot,t)\|_{L^2}^2+\|\partial^\alpha\Delta u(\cdot,t)\|_{L^2}^2)+2\lambda(\|\partial^\alpha\Delta u(\cdot,t)\|_{L^2}^2+\|\partial^\alpha\nabla\Delta u(\cdot,t)\|_{L^2}^2)\\
&\leqslant 2\sum_{\beta_1+\beta_2=\alpha,\ 1\leqslant|\beta_1|\leqslant M-2}\|\nabla\partial^{\beta_1}u(\cdot,t)\|_{L^\infty}\|\nabla\partial^{\beta_2}\Delta u(\cdot,t)\|_{L^2}\|\partial^\alpha\Delta u(\cdot,t)\|_{L^2}\\
&\quad+2\|\nabla\partial^\alpha u(\cdot,t)\|_{L^4}\|\nabla\Delta u(\cdot,t)\|_{L^4}\|\partial^\alpha\Delta u(\cdot,t)\|_{L^2}\\
&\leqslant C(1+\|u(\cdot,t)\|_{H^{M+1}}^2),
\end{aligned}\tag{26}$$

where we have used the induction assumption and the following facts:

$$\int_{R^2}\partial_y\partial^\alpha u\cdot\partial^\alpha\Delta u \quad dx \quad dy=0, \qquad \int_{R^2}\{u,\partial^\alpha\Delta u\}\cdot\partial^\alpha\Delta u \quad dx \quad dy=0, \quad \forall t\geqslant 0,$$

$$\|\nabla\partial^{\beta_1}u(\cdot,t)\|_{L^\infty}\leqslant C\|\nabla\partial^{\beta_1}u(\cdot,t)\|_{H^2},$$

$$\|\nabla\partial^{\alpha}u(\cdot,t)\|_{L^4}\leqslant C\|\nabla\partial^{\alpha}u(\cdot,t)\|_{L^2}^{1/2}\|\nabla\partial^{\alpha}u(\cdot,t)\|_{H^1}^{1/2},$$

$$\|\nabla\Delta u(\cdot,t)\|_{L^4}\leqslant C\|\nabla\Delta u(\cdot,t)\|_{L^2}^{1-1/2(M-2)}\|\nabla\Delta u(\cdot,t)\|_{H^{M-2}}^{1/2(M-2)}.$$

Summing over $|\alpha|=M-1$ in (26) and applying Gronwall's inequality, we have

$$\|u(\cdot,t)\|_{H^{M+1}}^2+\lambda\int_0^t\|u(\cdot,\tau)\|_{H^{M+2}}^2d\tau\leqslant C(T,\|u_0\|_{H^{M+1}}),\qquad \forall T>0,\quad t\in[0,T],\tag{27}$$

where constant $C(\cdots)$ is independent of λ in the case $k=0$.

By induction, this lemma is proved.

III. SOLUTION OF THE PERTURBED HASEGAWA–MIMA EQUATION

It is easy to check that $e^{t\lambda\Delta}$ is the analytic semigroup generated by $\lambda\Delta$ in $L^p(R^2)$ $(2\leqslant p<\infty)$. In what follows, we apply the abstract semigroup theory and its methods to establish the existence and uniqueness of the local solution (in time t) for the problem (4) and (5). Thanks to the estimate (24), we can extend the local solution to the global solution.

Lemma 4: Let $u_0\in H^m(R^2)$, $m\geqslant 4$. Then for all time $0<T<\infty$ there exists a unique solution u of problem (4) and (5) such that $u\in C([0,T];H^m(R^2))$. Moreover, if $k=0$, then we have

$$\sup_{0\leqslant t\leqslant T}\|u(\cdot,t)\|_{H^m}\leqslant C,\tag{28}$$

where constant C is independent of λ.

Proof: Let $w=u-\Delta u$. Then $u=(1-\Delta)^{-1}w$ and Eqs. (4) and (5) are rewritten

$$\partial_t w+k\partial_y(1-\Delta)^{-1}w+\{(1-\Delta)^{-1}w,w\}-\lambda\Delta w=0,\tag{29}$$

$$w(x,y,t)|_{t=0}=w_0(x,y)=u_0-\Delta u_0.\tag{30}$$

As is well known, $\lambda\Delta$ generates a analytic semigroup $S(t)=e^{t\lambda\Delta}$ in $L^2(R^2)$. Let

$$Y=\{w|w\in C([0,T];H^m(R^2)),\quad t^\alpha w(t)\in C^\alpha((0,T];H^m(R^2)),\quad w(0)=w_0,$$

$$\|w\|_{C([0,T];H^m)}+[t^\alpha w]_{C^\alpha((0,T];H^m)}\leqslant\rho,\quad 0<\alpha<1,\quad m\geqslant 2\}.$$

Define a nonlinear operator Γ on Y, by $\Gamma(w)=v$, where v is the solution of the following problem:

$$\partial_t v+k\partial_y(1-\Delta)^{-1}w+\{(1-\Delta)^{-1}w,w\}-\lambda\Delta v=0,\qquad w(0)=w_0.$$

Note that $\xi/(1+|\xi|^2)$ is a multiplier for $L^p(R^2)$ $(1<p<\infty)$. We have

$$\|\nabla(1-\Delta)^{-1}w(\cdot,t)\|_{L^p}\leqslant C\|w(\cdot,t)\|_{L^p},\qquad \forall p>1.$$

By Theorem 4.3.5 of Ref. 9 (pp. 137–139), for every $w\in Y$, $\Gamma(w)\in C([0,T];H^m(R^2))$ and $t^\alpha\Gamma(w)\in C^\alpha((0,T];H^m(R^2))$. Then, repeating the same procedure as that produced in the proof of Theorem 8.1.1 of Ref. 9 (pp. 290–294), there exists $T>0$ and $\rho>0$ such that $\Gamma: Y\to Y$ is a contraction, i.e., there exists $T>0$ and a unique local solution u of problem (4) and (5) such that $u\in C([0,T];H^m(R^2))$ $(m\geqslant 4)$. Employing the estimates of Lemma 3, we can extend this local solution into a unique global solution such that this global solution satisfies the estimate (28).

This completes the proof of the lemma.

Lemma 5: Let $u_0 \in H^2(R^2)$. *Then for all time* $0<T<\infty$ *there exists a solution* u *of problem (4) and (5) such that* $u \in C([0,T];H^2(R^2))$ *and*

$$\sup_{0\leqslant t\leqslant T} \|u(\cdot,t)\|_{H^2} \leqslant C. \tag{31}$$

Moreover, if $u_0 \in H^2(R^2)\cap W^2_\infty(R^2)$, *then the solution* u *of (4) and (5) is unique and for all* $2<p<\infty$ *we have*

$$\sup_{0\leqslant t\leqslant T} \|u(\cdot,t)\|_{W^2_p} \leqslant C(1+pT^2), \tag{32}$$

$$\sup_{0\leqslant t\leqslant T} \|u(\cdot,t)\|_{W^2_\infty} \leqslant C \qquad \textit{only for the case of } k=0. \tag{33}$$

Here the above constants C *are independent of* T, p *and* λ.

Proof: Let $u_{0\epsilon}=\eta_\epsilon * u_0$, $\epsilon>0$, $\eta_\epsilon(x,y)=(1/\epsilon^2)\,\eta_\epsilon(x/\epsilon, y/\epsilon)$, where η is the standard mollifier. Then $u_{0\epsilon}\in H^4(R^2)$, $\|u_{0\epsilon}\|_{L^\infty}\leqslant\|u_0\|_{L^\infty}$ and $\|u_{0\epsilon}-u_0\|_{H^2}\to 0$ as $\epsilon\to 0$.

Consider Eq. (4) with initial datum

$$u(x,y,0)=u_{0\epsilon}(x,y). \tag{34}$$

Applying the results of Lemma 4, for all time $0<T<\infty$ there exists a unique solution u_ϵ of the problem (4) and (34) such that $u_\epsilon\in C([0,T];H^4(R^2))$. Thanks to the estimates (6)–(8), let $\epsilon\to 0$. We obtain that there exists a global solution u for the problem (4) and (5) such that $u\in C([0,T];H^2(R^2))$ and $\sup_{0\leqslant t\leqslant T}\|u(\cdot,t)\|_{H^2}\leqslant C$; moreover, if $u_0\in H^2(R^2)\cap W^2_\infty(R^2)$, then for all $2<p<\infty$ we have

$$\sup_{0\leqslant t\leqslant T} \|u(\cdot,t)\|_{W^2_p} \leqslant C(1+pT^2),$$

$$\sup_{0\leqslant t\leqslant T} \|u(\cdot,t)\|_{W^2_\infty} \leqslant C \qquad \text{only for the case of } k=0,$$

where constants C are independent of λ.

Assume that there are two solutions u and v of problem (4) and (5) such that

$$u,v\in C([0,T];W^2_p(R^2)), \qquad \forall p\in[2,\infty), \quad 0<T<\infty,$$

$$\sup_{0\leqslant t\leqslant T} \max\{\|u(\cdot,t)\|_{H^2},\|v(\cdot,t)\|_{H^2}\}\leqslant C, \tag{35}$$

$$\sup_{0\leqslant t\leqslant T} \max\{\|u(\cdot,t)\|_{W^2_p},\|v(\cdot,t)\|_{W^2_p}\}\leqslant C(1+pT^2), \qquad \forall p>2, \tag{36}$$

where constants C are independent of λ. Let $w=u-v$. Then w is the solution of the following problem:

$$\partial_t(w-\Delta w)+k\partial_y w+\{u,\Delta w\}+\{w,\Delta v\}-\lambda\Delta(w-\Delta w)=0, \tag{37}$$

$$w(x,y,0)=0. \tag{38}$$

Taking the scalar product of $2w$ and the equation (37), and then integrating the result over R^2 for the space variable (x,y), we have

$$\frac{d}{dt}\|w(\cdot,t)\|_{H^1}^2+\lambda\int_{R^2}|(|\nabla w|^2+|\Delta w|^2)(x,y,t)\quad dx\quad dy$$
$$\leqslant C(1+pt^2)^{1+2/p}\|\nabla w(\cdot,t)\|_{L^2}^{2-2/p},\qquad \forall p>2,\quad t\geqslant 0, \tag{39}$$

where we have used estimate (35) and (36) and the following facts:

$$\int_{R^2}\{w,\Delta v\}w\quad dx\quad dy=0,$$

$$\int_{R^2}\{u,\Delta w\}w\quad dx\quad dy=\int_{R^2}((u_{xx}-u_{yy})w_xw_y+u_{xy}(w_yw_y-w_xw_x))\quad dx\quad dy$$
$$\leqslant\|\Delta u(\cdot,t)\|_{L^p}\|\nabla w(\cdot,t)\|_{L^{2p/(p-2)}}\|\nabla w(\cdot,t)\|_{L^2}$$
$$\leqslant C(1+pt^2)^{1+2/p}\|\nabla w(\cdot,t)\|_{L^2}^{2-2/p},\qquad \forall p>2.$$

From (39), we get

$$\|w(\cdot,t)\|_{H^1}^2\leqslant(Cp^2(1+t^2)^2t)^p,\qquad \forall p>2,\quad t\geqslant 0, \tag{40}$$

where constant C is independent of time t, p and λ. Therefore, there exists a $T>0$ such that $C(1+T^2)^2T\leqslant\frac{1}{2}$. Let $p\to\infty$. One then has

$$\|w(\cdot,t)\|_{H^1}^2=0,\qquad \forall t\in[0,T]. \tag{41}$$

This completes the proof of uniqueness of solution for problem (4) and (5).

Repeating the same procedure as that produced in the proof of Lemma 5, we can prove the following lemma.

Lemma 6: Let $u_0\in H^3(R^2)\cap W_\infty^2(R^2)$. Then for all time $0<T<\infty$ there is a unique solution u of problem (4) and (5) such that $u\in C([0,T];H^3(R^2))$. Moreover, if $k=0$, then

$$\sup_{0\leqslant t\leqslant T}\|u(\cdot,t)\|_{H^3}+\sup_{0\leqslant t\leqslant T}\|u(\cdot,t)\|_{W_\infty^2}\leqslant C, \tag{42}$$

where constant C is independent of λ.

IV. SOLUTION OF THE HASEGAWA–MIMA EQUATION

The proof of Theorem 1: Using Lemmas 4 and 6, let $\lambda\to 0$. We then have that there exists a global solution u of the problem (1) and (2) such that $u\in L^\infty([0,T];H^m(R^2))$. Employing (3), we get $u_t\in L^\infty([0,T];H^{m-1}(R^2))$. Repeating the same procedure as that produced in the proof of Lemma 5, we can obtain that the regular solution of problem (1) and (2) is unique. Theorem 1 is proved.

The proof of Theorem 2: Using Lemma 5, let $\lambda\to 0$. We then have that there exists a global solution u of the problem (1) and (2) such that $u\in L^\infty([0,T];H^2(R^2))$. Employing (3), we get $u_t\in L^\infty([0,T];H^1(R^2))$. If $u_0\in H^2(R^2)\cap W_\infty^2(R^2)$, repeat the same procedure as that produced in the proof of Lemma 5. We can then obtain that the weak solution of problem (1) and (2) is unique. Theorem 2 is proved.

(Received 17 October 2003; accepted 17 December 2003)

We study eigenvalue distribution of the adjacency matrix $A^{(N,p)}$ of weighted random graphs $\Gamma=\Gamma_{N,p}$. We assume that the graphs have N vertices and the average number of edges attached to one vertex is p. To each edge of the graph e_{ij} we assign a weight given by a random variable a_{ij} with zero mathematical expectation and all moments finite. In the first part of the paper, we consider the moments of normalized eigenvalue counting function $\sigma_{N,p}$ of $A^{(N,p)}$. Assuming all moments of a finite, we obtain recurrent relations that determine the moments of the limiting measure $\sigma_p=\lim_{N\to\infty}\sigma_{N,p}$. The method developed is applied to the Laplace operator Δ_Γ closely related with $A^{(N,p)}$. Using the recurrent relations, we analyze the form of σ_p for the both of random matrix families. In the second part of the paper we consider the resolvents $G^{(A,\Delta)}(z)$ of $A^{(N,p)}$ and Δ_Γ of $\Gamma_{N,p}$ and study the functions $f_N^{(A,\Delta)}(z,u)=(1/N)\,\Sigma_{k=1}^N \exp\{-uG_{kk}^{(A,\Delta)}(z)\}$ in the limit $N\to\infty$. We derive closed equations that uniquely determine the limiting functions $f^{(A,\Delta)}(z,u)$. These equations allow us to prove the existence of the limiting σ_p for adjacency matrix and the Laplace operator under a rather weak condition that only the fourth moment of a_{ij} is finite. Besides, equations for $f^{(A,\Delta)}(z,u)$ give us the asymptotic expansions for the Stieltjes transform of the limiting σ_p with respect to z^{-k} and p^k. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1667610]

I. INTRODUCTION

The spectral theory of graphs is an actively developing field of mathematics involving a variety of methods and deep results (see Refs. 5, 6, and 11). Given a graph with N vertices, one can associate with it many different matrices, but the most studied are the adjacency matrix and the Laplacian matrix of the graph. Commonly, the set of N eigenvalues of the adjacency matrix is referred to as the spectrum of the graph. In these studies, the dimension of the matrix N is usually regarded as a fixed parameter. The spectra of infinite graphs is considered in certain particular cases of graphs having a certain regular structure (see, for example, Ref. 12).

Another large class of graphs, where the limiting transition $N\to\infty$ provides a natural approximation, is represented by random graphs.[4,13] In this branch, geometrical and topological properties of graphs are studied for a wide variety of random graph ensembles. One of the classes of the prime reference is the *binomial random graph* originating by P. Erdős (see, e.g., Ref. 13). Given a number $p_N\in(0,1)$, this family of graphs $\mathbf{G}(N,p_N)$ is defined by taking as Ω the set of all graphs on N vertices with the probability

$$P(G)=p_N^{e(G)}(1-p_N)^{\binom{N}{2}-e(G)}, \tag{1.1}$$

where $e(G)$ is the number of edges of G. Most of the random graphs studies are devoted to the cases where $p_N\to 0$ as $N\to\infty$.

[a]Author to whom all correspondence should be addressed. Electronic mail: shcherbi@flint.ilt.kharkov.ua

Intersection of these two branches of the theory of graphs contains the spectral theory of random graphs that is still poorly explored. However, a number of powerful tools can be employed here because the ensemble of random symmetric $N\times N$ adjacency matrices A_N is a particular representative of the random matrix theory, where the limiting transition $N\to\infty$ has been intensively studied during half of century since the pioneering works by E. Wigner.[22] Initiated by theoretical physics applications, the spectral theory of random matrices has revealed deep nontrivial links with many fields of mathematics.

Spectral properties of random matrices corresponding to (1.1) were examined in the limit $N\to\infty$ both in numerical and theoretical physics studies.[7–9,18,20,21] There are two major asymptotic regimes: $p_N\gg 1/N$ and $p_N=O(1/N)$ and corresponding models can be called the *dilute random matrices* and *sparse random matrices*, respectively. The first studies of spectral properties of sparse and dilute random matrices in the physical literature are related to Refs. 20, 21, and 18, where equations for the limiting density of states of sparse random matrices were derived. In Refs. 18 and 10 a number of important results on the universality of the correlation functions and the Anderson localization transition were obtained. Unfortunately, all these results were obtained with nonrigorous replica and supersymmetry methods.

On a mathematical level of rigour, the eigenvalue distribution of dilute random matrices was studied in Ref. 16. It was shown that the normalized eigenvalue counting function of

$$\frac{1}{\sqrt{Np_N}}A_{N,p_N} \tag{1.2}$$

converges in the limit $N,p_N\to\infty$ to the distribution of explicit form known as the semicircle or Wigner law.[22] The moments of this distribution verify the well-known recurrent relation for the Catalan numbers and can be found explicitly. Therefore, one can say that the dilute random matrices represent explicitly solvable model (see also Refs. 20 and 21).

In the series of papers in Refs. 2–4 and simultaneously in Ref. 15, the adjacency matrix and the Laplace matrix of random graphs (1.1) with $p_N=pN$ were studied. It was shown that this sparse random matrix ensemble can also be viewed as the explicitly solvable model. In particular, one can derive recurrent relations that determine the moments of the limiting eigenvalue distribution of $A_{N,pN}$, $N\to\infty$, depending on given value of p.

In the present paper we generalize the results of Refs. 3 and 15 to the case of weighted random graphs. We study also the resolvent of the adjacency matrix and the Laplace operator of large weighted random graphs and derive rigorously equations for the Stieltjes transform $g(z)$ of the limiting eigenvalue distribution, obtained initially in Refs. 20, 21, and 18 by using the replica and the supersymmetry approaches. We stress that our approach allows us to prove the existence of the limiting eigenvalue distribution under rather weak conditions, when only the fourth moment of a_{ij} is required to be bounded. Using our results it is not difficult to obtain the asymptotic expansions for $g(z)$ with respect to z^{-k}. Since it is well known that the coefficients of this expansion are the moments of the limiting IDS, we rediscover the recurrent formulas for the moments. Besides, constructing the asymptotic expansion of $g(z)$ with respect to p^k, it is easy to show that this expansion is convergent for $p<1$. Since in the case $a_{ij}=1$ the coefficients of this expansion are the rational functions on z, we can conclude that the limiting spectrum is pure point and consists of the spectra of finite blocks only.

II. MAIN RESULTS

Let $\mathcal{V}_N$ denotes the set of N vertices $v_1,v_2,\ldots,v_N$. We define the set $\mathcal{F}_{\mathcal{V}_N}=\mathcal{V}_N\to\mathbf{R}$ of all real functions $f=(f(v_1),f(v_2),\ldots,f(v_N))$. Let us assume that each pair of vertices of $\mathcal{V}_N$ is either connected by one nonoriented edge or not connected. Let us denote by E_N the set of the edges and by $\Gamma_N=(\mathcal{V}_N,E_N)$ the corresponding graph.

Assume that each edge $e=(v_i,v_j)\in E_N$ is assigned by the real weight $\xi(e)$. Then one can define a linear operator $\Delta_\Gamma^{(\xi)}:\mathcal{F}_{\mathcal{V}_N}\to\mathcal{F}_{\mathcal{V}_N}$ by the relation

$$\Delta_\Gamma^{(\xi)}(f(v_i))=\sum_{j:v_j\sim v_i}\xi(v_i,v_j)\cdot[f(v_i)-f(v_j)], \tag{2.1}$$

where the sum goes over all vertices v_j adjacent to given v_i. One can consider the operator $\Delta_\Gamma^{(\xi)}$ as a generalization of the discrete analog of the Laplace operator on the graph Γ_N.

Clearly, $\Delta_\Gamma^{(\xi)}$ is a real symmetric $N\times N$ matrix that can be represented in the form

$$\Delta_\Gamma^{(\xi)}=B^{(N,\xi)}-A^{(N,\xi)},$$

where $A^{(N,\xi)}$ is a weighted adjacency matrix of Γ_N,

$$A_{ij}^{(N,\xi)}=\begin{cases}\xi(v_i,v_j), & \text{if } v_i\sim v_j,\\ 0, & \text{if } v_i\not\sim v_j,\end{cases} \tag{2.2}$$

and $B^{(N,\xi)}$ is a diagonal matrix

$$B_{ii}^{(N,\xi)}=\sum_{j:v_j\sim v_i}\xi(v_i,v_j).$$

Note that $A_{ii}^{(N,\xi)}=0$ and

$$\Delta_\Gamma^{(\xi)}=\mathrm{diag}[(MA^{(N,\xi)})]-A^{(N,\xi)}, \tag{2.3}$$

where

$$M_{ij}=1-\delta_{ij}=\begin{cases}0, & \text{if } i=j,\\ 1, & \text{if } i\neq j.\end{cases}$$

The set of eigenvalues $\lambda_1\leqslant\cdots\leqslant\lambda_N$ of $A^{(N,\xi)}$ is referred to as the spectrum of the graph Γ.

With these definitions in hand, we can introduce the randomly weighted adjacency matrix of random binomial graphs. In this case the weights ξ are represented by the following family of random variables. Let $\Xi=\{a_{ij},\ \ i\leqslant j,\ \ i,j\in\mathbf{N}\}$ be the set of jointly independent identically distributed (i.i.d.) random variables defined on the same probability space and possessing the moments

$$\mathbf{E}a_{ij}^k=X_k<\infty\quad\forall\ \ i,j,k\in\mathbf{N}, \tag{2.4}$$

where $\mathbf{E}$ denotes the mathematical expectation corresponding to Ξ. We set $a_{ji}=a_{ij}$ for $i\leqslant j$.

Given $0<p\leqslant N$, let us define the family $D_N^{(p)}=\{d_{ij}^{(N,p)},\ \ i\leqslant j,\ \ i,j\in\overline{1,\ N}\}$ of jointly independent random variables

$$d_{ij}^{(N,p)}=\begin{cases}\dfrac{1}{\sqrt{p}}, & \text{with probability } p/N,\\ 0, & \text{with probability } 1-p/N.\end{cases} \tag{2.5}$$

We set $d_{ji}=d_{ij}$ and assume that $\Lambda_N^{(p)}$ is independent of Ξ.

Now one can consider the real symmetric matrix $A^{(N,p)}(\omega)$,

$$[A^{(N,p)}]_{ij}=a_{ij}d_{ij}^{(N,p)}, \tag{2.6}$$

that has N real eigenvalues $\lambda_1^{(N,p)}\leqslant\lambda_2^{(N,p)}\leqslant\cdots\leqslant\lambda_N^{(N,p)}$.

The normalized eigenvalue counting function [or integrated density of states (IDS)] of A is determined by the formula

$$\sigma(\lambda;A^{(N,p)})=\frac{\sharp\{j:\lambda_j^{(N,p)}<\lambda\}}{N}.$$

Similarly we define $\sigma(\lambda;\Delta_\Gamma^{(\xi)})$.

In this paper we study the normalized eigenvalue counting functions by two complementary approaches: the moments and the resolvent techniques. Corresponding results are represented in the following two subsections.

A. Moment relations approach

The first group of results concerns the averaged moments

$$M_k^{(N,p)}=\mathbf{E}\left\{\int \lambda^k d\sigma(\lambda;A^{(N,p)})\right\}.$$

Theorem 1: *Assuming conditions (2.4), there exist limits*

$$\lim_{N\to\infty} M_s^{(N,p)}=\begin{cases} m_k^{(p)}=\sum_{i=0}^{k} S(k,i), & if\ \ s=2k,\\ 0, & if\ \ s=2k-1,\end{cases} \tag{2.7}$$

where numbers $\mathrm{S}(k,i)$ *are determined by the system of recurrent relations*

$$\mathrm{S}(l,r)=\sum_{f=1}^{r}\binom{r-1}{f-1}\cdot\frac{X_{2f}}{p^{f-1}}\cdot\sum_{u=0}^{l-r}\mathrm{S}(l-u-f,r-f)\cdot\sum_{v=0}^{u}\binom{f+v-1}{f-1}\cdot\mathrm{S}(u,v) \tag{2.8}$$

with the initial condition $S(l,0)=\delta_{l,0}$.

The next theorem deals with the moments

$$L_s^{(N,p)}=\mathbf{E}\left\{\int \lambda^s d\sigma(\lambda;\Delta_\Gamma)\right\}.$$

Theorem 2: *Assume that (2.4) holds. Then, given* $s\in\mathbf{N}$, *there exists the limit*

$$\lim_{N\to\infty} L_s^{(N,p)}=l_s^{(p)}=\sum_{i=0}^{s}\hat{\mathrm{S}}(s,i), \tag{2.9}$$

where numbers $\hat{\mathrm{S}}(s,i)$ *are determined by the system of recurrent relations*

$$\hat{\mathrm{S}}(l,r_1)=\sum_{g_1=1}^{r_1}\binom{r_1-1}{g_1-1}\cdot\left(\hat{\mathrm{S}}(l-g_1,r_1-g_1)\cdot\frac{X_{g_1}}{p^{g_1/2-1}}+\sum_{d=r_1-g_1}^{l-r_1}\hat{\mathrm{S}}(d,r_1-g_1)\cdot\sum_{g_2=1}^{l-d-g_1}\binom{g_1+g_2-1}{g_1-1}\right.$$
$$\left.\cdot\frac{X_{g_1+g_2}}{p^{(g_1+g_2)/2-1}}\sum_{r_2=1}^{l-d-g_1-g_2}\binom{r_2+g_2-1}{g_2-1}\cdot\hat{\mathrm{S}}(l-d-g_1-g_2,r_2)\right) \tag{2.10}$$

with the initial condition

$$\hat{\mathrm{S}}(l,0)=\delta_{l,0}.$$

We discuss these results later. Let us only note that if $a_{ij}\equiv 1$ and $p=1$, then $A^{(N,1)}$ becomes exactly the adjacency matrix of Γ and $\Delta_\Gamma^{(a)}$ takes the form of the Laplace operator on the graph. In this case formula (2.8) is reduced to

$$\mathrm{S}(l,r)=\sum_{f=1}^{r}\binom{r-1}{f-1}\cdot\sum_{u=0}^{l-r}\mathrm{S}(l-u-f,r-f)\cdot\sum_{v=0}^{u}\binom{f+v-1}{f-1}\cdot\mathrm{S}(u,v)\,. \tag{2.11}$$

This system of recurrent relations is obtained for the first time in Ref. 15. It is simpler than that derived in Ref. 2 to determine $m_k^{(1)}$ in (2.7). The difference is that our system (2.8) has one variable of summation less than the system of Ref. 2. We explain this difference at the end of Sec. IV.

In the case $a_{ij}\equiv 1$ and $p=1$ formulas (2.10) reduce to

$$\hat{\mathrm{S}}(l,r_1)=\sum_{g_1=1}^{r_1}\binom{r_1-1}{g_1-1}\cdot\Bigg(\hat{\mathrm{S}}(l-g_1,r_1-g_1)+\sum_{d=r_1-g_1}^{l-r_1}\hat{\mathrm{S}}(d,r_1-g_1)\cdot\sum_{g_2=1}^{l-d-g_1}\binom{g_1+g_2-1}{g_1-1}\cdot\sum_{r_2=1}^{l-d-g_1-g_2}\binom{r_2+g_2-1}{g_2-1}\cdot\hat{\mathrm{S}}(l-d-g_1-g_2,r_2)\Bigg).$$

B. Resolvent approach

The resolvent approach is a powerful tool of the spectral theory in general and the spectral theory of random matrices also. In particular, it allows us to simplify and generalize the pioneer method of Wigner[22] (based on the analysis of the moments of σ) used to study the IDS of the ensemble with independent Gaussian entries. The resolvent approach produces also a lot of new results (see, e.g., Refs. 16 and 19, which are review papers, and references therein). It is well known that the trace of the resolvent is the Stiltjes transform $g_N(z)$ of the normalized counting function of the matrix. Since the Stiltjes transform uniquely determines the measure, the proof of the existence of the limiting IDS is equivalent to the proof of the existence of the limit $\lim_{N\to\infty}g_N(z)=g(z)$. Besides, the equations for $g(z)$ give complete information about the limiting IDS.

For any z: $\Re z>0$ consider the function $f_N(u,z):\mathbf{R}_+\to\mathbf{C}$:

$$f_N(u,z)=\frac{1}{N}\sum_{k=1}^{N}e^{-ua_k^2G_{kk}^{(N,p)}(z)},\quad G_{kk}^{(N,p)}(z)=(z-iA^{(N,p)})_{kk}^{-1}, \tag{2.12}$$

where $\{a_i\}_{i=1}^{\infty}$ is a family of i.i.d. random variables which do not depend on $\{a_{i,j}\}_{i<j}^{\infty}$ and have the same probability distribution as $a_{1,2}$.

Theorem 3: *Assume that* $\mu(a)=\mathbf{E}\{\theta(a-a_{i,j})\}$, *the probability distribution of* $a_{i,j}$, *possesses the property*

$$\int a^4d\mu(a)=X_4<\infty. \tag{2.13}$$

Then (i) the variance of the function $f_N(u,z)$ *defined by (2.12) vanishes in the limit* $N\to\infty$:

$$\lim_{N\to\infty}\mathbf{E}\{|f_N(u,z)-\mathbf{E}\{f_N(u,z)\}|^2\}=0; \tag{2.14}$$

(ii) there exists the limit

$$\lim_{N\to\infty}\mathbf{E}\{f_N(u,z)\}=f(u,z); \tag{2.15}$$

and (iii) if we consider the class $\mathcal{C}$ *of functions which are analytic with respect to* z: $\Re z>0$ *and for any fixed* z: $\Re z>0$ *possessing the norm*

$$\|f(u,z)\| = \max_{u>0} \frac{|f(u,z)|}{\sqrt{1+u}}, \tag{2.16}$$

then the limiting function is the unique solution in $\mathcal{C}$ of the functional equation

$$f(u,z) = 1 - u^{1/2} e^{-p} \int |a| d\mu(a) \int_0^\infty dv \, \frac{\mathcal{J}_1(2|a|\sqrt{uv})}{\sqrt{v}} \exp\{-zv + pf(v/p,z)\}, \tag{2.17}$$

where $\mathcal{J}_1(\zeta)$ is the Bessel function

$$\mathcal{J}_1(\zeta) = \frac{\zeta}{2} \sum_{k=0}^{\infty} \frac{(-\zeta^2/4)^k}{k!(k+1)!}. \tag{2.18}$$

It is easy to see that Eq. (2.17) coincides with that obtained in Refs. 20 and 18 by the replica trick and supersymmetry approach, respectively, by using the assumption that the solution of the problem is replica symmetric (or an equivalent assumption for the saddle point method). Our proof is rigorous and it needs no additional assumption.

One can easily see that

$$-\frac{\partial}{\partial u} f_N(u,z)\bigg|_{u=0} = \frac{X_2}{N} \sum_{k=1}^{N} \mathbf{E}\{G_{kk}^{(N,p)}(z)\} = X_2 \mathbf{E}\{i g_{N,p}(-iz)\},$$

where $g_{N,p}(z)$ is the Stieltjes transform of the normalized counting function $\sigma(\lambda, A^{(N,p)})$:

$$g_{N,p}(z) = \int \frac{d\sigma(\lambda, A^{(N,p)})}{\lambda - z}.$$

Hence, Theorem 3 implies that for any z: $\Im z \neq 0$

$$\lim_{N\to\infty} \mathbf{E}\{|g_{N,p}(z) - \mathbf{E}\{g_{N,p}(z)\}|^2\} = 0,$$

i.e., the fluctuations of $g_{N,p}(z)$ vanish in the limit $N \to \infty$. And (2.15) implies that

$$g(z) = \lim_{N\to\infty} \mathbf{E}\{g_{N,p}(z)\} = -X_2^{-1} \frac{\partial}{\partial u} f(u,z)\bigg|_{u=0}. \tag{2.19}$$

Thus, Theorem 3 states that under condition (2.13) there exists the weak limit $\sigma(\lambda, A)$ of the normalized counting measure $\sigma(\lambda, A^{(N,p)})$ and the Stieltjes transform $g_p(-iz)$ can be obtained as the first derivative of the solution of (2.17).

If the random variables $\{a_{i,j}\}$ possess the $2m$th moments, then on the basis of (2.17) it is easy to construct an asymptotic expansion of the function $f(u,z)$ in z^{-k} up to z^{-2m}:

$$f(u,z) = \sum_{k=0}^{2m} z^{-k} P_k(u) + o(z^{-2m}), \quad z \to \infty,$$

where $P_k(u)$ are some polynomials. Since for any polynomial $P(u)$

$$u^{1/2} e^{-p} \int |a| d\mu(a) \int_0^\infty dv \, \frac{\mathcal{J}_1(2|a|\sqrt{uv})}{\sqrt{v}} \exp\{-zv\} P(v) = O(z^{-1}),$$

this expansion gives us recurrent formulas which express the coefficients of $P_k(u)$ via the coefficients of $P_{k-1}(u),\dots,P_1(u)$. By (2.19) it is evident that the coefficient c_{k1} of $P_k(u)$ near u is the kth coefficient of the expansion of $g_p(-iz)$, in z^{-k}. So, $c_{k1}=(-i)^k M_k$, where M_k is the kth moment of the limiting measure $\sigma(\lambda)$.

Similarly, one can construct an expansion of $g(z)$ with respect to p^k. To this end it is more convenient to study the case when $a_{ij}=1$ and $d_{ij}=0,1$ with probabilities $1-p/N$ and p/N, respectively. It is equivalent to the change of variables $z\to zp^{-1/2}$, $u\to up^{-1/2}$. Then we get the equation

$$\tilde f(u,z)=1-u^{1/2}e^{-p}\int_0^\infty dv\,\frac{\mathcal{J}_1(2\sqrt{uv})}{\sqrt{v}}\cdot\exp\{-zv+p\tilde f(v,z)\}. \tag{2.20}$$

Let us seek the expansion of the form $\tilde f(u,z)=1+\Sigma p^k f_k(u,z)$. Since on the r.h.s. of (2.20) we have the exponent of $p(\tilde f(u,z)-1)$, it is evident that (2.20) gives us the recurrent formula for $f_k(u,z)$ and $f_k(u,z)$ is a linear combination of the functions $e^{-uR_{k,l}(z)}$ $(l=1,\dots,k!)$ with $R_{k,l}(z)$ being rational functions of z. It is easy to prove that the expansion is convergent, if $p<1$. Therefore we can differentiate it with respect to u. Hence, for the function $\tilde g(z)$ defined as in Remark 1, we get the convergent expansion $\tilde g(z)=\Sigma p^k\tilde R_k(z)$, where $\tilde R_k(z)$ are the rational functions of z. Thus, we can state that for $p<1$ the spectrum of the adjacency matrix consists only from the spectrum of finite graphs.

Now let us study the IDS of the Laplace operator of the random graph. To this end for any z: $\Re z>0$ define the function $f_N^{(\Delta)}(u,z):\mathbf{R}_+\to\mathbf{C}$:

$$f_N^{(\Delta)}(u,z)=\frac{1}{N}\sum_{k=1}^N e^{-iua_k-ua_k^2G_{kk}^{(\Delta,N,p)}(z)},\quad G_{kk}^{(\Delta,N,p)}(z)=(z-iL^{(N,p)})_{kk}^{-1}, \tag{2.21}$$

where $\{a_i\}_{i=1}^\infty$ are defined by the same way as in (2.12).

Theorem 4: *Let the distribution of $a_{j,k}$ satisfy condition (2.13). Then*

(i) fluctuations of the function $f_N^{(\Delta)}(u,z)$ defined by (2.21) vanish in the limit $N\to\infty$:

$$\lim_{N\to\infty}\mathbf{E}\{|f_N^{(\Delta)}(u,z)-\mathbf{E}\{f_N^{(\Delta)}(u,z)\}|^2\}=0, \tag{2.22}$$

(ii) there exists the limit

$$\lim_{N\to\infty}\mathbf{E}\{f_N^{(\Delta)}(u,z)\}=f^{(\Delta)}(u,z), \tag{2.23}$$

and (iii) the limiting function is the unique solution in the class $\mathcal{C}$ defined in Theorem 3 of the functional equation

$$f^{(\Delta)}(u,z)=\hat\mu(-u)-u^{1/2}e^{-p}\int|a|e^{-iau}d\mu(a)\int_0^\infty dv\,\frac{\mathcal{J}_1(2|a|\sqrt{uv})}{\sqrt{v}}\exp\{-zv+pf^{(\Delta)}(v/p,z)\}, \tag{2.24}$$

where $\hat\mu(u)=\int e^{iua}d\mu(a)$ is the Fourier transform of the measure $\mu(a)$, defined in Theorem 3.

III. MOMENTS AND TREES

In this section we give an outlook of the method of computing moments. Rigorous description is given in the next section.

To study the mathematical expectation

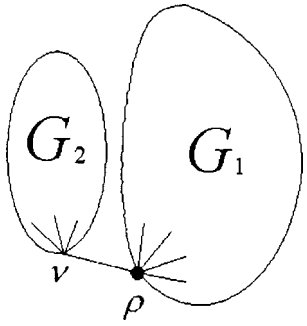

FIG. 1. Decomposition of τ_m by the first edge (ρ, ν).

$$\mathbf{E}\frac{1}{N}\mathrm{Tr}(\mathrm{A}^{(N,p)})^k=\frac{1}{N}\sum_{i_l=1}^{N}\mathbf{E}\{A_{i_1i_2}^{(N,p)}A_{i_2i_3}^{(N,p)}\cdots A_{i_ki_1}^{(N,p)}\}, \tag{3.1}$$

we give a further development to the method originated by E. Wigner (see, e.g., Ref. 22). In this approach the set of variables $I_k=\{i_1,i_2,\ldots,i_k,i_1\}$, $i_l\in\overline{1,\ N}$, is regarded as a set of trajectories (walks) W_k of k steps. Each walk provides a contribution $\mathbf{E}\{A_{i_1i_2}^{(N,p)}A_{i_2i_3}^{(N,p)}\cdots A_{i_ki_1}^{(N,p)}\}$. This mathematical expectation is nonzero only when each step (i_j,i_{j+1}) appears an even number of times in this walk W_k. The order and the number of repetitions of the steps leads to partition of the set $\{W_k\}$ of the walks into the classes of equivalence.

In the case of the Wigner ensemble $A^{(N,N)}$, the classes of equivalence were labeled by the plane rooted trees τ_l of l edges for $k=2l$. Such a tree can be run over by $2l$ steps starting and finishing at the root and passing each edge two times exactly (there and back). This path is made in the lexicographical order. This means that each time when there is a choice where to go, the most left edge is passed. The set T_l of all trees τ_l contains $C_l=(2l)!/l!(l+1)!$ elements.

The situation is more delicate in the case of dilute matrices (2.6), when p is fixed and $N\to\infty$. In Ref. 14 it is shown that the leading contribution to (3.1) in this limit is provided by the walks $I_k, k=2l$, that fall into the classes of equivalence described as follows.

We consider an element $\tau_m\in T_m, m\leqslant l$, and construct a path of $2l$ steps over this tree. Each edge is passed even number of times. If $m<l$, then there exist one or several edges passed an even number of times, which is greater than 2. This path is made in the lexicographical order that chooses the most left edge among those that are yet not passed. The number of such paths and the corresponding contribution were estimated in Ref. 14.

The case of a nonweighted adjacency matrix and corresponding Laplace operator is considered in Refs. 2 and 15, where these paths were computed exactly and recurrent relations for their number were obtained.

In the present paper we develop the method to compute these paths and corresponding contributions in the case of weighted matrices. It is similar to the method of decomposition of trees by one edge that is a well-known combinatorial tool to obtain recurrent relations needed.

Let us briefly describe our method. Consider a tree τ_m with m edges and the root ρ and denote by (ρ,ν) the edge that is passed first. If one removes this edge, one gets two subtrees G_2 and G_1 (see Fig. 1).

Denote by f the number of passages $\rho\to\nu$. Then the path over the tree τ_m is described as follows: after the first passage $\rho\to\nu$ one enters the tree G_2 and goes over its edges. Each time when one gets into the vertex ν, there is a choice of where to go: either to the leave G_u and enter the subtree G_1 by $\nu\to\rho$, or to continue the path over G_2. It is clear that the paths over the subtrees G_2 and G_1 are performed independently. More precisely, when leaving the subtree G_1, one keeps the information about its part already passed. Returning back to it by the passage $\nu\to\rho$, we continue this path with no regard to what part of the path over G_1 is performed. The

number of passages f over the edge (ρ,ν) in direction $(\overrightarrow{\rho,\nu})$ determines the weight factor $\mathbf{E}a^{2f}=X_{2f}$.

This splitting of trees (and paths) in two parts leads to the recurrent relations for the number of the paths and corresponding contributions.

Certainly this brief presentation does not reflect all of the details of the procedure. Moreover, in the rigorous proof we study the classes of walks W_k directly and the trees arise as somehow supplementary objects. We used them here as more visual illustrations than the walks.

IV. PROOF OF THEOREM 1

A. Walks and contributions

Using independence of families Ξ and $\Lambda_N^{(p)}$, we have

$$\begin{aligned}
M_k^{(N,p)} &= \int \mathbf{E}\{\lambda^k d\sigma_{A^{(N,p)}}\} \\
&= \mathbf{E}\left(\frac{1}{N}\sum_{i=1}^{N}[\lambda_i^{(N,p)}]^k\right) \\
&= \frac{1}{N}\mathbf{E}(Tr[A^{(N,p)}]^k) \\
&= \frac{1}{N}\sum_{j_1=1}^{N}\sum_{j_2=1}^{N}\cdots\sum_{j_k=1}^{N}\mathbf{E}(A_{j_1,j_2}^{(N,p)}A_{j_2,j_3}^{(N,p)}\cdots A_{j_k,j_1}^{(N,p)}) \\
&= \frac{1}{N}\sum_{j_1=1}^{N}\sum_{j_2=1}^{N}\cdots\sum_{j_k=1}^{N}\mathbf{E}(a_{j_1,j_2}a_{j_2,j_3}\cdots a_{j_k,j_1})\cdot\mathbf{E}(d_{j_1,j_2}^{(N,p)}d_{j_2,j_3}^{(N,p)}\cdots d_{j_k,j_1}^{(N,p)}). \qquad (4.1)
\end{aligned}$$

Consider $W_k^{(N)}$ the set of closed walks of k steps over the set $\overline{1,\ N}$:

$$W_k^{(N)}=\{w=(w_1,w_2,\ldots,w_k,w_{k+1}=w_1):\forall i\in\overline{1,\ k+1}\quad w_i\in\overline{1,\ N}\}.$$

For $w\in W_k^{(N)}$ let us denote $a(w)=\Pi_{i=1}^k a_{w_i,w_{i+1}}$ and $d^{(N,p)}(w)=\Pi_{i=1}^k d_{w_i,w_{i+1}}^{(N,p)}$. Then we have

$$M_k^{(N,p)}=\frac{1}{N}\sum_{w\in W_k^{(N)}}\mathbf{E}a(w)\cdot\mathbf{E}d^{(N,p)}(w). \qquad (4.2)$$

Let $w\in W_k^{(N)}$ and $f,g\in\overline{1,\ N}$. Denote by $n_w(f,g)$ the number of steps $f\to g$ and $g\to f$:

$$n_w(f,g)=\sharp\{i\in\overline{1,k}:\ (w_i=f\wedge w_{i+1}=g)\vee(w_i=g\wedge w_{i+1}=f)\}.$$

Then

$$\mathbf{E}a(w)=\prod_{f=1}^{N}\prod_{g=f}^{N}X_{n_w(f,g)}.$$

Given $w\in W_k^{(N)}$, let us define the sets $V_w=\cup_{i=1}^k\{w_i\}$ and $E_w=\cup_{i=1}^k\{(w_i,w_{i+1})\}$, where (w_i,w_{i+1}) is a nonordered pair. It is easy to see that $G_w=(V_w,E_w)$ is a simple nonoriented graph and the walk w covers the graph G_w. Let us call G_w the skeleton of walk w. We denote by $n_w(e)$ the number of passages of the edge e by the walk w in direct and inverse directions. For $(w_j,w_{j+1})=e_j\in E_w$ let us denote $a_{e_j}=a_{w_j,w_{j+1}}=a_{w_{j+1},w_j}$. Then we obtain

$$\mathbf{E}a(w)=\prod_{e\in E_w}\mathbf{E}a_e^{n_w(e)}=\prod_{e\in E_w}X_{n_w(e)}.$$

Similarly we can write

$$\mathbf{E}d^{(N,p)}(w)=\prod_{e\in E_w}\mathbf{E}([d_e^{(N,p)}]^{n_w(e)})=\prod_{e\in E_w}\frac{1}{N\cdot p^{n_w(e)/2-1}}.$$

Then, we can rewrite (4.2) in the form

$$M_k^{(N,p)}=\frac{1}{N}\sum_{w\in W_k^{(N)}}\prod_{e\in E_w}\frac{X_{n_w(e)}}{N\cdot p^{n_w(e)/2-1}}=\sum_{w\in W_k^{(N)}}\left(\frac{1}{N^{|E_w|+1}\cdot p^{k/2-|E_w|}}\prod_{e\in E_w}X_{n_w(e)}\right)=\sum_{w\in W_k^{(N)}}\theta(w), \tag{4.3}$$

where $\theta(w)$ is the contribution of the walk w to the mathematical expectation of the corresponding moment. To perform the limiting transition $N\to\infty$ it is natural to separate W_k^N into classes of equivalence. Walks $w^{(1)}$ and $w^{(2)}$ are equivalent, $w^{(1)}\sim w^{(2)}$, if and only if there exists a bijection f between the sets of vertices $V_w^{(1)}$ and $V_w^{(2)}$ such that for $i=1,2,\ldots,k$, $w_i^{(2)}=f(w_i^{(1)})$,

$$w^{(1)}\sim w^{(2)}\ \Leftrightarrow\ \exists f:\ V_w^{(1)}\overset{bij}{\to}V_w^{(2)}:\ \forall\ \ i\in\overline{1,\ k+1}\quad w_i^{(2)}=f(w_i^{(1)}).$$

Let us denote by $[w]$ the class of equivalence of walk w and by $C_k^{(N)}$ the set of such classes. It is obvious that if two walks $w^{(1)}$ and $w^{(2)}$ are equivalent, then their contributions are equal:

$$w^{(1)}\sim w^{(2)}\ \Rightarrow\theta(w^{(1)})=\theta(w^{(2)}).$$

Cardinality of the class of equivalence $[w]$ is equal the number of all mappings $f:V_w\to R_f\subset\overline{1,\ N}$ i.e., $N\cdot(N-1)\cdot\cdots\cdot(N-|V_w|+1)$. Then we can rewrite (4.3) in the form

$$\begin{aligned}M_k^{(N,p)}&=\sum_{w\in W_k^{(N)}}\left(\frac{1}{N^{|E_w|+1}\cdot p^{k/2-|E_w|}}\prod_{e\in E_w}X_{n_w(e)}\right)\\&=\sum_{[w]\in CW_k^{(N)}}\left(\frac{N\cdot(N-1)\cdot\cdots\cdot(N-|V_w|+1)}{N^{|E_w|+1}\cdot p^{k/2-|E_w|}}\prod_{e\in E_w}X_{n_w(e)}\right)\\&=\sum_{[w]\in CW_k^{(N)}}\hat{\theta}([w]).\end{aligned} \tag{4.4}$$

B. Minimal and essential walks

To consider the set $C_k^{(N)}$, it is convenient to relate a given class of equivalence $[w]$ with one particular walk from this class. More precisely, we give the rule to determine this walk that we will call the minimal walk.

Definition 1: The walk w is a minimal walk, if w_1 (the root of walk) has the number 1 and the number of each new vertex is equal to the number of all already passed vertices plus 1.

Example 1: The sequences (1,2,1,2,3,1,4,2,1,4,3,1) and (1,2,3,2,4,2,3,2,1,2,4,1,5,1) represent the minimal walks.

Let us denote the set of all minimal walks of $W_k^{(N)}$ by $MW_k^{(N)}$. It is clear that there is only one minimal walk at each class of equivalence and vice versa. Therefore we can rewrite (4.4) in the form

$$M_k^{(N,p)}=\sum_{w\in MW_k^{(N)}}\left(\frac{N\cdot(N-1)\cdot\cdots\cdot(N-|V_w|+1)}{N^{|E_w|+1}\cdot p^{k/2-|E_w|}}\prod_{e\in E_w}X_{n_w(e)}\right)=\sum_{w\in MW_k^{(N)}}\hat{\theta}([w]). \tag{4.5}$$

Walk w of $W_k^{(N)}$ has at least k vertices. Hence, $MW_k^{(1)}\subset MW_k^{(2)}\subset\cdots\subset MW_k^{(i)}\subset\cdots\subset MW_k^{(k)}=MW_k^{(k)}=\cdots$. It is natural to denote $MW_k=MW_k^{(k)}$. Then (4.5) can be written as

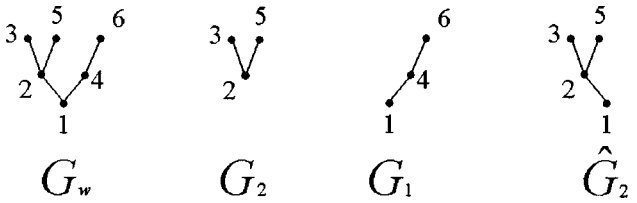

FIG. 2. Examples of G_2, G_1, $\hat{G}_2$.

$$
\begin{aligned}
m_k^{(p)} &= \lim_{N\to\infty} M_k^{(N,p)} \\
&= \lim_{N\to\infty} \sum_{w\in MW_k} \left(\frac{N\cdot(N-1)\cdot\cdots\cdot(N-|V_w|+1)}{N^{|E_w|+1}\cdot p^{k/2-|E_w|}} \prod_{e\in E_w} X_{n_w(e)} \right) \\
&= \lim_{N\to\infty} \sum_{w\in MW_k} \left(N^{|V_w|-|E_w|-1} \prod_{e\in E_w} \frac{X_{n_w(e)}}{p^{k/2-1}} \right). \qquad (4.6)
\end{aligned}
$$

The set MW_k is finite. Regarding this and (4.6), we conclude that the minimal walk w has nonvanishing contribution, if $|V_w|-|E_w|-1\geqslant 0$. But for each simple connected graph $G=(V,E)$, $|V_w|\leqslant|E_w|+1$, and the equality takes place if and only if the graph G is a tree.

Definition 2: The minimal walk w is an essential walk, if its contribution in the limit $N\to\infty$ is not zero.

Clearly, each essential walk is a minimal walk that has a tree as a skeleton and vice versa. Then the number of passages of each edge e belonging to the essential walk w is even. Hence, the limiting mathematical expectation $m_k^{(p)}$ depends only on the even moments of random variable of a. It is clear that the limiting mathematical expectation $\lim_{N\to\infty} M_{2s+1}^{(N,p)}$ is equal to zero.

C. First edge decomposition of essential walks

Let us start with necessary definitions. The first vertex $w_1=1$ of the essential walk w is called the root of the walk. We denote it by ρ. Let us denote the second vertex $w_2=2$ of the essential walk w by ν. We denote by l half of walk's length and by r the number of steps of w starting from root ρ. In Sec. III we explained that we derive the recurrent relations by splitting of the walk (or of the tree) into two parts. To describe this procedure, it is convenient to consider the set of the essential walks of length $2l$ such that they have r steps starting from the root ρ. We denote this set by $\Lambda(l,r)$. One can see that this description is exact, in the sense that it is minimal and gives complete description of the walks we need. Denote by $S(l,r)$ the sum of contributions of the walk of $\Lambda(l,r)$. Let us remove the edge $(\rho,\nu)=(1,2)$ from G_w and denote by $\hat{G}_w$ the graph obtained. The graph $\hat{G}_w$ has two components. Denote the component that contains the vertex ν by G_2 and the component containing the root ρ by G_1. Add the edge (ρ,ν) to the edge set of the tree G_2. Denote the result of this operation by $\hat{G}_2$. In Fig. 2 one can see examples of G_2, G_1, $\hat{G}_2$. Denote by u the half of the walk's length over the tree G_2 and by f the number of steps (ρ,ν) in the walk w. It is clear that the following inequalities hold for all essential walks (except the walk of length zero): $1\leqslant f\leqslant r$, $r+u\leqslant l$. Let us denote by $\Lambda_1(l,r,u,f)$ the set of the essential walks with fixed parameters l, r, u, f and by $S_1(l,r,u,f)$ the sum of contributions of the walks of $\Lambda_1(l,r,u,f)$. Denote by $\Lambda_2(l,r)$ the set of the essential walks of $\Lambda(l,r)$ such that their skeleton has only one edge attached the root ρ. Also we denote by $S_2(l,r)$ the sum of contributions of the walk of $\Lambda_2(l,r)$. Now we can formulate the first lemma of decomposition. It allows express S as a function of the S, S_2.

Lemma 1 (First decomposition lemma): The following relation holds,

$$
\mathrm{S}(l,r)=\sum_{f=1}^{r}\sum_{u=0}^{l-r}\mathrm{S}_1(l,r,u,f), \qquad (4.7)
$$

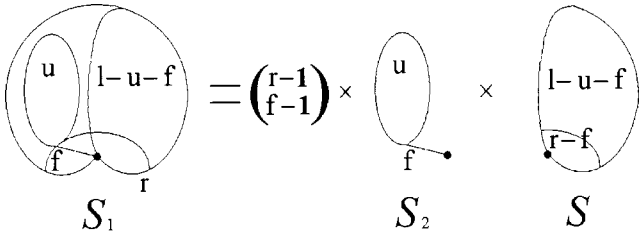

FIG. 3. Decomposition of Λ_1.

where

$$S_1(l,r,u,f)=\binom{r-1}{f-1}\cdot S_2(f+u,f)\cdot S(l-u-f,r-f). \tag{4.8}$$

Proof: The first equality is obvious. The second equality follows from the bijection

$$\Lambda_1(l,r,u,f)\overset{bij}{\to}\Lambda_2(f+u,f)\times\Lambda(l-u-f,r-f)\times\Theta_1(r,f), \tag{4.9}$$

where $\Theta_1(r,f)$ is the set of sequences of 0 and 1 of length r such that there are exactly f symbols 1 in the sequence and the first symbol is 1. Equality (4.8) is illustrated by Fig. 3.

Let us construct this mapping F. Regarding one particular essential walk w of $\Lambda_1(l,r,u,f)$, we consider the first edge e_1 of the graph G_w and separate w in two parts, the left and the right ones with respect to this edge e_1. Then we add a special code that determines the transitions from the left part to the right one and back through the root ρ. Obviously these two parts are walks, but not necessarily minimal walks. Then we minimize these walks. This decomposition is constructed by the following algorithm. We run over w and simultaneously draw the left part, the right part, and the code. If the current step belongs to G_1, we add it to the first part, otherwise we add this step to the second part. The code is constructed as follows. Each time the walk leaves the root the sequence is enlarged by one symbol. If the current step is (ρ,ν) and "0" otherwise, this symbol is "1." It is clear that the first element of the sequence is "1," the number of signs "1" is equal to f, and the full length of the sequence is r. Now we minimize the left and the right parts. Thus, we have constructed the decomposition of the essential walk w and the mapping F.

Example 2: For $w=(1,2,1,2,3,2,1,4,1,2,5,2,1,4,6,4,1,2,5,2,3,2,3,2,1,4,1)$ the left part, the right one, and the code are $(1,2,1,2,3,2,1,2,4,2,1,2,4,2,3,2,3,2,1)$, $(1,2,1,2,3,2,1,2,1)$, $(1,1,0,1,0,1,0)$, respectively.

Let us denote the left part by $(w^{(f)})$ and the right part by $(w^{(s)})$. These parts are really walks with the root ρ. For each edge e in the tree $\hat{G}_2$ the number of passages of e of the essential walk w is equal to the corresponding number of passages of e of the left part $(w^{(f)})$. Also for each edge e belonging to the tree G_1 the number of passages of e of essential walk w is equal to the corresponding number of passages of e of the right part $(w^{(s)})$. The weight of the essential walk is multiplicative with respect to edges. Then the weight of the essential walk w is equal to the product of weights of left and right parts. The walk of zero length has unit weight. Combining this with (4.9), we obtain

$$S_1(l,r,u,f)=|\Theta_1(r,f)|\cdot S_2(f+u,f)\cdot S(l-u-f,r-f). \tag{4.10}$$

Taking into account that $|\Theta_1(r,f)|=\binom{r-1}{f-1}$, we derive from (4.10) (4.8).

Now let us prove that for any given elements $w^{(f)}$ of $\Lambda_2(f+u,f)$, $w^{(s)}$ of $\Lambda(l-u-f,r-f)$, and the sequence $\theta\in\Theta_1(r,f)$, one can construct one and only one element w of $\Lambda_1(l,r,u,f)$. We do this with the following gathering algorithm. We go along either $w^{(f)}$ or $w^{(s)}$ and simultaneously draw the walk w. The switch from $w^{(f)}$ to $w^{(s)}$ and back is governed by the

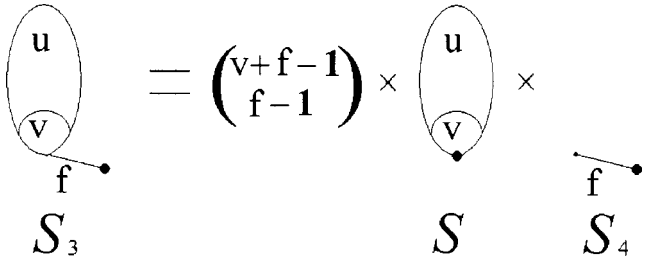

FIG. 4. Decomposition of Λ_3.

code sequence θ. In fact, this procedure is inverse to the decomposition procedure described above up to the fact that $w^{(s)}$ is minimal. This difficulty can be easily resolved, for example, by coloring vertices of $w^{(f)}$ and $w^{(s)}$ in red and blue colors, respectively. Certainly, the common root of $w^{(f)}$ and $w^{(s)}$ has only one color. To illustrate the gathering procedures we give the following example.

Example 3: For $w^{(f)}=(1,2,1,2,3,2,1,2,4,2,1,2,4,2,3,2,3,2,1)$, $w^{(s)}=(1,2,1,2,3,2,1,2,1)$, $\theta=(1,1,0,1,0,1,0)$ the gathering procedure gives $w=(1,2,1,2,3,2,1,4,1,2,5,2,1,4,6,4,1,2,5,2,3,2,3,2,1,4,1)$.

It is clear that the decomposition and gathering are injective mappings. Their domains are finite sets, and therefore the corresponding mapping (4.9) is bijective. This completes the proof of Lemma 1. ■

To formulate Lemma 2, let us give necessary definitions. We denote by v the number of steps starting from the root ρ except the step $(\widetilde{\rho,\nu})$ and by $\Lambda_3(u+f,f,v)$ the set of essential walks of $\Lambda_2(u+f,f)$ with fixed parameter v. Also we denote by $S_3(u+f,f,v)$ the sum of weights of walks of $\Lambda_3(u+f,f,v)$. Let us denote by $G_{1,2}$ the graph consisting of only one edge (ρ,ν) and by $\Lambda_4(f)$ the set of essential walks of length $2f$ such that their skeleton coincides with the graph $G_{1,2}$. It is clear that $\Lambda_4(f)$ consists of only the one walk (1,2,1,2,...,2,1) of weight X_{2f}/p^{f-1}. The previous lemma allows us to express S_2 as a function of S. The next lemma allows us to express S_2 as a function of S. Thus, two lemmas allow us to express S as a function of S.

Lemma 2 (Second decomposition lemma):

$$S_2(f+u,f)=\sum_{v=0}^{u} S_3(f+u,f,v), \tag{4.11}$$

$$S_3(f+u,f,v)=\binom{f+v-1}{f-1}\cdot\frac{X_{2f}}{p^{f-1}}\cdot S(u,v). \tag{4.12}$$

The first equality is trivial, the second one follows from the bijection

$$\Lambda_3(f+u,f,v)\overset{bij}{\to}\Lambda_4(u,v)\times\Lambda_4(f)\times\Theta_2(f+v,f), \tag{4.13}$$

where $\Theta_2(f+v,f)$ is the set of sequences of 0 and 1 of length $f+v$ such that there are exactly f symbols 1 in the sequence and the last symbol of it is 1. The proof is analogous to the proof of the first decomposition lemma. Equality (4.12) is illustrated by Fig. 4.

D. Recurrent relations for S

Combining these two decomposition lemmas and changing the order of summation, we get the recurrent relations

$$S(l,r)=\sum_{f=1}^{r}\binom{r-1}{f-1}\cdot\frac{X_{2f}}{p^{f-1}}\cdot\sum_{u=0}^{l-r} S(l-u-f,r-f)\cdot\sum_{v=0}^{u}\binom{f+v-1}{f-1}\cdot S(u,v),$$

with the initial condition $\mathrm{S}(l,0)=\delta_l$. This gives (2.8).

Using this system of recurrent relations, one can obtain information about limiting σ. For example, one can observe that the support of the limiting measure σ is unbounded even when the support of the distribution of $\{a_{i,j}\}$ is finite. This fact follows from inequality

$$M_{4k}\geqslant(\mathrm{C}\cdot k)^k, \tag{4.14}$$

where C is a constant. To explain (4.14), let us denote by Ψ the set of essential walks of length $4k$ such that the root ρ belongs to each of the edges of the skeleton and each edge is passed four times. The weight of the essential walk of Ψ is equal to $(X_4/p)^k$. The cardinality of Ψ equals $(2k-1)!!$. This implies (4.14).

Finally, let us note that using the technique developed, one can derive recurrent relations that determine the coefficients of $1/p$-expansion of $m_l^{(p)}$:

$$m_l^{(p)}=\sum_{i=0}^{l-1}\left(\sum_{r=0}^{l}\mathrm{S}(l,r,i)\right)\cdot\frac{1}{p^{\overline{i}}}. \tag{4.15}$$

Then we get

$$\begin{aligned}\mathrm{S}(l,r,i)=&\sum_{f=1}^{r}\binom{r-1}{f-1}\cdot X_{2\,f}\cdot\sum_{u=0}^{l-r}\sum_{j=0}^{(l-u-f-1)\cdot(1-\delta_{l-u-f})}\mathrm{S}(l-u-f,r-f,j)\\&\cdot\sum_{v=0}^{u}\binom{f+v-1}{f-1}\cdot\mathrm{S}(u,v,i-f-j+1)\end{aligned} \tag{4.16}$$

with the initial condition $S(l,0,i)=\delta_l\cdot\delta_i$. We do not explain the detail of this derivation. Similar formulas are obtained in Ref. 2. The difference is that in Ref. 2 matrices are not normalized by $1/\sqrt{p}$. This leads to expressions for $1/p$-terms different from our (4.16). Relations (4.12) provide more information about the properties of $m_l^{(p)}$ than relations (2.8). As the result, (4.13) are more cumbersome than (2.8).

V. LAPLACE OPERATOR

Regarding the Laplace operator, we have to modify our method. In this case the random variable Δ_{ii} is given by the sum of A_{ij} and therefore is dependent on random variables a_{ij}. Each of the nondiagonal entries differs from the corresponding entry of the weighted adjacency matrix by the sign only. Each diagonal entry of $\Delta_\Gamma^{(\xi)}$ equals the sum of all entries of the same line of the corresponding weighted adjacency matrix. Taking into account this observation one can write

$$\begin{aligned}L_s^{(N,p)}&=\mathbf{E}\left\{\int\lambda^s d\sigma(\lambda;\Delta_\Gamma)\right\}\\&=\mathbf{E}\frac{1}{N}\mathrm{Tr}[\Delta_\Gamma]^s\\&=\mathbf{E}\frac{1}{N}\mathrm{Tr}[B-A]^s\\&=\sum_{i\in\overline{1,N}^s}\sum_{b\in\{0,1\}^s}\mathbf{E}(K_{i_1i_2}^{(b_1)}\cdot K_{i_2i_3}^{(b_2)}\cdot\cdots\cdot K_{i_si_1}^{(b_s)}),\end{aligned} \tag{5.1}$$

where $K_{ij}^{(0)}=-A_{ij}$, $K_{ij}^{(1)}=B_{ij}$. Let us introduce the symbol

$$M_{ij}=1-\delta_{ij}=\begin{cases}0, & \text{if } i=j,\\ 1, & \text{if } i\neq j.\end{cases}$$

then B can be rewritten in the form

$$B_{ij}=\begin{cases}0, & \text{if } i\neq j,\\ \sum_{l=1}^{N} A_{il}\cdot M_{li}, & \text{if } i=j.\end{cases} \tag{5.2}$$

Given numbers $b_1,b_2,\ldots,b_s$, we substitute (5.2) into (5.1) and change the order of sums over l's and $\mathbf{E}\{\cdot\}$ and observe that the mathematical expectation depends on the product of A's only. The difference between this representation and that of (4.1) is that the moment $L_s^{(N,p)}$ is expressed as the sum of weights of closed walks of s steps. A step can be usual or special (double). Let us explain the nature of the special step that corresponds to the factor $A_{ij}\cdot M_{ji}$. We denote it by an arrow from i to j. To turn back to the walk we add the step $(\overrightarrow{j,i})$ which is represented by M_{ji}. This step can be regarded as the imaginary one because it does not contribute to the length of the walk and to the weight (mathematical expectation) of the walk. In the figures we denote the special step corresponding to the factor $A_{ij}\cdot M_{ji}$ by an arrow from i to j.

As before, we determine the classes of equivalence of the walks, the minimal walks, and the essential walks. In the case of Δ_Γ the essential walks are the minimal walks that have a tree as a skeleton. Each of the usual steps $(\overrightarrow{j,k})$ of the essential walk corresponds to one usual step $(\overrightarrow{k,j})$ only. Then, if there are b usual steps $(\overrightarrow{j,k})$, c special steps $(\overrightarrow{j,k})$, and d special steps $(\overrightarrow{k,j})$, then the edge (k,j) has the weight $(-1)^{2b}\cdot X_{2b+c+d}=X_{2b+c+d}$.

Let us give necessary definitions and formulate two analogs of the decomposition lemmas. Denote by l the number of usual and special steps of the essential walk w, by r_1 the number of steps starting from the root ρ and by f the number of usual and special steps $(\overrightarrow{\rho,\nu})$. We denote by $\hat{\Lambda}(l,r_1)$ the set of the essential walks of l steps such that they have r_1 steps starting from the root ρ and by $\hat{\mathrm{S}}(l,r_1)$ the sum of contributions of the walk of $\hat{\Lambda}(l,r_1)$. Let d be the length of the walk over the tree G_1. Denote by $\hat{\Lambda}_1(l,r_1,d,f)$ the set of essential walks with fixed parameters l, r_1, d, and f and by $\hat{\mathrm{S}}_1(l,r_1,d,f)$ the sum of weights of walks of $\hat{\Lambda}_1(l,r_1,d,f)$. Let us denote by $\hat{\Lambda}_2(l,r_1)$ the set of essential walks of $\hat{\Lambda}(l,r_1)$ such that their skeleton has only one edge attached to the root ρ and by $\hat{\mathrm{S}}_2(l,r_1)$ the sum of contributions of the walks of $\hat{\Lambda}_2(l,r_1)$.

Lemma 3 (Third decomposition lemma):

$$\hat{\mathrm{S}}(l,r_1)=\sum_{f=1}^{r_1}\sum_{d=0}^{l-f}\hat{\mathrm{S}}_1(l,r_1,d,f), \tag{5.3}$$

$$\hat{\mathrm{S}}_1(l,r_1,d,f)=\binom{r_1-1}{f-1}\cdot\hat{\mathrm{S}}_2(l-d,f)\cdot\hat{\mathrm{S}}(d,r_1-f). \tag{5.4}$$

The first equality is trivial and the second one follows from the bijection

$$\hat{\Lambda}_1(l,r_1,d,f)\overset{bij}{\to}\hat{\Lambda}_2(l-d,f)\times\hat{\Lambda}(d,r_1-f)\times\Theta_1(r_1,f). \tag{5.5}$$

The proof is analogous to the proof of the first decomposition lemma. Equality (5.4) is illustrated by Fig. 5.

To formulate the fourth decomposition lemma, let us give necessary definitions. We denote by r_2 the number of steps starting from the root ρ [excepting the usual and special steps $(\overrightarrow{\rho,\nu})$], by n the number of usual steps $(\overrightarrow{\rho,\nu})$, by f_1 the number of special steps $(\overrightarrow{\rho,\nu})$ and by f_2 the number of special steps $(\overrightarrow{\nu,\rho})$. Denote by $\hat{\Lambda}_3(l,n,f_1,f_2,r_2)$ the set of essential walks with fixed parameters l, n, f_1, f_2, r_2 such that their skeletons have only one edge attached to the root ρ. Let

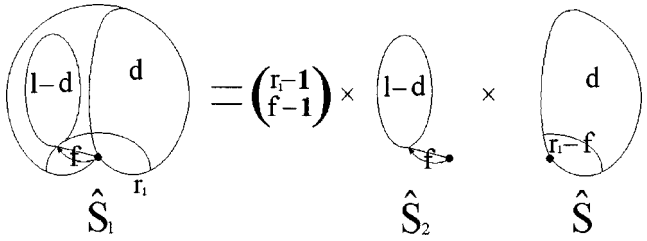

FIG. 5. Decomposition of $\hat{\Lambda}_1$.

$\hat{S}_3(l,n,f_1,f_2,r_2)$ be the sum of weights of walks of $\hat{\Lambda}_3(l,n,f_1,f_2,r_2)$. Denote by $\hat{\Lambda}_4(n,f_1,f_2)$ the set of essential walks of length $2n+f_1+f_2$ with fixed parameters n, f_1, f_2 such that their skeletons coincide with the graph $G_{1,2}$. It is not hard to see that for the case $n\geqslant 1$ one has the equality $|\hat{\Lambda}_4(n,f_1,f_2)|=\binom{n+f_1}{n}\cdot\binom{n+f_2-1}{n-1}$. It is clear that each of the walks of $\hat{\Lambda}_4(n,f_1,f_2)$ has the weight $X_{2n+f_1+f_2}/p^{n+f_1/2+f_2/2-1}$.

Lemma 4 (Fourth decomposition lemma):

$$\hat{S}_2(l,r_1,d,f)=\sum_{n=0}^{\min\{[(l-d)/2)],f\}}\ \sum_{f_2=0}^{l-d-f-n}\ \sum_{r_2=0}^{l-d-f-n-f_2}\hat{S}_3(l-d,n,f-n,f_2,r_2), \tag{5.6}$$

$$\hat{S}_3(l-d,n,f_1,f_2,r_2)=\begin{cases}\binom{n+f_2+r_2-1}{r_2}\cdot\binom{n+f_1}{n}\cdot\binom{n+f_2-1}{n-1}\cdot\hat{S}(l-d-n-f-f_2,r_2), & \text{if } n\geqslant 1,\\ \delta_{l-d-f_1}\delta_{f_2}\delta_{r_2}\dfrac{X_{2n+f_1+f_2}}{p^{n+f_1/2+f_2/2-1}}, & \text{if } n=0.\end{cases} \tag{5.7}$$

The first equality is trivial and the second one follows from the bijection

$$\hat{\Lambda}_2(l-d,n,f_1,f_2,r_2)\overset{bij}{\to}\hat{\Lambda}(l-d-2n-f_1-f_2,r_2)\times\hat{\Lambda}_3(n,f_1,f_2)\times\Theta_2(n+f_2+r_2,n+f_2). \tag{5.8}$$

The proof is analogous to the proof of the first decomposition lemma. Equation (5.7) is illustrated by Fig. 6.

Combining these two lemmas, we get an expression for $\hat{S}$. This expression is the sum over all admissible values of f,d,n,f_2,r_2. Let us change the order of summation. On the one hand, the number n of usual steps $(\overrightarrow{\rho,\nu})$ is not greater than the number f of all steps $(\overrightarrow{\rho,\nu})$; on the other hand, the inequality $2n+f_1\leqslant l$ holds because each of the usual steps $(\overrightarrow{\rho,\nu})$ corresponds to the step

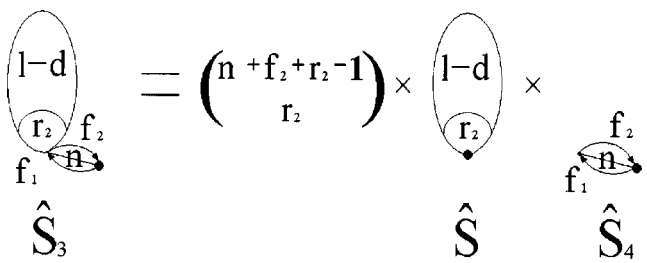

FIG. 6. Decomposition of $\hat{\Lambda}_3$.

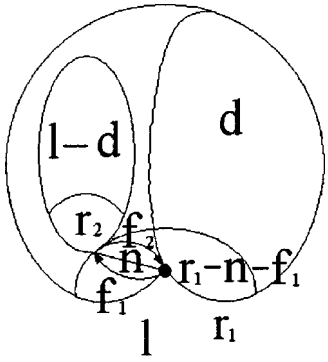

FIG. 7. Relations between parameters.

$(\overrightarrow{\nu,\rho})$. Then $n\leqslant\min(r_1,l-r_1)$. The number f_1 of special steps $(\overrightarrow{\rho,\nu})$ is not greater than the number r_1 of all steps starting from the root ρ minus the number n of usual steps $(\overrightarrow{\rho,\nu})$. Then f_1 changes from 0 to r_1-n. Now there are only $l-r_1-n$ free steps. Then the number f_2 of special steps $(\overrightarrow{\nu,\rho})$ can be changed from 0 to $l-r_1-n$. Now it remains $l-r_1-n-f_2$ free steps. The walk's length d over the tree G_1 is not less than the number r_1 of steps starting from the root ρ minus the number $n+f_1$ of steps $(\overrightarrow{\rho,\nu})$. Then $r_1-f_1-n\leqslant d\leqslant l-r_1-n-f_2$. Now there are only $l-d-2n-f_1-f_2$ free steps. In the case $n=0$, the expression is simplified to $\Sigma_{f_1=1}^{r_1}C_{r_1-1}^{f_1-1}\cdot\hat{\mathrm{S}}(l-f_1,r_1-f_1)$. The relations described above are illustrated by Fig. 7:

$$\begin{aligned}\hat{\mathrm{S}}(l,r_1)=&\sum_{n=1}^{\min(r_1,\,l-r_1)}\sum_{f_1=0}^{r_1-n}\binom{n+f_1}{n}\binom{r_1-1}{n+f_1-1}\cdot\sum_{f_2=0}^{l-r_1-n}\binom{n+f_2-1}{n-1}\cdot\frac{X_{(2n+f_1+f_2)}}{p^{(2n+f_1+f_2)/2-1}}\\&\times\sum_{d=r_1-f_1-n}^{l-r_1-n-f_2}\hat{\mathrm{S}}(d,r_1-n-f_1)\cdot\sum_{r_2=0}^{l-d-2n-f_1-f_2}\binom{r_2+f_2+n-1}{r_2}\cdot\hat{\mathrm{S}}(l-d-2n-f_1-f_2,r_2)\\&+\sum_{f_1=1}^{r_1}\binom{r_1-1}{f_1-1}\cdot\hat{\mathrm{S}}(l-f_1,r_1-f_1)\end{aligned}\tag{5.9}$$

with the initial condition

$$\hat{\mathrm{S}}(l,0)=\delta_{l,0}.$$

Let us denote $g_1=f_1+n$, and $g_2=f_2+n$. Using the identity $\Sigma_{n=1}^{\min\{g_1,g_2\}}\binom{g_1}{n}\cdot\binom{g_2-1}{n-1}=\binom{g_1+g_2-1}{g_1-1}$ and (5.9), we get

$$\begin{aligned}\hat{\mathrm{S}}(l,r_1)=&\sum_{g_1=1}^{r_1}\binom{r_1-1}{g_1-1}\cdot\Bigg(\hat{\mathrm{S}}(l-g_1,r_1-g_1)\cdot\frac{X_{g_1}}{p^{g_1/2-1}}+\sum_{d=r_1-g_1}^{l-r_1}\hat{\mathrm{S}}(d,r_1-g_1)\\&\cdot\sum_{g_2=1}^{l-d-g_1}\binom{g_1+g_2-1}{g_1-1}\cdot\frac{X_{g_1+g_2}}{p^{(g_1+g_2)/2-1}}\sum_{r_2=1}^{l-d-g_1-g_2}\binom{r_2+g_2-1}{g_2-1}\cdot\hat{\mathrm{S}}(l-d-g_1-g_2,r_2)\Bigg).\end{aligned}$$

If $a_{ij}\equiv1$ and $p=1$, we obtain

$$\hat{\mathrm{S}}(l,r_1)=\sum_{g_1=1}^{r_1}\binom{r_1-1}{g_1-1}\cdot\Bigg(\hat{\mathrm{S}}(l-g_1,r_1-g_1)+\sum_{d=r_1-g_1}^{l-r_1}\hat{\mathrm{S}}(d,r_1-g_1)\cdot\sum_{g_2=1}^{l-d-g_1}\binom{g_1+g_2-1}{g_1-1}$$
$$\cdot\sum_{r_2=1}^{l-d-g_1-g_2}\binom{r_2+g_2-1}{g_2-1}\cdot\hat{\mathrm{S}}(l-d-g_1-g_2,r_2)\Bigg).$$

If we want to find the coefficients of $1/p$-expansion of $l_k^{(p)}$,

$$l_k^{(p)}=\sum_{i=-k}^{k-2}\Bigg(\sum_{r_1=0}^{k}\hat{\mathrm{S}}(k,r_1,i)\Bigg)\cdot\frac{1}{p^{i/2}},\tag{5.10}$$

we can apply the method described above. Then after some calculations we get the following recurrent relations:

$$\hat{\mathrm{S}}(k,r_1,i)=\sum_{g_1=1}^{r_1}\binom{r_1-1}{g_1-1}\cdot\Bigg(\hat{\mathrm{S}}(k-g_1,r_1-g_1,i+2-g_1)\cdot X_{g_1}+\sum_{d=r_1-g_1}^{k-r_1}\sum_{j=-d}^{d-2\cdot(1-\delta_d)}\hat{\mathrm{S}}(d,r_1-g_1,j)$$
$$\cdot\sum_{g_2=1}^{k-d-g_1}\binom{g_1+g_2-1}{g_1-1}\cdot\frac{X_{g_1+g_2}}{p^{(g_1+g_2)/2-1}}\cdot\sum_{r_2=1}^{k-d-g_1-g_2}\binom{r_2+g_2-1}{g_2-1}$$
$$\cdot\hat{\mathrm{S}}(k-d-g_1-g_2,r_2,i+2-g_1-g_2-j)\Bigg)\tag{5.11}$$

with the initial condition $\hat{\mathrm{S}}(l,0,i)=\delta_{l,0}\cdot\delta_{i,0}$.

Similar formulas are obtained in Ref. 2. The difference is that in Ref. 2 matrices are not normalized by $1/\sqrt{p}$. This leads to expressions for $1/p$-terms different from our (5.11).

In conclusion, let us discuss the limiting transition $p\to\infty$ in (2.8) and (2.10). Regarding the first sum of the relation for the limiting moments of the adjacency matrix (2.8), one can easily observe that the terms with $f>1$ vanish in the limit of infinite p. Then gathering (2.8) with (2.7) leads to the recurrent relations

$$m_k=X_2\sum_{u=0}^{k-1}m_{k-1-u}m_u$$

that certainly determine the semicircle law.[22]

Let us turn to the Laplace case. In general, it is impossible to pass to the limit $p\to\infty$ in relations (2.10) because there is the term of the order $p^{1/2}$. However, if one passes to the case of random variables a with zero mean value, $X_1=0$, then the limit $p\to\infty$ leads to the following recurrent relations:

$$\hat{\mathrm{S}}(l,r_1)=X_2\cdot\Bigg((r_1-1)\cdot\hat{\mathrm{S}}(l-2,r_1-2)+\sum_{d=r_1-1}^{l-r_1}\hat{\mathrm{S}}(d,r_1-1)\cdot\sum_{r_2=1}^{l-d-2}\hat{\mathrm{S}}(l-d-2,r_2)\Bigg)\tag{5.12}$$

with the initial condition $\hat{\mathrm{S}}(l,0)=\delta_{l,0}$.

These recurrent relations obviously differ from those for the semicircle law. Using the resolvent approach, we show at the end of Sec. 6 that the limiting moments

$$l_s=\lim_{p\to\infty}l_s^{(p)}=\sum_{i=0}^{s}\hat{S}(s,i)$$

determine the distribution known as the deformed semicircle law (see Ref. 16).

VI. PROOFS OF THEOREMS 3 AND 4

Proof of Theorem 3: It is easy to see that $G_{11}^{(N,p)}(z)$ can be represented in the form

$$G_{11}^{(N,p)}(z)=\left(z+\sum_{j,k=2}^{N} \widetilde{G}_{jk}^{(N-1,p)} A_{1j}^{(N,p)} A_{1k}^{(N,p)} \right)^{-1}, \tag{6.1}$$

where the matrix $\{\widetilde{G}_{ij}^{(N-1,p)}(z)\}_{i,j=2}^{N}$ is the resolvent of the matrix $i\widetilde{A}^{(N-1,p)}$, which can be obtained from $A^{(N,p)}$ if we replace $\{A_{1j}^{(N,p)}\}_{j=2}^{N}$, $\{A_{j1}^{(N,p)}\}_{i=2}^{N}$ by zeros. We remark here that in order to simplify formulas in this section we assume that $A_{jj}^{(N,p)}=0$. The general case can be studied in the same way. Let us use the formula (see Ref. 1)

$$e^{-ua^2R}=1-u^{1/2}|a|\int_0^\infty dv\,\frac{\mathcal{J}_1(2|a|\sqrt{uv})}{\sqrt{v}}\exp\{-R^{-1}v\}, \tag{6.2}$$

which is valid for any $u\geqslant 0$, $\Re R>0$. Then, on the basis of (6.1), we get

$$\exp\{-ua_1^2G_{11}^{(N,p)}\}=1-u^{1/2}|a_1|\int_0^\infty dv\,\frac{\mathcal{J}_1(2|a_1|\sqrt{uv})}{\sqrt{v}}\exp\left\{-zv-v\sum_{j,k=2}^{N}\widetilde{G}_{ij}^{(N-1,p)}A_{1i}^{(N,p)}A_{1j}^{(N,p)}\right\}. \tag{6.3}$$

Denote

$$\widetilde{R}_N=\sum_{j\neq k}\widetilde{G}_{jk}^{(N-1,p)}A_{1j}^{(N,p)}A_{1k}^{(N,p)}. \tag{6.4}$$

One can see easily that

$$\mathbf{E}\{|\widetilde{R}_N|^2\}\leqslant 2\,\frac{X_2^2}{N|\Re z|^2}+\frac{p^2X_1^4}{N^2|\Re z|^2}+\frac{pX_1^2X_2}{N^2|\Re z|^2}. \tag{6.5}$$

Indeed,

$$\begin{aligned}\mathbf{E}\{|\widetilde{R}_N|^2\}=&\sum_{j_1\neq j_2\neq k_1\neq k_2}\mathbf{E}\{G_{j_1k_1}^{(N-1,p)}\overline{\widetilde{G}_{j_2k_2}^{(N-1,p)}}A_{1j_1}^{(N,p)}A_{1j_2}^{(N,p)}A_{1k_1}^{(N,p)}A_{1k_2}^{(N,p)}\}\\&+4\sum_{j,k_1\neq k_2}\mathbf{E}\{\widetilde{G}_{jk_1}^{(N-1,p)}\overline{\widetilde{G}_{jk_2}^{(N-1,p)}}|A_{1j}^{(N,p)}|^2A_{1k_1}^{(N,p)}A_{1k_2}^{(N,p)}\}\\&+2\sum_{j\neq k}\mathbf{E}\{\widetilde{G}_{jk}^{(N-1,p)}\overline{\widetilde{G}_{jk}^{(N-1,p)}}|A_{1j}^{(N,p)}|^2|A_{1k}^{(N,p)}|^2\}=I+4II+2III.\end{aligned} \tag{6.6}$$

Averaging with respect to $\{A_{1,i}^{(N,p)}\}_{i=2}^{N}$ and using the fact that $\{\widetilde{G}_{ij}^{(N-1,p)}(z)\}_{i,j=2}^{N}$ do not depend on $A_{1,i}^{(N,p)}$, we obtain

$$I\leqslant X_1^4\frac{p^2}{N^2}\mathbf{E}\left\{\left|N^{-1}\sum_{j,k}(z-i\widetilde{A}^{(N-1,p)})_{jk}^{-1}\right|^2\right\}\leqslant\frac{p^2X_1^4}{N^2|\Re z|^2},$$

$$II\leqslant X_1^2X_2\frac{p}{N^3}\sum_{k_1\neq k_2}\mathbf{E}\{[(z-i\widetilde{A}^{(N-1,p)})(\overline{z}+i\widetilde{A}^{(N-1,p)})]_{k_1k_2}^{-1}\}\leqslant\frac{pX_1^2X_2}{N^2|\Re z|^2},$$

$$III\leqslant\frac{X_2^2}{N^2}\sum_{k}\mathbf{E}\{[(z-i\widetilde{A}^{(N-1,p)})(\overline{z}+i\widetilde{A}^{(N-1,p)})]_{kk}^{-1}\}\leqslant\frac{X_2^2}{N|\Re z|^2}.$$

Besides, since evidently

$$\Re\left\{\sum \widetilde{G}_{ij}^{(N-1,p)}A_{1i}^{(N,p)}A_{1j}^{(N,p)}\right\}\geqslant 0,\quad \Re\left\{\sum \widetilde{G}_{jj}^{(N-1,p)}\left|A_{jj}^{(N,p)}\right|^2\right\}\geqslant 0,$$

the inequality $|e^{-z_1}-e^{-z_2}|\leqslant|z_1-z_2|$ (valid for $\Re z_1,\Re z_2\geqslant 0$) and (6.3) imply

$$\exp\{-ua_1^2G_{11}^{(N,p)}\}=1-u^{1/2}|a_1|\int_0^\infty dv\,\frac{\mathcal{J}_1(2|a_1|\sqrt{uv})}{\sqrt{v}}\times\exp\left\{-zv-v\sum \widetilde{G}_{ij}^{(N-1,p)}|A_{1j}^{(N,p)}|^2\right\}+\tilde{r}_N(u),\tag{6.7}$$

where

$$|\tilde{r}_N(u)|\leqslant|\widetilde{R}_N|u^{1/2}|a_1|\int_0^\infty dv\left|\frac{\mathcal{J}_1(2|a_1|\sqrt{uv})}{\sqrt{v}}e^{-zv}\right|\leqslant C|\widetilde{R}_N|u^{1/2}|a_1||\Re z|^{-3/2}.$$

Here and below we denote by C some constants (different in different formulas), which do not depend on N,z,p. Taking into account (6.5), we get

$$\mathbf{E}\{|\tilde{r}_N(u)|^2\}\leqslant\frac{Cup}{N|\Re z|^3}.\tag{6.8}$$

Averaging with respect to a_1 and $\{A_{1,i}^{(N,p)}\}_{i=2}^N$ we obtain

$$\begin{aligned}\mathbf{E}\{\exp\{-ua_1^2G_{11}^{(N,p)}\}\}&=1-u^{1/2}\int d\mu(a_1)|a_1|\int_0^\infty dv\,\frac{\mathcal{J}_1(2|a_1|\sqrt{uv})}{\sqrt{v}}\\&\quad\times\mathbf{E}\left\{\exp\left\{-zv-v\sum_{j=2}^N \widetilde{G}_{jj}^{(N-1,p)}|A_{1j}^{(N,p)}|^2\right\}\right\}+r_N(u),\\ r_N(u)&\leqslant\frac{C(up)^{1/2}}{N^{1/2}|\Re z|^{3/2}}.\end{aligned}\tag{6.9}$$

Taking into account that $\{\widetilde{G}_{ij}^{(N-1,p)}(z)\}_{i,j=2}^N$ do not depend on $A_{1,i}^{(N,p)}$, we obtain

$$\begin{aligned}\mathbf{E}\left\{\exp\left\{-v\sum G_{jj}^{(N-1,p)}|A_{1j}^{(N,p)}|^2\right\}\right\}&=\mathbf{E}\left\{\prod_{j=2}^N\left(\left(1-\frac{p}{N}\right)+\frac{p}{N}e^{-va_{1j}^2\widetilde{G}_{jj}^{(N-1,p)}/p}\right)\right\}\\&=e^{-p}\mathbf{E}\{\exp\{p\widetilde{f}_{N-1}(v/p,z)\}\}+R_N(v),\\ |R_N(v)|&\leqslant\frac{Cp^2}{N}.\end{aligned}\tag{6.10}$$

Let us prove that $\widetilde{f}_{N-1}(v/p,z)=(1/N)\,\Sigma e^{-va_{1j}^2\widetilde{G}_{jj}^{(N-1,p)}/p}$ can be replaced by $f_N(v/p,z)$. To this end consider the matrices $A^{(N,p)}(t)=(1-t)A^{(N,p)}+t\tilde{A}^{(N-1,p)}$, $G(t,z)=(z-iA^{(N,p)}(t))^{-1}$ and the function

$$f_N(u,z,t)=\frac{1}{N}\sum_{i=1}^N e^{-ua_i^2G_{ii}(t,z)}.\tag{6.11}$$

It is easy to see that

$$\left|\widetilde{f}_{N-1}(u,z)-f_N(u,z)+\frac{1}{Nz}\right|=\left|\frac{1}{Nz}+\frac{1}{N}\sum_{i=2}^{N}e^{-ua_i^2\widetilde{G}_{ii}^{(N-1,p)}(z)}-\frac{1}{N}\sum_{i=1}^{N}e^{-ua_i^2G_{ii}(z)}\right|$$

$$=|f_N(u,z,1)-f_N(u,z,0)|$$

$$=\left|\int_0^1 dt\,\frac{d}{dt}f_N(u,z,t)\right|$$

$$=2\left|\int_0^1 dt\,\frac{u}{N}\sum_{i=2}^{N}a_i^2G_{ij}(z,t)A_{j1}^{(N,p)}G_{1i}(z,t)e^{-ua_i^2G_{ii}(z,t)}\right|$$

$$\leqslant 2\,\frac{u}{N|\Re z|^2}\left[\sum_{j=2}^{N}|a_i|^4\right]^{1/2}\left[\sum_{j=2}^{N}|A_{j1}^{(N,p)}|^2\right]^{1/2}, \tag{6.12}$$

where we have used that $\|G(t,z)\|\leqslant|\Re z|^{-1}$. Therefore, for any $u\in\mathbf{R}$,

$$\mathbf{E}\{|\widetilde{f}_{N-1}(u,z)-f_N(u,z)|^2\}\leqslant\frac{u^2X_4^{1/2}X_2^{1/2}}{|\Re z|^4N}+\frac{1}{N^2|z|^2}. \tag{6.13}$$

Hence, (6.9) and (6.10) could be rewritten as

$$\mathbf{E}\{f_N(u,z)\}=1-u^{1/2}e^{-p}\int|a_1|d\mu(a_1)\int_0^\infty dv\,\frac{\mathcal{J}_1(2|a_1|\sqrt{uv})}{\sqrt{v}}e^{-zv}\mathbf{E}\{e^{pf_N(v/p,z)}\}+r_N'(v),$$

$$\mathbf{E}\{|r_N'^2(u)|\}\leqslant\frac{Cp^2u}{|\Re z|^4N}. \tag{6.14}$$

Now let us prove (2.14). Denote

$$\delta_N(z,u)=f_N(z,u)-\mathbf{E}\{f_N(z,u)\}$$

and observe that due to the symmetry of the problem

$$\mathbf{E}\{\delta_N^2(z,u)\}=\frac{N-1}{N}(\mathbf{E}\{e^{-ua_1^2G_{11}(z)}e^{-ua_2^2G_{22}(z)}\}-\mathbf{E}\{e^{-ua_1^2G_{11}(z)}\}\mathbf{E}\{e^{-ua_2^2G_{22}(z)}\})+O(N^{-1}). \tag{6.15}$$

We shall use the formulas [cf. (6.1)]

$$G_{\ell\ell}^{(N,p)}=\left[\left(z+\sum_{j,k=3}^{N}\widetilde{G}_{jk}^{(N-2,p)}A_{\ell j}^{(N,p)}A_{\ell k}^{(N,p)}\right)-\left(\sum_{j,k=3}^{N}\widetilde{G}_{jk}^{(N-2,p)}A_{1j}^{(N,p)}A_{2k}^{(N,p)}\right)^2\right.$$

$$\left.\times\left(z+\sum_{j,k=3}^{N}\widetilde{G}_{jk}^{(N-2,p)}A_{\underline{\ell},j}^{(N,p)}A_{\underline{\ell}k}^{(N,p)}\right)^{-1}\right]^{-1}. \tag{6.16}$$

Here $\ell=1,2$, $\underline{\ell}=3-\ell$ and $\widetilde{G}^{(N-2,p)}=(z-i\widetilde{A}^{(N-2,p)})^{-1}$, where $\widetilde{A}^{(N-2,p)}$ can be obtained from $A^{(N,p)}$ by replacing $A_{1j}^{(N,p)},A_{2j}^{(N,p)}$ $A_{j1}^{(N,p)},A_{j2}^{(N,p)}$ $(j=3,\ldots,N)$ by zeros. Similarly to (6.5), one can get that

$$\mathbf{E}\left\{\left|\sum\widetilde{G}_{jk}^{(N-2,p)}A_{1j}^{(N,p)}A_{2k}^{(N,p)}\right|^2\right\}\leqslant\frac{Cp}{N|\Re z|^2},\quad\mathbf{E}\left\{\left|\sum_{j\neq k}\widetilde{G}_{jk}^{(N-2,p)}A_{\ell j}^{(N,p)}A_{\ell k}^{(N,p)}\right|^2\right\}\leqslant\frac{Cp}{N|\Re z|^2}.$$

Hence, using (6.2), similarly to (6.3)–(6.6), we get

$$\mathbf{E}\{e^{-ua_1^2G_{11}^{(N,p)}}e^{-ua_2^2G_{22}^{(N,p)}}\}-\mathbf{E}\{e^{-ua_1^2G_{11}^{(N,p)}}\}\mathbf{E}\{e^{-ua_2^2G_{22}^{(N,p)}}\}$$
$$=ue^{-2p}\int|a_1||a_2|d\mu(a_1)d\mu(a_2)\int_0^\infty\int_0^\infty dv_1dv_2\frac{\mathcal{J}_1(2|a_1|\sqrt{uv_1})\mathcal{J}_1(2|a_2|\sqrt{uv_2})}{\sqrt{v_1v_2}}e^{-zv_1-zv_2}$$
$$\times[\mathbf{E}\{e^{p\tilde{f}_{N-2}(v_1/p,z)}e^{p\tilde{f}_{N-2}(v_2/p,z)}\}-\mathbf{E}\{e^{p\tilde{f}_{N-2}(v_1/p,z)}\}\mathbf{E}\{e^{p\tilde{f}_{N-2}(v_2/p,z)}\}]+\tilde{r}_N(u), \tag{6.17}$$
$$\mathbf{E}\{|\tilde{r}_N(u)|\}\leq\frac{Cp}{N|\Re z|^2}.$$

By the same way as in (6.11)–(6.13) it is easy to prove that the estimate (6.13) remains valid if we replace $\tilde{f}_{N-1}(u,z)$ by $\tilde{f}_{N-2}(u,z)$. Thus inequalities (6.17) remain valid if we replace $\tilde{f}_{N-2}(u,z)$ by $f_N(u,z)$ on the r.h.s. of (6.17).

Besides, since

$$|f_N(v,z)|\leq\max_i e^{-ua_i^2\Re G_{ii}^{(N,p)}}\leq 1, \tag{6.18}$$

we have the bound

$$|\mathbf{E}\{e^{pf_N(v_1/p,z)}e^{pf_N(v_2/p,z)}\}-\mathbf{E}\{e^{pf_N(v_1/p,z)}\}\mathbf{E}\{e^{pf_N(v_2/p,z)}\}|$$
$$\leq 4e^{2p}p^2(\mathbf{E}\{|\delta_N(v_1/p,z)|^2\}+\mathbf{E}\{|\delta_N(v_2/p,z)|^2\}). \tag{6.19}$$

Let us take the norm (2.16) and consider the Banach space $\mathcal{B}$ of all the functions $\phi:\mathbf{R}_+\to\mathbf{C}$ which possess this norm. Consider $\phi_z(u)=\delta_N(u,z)$.

Then, using (6.19) and the inequality $|\mathcal{J}_1(x)|\leq 1$ (see Ref. 1), on the basis of (6.15)–(6.18) we get

$$\mathbf{E}\{\|\delta_N(u,z)\|^2\}\leq\frac{8X_2e^{2p}p^2\pi}{|\Re z|}\left(1+\frac{1}{2p|\Re z|}\right)\mathbf{E}\{\|\delta_N(u,z)\|^2\}+\frac{C}{N}. \tag{6.20}$$

Hence, it is evident that there exists $M>0$, such that for any $z:\Re z>M$

$$\mathbf{E}\{\|\delta_N(u,z)\|^2\}\leq\frac{C}{N}. \tag{6.21}$$

Thus, for any $z:\Re z>M$, Eq. (6.14) can be rewritten in the form

$$\mathbf{E}\{f_N(u,z)\}=1-u^{1/2}e^{-p}\int|a|d\mu(a)\int_0^\infty dv\,\frac{\mathcal{J}_1(2|a|\sqrt{uv})}{\sqrt{v}}e^{-zv}e^{p\mathbf{E}\{f_N(v/p,z)\}}+\tilde{r}'_N(u),$$
$$\mathbf{E}\{|\tilde{r}'^2_N(u)|\}\leq\frac{Cp^2u}{N}. \tag{6.22}$$

Define the operator $F_z:\mathcal{B}\to\mathcal{B}$ of the form

$$F_z(\phi)(u)=1-u^{1/2}e^{-p}\int|a|d\mu(a)\int_0^\infty dv\,\frac{\mathcal{J}_1(2|a|\sqrt{uv})}{\sqrt{v}}e^{-zv}e^{p\phi(v/p)}. \tag{6.23}$$

Then for any ϕ_1, ϕ_2 $\|\phi_{1,2}\|\leq 1$

$$\|F_z(\phi_1)-F_z(\phi_2)\|\leqslant X_2^{1/2}\int_0^\infty \frac{dv}{\sqrt{v}}e^{-|\Re z|v}e^{v^{1/2}/p^{1/2}}\|\phi_1-\phi_2\|\leqslant \frac{2X_2^{1/2}\sqrt{\pi}e^{1/4p|\Re z|}}{|2\Re z|^{1/2}}\|\phi_1-\phi_2\|.$$

Hence, there exists $M_1>0$, such that for all $z:\Re z>M_1$

$$\|F_z(\phi_1)-F_z(\phi_2)\|\leqslant \tfrac{1}{2}\|\phi_1-\phi_2\|.$$

Thus, if we denote by $B_{0,1}=\{\phi:\|\phi\|\leqslant 1\}$ the ball of radius 1 centered in the origin, then we obtain that $F_z:B_{0,1}\to B_{0,1}$ and the restriction F_z on $B_{0,1}$ is a contraction. Therefore, there exists the unique fixed point $f(u,z)$ of the mapping $F_z:B_{0,1}\to B_{0,1}$ which is a solution of (2.17), and $\mathbf{E}\{f_N(u,z)\}\to f(u,z)$, as $N\to\infty$. But since $\mathbf{E}\{f_N(u,z)\}$ for any z: $\Re z>0$ is an analytical function, the uniqueness theorem of complex analysis guarantees that Eq. (2.17) has a solution for any $z:\Re z>0$ and $\mathbf{E}\{f_N(u,z)\}\to f(u,z)$, as $N\to\infty$.

Similarly, since $\delta_N(u,z)$ is a bounded analytical function, $\mathbf{E}\{\|\delta_N(u,z)\|^2\}\to 0$ $(N\to\infty)$ implies that $\mathbf{E}\{\|\delta_N(u,z)\|^2\}\to 0$ for any $z:\Re z>0$.

Proof of Theorem 4: The proof of Theorem 4 repeats almost literally the proof of Theorem 3. We use the formula [cf. (6.3)]

$$G_{11}^{(\Delta,N,p)}(z)=\left(z+i\sum_{j=2}^N A_{1j}^{(N,p)}+\sum_{j,k=2}^N \tilde{G}_{jk}^{(\Delta,N-1,p)}A_{1j}^{(N,p)}A_{1k}^{(N,p)}\right)^{-1}, \tag{6.24}$$

where $\{\tilde{G}_{ij}^{(\Delta,N-1,p)}(z)\}_{i,j=2}^N$ is the resolvent of the matrix $i\Delta^{(N-1,p)}$, obtained from $\Delta^{(N,p)}$ by replacing $\{A_{1j}^{(N,p)}\}_{j=2}^N$ $\{A_{j1}^{(N,p)}\}_{j=2}^N$ with zeros. Then, similarly to (6.2)–(6.22) we obtain

$$\mathbf{E}\{f_N^{(\Delta)}(u,z)\}=\hat{\mu}(-u)-u^{1/2}e^{-p}\int |a|e^{iua}d\mu(a)\int_0^\infty dv\,\frac{\mathcal{J}_1(2|a|\sqrt{uv})}{\sqrt{v}}e^{-zv}e^{p\mathbf{E}\{f_N^{(\Delta)}(v/p,z)\}}$$

$$+\tilde{r}_N'(u),\quad \mathbf{E}\{|\tilde{r}_N'^2(u)|\}\leqslant\frac{Cp^2u}{N}. \tag{6.25}$$

Then we consider the Banach space $\mathcal{B}$ with the norm (2.16) and the operator $F_z^{(\Delta)}:\mathcal{B}\to\mathcal{B}$ of the form

$$F_z^{(\Delta)}(\phi)(u)=\hat{\mu}(-u)-u^{1/2}e^{-p}\int |a|e^{iua}d\mu(a)\int_0^\infty dv\,\frac{\mathcal{J}_1(2|a|\sqrt{uv})}{\sqrt{v}}e^{-zv}\cdot e^{p\phi(v/p)}. \tag{6.26}$$

It is easy to see that there exists $M_1>0$, such that for any $z:\Re z>M_1$ the operator $F_z^{(\Delta)}:B_{0,1}\to B_{0,1}$ and its restriction to $B_{0,1}$ is a contraction.

Hence, there exists the unique fixed point $f^{(\Delta)}(u,z)$, which is a solution of (2.24), and $\mathbf{E}\{f_N^{(\Delta)}(u,z)\}\to f^{(\Delta)}(u,z)$, as $N\to\infty$. Similarly to Theorem 3 the statement of Theorem 4 can be derived from this fact.

In conclusion let us discuss the limiting transition $p\to\infty$. Assume that $X_1=0$. Then in the case of the adjacency matrix, by using formula (6.1) we can write

$$G_{11}^{(N,p)}(z)=\left(z+\sum_{j=2}^N \tilde{G}_{jj}^{(N-1,p)}\frac{X_2}{N}+\tilde{R}_N+R_p\right)^{-1}, \tag{6.27}$$

where $\tilde{R}_N$ is defined by (6.4) and

$$R_p=\sum_{j,k=2}^N \tilde{G}_{jj}^{(N-1,p)}(A_{1,j}^2-\mathbf{E}\{A_{1,j}^2\}).$$

Then, since $X_1=0$, in view of (6.5) $\mathbf{E}\{|\tilde{R}_N|^2\}\to 0$, as $N\to\infty$ and

$$\mathbf{E}\{|R_p|^2\}\leqslant\sum_{j=2}^{N}|\tilde{G}_{jj}^{(N-1,p)}|^2\frac{X_4}{Np}+O(|\Re z|^{-2}N^{-1})=O(|\Re z|^{-2}p^{-1})+O(|\Re z|^{-2}N^{-1}).$$

Besides, similarly to the above consideration, it is easy to conclude that

$$\mathbf{E}\{|N^{-1}\mathrm{Tr}\ \tilde{G}^{(N-1,p)}-N^{-1}\mathrm{Tr}\ G^{(N,p)}|^2\}\to 0,$$

$$\mathbf{E}\{|N^{-1}\mathrm{Tr}\ G^{(N,p)}-\mathbf{E}\{N^{-1}\mathrm{Tr}\ G^{(N,p)}\}|^2\}\to 0,\quad N\to\infty.$$

We remark also that this self-averaging property can be obtained directly from Theorem 3 (see Sec. 2.2).

Thus, we get that if $g_{N,p}(z)=N^{-1}\mathrm{Tr}\ (A^{(N,p)}-z)^{-1}$, then

$$\mathbf{E}\{ig_{N,p}(-iz)\}=(z+X_2\mathbf{E}\{ig_{N,p}(-iz)\})^{-1}+o(1).$$

Similarly to the proof of Theorem 3, we conclude that for $|\Re z|$ large enough $\mathbf{E}\{g_{N,p}(-iz)\}\to g(-iz)$, as $N,p\to\infty$, where $g(z)$ is the solution of the equation

$$g(z)=(X_2g(z)-z)^{-1},$$

satisfying condition $\Re g(z)\Re z>0$. So we have got once more the result of Ref. 16 that if $X_1=0$ and $N,p\to\infty$, then the IDS of $A^{(N,p)}$ tends to the Wigner semicircle law.

By the same way, using formula (6.24), we get for the $G^{(\Delta,N,p)}(z)$

$$G_{11}^{(\Delta,N,p)}(z)=\left(z+i\sum_{j=2}^{N}A_{1j}^{(N,p)}+\frac{X_2}{N}\mathbf{E}\{\mathrm{Tr}\ G^{(\Delta,N,p)}(z)\}\right)^{-1}+O(|\Re z|^{-2}p^{-1})+O(|\Re z|^{-2}N^{-1}).\tag{6.28}$$

Thus, since $\Sigma_{j=2}^{N}A_{1j}^{(N,p)}$ converge in distribution as $N,p\to\infty$ to the Gaussian random variable with zero mean and the variance X_2, we get from (6.28) the equation

$$\mathbf{E}\{ig_{N,p}^{(\Delta)}(-iz)\}=\int\frac{e^{-v^2/2}dv}{\sqrt{2\pi}}(z+iv+\mathbf{E}\{ig_{N,p}^{(\Delta)}(-iz)\})^{-1}$$

and so we conclude that there exists

$$\lim_{N,p\to\infty}\mathbf{E}\{ig_{N,p}^{(\Delta)}(iz)\}=ig^{(\Delta)}(iz),$$

where $ig^{(\Delta)}(iz)$ is defined by the equation

$$g^{(\Delta)}(-iz)=\int\frac{e^{-v^2/2}dv}{\sqrt{2\pi}}(iz-v-X_2g_{N,p}^{(\Delta)}(-iz))^{-1}\tag{6.29}$$

and the condition $\Re g(z)\Re z>0$. The last equation determines the Stieltjes transform of the deformed Wigner law (see Ref. 16). The semicircle distribution is ''deformed'' by the normal one and this makes the support of the corresponding IDS to be infinite. The moments of this deformed Wigner law are determined by relations (5.12).

Regarding the matrix of the Laplace operator (2.3), it is easy to explain the result (6.29). The diagonal term B of (2.3) is given by the sum of approximately p independent random variables a and this sum is normalized by $\sqrt{p}$. So, if the mathematical expectation of a equals to zero, the order of magnitude of the diagonal term of (2.3) remains finite as $p\to\infty$ and this equalizes it with

the matrix $A^{(N,p)}$. Since the elements of these random matrices A and B become statistically independent in the limit $p \to \infty$, the limiting IDS results in the semicircle law given by A deformed by the normal distribution provided by B.

The determination of all syzygies for the dependent polynomial invariants of the Riemann tensor. I. Pure Ricci and pure Weyl invariants

A. E. K. Lim and J. Carminati
Mathematics and Computational Theory Group, School of Information Technology, Deakin University, Waurn Ponds, Victoria 3217, Australia

(Received 8 September 2003; accepted 14 December 2003)

In this paper, we shall consider all pure Ricci and pure Weyl scalar invariants of any degree, in a four-dimensional Lorentzian space. We present a general graph-theoretic based reduction algorithm which decomposes, using syzygies, any pure invariant in terms of the independent base invariants $\{r_1,r_2,r_3\}$ or $\{w_1,w_2\}$ [E. Zakhary and J. Carminati, J. Math. Phys. **42**, 1474 (2001)]. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1646431]

I. INTRODUCTION

In recent years, there has been a considerable resurgence of interest into the classic problem of determining a complete[1] set of polynomial invariants of the Riemann tensor in a four-dimensional Lorentzian space.[2–19] Apart from being important in the classification of the Riemann tensor and in general the equivalence problem, the invariants also play a crucial role in revealing interesting geometrical properties of space–time.

Recall that an invariant of a set of tensors in n dimensions is classically defined to be a polynomial function of the components of those tensors that is invariant under some group of transformations [in our case, the Lorentz Group or SO(1,3)] of the tensors. A *complete set*, $I=\{I_1,I_2,\ldots,I_n\}$, of invariants is one having the property that any polynomial invariant can be expressed as a *polynomial* in $I_1,I_2,\ldots,I_n$, and no invariant in the set can be so expressed in terms of the remaining I_i. Note that an *algebraically independent* set of invariants, $\{I_1,I_2,\ldots,I_n\}$, is one for which an algebraic function, f, such that $f(I_1,I_2,\ldots,I_n)=0$ implies that $f\equiv 0$. The main theorems of invariant theory are the following.[6,20]

First fundamental theorem: *Any polynomial invariant of a set of tensors can be expressed as a linear combination of complete contractions of products of those tensors, together with the metric or* $\epsilon_{j_1\ldots j_n}$.

Second fundamental theorem: *Any identity between the invariants of a set of tensors in n dimensions can be obtained as a consequence of the fact that skew-symmetrizing over* $n+1$ *indices will annihilate any tensor*.

Recently, Sneddon[7] has determined a complete set of invariants, K, using matrix theory. The set K consists of 38 real invariants of maximum degree 12. Hence, due to their high degree and complexity, their usefulness would tend to be rather limited. To arrive at a more ''manageable'' set, the concept of algebraic independence was introduced and this reduced the number of invariants to 18 with maximum degree 6.[11–13] However, despite these contributions to the classic problem, the explicit relationships between dependent and independent invariants via syzygies[21] are still not completely understood. Indeed apart from a few special ''exact'' identities, the best that has been achieved so far is a numerical procedure leading to approximate relations.[6]

In this paper we intend to address this problem for the pure Weyl and pure Ricci invariants. We denote the sets of pure Weyl and pure Ricci invariants as $\mathcal{W}$ and $\mathcal{R}$, respectively. In the SL(2,C) representation, these polynomial invariants can be equivalently defined as complete contractions of arbitrary products of either Ψ_{ABCD} or $\Phi_{AB\dot{A}\dot{B}}$, but not both. Initially, we consider the sets of pure Weyl and Ricci invariants, $\hat{\mathcal{W}}$ and $\hat{\mathcal{R}}$, where there is an even number of index

contractions between any pair of spinors. We derive the general expression for the syzygies relating any invariant within $\hat{\mathcal{R}}$ or $\hat{\mathcal{W}}$ to the invariants $\{r_1,r_2,r_3\}$ or $\{w_1,w_2\}$,[11] respectively. Furthermore, we introduce a graph-theoretical approach to establish that any pure invariant outside $\hat{\mathcal{W}}$ and $\hat{\mathcal{R}}$ is expressible as a polynomial syzygy of the invariants within these sets. This, in part, answers the question partially alluded to by Bonanos.[3,22] We shall then present a general reduction algorithm which decomposes using syzygies, any pure invariant in terms of $\{r_1,r_2,r_3\}$ and $\{w_1,w_2\}$.

II. GRAPHICAL REPRESENTATION OF THE INVARIANTS

We introduce a graphical notation, where any pure invariant may be represented as a directed multigraph. We shall call the ''lines'' in a directed graph *arcs*, and their undirected counterparts *edges*.

Definition 1: We associate a unique directed multigraph G_N with each pure Weyl invariant N. The directed multigraph G_N consists of a vertex set $V=\{v_1,v_2,\ldots,v_n\}$, where each element of V is uniquely associated with each Weyl spinor, an arc set $E=V\times V$, and a function m: $V\times V\rightarrow\{0,1,2,3,4\}$. The multiplicity $m(v_j,v_k)$ of the arc $(v_j,v_k)\in E$ is the number of contractions between lower indices on the spinor v_j and upper indices on the spinor v_k.

It follows from this definition that the *underlying undirected graph* of G_N, which is obtained by deleting all directions from the arcs of G_N, must be a 4-regular multigraph. Reversing the direction of one arc is equivalent to raising the lower index and dropping the upper index in a pair of contracted indices, and has the effect of changing the overall sign of the invariant. For clarity, we shall, where required, use the subscript G_N to denote the multiplicity of the arc (v_j,v_k) in the specific graph G_N as $m_{G_N}(v_j,v_k)$.

We must first address the matter of conflicting definitions of degree. Each vertex in the underlying undirected graph of G_N is adjacent to four edges. In graph theoretic terms, the degree of each vertex in this underlying graph is therefore four. However, the degree of the polynomial invariant N is equivalent to the order (number of vertices) of its associated graph, G_N. We will use the phrase polynomial degree when referring to degree in the latter context.

We describe N as being connected if and only if G_N is a connected graph, otherwise we say N is disconnected. If G_N is disconnected, its components (connected subgraphs) would correspond to the connected factors of the disconnected invariant, N.

For the pure Weyl invariant, N, we define the $n\times n$ matrix, $A(G_N)$ to be the adjacency matrix of G_N, where its vertex set $V(G_N)$ possesses n vertices corresponding to the n Weyl spinors contracted to form N. Each element a_{jk} of $A(G_N)$,

$$A(G_N)=[a_{jk}],$$

$$a_{jk}=m(v_j,v_k),\quad j,k=1,2,\ldots,n \tag{1}$$

is equivalent to the multiplicity of the arc from vertex v_j to vertex v_k. The sum of the entries in row j corresponds to the outdegree of v_j, whereas the sum of the entries in column k corresponds to the indegree of v_k. Loops, which are arcs leaving and entering the same vertex, would actually correspond to contraction within a single Weyl spinor and the resulting invariant will be identically zero. Hence, we can assume that no loops are present in the graphs and $a_{jj}=m(v_j,v_j)=0$ without loss of generality. Since the sum of the outdegree and the indegree at each vertex must be four, the following condition holds:

$$\sum_{k=1}^{n}(a_{jk}+a_{kj})=4,\quad j=1,2,\ldots,n.$$

Three examples of graphical representations of fifth-degree (polynomial), pure Weyl invariants are depicted in Fig. 1.

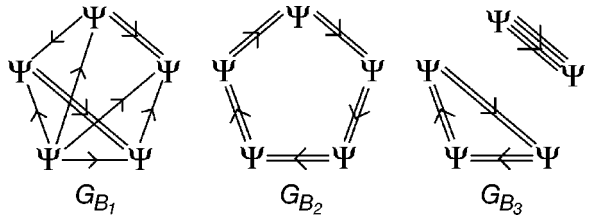

FIG. 1. Graphical representations of three pure Weyl invariants.

Graphs G_{B_1}, G_{B_2}, and G_{B_3} represent the invariants $B_1=\Psi_{AB}{}^{C}{}_{D}\Psi^{ABEF}\Psi_{E}{}^{GHJ}\times\Psi_{FCJK}\Psi^{D}{}_{GH}{}^{K}$, $B_2=\Psi_{AB}{}^{CD}\Psi_{CD}{}^{EF}\Psi_{EF}{}^{GH}\Psi_{GH}{}^{JK}\Psi_{JK}{}^{AB}$, and $B_3=\Psi_{ABCD}\Psi^{ABCD}\Psi_{EF}{}^{GH}\times\Psi_{GH}{}^{IJ}\Psi_{IJ}{}^{EF}$, and are associated with the matrices:

$$A(G_{B_1})=\begin{bmatrix}0&2&0&0&1\\0&0&0&0&0\\0&1&0&0&0\\1&1&1&0&1\\0&0&2&0&0\end{bmatrix},\quad A(G_{B_2})=\begin{bmatrix}0&2&0&0&0\\0&0&2&0&0\\0&0&0&2&0\\0&0&0&0&2\\2&0&0&0&0\end{bmatrix},$$

$$A(G_{B_3})=\begin{bmatrix}0&4&0&0&0\\0&0&0&0&0\\0&0&0&2&0\\0&0&0&0&2\\0&0&2&0&0\end{bmatrix}.$$

Invariants B_1 and B_2 are connected, whereas invariant B_3 is disconnected, and possesses two connected factors of lower polynomial degree: $\Psi_{ABCD}\Psi^{ABCD}$ and $\Psi_{EF}{}^{GH}\Psi_{GH}{}^{IJ}\Psi_{IJ}{}^{EF}$.

A directed multigraph G is *oriented* iff $m(v_j,v_k)=0$ whenever $m(v_k,v_j)\neq 0$ for $j\neq k$. It will be convenient for us to work with the oriented directed multigraph $G_{N'}$, which is formed by reversing the directions of edges of G_N as necessary to satisfy the above condition. $A(G_{N'})$ can be formed from $A(G_N)$ as follows:

$$A(G_{N'})=[a'_{jk}],\quad j,k=1,2,\ldots,n,$$

where

$$a'_{jk}=\begin{cases}a_{jk}+a_{kj}, & j<k,\\ 0, & j\geqslant k.\end{cases}\tag{2}$$

The invariant N is equivalent to its oriented form N' up to a sign; the exact relationship being given by

$$N'=(-1)^{\sigma}N,\tag{3}$$

where

$$\sigma=\sum_{j>k}a_{jk},$$

σ being the number of arcs that have been reversed.

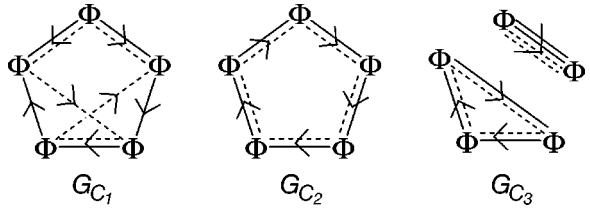

FIG. 2. Graphical representations of three pure Ricci invariants.

The graphical representation of the Ricci invariants is defined in a similar fashion to that of the Weyl invariants.

Definition 2: We associate a unique directed multigraph G_N, with each pure Ricci invariant N. The directed multigraph G_N consists of a vertex set $V=\{v_1,v_2,\ldots,v_n\}$, where each element of V is uniquely associated with each Ricci spinor, an arc set $E=V\times V$, and two functions: $m^S:V\times V\to\{0,1,2\}$, *and* $m^D:V\times V\to\{0,1,2\}$. *Each arc* $(v_j,v_k)\in E$ *is associated with two multiplicities: the number of contractions between lower undotted indices on the spinor* v_j *and upper undotted indices on the spinor* v_k *is* $m^S(v_j,v_k)$, *whereas the number of contractions between lower dotted indices on the spinor* v_j *and upper dotted indices on the spinor* v_k *is* $m^D(v_j,v_k)$.

The graph G_N possesses two distinct types of arcs. Solid arcs correspond to contractions between undotted indices and dashed arcs correspond to contractions between dotted indices. The multiplicities of the solid and dashed arcs (v_j,v_k) are $m^S(v_j,v_k)$ and $m^D(v_j,v_k)$, respectively. We associate with each type of arc an *arc characteristic*, ϖ which is 1 for a solid arc and i for a dashed arc. The total multiplicity between v_j and v_k, $m(v_j,v_k)$ is therefore defined as follows:

$$m(v_j,v_k)=m^S(v_j,v_k)+im^D(v_j,v_k). \tag{4}$$

An analogous distinction between irreducible and reducible invariants can also be made for these invariants. Three examples of graphical representations of fifth-degree, pure Ricci invariants are depicted in Fig. 2. Graphs G_{C_1}, G_{C_2}, and G_{C_3} represent the invariants $C_1=\Phi_{AB\dot{A}\dot{B}}\Phi^{A}{}_{C}{}^{\dot{A}\dot{C}}\Phi^{C}{}_{D}{}^{\dot{D}}{}_{\dot{D}}{}^{\dot{E}}\Phi^{D}{}_{E}{}^{\dot{C}}{}_{\dot{C}}{}^{\dot{D}}\Phi^{BE\dot{B}}{}_{\dot{E}}$, $C_2=\Phi_{A}{}^{B}{}_{\dot{A}}{}^{\dot{B}}\Phi_{B}{}^{C}{}_{\dot{B}}{}^{\dot{C}}\Phi_{C}{}^{D}{}_{\dot{C}}{}^{\dot{D}}\Phi_{D}{}^{E}{}_{\dot{D}}{}^{\dot{E}}\Phi_{E}{}^{A}{}_{\dot{E}}{}^{\dot{A}}$, and $C_3=\Phi_{AB\dot{A}\dot{B}}\Phi^{AB\dot{A}\dot{B}}\Phi_{E}{}^{F}{}_{\dot{E}}{}^{\dot{F}}\Phi_{F}{}^{G}{}_{\dot{F}}{}^{\dot{G}}\Phi_{G}{}^{E}{}_{\dot{G}}{}^{\dot{E}}$. Invariants C_1 and C_2 are connected, whereas invariant C_3 is disconnected, and possesses two connected factors of lower degree: $\Phi_{AB\dot{A}\dot{B}}\Phi^{AB\dot{A}\dot{B}}$ and $\Phi_{E}{}^{F}{}_{\dot{E}}{}^{\dot{F}}\Phi_{F}{}^{G}{}_{\dot{F}}{}^{\dot{G}}\Phi_{G}{}^{E}{}_{\dot{G}}{}^{\dot{E}}$. As in the case for the pure Weyl invariants, reversing the direction of any one arc has the effect of changing the overall sign of the invariant.

For the pure Ricci invariants, applying the definition of $m(v_j,v_k)$ in Eq. (4) to the adjacency matrix definition in Eq. (1) introduces a generalized adjacency matrix consisting of complex entries a_{jk}.

The invariants C_1, C_2, and C_3 in Fig 2. are thus associated with the matrices:

$$A(G_{C_1})=\begin{bmatrix} 0 & 1+i & 0 & 0 & 1+i \\ 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1+i & 0 \\ 0 & i & 0 & 0 & 1 \\ 0 & 0 & i & 0 & 0 \end{bmatrix},$$

$$A(G_{C_2})=\begin{bmatrix} 0 & 1+i & 0 & 0 & 0 \\ 0 & 0 & 1+i & 0 & 0 \\ 0 & 0 & 0 & 1+i & 0 \\ 0 & 0 & 0 & 0 & 1+i \\ 1+i & 0 & 0 & 0 & 0 \end{bmatrix},$$

FIG. 3. The graphs corresponding to a pure Ricci invariant and its conjugate.

$$A(G_{C_3})=\begin{bmatrix} 0 & 2+2i & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1+i & 0 \\ 0 & 0 & 0 & 0 & 1+i \\ 0 & 0 & 1+i & 0 & 0 \end{bmatrix}.$$

The sum of the real parts of the entries in row j corresponds to the solid-arc outdegree of v_j, whereas the sum of the real parts of the entries in column k corresponds to the solid-arc indegree of v_k. An analogous condition relating the imaginary parts of the matrix entries and the dashed arcs holds. Also, loops are assumed not to be present in these graphs, and consequently $a_{jj}=0$. Since the sum of the outdegree and the indegree at each vertex must be two for both types of arc, the following condition holds:

$$\sum_{k=1}^{n}(a_{jk}+a_{kj})=2+2i, \quad j=1,2,\ldots,n.$$

Equation (4) allows us to directly extend the definition of orientedness to the graphs associated with pure Ricci invariants: G_N is *oriented* iff $m(v_j,v_k)=0$ whenever $m(v_k,v_j)\neq 0$ for $j\neq k$. Given a pure Ricci invariant N, its oriented form N' satisfies the conditions in Eqs. (2) and (3), where the number σ of arcs reversed to form N' from N is given by

$$\sigma=\sum_{j>k}(x_{jk}+y_{jk}),$$

where $a_{jk}=x_{jk}+iy_{jk}$.

When dealing with the pure Ricci invariants, it will be useful to consider the graphical representation of the conjugate of an invariant. Given some pure Ricci invariant N, the graph $G_{\bar{N}}$ associated with its conjugate $\bar{N}$ is obtained from G_N simply by replacing all solid arcs with dashed arcs, and all dashed arcs with solid arcs. Since $\Phi_{AB\dot{A}\dot{B}}$ is Hermitian, all pure Ricci invariants are real quantities.

For example, the graph G_H associated with the pure Ricci invariant H is given in Fig. 3. The aforementioned interchange of solid and dashed arcs will provide the graph, $G_{\bar{H}}$ associated with the conjugate of H, which is equal to H itself.

III. THE PURE WEYL INVARIANTS

A. Properties of the set $\hat{\mathcal{W}}$

The set $\hat{\mathcal{W}}\subset\mathcal{W}$ is defined to be the set of all pure Weyl invariants such that all contractions between Weyl spinors occur pairwise, and the contractions belonging to each pair have the same direction, i.e., are both from lower indices to upper indices or vice versa. Thus, a pure Weyl invariant, N, is a member of the set $\hat{\mathcal{W}}$ iff every arc in G_N is of even multiplicity, i.e., $A(G_N)$ contains no odd integer elements. In Fig. 1, the invariant corresponding to B_1 does not belong to $\hat{\mathcal{W}}$, whereas the invariants corresponding to B_2 and B_3 are members of $\hat{\mathcal{W}}$.

Consider the set $\hat{\mathcal{W}}^c \subset \hat{\mathcal{W}}$, which consists of the connected invariants within $\hat{\mathcal{W}}$.

Lemma 1: All elements of $\hat{\mathcal{W}}$ are either elements of $\hat{\mathcal{W}}^c$, or are expressible as products of elements of $\hat{\mathcal{W}}^c$.

Proof: Obvious. ■

Lemma 2: For every integer $n \geqslant 2$, there exists a unique element of $\hat{\mathcal{W}}^c$, with polynomial degree n. We denote this element as $\hat{\mathcal{W}}^c(n)$.

Proof: The cases where the polynomial degree is 2 or 3 are trivial. Consider a *connected* directed multigraph G possessing $n>3$ vertices and a 4-regular underlying graph. We require that every arc be of even multiplicity, and arcs of multiplicity four, which would result in a disconnected graph, are not permitted. Therefore, G possesses n distinct arcs, and each arc must be of multiplicity two. Since graphs possessing loops are disregarded, it also follows that each vertex in G is incident with two distinct arcs. By appealing to elementary graph theory, which states that a graph is a n-cycle iff it is a connected 2-regular graph possessing n vertices, we conclude that G is a n-cycle with each edge replaced by an arc of multiplicity two. Given any two such directed multigraphs, we can transform one into the other by reorienting its arcs; i.e., their associated invariants are identical up to a sign. Given that all arcs in G are of multiplicity two, this transformation will leave the sign of its associated invariant unchanged. Hence for each n, there must be a unique invariant belonging to $\hat{\mathcal{W}}^c$. ■

We shall now construct the general formula relating any invariant in $\hat{\mathcal{W}}$ to the invariants w_1 and w_2. We begin by considering the members of $\hat{\mathcal{W}}^c$ in the standard canonical frame, where $\Psi_1=\Psi_3=0$. We construct the spinor ${}^n\Omega_{AB}{}^{CD}$ *via* consecutive pairwise contractions of n Weyl spinors and collect its dyad expansion as follows:

$$
\begin{aligned}
{}^n\Omega_{AB}{}^{CD} &= \underbrace{\Psi_{ABXY}\,\Psi^{XY}{}_{ZT}\,\Psi^{ZT}{}_{EF}\cdots\Psi^{GHCD}}_{n \text{ factors, } n\geq 2} \\
&= {}^nP_0\,\iota_A\,\iota_B\,\iota^C\iota^D + {}^nP_{2s}(o_A\,o_B\,\iota^C\iota^D + o^C o^D\,\iota_A\,\iota_B) \\
&\quad + {}^nP_{2a}(o_A\,o^C\,\iota_B\,\iota^D + o_A\,o^D\,\iota_B\,\iota^C + o_B\,o^C\,\iota_A\,\iota^D + o_B\,o^D\,\iota_A\,\iota^C) \\
&\quad + {}^nP_4 o_A\,o_B\,o^C o^D.
\end{aligned}
$$

It is straightforward to show that the coefficients ${}^nP_0$, ${}^nP_{2s}$, ${}^nP_{2a}$, and ${}^nP_4$ obey the following recursion relations:

$$
\begin{aligned}
{}^nP_0 &= {}^{n-1}P_0\Psi_2 + {}^{n-1}P_{2s}\Psi_0, \\
{}^nP_{2s} &= {}^{n-1}P_{2s}\Psi_2 + {}^{n-1}P_4\Psi_0, \\
{}^nP_{2a} &= -2({}^{n-1}P_{2a}\Psi_2), \\
{}^nP_4 &= {}^{n-1}P_4\Psi_2 + {}^{n-1}P_{2s}\Psi_4,
\end{aligned}
\tag{5}
$$

where

$$
{}^1P_0=\Psi_0, \quad {}^1P_{2s}={}^1P_{2a}=\Psi_2, \quad {}^1P_4=\Psi_4.
$$

From these recursion relations, we derive the following expressions for the coefficients:

$$
{}^nP_{2s} = \sum_{k=0}^{\lfloor n/2 \rfloor} \binom{n}{2k} (\Psi_0\Psi_4)^k\,\Psi_2{}^{n-2k},
$$

$$
{}^nP_{2a} = (-2)^{n-1}\,\Psi_2^n,
$$

$$
{}^nP_0 = \sum_{k=0}^{\lfloor (n-1)/2 \rfloor} \binom{n}{2k+1} \Psi_0 (\Psi_0\Psi_4)^k\,\Psi_2{}^{n-2k-1},
$$

$$ {}^{n}P_4 = \sum_{k=0}^{\lfloor (n-1)/2 \rfloor} \binom{n}{2k+1} \Psi_4 (\Psi_0 \Psi_4)^k \Psi_2^{\,n-2k-1}. $$

Since $\hat{\mathcal{W}}^c(n)$ is the trace of ${}^{n}\Omega_{AB}{}^{CD}$, it follows that the formula for $\hat{\mathcal{W}}^c(n)$ in the standard canonical frame, in terms of the Weyl curvature components, is

$$ \hat{\mathcal{W}}^c(n) = {}^{n}\Omega_{AB}{}^{AB} = 2({}^{n}P_{2s} - {}^{n}P_{2a}) = (-2\Psi_2)^n + 2\sum_{k=0}^{\lfloor n/2 \rfloor} \binom{n}{2k} (\Psi_0 \Psi_4)^k \Psi_2^{\,n-2k}. $$

The following general syzygy relation can be derived from Eq. (5):

$$ \hat{\mathcal{W}}^c(n) = \tilde{w}_1 \hat{\mathcal{W}}^c(n-2) + \tilde{w}_2 \hat{\mathcal{W}}^c(n-3), \quad n>3, \quad \hat{\mathcal{W}}^c(1) = 0, \tag{6} $$

where

$$ \tilde{w}_1 = \frac{\hat{\mathcal{W}}^c(2)}{2} = \frac{1}{2} \Psi_{ABCD} \Psi^{ABCD} = 3 w_1 $$

and

$$ \tilde{w}_2 = \frac{\hat{\mathcal{W}}^c(3)}{3} = \frac{1}{3} \Psi_{AB}{}^{CD} \Psi_{CD}{}^{EF} \Psi_{EF}{}^{AB} = 2 w_2 . $$

All invariants belonging to $\hat{\mathcal{W}}^c$ in an arbitrary frame can therefore be expressed as a polynomial function of the Weyl invariants w_1 and w_2,

$$ \hat{\mathcal{W}}^c(n) = n \sum_{2p+3q=n} \frac{(p+q-1)!}{p!\,q!} \tilde{w}_1^p \tilde{w}_2^q . $$

Hence, as a consequence of Lemmas 1 and 2 and this relation for $\hat{\mathcal{W}}^c(n)$, we can express any invariant within $\hat{\mathcal{W}}$ as a polynomial function of w_1 and w_2.

B. Invariants outside $\hat{\mathcal{W}}$

The pure Weyl invariants outside $\hat{\mathcal{W}}$ are associated with graphs that possess arcs of odd multiplicity. If we can express these invariants as polynomials of invariants belonging to $\hat{\mathcal{W}}$, we will have found the syzygies relating these invariants to w_1 and w_2. As a consequence of the second fundamental theorem, any polynomial syzygy relating the invariants outside $\hat{\mathcal{W}}$ to the invariants inside $\hat{\mathcal{W}}$ must be a consequence of the following identity:

$$ 3\varepsilon_{A[B}\varepsilon_{CD]} = \varepsilon_{AB}\varepsilon_{CD} + \varepsilon_{AC}\varepsilon_{DB} + \varepsilon_{AD}\varepsilon_{BC} \equiv 0, $$

which may be rewritten as

$$ \varepsilon_{AB}\varepsilon^{CD} = \delta_A^C \delta_B^D - \delta_A^D \delta_B^C . \tag{7} $$

Contracting the identity in Eq. (7) with $\Psi^A{}_{FGH}\Psi^{BJKL}\Psi_{CSTU}\Psi_D{}^{XYZ}$ leads to the following identity which transforms a pair of contractions spanning four distinct Weyl spinors:

$$ \Psi_{CSTU}\Psi^C{}_{FGH}\Psi_D{}^{XYZ}\Psi^{DJKL} = \Psi_{CSTU}\Psi^D{}_{FGH}\Psi_D{}^{XYZ}\Psi^{CJKL} + \Psi_{CSTU}\Psi_{BFGH}\Psi^{CXYZ}\Psi^{BJKL}. \tag{8} $$

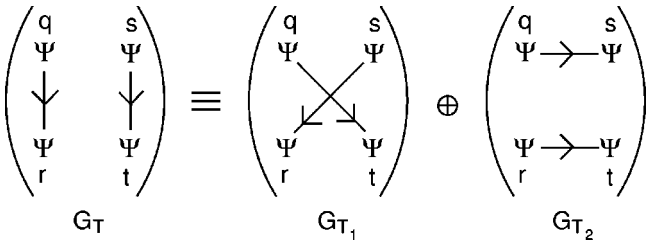

FIG. 4. The identity in Eq. (8) expressed in graphical notation.

In graphical notation, this identity is represented by transforming a pair of arcs spanning four distinct vertices (Fig. 4). The contracted spinor associated with the graph on the left-hand side (LHS) of the equation is the sum of the two contracted spinors associated with the two graphs on the right-hand side (RHS) of the equation, i.e., $T=T_1+T_2$. The vertices labeled q, r, s, and t correspond to the first, second, third, and fourth spinor in each term in Eq. (8), respectively.

In the graphical representation, we shall use the symbol $\oplus$ to denote addition of the associated spinors of two graphs. As expected, these edge transformations preserve the degree of each vertex. Contracting Eq. (7) (or its conjugate) with appropriate products of four Ricci spinors will provide the Ricci identities analogous to the Weyl identity in Eq. (8) where either a pair of solid arcs, or a pair of dashed arcs, are transformed. From now on, we shall simply refer to the graphical forms of these identities arising from Eq. (7) (or its conjugate) as ''the identity.'' The arc transformations in the graphical Ricci identities directly resemble those of the Weyl identity depicted in Fig. 4. Note that if the pair of contractions transformed do not span four distinct spinors, Eq. (7) results in a trivial identity.

We can establish the following properties of $G_{N'}$.

Lemma 3: The total number of arcs of odd multiplicity incident with each vertex of $G_{N'}$ is even (or zero).

Proof: This immediately follows from the fact that $G_{N'}$ is oriented and every vertex in the underlying undirected graph of $G_{N'}$ is of degree four. ■

Lemma 4: For any pure Weyl invariant $N \notin \hat{\mathcal{W}}$, the number of distinct arcs of odd multiplicity in $G_{N'}$ is even, and greater than or equal to four.

Proof: By elementary graph theory, if $G_{N'}$ possesses n vertices, the sum of all arc multiplicities in $G_{N'}$ will be $2n$. Since the sum of all even arc multiplicities is even, it follows that there must be an even number of odd multiplicities. Suppose we had some $G_{N'}$ possessing only two arcs of odd multiplicity. By Lemma 3, it follows that both these arcs must connect one pair of vertices v_j and v_k, where both $m(v_j,v_k)$ and $m(v_k,v_j)$ are odd. This contradicts the fact that $G_{N'}$ is oriented. Thus, if $N \notin \hat{\mathcal{W}}$, the minimum number of arcs of odd multiplicity in $G_{N'}$ is four. ■

We now intend to focus on the arcs of odd multiplicity in $G_{N'}$, and apply the arc transformations in the identity to pair up these arcs. Consider the subgraph, $S_{N'}$, of the oriented directed graph, $G_{N'}$ where $m_{S_{N'}}(v_j,v_k)=1$ iff $m_{G_{N'}}(v_j,v_k)$ is odd, and $m_{S_{N'}}(v_j,v_k)=0$ otherwise. Recall that the union of two graphs is defined such that $V(G_1 \cup G_2)=V(G_1)\cup V(G_2)$ and $E(G_1 \cup G_2)=E(G_1)\cup E(G_2)$. Thus, $G_{N'}$ may be considered as the union of two edge-disjoint subgraphs, $S_{N'}$, and $G^S_{N'}$, which contains the arcs of even multiplicity in $G_{N'}$,

$$G_{N'}=S_{N'}\cup G^S_{N'}, \tag{9}$$

and where the adjacency matrices of these three graphs are related as follows:

$$A(G_{N'})=A(S_{N'})+A(G^S_{N'}). \tag{10}$$

The elements of $A(S_{N'})$ and $A(G^S_{N'})$ may be obtained directly from the elements a'_{jk} of $A(G_{N'})$, in the following manner:

$$A(S_{N'}) = [a'_{jk} \bmod 2],$$

$$A(G^S_{N'}) = [a'_{jk} - (a'_{jk} \bmod 2)]. \tag{11}$$

We can now state our main theorem.

Theorem 1: *For any pure Weyl invariant $N \notin \hat{\mathcal{W}}$, $S_{N'}$ is expressible, using the identity, as a finite sum of graphs consisting only of arcs of even multiplicity, $\tilde{S}_j$,*

$$S_{N'} \equiv \bigoplus_{j=1}^{n} c_j \tilde{S}_j, \tag{12}$$

where the coefficients c_j are rational numbers.

The graph $G_{N'}$ may then be expressed as

$$G_{N'} \equiv \bigoplus_{j=1}^{n} c_j G_{X_j},$$

where

$$G_{X_j} = G^S_{N'} \cup \tilde{S}_j. \tag{13}$$

The invariant N' then obeys the following identity:

$$N' = \sum_{j=1}^{n} c_j X_j, \tag{14}$$

where $X_j \in \hat{\mathcal{W}}$, $j = 1,2,\ldots,n$.

Proof: It immediately follows from Lemmas 3 and 4 that $S_{N'}$ possesses an even number of arcs and each of its connected components of its underlying undirected graph is Eulerian. For the purpose of proving this theorem, we reorient the arcs of $S_{N'}$ to form a digraph $S_{N''}$ such that each

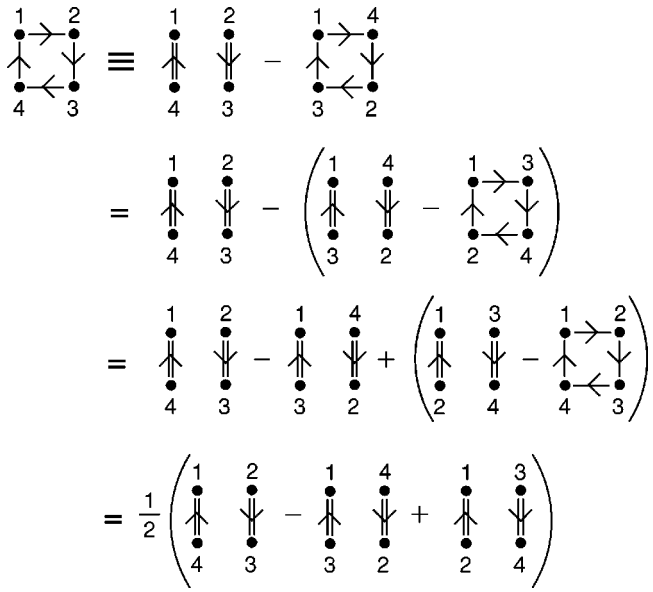

FIG. 5. Complete decomposition of a 4-circuit into graphs consisting solely of arcs of even multiplicity.

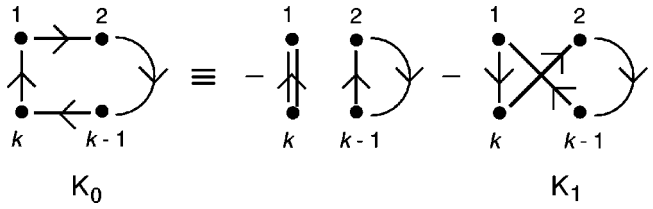

FIG. 6. First stage in the decomposition of a k-circuit.

component of $S_{N''}$ has a (directed) Euler circuit. If the number of arcs reoriented is σ', then the invariant N'' corresponding to the graph $G^S_{N'} \cup S_{N''}$ is equivalent to $(-1)^{\sigma'} N'$; and the original invariant N is given by $(-1)^{\sigma+\sigma'} N''$. For convenience, we shall use the term k-circuit to mean a circuit of length k.

Case 1: $S_{N''}$ is connected.

In this case $S_{N''}$ possesses a Eulerian circuit of even length; the smallest possible circuit consists of four edges. Consider the simplest case where $S_{N''}$ is a 4-circuit. As Fig. 5 shows, application of the identity relates this circuit to two new graphs: one of which possesses paired edges and the other being a new 4-circuit.[23] This new circuit can be decomposed in a similar fashion, and ultimately we return to the original 4-circuit, with opposite sign. We can then solve for an expression relating $S_{N''}$ to graphs where all vertices are paired, and by taking the union of all terms in this expression with $G^S_{N'}$, it can be used to construct the polynomial syzygy relating N to invariants within $\hat{\mathcal{W}}$ according to Eqs. (13) and (14).

Next, we establish that when $S_{N''}$ possesses an Euler circuit of length $k \geqslant 6$, where k is even, it is expressible entirely in terms of $(k-2)$-circuits modulo the identity. We begin by denoting the Euler circuit of $S_{N''}$ as K_0, and sequentially label each vertex as shown in Fig. 6. The curved arrow in K_0 corresponds to a directed path of length $k-3$. Applying the arc transformation of Fig. 4 on the arcs $(1,2)$ and $(k-1,k)$, depicted in bold, and reorienting the direction of various arcs and changing signs appropriately result in the identity shown in Fig. 6. This expresses K_0 in terms of a $(k-2)$-circuit (the remaining two edges may be oriented to form an edge of multiplicity two), and a new k-circuit, denoted K_1. It will be convenient to represent these k-circuits as their vertex sequences, where we adopt the convention that each sequence begins and ends at the vertex labeled 1. We omit the final 1 in the sequence, as it is understood to be present. Thus, we represent the circuit K_0 as $(1,2,3,\ldots,k-2,k-1,k)$, and K_1 as $(1,k,2,\ldots,k-3,k-2,k-1)$.

We subsequently transform the arcs $(1,k)$ and $(k-2,k-1)$ in K_1 to produce another $(k-2)$-circuit, and K_2, which is a k-circuit possessing the vertex sequence $(1,k-1,k,\ldots k-4,k-3,k-2)$ (Fig. 7). Note that the arcs transformed in K_1 are distinct from the arcs formed from the transformation of K_0 in the previous step, i.e., $(k,2)$ and $(k-1,1)$. This is necessary to ensure that we do not derive trivial relationships such as $0=0$. Hence, we shall always choose to transform two arcs in the k-circuits such that the first arc connects the first two vertices in the vertex sequences, and the second arc connects the last two vertices in the vertex sequences.

At each step, the k-circuit is expressed as a $(k-2)$-circuit, together with a new k-circuit with opposite sign. After n steps following this procedure, we obtain an expression for K_0 which is the

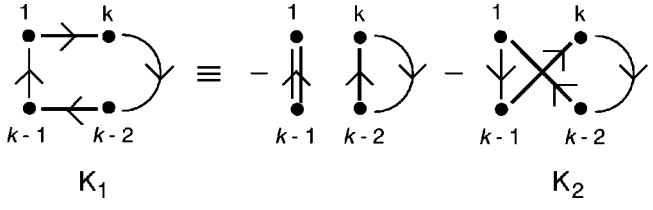

FIG. 7. Second stage in the decomposition of a k-circuit.

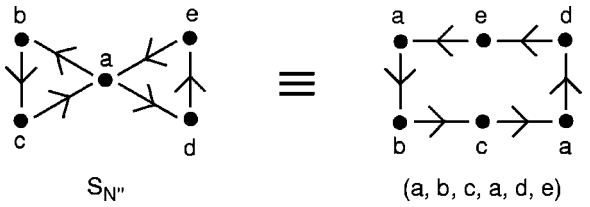

FIG. 8. Expression of an unpaired subgraph possessing a vertex of degree four as an equivalent vertex sequence.

sum of n terms associated with $(k-2)$-circuits, and $(-1)^n K_n$. The vertex sequence of K_{n+1} can be obtained by applying the permutation

$$\begin{pmatrix} 1 & 2 & 3 & 4 & \cdots & k-3 & k-2 & k-1 & k \\ 1 & k & 2 & 3 & \cdots & k-4 & k-3 & k-2 & k-1 \end{pmatrix} \tag{15}$$

on the vertex sequence of K_n. This permutation is of order $k-1$, therefore $K_{k-1} \equiv K_0$, and since $k-1$ is odd, we will return to the original circuit with opposite sign after $k-1$ steps. We are thus able to solve for K_0 to obtain an equivalent expression entirely in terms of $(k-2)$-circuits after $k-1$ steps.

Repeating this procedure with each of these $(k-2)$-circuits will then result in an expression for K_0 entirely in terms of $(k-4)$-circuits. Further repetition of this process will successively reduce the lengths of the circuits by two, and we eventually express K_0 in terms of 4-circuits. By Fig. 5, we can then express K_0 as a finite sum of graphs which only possess arcs of even multiplicity.

In the above discussion all vertices in the circuit have been labeled as distinct. This would correspond to the case where all vertices in the underlying graph of $S_{N''}$ are of degree two. In the event that vertices of degree four are present in the underlying graph of $S_{N''}$, these vertices will occur twice in the vertex sequence of a Eulerian circuit of $S_{N''}$. For example, if $S_{N''}$ is the graph in Fig. 8, then it corresponds to the vertex sequence (a,b,c,a,d,e).

This Eulerian circuit is still of even length, and despite the fact that vertex a appears twice in the vertex sequence, we may decompose it in the manner described above to ultimately pair all the arcs in $S_{N''}$. Owing to the vertex repetition in the vertex sequence, graphs possessing loops will be formed during this decomposition. In the vertex sequence representation, these would correspond to sequences with identical vertices next to each other. Whenever such graphs are formed, they ultimately correspond to expressions possessing spinors of the form $\Psi_A{}^{AXY}$ or $\Psi_{AB}{}^{AB}$. These expressions are identically zero and thus at any stage of the decomposition, graphs possessing loops may be removed from the sum in Eq. (12) as they are formed.

Case 2: $S_{N''}$ is disconnected.

Suppose that $S_{N''}$ consists of two disjoint circuits of length m and n, respectively. By Lemmas 3 and 4, $m+n$ must be even. By transforming a pair of arcs such that one arc comes from each circuit, $S_{N''}$ may be expressed in terms of graphs consisting of single circuits of length $m+n$, reducing the problem to Case 1 (Fig. 9). The extension of this result to three or more disjoint cycles is obvious.

We have established that using the arc transformation of Fig. 4, the subgraph $S_{N''}$ may be expressed equivalently as the sum of graphs consisting solely of arcs of multiplicity two, and we

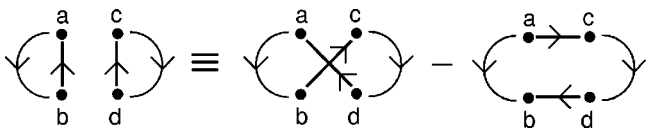

FIG. 9. Expression of two disjoint unpaired subgraphs of length m and n in terms of single circuits of length $m+n$.

get the corresponding decomposition of $S_{N'}$ [Eq. (12)] by multiplying both sides of this equation by $(-1)^{\sigma'}$. Taking the union of both sides of Eq. (12) with $G^S_{N'}$ will therefore provide the decomposition of $G_{N'}$ in terms of graphs consisting solely of arcs of even multiplicity [Eq. (13)]. The associated invariant identity then expresses N' as a polynomial of invariants within $\hat{\mathcal{W}}$ [Eq. (14)]. ■

In the preceding section it was established that every invariant within $\hat{\mathcal{W}}$ is expressible as a polynomial function of the base invariants w_1 and w_2. *Hence it follows from Theorem 1 that any pure Weyl invariant is expressible as a polynomial function of the base invariants* w_1 *and* w_2.

IV. THE PURE RICCI INVARIANTS

A. Properties of the set $\hat{\mathcal{R}}$

We define the set $\hat{\mathcal{R}} \subset \mathcal{R}$ to be the set of all pure Ricci invariants such that consecutive contractions between spinors also occur pairwise, where each pair of contractions consists of one contraction between a pair of undotted indices, and one contraction between a pair of dotted indices, such that both of these contractions are in the same direction. For convenience, we will call such a pair of contractions a *couple*, and any arc not belonging to a couple is said to be uncoupled. If $N \in \hat{\mathcal{R}}$, then all of the elements of its associated adjacency matrix, $A(G_N)$ satisfy the condition $x_{jk}=y_{jk}$, and every element of $A(G_N)$ is an integral multiple of $1+i$. In Fig. 2, the invariant corresponding to C_1 does not belong to $\hat{\mathcal{R}}$, whereas the invariants corresponding to C_2 and C_3 are members of $\hat{\mathcal{R}}$. In terms of the graphical representation adopted here, if $N \in \hat{\mathcal{R}}$, then the arcs of G_N are paired such that $\forall (v_j, v_k) \in E(G_N)$, $m^S(v_j, v_k) = m^D(v_j, v_k)$.

Let $\hat{\mathcal{R}}^c$, $\hat{\mathcal{R}}^c \subset \hat{\mathcal{R}}$, denote the set of all connected invariants within $\hat{\mathcal{R}}$. We can establish two properties of this set.

Lemma 5: All elements of $\hat{\mathcal{R}}$ *are either elements of* $\hat{\mathcal{R}}^c$, *or are expressible as products of elements of* $\hat{\mathcal{R}}^c$.

Proof: Obvious. ■

Lemma 6: For every integer $n \geqslant 2$, *there exists a unique element of* $\hat{\mathcal{R}}^c$ *with polynomial degree* n. *We denote this element as* $\hat{\mathcal{R}}^c(n)$.

Proof: This is obviously true for $n=2,3$. Consider a *connected* directed multigraph G possessing $n>3$ vertices. We require that every vertex in the underlying graph of G be adjacent to two solid edges and two dashed edges, and that arcs are paired in couples, resulting in equal multiplicities of solid and dashed arcs between any given pair of vertices (v_j, v_k). The presence of two such couples between a pair of vertices would result in a disconnected graph, hence there is at most one couple between every pair of vertices. Therefore, G possesses n distinct couples. Since graphs possessing loops are disregarded, it also follows that each vertex in G is adjacent to two distinct couples. By appealing to elementary graph theory, which states that a graph is a n-cycle iff it is a connected 2-regular graph possessing n vertices, we conclude that G is a n-cycle with each edge replaced by a couple. Given any two such directed multigraphs, we can transform one into the other by reversing the directions of couples. This transformation reverses the direction of an even number of arcs and will leave the sign of its associated invariant unchanged. Hence there must be a unique invariant belonging to $\hat{\mathcal{R}}^c$ for each n. ■

We begin the construction of the general formula relating the invariants in $\hat{\mathcal{R}}$ to the invariants r_1, r_2, and r_3 by considering the members of $\hat{\mathcal{R}}^c$ in the standard canonical frame, where $\Phi_{10} = \Phi_{01} = \Phi_{21} = \Phi_{12} = 0$. The spinor ${}^n\chi_A{}^Y{}_{\dot{A}}{}^{\dot{Y}}$, which is constructed *via* consecutive couple-by-couple contractions of n Ricci spinors ($n \geqslant 2$), may be written as

$$
\begin{aligned}
{}^{n}\chi_{A}{}^{Y}{}_{\dot{A}}{}^{\dot{Y}} &= \underbrace{\Phi_{AB\dot{A}\dot{B}}\,\Phi^{B}{}_{C}{}^{\dot{B}}{}_{\dot{C}}\,\Phi^{C}{}_{D}{}^{\dot{C}}{}_{\dot{D}}\,\Phi^{D}{}_{E}{}^{\dot{D}}{}_{\dot{E}}\cdots\Phi^{XY\dot{X}\dot{Y}}}_{n\ \text{factors},\ n\geqslant 2}\\
&= {}^{n}Q_{00}\,\iota_{A}\,\iota^{Y}\bar{\iota}_{\dot{A}}\bar{\iota}^{\dot{Y}} + {}^{n}Q_{11s}(o_{A}\,\iota^{Y}\bar{o}_{\dot{A}}\bar{\iota}^{\dot{Y}} + o^{Y}\iota_{A}\bar{o}^{\dot{Y}}\bar{\iota}_{\dot{A}})\\
&\quad + {}^{n}Q_{11a}(o_{A}\,\iota^{Y}\bar{o}^{\dot{Y}}\bar{\iota}_{\dot{A}} + o^{Y}\iota_{A}\bar{o}_{\dot{A}}\bar{\iota}^{\dot{Y}}) + {}^{n}Q_{20}\,o_{A}\,o^{Y}\bar{\iota}_{\dot{A}}\bar{\iota}^{\dot{Y}}\\
&\quad + {}^{n}Q_{02}\,\iota_{A}\,\iota^{Y}\bar{o}_{\dot{A}}\bar{o}^{\dot{Y}} + {}^{n}Q_{22}\,o_{A}\,o^{Y}\bar{o}_{\dot{A}}\bar{o}^{\dot{Y}}.
\end{aligned}
$$

It can be shown that the coefficients ${}^{n}Q_{00}$, ${}^{n}Q_{11s}$, ${}^{n}Q_{11a}$, ${}^{n}Q_{20}$, ${}^{n}Q_{02}$, and ${}^{n}Q_{22}$ obey the following recursion relations:

$$
\begin{aligned}
{}^{n}Q_{00} &= {}^{n-1}Q_{00}\Phi_{11} + {}^{n-1}Q_{11s}\Phi_{00},\\
{}^{n}Q_{11s} &= {}^{n-1}Q_{11s}\Phi_{11} + {}^{n-1}Q_{00}\Phi_{22},\\
{}^{n}Q_{11a} &= -\,{}^{n-1}Q_{11a}\Phi_{11} - {}^{n-1}Q_{02}\Phi_{20},\\
{}^{n}Q_{20} &= -\,{}^{n-1}Q_{20}\Phi_{11} - {}^{n-1}Q_{11a}\Phi_{20},\\
{}^{n}Q_{02} &= -\,{}^{n-1}Q_{02}\Phi_{11} - {}^{n-1}Q_{11a}\Phi_{02},\\
{}^{n}Q_{22} &= {}^{n-1}Q_{22}\Phi_{11} + {}^{n-1}Q_{11s}\Phi_{22},
\end{aligned}
\tag{16}
$$

where

$$
{}^{1}Q_{00} = \Phi_{00},\quad {}^{1}Q_{11s} = {}^{1}Q_{11a} = \Phi_{11},\quad {}^{1}Q_{20} = \Phi_{20},\quad {}^{1}Q_{02} = \Phi_{02},\quad {}^{1}Q_{22} = \Phi_{22}.
$$

The following expressions for the coefficients can be derived using these recursion relations:

$$
{}^{n}Q_{00} = \sum_{j=0}^{\lfloor (n-1)/2\rfloor}\binom{n}{2j+1}\Phi_{00}\,(\Phi_{00}\Phi_{22})^{j}\,\Phi_{11}^{n-2j-1},
$$

$$
{}^{n}Q_{11s} = \sum_{j=0}^{\lfloor n/2\rfloor}\binom{n}{2j}\,(\Phi_{00}\Phi_{22})^{j}\,\Phi_{11}^{n-2j},
$$

$$
{}^{n}Q_{11a} = (-1)^{n+1}\sum_{j=0}^{\lfloor n/2\rfloor}\binom{n}{2j}\,(\Phi_{20}\Phi_{02})^{j}\,\Phi_{11}^{n-2j},
$$

$$
{}^{n}Q_{20} = (-1)^{n+1}\sum_{j=0}^{\lfloor (n-1)/2\rfloor}\binom{n}{2j+1}\Phi_{20}\,(\Phi_{20}\Phi_{02})^{j}\,\Phi_{11}^{n-2j-1},
$$

$$
{}^{n}Q_{02} = (-1)^{n+1}\sum_{j=0}^{\lfloor (n-1)/2\rfloor}\binom{n}{2j+1}\Phi_{02}\,(\Phi_{20}\Phi_{02})^{j}\,\Phi_{11}^{n-2j-1},
$$

$$
{}^{n}Q_{22} = \sum_{j=0}^{\lfloor (n-1)/2\rfloor}\binom{n}{2j+1}\Phi_{22}\,(\Phi_{00}\Phi_{22})^{j}\,\Phi_{11}^{n-2j-1}.
$$

The nth degree invariant $\hat{\mathcal{R}}^{c}(n)$ is the trace of ${}^{n}\chi_{A}{}^{Y}{}_{\dot{A}}{}^{\dot{Y}}$. We can therefore express the invariants in $\hat{\mathcal{R}}^{c}$, in the standard canonical frame, in terms of the Ricci curvature components,

$$ {}^{n}\chi_{A}{}^{A}{}_{\dot{A}}{}^{\dot{A}}=2({}^{n}Q_{11s}-{}^{n}Q_{11a})=2\sum_{j=0}^{\lfloor n/2\rfloor}\binom{n}{2j}((\Phi_{00}\Phi_{22})^{j}+(-1)^{n}(\Phi_{20}\Phi_{02})^{j})\,\Phi_{11}^{n-2j}. $$

The following general syzygy relation can be derived from Eqs. (16):

$$ \hat{\mathcal{R}}^{c}(n)=\tilde{r}_{1}\hat{\mathcal{R}}^{c}(n-2)+\tilde{r}_{2}\hat{\mathcal{R}}^{c}(n-3)+\tilde{r}_{3}\hat{\mathcal{R}}^{c}(n-4),\quad n>4,\quad \hat{\mathcal{R}}^{c}(1)=0, \tag{17} $$

where

$$ \tilde{r}_{1}=\frac{\hat{\mathcal{R}}^{c}(2)}{2}=\frac{1}{2}\Phi_{AB\dot{A}\dot{B}}\Phi^{AB\dot{A}\dot{B}}=\frac{3}{2}r_{1}, $$

$$ \tilde{r}_{2}=\frac{\hat{\mathcal{R}}^{c}(3)}{3}=\frac{1}{3}\Phi_{AB\dot{A}\dot{B}}\Phi^{BC\dot{B}\dot{C}}\Phi^{A}{}_{C}{}^{\dot{A}}{}_{\dot{A}}=r_{2}, $$

$$ \tilde{r}_{3}=\frac{2\hat{\mathcal{R}}^{c}(4)-[\hat{\mathcal{R}}^{c}(2)]^{2}}{8}=\frac{1}{4}[\Phi_{AB\dot{A}\dot{B}}\Phi^{BC\dot{B}\dot{C}}\Phi_{CD\dot{C}\dot{D}}\Phi^{DA\dot{D}\dot{A}}-2\tilde{r}_{1}^{2}]=\frac{3}{16}(4r_{3}-3r_{1}^{2}). $$

All invariants belonging to $\hat{\mathcal{R}}^{c}$ in an arbitrary frame can therefore be expressed as a polynomial function of the pure Ricci invariants r_1, r_2, and r_3, as follows:

$$ \hat{\mathcal{R}}^{c}(n)=n\sum_{2p+3q+4r=n}\frac{(p+q+r-1)!}{p!q!r!}\tilde{r}_{1}^{p}\tilde{r}_{2}^{q}\tilde{r}_{3}^{r}. $$

Thus, as a consequence of Lemmas 5 and 6 and this relation for $\hat{\mathcal{R}}^{c}(n)$, we can express any invariant within $\hat{\mathcal{R}}$ as a polynomial function of r_1, r_2, and r_3.

B. Invariants outside $\hat{\mathcal{R}}$

If the pure Ricci invariant $N\notin\hat{\mathcal{R}}$, then G_N possesses uncoupled arcs. In order to relate N to the invariants within $\hat{\mathcal{R}}$, we need to apply the identity to G_N to form couples from the uncoupled arcs. In this case, the identity is applied to transform either two solid arcs spanning four distinct vertices, or two dashed arcs spanning four distinct vertices.

The graph $G_{N'}$ satisfies the following properties.

Lemma 7: For each vertex of $G_{N'}$, the total number of uncoupled arcs incident with it is even (or zero), and these uncoupled arcs consist of an equal number of solid and dashed arcs.

Proof: Each vertex of $G_{N'}$ is incident with two solid arcs and two dashed arcs. Removing couples incident with a vertex will leave behind an equal number of uncoupled solid arcs and uncoupled dashed arcs incident with this vertex. ■

Lemma 8: For any pure Ricci invariant $N\notin\hat{\mathcal{R}}$, the total number of distinct uncoupled arcs in $G_{N'}$ is even, and greater than or equal to four. These uncoupled arcs consist of an equal number of solid and dashed arcs.

Proof: If $G_{N'}$ possesses n vertices, the sum of all solid arc multiplicities in $G_{N'}$ will be n, and the sum of all dashed arc multiplicities in $G_{N'}$ will be n. Since each couple consists of one solid and one dashed arc, it follows that there must be an equal number of solid and dashed uncoupled arcs in $G_{N'}$. Suppose we had some $G_{N'}$ possessing only two uncoupled arcs. By Lemma 7, it follows that both these arcs must connect one pair of vertices v_j and v_k, where $m^{S}(v_j,v_k)=m^{D}(v_k,v_j)=1$, or $m^{D}(v_j,v_k)=m^{S}(v_k,v_j)=1$. This contradicts the fact that $G_{N'}$ is oriented. Thus, if $N\notin\hat{\mathcal{R}}$, the minimum number of uncoupled arcs in $G_{N'}$ is four. ■

We construct the unpaired subgraph $S_{N'}$ of $G_{N'}$ by removing couples from $G_{N'}$. We define the relative arc abundance between a pair of vertices v_j,v_k as the function δ: $(v_j,v_k)\rightarrow\{-2,-1,0,1,2\}$ where $\delta(v_j,v_k)=m^{S}_{G_{N'}}(v_j,v_k)-m^{D}_{G_{N'}}(v_j,v_k)$. If $\delta(v_j,v_k)>0$ then $m^{S}_{S_{N'}}(v_j,v_k)$

$=\delta(v_j,v_k)$ and $m^D_{S_{N'}}(v_j,v_k)=0$. However, if $\delta(v_j,v_k)<0$ then $m^D_{S_{N'}}(v_j,v_k)=-\delta(v_j,v_k)$ and $m^S_{S_{N'}}(v_j,v_k)=0$. Finally, if $\delta(v_j,v_k)=0$ then $m^S_{S_{N'}}(v_j,v_k)=m^D_{S_{N'}}(v_j,v_k)=0$.

As an immediate consequence of Lemma 8, the relative arc abundance function satisfies the following global property:

$$\sum_{V(G_{N'})}\delta(v_j,v_k)=0.$$

As in the case of the pure Weyl invariants, $G_{N'}$ may be considered to be the union of two edge-disjoint subgraphs [Eq. (9)]: $S_{N'}$, and $G^S_{N'}$, where $G^S_{N'}$ contains all of the couples present in $G_{N'}$. The adjacency matrices of these three graphs also satisfy the condition in Eq. (10), and the elements of $A(S_{N'})$ and $A(G^S_{N'})$ are related to the elements of $A(G_{N'})$, a'_{jk} in the following manner:

$$A(S_{N'})=[\eta_{jk}],$$

$$A(G^S_{N'})=[a'_{jk}-\eta_{jk}],$$

where

$$\eta_{jk}=\begin{cases}\delta(v_j,v_k), & \delta(v_j,v_k)\geqslant 0,\\ -i\,\delta(v_j,v_k), & \delta(v_j,v_k)<0.\end{cases} \tag{18}$$

Every nonzero entry in $A(S_{N'})$ is either real or imaginary. We will make use of the following property of $S_{N'}$.

Lemma 9: The arcs in $S_{N'}$ may be reoriented to form $S_{N''}$, such that each component of $S_{N''}$ is a single directed Euler circuit consisting of alternating solid and dashed arcs.

Proof: Suppose $S_{N'}$ is connected. Lemma 8 requires that $S_{N'}$ possesses an even number of arcs. It also follows from Lemma 7 that each vertex of its underlying undirected graph U_S is incident with an equal number of solid and dashed edges. We begin by constructing an alternating path in the following manner. We start at vertex v_a in U_S and take any edge incident with v_a. If we approach a vertex v_b via a solid edge, the number of unused dashed edges incident with v_b will exceed the number of unused solid edges incident with v_b by one. Similarly, if we approach v_b via a dashed edge, the number of unused solid edges incident with v_b will exceed the number of unused dashed edges incident with v_b by one. Hence at any vertex we come to, we can always leave by an unused edge of different type. Since U_S is finite, we will eventually return to v_a, approaching it via an edge of different type from the edge we used to leave it in the first place. Hence it follows that any vertex in U_S lies on a circuit consisting of alternating solid and dashed edges.

Let C be the longest such circuit in U_S. If C contains every edge in U_S then it is a Euler circuit and the lemma is true. Otherwise, if C does not contain every edge in U_S, we subtract the edges of C from U_S to give U_{S-C}. Each vertex in U_{S-C} must be incident with an equal number of solid and dashed edges. Since U_S is connected, C and U_{S-C} must have a vertex V in common. It follows from the previous paragraph that V must lie on a circuit C_1 consisting of alternating solid and dashed edges in the component of U_{S-C} containing V. Given the circuit C $(\ldots v_e,V,v_f,\ldots)$ and the circuit C_1 $(\ldots v_s,V,v_t,\ldots)$, where, without loss of generality, we assume the edges (v_e,V) and (v_s,V) are solid and the edges (V,v_f) and (V,v_t) are dashed, we can construct an alternating circuit C_2 $(\ldots v_e,V,v_t,\ldots v_s,V,v_f,\ldots)$. Thus, C_2 is longer than C, which contradicts the assumption that C is the longest circuit in U_S. Hence, the longest such C must contain every edge in U_S and be a Euler circuit. We can subsequently reorient the arcs in $S_{N'}$ to form a directed alternating Euler circuit.

If $S_{N'}$ is not connected, we first remove any isolated vertices present in $S_{N'}$, as these are components of $S_{N'}$ that do not possess any arcs. We can then apply the above argument individu-

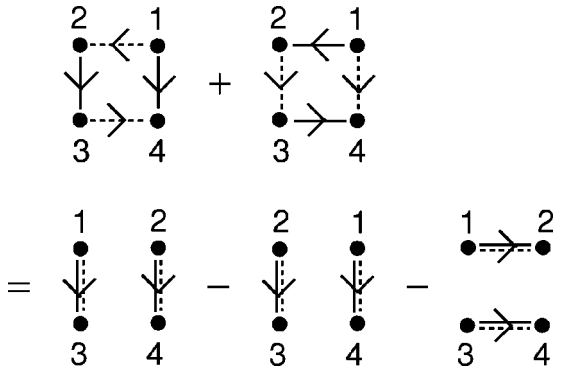

FIG. 10. Decomposition of an alternating 4-circuit into couples.

ally to each of the remaining connected components to show that each component may be reoriented as required. ■

We can now state the main result of this section.

Theorem 2: *For any pure Ricci invariant $N \notin \hat{\mathcal{R}}$, the sum $S_{N'} \oplus \overline{S_{N'}}$ is expressible, using the identity, as a finite sum of graphs consisting only of couples, $\tilde{S}_j$,*

$$S_{N'} \oplus \overline{S_{N'}} \equiv \overset{n}{\underset{j=1}{\oplus}} c_j \tilde{S}_j , \tag{19}$$

where $\overline{S_{N'}}$ is the graph $S_{N'}$ with solid arcs replaced by dashed arcs and dashed arcs replaced by solid arcs, and the coefficients c_j are rational numbers.

The sum $G_{N'} \oplus G_{\overline{N'}}$ may then be expressed as

$$G_{N'} \oplus G_{\overline{N'}} \equiv \overset{n}{\underset{j=1}{\oplus}} c_j G_{X_j},$$

where

$$G_{X_j} = G^S_{N'} \cup \tilde{S}_j , \tag{20}$$

and it follows that the invariant N' is given by

$$2N' = \sum_{j=1}^{n} c_j X_j , \tag{21}$$

where $X_j \in \hat{\mathcal{R}}$, $j = 1,2,\ldots,n$

Proof: We first orient $S_{N'}$ to obtain $S_{N''}$, and let σ' be the total number of arcs reoriented. Then, the invariant N'' corresponding to the graph $G^S_{N'} \cup S_{N''}$ is equal to $(-1)^{\sigma'} N'$. Therefore, $N = (-1)^{\sigma+\sigma'} N''$.

Case 1: $S_{N''}$ is connected.

By Lemmas 8 and 9, $S_{N''}$ consists of a single Eulerian circuit which is alternating, i.e., it consists of alternating solid and dashed arcs and has an even number of arcs. The smallest such circuit possible consists of four arcs.

Consider the simplest case where $S_{N''}$ is an alternating 4-circuit. Performing arc transformations analogous to those shown in Fig. 4 results in an identity whereby the sum of $S_{N''}$ and its "conjugate," $\overline{S_{N''}}$ is expressed in terms of graphs consisting entirely of couples (Fig. 10).

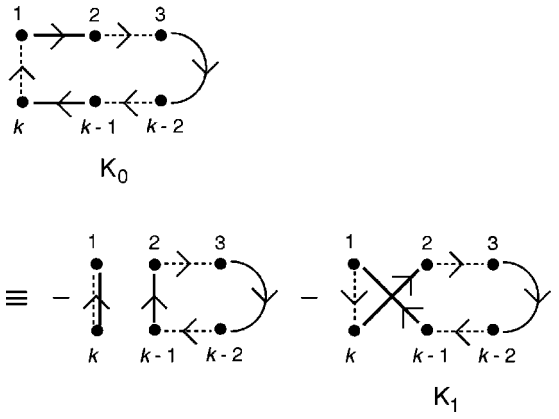

FIG. 11. First stage of the decomposition of an alternating k-circuit.

Taking the union of the left-hand side of Eq. (19) with $G^S_{N'}$ gives the sum $(G^S_{N'} \cup S_{N''}) \oplus (G^S_{N'} \cup \overline{S_{N''}})$. The first term is simply $G_{N''}$ the graph associated with N''. The graph $G^S_{N'}$ consists solely of couples, and is therefore invariant under the interchange of solid and dashed arcs. Hence, $G^S_{N'} \cup \overline{S_{N''}}$ is the graph $G_{N''}$ with solid and dashed arcs interchanged, and is hence associated with $\overline{N''}$, which is equivalent to N''. Taking the union of the right-hand side with $G^S_{N'}$ results in graphs consisting solely of coupled arcs. Hence, in this case, N'' can be expressed entirely in terms of invariants belonging to $\hat{\mathcal{R}}$. We emphasize that while $S_{N''}$ and its "conjugate" (solid–dashed arc interchange) $\overline{S_{N''}}$ are distinct graphs, their respective unions with $G^S_{N'}$ are associated with the same pure Ricci invariant owing to the fact that pure Ricci invariants are real.

Next, we extend this to show that when $S_{N''}$ is an alternating k-circuit, where k is even and $k \geqslant 6$, the sum $S_{N''} \oplus \overline{S_{N''}}$ is expressible entirely in terms of alternating $(k-2)$-circuits modulo the identity. Following what was done in the preceding section, we denote $S_{N''}$ as K_0 and represent it as the vertex sequence $(1,2,3,\ldots,k-2,k-1,k)$. Applying the identity on the solid arcs $(1,2)$ and $(k-1,k)$, depicted in bold, and reorienting the direction of various arcs and changing signs appropriately result in an expression for K_0 in terms of an alternating $(k-2)$-circuit and a new alternating k-circuit, K_1, possessing the vertex sequence $(1,k,2,\ldots,k-3,k-2,k-1)$ (Fig. 11).

The subsequent transformation of the dashed arcs $(1,k)$ and $(k-2,k-1)$ in K_1 produces another alternating $(k-2)$-circuit, and K_2, which is an alternating k-circuit which possesses the vertex sequence $(1,k-1,k,\ldots k-4,k-3,k-2)$ (Fig. 12). As before, we always choose to transform two arcs in the circuit such that the first arc connects the first two vertices in the vertex

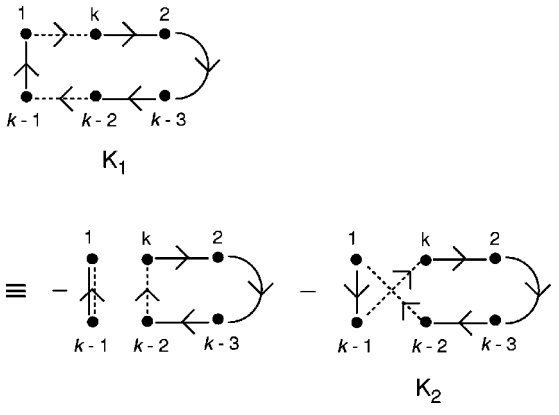

FIG. 12. Second stage of the decomposition of an alternating k-circuit.

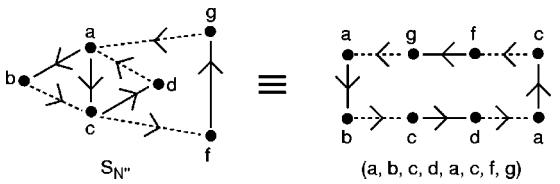

FIG. 13. Expression of a Ricci unpaired subgraph possessing a vertex of degree four as an equivalent vertex sequence.

sequence, and the second arc connects the last two vertices in the vertex sequence. For example, the arcs transformed in $K_0=(1,2,3,\ldots,k-2,k-1,k)$ were the solid arcs $(1,2)$ and $(k-1,k)$. This leads to $K_1=(1,k,2,\ldots,k-3,k-2,k-1)$, and the dashed arcs $(1,k)$ and $(k-2,k-1)$ are chosen from it for the next transformation. Thus, in the alternating circuit K_j, the pair of chosen vertices will be solid or dashed when j is even or odd, respectively.

After n applications of this procedure, we obtain an expression for K_0 which is the sum of n terms associated with $(k-2)$-circuits and $(-1)^n K_n$. The vertex sequence of K_{n+1} can be obtained by applying the permutation (15) on the vertex sequence of K_n and interchanging solid arcs with dashed arcs. For example, $K_0=(1,2,3,\ldots,k-2,k-1,k)$ and its first arc $(1,2)$ is solid. Applying permutation (15) on its vertex sequence and interchanging solid and dashed arcs give $K_1=(1,k,2,\ldots,k-3,k-2,k-1)$ with a dashed first arc $(1,k)$. Permutation (15) is of order $k-1$, therefore the vertex sequence of K_{k-1} will be identical to the vertex sequence of K_0, namely $(1,2,3,\ldots,k-2,k-1,k)$. However, since $k-1$ is odd, K_{k-1} will possess solid arcs between the vertices where K_0 possesses dashed arcs and vice versa. Thus $K_{k-1}\equiv\overline{K_0}$ and we are able to express the sum $K_0+\overline{K_0}$ entirely in terms of alternating $(k-2)$-circuits after $k-1$ steps.

Repeating this procedure with each of these alternating $(k-2)$-circuits leads to the fact that the sum of each $(k-2)$-circuit and its conjugate is expressible entirely in terms of alternating $(k-4)$-circuits. Thus $K_0+\overline{K_0}$ is expressible entirely in this form. Further repetition of this process will successively reduce the lengths of the circuits by two at each stage, and we eventually express $K_0+\overline{K_0}$ in terms of alternating 4-circuits. By Fig. 10, we can then express $K_0+\overline{K_0}$ as a finite sum of graphs which only possess coupled arcs.

In the event that vertices of degree four are present in the underlying graph of K_0, these vertices will occur twice in the vertex sequence of K_0. For example, the graph $S_{N''}$ in Fig. 13 corresponds to the vertex sequence (a,b,c,d,a,c,f,g). We can still decompose K_0 in the above manner, noting that whenever graphs with loops are formed by the arc transformations, they ultimately correspond to expressions possessing spinors of the form $\Phi_{A}{}^{A}{}_{B}{}^{\dot{C}}$, $\Phi_{B}{}^{C}{}_{A}{}^{\dot{A}}$ or $\Phi_{A}{}^{A}{}_{A}{}^{\dot{A}}$. These expressions are identically zero and thus at any stage of the decomposition, graphs possessing loops may be removed from the sum in Eq. (19) as they are formed.

Case 2: $S_{N''}$ is disconnected.

This reduces to Case 1 in a similar fashion to the pure Weyl invariants.

We have shown that the sum $S_{N''}\oplus\overline{S_{N''}}$ may be expressed equivalently as the sum of graphs consisting solely of couples via the application of the identity in Fig. 4. Multiplying both sides of this equation by $(-1)^{\sigma'}$ provides corresponding decomposition of $S_{N'}\oplus\overline{S_{N'}}$ [Eq. (19)]. Taking the union of both sides of Eq. (19) with $G^{S}_{N'}$ will therefore provide the decomposition of $G_{N'}\oplus G_{\overline{N'}}$ in terms of graphs consisting solely of couples [Eq. (20)]. The associated invariant identity, and the fact that $\overline{N'}=N'$, finally provides the expression for N' as a polynomial of invariants within $\hat{\mathcal{R}}$ [Eq. (21)]. ■

In the preceding section we established that every invariant within $\hat{\mathcal{R}}$ is expressible as a polynomial function of the base invariants r_1, r_2, and r_3. *It therefore follows from this theorem that any pure Ricci invariant is expressible as a polynomial function of the base invariants r_1, r_2, and r_3.*

V. COMPUTER IMPLEMENTATION

The proofs of Theorems 1 and 2 are constructive and provide general algorithms for the decomposition of any pure Weyl or Ricci invariant into a polynomial function of the basis invariants $\{w_1,w_2\}$ and $\{r_1,r_2,r_3\}$. The pure invariant N is provided as input in the form of its associated oriented matrix $A(G_{N'})$. It will be clear from the nature of the matrix entries (real or complex) whether the invariant is a pure Weyl or pure Ricci invariant. The matrices $A(S_{N'})$ and $A(G^S_{N'})$ are obtained from $A(G_{N'})$ using Eqs. (11) or (18). $A(S_{N'})$ is analyzed to determine whether $S_{N'}$ is connected, and if it is not connected, transformations are made to express $S_{N'}$ in terms of connected graphs (Case 2 of Theorems 1 and 2). These graphs are reoriented to form directed circuits while keeping track of any necessary sign changes. Each circuit is expressed as a vertex sequence.

We shall provide the decomposition algorithm in terms of vertex sequences because this construction, which we use in the proof of the syzygy theorems, assures us that the decomposition process will terminate, and not give a trivial relation. We start by denoting each oriented circuit as a list containing a multiplicative factor associated to that particular circuit and a second list corresponding to the vertex sequence of the circuit. For example, if $S_{N''}$ is a single connected k-circuit, it shall be denoted as $[1,[1,2,3,\ldots,k-2,k-1,k]]$, where the multiplicative factor is initially set as 1.

Transformation in the manner depicted by Fig. 6 and suitable arc reorientations will result in this particular circuit being expressed as the sum of two graphs:

$$[+1,[k,1],[2,3,\ldots,k-2,k-1]] \quad \text{and} \quad [-1,[1,k,2,\ldots,k-3,k-2,k-1]].$$

The first graph possesses two subgraphs: a 2-circuit connecting the kth and first vertices in the original sequence, and a $(k-2)$-circuit connecting the middle $k-2$ vertices in the original sequence. The 2-circuit $[k,1]$ may be considered to be, after reversing one edge and changing sign, an edge of multiplicity two between k and 1 in the case of the Weyl invariants, and a couple between k and 1 in the case of the Ricci invariants. The second graph is a k-circuit, and the vertex sequence of this k-circuit is obtained by applying the permutation (15) on the original vertex sequence (Fig. 6).

After $k-1$ successive transformations of the residual k-circuit, the original graph is expressed as the sum of the negative of the original k-circuit (or its ''conjugate'' in the case of the pure Ricci invariants) and $k-1$ terms, each containing an arc of multiplicity two (or a couple) and a $(k-2)$-circuit. We can thus solve for the original k-circuit, causing the multiplicative factors associated with the $(k-2)$-circuits to halve. Each $(k-2)$-circuit is passed to the reduction algorithm again and the reduction occurs recursively until the original circuit is expressed entirely in terms of 2-circuits. Each 2-circuit $[a,b]$ is transformed into arcs of even multiplicity (or couples) $\{a,b\}$ by reorienting one arc in each 2-circuit and changing sign appropriately, i.e, $[c,[a,b],\ldots]=[-c,\{a,b\},\ldots]$. Each graph consisting solely of even multiplicity arcs or couples is subsequently translated back into matrix form and added to $G^S_{N'}$ to obtain each term in the syzygy of N' as per Eqs. (13) and (14), or (20) and (21).

For example, consider the case where $S_{N'}$ is a single Eulerian 6-circuit, originating from a pure Weyl invariant. We represent $S_{N'}$ as $[1,[1,2,3,4,5,6]]$. Transforming the 6-circuit five times and solving for $S_{N'}$ gives the following decomposition of $S_{N'}$ into 2-circuits and 4-circuits. Figure 14 depicts this stage of the decomposition,

$$\begin{aligned} S_{N'}=&[\tfrac{1}{2},[6,1],[2,3,4,5]]+[-\tfrac{1}{2},[5,1],[6,2,3,4]]+[\tfrac{1}{2},[4,1],[5,6,2,3]] \\ &+[-\tfrac{1}{2},[3,1],[4,5,6,2]]+[\tfrac{1}{2},[2,1],[3,4,5,6]]. \end{aligned} \tag{22}$$

Each 4-circuit is expressible via the reduction algorithm as three terms involving solely 2-circuits. Therefore $S_{N'}$ is equivalent to the following expansion:

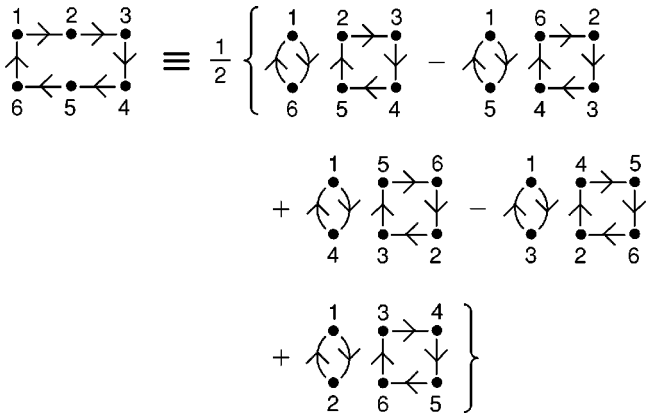

FIG. 14. Decomposition of a 6-circuit into 4-circuits and 2-circuits.

$$
\begin{aligned}
S_{N'} = {} & [\tfrac{1}{4},[6,1],[5,2],[3,4]] + [-\tfrac{1}{4},[6,1],[4,2],[5,3]] + [\tfrac{1}{4},[6,1],[3,2],[4,5]] \\
& + [-\tfrac{1}{4},[5,1],[4,6],[2,3]] + [\tfrac{1}{4},[5,1],[3,6],[4,2]] + [-\tfrac{1}{4},[5,1],[2,6],[3,4]] \\
& + [\tfrac{1}{4},[4,1],[3,5],[6,2]] + [-\tfrac{1}{4},[4,1],[2,5],[3,6]] + [\tfrac{1}{4},[4,1],[6,5],[2,3]] \\
& + [-\tfrac{1}{4},[3,1],[2,4],[5,6]] + [\tfrac{1}{4},[3,1],[6,4],[2,5]] + [-\tfrac{1}{4},[3,1],[5,4],[6,2]] \\
& + [\tfrac{1}{4},[2,1],[6,3],[4,5]] + [-\tfrac{1}{4},[2,1],[5,3],[6,4]] + [\tfrac{1}{4},[2,1],[4,3],[5,6]]. \qquad (23)
\end{aligned}
$$

Each 2-circuit may then be converted into an arc of multiplicity two by reorienting one arc in each circuit as described previously. Therefore,

$$
\begin{aligned}
S_{N'} = {} & [-\tfrac{1}{4},\{6,1\},\{5,2\},\{3,4\}] + [\tfrac{1}{4},\{6,1\},\{4,2\},\{5,3\}] + [-\tfrac{1}{4},\{6,1\},\{3,2\},\{4,5\}] \\
& + [\tfrac{1}{4},\{5,1\},\{4,6\},\{2,3\}] + [-\tfrac{1}{4},\{5,1\},\{3,6\},\{4,2\}] + [\tfrac{1}{4},\{5,1\},\{2,6\},\{3,4\}] \\
& + [-\tfrac{1}{4},\{4,1\},\{3,5\},\{6,2\}] + [\tfrac{1}{4},\{4,1\},\{2,5\},\{3,6\}] + [-\tfrac{1}{4},\{4,1\},\{6,5\},\{2,3\}] \\
& + [\tfrac{1}{4},\{3,1\},\{2,4\},\{5,6\}] + [-\tfrac{1}{4},\{3,1\},\{6,4\},\{2,5\}] + [\tfrac{1}{4},\{3,1\},\{5,4\},\{6,2\}] \\
& + [-\tfrac{1}{4},\{2,1\},\{6,3\},\{4,5\}] + [\tfrac{1}{4},\{2,1\},\{5,3\},\{6,4\}] + [-\tfrac{1}{4},\{2,1\},\{4,3\},\{5,6\}]. \qquad (24)
\end{aligned}
$$

Taking the union of this expression with $G^S_{N'}$ then gives the expression relating $G_{N'}$ to 15 graphs possessing only arcs of even multiplicity. This expression can be immediately converted into the identity relating N' to invariants within $\hat{\mathcal{W}}$, and from there, to the base invariants w_1 and w_2.

In the event that $S_{N'}$ is a single oriented alternating circuit of length six, originating from a pure Ricci invariant, the decomposition occurs in a very similar fashion. Applying the decomposition as detailed in Theorem 2 expresses the sum $S_{N'} \oplus \overline{S_{N'}}$ as the sum of five terms, each consisting of a 2-circuit and a 4-circuit. Since both $S_{N'}$ and $\overline{S_{N'}}$ correspond to the same invariant N' after taking their unions with $G^S_{N'}$ (see the proof of Theorem 2), we can associate $S_{N'} \oplus \overline{S_{N'}}$ with $2N'$, resulting in the validity of the application of the identity in Eq. (22) to this case. Extending this argument yields the result that Eqs. (23) and (24), also apply in the pure Ricci case. Equation (24) thus leads to the syzygy relating N' to the invariants within $\hat{\mathcal{R}}$, and, from there, to r_1, r_2, and r_3. Examples of this decomposition process for both pure Weyl and Ricci invariants are given in the Appendix.

It should be noted that the arc transformation in Fig. 4 (or its dashed arc form) also corresponds to well-defined operations on the elements of the matrix representations of these graphs, i.e., the elements of the matrices $A(G_{N_1})=[b_{jk}]$ and $A(G_{N_2})=[c_{jk}]$ corresponding to the graphs G_{N_1} and G_{N_2} obtained via operating on arcs (q,r) and (s,t) in $G_{N'}$, are equal to the matrix elements of $A(G_{N'})=[a_{jk}]$ with the exception of the following:

$$b_{qr}=c_{qr}=a_{qr}-\varpi, \quad b_{st}=c_{st}=a_{st}-\varpi,$$
$$b_{qt}=a_{qt}+\varpi, \quad b_{sr}=a_{sr}+\varpi,$$
$$c_{qs}=a_{qs}+\varpi, \quad c_{rt}=a_{rt}+\varpi, \tag{25}$$

where ϖ is the arc-characteristic of the two arcs being transformed. We note that the transformation can only occur between two arcs of the same type, and hence produces new arcs with the same characteristic. It follows that each transformation as described above has a unique characteristic, ϖ. Owing to the trace-free character of Ricci and Weyl spinors, if at any stage of the decomposition a matrix with a nonzero trace is formed, we can just remove this matrix from the sum, and proceed as usual.

VI. SUMMARY AND CONCLUDING REMARKS

In this paper, we have introduced a radically new approach to the classical problem of determining an independent set of polynomial invariants of the Riemann tensor. It is already well known that $\{w_1,w_2\}$ and $\{r_1,r_2,r_3\}$ form complete sets for the pure Weyl and Ricci invariants, respectively. However, our work builds on this knowledge by providing explicit formulas relating invariants within the special families $\hat{\mathcal{W}}$ and $\hat{\mathcal{R}}$ of pure Weyl and Ricci invariants to these sets, and subsequently proving constructively that all other invariants may be related to these families. We can therefore now explicitly construct the polynomial syzygies relating any pure invariant to members of the aforementioned complete sets.

We have laid down a fundamental framework that intimately links spinors to graphs. It is within this graph-theoretic setting that the construction of invariants becomes quite transparent and readily leads to algorithms which may be easily implemented on a computer. Our application of this formalism has thus far been limited to the pure Weyl and pure Ricci invariants. However, this approach is readily extendable to the mixed invariants. Work in this direction is currently in progress and our results thus far look quite promising. This work will be reported in a subsequent paper. Finally, we hope that the formulation established in this paper may well prove to be of broader interest generally.

APPENDIX

Example 1: $N'=\Psi_{ABCD}\Psi^{A}{}_{EFG}\Psi^{BEF}{}_{H}\Psi^{H}{}_{JKL}\Psi^{JKL}{}_{M}\Psi^{CDGM}$.

The graph $G_{N'}$ associated with N' is shown in Fig. 15. The vertices of $G_{N'}$ are labeled as a necessary step for the construction of its associated matrix $A(G_{N'})$. All matrices in this example are with respect to the vertex ordering $\{a,b,c,d,e,f\}$,

$$A(G_{N'})=\begin{bmatrix} 0 & 1 & 1 & 0 & 0 & 2 \\ 0 & 0 & 2 & 0 & 0 & 1 \\ 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 3 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 & 0 & 0 \end{bmatrix}.$$

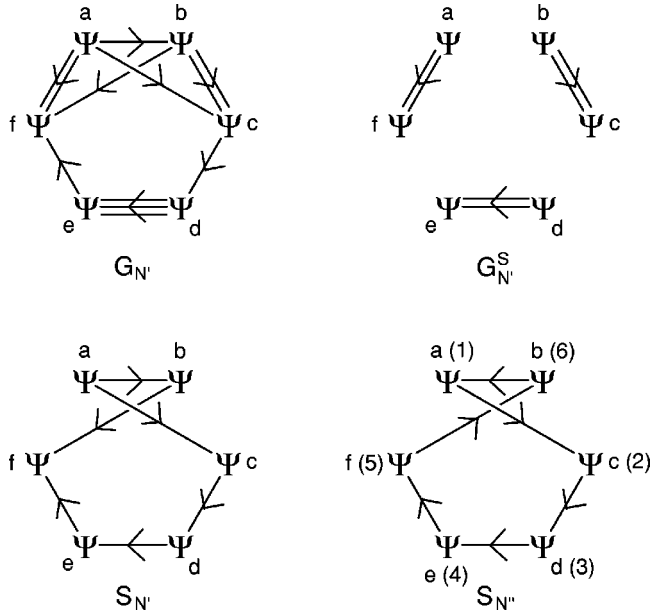

FIG. 15. Graphs associated with the decomposition process in Example 1.

The arc set of $G_{N'}$ is partitioned to give two subgraphs: $G^S_{N'}$ and $S_{N'}$, and their associated matrices $A(G^S_{N'})$ and $A(S_{N'})$ are related to $A(G_{N'})$ via Eq. (11),

$$A(G^S_{N'})=\begin{bmatrix} 0 & 0 & 0 & 0 & 0 & 2 \\ 0 & 0 & 2 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 2 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \end{bmatrix}, \quad A(S_{N'})=\begin{bmatrix} 0 & 1 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 & 0 & 0 \end{bmatrix}.$$

As expected, the arcs in $S_{N'}$ may be reoriented to form an Eulerian circuit. Reorienting the two arcs (a,b) and (b,f) in $S_{N'}$ allows us to form the 6-circuit $S_{N''}$. This circuit can be expressed as a vertex sequence of the form introduced in the computer implementation section by making the identification $\{1=a,2=c,3=d,4=e,5=f,6=b\}$. In this notation, $S_{N''}=[1,[1,2,3,4,5,6]]$. Since an even number of arcs were reoriented to form $S_{N''}$ from $S_{N'}$, the invariant, N'' associated with $(S_{N''}\cup G^S_{N'})$ will be identically equal to N'.

Equation (24) provides the decomposition of $S_{N''}$ in terms of graphs consisting solely of arcs of multiplicity two. Taking the union of this equation with $G^S_{N'}$ will give the relationship between N' and the invariants within $\hat{\mathcal{W}}$. This may be practically achieved by constructing an appropriate matrix and adding it to $A(G^S_{N'})$. For example, the first term in Eq. (24), $\tilde{S}_1=[-\frac{1}{4}, \{6,1\},\{5,2\},\{3,4\}]$ will be associated with the matrix $A(\tilde{S}_1)$ corresponding to edges of multiplicity two between the three pairs of vertices $\{b,a\}$, $\{f,c\}$, and $\{d,e\}$. The precise directions of these arcs of multiplicity two are not important, because changing the direction of any arc of multiplicity two will leave the original invariant unchanged. Therefore, we can reorient these arcs of multiplicity two as necessary to form upper triangular matrices, which is a condition for the orientedness of the graphs,

$$A(\tilde{S}_1)=\begin{bmatrix}0&2&0&0&0&0\\0&0&0&0&0&0\\0&0&0&0&0&2\\0&0&0&0&2&0\\0&0&0&0&0&0\\0&0&0&0&0&0\end{bmatrix}.$$

Thus, the first term in the syzygy, G_{X_1} will be associated with the matrix

$$A(G_{X_1})=A(G^S_{N'})+A(\tilde{S}_1)=\begin{bmatrix}0&2&0&0&0&2\\0&0&2&0&0&0\\0&0&0&0&0&2\\0&0&0&0&4&0\\0&0&0&0&0&0\\0&0&0&0&0&0\end{bmatrix}.$$

Hence, from the matrix, it can be determined that the first term X_1, in the syzygy relating N' to the invariants within $\hat{\mathcal{W}}$, is equivalent to $-\frac{1}{4}\hat{\mathcal{W}}^c(2)\hat{\mathcal{W}}^c(4)$. After doing the same for the remaining terms in Eq. (24), and cancellation of like terms with opposite signs, the following expression for N' is obtained:

$$N'=\tfrac{1}{4}[\hat{\mathcal{W}}^c(2)]^3-\tfrac{1}{2}\hat{\mathcal{W}}^c(2)\hat{\mathcal{W}}^c(4)=2\tilde{w}_1^3-2\tilde{w}_1^3=0.$$

Example 2: $N'=\Psi_{ABCD}\Psi^{ABC}{}_E\Psi^E{}_{FGH}\Psi^F{}_{JKL}\Psi^{JK}{}_{MN}\Psi^{DMN}{}_P\Psi^{GHLP}$.

The graph $G_{N'}$ is drawn and its vertices labeled as shown in Fig. 16. The matrices are constructed with respect to the ordering $\{a,b,c,d,e,f,g\}$.

Partitioning the arc set of $G_{N'}$ as previously described gives the graphs $G^S_{N'}$ and $S_{N'}$, where

$$A(G^S_{N'})=\begin{bmatrix}0&2&0&0&0&0&0\\0&0&0&0&0&0&0\\0&0&0&0&0&0&2\\0&0&0&0&2&0&0\\0&0&0&0&0&2&0\\0&0&0&0&0&0&0\\0&0&0&0&0&0&0\end{bmatrix},\quad A(S_{N'})=\begin{bmatrix}0&1&0&0&0&1&0\\0&0&1&0&0&0&0\\0&0&0&1&0&0&0\\0&0&0&0&0&0&1\\0&0&0&0&0&0&0\\0&0&0&0&0&0&1\\0&0&0&0&0&0&0\end{bmatrix}.$$

Reorienting the two arcs (a,f) and (f,g) and removing the isolated vertex e transforms $S_{N'}$ into $S_{N''}$, which can be expressed in vertex sequence notation as [1,[1,2,3,4,5,6]] after making the identification $\{1=a,2=b,3=c,4=d,5=g,6=f\}$. The invariant N'' corresponding to $(S_{N''}\cup G^S_{N'})$ is equal to N' as an even number of arcs were reoriented. Taking the union of Eq. (24) with $G^S_{N'}$ then gives the syzygy relating N' to invariants within $\hat{\mathcal{W}}$, and from there, to w_1 and w_2.

Following the procedure described in the previous example gives the following expression for N':

$$N'=\tfrac{1}{4}[\hat{\mathcal{W}}^c(2)]^2\hat{\mathcal{W}}^c(3)-\tfrac{1}{2}\hat{\mathcal{W}}^c(2)\hat{\mathcal{W}}^c(5)=-2\tilde{w}_1^2\tilde{w}_2=-36w_1^2w_2.$$

Example 3: $N'=\Phi_{AB\dot{A}\dot{B}}\Phi_{CD}{}^{\dot{A}}{}_{\dot{C}}\Phi^D{}_E{}^{\dot{B}}{}_{\dot{E}}\Phi^A{}_{FD\dot{F}}\Phi^B{}_G{}^{\dot{D}}{}_{\dot{G}}\Phi^E{}_H{}^{\dot{E}}{}_{\dot{H}}\Phi^{GH\dot{G}\dot{H}}\Phi^{CF\dot{C}\dot{F}}$.

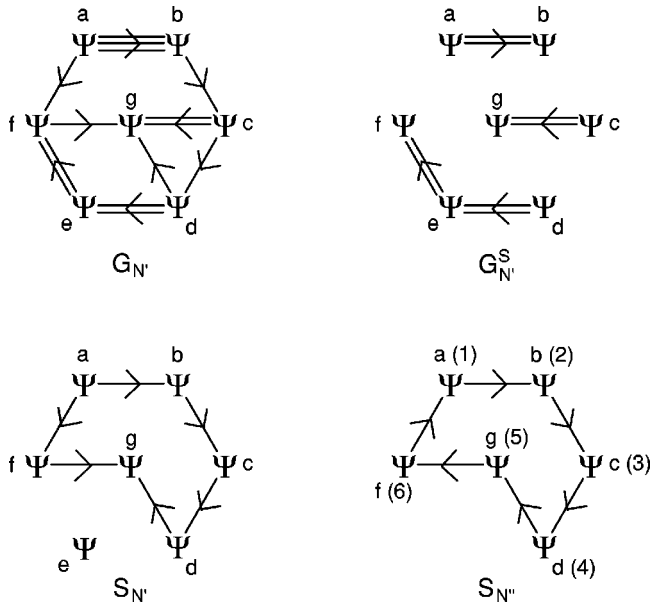

FIG. 16. Graphs associated with the decomposition process in Example 2.

The graph $G_{N'}$ is drawn and its vertices labeled as shown in Fig. 17. The matrices are constructed with respect to the ordering $\{a,b,c,d,e,x,y,z\}$.

Partitioning the arc set of $G_{N'}$ as previously described gives the graphs $G^S_{N'}$ and $S_{N'}$, where

$$A(G^S_{N'})=\begin{bmatrix} 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1+i \\ 0 & 0 & 0 & 0 & 0 & 1+i & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1+i \\ 0 & 0 & 0 & 0 & 0 & 0 & 1+i & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 1+i & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \end{bmatrix},$$

$$A(S_{N'})=\begin{bmatrix} 0 & i & i & 1 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & i & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \end{bmatrix}.$$

Reorienting the two edges (a,c) and (a,e) and removing all isolated vertices transforms $S_{N'}$ into $S_{N''}$, which can be expressed in vertex sequence notation as [1,[1,2,3,4,5,6]] after making the identification $\{1=a,2=b,3=c,4=a,5=d,6=e\}$. The invariant $(S_{N''}\cup G^S_{N'})$ is equal to N' as an even number of edges were reoriented. Note that the degree-4 vertex a is represented twice in

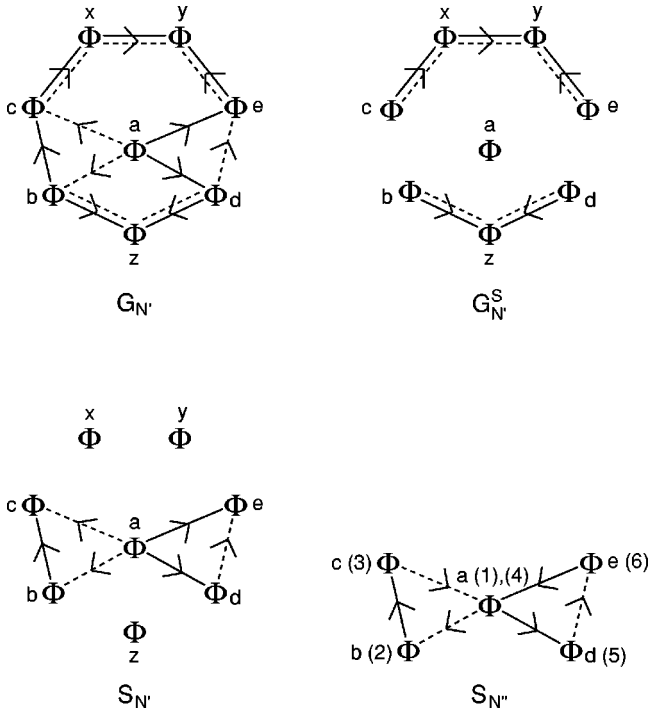

FIG. 17. Graphs associated with the decomposition process in Example 3.

this sequence; the labels 4 and 1 both represent the same vertex, a. The decomposition of Eqs. (22)–(24) are still valid, however, any terms in these equations that have vertex 4 adjacent to vertex 1 within the same circuit can be immediately disregarded as they ultimately correspond to graphs with loops at vertex a and are therefore associated with invariants which are identically zero. As a consequence, we only need to consider 12 terms in Eq. (24) in this case. The first term in Eq. (24), $\tilde{S}_1=[-\frac{1}{4},\{6,1\},\{5,2\},\{3,4\}]$ will be associated with the matrix corresponding to couples between the three pairs of vertices $\{e,a\}$, $\{d,b\}$, and $\{c,a\}$. The precise direction of these couples are not important, because changing the direction of any couple will leave the original invariant unchanged. Therefore, we are able to reorient these couples as necessary to form upper-triangular matrices,

$$A(\tilde{S}_1)=\begin{bmatrix} 0 & 0 & 1+i & 0 & 1+i & 0 & 0 & 0 \\ 0 & 0 & 0 & 1+i & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \end{bmatrix}.$$

Thus, the first term in the syzygy, G_{X_1} will be associated with the matrix,

$$A(G_{X_1})=A(G^S_{N'})+A(\tilde{S}_1)=\begin{bmatrix} 0 & 0 & 1+i & 0 & 1+i & 0 & 0 & 0 \\ 0 & 0 & 0 & 1+i & 0 & 0 & 0 & 1+i \\ 0 & 0 & 0 & 0 & 0 & 1+i & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1+i \\ 0 & 0 & 0 & 0 & 0 & 0 & 1+i & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 1+i & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \end{bmatrix}$$

Hence, it follows that the first term, X_1, in the syzygy relating N' to the invariants within $\hat{\mathcal{R}}$ is $-\frac{1}{4}\hat{\mathcal{R}}^c(3)\hat{\mathcal{R}}^c(5)$. Doing the same for the remaining terms in Eq. (24) then gives the syzygy relating N' to invariants within $\hat{\mathcal{R}}$, and, from there, to r_1, r_2, and r_3. Following this procedure yields

$$N'=\hat{\mathcal{R}}^c(8)-\tfrac{1}{2}\{\hat{\mathcal{R}}^c(3)\hat{\mathcal{R}}^c(5)+[\hat{\mathcal{R}}^c(4)]^2\}=\tfrac{1}{2}\tilde{r}_2^2\tilde{r}_1-4\tilde{r}_3^2=\tfrac{3}{64}(16r_2^2r_1-48r_3^2+72r_1^2r_3-27r_1^4).$$

[1] The classic problem involves "polynomial" completeness whereas recently the idea of algebraic completeness was introduced (see Ref. 11).

We study an inverse problem for the Zakharov–Shabat system which is motivated by an application to the design of co-directional couplers with prescribed response properties. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1645977]

I. STATEMENT OF DIRECT AND INVERSE PROBLEM

In this paper we are interested in an inverse problem for a system of ordinary differential equations which arises in the design of optical fiber devices. In the direct problem, we are given a coupling coefficient $q(x)$, which is a bounded, complex valued function on $[0,X]$. For any $k \in \mathbb{C}$ and $x \in [0,X]$ let $A=A(x,k), B=B(x,k)$ denote the solution of

$$\frac{\partial A}{\partial x} = ikA + q^*B, \quad \frac{\partial B}{\partial x} = -ikB \pm qA, \tag{1.1}$$

with initial conditions

$$A(0,k)=1, \quad B(0,k)=0. \tag{1.2}$$

The corresponding inverse problem is to determine $q(x)$ on $[0,X]$ given the scattering data,

$$\{B(X,k): k \in \mathbb{R}\}. \tag{1.3}$$

A closely related problem is the system (1.1) with boundary conditions

$$A(0,k)=1, \quad B(X,k)=0, \tag{1.4}$$

in which case the data for the inverse problem is

$$\{B(0,k): k \in \mathbb{R}\}. \tag{1.5}$$

For convenience of reference, let us refer to (1.1)–(1.2)–(1.3) as $\mathbf{P1}_{\pm}$ and (1.1)–(1.4)–(1.5) as $\mathbf{P2}_{\pm}$. [$\pm$ refers to the sign in the second equation of (1.1). Here and elsewhere when the symbols $\pm$ and $\mp$ are used it is understood that the top sign pertains to (1.1) in the $+q$ case and the lower sign to the $-q$ case.] Below we will say more about the distinctions among these four cases.

The system (1.1) is often referred to as the Zakharov–Shabat system, following the original work of Zakharov and Shabat[23] showing that the Cauchy problem for the cubic Schrödinger equation,

$$i\Psi_t = \Psi_{xx} \mp \Psi^2\Psi^*, \tag{1.6}$$

can be solved by means of an inverse scattering transform based on $\mathbf{P2}_{\pm}$. In Ref. 23 the spatial domain $[0,X]$ is replaced by $\mathbb{R}$, but if q in $\mathbf{P2}_{\pm}$ is extended to be 0 outside of $[0,X]$ then the problem coincides with that of Ref. 23. This theory has been elaborated in many books and papers; see, e.g., Refs. 1, 5, 20, 23, 24. See also Ref. 3 for a generalization of the $+q$ case to a $2N$ component system. The system (1.1) also arises in the description of the propagation of coupled

a)Electronic mail: psacks@iastate.edu

modes of electromagnetic waves in a waveguide. When the coefficient in the second equation is $+q$ one has the so-called contra-directional case, while $-q$ is the co-directional case. We mention also that (1.1) is related by a simple change of variables to the Dirac system for which direct and inverse scattering theory is of interest; see, for example, Refs. 6, 12.

The main motivation for the study of $\mathbf{P1}_-$ is the works,[11,13] in which this problem arises in connection with the design of optical fiber devices with certain prescribed properties. In this paper we will allow both choices of sign in (1.1) since it seems to be conventional in the literature to do so, and is of mathematical interest, but we do not know of any specific application for $\mathbf{P1}_+$. Problem $\mathbf{P2}_\pm$ has arisen in a larger number of recent works concerned with the design of fiber gratings (e.g., Refs. 9, 15, 19, 20, 22; see also Ref. 17 for a corresponding time domain problem), the $+$ sign being usually the physically significant case here. As mentioned above, $\mathbf{P2}_\pm$ is by now fairly well understood from a theoretical point of view—these papers are more concerned with computational issues.

Let us emphasize, however, that in the sort of application just mentioned, the questions of ultimate importance have to do with the *design* of the coupling coefficient q rather than *reconstruction* of q. The literature on inverse scattering is concerned almost entirely with reconstruction, so that uniqueness of solutions and, to a somewhat lesser extent, characterization of the data for which a solution exists, are the principal concerns. By contrast in a design problem we seek to choose a coefficient q so as to obtain a physical system with prescribed properties, and in many cases these are idealized properties which are not physically realizable. [For example, $B(X,k) \equiv 0$ outside of some k interval.] From the mathematical point of view it means we are given data for which no solution exists, and we attempt to find a solution anyway—or, less facetiously, obtain an ''optimal'' solution in some sense. There seems to be very little mathematical analysis of the design problem from this point of view (see, e.g., Ref. 10 for some such work), even for the simpler case of Schrödinger scattering and none will be given in this paper either. However we do believe this is an important problem for future investigation, and that the material in this paper on the reconstruction problem for $\mathbf{P1}_\pm$ will be useful for that.

To conclude this Introduction we discuss the difference in character between problems $\mathbf{P1}_\pm$ and $\mathbf{P2}_\pm$, due to the different side conditions. In certain cases (see Sec. III) there is an exact correspondence to an inverse scattering problem for a potential $V(x)$ in the more familiar Schrödinger equation. The case of $\mathbf{P2}_\pm$ corresponds to data being $L(k)$, the left hand reflection coefficient (see below for a review of the definitions) whereas in the case of $\mathbf{P1}_\pm$ the data amounts to $L(k)/T(k)$, the ratio of the reflection coefficient to the transmission coefficient. The use of L/T as basic scattering data, in the case of a real V, has appeared in a few previous papers (Refs. 16, 18), but usually in a somewhat artificial way. Here it seems that there is a clear physical motivation. In the Schrödinger scattering case it is not difficult to show that L/T uniquely determines L and hence the potential, at least if there are no bound states (see Ref. 4 for a careful study of multiplicity results when bound states are allowed), and we will derive the analogous result for $\mathbf{P1}_\pm$. The proof relies on analytic continuation, and thus does not immediately show how known numerical techniques for $\mathbf{P2}_\pm$ could be adapted to $\mathbf{P1}_\pm$. From another point of view the inverse problem $\mathbf{P2}_\pm$ is ''local in depth,'' whereas $\mathbf{P1}_\pm$ is not, meaning that layer stripping type methods cannot be used, at least in any direct way. One alternative computational approach, somewhat analogous to Ref. 18, will be discussed in Sec. VII.

II. CONSERVATION OF ENERGY AND BOUND STATES

Clearly a solution of (1.1), (1.2) exists on $[0,X]$ for any $k \in \mathbb{C}$. Extending q by zero for $x \notin [0,X]$ we may assume when convenient that $A(x,k), B(x,k)$ are defined for all $x \in \mathbb{R}, k \in \mathbb{C}$. If we let

$$E(x,k) = (|A(x,k)|^2 \mp |B(x,k)|^2), \tag{2.1}$$

then a simple calculation gives

$$\frac{\partial E}{\partial x} = i(k-k^*)(|A(x,k)|^2 \pm |B(x,k)|^2). \tag{2.2}$$

In particular for $k \in \mathbb{R}$,

$$|A(X,k)|^2 \mp |B(X,k)|^2 \equiv 1. \tag{2.3}$$

A bound state of (1.1) is a nonzero solution of (1.1) for some fixed $k \in \mathbb{C}$ with $A(\cdot,k), B(\cdot,k) \in L^2(\mathbb{R})$. Such solutions are impossible in the $+q$ case of (1.1) since by (2.2) and the fact that E must be exponentially decaying at $\pm\infty$ we must have $\operatorname{Im} k \neq 0$ and

$$0 = \int_{-\infty}^{\infty} \frac{\partial E}{\partial x}(x,k)\, dx = i(k-k^*) \int_{-\infty}^{\infty} (|A(x,k)|^2 + |B(x,k)|^2)\, dx. \tag{2.4}$$

In the $-q$ case bound states may exist, although only for sufficiently large q. This is in contrast to the standard Schrödinger scattering case in which any potential $V(x) \leqslant 0, V(x) \not\equiv 0$ has at least one bound state. As is well known, it is the existence of such bound states which give rise to the existence of solitary wave solutions of the cubic Schrödinger equation (1.6).

It is easy to check that if $\operatorname{Im} k < 0$ and $A(X,k) = 0$ then both components are either identically zero or exponentially decaying at both $\pm\infty$, hence $\{A(x,k), B(x,k)\}$ is a bound state.

III. RELATION TO OTHER FORMS OF SCATTERING DATA

Consider the special case that $\pm q = q^*$, i.e., q is real in the $+q$ case or imaginary in the $-q$ case. If we set $\psi = A + B$ then straightforward computation gives

$$\psi'' + (k^2 - V(x))\psi = 0, \tag{3.1}$$

where $V = \pm q' + q^2$, a Schrödinger equation with (possibly complex) potential V.

Proceeding as in the case of a real potential (e.g., Refs. 5, 7, 8) we introduce the standard fundamental set of solutions ψ_-, ψ_+ of (3.1) which satisfy

$$\psi_-(x,k) = \begin{cases} e^{ikx} + L(k)e^{-ikx}, & x < 0, \\ T(k)e^{ikx}, & x > X; \end{cases} \tag{3.2}$$

$$\psi_+(x,k) = \begin{cases} T(k)e^{-ikx}, & x < 0, \\ e^{-ikx} + R(k)e^{ikx}, & x > X; \end{cases} \tag{3.3}$$

where L, R are left and right hand reflection coefficients and T is the transmission coefficient. (It may be checked that even in the case of complex V, the left and right transmission coefficients coincide.)

From (1.2) we clearly have

$$A(x,k) = e^{ikx}, \quad B(x,k) = 0, \quad x < 0, \tag{3.4}$$

and

$$B(x,k) = B(X,k)e^{-ik(x-X)}, \quad A(x,k) = A(X,k)e^{ik(x-X)}, \quad x > X. \tag{3.5}$$

From (3.4) it follows that

$$\psi(x,k) = \psi_-(x,k) - \frac{L(k)}{T(k)}\psi_+(x,k), \tag{3.6}$$

so that

$$\psi(x,k)=\left(T(k)-\frac{L(k)R(k)}{T(k)}\right)e^{ikx}-\frac{L(k)}{T(k)}e^{-ikx},\quad x>X. \tag{3.7}$$

From this and (3.5) then

$$A(X,k)=e^{ikX}\left(T(k)-\frac{L(k)R(k)}{T(k)}\right),\quad B(X,k)=-e^{-ikX}\frac{L(k)}{T(k)}. \tag{3.8}$$

At least in the case of real q, the expression for $A(X,k)$ can be further simplified, using standard identities for Schrödinger scattering, to

$$A(X,k)=\frac{e^{ikX}}{T(k)^*},\quad k\in\mathbb{R}. \tag{3.9}$$

The inverse problem $\mathbf{P1}_{\pm}$ thus corresponds, in such a case, to Schrödinger inverse scattering in which the available data is the ratio L/T of a reflection and transmission coefficient. By comparison, the data for problem $\mathbf{P2}_{\pm}$ would be simply $L(k)$, by a similar calculation, and so amounts to a familiar problem. It is well known (e.g., Refs. 5, 7, 8) that a real V is uniquely determined by $L(k)$ if no bound states are present.

IV. UNIQUENESS

In the Schrödinger scattering case, when V has no bound states it is not hard to see that L/T uniquely determines L and hence V. Uniqueness for $\mathbf{P1}_{\pm}$ amounts to essentially the same thing for the system (1.1).

Theorem 1: *There is at most one solution of* $\mathbf{P1}_{+}$, *and the same is true of* $\mathbf{P1}_{-}$ *if there are no bound states*.

Proof: First note from (2.3) that $|A(X,k)|$ is known from the data, and it is not hard to check that

$$A(X,k)=a^*(k^*)e^{ikX}, \tag{4.1}$$

where $a(k)$ is defined in Eq. (1.3.3a) in Ref. 1 (again with the understanding that q has been extended by zero outside of $[0,X]$). The function a is entire and $a(k)\to 1$ as $|k|\to\infty$ in the upper half plane.

Recall from Sec. II that there can be no bound states in the case of $\mathbf{P1}_{+}$, and the same is true in the case of $\mathbf{P1}_{-}$ by hypothesis. From the last remark in Sec. II it follows that $A(X,k)$ has no zeros in the lower half of the complex plane. Thus $g(k):=\log(A(X,k)e^{-ikX})$ is analytic in the lower half plane and tends to zero as $|k|\to\infty$. It follows by the usual Hilbert transform relation that the imaginary part of g on the real axis is uniquely determined by its real part, that is to say, the phase of $A(X,k)$ may be determined from $|A(X,k)|$, and so $A(X,k)$ is itself known. Finally one may check that

$$\{A(X-x,-k)/A(X,-k),-B(X-x,-k)/A(X,-k)\} \tag{4.2}$$

is a solution pair of (1.1) with $q(x)$ replaced by $q(x-X)$, satisfying side conditions (1.4) and having known scattering data (1.5). Thus q is uniquely determined according to the standard results about problems $\mathbf{P2}_{\pm}$. □

In the Schrödinger scattering case it is known (e.g., Theorem 2.3 of Ref. 18) that L/T does not uniquely determine the potential in the presence of bound states, hence we expect that the ''no bound state'' hypothesis in the case of $\mathbf{P1}_{-}$ cannot be dispensed with. Numerical examples (see Sec. VII below) also indicate this quite clearly. On the other hand in the more conventional case of Schrödinger scattering with data L, even though bound state data is needed in general to

uniquely determine a potential, this is not the case if V is known to be supported in a half line (Refs. 2, 14), i.e., $L(k)$ alone suffices to determine V in such a case. We conjecture that the same is true for $\mathbf{P2}_-$.

V. TIME DOMAIN PROBLEM

It is well known that problem $\mathbf{P2}_\pm$ can be analyzed in terms of an associated hyperbolic ''time domain'' problem, which is recalled in (6.2) below; see, e.g., Refs. 9, 17, 19, 20. Here we derive a corresponding hyperbolic problem (5.15) for $\mathbf{P1}_\pm$. We remark that in the case of $\mathbf{P2}_\pm$ the derivation of (6.2) requires an assumption that there be no bound states, but this hypothesis is not needed in the case of (5.15).

Let $\{a(x,t),b(x,t)\}$ denote solutions of the hyperbolic problem in $\mathbb{R}^2$,

$$a_t+a_x=q^*(x)b, \quad b_t-b_x=\mp q(x)a, \tag{5.1}$$

$$a(0,t)=\delta(t), \quad b(0,t)=0. \tag{5.2}$$

Regarding this as an evolution equation in the space variable x we see by the standard domain of dependence considerations that the support of the solution is in the triangle $\{(x,t):|t|\leqslant x<X\}$. Taking the Fourier transform in t, using the convention

$$\hat{f}(k)=\int_{-\infty}^{\infty} f(t)e^{ikt}\,dt, \tag{5.3}$$

we find that

$$-ik\hat{a}+\hat{a}_x=q^*\hat{b}, \quad -ik\hat{b}-\hat{b}_x=\mp q\hat{a} \tag{5.4}$$

and

$$\hat{a}(0,k)=1, \quad \hat{b}(0,k)=0. \tag{5.5}$$

That is to say $A(x,k)=\hat{a}(x,k), B(x,k)=\hat{b}(x,k)$ is the solution of (1.1), (1.2), since the solution is unique.

By a standard propagation of singularity (geometric optics) arguments, we may obtain equivalent characteristic boundary conditions for a,b. The solution with $q\equiv 0$ is $a(x,t)=\delta(x-t), b(x,t)=0$, thus near the characteristic $t=x$ we should have

$$a(x,t)=\delta(x-t)+\alpha(x)H(x-t)+ \text{ smoother terms}, \tag{5.6}$$

$$b(x,t)=\beta(x)H(x-t)+ \text{ smoother terms}, \tag{5.7}$$

where H denotes the unit step function and α, β are transport coefficients to be determined. Inserting these expansions into (5.1) and matching the coefficients of the most singular terms we get

$$\alpha(x)=\pm\frac{1}{2}\int_0^x |q(s)|^2\,ds, \quad \beta(x)=\pm\frac{1}{2}q(x). \tag{5.8}$$

When we carry out a similar calculation on the lower characteristic $t=-x$, substituting

$$a(x,t)=\alpha(x)H(x+t)+ \text{ smoother terms}, \tag{5.9}$$

$$b(x,t)=\beta(x)H(x+t)+ \text{ smoother terms}, \tag{5.10}$$

the relations

$$\alpha(x)=0, \quad -\beta'(x)=\mp q(x)\alpha(x) \tag{5.11}$$

are obtained. Thus

$$\alpha(x)=0, \quad \beta(x)=\beta(0), \tag{5.12}$$

and the continuity of a,b from inside the cone $|t|<x$ then gives

$$\beta(0)=\pm\tfrac{1}{2}q(0). \tag{5.13}$$

Note that

$$A(X,k)=\int_{-X}^{X}a(X,t)e^{ikt}\,dt, \quad B(X,k)=\int_{-X}^{X}b(X,t)e^{ikt}\,dt, \tag{5.14}$$

from which it follows that $A(X,\cdot),B(X,\cdot)$ are bandlimited functions, hence uniquely determined by appropriate sampling.

We may now reformulate the inverse problem $\mathbf{P1}_{\pm}$ as an overdetermined boundary value problem: If $B(X,k)$ is the data corresponding to q then there exist $\{a(x,t),b(x,t)\}$ such that

$$a_t+a_x=q^*(x)b, \quad b_t-b_x=\mp q(x)a, \quad |t|<x<X, \tag{5.15a}$$

$$b(x,x)=\pm\frac{1}{2}q(x), \quad 0<x<X, \tag{5.15b}$$

$$a(x,-x)=0, \quad 0<x<X, \tag{5.15c}$$

$$b(X,t)=\frac{1}{2\pi}\int_{-\infty}^{\infty}B(X,k)e^{-ikt}\,dk, \quad |t|<X. \tag{5.15d}$$

Note that the additional characteristic boundary conditions,

$$a(x,x)=\pm\frac{1}{2}\int_{0}^{x}|q(s)|^2\,ds, \quad b(x,-x)=\pm\frac{1}{2}q(0), \quad 0<x<X, \tag{5.16}$$

follow from (5.15), consistently with the expressions for $\alpha(x)$ in (5.8) and $\beta(x)$ in (5.12).

VI. NONLINEAR PLANCHEREL IDENTITY

In the context of inverse scattering for the Helmholtz equation, Sylvester, Winebrenner, and Gylys-Colwell[21] discovered an interesting identity relating the L^2 norm of the coefficient to a certain nonlinear functional of the scattering data. It was referred to as a nonlinear Plancherel identity because in the weak scattering limit, the coefficient to data mapping becomes the Fourier transform, and so the identity in question goes over to the classical Plancherel equality. In this section we will state and prove an analogous property for the inverse scattering problem $\mathbf{P1}_{\pm}$. For the proof we will need a corresponding result for $\mathbf{P2}_{\pm}$, which as far as we know is also new, although the proof follows closely the pattern of Ref. 21.

Before proceeding let us note that if we set $R(x,k)=B(x,k)/A(x,k)$ then it is easy to check that R satisfies the Riccati type equation,

$$\frac{\partial R}{\partial x}=-2ikR(x,k)-q^*(x)R(x,k)^2\pm q(x), \tag{6.1}$$

at least provided that $A(x,k)\neq 0$. Numerical methods for $\mathbf{P2}_{\pm}$ have been developed which exploit (6.1) and the fact that $R(0,k),R(X,k)$ are known from the data and side conditions (Refs. 9, 19). For $\mathbf{P1}_{\pm}$, however, we only know that $R(0,k)=0$ and have no explicit way to obtain $R(X,k)$.

We also will make use of the analog of (5.15) for $\mathbf{P2}_{\pm}$ which is the following: If $B(0,k)$ is the data corresponding to q there exists $\{a(x,t),b(x,t)\}$ such that

$$a_t+a_x=q^*(x)b, \quad b_t-b_x=\mp q(x)a, \quad 0<x<t, \tag{6.2a}$$

$$b(x,x)=\mp\frac{1}{2}q(x), \quad x>0, \tag{6.2b}$$

$$a(0,t)=0, \quad t>0, \tag{6.2c}$$

$$b(0,t)=\frac{1}{2\pi}\int_{-\infty}^{\infty}B(0,k)e^{-ikt}\,dk, \quad t>0. \tag{6.2d}$$

Here we are again regarding $q(x)$ as defined to be zero outside of $[0,X]$. In the case of $\mathbf{P2}_{-}$ we must assume in addition that no bound states exist, so that $b(0,t)$ is Fourier transformable with respect to time. This solution corresponds to (5.1) with side conditions

$$a(x,t)=\delta(x-t), \quad b(x,t)=0, \quad t<0, \tag{6.3}$$

and may be derived in a manner analogous to (5.15). See also Refs. 17, 20 for more about (6.2). In particular $\{a,b\}$ may be viewed as a solution of (6.2a) for all t, which is zero for $t<x$. Since $b(0,t)=0$ for $t<0$ it follows that $B(0,k)$ is analytic in the upper half of the complex plane.

Theorem 2: *In the case of problem* $\mathbf{P2}_{+}$ *we have*

$$-\int_{-\infty}^{\infty}\log(1-|B(0,k)|^2)\,dk=\pi\int_0^X|q(x)|^2\,dx, \tag{6.4}$$

and in the case of problem $\mathbf{P1}_{+}$ *we have*

$$\int_{-\infty}^{\infty}\log(1+|B(X,k)|^2)\,dk=\pi\int_0^X|q(x)|^2\,dx. \tag{6.5}$$

Proof: First consider the case of $\mathbf{P2}_{+}$. Note from (2.1), (2.2) that $|A(x,k)|^2-|B(x,k)|^2$ is equal to the constant $|A(X,k)|^2$ for real k; hence $A(x,k)=0$ is impossible for $k\in\mathbb{R}$ or $x\in[0,X]$. Now multiply (6.1) by $R(x,k)^*$ to get

$$R(x,k)^*\frac{\partial R}{\partial x}(x,k)=-2ik|R(x,k)|^2-q^*(x)R(x,k)|R(x,k)|^2+q(x)R(x,k)^*. \tag{6.6}$$

Taking the real part of this identity gives

$$\frac{\partial}{\partial x}|R(x,k)|^2=2(1-|R(x,k)|^2)\,\mathrm{Re}\,(q^*(x)R(x,k)) \tag{6.7}$$

or

$$-\frac{\partial}{\partial x}\log(1-|R(x,k)|^2)=2\,\mathrm{Re}\,(q^*(x)R(x,k)). \tag{6.8}$$

We next claim that

$$\int_{-\infty}^{\infty} R(x,k)\,dk = -\frac{\pi}{2} q(x), \quad 0 \leqslant x \leqslant X. \tag{6.9}$$

Given this, we integrate both sides of (6.8) with respect to k to get

$$\frac{\partial}{\partial x} \int_{-\infty}^{\infty} \log(1-|R(x,k)|^2)\,dk = \pi |q(x)|^2. \tag{6.10}$$

Finally integrate with respect to x from 0 to X, using the fact that $R(0,k)=B(0,k)$, $R(X,k)=0$ to obtain (6.4).

To verify the claim (6.9), consider first the case $x=0$ in which case $R(0,k)=B(0,k)$, the Fourier transform of $b(0,t)$. Since $b(0,0+)=\lim_{t\to 0+} b(0,t) = -q(0)/2$ and $b(0,0-) = \lim_{t\to 0-} b(0,t)=0$, it follows that $1/2\pi \int_{-\infty}^{\infty} B(0,k)$; the inverse Fourier transform of $B(0,k)$ evaluated at $t=0$ is the average of the one sided limits of $b(0,t)$, i.e.,

$$\int_{-\infty}^{\infty} R(0,k)\,dk = \int_{-\infty}^{\infty} B(0,k) = 2\pi\left(-\frac{q(0)}{4}\right), \tag{6.11}$$

which is the required result.

Now for any fixed $x_0 \in [0,X]$ it is not hard to check that $R(x_0,k)=\tilde{B}(x_0,k)$ where $\tilde{A},\tilde{B}$ solves

$$\tilde{A}' = ikA + q^*\tilde{B}, \quad \tilde{B}' = -ikB + q\tilde{A}, \quad x_0 < x < X, \tag{6.12}$$

$$\tilde{A}(x_0,k)=1, \quad \tilde{B}(X,k)=0. \tag{6.13}$$

The argument in the previous paragraph shows that $\int_{-\infty}^{\infty} \tilde{B}(x_0,k)\,dk = -(\pi/2)\,q(x_0)$ and so (6.9) follows for all $x \in [0,X]$.

In the case of problem $\mathbf{P1}_+$, if $A(x,k),B(X,k)$ is the solution of (1.1), (1.2), and

$$A_1(x,k) = \frac{A(X-x,-k)}{A(X,-k)}, \quad B_1(x,k) = -\frac{B(X-x,-k)}{A(X,-k)}; \tag{6.14}$$

then one easily checks that $A_1(x,k),B_1(x,k)$ satisfies (1.1), (1.4) with coefficient $q(x)$ replaced by $q_1(x)=q(X-x)$. From the first part of the proof it then follows that

$$\begin{aligned}
\pi \int_0^X |q(x)|^2\,dx &= \pi \int_0^X |q_1(x)|^2\,dx \\
&= -\int_{-\infty}^{\infty} \log(1-|B_1(0,k)|^2)dk \\
&= -\int_{-\infty}^{\infty} \log(1-|R(X,k)|^2)dk \\
&= -\int_{-\infty}^{\infty} \log\left(\frac{1}{1+|B(X,k)|^2}\right)dk,
\end{aligned} \tag{6.15}$$

where in the last equality we used the conservation property (2.3). The conclusion (6.5) follows.□

Using the elementary inequalities $\log(1+r) \leqslant r, r \geqslant 0$ and $r \leqslant -\log(1-r)$ for $0 \leqslant r \leqslant 1$ and the fact that $|B(0,k)| \leqslant 1$ in $\mathbf{P2}_+$ we obtain the immediate corollaries,

$$\int_{-\infty}^{\infty} |B(X,k)|^2\,dk \geqslant \pi \int_0^X |q(x)|^2\,dx, \tag{6.16}$$

in the case of $\mathbf{P2}_+$ and

$$\int_{-\infty}^{\infty} |B(0,k)|^2\, dk \leqslant \pi \int_0^X |q(x)|^2\, dx, \tag{6.17}$$

in the case of $\mathbf{P1}_+$.

Similar properties can be proved for problems $\mathbf{P1}_-$, $\mathbf{P2}_-$ with further restrictions.

Theorem 3: *Assume that there are no bound states and that* $A(x,k) \neq 0$ *for* $x \in [0,X]$ *and* $k \in \mathbb{R}$. *Then in the case of problem* $\mathbf{P2}_-$ *we have*

$$\int_{-\infty}^{\infty} |B(0,k)|^2\, dk \geqslant \int_{-\infty}^{\infty} \log(1+|B(0,k)|^2)\, dk = \pi \int_0^X |q(x)|^2\, dx, \tag{6.18}$$

and in the case of problem $\mathbf{P1}_-$ *we have*

$$\int_{-\infty}^{\infty} |B(X,k)|^2\, dk \leqslant -\int_{-\infty}^{\infty} \log(1-|B(X,k)|^2)\, dk = \pi \int_0^X |q(x)|^2\, dx. \tag{6.19}$$

VII. CONSTRUCTIVE METHODS

A simple approximate solution for $\mathbf{P2}_\pm$ which may nevertheless be quite accurate for sufficiently small q's is the Born approximation. If we replace q by $q_0 + \epsilon q_1$ with corresponding solutions $A_0 + \epsilon A_1, B_0 + \epsilon B_1$ and match powers of ϵ we get $A_0(x,k) = e^{ikx}, B_0(x,k) = 0$ and

$$B_1' + ikB_1 = \pm q(x) e^{ikx}. \tag{7.1}$$

Solving with $B_1(0,k) = 0$ leads to

$$B_1(X,k) = \pm e^{-ikX} \int_0^X q(s) e^{2iks}\, ds, \tag{7.2}$$

and so by Fourier inversion,

$$q(x) \approx \pm \frac{1}{\pi} \int_{-\infty}^{\infty} B(X,k) e^{-ik(2x-X)}\, dk. \tag{7.3}$$

The same result may be obtained by ignoring the quadratic term in (6.1), or from (5.15) as explained below. This formula is exploited in Ref. 11 (also Ref. 22 in the case of $\mathbf{P2}_\pm$). An improved method based on the calculation of transfer matrices for piecewise constant q is presented in Ref. 13.

Several types of exact methods may be derived by first transforming the data for $\mathbf{P1}_\pm$ to that of $\mathbf{P2}_\pm$, in the manner indicated by the proof of the uniqueness result Theorem 1. From the data and (2.3) one may obtain $|A(X,k)|$; a Hilbert transform calculation of $\log|A(X,k)|$ then yields $A(X,k)$ from which we obtain data for a reflected version of $\mathbf{P2}_\pm$, according to (4.2). One can then proceed to use one of the methods which have been developed for a numerical solution of $\mathbf{P2}_\pm$, e.g., Refs. 9, 15, 19, 20. For this transformation it is necessary to assume that there are no bound states. Furthermore the Hilbert transform step may present numerical difficulties if $B(X,k)$ is known only on a coarse grid of k values, whereas coarse sampling need not in itself be a problem due to the bandlimitation property of $B(X,k)$ discussed above.

A final possibility for an exact method which we discuss in more detail is based on the equivalent time domain problem (5.15). Let us define the mapping $q \mapsto \Lambda(q)$ by $\Lambda(q)(t) = b(X,t), |t| < 1$ where $\{a(x,t), b(x,t)\}$ is the solution pair of the well-posed characteristic boundary value problem, (5.15a)–(5.15c). We may then attempt to obtain q as the solution of the nonlinear operator equation,

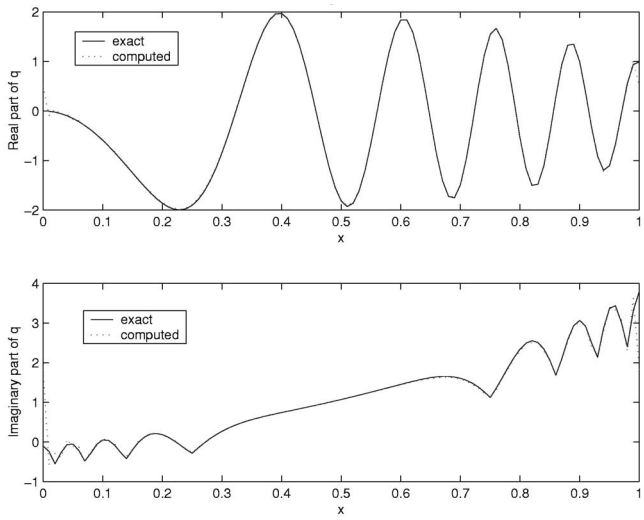

FIG. 1. Reconstruction of real and imaginary parts of smaller coupling coefficient $q(x)$ in **P1**$_-$ by the iteration scheme (7.8).

$$\Lambda(q)=g, \tag{7.4}$$

where $g(t)=b(X,t)$ is known from the given data. Recalling that $b(X,t)$ has support in $[-X,X]$ it follows from (5.14) that we may represent g as a Fourier series,

$$b(X,t)=\frac{1}{2X}\sum_{n=-\infty}^{\infty} B\left(X,\frac{n\pi}{X}\right)e^{-in\pi t/X}, \tag{7.5}$$

involving only sampled values of $B(X,k)$. Of course in theory $b(X,t)$ is uniquely determined by the data $\{B(X,k_n)\}_{n=1}^{\infty}$ where k_n is any sequence with a finite limit point, or a sequence tending to $\pm\infty$ with an appropriate asymptotic spacing. The coefficients in (7.5) will typically decay at a rate $O(1/n)$ and no faster, unless additional smoothness assumptions are made on q (or more presicely on the X periodic extension of q).

A simple iterative scheme is the Newton–Kantorovich method,

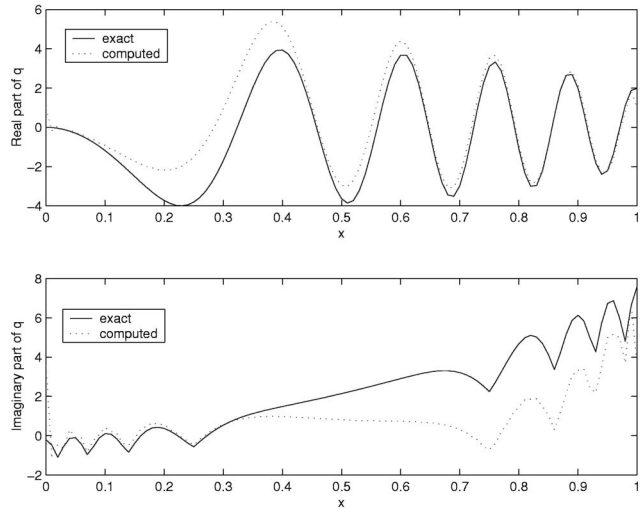

FIG. 2. Reconstruction of real and imaginary parts of larger coupling coefficient $q(x)$ in **P1**$_-$ by the iteration scheme (7.8).

$$q_{n+1}=q_n-D\Lambda(0)^{-1}(\Lambda(q_n)-g), \tag{7.6}$$

where the Fréchet derivative $D\Lambda(0)$ is easily found to be

$$D\Lambda(0)\zeta(t)=\pm\frac{1}{2}\zeta\left(\frac{X+t}{2}\right). \tag{7.7}$$

The resulting scheme is thus explicitly

$$q_{n+1}(x)=q_n(x)\pm 2g(2x-X)\mp 2\Lambda(q_n)(2x-X), \tag{7.8}$$

initialized, for example, by $q_0(x)=0$, in which case $q_1(x)=D\Lambda(0)^{-1}g(x)=\pm 2g(2x-X)$ is the same as the Born approximation mentioned above, which could also be used as the initial guess.

If the coupling coefficient q is sufficiently small then convergence of q_n to q in $L^2(0,X)$ can be shown, essentially by the inverse function theorem and the fact that Λ can be shown to have suitable differentiability properties. The proof is very similar, e.g., to that of Corollary 3.1 of Ref. 18.

In general the scheme is not globally convergent. In the case of $\mathbf{P1}_+$ the inverse problem has a unique solution which must also be the unique solution of $\Lambda(q)=g$, so if the sequence q_n converges at all then it must be to the solution q. In the case of $\mathbf{P1}_-$ the solution is not unique in general, so the sequence q_n may converge to some other solution of the inverse problem.

In Fig. 1 a reconstruction is displayed together with the exact coupling coefficient for $\mathbf{P1}_-$. In this example $X=1$, and the data $B(1,n\pi)$ is used for $|n|\leqslant 50$ to approximate $b(1,t)$ using (7.5). The direct problem (1.1)–(1.2) was solved using ode45 in MATLAB, and the time domain map Λ was approximated by means of a straightforward finite difference scheme in characteristic coordinates, with grid size extrapolation to improve the accuracy. The relative error in q is about 15%, but essentially all of this may be attributed to the error in $b(1,t)$ due to the truncation error in (7.5). That is to say, if we used more (or fewer) terms we will always find that the relative error in the computed q is comparable to the relative error in $b(1,t)$. The results are very similar if we repeat the calculation for $\mathbf{P1}_+$.

For a second example we replace q in the previous case by $2q$. We now find that the sequence q_n does not converge at all in the case of $\mathbf{P1}_+$, while in the case of $\mathbf{P1}_-$ the sequence converges, but to a different solution displayed in Fig. 2, consistent with the earlier discussion of nonuniqueness. It seems clear that some alternative optimization approach could be used to obtain the original q, provided a sufficiently accurate initial guess were available. We note that in the first example the identity (6.19) is satisfied, while in the second example it is satisfied by the computed $q(x)$, not by the original q, leading one to surmise that the result of the computational method just described will be the unique choice of q with the prescribed data (1.3) but with no bound states.

The Johns Hopkins University Applied Physics Laboratory, 11100 Johns Hopkins Road, Laurel, Maryland 20723

(Received 27 June 2003; accepted 27 December 2003)

Margetis and Fikioris, apparently unaware of the earlier results available in the literature, used an elaborate Mellin transform technique to obtain an asymptotic approximation for a particular case of a Bessel function integral. Here, the earlier, more general results are pointed out. © *2004 American Institute of Physics.*
[DOI: 10.1063/1.1650536]

In Sec. III of a recent paper, Margetis and Fikioris[1] use the Mellin transform technique to obtain an asymptotic expansion up to the order $O(\lambda^{-7/2})$ for the particular case $\mu=\nu=0$ of the integral

$$I(\lambda)=\int_0^{\pi/2} J_\mu(\lambda \sin\theta) J_\nu(\lambda \sin\theta) d\theta, \tag{1}$$

where J_μ is the μth-order Bessel function of the first kind and λ is a large parameter tending to infinity. Their application of this technique, which is elaborated in Ref. 13 of their paper,[1] differs in many technical details from the earlier work (see below), where the Mellin transforms were applied to more general cases of integral (1). A major difference that should be noted here is a clever use by Margetis and Fikioris[1] of an integration path in the complex θ-plane in order to obtain the contributions oscillatory in λ, which arise from the upper limit of integration in (1).

An asymptotic expansion of integral (1) up to the order $O(\lambda^{-3/2})$ for the particular $\mu=\nu=0$ case was originally obtained by Stoyanov and Farrell[2] by a straightforward method based on a heuristic approach. Referring to their paper,[2] Margetis and Fikioris[1] remark that "These authors calculate only the first three terms of the asymptotic expansion [...]. Their method does not make use of the Mellin transform technique." We point out that the Mellin transform technique was previously used by Wong[3,4] to obtain the asymptotic expansion up to the order $O(\lambda^{-3})$ for a more general case $\mu=\nu>-1/2$ of integral (1). Then, Stoyanov, Farrell, and Bird[5] used both the straightforward method originally introduced in Ref. 2 and the Mellin-transform technique with certain simplifications and modifications to obtain the asymptotic expansions to the same order for the general case $\mathrm{Re}(\mu+\nu)>-1$ of integral (1), as well as for another, Hankel-type integral. Furthermore, the complete (i.e., infinite) asymptotic expansions for the two integrals treated in Ref. 5 have also been obtained by Stoyanov, Farrell, and Bird[6] by using the generalized hypergeometric and Meijer functions.

ACKNOWLEDGMENT

I thank Dr. A. J. Stoyanov for bringing the Margetis and Fikioris paper (Ref. 1) to my attention and for independently verifying some of the results therein.

(Received 19 September 2003; accepted 18 December 2003; published 30 March 2004)

We introduce the free $N=1$ supersymmetric derivation ring and prove the existence of an exact sequence of supersymmetric rings and linear transformations. We apply necessary and sufficient conditions arising from this exact supersymmetric sequence to obtain the essential relations between conserved quantities, gradients and the $N=1$ super Korteweg–de Vries (KdV) hierarchy. We combine this algebraic approach with an analytic analysis of the super heat operator. We obtain the explicit expression for the Green's function of the super heat operator in terms of a series expansion and discuss its properties. The expansion is convergent under the assumption of bounded bosonic and fermionic potentials. We show that the asymptotic expansion when $t\to 0^+$ of the Green's function for the superheat operator evaluated over its diagonal generates all the members of the $N=1$ super KdV hierarchy. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1650047]

I. INTRODUCTION

The analysis of supersymmetric quantum problems has been recently considered in several relevant physical contexts. At very high energies one way of studying the M-theory, which has been proposed as a theory of unification of all known interactions in nature, is through Matrix models describing supersymmetric quantum problems. The supersymmetry is one of the relevant ingredients of these models. In particular the presence of supersymmetry may change completely the spectrum of the quantum Hamiltonian. The bosonic Hamiltonian in the case of the $D=11$ supermembrane, with Minkowski target space, has a discrete spectrum while its supersymmetric extension has a continuous spectrum. Moreover in that case the Green's function does not admit a representation in terms of the Feynman path integral since the potential is not bounded from below in some directions in spite of the fact that the SUSY Hamiltonian is nonnegative. These systems are very closely related to certain supersymmetric integrable systems. These models in themselves are a great help in understanding integrable systems. The $N=1,2$ supersymmetric extensions of the Korteweg–de Vries (KdV) equations were found several years ago,[1–4] while $N=3$ and $N=4$ have been considered more recently in Refs. 5, 6, 7. The bi-Hamiltonian structure of the super KdV equations was studied in Refs. 8, 9. For a review of $N=1$ and $N=2$ super KdV equations see Ref. 10. Extensions of the supersymmetric model have been proposed in Ref. 11.

In the first part of this work we focus on the algebraic structure of $N=1$ supersymmetric

[a)]Electronic mail: sandrea@usb.ve
[b)]Electronic mail: arestu@usb.ve
[c)]Electronic mail: asotomay@zeus.unexpo.edu.ve

models. We introduce the ''Free SUSY derivation ring on a single fermionic generator'' which contains a parity automorphism, a canonical superderivation and a supersymmetric gradient operator. We established an exact sequence of SUSY rings and linear transformations. Several of these relations were already known in the literature.[2,12] This is a general algebraic construction valid for one-dimensional supersymmetric models. Using necessary and sufficient conditions arising from the exact sequence we obtain the essential relations between conserved quantities, gradients and the $N=1$ SKdV hierarchy. In the second part of this work we use the exact sequence together with an analytic analysis of the super heat kernel to show that the asymptotic expansion when $t\to 0^+$ of the Green's function for the superheat operator, evaluated over its diagonal, generates all the left hand members of the SKdV hierarchy. Using the symmetry properties of that Green's function we obtain an iterative procedure to obtain all the gradients and members of the SKdV hierarchy. The algebraic approach arising from the exact SUSY sequence together with the analytic approach arising from the analysis of the Green's function of the super heat operator combine to give a satisfactory description of the SKdV hierarchy.

II. THE FREE SUPERSYMMETRIC DERIVATION RING ON A SINGLE FERMIONIC GENERATOR

A. Definitions

A ring $\mathcal{A}$ is associative but not necesarily commutative. It is ''oriented'' when there is given a ring automorphism $P:\mathcal{A}\to\mathcal{A}$ satisfying $P^2=I$, as well as $P(f+g)=Pf+Pg$ and $P(fg)=(Pf)(Pg)$. An element f of $\mathcal{A}$ is ''oriented'' when $Pf=\pm f$, f being called ''bosonic'' when $Pf=f$ and ''fermionic'' when $Pf=-f$. The oriented ring $(\mathcal{A},P)$ is said to be ''commutative'' when

$$fg=gf(-1)^{\sigma\tau}$$

wherever $f,g\in\mathcal{A}$ satisfy $Pf=(-1)^{\sigma}f$, $Pg=(-1)^{\tau}g$. In this situation the commutation formula,

$$uf=f(P^{\sigma}u),$$

holds for all $u\in\mathcal{A}$, given that $Pf=(-1)^{\sigma}f$; this follows from $u=u_0+u_1=\text{boson}+\text{fermion}$. A linear map $D:\mathcal{A}\to\mathcal{A}$ is called an ''ordinary derivation'' when

$$DP=PD,$$

$$D(uv)=(Du)v+u(Dv),$$

for all $u,v\in\mathcal{A}$, and is called a ''superderivation'' when

$$DP=-PD,$$

$$D(uv)=(Du)v+(Pu)(Dv).$$

The two definitions may be combined by saying that $\Pi(D)=(-1)^{\delta}$ when

$$DP=(-1)^{\delta}PD,$$

$$D(uv)=(Du)v+(P^{\delta}u)Dv.$$

Then, if $(\mathcal{A},P)$ is commutative and f satisfies $Pf=(-1)^{\sigma}f$, the product fD will also be a derivation, with

$$\Pi(fD)=(-1)^{\sigma+\delta}.$$

Thus a fermionic f times a bosonic D will be a fermionic fD, and similarly for the other three cases.

B. Construction of the ring $\mathcal{A}$

We may begin with the commutative ring $\mathcal{B}$ of all polynomials in the commuting letters $b_2, b_4, b_6, \ldots$. The ordinary derivations $\partial/\partial b_n : \mathcal{B} \to \mathcal{B}$ all commute, as n runs through even positive integers. Then $\mathcal{A}$ is the supersymmetric extension of $\mathcal{B}$, constructed as follows. Let $\mathbb{M} = \{1,3,5,\ldots\}$ be the set of all positive odd numbers, and let $2^{\mathbb{M}} = \{\phi, 1, 3, 13, \ldots\}$ be the collection of all finite subsets of $\mathbb{M}$, including the empty set ϕ. Then $\mathcal{A}$ is to consist of all finitely supported functions $f : 2^{\mathbb{M}} \to \mathcal{B}$. The product of two elements f and g, evaluated at a finite subset $E \subset \mathbb{M}$, is defined to be

$$(fg)(E) = \sum_{A \cup B = E} f(A) g(B) \varepsilon(A,B).$$

Here the function $\varepsilon : 2^{\mathbb{M}} \times 2^{\mathbb{M}} \to \{-1,0,1\}$ is defined to be

$$\varepsilon(A,B) = \prod_{a \in A} \prod_{b \in B} \varepsilon(a,b),$$

where $\varepsilon : \mathbb{M} \times \mathbb{M} \to \{-1,0,1\}$ is defined by

$$\varepsilon(a,b) = \begin{cases} 1, & a < b, \\ 0, & a = b, \\ -1, & a > b. \end{cases}$$

If the number of elements in E is $|E|$, then the above sum has $2^{|E|}$ terms, since $\varepsilon(A,B) \neq 0$ only occurs when A and B are disjoint. The parity automorphism $P : \mathcal{A} \to \mathcal{A}$ is given by $(Pf)(E) = f(E)(-1)^{|E|}$.

The easy formula $\varepsilon(A,B) = \varepsilon(B,A)(-1)^{|A||B|}$ makes it clear that $(\mathcal{A}, P)$ is commutative.

When $B, C \subset \mathbb{M}$ are disjoint, one has $\varepsilon(A, B \cup C) = \varepsilon(A,B)\varepsilon(A,C)$. This shows that the product operation is associative, the value of $(fg)h = f(gh)$ on $E \subset \mathbb{M}$ being given by

$$\sum_{A \cup B \cup C = E} f(A) g(B) h(C) \varepsilon(A,B) \varepsilon(A,C) \varepsilon(B,C).$$

This completes the construction of the oriented ring $(\mathcal{A}, P)$. The generating elements $a_1, a_2, a_3, \ldots \in \mathcal{A}$ are now to be identified.

The inclusion $\mathcal{B} \subset \mathcal{A}$ is realized by associating each $b \in \mathcal{B}$ with that function $2^{\mathbb{M}} \to \mathcal{B}$ which sends the empty set ϕ to b, and everything else to zero. Thus, for m even, $a_m(\phi) = b_m$ and $a_m(E) = 0$ for all nonempty $E \subset \mathbb{M}$.

When p is an odd positive integer, $a_p : 2^{\mathbb{M}} \to \mathcal{B}$ is defined by $a_p(p) = 1 \in \mathcal{B}$ and $a_p(E) = 0$ for all other finite subsets of $\mathbb{M}$.

This gives us $\{a_1, a_2, a_3, \ldots\} \subset \mathcal{A}$.

Evidently $Pa_n = (-1)^n a_n$. Further, if $1 \leqslant p_1 < p_2 < \cdots < p_n$ are odd, the product $a_{p_1} a_{p_2} \cdots a_{p_m} \in \mathcal{A}$ takes the value $+1$ on the subset $\{p_1, p_2, \ldots, p_n\} \subset \mathbb{M}$ and zero everywhere else. Therefore every element of $\mathcal{A}$ may be written as a finite polynomial in the elements $a_1, a_2, a_3, \ldots$.

C. Derivations of $\mathcal{A}$

The fundamental superderivation of $\mathcal{A}$ is defined by

$$D=a_2\frac{\partial}{\partial a_1}+a_3\frac{\partial}{\partial a_2}+a_4\frac{\partial}{\partial a_3}+\cdots.$$

It sends $a_1\to a_2\to a_3\to\cdots$, exchanging bosons and fermions. This suggests that $(\mathcal{A},P,D)$ is in some sense the natural model of an oriented superderivation ring generated by a single fermion a_1.

The square of a superderivation is an ordinary derivation. Thus D^2 restricted to $\mathcal{B}\subset\mathcal{A}$ sends $a_2\to a_4\to a_6\to\cdots$, and the pair $(\mathcal{B},D^2)$ can be called the free bosonic derivation ring on a single generator.

The inclusions $D\mathcal{A}_n\subset\mathcal{A}_n$ which follow from $DE=ED$ will be used later in the proofs of the exact sequence.

D. The supersymmetric gradient operator

Given $h\in\mathcal{A}$ we ask whether $f\subset\mathcal{A}$ exists with $h=Df$. A linear operator $M:\mathcal{A}\to\mathcal{A}$ with $MD=0$ would give at least a necessary condition.

In analogy with the bosonic case, for which it is known the gradient operator M, it can be found that the SUSY M operator has the expression

$$M=\frac{\partial}{\partial a_1}+D\frac{\partial}{\partial a_2}-D^2\frac{\partial}{\partial a_3}-D^3\frac{\partial}{\partial a_4}+D^4\frac{\partial}{\partial a_5}+\cdots.$$

It is a linear operator sending $\mathcal{A}$ into itself, and we have seen that the equation $Mh=0$ is a necessary condition for the existence of $f\in\mathcal{A}$ with $Df=h$.

Later it will be shown that the condition $Mh=0$ is also sufficient. (With respect to parity we note that $PM=-MP$.)

E. Operators and adjoints

Given $(\mathcal{A},P,D)$ as constructed: a ''differential operator'' is a linear map of $\mathcal{A}$ into itself having the form

$$L=\sum_0^N l_nD^n,$$

with coefficients $l_n\in\mathcal{A}$. L is the identically zero map $\mathcal{A}\to\mathcal{A}$ if and only if all the coefficients are zero.

Then $\mathcal{O}_p\mathcal{A}$ is defined to be the set of all differential operators. It is an associative ring: the composition of two operators has the same form, because $D_n(fI)$ can be expanded as a finite sum $\Sigma_{r=0}^n g_rD^r$, by using the defining property of D on products of elements of $\mathcal{A}$.

Composing L with the parity automorphism $P:\mathcal{A}\to\mathcal{A}$ we find that

$$PLP=\sum_0^N (Pl_n)(-D)^n.$$

Therefore $O_p\mathcal{A}$ is also an oriented ring, its parity automorphism given by $L\to PLP$. As before, L can be called ''oriented'' if $PL=\pm LP$, ''fermionic'' in one case and ''bosonic'' in the other.

We now ask how to integrate by parts in $\mathcal{A}$. Suppose $u,v\in\mathcal{A}$ are oriented elements with $Pu=u(-1)^\alpha, Pv=v(-1)^\beta$. Starting with $D\in\mathcal{O}_p$, we compute

$$\begin{aligned} D(uv) &= (Du)v + (-1)^{\alpha} u(Dv) \\ &= (Du)v + (-1)^{\alpha}(Dv)u(-1)^{\alpha(\beta+1)} \\ &= (Du)v + (Dv)u(-1)^{\alpha\beta}. \end{aligned}$$

This can be written as $(Du)v \equiv (-Dv)u(-1)^{\alpha\beta}$ if the congruence notation $f \equiv g$ in $\mathcal{A}$ is defined to mean that $f - g = Dh$ for some $h \in \mathcal{A}$.

More generally, L and $L^* \in \mathcal{O}_p\mathcal{A}$ may be said to be "mutually adjoint" if

$$(Lu)v \equiv (L^*v)u(-1)^{\alpha\beta},$$

for all oriented u, v as above. Thus, $D^* = -D$, while a zeroth order operator $l_0 I$ is its own adjoint.

The uniqueness of the adjoint operator is argued as follows: if $L = 0$ then every $h = L^*v$ satisfies $hu \equiv 0$ for all $u \in \mathcal{A}$. However, it can be shown that for any nonzero $h \in \mathcal{A}$ there exist u such that hu cannot be of the form Df for any $f \in \mathcal{A}$.

Consequently, $L = 0$ in $\mathcal{O}_p\mathcal{A}$ implies that all $L^*v = 0$ in $\mathcal{A}$, and hence $L^* = 0$ in $\mathcal{O}_p\mathcal{A}$. This shows that any $L \in \mathcal{O}_p\mathcal{A}$ can have at most one adjoint $L^* \in \mathcal{O}_p\mathcal{A}$, and furthermore that $(L^*)^* = L$.

The commutation of the constructions $L \to PLP$ and $L \to L^*$ is shown by applying P to the congruence,

$$(LPu)Pv \equiv (L^*Pv)Pu(-1)^{\alpha\beta}.$$

Thus if L has an adjoint then so does PLP, and

$$(PLP)^* = PL^*P.$$

The existence of adjoints for all differential operators must now be shown.

Proposition: Suppose $K, L \in \mathcal{O}_p\mathcal{A}$ have adjoints, and that $PKP = K(-1)^{\kappa}, PLP = L(-1)^{\lambda}$. Then KL has an adjoint, and it is given by

$$(KL)^* = L^*K^*(-1)^{\kappa\lambda}.$$

The proposition generalizes inmediately to finite products of operators $L_1 L_2 \cdots L_m$ in which each L_k has an adjoint and is oriented with $PL_kP = L_k(-1)^{\lambda_k}$. Then

$$(L_1 L_2 \cdots L_m)^* = (L_m^* L_{m-1}^* \cdots L_1^*)(-1)^{\mu},$$

$$\mu = \sum_{1 \le i < j \le m} \lambda_i \lambda_j .$$

Thus lD^k, when $Pl = \pm l$, has an adjoint $\pm D^k(lI)$, the sign depending on k and the parity of l. This proves that every $L \in \mathcal{O}_p\mathcal{A}$ possesses a unique adjoint $L^* \in \mathcal{O}_p\mathcal{A}$, the bijection $L \leftrightarrow L^*$ satisfying $(L^*)^* = L$.

We conclude by computing the adjoint of $D^p l D^q, p + q = m$. If $Pl = -l$ then all the $m+1$ exponents are $+1$ and $\mu = m(m+1)/2$.

Then

$$\begin{aligned} (D^p l D^q)^* &= (-D)^q l (-D)^p (-1)^{m(m+1)/2} \\ &= D^q l D^p (-1)^{m + m(m+1)/2} \\ &= D^q (P^m l) D^p (-1)^{m(m+1)/2}. \end{aligned}$$

On the other hand, if $Pl = +l$ then all but one of the exponents $\lambda_1, \ldots, \lambda_{m+1}$ is $+1$, the remaining exponent being zero. Then

$$(D^p l D^q)^* = (-D)^q l (-D)^p (-1)^{m(m-1)/2}$$
$$= D^q l D^p (-1)^{m(m+1)/2}$$
$$= D^q (P^m l) D^p (-1)^{m(m+1)/2}.$$

But every $l \in \mathcal{A}$ is uniquely the sum of a boson and a fermion. Therefore, for any $l \in \mathcal{A}$ and any nonnegative integers p and q, the adjoint of $D^p l D^q \in \mathcal{O}_p \mathcal{A}$ is given by

$$(D^p l D^q)^* = D^q (P^m l) D^p (-1)^{m(m+1)/2},$$

where $p+q=m$.

F. Frechet derivative

The construction of the Frechet derivative operator gives a linear map $\mathcal{A} \to \mathcal{A}$, sending $f \to L_f$. Given $f(a_1, a_2, \ldots, a_n)$ an element of $\mathcal{A}$, the action of L_f on a fermionic element $v \in \mathcal{A}, Pv = -v$, may be defined by

$$L_f v = \frac{d}{d\epsilon}\bigg|^{\epsilon=0} f(a_1 + \epsilon v, a_2 + \epsilon D v, \ldots, a_n + \epsilon D^{n-1} v).$$

The coefficients of L_f are obtained as follows. If q is odd and $f = g a_q h$ with g and h independent of a_q, we have $(\partial/\partial a_q) f = (Pg)h$, while $g(D^{q-1}v)h = g(Ph)(D^{q-1}v)$ since $D^{q-1}v$ is fermionic. Therefore $D^{q-1}v$ is multiplied on the left by $(P(\partial/\partial a_q) f)$. If m is even then $\partial/\partial a_m$ is an ordinary derivation and $D^{m-1}v$ is bosonic. In this case there is no anticommutation, and $D^{m-1}v$ is multiplied on the left by $\partial f/\partial a_m$. Combining these two cases, we obtain the general formula

$$L_f = \sum_{n=1}^{\infty} \left(P^n \frac{\partial f}{\partial a_n} \right) D^{n-1},$$

which gives the Frechet derivative operator $L_f \in \mathcal{O}_p \mathcal{A}$ for any $f \in \mathcal{A}$.

Applying L_f to the generating element $a_1 \in \mathcal{A}$ we get

$$L_f a_1 = \sum_{n=1}^{\infty} \left(P^n \frac{\partial f}{\partial a_n} \right) a_n.$$

But $h a_n = a_n (P^n h)$ for all $h \in \mathcal{A}$. Hence $L_f a_1 = Ef$, connecting L_f to the Euler operator E.

The adjoint operator to L_f may be written down using the results of the previous section:

$$L_f^* = \sum_{n=1}^{\infty} (-1)^{n(n-1)/2} D^{n-1} \left(\left(P \frac{\partial f}{\partial a_n} I \right) \right).$$

Applying the operator parity automorphism $K \to PKP$ we get

$$P L_f^* P = \sum_{n=1}^{\infty} (-1) \frac{n(n-1)}{2} (-D)^{n-1} \left(\frac{\partial f}{\partial a_n} I \right).$$

The coefficient of the identity operator is readily accessible since

$$D^{n-1} \left(\frac{\partial f}{\partial a_n} I \right) = \left(D^{n-1} \frac{\partial f}{\partial a_n} \right) I + (?) D + \cdots.$$

After checking the $\pm$ signs we see that this coefficient is just the supersymmetric gradient Mf of f: thus

$$L_f^* = (PMf)I + (?)D + \cdots .$$

Going back to the equation $Mh=0$, we see that this condition would imply the existence of $K \in \mathcal{O}_p\mathcal{A}$ satisfying $L_h^* = KD$ and hence also $L_h = \pm DK^*$ if h is oriented. Applying this operator equation to the generating element $a_1 \in \mathcal{A}$, we find that $Eh = Df$ for some $f \in \mathcal{A}$.

Thus $Mh=0$ implies $h \equiv 0$, at least when h is oriented and $Eh = nh, n>0$. But the two extra conditions are no obstacle.

Proposition: Given $h \in \mathcal{A}$, with a zero constant term. Then $Mh=0$ if and only if $h = Df$ for some $f \in \mathcal{A}$.

Proof: The equation $PM = -MP$ shows that $h \pm Ph$ also has a zero gradient. Replacing h by either summand in $h = boson + fermion$, we may suppose that h is oriented. The presentation,

$$\mathcal{A} = \mathcal{A}_0 \oplus \mathcal{A}_1 \oplus \mathcal{A}_2 \oplus \cdots ,$$

by eigenspaces of the Euler operator permits h to be written as $h = h_0 + h_1 + h_2 + \cdots$, in which $h_0 = 0$ by hypothesis. Then, since $M\mathcal{A}_n \subset \mathcal{A}_{n-1}$ the condition $Mh=0$ implies $Mh_n = 0$ for all $n \geqslant 1$.

By what was said earlier, there exist f_n with $Df_n = Eh_n = nh_n$. Therefore $h = D(f_1 + \frac{1}{2}f_2 + \frac{1}{3}f_3 + \cdots)$ and the proof is complete.

In the next section we will need to know the interaction between the $f \to L_f$ construction and the parity automorphism $P: \mathcal{A} \to \mathcal{A}$. The formula $L_{Pf} = -PL_fP$ is easily verified by

$$\left(P^n \frac{\partial}{\partial a_n} Pf \right) D^{n-1} = (-1)^n \left(P^{n+1} \frac{\partial f}{\partial a_n} \right) D^{n-1}$$

$$= -\left(P\left(P^n \frac{\partial f}{\partial a_n} \right) \right) (-D)^{n-1}.$$

G. Gradients and operators

We wish to determine which elements $g \in \mathcal{A}$ are of the form Mh for some $h \in \mathcal{A}$: in the applications this asks which g are gradients of possible conserved quantities. Here are two facts, that can be proven easily.

(i) For any $f \in \mathcal{A}$, the Frechet derivative operators of f and of Df are connected by the equation

$$L_{Df} = DL_f .$$

(ii) When $g = Mh$, the Frechet derivative operator of g is antisymmetric:

$$L_g^* = -L_g .$$

Evidently the second fact gives a necessary condition for g to be a gradient. But it is also sufficient.

Proposition: Given $g \in \mathcal{A}$. The antisymmetry equation $L_g^* = -L_g$ in $\mathcal{O}_p\mathcal{A}$ is necessary and sufficient for the existence of h with $Mh = g$.

Proof: Suppose first that g is oriented and satisfies $Eg = ng, n \geqslant 0$, as well as the hypothesis $L_g^* = -L_g$. If $Pg = g(-1)^\nu$, then the Frechet derivative operator of element $h = a_1 g$ is given by

$$L_h = (Pg)I + \sum_{n=1}^{\infty} \left(P^n (-1)^n a_1 \frac{\partial g}{\partial a_n} \right) D^{n-1}$$

$$= (Pg)I + a_1 L_g .$$

From $L_{Pg}=-PL_gP$ we see that L_g has orientation opposite to that of g, that is, $PL_gP=L_g(-1)^{\nu+1}$. This permits the adjoint of L_h to be calculated as

$$L_h^*=(Pg)I+L_g^*(a_1I)(-1)^{\nu+1}$$
$$=(-1)^{\nu}\{gI+L_g(a_1I)\}.$$

This shows that $(-1)^{\nu}L_h^*=(g+Eg)+(?)D+\cdots$.

But it was seen before that $L_h^*=(PMh)I+(?)D+\cdots$. Observing $PM=-MP$ and $Ph=h(-1)^{\nu+1}$, we conclude that $M(a_1g)=g+Eg=(n+1)g$ in consequence of three assumptions made at the beginning of this proof. Returning now to the general case, we note that operator adjoints, Frechet derivative operators, and the parity automorphism are interconnected by

$$(PL_gP)^*=PL_g^*P=L_{Pg}=-PL_gP.$$

Thus, if $g\in\mathcal{A}$ has an antisymmetric Frechet derivative operator then so do Pg and $g\pm Pg$. Hence it suffices to treat only the case of oriented g. Expanding $g=g_0+g_1+g_2+\cdots$ by homogeneous components in $\mathcal{A}_0\oplus\mathcal{A}_1\oplus\cdots$, we observe that the coefficients of L_{g_n} and $L_{g_n}^*$ fall within $\mathcal{A}_{n-1}$. Therefore the antisymmetry of L_g implies the antisymmetry of all the L_{g_n}. From what was said before $g=Mh$ with $h=a_1(g_0+\frac{1}{2}g_1+\frac{1}{3}g_2+\cdots)$.

This completes the proof.

H. Summary: the exact sequence

A ring $\mathcal{A}$, the "free SUSY derivation ring on a single fermionic generator" has been constructed. It has a parity automorphism P, a canonical superderivation D, and a SUSY gradient operator M.

Necessary and sufficient conditions have been given for recognizing which elements of $\mathcal{A}$ are derivatives and which are gradients. In terms of the SUSY gradient operator M, the Frechet derivative operator L_g, and the operator adjoint construction $L\to L^*$, these conditions are expressed by the following exact sequence of rings and linear transformations:

$$\begin{array}{llll} O_p\mathcal{A}\leftarrow & \mathcal{A}\leftarrow & \mathcal{A}\leftarrow & \mathcal{A}\leftarrow\mathbb{R}\leftarrow 0 \\ & & Df\leftarrow & f \\ & Mh\leftarrow & h & \\ L_g+L_g^*\leftarrow & g. & & \end{array}$$

The sequence is exact in that the kernals of the outgoing transformations coincide with the images of the incoming transformations.

III. THE SUSY HEAT OPERATOR

The ordinary heat equation with potential $u(x)$ and temperature function $f(x,t)$ is

$$L_uf=0,\quad L_u=\frac{\partial}{\partial t}-\Delta+u(x).$$

Its Green's function evaluated at a field point $p=(x,t)$ and source point $q=(x',0)$ may be written as $G(p,q)=\mathcal{G}_t(x,x')$. For fixed x' and variable x and t it satisfies the above heat equation with initial value

$$\lim_{t\downarrow 0}\quad \mathcal{G}_t(x,x')=\delta(x-x').$$

When the potential is zero the Green's function is

$$g_t(x-x')\equiv g(x-x',t)=\frac{1}{\sqrt{4\pi t}}\exp\left(-\frac{(x-x')^2}{4t}\right).$$

It has the basic properties

$$\text{(i)}\quad g_t(x-x')>0;$$

$$\text{(ii)}\quad \int_{\mathbb{R}^n} g_t(x-x')dx=1;$$

$$\text{(iii)}\quad g_{t+s}(x-x')=\int_{\mathbb{R}^n} g_s(y-x')g_t(x-y)dy. \tag{1}$$

These properties allow the definition of the conditional Wiener measure, which may be used to express the Green's function $\mathcal{G}_t(x,x')$ of the operator L_u by the Feyman–Kac formula,[13] when the potential $u(x)$ is real and bounded from below.

For bounded potentials the Green's function admits an asymptotic expansion,

$$\mathcal{G}_t(x,x')=g(x-x',t)\sum_{n=0}^{\infty}\frac{1}{n!}a_n(x,x')t^n,$$

in which the coefficients $a_n(x,x')$ are determined recursively by $a_0(x,x')=1$,

$$(n+(x-x')\partial_x)a_n(x,x')=(\partial_x^2+u(x))a_{n-1}(x,x').$$

On the diagonal $x=x'$, one has

$$a_n(x,x)=g_n(u(x),u'(x),\ldots),$$

a finite polynomial in the potential function $u(x)$ and its derivatives.

Then the equations of the KdV hierarchy,[14] for unknown functions $w(x,t)$, are

$$w_t=\frac{\partial}{\partial x}g_n(w,w_x,w_{xx},\ldots).$$

We now present a supersymmetric extension of this construction. The potential and the temperature function now have their values in an exterior algebra Λ, also called a Grassmann algebra.

If anticommuting generators of Λ are written as $\theta,\theta_2,\theta_3,\ldots,\theta_m$ then every element of Λ has a unique presentation,

$$\Phi=\xi+\theta u,$$

where ξ and u are in the subalgebra of Λ generated by $\theta_2,\theta_3,\ldots,\theta_m$. Then, defining $\partial_\theta\Phi=u$, we obtain a superderivation $\partial_\theta:\Lambda\to\Lambda$, that is,

$$\partial_\theta(\Phi_1\Phi_2)=(\partial_\theta\Phi_1)\Phi_2+\overline{\Phi}_1(\partial_\theta\Phi_2),$$

where $\Phi\to\overline{\Phi}$ is the parity automorphism of Λ.

The operator $D=\partial_\theta+\theta\partial_x$ then acts on "superfields," that is, on differentiable functions $\mathbb{R}\to\Lambda$. Using Φ_1 and Φ_2 to designate superfields, one can check

$$D(\Phi_1\Phi_2)=(D\Phi_1)\Phi_2+\overline{\Phi}_1(D\Phi_2),$$

$$D^2=\partial_x.$$

It will be assumed that the potential Φ is fermionic: $\overline{\Phi}=-\Phi$ meaning that $\overline{\xi}=-\xi$ and $\overline{u}=u$.

If we take the dimension of x to be 1:

$$[x]=1,$$

then one must have

$$[\theta]=\tfrac{1}{2},$$

$$[D]=-\tfrac{1}{2};$$

consequently,

$$[u]=-2,$$

$$[\Phi]=[\xi]=-\tfrac{3}{2}.$$

The most general supersymmetric extension of L_u, assuming positive powers of D, becomes then

$$\mathbf{L}=\frac{\partial}{\partial t}-(D^4-D\Phi+\lambda\Phi D),$$

where λ is a constant, dimensionless parameter.

When the superpotential Φ is zero, it reduces to the heat operator, while if $\xi=0$ and $\theta=0$ it reduces to L_u.

The parameter λ already appeared in the analysis of Mathieu[1] for all supersymmetric extensions of the KdV equation. The case $\lambda=1$ was related to the integrable supersymmetric extension of the KdV equation. We will consider in what follows $\lambda=1$.

There are two supersymmetric extensions of $\delta(x-x')$.

$\delta(x-x')\delta(\theta-\theta')$ and $\delta(x-x'-\theta\theta')=\delta(x-x')-\theta\theta'\delta'(x-x')$ are both invariants under the supersymmetric transformations,

$$x\to x+\theta\eta,\quad \theta\to\theta+\eta,$$

$$x'\to x'+\theta'\eta,\quad \theta'\to\theta'+\eta. \tag{2}$$

We may then consider two Green's functions according to each possible initial condition. We will denote the corresponding Green's function by $\mathbf{K}_t(x,x',\theta,\theta')$ and $\mathbf{G}_t(x,x',\theta,\theta')$, respectively.

The Green's function for the potential Φ, as a function of the source point $q=(x',0)$ and field point $p=(x,t)$, is to be a function $\mathbf{K}_t(x,x',\theta,\theta')$, $\mathbf{G}_t(x,x',\theta,\theta')$ having values in Λ and satisfying $\mathbf{L}\mathbf{K}_t=0$,$\mathbf{L}\mathbf{G}_t=0$ when $t>0$, while $\lim_{t\downarrow 0}\mathbf{K}_t=\delta(x-x')\delta(\theta-\theta')$, $\lim_{t\downarrow 0}\mathbf{G}_t=\delta(x-x')-\theta\theta'\delta'(x-x')$.

$\mathbf{K}_t$ and $\mathbf{G}_t$ are related by

$$-D'\mathbf{K}_t=\mathbf{G}_t,$$

in which

$$D'=\frac{\partial}{\partial\theta'}+\theta'\frac{\partial}{\partial x'}$$

is the superderivative with respect to (x',θ').

The Green's function $\mathbf{K}_t$ may then be expressed as

$$\mathbf{K}_t(x,x';\theta,\theta')=\mathcal{K}_t(x-x',\theta-\theta')-\langle\tilde{D}[\Phi(\tilde{x},\tilde{\theta})\mathcal{K}_{\tilde{t}}(\tilde{x}-x',\tilde{\theta}-\theta')]\mathcal{K}_{t-\tilde{t}}(x-\tilde{x},\theta-\tilde{\theta})\rangle_{\tilde{x},\tilde{t},\tilde{\theta}}$$
$$+\langle\langle\tilde{D}[\Phi(\tilde{x},\tilde{\theta})\mathcal{K}_{\tilde{t}}(\tilde{x}-x',\tilde{\theta}-\theta')]\tilde{\tilde{D}}[\Phi(\tilde{\tilde{x}},\tilde{\tilde{\theta}})\mathcal{K}_{\tilde{\tilde{t}}-\tilde{t}}(\tilde{\tilde{x}}-\tilde{x},\tilde{\tilde{\theta}}-\tilde{\theta})]$$
$$\times\mathcal{K}_{t-\tilde{\tilde{t}}}(x-\tilde{\tilde{x}},\theta-\tilde{\tilde{\theta}})\rangle_{\tilde{x},\tilde{t},\tilde{\theta}}\rangle_{\tilde{\tilde{x}},\tilde{\tilde{t}},\tilde{\tilde{\theta}}}-\cdots,$$

where

$$\mathcal{K}_t(x-x',\theta-\theta')=g_t(x-x')(\theta-\theta'),$$

$$0<\tilde{t}<\tilde{\tilde{t}}<\cdots<t,$$

$$\tilde{D}=\tilde{\theta}\frac{\partial}{\partial\tilde{x}}+\frac{\partial}{\partial\tilde{\theta}},$$

and

$$\langle\cdot\rangle_{\tilde{x},\tilde{t},\tilde{\theta}}=\int\frac{\partial}{\partial\tilde{\theta}}(\cdot)|_{\tilde{\theta}=0}\,d\tilde{x}\,d\tilde{t}.$$

The integration on $\tilde{x}$ is over $\mathbb{R}$, the integration on the $\tilde{t}$ variable is according to the above ordering while the integration on the odd coordinate means $[\partial/\partial\tilde{\theta}]_{\tilde{\theta}=0}$ and it must be performed in the order indicated in our formula. We will show that this series expansion is convergent, under the assumption of bounded potentials.

The generic term of the expansion may be constructed from the previous one replacing $\mathcal{K}_{t-\tilde{\tilde{t}}}(x-\tilde{\tilde{x}},\theta-\tilde{\tilde{\theta}})$ by $\hat{D}[\Phi(\hat{x},\hat{\theta})\mathcal{K}_{\hat{t}-\tilde{\tilde{t}}}(\hat{x}-\tilde{\tilde{x}},\hat{\theta}-\tilde{\tilde{\theta}})]\mathcal{K}_{t-\hat{t}}(x-\hat{x},\theta-\hat{\theta})$ and performing an overall integration on $\hat{x},\hat{\theta},\hat{t}$ where this point is an intermediate one with $\tilde{\tilde{t}}<\hat{t}<t$.

The explicit expansion for $\mathbf{G}_t$ turns out to be, after some calculations,

$$\mathbf{G}_t(x,x';\theta,\theta')=g_t(x-x'-\theta\theta')-\langle\Phi(\tilde{x},\tilde{\theta})g_{\tilde{t}}(\tilde{x}-x'-\tilde{\theta}\theta')g_{t-\tilde{t}}(x-\tilde{x}-\theta\tilde{\theta})\rangle_{\tilde{x},\tilde{t},\tilde{\theta}}$$
$$+\langle\langle\Phi(\tilde{x},\tilde{\theta})g_{\tilde{t}}(\tilde{x}-x'-\tilde{\theta}\theta')\Phi(\tilde{\tilde{x}},\tilde{\tilde{\theta}})g_{\tilde{\tilde{t}}-\tilde{t}}(\tilde{\tilde{x}}-\tilde{x}-\tilde{\tilde{\theta}}\tilde{\theta})g_{t-\tilde{\tilde{t}}}(x-\tilde{\tilde{x}}-\theta\tilde{\tilde{\theta}})\rangle_{\tilde{x},\tilde{t},\tilde{\theta}}\rangle_{\tilde{\tilde{x}},\tilde{\tilde{t}},\tilde{\tilde{\theta}}}$$
$$-\cdots.$$

The generic term of the expansion may be constructed from the previous one replacing $g_{t-\tilde{\tilde{t}}}(x-\tilde{\tilde{x}}-\theta\tilde{\tilde{\theta}})$ by $\Phi(\hat{x},\hat{\theta})g_{\hat{t}-\tilde{\tilde{t}}}(\hat{x}-\tilde{\tilde{x}}-\hat{\theta}\tilde{\tilde{\theta}})g_{t-\hat{t}}(x-\hat{x}-\theta\hat{\theta})$ and performing an overall integration on $\hat{x},\hat{\theta},\hat{t}$ where this point is an intermediate one with $\tilde{\tilde{t}}<\hat{t}<t$.

In the bosonic limit, when $\xi(x)=0$ and $\theta=\theta'=0$, the integration on the odd variables $\tilde{\theta}$ becomes straightforward and the formula reduces to

$$\mathbf{G}_t(x,x';0,0)|_{\xi=0}=g_t(x-x')-\langle u(\tilde{x})g_{\tilde{t}}(\tilde{x}-x')g_{t-\tilde{t}}(x-\tilde{x})\rangle_{\tilde{x},\tilde{t}}$$
$$+\langle\langle u(\tilde{x})g_{\tilde{t}}(\tilde{x}-x')u(\tilde{\tilde{x}})g_{\tilde{\tilde{t}}-\tilde{t}}(\tilde{\tilde{x}}-\tilde{x})g_{t-\tilde{\tilde{t}}}(x-\tilde{\tilde{x}})\rangle_{\tilde{x},\tilde{t}}\rangle_{\tilde{\tilde{x}},\tilde{\tilde{t}}}-\cdots.$$

This is exactly the Green's function $\mathcal{G}$ for the operator $L_u=\partial_t-\Delta-u(x)$. If we assume $u(x)$ to be bounded and continuous:

$$|u(x)|<M,$$

it then follows, using the semigroup property for the Green's function, that

$$|\mathcal{G}_t(x,x')| < e^{tM} g_t(x-x').$$

It may also be shown that the convergent expansion for $\mathcal{G}_t(x,x')$ is equal to the Feynman–Kac formula,

$$\mathcal{G}_t(x,x') = \int dW_t(x,x') \exp\left(- \int_{-t/2}^{+t/2} u(x(s)) ds \right),$$

where $dW_t(x,x')$ denotes the Wiener measure for the continuous paths between x' and x. When $u(x)$ is real and bounded both formulas are exactly the same. However, the Feynman–Kac formula may be established even when $u(x)$ is bounded from below and $\Delta + u(x)$ is (essentially) self-adjoint, while the expansion in terms of the potential is valid when u is bounded without assuming the self-adjoint property of the operator.

$\mathcal{G}_t(x,x')$ is positive. This property arises directly from the Feynman–Kac formula.

It also satisfies

$$\mathcal{G}_t(x,x') = \mathcal{G}_t(x',x),$$

under the interchange of the positions of the field point and the source one.

In the next section we will analyze these properties for the supersymmetric extensions we are considering.

IV. THE SUSY GREEN'S FUNCTION AND THE SKdV HIERARCHY

The Green's function $\mathbf{G}_t$ depends on x, θ and x', θ' and on the components of the superpotential u and ξ. In order to analyze the transformation law, under supersymmetry, of $\mathbf{G}_t$ we will write explicitly its dependence on u and ξ, $\mathbf{G}_t(x,x';\theta,\theta';u,\xi)$. Under the supersymmetric transformations:

$$x \to x + \delta x = x - \eta\theta,$$

$$\theta \to \theta + \delta\theta = \theta + \eta,$$

$$\Phi \to \Phi + \delta\Phi = \Phi - \eta u(x) + \eta\theta\xi'(x),$$

the components of Φ transforms as

$$u \to u + \delta u = u - \eta\xi',$$

$$\xi \to \xi + \delta\xi = \xi - \eta u.$$

$\mathbf{G}_t$ is then invariant under these transformations. That is,

$$\mathbf{G}_t(x+\delta x, x'+\delta x'; \theta+\delta\theta, \theta'+\delta\theta'; u+\delta u, \xi+\delta\xi) = \mathbf{G}_t(x,x';\theta,\theta';u,\xi). \tag{3}$$

To show this invariance property of $\mathbf{G}_t$ we notice that

$$(\Phi + \delta\Phi)(\tilde{x},\tilde{\theta}) = \Phi(\tilde{x} - \delta\tilde{x}, \tilde{\theta} - \delta\tilde{\theta}).$$

We then evaluate the left hand member of (3) using the previous expansion formula and perform a change of variable at each intermediate point $\tilde{x},\tilde{\theta}$:

$$\tilde{x} \to \tilde{x}_1 = \tilde{x} - \delta\tilde{x},$$

$$\tilde{\theta} \to \tilde{\theta}_1 = \tilde{\theta} - \delta\tilde{\theta},$$

with a Jacobian equal to 1.

We then use the property that the combination $(\tilde{\tilde{x}}-\tilde{x}-\tilde{\tilde{\theta}}\tilde{\theta})$ is invariant under this change of coordinates. We end up with the relation (3).

The other symmetry of the SUSY Green's function $\mathbf{G}_t$ is

$$\mathbf{G}_t(x,x';\theta,\theta';u,\xi)=\mathbf{G}_t(x,x';\theta',\theta;u,\xi). \tag{4}$$

It follows by performing changes of variables on the time arguments at each integrand on each term of the expansion. In terms of the components of $\mathbf{G}_t$ it means

$$\mathbf{G}_t(x,x';\theta,\theta')=A_t(x,x')+\theta' B_t(x,x')+\theta C_t(x,x')+\theta\theta' D_t(x,x'),$$

$$A_t(x,x')=A_t(x',x),$$

$$B_t(x,x')=C_t(x',x),$$

$$D_t(x,x')=-D_t(x',x).$$

We will now evaluate $\mathbf{G}_t$ by performing all integrations on the odd variables. We start evaluating $\mathbf{G}_t(x,x';0,0;u,\xi)$. We denote

$$\tilde{x},\tilde{t}\Rightarrow\tilde{\tilde{x}},\tilde{\tilde{t}}=\mathcal{G}^{\tilde{}}_{\tilde{t}-\tilde{t}}(\tilde{\tilde{x}},\tilde{x}),\ \text{the bosonic propagator;}$$

$$\tilde{x},\tilde{t}\rightsquigarrow\tilde{\tilde{x}},\tilde{\tilde{t}}=-\frac{1}{2}\frac{(\tilde{\tilde{x}}-\tilde{x})}{(\tilde{\tilde{t}}-\tilde{t})}g^{\tilde{}}_{\tilde{t}-\tilde{t}}(\tilde{\tilde{x}}-\tilde{x});\ \text{the fermionic propagator.}$$

An arrow followed by a vertex $\xi(\tilde{\tilde{x}})$ denotes multiplication of the propagator by the vertex and integration on the corresponding coordinates $\tilde{\tilde{x}},\tilde{\tilde{t}}$.

The Green's function at $\theta=\theta'=0$ may then be expressed by

$$\mathbf{G}_t(x,x';0,0;u,\xi)=x',t'\Rightarrow x,t+x',t'\Rightarrow\xi\rightsquigarrow\xi\Rightarrow x,t+x',t'\Rightarrow\xi\rightsquigarrow\xi\Rightarrow\xi\rightsquigarrow\xi\Rightarrow x,t$$
$$+x',t'\Rightarrow\xi\rightsquigarrow\xi\Rightarrow\xi\rightsquigarrow\xi\Rightarrow\xi\rightsquigarrow\xi\Rightarrow x,t+\cdots.$$

It can be shown that this expansion on the fermionic vertex ξ is convergent provided $u(x)$ is bounded and $\xi(x)$ is bounded in the following sense. It is possible to express the product

$$\xi(\tilde{\tilde{x}})\xi(\tilde{\tilde{x}})=\frac{1}{2}(x-\tilde{\tilde{x}})f(\tilde{\tilde{x}},\tilde{x}), \tag{5}$$

since the left hand member is antisymmetric on $\tilde{x}\leftrightarrow\tilde{\tilde{x}}$. We assume then that

$$|u(x)|<M,$$

$$f(\tilde{\tilde{x}},\tilde{x})<M^2. \tag{6}$$

The square arises from dimensional arguments. In fact, let us remember that $[\xi]=-3/2$ and $[u]=-2$ and hence $[f]$ must be -4. After replacing (5) in the expression of $\mathbf{G}_t(x,x';0,0;u,\xi)$, the contributions of the fermionic propagator times the fermionic vertices may be worked out in terms of derivatives of g_t. One may then use (6) and the semigroup properties for g_t to obtain a bound for the series expansion of $\mathbf{G}_t(x,x';0,0;u,\xi)$.

The complete expression for $\mathbf{G}_t(x,x';\theta,\theta')$, expressed in terms of its value at $\theta=\theta'=0$, is the following:

$$\mathbf{G}_t(x,x';\theta,\theta')=\mathbf{G}_t(x,x',0,0)-\theta\langle\mathbf{G}_{t-t'}^{\sim}(\tilde{x},x',0,0)\xi(\tilde{x})g'_{t-\tilde{t}}(x-\tilde{x})\rangle_{\tilde{x},\tilde{t}}$$
$$+\theta'\langle\xi(\tilde{x})g'_{t-t'}(\tilde{x}-x')\mathbf{G}_{t-\tilde{t}}(x,\tilde{x},0,0)\rangle_{\tilde{x},\tilde{t}}$$
$$-\theta\theta'\langle\langle\xi(\tilde{x})g'_{t-t'}(\tilde{x}-x')\mathbf{G}_{\tilde{t}-\tilde{t}}^{\tilde{}}(\tilde{\tilde{x}},\tilde{x};0,0)\xi(\tilde{\tilde{x}})g'_{t-\tilde{t}}(x-\tilde{\tilde{x}})\rangle_{\tilde{x},\tilde{t}}\rangle_{\tilde{\tilde{x}},\tilde{\tilde{t}}}.$$

Just as in the bosonic case, $\mathbf{G}_t$ possesses an asymptotic expansion:

$$\mathbf{G}_t(x,x',\theta,\theta')=g_t(x-x'-\theta\theta')\sum_{k=0}^{\infty}\frac{t^k}{k!}\Gamma_k(x,x'),$$

in which each term has the form

$$\Gamma_k(x,x')=A_k(x,x')+\theta B_k(x,x')+\theta' C_k(x,x')+\theta\theta' D_k(x,x').$$

The approximation of $\mathbf{G}_t$ by its asymptotic expansion proves that A_k, B_k, C_k, D_k have the same x,x' symmetry as noted before. As before, Γ_k is constructed from the potential $\Phi(x)=\xi(x)+\theta u(x)$ by an iterative procedure starting with $\Gamma_0(x,x')=1$.

Formally equating x with x' and θ with θ' we define

$$g_k(x)=A_k(x,x)+2\theta B(x,x).$$

This must be a polynomial in $\xi(x)$, $u(x)$, and their derivatives. But it turns out to be expressible as a polynomial in $\Phi=\xi+\theta u, D\Phi=u+\theta\partial_x\xi, D^2\Phi=\partial_x\xi+\theta\partial_x u,\ldots$.

These polynomials can be seen as elements of the free supersymmetric derivation ring on a single fermionic generator, but in the notation $\Phi=a_1, D\Phi=a_2,\ldots$.

The first few such polynomials are

$$g_2=-a_2,$$

$$g_6=-a_6+3a_2^2-2a_1a_3,$$

$$g_{10}=(-a_{10}+10a_2a_6+5a_4^2-10a_2)^3-(4a_1a_7+a_3a_5-15a_1a_2a_3).$$

They have been shown to be gradients of conserved quantities of the SKdV[1] equation, whose unknown function $\Omega(x,t)$ is to satisfy

$$\Omega_t=-D^6\Omega+3\Omega(D^3\Omega)+3((D\Omega)(D^2\Omega)).$$

The symmetry of the asymptotic Green's function permits the derivation, after several calculations, of the recursive algorithm,

$$D^2g_{n+4}=(D^6+2a_1D^3-4a_2D^2+a_3D-2a_4I)g_n-a_1l_n,$$

$$D^2l_n=-a_2Dg_n+a_3g_n.$$

The members of the super KdV hierarchy are then given by Mg_n with

$$M=D^5-3a_1D^2-a_2D-2a_3I.$$

In particular Mg_2 is the super KdV equation of Mathieu,[1] the same one appearing above.

One may use necessary and sufficient conditions arising from the exact sequence established in Sec. II to show g_n are the gradients of conserved quantities of the SKdV hierarchy.

V. CONCLUSIONS

We introduced the free $N=1$ supersymmetric derivation ring. We established the exact sequence of supersymmetric rings and linear transformations:

$$\begin{array}{llll} O_p\mathcal{A}\leftarrow & \mathcal{A}\leftarrow & \mathcal{A}\leftarrow & \mathcal{A}\leftarrow\mathbb{R}\leftarrow 0 \\ & & Df\leftarrow & f \\ & Mh\leftarrow & h & \\ L_g+L_g^*\leftarrow & g. & & \end{array}$$

Several of these relations were already known in the literature.[2,12]

We used necessary and sufficient conditions arising from this exact sequence to obtain the essential relations between conserved quantities, gradients, and the $N=1$ super KdV hierarchy. We combine these algebraic conditions together with an analytical analysis of the superheat operator,

$$\mathbf{L}=\frac{\partial}{\partial t}-(D^4-D\Phi+\Phi D).$$

We found an explicit series expansion for the Green's function of the superheat operator and discussed its properties. The expansion is convergent under the assumption of bounded bosonic and fermionic potentials as established in Sec. IV. This analysis may be relevant since there is no rigorous Feynman–Kac formula for the fermionic case.

Finally we show that the asymptotic expansion when $t\rightarrow 0^+$ of the Green's function of $\mathbf{L}$, evaluated over its diagonal, generates all the members of the $N=1$ super KdV hierarchy.

The exact sequence of SUSY rings and linear transformations may also be constructed with $N>1$ SUSY generators; we hope to discuss this extension elsewhere. We expect that the algebraic construction established in the first part of this work may have a natural extension for more general finite-dimensional quantum systems. This would be of great help in understanding, for example, the quantum behavior of the supermembrane and super D-brane theories.[15–17]

The polysymplectic formalism in local field theory, developed by Günther [J. Diff. Geom. **25**, 23 (1987)], is revised. A new approach and new results on momentum maps and reduction are given. © *2004 American Institute of Physics.*
[DOI: 10.1063/1.1688433]

I. INTRODUCTION

Günther's paper[1] gives a geometric Hamiltonian formalism for field theories. The crucial device is the introduction of a vector-valued generalization of a symplectic form, called a polysymplectic form. One of the advantages of this formalism is that one only needs the tangent and cotangent bundle of a manifold to develop it.

In this paper our purpose is, first, to clarify the Günther's formalism, second, give new results on momentum maps and reduction for this formalism.

We describe his polysymplectic formalism using a standard notation as that in the Abraham–Marsden[2] book. We show that the polysymplectic structures used by Günther to develop his formalism could be replaced by the k-symplectic structures defined by Awane.[3–5] So this formalism could be called the k-symplectic formalism.

We believe that this clarifies Günther's paper.[1] We present new examples of the formalism, new results about momentum maps, and we extend the reduction procedures by Marsden and Weinstein and Kostant-Souriau to polysymplectic manifolds.

Let us remark here that the polysymplectic formalism developed by Sardanashvily and co-workers,[6,7] based on a vector valued form on some associated fiber bundle, is a different description of classical field theories of first order than the polysymplectic formalism proposed by Günther.

In Secs. II–IV we develop the Günther's formalism: in Sec. II the field theoretic phase space is introduced as the Whitney sum $(T^1_k)^*Q$ of k-copies of the cotangent bundle T^*Q of a manifold Q. This space is the canonical example of polysymplectic manifold. A particular case of polysymplectic manifolds are the k-symplectic manifolds (see Refs. 3–5, 8, and 9).

The field theoretic state space is introduced in Sec. II as the Whitney sum T^1_kQ of k-copies of the tangent bundle TQ of a manifold Q. This manifold has a canonical k-tangent structure defined by k tensor fields of type (1, 1) satisfying certain algebraic properties. The k-tangent manifolds were introduced by de León *et al.*,[10,11] and they generalize the tangent manifolds (see Refs. 12–17).

Section III is devoted to give a geometric interpretation of the second order partial differential equations. Here we show that these equations can be characterized using the canonical k-tangent structure of T^1_kQ, which generalizes the case of Classical Mechanics.

Hamiltonian and Lagrangian formalisms are developed in Sec. IV. We present two new ex-

[a]Electronic mail: angelmrey@edu.xunta.es
[b]Electronic mail: modesto@zmat.usc.es

amples, the electrostatic equations as an example of the Hamiltonian formalism, and the theory of a vibrating string as an example of the Lagrangian formalism.

We prove that the Lagrangian formalism can be developed using the canonical k-tangent structure of T^1_kQ, or the Legendre transformation by Günther.[1]

A natural extension of these formalisms is the geometric description of first order classical field theories given in terms of k-cosymplectic manifolds. This description can be found in Refs. 18 and 19.

In Sec. V we discuss symmetries and conservation laws of classical field theories in terms of momentum maps generalizing the concept of momentum map in mechanics. Some results on conservation laws and a Noether theorem obtained by Günther[1] are recalled. We extend the results about momentum maps in T^*Q and TQ, to the polysymplectic manifolds $(T^1_k)^*Q$ and T^1_kQ. In fact we show that the conservation law, given in Theorem 4.2.2 of Abraham–Marsden,[2] for a symplectic manifold, can be extended to $(T^1_k)^*Q$. We also present a generalized Noether theorem on T^1_kQ, which is a generalization of Corollary 4.2.14 by Abraham–Marsden.[2]

Reduction for symplectic manifolds is generalized to the polysymplectic structures in Sec. VI. So, we obtain "the reduced phase space" M_μ of a polysymplectic manifold, we give an explicit realization of M_μ for $M=(T^1_k)^*Q$, and we reduce the Hamiltonian $H:(T^1_k)^*Q\to\mathbb{R}$ to M_μ. An example of reduction for the left action of G on $(T^1_k)^*G$, where G is a Lie group, is presented. We study the particular case $G=\mathrm{SO}(3)\overset{k}{\times}\cdots\times\mathrm{SO}(3)$.

Finally, let us remark that the reduction problem was also discussed in the different frameworks of the classical field theory, the GIMMSY[20] paper is probably the most ambitious program to develop full description of the reduction theory, not only on the finite dimensional setting by the multisymplectic form, but also on the infinite dimensional setting of the associated Cauchy space.

II. POLYSYMPLECTIC MANIFOLDS

A. The cotangent bundle of k^1-covelocities of a manifold

Let Q be a differentiable manifold of dimension n, $\tau_Q:TQ\to Q$ its tangent bundle and $\tau^*_Q:T^*Q\to Q$ its cotangent bundle. Let us denote by $(T^1_k)^*Q=T^*Q\overset{k}{\oplus}\cdots\oplus T^*Q$ the Whitney sum of k copies of T^*Q, with projection map $\tau^*:(T^1_k)^*Q\to Q$, $\tau^*(\alpha_1(q),\ldots,\alpha_k(q))=q$.

$(T^1_k)^*Q$ can be canonically identified with the vector bundle $J^1(Q,\mathbb{R}^k)_0$ of k^1-covelocities of the manifold Q, the manifold of 1-jets of maps with target at $0\in\mathbb{R}^k$ and projection map $\tau^*:J^1(Q,\mathbb{R}^k)_0\to Q$, $\tau(j^1_{q,0}\sigma)=q$, say,

$$J^1(Q,\mathbb{R}^k)_0\equiv T^*Q\overset{k}{\oplus}\cdots\oplus T^*Q,$$

$$j^1_{q,0}\sigma\equiv(\mathrm{d}\sigma^1(q),\ldots,\mathrm{d}\sigma^k(q)),$$

where $\sigma^A=\pi_A\circ\sigma:Q\to\mathbb{R}$ is the Ath component of σ, and $\pi_A:\mathbb{R}^k\to\mathbb{R}$ is the canonical projection $1\leqslant A\leqslant k$. For this reason we shall also call to $(T^1_k)^*Q$ *the bundle of k^1-covelocities of the manifold Q*.

If (q^i) are local coordinates on $U\subseteq Q$, then the induced local coordinates (q^i,p_i), $1\leqslant i\leqslant n$, on $T^*U=(\tau^*_Q)^{-1}(U)$, are given by

$$q^i(\alpha_q)=q^i(q),\quad p_i(\alpha_q)=\alpha_q\left(\frac{\partial}{\partial q^i}(q)\right),\tag{1}$$

and the induced local coordinates (q^i,p^A_i), $1\leqslant i\leqslant n$, $1\leqslant A\leqslant k$, on $(T^1_k)^*U=(\tau^*)^{-1}(U)$ are given by

$$q^i(\alpha_1(q),\ldots,\alpha_k(q))=q^i(q),\quad p^A_i(\alpha_1(q),\ldots,\alpha_k(q))=\alpha_A(q)\left(\frac{\partial}{\partial q^i}(q)\right).$$

Let us denote by $\{r_1,\ldots,r_k\}$ the canonical basis of $\mathbb{R}^k$.

Definition II.1 (Günther[1]): A closed nondegenerate $\mathbb{R}^k$-valued 2-form,

$$\overline{\omega}=\sum_{A=1}^{k}\omega_A\otimes r_A,$$

on a manifold M of dimension N is called a polysymplectic form. *The pair $(M,\overline{\omega})$ is called a* polysymplectic manifold.

We shall introduce now the *canonical polysymplectic structure* on $(T^1_k)^*Q$. The canonical polysymplectic structure $\overline{\omega}=\Sigma^k_{A=1}(\omega_0)_A\otimes r_A$, on $(T^1_k)^*Q$ is defined by

$$(\omega_0)_A=(\tau^*_A)^*(\omega_0),\quad 1\leqslant A\leqslant k,$$

where $\tau^*_A:(T^1_k)^*Q\to T^*Q$ is the projection on the Ath-copy T^*Q of $(T^1_k)^*Q$, and $\omega_0=-\mathrm{d}\theta_0$ is the canonical symplectic structure of T^*Q, being θ_0 the Liouville 1-form defined by

$$\theta_0(\alpha_q)(\tilde{X}_{\alpha_q})=\alpha_q((\tau^*_Q)_*(\alpha_q)(\tilde{X}_{\alpha_q})),\quad \alpha_q\in T^*Q,\ \tilde{X}_{\alpha_q}\in T_{\alpha_q}(T^*Q).$$

One can also define the 2-forms $(\omega_0)_A$ by $(\omega_0)_A=-d(\theta_0)_A$ where $(\theta_0)_A=(\tau^*_A)^*\theta_0$. Thus the canonical symplectic structure on T^*Q is locally given by

$$\omega_0=-\mathrm{d}\theta_0=-d(p_i\,\mathrm{d}q^i)=\mathrm{d}q^i\wedge\mathrm{d}p_i,\tag{2}$$

and the canonical polysymplectic structure $((\omega_0)_1,\ldots,\omega_0)_k)$ on $(T^1_k)^*Q$ is locally given by

$$(\omega_0)_A=-d(\theta_0)_A=-d(p^A_i\,\mathrm{d}q^i)=\mathrm{d}q^i\wedge\mathrm{d}p^A_i.\tag{3}$$

Definition II.2 (Günther[1]): A polysymplectic form $\overline{\omega}$ on a manifold M is called standard *iff for every point of M there exists a local coordinates system such that ω_A is written locally as in (3).*

So the canonical polysymplectic form $\overline{\omega}$ on $(T^1_k)^*Q$ is standard.

B. The tangent bundle of k^1-velocities of a manifold

For an arbitrary manifold Q, let us denote by T^1_kQ the Whitney sum $TQ\overset{k}{\oplus\cdots\oplus}TQ$ of k copies of TQ, with projection $\tau:T^1_kQ\to Q$, $\tau(v_1(q),\ldots,v_k(q))=q$.

T^1_kQ can be identified with the manifold $J^1_0(\mathbb{R}^k,Q)$ of the k^1-velocities of Q, that is, 1-jets of maps with source at $0\in\mathbb{R}^k$ and with projection map $\tau:T^1_kQ\to Q$, $\tau(j^1_{0,q}\sigma)=\sigma(0)=q$, say

$$J^1_0(\mathbb{R}^k,Q)\equiv TQ\overset{k}{\oplus\cdots\oplus}TQ,$$

$$j^1_{0,q}\sigma\equiv(v_1(q),\ldots,v_k(q)),$$

where $q=\sigma(0)$ and $v_A=\sigma_*(0)[(\partial/\partial t^A)(0)]$.

So we shall call T^1_kQ *the tangent bundle of k^1-covelocities of Q*. If (q^i) are local coordinates on $U\subseteq Q$ then the induced local coordinates (q^i,v^i), $1\leqslant i\leqslant n$, on $TU=\tau_Q^{-1}(U)$ are given by

$$q^i(v_q)=q^i(q),\quad v^i(v_q)=v_q(q^i),$$

and the induced local coordinates (q^i,v^i_A), $1\leqslant i\leqslant n$, $1\leqslant A\leqslant k$, on $T^1_kU=\tau^{-1}(U)$ are given by

$$q^i(v_1(q),\ldots,v_k(q))=q^i(q),\quad v^i_A(v_1(q),\ldots,v_k(q))=v_A(q)(q^i).$$

We shall introduce now the *canonical k-tangent structure* on T^1_kQ.

Definition II.3: For a vector X_q at Q, and for $A=1,\ldots,k$, we define its vertical A-lift $(X_q)^A$ as the vector on T^1_kQ given by

$$(X_q)^A(v_1(q),\ldots,v_k(q))=\frac{d}{ds}(v_1(q),\ldots,v_{A-1}(q),v_A(q)+sX_q,v_{A+1}(q),\ldots,v_k(q))_{|_{s=0}}$$

for all points $(v_1(q),\ldots,v_k(q))\in T_k^1Q$.

In local coordinates we have

$$(X_q)^A=a^i\frac{\partial}{\partial v_A^i} \tag{4}$$

for a vector $X_q=a^i(\partial/\partial q^i)$.

The *canonical k-tangent structure* on T_k^1Q is the set $(S^1,\ldots,S^k)$ of tensor fields of type (1, 1) defined by

$$S^A(v)(Z_v)=(\tau_*(v)(Z_v))^A,\quad \text{for all } Z_v\in T_v(T_k^1Q),\quad v=(v_1(q),\ldots,v_k(q)),$$

for each $A=1,\ldots,k$.

From (4) we have in local coordinates

$$S^A=\frac{\partial}{\partial v_A^i}\otimes dq^i. \tag{5}$$

The tensors S^A can be regarded as the $(0,\ldots,0,\overset{A}{1},0,\ldots,0)$-lift of the identity tensor on Q to T_k^1Q defined by Morimoto.[21]

Remark II.1: The k-tangent manifolds were introduced as a generalization of the tangent manifolds by de León *et al.*[10,11] The canonical model of these manifolds is T_k^1Q with the structure given by $(S^1,\ldots,S^k)$.

To develop later the Lagrangian formalism, we shall construct now a polysymplectic structure on T_k^1Q, for each regular Lagrangian $L:T_k^1Q\to\mathbb{R}$, using its canonical k-tangent structure.

Definition II.4: A Lagrangian $L:T_k^1Q\to\mathbb{R}$ *is called regular if and only if*

$$\det\left(\frac{\partial^2L}{\partial v_A^i\partial v_B^j}\right)\neq 0,\quad 1\leqslant i,j\leqslant n,\quad 1\leqslant A,B\leqslant k. \tag{6}$$

Let us consider the 1-forms $(\theta_L)_A=dL\circ S^A$, $1\leqslant A\leqslant k$. In a local coordinates system (q^i,v_A^i) we have

$$(\theta_L)_A=\frac{\partial L}{\partial v_A^i}dq^i,\quad 1\leqslant A\leqslant k. \tag{7}$$

Introducing the following 2-forms $(\omega_L)_A=-d(\theta_L)_A$, $1\leqslant A\leqslant k$, one can easily prove the following proposition.

Proposition II.1: $L:T_k^1Q\to\mathbb{R}$ *is a regular Lagrangian if and only if* $((\omega_L)_1,\ldots,(\omega_L)_k)$ *is a polysymplectic structure on* T_k^1Q. ■

This polysymplectic structure, associated to L, was also introduced by Günther[1] using the Legendre transformation.

The Legendre map $FL:T_k^1Q\to(T_k^1)^*Q$, was introduced by Günther,[1] and we rewrite it as follows: if $(v_1(q),\ldots,v_k(q))\in(T_k^1)_qQ$,

$$[FL(v_1(q),\ldots,v_k(q))]^A(w_q)=\frac{d}{ds}L(v_1(q),\ldots,v_A(q)+sw_q,\ldots,v_k(q))_{|s=0},$$

for each $A=1,\ldots,k$. We deduce that FL is locally given by

$$(q^i, v^i_A) \to \left(q^i, \frac{\partial L}{\partial v^i_A} \right). \tag{8}$$

In fact, from (7) and (8), we easily obtain the following Lemma.

Lemma II.1: For every $1 \leqslant A \leqslant k$, $(\omega_L)_A = (FL)^*(\omega_0)_A$, *where* $(\omega_0)_1, \ldots, (\omega_0)_k$ *are the 2-forms of the canonical polysymplectic structure.* ■

Then, from (8) we obtain the following.

Proposition II.2: Let L be a Lagrangian. The following conditions are equivalent: (1) L is regular, (2) FL is a local diffeomorphism. (3) $((\omega_L)_1, \ldots, (\omega_L)_k)$ *is a polysymplectic structure on* $T^1_k Q$. ■

III. SECOND ORDER PARTIAL DIFFERENTIAL EQUATIONS ON $T^1_k Q$

A. *k*-vector fields

Let M be an arbitrary manifold and $\tau: T^1_k M \to M$ its tangent bundle of k^1-velocities.

Definition III.1: A section $X: M \to T^1_k M$ *of the projection* τ *will be called a* k-vector field *on* M.

Since $T^1_k M$ is the Whitney sum $TM \overset{k}{\oplus \cdots \oplus} TM$ of k copies of TM, we deduce that a k-vector field X defines a family of k-vector fields $X_1, \ldots, X_k$ on M by projecting X onto every factor.

Definition III.2: An integral section of the k-vector field $(X_1, \ldots, X_k)$ *passing through a point* $x \in M$ *on* M *is a map* $\phi: U_0 \subset \mathbb{R}^k \to M$, *defined on some neighborhood* U_0 *of* $0 \in \mathbb{R}^k$, *such that*

$$\phi(0) = x, \quad \phi_*(t)\left(\frac{\partial}{\partial t^A}(t) \right) = X_A(\phi(t)) \quad \textit{for all } t \in U_0, \quad 1 \leqslant A \leqslant k, \tag{9}$$

or equivalently, ϕ *satisfies* $X \circ \phi = \phi^{(1)}$, *where* $\phi^{(1)}$ *is the first prolongation of* ϕ *defined by*

$$\phi^{(1)}: U_0 \subset \mathbb{R}^k \to T^1_k M,$$

$$t \to \phi^{(1)}(t) = j^1_0 \phi_t, \quad \phi_t(\overline{t}) = \phi(\overline{t} + t),$$

for all $\overline{t}, t \in \mathbb{R}^k$ *such that* $\overline{t} + t \in U_0$.

In local coordinates,

$$\phi^{(1)}(t^1, \ldots, t^k) = \left(\phi^i(t^1, \ldots, t^k), \frac{\partial \phi^i}{\partial t^A}(t^1, \ldots, t^k) \right), \quad 1 \leqslant A \leqslant k, \ 1 \leqslant i \leqslant n. \tag{10}$$

We say that a k-vector field $(X_1, \ldots, X_k)$ on M is integrable if there is an integral section passing through each point of M.

Remark III.1: Let us consider the trivial bundle $\pi: E = \mathbb{R}^k \times M \to \mathbb{R}^k$. A jet field γ on π (see Ref. 22) is a section of the projection $\pi_{1,0}: J^1\pi \equiv \mathbb{R}^k \times T^1_k M \to E \equiv \mathbb{R}^k \times M$. If we identify each k-vector field X on M with the jet field $\gamma = (id_{R^k}, X)$, that is $\gamma(t,q) = (t, X_1(q), \ldots, X_k(q))$, then the integral sections of the jet field γ correspond to the *solutions* of the k-vector field X.

We remark that if ϕ is an integral section of a k-vector field $(X_1, \ldots, X_k)$ then each curve on M defined by $\phi_A = \phi \circ h_A$, where $h_A: \mathbb{R} \to \mathbb{R}^k$ is the natural inclusion $h_A(s) = (0, \ldots, \overset{A}{0}, s, 0, \ldots, 0)$, is an integral curve of the vector field X_A on M, with $1 \leqslant A \leqslant k$.

B. Second order partial differential equations on $T^1_k Q$

The aim of this section is to characterize the integrable k-vector fields on $T^1_k Q$ such that their integral sections are canonical prolongations of maps from $\mathbb{R}^k$ to Q.

Definition III.3: A k-vector field on T^1_kQ, that is, a section $\xi\equiv(\xi_1,\ldots,\xi_k):T^1_kQ\to T^1_k(T^1_kQ)$ of the projection $\tau_{T^1_kQ}:T^1_k(T^1_kQ)\to T^1_kQ$, is a second order partial differential equation (SOPDE) *if and only if it is also a section of the vector bundle $T^1_k(\tau):T^1_k(T^1_kQ)\to T^1_kQ$, where $T^1_k(\tau)$ is defined by $T^1_k(\tau)(j^1_0\sigma)=j^1_0(\tau\circ\sigma)$.*

From a direct computation in local coordintes we obtain that the local expression of a SOPDE ξ is

$$\xi_A(q^j,v^j_C)=v^i_A\frac{\partial}{\partial q^i}+(\xi_A)^i_B(q^j,v^j_C)\frac{\partial}{\partial v^i_B},\quad 1\leqslant A\leqslant k. \tag{11}$$

From (9), (10), and (11) we deduce the following proposition.

Proposition III.1: Let ξ be an integrable k-vector field on T^1_kQ. The necessary and sufficient condition for ξ to be a second order partial differential equation is that its integral sections are first prolongations $\phi^{(1)}$ of maps $\phi:\mathbb{R}^k\to Q$. That is

$$\xi_A(\phi^{(1)}(t))=(\phi^{(1)})_*(t)\left(\frac{\partial}{\partial t^A}(t)\right),$$

for all $A=1,\ldots,k$. These maps ϕ will be called solutions of the SOPDE ξ.

From (10) and (11) we have the following.

Proposition III.2: $\phi:\mathbb{R}^k\to Q$ is a solution of the SOPDE $\xi=(\xi_1,\ldots,\xi_k)$, locally given by (11), if and only if

$$\frac{\partial^2\phi^i}{\partial t^A\partial t^B}(t)=(\xi_A)^i_B(\phi^{(1)}(t)).$$

If $\xi:T^1_kQ\to T^1_k(T^1_kQ)$ is an integrable SOPDE, then for all integral sections $\sigma:U\subset\mathbb{R}^k\to T^1_kQ$ we have $(\tau\circ\sigma)^{(1)}=\sigma$, where $\tau:T^1_kQ\to Q$ is the canonical projection.

Now we show how to characterize the SOPDE's using the canonical k-tangent structure of T^1_kQ.

Definition III.4: The Liouville vector field C on T^1_kQ is the infinitesimal generator of the following flow:

$$\mathbb{R}\times T^1_kQ\to T^1_kQ,$$

$$(s,(v_1(q),\ldots,v_k(q)))\to(e^s v_1(q),\ldots,e^s v_k(q)),$$

and in local coordinates has the form

$$C=\sum_{i,B} v^i_B\frac{\partial}{\partial v^i_B}. \tag{12}$$

We can write $C=C_1+\cdots+C_k$ where C_A are the canonical vector fields on T^1_kQ given by the following flows:

$$\mathbb{R}\times T^1_kQ\to T^1_kQ,$$

$$(s,(v_1(q),\ldots,v_k(q)))\to(v_1(q),\ldots,v_{A-1}(q),e^s v_A(q),v_{A+1}(q),\ldots,v_k(q)).$$

In local coordinates,

$$C_A=\sum_i v^i_A\frac{\partial}{\partial v^i_A}. \tag{13}$$

From (5), (11), (12), and (13) we deduce the following.

Proposition III.3: A k-vector field $\xi=(\xi_1,\ldots,\xi_k)$ *on* T^1_kQ *is a SOPDE if and only if* $S^A(\xi_A)=C_A$, *for all* $1\leqslant A\leqslant k$, *where* $(S^1,\ldots,S^k)$ *is the canonical k-tangent structure on* T^1_kQ.

IV. HAMILTONIAN AND LAGRANGIAN FORMALISMS

A. Hamiltonian formalism

We recall the Hamilton formalism developed by Günther[1] using polysymplectic structures, showing that the role played by symplectic manifolds in classical mechanics is here played by the polysymplectic manifolds.

Let $(M,\omega_A,1\leqslant A\leqslant k)$ be a polysymplectic manifold and let us consider the vector bundle morphism $\Omega^\sharp$ defined by

$$\begin{aligned}&\Omega^\sharp:\quad T^1_kM\to T^*M,\\ &(X_1,\ldots,X_k)\to\Omega^\sharp(X_1,\ldots,X_k)=\sum_{A=1}^{k}\imath_{X_A}\omega_A\,.\end{aligned}\tag{14}$$

Definition IV.1: Let $H:M\to\mathbb{R}$ *be a function on M. Any k-vector field* $(X_1,\ldots,X_k)$ *on M such that*

$$\Omega^\sharp(X_1,\ldots,X_k)=\mathrm{d}H\tag{15}$$

will be called an evolution k-vector field on M associated with the Hamiltonian function H.

It should be noticed that in general the solution to the above equation is not unique. In fact the solutions are given by $(X_1,\ldots,X_k)+(\ker\Omega^\sharp)$.

If M is a standard manifold we have coordinates (q^i,p^A_i) on M. Then from Definition III.2, (14) and (15) we deduce the following.

Proposition IV.1: If $(X_1,\ldots,X_k)$ *is an integrable evolution k-vector field associated to H, then its integral sections* $\phi(t^B)\equiv(\phi^i(t^B),\phi^A_i(t^B))$ *are solutions of the Hamilton field equations corresponding to H,*

$$\frac{\partial H}{\partial q^i}=-\sum_{A=1}^{k}\frac{\partial\phi^A_i}{\partial t^A},\quad \frac{\partial H}{\partial p^A_i}=\frac{\partial\phi^i}{\partial t^A},\quad 1\leqslant i\leqslant n,\quad 1\leqslant A\leqslant k.\tag{16}$$

Remark IV.1: The *k*-symplectic manifolds were introduced in Awane[3–5] and they coincide with the *standard polysymplectic* manifolds. In the Hamiltonian formalism Günther uses a standard polysymplectic manifold in order to have local coordinates (q^i,p^A_i), which is equivalent to consider a *k*-symplectic manifold. We explain this now.

Definition IV.2 (Awane[3]): A k-symplectic structure on a manifold M of dimension $N=n+kn$ *is a family* $(\omega_A,V;1\leqslant A\leqslant k)$, *where each* ω_A *is a closed 2-form and V is an integrable nk-dimensional distribution on M such that*

$$(i)\quad \omega_{A_{]V\times V}}=0,\quad (ii)\quad \bigcap_{A=1}^{k}\ker\omega_A=\{0\}.$$

In this case (M,ω_A,V) *is called a k-symplectic manifold.*

Theorem IV.1 *(Awane[3]): Let* $(\omega_A,V;1\leqslant A\leqslant k)$ *be a k-symplectic structure on M. About every point of M we can find a local coordinate system* (q^i,p^A_i), $1\leqslant i\leqslant n$, $1\leqslant A\leqslant k$, *such that*

$$\omega_A=\mathrm{d}q^i\wedge\mathrm{d}p^A_i,\quad 1\leqslant A\leqslant k.\tag{17}$$

The canonical model of *k*-symplectic manifolds is also $(T^1_k)^*Q$ and the canonical *k*-symplectic structure $(\omega_A,V;1\leqslant A\leqslant k)$, on $(T^1_k)^*Q$ is given by

$$\omega_A=(\omega_0)_A=(\tau_A^*)^*(\omega_0),\quad V(j^1_{q,0}\sigma)=\ker(\tau^*)_*(j^1_{q,0}\sigma).$$

Therefore, the 2-forms of the canonical polysymplectic structure and the canonical k-symplectic structure on $(T^1_k)^*Q$ coincide.

From (17) we know that the standard polysymplectic structures and the k-symplectic structures coincide. Indeed, if $\overline{\omega}=\Sigma_{A=1}^k\omega_A\otimes r_A$ is a standard polysymplectic structure on M, given a local adapted coordinate system (q^i,p_i^A) we can define, locally, the distribution V, of dimension nk, by $\mathrm{d}q^1=\cdots=\mathrm{d}q^n=0$. Then, $(\omega_1,\ldots,\omega_k,V)$ is a k-symplectic structure on M.

For this reason, the Günther's formalism, called polysymplectic formalism, could be called k-symplectic formalism.

Example IV.1: We shall use the above formalism to obtain an intrinsic version for the electrostatic equations. Consider $\mathbb{R}^3$ with a metric g with components g_{ij}. Let $\sigma:\mathbb{R}^3\to\mathbb{R}$ be the electric potential and $P=(P_1,P_2,P_3):\mathbb{R}^3\to\mathbb{R}^3$ the electric field. Denote by (t^1,t^2,t^3) the standard coordinates on $\mathbb{R}^3$, and set $\sqrt{g}=\sqrt{\det g_{ij}}$. By $r(t)$ we denote the scalar function which gives the density of electric charge on $\mathbb{R}^3$.

In this example we suppose that $r(t)$ is constant $r(t)=r$, that is, the distribution of the electric charge is constant on $\mathbb{R}^3$, and that the metric g on $\mathbb{R}^3$ is the Euclidean metric.

Let us consider on $M=(T^1_3)^*\mathbb{R}$ the canonical polysymplectic structure $((\omega_0)_1,(\omega_0)_2,(\omega_0)_3)$. We denote by (q,p^1,p^2,p^3) the local coordinates on $(T^1_3)^*\mathbb{R}$ induced by the standard coordinate (q) on $\mathbb{R}$, and define a Hamiltonian function $H:(T^1_3)^*\mathbb{R}\to\mathbb{R}$ by

$$H(q,p^1,p^2,p^3)=4\pi rq+\frac{1}{2}\sum_{A=1}^{3}(p^A)^2.$$

Consider the equation

$$\Omega^\sharp(X_1,X_2,X_3)=\sum_{A=1}^{3}\imath_{X_A}(\omega_0)_A=\mathrm{d}H, \tag{18}$$

where (X_1,X_2,X_3) is a 3-vector field on $(T^1_3)^*\mathbb{R}$.

Let $\phi:\mathbb{R}^3\to(T^1_3)^*\mathbb{R},\phi(t)=(\psi(t),\psi^1(t),\psi^2(t),\psi^3(t))$ be an integral section of an evolution 3-vector field which is a solution of (18). Then we obtain

$$4\pi r=-\left(\frac{\partial\psi^1}{\partial t^1}+\frac{\partial\psi^2}{\partial t^2}+\frac{\partial\psi^3}{\partial t^3}\right),\quad \psi^A=\frac{\partial\psi}{\partial t^A},\quad 1\leqslant A\leqslant 3,$$

which are the electrostatic equations, and then the components $\psi(t)$ and $(\psi^1(t),\psi^2(t),\psi^3(t))$ of ϕ are the electric potential σ and the electric field $P=(P_1,P_2,P_3)$ on $\mathbb{R}^3$, respectively. So Eq. (18) is a geometric version of the electrostatic equations.

B. Lagrangian formalism

In classical mechanics the symplectic structure of Hamiltonian theory and the tangent structure of Lagrangian theory play complementary roles (see Refs. 13, 15, and 16).

In this section, we recall the Lagrangian formalism developed by Günther[1] using the polysymplectic structures. Here we can see how the polysymplectic structures and the k-tangent structures play also a complementary role in field theory.

Given a Lagrangian function of the form $L=L(q^i,v^i_A)$ one obtains, by using a variational principle, the *generalized Euler–Lagrange equations* for L:

$$\sum_{A=1}^{k}\frac{d}{\mathrm{d}t^A}\left(\frac{\partial L}{\partial v^i_A}\right)-\frac{\partial L}{\partial q^i}=0,\quad v^i_A=\frac{\partial q^i}{\partial t^A}. \tag{19}$$

Let $L:T^1_kQ\to\mathbb{R}$ be a regular Lagrangian and let us consider the polysymplectic structure $((\omega_L)_1,\ldots,(\omega_L)_k)$ on T^1_kQ defined by L. Let us observe that when L is regular then $((\omega_L)_1,\ldots,(\omega_L)_k,V)$ is a k-symplectic structure on T^1_kQ.

Let $\Omega_L^\sharp:T^1_k(T^1_kQ)\to T^*(T^1_kQ)$ be the morphism defined by $((\omega_L)_1,\ldots,(\omega_L)_k)$ as in (14), we can set the following equation:

$$\Omega_L^\sharp(X_1,\ldots,X_k)=\mathrm{d}E_L, \tag{20}$$

where $E_L=C(L)-L$, and C is the Liouville vector field on T^1_kQ.

Proposition IV.2: Let L be a regular Lagrangian. If $\xi=(\xi_1,\ldots,\xi_k)$ is a solution of (20) then it is a SOPDE. Moeover if ξ is integrable then the solutions of ξ are solutions of the Euler–Lagrange equations (19).

Proof: It is a direct computation in local coordinates using (6), (7), (11), and (12). ■

Example IV.2: In this example we consider the theory of a vibrating string. Coordinates (t^1,t^2) are interpreted as the time and the distance along the string, respectively. If $\phi(t^1,t^2)$ denotes the displacement of each point of the string as function of the time t^1 and the position t^2, the motion equations are

$$\sigma\frac{\partial^2\phi}{\partial(t^1)^2}-\tau\frac{\partial^2\phi}{\partial(t^2)^2}=0, \tag{21}$$

where σ and τ are certain constants of the mechanical system.

We shall show that the equations (21) can be described as the Euler–Lagrange equations associated to a Lagrangian L defined on the jet bundle T^1_kQ with $Q=\mathbb{R}$ and $k=2$. Let us denote by (x,v_1,v_2) the coordinates of $T^1_2\mathbb{R}$ and consider the Lagrangian

$$L:\quad T^1_2\mathbb{R}\to\mathbb{R},$$

$$(x,v_1,v_2)\to\tfrac{1}{2}(\sigma v_1^2-\tau v_2^2).$$

Since L is regular there exists a polysymplectic structure, $((\omega_L)_1,(\omega_L)_2)$, associated to L given in local coordinates by $(\omega_L)_1=\sigma\ \mathrm{d}v_1\wedge\mathrm{d}x$, $(\omega_L)_2=-\tau\,\mathrm{d}v_2\wedge\mathrm{d}x$.

The energy $E_L=C(L)-L$ is locally given by $E_L=\frac{1}{2}(\sigma v_1^2-\tau v_2^2)$ and

$$\mathrm{d}E_L=\sigma v_1\,\mathrm{d}v_1-\tau v_2\,\mathrm{d}v_2. \tag{22}$$

Now we consider the map $\Omega_L^\sharp:T^1_2(T^1_2\mathbb{R})\to T^*(T^1_2\mathbb{R})$, and let us suppose that there exists (ξ_1,ξ_2) solution of the equation

$$\Omega_L^\sharp(\xi_1,\xi_2)=\imath_{X_1}(\omega_L)_1+\imath_{X_2}(\omega_L)_2=\mathrm{d}E_L, \tag{23}$$

then, from Proposition IV.2 we know that (ξ_1,ξ_2) is a SOPDE. Let us suppose that $(\xi_1,\xi_2)\in T^1_2(T^1_2\mathbb{R})$ are locally given by

$$\xi_A=v_A\frac{\partial}{\partial x}+(\xi_A)_1\frac{\partial}{\partial v_1}+(\xi_A)_2\frac{\partial}{\partial v_2},\quad 1\leqslant A\leqslant 2, \tag{24}$$

thus, if (ξ_1,ξ_2) is a solution of $\Omega_L^\sharp(\xi_1,\xi_2)=\mathrm{d}E_L$, from (22) and (24) we have

$$\sigma(\xi_1)_1-\tau(\xi_2)_2=0. \tag{25}$$

If $\phi:\mathbb{R}^2\to\mathbb{R}$, $\phi=\phi(t_1,t_2)$ is a solution of $\xi=(\xi_1,\xi_2)$, then from Proposition III.2 and (25) we obtain

$$0=\sigma(\xi_1)_1-\tau(\xi_2)_2=\sigma\frac{\partial\phi}{\partial t_1^2}-\tau\frac{\partial\phi}{\partial t_2^2},$$

thus equation (23) is a geometric version for the equations (21).

V. THE MOMENTUM MAP

Let G be a Lie group and $\mathcal{G}$ its Lie algebra. We shall use the notations $\mathcal{G}^k=\mathcal{G}\times\overset{k}{\cdots}\times\mathcal{G}$ and $\mathcal{G}^k{}^*=(\mathcal{G}\times\overset{k}{\cdots}\times\mathcal{G})^*$.

The adjoint representation $\mathrm{Ad}:G\to\mathrm{Aut}(\mathcal{G})$ induces, for any $g\in G$, the map $\mathrm{Ad}_g^k:\mathcal{G}^k\to\mathcal{G}^k$ defined by

$$\mathrm{Ad}_g^k(\xi_1,\ldots,\xi_k)=(\mathrm{Ad}_g\xi_1,\ldots,\mathrm{Ad}_g\xi_k),\quad(\xi_1,\ldots,\xi_k)\in\mathcal{G}^k,$$

and thus an action $\Phi:G\times\mathcal{G}^k\to\mathcal{G}^k$, defined by

$$\Phi(g,\eta)=\mathrm{Ad}_g^k(\eta),\quad g\in G,\quad \eta=(\eta_1,\ldots,\eta_k)\in\mathcal{G}^k,$$

and we shall call it the *k-adjoint action* of G on $\mathcal{G}^k$.

The representation $\mathrm{Ad}^k:G\to\mathrm{Aut}(\mathcal{G}^k)$, $g\to\mathrm{Ad}_g^k$, induces $\mathrm{ad}^k=(\mathrm{Ad}^k)_*(e):\mathcal{G}\to\mathrm{End}(\mathcal{G}^k)$, which is given by

$$\mathrm{ad}_\xi^k(\xi_1,\ldots,\xi_k)=(\mathrm{ad}_\xi\xi_1,\ldots,\mathrm{ad}_\xi\xi_k),\quad \xi\in\mathcal{G},(\xi_1,\ldots,\xi_k)\in\mathcal{G}^k,$$

where $\mathrm{ad}_\xi\xi_A=[\xi,\xi_A]$.

Now, for any $g\in G$ we define $\mathrm{Ad}_g^k{}^*:\mathcal{G}^k{}^*\to\mathcal{G}^k{}^*$ by

$$\mathrm{Ad}_g^k{}^*(\mu)=\mu\circ\mathrm{Ad}_g^k,\quad \mu\in\mathcal{G}^k{}^*,$$

and we define *k-coadjoint action* $\Phi:G\times\mathcal{G}^k{}^*\to\mathcal{G}^k{}^*$ by

$$\Phi(g,\mu)=\mathrm{Ad}_{g^{-1}}^k{}^*(\mu),\quad g\in G,\quad \mu\in\mathcal{G}^k{}^*. \tag{26}$$

The representation $\mathrm{Ad}^k{}^*:G\to\mathrm{Aut}(\mathcal{G}^k{}^*)$, $g\to\mathrm{Ad}_g^k{}^*$, induces $\mathrm{ad}^k{}^*=(\mathrm{Ad}^k{}^*)_*(e):\mathcal{G}\to\mathrm{End}(\mathcal{G}^k{}^*)$, given by

$$(\mathrm{ad}_\xi^k{}^*(\alpha))(\xi_1,\ldots,\xi_k)=(\alpha\circ\mathrm{ad}_\xi^k)(\xi_1,\ldots,\xi_k),\quad \alpha\in\mathcal{G}^k{}^*,(\xi_1,\ldots,\xi_k)\in\mathcal{G}^k.$$

Definition V.1: Let $(M,\omega_1,\ldots,\omega_k)$ be a polysymplectic manifold. An action $\Phi:G\times M\to M$ of the Lie group G on M, is called polysymplectic if $\Phi_g^*\omega_A=\omega_A$ for all $g\in G$ and all $A=1,\ldots,k$.

If $\mathcal{G}=T_eG$ is the Lie algebra of the Lie group G, then for any $\xi\in\mathcal{G}$ we consider the fundamental vector field ξ_M defined by

$$\xi_M(x)=(\Phi_x)_*(e)(\xi)=\frac{d}{\mathrm{d}s}\Phi(\exp s\xi,x)_{|s=0},\quad x\in M.$$

Definition V.2: Let (M,ω) be a symplectic manifold with a symplectic action $\Psi:G\times M\to M$. The map $J:M\to\mathcal{G}^*$ is said to be a momentum map for the action Ψ if

$$i_{\xi_M}\omega=\mathrm{d}\hat{J}(\xi),\quad \textit{for all}\quad \xi\in\mathcal{G}, \tag{27}$$

where $\hat{J}(\xi):M\to\mathbb{R}$ is the map defined by $\hat{J}(\xi)(x)=J(x)(\xi)$, $x\in M$.

Taking into account (14) we introduce the following definition.

Definition V.3: Let $(M,\omega_1,\ldots,\omega_k)$ be a polysymplectic manifold. The map $J:M\to\mathcal{G}^k{}^*$ is said to be a momentum map for the action Φ if

$$\sum_{A=1}^{k} i_{(\xi_A)_M}\omega_A = \mathrm{d}\hat{J}(\xi_1,\ldots,\xi_k), \quad \textit{for all } (\xi_1,\ldots,\xi_k)\in \mathcal{G}\times\overset{k}{\cdots}\times\mathcal{G}, \tag{28}$$

where $\hat{J}(\xi_1,\ldots,\xi_k):M\to\mathbb{R}$ *is the map defined by*

$$\hat{J}(\xi_1,\ldots,\xi_k)(x) = J(x)(\xi_1,\ldots,\xi_k), \quad x\in M.$$

Our definition of momentum map coincides with the definition given by Günther[1] in Remark 6.6. Let us observe that if J is a momentum map

$$d(\hat{J}(0,\ldots,\overset{A}{0},\xi,0,\ldots,0)) = i_{\xi_M}\omega_A \quad , \forall \xi\in\mathcal{G}, \ \ 1\leqslant A\leqslant k. \tag{29}$$

Definition V.4: A momentum map $J:M\to(\mathcal{G}\times\overset{k}{\cdots}\times\mathcal{G})^*$ *is called* $\mathrm{Ad}^{k}{}^*$*-equivariant if*

$$J(\Phi_g(x)) = \mathrm{Ad}^{k*}_{g^{-1}}J(x) \quad , \forall g\in G, x\in M. \tag{30}$$

In the following theorem, we resume Theorem 6.2, Proposition 6.8, and Theorem 6.10 of Günther,[1] given by (i), (ii), and (iii), respectively.

Theorem V.1: *Let* Φ *be a polysymplectic action of* G *on* M*. Let* H *be a* G*-invariant Hamiltonian function, and let* $\phi:U\to M$ *be an integral section of a evolution* k*-vector field* $((X_H)_1,\ldots,(X_H)_k)$ *associated with the Hamiltonian function* H*.*

(i) Let us suppose that Φ *is a strongly polysymplectic action, which means*

$$i_{\xi_M}\omega_A = \mathrm{d}F^A_\xi, \quad \textit{for all } \xi\in\mathcal{G}, \quad 1\leqslant A\leqslant k, \tag{31}$$

for some function $F_\xi:M\to\mathbb{R}^k$*. Then Trace* $d(F_\xi\circ\phi)=0$*, that is*

$$\sum_{A=1}^{k} d(F^A_\xi\circ\phi)(t)\left(\frac{\partial}{\partial t^A}(t)\right) = 0.$$

(ii) Let us suppose that Φ *has momentum map* J*. Then Trace* $d(P\circ\phi)=0$*, that is*

$$\sum_{A=1}^{k} d(P^A\circ\phi)(t)\left(\frac{\partial}{\partial t^A}(t)\right) = 0,$$

where $P^A = \hat{J}(0,\ldots,\overset{A}{0},\xi,0,\ldots,0):M\to\mathbb{R}$ *for all* $\xi\in\mathcal{G}$*.*

(iii) Let us assume that $\Omega = -d\theta$ *and* θ *are* G*-invariant. Then Trace* $d(\theta(\xi_M)\circ\phi)=0$*, that is*

$$\sum_{A=1}^{k} d(\theta^A(\xi_M)\circ\phi)(t)\left(\frac{\partial}{\partial t^A}(t)\right) = 0, \quad \textit{for all } \xi\in\mathcal{G}.$$

Proof: It is a consequence of (9), (14), (28), (31) and the fact that H is G-invariant. ■

Günther[1] remarks that (i) and (ii) are a version of the classical Noether theorem, which says that the infinitesimal generators of canonical transformations induce conserved currents; (iii) is the usual version of the field theoretic Noether theorem.

The following theorem, which generalizes the Theorem 4.2.10 in Abraham–Marsden,[2] will allow us to construct momentum maps for the manifolds $(T^1_k)^*Q$ and T^1_kQ. It is equivalent to the Proposition 6.9 in Günther.[1]

Theorem V.2: *Let Φ be a polysymplectic action of the Lie group G on the polysymplectic manifold $(M,\omega_1,\ldots,\omega_k)$. If we assume that the polysymplectic structure ω_A is exact, that is $\omega_A=-\mathrm{d}\theta_A$, and the action leaves each θ_A invariant, that is $\Phi_g^*\theta_A=\theta_A$ for all $g\in G$, then $J:M\to(\mathcal{G}\times\overset{k}{\cdots}\times\mathcal{G})^*$ defined by*

$$J(x)(\xi_1,\ldots,\xi_k)=\sum_{A=1}^{k}(\theta_A)(x)((\xi_A)_M(x)),\quad x\in M,(\xi_1,\ldots,\xi_k)\in\mathcal{G}\times\overset{k}{\cdots}\times\mathcal{G},\tag{32}$$

is an $\mathrm{Ad}^k{}^*$-equivariant momentum map for the action Φ.

Proof: Since $\mathcal{L}_{(\xi_A)_M}\theta^A=0$ we obtain $i_{(\xi_A)_M}\mathrm{d}\theta_A=-d(\theta_A(\xi_A)_M)$, and from (28) we obtain (32). To prove $\mathrm{Ad}^k{}^*$-equivariance we must show that

$$\hat{J}(\xi_1,\ldots,\xi_k)(\Phi_g(x))=\mathrm{Ad}^{k*}_{g^{-1}}J(x)(\xi_1,\ldots,\xi_k)=J(x)(\mathrm{Ad}_{g^{-1}}\xi_1,\ldots,\mathrm{Ad}_{g^{-1}}\xi_k),$$

that is,

$$\sum_{A=1}^{k}\theta_A((\xi_A)_M)(\Phi_g(x))=\sum_{A=1}^{k}\theta_A(x)((\mathrm{Ad}_{g^{-1}}\xi_A)_M(x)).$$

But this follows immediately from the identity $(\mathrm{Ad}_{g^{-1}}\xi)_M=(\Phi_g)^*\xi_M$, $\xi\in\mathcal{G}$, together with the invariance of each θ_A under Φ_g. ∎

Now, following Abraham–Marsden,[2] we extend the results about momentum maps in T^*Q and TQ, to the polysymplectic manifolds $(T^1_k)^*Q$ and T^1_kQ.

If $f:Q\to Q$, is a diffeomorphism then we can define the diffeomorphism $T^k{}^*f:(T^1_k)^*Q\to(T^1_k)^*Q$, by

$$T^k{}^*f(\alpha_1(q),\ldots,\alpha_k(q))=(\alpha_1(q)\circ f_*(f^{-1}(q)),\ldots,\alpha_k(q)\circ f_*(f^{-1}(q))).$$

Proposition V.1: For any diffeomorphism $f:Q\to Q$ we have $(T^k{}^*f)^*(\theta_0)_A=(\theta_0)_A$ and $(T^k{}^*f)^*(\omega_0)_A=(\omega_0)_A$, where $(\omega_0)_A=-d(\theta_0)_A$, $1\leqslant A\leqslant k$, is the canonical polysymplectic structure on $(T^1_k)^*Q$.

Proof: Analogous to the proof of Theorem 4.2.10 in Abraham–Marsden,[2]

$$(T^k{}^*f)^*(\theta_0)_A=(\tau_A^*\circ T^k{}^*f)^*\theta_0=(T^*f\circ\tau_A^*)^*\theta_0=((\tau_A^*)^*\circ(T^*f)^*)\theta_0=(\tau_A^*)^*\theta_0=(\theta_0)_A.$$

∎

An action $\Phi:G\times Q\to Q$ can be lifted to an action $\Phi^{T^*}:G\times(T^1_k)^*Q\to(T^1_k)^*Q$ defining

$$\Phi^{T^*}(g,(\alpha_1(q),\ldots,\alpha_k(q)))=(\alpha_1(q)\circ(\Phi_{g^{-1}})_*(\Phi_g(q)),\ldots,\alpha_k(q)\circ(\Phi_{g^{-1}})_*(\Phi_g(q))).\tag{33}$$

Let us observe that $(\Phi^{T^*})_g=T^k{}^*\Phi_{g^{-1}}$, then from Proposition V.1 and Theorem V.2, we obtain the following.

Corollary V.1: (i) If Φ is an action of G on Q then Φ^{T^*} is a polysymplectic action of G on $(T^1_k)^*Q$.

(ii) Φ^{T^*} has an $\mathrm{Ad}^k{}^*$-equivariant momentum map $J:(T^1_k)^*Q\to(\mathcal{G}\times\overset{k}{\cdots}\times\mathcal{G})^*$ given by

$$J(u)(\xi_1,\ldots,\xi_k)=\sum_{A=1}^{k}(\theta_0)_A(u)(\xi_{(T^1_k)^*Q}(u))=\sum_{A=1}^{k}\alpha_A(q)((\xi_A)_Q(q)),\tag{34}$$

where $u=(\alpha_1(q),\ldots,\alpha_k(q))$.

Proof: (i) It is a consequence of Proposition V.1.

(ii) It is a consequence of Theorem V.2 and the following identity:

$$(\theta_0)_A(u)((\xi_A)_{(T^1_k)^*Q}(u)) = ((\tau_A^*)^*\theta_0)(u)(\xi_A)_{(T^1_k)^*Q}(u)$$
$$= \theta_0(\tau_A^*(u))((\tau_A^*)_*(u)(\xi_A)_{(T^1_k)^*Q}(u))$$
$$= \tau_A^*(u)((\tau_Q^*\circ\tau_A^*)_*(u)(\xi_{(T^1_k)^*Q}(u))) = \alpha_A(q)((\xi_A)_Q(q)),$$

where in the last identity we have used that $\tau_Q^*\circ\tau_A^* = \tau^*$ and $(\tau^*)_*(\xi_{(T^1_k)^*Q}) = \xi_Q\circ\tau^*$. ■

When the manifold M is $(T^1_k)^*Q$ and we have a momentum map J on $(T^1_k)^*Q$, then for each fixed $A=1,\ldots,k$, we can define the map $J_A: T^*Q\to\mathcal{G}^*$ by

$$J_A(\alpha_q)(\xi) = J(0,\ldots,0,\overset{A}{\alpha_q},0,\ldots,0)(0,\ldots,0,\overset{A}{\xi},0,\ldots,0)\,, \tag{35}$$

where α_q and ξ are in the Ath position, $q\in Q$.

If we denote by $i_A: T^*Q\to(T^1_k)^*Q$ the inclusion map $\alpha_q\to(0,\ldots,0,\overset{A}{\alpha_q},0,\ldots,0)$ then

$$\hat{J}_A(\xi)(\alpha_q) = \hat{J}(0,\ldots,0,\overset{A}{\xi},0,\ldots,0)(0,\ldots,0,\overset{A}{\alpha_q},0,\ldots,0) = (\hat{J}(0,\ldots,0,\overset{A}{\xi},0,\ldots,0)\circ i_A)(\alpha_q)\,.$$

Lemma V.1: J_A is a momentum map on T^*Q.

Proof: For any $\xi\in\mathcal{G}$, $\alpha_q\in T^*Q$, $v_{\alpha_q}\in T_{\alpha_q}(T^*Q)$, we have

$$\mathrm{d}\hat{J}_A(\xi)(\alpha_q)(v_{\alpha_q}) = [\mathrm{d}\hat{J}(0,\ldots,0,\overset{A}{\xi},0,\ldots,0)(i_A(\alpha_q))\circ\mathrm{d}i_A(\alpha_q)](v_{\alpha_q})$$
$$= (i_{\xi_{(T^1_k)^*Q}}\omega_A)(i_A(\alpha_q))[(i_A)_*(\alpha_q)(v_{\alpha_q})]$$
$$= (i_{\xi_{(T^1_k)^*Q}}(\tau_A^*)^*\omega_0)(i_A(\alpha_q))[(i_A)_*(\alpha_q)(v_{\alpha_q})]$$
$$= \omega_0(\tau_A^*(i_A(\alpha_q)))\,((\tau_A^*)_*(i_A(\alpha_q))(\xi_{(T^1_k)^*Q}(i_A(\alpha_q))),(\tau_A^*\circ i_A)_*(\alpha_q)(v_{\alpha_q}))$$
$$= \omega_0(\alpha_q)\,(\xi_{T^*Q}(\alpha_q),v_{\alpha_q})\,.$$

We have used that $(\tau_A^*)_*(\xi_{(T^1_k)^*Q}) = \xi_{T^*Q}\circ\tau_A^*$, which holds from $\tau_A^*\circ\Phi^{T^*}_{(\alpha_1,\ldots,\alpha_k)} = \Psi_{\alpha_A}\circ\tau_A^*$ where $\Psi: G\times T^*Q\to T^*Q$ is the canonical action induced by the action $\Phi: G\times Q\to Q$. ■

The conservation law given in Theorem 4.2.2 in Abraham–Marsden[2] for a symplectic manifold can be extended in the following way to $(T^1_k)^*Q$.

Proposition V.2: Let Φ be an action of G on Q, Ψ^{T^*} the induced action of G on T^*Q, and Φ^{T^*} the induced action of G on $(T^1_k)^*Q$.

Let J be the $\mathrm{Ad}^k{}^*$-equivariant momentum map given in (34) and let J_Q be one of the momentum maps on T^*Q induced by J.

If X is a vector field on $(T^1_k)^*Q$, then we have the following.

(i) J is an integral for X if and only if J_Q is an integral for all $(\tau_A^*)_*X$, $1\leqslant A\leqslant k$.

(ii) If $\phi:\mathbb{R}^k\to(T^1_k)^*Q$ is an integral section of an integrable evolution k-vector field $((X_H)_1,\ldots,(X_H)_k)$ and J is an integral for all $(X_H)_A$, then J is constant along ϕ.

Proof: (i) From (28) and the identities

$$i_{\xi_{T^*Q}}\omega_0 = \mathrm{d}\hat{J}_Q(\xi)\,,\quad \forall\,\xi\in\mathcal{G},\quad \omega_A = (\tau_A^*)^*\omega_0\,,\quad (\tau_A^*)_*(\xi_A)_{(T^1_k)^*Q} = (\xi_A)_{T^*Q}\circ\tau_A^*\,, \tag{36}$$

$$\hat{J}(\xi_1,\ldots,\xi_k) = \sum_{A=1}^{k}\hat{J}(0,\ldots,0,\overset{A}{\xi_A},0,\ldots,0)\,, \tag{37}$$

we deduce

$$\mathrm{d}\hat{J}(\xi_1,\ldots,\xi_k)(X)=\sum_{B=1}^{k} d(\hat{J}_Q(\xi_B)\circ\tau_B^*)(X). \tag{38}$$

Let us suppose that J is an integral of X. So, taking $\xi_A=\xi$ and $\xi_B=0$ for all $B\neq A$ we obtain from (38) $\mathrm{d}\hat{J}_Q((\tau_A^*)_*X)=0$, for each A, $1\leqslant A\leqslant k$. Therefore J_Q is an integral for $(\tau_A^*)_*X$, $A=1,\ldots,k$.

Now let us suppose that J_Q is an integral for all $(\tau_A^*)_*X$, then from (38) we deduce that J is an integral for X.

(ii) By Definition III.2 we have

$$0=(X_H)_A(\phi(t))(\hat{J}(\xi_1,\ldots,\xi_k))=\frac{\partial}{\partial t^A}(t)(\hat{J}(\xi_1,\ldots,\xi_k)\circ\phi).$$

■

A generalized Noether theorem, which is a generalization of Corollary 4.2.14 in Abraham–Marsden[2] is the following.

Corollary V.2: Let G act on Q by $\Phi:G\times Q\to Q$ and let Φ^T denote the k-tangent action $\Phi^T:G\times T_k^1Q\to T_k^1Q$, defined by

$$\Phi^T(g,v_1(q),\ldots,v_k(q))=((\Phi_g)_*(q)(v_1(q)),\ldots,(\Phi_g)_*(q)(v_k(q)))$$

for all $(v_1(q),\ldots,v_k(q))\in T_k^1Q$, $q\in Q$, $g\in G$.

Let L be a regular Lagrangian on T_k^1Q with $(\theta_L)_A=(FL)^*(\theta_0)_A$, as usually. If we suppose that L is invariant under the action Φ^T, that is $L\circ\Phi_g^T=L$, for all $g\in G$, then we have the following.

(i) $(\Phi_g^T)^*(\theta_L)_A=(\theta_L)_A$, for all $g\in G$, $A=1,\ldots,k$;

(ii) the momentum map $J:T_k^1Q\to(\overset{k}{\mathcal{G}\times\cdots\times\mathcal{G}})^*$ for the action Φ^T is given by

$$J(u)(\xi_1,\ldots,\xi_k)=\sum_{A=1}^{k}\tau_A^*(FL(u))((\xi_A)_Q(q)), \tag{39}$$

and it is $\mathrm{Ad}^k{}^*$-equivariant.

Proof: (i) Using the definition of FL and the invariance of L under the action Φ^T we obtain $FL\circ\Phi_g^T=\Phi_g^{T^*}\circ FL$. Then, from Corollary V.1 and since $FL\circ\Phi_g^T=\Phi_g^{T*}\circ FL$ we obtain easily that $(\Phi_g^T)^*(\theta_L)_A=(\theta_L)_A$.

(ii) It is a consequence of Theorem V.2 and the fact that

$$(\theta_L)_A(u)(\xi_A)_{T_k^1Q}(u)=\tau_A^*(FL(u))((\xi_A)_Q(\tau^*(u))),$$

which can be obtained as follows:

$$\begin{aligned}(\theta_L)_A(u)(\xi_A)_{T_k^1Q}(u)&=((FL)^*(\theta_0)_A)(u)((\xi_A)_{T_k^1Q}(u))\\&=(\tau_A^*)^*\theta_0(FL(u))((FL)_*(u)(\xi_A)_{T_k^1Q}(u))\\&=\theta_0(\tau_A^*(FL(u)))((\tau_A^*\circ FL)_*(u)(\xi_A)_{T_k^1Q}(u))\\&=\tau_A^*(FL(u))((\tau_Q^*\circ\tau_A^*\circ FL)_*(u)(\xi_{T_k^1Q}(u)))\\&=\tau_A^*(FL(u))(\xi_A)_Q(\tau^*(u)),\end{aligned}$$

where in the last identity we have used that $\tau_Q^*\circ\tau_A^*\circ FL=\tau_Q$ and $(\tau_Q)_*(\xi_A)_{T_k^1Q}=\xi_Q$. ■

Example V.1: Let us consider any Riemannian metric $g=\langle\,,\rangle$ on a manifold Q. The Lagrangian $L=\frac{1}{2}g_{ij}(q)v_A^i v_B^j$ on T_k^1Q is regular and the Legendre tranformation $FL:T_k^1Q\to(T_k^1)^*Q$ is locally given by $(q^i,v_A^i)\to(q^i,p_i^A=g_{ij}(q)v_A^j)$. Then working on T_k^1Q, Corollary V.2 gives the momentum map

$$J(u)(\xi_1,\ldots,\xi_k)=\sum_{A=1}^{k}\tau_A^*(FL(u))(\xi_A(q))=\sum_{A=1}^{k}g(q)(v_A(q),\xi_A(q)) \tag{40}$$

for all $u=(v_1(q),\ldots,v_k(q))\in T_k^1Q$.

VI. REDUCTION

Let $(M,\omega_1,\ldots,\omega_k)$ be a polysymplectic manifold and $\Phi:G\times M\to M$ a polysymplectic action of the Lie group G on M. If $\mathcal{G}$ is the Lie algebra of G we have

$$T_p(Gp)=\{\xi_M(p)\,|\,\xi\in\mathcal{G}\},\quad \forall p\in M, \tag{41}$$

where Gp is the orbit of p and ξ_M is the fundamental vector field of M, under Φ, corresponding to ξ.

Let us assume that this action has an Ad^k*-equivariant momentum map $J:M\to\mathcal{G}^k*$. For $\mu\in\mathcal{G}^k*$, we denote by $G_\mu=\{g\in G\,|\,\mathrm{Ad}^{k*}_{g^{-1}}(\mu)=\mu\}$ the isotropy subgroup of G under the k-coadjoint action. The orbit space $M_\mu=J^{-1}(\mu)/G_\mu$ is well defined. If $\mu\in\mathcal{G}^k*$ is a regular value of J, then $J^{-1}(\mu)$ is a submanifold of M and if we assume that G_μ acts freely and properly on $J^{-1}(\mu)$ then we know that M_μ is a manifold, being the canonical projection $\pi_\mu:J^{-1}(\mu)\to M_\mu$ a submersion.

For the proof of the next theorem (which generalizes the Theorem 4.3.1 in Ref. 2) it is important to find next result.

Lemma VI.1: Under the conditions above, for any $p\in J^{-1}(\mu)$, we have the following:

(i) $T_p(G_\mu p)=T_p(Gp)\cap T_p(J^{-1}(\mu))$;

(ii) $T_p(J^{-1}(\mu))$ is the $(\Sigma_{A=1}^k\omega_A\otimes r^A)$-orthogonal complement of $T_p(Gp)$.

Proof: The proof of assertion (i) is exactly the same as that in Lemma 4.3.2 in Abraham–Marsden.[2] The assertion (ii) is an immediate consequence of (28) and the identity $T_p(J^{-1}(\mu))=ker\,J_*(p)$. ■

Theorem VI.1: *Let $(M,\omega_1,\ldots,\omega_k)$ be a polysymplectic manifold on which the Lie group acts polysymplectically and let $J:M\to\mathcal{G}^k*$ be an Ad^k*-equivariant momentum map for this action. Assume that $\mu\in\mathcal{G}^k*$ is a regular value of J and that the isotropy group G_μ, under the Ad^k* action on $\mathcal{G}^k*$, acts freely and properly on $J^{-1}(\mu)$. Then $M_\mu=J^{-1}(\mu)/G_\mu$ has a unique polysymplectic structure $((\omega_\mu)_1,\ldots,(\omega_\mu)_k)$ with the property*

$$\pi_\mu^*(\omega_\mu)_A=i_\mu^*\omega_A,\quad \forall A=1,\ldots,k,$$

where $\pi_\mu:J^{-1}(\mu)\to M_\mu$ is the canonical projection and $i_\mu:J^{-1}(\mu)\to M$ is the inclusion.

Proof: We define $(\omega_\mu)_A$ by

$$((\omega_\mu)_A([v],[w])=\omega_A(v,w),\quad \forall v,w\in T_p(J^{-1}(\mu)),$$

where $[v]=(\pi_\mu)_*(p)(v)$ and $[w]=(\pi_\mu)_*(p)(w)$. Since π_μ and $(\pi_\mu)_*$ are surjective the 2-forms $(\omega_\mu)_A$, $A=1,\ldots,k$ are unique.

From (ii) in Lemma VI.1 we deduce that $\omega_A(\xi_M,v)=0$ for all $v\in T_p(J^{-1}(\mu))$, therefore since $T_{[p]}(J^{-1}(\mu)/G_\mu)=T_p(J^{-1}(\mu))/T_p(G_\mu p)$ we deduce from (41) that $(\omega_\mu)_A$ is well defined. The assertion $\pi_\mu^*(\omega_\mu)_A=i_\mu^*\omega_A$ is evident, from it one obtains that $(\pi_\mu)^*(d(\omega_\mu)_A)=0$, and since π_μ and $(\pi_\mu)_*$ are surjective then $d(\omega_\mu)_A=0$.

For nondegeneracy of $((\omega_\mu)_1,\ldots,(\omega_\mu)_k)$, suppose

$$\sum_{A=1}^{k} (\omega_\mu)_A([v],[w])=0, \quad \text{for all } w\in T_pJ^{-1}(\mu),$$

hence $\omega_A(v,w)=0$ for all $w\in T_p(J^{-1}(\mu))$ and for all $A\in\{1,\ldots,k\}$. Now using (ii) of Lemma VI.1 we deduce that $v\in T_p(Gp)$ and from (i) of the same Lemma we obtain that $v\in T_p(G_\mu p)$. Therefore $[v]=0$ since $T_{[p]}(J^{-1}(\mu)/G_\mu)=T_p(J^{-1}(\mu))/T_p(G_\mu p)$. ■

Theorem VI.2: *Let us consider $M=(T^1_k)^*Q$ with the canonical polysymplectic structure. Let Φ^{T^*} be the polysymplectic action (33) on M and J the momentum map given by (34).*

Under the assumptions of the Theorem VI.1, if $H:(T^1_k)^*Q\to\mathbb{R}$ is a Hamiltonian such that

(a) H is invariant under the action Φ^{T^*}

(b) there exists an evolution k-vector field $((X_H)_1,\ldots,(X_H)_k)$ associated with H which are invariant

$$(\Phi^{T^*}_g)_*(X_H)_A=(X_H)_A, \quad \forall A=1,\ldots,k, \ \ \forall g\in G_\mu \tag{42}$$

and

$$J \text{ is an integral for all } (X_H)_A, \quad A=1,\ldots,k, \tag{43}$$

then we have the following.

(i) For each $A=1,\ldots,k$, the flow F^A_t of $(X_H)_A$ leaves $J^{-1}(\mu)$ invariant and commutes with the action of G_μ on $J^{-1}(\mu)$, and so it induces canonically a flow H^A_t on M_μ satisfying $\pi_\mu\circ F^A_t=H^A_t\circ\pi_\mu$.

(ii) If Y_A is the generator of H^A_t, then $(Y_1,\ldots,Y_k)$ is an evolution k-vector field on M_μ associated with a Hamiltonian function $H_\mu:M_\mu\to\mathbb{R}$ satisfying $H_\mu\circ\pi_\mu=H\circ i_\mu$. Such H_μ is called the reduced Hamiltonian.

Proof: (i) From (43), for each $A=1,\ldots,k$ and each $\alpha\in J^{-1}(\mu)$, we have $J(F^A_t(\alpha))=J(\alpha)=\mu$, $A=1,\ldots,k$, and then $F^A_{t\,|J^{-1}(\mu)}:J^{-1}(\mu)\to J^{-1}(\mu)$.

From (42) we deduce that $F^A_t\circ\Phi^{T^*}_g=\Phi^{T^*}_g\circ F^A_t$, for all $g\in G_\mu$, $A=1,\ldots,k$. This property lets us define an induced flow H^A_t on M_μ, for each $A=1,\ldots,k$, by $H^A_t([\alpha])=[F^A_t(\alpha)]$, $[\alpha]\in M_\mu$. Now the identity $\pi_\mu\circ F^A_t=H^A_t\circ\pi_\mu$, is obvious for all $A=1,\ldots,k$.

(ii) Since H is invariant under the action of G, we can define the function $H_\mu:M_\mu\to\mathbb{R}$ by $H_\mu([\alpha])=H(\alpha)$, for all $[\alpha]\in M_\mu$. So, we have

$$H_\mu\circ\pi_\mu=H\circ i_\mu. \tag{44}$$

Since $\pi_\mu\circ F^A_t=H^A_t\circ\pi_\mu$, we have

$$(\pi_\mu)_*\circ(X_H)_A=Y_A\circ\pi_\mu, \quad 1\leqslant A\leqslant k. \tag{45}$$

Using $i^*_\mu\omega_A=\pi^*_\mu(\omega_\mu)_A$, (44) and (45), one easily proves that $\mathrm{d}H_\mu=\Sigma^k_{A=1}i_{Y_A}(\omega_\mu)_A$, that is, $(Y_1,\ldots,Y_k)$ is an evolution k-vector field on M_μ associated with the reduced Hamiltonian function H_μ. ■

Remark VI.1: If each flow F^A_t preserves ω_A, that is $(F^A_t)^*\omega_A=\omega_A$, for all $A=1,\ldots,k$, then each flow H^A_t preserves $(\omega_\mu)_A$, that is $(H^A_t)^*(\omega_\mu)_A=(\omega_\mu)_A$, for all $A=1,\ldots,k$.

Indeed, from the fact

$$\begin{aligned}\pi^*_\mu(H^A_t)^*(\omega_\mu)_A&=(H^A_t\circ\pi_\mu)^*(\omega_\mu)_A\\&=(\pi_\mu\circ F^A_t)^*(\omega_\mu)_A=(F^A_t)^*\pi^*_\mu(\omega_\mu)_A=(F^A_t)^*i^*_\mu\omega_A=i^*_\mu\omega_A=\pi^*_\mu(\omega_\mu)_A\end{aligned}$$

and taking into account that π^*_μ is a surjective submersion, we obtain the assertion.

Next, we shall show that in the case of $M=(T^1_k)^*Q$, the reduced manifold M_μ is in fact the k-cotangent bundle $(T^1_k)^*(Q/G_\mu)$ of the manifold $Q_\mu=Q/G_\mu$ if $\mathcal{G}=\mathcal{G}_\mu$ where $\mu\in\mathcal{G}^{k*}$ is a regular value of J.

Theorem VI.3: *Let G act on Q and hence on $(T^1_k)^*Q$ as in (33) and let J be the Ad^{k*}-equivariant momentum map defined in (34). We suppose that all conditions from hypothesis of the Theorem VI.1 hold and that G_μ acts freely and properly on Q. Additionally, we assume that there exist G_μ-equivariant 1-forms $(\alpha_\mu)_1,\ldots,(\alpha_\mu)_k$ on Q, such that $((\alpha_\mu)_1,\ldots,(\alpha_\mu)_k)\in J^{-1}(\mu)$ and we define on $(T^1_k)^*Q$ the polysymplectic structure*

$$(\Omega_\mu)_A=(\omega_0)_A-(\tau_Q^*)^*d(\alpha_\mu)_A,\quad A=1,\ldots,k,$$

where $\tau_Q^*:(T^1_k)^*Q\to Q$ is the canonical projection, which allow us to consider on $(T^1_k)^*Q_\mu$ the corresponding induced polysymplectic structure.

Then there is an induced polysymplectic embedding $\Phi_\mu:M_\mu\to(T^1_k)^*Q_\mu$ onto a subbundle over Q_μ and this map Φ_μ is a diffeomorphism if and only if $\mathcal{G}=\mathcal{G}_\mu$.

Proof: Since $T^*Q_\mu=F_\mu/G_\mu$ where $F_\mu=\{\alpha_q\in T^*Q\mid\alpha_q(\xi_Q(q))=0,\forall\xi\in\mathcal{G}_\mu\}$, we have

$$(T^1_k)^*Q_\mu=(F_\mu/G_\mu)\overset{k}{\oplus\cdots\oplus}(F_\mu/G_\mu)=(F_\mu\overset{k}{\oplus\cdots\oplus}F_\mu)/G_\mu,$$

where

$$F_\mu\overset{k}{\oplus\cdots\oplus}F_\mu=\{(\alpha_1(q),\ldots,\alpha_k(q))\in(T^1_k)^*Q\mid\alpha_A(q)(\xi_Q(q))=0,\forall\xi\in\mathcal{G}_\mu,A=1,\ldots,k\}.$$

On the other hand,

$$J^{-1}(\mu)=\left\{(\alpha_1(q),\ldots,\alpha_k(q))\in(T^1_k)^*Q\,\middle|\,\sum_{A=1}^{k}\alpha_A(q)((\xi_A)_Q(q))=\mu(\xi_1,\ldots,\xi_k),\forall\xi_1,\ldots,\xi_k\in\mathcal{G}\right\},$$

and we define $\Psi_\mu:J^{-1}(\mu)\to F_\mu\overset{k}{\oplus\cdots\oplus}F_\mu$ by

$$\Psi_\mu(\alpha_1(q),\ldots,\alpha_k(q))=(\alpha_1(q)-(\alpha_\mu)_1(q),\ldots,\alpha_k(q)-(\alpha_\mu)_k(q)).$$

Since $(\alpha_1(q),\ldots,\alpha_k(q)),(\underset{A}{(\alpha_\mu)_1}(q),\ldots,(\alpha_\mu)_k(q))\in J^{-1}(\mu)$, we have that $(\alpha_\mu)_A(q)(\xi_Q(q))=\alpha_A(q)(\xi_Q(q))=\mu(0,\ldots,0,\xi,0,\ldots,0)$ for each $A=1,\ldots,k$, and therefore Ψ_μ is well defined.

The map Ψ_μ is a translation in each component and it is polysymplectic, that is, for any $A=1,\ldots,k$, we have

$$\Psi_\mu^*((\Omega_\mu)_{A|F_\mu\overset{k}{\oplus\cdots\oplus}F_\mu})=(\omega_0)_{A|J^{-1}(\mu)}.$$

In fact, a simple computation shows that $\Psi_\mu^*((\theta_0)_A)+(\tau_Q^*)^*(\alpha_\mu)_A=(\theta_0)_{A|J^{-1}(\mu)}$. Also, Ψ_μ is an embedding (if and only if $\mathcal{G}=\mathcal{G}_\mu$).

Since $(\alpha_\mu)_1,\ldots,(\alpha_\mu)_k$ are G_μ-equivariant and as a consequence of definition of Φ^{T^*}, the map Ψ_μ passes to the quotient defining

$$\Phi_\mu:M_\mu\equiv J^{-1}(\mu)/G_\mu\to(T^1_k)^*Q_\mu\equiv(F_\mu/G_\mu)\overset{k}{\oplus\cdots\oplus}(F_\mu/G_\mu)$$

by

$$\Phi_\mu([\alpha_1(q),\ldots,\alpha_k(q)])=([\alpha_1(q)-(\alpha_\mu)_1(q)],\ldots,[\alpha_k(q)-(\alpha_\mu)_k(q)]).$$

Clearly Φ_μ is an embedding (and onto if and only if $\mathcal{G}=\mathcal{G}_\mu$). The induced polysymplectic

structure $((\tilde{\Omega}_\mu)_A, 1\leqslant A\leqslant k)$ on $(T^1_k)^*Q_\mu$ defined by the polysymplectic structure $((\Omega_\mu)_A, 1\leqslant A\leqslant k)$ on $(T^1_k)^*Q$ allow us to consider the polysymplectic structure $(\Phi^*_\mu(\tilde{\Omega}_\mu)_A, 1\leqslant A\leqslant k)$ on M_μ. It is easy to see that $\pi^*_\mu(\Phi^*_\mu(\tilde{\Omega}_\mu)_A)=i^*_\mu\omega_A$ and from unicity of Theorem VI.1 it follows that Φ_μ is polysymplectic. ■

Example of reduction: Let G be a Lie group and denote by $\Lambda: G\times G\to G$ the action of G on itself by left translations, that is, $\Lambda_g=L_g$ for all $g\in G$. Let Λ^{T^*} be the induced action on $(T^1_k)^*G$ defined in (33). Since $\xi_G(g)=(R_g)_*(e)(\xi)$ for any $\xi\in\mathcal{G}$ and for any $g\in G$, from (34) we know that the momentum map $J:(T^1_k)^*G\to\mathcal{G}^{k*}$ of this action is

$$J(\alpha_1(g),\ldots,\alpha_k(g))(\xi_1,\ldots,\xi_k)=\sum_{A=1}^{k}\alpha_A(g)((\xi_A)_G(g))=\sum_{A=1}^{k}\alpha_A(g)((R_g)_*(e)\xi_A),$$

and then $J^{-1}(\mu)$ is given by

$$\left\{(\alpha_1(g),\ldots,\alpha_k(g))\in(T^1_k)^*G\,\middle|\,\sum_{A=1}^{k}\alpha_A(g)((R_g)_*(e)\xi_A)=\mu(\xi_1,\ldots,\xi_k),\ \forall\xi_1,\ldots,\xi_k\in\mathcal{G}\right\},$$

for any $\mu\in\mathcal{G}^{k*}$ (each $\mu\in\mathcal{G}^{k*}$ is a regular value of J).

If we consider, for each $A=1,\ldots,k$ the right-invariant 1-form $(\alpha_\mu)_A$, defined by

$$(\alpha_\mu)_A(g)=\mu\circ i_A\circ(R_{g^{-1}})_*(g),\quad \forall g\in G,$$

where $i_A:\mathcal{G}\to\mathcal{G}^k$ is the natural inclusion, $i_A(\xi)=(0,\ldots,0,\overset{A}{\xi},0,\ldots,0)$, then

$$J^{-1}(\mu)=\{((\alpha_\mu)_1(g),\ldots,(\alpha_\mu)_k(g))\,|\,g\in G\}\tag{46}$$

and therefore $J^{-1}(\mu)$ can be identified with G.

By a direct computation it is easy to see that

$$G_\mu=\{g\in G\,|\,(L_g)^*(\alpha_\mu)_A=(\alpha_\mu)_A,\ \forall A=1,\ldots,k\},$$

which means that G_μ acts on $J^{-1}(\mu)$ by left translations.

Thus $J^{-1}(\mu)/G_\mu\equiv G/G_\mu\equiv G\cdot\mu\subset\mathcal{G}^{k*}$, that is, the reduced phase space is naturally identifiable with the orbit of μ in $\mathcal{G}^{k*}$ under the k-coadjoint action, from which we deduce (using Theorem VI.1) that $G\cdot\mu$ is a polysymplectic manifold. For $k=1$ this is the statement of the Kirillov–Konstant–Souriau theorem.

Now, we want to compute explicitly the polysymplectic structure $((\omega_\mu)_A, 1\leqslant A\leqslant k)$ on $G\cdot\mu$. Let $\rho: J^{-1}(\mu)\to G\cdot\mu$ be the map given by $((\alpha_\mu)_1(g),\ldots,(\alpha_\mu)_k(g))\to \mathrm{Ad}^{k*}_{g^{-1}}(\mu)$ so that from Theorem VI.1 $\rho^*(\omega_\mu)_A=i^*_\mu(\omega_0)_A$, for all $1\leqslant A\leqslant k$, where $((\omega_0)_A, 1\leqslant A\leqslant k)$ is the canonical polysymplectic structure on $(T^1_k)^*G$ and $i_\mu: J^{-1}(\mu)\to(T^1_k)^*G$ is the natural inclusion.

First we compute $i^*_\mu(\omega_0)_A$. Let us observe that

$$T_{\alpha_\mu(g)}J^{-1}(\mu)=\{(\alpha_\mu\circ R_g)_*(e)(\xi)\,|\,\xi\in\mathcal{G}\},$$

because $J^{-1}(\mu)$ is the graph of $\alpha_\mu: G\to J^{-1}(\mu)$, $\alpha_\mu(g)=((\alpha_\mu)_1(g),\ldots,(\alpha_\mu)_k(g))$. Then

$$\begin{aligned}
&i^*_\mu(\omega_0)_A(\alpha_\mu(g))((\alpha_\mu)_*(g)((R_g)_*(e)(\xi)),(\alpha_\mu)_*(g)((R_g)_*(e)(\eta)))\\
&\quad=((\alpha_\mu)_A)^*\ \omega_0\ (g)((R_g)_*(e)(\xi),(R_g)_*(e)(\eta))\\
&\quad=-d(\alpha_\mu)_A(g)((R_g)_*(e)(\xi),(R_g)_*(e)(\eta))\\
&\quad=-d(\alpha_\mu)_A(\tilde{X}_\xi,\tilde{X}_\eta)(g)=(\alpha_\mu)_A([\tilde{X}_\xi,\tilde{X}_\eta])(g)=-(\alpha_\mu)_A(\tilde{X}_{[\xi,\eta]})(g)=-(\mu\circ i_A)([\xi,\eta]),
\end{aligned}\tag{47}$$

where $\tilde{X}_\xi$, $\tilde{X}_\eta$ are the right invariant vector fields corresponding to $\xi, \eta \in \mathcal{G}$, respectively.

On the other hand, we obtain by a direct computation

$$\rho^*(\omega_\mu)_A(\alpha_\mu(g))((\alpha_\mu)_*(g)((R_g)_*(e)(\xi)),(\alpha_\mu)_*(g)((R_g)_*(e)(\eta)))$$
$$=(\omega_\mu)_A(\mathrm{Ad}^{k*}_{g^{-1}}\mu)((\mathrm{Ad}_g\xi)_{\mathcal{G}^k*}(\mathrm{Ad}^{k*}_{g^{-1}}\mu),(\mathrm{Ad}_g\eta)_{\mathcal{G}^k*}(\mathrm{Ad}^{k*}_{g^{-1}}\mu)). \tag{48}$$

Therefore, from (47) and (48) we have

$$(\omega_\mu)_A(\mathrm{Ad}^{k*}_{g^{-1}}\mu)(\xi_{\mathcal{G}^k*}(\mathrm{Ad}^{k*}_{g^{-1}}\mu),\eta_{\mathcal{G}^k*}(\mathrm{Ad}^{k*}_{g^{-1}}\mu))=-(\mathrm{Ad}^*_{g^{-1}}(\mu\circ i_A))([\xi,\eta]), \tag{49}$$

for any element $\mathrm{Ad}^{k*}_{g^{-1}}\mu \in G\cdot\mu$.

Remark VI.2: Let us observe that the forms of the polysymplectic structure $((\omega_\mu)_A, 1\leqslant A \leqslant k)$ on $G\cdot\mu$ coincides with the forms obtained by Awane.[4,5]

Example VI.1: Now we will describe the reduction in the case $G=\mathrm{SO}(3)\times\overset{k}{\cdots}\times\mathrm{SO}(3)$.

A basis for the Lie algebra so(3) of the Lie group SO(3) is

$$E_1=\begin{pmatrix}0&0&0\\0&0&-1\\0&1&0\end{pmatrix},\quad E_2=\begin{pmatrix}0&0&1\\0&0&0\\-1&0&0\end{pmatrix},\quad E_3=\begin{pmatrix}0&-1&0\\1&0&0\\0&0&0\end{pmatrix}.$$

The map $j:\mathbb{R}^3\to\mathrm{so}(3):x=x_1e_1+x_2e_2+x_3e_3\mapsto X=x_1E_1+x_2E_2+x_3E_3$ is an isomorphism of the Lie algebras $(\mathbb{R}^3,\times)$ and $(\mathrm{so}(3),[\,,\,])$ where $\times$ denotes the vectorial product. With this isomorphism the action of so(3) on $\mathbb{R}^3$ is given by

$$j(x)\,y=\begin{pmatrix}0&-x_3&x_2\\x_3&0&-x_1\\-x_2&x_1&0\end{pmatrix}\begin{pmatrix}y_1\\y_2\\y_3\end{pmatrix}=x\times y\,. \tag{50}$$

The isomorphism $\kappa:\mathbb{R}^3\to\mathrm{so}(3)^*$ is given by $\kappa(x)=x_1E^1+x_2E^2+x_3E^3$ and so

$$\kappa(x)(j(y))=\langle x,y\rangle\,, \tag{51}$$

where E^1,E^2,E^3 is the dual basis of E_1,E_2,E_3.

It is well known that, the adjoint representation $\mathrm{Ad}:\mathrm{SO}(3)\to\mathrm{Aut}(\mathrm{so}(3))$ is given by

$$\mathrm{Ad}_A(j(x))=j(Ax)\,. \tag{52}$$

Thus, the adjoint representation $\mathrm{Ad}:\mathrm{SO}(3)\times\overset{k}{\cdots}\times\mathrm{SO}(3)\to\mathrm{Aut}(\mathrm{so}(3)^*\oplus\overset{k}{\cdots}\oplus\mathrm{so}(3)^*)$ is given by

$$\mathrm{Ad}_{(A_1,\ldots,A_k)}(j(x_1),\ldots,j(x_k))=(j(A_1x_1),\ldots,j(A_kx_k))\,, \tag{53}$$

where $(A_1,\ldots,A_k)\in\mathrm{SO}(3)\times\overset{k}{\cdots}\times\mathrm{SO}(3)$, $(x_1,\ldots,x_k)\in\mathbb{R}^3\times\overset{k}{\cdots}\times\mathbb{R}^3$.

We shall use the following isomorphisms:

$$\mathrm{so}(3)^*\oplus\overset{k}{\cdots}\oplus\mathrm{so}(3)^*\overset{F}{\to}(\mathrm{so}(3)\times\overset{k}{\cdots}\times\mathrm{so}(3))^*,$$

$$(\alpha_1,\ldots,\alpha_k)\to F(\alpha_1,\ldots,\alpha_k),$$

where $F(\alpha_1,\ldots,\alpha_k)(X_1,\ldots,X_k)=\Sigma_{i=1}^k\alpha_i(X_i)$, and

$$(\mathrm{so}(3)\times\overset{k}{\cdots}\times\mathrm{so}(3))^*\overset{F^{-1}}{\to}\mathrm{so}(3)^*\oplus\overset{k}{\cdots}\oplus\mathrm{so}(3)^*,$$

$$\mu \to F^{-1}(\mu) = (\mu \circ i_1, \ldots, \mu \circ i_k),$$

where $i_j(X) = (0,\ldots,0,\overset{j}{X},0,\ldots,0)$.

From (51) we have

$$F(\kappa(x_1),\ldots,\kappa(x_k))(j(y_1),\ldots,j(y_k)) = \sum_{\alpha=1}^{k} \langle x_\alpha, y_\alpha \rangle . \tag{54}$$

Let us denote by $G = \mathrm{SO}(3) \overset{k}{\times \cdots \times} \mathrm{SO}(3)$ and by $\mathcal{G} = \mathrm{so}(3) \overset{k}{\oplus \cdots \oplus} \mathrm{so}(3)$ its Lie algebra. Now we shall describe the k-coadjoint orbit of

$$\mu \in \mathcal{G}^{k*} = ((\mathrm{so}(3) \overset{k}{\oplus \cdots \oplus} \mathrm{so}(3)) \overset{k}{\times \cdots \times} (\mathrm{so}(3) \overset{k}{\oplus \cdots \oplus} \mathrm{so}(3)))^* .$$

Let $\mu : \mathcal{G} \overset{k}{\times \cdots \times} \mathcal{G} \to \mathbb{R}$ be an element of $\mathcal{G}^{k*}$. We define $\mu_\alpha \in \mathcal{G}^*$ by $\mu_\alpha = \mu \circ i_\alpha$ where $i_\alpha : \mathcal{G} \to \mathcal{G} \overset{k}{\times \cdots \times} \mathcal{G}$ is the inclusion in the α-factor, that is, $i_\alpha(X_1,\ldots,X_k) = (0,\ldots,0,(X_1,\ldots,X_k),0,\ldots,0)$.

Let $(\hat{\mu}_\alpha)_\beta \in \mathbb{R}^3$ such that $\mu_\alpha = F(\kappa((\hat{\mu}_\alpha)_1),\ldots,\kappa((\hat{\mu}_\alpha)_k))$. Then from (26), (52), and (54) the k-coadjoint action is given by

$$\Phi((A_1,\ldots,A_k),\mu) = \mathrm{Ad}^{k*}_{(A_1^{-1},\ldots,A_k^{-1})}(\mu) = \sum_{\alpha,\beta}^{k} \langle A_\beta(\hat{\mu}_\alpha)_\beta, j^{-1}(-) \rangle . \tag{55}$$

Thus, using the above identifications, from (55) we deduce that the k-coadjoint action

$$\Phi : G \times (\mathcal{G} \overset{k}{\times \cdots \times} \mathcal{G})^* \to (\mathcal{G} \overset{k}{\times \cdots \times} \mathcal{G})^*$$

with $G = \mathrm{SO}(3) \overset{k}{\times \cdots \times} \mathrm{SO}(3)$ and $\mathcal{G} = \mathrm{so}(3) \overset{k}{\oplus \cdots \oplus} \mathrm{so}(3)$, can be identified with the natural action

$$\Phi : G \times (\mathbb{R}^3 \overset{k}{\times \cdots \times} \mathbb{R}^3) \overset{k}{\times \cdots \times} (\mathbb{R}^3 \overset{k}{\times \cdots \times} \mathbb{R}^3) \to (\mathbb{R}^3 \overset{k}{\times \cdots \times} \mathbb{R}^3) \overset{k}{\times \cdots \times} (\mathbb{R}^3 \overset{k}{\times \cdots \times} \mathbb{R}^3),$$

$$\begin{aligned} &\Phi((A_1,\ldots,A_k),((x_1)_1,\ldots,(x_1)_k),\ldots,((x_k)_1,\ldots,(x_k)_k)) \\ &\quad = ((A_1(x_1)_1,\ldots,A_k(x_1)_k),\ldots,(A_1(x_k)_1,\ldots,A_k(x_k)_k)) . \end{aligned}$$

Then, the k-coadjoint orbit $(\mathrm{SO}(3) \overset{k}{\times \cdots \times} \mathrm{SO}(3)) \cdot \mu$ of μ is

$$\begin{aligned} &\{((A_1(\hat{\mu}_1)_1,\ldots,A_k(\hat{\mu}_1)_k),\ldots,(A_1(\hat{\mu}_k)_1,\ldots,A_k(\hat{\mu}_k)_k)) \mid A_\alpha \in \mathrm{SO}(3),\ \alpha = 1,\ldots,k\} \subset \mathbb{S}^2(\|(\hat{\mu}_1)_1\|) \\ &\quad \times \cdots \times \mathbb{S}^2(\|(\hat{\mu}_1)_k\|) \overset{k}{\times \cdots \times} \mathbb{S}^2(\|(\hat{\mu}_k)_1\|) \times \cdots \times \mathbb{S}^2(\|(\hat{\mu}_k)_k\|), \end{aligned}$$

where $\mathbb{S}^2(\|(\hat{\mu}_\alpha)_\beta\|)$ is the sphere of radius $\|(\hat{\mu}_\alpha)_\beta\|$ in $\mathbb{R}^3$, $\alpha,\beta = 1,\ldots,k$. Obviously each orbit is diffeomorphic to $\mathbb{S}^2 \overset{k}{\times \cdots \times} \mathbb{S}^2$.

From the example of reduction above we know that the orbit $(\mathrm{SO}(3) \overset{k}{\times \cdots \times} \mathrm{SO}(3)) \cdot \mu$ is a polysymplectic manifold. From (49) and (52) we obtain the polysymplectic structure of $G \cdot \mu$: if $\mathbf{A} \equiv (A_1,\ldots,A_k) \in G$, $\mathbf{X} = (X_1,\ldots X_k), \mathbf{Y} = (Y_1,\ldots Y_k) \in \mathcal{G}$, the polysymplectic structure is given by

$$(\omega_\mu)_\alpha(\mathbf{A}\cdot\mu)(\mathbf{X}_{\mathcal{G}^{k*}}(\mathbf{A}\cdot\mu), \mathbf{Y}_{\mathcal{G}^{k*}}(\mathbf{A}\cdot\mu)) = -\sum_{\beta=1}^{k} \langle A_\beta(\hat{\mu}_\alpha)_\beta, x_\beta \times y_\beta \rangle , \quad \alpha = 1,\ldots,k,$$

where $j(x_\beta) = X_\beta, j(y_\beta) = Y_\beta$. In fact we have

$$
\begin{aligned}
&(\omega_\mu)_\alpha((A_1,\ldots,A_k)\cdot\mu)(\mathbf{X}_{\mathcal{G}^k*}((A_1,\ldots,A_k)\cdot\mu),\mathbf{Y}_{\mathcal{G}^k*}((A_1,\ldots,A_k)\cdot\mu))\\
&\quad=-\mathrm{Ad}^*_{(A_1,\ldots,A_k)^{-1}}(\mu\circ i_\alpha)([(X_1,\ldots,X_k),(Y_1,\ldots,Y_k)])\\
&\quad=-\mathrm{Ad}^*_{(A_1,\ldots,A_k)^{-1}}(\mu\circ i_\alpha)([X_1,Y_1],\ldots,[X_k,Y_k])\\
&\quad=-((\mu\circ i_\alpha)\circ\mathrm{Ad}_{(A_1,\ldots,A_k)^{-1}})(j(x_1\times y_1),\ldots,j(x_k\times y_k))\\
&\quad=-(\mu\circ i_\alpha)(j(A_1^{-1}(x_1\times y_1)),\ldots,j(A_k^{-1}(x_k\times y_k)))\\
&\quad=-F(\kappa((\hat\mu_\alpha)_1),\ldots\kappa((\hat\mu_\alpha)_k))(j(A_1^{-1}(x_1\times y_1)),\ldots,j(A_k^{-1}(x_k\times y_k)))\\
&\quad=-\sum_{\beta=1}^{k}\langle(\hat\mu_\alpha)_\beta,(A_\beta)^{-1}(x_\beta\times y_\beta)\rangle=-\sum_{\beta=1}^{k}\langle A_\beta(\hat\mu_\alpha)_\beta,x_\beta\times y_\beta\rangle,
\end{aligned}
$$

where the Lie bracket $[X,Y]$ in so(3) is identified with the vectorial product $x\times y$ in $\mathbb{R}^3$.

In the case $k=1$, it is well known that the coadjoint orbit $\mathrm{SO}(3)\cdot\mu\subset\mathrm{so}(3)^*\simeq\mathbb{R}^3$ is the sphere $\mathbb{S}^2(\|\mu\|)$ of radius $\|\mu\|$ and the symplectic structure is

$$
\omega_\mu(A\cdot\mu)(X_{\mathcal{G}*}(A\cdot\mu),Y_{\mathcal{G}*}(A\cdot\mu))=-\langle A\hat\mu,x\times y\rangle,\quad \kappa(\hat\mu)=\mu\ ,
$$

that is, the area element given by the normal vector $A\hat\mu$ applied to the tangent vectors x and y. (Also see Refs. 23–31.)

(Received 1 December 2003; accepted 21 January 2004; published 31 March 2004)

By applying higher powers of Bogoliubov's transformation operator $b^\dagger = \nu^* a + \mu^* a^\dagger$ to the even and odd coherent states we construct mathematically two new types of quantum states. Various special functions and mathematical formulations are used to obtain the matrix elements for the states in the coherent state representation. The nonclassical nature of these states is found to be related to their quantum coherence in phase space. The interference effects can also be regarded as a consequence of the oscillatory behavior of the special functions in the structure of the states. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1688434]

I. INTRODUCTION

Since the even and odd coherent states were proposed by Dodonov *et al.* in 1974[1] and Hillery in 1987[2] for a single mode field they have attracted considerable attention in quantum optics. The quantum properties of these states have been studied in detail,[3,4] and various schemes for their realization have been proposed.[5–8] In addition, multimode even and odd coherent fields[9] as well as certain excited states related to the even and odd states[10] have been investigated as important types of nonclassical fields. In recent years the possible application of similar superpositions of even and odd states have been proposed as quantum entangled states which may be used to realize quantum teleportation.[11,12]

Through a new mathematical formulation we define two general classes of quantum states which are broader than the even/odd coherent states[1,2] and the excited even/odd coherent states.[10] They are generated by m-fold application of Bogoliubov's transformation operator $b^\dagger$, also known as the pseudocreation operator, on the even/odd coherent states to obtain what we call, respectively, the generalized excited even/odd coherent states. It is our purpose to construct these states in the coherent state representation which can describe the relationship and properties of these states. We also examine the nonclassical behavior of several quasiprobability distributions, and the influence of the phase relation between two parameters μ and ν on the probability distributions of these nonclassical fields. Our results show that these states are in fact two new general classes of quantum states which exhibit remarkable nonclassical characteristics different from previously known states.[1,2,10,13–15]

II. REPRESENTATIONS OF TWO NEW CLASSES OF QUANTUM STATES

We consider a single mode of the field described in terms of the boson annihilation and creation operators a and $a^\dagger$. The even $|\alpha\rangle_E$ and odd $|\alpha\rangle_O$ coherent states can be defined as the eigenstates of the double-annihilation operator aa,

$$aa|\alpha\rangle_{E(O)} = \alpha^2 |\alpha\rangle_{E(O)}, \tag{1}$$

a)Electronic mail: wuweio@yahoo.com

and may be written explicitly as

$$|\alpha\rangle_E=\frac{1}{\sqrt{\cosh(|\alpha|)^2}}\sum_{n=0}^{\infty}\frac{\alpha^{2n}}{\sqrt{(2n)!}}|2n\rangle, \tag{2}$$

$$|\alpha\rangle_O=\frac{1}{\sqrt{\sinh(|\alpha|)^2}}\sum_{n=0}^{\infty}\frac{\alpha^{2n+1}}{\sqrt{(2n+1)!}}|2n+1\rangle. \tag{3}$$

The even/odd coherent states can also be written as the superposition of two coherent states $|\alpha\rangle$ and $|-\alpha\rangle$, which have the form

$$|\alpha\rangle_E=\tfrac{1}{2}\exp(\tfrac{1}{2}|\alpha|^2)[\cosh|\alpha|^2]^{-1/2}(|\alpha\rangle+|-\alpha\rangle), \tag{4}$$

$$|\alpha\rangle_O=\tfrac{1}{2}\exp(\tfrac{1}{2}|\alpha|^2)[\sinh|\alpha|^2]^{-1/2}(|\alpha\rangle-|-\alpha\rangle), \tag{5}$$

where $|\pm\alpha\rangle$ is a coherent state. We now make use of a linear transformation of the annihilation and creation operators or the Bogoliubov transformation operator b, defined by

$$b=b(\mu,\nu)=\mu a+\nu a^{\dagger}, \tag{6}$$

where the complex parameters μ and ν obey $|\mu|^2-|\nu|^2=1$, $\mu,\nu\in C$. The basic operators b and $b^{\dagger}$ satisfy the same canonical commutation relation as $a,a^{\dagger}$, i.e.,

$$[b(\mu,\nu),b^{\dagger}(\mu^*,\nu^*)]=1. \tag{7}$$

This transformation operator b was first used by Bogoliubov in solid state physics[16] and later by Yuen to derive his two-photon coherent states.[14] Its Hermitian adjoint operator $b^{\dagger}(\mu^*,\nu^*)$ is

$$b^{\dagger}(\mu^*,\nu^*)=\nu^* a+\mu^* a^{\dagger}. \tag{8}$$

We now apply the Bogoliubov operator $b^{\dagger}(\mu^*,\nu^*)$ m-times to the even/odd coherent states[1,2] based on the above representation and obtain two new types of quantum states, the generalized excited even coherent states $|\alpha,m,\mu,\nu\rangle_E$ (GEECS) and the generalized excited odd coherent states $|\alpha,m,\mu,\nu\rangle_O$ (GEOCS). They may be written, respectively, as

$$|\alpha,m,\mu,\nu\rangle_E=N_E^{1/2}b^{\dagger m}|\alpha\rangle_E \tag{9}$$

and

$$|\alpha,m,\mu,\nu\rangle_O=N_O^{1/2}b^{\dagger m}|\alpha\rangle_O, \tag{10}$$

where m is a non-negative integer, and $N_E^{1/2}$ and $N_O^{1/2}$ are normalization constants.

In order to examine the properties of the generalized excited even/odd coherent states, we need to obtain the matrix elements based on the coherent state representations of Eqs. (9) and (10). The general matrix elements $A_{\lambda,\rho}^{n,m}(\alpha^*,\beta)$ and $B_{\lambda,\rho}^{n,m}(\alpha^*,-\beta)$ can be defined as

$$A_{\lambda,\rho}^{n,m}(\alpha^*,\beta)=\langle\alpha|b^n a^{\lambda}a^{\dagger\rho}b^{\dagger m}|\beta\rangle, \tag{11}$$

$$B_{\lambda,\rho}^{n,m}(\alpha^*,-\beta)=\langle\alpha|b^n a^{\lambda}a^{\dagger\rho}b^{\dagger m}|-\beta\rangle. \tag{12}$$

To calculate the matrix elements we need to employ the mathematical formulas of Refs. 10, 15, and 17, so from Eqs. (6), (7), and (8) we have

$$b^{\dagger m}(\mu^*,\nu^*)=[\nu^* a+\mu^* a^\dagger]^m=\sum_{k=0}^{[m/2]}\sum_{M=0}^{m-2k} d^m_{M,m-2k-M}(\mu^*,\nu^*)a^{\dagger M}a^{m-2k-M}, \tag{13}$$

where $d^m_{M,N}(\mu^*,\nu^*)$ is a c-number factor defined by

$$d^m_{M,N}(\mu^*,\nu^*)=\frac{m!}{M!N!(m-M-N)!!}(\nu^*)^{1/2(m-M+N)}(\mu^*)^{1/2(m+M-N)}. \tag{14}$$

We thus have

$$\begin{aligned}A^{n,m}_{\lambda,\rho}(\alpha^*,\beta)&=\langle\alpha|b^n a^\lambda a^{\dagger\rho}b^{\dagger m}|\beta\rangle\\&=\sum_{M,N}^{m}\sum_{K,L}^{n} d^m_{M,N}(\mu^*,\nu^*)d^n_{K,L}(\mu,\nu)\alpha^{*L}\beta^N\langle\alpha|a^{(K+\lambda)}a^{\dagger(M+\rho)}|\beta\rangle,\end{aligned} \tag{15}$$

$$\begin{aligned}B^{n,m}_{\lambda,\rho}(\alpha^*,-\beta)&=\langle\alpha|b^n a^\lambda a^{\dagger\rho}b^{\dagger m}|-\beta\rangle\\&=\sum_{M,N}^{m}\sum_{K,L}^{n} d^m_{M,N}(\mu^*,\nu^*)d^n_{K,L}(\mu,\nu)\alpha^{*L}(-\beta)^N\langle\alpha|a^{(K+\lambda)}a^{\dagger(M+\rho)}|-\beta\rangle.\end{aligned} \tag{16}$$

We now calculate the matrix elements explicitly. To do this, we set

$$G^{M+\rho}_{K+\lambda}(\alpha^*,\beta,-\alpha^*\beta)=\langle\alpha|\beta\rangle F^{M+\rho}_{K+\lambda}(\alpha^*,\beta,-\alpha^*\beta), \tag{17}$$

where

$$F^{M+\rho}_{K+\lambda}(\alpha^*,\beta,-\alpha^*\beta)=\begin{cases}\beta^{[(K+\lambda)-(M+\rho)]}(M+\rho)!L^{[(K+\lambda)-(M+\rho)]}_{(M+\rho)}(-\alpha^*\beta),\\ \qquad (k+\lambda)\geqslant(m+\rho),\\ \alpha^{*[(M+\rho)-(K+\lambda)]}(K+\lambda)!L^{[(M+\rho)-(K+\lambda)]}_{(K+\lambda)}(-\alpha^*\beta),\\ \qquad (k+\lambda)\leqslant(m+\rho).\end{cases} \tag{18}$$

In deriving (13)–(16) we have employed the associated Laguerre polynomial $L^{(k)}_m(x)$ and the normally ordered expression of the operator

$$L^{(k)}_m(x)=\sum_{n=0}\frac{(m+k)!(-x)^n}{(m-n)!n!(n+k)!}\quad(k>-1), \tag{19}$$

$$a^n a^{\dagger m}=\begin{cases}n!m!\sum_{l=0}^{m}\dfrac{a^{\dagger l}a^{l+n-m}}{(m-l)!l!(l+n-m)!}, & n\geqslant m,\\ n!m!\sum_{l=0}^{m}\dfrac{a^{\dagger(l+m-n)}a^l}{(m-l)!l!(l+m-n)!}, & n\leqslant m.\end{cases} \tag{20}$$

To determine the upper and lower limits of the fourfold summation $\Sigma^m_{M,N}\Sigma^n_{K,L}$ we use Eq. (14) to find the optimum values of M and N. It is easy to see that for any numbers r and k we may choose N to be

$$N=m-M-2r=\begin{cases}2k-2r & \text{when } m-\mathrm{M} \text{ is even},\\ (2k+1)-2r & \text{when } m-\mathrm{M} \text{ is odd}.\end{cases} \tag{21}$$

If we select $r=0$ then N is a series of non-negative integers $2k+1,2k,2k-1,\ldots,2,1,0$. This shows that the even and odd numbers appear alternately, and the upper limit of M is $2k+1$ or $2k$,

$$M=\begin{cases} m-2k, & k=0,1,2,\ldots\ [m/2], \\ m-(2k+1), & k=0,1,2,\ldots\ [(m-1)/2]. \end{cases} \tag{22}$$

Similarly, when K is even or odd, we have

$$L=\begin{cases} 2k-2r & \text{when } n-K \text{ is even}, \\ (2k+1)-2r & \text{when } n-K \text{ is odd}, \end{cases} \tag{23}$$

and so

$$K=\begin{cases} n-2k, & k=0,1,2,\ldots\ [n/2], \\ n-(2k+1), & k=0,1,2,\ldots\ [(n-1)/2]. \end{cases} \tag{24}$$

Furthermore, we can rewrite the matrix element $A^{n,m}_{\lambda,\rho}(\alpha^*,\beta)$ of Eq. (15) as the sum of an even and odd term,

$$\begin{aligned} \langle\alpha|b^n a^\lambda a^{\dagger\rho} b^{\dagger m}|\beta\rangle &= \sum_{M,N}^{m}\sum_{K,L}^{n} d^m_{M,N}(\mu^*,\nu^*) d^n_{K,L}(\mu,\nu)\alpha^{*L}\beta^N \langle\alpha|a^{(K+\lambda)}a^{\dagger(M+\rho)}|\beta\rangle \\ &= g_{2k}+g_{2k+1}. \end{aligned} \tag{25}$$

Next we note that after inserting Eqs. (21)–(24) into (14) we obtain

$$\begin{aligned} g_{2k} &= \sum_{k=0}^{[m/2]}\sum_{r=0}^{k} \frac{G^{m-2k+\rho}_{K+\lambda} m!\,\mu^{*(m-2k+r)}\nu^{*(2k-r)}\beta^{(2k-2r)}}{(m-2k)!(2k-2r)!(2r)!!} \\ &\quad\times \sum_{k=0}^{[n/2]}\sum_{r=0}^{k} \frac{n!\,\mu^{(n-2k+r)}\nu^{(2k-r)}\alpha^{*(2k-2r)}}{(n-2k)!(2k-2r)!(2r)!!} \\ &= \mu^{*m}\sum_{k=0}^{[m/2]} \frac{G^{m-2k+\rho}_{K+\lambda} m!}{(m-2k)!(2k)!}\left(i\sqrt{\frac{\nu^*}{\mu^*}}\right)^{2k} H_{2k}\left(i\sqrt{\frac{\nu^*}{\mu^*}}\beta\right) \\ &\quad\times \mu^{n}\sum_{k=0}^{[n/2]} \frac{G^{n-2k+\rho}_{K+\lambda} n!}{(n-2k)!(2k)!}\left(i\sqrt{\frac{\nu}{\mu}}\right)^{2k} H_{2k}\left(i\sqrt{\frac{\nu}{\mu}}\alpha^*\right) \end{aligned} \tag{26}$$

and

$$\begin{aligned} g_{2k+1} &= \sum_{k=0}^{[(m-1)/2]}\sum_{r=0}^{k} \frac{G^{m-(2k+1)+\rho}_{K+\lambda} m!\,\mu^{*[m-(2k+1)+r]}\nu^{*[(2k+1)-r]}\beta^{[(2k+1)-2r]}}{[m-(2k+1)]![(2k+1)-2r]!(2r)!!} \\ &\quad\times \sum_{k=0}^{[(n-1)/2]}\sum_{r=0}^{k} \frac{n!\,\mu^{[n-(2k+1)+r]}\nu^{[(2k+1)-r]}\alpha^{*[(2k+1)-2r]}}{[n-(2k+1)]![(2k+1)-2r]!(2r)!!} \\ &= \mu^{*m}\sum_{k=0}^{[(m-1)/2]} \frac{G^{m-(2k+1)+\rho}_{K+\lambda} m!}{[m-(2k+1)]!(2k+1)!}\left(i\sqrt{\frac{\nu^*}{\mu^*}}\right)^{2k+1} H_{2k+!}\left(i\sqrt{\frac{\nu^*}{\mu^*}}\beta\right) \\ &\quad\times \mu^{n}\sum_{k=0}^{[(n-1)/2]} \frac{G^{n-(2k+1)+\rho}_{K+\lambda} n!}{[n-(2k+1)]!(2k+1)!}\left(i\sqrt{\frac{\nu}{\mu}}\right)^{2k+1} H_{2k+1}\left(i\sqrt{\frac{\nu}{\mu}}\alpha^*\right). \end{aligned} \tag{27}$$

In deriving (26) and (27) we have used the even and odd order Hermite polynomials

$$H_{2k}(x)=(2k)!\sum_{r=0}^{k}\frac{(-1)^r x^{2k-2r}}{(2k-2r)!(2r)!!}, \tag{28}$$

$$H_{2k+1}(x)=(2k+1)!\sum_{r=0}^{k}\frac{(-1)^r x^{(2k+1)-2r}}{[(2k+1)-2r]!(2r)!!}. \tag{29}$$

In Eqs. (26)–(27), we should take note of the range of m and n. It can be proved that, no matter whether m and n are even or odd, we always have $g_{2k}=g_{2k+1}$ for $k=[m/2],[(m-1)/2]$ (or $[n/2],[(n-1)/2]$). We now rewrite the upper and lower limits of M by replacing $2k$ [or $(2k+1)$] with s and of K by replacing $2k$ [or $(2k+1)$] with t, so that

$$A^{n,m}_{\lambda,\rho}(\alpha^*,\beta)=\langle\alpha|\beta\rangle\sum_{s=0}^{m}\sum_{t=0}^{n}F^{m+\rho-s}_{n+\lambda-t}(\beta,\alpha^*,-\alpha^*\beta)R^m_s(\mu^*,\nu^*,\beta)S^n_t(\mu,\nu,\alpha^*), \tag{30}$$

$$B^{n,m}_{\lambda,\rho}(\alpha^*,-\beta)=\langle\alpha|-\beta\rangle\sum_{s=0}^{m}\sum_{t=0}^{n}F^{m+\rho-s}_{n+\lambda-t}(-\beta,\alpha^*,\alpha^*\beta)R^m_s(\mu^*,\nu^*,-\beta)S^n_t(\mu,\nu,\alpha^*), \tag{31}$$

where

$$F^p_q(\beta,\alpha^*,-\alpha^*\beta)=\begin{cases}p!\beta^{(q-p)}L_p^{(q-p)}(-\alpha^*\beta), & q\geqslant p,\\ q!\alpha^{*(p-q)}L_q^{(p-q)}(-\alpha^*\beta), & q\leqslant p,\end{cases} \tag{32}$$

$$R^m_s(\mu^*,\nu^*,\beta)=\mu^{*m}\binom{m}{s}\left(i\sqrt{\frac{\nu^*}{\mu^*}}\right)^s H_s\left(\frac{1}{i}\sqrt{\frac{\nu^*}{\mu^*}}\beta\right), \tag{33}$$

$$S^n_t(\mu,\nu,\alpha^*)=\mu^n\binom{n}{t}\left(i\sqrt{\frac{\nu}{\mu}}\right)^t H_t\left(\frac{1}{i}\sqrt{\frac{\nu}{\mu}}\alpha^*\right). \tag{34}$$

In order to solve the matrix element equations (30) and (31) by means of a general approach, we modify the elements by replacing α^* with $-\alpha^*$ and β with $-\beta$. We can show the following:

(i) when $(n+\lambda)-(m+\rho)$ is even,

$$\begin{aligned}A^{n,m}_{\lambda,\rho}(\alpha^*,\beta)&=A^{n,m}_{\lambda,\rho}(-\alpha^*,-\beta),\\ B^{n,m}_{\lambda,\rho}(\alpha^*,-\beta)&=B^{n,m}_{\lambda,\rho}(-\alpha^*,\beta);\end{aligned} \tag{35}$$

(ii) when $(n+\lambda)-(m+\rho)$ is odd,

$$\begin{aligned}A^{n,m}_{\lambda,\rho}(\alpha^*,\beta)&=-A^{n,m}_{\lambda,\rho}(-\alpha^*,-\beta),\\ B^{n,m}_{\lambda,\rho}(\alpha^*,-\beta)&=-B^{n,m}_{\lambda,\rho}(-\alpha^*,\beta).\end{aligned} \tag{36}$$

The normalization constants N_E and N_O in Eqs. (9) and (10) can thus be readily obtained in the coherent state representation when $m=n$, $\alpha=\beta$, and $\lambda=\rho=0$,

$$N_E={}_E\langle\alpha|b^m b^{\dagger m}|\alpha\rangle_E=\frac{\exp(|\alpha|^2)[A^m(\alpha)+B^m(\alpha)]}{2\cosh(|\alpha|^2)}, \tag{37}$$

$$N_O={}_O\langle\alpha|b^m b^{\dagger m}|\alpha\rangle_O=\frac{\exp(|\alpha|^2)[A^m(\alpha)-B^m(\alpha)]}{2\sinh(|\alpha|^2)}. \tag{38}$$

We note here that $J^m_{\lambda,\rho}(\alpha)$ and $K^m_{\lambda,\rho}(\alpha)$ are related by a set of the sum of the matrix elements $A^m_{\lambda,\rho}(\alpha^*,\alpha)$ and $B^m_{\lambda,\rho}(\alpha^*,-\alpha)$,

$$J^{m}_{\lambda,\rho}(\alpha)=J^{m,m}_{\lambda,\rho}(\alpha^*,\alpha)=A^{m,m}_{\lambda,\rho}(\alpha^*,\alpha)+B^{m,m}_{\lambda,\rho}(\alpha^*,-\alpha), \tag{39}$$

$$K^{m}_{\lambda,\rho}(\alpha)=K^{m,m}_{\lambda,\rho}(\alpha^*,\alpha)=A^{m,m}_{\lambda,\rho}(\alpha^*,\alpha)-B^{m,m}_{\lambda,\rho}(\alpha^*,-\alpha), \tag{40}$$

$$J^{m}(\alpha)=A^{m}(\alpha)+B^{m}(\alpha), K^{m}(\alpha)=A^{m}(\alpha)-B^{m}(\alpha), \tag{41}$$

where λ and ρ are non-negative integers.

III. QUASIPROBABILITY FUNCTION OF THE QUANTUM STATES

We shall use the general matrix elements $A^{n,m}_{\lambda,\rho}(\alpha^*,\beta)$, $B^{n,m}_{\lambda,\rho}(\alpha^*,-\beta)$, $A^{n,m}_{\lambda,\rho}(-\alpha^*,-\beta)$, and $B^{n,m}_{\lambda,\rho}(-\alpha^*,\beta)$ defined above, and calculate the quantum statistical properties of these new types of quantum states. It is well known that the quasiprobability distribution functions are extremely useful in the mathematical description of quantum mechanical systems.[13,18–20] They include the P function, Q function, and Wigner function, which are all closely related to the quantum statistical behavior of a microscopic system. Our results are expected to give distribution functions characteristic of quantum fields.[21] To this purpose we first consider the fact that the P, Q, and W functions may be obtained in the integral form of the density matrix $\rho=(1/\pi)\int P(z)|z\rangle\langle z|\mathrm{d}^2z$, where $|z\rangle$ is the coherent state. We have thus established the relationship between the matrix and the mathematical structure of the GEECS and GEOCS in the coherent state space.

A. *P* function representation

To determine the P distribution of the $|\alpha,m,\mu,\nu\rangle_{E(O)}$ state it is customary to use the Glauber–Sudarshan representation, so the density matrix is

$$\rho=|\alpha,m,\mu,\nu\rangle_{E(O)(O)E}\langle\alpha,m,\mu,\nu|=\int P_{GEE(GEO)}(z)|z\rangle\langle z|\mathrm{d}^2z. \tag{42}$$

By the double-Fourier transform[22] we have

$$P_{GEE(GEO)}(z)=\frac{e^{|z|^2}}{\pi^2}\int \mathrm{d}^2\beta\langle-\beta|\alpha,m,\mu,\nu\rangle_{E(O)(O)E}\langle\alpha,m,\mu,\nu|\beta\rangle\times\exp[z\beta^*-z^*\beta], \tag{43}$$

where $[z\beta^*-z^*\beta]$ is an imaginary variable which is known to be integrable and satisfies

$$\int \mathrm{d}^2\beta\exp[\pm(z\beta^*-z^*\beta)]=\pi^2\delta^2(z). \tag{44}$$

We thus have

$$P_{GEE}(\alpha,z)=\frac{e^{|z|^2-|\alpha|^2}}{J^m(\alpha)}\sum_{s=0}^{m}\sum_{t=0}^{m}R^m_s(\mu^*,\nu^*,\alpha)S^n_t(\mu,\nu,\alpha^*)\frac{\partial^{(2m-s-t)}}{\partial z^{(m-s)}\partial z^{*(m-t)}}\{(-1)^{s+t}\delta^2(z-\alpha)$$
$$+\delta^2(z+\alpha)+(-1)^s\delta(z-\alpha)\delta(z+\alpha)^*+(-1)^t\delta(z+\alpha)\delta(z-\alpha)^*\}, \tag{45}$$

$$P_{GEO}(\alpha,z)=\frac{e^{|z|^2-|\alpha|^2}}{k^m(\alpha)}\sum_{s=0}^{m}\sum_{t=0}^{m}R^m_s(\mu^*,\nu^*,\alpha)S^n_t(\mu,\nu,\alpha^*)\frac{\partial^{(2m-s-t)}}{\partial z^{(m-s)}\partial z^{*(m-t)}}\{(-1)^{s+t}\delta^2(z-\alpha)$$
$$+\delta^2(z+\alpha)-(-1)^s\delta(z-\alpha)\delta(z+\alpha)^*-(-1)^t\delta(z+\alpha)\delta(z-\alpha)^*\}. \tag{46}$$

In deriving (45) and (46), we have utilized Eqs. (33) and (34), and the relationship

$$R^m_s(\mu^*,\nu^*,-\alpha)=(-1)^sR^m_s(\mu^*,\nu^*,\alpha),$$
$$S^m_t(\mu,\nu,-\alpha^*)=(-1)^tS^m_t(\mu,\nu,\alpha^*), \tag{47}$$

which can be easily proved for $\alpha=-\alpha$, $\alpha^*=-\alpha^*$. From the double δ-function we see that $P_{GEE}(\alpha,z)$ and $P_{GEO}(\alpha,z)$ are extremely singular, which is a characteristic typical of nonclassical states. In particular, for the parameter values $\nu=0$ and $\mu=1$, the distribution functions $P_{GEE}(\alpha,z)$ and $P_{GEO}(\alpha,z)$ reduce to $P_{EE}(\alpha,z)$ and $P_{EO}(\alpha,z)$, which are the P functions of the excited even/odd coherent states from previously known states.[10]

B. *Q* function representation

The quasiprobability Q function, also known as the Husimi function, is given in the diagonal element of the density matrix ρ associated with the GEECS and GEOCS states,

$$Q_{GEE}(\alpha,z)=\frac{1}{\pi J^m(\alpha)}\sum_{s=0}^{m}\sum_{t=0}^{m}R_s^m(\mu^*,\nu^*,\alpha)S_t^m(\mu,\nu,\alpha^*)z^{*(m-s)}z^{(m-t)}$$
$$\times\{\exp[-|z-\alpha|^2]+(-1)^{s+t}\exp[-|z+\alpha|^2]+(-1)^t$$
$$\times\exp[-z^*(z-\alpha)-\alpha^*(z+\alpha)]+(-1)^s\exp[-z^*(z+\alpha)+\alpha^*(z-\alpha)]\}, \tag{48}$$

$$Q_{GEO}(\alpha,z)=\frac{1}{\pi K^m(\alpha)}\sum_{s=0}^{m}\sum_{t=0}^{m}R_s^m(\mu^*,\nu^*,\alpha)S_t^m(\mu,\nu,\alpha^*)z^{*(m-s)}z^{(m-t)}$$
$$\times\{\exp[-|z-\alpha|^2]+(-1)^{s+t}\exp[-|z+\alpha|^2]-(-1)^t$$
$$\times\exp[-z^*(z-\alpha)-\alpha^*(z+\alpha)]-(-1)^s\exp[-z^*(z+\alpha)+\alpha^*(z-\alpha)]\}. \tag{49}$$

Because the GEECS and GEOCS are superpositions of the coherent states $|\alpha\rangle$ and $|-\alpha\rangle$, a three-dimensional plot in phase space with respect to the complex number $z=x+iy$ of their $Q_{GEE}(\alpha,z)$ and $Q_{GEO}(\alpha,z)$ functions displays two peaks when $\arg\nu=\arg\mu$, $\arg\nu=-\arg\mu$, and $\alpha=\alpha_1+i\alpha_2$. Figures 1(a) and 1(b) show the $Q_{GEE}(\alpha,z)$ and $Q_{GEO}(\alpha,z)$ distributions, which can be seen even more clearly by projecting symmetrically about x onto a two-dimensional complex plane. However, we observe that for a given μ, ν, and m the functions $Q_{GEE}(\alpha,z)$ and $Q_{GEO}(\alpha,z)$ for a Schrödinger-cat-like state can be analytically derived from the definitions in (9) and (10). We see from Fig. 1(a) that $Q_{GEE}(\alpha,z)$ has two split peaks which then move in opposite directions with appropriate choices of μ and ν when m and $|\alpha|$ are fixed, and as the parameter ν increases ($\nu=-0.4,-0.6$, and -1), oscillations appear between the two peaks. As the value of ν increases, the oscillations become more pronounced and the peaks smaller. In Fig. 1(b) for the function $Q_{GEO}(\alpha,z)$, as the degree of excitation m increases the two peaks move in opposite directions while their height decreases and their distance becomes wider for $\nu=-0.8$ ($m=0,2$, and 4, respectively). No matter how the parameters ν, μ, and m are chosen for $\arg\alpha=\pi/2$, the $Q_{GEE}(\alpha,z)$ and $Q_{GEO}(\alpha,z)$ functions always exhibit some oscillatory behavior. This is related to the negative parts of the Wigner function since the Q function can be regarded as a smoothed Wigner function.

C. Wigner function representation

The Wigner function is also a useful measure for studying the nonclassical features of quantum states. The form through the density operator associated with the coherent state representation is given by

$$W(z)=\frac{2e^{2|z|^2}}{\pi^2}\int d^2\langle-\beta|\rho|\beta\rangle\exp[2(z\beta^*-z^*\beta)]. \tag{50}$$

Because the above case is an imaginary variable transformation in the complex plane, we can use integration and Leibnitz's formulas,

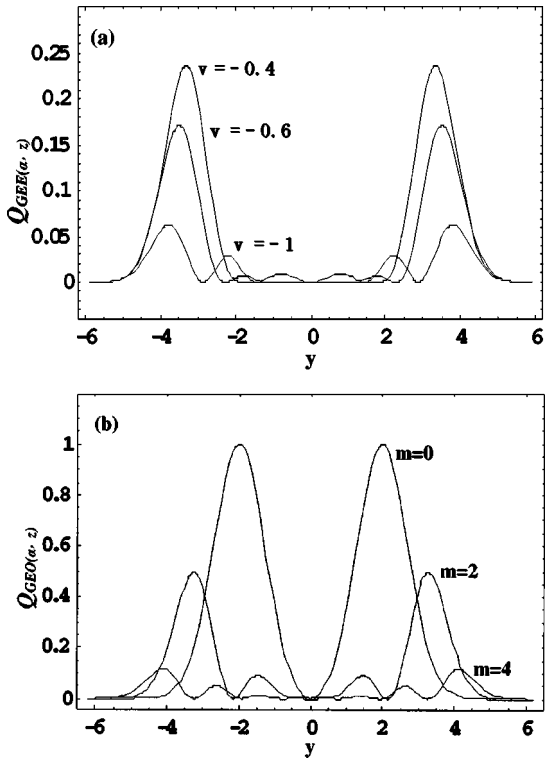

FIG. 1. The Q function of $Q_{GEE}(\alpha,z)$ and $Q_{GEO}(\alpha,z)$ in the case of $\alpha_1=0$, $\alpha_2=2$, $\arg\nu=\arg\mu$, for (a) $m=3$, $\nu=-0.4,-0.6,-1$ and (b) $\nu=-0.8$, $m=0,2,4$.

$$\int \frac{\mathrm{d}^2\beta}{\pi}[\zeta|\beta|^2+\xi^*|\beta|+\eta\beta^*]=\left(-\frac{1}{\zeta}\right)\exp\left(-\frac{\xi\eta}{\zeta}\right) \quad (\zeta\geqslant -1) \tag{51}$$

and

$$\left(\frac{\partial^{2n}}{\partial\xi^{*n}\partial\xi^n}\right)e^{-\xi^*\xi}=(-1)^n n!\,e^{-\xi^*\xi}L_n(-|\xi|^2). \tag{52}$$

From Eq. (50) and after performing a two-dimensional Fourier transformation, the $W_{GEE}(\alpha,z)$ and $W_{GEO}(\alpha,z)$ functions can be expressed in the following form:

$$\begin{aligned}W_{GEE}(\alpha,z)=&\frac{2e^{2|z|^2-|\alpha|^2}}{\pi J^m(\alpha)}\sum_{s=0}^{m}\sum_{t=0}^{m}R_s^m(\mu^*,\nu^*,\alpha)S_t^n(\mu,\nu,\alpha^*)\\&\times\{\exp[|\xi|^2]G_{m-t}^{m-s}[\xi^*,\xi,|\xi|^2]+(-1)^{s+t}\exp[|\eta|^2]G_{m-t}^{m-s}[\eta^*,\eta,|\eta|^2]+(-1)^t\\&\times\exp[-\eta^*\xi]G_{m-t}^{m-s}[\eta^*,\xi,\eta^*\xi]+(-1)^s\exp[-\xi^*\eta]G_{m-t}^{m-s}[\xi^*,\eta,\xi^*\eta]\},\end{aligned} \tag{53}$$

$$\begin{aligned}W_{GEO}(\alpha,z)=&\frac{2e^{2|z|^2-|\alpha|^2}}{\pi K^m(\alpha)}\sum_{s=0}^{m}\sum_{t=0}^{m}R_s^m(\mu^*,\nu^*,\alpha)S_t^n(\mu,\nu,\alpha^*)\\&\times\{\exp[|\xi|^2]G_{m-t}^{m-s}[\xi^*,\xi,|\xi|^2]+(-1)^{s+t}\exp[|\eta|^2]G_{m-t}^{m-s}[\eta^*,\eta,|\eta|^2]-(-1)^t\\&\times\exp[-\eta^*\xi]G_{m-t}^{m-s}[\eta^*,\xi,\eta^*\xi]-(-1)^s\exp[-\xi^*\eta]G_{m-t}^{m-s}[\xi^*,\eta,\xi^*\eta]\},\end{aligned} \tag{54}$$

where $\xi=2z-\alpha$, $\eta=2z+\alpha$, and

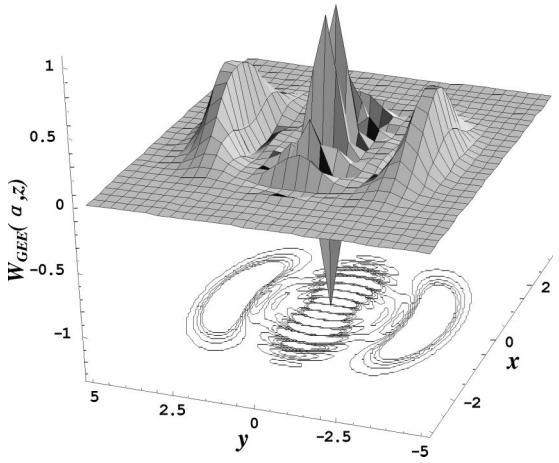

FIG. 2. The Wigner function $W_{GEE}(\alpha,z)$ in the case of $\alpha_1=0$, $\alpha_2=2$, $\nu=-0.1$, $\arg\nu=\arg\mu$ for $m=3$.

$$G_q^p(\xi,\eta^*,\eta^*\xi)=\begin{cases}(-1)^p p!\,\xi^{(q-p)}L_p^{(q-p)}(\eta^*\xi), & q\geqslant p,\\ (-1)^q q!\,\eta^{*(p-q)}L_q^{(p-q)}(\eta^*\xi), & q\leqslant p.\end{cases} \tag{55}$$

Exact analytical expressions for the generalized excited even/odd coherent states when ν, μ, and m are varied can be obtained from expressions (53) and (54). Let us look at the special case of $\arg\alpha=\arg(\alpha_1+i\alpha_2)=\pi/2$, i.e., corresponding to $\alpha_1=0,\alpha_2=2$. The nonclassical properties of the GEECS and GEOCS can be seen even more clearly by projecting the three-dimensional plots of $W_{GEE}(\alpha,z)$ and $W_{GEO}(\alpha,z)$ onto the two-dimensional (x,y) plane. Figures 2 and 3 show the distributions of the $W_{GEE}(\alpha,z)$ and $W_{GEO}(\alpha,z)$ contours for different values of ν, μ, m, and $|\alpha|$. We see that $W_{GEE}(\alpha,z)$ is a function of a complex number $z=x+iy$ when $\arg\nu=\arg\mu$. As the degree of excitation increases ($m>1$) the peak of the $W_{GEE}(\alpha,z)$ function begins to split into two peaks, which then move in opposite directions when $\nu=-0.1$ and $m=2$, as can be seen in Fig. 2. For the GEOCS state in Fig. 3, the $W_{GEO}(\alpha,z)$ function also splits into two peaks when m and $|\alpha|$ are fixed, and the distance between them increases as ν becomes more negative. Both sets of contours are symmetrical about the $y=0$ plane, exhibiting the two mirror-symmetrical Gaussian hills of the Wigner function distributions and reflecting the superposition of the Schrödinger cat-like state. At the center where the two peaks split there are marked oscillations. We see that the

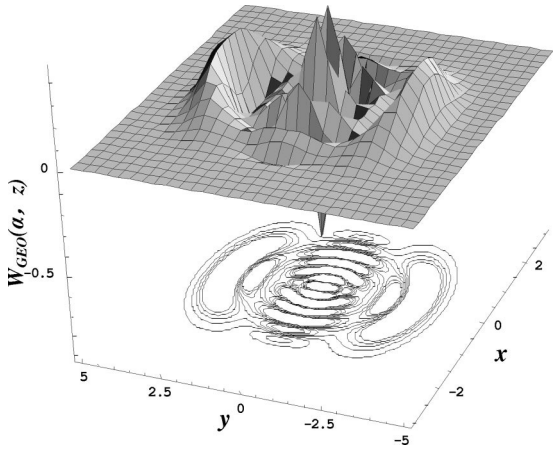

FIG. 3. The Wigner function $W_{GEO}(\alpha,z)$ in the case of $\alpha_1=0$, $\alpha_2=2$, $m=2$, $\arg\nu=\arg\mu$ for $\nu=-0.5$.

greater the value of m for the GEECS, the stronger the oscillation between the two highest peaks. On the other hand, the GEOCS state is also greatly affected by changes in ν and μ.

IV. CONCLUSION

By means of specific mathematical procedures we have obtained two new classes of quantum states in the coherent state representation. The general expressions for these states reduce to previously known quantum states for special values of the parameters given. For example, when $\nu=0$ and $\mu=1$, they reduce to the excited even/odd coherent states,[10] which further reduce to the even/odd coherent states when $m=0$.[1,2] Through numerical computation of various quantum properties, i.e., the P function, Q function, and Wigner function, we find that these new states exhibit highly nonclassical characteristics. The quantum interference patterns are very pronounced and narrow, while parts of the central region of the Wigner function are negative. It is obvious that these results all deviate considerably from a Gaussian distribution. The oscillatory behavior of the states is due to the structure of their formulation; since they are superpositions of the coherent states $|\alpha\rangle$ and $|-\alpha\rangle$ their probability distributions undergo destructive or constructive interference. We can also see that the interference effects are a consequence of the oscillatory nature of the associated Laguerre and Hermite polynomials, and the exponential factors which make up the functions $R_s^m(\mu^*,\nu^*,\beta), S_t^n(\mu,\nu,\alpha^*)$, and $G_q^p(\eta^*,\xi,\eta^*\xi)$ in the Wigner function.

(Received 11 November 2003; accepted 16 January 2004; published 31 March 2004)

We study transitions in the topological structure of a family of divergence-free vector fields $u(\cdot,t)$ near an interior point. It is shown that structural bifurcation occurs at t_0 if $u(\cdot,t_0)$ has an isolated degenerate singular point $x_0 \in \mathring{M}$ with zero index and nonzero Jacobian at x_0, and with nonzero acceleration in the direction normal to the (unique) eigenspace of the Jacobian. This result is carried out by analyzing the orbit structure of u near such an isolated degenerate interior singular point of $u(\cdot,t_0)$. Applications to typical interior separation phenomena in two-dimensional fluid flows are addressed as well. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1689005]

I. INTRODUCTION

The main objective of this paper is to derive a rigorous kinematic theory for the typical interior separation phenomena in two-dimensional fluid flows. This is part of a research program on the use of topological ideas to study the spatial–temporal structure of 2D incompressible fluid flows in physical space, along with its stability and bifurcations. This program consists of research in two areas: (a) the study of the topological structure of divergence-free vector fields, and its evolution in time or with respect to an arbitrary parameter, and (b) the study of the structure and evolution of velocity fields for 2D incompressible fluid flows governed by a class of equations that comprises the Navier–Stokes equations, the Euler equations, and the quasigeostrophic equations of rotating flows. The objectives of this research program are consistent with the program by Newton and his collaborators, using in particular the vorticity in their analysis; see Ref. 6 and the reference therein.

In this paper, we address structural bifurcation for a family of divergence-free vector fields $u(\cdot,t)$ near an interior point. Structural bifurcation near boundary singular points was carried out by the authors in collaboration with Michael Ghil, leading to a rigorous characterization for boundary layer separation for 2D incompressible fluid flows; see Refs. 2 and 3 and the survey article[5] for details.

More precisely, we shall show that structural bifurcation occurs at t_0 if $u(\cdot,t_0)$ has an isolated degenerate singular point $x_0 \in \mathring{M}$ with zero index and nonzero Jacobian at x_0, and with nonzero acceleration in the direction normal to the (unique) eigenspace of the Jacobian.

Technically speaking, the main results are carried out by analyzing the orbit structure of u near such an isolated degenerate interior singular point of $u(\cdot,t_0)$. We now summarize the analysis. For this purpose, we consider the Taylor expansion of the divergence-free vector fields $u(\cdot,t)$ at t_0 $(0<t_0<T)$

$$u(x,t)=u^0(x)+(t-t_0)u^1(x)+o(|t-t_0|),$$

a)Electronic mail: showang@indiana.edu

$$u^0(x)=u(x,t_0),$$

$$u^1(x)=\frac{\partial}{\partial t}u(x,t_0).$$

First we observe by the structural stability theorem, Theorem 2.4, that structural bifurcation can only occur near a degenerate singular point x_0, i.e., the determinant of the Jacobian of u at x_0 is zero: $\det Du(x_0)=0$. Generically, we only have to examine then the case where Jacobian itself is not zero: $Du(x_0)\neq 0$; see Theorem 5.5.

Second, further analysis shows that a degenerate singular point $x_0\in\mathring{M}$ of $u\in D^r(TM)$ $(r\geqslant 1)$ with nonzero Jacobian $Du(x_0)\neq 0$ can only be one of the three cases:

(1) a degenerate center,
(2) a degenerate saddle such that the four orbits connected to x_0 are tangent to each other at x_0, and
(3) a point with $\mathrm{ind}(u,x_0)=0$ such that the angle between the two orbits connected to x_0 is zero.

Again, the genericity result given in Theorem 5.5 shows that we only have to consider the structural bifurcation in the third case, i.e., near an interior degenerate singular point such that $\mathrm{ind}(u,x_0)=0$ and the angle between the two orbits connected to x_0 is zero.

Third, when $Du(x_0)\neq 0$ but $\det Du(x_0)=0$, there is a unique eigendirection of $Du(x_0)$ corresponding to the zero eigenvalue. Let e_1 be the eigenvector, and e_2 is orthogonal to e_1. Then we are able to derive the main theorems of this paper, Theorems 4.4 and 4.5. In addition to detailed characterization of the structural transition near the bifurcation point, in particular, we are able to show that structural bifurcation occurs at (t_0,x_0) if x_0 is an isolated degenerate singular point of $u^0(x)$, and

$$\mathrm{ind}(u^0,x_0)=0,$$

$$Du^0(x_0)\neq 0,$$

$$u^1(x_0)\cdot e_2\neq 0.$$

Fourth, the bifurcation obtained in these two theorems corresponds directly to typical interior separation phenomena in two-dimensional fluid flows, and is generic; see Theorems 5.2 and 5.5.

The paper is organized as follows. In Sec. II, we recall some preliminaries, including a structural stability theorem, and a singularity classification theory for 2D divergence-free vector fields. Section III classifies interior degenerate singular points, and identifies some useful and easy to verify kinematic conditions. Section IV states and proves the main structural bifurcation theorems. Genericity and connections to interior separation phenomena of fluid flows are given in Sec. V.

II. PRELIMINARIES

We first recall some basic facts and definitions on structural stability and bifurcation of divergence-free vector fields. Let $M\subset\mathbb{R}^2$ be a closed and bounded domain with C^r $(r\geqslant 1)$ boundary ∂M. Let TM be the tangent bundle of M, and $C^r(TM)$ be the space of all C^r vector fields on M. Let

$$D^r(TM)=\{v\in C^r(TM)\,|\,v_n|_{\partial M}=0,\ \mathrm{div}\,v=0\},$$

where n is the unit outward normal vector on ∂M and $v_n=v\cdot n$.

The structural stability theorems of divergence-free vector fields with various boundary conditions, obtained by the authors in Ref. 4, are useful in the study of structural bifurcation. Here, we only introduce the structural stability theorem in $D^r(TM)$ (for divergence-free vector fields with no-normal flows).

Definition 2.1: Two vector fields $u,v \in D^r(TM)$ are called topologically equivalent in $D^r(TM)$ if there exists a homeomorphism of $\varphi: M \to M$, which maps orbits of u to orbits of v and preserves their orientation.

Definition 2.2: A vector field $v \in$ is called structurally stable in $D^r(TM)$ if there exists a neighborhood $\mathcal{O} \subset D^r(TM)$ of v such that for any $u \in \mathcal{O}$, u and v are topologically equivalent.

Definition 2.3: Let $u \in C^1([0,T], D^r(TM))$. We say that $u(x,t)$ has a bifurcation in its local structure in a neighborhood $U \subset M$ of x_0 at t_0 $(0<t_0<T)$ if, for any $t^- < t_0$ and $t_0 < t^+$ with t^- and t^+ sufficiently close to t_0, the vector fields $u(\cdot,t^-)$ and $u(\cdot,t^+)$ are not topologically equivalent locally in $U \subset M$, and we say that $u(\cdot,t)$ has a bifurcation at t_0 in its global structure if $U = M$.

A point $p \in M$ is called a singular point of $u \in D^r(TM)$ if $u(p)=0$; a singular point p of u is called nondegenerate if the Jacobian matrix $Du(p)$ is invertible; u is called regular if all singular points are nondegenerate. Then the following theorem provides necessary and sufficient conditions for structural stability of a divergence-free vector field in $D^r(TM)$.

Theorem 2.4 (Ma and Wang[4]): *A divergence-free vector field $u \in D^r(TM)$ $(r \geqslant 1)$ is structurally stable in $D^r(TM)$ if and only if*

(1) u is regular;
(2) all interior saddle points of u are self-connected; and
(3) each saddle point of u on ∂M is connected only to saddle points on the same connected component of ∂M.

Moreover, the set of all structurally stable vector fields is open and dense in $D^r(TM)$.

From the above definitions and the structural stability theorem, the local structural bifurcation can only occur at degenerate singularity points. For bifurcation near boundary points, we refer the interested reader to Ref. 2. Here in this paper we address the bifurcation near an interior singular point.

For this purpose, let $p \in M$ be an isolated singular point of $v \in C_n^r(TM)$; then

$$\mathrm{ind}(v,p) = \deg(v,p),$$

where $\deg(v,p)$ is the Brouwer degree of v at p.

Let $p \in \partial M$ be an isolated singular point of v, and $\tilde{M} \subset \mathbb{R}^2$ be an extension of M, i.e., $M \subset \tilde{M}$ such that $p \in \tilde{M}$ is an interior point of $\tilde{M}$. In a neighborhood of p in $\tilde{M}$, v can be extended by reflection to $\tilde{v}$ such that p is an interior singular point of $\tilde{v}$, thanks to the no-normal flow condition, i.e., $v \cdot n|_{\partial M} = 0$. Then we define the index of v at $p \in \partial M$ by

$$\mathrm{ind}(v,p) = \tfrac{1}{2}\,\mathrm{ind}(\tilde{v},p).$$

Let $p \in M$ be an isolated singular point of $v \in C_n^r(TM)$. An orbit γ of v is said to be a stable orbit (respectively, an unstable orbit) connected to p, if the limit set $\omega(x)=p$ [respectively, $\alpha(x)=p$] for $x \in \gamma$.

Theorem 2.5 (Ref. 2): *Let $p \in M$ be an isolated singular point of $v \in D^r(TM)$, $r \geqslant 1$. Then p is connected only to a finite number of orbits and the stable and unstable orbits connected to p alternate when tracing a closed curve around p. Furthermore,*

(1) when $p \in \mathring{M}$, p has $2n$ $(n \geqslant 0)$ orbits, n of which are stable, and the other n unstable, while the index of p is

$$\mathrm{ind}(v,p) = 1 - n,$$

(2) when $p \in \partial M$, p has $n+2$ $(n \geqslant 2)$ orbits, two of which are on the boundary ∂M, and the index of p is

$$\mathrm{ind}(v,p) = -\frac{n}{2}.$$

III. INTERIOR DEGENERATE SINGULARITIES

A. Characterization of degenerate singularities with nonzero Jacobian

The structural stability theorem (Theorem 2.4) suggests studying the structure of divergence-free vector fields near degenerate singular points. To this end, we now introduce some lemmas characterizing degenerate interior singularities with nonzero Jacobians, which are useful for studying interior structural bifurcation.

Lemma 3.1: Let $u \in D^r(TM)$ $(r \geqslant 1)$, and $x_0 \in \mathring{M}$ be an isolated singular point of u. If the index $\mathrm{ind}(u,x_0) \neq 1,0,-1$, *then the Jacobian matrix*

$$Du(x_0) = 0. \tag{3.1}$$

Proof: By Theorem 2.5, the index of an interior singular point of a divergence-free vector field is determined by the $2n$ $(n \geqslant 0)$ orbits connected to x_0, i.e., $\mathrm{ind}(u,x_0) = 1-n$. Hence, by assumption, $n \geqslant 3$.

Let γ be an orbit of u connected to x_0. Let (x_1,x_2) be the orthogonal coordinate system with x_0 as its origin, and with its x_1-axis tangent to γ at x_0. Then u can be expressed locally by

$$\begin{aligned} u(x) &= \begin{pmatrix} a & b \\ c & -a \end{pmatrix} \begin{pmatrix} x_1 \\ x_2 \end{pmatrix} + o(|x|), \\ Du(x_0) &= Du(0) = \begin{pmatrix} a & b \\ c & -a \end{pmatrix}. \end{aligned} \tag{3.2}$$

We shall prove that $a = b = c = 0$ in several steps as follows.

Step 1: We show that $a = c = 0$. By definition, the x_1-axis is tangent to γ at $x_0 = 0$, which yields

$$\lim_{\substack{x \in \gamma \\ x \to 0}} \frac{u_2(x)}{u_1(x)} = 0. \tag{3.3}$$

In addition, for $(x_1,x_2) \in \gamma$, $x_2 = o(|x_1|)$. Hence, we infer from (3.2) and (3.3) that

$$\lim_{\substack{x \in \gamma \\ x \to 0}} \frac{u_2(x)}{u_1(x)} = \lim_{\substack{x \in \gamma \\ x \to 0}} \frac{cx_1 - ax_2 + o(|x|)}{ax_1 + bx_2 + o(|x|)} = \lim_{\substack{x \in \gamma \\ x_1 \to 0}} \frac{cx_1 + o(|x_1|)}{ax_1 + o(|x_1|)} = \frac{c}{a} = 0.$$

Hence $c = 0$. By $\mathrm{ind}(u,x_0) \neq 1,-1$, the singular point x_0 of u is degenerate. Therefore $c = 0$ implies that $a = 0$.

Hence when $\mathrm{ind}(u,x_0) \neq 1,-1$, u can be expressed near $x_0 = 0$ as

$$\begin{aligned} u_1(x) &= bx_2 + o(|x|), \\ u_2(x) &= o(|x|). \end{aligned} \tag{3.4}$$

Step 2: Consider the case where there is another orbit γ_1 of u connected to x_0, and the angle between γ_1 and γ is θ different from 0 and π. Then by (3.4) we deduce that

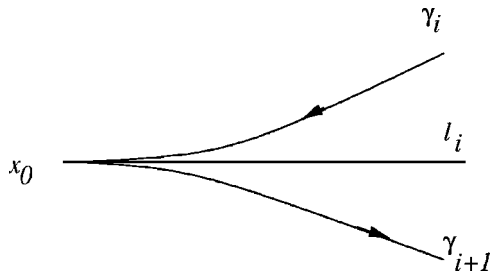

FIG. 1. Sketch illustrating the proof of Lemma 3.1.

$$\lim_{\substack{x\in\gamma_1\\ x\to 0}}\frac{u_2(x)}{u_1(x)}=\lim_{\substack{x\in\gamma_1\\ x\to 0}}\frac{o(|x|)}{bx_2+o(|x|)}=\tan\theta\neq 0$$

which yields that $b=0$. Hence (3.1) holds true in this case.

Step 3: Consider the case where all orbits connected to x_0 are tangent to γ at x_0. Let $O\in M$ be a sufficiently small neighborhood of x_0, F_i $(1\leqslant i\leqslant 2n)$ be the domains in O enclosed by the orbits connected to x_0, and the θ_i be the angle of the boundary of F_i at x_0. It is easy to see that in each F_i with $\theta_i=0$, there exists at least a curvilinear segment ℓ_i, with x_0 being its end point, such that $u_1(x)=0$, $x\in\ell_i$ (see Fig. 1). Hence, there are at least $2(n-1)$ curvilinear segments in O with x_0 as their common end point where $u_1=0$. On the other hand, by the implicit function theorem, if $b\neq 0$ in (3.4), then there is a unique curve $L\subset O$ with $x_0\in L$ such that $u_1(x)=0$, $x\in L$, i.e., there are only two line segments $L=\ell_1\cup\ell_2$ in O along which $u_1=0$; hence if $n\geqslant 3$ it follows that $b=0$ and (3.1) holds true.

This completes the proof of this lemma. □

Lemma 3.2: Let $u\in D^r(TM)$ $(r\geqslant 1)$, and $x_0\in\mathring{M}$ be an isolated singular point of u. If the index $\mathrm{ind}(u,x_0)=0$, *and the angle θ between the two orbits connected to x_0 is different from* 0, *then (3.1) holds true.*

Proof: By Step 2 in the proof of Lemma 3.1, it suffices to prove (3.1) when $\theta=\pi$. In this case the two orbits γ_1 and γ_2 connected to x_0 form a curve Γ with the x_1-axis tangent to Γ at x_0. By Theorem 2.5, it is obvious that for any $x_2>0$ sufficiently small, we have

$$\mathrm{sign}\,u_1(0,x_2)=\mathrm{sign}\,u_1(0,-x_2),$$

which, together with (3.4), yields that $b=0$. This proof is complete. □

From Lemma 3.1, we see that a degenerate singular point $x_0\in\mathring{M}$ of $u\in D^r(TM)$ $(r\geqslant 1)$ with nonzero Jacobian $Du(x_0)\neq 0$ can only be one of the three cases:

(1) a degenerate center;
(2) a degenerate saddle such that the four orbits connected to x_0 are tangent to each other at x_0; and
(3) a point with $\mathrm{ind}(u,x_0)=0$ such that the angle between the two orbits connected to x_0 is zero.

We now take a further examination of these cases.

Let $x_0\in\mathring{M}$ be an isolated degenerate singular point of $u\in D^r(TM)$ $(r\geqslant 1)$ with nonzero Jacobian, $Du(x_0)\neq 0$. Since $Du(x_0)$ is a degenerate matrix, $Du(x)$ has an eigenvector e_1 satisfying

$$Du(x_0)e_1=0,\quad |e_1|=1. \tag{3.5}$$

Let e_2 be a unit vector, which is orthogonal to e_1, and satisfies that

$$Du(x_0)e_2=\alpha e_1, \tag{3.6}$$

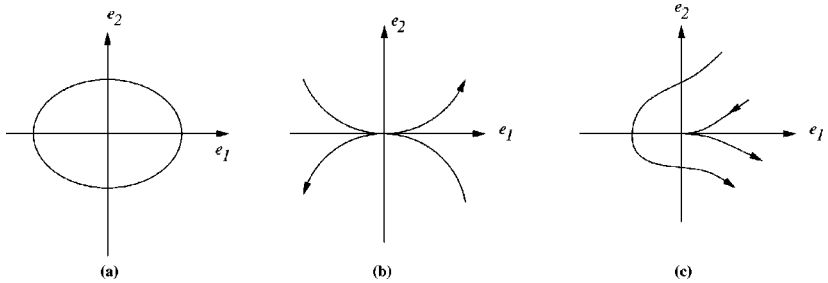

FIG. 2. (a) The case with index 1, (b) the case with index -1, and (c) the case with index 0.

for some constant $\alpha \neq 0$.

For simplicity, we always take the orthogonal coordinate system (x_1, x_2) with the origin at x_0, x_1-axis and x_2-axis pointing, respectively, in the e_1 and e_2 directions. In this case, the matrix $Du(x_0)$ and the vectors e_1, e_2 can be written as follows:

$$Du(x_0) = Du(0) = \begin{pmatrix} 0 & \alpha \\ 0 & 0 \end{pmatrix}, \quad \alpha \neq 0,$$
$$e_1 = (1,0), \quad e_2 = (0,1). \tag{3.7}$$

Geometrically, e_1 and e_2 can be illustrated as in Fig. 2.

B. Index and kinematic conditions

We now make connections between the index of u at x_0 and different orders of u in its Taylor expansion near x_0. Let $x_0 \in \mathring{M}$ be an isolated degenerate singular point of u, and

$$Du(x_0) \neq 0, \tag{3.8}$$

$$\frac{\partial^m (u(x_0) \cdot e_2)}{\partial e_1^m} \begin{cases} = 0, & 1 \leqslant m < n, \\ \neq 0, & m = n. \end{cases} \tag{3.9}$$

Under the conditions (3.8) and (3.9), the vector field $u(x)$ has the Taylor expansion, by (3.7), as follows:

$$u(x) = \begin{cases} \alpha x_2 + f(x_1) + x_2 g_1(x), \\ \beta x_1^n - x_2 f'(x_1) + x_2^2 g_2(x) + o(|x_1|^n), \end{cases} \tag{3.10}$$

where $\alpha, \beta \neq 0$, $f(x_1) = o(|x_1|)$, and $g_i(0) = 0$ $(i = 1,2)$. Let $k = \deg f$ be defined by

$$\lim_{z \to 0} \frac{f(z)}{z^k} = \lambda \neq 0, \quad k \leqslant \infty.$$

Lemma 3.3: Let $x_0 \in \mathring{M}$ be an isolated degenerate singular point of u satisfying (3.8) and (3.9).

(1) If $2k > n+1$, then

$$\operatorname{ind}(u, x_0) = \begin{cases} 0, & \text{as } n = \text{even}, \\ -1, & \text{as } n = \text{odd and } \alpha \cdot \beta > 0 \text{ in (3.10)}, \\ 1, & \text{as } n = \text{odd and } \alpha \cdot \beta < 0. \end{cases}$$

(2) If either $2k < n+1$, or $2k = n+1$ and $\alpha\beta \neq -k\lambda^2$, then $\operatorname{ind}(u, x_0) = -1$.

Proof: Proof of Assertion (1). Let

$$u_t(x)=\begin{cases}\alpha x_2+t[f(x_1)+x_2g_1(x)],\\ \beta x_1^n+t[-x_2f'(x_1)+x_2^2g_2(x)+o(|x_1|^n)],\end{cases}$$

where $0\leqslant t\leqslant 1$. Since $2k-1>n$, it is easy to see that there exists a neighborhood $U\subset M$ of x_0 $(=0)$, such that $u_t(x)$ has only a singular point $x=0$ in U for all $t\in[0,1]$. By the homotopy invariance of the index, we derive that

$$\mathrm{ind}(u_0,x_0)=\mathrm{ind}(u_1,x_0)=\mathrm{ind}(u,x_0). \tag{3.11}$$

In a neighborhood of $x=0$, orbits of $u_0=(\alpha x_2,\beta x_1^n)$ are given by the following equations:

$$\frac{\alpha}{2}x_2^2-\frac{\beta}{n+1}x_1^{n+1}=C,\quad 0\leqslant|C|<\delta. \tag{3.12}$$

Obviously, we can see from (3.12) that if $n=$ even, the flow of u_0 in a neighborhood of $x=0$ is as shown in Fig. 2(c). If $n=$ odd, when $\alpha\cdot\beta>0$ (respectively, $\alpha\cdot\beta<0$) the flows of u_0 looks as shown in Fig. 2(b) [respectively, as shown in Fig. 2(a)]. Thus, we derive from (3.11) this claim.

Proof of assertion (2): We take $\varepsilon>0$ sufficiently small, and consider singular points of the following vector field near $x=0$:

$$u_\varepsilon=\begin{cases}\alpha x_2+f(x_1)+x_2g_1(x),\\ \beta x_1^n-x_2f'(x_1)+x_2^2g_2(x)+o(|x_1|^n)-\varepsilon.\end{cases}$$

By assumption, f can be expressed near $x=0$ by

$$f(x_1)=\lambda x_1^k+o(|x_1|^k),\quad \lambda\neq 0,\ 1<k\leqslant\frac{n+1}{2}.$$

Thus, singular points of u_ε in a small neighborhood of $x=0$ satisfy the equation below

$$\begin{aligned}x_2&=-\frac{\lambda}{\alpha}x_1^k+o(|x_1|^k),\\ \beta x_1^n&+\frac{1}{\alpha}k\lambda^2x_1^{2k-1}=\varepsilon+o(|x_1|^{2k-1}).\end{aligned} \tag{3.13}$$

Obviously, when $2k-1<n$, or $2k-1=n$ and $\alpha\beta\neq-k\lambda^2$, (3.13) has a unique solution

$$x_\varepsilon\sim\left(C\varepsilon^{1/(2k-1)},-\frac{\lambda}{\alpha}C^k\varepsilon^{k/(2k-1)}\right),$$

where

$$C=\begin{cases}\alpha k^{-1}\lambda^{-2},\quad \text{as } 2k-1<n,\\ \alpha(\alpha\beta+\lambda^2)^{-1},\quad \text{as } 2k-1=n \text{ and } \alpha\beta\neq k\lambda^2.\end{cases}$$

It is easy to check that

$$\mathrm{sign}\det Du_\varepsilon(x_\varepsilon)=-1, \tag{3.14}$$

for any $\varepsilon>0$ sufficiently small. By the invariance of index sums in a small domain with a perturbation we refer from (3.14) that $\mathrm{ind}(u,x_0)=-1$. The proof of this lemma is complete. □

IV. STRUCTURAL BIFURCATION NEAR INTERIOR SINGULAR POINTS WITH INDEX ZERO

A. Main theorems

Let $u \in C^1([0,T],D^r(TM))$ $(r \geqslant 1)$ be a one-parameter family of divergence-free vector fields. We consider the Taylor expansion of $u(x,t)$ at t_0 $(0<t_0<T)$,

$$u(x,t)=u^0(x)+(t-t_0)u^1(x)+o(|t-t_0|),$$

$$u^0(x)=u(x,t_0), \tag{4.1}$$

$$u^1(x)=\frac{\partial}{\partial t}u(x,t_0).$$

We start with the following assumptions for the structural bifurcation.

Assumption (H_1)*:* Let $x_0 \in \mathring{M}$ be an isolated degenerate singular point of $u^0(x)$. Suppose that

$$\mathrm{ind}(u^0,x_0)=0, \tag{4.2}$$

$$Du^0(x_0)\neq 0, \tag{4.3}$$

$$u^1(x_0)\cdot e_2 \neq 0, \tag{4.4}$$

where e_2 is the unit vector defined as in (3.6).

Assumption (H_2)*:* Under the conditions of Assumption (H_1), we also assume that $u^0 \in C^n$ near $x_0 \in \mathring{M}$ for some $n \geqslant 2$, and

$$\frac{\partial^k (u^0(x_0)\cdot e_2)}{\partial e_1^k}\begin{cases} =0, & \text{for } 1\leqslant k<n=\text{even},\\ \neq 0, & \text{for } k=n=\text{even}. \end{cases} \tag{4.5}$$

Remark 4.1: The conditions (4.2) and (4.3) imply by Lemma 3.2 that the flows of u^0 near x_0 is as shown in Fig. 2(c), i.e., both orbits of u^0 connected to x_0 are tangent to each other at x_0, and the eigenvector e_1 of $Du(x_0)$ is their common tangent vector. We shall see later that the conditions (4.2) and (4.3) are generic for the interior structural bifurcation.

Remark 4.2: In view of fluid mechanics applications, condition (4.4) is equivalent to nonzero acceleration of the flow in the orthogonal direction to the eigenvector e_1 of $Du(x_0)$. This is a natural condition for the structural bifurcation.

Remark 4.3: Condition (4.5) is a technical condition, which by Lemma 3.3 ensures the regularity of the bifurcated singular points of $u(x,t)$ from (x_0,t_0). In addition, from (3.7) we can see that the integer number n satisfying (4.5) must be $n \geqslant 2$.

The interior structural bifurcation of $u(x,t)$ near a singular point with index zero is described by the following theorems.

Theorem 4.4: *Let* $u \in C^1([0,T],D^r(TM))$ $(r \geqslant 1)$ *satisfy Assumption* (H_1)*. Then*

(1) the vector field u has a bifurcation in its local structure at (x_0,t_0)*. More precisely,* $u(x,t)$ *has no singular point in a small neighborhood of* x_0 *for any* $t<t_0$ *(or* $t>t_0$*) sufficiently close to* t_0*, and* $u(x,t)$ *bifurcates at least two singular points from* x_0 *as* $t>t_0$ *(or* $t<t_0$*), and*

(2) if $x_0 \in \mathring{M}$ *is a unique singular point with index zero of* u^0*, then* $u(x,t)$ *has a bifurcation in its global structure at* $t=t_0$*.*

Theorem 4.5: *Let* $u \in C^1([0,T],D^r(TM))$ $(r \geqslant 1)$ *satisfy Assumption* (H_2)*. Then,* $u(x,t)$ *bifurcates from* (x_0,t_0) *exactly two nondegenerate singular points, one of which is a center and another is a saddle.*

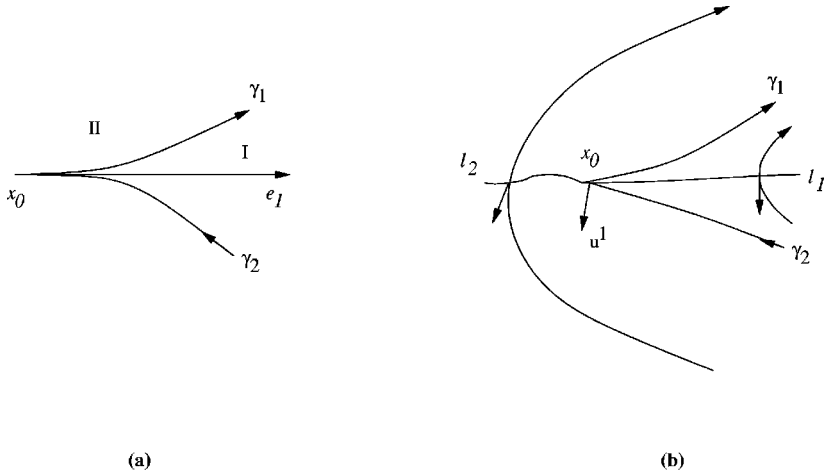

FIG. 3. Sketch illustrating the proof of Theorem 4.4.

Remark 4.6: Both Theorems 4.4 and 4.5 study structural bifurcation of u near an interior point x_0 with $\mathrm{ind}(u^0,x_0)=0$. When $\mathrm{ind}(u^0,x_0)$ is different from zero, interior structural bifurcation may not occur as we shall see in Examples 5.6 and 5.7. In addition, Theorem 5.5 shows that the bifurcation given in Theorems 4.4 and 4.4 is generic.

This is quite different from the structural bifurcation near a boundary singular point; see Refs. 2 and 3. We have shown in Refs. 2 and 3 that under suitable necessary conditions, $u(x,t)$ will always be a structural bifurcation near a boundary singular point with index different from $-1/2$. Reference 2 considers vector fields with free-slip boundary conditions, while Ref. 3 deals with vector fields with Dirichlet boundary conditions, which is related to boundary layer separation problems in viscous fluid flows.

B. Proof of Theorem 4.4

To investigate the structural bifurcation of $u(x,t)$ at t_0, by the Taylor expansion (4.1) and condition (4.4) it suffices to consider only the topological structure of the first-order approximation $u^0 \pm \varepsilon u^1$ of (4.1) for $\varepsilon>0$ sufficiently small.

By Lemma 3.2, let γ_1 and γ_2 be the two orbits of $u^0(x)$ connected to $x_0 \in \mathring{M}$. The eigenvector e_1 of $Du^0(x_0)$ is a common tangent vector of γ_1 and γ_2 at x_0 [see Fig. 3(a)].

Both orbits γ_1 and γ_2 divide a neighborhood of x_0 into open domains I and II as shown in Fig. 3(a). Since the angles between e_1 and the vectors of u^0 on γ_1 and γ_2 vary from 0 to π, and by assumption that angle θ between e_1 with $u^1(x_0)$ satisfies $0<\theta<\pi$, there exist curves ℓ_1 in domain I and curve ℓ_2 in domain II connected to x_0, such that u^1 are parallel to u^0 on ℓ_1 and ℓ_2 [see Fig. 3(b)]. Obviously the singular points of $u^0 \pm \varepsilon u^1$ are only on the curves as ℓ_1 and ℓ_2. Without loss of generality, we assume that u^0 and u^1 have a reverse orientation on ℓ_1 and ℓ_2, i.e., u^0 and $-\varepsilon u^1$ have the same orientation on ℓ_1 and ℓ_2. By condition (4.4) it follows that $u^0 - \varepsilon u^1$ has no singular points in ℓ_1 and ℓ_2, and therefore has no singular points in a neighborhood of x_0. Because $x_0 \in \mathring{M}$ is an isolated singular point of u^0, the values $|u^0(x)|$ are variant from 0 to a $\delta>0$ sufficiently small on ℓ_1 and ℓ_2, i.e.,

$$0<|u^0(x)|<\delta \quad \forall\ x \in \ell_1 \cup \ell_2,$$
$$\sup_{\ell_1 \cup \ell_2}|u^0|=\delta, \quad \inf_{\ell_1 \cup \ell_2}|u^0|=0. \tag{4.6}$$

It follows from (4.6) that there is an $\varepsilon_0>0$ sufficiently small such that for any $0<\varepsilon<\varepsilon_0$ the vector field $u^0+\varepsilon u^1$ has at least a singular point on each of ℓ_1 and ℓ_2, i.e., $u^0+\varepsilon u^1$ has at least two singular points near x_0. Thus, $u^0+\varepsilon u^1$ and $u^0-\varepsilon u^1$ are not topologically equivalent in a neighborhood of x_0. The first assertion is proved.

Obviously, if x_0 is a unique singular point of $u^0(x)$ with index zero, then $u^0+\varepsilon u^1$ and $u^0-\varepsilon u^1$ are not topologically equivalent on M. Hence, $u(x,t)$ has a globally structural bifurcation at $t=t_0$. This theorem is proved. □

C. Proof of Theorem 4.5

By Assumption (H_2) and Lemma 3.3 the vector field $u^0(x)$ has the Taylor expansion at x_0 $(x=0)$ as follows:

$$u^0(x)=\begin{cases}\alpha x_2+f(x_1)+x_2g_1(x),\\ \beta x_1^{2m}-x_2f'(x_1)+x_2g_2(x)+o(|x_1|^{2m}),\end{cases} \tag{4.7}$$

where $\alpha\neq 0$, $\beta\neq 0$, and

$$\begin{aligned} &f(x_1)=o(|x_1|^{m+1/2}),\\ &f'(x_1)=o(|x_1|^{m-1/2}),\\ &g_i(0)=0 \quad (i=1,2).\end{aligned} \tag{4.8}$$

By (4.4), we have

$$u^1(x)=\begin{cases}\lambda_1+h_1(x),\\ \lambda_2+h_2(x),\end{cases} \tag{4.9}$$

where $\lambda_2\neq 0$ and $h_i(x)=O(|x|)$, $i=1,2$.

By Theorem 4.4, one of $u^0\pm\varepsilon u^1$ has no singular points, and another has at least two singular points near x_0 for all $\varepsilon>0$ sufficiently small. We assume that $u^0-\varepsilon u^1$ has singular points, i.e., $\beta>0$ in (4.7) and $\lambda_2>0$ in (4.9). We need to prove that the equations below have exactly two solutions

$$\alpha x_2+x_2g_1(x)=\lambda_1\varepsilon+\varepsilon h_1(x)-f(x_1), \tag{4.10}$$

$$\beta x_1^{2m}-x_2f'(x_1)+x_2^2g_2(x)=o(|x_1|^{2m})=\lambda_2\varepsilon+\varepsilon h_2(x). \tag{4.11}$$

By the implicit function theorem, we derive from (4.8) and (4.10) that

$$\begin{aligned} &x_2=\alpha^{-1}\lambda_1\varepsilon-f(x_1)+G(\varepsilon,x_1),\\ &G(\varepsilon,x_1)=o(|\varepsilon|,|x_1|^{m+1/2}).\end{aligned} \tag{4.12}$$

Setting (4.12) in (4.11), we get the algebraic equation

$$\beta x_1^{2m}=\lambda_2\varepsilon+\alpha^{-1}\lambda_1\varepsilon f'(x_1)+\varepsilon\cdot O(|x|)+o(|\varepsilon|,|x_1|^{2m}), \tag{4.13}$$

where $\beta,\lambda_2>0$. It is clear that for any $\varepsilon>0$ sufficiently small, the equation (4.13) has exactly two solutions

$$x_1=\pm(\beta^{-1}\lambda_2)^{1/2m}\varepsilon^{1/2m}+o(\varepsilon^{1/2m}).$$

Thus, we deduce that the vector field $u^0-\varepsilon u^1$ has exactly two singular points $x(\varepsilon)=(x_1(\varepsilon),x_2(\varepsilon))$ as follows:

$$x_1^{\pm}(\varepsilon)=\pm(\beta^{-1}\lambda_2)^{1/2m}\varepsilon^{1/2m}+o(\varepsilon^{1/2m}),$$
$$x_2^{\pm}(\varepsilon)=\alpha^{-1}\lambda_1\varepsilon+o(\varepsilon,|x_1^{\pm}|^{m+1/2}). \tag{4.14}$$

Finally, we shall show that $x^{\pm}(\varepsilon)$ are nondegenerate for all $\varepsilon>0$ sufficiently small. By $\operatorname{div} u=0$, we have

$$\begin{aligned}\det D(u^0-\varepsilon u^1)_{x=x(\varepsilon)}&=-\left(\frac{\partial}{\partial x_1}(u_1^0-\varepsilon u_1^1)\right)^2-\frac{\partial}{\partial x_2}(u_1^0-\varepsilon u_1^1)\cdot\frac{\partial}{\partial x_1}(u_2^0-\varepsilon u_2^1)\\&=[\text{by (4.8) and (4.14)}]\\&=\pm 2m\alpha\beta(\beta^{-1}\lambda_2)^{(2m-1)/2m}\varepsilon^{(2m-1)/2m}+o(\varepsilon^{(2m-1)/2m}),\end{aligned}$$

which yields that

$$\det D(u^0-\varepsilon u^1)\begin{cases}>0, & \text{as } x=x^-,\\ <0, & \text{as } x=x^+.\end{cases}$$

Thus, we prove that $u^0-\varepsilon u^1$ has exactly two singular points x^+ and x^- for any $\varepsilon>0$ sufficiently small, and x^- is a center, x^+ is a saddle, which are nondegenerate. This proof is complete. □

V. APPLICATIONS TO INTERIOR SEPARATION OF FLUID FLOWS

A. Interior separation of fluid flows

We start with a typical example, illustrating how structural bifurcation occurs in the interior of fluid flows.

Let $u\in C^1([0,T],D^r(TM))$, and $x_0\in\mathring{M}$ be an isolated singular point of $u^0(x)=u(x,t_0)$, $0<t_0<T$.

Example 5.1: Consider the case where the index of $u^0(x)$ at the singular point $x_0\in\mathring{M}$ is zero, and the Jacobian matrix at x_0 is nonzero, i.e.,

$$\operatorname{ind}(u^0,x_0)=0,\quad Du^0(x_0)\neq 0.$$

The structural bifurcation occurs as shown in Fig. 4, which corresponds to interior separation phenomena in fluid mechanics.

When $t=t_0-\varepsilon$ with $\varepsilon>0$ small, the flow of $u(x,t_0-\varepsilon)$ given by Fig. 4(a) exhibits no singular points in a neighborhood of x_0. At $t=t_0$, $u^0=u(x,t_0)$ is given by Fig. 4(b), which has an isolated singular point $x_0\in\mathring{M}$ with index zero. When $t=t_0+\varepsilon$ for $\varepsilon>0$ small, $u(x,t_0+\varepsilon)$ is given by either Fig. 4(c) or Fig. 4(c′) or even more complicated circulation patterns in the back flow region. As we shall see in Theorem 5.5, the flow pattern given by Fig. 4(c) is generic. In other words, the flow transition from Fig. 4(a), to Fig. 4(b), and then to Fig. 4(c), or vice versa, is in general the pattern transition obtained both experimentally and numerically. For instance, in the axisymmetric plume shown Fig. 5, which is reproduced from Ref. 1, the three ''bubbles'' were caused by interior separation as described here.

We now address interior flow separation from a rigorous analysis point of view.

Theorem 5.2: *Let $u\in C^1([0,T],D^1(TM))$ satisfy Assumption (H_1). Then*

(1) there must be some centers of u separated from $x_0\in\mathring{M}$ as shown schematically in either Fig. 4(c) or Fig. 4(c′);
(2) the centers (back flows) are enclosed by a closed orbit line $\gamma(t)$ consisting of orbits of $u(\cdot,t)$, and $\gamma(t)$ converges/shrinks to x_0 as $t\to t_0$; and
(3) if Assumption (H_2) is satisfied, then the center separated from $x_0\in\mathring{M}$ is unique, as shown in Fig. 4(c).

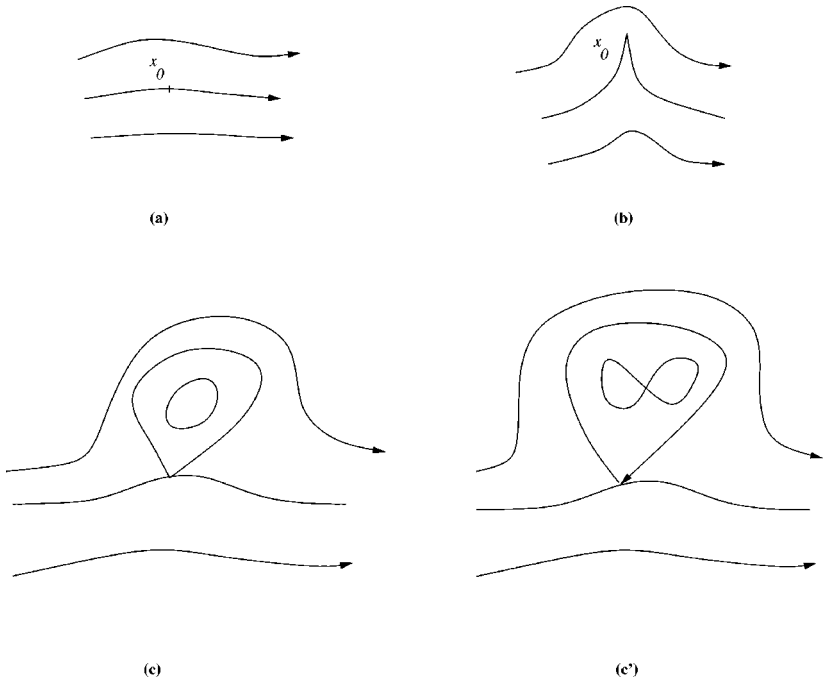

FIG. 4. Schematic of structural bifurcation for the case index $(u^0, x_0) = 0$, a typical case in fluid flows.

The centers in Figs. 4(c) and 4(c′) correspond, in a real fluid, to isolated vortices or, in the case of figure-eight ones, to pairs of co-rotating vortices. This theorem is a direct corollary of Theorems 4.4 and 4.5 and a stability lemma of extended orbits.

We now introduce this stability lemma.

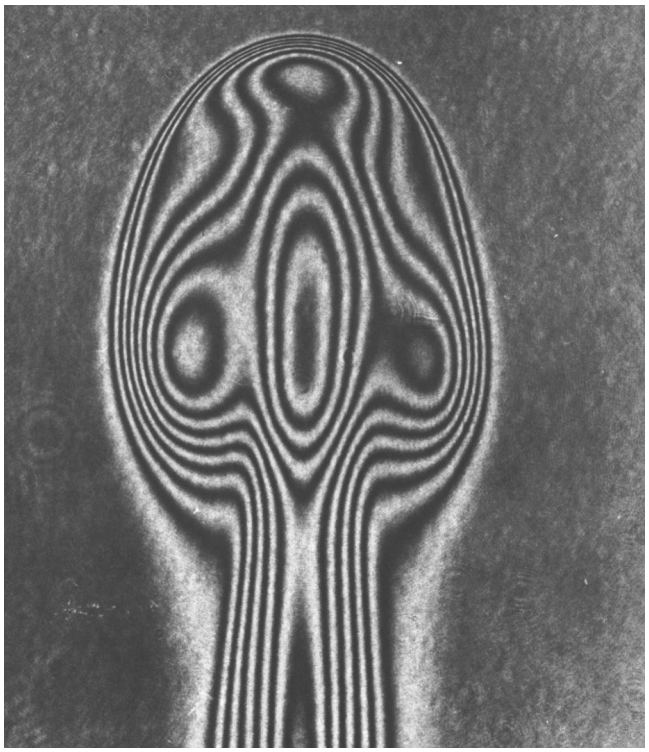

FIG. 5. The three ''bubbles'' in the axis symmetric plume, generated by interior bifurcations, reproduced from Ref. 1.

Definition 5.3: Let $v \in C^r(TM)$ be a vector field. A curve $\gamma \subset M$ is called an extended orbit of v, if

(i) it is a union of curves

$$\gamma = \bigcup_{i=1} \gamma_i;$$

(ii) either γ_i is an orbit of v, or γ_i consists of both orbits and singular points of v, and

(iii) if γ_i and γ_{i+1} are orbits of v, then the ω-limit set of γ_i is the α-limit set of γ_{i+1},

$$\omega(\gamma_i) = \alpha(\gamma_{i+1}),$$

namely, the end points of γ_i are singular points of v, and the starting end point of γ_{i+1} is the finishing end point of γ_i.

The point $\varphi_1 = \alpha(\gamma_1)$ is called the starting point of the extended orbit γ.

We have the following stability lemma for extended orbits. The result of this lemma has been proved by Ma and Wang[4] in Step 2 of the proof of Lemma 4.5 in their paper. This lemma is quite useful in analyzing the orbits of families of vector fields, and thus in solving some problems in 2D incompressible fluid flows. Here we only state the result.

Lemma 5.4: (stability of extended orbits, Ref. 4) Let $v^n \in C^r(TM)$ be a sequence of vector fields with $\lim_{n\to\infty} v^n = v \in C^r(TM)$. Suppose that $\gamma^n \subset M$ is an extended orbit of v^n and the starting points p_1^n of γ^n converge to p_1. Then the extended orbits γ^n of v^n converge to an extended orbit γ of v with starting point p_1.

B. Genericity of structural bifurcation with index zero

In the following, we shall show that the type of structural bifurcation as shown in Fig. 4(c), i.e., one center interior separation, is generic in the interior structural bifurcation. This is remarkably different from the structural bifurcation near the boundary.[2,3,5] It also explains why interior separation to multiple centers and the interior flow separation from the singularities with nonzero index are seldom observed in fluid motions.

Let $x_0 \in \mathring{M}$ and $0 < t_0 < T$ be given. We define a topological space $B \subset C^1([0,T], D^2(TM))$ as follows:

$$B = \{u \in C^1([0,T], D^2(TM)) \,|\, u^0(x_0) = 0, \det Du^0(x_0) = 0, u^0 = u(\cdot, t_0)\}$$

with the topology of $C^1([0,T], D^2(TM))$. Obviously, the space B contains all vector fields in $C^1([0,T], D^2(TM))$, which have a bifurcation in their local structure at (x_0, t_0). It is easy to see that the set

$$B_0 = \left\{ u \in B \;\middle|\; Du^0(x_0) \neq 0,\ \frac{\partial^2 (u^0(x_0) \cdot e_2)}{\partial e_1^2} \neq 0,\ u^1(x_0) \cdot e_2 \neq 0 \right\}$$

is open and dense in B, where e_1 and e_2 are as in (3.5) and (3.6), and $u^1(x) = (\partial/\partial t)\, u(x, t_0)$. From Lemma 3.3, it immediately follows the following genericity theorem of structural bifurcation.

Theorem 5.5 (Genericity of structural bifurcation): *For any $u \in B_0$, u has a bifurcation in its local structure at (x_0, t_0). More precisely, u bifurcates from (x_0, t_0) exactly two nondegenerate singular points, one of which is a center and another is a saddle, as shown in Figs. 4(a)–4(c). Moreover, the set B_0 is open and dense in the topological space B, which contains all vector fields in $C^1([0,T], D^2(TM))$ having a locally structural bifurcation at (x_0, t_0).*

Proof: If $u \in B_0$, then $u^0 \in D^2(TM)$, and u^0 has the Taylor expansion (3.10) with $n = 2$, and

$$\deg f = k \geqslant 2 \quad [\text{by } f \in C^2 \text{ and } f(z) = o(|z|)].$$

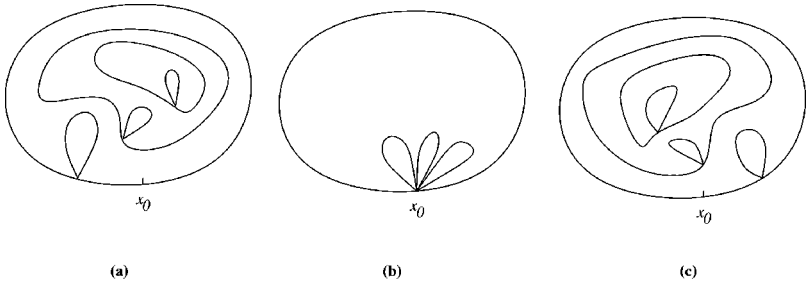

FIG. 6. Schemaatic phase diagrams, showing no structural bifurcation, as explained in Example 5.6.

Hence, by Lemma 3.3, we have

$$\mathrm{ind}(u^0,x_0)=0.$$

Then this theorem follows from Theorems 4.4–4.5. The proof is complete. □

C. Examples of no structural bifurcation

We know that for a locally structurally stable singular point of a vector field $v\in D^r(TM)$, its index obeys

$$\mathrm{ind}(v,x_0)=\begin{cases}-\frac{1}{2}, & x_0\in\partial M,\\ -1 \text{ or } +1, & x\in\mathring{M}.\end{cases}$$

For a vector field $u(x,t)=u^0(x)+(t-t_0)u^1(x)+o(|t-t_0|)$ the structural bifurcation theorem given in Ref. 2 amounts to saying that if x_0 is a boundary singular point with $\mathrm{ind}(u^0,x_0)\neq-\frac{1}{2}$ and $u^1(x_0)\neq 0$ for $x_0\in\partial M$, then $u(x,t)$ has a bifurcation in its local structure at (x_0,t_0). However, for an interior singular point $x_0\in\mathring{M}$ of u^0 with $\mathrm{ind}(u^0,x_0)\neq 1$ or -1, the vector field $u(x,t)$ may have no structural bifurcation near (x_0,t_0). In the following, we give two examples to show this.

Example 5.6: Figures 6(a)–6(c) illustrates a structural evolution of a vector field $u(x,t)$ near $x_0\in\mathring{M}$ as time t crosses t_0, where $\mathrm{ind}(u^0,x_0)=-n$ $(n>1)$, $u^0=u(x,t_0)$, and $u^1(x_0)=(\partial/\partial t)\,u(x_0,t)\neq 0$.

In Fig. 6, we see that the vector fields $u(x,t_0-\varepsilon)$ given by (a) and $u(x,t_0-\varepsilon)$ given by (c) are topologically equivalent for all $\varepsilon>0$ small. Hence, $u(x,t)$ has no structural bifurcation at (x_0,t_0).

Example 5.7: Let $\mathrm{ind}(u^0,x_0)=0$, and $Du^0(x_0)=0$, and the structure of u^0 near x_0 is illustrated by Fig. 7(a).

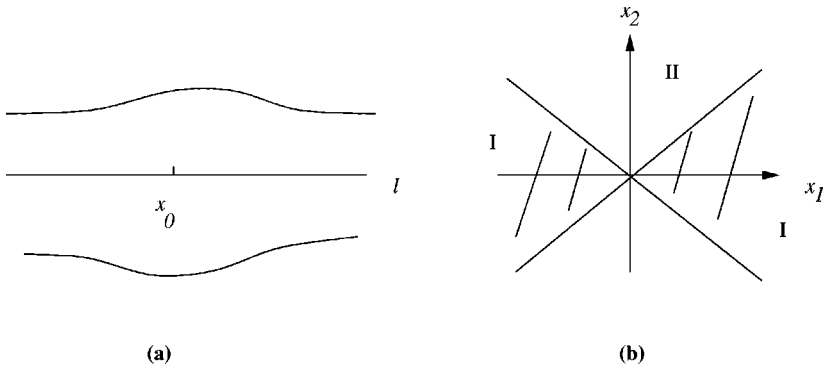

FIG. 7. Sketch showing no bifurcation given in Example 5.7.

Let the x_1-axis of the coordinate system in Fig. 7(b) be tangent to the orbit line ℓ in (a) at x_0. The angles between $u^0(x)$ and the x_1-axis near x_0 vary in the shadow domain I in (b). Hence if the angle between $u^1(x_0)$ and the x_1-axis is in the domain II in (b), then $u^1(x)$ is transversal to $u^0(x)$ near x_0, which implies that the vector field $u(x,t)=u^0(x)+(t-t_0)u^1+o(|t-t_0|^2)$ has no structural bifurcation near (x_0,t_0).

On the exterior structure of graphs*

Daniel Kastler[a)]
CPT-CNRS Luminy, Case 907, F 13288 Marseille Cedex 9, France

(Received 30 October 2003; accepted 6 November 2003; published 1 April 2004)

After a detailed *ab initio* description of the exterior structure of graphs as handled by Connes and Kreimer in their work on renormalization (illustrated by the example of the ϕ^3 model in six dimensions) we spell out in detail their study of the Lie algebra of infinitesimal characters and of the group of characters of the Hopf algebra of Feynman graphs. © *2004 American Institute of Physics.*
[DOI: 10.1063/1.1639958]

I. INTRODUCTION

These notes are a comment on basic aspects of the Connes–Kreimer work[1] describing renormalization in terms of a Hopf algebra **H** of Feynman graphs. They consign our effort to understand the central, but in Ref. 1 somewhat periferally treated notion of ''exterior structure of graphs,'' we offer them as an aid to comprehension providing missing or understressed details. Prior to the exterior structure, the somewhat involved recipe for the Hopf coproduct is spelled out in detail.

As an application we give detailed descriptions of the Lie algebra **L** of infinitesimal characters of **H** (as the semidirect product of its Lie subalgebra $\mathbf{L}_c$ by its Abelian ideal $\mathbf{L}_0$), and of the group **G** of characters of **H** (as the semidirect product of its subgroup $\mathbf{G}_c$ by its Abelian normal subgroup $\mathbf{G}_0$).

As in Ref. 1 we discuss the case of the ϕ^3 model $d=6$ with Lagrangian

$$L=\tfrac{1}{2}(\partial\phi)^2+\tfrac{1}{2}m^2\phi^2+g_{\mathrm{dim}}\phi^3 \quad (g_{\mathrm{dim}}=\mu^{3-d/2}g). \tag{$*$}$$

II. NAKED GRAPHS

(i) A *naked graph* Γ is a (nonvoid) set of *lines* and *vertices*, where each vertex touches at least one line and each line touches at least one vertex. There are thus two kinds of lines: indeed a line

(1) either touches two vertices (*internal lines*), or
(2) touches one vertex at one of its extremities (*external lines*).

(ii) In the case of the model (*) above a vertex [generally one has as many types of vertices as there are terms in the Lagrangian, each term yielding one type of vertex]

(1) either touches three lines (*three-vertices*): then drawn as ⅄ (standing for $g_{\mathrm{dim}}\phi^3$), or
(2) touches two lines (*two-vertices*), of either the kind $\overset{\times}{\underset{(0)}{\text{-}\,\text{-}}}$, or the kind $\overset{\times}{\underset{(1)}{\text{-}\,\text{-}}}$ [standing, respectively, for $m^2\phi^2$ and $\partial\phi)^2$].

(iii) We consider only naked graphs with $N\geqslant 2$ external lines. We discard the *vacuum-graphs* ($N=0$) and the *tadpoles* (N=1).

(iv) We retain only 1PI (*one-particle-irreducible*) naked graphs, namely,

(1) connected,

*Dedicated to Rudolf Haag on his eightieth birthday.
a)Electronic mail: kastler.daniel@wanadoo.fr

(2) which cannot be disconnected by cutting one interior line [Observe that an exterior line of a 1PI graph cannot touch a two-vertex. The graphs $\overset{\text{-}\times\text{-}}{(0)}$, $\overset{\text{-}\times\text{-}}{(1)}$, and $\curlywedge$ are not disconnectable by cutting an interior line, they have to be explicitly discarded.],
(3) having at least one loop (this discards the graphs $\overset{\text{-}\times\text{-}}{(0)}$ or $\overset{\text{-}\times\text{-}}{(1)}$ and $\curlywedge$).

(v) Terminology and notation: the set of 1PI naked graphs is as follows the union $\mathbb{V}\cup\mathbb{S}$:

(1) the 1PI naked graphs with $N>2$ external lines are called *N-vertex graphs*. Their set is denoted by $\mathbb{V}_N$ with $\mathbb{V}=\cup_{N>2}\mathbb{V}_N$.
(2) the 1PI naked graph with two external lines are called *self-energy graphs*. Their set is denoted by $\mathbb{S}$.

(vi) A special role will be played by the superficially divergent graphs, whose set is $\mathbb{V}_3\cup\mathbb{S}$ in the case of our model (*).

III. DRESSED GRAPHS

(i) For the 1PI graph with $N\geqslant 2$ external lines we set

$$E_\Gamma=\{(p_1,\ldots,p_N)\in\mathbb{R}^n;p_1+\cdots+p_N=0\} \tag{1}$$

and select appropriate sets $S(E_\Gamma)$ of test functions and dual set $S'(E_\Gamma)$ of distributions. [For $\Gamma\in\mathbb{V}_3$, respectively, $\Gamma\in\mathbb{S}$, $S(E_\Gamma)$ should contain the constants, respectively, the constants and the function p^2.] A *dressed graph* is a couple (Γ,σ), $\Gamma\in\mathbb{V}\cup\mathbb{S}$, $\sigma\in S'(E_\Gamma)$ linear in its *external structure* σ. For a fixed $\Gamma\in\mathbb{V}\cup\mathbb{S}$ we identify the vector spaces $(\Gamma,S'(E_\Gamma))$ and $S'(E_\Gamma)$.

(ii) For $\Gamma\in\mathbb{V}_3$ with $\phi_0(p)=1$, $p\in E_\Gamma$, we constrain $\sigma_0\in S'(E_\Gamma)$ as follows [this specifies σ_0 up to a choice depending on the type of theory at hand; we then set $\Gamma_{(0)}=(\Gamma,\sigma_0)$]:

$$\langle\sigma_0,\phi_0\rangle=1 \tag{2}$$

yielding the codimension-1 annihilator: with associated dual direct splitting

$$S(E_\Gamma)_0=\{\mathrm{f}\in S(E_\Gamma);\langle\sigma_0,f\rangle=0\}, \tag{3}$$

$$\begin{cases} S(E_\Gamma)=\mathbb{C}\phi_0\oplus S(E_\Gamma)_0, \\ S'(E_\Gamma)=\mathbb{C}\sigma_0\oplus\phi_0^\perp. \end{cases} \tag{4}$$

[A *dual direct splitting* of a pair (Σ,V) of vector spaces in separating duality $\langle\cdot,\cdot\rangle$ is a pair of direct splittings

$$\begin{cases} V=U\oplus W, \\ \Sigma=\Theta\oplus\Psi \end{cases}$$

such that the pairs (Θ,U) and (Ψ,V) are both in separating duality, and one has $\langle\Theta\oplus 0,0\oplus W\rangle=\langle 0\oplus\Psi,\mathrm{U}\oplus 0\rangle=0$. Observe that the described situation follows from the latter requirement if the pairs (Σ,V) and (Θ,U) are both in separating duality.]

(iii) For $\Gamma\in\mathbb{S}$, with $\phi_0(p)=m^2$, $\phi_1(p)=p^2$, $p\in E_\Gamma$, we specify as follows σ_0, $\sigma_1\in S'(E_\Gamma)$:

$$\begin{cases}\langle\sigma_0,\phi_0\rangle=1 \\ \langle\sigma_0,\phi_1\rangle=0,\end{cases}\quad\begin{cases}\langle\sigma_1,\phi_0\rangle=0 \\ \langle\sigma_1,\phi_1\rangle=1,\end{cases} \tag{5}$$

yielding the codimension-2 annihilator and associated dual direct splitting

$$S(E_\Gamma)_0=\{f\in(S(E_\Gamma);\langle\sigma_0,f\rangle=\langle\sigma_1,f\rangle=0\}, \tag{6}$$

$$\begin{cases} S(E_\Gamma)=\mathbb{C}\phi_0+\mathbb{C}\phi_1 \quad \oplus \quad S(E_\Gamma)_0, \\ S'(E_\Gamma)=\mathbb{C}\sigma_0+\mathbb{C}\sigma_1 \quad \oplus \quad \mathbb{C}\phi_0^\perp\cap\mathbb{C}\phi_1^\perp. \end{cases} \tag{7}$$

[(5) specifies σ_0 and σ_1 up to a choice depending on the type of theory at hand. We set $\Gamma_{(0)}=(\Gamma,\sigma_0)$, $\Gamma_{(1)}=(\Gamma,\sigma_1)$. Note that we chose our notational conventions in such a way that the cases $\Gamma\in\mathbb{V}_3$ and $\Gamma\in\mathbb{S}$ differ merely in that the index i has the single value 0 for $\mathbb{V}_3$, and ranges over $\{0,1\}$ for $\mathbb{S}$.]

IV. THE HOPF ALGEBRA H

We wrote this paper so that the hurried reader can skip this section at first reading.

(i) As an algebra **H** is the symmetric (i.e., polynomial) algebra

$$\mathbf{H}=\oplus_{n\in\mathbb{N}}\mathbf{V}^{\vee n}=\mathbb{C}\mathbb{1}+\oplus_{n\geqslant 1}\mathbf{V}^{\vee n} \tag{8}$$

over the vector space

$$\mathbf{V}=\oplus_{\Gamma\in\mathbb{V}\cup\mathbb{S}}S'(E_\Gamma) \quad \text{(finite direct sums)} \tag{9}$$

of finite direct sums $\oplus_{\Gamma\in\mathbb{V}\cup\mathbb{S}}(\Gamma,\sigma)$ of dressed 1PI graphs (Γ,σ), $\Gamma\in\mathbb{V}\cup\mathbb{S}$, $\sigma\in S'(E_\Gamma)$. [Note that **V** is in separating duality with $\mathbf{V}'=\oplus_{\Gamma\in\mathbb{V}\cup\mathbb{S}}S(E_\Gamma)$ consisting of finite direct sums of pairs (Γ,f), $\Gamma\in\mathbb{V}\cup\mathbb{S}$, $f\in S(E_\Gamma)$, the duality being specified by $\langle(\Gamma,f),(\Gamma',\sigma)\rangle=\delta_{\Gamma\Gamma'}\langle\sigma,f\rangle$. We shall write $(\Gamma,\phi_i)=\Gamma^{(i)}$, $i=0$ if $\Gamma\in\mathbb{V}$, $i=0$ or 1 if $\Gamma\in\mathbb{S}$.]

(ii) Counit ϵ: linear multiplicative s.t. $\epsilon(\lambda\mathbb{1})=\lambda$, $\lambda\in\mathbb{C}$, and Ker $\epsilon=\mathbf{H}^+=\oplus_{n\geqslant 1}\mathbf{V}^{\wedge n}$.

(iii) Coproduct Δ: it suffices to specify Δ σ-linearly on all symbols (Γ,σ), $\Gamma\in\mathbb{V}\cup\mathbb{S}$, $\sigma\in(S'(E_\Gamma)$. Denoting by $\underline{\Gamma}$, γ the vacuum graphs obtained from the naked graph Γ, γ by removing all its (open) external lines we define a *subgraph* γ of Γ (consisting of some vertices of Γ and the lines touching them) as *admissible* whenever

(1) $\gamma\in\mathbb{V}_3\cup\mathbb{S}$ ($\Leftrightarrow\gamma$ is superficially divergent),
(2) $\gamma\underset{\neq}{\subset}\underline{\Gamma}$,
(3) γ is obtained from γ by adding to it all lines of Γ (interior and exterior) touching it. The dressed graphs $\gamma_{(i)}$, $i=0$ or 0,1, are then those in III(ii), respectively, (iii). We then specify the linear multiplicative coproduct Δ by asking $\Delta\mathbb{1}=\mathbb{1}\otimes\mathbb{1}$ and

$$\Delta(\Gamma,\sigma)=(\Gamma,\sigma)\otimes\mathbb{1}+\mathbb{1}\otimes(\Gamma,\sigma)+\Delta'(\Gamma,\sigma), \quad (\Gamma,\sigma)\in\mathbf{V}, \tag{10}$$

with

$$\Delta'(\Gamma,\sigma)=\Sigma\Pi\gamma_{(i)}\otimes(\Gamma/\Pi\gamma_{(i)},\sigma) \tag{11}$$

the sum being over all products $\Pi\gamma_{(i)}$ s.t.

(1) all factors γ are admissible, the mutual intersections of the corresponding γ being all void (the γ themselves may intersect),
(2) the sum is over all combinations of indices.

The graph $\Gamma/\Pi\gamma_{(i)}$ is obtained by replacing in Γ each $\gamma_{(i)}$ by the vertex with label (i).

These requirements yield an $\mathbb{N}$-graded connected bialgebra for the grading defined by the number of loops ($\geqslant 1$, cf. Ref. 2, (iv)), hence a Hopf algebra by Ref. 2 Proposition 2.7, moreover a CMK Hopf algebra in the sense of Ref. 2 Definition 3.1 suitably generalized. [The definition of CMK-algebras in Ref. 2 **3** should be altered to accommodate graphs with exterior structure: replace the basis $\{x_i\}$ of **V** by a direct sum $\mathbf{V}=\oplus_i X_i$ (in our case $\oplus_{\Gamma\in\mathbb{V}\cup\mathbb{S}}S'(E_\Gamma)$).]

V. THE LIE ALGEBRA L

At the cost of some duplication we wrote this section in a manner independent of the preceding one. The notion of CMK algebra should be adapted to our situation as we just mentioned.

Since **H** is a CMK Hopf algebra its Lie algebra of algebraic infinitesimal characters is the algebraic dual of $\mathbf{V}=\oplus_{\Gamma\in\mathbb{V}\cup\mathbb{S}}S'(\mathrm{E}_\Gamma)$, cf. Ref. 2 Proposition 3.3. In order to deal with a reasonable topological dual **L** of **V** we *define* **L** as the above subset $\mathbf{V}'$:

$$\mathbf{L}\cong\mathbf{V}'=\oplus_{\Gamma\in\mathbb{V}\cup\mathbb{S}}S(E_\Gamma)\quad(\text{finite direct sums of elements }(\Gamma,f)\in\mathbf{L},f\in S(E_\Gamma)),\tag{12a}$$

the linear form (Γ,f), $\mathrm{f}\in S(E_\Gamma)$ (vanishing on $\mathbb{C}\mathbb{1}\cup(\oplus_{\mathrm{n}\geqslant 2}\mathbf{V}^{\vee n})$ taking on **V** the values:

$$\langle(\Gamma,f),(\Gamma',\sigma)\rangle=\delta_{\Gamma\Gamma'}\langle\sigma,f\rangle,\quad(\Gamma',\sigma)\in\mathbf{V},\sigma\in S(E_{\Gamma'}).\tag{12b}$$

This choice will actually ensure that $[Z_1{*}Z_2]\in\mathbf{L}$ for Z_1, $Z_2\in\mathbf{L}$ as shown by the computation of the Lie bracket $[Z_1{*}Z_2]=Z_1{*}Z_2-Z_2{*}Z_1$, Z_1, $Z_2\in\mathbf{L}$, to which we now proceed. Since the elements of **L** are concentrated in polynomial grade one, computing $\langle Z_1{*}Z_2,x\rangle=\langle Z_1\otimes Z_2,\Delta' x\rangle$ for Z_1, $Z_2\in\mathbf{L}$, $x\in\mathbf{H}^{\wedge|}=\mathbf{V}$, involves the special case of Δ' in (11) where all products Π figuring there have only one factor: Δ' is then replaced by a reduced algorithm Δ'_{r} which we now describe *ab initio*: one has for $\Gamma\in\mathbb{V}\cup\mathbb{S}$:[3]

$$\Delta'_r(\Gamma,\sigma)=\sum_{\gamma\ll\Gamma}\sum_i\ \gamma_{(i)}\otimes(\Gamma/\gamma_{(i)},\sigma).\tag{13a}$$

(i) Recall that a subgraph $\gamma\subset\Gamma$ of $\Gamma\in\mathbb{V}\cup\mathbb{S}$ is *admissible* (notation $\gamma\ll\Gamma$) whenever

(a) $\gamma\in\mathbb{V}_3\cup\mathbb{S}$ ($\Leftrightarrow\gamma$ is superficially divergent),
(b) $\gamma\subsetneqq\Gamma$
(c) γ is obtained from γ by adding to it all the open lines of Γ (interior and exterior) which it touches.

The dressed graphs $\gamma_{(i)}$, $i=0$ or 0, 1, are then those encountered above.

(ii) The graph $\Gamma/\gamma_{(i)}$ obtained by replacing γ

(1) by $\curlywedge$ if γ is a 3-vertex graph (we might then as well write Γ/γ),
(2) by $\overset{\text{-}\times\text{-}}{(i)}$, $i=1$ or 2, if γ is a self-energy graph.

If we separate the contributions of 3-vertex and self-energy graphs, (13a) reads

$$\Delta'_r(\Gamma,\sigma)=\sum_{\gamma\ll\Gamma,\,\gamma\in\mathbb{V}_3}\gamma_{(0)}\otimes(\Gamma/\gamma,\sigma)+\sum_{\gamma\ll\Gamma,\,\gamma\in\mathbb{S}}\sum_{i=1,2}\gamma_{(i)}\otimes(\Gamma/\gamma_{(i)},\sigma).\tag{13b}$$

We have now owing to (13a) and (12b) for $Z_1=(\Gamma_1,f_1)$, $Z_2=(\Gamma_2,\mathrm{f}_2)\in\mathbf{L}$, $(\Gamma,\sigma)\in\mathbf{V}$, Γ_1, Γ_2, $\Gamma\in\mathbb{V}\cup\mathbb{S}$, $f_1\in S(\mathrm{E}_{\Gamma_1})f_2\in S(\mathrm{E}_{\Gamma_2})$, $\sigma\in S'(E_\Gamma)$:

$$\langle Z_1{*}Z_2,(\Gamma,\sigma)\rangle=\langle Z_1\otimes Z_2,(\Delta'_{\mathrm{r}}(\Gamma,\sigma)\rangle=\sum_{\gamma\ll\Gamma}\sum_i\ \delta_{\Gamma_1\gamma}\langle\sigma_i,f_1\rangle\delta_{\Gamma_2\Gamma/\gamma_{(i)}}\langle\sigma,f_2\rangle,\tag{14}$$

which, introducing the notation:

$$n_i(\Gamma_1,\Gamma_2;\Gamma)=\#\{\gamma\subset\Gamma\ \text{ admissible};\gamma\cong\Gamma_1\ \text{ and }\Gamma/\gamma_{(\mathrm{i})}\cong\Gamma_2\},\quad\Gamma_1,\Gamma_2,\Gamma\in\mathbb{V}\cup\mathbb{S},\tag{15}$$

is turned into

$$\langle Z_1 * Z_2, (\Gamma,\sigma)\rangle = \sum_i n_i(\Gamma_1,\Gamma_2;\Gamma)\langle \sigma_i f_1\rangle\langle \sigma, f_2\rangle = \sum_i n_i(\Gamma_1,\Gamma_2;\Gamma)\langle \sigma_i, f_1\rangle\langle (\Gamma,f_2),(\Gamma,\sigma)\rangle. \tag{16a}$$

In other terms one has in restriction to **V**:

$$Z_1 * Z_2|_{\mathbf{V}} = \sum_{\Gamma\in\mathbb{V}\cup\mathbb{S}} \sum_i n_i(\Gamma_1,\Gamma_2;\Gamma)\langle \sigma_i, f_1\rangle(\Gamma,f_2). \tag{16b}$$

Note that nonvanishing of $n_i(\Gamma_1,\Gamma_2;\Gamma)$ requires the two facts:

$$\Gamma_1 \in \mathbb{V}_3\cup\mathbb{S} \quad (\Leftrightarrow \Gamma_1 \text{ is superficially divergent}), \tag{$*_1$}$$

$$\Gamma \text{ and } \Gamma_2 \text{ have the same external lines.} \tag{$*_2$}$$

From (16a) follows

$$[Z_1 * Z_2] = \sum_{\Gamma\in\mathbb{V}\cup\mathbb{S}} \sum_i n_i(\Gamma_1,\Gamma_2;\Gamma)\langle \sigma_i, f_1\rangle(\Gamma,f_2) - \sum_{\Gamma'\in\mathbb{V}\cup\mathbb{S}} \sum_i n_i(\Gamma_2,\Gamma_1;\Gamma')\langle \sigma_i, f_2\rangle(\Gamma',f_1)] \tag{17}$$

the bracket $[Z_1 * Z_2]$ thus belongs actually to **L**.

Consider now the subspace $\mathbf{L}_0$ of **L** spanned by the annihilator (3) and (6), recalled to be

$$S(E_\Gamma)_0 = \{f\in(S(E_\Gamma) \text{ s.t. } \begin{cases} \langle \sigma_0, f\rangle = 0\} & \text{if } \Gamma\in\mathbb{V}_3 \\ \langle \sigma_0, f\rangle = \langle \sigma_1, f\rangle = 0 & \text{if } \Gamma\in\mathbb{S}\end{cases}, \tag{18}$$

together with the (Γ,f), $\Gamma\in\cup_{n>3}\mathbb{V}_n$, $f\in(S(E_\Gamma)$; and further the subspace $\mathbf{L}_c$ of **L** spanned by the (Γ,f), $\Gamma\in\mathbb{V}_3\cup\mathbb{S}$, $f\in(E_\Gamma)_c$=linear span of

$$\begin{cases} \phi_0 = 0 & \text{if } \Gamma\in\mathbb{V}_3 \\ \phi_0 \text{ and } \phi_1 & \text{if } \Gamma\in\mathbb{S}^{\cdot}\end{cases}$$

Those definitions are subsumed by the dual direct splitting

$$\begin{cases} \mathbf{V} = \mathbf{V}_c = \text{lin}\{(\Gamma,\sigma_i),\Gamma\in\mathbb{V}_3\cup\mathbb{S}\} & \oplus & \mathbf{L}_c^{\perp} \\ \mathbf{L} = \mathbf{L}_c = \text{lin}\{(\Gamma,\phi_i),\Gamma\in\mathbb{V}_3\cup\mathbb{S}\} & \oplus & \mathbf{L}_0 = \text{lin}\{(\Gamma,f),\Gamma\in\mathbb{V}_3\cup\mathbb{S}, f\in S(E_\Gamma)_0\} \\ & & \quad + \text{lin}\{(\Gamma,f),\Gamma\in\cup_{n>3}\mathbb{V}_n, f\in S(E_\Gamma)\} \end{cases} \tag{19}$$

Lemma 1: (i) One has $\mathbf{L}_0 * \mathbf{L}|_{\mathbf{V}} = 0$, thus $[\mathbf{L}_0 * \mathbf{L}_0]$ vanishes: $\mathbf{L}_0$ is an Abelian Lie subalgebra of **L**.

(ii) One has $[\mathbf{L} * \mathbf{L}_0] \subset \mathbf{L}_0$: $\mathbf{L}_0$ is a Lie ideal of **L**.

(iii) One has $[\mathbf{L}_c * \mathbf{L}_c] \subset \mathbf{L}_c$: $\mathbf{L}_c$ is a Lie subalgebra of **L**.

Proof: (i) If $Z_1\in\mathbf{L}_0$ in (16a) one has $\Gamma_1\in\mathbb{V}_3\cup\mathbb{S}$ by ($*_1$), Γ_1 thus lies in the first summand of $\mathbf{L}_0$ in (19) whence $f_1\in S(E_\Gamma)_0$, thus by (18) the vanishing of $\langle \sigma_i, f_1\rangle$ right-hand side of (16b).

(ii) By (i) (17) reads for $Z_1\in\mathbf{L}$ and $Z_2\in\mathbf{L}_0$:

$$[Z_1 * Z_2] = \sum_{\Gamma\in\mathbb{V}\cup\mathbb{S}} \sum_i n_i(\Gamma_1,\Gamma_2;\Gamma)\langle \sigma_i, f_1\rangle(\Gamma,f_2), \tag{20}$$

which, owing to ($*_2$), belongs to $\mathbf{L}_0$.

(iii) We make Z_1, $Z_2\in\mathbf{L}_c$ in (17), then Γ_1, $\Gamma_2\in\mathbb{V}_3\cup\mathbb{S}$ by (19). Now ($*_2$) says that Γ, respectively, Γ', have the same external lines as Γ_2, respectively, Γ_1, they thus both belong to $\mathbb{V}_3\cup\mathbb{S}$ hence the right-hand side of (17) belongs to $\mathbf{L}_c$.

The next theorem describes the structure of $\mathbf{L}$ by first stating how $\mathbf{L}$ is built up from $\mathbf{L}_c$ and $\mathbf{L}_0$ (moral of the preceding Lemma); and then formulating the Lie bracket of $\mathbf{L}_c$ (for that matter its pre-Lie product) in terms of ''grafting the graph of the first factor at the vertices of the second''—a basic algorithm aspect of the theory.

Theorem A: (i) The Lie algebra $\mathbf{L}$ is the semidirect product of its subalgebra $\mathbf{L}_c$ by its Abelian ideal $\mathbf{L}_0$ (cf. Appendix B):

$$\mathbf{L}=\mathbf{L}_c \ltimes \mathbf{L}_0 . \tag{21}$$

(ii) After regauging as follows the basis of $\mathbf{L}_c$:

$$\Gamma^{(i)} \to \Gamma'^{(i)} = S(\Gamma)\Gamma^{(i)}, \quad \Gamma^{(i)}=(\Gamma,\phi_i)\in \mathbf{L}_c , \tag{22}$$

where $S(\Gamma)$ is the number of automorphisms of the naked graph Γ [mappings of the naked graph onto itself which do not change it] we have

$$[\Gamma_1'^{(i)} * \Gamma_2'^{(j)}] = \sum_v (\Gamma_1'^{(i)} \circ_v \Gamma_2')^{(\mathrm{j})} - \sum_v (\Gamma_2'^{(j)} \circ_v \Gamma_1')^{(i)}, \quad \Gamma_1'^{(i)},\ \Gamma_2'^{(j)} \in \mathbf{L}_c , \tag{23a}$$

in fact separately

$$\Gamma_1'^{(i)} * \Gamma_2'^{(j)}|_{\mathrm{v}} = \sum_v (\Gamma_1'^{(i)} \circ_v \Gamma_2')^{(j)}, \quad \Gamma_1'^{(i)},\ \Gamma_2'^{(j)} \in \mathbf{L}_c , \tag{23b}$$

a sum over vertices v of Γ_2', where the notation $(\Gamma_1'^{(i)} \circ_v \Gamma_2')^{(j)}$ stands for *grafting* $\Gamma_1'^{(i)}$ *on* Γ_2' *at* v, namely:

(1) if $\Gamma^{(i)}=\Gamma^{(0)}=(\Gamma_1,\phi_0)$ with $\Gamma_1 \in \mathbb{V}_3$, the sum is over the three-vertices v of Γ_2, with the dressed graph $(\Gamma_1'^{(i)} \circ_v \Gamma_2')^{(j)}$ obtained by replacing the vertex $v=$  by the naked graph $\Gamma_1=$  (for an arbitrary order of the legs of both objects),

(2) if $\Gamma^{(i)}=\Gamma^{(0)}=(\Gamma_1,\phi_0)$ with $\Gamma_1 \in \mathbb{S}$, the sum is over the two-vertices v of Γ_2 of the type $\overset{\times}{\underset{(0)}{\cdot\!\cdot}}$, with the dressed graph $(\Gamma_1'^{(i)} \circ_v \Gamma_2')^{(j)}$ obtained by replacing the vertex $v=\overset{\times}{\underset{(0)}{\cdot\!\cdot}}$ by the naked graph $\Gamma_1=$  (for an arbitrary order of the legs of both objects),

(3) if $\Gamma^{(i)}=\Gamma^{(1)}=(\Gamma_1,\phi_1)$ with $\Gamma_1 \in \mathbb{S}$, the sum is over the two-vertices v of Γ_2 of the type $\overset{\times}{\underset{(1)}{\cdot\!\cdot}}$, with the dressed graph $(\Gamma_1'^{(i)} \circ_v \Gamma_2')^{(j)}$ obtained by replacing the vertex $v=\overset{\times}{\underset{(1)}{\cdot\!\cdot}}$ by the naked graph $\Gamma_1=$  (for an arbitrary order of the legs of both objects).

Summarizing this somewhat lenghty recipe: (23b) is a sum over vertices v of $\Gamma_2'^{(j)}$ ''of type $\Gamma_1'^{(i)}$'' by graphs replacing these vertices (irrespective of the order of legs) by the naked graph Γ_1. In conformity with $(*_2)$ all those graphs have the same exterior structure as Γ_2. Convention (22) aims at getting a sum (23b) without coefficients.

Proof: (i) Indeed $\mathbf{L}$ is the direct sum $\mathbf{L}_c \oplus \mathbf{L}_0$ of the subalgebra $\mathbf{L}_c$ and the ideal $\mathbf{L}_0$ (cf. Appendix B).

(ii) Check of (23b): let $\Gamma_1^{(i)}$, $\Gamma_2^{(j)} \in \mathbf{L}_c$ with $\Gamma_1'^{(i)}$, $\Gamma_2'^{(j)}$ as in (22): we have by (16b) owing to $(*_1)$:

$$\Gamma_1^{(i)} * \Gamma_2^{(j)}|_{\mathrm{v}} = \sum_{\Gamma \in \mathbb{V}_3 \cup \mathbb{S}} \sum_i n_k(\Gamma_1,\Gamma_2;\Gamma)\,\delta_{ki}(\Gamma,\phi_j) = \sum_{\Gamma \in \mathbb{V}_3 \cup \mathbb{S}} \sum_i n_i(\Gamma_1,\Gamma_2;\Gamma)(\Gamma,\phi_j),$$

where $\Gamma_1 \cong \gamma$ whilst $\Gamma_2 \cong \Gamma/\gamma_{(i)}$ for $\gamma \subset \Gamma$ admissible, i.e., $(\Gamma,\phi_{\mathrm{j}})$ is a multiple of $(\Gamma_1'^{(i)} \circ_{\mathrm{v}} \Gamma_2')^{(j)}$: we have to find which multiple. Now from the definition (15) of $n_i(\Gamma_1,\Gamma_2;\Gamma)$ follows that $S(\Gamma_1)S(\Gamma_2)n_i(\Gamma_1,\Gamma_2;\Gamma)$ is the number $S(\Gamma)$ of automorphisms of the naked graph Γ. Equation (16a) is thus turned into (23b).

VI. THE GROUP G

Call $\mathbf{G}$ the group of continuous characters of $\mathbf{H}$, viz., the subgroup of its algebraic characters χ (cf. Ref. 2, Definition 12, Proposition 13) for which $\langle\chi,(\Gamma,\sigma)\rangle$, $\Gamma\in\mathbb{V}\cup\mathbb{S}$, $\sigma\in S'(E_\Gamma)$ is continuous in σ. By multiplicativity $\chi\in\mathbf{G}$ is uniquely determined by its restriction $\chi|_{\mathbf{V}'}$ each continuous linear form of $\mathbf{V}$ being the restriction of a unique $\chi\in\mathbf{G}$ (its "multiplicative extension": the restriction $\chi\to\chi|_{\mathbf{V}}$ and the multiplicative extension $\chi|_{\mathbf{V}}\to\chi$ are inverse of each other). We will accordingly handle the elements $\chi\in\mathbf{G}$ by handling their restrictions $\chi|_{\mathbf{V}}$. Recall that the product of $\mathbf{G}$ is the convolution product $*$ (under which $\mathbf{G}$ is closed), hence that its unit element is the counit ϵ of $\mathbf{H}$.

Call $\mathbf{H}_c$ the smallest subalgebra of $\mathbf{H}$ containing the (Γ,σ_i), $\Gamma\in\mathbb{V}_3\cup\mathbb{S}$, $i=0$ for $\Gamma\in\mathbb{V}_3$, $i=0$ or 1 for $\Gamma\in\mathbb{S}$ (equivalently $\mathbf{H}_c=\mathbb{C}1+\oplus_{n\geqslant 1}\mathbf{V}_c^{\vee n}$). Definitions (10) and (11) of the coproduct of $\mathbf{H}$ implying the inclusion $\Delta\mathbf{V}_c\subset\mathbf{H}_c\otimes\mathbf{H}_c$, hence $\Delta\mathbf{H}_c\subset\mathbf{H}_c\otimes\mathbf{H}_c$ by the multiplicativity of Δ, $\mathbf{H}_c$ is a Hopf subalgebra of $\mathbf{H}$ whose counit is the restriction $\epsilon|_{\mathbf{H}_c}$.

Denoting by $\mathbf{G}_c$ the subgroup of algebraic characters of $\mathbf{H}_c$ continuous for the topology of the exterior structure, the restriction ρ to $\mathbf{H}_c$ of the characters of $\mathbf{G}$:

$$\rho\chi=\chi|_{\mathbf{H}_c},\quad \chi\in\mathbf{G} \tag{24}$$

is a group homomorphism: $\mathbf{G}\to\mathbf{G}_c$ whose kernel $\mathbf{G}_0$ is the normal subgroup of $\mathbf{G}$ consisting of the $\chi\in\mathbf{G}$ restricting on $\mathbf{H}_c$ to the unit character, viz., the counit $\epsilon|_{\mathbf{H}_c}$ of $\mathbf{H}_c$. Since ϵ is multiplicative, a $\chi\in\mathbf{G}$ belongs to $\mathbf{G}_0$ iff $\chi|_{\mathbf{V}_c}$ coincides with $\epsilon|_{\mathbf{V}_c}=0$:

$$\mathbf{G}_0=\{\chi\in\mathbf{G};\chi|_{\mathbf{H}_c}=\epsilon|_{\mathbf{H}_c}\}=\{\chi\in\mathbf{G};\chi\ \text{vanishes on}\ \mathbf{V}_c\}. \tag{25}$$

Lemma 2: (i) $\mathbf{G}_0$ is an Abelian normal subgroup of $\mathbf{G}$.
(ii) Defining ρ': $\mathbf{G}_c\to\mathbf{G}$ by

$$\rho'\psi(\text{abbreviated}\ \tilde{\psi})=\begin{cases}\psi & \text{on}\ \mathbf{V}_c\\ 0 & \text{on}\ \mathbf{L}_c^{\perp},\end{cases}\quad \psi\in\mathbf{G}_c, \tag{26}$$

yields the lift of a split exact sequence of group homomorphisms:

$$1\to\mathbf{G}_0\to\mathbf{G}\underset{\rho'}{\overset{\rho}{\leftrightarrows}}\mathbf{G}_c\to 1, \tag{27a}$$

that is ρ' is a group homomorphism fulfilling:

$$\rho\circ\rho'=\mathrm{id}_{\mathbf{G}_c}. \tag{27b}$$

Proof: (i) We noted that $\mathbf{G}_0$ is normal. Proof that $\mathbf{G}_0$ is Abelian: let χ_0, $\chi_0'\in\mathbf{G}_0$, we have for all dressed graphs (Γ,σ), using (25) and the fact that (10), (11) imply $\Delta'(\Gamma,\sigma)\in\mathbf{H}_c\otimes\mathbf{H}$:

$$\langle\chi_0*\chi_0',(\Gamma,\sigma)\rangle=\langle\chi_0\otimes\chi_0',\Delta(\Gamma,\sigma)\rangle=\langle\chi_0\otimes\chi_0',(\Gamma,\sigma)\otimes 1+1\otimes(\Gamma,\sigma)+\Delta'(\Gamma,\sigma)\rangle$$

$$=\langle\chi_0,(\Gamma,\sigma)\rangle+\langle\chi_0',(\Gamma,\sigma)\rangle+\langle\chi_0\otimes\chi_0',\Delta'(\Gamma,\sigma)\rangle=\langle\chi(\Gamma,\sigma)\rangle+\langle\chi',(\Gamma,\sigma)\rangle.$$

(ii) It suffices to check (27) which is obvious from (26).

Theorem B: (i) $\mathbf{G}$ is the semi-direct product [One has to make a choice of the order of factors in the definition of the semidirect product of groups. This choice is adapted to the order of factors in the definition of the semidirect product of Lie algebra in Theorem A above—changing to the opposite order of factors follows from a trivial calculation.] of its subgroups $\rho'\mathbf{G}_c\cong\mathbf{G}_c$ and $\mathbf{G}_0$: we have $\rho'\mathbf{G}_c\cap\mathbf{G}_0=\{\epsilon\}$ and $\mathbf{G}=\rho'\mathbf{G}_c*\mathbf{G}_0$. Consequently each $\chi\in\mathbf{G}$ is uniquely written as a product

$$\chi=\tilde{\psi}*\chi_0 \quad \text{with} \quad \tilde{\psi}=\rho'\psi\in\rho'\mathbf{G}_c(\psi\in\rho\mathbf{G}_c), \quad \text{and} \quad \chi_0\in\mathbf{G}_0, \tag{28a}$$

specifically

$$\tilde{\psi}=(\rho'\circ\rho)\chi \quad (\psi=\rho\chi) \quad \text{and} \quad \chi_0=[(\rho'\circ\rho)\chi]^{-1}*\chi. \tag{28b}$$

(ii) The product in $\mathbf{G}$ then reads

$$(\tilde{\psi}*\chi_0)*(\tilde{\psi}'*\chi_0')=(\tilde{\psi}*\tilde{\psi}')*[(\mathrm{ad}\,\tilde{\psi}'^{-1}(\chi_0))*\chi_0'], \tag{29a}$$

where

$$\mathrm{ad}\,\chi(\chi_0)=\chi*\chi_0*\chi^{-1}\in\mathbf{G}_0, \quad \chi_0\in\mathbf{G}_0, \ \chi\in\mathbf{G}, \tag{29b}$$

yields a group homomorphism [Trivial on $\mathbf{G}_0$, its interesting part is its restriction to $\rho'\mathbf{G}_c$, cf. (29a).] ad: $\mathbf{G}\to\mathrm{Aut}\,\mathbf{G}_0$ into the automorphism group of $\mathbf{G}_0$.

(iii) $\mathrm{ad}(\rho'\mathbf{G}_c)$ acts as follows: one has with the sum as specified in (11) for $\tilde{\psi}\in\rho'\psi$, $\psi\in\mathbf{G}_c$, $\chi_0\in\mathbf{G}_0$:

$$\langle\mathrm{ad}\,\tilde{\psi}(\chi_0),(\Gamma,\sigma)\rangle=\langle\chi_0,(\Gamma,\sigma)\rangle+\Sigma\langle\psi,\Pi\gamma_{(i)}\rangle\langle\chi_0,(\Gamma/\Pi\gamma_{(i)},\sigma)\rangle, \quad \Gamma\in\mathbb{V}\cup\mathbb{S}, \ \sigma\in S'(E_\Gamma). \tag{30}$$

Proof: (i) Check of $\rho'\mathbf{G}_c\cap\mathbf{G}_0=\{\epsilon\}$: if $\psi\in\mathbf{G}_c$ fulfills $\rho'\psi\in\mathbf{G}_0$ we have using (27b) $(\rho\circ\rho')\psi=\psi=\epsilon_c$, thus $\rho'\psi=\epsilon$ since ρ' is a homomorphism of groups.

Uniqueness of the decomposition (28a), (28b):

$$\rho'\psi*\chi_0=\rho'\psi'*\chi_0' \ \text{ implies } \ (\rho'\psi)^{-1}*\rho'\psi'=\chi_0*(\chi_0')^{-1}\in\rho'\mathbf{G}_c\cap\mathbf{G}_0=\{\epsilon\}.$$

Existence of the decomposition (28a), (28b):

(1) one has $\chi_0\in\mathbf{G}_0$, indeed by (27b) $\rho\chi_0=[(\rho\circ\rho'\circ\rho)\chi]^{-1}*\rho\chi=(\rho\chi)*(\rho\chi)^{-1}=\epsilon$,
(2) one has (28a), indeed $\rho'\psi*\chi_0=(\rho'\circ\rho)\chi*\chi_0=(\rho'\circ\rho)\chi*[(\rho'\circ\rho)\chi]^{-1}*\chi=\chi$.

(ii) Check of (29a): we have: $\tilde{\psi}*\chi_0*\tilde{\psi}'*\chi_0'=\tilde{\psi}*\tilde{\psi}'*\tilde{\psi}'^{-1}*\chi_0*\tilde{\psi}'*\chi_0'$.

(iii) First notice that (30) makes sense, $\langle\psi,\Pi\gamma_{(i)}\rangle$ denoting the value of $\Pi\gamma_{(i)}\in\mathbf{H}_c$ for $\psi\in\mathbf{G}_c$. We check (30) separately for (Γ,σ) in the complementary subspaces $\mathbf{V}_c$ and $\mathbf{L}_c^\perp$, cf. (19).

For $(\Gamma,\sigma)\in\mathbf{V}_c$, $\langle\mathrm{ad}\,\tilde{\psi}(\chi_0),(\Gamma,\sigma)\rangle$ and $\langle\chi_0,(\Gamma,\sigma)\rangle$ vanish by (25): indeed $\chi_0\in\mathbf{G}_0$ by assumption whence $\mathrm{ad}\,\tilde{\psi}(\chi_0)\in\mathbf{G}_0$ by normality of $\mathbf{G}_0$; furthermore $\langle\chi_0,(\Gamma/\Pi\gamma_{(i)},\sigma)\rangle$ vanishes by (25) because $(\Gamma/\Pi\gamma_{(i)},\sigma)\in\mathbf{V}_c$ has the exterior structure σ.

Assume now $(\Gamma,\sigma)\in\mathbf{L}_c^\perp$, our assumption $\tilde{\psi}\in\rho'\psi$, $\psi\in\mathbf{G}_c$, entailing $\tilde{\psi}|_{\mathbf{V}}\in\mathbf{L}_c$. Recalling

$$\Delta'(\Gamma,\sigma)=\Sigma\Pi\gamma_{(i)}\otimes(\Gamma/\Pi\gamma_{(i)},\sigma)\in\mathbf{H}_c\otimes\mathbf{V}_c, \tag{11}$$

for convenience, we compute the left-hand side of (30):

$$\begin{aligned}\langle\mathrm{ad}\,\tilde{\psi}(\chi_0),(\Gamma,\sigma)\rangle&=\langle\tilde{\psi}*\chi_0*\tilde{\psi}^{-1},(\Gamma,\sigma)\rangle=\langle(\psi*\chi_0)\otimes\tilde{\psi}^{-1},\Delta(\Gamma,\sigma)\rangle\\&=\langle(\tilde{\psi}*\chi_0)\otimes\tilde{\psi}^{-1},(\Gamma,\sigma)\otimes\mathbb{1}+\mathbb{1}\otimes(\Gamma,\sigma)+\Delta'(\Gamma,\sigma)\rangle\\&=\langle\tilde{\psi}*\chi_0,(\Gamma,\sigma)\rangle+\langle\tilde{\psi}^{-1},(\Gamma,\sigma)\rangle+\langle\psi*\chi_0,\Delta'(\Gamma,\sigma)\rangle.\end{aligned}$$

Now $\langle\tilde{\psi}^{-1},(\Gamma,\sigma)\rangle=0$ since $\tilde{\psi}^{-1}|_{\mathbf{V}}\in\mathbf{L}_c$. And $\langle\tilde{\psi}*\chi_0,\Delta'(\Gamma,\sigma)\rangle=0$ by (25) and (11), we are thus left with

$$\begin{aligned}\langle\tilde{\psi}*\chi_0,(\Gamma,\sigma)\rangle&=\langle\tilde{\psi}\otimes\chi_0,\Delta(\Gamma,\sigma)\rangle\\&=\langle\tilde{\psi}\otimes\chi_0,(\Gamma,\sigma)\otimes\mathbb{1}+\mathbb{1}\otimes(\Gamma,\sigma)+\Delta'(\Gamma,\sigma)\rangle\\&=\langle\tilde{\psi},(\Gamma,\sigma)\rangle+\langle\chi_0,(\Gamma,\sigma)\rangle+\langle\tilde{\psi}\otimes\chi_0,\Delta'(\Gamma,\sigma)\rangle\\&=\langle\chi_0,(\Gamma,\sigma)\rangle+\langle\tilde{\psi}\otimes\chi_0,\Delta'(\Gamma,\sigma)\rangle,\end{aligned}$$

because, as above, $\langle\tilde{\psi},(\Gamma,\sigma)\rangle=0$, since $\tilde{\psi}|_{\mathbf{V}}\in\mathbf{L}_c$. Plugging in (11) we finally get

$$\langle\tilde{\psi}*\chi_0,\Delta'(\Gamma,\sigma)\rangle=\langle\tilde{\psi},\Sigma\Pi\gamma_{(i)}\rangle+\chi_0,(\Gamma/\Pi\gamma_{(i)},\sigma),$$

where the first term can be written as in (30) in view of (27a).

ACKNOWLEDGMENT

The numerous improvements of the present version of these notes over a previous attempt are largely due to the remarks of Raymond Stora whom I thank for instructive discussions.

APPENDIX A: THE AUGMENTATION IDEAL

Here is a more synthetic version of results scattered in Ref. 2.

Proposition: Let $\mathbf{H}(\wedge,\mathbb{1}=e1,\Delta,\epsilon)=\oplus_{n\in\mathbb{N}}\mathbf{H}^n$, $\mathbf{H}^n=\{h\in\mathbf{H},Yh=nh\}$, *be an* $\mathbb{N}$*-graded connected Hopf algebra* (i.e., $\mathbf{H}^0=\mathbb{C}\mathbb{1}$) *with augmentation ideal* $\mathbf{H}^+=\mathrm{Ker}\,\epsilon$ *and assume in addition that* $\mathbf{H}=\oplus_{n\in\mathbb{N}}\mathbf{V}^{\vee n}$, $\mathbf{V}$ *is a linear subspace of* $\mathbf{H}^+$ *spanned by Y-homogeneous elements. We have*:

$$\mathbf{H}=\mathbb{C}\mathbb{1}\oplus\mathbf{H}^+,\tag{A1}$$

$$\mathbf{H}^+=\oplus_{n\geqslant 1}\mathbf{H}^n,\tag{A2}$$

$$\mathbf{H}^+=\oplus_{n\geqslant 1}\mathbf{V}^{\vee n}.\tag{A3}$$

Subsuming we have the threefold equation

$$\mathbf{H}=\mathbb{C}\mathbb{1}\oplus\begin{Bmatrix}\mathbf{H}^+\\ H_{n\epsilon 1}\mathbf{H}^n\\ H_{n\epsilon 1}\mathbf{V}^{\Delta n}.\end{Bmatrix}\tag{A4}$$

Proof: (A1) holds for arbitrary Hopf algebras for which $e\epsilon$ is an idempotent with image $\mathbb{C}\mathbb{1}$ and kernel $\mathbf{H}^+=\mathrm{Ker}\,\epsilon$, indeed one has for $h\in\mathbf{H}$: $e\epsilon(e\epsilon h)=e\epsilon(\epsilon(h)\mathbb{1})=e(\epsilon(h))=e\epsilon h$ with $\mathrm{Im}\,e\epsilon=\mathbb{C}\mathbb{1}$ since $e\epsilon(h)=\epsilon(h)\mathbb{1}$ and $e\epsilon(\mathbb{1})=e1=\mathbb{1}$; and with $\mathrm{Ker}\,e\epsilon=\mathbf{H}^+$ since $e\epsilon(h)=\epsilon(h)\mathbb{1}=0$ holds iff $\epsilon(h)=0$.

(A2) is a property of $\mathbb{N}$-graded connected Hopf algebras: check of $\supset$: since $\epsilon\circ Y=0$ (cf. Ref. 2, **2.2** (ii)) for $h\in\mathbf{H}^n$, $\geqslant 1$, $0=\epsilon(Yh)=n\epsilon(h)$ implies $\epsilon(h)=0$. Check of $\subset$: let $h\in\mathbf{H}^+$: by connectivity $h=\lambda\mathbb{1}+h'$ with, $\lambda\in\mathbb{C}$ and $h'\in\oplus_{n\geqslant 1}\mathbf{H}^n$. Hence $\epsilon(h)=0=\lambda+\epsilon(h')=\lambda$ by what precedes, thus $h=h'\in\oplus_{n\geqslant 1}\mathbf{H}^n$.

(A3): check of $\supset$: by definition $\mathbf{V}\subset\mathbf{H}^+$. Hence $\mathbf{V}^{\vee n}\subset\mathbf{H}^{+\vee n}\subset\mathbf{H}^+$. Check of $\subset$: by definition each $h\in\mathbf{H}$ is of the form $h=\lambda\mathbb{1}+h''$, $\lambda\in\mathbb{C}$, $h''\in\oplus_{n\geqslant 1}\mathbf{V}^{\vee n}$. If $h\in\mathbf{H}^+\epsilon(h)=\lambda+0$, hence $\lambda=0$, $h\in\oplus_{n\geqslant 1}\mathbf{V}^{\vee n}$.

APPENDIX B: SEMIDIRECT PRODUCT OF LIE ALGEBRAS

In what follows the ground field is $\mathbb{C}$, or, for that matter, any field of characteristic zero.

Definition-Lemma: Let $\mathbf{L}'$ and $\mathbf{J}$ be two Lie algebras. The *semidirect product* $\mathbf{L}$ *of* $\mathbf{L}'$ *by* $\mathbf{J}$ (denoted by $\mathbf{L}=\mathbf{L}'\ltimes\mathbf{J}$) is defined either as

(i) the vector space $\mathbf{L}'\oplus\mathbf{J}$ with Lie bracket given as follows in terms of the Lie brackets of $\mathbf{L}'$ and $\mathbf{J}$: with $x,y\in\mathbf{L}'$, $j,k\in\mathbf{J}$:

(1) $[x\oplus 0,y\oplus 0]=[x,y]\oplus 0$, $x,y\in\mathbf{L}'$,
(2) $[0\oplus \mathrm{j},0\oplus \mathrm{k}]=0\oplus[j,k]$, $j,k\in\mathbf{J}$,
(3) $[x\oplus 0,0\oplus j]=-[0\oplus j,x\oplus 0]=0\oplus\theta(x)j$, $x\in\mathbf{L}'$, $j\in\mathbf{J}$,

where θ is a Lie algebra homomorphism from $\mathbf{L}'$ to the Lie algebra of derivations of $\mathbf{J}$.

(ia) *This defines a Lie algebra* $\mathbf{L}$.

(ii) the Lie algebra $\mathbf{L}=\mathbf{L}'\oplus\mathbf{J}$ where $\mathbf{L}'$ is a Lie subalgebra and $\mathbf{J}$ is a Lie ideal.

Proof: Check of (ia) from (i): antisymmetry of the Lie bracket is obvious. The Jacobi identify $J(X,Y,Z)=[X,[Y,Z]]+[Y,[Z,X]]+[Z,[X,Y]]=0$ is checked as follows: with $x,y,z\in\mathbf{L}'$, $j,k,l\in\mathbf{J}$:

$$J(x\oplus 0,y\oplus 0,z\oplus 0)=0\Leftarrow\mathbf{L}' \text{ is a Lie algebra: indeed one has}$$

$$[x\oplus 0,[y\oplus 0,z\oplus 0]]=[x\oplus 0,[y,z]\oplus 0]=[x,[y,z]]\oplus 0$$

$$J(0\oplus j,0\oplus k,0\oplus l)=0\Leftarrow\mathbf{J} \text{ is a Lie algebra: indeed one has}$$

$$[0\oplus j,[0\oplus k,0\oplus l]=[0\oplus j,0\oplus[k,l]=0\oplus[j,[k,l]$$

$$J(0\oplus j,y\oplus 0,z\oplus 0)=0\Leftarrow\theta([y,z])=\theta(y)\theta(z)-\theta(z)\theta(y)\text{: indeed one has}$$

$$[0\oplus j,[y\oplus 0,z\oplus 0]]+[y\oplus 0[z\oplus 0,0\oplus j]]+[z\oplus 0,[0\oplus j,y\oplus 0]]$$

$$=[0\oplus j,[y,z]]\oplus 0]+[y\oplus 0,0\oplus\theta(x)j]-[z\oplus 0,0\oplus\theta(y)j]$$

$$=-0\oplus\theta([y,z])j+0\oplus\theta(y)\theta(z)j-0\oplus\theta(z)\theta(y)j$$

$$=-0\oplus(-\theta([y,z]+\theta(y)\theta(z)-\theta(z)\theta(y))j$$

$$J(0\oplus j,0\oplus k,z\oplus 0)=0\Leftarrow\theta(z) \text{ is a derivation of } \mathbf{J} \text{ indeed one has}$$

$$[0\oplus j,[0\oplus k,z\oplus 0]]+[0\oplus k,[z\oplus 0,0\oplus j]]+[z\oplus 0,[0\oplus j,0\oplus k]]$$

$$=-[0\oplus j,0\oplus\theta(z)k]+[0\oplus k,0\oplus\theta(z)j]+[z\oplus 0,0\oplus[j,k]]$$

$$=-0\oplus[j,\theta(z)k]+0\oplus[k,\theta(z)j]+0\oplus\theta(z)[j,k]$$

$$=0\oplus(\theta(z)[j,k]-[\theta(z)j,k]-[j,\theta(z)k])$$

Implication $(i)\Rightarrow(ii)$: obvious.

Implication (ii)⇒(i): (1) respectively, (2) are the definition of the brackets of the Lie subalgebras $\mathbf{L}'$ respectively $\mathbf{J}$. the first equation (3) is obvious, the second arises from the fact that $\mathbf{J}$ is a Lie ideal, with $\theta(x)$ depending linearly on x. The fact that $\theta(x)$ is a derivation of $\mathbf{J}$, and that θ a Lie-algebra map results from former arguments in the reversed direction.

We find an upper bound for geodesic distances associated to monotone Riemannian metrics on positive definite matrices and density matrices. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1689000]

I. INTRODUCTION

The notion and importance of Fisher information is well established in statistics and probability theory. As a measure of distinguishability of probability densities, the Fisher information was used by Rao to define a Riemannian metric on probability spaces. On the simplex of probability vectors $\mathcal{P}_n=\{p=(p_1,\ldots,p_n),\ \Sigma_i p_i=1, p_i>0, i=1,\ldots,n\}$, this is the unique metric contracting under Markovian mappings, by the Chentsov uniqueness theorem. On $\mathcal{P}_n$, the Fisher metric is

$$\lambda_p(x,y)=\sum_i p_i^{-1}x_i y_i, \quad x,y\in T_p\mathcal{P}_n.$$

The geometry of $\mathcal{P}_n$ with this metric is quite simple. By

$$p\mapsto 2(\sqrt{p_1},\ldots,\sqrt{p_n}), \tag{1}$$

it is isometric with an open subset in the sphere of radius 2 in $\mathbb{R}^n$.[5] The metric can be extended to the set $\mathcal{M}_n=\{p=(p_1,\ldots,p_n),\ p_i>0\}$ of all finite (strictly positive) measures on the set $\{1,\ldots,n\}$. Using the isometry (1) and elementary geometry in R^n, we may compute the geodesic distance for the Fisher metric in $\mathcal{P}_n$ and $\mathcal{M}_n$:

$$D(p,q)=2\arccos\left(\sum_i \sqrt{p_i}\sqrt{q_i}\right), \quad p,q\in\mathcal{P}_n$$

(the Bhattacharya distance) and

$$d(p,q)=2\left(\sum_i (\sqrt{p_i}-\sqrt{q_i})^2\right)^{1/2}, \quad p,q\in\mathcal{M}_n.$$

The last expression is related to the Hellinger distance $H(p,q)$ by $d(p,q)=\sqrt{2H(p,q)}$. The Hellinger distance belongs to the family of Cziszár's f-divergences

$$D_f(p,q)=\int f(q/p)dp.$$

Here f is a convex function. As it was shown in Ref. 1, the metric given by the Hessian of f-divergence is a constant multiple of the Fisher metric.

In the case of a quantum system, the situation becomes more complicated. In the simplest case, the states of the system are represented by density matrices. In analogy with manifolds of classical probability densities, a quantum version of the Fisher information metric must be de-

a)Electronic mail: jenca@mat.savba.sk

creasing under stochastic maps. Contrary to the classical case, this monotonicity condition does not specify the metric uniquely. In fact, it was shown by Petz that the monotone metrics can be labeled by operator-monotone functions.

As it was mentioned in Ref. 5, there is no general formula for geodesic path and distance for monotone metrics. Explicit expressions are known only in two particular cases, namely the Bures metric and the Wigner–Yanase metric. In the present paper, we find an upper bound for the geodesic distances for all monotone metrics. This is done in a simple way: Following Uhlmann,[18,19] we obtain the Bures geodesics from certain purifying lifts of curves of density matrices and then make use of a duality relation between the smallest (Bures) and the largest (RLD) of monotone metrics. It is also shown that this upper bound is related to a particular noncommutative version of the Hellinger distance.

II. THE MANIFOLD AND MONOTONE METRICS

Let M_n be the algebra of n by n complex matrices. The set of faithful positive linear functionals on M_n is identified with the cone of positive definite matrices. This set, with the differentiable manifold structure inherited from M_n, will be denoted by $\mathcal{M}$. Let $\mathcal{D}\subset\mathcal{M}$ denote the submanifold of density matrices in $\mathcal{M}$, that is,

$$\mathcal{D}=\{\rho\in\mathcal{M}:\mathrm{Tr}\,\rho=1\}.$$

The tangent space to $\mathcal{M}$ at $\rho\in\mathcal{M}$ is $T_\rho\mathcal{M}=\{x\in M_n:x=x^*\}$. If $\rho\in\mathcal{D}$, then the tangent space $T_\rho\mathcal{D}$ is the subspace of traceless matrices in $T_\rho\mathcal{M}$.

Let λ be a Riemannian metric on $\mathcal{M}$. Then we will say that λ is a monotone metric if

$$\lambda_{T(\rho)}(T(h),T(h))\leqslant\lambda_\rho(h,h),\quad \rho\in\mathcal{M},\ \ h\in T_\rho\mathcal{M},$$

for all completely positive trace preserving maps T. It is an important result of Petz[16] that a Riemannian metric is monotone if and only if it has the form

$$\lambda_\rho(h,k)=\mathrm{Tr}\,hJ_\rho(k),$$

where J_ρ is given by the operator mean

$$J_\rho=R_\rho^{-1}[f(L_\rho/R_\rho)]^{-1}. \tag{2}$$

Here L_ρ and R_ρ are the left and the right multiplication operators and $f:(0,\infty)\to\mathbb{R}$ is an operator monotone function which is symmetric, that is, $f(t)=tf(t^{-1})$. It is immediate from (2) that under the normalization $f(1)=1$, any monotone metric is equal to the Fisher metric on commutative submanifolds. Moreover, we have

$$\frac{2t}{1+t}\leqslant f(t)\leqslant\frac{1+t}{2}$$

for all symmetric normalized operator monotone functions.[12] Accordingly, there is a greatest and a smallest element in the set of monotone metrics.

The smallest monotone metric is obtained for $f(t)=(1+t)/2$. It is called the Bures metric because it is related to the Bures distance (see also Sec. IV). The operator

$$J_\rho(h)=g,\quad \rho g+g\rho=2h,$$

is the symmetric logarithmic derivative (see Refs. 9, 18, and 2).

The greatest monotone metric corresponds to the function $f(t)=2t/(1+t)$. In this case J_ρ is the right logarithmic derivative (RLD)

$$J_\rho(h)=\tfrac{1}{2}(\rho^{-1}h+h\rho^{-1})$$

(see Refs. 9, 16, and 17). More examples of monotone metrics can be found in Sec. V.

III. STANDARD REPRESENTATION AND MONOTONE METRICS

The standard representation of the algebra M_n is obtained if M_n is endowed with the Hilbert–Schmidt inner product

$$\langle x,y\rangle=\mathrm{Tr}\,x^*y.$$

Let us denote the resulting Hilbert space by H. Then M_n is represented on H by

$$\phi:M_n\to\mathcal{B}(H),\quad a\mapsto L_a,$$

where L_a is the left multiplication operator $L_aw=aw$, $w\in H$. Each element ρ in $\mathcal{M}$ has a vector representative, or purification, w in H, such that

$$\mathrm{Tr}\,\rho a=\langle w,L_aw\rangle\quad\forall a\in M_n.$$

Then $w\in H$ is a vector representative of $\rho\in\mathcal{M}$ if and only if $\rho=ww^*$.

Let ρ_t, $t\in I$, be a smooth curve in $\mathcal{M}$. A curve w_t in H, such that w_t is a vector representative of ρ_t for all $t\in I$, is called a lift of ρ_t. In this case, the tangent vectors are related by

$$\dot\rho_t=\dot w_tw_t^*+w_t\dot w_t^*. \tag{3}$$

Let us denote the corresponding projection of the tangent spaces $T_wH\to T_{ww^*}\mathcal{M}$ by Π.

Let $w_0w_0^*=\rho_0$. There are many lifts of ρ_t through w_0. Among such lifts, there is a unique lift with minimal Hilbert space length

$$l_H(w_t)=\int_I\sqrt{\langle\dot w_t,\dot w_t\rangle}dt.$$

It will be called the horizontal lift.

The horizontal lift was introduced in Refs. 18 and 19, where the geometric phase was extended to mixed states. It was shown that the above minimalization problem leads to the condition

$$w_t^*\dot w_t=\dot w_t^*w_t \tag{4}$$

for all t. The curves w_t in H, satisfying this condition, are called horizontal curves. The tangent vectors to horizontal curves at $w\in H$ form a real vector subspace $H_w=\{gw,\ g=g^*\}$. Let H_w be endowed with the inner product $\mathrm{Re}\langle\cdot,\cdot\rangle$. Then it is a real Hilbert space, called the horizontal subspace. For each $h\in T_{ww^*}\mathcal{M}$, there is a unique element $\hat h$ in H_w satisfying $h=\Pi(\hat h)$. It follows that the inner product in H_w can be projected onto $T_{ww^*}\mathcal{M}$. As it turns out, this projection defines a Riemannian metric on $\mathcal{M}$. Moreover,

$$4\,\mathrm{Re}\,\langle\hat h,\hat k\rangle=2\,\mathrm{Tr}\,h(L_\rho+R_\rho)^{-1}(k),\quad h,k\in T_\rho\mathcal{M}, \tag{5}$$

is exactly the Bures metric.

The commutant of $\phi(M_n)$ is the algebra of right multiplication operators $R_aw=wa$, $a\in M_n$, on H. For each $\sigma\in\mathcal{M}$, there is an element $w\in H$ such that

$$\langle w,R_aw\rangle=\mathrm{Tr}\,\sigma a.$$

This element is given by $\sigma=w^*w$. For each curve σ_t in $\mathcal{M}$, let us consider the curves w_t in H satisfying $w_t^*w_t=\sigma_t$. The tangent vectors of such curves satisfy $\dot{\sigma}_t=\tilde{\Pi}(\dot{w}_t)$, where $\tilde{\Pi}:T_wH \to T_{w^*w}\mathcal{M}$ is given by

$$\tilde{\Pi}(x)=x^*w+w^*x.$$

We may now proceed exactly as before, choosing for each σ_t the shortest of these curves. It is quite clear that w_t is the shortest curve if and only if w_t^* is horizontal; equivalently, $\dot{w}_t\in\tilde{H}_{w_t}$ $:=\{w_tg,\ g=g^*\}$ for all t. Moreover, we have

$$x\in H_w\Leftrightarrow x^*\in\tilde{H}_{w^*}. \tag{6}$$

If we now project the real Hilbert space structure from $\tilde{H}_w$ to $T_{w^*w}\mathcal{M}$, using the projection $\tilde{\Pi}$, we will, of course, get the Bures metric again. On the other hand, it is easy to see that for each ρ $=ww^*$ and $h\in T_\rho\mathcal{M}$, $\tilde{h}:=\frac{1}{2}h(w^*)^{-1}$ is the unique element in $\tilde{H}_w$ satisfying $h=\Pi(\tilde{h})$. We may therefore define

$$\lambda_\rho(h,k):=4\ \mathrm{Re}\langle\tilde{h},\tilde{k}\rangle=\tfrac{1}{2}\mathrm{Tr}\,\rho^{-1}(hk+kh), \tag{7}$$

which is the RLD metric. This shows that there is a duality relation between the Bures metric and RLD (see also Refs. 14 and 10).

IV. THE GEODESIC DISTANCES

Let λ be a Riemannian metric on $\mathcal{M}$. A curve ρ_t, $t\in[0,1]$, is a geodesic path in $\mathcal{M}$ if its length

$$l_\lambda(\rho_t)=\int_0^1\sqrt{\lambda_{\rho_t}(\dot{\rho}_t,\dot{\rho}_t)}dt$$

is the minimum of lengths of all curves connecting ρ_0 and ρ_1. This length is then the geodesic distance of ρ_0 and ρ_1. Let us denote by d_λ the geodesic distance for the metric λ in $\mathcal{M}$ and by D_λ the geodesic distance in $\mathcal{D}$.

For the Bures metric, the geodesic paths and distances were obtained by Uhlmann[18,19] as follows. Let ρ_0 and ρ_1 be two elements in $\mathcal{M}$ and let ρ_t be a curve connecting them. If w_t is the horizontal lift of ρ_t, then by (5)

$$l_{\mathrm{Bures}}(\rho_t)=2l_H(w_t),$$

hence minimizing the Bures length means minimizing the Hilbert space length of horizontal lifts of curves connecting ρ_0 and ρ_1. From the definition of horizontality, this minimum is attained at the line segment $w_t=tw_1+(1-t)w_0$, such that $\|w_0-w_1\|$ is minimal over $w_0w_0^*=\rho_0$, $w_1w_1^*$ $=\rho_1$. This happens if and only if w_1 and w_0 are parallel amplitudes, that is, these satisfy Uhlmann's parallelity condition

$$w_1^*w_0\geqslant 0. \tag{8}$$

For each w_0 there is a unique w_1 parallel to w_0, given by[19]

$$w_1=\rho_0^{-1/2}(\rho_0^{1/2}\rho_1\rho_0^{1/2})^{1/2}\rho_0^{-1/2}w_0.$$

The geodesic path in $\mathcal{M}$, connecting ρ_0 and ρ_1, is then

$$\rho_t=(tw_1+(1-t)w_0)(tw_1+(1-t)w_0)^*,$$

and the geodesic distance is

$$d_{\mathrm{Bures}}(\rho_0,\rho_1)=2\|w_0-w_1\|=2\sqrt{\mathrm{Tr}\,\rho_0+\mathrm{Tr}\,\rho_1-2\mathrm{Tr}\,(\rho_0^{1/2}\rho_1\rho_0^{1/2})^{1/2}}.$$

This is called the Bures distance.

Let ρ_t now be a curve in $\mathcal{D}$. Then all lifts of ρ_t are curves on the unit sphere S in H. If w_0, $w_1\in S$, the shortest curve connecting them lies on the large circle in S through them. The length of such arcs for $w_0w_0^*=\rho_0$ and $w_1w_1^*=\rho_1$ is minimal if w_0 and w_1 are parallel amplitudes and, by definition, in this case the arc is also horizontal. Hence, the Bures geodesic in $\mathcal{D}$ is

$$\rho_t=\frac{(w_0+(1-t)w_1)(tw_0+(1-t)w_1)^*}{\|tw_0+(1-t)w_1)\|^2}$$

for parallel amplitudes w_0 and w_1 and the Bures distance

$$D_{\mathrm{Bures}}(\rho_0,\rho_1)=2\arccos\mathrm{Tr}\,w_0w_1^*=2\arccos\mathrm{Tr}\,(\rho_0^{1/2}\rho_1\rho_0^{1/2})^{1/2}.$$

The duality of the Bures and RLD metrics leads to the following upper bound for the RLD geodesic distance.

Proposition 4.1: Let $\rho_0,\ \rho_1\in\mathcal{M}$. *Then*

$$d_{\mathrm{RLD}}(\rho_0,\rho_1)\leqslant d_{\mathrm{Bures}}(\rho_0,\rho_0^{-1/2}(\rho_0\#\rho_1)^2\rho_0^{-1/2}),$$

where

$$\rho_0\#\rho_1=\rho_0^{1/2}(\rho_0^{-1/2}\rho_1\rho_0^{-1/2})^{1/2}\rho_0^{1/2}$$

is the geometric mean. If ρ_0 and ρ_1 are in $\mathcal{D}$, the same holds for geodesic distances D_{RLD} and D_{Bures}.

Proof: Let $w_0=\rho_0^{1/2}$ and let $w\in H$ be such that w_0 and w satisfy the parallelity condition (8). Then the curve $w_t=tw+(1-t)w_0$ is the horizontal lift of the Bures geodesic connecting ρ_0 and ww^*, in particular, $\dot{w}_t\in H_{w_t}$ for all t. Then w_t^* is a lift of a curve ρ_t in $\mathcal{M}$, connecting ρ_0 and w^*w and by (6), $\dot{w}_t^*\in\tilde{H}_{w_t^*}$. Consequently, by (7),

$$d_{\mathrm{RLD}}(\rho_0,w^*w)\leqslant l_{\mathrm{RLD}}(\rho_t)=2\|w^*-w_0^*\|=2\|w-w_0\|=d_{\mathrm{Bures}}(\rho_0,ww^*).$$

From the parallelity condition, $w=qw_0$ for some $q=q^*>0$. Let us choose w such that

$$\rho_1=w^*w=\rho_0^{1/2}q^2\rho_0^{1/2}.$$

Then $q=(\rho_0^{-1/2}\rho_1\rho_0^{-1/2})^{1/2}$ and

$$ww^*=\rho_0^{-1/2}(\rho_0\#\rho_1)^2\rho_0^{-1/2}.$$

The statement for distances in $\mathcal{D}$ is proved exactly the same way. □

Remark 4.1: Let w_0, w and q be as in the proof of the previous proposition. Then we have

$$\|w_0-w\|^2=\mathrm{Tr}\,\rho_0+\mathrm{Tr}\,\rho_1-2\mathrm{Tr}\,\rho_0q$$

and

$$d_{\mathrm{Bures}}(\rho_0,\rho_0^{-1/2}(\rho_1\#\rho_0)^2\rho_0^{-1/2})=2\sqrt{\mathrm{Tr}\,\rho_0+\mathrm{Tr}\,\rho_1-2\mathrm{Tr}\,\rho_0\#\rho_1}\tag{9}$$

so that ρ_0 and ρ_1 can be exchanged.

Remark 4.2: Let $\rho_t = w_t^* w_t$ and q be as in the proof of Proposition 4.1. Then, in general, ρ_t is not the RLD geodesic. Indeed, it can be easily computed that for the RLD metric, the geodesic equation reads

$$\ddot{\rho}_t + \frac{1}{L_{\rho_t} + R_{\rho_t}}(\dot{\rho}_t^2) - \dot{\rho}_t \rho_t^{-1} \dot{\rho}_t = a(t)\dot{\rho}_t,$$

where a is a smooth function $a: I \to \mathbb{R}$ (see also Ref. 3). We have

$$\rho_t = w_t^* w_t = \rho_0^{1/2}(1 + t(q-1))^2 \rho_0^{1/2}.$$

It can be shown by direct computation that the geodesic equation is satisfied if and only if

$$q(\rho_0 q - q\rho_0) = (\rho_0 q - q\rho_0)q,$$

which, for self-adjoint operators, implies $q\rho_0 = \rho_0 q$. It follows that the inequality in Proposition 4.1 is strict, unless ρ_0 and ρ_1 commute. In that case, the geodesic distances are the same for all monotone metrics.

In Ref. 17, a class of generalized relative entropies

$$H_g(\rho_0, \rho_1) = \operatorname{Tr} \rho_0 g(\rho_0^{-1/2} \rho_1 \rho_0^{-1/2})$$

was introduced; here g is an operator convex function. This is a noncommutative version of the f-divergence. It was shown in Ref. 17 that the generalized entropy H_g leads to a constant multiple of the RLD metric for infinitesimaly close elements in $\mathcal{D}$.

It is easy to see that the right hand side of (9) is equal to $\sqrt{2H_{g_0}(\rho_0, \rho_1)}$, where

$$g_0(t) = 2 + 2t - 4t^{1/2}. \tag{10}$$

Note that on commuting elements, H_{g_0} is equal to the Hellinger distance.

By maximality of the RLD metric, we obtain the following.

Corollary 4.1: Let $\rho_0, \rho_1 \in \mathcal{M}$ and let λ be a monotone metric. Then

$$d_{\text{Bures}}(\rho_0, \rho_1) \leq d_\lambda(\rho_0, \rho_1) \leq \sqrt{2H_{g_0}(\rho_0, \rho_1)} < 2\sqrt{\operatorname{Tr}\rho_0 + \operatorname{Tr}\rho_1}.$$

If $\rho_0,\ \rho_1 \in \mathcal{D}$, then

$$2 \arccos \operatorname{Tr}(\rho_0^{1/2} \rho_1 \rho_0^{1/2})^{1/2} \leq D_\lambda(\rho_0, \rho_1) \leq 2 \arccos \operatorname{Tr} \rho_0 \# \rho_1 < \pi.$$

V. THE WYD METRICS

The Wigner–Yanase–Dyson (WYD) metrics are defined by

$$\lambda_\rho^\alpha(h,k) = \frac{\partial^2}{\partial t \partial s} \operatorname{Tr} f_\alpha(\rho + th) f_{-\alpha}(\rho + sk)\big|_{s,t=0},$$

where

$$f_\alpha(x) = \begin{cases} \dfrac{2}{1-\alpha} x^{(1-\alpha)/2}, & \alpha \neq 1, \\ \log(x), & \alpha = 1. \end{cases}$$

As it was shown in Ref. 8, these metrics are monotone for $\alpha\in[-3,3]$. The family of WYD metrics is important in quantum information geometry (see Refs. 7, 11, and 6). As special cases, for $\alpha=\pm1$, we get the well known Bogoljubov–Kubo–Mori metric and for $\alpha=\pm3$ we get the RLD metric.

The smallest in this family is the Wigner–Yanase (WY) metric, obtained for $\alpha=0$. The WY metric has the form

$$\lambda_\rho(h,k)=4\,\mathrm{Tr}\,h(\sqrt{L_\rho}+\sqrt{R_\rho})^{-2}(k).$$

The corresponding geodesic path and distance was computed in Ref. 5, using a noncommutative version of the square root map (1) and a pullback technique. We will show that these can also be easily obtained using a similar method as in the Bures case.

Let ρ_t be a curve in $\mathcal{M}$. Among its lifts $w_tw_t^*=\rho_t$, we will again choose a horizontal one. In this case, the lift w_t is horizontal if it is contained in the natural positive cone at w_0, that is, if $w_t=\rho_t^{1/2}u_0$ for all t. In this case, the horizontal subspace is $H_w^0=\{gu,\ g=g^*\}$, where $w=\rho^{1/2}u$ is the polar decomposition of w. Each tangent vector $h\in T_{ww^*}\mathcal{M}$ has a unique horizontal lift $h^0=gu\in H_w^0$, such that $h=\Pi(h^0)=g\rho^{1/2}+\rho^{1/2}g$. The induced metric

$$\lambda_\rho(h,k)=4\,\mathrm{Re}\langle h^0,k^0\rangle=4\,\mathrm{Tr}\,h(L_\rho^{1/2}+R_\rho^{1/2})^{-2}(k)$$

is the WY metric. Note that in this case $x\in H_w^0$ if and only if $x^*\in H_{w^*}^0$, so that the WY metric is self-dual, in the sense mentioned in Sec. III. Let us also remark that it is possible to obtain all the monotone metrics in a similar manner (see Refs. 4 and 10).

Now let ρ_0 and ρ_1 be in $\mathcal{M}$ and let ρ_t be a curve connecting them. Again, the WY length of ρ_t is twice the Hilbert space length of its horizontal lift $w_t=\rho_t^{1/2}u_0$. Therefore, ρ_t is the geodesic path if $w_t=t\rho_1^{1/2}u_0+(1-t)\rho_0^{1/2}u_0$, that is,

$$\rho_t=(t\rho_1^{1/2}+(1-t)\rho_0^{1/2})^2$$

and the geodesic distance is

$$d_{\mathrm{WY}}(\rho_0,\rho_1)=2\|\rho_0^{1/2}-\rho_1^{1/2}\|=2\sqrt{\mathrm{Tr}\,\rho_0+\mathrm{Tr}\,\rho_1-2\,\mathrm{Tr}\,\rho_0^{1/2}\rho_1^{1/2}}.$$

Similarly, if $\rho_0,\ \rho_1\in\mathcal{D}$, then ρ_t is a geodesic path if and only if w_t lies on the large circle connecting $\rho_0^{1/2}u_0$ and $\rho_1^{1/2}u_0$. Hence

$$\rho_t=\frac{(t\rho_1^{1/2}+(1-t)\rho_0^{1/2})^2}{\|t\rho_1^{1/2}+(1-t)\rho_0^{1/2}\|^2}$$

and

$$D_{\mathrm{WY}}(\rho_0,\rho_1)=2\arccos\mathrm{Tr}\,\rho_0^{1/2}\rho_1^{1/2}.$$

Let us denote by $\Delta_{\sigma,\rho}=L_\sigma R_\rho^{-1}$ the relative modular operator. In Ref. 15, a class of quasi-entropies was introduced by

$$S_g(\rho,\sigma)=\mathrm{Tr}\,\rho^{1/2}g(\Delta_{\sigma,\rho})(\rho^{1/2}),$$

where g is an operator convex function. This is another quantum version of the f-divergences. It is easy to see that

$$d_{WY}(\rho_0,\rho_1)=\sqrt{2S_{g_0}(\rho_0,\rho_1)},\tag{11}$$

where g_0 is given by (10). It was proved in Ref. 13 that each monotone metric can be obtained as the Hessian of S_g for a suitable operator convex function g. The choice $g=g_0$ leads to the WY metric.

From the previous section and the fact that the WY metric is the least element in the family of WYD metrics, we obtain the following.

Corollary 5.1: Let λ *be a WYD metric and* $\rho_0,\rho_1\in\mathcal{M}$. *Then*

$$\sqrt{2S_{g_0}(\rho_0,\rho_1)}=d_{\mathrm{WY}}(\rho_0,\rho_1)\leq d_\lambda(\rho_0,\rho_1)\leq\sqrt{2H_{g_0}(\rho_0,\rho_1)},$$

where $g_0(t)=2+2t-4t^{1/2}$. If $\rho_0,\rho_1\in\mathcal{D}$, *then*

$$2\arccos\mathrm{Tr}\,\rho_0^{1/2}\rho_1^{1/2}\leq D_\lambda(\rho_0,\rho_1)\leq 2\arccos\mathrm{Tr}\,\rho_0\#\rho_1.$$

Locality and orthomodular structure of compound systems

Teppei Watanabe[a)]
Division of Physics, Graduate School of Science, Hokkaido University, Sapporo 060-0810, Japan

(Received 16 January 2003; accepted 4 February 2004; published 1 April 2004)

A P-lattice is defined as a σ-complete, orthomodular atomic lattice $\mathcal{L}$ which is formed by the set of propositions of a physical system. A composition of physical systems in the framework of P-lattices is considered and some notions of locality are given. It is shown that the following statements about compound systems are equivalent. (a) All atoms of a compound system are reducible to those of its subsystems. (b) All pure states of a compound system are separable into those of its subsystems. (c) A compound system has statistical property independence. (d) At least one of the subsystems is classical. (e) Bell-type inequalities hold. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1690490]

I. INTRODUCTION

According to so-called logico-algebraic approaches to physics, one of the differences between classical and quantum mechanics is in whether distributive law holds in their propositional structures; the lattices of observational propositions in classical mechanics are distributive and those in quantum mechanics are not (see, e.g., Ref. 1).

On the other hand, Bell[2] found another difference. He showed that stochastic inequalities following from a kind of locality condition, which holds for classical mechanics, can be violated by quantum mechanical predictions. According to experimental results and philosophical discussions, one must recognize some nonlocality in quantum mechanics (henceforce *Bell-type arguments*).

The questions now arise: Is there any relation between the two new features of quantum mechanics, i.e., nondistributivity and nonlocality? For example, could the nondistributive propositional structure of a compound system imply the nonlocal feature of the system? Or, would these features merely tell how large the differences between classical and quantum picture of reality are? Studies which have been made on the matter can be divided into two groups: One group, which focuses on the role of joint probabilities in the Bell-type arguments, studies connections between propositional structures and certain stochastic inequalities for them.[3–6] The other group, which focuses on the role of locality in the Bell-type arguments, formulates locality conditions for propositional structures and studies connections between nonlocality and nondistributivity.[7–13]

However, very few attempts[14] have been made to unify the two ways. What seems to be lacking is a logical and conceptual clarification of notions such as ''classicality'' and ''locality'' in the Bell-type arguments. The purpose of this article is to clarify these notions within a lattice-theoretical approach, and to establish the logical connections among propositional structures of sub- and compound systems, locality conditions and Bell-type inequalities.

II. PROPOSITIONAL STRUCTURES OF PHYSICAL SYSTEMS

Presupposing definitions of standard lattice-theoretical notions (see, e.g., Ref. 15), let us begin with basic definitions and notations for our arguments (see also Ref. 10).

[a)]Electronic mail: teppei@hps.sci.hokudai.ac.jp

A *P-lattice* is a σ-complete, orthomodular atomic lattice $\mathcal{L}$ which is formed by the set of propositions of a physical system.[16] A distributive P-lattice is called *classical*, which is isomorphic to the Borel σ-field of some phase space in classical mechanics. An irreducible P-lattice is called *quantum*, which is isomorphic to the lattice of all closed subspaces of some Hilbert space.

For notation, $(a,b)\,\mathsf{C}$ denotes that elements $a,b\in\mathcal{L}$ commute with each other, $\mathcal{C}(\mathcal{L})$ stands for the center of $\mathcal{L}$, and $\mathcal{A}(\mathcal{L})$ for the set of all atoms of $\mathcal{L}$.

A σ-additive probability measure m on a P-lattice $\mathcal{L}$ is called a *state*, and the set of states is denoted by $\mathcal{M}$. The set $\mathcal{M}$ is σ-convex. An element of the extremal subset $\mathcal{M}_p$ of $\mathcal{M}$ is called a *pure state*. Further, we shall suppose the Jauch–Piron condition for pure states, i.e., $m(a)=1=m(b)$ imply $m(a\wedge b)=1$ for any $m\in\mathcal{M}_p$.

A pair $(\mathcal{L},\mathcal{M}_p)$ of a P-lattice $\mathcal{L}$ and a set $\mathcal{M}_p$ of pure states on $\mathcal{L}$ is called *complete* if there is a bijective correspondence between $\mathcal{A}(\mathcal{L})$ and $\mathcal{M}_p$ such that $m(x)=1$ for all $x\in\mathcal{A}(\mathcal{L})$ and all $m\in\mathcal{M}_p$. A complete pair $(\mathcal{L},\mathcal{M}_p)$ is called a *physical system*. We shall say that a physical system is *classical* (resp. *quantum*) if the P-lattice is classical (resp. quantum).

Let $\mathcal{S}$ be a set of pure states on a P-lattice $\mathcal{L}$. We say that a state m is the *superposition* of the states in $\mathcal{S}$ if

$$\mathcal{S}(a)=1\ \ [\text{i.e., } s(a)=1\ \ \text{for}\ \ \forall s\in\mathcal{S}]\Rightarrow m(a)=1\,\text{for}\ \ \forall a\in\mathcal{L}.$$

If $(\mathcal{L},\mathcal{M}_p)$ is a physical system, we put $\overline{\mathcal{S}}=\{m\in\mathcal{M}_p|\mathcal{S}(a)=1\Rightarrow m(a)=1\}$ for any $\mathcal{S}\subseteq\mathcal{M}_p$.

In the following sections, we prove some theorems. For their proofs, we shall appeal frequently to the following two theorems:

Theorem 1 (e.g., Ref. 17, Lemma 3.10): *Let $\mathcal{L}$ be a σ-complete orthomodular lattice, and let $a,b_1,b_2,\ldots$ be elements of $\mathcal{L}$. If $(a,b_i)\,\mathsf{C}$ for all i, then $(a,b_i^{\perp})\,\mathsf{C}$, $(a,\vee b_i)\,\mathsf{C}$ and $(a,\wedge b_i)\,\mathsf{C}$.*

Theorem 2 [Foulis–Holland (e.g., Ref. 18, Theorem 3)]: *Let $\mathcal{L}$ be an orthomodular lattice, and let a,b,c be elements of $\mathcal{L}$. If one of them commutes with the other two, then triple (a,b,c) is distributive.*

III. DESCRIPTIONS OF COMPOUND SYSTEMS

Over the last few decades, a considerable number of studies have been made on the description of compound systems in lattice-theoretical approaches. Unfortunately, there is a well-known open problem in the case of compound systems consisting of two quantum subsystems.[7–12,19] However, our purposes are not to deal with the problem but to consider some properties in compound systems if such a description is possible. With this problem in mind, let us now turn to our task.

We shall be almost exclusively concerned with a compound system S consisting of two subsystems S_1 and S_2. Let us state how to describe the situation in terms of P-lattices. By using P-lattices $\mathcal{L}_i$ associated with subsystems S_i $(i=1,2)$, we define a P-lattice associated with the compound system S as follows.[10,13]

Definition 1: Let $\mathcal{L}_1$ and $\mathcal{L}_2$ be P-lattices. A P-lattice $\mathcal{L}$ is called a compound P-lattice if

(i) *there exist two injective σ-orthohomomorphisms $h_i:\mathcal{L}_i\to\mathcal{L}(i=1,2)$,*
(ii) *$h_1(p)\wedge h_2(q)\in\mathcal{A}(\mathcal{L})$ for every $p\in\mathcal{A}(\mathcal{L}_1)$, $q\in\mathcal{A}(\mathcal{L}_2)$,*
(iii) *$(h_1(a),h_2(b))\,\mathsf{C}$ for every $a\in\mathcal{L}_1$, $b\in\mathcal{L}_2$, and*
(iv) *$h_1(\mathcal{L}_1)\cup h_2(\mathcal{L}_2)$ generates $\mathcal{L}$.*

Further, by using physical systems $(\mathcal{L}_i,\mathcal{M}_{p_i})$ associated with S_i $(i=1,2)$, we define a physical system associated with S as follows.[10]

Definition 2: Let $(\mathcal{L}_1,\mathcal{M}_{p_1})$ and $(\mathcal{L}_2,\mathcal{M}_{p_2})$ be physical systems. We say that a physical system $(\mathcal{L},\mathcal{M}_p)$ is a compound physical system of $(\mathcal{L}_1,\mathcal{M}_{p_1})$ and $(\mathcal{L}_2,\mathcal{M}_{p_2})$ if there exist mappings α,β such that

(i) $\alpha:\mathcal{L}_1\times\mathcal{L}_2\to\mathcal{L}$, $\beta:\mathcal{M}_{p_1}\times\mathcal{M}_{p_2}\to\mathcal{M}_p$,
$$\beta(m_1,m_2)(\alpha(a_1,a_2))=m_1(a_1)m_2(a_2) \quad \text{for} \quad a_i\in\mathcal{L}_i, m_i\in\mathcal{M}_{p_i}(i=1,2),$$
(ii) $\{m\in\mathcal{M}_p|m(a)=1\}=\overline{\{\beta(m_1,m_2)|\beta(m_1,m_2)(a)=1\}}$ *for* $a\in\mathcal{L}$ *of the form*
$$a=\wedge_{k=1}^{N}\alpha(a_1^k,a_2^k), \quad a_i^k\in\mathcal{L}_i \quad (i=1,2) \quad \textit{or}$$
$$a=\alpha(a_1,I_2)^{\perp}, \quad a_1\in\mathcal{L}_1 \quad \textit{or} \quad a=\alpha(I_1,a_2)^{\perp}, \quad a_2\in\mathcal{L}_2,$$
(iii) $\alpha[\mathcal{L}_1\times\mathcal{L}_2]$ *generates* $\mathcal{L}$, *and*
(iv) $\beta[\mathcal{M}_{p_1}\times\mathcal{M}_{p_2}]=\mathcal{M}_p$.

A connection between compound P-lattices and compound physical systems is given by the following theorem.

Theorem 3 (Ref. 10, Theorem 4): *Let* $(\mathcal{L},\mathcal{M}_p)$ *be a compound physical system of* $(\mathcal{L}_1,\mathcal{M}_{p_1})$ *and* $(\mathcal{L}_2,\mathcal{M}_{p_2})$. *Let us put*
$$h_1:\mathcal{L}_1\to\mathcal{L} \ , \ a_1\mapsto\alpha(a_1,I_2), \quad h_2:\mathcal{L}_2\to\mathcal{L} \ , \ a_2\mapsto\alpha(I_1,a_2).$$
Then $\mathcal{L}$ *is a compound P-lattice of* $\mathcal{L}_1$ *and* $\mathcal{L}_2$.

From these definitions, the following expected results are obtained. (For similar result in other schemes, see Ref. 11.)

Theorem 4 (Ref. 20, Corollaries 1 and 2): *Let* $(\mathcal{L},\mathcal{M}_p)$ *be a compound physical system of* $(\mathcal{L}_1,\mathcal{M}_{p_1})$ *and* $(\mathcal{L}_2,\mathcal{M}_{p_2})$.

(i) $\mathcal{L}$ *is distributive if and only if both* $\mathcal{L}_1$ *and* $\mathcal{L}_2$ *are distributive.*
(ii) $\mathcal{L}$ *is irreducible if and only if both* $\mathcal{L}_1$ *and* $\mathcal{L}_2$ *are irreducible.*

This theorem seems to assure that Definitions 1 and 2 grasp the notion of composition which classical and quantum mechanics have in common.

IV. SUFFICIENT CONDITIONS FOR BELL-TYPE INEQUALITIES

In this section, we shall consider some important notions concerning Bell-type arguments, and examine connections among them. Furthermore, we shall show that these notions are sufficient conditions for deriving Bell-type inequalities mentioned later. Let us begin with some definitions.

Definition 3: Let $(\mathcal{L},\mathcal{M}_p)$ *be a compound physical system of* $(\mathcal{L}_1,\mathcal{M}_{p_1})$ *and* $(\mathcal{L}_2,\mathcal{M}_{p_2})$.

(1) We say that $(\mathcal{L},\mathcal{M}_p)$ *has property reducibility if the set of all atoms of* $\mathcal{L}$ *is of the form*
$$\mathcal{A}(\mathcal{L})=\{h_1(q_1)\wedge h_2(q_2)|q_1\in\mathcal{A}(\mathcal{L}_1),q_2\in\mathcal{A}(\mathcal{L}_2)\}.$$
(2) We say that $(\mathcal{L},\mathcal{M}_p)$ *has state separability if the set of all pure states on* $\mathcal{L}$ *is of the form*
$$\mathcal{M}_p=\beta[\mathcal{M}_{p_1}\times\mathcal{M}_{p_2}].$$

Intuitively, the property reducibility means that all physical properties of a whole system are merely the sum of, or are supervenient on, those of its subsystems. (We say that there exists a *holistic property* in a compound physical system, if it does not have property reducibility.) The state separability reflects a notion that spatially separated systems always possess states of their own, which determine the state assigned to the compound system. (We say that there exists a *nonseparable state* in a compound physical system, if it does not have state separability.)

Remark that from a philosophical point of view, the notions of reducibility and separability should be distinguished from each other as Healey[21] pointed out; that is, while the term ''reducibility'' is used to describe part-whole relations, the term ''separability'' is based on spatio-temporal relations. However, we shall identify these notions by virtue of the following theorem.

Theorem 5: *Let* $(\mathcal{L},\mathcal{M}_p)$ *be a compound physical system of* $(\mathcal{L}_1,\mathcal{M}_{p_1})$ *and* $(\mathcal{L}_2,\mathcal{M}_{p_2})$. *The following statements are equivalent.*

(a) $(\mathcal{L},\mathcal{M}_p)$ *has property reducibility.*
(b) $(\mathcal{L},\mathcal{M}_p)$ *has state separability.*

Proof: [(a)⇒(b)]: Since $(\mathcal{L},\mathcal{M}_p)$ is complete, there is an atom $a\in\mathcal{A}(\mathcal{L})$ such that $m(a)=1$ for any $m\in\mathcal{M}_p=\beta[\mathcal{M}_{p_1}\times\mathcal{M}_{p_2}]$. From (a), there exist $x\in\mathcal{A}(\mathcal{L}_1)$ and $y\in\mathcal{A}(\mathcal{L}_2)$ such that $a=h_1(x)\wedge h_2(y)=\alpha(x,I_2)\wedge\alpha(I_1,y)=\alpha(x,y)$ (where last equality is due to Proposition 2 of Ref. 10). Further, there exist $m_1\in\mathcal{M}_{p_1}$ and $m_2\in\mathcal{M}_{p_2}$ such that $m_1(x)=1$ and $m_2(y)=1$, and we have

$$m(\alpha(x,y))=1=m_1(x)m_2(y)=\beta(m_1,m_2)(\alpha(x,y)).$$

Then we get $m=\beta(m_1,m_2)\in\beta[\mathcal{M}_{p_1}\times\mathcal{M}_{p_2}]$, and hence $\overline{\beta[\mathcal{M}_{p_1}\times\mathcal{M}_{p_2}]}\subseteq\beta[\mathcal{M}_{p_1}\times\mathcal{M}_{p_2}]$. It is obvious by definition that the opposite inclusion holds. As a result we have $\overline{\beta[\mathcal{M}_{p_1}\times\mathcal{M}_{p_2}]}=\beta[\mathcal{M}_{p_1}\times\mathcal{M}_{p_2}]$.

[(b)⇒(a)]: There exist $m_1\in\mathcal{M}_{p_1}$ and $m_2\in\mathcal{M}_{p_2}$ such that $m=\beta(m_1,m_2)$ for any $m\in\mathcal{M}_p=\beta[\mathcal{M}_{p_1}\times\mathcal{M}_{p_2}]$. Further, there exist $x\in\mathcal{A}(\mathcal{L}_1)$ and $y\in\mathcal{A}(\mathcal{L}_2)$ such that $m_1(x)=1$ and $m_2(y)=1$ for m_1 and m_2. Then we have

$$1=m_1(x)m_2(y)=\beta(m_1,m_2)(\alpha(x,y))=m(\alpha(x,y)),$$

which means that an atom corresponding to $m\in\mathcal{M}_p$ is of the form $\alpha(x,y)=h_1(x)\wedge h_2(y)$. Therefore we get $\mathcal{A}(\mathcal{L})=\{h_1(q_1)\wedge h_2(q_2)|q_1\in\mathcal{A}(\mathcal{L}_1),q_2\in\mathcal{A}(\mathcal{L}_2)\}$. □

As a consequence, we shall simply say in the following argument that $(\mathcal{L},\mathcal{M}_p)$ has *separability* if it has one (hence both) of these features.

An implication of having separability is shown in the following theorem, which has been given by Pykacz and Santos.[14] (Their scheme is slightly different from ours, but the method of their proof can be applied to ours.)

Theorem 6 (Ref. 14, Theorem 2): *Let* $(\mathcal{L},\mathcal{M}_p)$ *be a compound physical system of* $(\mathcal{L}_1,\mathcal{M}_{p_1})$ *and* $(\mathcal{L}_2,\mathcal{M}_{p_2})$. *If* $(\mathcal{L},\mathcal{M}_p)$ *has state separability, the following Clauser–Horne version of Bell's inequalities,*

$$\begin{aligned}&m(\,h_1(a)\wedge h_2(b)\,)+m(\,h_1(c)\wedge h_2(b)\,)+m(\,h_1(c)\wedge h_2(d)\,)\\&\quad-m(\,h_1(a)\wedge h_2(d)\,)-m(\,h_1(c)\,)-m(\,h_2(b)\,)\leqslant 0,\end{aligned}\tag{1}$$

holds for any $m\in\mathcal{M}_p$ *and for any quadruple* $(h_1(a),h_2(b),h_1(c),h_2(d))$, *where* $a,c\in\mathcal{L}_1$ *and* $b,d\in\mathcal{L}_2$.

Let us suppose that the inequalities (1) are violated in some compound physical system. Then, Theorem 6 tells us that such a system cannot have separability. That is, such a system is either (i) that there is an atomic property which cannot be reducible to the properties possessed by its subsystems, or (ii) that the subsystems do merely not possess any of thier own properties. This seems to be the reason that violations of Bell's inequalities in quantum mechanics have been regarded as problematic.

So far, we have seen a connection between separability and Bell-type inequalities. Recall that, for example, the property reducibility is a restriction on the set of all atoms of a compound physical system. The questions now arise: For what structure is such a restriction permitted? Or, more directly, *from what structure are Bell-type inequalities derived?* As for the former question, the following theorem has been proved by the author.[13]

Theorem 7 (Ref. 13, Corollary): *Let* $(\mathcal{L},\mathcal{M}_p)$ *be a compound physical system of* $(\mathcal{L}_1,\mathcal{M}_{p_1})$ *and* $(\mathcal{L}_2,\mathcal{M}_{p_2})$. *The statement* (a) *in Theorem 5 is equivalent to the following statement.*
(c) At least one of $\mathcal{L}_1$ *and* $\mathcal{L}_2$ *is distributive.*

Consequently, we can see that the statements (a), (b) and (c) are equivalent. Finally, with the aid of Theorem 6, we can show a new connection among propositional structures of sub- and compound system and Bell-type inequalities.

Theorem 8: *Let* $(\mathcal{L},\mathcal{M}_p)$ *be a compound physical system of* $(\mathcal{L}_1,\mathcal{M}_{p_1})$ *and* $(\mathcal{L}_2,\mathcal{M}_{p_2})$. *If at least one of* $\mathcal{L}_1$ *and* $\mathcal{L}_2$ *is distributive, the Clauser–Horne version of Bell's inequalities (1) hold for any* $m\in\mathcal{M}_p$ *and for any quadruple* $(h_1(a),h_2(b),h_1(c),h_2(d))$, *where* $a,c\in\mathcal{L}_1$ *and* $b,d\in\mathcal{L}_2$.

It should be noticed that there are seemingly no locality conditions in the statement of Theorem 8.

V. A NECESSARY CONDITION FOR BELL-TYPE INEQUALITIES

In the previous section, we considered a question such that: From what structure are Bell-type inequalities derived? And we answered the question by establishing Theorem 8. Now we must ask the converse question, to which little attention has been given: *What structure do Bell-type inequalities imply?* More accurately, *what structure does the compound physical system have if Bell-type inequalities always hold for the system?* In this section, we shall try to answer the question.

The following lemma is helpful for our purpose.

Lemma 1: Let $(\mathcal{L},\mathcal{M}_p)$ *be a physical system such that* $\mathcal{L}$ *is nondistributive. Then, for any distinct atoms* $x,y\in\mathcal{A}(\mathcal{L})$ *such that* x *is not orthogonal to* y,

$$m(x)=1 \quad\Rightarrow\quad m(y)\neq 0,1 \quad \text{for} \quad m\in\mathcal{M}_p.$$

Proof: Suppose that $m(x)=1$.

(i) In the case of $m(y)=1$:
Due to the Jauch–Piron condition, we have $m(x\wedge y)=1$. On the other hand, since x and y are distinct atoms, it follows that $x\wedge y=\varnothing$ so that $m(x\wedge y)=0$, which is a contradiction.

(ii) In the case of $m(y)=0$:
$$1=m(x)\leqslant m(x\vee y)=m(\{(x\vee y)\wedge y^{\perp}\}\vee y)=m((x\vee y)\wedge y^{\perp})+m(y)=m((x\vee y)\wedge y^{\perp}).$$
Hence $m((x\vee y)\wedge y^{\perp})=1$. Due to the Jauch–Piron condition and due to the fact that $x\wedge y^{\perp}=\varnothing$, it follows that $1=m(\{(x\vee y)\wedge y^{\perp}\}\wedge x)=m(\varnothing)=0$, which is a contradiction.

So we conclude that $m(y)\neq 0,1$. □

We shall now answer the question mentioned above. The following theorem, which is the converse of Theorem 8, is also true.

Theorem 9: *Let* $(\mathcal{L},\mathcal{M}_p)$ *be a compound physical system of* $(\mathcal{L}_1,\mathcal{M}_{p_1})$ *and* $(\mathcal{L}_2,\mathcal{M}_{p_2})$. *If the following Clauser–Horne version of Bell's inequalities*

$$m(\,h_1(a)\wedge h_2(b)\,)+m(\,h_1(c)\wedge h_2(b)\,)+m(\,h_1(c)\wedge h_2(d)\,)$$
$$-m(\,h_1(a)\wedge h_2(d)\,)-m(\,h_1(c)\,)-m(\,h_2(b)\,)\leqslant 0$$

holds for any $m\in\mathcal{M}_p$ *and for any quadruple* $(h_1(a),h_2(b),h_1(c),h_2(d))$, *where* $a,c\in\mathcal{L}_1$ *and* $b,d\in\mathcal{L}_2$, *then at least one of* $\mathcal{L}_1$ *and* $\mathcal{L}_2$ *is distributive.*

Proof: Suppose that both $\mathcal{L}_1$ and $\mathcal{L}_2$ are nondistributive. Then we can choose distinct atoms $a,a',c,c'\in\mathcal{A}(\mathcal{L}_1)$ such that $a\perp a'$, $c\perp c'$ and $a\vee a'=c\vee c'$. Similarly, choose distinct $b,b',d,d'\in\mathcal{A}(\mathcal{L}_2)$ such that $b\perp b'$, $d\perp d'$ and $b\vee b'=d\vee d'$. Let X denote $a\vee a'$ and Y denote $b\vee b'$. It is easily seen that

$$(h_1(a)\wedge h_2(b))\vee(h_1(a)\wedge h_2(b'))\vee(h_1(a')\wedge h_2(b))\vee(h_1(a')\wedge h_2(b'))=h_1(X)\wedge h_2(Y).$$

Therefore, it follows that $\dim(h_1(X)\wedge h_2(Y))=4$. [Remark that by definition, for example, $h_1(a)\neq h_2(b)$.]

First, we shall show that $\Gamma:=(h_1(c')\vee h_2(d))\wedge(h_1(a)\vee h_2(b'))\wedge(h_1(a')\vee h_2(d'))$ is not a null element $\varnothing$. If $\Gamma=\varnothing$, then

$$h_1(X)\wedge h_2(Y)=h_1(X)\wedge h_2(Y)\wedge\Gamma^{\perp}$$
$$=h_1(X)\wedge h_2(Y)\wedge[(h_1(c')^{\perp}\wedge h_2(d)^{\perp})\vee(h_1(a)^{\perp}\wedge h_2(b')^{\perp})\vee(h_1(a')^{\perp}\wedge h_2(d')^{\perp})]. \tag{2}$$

Due to Theorem 1, $h_1(X)\wedge h_2(Y)$ commutes with $h_1(c')^{\perp}\wedge h_2(d)^{\perp}$, $h_1(a)^{\perp}\wedge h_2(b')^{\perp}$ and $h_1(a')^{\perp}\wedge h_2(d')^{\perp}$. Hence (2) reduces to

$$(h_1(c)\wedge h_2(d'))\vee(h_1(a')\wedge h_2(b))\vee(h_1(a)\wedge h_2(d)). \tag{3}$$

Since the element (3) is a join of three atoms, its dimension is less than or equal to 3, which contradicts with $\dim(h_1(X)\wedge h_2(Y))=4$. So we conclude that $\Gamma\neq\varnothing$. By atomicity of $\mathcal{L}$, there exists an atom q such that $q\leqslant\Gamma$. It follows that $q\leqslant\Gamma\leqslant(h_1(c')\vee h_2(d))\wedge(h_1(a')\vee h_2(d'))$. By using the fact that $h_2(d)$ commutes with $h_1(c')$ and $h_1(a')\vee h_2(d')$ (due to Theorem 1) and by applying Foulis–Holland's theorem, we have

$$q\leqslant(h_1(c')\vee h_2(d))\wedge(h_1(a')\vee h_2(d'))$$
$$=[h_1(c')\wedge(h_1(a')\vee h_2(d'))]\vee[h_2(d)\wedge(h_1(a')\vee h_2(d'))]$$
$$=(h_1(c')\wedge h_2(d'))\vee(h_1(a')\wedge h_2(d))\leqslant h_1(X)\wedge h_2(Y).$$

Second, we shall consider a pure state m such that $m(q)=1$. Since

$$q\leqslant h_1(c')\vee h_2(d),\ h_1(a)\vee h_2(b'),\ h_1(a')\vee h_2(d'),$$

we have

$$1=m(h_1(c')\vee h_2(d))=m(h_1(a)\vee h_2(b'))=m(h_1(a')\vee h_2(d')),$$

or, equivalently, we have

$$0=m(h_1(c')^{\perp}\wedge h_2(d)^{\perp})=m(h_1(a)^{\perp}\wedge h_2(b')^{\perp})=m(h_1(a')^{\perp}\wedge h_2(d')^{\perp}).$$

Since $X\wedge c^{\perp}=c'\leqslant c^{\perp}$, i.e., $c\leqslant c'^{\perp}$ so that $h_1(c)\wedge h_2(d)^{\perp}\leqslant h_1(c'^{\perp})\wedge h_2(d)^{\perp}=h_1(c')^{\perp}\wedge h_2(d)^{\perp}$, we obtain $m(h_1(c)\wedge h_2(d)^{\perp})=0$. Similarly, we obtain

$$m(h_1(a)^{\perp}\wedge h_2(b))=m(h_1(a)\wedge h_2(d))=0. \tag{4}$$

Hence we have

$$m(h_1(c))=m(h_1(c)\wedge h_2(d))+m(h_1(c)\wedge h_2(d)^{\perp})=m(h_1(c)\wedge h_2(d)), \tag{5}$$

$$m(h_2(b))=m(h_1(a)\wedge h_2(b))+m(h_1(a)^{\perp}\wedge h_2(b))=m(h_1(a)\wedge h_2(b)). \tag{6}$$

Third, we shall show that q is not orthogonal to $h_1(c)\wedge h_2(b)$. Since $q\leqslant h_1(X)\wedge h_2(Y)$, it follows that

$$q\wedge(h_1(c)\wedge h_2(b))^{\perp}=q\wedge h_1(X)\wedge h_2(Y)\wedge(h_1(c)\wedge h_2(b))^{\perp}$$
$$=q\wedge[(h_1(c')\wedge h_2(Y))\vee(h_1(X)\wedge h_2(b'))]$$
$$\leqslant\Gamma\wedge[(h_1(c')\wedge h_2(Y))\vee(h_1(X)\wedge h_2(b'))]$$
$$=(h_1(c')\vee h_2(d))\wedge(h_1(a)\vee h_2(b'))\wedge(h_1(a')\vee h_2(d'))$$
$$\wedge[(h_1(c')\wedge h_2(Y))\vee(h_1(X)\wedge h_2(b'))]. \tag{7}$$

By using Theorem 1, it follows that $h_1(c')\wedge h_2(Y)$ commutes with $h_1(c')\vee h_2(d)$ and $h_1(X)\wedge h_2(b')$. Then, by applying Foulis–Holland's theorem, we can see

$$\begin{aligned}&(h_1(c')\vee h_2(d))\wedge[(h_1(c')\wedge h_2(Y))\vee(h_1(X)\wedge h_2(b'))]\\&\quad=[(h_1(c')\vee h_2(d))\wedge(h_1(c')\wedge h_2(Y))]\vee[(h_1(c')\vee h_2(d))\wedge(h_1(X)\wedge h_2(b'))]\\&\quad=(h_1(c')\wedge h_2(Y))\vee[(h_1(c')\wedge h_1(X)\wedge h_2(b'))\vee(h_2(d)\wedge h_1(X)\wedge h_2(b'))]\\&\quad=(h_1(c')\wedge h_2(Y))\vee(h_1(c')\wedge h_2(b'))=h_1(c')\wedge h_2(Y).\end{aligned}\tag{8}$$

Therefore, by applications of Foulis–Holland's theorem, the right-hand side of (7) reduces to

$$\begin{aligned}&h_1(c')\wedge h_2(Y)\wedge(h_1(a)\vee h_2(b'))\wedge(h_1(a')\vee h_2(d'))\\&\quad=[(h_1(c')\wedge h_2(Y)\wedge h_1(a))\vee(h_1(c')\wedge h_2(Y)\wedge h_2(b'))]\wedge(h_1(a')\vee h_2(d'))\\&\quad=h_1(c')\wedge h_2(b')\wedge(h_1(a')\vee h_2(d'))\\&\quad=h_1(c')\wedge[(h_1(a')\wedge h_2(b'))\vee(h_2(b')\wedge h_2(d'))]=h_1(c')\wedge h_1(a')\wedge h_2(b')=\varnothing.\end{aligned}$$

Hence we conclude that $q\wedge(h_1(c)\wedge h_2(b))^{\perp}=\varnothing$, i.e., the atom q is not orthogonal to $h_1(c)\wedge h_2(b)$. By virtue of Lemma 1, we obtain

$$m(h_1(c)\wedge h_2(b))\neq 0.\tag{9}$$

Finally, we shall show that our supposition for $\mathcal{L}_1$ and $\mathcal{L}_2$ leads to a contradiction. By the premise of the theorem, the following inequality,

$$\begin{aligned}&m(h_1(a)\wedge h_2(b))+m(h_1(c)\wedge h_2(b))+m(h_1(c)\wedge h_2(d))\\&\quad-m(h_1(a)\wedge h_2(d))-m(h_1(c))-m(h_2(b))\leqslant 0,\end{aligned}\tag{10}$$

holds for our choice of a,b,c,d and m. From (5) and (6), this inequality reduces to

$$m(h_1(c)\wedge h_2(b))\leqslant m(h_1(a)\wedge h_2(d)).\tag{11}$$

However, it follows from (4) that $m(h_1(c)\wedge h_2(b))=0$, which contradicts with (9). Therefore, we conclude that at least one of $\mathcal{L}_1$ and $\mathcal{L}_2$ must be distributive. □

We would like to add one to our results. The following notion often appears in Bell-type arguments.

Definition 4: Let $(\mathcal{L},\mathcal{M}_p)$ *be a compound physical system of* $(\mathcal{L}_1,\mathcal{M}_{p_1})$ *and* $(\mathcal{L}_2,\mathcal{M}_{p_2})$. *We say that* $(\mathcal{L},\mathcal{M}_p)$ *has statistical property independence if for any state* $m\in\mathcal{M}_p$ *and for any* $x\in\mathcal{L}_1$ *and* $y\in\mathcal{L}_2$ *it holds that*

$$m(h_1(x)\wedge h_2(y))=m(h_1(x))\,m(h_2(y)).$$

Further, we say that there exists a *nonlocal correlation* in a compound physical system, if it does not have statistical property independence. The following theorem can be obtained.

Theorem 10: *Let* $(\mathcal{L},\mathcal{M}_p)$ *be a compound physical system of* $(\mathcal{L}_1,\mathcal{M}_{p_1})$ *and* $(\mathcal{L}_2,\mathcal{M}_{p_2})$. *The statement* (b) *in Theorem 5 is equivalent to the following statement.*

(d) $(\mathcal{L},\mathcal{M}_p)$ *has statistical property independence.*

Proof: [(b)⇒(d)]: Since there exist some $m_1\in\mathcal{M}_{p_1}$ and $m_2\in\mathcal{M}_{p_2}$ for any state $m\in\beta[\mathcal{M}_{p_1}\times\mathcal{M}_{p_2}]$, it follows that for any $x\in\mathcal{L}_1$ and $y\in\mathcal{L}_2$

TABLE I. $(\mathcal{L}_1,\mathcal{M}_{p_1})$ and $(\mathcal{L}_2,\mathcal{M}_{p_2})$ are physical systems respectively associated with systems S_1 and S_2. $(\mathcal{L},\mathcal{M}_p)$ is the compound physical system of them. This table shows connections among features of $\mathcal{L}_1$ and $\mathcal{L}_2$, those of $(\mathcal{L},\mathcal{M}_p)$ and the Clauser-Horne version of Bell's inequalities (12).

$\mathcal{L}_1$	$\mathcal{L}_2$	Properties of $(\mathcal{L},\mathcal{M}_p)$	Bell-type inequalities (12)
Distributive	Distributive	Distributive and separable	○
Either (not both) distributive		Nondistributive and separable	○
Nondistributive	Nondistributive	Nondistributive and nonseparable	×

$$m(h_1(x)\wedge h_2(y))=\beta(m_1,m_2)(\alpha(x,y))=m_1(x)m_2(y)=m_1(x)m_2(I_2)m_1(I_1)m_2(y)$$
$$=\beta(m_1,m_2)(\alpha(x,I_2))\,\beta(m_1,m_2)(\alpha(I_1,y))=m(h_1(x))\,m(h_2(y)),$$

which shows that $(\mathcal{L},\mathcal{M}_p)$ has statistical property independence.

[(d)⇒(b)]: Suppose that $(\mathcal{L},\mathcal{M}_p)$ has statistical property independence. Then, by virtue of Theorem 2 of Ref. 14, it follows that the Clauser–Horne version of Bell's inequalities (1) holds for any $m\in\mathcal{M}_p$ and for any $a,c\in\mathcal{L}_1$ and $b,d\in\mathcal{L}_2$. Due to Theorem 9, we conclude that at least one of $\mathcal{L}_1$ and $\mathcal{L}_2$ is distributive. This statement is equivalent to the statement (b) by Theorem 5 and 7. □

VI. CONCLUDING REMARKS

In summary, we have the following results.

Corollary: Let $(\mathcal{L},\mathcal{M}_p)$ be a compound physical system of $(\mathcal{L}_1,\mathcal{M}_{p_1})$ and $(\mathcal{L}_2,\mathcal{M}_{p_2})$. The following statements are equivalent.

(a) $(\mathcal{L},\mathcal{M}_p)$ has property reducibility.
(b) $(\mathcal{L},\mathcal{M}_p)$ has state separability.
(c) At least one of $\mathcal{L}_1$ and $\mathcal{L}_2$ is distributive.
(d) $(\mathcal{L},\mathcal{M}_p)$ has statistical property independence.
(e) The Clauser–Horne version of Bell's inequalities

$$m(\,h_1(a)\wedge h_2(b)\,)+m(\,h_1(c)\wedge h_2(b)\,)+m(\,h_1(c)\wedge h_2(d)\,)$$
$$m(\,h_1(a)\wedge h_2(d)\,)-m(\,h_1(c)\,)-m(\,h_2(b)\,)\leqslant 0 \tag{12}$$

hold for any $m\in\mathcal{M}_p$ and for any $a,\ c\in\mathcal{L}_1$ and $b,\ d\in\mathcal{L}_2$.

Or, equivalently, we have the following.

Corollary: Let $(\mathcal{L},\mathcal{M}_p)$ be a compound physical system of $(\mathcal{L}_1,\mathcal{M}_{p_1})$ and $(\mathcal{L}_2,\mathcal{M}_{p_2})$. The following statements are equivalent.
(a′) There exists a holistic property in $(\mathcal{L},\mathcal{M}_p)$.
(b′) There exists a nonseparable state in $(\mathcal{L},\mathcal{M}_p)$.
(c′) Both $\mathcal{L}_1$ and $\mathcal{L}_2$ are nondistributive.
(d′) There exists a nonlocal correlation in $(\mathcal{L},\mathcal{M}_p)$.
(e′) The Clauser–Horne version of Bell's inequalities (12) violate for some $m\in\mathcal{M}_p$ and for some $a,c\in\mathcal{L}_1$ and $b,d\in\mathcal{L}_2$.

The connections among distributivity of P-lattices, the separability and the Bell-type inequalities (12) are summarized as in Table I.

In conclusion, we would like to state the following two points.

(I) According to Pykacz and Santos,[14] it has been an open question whether Gisin's result[22] within the usual Hilbert-space formalism for quantum mechanics, which has shown that for any entangled state there are projectors violating Bell's inequalities, could be also obtained within lattice-theoretical approaches. Now, our results partially answer the question. That is, it follows

from our results that if the system has nonseparable states, there exists at least one pair of a state and elements violating Bell-type inequalities (12). Remark that it is still an open question whether for *any* nonseparable state there are elements violating inequalities (12).

(II) It is important to distinguish two type of nondistributivity (nonclassicality) of compound physical systems; one results from the case where only one of $\mathcal{L}_1$ and $\mathcal{L}_2$ is nonclassical. Another results from the case where both $\mathcal{L}_1$ and $\mathcal{L}_2$ are nonclassical. Only for the latter case the Bell-type inequalities (12) can be violated (see Table I). Therefore, *nonclassicality of a compound physical system by itself has nothing to do with whether Bell-type inequalities for the system are violated or not*. In order to see the relation, we need to refer to a whole construction of the system.

Anisotropic scattering kernel: Generalized and modified Maxwell boundary conditions

S. Kokou Dadzie[a] and J. Gilbert Méolans[b]
Polytech'Marseille, Département de Mécanique Energétique—UMR CNRS 6595, 5, rue Enrico Fermi, 13453 Marseille cedex 13, France

(Received 28 October 2003; accepted 30 January 2004; published 1 April 2004)

This article presents a model of a scattering kernel of boundary conditions for the Boltzmann equation. The proposed scattering kernel is based on an anisotropic accommodation argument. Three parameters equal to the momentum accommodation coefficients are shown as characterizing the influence of each direction. First the new scattering kernel is derived from a phenomenological criticism of the first form of the scattering kernel proposed by Maxwell; then the same result is established from an analytic approach based on the spectral nature of the linear integral operator associated to the scattering kernel problem. As a result, the model provides a correct form of scattering kernel to handle the influence of each direction in particle collisions with the wall. Finally independent accommodation of each internal mode is added to extend the model to the case of polyatomic gases. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1690491]

I. INTRODUCTION

The problem of writing good boundary conditions for the Boltzmann equation in rarefied gas flows is to find an operator called the scattering kernel in kinetic theory. The first known scattering kernel was proposed by Maxwell and is based on phenomenological argument.[1] However, in various situations this kernel fails to reproduce correctly the phenomena occurring at the wall.[2,3] Indeed the Maxwell boundary condition corresponds to an isotropic conception of the reflection at the wall; so, in this approach, the three velocity components are considered as equivalent in the accommodation process.

Another class of scattering kernel is the CL (*Cercignani–Lampis*) model by Cercignani *et al.*[3,4] The authors extend the research to a more general field of operators and obtain a more flexible model. However, as is well-known, this class of scattering kernels is not totally efficient to describe physically gas behavior close to the wall.[4] Moreover, some results in particle simulation of rarefied gas flows seem to show that none of the existing models of the scattering kernel can reproduce all the features of the real gas dynamics.[5]

Generally the existing models of the scattering kernel do not describe the interplay between the different degrees of freedom (i.e., the three velocity components of the particle and its internal energy modes) in interaction with the wall.[5] This would explain the partial inefficiency of these models to reproduce the behavior of high speed nonequilibrium flows near the wall. The main purpose of this article is to propose a new model of scattering kernel by considering more possible reflection types of particles at the wall. In this way we attempt to eliminate any isotropic character of momentum accommodation in the velocity reflection process, and we introduce three coefficients to take into account the influence of the velocity directions.

From Sec. II to Sec. VI, we consider only unstructured atom-like molecules. In Sec. II the basic conditions required for a scattering kernel are briefly analyzed and discussed. In Sec. III the Maxwell phenomenological argument is recalled and we present the new model. In Sec. IV we

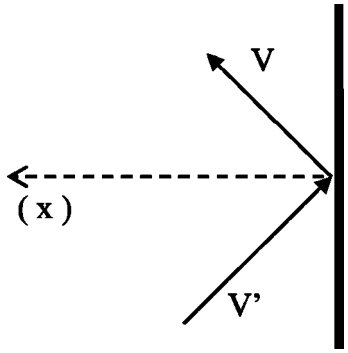

FIG. 1. Particle hitting the wall.

develop a consistent analytical approach to build the new scattering kernel. In Sec. V the coefficients introduced in the modeling are shown to equal the well known momentum accommodation coefficients. Finally, in Sec. VI the new kernel is involved in a more complete model characterizing molecules with internal modes by using a phenomenological derivation.

II. CONDITIONS REQUIRED FOR THE SCATTERING KERNELS

Let us consider a particle hitting the wall, as shown in Fig. 1. V' is the velocity of the impinging gas particle referred to the wall, $V'=(V'_x,V'_y,V'_z)\in\{\Omega'=\mathbb{R}_-\times\mathbb{R}\times\mathbb{R}\}$ and V is the velocity of the reflected one referred to the wall, $V=(V_x,V_y,V_z)\in\{\Omega=\mathbb{R}_+\times\mathbb{R}\times\mathbb{R}\}$. These velocities reduce to peculiar velocities when the slip velocity at the wall is neglected. V_R is defined as $V_R=(-V_x,V_y,V_z)$.

The kernel, $B(V',V)$, is the density of probability that a molecule impinging the wall at any point X of the wall with velocity V' is reflected at the same point with velocity V. This kernel, which turns the impinging particles at the wall into reflected ones, must satisfy some basic physical conditions. The least obvious of them is the reciprocity relation. This relation is a necessary condition for a good scattering kernel in the kinetic theory of gases.[6,7]

According to the scattering kernel probability density property, kernel $B(V',V)$ must satisfy

$$B(V',V)\geqslant 0 \quad , \tag{1}$$

and also the normalization condition

$$\int_\Omega B(V',V)d_V=1. \tag{2}$$

Finally, the balance of particles hitting the wall at position X and reflected with velocity V at a given time may be written[8]

$$V_x f(V)=\int_{\Omega'}|V'_x|f(V')B(V',V)d_{V'}, \tag{3}$$

where $f(V)$ is the gas particle distribution function given by the Boltzmann equation.

In the thermodynamic equilibrium state between the gas and the wall at the same temperature, the time reversibility assumption of the thermodynamic equilibrium state may be formulated as follows:[3,7,9] the number of gas particles which hit the wall during time t, with velocity V', and reflect with velocity V at position X of the wall, is equal to the number of particles with incident velocity $-V$ reflected with velocity $-V'$ at the same time t, at the same position X of the wall. This may be written

$$|V'_x| f_0(V') B(V', V) = |V_x| f_0(-V) B(-V, -V'), \tag{4}$$

where $f_0(V) = n/(C_w\sqrt{\pi})^3 e^{-\|V\|^2/C_w^2}$ is the Maxwellian distribution function of the gas in equilibrium state at the temperature of the wall. $C_w^2 = 2kT_w/m$, where T_w is the wall temperature, k is the Boltzmann constant, m is the molecular mass of gaseous particles and n is their numerical density. The time reversibility assumption means that all detailed balancing of energy exchange between the gas and the wall in the thermodynamic equilibrium state at any time t is equal to zero. This state of thermodynamic equilibrium between the gas and the wall at the same temperature is a reference state. Owing to this fact, any scattering kernel in kinetic theory must be validated by the property (4), called the reciprocity relation.

Note that the normalization condition (2) is equivalent to

$$\int_{\Omega'} B(-V, -V'_R) d_{V'} = 1.$$

From this remark, the reciprocity relation also leads to

$$\int_{\Omega'} |V'_x| f_0(V') B(V'_R, V) d_{V'} = |V_x| f_0(-V). \tag{4'}$$

It is also necessary to note that the required conditions formulated above characterize a physical situation at the wall involving the conservation of the particle flux and then a binary and short interaction between the solid atoms and gaseous particles.[9] So the model presented here excludes the gas dissociation and various steps involved in catalysis (chemical reaction at the wall, adsorption, etc.).

III. PHENOMENOLOGICAL APPROACH TO SCATTERING KERNELS

A. Maxwell scattering kernel

The first form of the scattering kernel proposed by Maxwell is given by

$$B_M(V', V) = (1-\alpha)\,\delta(V - V'_R) + \alpha \frac{2}{C_w^4 \pi} V_x e^{-\|V\|^2/C_w^2}. \tag{5}$$

$B_M(V', V)$ is a linear combination of two elementary kernels: the Dirac function for the specular reflection part and the exponential function for the diffuse reflection part at temperature T_w of the wall; α, called the accommodation coefficient, represents the weight of the diffusion in the gas collision process at the wall.

Before writing this scattering kernel Maxwell made several phenomenological comments on the nature of the surface in contact with the gas, which can be found in the appendix of Ref. 1. First, he assumed the surface to be a ''perfectly elastic smooth surface.'' Then each molecule striking the surface had its normal component reversed while the other components were not altered by the impact; the scattering kernel in this case was simply given by $\delta(V - V'_R)$. Second, he assumed the surface to be a perfectly absorbing surface so that each particle hitting the wall was absorbed before being reemitted, and the velocity of each reemitted particle was oriented from the surface towards the gas. But the probability of any particular magnitude and direction of its velocity would be the same as in a gas at rest in the thermal equilibrium state at the temperature of the wall; in this case, this led to the diffusive scattering kernel given by $(2/C_w^4\pi)\, V_x e^{-\|V\|^2/C_w^2}$.

Finally, Maxwell decided to consider the real reflecting surfaces as an intermediate surface between these two extreme perfect surfaces and then proposed the linear combination (5).

In our view, the scattering process on a real surface must be more complicated than those described by the sum of the scattering kernels of the two extreme perfect surfaces. It is easily seen that the two elementary scattering kernels written for the two perfect surfaces are isotropic ones;

this is reasonable for these two types of perfect surfaces. Then, using a linear combination of these two elementary scattering kernels, the result will still be an isotropic one, but we cannot be sure that a scattering kernel characterizing any real surface is an isotropic one. Moreover, in the kernel (5), the weight of the diffusion in any direction is represented by the same coefficient α: this description cannot be considered as correct, as pointed out by various authors.[2,10]

B. Our scattering kernel proposal

In order to write a general scattering kernel for any kind of real surface, we return to the investigation of various possible types of accommodation which can occur during a particle collision with the wall. Then we have to consider a more general type of accommodation than the isotropic one, in which of course the normal component of the incoming particle velocity must be reversed during the collision. We can thus assume elementary processes where diffusive and specular reflection are mixed: each of the velocity components can be altered or not by the wall independently of others. This argument leads us to consider the eight elementary operators listed below:

$$B_0(V',V)=\delta(V_x+V_x')\,\delta(V_y-V_y')\,\delta(V_z-V_z'), \tag{6a}$$

$$B_{yz}(V',V)=\frac{1}{\pi C_w^2}\,\delta(V_x+V_x')e^{-V_y^2/C_w^2}e^{-V_z^2/C_w^2},$$

$$B_{xz}(V',V)=\frac{2}{C_w^3\sqrt{\pi}}V_x\delta(V_y-V_y')e^{-V_x^2/C_w^2}e^{-V_z^2/C_w^2},$$

$$B_{xy}(V',V)=\frac{2}{C_w^3\sqrt{\pi}}V_x\delta(V_z-V_z')e^{-V_x^2/C_w^2}e^{-V_y^2/C_w^2},$$

$$B_{xyz}(V',V)=\frac{2}{\pi C_w^4}V_x e^{-V_x^2/C_w^2}e^{-V_y^2/C_w^2}e^{-V_z^2/C_w^2}, \tag{6b}$$

$$B_z(V',V)=\frac{1}{C_w\sqrt{\pi}}\,\delta(V_x+V_x')\,\delta(V_y-V_y')e^{-V_z^2/C_w^2},$$

$$B_y(V',V)=\frac{1}{C_w\sqrt{\pi}}\,\delta(V_x+V_x')\,\delta(V_z-V_z')e^{-V_y^2/C_w^2},$$

$$B_x(V',V)=\frac{2}{C_w^2}V_x\delta(V_y-V_y')\,\delta(V_z-V_z')e^{-V_x^2/C_w^2}.$$

It is easy to show that each of these elementary kernels satisfies positivity and normalization conditions. These kernels also satisfy the reciprocity relation (more details are given in Appendix A). The coefficients appearing in front of each operator are normalizing coefficients obtained by calculating $\int_\Omega B_\kappa(V',V)d_V$.

Each of these elementary kernels represents a particular possible situation of accommodation. Then the complete scattering kernel will be a linear combination of the elementary kernels in which the combination coefficients will represent the weight of each kind of accommodation at the wall. This complete scattering kernel may be written

$$B(V',V)=\sum_\kappa \mu_\kappa B_\kappa(V',V), \tag{7}$$

with

$$\sum_{\kappa} \mu_{\kappa} = 1. \tag{8}$$

If we introduce three coefficients, α_j $(j=1,2,3)$ satisfying $\alpha_j \in [0,1]$, to quantify the influence of each direction in a particle accommodation process by the wall, and taking into account condition (8), the coefficients μ_{κ} may be written

$$\begin{gathered}\mu_{xz} = \alpha_x \alpha_z (1-\alpha_y), \quad \mu_{xy} = \alpha_x \alpha_y (1-\alpha_z), \quad \mu_{yz} = \alpha_y \alpha_z (1-\alpha_x), \\ \mu_x = \alpha_x (1-\alpha_y)(1-\alpha_z), \quad \mu_{xyz} = \alpha_x \alpha_y \alpha_z, \quad \mu_0 = (1-\alpha_x)(1-\alpha_y)(1-\alpha_z), \\ \mu_y = \alpha_y (1-\alpha_x)(1-\alpha_z), \quad \mu_z = \alpha_z (1-\alpha_x)(1-\alpha_y).\end{gathered} \tag{9}$$

According to this last relationship, the complete scattering kernel (7) satisfies the positivity and the normalization properties. It obviously satisfies the reciprocity relation since the elementary kernels satisfy it.

It is clear that neglecting the elementary kernels with incomplete diffusion or incomplete specular reflection in the full scattering kernel (7), the result reduces to the sum of the kernels (6a) and (6b) which represents the Maxwell scattering kernel. Moreover, it is easy to show that the Maxwell boundary conditions give satisfactory results for values of α close to 1: indeed, if the gas is in a state very close to thermodynamic equilibrium at the temperature of the wall, the most important reflection is the reflection with complete accommodation in all directions.

In the following section, an analytical method to build the complete scattering kernel (7) is presented.

IV. ANALYTICAL FORMULATION OF THE NEW SCATTERING KERNEL

Let us consider the problem of finding operator $B(V',V)$, satisfying the conditions listed in Sec. II, and let us write the transformation

$$K(V,V') = [|V_x'| f_0(V')]^{1/2} [|V_x| f_0(V)]^{-1/2} B(V_R', V). \tag{10}$$

Since $f_0(V)$ is a known function, the problem of finding $B(V',V)$ is equivalent to finding $K(V,V')$. Instead of studying the problem in $K(V,V')$, we can study the linear integral associated operator A defined by the relation

$$A(\psi) = \int_{\Omega'} K(V,V') \psi(V') d_{V'}. \tag{11}$$

This integral operator is defined in the Hilbert space of square summable functions of V noted $L^2(\Omega)$ [i.e., $\psi(V) \in L^2(\Omega)$], where the scalar product is defined as follows:

$$\langle \psi, \varphi \rangle = \int_{\Omega} \psi(V) \varphi(V) d_V.$$

Therefore, the problem is reduced to an eigenvalue problem, and then to discussing the spectral nature of operator A.

It is to be noted that the above formulation of the scattering kernel problem, through the transformation (10), is especially convenient to solve the linearized form of the Boltzman equation (LBE).[11,12]

Assuming that the operator A has a purely discrete spectrum, its kernel $K(V,V')$ can be written

$$K(V,V')=\sum_{n=0}^{\infty}\lambda^n\psi^n(V)\psi^n(V'), \tag{12}$$

where $\psi^n(V)\in L^2(\Omega)$ is an eigenfunction of the operator A and λ^n is its corresponding eigenvalue. According to positivity and normalization conditions required in $B(V',V)$, the operator A must be non-negative and its eigenvalues satisfy $\lambda^n\in[0,1]$ for any $n\in\mathbb{N}$.

From now the eigenfunction $\psi^n(V)$ is assumed to be in the form

$$\psi_r(V_x)\psi_l(V_y)\psi_m(V_z)=\prod_{j=1}^{3}\psi_{k_j}(V_j).$$

Since the eigenfunction $\psi^n(V)$ is a square summable function, we have $\psi_{k_j}(V_j)\in L^2(\Omega_j)$, where Ω_j denotes the scalar space associated to V_j. Moreover, the family of the function set $\psi_{k_j}(V_j)$, $k_j\in\mathbb{N}$, must be a function basis of the Hilbert space $L^2(\Omega_j)$ [note that this assumption will lead immediately to the coming property (16)]. The eigenvalues of operator A become λ_{rlm}, and we can assume $\lambda_{rlm}=\lambda_r\lambda_l\lambda_m$, in respect to the respective scalar products in the different Hilbert spaces $L^2(\Omega_j)$ and $L^2(\Omega)$. Finally, the expression (12) can be replaced by

$$K(V,V')=\sum_{r,l,m}\lambda_r\lambda_l\lambda_m\psi_r(V_x)\psi_l(V_y)\psi_m(V_z)\psi_r(V_x')\psi_l(V_y')\psi_m(V_z'). \tag{13}$$

The sum in the right member of (13) can be written as the product of three infinite sums:

$$K(V,V')=\prod_{j=1}^{3}\sum_{k=0}^{\infty}\lambda_{k_j}\psi_{k_j}(V_j)\psi_{k_j}(V_j'). \tag{14}$$

Let us put

$$\psi_{0_x}(V_x)=\frac{\sqrt{2}}{C_w}|V_x|^{1/2}e^{-V_x^2/2C_w^2},$$

$$\psi_{0_y}(V_y)=(C_w\sqrt{\pi})^{-1/2}e^{-V_y^2/2C_w^2},$$

$$\psi_{0_z}(V_z)=(C_w\sqrt{\pi})^{-1/2}e^{-V_z^2/2C_w^2}.$$

Each of $\psi_{0_j}(V_j)$ functions satisfies

$$\|\psi_{0_j}(V_j)\|_j^2=\int_{\Omega_j}[\psi_{0_j}(V_j)]^2dV_j=1.$$

From the relation $(4')$, it may be deduced that the function $\psi^0(V)=\psi_{0_x}(V_x)\psi_{0_y}(V_y)\psi_{0_z}(V_z)$ is an eigenfunction of operator A, associated to eigenvalue $\lambda_{0_x}\lambda_{0_y}\lambda_{0_z}=1$ (see demonstration in Appendix B). This first eigenfunction takes an important part in the solution of the problem because it corresponds to the maximal eigenvalue of A, and so leads to an equilibrium state. Indeed, in the equilibrium state between the gas and the wall, the most physically convenient scattering kernel is the complete accommodation kernel, which is assigned here to $\psi^0(V)$. Therefore any good model of a scattering kernel must converge to this equilibrium scattering kernel. This point matches the basic assumption founding the reciprocity relation which is that any scattering kernel must be valid when a thermodynamic equilibrium exists between the gas and the wall.

In agreement with the concept of three distinguishable degrees of freedom in the reflection process, we introduce three coefficients α_j, related to the set of eigenvalues by $\lambda_{0_j}=1$ and $\lambda_{k_j}=(1-\alpha_j)$ for $k\neq 0$ with $\alpha_j\in[0,1]$; relation (14) becomes

$$K(V,V')=\prod_{j=1}^{3}\left(\psi_{0_j}(V_j)\psi_{0_j}(V_j')+(1-\alpha_j)\sum_{k=1}^{\infty}\psi_{k_j}(V_j)\psi_{k_j}(V_j')\right), \tag{15}$$

which may be rewritten

$$K(V,V')=\prod_{j=1}^{3}\left(\alpha_j\psi_{0_j}(V_j)\psi_{0_j}(V_j')+(1-\alpha_j)\sum_{k=0}^{\infty}\psi_{k_j}(V_j)\psi_{k_j}(V_j')\right).$$

Finally, by using the following property,

$$\sum_{k=0}^{\infty}\psi_{k_j}(V_j)\psi_{k_j}(V_j')=\delta(V_j-V_j'), \tag{16}$$

we obtain the result

$$K(V,V')=\prod_{j=1}^{3}\left(\alpha_j\psi_{0_j}(V_j)\psi_{0_j}(V_j')+(1-\alpha_j)\,\delta(V_j-V_j')\right). \tag{17}$$

By developing the product (17) we obtain $K(V,V')$ as a sum of elementary operators as follows:

$$K(V,V')=\sum_{\kappa}\mu_\kappa K_\kappa(V,V'), \tag{18}$$

where μ_κ is given again by the relations (9) of Sec. III, and where the elementary operators $K_\kappa(V,V')$ are written below:

$$\begin{aligned}
K_0(V,V')&=\delta(V_x-V_x')\,\delta(V_y-V_y')\,\delta(V_z-V_z'),\\
K_{yz}(V,V')&=\frac{1}{\pi C_w^2}\,\delta(V_x-V_x')e^{-V_y^2/2C_w^2}e^{-V_z^2/2C_w^2}e^{-V_y'^2/2C_w^2}e^{-V_z'^2/2C_w^2},\\
K_{xz}(V,V')&=\frac{2}{C_w^3\sqrt{\pi}}|V_xV_x'|^{1/2}\delta(V_y-V_y')e^{-V_x^2/2C_w^2}e^{-V_z^2/2C_w^2}e^{-V_x'^2/2C_w^2}e^{-V_z'^2/2C_w^2},\\
K_{xy}(V,V')&=\frac{2}{C_w^3\sqrt{\pi}}|V_xV_x'|^{1/2}\delta(V_z-V_z')e^{-V_x^2/2C_w^2}e^{-V_y^2/2C_w^2}e^{-V_x'^2/2C_w^2}e^{-V_y'^2/2C_w^2},\\
K_{xyz}(V,V')&=\frac{2}{\pi C_w^4}|V_xV_x'|^{1/2}e^{-V_x^2/2C_w^2}e^{-V_y^2/2C_w^2}e^{-V_z^2/2C_w^2}e^{-V_x'^2/2C_w^2}e^{-V_y'^2/2C_w^2}e^{-V_z'^2/2C_w^2},\\
K_z(V,V')&=\frac{1}{C_w\sqrt{\pi}}\,\delta(V_x-V_x')\,\delta(V_y-V_y')e^{-V_z^2/C_w^2}e^{-V_z'^2/C_w^2},\\
K_y(V,V')&=\frac{1}{C_w\sqrt{\pi}}\,\delta(V_x-V_x')\,\delta(V_z-V_z')e^{-V_y^2/2C_w^2}e^{-V_y'^2/2C_w^2},
\end{aligned} \tag{19}$$

$$K_x(V,V')=\frac{2}{C_w^2}|V_xV_x'|^{1/2}\delta(V_y-V_y')\,\delta(V_z-V_z')e^{-V_x^2/2C_w^2}e^{-V_x'^2/2C_w^2}.$$

It is easy to verify that the elementary operators $K_\kappa(V,V')$ given above correspond to the elementary kernels $B_\kappa(V',V)$ given in Sec. III, through transformation (10); so the complete operator $K(V,V')$ obtained from relation (18) corresponds exactly to the scattering kernel given by relation (7).

Referring now directly to Eqs. (15) and (13), it is clear that our choice corresponds to a spectral expansion of $K(V,V')$ involving eight different eigenvalues, namely, 1, $(1-\alpha_x)$, $(1-\alpha_y)$, $(1-\alpha_z)$, $(1-\alpha_x)(1-\alpha_y)$, $(1-\alpha_x)(1-\alpha_z)$, $(1-\alpha_y)(1-\alpha_z)$,$(1-\alpha_x)(1-\alpha_y)\times(1-\alpha_z)$. Of course this choice also corresponds to a degeneracy of the eigenfunction space associated to each eigenvalue, except for the maximum eigenvalue; therefore, as shown above, it is not necessary to specify the eigenfunctions.

As is well known, the classical CL model and its extensions by Lord[13,14] to polyatomic molecules are derived from another procedure based on a more general relation:[12]

$$K(V,V')=\sum_{n,m=0}^{\infty}\lambda^{nm}\varphi^n(V)\varphi^m(V'), \tag{20}$$

where the φ^k function is specified. As it can be seen, kernels built on this general form could not automatically insure the properties listed above for good scattering kernels (i.e., positivity, normalization, and reciprocity properties).[12] Moreover, in these CL scattering kernel models the normal and the tangential components of the velocity of the molecule colliding with the wall are considered as independent, and then the scattering kernel is written separately in normal and tangential parts. This aspect of the CL models was recently criticized as not allowing interplay between the various components of the impinging particle velocity.[5]

V. RELATIONS WITH ACCOMMODATION COEFFICIENTS

In this section the physical meaning of the parameters involved in the kernel is clarified. So doing, we prove that the α_j coefficients respectively equal the accommodation coefficients β_j of the momentum components.

First μ_κ may be easily shown to represent the weight of particles reflected according to the process κ in the flux of reflected particles. This property appears obvious when integrating the two members of Eq. (3) over the reflected velocity range, using $B(V',V)$ expressions given in relations (7) and (9). Moreover, the scattering is built using three independent coefficients α_j: then it can be seen that taking into account condition (8), the μ_κ coefficients are necessarily given by relations (9).

On the other hand, the momentum accommodation coefficients β_j are defined as[9]

$$\beta_j=\frac{\Phi_j^- -\Phi_j^+}{\Phi_j^- -\Phi_j^e}. \tag{21}$$

where Φ_j^- is the incoming flux at the wall of the momentum j component, Φ_j^+ is the corresponding reflected flux, and Φ_j^e is the reflected flux in the hypothetical situation of perfect accommodation to the wall. These various momentum fluxes may be written for each component:

$$\Phi_j^-=\int_{\Omega'}m|V_x'|V_j'f^-(V')d_{V'},$$
$$\Phi_j^+=\int_{\Omega}m|V_x|V_jf^+(V)d_V, \tag{22}$$

where $f^-(V)$ and $f^+(V)$ are respectively the incident and the reflected distribution function. Remembering that $f^+(V)$ is given by (3) and using expression (7) of $B(V',V)$, Φ_j^+ is written

$$\Phi_j^+ = \int_{\Omega'} m|V_x'| f^-(V') \sum_\kappa \mu_\kappa \left(\int_\Omega V_j B_\kappa(V',V) d_V \right) d_{V'} . \tag{23}$$

And Φ_j^e for total perfect accommodation (i.e., $\alpha_x = \alpha_x = \alpha_x = 1$) is written

$$\Phi_j^e = \int_{\Omega'} m|V_x'| f^-(V') \left(\int_\Omega V_j B_{xyz}(V',V) d_V \right) d_{V'} . \tag{24}$$

A. Calculation of β_y and β_z

First the case $V_j = V_y$ is dealt with.

According to the expression of $B_{xyz}(V',V)$, $V_y B_{xyz}(V',V)$ is an odd function of the V_y component, therefore,

$$\int_\Omega V_y B_{xyz}(V',V) d_V = 0$$

and then $\Phi^e = 0$, so we can write

$$\beta_y = 1 - \frac{\Phi_y^+}{\Phi_y^-}.$$

On the other hand, looking at relation (23), the contribution of each partial kernel $B_\kappa(V',V)$ in Φ_y^+ expression can be estimated separately by

$$\int_\Omega V_y B_\kappa(V',V) d_V .$$

Each of these partial integrals can be calculated easily and give for any κ either 0 or V_y'. As a result we obtain

$$\sum_\kappa \mu_\kappa \int_\Omega V_y B_\kappa(V',V) d_V = V_y'(\mu_0 + \mu_x + \mu_z + \mu_{xz}),$$

and

$$\Phi_j^+ = (\mu_0 + \mu_x + \mu_z + \mu_{xz}) \Phi_j^- .$$

It results directly that

$$\beta_y = 1 - (\mu_0 + \mu_x + \mu_z + \mu_{xz}),$$

which, according to the normalization condition (8), is also equal to

$$\beta_y = \mu_y + \mu_{xy} + \mu_{yz} + \mu_{xyz} . \tag{25}$$

Similarly we obtain for β_z

$$\beta_z = \mu_z + \mu_{xz} + \mu_{yz} + \mu_{xyz} . \tag{26}$$

By using the μ_κ expressions given by relations (9), Eqs. (25) and (26) lead to

$$\beta_y = \alpha_y \tag{27}$$

and

$$\beta_z = \alpha_z. \tag{28}$$

B. Calculation of β_x

Now $V_j = V_x$ is considered.

Using the same definition of the various fluxes with respect to the sign of the incident flux, we can write

$$\Phi_x^- = \int_{\Omega'} m V_x'^2 f^-(V') d_{V'}. \tag{29}$$

The calculation of the partial integrals involved in relation (23),

$$\int_\Omega V_x B_\kappa(V', V) d_V,$$

gives in this case either $-V_x'$ or $C_w\sqrt{\pi}/2$ for any κ. As a result we obtain

$$\sum_\kappa \mu_\kappa \int_\Omega V_x B_\kappa(V', V) d_V = -V_x'(\mu_0 + \mu_y + \mu_z + \mu_{yz}) + \frac{C_w\sqrt{\pi}}{2}(\mu x + \mu_{xy} + \mu_{xz} + \mu_{xyz}).$$

Using the flux expressions (29) and (23), this result leads to

$$\Phi_x^- - \Phi_x^+ = (1 - (\mu_0 + \mu_y + \mu_z + \mu_{yz}))\Phi_x^- - \frac{C_w\sqrt{\pi}}{2}(\mu_x + \mu_{xy} + \mu_{xz} + \mu_{xyz}) \int_{\Omega'} m|V_x'| f^-(V') d_{V'}.$$

We also have

$$\int_\Omega V_x B_{xyz}(V', V) d_V = \frac{C_w\sqrt{\pi}}{2}$$

and so

$$\Phi_x^- - \Phi_x^e = \Phi_x^- - \frac{C_w\sqrt{\pi}}{2} \int_{\Omega'} m|V_x'| f^-(V') d_{V'}.$$

Consequently, remembering condition (8), it results that

$$\beta_x = \mu_x + \mu_{xy} + \mu_{xz} + \mu_{xyz}. \tag{30}$$

Replacing μ_κ by relations (9) once more, the result shows

$$\beta_x = \alpha_x.$$

The classical Maxwell model predicted the same value of the various accommodation coefficients.[9] However it is well-known, notably from the measurements of accommodation coefficients by various procedures,[15–17] that these coefficients do not have the same value; and this description of equivalent accommodation is not physically consistent.[18] In the new model we can see that the three parameters introduced in the theoretical modelling equal the three accommodation coefficients of momentum component fluxes which are basically different.

VI. EXTENSION OF THE NEW MODEL TO POLYATOMIC GASES

In polyatomic gases the internal state of a molecule is characterized by the rotational and vibrational energies, E_{ir} and E_{iv}, and depends on quantum numbers ir and iv. In addition, because of the degeneracy of rotational levels, a weight factor ($g_{ir}=2ir+1$) is involved in the distribution function expression. The distribution functions of impinging and emerging particles are linked by the following relation [generalizing relation (3)]:[9,19]

$$V_x f_i^+(V,E_{ir},g_{ir},E_{iv}) = \sum_{ir',iv'} \int_{\Omega'} |V_x'| f^-(V',E_{ir'},g_{ir'},E_{iv'}) P_G(V',E_{ir'},g_{ir'},E_{iv'},V,E_{ir},g_{ir},E_{iv}) d_{V'}, \tag{31}$$

where $P_G(V',E_{ir'},g_{ir'},E_{iv'},V,E_{ir},g_{ir},E_{iv})$ is the generalized scattering kernel for molecules considered with internal modes. Of course normalization and non-negative conditions are easily generalized to

$$\sum_{ir,iv} \int_{\Omega} P_G(V',E_{ir'},g_{ir'},E_{iv'},V,E_{ir},g_{ir},E_{iv}) d_V = 1 \tag{32}$$

and

$$P_G(V',E_{ir'},g_{ir'},E_{iv'},V,E_{ir},g_{ir},E_{iv}) \geqslant 0. \tag{33}$$

Furthermore, for the reciprocity condition, we admit the form given by Kuscer[9] which, excluding external magnetic fields, assumes the form

$$\begin{aligned} &|V_x'| e^{-\|V'\|^2/C_w^2} e^{-\varepsilon_{ir'}} e^{-\varepsilon_{iv'}} (2ir'+1) P_G(V',E_{ir'},E_{iv'},V,E_{ir},E_{iv}) \\ &\quad = V_x e^{-\|V\|^2/C_w^2} e^{-\varepsilon_{ir}} e^{-\varepsilon_{iv}} (2ir+1) P_G(-V,E_{ir},E_{iv},-V',E_{ir'},E_{iv'}), \end{aligned} \tag{34}$$

with

$$\varepsilon_{ir} = \frac{E_{ir}}{kT_w}, \quad \varepsilon_{iv} = \frac{E_{iv}}{kT_w}. \tag{35}$$

Reference 19 presents, phenomenologically, a scattering kernel P characterizing the interaction of diatomic molecules with internal modes at the wall (this kernel P is recalled in Appendix C). In kernel P the translation mode was taken as a whole (without interplay between the three translational degrees of freedom), so, when applied to unstructured molecules, P reduced to a classical Maxwell kernel. Nevertheless, a partial accommodation concept was employed in the P derivation allowing different accommodations of the various modes (translation, rotation, vibration). In fact, this concept was analogous to those used in the new model to disconnect the three translation degrees in the accommodation process. From Ref. 19, P may be immediately rewritten:

$$\begin{aligned} P = &\left((1-\alpha_\theta)\delta(V-V_R') + \alpha_\theta \frac{2}{C_w^4 \pi} V_x e^{-V^2/C_w^2} \right) ((1-\alpha_r)(1-\alpha_v)\tilde{P}_0 + \alpha_v(1-\alpha_r)\tilde{P}_v \\ &+ \alpha_r(1-\alpha_v)\tilde{P}_r + \alpha_v\alpha_r\tilde{P}_{rv}), \end{aligned} \tag{36}$$

where α_θ, α_v and α_r are real parameters independent of the microscopic state of the molecules and are considered in [0,1], and

$$\tilde{P}_0=\delta(E_{ir'}-E_{ir})\,\delta(E_{iv'}-E_{iv})\ , \quad \tilde{P}_{rv}=\frac{e^{-\varepsilon_{ir}}}{Q_r}(2i_r+1)\,\frac{e^{-\varepsilon_{iv}}}{Q_v},$$

$$\tilde{P}_v=\delta(E_{ir'}-E_{ir})\,\frac{e^{-\varepsilon_{iv}}}{Q_v}\ , \quad \tilde{P}_r=\frac{e^{-\varepsilon_{ir}}}{Q_r}(2ir+1)\,\delta(E_{iv'}-E_{iv}).$$

The quantities Q_v and Q_r involved in $\tilde{P}_\chi$ $(\chi=v,r,rv)$ are the partition functions defined at the wall temperature:

$$Q_r=\sum_{iv}\ (2ir+1)e^{-\varepsilon_{ir}}\ , \quad Q_v=\sum_{iv}\ e^{-\varepsilon_{iv}}.$$

Now, in operator P in (36), let us replace the first parenthesis corresponding to the classical Maxwell scattering kernel by the new kernel proposed in relation (7) and (9). So a general scattering kernel is obtain in the form

$$P_G=\left(\sum_\kappa\ \mu_\kappa^* B_\kappa(V',V)\right)((1-\alpha_r)(1-\alpha_v)\tilde{P}_0+\alpha_v(1-\alpha_r)\tilde{P}_v+\alpha_r(1-\alpha_v)\tilde{P}_r+\alpha_v\alpha_r\tilde{P}_{rv}), \tag{37}$$

where the μ_κ^* are expressed by relations (9) using the directional parameters α_x^*, α_y^*, and α_z^*. The superscript $(*)$ is used to indicate that the physical meaning of the three parameters is not yet shown in the polyatomic modeling frame.

Considering the properties of its parts, P_G visibly satisfies the normalization and nonnegativity conditions. Furthermore, P_G is a sum of partial operators assuming the factorized form $\tilde{P}_\chi B_\kappa$ (where χ refers to the internal accommodation process). It is clear that the B_κ satisfying condition (4) implies that $\tilde{P}_\chi B_\kappa$ satisfies the generalized reciprocity condition (34). Consequently, P_G also satisfies (34) as a linear combination of $\tilde{P}_j B_\kappa$ terms. So a good anisotropic scattering kernel P_G has been obtained phenomenologically.

Furthermore, in relation (37) the part in the first parenthesis of the second member concerns the translation mode. Introducing into it α_θ defined as $\alpha_\theta=1-\mu_0^*=\Sigma_{\kappa\neq 0}\mu_\kappa^*$, this part assumes the form

$$P_G=(1-\alpha_\theta)\,\delta(V-V_R')+\alpha_\theta\sum_{\kappa\neq 0}\ \lambda_\kappa^* B_\kappa(V',V), \tag{38}$$

where

$$\lambda_\kappa^*=\frac{\mu_\kappa^*}{\alpha_\theta}, \quad \sum_{\kappa\neq 0}\ \lambda_\kappa^*=1. \tag{39}$$

In this last form the complete specular reflection appears separately from all the processes in which partial or complete accommodation occurs.

Integrating on velocity and summing over quantum numbers on the left and right sides of Eq. (31), it is easily shown that μ_κ^* represents (as μ_κ for the unstructured molecules) the part of the particle flux reflected according to the directional process κ. The analytical systematic derivation of P_G and further physical interpretation of α_x^*, α_y^*, α_z^*, α_v, α_r, and α_θ will be presented in a subsequent study.

Regarding now the process from the point of view of energy transfer, the comments given in Ref. 19 can be extended. The thermal kinetic energy of the particle flow may be exchanged in collisions at the wall: at the statistical level the specular kernels reflect the effect of elastic collisions at the wall for the translational mode, while diffusive kernels represent the effects of inelastic collisions for this same mode. In the present model the influence of these inelastic

collisions is considered independently for each translational degree (i.e., for each direction). Statistically the scattered distribution function is no longer accommodated in the same way according to the normal and tangential directions: and on the microscopic level this means that the kinetic energy transfers of an impinging molecule change according to its velocity direction with respect to the wall.

In the same manner the three energy modes may interplay when exchanging energy at the wall, and, so, in operators $\tilde{P}_0$, $\tilde{P}_r$, $\tilde{P}_v$, and $\tilde{P}_{rv}$ the effects of elastic or inelastic collisions for each internal mode appear independently.

VII. DISCUSSION

The new model proposed in this article presents many aspects which allow realistic gas surface interactions to be described. First, the model takes into account the anisotropic effects in the interacting process at the wall. This anisotropic character of the surface derives basically from its physical properties and/or from its suitable treatment. Consequently the real physical properties of the wall are embedded in the three accommodation coefficients of the momentum components. Existing models rarely involve three directional parameters as the present model does: the former approaches using a three parameter representation[2,20] are based on the suggestion of a shifted Maxwellian to describe the reemitted distribution function of a monatomic gas from a solid surface and the parameters are arbitrary constants.[21] Here the new model gives an anisotropic description of the interaction in the sense employed by Kuscer[9] i.e., the new kernel operator is no longer invariant under rotation about the normal axis at the solid surface; moreover, in the new model the parameters are shown to be the accommodation coefficients themselves so it is possible to relate them to physical measurements.[15–18,22] In addition, in polyatomic cases, the present model allows independent accommodation processes at the wall for the various energy modes which seems a realistic description if, for example, the very different situations occurring at the wall for vibrational or translational accommodation are kept in mind.[23,24] Then, it is to be noted that the present model also appears as an improvement with respect to two well-known criticisms opposed to the methods based on the scattering kernel concept. The first criticism formulated by Cercignani[3] concerns the Maxwellian-type kernel: for a given monochromatic beam this model predicts a sharp maximum in the number of molecules at the angle corresponding to specular reflection, which is contradicted by experiments;[25] it is clear that this maximum is smoothed in the new model [see relation (38)]. The second criticism recently formulated by Bruno *et al.*,[5] is not completely justified because it is based, in a part, on studies of reactive or dissociated flows, and, as is well-known, the scattering kernel modeling cannot give correct results in such a case because of the assumption of the wall impermeability involved in it. But, on the other hand, the comments of the authors requiring the introduction of interplay between the velocity directions and the various energy modes is, in our opinion, completely justified. In the present model, precisely such an interplay is present, and the separating procedure of velocity components, which appears in the CL models[3] (also when extended to internal modes[13,14,26]) is not employed here.

A final argument in defense of the new model is its simplicity: as seen above the physical interpretation of the various parts of the kernel is straightforward. Moreover, the model is easy-to-use: first the calculations are simplified because the kernel only depends on the reflected microscopic space parameters; then, from the account of different kinds of accommodation of the moment components a preponderant weight can be given to a particular accommodation process, so the model may be easily simplified according to the geometrical symmetry or the physical conditions of the problem.

VIII. CONCLUDING REMARKS

We have derived an anisotropic model of a scattering kernel. For the unstructured molecules, three directional parameters involved in the model have been shown to be equal to the accommodation coefficients of the fluxes of the momentum components at the wall.

We have also extended the new model to polyatomic structured molecules. In this domain only a phenomenological derivation has been presented. The corresponding analytical method and further calculations to relate parameters α_x^*, α_y^*, α_z^*, α_v, α_r, α_θ to the accommodation coefficients β_j of momentum fluxes and to accommodation coefficients of the energy fluxes will be presented in a subsequent study. These relationships are not expected to be very simple, especially because the constant parameters introduced in the model refer to direct exchanges between each molecular mode and the wall, while the energy accommodation coefficients involve direct exchange with the wall for each mode and also intermode exchanges. Finally, even if not yet confirmed in applications, many arguments have been developed, showing the consistency, physical pertinence and usefulness of the new scattering kernel.

APPENDIX A: $B_\kappa(V',V)$ SATISFIES THE RECIPROCITY RELATION

The property for operator B_{zy} is demonstrated. For the rest of the operators the demonstrations are similar:

$$|V_x'| f_0(V') B_{zy}(V',V) = |V_x'| \frac{n}{(C_w\sqrt{\pi})^3} e^{-\|V'\|^2/C_w^2} \frac{1}{\pi C_w^2} \delta(V_x + V_x') e^{-V_y^2/C_w^2} e^{-V_z^2/C_w^2},$$

and

$$|V_x| f_0(-V) B_{zy}(-V,-V') = |V_x| \frac{n}{(C_w\sqrt{\pi})^3} e^{-\|V\|^2/C_w^2} \frac{1}{\pi C_w^2} \delta(V_x + V_x') e^{-V_y'^2/C_w^2} e^{-V_z'^2/C_w^2}.$$

In these two expressions, there appear the same terms in y and z; the full equality of both the expressions comes from the property of the Dirac function.

APPENDIX B: ψ^0 AS AN EIGENFUNCTION OF OPERATOR A

$$A(\psi^0) = \int_{\Omega'} [|V_x'| f_0(V')]^{1/2} [|V_x| f_0(V)]^{-1/2} B(V_R', V) \psi^0(V') dV'.$$

Replacing ψ^0 and $f_0(V)$ by their expression in this integral: $\psi^0 = (\sqrt{2}/C_w^2\sqrt{\pi})\,|V_x|^{1/2} e^{-\|V\|^2/2C_w^2}$ and $f_0(V) = (n/(C_w\sqrt{\pi})^3)\, e^{-\|V\|^2/C_w^2}$, it is found

$$A(\psi^0) = \frac{\sqrt{2}}{C_w^2\sqrt{\pi}} \int_{\Omega'} |V_x|^{-1/2} |V_x'| e^{\|V\|^2/2C_w^2} e^{-\|V'\|^2/C_w^2} B(V_R', V) dV'.$$

The reciprocity relation $(4')$ leads to

$$\int_{\Omega'} |V_x'| e^{-\|V'\|^2/C_w^2} B(V_R', V) dV' = |V_x| e^{-\|V\|^2/C_w^2},$$

and, consequently,

$$A(\psi^0) = \frac{\sqrt{2}}{C_w^2\sqrt{\pi}} |V_x|^{1/2} e^{-\|V\|^2/2C_w^2} = \psi^0.$$

APPENDIX C: KERNEL OPERATOR OF REF. 19

The full scattering kernel of Ref. 19 is given by

$$P=(1-\alpha_\theta)(1-\alpha_r)(1-\alpha_v)P_1+(1-\alpha_\theta)(1-\alpha_r)\alpha_v P_2+(1-\alpha_\theta)\alpha_r(1-\alpha_v)P_3+(1-\alpha_\theta)$$
$$\times\alpha_r\alpha_v P_4+\alpha_\theta(1-\alpha_r)(1-\alpha_v)P_5+\alpha_\theta\alpha_r(1-\alpha_v)P_6+\alpha_\theta(1-\alpha_r)\alpha_v P_7+\alpha_\theta\alpha_r\alpha_v P_8,$$

where $\alpha_\theta,\alpha_r,\alpha_v$ are real parameters independent of the microscopic state of the molecules. The specular operators with elastic and inelastic parts for each internal mode are given by

$$P_1=\delta(V'-V_R)\quad\delta(E'_{ir}-E_r)\,\delta(E'_{iv}-E_v),$$

$$P_2=\delta(V'-V_R)\quad\delta(E'_{ir}-E_r)\,\frac{e^{-\varepsilon_{iv,w}}}{Q_{v,w}},$$

$$P_3=\delta(V'-V_R)\,\frac{e^{-\varepsilon_{ir,w}}}{Q_{r,w}}(2ir+1)\,\delta(E'_{iv}-E_v),$$

$$P_4=\delta(V'-V_R)\,\frac{e^{-\varepsilon_{ir,w}}}{Q_{r,w}}(2ir+1)\,\frac{e^{-\varepsilon_{iv,w}}}{Q_{v,w}}.$$

The diffusive operators with elastic and inelastic parts, for each internal mode, are given by

$$P_5=\frac{2}{\pi C_w^4}V_x e^{-v_w^2}\delta(E_{ir}-E'_{ir})\,\delta(E_{iv}-E'_{iv}),$$

$$P_6=\frac{2}{\pi C_w^4}V_x e^{-v_w^2}\frac{e^{-\varepsilon_{ir,w}}}{Q_{r,w}}(2ir+1)\,\delta(E_{iv}-E'_{iv}),$$

$$P_7=\frac{2}{\pi C_w^4}V_x e^{-v_w^2}\delta(E_{ir}-E'_{ir})\,\frac{e^{-\varepsilon_{iv,w}}}{Q_{v,w}},$$

$$P_8=\frac{2}{\pi C_w^4}V_x e^{-v_w^2}\frac{e^{-\varepsilon_{ir,w}}}{Q_{r,w}}(2ir+1)\,\frac{e^{-\varepsilon_{iv,w}}}{Q_{v,w}},$$

with

$$\frac{1}{C_w^4}=\left(\frac{m}{2kT_w}\right)^2.$$

In Ref. 19, E_r and E_v defined as mean energy per molecule have been used by error. The correct parameters to use anywhere in this reference are E_{ir} and E_{iv}.

(Received 20 August 2001; accepted 4 February 2004; published 1 April 2004)

We study the discrete part of spectrum of a singular non-self-adjoint second-order differential equation on a semiaxis with an operator coefficient. Its boundedness is proved. The result is applied to the Schrödinger boundary value problem $-\Delta u + q(x)u = \lambda^2 u$, $u|_{\partial D} = 0$, with a complex potential $q(x)$ in an angular domain. [DOI: 10.1063/1.1695446]

I. INTRODUCTION

As is known, the Schrödinger problem with a complex potential appeared in the theory of quantum mechanical systems with dissipative energy (see Refs. 1 and 9). As for non-self-adjoint operators, they arose, in general, of studying nonclosed physical systems (see Refs. 5 and 9; for details we refer to Refs. 4 and 6). In this paper we study the discrete part of spectrum of the non-self-adjoint operator L_α, generated in the Hilbert space $L_2((0,\infty),l_2)$ by the expression

$$L_\alpha u = -\frac{d^2u}{dx^2} + \frac{\beta(\alpha)}{x^2}u + Q(x)u$$

and the boundary condition

$$u(0) = 0,$$

where

$$\beta(\alpha) = \left\{\left(\left(\frac{k\pi}{\alpha}\right)^2 - \frac{1}{4}\right)\delta_{kj}\right\}, \quad k,j = 1,2,..., \quad Q(x) = \{q_{jk}(x)\}_{j,k=1}^{\infty},$$

$v_k = k\pi/\alpha \notin Z$ $(k = 1,2,...)$, $q_{jk}(x) = q_{kj}(x)$ is a complex-valued function, $Q(x)$, $x \in [0,\infty)$, is an l_2-valued function such that $\|Q(x)\| \leqslant Ce^{-\epsilon x}$ with some $\epsilon > 0$ [$\|Q(x)\|$ denotes the norm of the operator $Q(x)$ acting in the space l_2].

In the case where $\beta(\alpha) = \{l(l+1)\delta_{lj}\}$, $l = 0,1,2,...$, the spectrum of L_α was investigated, and the expansions in its eigenfunctions were obtained (see Ref. 7). Using the general spectral theory of self-adjoint operators, the expansions in eigenvectors of L_α were studied in Ref. 3 for $q_{kj}(x) = \overline{q}_{jk}(x)$, $\beta(\alpha) = \{l_j(l_j+1)\delta_{jk}\}$, where the numbers $l_j \geqslant 0$ are such that $\lim_{j\to\infty} l_j = \infty$. In this case the operator L_α is self-adjoint in the space $L_2((0,\infty),l_2)$. But in the situation under consideration L_α is non-self-adjoint, and there is no a general theory to investigate its spectrum. Therefore we start from studying the characteristic properties of L_α.

In what follows we denote by $L_{2,\epsilon}((0,\infty),l_2)$ the set of l_2-valued vector functions $f(x) = (f_1(x),f_2(x),\ldots,f_n(x),\ldots)$, strongly measurable on $[0,\infty)$ and satisfying the condition

$$\int_0^\infty \|f(x)\|^2 e^{-\epsilon x}dx=\int_0^\infty \sum_{j=1}^\infty |f_j(x)|^2 e^{-\epsilon x}dx<\infty.$$

The set $L_{2,\epsilon}=L_{2,\epsilon}((0,\infty),l_2)$ is a separable Hilbert space with respect to the inner product

$$(f,g)=\int_0^\infty (f(x),g(x))^2 e^{-\epsilon x}dx$$

[here $(f(x),g(x))$ denotes the inner product in l_2]. We also set $L_{2,0}((0,\infty),l_2)=L_2((0,\infty),l_2)$.

II. INVESTIGATION OF THE DISCRETE PART OF SPECTRUM

Let L_0 be the operator defined in $L_2((0,\infty),l_2)$ by the differential expression

$$L_0u=-\frac{d^2u}{dx^2}+\frac{\beta(\alpha)}{x^2}u$$

and the boundary condition

$$u(0)=0.$$

It is obvious that the operator L_0 is self-adjoint.

By $G_\alpha(\tau,t,\lambda)$ we mean the resolvent kernel of the operator L_α:

$$G_\alpha(\tau,t,\lambda)=\frac{\pi}{2i}\sqrt{\tau t}\times\begin{cases}\{J_{v_k}(\lambda t)H_{v_k}^{(1)}(\lambda\tau)\delta_{kj}\} & \text{if } \tau>t\\ \{J_{v_k}(\lambda\tau)H_{v_k}^{(1)}(\lambda t)\delta_{kj}\} & \text{if } \tau\leqslant t,\end{cases}$$

where $J_v(x)$ and $H_v^{(1)}(x)$ are the Bessel and Hankel functions of the first kind, respectively. If we apply $(L_0-\lambda^2)^{-1}$ to both sides of the equation $L_\alpha u=\lambda^2 u$, we will get

$$u(\tau,\lambda)=\int_0^\infty G_\alpha(\tau,t,\lambda)Q(t)u(t,\lambda)dt. \tag{2.1}$$

Evidently that the set of λ for which Eq. (2.1) has a nontrivial solution coincides with the eigenvalue set of the equation $L_\alpha u=\lambda^2 u$. Since $G_\alpha(\tau,t,\lambda)$ is a diagonal matrix,

$$\|G_\alpha(\tau,t,\lambda)\|_{l_2}=\frac{\pi}{2}\max_{v_k}\sqrt{\tau t}|J_{v_k}(\lambda t)H_{v_k}^{(1)}(\lambda\tau)|.$$

It follows from Ref. 2 that

$$\sqrt{\tau t}J_{v+n}(\lambda t)H_{v+n}^{(1)}(\lambda\tau)=\frac{n!\Gamma(v)\lambda^v 2^{v-1}}{\pi\Gamma(n+2v)}(\tau t)^{v+(1/2)}\int_{-1}^1\frac{H_v^{(1)}(\lambda\sqrt{\tau^2+t^2-2\tau ts})}{(\sqrt{\tau^2+t^2-2\tau ts})}\times C_n^v(s)(1-s^2)^{v-(1/2)}ds, \tag{2.2}$$

where $C_n^v(s)$ is the Gegenbauer function,[12] and if $\operatorname{Re} v>-\frac{1}{2}$, $-(\pi/2)<\arg\lambda<3\pi/2$, $x>0$, then

$$H_v^{(1)}(\lambda x)=\frac{x^v e^{i(\lambda v-(\pi/2)v-(\pi/4))}}{\Gamma\left(v+\frac{1}{2}\right)}\int_0^\infty\left(1+\frac{it}{2\lambda}\right)^{v-(1/2)}t^{v-(1/2)}e^{-xt}dt. \tag{2.3}$$

Let us estimate $\sqrt{\tau t}J_{v+n}(\lambda t)H_{v+n}^{(1)}(\lambda\tau)$ when $0<v\leqslant 1/2$.

Taking into account that for each $\lambda\in(-(\pi/2)<\arg\lambda<(3\pi/2))$ there exists a positive number β such that $|2\lambda+it|\geqslant\beta$ and $|2\lambda+it|^{\upsilon-(1/2)}\leqslant\beta^{\upsilon-(1/2)}$ as $0<\upsilon\leqslant 1/2$, we obtain from (2.3) the inequality

$$|H_{\upsilon}^{(1)}(\lambda x)|\leqslant C_1\frac{x^{\upsilon}}{\sqrt{|\lambda|}}e^{-(\operatorname{Im}\lambda)x}\frac{1}{|\lambda|^{\upsilon-(1/2)}}\int_0^{\infty}t^{\upsilon-(1/2)}e^{-xt}dt=C_2\frac{e^{-\operatorname{Im}\lambda x}}{|\lambda|^{\upsilon}\sqrt{x}},\quad \tau\leqslant t,$$

where C_1 and C_2 are some constants, whence

$$\begin{aligned}&\sqrt{\tau t}|J_{\upsilon+n}(\lambda\tau)H_{\upsilon+n}^{(1)}(\lambda t)|\\&\quad\leqslant\frac{Cn!\Gamma(\upsilon)(\tau t)^{\upsilon+1/2}}{\Gamma(n+2\upsilon)}e^{-\operatorname{Im}\lambda|\tau-\operatorname{sign}(\operatorname{Im}\lambda)t|}\int_0^{\infty}\frac{C_n^{\upsilon}(\cos\gamma)(\sin\gamma)^{2\upsilon}}{(1-\cos\gamma)^{\upsilon/2+1/4}\tau^{\upsilon+1/2}}d\gamma,\quad \tau\leqslant t.\end{aligned}\tag{2.4}$$

Since for large n,

$$|C_n^{\upsilon}(\cos\gamma)|\leqslant\frac{C\Gamma(n+2\upsilon)}{\sqrt{n}\Gamma(2\upsilon)\Gamma(n+\upsilon+1/2)(\sin\gamma)^{\upsilon}}$$

(see Ref. 12), inequality (2.4) implies the estimate

$$\begin{aligned}|\sqrt{\tau t}J_{\upsilon+n}(\lambda\tau)H_{\upsilon+n}^{(1)}(\lambda t)|&\leqslant\frac{Cn!t^{\upsilon+1/2}}{\sqrt{n}\Gamma(n+\upsilon+1/2)}\int_0^{\pi}\frac{\sin^{\upsilon}\alpha}{(1-\cos\alpha)^{\upsilon/2+1/4}}d\alpha\\&=C_1\frac{t^{\upsilon+(1/2)}}{n^{\upsilon}}e^{(-\operatorname{Im}\lambda|\tau-\operatorname{sign}(\operatorname{Im}\lambda)t|)}.\end{aligned}$$

In the same way, we obtain

$$\sqrt{\tau t}|J_{\upsilon+n}(\lambda t)H_{\upsilon+n}^{(1)}(\lambda\tau)|\leqslant C\frac{t^{\upsilon+(1/2)}}{n^{\upsilon}}e^{(-\operatorname{Im}\lambda|\tau-\operatorname{sign}(\operatorname{Im}\lambda)t|)}\quad\text{as}\quad\tau\geqslant t.$$

So, if n is large, the estimate

$$\forall\tau\in[0,\infty),\quad\forall t\in[0,\infty),$$

$$\sqrt{\tau t}|J_{\upsilon+n}(\lambda x_<)H_{\upsilon+n}^{(1)}(\lambda x_>)|\leqslant C\frac{1}{n^{\upsilon}}(\tau^{\upsilon+(1/2)}+t^{\upsilon+(1/2)})e^{(-\operatorname{Im}\lambda|\tau-\operatorname{sign}(\operatorname{Im}\lambda)t|)}\tag{2.5}$$

is valid, where $x_<=\min(\tau,t)$, $x_>=\max(\tau,t)$.

If we let $\upsilon\to 0$, then, as is known from Ref. 2,

$$C_n^{\upsilon}(\cos\gamma)\sim\frac{\Gamma(n+2\upsilon)\Gamma(\upsilon+\frac{1}{2})}{\sqrt{n\pi}\Gamma(2\upsilon)\Gamma(n+\upsilon+\frac{1}{2})}\left\{\frac{\cos[(n+\upsilon)\gamma-\frac{1}{2}\gamma\pi]}{(\sin\gamma)^{\upsilon}}+O(n^{-(3/2)})\right\}\quad\text{as}\quad n\to\infty.$$

Therefore for $\tau<t$ and $\upsilon\to 0$, we have

$$\sqrt{\tau t}J_{v+n}(\lambda\tau)H^{(1)}_{v+n}(\lambda t)\sim C\frac{\lambda^v\Gamma(n+1)(\tau t)^{v+(1/2)}}{\sqrt{n}\Gamma\left(n+v+\frac{1}{2}\right)}\int_0^\pi\frac{H^{(1)}_v(\lambda\sqrt{\tau^2+t^2-2\tau t\gamma})}{(\sqrt{\tau^2+t^2-2\tau+\gamma})^v}\cos n\gamma d\gamma$$

$$\sim Ct^{v+(1/2)}e^{(-\operatorname{Im}\lambda|\tau-\operatorname{sign}(\operatorname{Im}\lambda)t|)}\int_0^\pi\lambda^v\tau^{v+(1/2)}$$

$$\times e^{(\operatorname{Im}\lambda|\tau-\operatorname{sign}(\operatorname{Im}\lambda)t|)}\frac{H^{(1)}_v(\lambda\sqrt{\tau^2+t^2-2\tau t\gamma})}{(\sqrt{\tau^2+t^2-2\tau+\gamma})^v}(\sin\gamma)^v\cos n\gamma d\gamma. \tag{2.6}$$

Since

$$\left|\lambda^v(\tau t)^{v+(1/2)}e^{(\operatorname{Im}\lambda|\tau-\operatorname{sign}(\operatorname{Im}\lambda)t|)}\frac{H^{(1)}_v(\lambda\sqrt{\tau^2+t^2-2\tau t\gamma})}{(\sqrt{\tau^2+t^2-2\tau+\gamma})^v}(\sin\gamma)^v\right|\leqslant\frac{C}{(1-\cos\gamma)^{1/4}},$$

and

$$\int_0^\pi\frac{d\alpha}{(1-\cos\alpha)^{1/4}}<\infty,$$

the coefficient of $\cos n\gamma$ in (2.6) is absolutely integrable. By the Riemann–Lebesgue Lemma,

$$\sqrt{\tau t}|J_{v+n}(\lambda\tau)H^{(1)}_{v+n}(\lambda t)|=o(1)t^{v+(1/2)}e^{(-\operatorname{Im}\lambda|\tau-\operatorname{sign}(\operatorname{Im}\lambda)t|)}, \tag{2.7}$$

where $o(1)\to 0$ as $n\to\infty$.

A similar argument yields

$$\sqrt{\tau t}|J_{v+n}(\lambda\tau)H^{(1)}_{v+n}(\lambda t)|=o(1)\tau^{v+(1/2)}e^{(-\operatorname{Im}\lambda|\tau-\operatorname{sign}(\operatorname{Im}\lambda)t|)}\quad\text{as}\quad\tau<t. \tag{2.8}$$

Formulas (2.5), (2.7), and (2.8) imply that

$$\sqrt{\tau t}|J_{v+n}(\lambda\tau)H^{(1)}_{v+n}(\lambda t)|=(\tau^{v+1/2}+t^{v+1/2})o(1)e^{(-\operatorname{Im}\lambda|\tau-\operatorname{sign}(\operatorname{Im}\lambda)t|)}, \tag{2.9}$$

where $\lim_{n\to\infty}o(1)=0$ and $0\leqslant\tau,\ t<\infty$.

Analogously, it can be shown that (2.9) holds if $\frac{1}{2}<v<1$.

One can see from estimate (2.9) that for all τ and t, the diagonal entries of the matrix $G_\alpha(\tau,t,\lambda)$ become vanishingly small with $n\to\infty$. In view of (2.2), the function $G_\alpha(\tau,t,\lambda)$, whose values are operators in l_2, is an analytic function of λ in the domain $-(\pi/2)<\arg\lambda<(3\pi/2)$. We summarize the above assertions in the following lemma:

Lemma: For all τ and t, and $-(\pi/2)<\arg\lambda<(3\pi/2)$, the matrix $G_\alpha(\tau,t,\lambda)$ is a compact operator in l_2. If we fix τ and t, then $G_\alpha(\tau,t,\lambda)$ is an analytic operator function of λ in the domain $-(\pi/2)<\arg\lambda<(3\pi/2)$.

Let

$$S_\epsilon=\left\{\lambda\in C:-\frac{\pi}{2}<\arg\lambda<\frac{3\pi}{2},\operatorname{Im}\lambda>-\frac{\epsilon}{2}\right\}.$$

The following theorem holds:

Theorem 1: If $\lambda\in S_\epsilon$, then the integral operator on the right-hand side of (2.1) is compact in $L_{2,\epsilon}((0,\infty),l_2)$.

Proof: First of all we note that the operator $G_\alpha(\tau,t,\lambda)Q(t)$ is compact as a product of the compact operator G_α and the bounded operator Q acting in l_2. By (2.9), under the conditions on $Q(x)$ the inequality

$$\|G_\alpha(\tau,t,\lambda)Q(t)\| \leqslant C \max_{\tau,t}(\tau^{\nu+1/2}+t^{\nu+1/2})e^{-\operatorname{Im}\lambda|\tau-\operatorname{sign}(\operatorname{Im}\lambda)t|}e^{-\epsilon t} \tag{2.10}$$

is fulfilled.

Denote by E_N the infinite diagonal matrix whose first N entries on the main diagonal are 1 and all the rest are equal to 0. It follows from (2.10) that the kernel

$$A_N(\tau,t,\lambda)=G_\alpha(\tau,t,\lambda)E_NQ(t)E_N$$

is of Hilbert–Schmidt-type in $L_{2,\epsilon}((0,\infty),l_2)$ as $\lambda\in S_\epsilon$.

If $\lambda\in S_\epsilon$, then the sequence of kernels A_N converges to $G_\alpha(\tau,t,\lambda)$ $(N\to\infty)$ in the norm of an operator in $L_{2,\epsilon}(0,\infty;l_2)$. Since a limit of a sequence of compact operators is a compact operator, the proof is complete.

Let us consider the following integral equation:

$$u(t)=v(t)-\int_0^\infty G_\alpha(\tau,t,\lambda)Q(t)u(t)dt, \tag{2.11}$$

where $v(\tau)\in L_{2,\epsilon}((0,\infty),l_2)$ and $u(\tau)\in L_{2,\epsilon}((0,\infty),l_2)$ are a known and unknown vector-valued functions, respectively.

Theorem 2: Equation (2.9) is solvable in $L_{2,\epsilon}((0,\infty),l_2)$ for all $\lambda\in S_\epsilon$ except for at most a countable set of points from this set. If there exists infinitely many points λ for which this equation is not solvable, then the limit points of such λ belong to the boundary of S_ϵ.

Proof: The integral equation (2.9) may be written in the form

$$u=v-A(\lambda)u. \tag{2.12}$$

By Lemma and Theorem 1, $A(\lambda)$ is an analytic function of $\lambda\in S_\epsilon$, whose values are compact operators in l_2.

As is done in Ref. 8, it can be shown that Eq. (2.10) has a unique solution for $\lambda\in S_\epsilon$ with large $|\lambda|$. It follows from the Gohberg theorem (see Ref. 10, Chap. I, Theorem 5.1) that the number of points, at which the operator $I-A(\lambda)$ has no inverse, is not greater than countable, and if there exists infinitely many such points, their limit points belong to the boundary of S_ϵ. This completes the proof of the theorem.

Theorem 3: The number $\lambda^2(\operatorname{Im}\lambda>0)$ is an eigenvalue of the operator L_α if and only if Eq. (2.1) has no nontrivial solutions in $L_{2,\epsilon}((0,\infty),l_2)$.

Proof: Assume that $\lambda^2(\operatorname{Im}\lambda>0)$ is an eigenvalue of L_α, and $u(\tau,\lambda)$ is the corresponding eigenfunction. Then $u(\tau,\lambda)$ satisfies (2.1). Since $u(\tau,\lambda)\in L_2((0,\infty),l_2)$, we have $u(\tau,\lambda)\in L_{2,\epsilon}((0,\infty),l_2)$. This shows that the sufficiency is fulfilled.

To prove the necessity, suppose that the vector-valued function $u(\tau,\lambda)\in L_{2,\epsilon}(0,\infty;l_2)$ satisfies Eq. (2.1). Then $Q(t)u(t,\tau)$ belongs to $L_2((0,\infty),l_2)$. Since $G_\alpha(t,\tau,\lambda)$ is the resolvent kernel of the self-adjoint operator L_0, $u(\tau,\lambda)\in L_2(0,\infty;l_2)$.

Applying the expression

$$-\frac{d^2}{d\tau^2}+\frac{B(\alpha)}{\tau^2}-\lambda^2$$

to both sides of (2.1) makes sure that

$$-\frac{d^2u}{d\tau^2}+\frac{B(\alpha)u}{\tau^2}+Q(\tau)u=\lambda^2u.$$

As is seen from (2.1), the boundary condition $u(0)=0$ is satisfied, too. So, the number λ^2 is an eigenvalue of the operator L_α, which is what had to be proved.

In Ref. 11 (see also Ref. 3), it was shown that the operator L_α has no positive eigenvalues. Using Theorems 2 and 3, we arrive at the following result:

Theorem 4: The discrete part of spectrum of L_α forms a bounded set. If this set is infinite then it has only one limit point which is equal to zero.

Example: Let D be an angular domain in the plane $x=(x_1,x_2)$ with center at zero and angle α. Moreover, α is chosen in the way that $v_k=(k\pi/\alpha)\notin Z\ (n=1,2,...)$. In the space $L_2(D)$ we consider the operator L generated by the Schrödinger differential expression

$$Lu=-\Delta u+q(x)u$$

and the boundary condition $u|_{\partial D}=0$. We assume also that the condition $|q(x)|\leqslant ce^{-\epsilon|x|}$, $\epsilon>0$, is satisfied.

Let $\phi_n(\varphi)=\sqrt{(2/\alpha)}\sin(\pi n/\alpha)\varphi$. The functions $\{\phi_n(\varphi)\}_{n=1}^{\infty}$ form a complete orthonormal system in $L_2(0,\alpha)$. We look for a solution of the equation $Lu=\lambda^2u$ in polar coordinates so that

$$u(x,\lambda)=\sum_{j=1}^{\infty}\frac{1}{\sqrt{r}}u_j(r,\lambda)\phi_j(\varphi)\quad(r=|x|).$$

Then determination of the eigenvalues of the operator L is reduced to finding those of the operator L_α. As a result, we can state that the eigenvalues of the non-self-adjoint operator L form a bounded set, and if this set has a limit point, then this limit point is equal to zero.

We consider the time evolution of states for continuous infinite particle systems which corresponds to nonequilibrium diffusion dynamics. For initial states μ_0 which are perturbations of the equilibrium we obtain a bound for finite volume nonequilibrium correlation functions and their continuity in time uniformly in volume for any finite time interval. This gives the possibility to construct the time evolution of correlation functions and corresponding states in the thermodynamic limit. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1690489]

I. INTRODUCTION

A diffusion of an interacting infinite particle system can be described by an infinite system of stochastic differential equations of the so-called gradient type:

$$dx_i(t) = -\sum_{j,i\neq j} \nabla\phi(x_i(t)-x_j(t))dt + \sqrt{\frac{2}{\beta}}\quad dw_i(t). \tag{1.1}$$

Here $\phi:\mathbb{R}^d\backslash\{0\}\to\mathbb{R}$ $(\phi(x)=\phi(-x))$ is an interaction potential, $w_i(t)$ are independent standard Wiener processes in $\mathbb{R}^d$ and the parameter $\beta>0$ is the inverse temperature of the system. The physical background and motivation can be found in the article by Spohn[1] and references therein. The set of positions $\{x_i\}_{i\in\mathbb{N}}$ of identical particles is a locally finite subset in $\mathbb{R}^d$ and the set of all such subsets is the *configuration space* Γ:

$$\Gamma := \{\gamma\subset\mathbb{R}^d \quad | \quad |\gamma\cap K|<\infty \quad \textit{for any compact} \quad K\subset\mathbb{R}^d\},$$

where $|A|$ is the cardinality of A. Heuristically, any Gibbs measure μ on Γ corresponding to the interaction ϕ and the inverse temperature β is a stationary measure of the Markov process defined by (1.1). The corresponding Markov generator can be calculated by Ito's formula and defined in $L^2(\Gamma,\mu)$ on some domain of smooth cylinder functions F by the following expression:

$$(HF)(\gamma) = \sum_{x\in\gamma}\left(-\frac{1}{\beta}\Delta_x + \nabla_x U_\phi(\gamma)\cdot\nabla_x\right)F(\gamma), \tag{1.2}$$

[c)]Electronic mail: roeckner@mathematik.uni-bielefeld.de

where

$$U_\phi(\gamma)=\sum_{\{x,y\}\subset\gamma}\phi(x-y),\quad \nabla_x U_\phi(\gamma)=\sum_{y\in\gamma\setminus x}\nabla\phi(x-y),\quad x\in\gamma. \tag{1.3}$$

Under some natural restrictions on the class of interaction potentials ϕ the generator H has a self-adjoint extension in $L^2(\Gamma,\mu)$ (see Ref. 2).

A rigorous study of (1.1) has been initiated by Lang[3] who has proved the existence of the so-called equilibrium stochastic dynamics which corresponds to (1.1) for a superstable, three times continuously differentiable potential with finite range. In more recent works by Osada,[4] Yoshida[5] and Albeverio *et al.*[2] the equilibrium stochastic dynamics was constructed by Dirichlet form methods for a wide class of potentials ϕ. The existence of the nonequilibrium dynamics was proved by Rost[6] and Lippner[7] in the one-dimensional case and by Fritz[8] for smooth superstable finite range potentials in the case $d\leqslant 4$.

To construct the nonequilibrium dynamics one can consider the corresponding semigroup $T_t=e^{-t\tilde{H}}$ on some class $\mathcal{F}(\Gamma)$ of observables $F:\Gamma\to\mathbb{R}$ defined by the Kolmogorov equation

$$\frac{\partial F_t}{\partial t}=-\tilde{H}F_t,\quad F_0\in\mathcal{F}(\Gamma), \tag{1.4}$$

where $\tilde{H}$ is the Friedrichs extension of H on $L^2(\Gamma,\mu)$ for some fixed Gibbs measure μ. On the other hand, instead of the evolution of observables one can consider the evolution of states, i.e., the evolution of probability measures on Γ. Such evolution is defined by the adjoint semigroup via the following equation:

$$\frac{d}{dt}\mu_t=-H^*\mu_t. \tag{1.5}$$

In the case of a finite particle system this equation can be rewritten in terms of the densities $\mathcal{D}(t,\gamma)$ w.r.t. Lebesgue measure $d\gamma=dx_1\cdots dx_N$ ($|\gamma|=N<\infty$). Then (1.5) is, sometimes, called the generalized Smoluchowski equation (see, e.g., Ref. 9).

For infinite particle systems initial states μ_0 are not absolutely continuous w.r.t. any standard measure and the time evolution of densities has no rigorous sense. Below we consider an alternative approach in terms of correlation functions which correspond to the states of the system. To define these correlation functions we introduce the space of *finite configurations* Γ_0:

$$\Gamma_0:=\bigcup_{n\in\mathbb{N}_0}\Gamma^{(n)},\quad \Gamma^{(n)}:=\{\gamma\in\Gamma\ \mid\ |\gamma|=n\},\quad \mathbb{N}_0=\mathbb{N}\cup\{0\}. \tag{1.6}$$

Γ_0 is naturally equipped with the Borel σ-algebra $\mathfrak{B}(\Gamma_0)$ given by the disjoint union of the measurable spaces $(\Gamma^{(n)},\mathfrak{B}(\Gamma^{(n)}))$. For any bounded $Y\in\mathfrak{B}(\mathbb{R}^d)$ the topology of

$$\Gamma_Y^{(n)}:=\{\gamma\in\Gamma\ \mid\ \gamma\cap(\mathbb{R}^d\setminus Y)=\varnothing,\ |\gamma|=n\}$$

is induced by the bijection between $\Gamma_Y^{(n)}$ and the symmetrization $\tilde{Y}^n/S_n$ of $\tilde{Y}^n$ (see Ref. 10 for details), where S_n is the permutation group over $\{1,\ldots,n\}$,

$$\tilde{Y}^n:=\{(x_1,\ldots,x_n)\ \mid\ x_i\in Y,\ x_i\neq x_j, i\neq j\},$$

and we denote by $\Gamma_Y=\cup_{n=0}^\infty\Gamma_Y^{(n)}$ the set of configurations in Y.

Starting with an intensity measure $\sigma=zdx$ ($z>0$) on $\mathfrak{B}(\mathbb{R}^d)$ we introduce the product-measure $\sigma^{\otimes n}$ on $(\mathbb{R}^d,\mathfrak{B}(\mathbb{R}^{dn}))$ and denote $\sigma^{(n)}:=\sigma^{\otimes n}\circ(s_n)^{-1}$, where s_n is the map $s_n:\mathbb{R}^{dn}\ni(x_1,\ldots,x_n)\mapsto\{x_1,\ldots,x_n\}\in\Gamma^{(n)}$. The Lebesgue–Poisson measure λ_σ on $\mathfrak{B}(\Gamma_0)$ is defined by the formula

$$\lambda_\sigma := \sum_{n\geqslant 0} \frac{1}{n!}\sigma^{(n)}. \tag{1.7}$$

Definition 1.1: Let $G:\Gamma_0\to\mathbb{R}$ *be a measurable function with local support [i.e., there exists a bounded* $\Lambda\in\mathfrak{B}(\mathbb{R}^d)$ *such that* $G\restriction(\Gamma_0\setminus\Gamma_\Lambda)=0$*]. Define the function* KG: $\Gamma\to\mathbb{R}$ *as*

$$(KG)(\gamma) := \sum_{\eta\Subset\gamma} G(\eta). \tag{1.8}$$

The summation in (1.8) is taken over all finite subconfigurations $\eta\subset\gamma$.

Remark 1.1: Functions on Γ can be considered as *observables* of our infinite particle system, and functions on Γ_0 can be interpreted as *quasi-observables*. The mapping (1.8) was introduced by Lenard[11] in order to give an abstract definition of the correlation functions in classical statistical mechanics. For a detailed study of properties of the K-transform in the framework of harmonic analysis on configuration spaces we refer to Refs. 12–14.

For a given probability measure μ on $\mathfrak{B}(\Gamma)$ one can define the correlation measure ρ_μ on $\mathfrak{B}(\Gamma_0)$ by

$$\rho_\mu(A) := \int_\Gamma (K\mathbb{1}_A)(\gamma)\mu(d\gamma), \tag{1.9}$$

where $\mathbb{1}_A$ is the indicator function of a set $A\in\mathfrak{B}(\Gamma_0)$. Assuming that ρ_μ is absolutely continuous w.r.t. λ_σ we can define the correlation functional

$$k(\eta) = k_\mu(\eta) := \frac{d\rho_\mu}{d\lambda_\sigma}(\eta). \tag{1.10}$$

In statistical physics it is useful to work with the corresponding family of correlation functions

$$k^{(n)} := k\restriction\Gamma^{(n)}, \quad n\geqslant 0. \tag{1.11}$$

Under certain general conditions on the interaction potential the correlation functions $k^{(n)} = k^{(n)}(x_1,\ldots,x_n) := k^{(n)}(x)_n$ are bounded measurable functions on some Banach space (for example, E_ξ in Ref. 15). For any $G\in L^1(\Gamma_0,\rho_\mu)$ the following formula is true (see Ref. 12 for details):

$$\int_\Gamma (KG)(\gamma)\mu(d\gamma) = \int_{\Gamma_0} G(\eta)\rho_\mu(d\eta) = \int_{\Gamma_0} G(\eta)k(\eta)\lambda_\sigma(d\eta). \tag{1.12}$$

To construct the dynamics for correlation functions, let us consider the K-transform of the generator H which is defined by

$$\hat{H} = K^{-1}HK \tag{1.13}$$

on a proper set $\mathcal{F}_0(\Gamma_0)$ of functions on Γ_0 (quasi-observables). The corresponding evolution of quasi-observables is given then by the following equation:

$$\frac{\partial G_t}{\partial t} = -\hat{H}G_t, \quad G_0\in\mathcal{F}_0(\Gamma_0). \tag{1.14}$$

We can define the time evolution of correlation functions via the duality relation:

$$\int_{\Gamma_0} G_t(\eta)k_0(\eta)\lambda_\sigma(d\eta) = \int_{\Gamma_0} G_0(\eta)k_t(\eta)\lambda_\sigma(d\eta). \tag{1.15}$$

Then the adjoint operator $(\hat{H})^* =: H_B$ in $L^2(\Gamma_0, \lambda_\sigma)$ is the generator of the evolution semigroup for the correlation functional, i.e.,

$$\frac{\partial}{\partial t} k_t = -H_B k_t . \tag{1.16}$$

Using (1.2) and (1.13)–(1.15) we can show that (1.16) has the following form (see Ref. 14):

$$\frac{\partial}{\partial t} k_t(\eta) = \sum_{x \in \eta} \nabla_x \left[\frac{1}{\beta} \nabla_x k_t(\eta) + \nabla_x U_\phi(\eta) k_t(\eta) + \int dx' \nabla \phi(x - x') k_t(x' \cup \eta) \right], \quad \eta \in \Gamma_0 . \tag{1.17}$$

In terms of the correlation functions this equation has the following hierarchical structure:

$$\frac{\partial}{\partial t} k_t^{(m)}(x)_m = \frac{1}{\beta} \sum_{j=1}^{m} \Delta_{x_j} k_t^{(m)}(x)_m + \sum_{j=1}^{m} \sum_{k \neq j}^{m} ((\nabla \phi)(x_j - x_k) \nabla_{x_j} + (\Delta \phi)(x_j - x_k)) k_t^{(m)}(x)_m$$
$$+ \sum_{j=1}^{m} \int_{\mathbb{R}^d} dx' [(\nabla \phi)(x_j - x') \nabla_{x_j} + (\Delta \phi)(x_j - x')] k_t^{(m+1)}((x)_m, x') . \tag{1.18}$$

This equation appeared for the first time on a heuristic level in Ref. 16. In the present context the hierarchy (1.16)–(1.18) is a direct consequence of the Kolmogorov equation (1.4). It is called sometimes the Bogoliubov diffusion hierarchy and it is analogous to the BBGKY hierarchy for Hamiltonian dynamics. Note that some approaches to investigating this chain of equations in the case of a smooth interaction potential ϕ were proposed in Refs. 17–20.

The problem of existence of solutions of hierarchy (1.18) is additionally complicated by the fact that one should check that the obtained solution k_t corresponds to some state μ_t. Otherwise we cannot prove that we construct the evolution of some initial state μ_0. This problem was not discussed in Refs. 17–20. More precisely, for regular types of interaction potentials, low particle density and sufficiently small interval of time evolution the solution of the diffusion hierarchy (1.18) in the thermodynamic limit was obtained without any analysis of the existence of the dynamics for the corresponding states. In this article we obtain the existence of state μ_t using a general theorem about the connection between states and positive-definiteness of the corresponding correlations functions.[14,21]

Remark 1.2: Note that in theoretical physics a hierarchical system of equations is accepted very often as the definition of the dynamics of an infinite particle system. Such situation takes place, e.g., in Hamiltonian dynamics where the BBGKY hierarchy is considered as the definition of the evolution. Let us mention that, in general, connections between the BBGKY hierarchy approach and the state evolution are not investigated enough as pointed out in Ref. 22, Sec. 3.3. From the physical point of view the property of positivity for correlation functions is very important. But it is not enough to reconstruct the corresponding state.[11] A constructive condition which guarantees such reconstruction was proposed in Ref. 12 (see also Ref. 21). This is the positive-definiteness of the sequence of correlation functions [see below (2.25)–(2.27)]. The situation is the same as in the classical problem of momentum (see, e.g., Ref. 23). From this point of view many results on existence of solutions of the BBGKY hierarchy (see, e.g., Refs. 24 and 25) should be completed by a proof for the existence of the dynamics of states for every particular class of models, as it has been done for stationary solutions in Ref. 26 and for the one-dimensional nonstationary case in Ref. 27.

In this article we consider some class of singular superstable interactions (see Sec. III). Our main strategy is based on a construction of the semigroup p_B^t which corresponds to the evolution equation (1.16). For appropriate initial data k_0 it provides a global solution to the diffusion hierarchy (1.16)–(1.18):

$$k_t(\eta)=(p_B^t k_0)(\eta). \tag{1.19}$$

We obtain an expression for the operator p_B^t which can be easily defined on the Banach space $L^1_\beta(\Gamma_0,\lambda_{\xi\sigma})$ of $\lambda_{\xi\sigma}$-integrable functionals for some appropriate weight ξ (see Sec. II). But for most cases, which are interesting from a physical point of view, the correlation functionals of initial particle distributions do not belong to $L^1_\beta(\Gamma_0,\lambda_{\xi\sigma})$. Typically, they are only bounded and we need to extend the domain of the operator p_B^t to some class of bounded functionals. But from our point of view it would be very naive to hope that a global solution to the hierarchy (1.16)–(1.18) can be obtained for all initial data. Even in the case of a finite number of particles the singularity of the interaction potential does not allow us to define the evolution of arbitrary initial state. Generally speaking one can expect existence of a solution only if the initial correlation functions are chosen in a proper way. In this article we consider a class of initial functionals which correspond to some perturbations of the equilibrium state $\mu=\mu_\phi$ which is constructed by ϕ. The idea is that, as the equilibrium state is a perturbation of the free state (Poisson ideal gas), the nonequilibrium state should be some perturbation of the equilibrium Gibbs state. Such a choice of the initial state is very natural from a physical point of view and were used by many authors. Our main result (Theorem 4.1) is the following. Consider an initial state μ_0 which corresponds to a superstable potential

$$V=\phi+\psi, \tag{1.20}$$

where ϕ is the potential by which our dynamics (1.1) is governed and ψ is a superstable, lower regular interaction potential (see Sec. III). For the given measure μ_0 we consider a family of finite volume measures μ_0^Λ [for bounded $\Lambda\in\mathfrak{B}(\mathbb{R}^d)$] and the corresponding family of initial correlation functionals $k_0^\Lambda(\eta)$:[15]

$$k_0^\Lambda(\eta)=\int_{\Gamma_0}\lambda_\sigma(d\gamma)\mathcal{D}_0^\Lambda(\eta\cup\gamma) \tag{1.21}$$

with

$$\mathcal{D}_0^\Lambda(\eta)=Z_\Lambda^{-1}\mathbb{1}_{\Gamma_\Lambda}(\eta)e^{-\beta U_V(\eta)},\quad \eta\in\Gamma_0, \tag{1.22}$$

$$Z_\Lambda=\int_{\Gamma_0}\lambda_\sigma(d\eta)\mathbb{1}_{\Gamma_\Lambda}(\eta)e^{-\beta U_V(\eta)}. \tag{1.23}$$

For such initial correlation functionals we construct a solution of (1.16) as

$$k_t^\Lambda(\eta)=(p_B^t k_0^\Lambda)(\eta). \tag{1.24}$$

Our main technical result consists in the proof of a bound, uniform in Λ, for these correlation functionals:

$$k_t^\Lambda(\eta)\leqslant c_1^{|\eta|},\quad \eta\in\Gamma_0\quad c_1=c_1(z,\beta,T),\quad t\in[0,T], \tag{1.25}$$

for any time interval $[0,T]$. We obtain this result using the well-known technique of superstability estimates in classical statistical mechanics[28] and its generalization to the quantum case with Boltzman statistics.[29]

In our case this technique needs some modification. We should also note that as in Ref. 29 we need the restriction $d\leqslant 3$ on the dimension d of the system. It is connected with estimating the contribution of long Wiener trajectories in a functional integral representation for the correlation functions. Using (1.25) and the continuity in time (uniformly in Λ) [see (4.27)] we conclude that there exists a thermodynamic limit for k_t^Λ and these limit functionals k_t satisfy the equation (1.16) in a weak sense.

The structure of this paper is as follows: In Sec. II we construct the operator p_B^t and derive a representation for k_t^Λ. In Sec. III we discuss the class of interactions. In Sec. IV we recall some auxiliary constructions and formulate our main result. The proof of the main theorem is presented in Sec. V. The basic technical lemmas are outlined in the Appendix.

II. CORRELATION FUNCTIONS

In this section we construct the semigroup connected with the diffusion hierarchy (1.16)–(1.18) and derive a representation for the finite volume correlation functions (1.24). Let us define an operator K_0 on quasi-observables as

$$K_0G := (KG)\restriction\Gamma_0. \tag{2.1}$$

Then we can construct the operator

$$H_F := K_0\hat{H}K_0^{-1}. \tag{2.2}$$

On smooth quasi-observables the operator H_F acts by the following formulas

$$H_FG = ((H_FG)^{(n)}(x)_n)_{n=0}^\infty, \quad G = ((G)^{(n)}(x)_n)_{n=0}^\infty, \tag{2.3}$$

where

$$(H_FG)^{(n)}(x)_n = (H_F^{(n)}G^{(n)})(x)_n = \sum_{j=1}^n \left(-\frac{1}{\beta}\Delta_{x_j} + \nabla_{x_j}U_\phi(x)_n\cdot\nabla_{x_j}\right)G^{(n)}(x)_n. \tag{2.4}$$

$H_F^{(n)}$ is the generator of the stochastic dynamics for an n-particle system:

$$dx_i(t) = -\sum_{i\neq j=1}^n \nabla\phi(x_i(t)-x_j(t))dt + \sqrt{\frac{2}{\beta}}\quad dw_i(t), \quad i=1,\dots,n. \tag{2.5}$$

The problem of existence of the stochastic dynamics (2.5) with a singular potential is analyzed in Refs. 30 and 31. The operator $H_F^{(n)}$ is generated by the Dirichlet form

$$(H_F^{(n)}G^{(n)},G^{(n)})_{L^2(\Gamma_0^{(n)},\mu_\phi^{(n)})} = \frac{1}{\beta}\sum_{j=1}^n \int_{\Gamma_0^{(n)}} |\nabla_jG^{(n)}|^2 d\mu_\phi^{(n)}, \tag{2.6}$$

where

$$\mu_\phi^{(n)} := e^{-\beta U_\phi(\cdot)_n}\sigma^{(n)} \tag{2.7}$$

and $\sigma^{(n)}$ is defined in (1.7).

Then using (1.14)–(1.15) and (2.1)–(2.2) one can write for p_B^t the following representation:

$$p_B^t = e^{-tH_B} = K_0^* e^{-tH_F^*}(K_0^{-1})^* = De^{-tH_F^*}D^{-1}. \tag{2.8}$$

Here the operators $D := K_0^*$ and D^{-1} are defined in $L^1(\Gamma_0,\lambda_{\xi\sigma})$, $\xi>2$, by the following formulas (see Ref. 12 for details):

$$(DF)(\eta) = \int_{\Gamma_0}\lambda_\sigma(d\gamma)F(\eta\cup\gamma), \tag{2.9}$$

$$(D^{-1}F)(\eta) = \int_{\Gamma_0}\lambda_\sigma(d\gamma)(-1)^{|\gamma|}F(\eta\cup\gamma). \tag{2.10}$$

Remark 2.1: In our approach the representation (2.8) for p_B^t is a direct consequence of the Kolmogorov equation (1.4) without any reference to the hierarchical structure of (1.17) and (1.18). In the same way from the Liouville equation one can obtain the corresponding representation for the Hamiltonian dynamics.[14] Representations like (2.8) appeared earlier. They were obtained by application of the method of ''creation'' and ''annihilation'' operators for classical statistical mechanics (see Refs. 32–35). For connections with the diffusion hierarchy see Ref. 19.

Remark 2.2: It will be clear from the considerations below that in the case of a stable interaction potential ϕ for which $-\Delta\phi$ is also stable, the operator p_B^t can be defined on a Banach space $L_{\beta,\xi}$ with the norm

$$\|G\|_{\beta,\xi}=\int_{\Gamma_0}\lambda_{\xi\sigma}(d\eta)e^{(1/2)\beta U_\phi(\eta)}|G(\eta)|<\infty,\quad G\in L^1_{\beta,\xi}. \tag{2.11}$$

To obtain a representation for finite volume correlation functions k_t^Λ we take into account the definition of the operator D and rewrite (1.21) in the form

$$k_0^\Lambda(\eta)=(D\mathcal{D}_0^\Lambda)(\eta). \tag{2.12}$$

Then due to (2.8) and (1.20) the following representation is true:

$$k_t^\Lambda(\eta)=\left(D\left[e^{-tH_F^*}\left(\frac{1}{Z_\Lambda}e^{-\beta U_\phi}e^{-\beta U_\psi}\mathbb{1}_{\Gamma_\Lambda}\right)\right]\right)(\eta)=\left(D\left[\frac{1}{Z_\Lambda}e^{-tH_F}(e^{-\beta U_\psi}\mathbb{1}_{\Gamma_\Lambda})e^{-\beta U_\phi}\right]\right)(\eta), \tag{2.13}$$

where we use the fact that the operator H_F [see (2.4)] is a self-adjoint operator in $L^2(\Gamma_0,e^{-\beta U_\phi}\lambda_\sigma)$.

Now, to get an integral representation for k_t^Λ we use a functional integral representation for the operator e^{-tH_F} in (2.13). First of all, note that the operator H_F has the Fock structure (2.3) and (2.4), so we only need a representation for $e^{-tH_F^{(n)}}$ in $L^2(\Gamma_0^{(n)},\mu_\phi^{(n)})$. To get it we use the well-known ground state transformation (see, e.g., Ref. 36, Sec. 2, and Ref. 23, Chap. 7)

$$L^2(\Gamma_0^{(n)},\mu_\phi^{(n)})\ni f\mapsto e^{-(1/2)\beta U_\phi}f\in L^2(\Gamma_0^{(n)},\sigma^{(n)}). \tag{2.14}$$

The corresponding generator $\tilde{H}_F^{(n)}$ in $L^2(\Gamma_0^{(n)},\sigma^{(n)})$ has the following form,

$$\tilde{H}_F^{(n)}=-\frac{1}{\beta}\sum_{j=1}^n\Delta_{x_j}+\tilde{V}(x)_n, \tag{2.15}$$

with the effective potential

$$\tilde{V}(x)_n=\tilde{V}^+(x)_n+\tilde{V}^{(-\Delta\phi)}(x)_n:=\sum_{j=1}^n\left(\frac{\beta}{4}|\nabla_{x_j}U_\phi(x)_n|^2-\frac{1}{2}\Delta_{x_j}U_\phi(x)_n\right). \tag{2.16}$$

For the domain of the operator $\tilde{H}_F^{(n)}$ we have $\mathfrak{D}(\tilde{H}_F^{(n)})\supset C_0^\infty(\Gamma_0^{(n)})$, where $C_0^\infty(\Gamma_0^{(n)})$ denotes C^∞-functions on $\Gamma_0^{(n)}$ with compact supports. It can be shown that for any superstable potential ϕ the effective potential $\tilde{V}(x)_n$ is bounded from below for any fixed n. But for the class of potentials under consideration it is even superstable (see Sec. III). Therefore, we can apply the Feynman–Kac formula for the kernel of the semigroup $e^{-t\tilde{H}_F^{(n)}}$, where $\tilde{H}_F^{(n)}$ is considered in the sense of a form sum (2.15) Ref. 37, Chap. 2. As a result, we get

$$(e^{-tH_F^{(n)}})((x)_n;(y)_n)=e^{(1/2)\beta U_\phi(x)_n-(1/2)\beta U_\phi(y)_n}\int_{(\Omega^{t\beta})^n}\prod_{j=1}^n W^{t\beta}_{x_j;y_j}(d\omega_j)e^{-\beta\int_0^{t\beta}d\tau\tilde{V}(\omega(\tau))_n}, \tag{2.17}$$

where

$$\Omega^{t_\beta} := C([0,t_\beta] \to \mathbb{R}^d), \quad t_\beta = t\beta^{-1}, \tag{2.18}$$

$W^{t_\beta}_{x;y}$ is the conditional Wiener measure on the space Ω^{t_β} with conditions $\omega_j(t_\beta) = x_j$ and $\omega_j(0) = y_j$. It implies the following useful representation:

$$k_t^\Lambda(\eta) = \int_{\mathbb{R}^{dm}} d\xi \int_{(\Omega^{t_\beta})^m} W^{t_\beta}_{\eta;\xi}(d\omega)_m \rho_t^\Lambda(\omega)_m, \tag{2.19}$$

where $\eta = \{x_1, \ldots, x_m\}$, $\xi = \{y_1, \ldots, y_m\}$, $d\xi = dy_1 \cdots dy_m$, and

$$\rho_t^\Lambda(\omega)_m = \sum_{n \geqslant 0} \frac{1}{n!} \int \tilde{\sigma}_\Lambda(\omega_{m+1}) \cdots \int \tilde{\sigma}_\Lambda(\omega_{m+n}) \tilde{D}_0^\Lambda(\omega(0))_{m+n} e^{-\tilde{U}(\omega)_{m+n}}. \tag{2.20}$$

In (2.20) we use the following notations:

$$\tilde{U}(\omega)_{m+n} := \frac{1}{2}\beta U_\phi(x)_{m+n} + \int_0^{t_\beta} d\tau [U_{-\Delta\phi}(\omega(\tau))_{m+n} + U^+_{\nabla\phi}(\omega(\tau))_{m+n}], \tag{2.21}$$

$$U^+_{\nabla\phi}(x)_{m+n} := \sum_{j=1}^{m+n} \left[\frac{1}{4}\beta |\nabla_{x_j} U_\phi(x)_{m+n}|^2 \right] \geqslant 0, \tag{2.22}$$

$$\tilde{D}_0^\Lambda(\omega(0))_{m+n} := e^{(1/2)\,\beta U_\phi(\omega(0))_{m+n}} \mathcal{D}_0^\Lambda(\omega(0))_{m+n}, \tag{2.23}$$

and

$$\int \tilde{\sigma}_\Lambda(d\omega)(\cdots) = z \int dx \int_\Lambda dy \int W^{t_\beta}_{x;y}(d\omega)(\cdots). \tag{2.24}$$

A representation like (2.19) and (2.20) was obtained also in Refs. 17 and 18 as the generalized solution of the finite volume diffusion hierarchy (1.18).

Remark 2.3: It is not hard to show that the sequence $k_t^\Lambda(\eta)$ is positive-definite in the sense of Refs. 12 and 13, which is the following.

Definition 2.1:[13] The sequence $k_t^\Lambda(\eta)$ is positive-definite if

$$\int_{\Gamma_0} (G \star \overline{G})(\eta) k_t^\Lambda(\eta) \lambda_\sigma(d\eta) \geqslant 0 \quad \textit{for all } G \in B_{bs}(\Gamma_0). \tag{2.25}$$

Here $B_{bs}(\Gamma_0)$ is the set of all bounded measurable functions with bounded support, $\overline{G}$ denotes the complex conjugate of G, and $\star$-star is the convolution, which is defined in the following way:

$$K(G_1 \star G_2) = KG_1 \cdot KG_2. \tag{2.26}$$

(See Ref. 13 for details.)

Now, inserting (1.24) into (2.25) and using the representation (2.8), (2.12), (2.17) and the property (2.26) (which is true, also, for K_0 [see (2.1)] we obtain

$$\int_{\Gamma_0}(G\star\overline{G})(\eta)p_t D\mathcal{D}_0^{\Lambda}(\eta)\lambda_\sigma(d\eta)$$

$$=\int_{\Gamma_0}(G\star\overline{G})(\eta)K_0^* e^{-tH_F^*}D^{-1}D\mathcal{D}_0^{\Lambda}(\eta)\lambda_\sigma(d\eta)$$

$$=\int_{\Gamma_0}e^{-tH_F}(K_0G)(\eta)(K_0\overline{G})(\eta)\mathcal{D}_0^{\Lambda}(\eta)\lambda_\sigma(\eta)$$

$$=\int_{\Gamma_0}\lambda_\sigma(d\eta)\int_{(\mathbb{R}^d)^{|\eta|}}d\eta'(e^{-tH_F^{|\eta|}})(\eta|\eta')|(K_0G)(\eta')|^2\mathcal{D}_0^{\Lambda}(\eta)\geqslant 0 \qquad (2.27)$$

Positive definiteness together with the bound (1.25) gives a possibility to reconstruct the corresponding sequence of states (measures) μ_t^{Λ}.

Representation (2.19) and (2.20) is reminiscent to the representation of reduced density matrices by correlation functionals in quantum statistical mechanics with Boltzman statistics (see Refs. 38 and 39). This analogy enables us to apply powerful techniques from quantum statistical mechanics in the considered model. Following Ref. 40, we construct the configuration space $\Gamma_{\Omega^{t_\beta}}$ over the space Ω^{t_β} of Wiener trajectories in $\mathbb{R}^d$. Define configuration $\tilde{\gamma}$ as the infinite set of trajectories $\omega\in\Omega^{t_\beta}$ such that the set of values of these trajectories at time $\tau=0$ is a configuration $\gamma^0\in\Gamma$. Then define the configuration space of trajectories with initial points $\omega(0)$ in $\Lambda\in\mathfrak{B}_c(\mathbb{R}^d)$:

$$\Gamma_{\Omega^{t_\beta}_\Lambda}:=\{\tilde{\gamma}\in\Gamma_{\Omega^{t_\beta}}|\,\gamma^0\in\Gamma_\Lambda\}.$$

In the same way the Lebesgue–Poisson measure $\lambda_{\tilde{\sigma}}^{\Lambda}$ with intensity measure $\tilde{\sigma}_\Lambda$ is defined by (1.7). Then for the "correlation functionals" $\rho_t^{\Lambda}(\tilde{\eta})$, $\tilde{\eta}\in\Gamma_{\Omega^{t_\beta}_\Lambda}$, the following representation is true:

$$\rho_t^{\Lambda}(\tilde{\eta})=\int_{\Gamma_{\Omega^{t_\beta}_\Lambda}}\lambda_{\tilde{\sigma}}^{\Lambda}(d\tilde{\gamma})\tilde{D}_0^{\Lambda}(\eta^0\cup\gamma^0)e^{-\tilde{U}(\tilde{\eta}\cup\tilde{\gamma})}, \qquad (2.28)$$

where $\tilde{U}(\tilde{\eta}\cup\tilde{\gamma})$ is defined by (2.21) with $\tilde{\eta}\cup\tilde{\gamma}=\{\omega_1,\ldots,\omega_{m+n}\}$ and $\tilde{D}_0^{\Lambda}$ as defined in (2.23).

Remark 2.4: In the following we write $\eta,\gamma,\xi,\ldots,\Omega,\Omega_\Lambda$, instead of $\tilde{\eta},\tilde{\gamma},\tilde{\xi},\ldots,\Omega^{t_\beta},\Omega^{t_\beta}_\Lambda$ and $\eta^\tau,\gamma^\tau,\xi^\tau,\ldots,\ldots,\tau\in[0,t_\beta]$ for the sets of values of the corresponding configurations at time τ. Note that these sets for $\tau>0$ are not configurations in Γ_0 because some points of their values can coincide (intersection of trajectories).

III. THE CLASS OF INTERACTION POTENTIALS

In this section we describe a class of interaction potentials which allow us to solve the problem formulated in the Introduction. As it was mentioned in Remark 2.2, even to define the operator p_B^t on $L^1_{\beta,\xi}$ we have to consider a rather narrow class of interaction potentials. The restrictions on the potential imposed below are, however, rather dictated by the technique of the superstability estimates for functional integrals. We hope that the stochastic dynamics, actually, exists for a more wide class of potentials and initial states. This point of view is supported by the fact that the equilibrium stochastic dynamics exists for a wide class of physically reasonable potentials (see, e.g., Ref. 2).

To define the said class of superstable interactions we denote by $\overline{\Delta}$ a partition of $\mathbb{R}^d$ into half open unit cubes Δ centered at the points $r\in\mathbb{Z}^d$ (see Ref. 28 for details):

$$\mathbb{R}^d=\bigcup_{\Delta\subset\overline{\Delta}}\Delta,\quad \forall\Delta,\Delta'\in\overline{\Delta},\quad \Delta\cap\Delta'=\varnothing.$$

We assume the following conditions to hold:
(A1) Smoothness:

$$\phi, \quad \psi \in C^3(\mathbb{R}^d \backslash \{0\}).$$

(A2) Superstability:

$$\forall i = 1,2,3 \quad \exists A_i > 0, \quad B_i \geqslant 0: \quad U_{v_i}(\gamma) \geqslant \sum_{\Delta \in \Delta}{}_{-} (A_i |\gamma_\Delta|^2 - B_i |\gamma_\Delta|),$$

with $v_1 = \phi$, $v_2 = -\Delta\phi$ and $v_3 = \psi$.
(A3) Lower-regularity:
For any $X, Y \subset \mathbb{R}^d$ and configurations $\gamma_X \in \Gamma_X$, $\gamma_Y \in \Gamma_Y$, define

$$W_{v_i}(\gamma_X | \gamma_Y) = \sum_{x \in \gamma_X, y \in \gamma_Y} v_i(x-y). \tag{3.1}$$

Then

$$-W_{v_i}(\gamma_X | \gamma_Y) \leqslant \sum_{\Delta, \Delta' \in \Delta}{}_{-} \Psi_{v_i}(\Delta, \Delta') |\gamma_\Delta| |\gamma_{\Delta'}|, \tag{3.2}$$

where

$$\Psi_v(\Delta, \Delta') = \sup_{x \in \Delta, x' \in \Delta'} v_-(x - x'),$$

and $v_- = -\min(v, 0)$. We also require the existence of positive decreasing functions $\Psi_i(k)$ on positive integers such that

$$\Psi_i(k) \geqslant \sup_{\Delta, \Delta' \in \bar{\Delta}; d(\Delta, \Delta') = k} \Psi_{v_i}(\Delta, \Delta') \tag{3.3}$$

and

$$\sum_{k=0}^{\infty} \Psi_i(k) k^{d + \mu_i - 1} = F_{\mu_i} < +\infty \tag{3.4}$$

with $\mu_1 = \mu_3 > \frac{1}{2}$, $\mu_2 > -\frac{3}{2}$ and

$$d(\Delta, \Delta') = \max_{1 \leqslant \alpha \leqslant d} \inf_{x \in \Delta, x' \in \Delta'} |x^{(\alpha)} - x'^{(\alpha)}|.$$

Now we describe some class Φ of potentials which satisfy (A.1)–(A.3). Let

$$\begin{gathered} \phi(x) = \phi_+(x) + \phi_{st}(x), \\ \phi_+(0) = +\infty, \quad \phi_+(x) > 0, \end{gathered} \tag{3.5}$$

$$\begin{gathered} -\Delta\phi_+(0) = +\infty, \quad -\Delta\phi_+(x) > 0, \\ \phi_{st}(x) = \frac{1}{(2\pi)^d} \int dk e^{ixk} \tilde{\phi}(k), \quad \phi(k) \geqslant 0, \end{gathered} \tag{3.6}$$

$$\int dk\tilde{\phi}(k)<\infty, \quad \int dkk^2\tilde{\phi}(k)<\infty. \tag{3.7}$$

As an example (for $d=3$) of such a potential we can choose some function which has an asymptotic behavior near the origin like

$$\phi_+(x)\sim\frac{C_1}{|x|^\alpha}, \quad 0<\alpha\leqslant 1 \quad for \quad |x|<r_0, \quad r_0>0,$$

and is sufficiently fast decreasing as $|x|\nearrow+\infty$. This is clear from a direct calculation which gives

$$-\Delta\frac{1}{|x|^\alpha}=\frac{\alpha(1-\alpha)}{|x|^{\alpha+2}}, \tag{3.8}$$

which is positive for $\alpha<1$.

IV. RUELLE'S CONSTRUCTIONS. MAIN RESULT

Our main technical tool is the technique of superstability estimates proposed by Ruell[28] for classical statistical mechanics. Later Esposito *et al.*[29] generalized this technique for the case of quantum statistical mechanics and proved the boundedness of the reduced density matrices (RDMs) for the Maxwell–Boltzmann statistics.

In this section we briefly recall some basic constructions which were made in Refs. 28 and 29.

A. Λ_q-cubs

For some $\alpha>0$ (to be fixed later) let

$$l_q=[e^{\alpha q}], \quad q\in\mathbb{N}, \tag{4.1}$$

where $[x]$ is the integer part of $x\in\mathbb{R}^+$ and

$$\Lambda_q=[-l_q-\tfrac{1}{2},l_q+\tfrac{1}{2}]^d, \quad |\Lambda_q|=(2l_q+1)^d. \tag{4.2}$$

We also set the origin in the center of some cube $\Delta_1\in\overline{\Delta}$. So, every cube Λ_q is the union of cubes Δ from $\overline{\Delta}$. And for convenience we suppose that for one of the trajectories $\omega\in\eta$ we have $\omega(0)=0\in\Delta_1\subset\mathbb{R}^d$. Following Ref. 29 we also introduce the sequence

$$\varphi(q)=q|\Lambda_q|. \tag{4.3}$$

We extensively use the following properties (see Ref. 29 for details). For given $\varepsilon>0$, $\alpha>0$ $\exists s_0$ such that for $s\geqslant s_0$

$$1+\alpha<\frac{l_{s+1}}{l_s}<e^{\alpha(1+\varepsilon)},$$

$$\frac{\varphi(s+1)}{\varphi(s)}<e^{\alpha(d+\varepsilon(d+1))}, \tag{4.4}$$

or for $\varepsilon<\varepsilon_0=1-2\alpha e^{2\alpha}$ (α is sufficiently small)

$$\frac{l_{s+1}}{l_s}<1+2\alpha,$$

$$\frac{\varphi(s+1)}{\varphi(s)}<(1+2\alpha)^{d+1}. \tag{4.5}$$

We also need the following lemma:
Lemma 4.1 (see Ref. 29): Let

$$r(k)=\min\{r\in\mathbb{N}|l_{q+r}>l_q+k,\quad \forall q\geqslant 1,\quad k\in\mathbb{N}\}. \tag{4.6}$$

Then

$$r(k)\leqslant 1+\frac{1}{\alpha}\log(k+2). \tag{4.7}$$

B. An extension of the functionals $\rho_t^\Lambda(\eta)$

The functionals ρ_t^Λ are defined on the configuration space Γ_{Ω_Λ}, where Ω_Λ is the space of continuous trajectories $\omega(\tau)$ [see (2.18)] with $\omega(0)\in\Lambda$. But in the construction we are going to apply we need to consider functionals ρ_t^Λ on the trajectories which take values in the bounded cube Λ_q or in its compliment Λ_q^c. In this case some trajectories can be discontinuous because they take their values in Λ_q not for all $\tau\in[0,t_\beta]$ but only in some intervals $[\tau_1,\tau_2]$, $[\tau_3,\tau_4]$, etc. So for $\tau\in(\tau_2,\tau_3),\ldots$ they are not defined. In this case the definition of $\tilde{U}(\eta_{\Lambda_q}\cup\gamma)$ and therefore $\rho_t^\Lambda(\eta_{\Lambda_q})$ becomes ambiguous. To avoid these difficulties we repeat the construction proposed in Ref. 29.

Let $\mathfrak{B}([0,t_\beta])$ be the σ-algebra of Borel sets in $[0,t_\beta]$ with Ω_B the set of all measurable functions:

$$\tilde{\omega}:B\to\mathbb{R}^d,\quad B\in\mathfrak{B}([0,t_\beta]). \tag{4.8}$$

Now we define a new configuration space by

$$\Gamma_{\tilde{\Omega}}=\bigcup_{n\geqslant 0}\Gamma_{\tilde{\Omega}}^{(n)}, \tag{4.9}$$

where for $n=0$ $\Gamma_{\tilde{\Omega}}^{(0)}$ is a nonempty set which, however, consists of the trajectories $\tilde{\omega}$ whose domain B have zero Lebesgue measure and

$$\Gamma_{\tilde{\Omega}}^{(n)}=\tilde{\Omega}_1^{\otimes n-symm},\quad \tilde{\Omega}_1=\bigcup_{B\in\mathfrak{B}([0,t_\beta])}\Omega_B. \tag{4.10}$$

Then, instead of $\tilde{U}(\omega)_{m+n}=\tilde{U}(\eta\cup\gamma)$, $\eta=\{\omega_1,\ldots,\omega_m\}$, $\gamma=\{\omega_{m+1},\ldots,\omega_{m+n}\}$ we define $\tilde{U}(\tilde{\eta}\cup\gamma)$ by the same formula (2.21) and (2.22), but instead of $U_{v_k}(\omega(\tau))_{m+n}$, $k=1,2$ ($v_1=\phi, v_2=-\Delta\phi$) we set for $\tilde{\omega}_j\in\tilde{\Omega}_1$

$$\sum_{1\leqslant i<j\leqslant m+n}\chi_{D(\tilde{\omega}_i)\cap D(\tilde{\omega}_j)}(\tau)v_k(\tilde{\omega}_i(\tau)-\tilde{\omega}_j(\tau)), \tag{4.11}$$

where $D(\tilde{\omega})$ is the domain of $\tilde{\omega}$. For fixed $\tilde{\eta}\in\Gamma_{\tilde{\Omega}}$ the function

$$\tilde{U}(\tilde{\eta}\cup\cdot):\Gamma_\Omega\to\mathbb{R}$$

is measurable on Γ_Ω w.r.t. the σ-algebra of Borel sets corresponding to the topology of point-wise convergence (see Ref. 29 for details). Finally, we define

$$\tilde{\rho}_t^\Lambda(\tilde{\eta})=\int_{\Gamma_{\Omega_\Lambda}}\lambda_{\tilde{\sigma}}^\Lambda(d\tilde{\gamma})\tilde{D}_0^\Lambda(\tilde{\eta}^0\cup\gamma^0)e^{-\tilde{U}(\tilde{\eta}\cup\gamma)}, \tag{4.12}$$

which is an extension of definition (2.28) [here $\tilde{\eta}$ has a different sense than in (2.28) (see Remark 2.4)].

It is clear that for $\eta \in \Gamma_{\Omega_\Lambda}$

$$\rho_t^\Lambda(\eta) = \tilde{\rho}_t^\Lambda(\tilde{\eta}). \tag{4.13}$$

Then for any bounded measurable $X \subset \Lambda$ we define the map $\pi_X : \Gamma_{\Omega_\Lambda} \to \Gamma_{\tilde{\Omega}_\Lambda}$, such that for any $\gamma \in \Gamma_{\Omega_\Lambda}$

$$\pi_X \gamma = (\pi_X \omega_1, \ldots, \pi_X \omega_{|\gamma|}), \tag{4.14}$$

where $\pi_X \omega_j \in \tilde{\Omega}_\Lambda$ and its domain is the measurable set

$$B = \{\tau \in [0, t_\beta] \,|\, \omega(\tau) \in X\}.$$

If B has nonzero Lebesgue measure, then $(\pi_X \omega)(\tau) = \omega(\tau)$, $\tau \in B$, and if B has zero measure, then $\pi_X \omega \in \Gamma_{\tilde{\Omega}}^{(0)}$. We need also the map $s : \Gamma_{\Omega_\Lambda} \to \Gamma_{\tilde{\Omega}_\Lambda}$, which is

$$\gamma \to s(\gamma) = \bigcup_{\Delta \in \overline{\Delta}} \pi_\Delta \gamma. \tag{4.15}$$

The union is taken over all $\Delta \in \overline{\Delta}$, such that $\pi_\Delta \gamma$ has a domain of nonzero Lebesgue measure. It is clear that

$$\tilde{\rho}_t^\Lambda(\tilde{\eta}) = \tilde{\rho}_t^\Lambda(s(\eta)). \tag{4.16}$$

C. Partitions of Γ_{Ω_Λ}

For every $\tau \in [0, t_\beta]$ and a given configuration $\tilde{\eta} \in \Gamma_{\tilde{\Omega}_\Lambda}$ we introduce some characteristics of a given configuration $\gamma \in \Gamma_{\Omega_\Lambda}$:

$$E_q^\tau(\xi) = E_{\Lambda_q}^\tau(\xi) = \sum_{\Delta \subset \Lambda_q} |\xi_\Delta^\tau|^2, \quad \xi = \tilde{\eta} \cup \gamma, \tag{4.17}$$

where $|\xi_\Delta^\tau|$ is the number of all trajectories from ξ which take values in Δ at time τ. We also denote $E^\tau(\xi)$ by the same expression (4.17) with summation over all $\Delta \in \overline{\Delta}$.

Then we define three factors

$$E_q^{(1)}(\xi) = E_q^{t_\beta}(\xi), \tag{4.18}$$

$$E_q^{(2)}(\xi) = \int_0^{t_\beta} d\tau E_q^\tau(\xi), \tag{4.19}$$

$$E_q^{(3)}(\xi) = E_q^0(\xi), \tag{4.20}$$

which correspond to the factors $\exp\{-1/2\beta U_\phi(\tilde{\eta}^{t_\beta} \cup \gamma^{t_\beta}\}$, $\exp\{\beta U_{\Delta\phi}(\tilde{\eta} \cup \gamma)\}$ and $\tilde{D}_0^\Lambda(\tilde{\eta}^0 \cup \gamma^0)$, respectively, to be controlled, and define

$$E_q(\xi) = \sum_{i=1}^{3} E_q^{(i)}(\xi). \tag{4.21}$$

Following Ref. 29 we can now construct a partition of Γ_{Ω_Λ} in the following way. For some large integer q_0 (to be fixed later) we introduce

$$\Gamma_{q_0-1}=\{\gamma\in\Gamma_{\Omega_\Lambda}|E_m(\xi)\leqslant\varphi(m) \quad \text{for all} \quad m\geqslant q_0-1\}, \tag{4.22}$$

and for $q\geqslant q_0$

$$\Gamma_q=\{\gamma\in\Gamma_{\Omega_\Lambda}|E_{q-1}(\xi)>\varphi(q-1), \quad \text{but} \quad E_m(\xi)\leqslant\varphi(m) \quad \text{for} \quad m\geqslant q\}. \tag{4.23}$$

Then for $q\geqslant q_0-1$ let $\chi_q(\gamma)$ be an indicator function of the set Γ_q and for the partition

$$\Gamma_{\Omega_\Lambda}=\bigcup_{q\geqslant q_0-1}\Gamma_q \tag{4.24}$$

we consider the partition of the unity:

$$1=\sum_{q\geqslant q_0-1}\chi_q(\gamma). \tag{4.25}$$

D. Main result

Theorem 4.1: *For the interactions $\phi(x)$ $(x\in\mathbb{R}^d,\ d\leqslant 3)$, which satisfy (A1)–(A3), and for initial distributions (1.21)–(1.23) there exist constants $c_1=c_1(z,\beta,T)$ and $c_2=c_2(z,\beta,T)$ such that*

$$k_t^\Lambda(x)_m\leqslant c_1^m, \quad \eta\equiv\{x_1,\ldots,x_m\}\in\Gamma_\Lambda. \tag{4.26}$$

For any $t_1,t_2\in[0,T]$

$$|\langle k_{t_1}^\Lambda,\varphi\rangle-\langle k_{t_2}^\Lambda,\varphi\rangle|\leqslant c_2^m\|\varphi\|_m|t_1-t_2|, \tag{4.27}$$

uniformly in Λ and $t\in[0,T]$. Here

$$\langle k_t^\Lambda,\varphi\rangle=\int_{\mathbb{R}^{dm}}k_t^\Lambda(x)_m\varphi(x)_m(dx)^m, \tag{4.28}$$

where $(dx)^m=dx_1\cdot\cdots\cdot dx_m$, for $(x)_m=\{x_1,\ldots,x_m\}$, $\varphi\in C_0^\infty(\mathbb{R}^{dm})$,

$$c_2^m=\max\{m\xi_1^m\beta^{-1}, \quad m(m-1)\xi_1^m, \quad m\xi_1^{m+1}\}, \tag{4.29}$$

and

$$\|\varphi\|_m=\max_{1\leqslant j\leqslant m}\|\Delta_j\varphi\|_{L^1(\mathbb{R}^{md})}+\max_{j\neq k}\|\nabla_j\varphi\cdot\nabla_k\phi\|_{L^1(\mathbb{R}^{md})}+\max_j\|\nabla\phi\|_{L^1(\mathbb{R}^d)}\|\nabla_j\varphi\|_{L^1(\mathbb{R}^{md})}. \tag{4.30}$$

Remark 4.1: For potentials $\phi\in\Phi$ it is clear that $\|\nabla\phi\|_{L^1(\mathbb{R}^d)}<\infty$ (see Sec. III).

Remark 4.2: From (4.26), by compactness, we can choose a sequence $(\Lambda_n)_{n=1}^\infty$, $\Lambda_n\subset\Lambda_{n+1}$, $\Lambda_n\nearrow\mathbb{R}^d$, so that we get a limit point (in the weak sense) for $k_t^{\Lambda_n}$. Hence by diagonal argument we obtain the existence of a corresponding limit for any rational $t\in[0,T]$. Then from the continuity property (4.27) the existence of a weak-limit for k_t^Λ follows for all $t\in[0,T]$. And, finally, using positive-definiteness [see Remark 2.3, (2.25)–(2.27)] of k_t^Λ for any $\Lambda\subset\mathbb{R}^d$ we get a limit state μ_t (not unique), such that $K^*\mu_t=\rho_{\mu_t}=k_t\lambda_\sigma$.

V. PROOF OF THE MAIN THEOREM

First we note that neglecting the positive part of the effective potential $\tilde{V}(x)_n$ [see (2.16)] we get

$$\tilde{\rho}^{\Lambda}_{t_\beta}(\tilde{\eta}_\Lambda) \leqslant \tilde{\tilde{\rho}}^{\Lambda}_{t_\beta}(\tilde{\eta}_\Lambda), \tag{5.1}$$

where

$$\tilde{\tilde{\rho}}^{\Lambda}_{t_\beta}(\tilde{\eta}_\Lambda) = \tilde{\rho}^{\Lambda}_{t_\beta}(\tilde{\eta}_\Lambda)\big|_{\tilde{V}^+ \equiv 0}.$$

Then, the main technical point of the proof is the following proposition.

Proposition 5.1: Under the same hypothesis as in Theorem 4.1 there exist a small $\alpha > 0$, a sufficiently large integer $q_0 = q_0(\alpha)$, constants $h(q_0), K(q_0)$, and a positive decreasing function $\varepsilon(q)$ such that

$$\tilde{\tilde{\rho}}^{\Lambda}_{t_\beta}(\tilde{\eta}_\Lambda) \leqslant C_0 e^{-(1/4)\,\beta A E(\eta_{\Lambda_{q_0}})} \tilde{\tilde{\rho}}^{\Lambda}_{t_\beta}(\tilde{\eta}_{\Lambda^c_{q_0}}) + \sum_{q \geqslant q_0} C_q e^{-(1/4)\,\beta A E(\tilde{\eta}_{\Lambda_q})} \tilde{\tilde{\rho}}^{\Lambda}_{t_\beta}(\tilde{\eta}_{\Lambda^c_q}), \tag{5.2}$$

with

$$A = \min\{A_1, \quad 2A_2, \quad A_3\},$$

$$C_0 = e^{h(q_0)+K(q_0)}, \quad C_q = e^{-(1/8)\,\beta A \varphi(q-1)+\varepsilon(q)\varphi(q-1)+K(q_0)}, \quad q \geqslant q_0.$$

The proof of Theorem 4.1 follows from the next lemma.

Lemma 5.1: Let

$$S(\tilde{\eta}) = \{\Delta \in \overline{\Delta} \,|\, \exists\, \tau \in [0, t_\beta] \quad \textit{and} \quad \omega \in \tilde{\eta} \quad \textit{such that} \quad \omega(\tau) \in \Delta\}.$$

Then

$$\rho^{\Lambda}_{t_\beta}(\tilde{\eta}) \leqslant e^{-(1/4)\,\beta A E(\tilde{\eta}) + \delta |S(\tilde{\eta})|}, \tag{5.3}$$

with $\delta > \log D$, $D = C_0 + \Sigma_{q \geqslant q_0} C_q$.

Proof: We shall proceed by induction. Let $\tilde{\eta}'$ be a subconfiguration of $\tilde{\eta}$. We assume that (5.2) is true for any such $\tilde{\eta}'$. Then from (5.2)

$$\begin{aligned}\tilde{\tilde{\rho}}^{\Lambda}_{t_\beta}(\tilde{\eta}_\Lambda) &\leqslant C_0 e^{-AE(\tilde{\eta}_{\Lambda_{q_0}}) - AE(\tilde{\eta}_{\Lambda^c_{q_0}}) + \delta |S(\tilde{\eta}_{\Lambda^c_{q_0}})|} + \sum_{q \geqslant q_0} C_q e^{-AE(\tilde{\eta}_{\Lambda_q}) - AE(\tilde{\eta}_{\Lambda^c_q}) + \delta |S(\tilde{\eta}_{\Lambda^c_q})|} \\ &\leqslant e^{-AE(\tilde{\eta}_\Lambda) + \delta |S(\tilde{\eta}_\Lambda)|},\end{aligned}$$

since $|S(\tilde{\eta}_{\Lambda^c_q})| \leqslant |S(\tilde{\eta}_\Lambda)| - 1$. Taking into account (5.1) we get (5.3). □

Proof of Theorem 4.1: Using (5.3) from (2.19) we get

$$k^{\Lambda}_t(x)_m \leqslant z^m \prod_{j=1}^{m} \int dy_j \int W^{t_\beta}_{x_j, y_j}(d\omega_j) e^{-AE(\omega_j) + \delta |S(\omega_j)|}.$$

Using the Schwartz inequality, the estimate [see Ref. 29, (A.21)]

$$\int W^{t_\beta}_{x,y}(d\omega) e^{2\delta |S(\omega)|} \leqslant (2\pi t_\beta)^{-d/2} I(2\delta), \quad I(2\delta) = \int W^{t_\beta}_{0,0}(d\omega) e^{2\delta |S(\omega)|},$$

and the trivial estimate

$$\int dy \left(\int W^{t_\beta}_{x,y}(d\omega) \right)^{1/2} \leqslant 2^{3d/4} \pi^{d/4} t^{d/4}$$

we obtain (4.26) with

$$c_1 = z((4\pi)^d I(2\delta))^{1/2}.$$

In the same way one can prove Eq. (4.27). Indeed, we have by (1.18) that

$$\langle k^\Lambda_{t_1}, \varphi\rangle - \langle k^\Lambda_{t_2}, \varphi\rangle = \int_{t_1}^{t_2} d\tau \left\langle \frac{dk^\Lambda_\tau}{d\tau}, \varphi \right\rangle$$

$$= \int_{t_1}^{t_2} d\tau \sum_{j=1}^{m} [\langle k^\Lambda_\tau, \Delta_j \varphi\rangle - \langle k^\Lambda_\tau, \nabla_j \varphi \cdot \nabla_j U_\phi\rangle - \langle\langle k^\Lambda_\tau, \nabla_j \phi\rangle \nabla_j \varphi\rangle].$$

Using (4.26) we get (4.27) with the constants (4.29) and (4.30). □

Proof of Proposition 5.1: Inserting (4.25) into (4.12) we get

$$\tilde{\tilde{\rho}}^\Lambda_t(\tilde{\eta}_\Lambda) = \sum_{q \geqslant q_0 - 1} I_q(\tilde{\eta}_\Lambda), \tag{5.4}$$

with

$$I_q(\tilde{\eta}_\Lambda) = \int \lambda^\Lambda_{\tilde{\sigma}}(d\gamma) \chi_q(\gamma) \tilde{D}^\Lambda_0(\tilde{\eta}^0_\Lambda \cup \gamma^0) e^{-\tilde{\tilde{U}}(\tilde{\eta}\cup\gamma)}, \tag{5.5}$$

where

$$\tilde{\tilde{U}}(\tilde{\eta}\cup\gamma) = \tilde{U}(\tilde{\eta}\cup\gamma) - \tilde{V}^+(\eta\cup\gamma). \tag{5.6}$$

To estimate (5.5) we construct a further partition of Γ_q:[29]

$$\Gamma_q = \Gamma_{q,\Lambda} = \Gamma_{q,\Lambda_q} \cup \Gamma_{q,\Lambda^c_q} \cup \Gamma^s_{q,\partial\Lambda_q} \cup \Gamma^l_{q,\partial\Lambda_q},$$

where Γ_{q,Λ_q} is the configuration of those trajectories which are completely contained in Λ_q, Γ_{q,Λ^c_q} are trajectories completely outside of Λ_q, i.e., in Λ^c_q, $\Gamma^s_{q,\partial\Lambda_q}$ are short trajectories, which cross the boundary of Λ_q but do not leave Λ_{q+2} and $\Gamma^l_{q,\partial\Lambda_q}$ are long trajectories, which cross $\partial\Lambda_q$ and leave Λ_{q+2}. By the infinite-divisibility of the Poisson–Lebesgue measure $\lambda_{\tilde{\sigma}}$, for any function $F(\gamma) \in L^1(\Gamma_{\Omega_\Lambda}, \lambda^\Lambda_{\tilde{\sigma}})$ which can be represented as

$$F(\gamma) = F_1(\gamma_{\Lambda_q}) F_2(\overline{\gamma}_{\Lambda^c_q}) F_3(\zeta_{\partial\Lambda_q}) F_4(\overline{\zeta}_{\partial\Lambda_q}) \tag{5.7}$$

for

$$\gamma = \gamma_{\Lambda_q} \cup \overline{\gamma}_{\Lambda^c_q} \cup \zeta_{\partial\Lambda_q} \cup \overline{\zeta}_{\partial\Lambda_q}, \quad \gamma_{\Lambda_q} \in \Gamma_{\Lambda_q}, \quad \overline{\gamma}_{\Lambda^c_q} \in \Gamma_{\Lambda^c_q}, \quad \zeta_{\partial\Lambda_q} \in \Gamma^s_{\partial\Lambda_q}, \quad \overline{\zeta}_{\partial\Lambda_q} \in \Gamma^l_{\partial\Lambda_q}$$

the following formula is true:

$$\int \lambda^\Lambda_{\tilde{\sigma}}(d\gamma) F(\gamma) = \int_{\Gamma_{q,\Lambda_q}} \lambda^{\Lambda_q}_{\tilde{\sigma}}(d\gamma) F_1(\gamma) \int_{\Gamma_{q,\Lambda^c_q}} \lambda^{\Lambda^c_q}_{\tilde{\sigma}}(d\overline{\gamma}) F_2(\overline{\gamma})$$

$$\times \int_{\Gamma^s_{q,\partial\Lambda_q}} \lambda^\Lambda_{\tilde{\sigma}}(d\zeta) F_3(\zeta) \int_{\Gamma^l_{q,\partial\Lambda_q}} \lambda^\Lambda_{\tilde{\sigma}}(d\overline{\zeta}) F_4(\overline{\zeta}).$$

But in our case the function

$$F(\gamma)=\chi_q(\gamma)\tilde{D}_0^{\Lambda}(\tilde{\eta}_{\Lambda}^0\cup\gamma_{\Lambda}^0)e^{-\tilde{\tilde{U}}(\tilde{\eta}\cup\gamma)} \tag{5.8}$$

does not satisfy (5.7). So, our next step is to estimate (5.8) as a product of some functions as in (5.7).

Due to (5.6), (2.21) and (2.22) we have

$$\tilde{\tilde{U}}(\tilde{\eta}\cup\gamma)=\frac{1}{2}\beta U_{v_1}(\tilde{\eta}^{t_\beta}\cup\gamma^{t_\beta})+\beta\int_0^{t_\beta}d\tau U_{v_2}(\tilde{\eta}^{\tau}\cup\gamma^{\tau}),$$

with $v_1=\phi$, and $v_2=-\Delta\phi$. Then for any $\tau\in[0,t_\beta]$ we can write for the energy $U_{v_i}(\tilde{\eta}^{\tau}\cup\gamma^{\tau})$ the following decomposition:

$$\begin{aligned}U_{v_i}(\tilde{\eta}^{\tau}\cup\gamma^{\tau})=&U_{v_i}(\tilde{\eta}^{\tau}_{\Lambda_q}\cup\gamma^{\tau}_{\Lambda_q}\cup(\pi_{\Lambda_q}\zeta)^{\tau}\cup(\pi_{\Lambda_q}\overline{\zeta})^{\tau})+U_{v_i}(\tilde{\eta}^{\tau}_{\Lambda_q^c}\cup\overline{\gamma}^{\tau}_{\Lambda_q^c})+U_{v_i}((\pi_{\Lambda_q^c}\zeta)^{\tau}\cup(\pi_{\Lambda_q^c}\overline{\zeta})^{\tau})\\&+W_{v_i}(\tilde{\eta}^{\tau}_{\Lambda_q}\cup\gamma^{\tau}_{\Lambda_q}\cup(\pi_{\Lambda_q}\zeta)^{\tau}\cup(\pi_{\Lambda_q}\overline{\zeta})^{\tau}|\tilde{\eta}^{\tau}_{\Lambda_q^c}\cup\overline{\gamma}^{\tau}_{\Lambda_q^c}\cup(\pi_{\Lambda_q^c}\zeta)^{\tau}\cup(\pi_{\Lambda_q^c}\overline{\zeta})^{\tau})\\&+W_{v_i}(\tilde{\eta}^{\tau}_{\Lambda_q^c}\cup\overline{\gamma}^{\tau}_{\Lambda_q^c}|(\pi_{\Lambda_q^c}\zeta)^{\tau})+W_{v_i}(\tilde{\eta}^{\tau}_{\Lambda_q^c}\cup\overline{\gamma}^{\tau}_{\Lambda_q^c}|(\pi_{\Lambda_q^c}\overline{\zeta})^{\tau}),\end{aligned} \tag{5.9}$$

where in the same way as for $\tilde{U}$ we use the substitution (4.11) to define the interaction energy W_{v_i} for $\tilde{\omega}\in\tilde{\Omega}_1$. Now to estimate the various terms in (5.9) we prove some lemmas.

Lemma 5.2: For each positive, integer q and $\tau\in[0,t_\beta]$

$$U_{v_i}(\tilde{\eta}^{\tau}_{\Lambda_q}\cup\gamma^{\tau}_{\Lambda_q}\cup(\pi_{\Lambda_q}\zeta)^{\tau}\cup(\pi_{\Lambda_q}\overline{\zeta})^{\tau})\geqslant\frac{1}{4}A_iE_q^{\tau}(\xi)+\frac{1}{2}A_iE_q^{\tau}(\tilde{\eta}_{\Lambda_q})-\frac{B_i^2}{A_i}|\Lambda_q|. \tag{5.10}$$

Proof: The proof follows from Lemma A.1 (see the Appendix) and the definition of $E_q^{\tau}(\xi)$. □

By the stability condition we have

$$U_{v_i}((\pi_{\Lambda_q^c}\zeta)^{\tau}\cup(\pi_{\Lambda_q^c}\overline{\zeta})^{\tau})\geqslant-B_i(|\zeta|+|\overline{\zeta}|). \tag{5.11}$$

Lemma 5.3: Let ξ_a and ξ_a' be subconfigurations of $\xi\in\Gamma_q$ and ξ_a contained in Λ_{q+a} and ξ_a' in Λ_q^c. Then for any $\tau\in[0,t_\beta]$ there exist a small enough α, sufficiently large $q_0^{(1)}$, a constant $h_i^{(a)}(q_0^{(1)})$ and a decreasing function $\varepsilon_i^{(a)}(q)$ on the integers, such that for each $q\geqslant q_0^{(1)}-1$

$$-W_{v_i}(\xi_a^{\tau}|\xi_a'^{\tau})\leqslant\begin{cases}h_i^{(a)}(q_0^{(1)}) & \text{for } q=q_0^{(1)}-1,\\ \varepsilon_i^{(a)}(q)\varphi(q-1) & \text{for } q\geqslant q_0^{(1)}.\end{cases} \tag{5.12}$$

Remark 5.1: We use Lemma 5.3 with $a=0$ for the fourth term in (5.9) ($\xi_0=\tilde{\eta}_{\Lambda_q}\cup\gamma_{\Lambda_q}$, $\xi_0'=\tilde{\eta}_{\Lambda_q^c}\cup\overline{\gamma}_{\Lambda_q^c}\cup\pi_{\Lambda_q^c}\xi\cup\pi_{\Lambda_q^c}\overline{\zeta}$) and with $a=2$ for the fifth term of (5.9) ($\xi_2=\pi_{\Lambda_q^c}\zeta$, $\xi_2'=\tilde{\eta}_{\Lambda_q^c}\cup\overline{\gamma}_{\Lambda_q^c}$).

Proof: Let us prove the lemma for $a=0$, $i=1$ and for $q\geqslant q_0^{(1)}$ which we chose later. Taking $i=1$, $a=0$ and $\tau=t_\beta$ in Lemma A.2 and using the fact that

$$E^{(1)}_{q+1\setminus q-1}(\xi^{t_\beta})\leqslant E_{q+1\setminus q-1}(\xi)=E_{q+1}(\xi)-E_{q-1}(\xi)$$

and because of $\xi\in\Gamma_q$, $E_{q-1}(\xi)>\varphi(q-1)$ and $E_m(\xi)\leqslant\varphi(m)$ for $m\geqslant q$, we have

$$-W_{v_1}(\xi_0^{t_\beta}|\xi_0'^{t_\beta}) \leqslant \frac{1}{2}F_{\mu_1}[\varphi(q+1)-\varphi(q-1)]+\frac{1}{2}\beta\varepsilon_1^{(1)}(q)\varphi(q) + \frac{1}{2}\beta\varepsilon_2^{(2)}(q)\varphi(q)\sum_{k=1}^{\infty}(a_k^{(1)}-a_{k+1}^{(1)})\varphi(q+k+1), \tag{5.13}$$

where $a_k^{(1)}=\Psi_1(l_{q+k}-l_q)$. Then from (4.5) we have

$$\varphi(q+1)-\varphi(q-1)<[(1+2\alpha)^{2d+2}-1]\varphi(q-1), \tag{5.14}$$

$$\varphi(q)<(1+2\alpha)^{d+1}\varphi(q-1). \tag{5.15}$$

From the definitions (4.1)–(4.3), choosing α sufficiently small and

$$q_0^{(1)}>-\frac{2}{\alpha}\log(1-e^{-2\alpha}), \tag{5.16}$$

it is easy to calculate that $q+k+1<(2/\alpha)\log(l_{q+k+1}-l_q+1)$ and

$$\sum_{k=1}^{\infty}(a_k^{(1)}-a_{k+1}^{(1)})\varphi(q+k+1)\leqslant c(\alpha)\sum_{l_{q+1}-l_q}^{\infty}\Psi_1(m)(2m+1)^d\log(m+1)=c(\alpha)\varepsilon_0(q) \tag{5.17}$$

with $c(\alpha)=2\alpha^{-1}(1+\alpha)$. Now from (5.13)–(5.16) we have (5.12) for $q\geqslant q_0^{(1)}$ with

$$\varepsilon_1^{(0)}(q)=\tfrac{1}{2}\beta F_{\mu_1}[(1+2\alpha)^{2d+2}-1]+\tfrac{1}{2}\beta\varepsilon_1^{(1)}(q)(1+2\alpha)^{d+1} + \tfrac{1}{2}\beta\varepsilon_2^{(1)}(q)(1+2\alpha)^{d+1}c(\alpha)\varepsilon_0(q). \tag{5.18}$$

The proofs for the cases $i=2$ and $a=2,i=1,2$ are the same.

Now we consider the case $q=q_0^{(1)}-1$. The only difference in the proof lies in estimating the first term in Eq. (A2). As $\gamma\in\Gamma_{q_0-1}$ this term cannot be very small and we estimate it by

$$E^{t_\beta}_{q_0^{(1)}\setminus q_0^{(1)}-2}(\xi^{t_\beta})\leqslant E_{q_0}(\xi)\leqslant\varphi(q_0^{(1)}).$$

Then inequality (5.12) for $q=q_0^{(1)}-1$ holds with

$$h_i^{(a)}=[\tfrac{1}{2}\beta F_{\mu_i}+\tfrac{1}{2}\beta\varepsilon_1^{(i)}(q_0^{(1)})+\tfrac{1}{2}\beta\varepsilon_2^{(i)}(q_0^{(i)})]\varepsilon(q_0^{(1)}).$$

□

And finally the sixth term of (5.9) can be estimated by

Lemma 5.4: Let $\overline{\zeta}$ be some subconfiguration of $\gamma\in\Gamma_q$, contained in Λ_m, $m>q$. Then there exist a $q_0^{(2)}$ large enough and some constant $b=b(\alpha,d)$, such that for each $q\geqslant q_0^{(2)}$

$$-\tfrac{1}{2}\beta W_{v_1}((\pi_{\Lambda_q^c}\overline{\zeta})^{t_\beta}|\,\widetilde{\eta}^{t_\beta}_{\Lambda_q^c}\cup(\pi_{\Lambda_q^c}\gamma)^{t_\beta})\leqslant\tfrac{1}{2}\beta bF_{\mu_1}|\overline{\zeta}|\varphi(m)^{1/2}, \tag{5.19}$$

$$-\beta W_{v_2}(\pi_{\Lambda_q^c}\overline{\zeta}|\,\widetilde{\eta}_{\Lambda_q^c}\cup\pi_{\Lambda_q^c}\gamma)\leqslant tbF_{\mu_2}|\overline{\zeta}|\varphi(m)^{1/2}. \tag{5.20}$$

Proof: The proofs of (5.19) and (5.20) are almost the same. Let us prove for example (5.19). Using Lemma A.3. with $\tau=t_\beta$, $\xi_1=\pi_{\Lambda_q^c}\overline{\zeta}$, $\xi_2=\widetilde{\eta}_{\Lambda_q^c}\cup\pi_{\Lambda_q^c}\gamma$ and taking into account that for $m>q$

$$E^{t_\beta}_{m+r(k)}(\xi) \leqslant E_{m+r(k)}(\xi) \leqslant \varphi(m+r(k)),$$

as $\xi = \tilde{\eta} \cup \gamma$ and $\gamma \in \Gamma_q$ we get

$$-\frac{1}{2}\beta W_{v_1}(\cdots|\cdots) \leqslant \frac{1}{2}\beta b_1 |\overline{\zeta}| \sum_{k=1}^{\infty} \Psi_1(k)(k+1)^{(d-1)/2} \varphi(m+r(k))^{1/2}.$$

[See for $r(k)$ Eqs. (4.6) and (4.7).] Using (4.4), (4.7) and (3.4) we get (5.19) with $b = b_1 \exp[\alpha/2(d+\varepsilon(d+1))] 2^{d-1+\mu}$, $\varepsilon = \min\{1-2\alpha e^{2\alpha}, (2\mu-1)(\alpha+1)^{-1}\}$ and $q_0^{(2)} = s_0$ (see (4.4), (4.5) for definition of s_0). □

And finally we present some inequalities for the initial density distribution (1.21)–(1.23).

Lemma 5.5: Let the potentials ϕ and ψ satisfy (A.1)–(A.3). *Then*

1^o. *For any $\Lambda_q \subset \Lambda$, $q \geqslant q_0 - 1$, and $\xi^0_\Lambda \in \Gamma_q$ there exist $A_3 > 0$ and $B_3 \geqslant 0$ such that*

$$\tilde{D}^\Lambda_0(\xi^0_\Lambda) \leqslant e^{[-A_3\beta\Sigma_{\Delta\subset\Lambda_q}|\xi^0_\Delta|^2 + B_3\beta\Sigma_{\Delta\subset\Lambda_q}|\xi^0_\Delta|]} \tilde{D}^\Lambda_0(\xi^0_{\Lambda^c_q}) \tag{5.21}$$

2^o. *For any partition*

$$\xi_{\Lambda^c_q} = \overline{\xi}^0_{\Lambda_s \cap \Lambda^c_q} \cup \tilde{\xi}^0_{\Lambda^c_q}, \quad \overline{\xi}^0_{\Lambda_s \cap \Lambda^c_q} \cap \tilde{\xi}^0_{\Lambda^c_q} = \varnothing, \quad s > q, \tag{5.22}$$

there exists $C_3 \geqslant 0$ such that

$$\tilde{D}^\Lambda_0(\xi^0_{\Lambda^c_q}) \leqslant e^{C_3\beta|\overline{\xi}^0_{\Lambda_s\cap\Lambda^c_q}|\varphi(s)^{1/2}} \tilde{D}^\Lambda_0(\tilde{\xi}^0_{\Lambda^c_q}). \tag{5.23}$$

Proof: The proof is a direct consequence of Ruelle's technique.[28]

Now we collect all the estimates (5.10)–(5.12), (5.19), (5.20), (5.21), and (5.23) to obtain for $q \geqslant q_0 = \max\{q_0^{(1)}, q_0^{(2)}\}$ [see (5.16)]:

$$I_q(\tilde{\eta}_\Lambda) \leqslant e^{-(1/4)\,\beta A E_q(\tilde{\eta}_{\Lambda_q}) - (1/8)\,\beta A\varphi(q-1) + \varepsilon_0(q)\varphi(q-1) + \varepsilon_1(q)\varphi(q-1)} \int \lambda^{\Lambda_q}_{\tilde{\sigma}}(d\gamma) \int \lambda^{\Lambda_{q+2}}_{\tilde{\sigma}}(d\zeta) e^{B|\zeta|}$$
$$\times \int \lambda^{\Lambda^c_q}_{\tilde{\sigma}}(d\overline{\gamma}) e^{-\tilde{\tilde{U}}(\tilde{\eta}_{\Lambda^c_q}\cup\overline{\gamma})} \tilde{D}^{\Lambda^c_q}_0(\tilde{\eta}^0_{\Lambda^c_q} \cup \overline{\gamma}^0) \prod_{m \geqslant q+3} \int \lambda^{\Lambda_m}_{\tilde{\sigma}}(d\overline{\zeta}^{(m)}) e^{B|\overline{\zeta}^{(m)}| + C|\overline{\zeta}^{(m)}|\varphi(m)^{1/2}} \tag{5.24}$$

with

$$A = \min\{A_1, \quad 2A_2, \quad 2A_3\},$$

$$B = \max\{\tfrac{1}{2}\beta B_1, \quad TB_2, \quad \beta B_3\},$$

$$C = \max\{\tfrac{1}{2}\beta b F_{\mu_1}, \quad TbF_{\mu_2}, \quad C_3\},$$

and

$$\epsilon_0(q) = \frac{(1+2\alpha)^{d+1}}{q}\left[\frac{\beta B_1^2}{2A_1} + \frac{TB_2^2}{A_2} + \frac{\beta B_3^2}{A_3}\right],$$

$$\varepsilon_1(q) = \sum_{i\in\{1,2\}} \sum_{a\in\{0,2\}} \varepsilon_i^{(a)}(q). \tag{5.25}$$

Now from the definition of the Poisson–Lebesgue measure we get

$$\int \lambda_{\tilde{\sigma}}^{\Lambda_q}(d\gamma) \leqslant e^{\varepsilon_2(q)\varphi(q-1)}, \quad \varepsilon_2(q) = \frac{z(1+2\alpha)^{d+1}}{q}, \tag{5.26}$$

$$\int \lambda_{\tilde{\sigma}}^{\Lambda_{q+2}}(d\zeta) e^{B|\zeta|} \leqslant e^{\varepsilon_3(q)\varphi(q-1)}, \quad \varepsilon_3(q) = \frac{z(1+2\alpha)^{3d+3}}{q} e^B, \tag{5.27}$$

$$\int \lambda_{\tilde{\sigma}}^{\Lambda_q^c}(d\overline{\gamma}) e^{-\tilde{\tilde{U}}(\tilde{\eta}_{\Lambda_q^c} \cup \overline{\gamma})} \tilde{D}_0^{\Lambda_q^c}(\tilde{\eta}^0_{\Lambda_q^c} \cup \overline{\gamma}^0) \leqslant \tilde{\tilde{\rho}}_{t_\beta}^{\Lambda}(\tilde{\eta}_{\Lambda_q^c}). \tag{5.28}$$

Applying the same arguments as in (5.26) and (5.27), making a partition of all long trajectories $\overline{\zeta}$ in (5.24) according to their lengths and using the resummation formula we get

$$I_q^{(4)} \equiv \prod_{m \geqslant q+3} \int \lambda_{\tilde{\sigma}, \partial\Lambda_q}^{\Lambda_m}(d\overline{\zeta}^{(m)}) e^{B|\overline{\zeta}^{(m)}| + C|\overline{\zeta}^{(m)}|\varphi(m)^{1/2}}$$

$$= \sum_{k=0}^{\infty} \frac{e^{Bk}}{k!} \sum_{m_1, \ldots, m_k \geqslant q+3} \int \tilde{\sigma}_{\Lambda_{m_1}}(d\overline{\zeta}^{(m_1)}) \cdots \tilde{\sigma}_{\Lambda_{m_k}}(d\overline{\zeta}^{(m_k)}) e^{C\Sigma_{j=1}^k \varphi(m_j)^{1/2}}.$$

Then we use (see Ref. 29 or 38)

$$\int \tilde{\sigma}_{\Lambda_m}(d\overline{\zeta}^{(m)}) \leqslant z \frac{|\Lambda_m|}{(2\pi t_\beta)^{d/2}} e^{-c\,(l_m^2/2t_\beta)(\alpha^2/(1+2\alpha)^4}$$

with $c = c(d)$ and get

$$I_q^{(4)} \leqslant e^{ze^B f(T_\beta)}, \quad T_\beta = T/\beta, \tag{5.29}$$

where

$$f(T_\beta) = \sum_{m \geqslant q_0+3} (2l_m+1)^d \exp\left\{ -c \frac{l_m^2}{2t_\beta} \frac{\alpha^2}{(1+2\alpha)^4} + Cm^{1/2}(2l_m+1)^{d/2} \right\}.$$

Obviously we have $f(T_\beta) < \infty$ for $d \leqslant 3$.

As a result we get (5.1) for $q \geqslant q_0$ with $\varepsilon(q) = \Sigma_{0 \leqslant j \leqslant 3} \varepsilon_j(q)$ and $K = ze^B f(T_\beta)$.

In the same way we have for $q = q_0 - 1$

$$I_{q_0-1} \leqslant e^{-1/4\,\beta A E_{q_0}(\tilde{\eta}_{\Lambda_{q_0}}) + h(q_0) + K} \tilde{\rho}^{\Lambda}(\tilde{\eta}_{\Lambda_{q_0}^c}),$$

with

$$h(q_0) = \sum_{i \in \{1,2\}} \sum_{a \in \{0,2\}} h_i^{(a)}(q_0).$$

As a result we get (5.1) from (5.24), (5.26)–(5.29) with $\varepsilon(q) = \Sigma_{0 \leqslant j \leqslant 3} \varepsilon_j(q)$ and $K(q_0) = ze^B f(T_\beta)$. □

APPENDIX: PROOF OF THE BASIC LEMMAS

Lemma A.1: For any $\tau\in[0,t_\beta]$ *and* $q\in\mathbb{N}$ *and* $\tilde{\eta}^\tau,\gamma^\tau\subset\Lambda_q$,

$$U_{v_i}(\tilde{\eta}^\tau_{\Lambda_q}\cup(\pi_{\Lambda_q}\gamma)^\tau)\geqslant\frac{1}{4}A_iE^\tau_q(\xi^\tau)+\frac{1}{2}A_iE^\tau_q(\tilde{\eta}^\tau_{\Lambda_q})-\frac{B_i^2}{A_i}|\Lambda_q|. \tag{A1}$$

Proof: From the superstability condition (A.2) (see Sec. III) we obtain

$$U_{v_i}(\tilde{\eta}^\tau_{\Lambda_q}\cup(\pi_{\Lambda_q}\gamma)^\tau)\geqslant A_i\sum_{\Delta\subset\Lambda_q}|\xi^\tau_\Delta|^2-B_i\sum_{\Delta\subset\Lambda_q}|\xi^\tau_\Delta|.$$

Then (A1) follows from the inequalities $-n\geqslant-A_in^2/4B_i-B_i/A_i$ and $E^\tau_q(\xi)\geqslant E^\tau_q(\tilde{\eta})$. □

Lemma A.2: Let $\tau\in[0,t_\beta]$, $q\in\mathbb{N}$ *and* $\xi_1\in\Gamma_{\tilde{\Omega}_{\Lambda_{q+a}}}$ *with* $a=0$ *or* $a=2$, $\xi\in\Gamma_{\tilde{\Omega}_{\Lambda_q^c}}$, $\xi_1\cup\xi_2\subset\xi\in\Gamma_q$. *Then there exist positive, decreasing functions* $\varepsilon_1^{(i)}(q),\varepsilon_2^{(I)}(q)$ *such that*

$$-W_{v_i}(\xi_1^\tau|\xi_2^\tau)\leqslant F_{\mu_i}E^\tau_{q+a+1\setminus q-1}(\xi)+\varepsilon_1^{(i)}(q)E^\tau_{q+a}(\xi)+\varepsilon_2^{(i)}(q)\varphi(q)\sum_{k=1}^{\infty}(a_k^i-a_{k+1}^i)E^\tau_{q+a+k+1}(\xi), \tag{A2}$$

with $a_k^i=\Psi_i(l_{q+a+k}-l_{q+a})$.

Proof: From the regularity assumption (A3),

$$-W_{v_i}(\xi_1^\tau|\xi_2^\tau)\leqslant\frac{1}{2}\sum_{\Delta\subset\Lambda_{q+a}}\sum_{\Delta'\subset\Lambda_q^c}\Psi_i(\Delta,\Delta')[|\xi^\tau_\Delta|^2+|\xi^\tau_{\Delta'}|^2]. \tag{A3}$$

According to the partitions $\Lambda_{q+a}=\Lambda_{q+a-1}\cup(\Lambda_{q+a}\setminus\Lambda_{q+a-1})$, $\Lambda_q^c=(\Lambda_{q+a+1}\setminus\Lambda_q)\cup\Lambda^c_{q+a+1}$ we write down the r.h.s. of (A3) as

$$\begin{aligned}
-W_{v_i}(\xi_1^\tau|\xi_2^\tau)\leqslant&\frac{1}{2}\sum_{\Delta\subset\Lambda_{q+a}\setminus\Lambda_{q-1}}\sum_{\Delta'\subset\Lambda_{q+a+1}\setminus\Lambda_q}\Psi_i(\Delta,\Delta')|\xi^\tau_\Delta|^2\\
&+\frac{1}{2}\sum_{\Delta\subset\Lambda_{q-1}}\sum_{\Delta'\subset\Lambda_{q+a+1}\setminus\Lambda_q}\Psi_i(\Delta,\Delta')|\xi^\tau_\Delta|^2+\frac{1}{2}\sum_{\Delta\subset\Lambda_{q+a}}\sum_{\Delta'\subset\Lambda^c_{q+a+1}}\Psi_i(\Delta,\Delta')|\xi^\tau_\Delta|^2\\
&+\frac{1}{2}\sum_{\Delta\subset\Lambda_{q+a}}\sum_{\Delta'\subset\Lambda_{q+a+1}\setminus\Lambda_q}\Psi_i(\Delta,\Delta')|\xi^\tau_\Delta|^2\\
&+\frac{1}{2}\sum_{\Delta\subset\Lambda_{q+a}}\sum_{\Delta'\subset\Lambda^c_{q+a+1}}\Psi_i(\Delta,\Delta')|\xi^\tau_{\Delta'}|^2\\
\leqslant&\frac{1}{2}F_{\mu_i}E^\tau_{q+a\setminus q-1}(\xi)+\frac{1}{2}F^{(i)}(l_q-l_{q-1})E^\tau_{q-1}(\xi)+\frac{1}{2}F^{(i)}(l_{q+a+1}-l_{q+a})E^\tau_{q+a}(\xi)\\
&+\frac{1}{2}F_{\mu_i}E^\tau_{q+a+1\setminus q}(\xi)+\frac{1}{2}\sum_{\Delta\in\Lambda_{q+a}}\sum_{k=1}^{\infty}\Psi_i(l_{q+a+k}-l_{q+a})E_{q+a+k+1\setminus q+a+k}(\xi)\\
\leqslant&F_{\mu_i}E^\tau_{q+a+1\setminus q-1}(\xi)+F^{(i)}(l_q-l_{q-1})E^\tau_{q+a}(\xi)\\
&+\frac{1}{2}|\Lambda_{q+a}|\sum_{k=1}^{\infty}(a_k-a_{k+1})E^\tau_{q+a+k+1}(\xi),
\end{aligned}$$

where we have used the summation over layers $\Lambda_{q+a+k+1}\backslash\Lambda_{q+a+k}$, some resummation formula. As a result we obtain (A2) with $\varepsilon_1^{(i)}(q)=F^{(i)}(l_q-l_{q-1})=\sup_{\Delta\in\Lambda_{q-1}}\Sigma_{\Delta'\in\Lambda_q^c}\Psi_i(\Delta,\Delta')$ and $\varepsilon_2^{(i)}=2^{-1}(q+a)^{-1}$. □

Lemma A.3: Let $\tau\in[0,t_\beta]$, $q\in\mathbb{N}$, ξ_1 *contained in* Λ_s, $s>q$, ξ_2, *contained in* Λ_q^c *and* $\xi_1\cup\xi_2\subset\xi\in\Gamma_q$. *Then there exists* $q_0^{(2)}$ *such that for* $q\geqslant q_0^{(2)}$

$$-W_{v_i}(\xi_1^\tau|\xi_2^\tau)\leqslant b_1|\xi_1^\tau|\sum_{k=0}^{\infty}\Psi_i(k)(k+1)^{(d-1)/2}(E^\tau_{s+r(k)}(\xi))^{1/2}, \tag{A4}$$

with $b_1=b_1(d)$ *and* $r(k)$, *which is defined in (4.6).*

Proof: Using the regularity assumption (A.3) and Schwartz inequality we get

$$\begin{aligned}-W_{v_i}(\xi_1^\tau|\xi_2^\tau)&\leqslant\sum_{\Delta\in\Lambda_s}\sum_{\Delta'\in\Lambda_q^c}\Psi(\Delta,\Delta')|\xi^\tau_{1,\Delta}||\xi^\tau_{2,\Delta'}|\\&\leqslant\sum_{k=0}^{\infty}\Psi_i(k)\sum_{\Delta\in\Lambda_s}|\xi^\tau_{1,\Delta}|\left(\sum_{\Delta',d(\Delta,\Delta')=k}1^2\right)^{1/2}\left(\sum_{\Delta',d(\Delta,\Delta')=k}|\xi^\tau_{2,\Delta'}|^2\right)^{1/2}.\end{aligned}$$

(Received 9 January 2004; accepted 26 January 2004; published 2 April 2004)

Using the analogy with stationary axisymmetric solutions, we present a method to generate new analytic cosmological solutions of Einstein's equation belonging to the class of T^3 Gowdy cosmological models. We show that the solutions can be generated from their data at the initial singularity and present the formal general solution for arbitrary initial data. We exemplify the method by constructing the Kantowski–Sachs cosmological model and a generalization of it that corresponds to an unpolarized T^3 Gowdy model. © *2004 American Institute of Physics.*

I. INTRODUCTION

Gowdy metrics,[1,2] which are exact solutions of Einstein's vacuum field equations, represent cosmological models with various possible topologies ($S^3, S^1\times S^2, T^3$) and are spatially compact inhomogeneous space–times admitting two commuting spacelike Killing vector fields. They are of special importance for the study of formation of singularities in general relativity. Many efforts[3–6] have been made in order to derive and analyze these types of solutions, especially by using numerical methods. The physical structure of these metrics is sufficiently simple to expect that the singularities can be analyzed in detail, but their mathematical structure is sufficiently complicated so that the global dynamical behavior is still far from being completely understood. One of the most intriguing questions concerns the structure of the curvature singularity that is expected to appear at certain spacelike boundary of the associated space–time. Many studies have been devoted to the so-called ''asymptotically velocity term dominated'' (AVTD) behavior which states that near the singularity each point in space is characterized by a different spatially homogeneous cosmology.[8] The idea of AVTD behavior was originally proposed in Ref. 9 more than 30 years ago, but is still being debated. Numerical analysis of the Gowdy models have shown that they do become AVTD near the singularity, except at a set of isolated points, where there are ''spikes'' in the behavior of the metric functions. The origin of these spikes is investigated in Ref. 6. Gowdy metrics have been also analyzed as toy models in quantum midisuperspace gravity.[7]

Numerical methods have been extensively used to investigate Gowdy models, but only recently it has been argued that solutions generating techniques can be applied in this case[10–12] to generate new solutions and that even a ''simple change of coordinates'' can be applied to reinterpret certain stationary axisymmetric solutions as $S^1\times S^2$ Gowdy cosmological models.[13] The reason why these methods can be used also in this case is due to the well-known fact that the solution generating techniques are applicable to any space–time which admits two (commuting) Killing vector fields. In this work, we will concentrate on T^3 Gowdy cosmological models and will see that a complex coordinate transformation, together with a complex change of metric functions, allows us to apply in a straightforward manner the well-known solution generating

*We would like to dedicate this work to the memory of Professor Nail Sibgatullin who unexpectly passed away on March 12, 2004.

b)Electronic mail: quevedo@physics.ucdavis.edu

techniques that have been intensively used for stationary axisymmetric solutions.

This paper is organized as follows: In Sec. II we derive the ''transformation'' that relates stationary axisymmetric solutions with Gowdy T^3 models. We will show that due to this analogy, the AVTD behavior in Gowdy T^3 is mathematically equivalent to the behavior of stationary asixymmetric solutions near the axis of symmetry. In Sec. III we show that Sibgatullin's method for constructing solutions can be applied in the case of Gowdy T^3 models and in Sec. IV we present several examples of exact solutions generated by using this method. Finally, Sec. V is devoted to the conclusions and some remarks about different possibilities of generalizing the results derived in this work.

II. STATIONARY AXISYMMETRIC SOLUTIONS AND GOWDY T^3 MODELS

Consider the line element for stationary axisymmetric spacetimes in the Lewis–Papapetrou form[14]

$$ds^2=-e^{2\psi}(dT+\omega d\phi)^2+e^{-2\psi}[e^{2\gamma}(d\rho^2+dz^2)+\rho^2 d\phi^2], \tag{1}$$

where ψ, ω, and γ are functions of the nonignorable coordinates ρ and z. The ignorable coordinates T and ϕ are associated with the two Killing vector fields $\eta_{\mathrm{I}}=\partial/\partial T$ and $\eta_{\mathrm{II}}=\partial/\partial\phi$. The field equations take the form

$$\psi_{\rho\rho}+\frac{1}{\rho}\psi_\rho+\psi_{zz}+\frac{e^{4\psi}}{2\rho^2}(\omega_\rho^2+\omega_z^2)=0, \tag{2}$$

$$\omega_{\rho\rho}-\frac{1}{\rho}\omega_\rho+\omega_{zz}+4(\omega_\rho\psi_\rho+\omega_z\psi_z)=0, \tag{3}$$

$$\gamma_\rho=\rho(\psi_\rho^2-\psi_z^2)-\frac{e^{4\psi}}{4\rho^2}(\omega_\rho^2-\omega_z^2), \tag{4}$$

$$\gamma_z=2\rho\psi_\rho\psi_z-\frac{1}{2\rho}e^{4\psi}\omega_\rho\omega_z, \tag{5}$$

where the lower indices represent partial derivative with respect to the corresponding coordinate.

Consider now the following coordinate transformation $(\rho,t)\rightarrow(\tau,\sigma)$ and the complex change of coordinates $(\phi,z)\rightarrow(\delta,\chi)$ defined by

$$\rho=e^{-\tau},\quad T=\sigma,\quad z=i\chi,\quad \phi=i\delta, \tag{6}$$

and introduce the functions P, Q, and λ by means of the relationships

$$\psi=\frac{1}{2}(P-\tau),\quad Q=i\omega,\quad \gamma=\frac{1}{2}\left(P-\frac{\lambda}{2}-\frac{\tau}{2}\right). \tag{7}$$

Introducing Eqs. (6) and (7) into the line element (1), we obtain

$$-ds^2=e^{-\lambda/2}e^{\tau/2}(-e^{-2\tau}d\tau^2+d\chi^2)+e^{-\tau}[e^P(d\sigma+Qd\delta)^2+e^{-P}d\delta^2]. \tag{8}$$

Let us take $\tau\geqslant 0$ (what seems reasonable in virtue that the radial coordinate $\rho=e^{-\tau}\geqslant 0$) and ''compactify'' the new coordinates as $0\leqslant\chi,\ \sigma,\ \delta\leqslant 2\pi$ (a less reasonable condition since in general $-\infty<z<+\infty$ and $T\geqslant 0$). The line element (8) with the coordinates τ, χ, σ, and δ in the range given above is known as the line element for Gowdy T^3 cosmological models.[6] Furthermore, one can verify by direct calculation that the action of the transformations (6) and (7) on the field

equations (2)–(5) yields exactly the field equations for the Gowdy cosmological models which after some algebraic manipulations can be written as a set of two second order differential equations for P and Q,

$$P_{\tau\tau}-e^{-2\tau}P_{\chi\chi}-e^{2P}(Q_\tau^2-e^{-2\tau}Q_\chi^2)=0, \tag{9}$$

$$Q_{\tau\tau}-e^{-2\tau}Q_{\chi\chi}+2(P_\tau Q_\tau-e^{-2\tau}P_\chi Q_\chi)=0, \tag{10}$$

and two first order differential equations for λ

$$\lambda_\tau=P_\tau^2+e^{-2\tau}P_\chi^2+e^{2P}(Q_\tau^2+e^{-2\tau}Q_\chi^2), \tag{11}$$

$$\lambda_\chi=2(P_\chi P_\tau+e^{2P}Q_\chi Q_\tau). \tag{12}$$

It should be emphasized that this method for ''deriving'' the Gowdy line element from the stationary axisymmetric one involves real as well as complex transformations at the level of coordinates and metric functions. It is, therefore, necessary to demand that the resulting metric functions P, Q, and λ be real. That means that in general it is not possible to take an axisymmetric stationary solution and apply the transformations to obtain a Gowdy cosmological model. If the resulting functions are not real, they cannot be physical reasonable solutions to the real equations (9)–(12). These transformations can be used only as a guide to get some insight into the form of the new solutions. In any case, the corresponding field equations have to be invoked in order to confirm the correctness of the solution.

A very useful form for analyzing the field equations of space–times with two (commuting) Killing vector fields is the Ernst representation. In fact, this convenient form for the field equations was first proposed for axisymmetric stationary solutions,[15] but since then it has been applied in many different configurations.[16–18] Here we will present the Ernst representation of the main field equations (9) and (10) which is especially adapted to the coordinates used here. To this end, let us introduce a new coordinate t and a new function $R=R(t,\chi)$ by means of the equations[10–13]

$$t=e^{-\tau}, \quad R_t=te^{2P}Q_\chi, \quad R_\chi=te^{2P}Q_t. \tag{13}$$

Then, the field equation (9) can be expressed as

$$t^2\left(P_{tt}+\frac{1}{t}P_t-P_{\chi\chi}\right)+e^{-2P}(R_t^2-R_\chi^2)=0, \tag{14}$$

whereas Eq. (10) for the function Q turns out to be equivalent to the integrability condition $R_{t\chi}=R_{\chi t}$. However, an alternative and convenient equation is obtained by introducing Eq. (13) directly into Eq. (10). So we obtain

$$te^P\left(R_{tt}+\frac{1}{t}R_t-R_{\chi\chi}\right)-2[(te^P)_tR_t-(te^P)_\chi R_\chi]=0, \tag{15}$$

an equation which of course becomes an identity if the integrability condition $R_{t\chi}=R_{\chi t}$ is satisfied. We can now introduce the complex Ernst potential E and the complex gradient operator D as

$$E=te^P+iR, \quad \text{and} \quad D=\left(\frac{\partial}{\partial t},i\frac{\partial}{\partial\chi}\right), \tag{16}$$

which allow us to write the main field equations in the *Ernst-type representation*

$$\mathrm{Re}(E)\left(D^2E+\frac{1}{t}Dt\,DE\right)-(DE)^2=0. \tag{17}$$

It is easy to verify that the field equations (14) and (15) can be obtained as the real and imaginary part of the Ernst equation (17), respectively. For the sake of completeness, we rewrite the system of first order, partial, differential equations (11) and (12) in terms of the Ernst potential:

$$\lambda_t = -\frac{t}{2}(C_+ C_+^* + C_- C_-^*), \tag{18}$$

$$\lambda_\chi = -\frac{t}{2}(C_+ C_+^* - C_- C_-^*), \tag{19}$$

where

$$C_\pm = \frac{1}{\mathrm{Re}(E)}(E_t \pm E_\chi) - \frac{1}{t}, \tag{20}$$

and the asterisk denotes complex conjugation.

If the Ernst potential E is known, then it is easy to recover the metric functions P, Q, and λ which enter the line element (8) of Gowdy T^3 cosmological models. In fact, from Eq. (16) one can algebraically construct the functions P and R. Then the function Q can be obtained by solving the system of two first order partial differential equations given in (13). Notice that the integrability condition of this last system is satisfied by virtue of Eq. (17). Finally, the system (18) and (19) for the function λ can be solved by quadratures since its integrability condition coincides with the Ernst equation (17). Consequently, all the information about any Gowdy T^3 cosmological model is contained in the corresponding Ernst potential.

One of the most important properties of the Ernst representation (17) is that it is very appropriate to investigate the symmetries of the field equations. In particular, the symmetries of the Ernst equation for stationary axisymmetric spacetimes have been used to develop the modern solution generating techniques,[19] like the Bäcklund method, Belinsky–Zakharov inverse scattering method, the Hoenselaers–Kinnersley–Xanthopoulos method, and others (for an introductory review and detailed references, see Ref. 20). In all these methods it is necessary to start from a given ''seed'' solution which has to be specified in the whole space–time (except, perhaps, in the regions where the metric possesses true curvature singularities). An alternative approach for exploring the symmetries inherent in the Ernst equation was explicitly developed by Sibgatullin[21] and consists of constructing exact solutions to the Ernst equation from initial data specified only on certain hypersurface (submanifold) of the space–time. For instance, in the case of stationary axisymmetric space–times, Sibgatullin's method allows one to construct exact solutions from their data on the axis of symmetry. In the following sections we will show that Sibgatullin's method can be applied in the case of Gowdy cosmological models and will present several examples of its application.

III. CONSTRUCTING SOLUTIONS FROM AVTD DATA

As we have mentioned above, an important property of Gowdy cosmological models is its AVTD behavior near the initial singularity. In the case of T^3 models it can be shown that the singularity is approached in the limit $\tau \to \infty$. The AVTD behavior implies that at the singularity all spatial derivatives of the field equations can be neglected and only the temporal behavior is relevant. On the other hand, the transformation (6) indicates that the limit $\tau \to \infty$ is equivalent to the limit $\rho \to 0$; however, this is true only at the level of coordinates and a more detailed analysis is necessary to make sure that this analogy is also valid at the level of explicit solutions. To this end, let us consider the system of partial differential equations for ψ and ω given in Eqs. (2) and (3). If we neglect the spatial dependence on z, which accoring to the transformation (6) is equivalent to the spatial dependence on χ in Gowdy models, then we obtain a system of differential equations which can be solved by quadratures and yields

$$\psi=\tfrac{1}{2}\ln[a(\rho^{1+c}+b^2\rho^{1-c})],\quad \omega=\frac{ib}{a(\rho^{1+c}+b^2\rho^{1-c})}+id, \tag{21}$$

where a, b, c, and d are arbitrary real functions of z. Clearly, this solution is meaningless when considered as a stationary axisymmetric spacetime. However, if we now follow the prescription given in Eqs. (6) and (7) for obtaining Gowdy models, we will find that solution (21) ''corresponds'' to the Gowdy model

$$P=\ln[a(e^{-c\tau}+b^2e^{c\tau})],\quad Q=\frac{b}{a(e^{-2c\tau}+b^2)}+d, \tag{22}$$

where now a, b, c, and d are to be considered as arbitrary real functions of the coordinate χ. It is straightforward to verify that the expressions given in Eq. (22) satisfy the Gowdy field equations (9) and (10) in its ''truncated'' form, i.e., when the spatial derivatives are neglected. The solution (22) is known in the literature as the AVTD solution for Gowdy T^3 models[6] and dictates the behavior of these models near the singularity $\tau\to\infty$. Thus, we have ''derived'' the AVTD solution starting from its stationary axisymmetric counterpart. This is a further indication that the behavior of Gowdy models at the initial singularity is mathematically equivalent to the behavior of stationary axisymmetric solutions at the axis. For the sake of completeness we also quote here the value of the function λ corresponding to the AVTD solution (22) that can be obtained by integrating Eq. (11):

$$\lambda=\lambda_0-c^2\ln t, \tag{23}$$

where λ_0 is an additive constant. Furthermore, the corresponding AVTD Ernst potential can be obtained by introducing Eq. (22) into Eqs. (16) and (17). Then,

$$E=a[e^{-(1+c)\tau}+b^2e^{-(1-c)\tau}]+iR^{\mathrm{avtd}}\quad\text{with}\quad R^{\mathrm{avtd}}_{\chi}=-2abc. \tag{24}$$

If we define

$$E(\tau\to\infty,\chi)=e(\chi) \tag{25}$$

as the Ernst potential at the singularity, we see from Eq. (24) that for $c\in(-1,1)$ only the imaginary part remains, $e(\chi)=iR^{\mathrm{avtd}}$. This means that the real part of $e(\chi)$ is arbitrary and since R^{avtd} is given in terms of the real part it is also arbitrary. If $c\notin(-1,1)$, the Ernst potential diverges at the singularity for arbitrary values of the functions a and b. In the limiting case $c=\pm1$, the Ernst potential at the singularity is regular, but again no conditions appear for the behavior of the functions a and b. Consequently, the AVTD behavior does not impose any conditions on the function $e(\chi)$. We will now see that it is possible to use this function to construct the corresponding Ernst potential $E(\tau,\chi)$.

Sibgatullin's method[21] has been developed to construct exact stationary axisymmetric solutions starting from their data on the axis of symmetry. It is based upon the fact that the Ernst equation possesses symmetry properties associated with an infinite-dimensional Lie group which transforms one solution of this equation into another solution of the same equation. This implies remarkable analyticity properties that make it possible to reduce the Ernst equation to a system of linear integral equations which can be integrated explicitly if initial data is known, for instance, on the axis of symmetry. It is clear that the Ernst-type representation (17) possesses similar symmetry properties. On the other hand, we have shown that the behavior of stationary axisymmetric solutions near the axis is mathematically equivalent to the behavior of Gowdy T^3 cosmological models near the singularity. Thus, it should be possible to construct Gowdy cosmological models starting from the value of the corresponding Ernst potential at the singularity. It turns out that Sibgatullin's method can be generalized in a straightforward manner to include the case of Gowdy models. A detailed explanation of the procedure necessary to obtain the system of linear integral equations

associated with the Ernst equation is given in Ref. 21. Here we will only quote the main steps of the construction. Assume that the value of the Ernst potential is known at the initial singularity, i.e., $e(\chi)$ is given. Then, the Ernst potential can be generated by means of the integral equation

$$E(t,\chi)=\frac{1}{\pi}\int_{-1}^{1}\frac{e(\xi)\mu(\xi)}{\sqrt{1-s^2}}ds, \tag{26}$$

where the unknown function $\mu(\xi)$ has to be found from the singular integral equation

$$\int_{-1}^{1}\frac{\mu(\xi)[e^*(\eta)+e(\xi)]}{(s-\kappa)\sqrt{1-s^2}}ds=0, \tag{27}$$

with the normalization condition

$$\int_{-1}^{1}\frac{\mu(\xi)}{\sqrt{1-s^2}}ds=\pi, \tag{28}$$

where $\xi=\chi+ts,\ \eta=\chi+t\kappa,$ with $s,\kappa\in[-1,1]$.

Notice that for this method no condition is imposed on the behavior of $e(\chi)$. This is in accordance with the result obtained above about the AVTD behavior of the Ernst potential near the singularity. Once $e(\chi)$ is given in any desired form, one only has to calculate the integral (26) to find the Ernst potential. However, to calculate this integral one first has to find the function $\mu(\xi)$ by means of the singular equation (27) and the normalization condition (28). In practice, for a given $e(\xi)$ one has to make a reasonable ansatz for $\mu(\xi)$ such that it allows the existence of solutions for the integral singular equation (27).

IV. EXAMPLES OF GOWDY T^3 MODELS

The cases where the Ernst potential at the initial singularity behaves as a rational function are relatively easy to analyze. In this section we will present two such examples. Let us consider the following simple example of an Ernst potential at the singularity

$$e(\chi)=\frac{\chi_0-\chi}{\chi_0+\chi}, \tag{29}$$

where χ_0 is a real constant. The first step of the construction is to find the unknown function μ according to Eqs. (27) and (28). A reasonable ansatz is again a rational function[21]

$$\mu=A_0+\frac{A_1}{\xi-\xi_1}, \tag{30}$$

where ξ_1 is the root of the equation $e(\xi)+\tilde{e}(\xi)=0$ (in this case $\xi_1=\chi_0$) and A_0, A_1, are functions of t and χ. To handle the integrals which follow from the singular integral equation we use the following standard formulas

$$\int_{-1}^{1}\frac{ds}{\sqrt{1-s^2}}=\pi, \tag{31}$$

$$\int_{-1}^{1}\frac{ds}{(a+isb)\sqrt{1-s^2}}=\frac{\pi}{\sqrt{a^2+b^2}}, \tag{32}$$

$$\int_{-1}^{1}\frac{ds}{(s-\kappa)(s-\gamma)\sqrt{1-s^2}}=\frac{\pi}{(\kappa-\gamma)\sqrt{\gamma^2-1}}, \tag{33}$$

where a, b, and γ are arbitrary constants.

Introducing Eq. (30) into the normalization condition (28), we obtain

$$A_0+\frac{A_1}{r_-}=1, \tag{34}$$

where $r_-=\sqrt{(\chi-\chi_0)^2-t^2}$, whereas the integral singular equation (27) leads to

$$A_0-\frac{A_1(r_++r_-)}{2\chi_0 r_-}=0\,. \tag{35}$$

The last two equations can be used to find the explicit values of A_0 and A_1 which then can be replaced in the result of the integration of Eq. (26) and yield

$$E(t,\chi)=-A_0-\frac{A_1-2\chi_0A_0}{r_+}=\frac{2\chi_0-r_+-r_-}{2\chi_0+r_++r_-}, \tag{36}$$

where $r_+=\sqrt{(\chi+\chi_0)^2-t^2}$. It is easy to check that indeed this is a solution to the Ernst equation (17). Since the resulting Ernst potential is real, the solution corresponds to a polarized ($Q=0$) Gowdy model. The expression for the metric function P can easily be obtained from the definition (16) and Eq. (36), and the remaining function λ can be calculated (up to an additive constant) by quadratures from Eqs. (18) and (19):

$$\lambda=\ln\left[\frac{1}{t}\frac{(r_+r_-)^2}{(r_++r_-+2\chi_0)^4}\right]. \tag{37}$$

The physical significance of this solution becomes plausible in a different system of coordinates which we introduce in two steps. Let us first introduce in the (τ,χ)-sector of the line element (8) coordinates x and y by means of the relationships

$$e^{-2\tau}=t^2=\chi_0^2(1-x^2)(1-y^2),\quad \chi=\chi_0xy, \tag{38}$$

or the inverse transformation law

$$x=\frac{r_++r_-}{2\chi_0},\quad y=\frac{r_+-r_-}{2\chi_0}, \tag{39}$$

so that the metric functions become

$$P=\ln\left[\frac{1-x}{\chi_0\sqrt{(1-x^2)(1-y^2)}(1+x)}\right],\quad \lambda=\ln\left[\frac{(x^2-y^2)^2}{\chi_0\sqrt{(1-x^2)(1-y^2)}(1+x)^4}\right]. \tag{40}$$

The second transformation affects now all the sectors of the line element (8) and is defined by

$$x=\frac{T}{\chi_0}-1,\quad y=\cos\theta,\quad \sigma=r,\quad \delta=\phi. \tag{41}$$

Then, after some algebraic manipulations, the metric can be written as

$$-ds^2=-\left(\frac{2\chi_0}{T}-1\right)^{-1}dT^2+\left(\frac{2\chi_0}{T}-1\right)dr^2+T^2(d\theta^2+\sin^2\theta d\phi^2), \tag{42}$$

an expression that can immediately be recognized as the Kantowski–Sachs cosmological model.[23,24] Thus, we have shown that the Kantowski–Sachs metric can be constructed from the value of its Ernst potential at the singularity (29).

Consider now the more general case

$$e(\chi)=\frac{\chi_0-\chi-i\chi_1}{\chi_0+\chi+i\chi_1}, \tag{43}$$

where χ_0 and χ_1 are real constants. The unknown function $\mu(\xi)$ can be sought in the form

$$\mu=A_0+\frac{A_1}{\xi-\xi_1}+\frac{A_2}{\xi-\xi_2}, \tag{44}$$

where $\xi_{1,2}=\pm\alpha=\pm\sqrt{\chi_0^2-\chi_1^2}$ are the roots of the equation $e(\xi)+e^*(\xi)=0$. Substituting Eq. (44) in the integral equation (27) we obtain the system

$$-A_0+\frac{A_1}{\chi_0+i\chi_1+\alpha}+\frac{A_2}{\chi_0+i\chi_1-\alpha}=0\,, \tag{45}$$

$$-\frac{A_1(\alpha+i\chi_1)}{r_-(\chi_0+i\chi_1+\alpha)}+\frac{A_2(\alpha-i\chi_1)}{r_+(\chi_0+i\chi_1-\alpha)}=0\,, \tag{46}$$

where $r_\pm=\sqrt{(\chi\pm\alpha)^2-t^2}$. On the other hand, the normalization condition (28) yields

$$A_0+\frac{A_1}{r_-}+\frac{A_2}{r_+}=1\,, \tag{47}$$

an equation which together with Eqs. (45) and (46) form a closed algebraic system that determines the coefficients of the function μ:

$$\begin{aligned}
A_0&=\frac{\alpha(r_++r_-)+i\chi_1(r_+-r_-)}{\alpha(r_++r_-)+i\chi_1(r_+-r_-)+2\alpha\chi_0},\\
A_1&=\frac{r_-(\alpha-i\chi_1)(\chi_0+i\chi_1+\alpha)}{\alpha(r_++r_-)+i\chi_1(r_+-r_-)+2\alpha\chi_0},\\
A_2&=\frac{r_+(\alpha+i\chi_1)(\chi_0+i\chi_1-\alpha)}{\alpha(r_++r_-)+i\chi_1(r_+-r_-)+2\alpha\chi_0}.
\end{aligned} \tag{48}$$

Finally, we calculate the Ernst potential according to Eq. (26) and obtain

$$E(t,\chi)=-A_0+\frac{A_1(\chi_0-i\chi_1-\alpha)}{r_-(\chi_0+i\chi_1+\alpha)}+\frac{A_2(\chi_0-i\chi_1+\alpha)}{r_+(\chi_0+i\chi_1-\alpha)}=\frac{2\alpha\chi_0-\alpha(r_++r_-)-i\chi_1(r_+-r_-)}{2\alpha\chi_0+\alpha(r_++r_-)+i\chi_1(r_+-r_-)}. \tag{49}$$

The calculation of the corresponding metric functions can be carried out as described in the last section. When integrating the systems of first order differential equations (13) for Q and (18) and (19) for λ, constants of integration appear which we choose such that a simpler representation is obtained in terms of the coordinates used. To write down the final form of the metric functions it is convenient to use the coordinates (x, y) as defined in Eq. (39) with χ_0 replaced by α. Then

$$P=\ln\frac{\chi_0^2-\alpha^2x^2-\chi_1^2y^2}{\alpha\sqrt{(1-x^2)(1-y^2)}[(\chi_0+\alpha x)^2+\chi_1^2y^2]}\,, \tag{50}$$

$$Q=\frac{2\chi_1\chi_0(1-y^2)(\chi_0+\alpha x)}{\chi_0^2-\alpha^2x^2-\chi_1^2y^2}, \tag{51}$$

$$\lambda=\ln\frac{\chi_0^3(x^2-y^2)^2}{\sqrt{(1-x^2)(1-y^2)}[(\chi_0+\alpha x)^2+\chi_1^2y^2]^2}. \tag{52}$$

This metric corresponds to an unpolarized generalization of the Kantowski–Sachs cosmological model which is obtained in the limiting case $\chi_1=0$.

It is easy to see that near the singularity ($\tau\to\infty$) the general Ernst potential (49) approaches the corresponding AVTD potential as given in Eq. (43). This could be interpreted as an indirect proof of the AVTD behavior of the solution obtained here. A more direct proof can be given by analyzing the hyperbolic velocity $v=\sqrt{P_\tau^2+e^{2P}Q_\tau^2}$ (see Ref. 4). In terms of the coordinates x and y, the hyperbolic velocity of the solutions (50) and (51) is given as a rather cumbersome expression. Nevertheless, it is possible to perform an analysis of its behavior by considering the different domains of the coordinates according to the definition equation (39). One can show that in general $0\leqslant v<1$ which according to Ref. 4 implies that the solution is AVTD.

An important property of the method presented here is that it allows us to calculate an arbitrary Gowdy T^3 cosmological solution with any degree of accuracy. To this end, let us expand in Eq. (26) the value of the Ernst potential $e(\xi)$ in Fourier series,

$$e(\xi)=\sum_{k=0}^{\infty} e_k(t,\chi)\cos(k\varphi), \tag{53}$$

where $e_0=e(\chi)$ and we have represented the parameter s as $s=\cos\varphi$. Then the unknown function $\mu(\xi)$ can be expanded in a similar way,

$$\mu(\xi)=\sum_{k=0}^{\infty} \mu_k(t,\chi)\cos(k\varphi). \tag{54}$$

The normalization condition (28) can easily be calculated and implies that $\mu_0=1$. Furthermore, the general solution of the integral equation (26) can be written as[21]

$$E(t,\chi)=e(\chi)+\frac{1}{2}\sum_{k=1}^{\infty} e_k\mu_k. \tag{55}$$

According to Eq. (27), the coefficients μ_k have to satisfy the following system of algebraic equations:

$$\sum_{l=1}^{\infty} \mu_k(e_{k+l}-e^*_{k+l}+e_{|k-l|}-e^*_{|k-l|})=-2e_k. \tag{56}$$

Thus, once the value of the Ernst potential is given at the initial singularity [$e(\chi)=E(\chi,\tau\to\infty)$] the general solution of the Ernst equation reduces to an infinite series with coefficients satisfying a set of pure algebraic equations.

V. CONCLUSIONS

We have shown that it is possible to generate Gowdy T^3 cosmological models starting from their data near the initial singularity. To this end, we first show that the Gowdy T^3 line element can be obtained from the line element of stationary axisymmetric solutions by means of complex transformation that involves the metric functions and the coordinates. The behavior of stationary axisymmetric solutions at the axis of symmetry is shown to be mathematically equivalent to the

behavior of Gowdy T^3 models near the singularity. In particular, we have derived the AVTD solution from its stationary axisymmetric counterpart. We then use the Ernst representation of the field equations and apply Sibgatullin's method to the Ernst potential which can be given at the singularity as any arbitrary function of the angle coordinate χ. In particular, we have shown that the Kantowski–Sachs cosmological model can be derived in this manner by starting from a specific form of the Ernst potential in terms of a rational function. We then have found an unpolarized generalization of the Kantowski–Sachs cosmological model. This generalization has been obtained in the same way as the Kerr metric is obtained from its value at the axis of symmetry by using Sibgatullin's method.[21] It is possible to consider more general examples of Ernst potentials at the axis in terms of rational functions. It turns out that the system of integral equations (27) and (28) forms a closed algebraic system from which the value of the function $\mu(\xi)$ can be found and the expression for the Ernst potential can be calculated.[22] This method could also be applied in the case of Gowdy cosmological models considered here.

By expanding the value of the Ernst potential at the singularity in terms of a Fourier series, it is possible to write explicitly the general solution for this type of models (including the unpolarized case) by using only a recurrence algebraic formula. This is a result that could find some application in numerical investigations since it allows us to ''control'' the accuracy of the analysis by truncating the series at any desired level.

(Received 2 April 2003; accepted 6 February 2004; published 2 April 2004)

The problem of an origin of the Solari–Kochetov extra-phase contribution to the naive semiclassical form of a generalized phase-space propagator is addressed with the special reference to the su(2) spin case which is the most important in applications. While the extra-phase correction to a flat phase-space propagator can straightforwardly be shown to appear as a difference between the principal and the Weyl symbols of a Hamiltonian in the next-to-leading order expansion in the semiclassical parameter, the same statement for the semiclassical spin coherent-state propagator holds provided the Holstein–Primakoff representation of the su(2) algebra generators is employed. © *2004 American Institute of Physics.*

I. INTRODUCTION

The spin coherent-state path integral appears to be very useful in many physical problems that involve quantum su(2) spins. In particular, one of its most significant practical applications is the study of spin tunneling in the semiclassical limit.[1–4] However, as it was remarked in Ref. 5, the straightforward computation of the semiclassical propagator[6] or the tunnel splitting[7] yields results that are incorrect beyond the leading semiclassical order. Examples of other systems where the large spin limit gives a good qualitative picture, while the first quantum correction is either ignored or fixed by heuristic considerations, can be found in Ref. 8.

Recently, Stone *et al.*[5] have restored the reliability of the semiclassical expression for the spin coherent-state propagator, thus effectively rehabilitating the use of the continuous-time spin coherent-state path integral. The crucial point in that approach is the recognition of an importance and the explanation of the origin of a previously discovered quantum correction[9–11] to the naive form of the semiclassical coherent-state propagator. It has been pointed out that the functional determinant arising from the evaluation of the functional integral about the classical path possesses a U(1) gauge anomaly, its proper regularization resulting in the extra-phase contribution. Originally Solari[9] obtained this extra-phase correction through a careful calculation of the path integral in the discrete-time approximation. Kochetov[10] derived it independently considering the continuous-time version of the spin coherent-state path integral in the semiclassical limit. A discrete-time evaluation similar to that of Solari was carried out by Vieira and Sacramento[11] who have also reproduced the same result.

The relevance of the Solari–Kochetov phase has been justified in the application of the spin coherent-state path integral to the calculation of the tunnel splitting of the classically degenerate ground state for a family of models that includes a realistic approximation to the molecular magnet Fe_8.[8] It has been also noticed in Ref. 12 that the modification of the Gutzwiller trace formula[13] for systems with a coupling of the translational and spin degrees of freedom should also contain this extra phase in the combined limit $\hbar \to 0$, $S \to \infty$, $\hbar S = \text{const}$.

In this article we offer a point of view on the origin of the Solari–Kochetov phase, which complements the analysis made in Ref. 5.

a)Electronic mail: pletmikh@tfp.physik.uni-karlsruhe.de

To establish our notations we briefly outline in Sec. II some basic facts concerning quantization on cotangent bundles and coadjoint group orbits, the phase space manifolds that are most frequently encountered in applications. In Sec. III we consider in detail semiclassical propagators on flat phase spaces. We observe that the arising extra phase can be interpreted as a difference between the principal and the Weyl symbols of a Hamiltonian in the next-to-leading order in $\hbar$. On the other hand, various symbols, or various quantization schemes, are closely related to the operator ordering procedures. One can then alternatively state that the extra phase is the difference between the naive classical Hamiltonian and the expectation value of the Weyl-ordered operator.[14] Obviously, both formulations are equivalent, though the former provides a more efficient way to compute the extra phases, since it is based on the Wigner–Weyl calculus and implies an extensive use of the Moyal formula.[15]

In Sec. IV we discuss the semiclassical spin coherent-state propagator and its specific ingredient—the Solari–Kochetov phase. We also briefly outline the relation between the covariant and contravariant quantization schemes which are usually employed for the path integral construction in the spin case.

To obtain the Solari–Kochetov phase using the analogy with the flat case we, in the first place, need a proper definition of a Weyl symbol of the quantum spin Hamiltonian. The point is that a standard Weyl quantization is well-defined on a classical phase space M, provided it appears as a cotangent bundle to a certain configuration space Q, $M=T^*Q$. While Q may in principle be a compact manifold, T^*Q is always noncompact. A classical phase space of a spin is, however, a compact finite volume manifold, the two-sphere S^2, which is not a cotangent bundle. Therefore, there does not seem to exist any natural global definition of appropriate Weyl symbols of the su(2) spin operators.

To partly circumvent this apparent difficulty, we employ in Sec. V a special Holstein–Primakoff representation of the su(2) algebra.[16] It expresses the su(2) generators in terms of $\hat{a}$, $\hat{a}^\dagger$, $\hat{a}^\dagger\hat{a}$—the standard generators of the Heisenberg–Weyl algebra, and allows for a formal application of the standard Wigner–Weyl calculus to spin Hamiltonians. We then are able to define the Weyl symbols of the spin operators, provided the semiclassical representations of su(2) are considered, and to determine their difference from the components of the classical spin. This difference appears to be well-defined in the semiclassical limit $S\to\infty$, exactly reproducing the Solari–Kochetov phase.

II. PHASE-SPACE QUANTIZATION

The classical phase space can be thought of as a pair (M,w) where M is a $2n$-dimensional Riemannian manifold and w stands for a closed nondegenerate symplectic two-form on it. A group of canonical transformations G acting on M transitively leaves w invariant. Quantization on M amounts to constructing a complex line bundle over M with a connection one-form θ such that $d\theta=w$. A quantum Hilbert space is then constructed out of sections of the bundle. When lifted to the bundle, the action of G gives rise to a unitary but reducible representation of G. In order to select an irreducible component, the action of G is restricted to the subspace of those sections which are covariantly constant along n linearly independent vector fields $\chi_1,\ldots,\chi_n$ on M such that $w(\chi_i,\chi_j)=0$. This procedure is usually referred to as fixing of the polarization.[17]

To illustrate these definitions we briefly discuss two examples of phase spaces, which appear to be our main concern here, cotangent bundles and coadjoint group orbits.

Local coordinates on a cotangent bundle $M=T^*Q$ can always be separated into "coordinates," q^j, and "momenta," p_j, which are canonically conjugated to the q^j, with the globally defined canonical symplectic one-form $\theta=(1/\hbar)(p^j dq_j-q^j dp_j)$. Covariantly constant sections $f(q,p)$ along the vector field $\chi=\partial_p$ (we put for simplicity $n=1$) are then defined by

$$\nabla_p f:=(\partial_p+i\theta_p)f=0, \tag{1}$$

where $f(q,p)\sim e^{ipq/\hbar}\psi(q)$. The quantum Hilbert space appears then as the space of square-integrable functions $\psi(q)$. When considering the time evolution, one usually picks up initial and

final states as the eigenstates of the operator $\hat{q}$, $\hat{q}|q_0\rangle = q_0|q_0\rangle$, which corresponds to the choice $\psi(q) \sim \delta(q-q_0)$. Analogously, the choice $\chi = \partial_q$ results in quantization in terms of the p-dependent sections, $f(q,p) \sim e^{-ipq/\hbar}\psi(p)$. In the following we will be considering quantum propagators on T^*Q having the form

$$K(p_f, q_i, T) := \langle p_f | e^{-i\hat{H}T/\hbar} | q_i \rangle, \tag{2}$$

where initial and final quantum states belong to different polarizations.

Formally, the Weyl symbol of the operator $\hat{H}(\hat{q},\hat{p})$ is given by

$$H_W(q,p) = \int_Q dx \sqrt{g} e^{ipx/\hbar} \langle q - x/2 | \hat{H} | q + x/2 \rangle, \tag{3}$$

where g denotes the determinant of a restriction of a full metric tensor onto Q. As already said, the separation of the local coordinates into (q,p) is defined on a cotangent bundle globally (because θ exists globally). Accordingly, the symbol $H_W(q,p)$ is defined on the phase space manifold T^*Q globally as well.

The second important class of classical phase spaces is the so-called coadjoint orbits of Lie groups.[17] These symplectic G-homogeneous manifolds appear as natural classical phase spaces in the instances where quantum Hamiltonians allow for representations in terms of the Lie group generators. For example, the quantum spin dynamics is governed by a Hamiltonian built out of the su(2) generators. Spin classical phase space appears then as an SU(2) orbit—the two-sphere S^2,[18] which is a compact curved manifold. It can be covered by two local charts with complex coordinates $(z,\overline{z})$ and $(w,\overline{w})$ defined by projections from the North and South Poles, respectively.

Since there is no globally defined symplectic one-form on S^2, it does not admit a global separation of coordinates into q's and p's. Instead, the locally defined su(2) symplectic one-forms (in the representation with spin S) $\theta_1 = iS(\overline{z}dz - zd\overline{z})/(1+|z|^2)$ and $\theta_2 = iS(\overline{w}dw - wd\overline{w})/(1+|w|^2)$, where $w = 1/z$, are related in the charts' overlap by a U(1) gauge transformation, $\theta_1 = \theta_2 + iSd\log(z/\overline{z})$.

The covariantly constant section of the monopole $P(S^2, U(1))$ bundle that forms a quantum Hilbert space for spin can be chosen as an su(2) coherent state. In particular,

$$\nabla_{\overline{z}} |z\rangle_1 := (\partial_{\overline{z}} + i\theta_{1\ \overline{z}})|z\rangle_1 = 0, \tag{4}$$

where $|z\rangle_1$ denotes the su(2) coherent state in the local chart $(z,\overline{z})$. The su(2) quantum phase-space propagator can then be written down in the form

$$K(\overline{z_f}, z_i, T) := {}_1\langle z_f | e^{-i\hat{H}T/\hbar} | z_i \rangle_1, \tag{5}$$

where the initial and final states belong to different polarizations.

Given a spin quantum Hamiltonian $\hat{H}$, its classical symbol may be conveniently chosen as an expectation value in the coherent state, the so-called covariant symbol of the spin-dependent operator, $H_1^{cov}(\overline{z},z) = {}_1\langle z|\hat{H}|z\rangle_1$. In spite of its appearance, this symbol is defined globally on S^2: the $P(S^2,U(1))$ local sections are related in the charts' overlap by the U(1) gauge transformation

$${}_2\langle 1/z | z \rangle_1 = (z/\overline{z})^S \in U(1). \tag{6}$$

Therefore, $H_1^{cov}(\overline{z},z) = H_2^{cov}(\overline{w},w)$ for $w = 1/z$.

Concluding the section, we may state: though it might be in principle possible to construct a Weyl symbol for the su(2) spin locally on S^2, there seems to be no way to extend such a definition globally to the whole sphere.

III. FLAT PHASE-SPACE PROPAGATOR

The well-known van Vleck representation for the semiclassical propagator on a flat configuration space[19] has its counterpart in the phase space T^*R^2 which is the semiclassical approximation for the propagator (2)

$$K(p_f,q_i,T)=\frac{1}{\sqrt{2\pi\hbar}}\left(-\frac{\partial^2\mathcal{R}_{cl}}{\partial p_f\partial q_i}\right)^{1/2}e^{i\mathcal{R}_{cl}(p_f,q_i,T)/\hbar}, \tag{7}$$

where

$$\mathcal{R}_{cl}(p_f,q_i,T)=-\frac{1}{2}(p_f q_{cl}(T)+p_{cl}(0)q_i)+\int_0^T dt\left(-\frac{1}{2}(\dot{p}_{cl}q_{cl}-p_{cl}\dot{q}_{cl})-H(q_{cl},p_{cl})\right). \tag{8}$$

The classical dynamics of the system is governed by the principal symbol $H(q,p)$ of the quantum Hamiltonian $\hat{H}$:

$$\dot{q}=\frac{\partial H(q,p)}{\partial p},\quad q(0)=q_i, \tag{9}$$

$$\dot{p}=-\frac{\partial H(q,p)}{\partial q},\quad p(T)=p_f. \tag{10}$$

We would also call $H(q,p)$ the naive classical Hamiltonian since it can be obtained by just "dropping hats" in $\hat{H}$.

Formally, the principal symbol $H(q,p)$ is obtained in the limit $\hbar\to 0$ of the Weyl symbol (3). The Weyl symbol of the product of two operators is given by the Moyal product[15] of two respective symbols. The Moyal formula can be written in the symbolic form

$$(\hat{F}\hat{G})_W=F_W{*}G_W=F_W\,e^{i\hbar\mathcal{L}/2}\,G_W, \tag{11}$$

where the operator

$$\mathcal{L}=\frac{\overleftarrow{\partial}}{\partial q}\frac{\overrightarrow{\partial}}{\partial p}-\frac{\overleftarrow{\partial}}{\partial p}\frac{\overrightarrow{\partial}}{\partial q} \tag{12}$$

is associated with the Poisson bracket

$$F_W\mathcal{L}G_W=\{F_W,G_W\}_{q,p}=\frac{\partial F_W}{\partial q}\frac{\partial G_W}{\partial p}-\frac{\partial F_W}{\partial p}\frac{\partial G_W}{\partial q}. \tag{13}$$

Expanding (11) into a series of $\hbar$, we obtain the leading and the next-to-leading contributions to the Moyal formula

$$(\hat{F}\hat{G})_W=F_W G_W+\frac{i\hbar}{2}\{F_W,G_W\}_{q,p}+O(\hbar^2). \tag{14}$$

Respectively, the leading contribution to the Weyl symbol of the commutator

$$([\hat{F},\hat{G}])_W=(\hat{F}\hat{G}-\hat{G}\hat{F})_W=F_W{*}G_W-G_W{*}F_W=i\hbar\{F_W,G_W\}_{q,p}+O(\hbar^3) \tag{15}$$

establishes the "correspondence principle" between commutators and Poisson brackets.

However, the expression (7) is, in general, incorrect. Besides the Morse index that accounts for the number of conjugate points,[20] there may appear another discrepancy between the repre-

sentation of (7) and that of a correct asymptotic propagator. It happens when the quantum Hamiltonian contains the terms that mix $\hat{q}$ and $\hat{p}$. Unless $\hat{H}$ is Weyl (symmetrically) ordered, it is not sufficient to take into account just the principal symbol $H(q,p)$ for the calculation of $\mathcal{R}_{cl}$.

Thus, we make here the following proposition: in the semiclassical evaluation of the propagator of type (7) it is necessary to use the Weyl symbol of the quantum Hamiltonian:

$$H_W(q,p)=H(q,p)-\delta H(q,p)+O(\hbar^2), \quad \delta H(q,p)\sim O(\hbar). \tag{16}$$

Though the classical dynamics is governed by the principal symbol, or naive classical Hamiltonian, $H(q,p)$, the next order term $\delta H(q,p)$ divided by $\hbar$, nevertheless, contributes to the phase of the semiclassical propagator. If the quantum Hamiltonian is a polynomial in $\hat{q}$ and $\hat{p}$, it is easy to calculate $\delta H(q,p)$ using the Moyal formula (14) and the obvious fact that $(\hat{q})_W=q$ and $(\hat{p})_W=p$.

Let us introduce the complex variables

$$\alpha=\frac{1}{\sqrt{2}}(q+ip), \quad \overline{\alpha}=\frac{1}{\sqrt{2}}(q-ip). \tag{17}$$

They are normalized to be the Weyl symbols of the operators

$$\hat{A}=\frac{1}{\sqrt{2}}(\hat{q}+i\hat{p}), \quad \hat{A}^{\dagger}=\frac{1}{\sqrt{2}}(\hat{q}-i\hat{p}), \tag{18}$$

which satisfy the commutation relation

$$[\hat{A},\hat{A}^{\dagger}]=\hbar. \tag{19}$$

We can define the Weyl symbols $F_W(\overline{\alpha},\alpha)$ and $G_W(\overline{\alpha},\alpha)$ and the Poisson bracket

$$\{F_W(\overline{\alpha},\alpha),G_W(\overline{\alpha},\alpha)\}_{\overline{\alpha},\alpha}=i\left(\frac{\partial F_W}{\partial\overline{\alpha}}\frac{\partial G_W}{\partial\alpha}-\frac{\partial F_W}{\partial\alpha}\frac{\partial G_W}{\partial\overline{\alpha}}\right) \tag{20}$$

by making a change of variables (17) in $F_W(q,p)$ and $G_W(q,p)$ and in the Poisson bracket (13), respectively. In turn, after the transformation (18) the operator which is Weyl-ordered in $\hat{A},\hat{A}^{\dagger}$ converts into the operator Weyl-ordered in $\hat{q},\hat{p}$. Note also that for the Weyl-ordered operator (either in $\hat{A},\hat{A}^{\dagger}$ or in $\hat{q},\hat{p}$), its Weyl symbol yields the principal symbol, the higher order terms being identically zero. This justifies the above definition of the Weyl symbols $F_W(\overline{\alpha},\alpha)$ and $G_W(\overline{\alpha},\alpha)$.

Taking into account a definite correspondence between the symbols and the ordering procedures, we can therefore interpret the emergence of the extra phase $\delta H/\hbar$ as an artifact of the operator ordering.

For a more detailed explanation, we would like to discuss the results of Ref. 21. In particular, there has been established the relation between semiclassical results for a propagator obtained within different quantization schemes. The ''λ-quantization'' infers the choice of the λ-symbol[22]

$$H^{(\lambda)}(\overline{\alpha},\alpha)=\mathrm{Tr}[\hat{H}\hat{R}_{\lambda}(\overline{\alpha},\alpha)], \quad \lambda\in[0,1], \tag{21}$$

where

$$\hat{R}_{\lambda}(\overline{\alpha},\alpha)=\frac{1}{\pi\hbar}\int d^2\xi e^{-(1-2\lambda)\overline{\xi}\xi/2\hbar}e^{\{\xi(\overline{\alpha}-\hat{A}^{\dagger})-\overline{\xi}(\alpha-\hat{A})\}/\hbar}. \tag{22}$$

The particular cases of $\lambda=0,\frac{1}{2},1$ correspond to the covariant (coherent-state), Weyl and contravariant symbols, respectively. The arbitrary λ-symbol is linked to the covariant symbol through the relation

$$H^{(0)}(\overline{\alpha},\alpha)=(\hat{T}_\lambda(\Delta)H^{(\lambda)})(\overline{\alpha},\alpha),\quad \hat{T}_\lambda(\Delta)=e^{\hbar\lambda\Delta}, \tag{23}$$

where $\Delta=\partial^2/\partial\alpha\partial\overline{\alpha}$ is the Laplace–Beltrami operator on the complex plane.

In the semiclassical limit $\hbar\to 0$ the expression (23) can be expanded as

$$H^{(0)}=H^{(\lambda)}+\hbar\lambda\Delta H^{(\lambda)}+O(\hbar^2). \tag{24}$$

Therefore, for arbitrary $\lambda,\lambda'\in[0,1]$ we have

$$H^{(\lambda')}=H^{(\lambda)}-\hbar(\lambda'-\lambda)\Delta H^{(\lambda)}+O(\hbar^2). \tag{25}$$

The expression for the semiclassical propagator reads[21]

$$K_{scl}^{flat}=\left(i\frac{\partial^2\mathcal{R}_{cl}^{(\lambda)}}{\partial\overline{\alpha}_f\partial\alpha_i}\right)^{1/2}\exp\left\{i\frac{\mathcal{R}_{cl}^{(\lambda)}}{\hbar}+i\left(\frac{1}{2}-\lambda\right)\int_0^T B^{(\lambda)}dt\right\}, \tag{26}$$

where

$$\mathcal{R}^{(\lambda)}(\overline{\alpha}_f,\alpha_i,T)=-\frac{i}{2}(\overline{\alpha}_f\alpha_{cl}(T)+\overline{\alpha}_{cl}(0)\alpha_i-|\alpha_f|^2-|\alpha_i|^2)$$
$$+\int_0^T dt\left(-\frac{i}{2}(\dot{\overline{\alpha}}_{cl}\alpha_{cl}-\overline{\alpha}_{cl}\dot{\alpha}_{cl})-H^{(\lambda)}(\overline{\alpha}_{cl},\alpha_{cl})\right) \tag{27}$$

and

$$B^{(\lambda)}=\Delta H^{(\lambda)}=\Delta H^{(1/2)}+O(\hbar)=\Delta H^{(0)}+O(\hbar). \tag{28}$$

The terms of the order $O(\hbar)$ in $B^{(\lambda)}$ as well as the dependence of the prefactor on λ are inessential due to the very structure of the asymptotic expression (26). $O(\hbar)$-terms are also negligible in the classical equations of motion:

$$\dot{\alpha}=-i\frac{\partial H^{(\lambda)}}{\partial\overline{\alpha}}+O(\hbar),\quad \alpha(0)=\alpha_i, \tag{29}$$

$$\dot{\overline{\alpha}}=i\frac{\partial H^{(\lambda)}}{\partial\alpha}+O(\hbar),\quad \overline{\alpha}(T)=\overline{\alpha}_f. \tag{30}$$

Note that for $\lambda=\frac{1}{2}$ (Weyl quantization) the B-term drops out from (26). Since the semiclassical propagator should not depend on λ, i.e., on the choice of the quantization scheme, the extra-phase correction just compensates for the difference between λ and Weyl symbols in the next-to-leading order in $\hbar$ [see (25) for $\lambda'=\frac{1}{2}$].

Suppose that the quantum Hamiltonian $\hat{H}$ belongs to a family of specifically ordered Hamiltonians,[23] also parametrized by $\lambda\in[0,1]$,

$$\hat{H}_\lambda(\hat{A}^\dagger,\hat{A})=\frac{1}{(\pi\hbar)^2}\int d^2\alpha d^2\beta H(\overline{\alpha},\alpha)e^{(1-2\lambda)\overline{\beta}\beta/2\hbar}e^{\{\beta(\overline{\alpha}-\hat{A}^\dagger)-\overline{\beta}(\alpha-\hat{A})\}/\hbar}, \tag{31}$$

where the particular cases of $\lambda=0,\frac{1}{2},1$ correspond to the normal, Weyl and antinormal orderings, respectively. One can establish the one-to-one correspondence between the operators (31) and the

symbols (21). It follows from the observation that the λ-symbol of the λ-ordered operator yields the principal symbol $H(\overline{\alpha},\alpha)$. Thus, the result (26) of Ref. 21 actually proves our proposition for the Hamiltonians (31).

The problem of the extra-phase contribution was often encountered in the coherent-state semiclassics based on the covariant quantization scheme. We can illustrate it with the following example.

Let us consider the normally ordered operator

$$\hat{H}_{\lambda=0}=\sum_{m,n} h_{mn}\hat{A}^{\dagger m}\hat{A}^{n}. \tag{32}$$

Its covariant (coherent-state) symbol

$$H^{(0)}(\overline{\alpha},\alpha)=\langle\alpha|\hat{H}_0|\alpha\rangle=\sum_{m,n} h_{mn}\overline{\alpha}^{m}\alpha^{n} \tag{33}$$

is found from (21) with $\lambda=0$, or, equivalently, by taking an expectation value in the Heisenberg-Weyl coherent state

$$|\alpha\rangle=e^{-\overline{\alpha}\alpha/2\hbar}e^{\alpha\hat{A}^{\dagger}/\hbar}|0\rangle, \quad \langle\alpha|\alpha\rangle=1. \tag{34}$$

Obviously, the covariant symbol (33) coincides with the principal symbol.

The Weyl symbol of (32) is

$$H^{(1/2)}=\sum_{m,n} h_{mn}\overline{\alpha}^{m}\alpha^{n}+\frac{i\hbar}{2}\sum_{m,n} h_{mn}\{\overline{\alpha}^{m},\alpha^{n}\}_{\overline{\alpha},\alpha}+O(\hbar^2)=H^{(0)}-\frac{\hbar}{2}\Delta H^{(0)}+O(\hbar^2). \tag{35}$$

Thus, we can deduce that

$$\frac{\delta H}{\hbar}=\frac{1}{2}\Delta H^{(0)}. \tag{36}$$

The same expression for the phase correction has been derived in Ref. 24, where the WKB approximation in the Bargmann representation has been considered. In the case $h_{11}=\omega$ and $h_{mn}=0$ for $m,n\neq 1$, we see that $\delta H/\hbar=\omega/2$. When multiplied by T, it exactly coincides with the required phase correction to the semiclassical coherent-state propagator of the harmonic oscillator. Its inclusion is sometimes referred to as a restoration of zero-point energy in the first order of $\hbar$.

IV. SEMICLASSICAL SPIN COHERENT-STATE PROPAGATOR

A quantum spin Hamiltonian $\hat{H}=\hat{H}(\hat{\mathbf{s}})$ is a function of spin algebra generators which satisfy the su(2) commutation relations

$$[\hat{s}_+,\hat{s}_-]=2\hat{s}_3, \quad [\hat{s}_3,\hat{s}_\pm]=\pm\hat{s}_\pm, \tag{37}$$

where $\hat{s}_\pm=\hat{s}_1\pm i\hat{s}_2$.

There actually exist two quantization schemes for spin[25]—covariant and contravariant—that are usually employed for the path-integral construction and its further semiclassical approximations.

The covariant quantization scheme is based on the coherent-state representation of the quantum Hamiltonian: the covariant symbol is defined as an expectation value

$$H^{cov}(\overline{z},z)\equiv H(\overline{z},z)={}_1\langle z|\hat{H}|z\rangle_1 \tag{38}$$

in the spin coherent state

$$|z\rangle_1=(1+\overline{z}z)^{-S}e^{z\hat{s}_+}|S,-S\rangle, \quad {}_1\langle z|z\rangle_1=1, \tag{39}$$

where $|S,-S\rangle$ is the lowest spin state in the $2S+1$-dimensional representation of SU(2). The second family of the spin coherent states is given by

$$|w\rangle_2=(1+\overline{w}w)^{-S}e^{w\hat{s}_-}|S,S\rangle, \quad {}_2\langle w|w\rangle_2=1, \tag{40}$$

$|S,S\rangle$ being the highest spin state.

In the sequel, all spin coherent states will be drawn from the first family, $|z\rangle:=|z\rangle_1$.

The spin coherent-state propagator (5) can be approximated in the semiclassical limit $S\to\infty$ by

$$K_{scl}(\overline{z}_f,z_i,T)=\left(i\frac{(1+\overline{z}_f z_{cl}(T))(1+\overline{z}_{cl}(0)z_i)}{2S}\frac{\partial^2\mathcal{R}_{cl}}{\partial z_i\partial\overline{z}_f}\right)^{1/2}e^{i\mathcal{R}_{cl}(\overline{z}_f,z_i,T)+(i/2)\int_0^T\phi_{SK}(t)dt}. \tag{41}$$

The validity of this formula has been proven in Ref. 5. It has been also shown that the degree of its accuracy, assuming errors of at most $O(1/S)$, is uniform in T.

The leading contribution to the phase of K_{scl} is the classical action

$$\begin{aligned}\mathcal{R}_{cl}(\overline{z}_f,z_i,T)=&-iS\{\ln[(1+\overline{z}_f z_{cl}(T))(1+\overline{z}_{cl}(0)z_i)]-\ln[(1+|z_f|^2)(1+|z_i|^2)]\}\\&+\int_0^T\left\{-iS\frac{\dot{\overline{z}}_{cl}z_{cl}-\overline{z}_{cl}\dot{z}_{cl}}{1+\overline{z}_{cl}z_{cl}}-H(\overline{z}_{cl},z_{cl})\right\}dt.\end{aligned} \tag{42}$$

(Note the distinction up to a factor of i in our notation and that of Ref. 5 as well as the difference in the normalization of the spin coherent states.) Classical trajectories $z_{cl}(t),\overline{z}_{cl}(t)$ are to be found from the classical equations of motion

$$\dot{z}=-i\frac{(1+\overline{z}z)^2}{2S}\frac{\partial H}{\partial\overline{z}}, \quad z(0)=z_i, \tag{43}$$

$$\dot{\overline{z}}=i\frac{(1+\overline{z}z)^2}{2S}\frac{\partial H}{\partial z}, \quad \overline{z}(T)=z_f. \tag{44}$$

The Solari–Kochetov phase, or the first quantum phase correction to K_{scl}, is expressed through

$$\phi_{SK}(t)=\frac{1}{2}\left(\frac{\partial}{\partial\overline{z}}\frac{(1+\overline{z}z)^2}{2S}\frac{\partial H}{\partial z}+\frac{\partial}{\partial z}\frac{(1+\overline{z}z)^2}{2S}\frac{\partial H}{\partial\overline{z}}\right)\Bigg|_{z=z_{cl},\overline{z}=\overline{z}_{cl}} \tag{45}$$

and represents the main subject of our discussion.

In particular, for a Hamiltonian linear in the spin operators

$$\hat{H}=\mathbf{C}\cdot\hat{\mathbf{s}}=\tfrac{1}{2}C_+\hat{s}_-+\tfrac{1}{2}C_-\hat{s}_+ +C_3\hat{s}_3, \tag{46}$$

where $C_\pm=C_1\pm iC_2$, we obtain the spin coherent-state symbol

$$H(\overline{z},z)=S\frac{C_+z+C_-\overline{z}}{1+\overline{z}z}-SC_3\frac{1-\overline{z}z}{1+\overline{z}z}, \tag{47}$$

and the Solari–Kochetov phase correction

$$\tfrac{1}{2}\phi_{SK}=-\tfrac{1}{4}(C_+z_{cl}+C_-\overline{z}_{cl})+\tfrac{1}{2}C_3. \tag{48}$$

Another example is the Hamiltonian of the Lipkin–Meshkov–Glick (LMG) model[26]

$$\hat{H}_{LMG}=\frac{w}{\sqrt{2}(2S-1)}(\hat{s}_+^2+\hat{s}_-^2)+\frac{Sw}{\sqrt{2}}, \tag{49}$$

which is quadratic in the spin operators. In this case we have

$$H_{LMG}(\bar{z},z)=\sqrt{2}Sw\frac{\bar{z}^2+z^2}{(1+\bar{z}z)^2}+\frac{Sw}{\sqrt{2}} \tag{50}$$

and

$$\frac{1}{2}\phi_{SK}^{LMG}=-\frac{w}{\sqrt{2}}\frac{(\bar{z}^2+z^2)(2+\bar{z}z)}{(1+\bar{z}z)^2}. \tag{51}$$

The latter has been calculated in Ref. 8, and its inclusion into the semiclassical propagator has provided the correct result for the tunnel splitting of the ground state in the LMG model.

To complete the presentation of the semiclassical spin propagator, we would also like to mention another quantization scheme which relies on the contravariant symbol $H^{ctr}(\bar{z},z)$ given by

$$\hat{H}=\frac{2S+1}{\pi}\int\frac{d^2z}{(1+\bar{z}z)^2}H^{ctr}(\bar{z},z)|z\rangle\langle z|. \tag{52}$$

As follows from Ref. 25, the relation between the covariant and contravariant symbols in the semiclassical limit $S\to\infty$ reads

$$H^{cov}(\bar{z},z)=[1+\Delta+O(1/S^2)]H^{ctr}(\bar{z},z), \tag{53}$$

where

$$\Delta=\frac{(1+\bar{z}z)^2}{2S}\frac{\partial^2}{\partial z\partial\bar{z}} \tag{54}$$

is the Laplace–Beltrami operator acting on the complex projective plane $CP^1=S^2$ which is a Kähler homogeneous manifold SU(2)/U(1). In view of (53), one may convert formula (41) into a form suitable for the quantization by contravariant symbols.

V. SOLARI–KOCHETOV PHASE FROM HOLSTEIN–PRIMAKOFF REPRESENTATION

Now we would like to derive the Solari–Kochetov phase exploiting the paradigm of the Sec. III. For this purpose we employ the Holstein–Primakoff representation[16] for the spin operators

$$\begin{aligned}\hat{s}_+&=\hat{s}_1+i\hat{s}_2=\hat{a}^\dagger\sqrt{2S-\hat{a}^\dagger\hat{a}},\\ \hat{s}_-&=\hat{s}_1-i\hat{s}_2=\sqrt{2S-\hat{a}^\dagger\hat{a}}\,\hat{a},\\ \hat{s}_3&=\hat{a}^\dagger\hat{a}-S,\end{aligned} \tag{55}$$

in terms of the standard annihilation and creation operators $\hat{a}$ and $\hat{a}^\dagger$ with the commutation relation $[\hat{a},\hat{a}^\dagger]=1$. It is easy to check that the operators (55) satisfy the su(2) algebra (37) as well as

$$\tfrac{1}{2}(\hat{s}_+\hat{s}_-+\hat{s}_-\hat{s}_+)+\hat{s}_3^2=S(S+1). \tag{56}$$

Besides the representation (55), there actually exist other representations of the spin algebra in terms of bosonic operators. For the review of their properties and applications in physics, we refer to Refs. 27 and 28.

It is also worth mentioning that in Ref. 29, where the instanton picture of spin tunneling in the LMG model was also considered, the sort of the Holstein–Primakoff representation was used in order to obtain the correct ground-state energy splitting. The authors established some heuristic rule which, however, required an adequate interpretation (see Discussion in Ref. 29). Our approach will allow us to refine their prescription and to establish the link to the consideration of the LMG model made in Ref. 8.

Let us introduce the semiclassical parameter $h=1/(2S)$ and define $\hat{A}=\hat{a}\sqrt{h}$ and $\hat{A}^\dagger=\hat{a}^\dagger\sqrt{h}$, such that

$$[\hat{A},\hat{A}^\dagger]=h. \tag{57}$$

We also define the operators

$$\begin{aligned}\hat{S}_+&=h\hat{s}_+=\hat{A}^\dagger\sqrt{1-\hat{A}^\dagger\hat{A}},\\ \hat{S}_-&=h\hat{s}_-=\sqrt{1-\hat{A}^\dagger\hat{A}}\,\hat{A},\\ \hat{S}_3&=h\hat{s}_3=\hat{A}^\dagger\hat{A}-\tfrac{1}{2},\end{aligned} \tag{58}$$

which satisfy the commutation relations

$$[\hat{S}_+,\hat{S}_-]=2h\hat{S}_3,\quad [\hat{S}_3,\hat{S}_\pm]=\pm h\hat{S}_\pm. \tag{59}$$

The square root in (58) should be understood as an expansion in a Taylor series

$$\sqrt{1-x}=1+\sum_{l=1}^{\infty} b_l x^l \tag{60}$$

with x replaced by $\hat{A}^\dagger\hat{A}$.

One can immediately notice that the operators (58), when expressed through $\hat{A}$ and $\hat{A}^\dagger$, do not depend explicitly on h, and that (57) is similar to (19). This enables us to apply formally the Moyal formula (14) with the Poisson bracket (20) to the operators (58), replacing everywhere $\hbar$ by h. Considering α and $\overline{\alpha}$ to be the ''Weyl symbols'' of $\hat{A}$ and $\hat{A}^\dagger$, respectively, we can thus define the ''Weyl symbols'' of the operators (58).

First we find

$$(\hat{A}^\dagger\hat{A})_W=\overline{\alpha}\alpha-\frac{h}{2}+O(h^2), \tag{61}$$

$$(\hat{A}\hat{A}^\dagger)_W=\overline{\alpha}\alpha+\frac{h}{2}+O(h^2), \tag{62}$$

$$((\hat{A}^\dagger\hat{A})^l)_W=(\overline{\alpha}\alpha)^l-\frac{hl}{2}(\overline{\alpha}\alpha)^{l-1}+O(h^2). \tag{63}$$

Exploiting the latter relation and the trivial equality

$$\frac{d}{dx}\sqrt{1-x}=-\frac{1}{2\sqrt{1-x}}=\sum_{l=1}^{\infty} l b_l x^{l-1} \tag{64}$$

we establish

$$(\sqrt{1-\hat{A}^\dagger\hat{A}})_W=\sqrt{1-\overline{\alpha}\alpha}+\frac{h}{4}\frac{1}{\sqrt{1-\overline{\alpha}\alpha}}+O(h^2). \tag{65}$$

Further use of the Moyal formula (14) leads to the desired definitions

$$(\hat{S}_+)_W=(\hat{A}^\dagger\sqrt{1-\hat{A}^\dagger\hat{A}})_W=\overline{\alpha}\sqrt{1-\overline{\alpha}\alpha}+\frac{h}{2}\frac{\overline{\alpha}}{\sqrt{1-\overline{\alpha}\alpha}}+O(h^2),$$

$$(\hat{S}_-)_W=(\sqrt{1-\hat{A}^\dagger\hat{A}}\hat{A})_W=\alpha\sqrt{1-\overline{\alpha}\alpha}+\frac{h}{2}\frac{\alpha}{\sqrt{1-\overline{\alpha}\alpha}}+O(h^2), \tag{66}$$

$$(\hat{S}_3)_W=\left(\hat{A}^\dagger\hat{A}-\frac{1}{2}\right)_W=\overline{\alpha}\alpha-\frac{1}{2}-\frac{h}{2}+O(h^2).$$

We can construct the approximate realization of the su(2) algebra with respect to the Poisson bracket (20). Taking into account (15) and the commutation relations (59) we deduce that

$$i\{(\hat{S}_+)_W,(\hat{S}_-)_W\}_{\overline{\alpha},\alpha}=2(\hat{S}_3)_W+O(h^2), \tag{67}$$

$$i\{(\hat{S}_3)_W,(\hat{S}_\pm)_W\}_{\overline{\alpha},\alpha}=\pm(\hat{S}_\pm)_W+O(h^2). \tag{68}$$

These formulas can be checked by straightforward calculation using (66).

There exists, however, a subtlety that should be spelled out here. The spin operators (58) act in the finite Hilbert space in contrast to the operators $\hat{q},\hat{p}$ and $\hat{H}(\hat{q},\hat{p})$ in the flat case which act in a different—infinite—Hilbert space. Nevertheless, the ''Weyl symbols'' (66) of the operators (58) do make sense locally in the semiclassical limit $h\to 0$, and, as we shall see, reproduce the Solari–Kochetov phase. Similarly to the flat case, we are going to recognize it for a Hamiltonian linear in the spin operators

$$\hat{H}=\frac{1}{h}\mathbf{C}\cdot\hat{\mathbf{S}}=\frac{1}{h}\left[\frac{1}{2}C_+\hat{S}_-+\frac{1}{2}C_-\hat{S}_++C_3\hat{S}_3\right] \tag{69}$$

in the difference between its principal and ''Weyl symbols''

$$H(\overline{\alpha},\alpha)-H_W(\overline{\alpha},\alpha)=\delta H(\overline{\alpha},\alpha)+O(h). \tag{70}$$

[There is a small distinction in notations in comparison with the flat case since the classical action and the naive classical Hamiltonian for spin are already divided by the semiclassical parameter h and therefore $H(\overline{\alpha},\alpha)$ and $\delta H(\overline{\alpha},\alpha)$ are of order $O(h^{-1})$ and $O(1)$, respectively.]

According to (66) the principal symbol and the next-order correction of (69) are given, respectively, by

$$H(\overline{\alpha},\alpha)=\frac{1}{h}\left[\frac{1}{2}C_+\alpha\sqrt{1-\overline{\alpha}\alpha}+\frac{1}{2}C_-\overline{\alpha}\sqrt{1-\overline{\alpha}\alpha}+C_3\left(\overline{\alpha}\alpha-\frac{1}{2}\right)\right], \tag{71}$$

$$\delta H(\overline{\alpha},\alpha)=-\frac{C_+\alpha+C_-\overline{\alpha}}{4\sqrt{1-\overline{\alpha}\alpha}}+\frac{1}{2}C_3. \tag{72}$$

To compare these expressions with (47) and (48), respectively, we use the Darboux transformation

$$z=\frac{\alpha}{\sqrt{1-\bar{\alpha}\alpha}},\quad \bar{z}=\frac{\bar{\alpha}}{\sqrt{1-\bar{\alpha}\alpha}}. \tag{73}$$

It makes the Kähler symplectic structure locally flat and converts the classical equations of motion (44) into

$$\dot{\alpha}=-ih\frac{\partial H(\bar{\alpha},\alpha)}{\partial\bar{\alpha}}+O(h),\quad \dot{\bar{\alpha}}=ih\frac{\partial H(\bar{\alpha},\alpha)}{\partial\alpha}+O(h). \tag{74}$$

The terms $O(h)$ appear due to the finiteness of the $(\alpha,\bar{\alpha})$ phase space which is a disc on the complex plane. However, they become negligible as $h\to 0$. All the other terms in (74) have the order $O(1)$.

Thus, after the transformation (73) we observe the coincidence of the principal symbols (47) and (71) and obtain the desired relation

$$\tfrac{1}{2}\phi_{SK}=\delta H. \tag{75}$$

Our consideration is not restricted to the case of Hamiltonians linear in spin operators. The formula (75) can be proved valid when the Hamiltonian is a more general element of the enveloping algebra (i.e., a polynomial in spin operators).

Let us consider, for example, the Hamiltonian

$$\hat{H}=c\cdot\frac{(2S-n)!}{(2S-1)!}(\hat{s}_+^n+\hat{s}_-^n), \tag{76}$$

where n is an arbitrary integer number. For $n=2$ and $c=w/\sqrt{2}$ it coincides (up to the constant factor) with the Hamiltonian of the LMG model (49).

We note that it is important to introduce the S-dependent coefficient in (76) so that to make the respective covariant symbol proportional to S:

$$H^{cov}=c\cdot 2S\frac{\bar{z}^n+z^n}{(1+\bar{z}z)^n}. \tag{77}$$

This allows us to identify (77) with the principal symbol, or classical Hamiltonian, which contains the leading-in-S term only.

First, we calculate the Solari–Kochetov phase according to the original formula (45), and obtain

$$\frac{1}{2}\phi_{SK}=-c\cdot\frac{n}{2}\frac{(\bar{z}^n+z^n)(n+\bar{z}z)}{(1+\bar{z}z)^n}. \tag{78}$$

Now we would like to show that the same expression can be obtained from (75) using the Holstein–Primakoff representation. We rewrite the Hamiltonian (76) in terms of the operators (58),

$$\hat{H}=c\cdot h^{-n}\frac{(h^{-1}-n)!}{(h^{-1}-1)!}(\hat{S}_+^n+\hat{S}_-^n), \tag{79}$$

and find its ''Weyl symbol''

$$(\hat{H})_W = c\cdot\frac{1}{h}\left(1+\frac{hn(n-1)}{2}\right)\left[\frac{\overline{z}^n+z^n}{(1+\overline{z}z)^n}+\frac{hn}{2}\,\frac{\overline{z}^n+z^n}{(1+\overline{z}z)^{n-1}}\right]+O(h)$$
$$=c\cdot\left[\frac{1}{h}\,\frac{\overline{z}^n+z^n}{(1+\overline{z}z)^n}+\frac{n}{2}\,\frac{(\overline{z}^n+z^n)(n+\overline{z}z)}{(1+\overline{z}z)^n}\right]+O(h). \tag{80}$$

This expression is derived due to

$$(\hat{S}_+^n)_W=(\overline{\alpha}\sqrt{1-\overline{\alpha}\alpha})^n+\frac{hn}{2}\,\overline{\alpha}^n(\sqrt{1-\overline{\alpha}\alpha})^{n-2}+O(h^2)=\frac{\overline{z}^n}{(1+\overline{z}z)^n}+\frac{hn}{2}\,\frac{\overline{z}^n}{(1+\overline{z}z)^{n-1}}+O(h^2), \tag{81}$$

$$(\hat{S}_-^n)_W=(\alpha\sqrt{1-\overline{\alpha}\alpha})^n+\frac{hn}{2}\,\alpha^n(\sqrt{1-\overline{\alpha}\alpha})^{n-2}+O(h^2)=\frac{z^n}{(1+\overline{z}z)^n}+\frac{hn}{2}\,\frac{z^n}{(1+\overline{z}z)^{n-1}}+O(h^2), \tag{82}$$

and

$$\frac{(N-n)!}{N!}=N^{-n}\left(1+\frac{1}{N}\,\frac{n(n-1)}{2}+O\left(\frac{1}{N^2}\right)\right), \tag{83}$$

for $N\equiv 2S=h^{-1}$. The relations (73) have been also employed.

Thus, we see that the leading term in (80) coincides with (77), and the next-to-leading term is in agreement with (78). We note that in our derivation of the Solari–Kochetov phase it was important to expand in a series of h the h-dependent coefficient—the ratio of two factorials—which was inherited from the quantum Hamiltonian (79).

VI. DISCUSSION

We put forward a proposition to determine the extra-phase correction in the semiclassical expression for a propagator as the difference between the principal and the Weyl symbol of the quantum Hamiltonian. Based on the Wigner–Weyl calculus, it becomes a well-defined and efficient computational prescription.

We offered to exploit this paradigm for the case of the spin propagator, making use of the Holstein–Primakoff representation of the su(2) algebra. However, there exists a subtle issue concerning the finiteness of the spin Hilbert space. It also shows up on the classical level: the classical phase space in such a representation is a flat disc which has finite volume. Nevertheless, in the semiclassical limit $S\to\infty$ the difference between the principal and the ''Weyl symbols'' appears to be well-defined. This is also confirmed by the possibility to construct the su(2) algebra realization in terms of the Poisson bracket $i\{\cdot,\cdot\}_{\overline{\alpha},\alpha}$ with the required accuracy [modulo terms $O(h^2)$]. Obviously, this amounts to defining the spin Weyl symbols only locally.

We applied the developed prescription for the calculation of the phase correction to the semiclassical spin coherent-state propagator for systems with the Hamiltonian which is either linear or nonlinear in spin operators. The presented consideration can be straightforwardly generalized for any Hamiltonian which is a polynomial in spin operators. Our prescription is rather simple from a computational point of view, and it does not require the use of the polynomial tensor operators (cf. Ref. 14).

In summary, we would like to motivate the usefulness of the ''Weyl symbol'' for spin with the following reference. The idea to introduce such a symbol is employed in order to reveal the similarity between the phase corrections to the semiclassical flat and spin propagators, and it appears quite naturally when one considers the semiclassical limit of the Holstein–Primakoff (HP) representation including the next-to-leading term. In Ref. 29 the Lipkin–Meshkov–Glick (LMG) model (quadratic in spin) has been considered using the sort of the HP representation. The authors recognized the necessity of the phase correction to the semiclassical spin propagator within their

approach and formulated the heuristic rule for its calculation. However, they stated the lack of its adequate interpretation. On the other hand, the consideration of the LMG model made in Ref. 8 uses the original Solari–Kochetov expression for the phase correction. The relation between these two approaches is missing, although both of them have led to the correct result. Thus, introducing the ''Weyl symbol'' for spin helps to bridge the gap between two different interpretations of the same extra-phase correction.

ACKNOWLEDGMENTS

The author would like to thank Evgueny Kochetov for many stimulating discussions, critical reading of the manuscript and suggestions that helped to improve the presentation considerably. Matthias Brack, Hajo Leschke, Simone Warzel and Oleg Zaitsev are acknowledged for their useful comments. The work has been supported by the Deutsche Forschunsgemeinschaft and by a travel grant of the Heisenberg-Landau program.

Institute of Physics, University of Sao Paulo, P. O. Box 66318, 05315-970 Sao Paulo, Brazil

(Received 10 October 2003; accepted 19 February 2004; published 2 April 2004)

Various Green functions of the Dirac equation with a magnetic-solenoid field (the superposition of the Aharonov–Bohm field and a collinear uniform magnetic field) are constructed and studied. The problem is considered in $2+1$ and $3+1$ dimensions for the natural extension of the Dirac operator (the extension obtained from the solenoid regularization). Representations of the Green functions as proper time integrals are derived. The nonrelativistic limit is considered. For the sake of completeness the Green functions of the Klein–Gordon particles are constructed as well. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1699483]

I. INTRODUCTION

In the present paper we continue our previous study[1–3] of the Dirac equation with a magnetic-solenoid field, constructing and studying various Green functions of this equation. We recall that the magnetic-solenoid field is the collinear superposition of the constant uniform magnetic field and the Aharonov–Bohm (AB) field. The AB field is a field of an infinitely long and infinitesimally thin solenoid. Recently the interest in such a field configuration has been renewed in connection with planar physics problems, quantum Hall effect, and the Aharonov–Bohm effect in cyclotron and synchrotron radiations.[4–9]

In principle, the Green functions can be constructed whenever complete sets of solutions of the Dirac equations are available. In this connection, one should recall that solutions of the Dirac equation with the magnetic-solenoid field in $2+1$ and $3+1$ dimensions were obtained in Ref. 1. The singularity of the AB field demands a special attention to the correct definition of the Dirac operator. The need for self-adjoint extensions in the case of the Dirac Hamiltonian with the pure AB field in $2+1$ dimensions was recognized in Refs. 10 and 11 where certain boundary conditions at the origin were established. The regularized case and peculiarities of the behavior of a spinning particle in the presence of the magnetic string were considered in Refs. 12 and 13. The problem of the self-adjoint extension of the Dirac operator with the magnetic-solenoid field was studied in Refs. 2, 3, and 14. In $2+1$ dimensions, a one-parametric family of self-adjoint Dirac Hamiltonians specified by the corresponding boundary conditions at the AB solenoid was constructed, and the spectrum and eigenfunctions for each value of the extension parameter were found. In $3+1$ dimensions, a two-parametric family of the self-adjoint Dirac Hamiltonians was constructed on the condition that the spin polarization is conserved. The corresponding spectrum and eigenfunctions for each value of the extension parameters were found as well. In Refs. 2 and 3 the procedure of solenoid regularization was also considered. The procedure implies considering the finite solenoid and then making its radius go to zero. This procedure specifies some particular boundary conditions. The values of the extension parameters corresponding to the solenoid regularization case were determined in $2+1$ and $3+1$ dimensions. Further, we call the corresponding extension the natural extension. Nonrelativistic propagators for the spinless and spin-1/2 particle

[a]Present address: Departamento de Fisica e Quimica, UNESP, Campus de Guaratingueta, Brazil. On leave from Tomsk State University, 634041, Russia. Electronic mail: gavrilovsp@hotmail.com

moving in the pure AB field were considered mainly in the relation to the AB effect. The propagator of the spinless particle was found in Refs. 15, 16, and 17 as a sum of partial propagators corresponding to homotopically different paths in the covering space of the physical background. The nonrelativistic propagator of the spin-1/2 particle in the AB field for a particular value of the self-adjoint extension parameter was discussed in Ref. 18. The relativistic scalar case for the AB field was studied in Ref. 19. The propagators and the AB effect in general gauge theories were considered in Refs. 20 and 21. Recently, vacuum polarization effects in the AB field have aroused great interest, see, for example, Refs. 22 and 23 and references therein.

In the present paper, we construct and study the Green functions of the Dirac particle in the magnetic-solenoid field in $2+1$ and $3+1$ dimensions. The physical importance of the problem is stressed by the fact that the knowledge of the Green functions in such a configuration allows one to study quantum (and quantum field) effects in the magnetic-solenoid field on a regular base. A technical specificity of the problem is related to the necessity to take into account all the peculiarities related to the self-adjoint extension problem of the Dirac operator in the background under consideration. In Sec. II we consider the $(2+1)$-dimensional case in detail. Here, constructing the Green functions, we use the exact solutions of the Dirac equation that are related to the specific values of the extension parameter. These values correspond to the natural extension, see above. The representations of the Green functions as proper time integrals are derived. In addition, we calculate the nonrelativistic Green functions as well. In Sec. III we extend the results to the $(3+1)$-dimensional case. In the Appendix, for the sake of completeness, we present the Green functions of the relativistic scalar particle.

We note that the magnetic-solenoid field belongs to such type of fields that do not violate the vacuum stability. For such fields a unique stable vacuum exists, and quantum field definitions of the Green functions below hold true.[24] In particular, the causal propagator $S^c(x,x')$ and the anticausal propagator $S^{\bar{c}}(x,x')$ are defined by the expressions

$$S^c(x,x')=i\langle 0|T\hat{\psi}(x)\hat{\bar{\psi}}(x')|0\rangle, \tag{1}$$

$$S^{\bar{c}}(x,x')=i\langle 0|\hat{\psi}(x)\hat{\bar{\psi}}(x')T|0\rangle, \tag{2}$$

where $\hat{\psi}(x)$ is the quantum spinor field in the Furry representation, satisfying the Dirac equation with the magnetic-solenoid field, $|0\rangle$ is the vacuum in this representation. The symbol of the T-product acts on both sides: it orders the field operators to its right-hand side and antiorders them to its left-hand side. The functions $S^c(x,x')$, $S^{\bar{c}}(x,x')$ can be expressed via the functions $S^{\mp}(x,x')$,

$$S^c(x,x')=\theta(\Delta x^0)S^-(x,x')-\theta(-\Delta x^0)S^+(x,x'), \quad \Delta x^0=x^0-x^{0\prime}, \tag{3}$$

$$S^{\bar{c}}(x,x')=\theta(-\Delta x^0)S^-(x,x')-\theta(\Delta x^0)S^+(x,x'), \tag{4}$$

and the latter can be calculated via a complete set ${}_{\pm}\psi_a(x)$ of solutions of the Dirac equation with the magnetic-solenoid field as

$$S^{\mp}(x,x')=i\sum_a {}_{\pm}\psi_a(x)\,\overline{{}_{\pm}\psi_a(x')}. \tag{5}$$

The solutions with the subscript $(+)$ belong to the positive energy spectrum, whereas the solutions with the subscript $(-)$ belong to the negative energy spectrum. Via a all possible quantum numbers are denoted.

The Dirac equation with the magnetic-solenoid field has the form

$$(\gamma^\nu P_\nu - M)\psi(x)=0. \tag{6}$$

Here $P_\nu = i\partial_\nu - qA_\nu(x)$, $x=(x^\nu)$, q is an algebraic charge, for electrons $q=-e<0$, M is the electron mass, and $A_\nu(x)$ are potentials of the magnetic-solenoid field. In the $(3+1)$-dimensional case $\nu=0,1,2,3$ and γ^ν are the corresponding gamma-matrices. In the $(2+1)$-dimensional case $\nu=0,1,2$ and in what follows, we employ the letter Γ to denote the gamma-matrices. We use for these matrices the following representation:

$$\Gamma^0=\sigma^3, \quad \Gamma^1=i\sigma^2, \quad \Gamma^2=-i\sigma^1,$$

where σ^i are the Pauli matrices. In cylindric coordinates (φ,r), $x^1=r\cos\varphi$, $x^2=r\sin\varphi$, the potentials of the magnetic-solenoid field have the form

$$A_0=0, \quad eA_1=[l_0+\mu+A(r)]\frac{\sin\varphi}{r}, \quad eA_2=-[l_0+\mu+A(r)]\frac{\cos\varphi}{r},$$

$$(A_3=0 \text{ in } 3+1), \quad A(r)=eBr^2/2. \tag{7}$$

Here B is the magnitude of the uniform magnetic field, and the magnitude B^{AB} of the AB field is given by the expression $B^{\mathrm{AB}}=\Phi\,\delta(x^1)\,\delta(x^2)$, where Φ is the AB-solenoid flux, $(l_0+\mu)=\Phi/\Phi_0$, $\Phi_0=2\pi/e$. It is supposed that l_0 is integer and $0\leqslant\mu<1$.

The functions $S^{\mp}(x,x')$ obey the Dirac equation (6), whereas the causal and anticausal propagators obey the nonhomogeneous Dirac equations:

$$(\gamma^\nu P_\nu - M)S^c(x,x') = -\delta(x-x'), \quad (\gamma^\nu P_\nu - M)S^{\bar{c}}(x,x') = \delta(x-x').$$

We note that the commutation function $S(x,x')$, the advanced $S^{\mathrm{adv}}(x,x')$ and the retarded $S^{\mathrm{ret}}(x,x')$ Green functions can be expressed in terms of $S^c(x,x')$, $S^{\bar{c}}(x,x')$ as follows:

$$S(x,x')=S^-(x,x')+S^+(x,x')=\mathrm{sgn}(\Delta x^0)[S^c(x,x')-S^{\bar{c}}(x,x')], \tag{8}$$

$$S^{\mathrm{adv}}(x,x')=-\theta(-\Delta x^0)S(x,x'), \quad S^{\mathrm{ret}}(x,x')=\theta(\Delta x^0)S(x,x'). \tag{9}$$

II. 2+1 DIMENSIONAL CASE

A. Sets of exact solutions

First we study the $(2+1)$-dimensional case, for which, as known,[2,3] the Dirac operator with the magnetic-solenoid field in $2+1$ dimensions possesses a one-parameter family of self-adjoint extensions. That provides a one-parameter family of boundary conditions at the origin. Following Refs. 2 and 3, we denote the extension parameter as Θ. Generally speaking, the AB symmetry is violated for the spinning particle, which is therefore sensible to the solenoid flux sign. As was demonstrated in Refs. 2 and 3, the values $\Theta=\pm\pi/2$ correspond to the natural extension, $\Theta=-\pi/2$ if the flux is positive and $\Theta=\pi/2$ if the flux is negative. Below we present a set of solutions ${}_\pm\psi_a(x)$ of (6) which we will use for Green function construction according to the formulas (5). We consider the problem separately for two values of the extension parameter.

We start with the case $\Theta=-\pi/2$. The positive energy spectrum is given by ${}_+\varepsilon$ and the negative energy spectrum is given by ${}_-\varepsilon$,

$${}_+\varepsilon=-{}_-\varepsilon=\sqrt{M^2+\omega}. \tag{10}$$

Both branches are determined by the spectrum of the quantity ω which is defined below. The solutions ${}_\pm\psi_a(x)$ can be expressed via the solutions $u(x)$ of the squared Dirac equation. The latter solutions have the form

$$\begin{gathered} {}_\pm u_{m,l,\sigma}(x)=e^{-i\,{}_\pm\varepsilon x^0}u_{m,l,\sigma}(x_\perp), \\ x_\perp=(x^1,x^2), \quad m=0,1,\ldots, \quad l=0,\pm1,\ldots, \quad \sigma=\pm1, \end{gathered} \tag{11}$$

where

$$u_{m,l,\sigma}(x_\perp)=\sqrt{\gamma}g_l(\varphi)\phi_{m,l,\sigma}(r)v_\sigma, \quad l\neq 0,$$

$$u_{m,0,+1}(x_\perp)=\sqrt{\gamma}g_0(\varphi)\phi_{m,0,+1}(r)v_{+1},$$

$$u_{m,0,-1}(x_\perp)=\sqrt{\gamma}g_0(\varphi)\phi^{ir}_{m,-1}(r)v_{-1}, \quad \gamma=e|B|,$$

and

$$g_l(\varphi)=\frac{1}{\sqrt{2\pi}}\exp\left\{i\varphi\left[l-l_0-\frac{1}{2}(1+\sigma^3)\right]\right\},$$

$$v_{+1}=\begin{pmatrix}1\\0\end{pmatrix}, \quad v_{-1}=\begin{pmatrix}0\\1\end{pmatrix}.$$

The functions $\phi_{m,l,\sigma}(r)$, $\phi^{ir}_{m,-1}(r)$ are expressed via the Laguerre functions $I_{m+\alpha,m}(\rho)$ as

$$\begin{gathered}\phi_{m,l,\sigma}(r)=I_{m+|\nu|,m}(\rho), \quad \phi^{ir}_{m,-1}(r)=I_{m-\mu,m}(\rho),\\ \rho=\gamma r^2/2, \quad \nu=\mu+l-(1+\sigma)/2.\end{gathered} \tag{12}$$

We recall that the Laguerre functions $I_{m+\alpha,m}(\rho)$ are related to the Laguerre polynomials $L^\alpha_m(x)$ [8.970, 8.972.1 (Ref. 25)] as

$$I_{m+\alpha,m}(x)=\sqrt{\frac{m!}{\Gamma(m+\alpha+1)}}e^{-x/2}x^{\alpha/2}L^\alpha_m(x).$$

For the magnetic field $B>0$, the spectrum of ω corresponding to the functions $u_{m,l,\sigma}(x_\perp)$ is

$$\omega=\begin{cases}2\gamma(m+l+\mu), & l-(1+\sigma)/2\geqslant 0,\\ 2\gamma(m+(1+\sigma)/2), & l-(1+\sigma)/2<0,\end{cases} \tag{13}$$

except the functions $u_{m,0,-1}(x_\perp)$ for which the spectrum of ω is

$$\omega=2\gamma m. \tag{14}$$

Then the complete set ${}_\pm\psi_a$ with $a=(m,l)$ has the form

$${}_\pm\psi_{m,l}(x)=N(\Gamma P+M)\,{}_\pm u_{m,l,-1}(x). \tag{15}$$

The latter form provides correct expressions both for $\omega\neq 0$ and $\omega=0$, since the states with $\omega=0$ can only be expressed in terms of the spinors with $\sigma=-1$ [we note that ${}_+\psi\equiv 0$ for $\omega=0$, nevertheless it is convenient to remain in (11) u_+ with ${}_+\varepsilon=M$]. The normalization factor with respect to the usual inner product $(\psi,\psi')=\int\psi^\dagger(x)\psi'(x)\mathrm{d}\mathbf{x}$ reads

$$N=\begin{cases}[2|{}_\pm\varepsilon|(|{}_\pm\varepsilon|-M)]^{-1/2}, & \omega\neq 0,\\ [2M]^{-1}, & \omega=0.\end{cases}$$

The quantum number l characterizes the angular momentum of the particle, m is the radial quantum number, see Ref. 1.

For $B<0$ the spectrum of states differs nontrivially from the expressions given by Eqs. (13) and (14). Here ω corresponding to $u_{m,l,\sigma}(r)$ is

$$\omega=\begin{cases} 2\gamma(m-l+1-\mu), & l-(1+\sigma)/2<0, \\ 2\gamma(m+(1-\sigma)/2), & l-(1+\sigma)/2\geqslant 0, \end{cases} \tag{16}$$

except the functions $u_{m,0,-1}(x_\perp)$ for which the spectrum of ω is

$$\omega=2\gamma(m+1-\mu). \tag{17}$$

Now we go to the case with the extension parameter $\Theta=\pi/2$. We recall that one needs for self-adjoint extensions of the radial Dirac Hamiltonian only in the subspace $l=0$ to which we refer to as the critical subspace. Thus, the only solutions in the $l=0$ subspace must be subjected to the one of asymptotic condition from a one-parametric family of boundary conditions as $r\to 0$. By this reason for $\Theta=\pi/2$, the solutions only differ from (11) in the subspace $l=0$,

$$\begin{gathered} u_{m,0,+1}(x_\perp)=\sqrt{\gamma}g_0(\varphi)\phi^{ir}_{m,+1}(r)\upsilon_{+1}, \quad \phi^{ir}_{m,+1}(r)=I_{m+\mu-1,m}(\rho), \\ u_{m,0,-1}(x_\perp)=\sqrt{\gamma}g_0(\varphi)\phi_{m,0,-1}(r)\upsilon_{-1}, \end{gathered} \tag{18}$$

where the spectrum for $u_{m,0,+1}(x_\perp)$ is given as

$$\omega=2\gamma(m+\mu), \quad B>0, \tag{19}$$

$$\omega=2\gamma m, \quad B<0. \tag{20}$$

B. Construction of Green functions

The main point in constructing the Green functions is the summations in the representation (5). In the case under consideration, this summation can be done with the help of special relations which can be established for the solutions of the Dirac equation.

Let us start with the calculation of the Green functions for the extension parameter $\Theta=-\pi/2$ and $B>0$. In this case, taking into account that the eigenfunctions u of the equation $[(\Gamma P_\perp)^2+\omega]u=0$ corresponding to any $\omega\neq 0$ obey the equations

$$\begin{gathered} \Gamma P_\perp\, {}_\pm u_{m_+,l,-\sigma}(x)=-i\sqrt{\omega}\,{}_\pm u_{m_-,l,\sigma}(x), \quad l\leqslant 0, \quad P_\perp=(0,P_1,P_2), \\ \Gamma P_\perp\, {}_\pm u_{m,l,-\sigma}(x)=i\sqrt{\omega}\,{}_\pm u_{m,l,\sigma}(x), \quad l\geqslant 1, \quad m_\pm=m+(1\pm\sigma)/2, \end{gathered} \tag{21}$$

and the explicit form of the solutions ${}_\pm\psi_{m,l}$, one can verify that for $|\varepsilon|\neq M$ the following relations hold true:

$$\begin{gathered} {}_\pm\psi_{m,l}(x)\,{}_\pm\overline{\psi}_{m,l}(x')=(\Gamma P+M)\frac{1}{2\,{}_\pm\varepsilon}e^{-i\,{}_\pm\varepsilon\Delta x^0}\sum_{\sigma=\pm 1}\phi_{m_-,l,\sigma}(x_\perp,x'_\perp)\Xi_\sigma, \quad l\leqslant 0, \\ {}_\pm\psi_{m,l}(x)\,{}_\pm\overline{\psi}_{m,l}(x')=(\Gamma P+M)\frac{1}{2\,{}_\pm\varepsilon}e^{-i\,{}_\pm\varepsilon\Delta x^0}\sum_{\sigma=\pm 1}\phi_{m,l,\sigma}(x_\perp,x'_\perp)\Xi_\sigma, \quad l\geqslant 1, \end{gathered} \tag{22}$$

where

$$\begin{gathered} \phi_{m,l,\sigma}(x_\perp,x'_\perp)=\frac{\gamma}{2\pi}e^{i[l-l_0-(1+\sigma)/2]\Delta\varphi}I_{m+\alpha,m}(\rho)I_{m+\alpha,m}(\rho'), \\ \Delta\varphi=\varphi-\varphi', \quad \alpha=\begin{cases} \mu+l-(1+\sigma)/2, & l\geqslant 1, \\ -[\mu+l-(1+\sigma)/2], & l\leqslant 0, \end{cases} \quad \Xi_{\pm 1}=(1\pm\sigma^3)/2. \end{gathered} \tag{23}$$

The above relations and Eqs. (3) and (5) allow us to represent the causal Green function in the following form:

$$S^c(x,x')=(\Gamma P+M)\Delta^c(x,x'),$$
$$\Delta^c(x,x')=i\sum_{m,l,\sigma}\left[\theta(\Delta x^0)\frac{e^{-i_+\varepsilon\Delta x^0}}{2_+\varepsilon}-\theta(-\Delta x^0)\frac{e^{-i_-\varepsilon\Delta x^0}}{2_-\varepsilon}\right]\phi_{m,l,\sigma}(x_\perp,x'_\perp)\Xi_\sigma. \tag{24}$$

Then we can use the representations

$$\theta(\Delta x^0)\frac{e^{-i_+\varepsilon\Delta x^0}}{2_+\varepsilon}-\theta(-\Delta x^0)\frac{e^{-i_-\varepsilon\Delta x^0}}{2_-\varepsilon}=\frac{1}{2\pi i}\int_{-\infty}^{\infty}\frac{e^{-ip_0\Delta x^0}}{\varepsilon^2-p_0^2-i\epsilon}\mathrm{d}p_0, \tag{25}$$

$$\frac{1}{\varepsilon^2-p_0^2-i\epsilon}=i\int_0^\infty e^{-i(\varepsilon^2-p_0^2)s}\,\mathrm{d}s, \tag{26}$$

in Eq. (24). Integrating over p_0, we obtain finally

$$\Delta^c(x,x')=\int_0^\infty f(x,x',s)\mathrm{d}s,$$
$$f(x,x',s)=\frac{1}{2(\pi s)^{1/2}}e^{(-i\Delta x_0^2/4s)}e^{i\pi/4}e^{-iM^2s}i\sum_{m,l,\sigma}e^{-i\omega s}\phi_{m,l,\sigma}(x_\perp,x'_\perp)\Xi_\sigma. \tag{27}$$

The path of the integration over s is deformed so that it goes slightly below the singular points $s_k=k\pi/\gamma$, $k=1,2,\ldots$.

Using (5), (22), and the representation

$$-\theta(-\Delta x^0)\frac{e^{-i_+\varepsilon\Delta x^0}}{2_+\varepsilon}+\theta(\Delta x^0)\frac{e^{-i_-\varepsilon\Delta x^0}}{2_-\varepsilon}=\frac{1}{2\pi i}\int_{-\infty}^{\infty}\frac{e^{-ip_0\Delta x^0}}{\varepsilon^2-p_0^2+i\epsilon}\mathrm{d}p_0,$$
$$\frac{1}{\varepsilon^2-p_0^2+i\epsilon}=i\int_{-0}^{-\infty}e^{-i(\varepsilon^2-p_0^2)s}\,\mathrm{d}s, \tag{28}$$

instead of (25) and (26) we obtain from (4),

$$S^{\bar c}(x,x')=(\Gamma P+M)\Delta^{\bar c}(x,x'),\quad \Delta^{\bar c}(x,x')=\int_{-0}^{-\infty}f(x,x',s)\mathrm{d}s, \tag{29}$$

where $f(x,x',s)$ is given by Eq. (27). The negative values for s are defined as $s=|s|e^{-i\pi}$, and the path of integration over s is deformed so that it goes slightly below the singular points $-s_k$.

We now consider the summations in (27). Applying the formula [8.976(1) (Ref. 25)] we can sum over m to get

$$\sum_{m=0}^{\infty}e^{-i2m\gamma s}I_{m+\alpha,m}(\rho)I_{m+\alpha,m}(\rho')=\exp\left\{\frac{i}{2}(\rho+\rho')\cot(\gamma s)\right\}\frac{e^{i\alpha\gamma s}e^{i\gamma s}}{2i\sin(\gamma s)}e^{-i\pi\alpha/2}J_\alpha(z),$$
$$z=\sqrt{\rho\rho'}/\sin(\gamma s), \tag{30}$$

where $J_\alpha(z)$ are the Bessel functions [8.402 (Ref. 25)], and for negative s we take $\arg s=-\pi+0$.

Similar results can be obtained for the case $B<0$. Here one should use the solutions corresponding to the spectrum of ω (16) and (17). Then these results can be united to obtain expressions which hold true for any sign of B,

$$f(x,x',s)=\sum_{l=-\infty}^{\infty} f_l(x,x',s), \quad f_l(x,x',s)=A(s)\sum_{\sigma=\pm 1}\Phi_{l,\sigma}(s)e^{-i\sigma eBs}\Xi_\sigma,$$
$$A(s)=\frac{eB}{8\pi^{3/2}s^{1/2}\sin(eBs)}\exp\left\{\frac{i\pi}{4}-iM^2s-il_0\Delta\varphi\right\}$$
$$\times\exp\left\{-\frac{i(\Delta x_0)^2}{4s}+\frac{ieB}{4}(r^2+r'^2)\cot(eBs)\right\}, \tag{31}$$

$$\Phi_{l,\sigma}(s)=e^{il_\sigma\Delta\varphi}e^{-i(l_\sigma+\mu)eBs}e^{-i\pi|l_\sigma+\mu|/2}J_{|l_\sigma+\mu|}(z), \quad l_\sigma=l-(1+\sigma)/2, \quad l\neq 0,$$
$$\Phi_{0,+1}(s)=e^{-i\Delta\varphi}e^{i(1-\mu)eBs}e^{-i\pi(1-\mu)/2}J_{1-\mu}(z), \quad \Phi_{0,-1}(s)=e^{-i\mu eBs}e^{i\pi\mu/2}J_{-\mu}(z). \tag{32}$$

Now we consider the summation over l. One can see that the following relations hold true:

$$\sum_{l=1}^{\infty}\Phi_{l,-1}(s)=\sum_{l=1}^{\infty}\Phi_{l+1,+1}(s)=e^{-i\mu eBs}Y(z,\Delta\varphi-eBs,\mu),$$

$$\sum_{l=-1}^{-\infty}\Phi_{l,-1}(s)=\sum_{l=-1}^{-\infty}\Phi_{l+1,+1}(s)=e^{-i\mu eBs}Y(z,-\Delta\varphi+eBs,-\mu),$$

where

$$Y(z,\eta,\mu)=a_1(z)+\tilde{Y}(z,\eta,\mu), \quad \tilde{Y}(z,\eta,\mu)=\sum_{l=2}^{\infty}a_l(z), \quad a_l(z)=e^{i\eta l}(-i)^{l+\mu}J_{l+\mu}(z). \tag{33}$$

The evaluation of the sum in (33) can be done in a similar way to what was done in Ref. 26. There exist all $\partial_z a_l(z)$ on the half-line, $0<z<\infty$, and the relation [8.471 (2) (Ref. 25)], $\partial_z J_\nu(z)=[J_{\nu-1}(z)-J_{\nu+1}(z)]/2$, can be used. The series $\tilde{Y}(z,\eta,\mu)$ converges and the series of derivatives $\Sigma_{l=2}^{\infty}\partial_z a_l(z)$ converges uniformly in $(0,\infty)$. It is a sufficient condition to write down $\partial_z\tilde{Y}(z,\eta,\mu)=\Sigma_{l=2}^{\infty}\partial_z a_l(z)$. Thus, one arrives to a differential equation with respect to $Y(z,\eta,\mu)$,

$$\frac{d}{dz}Y(z,\eta,\mu)=-Y(z,\eta,\mu)i\cos\eta+\frac{1}{2}(-i)^{\mu}[-ie^{i\eta}J_\mu(z)+J_{1+\mu}(z)]. \tag{34}$$

that is true on the half-line, $0<z<\infty$. The solution of (34) reads

$$Y(z,\eta,\mu)=\frac{1}{2}(-i)^{\mu}\int_0^z e^{i(y-z)\cos\eta}[-ie^{i\eta}J_\mu(y)+J_{1+\mu}(y)]dy. \tag{35}$$

This is also valid for $Y(z,-\eta,-\mu)$.

It is useful to introduce the following function:

$$f_{nc}(x,x',s)=\sum_{l\neq 0}f_l(x,x',s).$$

It defines the part of the Green functions that is the same for all extensions. With the help of the function $Y(z,\eta,\mu)$ (33), (35) one can write

$$f_{nc}(x,x',s)=A(s)e^{-i\mu eBs}e^{-ieBs\sigma^3}\{Y(z,\Delta\varphi-eBs,\mu)+Y(z,-\Delta\varphi+eBs,-\mu)$$
$$+[e^{-i\pi\mu/2}J_{\mu}(z)-e^{-i(\Delta\varphi-eBs)}e^{-i\pi(1-\mu)/2}J_{1-\mu}(z)]\Xi_{+1}\}. \tag{36}$$

The function $f_0(x,x',s)$ is specific for each extension. It is reasonable to mark it with a superscript that assumes the values of the extension parameter. Thus, for $\Theta=-\pi/2$,

$$f_0^{(-\pi/2)}(x,x',s)=A(s)e^{-i\mu eBs}[e^{-i\Delta\varphi}e^{-i\pi(1-\mu)/2}J_{1-\mu}(z)\Xi_{+1}+e^{-ieBs\sigma^3}e^{i\pi\mu/2}J_{-\mu}(z)\Xi_{-1}]. \tag{37}$$

Accordingly, the function $f(x,x',s)$ acquires the same superscript,

$$f^{(-\pi/2)}(x,x',s)=f_{nc}(x,x',s)+f_0^{(-\pi/2)}(x,x',s). \tag{38}$$

For the extension parameter $\Theta=\pi/2$, one obtains

$$f_0^{(\pi/2)}(x,x',s)=A(s)e^{-i\mu eBs}[e^{-i\Delta\varphi}e^{-i\pi(\mu-1)/2}J_{\mu-1}(z)\Xi_{+1}+e^{-ieBs\sigma^3}e^{-i\pi\mu/2}J_{\mu}(z)\Xi_{-1}],$$
$$f^{(\pi/2)}(x,x',s)=f_{nc}(x,x',s)+f_0^{(\pi/2)}(x,x',s). \tag{39}$$

Besides, one can consider particles with "spin-down" polarization in $2+1$ dimensions. The corresponding wave functions $\psi^{(-1)}(x)$ can be presented as

$$\psi^{(-1)}(x)=\sigma^1(\Gamma P-M)u(x)\,,$$

where $u(x)$ are solutions (11) of the squared Dirac equation. The propagator related to such particles can be expressed in terms of the function $\Delta^c(x,x')$ (24),

$$S^c_{(-1)}(x,x')=-\sigma^1(\Gamma P-M)\Delta^c(x,x')\sigma^1\,.$$

At this point we should make some remarks.

One can see that there exists a simple relation between scalar Green functions and Green functions of the squared Dirac equation (for the above considered extensions). Consider this relation in the example of causal Green functions. First of all, we note that the Klein–Gordon equation differs from the squared Dirac equation by the Zeeman interaction term. Then we can see (remembering the origin of the quantum number l for both spinning and spinless particles) that the scalar propagator can be derived from $\Delta^c(x,x')$ by only retaining the terms with $\sigma=-1$ only. The term $eB\sigma^3$, which is responsible for the Zeeman interaction with the uniform magnetic field, has to be removed. The Zeeman interaction with the solenoid flux, influencing the terms with $l=0$, depends on the flux sign and can be repulsive or attractive. The repulsive contact interaction case is physically equivalent to the spinless case, since in both cases the corresponding wave functions vanish at the origin. The necessary boundary condition is realized for the extension parameter $\Theta=\pi/2$. Thus, one can obtain the scalar Green functions using the coefficients of Ξ_{-1} in $f_l(x,x',s)$ (31), (32) and $f_0^{(\pi/2)}(x,x',s)$ (39). By following such prescriptions, one arrives at the expression (A1) obtained by direct calculation.

In the spinless case there is no physically preferred orientation of the plane x^1x^2. Therefore, the solenoid flux direction does not matter, i.e., the AB symmetry, $l_0\to l_0+1$, is conserved. The direction of the uniform magnetic field does not matter as well. This can be observed from the explicit form of the Green functions (A1) where the change $B\to -B$ is equivalent to the choice of the opposite orientation of the plane, $l\to -l$, $\Delta\varphi\to-\Delta\varphi$, $\Phi\to-\Phi$. In the spinning case the given spin direction breaks the symmetry related to the plane orientation. The Zeeman interaction of the spin with the background violates the AB symmetry as well as the symmetry with respect to the change $B\to -B$.

As is known, influence of the solenoid flux on the particle is observed only when the flux is not equal to an integral number of quanta ($\mu\neq 0$). In this connection it is instructive to consider

the Green functions for the particular case $\mu=0$. We note that the part $f_{nc}(x,x',s)$ (36) of the function $f(x,x',s)$ is regular everywhere, while the part $f_0(x,x',s)$ is singular at the origin. Thus, taking the limit $\mu\to 0$ in (36) and using the relation $J_1(y)=-J_0'(y)$ we get

$$f_{nc}(x,x',s)=A(s)e^{-ieBs\sigma^3}\{e^{-iz\cos(\Delta\varphi-eBs)}-J_0(z)+[J_0(z)+ie^{-i(\Delta\varphi-eBs)}J_1(z)]\Xi_{+1}\}.$$

The corresponding expression for $f_0(x,x',s)$ can be obtained in the following way. We restrict the range of z to $0<\delta<z<\infty$, where $\delta\ll 1$. Then we take the limit $\mu\to 0$ and use the continuity of the Bessel functions with respect to its index. At the end we construct the analytic continuation of the obtained expressions over the interval $(0,\delta)$. Thus, starting from either (37) or (39) we get

$$f_0(x,x',s)=A(s)[-ie^{-i\Delta\varphi}J_1(z)\Xi_{+1}+e^{ieBs}J_0(z)\Xi_{-1}],$$

where the superscript is no longer necessary. Thus, the explicit form of $f(x,x',s)$ is

$$f(x,x',s)=\frac{eB}{8\pi^{3/2}s^{1/2}\sin(eBs)}\exp\left\{\frac{i\pi}{4}-\frac{i(\Delta x_0)^2}{4s}-iM^2s-ieBs\sigma^3\right\}$$
$$\times\exp\left\{-il_0\Delta\varphi+\frac{ieB}{4}(r^2+r'^2)\cot(eBs)-\frac{ieBrr'\cos(\Delta\varphi-eBs)}{2\sin(eBs)}\right\}. \quad (40)$$

Making a transformation to Cartesian coordinates in (40) and setting $l_0=0$, one can obtain the known result of the uniform magnetic field, see for example, Ref. 27.

C. Nonrelativistic case

Consideration of the Green functions in the background under question in the nonrelativistic case is important for various physical applications. Below we study this case in detail. The solutions of the Schrödinger equation for "spin-up" particles $(+)$ and antiparticles $(-)$ in the case $\Theta=-\pi/2$ read

$$_+\phi_{m,l}(x)=e^{-iEx^0}\sqrt{\frac{\gamma}{2\pi}}e^{i(l-l_0-1)\varphi}\phi_{m,l,+1}(r),\quad E=\frac{\omega_{m,l,\sigma}}{2M},$$
$$_-\phi_{m,l}(x)=e^{-iEx^0}\sqrt{\frac{\gamma}{2\pi}}e^{-i(l-l_0)\varphi}\phi_{m,l,-1}(r),\quad l\neq 0, \quad (41)$$

$$_-\phi_{m,0}(x)=e^{-iEx^0}\sqrt{\frac{\gamma}{2\pi}}e^{il_0\varphi}\phi^{ir}_{m,-1}(r), \quad (42)$$

where the values $\omega_{m,l,\sigma}$ are defined by m,l,σ with the help of formulas (13), (14) for $B>0$, and (16), (17) for $B<0$. The solutions $_+\phi_{m,l}(x)$ ($_-\phi_{m,l}(x)$) for the "spin-down" case can be obtained from the solutions $_-\phi_{m,l}(x)$ ($_+\phi_{m,l}(x)$) for the "spin-up" case with the change $\varphi\to-\varphi$ in (41), (42).

The retarded Green functions for particles and antiparticles are defined as

$$S^{\mathrm{ret},(\pm)}(x,x')=\theta(\Delta x^0)\sum_l S_l^{(\pm)}(x,x'),\quad S_l^{(\pm)}(x,x')=i\sum_m {}_\pm\phi_{m,l}(x)\,{}_\pm\phi^*_{m,l}(x'),$$
$$S^{(\pm)}_{nc}(x,x')=\sum_{l\neq 0}S_l^{(\pm)}(x,x'), \quad (43)$$

where the part $S^{(\pm)}_{nc}(x,x')$ is the same for all extensions, whereas $S_0^{(\pm)}(x,x')$ is specific for each extension. Carrying out the summations in (43) one obtains

$$S_l^{(\pm)}(x,x')=A_{nr}(x,x')e^{\mp i\gamma\tau}e^{\pm i(l_\pm-l_0)\Delta\varphi}e^{-i|l_\pm+\mu|\gamma\tau}e^{-i\pi|l_\pm+\mu|/2}J_{|l_\pm+\mu|}(z_{nr}),$$

$$A_{nr}(x,x')=\frac{\gamma}{4\pi\sin(\gamma\tau)}\exp\left[\frac{i}{2}(\rho+\rho')\cot(\gamma\tau)\right], \tag{44}$$

$$S_{nc}^{(+)}(x,x')=A_{nr}(x,x')e^{-il_0\Delta\varphi}e^{-i(1+\mu)eB\tau}\{e^{-i\pi\mu/2}J_\mu(z_{nr})-e^{-i\Delta\varphi}e^{ieB\tau}e^{-i\pi(1-\mu)/2}J_{1-\mu}(z_{nr})$$
$$+Y(z_{nr},\Delta\varphi-eB\tau,\mu)+Y(z_{nr},-\Delta\varphi+eB\tau,-\mu)\}, \tag{45}$$

$$S_{nc}^{(-)}(x,x')=A_{nr}(x,x')e^{il_0\Delta\varphi}e^{i(1-\mu)eB\tau}\{Y(z_{nr},-\Delta\varphi-eB\tau,\mu)+Y(z_{nr},\Delta\varphi+eB\tau,-\mu)\}, \tag{46}$$

$$z_{nr}=\sqrt{\rho\rho'}/\sin(\gamma\tau),\quad \tau=\Delta x^0/2M,\quad l_\pm=l-(1\pm1)/2,\quad l\neq0,$$

whereas for $l=0$,

$$S_0^{(+)(\mp\pi/2)}(x,x')=A_{nr}(x,x')e^{-i(l_0+1)\Delta\varphi}e^{-i\mu eB\tau}e^{\mp i\pi(1-\mu)/2}J_{\pm(1-\mu)}(z_{nr}), \tag{47}$$

$$S_0^{(-)(\mp\pi/2)}(x,x')=A_{nr}(x,x')e^{il_0\Delta\varphi}e^{i(1-\mu)eB\tau}e^{\pm i\pi\mu/2}J_{\mp\mu}(z_{nr}). \tag{48}$$

The Green function in the "spin-down" case can be obtained with the change $\Delta\varphi\to-\Delta\varphi$ in (44)–(48) and with the change $S^{(\pm)}$ by $S^{(\mp)}$ in all the functions $S(x,x')$ in (44)–(48). Thus, one can see that the Green functions for the nonrelativistic particle is irregular at $r=0$ when the contact interaction is attractive.

We note that for the limiting case $B=0$ (the uniform magnetic field is absent), $S_l^{(+)(-\pi/2)}(x,x')$ coincide with the known expression for the spinless particle,[15–17] which is natural in the case of a repulsive contact interaction. $S_l^{(+)(\pi/2)}(x,x')$ for $B=0$ coincide with the corresponding expressions obtained in Ref. 18.

III. 3+1 DIMENSIONAL CASE

To obtain the Green functions in $3+1$ dimensions we use the orthonormalized solutions ${}_\pm\Psi_{p_3,m,l,\sigma}(x)$ of the Dirac equation found in Refs. 2 and 3. The quantum numbers m, l have the same meaning as in the $(2+1)$-dimensional case, p_3 is the x^3 component of the momentum, and σ is the spin quantum number. The positive energy spectrum is given by ${}_+\varepsilon$ and the negative energy spectrum is given by ${}_-\varepsilon$. They both are expressed via the quantity ω as

$${}_+\varepsilon=-{}_-\varepsilon=\sqrt{M^2+p_3^2+\omega}. \tag{49}$$

The spectra of ω are given in (13), (14) for $B>0$, and in (16), (17) for $B<0$. For $\omega\neq0$, one can present the solutions ${}_\pm\Psi_{p_3,m,l,\sigma}$ in the following form:

$${}_\pm\Psi_{p_3,m,l,\sigma}(x)=N(\gamma^\nu P_\nu+M)\,{}_\pm U_{p_3,m,l,\sigma}(x),$$

$${}_\pm U_{p_3,m,l,\sigma}(x)=\frac{1}{\sqrt{2\pi}}\,e^{-i\,{}_\pm\varepsilon x^0-ip_3x^3}U_{m,l,\sigma}(x_\perp),$$

$$U_{m,l,\sigma}(x_\perp)=\begin{pmatrix}u_{m,l,\sigma}(x_\perp)\\ \sigma^3u_{m,l,\sigma}(x_\perp)\end{pmatrix},\quad N=[2|{}_\pm\varepsilon|(|{}_\pm\varepsilon|+p_3)]^{-1/2}, \tag{50}$$

whereas for $\omega=0$,

$${}_\pm\Psi_{p_3,0,l,-\xi}(x)=N(\gamma^\nu P_\nu+M)\,{}_\pm U_{p_3,0,l,-\xi}(x),\quad \xi=\mathrm{sgn}(B),$$

where $u_{m,l,\sigma}(x_\perp)$ are the two-spinors defined in (11).

We are going to construct the Green functions using the solutions that correspond to the natural extensions of the Dirac operator, i.e., for the extension parameters chosen as $\Theta_{+1}=\Theta_{-1}=\Theta$, and $\Theta=\pm\pi/2$. First we consider the case $\Theta=-\pi/2$, and $B>0$. We note that for $\omega\neq 0$,

$$\gamma^\nu P_{\perp\nu}U_{m,l,-\sigma}=i\sqrt{\omega}U_{m,l,\sigma}, \quad l\geqslant 1,$$
$$\gamma^\nu P_{\perp\nu}U_{m_+,l,-\sigma}=-i\sqrt{\omega}U_{m_-,l,\sigma}, \quad l\leqslant 0, \tag{51}$$

where $P_\perp=(0,P_1,P_2,0)$. The summations in (5) can be done similarly to the $(2+1)$-dimensional case by the help of some important relations derived by us for the solutions (50). Namely, for the states with a given $\omega\neq 0$, the following relations hold true:

$$\sum_{\sigma=\pm 1} {}_\pm\Psi_{p_3,m,l,\sigma}(x)\,{}_\pm\overline{\Psi}_{p_3,m,l,\sigma}(x')$$
$$=\sum_{\sigma=\pm 1}\frac{1}{2\,{}_\pm\varepsilon}(\gamma^\nu P_\nu+M)\frac{1}{2}(1+\sigma\Sigma^3)\,{}_\pm\phi_{p_3,m,l,\sigma}(x,x'), \quad l\geqslant 1,$$
$$\sum_{\sigma=\pm 1} {}_\pm\Psi_{p_3,m_+,l,-\sigma}(x)\,{}_\pm\overline{\Psi}_{p_3,m_+,l,-\sigma}(x')$$
$$=\sum_{\sigma=\pm 1}\frac{1}{2\,{}_\pm\varepsilon}(\gamma^\nu P_\nu+M)\frac{1}{2}(1+\sigma\Sigma^3)\,{}_\pm\phi_{p_3,m_+,l,-\sigma}(x,x'), \quad l\leqslant 0, \tag{52}$$

and for $\omega=0$, we have

$${}_\pm\Psi_{p_3,0,l,-1}(x)\,{}_\pm\overline{\Psi}_{p_3,0,l,-1}(x')=\frac{1}{2\,{}_\pm\varepsilon}(\gamma^\nu P_\nu+M)\frac{1}{2}(1-\Sigma^3)\,{}_\pm\phi_{p_3,0,l,-1}(x,x'),$$

where

$${}_\pm\phi_{p_3,m,l,\sigma}(x,x')=\frac{1}{2\pi}e^{-i\,{}_\pm\varepsilon\Delta x^0-ip_3\Delta x^3}\phi_{m,l,\sigma}(x_\perp,x'_\perp), \quad \Delta x^3=x^3-x'^3. \tag{53}$$

The functions $\phi_{m,l,\sigma}(x_\perp,x'_\perp)$ are defined in (23). Therefore,

$$S^c(x,x')=(\gamma^\nu P_\nu+M)\Delta^c(x,x'),$$
$$\Delta^c(x,x')=i\sum_{m,l,\sigma}\int_{-\infty}^{\infty}dp_3\frac{1}{2}(1+\sigma\Sigma^3)\Big[\theta(\Delta x^0)\frac{1}{2\,{}_+\varepsilon}\,{}_+\phi_{p_3,m,l,\sigma}(x,x')$$
$$-\theta(-\Delta x^0)\frac{1}{2\,{}_-\varepsilon}\,{}_-\phi_{p_3,m,l,\sigma}(x,x')\Big]. \tag{54}$$

Applying the relations (25),(26), one obtains the proper time integral representation for Δ^c,

$$\Delta^c(x,x')=\int_0^\infty f(x,x',s)ds, \quad f(x,x',s)=\sum_{l=-\infty}^{\infty}f_l(x,x',s),$$
$$f_l(x,x',s)=D(s)\sum_{\sigma=\pm 1}\Phi_{l,\sigma}(s)e^{-i\sigma eBs}\frac{1}{2}(1+\sigma\Sigma^3),$$

$$D(s)=\frac{eB}{16\pi^2 s\sin(eBs)}\exp\left\{\frac{i}{4s}[(\Delta x_3)^2-(\Delta x_0)^2]-iM^2 s\right\}$$
$$\times\exp\left\{-il_0\Delta\varphi+\frac{ieB}{4}(r^2+r'^2)\cot(eBs)\right\}, \tag{55}$$

where $\Phi_{l,\sigma}(s)$ are defined in (32).

Carrying out similar calculations for $B<0$ one can verify that (55) is valid for both signs of B. Therefore, for any sign of B, we get

$$f_{nc}(x,x',s)=\sum_{l\neq 0} f_l(x,x',s)=D(s)e^{-ieBs(\mu+\Sigma^3)}\Big\{Y(z,\Delta\varphi-eBs,\mu)+Y(z,-\Delta\varphi+eBs,-\mu)$$
$$+[e^{-i\pi\mu/2}J_\mu(z)-e^{-i(\Delta\varphi-eBs)}e^{-i\pi(1-\mu)/2}J_{1-\mu}(z)]\frac{1}{2}(1+\Sigma^3)\Big\},$$

$$f_0^{(-\pi/2)}(x,x',s)=\tfrac{1}{2}D(s)e^{-i\mu eBs}[e^{-i\Delta\varphi}e^{-i\pi(1-\mu)/2}J_{1-\mu}(z)(1+\Sigma^3)$$
$$+e^{ieBs}e^{i\pi\mu/2}J_{-\mu}(z)(1-\Sigma^3)],$$

$$f^{(-\pi/2)}(x,x',s)=f_{nc}(x,x',s)+f_0^{(-\pi/2)}(x,x',s), \tag{56}$$

Using the corresponding solutions for the case $\Theta=\pi/2$, we obtain

$$f_0^{(\pi/2)}(x,x',s)=\tfrac{1}{2}D(s)e^{-i\mu eBs}[e^{-i\Delta\varphi}e^{-i\pi(\mu-1)/2}J_{\mu-1}(z)(1+\Sigma^3)+e^{ieBs}e^{-i\pi\mu/2}J_\mu(z)(1-\Sigma^3)],$$

$$f^{(\pi/2)}(x,x',s)=f_{nc}(x,x',s)+f_0^{(\pi/2)}(x,x',s). \tag{57}$$

IV. SUMMARY

Various Green functions of the Dirac equation with the magnetic-solenoid field are constructed as sums over exact solutions of this equation. We stress that doing that we had to take into account all the peculiarities related to the self-adjoint extension problem of the Dirac operator in the background under consideration. Both $2+1$ and $3+1$ dimensional cases are considered. Compact form for the Green functions was obtained thanks to the important relations (22) and (52) derived by us for the exact solutions under consideration. The representations of the Green functions as proper time integrals are constructed. The kernels of the proper time integrals are represented both as infinite sums over the orbital quantum number l and as simple integrals. The Green functions are obtained for two natural self-adjoint extensions, one for the positive solenoid flux and the other one for the negative solenoid flux. The physical motivation for the choice of these extensions is their correspondence to the presence of the point-like magnetic field at the origin and their close relation to the MIT boundary conditions.[23,28,29] Thus, the considered cases are of most interest for applications. Other values of the extension parameter correspond to additional contact interactions,[30] and some of the values are of physical interest as well. To find a closed form of Green functions for the arbitrary value of the extension parameter is a more complicated task. The spectra of the corresponding extensions in the critical subspace are no longer periodic for such a situation that requires to apply more exquisite calculation methods. We suppose to consider this issue in the future.

In addition, the nonrelativistic Green functions are constructed. The latter Green functions are represented for all possible types of $2+1$ dimensional nonrelativistic particles.

APPENDIX

For the sake of completeness we consider here the Green functions for the scalar particle. They are defined by Eqs. (3), (4), (8), and (9), where $S^{\mp}(x,x')$ read

$$S^{\mp}(x,x') = \pm i \sum {}_{\pm}\phi_n(x)\, {}_{\pm}\phi_n^*(x'),$$

and ${}_{\pm}\phi_n(x)$ form a complete set of orthonormalized solutions of the Klein–Gordon equation. Here we consider the natural extension of the Klein–Gordon operator for which solutions in $2+1$ dimensions and the related spectrum read[3]

$${}_{\pm}\phi_{m,l}(x) = \frac{1}{\sqrt{2\varepsilon}}\, e^{-i\,{}_{\pm}\varepsilon x^0} \sqrt{\frac{\gamma}{2\pi}}\, e^{i(l-l_0)\varphi} I_{m+|l+\mu|,m}(\rho),$$

$${}_{\pm}\varepsilon = \pm\sqrt{M^2+\omega}, \quad \omega = \gamma[1+2m+|l+\mu|+\xi(l+\mu)],$$

$$l = 0,\pm 1,\pm 2,\ldots, \quad m = 0,1,2,\ldots .$$

Using Eqs. (25), (26), (28), and (30), we calculate the causal and anticausal propagators. They have the form

$$S^c(x,x') = \int_0^{\infty} f^{sc}(x,x',s)\mathrm{d}s, \quad S^{\bar{c}}(x,x') = \int_{-0}^{-\infty} f^{sc}(x,x',s)\mathrm{d}s,$$

$$f^{sc}(x,x',s) = \sum_l f_l^{sc}(x,x',s)\,,$$

$$f_l^{sc}(x,x',s) = A(s) e^{il\Delta\varphi} e^{-i(l+\mu)eBs} e^{-i\pi|l+\mu|/2} J_{|l+\mu|}\,, \tag{A1}$$

$$f^{sc}(x,x',s) = A(s) e^{-i\mu eBs}[e^{-i\pi\mu/2} J_{\mu}(z) + Y(z,\Delta\varphi - eBs,\mu) + Y(z,-\Delta\varphi + eBs,-\mu)],$$

where $A(s)$ is given in (31), and $Y(z,\eta,\mu)$ in (33), (35). The expression (A1) can be generalized for the $(D+1)$-dimensional case, where D is the number of spacial dimensions, with the substitution $A(s)$ in (A1) by $A^{(D)}(s)$,

$$A^{(D)}(s) = A(s)\exp\left\{\frac{i}{4s}\sum_{k=3}^{D}(\Delta x_k)^2\right\}\left(\frac{e^{-i\pi/2}}{4\pi s}\right)^{(D-2)/2}, \quad D \geqslant 3.$$

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 45, NUMBER 5 MAY 2004

The role of the irreducible representations of the Poincaré group in solving Maxwell's equations

Harry E. Moses[a)]
Applimath Company, 150 Tappan Street, Brookline, Massachusetts 02445

(Received 26 February 2003; accepted 25 November 2003; published 2 April 2004)

Maxwell's equations are universally solved when the charge and current densities are given, without reference to the transformation properties of the fields or charge density–current density four vector. However these transformation properties are generally held to be *essential* physical properties of the fields and the charge density–current density four-vector. They are required if the consequences of relativity are to hold. The way the fields and four-vectors transform constitutes a representation of the Poincaré group which can be reduced to the irreducible representations of that group first given by Wigner. The use of the irreducible representations corresponds to the expansion of the fields and currents into modes which have the simplest possible transformation properties. These modes can be identified as wave functions of particles of spin 1 and mass m $(0 \leqslant m < \infty)$. We compare the solutions of Maxwell's equations utilizing the ''usual'' time-dependent Green's function and the method introduced in this paper. The solutions are identical, if we assume that the fields created by the time-dependent sources have the same initial values for the fields. Among the new results, we demonstrate the mechanism by which one can transform transverse fields for which the charge density is zero to fields that are partially longitudinal and for which the charge density source is not zero under Poincaré transformations of the space–time coordinates. We give a concrete example of a transverse current density source and one for a longitudinal current density source and show that sources lead to a mass spectrum of the photons. Longitudinal current densities always lead to *noncausal* (as noncausal is commonly understood) solutions for the fields. © *2004 American Institute of Physics.*

I. INTRODUCTION AND SUMMARY

The Poincaré group is the Lorentz group to which is added the translations of space and time. It seems universally accepted that the electromagnetic fields transform under the Poincaré transformations as an antisymmetric tensor and the current–density, charge density transform as a four-vector, These requirements are at the heart of special relativity and its extension to general relativity. Maxwell's equations are invariant under transformations of this group. However, strange as it might seem, Maxwell's equations do not seem to have been solved under the requirement of Poincaré invariance as a constraint. The intent of this paper is to solve Maxwell's equations under this requirement. We proceed by expanding the field tensor and the current-density, charge-density four-vector into the irreducible representations of the Poincaré group first given by Wigner. Such representations are the simplest representations and the expansions *must* exist for invariance. This method of obtaining solutions leads to surprising results. Only the discrete zero mass and nonzero mass representations of spin 1 and positive energy are involved in the expansions. The zero-mass expansions can be used for transverse fields (i.e., photons), *only* if the mass zero components of transverse part of the current density vector vanishes. Second, if there is a transverse, time-dependent current density which does not have a time interval during which the current vanishes,

[a)]Electronic mail: b.moses@rcn.com

only nonzero mass representations may appear in the expansions of the currents and fields. However, once the zero mass components are removed in this latter case, the solution of Maxwell's equations obtained using the method of expansions of the present paper are identical to the ''usual'' solution obtained through the use of time-dependent Green's functions if the initial conditions of both methods of solution are the same.

Another result is that solutions of Maxwell's equations, with *longitudinal* current densities and corresponding charge densities as sources, are not causal even though the *transverse* field solutions originating from transverse current densities are! Possibly this paradox can be resolved by redefining causality.

Only nonzero mass representations can occur in the transverse current densities that are used as sources for transverse fields. Is it possible that when the sources are operative, photons have mass? What is the nature of these masses? Can they be sources of gravity or can they be attracted by other masses? It would seem difficult to answer these questions experimentally, but the use of Poincaré invariance brings the possibility of photons with mass to one's attention.

II. INTEGRATION OF MAXWELL'S EQUATIONS USING TIME-DEPENDENT GREEN'S FUNCTIONS

Maxwell's equations in Gaussian units are

$$\begin{aligned}
\vec{\nabla}\times\vec{E}(\vec{x};t) &= -\frac{1}{c}\frac{\partial\vec{H}(\vec{x};t)}{\partial t},\\
\vec{\nabla}\times\vec{H}(\vec{x};t) &= \frac{1}{c}\frac{\partial\vec{E}(\vec{x};t)}{\partial t}+\frac{4\pi}{c}\vec{j}(\vec{x};t),\\
\vec{\nabla}\cdot\vec{E}(\vec{x};t) &= 4\pi\rho(\vec{x};t),\\
\vec{\nabla}\cdot\vec{H}(\vec{x};t) &= 0\,.
\end{aligned} \tag{1}$$

We shall solve these equations using group theory. However, they can also be solved as an initial value problem using a time-dependent Green's function. Do these two methods give different results? To make the discussion as clear as we can, we shall address the problem of the creation of a transverse electromagnetic field by a pulsed transverse current density. Let the time interval that the pulse is on be given by $t_1<t<t_2$. We shall assume that there is no proper subinterval such that the transverse current density $\vec{j}(\vec{x};t)$ vanishes.[1] The solution of the initial value problem for the case that there is no electromagnetic field before the current density is turned on is[2]

$$\begin{aligned}
\vec{E}(\vec{x};t) &= \frac{4\pi}{c^2}\int_{t_1}^{t}\mathrm{d}t'\int\mathrm{d}\vec{x}'\,\frac{\partial^2}{\partial t^2}D(\vec{x}-\vec{x}';t-t')\vec{j}_T(\vec{x}',t'),\\
\vec{H}(\vec{x};t) &= \frac{4\pi}{c}\vec{\nabla}\times\int_{t_1}^{t}\mathrm{d}t'\int\mathrm{d}\vec{x}'\,\frac{\partial}{\partial t}D(\vec{x}-\vec{x}';t-t')\vec{j}_T(\vec{x}',t')\,.
\end{aligned} \tag{2}$$

In the above equations $t>t_1$. Moreover, the function $D(\vec{x};t)$ is

$$D(\vec{x};t)=\frac{1}{4\pi r}\eta(r-ct)\quad\text{where } r=|\vec{x}| \tag{3}$$

and $\eta(x)$ is the Heaviside function

$$\eta(x)=\begin{cases}0 & \text{if } x<0\\ 1 & \text{if } x\geqslant 0\,.\end{cases} \tag{4}$$

The current density $\vec{j}_T(\vec{x};t)$ is the transverse part of the current density.

We now state an important theorem. Let there be a second way of solving Maxwell's equations with the initial condition that the field be zero for $t<t_1$. The two methods of solution will yield the same result. The proof is simple. Let $\vec{\Delta}_E(\vec{x};t)$ and $\vec{\Delta}_H(\vec{x};t)$ be the difference of the fields of the two solutions. Then $\vec{\Delta}_E$ and and $\vec{\Delta}_H$ satisfy Maxwell's equations without current densities as a source. Then the requirement that the the two original fields be zero when $t<t_1$ leads immediately to $\vec{\Delta}_E=\vec{\Delta}_H\equiv 0$. The solution obtained using group theory and that using Green's functions will look different but will be the same. For the sake of completeness we shall indicate a vector potential $\vec{A}(\vec{x};t)$ in the radiation gauge which can be used to obtain the general transverse electromagnetic field of Eqs. (2) and (3),

$$\vec{A}(\vec{x};t)=-\frac{4\pi}{c}\int_{t_1}^{t}\mathrm{d}t'\int \mathrm{d}\vec{x}'\frac{\partial}{\partial t}D(\vec{x}-\vec{x}';t-t')\vec{j}_T(\vec{x}';t').$$

Then

$$\vec{E}(\vec{x};t)=-\frac{1}{c}\frac{\partial}{\partial t}\vec{A}(\vec{x};t),$$

$$\vec{H}(\vec{x};t)=\vec{\nabla}\times\vec{A}(\vec{x};t)\,. \tag{5}$$

III. EIGENFUNCTIONS OF THE CURL OPERATOR

The irreducible representations of the Poincaré group for zero mass representations are given in Ref. 3, and for nonzero mass representations in the format of Foldy and Shirokov.[4]

For the sake of brevity we shall assume that the reader has available two published papers in which the writer has expanded wave functions in terms of the finite mass and massless representations.[5,6] We shall also use the eigenfunctions of the curl operator discussed in Ref. 7. We shall repeat some of the material in Ref. 7 with slight changes in notation. The eigenfunctions of the curl operator constitute a generalization of the three-dimensional Fourier transformation. They enable us to handle simply problems involving the curl and divergence operators as they act on vector fields. Let us introduce three-component "vectors" [8] $\vec{Q}(\vec{p},\lambda)$ for $\lambda=0,\pm 1$ and a real vector $\vec{p}$ by

$$\vec{Q}(\vec{p},0)=-\frac{\vec{p}}{p},$$

$$\vec{Q}(\vec{p},\lambda)=-\frac{\lambda}{\sqrt{2}}\left(\frac{p_1(p_1+i\lambda p_2)}{p(p+p_3)}-1,\frac{p_2(p_1+i\lambda p_2)}{p(p+p_3)}-i\lambda,\frac{p_1+i\lambda p_2}{p}\right)\quad\text{for }\lambda=\pm 1\,. \tag{6}$$

These vectors satisfy the orthogonality and completeness relations

$$\vec{Q}^*(\vec{p},\lambda)\cdot\vec{Q}(\vec{p},\lambda')=\delta_{\lambda,\lambda'}\,,$$

$$\sum_{\lambda=0,\pm 1}Q_i^*(\vec{p},\lambda)Q_j(\vec{p},\lambda)=\delta_{i,j}\,. \tag{7}$$

In Eq. (7) $Q_i(\vec{p},\lambda)$ is the ith component of $\vec{Q}(\vec{p},\lambda)$.

Further properties of the vectors $\vec{Q}(\vec{p},\lambda)$ are

$$\vec{p}\cdot\vec{Q}(\vec{p},\lambda)=0 \qquad \text{for} \quad \lambda=\pm 1,$$

$$\vec{p}\cdot\vec{Q}(\vec{p},0)=-p \quad \text{where} \quad p=|\vec{p}|,$$

$$\vec{p}\times\vec{Q}(\vec{p},\lambda)=-i\lambda p\vec{Q}(\vec{p},\lambda), \tag{8}$$

$$\vec{Q}^*(\vec{p},\lambda)=-\vec{Q}(\vec{p},-\lambda) \qquad \text{for} \quad \lambda=\pm 1,$$

$$\vec{Q}^*(-\vec{p},\lambda)=-\frac{p_1-\lambda i p_2}{p_1+\lambda i p_2}\vec{Q}(\vec{p},\lambda)\,.$$

The eigenfunctions $\vec{\chi}(\vec{x}|\vec{p},\lambda)$ of the $\vec{\nabla}\times$ operator are

$$\vec{\chi}(\vec{x}|\vec{p},\lambda)=\frac{e^{i\vec{p}\cdot\vec{x}}}{(2\pi)^{3/2}}\vec{Q}(\vec{p},\lambda)\,. \tag{9}$$

From the orthogonality and completeness properties of the vectors $\vec{Q}(\vec{p},\lambda)$ [Eq. (7)] we deduce these properties of the vectors $\vec{\chi}(\vec{x}|\vec{p},\lambda)$,

$$\int d\vec{x}\,\vec{\chi}^*(\vec{x}|\vec{p},\lambda)\cdot\vec{\chi}(\vec{x}|\vec{p}\,',\lambda')=\delta_{\lambda,\lambda'}\delta(\vec{p}-\vec{p}\,'),$$

$$\sum_{\lambda=0,\pm 1}\int d\vec{p}\,\chi_i^*(\vec{x}|\vec{p},\lambda)\vec{\chi}(\vec{x}\,'|\vec{p},\lambda)=\delta_{i,j}\delta(\vec{x}-\vec{x}\,')\,, \tag{10}$$

where $\chi_i(\vec{x}|\vec{p},\lambda)$ is the ith component of $\vec{\chi}(\vec{x}|\vec{p},\lambda)$. These eigenvectors have the properties

$$\vec{\nabla}\times\vec{\chi}(\vec{x}|p,\lambda)=\lambda p\vec{\chi}(\vec{x}|\vec{p},\lambda),$$

$$\vec{\nabla}\cdot\vec{\chi}(\vec{x}|\vec{p},\lambda)=0 \qquad \text{for} \quad \lambda=\pm 1,$$

$$\vec{\nabla}\cdot\vec{\chi}(\vec{x}|\vec{p},0)=\frac{-ip}{(2\pi)^{3/2}}e^{i\vec{p}\cdot\vec{x}}, \tag{11}$$

$$\vec{\chi}^*(\vec{x}|\vec{p},\lambda)=-\frac{p_1-i\lambda p_2}{p_1+i\lambda p_2}\vec{\chi}(\vec{x}|-\vec{p},\lambda),$$

$$\int d\vec{x}\,\vec{\chi}^*(\vec{x}|\vec{p},\lambda)\cdot\vec{\chi}^*(\vec{x}|\vec{p}\,',\lambda')=-\frac{p_1-i\lambda p_2}{p_1+i\lambda p_2}\delta(\vec{p}+\vec{p}\,')\delta_{\lambda,\lambda'}\,.$$

From the properties of the eigenvectors we see that *every* vector $\vec{V}(\vec{x})$ can be decomposed uniquely into a sum of two vectors,

$$\vec{V}(\vec{x})=\vec{V}_L(\vec{x})+\vec{V}_T(\vec{x}), \tag{12}$$

where

$$\vec{V}_L(\vec{x})=\int d\vec{p}\,g(\vec{p},0)\vec{\chi}(\vec{x}|\vec{p},0),$$

$$\vec{V}_T(\vec{x})=\sum_{\lambda=\pm 1}\int d\vec{p}\,g(\vec{p},\lambda)\vec{\chi}(\vec{x}|\vec{p},\lambda) \quad \text{and where}$$

$$g(\vec{p},\lambda)=\int \mathrm{d}\vec{x}\,\vec{\chi}^{\,*}(\vec{x}|\vec{p},\lambda)\cdot\vec{V}(\vec{x})\,. \tag{13}$$

Since

$$\begin{aligned}\vec{\nabla}\times\vec{V}_L(\vec{x})&=0,\\ \vec{\nabla}\cdot\vec{V}_T(\vec{x})&=0,\end{aligned} \tag{14}$$

$\vec{V}_L(\vec{x})$ is the longitudinal part of $\vec{V}(\vec{x})$ and $\vec{V}_T(\vec{x})$ is the transverse part in the Helmholtz decomposition of the vector. It is seen that $\vec{V}_L(\vec{x})$ and $\vec{V}_T(\vec{x})$ are linearly independent. Indeed they are orthogonal in the following sense:

$$\int \mathrm{d}\vec{x}\,\vec{V}_L^{*}(\vec{x})\cdot\vec{V}_T(\vec{x})=0\,. \tag{15}$$

IV. THE SOLUTION OF THE TIME-DEPENDENT MAXWELL'S EQUATIONS USING GROUP THEORY

A. The Bateman–Cunningham form of the equations

We proceed to solve Maxwell's equations using the irreducible representations of the Poincaré group.

A very convenient way of writing Maxwell's equations is the following: Define the vector $\vec{\psi}(\vec{x};t)$ by

$$\vec{\psi}(\vec{x};t)=\vec{E}(\vec{x};t)-i\vec{H}(\vec{x};t)\,. \tag{16}$$

Then Maxwell's equations are

$$\begin{aligned}\vec{\nabla}\times\vec{\psi}(\vec{x};t)&=-i\frac{1}{c}\frac{\partial}{\partial t}\vec{\psi}(\vec{x};t)-4\pi\frac{\vec{j}(\vec{x};t)}{c},\\ \vec{\nabla}\cdot\vec{\psi}(\vec{x};t)&=4\pi\rho(\vec{x};t)\,.\end{aligned} \tag{17}$$

The vector $\vec{\psi}(\vec{x};t)$ undergoes relatively simple transformations under the coordinate transformations of the Poincaré group (see Refs. 5 and 6). Without going into details at this time, it can be shown that the helicity operator $\vec{P}\cdot\vec{J}/|\vec{P}|$, where $\vec{P}=\{P_1,P_2,P_3\}$ are the infinitesimal generators of the translations and $\vec{J}=\{J_1,J_2,J_3\}$ are the infinitesimal generators of the rotations, has only a finite number of point eigenvalues. Since imaginary mass and continuous zero mass have an *infinite* number of eigenvalues for the helicity operator, such representations are precluded in the expansion of $\vec{\psi}(\vec{x};t)$. Thus we need only consider discrete 0 mass representations and real mass representations for spin 1 in the expansion of $\vec{\psi}(\vec{x};t)$.

B. Mass and Maxwell's equations

One of the labels used in characterizing the irreducible representations is the *mass* m. The range of m is $0\leqslant m<\infty$. Let us denote the four-vector current density by $\iota(\vec{x};t)$:

$$\iota(\vec{x};t)\rightarrow\{c\rho(\vec{x};t),\vec{j}(\vec{x};t)\}. \tag{18}$$

The field $\vec{\psi}(\vec{x};t)$ is a sum of representations corresponding to m. It can be shown that the range and values of m in the decomposition of $\vec{\psi}(\vec{x};t)$ are the same as those for $\iota(\vec{x};t)$. Let us assume that m can take on discrete values $\{m_1,m_2,\ldots\}$ and continuous values in some range $\mathcal{R}$. Then

$\vec{\psi}(\vec{x};t)$ can be written as a sum of representations over the discrete values of m and an integral over the continuous values.[9] Then $\vec{\psi}(\vec{x};t)$ and $\iota(\vec{x};t)$ can be written as a sum of representations over the discrete values of m and an integral over the continuous values,

$$\vec{\psi}(\vec{x};t)=\sum_{m_i}\ \vec{\psi}_{m_i}(\vec{x};t)+\int_{\mathcal{R}}\mathrm{d}m\ \vec{\psi}_m(\vec{x};t),$$
$$\iota(\vec{x};t)=\sum_{m_i}\ \iota_{m_i}(\vec{x};t)+\int_{\mathcal{R}}\mathrm{d}m\ \iota_m(\vec{x};t)\ . \tag{19}$$

For any value of m, $\vec{\psi}_m(\vec{x};t)$ and $\iota_m(\vec{x};t)$ satisfy Maxwell's equations:

$$\vec{\nabla}\times\vec{\psi}_m(\vec{x};t)=-i\frac{1}{c}\frac{\partial}{\partial t}\vec{\psi}_m(\vec{x};t)-4\pi i\frac{\vec{j}_m(\vec{x};t)}{c},$$
$$\vec{\nabla}\cdot\vec{\psi}_m(\vec{x};t)=4\pi\rho_m(\vec{x};t)\ . \tag{20}$$

If we prescribe the irreducible representations in $\iota_m(\vec{x};t)$, we can find the irreducible representations in $\vec{\psi}_m(\vec{x};t)$ through these equations.

In the next sections we shall give the irreducible representations for $\vec{\psi}_m(\vec{x};t)$ and $\iota_m(\vec{x};t)$. Surprisingly, the case for which $m=0$ is quite different than that for which $m\neq 0$.[10]

V. THE REDUCTION OF $\vec{\psi}_m(\vec{x};t)$ AND $\iota_m(\vec{x};t)$ FOR ZERO MASS

The $m=0$ representations are considered first. They correspond to a point eigenvalue of m at $m=0$. We use the results of Ref. 6 with the notation of Ref. 7,

$$\vec{\psi}_0(\vec{x};t)=\vec{\psi}_{0,L}(\vec{x};t)+\vec{\psi}_{0,T}(\vec{x};t)\ , \tag{21}$$

where $\vec{\psi}_{0,L}(\vec{x};t)$ is the longitudinal part of $\vec{\psi}_0(\vec{x};t)$ and $\vec{\psi}_{0,T}(\vec{x};t)$ is the transverse part,

$$\vec{\psi}_{0,L}(\vec{x};t)=-\int\frac{\mathrm{d}\vec{p}}{p}[\vec{\chi}(\vec{x}|\vec{p},0)f_0(\vec{p},0)e^{-ipct}+\vec{\chi}^*(\vec{x}|\vec{p},0)h_0^*(\vec{p},0)e^{ipct}],$$
$$\vec{\psi}_{0,T}(\vec{x};t)=-\sum_{\lambda=\pm 1}\int\frac{\mathrm{d}\vec{p}}{p}[p^{-\lambda}\vec{\chi}(\vec{x}|\vec{p}\lambda)f_0(\vec{p},\lambda)e^{-ipct}+p^{\lambda}\vec{\chi}^*(\vec{x}|\vec{p},\lambda)h_0^*(\vec{p},\lambda)e^{ipct}]\ . \tag{22}$$

The functions $f_0(\vec{p},\lambda)$, $h_0(\vec{p},\lambda)$ transform under the irreducible representations of the Poincaré group for mass zero, positive energy, and helicity λ. We shall show how these functions may be obtained from similar functions in the expansion of $\iota_0(\vec{x};t)$.

The vector part of $\iota_0(\vec{x};t)$, which is the current density $\vec{j}_0(\vec{x};t)$, is expanded as[11]

$$\vec{j}_0(\vec{x};t)=\vec{j}_{0,L}(\vec{x};t)+\vec{j}_{0,T}(\vec{x};t)\ , \tag{23}$$

where $\vec{j}_{0,L}(\vec{x};t)$ is the longitudinal part of the current density and $\vec{j}_{0,T}(\vec{x};t)$ is the transverse part,

$$\frac{\vec{j}_{0,L}(\vec{x};t)}{c}=\int\mathrm{d}\vec{p}\,[\vec{\chi}(\vec{x}|\vec{p},0)k_0(\vec{p},0)e^{-icpt}+\chi^*(\vec{x}|\vec{p},0)k_0^*(\vec{p},0)e^{icpt}],$$
$$\frac{\vec{j}_{0,T}(\vec{x};t)}{c}=\sum_{\lambda=\pm 1}\int\frac{\mathrm{d}\vec{p}}{p}[\vec{\chi}(\vec{x}|\vec{p},\lambda)k_0(\vec{p},\lambda)e^{-icpt}+\vec{\chi}^*(\vec{x}|\vec{p},\lambda)k_0^*(\vec{p},\lambda)e^{icpt}]\ . \tag{24}$$

Finally, the charge density $\rho_0(\vec{x};t)$ is coupled to the longitudinal part of the current density through

$$\rho_0(\vec{x};t)=\frac{1}{(2\pi)^{3/2}}\int \mathrm{d}\vec{p}[k_0(\vec{p},0)e^{i(\vec{p}\cdot\vec{x}-cpt)}+k_0^*(\vec{p},0)e^{-i(\vec{p}\cdot\vec{x}-cpt)}\,. \tag{25}$$

The three amplitudes $k_0(\vec{p},\lambda)$ for $\lambda=0,\pm1$ *are independent of each other*. If $k_0(\vec{p},0)\equiv0$, then the current density is purely transverse and the charge density is zero. More generally, Maxwell's equations can be solved independently for the transverse and longitudinal fields. From the properties of the vectors $\vec{\chi}(\vec{x}|\vec{p},0)$, it is seen that the equation of continuity is satisfied:

$$\frac{\partial\rho_0(\vec{x};t)}{\partial t}+\vec{\nabla}\cdot\vec{j}_{0,L}(\vec{x};t)=0\,. \tag{26}$$

A. The solution of Maxwell's equations for the transverse fields in terms of the transverse current densities

Maxwell's equations for the transverse fields in terms of the transverse currents are

$$\vec{\nabla}\times\vec{\psi}_{0,T}(\vec{x};t)=-i\frac{1}{c}\frac{\partial}{\partial t}\vec{\psi}_{0,T}(\vec{x};t)-4\pi i\frac{\vec{j}_{0.T}(\vec{x};t)}{c},$$
$$\vec{\nabla}\cdot\vec{\psi}_{0,T}(\vec{x};t)=0\,. \tag{27}$$

We turn our attention to the first term of Eq. (27). It is not clear at this point whether this set of equations can be integrated. We shall show that *they cannot be integrated unless the transverse current density is identically zero*. The only solution, then, is a solution of Maxwell's equations without sources, i.e., a radiation field. One finds from Eq. (22)

$$\vec{\nabla}\times\vec{\psi}_{0,t}(\vec{x};t)+i\frac{1}{c}\frac{\partial}{\partial t}\vec{\psi}_{0.T}(\vec{x};t)=-\sum_{\lambda=\pm1}\int\frac{\mathrm{d}\vec{p}}{p}\{p^{-\lambda}p\times[\lambda+1]\vec{\chi}(\vec{x}|\vec{p},\lambda)f_0(\vec{p},\lambda)e^{-icpt}$$
$$+p^{\lambda}p[\lambda-1]\vec{\chi}^*(\vec{x}|\vec{p},\lambda)h_0^*(\vec{p},\lambda)e^{icpt}\}\,. \tag{28}$$

Summing over λ we have

$$\vec{\nabla}\times\vec{\psi}_{0,T}(\vec{x};t)+i\frac{1}{c}\frac{\partial}{\partial t}\vec{\psi}_{0,T}(\vec{x};t)=-2\int\frac{\mathrm{d}\vec{p}}{p}\{\vec{\chi}(\vec{x}|\vec{p},1)f_0(\vec{p},1)e^{-icpt}$$
$$-\vec{\chi}^*(\vec{x}|\vec{p},-1)h_0^*(\vec{p},-1)e^{icpt}\}\,, \tag{29}$$

or

$$\vec{\nabla}\times\vec{\psi}_{0,T}(\vec{x};t)+i\frac{1}{c}\frac{\partial}{\partial t}\vec{\psi}_{0,T}(\vec{x};t)=-2\int\frac{\mathrm{d}\vec{p}}{p}\{\vec{\chi}(\vec{x};t)f_0(\vec{p},1)e^{-icpt}+\ \mu(\vec{p},-1)\vec{\chi}(\vec{x}|-\vec{p},-1)$$
$$\times h_0^*(\vec{p},-1)e^{icpt}\}\,. \tag{30}$$

In Eq. (30) and later

$$\mu(\vec{p},\lambda)=\frac{p_1-i\lambda p_2}{p_1+i\lambda p_2}. \tag{31}$$

In Eq. (31) use $-\vec{p}$ as the variable of integration in the term involving $\vec{\chi}(\vec{x}|-\vec{p},-1)$. Then Eq. (30) leads to

$$\vec{\nabla}\times\vec{\psi}_{0,T}(\vec{x};t)+i\frac{1}{c}\frac{\partial}{\partial t}\vec{\psi}_{0,T}(\vec{x};t)=-2\int\frac{d\vec{p}}{p}[\vec{\chi}(\vec{x}|\vec{p},1)f_0(\vec{p},1)e^{-icpt}+\mu(\vec{p},-1)\vec{\chi}(\vec{x}|\vec{p},-1)h_0^*(-\vec{p},-1)e^{icpt}]. \tag{32}$$

Similarly,

$$\vec{j}_{0,T}(\vec{x};t)=\sum_{\lambda=\pm1}\int\frac{d\vec{p}}{p}\vec{\chi}(\vec{x}|\vec{p},\lambda)[k_0(\vec{p},1)e^{-icpt}-\mu(\vec{p},\lambda)k_0^*(-\vec{p},\lambda)e^{icpt}]. \tag{33}$$

The vectors $\vec{\chi}(\vec{x}|\vec{p},1)$ and $\vec{\chi}(\vec{x}|\vec{p},-1)$ are linearly independent. We first equate the coefficients on both sides of Eq. (27),

$$f_0(\vec{p},1)e^{-ipct}=2\pi i[k_0(\vec{p},1)e^{-icpt}-\mu(\vec{p},1)k_0^*(-\vec{p},1)e^{icpt}]. \tag{34}$$

On using the fact that e^{icpt} and e^{-icpt} are also linearly independent, we find on equating the coefficients of e^{icpt},

$$k_0(\vec{p},1)\equiv0. \tag{35}$$

Similarly

$$k_0(\vec{p},-1)\equiv0\,. \tag{36}$$

Thus from Eq. (33), we have the result that the *transverse current is zero for zero mass representations as a condition of integrability*.

The functions $f_0(\vec{p},-1)$ and $h_0(\vec{p},1)$ are not obtained by this substitution, since the coefficients in front of these quantities are zero. The amplitudes are arbitrary. The vector $\vec{\psi}_{0,T}(\vec{x};t)$ using these undetermined amplitudes, namely,

$$\vec{\psi}_{0,T}(\vec{x};t)=-\int\frac{d\vec{p}}{p}[\vec{\chi}(\vec{x}|\vec{p},-1)f_0(\vec{p},-1)e^{-icpt}\vec{\chi}^*(\vec{x}|\vec{p},1)h_0^*(\vec{p},1)e^{icpt}], \tag{37}$$

is an arbitrary solution of the *homogeneous* Maxwell's equations. The functions $f_0(\vec{p},-1)$ and $h_0(\vec{p},1)$ can be obtained by imposing initial conditions on the transverse electromagnetic fields $\vec{E}_{0,T}(\vec{x};t)$ and $\vec{H}_{0,T}(\vec{x};t)$ or, equivalently on $\vec{E}_{0,T}(\vec{x};t)$ and $(\partial/\partial t)\vec{E}_{0,T}(\vec{x};t)$.

B. The solution for the longitudinal fields in terms of the longitudinal current densities

The longitudinal field $\vec{\psi}_{0,L}(\vec{x};t)$ has as its expansion the first of Eq. (22). Since the right-hand side of Eq. (20) is real,

$$H_{0,L}\equiv0\,. \tag{38}$$

Thus we need only find $\vec{E}_{0,L}(\vec{x};t)$. The two equations from which $\vec{E}_{0,L}(\vec{x};t)$ can be calculated are

$$\vec{\nabla}\cdot\vec{E}_{0,L}(\vec{x};t)=4\pi\rho_{0,L}(\vec{x};t), \tag{39}$$

$$\frac{\partial}{\partial t}\vec{E}_{0,L}(\vec{x};t)=-4\pi\vec{j}_{0,L}(\vec{x};t). \tag{40}$$

The ''traditional'' way of finding $\vec{E}_{0,L}(\vec{x};t)$ is to use Eq. (39). Since $\vec{E}_{0,L}(\vec{x};t)$ is longitudinal, we may introduce the scalar potential $V_0(\vec{x};t)$:

$$\vec{E}_{0,L}(\vec{x};t)=-\vec{\nabla}V_0(\vec{x};t)\,. \tag{41}$$

Then, on substituting into Eq. (39), one obtains Poisson's equation,

$$\nabla^2 V_0(\vec{x};t) = -4\pi\rho_0(\vec{x};t)\,. \tag{42}$$

On using the well-known solution of Eq. (42), the longitudinal field is

$$\vec{E}_{0,L}(\vec{x};t) = \vec{\nabla}\int \mathrm{d}\vec{x}\frac{\rho_0(\vec{x};t)}{|\vec{x}-\vec{x}\,'|}\,. \tag{43}$$

This result is a generalization of the static situation. It has the consequence, however, that the longitudinal field will not be causal. A change in $\rho_0(\vec{x};t)$, in general, would cause a change in the field which is transmitted instantaneously over entire space. Moreover, from Eq. (43) it is seen that $\vec{E}_{0,L}(\vec{x};t)$ falls off as $1/r^2$, as is the case with most static fields.

To test this situation mathematically, Keller[12] has suggested using Eq. (40) to obtain the longitudinal fields, assuming that the current density, rather than the charge density, is given. The charge density is then obtained from Eq. (39). We shall give a simple example later to show that the use of current densities or charge densities gives the same results.

Using Eqs. (25) and (24) we see that both $\vec{j}_{0,L}(\vec{x};t)$ depend upon the *single* complex function $k_0(\vec{p},0)$. One finds

$$f_0(\vec{p},0) = h_0(\vec{p},0) = 4\pi k_0(\vec{p},0)\,. \tag{44}$$

Thus $\vec{\psi}_{0,L}(\vec{x};t)$ is real as before. *Any* complex function $k_0(\vec{p},0)$ can be used to provide a longitudinal electric field. On the other hand, *longitudinal electric fields cannot exist without a charge density*. Though we have shown this result for $m=0$, an identical proof holds for arbitrary positive values of m.

VI. THE REDUCTION OF $\vec{\psi}_m(\vec{x};t)$ AND $\iota_m(\vec{x};t)$ FOR NONZERO MASS SOLUTIONS OF MAXWELL'S EQUATIONS

We now consider nonzero mass expansions of $\vec{\psi}(\vec{x};t) = \vec{E}(\vec{x};t) - i\vec{H}(\vec{x};t)$ into the irreducible representations of the Poincaré group corresponding to nonzero mass m and spin 1. The subscript m will be used to indicate that we are working in such a representation. The energy $c\,\omega(m,p)$ will appear where

$$\omega(m,p) = \sqrt{m^2c^2+p^2}\,. \tag{45}$$

Equation (4.15) of Ref. 6 gives us the reduction of $\vec{\psi}_m(\vec{x};t)$ to the irreducible representations of mass m and spin 1 in the Foldy–Shirokov form. Using a vector notation the reduction is

$$\begin{aligned}\vec{\psi}_m(\vec{x};t) = mc\Bigg[\int \frac{\mathrm{d}\vec{p}}{\omega(m,p)} e^{i[\vec{p}\cdot\vec{x}-c\,\omega(m,p)t]}\Bigg\{\omega(m,p)\vec{f}_m(\vec{p}) - \frac{\vec{p}}{\omega(m,p)+mc}[\vec{p}\cdot\vec{f}_m(\vec{p})] \\ - i[\vec{p}\vec{f}_m(\vec{p})]\Bigg\} + \int \frac{\mathrm{d}\vec{p}}{\omega(m,p)} e^{-i[\vec{p}\cdot\vec{x}-c\,\omega(m,p)t]}\Bigg\{\omega(m,p)\vec{h}_m^{\,*}(\vec{p}) \\ - \frac{\vec{p}}{\omega(m,p)+mc}[\vec{p}\cdot\vec{h}_m^{\,*}(\vec{p})] - i[\vec{p}\times\vec{h}_m^{\,*}(\vec{p})]\Bigg\}\Bigg]\,.\end{aligned} \tag{46}$$

The vectors $\vec{f}_m(\vec{p})$ and $\vec{h}_m(\vec{p})$ are in the space of vectors on which the operators of the irreducible representations act.

In order to split $\vec{\psi}_m(\vec{x};t)$ into its transverse and longitudinal parts we introduce the helicity representation of Ref. 11. We expand the vectors $\vec{f}_m(\vec{p})$ and $\vec{h}_m(\vec{p})$ as follows:[13]

$$\vec{f}_m(\vec{p}) = \sum_{\lambda=0,\pm1} \vec{Q}(\vec{p},\lambda) i^{\lambda} f_m(\vec{p},\lambda),$$
$$\vec{h}_m(\vec{p}) = \sum_{\lambda=0,\pm1} \vec{Q}(\vec{p},\lambda) i^{\lambda} h_m(\vec{p},\lambda)\,. \tag{47}$$

Using the results of our earlier discussion of the eigenfunctions of the curl operator, we can now expand $\vec{\psi}_m(\vec{x};t)$ in terms of these eigenfunctions. We can thereby express $\vec{\psi}_m(\vec{x};t)$ as the sum of its longitudinal and transverse parts:[14]

$$\vec{\psi}_m(\vec{x};t) = \vec{\psi}_{m,L}(\vec{x};t) + \vec{\psi}_{m,T}(\vec{x};t), \tag{48}$$

where

$$\vec{\psi}_{m,L}(\vec{x};t) = 2\,\mathrm{Re}\, imc \int \frac{d\vec{p}}{\omega(m,p)} [\vec{\chi}(\vec{x}|\vec{p},0) f_m(\vec{p},0) e^{-ic\omega(m,p)t} + \vec{\chi}^*(\vec{x}|\vec{p},0) h_m^*(\vec{p},0) e^{ic\omega(m,p)t}]\,. \tag{49}$$

The transverse part, namely, $\vec{\psi}_{m,T}(\vec{x};t)$ is

$$\vec{\psi}_{m,T}(\vec{x};t) = mci \sum_{\lambda=\pm1} \lambda \int \frac{d\vec{p}}{\omega(m,p)} [(\omega(m,p) - \lambda p)\vec{\chi}(\vec{x}|\vec{p},\lambda) f_m(\vec{p},\lambda) e^{-ic\omega(m,p)t}$$
$$+ (\omega(m,p) + \lambda p)\vec{\chi}^*(\vec{x}|\vec{p},\lambda) h_m^*(\vec{p},\lambda) e^{ic\omega(m,p)t}]. \tag{50}$$

The reduction of the four-vector current density $\iota_m(\vec{x};t)$ into its longitudinal and transverse parts is similar. The longitudinal part $\vec{j}_{m,L}(\vec{x};t)$ is

$$\frac{\vec{j}_{m,L}(\vec{x};t)}{c} = 2\,\mathrm{Re}\, imc \sum_{\lambda=\pm1} \int d\vec{p}\,\vec{\chi}(\vec{x}|\vec{p},0) k_m(\vec{p},0) e^{-ic\omega(m,p)t}. \tag{51}$$

In the above and subsequent equations Re means "real part" of the mathematical expression which follows.

The transverse part of the current density, denoted by $\vec{j}_{m,T}(\vec{x};t)$ is

$$\frac{\vec{j}_{m,T}(\vec{x};t)}{c} = 2\,\mathrm{Re}\, imc \sum_{\lambda=\pm1} \lambda \int \frac{d\vec{p}}{\omega(m,p)} \vec{\chi}(\vec{x}|\vec{p},\lambda) k_m(\vec{p},\lambda) e^{-ic\omega(m,p)t}\,. \tag{52}$$

Finally, the charge density $\rho_m(\vec{x};t)$ is given in terms of the longitudinal component of the current density by

$$\rho(\vec{x};t) = -2\,\mathrm{Re}\frac{mc}{(2\pi)^{3/2}} \int \frac{d\vec{p}}{\omega(m,p)} k_m(\vec{p},0) e^{i[\vec{p}\cdot\vec{x} - c\omega(m,p)t}\,. \tag{53}$$

The transverse current density $j_{m,T}(\vec{x};t)$ satisfies the required divergence condition

$$\vec{\nabla}\vec{j}_{m,T}(\vec{x};t) = 0\,.$$

The longitudinal part of the current density and charge density satisfy the requisite equation of continuity:

$$\vec{\nabla}\cdot\vec{j}_{m,L}(\vec{x};t) + \frac{\partial\rho(\vec{x};t)}{\partial t} = 0\,.$$

There is an essential distinction between the $m=0$ and the $m\neq 0$ cases. In the $m=0$ case. the amplitudes $k_0(\vec{p},\lambda)$ transform into new amplitudes under changes of frame *which do not involve summations over* λ. That is, the variable λ is an *invariant* of all the transformations of the Poincaré group. A consequence is that longitudinal fields and current densities remain longitudinal fields and current densities under all transformations of the group. Similarly, transverse fields and current densities remain transverse fields and current densities under all the transformations. *This result is not true for nonzero mass*.[15]

A. The solution of Maxwell's equations for the transverse fields in terms of the transverse current densities

We want now to find the solution of Maxwell's equations for the transverse fields in terms of the transverse current densities. Thus we wish to solve

$$\vec{\nabla}\times\vec{\psi}_{m,T}(\vec{x};t)=-i\frac{1}{c}\frac{\partial}{\partial t}\vec{\psi}_{m,T}-4\pi i\frac{\vec{j}_{m,T}(\vec{x};t)}{c},$$
$$\vec{\nabla}\cdot\vec{\psi}_{m,T}(\vec{x};t)=0\,, \tag{54}$$

for $m\neq 0$.

As in the massless case, the second of Eq. (54) is trivially satisfied. Our attention is thus directed to the first of the equations. Then

$$f_m(\vec{p},\lambda)=-h_m(\vec{p},\lambda)=-\frac{4\pi i k_m(\vec{p},\lambda)}{m^2c^2}\qquad \text{for}\quad \lambda=\pm 1\,. \tag{55}$$

Hence,

$$\vec{\psi}_{m,T}(\vec{x};t)=\frac{4\pi}{mc}\sum_{\lambda=\pm 1}\lambda\int\frac{d\vec{p}}{\omega(m,p)}\{[(\omega(m,p)-\lambda p)\vec{\chi}(\vec{x}|\vec{p},\lambda)k_m(\vec{p},\lambda)e^{-ic\omega(m,p)t}]$$
$$+[(\omega(m,p)+\lambda p)\vec{\chi}^*(\vec{x}|\vec{p},\lambda)k_m^*(\vec{p},\lambda)e^{ic\omega(m,p)t}]\}. \tag{56}$$

However,

$$\vec{\psi}_{m,T}(\vec{x};t)=\vec{E}_{m,T}(\vec{x};t)-i\vec{H}_{m,T}(\vec{x};t) \tag{57}$$

so that

$$\vec{E}_{m,T}(\vec{x};t)=\frac{4\pi}{mc}\sum_{\lambda=\pm 1}\lambda\int d\vec{p}[\vec{\chi}(\vec{x}|\vec{p},\lambda)k_m(\vec{p},\lambda)e^{-ic\omega(m,p)t}+\vec{\chi}^*(\vec{x}|\vec{p},\lambda)k_m^*(\vec{p},\lambda)e^{ic\omega(m,p)t}], \tag{58}$$

$$\vec{H}_{m,T}(\vec{x};t)=-\frac{4\pi i}{mc}\sum_{\lambda=\pm 1}\int\frac{p\,d\vec{p}}{\omega(m,p)}[\vec{\chi}(\vec{x}|\vec{p},\lambda)k_m(\vec{p},\lambda)e^{-ic\omega(m,p)t}$$
$$-\vec{\chi}^*(\vec{x}|\vec{p},\lambda)k_m^*(\vec{p},\lambda)e^{ic\omega(m,p)t}]\,.$$

It is readily proved that the fields of Eq. (58) satisfy Maxwell's equations with the current given by Eq. (52). *For* $m\neq 0$ *the transverse current density determines the transverse electromagnetic field completely. There is no room for initial conditions*. One must add a solution of the homogeneous Maxwell's equations, which will contain modes of zero mass only, if initial conditions are to be imposed.

B. An example of a simple transverse current density and its transverse field

All transverse current densities and corresponding solutions for the fields are given by function $k_m(\vec{p},\lambda)$ for $\lambda=\pm 1$. We shall take the function $k_m(\vec{p},\lambda)$ to be particularly simple:

$$k_m(\vec{p},\lambda)=J\delta(p_x)\delta(p_y)\delta(p_z-P)\delta_{\lambda,\mu}. \tag{59}$$

In the above equation $\mu=+1$ or $\mu=-1$ and $P>O$. In analogy to the scalar case, the general transverse current and corresponding electromagnetic field are superpositions of such vector waves.[16] The current density $\vec{j}_{m,T}$ has an x and a y component,[17]

$$\begin{aligned} j_x(z;t)&=-\frac{1}{\sqrt{4\pi^3}}\frac{J}{\omega(m,P)}\sin[Pz-c\omega(m,P)t],\\ j_y(z;t)&=-\frac{1}{\sqrt{4\pi^3}}\frac{J\mu}{\omega(m,P)}\cos[Pz-c\omega(m,P)t],\\ j_z(z;t)&\equiv 0\,. \end{aligned} \tag{60}$$

We can now give the physical meaning of μ (or more generally λ). If μ or (λ) equals 1, $\vec{j}$ is *circularly* polarized in a direction *opposite* to the direction of propagation. If μ or λ equals -1, the wave is circularly polarized in the direction of propagation. Circular polarization is a more relativistic notion than linear polarization. Moreover, circular polarization has only *two* values, whereas linear polarization must be described by a continuum of values.

We can also find the electromagnetic fields, also circular polarized, from Eq. (54),

$$\begin{aligned} E_x(z;t)&=\frac{2J\mu}{m\sqrt{\pi}}\cos[Pz-c\omega(m,P)t],\\ E_y(z;t)&=-\frac{2J}{m\sqrt{\pi}}\sin[Pz-c\omega(m,P)t],\\ E_z(z;t)&\equiv 0,\\ H_x(z;t)&=-\frac{2J}{m\sqrt{\pi}}\frac{P}{\omega(m,P)}\sin[Pz-c\omega(m,P)t],\\ H_y(z;t)&=\frac{2J}{m\sqrt{\pi}}\frac{P\mu}{\omega(m,P)}\cos[Pz-c\omega(m,P)t],\\ H_z(z;t)&\equiv 0\,. \end{aligned} \tag{61}$$

It is perhaps useful to note that when $P\to\infty$ so that $\omega(m,P)\to P$, the solution for mass m becomes that for zero mass, i.e., for the source-free circularly polarized electromagnetic wave with amplitude $2J/m$. This result is consistent with the observation that when the momentum of a massive particle is sufficiently high, many results reduce to the case of a zero mass particle, i.e., a photon in the usual sense.

C. The solution for the longitudinal fields in terms of the longitudinal current densities

We now can proceed to find the longitudinal fields in terms of the charge densities and longitudinal current densities. In a development very close to that for the zero mass case we have

$$\vec{H}_{m,L}(\vec{x};t)\equiv 0,$$
$$f_m(\vec{p},0)=h_m(\vec{p},0)=4\pi k_m(\vec{p},0)\,. \tag{62}$$

The longitudinal electric field, longitudinal current density, and charge density are closely related superpositions of waves. Since these waves have a finite velocity for a given value of $\vec{p}$, they are causal in a sense. *Any* choice of $k_m(\vec{p},0)$ (including $m=0$) will lead to a longitudinal wave of mass m. We have thus given longitudinal currents which give rise to electric fields which are longitudinally polarized. In a later section we shall give a simple example of a longitudinal current density, charge density, and time-dependent longitudinal electric field, which gives a competing view about the notion of causality for longitudinal fields.

D. Transverse fields when there are no transverse current densities

It is clear, using the above-mentioned methods, that there can be no time-dependent longitudinal fields for $m\neq 0$ as well as $m=0$ if there are no longitudinal current densities and corresponding charge densities. We can also ask the question what are the *transverse* fields if there are no transverse currents. One can show that the only fields are the zero mass fields which we discussed earlier.

VII. THE INITIAL VALUE PROBLEM FOR ELECTROMAGNETIC FIELDS: GENERAL CONSIDERATIONS

Usually electromagnetic problems are solved in a time-independent setting. We are more interested, however, in cases in which the current density and charge density are pulsed time.[18] For this reason we use the time-dependent approach which uses the full set of the time-dependent Maxwell's equations. Thus let us consider current densities $\vec{j}(\vec{x};t)$ and charge densities $\rho(\vec{x};t)$ which are nonzero only during the time interval $t_1<t<t_2$.[19] Let us consider the case before the pulse is turned on, i.e., for $t<t_1$. The only solution of Maxwell's equations for transverse waves are those corresponding to $m=0$. The solution is found as an initial value problem in which $\vec{E}_{0,T}(\vec{x};t_0)$ and $\vec{H}_{0,T}(\vec{x};t_0)$ are given for $t_0<t_1$. The solution in terms of influence functions is identical to that of the nonrelativistic treatment (Ref. 6)

For $t>t_2$ our solution for the field is again a transverse field without a current source. The initial conditions are those for the homogeneous transverse field as $t\rightarrow t_2$ from below. For $t_1<t<t_2$ we require that the currents that contain nonzero mass modes be present. As we shall see in the following, we shall require that the range of mass is $0_+<m<\infty$. Single mass fields are exceptional if the current density is prescribed. In particular, the value of $m=0$ is *excluded* because there can be no transverse currents in this case. Instead, we can pick m as close to 0 as we like from above.

VIII. A SET OF FOUR-DIMENSIONAL EIGENFUNCTIONS OF THE CURL OPERATOR: EVALUATION OF THE EXPANSION COEFFICIENTS

A. Orthogonality of the eigenfunctions

For the sake of a more nearly ''manifestly covariant'' notation, we shall enlarge our definitions slightly. We define the four-dimensional eigenfunctions of the curl operator $\vec{\vec{\Xi}}(\vec{x};t|\vec{p},\lambda,m)$ by

$$\vec{\vec{\Xi}}(\vec{x};t|\vec{p},\lambda,m)=\frac{1}{(2\pi)^{1/2}}e^{-ic\omega(m,p)t}\vec{\chi}(\vec{x}|\vec{p},\lambda)\,. \tag{63}$$

Theorem: The four-dimensional eigenfunctions $\vec{\vec{\Xi}}(\vec{x};t|\vec{p},\lambda,m)$ satisfy the orthogonality relations

$$\int d\vec{x} \int_{-\infty}^{\infty} dt\, \vec{\Xi}^*(\vec{x};t|\vec{p},\lambda,m)\cdot\vec{\Xi}(\vec{x};t|\vec{p}\,'\lambda',m') = \frac{1}{c^3}\delta(\vec{p}-\vec{p}\,')\delta_{\lambda,\lambda'}\delta(m-m')\frac{\omega(m,p)}{m}. \tag{64}$$

From Eqs. (10) and (63),

$$\int d\vec{x} \int_{-\infty}^{\infty} dt\, \vec{\Xi}^*(\vec{x};t|\vec{p},\lambda,m)\cdot\vec{\Xi}(\vec{x};t|p',\lambda',m') = \frac{1}{2\pi}\delta(\vec{p}-\vec{p}\,')\int_{-\infty}^{\infty} dt \exp\{ict[\omega(m',p)-\omega(m,p)]\}$$

$$= \frac{1}{c}\delta(\vec{p}-\vec{p}\,')\delta_{\lambda,\lambda'}\delta[\omega(m',p)-\omega(m,p)]. \tag{65}$$

But on using δ-function identities and the fact that $m+m'\geqslant 0$,

$$\begin{aligned}\delta[\omega(m',p)-\omega(m,p)] &= \delta[(\omega(m',p)-\omega(m,p))(\omega(m',p)+\omega(m,p))] \\ &\quad\times[(\omega(m',p)+\omega(m,p))] \\ &= \delta[((m'c)^2+p^2)-((mc)^2+p^2)](\omega(m',p)+\omega(m,p)) \\ &= \frac{1}{c^2}\delta[(m'-m)(m'+m)](\omega(m',p)+\omega(m,p)) \\ &= \frac{1}{c^2}\delta(m'-m)\frac{\omega(m,p)}{m}.\end{aligned} \tag{66}$$

On using Eq. (66) in Eq. (65), Eq. (64) follows.

Finally, one can show

$$\int d\vec{x} \int_{-\infty}^{\infty} dt\, \vec{\Xi}^*(\vec{x};t|\vec{p},\lambda,m)\cdot\vec{\Xi}^*(\vec{x};t|\vec{p}\,',\lambda',m') = 0. \tag{67}$$

B. Eigenfunctions and eigenvalues of the mass

The functions $k_m(\vec{p},\lambda)$ are eigenfunctions corresponding to eigenvalues m in the continuous spectrum of the mass $0\leqslant m<\infty$ except in the following cases: If there are values of m in the vicinity of $m_1, m_2, \ldots$ such that

$$k_m(\vec{p},\lambda) = \delta(m-m_i)\hat{k}_{m_i}(\vec{p},\lambda) \tag{68}$$

and such that

$$\sum_{\lambda=\pm 1} m_i \int \frac{d\vec{p}}{\omega(m_i,p)}|\hat{k}_{m_i}(\vec{p},\lambda)|^2 < \infty, \tag{69}$$

then m_i is a *point* eigenvalue of the mass for which the corresponding eigenfunction is $\hat{k}_{m_i}(\vec{p},\lambda)$. Point eigenvalues can be added to the current density by choosing functions $\hat{k}_{m_i}(\vec{p},\lambda)$ which satisfy Eq. (69). Generally we shall be interested in nonzero point eigenvalues, since a zero point eigenvalue in the current density is a situation in which Maxwell's equations cannot be integrated. The case in which $m=0$ in the *continuous* spectrum contributes nothing.[20]

C. The completeness relation for the eigenfunctions

In a rather similar fashion one can obtain the completeness *Theorem* if there are no point eigenvalues m_i,

$$\sum_{\lambda=0,\pm1}\int_0^\infty m\,dm\int\frac{d\vec{x}}{\omega(m,p)}\Xi_i^*(\vec{x};t|\vec{p},\lambda,m)\Xi_j(\vec{x}';t'|\vec{p},\lambda,m)=\frac{1}{c^3}\delta_{i,j}\delta(\vec{x}-\vec{x}')\,\delta(t-t')\,. \tag{64a}$$

In Eq. (64a) $\Xi_i(\vec{x};t|\vec{p},\lambda,m)$ is the ith component of the vector $\vec{\Xi}(\vec{x};t|\vec{p},\lambda,m)$.

We shall now restrict our discussion to the $m>0$ case, since that for $m=0$ has already been discussed. For a general transverse current density $\vec{j}_T(\vec{x};t)$ we have the expansion

$$\frac{\vec{j}_T(\vec{x};t)}{c}=\sqrt{8\pi}\,c\,\mathrm{Re}\,i\sum_{\lambda=\pm1}\int_0^\infty m\,dm\int\frac{d\vec{p}}{\omega(m,p)}\vec{\Xi}(\vec{x};t|\vec{p},\lambda,m)k_m(\vec{p},\lambda)\,. \tag{70}$$

Thus for $\lambda=\pm1$,[21]

$$k_m(\vec{p},\lambda)=\frac{-ic^2}{\sqrt{2\pi}}\int_{-\infty}^\infty dt\int d\vec{x}\,\vec{\Xi}^*(\vec{x},t|\vec{p},\lambda,m)\cdot\vec{j}_T(\vec{x};t). \tag{71}$$

Also

$$\begin{aligned}\vec{E}_T(\vec{x};t)&=\mathrm{Re}\frac{\sqrt{128\pi^3}}{c^3}\sum_{\lambda=\pm1}\lambda\int_0^\infty\frac{dm}{m}\int d\vec{p}\,\vec{\Xi}(\vec{x};t|\vec{p},\lambda,m)k_m(\vec{p},\lambda),\\ \vec{H}_T(\vec{x};t)&=\mathrm{Re}\frac{\sqrt{128\pi^3}}{c^3}i\sum_{\lambda=\pm1}\int_0^\infty\frac{dm}{m}\int\frac{p\,d\vec{p}}{\omega(m,p)}\vec{\Xi}(\vec{x};t|\vec{p},\lambda,m)k_m(\vec{p},\lambda)\,.\end{aligned} \tag{72}$$

The longitudinal part of the current density is

$$\vec{j}_L(\vec{x};t)=2\sqrt{2\pi}\,c\,\mathrm{Re}\int_0^\infty m\,dm\int d\vec{p}\;\vec{\Xi}(\vec{x};t|\vec{p},0,m)k_m(\vec{p},0)\,. \tag{73}$$

The charge density is

$$\rho(\vec{x};t)=-2\,\mathrm{Re}\frac{1}{(2\pi)^{3/2}}\int_0^\infty m\,dm\int\frac{p\,d\vec{p}}{\omega(m,p)}k_m(\vec{p},0)\,e^{i[\vec{p}\cdot\vec{x}-c\omega(m,p)t]}\,. \tag{74}$$

The equation of continuity is again satisfied.

Because of the completeness and orthogonality relations, *any* current density $\vec{j}(\vec{x};t)=\vec{j}_T(\vec{x};t)+\vec{j}_L(\vec{x};t)$ can be expanded as in Eqs. (70) and (73). The charge density *must* be given by Eq. (74).[22] In the expansions we can include point eigenvalues m_i by requiring corresponding $\delta(m-m_i)$ functions in the coefficients $k_m(\vec{p},\lambda)$.

The expansions for the four-current density or for fields do not in themselves assure us that the theory is Poincaré-invariant. One must have the same expansions in *any* frame of reference. This invariance of expansions can be achieved by requiring the amplitudes $k_m(\vec{p},\lambda)$ to transform as mass m, spin 1, and positive energy representations in the helicity description of the irreducible representations of the Poincaré group.

IX. VELOCITY OF CURRENT DENSITY WAVES AND ELECTROMAGNETIC WAVES

Equations (54) and (55) indicate that for waves of a single frequency, current-density and fields, the waves propagate with a velocity $c\omega(m,p)/p$. That is, these waves propagate with a velocity greater than the speed of light. Relativity is generally thought to preclude this result. The usual reconciliation with relativity involves the assumption that we are dealing with a *group* and that it is the group whose velocity we require. The usual expressions for the group velocity follow:

$$v_g = c\left\{\frac{\partial}{\partial p}\omega(m,p)\right\}_{p=p_0} = \frac{cp_0}{\omega(m,p_0)} < c\,. \tag{75}$$

In deriving this result it is assumed that $k_m(\vec{p},\lambda)$ has a sharp peak at $p \equiv |\vec{p}| = p_0$.[23]

One of the difficulties which we have found is that one has approximate periodicity in p-space even when the peak is not extremely sharp.[24]

However, the principal difficulty, as pointed out by Stratton, is that it is hard to define velocity in a dispersive medium. When the mass is zero, velocity is relatively easy to define because the wave moves rigidly with increasing time. One can follow any point as it moves. When there is dispersion, it is not clear how to define velocity because the wave changes form with time.

X. IS A QUANTUM INTERPRETATION FOR MASSIVE PHOTONS POSSIBLE? A BASIS FOR CONJECTURES

We have not needed a quantum interpretation for the complex amplitudes $k_m(\vec{p},\lambda)$ to obtain our results. In the spirit of the application of group theory to quantum mechanics it is tempting to call the complex amplitudes $k_m(\vec{p},\lambda)$ wave functions of a particle of spin 1 and mass m. Perhaps one can be made more comfortable with this idea by reviewing the process by which the dynamical variables of relativistic quantum particles are introduced from classical analogues and how they are related to the infinitesimal generators of the Poincaré group. This relationship is implicit or explicit in most treatments of the application of the theory of Poincaré groups to elementary particle theory.

A. The infinitesimal generators of the Poincaré group

1. Poincaré transformations: Parametrization of the transformations

Let us consider the time–space four-vector x^μ with the components $\{x^0 = -x_0 = ct, x^i = x_i\}$ for $i = 1,2,3$. We define the *translation transformation* $T(a^\mu)$ as mapping x^μ into the four-vector x'^μ where

$$x^{\mu\prime} = T(a^\mu)x^\mu \equiv x^\mu - a^\mu. \tag{76}$$

The inverse transformation $T^{-1}(a^\mu)$ is

$$T^{-1}(a^\mu)x^\mu = x^\mu + a^\mu\,. \tag{77}$$

To define the pure rotation transformation and pure Lorentz transformation it is convenient to regard the four-vector x^μ as being a column vector which we shall denote by x_c. We use $\vec{x}$ to denote the vector which is made up of the space components of x_c. The proper *rotation transformation* is accomplished using a three-by-three matrix acting on $\vec{x}$ to produce a vector $\vec{x}'$. The transformation is such that the length of $\vec{x}'$ is equal to the length of $\vec{x}$ and the determinant of the matrix is unity. The component x^0 of x_c is unaffected by this transformation. The matrix is called the rotation matrix and is uniquely characterized by a vector $\vec{\theta}$. By one of Euler's theorems on rotations, *every proper rotation can be accomplished by a rotation around an axis*. The direction of $\vec{\theta}$ is the direction of the axis of rotation and $\theta = |\vec{\theta}|$, $(0 < \theta < 2\pi)$ is the angle of rotation. We therefore parametrize the rotation by $\vec{\theta}$ and denote both the rotation and the associated matrix by

$R(\vec{\theta})$. As is well known the product of two rotations is also a rotation. That is, if one performs two rotations one after the other, the resulting transformation is also a rotation. One says that the set of rotations form a group.

The *pure Lorentz transformation* maps the set of time–space coordinates from an initial frame to a moving from whose axes are parallel to the axes of the original frame and whose origins coincide at time $t=0$ in both frames. In addition one requires that the sign of time is preserved, or to use an accepted term, the transformation is orthochronous. The transformation and the associated 4×4 transformation matrix will be denoted by $L(\vec{\beta})$, where the direction of $\vec{\beta}$ points in the direction of the line connecting the origin of the moving frame to the origin of the fixed frame. The absolute value $\beta=|\vec{\beta}|$ is found from

$$\cosh\beta=\frac{1}{\sqrt{1-(v/c)^2}}, \tag{78}$$

where v is the velocity of the moving frame with respect to the original frame. The set of pure Lorentz transformations do *not* form a group, since the product of two Lorentz transformations involves the introduction of a rotation matrix.

The Poincaré group can have many parametrizations but the number of independent parameters is ten. We shall parametrize the group using the four parameters, which are the components of the column vector a^μ, the three components of $\vec{\theta}$, and the three components of $\vec{\beta}$. An element of the Poincaré transformation will be written as $G(a^\mu,\vec{\theta},\vec{\beta})$ where

$$G(a^\mu,\vec{\theta},\vec{\beta})=T(a^\mu)R(\vec{\theta}),L(\vec{\beta})\,. \tag{79}$$

The multiplication law

$$G(a^\mu,\vec{\theta},\vec{\beta})G(a^{\mu'},\vec{\theta}',\vec{\beta}')=G(a^{\mu''},\vec{\theta}'',\vec{\beta}'') \tag{80}$$

is obtained by carrying out the transformations of the four-vector x^μ in the order indicated. One will be able to find the set of parameters $a^{\mu''},\vec{\theta}'',\vec{\beta}''$ in terms of the sets $a^\mu,\vec{\theta},\vec{\beta}$ and $a^{\mu'},\vec{\theta}',\vec{\beta}'$. The transformations also include the identity $G(0,0,0)$ and the inverse of $G(a^\mu,\vec{\theta},\vec{\beta})$, namely $L(-\vec{\beta})R(-\vec{\theta})T(-a^\mu)$. The abstract Poincaré consists of elements which we shall also label by $G(a^\mu,\vec{\theta},\vec{\beta})$ which are in a one-to-one correspondence with the set of transformations. To have a representation of the group we must have Hilbert space upon which unitary operators $\mathcal{G}(a^\mu,\vec{\theta},\vec{\beta})$ acting on elements of the Hilbert space have the same multiplication properties as the abstract group elements $G(a^\mu.\vec{\theta},\vec{\beta})$. In general, the Hilbert space of representations can be split up into subspaces on which the operators of the representation can act without taking the vectors in the subspace out of the subspace. One of the objectives of representation theory is to find all of the subspaces which have no other proper subspaces in them that can support a representation. Each such subspace and the operators having the group properties acting on it constitute an *irreducible* representation of the group. What we have done in Refs. 5 and 6 and applied in the present paper is to show how one can obtain the irreducible representation of the electromagnetic fields and currents and find solutions of Maxwell's equations with sources in terms of the irreducible representations. Moreover, the solutions satisfy the relativistic properties required of them. In what follows we shall discuss the relationship between the group operators and the dynamical variables of relativistic particles to indicate where our conjecture comes from. Instead of using $\mathcal{G}$ as above to indicate the unitary operators which represent the group elements, we shall use G to prevent an overload of notation.

2. The infinitesimal generators of the representation

The group member $T(a^\mu)=G(a^\mu,0,0), R(\vec{\theta})=G(0,\vec{\theta},0), L(\vec{\beta})=G(0,0,\vec{\beta})$ can be written in the form

$$T(a^\mu)=\exp\left(i\sum_{\mu=0,1,2,3} a_\mu P^\mu\right),$$

$$R(\vec{\theta})=\exp(i\vec{\theta}\cdot\vec{J}), \tag{81}$$

$$L(\vec{\beta})=\exp(i\vec{\beta}\cdot\vec{K})\,.$$

In Eq. (81) P^μ ($\mu=0,1,2,3$) are Hermitian operators and are the infinitesimal generators of the translation operators. Similarly J^i and K^i are the infinitesimal generators of the rotation and pure Lorentz transformation operators.

One can find the commutation rules for the infinitesimal generators from the multiplication laws of the unitary operators $G(a^\mu,\vec{\theta},\vec{\beta})$. For later use it is convenient to introduce the operator $H=cP^0$, which will be called the energy operator or Hamiltonian. The commutation rules for the infinitesimal generators are

$$\begin{gathered}
[H,P^i]=0,\\
[P^i,P^j]=0,\\
[J^1,J^2]=J^3 \quad \text{(cyc.)},\\
[J^i,P^i]=0,\\
[J^1,P^2]=[P^1,J^2]=iP^3 \quad \text{(cyc.)},\\
[J^i,K^i]=0,\\
[J^1,K^2]=[K^1,K^2]=iK^3 \quad \text{(cyc.)},\\
[K^1,K^2]=-iJ^3 \quad \text{(cyc.)},\\
[K^i,H]=icP^i,\\
[K^i,P^j]=i\delta_{ij}\,.
\end{gathered} \tag{82}$$

We have indicated that the infinitesimal generators can be obtained from the finite unitary operators which represent the group. Remarkably, one can find *all* the irreducible representations of the infinitesimal generators and integrate them to obtain the unitary operators.

If the infinitesimal generators are given in an irreducible representation, then the operator M defined by

$$M=\frac{1}{c}\sqrt{\frac{H^2}{c^2}-\sum_{i=1}^{3}(P^i)^2} \tag{83}$$

is a real positive number called the ''mass.'' Those representations for which $M=0$ and which are of interest to us, are further classified by their helicity λ, again a constant for each representation which takes on one of the values $\lambda=0,\pm1$. These representations for which $\lambda=\pm1$ are identified with a free photon. For $M>0$ the helicity no longer labels the representation but the ''spin,'' which in our case is unity, is a label. The sign of the energy is another marker for the irreducible

representations for both $M=0$ and $M>0$. The negative energy representations are ''converted'' to positive energy representations through the use of anti-unitary operators. The ''wave functions'' which we have introduced in Sec. III are in the Hilbert space of the irreducible representations of the Poincaré group.

B. The dynamical variables of quantized relativistic particles

We shall motivate our conjectures that the irreducible representations of the Poincaré group introduce the notion of photons with mass. We shall show that knowing the irreducible representations of the Poincaré group is equivalent to knowing the quantum dynamical variables of a particle of spin 1.

Quantization of classical particle dynamics is carried out by replacing the classical Poisson bracket of two classical dynamical variables by a commutator of corresponding quantum operators divided by i times Planck's constant, i.e.,

$$\{a,b\}\rightarrow\frac{[A,B]}{i\hbar}.$$

In the above a and b are two classical dynamical variables and A,B are the corresponding quantum dynamical variables.

The dynamical variables of an unquantized relativistic particle are taken to be the three components of the momentum $p^i=p_i$, the energy $H=c\sqrt{m^2c^2+\Sigma_{i=1}^3(p^i)^2}$ and the angular momentum tensor $J^{\mu\nu}=x^\mu p^\nu-x^\nu p^\mu$.[25] The time-like component of the momentum four momentum–energy four-vector p^0 is $p^0=H/c$.

The angular momentum tensor is written in nonrelativistic form as

$$J^1=J^{23}\quad(\text{cyc.}),\tag{84}$$

$$K^i=J^{0i}.\tag{85}$$

The quantities J^i are the components of the angular momentum vector. The dynamical variables K^i are called ''boosts'' and are somewhat analogous to the position variables x^i.

We now denote the quantum dynamical variable analogues by the subscript ''q'' and the operators corresponding to the infinitesimal generators without this subscript. We find that the quantum variables satisfy the *same* commutation rules as the infinitesimal generators up to a scale factor. All the quantum relativistic dynamical variables are given by

$$\begin{aligned}P_q^i&=P^i\hbar,\\ J_q^i&=J^i\hbar,\\ K_q^i&=K^i\hbar,\\ H_q&=H\hbar.\end{aligned}\tag{86}$$

If m is the mass in the Poincaré description (dimension *time/length*^{2}) and m_q in the quantized particle description (dimension *mass*), then

$$m_q=m\hbar\ .\tag{87}$$

The functions which we have called $k_m(\vec{p},\lambda)$ are wave functions upon which the infinitesimal generators of the Poincaré representations *and* the dynamical variables of quantized relativistic particles act. It should also be noted that the quantum particle operators have the correct physical

dimensions. For example, if the Poincaré infinitesimal generators P^i (or rather their eigenvalues) have the dimension 1/*length*, then the eigenvalues of the particle operators P_q^i have the correct dimensions of linear momentum.

We shall give an example of how the commutation relations of the quantum operators are obtained from the Poisson brackets of the classical dynamical variables. Let K^1 and K^2 be the classical boost dynamical variables,

$$\begin{aligned} K^1 &= x^0 p^1 - x^1 p^0, \\ K^2 &= x^0 p^2 - x^2 p^0. \end{aligned} \tag{88}$$

Furthermore,

$$p^0 = \sqrt{m^2 c^2 + \sum_{i=1}^{3} (p^i)^2}. \tag{89}$$

Then the Poisson bracket of K^1, K^2 is

$$\{K^1, K^2\} = \sum_{i=1}^{3} \left[\frac{\partial K^1}{\partial x^i} \frac{\partial K^2}{\partial p^i} - \frac{\partial K^2}{\partial x^i} \frac{\partial K^1}{\partial p^i} \right]. \tag{90}$$

Also

$$\begin{aligned} \frac{\partial K^1}{\partial x^i} &= -\delta_{i1} p^0, \\ \frac{\partial K^2}{\partial p^i} &= -x^2 \frac{\partial p^0}{\partial p^i}. \end{aligned} \tag{91}$$

But

$$\frac{\partial p^0}{\partial p^i} = \frac{p^i}{p^0}. \tag{92}$$

Thus

$$\sum_{i=1}^{3} \left[\frac{\partial K^1}{\partial x^i} \frac{\partial K^2}{\partial p^i} \right] = x^2 p^1. \tag{93}$$

Similarly,

$$\sum_{i=1}^{3} \left[\frac{\partial K^2}{\partial x^i} \frac{\partial K^1}{\partial p^i} \right] = x^1 p^2. \tag{94}$$

Therefore the Poisson bracket is

$$\{K^1, K^2\} = x^2 p^1 - x^1 p^2 = -J^3. \tag{95}$$

To introduce quantization we replace K^1, K^2, J^3 by Hermitian operators and the Poisson bracket by the commutator

$$\{K^1, K^2\} \rightarrow \frac{[K_q^1, K_q^2]}{i\hbar} = -J_q^3, \tag{96}$$

or

$$[K_q^1, K_q^2] = -i\hbar J_q^3$$

as required.

XI. MOVING FRAMES OF REFERENCE AND THE CREATION OF LONGITUDINAL FIELDS FROM TRANSVERSE AND THE CONVERSE

We shall now prove that even if one starts out with a purely transverse current density and a transverse field in an original frame of reference, a longitudinal current density and field appear in a frame of reference moving with respect to the first. Moreover, in the moving frame there will be a charge density, even if there were none in the original frame in which Eq. (53) holds. For a purely transverse field $k_m(\vec{p},0) \equiv = 0$.

Let us consider a frame moving along the z axis such that the space coordinates of the moving frame remain parallel to those of the original frame and that the two frames coincide when the time t equals zero in both frames. Then the coordinates in the new frame are related to those of the old by

$$\begin{aligned} ct' &= \frac{ct}{\sqrt{1-(v/c)^2}}, \\ z' &= \frac{z}{\sqrt{1-(v/c)^2}} - ct\frac{v/c}{\sqrt{1-(v/c)^2}}, \\ x' &= x, \\ y' &= y. \end{aligned} \tag{97}$$

The amplitudes in the original frame will be denoted by $k_m(\vec{p},\lambda)$ and that in the moving frame by $k'_m(\vec{p},\lambda)$. Then the principal result of this section is taken from Ref. 11:

$$k'_m(\vec{p},\lambda) = \exp[i\beta\mathcal{J}_3]k_m(\vec{p},\lambda). \tag{98}$$

In Eq. (98) $\mathcal{J}_3$ is the infinitesimal boost operator which operates on $k_m(\vec{p},\lambda)$ in a manner described in Ref. 11. As before, the scalar β is related to the velocity v of the Lorentz transformation Eq. (97) as follows:

$$\cosh\beta = \frac{1}{\sqrt{1-(v/c)^2}}. \tag{99}$$

The exponent operator in Eq. (98) is a *global* operator which represents the effect of a *finite* Lorentz transformation as in Eq. (97). Let us consider the case in which the velocity of the moving frame v is much less than the velocity of light.[26] Then

$$\begin{aligned} \frac{v}{c} &\ll 1, \\ \beta &\approx \frac{v}{c}. \end{aligned} \tag{100}$$

For such velocities

$$\exp[i\beta\mathcal{J}_3]\approx 1+i\frac{v}{c}\mathcal{J}_3. \tag{101}$$

Thus on using Eq. (2.6) of Ref. 11

$$k'_m(\vec{p},\lambda)\approx\left[1-\frac{v\,\omega(m,p)}{c}\frac{\partial}{\partial p_3}\right]k_m(\vec{p},\lambda)+i\frac{v}{c}\frac{mc}{p^2}(p_1T_1+p_2T_2)k_m(\vec{p},\lambda). \tag{102}$$

The operators T_1 and T_2 act only on the variable $\lambda=0,\pm 1$ in $k_m(\vec{p},\lambda)$. It is these operators which can introduce longitudinal polarization even when the amplitude $k_m(\vec{p},0)\equiv 0$. Conversely, if the field is longitudinally polarized in the original frame, it will generally have a transverse component in the moving frame.[27]

To show how T_1 and T_2 act on $k_m(\vec{p},\lambda)$ we introduce the related operators $T^{\pm}$ through

$$T^{\pm}=T_1\pm T_2. \tag{103}$$

Then

$$\begin{aligned} T^+k_m(\vec{p},\lambda)&=\sqrt{2-\lambda}\,\sqrt{1+\lambda}\,k_m(\vec{p},\lambda-1),\\ T^-k_m(\vec{p},\lambda)&=\sqrt{2+\lambda}\,\sqrt{1-\lambda}\,k_m(\vec{p},\lambda+1)\,. \end{aligned} \tag{104}$$

From the above equation we see that our assertion is proved.

XII. A SIMPLE EXAMPLE: A SPHERE OF CONSTANT CHARGE DENSITY UNDER PULSED ROTATIONS

We shall consider the source of electromagnetic waves to be a sphere of radius a which contains a charge of uniform density ρ. The origin of the sphere is at the origin of coordinates. For time $t<-\tau$ and $t>\tau$, where $\tau>0$, the sphere is stationary. But for $-\tau<t<\tau$ the sphere rotates about the z axis with a constant angular velocity Ω. For $t<-\tau$ and $t>\tau$ there is no current at all, either transverse or longitudinal. Since the charge density is constant in time, the equation of continuity is trivially satisfied. For $-\tau<t<\tau$ the current is purely transverse and again the equation of continuity is satisfied.

A. The longitudinal field

We shall first dispose of the problem of finding the longitudinal current density and the longitudinal electromagnetic field. It is obvious that the longitudinal current density is zero and that the longitudinal field is a purely electrostatic field with only a radial component $E_r(r)$ given by

$$E_r(r)=\frac{Q}{r^2}\qquad \text{for}\quad r>a\,. \tag{105}$$

B. The transverse current density

The transverse current density $\vec{j}_T(\vec{x})$ during the time $-\tau<t<\tau$ is

$$\vec{j}_T(\vec{x})=\rho(r)\vec{v}\,, \tag{106}$$

$$\rho(r)=\begin{cases}\rho & \text{for}\quad r<a\\ 0 & \text{for}\quad r>a.\end{cases} \tag{107}$$

We define the vector angular velocity $\vec{\Omega}=\Omega\vec{k}$ where $\vec{k}$ is the unit vector on the z axis. Then $\vec{v}=\vec{\Omega}\times\vec{x}$.

Polar coordinates in $\vec{x}$ space will be denoted by $\{r,\hat{\theta},\hat{\phi}\}$. In $\vec{p}$ space they will be indicated by $\{p,\theta,\phi\}$. In terms of polar coordinates

$$\vec{j}_T(\vec{x})=\rho(r)\Omega r\sin\hat{\theta}\,\vec{a}_{\hat{\phi}} \tag{108}$$

for $-\tau<t<\tau$. For all other values of t, $\vec{j}_T\equiv 0$. The vector $\vec{a}_{\hat{\phi}}$ is the unit vector in $\vec{x}$ space in the $\hat{\phi}$ direction.

C. Generalized spherical harmonics

It is now convenient to introduce generalized spherical (or surface) harmonics $Y_j^{\mu,\lambda}(\theta,\phi)$. The number j is either 0 or a positive integer or half-odd integer. The numbers λ,μ take on the values $-j,-j+1,\ldots,j-1,j$. The generalized spherical harmonics are useful when describing functions, vectors, and tensors.[28] These functions are generalized spherical harmonics in the sense that a subset of them are ''ordinary'' spherical harmonics,

$$Y_j^{\mu,0}(\theta,\phi)\equiv Y_{j,\mu}(\theta,\phi) \tag{109}$$

when j is an integer.[29] The generalized spherical harmonics satisfy the following orthogonality and completeness relations:

$$\begin{aligned}&\int_0^{2\pi}\mathrm{d}\phi\int_0^{\pi}\sin\theta\,\mathrm{d}\theta\,Y_j^{m,n}{}^*(\theta,\phi)\,Y_{j'}^{m',n}(\theta,\phi)=\delta_{j,j'}\delta_{m,m'},\\&\sum_{j=|n|}^{\infty}\sum_{m=-j}^{j}Y_j^{m,n}(\theta,\phi)\,Y_j^{m,n}{}^*(\theta',\phi')\sin\theta=\delta(\theta-\theta')\,\delta(\phi-\phi').\end{aligned} \tag{110}$$

The spherical harmonics $Y_1^{\mu,\lambda}(\theta,\phi)$ play a central role. Explicitly they are given by[30]

$$\begin{aligned}Y_1^{1,1}(\theta,\phi)&=\frac{1}{4}\sqrt{\frac{3}{\pi}}(1+\cos\theta),\\Y_1^{1,0}(\theta,\phi)&=-\sqrt{\frac{3}{8\pi}}e^{i\phi}\sin\theta,\\Y_1^{1,-1}(\theta,\phi)&=\frac{1}{4}\sqrt{\frac{3}{\pi}}e^{2i\phi}(1-\cos\theta),\\Y_1^{0,1}(\theta,\phi)&=-\sqrt{\frac{3}{8\pi}}e^{-i\phi}\sin\theta,\\Y_1^{0,-1}(\theta,\phi)&=-\sqrt{\frac{3}{8\pi}}e^{i\phi}\sin\theta,\\Y_1^{-1,1}(\theta,\phi)&=\frac{1}{4}\sqrt{\frac{3}{\pi}}e^{-2i\phi}(1-\cos\theta),\\Y_1^{-1,0}(\theta,\phi)&=\sqrt{\frac{3}{8\pi}}e^{-i\phi}\sin\theta,\\Y_1^{-1,-1}(\theta,\phi)&=\frac{1}{4}\sqrt{\frac{3}{\pi}}(1+\cos\theta).\end{aligned} \tag{111}$$

D. Calculation of the wave function $k_m(\vec{p},\lambda)$

In this section we shall compute $k_m(\vec{p},\lambda)$ from the current density Eq. (108) by using Eq. (65). We only need find $k_m(\vec{p},\lambda)$ for $\lambda=\pm 1$, since the current density is transverse so that $k_m(\vec{p},0)\equiv 0$.

Through the use of the formulas for $\vec{\Xi}(\vec{x},t|\vec{p},\lambda,m)$,

$$k_m(\vec{p},\lambda)=\frac{\rho\Omega}{(2\pi)^2}\int_{-\tau}^{\tau}\mathrm{d}t\, e^{ic\omega(m,p)t}\int_0^{\infty}r^3\,\mathrm{d}r\int_0^{2\pi}\mathrm{d}\hat{\phi}\int_0^{\pi}\sin^2\hat{\theta}\,\mathrm{d}\hat{\theta}[\vec{a}_{\hat{\phi}}\cdot\vec{Q}^*(\vec{p},\lambda)]e^{-i\vec{p}\cdot\vec{x}}. \tag{112}$$

But

$$\int_{-\tau}^{\tau}\mathrm{d}t\, e^{ic\omega(m,p)t}=2\,\frac{\sin c\omega(m,p)\tau}{c\omega(m,p)}. \tag{113}$$

Now we shall evaluate the integral

$$\int_0^{2\pi}\mathrm{d}\hat{\phi}\int_0^{\pi}\mathrm{d}\hat{\theta}\sin^2\hat{\theta}[\vec{a}_{\hat{\phi}}\cdot\vec{Q}^*(\vec{p},\lambda)]e^{-i\vec{p}\cdot\vec{x}}.$$

We recollect that $\hat{\phi}$ and $\hat{\theta}$ refer to the polar angles of $\vec{x}$ and ϕ and θ refer to the polar angles of $\vec{p}$. The expression in square brackets in the above double integral involves the two sets of polar angles.

It can be shown that

$$\vec{a}_{\hat{\phi}}\cdot\vec{Q}^*(\vec{p},\lambda)=-i\sqrt{\frac{2\pi}{3}}\sum_{\mu=\pm 1}e^{-i\mu\hat{\phi}}Y_1^{\mu\lambda}(\theta,\phi). \tag{114}$$

Also

$$e^{-i\mu\hat{\phi}}\sin\hat{\theta}=\sqrt{\frac{8\pi}{3}}\,\mu Y_1^{*\mu 0}(\hat{\theta},\hat{\phi}) \tag{115}$$

and

$$e^{-i\vec{p}\cdot\vec{x}}=4\pi\sum_{q=0}^{\infty}\sum_{s=-q}^{q}(-i)^q j_q(pr)Y_q^{*s0}(\theta,\phi)Y_q^{s0}(\hat{\theta},\hat{\phi}). \tag{116}$$

In the above equation $j_n(x)$ is the usual spherical Bessel function. (Of course $p=|\vec{p}|$ and $r=|\vec{x}|$.) On using the orthogonality properties of the generalized spherical harmonics we have

$$k_m(\vec{p},\lambda)=-\frac{8}{3}\rho\Omega\,\frac{\sin\omega(m,p)c\tau}{c\omega(m,p)}\sum_{\mu=\pm 1}\mu Y_1^{\mu\lambda}(\theta,\phi)Y_1^{*\mu 0}(\theta,\phi)\int_0^a\mathrm{d}r\, r^3 j_1(pr). \tag{117}$$

On using the explicit forms for the generalized spherical harmonics

$$\sum_{\mu=\pm 1}\mu\, Y_1^{\mu\lambda}(\theta,\phi)Y_1^{*\mu 0}(\theta,\phi)=-\sqrt{2}\,\frac{3}{8\pi}\lambda e^{-i\lambda\phi}\sin\theta \tag{118}$$

and thus

$$k_m(\vec{p},\lambda)=\frac{\sqrt{2}}{\pi}\rho\Omega\,\frac{\sin[\omega(m,p)c\tau]}{c\omega(m,p)}\lambda e^{-i\lambda\phi}\sin\theta\int_0^a\mathrm{d}r\, r^3 j_1(pr). \tag{119}$$

We need only evaluate the integral. We give this integral below:

$$\int_0^a \mathrm{d}r\, r^3 j_1(pr) = \frac{1}{p^4} G(pa)\,, \tag{120}$$

where $G(x)$ is the function

$$G(x) = 3x\cos x + (-3+x^2)\sin x\,. \tag{121}$$

Thus we have found the transform of the current density explicitly as

$$k_m(\vec{p},\lambda) = \frac{\sqrt{2}}{\pi}\rho\Omega\,\frac{\sin[\omega(m,p)c\tau]}{c\,\omega(\vec{p},\lambda)}\lambda e^{-i\lambda\phi}\sin\theta\frac{1}{p^4}G(pa)\,. \tag{122}$$

One can also write Eq. (122) in terms of dimensionless variables,

$$k_m(\vec{p},\lambda) = \mathcal{C}\hat{k}_m(\vec{\hat{p}},\lambda)\,. \tag{123}$$

In Eq. (123) $\mathcal{C} = (\sqrt{2}/\pi)\rho\Omega a^3\tau$. The function $\hat{k}_m$ is the dimensionless form of k_m and is given in terms of the dimensionless variables $\hat{m}$, $\hat{p}$ and χ defined below:

$$\hat{k}_{\hat{m}}(\vec{\hat{p}},\lambda) = \frac{\sin[\sqrt{\hat{m}^2+\hat{p}^2}\,\chi]}{\sqrt{\hat{m}^2+\hat{p}^2}}\lambda e^{-i\lambda\phi}\sin\theta\frac{G(\hat{p})}{\hat{p}^4},$$

$$\hat{p} = pa,$$

$$\chi = \frac{c\tau}{a},$$

$$\hat{m} = mca\,. \tag{124}$$

When we consider $k_m(\vec{p},\lambda)$ to be a wave function used in fractions to provide probability distributions, we may set $\mathcal{C}$ to be equal to unity, since it cancels out in the numerator and denominator of the ratio. We can then drop the caret over the variables and evaluate probabilities in a dimensionless setting.

1. Use of $k_m(\vec{p},\lambda)$ to find the mass distribution for the rotating sphere of charge

It is not a difficult matter to find the electromagnetic field due to the rotating sphere of charge. The easiest way, perhaps, is to calculate $\vec{E}(\vec{x};t)$ and $\vec{H}(\vec{x};t)$ using Eq. (72). We focus our attention on finding the consequences of considering $k_m(\vec{p},\lambda)$ to be the wave function of a massive photon.

2. Consequences of the notion of a massive photon: Arguments for and against its existence

We shall use Eq. (122) as the wave function. We shall concentrate on obtaining the probability of finding the mass m in an interval when the current is on.

Knowledge of the wave function $k_m(\vec{p},\lambda)$ enables us to obtain the probability distribution $P(m)$ that the mass m lies in the interval Δ as

$$\int_\Delta P(m)\mathrm{d}m\,.$$

From quantum mechanics,

$$P(m)=\frac{m\sum_{\lambda=\pm1}\int_0^{2\pi}d\phi\int_0^{\pi}d\theta\sin\theta\int_0^{\infty}dp[p^2/\omega(m,p)]|k_m(\vec{p},\lambda)|^2}{\int_0^{\infty}dm\,m\sum_{\lambda=\pm1}\int_0^{2\pi}d\phi\int_0^{\pi}d\theta\sin\theta\int_0^{\infty}dp[p^2/\omega(m,p)]|k_m(\vec{p},\lambda)|^2}. \tag{125}$$

Then the probability that a measurement of mass m in a small interval Δ about m_0 is

$$P(m_0)\Delta\,. \tag{126}$$

At this point it seems desirable to give arguments for and against the existence of massive photons based on the requirements of relativity as a constraint on the solutions of Maxwell's equations. The principal reason for identifying $k_m(\vec{p},\lambda)$ with the photon wave function is that when this identification is carried out for the case of no current density, this identification leads to the correct results for zero-mass photons, including second quantization. Also one obtains the correct decompositions for both the real and complex vector fields and for solutions of the Dirac equation for both zero- and nonzero masses.[31] Furthermore, as indicated earlier, the function $k_m(\vec{p},\lambda)$ is the *only* wave function[32] for quantized relativistic particles of spin 1. The electromagnetic fields cannot be expressed in terms of any other function if they are to transform under Lorentz transformations in the customary way.

The principal argument against massive photons is that they have not yet been found. (But neither have they been sought for in modern times.) Another argument against their existence is that $P(m)$ which gives the mass distribution is, in our example, independent of the charge density ρ or angular velocity Ω of the rotating sphere of charge, though the strength of the electromagnetic field *does* depend on these quantities. Perhaps the independence of $P(m)$ on $\rho\Omega$ is one of the paradoxes of quantum theory as opposed to classical theory. A somewhat similar situation exists for the electron–positron field for which the ''sea of electrons'' is assumed to fill the negative energy band, even when no electron is lifted out of the sea and the sea cannot be observed.

XIII. EVALUATION OF THE PROBABILITY DISTRIBUTION OF MASS $P(m)$ IN OUR EXAMPLE

We shall now evaluate the probability distribution $P(m)$ of Eq. (125), which will give an indication of which masses to expect in our problem. The masses m are perhaps the most interesting aspect of photons with mass.

A. The evaluation of the denominator

We denote the denominator by D,

$$D=\sum_{\lambda=\pm1}\int_0^{2\pi}d\phi\int_0^{\pi}\sin^3\theta\int_0^{\infty}dm\,m\int_0^{\infty}\frac{dp}{p^6}\frac{\sin^2[\omega(m,p)\chi]}{[\omega(m,p)]^3}[G(p)]^2. \tag{127}$$

Summing over λ and integrating over θ and ϕ allow us to write

$$D=E\int_0^{\infty}dm\,m\int_0^{\infty}\frac{dp}{p^6}\frac{\sin^2[\omega(m,p)\chi]}{[\omega(m,p)]^3}[G(p)]^2\,. \tag{128}$$

In the above equation E is a numerical constant which will cancel out in the ratio of numerator and denominator in the expression for $P(m)$. We may thus set $E=1$. We shall now carry out the integration over m.

We introduce the variable ξ by

$$\xi=\omega(m,p)\chi\,.$$

Then

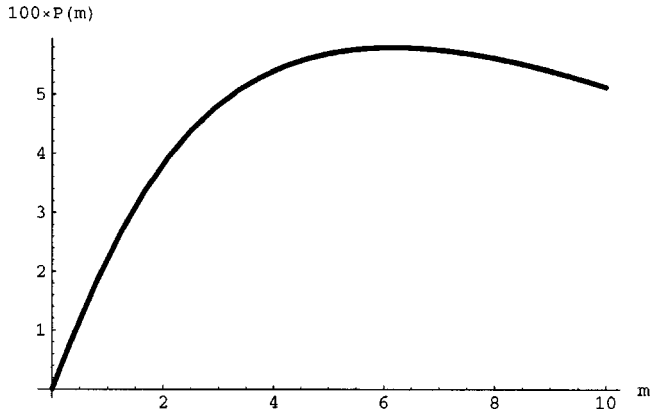

FIG. 1. The probability density $P(m)$ for $\chi=0.1$.

$$\int_0^\infty \mathrm{d}m \frac{m \sin^2[\omega(m,p)\chi]}{[\omega(m,p)]^3} = \chi \int_{\chi p}^\infty \frac{\sin^2 \xi}{\xi^2} = \chi\left[\frac{\pi}{2} - \mathrm{Si}(2\chi p) + \frac{\sin^2 \chi p}{\chi p}\right]. \tag{129}$$

Thus the denominator of the probability ratio is

$$D = \chi \int_0^\infty \frac{dp}{p^6}\left[\frac{\pi}{2} - \mathrm{Si}(2\chi p) + \frac{\sin^2 \chi p}{\chi p}\right]|G(p)|^2 . \tag{130}$$

This integral is a single integral over p which we shall evaluate numerically for several values of the nondimensional time χ.

B. The expression for the probability density

We shall now give the probability density $P(m)$ in terms of the dimensionless variables m,χ.

We shall denote the probability density, at the nondimensional time χ, by $P(m,\chi)$. The probability that a measurement of the mass m will give a value of m within an interval Δ about m at the nondimensional time χ is $P(m,\chi)\Delta$ where

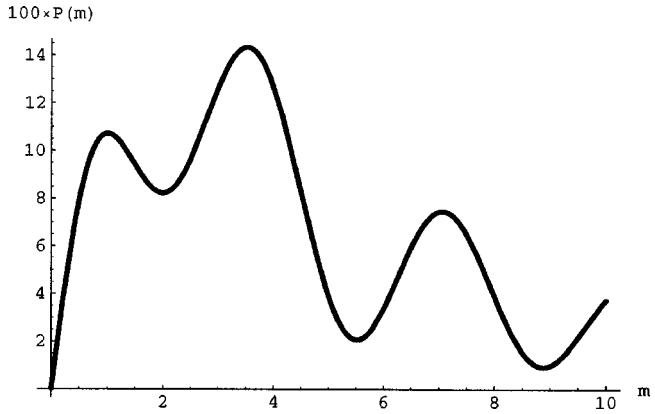

FIG. 2. The probability density $P(m)$ for $\chi=1.0$.

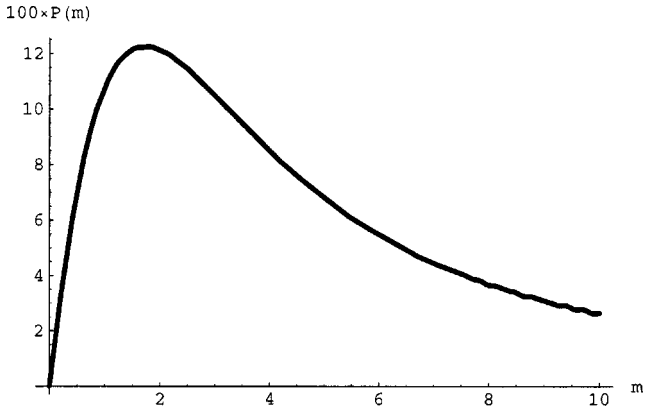

FIG. 3. The probability density $P(m)$ for $\chi=10.0$.

$$P(m,\chi)=\frac{1}{\chi}\frac{m\int_0^\infty \frac{dp}{p^6}\frac{\sin^2[\omega(m,p)\chi]}{[\omega(m,p)]^3}[G(p)]^2}{\int_0^\infty \frac{dp}{p^6}\left[\frac{\pi}{2}-\mathrm{Si}(2\chi p)+\frac{\sin^2\chi p}{\chi p}\right][G(p)]^2}. \tag{131}$$

C. Figures for $P(m)$ for several values of time interval of rotation

We have calculated and graphed $P(m)$ for three values of χ, namely, $\chi=0.1$, 1.0, and 10. These three values of χ are representative of the cases for which $c\tau$ is short, equal to long, respectively, compared to the radius a of the sphere which contains the charge (Figs. 1–3).[33]

It is clear from these graphs that there is a continuous distribution of masses for the problem which we have discussed. The writer hopes to obtain probability distributions for other transverse current distributions.

XIV. A DISCUSSION OF THE LONGITUDINAL FIELD: AN EXAMPLE OF A TIME-DEPENDENT LONGITUDINAL CURRENT DENSITY AND THE ASSOCIATED LONGITUDINAL ELECTRIC FIELD

Most of our discussion has centered on time-dependent transverse current densities and transverse electromagnetic fields because these are of great practical interest. But longitudinal current densities and longitudinal electric fields (there are no magnetic fields) also have properties which are surprising. We shall give an example which can, perhaps, be tested experimentally.

A. General considerations of longitudinal current densities and electric fields

Longitudinal current densities as a source of fields are much more easily treated mathematically than transverse current densities and fields. If we have a longitudinal current density, Maxwell's equations become

$$\frac{\partial}{\partial t}\vec{E}_L(\vec{x};t)=-4\pi\vec{j}_L(\vec{x};t),$$

$$\vec{H}_L(\vec{x};t)\equiv 0, \tag{132}$$

$$\vec{\nabla}\cdot\vec{E}_L(\vec{x};t)=4\pi\rho(\vec{x};t).$$

It would appear that we could use either the longitudinal current density $\vec{j}(\vec{x};t)$ or the charge density $\rho(\vec{x};t)$ and get the same answer. We shall see that this is, in fact, true.

We shall assume that the current density is pulsed and that it is zero for $t<-T<0$ and $t>T$. We can use Professor Keller's suggested method of solving Eq. (132) without reducing the fields and currents to irreducible representations of the Poincaré group. Thus we find the electric field $\vec{E}_L(\vec{x};t)$ from the first of Eq. (132):

$$\vec{E}_L(\vec{x};t)=\begin{cases}\vec{E}_{s0}(\vec{x}) & \text{for} \quad t<-T,\\ E_{s0}(\vec{x})-4\pi\int_{-T}^{t}\vec{j}_L(\vec{x};t')dt' & \text{for} \quad -T<t<T\\ E_{s0}(\vec{x})-4\pi\int_{-T}^{T}\vec{j}_L(\vec{x};t')dt' & \text{for} \quad t>T.\end{cases} \tag{133}$$

In the above equation $\vec{E}_{s0}(\vec{x})$ is the static electric field which may exist before the longitudinal current is pulsed. It could be due to a static charge density. When $t>T$, the electric field is again independent of time and may be regarded as the static field due to a charge distribution arising from the pulsed current. Thus for $t>T$ we write $\vec{E}_L(\vec{x};t)\equiv\vec{E}_{s1}(\vec{x})$. We first solve the problem for which $\vec{E}_{s0}(\vec{x})\equiv 0$. The charge density after the current density pulse has been initiated is then

$$\rho(\vec{x};t)=\begin{cases}\dfrac{1}{4\pi}\vec{\nabla}\cdot\vec{E}_L(\vec{x};t)\\ 0 \quad \text{for} \quad t<-T\\ -\displaystyle\int_{-T}^{t}dt'\,\vec{\nabla}\cdot\vec{j}_L(\vec{x},t') \quad \text{for} \quad t>-T.\end{cases} \tag{134}$$

Clearly the equation of continuity is satisfied.

B. Example: An expanding balloon with surface charge

As an example, we consider an expanding balloon, the surface of which has an index of refraction close to unity. The expansion starts at time $t=-T$, at which time the radius of the balloon is R_0 and continuous to time $t=T$ at which time the radius is R_1. The radius for any time t with $-T<t<T$ is denoted by $R(t)$. The radius is assumed to grow with constant velocity u. Thus

$$\begin{aligned}R(t)&=ut+\frac{R_1+R_0}{2},\\ u&=\frac{R_1-R_0}{2T}.\end{aligned} \tag{135}$$

The total charge in the balloon is Q which is uniformly distributed on the surface of the balloon. The charge distribution $\rho(\vec{x};t)$ is then

$$\rho(\vec{x};t)=\frac{Q}{4\pi}\frac{\delta(r-r(t))}{R^2(t)}. \tag{136}$$

Thus $\rho(\vec{x};t)$ depends only upon r and t. It is readily verified that

$$\int \mathrm{d}\vec{x}\,\rho(\vec{x};t)=Q \tag{137}$$

as required. The current density is

$$\vec{j}(\vec{x};t)=\begin{cases}\rho(\vec{x};t)\vec{u} & \text{for } -T<t<T\\ 0 \text{ for all other values of } t,\end{cases} \tag{138}$$

and $\vec{u}=u\vec{a}_r$ where $\vec{a}_r$ is e unit vector along the radius. We can find the electric field from Eq. (132). Initially we set $\vec{E}_{s0}=0$.

Then

$$\vec{E}_L(\vec{x};t)=\begin{cases}0 & \text{for } t<-T\\ -\dfrac{Q}{r^2} & \text{for } -T<t<T \text{ and } R_0<r<R(t)\\ -\dfrac{Q}{r^2}\vec{a}_r & \text{for } t>T \text{ and } R_0<r<R_1\,.\end{cases} \tag{139}$$

In all domains of space–time other than those appearing in Eq. (139) $\vec{E}_L(\vec{x};t)=0$.

This result for $\vec{E}_l(\vec{x};t)$ would be valid if the charge on the balloon were created instantaneously at time $t=-T$. A more realistic approach would be to put the charge on the balloon *before* the balloon began to expand. In this case

$$\vec{E}_{s0}(\vec{x};t)=\begin{cases}0 & \text{for } r<R_0\\ \dfrac{Q}{r^2}\vec{a}_r & \text{for } r>R_0\,.\end{cases} \tag{140}$$

We now add this field to the field of Eq. (139). We obtain

$$\vec{E}_{L\ total}=\begin{cases}0 & \text{for } r<R(t)\\ \dfrac{Q}{r^2}\vec{a}_r & \text{for } r>R(t).\end{cases} \tag{141}$$

This result is precisely the same as though we used Gauss's theorem as is generally done finding the field due to a spherical distribution of charge in elementary potential theory.

This result is general. One can use electrostatic theory with time-dependent source densities $\rho(\vec{x};t)$ to obtain longitudinal fields. We shall now prove this theorem in general. The proof is a generalization of a similar theorem for zero mass components of the field which we treated earlier.

Since $\vec{E}_L(\vec{x};t)$ is a longitudinal (i.e., irrotational) field, the field can be represented as a gradient of a scalar potential.

$$\vec{E}_L(\vec{x};t)=-\vec{\nabla}V(\vec{x};t). \tag{142}$$

Then the last of Eq. (132) becomes

$$\nabla^2V(\vec{x};t)=-4\pi\rho(\vec{x};t)\,. \tag{143}$$

This equation is, of course, Poisson's equation for potentials with a source distribution $\rho(\vec{x};t)$. Then the longitudinal field is easily solved for

$$\vec{E}_L(\vec{x};t)=\vec{\nabla}\int d\vec{x}\frac{\rho(\vec{x}';t)}{|\vec{x}-\vec{x}'|}. \tag{144}$$

Thus the *time-dependent* longitudinal field is easily obtained from a *time-dependent* source distribution. This result is a simple generalization of the method of obtaining electrostatic fields from source distributions.

There is an astonishing consequence. *Longitudinal fields are not causal! Maxwell's equations have noncausal solutions!* Longitudinal electric fields travel with infinite speed just as Newtonian gravitational fields do.

We are left with a problem, if causality, as usually understood, is to be preserved. It would seem that Maxwell's equations have to be modified. Otherwise, if we want to keep Maxwell's equations as they are, we shall have to alter our notion of the meaning of causality. From an experimental point of view, one should test whether indeed a change in the longitudinal fields travel with a finite speed if the source distribution is changed abruptly.

The problem of causality of all solutions of Maxwell's equations seems not to have been generally understood or discussed, at least in modern times.

To finish the discussion of longitudinal electric fields, the longitudinal current density can be found from the first of Eq. (132) or, equivalently, from the equation of continuity. If one starts with this current density and solves for the longitudinal field, one gets the same field that one started with and the same charge density. The circle is closed.

ACKNOWLEDGMENT

[8] These quantities strictly speaking are not vectors, since their transformation properties under rotations are not quite the proper ones. See Ref. 7 for the rotation properties of the eigenfunctions.

[9] One can introduce a measure function to describe the range of values of m.

[10] The helicity realization for $m \neq 0$ resembles the $m=0$ case more closely than the equivalent Foldy–Shirokov realization. When $m \to 0$, the mass helicity representation approaches the direct sum of *three* zero-mass representations corresponding to the three values of helicity of the nonzero mass representations. H. E. Moses, Ann. Phys. (N.Y.) **60**, 275 (1970).

[11] In Ref. 6 we have given the expansion of the real four-vector which is comprised of the scalar and vector potential satisfying the Lorentz condition. The same expansion applies to $\iota(\vec{x};t)$ when the equation of continuity is satisfied.

[12] J.B. Keller (private communication).

[13] We recollect that for a fixed value of $\vec{p}$ the vectors $\vec{Q}(\vec{p},\lambda)$ constitute a basis in three-dimensional space. We have absorbed some numerical factors in the functions $f_m(\vec{p})$ and $h_m(\vec{p})$.

[14] The functions $f_m(\vec{p},\lambda)$, $h_m(\vec{p},\lambda)$, and $k_m(\vec{p},\lambda)$ transform under the irreducible helicity representations of the Poincaré group (Ref. 11) corresponding to particles of mass m, spin 1, and *positive* energy.

[15] This consequence of the properties of Poincaré transformations will be discussed more fully in a later section.

[16] For simplicity we take J to be real.

[17] We have dispensed with the showing of several nonessential variables and constants.

[18] In practice this is the way to create source-free electromagnetic fields.

[19] The effect of repeated pulses, even those of different shapes in time and space, can be obtained by superposition.

[20] In integrals any point in the continuous spectrum is of zero measure.

[21] We have used Eq. (67). Moreover, we have made the replacement $\lambda k_m(\vec{p},\lambda) \to k_m(\vec{p},\lambda)$.

[22] Choosing the current density and evaluating the charge density later is close to the suggestion made by Professor J. B. Keller.

[23] J. A. Stratton, *Electromagnetic Theory* (McGraw-Hill, New York, 1941), p. 330ff. A rather complete discussion of group and phase velocity is given for one-dimensional propagation.

[24] H. E. Moses and A. F Quesada, J. Math. Phys. **15**, 748 (1974).

[25] The four-vector x^μ is not quantized because space and time cannot be quantized in the same way.

[26] This is often the case in experimental settings. One could, however, consider any velocity including high velocities encountered in astronomy and particle accelerators using the results of Ref. 10.

[27] This result suggests the possibility of generating transverse waves from longitudinal fields by launching the longitudinal fields in a moving frame of reference. We may study this matter more fully later.

Group averaging in the (p,q) oscillator representation of $SL(2,\mathbb{R})$

Jorma Louko[a] and Alberto Molgado[b]
School of Mathematical Sciences, University of Nottingham, Nottingham NG7 2RD, United Kingdom

(Received 19 January 2004; accepted 28 January 2004; published 5 April 2004)

We investigate refined algebraic quantization with group averaging in a finite-dimensional constrained Hamiltonian system that provides a simplified model of general relativity. The classical theory has gauge group $SL(2,\mathbb{R})$ and a distinguished $\mathfrak{o}(p,q)$ observable algebra. The gauge group of the quantum theory is the double cover of $SL(2,\mathbb{R})$, and its representation on the auxiliary Hilbert space is isomorphic to the (p,q) oscillator representation. When $p\geqslant 2$, $q\geqslant 2$ and $p+q\equiv 0 \pmod 2$, we obtain a physical Hilbert space with a nontrivial representation of the $\mathfrak{o}(p,q)$ quantum observable algebra. For $p=q=1$, the system provides the first example known to us where group averaging converges to an indefinite sesquilinear form. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1689001]

I. INTRODUCTION

In quantization of constrained systems, an elegant proposal to obtain a physical inner product is to average unconstrained quantum states in an auxiliary Hilbert space over the gauge group.[1–13] When the averaging is formulated within refined algebraic quantization[4,8,12] and converges in a sufficiently strong sense, it provides either the unique rigging map, and hence the unique inner product on the states that satisfy the constraints, or a proof that the system does not admit a rigging map.[8] Given the equivalence of refined algebraic quantization to a wide class of methods of choosing the physical inner product,[13,14] group averaging thus provides considerable control over the quantization.

When the gauge group is compact, the averaging necessarily converges. For a noncompact gauge group the averaging need not converge on all of the auxiliary Hilbert space $\mathcal{H}_{\text{aux}}$ but may still converge on a suitable dense linear subspace Φ, and this is sufficient for recovering the physical Hilbert space $\mathcal{H}_{\text{RAQ}}$. The choice of the test space Φ thus has a mathematical role in ensuring convergence, but it also has a deep physical role in that Φ determines the algebra of operators represented on $\mathcal{H}_{\text{RAQ}}$.[8,14] While quantization with group averaging can be carried out without the explicit construction of any physical observables, in concrete examples one may wish to choose Φ so that certain explicitly known physical observables of interest are contained in the algebra represented on $\mathcal{H}_{\text{RAQ}}$.

In this paper we study a quantum mechanical system whose constraints mimic the Hamiltonian structure of general relativity.[15] The constraint set consists of two ''Hamiltonian''-type constraints, quadratic in the momenta, and one ''momentum''-type constraint, linear in the momenta, and the classical gauge group generated by these constraints is $SL(2,\mathbb{R})$. The unreduced phase space is $T^*\mathbb{R}^{p+q}\simeq\mathbb{R}^{2(p+q)}$, where $p\geqslant 1$ and $q\geqslant 1$. The system was introduced by Montesinos, Rovelli and Thiemann with $p=q=2$,[16] and its quantization with $p=q=2$ was studied in Refs. 10 and 16–18 within Ashtekar's algebraic quantization,[19,20] in Ref. 21 within algebraic constraint quantization,[22,23] in Refs. 10 and 24–26 within group theoretic quantization,[27,28] and in Ref. 10 within refined algebraic quantization with group averaging.[4,8] All these quantizations

[a]Electronic mail: jorma.louko@nottingham.ac.uk
[b]Electronic mail: pmxam@nottingham.ac.uk

relied in one way or another on a distinguished classical $\mathfrak{o}(2,2)$ observable algebra, constructing a quantum theory in which these observables are promoted into quantum operators. Within group averaging,[10] it was in particular found that a judicious choice for the test space is necessary to achieve both convergence of the averaging and the inclusion of the $\mathfrak{o}(2,2)$ observables in the physical operator algebra.

For $p>2$ and $q=2$, the system has been studied in the context of a ''two-time'' physical interpretation in Refs. 29–32. The case $p=q=2$ is currently being studied[33] within the master constraint program.[34] Related systems with $\mathrm{SL}(2,\mathbb{R})$ gauge invariance have been studied in Refs. 35–37.

We wish to quantize this system with group averaging for general p and q, using test states built from eigenstates of the harmonic oscillator Hamiltonians that arise in the oscillator representation of $\mathrm{SL}(2,\mathbb{R})$.[38] When $p\geqslant 2$, $q\geqslant 2$ and $p+q\equiv 0 \pmod 2$, we obtain a quantum theory in which the classical $\mathfrak{o}(p,q)$ observables are promoted into a nontrivially represented operator algebra. When $(p,q)=(1,3)$ or $(3,1)$, we obtain a quantum theory with a one-dimensional physical Hilbert space that is annihilated by all the $\mathfrak{o}(p,q)$ observables. For other values of p and q we recover no physical Hilbert space. In particular, for $p=q=1$ the group averaging converges to an *indefinite* sesquilinear form, in a sense strong enough for the uniqueness theorem of Ref. 8 to imply that the system admits no rigging maps. This is the first example known to us in which group averaging fails to produce a Hilbert space owing to indefiniteness of the would-be inner product.
